General Precautions in the Handling of Microprocessing Unit and Microcontroller Unit Products

The following usage notes are applicable to all Microprocessing unit and Microcontroller unit products from Renesas. For detailed usage notes on the products covered by this document, refer to the relevant sections of the document as well as any technical updates that have been issued for the products.

1. Precaution against Electrostatic Discharge (ESD)
   A strong electrical field, when exposed to a CMOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop the generation of static electricity as much as possible, and quickly dissipate it when it occurs. Environmental control must be adequate. When it is dry, a humidifier should be used. This is recommended to avoid using insulators that can easily build up static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors must be grounded. The operator must also be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions must be taken for printed circuit boards with mounted semiconductor devices.
2. Processing at power-on
   The state of the product is undefined at the time when power is supplied. The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the time when power is supplied. In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the time when power is supplied until the reset process is completed. In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the time when power is supplied until the power reaches the level at which resetting is specified.
3. Input of signal during power-off state
   Do not input signals or an I/O pull-up power supply while the device is powered off. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements. Follow the guideline for input signal during power-off state as described in your product documentation.
4. Handling of unused pins
   Handle unused pins in accordance with the directions given under handling of unused pins in the manual. The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of the LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible.
5. Clock signals
   After applying a reset, only release the reset line after the operating clock signal becomes stable. When switching the clock signal during program execution, wait until the target clock signal is stabilized. When the clock signal is generated with an external resonator or from an external oscillator during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Additionally, when switching to a clock signal produced with an external resonator or by an external oscillator while program execution is in progress, wait until the target clock signal is stable.
6. Voltage application waveform at input pin
   Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between V_{IL} (Max.) and V_{IH} (Min.) due to noise, for example, the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between V_{IL} (Max.) and V_{IH} (Min.).
7. Prohibition of access to reserved addresses
   Access to reserved addresses is prohibited. The reserved addresses are provided for possible future expansion of functions. Do not access these addresses as the correct operation of the LSI is not guaranteed.
8. Differences between products
   Before changing from one product to another, for example to a product with a different part number, confirm that the change will not lead to problems. The characteristics of a microprocessing unit or microcontroller unit products in the same group but having a different part number might differ in terms of internal memory capacity, layout pattern, and other factors, which can affect the ranges of electrical characteristics, such as characteristic values, operating margins, immunity to noise, and amount of radiated noise. When changing to a product with a different part number, implement a system-evaluation test for the given product.

处理微处理单元和微控制器的一般注意事项 单位产品

以下使用说明适用于瑞萨的所有微处理单元和微控制器单元产品。有关详细的使用说明
本文档所涵盖的产品，请参阅文档的相关部分以及为产品发布的任何技术更新。

1. 防止静电放电(ESD)
   当暴露于CMOS器件时，强电场会导致栅极氧化物的破坏并最终降低器件的运行性能。脚步
   必须采取措施，尽可能停止静电的产生，并在出现时迅速消散。环境控制必须
   足够的。干燥时，应使用加湿器。建议避免使用容易产生静电的绝缘体。
   半导体器件必须在防静电容器、静电屏蔽袋或导电材料中储存和运输。所有测试和
   包括工作台和地板在内的测量工具必须接地。操作员还必须使用腕带接地。半导体
   不得赤手触摸设备。对于安装有半导体器件的印刷电路板，必须采取类似的预防措施。
2. 上电处理
   通电时产品的状态是不确定的。LSI内部电路的状态是不确定的，
   通电时寄存器设置和引脚未定义。在将复位信号施加到外部复位的成品中
   管脚，从通电到复位过程完成，管脚的状态不能保证。以类似的方式，引脚的状态
   在通过片内上电复位功能复位的产品中，从供电时间到供电达到
   指定重置的级别。
3. 断电状态下的信号输入
   请勿在设备断电时输入信号或IO上拉电源。输入此类信号或IO导致的电流注入
   上拉电源可能会导致故障，此时通过设备的异常电流可能会导致内部退化
   元素。请按照产品文档中所述的电源关闭状态下的输入信号指南进行操作。
4. 处理未使用的引脚
   按照手册中未使用引脚处理中给出的说明处理未使用的引脚。CMOS产品的输入引脚是
   一般处于高阻状态。在开路状态下使用未使用的引脚操作时，会在附近感应出额外的电磁噪声
   LSI，相关的直通电流在内部流动，并且由于将引脚状态错误识别为输入信号而发生故障
   成为可能。
5. 时钟信号
   应用复位后，只有在工作时钟信号稳定后才释放复位线。在程序中切换时钟信号时
   执行，等待目标时钟信号稳定。当时钟信号由外部谐振器或外部振荡器产生时
   在复位期间，确保只有在时钟信号完全稳定后才释放复位线。此外，当切换到时钟信号时
   在程序执行过程中由外部谐振器或外部振荡器产生，等待目标时钟信号稳定。
6. 输入引脚的电压施加波形
   由于输入噪声或反射波导致的波形失真可能会导致故障。如果CMOS器件的输入保持在VIL之间的区域
   (Max.)和VIH(Min.)由于噪音，例如，设备可能发生故障。小心，以防止颤动的噪音进入设备时，
   输入电平是固定的，并且在输入电平通过VIL(Max.)和VIH(Min.)之间的区域时的过渡期间也是如此。
7. 禁止访问保留地址
   禁止访问保留地址。保留地址是为将来可能的功能扩展提供的。不要访问这些
   不能保证LSI的正确操作。
8. 产品之间的差异
   在从一种产品更改为另一种产品之前，例如更改为具有不同部件号的产品，请确认更改不会导致问题。
   同一组中的微处理单元或微控制器单元产品的特性，但具有不同的部件号，其特性可能会有所不同
   内部存储器容量，布局模式和其他因素，这些因素会影响电气特性的范围，例如特性值，
   工作裕度、抗噪声能力和辐射噪声量。当更改为具有不同部件号的产品时，实施系统-
   给定产品的评估测试。

Table 1.7 Timers

Feature	Functional description
General PWM Timer (GPT)	The General PWM Timer (GPT) is a 32-bit timer with GPT32 × 2 channels and a 16-bit timer with GPT16 × 2 channels. PWM waveforms can be generated by controlling the up-counter, down-counter, or the up- and down-counter. In addition, PWM waveforms can be generated for controlling brushless DC motors. The GPT can also be used as a general-purpose timer. See section 21, General PWM Timer (GPT).
Port Output Enable for GPT (POEG)	The Port Output Enable (POEG) function can place the General PWM Timer (GPT) output pins in the output disable state See section 20, Port Output Enable for GPT (POEG).
Low power Asynchronous General Purpose Timer (AGT)	The low power Asynchronous General Purpose Timer (AGT) is a 16-bit timer that can be used for pulse output, external pulse width or period measurement, and counting external events. This timer consists of a reload register and a down counter. The reload register and the down counter are allocated to the same address, and can be accessed with the AGT register. See section 22, Low Power Asynchronous General Purpose Timer (AGT).
Realtime Clock (RTC)	The realtime clock (RTC) has two counting modes, calendar count mode and binary count mode, that are used by switching register settings. For calendar count mode, the RTC has a 100-year calendar from 2000 to 2099 and automatically adjusts dates for leap years. For binary count mode, the RTC counts seconds and retains the information as a serial value. Binary count mode can be used for calendars other than the Gregorian (Western) calendar. See section 23, Realtime Clock (RTC).
Watchdog Timer (WDT)	The Watchdog Timer (WDT) is a 14-bit down counter that can be used to reset the MCU when the counter underflows because the system has run out of control and is unable to refresh the WDT. In addition, the WDT can be used to generate a non-maskable interrupt or an underflow interrupt. See section 24, Watchdog Timer (WDT).
Independent Watchdog Timer (IWDT)	The Independent Watchdog Timer (IWDT) consists of a 14-bit down counter that must be serviced periodically to prevent counter underflow. The IWDT provides functionality to reset the MCU or to generate a non-maskable interrupt or an underflow interrupt. Because the timer operates with an independent, dedicated clock source, it is particularly useful in returning the MCU to a known state as a fail-safe mechanism when the system runs out of control. The IWDT can be triggered automatically by a reset, underflow, refresh error, or a refresh of the count value in the registers. See section 25, Independent Watchdog Timer (IWDT).

Table 1.8 Communication interfaces (1 of 2)

Feature	Functional description
Serial Communications Interface (SCI)	The Serial Communications Interface (SCI) × 4 channels have asynchronous and synchronous serial interfaces: • Asynchronous interfaces (UART and Asynchronous Communications Interface Adapter (ACIA)) • 8-bit clock synchronous interface • Simple IIC (master-only) • Simple SPI • Smart card interface • Manchester interface The smart card interface complies with the ISO/IEC 7816-3 standard for electronic signals and transmission protocol. SCIn (n = 0, 3, 4, 9) has FIFO buffers to enable continuous and full-duplex communication, and the data transfer speed can be configured independently using an on-chip baud rate generator. See section 27, Serial Communications Interface (SCI).
I^2C bus interface (IIC)	The I^2C bus interface (IIC) has 1 channel. The IIC module conforms with and provides a subset of the NXP I^2C (Inter-Integrated Circuit) bus interface functions. See section 28, I2C Bus Interface (IIC).
Serial Peripheral Interface (SPI)	The Serial Peripheral Interface (SPI) has 1 channel. The SPI provides high-speed full-duplex synchronous serial communications with multiple processors and peripheral devices. See section 30, Serial Peripheral Interface (SPI).

Table 1.7 Timers

Feature	功能说明
通用PWM定时器(GPT)	通用PWM定时器(GPT)是一个32位定时器，具有GPT32×2通道和一个16位定时器，具有GPT16×2通道。PWM波形可以通过控制加计数器、减计数器或加减计数器来产生。此外，可以生成PWM波形来控制无刷直流电机。GPT也可以用作通用定时器。请参见第21节，通用PWM定时器(GPT)。

低功耗异步通用 目的定时器(AGT)	低功耗异步通用定时器(AGT)是一个16位定时器，可用于脉冲输出、外部脉冲宽度或周期测量以及外部事件计数。该定时器由一个重载寄存器和一个递减计数器组成。重载寄存器和递减计数器分配到同一个地址，可以通过AGT寄存器访问。请参见第22节，低功耗异步通用定时器(AGT)。
实时时钟(RTC)	实时时钟(RTC)有两种计数模式，日历计数模式和二进制计数模式，通过切换寄存器设置使用。对于日历计数模式，RTC有一个从2000年到2099年的100年日历，并自动调整闰年的日期。对于二进制计数模式，RTC会计算秒数并将信息保留为序列值。二进制计数模式可用于公历（西方）以外的日历。请参阅第23节，实时时钟(RTC)。
看门狗定时器(WDT)	看门狗定时器(WDT)是一个14位递减计数器，可用于在计数器下溢时复位MCU，因为系统已失控且无法刷新WDT。此外，WDT可用于产生不可屏蔽中断或下溢中断。请参见第24节，看门狗定时器(WDT)。
独立看门狗定时器(IWDT)	独立看门狗定时器(IWDT)包含一个14位递减计数器，必须定期对其进行服务以防止计数器下溢。IWDT提供复位MCU或生成不可屏蔽中断或下溢中断的功能。由于定时器使用独立的专用时钟源运行，因此当系统失控时，它在将MCU作为故障安全机制返回到已知状态时特别有用。IWDT可以通过复位、下溢、刷新错误或寄存器中的计数值的刷新来自动触发。请参见第25节，独立看门狗定时器(IWDT)。

The module supports full-speed and low-speed (host controller only) transfer as defined in Universal Serial Bus Specification 2.0. The module has an internal USB transceiver and supports all of the transfer types defined in Universal Serial Bus Specification 2.0. 2.4 Security Attribution for Memory

In this MCU, SAU is not implemented and IDAU performs region definition for memory. IDAU divides the memory into 8 different areas as shown in Figure 2.2.

The code flash, the data flash, and the SRAM are divided into Secure (S), Non-secure (NS) and Non-secure callable (NSC) regions. These memory security attributions are set into the nonvolatile memory by the serial programming command when the device lifecycle is in SSD state. These memory security attributions are loaded into the IDAU and the memory controller before application execution. These memory security attributions cannot be updated by application but can read through the dedicated registers.

Note: When configuring, the memory regions should satisfy the setting condition of minimum address unit shown in Table 2.3.

2.4 内存安全归属

在这个MCU中，没有实现SAU，而IDAU为内存执行区域定义。IDAU将内存划分为8个不同的区域，如图2.2所示。

代码闪存、数据闪存和SRAM分为安全(S)、非安全(NS)和非安全可调用(NSC)区域。当设备生命周期处于SSD状态时，这些内存安全属性由串行编程命令设置到非易失性内存中。这些内存安全属性在应用程序执行之前被加载到IDAU和内存控制器中。这些内存安全属性不能由应用程序更新，但可以通过专用寄存器读取。

Note: 配置时，内存区域应满足表2.3所示的最小地址单元设置条件。

Table 2.3 S/NS and S/NSC boundary list

Boundary	Code flash	Data flash	SRAM
S/NS	32 KB	1 KB	8 KB

Each region has its dedicated ID as follows. For more details, see section 2.13. References.

IREGION (IDAU region number)	Description
0x0D	Non-secure SRAM
0x0E	Non-secure callable SRAM
0x0F	Secure SRAM
0x09	Non-secure data flash

2.5 Debug Function

2.5.1 Debugger connectivity

In this MCU, debug function is considered in three levels, DBG0, DBG1, DBG2. At DBG0, no debug function is available. DBG1 level is defined as non-secure debug in ARMv-8 and the debugger can only access defined non-secure debug accessible regions. DBG2 level is defined as secure debug in ARMv-8 and at this level, nonsecure and secure debug function is enabled and can be accessible from the debugger.

Debug level is determined by the Device Lifecycle Management (DLM) state of the product.

See Figure 2.1 for debugger accessible regions.

Table 2.4 shows the CPU debug function and conditions.

Table 2.4 CPU debug function and conditions (1 of 2)

Condition			Permitted debug function

Table 2.3 SNS和SNSC边界列表

Boundary	代码闪存	数据闪存	SRAM
S/NS	32 KB	1 KB	8 KB
S/NSC	1 KB	—	1 KB

每个区域都有其专用ID，如下所示。有关详细信息，请参阅第2.13节。参考。

IREGION (IDAU region number)	Description
0x0D	Non-secure SRAM
0x0E	Non-secure callable SRAM

2.5 调试功能

2.5.1 调试器连接

在本单片机中，调试功能分为三个层次，DBG0、DBG1、DBG2。在DBG0，没有调试功能可用。
DBG1级别在ARMv-8中定义为非安全调试，调试器只能访问已定义的非安全调试可访问区域。DBG2级别在ARMv-8中定义为安全调试，在此级别，启用了非安全和安全调试功能，并且可以从调试器访问。

调试级别由产品的设备生命周期管理(DLM)状态确定。

有关调试器可访问区域，请参见图2.1。

表2.4显示了CPU调试功能和条件。

Table 2.4 CPU调试功能和条件(1of2)

Condition			允许的调试功能

Connected	LCK_BOOT	DBG0	Debugger connection is not available
Connected	RMA_REQ	DBG0	Debugger connection is not available

Note 1. OCD connect is determined by the CDBGPWRUPREQ bit output in the SWJ-DP register. The bit can only be written by the OCD. However, the level of the bit can be confirmed by reading the DBGSTR.CDBGPWRUPREQ bit.

2.5.2 Emulator Connection

Renesas provides the emulator which supports both debugging using SWD or JTAG communication and serial programming using SCI communication. This emulator makes it easy to switch between debug-ging and serial programming.

Table 2.5 shows the pinout of 10 pin or 20 pin socket pinouts when using this emulator. The pinout of SWD and JTAG is ARM standard, and MD, TXD, RXD pins are added for the serial programming using SCI communication.

The serial programming interface must be used to program the TrustZone IDAU boundary register settings.

It is recommended to connect P300/SWCLK/TCK and P201/MD pins using wired OR circuit on the board to use both debugging and serial programming.

Table 2.5 Pin assign for emulator

2.5.3 Self-Hosted Debug Function

As described in section 2.6.6. CPUDSAR : CPU Debug Security Attribution Register, at the initial setting access from the CPU in non-secure state to CoreSight debug components is protected, that is, the non-secure access to Coresight debug components from the self-hosted debugger is not allowed when the debug level is DBG2 at the initial setting. Therfore, you must set CPUDSAR.CPUDSA0 to 1 to enable the full self-hosted debug function.

Table 2.4 CPU调试功能和条件(2of2)

Condition			允许的调试功能

Connected	LCK_BOOT	DBG0	调试器连接不可用
Connected	RMA_REQ	DBG0	调试器连接不可用
Connected	RMA_ACK	DBG2	所有调试功能均可用

注1.OCD连接由SWJ-DP寄存器中的CDBGPWUPREQ位输出决定。该位只能由OCD写入。
但是，可以通过读取DBGSTR.CDBGPWUPREQ位来确认该位的电平。

2.5.2 仿真器连接

瑞萨电子提供的仿真器支持使用SWD或JTAG通信进行调试和使用SCI通信进行串行编程。该仿真器可以轻松地在调试和串行编程之间切换。

表2.5显示了使用该仿真器时10针或20针插座的引脚排列。SWD和JTAG的管脚是ARM标准，并增加了MD、TXD、RXD引脚用于使用SCI通信的串行编程。

必须使用串行编程接口对TrustZoneIDAU边界寄存器设置进行编程。

建议使用板上的有线或电路连接P300SWCLKTCK和P201MD引脚，以同时使用调试和串行编程。

2.5.3 自托管调试功能

如第2.6.6节所述。CPUDSAR：CPUDebugSecurityAttributionRegister，在初始设置时从对CoreSight调试组件处于非安全状态的CPU受到保护，即当初始设置的调试级别为DBG2时，不允许自托管调试器对Coresight调试组件的非安全访问。因此，您必须将CPUDSAR.CPUDSA0设置为1以启用完全自托管调试功能。

Note: There is no restriction for the self-hosted debug function while the CPU is in the secure state.

2.5.4 Effect of Debug Function

The debug function effects inside and outside of CPU.

2.5.4.1 Low power mode

All CoreSight debug components can store the register settings even when the CPU enters Software Standby, Snooze or Deep Software Standby mode. However, AHB-AP cannot respond to On-Chip Debug (OCD) access in these low power modes. The OCD must wait for cancellation of the low power mode to access the CoreSight debug components. To request low power mode cancellation, the OCD can set the DBIRQ bit in the MCUCTRL register. For details, see section 2.6.5.2. MCUCTRL : MCU Control Register.

2.5.4.2 Reset

In OCD mode, some resets depend on the CPU status and the DBGSTOPCR register setting.

Table 2.6 Reset or interrupt and mode setting

Reset or interrupt name	Control in On-Chip Debug (OCD) mode	
	OCD break mode	OCD run mode
RES pin reset	Same as user mode	
Power-on reset	Same as user mode	
Independent watchdog timer reset/interrupt	Does not occur*1	Depends on DBGSTOPCR setting
Watchdog timer reset/interrupt	Does not occur*1	Depends on DBGSTOPCR setting
Voltage monitor 0 reset	Depends on DBGSTOPCR setting	
Voltage monitor 1 reset/interrupt	Depends on DBGSTOPCR setting

Note: In OCD break mode, the CPU is halted. In OCD run mode, the CPU is in OCD mode and the CPU is not halted.
Note 1. The IWDT and WDT always stop in this mode.

2.6 Programmers Model

2.6.1 Address Spaces

The MCU debug system includes two CoreSight Access Ports (AP):

- AHB-AP, which is connected to the CPU bus matrix and has the same access to the system address space as the CPU
- APB-AP, which has a dedicated address space (OCD address space) and is connected to the OCDREG registers.

Figure 2.3 shows a block diagram of the AP connection and address spaces.

Note: 当CPU处于安全状态时，自托管调试功能没有限制。

2.5.4 调试功能的效果

调试功能影响CPU内部和外部。

2.5.4.1 低功耗模式

即使CPU进入软件待机、贪睡或深度软件待机模式，所有CoreSight调试组件都可以存储寄存器设置。但是，AHB-AP在这些低功耗模式下无法响应片上调试(OCD)访问。OCD必须等待取消低功耗模式才能访问CoreSight调试组件。要请求取消低功耗模式，OCD可以设置MCUCTRL寄存器中的DBIRQ位。详见2.6.5.2节。MCUCTRL：MCU控制寄存器。

2.5.4.2 Reset

在OCD模式下，一些复位取决于CPU状态和DBGSTOPCR寄存器设置。

Table 2.6 复位或中断和模式设置

重置或中断名称	片上调试(OCD)模式下的控制	
	强迫症休息模式	强迫症运行模式

Note: 在OCD中断模式下，CPU停止。在OCD运行模式下，CPU处于OCD模式并且CPU不会停止。
注1.IWDT和WDT在此模式下始终停止。

2.6 程序员模型

2.6.1 地址空间

MCU调试系统包括两个CoreSight访问端口(AP)：

- AHB-AP，与CPU总线矩阵相连，与CPU具有相同的系统地址空间访问权限
- APB-AP，具有专用的地址空间（OCD地址空间）并连接到OCDREG寄存器。

图2.3显示了AP连接和地址空间的框图。

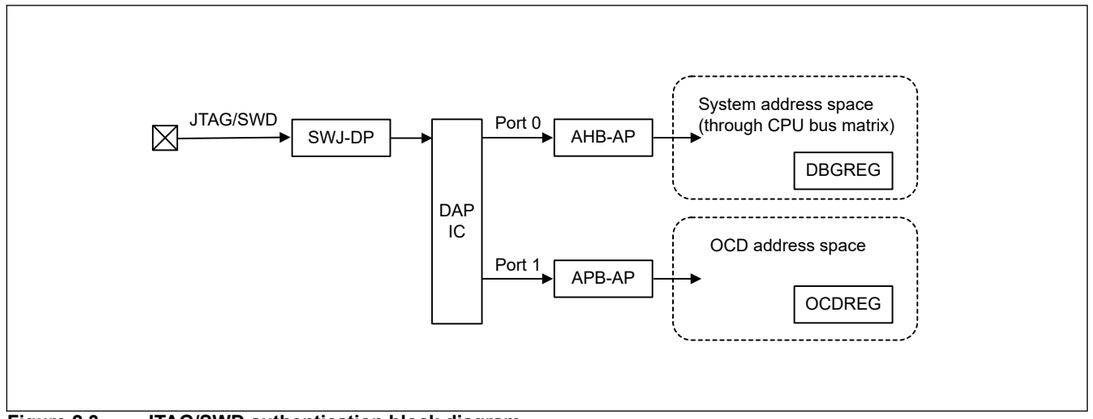

Figure 2.3 JTAG/SWD authentication block diagram

For debugging purposes, there are two register modules, DBGREG and OCDREG. DBGREG is located in the system address space and can be accessed from the OCD emulator, the CPU, and other bus masters in the MCU. OCDREG is located in the OCD address space and can only be accessed from the OCD tool. The CPU and other bus masters cannot access OCDREG.

2.6.2 Peripheral Address Map

In system address space, the Cortex-M33 core has a Private Peripheral Bus (PPB) which can be accessed only from CPU and OCD emulator. The PPB is expanded from the original implementation of the Cortex-M33 core for this MCU. Table 2.7 shows the address map of the MCU.

2.6.3 CoreSight ROM Table

The MCU contains two CoreSight ROM Tables, the processor and system ROM Tables. The Processor ROM Table contains entries which hold a list of debug components inside the processor. The System ROM Table contains entries of Processor ROM Table and others debug components outside the processor.

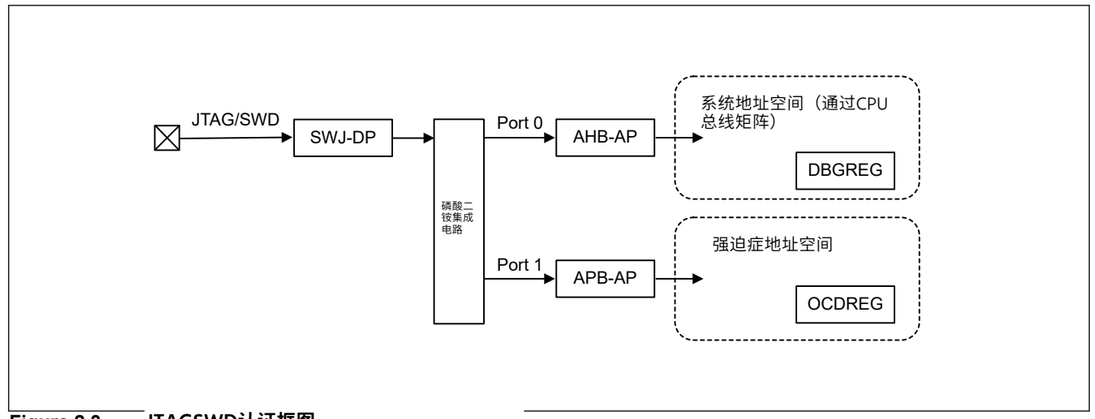

Figure 2.3 JTAGSWD认证框图

出于调试目的，有两个寄存器模块，DBGREG和OCDREG。DBGREG位于系统地址空间中，可以从OCD仿真器、CPU和MCU中的其他总线主控器访问。OCDREG位于OCD地址空间，只能从OCD工具访问。CPU和其他总线主机无法访问OCDREG。

2.6.2 外设地址映射

在系统地址空间中，Cortex-M33内核有一个专用外设总线(PPB)，只能从CPU和OCD仿真器访问。PPB是从该MCU的Cortex-M33内核的原始实现扩展而来的。表2.7显示了MCU的地址映射。

2.6.5.3 OCDREG CoreSight component registers

The OCDREG module provides the CoreSight component registers defined in the Arm CoreSight architecture.

0	CPUDSA0	CPU Debug Security Attribution 0 0: Secure 1: Non-secure	R/W
31:1	—	These bits are read as 1. The write value should be 1.	R/W

Note: Only secure access can write to this register. Both secure access and non-secure read access are allowed. Non-secure write access is denied, and no TrustZone access error is generated.

Note: This register is write-protected by PRCR register.

When Debug level of the MCU is DBG2, by guarding entire EPPB bus, the non-secure access from CPU to debug related components is completely controlled by the current value of the CPUDSA0 bit. Since this bit is modifiable only when CPU is in secure state, user must be aware of the CPUDSAR register before using Coresight debug components.

CPUDSA0 bit (CPU Debug Security Attribution 0)

Security attributes of register for accessing the debug component of the CPU.

0: Debug component can only be accessed with secure access.

1: There is no restriction on accessing the debug component.

2.6.7 Processing on Error response generated by CPU access

In addition to the specific-error detection specification of the Arm Cortex-M33 processor, this MCU also provides additional error information which is described in section 14, Buses.

This section describes how to handle the additional error information with no conflict to that of the Arm Cortex-M33 processor.

Table 2.15 shows error detection modules, which are also described in section 14, Buses. These error detection modules not only provide error information on the bus module, but also notify the processor to trigger the exception handler.

Table 2.15

	NMI/RESET request	Interrupt	Bus error status register	Error address register Error RW register
Slave TZF	NMISR.TZFST	Bus Fault*1 (Hard Fault)	BUS.BUSnERRSTAT.STERRSTAT	BUS.BTZFnERRADD BUS.BTZFnERRRW

Illegal address access error	—	Bus Fault	BUS.BUSnERRSTAT.ILERRSTAT	BUS.BUSnERRADD BUS.BUSnERRRW

Note 1. A Bus Fault can be treated as HardFault. *ARM® Cortex®-M33 Device Generic User Guide* in the References section 2.13. References

To prevent unexpected operation, when handling the exception, additional operation should be added into exception routing.

BusFault when occurred by error detected as shown in Table 2.15:

2.6.6 CPUDSAR:CPU调试安全属性寄存器

Base address: CPSCU = 0x4000_8000

Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CPUDSA0
重置后的值:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0

0	CPUDSA0	CPU调试安全属性0 0: Secure 1: Non-secure	R/W
31:1	—	这些位被读取为1。写入值应为1。	R/W

Note: 只有安全访问才能写入该寄存器。允许安全访问和非安全读取访问。拒绝非安全写入访问，并且不会生成TrustZone访问错误。

Note: 该寄存器由PRCR寄存器写保护。

当MCU的Debug级别为DBG2时，通过保护整个EPPB总线，CPU对调试相关组件的非安全访问完全由CPUDSA0位的当前值控制。由于该位仅在CPU处于安全状态时才可修改，因此用户在使用Coresight调试组件之前必须了解CPUDSAR寄存器。

CPUDSA0位（CPU调试安全属性0）

用于访问CPU调试组件的寄存器的安全属性。

0：只能通过安全访问访问调试组件。

1：对调试组件的访问没有限制。

2.6.7 CPU访问产生的错误响应的处理

除了ArmCortex-M33处理器的特定错误检测规范外，此MCU还提供第14节“总线”中描述的其他错误信息。

本节介绍如何处理与ArmCortex-M33处理器不冲突的附加错误信息。

表2.15显示了错误检测模块，这些模块也在第14节“总线”中进行了描述。这些错误检测模块不仅提供总线模块上的错误信息，还通知处理器触发异常处理程序。

Table 2.15

Slave TZF	NMISR.TZFST	总线故障*1 (Hard Fault)	BUS.BUSnERRSTAT.STERRSTAT	BUS.BTZFnERRADD BUS.BTZFnERRRW
从站总线错误	—	总线故障	BUS.BUSnERRSTAT.SLERRSTAT	BUS.BUSnERRADD BUS.BUSnERRRW
非法地址访问错误	—	总线故障	BUS.BUSnERRSTAT.ILERRSTAT	BUS.BUSnERRADD BUS.BUSnERRRW

注1.总线故障可被视为硬故障。参考2.13节中的ARM®Cortex®-M33设备通用用户指南。References

为防止意外操作，在处理异常时，应在异常路由中增加额外的操作。

检测到错误时发生的BusFault，如表2.15所示：

- See section 14, Buses for the error information in the corresponding register
- Clear the data in cache for the error address
- Clear the Error Status register in the bus module
- Service exception handling with Arm-guided operation

For a Bus Fault that is not detected in the Renesas-specific error detection module (occurred inside the Arm Cortex-M33 core), see the *ARM® Cortex®-M33 Device Generic User Guide* to handle this case.

In the system bus specification, there is a specific case for Slave TrustZone Filter, that is, if an error is selected to generate an NMI, then before the processor handles the Bus Fault exception, NMI with higher priority takes the exception first. Therefore, use the BusFault handler and not NMI handler to handle this error. In other words, the NMI status should be cleared but the error status bit should not be cleared to ensure that BusFault captures all the error information.

Figure 2.4 and Figure 2.5 show the recommended flows for NMI handler and BusFault handler for the errors described in Table 2.15.

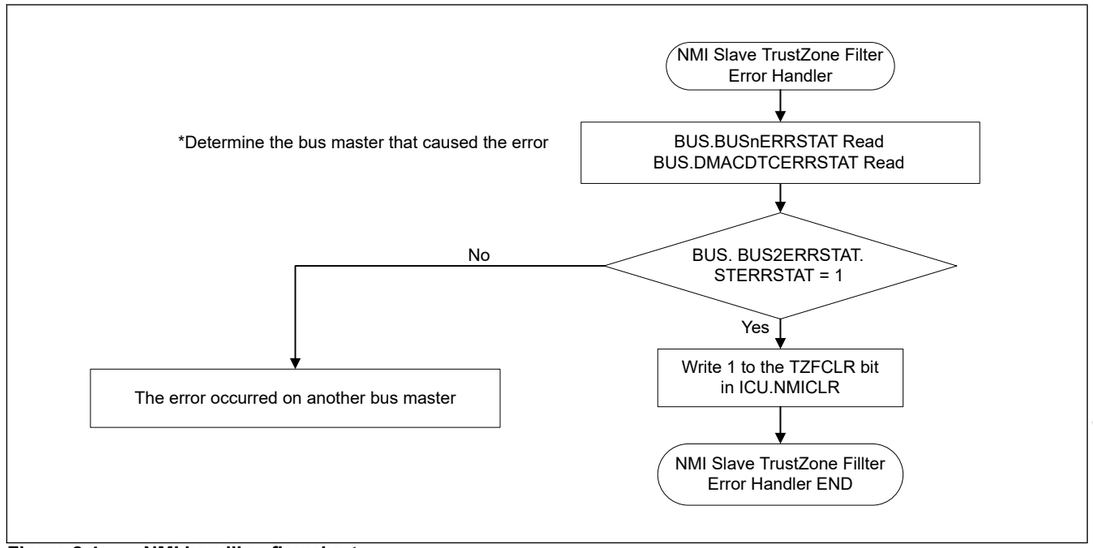

Figure 2.4 NMI handling flowchart

●相应寄存器中的错误信息见第14节，总线

●清除缓存中错误地址的数据

●清除总线模块中的错误状态寄存器

●服务异常处理，手臂引导操作

对于未在Renesas特定错误检测模块中检测到的总线故障（发生在ArmCortex-M33内核中），请参阅ARM®Cortex®-M33DeviceGenericUserGuide来处理这种情况。

在系统总线规范中，SlaveTrustZoneFilter有一个具体的案例，即如果选择了错误产生NMI，那么在处理器处理BusFault异常之前，优先级较高的NMI先处理该异常。因此，使用BusFault处理程序而不是NMI处理程序来处理此错误。换言之，应清除NMI状态但不应清除错误状态位，以确保BusFault捕获所有错误信息。

图2.4和图2.5显示了NMI处理程序和BusFault处理程序的推荐流程，用于处理中描述的错误

2.9 Break Point Unit

The MCU has Break Point Unit. See BreakPoint unit chapter of reference 1. in section 2.13. References for details about register description of this module.

2.10 CoreSight Time Stamp Generator

A CoreSight Time Stamp Generator provides a CPU clock-based timestamp to ITM and ETM.The timestamp is generated by a 64-bit counter. See reference 4. in section 2.13. References for details.

2.11 SysTick Timer

The MCU has SysTick timer that provides two 24-bit down counters, non-secure and secure counters. The timer can select SysTick timer clock (SYSTICCLK) or System clock (ICLK).

See section 8, Clock Generation Circuit and reference 1. in section 2.13. References for details.

Note: SysTick timer counter operation is enabled by signal synchronized with CPU clock. Therefore, the counter might not operate correctly if the CPU clock is slower than the SysTick timer clock. In other words, clock setting must satisfy the following: CPU clock ≥ Systick clock (LOCO: 32.768 kHz).

2.12 OCD Emulator Connection

In this product, the MCU confirms the access permission for Non-secure debug and Non-secure chip resources by checking Debug level is DBG1 or higher. For full access permission for debug and chip resources, Secure debug level DBG2 is required.

Figure 2.8 shows a block diagram of SWD authentication mechanism.

CoreSight时间戳生成器为ITM和ETM提供基于CPU时钟的时间戳。时间戳由64位计数器生成。请参见第2.13节中的参考4。详情参考。

2.11 SysTick Timer

MCU具有SysTick定时器，提供两个24位递减计数器、非安全计数器和安全计数器。定时器可以选择SysTick定时器时钟(SYSTICCLK)或系统时钟(ICLK)。

请参阅第8节，时钟生成电路和第2.13节中的参考1。详情参考。

Note: SysTick定时器计数器操作由与CPU时钟同步的信号启用。因此，如果CPU时钟比SysTick定时器时钟慢，计数器可能无法正确运行。换言之，时钟设置必须满足以下条件：CPU时钟≥Systick时钟（LOCO：32.768kHz）。

2.12 OCD模拟器连接

本产品中，MCU通过勾选确认非安全调试和非安全芯片资源的访问权限
调试级别为DBG1或更高。对于调试和芯片资源的完全访问权限，需要安全调试级别DBG2。

图2.8显示了SWD认证机制的框图。

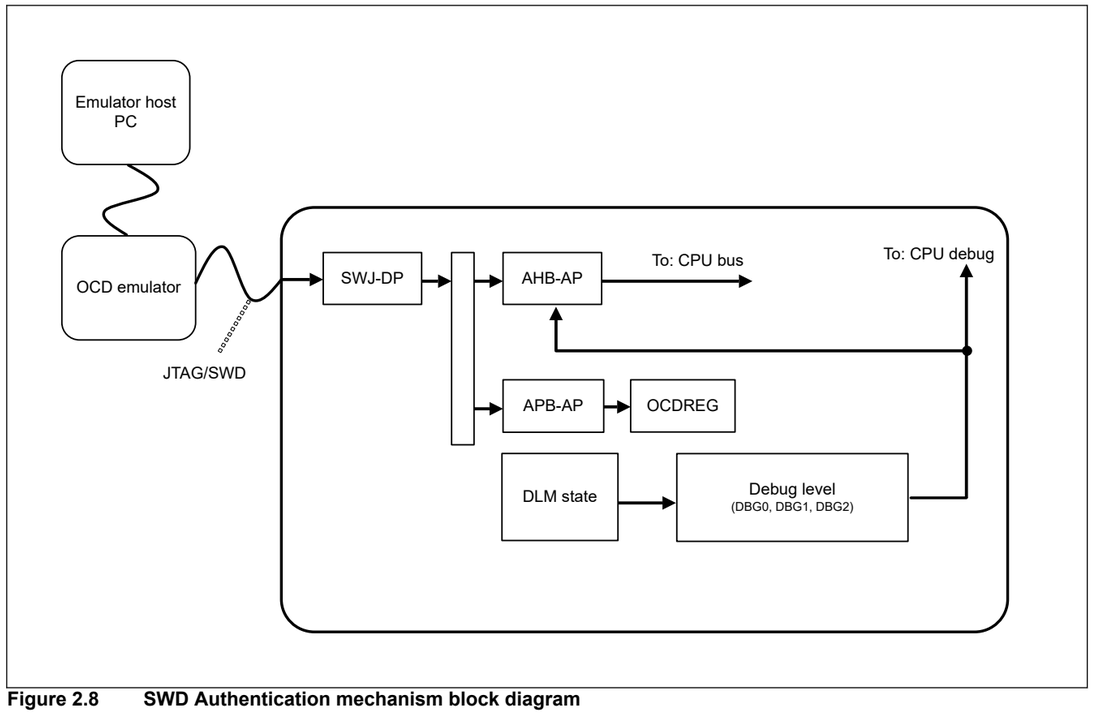

Figure 2.8 SWD Authentication mechanism block diagram

Three levels of debug capability are available, DBG0, DBG1, and DBG2, which correspond to the Device Level Management (DLM) states. When debug level is DBG0, access to debug components and system bus from OCD emulator is not permitted. When debug level is DBG1 or DBG2, the corresponding non-secure or secure debug components and system bus can be accessed from the OCD emulator. See Table 2.4 for more information about debug levels.

2.12.1 DBGEN

After the OCD emulator gets access permission, the OCD emulator must set the DBGEN bit in the System Control OCD Control Register (SYOCDCR). In addition, the OCD emulator must clear the DBGEN bit before disconnecting it. See section 10, Low Power Modes for details.

2.12.2 Restrictions on Connecting an OCD emulator

This section describes the restrictions on emulator access.

2.12.2.1 Starting connection while in low power mode

When starting a JTAG/SWD connection from an OCD emulator, the MCU must be in Normal or Sleep mode. If the MCU is in Software Standby, Snooze, or Deep Software Standby mode, the OCD emulator can cause the MCU to hang.

2.12.2.2 Changing low power mode while in OCD mode

When the MCU is in OCD mode, the low power mode can be changed. However, system bus access from AHB-AP is prohibited in Software Standby, Snooze or Deep Software Standby mode. Only SWJ-DP, APB-AP, and OCDREG can be accessed from the OCD emulator in these modes. Table 2.18 shows the restrictions.

Table 2.18 Restrictions by mode (1 of 2)

Active mode	Start OCD emulator connection	Change low power mode	Access AHB-AP and system bus	Access APB-AP and OCDREG
Normal	Yes	Yes	Yes	Yes

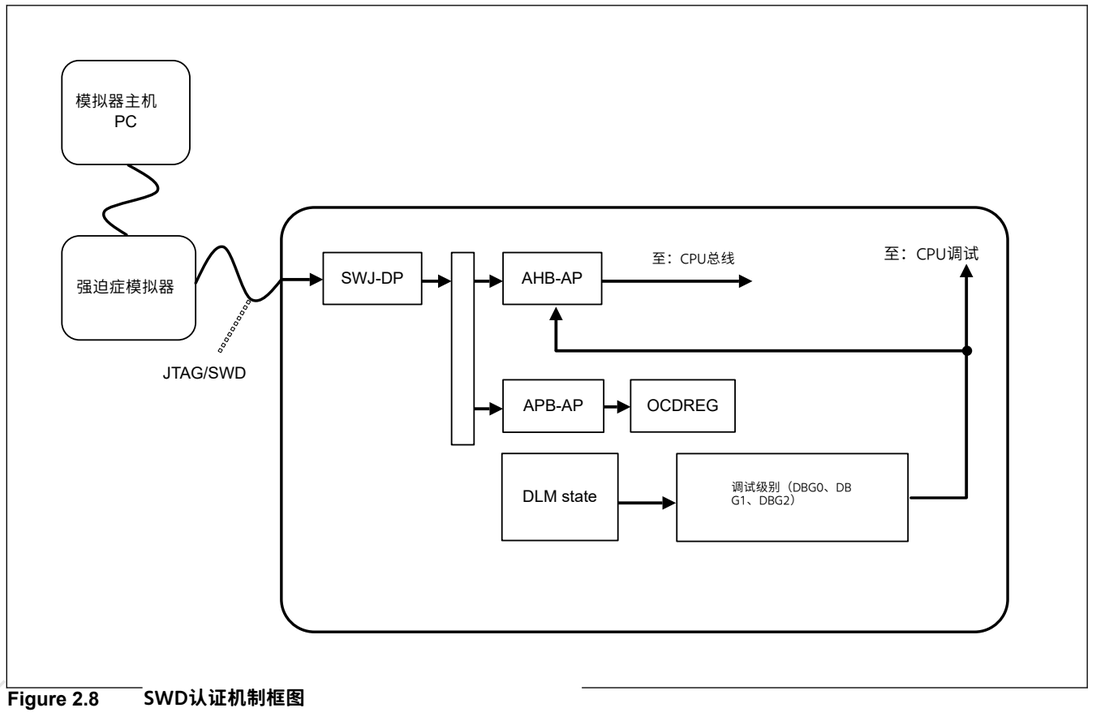

Figure 2.8 SWD认证机制框图

提供三个级别的调试能力，DBG0、DBG1和DBG2，它们对应于DeviceLevel管理(DLM)状态。当调试级别为DBG0时，不允许从OCD仿真器访问调试组件和系统总线。当调试级别为DBG1或DBG2时，可以从OCD仿真器访问相应的非安全或安全调试组件和系统总线。有关调试级别的更多信息，请参见表2.4。

2.12.1 DBGEN

OCD模拟器获得访问权限后，OCD模拟器必须设置SystemControlOCD中的DBGEN位控制寄存器(SYOCDCR)。此外，OCD仿真器必须在断开连接之前清除DBGEN位。有关详细信息，请参见第10节，低功耗模式。

2.12.2 连接强迫症模拟器的限制

本节介绍对仿真器访问的限制。

2.12.2.1 在低功耗模式下开始连接

从OCD仿真器启动JTAGSWD连接时，MCU必须处于正常或睡眠模式。如果MCU处于软件待机、贪睡或深度软件待机模式，OCD仿真器可能会导致MCU挂起。

2.12.2.2 在OCD模式下更改低功耗模式

当MCU处于OCD模式时，可以更改低功耗模式。但是，在软件待机、贪睡或深度软件待机模式下，禁止从AHB-AP访问系统总线。在这些模式下，只能从OCD仿真器访问SWJ-DP、APB-AP和OCDREG。表2.18显示了这些限制。

Table 2.18 模式限制(1of2)

主动模式	启动强迫症模拟器连接	更改低功耗模式	访问AHB-AP和系统总线	访问APB-AP和OCDREG
Normal	Yes	Yes	Yes	Yes

Table 2.18 Restrictions by mode (2 of 2)

Active mode	Start OCD emulator connection	Change low power mode	Access AHB-AP and system bus	Access APB-AP and OCDREG
Sleep	Yes	Yes	Yes	Yes
Software Standby	No	Yes	No	Yes
Snooze	No	Yes	No	Yes
Deep Software Standby	No	Yes	No	Yes

If system bus access is required in Software Standby, Snooze, or Deep Software Standby mode, set the MCUCTRL.DBIRQ bit in OCDREG to wake up the MCU from the low power modes. Simultaneously, by asserting the MCUCTRL.DBIRQ bit in OCDREG, the OCD emulator can wake up the MCU without starting CPU execution by using a CPU break.

2.12.2.3 Connecting sequence and JTAG/SWD authentication

1. Connect the OCD debugger to the MCU through the JTAG or SWD interface.
2. Set up SWJ-DP to access DAP bus.
   In the setup, the OCD emulator must assert CDBGPWRUPREQ in the SWJDP.
   Control Status Register, and then wait until CSDBGPWRUPACK in the same register is asserted.
3. Set the APB-AP to access OCDREG. This APB-AP is connected to DAP bus port 1.
4. Set MCUCTRL.CPUWAIT = 1.
5. Confirm the debug capability of device by reading MCUSTAT:
   - If Debug function is prohibited, this device is not able to debug.
   - If Debug function is enabled and secure debug is not available, only non-secure debug is available.
   - If Debug function is enabled and secure debug is available, full debug functions are available.

   If Debug function is available, set debug-related register then clear MCUCTRL.CPUWAIT = 0.
6. Set up the AHB-AP to access the system address space. The AHB-AP is connected to DAP bus port 0.
7. Set SYOCDCR.DBGEN to 1.
8. Start accessing the CPU debug resources using the AHB-AP.

Note: Debug level is determined by the current DLM state of product.

Table 2.18 模式限制(2of2)

主动模式	启动强迫症模拟器连接	更改低功耗模式	访问AHB-AP和系统总线	访问APB-AP和OCDREG
Sleep	Yes	Yes	Yes	Yes
软件待机	No	Yes	No	Yes
Snooze	No	Yes	No	Yes
深度软件待机	No	Yes	No	Yes

如果在软件待机、贪睡或深度软件待机模式下需要系统总线访问，则设置OCDREG中的MCUCTRL.DBIRQ位以将MCU从低功耗模式中唤醒。同时，通过置位OCDREG中的MCUCTRL.DBIRQ位，OCD仿真器可以在不使用CPU中断启动CPU执行的情况下唤醒MCU。

2.12.2.3 连接顺序和JTAGSWD认证

1.通过JTAG或SWD接口将OCD调试器连接到MCU。

2.设置SWJ-DP访问DAP总线。
在设置中，OCD仿真器必须在SWJDP中声明CDBGPWRUPREQ。
控制状态寄存器，然后等待同一寄存器中的CSDBGPWRUPACK被断言。

3.将APB-AP设置为访问OCDREG。此APB-AP连接到DAP总线端口1。

4. Set MCUCTRL.CPUWAIT = 1.

5.通过读取MCUSTAT确认设备的调试能力：
- ●如果Debug功能被禁止，则本设备无法调试。
- ●如果启用了Debug功能且没有安全调试，则只能进行非安全调试。
- ●如果启用了Debug功能并且可以使用安全调试，则可以使用完整的调试功能。

如果Debug功能可用，设置调试相关寄存器然后清除MCUCTRL.CPUWAIT=0。

6.设置AHB-AP访问系统地址空间。AHB-AP连接到DAP总线端口0。

7.将SOOCDCR.DBGEN设置为1。

8.开始使用AHB-AP访问CPU调试资源。

Note: 调试级别由产品的当前DLM状态决定。

3. Operating Modes

3.1 Overview

Table 3.1 shows the selection of operating modes by the mode-setting pin. For details, see section 3.2. Details of Operating Modes. Operation starts with the on-chip flash memory enabled, regardless of the mode in which operation started.

Table 3.1 Selection of operating modes by the mode-setting pin

Mode-setting pin (MD)	Operating mode	On-chip Flash
1	Single-chip mode	Enable
0	SCI / USB boot mode	Enable

3.2 Details of Operating Modes

3.2.1 Single-Chip Mode

In single-chip mode, all I/O pins are available for use as input or output port, inputs or outputs for peripheral functions, or as interrupt inputs.

When a reset is released while the MD pin is high, the MCU starts in single-chip mode and the on-chip flash is enabled.

3.2.2 SCI Boot Mode

In this mode, the on-chip flash memory programming routine (SCI boot program), stored in the boot area within the MCU, is used. The on-chip flash, including code flash memory and data flash memory, can be modified from outside the MCU by using a universal asynchronous receiver/transmitter (UART) SCI. For details, see section 40, Flash Memory. The MCU starts in SCI boot mode if the MD pin is held low on release from the reset state.

3.2.3 USB Boot Mode

In this mode, the on-chip flash memory programming routine (USB boot program), stored in the boot area within the MCU, is used. The on-chip flash, including code flash memory and data flash memory, can be modified from outside the MCU by using USB. For details, see section 40, Flash Memory. The MCU starts in USB boot mode if the MD pin is held low on release from the reset state.

3.3 Operating Modes Transitions

3.3.1 Operating Mode Transitions as Determined by the Mode-Setting Pin

Figure 3.1 shows operating mode transitions determined by the MD pin settings.

3. 操作模式

3.1 Overview

表3.1显示了通过模式设置引脚选择的工作模式。有关详细信息，请参阅第3.2节。经营详情模式。无论操作以何种模式开始，操作都会从启用片上闪存开始。

Table 3.1 通过模式设置引脚选择工作模式

Mode-setting pin (MD)	操作模式	On-chip Flash

3.2.2 SCI启动模式

在这种模式下，使用存储在MCU引导区域中的片上闪存编程例程（SCI引导程序）。片上闪存，包括代码闪存和数据闪存，可以通过使用通用异步接收发送器(UART)SCI从MCU外部进行修改。有关详细信息，请参阅第40节，闪存。如果MD引脚在从复位状态释放时保持低电平，则MCU以SCI启动模式启动。

3.2.3 USB启动模式

在这种模式下，使用存储在MCU引导区域中的片上闪存编程例程（USB引导程序）。片上闪存，包括代码闪存和数据闪存，可以通过USB从MCU外部进行修改。有关详细信息，请参阅第40节，闪存。如果MD引脚在从复位状态释放时保持低电平，则MCU在USB引导模式下启动。

Note: ✓ : Initialized
— : Not initialized
Note 1. For the initial value of each register, see section 8, Clock Generation Circuit.
Note 2. The RTC has a software reset. Some control bits are not initialized by all types of resets. For details on the target bits, see section 23, Realtime Clock (RTC).
Note 3. Depends on the setting of DPSBYCR.IOKEEP.
Note 4. Some control bits are not initialized by all types of resets. For details on the target bits, see section 14, Buses
Note 5. Reset does not occur while the debugger is connected (DBGSTR.CDBGPWRUPREQ = 1) even if On-chip debugger is disabled (SYOCDCR.DBGEN = 0).
Note 6. Reset does not occur while On-chip debugger is enabled (SYOCDCR.DBGEN = 1).

The RTC is not initialized by any reset source. SOSC and LOCO can be selected as the clock sources of the RTC.

Table 5.4 and Table 5.5 show the states of SOSC and LOCO when a reset occurs.

注1.关于各寄存器的初始值，请参阅第8节"时钟生成电路"。
注2.RTC具有软件复位功能。某些控制位并非由所有类型的复位初始化。有关目标位的详细信息，请参见第23节，实时时钟(RTC)。

注3.取决于DPSBYCR.IOKEEP的设置。
注4.并非所有类型的复位都会初始化一些控制位。有关目标位的详细信息，请参阅第14节，总线
注5.连接调试器(DBGSTR.CDBGPWRUPREQ=1)时不会发生复位，即使禁用片上调试器(SYOCDCR.DBGEN=0)。

注6.启用片上调试器(SYOCDCR.DBGEN=1)时不会发生复位。

RTC不会被任何复位源初始化。可选择SOSC和LOCO作为RTC的时钟源。

表5.4和表5.5显示了复位发生时SOSC和LOCO的状态。

		POR	Other

Table 5.5 States of LOCO when a reset occurs

		Reset source	
		POR, LVD0, LVD1, LVD2, Deep Software Standby (DEEPCUT[0] = 1)	Other
LOCO	Enable or disable	Initialized to enable	
	Oscillation accuracy*1	Initialized to accuracy before trimming by power-on (accuracy: ± 10%)	Continue with the accuracy that was trimmed by LOCOUTCR

Note 1. The LOCO User Trimming Control Register (LOCOUTCR) is reset by POR, LVD0, LVD1, LVD2, and Deep Software Standby (DEEPCUT[0] = 1) resets, returning the LOCO to the default oscillation accuracy. This can affect RTC accuracy if the RTC uses the LOCO (with a user trimming value in LOCOUTCR) as the RTC source clock. To restore the pre-reset LOCO oscillation accuracy, reload the required trimming value into LOCOUTCR after any of these resets.

When a reset is released, reset exception handling starts.

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. The value after reset depends on the reset source.
Note 2. Only 1 can be written to set the flag.

RSTSR2 determines whether a power-on reset caused the reset processing (cold start) or a reset signal input during operation caused the reset processing (warm start).

CWSF flag (Cold/Warm Start Determination Flag)

The CWSF flag indicates the type of reset processing, either cold start or warm start. The determines whether a power-on reset caused the reset processing (cold start) or a reset signal input during operation caused the reset processing (warm start). CWSF flag is initialized by a power-on reset. It is not initialized by a reset signal generated by the RES pin.

[Setting condition]

- When 1 is written by software. Writing 0 to CWSF does not set it to 0.

[Clearing condition]

- When a reset listed in Table 5.2 occurs.

5.3 Operation

5.3.1 RES Pin Reset

The RES pin generates this reset. When the RES pin is driven low, all the processing in progress is aborted and the MCU enters a reset state. To successfully reset the MCU, the RES pin must be held low for the power supply stabilization time specified at power-on.

When the RES pin is driven high from low, the internal reset is canceled after the post-RES cancellation wait time (t_{RESWT}) elapses. The CPU then starts the reset exception handling.

For details, see section 43, Electrical Characteristics.

5.3.2 Power-On Reset

The power-on reset (POR) is an internal reset generated by the power-on reset circuit. A power-on reset is generated under the following conditions.

1. If the RES pin is in a high level state when power is supplied
2. If the RES pin is in a high level state when VCC is below V_{POR}

After VCC exceeds V_{POR} and the specified power-on reset time (t_{POR}) elapses, the CPU starts the reset exception handling. The power-on reset time is a stabilization period of the external power supply and the MCU circuit.

注2.只能写入1来设置标志。

RSTSR2判断是上电复位导致复位处理（冷启动）还是操作期间输入的复位信号导致复位处理（热启动）。

CWSF标志（冷暖启动确定标志）

CWSF标志指示复位处理的类型，冷启动或热启动。确定是上电复位导致复位处理（冷启动）还是操作期间输入的复位信号导致复位处理（热启动）。CWSF标志由上电复位初始化。它不会被RES引脚产生的复位信号初始化。

[Setting condition]

●软件写入1时。将0写入CWSF不会将其设置为0。

[Clearing condition]

●发生表5.2中列出的复位时。

5.3 Operation

5.3.1 RES引脚复位

RES引脚产生此复位。当RES引脚被驱动为低电平时，所有正在进行的处理都被中止，MCU进入复位状态。要成功复位MCU，RES引脚必须在上电时指定的电源稳定时间内保持低电平。

当RES引脚从低电平驱动为高电平时，内部复位会在RES取消后等待时间(tRESWT)过去后取消。CPU然后开始复位异常处理。

有关详细信息，请参阅第43节，电气特性。

5.3.2 Power-On Reset

上电复位（POR）是由上电复位电路产生的内部复位。在以下条件下会产生上电复位。

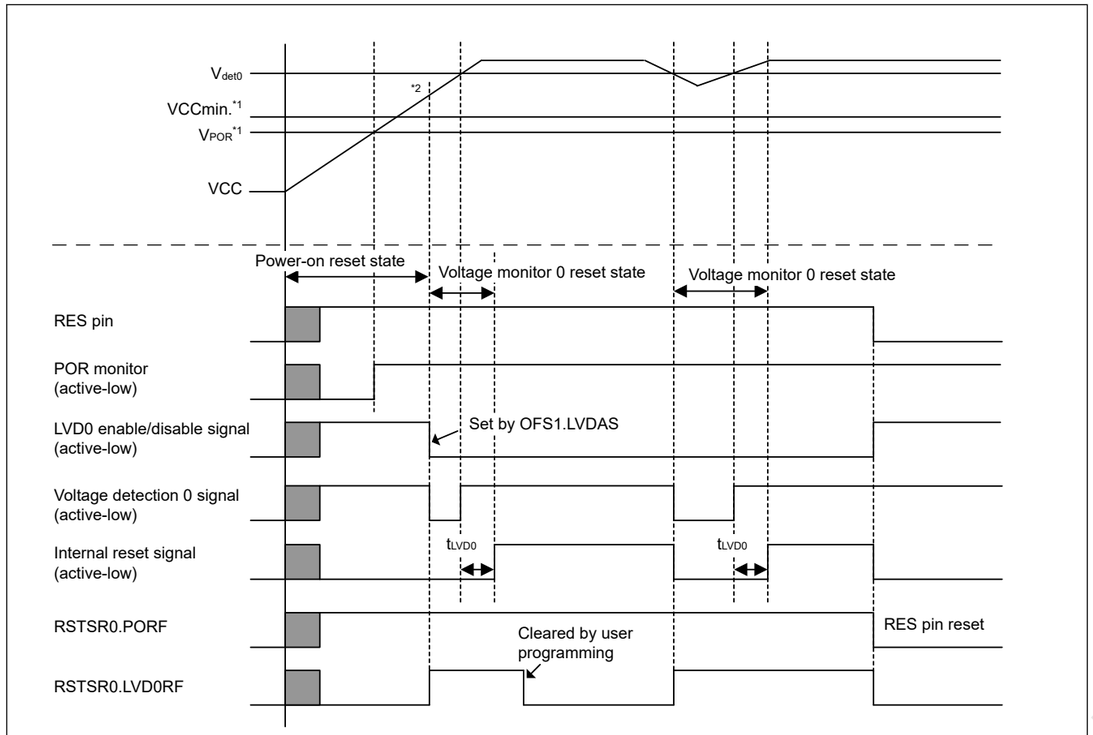
1.如果RES引脚在供电时处于高电平状态

2.如果VCC低于VPOR时RES管脚处于高电平状态

在VCC超过VPOR并且经过指定的上电复位时间(tPOR)后，CPU开始复位异常处理。
上电复位时间是外部电源和MCU电路的稳定期。

After a power-on reset is generated, the PORF flag in the RSTSR0 is set to 1. The PORF flag is initialized by the RES pin reset. When VCC falls below V_{POR}, a power-on reset state is occurred.

Figure 5.1 shows example of operations during a power-on reset.



Note: For details on the electrical characteristics, see section 43, Electrical Characteristics.
Note 1. V_{POR} shows a power-on reset detection level, and VCCmin shows the minimum guaranteed voltage of MCU.
Note 2. At power-on, VCC should rise to the minimum guaranteed voltage before the power-on reset is released.

Figure 5.1 Example of operations during a power-on reset

5.3.3 Voltage Monitor Reset

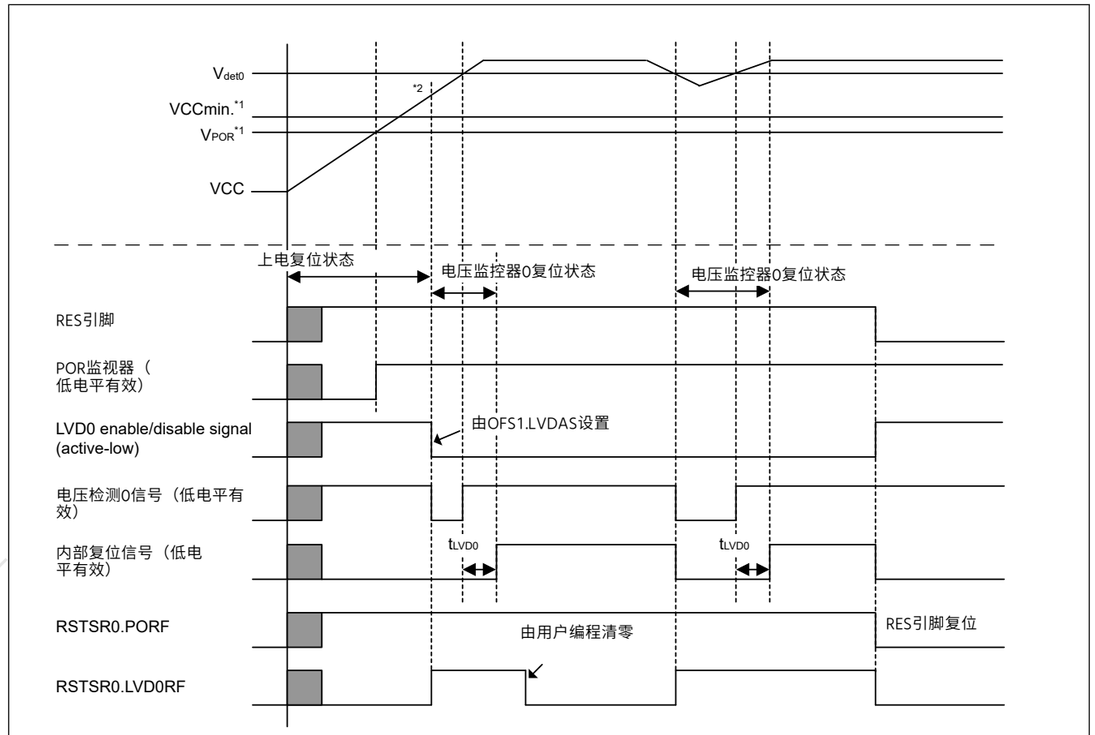
The voltage monitor i (i = 0, 1, 2) reset is an internal reset generated by the voltage monitor i circuit. If the Voltage Detection 0 Circuit Start (LVDAS) bit in the Option Function Select Register 1 (OFS1) is 0 (voltage monitor 0 reset is enabled after a reset) and VCC falls below V_{det0}, the RSTSR0.LVD0RF flag becomes 1 and the voltage detection circuit generates voltage monitor 0 reset. Clear the OFS1.LVDAS bit to 0 if the voltage monitor 0 reset is to be used. After VCC exceeds V_{det0} and the voltage monitor 0 reset time (t_{LVD0}) elapses, the internal reset is canceled and the CPU starts the reset exception handling.

When the Voltage Monitor 1 Interrupt/Reset Enable bit (RIE) is set to 1 (enabling generation of a reset or interrupt by the voltage detection circuit) and the Voltage Monitor 1 Circuit Mode Select bit (RI) is set to 1 (selecting generation of a reset in response to detection of a low voltage) in Voltage Monitor 1 Circuit Control Register 0 (LVD1CR0), the RSTSR0.LVD1RF flag is set to 1 and the voltage detection circuit generates a voltage monitor 1 reset if VCC falls to or below V_{det1}.

Likewise, when the Voltage Monitor 2 Interrupt/Reset Enable bit (RIE) is set to 1 (enabling generation of a reset or interrupt by the voltage detection circuit) and the Voltage Monitor 2 Circuit Mode Select bit (RI) is set to 1 (selecting generation of a reset in response to detection of a low voltage) in Voltage Monitor 2 Circuit Control Register 0 (LVD2CR0), the RSTSR0.LVD2RF flag is set to 1 and the voltage detection circuit generates a voltage monitor 2 reset if VCC falls to or below V_{det2}.

上电复位产生后，RSTSR0中的PORF标志设置为1。PORF标志由RES引脚复位初始化。当VCC低于VPOR时，会发生上电复位状态。

图5.1显示了上电复位期间的操作示例。



Note: 有关电气特性的详细信息，请参见第43节，电气特性。
注1.VPOR表示上电复位检测电平，VCCmin表示MCU的最低保证电压。
注2.上电时，VCC应上升到上电复位解除前的最低保证电压。

Figure 5.1 上电复位时的动作示例

5.3.3 电压监视器复位

电压监视器i(i=0 1 2)复位是由电压监视器i电路产生的内部复位。如果电压选项功能选择寄存器1(OFS1)中的检测0电路启动(LVDAS)位为0（复位后使能电压监视器0复位）且VCC低于Vdet0时，RSTSR0.LVD0RF标志变为1，电压检测电路生成电压监视器0复位。如果要使用电压监视器0复位，则将OFS1.LVDAS位清零。在VCC超过Vdet0并且经过电压监视器0复位时间(tLVD0)后，内部复位被取消，CPU开始复位异常处理。

当电压监控器1中断复位允许位(RIE)设置为1（允许电压检测电路产生复位或中断）并且电压监控器1电路模式选择位(RI)设置为1（选择产生电压监控器1电路控制寄存器0(LVD1CR0)中的低电压检测复位响应，RSTSR0.LVD1RF标志设置为1，如果VCC降至或低于V，电压检测电路产生电压监控器1复位det1。

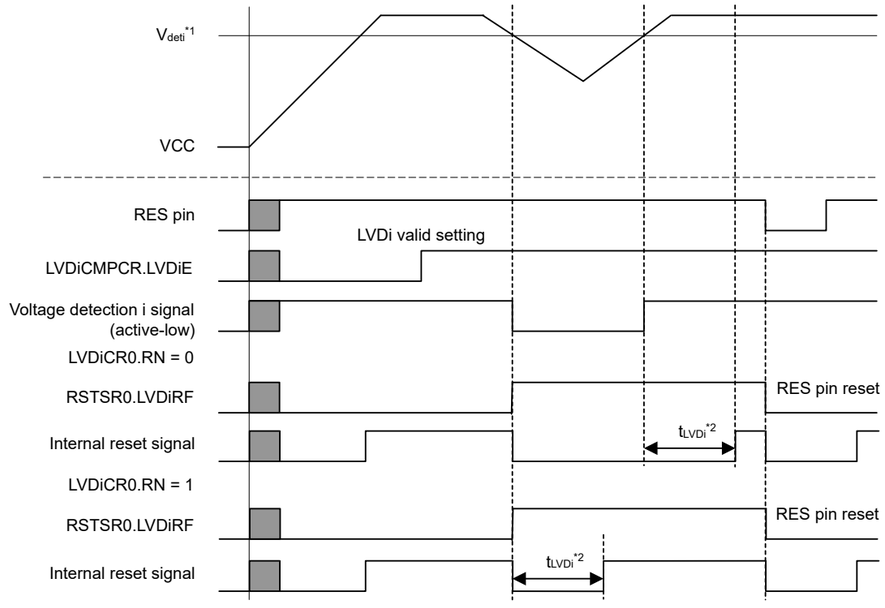
同样，当电压监视器2中断复位使能位(RIE)设置为1（允许电压检测电路产生复位或中断）并且电压监视器2电路模式选择位(RI)设置为1（选择在电压监控器2电路控制寄存器0(LVD2CR0)中响应检测到低电压产生复位），RSTSR0.LVD2RF标志设置为1，如果VCC下降到或电压检测电路产生电压监控器2复位低于Vdet2。

Similarly, timing for release from the voltage monitor 1 reset state is selectable with the Voltage Monitor 1 Reset Negate Select bit (RN) in the LVD1CR0. When the LVD1CR0.RN bit is 0 and VCC falls to or below V_{det1}, the CPU is released from the internal reset state and starts reset exception handling when the LVD1 reset time (t_{LVD1}) elapses after VCC rises above V_{det1}. When the LVD1CR0.RN bit is 1 and VCC falls to or below V_{det1}, the CPU is released from the internal reset state and starts reset exception handling when the LVD1 reset time (t_{LVD1}) elapses.

Likewise, timing for release from the voltage monitor 2 reset state is selectable by setting the Voltage Monitor 2 Reset Negate Select bit (RN) in the LDV2CR0 register.

Detection levels V_{det1} and V_{det2} can be changed in the Voltage Monitoring Comparator Control Register (LVD1CMPCR/ LVD2CMPCR).

Figure 5.2 shows example of operations during voltage monitor 1 and 2 resets. For details on the voltage monitor 1 reset and voltage monitor 2 reset, see section 7, Low Voltage Detection (LVD).



Note: For details on the electrical characteristics, see section 43, Electrical Characteristics.
Note 1. V_{deti} indicates the detection level of a voltage monitor 1 reset and a voltage monitor 2 reset (i = 1, 2).
Note 2. t_{LVDi} indicates the time for a voltage monitor 1 reset and a voltage monitor 2 reset (i = 1, 2).

Figure 5.2 Example of operations during voltage monitor 1 and voltage monitor 2 resets

5.3.4 Deep Software Standby Reset

This is an internal reset generated when deep software standby mode is canceled by an interrupt.

When a deep software standby mode cancelation source is generated, a deep software standby reset is generated. The deep software standby reset is canceled after t_{DSBY} (return time after deep software standby mode cancelation) has elapsed. At the same time, deep software standby mode is also canceled.

When t_{DSBYWT} (wait time after deep software standby mode cancelation) has elapsed after deep software standby mode has been canceled, the internal reset is canceled and the CPU starts the reset exception handling.

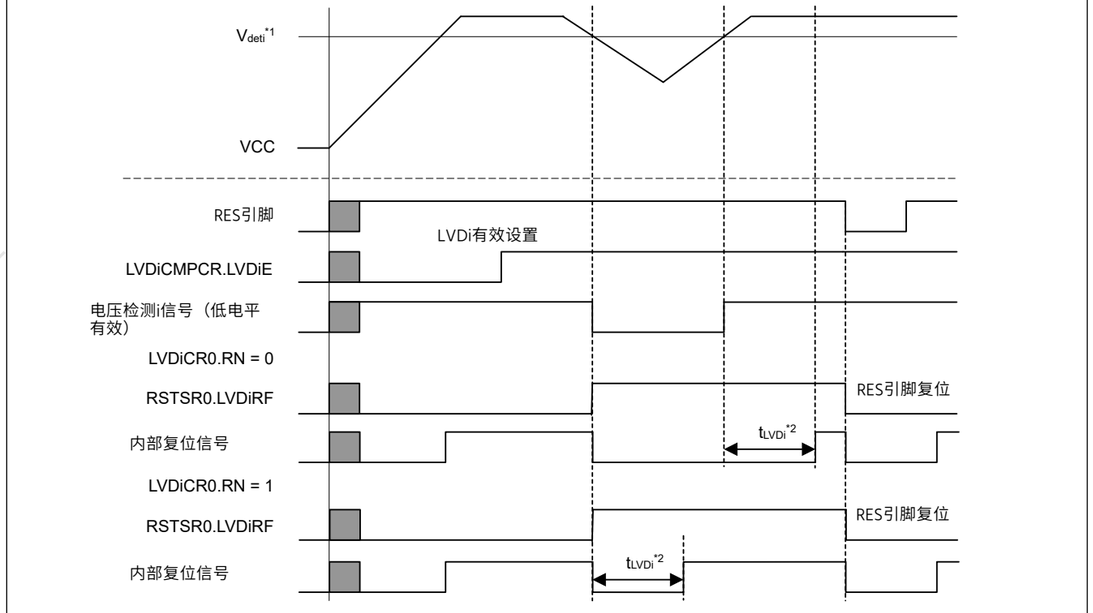
For details of the deep software standby reset, see section 10, Low Power Modes.

类似地，从电压监视器1复位状态释放的时间可以通过LVD1CR0中的电压监视器1复位否定选择位(RN)来选择。当LVD1CR0.RN位为0且VCC下降到或低于Vdet1时，CPU从内部复位状态中释放并在VCC上升到Vdet1以上后经过LVD1复位时间(tLVD1)时开始复位异常处理。当LVD1CR0.RN位为1且VCC下降到或低于Vdet1时，CPU会从内部复位状态中释放，并在LVD1复位时间(tLVD1)过去后开始复位异常处理。

同样，从电压监视器2复位状态释放的时间可通过设置电压监视器2复位来选择LDV2CR0寄存器中的取反选择位(RN)。

检测电平Vdet1和Vdet2可以在电压监控比较器控制寄存器(LVD1CMPCR LVD2CMPCR).

图5.2显示了电压监视器1和2复位期间的操作示例。有关电压监视器1复位和电压监视器2复位的详细信息，请参见第7节，低电压检测(LVD)。



Note: 有关电气特性的详细信息，请参见第43节，电气特性。
注1.Vdeti表示电压监视器1复位和电压监视器2复位(i=1 2)的检测电平。
注2.tLVDi表示电压监视器1复位和电压监视器2复位(i=1 2)的时间。

Figure 5.2 电压监控器1和电压监控器2复位期间的操作示例

5.3.4 深度软件待机复位

这是当深度软件待机模式被中断取消时产生的内部复位。

当产生深度软件待机模式取消源时，将产生深度软件待机复位。在经过tDSBY（深度软件待机模式取消后的返回时间）后，深度软件待机复位被取消。同时，深度软件待机模式也被取消。

在深度软件待机模式取消后经过tDSBYWT（深度软件待机模式取消后的等待时间）时，内部复位被取消，CPU开始复位异常处理。

有关深度软件待机复位的详细信息，请参见第10节，低功耗模式。

5.3.5 Independent Watchdog Timer Reset

The independent watchdog timer reset is an internal reset generated from the Independent Watchdog Timer (IWDT). Output of the reset from the IWDT can be selected in the Option Function Select Register 0 (OFS0).

When output of the independent watchdog timer reset is selected, the reset is generated if the IWDT underflows, or if data is written when refresh operation is disabled. When the internal reset time (t_{RESW2}) elapses after the independent watchdog timer reset is generated, the internal reset is canceled and the CPU starts the reset exception handling.

For details on the independent watchdog timer reset, see section 25, Independent Watchdog Timer (IWDT).

5.3.6 Watchdog Timer Reset

The watchdog timer reset is an internal reset generated from the Watchdog Timer (WDT). Output of the reset from the WDT can be selected in the WDT Reset Control Register (WDTRCR) or Option Function Select register 0 (OFS0).

When output of the watchdog timer reset is selected, a watchdog timer reset is generated if the WDT underflows, or if data is written when refresh operation is disabled. When the internal reset time (t_{RESW2}) elapses after the watchdog timer reset is generated, the internal reset is canceled and the CPU starts the reset exception handling.

For details on the watchdog timer reset, see section 24, Watchdog Timer (WDT).

5.3.7 Software Reset

The software reset is an internal reset generated by a software setting of the SYSRESETREQ bit in the AIRCR register in the Arm core. When the SYSRESETREQ bit is set to 1, a software reset is generated. When the internal reset time (t_{RESW2}) elapses after the software reset is generated, the internal reset is canceled and the CPU starts the reset exception handling.

For details on the SYSRESETREQ bit, see the *ARM® Cortex®-M33 Technical Reference Manual*.

5.3.8 Determination of Cold/Warm Start

Read the CWSF flag in RSTSR2 to determine the cause of reset processing. This flag indicates whether a power-on reset caused the reset processing (cold start) or a reset signal input during operation caused the reset processing (warm start).

The CWSF flag is set to 0 when a power-on reset occurs (cold start), otherwise the flag is not set to 0. The flag is set to 1 when 1 is written to it through software. It is not set to 0 even on writing 0 to it.

Figure 5.3 shows an example of cold/warm start determination operation.

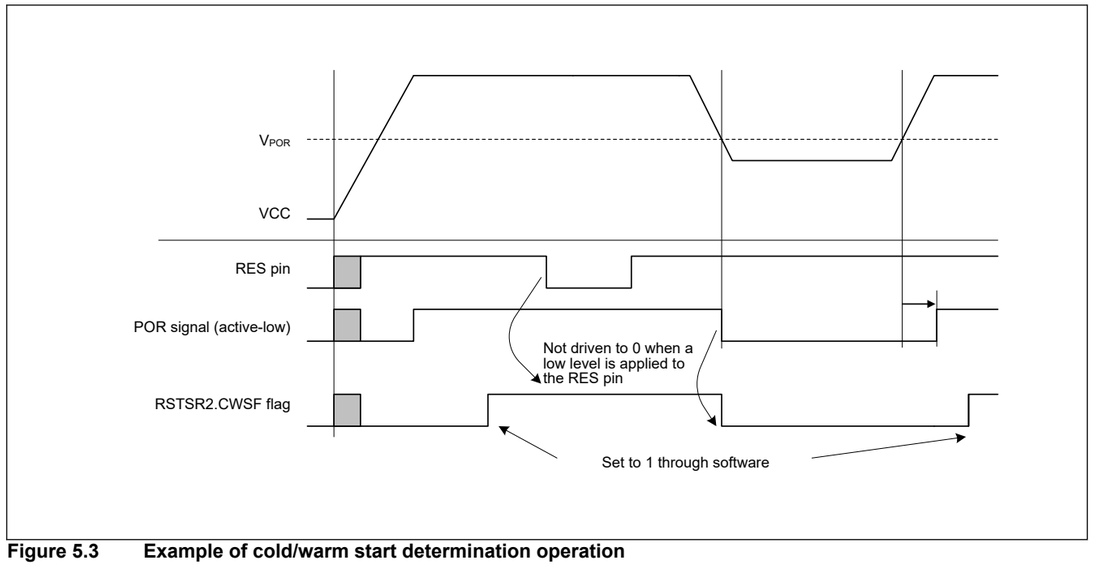


Figure 5.3 Example of cold/warm start determination operation

5.3.5 独立看门狗定时器复位

独立看门狗定时器复位是由独立看门狗定时器（IWDT）产生的内部复位。可以在选项功能选择寄存器0(OFS0)中选择IWDT的复位输出。

Whenoutputoftheindependentwatchdogtimerresetisselected theresetisgeneratediftheIWDTunderflows orifdataiswrittenwhenrefreshoperationisdisabled.当独立看门狗定时器复位产生后经过内部复位时间(tRESW2)时，内部复位被取消，CPU开始复位异常处理。

有关独立看门狗定时器复位的详细信息，请参见第25节，独立看门狗定时器(IWDT)。

5.3.6 看门狗定时器复位

看门狗定时器复位是由看门狗定时器(WDT)产生的内部复位。WDT的复位输出可以在WDT复位控制寄存器(WDTRCR)或选项功能选择寄存器0(OFS0)中选择。

选择看门狗定时器复位输出时，如果WDT下溢，或者在禁止刷新操作时写入数据，则会产生看门狗定时器复位。在产生看门狗定时器复位后经过内部复位时间(tRESW2)时，内部复位被取消，CPU开始复位异常处理。

有关看门狗定时器复位的详细信息，请参见第24节，看门狗定时器(WDT)。

5.3.7 软件复位

软件复位是通过软件设置Arm内核的AIRCR寄存器中的SYSRESETREQ位产生的内部复位。当SYSRESETREQ位设置为1时，会产生软件复位。当软件复位产生后经过内部复位时间(tRESW2)时，内部复位被取消，CPU开始复位异常处理。

有关SYSRESETREQ位的详细信息，请参阅ARM®Cortex®-M33技术参考手册。

5.3.8 冷暖启动的测定

读取RSTSR2中的CWSF标志以确定复位处理的原因。该标志指示是上电复位导致复位处理（冷启动）还是操作期间输入的复位信号导致复位处理（热启动）。

当发生上电复位（冷启动）时，CWSF标志设置为0，否则该标志不设置为0。当通过软件向其写入1时，该标志设置为1。即使向其写入0，它也不会设置为0。

图5.3显示了冷暖启动确定操作的示例。

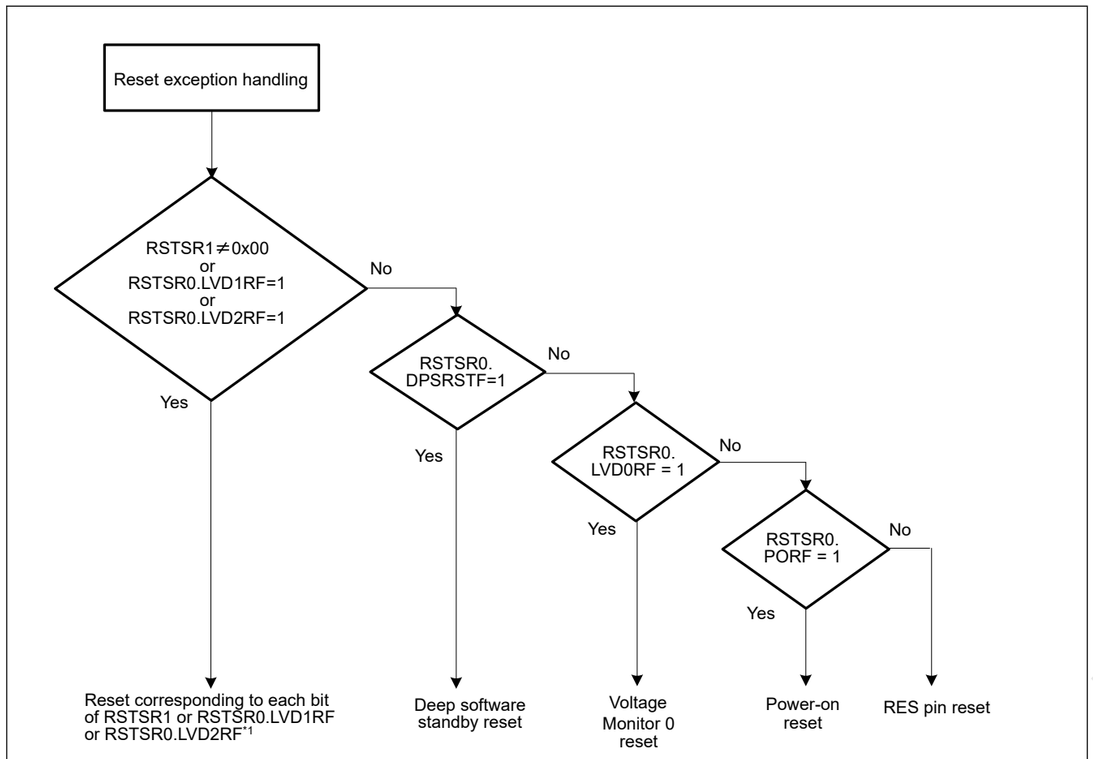
5.3.9 Determination of Reset Generation Source

Read RSTSR0 and RSTSR1 to determine which reset executes the reset exception handling.

Figure 5.4 shows an example of the flow to identify a reset generation source. The reset flag must be written with 0 after it is read as 1.



Note 1. When resets are generated simultaneously by two or more sources, the two or more corresponding reset flags will be set to 1.

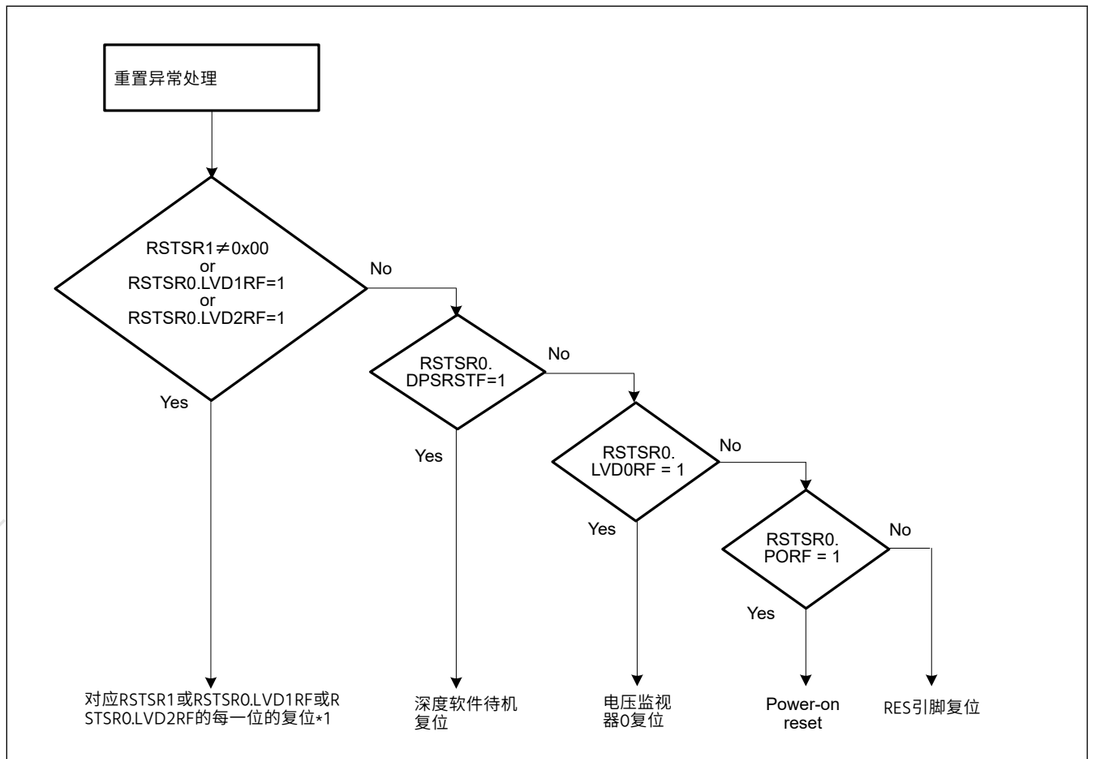
5.3.9 复位产生源的确定

读取RSTSR0和RSTSR1以确定哪个复位执行复位异常处理。

图5.4显示了识别复位产生源的流程示例。复位标志读为1后必须写为0。



注1.当两个或多个源同时产生复位时，两个或多个相应的复位标志将设置为1。

Only secure developer can program OFS1_SEC and OFS1_SEL registers. OFS1_SEC register is for secure developer, and OFS1 register is for non-secure developer. The applied setting value is determined by the setting value of the corresponding bit in OFS1_SEL register. For details, see section 6.3.3. Security attribution of option-setting memory.

VDSEL[1:0] bits (Voltage Detection 0 Level Select)

The VDSEL[1:0] bits select the voltage detection level of the voltage detection 0 circuit.

The LVDAS bit selects whether the voltage monitor 0 reset is enabled or disabled after a reset.

HOCOEN bit (HOCO Oscillation Enable)

The HOCOEN bit selects whether the HOCO oscillation is enabled or disabled after a reset. Setting this bit to 0 allows the HOCO oscillation to start before the CPU starts operation, which reduces the wait time for oscillation stabilization.

Note: When the HOCOEN bit is set to 0, the system clock source is not switched to HOCO. The system clock source is only switched to HOCO by setting the Clock Source Select bits (SCKSCR.CKSEL[2:0]). To use the HOCO clock, you must set the OFS1.HOCOFRQ0 bit to an optimum value.

HOCOFRQ0[1:0] bits (HOCO Frequency Setting 0)

The HOCOFRQ0[1:0] bits specify the HOCO frequency after a reset as 16, 18, or 20 MHz.

VDSEL[1:0]位（电压检测0电平选择）

VDSEL[1:0]位选择电压检测0电路的电压检测电平。

LVDAS位（电压检测0电路启动）

LVDAS位选择在复位后是启用还是禁用电压监视器0复位。

HOCOEN位（HOCO振荡使能）

HOCOEN位选择在复位后是启用还是禁用HOCO振荡。将此位设置为0允许在CPU开始运行之前启动HOCO振荡，减少了振荡稳定的等待时间。

Note: 当HOCOEN位设置为0时，系统时钟源不切换到HOCO。系统时钟源只能通过设置时钟源选择位(SCKSCR.CKSEL[2:0])切换到HOCO。要使用HOCO时钟，您必须将OFS1.HOCOFRQ0位设置为最佳值。

HOCOFRQ0[1:0]位（HOCO频率设置0）

HOCOFRQ0[1:0]位指定复位后的HOCO频率为16、18或20MHz。

Note 1. The value in a blank product is 0xFFFFFFFF. It is set to the value written by your application.

Only secure developer can program BPS_SEC and BPS_SEL registers. BPS_SEC register is for secure developer, and BPS register is for non-secure developer. The applied setting value is determined by the setting value of the corresponding bit in BPS_SEL register. For details, see section 6.3.3. Security attribution of option-setting memory.

The BPS and BPS_SEC registers invalidate the programming and erasure to the code flash memory. When the bit of this register is set to 0, the programming and erasure to the corresponding block are invalid. Figure 6.2 shows the code flash block structure of each product. Figure 6.3 shows the relationship between the bit of register and the block number. Unused bits are reserved and should be set to 1.

PBPS_SEC: 0x0100_A260

Bit position:	31	0
Bit field:

Note 1. The value in a blank product is 0xFFFFFFFF. It is set to the value written by your application.

Only secure developer can program PBPS_SEC register. PBPS_SEC register is for secure developer, and PBPS register is for non-secure developer. The applied setting value is determined by the setting value of the corresponding bit in BPS_SEL register. For details, see section 6.3.3. Security attribution of option-setting memory. The security attribution register is same BPS_SEL register between the block protection and permanent block protection.

The PBPS and PBPS_SEC registers invalidate writes to bits of BPS and BPS_SEC. The bit of this register can be set to 0 when corresponding bit of BPS and BPS_SEC is set to 0. When the bit of this register is set to 0, writing the corresponding bit of BPS and BPS_SEC register is invalid. Once the bit of this register is set to 0, it is impossible to change the bit to 1. Table 6.2 shows the relationship between the bit of applied PBPS and bit of applied BPS.

The relationship between the bit of this register and the block number is same as BPS and BPS_SEC registers (section 6.2.4. BPS, BPS_SEC, BPS_SEL : Block Protect Setting Register). Unused bits are reserved and should be set to 1.

6.3 Setting Option-Setting Memory

6.3.1 Allocation of Data in Option-Setting Memory

Programming data is allocated to the addresses in the option-setting memory shown in Figure 6.1. The allocated data is used by tools such as a flash programming software or an on-chip debugger.

Note: Programming formats vary depending on the compiler. See the compiler manual for details.

6.3.2 Setting Data for Programming Option-Setting Memory

Allocating data according to the procedure described in section 6.3.1. Allocation of Data in Option-Setting Memory, alone does not actually write the data to the option-setting memory. You must also follow one of the actions described in this section.

(1) Changing the option-setting memory by self-programming

Use the configuration setting command to write data to the option-setting memory in the configuration setting area.

The option-setting memory does not support background operations (BGO). When write the option-setting memory, jump to SRAM after copying writing softwere to SRAM.

For details of the configuration setting command, see section 40, Flash Memory.

(2) Debugging through an OCD or programming by a flash writer

This procedure depends on the tool in use, see the tool manual for details.

The MCU provides two setting procedures:

6.2.5 PBPS PBPS_SEC:永久块保护设置寄存器

Address: PBPS: 0x0100_A1E0
PBPS_SEC: 0x0100_A260

Bit position:	31	0
Bit field:		
重置后的值:	用户设置*1	

注1.空白产品中的值为0xFFFFFFFF。它设置为您的应用程序写入的值。

只有安全的开发人员才能对PBPS_SEC寄存器进行编程。PBPS_SEC寄存器用于安全开发者，PBPS寄存器用于非安全开发者。应用的设置值由BPS_SEL寄存器中相应位的设置值决定。详见6.3.3节。选项设置内存的安全属性。安全属性寄存器与块保护和永久块保护之间的BPS_SEL寄存器相同。

PBPS和PBPS_SEC寄存器使对BPS和BPS_SEC位的写入无效。当BPS和BPS_SEC的对应位设置为0时，该寄存器的位可以设置为0。当该寄存器的位设置为0时，写入BPS和BPS_SEC寄存器的对应位无效。一旦该寄存器的位设置为0，就无法将该位更改为1。表6.2显示了应用PBPS位和应用BPS位之间的关系。

该寄存器的位与块号的关系与BPS和BPS_SEC寄存器相同（第6.2.4节）。
BPS、BPS_SEC、BPS_SEL：块保护设置寄存器）。未使用的位被保留，应设置为1。

Table 6.2 PBPS、PBPS_SEC的位与BPS、BPS_SEC的位的关系

应用PBPS的位	应用BPS的点滴	Content
1	1	对相应块的编程和擦除是有效的。
1	0	对相应块的编程和擦除无效。该保护可以通过FBPROT0或FBPROT1寄存器取消。
0	1	不能设置这个条件
0	0	对相应块的编程和擦除永久无效

6.3 设置选项设置内存

6.3.1 选项设置内存中的数据分配

编程数据被分配到图6.1所示的选项设置存储器中的地址。分配的数据由闪存编程软件或片上调试器等工具使用。

Note: 编程格式因编译器而异。有关详细信息，请参阅编译器手册。

6.3.2 编程选项设置存储器的设置数据

根据第6.3.1节中描述的程序分配数据。选项设置内存中的数据分配，单独并不实际将数据写入选项设置内存。您还必须遵循本节中描述的操作之一。

(1) 通过自编程更改选项设置存储器

使用配置设置命令将数据写入配置设置区的选项设置内存。

选项设置内存不支持后台操作(BGO)。写入选项设置内存时，跳转到
将写入软件复制到SRAM后的SRAM。

有关配置设置命令的详细信息，请参见第40节，闪存。

(2) 通过OCD进行调试或通过闪存写入器进行编程

此过程取决于所使用的工具，详细信息请参见工具手册。

MCU提供两种设置程序：

- Read the data allocated as described in section 6.3.1. Allocation of Data in Option-Setting Memory, from an object file or Motorola S-format file generated by the compiler, and write the data to the MCU
- Use the GUI interface of the tool to program the same data as allocated in section 6.3.1. Allocation of Data in Option-Setting Memory.

6.3.3 Security attribution of option-setting memory

Some functionality has 3 registers for non-secure (FUNC NAME), and secure (FUNC NAME_SEC), and security attribution (FUNC NAME_SEL). Only secure developer can set the registers for secure and security attribution. As shown in Figure 6.4, when the bit of security attribution register is set to 0, the corresponding bit of secure register is applied. When the bit of security attribution register is set to 1, the corresponding bit of non-secure register is applied.

For example, if the secure developer wants to configure LVD of OFS1 as secure, HOCO of OFS1 as non-secure, the secure developer needs to set OFS1_SEL as follows.

OFS1_SEL = 0xFFFF_FFF8

By this setting, LVDAS and VDSEL[1:0] values of OFS1_SEC and HOCOFRQ0[1:0] and HOCOEN values of OFS1 are applied to MCU. The reserved bits of the security attribution register (FUNC NAME_SEL) should be set to 1.

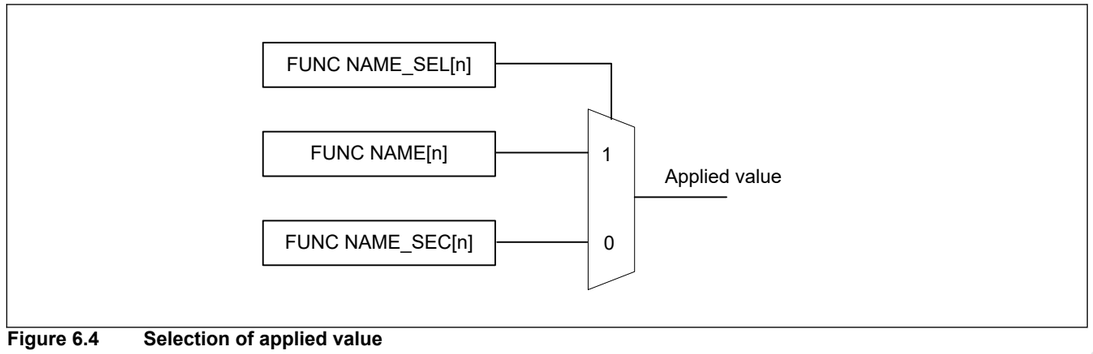

Figure 6.4 Selection of applied value

6.3.4 Timing of the Setting Value

For SAS, BPS, BPS_SEC, PBPS, and PBPS_SEC registers, the setting value of the related startup area and block protection is applied immediately after programming. For other registers, the setting value is applied after the MCU is reset.

In case the programming using the serial programming mode in customer's factory, be careful that the block protection for secure user is applied after MCU is reset. Because initial value of the security attribution registers of block protection (BPS_SEL) is 1 (non-secure), the block protection setting for secure developer (BPS_SEC/PBPS_SEC) is not applied until MCU is reset even if the corresponding bit of BPS_SEL is programmed to 0 (secure).

6.4 Usage Notes

6.4.1 Data for Programming Reserved Areas and Reserved Bits in the Option-Setting Memory

When reserved areas and reserved bits in the option-setting memory are within the scope of programming, write 1 to all bits of reserved areas and all reserved bits. If 0 is written to these bits, normal operation cannot be guaranteed.

●读取第6.3.1节所述分配的数据。在选项设置内存中分配数据，从编译器生成的目标文件或摩托罗拉S格式文件，并将数据写入MCU

●使用工具的GUI界面对6.3.1节分配的相同数据进行编程。OptionSetting内存中的数据分配。

6.3.3 选项设置内存的安全属性

某些功能具有3个用于非安全(FUNCNAME)、安全(FUNCNAME_SEC)和安全属性(FUNCNAME_SEL)的寄存器。只有安全的开发人员才能设置安全和安全属性的寄存器。如图6.4所示，当安全属性寄存器的位设置为0时，应用安全寄存器的相应位。当安全属性寄存器的位设置为1时，应用非安全寄存器的相应位。

例如，如果安全开发者要将OFS1的LVD配置为安全，将OFS1的HOCO配置为非安全，则安全开发者需要如下设置OFS1_SEL。

OFS1_SEL = 0xFFFF_FFF8

通过此设置，OFS1_SEC和HOCOFRQ0[1:0]的LVDAS和VDSEL[1:0]值以及OFS1的HOCOEN值将应用于MCU。安全属性寄存器(FUNCNAME_SEL)的保留位应设置为1。

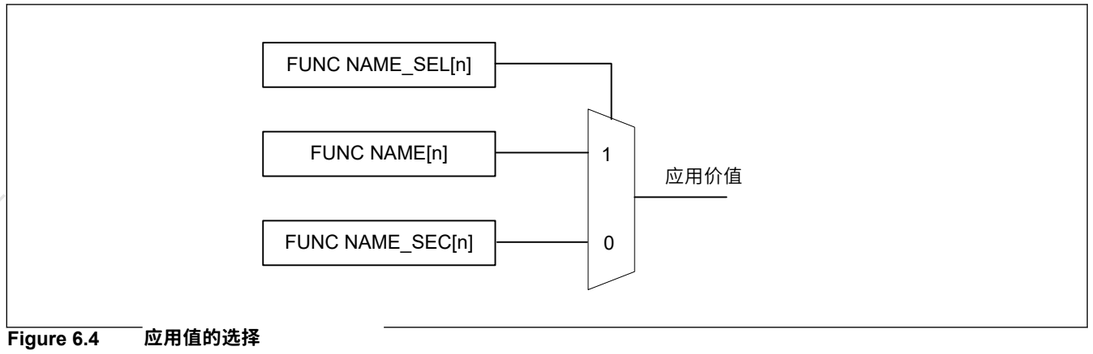

Figure 6.4 应用值的选择

6.3.4 设定值的时机

对于SAS、BPS、BPS_SEC、PBPS和PBPS_SEC寄存器，编程后立即应用相关启动区域和块保护的设置值。对于其他寄存器，设置值在MCU复位后应用。

如果在客户工厂使用串行编程模式进行编程，请注意在MCU复位后应用安全用户的块保护。因为块保护(BPS_SEL)的安全属性寄存器的初始值为1（非安全），所以即使BPS_SEL的相应位被编程为0（安全）。

6.4 使用说明

6.4.1 用于编程选项设置中的保留区域和保留位的数据 Memory

当期权设置内存中的保留区域和保留位在编程范围内时，将1写入保留区域和所有保留位的所有位。如果将0写入这些位，则无法保证正常操作。

7. Low Voltage Detection (LVD)

7.1 Overview

The Low Voltage Detection (LVD) module monitors the voltage level input to the VCC pin. The detection level can be selected by register settings. The LVD module consists of three separate voltage level detectors (LVD0, LVD1, LVD2). LVD0, LVD1, and LVD2 measure the voltage level input to the VCC pin. LVD registers allow your application to configure detection of VCC changes at various voltage thresholds.

Voltage monitor registers are used to configure the LVD to trigger an interrupt, event link output, or reset when the thresholds are crossed.

Table 7.1 lists the LVD specifications. Figure 7.1 shows a block diagram of the voltage monitor 0 reset generation circuit. Figure 7.2 shows a block diagram of the voltage monitor 1 interrupt and reset circuit, and Figure 7.3 shows a block diagram of the voltage monitor 2 interrupt and reset circuit.

7. 低电压检测(LVD)

7.1 Overview

低电压检测(LVD)模块监控输入到VCC引脚的电压电平。检测等级可以通过寄存器设置来选择。LVD模块由三个独立的电压电平检测器（LVD0、LVD1、LVD2）组成。LVD0、LVD1和LVD2测量输入到VCC引脚的电压电平。LVD寄存器允许您的应用程序配置在各种电压阈值下检测VCC变化。

电压监控寄存器用于配置LVD，以在超过阈值时触发中断、事件链接输出或复位。

表7.1列出了LVD规格。图7.1显示了电压监视器0复位产生电路的框图。

Table 7.7 Procedures for setting bits related to voltage monitor 2 interrupt and voltage monitor 2 reset so that voltage monitoring stops

Step		Voltage monitor 2 interrupt (voltage monitor 2 ELC event output), voltage monitor 2 reset
Settings to stop enabling output	1	Set LVD2CR0.CMPE = 0 to disable output of the comparison results from voltage monitor 2.
	2	Wait for at least 2n + 3 cycles of the LOCO, where n = 2, 4, 8, or 16, and the sampling clock for the digital filter is the LOCO frequency-divided by n.*2
	3	Set LVD2CR0.RIE = 0 to disable the voltage monitor 2 interrupt or reset.*1
Stopping the digital filter	4	Set LVD2CR0.DFDIS = 1 to disable the digital filter. *2 *3
Stopping the voltage detection 2 circuit	5	Set LVD2CMPCR.LVD2E = 0 to disable the voltage detection 2 circuit.

Note 1. Step 3 is not required if only the ELC event signal is to be output.
Note 2. Steps 2 and 4 are not required if the digital filter is not in use.
Note 3. To disable the digital filter from its enabled state and then re-enable it, disable it and wait for at least 2 LOCO clock cycles before re-enabling it.

If the voltage monitor 2 interrupt or reset setting is to be made again after it is used and stopped once, you can omit the following steps in the procedures for stopping and setting, depending on the conditions:

- Setting the voltage detection 2 is not required if the settings for the circuit do not change.
- Setting the digital filter is not required if the settings for the circuit do not change.
- Setting the voltage monitor 2 interrupt or reset is not required if the settings for the voltage monitor 2 interrupt or voltage monitor 2 reset do not change.

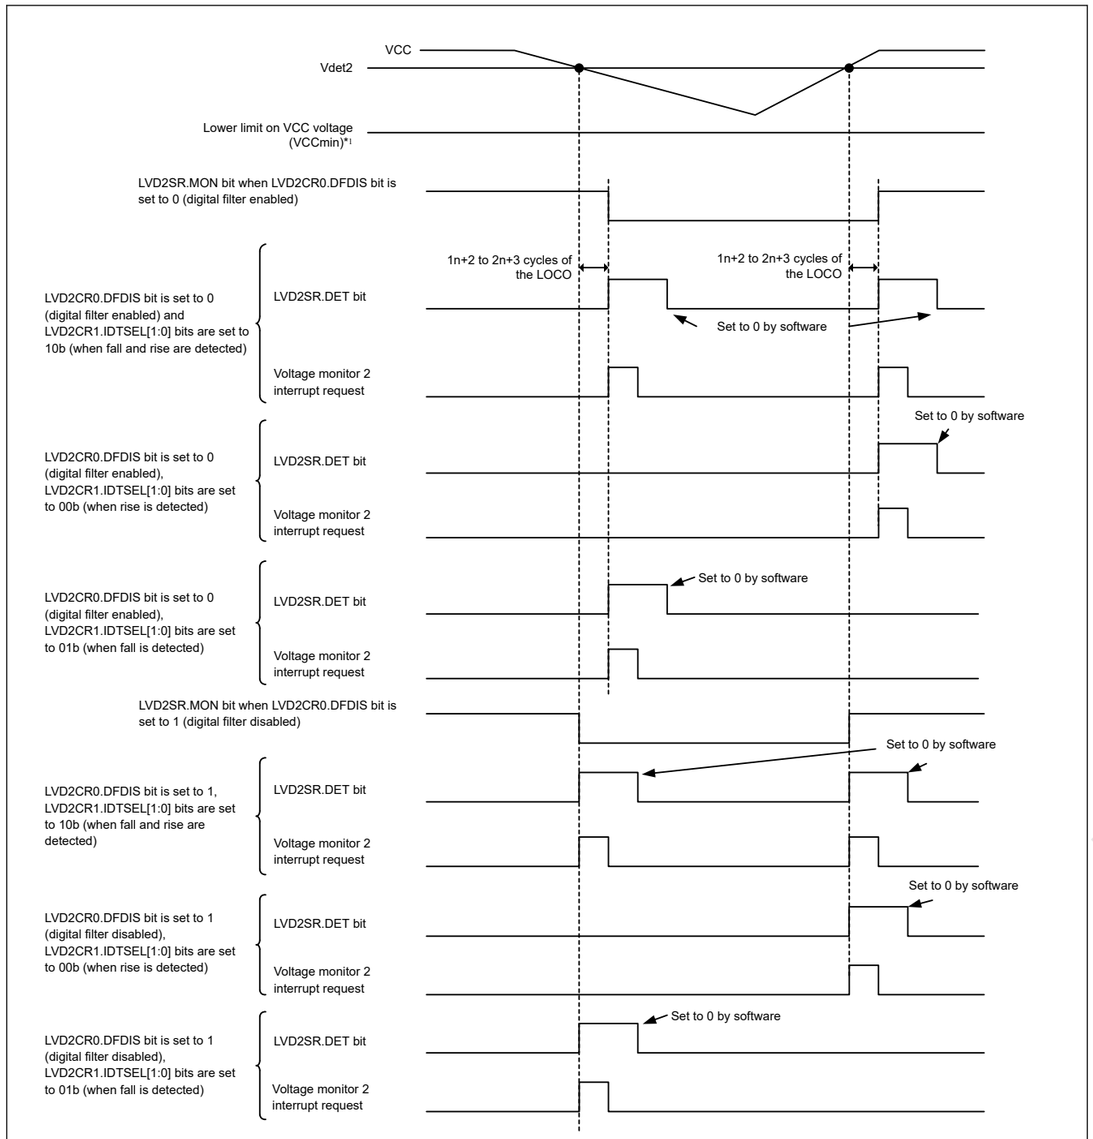
Table 7.7 设置与电压监控器2中断和电压监控器2相关的位以使电压监控器停止的步骤

Step		电压监控器2中断（电压监控器2ELC事件输出），电压监控器2复位
停止启用输出的设置	1	设置LVD2CR0.CMPE=0以禁用电压监视器2的比较结果输出。
	2	等待至少2n+3个LOCO周期，其中n=2、4、8或16，数字滤波器的采样时钟是LOCO分频的n。*2
	3	设置LVD2CR0.RIE=0以禁用电压监视器2中断或复位。*1
停止数字滤波器	4	设置LVD2CR0.DFDIS=1以禁用数字滤波器。*2*3
停止电压检测2电路	5	设置LVD2CMPCR.LVD2E=0以禁用电压检测2电路。

注1.如果只输出ELC事件信号，则不需要步骤3。
注2.如果不使用数字滤波器，则不需要步骤2和4。
注3.要从启用状态禁用数字滤波器然后重新启用它，请禁用它并等待至少2个LOCO时钟周期，然后再重新启用它。

如果电压监测器2的中断或复位设置在使用和停止一次后再次进行，可以根据情况省略停止和设置过程中的以下步骤：

- ●如果电路的设置不变，则不需要设置电压检测2。
- ●如果电路的设置不变，则不需要设置数字滤波器。
- ●如果电压监视器2中断或电压监视器2复位的设置没有改变，则不需要设置电压监视器2中断或复位。



Note: n: Frequency of the sampling clock for the digital filter is the LOCO frequency divided by n
Note 1. When the voltage monitor 0 reset is not in use, use at VCC ≥ VCCmin.

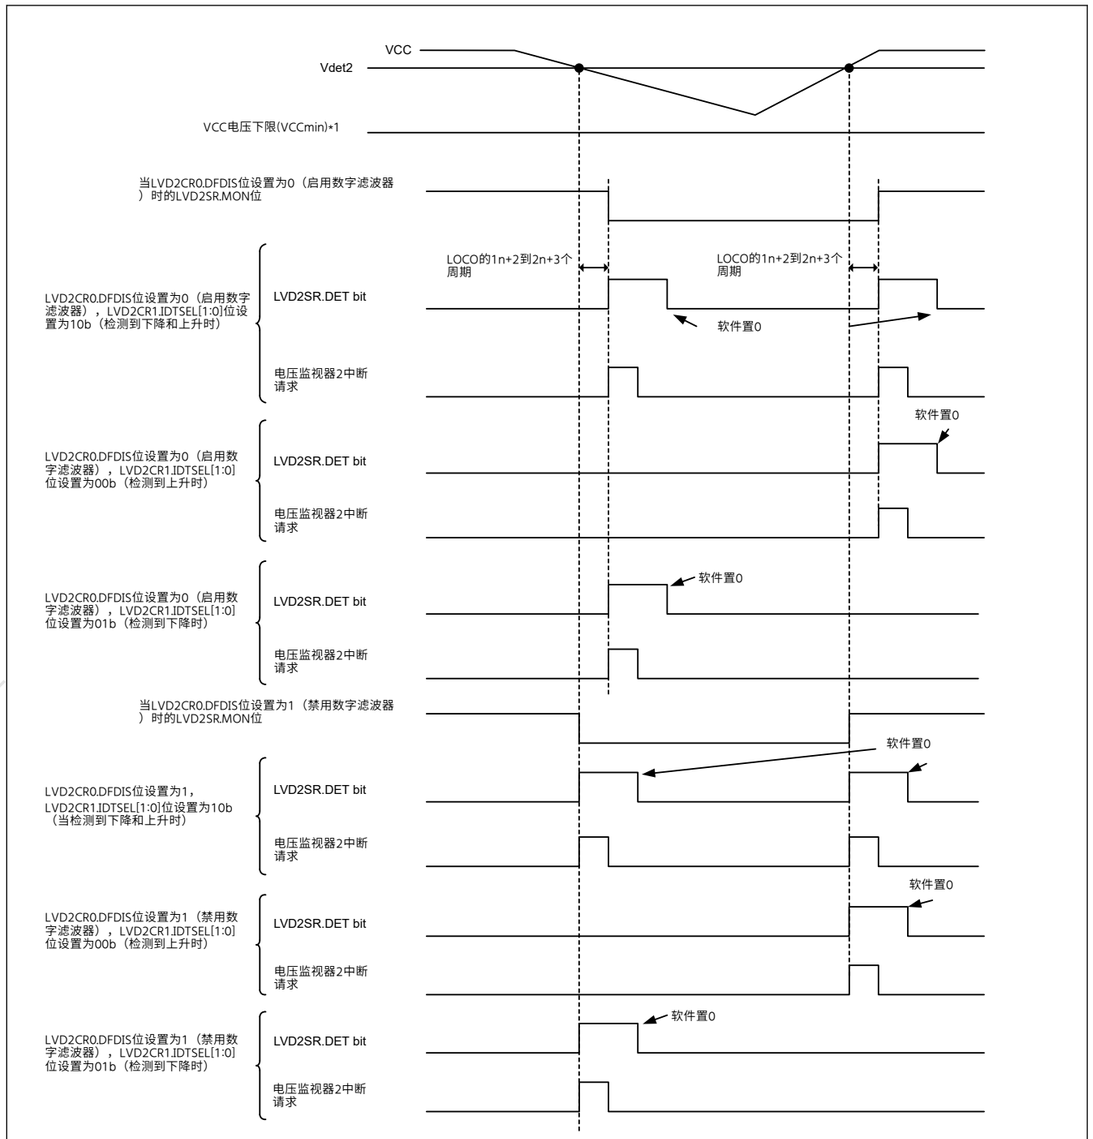
Figure 7.6 Example of voltage monitor 2 interrupt operation

7.7 Event Link Controller (ELC) Output

The LVD can output the event signals to the Event Link Controller (ELC).

(1) V_{det1} Crossing Detection Event

The LVD outputs the event signal when it detects that the voltage has passed the V_{det1} voltage while both the voltage detection 1 circuit and the voltage monitor 1 circuit comparison result output are enabled.



Note: n：数字滤波器的采样时钟频率是LOCO频率除以n
注1.不使用电压监视器0复位时，请在VCC≥VCCmin时使用。

Figure 7.6 电压监视器2中断操作示例

7.7 事件链接控制器(ELC)输出

LVD可以将事件信号输出到事件链接控制器(ELC)。

(1) Vdet1交叉检测事件

当电压检测1电路和电压监视器1电路比较结果输出都启用时，LVD检测到电压已超过Vdet1电压时输出事件信号。

(2) V_{det2} Crossing Detection Event

The LVD outputs the event signal when it detects that the voltage has passed the V_{det2} voltage while both the voltage detection 2 circuit and the voltage monitor 2 circuit comparison result output are enabled.

When enabling the event link output function of the LVD, you must enable the LVD before enabling the LVD event link function of the ELC. To stop the event link output function of the LVD, you must stop the LVD before disabling the LVD event link function of the ELC.

7.7.1 Interrupt Handling and Event Linking

The LVD provides bits to separately enable or disable the voltage monitor 1 and 2 interrupts. When an interrupt source is generated and the interrupt is enabled by the interrupt enable bit, the interrupt signal is output to the CPU.

In contrast, as soon as an interrupt source is generated, an event link signal is output as the event signal to the other module through the ELC, regardless of the state of the interrupt enable bit.

It is possible to output voltage monitor 1 and 2 interrupts in Software Standby and Deep Software Standby modes. The event signals for the ELC in Software Standby and Deep Software Standby modes are output as follows:

- When a V_{det1} or V_{det2} passage events is detected in Software Standby mode, event signals are not generated for the ELC because the clock is not supplied in Software Standby mode. Because the V_{det1} and V_{det2} passage detection flags are saved, when the clock supply resumes after returning from Software Standby mode, the event signals for the ELC are output based on the state of the V_{det1} and V_{det2} detection flags.
- When a Vdet1 or Vdet2 passage events are detected in Deep Software Standby mode, event signals are not generated for the ELC.

(2) Vdet2交叉检测事件

当电压检测2电路和电压监测器2电路比较结果输出都启用时，LVD检测到电压已超过Vdet2电压时输出事件信号。

使能LVD的事件链接输出功能时，必须先使能LVD，再使能ELC的LVD事件链接功能。要停止LVD的事件链接输出功能，必须先停止LVD，然后再禁用ELC的LVD事件链接功能。

7.7.1 中断处理和事件链接

LVD提供位来分别启用或禁用电压监视器1和2中断。当产生中断源并通过中断使能位使能中断时，将中断信号输出到CPU。

相反，一旦产生中断源，无论中断使能位的状态如何，都会通过ELC将事件链接信号作为事件信号输出到其他模块。

在软件待机和深度软件待机模式下，可以输出电压监视器1和2中断。软件待机和深度软件待机模式下ELC的事件信号输出如下：

- 当在软件待机模式下检测到Vdet1或Vdet2通过事件时，不会为ELC，因为在软件待机模式下不提供时钟。因为保存了Vdet1和Vdet2通过检测标志，所以当从软件待机模式恢复后时钟供应恢复时，ELC的事件信号将根据Vdet1和Vdet2检测标志的状态输出。
- 当在深度软件待机模式下检测到Vdet1或Vdet2通过事件时，不会为ELC生成事件信号。

Those clock frequency ranges must be satisfied even if the HOCO has its maximum or minimum frequency when not using FLL function. (See section 43, Electrical Characteristics).

闪存和SRAM在每个等待周期设置中也有一个允许的工作频率范围。（参见第38节，SRAM，第40节，闪存）即使HOCO在不使用FLL功能时具有其最大或最小频率，也必须满足这些时钟频率范围。（见第43节，电气特性）。

The SCKSCR register selects the clock source for the system clock.

CKSEL[2:0] bits (Clock Source Select)

The CKSEL[2:0] bits select the source for the following modules:

- System clock (ICLK)
- Peripheral module clocks (PCLKA, PCLKB, PCLKC, and PCLKD)
- FlashIF clock (FCLK)

The bits select from one of the following sources:

- Low-speed on-chip oscillator (LOCO)
- Middle-speed on-chip oscillator (MOCO)
- High-speed on-chip oscillator (HOCO)
- Main clock oscillator (MOSC)
- Sub-clock oscillator (SOSC)
- PLL

The operating state of each clock source is controlled not only by the clock oscillation enable settings but also by the operating modes of the product. Some clock sources might be forcibly stopped depending on the product operating mode being used.

Check the operation state of clock sources in each product operating mode, and do not select the clock source to be stopped in SCKSCR. The clock sources should be switched when there are no occurring internal asynchronous interrupt. For details, see section 10, Low Power Modes.

SCKSCR寄存器选择系统时钟的时钟源。

CKSEL[2:0]位（时钟源选择）

CKSEL[2:0]位选择以下模块的源：

●系统时钟（ICLK）

●外设模块时钟（PCLKA、PCLKB、PCLKC和PCLKD）

- FlashIF clock (FCLK)

这些位从以下来源之一中选择：

- Low-speed on-chip oscillator (LOCO)
- Middle-speed on-chip oscillator (MOCO)
- High-speed on-chip oscillator (HOCO)

●主时钟振荡器（MOSC）

- Sub-clock oscillator (SOSC)
- PLL

每个时钟源的工作状态不仅由时钟振荡使能设置控制，还由产品的工作模式控制。根据所使用的产品操作模式，某些时钟源可能会被强制停止。

检查各产品工作模式下时钟源的运行状态，不要在SCKSCR中选择要停止的时钟源。当没有发生内部异步中断时，应切换时钟源。有关详细信息，请参阅第10节，低功耗模式。

PLLCR寄存器控制PLL电路的操作。

PLLSTP bit (PLL Stop Control)

This bit runs or stops the PLL circuit.

If the main clock oscillator is to be selected as the clock source for the PLL by the PLLCCR.PLSRCSEL bit, the Main Clock Oscillator Wait Control Register (MOSCWTCR) must be set.

After the PLLSTP bit setting is changed to run the PLL, only use the PLL clock after confirming that the OSCSF.PLLSF bit is set to 1. That is, a fixed time for stabilization is required after starting the PLL operation. A fixed time is also required for oscillation to stop after stopping the PLL operation. Additionally, apply the following limitations when starting and stopping the PLL operation by the PLLSTP bit:

- After stopping the PLL, confirm that the OSCSF.PLLSF bit is 0 before restarting the PLL.
- Confirm that the PLL is operating and that the OSCSF.PLLSF bit is 1 before stopping the PLL.
- Regardless of whether the PLL clock is selected as the system clock, confirm that the OSCSF.PLLSF is set to 1 before executing a WFI instruction to place the MCU in Software Standby or Deep Software Standby mode after operating the PLL.
- When transitioning to Software Standby or Deep Software Standby mode after stopping the PLL, confirm that the OSCSF.PLLSF bit is cleared to 0 before executing a WFI instruction.

Writing 1 to the PLLSTP bit is prohibited when SCKSCR.CKSEL[2:0] = 101 (system clock source = PLL).

Confirm the following conditions before writing 0 to PLLSTP:

- When PLL source clock = MOSC: MOSCCR.MOSTP = 0 (MOSC is enabled)
- When PLL source clock = HOCO: HOCOCR.HCSTP = 0 (HOCO is enabled).

PLLSTP位（PLL停止控制）

该位运行或停止PLL电路。

如果要通过PLLCCR.PLSRCSEL位选择主时钟振荡器作为PLL的时钟源，则Main
必须设置时钟振荡器等待控制寄存器(MOSCWTCR)。

更改PLLSTP位设置以运行PLL后，只有在确认OSCSF.PLLSF位设置为1后才能使用PLL时钟。即，启动PLL操作后需要固定的稳定时间。在停止PLL操作后，振荡停止也需要一段固定的时间。此外，在通过PLLSTP位启动和停止PLL操作时应用以下限制：

●停止PLL后，请确认OSCSF.PLLSF位为0，然后再重新启动PLL。

●在停止PLL之前，确认PLL正在运行并且OSCSF.PLLSF位为1。

●无论是否选择PLL时钟作为系统时钟，在执行WFI指令之前确认OSCSF.PLLSF设置为1，以便在操作PLL后将MCU置于软件待机或深度软件待机模式。

●在停止PLL后转换到软件待机或深度软件待机模式时，请确认OSCSF.PLLSF位在执行WFI指令之前被清除为0。

当SCKSCR.CKSEL[2:0]=101（系统时钟源=PLL）时，禁止向PLLSTP位写入1。

●当PLL源时钟=HOCO时：HOCOCR.HCSTP=0（启用HOCO）。

Note 1. MOMCR register must be set before setting MOSTP to 0.

If the security attribution is configured as Non-secure:

Note 1. The SOMCR register must be set before setting SOSTP to 0.

The SOSCCR register controls the sub-clock oscillator.

SOSTP bit (Sub Clock Oscillator Stop)

The SOSTP bit starts or stops the sub-clock oscillator. When changing the value of the SOSTP bit, only execute subsequent instructions after reading the bit to check that the value is updated. Use the SOSTP bit when using the sub-clock oscillator as the source for a peripheral module, for example the RTC. When using the sub-clock oscillator, set the Sub-Clock Oscillator Mode Control Register (SOMCR) before setting SOSTP to 0.

The following restrictions apply when starting and stopping the operation:

- After stopping the sub-clock oscillator, allow a stop interval of at least 5 SOSC clock cycles before restarting it
- After setting the SOSTP bit to 0, use the sub-clock only after the sub-clock oscillation stabilization time ($t_{SUBOSCWT}$) has elapsed.
- Regardless of whether the sub-clock oscillator is selected as the system clock, confirm that the sub-clock oscillation is stable before executing a WFI instruction to place the MCU in Software Standby or Deep Software Standby mode
- When a transition to Software Standby or Deep Software Standby mode is to follow the setting to stop the sub-clock oscillator, wait for at least 3 SOSC clock cycles before executing the WFI instruction.

Writing 1 to SOSTP is prohibited under the following condition:

- SCKSCR.CKSEL[2:0] = 100b (system clock source = SOSC).

在以下情况下禁止向MOSTP写入1：

●SCKSCR.CKSEL[2:0]=011b（系统时钟源=MOSC）。

注1.在将SOSTP设置为0之前，必须设置SOMCR寄存器。

SOSCCR寄存器控制副时钟振荡器。

SONTP位（副时钟振荡器停止）

SONTP位启动或停止副时钟振荡器。更改SOTP位的值时，仅在读取该位后执行后续指令以检查该值是否已更新。当使用副时钟振荡器作为外围模块（例如RTC）的源时，使用SOTP位。使用副时钟振荡器时，请先设置副时钟振荡器模式控制寄存器(SOMCR)，然后再将SOSTP设置为0。

启动和停止操作时适用以下限制：

●子时钟振荡器停止后，在重新启动之前允许至少5个SOSC时钟周期的停止间隔

●将SOSTP位设置为0后，仅在副时钟振荡稳定时间(tSUBOSCWT)过去后使用副时钟。

●无论是否选择副时钟振荡器作为系统时钟，在执行WFI指令之前确认副时钟振荡稳定，使MCU进入软件待机或深度软件待机模式

●当转换到软件待机或深度软件待机模式是按照设置停止副时钟振荡器，在执行WFI指令之前至少等待3个SOSC时钟周期。

在以下情况下禁止向SOTP写入1：

Note: If the security attribution is configured as secure:

- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The LOCOCR register controls the LOCO clock.

LCSTP bit (LOCO Stop)

The LCSTP bit starts or stops the LOCO clock.

After setting the LCSTP bit to 0 to start the LOCO clock, only use the clock after the LOCO clock-oscillation stabilization wait time (t_{LOCOWT}) elapses. A fixed stabilization wait time is required after setting the LOCO clock to start operation. A fixed wait time is also required after setting the LOCO clock to stop.

The following restrictions apply when starting and stopping operation:

- After stopping the LOCO clock, allow a stop interval of at least 5 LOCO clock cycles before restarting it
- Confirm that LOCO oscillation is stable before stopping the LOCO clock
- Regardless of whether the LOCO is selected as the system clock, confirm that LOCO oscillation is stable before executing a WFI instruction to place the MCU in Software Standby or Deep Software Standby mode
- When a transition to Software Standby or Deep Software Standby mode is to follow the setting to stop the LOCO clock, wait for at least 3 LOCO cycles before executing the WFI instruction.

Writing 1 to LCSTP is prohibited under the following condition:

- SCKSCR.CKSEL[2:0] = 010b (system clock source = LOCO).

Because the LOCO clock measures the wait time for other oscillators, it continues to oscillate while measuring this time, regardless of the setting in LOCOCR.LCSTP. As a result, the LOCO clock might be unintentionally supplied even when the LCSTP is set to stop.

LOCOCR寄存器控制LOCO时钟。

LCSTP bit (LOCO Stop)

LCSTP位启动或停止LOCO时钟。

将LCSTP位设置为0以启动LOCO时钟后，仅在LOCO时钟振荡稳定等待时间(tLOCOWT)过去后使用时钟。设置LOCO时钟开始运行后，需要一个固定的稳定等待时间。将LOCO时钟设置为停止后，还需要一个固定的等待时间。

启动和停止操作时适用以下限制：

●停止LOCO时钟后，在重新启动之前允许至少5个LOCO时钟周期的停止间隔

●在停止LOCO时钟之前确认LOCO振荡稳定

●无论是否选择LOCO作为系统时钟，在执行WFI指令将MCU置于软件待机或深度软件待机模式之前，请确认LOCO振荡稳定

●当转换到软件待机或深度软件待机模式是按照设置停止LOCO时钟时，在执行WFI指令之前至少等待3个LOCO周期。

在以下情况下禁止向LCSTP写入1：

●SCKSCR.CKSEL[2:0]=010b（系统时钟源=LOCO）。

因为LOCO时钟测量其他振荡器的等待时间，所以无论LOCOCR.LCSTP中的设置如何，它都会在测量该时间时继续振荡。因此，即使LCSTP设置为停止，也可能会无意中提供LOCO时钟。

Note 1. The HCSTP bit value after a reset is 0 when the OFS1.HOCOEN bit is 0. It is 1 when the OFS1.HOCOEN bit is 1.
Note 2. If you are using the HOCO (HCSTP = 0), set the OFS1.HOCOFRQ0[1:0] bit to an optimum value.

The HOCOCR register controls the HOCO clock.

HCSTP bit (HOCO Stop)

The HCSTP bit starts or stops the HOCO clock.

After setting the HCSTP bit to 0 to start the HOCO clock, confirm that the OSCSF.HOCOSF is set to 1 before using the clock. When OFS1.HOCOEN is set to 0, confirm that OSCSF.HOCOSF is also set to 1 before using the HOCO clock. A fixed stabilization wait time is required after setting the HOCO clock to start operation. A fixed wait time is also required after setting the HOCO clock to stop.

The following limitations apply when starting and stopping operation:

- After stopping the HOCO clock, confirm that the OSCSF.HOCOSF is 0 before restarting the HOCO clock.
- Confirm that the HOCO clock operates and that the OSCSF.HOCOSF is 1 before stopping the HOCO clock.
- Regardless of whether the HOCO clock is selected as the system clock, confirm that the OSCSF.HOCOSF is set to 1 before executing a WFI instruction to place the MCU in Software Standby or Deep Software Standby mode after setting HOCO operation with the HCSTP bit.
- When a transition to Software Standby or Deep Software Standby mode is to follow the setting of the HOCO clock to stop, confirm that the OSCSF.HOCOSF is set to 0 after setting the HOCO clock and before executing the WFI instruction.

Writing 1 to HCSTP is prohibited under the following conditions:

- SCKSCR.CKSEL[2:0] = 000b (system clock source = HOCO).
- PLLCCR.PLSRCSEL = 1 (PLL source clock = HOCO) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL)

- PLL2CCR.PL2SRCSEL = 1 (PLL2 source clock = HOCO) and PLL2CR.PLL2STP = 0 (PLL2 is operating)

将HCSTP位设置为0以启动HOCO时钟后，在使用时钟之前确认OSCSF.HOCOSF设置为1。当OFS1.HOCOEN设置为0时，请在使用HOCO时钟之前确认OSCSF.HOCOSF也设置为1。设置HOCO时钟开始运行后，需要一个固定的稳定等待时间。将HOCO时钟设置为停止后，还需要一个固定的等待时间。

启动和停止操作时适用以下限制：

●停止HOCO时钟后，确认OSCSF.HOCOSF为0，再重新启动HOCO时钟。

●在停止HOCO时钟之前，请确认HOCO时钟运行并且OSCSF.HOCOSF为1。

●无论是否选择HOCO时钟作为系统时钟，确认OSCSF.HOCOSF设置为1

The MOCOCR register controls the MOCO clock.

MCSTP bit (MOCO Stop)

The MCSTP bit starts or stops the MOCO clock.

After setting MCSTP to 0, use the MOCO clock only after the MOCO clock oscillation stabilization time (t_{MOCOWT}) elapses. A fixed stabilization wait time is required after setting the MOCO clock to start operation. A fixed wait time is also required for oscillation to stop after setting the MOCO clock to stop operation.

The following restrictions apply when starting and stopping the oscillator:

- After stopping the MOCO clock, allow a stop interval of at least 5 MOCO clock cycles before restarting it
- Confirm that MOCO clock oscillation is stable before stopping the MOCO clock
- Regardless of whether the MOCO clock is selected as the system clock, confirm that MOCO clock oscillation is stable before executing a WFI instruction to place the MCU in Software Standby or Deep Software Standby mode
- When a transition to Software Standby or Deep Software Standby mode is to follow the setting to stop the MOCO clock, wait for at least 3 MOCO clock cycles before executing the WFI instruction.

Writing 1 to MCSTP is prohibited under the following condition:

- SCKSCR.CKSEL[2:0] = 001b (system clock source = MOCO).

Writing 1 to the MCSTP bit (stopping the MOCO) is prohibited if oscillation stop detection is enabled in the Oscillation Stop Detection Control Register (OSTDCR.OSTDE).

In addition, you must disable FLL by setting the FLLEN bit to 0 before transitioning to Software Standby mode.

6	PLL2SF	PLL2 Clock Oscillation Stabilization Flag 0: The PLL2 clock is stopped, or oscillation of the PLL2 clock is not stable yet 1: The PLL2 clock is stable	R
7	—	These bits are read as 0.	R

Note 1. The value after reset depends on the OFS1.HOCOEN setting.
When OFS1.HOCOEN = 1 (disable HOCO), the value after reset of HOCOSF is 0.
When OFS1.HOCOEN = 0 (enable HOCO), the HOCOSF value is set to 0 immediately after reset is released, and the HOCOSF value is set to 1 after the HOCO oscillation stabilization wait time elapses.

Note 2. This is true when an appropriate value is set in the Wait Control register for the main clock oscillator. If the wait time value is not sufficient, the oscillation stabilization flag is set to 1 and supply of the clock signal to the internal circuits starts before oscillation is stable.

This register is not controlled by CGFSAR register.

The OSCSF register contains flags to indicate the operating status of the counters in the oscillation stabilization wait circuits for the individual oscillators. After oscillation starts, these counters measure the wait time until each oscillator output clock is supplied to the internal circuits. An overflow of a counter indicates that the clock supply is stable and available for the associated circuit.

HOCOSF flag (HOCO Clock Oscillation Stabilization Flag)

The HOCOSF flag indicates the operating status of the counter that measures the wait time for the high-speed clock oscillator (HOCO). When OFS1.HOCOEN is set to 0, confirm that OSCSF.HOCOSF is set to 1 before using the HOCO clock.

注1.复位后的值取决于OFS1.HOCOEN的设置。
当OFS1.HOCOEN=1（禁用HOCO）时，HOCOSF复位后的值为0。
当OFS1.HOCOEN=0（启用HOCO）时，释放复位后立即将HOCOSF值设置为0，并在经过HOCO振荡稳定等待时间后将HOCOSF值设置为1。

注2.当主时钟振荡器的等待控制寄存器中设置了适当的值时，这是正确的。如果等待时间值不够，则将振荡稳定标志设置为1，并在振荡稳定之前开始向内部电路提供时钟信号。

该寄存器不受CGFSAR寄存器控制。

OSCSF寄存器包含用于指示各个振荡器的振荡稳定等待电路中的计数器的操作状态的标志。振荡开始后，这些计数器测量等待时间，直到每个振荡器输出时钟被提供给内部电路。计数器溢出表明时钟供应稳定并可用于相关电路。

HOCOSF标志（HOCO时钟振荡稳定标志）

HOCOSF标志指示测量高速时钟振荡器(HOCO)等待时间的计数器的操作状态。当OFS1.HOCOEN设置为0时，请在使用HOCO时钟之前确认OSCSF.HOCOSF设置为1。

For the PLL oscillation stabilization time, see section 43, Electrical Characteristics.

[Clearing condition]

- When the PLL is operating and then is deactivated because the PLLCR.PLLSTP bit is set to 1.

PLL2SF flag (PLL2 Clock Oscillation Stabilization Flag)

The OSTDCR register controls the oscillation stop detection function.

OSTDIE bit (Oscillation Stop Detection Interrupt Enable)

The OSTDIE bit enables the oscillation stop detection function interrupt. It also controls whether oscillation stop detection is reported to the POEG.

If the Oscillation Stop Detection flag in the Oscillation Stop Detection Status Register (OSTDSR.OSTDF) requires clearing, set the OSTDIE bit to 0 before clearing OSTDF. Wait for at least 2 PCLKB cycles before setting the OSTDIE bit to 1. By reading the I/O register whose access cycle number is defined by PCLKB, it is possible to secure waiting time of 2 or more cycles of PCLKB.

OSTDE bit (Oscillation Stop Detection Function Enable)

The OSTDE bit enables the oscillation stop detection function.

When the OSTDE bit is 1 (enabled), the MOCO stop bit (MOCOCR.MCSTP) is set to 0 and the MOCO operation starts. The MOCO clock cannot be stopped while the oscillation stop detection function is enabled. Writing 1 to the MOCOCR.MCSTP bit (MOCO stopped) is invalid.

When the Oscillation Stop Detection flag in the Oscillation Stop Detection Status Register (OSTDSR.OSTDF) is 1 (main clock oscillation stop detected), writing 0 to the OSTDE bit is invalid.

The OSTDE bit must be set to 0 before transitioning to Software Standby or Deep Software Standby mode. To transition to Software Standby or Deep Software Standby mode, first set the OSTDE bit to 0, then execute the WFI instruction.

The following restrictions apply when using the oscillation stop detection function:
In low-speed mode, selecting division by 1, 2, 4, 8 for ICLK, FCLK, PCLKA, PCLKB, PCLKC, and PCLKD is prohibited.

OSTDCR寄存器控制振荡停止检测功能。

OSTDIE位（振荡停止检测中断使能）

OSTDIE位使能振荡停止检测功能中断。它还控制是否将振荡停止检测报告给POEG。

如果振荡停止检测状态寄存器(OSTDSR.OSTDF)中的振荡停止检测标志需要清零，则在清零OSTDF之前将OSTDIE位设置为0。在将OSTDIE位设置为1之前等待至少2个PCLKB周期。通过读取访问周期数由PCLKB定义的IO寄存器，可以确保2个或更多PCLKB周期的等待时间。

OSTDE位（振荡停止检测功能使能）

OSTDE位使能振荡停止检测功能。

当OSTDE位为1（使能）时，MOCO停止位（MOCOCR.MCSTP）设置为0，MOCO操作开始。
MOCO时钟在振荡停止检测功能启用时不能停止。将1写入MOCOCR.MCSTP位（MOCO停止）无效。

当振荡停止检测状态寄存器(OSTDSR.OSTDF)中的振荡停止检测标志为1（检测到主时钟振荡停止）时，向OSTDE位写入0无效。

在转换到软件待机或深度软件待机模式之前，必须将OSTDE位设置为0。过渡到软件待机或深度软件待机模式，首先将OSTDE位设置为0，然后执行WFI指令。

使用振荡停止检测功能时有以下限制：
在低速模式下，禁止为ICLK、FCLK、PCLKA、PCLKB、PCLKC和PCLKD选择1、2、4、8分频。

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

Note 1. This bit can only be set to 0. This bit is cleared to 0 by writing 0 after reading it as 1.

The OSTDSR register indicates the stop detection status of the main clock oscillator.

OSTDF flag (Oscillation Stop Detection Flag)

The OSTDF flag indicates the main clock oscillator status. When this flag is 1, it indicates that the main clock oscillation stop was detected. After this stop is detected, the OSTDF flag is not set to 0 even when the main clock oscillation is restarted. The OSTDF bit is cleared to 0 by writing 0 after reading it as 1.

At least 3 ICLK cycles of wait time are required between writing 0 to OSTDF and reading it as 0. If the OSTDF flag is set to 0 when the main clock oscillation is stopped, the OSTDF flag becomes 0 then returns to 1.

The OSTDF flag cannot be set to 0 under the following conditions:

- SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC).
- PLLCCR.PLSRCSEL = 0 (PLL source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (System clock source = PLL)

The OSTDF flag must be set to 0 after switching the clock source to sources other than the main clock oscillator and PLL.

[Setting condition]

- The main clock oscillator is stopped when OSTDCR.OSTDE = 1 (oscillation stop detection function enabled).

[Clearing condition]

- 1 is read and then 0 is written when the SCKSCR.CKSEL[2:0] bits are neither 011b (system clock is MOSC) nor 101b (system clock is PLL) and PLLCCR.PLSRCSEL bit is not 0 (PLL source clock is MOSC).

如果安全属性配置为非安全：●

允许安全和非安全访问。

注1.该位只能设置为0。读为1后写入0清除该位为0。

OSTDSR寄存器指示主时钟振荡器的停止检测状态。

OSTDF标志（振荡停止检测标志）

OSTDF标志指示主时钟振荡器状态。该标志为1时，表示检测到主时钟振荡停止。检测到此停止后，即使重新启动主时钟振荡，OSTDF标志也不会设置为0。OSTDF位在读为1后写入0清零。

从向OSTDF写入0到将其读取为0之间至少需要3个ICLK周期的等待时间。如果在主时钟振荡停止时将OSTDF标志设置为0，则OSTDF标志变为0然后返回1。

在以下情况下，OSTDF标志不能设置为0：

●SCKSCR.CKSEL[2:0]=011b（系统时钟源=MOSC）。

●PLLCCR.PLSRCSEL=0（PLL源时钟=MOSC）和SCKSCR.CKSEL[2:0]=101b（系统时钟源=PLL）

将时钟源切换到主时钟振荡器和PLL以外的源后，必须将OSTDF标志设置为0。

[Setting condition]

●当OSTDCR.OSTDE=1（振荡停止检测功能使能）时，主时钟振荡器停止。

[Clearing condition]

●当SCKSCR.CKSEL[2:0]位既不是011b（系统时钟为MOSC）也不是101b（系统时钟为PLL）且PLLCCR.PLSRCSEL位不为0（PLL源时钟为MOSC）。

MSTS[3:0] bits (Main Clock Oscillator Wait Time Setting)

The MSTS[3:0] bits specify the oscillation stabilization wait time for the main clock oscillator.

Set the main clock oscillation stabilization time to a period longer than or equal to the stabilization time recommended by the oscillator manufacturer. When the main clock is input externally, set these bits to 0x0 because the oscillation stabilization time is not required.

The wait time set in these bits is counted using: 1 cycle (µs) = 1/(fLOCO[MHz] × 8) = 1/(0.032768 × 8) = 3.81 (µs) (min.) The LOCO clock automatically oscillates when necessary, regardless of the value of the LOCO.LCSTP bit. After the specified wait time elapses, supply of the main clock starts internally in the MCU, and the OSCSF.MOSCSF flag is set to 1. If the specified wait time is short, supply of the main clock starts before oscillation of the clock becomes stable.

Only rewrite the MOSCWTCR register when the MOSCCR.MOSTP bit is 1 and the OSCSF.MOSCSF flag is 0. Do not rewrite this register under any other conditions.

The MODRV[1:0] bit switches the drive capability of the main clock oscillator.

MOSEL bit (Main Clock Oscillator Switching)

The MOSEL bit switches the source for the main clock oscillator.

MSTS[3:0]位（主时钟振荡器等待时间设置）

MSTS[3:0]位指定主时钟振荡器的振荡稳定等待时间。

将主时钟振荡稳定时间设置为大于或等于振荡器制造商推荐的稳定时间。当主时钟从外部输入时，将这些位设置为0x0，因为不需要振荡稳定时间。

这些位中设置的等待时间使用以下公式计算：1个周期(µs)=1(fLOCO[MHz]×8)=1(0.032768×8)=3.81(µs)(min.)
无论LOCO.LCSTP位的值如何，LOCO时钟都会在必要时自动振荡。经过指定的等待时间后，MCU内部开始提供主时钟，并将OSCSF.MOSCSF标志设置为1。如果指定的等待时间短，则在时钟振荡稳定之前开始提供主时钟.

仅当MOSCCR.MOSTP位为1且OSCSF.MOSCSF标志为0时才重写MOSCWTCR寄存器。在任何其他情况下请勿重写此寄存器。

The USBCKCR register controls the USB clock.

When switching the clock source, ensure that the clock before the switch and the clock after the switch generate stable output. To change the set value of USBCKDIVCR.USBCKDIV[2:0] and USBCKSEL[2:0], use the following procedure:

1. Write 1 to USBCKSREQ.
2. Poll until USBCKSRDY is read as 1. While USBCKSRDY = 1, no clock is output to USBCLK.
3. Write to USBCKDIVCR.USBCKDIV[2:0] and USBCKSEL[2:0].
4. Write 0 to USBCKSREQ.
5. Poll until USBCKSRDY is read as 0.
6. When USBCKSRDY becomes 0, USBCLK starts to output. Clock switching is complete.

When transitioning to Software Standby or Deep Software Standby mode, do not execute the WFI instruction while performing clock switching. That is, do not execute the WFI instruction when USBCKSREQ = 1 and USBCKSRDY = 0, or when USBCKSREQ = 0 and USBCKSRDY = 1.

Trace Clock Control Register controls switching the trace clock.

TRCKCR can be written only when the debugger is connected (DBGSTR.CDBGPWRUPREQ = 1).

When the debugger is not connected, it is not necessary to change TRCK[3:0] even if the TRCLK frequency is higher than the maximum value of the specification.

Change the TRCLK frequency in the state of TRCKEN = 0.

Factor of the initialization of TRCKCR register is all resets.

8.3 Main Clock Oscillator

To supply the clock signal to the main clock oscillator, use one of the following ways:

- Connect an oscillator
- Connect the input of an external clock signal.

8.3.1 Connecting a Crystal Resonator

Figure 8.4 shows an example of connecting a crystal resonator. A damping resistor (Rd) can be added, if required.

Because the resistor values vary according to the resonator and the oscillation drive capability, use values recommended by the resonator manufacturer. If the manufacturer recommends using an external feedback resistor (Rf), insert an Rf between EXTAL and XTAL by following the instructions.

When connecting a resonator to supply the clock, the frequency of the resonator must be in the frequency range of the resonator for the main clock oscillator as described in Table 8.1.

未连接调试器时，即使TRCLK频率高于规范的最大值，也无需更改TRCK[3:0]。

在TRCKEN=0的状态下改变TRCLK频率。

TRCKCR寄存器初始化的因素是所有的复位。

8.3 主时钟振荡器

要将时钟信号提供给主时钟振荡器，请使用以下方法之一：

●连接振荡器

●连接外部时钟信号的输入。

8.3.1 连接晶体谐振器

图8.4显示了连接晶体谐振器的示例。如果需要，可以添加一个阻尼电阻器(Rd)。

由于电阻值因谐振器和振荡驱动能力而异，请使用谐振器制造商推荐的值。如果制造商建议使用外部反馈电阻器(Rf)，请按照说明在EXTAL和XTAL之间插入一个Rf。

连接谐振器以提供时钟时，谐振器的频率必须在表8.1中所述的主时钟振荡器的谐振器频率范围内。

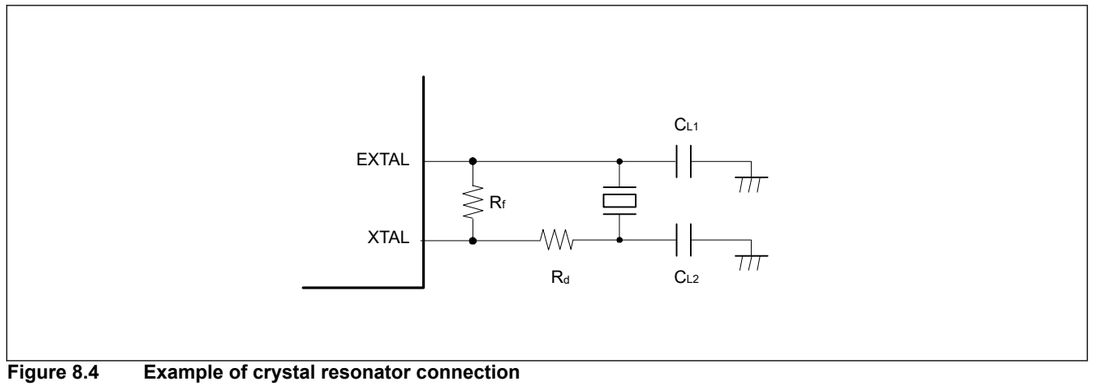

Figure 8.4 Example of crystal resonator connection

Figure 8.5 shows an equivalent circuit of the crystal resonator.

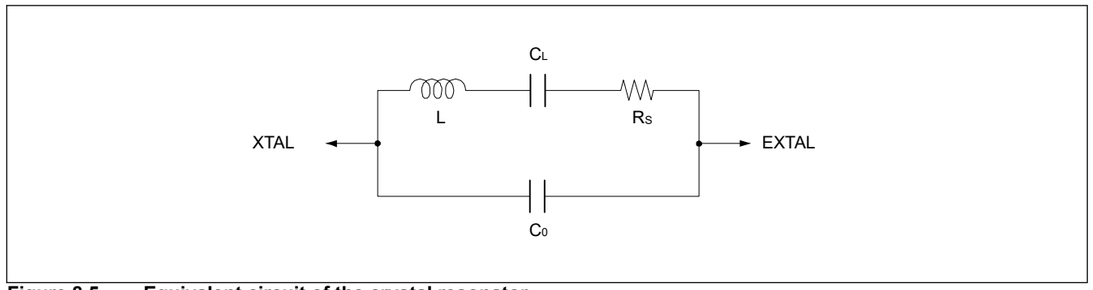

Figure 8.5 Equivalent circuit of the crystal resonator

8.3.2 External Clock Input

Figure 8.6 shows an example of connecting an external clock input. To operate the oscillator with an external clock signal, set the MOMCR.MOSEL bit to 1. The XTAL pin becomes high impedance.

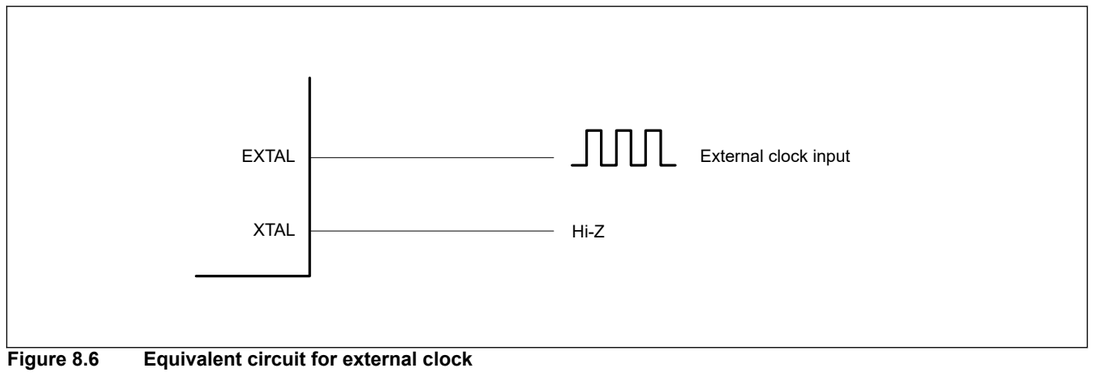

Figure 8.6 Equivalent circuit for external clock

8.3.3 Notes on External Clock Input

The frequency of the external clock input can only be changed when the main clock oscillator is stopped. Do not change the frequency of the external clock input when the setting of the Main Clock Oscillator Stop bit (MOSCCR.MOSTP) is 0.

8.4 Sub-Clock Oscillator

The only way of supplying a clock signal to the sub-clock oscillator is by connecting a crystal oscillator.

图8.6显示了连接外部时钟输入的示例。要使用外部时钟信号操作振荡器，请将MOMCR.MOSEL位设置为1。XTAL引脚变为高阻抗。

8.3.3 外部时钟输入注意事项

外部时钟输入的频率只有在主时钟振荡器停止时才能改变。当主时钟振荡器停止位(MOSCCR.MOSTP)设置为0时，请勿更改外部时钟输入的频率。

8.4 Sub-Clock Oscillator

向副时钟振荡器提供时钟信号的唯一方法是连接晶体振荡器。

8.4.1 Connecting a 32.768-kHz Crystal Resonator

To supply a clock to the sub-clock oscillator, connect a 32.768-kHz crystal resonator as shown in Figure 8.7. A damping resistor (Rd) can be added, if necessary. Because the resistor values vary according to the resonator and the oscillation drive capability, use values recommended by the resonator manufacturer. If the resonator manufacturer recommends the use of an external feedback resistor (Rf), insert an Rf between XCIN and XCOUT by following the instructions. When connecting a resonator to supply the clock, the frequency of the resonator must be in the frequency range of the resonator for the sub-clock oscillator as described in Table 8.1.

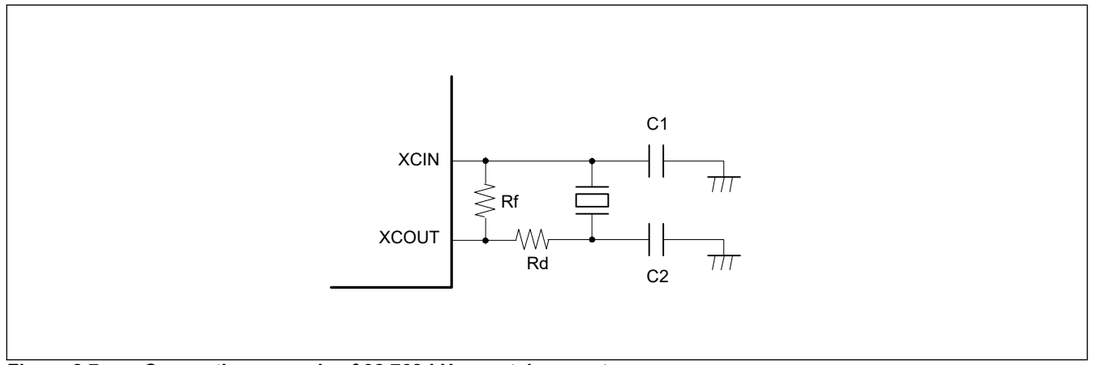

Figure 8.7 Connection example of 32.768-kHz crystal resonator

Figure 8.8 shows an equivalent circuit for the 32.768-kHz crystal resonator.

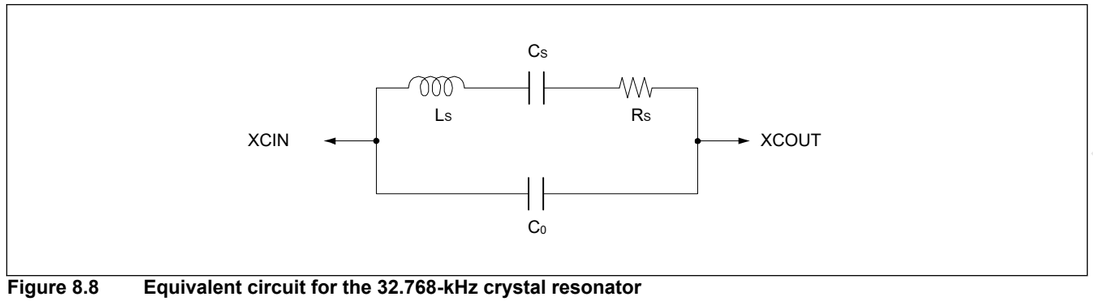

Figure 8.8 Equivalent circuit for the 32.768-kHz crystal resonator

8.4.2 Pin Handling When the Sub-Clock Oscillator Is Not Used

When the sub-clock oscillator is not in use, connect the XCIN pin to VSS through a resistor (to pull VSS down) and leave the XCOUT pin open as shown in Figure 8.9. In addition, if an oscillator is not connected, set the Sub-Clock Oscillator Stop bit (SOSCCR.SOSTP) to 1 to stop the oscillator.

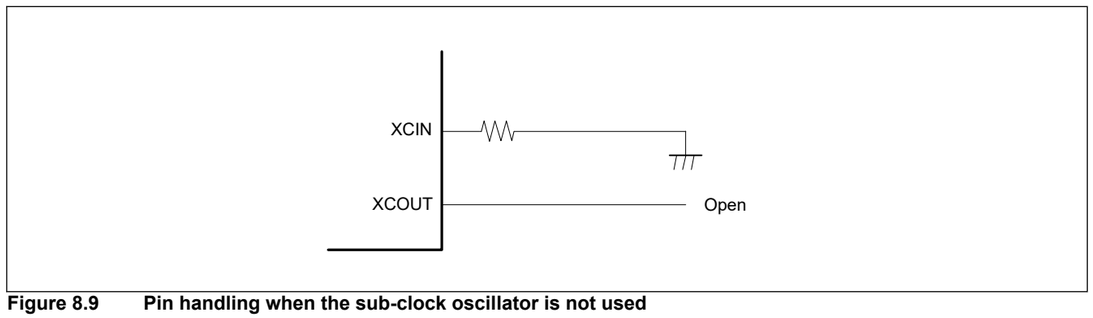

Figure 8.9 Pin handling when the sub-clock oscillator is not used

8.4.1 连接32.768kHz晶体谐振器

要为副时钟振荡器提供时钟，请连接一个32.768-kHz晶体谐振器，如图8.7所示。如有必要，可以添加阻尼电阻器(Rd)。由于电阻值因谐振器和振荡驱动能力而异，请使用谐振器制造商推荐的值。如果谐振器制造商建议使用外部反馈电阻器(Rf)，请按照说明在XCIN和XCOUT之间插入一个Rf。连接谐振器以提供时钟时，谐振器的频率必须在表8.1中所述的副时钟振荡器的谐振器频率范围内。

8.4.2 不使用副时钟振荡器时的引脚处理

不使用副时钟振荡器时，通过一个电阻将XCIN引脚连接到VSS（将VSS下拉）并使XCOUT引脚保持开路，如图8.9所示。此外，如果未连接振荡器，请将副时钟振荡器停止位(SOSCCR.SOSTP)设置为1以停止振荡器。

8.5 Oscillation Stop Detection Function

8.5.1 Oscillation Stop Detection and Operation after Detection

The oscillation stop detection function detects the main clock oscillator stop. When oscillation stop is detected, the system clock switches as follows:

- If an oscillation stop is detected with SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC), the system clock source switches to the MOCO clock.
- If an oscillation stop is detected with PLLCCR.PLSRCSEL = 0 (PLL source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL), PLL clock remains the system clock source. However, the frequency becomes a free-running oscillation frequency.

An oscillation stop detection interrupt request can be generated when an oscillation stop is detected. In addition, the General PWM Timer (GPT) output can be forced to a high-impedance state on detection.

The main clock oscillation stop is detected when the input clock remains at 0 or 1 for a certain period, for example, when a malfunction occurs in the main clock oscillator. See section 43, Electrical Characteristics.

Switching between the main clock oscillator and the MOCO clock or between the PLL clock and PLL free-running clock is controlled by the Oscillation Stop Detection Flag (OSTDSR.OSTDF).

OSTDF controls the switched clock as follows:

- When SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC):
  - When OSTDF changes from 0 to 1, the clock source switches to the MOCO clock.
  - When OSTDF changes from 1 to 0, the clock source switches back to MOSC.
- When PLLCCR.PLSRCSEL = 0 (PLL source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (System clock source = PLL):
  - When OSTDF changes 0 to 1, the clock source switches to the PLL free-running oscillation clock.
  - When OSTDF changes 1 to 0, the clock source switches back to PLL.

To switch the clock source to the main clock or PLL clock again after the oscillation stop detection, set the CKSEL[2:0] bits to a clock source other than the main clock or PLL clock and clear the OSTDF flag to 0. Also, check that the OSTDF flag is not 1, then set the CKSEL[2:0] bits to the main clock or PLL clock after the specified oscillation stabilization time elapses.

After a reset release, the main clock oscillator is stopped and the oscillation stop detection function is disabled. To enable the oscillation stop detection function, activate the main clock oscillator and write 1 to the oscillation stop detection function enable bit (OSTDCR.OSTDE) after a specified oscillation stabilization time elapses.

The oscillation stop detection function detects when the main clock is stopped by an external cause. Therefore, the oscillation stop detection function must be disabled before the main clock oscillator is stopped by software or a transition is made to Software Standby or Deep Software Standby mode.

The oscillation stop detection function switches all clocks that can be selected as the MOSC clock except CLKOUT to the MOCO (when system clock is MOSC) or PLL free-running (when system clock is PLL).

The system clock (ICLK) frequency during the MOCO(when system clock is MOSC) or PLL free-running (when system clock is PLL) operation is specified by the MOCO oscillation frequency and the division ratio set by the system clock select bits (SCKDIVCR.ICK[2:0])

8.5 振荡停止检测功能

8.5.1 振荡停止检测和检测后操作

振荡停止检测功能检测主时钟振荡器停止。当检测到振荡停止时，系统时钟切换如下：

●如果通过SCKSCR.CKSEL[2:0]=011b（系统时钟源=MOSC）检测到振荡停止，则系统时钟源切换到MOCO时钟。

●如果在PLLCCR.PLSRCSEL=0（PLL源时钟=MOSC）的情况下检测到振荡停止并且SCKSCR.CKSEL[2:0]=101b（系统时钟源=PLL），PLL时钟仍然是系统时钟源。然而，该频率变为自由运行的振荡频率。

当检测到振荡停止时，可以产生一个振荡停止检测中断请求。此外，一般PWM定时器(GPT)输出可在检测时强制为高阻抗状态。

当输入时钟保持在0或1一段时间，例如，当主时钟振荡器发生故障时，检测到主时钟振荡停止。参见第43节，电气特性。

主时钟振荡器和MOCO时钟之间或PLL时钟和PLL自由运行时钟之间的切换由振荡停止检测标志(OSTDSR.OSTDF)控制。

OSTDF控制切换时钟如下：

●当SCKSCR.CKSEL[2:0]=011b时（系统时钟源=MOSC）：

当OSTDF从0变为1时，时钟源切换到MOCO时钟。

当OSTDF从1变为0时，时钟源切换回MOSC。

●当PLLCCR.PLSRCSEL=0（PLL源时钟=MOSC）且SCKSCR.CKSEL[2:0]=101b（系统时钟源=PLL）时：

当OSTDF由0变为1时，时钟源切换到PLL自由运行振荡时钟。

当OSTDF由1变为0时，时钟源切换回PLL。

要在检测到振荡停止后再次将时钟源切换为主时钟或PLL时钟，请将CKSEL[2:0]位设置为主时钟或PLL时钟以外的时钟源，并将OSTDF标志清零。另外，检查OSTDF标志不为1，然后在指定的振荡稳定时间过去后将CKSEL[2:0]位设置为主时钟或PLL时钟。

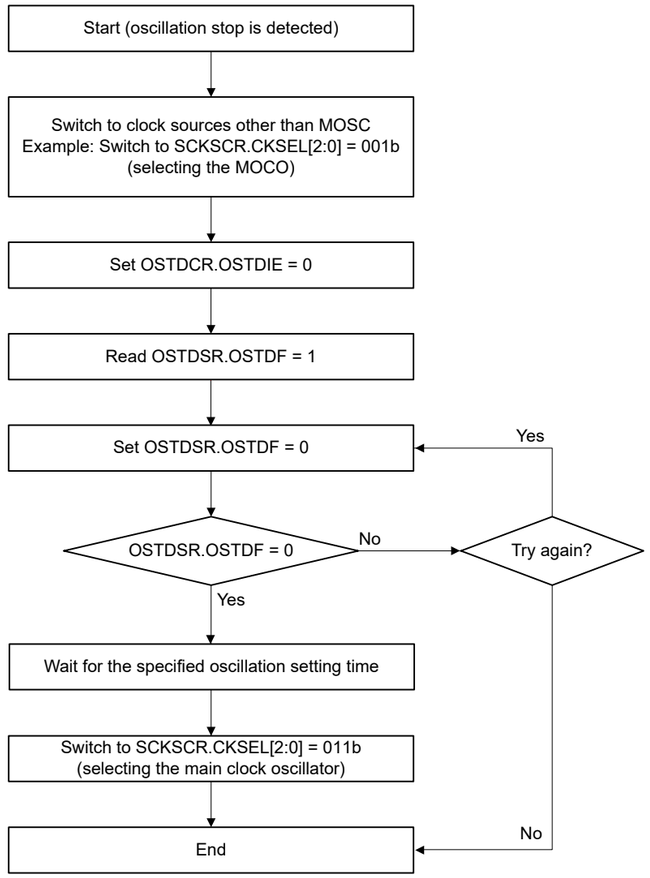
复位释放后，主时钟振荡器停止，振荡停止检测功能被禁用。要使能振荡停止检测功能，激活主时钟振荡器并在经过指定的振荡稳定时间后将1写入振荡停止检测功能使能位(OSTDCR.OSTDE)。

振荡停止检测功能检测主时钟何时因外部原因停止。因此，必须在软件停止主时钟振荡器或转换到软件待机或深度软件待机模式之前禁用振荡停止检测功能。

振荡停止检测功能将除CLKOUT之外的所有可选择作为MOSC时钟的时钟切换到MOCO（系统时钟为MOSC时）或PLL自由运行（系统时钟为PLL时）。

MOCO（系统时钟为MOSC时）或PLL自由运行（系统时钟为PLL时）操作期间的系统时钟（ICLK）频率由MOCO振荡频率和系统时钟选择位（SCKDIVCR）设置的分频比指定.ICK[2:0])

Example of returning when CKSEL[2:0] = 011b (selecting the main clock oscillator) after an oscillation stop is detected



Note: On return from the oscillation-stopped state, the factor responsible for stopping the main clock oscillation circuit must be removed from the system to allow oscillation to resume.

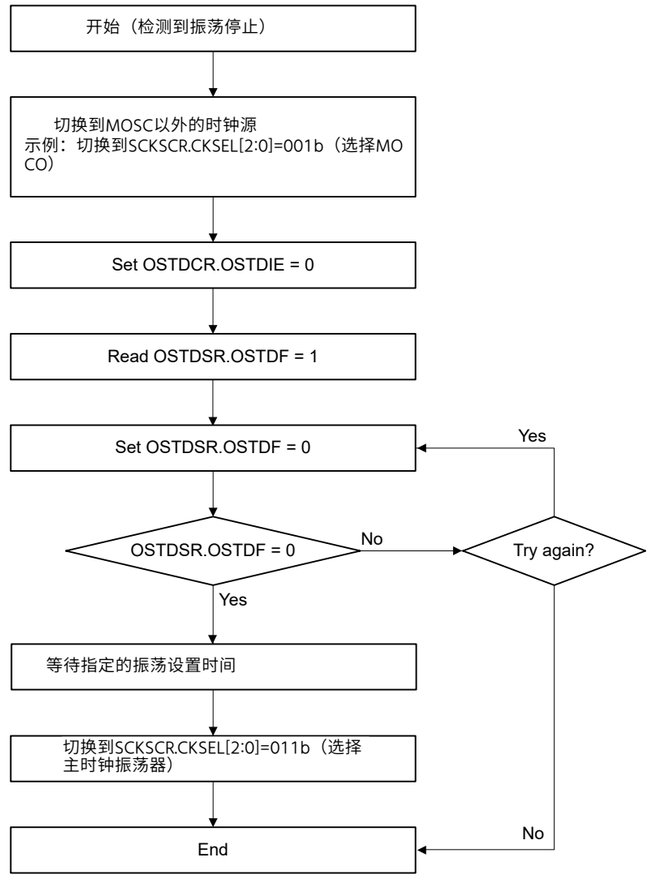
Figure 8.10 Flow of recovery on detection of oscillator stop

8.5.2 Oscillation Stop Detection Interrupts

An oscillation stop detection interrupt (MOSC_STOP) is generated when the Oscillation Stop Detection Flag (OSTDSR.OSTDF) is 1 and the Oscillation Stop Detection Interrupt Enable bit in the Oscillation Stop Detection Control Register (OSTDCR.OSTDIE) is 1 (enabled). The Port Output Enable for GPT (POEG) is notified of the main clock oscillator stop. On receiving the notification, the POEG sets the Oscillation Stop Detection Flag in the POEG Group n Setting Register (POEGGn.OSTPF) to 1 (n = A, B, C, D).

After the oscillation stop is detected, wait at least 10 PCLKB clock cycles before writing to the POEGGn.OSTPF flag. When the OSTDSR.OSTDF flag requires clearing, do so after clearing the Oscillation Stop Detection Interrupt Enable bit in the Oscillation Stop Detection Control Register (OSTDCR.OSTDIE). Wait at least 2 PCLKB clock cycles before setting the OSTDCR.OSTDIE bit to 1 again. A longer PCLKB wait time might be required, depending on the number of cycles required to read a given I/O register.

检测到振荡停止后CKSEL[2:0]=011b（选择主时钟振荡器）时返回的示例



Note: 在从振荡停止状态返回时，必须从系统中移除负责停止主时钟振荡电路的因素以允许振荡恢复。

Figure 8.10 检测到振荡器停止时的恢复流程

8.5.2 振荡停止检测中断

当振荡停止检测标志(OSTDSR.OSTDF)为1且振荡停止检测控制寄存器(OSTDCR.OSTDIE)中的振荡停止检测中断使能位为1（使能）时，将产生一个振荡停止检测中断(MOSC_STOP)。GPT端口输出使能(POEG)被通知主时钟振荡器停止。收到通知后，POEG将POEG组n设置寄存器(POEGGn.OSTPF)中的振荡停止检测标志设置为1(n=A B C D)。

检测到振荡停止后，至少等待10个PCLKB时钟周期，然后再写入POEGGn.OSTPF标志。
当需要清除OSTDSR.OSTDF标志时，请在清除振荡停止检测控制寄存器(OSTDCR.OSTDIE)中的振荡停止检测中断使能位后执行此操作。至少等待2个PCLKB时钟周期，然后再将OSTDCR.OSTDIE位设置为1。可能需要更长的PCLKB等待时间，具体取决于读取给定IO寄存器所需的周期数。

The oscillation stop detection interrupt is a non-maskable interrupt. 8.8 Usage Notes

8.8.1 Notes on Clock Generation Circuit

The frequency of the following clocks supplied to each module changes according to the setting of the SCKDIVCR register:

- System clock (ICLK)
- Peripheral module clocks (PCLKA, PCLKB, PCLKC, and PCLKD)
- FlashIF clock (FCLK)

Each frequency must meet the following conditions:

- Each frequency must be selected within the operation-guaranteed range of the operating frequency (f) specified in the AC characteristics. See section 43, Electrical Characteristics.
- The system clock, peripheral module clock must be set according to Table 8.2.

To ensure correct processing after the clock frequency changes, first write to the relevant Clock Control register to change the frequency, then read the value from the register, and finally perform the subsequent processing.

8.8.2 Notes on Resonator

Because various resonator characteristics relate closely to your board design, adequate evaluation is required before use. See the resonator connection example in Figure 8.7. The circuit constants for the resonator depend on the resonator to be used and the stray capacitance of the mounting circuit. Therefore, consult the resonator manufacturer when determining the circuit constants. The voltage to be applied between the resonator pins must be within the absolute maximum rating.

8.8.3 Notes on Board Design

When using a crystal resonator, place the resonator and its load capacitors as close to the XTAL and EXTAL pins as possible. Other signal lines should be routed away from the oscillation circuit as shown in Figure 8.13 to prevent electromagnetic induction from interfering with correct oscillation. Figure 8.13 shows the case which the main clock oscillator is used. In case of sub-clock oscillator, it is also same as Figure 8.13.

CLKOUT从CLKOUT引脚外部输出，用于时钟或蜂鸣器输出。CLKOUT被输出到CKOCR.CKOEN设置为1时的CLKOUT引脚。仅更改CKODIV[2:0]或CKOSEL[2:0]位中的值CKOCR.CKOEN位为0时的CKOCR。

CLKOUT时钟频率在以下位中指定：

●CKOCR中的CKODIV[2:0]或CKOSEL[2:0]

●OFS1中的HOCOFRQ0[1:0]位

8.7.12 JTAG Clock (JTAGTCK)

JTAG时钟(JTAGTCK)是JTAG的时钟。

JTAGTCK由JTAG外部时钟(TCK)生成。

8.8 使用说明

8.8.1 时钟产生电路注意事项

提供给每个模块的以下时钟的频率根据SCKDIVCR寄存器的设置而变化：

●系统时钟（ICLK）

●外设模块时钟（PCLKA、PCLKB、PCLKC和PCLKD）

- FlashIF clock (FCLK)

每个频率必须满足以下条件：

●各频率必须在交流特性规定的工作频率(f)的工作保证范围内选择。参见第43节，电气特性。

●系统时钟、外围模块时钟必须按照表8.2设置。

为保证时钟频率改变后的正确处理，首先写入相关的ClockControl寄存器改变频率，然后从该寄存器中读取值，最后进行后续处理。

8.8.2 谐振器注意事项

由于各种谐振器特性与您的电路板设计密切相关，因此在使用前需要进行充分评估。请参见图8.7中的谐振器连接示例。谐振器的电路常数取决于要使用的谐振器和安装电路的杂散电容。因此，在确定电路常数时，请咨询谐振器制造商。施加在谐振器引脚之间的电压必须在绝对最大额定值范围内。

8.8.3 电路板设计注意事项

使用晶体谐振器时，将谐振器及其负载电容尽可能靠近XTAL和EXTAL引脚。其他信号线应远离振荡电路，如图8.13所示，以防止电磁感应干扰正确的振荡。图8.13显示了使用主时钟振荡器的情况。如果是副时钟振荡器，也与图8.13相同。

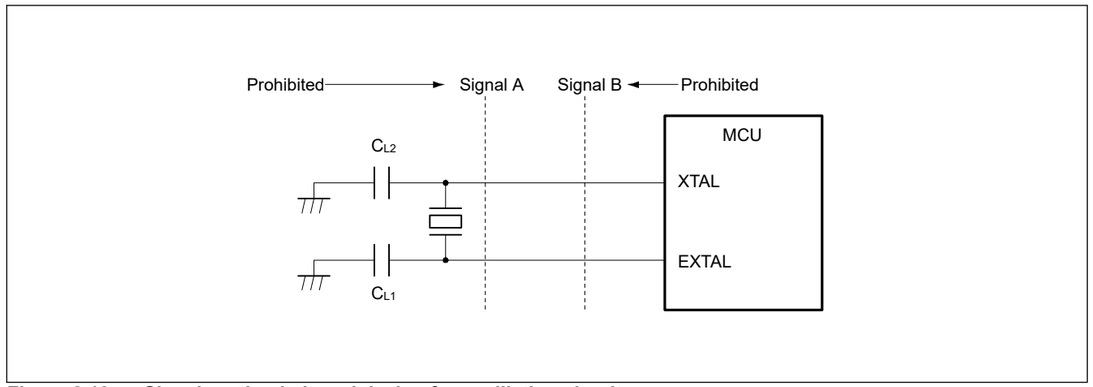

Figure 8.13 Signal routing in board design for oscillation circuit

8.8.4 Notes on Resonator Connect Pin

When the main clock is not used, the EXTAL and XTAL pins can be used as general ports. When these pins are used as general ports, the main clock must be stopped (MOSCCR.MOSTP bit should be set to 1).

8.8.5 Notes on Using Sub-Clock Oscillator

The output of the P212 (EXTAL), P213 (XTAL) pins may affect the oscillation by the sub-clock oscillator.

If the sub-clock oscillator is used, implement board design so as not to affect the oscillation. Renesas strongly recommends setting the DSCR[1:0] bits to 00b or 01b when using the P212 (EXTAL), P213 (XTAL) as output pins and using the sub-clock oscillator.

In addition, when using the sub-clock oscillator in middle drive capability (SOMCR.SODRV1 = 1), Renesas recommecds setting the DSCR[1:0] bits to 00b when using the P212 (EXTAL), P213 (XTAL) as output pins and using the sub-clock oscillator.

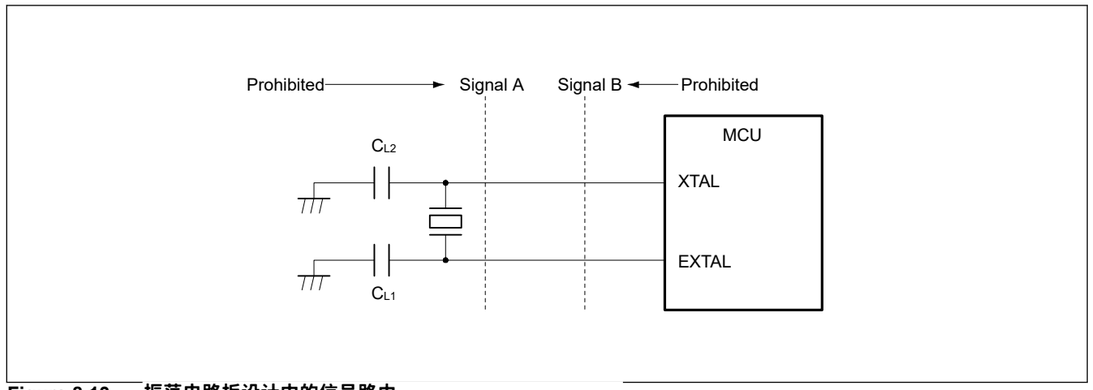

Figure 8.13 振荡电路板设计中的信号路由

8.8.4 谐振器连接引脚注意事项

当不使用主时钟时，EXTAL和XTAL引脚可用作通用端口。当这些引脚用作通用端口时，必须停止主时钟（MOSCCR.MOSTP位应设置为1）。

8.8.5 使用副时钟振荡器的注意事项

P212(EXTAL)、P213(XTAL)引脚的输出可能会影响副时钟振荡器的振荡。

如果使用副时钟振荡器，请在不影响振荡的情况下进行板卡设计。当使用P212(EXTAL)、P213(XTAL)作为输出引脚并使用副时钟振荡器时，瑞萨强烈建议将DSCR[1:0]位设置为00b或01b。

此外，当在中间驱动能力（SOMCR.SODRV1=1）中使用副时钟振荡器时，瑞萨建议在使用P212（EXTAL）、P213（XTAL）作为输出引脚时将DSCR[1:0]位设置为00b并使用副时钟振荡器。

9.3 Operation

9.3.1 测量时钟频率

CAC使用CACREF引脚输入或内部时钟作为参考来测量时钟频率。图9.2显示了CAC的操作示例。

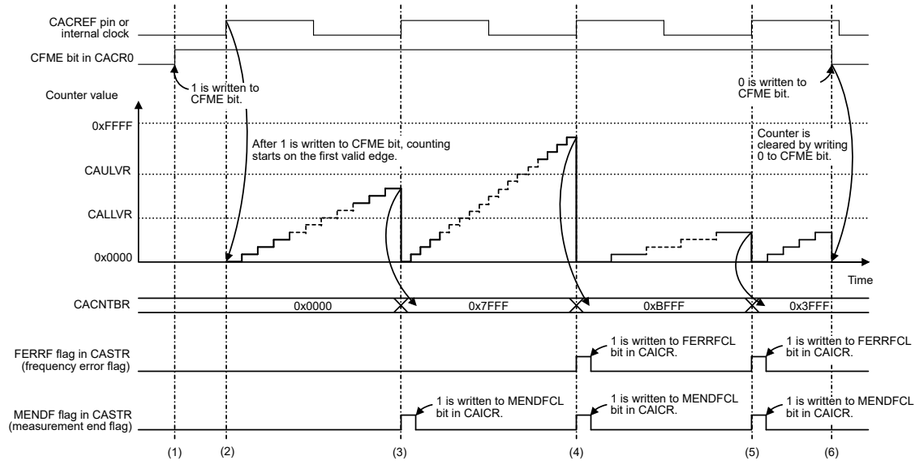

Figure 9.2 CAC operating example

The events in Figure 9.2 are:

1. When the CACREF pin input is used as reference (CACR1.CACREFE = 1), frequency measurement is enabled by writing 1 to the CACR0.CFME bit while the CACR2.RPS bit is set to 0 and the CACR1.CACREFE bit is set to 1. When the internal clock is used as reference (CACR1.CACREFE = 0), frequency measurement is enabled by writing 1 to the CACR0.CFME bit while the CACR2.RPS bit is set to 1.
2. When the CACREF pin input is used as reference, after 1 is written to the CFME bit, the timer starts up-counting if the valid edge selected by the CACR1.EDGES[1:0] bits (rising edge (CACR1.EDGES[1:0] = 00b) in Figure 9.2) is input from the CACREF pin. When the internal clock is used as reference, after 1 is written to the CFME bit, the timer starts up-counting if the valid edge selected by the CACR1.EDGES[1:0] bits (rising edge (CACR1.EDGES[1:0] = 00b) in Figure 9.2) is input based on the clock source selected by the CACR2.RSCS[2:0] bits.
3. When the next valid edge is input, the counter value is transferred to CACNTBR and compared with the values in CAULVR and CALLVR. If both CACNTBR ≤ CAULVR and CACNTBR ≥ CALLVR are true, only the MENDF flag in CASTR is set to 1, because the clock frequency is correct. If the MENDIE bit in CAICR is 1, a measurement end interrupt is generated.
4. When the next valid edge is input, the counter value is transferred to CACNTBR and compared with the values in CAULVR and CALLVR. If CACNTBR > CAULVR, the FERRF flag in CASTR is set to 1, because the clock frequency is erroneous. If the FERRIE bit in CAICR is 1, a frequency error interrupt is generated. The MENDF flag in CASTR is set to 1 at the end of measurement. If the MENDIE bit in CAICR is 1, a measurement end interrupt is generated.
5. When the next valid edge is input, the counter value is transferred to CACNTBR and compared with the values in CAULVR and CALLVR. If CACNTBR < CALLVR, the FERRF flag in CASTR is set to 1, because the clock frequency is erroneous. If the FERRIE bit in CAICR is 1, a frequency error interrupt is generated. The MENDF flag in CASTR is set to 1 at the end of measurement. If the MENDIE bit in CAICR is 1, a measurement end interrupt is generated.
6. When the CFME bit in CACR0 is 1, the counter value is transferred to CACNTBR and compared with the values in CAULVR and CALLVR every time a valid edge is input. Writing 0 to the CFME bit in CACR0 clears the counter and stops up-counting.

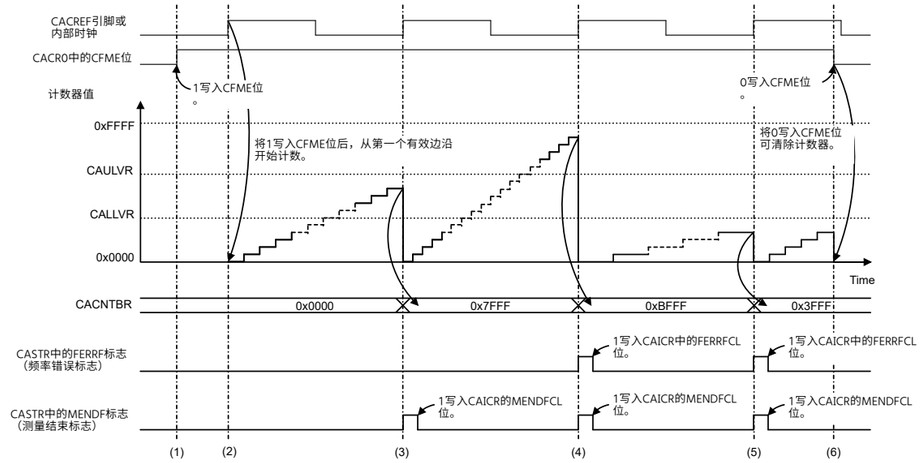

Figure 9.2 CAC操作示例

图9.2中的事件是：

1.当CACREF引脚输入用作参考时（CACR1.CACREFE=1），频率测量通过以下方式启用
将1写入CACR0.CFME位，同时将CACR2.RPS位设置为0，并将CACR1.CACREFE位设置为1。当内部时钟用作参考时(CACR1.CACREFE=0)，频率测量通过以下方式启用将1写入CACR0.CFME位，同时CACR2.RPS位设置为1。

2.当CACREF引脚输入用作参考时，向CFME位写入1后，如果CACR1.EDGES[1:0]位选择的有效沿（上升沿（CACR1.EDGES图9.2中的[1:0]=00b))从CACREF引脚输入。当内部时钟用作参考时，CFME位写入1后，如果CACR1.EDGES[1:0]位选择的有效沿（上升沿（CACR1.EDGES[1:图9.2中的0]=00b))根据CACR2.RSCS[2:0]位选择的时钟源输入。

3.当输入下一个有效边沿时，计数器值被传送到CACNTBR并与中的值进行比较
CAULVR和CALLVR。如果CACNTBR≤CAULVR和CACNTBR≥CALLVR都为真，则只有MENDF标志CASTR设置为1，因为时钟频率正确。如果CAICR中的MENDIE位为1，则产生测量结束中断。

4.当输入下一个有效边沿时，计数器值被传送到CACNTBR并与中的值进行比较
CAULVR和CALLVR。如果CACNTBR>CAULVR，则CASTR中的FERRF标志设置为1，因为时钟频率错误。如果CAICR中的FERRIE位为1，则产生频率错误中断。CASTR中的MENDF标志在测量结束时设置为1。如果CAICR中的MENDIE位为1，则产生测量结束中断。

5.当输入下一个有效边沿时，计数器值被传送到CACNTBR并与中的值进行比较
CAULVR和CALLVR。如果CACNTBR<CALLVR，则CASTR中的FERRF标志设置为1，因为时钟频率错误。如果CAICR中的FERRIE位为1，则产生频率错误中断。CASTR中的MENDF标志在测量结束时设置为1。如果CAICR中的MENDIE位为1，则产生测量结束中断。

6.当CACR0中的CFME位为1时，每次输入有效边沿时，计数器值被传送到CACNTBR并与CAULVR和CALLVR中的值进行比较。向CACR0中的CFME位写入0将清除计数器并停止向上计数。

9.3.2 Digital Filtering of Signals on CACREF Pin

The CACREF pin has a digital filter, and levels on the CACREF pin are transmitted to the internal circuitry after three consecutive matches in the selected sampling interval. The same level continues to be transmitted internally until the level on the pin has three consecutive matches again. Enabling or disabling of the digital filter and its sampling clock are selectable.

The counter value transferred to CACNTBR might be in error by up to 1 cycle of the sampling clock because of the difference between the phases of the digital filter and the signal input to the CACREF pin. When a frequency dividing clock is selected as a count source clock, the counter value error is obtained using the following formula:

Counter value error = (1 cycle of the count source clock)/ (1 cycle of the sampling clock)

9.4 Interrupt Requests

The CAC generates three types of interrupt requests:

- Frequency error interrupt
- Measurement end interrupt
- Overflow interrupt

When an interrupt source is generated, the associated status flag is set to 1. Table 9.3 provides information on the CAC interrupt requests.

Table 9.3 CAC interrupt requests

Interrupt request	Interrupt enable bit	Status flag	Interrupt sources
Frequency error interrupt	CAICR.FERRIE	CASTR.FERRF	The result of comparing CACNTBR with CAULVR and CALLVR is either CACNTBR > CAULVR or CACNTBR < CALLVR
Measurement end interrupt	CAICR.MENDIE	CASTR.MENDF	• Valid edge is input from the CACREF pin or internal clock • Measurement end interrupt does not occur at the first valid edge after writing 1 to the CACR0.CFME bit
Overflow interrupt	CAICR.OVFIE	CASTR.OVFF	Counter overflows

9.5 Usage Notes

9.5.1 Settings for the Module-Stop Function

The Module Stop Control Register C (MSTPCRC) can enable or disable CAC operation. The CAC module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

9.3.2 CACREF引脚上的信号数字滤波

CACREF引脚有一个数字滤波器，CACREF引脚上的电平在选定的采样间隔内连续三个匹配后传输到内部电路。同一电平继续在内部传输，直到引脚上的电平再次连续匹配三个。可选择启用或禁用数字滤波器及其采样时钟。

由于数字滤波器的相位和输入到CACREF引脚的信号之间存在差异，传输到CACNTBR的计数器值可能会出现最多1个采样时钟周期的误差。Whenafrequencydividingclockisselectedasacountsourceclock thecountervalueerrorisobtainedusingthefollowingformula:

计数器值误差=（计数源时钟的1个周期）（采样时钟的1个周期）

9.4 中断请求

CAC产生三种类型的中断请求：

●频率错误中断

●测量结束中断

●溢出中断

产生中断源时，相关状态标志设置为1。表9.3提供了有关CAC中断请求的信息。

Table 9.3 CAC中断请求

中断请求	中断使能位	状态标志	中断源
频率错误中断	CAICR.FERRIE	CASTR.FERRF	CACNTBR与CAULVR和CALLVR比较的结果是CACNTBR>CAULVR或CACNTBR<CALLVR
测量结束中断	CAICR.MENDIE	CASTR.MENDF	• 有效边沿从CACREF引脚或内部时钟输入 • 将1写入CACR0.CFME位后，在第一个有效边沿不发生测量结束中断
溢出中断	CAICR.OVFIE	CASTR.OVFF	计数器溢出

模块停止控制寄存器C(MSTPCRC)可以启用或禁用CAC操作。CAC模块在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

Note 1. In IWDT-dedicated on-chip oscillator and IWDT, operating or stopping is selected by setting the IWDT Stop Control bit (IWDTSTPCTL) in Option Function Select register 0 (OFS0) in IWDT auto start mode. In WDT, operating or stopping is selected by setting the WDT Stop Control bit (WDTSTPCTL) in Option Function Select Register 0 (OFS0) in WDT auto start mode.Power consumption can be reduced in Normal and Sleep modes by selecting an appropriate operating power control mode according to the operating frequency.

Note: 可选择的意思是可以通过控制寄存器来选择操作或不操作。
停止（Retained）表示内部寄存器的内容被保留但操作被暂停。
禁止操作意味着在进入软件待机模式之前必须停止该功能。
停止（未定义）表示内部寄存器的内容未定义，内部电路的电源被切断。
进入贪睡模式后，一旦提供PCLK，所有模块停止位为0的模块都会启动。为了避免贪睡模式下的功耗增加，在进入软件待机模式之前，必须将在贪睡模式下不需要的模块的模块停止位设置为1。

注1.在IWDT专用内部振荡器和IWDT中，通过设置IWDT停止控制位来选择操作或停止
(IWDTSTPCTL)在IWDT自动启动模式下选项功能选择寄存器0(OFS0)。在WDT中，通过在WDT自动启动模式下设置选项功能选择寄存器0(OFS0)中的WDT停止控制位(WDTSTPCTL)来选择操作或停止。通过选择适当的操作功率控制，可以在正常和睡眠模式下降低功耗模式根据工作频率。

注2.当时钟输出源选择位(CKOCR.CKOSEL[2:0])设置为010b(LOCO)和100b(SOSC)以外的值时停止。

注3.当AGT02.AGTMR1.TCK[2:0]位选择100b(AGTLCLK)或110b(AGTSCLK)时，AGT0可以进行AGT2操作。

AGT1/AGT3 operation is possible when 100b (AGTLCLK), 110b (AGTSCLK) or 101b (Underflow event signal from AGT0/AGT2) is selected by the AGT1/3.AGTMR1.TCK[2:0] bits.
When 100b (AGTLCLK) is selected by AGTn.AGTMR1.TCK[2:0] bits (n = 0, 1, 2, 3), the DPSBYCR.DEEPCUT[1:0] bits must set to 00b before entering Deep Software Standby mode.

Note 4. IIC0 wakeup interrupt is available.
Note 5. When using SCI0 in Snooze mode, MOSCCR.MOSTP and PLLCR.PLLSTP and PLL2CR.PLL2STP bits must be 1.
Note 6. Serial communication modes of SCI0 is only in asynchronous mode.
Note 7. Event lists the restrictions described in section 10.10.13. ELC Events in Snooze Mode.
Note 8. If the DPSBYCR.DEEPCUT[1:0] bits are 00b, the oscillator status is the same as before entering Deep Software Standby mode. When the DPSBYCR.DEEPCUT[1:0] bits are not 00b, the oscillator stops when the MCU enters Deep Software Standby mode.
Note 9. If the DPSBYCR.DEEPCUT[1:0] bits are 00b, data in the Standby SRAM is retained in Deep Software Standby mode. When the DPSBYCR.DEEPCUT[1:0] bits are not 00b, data in the Standby SRAM is undefined in Deep Software Standby mode.
Note 10. If the DPSBYCR.DEEPCUT[1:0] bits are 00b, the values of the USB resume detection circuit registers are retained and detection of USB resumption is enabled, and the values of other registers are undefined in Deep Software Standby mode. When the DPSBYCR.DEEPCUT[1:0] bits are not 00b, the values of all registers are undefined in Deep Software Standby mode.
Note 11. When the RCR4.RCKSEL bit set to 1 (LOCO), the DPSBYCR.DEEPCUT[1:0] bits must set to 00b before entering Deep Software Standby mode.
Note 12. When using LVD in Deep Software Standby mode, DPSBYCR.DEEPCUT[1:0] bits must be 00b or 01b before entering Deep Software Standby mode.
Note 13. When the MCU enters Deep Software Standby mode with the DPSBYCR.DEEPCUT[1:0] bits set to 11b, the LVD circuit stops and the low-power function of the power-on reset circuit is enabled.
Note 14. AGT5 operation is possible when 100b (AGTLCLK) or 110b (AGTSCLK) is selected by the AGT5.AGTMR1.TCK[2:0] bits.
Note 15. When using the 12-bit A/D Converter in Snooze mode, the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits must be 1.

Note 1. To use the interrupt request as a trigger for exiting the Snooze mode, the request must be selected in SELSR0 . See section 13, Interrupt Controller Unit (ICU) for the setting of SELSR0. When a trigger selected in SELSR0 occurs after executing WFI instruction and during the transition from Normal mode to Software Standby mode, the request might or might not be accepted, depending on the timing of the occurrence.
Note 2. Only one of either SCI0_AM or SCI0_RXI_OR_ERI can be set.

当AGT13.AGTMR1.TCK[2:0]位选择100b(AGTLCLK)、110b(AGTSCLK)或101b（来自AGT0AGT2的下溢事件信号）时，AGT1AGT3操作是可能的。当AGTn.AGTMR1.TCK[2:0]位(n=0 1 2 3)选择100b(AGTLCLK)时，DPSBYCR.DEEPCUT[1:0]位必须在进入深度软件待机之前设置为00b模式。

注4.IIC0唤醒中断可用。
注5.在贪睡模式下使用SCI0时，MOSCCR.MOSTP和PLLCR.PLLSTP和PLL2CR.PLL2STP位必须为1。

注11.当RCR4.RCKSEL位设置为1(LOCO)时，DPSBYCR.DEEPCUT[1:0]位必须在进入深度软件之前设置为00b
待机模式。
注12.在深度软件待机模式下使用LVD时，DPSBYCR.DEEPCUT[1:0]位在进入深度之前必须为00b或01b
软件待机模式。
注13.当MCU进入深度软件待机模式且DPSBYCR.DEEPCUT[1:0]位设置为11b时，LVD电路停止并启用上电复位电路的低功耗功能。

注14.当AGT5.AGTMR1.TCK[2:0]位选择100b(AGTLCLK)或110b(AGTSCLK)时，可以进行AGT5操作。
注15.在贪睡模式下使用12位AD转换器时，ADCMPCR.CMPAE和ADCMPCR.CMPBE位必须为1。

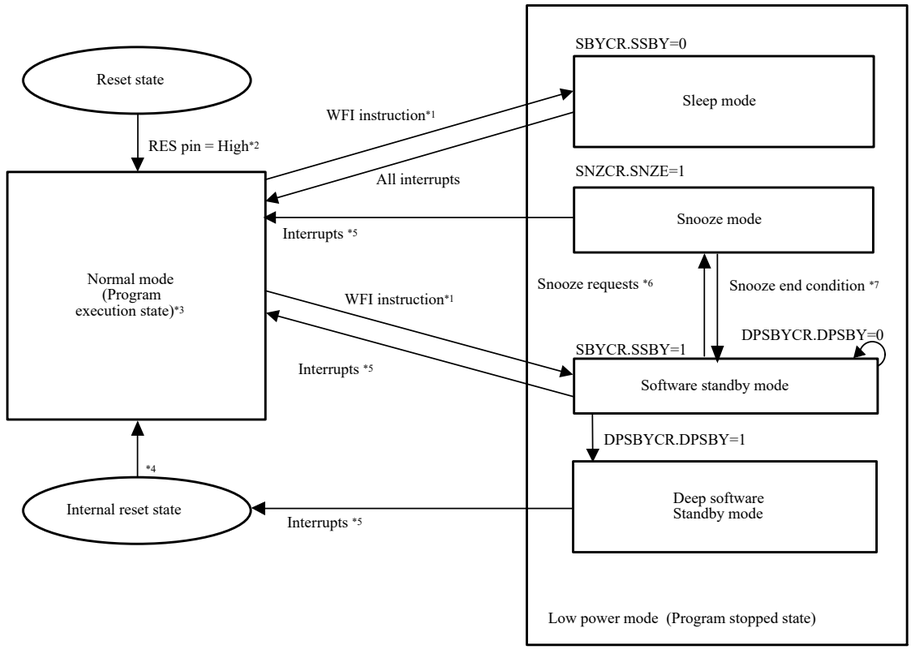
注1.要将中断请求用作退出贪睡模式的触发器，必须在SELSR0中选择该请求。见第13节，
用于设置SELSR0的中断控制器单元(ICU)。当SELSR0中选择的触发发生在执行WFI指令之后以及从正常模式到软件待机模式的转换期间，请求可能会或可能不会被接受，具体取决于发生的时间。

注2.只能设置SCI0_AM或SCI0_RXI_OR_ERI之一。

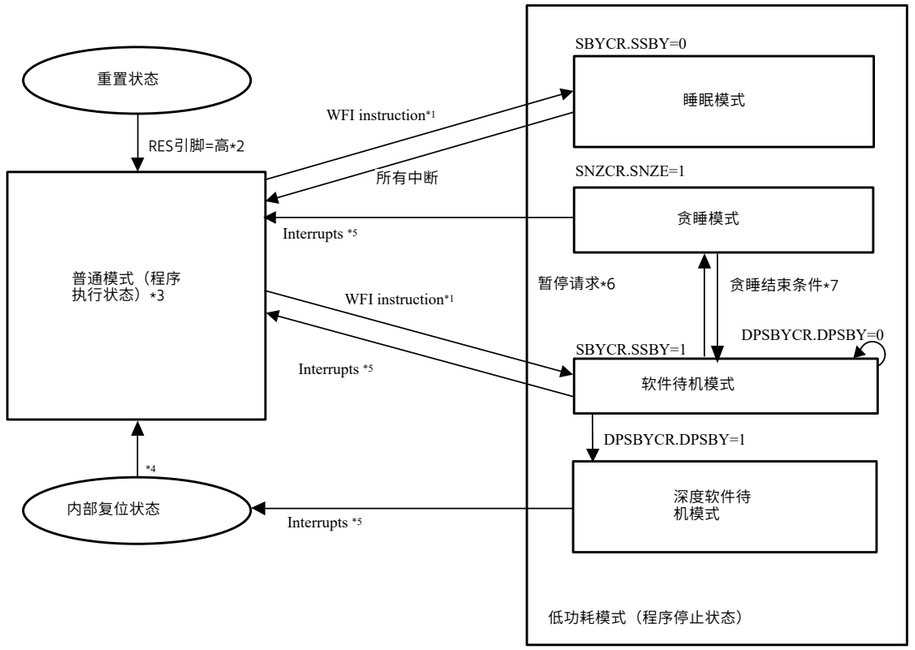
Note 3. The event which is enabled by the SNZEDCRn must not be used.



Note 1. When an interrupt that acts as a trigger for cancel is received during a transition to the program-stopped state after the execution of a WFI instruction, the MCU executes interrupt exception handling instead of transitioning to low power mode.
Note 2. The MOCO clock is the source of the operating clock following a transition from the reset state to Normal mode.
Note 3. The transition to Normal mode is made because of an interrupt from Sleep mode, Snooze mode, or Software Standby mode. The clock source is the same as before entering the low power mode.
Note 4. When an available interrupt request is generated, an internal reset (Deep Software Standby reset) is generated over a fixed period. Canceling of Deep Software Standby mode accompanies release from the internal reset state, and then the MCU transitions to Normal mode and executes reset exception processing with the MOCO clock as the source of the operating clock.
Note 5. See Table 10.3
Note 6. See Table 10.7
Note 7. See Table 10.9

Figure 10.1 Mode Transitions

注3.不得使用由SNZEDCRn启用的事件。



注1.在WFI指令执行后转换到程序停止状态期间，如果接收到用作取消触发的中断，MCU将执行中断异常处理，而不是转换到低功耗模式。

注2.MOCO时钟是从复位状态转换到正常模式后的工作时钟源。
注3.由于休眠模式、贪睡模式或软件待机模式的中断，会转换到正常模式。时钟源与进入低功耗模式前相同。

注4.当产生可用中断请求时，会在固定周期内产生内部复位（深度软件待机复位）。深度软件待机模式的取消伴随着内部复位状态的释放，然后MCU转换到正常模式并以MOCO时钟作为工作时钟源执行复位异常处理。

If the security attribution is configured as Non-secure:

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

SSBY bit (Software Standby Mode Select)

The SSBY bit specifies the transition destination after a WFI instruction is executed.

When the SSBY bit is set to 1, the MCU enters Software Standby mode after execution of a WFI instruction. When the MCU returns to Normal mode from Software Standby mode by an interrupt, the SSBY bit remains 1. The SSBY bit can be cleared by writing 0 to it.

While the OSTDCR.OSTDE bit is 1, setting of the SSBY bit is ignored. Even if SSBY bit is 1, the MCU enters Sleep mode on execution of a WFI instruction.

SSBY位（软件待机模式选择）

SSBY位指定执行WFI指令后的转移目标。

当SSBY位设置为1时，MCU在执行WFI指令后进入软件待机模式。当。。。的时候
MCU通过中断从软件待机模式返回到正常模式，SSBY位保持为1。SSBY位可以通过向其写入0来清除。

当OSTDCR.OSTDE位为1时，忽略SSBY位的设置。即使SSBY位为1，MCU也会在执行WFI指令时进入休眠模式。

While the FENTRYR.FENTRYC bit is 1 setting of the SSBY bit is ignored. Even if SSBY bit is 1, the MCU enters Sleep mode on execution of a WFI instruction.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

The OPCCR register is used to reduce power consumption in Normal and Sleep modes by specifying a lower operating frequency. For the procedure to change the operating power control modes, see section 10.5. Function for Lower Operating Power Consumption.

When transitioning from Software Standby mode to Normal or Snooze mode, the settings in the OPCCR.OPCM[1:0] and SOPCCR.SOPCM bits are as follows, regardless of their settings before entering Software Standby mode:

- OPCCR.OPCM[1:0] = 00b (High-speed mode)
- SOPCCR.SOPCM = 0b (not Subosc-speed mode).

If Software Standby mode is canceled before the transition to Software Standby completes, the OPCCR.OPCM[1:0] and SOPCCR.SOPCM bits retain their settings from before the WFI instruction is executed. If this causes any problem, set the MCU to High-speed mode during the exception handling procedure when canceling Software Standby mode.

如果安全属性配置为非安全：●

Note: 在重写该寄存器之前将PRCR.PRC1位设置为1（允许写入）。

OPCCR寄存器用于通过指定较低的工作频率来降低 正常和休眠模式下的功耗。有关更改运行功率控制模式的步骤，请参阅第10.5节。降低运行功耗的功能。

当从软件待机模式转换到正常或贪睡模式时，OPCCR.OPCM[1:0]中的设置和SOPCCR.SOPCM位如下，无论它们在进入软件待机模式之前的设置如何：

- OPCCR.OPCM[1:0] = 00b (High-speed mode)
- SOPCCR.SOPCM = 0b (not Subosc-speed mode).

如果在转换到软件待机完成之前取消软件待机模式，则OPCCR.OPCM[1:0]和SOPCCR.SOPCM位保留其在执行WFI指令之前的设置。如果这导致任何问题，请设置取消软件待机模式时，MCU在异常处理过程中进入高速模式。

OPCM[1:0] bits (Operating Power Control Mode Select)

The OPCM[1:0] bits select the operating power control mode in Normal and Sleep modes. Table 10.4 shows the relationship between the operating power control modes and the OPCM[1:0] and SOPCM settings.

OPCMTSF flag (Operating Power Control Mode Transition Status Flag)

The OPCMTSF flag indicates the switching control state when the operating power control mode is switched. This flag becomes 1 when the OPCM bit is written, and 0 when mode transition completes. Read this flag and confirm that it is 0 before proceeding.

10.2.10 SOPCCR : Sub Operating Power Control Register

4	SOPCMTSF	Operating Power Control Mode Transition Status Flag 0: Transition completed 1: During transition	R

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

The SOPCCR register is used to reduce power consumption in Normal mode and Sleep mode. Setting this register initiates entry to and exit from Subosc-speed mode. Subosc-speed mode is available only when using the sub-clock oscillator or LOCO without dividing the frequency.

For the procedure to change operating power control modes, see section 10.5. Function for Lower Operating Power Consumption.

SOPCM bit (Sub Operating Power Control Mode Select)

The SOPCM bit selects the operating power control mode in Normal and Sleep modes. Setting this bit to 1 allows transition to Subosc-speed mode. Setting this bit to 0 allows a return to the operating mode (operating mode set by OPCCR.OPCM[1:0]) that was active before the transition to Subosc-speed mode.

When transitioning from Software Standby mode to Normal mode or Snooze mode, the OPCCR.OPCM[1:0] and SOPCCR.SOPCM settings are as follows, regardless of their settings before entering Software Standby mode:

- OPCCR.OPCM[1:0] = 00b (High-speed mode)
- SOPCCR.SOPCM = 0b (not Subosc-speed mode)

If Software Standby mode is canceled before the transition to Software Standby completes, the OPCCR.OPCM[1:0] and SOPCCR.SOPCM bits retain their settings from before the WFI instruction is executed. If this causes any problem, set the MCU to High-speed mode during the exception handling procedure when canceling Software Standby mode.

Table 10.4 shows the relationship between the operating power control modes, the OPCM[1:0], and SOPCM bits settings.

OPCM[1:0]位（工作电源控制模式选择）

OPCM[1:0]位选择正常和休眠模式下的工作功率控制模式。表10.4显示了工作功率控制模式与OPCM[1:0]和SOPCM设置之间的关系。

OPCMTSF标志（工作电源控制模式转换状态标志）

OPCMTSF标志指示切换操作功率控制模式时的切换控制状态。该标志在OPCM位被写入时变为1，在模式转换完成时变为0。阅读此标志并确认其为0，然后再继续。

- 忽略非安全写入访问，不会生成TrustZone访问错误。

如果安全属性配置为非安全：●
允许安全和非安全访问。

Note: 在重写该寄存器之前将PRCR.PRC1位设置为1（允许写入）。

SOPCCR寄存器用于降低正常模式和休眠模式下的功耗。设置该寄存器启动进入和退出Subosc速度模式。Subosc速度模式仅在使用副时钟振荡器或LOCO而不分频时可用。

有关更改操作功率控制模式的步骤，请参阅第10.5节。降低操作功率的功能
Consumption.

SOPCM位（副工作功率控制模式选择）

SOPCM位选择正常和休眠模式下的工作功率控制模式。将此位设置为1允许转换到Subosc速度模式。将此位设置为0允许返回到转换到Subosc速度模式之前处于活动状态的操作模式（由OPCCR.OCM[1:0]设置的操作模式）。

当从软件待机模式转换到正常模式或贪睡模式时，OPCCR.OCM[1:0]和SOPCCR.SOPCM设置如下，无论其进入软件待机模式前的设置如何：

- OPCCR.OPCM[1:0] = 00b (High-speed mode)
- SOPCCR.SOPCM = 0b (not Subosc-speed mode)

如果在转换到软件待机完成之前取消软件待机模式，则OPCCR.OPCM[1:0]和SOPCCR.SOPCM位保留其在执行WFI指令之前的设置。如果这导致任何问题，请设置取消软件待机模式时，MCU在异常处理过程中进入高速模式。

表10.4显示了工作功率控制模式、OPCM[1:0]和SOPCM位设置之间的关系。

SOPCMTSF flag (Operating Power Control Mode Transition Status Flag)

The SOPCMTSF flag indicates the switching control state when the operating power control mode is switched to or from Subosc-speed mode. This flag becomes 1 when the SOPCM bit is written, and 0 when mode transition completes. Read this flag and confirm that it is 0 before proceeding.

Table 10.4 shows each operating power control mode.

Table 10.4 Operating power control mode

Operating power control mode	OPCM[1:0] bits	SOPCM bit	Power consumption
High-speed mode	00b	0	High
Low-speed mode	11b	0	↓
Subosc-speed mode	xxb	1	Low

For details about the operating frequency range, see section 43, Electrical Characteristics.

Each operating power control mode is described below.

- High-speed mode
  After a reset cancellation, the MCU is activated in this mode.
- Low-speed mode
  The following constraints apply in low-speed mode:
  - Programming and erasure operations for the flash memory are prohibited
  - Using the PLL or PLL2 is prohibited. See section 10.10.1. Register Access

  In this mode, lower power consumption is possible than in High-speed mode when the same operation is performed under the same conditions, such as operating frequency.
- Subosc-speed mode
  The following constraints apply in Subosc-speed mode:
  - Programming and erasure operations for the flash memory are prohibited
  - Reading of the data flash is prohibited
  - Using MOSC, PLL, PLL2, MOCO, or HOCO is prohibited. See section 10.10.1. Register Access
  - Using the divided clock for ICK or FCK is prohibited. See section 10.10.1. Register Access
  - Using the oscillation stop detection function of the main clock oscillator is prohibited.

  In this mode, lower power consumption is possible than in low-speed mode when the same operation is performed under the same conditions, such as operating frequency.

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

RXDREQEN bit (RXD0 Snooze Request Enable)

The RXDREQEN bit specifies whether to detect a falling edge of the RXD0 pin in Software Standby mode. This bit can be used only when SCI0 is operating in asynchronous mode. To detect a falling edge of the RXD0 pin, set this bit before entering Software Standby mode. When this bit is set to 1, a falling edge of the RXD0 pin in Software Standby mode causes the MCU to enter Snooze mode.

SNZDTCEN bit (DTC Enable in Snooze mode)

The SNZDTCEN bit specifies whether to use the DTC and SRAM in Snooze mode. To use the DTC and SRAM in Snooze mode, set this bit to 1 before entering Software Standby mode. When this bit is set to 1, the DTC can be activated by setting IELSRn register.

SNZE bit (Snooze mode Enable)

The SNZE bit specifies whether to enable a transition from Software Standby mode to Snooze mode. To use Snooze mode, set this bit to 1 before entering Software Standby mode. When this bit is set to 1, a trigger as shown in Table 10.7 in Software Standby mode causes the MCU to enter Snooze mode. After the MCU transitions from Software Standby mode or Snooze mode to Normal mode, set 0 to the SNZE bit once then set it before re-entering Software Standby mode. For details, see section 10.8, Snooze Mode.

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

The DPSBYCR register controls the Deep Software Standby mode.

DPSBYCR is not initialized by the internal reset signal that is the source to cancel the Deep Software Standby mode. For details, see section 5, Resets.

DEEPCUT[1:0] bit (Power-Supply Control)

The DEEPCUT[1:0] bits control the internal power supply to the standby RAM, Low-speed on-chip oscillator, AGT, and USBFS resume detecting unit in Deep Software Standby mode. In addition, these bits control the state of LVD and power-on reset circuit in Deep Software Standby mode.

When a USBFS suspend/resume interrupt is used as a Deep Software Standby mode Cancelling source, the DEEPCUT[1:0] bits must be set to 00b.

When an LVD interrupt is used in Deep Software Standby mode, the DEEPCUT[1:0] bits must be set to 00b or 01b.

For lower power consumption, set the DEEPCUT[1:0] bits to 11b so that the LVD is stopped and the low power consumption function of the power-on reset circuit is enabled.

Regardless of the DEEPCUT [1: 0] bit setting, during deep software standby mode, internal power supply to SRAM other than standby SRAM is stopped.

When a deep standby mode is used, set DPSWCR.WTSTS bits depending on the value of DEEPCUT[1] before entering Deep Software Standby mode.

IOKEEP bit (I/O Port Rentention)

In Deep Software Standby mode, I/O ports keep the same states as in the Software Standby mode. The IOKEEP bit specifies whether to reset the state of the I/O ports or not when the Deep Software Standby mode is canceled.

DPSBY bit (Deep Software Standby)

The DPSBY bit controls transitions to Deep Software Standby mode.

When the WFI instruction is executed while SBYCR.SSBY bit and DPSBYCR.DPSBY bit are both 1, the MCU enters Deep Software Standby mode through Software Standby mode.

The DPSBY bit remains 1 when Deep Software Standby mode is canceled by certain pins which are sources of external pin interrupts (NMI, IRQn-DS (n = 0, 1, 4 to 9) or a peripheral interrupt (RTC alarm, RTC interval, USB suspend/resume, voltage monitor 1, or voltage monitor 2). Write 0 to this bit to clear it.

DPSBYCR寄存器控制深度软件待机模式。

DPSBYCR不会由作为取消深度软件待机模式的源的内部复位信号初始化。有关详细信息，请参阅第5节，重置。

DEEPCUT[1:0] bit (Power-Supply Control)

DEEPCUT[1:0]位控制深度软件待机模式下待机RAM、低速片上振荡器、AGT和USBFS恢复检测单元的内部电源。此外，这些位在深度软件待机模式下控制LVD和上电复位电路的状态。

当USBFS挂起恢复中断用作深度软件待机模式取消源时，DEEPCUT[1:0]位必须设置为00b。

在深度软件待机模式下使用LVD中断时，DEEPCUT[1:0]位必须设置为00b或01b。

为降低功耗，将DEEPCUT[1:0]位设置为11b，使LVD停止并启用上电复位电路的低功耗功能。

无论DEEPCUT[1:0]位设置如何，在深度软件待机模式下，除待机SRAM之外的SRAM内部电源都会停止。

当使用深度待机模式时，在进入之前根据DEEPCUT[1]的值设置DPSWCR.WTSTS位
深度软件待机模式。

IOKEEP位（IO端口保留）

在深度软件待机模式下，IO端口保持与软件待机模式相同的状态。IOKEEP位指定当深度软件待机模式被取消时是否复位IO端口的状态。

DPSBY位（深度软件待机）

DPSBY位控制向深度软件待机模式的转换。

当SBYCR.SSBY位和DPSBYCR.DPSBY位均为1时执行WFI指令，MCU进入
深度软件待机模式到软件待机模式。

当某些引脚取消深度软件待机模式时，DPSBY位保持1，这些引脚是外部引脚中断（NMI、IRQn-DS（n=0、1、4到9）或外设中断（RTC警报、RTC间隔、USB暂停恢复、电压监控器1或电压监控器2).向该位写入0以清除它。

The DPSBY bit setting is invalid when OFS0.IWDTSTPCTL bit is 0 (counting continues) regardless of the setting in OFS0.IWDTSTRT bit. In that case, even when SBYCR.SSBY bit is 1 and the DPSBY bit is 1, the transition after the execution of a WFI instruction is to Software Standby mode.

The setting of the DPSBY bit is invalid when voltage monitor 1 reset is enabled (LVD1CR0.RI = 1) or when a voltage monitor 2 reset is enabled (LVD2CR0.RI = 1). In this case, even when the SBYCR.SSBY bit is 1 and the DPSBY bit is 1, the transition after the execution of a WFI instruction is to Software Standby mode.

If the security attribution is configured as Non-secure:

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

The DPSWCR register sets the wait stabilization time when a Deep Software Standby mode is canceled by certain pins that are the sources of external pin interrupts or a peripheral interrupt such as RTC alarm, RTC interval, and USB suspend/ resume.

During a wait stabilization period set in this register, a Deep Software Standby reset occurs, and the MCU is initialized.

The DPSWCR register is not initialized with the internal reset signal by the cancellation of the Deep Software Standby mode. For details, see section 5, Resets.

When a deep standby mode is used, set DPSWCR.WTSTS bits according to the value of DPSBYCR.DEEPCUT[1] before entering Deep Software Standby mode.

When DPSBYCR.DEEPCUT[1]=0, you can set DPSWCR.WTSTS to the wait cycle for fast recovery.

When DPSBYCR.DEEPCUT[1]=1, you must set DPSWCR.WTSTS to the wait cycle for slow recovery.

DPSWCR寄存器设置当某个引脚取消深度软件待机模式时的等待稳定时间，这些引脚是外部引脚中断或外设中断（如RTC警报、RTC间隔和USB挂起恢复）的源。

在此寄存器中设置的等待稳定期间，会发生深度软件待机复位，并且初始化MCU。

通过取消深度软件待机模式，DPSWCR寄存器不会使用内部复位信号进行初始化。有关详细信息，请参阅第5节，重置。

当使用深度待机模式时，在进入深度软件待机模式之前，根据DPSBYCR.DEEPCUT[1]的值设置DPSWCR.WTSTS位。

当DPSBYCR.DEEPCUT[1]=0时，可以设置DPSWCR.WTSTS为等待周期，以便快速恢复。

DPSIER0 is not initialized by the internal reset signal used as Deep Software Standby mode Cancelling source. For details, see section 5, Resets.

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

Each flag is set to 1 when the corresponding cancel request is generated.

Each flag may be set to 1 when a cancel request is generated in any mode (not only in Deep Software Standby mode) or when the setting of DPSIER3 is modified. Therefore, a transition to Deep Software Standby mode should be made after DPSIFR3 is cleared to 0x00.

To clear DPSIFR3 to 0x00 after modifying DPSIER3, wait for at least 6 PCLKB cycles, read DPSIFR3, and then write 0 to DPSIFR3. Six or more PCLKB cycles can be secured, for example, by reading DPSIER3.

DPSIFR3 is not initialized by the internal reset signal used as Deep Software Standby mode Cancelling source. For details, see section 5, Resets.

DUSBFS0IF flag (USBFS0 Suspend/Resume Deep Standby Cancel Flag)

The DUSBFS0IF flag is the flag for USBFS0 that indicates that a cancel request by the USBFS0 suspend/resume has been generated.

[Setting condition]

A cancel request by the USBFS0 suspend/resume is generated

[Clearing condition]

Writing 0 to each flag after 1 is read.

DAGT1IF flag (AGT1 Underflow Deep Standby Cancel Flag)

This flag indicates that a cancel request by the AGT1 underflow has been generated.

[Setting condition]

A cancel request by the AGT1 underflow is generated

[Clearing condition]

Writing 0 to each flag after 1 is read.

DAGT3IF flag (AGT3 Underflow Deep Standby Cancel Flag)

This flag indicates that a cancel request by the AGT3 underflow has been generated.

[Setting condition]

A cancel request by the AGT3 underflow is generated

[Clearing condition]

Writing 0 to each flag after 1 is read.

修改DPSIER3后要清除DPSIFR3为0x00，等待至少6个PCLKB周期，读取DPSIFR3，然后将0写入DPSIFR3.例如，可以通过读取DPSIER3来确保六个或更多PCLKB周期。

DPSIFR3未被用作深度软件待机模式取消源的内部复位信号初始化。有关详细信息，请参阅第5节，重置。

当DBGSTR.CDBGPWRUPREQ=1（调试器已连接）时，可以写入SOOCDCR。

SYOCDCR is not initialized by the internal reset signal that is the source to cancel the Deep Software Standby mode.

DOCDF flag (Deep Software Standby OCD flag)

DOCDF flag indicates that a cancel request of Deep Software Standby mode by the MCUCTRL.DBIRQ bit has been generated. DOCDF flag is set to 1 when a cancel request is generated. This flag may be set to 1 when a cancel request is generated in any mode (not only in Deep Software Standby mode). Therefore, a transition to Deep Software Standby mode must be made after DOCDF flag is cleared to 0.

[Setting condition]

- A cancel request by the MCUCTRL.DBIRQ is generated

[Clearing condition]

- Writing 0 to the flag after reading the bit as 1
- When DBGEN bit is 0

DBGEN bit (Debugger Enable bit)

The DBGEN bit enables the on-chip debug mode. This bit must be set to 1 first in the on-chip debugger mode.

[Setting condition]

- Writing 1 to the bit when the debugger is connected.

[Clearing condition]

- Power-on reset is generated
- Writing 0 to the bit.

Note: Certain restrictions apply in terms of the MCU states in which the DBGEN bit can be set to 1. For details, see section 2.12.2. Restrictions on Connecting an OCD emulator.

10.2.30 LDOSCR:LDO Stop Control Register

1	LDOSTP1	LDO1 Stop 0: LDO1 is enabled 1: LDO1 is stopped	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

The internal voltage is supplied from multiple built-in linear regulators (LDO). If you do not use the SCE9, LDO self-power consumption can be reduced by setting LDOSCR register to stop LDO0 and LDO1. The setting of the LDOSTPn bit must be changed under the following conditions:

SOOCDCR不会由作为取消深度软件待机模式的源的内部复位信号初始化。

DOCDF标志（深度软件待机OCD标志）

DOCDF标志指示已通过MCUCTRL.DBIRQ位生成了深度软件待机模式的取消请求。生成取消请求时，DOCDF标志设置为1。当在任何模式下（不仅在深度软件待机模式下）生成取消请求时，此标志可能设置为1。因此，必须在DOCDF标志清零后转换到深度软件待机模式。

[Setting condition]

●MCUCTRL.DBIRQ产生取消请求

[Clearing condition]

●读取位为1后向标志位写入0

●DBGEN位为0时

DBGEN位（调试器启用位）

DBGEN位使能片上调试模式。在片上调试器模式下，该位必须首先设置为1。

[Setting condition]

●连接调试器时向该位写入1。

[Clearing condition]

●产生上电复位

●向该位写入0。

Note: 某些限制适用于可以将DBGEN位设置为1的MCU状态。有关详细信息，请参阅第2.12.2节。连接强迫症模拟器的限制。

如果安全属性配置为非安全：●

Note: 在重写该寄存器之前将PRCR.PRC1位设置为1（允许写入）。

内部电压由多个内置线性稳压器(LDO)提供。如果不使用SCE9，可以通过设置LDOSCR寄存器停止LDO0和LDO1来降低LDO自功耗。LDOSTPn位的设置必须在以下条件下更改：

- PLL, PLL2 and MOSC are stopped
- CPU clock and peripheral module clock are 2MHz or less
- All modules other than the DMAC, DTC, and SRAM modules are in the module-stop state

After changing the value of LDOSTPn, you must also insert a wait time of at least 10 µs to stabilize the power supply capacity of the LDO. The recommended method to measure the wait time is through software. Be sure to consider the worst-case conditions to ensure that the required wait time elapses.

This register is initialized by all reset factors. In addition, this register is initialized in the Deep Software Standby mode.

Figure 10.2 shows the flow for stopping LDO0 and LDO1, Figure 10.3 shows the flow for restarting LDO0 and LDO1.

Note: SYOCDCR.DBGEN setting should be changed when the LDOSTPn bits are 0. It is possible to set the LDOSTPn bits to 1 after changing the SYOCDCR.DBGEN setting.

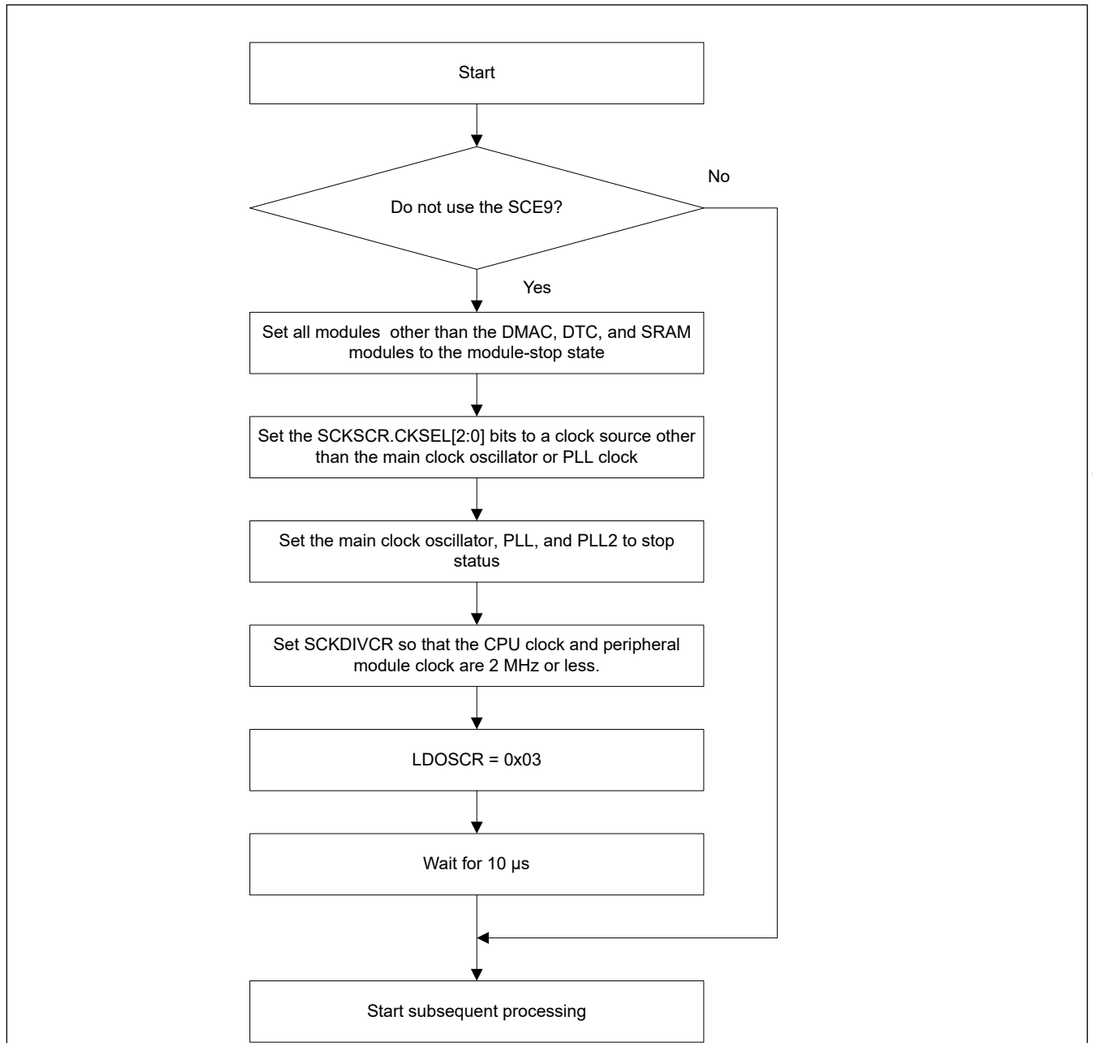

Figure 10.2 The flow for stopping LDO0 and LDO1

●PLL、PLL2和MOSC停止
●CPU时钟和外围模块时钟为2MHz或更低
●除DMAC、DTC和SRAM模块之外的所有模块都处于模块停止状态

改变LDOSTPn的值后，还必须插入至少10µs的等待时间，以稳定LDO的供电能力。测量等待时间的推荐方法是通过软件。请务必考虑最坏情况，以确保经过所需的等待时间。

该寄存器由所有复位因素初始化。此外，该寄存器在深度软件待机模式下初始化。

图10.2显示了停止LDO0和LDO1的流程，图10.3显示了重新启动LDO0和LDO1的流程。

Note: 当LDOSTPn位为0时，应更改SOOCDCR.DBGEN设置。可以在更改SOOCDCR.DBGEN设置后将LDOSTPn位设置为1。

This MCU has a built-in LDO dedicated to PLL2. If you never use PLL2, the PL2LDOSCR can be configured to stop the LDO dedicated to PLL2 in order to reduce the quiescent current of that LDO.

Do not write 0 again after writing 1 to PL2LDOSTP.

When PL2LDOSTP is 1, do not write 0 to PLL2CR.PLL2STP.

When PLL2CR.PLL2STP is 0, do not write 1 to PL2LDOSTP.

This register is initialized by only POR reset.

10.3 Reducing Power Consumption by Switching Clock Signals

The clock frequency changes when the SCKDIVCR register is set.

For information on module and clock associations, see section 8.2.2. SCKDIVCR : System Clock Division Control Register.

10.4 Module-Stop Function

The module stop function can stop the clock supply set for each peripheral module.

When the MSTPmi bit (m = A to E, i = 31 to 0) in MSTPCRn (n = A to E) is set to 1, the specified module stops operating and enters the module-stop state, but the CPU continues to operate independently. Setting the MSTPmi bit to 0 cancels the module-stop state, allowing the module to resume operation at the end of the bus cycle.

After a reset is canceled, all modules other than the DMAC, DTC and SRAMn modules are placed in the module-stop state. Do not access the module while the corresponding MSTPmi bit is 1. Additionally, do not set 1 to the MSTPmi bit while the corresponding module is accessed.

10.5 Function for Lower Operating Power Consumption

By selecting an appropriate operating power consumption control mode according to the operating frequency, power consumption can be reduced in Normal mode, Sleep mode, and Snooze mode.

10.5.1 Setting Operating Power Control Mode

Ensure the operating condition such as the frequency range is always within the specified range before and after switching the operating power control modes.

This section provides example procedures for switching operating power control modes.

Table 10.5 Available oscillators in each mode

Mode	Oscillator						
	PLL, PLL2	High-speed on-chip oscillator	Middle-speed on-chip oscillator	Low-speed on-chip oscillator	Main clock oscillator	Sub-clock oscillator	IWDT-dedicated on-chip oscillator
High-speed	Available	Available	Available	Available	Available	Available	Available
Low-speed	N/A	Available	Available	Available	Available	Available	Available
Subosc-speed	N/A	N/A	N/A	Available	N/A	Available	Available

(1) Switching from a higher power mode to a lower power mode

Example 1: From High-speed mode to Low-speed mode:

(Operation begins in High-speed mode)

1. Change the oscillator to what is used in Low-speed mode. Set the frequency of each clock lower than the maximum operating frequency in Low-speed mode.
2. Turn off the oscillator that is not required in Low-speed mode.
3. Confirm that the OPCCR.OPCMTSF flag is 0 (indicates transition completed).
4. Set the OPCCR.OPCM[1:0] bits to 11b (Low-speed mode).
5. Confirm that OPCCR.OPCMTSF flag is 0 (indicates transition completed).

该MCU具有专用于PLL2的内置LDO。如果您从不使用PLL2，可以将PL2LDOSCR配置为停止LDO专用于PLL2，以降低该LDO的静态电流。

向PL2LDOSTP写入1后不要再写入0。

当PL2LDOSTP为1时，不要将0写入PLL2CR.PLL2STP。

当PLL2CR.PLL2STP为0时，不要将1写入PL2LDOSTP。

该寄存器仅由POR复位初始化。

10.3 通过切换时钟信号降低功耗

设置SCKDIVCR寄存器时，时钟频率会发生变化。

有关模块和时钟关联的信息，请参见第8.2.2节。SCKDIVCR:系统时钟分频控制Register.

10.4 Module-Stop Function

模块停止功能可以停止为每个外围模块设置的时钟供应。

当MSTPCRn(n=AtoE)中的MSTPmi位(m=AtoE i=31to0)设置为1时，指定模块停止运行并进入module-stop状态，但CPU继续运行独立。将MSTPmi位设置为0可取消模块停止状态，允许模块在总线周期结束时恢复运行。

取消复位后，除DMAC、DTC和SRAMn模块之外的所有模块都置于模块停止状态。相应的MSTPmi位为1时不要访问模块。另外，访问相应的模块时不要将MSTPmi位设置为1。

10.5 降低运行功耗的功能

通过根据工作频率选择合适的工作功耗控制模式，可以在正常模式、睡眠模式和贪睡模式下降低功耗。

10.5.1 设置工作电源控制模式

确保在切换工作功率控制模式前后，频率范围等工作条件始终在规定范围内。

本节提供切换操作电源控制模式的示例程序。

10.6 Sleep Mode

10.6.1 Transitioning to Sleep Mode

When a WFI instruction is executed while SBYCR.SSBY bit is 0, the MCU enters Sleep mode. In this mode, the CPU stops operating but the contents of its internal registers are retained. Other peripheral functions do not stop. Available resets or interrupts in Sleep mode cause the MCU to cancel Sleep mode. All interrupt sources are available. If using an interrupt to cancel Sleep mode, you must set the associated IELSRn register before executing a WFI instruction. For details, see section 13, Interrupt Controller Unit (ICU).

Counting by IWDT stops when the MCU enters Sleep mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 1 (IWDT stops in Sleep mode, Software Standby mode, or Snooze mode).

Counting by IWDT continues when the MCU enters Sleep mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 0 (IWDT does not stop in Sleep mode, Software Standby mode, or Snooze mode).

Counting by WDT stops when the MCU enters Sleep mode while the WDT is in auto start mode and the OFS0.WDTSTPCTL bit is 1 (WDT stops in Sleep mode). Similarly, counting by WDT stops when the MCU enters Sleep mode while the WDT is in register start mode and the WDTCSTPR.SLCSTP bit is 1 (WDT stops in Sleep mode).

2.确认除副时钟振荡器之外的所有时钟源都已停止。

10.6 睡眠模式

10.6.1 转换到睡眠模式

当SBYCR.SSBY位为0时执行WFI指令，MCU进入休眠模式。在这种模式下，CPU停止运行，但其内部寄存器的内容被保留。其他外围功能不会停止。休眠模式下可用的复位或中断会导致MCU取消休眠模式。所有中断源均可用。如果使用中断取消休眠模式，则必须在执行WFI指令之前设置相关的IELSRn寄存器。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

当MCU进入休眠模式且IWDT处于自动启动模式且OFS0.IWDTSTPCTL位为1（IWDT在休眠模式、软件待机模式或贪睡模式下停止）。

当MCU进入休眠模式且IWDT处于自动启动模式且OFS0.IWDTSTPCTL位为0（IWDT在休眠模式、软件待机模式或贪睡模式下不停止）时，IWDT继续计数。

当MCU进入休眠模式且WDT处于自动启动模式且OFS0.WDTSTPCTL位为1（WDT在休眠模式下停止）。同样，当MCU进入休眠模式且WDT处于寄存器启动模式且WDTCSTPR.SLCSTP位为1（WDT在休眠模式下停止）时，WDT停止计数。

Counting by WDT continues when the MCU enters Sleep mode while the WDT is in auto start mode and the OFS0.WDTSTPCTL bit is 0 (WDT does not stop in Sleep mode). Similarly, counting by WDT continues when the MCU enters Sleep mode while the WDT is in register start mode and the WDTCSTPR.SLCSTP bit is 0 (WDT does not stop in Sleep mode).

10.6.2 Canceling Sleep Mode

Sleep mode is canceled by:

- An interrupt
- A RES pin reset
- A power-on reset
- A voltage monitor reset
- An SRAM parity error reset
- A bus master MPU error reset
- A TrustZone error reset
- A reset caused by an IWDT or a WDT underflow

The operations are as follows:

1. Canceling by an interrupt
   When an available interrupt request is generated, Sleep mode is canceled and the MCU starts the interrupt handling.
2. Canceling by RES pin reset
   When the RES pin is driven low, the MCU enters the reset state. Be sure to keep the RES pin low for the time period specified in section 43, Electrical Characteristics. When the RES pin is driven high after the specified time period, the CPU starts the reset exception handling.
3. Canceling by IWDT reset
   - Sleep mode is canceled by an internal reset generated by an IWDT underflow and the MCU starts the reset exception handling. However, IWDT stops in Sleep mode and an internal reset for canceling Sleep mode is not generated in the following conditions:
   - OFS0.IWDTSTRT = 0 and OFS0.IWDTSTPCTL = 1.
4. Canceling by WDT reset
   Sleep mode is canceled by an internal reset generated by a WDT underflow and the MCU starts the reset exception handling. However, WDT stops in Sleep mode even when counting in Normal mode and an internal reset for canceling Sleep mode is not generated in the following conditions:
   - OFS0.WDTSTRT = 0 (auto start mode) and OFS0.WDTSTPCTL = 1
   - OFS0.WDTSTRT = 1 (register start mode) and WDTCSTPR.SLCSTP = 1.
5. Canceling by other resets available in Sleep mode
   Sleep mode is canceled by other resets and the MCU starts the reset exception handling.

Note: For details on proper setting of the interrupts, see section 13, Interrupt Controller Unit (ICU).

10.7 Software Standby Mode

10.7.1 Transitioning to Software Standby Mode

When a WFI instruction is executed while SBYCR.SSBY bit is 1 and DPSBYCR.DPSBY bit is 0, the MCU enters Software Standby mode. In this mode, the CPU, most of the on-chip peripheral functions and the oscillators stop. However, the contents of the CPU internal registers and SRAM data, the states of on-chip peripheral functions and the I/O ports are retained. Software Standby mode allows significant reduction in power consumption because most of the oscillators stops in this mode. Table 10.2 shows the status of each on-chip peripheral functions and oscillators. Available resets or interrupts in Software Standby mode make the MCU to cancel Software Standby mode. See Table 10.3 for available interrupt sources and section 13.2.18. WUPEN0 : Wake Up Interrupt Enable Register 0, section 13.2.19. WUPEN1 : Wake Up interrupt enable register 1 for information on waking up the MCU from Software Standby mode. If using an interrupt to cancel an

当MCU进入休眠模式且WDT处于自动启动模式且
OFS0.WDTSTPCTL位为0（WDT在休眠模式下不停止）。同样，当MCU进入休眠模式且WDT处于寄存器启动模式且WDTCSTPR.SLCSTP位为0（WDT在休眠模式下不会停止）时，WDT继续计数。

10.6.2 取消睡眠模式

睡眠模式通过以下方式取消：

- ●中断
- ●ARES引脚复位
- A power-on reset
- ●电压监视器复位
- ●SRAM奇偶校验错误复位
- ●总线主控MPU错误复位
- ●TrustZone错误重置
- ●IWDT或WDT下溢引起的复位

操作如下：

1.中断取消
当产生可用的中断请求时，休眠模式被取消，MCU开始中断处理。

2.通过RES引脚复位取消
当RES引脚驱动为低电平时，MCU进入复位状态。请务必在第43节“电气特性”中指定的时间段内保持RES引脚为低电平。当RES引脚在指定时间后被驱动为高电平时，CPU开始复位异常处理。

3.IWDT复位取消
- ●休眠模式由IWDT下溢产生的内部复位取消，MCU开始复位异常处理。但是，IWDT在休眠模式下停止，并且在以下情况下不会产生用于取消休眠模式的内部复位：
- OFS0.IWDTSTRT = 0 and OFS0.IWDTSTPCTL = 1.

4.WDT复位取消
睡眠模式由WDT下溢产生的内部复位取消，MCU启动复位异常处理。但是，即使在正常模式下计数，WDT也会在休眠模式下停止，并且在以下情况下不会产生用于取消休眠模式的内部复位：

- ●OFS0.WDTSTRT=0（自动启动模式）和OFS0.WDTSTPCTL=1
- ●OFS0.WDTSTRT=1（寄存器启动模式）和WDTCSTPR.SLCSTP=1。

5.通过睡眠模式下可用的其他复位取消
休眠模式被其他复位取消，MCU开始复位异常处理。

Note: 有关正确设置中断的详细信息，请参阅第13节，中断控制器单元(ICU)。

10.7 软件待机模式

10.7.1 过渡到软件待机模式

当SBYCR.SSBY位为1且DPSBYCR.DPSBY位为0时执行WFI指令，MCU进入软件待机模式。在这种模式下，CPU、大部分片上外围功能和振荡器停止。但是，CPU内部寄存器和SRAM数据的内容、片上外围功能的状态和IO端口的状态会被保留。软件待机模式可显着降低功耗，因为大多数振荡器在此模式下停止。表10.2显示了每个片上外围功能和振荡器的状态。软件待机模式下可用的复位或中断使MCU取消软件待机模式。有关可用的中断源，请参见表10.3和第13.2.18节。WUPEN0：唤醒中断使能寄存器0，第13.2.19节。WUPEN1：唤醒中断使能寄存器1，用于将MCU从软件待机模式唤醒的信息。如果使用中断取消

interrupt, you must set the associated IELSRn register before executing a WFI instruction. For details, see section 13, Interrupt Controller Unit (ICU).

Clear DMAST.DMST bit and DTCST.DTCST bit to 0 before executing WFI instruction except when using DTC in Snooze mode. If DTC is required in Snooze mode, set DTCST.DTCST bit to 1 before executing a WFI instruction.

Counting by the IWDT stops if the MCU enters Software Standby mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 1 (IWDT stops in Sleep, Software Standby or Snooze mode).

Counting by the IWDT continues if the MCU enters Software Standby mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 0 (IWDT does not stop in Sleep, Software Standby or Snooze mode).

WDT stops counting when the MCU enters Software Standby mode because the PCLKB stops.

Do not enter Software Standby mode while OSTDCR.OSTDE = 1 (oscillation stop detection function is enabled). To enter Software Standby mode, execute a WFI instruction after disabling the oscillation stop detection function (OSTDCR.OSTDE = 0). In case of executing WFI instruction while OSTDCR.OSTDE = 1, the MCU enters Sleep mode even if SBYCR.SSBY = 1.

Do not enter Software Standby mode while the flash memory is programming or erasing. To enter Software Standby mode, execute a WFI instruction after programming or erasing procedure completes.

Table 10.6 shows the setting of the related control bits and the modes to enter after executing WFI instruction.

10.7.2 Canceling Software Standby Mode

Software Standby mode is canceled by:

- An available interrupt shown in Table 10.3
- A RES pin reset
- A power-on reset
- A voltage monitor reset
- A reset caused by an IWDT underflow.

On exiting Software Standby mode, the oscillators that operate before the transition to the mode restart. After all the oscillators are stabilized, the MCU returns to Normal mode from Software Standby mode. See section 13.2.18. WUPEN0 : Wake Up Interrupt Enable Register 0, section 13.2.19. WUPEN1 : Wake Up interrupt enable register 1 for information on how to wake up the MCU from Software Standby mode.

You can cancel Software Standby mode in any of the following ways:

1. Canceling by an interrupt

中断，您必须在执行WFI指令之前设置相关的IELSRn寄存器。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

在执行WFI指令之前将DMAST.DMST位和DTCST.DTCST位清除为0，除非在贪睡模式下使用DTC。如果在贪睡模式下需要DTC，请在执行WFI指令之前将DTCST.DTCST位设置为1。

如果MCU进入软件待机模式，而IWDT处于自动启动模式并且OFS0.IWDTSTPCTL位为1（IWDT在休眠、软件待机或贪睡模式下停止）。

如果MCU进入软件待机模式，而IWDT处于自动启动模式并且OFS0.IWDTSTPCTL位为0（IWDT在休眠、软件待机或贪睡模式下不停止）。

当MCU进入软件待机模式时，WDT停止计数，因为PCLKB停止。

OSTDCR.OSTDE=1时不要进入软件待机模式（振荡停止检测功能启用）。要进入软件待机模式，请在禁用振荡停止检测功能(OSTDCR.OSTDE=0)后执行WFI指令。如果在OSTDCR.OSTDE=1时执行WFI指令，即使SBYCR.SSBY=1，MCU也会进入休眠模式。

闪存正在编程或擦除时，请勿进入软件待机模式。要进入软件待机模式，请在编程或擦除过程完成后执行WFI指令。

表10.6显示了相关控制位的设置以及执行WFI指令后进入的模式。

10.7.2 取消软件待机模式

软件待机模式通过以下方式取消：

●可用中断如表10.3所示

●ARES引脚复位

- A power-on reset

●电压监视器复位

●IWDT下溢引起的复位。

在退出软件待机模式时，在转换到模式之前工作的振荡器会重新启动。在所有振荡器稳定后，MCU从软件待机模式返回到正常模式。请参阅第13.2.18节。WUPEN0：唤醒中断使能寄存器0，第13.2.19节。WUPEN1：唤醒中断使能寄存器1，用于了解如何将MCU从软件待机模式唤醒。

您可以通过以下任一方式取消软件待机模式：

1.中断取消

When an available interrupt request (see Table 10.3) is generated, an oscillator that operates before the transition to Software Standby mode restarts. After all the oscillators are stabilized, the MCU returns to Normal mode from Software Standby mode and starts the interrupt handling.

2. Canceling by a RES pin reset
When the RES pin is driven low, the MCU enters the reset state, and the oscillators whose default status is operating, start the oscillation. Be sure to keep the RES pin low for the time period specified in section 43, Electrical Characteristics. When the RES pin is driven high after the specified time period, the CPU starts the reset exception handling.
3. Canceling by a power-on reset
Software Standby mode is canceled by a power-on reset and the MCU starts the reset exception handling.
4. Canceling by a voltage monitor reset
Software Standby mode is canceled by a voltage monitor reset from the voltage detection circuit and the MCU starts the reset exception handling.
5. Canceling by IWDT reset
Software Standby mode is canceled by an internal reset generated by an IWDT underflow and the MCU starts the reset exception handling. However, IWDT stops in Software Standby mode and an internal reset for canceling Software Standby mode is not generated in the following condition:
   - OFS0.IWDTSTRT = 0 and OFS0.IWDTSTPCTL = 1.

10.7.3 Example of Software Standby Mode Application

Figure 10.4 shows an example of entry to Software Standby mode on detection of a falling edge of the IRQn pin, and exit from Software Standby mode by a rising edge of the IRQn pin.

In this example, an IRQn pin interrupt is accepted with the IRQCRi.IRQMD[1:0] bits of the ICU set to 00b (falling edge) in Normal mode, and the IRQCRi.IRQMD[1:0] bits are set to 01b (rising edge). After that, the SBYCR.SSBY bit is set to 1 and a WFI instruction is executed. As a result, entry to Software Standby mode completes and exit from Software Standby mode is initiated by a rising edge of the IRQn pin.

Setting the ICU is also required to exit Software Standby mode. For details, see section 13, Interrupt Controller Unit (ICU).
The oscillation stabilization time in Figure 10.4 is specified in section 43, Electrical Characteristics.

当一个可用的中断请求（见表10.3）产生时，一个振荡器在转换到
软件待机模式重新启动。在所有振荡器稳定后，MCU从软件返回到正常模式
待机模式并启动中断处理。

2.通过RES引脚复位取消
当RES引脚驱动为低电平时，MCU进入复位状态，默认状态为工作的振荡器开始振荡。请务必在第43节“电气特性”中指定的时间段内保持RES引脚为低电平。当RES引脚在指定时间后被驱动为高电平时，CPU开始复位异常处理。

3.上电复位取消
软件待机模式通过上电复位取消，MCU启动复位异常处理。

4.通过电压监视器复位取消
软件待机模式通过电压检测电路的电压监视器复位取消，MCU开始复位异常处理。

5.IWDT复位取消
软件待机模式由IWDT下溢产生的内部复位取消，MCU开始复位异常处理。但是，IWDT在软件待机模式下停止，并且在以下情况下不会产生用于取消软件待机模式的内部复位：

- OFS0.IWDTSTRT = 0 and OFS0.IWDTSTPCTL = 1.

10.7.3 软件待机模式应用示例

图10.4显示了在检测到IRQn引脚的下降沿进入软件待机模式并在IRQn引脚的上升沿退出软件待机模式的示例。

在此示例中，接受IRQn引脚中断，同时ICU的IRQCRi.IRQMD[1:0]位设置为00b（下降沿）
正常模式，并且IRQCRi.IRQMD[1:0]位设置为01b（上升沿）。之后，SBYCR.SSBY位设置为1并执行WFI指令。因此，软件待机模式的进入完成，软件待机模式的退出由IRQn引脚的上升沿启动。

退出软件待机模式也需要设置ICU。有关详细信息，请参阅第13节，中断控制器单元(ICU)。
图10.4中的振荡稳定时间在第43节“电气特性”中指定。

10.8 Snooze Mode

10.8.1 Transition to Snooze Mode

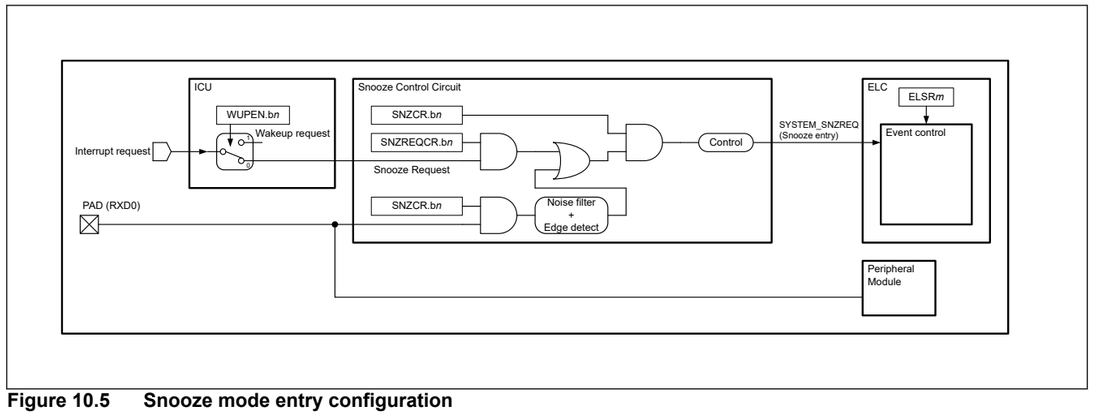

Figure 10.5 Snooze mode entry configuration

When the snooze control circuit accepts an available snooze request in Software Standby mode, the MCU transfers to Snooze mode. In this mode, some peripheral modules operates without waking the CPU. The peripheral modules that can operate in Snooze mode are shown in Table 10.2. Also, DTC operation in Snooze mode can be selected by the setting of SNZCR.SNZDTCEN bit.

Table 10.7 shows the Snooze requests that switch the MCU from Software Standby mode to Snooze mode. To use the listed Snooze requests as a trigger to switch to Snooze mode, the corresponding SNZREQENn bit of the SNZREQCRn register or RXDREQEN bit of SNZCR register must be set before entering Software Standby mode.

当贪睡控制电路在软件待机模式下接受一个可用的贪睡请求时，MCU转移到贪睡模式。在这种模式下，一些外围模块在不唤醒CPU的情况下运行。可在贪睡模式下运行的外围模块如表10.2所示。此外，可以通过设置SNZCR.SNZDTCEN位来选择贪睡模式下的DTC操作。

When AGT3 is used for Snooze request factor, Snooze end factor is not allowed to set AGT1 (only AGT3).

Clear the DMAST.DMST and DTCST.DTCST bits to 0 before executing a WFI instruction, except when using the DTC in Snooze mode. If the DTC is required in Snooze mode, set the DTCST.DTCST bit to 1 before executing a WFI instruction.

10.8.2 Canceling Snooze Mode

Snooze mode is canceled by an interrupt request that is available in Software Standby mode or a reset. Table 10.3 shows the requests that can be used to exit each mode. After canceling the Snooze mode, the MCU enters Normal mode and proceeds with exception processing for the given interrupt or reset. The action triggered by the interrupt requests, selected in SELSR0, cancels Snooze mode. Interrupt canceling Snooze mode must be selected in IELSRn to link to the NVIC for the corresponding interrupt handling. See section 13, Interrupt Controller Unit (ICU) for information on SELSR0 and IELSRn registers.

10.8.2 取消贪睡模式

贪睡模式由软件待机模式下可用的中断请求或复位取消。表10.3显示了可用于退出每种模式的请求。取消贪睡模式后，MCU进入正常模式并继续对给定中断或复位进行异常处理。在SELSR0中选择的中断请求触发的动作取消贪睡模式。必须在IELSRn中选择中断取消贪睡模式以链接到NVIC以进行相应的中断处理。有关SELSR0和IELSRn寄存器的信息，请参见第13节，中断控制器单元(ICU)。

10.8.3 Returning from Snooze Mode to Software Standby Mode

Table 10.8 shows the snooze end request that can be used as triggers to return to Software Standby mode. The snooze end requests are available only in Snooze mode. If the requests are generated when the MCU is not in Snooze mode, they are ignored. When multiple requests are selected, each of the requests invokes transition to Software Standby mode from Snooze mode.

Table 10.9 shows the snooze end conditions that consist of the snooze end requests and the conditions of the peripheral modules. The SCI0, ADC12, and DTC modules can keep the MCU in Snooze mode until they complete the operation. However, an AGTn (n = 1, 3) underflow as a trigger to return to Software Standby mode cancels Snooze mode without waiting for the completion of SCI0 operation.

Figure 10.7 shows the timing diagram for the transition from Snooze mode to Software Standby mode. This mode transition occurs according to which snooze end requests are set in the SNZEDCR0 register. A snooze request is cleared automatically after returning to Software Standby mode.

10.8.3 从贪睡模式返回到软件待机模式

表10.8显示了可用作返回到软件待机模式的触发器的贪睡结束请求。贪睡结束请求仅在贪睡模式下可用。如果请求是在MCU未处于贪睡模式时生成的，则它们将被忽略。选择多个请求时，每个请求都会从贪睡模式转移到软件待机模式。

表10.9显示了贪睡结束条件，包括贪睡结束请求和外围模块的条件。SCI0、ADC12和DTC模块可以让MCU保持在贪睡模式，直到它们完成操作。但是，AGTn(n=1 3)下溢作为返回软件待机模式的触发器会取消贪睡模式，而无需等待SCI0操作完成。

图10.7显示了从贪睡模式转换到软件待机模式的时序图。该模式转换根据SNZEDCR0寄存器中设置的贪睡结束请求发生。返回软件待机模式后，贪睡请求会自动清除。

10.9.1 Transitioning to Deep Software Standby Mode

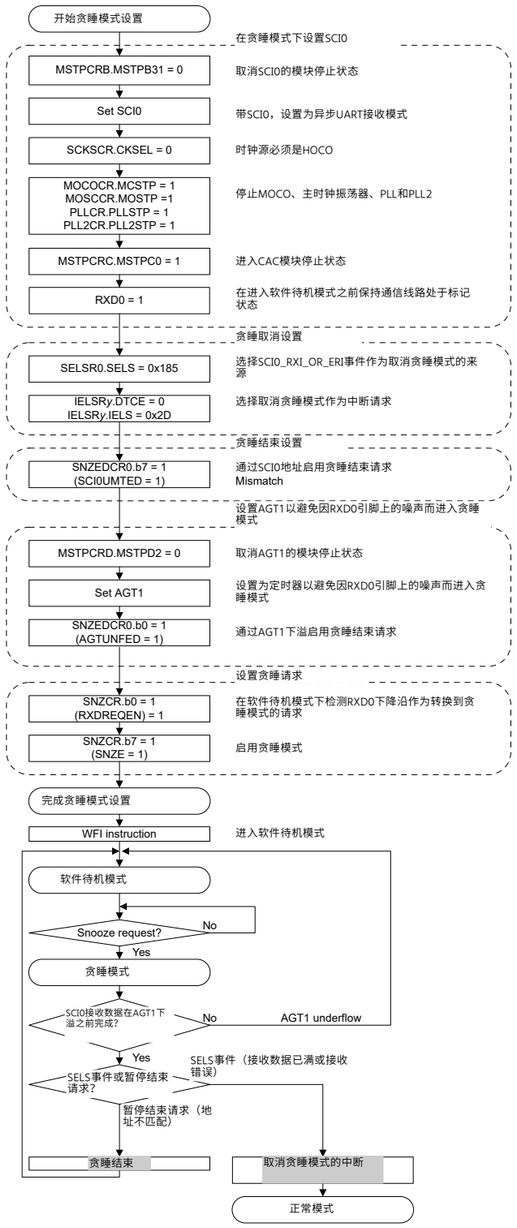

Figure 10.9 在Snooze模式进入使用SCI0的设置示例

10.9 深度软件待机模式

10.9.1 过渡到深度软件待机模式

When a WFI instruction is executed with the SBYCR.SSBY and DPSBYCR.DPSBY bits set to 1, the MCU enters Deep Software Standby mode. See Table 10.6 for the setting of the related control bits. In this mode, the CPU, on-chip peripheral functions (except for RTC alarm, RTC interval, and USB suspend/resume detecting unit), SRAM (except for standby RAM), and all oscillators (except for Sub-clock oscillator and Low-speed on-chip oscillator) are stopped. Also because the internal power supply to these modules is stopped, power consumption is remarkably reduced. The contents of all CPU registers and internal peripheral modules (except for RTC alarm, RTC interval, and USB suspend/resume detecting unit) become undefined.

Data in the standby SRAM are preserved if the setting of the DEEPCUT[1:0] bits are 00b. If the setting of the DEEPCUT[1:0] bits are 01b, the internal power supply to the standby SRAM and the USB resume detecting unit is cut off, reducing power consumption. Data in the standby SRAM becomes undefined at this time. If the setting of the DEEPCUT[1:0] bits are 11b, the internal power supply to the standby SRAM, and the USB resume detecting unit is cut off, the LVD is stopped, and the low-power-consumption function of the power-on reset circuit is enabled, so power consumption is further reduced. For details, see section 43, Electrical Characteristics.

When the MCU enters Deep Software Standby mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 1, power supply to the IWDT-dedicated clock and the IWDT is cut off, and counting by the IWDT stops.

When OFS0.IWDTSTPCTL bit is 0, the MCU enters Software Standby mode instead of Deep Software Standby mode, regardless of the setting of OFS0.IWDTSTRT bit or DPSBYCR.DPSBY bit. If OFS0.IWDTSTPCTL bit is 0 while OFS0.IWDTSTRT bit is 0 (auto start mode), IWDT-dedicated clock and IWDT continues the operation.

When LVD1CR0.RI = 1 (voltage monitor 1 reset selected) or LVD2CR0.RI = 1 (voltage monitor 2 reset selected), the MCU enters Software Standby mode instead of Deep Software Standby mode. The I/O port states are the same as in Software Standby mode.

Note: Conditions on the DTC, DMAC, and IWDT for transitioning to Software Standby mode should be met before the WFI instruction is executed. For details, see section 10.7. Software Standby Mode.

10.9.2 Cancelling Deep Software Standby Mode

Deep Software Standby mode is canceled by:

- An interrupt shown in Table 10.3
- A RES pin reset
- A power-on reset
- A voltage monitor 0 reset.

(1) Cancelling by an interrupt

Cancelling by interrupts is controlled by DPSIERn (n = 0 to 3) and DPSIFRn (n = 0 to 3). When a Deep Software Standby Cancelling interrupt is generated, the corresponding flag in DPSIFRn is set to 1. If the interrupt is enabled in DPSIERn, Deep Software Standby mode is canceled. Rising edge or falling edge can be selected by DPSIEGRn (n = 0 to 2). The interrupts for which an edge can be selected are the NMI, IRQn-DS (n = 0, 1, 4 to 9), voltage monitor 1, and voltage monitor 2 interrupts. When a Deep Software Standby mode canceling request occurs, the internal power is supplied and MOCO starts oscillating, and an internal reset (Deep Software Standby reset) is generated for the entire MCU.

The stable MOCO clock is supplied to the entire MCU and Deep Software Standby reset is canceled. The MCU starts reset exception handling.

When Deep Software Standby mode is canceled by an external interrupt pin or internal interrupt signal, the RSTSR0.DPSRSTF flag is set to 1.

(2) Cancelling by RES pin reset

When the RES pin is driven low, the MCU cancels Deep Software Standby mode and enters the reset state. Keep the RES pin low for the time specified in section 43, Electrical Characteristics. When RES pin is driven high after the specified time period, the CPU starts the reset exception handling.

(3) Cancelling by a power-on reset

Deep Software Standby mode is canceled by a power-on reset and the MCU starts the reset exception handling.

当在SBYCR.SSBY和DPSBYCR.DPSBY位设置为1的情况下执行WFI指令时，MCU进入Deep
软件待机模式。相关控制位的设置见表10.6。在此模式下，CPU、片上外围功能（RTC闹钟、RTC间隔和USB暂停恢复检测单元除外）、SRAM（备用RAM除外）和所有振荡器（副时钟振荡器和Low-速度片上振荡器）停止。此外，由于这些模块的内部电源停止，功耗显着降低。所有CPU寄存器和内部外围模块（RTC警报、RTC间隔和USB暂停恢复检测单元除外）的内容变为未定义。

如果DEEPCUT[1:0]位的设置为00b，则保留备用SRAM中的数据。如果DEEPCUT[1:0]位设置为01b，则内部对待机SRAM和USB恢复检测单元的供电被切断，从而降低功耗。此时备用SRAM中的数据变为未定义。如果DEEPCUT[1:0]位设置为11b，则内部对待机SRAM的供电，以及USB恢复检测单元被切断，LVD停止，电源的低功耗功能-on复位电路使能，因此功耗进一步降低。有关详细信息，请参阅第43节，电气特性。

当MCU在IWDT处于自动启动模式且OFS0.IWDTSTPCTL位为1时进入深度软件待机模式时，IWDT专用时钟和IWDT的电源被切断，IWDT的计数停止。

当OFS0.IWDTSTPCTL位为0时，MCU进入软件待机模式而不是深度软件待机模式，无论OFS0.IWDTSTRT位或DPSBYCR.DPSBY位如何设置。如果OFS0.IWDTSTPCL位为0而OFS0.IWDTSTRT位为0（自动启动模式），IWDT专用时钟和IWDT继续运行。

当LVD1CR0.RI=1（选择电压监视器1复位）或LVD2CR0.RI=1（选择电压监视器2复位）时，MCU进入软件待机模式而不是深度软件待机模式。IO端口状态与软件待机模式相同。

Note: 在执行WFI指令之前，应满足DTC、DMAC和IWDT转换到软件待机模式的条件。有关详细信息，请参阅第10.7节。软件待机模式。

10.9.2 取消深度软件待机模式

深度软件待机模式通过以下方式取消：

●表10.3所示的中断

●ARES引脚复位

- A power-on reset

●电压监视器0复位。

(1) 通过中断取消

中断取消由DPSIERn(n=0到3)和DPSIFRn(n=0到3)控制。深度软件待机时
产生取消中断时，DPSIFRn中的相应标志置1。如果在DPSIERN中使能中断，
深度软件待机模式被取消。上升沿或下降沿可以通过DPSIEGRn(n=0到2)选择。可以为其选择边沿的中断是NMI、IRQn-DS（n=0、1、4到9）、电压监视器1和电压监视器2中断。当产生深度软件待机模式取消请求时，内部电源被提供，MOCO开始振荡，并为整个MCU产生内部复位（深度软件待机复位）。

为整个MCU提供稳定的MOCO时钟，并取消深度软件待机复位。MCU开始复位异常处理。

当深度软件待机模式被外部中断引脚或内部中断信号取消时，
RSTSR0.DPSRSTF标志设置为1。

(2) 通过RES引脚复位取消

当RES引脚驱动为低电平时，MCU取消深度软件待机模式并进入复位状态。在第43节"电气特性"中指定的时间内保持RES引脚为低电平。当RES引脚在指定时间段后被驱动为高电平时，CPU开始复位异常处理。

(3) 通过上电复位取消

深度软件待机模式通过上电复位取消，MCU启动复位异常处理。

(4) Cancelling by a voltage monitor 0 reset

Deep Software Standby mode is canceled by a voltage monitor 0 reset from the voltage detection circuit and the MCU starts the reset exception handling.

10.9.3 Pin States when Deep Software Standby mode is Canceled

In Deep Software Standby mode, the I/O ports retain the same states from Software Standby mode. The MCU is initialized by an internal reset generated when Deep Software Standby mode is canceled, and reset exception handling starts immediately. The DPSBYCR.IOKEEP bit setting determines whether to initialize the I/O ports or to retain the I/O ports states for Software Standby mode. The following is the state of the I/O ports for each bit setting:

- When the DPSBYCR.IOKEEP bit = 0
  I/O ports are initialized by an internal reset generated when Deep Software Standby mode is canceled.
- When the DPSBYCR.IOKEEP bit = 1
  Although the MCU is initialized by an internal reset generated when Deep Software Standby mode is canceled, the I/O ports retain their states from Software Standby mode regardless of the MCU internal state. The I/O ports states remain unchanged from Software Standby mode even when settings are made to the I/O ports or peripheral modules. The retained I/O ports states are released by clearing the DPSBYCR.IOKEEP bit to 0, and the MCU operates according to the internal state. The DPSBYCR.IOKEEP bit is not initialized by any internal reset generated when Deep Software Standby mode is canceled.

10.9.4 Example of Deep Software Standby Mode Application

(1) Entering and exiting Deep Software Standby mode

Figure 10.10 shows an example where a transition to Deep Software Standby mode is made at the falling edge of the IRQn-DS pin, and exiting Deep Software Standby mode is made at the rising edge of the IRQn-DS pin. In this example, an IRQn interrupt is accepted with the IRQCRi.IRQMD[1:0] bits of the ICU set to 00b (falling edge). After the DPSIEGRy.DIRQnEG (y = 0 or 1, n = 0,1,4 to 9) bit is set to 1 (rising edge) and the SBYCR.SSBY bit and DPSBYCR.DPSBY bit are both set to 1, the WFI instruction is executed. As a result, the MCU transitions to Deep Software Standby mode. Deep Software Standby mode is then canceled on the rising edge of the IRQn-DS pin.

(4) 通过电压监视器取消0复位

深度软件待机模式通过电压检测电路的电压监视器0复位取消，MCU开始复位异常处理。

10.9.3 取消深度软件待机模式时的引脚状态

在深度软件待机模式下，IO端口保持与软件待机模式相同的状态。MCU通过取消深度软件待机模式时产生的内部复位进行初始化，并立即开始复位异常处理。DPSBYCR.IOKEEP位设置确定是初始化IO端口还是保留软件待机模式下的IO端口状态。以下是每个位设置的IO端口状态：

- 当DPSBYCR.IOKEEP位=0时
  IO端口由取消深度软件待机模式时产生的内部复位进行初始化。
- 当DPSBYCR.IOKEEP位=1时
  虽然MCU由取消深度软件待机模式时产生的内部复位来初始化，但无论MCU内部状态如何，IO端口仍会保持软件待机模式下的状态。即使对IO端口或外围模块进行了设置，IO端口状态在软件待机模式下也保持不变。通过将DPSBYCR.IOKEEP位清0来释放保留的IO端口状态，MCU根据内部状态运行。DPSBYCR.IOKEEP位不会被取消深度软件待机模式时产生的任何内部复位初始化。

10.9.4 深度软件待机模式应用示例

(1) 进入和退出深度软件待机模式

图10.10显示了一个示例，其中在IRQnDS引脚的下降沿转换到深度软件待机模式，在IRQn-DS引脚的上升沿退出深度软件待机模式。在此示例中，接受IRQn中断，同时ICU的IRQCRi.IRQMD[1:0]位设置为00b（下降沿）。在DPSIEGRy.DIRQnEG（y=0或1，n=0 1 4到9）位设置为1（上升沿）并且SBYCR.SSBY位和

DPSBYCR.DPSBY位都设置为1，执行WFI指令。因此，MCU过渡到DeepSoftware待机模式。然后在IRQn-DS引脚的上升沿取消深度软件待机模式。

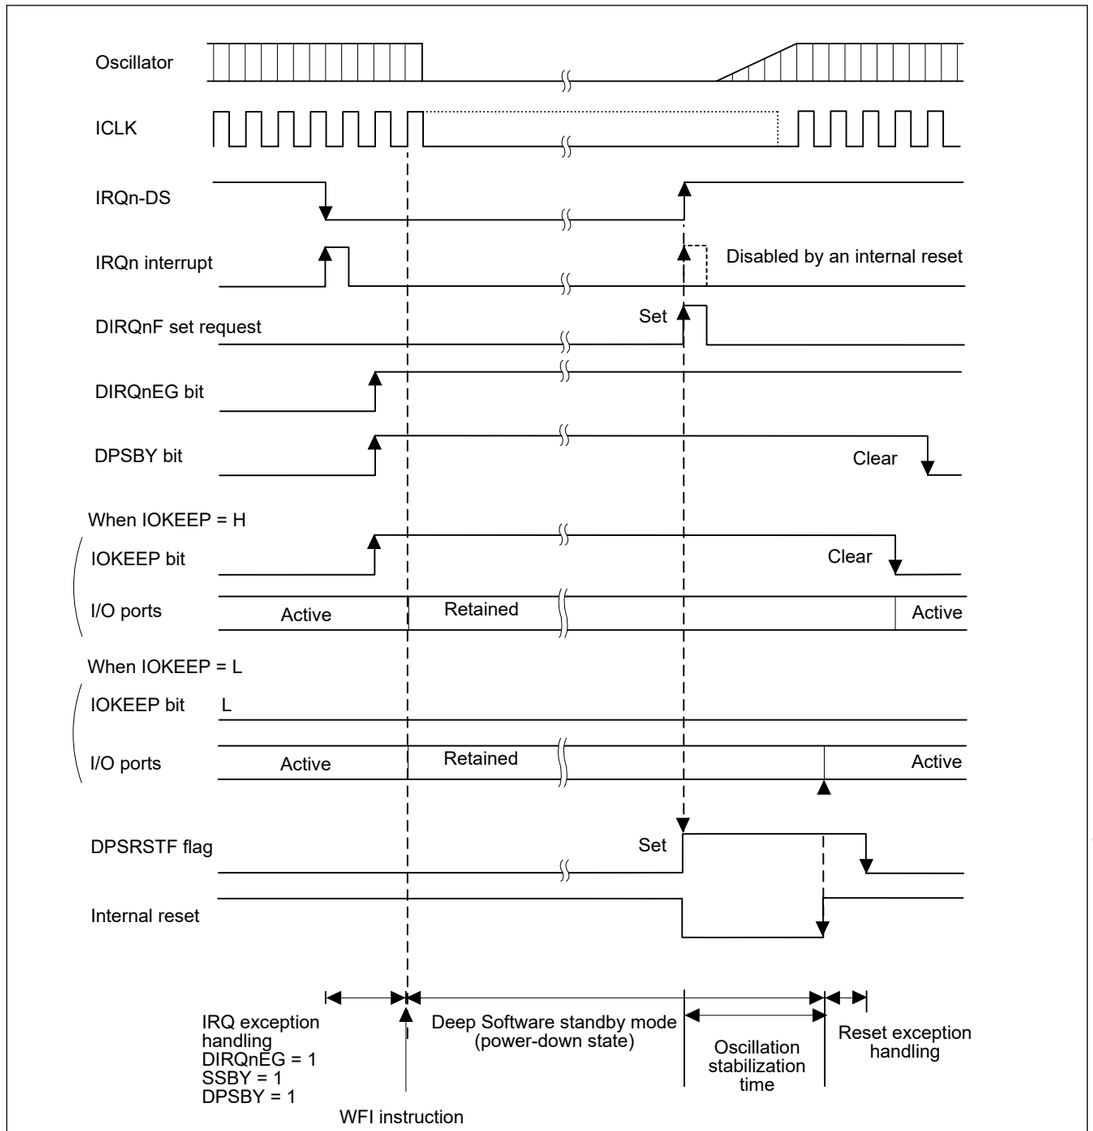

Figure 10.10 Example of Deep Software Standby Mode Application

10.9.5 Usage Flow for Deep Software Standby Mode

Figure 10.11 shows an example flow for using Deep Software Standby mode.

In this example, the RSTSR0.DPSRSTF flag of the reset function is read after the reset exception handling to determine whether a reset was generated by the RES pin or by the cancellation of Deep Software Standby mode.

For a reset by the RES pin, the MCU transitions to Deep Software Standby mode after the required register settings are made.

For a reset by cancellation of Deep Software Standby mode, the DPSBYCR.IOKEEP bit is cleared to 0 after the I/O port settings are made.

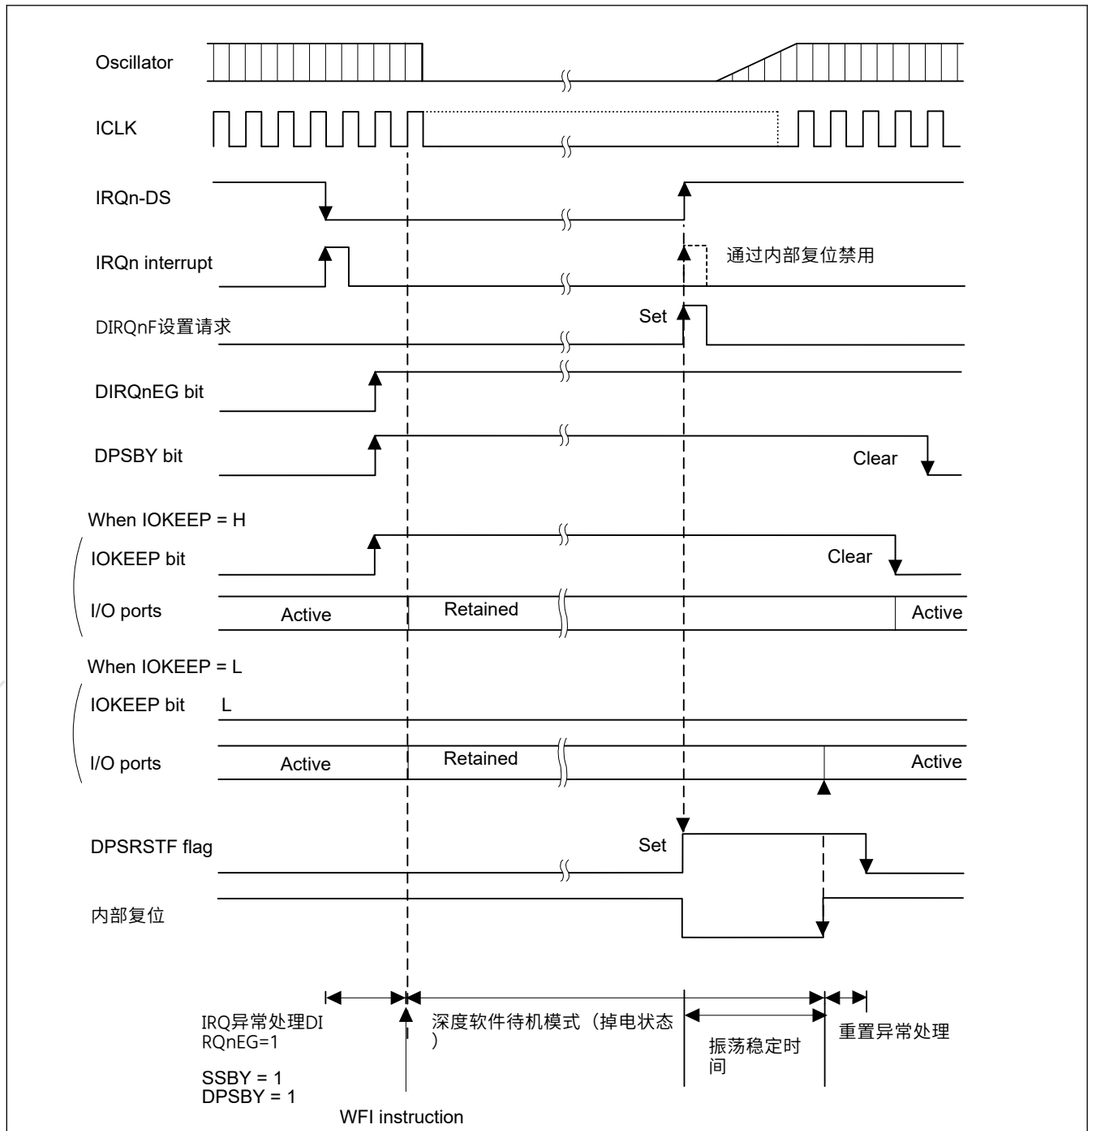

Figure 10.10 深度软件待机模式应用示例

10.9.5 深度软件待机模式的使用流程

图10.11显示了使用深度软件待机模式的示例流程。

在本例中，复位功能的RSTSR0.DPRSTF标志在复位异常处理后被读取，以确定复位是由RES引脚产生还是由深度软件待机模式的取消产生。

对于通过RES引脚进行的复位，在进行所需的寄存器设置后，MCU会转换到深度软件待机模式。

对于通过取消深度软件待机模式进行的复位，在IO端口设置完成后DPSBYCR.IOKEEP位被清零。

10.10.2 I/O Port pin states

The I/O port pin states in Software Standby mode, Deep Software Standby and Snooze mode, unless modifying in Snooze mode, are the same before entering the modes. Therefore, power consumption is not reduced while the output signals are held high.

10.10.3 Module-Stop State of DTC, DMAC

Before writing 1 to MSTPCRA.MSTPA22, clear the DMAST.DMST bit of the DMAC and the DTCST.DTCST bit of the DTC to 0. For details, see section 16, DMA Controller (DMAC) and section 17, Data Transfer Controller (DTC).

10.10.4 Internal Interrupt Sources

Interrupts do not operate in the module-stop state. If setting the module-stop bit while an interrupt request is generated, a CPU interrupt source or a DTC or DMAC startup source cannot be cleared. Always disable the associated interrupts before setting the module-stop bits.

10.10.5 Input Buffer Control by DIRQnE Bit

Setting the DPSIERy.DIRQnE (y = 0 or 1, n = 0, 1, 4 to 9) bit to 1 enables the associated input buffer of the IRQn-DS (n = 0, 1, 4 to 9) pins. Although inputs to these pins are sent to the DPSIFRy.DIRQnF (y = 0 or 1, n = 0, 1, 4 to 9) bits, they are not sent to the interrupt controller (ICU), peripheral modules, and I/O ports.

10.10.6 Transitioning to Low Power Modes

Because the MCU does not support wakeup by events, do not enter the low power modes such as Sleep mode, Software Standby mode or Deep Software Standby Mode by executing a WFE instruction. Also, do not set the SLEEPDEEP bit of the System Control Register in the Cortex-M33 core because the MCU does not support low power modes by SLEEPDEEP.

10.10.7 Timing of WFI Instruction

It is possible for the WFI instruction to be executed before I/O register write is completed, in which case operation might not be as intended. This can happen if the WFI is placed immediately after a write to an I/O register. To avoid this problem, read back the register that was written to confirm that the write completed.

(5) 贪睡模式下的无效寄存器写访问

不要在贪睡模式下写入本节中列出的寄存器。必须在进入软件待机模式之前设置它们。

[Registers]

- SNZCR, SNZEDCRn, SNZREQCRn.

(6) 对FLWT.FLWT[2:0]的写入访问无效

在所列条件下，请勿将000b以外的任何值写入FLWT.FLWT[2:0]位。

[Conditions]

- SOPCCR.SOPCM = 1 (Subosc-speed mode)

(7) 当PRCR.PRC1为0时，写入访问无效

当PRCR.PRC1位为0时，不要写入本节中列出的寄存器。

[Registers]

- SBYCR, SNZCR, SNZEDCRn, SNZREQCRn, OPCCR, SOPCCR, DPSBYCR, DPSWCR, DPSIERn, DPSIFRn, DPSIGRn, SYOCDCR, LDOSCR, PL2LDOSCR

(8) 当PRCR.PRC4位为0时，写访问无效

当PRCR.PRC4位为0时，不要写入本节中列出的寄存器。

[Registers]

- LPMSAR, DPFSAR

10.10.2 IO端口引脚状态

软件待机模式、深度软件待机和贪睡模式下的IO端口引脚状态，除非在贪睡模式下进行修改，否则在进入这些模式之前是相同的。因此，当输出信号保持为高时，功耗不会降低。

10.10.3 DTC、DMAC的模块停止状态

在将1写入MSTPCRA.MSTPA22之前，清除DMAC的DMAST.DMST位和DTCST.DTCST位DTC为0。有关详细信息，请参阅第16节，DMA控制器(DMAC)和第17节，数据传输控制器(DTC)。

10.10.4 内部中断源

中断不会在模块停止状态下运行。如果在产生中断请求时设置模块停止位，则无法清除CPU中断源或DTC或DMAC启动源。在设置模块停止位之前，始终禁用相关的中断。

10.10.5 通过DIRQnE位控制输入缓冲器

将DPSIERy.DIRQnE（y=0或1，n=0、1、4到9）位设置为1会启用IRQn-DS（n=0、1、4到9）引脚的相关输入缓冲器。尽管这些引脚的输入被发送到DPSIFRy.DIRQnF（y=0或1，n=0、1、4到9）位，但它们不会被发送到中断控制器(ICU)、外设模块和IO端口。

10.10.6 过渡到低功耗模式

由于MCU不支持事件唤醒，请勿进入睡眠模式、软件等低功耗模式待机模式或深度软件待机模式通过执行WFE指令。此外，不要设置Cortex-M33内核中系统控制寄存器的SLEEPDEEP位，因为MCU不支持SLEEPDEEP的低功耗模式。

10.10.7 WFI指令的时间安排

WFI指令可能在IO寄存器写入完成之前执行，在这种情况下操作可能不会按预期进行。如果在写入IO寄存器后立即放置WFI，则会发生这种情况。为避免此问题，请回读已写入的寄存器以确认写入已完成。

10.10.8 Writing to the WDT/IWDT Registers by DTC or DMAC in Sleep Mode or Snooze Mode

Do not write to the WDT or IWDT registers by the DTC or DMAC while WDT or IWDT is stopped after entering Sleep mode or Snooze mode.

10.10.9 Oscillators in Snooze Mode

Oscillators that stop on entering Software Standby mode automatically restart when a trigger for switching to Snooze mode is generated. The MCU does not enter Snooze mode until all the oscillators stabilize. If in Snooze mode, you must disable oscillators that are not required in Snooze mode before entering Software Standby mode. Otherwise, the transition from Software Standby mode to Snooze mode takes longer.

10.10.10 Snooze Mode Entry by RXD0 Falling Edge

When the SNZCR.RXDREQEN bit is 1, the falling edge of RXD0 pin is used to switch MCU from Software Standby mode to Snooze mode when using UART of SCI0 in Snooze mode. In this case an interrupt such as SCI0_ERI, SCI0_RXI or an address mismatch event is used as the source for canceling Snooze mode. However noise on the RXD0 pin might cause the MCU to transfer from Software Standby mode to Snooze mode unexpectedly. In this case if the MCU does not receive RXD0 data after the noise, an interrupt such as SCI0_ERI or SCI0_RXI, or an address mismatch event is not generated and the MCU stays in Snooze mode. This can be avoided by using AGTn (n = 1, 3) underflow interrupt to return to Software Standby mode or Normal mode unless otherwise UART receive data is completed before AGTn (n = 1, 3) underflow. However, do not use the AGTn (n = 1, 3) underflow as a source to return to Software Standby mode during an UART communication. This causes the UART to stop the operation in a half-finished state.

10.10.11 Using UART of SCI0 in Snooze Mode

When using UART in Snooze mode, ensure that the snooze request (RXD0 falling edge) does not conflict with the wakeup requests set by the WUPEN register, otherwise UART cannot be guaranteed.

When using UART in Snooze mode, the following conditions must be satisfied:

- The clock source must be HOCO
- MOCO, PLL, PLL2, and the main clock oscillator must be stopped before entering Software Standby mode
- The RXD0 pin must be kept high before entering Software Standby mode
- A transition to Software Standby mode must not occur during an SCI0 communication
- The MSTPCRC.MSTPC0 bit must be 1 before entering Software Standby mode.

10.10.12 Conditions of A/D Conversion Start in Snooze Mode

ADC120 can only be triggered by the ELC in Snooze mode. Do not use software trigger or ADTRGn (n = 0) pin.

10.10.13 ELC Events in Snooze Mode

This section lists available ELC events in Snooze mode. Do not use any other events. If starting peripheral modules for the first time after entering Snooze mode, the Event Link Setting Register (ELSRn) must set a Snooze mode entry event (SYSTEM_SNZREQ) as the trigger.

- Snooze mode entry (SYSTEM_SNZREQ)
- DTC transfer end (DTC_DTCEND)
- ADC120 window A/B compare match (ADC120_WCMPM)
- ADC120 window A/B compare mismatch (ADC120_WCMPUM)
- Data operation circuit interrupt (DOC_DOPCI).

10.10.14 Module-Stop Bit Write Timing

10.10.8 在睡眠模式或贪睡模式下通过DTC或DMAC写入WDTIWDT寄存器 Mode

当WDT或IWDT在进入休眠模式或贪睡模式后停止时，请勿通过DTC或DMAC写入WDT或IWDT寄存器。

10.10.9 贪睡模式下的振荡器

进入软件待机模式时停止的振荡器会在生成切换到贪睡模式的触发器时自动重新启动。在所有振荡器稳定之前，MCU不会进入贪睡模式。如果处于贪睡模式，您必须在进入软件待机模式之前禁用贪睡模式中不需要的振荡器。否则，从软件待机模式到贪睡模式的转换需要更长的时间。

10.10.10 通过RXD0下降沿进入贪睡模式

当SNZCR.RXDREQEN位为1时，在贪睡模式下使用SCI0的UART时，RXD0引脚的下降沿用于将MCU从软件待机模式切换到贪睡模式。在这种情况下，中断如SCI0_ERI、SCI0_RXI或地址不匹配事件被用作取消贪睡模式的源。然而，RXD0引脚上的噪声可能会导致MCU意外地从软件待机模式转换到贪睡模式。在这种情况下，如果MCU没有收到

噪声后的RXD0数据，如SCI0_ERI或SCI0_RXI等中断，或地址不匹配事件不产生，MCU保持在贪睡模式。这可以通过使用AGTn(n=1 3)下溢中断返回到软件待机模式或正常模式来避免，除非在AGTn(n=1 3)下溢之前完成UART接收数据。但是，不要使用AGTn(n=1 3)下溢作为UART通信期间返回软件待机模式的源。这会导致UART在半完成状态下停止操作。

10.10.11 在贪睡模式下使用SCI0的UART

在Snooze模式下使用UART时，确保Snooze请求（RXD0下降沿）与WUPEN寄存器设置的唤醒请求不冲突，否则无法保证UART。

在Snooze模式下使用UART时，必须满足以下条件：

●时钟源必须是HOCO
●MOCO、PLL、PLL2和主时钟振荡器必须在进入软件待机模式之前停止
●进入软件待机模式前，RXD0引脚必须保持高电平
●在SCI0通信期间不得转换到软件待机模式
●MSTPCRC.MSTPC0位必须为1才能进入软件待机模式。

10.10.12 贪睡模式下AD转换开始的条件

ADC120只能由ELC在贪睡模式下触发。不要使用软件触发或ADTRGn(n=0)引脚。

10.10.13 贪睡模式下的ELC事件

本节列出了贪睡模式下可用的ELC事件。不要使用任何其他事件。如果进入贪睡模式后第一次启动外围模块，事件链接设置寄存器（ELSRn）必须设置贪睡模式进入事件（SYSTEM_SNZREQ）作为触发器。

●贪睡模式条目(SYSTEM_SNZREQ)
●DTC传输结束（DTC_DTCEND）
●ADC120窗口AB比较匹配(ADC120_WCMPM)
●ADC120窗口AB比较不匹配(ADC120_WCMPUM)
●数据操作电路中断（DOC_DOPCI）。

10.10.14 模块停止位写时序

It is possible that access to I/O register may be executed before the corresponding module-stop bit write completed. In this case, access to I/O register may not proceed as intended. To avoid this issue, before accessing I/O register, read back the module-stop bit that was written to confirm that the write completed.

在相应的模块停止位写入完成之前，可能会执行对IO寄存器的访问。在这种情况下，对IO寄存器的访问可能不会按预期进行。为避免此问题，在访问IO寄存器之前，请回读已写入的模块停止位以确认写入已完成。

11. Battery Backup Function

11.1 Overview

The MCU provides a battery backup function that maintains partial battery powering in the event of a power loss. Switching between VCC and VBATT, the battery-powered area includes RTC, SOSC, and backup memory.

During normal operation, the battery-powered area is powered by the main power supply, the VCC pin. When a VCC voltage drop is detected, the power source switches to the dedicated battery backup power pin, the VBATT pin. When the voltage rises again, the power source switches back from VBATT to VCC.

11.1.1 Features of Battery Backup Function

The features include:

- Battery power supply switch
- Backup registers
- Time capture pin detection

11.1.2 Battery Power Supply Switch

When the voltage applied to the VCC pin drops, this feature switches the power supply from the VCC pin to the VBATT pin. When the voltage rises, it switches the power supply from the VBATT pin back to the VCC pin.

11.1.3 Backup Registers

The battery-powered area provides 128-byte backup registers. These registers retain data when power is supplied from the VBATT pin even when the VCC pin is in the power-off state.

11.1.4 Time Capture Pin Detection

The RTC detects input level changes on the time capture pin. For more information, see section 23, Realtime Clock (RTC).

Note: When VCC is < $V_{DETBATT}$ and > (VBATT + 0.6 V), the injected current flows from the VCC to the VBATT pin through an internal diode. If the power supply battery connected to the VBATT pin cannot support this current injection, for example if the battery is not rechargeable, Renesas strongly recommends that you connect through a low-voltage threshold diode between the power supply battery and the VBATT pin.

Note: You must enable voltage monitor 0 reset to use the battery backup function. The voltage monitor 0 level must be higher than the VBATT switch level.

Figure 11.1 shows the configuration of the battery backup function.

11. 电池备份功能

11.1 Overview

MCU提供电池备份功能，可在断电时保持部分电池供电。在VCC和VBATT之间切换，电池供电区域包括RTC、SOSC和备份存储器。

在正常工作期间，电池供电区域由主电源VCC引脚供电。当检测到VCC电压下降时，电源切换到专用电池备用电源引脚VBATT引脚。当电压再次上升时，电源从VBATT切换回VCC。

11.1.1 电池备份功能的特点

特点包括：

- 电池供电开关
- 备份寄存器
- 时间捕捉引脚检测

11.1.2 电池电源开关

当施加到VCC引脚的电压下降时，此功能将电源从VCC引脚切换到VBATT引脚。当电压上升时，它将电源从VBATT引脚切换回VCC引脚。

11.1.3 备份寄存器

电池供电区提供128字节的备份寄存器。这些寄存器在供电时保留数据
VBATT引脚即使在VCC引脚处于断电状态时。

11.1.4 时间捕捉引脚检测

RTC检测时间捕捉引脚上的输入电平变化。有关详细信息，请参阅第23节，实时时钟(RTC)。

Note: 当VCC<VDETBATT且>(VBATT+0.6V)时，注入电流通过内部二极管从VCC流向VBATT引脚。如果连接到VBATT引脚的电源电池不能支持这种电流注入，例如，如果电池不可充电，瑞萨强烈建议您通过电源电池和VBATT引脚之间的低压阈值二极管进行连接。

Note: 您必须启用电压监视器0复位才能使用电池备份功能。电压监视器0电平必须高于VBATT开关电平。

VBAE bit (VBATT backup register access enable bit)

You must write 1 to VBAE before accessing VBTBKR and you must write 0 to VBAE after finishing all access (write or read) to VBTBKR. If you do not write 0 to VBAE, the data of VBTBKR is not kept in VBATT mode.

To access VBTBKR, wait for at least 500 ns after writing 1 to VBAE, and then access VBTBKR.

Before entering the deep software standby mode, you must write 0 to VBAE.

To enter the deep software standby mode, wait for at least 250 ns after writing 0 to VBAE, then enter the deep software standby mode.

If you do not use VBTBKR, you should change VBAE to 0 to reduce power consumption of VBTBKR.

11.3 Operation

11.3.1 Battery Backup Function

When the voltage on the VCC pin drops, power can be supplied to the RTC and sub-clock oscillator from the VBATT pin. When a drop of power supply from VCC pin is detected, the power connection switches from VCC pin to the VBATT pin. The power supply from the VCC pin is resumed when the voltage on the VCC pin exceeds $V_{DETBATT}$. This power supply change does not affect the RTC operation.

You must enable voltage monitor 0 reset to use the battery backup function. The RTC supports time capture detection, triggered by a change of the time capture pin input level.

The VBATT pin supplies power to the following modules:

- RTC
- Sub-clock oscillator (including XCIN and XCOUT pins)
- VBATT Backup Register

11.3 Operation

11.3.1 电池备份功能

当VCC引脚上的电压下降时，可以从VBATT引脚为RTC和副时钟振荡器供电。当检测到来自VCC引脚的电源下降时，电源连接从VCC引脚切换到VBATT引脚。当VCC引脚上的电压超过VDETBATT时，重新从VCC引脚供电。此电源更改不会影响RTC操作。

您必须启用电压监视器0复位才能使用电池备份功能。RTC支持时间捕捉检测，由时间捕捉引脚输入电平的变化触发。

VBATT引脚为以下模块供电：

- RTC
- ●副时钟振荡器（包括XCIN和XCOUT引脚）
- ●VBATT备份寄存器

Note: For details, see section 43, Electrical Characteristics.
Note 1. $V_{DETBATT}$ indicates the threshold level of the power supply change between the VCC pin and the VBATT pin.

Figure 11.2 Switching sequence of Battery backup function.

11.3.2 VBATT Battery Power Supply Switch Usage

The battery power supply switch can switch the power supply from the VCC pin to the VBATT pin when the voltage being applied to the VCC pin drops. When the voltage rises, this switch changes the power supply from the VBATT pin to the VCC pin.

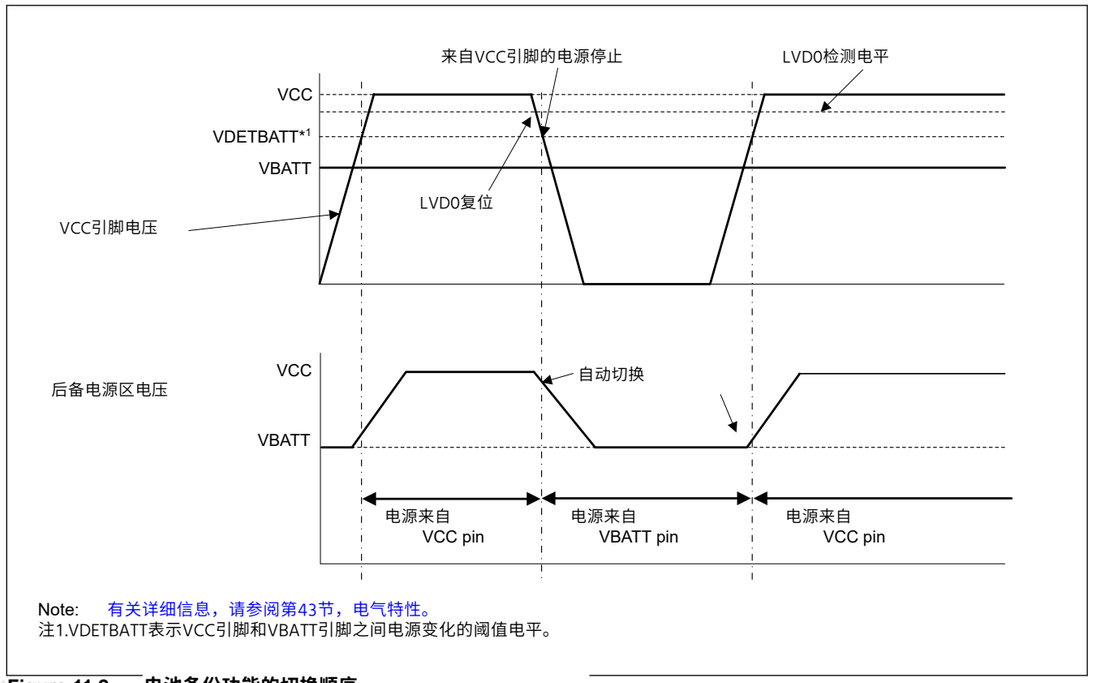
Note: The battery backup function should be used after the voltage monitor 0 reset is enabled (OFS1.LVDAS bit is 0). Voltage monitor 0 level should be higher than VBATT switch level.

11.3.3 VBATT Backup Register Usage

Use the VBATT backup registers VBTBKRn, where n = 0 to 127, to store or restore data with an 8-bit read or write operation.

11.4 Usage Notes

1. Operation of the sub-clock oscillator and RTC are not guaranteed when the voltage level on VBATT is lower than the guaranteed operation range. Initialize the RTC when the VBATT pin falls below the guaranteed operating voltage and then powers up again.
2. A reset generated while writing to registers described in this section might destroy the register value.
3. When VCC is higher than $V_{DETBATT}$, the VCC pin and VBATT pin are separated. When VCC is lower than $V_{DETBATT}$ and the switch is connected to the VBATT pin, and if the voltage on VBATT drops lower than (VCC - 0.6 V), current might flow into the VBATT pin through the parasitic diode between the VCC and VBATT pins.
4. During RTC operation using the voltage from the VBATT pin and the I/O ports within the backup, the power supply area can only be used as time capture event input pins for the RTC.



Note: 有关详细信息，请参阅第43节，电气特性。
注1.VDETBATT表示VCC引脚和VBATT引脚之间电源变化的阈值电平。

Figure 11.2 电池备份功能的切换顺序。

11.3.2 VBATT电池电源开关使用

当施加到VCC引脚的电压下降时，电池电源开关可以将电源从VCC引脚切换到VBATT引脚。当电压上升时，该开关将电源从VBATT引脚切换到VCC引脚。

Note: 电池备份功能应在电压监视器0复位使能（OFS1.LVDAS位为0）后使用。
电压监视器0电平应高于VBATT开关电平。

11.3.3 VBATT备份寄存器使用

使用VBATT备份寄存器VBTBKRn，其中n=0到127，通过8位读取或写入操作来存储或恢复数据。

11.4 使用说明

1.当VBATT上的电压电平低于保证工作范围时，不保证副时钟振荡器和RTC的工作。当VBATT引脚低于保证工作电压时初始化RTC，然后再次上电。

2.写入本节中描述的寄存器时产生的复位可能会破坏寄存器值。

3.当VCC高于VDETBATT时，VCC管脚和VBATT管脚是分开的。当VCC低于VDETBATT并且开关连接到VBATT引脚时，如果VBATT上的电压低于（VCC0.6V），电流可能会通过VCC和VBATT引脚之间的寄生二极管流入VBATT引脚。

4.RTC操作期间，使用来自VBATT引脚和备份内部IO端口的电压，电源区域只能用作RTC的时间捕捉事件输入引脚。

13. Interrupt Controller Unit (ICU)

13.1 Overview

The Interrupt Controller Unit (ICU) controls which event signals are linked to the Nested Vector Interrupt Controller (NVIC), the DMA Controller (DMAC), and the Data Transfer Controller (DTC) modules. The ICU also controls non-maskable interrupts.

Table 13.1 lists the ICU specifications, Figure 13.1 shows a block diagram, and Table 13.2 lists the I/O pins.

Table 13.1 ICU specifications

Low power modes		• Sleep mode: return is initiated by non-maskable interrupts or any other interrupt source • Software Standby mode: return is initiated by non-maskable interrupts. Interrupt can be selected in the WUPEN register. • Snooze mode: return is initiated by non-maskable interrupts. Interrupt can be selected in the SELSR0 and WUPEN registers. See section 13.2.17. SELSR0 : SYS Event Link Setting Register and section 13.2.18. WUPEN0 : Wake Up Interrupt Enable Register 0, section 13.2.19. WUPEN1 : Wake Up interrupt enable register 1.
TrustZone Filter		Available

Note 1. For the DMAC and DTC activation sources, see Table 13.4.
Note 2. Non-maskable interrupts can be enabled only once after a reset release.
Note 3. These non-maskable interrupts can also be used as maskable interrupts. When used as maskable interrupts, do not change the value of the NMIER register from the reset state. To enable voltage monitor 1 and voltage monitor 2 interrupts, set the LVD1CR1.IRQSEL and LVD2CR1.IRQSEL bits to 1.
Note 4. Low level: interrupt detection is not canceled if you do not clear it after a detection.
Note 5. These non-maskable interrupt sources cannot be recovered if the request source clock is stopped during low power mode.

SANMI bit (Security attributes of registers for nonmaskable interrupt)

Security attributes of registers for non-maskable interrupt. The target registers are as follows:

- NMIER
- NMICLR
- NMICR

The value of AIRCR.BFHFNMINS bit [13] in Application Interrupt and Reset Control Register of ARM CPU should be the same as the value of security attribution. The initial values of AIRCR.BFHFNMINS and the SANMI bits are different. AIRCR.BFHFNMINS is secure and SANMI is non-secure. Polarity has the same meaning so program these to match.

Note: Only one of Secure and Non-Secure can set security attribution for non-maskable interrupt-related registers. If you program the Secure attribute as secure, it always goes to the Secure interrupt handler. To release any of the non-maskable interrupt sources to the non-secure user, write a function to execute a nonsecure program from the interrupt handler for Secure.

Note: This register is write-protected by PRCR register.

SADMACn bits (Security attributes of registers for DMAC channel)

Security attributes of registers for DMAC channel. This register is referred to as the security attribute of the ICU and DMAC registers.

The controlled ICU register is:

- DELSRn

The controlled DMAC registers are:

- DMACn.DMSAR
- DMACn.DMSRR
- DMACn.DMDAR
- DMACn.DMDRR
- DMACn.DMCRA
- DMACn.DMCRB

Note: 该寄存器由PRCR寄存器写保护。

SANMI位（不可屏蔽中断的寄存器的安全属性）

不可屏蔽中断的寄存器的安全属性。目标寄存器如下：

- NMIER
- NMICLR
- NMICR

ARMCPU的应用中断和复位控制寄存器AIRCR.BFHFNMINSbit[13]的值应与安全属性的值相同。AIRCR.BFHFNMINS和SANMI位的初始值不同。AIRCR.BFHFNMINS是安全的，而SANMI是不安全的。极性具有相同的含义，因此请对它们进行编程以匹配。

Note: 只有Secure和Non-Secure之一可以为不可屏蔽的中断相关寄存器设置安全属性。如果您将Secure属性编程为安全，则它始终会转到Secure中断处理程序。要将任何不可屏蔽的中断源释放给非安全用户，请编写一个函数以从Secure的中断处理程序执行非安全程序。

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

IRQCRi register changes must satisfy the following conditions:

- For a CPU interrupt or DTC trigger:
  Change the IRQCRi register value before setting the target IELSRn register (n = 0 to 95).
  The register value should be changed only when the value of the target IELSRn register is 0x0000.
- For a DMAC trigger:
  Change the IRQCRi register value before setting the target DELSRn register (n = 0 to 7).
  The register value should be changed only when the value of the target DELSRn register is 0x0000.
- For a wakeup enable signal:
  Change the IRQCRi register setting before setting the target WUPEN0.IRQWUPEN[n] (n = 0 to 9, 13). The register value should be changed when the target WUPEN0.IRQWUPEN[n] is 0.

IRQMD[1:0] bits (IRQi Detection Sense Select)

The IRQMD[1:0] bits set the detection sensing method for the IRQi external pin interrupt sources. For more information about the settings, see section 13.5.6. External Pin Interrupts.

FCLKSEL[1:0] bits (IRQi Digital Filter Sampling Clock Select)

The FCLKSEL[1:0] bits select the digital filter sampling clock for the IRQi external pin interrupt request pins, selectable to:

- PCLKB (every cycle)
- PCLKB/8 (once every 8 cycles)
- PCLKB/32 (once every 32 cycles)
- PCLKB/64 (once every 64 cycles)

For details of the digital filter, see section 13.5.5. Digital Filter.

● 忽略非安全写入访问，不会生成TrustZone访问错误。
如果安全属性配置为非安全：●

IRQCRi寄存器更改必须满足以下条件：

●对于CPU中断或DTC触发：
在设置目标IELSRn寄存器（n=0到95）之前更改IRQCRi寄存器值。
仅当目标IELSRn寄存器的值为0x0000时才应更改寄存器值。

- For a DMAC trigger:
  在设置目标DELSRn寄存器（n=0到7）之前更改IRQCRi寄存器值。
  仅当目标DELSRn寄存器的值为0x0000时，才应更改寄存器值。

●对于唤醒使能信号：
在设置目标WUPEN0.IRQWUPEN[n]（n=0到9、13）之前更改IRQCRi寄存器设置。当目标WUPEN0.IRQWUPEN[n]为0时，应更改寄存器值。

IRQMD[1:0]位（IRQi检测检测选择）

IRQMD[1:0]位设置IRQi外部引脚中断源的检测检测方法。有关设置的更多信息，请参阅第13.5.6节。外部引脚中断。

FCLKSEL[1:0]位（IRQi数字滤波器采样时钟选择）

FCLKSEL[1:0]位选择IRQi外部引脚中断请求引脚的数字滤波器采样时钟，可选择：

- PCLKB (every cycle)
- PCLKB/8 (once every 8 cycles)
- PCLKB/32 (once every 32 cycles)
- PCLKB/64 (once every 64 cycles)

关于数字滤波器的详细信息，请参阅13.5.5节。数字滤波器。

FLTEN bit (IRQi Digital Filter Enable)

The FLTEN bit enables the digital filter used for the IRQi external pin interrupt sources. The digital filter is enabled when the IRQCRi.FLTEN bit is 1 and disabled when the IRQCRi.FLTEN bit is 0. The IRQi pin level is sampled at the clock cycle specified in the IRQCRi.FCLKSEL[1:0] bits. When the sampled level matches three times, the output level from the digital filter changes. For details of the digital filter, see section 13.5.5. Digital Filter.

13.2.11 NMISR : Non-Maskable Interrupt Status Register

13	TZFST	TrustZone Filter Error Status Flag 0: Interrupt not requested 1: Interrupt requested	R
15:14	—	These bits are read as 0.	R

The NMISR register monitors the status of non-maskable interrupt sources. Writes to the NMISR register are ignored. The setting in the Non-Maskable Interrupt Enable Register (NMIER) does not affect the status flags in this register. Before the end of the non-maskable interrupt handler, check that all of the bits in this register are set to 0 to confirm that no other NMI requests are generated during handler processing.

FLTEN位（IRQi数字滤波器使能）

FLTEN位使能用于IRQi外部引脚中断源的数字滤波器。当IRQCRi.FLTEN位为1时启用数字滤波器，当IRQCRi.FLTEN位为0时禁用数字滤波器。IRQi引脚电平在IRQCRi.FCLKSEL[1:0]位中指定的时钟周期进行采样。当采样电平匹配3次时，数字滤波器的输出电平会发生变化。关于数字滤波器的详细信息，请参阅13.5.5节。数字滤波器。

NFCLKSEL[1:0] bits (NMI Digital Filter Sampling Clock Select)

The NFCLKSEL[1:0] bits select the digital filter sampling clock for the NMI pin interrupts, selectable to:

- PCLKB (every cycle)
- PCLKB/8 (once every 8 cycles)

For details of the digital filter, see section 13.5.5. Digital Filter.

NFLTEN bit (NMI Digital Filter Enable)

The NFLTEN bit enables the digital filter used for NMI pin interrupts. The filter is enabled when NFLTEN is 1, and disabled when NFLTEN is 0. The NMI pin level is sampled at the clock cycle specified in NFCLKSEL[1:0]. When the sampled level matches three times, the output level from the digital filter changes. For details of the digital filter, see section 13.5.5. Digital Filter.

The IELS[8:0] bits link an event signal to the associated NVIC or DTC module. Event options are classified into 8 groups (groups 0 to 7). For details, see Table 13.3 and Table 13.4.

NFCLKSEL[1:0]位（NMI数字滤波器采样时钟选择）

NFCLKSEL[1:0]位选择用于NMI引脚中断的数字滤波器采样时钟，可选择：

- PCLKB (every cycle)
- PCLKB/8 (once every 8 cycles)
- PCLKB/32 (once every 32 cycles)
- PCLKB/64 (once every 64 cycles)

关于数字滤波器的详细信息，请参阅13.5.5节。数字滤波器。

NFLTEN位（NMI数字滤波器使能）

NFLTEN位使能用于NMI引脚中断的数字滤波器。滤波器在NFLTEN为1时启用，在NFLTEN为0时禁用。NMI引脚电平在NFCLKSEL[1:0]中指定的时钟周期进行采样。当采样电平匹配3次时，数字滤波器的输出电平会发生变化。关于数字滤波器的详细信息，请参阅13.5.5节。数字滤波器。

- 忽略非安全写入访问，不会生成TrustZone访问错误。

如果安全属性配置为非安全：●
允许安全和非安全访问。

Note: 该寄存器需要半字或字访问。

注1.禁止向IR标志写入1。

IELSRn寄存器选择NVIC使用的IRQi源。详见表13.3。IELSRn对应于NVICIRQ输入源编号，其中n=0到95。

IELS[8:0]位（ICU事件链接选择）

IELS[8:0]位将事件信号链接到相关的NVIC或DTC模块。事件选项分为8组（组0到7）。详见表13.3和表13.4。

IR flag (Interrupt Status Flag)

The IR status flag indicates an individual interrupt request from the event specified in IELS[8:0].

[Setting condition]

When an interrupt request is received from the associated peripheral module or IRQi pin.

[Clearing condition]

- The IR flag is cleared to 0 by writing 0.
- At the time other than the final transfer transfer end in DTC transfer during DTCE = 1, IR flag repeat set and cleared by Hardware.

When DTC transfer except last transfer is completed (DTCE bit is changed from 1 to 0).

During DTCE = 1, write 0 to IR register is prohibited.

In the case of level detection, clear of the IR flag should follow the steps below.

1. Negate the input interrupt signal.
2. Read access the peripheral once and wait for 2 clock cycles of the target module clock.
3. Clear the IR flag by writing 0.

DTCE bit (DTC Activation Enable)

When the DTCE bit is set to 1, the associated event is selected as the source for DTC activation.

[Setting condition]

- When 1 is written to the DTCE bit.

[Clearing condition]

- When the specified number of transfers is complete. For chain transfers, when the specified number of transfers for the last chain transfer is complete.
- When 0 is written to the DTCE bit.

Note: Error during DTC transfer

If an error response occurs during DTC transfer, the DTC notifies the ICU that an error has occurred. ICU clears all bits of the target IELSRn (n = 0 to 95). IELSRn that is not the target is not cleared.

Note: DTC transfer error in snooze mode

When an error occurs in DTC transfer in Snooze mode, ICU issues a wakeup request. However, interrupt requests are not issued automatically. See section 17, Data Transfer Controller (DTC) for how to set the interrupt when a DTC error occurs.

13.2.16 DELSRn : DMAC Event Link Setting Register n (n = 0 to 7)

Base address: ICU = 0x4000_6000

Offset address: 0x280 + 0x4 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IR标志（中断状态标志）

IR状态标志指示来自IELS[8:0]中指定事件的单个中断请求。

[Setting condition]

当从相关外设模块或IRQi引脚接收到中断请求时。

[Clearing condition]

●IR标志通过写入0清除为0。

●在DTCE=1期间DTC传输中最后传输传输结束以外的时间，IR标志由硬件重复设置和清除。

完成最后一次传输以外的DTC传输时（DTCE位从1变为0）。

在DTCE=1期间，禁止向IR寄存器写入0。

在电平检测的情况下，清除IR标志应遵循以下步骤。

1.取反输入中断信号。

2.对外设进行一次读取访问，并等待目标模块时钟的2个时钟周期。

3.写0清除IR标志。

DTCE位（DTC激活使能）

当DTCE位设置为1时，相关事件被选为DTC激活源。

[Setting condition]

●当1写入DTCE位时。

[Clearing condition]

●当指定数量的传输完成时。对于链式转移，当最后一次链式转移的指定转移次数完成时。

●当0写入DTCE位时。

Note: DTC传输期间出错

如果在DTC传输期间发生错误响应，则DTC会通知ICU发生了错误。ICU清除目标IELSRn(n=0到95)的所有位。不是目标的IELSRn不会被清除。

Note: 贪睡模式下的DTC传输错误

当贪睡模式下的DTC传输发生错误时，ICU会发出唤醒请求。但是，不会自动发出中断请求。有关如何在发生DTC错误时设置中断，请参见第17节，数据传输控制器(DTC)。

- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. Writing 1 to the IR flag is prohibited.

DELS[8:0] bit (DMAC Event Link Select)

The DELS[8:0] bits link an event signal to the associated DMAC module. Do not set the same event number in multiple DELSRn registers.

IR flag (DMAC Activation Request Status flag)

The IR flag is the status flag of a DMAC activation request. This flag is associated with the DELS[8:0] bits of this register.

[Setting condition]

- The flag is set to 1 when a DMAC activation request is generated from the associated peripheral module or IRQi pin.

[Clearing conditions]

- When 0 is written to the flag
- At the start of a DMA transfer after the DMAC activation request is issued.

Note: The IR flag is automatically cleared after completion of DMA transfer, so do not write 0 unless an abort occurs. DMA transfer operation when 0 is written cannot be guaranteed.

Note: Error during DMAC transfer

If an error response occurs during DMAC transfer, the DMAC notifies the ICU that an error has occurred.

The ICU clears all bits of the target channel of DELSRn (n = 0 to 7). DELSRn that is not the target channel is not cleared.

DELS[8:0]位（DMAC事件链接选择）

DELS[8:0]位将事件信号链接到相关的DMAC模块。不要在多个中设置相同的事件编号

[Setting condition]

●当相关外设模块或IRQi引脚产生DMAC激活请求时，该标志设置为1。

[Clearing conditions]

●标志写入0时

●在发出DMAC激活请求后开始DMA传输。

Note: IR标志在DMA传输完成后自动清除，因此除非发生中止，否则不要写0。无法保证写入0时的DMA传输操作。

Note: DMAC传输期间出错

如果在DMAC传输期间发生错误响应，则DMAC会通知ICU发生了错误。

The SELSR0 register selects the events that wake up the CPU from Snooze mode. You can use only the events listed in Table 13.4 checked as “Canceling Snooze mode using SELSR0”. Events specified in this register are defined as ICU_SNZCANCEL in Table 13.4. When ICU_SNZCANCEL is selected in the IELSRn.IELS[8:0] bits, the SELSR0 event interrupt occurs.

Caution: For security attribution added to parts related to a series of actions, make sure to match all security attribution so that security holes cannot be created.

13.4 Interrupt Operation

The ICU performs the following functions:

- Detecting interrupts
- Enabling and disabling interrupts
- Selecting interrupt request destinations such as CPU interrupt, DTC activation, and DMAC activation.

13.4.1 Detecting Interrupts

The ICU selects an event source input from a peripheral function interrupt or an external pin interrupt with IELSRn.IELS[8:0].

The accepted interrupt source sets the IELSRn.IR to 1 and sends an interrupt request to the NVIC.

External pin interrupt requests are detected by either:

- Edges (falling edge, rising edge, or rising and falling edges)
- Level (low level) of the interrupt signal.

Set the IRQCRi.IRQMD[1:0] bits to select the detection mode for the IRQi pins. For interrupt sources associated with peripheral modules, see Table 13.3 and Table 13.4. Events must be accepted by the NVIC before an interrupt occurs and is accepted by the CPU.

13.4 中断操作

ICU执行以下功能：

●检测中断
●启用和禁用中断
●选择中断请求目标，例如CPU中断、DTC激活和DMAC激活。

13.4.1 检测中断

ICU通过IELSRn.IELS[8:0]从外围功能中断或外部引脚中断选择事件源输入。

接受的中断源将IELSRn.IR设置为1，并向NVIC发送中断请求。

外部引脚中断请求通过以下任一方式检测：

●边沿（下降沿、上升沿或上升沿和下降沿）
●中断信号的电平（低电平）。

设置IRQCRi.IRQMD[1:0]位以选择IRQi引脚的检测模式。对于与外围模块相关的中断源，请参见表13.3和表13.4。事件必须在中断发生之前被NVIC接受并被CPU接受。

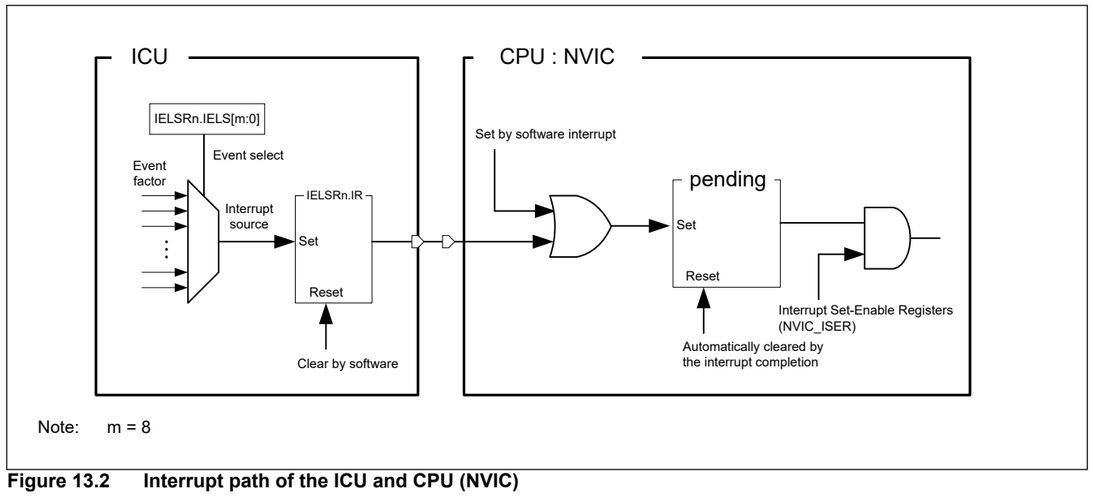

Figure 13.2 Interrupt path of the ICU and CPU (NVIC)

13.5 Interrupt setting procedure

13.5.1 Enabling Interrupt Requests

The procedure for enabling an interrupt request is as follows:

1. Set the Interrupt Set-Enable register (NVIC_ISER).
2. Set the IELSRn.IELS[8:0] bits as the interrupt source.
3. Specify the operation settings for the event source, such as DMAC activation (DELSRn.DELS[8:0]), snooze mode cancellation (SELSR0.SELS[8:0]), software standby mode cancellation (WUPEN register setting).

13.5.2 Disabling Interrupt Requests

The procedure to disable the interrupt request is as follows:

1. Disable the operation settings for the event source, such as DMAC activation (DELSRn.DELS[8:0]), snooze mode cancellation (SELSR0.SELS[8:0]), software standby mode cancellation (WUPEN register setting).
2. Clear the interrupt source setting (IELSRn.IELS[8:0] = 0x00).
3. Clear the interrupt status flag (IELSRn.IR = 0).
4. Clear the interrupt Clear-Enable register (NVIC_ICER) and interrupt Clear-Pending register (NVIC_ICPR).

13.5.3 Polling for interrupts

The procedure for polling for interrupt requests is as follows:

1. Set the Interrupt Clear-Enable register (NVIC_ICER).
2. Set the IELSRn.IELS[8:0] bits as the interrupt source.
3. Specify the operation settings for the event source, such as DMAC activation (DELSRn.DELS[8:0]), snooze mode cancellation (SELSR0.SELS[8:0]), software standby mode cancellation (WUPEN register setting).
4. Poll the interrupt Set-Pending register (NVIC_ISPR).

13.5.4 Selecting Interrupt Request Destinations

The available destinations are fixed for each interrupt, as described in Table 13.3, Table 13.4.

The interrupt output destination, CPU, DMAC, or DTC can be independently selected for each interrupt source.

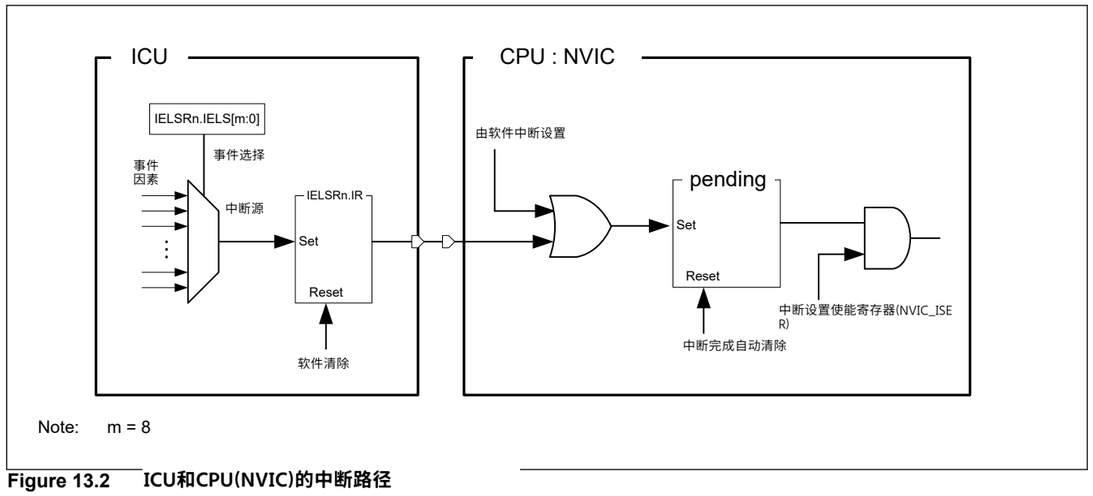

Figure 13.2 ICU和CPU(NVIC)的中断路径

13.5 中断设置程序

13.5.1 启用中断请求

使能中断请求的过程如下：

1.设置中断设置使能寄存器(NVIC_ISER)。

2.将IELSRn.IELS[8:0]位设置为中断源。

3.指定事件源的操作设置，例如DMAC激活（DELSRn.DELS[8:0]）、贪睡模式取消（SELSR0.SELS[8:0]）、软件待机模式取消（WUPEN寄存器设置）。

13.5.2 禁用中断请求

禁用中断请求的过程如下：

1.禁用事件源的操作设置，例如DMAC激活（DELSRn.DELS[8:0]）、贪睡模式取消（SELSR0.SELS[8:0]）、软件待机模式取消（WUPEN寄存器设置）。

2.清除中断源设置（IELSRn.IELS[8:0]=0x00）。

3.清除中断状态标志（IELSRn.IR=0）。

4.清除中断清除启用寄存器（NVIC_ICER）和中断清除挂起寄存器（NVIC_ICPR）。

13.5.3 轮询中断

轮询中断请求的过程如下：

1.设置中断清除启用寄存器(NVIC_ICER)。

2.将IELSRn.IELS[8:0]位设置为中断源。

3.指定事件源的操作设置，例如DMAC激活（DELSRn.DELS[8:0]）、贪睡模式取消（SELSR0.SELS[8:0]）、软件待机模式取消（WUPEN寄存器设置）。

4.轮询中断设置挂起寄存器(NVIC_ISPR)。

13.5.4 选择中断请求目标

每个中断的可用目的地都是固定的，如表13.3和表13.4中所述。

可以为每个中断源独立选择中断输出目标、CPU、DMAC或DTC。

Use an interrupt request destination setting that is indicated by a "✓" in the event list (see section 13.3.2. Event Number).

Note: Setting the same interrupt source for IELSRn and DELSRn is prohibited.

If the DMAC or DTC is selected as the destination for requests from an IRQi pin, you must set the IRQCRi.IRQMD[1:0] bits for that interrupt to select edge detection.

13.5.4.1 CPU interrupt request

When IELSRn.DTCE = 0, the event specified in the IELSRn register is output to the NVIC. Set the IELSRn.IELS[8:0] bits to the target event and set the IELSRn.DTCE bit to 0.

13.5.4.2 DTC activation

When IELSRn.DTCE = 1, the event specified in the IELSRn register is output to the DTC. Use the following procedure:

1. Set the IELSRn.IELS[8:0] bits to the target event and set the IELSRn.DTCE bit to 1.
2. Set the DTC Module Start bit (DTCST.DTCST) to 1.

Table 13.5 shows operation when the DTC is the interrupt request destination.

Table 13.5 Operation when DTC becomes interrupt request destination

Interrupt request destination	DISEL*1	Remaining transfer operations	Operation per request	IR*2	Interrupt request destination after transfer
DTC*3	1	≠ 0	DTC transfer → CPU interrupt	Cleared on interrupt acceptance by the CPU	DTC
		= 0	DTC transfer → CPU interrupt	Cleared on interrupt acceptance by the CPU	CPU(IELSRn.DTCE bit is cleared)
	0	≠ 0	DTC transfer	Cleared at the start of DTC data transfer after reading DTC transfer data	DTC
		= 0	DTC transfer → CPU interrupt	Cleared on interrupt acceptance by the CPU	CPU(IELSRn.DTCE bit is cleared)

Note 1. DTC.MRB.DISEL bit controles the interrupt generates timing from DTC to CPU.
Note 2. When the IELSRn.IR flag is 1, an interrupt request (DTC activation request) that occurs again is ignored.
Note 3. For chain transfers, DTC transfer continues until the last chain transfer ends. The DISEL bit state and the remaining transfer count determine whether a CPU interrupt occurs, the IELSRn.IR flag clear timing, and the interrupt request destination after transfer. See Table 17.2 in section 17, Data Transfer Controller (DTC).

Note: Error during DTC transfer

If an error response occurs during DTC transfer, the DTC notifies the ICU that an error has occurred. ICU clears all bits of the target IELSRn (n = 0 to 95). IELSRn that is not the target is not cleared.

Note: DTC transfer error in snooze mode

When an error occurs in DTC transfer in Snooze mode, ICU issues a Wake Up request. However, interrupt requests are not issued automatically. See section 17, Data Transfer Controller (DTC) chapter for information on how to set the interrupt when a DTC error occurs.

13.5.4.3 DMAC Activation

Events specified in the DELSRn registers are output to the DMAC.

To set the interrupt source for DMAC, use the following procedure:

1. Set the DELSRn.DELS[8:0] bits to the event to activate the DMAC.
2. When using interrupts to CPU, set the IELSRn.IELS bit to factor of DMAC interrupt and IELSRn.DTCE bit to 0.
3. Set the activation source for the target DMAC channel (DMACm.DMTMD.DCTG[1:0]) to 01b (interrupt module detection).
4. Set the DMAC transfer enable bit for the target DMAC channel (DMACm.DMCNT.DTE) to 1.

使用事件列表中由"✓"指示的中断请求目标设置（参见第13.3.2节。事件编号）。

Note: 禁止为IELSRn和DELSRn设置相同的中断源。

如果选择DMAC或DTC作为来自IRQi引脚的请求的目标，则必须设置IRQCRi.IRQMD[1:0]位以使该中断选择边沿检测。

13.5.4.1 CPU中断请求

当IELSRn.DTCE=0时，将IELSRn寄存器中指定的事件输出到NVIC。将IELSRn.IELS[8:0]位设置为目标事件，并将IELSRn.DTCE位设置为0。

13.5.4.2 DTC activation

当IELSRn.DTCE=1时，将IELSRn寄存器中指定的事件输出到DTC。使用以下过程：

1.将IELSRn.IELS[8:0]位设置为目标事件，并将IELSRn.DTCE位设置为1。

2.将DTC模块起始位(DTCST.DTCST)设置为1。

表13.5显示了DTC是中断请求目标时的操作。

Table 13.5 DTC成为中断请求目标时的操作

中断请求目的地	DISEL*1	剩余的转移操作	按请求操作	IR*2	传输后的中断请求目的地
DTC*3	1	≠ 0	DTC传输→CPU中断	CPU接受中断时清零	DTC
		= 0	DTC传输→CPU中断	CPU接受中断时清零	CPU（IELSRn.DTCE位清零）
	0	≠ 0	DTC transfer	读取DTC传输数据后，在DTC数据传输开始时清零	DTC
		= 0	DTC传输→CPU中断	CPU接受中断时清零	CPU（IELSRn.DTCE位清零）

注1.DTC.MRB.DISEL位控制从DTC到CPU的中断产生时序。
注2.IELSRn.IR标志为1时，忽略再次发生的中断请求（DTC激活请求）。
注3.对于链式传输，DTC传输将持续到最后一个链式传输结束。DISEL位状态和剩余传输计数决定是否发生CPU中断、IELSRn.IR标志清除时序以及传输后的中断请求目的地。请参见第17节"数据传输控制器(DTC)"中的表17.2。

Note: DTC传输期间出错

如果在DTC传输期间发生错误响应，则DTC会通知ICU发生了错误。ICU清除目标IELSRn(n=0到95)的所有位。不是目标的IELSRn不会被清除。

Note: 贪睡模式下的DTC传输错误

当贪睡模式下的DTC传输发生错误时，ICU会发出唤醒请求。但是，不会自动发出中断请求。有关如何在发生DTC错误时设置中断的信息，请参见第17节，数据传输控制器(DTC)章节。

13.5.4.3 DMAC Activation

在DELSRn寄存器中指定的事件被输出到DMAC。

要为DMAC设置中断源，请使用以下过程：

1.将DELSRn.DELS[8:0]位设置为事件以激活DMAC。

2.当对CPU使用中断时，将IELSRn.IELS位设置为DMAC中断因素，并将IELSRn.DTCE位设置为0。

3.将目标DMAC通道（DMACm.DMTMD.DCTG[1:0]）的激活源设置为01b（中断模块检测）。

4.将目标DMAC通道(DMACm.DMCNT.DTE)的DMAC传输使能位设置为1。

5. Set the DMAC operation enable bit (DMAST.DMST) to 1.

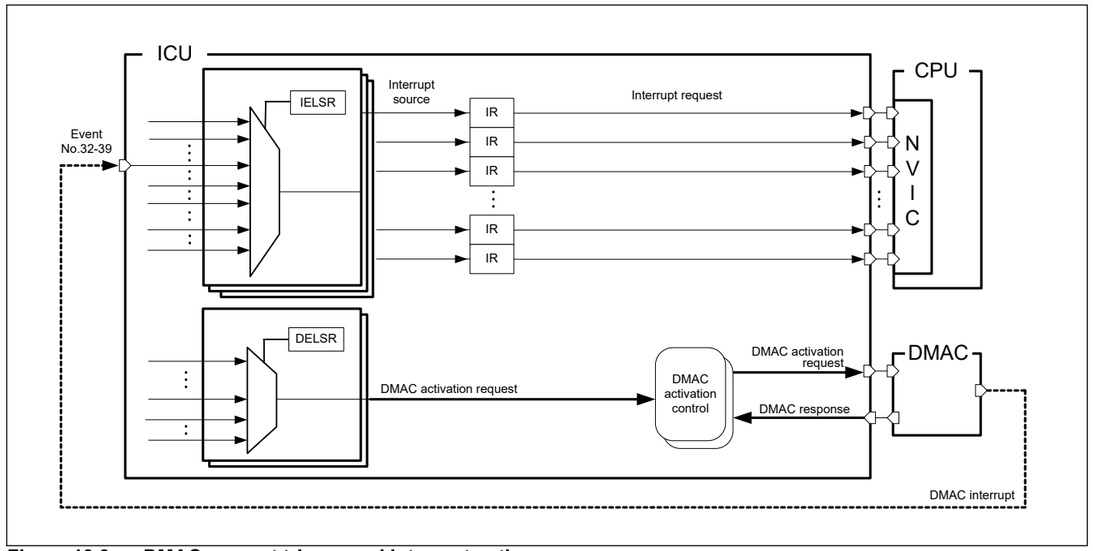

Figure 13.3 DMAC request trigger and interrupt path

Note: Error during DMAC transfer

If an error response occurs during DMAC transfer, the DMAC notifies the ICU that an error has occurred.

The ICU clears all bits of the target channel of DELSRn (n = 0 to 7). DELSRn that is not the target channel is not cleared.

13.5.5 Digital Filter

A digital filter function is provided for the external interrupt request pins IRQi, (i = 0 to 9, 13) and the NMI pin interrupt. It samples input signals on the filter PCLKB sampling clock, and removes any signal with a pulse width less than 3 sampling cycles.

To use the digital filter for an IRQi pin:

1. Set the sampling clock cycle to PCLKB, PCLKB/8, PCLKB/32, or PCLKB/64 in the IRQCRi.FCLKSEL[1:0] bits (i = 0 to 9, 13).
2. Set the IRQCRi.FLTEN bit (i = 0 to 9, 13) to 1 (digital filter enabled).

To use the digital filter for an NMI pin:

1. Set the sampling clock cycle to PCLKB, PCLKB/8, PCLKB/32, or PCLKB/64 in the NMICR.NFCLKSEL[1:0] bits.
2. Set the NMICR.NFLTEN bit to 1 (digital filter enabled).

Figure 13.4 shows an example of digital filter operation.

5.将DMAC操作使能位(DMAST.DMST)设置为1。

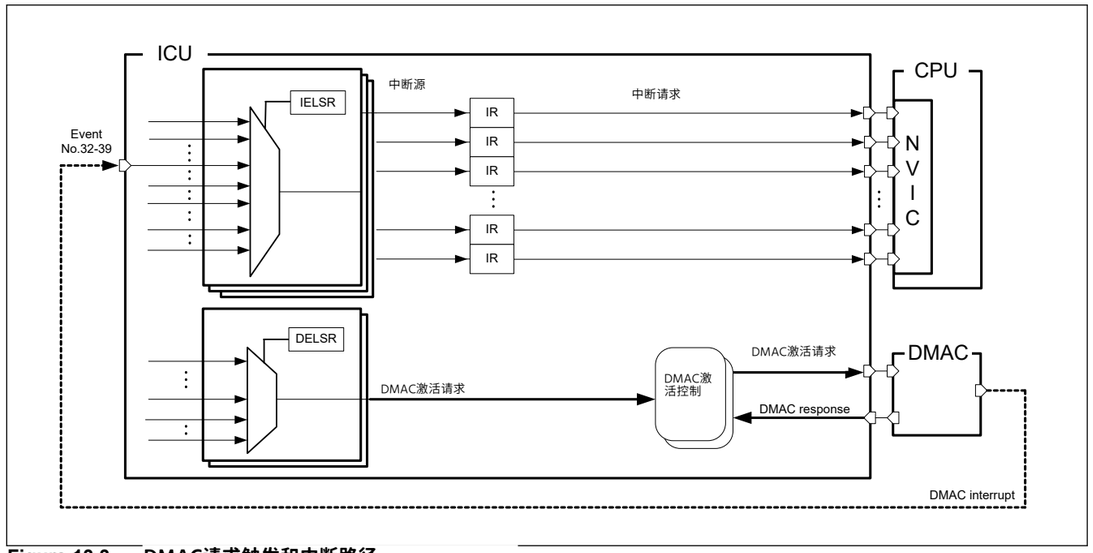

Figure 13.3 DMAC请求触发和中断路径

Note: DMAC传输期间出错

如果在DMAC传输期间发生错误响应，则DMAC会通知ICU发生了错误。

ICU清除DELSRn（n=0到7）的目标通道的所有位。不是目标通道的DELSRn不会被清除。

13.5.5 数字滤波器

为外部中断请求引脚IRQi(i=0to9 13)和NMI引脚中断提供了数字过滤功能。它在滤波器PCLKB采样时钟上对输入信号进行采样，并去除脉冲宽度小于3个采样周期的任何信号。

为IRQi引脚使用数字滤波器：

1.在IRQCRi.FCLKSEL[1:0]位（i=0到9、13）中将采样时钟周期设置为PCLKB、PCLKB8、PCLKB32或PCLKB64。

2.将IRQCRi.FLTEN位（i=0到9、13）设置为1（启用数字滤波器）。

要将数字滤波器用于NMI引脚：

1.在NMICR.NFCLKSEL[1:0]位中将采样时钟周期设置为PCLKB、PCLKB8、PCLKB32或PCLKB64。

2.将NMICR.NFLTEN位设置为1（启用数字滤波器）。

图13.4显示了数字滤波器操作的示例。

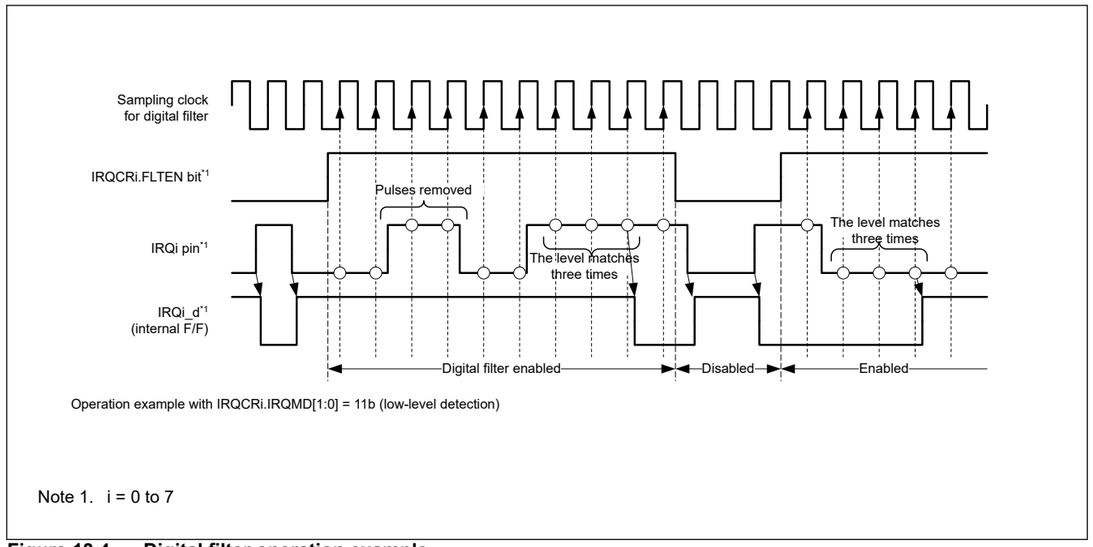

Figure 13.4 Digital filter operation example

Before entering Software Standby mode, disable the digital filters by clearing the IRQCRi.FLTEN and NMICR.NFLTEN bits. The ICU clock stops in Software Standby mode.

On exiting Software Standby, the circuit detects the edge by comparing the state before standby to the state after standby release. If the input changes during Software Standby, an incorrect edge might be detected. The digital filters can be enabled again after exiting Software Standby mode.

13.5.6 External Pin Interrupts

To use external pin interrupts:

1. Configure I/O ports settings
2. Clear the IRQCRi.FLTEN bit (i = 0 to 9, 13) to 0 (digital filter disabled).
3. Set the IRQMD[1:0] bits of the given IRQCRi register (i = 0 to 9, 13) to select the senses of detection.
4. Set the FCLKSEL[1:0] bits, and the FLTEN bit of the IRQCRi register.
5. Select the IRQ pin as follows:
   - If the IRQ pin is to be used for CPU interrupt requests, set the IELSRn.IELS[8:0] bits and the IELSRn.DTCE bit to 0.
   - If the IRQ pin is to be used for DTC activation, set the IELSRn.IELS[8:0] bits and the IELSRn.DTCE bit to 1.
   - If the IRQ pin is to be used for DMAC activation, set the DELSRn.DELS[8:0] bits.

13.6 Non-Maskable Interrupt Operation

The following sources can trigger a non-maskable interrupt:

- NMI pin interrupt
- Oscillation stop detection interrupt
- WDT underflow/refresh error interrupt
- IWDT underflow/refresh error interrupt
- Voltage monitor 1 interrupt
- Voltage monitor 2 interrupt
- SRAM parity error interrupt
- MPU bus master error interrupt

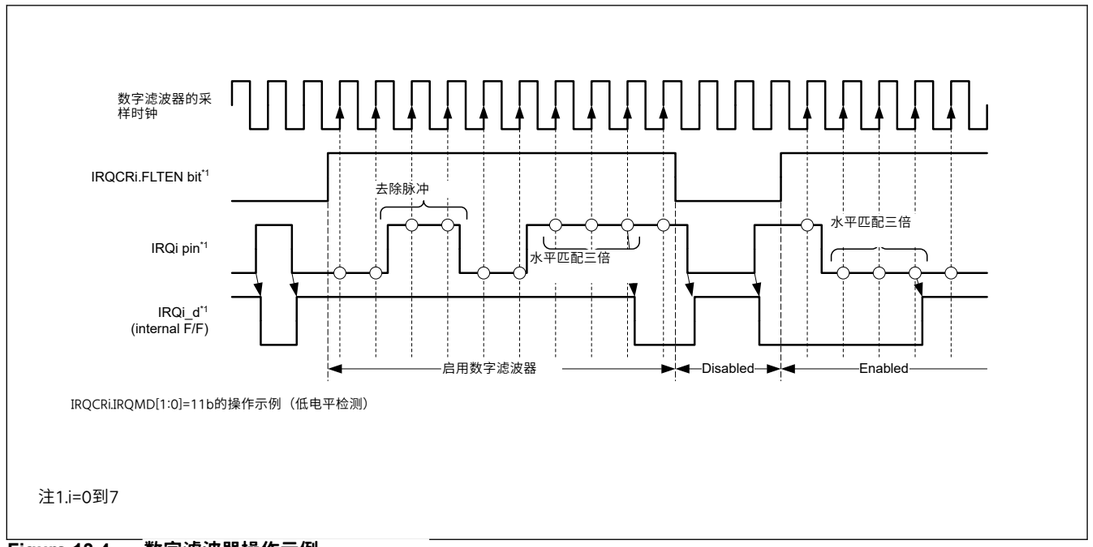

Figure 13.4 数字滤波器操作示例

在进入软件待机模式之前，通过清除IRQCRi.FLTEN和NMICR.NFLTEN位来禁用数字滤波器。ICU时钟在软件待机模式下停止。

在退出软件待机时，电路通过将待机前的状态与待机释放后的状态进行比较来检测边沿。如果在软件待机期间输入发生变化，则可能会检测到不正确的边沿。退出软件待机模式后，可以再次启用数字滤波器。

13.5.6 外部引脚中断

要使用外部引脚中断：

1.配置IO端口设置

2.将IRQCRi.FLTEN位（i=0到9、13）清零（禁用数字滤波器）。

3.设置给定IRQCRi寄存器（i=0到9 13）的IRQMD[1:0]位以选择检测意义。

4.设置FCLKSEL[1:0]位和IRQCRi寄存器的FLTEN位。

5.选择IRQ引脚如下：

- ●如果IRQ引脚用于CPU中断请求，请将IELSRn.IELS[8:0]位和IELSRn.DTCE位设置为0。
- ●如果IRQ引脚用于DTC激活，请将IELSRn.IELS[8:0]位和IELSRn.DTCE位设置为1。
- ●如果IRQ引脚用于激活DMAC，设置DELSRn.DELS[8:0]位。

13.6 不可屏蔽中断操作

以下源可以触发不可屏蔽中断：

- ●NMI引脚中断
- ●振荡停止检测中断
- ●WDT下溢刷新错误中断
- ●IWDT下溢刷新错误中断
- ●电压监控器1中断
- ●电压监测器2中断
- ●SRAM奇偶校验错误中断
- ●MPU总线主机错误中断

- TrustZone filter error interrupt

Non-maskable interrupts can only be used with the CPU, not to activate the DTC or DMAC. Non-maskable interrupts take precedence over all other interrupts. The non-maskable interrupt states can be verified in the Non-Maskable Interrupt Status Register (NMISR). Confirm that all bits in the NMISR are 0 before returning from the NMI handler.

Non-maskable interrupts are disabled by default. To use non-maskable interrupts:

1. Clear the NMICR.NFLTEN bit to 0 (digital filter disabled).
2. Set the NMIMD bit, NFCLKSEL[1:0] bits, and NFLTEN bit of NMICR register.
3. Write 1 to the NMICLR.NMICLR bit to clear the NMISR.NMIST flag to 0.
4. Enable the non-maskable interrupt by writing 1 to the associated bit in the Non-Maskable Interrupt Enable Register (NMIER).

After 1 is written to the NMIER register, subsequent write access to the NMIEN bit in NMIER is ignored. An NMI interrupt cannot be disabled when enabled, except by a reset.

The secure attribution managed within the Application Interrupt and Reset Control Register (AIRCR) of the Arm CPU must match the security attribution of NMI.

The NMI secure of the CPU is changed by AIRCR.BFHFNMINS. It is managed by software developers who manage Secure program.

13.6.1 Correspondence to TrustZone-M by NMI

Although there is only one NMI per CPU, multiple factors can be set. This section describes the procedure for mixing Secure and NonSecure programs of NMI. When doing so, the NMI-related registers of the ICU are set to Secure.

NMI-related registers:

- NMIER
- NMICR

Set "0" to ICUSARB.SANMI.

The value of AIRCR.BFHFNMINS[13] in the Application Interrupt and Reset Control Register of the ARM CPU must be the same as the value of security attribution. The initial values of AIRCR.BFHFNMINS and ICUSARB.SANMI are different.

AIRCR.BFHFNMINS is for secure and ICUSARB.SANMI is for non-secure. Polarity has the same meaning so program these to match.

If NMI is issued, jump to the NMI handler. When mixing secure and non-secure program, the NMI handler must branch according to the TrustZone-M rule. Figure 13.5 shows the flow.

●TrustZone过滤器错误中断

不可屏蔽中断只能用于CPU，不能激活DTC或DMAC。不可屏蔽中断优先于所有其他中断。不可屏蔽中断状态可以在不可屏蔽中断状态寄存器(NMISR)中验证。在从NMI处理程序返回之前，确认NMISR中的所有位都为0。

默认情况下禁用不可屏蔽中断。要使用不可屏蔽的中断：

1.将NMICR.NFLTEN位清为0（禁用数字滤波器）。

2.设置NMICR寄存器的NMIMD位、NFCLKSEL[1:0]位和NFLTEN位。

3.将1写入NMICLR.NMICLR位以将NMISR.NMIST标志清零。

4.通过将1写入不可屏蔽中断使能寄存器(NMIER)中的相关位来启用不可屏蔽中断。

将1写入NMIER寄存器后，随后对NMIER中的NMIEN位的写访问将被忽略。启用时不能禁用NMI中断，除非通过复位。

在ArmCPU的应用程序中断和复位控制寄存器(AIRCR)中管理的安全属性必须与NMI的安全属性相匹配。

CPU的NMI安全由AIRCR.BFHFNMINS更改。它由管理的软件开发人员管理
安全程序。

13.6.1 NMI与TrustZone-M的通信

虽然每个CPU只有一个NMI，但可以设置多个因素。本节介绍混合程序
NMI的安全和非安全程序。这样做时，ICU的NMI相关寄存器设置为Secure。

NMI-related registers:

- NMIER
- NMICR

将“0”设置为ICUSARB.SANMI。

ARMCPU的应用中断和复位控制寄存器AIRCR.BFHFNMINS[13]的值必须与安全属性的值相同。AIRCR.BFHFNMINS和ICUSARB.SANMI的初始值不同。

AIRCR.BFHFNMINS用于安全，ICURASB.SANMI用于非安全。极性具有相同的含义，因此请对它们进行编程以匹配。

如果发出NMI，则跳转到NMI处理程序。当混合安全和非安全程序时，NMI处理程序必须根据TrustZone-M规则进行分支。图13.5显示了流程。

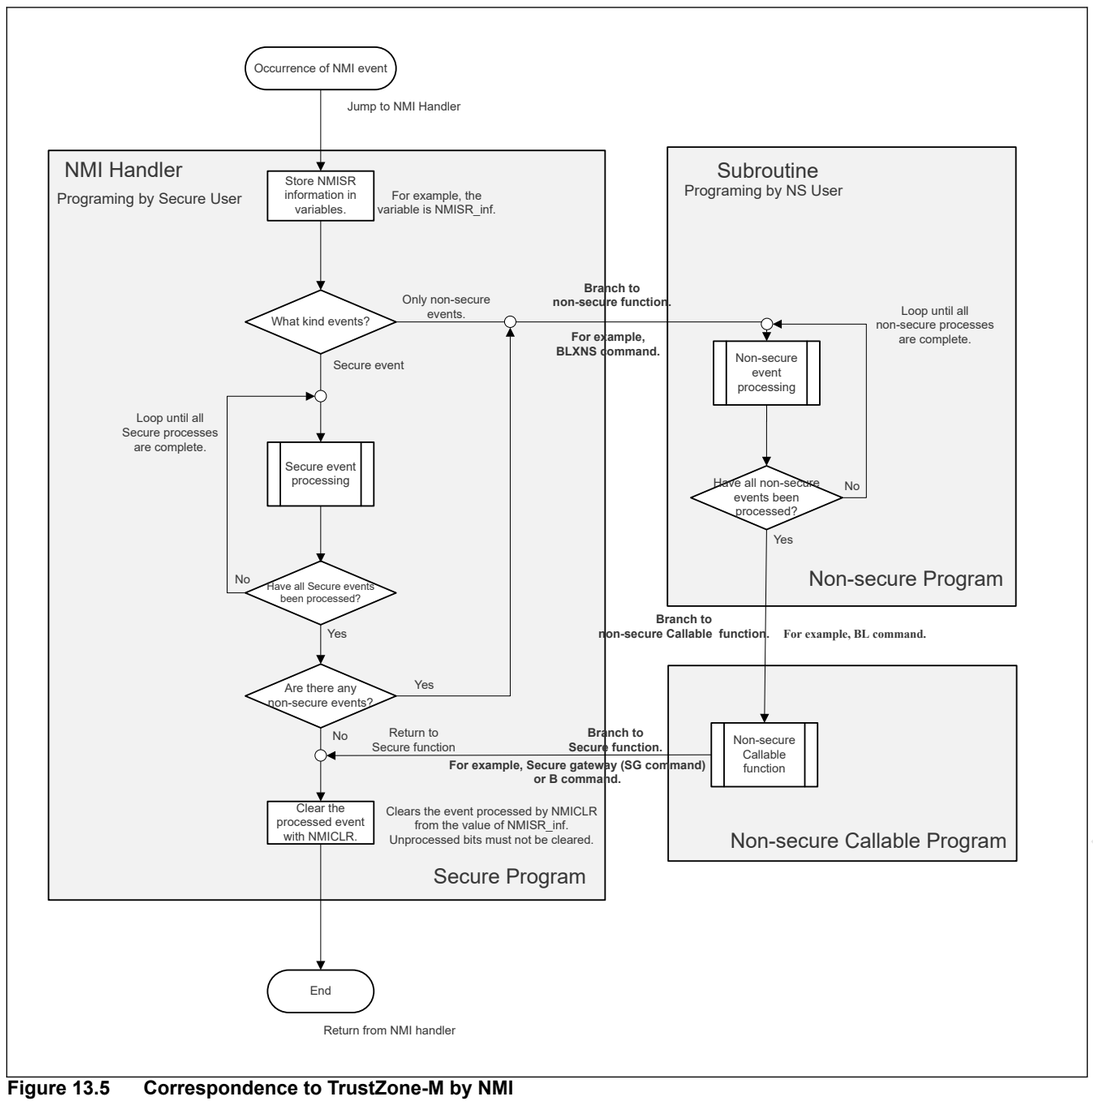

Figure 13.5 Correspondence to TrustZone-M by NMI

See the Arm documentation for details on how to move between secure and non-secure programs.

13.7 Return from Low Power Modes

Table 13.4 lists the interrupt sources that can be used to exit Sleep, Snooze, or Software Standby mode. For more information, see section 10, Low Power Modes.

13.7.1 Return from Sleep Mode

To return from Sleep mode in response to an interrupt:

non-maskable interrupt

- Use the NMIER register to enable the target interrupt request.

maskable interrupt

- Select the CPU as the interrupt request destination.

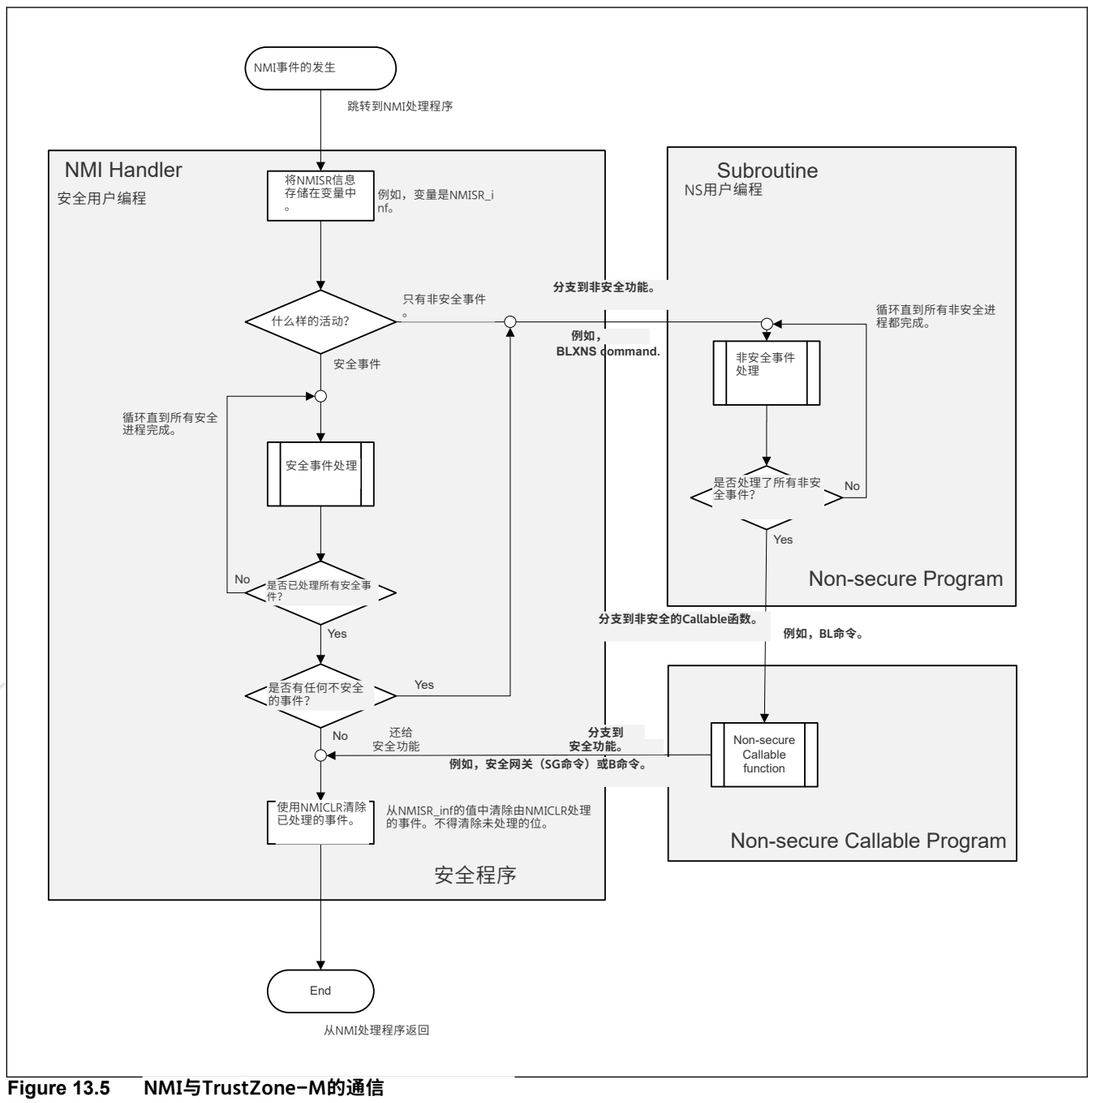

Figure 13.5 NMI与TrustZone-M的通信

有关如何在安全程序和非安全程序之间移动的详细信息，请参阅Arm文档。

13.7 从低功耗模式返回

表13.4列出了可用于退出休眠、贪睡或软件待机模式的中断源。有关详细信息，请参阅第10节，低功耗模式。

13.7.1 从睡眠模式返回

从睡眠模式返回以响应中断：

non-maskable interrupt

●使用NMIER寄存器启用目标中断请求。

maskable interrupt

●选择CPU作为中断请求目标。

- Enable the interrupt in the NVIC.

13.7.2 Return from Software Standby Mode

The ICU returns from Software Standby mode using a non-maskable interrupt or a maskable interrupt. For maskable interrupt of canceling source, see Table 13.4.

To return from Software Standby mode:

1. Select the interrupt source that enables return from Software Standby:
   - For non-maskable interrupts, use the NMIER register to enable the target interrupt request
   - For maskable interrupts, use the WUPEN register to enable the target interrupt request.
2. Select the CPU as the interrupt request destination
3. Enable the interrupt in the NVIC.

Interrupt requests through the IRQn pins that do not satisfy these conditions are not detected while the clock is stopped in Software Standby mode.

Similarly, request for a non-maskable interrupt from a request source whose clock is stopped in Software Standby mode cannot be detected.

Transition to/from Software Standby mode

1. Before Software Standby mode is entered, disable the digital filter for the interrupt source as a return target (IRQCRi.FLTEN = 0, NMICR.NFLTEN = 0).
2. To use the digital filter again after returning from Software Standby mode, enable the digital filter (IRQCRi.FLTEN = 1, NMICR.NFLTEN = 1).

13.7.3 Return from Snooze Mode

The ICU can return to Normal mode from Snooze mode using the interrupts provided for this mode.

To return to Normal mode from Snooze mode:

1. Set the number of the required interrupt request in SELSR0.SELS[8:0]
2. Set the value 0x02D (ICU_SNZCANCEL) in IELSRn.IELS[8:0] (n = 0 to 95).
3. Select the CPU as the interrupt request destination.
4. Enable the interrupt in the NVIC.

Interrupt requests through the non-maskable that do not satisfy the above conditions are not detected while the clock is stopped in snooze mode.

Note: In Snooze mode, a clock is supplied to the ICU. If an event selected in IELSRn is detected, the CPU acknowledges the interrupt after returning to Normal mode from Software Standby mode. If an event selected in DELSRn is detected, the DMAC can acknowledge the interrupt after returning to Normal mode from Software Standby mode.

13.8 Using the WFI Instruction with Non-Maskable Interrupts

Whenever a WFI instruction is executed, confirm that all status flags in the NMISR register are 0.

13.9 Reference

- ARM Limited., ARM® Cortex®-M33 Processor Technical Reference Manual (ARM 100230)

●在NVIC中启用中断。

13.7.2 从软件待机模式返回

ICU使用不可屏蔽中断或可屏蔽中断从软件待机模式返回。取消源的可屏蔽中断见表13.4。

从软件待机模式返回：

1.选择允许从软件待机返回的中断源：

●对于不可屏蔽的中断，使用NMIER寄存器使能目标中断请求

●对于可屏蔽中断，使用WUPEN寄存器启用目标中断请求。

2.选择CPU作为中断请求目的地

3.在NVIC中启用中断。

不满足这些条件的通过IRQn引脚的中断请求在时钟停止时不会被检测到
软件待机模式。

同样，无法检测到来自时钟在软件待机模式下停止的请求源的不可屏蔽中断请求。

从软件待机模式转换

1.在进入软件待机模式之前，禁用作为返回目标的中断源的数字滤波器（IRQCRi.FLTEN=0，NMICR.NFLTEN=0）。

2.要在从软件待机模式返回后再次使用数字滤波器，请启用数字滤波器（IRQCRi.FLTEN=1，NMICR.NFLTEN=1）。

13.7.3 从贪睡模式返回

ICU可以使用为该模式提供的中断从贪睡模式返回到正常模式。

要从贪睡模式返回正常模式：

1.在SELSR0.SELS[8:0]中设置所需中断请求的数量

2.在IELSRn.IELS[8:0]（n=0到95）中设置值0x02D(ICU_SNZCANCEL)。

3.选择CPU作为中断请求目标。

4.在NVIC中启用中断。

当时钟在贪睡模式下停止时，不会检测到通过不可屏蔽的不满足上述条件的中断请求。

Note: 在贪睡模式下，向ICU提供时钟。如果检测到在IELSRn中选择的事件，CPU在从软件待机模式返回到正常模式后确认中断。如果检测到在DELSRn中选择的事件，则DMAC可以在从软件待机模式返回正常模式后确认中断。

13.8 将WFI指令与不可屏蔽中断一起使用

每当执行WFI指令时，请确认NMISR寄存器中的所有状态标志为0。

14.2 Description of Buses

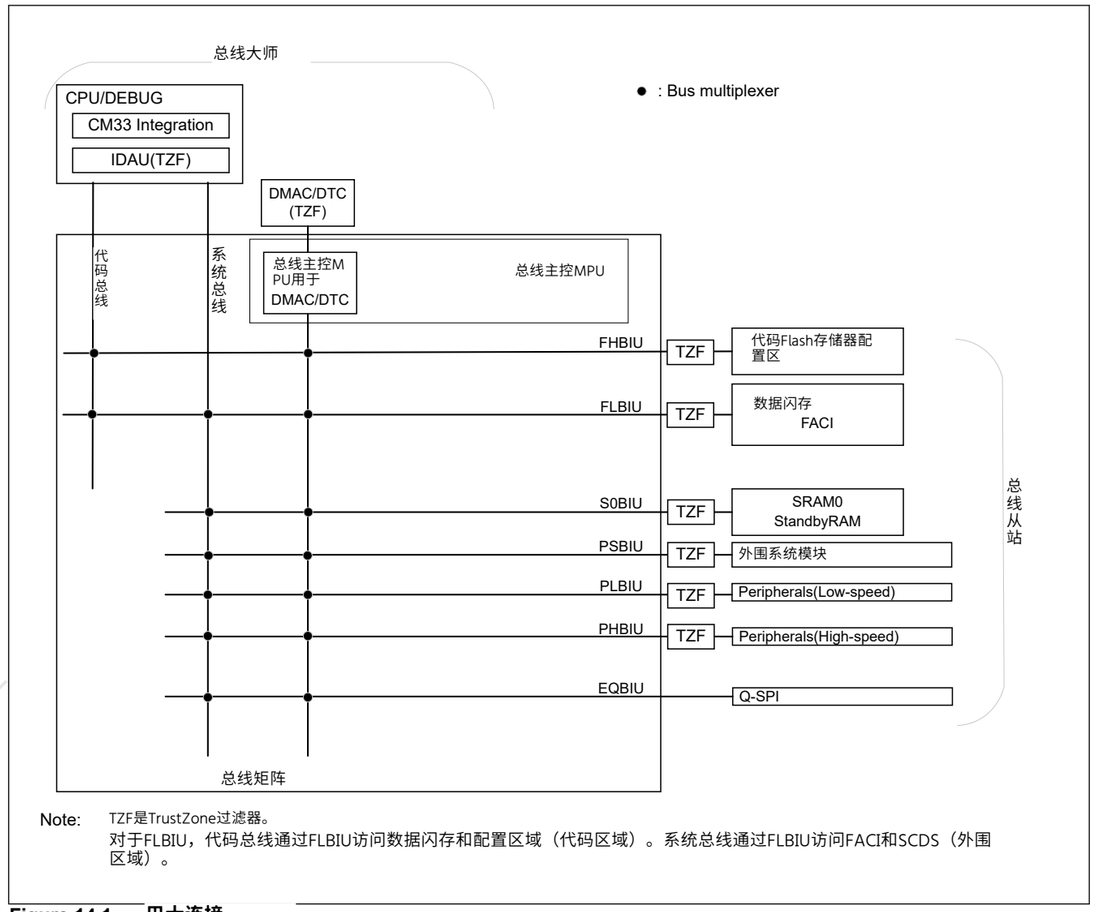
14.2.1 Arbitration

For arbitration between masters in each slave, fixed-priority and round-robin methods can be selected for each master. For details, see section 14.3.3. BUSSCNT<slave> : Slave Bus Control Register (<slave> = FHBIU, FLBIU, S0BIU, EQBIU), section 14.3.4. BUSSCNT<slave> : Slave Bus Control Register (<slave> = PSBIU, PLBIU, PHBIU).

14.2.2 Parallel Operation

Parallel operation is possible when different bus-master modules are requesting access to different slave modules.

Figure 14.2 shows an example of parallel operations. In this example, the CPU uses code bus and system bus for simultaneous access to FHBIU and S0BIU, respectively. Furthermore, the DMAC/DTC simultaneously accesses the peripheral bus during access to FHBIU and S0BIU by the CPU.



Note: TZF是TrustZone过滤器。
对于FLBIU，代码总线通过FLBIU访问数据闪存和配置区域（代码区域）。系统总线通过FLBIU访问FACI和SCDS（外围区域）。

Figure 14.1 巴士连接

14.2 巴士的描述

14.2.1 Arbitration

对于每个从属设备中的主设备之间的仲裁，可以为每个主设备选择固定优先级和循环方法。详见14.3.3节。BUSSCNT<slave>：从总线控制寄存器（<slave>=FHBIU、FLBIU、S0BIU、EQBIU），第14.3.4节。BUSSCNT<slave>:从总线控制寄存器(<slave>=PSBIU PLBIU PHBIU)。

14.2.2 并联运行

当不同的总线主模块请求访问不同的从模块时，并行操作是可能的。

图14.2显示了并行操作的示例。在本例中，CPU使用代码总线和系统总线分别同时访问FHBIU和S0BIU。此外，在CPU访问FHBIU和S0BIU期间，DMACDTC同时访问外围总线。

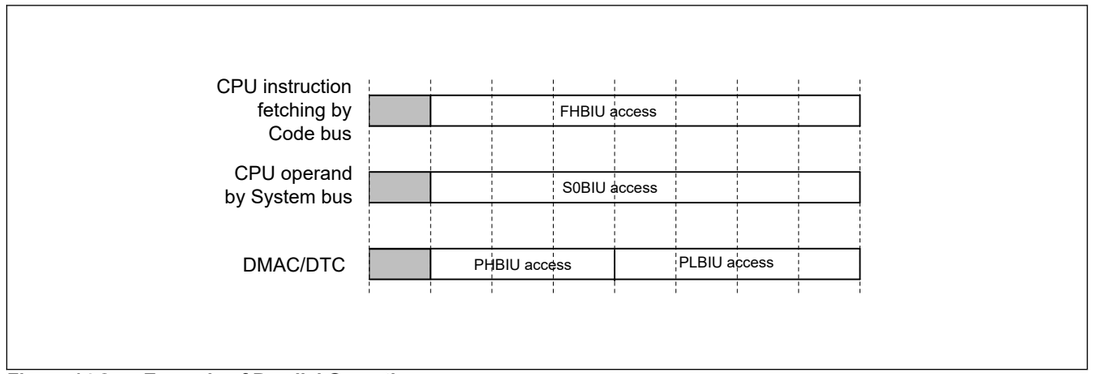


Figure 14.2 Example of Parallel Operations

14.2.3 Restrictions

(1) Restriction on Endian

Memory space must be little-endian in order to execute Cortex code.

(2) Bufferable write access

When CPU perform Bufferable Write access to PLBIU or PHBIU, if an STZF error occurs then the error response is invalidated. So there is no error flag will be set and no NMI / RESET request is generated.

When CPU perform Bufferable Write access to PHBIU, if a Slave BUS error occurs then the error response will become invalid and the error flag will not be set.

If error response is required, set the bus master to non-bufferable access.

(3) Access to reserved area of FLBIU and S0BIU

Access to the reserved area of FLBIU and S0BIU is prohibited. Operation is not guaranteed if accessed.

(4) Clock setting

The clock division ratio prohibits setting changes during bus access.

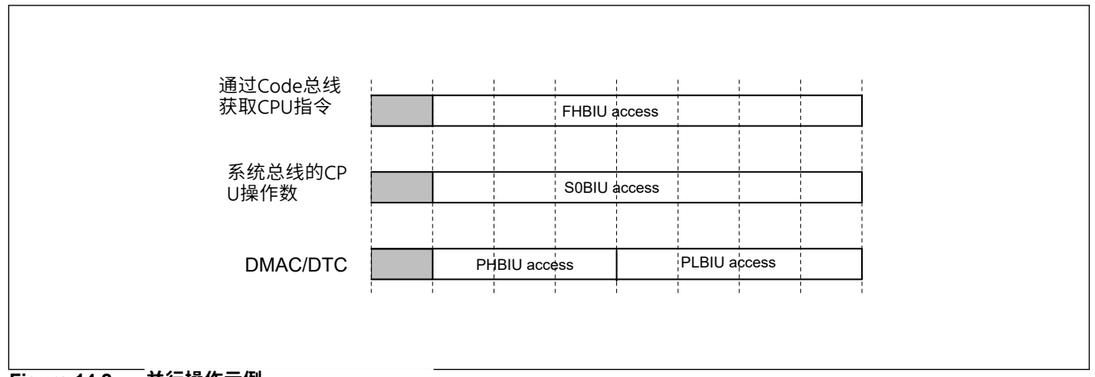

Figure 14.2 并行操作示例

14.2.3 Restrictions

(1) 对字节序的限制

为了执行Cortex代码，内存空间必须是little-endian。

(2) 可缓冲的写访问

当CPU对PLBIU或PHBIU执行BufferableWrite访问时，如果发生STZF错误，则错误响应无效。因此不会设置错误标志，也不会生成NMIRESET请求。

当CPU对PHBIU执行BufferableWrite访问时，如果发生SlaveBUS错误，则错误响应将变为无效且错误标志不会被设置。

如果需要错误响应，请将总线主机设置为非缓冲访问。

(3) 访问FLBIU和S0BIU的保留区

禁止访问FLBIU和S0BIU的保留区域。如果访问，则无法保证操作。

(4) 时钟设置

时钟分频比禁止在总线访问期间更改设置。

When writing 1 to DMACDTCERRCLR, stop the bus access that causes an error in DMAC/DTC.

14.4 Bus Error Monitoring Section

The bus error monitoring system monitors each individual area, and when an error is detected, an error is returned to the requesting master IP using the AHB-Lite error response protocol.

14.4.1 Bus Error Types

The following types of errors can occur on each bus:

- Illegal address access
- Bus master MPU error
- TrustZone Filter error
- Bus error transmitted from each slave IP

Table 14.2 lists the address ranges where access leads to illegal address access errors. The reserved area in the slave does not trigger an illegal address access error. For more information on the bus master MPU, see section 15, Memory Protection Unit (MPU).

14.4.2 Operations When a Bus Error Occurs

When a bus error occurs, operation is not guaranteed and the error is returned to the requesting master IP.

Figure 14.3 shows operation from each error detection to user notification on the bus.

注1.该位只能写入1。该位被读取为0。向该位写入0无效。

向DMACDTCERRCLR写入1时，停止导致DMACDTC错误的总线访问。

14.4 总线错误监控部分

总线错误监控系统监控每个单独的区域，当检测到错误时，使用AHB-Lite错误响应协议将错误返回给请求的主IP。

14.4.1 总线错误类型

每条总线上都可能发生以下类型的错误：

●非法地址访问

●总线主控MPU错误

●TrustZone过滤器错误

●从每个从IP传输的总线错误

表14.2列出了访问导致非法地址访问错误的地址范围。从机中的保留区域不会触发非法地址访问错误。有关总线主控MPU的更多信息，请参阅第15节，内存保护单元(MPU)。

14.4.2 发生总线错误时的操作

当发生总线错误时，无法保证操作，错误会返回到请求的主IP。

图14.3显示了从每个错误检测到总线上的用户通知的操作。

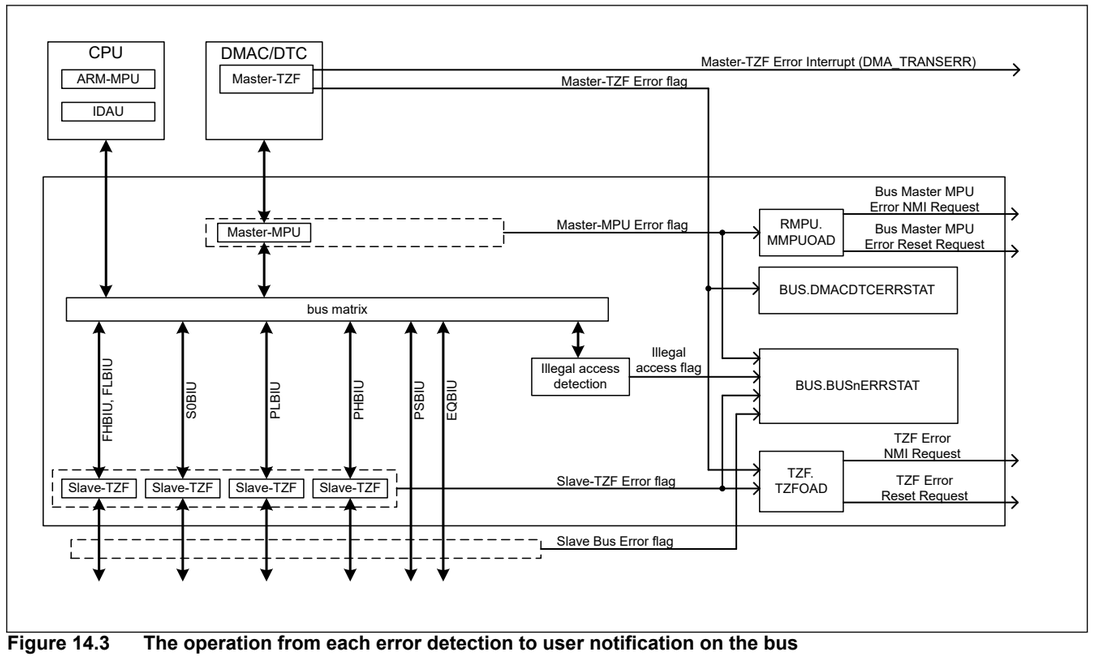

Figure 14.3 The operation from each error detection to user notification on the bus

(1) Bus Master MPU Error

The bus master of DMAC/DTC has a master MPU for access control of the set address area. The CPU does not have a master MPU because it has an Arm MPU. When a bus master MPU error is detected, an Error response is returned to the master. At the same time, perform the following steps:

1. Store the address of the error in BUSnERRADD (n = 3).
2. Store the read/write information of the error in BUSnERRRW (n = 3).
3. Set 1 to MMERRSTAT bit of BUSnERRSTAT (n = 3).

An NMI request or a reset request is generated according to the MMPUOAD.OAD setting (see section 15, Memory Protection Unit (MPU)). Since BUSnERRADD (n = 3), BUSnERRRW (n = 3), and BUSnERRSTAT (n = 3) are held until reset other than MPU- and TZF-related resets or cleared by BUSnERRCLR (n = 3), they can be verified in the NMI handler or after reset.

An NMI request is generated only on the first bus master MPU error after a reset or clearing of BUSnERRSTAT.MMERRSTAT (n = 3) bit by BUSnERRCLR (n = 3).

(2) Illegal Access Error

section 14.4.3. Conditions Leading to Illegal Address Access Errors, describes illegal access errors. When an illegal access error is detected, an Error response is returned to the master. At the same time, perform the following steps:

1. Store the address of the error in BUSnERRADD (n = 1 to 3).
2. Store the read/write information of the error in BUSnERRRW (n = 1 to 3).
3. Set 1 to ILERRSTAT bit of BUSnERRSTAT (n = 1 to 3).

NMI request and reset request are not generated. Since BUSnERRADD (n = 1 to 3), BUSnERRRW (n = 1 to 3), BUSnERRSTAT (n = 1 to 3) are held until reset other than MPU- and TZF-related resets or cleared by BUSnERRCLR (n = 1 to 3), they can be confirmed in the Bus Fault handler or the interrupt handler.

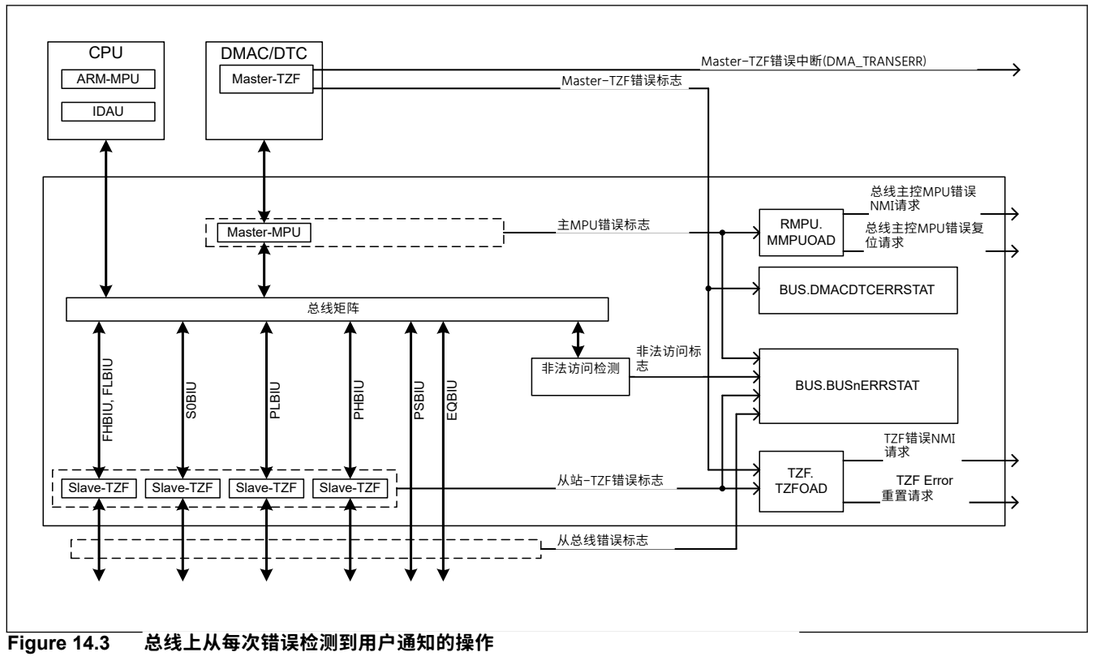

Figure 14.3 总线上从每次错误检测到用户通知的操作

(1) 总线主控MPU错误

DMACDTC的总线主控器有一个主控MPU，用于对设置的地址区域进行访问控制。CPU没有主MPU，因为它有一个ArmMPU。当检测到总线主控MPU错误时，会向主控返回错误响应。同时，执行以下步骤：

1.将错误地址存储在BUSnERRADD(n=3)中。

2.将错误的读写信息存入BUSnERRRW(n=3)。

3.将BUSnERRSTAT的MMERRSTAT位设置为1(n=3)。

根据MMPUOAD.OAD设置生成NMI请求或复位请求（参见第15节，内存保护单元（MPU））。由于BUSnERRADD(n=3)、BUSnERRRW(n=3)和BUSnERRSTAT(n=3)一直保持到除MPU和TZF相关复位之外的复位或被BUSnERRCLR(n=3)清除之前，它们可以在NMI中验证处理程序或重置后。

NMI请求仅在复位或清除后第一个总线主MPU错误时生成BUSnERRSTAT.MMERRSTAT(n=3)位由BUSnERRCLR(n=3)。

(2) 非法访问错误

第14.4.3节。导致非法地址访问错误的条件，描述非法访问错误。当检测到非法访问错误时，向主站返回错误响应。同时，执行以下步骤：

1.将错误地址存储在BUSnERRADD（n=1到3）中。

2.将错误的读写信息存入BUSnERRRW(n=1to3)。

3.将BUSnERRSTAT的ILERRSTAT位设置为1（n=1到3）。

不生成NMI请求和复位请求。由于BUSnERRADD（n=1到3）、BUSnERRRW（n=1到3），BUSnERRSTAT(n=1到3)保持到除MPU和TZF相关复位之外的复位或被BUSnERRCLR(n=1到3)清除之前，它们可以在总线故障处理程序或中断处理程序中确认。

(3) Master-TZF Error

As described in section 42, Security Features , DMAC/DTC has Master-TZF errors. When a Master-TZF error is detected, 1 is set to MTERRSTAT bit of DMACDTCERRSTAT, and because the DMAC/DTC does not perform bus access, no bus error information is stored in BTZF3ERRADD and BTZF3ERRRW.

An NMI request or reset request is generated according to the setting of TZFOAD.OAD. See section 16, DMA Controller (DMAC), section 17, Data Transfer Controller (DTC) for details on Master-TZF errors. Because DMACDTCERRSTAT is held until reset other than MPU- and TZF-related resets or cleared by DMACDTCERRCLR, they can be verified in the NMI handler or after reset.

An NMI request is generated only on the first Master-TZF error after reset or clearing of the DMACDTCERRSTAT.MTERRSTAT bit by DMACDTCERRCLR.

(4) Slave-TZF Error

As described in section 42, Security Features , FHBIU (code flash), FLBIU (data flash), S0BIU (SRAM), PHBIU and PLBIU have Slave-TZF errors. When a Slave-TZF error is detected, perform the following steps:

1. Store the address of the error in BTZFnERRADD (n = 1 to 3).
2. Store the read/write information of the error in BTZFnERRRW (n = 1 to 3).
3. Set 1 to STERRSTAT bit of BUSnERRSTAT (n = 1 to 3).

NMI request or reset request is generated according to the setting in TZFOAD.OAD. Since BTZFnERRADD (n = 1 to 3), BTZFnERRRW (n = 1 to 3), and BUSnERRSTAT (n = 1 to 3) are held until reset other than MPU- and TZF-related resets or cleared by BUSnERRCLR (n = 1 to 3), they can be verified in the NMI handler or after reset.

An NMI request is generated only on the first Slave-TZF error after a reset or clearing of the BUSnERRSTAT.STERRSTAT (n = 1 to 3) bit by BUSnERRCLR (n = 1 to 3).

(5) Slave Bus Error

Slave Bus Error occurs in the slave. When Slave Bus Error is detected, an Error response is returned to the master. At the same time, perform the following steps:

1. Store the address of the error in BUSnERRADD (n = 1 to 3)
2. Store the read/write information of the error in BUSnERRRW (n = 1 to 3)
3. Set 1 to SLERRSTAT bit of BUSnERRSTAT (n = 1 to 3).

An NMI request and reset request are not generated. Since BUSnERRADD (n = 1 to 3), BUSnERRRW (n = 1 to 3), and BUSnERRSTAT (n = 1 to 3) are held until reset other than MPU- and TZF-related resets or cleared by BUSnERRCLR (n = 1 to 3), they can be verified in the Bus Fault handler or interrupt handler. When a bus slave MPU error occurs, the error is returned to the requesting master IP and operation is not guaranteed.

14.4.3 Conditions Leading to Illegal Address Access Errors

Table 14.2 lists the address spaces for each bus that trigger illegal address access errors.

Table 14.2 Conditions leading to illegal address access errors (1 of 2)

Address	Slave bus	Master bus		
		CPU		DMA
		Code	System	
0x0000_0000 to 0x01FF_FFFF	FHBIU	—		—
0x0200_0000 to 0x07FF_FFFF	Reserved	E		E
0x0800_0000 to 0x0803_FFFF	FLBIU	—		—
0x0804_0000 to 0x0FFF_FFFF	Reserved	E		E
0x1000_0000 to 0x100F_FFFF	Reserved	—		E
0x1010_0000 to 0x1FFF_FFFF	Reserved	E		E

(3) Master-TZF Error

如第42节“安全功能”中所述，DMACDTC存在Master-TZF错误。当检测到Master-TZF错误时，将DMACDTCERRSTAT的MTERRSTAT位设置为1，并且由于DMACDTC不执行总线访问，因此BTZF3ERRADD和BTZF3ERRRW中不存储总线错误信息。

根据TZFOAD.OAD的设置生成NMI请求或复位请求。有关Master-TZF错误的详细信息，请参见第16节，DMA控制器(DMAC)，第17节，数据传输控制器(DTC)。因为除了MPU和TZF相关的复位或由DMACDTCERRCLR清除之外，DMACDTCERRSTAT一直保持到复位，所以可以在NMI处理程序中或在复位后对其进行验证。

NMI请求仅在复位或清除后第一个Master-TZF错误时生成DMACDTCERRCLR的DMACDTCERRSTAT.MTERRSTAT位。

(4) Slave-TZF Error

如第42节“安全特性”中所述，FHBIU（代码闪存）、FLBIU（数据闪存）、S0BIU（SRAM）、PHBIU和PLBIU有Slave-TZF错误。当检测到Slave-TZF错误时，执行以下步骤：

1.将错误地址存储在BTZFnERRADD(n=1to3)中。

2.将错误的读写信息存入BTZFnERRRW(n=1to3)。

3.将BUSnERRSTAT的STERRSTAT位设置为1（n=1至3）。

根据TZFOAD.OAD中的设置生成NMI请求或复位请求。由于BTZFnERRADD(n=1到3)、BTZFnERRRW(n=1到3)和BUSnERRSTAT(n=1到3)被保持到除MPU和TZF相关的复位或被BUSnERRCLR(n=1到3)清除之前，它们可以在NMI处理程序中或在重置后进行验证。

NMI请求仅在BUSnERRCLR（n=1至3）复位或清除BUSnERRSTAT.STERRSTAT（n=1至3）位后的第一个Slave-TZF错误时生成。

(5) 从总线错误

从站总线错误发生在从站。当检测到从站总线错误时，将向主站返回错误响应。同时，执行以下步骤：

1.将错误的地址存储在BUSnERRADD(n=1to3)

2.将错误的读写信息存入BUSnERRRW(n=1to3)

3.将BUSnERRSTAT的SLERRSTAT位设置为1（n=1至3）。

不会生成NMI请求和复位请求。由于BUSnERRADD(n=1到3)、BUSnERRRW(n=1到3)和BUSnERRSTAT(n=1到3)一直保持到除MPU和TZF相关复位之外的复位或被BUSnERRCLR(n=1到3)清除之前，它们可以在总线故障处理程序或中断处理程序中进行验证。当发生总线从MPU错误时，错误将返回到请求的主IP，并且无法保证操作。

14.4.4 Time-out

For some peripheral modules, a timeout error occurs with the module-stop function. When there is no response from the slave for a certain period of time, a timeout error is detected. A timeout error is returned to the requesting master IP using the AHB-Lite error response protocol.

15. Memory Protection Unit (MPU)

15.1 Overview

The MCU has one Memory Protection Unit (MPU).

Table 15.1 lists the MPU specifications, and Table 15.2 shows the behavior on detection of each MPU error.

Table 15.1 MPU specifications

Classification	Module/Function	Specifications
Illegal memory access	Arm® Cortex®-M33 CPU	• Arm CPU has a default memory map. If the CPU makes an illegal access, an exception interrupt occurs • The MPU can change a default memory map.
Memory protection	Arm MPU	Memory protection function for the CPU: • (8+8) region MPU with sub regions and background region for secure and non-secure.
	Bus master MPU	Memory protection function for each bus master except for the CPU: • DMAC/DTC: 8 regions

Table 15.2 Behavior on MPU error detection

MPU type	Notification type	Error Response by HRESP signal of AHB I/F	Bus Access on error detection	Storing of error access information
Arm MPU	• Hard fault	Not supported	• Does not correctly write access • Does not correctly read access	Stored in the Cortex-M33 processor
Bus Master MPU	• Reset or Non-maskable interrupts • Hard fault	Supported	• Write access ignore • Read access is read as 0	Stored

For information on error access for the Arm MPU, see section 15.4. References. For information on error access for other MPUs, see section 14.3. Register Descriptions and section 14.4. Bus Error Monitoring Section in section 14, Buses.

15.2 Arm MPU

The Arm MPU monitors the addresses accessed by the CPU across the entire address space (0x0000_0000 to 0xFFFF_FFFF) and provides support for:

- (8 + 8) protected regions
- When memory regions overlap, the processor generates a fault if a core access hits the overlapping regions
- Setting access permissions to protected region (Read, Write, Execution)
- Export of memory attributes to the system.

Arm MPU mismatches and permission violations invoke the programmable-priority MemManage fault (Hard Fault) handler. For details, see section 15.4. References.

15.3 Bus Master MPU

The bus master MPU monitors the addresses accessed by the bus masters in the entire address space (0x0000_0000 to 0xFFFF_FFFF). Access-control information can be set up to 8 regions in DMAC/DTC and monitor for access to each region is in accord with this information.

If access to a protected region is detected, the bus master MPU generates an internal reset or a non-maskable interrupt. For information on error access, see section 14.3. Register Descriptions and section 14.4. Bus Error Monitoring Section in section 14, Buses.

The access control information for each area consists of protected/not-protected to read or write.

Table 15.3 lists the specifications of the bus master MPU.

15.2 Arm MPU

ArmMPU监控整个地址空间（0x0000_0000到0xFFFF_FFFF）中CPU访问的地址，并支持：

●(8+8)个保护区
●当内存区域重叠时，如果核心访问命中重叠区域，处理器将产生故障
●设置对受保护区域的访问权限（读、写、执行）
●将内存属性导出到系统。

ArmMPU不匹配和权限违规调用可编程优先级MemManage故障（硬故障）处理程序。有关详细信息，请参阅第15.4节。参考。

15.3 总线主控MPU

总线主控MPU监控整个地址空间（0x0000_0000到0xFFFF_FFFF）中总线主控访问的地址。DMACDTC中最多可以设置8个区域的访问控制信息，每个区域的访问监控是否与该信息一致。

如果检测到对受保护区域的访问，总线主控MPU会产生内部复位或不可屏蔽中断。有关错误访问的信息，请参阅第14.3节。寄存器说明和第14.4节。第14节，总线中的总线错误监控部分。

每个区域的访问控制信息由受保护的不受保护的读或写组成。

Region n unit sets the ENABLE bit, the RP bit, and the WP bit each.

ENABLE bit (Region enable)

The ENABLE bit controls the enable or disable of DMAC/DTC region n (n = 0 to 7) unit.

When the ENABLE bit is set to 1, the RP bit and the WP bit control access permission for read and write protection to MMPUSDMACn (n = 0 to 7) and MMPUEDMACn (n = 0 to 7).

When the ENABLE bit is set to 0, access to DMAC region n (n = 0 to 7) is the outside region.

RP bit (Read protection)

The RP bit enables or disables read protection of DMAC/DTC region n (n = 0 to 7).

When the ENABLE bit is set to 1, the RP bit is available.

WP bit (Write protection)

The WP bit enables or disables write protection of DMAC/DTC region n (n = 0 to 7).

When the ENABLE bit is set to 1, the WP bit is available.

ENABLE bit (Bus Master MPU of DMAC enable)

The ENABLE bit controls enable or disable of the bus master MPU function of each master group.

When the ENABLE bit is set to 1, MMPUACDMACn (n = 0 to 7) is valid. When the ENABLE bit is set to 0, MMPUACDMACn (n = 0 to 7) is invalid for all regions. The bus master MPU function sets the ENABLE bit of each master group. When the ENABLE bit is set, write 0xA5 in KEY[7:0] at the same time.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writing to the ENABLE bit. When writing to the ENABLE bit, write 0xA5 in KEY[7:0] bits at the same time. When values other than 0xA5 are written to KEY[7:0] bits, the ENABLE bit is not updated. The KEY[7:0] bits are always read as 0x00.

15.3.2 Operation

15.3.2.1 Memory protection

The bus master MPU monitors memory access using control settings made individually for the access control regions. If access to a protected region is detected, the bus master MPU generates a memory protection error.

The bus master MPU can be set for up to 4 protected regions. Protected regions include those with overlapping permitted and protected regions, and those with two overlapping permitted regions.

The bus master MPU has group A. The memory protection function checks the address of the bus for the master group and all master group accesses are protected. The bus master MPU sets the permission for all of the regions after reset. Setting MMPUCTLA.ENABLE to 1 protects all of the regions. Each region sets up a permitted region within the protected region. If access to the protected region is detected, the bus master MPU generates an error.

Bus Master MPU can be set for up to 8 protection regions. It is protection region when set up of permission region and protection region overlaps. It is protection region when set up of two protection region overlaps.

Bus Master MPU has master groups of DMAC/DTC.

Memory protection checks the address of the bus which the master group unified. Therefore, all the access of a master group is detected by memory protection.

The region setting registers of the Bus Master MPU for DMAC/DTC can be set for secure access and Non-Secure access using the MMPUSARA register. Make secure access and Non-Secure access settings the same for each DMAC/DTC channel and the corresponding region setting registers of the Bus Master MPU.

Bus Master MPU is permission of all regions after reset. All region is protected by setting MMPUENDMAC.ENABLE = 1.

Each region sets up a permission region on the protection region. If access to the protected region is detected, Bus Master MPU will generate an error.

Figure 15.1 shows the use case of a bus master MPU.

Note: 必须通过半字访问写入。
禁止字节写访问。当执行字节写访问时，不能保证操作。

PROTECT位（寄存器保护）

PROTECT位启用或禁用对要保护的相关寄存器的写入。

MMPUOADPT.PROTECT控制以下寄存器：

- MMPUOAD

当PROTECT位同时置位时，使用半字访问将0xA5写入KEY[7:0]位。

KEY[7:0] bits (Key code)

KEY[7:0]位启用或禁用对PROTECT位的写入。同时写入PROTECT位时，将0xA5写入KEY[7:0]位。当其他值写入KEY[7:0]位时，PROTECT位不会更新。KEY[7:0]位总是读为0x00。

15.3.2 Operation

15.3.2.1 内存保护

总线主控MPU使用为访问控制区域单独进行的控制设置来监视内存访问。如果检测到对受保护区域的访问，则总线主控MPU会产生内存保护错误。

总线主控MPU最多可设置4个受保护区域。保护区包括允许区域和保护区域重叠的区域，以及两个允许区域重叠的区域。

总线主控MPU具有A组。内存保护功能检查主控组的总线地址，并保护所有主控组访问。总线主控MPU在复位后设置所有区域的权限。将MMPUCTLA.ENABLE设置为1可以保护所有区域。每个区域在受保护区域内设置一个允许区域。

如果检测到对受保护区域的访问，则总线主控MPU会产生错误。

总线主控MPU最多可设置8个保护区域。许可区域与保护区域的设置重叠时为保护区域。两个保护区域重叠设置时为保护区域。

总线主控MPU具有DMACDTC主控组。

内存保护检查主组统一的总线地址。因此，一个主组的所有访问都被内存保护检测到。

可以使用MMPUSARA寄存器为DMACDTC的总线主控MPU的区域设置寄存器设置安全访问和非安全访问。使每个DMACDTC通道和总线主控MPU的相应区域设置寄存器的安全访问和非安全访问设置相同。

BusMasterMPU是复位后所有区域的权限。通过设置MMPUENDMAC.ENABLE=1来保护所有区域。

每个区域在保护区域上设置一个权限区域。如果检测到对受保护区域的访问，则总线主控MPU会产生错误。

图15.1显示了总线主控MPU的用例。

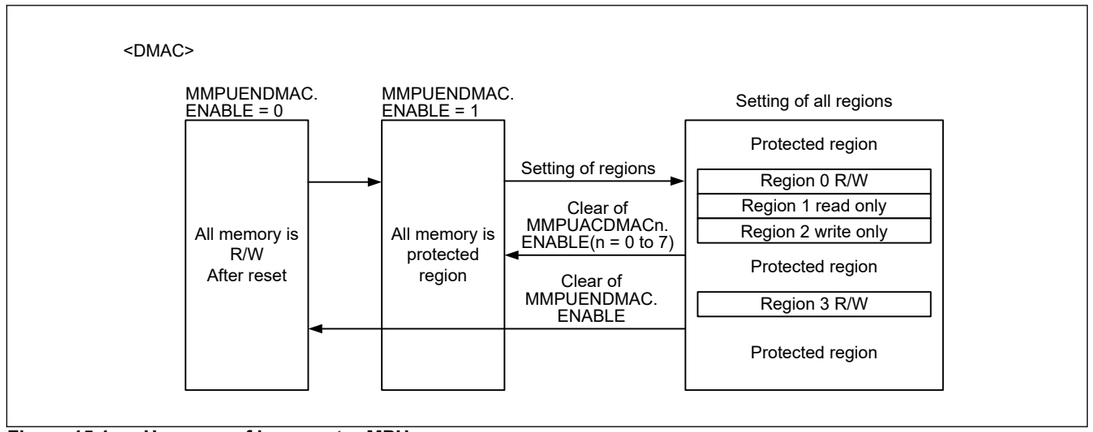

Figure 15.1 Use case of bus master MPU

Figure 15.2 shows the access permission or protection by the overlapping bus master MPU regions.

Access control for the overlapping regions is as follows:

- The region is handled as a protected region when output of one or more region units is a protected region
- The region is handled as a protected region when output of all region units is outside of the regions
- Other cases are handled as permitted regions.

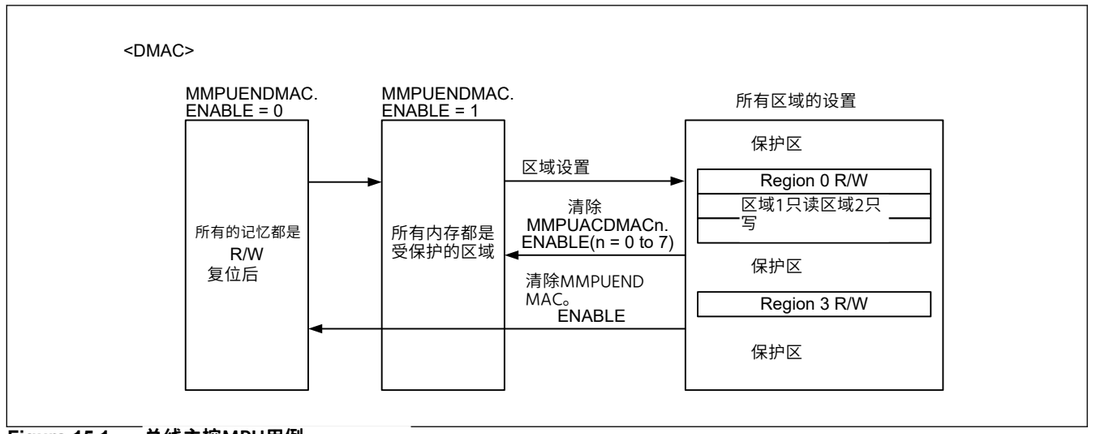

Figure 15.1 总线主控MPU用例

图15.2显示了重叠总线主控MPU区域的访问许可或保护。

重叠区域的访问控制如下：

●当一个或多个区域单元的输出为受保护区域时，该区域被视为受保护区域

●当所有区域单元的输出都在区域之外时，该区域被视为受保护区域

●其他情况按许可区域处理。

在重复传输模式和块传输模式下，为DMCRAH和DMCRAL设置相同的值。在重复传输模式和块传输模式中，位15到10固定为0。

(1) Normal Transfer Mode (DMTMD.MD[1:0] = 00b)

DMCRAL functions as a 16-bit transfer counter.

The number of transfer operations is one when the setting is 0x0001, and 65,535 when it is 0xFFFF. The value is decremented by one each time data is transferred.

When the setting is 0x0000, no specific number of transfer operations is set; data transfer is performed with the transfer counter stopped (free running function).

Free running function is not selected by DMTMD.TKP bit in normal transfer mode.

DMCRAH is not used in normal transfer mode. Write 0x0000 to DMCRAH.

(2) Repeat Transfer Mode (DMTMD.MD[1:0] = 01b)

DMCRAH specifies the repeat size and DMCRAL functions as a 10-bit transfer counter.

The number of transfer operations is one when the setting is 0x001, 1,023 when it is 0x3FF, and 1,024 when it is 0x000. In repeat transfer mode, a value in the range of 0x000 to 0x3FF (1 to 1,024) can be set for DMCRAH and DMCRAL.

Setting bits 15 to 10 in DMCRAL is invalid. Write 0 to these bits.

The value in DMCRAL is decremented by one each time data is transferred until it reaches 0x000, at which the value in DMCRAH is loaded into DMCRAL.

(3) Block Transfer Mode (DMTMD.MD[1:0] = 10b)

DMCRAH specifies the block size and DMCRAL functions as a 10-bit block size counter.

The block size is one when the setting is 0x001, 1,023 when it is 0x3FF, and 1,024 when it is 0x000. In block transfer mode, a value in the range of 0x000 to 0x3FF can be set for DMCRAH and DMCRAL.

Setting bits 15 to 10 in DMCRAL is invalid. Write 0 to these bits.

The value in DMCRAL is decremented by one each time data is transferred until it reaches 0x000, at which the value in DMCRAH is loaded into DMCRAL.

(4) Repeat-Block Transfer Mode (DMTMD.MD[1:0] = 11b)

DMCRAH specifies the block size and DMCRAL functions as a 10-bit block size counter.

The block size is one when the setting is 001h, 1023 when it is 3FFh, and 1024 when it is 000h. In repeat-block transfer mode, a value in the range of 000h to 3FFh can be set for DMCRAH and DMCRAL.

Setting bits 15 to 10 in DMCRAL is invalid. Write 0 to these bits.

The value in DMCRAL is decremented by one each time data is transferred until it reaches 000h, at which the value in DMCRAH is loaded into DMCRAL.

16.2.7 DMCRB : DMA Block Transfer Count Register

Base address: DMACn = 0x4000_5000 + 0x0040 × n (n = 0 to 7)

Offset address: 0x0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit field:	DMCRBL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

(1) 正常传输模式（DMTMD.MD[1:0]=00b）

DMCRAL用作16位传输计数器。

设置为0x0001时传输操作数为1，设置为0xFFFF时为65 535。每次传输数据时，该值减一。

设置为0x0000时，不设置具体的传输操作次数；在传输计数器停止的情况下执行数据传输（自由运行功能）。

在正常传输模式下，DMMTD.TKP位不选择自由运行功能。

DMCRAH不用于正常传输模式。将0x0000写入DMCRAH。

(2) 重复传输模式(DMTMD.MD[1:0]=01b)

DMCRAH指定重复大小，DMCRAL用作10位传输计数器。

设置为0x001时传输操作数为1，设置为0x3FF时为1 023，设置为0x000时为1 024。在重复传输模式下，可以为DMCRAH和DMCRAL设置0x000到0x3FF（1到1 024）范围内的值。

在DMCRAL中设置位15至10无效。将0写入这些位。

每次传输数据时，DMCRAL中的值减1，直到到达0x000，此时DMCRAL中的值DMCRAH被加载到DMCRAL中。

(3) 块传输模式（DMTMD.MD[1:0]=10b）

DMCRAH指定块大小，DMCRAL用作10位块大小计数器。

设置为0x001时块大小为1，设置为0x3FF时为1 023，设置为0x000时为1 024。在块传输模式下，可以为DMCRAH和DMCRAL设置0x000到0x3FF范围内的值。

在DMCRAL中设置位15至10无效。将0写入这些位。

每次传输数据时，DMCRAL中的值减1，直到到达0x000，此时DMCRAL中的值DMCRAH被加载到DMCRAL中。

(4) 重复块传输模式(DMTMD.MD[1:0]=11b)

DMCRAH指定块大小，DMCRAL用作10位块大小计数器。

设置为001h时块大小为1，设置为3FFh时为1023，设置为000h时为1024。在重复块传输模式下，可以为DMCRAH和DMCRAL设置000h到3FFh范围内的值。

在DMCRAL中设置位15至10无效。将0写入这些位。

每次传输数据时，DMCRAL中的值减1，直到达到000h，此时DMCRAL中的值DMCRAH被加载到DMCRAL中。

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Set the same value for DMCRBH and DMCRBL in repeat transfer mode, block transfer mode and repeat-block transfer mode.

DMCRBH specifies the number of block, repeat and repeat-block transfer operations, and DMCRBL functions as a 16-bit the number of block counter in block, repeat, repeat-block transfer mode, respectively.

The number of transfer operations is one when the setting is 0001h, 65,535 when it is FFFFh, and 65,536 when it is 0000h.

In repeat transfer mode, the value is decremented by one when the final data of one repeat size is transferred.

In block transfer mode and repeat-block transfer mode, the value is decremented by one when the final data of one block size is transferred.

In normal transfer mode, DMCRB is not used. The setting is invalid.

When DMTMD.TKP is 1 and final data of one repeat size or one block size is transferred, DMCRBL reloads value of DMCRBH automatically.

在重复传输模式、块传输模式和重复块传输模式中，将DMCRBH和DMCRBL设置为相同的值。

DMCRBH指定块、重复和重复块传输操作的数量，DMCRBL分别用作块、重复、重复块传输模式下的16位块数计数器。

设置为0001h时传输操作数为1，设置为FFFFh时为65 535，设置为0000h时为65 536。

在重复传输模式下，当传输一个重复大小的最终数据时，该值减一。

在块传输模式和重复块传输模式中，当传输一个块大小的最终数据时，该值减一。

在正常传输模式下，不使用DMCRB。设置无效。

当DMTMD.TKP为1并且传输一个重复大小或一个块大小的最终数据时，DMCRBL重新加载值
DMCRBH automatically.

DARIE bit (Destination Address Extended Repeat Area Overflow Interrupt Enable)

When an extended repeat area overflow on the destination address occurs while DARIE bit is set to 1, the DMCNT.DTE bit is cleared to 0. At the same time, the DMSTS.ESIF flag is set to 1 to indicate that an interrupt by an extended repeat area overflow on the destination address is requested.

When block transfer mode is used with the extended repeat area function, an interrupt is requested after completion of a 1-block size transfer. When setting 1 in the DMCNT.DTE bit of the channel for which a transfer has been stopped, the transfer is resumed from the state when the transfer is stopped.

When the extended repeat area is not specified for the destination address, this bit is ignored.

When set to repeat-block transfer mode, do not use this bit.

SARIE bit (Source Address Extended Repeat Area Overflow Interrupt Enable)

When an extended repeat area overflow on the source address occurs while SARIE bit is set to 1, the DMCNT.DTE bit is cleared to 0. At the same time, the DMSTS.ESIF flag is set to 1 to indicate that an interrupt by an extended repeat area overflow on the source address is requested.

When block transfer mode is used with the extended repeat area function, an interrupt is requested after completion of a 1-block size transfer. When setting 1 in the DMCNT.DTE bit of the channel for which a transfer has been stopped, the transfer is resumed from the state when the transfer is stopped.

When the extended repeat area is not specified for the source address, this bit is ignored.

When set to repeat-block transfer mode, do not use this bit.

RPTIE bit (Repeat Size End Interrupt Enable)

When RPTIE bit is set to 1 in repeat transfer mode, the DMCNT.DTE bit is cleared to 0 after completion of a 1-repeat size data transfer. At the same time, the DMSTS.ESIF flag is set to 1 to indicate that the repeat size end interrupt request has been generated. The repeat size end interrupt request can be generated even when the DMTMD.DTS[1:0] bits are 10b (= repeat area or block area is not specified).

When this bit is set to 1 in block transfer mode, the DMCNT.DTE bit is cleared to 0 after completion of a 1-block data transfer in the same way as repeat transfer mode. At the same time, the DMSTS.ESIF flag is set to 1 to indicate that the repeat size end interrupt request has been generated. The repeat size end interrupt request can be generated even when the DMTMD.DTS[1:0] bits are 10b (= repeat area or block area is not specified).

When set to repeat-block transfer mode, do not use this bit.

ESIE bit (Transfer Escape End Interrupt Enable)

ESIE bit enables or disables the transfer escape end interrupt requests (repeat size end interrupt request and extended repeat area overflow interrupt request) that are generated during DMA transfer.

The transfer escape end interrupt is generated when the DMSTS.ESIF flag is set to 1 with this bit set to 1. The transfer escape end interrupt is cleared by clearing this bit or the DMSTS.ESIF flag to 0.

DTIE bit (Transfer End Interrupt Enable)

DTIE bit enables or disables the transfer end interrupt request to be generated on completion of a specified number of data transfers.

The transfer end interrupt is generated when the DMSTS.DTIF flag is set to 1 with this bit set to 1. The transfer end interrupt is cleared by clearing this bit or the DMSTS.DTIF flag to 0.

DARIE位（目标地址扩展重复区域溢出中断允许）

当DARIE位设置为1时，当目标地址发生扩展重复区域溢出时，DMCNT.DTE位清零。同时，DMSTS.ESIF标志位设置为1，表示由请求目标地址上的扩展重复区域溢出。

当块传输模式与扩展重复区域功能一起使用时，在完成1块大小的传输后请求中断。将停止传输的通道的DMCNT.DTE位设置为1时，将从停止传输时的状态恢复传输。

当没有为目标地址指定扩展重复区域时，该位被忽略。

当设置为重复块传输模式时，不要使用该位。

SARIE位（源地址扩展重复区溢出中断使能）

当SARIE位被设置为1时，当源地址发生扩展重复区域溢出时，DMCNT.DTE位被清除为0。同时，DMSTS.ESIF标志被设置为1，表示由请求源地址上的扩展重复区域溢出。

当块传输模式与扩展重复区域功能一起使用时，在完成1块大小的传输后请求中断。将停止传输的通道的DMCNT.DTE位设置为1时，将从停止传输时的状态恢复传输。

当源地址没有指定扩展重复区域时，该位被忽略。

当设置为重复块传输模式时，不要使用该位。

RPTIE位（重复大小结束中断允许）

当RPTIE位在重复传输模式下设置为1时，DMCNT.DTE位在完成1次重复大小的数据传输后被清除为0。同时，将DMSTS.ESIF标志设置为1，表示已产生重复大小结束中断请求。即使DMTMD.DTS[1:0]位为10b（=未指定重复区域或块区域），也可以生成重复大小结束中断请求。

当该位在块传输模式下设置为1时，DMCNT.DTE位在完成1块数据传输后清零，方法与重复传输模式相同。同时，将DMSTS.ESIF标志设置为1，表示已产生重复大小结束中断请求。即使DMTMD.DTS[1:0]位为10b（=未指定重复区域或块区域），也可以生成重复大小结束中断请求。

当设置为重复块传输模式时，不要使用该位。

ESIE位（传输转义结束中断使能）

ESIE位启用或禁用在DMA传输期间产生的传输转义结束中断请求（重复大小结束中断请求和扩展重复区域溢出中断请求）。

当DMSTS.ESIF标志设置为1且该位设置为1时，将产生传输转义结束中断。通过清除该位或DMSTS.ESIF标志为0来清除传输转义结束中断。

DTIE位（传输结束中断允许）

DTIE位启用或禁用在完成指定数量的数据传输时生成的传输结束中断请求。

当DMSTS.DTIF标志设置为1且该位设置为1时，将产生传输结束中断。通过清除该位或DMSTS.DTIF标志为0来清除传输结束中断。

DARA[4:0] bits (Destination Address Extended Repeat Area)

DARA[4:0] bits specify the extended repeat area on the destination address. The extended repeat area function is realized by updating the specified lower address bits with the remaining upper address bits fixed. The size of the extended repeat area can be any power of two between 2 bytes and 128 Mbytes.

When the lower address overflows the extended repeat area by address increment, the start address of the extended repeat area is set. Similarly, when the lower address underflows the extended repeat area by address decrement, the end address of the extended repeat area is set.

When the repeat area or block area is specified as a transfer destination, do not specify the extended repeat area on the destination address. When repeat transfer or block transfer is selected, and when DMTMD.DTS[1:0] = 00b (the transfer destination is specified as the repeat area or block area), write 00000b in the DARA[4:0] bits.

In repeat-block transfer mode, write 00000b in the DARA[4:0] bits.

An interrupt can be requested when an overflow or underflow occurs in the extended repeat area with the DMINT.DARIE bit set to 1. Table 16.2 lists the settings and the corresponding extended repeat areas.

DADR bits (Destination Address Update Select After Reload)

In repeat-block transfer mode, this bit specifies the behavior of DMDAR after reloading DMDRR.

When this bit is set to 1, an index value ((DMDBSH-DMDBSL) × DataSize) is added to DMDAR after reloading DMDRR.

DARA[4:0]位（目标地址扩展重复区）

DARA[4:0]位指定目标地址上的扩展重复区域。扩展重复区功能是通过更新指定的低地址位来实现的，剩余的高地址位是固定的。扩展重复区域的大小可以是2字节到128MB之间的任意2次幂。

当低位地址以地址增量溢出扩展重复区域时，设置扩展重复区域的起始地址。类似地，当低位地址通过地址减量使扩展重复区域下溢时，设置扩展重复区域的结束地址。

将重复区域或块区域指定为传输目标时，请勿在目标地址上指定扩展重复区域。Whenrepeattransferorblocktransferisselected andwhenDMTMD.DTS[1:0]=00b(thetransferdestinationisspecifiedastherepeatareaorblockarea) write00000bintheDARA[4:0]bits.

在重复块传输模式下，将00000b写入DARA[4:0]位。

当DMINT.DARIE位设置为1的扩展重复区域发生上溢或下溢时，可以请求中断。表16.2列出了设置和相应的扩展重复区域。

DADR位（重载后目标地址更新选择）

在重复块传输模式下，该位指定重新加载DMDRR后DMDAR的行为。

当该位设置为1时，在重新加载DMDRR后将索引值((DMDBSH−DMDBSL)×DataSize)添加到DMDAR。

When this bit is set to 0, DMDAR only reloads DMDRR. This behavior is described in Table 16.13.

In normal, repeat or block transfer mode, this bit is ignored.

DM[1:0] bits (Destination Address Update Mode)

DM[1:0] bits select the mode of updating the destination address.

When increment is selected and the DMTMD.SZ[1:0] bits are set to 00b, 01b, and 10b, the destination address is incremented by 1, 2, and 4, respectively.

When decrement is selected and the DMTMD.SZ[1:0] bits are set to 00b, 01b, and 10b, the destination address is decremented by 1, 2, and 4, respectively.

When offset addition is selected, the offset specified by the DMOFR register is added to the address.

SARA[4:0] bits (Source Address Extended Repeat Area)

SARA[4:0] bits specify the extended repeat area on the source address. The extended repeat area function is realized by updating the specified lower address bits with the remaining upper address bits fixed. The size of the extended repeat area can be any power of two between 2 bytes and 128 Mbytes.

When the lower address overflows the extended repeat area by address increment, the start address of the extended repeat area is set. Similarly, when the lower address underflows the extended repeat area by address decrement, the end address of the extended repeat area is set.

When the repeat area or block area is specified as a transfer source, do not specify the extended repeat area on the source address. When repeat transfer or block transfer is selected, and when DMTMD.DTS[1:0] = 01b (the transfer source is specified as the repeat area or block area), write 00000b in the SARA[4:0] bits.

In repeat-block transfer mode, write 00000b in the SARA[4:0] bits.

An interrupt can be requested when an overflow or underflow occurs in the extended repeat area with the DMINT.SARIE bit set to 1. Table 16.2 lists the settings and the corresponding extended repeat areas.

SADR bits (Source Address Update Select After Reload)

In repeat-block transfer mode, this bit specifies the behavior of DMSAR after reloading DMSRR.

When this bit is set to 1, an index value ((DMSBSH-DMSBSL) × DataSize) is added to DMSAR after reloading DMSRR.

When this bit is set to 0, DMSAR only reloads DMSRR. This behavior is described in Table 16.12.

In normal, repeat or block transfer mode, this bit is ignored.

SM[1:0] bits (Source Address Update Mode)

SM[1:0] bits select the mode of updating the source address.

When increment is selected and the DMTMD.SZ[1:0] bits are set to 00b, 01b, and 10b, the source address is incremented by 1, 2, and 4, respectively.

When decrement is selected and the DMTMD.SZ[1:0] bits are set to 00b, 01b, and 10b, the source address is decremented by 1, 2, and 4, respectively.

When offset addition is selected, the offset specified by the DMOFR register is added to the address.

当该位设置为0时，DMDAR仅重新加载DMDRR。表16.13中描述了这种行为。

在正常、重复或块传输模式下，该位被忽略。

DM[1:0]位选择更新目标地址的模式。

选择偏移添加后，将DMOFR寄存器指定的偏移添加到地址中。

SARA[4:0]位（源地址扩展重复区）

SARA[4:0]位指定源地址上的扩展重复区域。扩展重复区功能是通过更新指定的低地址位来实现的，剩余的高地址位是固定的。扩展重复区域的大小可以是2字节到128MB之间的任意2次幂。

当低位地址以地址增量溢出扩展重复区域时，设置扩展重复区域的起始地址。类似地，当低位地址通过地址减量使扩展重复区域下溢时，设置扩展重复区域的结束地址。

当重复区域或块区域被指定为传输源时，不要在源地址上指定扩展重复区域。Whenrepeattransferorblocktransferisselected andwhenDMTMD.DTS[1:0]=01b(thetransfersourceisspecifiedastherepeatareaorblockarea) write 00000bintheSARA[4:0]bits.

在重复块传输模式下，将00000b写入SARA[4:0]位。

当DMINT.SARIE位设置为1的扩展重复区域发生上溢或下溢时，可以请求中断。表16.2列出了设置和相应的扩展重复区域。

SADR位（重载后源地址更新选择）

在重复块传输模式下，该位指定重新加载DMSRR后DMSAR的行为。

当该位设置为1时，在重新加载DMSRR后将索引值((DMSBSH−DMSBSL)×DataSize)添加到DMSAR。

当该位设置为0时，DMSAR仅重新加载DMSRR。这种行为在表16.12中描述。

在正常、重复或块传输模式下，该位被忽略。

SM[1:0]位（源地址更新模式）

SM[1:0]位选择更新源地址的模式。

16.2.13 DMREQ:DMA软件启动寄存器

Base address: DMACn = 0x4000_5000 + 0x0040 × n (n = 0 to 7)

7:5	—	这些位被读取为0。写入值应为0。	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

SWREQ bit (DMA Software Start)

When 1 is written to SWREQ bit, a DMA transfer request is generated. After DMA transfer is started in response to the request, this bit is cleared to 0 if the CLRS bit is set to 0. This bit is not cleared to 0 while the CLRS bit is set to 1. In this case, a DMA transfer request can be issued again after completion of a transfer.

Note that, however, setting this bit is valid and DMA transfer by software is enabled only when the DMTMD.DCTG[1:0] bits are set to 00b (DMAC activation source is software).

Setting this bit is invalid when the DMTMD.DCTG[1:0] bits are set to a value other than 00b.

To start DMA transfer by software with the CLRS bit being 0, ensure that the SWREQ bit is 0, and then write 1 to the SWREQ bit.

[Setting condition]

- When 1 is written to this bit.

[Clearing conditions]

- When a DMA transfer request by software is accepted and DMA transfer is started while the CLRS bit is set to 0 (the SWREQ bit is cleared after DMA transfer is started by software).
- When 0 is written to this bit.

CLRS bit (DMA Software Start Bit Auto Clear Select)

CLRS bit specifies whether to clear the SWREQ bit to 0 after DMA transfer is started in response to the DMA transfer request generated by setting the SWREQ bit to 1. With this bit set to 0, the SWREQ bit is cleared to 0 after DMA transfer is started. With this bit set to 1, the SWREQ bit is not cleared to 0. In this case, a DMA transfer request can be issued again after completion of a transfer.

16.2.14 DMSTS : DMA Status Register

Base address: DMACn = 0x4000_5000 + 0x0040 × n (n = 0 to 7)

Offset address: 0x1E

6:5	—	These bits are read as 0. The write value should be 0.	R
7	ACT	DMAC Active Flag 0: DMAC is in the idle state 1: DMAC is operating	R

Note: If the security attribution is configured as secure:

- Non-secure write access is ignored, and TrustZone access error is not generated.

- 忽略非安全写入访问，不会生成TrustZone访问错误。

如果安全属性配置为非安全：●

SWREQ位（DMA软件启动）

当SWREQ位写入1时，会产生DMA传输请求。响应请求启动DMA传输后，如果CLRS位设置为0，则该位清零。当CLRS位设置为1时，该位不清零。在这种情况下，DMA传输请求转让完成后可再次发行。

但是请注意，设置该位有效，并且仅当DMTMD.DCTG[1:0]位设置为00b（DMAC激活源是软件）时，才启用软件的DMA传输。

当DMTMD.DCTG[1:0]位设置为00b以外的值时，设置该位无效。

软件启动DMA传输时CLRS位为0，确保SWREQ位为0，然后将1写入
SWREQ bit.

[Setting condition]

●向该位写入1时。

[Clearing conditions]

●当CLRS位设置为0（软件启动DMA传输后SWREQ位清零）时，接受软件的DMA传输请求并启动DMA传输。

●当0写入该位时。

CLRS位（DMA软件起始位自动清除选择）

CLRS位指定在响应通过将SWREQ位设置为1产生的DMA传输请求启动DMA传输后是否将SWREQ位清零。该位设置为0，在DMA传输完成后SWREQ位清零开始了。该位设置为1时，SWREQ位不会被清除为0。在这种情况下，可以在传输完成后再次发出DMA传输请求。

Set the same value for DMSBSH and DMSBSL in repeat-block transfer mode. Write 00000000h to DMSBS in normal, repeat and block transfer mode.

DMSBSH specifies buffer size and DMSBSL functions as a 16-bit buffer size counter in repeat-block transfer mode. In repeat-block transfer mode, source repeat area is specified by DMSBSH.

When address update mode is incremented address or decremented address, this register means the numbers of data of whole buffer. When address update mode is offset addition, this register means the numbers of data of an individual buffer. In offset addition, setting DMSBSH and DMSBSL to 0x0000 is prohibited. When final data of one buffer size is transferred, DMSBSL reloads value of DMSBSH. When address update mode is fixed address, this register is ignored. Table 16.3 shows the setting values of DMA Source Buffer Size Register corresponding to Transfer Data Size in Source Address Update Mode.

In normal, repeat and block transfer mode, DMSBS is not used. The setting is invalid.

源地址递增或递减(SM=1xb)	不在乎	0x0000 (infinite) 0x0001 to 0xFFFF (1 to 65535)

在重复块传输模式下为DMSBSH和DMSBSL设置相同的值。在正常、重复和块传输模式下将00000000h写入DMSBS。

DMSBSH指定缓冲区大小，DMSBSL用作重复块传输模式下的16位缓冲区大小计数器。在重复块传输模式下，源重复区域由DMSBSH指定。

当地址更新模式为递增地址或递减地址时，该寄存器表示整个缓冲区的数据个数。当地址更新模式为偏移加法时，该寄存器表示单个缓冲区的数据个数。此外，禁止将DMSBSH和DMSBSL设置为0x0000。当传输一个缓冲区大小的最终数据时，DMSBSL重新加载DMSBSH的值。当地址更新模式为固定地址时，该寄存器被忽略。表16.3显示了与源地址更新模式下的传输数据大小相对应的DMA源缓冲区大小寄存器的设置值。

在正常、重复和块传输模式下，不使用DMSBS。设置无效。

Set the same value for DMDBSH and DMDBSL in repeat-block transfer mode. Write 00000000h to DMDBS in normal, repeat and block transfer mode.

DMDBSH specifies buffer size and DMDBSL functions as a 16-bit buffer size counter in repeat-block transfer mode. In repeat-block transfer mode, destination repeat area is specified by DMDBSH.

When address update mode is incremented address or decremented address, this register means the numbers of data of whole buffer. When address update mode is offset addition, this register means the numbers of data of an individual buffer. In offset addition, setting DMDBSH and DMDBSL to 0x0000 is prohibited. When final data of one buffer size is transferred, DMDBSL reloads value of DMDBSH. When address update mode is fixed address, this register is ignored. Table 16.4 shows the setting values of Destination Buffer Size Register corresponding to Transfer Data Size in Destination Address Update Mode.

In normal, repeat and block transfer mode, DMDBS is not used. The setting is invalid.

DMDBSH指定缓冲区大小，DMDBSL用作重复块传输模式下的16位缓冲区大小计数器。在重复块传输模式中，目标重复区域由DMDBSH指定。

当地址更新模式为递增地址或递减地址时，该寄存器表示整个缓冲区的数据个数。当地址更新模式为偏移加法时，该寄存器表示单个缓冲区的数据个数。此外，禁止将DMDBSH和DMDBSL设置为0x0000。当传输一个缓冲区大小的最终数据时，DMDBSL重新加载DMDBSH的值。当地址更新模式为固定地址时，该寄存器被忽略。表16.4显示了与Destination中的TransferDataSize对应的DestinationBufferSizeRegister的设置值

DMST bit (DMAC Operation Enable)

Setting the DMAST.DMST to 1 enables DMAC activation for all channels. When the DMST bit is set to 1 (DMAC activation is enabled), and 1 is written to the DMCNT.DTE bit (DMA transfer is enabled) for multiple channels, all of the associated channels can be placed in the transfer request ready state at the same time.

When the DMST bit clears to 0 during DMA transfer, DMA transfer is suspended after the current data transfer associated with a single transfer request completes. To resume DMA transfer, set the DMST bit to 1 again.

16.3 Operation

16.3.1 Transfer Mode

16.3.1.1 Normal Transfer Mode

In normal transfer mode, one data is transferred by one transfer request. A maximum of 65535 can be set as the number of transfer operations using the DMCRAL register. When these bits are set to 0x0000, no specific number of transfer operations is set; data transfer is performed with the transfer counter stopped (free running function). Setting DMCRB register is invalid in normal transfer mode. Except in free running function, a transfer end interrupt request can be generated after completion of the specified number of transfer operations.

Table 16.5 summarizes the register update operation in normal transfer mode, and Figure 16.2 shows the operation in normal transfer mode.

Table 16.5 Register Update Operation in Normal Transfer Mode

16.3.1.2 Repeat Transfer Mode

In repeat transfer mode, one data is transferred by one transfer request.

A maximum of 1K data can be set as a total repeat transfer size using DMCRA register.

A maximum of 64K can be set as the number of repeat transfer operations using DMCRB register; therefore, a maximum of 64M data (1K data × 64K counts of repeat transfer operations) can be set as a total data transfer size.

Note: 当DMECHSAM=1时，可以在安全状态和非安全状态下清零。DMECHSAM=0，在非安全状态下不能清零。

16.3.1.4 Repeat-Block Transfer Mode

Repeat-block transfer is the operation mode with the following functions added to the block transfer function.

Repeat function: Added function (ring buffer) to repeat specified address area.

Offset function: Multiple areas with offset can be specified within one block transfer.

The repeat function and the offset function can be used for both the transfer source and the transfer destination of repeat-block transfer.

Figure 16.5 shows an example of adding a repeat function to the transfer destination.

Figure 16.6 shows repeat-block transfer with an offset to the transfer destination.

In repeat-block transfer mode, a single block data is transferred by one transfer request.

A maximum of 1K data can be set as a total block transfer size using DMCRA of the DMACn.

A maximum of 64K can be set as the number of block transfer operations using DMCRB of the DMACn; therefore, a maximum of 64M data (1K data × 64K counts of block transfer operations) can be set as a total data transfer size.

重复块传输是在块传输功能中添加了以下功能的操作模式。

重复功能：增加了重复指定地址区域的功能（环形缓冲区）。

16.3.2 Extended Repeat Area Function

The DMAC supports a function to specify the extended repeat areas on the transfer source and destination addresses. With the extended repeat areas set, the address registers repeatedly indicate the addresses of the specified extended repeat areas.

The extended repeat areas can be specified separately to the transfer source address register (DMSAR) and transfer destination address register (DMDAR).

The extended repeat area on the source address is specified by the DMAMD.SARA[4:0] bits. The extended repeat area on the destination address is specified by the DMAMD.DARA[4:0] bits. The size can be specified separately for the source and destination sides.

However, the area (of transfer source or transfer destination) which is specified as the repeat area or block area should not be specified as the extended repeat area.

When the address register value reaches the end address of the extended repeat area and the extended repeat area overflows, DMA transfer is stopped and an interrupt by an extended repeat area overflow can be requested. When an overflow occurs in the extended repeat area on the transfer source while the DMINT.SARIE bit is set to 1, the DMSTS.ESIF flag is set to 1 and the DMCNT.DTE bit is cleared to 0 to stop DMA transfer. At this time, if the DMINT.ESIE bit is set to 1, an interrupt by an extended repeat area overflow is requested. When the DMINT.DARIE bit is set to 1, the destination address register becomes a target to apply the function. DMA transfer can be resumed by writing 1 to the DMCNT.DTE bit in the interrupt handling.

Figure 16.7 shows an example of the extended repeat area operation.

16.3.2 扩展重复区域功能

DMAC支持在传输源地址和目标地址上指定扩展重复区域的功能。通过设置扩展重复区域，地址寄存器重复指示指定扩展重复区域的地址。

扩展重复区域可以分别指定到传输源地址寄存器(DMSAR)和传输目标地址寄存器(DMDAR)。

源地址上的扩展重复区域由DMAMD.SARA[4:0]位指定。目标地址上的扩展重复区域由DMAMD.DARA[4:0]位指定。可以为源端和目标端分别指定大小。

但是，指定为重复区域或块区域的区域（传送源或传送目的地）不应指定为扩展重复区域。

当地址寄存器值到达扩展重复区的结束地址且扩展重复区溢出时，
DMA传输停止并且可以请求由扩展重复区域溢出引起的中断。当DMINT.SARIE位设置为1时传输源上的扩展重复区域发生溢出时，DMSTS.ESIF标志设置为1并且DMCNT.DTE位清零以停止DMA传输。此时，如果DMINT.ESIE位设置为1，则请求由扩展重复区域溢出引起的中断。当DMINT.DARIE位设置为1时，目标地址寄存器成为应用该功能的目标。可以通过在中断处理中向DMCNT.DTE位写入1来恢复DMA传输。

图16.7显示了扩展重复区域操作的示例。

Eight bytes are specified as an extended repeat area by the lower three bits of DMSAR (DMAMD.SARA[4:0] bits = 00011b). The data size is eight bits (DMTMD.SZ[1:0] = 00b).

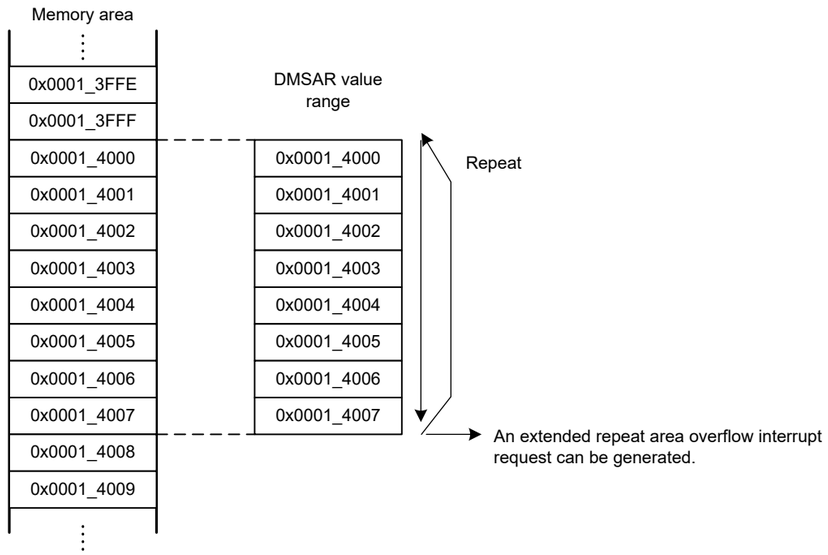

Figure 16.7 Example of Extended Repeat Area Operation

When an interrupt by an extended repeat area overflow is used in block transfer mode, the following should be taken into consideration.

When a transfer is stopped by an interrupt by an extended repeat area overflow, the address register must be set so that the block size is a power of 2 or the block size boundary is aligned with the extended repeat area boundary. When an overflow on the extended repeat area occurs during a transfer of one block, the interrupt by the overflow is suspended until transfer of the block is completed, and the transfer overruns.

Figure 16.8 shows an example when the extended repeat area function is used in block transfer mode.

八个字节由DMSAR的低三位指定为扩展重复区域（DMAMD.SARA[4:0]位=00011b）。数据大小为8位(DMTMD.SZ[1:0]=00b)。

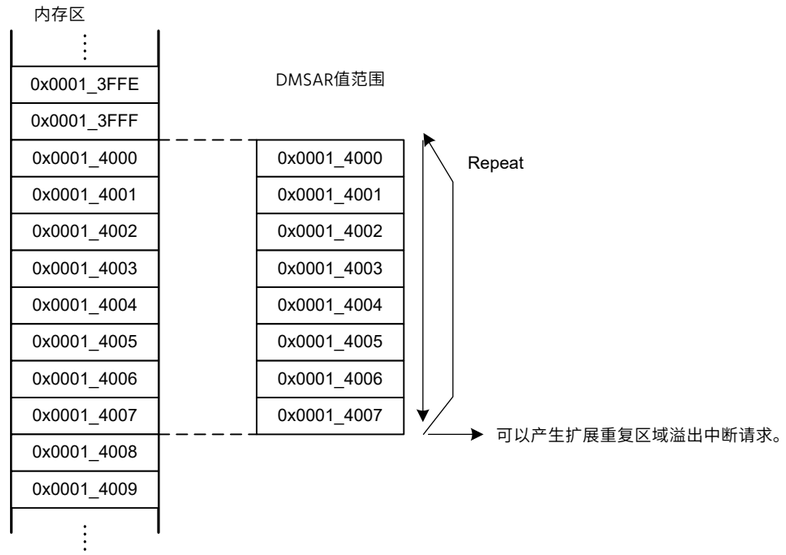

Figure 16.7 扩展重复区域操作示例

在块传输模式下使用扩展重复区域溢出中断时，应考虑以下事项。

当传输因扩展重复区域溢出中断而停止时，地址寄存器必须设置为块大小为2的幂或块大小边界与扩展重复区域边界对齐。当一个块的传输过程中扩展重复区域发生溢出时，溢出的中断被暂停，直到块的传输完成，传输溢出。

图16.8显示了在块传输模式下使用扩展重复区域功能的示例。

Eight bytes are specified as an extended repeat area by the lower three bits of DMSAR (DMAMD.SARA[4:0] bits = 00011b), block transfer mode with block size 5 is set (DMCRA = 0x0005_0005), and transfer source address is not specified as a block area. Data size is eight bits (DMTMD.SZ[1:0] bits = 00b).

16.3.3 Free-running Function

The DMAC supports free-running function. This function allows to transfer repeatedly without reconfiguring in interrupt handler.

16.3.3.1 In Normal Transfer Mode

In normal transfer mode, when DMCRA.DMCRAL bits are set to 0000h, no specific number of transfer operations is set; data transfer is performed with the transfer counter stopped.

For more information, see section 16.3.1.1. Normal Transfer Mode.

16.3.3.2 In Other Transfer Mode

In repeat, block and repeat-block transfer mode, the DMAC supports free-running function using the DMTMD.TKP bit. If the DMTMD.TKP bit is to be set to 1, the transfer is not stopped by completion of specified total number of transfer operations and reloads DMCRBH repeatedly.

Figure 16.9 show an example of block transfer operation without free-running function.

8个字节被DMSAR的低三位指定为扩展重复区域（DMAMD.SARA[4:0]bits=00011b），设置块大小为5的块传输模式（DMCRA=0x0005_0005），传输源地址为未指定为块区域。数据大小为8位（DMTMD.SZ[1:0]位=00b）。

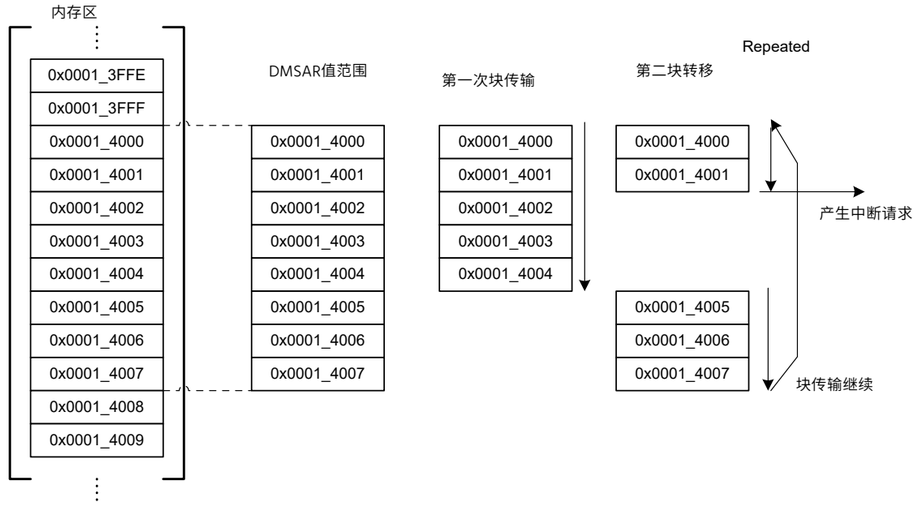

Figure 16.8 块传输模式下的扩展重复区域功能示例

16.3.3 Free-running Function

DMAC支持自由运行功能。此功能允许重复传输而无需在中断处理程序中重新配置。

16.3.3.1 在正常传输模式下

在正常传输模式下，当DMCRA.DMCRAL位设置为0000h时，不设置具体的传输操作数；在传输计数器停止的情况下执行数据传输。

有关详细信息，请参阅第16.3.1.1节。正常传输模式。

16.3.3.2 在其他传输模式下

在重复、块和重复块传输模式下，DMAC使用DMTMD.TKP位支持自由运行功能。如果要设置DMTMD.TKP位为1，则在完成指定的传输操作总数时不会停止传输并重复重新加载DMCRBH。

图16.9显示了一个没有自由运行功能的块传输操作示例。

16.3.4 Address Update Function using Offset

The source and destination addresses can be updated by fixing, increment, decrement, or offset addition. In normal, repeat and block transfer mode, when the offset addition is selected, the offset specified by the DMA offset register (DMOFR) is added to the address every time the DMAC performs one data transfer. This function realizes a data transfer where addresses are allocated to separated areas.

Offset subtraction can also be realized by setting a negative value in DMOFR. In this case, the negative value must be 2's complement.

图16.10显示了具有自由运行功能的块传输操作示例。

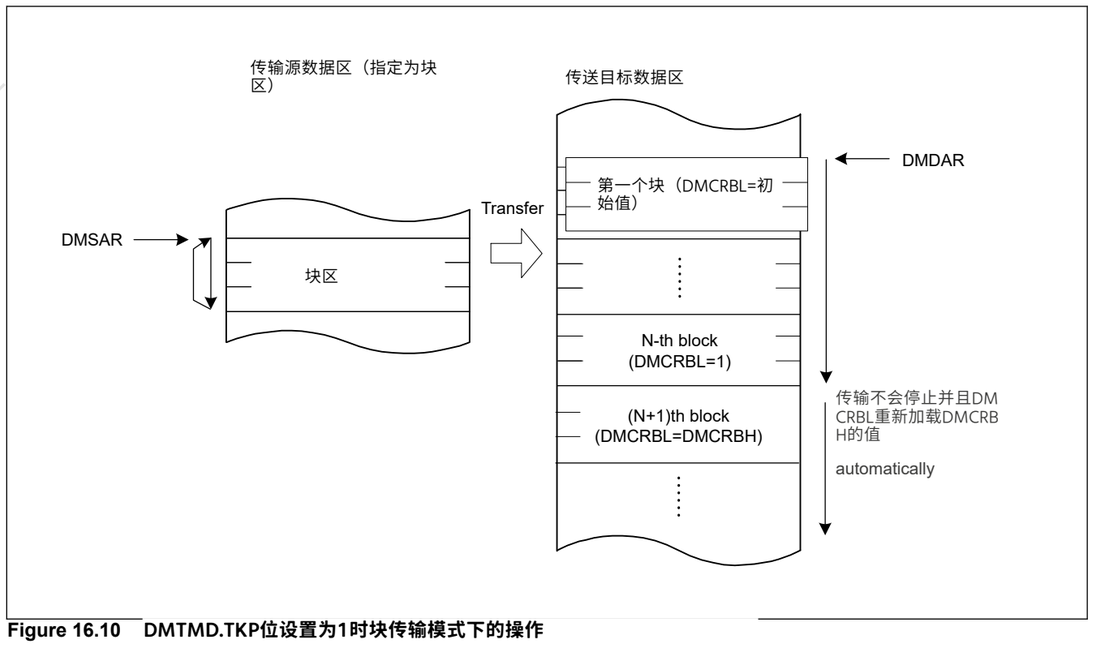

Figure 16.10 DMTMD.TKP位设置为1时块传输模式下的操作

16.3.4 使用偏移的地址更新功能

可以通过固定、递增、递减或偏移添加来更新源地址和目标地址。在正常的重复和块传输模式下，选择偏移添加时，每次DMAC执行一个数据传输时，DMA偏移寄存器（DMOFR）指定的偏移量都会添加到地址。该功能实现了将地址分配到不同区域的数据传输。

偏移量减法也可以通过在DMOFR中设置一个负值来实现。在这种情况下，负值必须是2的补码。

DMSBS or DMDBS are used instead of DMOFR in repeat-block transfer mode. For more information section 16.3.1.4. Repeat-Block Transfer Mode

Table 16.14 shows the address update method in each address update mode.

Table 16.14 Address Update Method in Each Address Update Mode

Address Update Mode	Settings of DMAMD.SM[1:0] and DMAMD.DM[1:0] for Address Update Modes	Address Update Method (for Different SZ[1:0] Settings in DMTMD)		
		SZ[1:0] = 00b	SZ[1:0] = 01b	SZ[1:0] = 10b
Address fixed	00b	Fixed		
Offset addition	01b	+DMOFR*1		
Increment	10b	+1	+2	+4
Decrement	11b	–1	–2	–4

Note 1. When setting a negative value in the DMA Offset Register, the value must be in two's complement, obtained by the following formula:
two's complement of a negative offset value = ~ (offset) + 1 (~ = bit inversion)

16.3.4.1 Basic Transfer Using Offset Addition

Figure 16.11 shows the setting of the following.

- The transfer data is 32 bits long
- Offset addition is set as the transfer source address update

地址固定	00b	Fixed		
偏移量加法	01b	+DMOFR*1		
Increment	10b	+1	+2	+4
Decrement	11b	–1	–2	–4

注1.在DMA偏移寄存器中设置负值时，该值必须是二进制补码，由以下公式获得：负偏移值的二进制补码=~(offset)+1(~=bitinversion)

16.3.4.1 使用偏移加法的基本传输

图16.11显示了使用偏移量加法进行地址更新的示例。

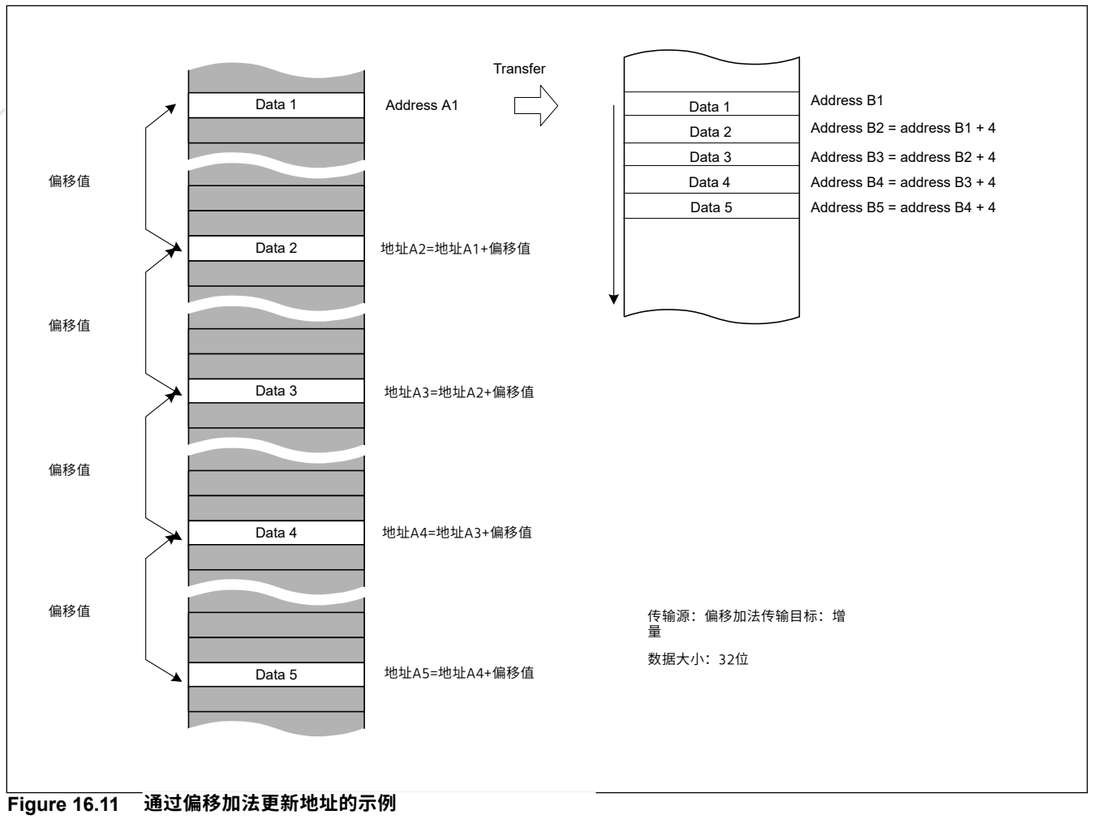

Figure 16.11 通过偏移加法更新地址的示例

图16.11显示了以下设置。

- 传输数据为32位长
- 偏移量加法设置为传输源地址更新

- Increment is set as the transfer destination address update mode

The second and subsequent data is each read from the transfer source address obtained by adding the offset value to the previous address. The data read from the addresses at the specified intervals is written to the continuous locations on the destination.

16.3.4.2 Example of XY Conversion Using Offset Addition

Figure 16.12 shows the XY conversion using offset addition in repeat transfer mode.

Settings are as follows:

- DMAMD.SM — Transfer source address update mode: Offset addition
- DMAMD.DM — Transfer destination address update mode: Destination address is incremented.
- DMTMD.SZ — Transfer data size select: 32 bits
- DMTMD.MD — Transfer mode select: Repeat transfer
- DMTMD.DTS — Repeat area select: The source is specified as the repeat area.
- DMOFR — Offset address: 0x10
- DMCRA — Repeat size: 0x4
- DMINT.RPTIE — The repeat size end interrupt is enabled.

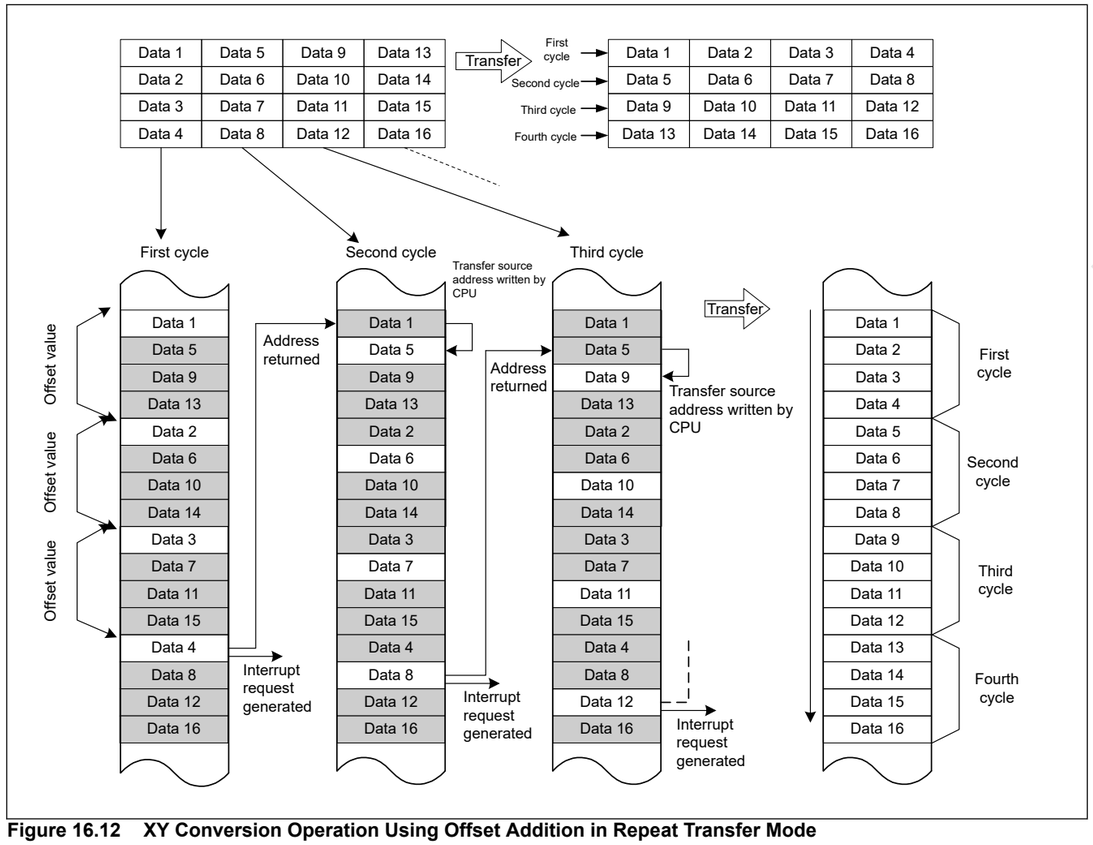

Figure 16.12 XY Conversion Operation Using Offset Addition in Repeat Transfer Mode

When a transfer starts, the offset value is added to the transfer source address every time data is transferred. The transfer data is written to continuous transfer destination addresses. When data 4 is transferred:

- The repeat size of data transfer is complete.

第二个和随后的数据分别从通过将偏移值与前一个地址相加而获得的传输源地址读取。以指定间隔从地址读取的数据被写入目标上的连续位置。

16.3.4.2 使用偏移加法的XY转换示例

图16.12显示了在重复传输模式下使用偏移添加的XY转换。

设置如下：

●DMAMD.SM—传输源地址更新模式：偏移量加法

●DMAMD.DM—传输目标地址更新模式：目标地址递增。

●DMTMD.SZ—传输数据大小选择：32位

●DMTMD.MD—传输模式选择：重复传输

●DMTMD.DTS—重复区域选择：源被指定为重复区域。

- DMOFR — Offset address: 0x10
- DMCRA — Repeat size: 0x4

●DMINT.RPTIE—启用重复大小结束中断。

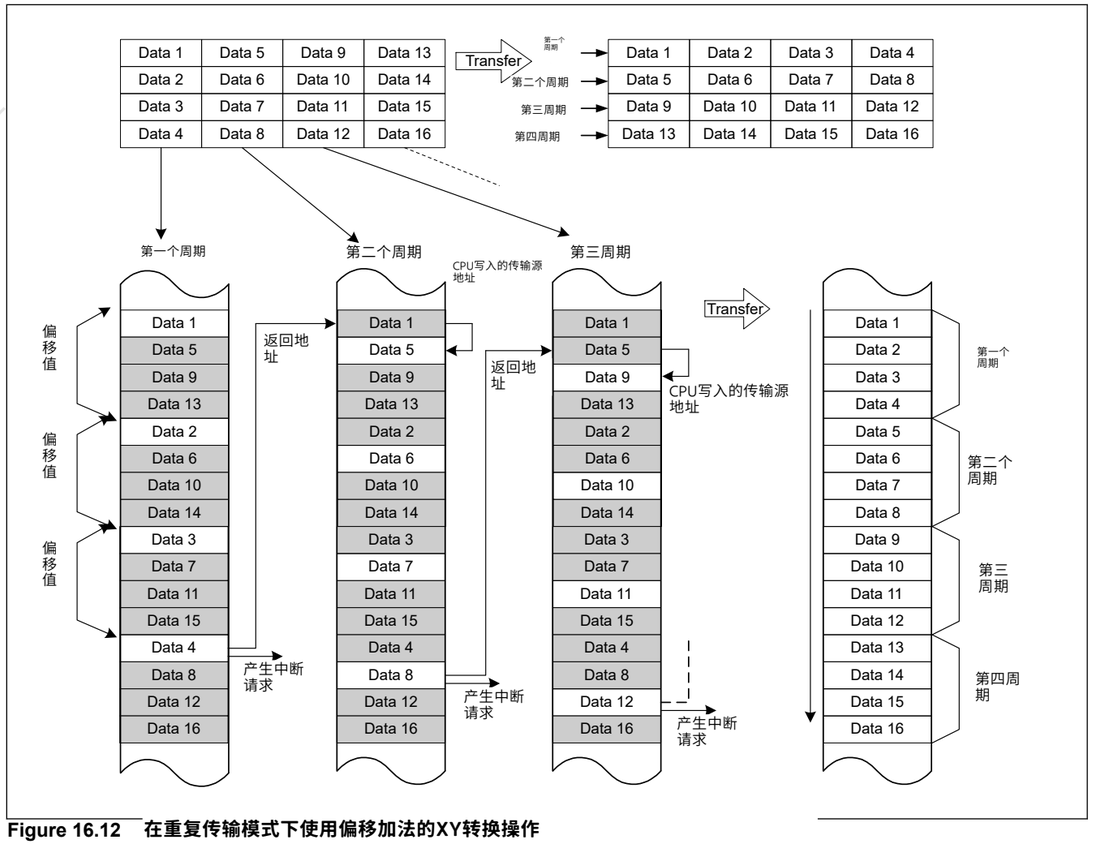

Figure 16.12 在重复传输模式下使用偏移加法的XY转换操作

传输开始时，每次传输数据时，都会将偏移值添加到传输源地址。传输数据被写入连续的传输目标地址。传输数据4时：

●数据传输的重复大小已完成。

- The transfer source address returns to the transfer start address (the address of data 1 on the transfer source).
- A repeat size end interrupt is requested.

During the time this interrupt pauses the transfer, the following operations are performed.

- DMSAR — Rewrite the DMA transfer source address to the address of data 5 (with the above example, the data 1 address + 4).
- DMCNT — Set the DTE bit to 1.

The DMA transfer is resumed from the state when the DMA transfer is stopped. After that, the operations described above are repeated until the transfer source data is transposed to the destination area (XY conversion).

Figure 16.13 shows a flowchart of the XY conversion.

●传输源地址返回传输起始地址（传输源上数据1的地址）。

●请求重复大小结束中断。

在此中断暂停传输期间，将执行以下操作。

●DMSAR—将DMA传输源地址重写为数据5的地址（在上面的示例中，数据1地址+4）。

●DMCNT—将DTE位设置为1。

DMA传输从DMA传输停止时的状态恢复。之后，重复上述操作，直到将传送源数据转置到目的地区域（XY转换）。

16.3.5 Address Update Function in Repeat-Block Transfer Mode

Repeat-block transfer mode is an extension of repeat transfer mode and block transfer mode. However, the detailed behavior of the address update is different from these two modes. Here are the details of the address update function in repeat-block transfer mode.

16.3.5.1 Fixed Address Mode

When DMAMD.SM[1:0] is set to 00b, the address update mode of the source is fixed address. And when DMAMD.DM[1:0] is set to 00b, the address update mode of the destination is fixed address.

In fixed address, the address is not updated from the initial value of DMSAR and DMDAR. If the block size (DMCRA) is larger than 1, the same data will be transferred multiple times for one request.

Figure 16.14 shows address update in fixed address.

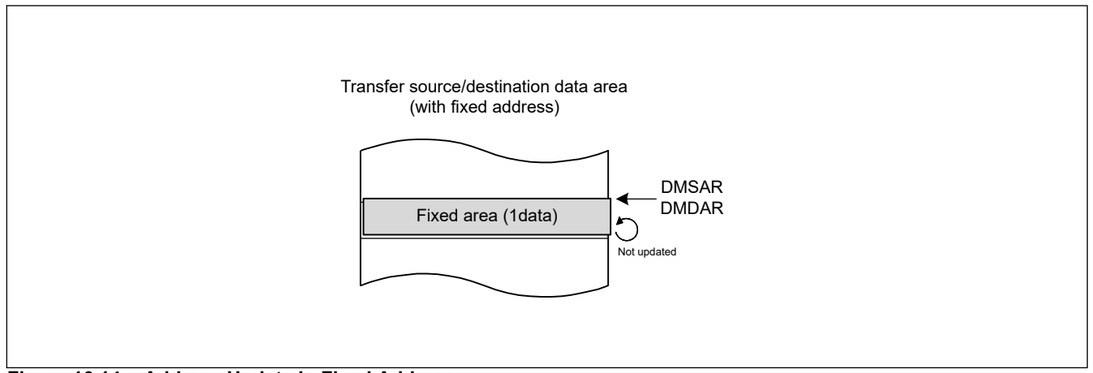

Figure 16.14 Address Update in Fixed Address

16.3.5.2 Incremental and Decremental Address mode

When DMAMD.SM[1:0] is set to 10b, the address update mode of the source is incremental address. And when DMAMD.DM[1:0] is set to 10b, the address update mode of the destination is incremental address. When DMAMD.SM[1:0] is set to 11b, the address update mode of the source is decremental address. And when DMAMD.DM[1:0] is set to 11b, the address update mode of the destination is decremental address.

In these update modes, the address is incremented or decremented according to the setting of DMTMD.SZ[1:0].

In these update modes DMSBS and DMDBS indicates a reload area. The unit of DMSBS and DMDBS is "number of data". At the start of transfer, DMSBSL and DMDBSL, which is the lower 16 bits of DMSBS and DMDBS, operates as a down counter and decrements each time one data transfer is performed. When the value becomes 1, DMSAR and DMDAR reloads the value of DMSRR and DMDRR.

Figure 16.15 shows address update in incremental address.

16.3.5 重复块传输模式中的地址更新功能

重复块传输模式是重　　复传输模式和块传输模式的扩展。但是，地址更新的详细行为与这两种模式不同。以下是重复块传输模式下地址更新功能的详细信息。

16.3.5.1 固定地址模式

当DMAMD.SM[1:0]设置为00b时，源的地址更新方式为固定地址。什么时候DMAMD.DM[1:0]设置为00b，目的地址更新方式为固定地址。

在固定地址中，地址不会从DMSAR和DMDAR的初始值更新。如果块大小（DMCRA）大于1，则一个请求将多次传输相同的数据。

图16.14显示了固定地址中的地址更新。

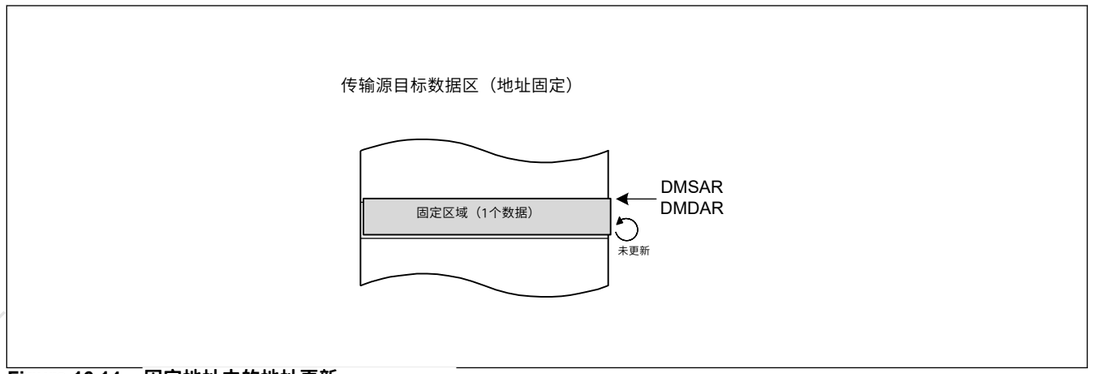

Figure 16.14 固定地址中的地址更新

16.3.5.2 递增和递减地址模式

当DMAMD.SM[1:0]设置为10b时，源地址更新方式为增量地址。什么时候DMAMD.DM[1:0]设置为10b，目的地址更新方式为增量地址。当DMAMD.SM[1:0]设置为11b时，源地址更新方式为递减地址。什么时候DMAMD.DM[1:0]设置为11b，目的地址更新方式为递减地址。

在这些更新模式中，地址根据DMTMD.SZ[1:0]的设置递增或递减。

在这些更新模式中，DMBSS和DMDBS表示重新加载区域。DMSBS和DMDBS的单位是"数据数"。在传输开始时，作为DMSBS和DMDBS的低16位的DMSBSL和DMDBSL作为递减计数器运行，并在每次执行数据传输时递减。当值变为1时，DMSAR和DMDAR重新加载DMSRR和DMDRR的值。

图16.15显示了增量地址中的地址更新。

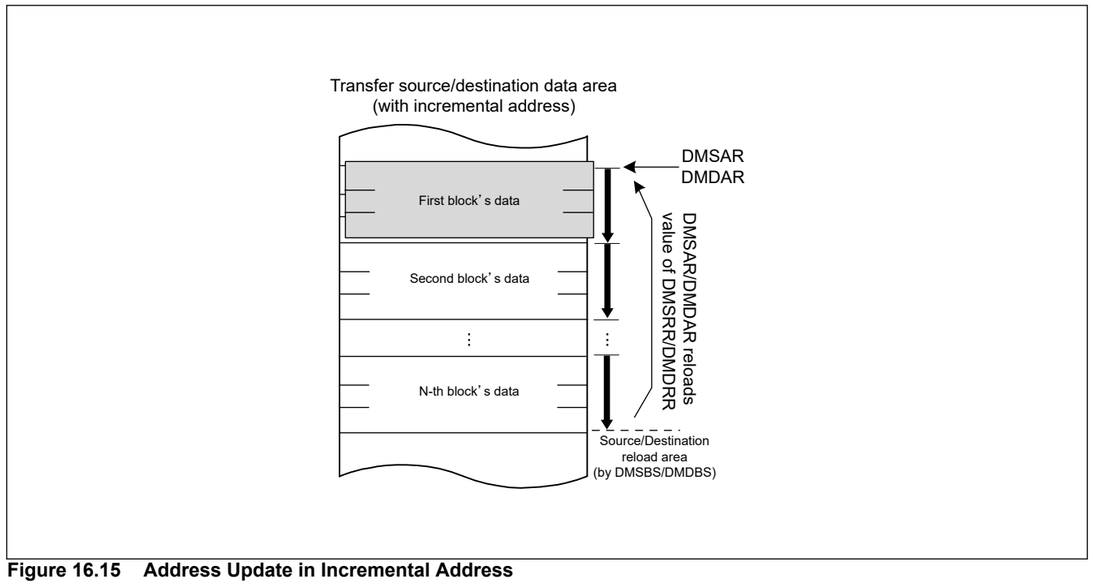

Figure 16.15 Address Update in Incremental Address

16.3.5.3 Offset Addition Mode

When DMAMD.SM[1:0] is set to 01b, the address update mode of the source is offset addition. And when DMAMD.DM[1:0] is set to 01b, the address update mode of the destination is offset addition.

In offset addition, DMSBS and DMDBS indicates reload area and also works as an access offset value. Unlike other transfer modes, DMOFR register is not used in repeat-block transfer mode. In offset addition, the unit of DMSBS and DMDBS is the number of blocks. When the transfer starts, DMCRAL operates as a down counter, DMSAR and DMDAR reloads the value of DMSRR and DMDRR every time one block is transferred. In addition, DMSBSL and DMDBSL, which is the lower 16 bits of DMSBS and DMDBS, also operates as a down counter and decrements every time one block is transferred. When the DMSBS and DMDBS value becomes 1, DMSAR and DMDAR reloads the value of DMSRR and DMDRR.

When DMAMD.SADR and DMAMD.DADR is set to 0, offset addition operation of the same area is repeated. DMDAR only reloads DMDRR. section 16.3.5.3. Offset Addition Mode shows address update in offset addition with DMAMD.SADR and DMAMD.DADR=0.

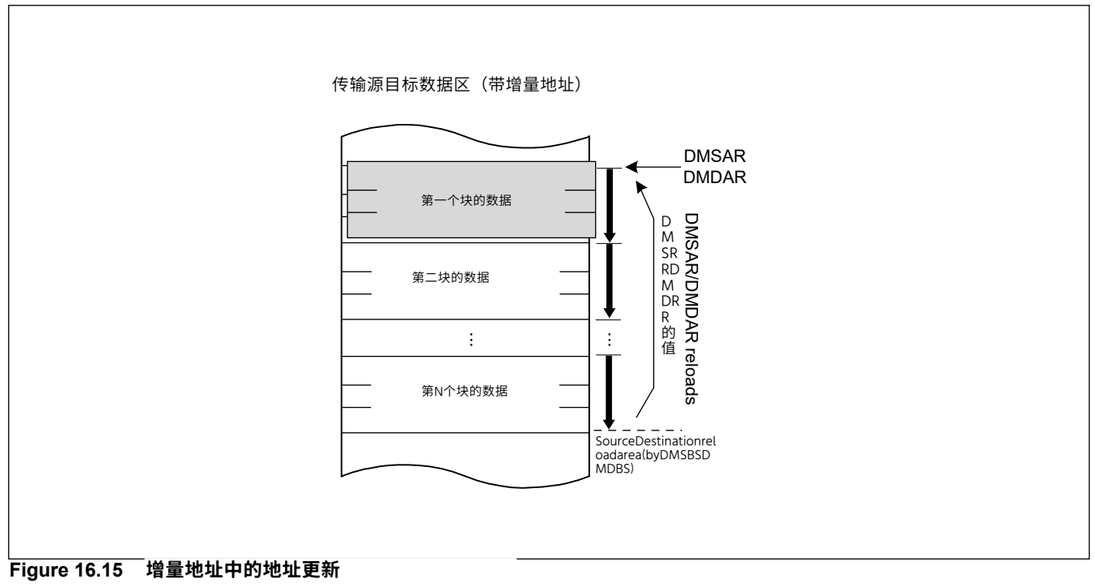

Figure 16.15 增量地址中的地址更新

16.3.5.3 偏移加法模式

当DMAMD.SM[1:0]设置为01b时，源地址更新方式为偏移加法。什么时候DMAMD.DM[1:0]设置为01b，目的地址更新方式为偏移加法。

除了偏移量之外，DMBSS和DMDBS表示重载区域，也用作访问偏移量值。与其他传输模式不同，DMOFR寄存器不用于重复块传输模式。除了偏移量之外，DMSBS和DMDBS的单位是块数。当传输开始时，DMCRAL作为一个递减计数器运行，DMSAR和DMDAR在每次传输一个块时重新加载DMSRR和DMDRR的值。此外，作为DMSBS和DMDBS的低16位的DMSBSL和DMDBSL也用作递减计数器，并且每传输一个块就递减。当DMSBS和DMDBS的值变为1时，DMSAR和DMDAR重新加载DMSRR和DMDRR的值。

当DMAMD.SADR和DMAMD.DADR设置为0时，重复相同区域的偏移添加操作。DMDAR仅重新加载DMDRR。第16.3.5.3节。偏移加法模式显示偏移加法中的地址更新，其中DMAMD.SADR和DMAMD.DADR=0。

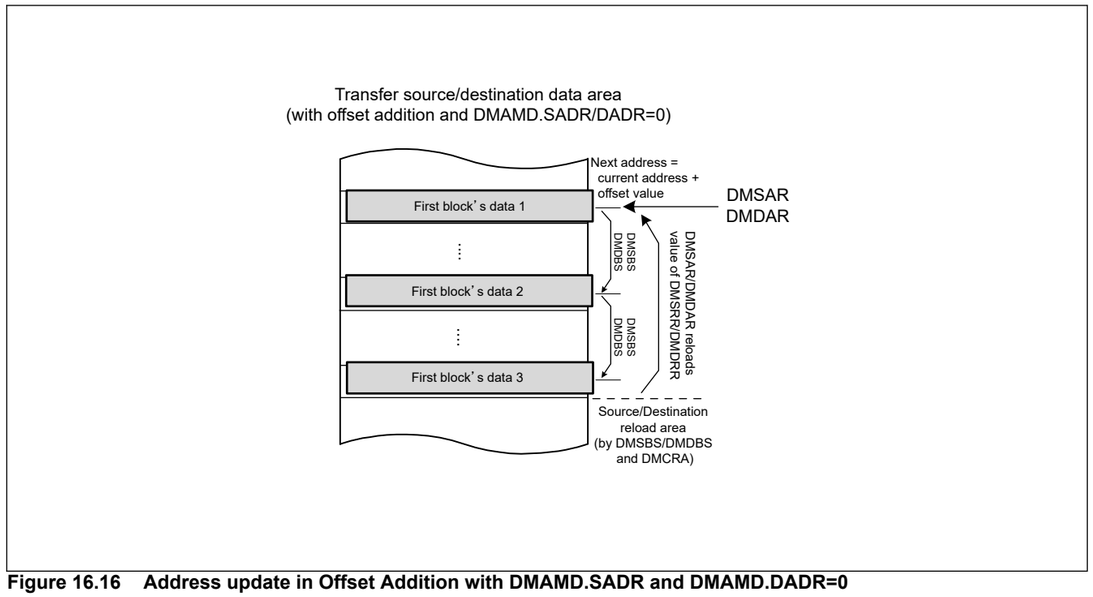

Figure 16.16 Address update in Offset Addition with DMAMD.SADR and DMAMD.DADR=0

When DMAMD.SADR and DMAMD.DADR is set to 1, the address is incremented by one data unit after DMSRR and DMDRR is reloaded by DMCRAL=1. In other words, an index value ((DMDBSH-DMDBSL) × DataSize) is added to DMDAR after DMDRR is reloaded. This behavior is used to implement multiple ring buffers. Figure 16.17 shows address update in offset addition with DMAMD.SADR and DMAMD.DADR=1.

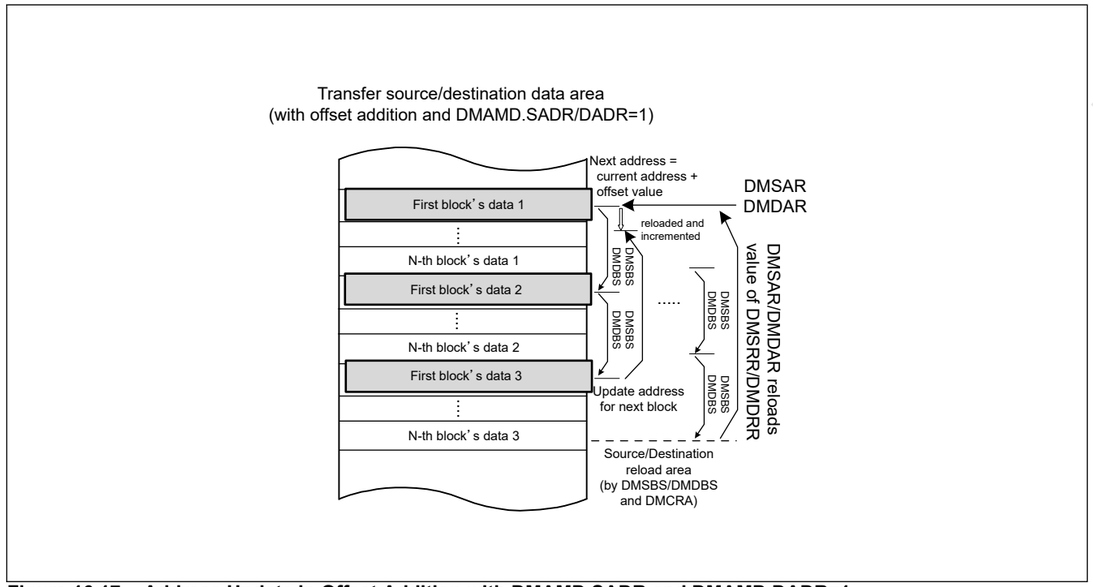

Figure 16.17 Address Update in Offset Addition with DMAMD.SADR and DMAMD.DADR=1

16.3.6 Example of Using Repeat-Block Transfer Mode

In repeat-block transfer mode, it is possible to realize repeated access to interval data and single or multiple ring buffers by combining the above address update modes. Following sections shows some usage examples.

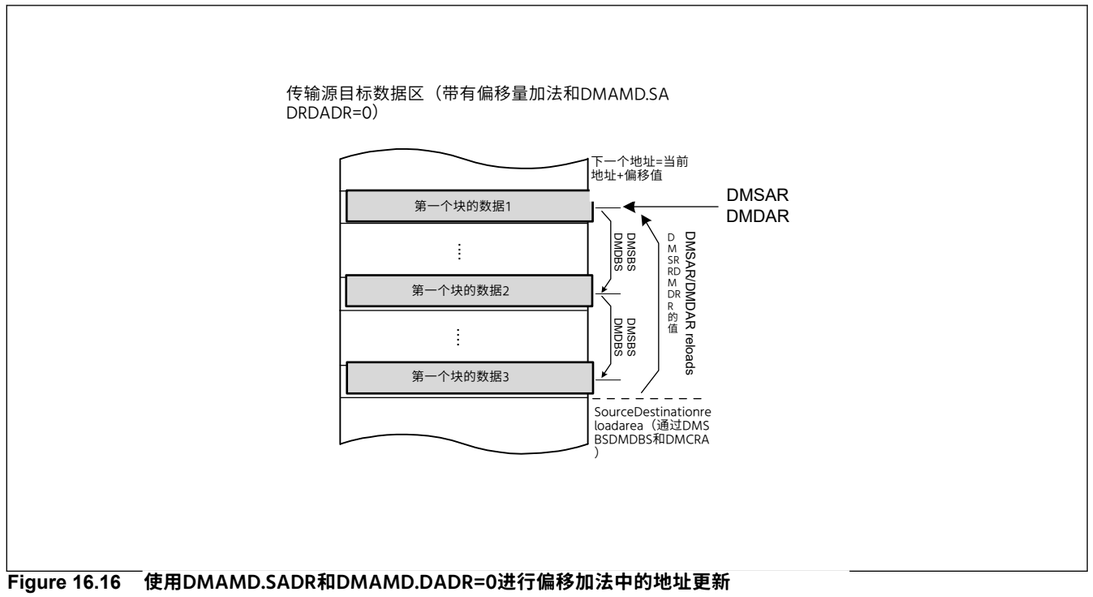

Figure 16.16 使用DMAMD.SADR和DMAMD.DADR=0进行偏移加法中的地址更新

当DMAMD.SADR和DMAMD.DADR设置为1时，在DMSRR和DMCRAL=1重新加载DMDRR后，地址增加一个数据单元。换句话说，一个索引值((DMDBSH−DMDBSL)×DataSize)被添加到
重新加载DMDRR后的DMDAR。此行为用于实现多个环形缓冲区。图16.17显示了DMAMD.SADR和DMAMD.DADR=1的偏移加法中的地址更新。

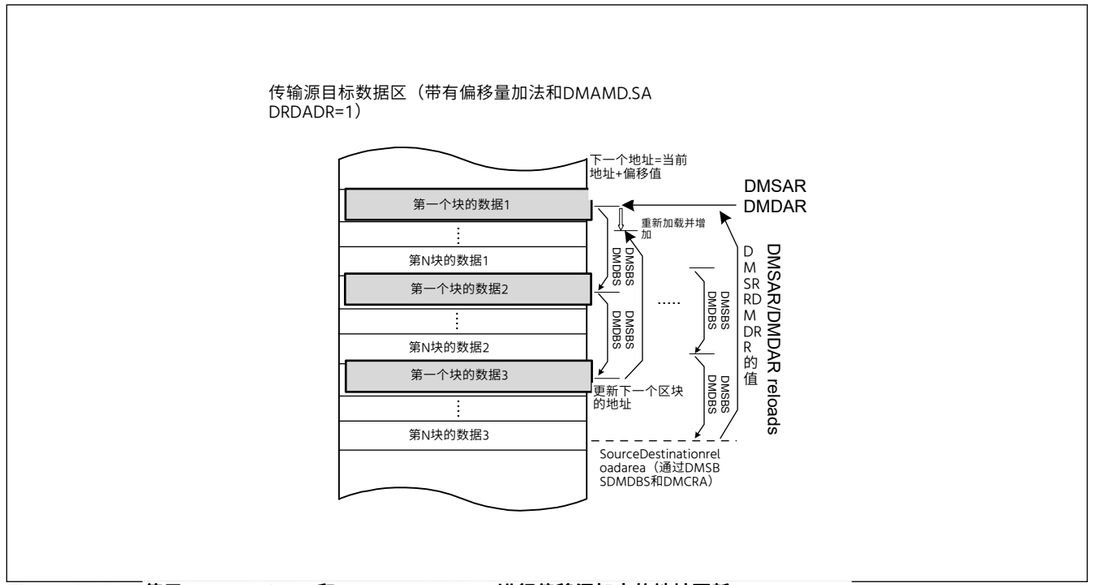

Figure 16.17 使用DMAMD.SADR和DMAMD.DADR=1进行偏移添加中的地址更新

16.3.6 使用重复块传输模式的示例

在重复块传输模式下，结合上述地址更新模式，可以实现对区间数据和单个或多个环形缓冲区的重复访问。以下部分显示了一些使用示例。

16.3.6.1 Interval Address to Single Ring Buffer

Figure 16.18 shows an example of reading interval ADDRn registers (data register) of ADC12 module and storing it in single ring buffer. It transfers 2 data every 4 halfwords per 1 request. DMSAR is incremented by one data every one request. This can be achieved by setting the transfer source to offset addition and DMAMD.SADR=1, the block size (DMCRA) to 2, and the transfer source offset (DMSBS) to 4. Table 16.15 shows setting of this example.

Table 16.15 Setting of use case: from interval address to single ring buffer

16.3.6.2 Unaligned Ring Buffer to Single Ring Buffer

Figure 16.19 shows an example of reading ADBUFn registers of ADC12 module (conversion result storage ring buffer) incrementally and storing it in single ring buffer. In this example, wrapping occurs because ADBUFn overflows in the fourth scan, but transfer source address of DMAC is also updated accordingly. This can be realized by setting the transfer source to incremental address and setting the DMSBS register to 16 which is the length of ADBUFn. This makes it possible to continue transfer without performing CPU processing using interrupts. Table 16.16 shows setting of this example.

16.3.6.1 单个环形缓冲区的间隔地址

图16.18显示了读取ADC12模块的间隔ADDRn寄存器（数据寄存器）并将其存储在单个环形缓冲区中的示例。它每1个请求每4个半字传输2个数据。DMSAR每请求一个数据就增加一个数据。这可以通过将传输源设置为偏移加法和DMAMD.SADR=1，将块大小(DMCRA)设置为2，将传输源偏移量(DMSBS)设置为4来实现。表16.15显示了此示例的设置。

图16.19显示了增量读取ADC12模块（转换结果存储环形缓冲区）的ADBUFn寄存器并将其存储在单个环形缓冲区中的示例。在本例中，由于ADBUFn在第四次扫描中溢出，因此发生了回绕，但DMAC的传输源地址也相应更新。这可以通过将传输源设置为增量地址并将DMSBS寄存器设置为16来实现，即ADBUFn的长度。这使得可以在不使用中断执行CPU处理的情况下继续传输。表16.16显示了此示例的设置。

Figure 16.20 shows an example of storing the continuous ADDRn registers (data register) of ADC12 module individually in multiple ring buffers. In this example, a ring buffer in which only the first element (ADDR0) in a single block is arranged in transfer order is created at the destination. Also, in the next area, create a ring buffer in which only the second element (ADDR1) is arranged in transfer order. In the following case, create a ring buffer of length N, which is defined by DMDBS. And the number of data elements in the block is 3, which is defined by DMCRA. 16.3.7 Activation Sources

Software, interrupt requests from the peripheral modules, and external interrupt requests can all be specified as DMAC activation sources. Set the DMTMD.DCTG[1:0] bits to select the activation source.

16.3.7.1 DMAC Activation by Software

When start DMA transfer by software, follow below procedure.

1. Set the DMTMD.DCTG[1:0] bits to 00b
2. Set the DMCNT.DTE bit to 1 (DMA transfer is enabled)
3. Set the DMAST.DMST bit set to 1 (DMAC activation enabled)
4. Set the DMREQ.SWREQ bit to 1 (DMA requested)

When the DMAC is activated by software while the DMREQ.CLRS bit is 0, the DMREQ.SWREQ bit is cleared to 0 after data transfer is started in response to a DMA transfer request.

When the DMAC is activated by software while the CLRS bit is 1, the SWREQ bit is not cleared to 0 after data transfer is started. In this case, a DMA transfer request is issued again after completion of a transfer.

16.3.7.2 DMAC Activation through Interrupt Requests from On-Chip Peripheral Modules or External Interrupt Requests

You can specify interrupt requests from on-chip peripheral modules and external interrupt requests as DMAC activation sources. The activation sources can be selected individually for each channel in ICU.DELSRn.DELS[8:0] (n = 0 to 7).

To start DMA transfer through an interrupt request from an on-chip peripheral module or an external interrupt request, follow the procedures as indicated below.

1. Set ICU.DELSRn.DELS[8:0] (n = 0 to 7) to the event number (select the DMAC event link).
2. Set the DMTMD.DCTG[1:0] bits to 01b (interrupts from the peripheral modules and the external interrupt pins).
3. Set the DMCNT.DTE bit to 1 (enable DMA transfer).
4. Set the DMAST.DMST bit set to 1 (DMAC activation enabled)

For interrupt requests specified as DMAC activation sources, see Table 13.3, in section 13, Interrupt Controller Unit (ICU).

16.3.8 Operation Timing

The following timing charts have indicated the number of execution cycles of the minimum.

Figure 16.21 and Figure 16.22 show DMAC operation timing examples.

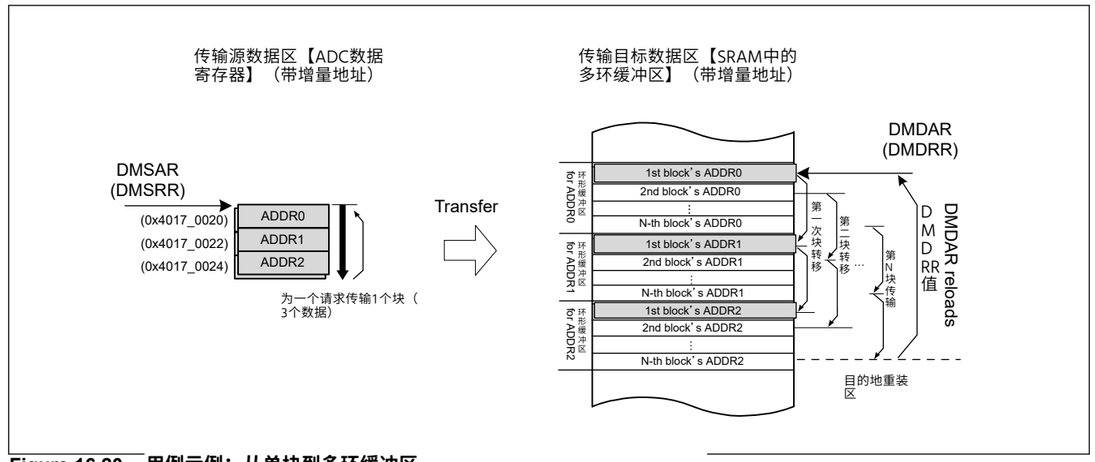

Figure 16.20 用例示例：从单块到多环缓冲区

16.3.7 激活源

软件、外设模块的中断请求和外部中断请求都可以指定为DMAC激活源。设置DMTMD.DCTG[1:0]位以选择激活源。

16.3.7.1 软件激活DMAC

当通过软件启动DMA传输时，请遵循以下步骤。

1.将DMTMD.DCTG[1:0]位设置为00b

2.将DMCNT.DTE位设置为1（启用DMA传输）

3.将DMAST.DMST位设置为1（启用DMAC激活）

4.将DMREQ.SWREQ位设置为1（请求DMA）

当DMREQ.CLRS位为0时由软件激活DMAC时，在响应DMA传输请求开始数据传输后，DMREQ.SWREQ位清零。

当CLRS位为1时由软件激活DMAC时，数据传输开始后SWREQ位不会被清零。在这种情况下，在传输完成后再次发出DMA传输请求。

16.3.7.2 通过来自片上外围模块或外部中断请求的中断请求激活DMAC

您可以将来自片上外围模块的中断请求和外部中断请求指定为DMAC激活源。可以为ICU.DELSRn.DELS[8:0]（n=0到7）中的每个通道单独选择激活源。

要通过来自片上外围模块的中断请求或外部中断请求启动DMA传输，请按照以下步骤操作。

1.将ICU.DELSRn.DELS[8:0]（n=0到7）设置为事件编号（选择DMAC事件链接）。

2.将DMTMD.DCTG[1:0]位设置为01b（来自外围模块和外部中断引脚的中断）。

3.将DMCNT.DTE位设置为1（启用DMA传输）。

4.将DMAST.DMST位设置为1（启用DMAC激活）

对于指定为DMAC激活源的中断请求，请参见第13节“中断控制器单元(ICU)”中的表13.3。

下面的时序图已经表明了最小的执行周期数。

Cr and Cw depend on the access destination. For the number of cycles for each access destination, see section 38, SRAM, section 40, Flash Memory, section 14, Buses. The frequency ratio of the system clock and the peripheral clock is also taken into consideration.

The unit for +1 in “Data Transfer (Read)” column is one system clock cycle (ICLK). For the operation example, see section 16.3.8. Operation Timing.

n: DMAC channel (n = 0 to 7)
Note 1. The DMAST.DMST bit setting does not necessarily have to follow the settings for the individual activation sources.

16.3.11 Starting DMA Transfer

To enable the DMA transfer, set the DMCNT.DTE bit to 1 (enable the DMA transfer), and then set the DMAST.DMST bit to 1 (enable the DMAC activation).

New activation requests are not accepted during the transfer of another DMAC channel or DTC. When the preceding transfer is complete, channel arbitration selects the DMA transfer request of the highest priority channel, and the DMA transfer of that channel starts. When the DMA transfer starts, the DMSTS.ACT flag is set to 1 (the DMAC is in the active state).

16.3.12 Registers during DMA Transfer

The DMAC registers are updated by a DMA transfer. The value to be updated differs according to the other settings and the transfer state. The registers to be updated are DMSAR, DMDAR, DMCRA, DMCRB, DMSBS, DMDBS, DMCNT, and DMSTS.

DMA Source Address Register (DMSAR)

When data has been transferred in response to one transfer request, the contents of DMSAR are updated to the address to be accessed by the next transfer request.

For details on register update operation in each transfer mode, see Table 16.5 to Table 16.13.

DMA Destination Address Register (DMDAR)

When data has been transferred in response to one transfer request, the contents of DMDAR are updated to the address to be accessed by the next transfer request.

For details on register update operation in each transfer mode, see Table 16.5 to Table 16.13.

DMA Transfer Count Register (DMCRA)

When data has been transferred in response to one transfer request, the count value is updated. The update operation depends on the transfer mode selected.

For details on register update operation in each transfer mode, see Table 16.5 to Table 16.13.

DMA Block Transfer Count Register (DMCRB)

When data has been transferred in response to one transfer request, the count value is updated. The update operation depends on the transfer mode selected.

For details on register update operation in each transfer mode, see Table 16.5 to Table 16.13.

DMA Source Buffer Size Register (DMSBS)

When data has been transferred in response to one transfer request, the count value is updated. The update operation depends on the transfer mode selected.

For details on register update operation in each transfer mode, refer to Table 16.8 to Table 16.13.

DMA Destination Buffer Size Register (DMDBS)

When data has been transferred in response to one transfer request, the count value is updated. The update operation depends on the transfer mode selected.

For details on register update operation in each transfer mode, refer to Table 16.8 to Table 16.13.

注1.DMAST.DMST位设置不一定要遵循各个激活源的设置。

16.3.11 启动DMA传输

要启用DMA传输，请将DMCNT.DTE位设置为1（启用DMA传输），然后将DMAST.DMST位设置为1（启用DMAC激活）。

在传输另一个DMAC通道或DTC期间不接受新的激活请求。当前面的传输完成后，通道仲裁选择最高优先级通道的DMA传输请求，该通道的DMA传输开始。当DMA传输开始时，DMSTS.ACT标志设置为1（DMAC处于活动状态）。

16.3.12 DMA传输期间的寄存器

DMAC寄存器由DMA传输更新。要更新的值根据其他设置和传输状态而有所不同。要更新的寄存器是DMSAR、DMDAR、DMCRA、DMRCB、DMSBS、DMDBS、DMCNT和DMSTS。

DMA源地址寄存器(DMSAR)

当响应一个传输请求而传输了数据时，DMSAR的内容将更新为下一个传输请求要访问的地址。

每种传输模式下寄存器更新操作的详细信息，请参见表16.5至表16.13。

DMA目标地址寄存器(DMDAR)

当响应一个传输请求传输了数据时，DMDAR的内容被更新为下一个传输请求要访问的地址。

每种传输模式下寄存器更新操作的详细信息，请参见表16.5至表16.13。

DMA传输计数寄存器(DMCRA)

当响应一个传输请求传输数据时，更新计数值。更新操作取决于选择的传输模式。

每种传输模式下寄存器更新操作的详细信息，请参见表16.5至表16.13。

DMA块传输计数寄存器(DMCRB)

当响应一个传输请求传输数据时，更新计数值。更新操作取决于选择的传输模式。

每种传输模式下寄存器更新操作的详细信息，请参见表16.5至表16.13。

DMA源缓冲区大小寄存器(DMSBS)

当响应一个传输请求传输数据时，更新计数值。更新操作取决于选择的传输模式。

有关各传输模式下的寄存器更新操作的详细信息，请参阅表16.8至表16.13。

DMA目标缓冲区大小寄存器(DMDBS)

当响应一个传输请求传输数据时，更新计数值。更新操作取决于选择的传输模式。

有关各传输模式下的寄存器更新操作的详细信息，请参阅表16.8至表16.13。

DMA Transfer Enable Bit (DMCNT.DTE)

Although the DMCNT.DTE bit enables or disables data transfer by the register write access, it is automatically cleared to 0 by the DMAC according to the DMA transfer state.

The conditions for clearing this bit by the DMAC are as follows:

- When the specified total volume of data transfer is completed
- When DMA transfer is stopped by the repeat size end interrupt
- When DMA transfer is stopped by the extended repeat area overflow interrupt
- When DMA transfer error occurs

Writing to the registers for the channels when the corresponding DMCNT.DTE bit is set to 1 is prohibited (except for DMCNT). In this case, writing must be performed after the bit is cleared to 0.

DMAC Active Flag (DMSTS.ACT)

The DMSTS.ACT flag indicates whether the DMACn is in the idle or active state.

This flag is set to 1 when the DMAC starts data transfer, and is cleared to 0 when data transfer in response to one transfer request is completed.

Even when DMA transfer is stopped by writing 0 to the DMCNT.DTE bit during DMA transfer, this flag remains 1 until DMA transfer is completed.

Transfer End Interrupt Flag (DMSTS.DTIF)

The DMSTS.DTIF flag is set to 1 after DMA transfer of the total transfer size of data is completed.

When both this flag and the DMINT.DTIE bit are set to 1, a transfer end interrupt is requested.

This flag is set to 1 when the DMA transfer bus cycle is completed and the DMSTS.ACT flag is cleared to 0 indicating the DMA transfer end.

This flag is automatically cleared to 0 when the DMCNT.DTE bit is set to 1 during the interrupt handling.

Transfer Escape End Interrupt Flag (DMSTS.ESIF)

The DMSTS.ESIF flag is set to 1 when a repeat size end interrupt or extended repeat area overflow interrupt is requested. When this bit and the DMINT.ESIE bit are set to 1, a transfer escape end interrupt is requested.

This flag is set to 1 when the bus cycle of the DMA transfer having caused the interrupt request is completed and the DMSTS.ACT flag is cleared to 0 indicating the DMA transfer end.

This flag is automatically cleared to 0 when the DMCNT.DTE bit is set to 1 during an interrupt handling.

Before sending an interrupt request from the DMAC to the CPU or the DTC, the interrupt control register must be set.

For details, see section 13, Interrupt Controller Unit (ICU).

16.3.13 Channel Priority

When multiple DMA transfer requests are present, the DMAC determines the priority of channels that have DMA transfer requests.

- The channel priority is fixed as follows: Channel 0 > Channel 1 > Channel 2 > Channel 3… > Channel 7 (Channel 0: Highest).

When a DMA transfer request is generated during data transfer, channel arbitration is started after the final data has been transferred, and DMA transfer of the higher-priority channel starts.

16.3.14 Channel Security

The security attribute of transfer access of DMACn, security attribute of access to register of DMACn, security attribute of access to the ICU.DELSRn register are controlled by ICUSARC.SADMACn bit. For details on the ICUSARC register, see section 13, Interrupt Controller Unit (ICU).

When the ICUSARC.SADMACn bit is 0, transfer of DMACn is secure access for both read and write. At the same time, the registers of channel n and the DELSRn register are protected from a non-secure access.

DMA传输使能位(DMCNT.DTE)

虽然DMCNT.DTE位通过寄存器写访问启用或禁用数据传输，但它会根据DMA传输状态由DMAC自动清零。

DMAC清除该位的条件如下：

- ●当指定的总数据传输量完成时
- ●当DMA传输因重复大小结束中断而停止时
- ●当DMA传输因扩展重复区域溢出中断而停止时
- ●发生DMA传输错误时

当相应的DMCNT.DTE位设置为1时，禁止写入通道的寄存器（除了DMCNT）。在这种情况下，必须在该位清0后进行写入。

DMAC活动标志(DMSTS.ACT)

DMSTS.ACT标志指示DMACn是处于空闲状态还是活动状态。

该标志在DMAC开始数据传输时设置为1，并在响应一个传输请求的数据传输完成时清除为0。

即使在DMA传输期间通过向DMCNT.DTE位写入0来停止DMA传输，该标志仍 保持为1，直到DMA传输完成。

传输结束中断标志(DMSTS.DTIF)

在数据的总传输大小的DMA传输完成后，DMSTS.DTIF标志设置为1。

当该标志和DMINT.DTIE位都设置为1时，请求传输结束中断。

当DMA传输总线周期完成并且DMSTS.ACT标志被清除为0时，该标志设置为1，表示DMA传输结束。

在中断处理期间，当DMCNT.DTE位设置为1时，该标志自动清零。

传输转义结束中断标志(DMSTS.ESIF)

当请求重复大小结束中断或扩展重复区域溢出中断时，DMSTS.ESIF标志设置为1。
当该位和DMINT.ESIE位设置为1时，请求传输转义结束中断。

当导致中断请求的DMA传输的总线周期完成并且DMSTS.ACT标志清零，表示DMA传输结束。

在中断处理期间，当DMCNT.DTE位设置为1时，该标志自动清零。

在从DMAC向CPU或DTC发送中断请求之前，必须设置中断控制寄存器。

有关详细信息，请参阅第13节，中断控制器单元(ICU)。

16.3.13 频道优先级

当存在多个DMA传输请求时，DMAC确定具有DMA传输请求的通道的优先级。

●通道优先级固定如下：通道0>通道1>通道2>通道3…>通道7（通道0：最高）。

如果在数据传输过程中产生DMA传输请求，则在传输完最终数据后启动通道仲裁，并开始高优先级通道的DMA传输。

16.3.14 渠道安全

DMACn的传输访问安全属性、DMACn寄存器访问安全属性、ICU.DELSRn寄存器访问安全属性由ICUUSARC.SADMACn位控制。有关ICUSARC寄存器的详细信息，请参见第13节，中断控制器单元(ICU)。

当ICUSARC.SADMACn位为0时，DMACn的传输对于读和写都是安全访问。同时，通道n的寄存器和DELSRn寄存器受到保护，不会被非安全访问。

When the ICUSARC.SADMACn bit is 1, transfer of DMACn is non-secure access for both read and write. At the same time, the registers of channel n and the DELSRn register are non-secure attributes.

Do not write to the ICUSARC.SADMACn bit while DMA transfer of same channel is enabled or a bus master is writing to the DMA registers of same channel.

Figure 16.23 shows security attribute about each DMAC channels.

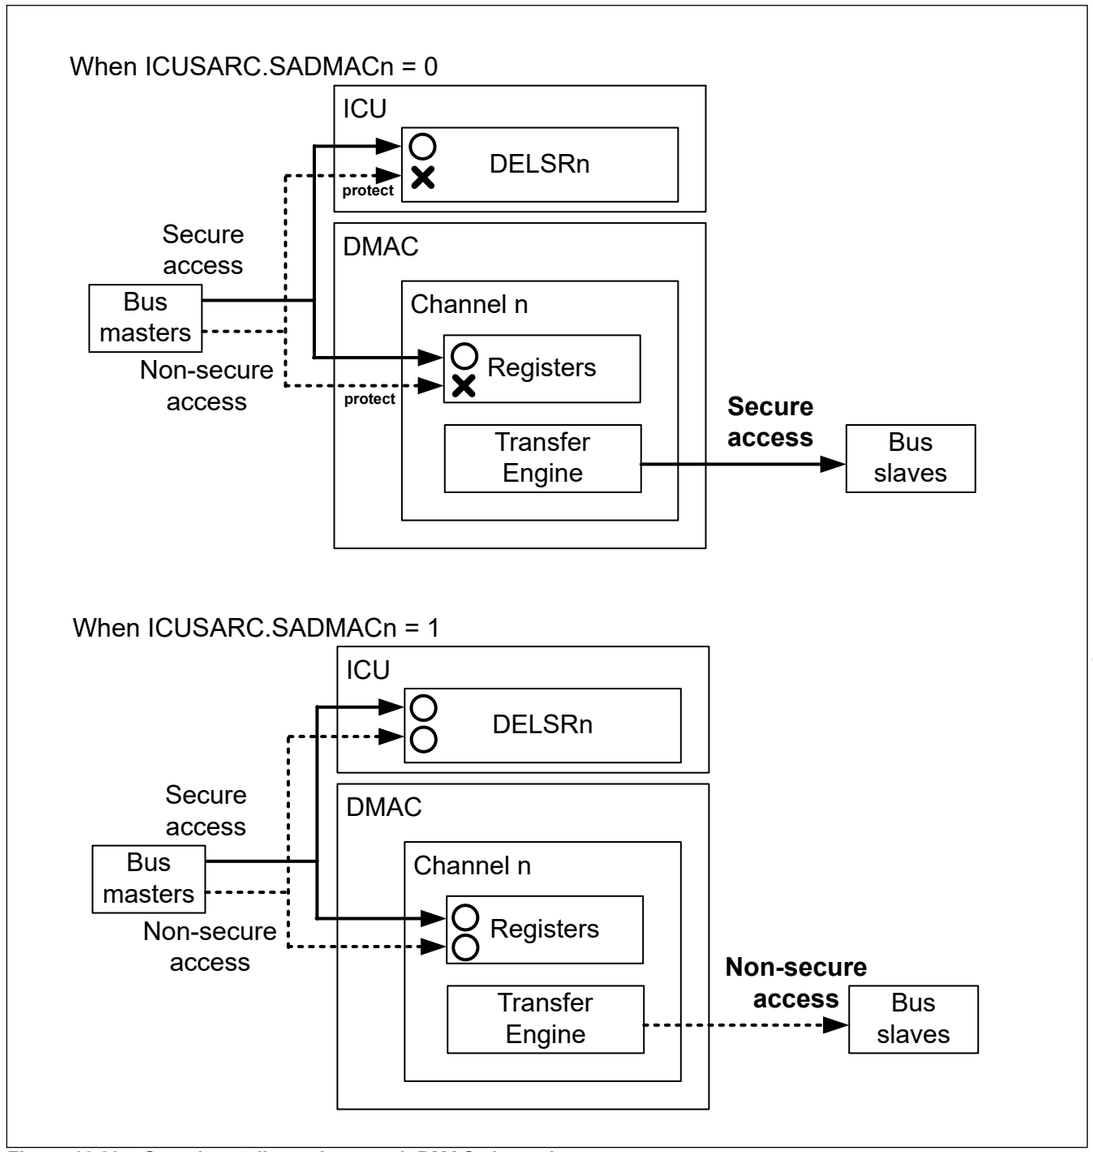

Figure 16.23 Security attribute about each DMAC channels

16.3.15 Master TrustZone Filter in DMAC

DMAC has the Master TrustZone Filter. The MasterTrustZone Filter in DMAC can detect the security areas of Flash area(code Flash and data Flash) and SRAM area defined by IDAU. When set No-secure channel accesses those addresses, it

当ICUSARC.SADMACn位为1时，DMACn的传输对于读和写都是非安全访问。同时，通道n的寄存器和DELSRn寄存器是非安全属性。

当启用同一通道的DMA传输或总线主机正在写入同一通道的DMA寄存器时，请勿写入ICUSARC.SADMACn位。

图16.23显示了每个DMAC通道的安全属性。

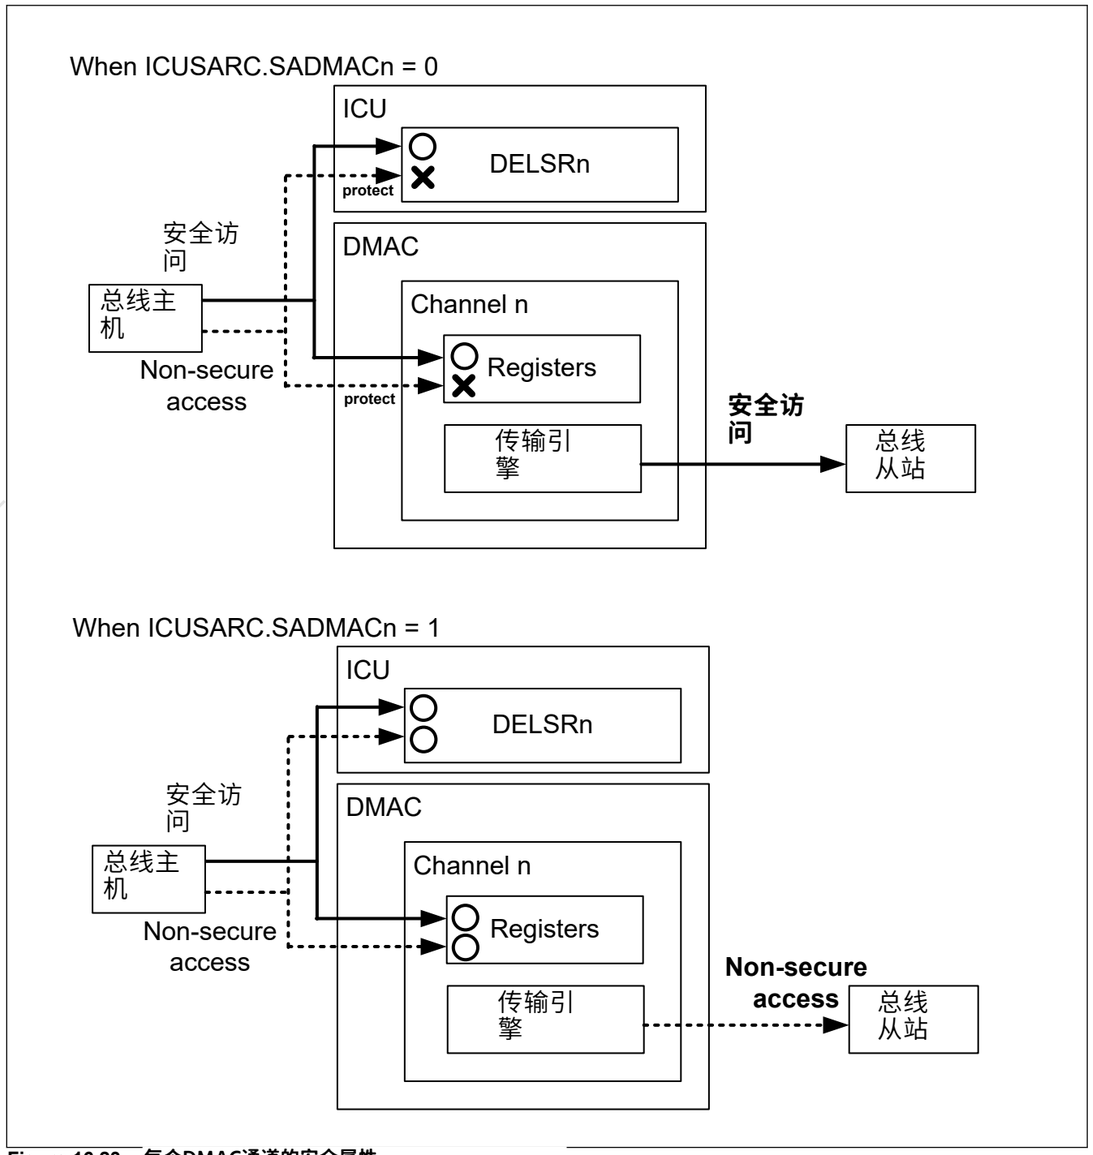

Figure 16.23 每个DMAC通道的安全属性

16.3.15 DMAC中的主TrustZone过滤器

DMAC具有MasterTrustZone过滤器。DMAC中的MasterTrustZoneFilter可以检测IDAU定义的Flash区域（代码Flash和数据Flash）和SRAM区域的安全区域。当设置无安全通道访问这些地址时，它

detects the security violation. Access of violation address is not performed. Detected the error is handled as the Master TrustZone Filter error.

16.4 Ending DMA Transfer

The operation for ending DMA transfer depends on the transfer end conditions. When DMA transfer ends, the DMCNT.DTE bit and the DMSTS.ACT flag are changed from 1 to 0, indicating that DMA transfer has ended.

16.4.1 Transfer End by Completion of Specified Total Number of Transfer Operations

(1) In Normal Transfer Mode (DMTMD.MD[1:0] = 00b)

When the value of DMCRAL changes from 1 to 0, DMA transfer ends on the corresponding channel, and the DMCNT.DTE bit is cleared to 0 and the DMSTS.DTIF flag is set to 1 at the same time. If the DMINT.DTIE bitT is 1 at this time, a transfer end interrupt request is issued to the CPU or the DTC.

(2) In Repeat Transfer Mode (DMTMD.MD[1:0] = 01b)

When the value of DMCRBL changes from 1 to 0, DMA transfer ends on the corresponding channel, and the DMCNT.DTE bit is cleared to 0 and the DMSTS.DTIF flag is set to 1 at the same time. If the DMINT.DTIE bit is 1 at this time, an interrupt request is issued to the CPU or the DTC.

If the DMTMD.TKP bit is 1 (in free-running function), the DMSTS.DTIF bit is set to 1, but the DMCNT.DTE bit is not cleared to 0.

(3) In Block Transfer Mode (DMTMD.MD[1:0] = 10b)

When the value of DMCRBL changes from 1 to 0, DMA transfer ends on the corresponding channel, and the DMCNT.DTE bit is cleared to 0 and the DMSTS.DTIF flag is set to 1 at the same time. If the DMINT.DTIE bit is 1 at this time, an interrupt request is issued to the CPU or the DTC.

Before sending an interrupt request from the DMAC to the CPU or the DTC, the interrupt control register must be set. For details, see section 13, Interrupt Controller Unit (ICU).

If the DMTMD.TKP bit is 1 (in free-running function),the DMSTS.DTIF bit is set to 1, but the DMCNT.DTE bit is not cleared to 0.

(4) In Repeat-Block Transfer Mode (DMTMD.MD[1:0] = 11b)

When the value of DMCRBL changes from 1 to 0, DMA transfer ends on the corresponding channel, and the DMCNT.DTE bit is cleared to 0 and the DMSTS.DTIF flag is set to 1 at the same time. If the DMINT.DTIE bit is 1 at this time, an interrupt request is issued to the CPU or the DTC.

Before sending an interrupt request from the DMAC to the CPU or the DTC, the interrupt control register must be set. For details, see section 13, Interrupt Controller Unit (ICU).

If the DMTMD.TKP bit is 1 (in free-running function),the DMSTS.DTIF bit is set to 1, but the DMCNT.DTE bit is not cleared to 0.

16.4.2 Transfer End by Repeat Size End Interrupt

In repeat transfer mode, a repeat size end interrupt is requested when transfer of a 1-repeat size of data is completed while the DMINT.RPTIE bit is set to 1. When the interrupt is requested to complete DMA transfer, the DMCNT.DTE bit is cleared to 0 and the DMSTS.ESIF flag is set to 1 even if the DMTMD.TKP bit is 1 (in free-running function). If the DMINT.ESIE bit is 1 at this time, an interrupt request is issued to the CPU or the DTC. Here, the transfer can be resumed by writing 1 to the DMCNT.DTE bit.

A repeat size end interrupt can be requested also in block transfer mode. In block transfer mode, the interrupt is requested in the same way as in repeat transfer mode when transfer of a 1-block size data is completed.

Repeat size end interrupt cannot be requested in repeat-block transfer mode.

Before sending an interrupt request from the DMAC to the CPU or the DTC, the interrupt control register must be set. For details, see section 13, Interrupt Controller Unit (ICU).

检测到安全违规。不执行违规地址的访问。检测到的错误作为MasterTrustZoneFilter错误处理。

16.4 结束DMA传输

结束DMA传输的操作取决于传输结束条件。当DMA传输结束时，DMCNT.DTE位和DMSTS.ACT标志由1变为0，表示DMA传输已经结束。

16.4.1 完成指定的转移操作总数后转移结束

(1) 在正常传输模式下（DMTMD.MD[1:0]=00b）

当DMCRAL的值由1变为0时，相应通道上的DMA传输结束，同时DMCNT.DTE位清0，同时DMSTS.DTIF标志置1。如果此时DMINT.DTIEbitT为1，则向CPU或DTC发出传输结束中断请求。

(2) 在重复传输模式下(DMTMD.MD[1:0]=01b)

当DMCRBL的值从1变为0时，相应通道上的DMA传输结束，同时DMCNT.DTE位清0，同时DMSTS.DTIF标志置1。如果此时DMINT.DTIE位为1，则向CPU或DTC发出中断请求。

如果DMTMD.TKP位为1（在自由运行功能中），则DMSTS.DTIF位设置为1，但DMCNT.DTE位不清除为0。

(3) 在块传输模式下(DMTMD.MD[1:0]=10b)

当DMCRBL的值从1变为0时，相应通道上的DMA传输结束，同时DMCNT.DTE位清0，同时DMSTS.DTIF标志置1。如果此时DMINT.DTIE位为1，则向CPU或DTC发出中断请求。

在从DMAC向CPU或DTC发送中断请求之前，必须设置中断控制寄存器。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

如果DMTMD.TKP位为1（在自由运行功能中），则DMSTS.DTIF位设置为1，但DMCNT.DTE位不清除为0。

(4) 在重复块传输模式下(DMTMD.MD[1:0]=11b)

当DMCRBL的值从1变为0时，相应通道上的DMA传输结束，同时DMCNT.DTE位清0，同时DMSTS.DTIF标志置1。如果此时DMINT.DTIE位为1，则向CPU或DTC发出中断请求。

在从DMAC向CPU或DTC发送中断请求之前，必须设置中断控制寄存器。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

如果DMTMD.TKP位为1（在自由运行功能中），则DMSTS.DTIF位设置为1，但DMCNT.DTE位不清除为0。

16.4.2 按重复大小结束传输结束中断

在重复传输模式下，当DMINT.RPTIE位设置为1时完成1次重复大小的数据传输时，请求重复大小结束中断。当请求中断以完成DMA传输时，DMCNT.DTE位即使DMTMD.TKP位为1（在自由运行功能中），清除为0并且DMSTS.ESIF标志设置为1。如果此时DMINT.ESIE位为1，则向CPU或DTC发出中断请求。在这里，可以通过将1写入DMCNT.DTE位来恢复传输。

在块传输模式下也可以请求重复大小结束中断。在块传输模式中，当1块大小的数据传输完成时，以与重复传输模式相同的方式请求中断。

在重复块传输模式下不能请求重复大小结束中断。

在从DMAC向CPU或DTC发送中断请求之前，必须设置中断控制寄存器。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

16.4.3 Transfer End by Interrupt on Extended Repeat Area Overflow

When an overflow on the extended repeat area occurs while the extended repeat area is specified and the DMINT.SARIE or DMINT.DARIE bit is set to 1 even if the DMTMD.TKP bit is 1 (in free-running function), an interrupt by an extended repeat area overflow is requested. When the interrupt is requested, the DMA transfer is terminated, the DMCNT.DTE bit is cleared to 0, and the ESIF flag in DMSTS is set to 1. If the DMINT.ESIE bit is 1 at this time, an interrupt request is issued to the CPU or the DTC.

Even if an interrupt by an extended repeat area overflow is requested during a read cycle, the following write cycle is performed.

In block transfer mode, even if an interrupt by an extended repeat area overflow is requested during a 1-block transfer, the remaining data in the block is transferred; transfer is terminated after a block transfer.

An interrupt by an extended repeat area overflow cannot be requested in repeat-block transfer mode.

Before sending an interrupt request from the DMAC to the CPU or the DTC, the interrupt control register must be set. For details, see section 13, Interrupt Controller Unit (ICU).

16.5 Processing on DMA Transfer Error

DMA transfer error occurs with the Master TrustZone Filter error in DMAC, the Slave TrustZone Filter error, the Master MPU error, the Slave Bus Error or the Illegal Access Error. If the access error occurs during the DMA transfer, the DMAC immediately stops the transfer of error occurred channel. At this time, the ICU setting of the corresponding channel is also cleared. If there is a request other than the channel which caused the error, it will be re-arbitration as it is.

When the transfer error occurs, DMCNT.DTE of the error causing channel is set to 0. Also, the error response is informed to the ICU.DELSRn of the corresponding channel is cleared. Write back to each register is not performed. Furthermore, it generates the error response detection interrupt request (DMA_TRANSERR) to notify that an error has occurred by DMAC/DTC transfer.

When the Master TrustZone Filter error occurs, the Slave TrustZone error occurs or the Master MPU error occurs, it is possible to confirm the error information of DMAC by selecting NMI. The DMAC error channel register is cleared by selecting reset. Under the conditions where NMI is generated due to transfer error in DMAC, two interrupts(NMI and DMAC_TRANSERR) are generated. In this case, NMI always responds first.

The error response detection interrupt request (DMA_TRANSERR) occurs when the Slave Bus error or the Illegal Access error occurs. Furthermore, it occurs after NMI when the error response detection interrupt request (DMA_TRANSERR) is not cleared in NMI handler.

section 16.5.1. Processing on NMI handler describes how to confirm the error information of the DMAC in the NMI handler.

section 16.5.2. Processing on Error response detection interrupt request (DMA_TRANSERR) handler describes how to confirm the error information of the DMAC in the DMA_TRANSERR handler.

Interrupts and the error information generated due to transfer errors are shown in section 16.6.2. Transfer Error Interrupt.

16.5.1 Processing on NMI handler

The cause of NMI due to the DMA transfer error is the Master TrustZone Filter error, the Slave TrustZone Filter error or the Master MPU error. When NMI occurs due to the DMAC transfer error, the error response detection interrupt request (DMA_TRANSERR) will occur after the end of NMI handler. It is possible to confirm the cause of the error and the DMAC channel in which the error occurred. When NMI occurs, perform the necessary processing according to the flow described in the ICU chapter.

Figure 16.24 shows the flow for confirm the channel that caused the Master TrustZone Filter Error in DMAC

Figure 16.25 shows the flow for confirm the channel that caused the Slave TrustZone Filter Error in DMAC

Figure 16.26 shows the flow for confirm the channel and Security Attribute that caused the Master MPU error in DMAC.

If completing all processing in NMI handler, it is possible to clear the error response detection interrupt request (DMA_TRANSERR) that occurs subsequently.

16.4.3 扩展重复区溢出中断传输结束

如果在指定扩展重复区域时扩展重复区域发生溢出，并且即使DMTMD.TKP位为1，DMINT.SARIE或DMINT.DARIE位也设置为1（在自由运行功能中），中断由请求扩展重复区域溢出。请求中断时，终止DMA传输，DMCNT.DTE位清0，DMSTS中的ESIF标志置1。如果此时DMINT.ESIE位为1，则发出中断请求到CPU或DTC。

即使在读取周期期间请求由扩展重复区域溢出引起的中断，也会执行下一个写入周期。

在块传输模式下，即使在1块传输期间请求扩展重复区域溢出中断，也会传输块中剩余的数据；块传输后终止传输。

在重复块传输模式下不能请求由扩展重复区域溢出引起的中断。

在从DMAC向CPU或DTC发送中断请求之前，必须设置中断控制寄存器。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

16.5 DMA传输错误处理

DMA传输错误发生在DMAC中的MasterTrustZoneFilter错误、SlaveTrustZoneFilter错误、Master MPU错误、从总线错误或非法访问错误。如果在DMA传输过程中发生访问错误，DMAC立即停止发生错误通道的传输。此时相应通道的ICU设置也被清除。如果存在引起错误的通道以外的请求，将按原样重新仲裁。

当发生传输错误时，错误引起通道的DMCNT.DTE设置为0。同时，错误响应被通知给ICU。相应通道的DELSRn被清除。不执行回写到每个寄存器。此外，它会生成错误响应检测中断请求(DMA_TRANSERR)，以通知DMACDTC传输发生错误。

当MasterTrustZoneFilter发生错误、SlaveTrustZone错误或MasterMPU错误时，可以通过选择NMI来确认DMAC的错误信息。通过选择复位来清除DMAC错误通道寄存器。在由于DMAC中的传输错误而产生NMI的情况下，会产生两个中断（NMI和DMAC_TRANSERR）。在这种情况下，NMI总是首先响应。

当发生SlaveBus错误或IllegalAccess错误时，会发生错误响应检测中断请求(DMA_TRANSERR)。此外，当NMI处理程序中未清除错误响应检测中断请求(DMA_TRANSERR)时，它会在NMI之后发生。

第16.5.1节。NMIhandler上的处理描述了如何在NMIhandler中确认DMAC的错误信息。

第16.5.2节。错误响应检测中断请求（DMA_TRANSERR）处理程序的处理描述了如何在DMA_TRANSERR处理程序中确认DMAC的错误信息。

因传输错误而产生的中断和错误信息见16.6.2节。传输错误中断。

16.5.1 在NMI处理程序上处理

由于DMA传输错误导致NMI的原因是MasterTrustZoneFilter错误、SlaveTrustZoneFilter错误或MasterMPU错误。当由于DMAC传输错误而发生NMI时，错误响应检测中断请求(DMA_TRANSERR)将在NMI处理程序结束后发生。可以确认错误的原因和发生错误的DMAC通道。当发生NMI时，按照ICU章节中描述的流程进行必要的处理。

如果完成NMI处理程序中的所有处理，则可以清除随后发生的错误响应检测中断请求(DMA_TRANSERR)。

It is possible to confirm the cause of the error and the DMAC channel in which the error occurred.

16.6 Interrupts

16.6.1 Transfer End Interrupt

Each DMAC channel can output an interrupt request (DMACn_INT) to the CPU or the DTC after transfer in response to one request is completed.

In repeat-block transfer mode, do not enable escape transfer end interrupt.

Table 16.21 lists the relation among the interrupt sources, the interrupt status flags, and the interrupt enable bits. Figure 16.33 shows the schematic logic diagram of interrupt outputs (DMACn (n = 0 to 7)). Figure 16.34 shows the DMAC interrupt handling routine to resume/terminate DMA transfer.

16.6.1 传输结束中断

每个DMAC通道可以在响应一个请求的传输完成后向CPU或DTC输出一个中断请求（DMACn_INT）。

在重复块传输模式下，不要启用转义传输结束中断。

表16.21列出了中断源、中断状态标志和中断使能位之间的关系。图16.33显示了中断输出(DMACn(n=0to7))的逻辑示意图。图16.34显示了用于恢复终止DMA传输的DMAC中断处理程序。

Specifically, the different procedures are used for canceling an interrupt to restart DMA transfer in the following two cases:

- When terminating a DMA transfer
- When continuing a DMA transfer

16.6.1.1 When Terminating a DMA Transfer

Write 0 to the DMSTS.DTIF flag to clear a transfer end interrupt, and to the DMSTS.ESIF flag to clear a repeat size interrupt and an extended repeat area overflow interrupt. The DMACn remains in the stop state. When starting another DMA transfer after that, set the appropriate registers, and set the DMCNT.DTE bit to 1 (DMA transfer enabled).

16.6.1.2 When Continuing a DMA Transfer

Write 1 to the DMCNT.DTE bit. The DMSTS.ESIF flag is automatically cleared to 0 (interrupt source cleared), and DMA transfer is resumed.

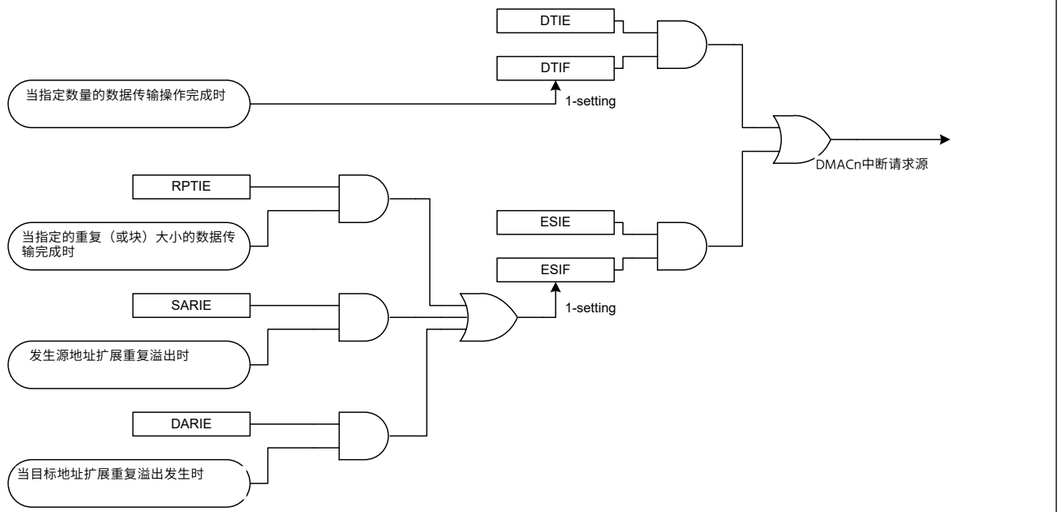

Figure 16.33 中断输出源（DMACn）逻辑示意图

具体来说，在以下两种情况下，不同的程序用于取消中断以重新启动DMA传输：

- ●终止DMA传输时
- ●继续DMA传输时

16.6.1.1 终止DMA传输时

将0写入DMSTS.DTIF标志以清除传输结束中断，写入DMSTS.ESIF标志以清除重复大小中断和扩展重复区域溢出中断。DMACn保持在停止状态。之后开始另一个DMA传输时，设置适当的寄存器，并将DMCNT.DTE位设置为1（启用DMA传输）。

16.6.1.2 继续DMA传输时

将1写入DMCNT.DTE位。DMSTS.ESIF标志自动清零（中断源清零），DMA传输恢复。

16.6.2 Transfer Error Interrupt

Error response detection interrupt request (DMA_TRANSERR) is generated from the DMAC/DTC when the transfer error is detected during DMAC transfer. The types of interrupts that occur when a DMAC transfer error occurs are listed in the Table 16.22. The Table 16.22 also shows error information stored when a transfer error occurs.

16.6.2 传输错误中断

在DMAC传输期间检测到传输错误时，从DMACDTC生成错误响应检测中断请求(DMA_TRANSERR)。发生DMAC传输错误时发生的中断类型在表16.22中列出。表16.22还显示了发生传输错误时存储的错误信息。

注意1.中断，当NMI请求在检测主MPU错误和Trustzone滤波器错误后选择为操作时中断。通过确认BUS.BUS3ERRSTAT和BUS.DMACDTCERRSTAT，判断是Master还是Slave。
注2.如果错误响应检测中断(DMA_TRANSERR)发生且MasterMPU的NMI或TrustZoneFilter的NMI未发生，则将其视为Illegaladdressaccesserror或SlaveBusError。也可以通过BUS.BUS3ERRSTAT和BUS来判断。DMACDTCERRSTAT。

Note that if the bus error occurs when writing the last data of transfer, the transfer end event and the error response detection interrupt (DMA_TRANSERR) occurs.

16.7 Event Link

Each DMAC channel outputs an event link request signal (DMACn_INT) every time it completes a data transfer, or a block transfer in block transfer mode.

For details, see section 18, Event Link Controller (ELC).

If a bus error occurs when writing the last data of transfer, a transfer end event and error response detection interrupt (DMA_TRANSERR) occurs.

16.8 Low-Power Consumption Function

Before entering the module-stop state or Software Standby mode, or Deep Software Standby mode, you must first set the DMAST.DMST bit to 0 (the DMAC module suspended), and use the settings in the sections that follow.

(1) Module-stop function

Writing 1 to the MSTPCRA.MSTPA22 bit enables the module-stop function of the DMAC. If a DMA transfer is in progress when 1 is written to the MSTPA22 bit, the transition to the module-stop state proceeds after the DMA transfer ends. Access to the DMAC registers is prohibited while the MSTPA22 bit is 1. Writing 0 to the MSTPA22 bit releases the DMAC from the module-stop state.

(2) Software Standby mode and Deep Software Standby mode

Use the settings described in section 10.7.1. Transitioning to Software Standby Mode, or in section 10.9.1. Transitioning to Deep Software Standby Mode .

If DMA transfer operations are in progress when the WFI instruction is executed, the DMA transfer completes before the transition to Software Standby mode or Deep Software Standby mode.

(3) Notes on low power consumption function

For information on the WFI instruction and register settings, see section 10.10.7. Timing of WFI Instruction.

To perform a DMA transfer after returning from a low power consumption mode, set the DMAST.DMST bit to 1 again. To use a request that is generated in Software Standby mode as an interrupt request to the CPU but not as a DMAC startup request, specify the CPU as the interrupt request destination, as described in section 13.4.1. Detecting Interrupts, and then execute the WFI instruction.

16.9 Usage Notes

16.9.1 Access to the Registers during DMA Transfer

Do not write to the following registers while the DMSTS.ACT flag of the same channel is set to 1 (DMAC active state) or the DMCNT.DTE bit of the same channel is set to 1 (DMA transfer enabled):

- DMSAR
- DMDAR
- DMCRA
- DMCRB
- DMTMD
- DMINT
- DMAMD
- DMOFR
- DMSBS
- DMDBS
- DMSRR

请注意，如果在写入传输的最后一个数据时发生总线错误，则会发生传输结束事件和错误响应检测中断（DMA_TRANSERR）。

16.7 活动链接

每个DMAC通道在每次完成数据传输或块传输模式下的块传输时都会输出一个事件链接请求信号(DMACn_INT)。

有关详细信息，请参阅第18节，事件链接控制器(ELC)。

如果在写入传输的最后一个数据时发生总线错误，则会发生传输结束事件和错误响应检测中断(DMA_TRANSERR)。

16.8 低功耗功能

在进入模块停止状态或软件待机模式或深度软件待机模式之前，您必须先设置DMAST.DMST位为0（DMAC模块挂起），并使用以下部分中的设置。

(1) Module-stop function

向MSTPCRA.MSTPA22位写入1可启用DMAC的模块停止功能。如果在向MSTPA22位写入1时正在进行DMA传输，则在DMA传输结束后继续转换到模块停止状态。当MSTPA22位为1时，禁止访问DMAC寄存器。将0写入MSTPA22位可将DMAC从模块停止状态释放。

(2) 软件待机模式和深度软件待机模式

使用第10.7.1节中描述的设置。转换到软件待机模式，或在第10.9.1节中。过渡到深度软件待机模式。

如果在执行WFI指令时DMA传输操作正在进行，则DMA传输在转换到软件待机模式或深度软件待机模式之前完成。

(3) 低功耗功能注意事项

有关WFI指令和寄存器设置的信息，请参阅第10.10.7节。WFI指令的时间安排。

要在从低功耗模式返回后执行DMA传输，请将DMAST.DMST位再次设置为1。要将在软件待机模式下生成的请求用作对CPU的中断请求但不用作DMAC启动请求，请将CPU指定为中断请求目标，如第13.4.1节所述。检测中断，然后执行WFI指令。

16.9 使用说明

16.9.1 在DMA传输期间访问寄存器

当同一通道的DMSTS.ACT标志设置为1（DMAC活动状态）或同一通道的DMCNT.DTE位设置为1（启用DMA传输）时，请勿写入以下寄存器：

- DMSAR
- DMDAR
- DMCRA
- DMCRB
- DMTMD
- DMINT
- DMAMD
- DMOFR
- DMSBS
- DMDBS
- DMSRR

- DMDRR
- ICUSARC

16.9.2 DMA Transfer to Reserved Areas

DMA transfer to the reserved areas is prohibited. If such an access is made, transfer results are not guaranteed. For details on the reserved areas, see section 4, Address Space.

16.9.3 Setting of DMAC Event Link Setting Register of the Interrupt Controller Unit (ICU.DELSRn n = 0 to 7)

The DMAC event link setting register (ICU.DELSRn) should be set while the DMA transfer enable bit (DMCNT.DTE) is cleared to 0 (DMA transfer is disabled). Moreover, the DTC activation enable register (ICU.IELSRn.DTCE (n = 0 to 95)) that corresponds to the same event number that has been set by the ICU.DELSRn register should not be set to 1. For details on the ICU.IELSRn.DTCE and ICU.DELSRn, see section 13, Interrupt Controller Unit (ICU).

16.9.4 Suspending or Restarting DMAC Activation

To suspend a DMAC activation request, write 0x00 to the DMAC Event Link select bits (ICU.DELSRn.DELS[8:0]). To restart the DMA transfer, write the event number to the ICU.DELSRn.DELS[8:0] bits following the settings shown in section 16.3.10. Activating the DMAC.

16.9.5 Precautions for Resuming DMA Transfer

A DMAC activation request might occur in the next request after a DMA transfer completes. If this happens, the DMA transfer starts and the DMAC activation request is held in the DMAC. To prevent this, stop the DMAC activation requests by setting the DELSRn.DELS[8:0] bits in the ICU to 0.

When a DMAC activation request occurs after the last round of the DMA transfer is generated, clear the DMAC activation request with either of the following approaches.

- Clear the DMAC activation request with a DMA dummy transfer.
- Set the DMCNT.DTE bit to 0 and then set the ICU.DELSRn.IR flag to 0.

See Figure 16.35.

16.9.2 DMA传输到保留区域

禁止对保留区域进行DMA传输。如果进行此类访问，则无法保证传输结果。有关保留区域的详细信息，请参阅第4节，地址空间。

16.9.3 中断控制器单元的DMAC事件链接设置寄存器的设置(ICU.DELSRnn=0到7)

DMAC事件链接设置寄存器(ICU.DELSRn)应在DMA传输启用位(DMCNT.DTE)清除为0（禁用DMA传输）时设置。此外，与ICU.DELSRn寄存器设置的相同事件编号对应的DTC激活使能寄存器(ICU.IELSRn.DTCE(n=0至95))不应设置为1。有关ICU的详细信息.IELSRn.DTCE和ICU.DELSRn，请参见第13节，中断控制器单元(ICU)。

16.9.4 暂停或重新启动DMAC激活

要暂停DMAC激活请求，请将0x00写入DMAC事件链接选择位(ICU.DELSRn.DELS[8:0])。要重新启动DMA传输，请按照第16.3.10节中所示的设置将事件编号写入ICU.DELSRn.DELS[8:0]位。激活DMAC。

16.9.5 恢复DMA传输的注意事项

DMA传输完成后的下一个请求中可能会出现DMAC激活请求。如果发生这种情况，DMA传输开始并且DMAC激活请求被保存在DMAC中。为防止这种情况，请通过将ICU中的DELSRn.DELS[8:0]位设置为0来停止DMAC激活请求。

当最后一轮DMA传输生成后出现DMAC激活请求时，可通过以下任一方法清除DMAC激活请求。

●使用DMA虚拟传输清除DMAC激活请求。
●将DMCNT.DTE位设置为0，然后将ICU.DELSRn.IR标志设置为0。

请参见图16.35。

17.2 Register Descriptions

MRA, MRB, SAR, DAR, CRA, and CRB are all DTC internal registers that cannot be directly accessed from the CPU. Values to be set in these DTC internal registers are placed in the SRAM area as transfer information. When an activation request is generated, the DTC reads the transfer information from the SRAM area and sets it in its internal registers. After the data transfer ends, the internal register contents are written back to the SRAM area as transfer information.

请参见第13.1节。第13节，中断控制器单元(ICU)中的概述，用于CPU中的DTC和NVIC之间的连接。

17.2 注册说明

MRA、MRB、SAR、DAR、CRA、CRB都是DTC内部寄存器，不能直接从CPU访问。在这些DTC内部寄存器中设置的值作为传输信息放置在SRAM区域中。当产生激活请求时，DTC从SRAM区域读取传输信息并将其设置在其内部寄存器中。数据传输结束后，内部寄存器内容作为传输信息回写到SRAM区域。

CHNE位（DTC链传输使能）

CHNE位启用链式传输。链传输条件由CHNS位选择。有关链式转移的详细信息，请参阅第17.4.6节。链转移。

Bit	Symbol	Function	R/W
7:0	CRAL	Transfer Counter A Lower Register Specify the transfer count.	—
15:8	CRAH	Transfer Counter A Upper Register Specify the transfer count.	—

Note: The function depends on the transfer mode.
Note: Set CRAH and CRAL to the same value in repeat transfer mode and block transfer mode.

The CRA register consists of 16 bits. CRAL is the lower 8 bits and CRAH is the upper 8 bits. CRA is used in normal mode.

CRAL and CRAH are used in repeat transfer mode and block transfer mode.

The CRA register cannot be accessed directly from the CPU. However, the CPU can access the SRAM area (transfer information (n) start address + 0x0E) and DTC transfers it automatically to and from the CRA register. See section 17.3.1. Allocating Transfer Information and DTC Vector Table.

(1) Normal transfer mode (MRA.MD[1:0] = 00b)

In normal transfer mode, CRA functions as a 16-bit transfer counter. The transfer count is 1, 65535, and 65536 when the set value is 0x0001, 0xFFFF, and 0x0000, respectively. The CRA value is decremented (-1) on each data transfer.

(2) Repeat transfer mode (MRA.MD[1:0] = 01b)

In repeat transfer mode, the CRAH register holds the transfer count and the CRAL register functions as an 8-bit transfer counter. The transfer count is 1, 255, and 256 when the set value is 0x01, 0xFF, and 0x00, respectively. The CRAL value is decremented (-1) on each data transfer. When it reaches 0x00, the CRAH value is transferred to CRAL.

(3) Block transfer mode (MRA.MD[1:0] = 10b)

In block transfer mode, the CRAH register holds the block size and the CRAL register functions as an 8-bit block size counter. The transfer count is 1, 255, and 256 when the set value is 0x01, 0xFF, and 0x00, respectively. The CRAL value is decremented (-1) on each data transfer. When it reaches 0x00, the CRAH value is transferred to CRAL.

Offset address: 0x0C + 0x4 × Vector number
(Inaccessible directly from the CPU. See section 17.3.1. Allocating Transfer Information and DTC Vector Table)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

The CRB sets the block transfer count for block transfer mode. The transfer count is 1, 65535, and 65536 when the set value is 0x0001, 0xFFFF, and 0x0000, respectively. The CRB value is decremented (-1) when the final data of a single block size is transferred. When normal transfer mode or repeat transfer mode is selected, this register is not used and the set value is ignored.

15:8	CRAH	传送计数器A高位寄存器 指定传输计数。	—

Note: 该功能取决于传输模式。
Note: 在重复传输模式和块传输模式下，将CRAH和CRAL设置为相同的值。

CRA寄存器由16位组成。CRAL是低8位，CRAH是高8位。CRA在正常模式下使用。

CRAL和CRAH用于重复传输模式和块传输模式。

CRA寄存器不能直接从CPU访问。但是，CPU可以访问SRAM区域（传输信息(n)起始地址+0x0E），DTC会自动将其传输到CRA寄存器或从CRA寄存器传输。请参阅第17.3.1节。分配传输信息和DTC向量表。

(1) 正常传输模式（MRA.MD[1:0]=00b）

在正常传输模式下，CRA用作16位传输计数器。当设置值为0x0001、0xFFFF和0x0000时，传输计数分别为1、65535和65536。CRA值在每次数据传输时递减(-1)。

(2) 重复传输模式(MRA.MD[1:0]=01b)

在重复传输模式下，CRAH寄存器保存传输计数，CRAL寄存器用作8位传输计数器。当设置值为0x01、0xFF和0x00时，传输计数分别为1、255和256。CRAL值在每次数据传输时递减(-1)。当它达到0x00时，CRAH值被传送到CRAL。

(3) 块传输模式（MRA.MD[1:0]=10b）

在块传输模式下，CRAH寄存器保存块大小，CRAL寄存器用作8位块大小计数器。当设置值为0x01、0xFF和0x00时，传输计数分别为1、255和256。CRAL值在每次数据传输时递减(-1)。当它达到0x00时，CRAH值被传送到CRAL。

The CRB cannot be accessed directly from the CPU. However, the CPU can access the SRAM area (transfer information (n) start address + 0x0C) and DTC transfers it automatically to and from the CRB register. See section 17.3.1. Allocating Transfer Information and DTC Vector Table.

17.2.8 DTCCR : DTC Control Register

7:5	—	These bits are read as 0. The write value should be 0.	R/W

RRS bit (DTC Transfer Information Read Skip Enable)

The RRS bit enables skipping of transfer information reads when vector numbers match. The DTC vector number is compared with the vector number in the previous activation process. When these vector numbers match and the RRS bit is set to 1, DTC data transfer is performed without reading the transfer information. However, when the previous transfer is a chain transfer, the transfer information is read regardless of the RRS bit.

When the transfer counter (CRA register) becomes 0 during the previous normal transfer and when the transfer counter (CRB register) becomes 0 during the previous block transfer, the transfer information is read regardless of the RRS bit value.

DTCST must be set to 0 before transitioning to one of the following state or mode:

17.3 Activation Sources

The DTC is activated by an interrupt request. Setting the ICU.IELSRn.DTCE bit to 1 enables activation of the DTC by the associated interrupt. The selector output *n* number set in ICU.IELSRn is defined as the interrupt vector number, where n = 0 to 95. For an enabled interrupt, the specific DTC interrupt source associated with each interrupt vector number *n* is selected in ICU.IELSRn.IELS[8:0] where n = 0 to 95, as listed in section 13.3.2. Event Number in section 13, Interrupt Controller Unit (ICU). For activation by software, see section 18.2.2. ELSEGRn : Event Link Software Event Generation Register n (n = 0, 1).

The interrupt vector number is equivalent to the DTC vector table number. After the DTC accepted an activation request, it does not accept another activation request until transfer for that single request is complete, regardless of the priority of the requests. When multiple activation requests are generated during a DTC transfer, a highest priority request is accepted on completion of the transfer. When multiple activation requests are generated while the DTC Module Start bit (DTCST.DTCST) is 0, the DTC accepts the highest priority request when DTCST.DTCST is subsequently set to 1. The smaller interrupt vector number has higher priority.

The DTC performs the following operations at the start of a single data transfer or for a chain transfer, after the last of the consecutive transfers:

- On completion of a specified round of data transfer, the ICU.IELSRn.DTCE bit is set to 0, and an interrupt request is sent to the CPU
- If the MRB.DISEL bit is 1, an interrupt request is sent to the CPU on completion of a data transfer
- For other transfers, the ICU.IELSRn.IR flag of the activation source is set to 0 at the start of the data transfer.

17.3.1 Allocating Transfer Information and DTC Vector Table

The DTC reads the start address of the transfer information associated with each activation source from the vector table and reads the transfer information starting at that address.

DTC has two vector tables, non-secure side or secure side. Because the interrupt vector number that serves as a trigger for DTC is divided into non-secure or secure. Place the vector table of the interrupt vector number of SA = 1 in DTCVBR which is the non-secure side. Place the vector table of interrupt number SA = 0 in DTCVBR_SEC which is the secure side.

The vector table must be located so that the lower 10 bits of the base address (start address) are 0. Use the DTC Vector Base Register (DTCVBR) to set the base address of the DTC vector table. Transfer information is allocated in the SRAM area. In the SRAM area, the start address of the transfer information *n* with vector number *n* must be 4n added to the base address in the vector table.

Figure 17.2 shows the relationship between the DTC vector table and transfer information. Figure 17.3 shows the allocation of transfer information in the SRAM area.

将0写入DTESTA将被忽略。

Note: 当DTEVSAM=1时，可以在安全状态和非安全状态下清零。DTEVSAM=0，在非安全状态下不能清零。

17.3 激活源

DTC由中断请求激活。将ICU.IELSRn.DTCE位设置为1可以通过相关中断激活DTC。ICU.IELSRn中设置的选择器输出n个数被定义为中断向量号，其中n=0到95。对于一个使能的中断，在ICU.IELSRn.IELS中选择与每个中断向量号n相关的特定DTC中断源[8:0]其中n=0到95，如第13.3.2节中所列。第13节，中断控制器单元(ICU)中的事件编号。关于通过软件激活，请参见第18.2.2节。ELSEGRn：事件链接软件事件生成寄存器n(n=0 1)。

中断向量编号相当于DTC向量表编号。在DTC接受激活请求后，它不会接受另一个激活请求，直到该单个请求的传输完成，无论请求的优先级如何。如果在DTC传输期间生成多个激活请求，则在传输完成时接受最高优先级的请求。当DTC模块起始位(DTCST.DTCST)为0时产生多个激活请求时，当DTCST.DTCST随后设置为1时，DTC接受最高优先级请求。较小的中断向量编号具有较高的优先级。

DTC在单次数据传输开始时执行以下操作，或者对于链式传输，在最后一次连续传输之后执行以下操作：

●完成指定轮次的数据传输后，ICU.IELSRn.DTCE位设置为0，并向CPU发送中断请求

●如果MRB.DISEL位为1，则在数据传输完成时向CPU发送中断请求

●对于其他传输，激活源的ICU.IELSRn.IR标志在数据传输开始时设置为0。

17.3.1 分配传输信息和DTC向量表

DTC从向量表中读取与每个激活源相关联的传输信息的起始地址，并读取从该地址开始的传输信息。

DTC有两个向量表，非安全端或安全端。因为作为DTC触发的中断向量号分为非安全和安全。将SA=1的中断向量号的向量表放在非安全端DTCVBR中。将中断号SA=0的向量表放在安全侧DTCVBR_SEC中。

向量表的定位必须使基地址（起始地址）的低10位为0。使用DTC向量基址寄存器(DTCVBR)设置DTC向量表的基地址。传输信息分配在SRAM区域中。在SRAM区域中，向量编号为n的传输信息n的起始地址必须与向量表中的基地址相加4n。

图17.2显示了DTC向量表和传输信息之间的关系。图17.3显示了SRAM区域中传输信息的分配。

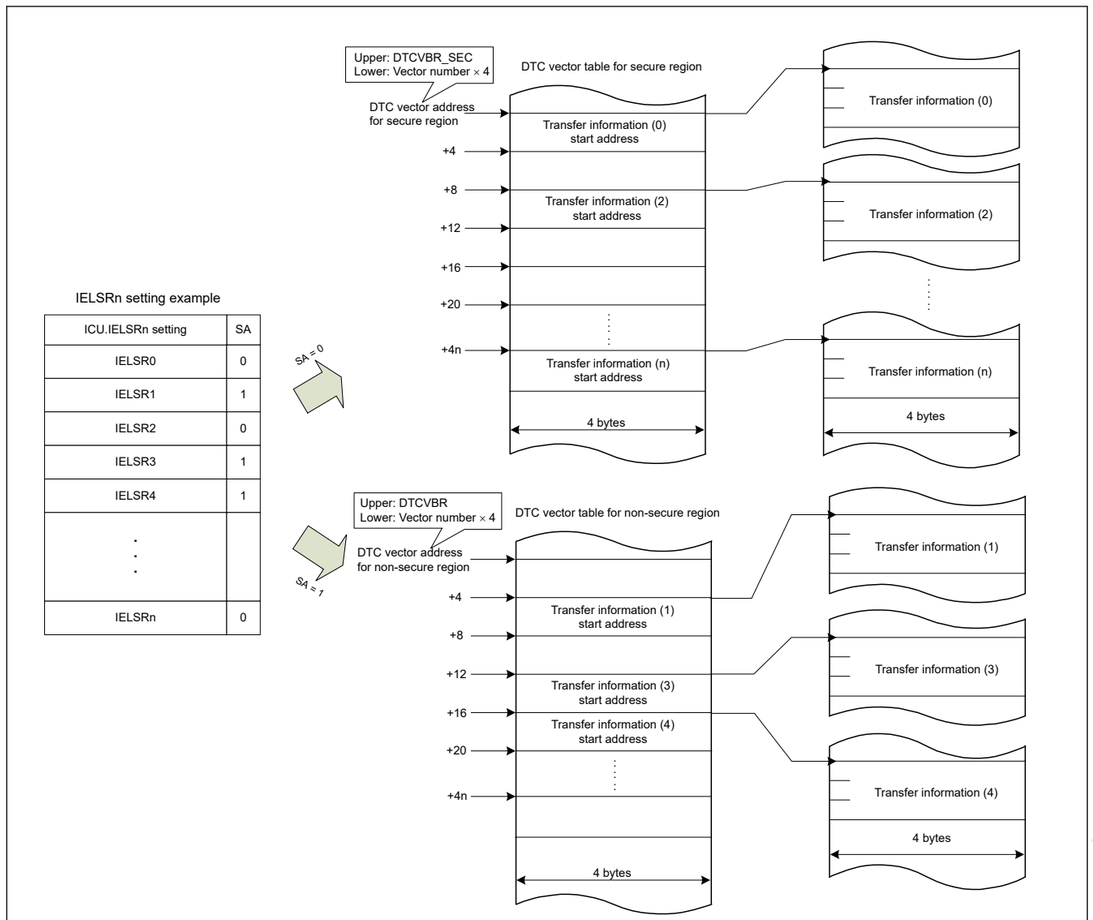

Figure 17.2 DTC vector table and transfer information

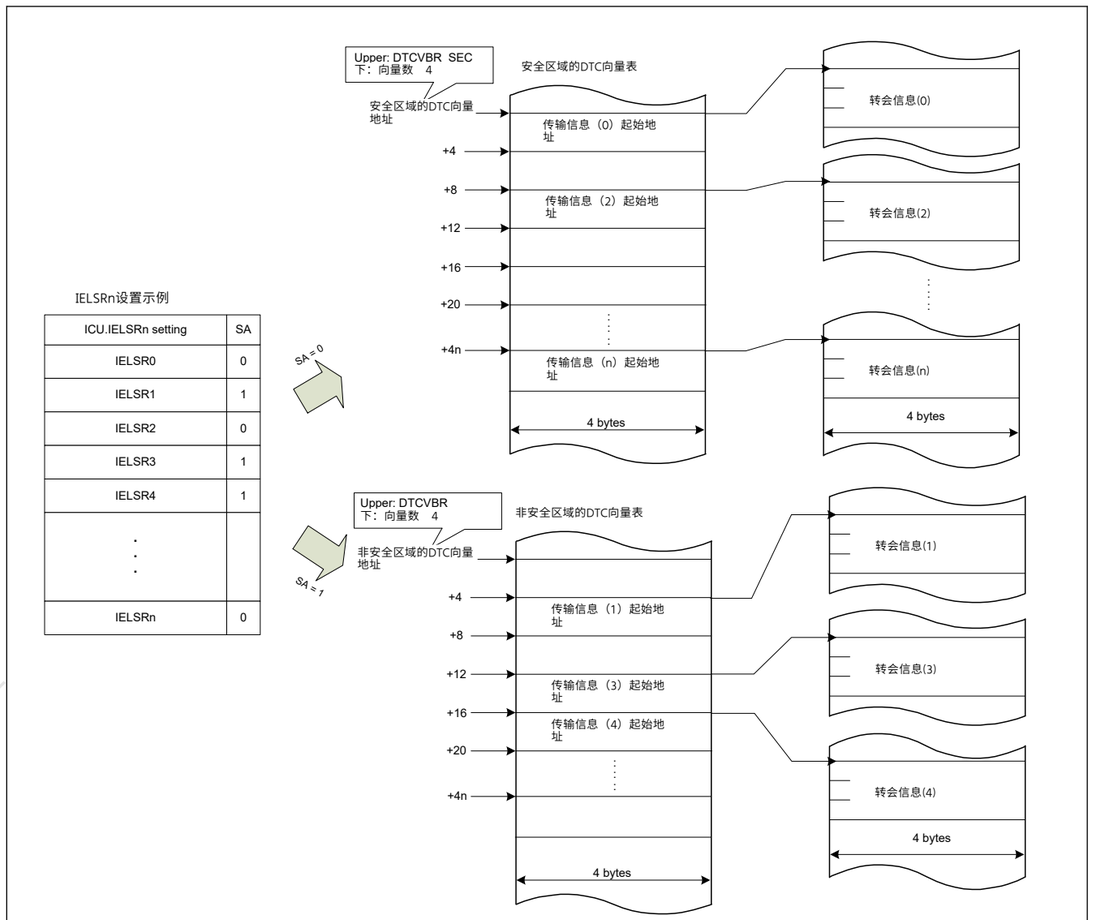

Figure 17.2 DTC向量表和传输信息

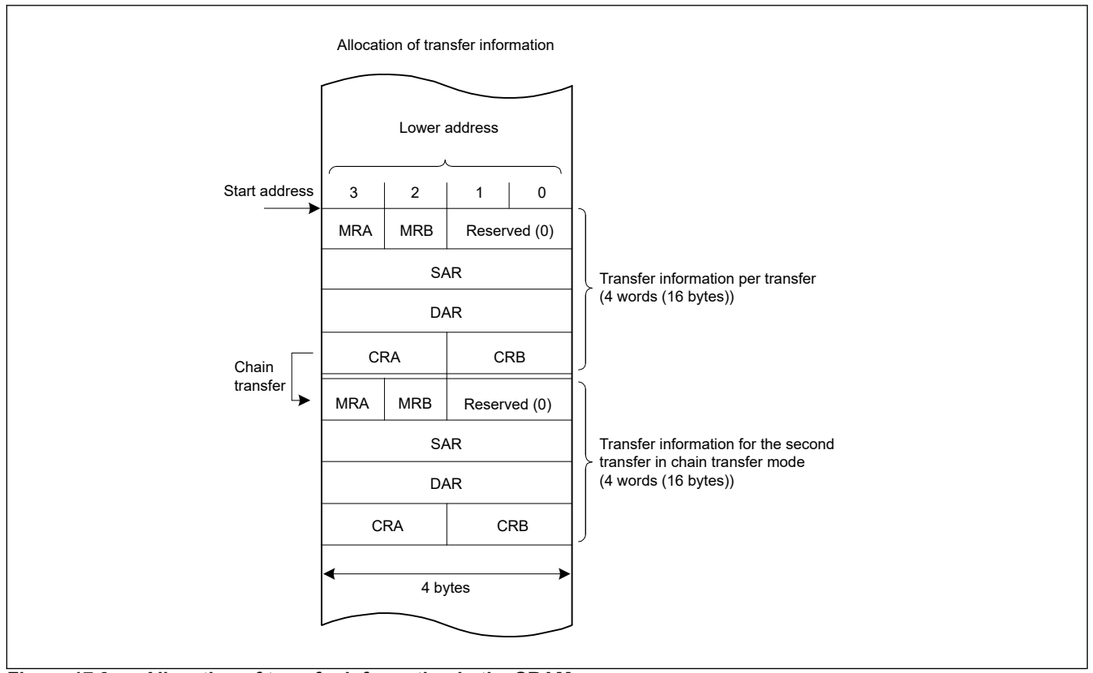

Figure 17.3 Allocation of transfer information in the SRAM area

17.4 Operation

The DTC transfers data according to the transfer information. Storage of the transfer information in the SRAM area is required before a DTC operation. When the DTC is activated, it reads the DTC vector associated with the vector number. The DTC reads the transfer information from the transfer information store address referenced by the DTC vector and transfers the data. After the data transfer, the DTC writes back the transfer information. Storing the transfer information in the SRAM area allows data transfer of any number of channels.

The transfer modes include:

- Normal transfer mode
- Repeat transfer mode
- Block transfer mode.

The DTC specifies a transfer source address in the SAR register and a transfer destination address in the DAR register. The values of these registers are incremented, decremented, or address-fixed independently after the data transfer.

Table 17.2 describes the DTC transfer modes.

Table 17.2 DTC transfer modes

Transfer mode	Data size transferred on single transfer request	Increment or decrement of memory address	Settable transfer count
Normal transfer mode	1 byte (8 bit), 1 halfword (16 bit), 1 word (32 bit)	Incremented or decremented by 1, 2, or 4 or address fixed	1 to 65536
Repeat transfer mode*1	1 byte (8 bit), 1 halfword (16 bit), 1 word (32 bit)	Incremented or decremented by 1, 2, or 4 or address fixed	1 to 256*3
Block transfer mode*2	Block size specified in CRAH (1 to 256 bytes, 1 to 256 halfwords (2 to 512 bytes), or 1 to 256 words (4 to 1024 bytes))	Incremented or decremented by 1, 2, or 4 or address fixed	1 to 65536

Note 1. Set the transfer source or transfer destination as the repeat area.
Note 2. Set the transfer source or transfer destination as the block area.

17.4 Operation

DTC根据传输信息传输数据。在进行DTC操作之前，需要在SRAM区域中存储传输信息。当DTC被激活时，它会读取与向量编号相关联的DTC向量。DTC从DTC向量引用的传输信息存储地址中读取传输信息并传输数据。数据传输后，DTC写回传输信息。将传输信息存储在SRAM区域中可以实现任意数量的通道的数据传输。

传输模式包括：

- ●普通传输模式
- ●重复传输模式
- ●块传输模式。

DTC指定SAR寄存器中的传输源地址和DAR寄存器中的传输目标地址。这些寄存器的值在数据传输后独立地递增、递减或固定地址。

表17.2描述了DTC传输模式。

Table 17.2 DTC传输模式

传输模式	在单个传输请求上传输的数据大小	内存地址的递增或递减	可设置的传输次数
正常传输模式	1个字节（8位）、1个半字（16位）、1个字（32位）	递增或递减1、2或4或固定地址	1 to 65536
重复传输模式*1	1个字节（8位）、1个半字（16位）、1个字（32位）	递增或递减1、2或4或固定地址	1 to 256*3

Note 3. After a data transfer of the specified count, the initial state is restored and operation restarts.

Setting the MRB.CHNE bit to 1 allows multiple transfers or chain transfer on a single activation source. It also enables a chain transfer when the specified data transfer is complete.

将MRB.CHNE位设置为1允许在单个激活源上进行多次传输或链式传输。当指定的数据传输完成时，它还启用链式传输。

Note 1. The transfer counter used depends on the transfer modes as follows:
Normal transfer mode — CRA register
Repeat transfer mode — CRAL register
Block transfer mode — CRB register

Note 2. On completion of a data transfer, the counters operate as follows:
1 → 0 in normal and block transfer modes
1 → CRAH in repeat transfer mode
(1 → *) in the table indicates both of these two operations, depending on the mode.

Note 3. Chain transfer can be selected for the second or subsequent transfers. The conditions for the combination of the second transfer and CHNE = 1 is omitted.

17.4.1 Transfer Information Read Skip Function

Reading of vector addresses and transfer information can be skipped by setting the DTCCR.RRS bit. When a DTC activation request is generated, the current DTC vector number is compared with the DTC vector number in the previous activation process. When these vector numbers match and the RRS bit is set to 1, the DTC data transfer is performed without reading the vector address and transfer information. However, when the previous transfer is a chain transfer, the vector address and transfer information are read. Additionally, when the transfer counter (CRA register) becomes 0 during the previous normal transfer, and when the transfer counter (CRB register) becomes 0 during the previous block transfer, transfer information is read regardless of the RRS bit. Figure 17.12 shows an example of a transfer information read skip.

To update the vector table and transfer information, set the RRS bit to 0, update the vector table and transfer information, then set the RRS bit to 1. The stored vector number is discarded by setting the RRS bit to 0. The updated DTC vector table and transfer information are read in the next activation process.

17.4.2 Transfer Information Write-Back Skip Function

When the MRA.SM[1:0] bits or the MRB.DM[1:0] bits are set to address fixed, a part of the transfer information is not written back. Table 17.4 lists the transfer information write-back skip conditions and the associated registers. The CRA and CRB registers are written back, and the write-back of the MRA and MRB registers is skipped.

注3.第二次及以后的转账可选择链式转账。省略了二次传输和CHNE=1的组合条件。

17.4.1 传输信息读取跳过功能

通过设置DTCCR.RRS位可以跳过向量地址和传输信息的读取。当产生DTC激活请求时，将当前DTC向量编号与之前激活过程中的DTC向量编号进行比较。当这些向量编号匹配且RRS位设置为1时，执行DTC数据传输而不读取向量地址和传输信息。但是，当上一次传输是链式传输时，会读取向量地址和传输信息。此外，如果在上次正常传输期间传输计数器（CRA寄存器）变为0，并且在前一次块传输期间传输计数器（CRB寄存器）变为0，则无论RRS位如何，都将读取传输信息。图17.12显示了传输信息读取跳过的示例。

要更新向量表和传输信息，请将RRS位设置为0，更新向量表和传输信息，然后将RRS位设置为1。通过将RRS位设置为0，丢弃存储的向量编号。更新的DTC向量在下一个激活过程中读取表和传输信息。

17.4.2 传输信息回写跳过功能

当MRA.SM[1:0]位或MRB.DM[1:0]位设置为地址固定时，部分传输信息不会被写回。表17.4列出了传输信息回写跳过条件和相关寄存器。回写CRA和CRB寄存器，跳过回写MRA和MRB寄存器。

17.4.3 Normal Transfer Mode

The normal transfer mode allows a 1-byte (8 bit), 1-halfword (16 bit), 1-word (32 bit) data transfer on a single activation source. The transfer count can be set to 1 to 65536. Transfer source and destination addresses can be independently set to increment, decrement, or fixed. This mode enables an interrupt request to the CPU to be generated at the end of a specified-count transfer.

Table 17.5 lists register functions in normal transfer mode, and Figure 17.5 shows the memory map of normal transfer mode.

17.4.3 正常传输模式

正常传输模式允许在单个激活源上传输1字节（8位）、1半字（16位）、1字（32位）数据。传输计数可以设置为1到65536。传输源地址和目标地址可以独立设置为递增、递减或固定。此模式允许在指定计数传输结束时向CPU生成中断请求。

17.4.4 Repeat Transfer Mode

The repeat transfer mode allows a 1-byte (8-bit), 1-halfword (16-bit), or 1-word (32-bit) data transfer on a single activation source. Transfer source or transfer destination for the repeat area must be specified in the MRB.DTS bit. The transfer count can be set from 1 to 256. When the specified transfer count is complete, the initial value of the address register specified in the repeat area is restored, the initial value of the transfer counter is restored, and transfer is repeated. The other address register is incremented or decremented continuously or remains unchanged.

When the transfer counter CRAL decrements to 0x00 in repeat transfer mode, the CRAL value is updated to the value set in the CRAH register. As a result, the transfer counter does not clear to 0x00, which disables interrupt requests to the CPU when the MRB.DISEL bit is set to 0. An interrupt request to the CPU is generated when the specified data transfer completes.

Table 17.6 lists the register functions in repeat transfer mode, and Figure 17.6 shows the memory map of repeat transfer mode.

17.4.4 重复传输模式

重复传输模式允许在单个激活源上传输1字节（8位）、1半字（16位）或1字（32位）数据。重复区域的传输源或传输目标必须在MRB.DTS位中指定。传输计数可设置为1到256。当指定的传输计数完成时，将恢复重复区域中指定的地址寄存器的初始值，恢复传输计数器的初始值，并重复传输。另一个地址寄存器连续递增或递减或保持不变。

当传输计数器CRAL在重复传输模式下递减到0x00时，CRAL值将更新为CRAH寄存器中设置的值。因此，传输计数器不会清为0x00，这会在MRB.DISEL位设置为0时禁用对CPU的中断请求。当指定的数据传输完成时，会向CPU发出中断请求。

表17.6列出了重复传输模式下的寄存器功能，图17.6显示了重复传输模式的内存映射。

17.4.5 Block Transfer Mode

The block transfer mode allows single-block data transfer on a single activation source. Transfer source or transfer destination for the block area must be specified in the MRB.DTS bit. The block size can be set from 1 to 256 bytes, 1 to 256 halfwords (2 to 512 bytes), or 1 to 256 words (4 to 1024 bytes). When transfer of the specified block completes, the initial values of the block size counter CRAL and the address register (the SAR register when the MRB.DTS = 1 or the DAR register when the DTS = 0) specified in the block area are restored. The other address register is incremented or decremented continuously or remains unchanged.

The transfer count (block count) can be set from 1 to 65536. This mode enables an interrupt request to the CPU to be generated at the end of the specified-count block transfer.

Table 17.7 lists the register functions in block transfer mode, and Figure 17.7 shows the memory map for block transfer mode.

Table 17.7 Register functions in block transfer mode

Register	Description	Value written back by writing transfer information
SAR	Transfer source address	• When MRB.DTS bit is 0 Increment, decrement, or fixed*1 • When MRB.DTS bit is 1 SAR register initial value.

17.4.5 块传输模式

块传输模式允许在单个激活源上进行单块数据传输。块区域的传输源或传输目标必须在MRB.DTS位中指定。块大小可以设置为1到256字节、1到256个半字（2到512字节）或1到256字（4到1024字节）。当指定块的传送完成时，块区域中指定的块大小计数器CRAL和地址寄存器（MRB.DTS=1时为SAR寄存器或DTS=0时为DAR寄存器）的初始值被恢复。另一个地址寄存器连续递增或递减或保持不变。

传输计数（块计数）可设置为1到65536。此模式允许在指定计数块传输结束时向CPU生成中断请求。

表17.7列出了块传输模式下的寄存器功能，图17.7显示了块传输模式下的存储器映射。

17.4.6 Chain Transfer

Setting the MRB.CHNE bit to 1 allows chain transfer to be performed continuously on a single activation source. If the MRB.CHNE is set to 1 and CHNS to 0, an interrupt request to the CPU is not generated on completion of the specified number of rounds of transfer or by setting the MRB.DISEL bit to 1. An interrupt request is sent to the CPU each time DTC data transfer is performed. Data transfer has no effect on the ICU.IELSRn.IR flag of the activation source.

The SAR, DAR, CRA, CRB, MRA, and MRB registers can be set independently of each other to define the data transfer. Figure 17.8 shows a chain transfer operation.

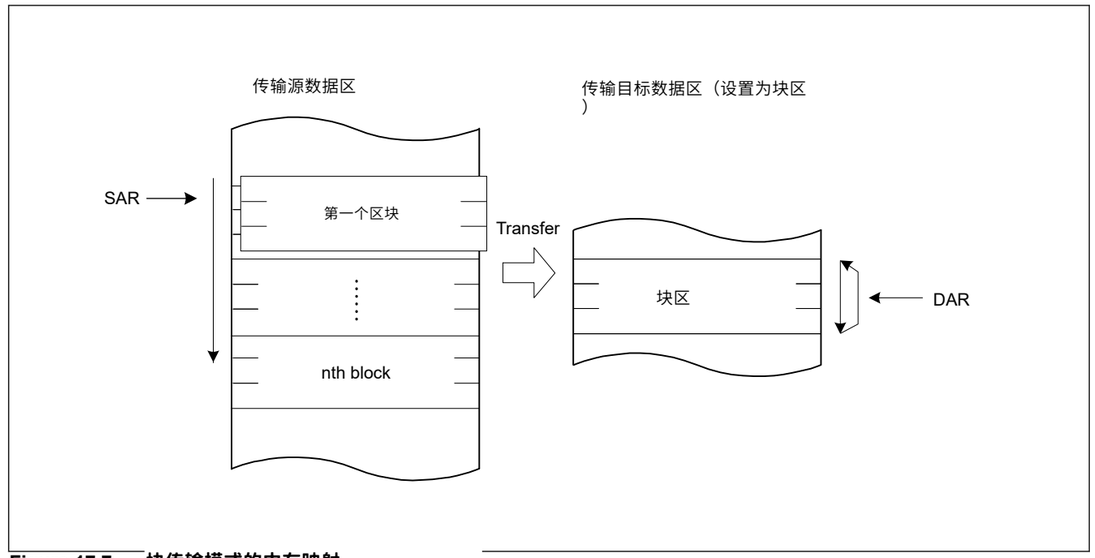

Figure 17.7 块传输模式的内存映射

17.4.6 链转移

将MRB.CHNE位设置为1允许在单个激活源上连续执行链传输。如果MRB.CHNE设置为1，CHNS设置为0，则在完成指定的传输轮数或将MRB.DISEL位设置为1时不会向CPU产生中断请求。中断请求被发送到每次执行DTC数据传输时CPU。数据传输对激活源的ICU.IELSRn.IR标志没有影响。

SAR、DAR、CRA、CRB、MRA和MRB寄存器可以相互独立设置以定义数据传输。

Writing 1 to the MRB.CHNE and CHNS bits enables chain transfer to be performed only after completion of the specified data transfer. In repeat transfer mode, chain transfer is performed after completion of the specified data transfer. For details on chain transfer conditions, see Table 17.2.

P: Block size (initial settings of CRAH and CRAL)
Cv: Cycles for access to vector transfer information storage destination
Ci: Cycles for access to transfer information storage destination address
Cr: Cycles for access to data read destination
Cw: Cycles for access to data write destination
The unit is for system clocks (ICLK) + 1 in the Vector read, Transfer information read, and Data transfer read columns and 2 in the Internal operation column.
Cv, Ci, Cr, and Cw vary depending on the corresponding access destination. For the number of cycles for respective access destinations, see section 38, SRAM, section 40, Flash Memory, and section 14, Buses.
The frequency ratio of the system clock and peripheral clock is also taken into consideration.
The DTC response time is the time from when the DTC activation source is detected until DTC transfer starts.
Table 17.8 does not include the time until DTC data transfer starts after the DTC activation source becomes active.

17.4.9 DTC Bus Mastership Release Timing

The DTC does not release the bus mastership during transfer information reads. Before the transfer information is read or written, the bus is arbitrated according to the priority determined by the bus master arbitrator. For bus arbitration, see section 14, Buses.

17.4.10 Vector Security

The security attribute of transfer access of DTC vector n and security attribute of access to the IELSRn(n = 0 to 95) register of ICU are controlled by SAIELSRn bit of ICUSARx(x = G,H or I) registers in CPSCU. For details on the CPSCU.ICUSARx registers, see section 13, Interrupt Controller Unit (ICU).

When the CPSCU.ICUSARx.SAIELSRn bit is 0, transfer of DTC vector n is secure access for both read and write. At the same time, the IELSRn register are protected from a non-secure access.

When the CPSCU.ICUSARx.SAIELSRn bit is 1, transfer of DTC vector n is non-secure access for both read and write. At the same time, the IELSRn register are non-secure attributes.

Do not write to the CPSCU.ICUSARx.SAIELSRn bit while DTC transfer is enabled or a bus master is writing to the DTC registers of same channel.

section 17.3.1. Allocating Transfer Information and DTC Vector Table shows security attribute about each DTC vectors.

17.4.11 Master TrustZone Filter in DTC

DTC has the Master TrustZone Filter. The Master TrustZone Filter in DTC can detect the security areas of Flash area(code Flash and data Flash) and SRAM area defined by IDAU. When no-secure accesses those addresses, it detects the security violation. Access of violation address is not performed. Detected the error is handled as the Master TrustZone Filter error.

17.5 DTC Setting Procedure

Before using the DTC, set the DTC Vector Base Register (DTCVBR). Set the ICU.IELSRn.IELS[8:0] bits to 0 to disable the interrupt in the NVIC and follow the procedure in Table 17.9 to set the DTC.

17.4.9 DTC总线主控释放时序

在传输信息读取期间，DTC不会释放总线主控权。在读取或写入传输信息之前，根据总线主仲裁器确定的优先级对总线进行仲裁。对于总线仲裁，请参见第14节，总线。

17.4.10 矢量安全

DTC向量n的传输访问的安全属性和对ICU的IELSRn(n=0到95)寄存器的访问的安全属性由CPSCU中ICUSARx(x=G H或I)寄存器的SAIELSRn位控制。有关CPSCU.ICUSARx寄存器的详细信息，请参见第13节，中断控制器单元(ICU)。

当CPSCU.ICUSARx.SAIELSRn位为0时，DTC向量n的传输对于读和写都是安全访问。同时，保护IELSRn寄存器免受非安全访问。

当CPSCU.ICUSARx.SAIELSRn位为1时，DTC向量n的传输对于读取和写入都是非安全访问。同时，IELSRn寄存器是非安全属性。

当DTC传输使能或总线主机正在写入同一通道的DTC寄存器时，请勿写入CPSCU.ICUSARx.SAIELSRn位。

第17.3.1节。分配传输信息和DTC向量表显示每个DTC向量的安全属性。

17.4.11 DTC中的主TrustZone过滤器

DTC具有MasterTrustZone过滤器。DTC中的MasterTrustZoneFilter可以检测IDAU定义的Flash区域（代码Flash和数据Flash）和SRAM区域的安全区域。当no-secure访问这些地址时，它会检测到安全违规。不执行违规地址的访问。检测到的错误作为MasterTrustZoneFilter错误处理。

17.5 DTC设置程序

在使用DTC之前，请设置DTC向量基址寄存器(DTCVBR)。将ICU.IELSRn.IELS[8:0]位设置为0以禁用NVIC中的中断，并按照表17.9中的程序设置DTC。

2	Set transfer information (MRA, MRB, SAR, DAR, CRA, and CRB)	Allocate transfer information (MRA, MRB, SAR, DAR, CRA, and CRB) in the data area. To set transfer information, see section 17.2. 6	Set the enable bit for an activation source interrupt	Set the enable bit for the activation source interrupts to 1. When a source interrupt is generated, the DTC is activated. To set the interrupt source enable bit, see the settings for the modules that are to be the activation sources.
7	Set the DTCST.DTCST bit to 1	Set the DTC Module Start bit (DTCST.DTCST) to 1.

Note: The DTCST.DTCST bit can be set even if the setting for each activation source is not completed.
Note: When used in non-secure state, DTCSAR.DTCSTSA = 1 or DTCST.DTCST = 1 must be set.
Note 1. When used in secure state, access DTCCR_SEC instead of DTCCR.

17.6 Examples of DTC Usage

17.6.1 Normal Transfer

This section provides an example of DTC usage and its application when receiving 128 bytes of data from an SCI.

(1) Transfer information settings

In the MRA register, select a fixed source address (MRA.SM[1:0] = 00b), normal transfer mode (MRA.MD[1:0] = 00b), and byte-sized transfer (MRA.SZ[1:0] = 00b). In the MRB register, specify incrementation of the destination address (MRB.DM[1:0] = 10b) and single data transfer by a single interrupt (MRB.CHNE = 0 and MRB.DISEL = 0). The MRB.DTS bit can be set to any value. Set the RDR register address of the SCI in the SAR register, the start address of the SRAM area for data storage in the DAR register, and 128 (0x0080) in the CRA register. The CRB register can be set to any value.

(2) DTC vector table settings

The start address of the transfer information for the RXI interrupt is set in the vector table for the DTC.

(3) ICU settings and DTC module activation

Set the ICU.IELSRn.DTCE bit to 1 and set ICU.IELSRn.IELS[8:0] as the SCI interrupt. The interrupt must be enabled in the NVIC. Set the DTCST.DTCST bit to 1.

(4) SCI settings

Enable the SCIn_RXI interrupt by setting the SCR.RIE bit in the SCI to 1. If a reception error occurs during the SCI receive operation, reception stops. To manage this, use settings that allow the CPU to accept receive error interrupts.

注1.在安全状态下使用时，访问DTCCR_SEC而不是DTCCR。

17.6 DTC使用示例

17.6.1 正常转移

本节提供从SCI接收128字节数据时的DTC用法及其应用示例。

(1) 传输信息设置

在MRA寄存器中，选择固定源地址（MRA.SM[1:0]=00b）、正常传输模式（MRA.MD[1:0]=00b）和字节大小传输（MRA.SZ[1:0]=00b)。在MRB寄存器中，指定目标地址的递增(MRB.DM[1:0]=10b)和单个中断的单个数据传输(MRB.CHNE=0和MRB.DISEL=0)。MRB.DTS位可以设置为任何值。在SAR寄存器中设置SCI的RDR寄存器地址，

SRAM区域用于DAR寄存器中的数据存储，以及CRA寄存器中的128(0x0080)。CRB寄存器可以设置为任何值。

(2) DTC向量表设置

RXI中断的传输信息的起始地址在DTC的向量表中设置。

(3) ICU设置和DTC模块激活

将ICU.IELSRn.DTCE位设置为1，并将ICU.IELSRn.IELS[8:0]设置为SCI中断。必须在NVIC中启用中断。将DTCST.DTCST位设置为1。

(4) SCI设置

通过将SCI中的SCR.RIE位设置为1来使能SCIn_RXI中断。如果在SCI接收操作期间发生接收错误，则接收停止。要管理此问题，请使用允许CPU接受接收错误中断的设置。

(5) DTC transfer

Each time a reception of 1 byte by the SCI is complete, an SCIn_RXI interrupt is generated to activate the DTC. The DTC transfers the received byte from the RDR of the SCI to the SRAM, after which the DAR register is incremented and the CRA register is decremented.

(6) Interrupt handling

After 128 rounds of data transfer are complete and the value in the CRA register becomes 0, an SCIn_RXI interrupt request is generated for the CPU. Complete the process in the handling routine for this interrupt.

17.6.2 Chain transfer

This section provides an example of chain transfer by the DTC and describes its use in the output of pulses by the General PWM Timer (GPT). You can use chain transfer to transfer PWM timer compare data and change the period of the PWM timer for the GPT.

For the first of the chain transfers, normal transfer mode is specified for transfer to the GPTm.GTCCRC register (m = 321, 322, 164, 165). For the second transfer, normal transfer mode is specified for transfer to the GPTm.GTCCRE register (m = 321, 322, 164, 165). For the third transfer of the chained transfer, normal transfer mode for transfer to the GPTm.GTPBR register (m = 321, 322, 164, 165) is specified. This is because clearing of the activation source and generation of an interrupt on completion of the specified number of transfers are restricted to the third of the chain transfers, that is, transfer while MRB.CHNE = 0.

The following example shows how to use the counter overflow interrupt with the GPT321.GTPR register as an activating source for the DTC.

(1) First transfer information setting

Set up transfer to the GPT321.GTCCRC register.

1. In the MRA register, select incrementation of the source address (MRA.SM[1:0] = 10b).
2. Set the transfer to normal transfer mode (MRA.MD[1:0] = 00b) and word-sized transfer (MRA.SZ[1:0] = 10b).
3. In the MRB register, select the destination address as fixed (MRB.DM[1:0] = 00b) and set up chain transfer (MRB.CHNE = 1 and MRB.CHNS = 0).
4. Set the SAR register to the first address of the data table.
5. Set the DAR register to the address of the GPT321.GTCCRC register.
6. Set the CRAH and CRAL registers to the size of the data table. The CRB register can be set to any value.

(2) Second transfer information setting

Set up for transfer to the GPT321.GTCCRE register.

1. In the MRA register, select incrementation of the source address (MRA.SM[1:0] = 10b).
2. Set the transfer to normal transfer mode (MRA.MD[1:0] = 00b) and word-sized transfer (MRA.SZ[1:0] = 10b).
3. In the MRB register, select the destination address as fixed (MRB.DM[1:0] = 00b) and set up chain transfer (MRB.CHNE = 1, MRB.CHNS = 0).
4. Set the SAR register to the first address of the data table.
5. Set the DAR register to the address of the GPT321.GTCCRE register.
6. Set the CRAH and CRAL registers to the size of the data table. The CRB register can be set to any value.

(3) Third transfer information set

Set up transfer to the GPT321.GTPBR register.

1. In the MRA register, select incrementation of the source address (MRA.SM[1:0] = 10b).
2. Set the transfer to normal transfer mode (MRA.MD[1:0] = 00b) and word-sized transfer (MRA.SZ[1:0] = 10b).
3. In the MRB register, select the destination address as fixed (MRB.DM[1:0] = 00b) and set up single data transfer per interrupt (MRB.CHNE = 0, MRB.DISEL = 0). The MRB.DTS bit can be set to any value.

(5) DTC transfer

每次SCI完成1个字节的接收，就会产生一个SCIn_RXI中断来激活DTC。DTC将接收到的字节从SCI的RDR传输到SRAM，之后DAR寄存器递增，CRA寄存器递减。

(6) 中断处理

在128轮数据传输完成且CRA寄存器中的值变为0后，向CPU产生SCIn_RXI中断请求。完成该中断处理程序中的处理。

17.6.2 链式转移

本节提供了一个DTC链传输的示例，并描述了它在General输出脉冲中的使用
PWM定时器(GPT)。您可以使用链式传输来传输PWM定时器比较数据并更改GPT的PWM定时器的周期。

对于第一个链传输，指定正常传输模式以传输到GPTm.GTCCRC寄存器（m=321、322、164、165）。对于第二次传输，为传输到GPTm.GTCCRE寄存器（m=321、322、164、165）指定正常传输模式。对于链式传输的第三次传输，指定用于传输到GPTm.GTPBR寄存器（m=321、322、164、165）的正常传输模式。这是因为在完成指定数量的传输时清除激活源和产生中断仅限于链传输的第三个，即在MRB.CHNE=0时传输。

以下示例显示如何使用GPT321.GTPR寄存器的计数器溢出中断作为DTC的激活源。

(1) 首次转账信息设置

设置传输到GPT321.GTCCRC寄存器。

1.在MRA寄存器中，选择源地址的递增(MRA.SM[1:0]=10b)。

2.将传输设置为正常传输模式（MRA.MD[1:0]=00b）和字长传输（MRA.SZ[1:0]=10b）。

3.在MRB寄存器中，选择固定的目标地址（MRB.DM[1:0]=00b）并设置链传输（MRB.CHNE=1和MRB.CHNS=0）。

4.将SAR寄存器设置为数据表的首地址。

5.将DAR寄存器设置为GPT321.GTCCRC寄存器的地址。

6.将CRAH和CRAL寄存器设置为数据表的大小。CRB寄存器可以设置为任何值。

(2) 二转信息设置

设置传输到GPT321.GTCCRE寄存器。

1.在MRA寄存器中，选择源地址的递增(MRA.SM[1:0]=10b)。

2.将传输设置为正常传输模式（MRA.MD[1:0]=00b）和字长传输（MRA.SZ[1:0]=10b）。

3.在MRB寄存器中，选择固定的目标地址（MRB.DM[1:0]=00b）并设置链传输（MRB.CHNE=1，MRB.CHNS=0）。

4.将SAR寄存器设置为数据表的首地址。

5.将DAR寄存器设置为GPT321.GTCCRE寄存器的地址。

6.将CRAH和CRAL寄存器设置为数据表的大小。CRB寄存器可以设置为任何值。

(3) 三转信息集

设置传输到GPT321.GTPBR寄存器。

1.在MRA寄存器中，选择源地址的递增(MRA.SM[1:0]=10b)。

2.将传输设置为正常传输模式（MRA.MD[1:0]=00b）和字长传输（MRA.SZ[1:0]=10b）。

3.在MRB寄存器中，选择固定的目标地址（MRB.DM[1:0]=00b）并设置每次中断的单次数据传输（MRB.CHNE=0，MRB.DISEL=0）。MRB.DTS位可以设置为任何值。

4. Set the SAR register to the first address of the data table.
5. Set the DAR register to the address of the GPT321.GTPBR register.
6. Set the CRA register to the size of the data table. The CRB register can be set to any value.

(4) Transfer information assignment

Place the transfer information for use in the transfer to the GPT321.GTPBR immediately after the transfer control information for use in the GPT321.GTCCRC and GPT321.GTCCRE registers.

(5) DTC vector table

In the DTC vector table, set the address where the transfer control information for use in transfer to the GPT321.GTCCRC and GPT321.GTCCRE registers starts.

(6) ICU setting and DTC module activation

1. Set the ICU.IELSRn.DTCE bit associated with the GPT321 counter overflow interrupt.
2. Set the ICU.IELSRn.IELS[8:0] bits and specify the GPT321 counter overflow.
3. Set the DTCST.DTCST bit to 1.

(7) GPT settings

1. Set the GPT321.GTIOR register so that the GTCCRA and GTCCRB registers operate as output compare registers.
2. Set the default PWM timer compare values in the GPT321.GTCCRA and GPT321.GTCCRB registers and the next PWM timer compare values in the GPT321.GTCCRC and GPT321.GTCCRE registers.
3. Set the default PWM timer period values in the GPT321.GTPR register and the next PWM timer period values in the GPT321.GTPBR register.
4. Set 1 to the output bit in PmnPFS.PDR, and set 00011b to the Peripheral Select bits in PmnPFS.PSEL[4:0].

(8) GPT activation

Set the GPT321.GTSTR.CSTRT bits to 1 to start the GPT321.GTCNT counter.

(9) DTC transfer

Each time a GPT321 counter overflow is generated with the GPT321.GTPR register, the next PWM timer compare values are transferred to the GPT321.GTCCRC and GPT321.GTCCRE registers. The setting for the next PWM timer period is transferred to the GPT321.GTPBR register.

(10) Interrupt handling

After the specified rounds of data transfer are complete, for example when the value in the CRA register for GPT transfer becomes 0, a GPT321 counter overflow interrupt request is issued for the CPU. Complete the process for this interrupt in the handling routine.

17.6.3 Chain Transfer when Counter = 0

The second data transfer is performed only when the transfer counter is set to 0 in the first data transfer, and the first data transfer information is repeatedly changed in the second transfer. Chain transfer enables transfers to be repeated 256 times or more.

The following procedure shows an example of configuring a 1-KB input buffer, where the input buffer is set so that its lower address starts with 0x00. Figure 17.13 shows a chain transfer when the counter = 0.

1. Set the normal transfer mode to input data for the first data transfer. Set the following:
   (a) Transfer source address = fixed.
   (b) CRA register = 0x0200 (512) times.
   (c) MRB.CHNE bit = 1 (chain transfer is enabled).
   (d) MRB.CHNS bit = 1 (chain transfer is performed only when the transfer counter is 0).

4.将SAR寄存器设置为数据表的首地址。
5.将DAR寄存器设置为GPT321.GTPBR寄存器的地址。
6.将CRA寄存器设置为数据表的大小。CRB寄存器可以设置为任何值。

(4) 转移信息分配

将用于传输到GPT321.GTPBR的传输信息放置在GPT321.GTCCRC和GPT321.GTCCRE寄存器中使用的传输控制信息之后。

(5) DTC向量表

在DTC向量表中，设置用于传输到GPT321.GTCCRC和GPT321.GTCCRE寄存器的传输控制信息的起始地址。

(6) ICU设置和DTC模块激活

1.设置与GPT321计数器溢出中断相关的ICU.IELSRn.DTCE位。
2.设置ICU.IELSRn.IELS[8:0]位并指定GPT321计数器溢出。
3.将DTCST.DTCST位设置为1。

(7) GPT settings

1.设置GPT321.GTIOR寄存器，使GTCCRA和GTCCRB寄存器作为输出比较寄存器运行。
2.在GPT321.GTCCRA和GPT321.GTCCRB寄存器中设置默认PWM定时器比较值，在GPT321.GTCCRC和GPT321.GTCCRE寄存器中设置下一个PWM定时器比较值。
3.在GPT321.GTPR寄存器中设置默认PWM定时器周期值，在GPT321.GTPBR寄存器中设置下一个PWM定时器周期值。
4.将PmnPFS.PDR中的输出位设置为1，并将PmnPFS.PSEL[4:0]中的外设选择位设置为00011b。

(8) GPT activation

将GPT321.GTSTR.CSTRT位设置为1以启动GPT321.GTCNT计数器。

(9) DTC transfer

每次使用GPT321.GTPR寄存器产生GPT321计数器溢出时，下一个PWM定时器比较值被传送到GPT321.GTCCRC和GPT321.GTCCRE寄存器。下一个PWM定时器周期的设置被传送到GPT321.GTPBR寄存器。

(10)中断处理

在指定轮次的数据传输完成后，例如当GPT传输的CRA寄存器中的值变为0时，会向CPU发出GPT321计数器溢出中断请求。在处理例程中完成该中断的处理。

17.6.3 Counter=0时的链式转移

仅当在第一次数据传输中将传输计数器设置为0时才执行第二次数据传输，并且在第二次传输中重复改变第一数据传输信息。链式转移使转移可以重复256次或更多。

以下过程显示了配置1KB输入缓冲区的示例，其中输入缓冲区设置为使其低地址从0x00开始。图17.13显示了当计数器=0时的链式传输。

1.将普通传输模式设置为第一次数据传输的输入数据。设置以下内容：
   (a) 传输源地址=固定。
   (b) CRA寄存器=0x0200(512)次。
   (c) MRB.CHNE位=1（启用链式传输）。
   (d) MRB.CHNS位=1（仅当传输计数器为0时才执行链式传输）。

(e) MRB.DISEL bit = 0 (an interrupt request to the CPU is generated when the specified data transfer completes).

2. Prepare the upper 8-bit address of the start address at every 512 times of the transfer destination address for the first data transfer in different area such as the flash. For example, when setting the input buffer to 0x8000 to 0x83FF, prepare 0x82 and 0x80.
3. For the second data transfer:
   (a) Set the repeat transfer mode (with transfer source and destination address = fixed.) to reset the transfer counter of the first data transfer.
   (b) Specify the CRA register in the first transfer information area for the transfer destination.
   (c) Set the MRB.CHNE bit = 1 (chain transfer is enabled).
   (d) Set the MRB.CHNS bit = 0 (select continuous chain transfer).
   (e) Set the MRB.DISEL bit = 0 (an interrupt request to the CPU is generated when the specified data transfer completes).
   (f) CRA register = 0x0101 (The transfer count is 1).
4. For the third data transfer:
   (a) Set the repeat transfer mode (with the source as the repeat area) to reset the transfer destination address of the first data transfer.
   (b) Specify the upper 8 bits of the DAR register in the first transfer information area for the transfer destination.
   (c) Set the MRB.CHNE bit = 0 (chain transfer is disabled).
   (d) Set the MRB.DISEL bit = 0 (an interrupt request to the CPU is generated when the specified data transfer completes).
   (e) When setting the input buffer to 0x8000 to 0x83FF, also set the transfer counter to 2.
5. The first data transfer is performed by an interrupt 512 times. When the transfer counter of the first data transfer becomes 0, the second data transfer starts. Set the transfer counter of the first data transfer to 0x0200. The lower 8 bits of the transfer destination address and the transfer counter of the first data transfer becomes 0x0200.
6. The second data transfer is performed by an interrupt 1 times. When the transfer counter of the first data transfer becomes 0, the third data transfer starts. Set the upper 8 bits of the transfer destination address of the first data transfer to 0x82. The lower 8 bits of the transfer destination address becomes 0x00 and the transfer counter of the first data transfer becomes 0x0200.
7. In succession, the first data transfer is performed by an interrupt 512 times as specified for the first data transfer. When the transfer counter of the first data transfer becomes 0, the second data transfer starts. Set the transfer counter of the first data transfer to 0x0200. The lower 8 bits of the transfer destination address and the transfer counter of the first data transfer becomes 0x0200.
8. The second data transfer is performed by an interrupt 1 times. When the transfer counter of the first data transfer becomes 0, the third data transfer starts. Set the upper 8 bits of the transfer destination address of the first data transfer to 0x80. The lower 8 bits of the transfer destination address becomes 0x00 and the transfer counter of the first data transfer becomes 0x0200.
9. Steps 5 to 8 are repeated indefinitely. Because the second data transfer is in repeat transfer mode, no interrupt request to the CPU is generated.

(e) MRB.DISEL位=0（指定数据传输完成时向CPU产生中断请求）。

2.在flash等不同区域的第一次数据传输中，每512次传输目标地址准备起始地址的高8位地址。比如设置输入缓冲区为0x8000到0x83FF时，准备0x82和0x80。

3.对于第二次数据传输：
   (a) 设置重复传输模式（传输源和目标地址=固定）以重置第一次数据传输的传输计数器。
   (b) 在传输目标的第一个传输信息区域中指定CRA寄存器。
   (c) 设置MRB.CHNE位=1（启用链式传输）。
   (d) 设置MRB.CHNS位=0（选择连续链传输）。
   (e) 设置MRB.DISEL位=0（当指定的数据传输完成时向CPU产生一个中断请求）。
   (f) CRA寄存器=0x0101（传输计数为1）。

4.对于第三次数据传输：
   (a) 设置重复传输模式（以源为重复区域）重置第一次数据传输的传输目标地址。
   (b) 在传输目标的第一个传输信息区域中指定DAR寄存器的高8位。
   (c) 设置MRB.CHNE位=0（禁用链传输）。
   (d) 设置MRB.DISEL位=0（当指定的数据传输完成时向CPU产生一个中断请求）。
   (e) 将输入缓冲区设置为0x8000到0x83FF时，还要将传输计数器设置为2。

5.第一次数据传输由中断执行512次。当第一次数据传输的传输计数器变为0，第二次数据传输开始。将第一次数据传输的传输计数器设置为0x0200。第一次数据传输的传输目标地址和传输计数器的低8位变为0x0200。

6.第二次数据传输由中断执行1次。当第一次数据传输的传输计数器变为0，开始第三次数据传输。将第一次数据传输的传输目标地址的高8位设置为0x82。传送目标地址的低8位变为0x00，第一次数据传送的传送计数器变为0x0200。

7.接连地，第一次数据传输由中断执行512次，如为第一次数据传输指定的那样。当第一次数据传输的传输计数器变为0时，第二次数据传输开始。将第一次数据传输的传输计数器设置为0x0200。第一次数据传输的传输目标地址和传输计数器的低8位变为0x0200。

8.第二次数据传输由中断执行1次。当第一次数据传输的传输计数器变为0，开始第三次数据传输。将第一次数据传输的传输目标地址的高8位设置为0x80。传送目标地址的低8位变为0x00，第一次数据传送的传送计数器变为0x0200。

9.步骤5到8无限重复。因为第二次数据传输是重复传输模式，所以不会产生对CPU的中断请求。

17.7 Processing on DTC Transfer Error

If the access error occurs during DTC transfer, the DTC immediately stops access during transfer. To stop only the vector number that caused the error, inform the vector number that caused the error to the ICU and clear the corresponding ICU setting. After that, if there is a request other than the vector number which caused the error, it will be re-arbitration as it is. The condition under which the transfer error occurs is indicated when TrustZone Filter in DTC detects a violation.

The error response is informed to ICU when the transfer error occurs. ICU clears the ICU.IELSRn of the corresponding vector number which caused the transfer error. Furthermore, it generates an error response detection interrupt to notify that an error has occurred by DMAC/DTC transfer. (section 17.8.2. Interrupt Request of Transfer Error). Write back to SRAM is not performed.

When the Master TrustZone Filter error occurs, the Slave TrustZone error occurs or the Master MPU error occurs, it is possible to confirm the error information of DTC by selecting NMI. The DTC error vector register is cleared by selecting reset. Under the conditions where NMI is generated due to transfer error in DTC, two interrupts(NMI and DMAC_TRANSERR) are generated. In this case, NMI always responds first.

The error response detection interrupt request (DMA_TRANSERR) occurs when the Slave Bus error or the Illegal Access error occurs. Furthermore, it occurs after NMI when the error response detection interrupt request (DMA_TRANSERR) is not cleared in NMI handler.

section 17.7.1. Processing on NMI handler describes how to confirm the error information of the DTC in the NMI handler. section 17.7.2. Processing on Error response detection interrupt request (DMA_TRANSERR) handler describes how to confirm the error information of the DTC in the DMA_TRANSERR handler.

17.7 DTC传输错误的处理

如果在DTC传输过程中发生访问错误，则DTC会在传输过程中立即停止访问。要仅停止导致错误的向量编号，请将导致错误的向量编号通知ICU并清除相应的ICU设置。之后，如果有引起错误的向量号以外的请求，将按原样重新仲裁。当DTC中的TrustZone过滤器检测到违规时，会指示发生传输错误的条件。

当发生传输错误时，将错误响应通知给ICU。ICU清除导致传输错误的相应向量号的ICU.IELSRn。此外，它会生成错误响应检测中断，以通知DMACDTC传输发生错误。（第17.8.2节。传输错误的中断请求）。不执行回写到SRAM。

当出现MasterTrustZoneFilter错误、SlaveTrustZone错误或MasterMPU错误时，可以通过选择NMI来确认DTC的错误信息。通过选择复位清除DTC错误向量寄存器。在由于DTC中的传输错误而产生NMI的情况下，会产生两个中断（NMI和DMAC_TRANSERR）。在这种情况下，NMI总是首先响应。

当发生SlaveBus错误或IllegalAccess错误时，会发生错误响应检测中断请求(DMA_TRANSERR)。此外，当NMI处理程序中未清除错误响应检测中断请求(DMA_TRANSERR)时，它会在NMI之后发生。

第17.7.1节。NMIhandler上的处理描述了如何在NMIhandler中确认DTC的错误信息。第17.7.2节。错误响应检测中断请求(DMA_TRANSERR)处理程序的处理描述了如何在DMA_TRANSERR处理程序中确认DTC的错误信息。

Interrupts and the error information generated due to transfer errors are shown in section 17.8.2. Interrupt Request of Transfer Error.

17.7.1 Processing on NMI handler

The cause of NMI due to the DMA transfer error is the Master TrustZone Filter error, the Slave TrustZone Filter error or the Master MPU error. When NMI occurs due to the DTC transfer error, the error response detection interrupt request (DMA_TRANSERR) will occur after the end of NMI handler. It is possible to confirm the cause of the error and the DTC vector number in which the error occurred. When NMI occurs, perform the necessary processing according to the flow described in the ICU chapter.

If completing all processing in NMI handler, it is possible to clear the error response detection interrupt request (DMA_TRANSERR) that occurs subsequently.

17.7.1 在NMI处理程序上处理

由于DMA传输错误导致NMI的原因是MasterTrustZoneFilter错误、SlaveTrustZoneFilter错误或
主控MPU错误。当由于DTC传输错误而发生NMI时，错误响应检测中断请求(DMA_TRANSERR)将在NMI处理程序结束后发生。可以确认错误的原因和发生错误的DTC向量编号。当发生NMI时，按照ICU章节中描述的流程进行必要的处理。

17.7.2 Processing on Error response detection interrupt request (DMA_TRANSERR) handler

The cause of error response detection interrupt request (DMA_TRANSERR) due to DMA transfer error is the Slave Bus Error or Illegal Access Error. Also, it occurs after the NMI handler error response detection interrupt request (DMA_TRANSERR) is not cleared by the NMI handler.

It is possible to confirm the cause of the error and the vector number of DTC in which the error occurred.

Error cause confirmation procedure is shown Figure 17.17.

17.8 Interrupt

17.8.1 Interrupt Request of Transfer End

When the DTC completes data transfer of the specified count or when data transfer with MRB.DISEL set to 1 is complete, a DTC activation source generates an interrupt to the CPU. Two types of interrupt are available: interrupts triggered by a DTC activation (per channel) and an interrupt triggered by the event signal DTC_COMPLETE (common to all channels). Interrupts to the CPU are controlled according to the settings in the NVIC and the ICU.IELSRn.IELS[8:0] bits. See section 13, Interrupt Controller Unit (ICU). The DTC prioritizes activation sources by granting the smaller interrupt vector numbers higher priority. The priority of interrupts to the CPU is determined by the NVIC priority.

17.8.2 Interrupt Request of Transfer Error

The error response detection interrupt request (DMA_TRANSERR) is generated from the DMAC/DTC when the transfer error is detected during DTC transfer. The types of interrupts that occur when the DTC transfer error occurs are listed in the Table 17.10. The Table 17.10 also shows error information stored when a transfer error occurs.

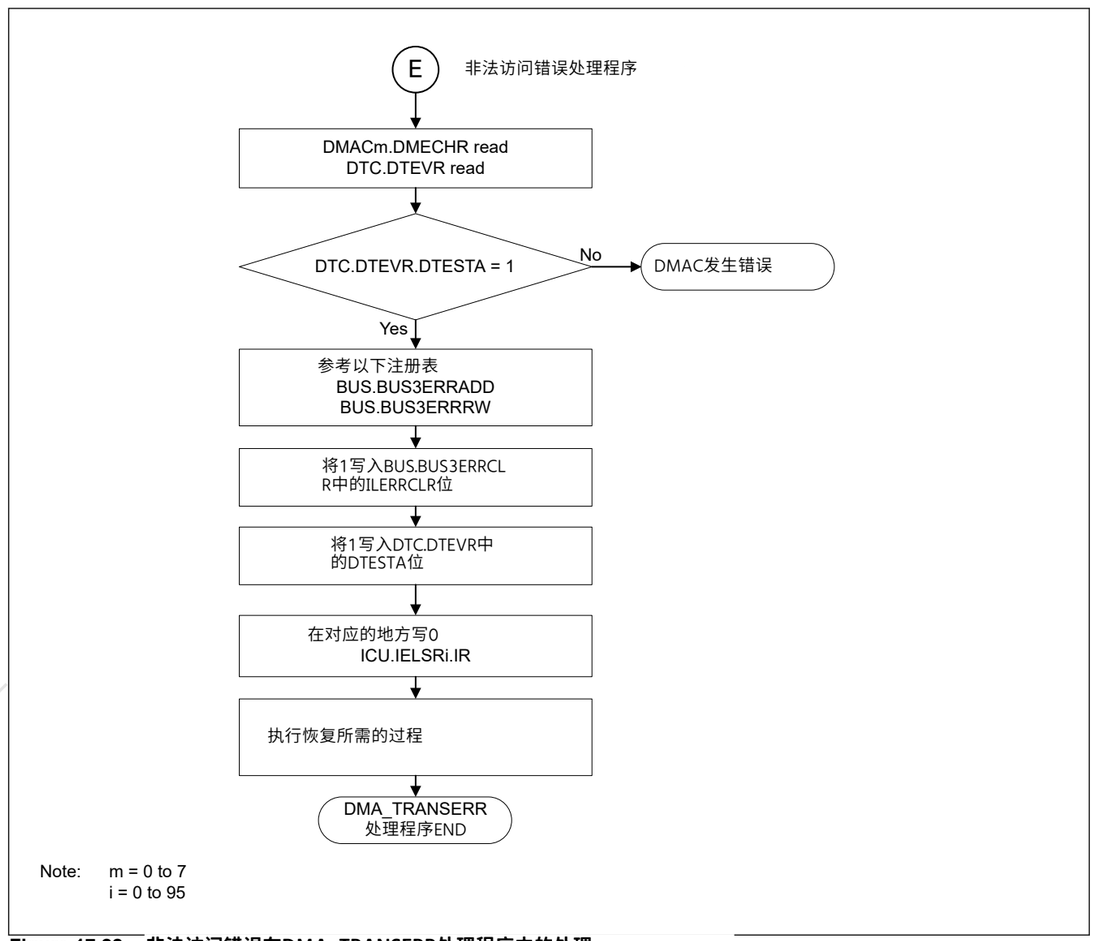

Figure 17.22 非法访问错误在DMA_TRANSERR处理程序中的处理

17.8 Interrupt

17.8.1 传输结束中断请求

当DTC完成指定计数的数据传输或MRB.DISEL设置为1的数据传输完成时，DTC激活源向CPU生成中断。有两种类型的中断可用：由DTC激活触发的中断（每个通道）和由事件信号DTC_COMPLETE触发的中断（所有通道通用）。CPU的中断根据NVIC和ICU.IELSRn.IELS[8:0]位中的设置进行控制。请参阅第13节，中断控制器单元(ICU)。DTC通过授予较小的中断向量编号较高的优先级来确定激活源的优先级。CPU中断的优先级由NVIC优先级决定。

17.8.2 传输错误中断请求

在DTC传输期间检测到传输错误时，从DMACDTC生成错误响应检测中断请求(DMA_TRANSERR)。发生DTC传输错误时发生的中断类型在表17.10中列出。表17.10还显示了发生传输错误时存储的错误信息。

Table 17.10 Interrupt and error information due to DMAC transfer error cause

Illegal Access Error	—*2	DMA_TRANSERR	BUS.BUS3ERRSTAT.ILERRSTAT*2	BUS.BUS3ERRADD BUS.BUS3ERRRW	DTC.DTEVR

Note 1. Interrupt generated, when NMI request selected as the operation after detection of the Master MPU error and The TrustZone Filter error. By confirming BUS.BUS3ERRSTAT and BUS.DMACDTCERRSTAT, judge whether it is the Master or the Slave.
Note 2. If the error response detection interrupt (DMA_TRANSERR) occurs and NMI of the Master MPU or NMI of the TrustZone Filter has not occurred, treat it as the Illegal address access error or the Slave Bus Error. It can be judged also by BUS.BUS3ERRSTAT and BUS. DMACDTCERRSTAT.

Note that if the bus error occurs when writing the last data of transfer, the transfer end event and the error response detection interrupt (DMA_TRANSERR) occurs.

17.9 Event Link

The DTC can produce an event link request on completion of one transfer request.

17.10 Low Power Consumption Function

Before transitioning to the module-stop function, Software Standby mode without Snooze mode transition, deep software standby mode, set the DTCST.DTCST bit to 0, and then perform the operations described in the following sections. The DTC is available in Snooze mode by setting the SYSTEM.SNZCR.SNZDTCEN bit to 1. See section 10, Low Power Modes.

(1) Module-stop function

Writing 1 to the MSTPCRA.MSTPA22 bit enables the module-stop function of the DTC. If the DTC transfer is in progress at the time, 1 is written to the MSTPCRA.MSTPA22 bit. The transition to the module-stop state proceeds after DTC transfer ends. While the MSTPCRA.MSTPA22 bit is 1, accessing the DTC registers is prohibited. Writing 0 to the MSTPCRA.MSTPA22 bit releases the DTC from the module-stop state.

(2) Software Standby mode, deep software standby mode

Use the settings described in section 10.7.1. Transitioning to Software Standby Mode or section 10.9.1. Transitioning to Deep Software Standby Mode.

If DTC transfer operations are in progress when the WFI instruction is executed, the transition to Software Standby mode or deep software standby mode follows the completion of the DTC transfer.

(3) Snooze Mode

When the snooze control circuit receives a snooze request in Software Standby mode, the MCU transfers to Snooze mode. See section 10.8.1. Transition to Snooze Mode. DTC operation in Snooze mode can be selected in the SYSTEM.SNZCR.SNZDTCEN bit. If DTC operation is enabled in Snooze mode, before transitioning to Software Standby mode, set the DTCST.DTCST bit to 1. To return to Software Standby mode through DTC, set SYSTEM.SNZEDCR0.DTCZRED or SYSTEM.SNZEDCR0.DTCNZRED to 1. See section 10.8.3. Returning from Snooze Mode to Software Standby Mode. SYSTEM.SNZEDCR0.DTCZRED enables or disables a snooze end request on completion of the last DTC transmission, detected on DTC transmission completion when CRA and CRB are 0. SYSTEM.SNZEDCR0.DTCNZRED enables or disables a snooze end request on a not last DTC transmission completion (CRA and CRB are not 0), detected on DTC transmission completion when CRA and CRB are not 0. The DTC activation request from the ICU is stopped during Software Standby mode but not stopped during Snooze mode.

注意1.中断，当NMI请求在检测主MPU错误和Trustzone滤波器错误后选择为操作时中断。通过确认BUS.BUS3ERRSTAT和BUS.DMACDTCERRSTAT，判断是Master还是Slave。
注2.如果错误响应检测中断(DMA_TRANSERR)发生且MasterMPU的NMI或TrustZoneFilter的NMI未发生，则将其视为Illegaladdressaccesserror或SlaveBusError。也可以通过BUS.BUS3ERRSTAT和BUS来判断。DMACDTCERRSTAT。

请注意，如果在写入传输的最后一个数据时发生总线错误，则会发生传输结束事件和错误响应检测中断（DMA_TRANSERR）。

17.9 活动链接

DTC可以在一个传输请求完成时产生一个事件链接请求。

17.10 低功耗功能

在转换到模块停止功能、没有贪睡模式转换的软件待机模式、深度软件待机模式之前，将DTCST.DTCST位设置为0，然后执行以下部分中描述的操作。通过将SYSTEM.SNZCR.SNZDTCEN位设置为1，可以在贪睡模式下使用DTC。请参阅第10节，低功耗

Modes.

(1) Module-stop function

向MSTPCRA.MSTPA22位写入1可启用DTC的模块停止功能。如果此时DTC传输正在进行，则将1写入MSTPCRA.MSTPA22位。在DTC传输结束后继续向模块停止状态的转换。当MSTPCRA.MSTPA22位为1时，禁止访问DTC寄存器。将0写入MSTPCRA.MSTPA22位可将DTC从模块停止状态释放。

(2) 软件待机模式，深度软件待机模式

使用第10.7.1节中描述的设置。转换到软件待机模式或第10.9.1节。过渡到深度软件待机模式。

如果在执行WFI指令时DTC传输操作正在进行，则在DTC传输完成后转换到软件待机模式或深度软件待机模式。

(3) 贪睡模式

当贪睡控制电路在软件待机模式下接收到贪睡请求时，MCU转入贪睡模式。请参阅第10.8.1节。过渡到贪睡模式。贪睡模式下的DTC操作可以在

SYSTEM.SNZCR.SNZDTCEN位。如果在贪睡模式下启用DTC操作，则在转换到软件待机模式之前，将DTCST.DTCST位设置为1。要通过DTC返回到软件待机模式，请将SYSTEM.SNZEDCR0.DTCZRED或SYSTEM.SNZEDCR0.DTCNZRED设置为1。请参阅第10.8.3节。从贪睡回来

模式到软件待机模式。SYSTEM.SNZEDCR0.DTCZRED在最后一次DTC传输完成时启用或禁用贪睡结束请求，当CRA和CRB为0时在DTC传输完成时检测到。SYSTEM.SNZEDCR0.DTCNZRED在非最后一次DTC传输时启用或禁用贪睡结束请求完成（CRA和CRB不为0），当CRA和CRB不为0时，在DTC传输完成时检测到。来自ICU的DTC激活请求在软件待机模式期间停止，但在贪睡模式期间不停止。

(4) Notes on Low Power Consumption Function

For the WFI instruction and the register setting procedure, see section 10, Low Power Modes.

To perform a DTC transfer after returning from a low power mode without a Snooze mode transition, set the DTCST.DTCST bit to 1 again.

To use a request that is generated in Software Standby mode as an interrupt request to the CPU but not as a DTC activation request, specify the CPU as the interrupt request destination as described in section 13.4.1. Detecting Interrupts, then execute the WFI instruction. If DTC operation is enabled in Snooze mode, do not use the module-stop function of the DTC.

17.11 Usage Notes

17.11.1 Transfer Information Start Address

You must set multiples of 4 for the transfer information start addresses in the vector table. Otherwise, such addresses are accessed with their lowest 2 bits regarded as 00b.

(4) 低功耗功能注意事项

关于WFI指令和寄存器设置过程，请参见第10节，低功耗模式。

要在从低功耗模式返回后执行DTC传输而不进行贪睡模式转换，请将DTCST.DTCST位再次为1。

要将在软件待机模式下生成的请求用作对CPU的中断请求，但不用作DTC激活请求，请按照第13.4.1节中的说明将CPU指定为中断请求目标。检测中断，然后执行WFI指令。如果在贪睡模式下启用DTC操作，请勿使用DTC的模块停止功能。

17.11 使用说明

17.11.1 传输信息起始地址

您必须为向量表中的传输信息起始地址设置4的倍数。否则，这些地址的最低2位被视为00b。

18.3 Operation

18.3.1 Relation between Interrupt Handling and Event Linking

Event number for an event link is the same as that for the associated interrupt source. For information on generating event signals, see the explanation in the chapter for each event source module.

18.3.2 Linking Events

When an event occurs and that event is already set as a trigger in the Event Link Setting Register (ELSRn), the associated module is activated. The operation of the module must be set up in advance. Table 18.4 lists the operations of modules when an event occurs.

Table 18.4 Module operations when event occurs

Module	Operations When Event is Input
GPT	• Start counting • Stop counting • Clear counting • Up counting • Down counting • Input capture
DAC12	Start D/A conversion
I/O Ports	• Change pin output based on the EORR (reset) or EOSR (set) • Latch pin state to EIDR • The following ports can be used for the ELC: PORT 1 PORT 2 PORT 3 PORT 4
ADC12	Start A/D conversion
DTC	Start DTC data transfer

18.3.3 Example of Procedure for Linking Events

To link events:

1. Set the operation of the module for which an event is to be linked.

Note: 只有安全访问才能写入该寄存器。允许安全访问和非安全读取访问，但不允许非安全写入访问，并且不会生成TrustZone访问错误。
Note: 该寄存器由PRCR寄存器写保护。

该寄存器指定寄存器ELSRn(n=16 17)的安全属性

18.3 Operation

18.3.1 中断处理和事件链接的关系

事件链接的事件编号与关联中断源的事件编号相同。有关生成事件信号的信息，请参阅每个事件源模块的章节中的说明。

18.3.2 链接事件

当事件发生并且该事件已在事件链接设置寄存器(ELSRn)中设置为触发器时，将激活相关模块。模块的操作必须提前设置好。表18.4列出了事件发生时模块的操作。

Table 18.4 事件发生时的模块操作

Module	输入事件时的操作
GPT	• 开始计数 • 停止计数 • 清除计数 • 向上计数 • 向下计数 • 输入捕捉
DAC12	开始DA转换
I/O Ports	• 根据EORR（复位）或EOSR（设置）更改引脚输出 • EIDR的锁存器引脚状态 • 以下端口可用于ELC: PORT 1 PORT 2 PORT 3 PORT 4
ADC12	开始AD转换
DTC	开始DTC数据传输

18.3.3 链接事件的过程示例

链接事件:

1.设置要链接事件的模块的操作。

2. Set the appropriate ELSRn.ELS[8:0] bits for the module to be linked.
3. Set the ELCR.ELCON bit to 1 to enable linkage of all events.
4. Configure the module from which an event is output and activate the module. The link between the two modules is now active.
5. To stop event linkage of modules individually, set 0 to the ELSRn.ELS[8:0] bit associated with the modules. To stop linkage of all the events, set the ELCR.ELCON bit to 0.

If event link output from the RTC is to be used, set the ELC after the RTC settings, for example, for initialization and time setting. Unintended events may be generated if RTC settings are made after the ELC settings.

If event link output from the LVD is to be used, set the ELC after setting the LVD. To disable the LVD, do so after setting 0x00 to the associated ELSRn register.

18.4 Usage Notes

18.4.1 Linking DMAC/DTC Transfer End Signals as Events

When linking the DMAC/DTC transfer end signals as events, do not set the same peripheral module as the DMAC/DTC transfer destination and event link destination. If set, the peripheral module might be started before DMAC/DTC transfer to the peripheral module is complete.

18.4.2 Setting Clocks

To link events, you must enable the ELC and the related modules. The modules cannot operate if the related modules are in the module-stop state or in low power mode in which the module is stopped (Software Standby mode or Deep Software Standby mode).

Some modules can perform in Snooze mode. For more information, see Table 18.3 and section 10, Low Power Modes.

18.4.3 Module-Stop Function Setting

The Module Stop Control Register C (MSTPCRC) can enable or disable ELC operation. The ELC is initially stopped after reset. Releasing the module-stop state enables access to the registers. The ELCON bit must be set to 0 before disabling ELC operation using the Module Stop Control Register. For more information, see Table 18.3 and section 10, Low Power Modes.

18.4.4 ELC Delay Time

In Figure 18.2, module A accesses module B through the ELC. There is a delay time in the ELC between module A and module B. Table 18.5 shows the ELC delay time.

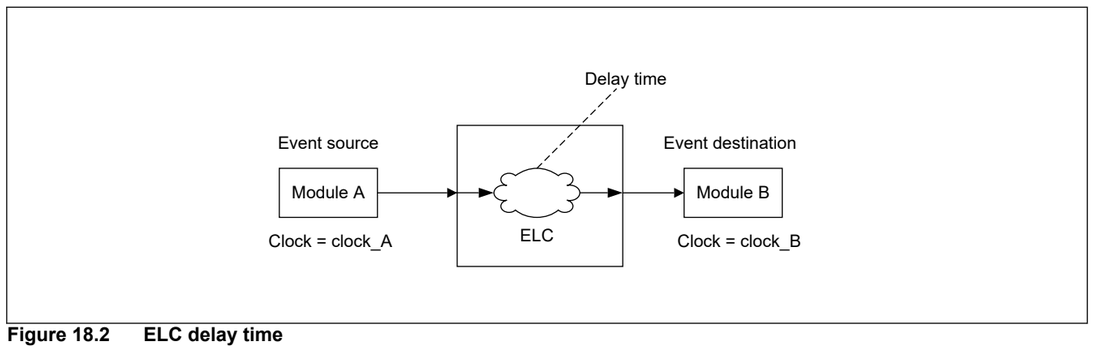

Figure 18.2 ELC delay time

Table 18.5 ELC delay time (1 of 2)

Clock domain	Clock frequency	ELC delay time
clock_A = clock_B	clock_A = clock_B	0 cycle

2.为要链接的模块设置适当的ELSRn.ELS[8:0]位。

3.将ELCR.ELCON位设置为1以启用所有事件的链接。

4.配置输出事件的模块并激活模块。两个模块之间的链接现在处于活动状态。

5.要单独停止模块的事件链接，请将与模块关联的ELSRn.ELS[8:0]位设置为0。要停止所有事件的链接，请将ELCR.ELCON位设置为0。

如果要使用RTC的事件链接输出，请在RTC设置之后设置ELC，例如，用于初始化和时间设置。如果在ELC设置之后进行RTC设置，则可能会产生意外事件。

如果要使用来自LVD的事件链接输出，请在设置LVD后设置ELC。要禁用LVD，请在将0x00设置为相关的ELSRn寄存器后执行此操作。

18.4 使用说明

18.4.1 将DMACDTC传输结束信号作为事件链接

将DMACDTC传输结束信号作为事件链接时，请勿将外设模块设置为DMACDTC传输目标和事件链接目标。如果设置，则外围模块可能会在DMACDTC传输到外围模块完成之前启动。

18.4.2 设置时钟

要链接事件，您必须启用ELC和相关模块。如果相关模块处于模块停止状态或模块停止的低功耗模式（软件待机模式或深度软件待机模式），则模块无法运行。

某些模块可以在贪睡模式下执行。有关详细信息，请参阅表18.3和第10节，低功耗模式。

18.4.3 模块停止功能设置

模块停止控制寄存器C(MSTPCRC)可以启用或禁用ELC操作。ELC在复位后最初停止。释放模块停止状态可以访问寄存器。在使用模块停止控制寄存器禁用ELC操作之前，必须将ELCON位设置为0。有关详细信息，请参阅表18.3和第10节，低功耗模式。

18.4.4 ELC延迟时间

在图18.2中，模块A通过ELC访问模块B。模块A和模块B之间的ELC中有一个延迟时间。表18.5显示了ELC延迟时间。

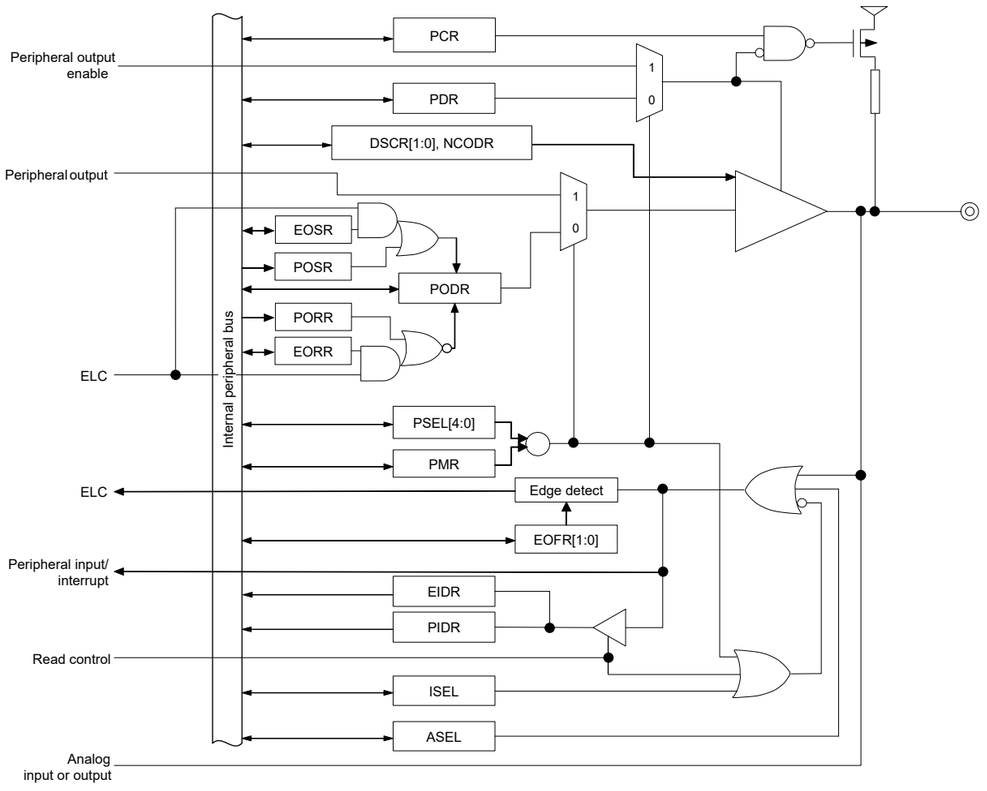
19. I/O Ports

19.1 Overview

The I/O port pins operate as general I/O port pins, I/O pins for peripheral modules, interrupt input pins, analog I/O, port group function for the ELC.

All pins except P109 (as TDO of JTAG ports) operate as input pins immediately after a reset, and pin functions are switched by register settings. The I/O ports and peripheral modules for each pin are specified in the associated registers.

Figure 19.1 shows a connection diagram for the I/O port registers. The configuration of the I/O ports differs for different packages. Table 19.1 lists the I/O port specifications by package and Table 19.2 lists the port functions.



Note: This figure shows a basic port configuration. The configuration differs depending on the ports.

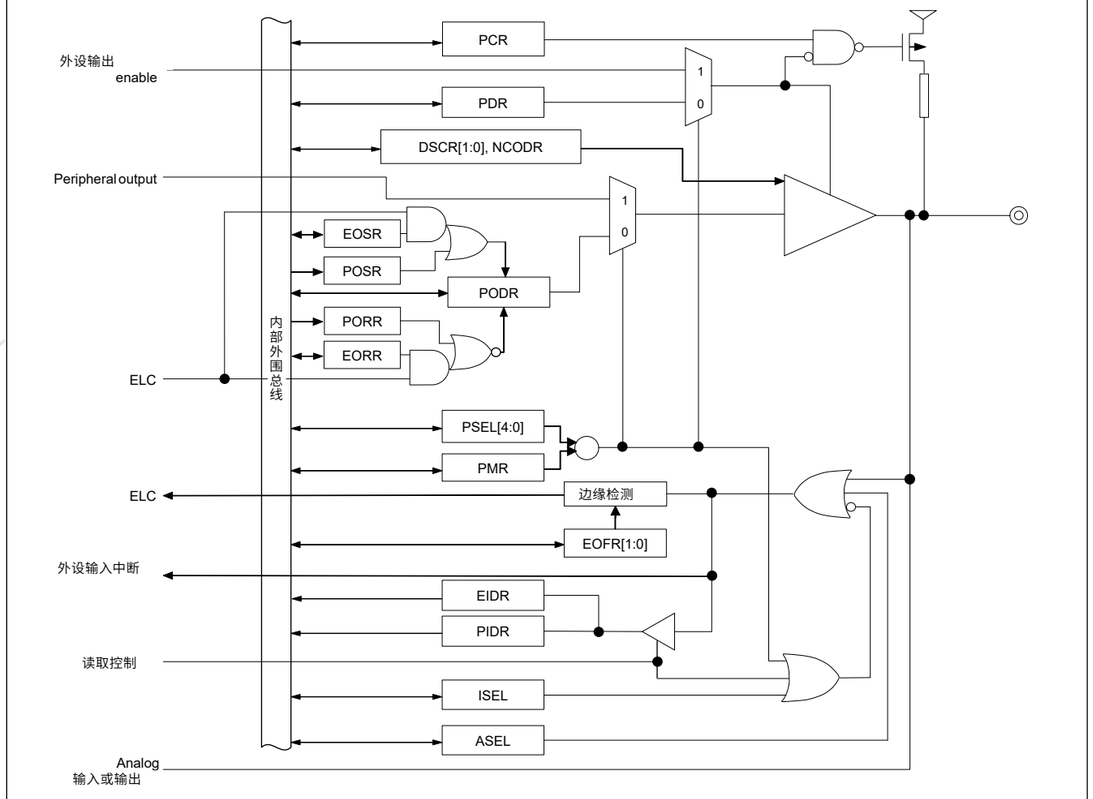
19. I/O Ports

19.1 Overview

IO端口引脚用作通用IO端口引脚、外围模块的IO引脚、中断输入引脚、模拟IO、ELC的端口组功能。

除P109外的所有引脚（作为JTAG端口的TDO）在复位后立即作为输入引脚工作，引脚功能通过寄存器设置切换。每个引脚的IO端口和外围模块在相关寄存器中指定。

图19.1显示了IO端口寄存器的连接图。不同封装的IO端口配置不同。表19.1按封装列出了IO端口规格，表19.2列出了端口功能。



Note: 此图显示了基本端口配置。配置因端口而异。

The Port Control Register 1 (PCNTR1/PODR/PDR) is a 32-bit or 16-bit read/write register that controls port direction and port output data. The PCNTR1 specifies the port direction and output data, and is accessed in 32-bit units. The PDRn (bits [15:0] in PCNTR1) and PODRn (bits [31:16] in PCNTR1) respectively, are accessed in 16-bit units.

PDRn bits (Pmn Direction)

The PDRn bits select the input or output direction for individual pins on the associated port when the pins are configured as general I/O pins. Each pin on port m is associated with a PORTm.PCNTR1.PDRn bit. The I/O direction can be specified in 1-bit unit. Bits associated with non-existent pins are reserved. Reserved bits are read as 0. The write value should be 0. In the case of input only ports, PDRn bits are reserved. See Table 19.2. The PDRn bit in the PORTm.PCNTR1 register serves the same function as the PDR bit in the PFS.PmnPFS register.

PODRn bits (Pmn Output Data)

The PODRn bits hold data to be output from the general I/O pins. Bits of non-existent port m are reserved. Reserved bits are read as 0. The write value should be 0. In the case of input only ports, PODRn bits are reserved. See Table 19.2. The PODRn bit in the PORTm.PCNTR1 register serves the same function as the PODR bit in the PFS.PmnPFS register.

19.2.2 PCNTR2/EIDR/PIDR : Port Control Register 2

端口控制寄存器1(PCNTR1PODRPDR)是一个32位或16位读写寄存器，用于控制端口方向和端口输出数据。PCNTR1指定端口方向和输出数据，并以32位为单位进行访问。PDRn（PCNTR1中的位[15:0]）和PODRn（PCNTR1中的位[31:16]）分别以16位为单位进行访问。

PDRn bits (Pmn Direction)

当引脚配置为通用IO引脚时，PDRn位选择相关端口上各个引脚的输入或输出方向。端口m上的每个引脚都与一个PORTm.PCNTR1.PDRn位相关联。可以以1位为单位指定IO方向。与不存在的引脚相关的位被保留。保留位读取为0。写入值应为0。在仅输入端口的情况下，保留PDRn位。见表19.2。PORTm.PCNTR1寄存器中的PDRn位与PFS.PmnPFS寄存器中的PDR位具有相同的功能。

PODRn位（Pmn输出数据）

PODRn位保存要从通用IO引脚输出的数据。不存在的端口m的位被保留。保留位读取为0。写入值应为0。在仅输入端口的情况下，保留PODRn位。见表19.2。PORTm.PCNTR1寄存器中的PODRn位与PFS.PmnPFS寄存器中的PODR位具有相同的功能。

Note: m = 0 to 5, n = 00 to 15
注1.x=1、2、3或4仅适用于EIDR
注2.端口1、2、3或4支持。

端口控制寄存器2(PCNTR2EIDRPIDR)允许使用32位或16位访问对Pmn状态和端口事件输入数据进行读取访问。

The PCNTR2 specifies the Pmn state and the port event input data, and is accessed in 32-bit units.

The PIDRn (bits [15:0] in PCNTR2) and EIDRn (bits [31:16] in PCNTR2) respectively, are accessed in 16-bit units. Bits associated with non-existent pins are reserved. Reserved bits are read as undefined.

PIDRn bits (Pmn State)

The PIDRn bits reflect the individual pin states of the port, regardless of the values set in PmnPFS.PMR and PORTm.PCNTR1.PDRn. The PIDRn bit in the PORTm.PCNTR2 register serves the same function as the PIDR bit in the PFS.PmnPFS register.

A pin state cannot be reflected in PIDRn when one of the following functions is enabled:

- RTC Time Capture input (RTCIC)
- Analog function (ASEL = 1)

EIDRn bits (Port Event Input Data)

The EIDRn bits latch a pin state when an ELC_PORTx signal occurs. Pin states can only be input to EIDRn when PmnPFS.PMR and PORTm.PCNTR1.PDRn are 0. When the PmnPFS.ASEL bit is set to 1, the associated pin state is not reflected in EIDRn.

19.2.3 PCNTR3/PORR/POSR : Port Control Register 3

The Port Control Register 3 (PCNTR3/PORR/POSR) is a 32-bit or 16-bit write register that controls the setting or resetting of the port output data.

The PCNTR3 controls the setting or resetting of the port output data, and is accessed in 32-bit units.

The POSRn (bits [15:0] in PCNTR3) and the PORRn (bits [31:16] in PCNTR3) respectively, are accessed in 16-bit units.

POSRn bits (Pmn Output Set)

POSR changes PODR when set by a software write. For example, for P100, when PORT1.PCNTR3.POSR00 = 1, PORT1.PCNTR1.PODR00 outputs 1. Bits associated with non-existent pins are reserved. The write value should always be 0. In the case of input only ports, POSRn bits are reserved. See Table 19.2.

PCNTR2指定Pmn状态和端口事件输入数据，并以32位为单位进行访问。

PIDRn（PCNTR2中的位[15:0]）和EIDRn（PCNTR2中的位[31:16]）分别以16位为单位进行访问。与不存在的引脚相关的位被保留。保留位被读取为未定义。

PIDRn bits (Pmn State)

PIDRn位反映端口的各个引脚状态，与PmnPFS.PMR和
PORTm.PCNTR1.PDRn。PORTm.PCNTR2寄存器中的PIDRn位与
PFS.PmnPFS register.

当启用以下功能之一时，引脚状态无法反映在PIDRn中：

●RTC时间捕捉输入(RTCIC)

●模拟功能（ASEL=1）

EIDRn位（端口事件输入数据）

当ELC_PORTx信号出现时，EIDRn位锁存引脚状态。引脚状态只能输入到EIDRn时
PmnPFS.PMR和PORTm.PCNTR1.PDRn为0。当PmnPFS.ASEL位设置为1时，相关引脚状态不会反映在EIDRn中。

端口控制寄存器3(PCNTR3PORRPOSR)是一个32位或16位写寄存器，用于控制端口输出数据的设置或复位。

PCNTR3控制端口输出数据的设置或复位，并以32位为单位进行访问。

POSRn（PCNTR3中的位[15:0]）和PORRn（PCNTR3中的位[31:16]）分别以16位为单位进行访问。

POSRn位（Pmn输出设置）

POSR在通过软件写入设置时改变PODR。例如，对于P100，当PORT1.PCNTR3.POSR00=1时，
PORT1.PCNTR1.PODR00输出1。与不存在的引脚相关的位被保留。写入值应始终为0。在仅输入端口的情况下，保留POSRn位。见表19.2。

PORRn bits (Pmn Output Reset)

PORR changes PODR when reset by a software write. For example, for P100, when PORT1.PCNTR3.PORR00 = 1, PORT1.PCNTR1.PODR00 outputs 0. Bits associated with non-existent pins are reserved. The write value should always be 0. In the case of input only ports, PORRn bits are reserved. See Table 19.2.

Note: When EORRn or EOSRn is set, writing is prohibited to PODRn, PORRn, and POSRn.
Note: PORRn and POSRn should not be set at the same time.

The Port Control Register 4 (PCNTR4/EORR/EOSR) is a 32-bit or 16-bit read/write register that controls the setting or resetting of the port output data by an event input from the ELC.

The PCNTR4 controls the setting or resetting of the port output data by an event input from the ELC, and is accessed in 32-bit units.

The EOSRn (bits [15:0] in PCNTR4) and EORRn (bits [31:16] in PCNTR4) respectively, are accessed in 16-bit units.

EOSRn bits (Pmn Event Output Set)

EOSR changes PODR when set because an ELC_PORTx signal occurs. For example, for P100 if PORT1.PCNTR4.EOSR00 is set to 1 when the ELC_PORTx occurs, PORT1.PCNTR1.PODR00 outputs 1. Bits associated with non-existent pins are reserved. The write value should always be 0. For input only ports, EOSRn bits are reserved. See Table 19.2.

EORRn bits (Pmn Event Output Reset)

EORR changes PODR when reset because an ELC_PORTx signal occurs. For example, for P100 if PORT1.PCNTR4.EORR00 = 1 when the ELC_PORTx occurs, PORT1.PCNTR1.PODR00 outputs 0. Bits associated with non-existent pins are reserved. The write value should always be 0. For input only ports, EORRn bits are reserved. See Table 19.2.

Note: When EORRn or EOSRn is set, writing is prohibited to PODRn, PORRn, and POSRn.

PORRN位（Pmn输出复位）

PORR在被软件写复位时改变PODR。例如，对于P100，当PORT1.PCNTR3.PORR00=1时，PORT1.PCNTR1.PODR00输出0。与不存在的引脚相关的位被保留。写入值应始终为0。在仅输入端口的情况下，保留PORRN位。见表19.2。

Note: 当设置EORRn或EOSRn时，禁止写入PODRn、PORRn和POSRn。
Note: PORRn和POSRn不应同时设置。

端口控制寄存器4(PCNTR4EORREOSR)是一个32位或16位读写寄存器，通过来自ELC的事件输入来控制端口输出数据的设置或复位。

PCNTR4通过来自ELC的事件输入来控制端口输出数据的设置或复位，并以32位为单位进行访问。

分别以16位为单位访问EOSRn（PCNTR4中的位[15:0]）和EORRn（PCNTR4中的位[31:16]）。

EOSRn位（Pmn事件输出设置）

EOSR在设置时会更改PODR，因为发生ELC_PORTx信号。例如，对于P100，如果在ELC_PORTx发生时PORT1.PCNTR4.EOSR00设置为1，则PORT1.PCNTR1.PODR00输出1。与不存在的引脚相关的位被保留。写入值应始终为0。对于仅输入端口，保留EOSRn位。见表19.2。

EORRN位（Pmn事件输出复位）

EORR会在复位时更改PODR，因为发生ELC_PORTx信号。例如，对于P100，如果PORT1.PCNTR4.EORR00=1当ELC_PORTx发生时，PORT1.PCNTR1.PODR00输出0。与不存在的引脚相关的位被保留。写入值应始终为0。对于仅输入端口，保留EORRN位。见表19.2。

Note: 当设置EORRn或EOSRn时，禁止写入PODRn、PORRn和POSRn。

Note: EORRn and EOSRn should not be set at the same time.

Port mn Pin Function Select Register (PmnPFS/PmnPFS_HA/PmnPFS_BY) is a 32-bit, 16-bit, or 8-bit read/write control register that selects the port mn pin function, and is accessed in 32-bit units. PmnPFS_HA (PmnPFS [15:0] bits) is accessed in 16-bit units. PmnPFS_BY (PmnPFS[7:0] bits) is accessed in 8-bit units.

The available Port mn pin depends on the product. For details, see Table 19.1

PODR bit (Port Output Data), PIDR bit (Port State), PDR bit (Port Direction)

The PDR, PIDR, and PODR bits serve the same function as the PCNTR. When these bits are read, the PCNTR value is read.

PCR bit (Pull-up Control)

The PCR bit enables or disables an input pull-up resistor on the individual port pins. When a pin is in the input state with the associated bit in PmnPFS.PCR set to 1, the pull-up resistor connected to the pin is enabled. When a pin is set as a general port output pin, or a peripheral function output pin, the pull-up resistor for the pin is disabled regardless of the PCR setting. The pull-up resistor is also disabled in the reset state. Bits associated with non-existent pins are reserved. Reserved bits are read as 0. The write value should be 0.

NCODR bit (N-Channel Open-Drain Control)

The NCODR bit specifies the output type for the port pins. Bits associated with non-existent pins are reserved. Reserved bits are read as 0. The write value should be 0.

DSCR[1:0] bits (Port Drive Capability)

The DSCR[1:0] bits switches the drive capacity of the port. If the drive capacity of a pin is fixed, the associated bit is a read/write bit, but the drive capacity cannot be changed. Bits associated with non-existent pins are reserved. Reserved bits are read as 0. The write value should be 0.

EOFR[1:0] bits (Event on Falling/Event on Rising)

The EOFR[1:0] bits select the edge detection method for the port group input signal. These bits support rising, falling, or both edge detections. When the EOFR[1:0] bits are set to 01b, 10b, or 11b, the input enable of the I/O cell is asserted. Following that, the event pulse is input from the external pin, and the GPIO outputs the event pulse to the ELC. Bits associated with non-existent pins are reserved. Reserved bits are read as 0. The write value should be 0.

端口mn引脚功能选择寄存器（PmnPFSPmnPFS_HAPmnPFS_BY）是选择端口mn引脚功能的32位、16位或8位读写控制寄存器，以32位为单位进行访问。PmnPFS_HA（PmnPFS[15:0]位）以16位为单位进行访问。PmnPFS_BY（PmnPFS[7:0]位）以8位为单位进行访问。

可用的端口mn引脚取决于产品。详见表19.1

PODR位（端口输出数据）、PIDR位（端口状态）、PDR位（端口方向）

PDR、PIDR和PODR位的功能与PCNTR相同。读取这些位时，将读取PCNTR值。

PCR bit (Pull-up Control)

PCR位启用或禁用各个端口引脚上的输入上拉电阻。当引脚处于输入状态且PmnPFS.PCR中的相关位设置为1时，连接到该引脚的上拉电阻被启用。当引脚设置为通用端口输出引脚或外围功能输出引脚时，无论PCR设置如何，该引脚的上拉电阻都被禁用。上拉电阻在复位状态下也被禁用。与不存在的引脚相关的位被保留。保留位读取为0。写入值应为0。

NCODR bit (N-Channel Open-Drain Control)

NCODR位指定端口引脚的输出类型。与不存在的引脚相关的位被保留。保留位读取为0。写入值应为0。

DSCR[1:0]位（端口驱动能力）

ISEL bit (IRQ Input Enable)

The ISEL bit specifies IRQ input pins. This setting can be used in combination with the peripheral functions, although an IRQn (external pin interrupt) of the same number must only be enabled for one pin. The ISEL bit for an unspecified IRQn is reserved.

ASEL bit (Analog Input Enable)

1. Specify it as a general I/O port in the Port Mode Control bit (PmnPFS.PMR).
2. Disable the pull-up resistor in the Pull-up Control bit (PmnPFS.PCR).
3. Specify the input in the Port Direction bit (PmnPFS.PDR). The pin state cannot be read at this point. The PmnPFS register is protected by the Write-Protect Register (PWPR). Release write-protect before modifying the register.

The ASEL bit for an unspecified analog I/O pin is reserved.

PMR bit (Port Mode Control)

The PMR bit specifies the port pin function. Bits associated with non-existent pins are reserved. The write value should be 0.

19.3 Operation

19.3.1 General I/O Ports

All pins except P108 to P110,and P300 operate as general I/O ports after reset. General I/O ports are organized as 16 bits per port and can be accessed by port with the Port Control Registers (PCNTRn, where n = 1 to 4), or by individual pins with the Port mn Pin Function Select register. For details on these registers, see section 19.2. Register Descriptions.

Each port has the following bits:

- Port Security Attribution register (PmSAR)(m = 0 to 5), which indicates the security attribution.
- Port Direction bit (PDRn), which selects input or output direction
- Port Output Data bit (PODRn), which holds data for output
- Port Input Data bit (PIDRn), which indicates the pin states
- Event Input Data bit (EIDRn), which indicates the pin state when an ELC_PORTn (n = 1, 2, 3 or 4) signal occurs
- Port Output Set bit (POSRn), which indicates the output value when a software write occurs
- Port Output Reset bit (PORRn), which indicates the output value when a software write occurs
- Event Output Set bit (EOSRn), which indicates the output value when an ELC_PORTn (n = 1, 2, 3 or 4) signal occurs
- Event Output Reset bit (EORRn), which indicates the output value when an ELC_PORTn (n = 1, 2, 3 or 4) signal occurs.

19.3.2 Port Function Select

The following port functions are available for configuring each pin:

- Security function: Security attribution for each pins
- I/O configuration: Complementary or open-drain output, pull-up control, and drive strength
- General I/O port: Port direction, output data setting, and read input data
- Alternate function: Configured function mapping to the pin.

Each pin is associated with a Port mn Pin Function Select register (PmnPFS), which includes the associated PODR, PIDR, and PDR bits. In addition, the PmnPFS register includes the following:

- PCR: Pull-up resistor control bit that turns the input pull-up MOS on or off
- NCODR: N-channel open-drain control bit that selects the output type for each pin
- DSCR[1:0]: Drive capacity control bit that selects the drive capacity
- EOFR[1:0]: For selecting the edge of the event that input from the port group
- ISEL: IRQ input enable bit to specify an IRQ input pin
- ASEL: Analog input enable bit to specify an analog pin
- PMR: Port mode bit to specify the pin function of each port
- PSEL[4:0]: Port function select bits to select the associated peripheral function.

These configurations can be made by a single-register access to the Port mn Pin Function Select register. For details, see section 19.2.5. PmnPFS/PmnPFS_HA/PmnPFS_BY : Port mn Pin Function Select Register (m = 0 to 5, n = 00 to 15).

19.3.3 Port Group Function for ELC

In the MCU, Port 1 to Port 4 are assigned for the ELC port group function.

19.3.3.1 Behavior When ELC_PORTn (n = 1, 2, 3 or 4) is Input from ELC

The MCU supports the two functions described in this section when an ELC_PORTn (n = 1, 2, 3 or 4) signal comes from the ELC.

19.3 Operation

19.3.1 通用IO端口

除P108至P110和P300外的所有引脚在复位后都作为通用IO端口工作。通用IO端口组织为每个端口16位，可以通过端口控制寄存器（PCNTRn，其中n=1到4）通过端口访问，或者通过端口mn引脚功能选择寄存器通过单个引脚访问。有关这些寄存器的详细信息，请参阅第19.2节。注册说明。

每个端口都有以下位：

●端口安全属性寄存器（PmSAR）（m=0～5），表示安全属性。
●端口方向位（PDRn），选择输入或输出方向
●端口输出数据位(PODRn)，用于保存输出数据
●端口输入数据位（PIDRn），指示引脚状态
●事件输入数据位(EIDRn)，当ELC_PORTn（n=1、2、3或4）信号发生时指示引脚状态
●端口输出设置位（POSRn），表示发生软件写时的输出值
●端口输出复位位（PORRn），表示发生软件写入时的输出值
●事件输出设置位（EOSRn），表示发生ELC_PORTn（n=1、2、3或4）信号时的输出值
●事件输出复位位（EORRn），指示发生ELC_PORTn（n=1、2、3或4）信号时的输出值。

19.3.2 端口功能选择

以下端口功能可用于配置每个引脚：

●安全功能：每个引脚的安全属性
●IO配置：互补或开漏输出、上拉控制和驱动强度
●通用IO口：端口方向、输出数据设置、读取输入数据
●备用功能：配置的功能映射到引脚。

每个引脚都与一个端口mn引脚功能选择寄存器(PmnPFS)相关联，该寄存器包括相关的PODR、PIDR和PDR位。此外，PmnPFS寄存器包括以下内容：

●PCR：上拉电阻控制位，打开或关闭输入上拉MOS
●NCODR：N沟道开漏控制位，用于选择每个引脚的输出类型
●DSCR[1:0]：驱动容量控制位，选择驱动容量
●EOFR[1:0]：用于选择从端口组输入的事件的边沿
●ISEL：IRQ输入使能位，用于指定IRQ输入引脚
●ASEL：模拟输入使能位，用于指定模拟引脚
●PMR：端口模式位，指定每个端口的引脚功能
●PSEL[4:0]：端口功能选择位，用于选择相关的外设功能。

这些配置可以通过单个寄存器访问端口mn引脚功能选择寄存器来进行。详见19.2.5节。PmnPFSPmnPFS_HAPmnPFS_BY：端口mn引脚功能选择寄存器（m=0到5，n=00到15）。

19.3.3 ELC的端口组功能

在MCU中，端口1到端口4被分配用于ELC端口组功能。

19.3.3.1 当ELC_PORTn（n=1、2、3或4）从ELC输入时的行为

当ELC_PORTn（n=1、2、3或4）信号来自ELC时，MCU支持本节中描述的两种功能。

(1) Input to EIDR

For the GPI function (PDR = 0 and PMR = 0 in the PmnPFS register), when an ELC_PORTn (n = 1, 2, 3 or 4) signal comes from the ELC, the input enable of the I/O cell is asserted, and data from the external pins is read into the EIDR bit. See Figure 19.2

For the GPO function (PDR = 1) or the peripheral mode (PMR = 1), 0 is input into the EIDR bit from the external pins.

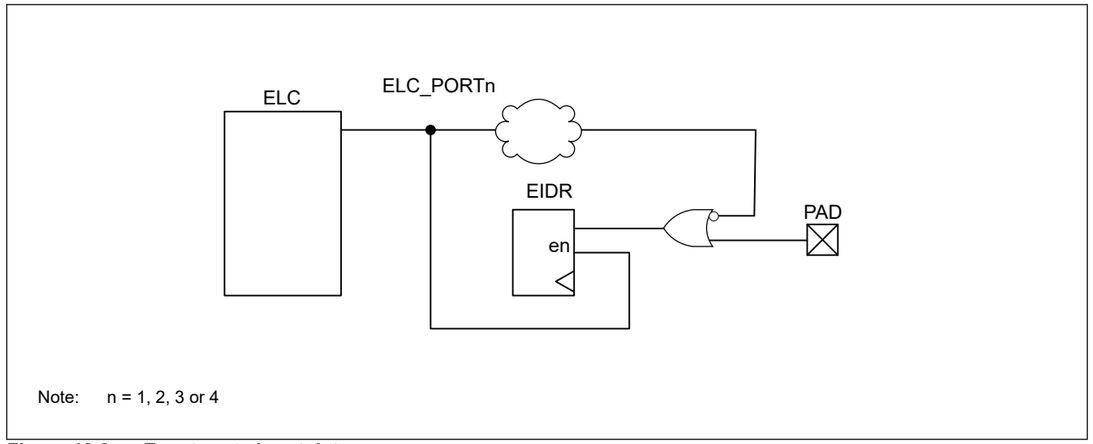

Figure 19.2 Event ports input data

(2) Output from PODR by EOSR and EORR

When an ELC_PORTn (n = 1, 2, 3 or 4) signal occurs, the data is output from the PODR to the external pin based on the settings in the EOSR and EORR registers.

- If EOSR is set to 1, when an ELC_PORTn (n = 1, 2, 3 or 4) signal occurs, the PODR register outputs 1 to the external pin. Otherwise, when EOSR = 0, the PODR value is retained.
- If EORR is set to 1, when ELC_PORTn (n = 1, 2, 3 or 4) signal occurs, the PODR register outputs 0 to the external pin. Otherwise, when EORR = 0, the PODR value is retained.

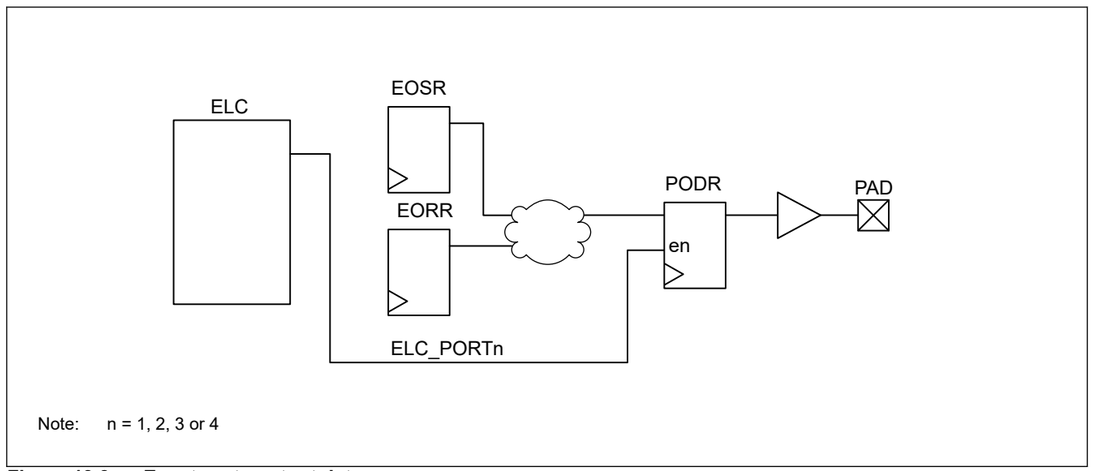

Figure 19.3 Event ports output data

(1) 输入到EIDR

对于GPI功能（PmnPFS寄存器中的PDR=0和PMR=0），当ELC_PORTn（n=1、2、3或4）信号来自ELC时，IO单元的输入使能有效，并且数据从外部引脚读入EIDR位。见图19.2

对于GPO功能(PDR=1)或外设模式(PMR=1)，0从外部引脚输入到EIDR位。

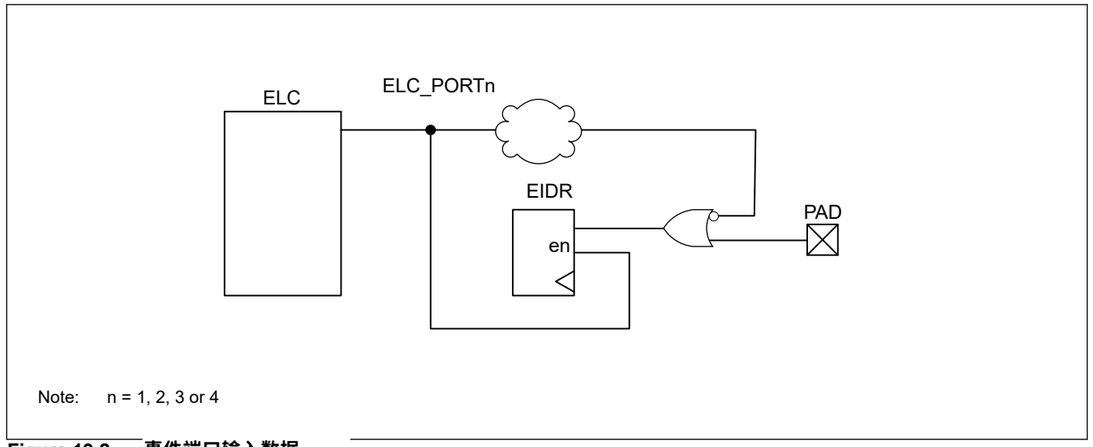

Figure 19.2 事件端口输入数据

(2) EOSR和EORR从PODR输出

当ELC_PORTn（n=1、2、3或4）信号发生时，数据会根据EOSR和EORR寄存器中的设置从PODR输出到外部引脚。

●如果EOSR设置为1，当ELC_PORTn(n=1 2 3or4)信号出现时，PODR寄存器输出1到外部引脚。否则，当EOSR=0时，保留PODR值。

●如果EORR设置为1，当ELC_PORTn(n=1 2 3or4)信号出现时，PODR寄存器输出0到外部引脚。否则，当EORR=0时，保留PODR值。

19.3.3.2 Behavior When an Event Pulse is Output to ELC

To output the event pulse from the external pins to the ELC, set the EOFR[1:0] bits in the PmnPFS register. For details, see section 19.2.5. PmnPFS/PmnPFS_HA/PmnPFS_BY : Port mn Pin Function Select Register (m = 0 to 5, n = 00 to 15). When the EOFR[1:0] bits are set, the input enable of the I/O cell is asserted.

Data from the external pin is the input. For example, for Port 1, when the data is input from P100 to P115, the data of those 16 pins is organized by OR logic. This data is formed into a one-shot pulse that goes to the ELC. The operation of PORTn (n = 2 to 4) is also the same as Port 1. See Figure 19.4.

19.3.3.2 事件脉冲输出到ELC时的行为

要将事件脉冲从外部引脚输出到ELC，请设置PmnPFS寄存器中的EOFR[1:0]位。详见19.2.5节。PmnPFSPmnPFS_HAPmnPFS_BY：端口mn引脚功能选择寄存器（m=0到5，n=00到15）。当EOFR[1:0]位被置位时，IO单元的输入使能被置位。

来自外部引脚的数据是输入。例如，对于端口1，当数据从P100输入到P115时，这16个引脚的数据由OR逻辑组织。该数据形成一个单次脉冲，该脉冲进入ELC。PORTn（n=2到4）的操作也与端口1相同。见图19.4。

Note 2. P108, P110, and P300 are recommended for pull up VCC (pulled up) through a resistor, because these pins are input pull-up enabled from the initial value (PmnPFS.PCR = 1).
Note 3. P109 is recommended for setting the direction to output (PCNTR1.PDRn = 1), because this pin is output from the initial value.

19.5 Usage Notes

19.5.1 Procedure for Specifying the Pin Functions

To specify the I/O pin functions:

1. Clear the B0WI bit in the PWPR register. This enables writing to the PFSWE bit in the PWPR register.*1
2. Set 1 to the PFSWE bit in the PWPR register. This enables writing to the PmnPFS register.*1
3. Clear the Port Mode Control bit in the PMR to 0 for the target pin to select the general I/O port.
4. Specify the I/O function for the pin through the PSEL[4:0] bits settings in the PmnPFS register.
5. Set the PMR bit to 1 as required to switch to the selected I/O function for the pin.
6. Clear the PFSWE bit in the PWPR register. This disables writing to the PmnPFS register.*1
7. Set 1 to the B0WI bit in the PWPR register. This disables writing to the PFSWE bit in the PWPR register.*1

Note 1. When the security attribution of Pmn is set to 0, set the PWPRS register to write to the PmnPFS register.

19.5.2 Procedure for Using Port Group Input

To use the port group input (port n (n = 1 to 4)):

1. Set the ELSRx.ELS[8:0] bits to all 0 to ignore unexpected pulses. For more information, see section 18, Event Link Controller (ELC).
2. Set the EOFR[1:0] bits of the PmnPFS register to specify the rising, falling, or both edge detections.
3. Execute a dummy read or wait for a short time, for example 100 ns. Ignoring of unexpected pulses depends on the initial value of the external pin.
4. Set the ELSRx.ELS[8:0] bits to enable the event signals.

19.5.3 Port Output Data Register (PODR) Summary

This register outputs data as follows:

1. Outputs 0 if PCNTR4.EORR is set to 1 when ELC_PORTn (n = 1, 2, 3 or 4) signal occurs.
2. Outputs 1 if PCNTR4.EOSR is set to 1 when ELC_PORTn (n = 1, 2, 3 or 4) signal occurs.
3. Outputs 0 if PCNTR3.PORR is set to 1.
4. Outputs 1 if PCNTR3.POSR is set to 1.
5. Outputs 0 or 1 because PCNTR1.PODRn is set.
6. Outputs 0 or 1 because PmnPFS.PODRn is set.

Numbers in this list correspond to the priority for writing to the PODRn. For example, if 1. and 3. from the list occur at the same time, the higher priority event 1. is executed.

注1.将PmnPFS.PMR、PmnPFS.ISEL、PmnPFS.PCR和PmnPFS.ASEL位清零。
注2.推荐使用P108、P110和P300通过电阻上拉VCC（上拉），因为这些引脚从初始值（PmnPFS.PCR=1）开始输入上拉使能。

注3.推荐使用P109设置输出方向（PCNTR1.PDRn=1），因为该引脚是从初始值输出的。

19.5 使用说明

19.5.1 指定引脚功能的步骤

要指定IO引脚功能：

1.将PWPR寄存器中的B0WI位清零。这允许写入PWPR寄存器中的PFSWE位。*1

2.将PWPR寄存器中的PFSWE位设置为1。这允许写入PmnPFS寄存器。*1

3.将PMR中的PortModeControl位清为0，以便目标引脚选择通用IO端口。

4.通过PmnPFS寄存器中的PSEL[4:0]位设置指定引脚的IO功能。

5.根据需要将PMR位设置为1，以切换到为引脚选择的IO功能。

6.将PWPR寄存器中的PFSWE位清零。这将禁止写入PmnPFS寄存器。*1

7.将PWPR寄存器中的B0WI位设置为1。这将禁止写入PWPR寄存器中的PFSWE位。*1

注1.当Pmn的安全属性设置为0时，设置PWPRS寄存器写入PmnPFS寄存器。

19.5.2 使用端口组输入的过程

要使用端口组输入（端口n（n=1到4））：

1.将ELSRx.ELS[8:0]位设置为全0以忽略意外脉冲。有关详细信息，请参阅第18节，事件链接控制器(ELC)。

2.设置PmnPFS寄存器的EOFR[1:0]位以指定上升沿、下降沿或两个边沿检测。

3.执行虚拟读取或等待一小段时间，例如100ns。忽略意外脉冲取决于外部引脚的初始值。

4.设置ELSRx.ELS[8:0]位以启用事件信号。

19.5.3 端口输出数据寄存器(PODR)摘要

该寄存器输出数据如下：

1.如果PCNTR4.EORR在ELC_PORTn（n=1、2、3或4）信号发生时设置为1，则输出0。

2.如果PCNTR4.EOSR在ELC_PORTn（n=1、2、3或4）信号发生时设置为1，则输出1。

3.如果PCNTR3.PORR设置为1，则输出0。

4.如果PCNTR3.POSR设置为1，则输出1。

5.输出0或1，因为PCNTR1.PODRn已设置。

6.输出0或1，因为PmnPFS.PODRn已设置。

此列表中的数字对应于写入PODRn的优先级。例如，如果列表中的1.和3.同时发生，则执行优先级较高的事件1.。

19.5.4 Notes on Using Analog Functions

To use an analog function, set the Port Mode Control bit (PMR) and the Port Direction bit (PDRn) to 0 so that the pin acts as a general input port. Next, set the Analog Input Enable bit (ASEL) in the Port mn Pin Function Select Register (PmnPFS.ASEL) to 1.

19.5.5 I/O Buffer Specification

The P402 port can be used as the RTC input, AGT input and other peripheral functions. Table 19.4 lists the P402 specifications.

Table 19.4 P402 specifications

I/O port	RTC and AGT			Other peripheral	
	RTC and AGT input enable register	RTC	AGT	other peripheral enable register	CAC, GPT, CAN, SCI, and interrupt
P402	VBTICTLR.VCH0INEN	RTCIC0	AGTIO0 AGTIO1 AGTIO2 AGTIO3	P402PFS.PSEL and PMR	For details, see section 19.6. Peripheral Select Settings for Each Product.

These RTC and AGT inputs are controlled by the VBTICTLR register. And this register is the highest priority which selecting the functions.

P402 can be used as IRQn-DS(n = 4, 14, 15) whether RTC and AGT inputs are selected or not. When using these interrupts, set the interrupt procedure after setting the VBTICTLR register. (see section 11.2.6. VBTICTLR : VBATT Input Control Register.)

See Figure 19.5.

The VBTICTLR register is not initialized on reset. Therefore, it is necessary to set the VBTICTLR register after reset as follows:

- When using RTC or AGT input: VBTICTLR = 0x01
- Without RTC or AGT input: VBTICTLR = 0x00

19.5.4 使用模拟功能的注意事项

要使用模拟功能，请将端口模式控制位(PMR)和端口方向位(PDRn)设置为0，以便引脚用作通用输入端口。接下来，将端口mn引脚功能选择寄存器(PmnPFS.ASEL)中的模拟输入启用位(ASEL)设置为1。

19.5.5 IO缓冲器规格

P402端口可用作RTC输入、AGT输入等外设功能。表19.4列出了P402规格。

Table 19.4 P402 specifications

IO端口	RTC和AGT			其他周边	
	RTC和AGT输入使能寄存器	RTC	AGT	其他外设使能寄存器CAC、GPT、CAN、SCI和中断	
P402	VBTICTLR.VCH0INEN	RTCIC0	AGTIO0 AGTIO1 AGTIO2 AGTIO3	P402PFS.PSEL and PMR	有关详细信息，请参阅第19.6节。外设选择每个产品的设置。

这些RTC和AGT输入由VBTICTLR寄存器控制。而这个寄存器是选择功能的最高优先级。

无论是否选择RTC和AGT输入，P402都可以用作IRQn-DS(n=4 14 15)。使用这些中断时，请在设置VBTICTLR寄存器后设置中断程序。（参见第11.2.6节。VBTICTLR：VBATT输入控制寄存器。）

请参见图19.5。

VBTICTLR寄存器在复位时未初始化。因此，复位后需要对VBTICTLR寄存器进行如下设置：

●使用RTC或AGT输入时：VBTICTLR=0x01

●无RTC或AGT输入：VBTICTLR=0x00

19.6 Peripheral Select Settings for Each Product

This section describes the pin function select configuration using the PmnPFS register. Some pin names have added _A, _B, or _C suffixes. When assigning IIC functionality, select the functional pins having the same suffix. The other pins can be selected regardless of the suffix. Assigning the same function to two or more pins simultaneously is prohibited.

1. In Pmn pin function select register(PmnPFS), the PSEL bits have to be set when the PMR bit of the target pin is 0. If the PSEL bits are set when the PMR bit is 1, the unexpected edges may be input at the input function or the unexpected pulses may be output to the external pin at the output function.
2. Only the allowed values (functions) should be specified in the PSEL bits of PmnPFS register. If a value which is not allowed for the register is specified, the correct operation is not guaranteed.
3. The single function should not be assigned to the multiple pins by PmnPFS register. When the GPT1, GPT5, SCI3, IIC0 or SPI0 are configured as secure and these pin function is being assigned to the pin which security attribution is set as secure by the PmSAR register, the write access to the PSEL bits for setting same function as secure pin in other pins is ignored when the security attribution of that pin is non-secure. For example, if the PSARE.PSARE30 bit is 0 (GPT1 is secure) and the P109PFS.PSEL bits is 00011b (pin function is GTIOC1A) and the P1SAR.109SA bit is 0 (P109 is secure), the write 00011b to the P405PFS.PSEL bits is ignored when the P4SAR.405SA bit is 1 (P405 is non-secure).

19.6 每个产品的外设选择设置

本节介绍使用PmnPFS寄存器的引脚功能选择配置。一些引脚名称添加了_A、_B或_C后缀。分配IIC功能时，选择具有相同后缀的功能管脚。无论后缀如何，都可以选择其他引脚。禁止将相同的功能同时分配给两个或多个引脚。

1.在Pmn引脚功能选择寄存器（PmnPFS）中，当目标引脚的PMR位为0时，必须设置PSEL位。如果在PMR位为1时设置PSEL位，可能会在输入功能或意外脉冲可能会在输出功能处输出到外部引脚。

2.PmnPFS寄存器的PSEL位只能指定允许的值（功能）。如果指定了寄存器不允许的值，则不能保证正确操作。

3.PmnPFS寄存器不应将单一功能分配给多个引脚。当GPT1、GPT5、SCI3、IIC0或SPI0配置为安全且这些引脚功能被分配给由PmSAR寄存器设置安全属性为安全的引脚时，对PSEL位的写访问以将相同功能设置为安全当该pin的安全属性为非安全时，其他pin中的pin将被忽略。例如，如果PSARE.PSARE30位为0（GPT1是安全的）并且P109PFS.PSEL位是00011b（引脚功能是GTIOC1A）并且P1SAR.109SA位是0（P109是安全的），则将00011b写入P405PFS当P4SAR.405SA位为1（P405不安全）时，.PSEL位被忽略。

4. The PORT0 and 5 have the analog functions such as A/D converter. When these pins are used as an analog function, for avoiding the loss of resolution, the PMR bit should be set to 0 and PDR bit should be set to 0. After that, ASEL bit should be set to 1

Note 1. To use this pin function, set the associated pin as a general input (set the PmnPFS.PDR and PmnPFS.PMR bits to 0).
Note 2. Use pins that have a letter appended to their names, for instance "_A" or "_B", to indicate group membership. For the interface, the AC portion of the electrical characteristics is measured for each group.
Note 3. There are two types of output buffer which are middle drive and high drive. Use the same drive buffer for output skew spec (t_{GTISK})

20. Port Output Enable for GPT (POEG)

20.1 Overview

The Port Output Enable (POEG) function can place the General PWM Timer (GPT) output pins in the output disable state in one of the following ways:

- Input level detection of the GTETRGn (n = A to D) pins
- Output-disable request from the GPT
- Oscillation stop detection of the clock generation circuit
- Register settings

The GTETRGn (n = A to D) pins can be used as GPT external trigger input pins.

Table 20.1 lists the POEG specifications, Figure 20.1 shows a block diagram, and Table 20.2 lists the input pins.

Table 20.1 POEG specifications

Parameter	Specifications
Output-disable control through input level detection	• The GPT output pins can be disabled when a GTETRGn rising edge or high level is sampled after polarity and filter selection.
Output-disable request from the GPT	• When the GTIOCxA pin and the GTIOCxB pin are driven to an active level simultaneously, the GPT generates an output-disable request to the POEG. Through reception of these requests, the POEG can control whether the GTIOCxA and GTIOCxB pins are output-disabled.
Output-disable control through oscillation stop detection	• The GPT output pins can be disabled when oscillation of the clock generation circuit stops.
Output-disable control by software (registers)	• The GPT output pins can be disabled by modifying the register settings.
Interrupt	• Interrupts can be generated by detecting the input level of external trigger input pins (GTETRGn pins). • Interrupts can be generated when all GPT output pins are driven to an active level simultaneously.
External trigger output to the GPT	• The GTETRGn signals can be output to the GPT after polarity and filter selection. (count start, count stop, count clear, up-count, down-count, or input capture function)
Noise filtering	• For input from the GTETRGn pins, PCLKB/1, PCLKB/8, PCLKB/32, or PCLKB/128 can be selected as the noise filtering clock. (Filtering is performed by sampling the input signals three times using the selected clock.) • Positive or negative polarity can be selected for any of the GTETRGn input pins. • Signal state after polarity and filter selection can be monitored.
TrustZone Filter	• Security attribution can be set for each groups.

Note: n = A to D, x = 1, 2, 4, 5

20. GPT(POEG)的端口输出使能

20.1 Overview

端口输出使能(POEG)功能可以通过以下方式之一将通用PWM定时器(GPT)输出引脚置于输出禁用状态：

●GTETRn(n=AtoD)引脚的输入电平检测
●来自GPT的输出禁用请求
●时钟发生电路的振荡停止检测
●注册设置

GTETRn(n=AtoD)引脚可用作GPT外部触发输入引脚。
表20.1列出了POEG规范，图20.1显示了框图，表20.2列出了输入引脚。

Table 20.1 POEG specifications

Parameter	Specifications
通过输入电平检测进行输出禁用控制	• 在极性和滤波器选择后采样GTETRn上升沿或高电平时，可以禁用GPT输出引脚。
来自GPT的输出禁用请求	• 当GTIOCxA引脚和GTIOCxB引脚同时被驱动为有效电平时，GPT向POEG生成一个输出禁用请求。通过接收这些请求，POEG可以控制GTIOCxA和GTIOCxB引脚是否输出禁用。
通过振荡停止检测进行输出禁用控制	• 当时钟生成电路的振荡停止时，可以禁用GPT输出引脚。
通过软件（寄存器）进行输出禁用控制	• 通过修改寄存器设置可以禁用GPT输出引脚。
Interrupt	• 可以通过检测外部触发输入引脚（GTETRn引脚）的输入电平来产生中断。 • 当所有GPT输出引脚同时驱动到有效电平时，可能会产生中断。
到GPT的外部触发输出	• GTETRn信号可以在极性和滤波器选择后输出到GPT。（计数开始、计数停止、计数清除、递增计数、递减计数或输入捕捉功能）
噪声过滤	• 对于来自GTETRn引脚的输入，可以选择PCLKB1、PCLKB8、PCLKB32或PCLKB128作为噪声过滤时钟。（通过使用所选时钟对输入信号进行3次采样来执行滤波。） • 可以为任何GTETRn输入引脚选择正极性或负极性。 • 可以监控极性和滤波器选择后的信号状态。
TrustZone Filter	• 可以为每个组设置安全属性。

The POEGGn (n = A to D) registers control the output-disable state of the GPT pins, interrupts, and the external trigger input to the GPT.

In the descriptions, POEGGn represents the POEGGn (n = A to D) registers.

20.3 Output-Disable Control Operation

If any of the following conditions is satisfied, the GTIOCxA, GTIOCxB, and the 3-phase PWM output for BLDC motor control pins can be set to output-disable:

- Input level or edge detection of the GTETRGn pins
  When POEGGn.PIDE is 1, the POEGGn.PIDF flag is set to 1.
- Output-disable request from the GPT
  When POEGGn.IOCE is 1, the POEGGn.IOCF flag is set to 1 if the disable request is enabled by GTINTAD. The GTINTAD.GRPABH and GTINTAD.GRPABL settings apply to the group selected by the GPT register GTINTAD.GRP[1:0] or OPSCR.GRP[1:0].
- Oscillation stop detection for the clock generation circuit
  While POEGGn.OSTPE is 1, the halt status of the main clock oscillator is detected and the POEGGn. OSTPF flag is set to 1.
- SSF bit setting
  When POEGGn.SSF is set to 1, the PWM output is disabled.

The output-disable state is controlled in the GPT module. The output-disable of the GTIOCxA and GTIOCxB pins is set in the GTINTAD.GRP[1:0], GTIOR.OADF[1:0], and GTIOR.OBDF[1:0] bits in GPTx. The output-disable of the 3-phase PWM output for BLDC motor control pins is set in the OPSCR.GRP[1:0] bits and OPSCR.GODF bit in GPT_OPS.

20.3.1 Pin Input Level Detection Operation

If the input conditions set in POEGGn.PIDE, POEGGn.NFCS[1:0], POEGGn.NFEN, and POEGGn.INV occur on the GTETRGn pins, the GPT output pins are output-disabled.

20.3.1.1 Digital Filter

Figure 20.2 shows high-level detection by the digital filter. When a high level associated with the POEGGn.INV polarity setting is detected three times consecutively with the sampling clock selected in POEGGn.NFCS[1:0] and POEGGn.NFEN, the detected level is recognized as high, and the GPT output pins are output-disabled. If even one low level is detected during this interval, the detected level is not recognized as high. In addition, in an interval where the sampling clock is not output, changes of the levels on the GTETRGn pins are ignored.

注2.复位后只能修改一次。

POEGGn(n=AtoD)寄存器控制GPT引脚的输出禁用状态、中断和GPT的外部触发输入。

在描述中，POEGGn代表POEGGn（n=A到D）寄存器。

20.3 输出禁用控制操作

如果满足以下任一条件，则GTIOCxA、GTIOCxB和BLDC电机控制引脚的3相PWM输出可设置为输出禁用：

●GTETRn引脚的输入电平或边沿检测
当POEGGn.PIDE为1时，POEGGn.PIDF标志设置为1。

●来自GPT的输出禁用请求
当POEGGn.IOCE为1时，如果禁用请求由GTINTAD启用，则POEGGn.IOCF标志设置为1。这GTINTAD.GRPABH和GTINTAD.GRPABL设置适用于GPT寄存器选择的组GTINTAD.GRP[1:0] or OPSCR.GRP[1:0].

●时钟产生电路的振荡停止检测
当POEGGn.OSTPE为1时，检测到主时钟振荡器的停止状态和POEGGn。OSTPF标志设置为1。

●SSF位设置
当POEGGn.SSF设置为1时，PWM输出被禁用。

输出禁用状态由GPT模块控制。GTIOCxA和GTIOCxB引脚的输出禁用在GPTx中的GTINTAD.GRP[1:0]、GTIOR.OADF[1:0]和GTIOR.OBDF[1:0]位中设置。BLDC电机控制引脚的3相PWM输出的输出禁用在GPT_OPS中的OPSCR.GRP[1:0]位和OPSCR.GODF位中设置。

20.3.1 引脚输入电平检测操作

如果在POEGGn.PIDE、POEGGn.NFCS[1:0]、POEGGn.NFEN和POEGGn.INV中设置的输入条件发生在GTETRn引脚，GPT输出引脚输出禁用。

20.3.1.1 数字滤波器

图20.2显示了数字滤波器的高电平检测。当在POEGGn.NFCS[1:0]和POEGGn.NFEN中选择的采样时钟连续3次检测到与POEGGn.INV极性设置相关的高电平时，检测到的电平被识别为高电平，并且GPT输出引脚为输出禁用。如果在此间隔期间甚至检测到一个低电平，则检测到的电平不会被识别为高电平。此外，在不输出采样时钟的时间间隔内，GTETRn引脚的电平变化被忽略。

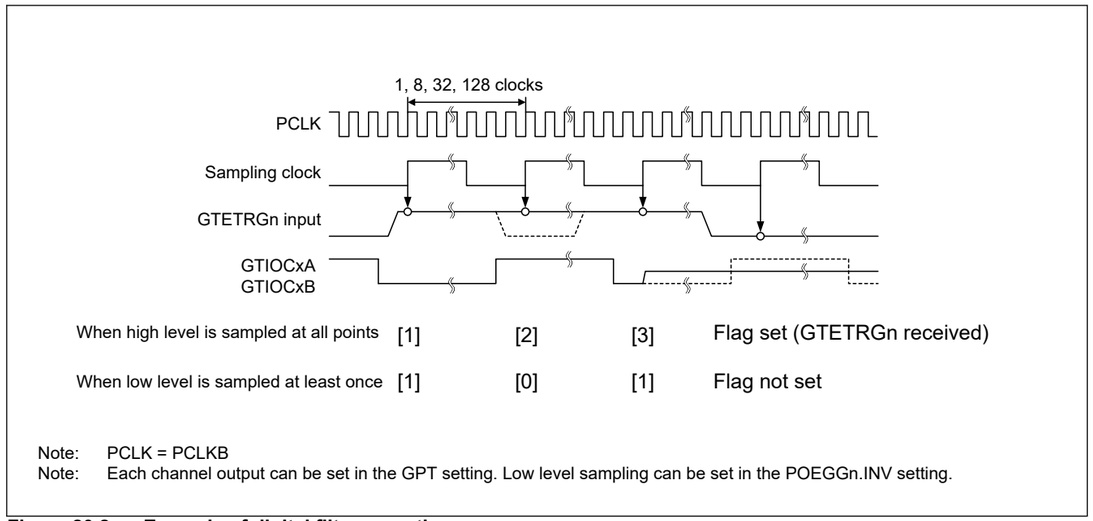

Figure 20.2 Example of digital filter operation

20.3.2 Output-Disable Requests from the GPT

For details on the operation, see the description for GTIOC Pin Output Negate Control in section 21, General PWM Timer (GPT).

20.3.3 Output-Disable Control Using Detection of Stopped Oscillation

When the oscillation stop detection function in the clock generation circuit detects stopped oscillation while POEGGn.OSTPE is 1, the GPT output pins are output-disabled for each group.

20.3.4 Output-Disable Control Using Registers

The GPT output pins can be directly controlled by writing 1 to the Software Stop flag, POEGGn.SSF.

20.3.5 Release from Output-Disable

To release the GPT output pins placed in the output-disable state, either return them to their initial state with a reset or clear all of the following flags:

- POEGGn.PIDF
- POEGGn.IOCF
- POEGGn.OSTPF
- POEGGn.SSF

Writing 0 to the POEGGn.PIDF flag is ignored (the flag is not cleared) if the external input pins, GTETRGn are not disabled and the POEGGn.ST bit is not set to 0.

Writing 0 to the POEGGn.IOCF flag is valid (the flag is cleared) only if all of the GTST.OABHF and GTST.OABLF flags in the GPT are set to 0.

Writing 0 to the POEGGn.OSTPF flag is ignored (the flag is not cleared) if the OSTDSR.OSTDF flag in the clock generation circuit is not set to 0. In addition, when the flag set and release occur at the same time, the flag set takes precedence.

Figure 20.3 shows the release timing for output-disable. The output-disable is released at the beginning of the next count cycle of the GPT after the flag is cleared.

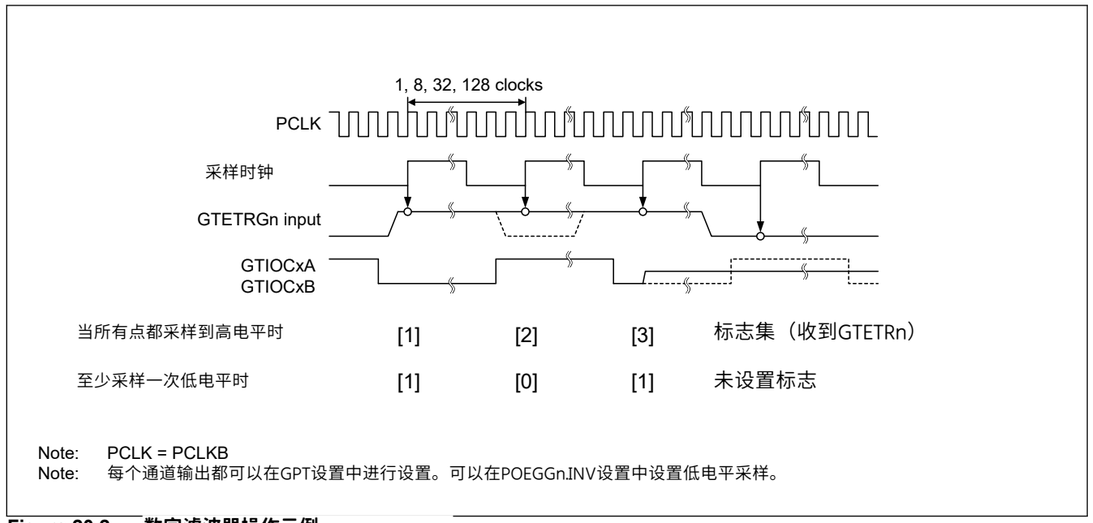

Figure 20.2 数字滤波器操作示例

20.3.2 来自GPT的输出禁用请求

有关操作的详细信息，请参见第21节通用PWM定时器(GPT)中对GTIOC引脚输出取反控制的说明。

20.3.3 使用停止振荡检测的输出禁用控制

当时钟发生电路中的振荡停止检测功能检测到停止振荡时
POEGGn.OSTPE为1，每组的GPT输出引脚输出禁用。

20.3.4 使用寄存器的输出禁用控制

GPT输出引脚可以通过将1写入软件停止标志POEGGn.SSF来直接控制。

20.3.5 从输出禁用释放

要释放处于输出禁用状态的GPT输出引脚，可以通过复位将它们返回到初始状态，或者清除以下所有标志：

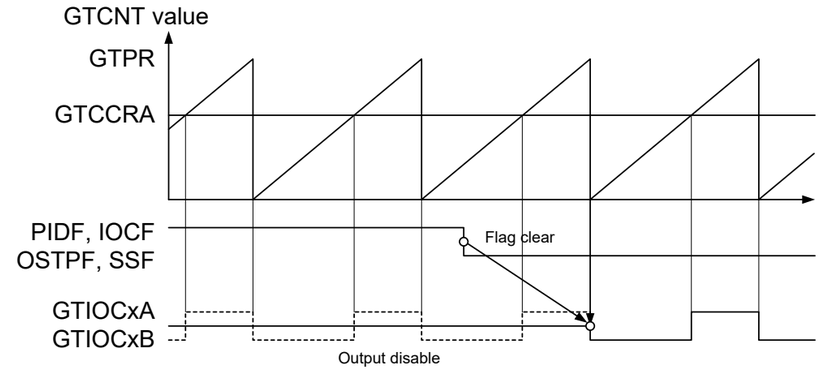
- POEGGn.PIDF
- POEGGn.IOCF
- POEGGn.OSTPF
- POEGGn.SSF

如果外部输入引脚GTETRn未被禁用且POEGGn.ST位未设置为0，则忽略向POEGGn.PIDF标志写入0（该标志不被清除）。

仅当GPT中的所有GTST.OABHF和GTST.OABLF标志都设置为0时，向POEGGn.IOCF标志写入0才有效（该标志被清除）。

如果时钟生成电路中的OSTDSR.OSTDF标志未设置为0，则忽略向POEGGn.OSTPF标志写入0（该标志不被清除）。此外，当标志设置和释放同时发生时，标志集优先。

图20.3显示了输出禁用的释放时序。标志清零后，在GPT的下一个计数周期开始时，输出禁用被释放。



Note: The base address of the registers are the same.

Figure 20.3 Output-disable release timing for GPT pin outputs

20.4 Interrupt Sources

The POEG generates an interrupt request when triggered by these sources:

- Output-disable control by the input level detection
- Output-disable request from the GPT

Table 20.3 lists the conditions for interrupt requests.

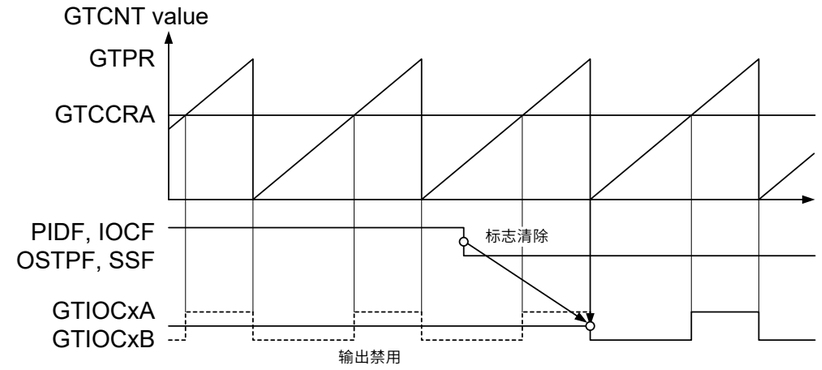
Table 20.3 Interrupt sources and conditions

Interrupt source	Symbol	Associated flag	Trigger conditions
POEG group A interrupt	POEG_GROUPA	POEGGA.IOCF	An output-disable request from a GPT disable request occurred
		POEGGA.PIDF	An output-disable request from the GTETRGA pin occurred
POEG group B interrupt	POEG_GROUPB	POEGGB.IOCF	An output-disable request from a GPT disable request occurred
		POEGGB.PIDF	An output-disable request from the GTETRGB pin occurred
POEG group C interrupt	POEG_GROUPC	POEGGC.IOCF	An output-disable request from a GPT disable request occurred
		POEGGC.PIDF	An output-disable request from the GTETRGC pin occurred
POEG group D interrupt	POEG_GROUPD	POEGGD.IOCF	An output-disable request from a GPT disable request occurred
		POEGGD.PIDF	An output-disable request from the GTETRGD pin occurred

20.5 External Trigger Output to the GPT

The POEG outputs signals generated by filtering and level detection of GTETRGn pins input signals as the GPT operation trigger signal for the following:

- Count start
- Count stop
- Count clear
- Up-count
- Down-count
- Input capture



Note: 寄存器的基地址相同。

Figure 20.3 GPT引脚输出的输出禁用释放时序

20.4 中断源

当这些源触发时，POEG会产生一个中断请求：

●通过输入电平检测进行输出禁止控制

●来自GPT的输出禁用请求

表20.3列出了中断请求的条件。

Table 20.3 中断源和条件

中断源	Symbol	相关标志	触发条件

20.5 到GPT的外部触发输出

POEG输出GTETRn管脚输入信号滤波和电平检测产生的信号作为GPT操作触发信号，用于以下用途：

●计数开始

●计数停止

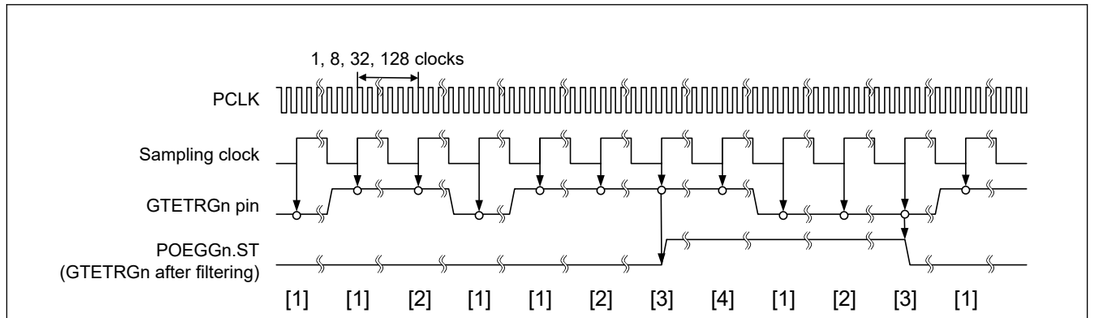
●清点

- Up-count
- Down-count

●输入捕捉

For the POEGGn.INV polarity setting signal, when the same level is input three times continuously with the sampling clock selected in POEGGn.NFCS[1:0] and POEGGn.NFEN, that value is output. Set the control registers the same as for the input level detection operation described in section 20.3.1. Pin Input Level Detection Operation The state after filtering can be monitored in POEGGn.ST.

Figure 20.4 shows the output timing of an external trigger to the GPT.



Note: PCLK = PCLKB
Note: Each channel output can be set in the GPT settings. Polarity can be reversed in POEGGn.INV.

Figure 20.4 Output timing of external trigger to the GPT

20.6 Usage Notes

20.6.1 Transition to Software Standby Mode

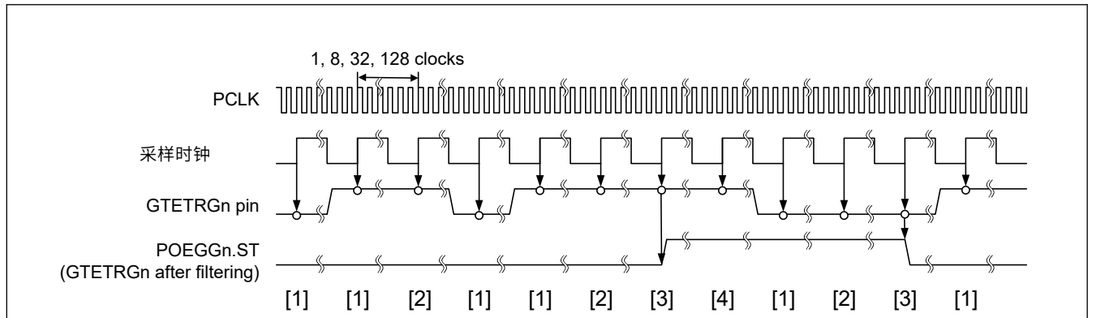
When using the POEG, do not invoke Software Standby mode. In this mode, the POEG stops and therefore output disable of the pins cannot be controlled.

20.6.2 Specifying Pins Associated with the GPT

The POEG controls output-disable only when a pin is associated with the GPT in the PmnPFS.PMR and PmnPFS.PSEL settings. When the pin is specified as a general I/O pin, the POEG does not perform output-disable control.

对于POEGGn.INV极性设置信号，当在POEGGn.NFCS[1:0]和POEGGn.NFEN中选择的采样时钟连续输入相同电平3次时，输出该值。控制寄存器的设置与20.3.1节中描述的输入电平检测操作相同。引脚输入电平检测操作滤波后的状态可以在POEGGn.ST中监控。

图20.4显示了外部触发到GPT的输出时序。



Note: PCLK = PCLKB
Note: 每个通道输出都可以在GPT设置中进行设置。POEGGn.INV中的极性可以颠倒。

Figure 20.4 外部触发到GPT的输出时序

20.6 使用说明

20.6.1 过渡到软件待机模式

使用POEG时，请勿调用软件待机模式。在此模式下，POEG停止，因此无法控制引脚的输出禁用。

20.6.2 指定与GPT关联的引脚

仅当引脚与PmnPFS.PMR和PmnPFS.PSEL设置中的GPT关联时，POEG才控制输出禁用。当引脚指定为通用IO引脚时，POEG不执行输出禁用控制。

GTWP enables or disables writing to registers to prevent accidental modification. Protection by the GTWP register is only for the writes by the CPU. GTWP does not protect registers from updates that occur in association with CPU writes.

WP bit (Register Write Disable)

The following is a list of write enabled or disabled registers:

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTDTCR, GTDVU, GTADSMR, GTICLF, GTPC.

STRWP bit (GTSTR.CSTRT Bit Write Disable)

The STRWP bit enables or disables starting the updating of counter values by writing to the CSTRTn bit (n = 1, 2, 4, 5) corresponding to a channel number in the GTSTR register.

The bit position of each CSTRTn bit in the GTSTR register is allocated to the channel with the corresponding number, and writing to the GTSTR register for any channel results in writing to the registers of all channels. The STRWP bit for each channel does not control writing but only controls updating of the CSTRT bit for the corresponding channel when simultaneously writing to all channels.

21.2 注册说明

21.2.1 GTWP:通用PWM定时器写保护寄存器

Base address: GPT32n = 0x4016_9000 + 0x0100 × n (n = 1, 2)

2	STPWP	GTSTP.CSTOP位写禁止 0：允许写入位1：禁止写入位	R/W

31:16	—	这些位被读取为0。写入值应为0。	R/W

GTWP启用或禁用写入寄存器以防止意外修改。GTWP寄存器的保护只针对CPU的写操作。GTWP不保护寄存器免受与CPU写入相关的更新。

WP位（寄存器写禁止）

以下是写启用或禁用寄存器的列表：

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTDTCR, GTDVU, GTADSMR, GTICLF, GTPC.

STRWP位（GTSTR.CSTRT位写入禁用）

STRWP位通过写入与GTSTR寄存器中的通道号对应的CSTRTn位(n=1 2 4 5)来启用或禁用开始更新计数器值。

GTSTR寄存器中每个CSTRTn位的位位置分配给对应编号的通道，对任何通道写入GTSTR寄存器都会导致写入所有通道的寄存器。每个通道的STRWP位不控制写入，而仅在同时写入所有通道时控制相应通道的CSTRT位的更新。

Therefore, when writing to the CSTRT bits of a channel for which the setting of the STRWP bit is 1(disabling writing), the CSTRT bit for the given channel is not updated, but the CSTRT bits corresponding to channel for which the setting of the STRWP bit is 0 (enabling writing) are updated. For example, when the setting of the GPTn.GTWP.STRWP bit is 0 (enabling writing), writing 1 to the GPT_{n+1}.GTSTR.CSTRTn bit when its current setting is 0 causes the value to be updated, and the GPTn.GTCNT counter starts to run. When the setting of the GPTn.GTWP.STRWP bit is 1 (disabling writing), writing 1 to the GPT_{n+1}.GTSTR.CSTRTn bit when its current setting is 0 leaves the bit with the value 0, and the GPTn.GTCNT counter does not run.

If you want to protect all bits in the GTSTR register from being updated, set the STRWP bits of all channels to 1.

STPWP bit (GTSTP.CSTOP Bit Write Disable)

The STPWP bit enables or disables starting the updating of counter values by writing to the CSTOPn bit (n = 1, 2, 4, 5) corresponding to a channel number in the GTSTP register.

The bit position of each CSTOPn bit in the GTSTP registers is allocated to the channel with the corresponding number, and the writing to the GTSTP register for any channel results in writing to the registers of all channels. The STPWP bit for each channel does not control writing but only controls updating of the CSTOP bit for the corresponding channel when simultaneously writing to all channels.

Therefore, when writing to the CSTOP bits of a channel for which the setting of the STPWP bit is 1(disabling writing), the CSTOP bit for the given channel is not updated, but the CSTOP bits corresponding to channel for which the setting of the STPWP bit is 0 (enabling writing) are updated. For example, when the setting of the GPTn.GTWP.STPWP bit is 0 (enabling writing), writing 1 to the GPT_{n+1}.GTSTP.CSTOPn bit when its current setting is 0 causes the value to be updated, and the GPTn.GTCNT counter is stopped. When the setting of the GPTn.GTWP.STPWP bit is 1 (disabling writing), writing 1 to the GPT_{n+1}.GTSTP.CSTOPn bit when its current setting is 0 leaves the bit with the value 0, and the GPTn.GTCNT counter is not stopped.

If you want to protect all bits in the GTSTP register from being updated, set the STPWP bits of all channels to 1.

CLRWP bit (GTCLR.CCLR Bit Write Disable)

CLRWP bit enables or disables starting the updating of counter values by writing to the CCLRn bit (n = 1, 2, 4, 5) corresponding to a channel number in the GTCLR register.

The bit position of each CCLRn bit in the GTCLR registers is allocated to the channel with the corresponding number, and the writing to the GTCLR register for any channel results in writing to the registers of all channels. The CLRWP bit for each channel does not control writing but only controls updating of the CCLR bit for the corresponding channel when simultaneously writing to all channels.

Therefore, when writing to the CCLR bits of a channel for which the setting of the CLRWP bit is 1(disabling writing), the CCLR bit for the given channel is not updated, but the CCLR bits corresponding to channel for which the setting of the CLRWP bit is 0 (enabling writing) are updated. For example, when the setting of the GPTn.GTWP.CLRWP bit is 0 (enabling writing), writing 1 to the GPT_{n+1}.GTCLR.CCLRn bit when its current setting is 0 causes the value to be updated, and the GPTn.GTCNT counter is cleared. When the setting of the GPTn.GTWP.CLRWP bit is 1 (disabling writing), writing 1 to theGPT_{n+1}.GTCLR.CCLRn bit when its current setting is 0 leaves the bit with the value 0, and the GPTn.GTCNT counter is not cleared.

If you want to protect all bits in the GTCLR register from being updated, set the CLRWP bits of all channels to 1.

CMNWP bit (Common Register Write Disabled)

CMNWP bit enables or disables starting the updating of counter values by writing to the SECSELn bit (n = 1, 2, 4, 5) corresponding to a channel number in the GTSECSR register or to the GTSECR register.

The bit position of each SECSEL bit in the GTSECSR registers is allocated to the channel with the corresponding number, and the writing to the GTSECSR register for any channel results in writing to the registers of all channels. Writing to the GTSECR register of any channel leads to writing to the registers of all channels. The CMNWP bit for each channel does not control writing but only controls updating of the SECSEL bit and the GTSECR register value for the corresponding channel when simultaneously writing to all channels.

Therefore, when writing to the SECSEL bit and the GTSECR register value of a channel for which the setting of the CMNWP bit is 1(disabling writing), the SECSEL bit and the GTSECR register value for the given channel is not updated, but the SECSEL bit and the GTSECR register value corresponding to channel for which the setting of the CMNWP bit is 0 (enabling writing) are updated.

因此，当写入STRWP位设置为1（禁止写入）的通道的CSTRT位时，
给定通道的CSTRT位不会更新，但对应于其设置的通道的CSTRT位
STRWP位为0（允许写入）被更新。例如，当GPTn.GTWP.STRWP位的设置为0（允许写入）时，当前设置为0时向GPTn+1.GTSTR.CSTRTn位写入1会导致值被更新，并且GPTn.GTCNT计数器开始运行。当GPTn.GTWP.STRWP位设置为1时（禁止写入），当前设置为0时向GPTn+1.GTSTR.CSTRTn位写入1使该位保留值为0，并且GPTn.GTCNT计数器不运行。

如果要保护GTSTR寄存器中的所有位不被更新，请将所有通道的STRWP位设置为1。

STPWP位（GTSTP.CSTOP位写入禁用）

STPWP位通过写入与GTSTP寄存器中的通道号对应的CSTOPn位(n=1 2 4 5)来启用或禁用开始更新计数器值。

GTSTP寄存器中每个CSTOPn位的位位置分配给对应编号的通道，对任何通道写入GTSTP寄存器都会导致写入所有通道的寄存器。每个通道的STPWP位不控制写入，而仅控制同时写入所有通道时相应通道的CSTOP位的更新。

因此，当写入STPWP位设置为1的通道的CSTOP位（禁止写入）时，给定通道的CSTOP位不会更新，但对应于其设置的通道的CSTOP位STPWP位为0（允许写入）被更新。例如，当GPTn.GTWP.STPWP位的设置为0（使能写入）时，当前设置为0时向GPTn+1.GTSTP.CSTOPn位写入1会导致值被更新，并且GPTn.GTCNT计数器停止。当GPTn.GTWP.STPWP位设置为1（禁止写入）时，将1写入

GPTn+1.GTSTP.CSTOPn位在其当前设置为0时保留该位的值0，并且GPTn.GTCNT计数器不会停止。

如果要保护GTSTP寄存器中的所有位不被更新，请将所有通道的STPWP位设置为1。

CLRWP位（GTCLR.CCLR位写入禁止）

CLRWP位通过写入与GTCLR寄存器中的通道号对应的CCLRn位(n=1 2 4 5)来启用或禁用开始更新计数器值。

GTCLR寄存器中每个CCLRn位的位位置分配给对应编号的通道，对任何通道写入GTCLR寄存器都会导致写入所有通道的寄存器。每个通道的CLRWP位不控制写入，而仅在同时写入所有通道时控制相应通道的CCLR位的更新。

因此，当写入CLRWP位设置为1（禁止写入）的通道的CCLR位时，
给定通道的CCLR位不会更新，但对应于其设置的通道的CCLR位
CLRWP位为0（允许写入）被更新。例如，当GPTn.GTWP.CLRWP位的设置为0（使能写入）时，当前设置为0时向GPTn+1.GTCLR.CCLRn位写入1会导致值被更新，并且GPTn.GTCNT计数器清零。当GPTn.GTWP.CLRWP位设置为1时（禁止写入），当当前设置为0时向GPTn+1.GTCLR.CCLRn位写入1使该位保留值为0，并且GPTn.GTCNT计数器未清除。

如果要保护GTCLR寄存器中的所有位不被更新，请将所有通道的CLRWP位设置为1。

CMNWP位（公共寄存器写入禁用）

CMNWP位通过写入与GTSECSR寄存器或GTSECR寄存器中的通道号相对应的SECSELn位(n=1 2 4 5)来启用或禁用开始更新计数器值。

GTSECSR寄存器中每个SECSEL位的位位置分配给对应编号的通道，对任何通道写入GTSECSR寄存器都会导致写入所有通道的寄存器。写入任何通道的GTSECR寄存器会导致写入所有通道的寄存器。每个通道的CMNWP位不控制写入，而仅在同时写入所有通道时控制相应通道的SECSEL位和GTSECR寄存器值的更新。

因此，当写入通道的SECSEL位和GTSECR寄存器值时，
CMNWP位为1（禁止写入），给定通道的SECSEL位和GTSECR寄存器值不更新，但与CMNWP位设置为0的通道对应的SECSEL位和GTSECR寄存器值（允许写入）已更新。

For example, when the setting of the GPTn.GTWP.CMNWP bit is 0 (enabling writing), writing to the GPT_{n+1}.GTSECSR.SECSELn bit causes the value of the GPTn.GTSECSR.SECSELn bit to be updated. In the same way, writing to the GPT_{n+1}.GTSECR register updates the value of the GPTn.GTSECR register. When the setting of the GPTn.CMNWP bit is 1 (disabling writing), writing to the GPT_{n+1}.GTSECSR.SECSELn bit does not cause the value of the GPTn.GTSECSR.SECSELn bit to be updated. In the same way, writing to the GPT_{n+1}.GTSECR register does not update the value of the GPTn.GTSECR register.

If you want to protect all bits in the GTSECSR and GTSECR registers from being updated, set the CMNWP bits of all channels to 1.

PRKEY[7:0] bit (GTWP Key Code)

This bit controls whether the WP, STRWP, STPWP, CLRWP, and CMNWP bits can be overwritten.

21.2.2 GTSTR : General PWM Timer Software Start Register

Base address: GPT32n = 0x4016_9000 + 0x0100 × n (n = 1, 2)
GPT16m = 0x4016_9000 + 0x0100 × m (m = 4, 5)

Offset address: 0x04

Bit position:	31																													0
Bit field:	CSTRT31 to CSTRT0																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CSTRT0 to CSTRT31*1	Channel n GTCNT Count Start (n is the same as the bit position value) 0: GTCNT counter is not started 1: GTCNT counter is started	R/W

Note 1. The bits that can be used vary depending on the product. The n in CSTRTn is the same as the GPT channel number. For this product, n is 1, 2, 4, 5.

The GTSTR starts the GTCNT counter operation for each channel n, where n = 1, 2, 4, 5.

The GTSTR bit number represents the channel number. The GTSTR register of each channel is shared by all of the channels. The GTCNT counter starts for the channel associated with the GTSTR bit number where 1 is written. Writing 0 has no effect on the status of GTCNT counter and the value of GTSTR register.

The bit corresponding to channel which security attribution is configured as secure can be read by non-secure access but cannot be written by non-secure access. For example, if GPT channel n is configured as secure and other GPTs are configured as non-secure, the CSTRTn bit cannot be written by non-secure access to GTSTR register in GPT channel n + 1, and the GTCNT counter operation status of GPT channel n is not changed. When the GTSTR register in GPT channel n + 1 is read by non-secure access in the same security configuratin as the previous example, the GTCNT counter operation status of GPT channel n ($CSTRT_n$ bit) can be read.

For the association between module names and channel numbers, see Figure 21.2.

CSTRTn bits (Channel n GTCNT Count Start (n = 1, 2, 4, 5))

The CSTRTn bits start channel n of the GTCNT counter operation. Writing to the GTSTR.CSTRTn bit (n = 1, 2, 4, 5) has no effect unless the GTSSR.CSTRT bit is set to 1.

The read data shows the counter status of each channel (GTCR.CST bit). A value of 0 means the counter is stopped and 1 means the counter is running.

例如，当GPTn.GTWP.CMNWP位设置为0（允许写入）时，写入GPTn+1.GTSECSR.SECSELn位导致GPTn.GTSECSR.SECSELn位的值被更新。同样，写入GPTn+1.GTSECR寄存器会更新GPTn.GTSECR寄存器的值。当GPTn.CMNWP位设置为1（禁止写入）时，写入GPTn+1.GTSECSR.SECSELn位不会导致GPTn.GTSECSR.SECSELn位的值更新。同样，写入GPTn+1.GTSECR寄存器不会更新GPTn.GTSECR寄存器的值。

如果要保护GTSECSR和GTSECR寄存器中的所有位不被更新，请将所有通道的CMNWP位设置为1。

PRKEY[7:0]位（GTWP密钥代码）

该位控制是否可以覆盖WP、STRWP、STPWP、CLRWP和CMNWP位。

注1.可使用的钻头因产品而异。CSTRTn中的n与GPT通道号相同。对于该产品，n为1、2、4、5。

GTSTR为每个通道n启动GTCNT计数器操作，其中n=1、2、4、5。

GTSTR位号代表通道号。每个通道的GTSTR寄存器由所有通道共享。GTCNT计数器针对与写入1的GTSTR位号关联的通道启动。写0对GTCNT计数器的状态和GTSTR寄存器的值没有影响。

安全属性配置为安全的通道对应的位可以被非安全访问读取，但不能被非安全访问写入。例如，如果GPT通道n配置为安全，而其他GPT配置为非安全，则不能通过非安全访问GPT通道n+1中的GTSTR寄存器来写入CSTRTn位，以及GPT的GTCNT计数器操作状态频道n不变。当GPT通道n+1中的GTSTR寄存器通过与上例相同的安全配置中的非安全访问读取时，可以读取GPT通道n的GTCNT计数器操作状态（CSTRTn位）。

模块名称与通道号的对应关系见图21.2。

CSTRTn位（通道nGTCNT计数开始（n=1、2、4、5））

CSTRTn位启动GTCNT计数器操作的通道n。除非将GTSSR.CSTRT位设置为1，否则写入GTSTR.CSTRTn位（n=1、2、4、5）无效。

读取的数据显示每个通道的计数器状态（GTCR.CST位）。0表示计数器停止，1表示计数器正在运行。

21.2.3 GTSTP : General PWM Timer Software Stop Register

Base address: GPT32n = 0x4016_9000 + 0x0100 × n (n = 1, 2)
GPT16m = 0x4016_9000 + 0x0100 × m (m = 4, 5)

31:0	CSTOP0 to CSTOP31*1	Channel n GTCNT Count Stop (n is the same as the bit position value) 0: GTCNT counter is not stopped 1: GTCNT counter stopped	R/W

Note 1. The bits that can be used vary depending on the product. The n in CSTOPn is the same as the GPT channel number. For this product, n is 1, 2, 4, 5.

The GTSTP stops the GTCNT counter operation for each channel n, where n = 1, 2, 4, 5.

The GTSTP bit number represents the channel number. The GTSTP register of each channel is shared by all the channels. The GTCNT counter stops for the channel associated with the GTSTP bit number where 1 is written. Writing 0 has no effect on the status of the GTCNT counter and the value of GTSTP register.

The bit corresponding to channel which security attribution is configured as secure can be read by non-secure access but cannot be written by non-secure access. For example, if GPT channel n is configured as secure and other GPTs are configured as non-secure, the CSTOPn bit cannot be written by non-secure access to GTSTP register in GPT channel n + 1, and the GTCNT counter operation status of GPT channel n is not changed. When the GTSTP register in GPT channel n + 1 is read by non-secure access in the same security configuratin as the previous example, the GTCNT counter operation status of GPT channel n (CSTOPn bit) can be read.

For the association between module names and channel numbers, see Figure 21.2.

CSTOPn bits (Channel n GTCNT Count Stop (n = 1, 2, 4, 5))

The CSTOPn bits stop channel n of the GTCNT counter operation. Writing to the GTSTP.CSTOPn bit (n = 1, 2, 4, 5) has no effect unless the GTPSR.CSTOP bit is set to 1. The read data shows the counter status of each channel (invert of GTCR.CST bit). A value of 0 means the counter is running and 1 means the counter is stopped.

Note 1. The bits that can be used vary depending on the product. The n of CCLRn is the same as the GPT channel number. For this product, n is 1, 2, 4, 5.

The GTCLR is a write-only register that clears the GTCNT counter operation for each channel n, where n = 1, 2, 4, 5.

GTCLR是一个只写寄存器，用于清除每个通道n的GTCNT计数器操作，其中n=1、2、4、5。

The GTCLR bit number represents the channel number. The GTCLR register of each channel is shared by all the channels. The GTCNT counter is cleared for the channel associated with the GTCLR bit number where 1 is written. Writing 0 has no effect on the status of GTCNT counter.

The bit corresponding to channel which security attribution is configured as secure can not be written by non-secure access. For example, if GPT channel n is configured as secure and other GPTs are configured as non-secure, the CCLRn bit cannot be written by non-secure access to GTCLR register in GPT channel n + 1, and the GTCNT counter of GPT channel n is not cleared.

For the association between module names and channel numbers, see Figure 21.2.

CCLRn bits (Channel n GTCNT Count Clear (n = 1, 2, 4, 5))

When the counting direction flag is set for decrement (GTST.TUCF flag = 0) with saw-wave mode selected in the GTCR.MD[2:0] bits, the value of the GTCNT counter becomes that of the corresponding GTPR register in response to writing 1 to the CCLRn bit. The value of the counter becomes 0x0000 0000 with other settings. These bits are read as 0.

The GTUPSR sets the source to count up the GTCNT counter.

When at least one bit in the GTUPSR register is set to 1, the GTCNT counter is counted up by the source that is set to 1 in this register. In this case, GTCR.TPCS has no effect.

Number of increment in counting is one even when multiple sources are generated simultaneously.

Inputs from GTETRGn (n = A to D) pins are input to the GPT via the POEG. Set the polarity of these signals with the POEG.

GTUPSR将源设置为对GTCNT计数器进行计数。

当GTUPSR寄存器中的至少一位设置为1时，GTCNT计数器由该寄存器中设置为1的源进行计数。在这种情况下，GTCR.TPCS无效。

即使同时生成多个源，计数中的增量数也是1。

来自GTETRn（n=A到D）引脚的输入通过POEG输入到GPT。设置这些信号的极性

The GTDNSR sets the source to count down the GTCNT counter.

When at least one bit in the GTDNSR register is set to 1, the GTCNT counter is counted down by the source that is set to 1 in this register. In this case, GTCR.TPCS has no effect.

Number of decrement in counting is one even when multiple sources are generated simultaneously.

Inputs from GTETRGn (n = A to D) pins are input to the GPT via the POEG. Set the polarity of these signals with the POEG.

GTDNSR将源设置为对GTCNT计数器进行倒计时。

当GTDNSR寄存器中的至少一位设置为1时，GTCNT计数器由该寄存器中设置为1的源进行倒数计数。在这种情况下，GTCR.TPCS无效。

即使同时生成多个源，计数的减量也是一。

GTUDDTYC设置GTCNT计数的方向（向上计数或向下计数），并设置GTIOCnAGTIOCnB引脚输出。

该设置在事件计数操作期间无效。

Count Direction:

- In saw-wave mode.
  When the UD value is set to 0 during up-counting, the count direction changes at an overflow (the timing synchronous with count clock after the GTCNT value becomes the GTPR value). When the UD value is set to 1 during down-counting, the count direction changes at an underflow (the timing synchronous with count clock after the GTCNT value becomes 0).
  When the UD value changes from 1 to 0 with the UDF bit being 0 and while counting stops, the counter starts up-counting and the count direction changes at an overflow (the timing synchronous with count clock after the GTCNT value becomes the GTPR value). When the UD value changes from 0 to 1 with the UDF bit being 0 and while counting stops, the counter starts down-counting and the count direction changes at an underflow (the timing synchronous with count clock after the GTCNT value becomes 0).
  When the UDF bit is set to 1 while counting stops, the UD bit value is reflected in the count direction when counting starts.
- In triangle-wave mode.
  When the UD value changes during counting, the count direction does not change. When the UD value changes while the UDF bit is 0 and counting stops, the change is not reflected in the count direction when counting starts.
  When the UDF bit is set to 1 while counting is stopped, the UD value is reflected in the count direction when counting starts.

UD bit (Count Direction Setting)

The UD bit sets the count direction (up-counting or down-counting) for GTCNT.

UDF bit (Forcible Count Direction Setting)

The UDF bit forcibly sets the count direction when GTCNT starts operation as the UD value. Only 0 should be written to this bit during counter operation. When 1 is written to this bit while counting stops, return this bit to 0 before counting starts.

Output duty

- In saw-wave mode.
  When the OADTY/OBDTY value changes during up-counting, the duty is reflected at an overflow (GTCNT = GTPR).
  When the OADTY/OBDTY value is changed during down-counting, the duty is reflected at an underflow (GTCNT = 0).
  When the OADTY/OBDTY value is changed with the OADTYF/OBDTYF bit being 0 and while counting stops the output duty is not reflected at the starting counter operation. When the count direction is up, the output duty is reflected at an overflow (GTCNT = GTPR). When the count direction is down, the output duty is reflected at an underflow (GTCNT = 0).
  When the OADTY/OBDTY value is changed with the OADTYF/OBDTYF bit being 1 and while counting stops, the output duty is reflected at starting counter operation.
- In triangle-wave mode.
  When the OADTY/OBDTY value changes during counting, the duty is reflected at an underflow.
  When the OADTY/OBDTY value is changed with the OADTYF/OBDTYF bit being 0 and while counting stops, the output duty is not reflected at the starting counter operation. The output duty is reflected at an underflow.
  When the OADTY/OBDTY value is changed with the OADTYF/OBDTYF bit being 1 and while counting stops, the output duty is reflected at starting counter operation.

In both saw-wave mode and triangle-wave mode, when the OADTYF/OBDTYF bit is set back to 0 and the OADTY[1:0]/OBDTY[1:0] bits are set after setting the OADTYF/OBDTYF bit to 1 and setting the OADTY[1:0]/OBDTY[1:0] bits for the duty of first cycle while count operation is stopped, these duty-cycle set during stopping count operation are reflected in the first cycle and the second cycle after starting count operation.

OmDTY[1:0] bits (GTIOCnm Output Duty Setting) (m = A, B)

The OmDTY[1:0] bits set the output duty (0%, 100% or compare match control) of the GTIOCm pin.

OmDTYF bit (Forcible GTIOCnm Output Duty Setting) (m = A, B)

The OmDTYF bit forcibly sets the output duty cycle to the OmDTY setting. Set this bit to 0 during counter operation.

Count Direction:

●在锯齿波模式下。
如果在向上计数期间将UD值设置为0，则计数方向会在溢出时发生变化（GTCNT值变为GTPR值后与计数时钟同步的时序）。在递减计数期间将UD值设置为1时，计数方向会在下溢（GTCNT值变为0后与计数时钟同步的时序）下发生变化。当UDF位为0时UD值从1变为0并且在计数停止时，计数器开始计数并且计数方向在溢出时改变（在GTCNT值变为GTPR值之后与计数时钟同步的时序）。当UDF位为0且UD值从0变为1且计数停止时，计数器开始递减计数并且计数方向在下溢时改变（GTCNT值变为0后与计数时钟同步的时序）。当计数停止时UDF位设置为1时，UD位值在计数开始时反映在计数方向上。

●三角波模式。
计数过程中UD值变化时，计数方向不变。当UDF位为0时UD值发生变化并且计数停止时，该变化不会反映在计数开始时的计数方向上。当计数停止时UDF位设置为1时，UD值在计数开始时反映在计数方向上。

UD位（计数方向设置）

UD位设置GTCNT的计数方向（向上计数或向下计数）。

UDF位（强制计数方向设置）

当GTCNT开始操作时，UDF位将计数方向强制设置为UD值。在计数器操作期间，只能将0写入该位。当计数停止时向该位写入1时，在计数开始前将该位返回0。

输出占空比

●在锯齿波模式下。
当OADTYOBDTY值在递增计数期间发生变化时，占空比反映在溢出处(GTCNT=GTPR)。
在递减计数期间更改OADTYOBDTY值时，占空比反映为下溢(GTCNT=0)。在OADTYFOBDTYF位为0的情况下更改OADTYOBDTY值并且在计数停止时，输出占空比不会反映在启动计数器操作中。当计数方向向上时，输出占空比反映在溢出处(GTCNT=GTPR)。当计数方向向下时，输出占空比反映为下溢(GTCNT=0)。当OADTYFOBDTYF位为1并改变OADTYOBDTY值时，当计数停止时，输出占空比反映在开始计数器操作时。

●三角波模式。
当计数期间OADTYOBDTY值发生变化时，占空比反映为下溢。
在OADTYFOBDTYF位为0的情况下更改OADTYOBDTY值并且在计数停止时，输出占空比不会反映在开始计数器操作中。输出占空比反映在下溢处。当OADTYFOBDTYF位为1并改变OADTYOBDTY值时，当计数停止时，输出占空比反映在开始计数器操作时。

在锯齿波模式和三角波模式下，当OADTYFOBDTYF位被设置回0并且OADTY[1:0]OBDTY[1:0]位在设置OADTYFOBDTYF位为1并设置OADTY[1:0]OBDTY[1:0]位用于计数操作停止时第一个周期的占空比，这些在停止计数操作期间设置的占空比反映在开始计数操作后的第一个周期和第二个周期中。

OmDTY[1:0]位（GTIOCnm输出占空比设置）（m=A，B）

OmDTY[1:0]位设置GTIOCm引脚的输出占空比（0%、100%或比较匹配控制）。

OmDTYF位（强制GTIOCnm输出占空比设置）（m=A，B）

OmDTYF位强制将输出占空比设置为OmDTY设置。在计数器操作期间将此位设置为0。

OmDTYR bit (GTIOCnm Output Value Selecting after Releasing 0%/100% Duty Setting) (m = A, B)

The OmDTYR bit selects the value that is the object of output retained or toggled at cycle end, when the control changes from 0% or 100% duty setting to compare match for the GTIOCm pin and GTIOR.GTIOm[3:2] bits are set to 00b (output retained at cycle end) or the GTIOR.GTIOm[3:2] bits are set to 11b (output toggled at cycle end).

The GPT internally continues to perform compare match operation during duty-cycle 0% or 100% operation. When the OmDTYR bit is 1, the value after the period has elapsed due this compare match operation is target for the GTIOm[3:2] bits.

OmDTYR位（释放0%100%占空比设置后选择GTIOCnm输出值）（m=A、B）

当控制从0%或100%占空比设置更改为GTIOCm引脚的比较匹配且GTIOR.GTIOm[3:2]位设置00b（输出在循环结束时保留）或GTIOR.GTIOm[3:2]位设置为11b（输出在循环结束时切换）。

在占空比0%或100%操作期间，GPT在内部继续执行比较匹配操作。当OmDTYR位为1时，由于此比较匹配操作而经过一段时间后的值是GTIOm[3:2]位的目标。

The GTIOR sets the functions of the GTIOCnA and GTIOCnB pins.

GTIOA[4:0] bits (GTIOCnA Pin Function Select)

The GTIOA[4:0] bits select the GTIOCnA pin function. For details, see Table 21.4.

OADFLT bit (GTIOCnA Pin Output Value Setting at the Count Stop)

The OADFLT bit sets whether the GTIOCnA pin outputs high or low when counting stops.

OAHLD bit (GTIOCnA Pin Output Setting at the Start/Stop Count)

The OAHLD bit specifies whether the GTIOCnA pin output level is retained or the level at the start or stop of counting depends on the register setting.

When the OAHLD bit is set to 0:

- The value specified in bit [4] of the GTIOA[4:0] bits is output when counting starts
- The value specified in the OADFLT bit is output when counting stops
- If the OADFLT bit is modified while counting stops, the new value is immediately reflected in the output.

When the OAHLD bit is set to 1:

- The output is retained when counting starts or stops.

OAE bit (GTIOCnA Pin Output Enable)

The OAE bit disables or enables the GTIOCnA pin output.

When GTCCRA register is used as the input capture register (at least one bit in the GTICASR register is set to 1), the GTIOCnA pin does not output regardless of the OAE bit value.

OADF[1:0] bits (GTIOCnA Pin Disable Value Setting)

The OADF[1:0] bits select the output value of the GTIOCnA pin when an output disable request occurs.

GTIOR设置GTIOCnA和GTIOCnB引脚的功能。

GTIOA[4:0]位（GTIOCnA引脚功能选择）

GTIOA[4:0]位选择GTIOCnA引脚功能。详见表21.4。

OADFLT位（计数停止时的GTIOCnA引脚输出值设置）

OADFLT位设置当计数停止时GTIOCnA引脚输出高电平还是低电平。

OAHLD位（开始停止计数时的GTIOCnA引脚输出设置）

OAHLD位指定是保留GTIOCnA引脚输出电平还是计数开始或停止时的电平取决于寄存器设置。

当OAHLD位设置为0时：

●GTIOA[4:0]位的位[4]中指定的值在计数开始时输出

●计数停止时输出OADFLT位中指定的值

●如果在计数停止时修改OADFLT位，则新值会立即反映在输出中。

当OAHLD位设置为1时：

●计数开始或停止时保持输出。

OAE位（GTIOCnA引脚输出使能）

OAE位禁用或启用GTIOCnA引脚输出。

当GTCCRA寄存器用作输入捕捉寄存器时（GTICASR寄存器中至少有一位设置为1），无论OAE位值如何，GTIOCnA引脚都不输出。

OADF[1:0]位（GTIOCnA引脚禁用值设置）

当出现输出禁用请求时，OADF[1:0]位选择GTIOCnA引脚的输出值。

NFAEN bit (Noise Filter A Enable)

The NFAEN bit disables or enables the noise filter for input from the GTIOCnA pin. Because changing the value of the bit might lead to the internal generation of an unexpected edge, select the output compare function for the relevant pin in the GTIOR register before doing so.

NFCSA[1:0] bits (Noise Filter A Sampling Clock Select)

The NFCSA[1:0] bits set the sampling interval for the noise filter of the GTIOCnA pin. When setting these bits, wait for 2 cycles of the selected sampling interval before setting the input capture function.

GTIOB[4:0] bits (GTIOCnB Pin Function Select)

The GTIOB[4:0] bits select the GTIOCnB pin function. For details, see Table 21.4.

OBDFLT bit (GTIOCnB Pin Output Value Setting at the Count Stop)

The OBDFLT bit sets whether the GTIOCnB pin outputs high or low when counting stops.

OBHLD bit (GTIOCnB Pin Output Setting at the Start/Stop Count)

The OBHLD bit specifies whether theGTIOCnB pin output level is retained or the level at the start or stop of counting depends on the register setting.

When the OBHLD bit is set to 0:

- The value specified in bit [4] of the GTIOB[4:0] bits is output when counting starts
- The value specified in the OBDFLT bit is output when counting stops
- If the OBDFLT bit is modified while counting stops, the new value is immediately reflected in the output.

When the OBHLD bit is set to 1:

- The output is retained when counting starts or stops.

OBE bit (GTIOCnB Pin Output Enable)

The OBE bit disables or enables the GTIOCnB pin output.

When GTCCRB register is used as the input capture register (at least one bit in the GTICBSR register is set to 1), the GTIOCnB pin does not output regardless of the OBE bit value.

OBDF[1:0] bits (GTIOCnB Pin Disable Value Setting)

The OBDF[1:0] bits select the output value of the GTIOCnB pin, when an output disable request occurs.

NFBEN bit (Noise Filter B Enable)

The NFBEN bit disables or enables the noise filter for input from the GTIOCnB pin. Because changing the value of the bit might lead to the internal generation of an unexpected edge, select the output compare function for the relevant pin in the GTIOR register before doing so.

NFCSB[1:0] bits (Noise Filter B Sampling Clock Select)

The NFCSB[1:0] bits set the sampling interval for the noise filter of the GTIOCnB pin. When setting these bits, wait for 2 cycles of the selected sampling interval before setting the input capture function.

NFAEN位（噪声滤波器A使能）

NFAEN位禁用或启用来自GTIOCnA引脚的输入的噪声滤波器。因为改变该位的值可能会导致内部产生意外边沿，所以在此之前选择GTIOR寄存器中相关引脚的输出比较功能。

NFCSA[1:0]位（噪声滤波器A采样时钟选择）

NFCSA[1:0]位设置GTIOCnA引脚噪声滤波器的采样间隔。设置这些位时，请等待所选采样间隔的2个周期，然后再设置输入捕捉功能。

GTIOB[4:0]位（GTIOCnB引脚功能选择）

GTIOB[4:0]位选择GTIOCnB引脚功能。详见表21.4。

OBDFLT位（计数停止时GTIOCnB引脚输出值设置）

OBDFLT位设置当计数停止时GTIOCnB引脚输出高电平还是低电平。

OBHLD位（GTIOCnB引脚输出设置在开始停止计数）

OBHLD位指定是保留GTIOCnB引脚输出电平还是计数开始或停止时的电平取决于寄存器设置。

当OBHLD位设置为0时：

- ●GTIOB[4:0]位的位[4]中指定的值在计数开始时输出
- ●计数停止时输出OBDFLT位中指定的值
- ●如果在计数停止时修改了OBDFLT位，则新值会立即反映在输出中。

当OBHLD位设置为1时：

- ●计数开始或停止时保持输出。

OBE位（GTIOCnB引脚输出使能）

OBE位禁用或启用GTIOCnB引脚输出。

当GTCCRB寄存器用作输入捕捉寄存器时（GTICBSR寄存器中至少有一位设置为1），无论OBE位值如何，GTIOCnB引脚都不输出。

OBDF[1:0]位（GTIOCnB引脚禁用值设置）

当输出禁用请求发生时，OBDF[1:0]位选择GTIOCnB引脚的输出值。

NFBEN位（噪声滤波器B启用）

NFBEN位禁用或启用来自GTIOCnB引脚的输入的噪声滤波器。因为改变该位的值可能会导致内部产生意外边沿，所以在此之前选择GTIOR寄存器中相关引脚的输出比较功能。

NFCSB[1:0]位（噪声滤波器B采样时钟选择）

NFCSB[1:0]位设置GTIOCnB引脚噪声滤波器的采样间隔。设置这些位时，请等待所选采样间隔的2个周期，然后再设置输入捕捉功能。

Note 2. When the timing of a cycle end and the timing of a GTCCRA/GTCCRB compare match are the same in a compare-match operation, the b3 and b2 settings are given priority in saw-wave PWM mode, and the b1 and b0 settings are given priority in any other mode.

Note 3. In event count operation where at least one bit in GTUPSR or GTDNSR is set to 1, the setting of b3 and b2 is ignored.

The GTINTAD enables or disables interrupt requests and output disable requests.

GRP[1:0] bits (Output Disable Source Select)

These bits select the group of output disable request from GPT to POEG and the group of output disable for GTIOCnA pin and GTIOCnB pin from POEG to GPT.

The output disable request to POEG is output to the group selected in the GRP[1:0] bit, with dead-time errors, simultaneous high output, and simultaneous low output factors following their respective disable request enable bits.

GTST.ODF shows the request of the output disable source group that is selected with the GRP[1:0] bits. Set the GRP[1:0] bits when both GTIOR.OAE and GTIOR.OBE bits are 0.

GRPABH bit (Same Time Output Level High Disable Request Enable)

The GRPABH bit enables or disables the output disable request when the GTIOCnA pin and GTIOCnB pin output 1 at the same time.

GRPABL bit (Same Time Output Level Low Disable Request Enable)

The GRPABL bit enables or disables the output disable request when the GTIOCnA pin and GTIOCnB pin output 0 at the same time.

[Clearing conditions]

●当OAE和OBE位都设置为1时，GTIOCnA引脚输出值与GTIOCnB引脚输出值不同

●OAE位或OBE位都设置为0。

The compare-target signals to generate the OABHF/OABLF flag are the compare match outputs (PWM outputs) signals before they are masked by the output disable function. Even during the output disable condition, compare match operation continues internally, where the OABHF or OABLF flag is updated based on the operation results.

The GTBER register provides settings for the buffer operation. Set the GTBER register while the GTCNT counter is stopped.

BD0 bit (GTCCR Buffer Operation Disable)

The BD0 bit disables the buffer operation using GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, and GTCCRF combined.

When GTDTCR.TDE is 1 and when BD0 is set to 0, GTCCRB does not perform buffer operation. The GTCCRB register is automatically set to a compare match value for negative-phase waveform with dead time.

A value for the BD0 bit in the channel related to the position of the bit written with 1 by the GTSECSR register can be set when 1 is written to the GTSECR.SBDCE or GTSECR.SBDCD.

BD1 bit (GTPR Buffer Operation Disable)

The BD1 bit disables the buffer operation using GTPR and GTPBR combined.

A value for the BD1 bit in the channel related to the position of the bit written with 1 by the GTSECSR register can be set when 1 is written to the GTSECR.SBDPE or GTSECR.SBDPD.

CCRA[1:0] bits (GTCCRA Buffer Operation)

The CCRA[1:0] bits set the buffer operation with GTCCRA, GTCCRC, and GTCCRD combined. When the buffer operation is restricted by the operating mode set in GTCR, the GTCR setting is given priority.

The buffer operation mode is fixed in saw-wave one-shot pulse mode or triangle-wave PWM mode 3 (64-bit transfer at trough).

CCRB[1:0] bits (GTCCRB Buffer Operation)

The CCRB[1:0] bits set the buffer operation using GTCCRB, GTCCRE, and GTCCRF combined. When the buffer operation is restricted by the operating mode set in GTCR, the GTCR setting is given priority.

The buffer operation mode is fixed in saw-wave one-shot pulse mode or triangle-wave PWM mode 3 (64-bit transfer at trough).

PR[1:0] bits (GTPR Buffer Operation)

The PR[1:0] bits set the buffer operation with GTPR and GTPBR combined.

CCRSWT bit (GTCCRA and GTCCRB Forcible Buffer Operation)

Writing 1 to the CCRSWT bit forces a buffer transfer of GTCCRA and GTCCRB. This bit automatically returns to 0 after the 1 is written. This bit is read as 0, and is valid only when counting is stopped with a compare match operation specified.

GTBER寄存器提供缓冲区操作的设置。在GTCNT计数器停止时设置GTBER寄存器。

BD0位（GTCCR缓冲区操作禁用）

BD0位使用GTCCRA、GTCCRB、GTCCRC、GTCCRD、GTCCRE和GTCCRF组合禁用缓冲区操作。

当GTDTCR.TDE为1且BD0设置为0时，GTCCRB不执行缓冲操作。GTCCRB寄存器自动设置为带有死区时间的负相位波形的比较匹配值。

当向GTSECR.SBDCE或GTSECR.SBDCD写入1时，可以设置与由GTSECSR寄存器写入1的位的位置相关的通道中的BD0位的值。

BD1位（GTPR缓冲区操作禁用）

BD1位禁用使用GTPR和GTPBR组合的缓冲区操作。

当向GTSECR.SBDPE或GTSECR.SBDPD写入1时，可以设置与由GTSECSR寄存器写入1的位的位置相关的通道中的BD1位的值。

GTDTCR enables automatic setting of a compare match value for negative-phase waveform with dead time. GPT has a dead time control function and the GTDVU register is used for setting dead time value.

TDE bit (Negative-Phase Waveform Setting)

The TDE bit specifies whether to use GTDVU. When GTDVU is used, the compare match value for a negative-phase waveform with dead time obtained by the compare match value of a positive-phase waveform (GTCCRA) and the dead time value (GTDVU) is automatically set in GTCCRB.

The TDE bit setting is ignored in saw-wave PWM mode, and the GTCCRB is not automatic setting.

The GTCCRB value is automatically set and has the following upper and lower limit values. If the obtained GTCCRB value is not within the upper or lower limit, the following limit value is set in GTCCRB.

- Triangle waves:
  Upper limit value: GTPR − 1
  Lower limit value: 1 in up-counting, 0 in down-counting
- Saw-wave one-shot pulse mode:
  Upper limit value: GTPR
  Lower limit value: 0.

GTDTCR可以自动设置带死区时间的负相位波形的比较匹配值。GPT具有死区时间控制功能，GTDVU寄存器用于设置死区时间值。

TDE位（负相位波形设置）

TDE位指定是否使用GTDVU。使用GTDVU时，通过正相波形的比较匹配值(GTCCRA)和死区时间值(GTDVU)获得的带死区时间的负相波形的比较匹配值自动设置在GTCCRB中。

TDE位设置在锯齿波PWM模式下被忽略，GTCCRB不是自动设置。

The GTICLF register sets the logical operation function between compare match outputs. The logical operation is performed with the signals that the duty 0%/100% control is performed after compare match control. (The output disable control is performed with the signal after logical operation.)

Access in 8-bit units to GTICLF is prohibited.

ICLFm[2:0] bit (GTIOCm Output Logical Operation Function Select) (m = A, B)

These bits select the logical operation function between signals before performing output disable control for GTIOCm. To prevent hazard to the GPT output, the signal after logical operation is latched with PCLKD. After latching, the output disable control is performed. When the logical operation function which causes the delay of 1 PCLKD is selected, the output enable signal is also delayed with 1 PCLKD and input to the output disable control.

The GTPC register counts the number of period.

PCEN bit (Period Count Function Enable)

This bit enables or disables period count function.

Writing is available when counting is both in progress and stopped.

When 1 is written to either the GTSECR.SPCE bit or the GTSECR.SPCD bit, the value is simultaneously set to the PCEN bit in the channels set to 1 by the GTSECSR register.

ASTP bit (Automatic Stop Function Enable)

This bit enables or disables the GTCNT counter automatic stopping after finishing counting the number of period.

When the PCEN bis is 0, writing is available.

When the PCEN bit is 1, writing is disabled.

When the PCEN bit is 1, the ASTP bit is 1, and the PCNT counter is stopped at PCNT = 0, the GTCNT counter is also stopped. When the ASTP bit is 0, the GTCNT counter continues to count.

PCNT[11:0] bit (Period Counter)

This counter counts the number of period.

When the PCEN bis is 0, writing the number of period is available.

When the PCEN bit is 1, writing is disabled, and down-counting is performed at the end of period. In saw-wave mode, the end of period refers to overflow, underflow, or counter clearing. In triangle-wave mode, it refers to trough.

When the PCNT counter is 1 at the end of period, it becomes 0 and counting is stopped.

When the GTCNT counter is stopped while period count function is enabled, the PCNT counter keeps its value. When the GTCNT counter restarts counting and the PCEN bit is 1, the PCNT counter restarts down-counting from the hold value.

GTPC寄存器计算周期数。

PCEN位（周期计数功能使能）

该位启用或禁用周期计数功能。

当计数正在进行和停止时，可以写入。

当1写入GTSECR.SPCE位或GTSECR.SPCD位时，该值同时设置到由GTSECSR寄存器设置为1的通道中的PCEN位。

ASTP位（自动停止功能使能）

该位使能或禁止GTCNT计数器在完成周期数计数后自动停止。

当PCENbis为0时，可以写入。

当PCEN位为1时，禁止写入。

当PCEN位为1，ASTP位为1，PCNT计数器在PCNT=0时停止，GTCNT计数器也停止。当ASTP位为0时，GTCNT计数器继续计数。

PCNT[11:0] bit (Period Counter)

该计数器计算周期数。

当PCENbis为0时，可写入周期数。

当PCEN位为1时，写入被禁止，并且在周期结束时执行递减计数。在锯齿波模式下，周期结束是指上溢、下溢或计数器清零。在三角波模式中，它指的是波谷。

当PCNT计数器在周期结束时为1时，它变为0并停止计数。

当GTCNT计数器停止而周期计数功能使能时，PCNT计数器保持其值。当。。。的时候GTCNT计数器重新开始计数且PCEN位为1，PCNT计数器重新从保持值开始向下计数。

When the PCEN bit is changed from 0 to 1 while the PCNT counter is 0 and the ASTP bit is 1, the GTCNT counter is stopped at the count clock immediately after that.

The GTSECSR register selects an intended channel n (n = 1, 2, 4, 5) for updating an operation enable bit by the GTSECR register. A bit position for the GTSECSR register indicates a channel number. The GTSECSR register of each channel is a common register, and writing 1 to a bit in the GTSECSR register in any channel and updating it changes a channel, related to the position of the bit written with 1 by the GTSECSR register, to be simultaneously controlled of the operation enable bit by the GTSECR register.

The bit corresponding to channel which security attribution is configured as secure can be read by non-secure access but cannot be written by non-secure access. For example, if GPT channel n is configured as secure and other GPTs are configured as non-secure, the SECSELn bit cannot be written by non-secure access to $GPT32_{n+1}$.GTSECSR register, and

GTSECSR寄存器选择预期通道n(n=1 2 4 5)用于通过GTSECR寄存器更新操作使能位。GTSECSR寄存器的位位置表示通道号。每个通道的GTSECSR寄存器是一个公共寄存器，在任何通道的GTSECSR寄存器中写入1并更新它会改变一个通道，与GTSECSR寄存器写入1的位的位置有关，被同时控制GTSECR寄存器的操作使能位。

安全属性配置为安全的通道对应的位可以被非安全访问读取，但不能被非安全访问写入。例如，如果GPT通道n配置为安全且其他GPT配置为非安全，则无法通过对GPT32n+1.GTSECSR寄存器的非安全访问来写入SECSELn位，并且

the simultaneous control status of GPT channel n is not changed. When the GPT32$_{n+1}$.GTSECSR register is read by non-secure access in the same security configuratin as the previous example, the simultaneous control status of GPT channel n (SECSELn bit) can be read.

Access in 8-bit or 16-bit units to GTSECSR is prohibited, and it should be accessed in 32-bit units.

SECSELn bit (Operation Enable Bit Simultaneous Control Channel Select) (n = 1, 2, 4, 5)

The GTSECR register simultaneously updates the value for operation enable bits of a channel set by the GTSECSR register.

GTSECR寄存器同时更新由GTSECSR寄存器设置的通道的操作使能位的值。

将1写入任何通道的GTSECR寄存器中的位并更新它会更新所有通道的操作使能位，这与所有GTSECSR寄存器写入1的位的位置有关。

The GTSECR register of channel which security attribution is configured as secure can not be written by non-secure access. For example, if GPT0 is configured as secure and other GPTs are configured as non-secure, the GPT0.GTSECR register can not be written by non-secure access to GPT1.GTSECR register even if the simulataneous control of GPT0 is enabled, and the simultaneous control status of GPT0 is not changed.

Setting enable and disable bits for the same operation enable bit to 1 in the GTSECR is prohibited.

A bit written to 1 is automatically cleared. When the GTSECR is read, 0 is read.

Access in 8-bit or 16-bit units to the GTSECR register is prohibited, and it should be accessed in 32-bit units.

SBDCE bit (GTCCR Register Buffer Operation Simultaneous Enable)

When 1 is written to this bit, 0 is simultaneously set to a GTBER.BD[0] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTCCRA, GTCCRC, and GTCCRD registers and using the GTCCRB, GTCCRE, and GTCCRF registers are enabled.

Simultaneous setting of SBDCE and SBDCD bits to 1 is prohibited.

SBDPE bit (GTPR Register Buffer Operation Simultaneous Enable)

When 1 is written to this bit, 0 is simultaneously set to a GTBER.BD[1] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTPR and GTPBR registers are enabled.

Simultaneous setting of SBDPE and SBDPD bits to 1 is prohibited.

SBDCD bit (GTCCR Register Buffer Operation Simultaneous Disable)

When 1 is written to this bit, 1 is simultaneously set to a GTBER.BD[0] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTCCRA, GTCCRC, and GTCCRD registers and using the GTCCRB, GTCCRE, and GTCCRF registers are disabled.

Simultaneous setting of SBDCE and SBDCD bits to 1 is prohibited.

SBDPD bit (GTPR Register Buffer Operation Simultaneous Disable)

When 1 is written to this bit, 1 is simultaneously set to a GTBER.BD[1] bit in the channels set to 1 by the GTSECSR register, and buffer operations using the GTPR and GTPBR registers are disabled.

Simultaneous setting of SBDPE and SBDPD bits to 1 is prohibited.

SPCE bit (Period Count Function Simultaneous Enable)

When 1 is written to this bit, 1 is simultaneously set to GTPC.PCEN bit in the channels set to 1 by the GTSECSR register, and period count function is enabled.

Simultaneous setting of SPCE and SPCD bits to 1 is prohibited.

SPCD bit (Period Count Function Simultaneous Disable)

When 1 is written to this bit, 0 is simultaneously set to GTPC.PCEN bit in the channels set to 1 by the GTSECSR register, and period count function is disabled.

Simultaneous setting of SPCE and SPCD bits to 1 is prohibited.

21.3 Operation

21.3.1 Basic Operation

Each channel has a 32-bit and 16-bit timer that performs a periodic count operation using the count clock and hardware sources. The count function provides both up-counting and down-counting. The GTPR controls the count cycle.

When the GTCNT counter value matches the value in GTCCRA or GTCCRB, the output from the associated GTIOCnA or GTIOCnB can be changed (n = 1, 2, 4, 5) . GTCCRA or GTCCRB can be used as an input capture register with hardware resources.

GTCCRC and GTCCRD can function as buffer registers for GTCCRA. GTCCRE and GTCCRF can function as buffer registers for GTCCRB.

安全属性配置为安全的通道的GTSECR寄存器不能被非安全访问写入。例如，如果GPT0配置为安全，而其他GPT配置为非安全，则即使GPT0的同时控制使能，也不能通过非安全访问GPT1.GTSECR寄存器来写入GPT0.GTSECR寄存器，并且GPT0的同时控制状态不变。

禁止在GTSECR中将同一操作使能位的使能位和禁用位设置为1。

写入1的位会自动清除。读取GTSECR时，读取0。

禁止以8位或16位为单位访问GTSECR寄存器，应以32位为单位进行访问。

SBDCE位（GTCCR寄存器缓冲区操作同时使能）

向该位写入1时，同时将GTSECSR寄存器设置为1的通道中的GTBER.BD[0]位设置为0，并使用GTCCRA、GTCCRC和GTCCRD寄存器以及使用GTCCRB、GTCCRE进行缓冲操作 和GTCCRF寄存器被启用。

禁止将SBDCE和SBDCD位同时设置为1。

SBDPE位（GTPR寄存器缓冲区操作同时使能）

禁止将SBDPE和SBDPD位同时设置为1。

SBDCD位（GTCCR寄存器缓冲区操作同时禁用）

当向该位写入1时，同时将1设置为由GTSECSR寄存器设置为1的通道中的GTBER.BD[0]位，并使用GTCCRA、GTCCRC和GTCCRD寄存器以及使用GTCCRB、GTCCRE进行缓冲操作 和GTCCRF寄存器被禁用。

禁止将SBDCE和SBDCD位同时设置为1。

SBDPD位（GTPR寄存器缓冲区操作同时禁用）

当向该位写入1时，同时将1设置到由GTSECSR寄存器设置为1的通道中的GTBER.BD[1]位，并且禁用使用GTPR和GTPBR寄存器的缓冲操作。

禁止将SBDPE和SBDPD位同时设置为1。

SPCE位（周期计数功能同时使能）

向该位写入1时，通过GTSECSR寄存器设置为1的通道中的GTPC.PCEN位同时设置为1，并启用周期计数功能。

禁止将SPCE和SPCD位同时设置为1。

SPCD位（周期计数功能同时禁用）

当向该位写入1时，同时将GTSECSR寄存器设置为1的通道中的GTPC.PCEN位设置为0，并且禁用周期计数功能。

禁止将SPCE和SPCD位同时设置为1。

21.3 Operation

21.3.1 基本操作

每个通道都有一个32位和16位定时器，它们使用计数时钟和硬件源执行周期性计数操作。计数功能提供向上计数和向下计数。GTPR控制计数周期。

当GTCNT计数器值与GTCCRA或GTCCRB中的值匹配时，相关GTIOCnA或
GTIOCnB可以更改(n=1 2 4 5)。GTCCRA或GTCCRB可用作具有硬件资源的输入捕捉寄存器。

GTCCRC和GTCCRD可以作为GTCCRA的缓冲寄存器。GTCCRE和GTCCRF可以作为GTCCRB的缓冲寄存器。

21.3.1.1 Counter operation

(1) Counter start and stop

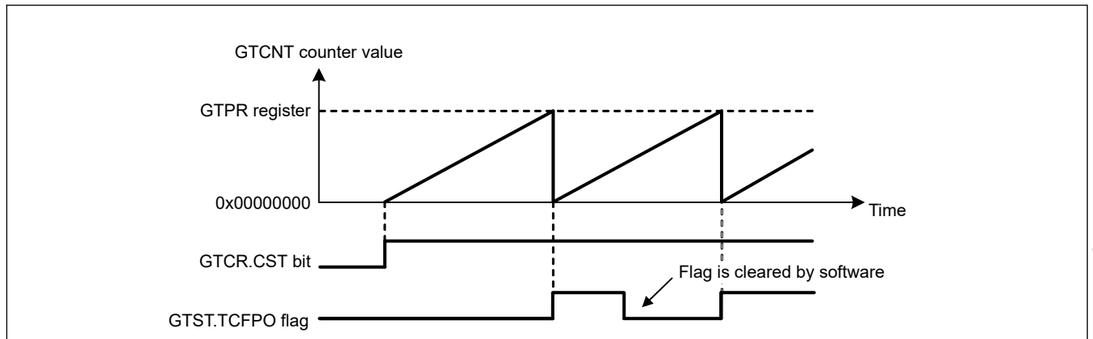
The counter of each channel starts the count operation when GTCR.CST is set to 1, and stops counting when the bit is set to 0. The GTCR.CST bit value is changed by the following sources:

- Writing to GTCR register
- Writing 1 to the bit in GTSTR associated with the GPT channel number when the GTSSR.CSTRT bit set to 1
- Writing 1 to the bit in GTSTP associated with the GPT channel number when the GTPSR.CSTOP bit set to 1
- The hardware source selected in the GTSSR register
- The hardware source selected in the GTPSR register.
- Completion of the period count function while the GTPC.ASTP bit is 1.

(2) Periodic count operation in up-counting by count clock

The GTCNT counter in each channel starts up-counting when the associated GTCR.CST bit is set to 1 with GTUPSR and GTDNSR registers set to 0x00000000. When the GTCNT value changes from the GTPR value to 0 (overflow), the GTST.TCFPO flag is set to 1, and the overflow interrupt(GPTn_OVF) is also generated. After GTCNT overflows, up-counting resumes from 0x00000000.

Figure 21.3 shows an example of a periodic count operation in up-counting by the count clock.



Note: The base address of registers are the same.

6	Start count operation	Set the GTCR.CST bit to 1 to start count operation.

21.3.1.1 计数器操作

(1) 计数器启动和停止

当GTCR.CST设置为1时，每个通道的计数器开始计数操作，并在该位设置为0时停止计数。GTCR.CST位值由以下来源改变：

- 写入GTCR寄存器
- 当GTSSR.CSTRT位设置为1时，将1写入GTSTR中与GPT通道号相关的位
- 当GTPSR.CSTOP位设置为1时，将1写入GTSTP中与GPT通道号相关的位
- GTSSR寄存器中选择的硬件源
- GTPSR寄存器中选择的硬件源。
- GTPC.ASTP位为1时完成周期计数功能。

(2) 计数时钟递增计数中的周期计数操作

当相关的GTCR.CST位通过GTUPSR和GTDNSR寄存器设置为0x00000000。当GTCNT值从GTPR值变为0（溢出）时，GTST.TCFPO标志置1，同时产生溢出中断(GPTn_OVF)。GTCNT溢出后，向上计数从0x00000000重新开始。

图21.3显示了计数时钟递增计数中的周期性计数操作的示例。

(3) Periodic count operation in down-counting by count clock

The GTCNT counter in each channel can perform down-counting by setting GTUDDTYC.UD with GTUPSR and GTDNSR registers set to 0x00000000. When GTCNT changes from 0 to the GTPR value (underflow), GTST.TCFPU is set to 1, and the underflow interrupt(GPTn_UDF) is also generated. After the GTCNT counter underflows, down-counting resumes from the GTPR value.

Figure 21.4 shows an example of periodic count operation in down-counting by the count clock.

2	Set count direction	Select the count direction with the GTUDDTYC register. In Figure 21.4, after 10b is set in the GTUDDTYC[1:0] bits, 00b is set in the GTUDDTYC[1:0] bits (down-counting).
3	Select count clock	Select the count clock with the GTCR.TPCS[3:0] bits.
4	Set cycle	Set the cycle in the GTPR register.
5	Set initial value for counter	Set the initial value in the GTCNT counter. In Figure 21.4, the GTPR register value is set.
6	Start count operation	Set the GTCR.CST bit to 1 to start count operation. In Figure 21.4, 1 is set in the CST bit.

(4) Event count operation in up-counting using hardware sources

The GTCNT counter in each channel can perform up-counting using hardware sources as set in GTUPSR.

When GTUPSR is set to enable, the count clock selected in GTCR.TPCS[3:0] and the count direction selected in GTUDDTYC.UD are ignored. If up-counting and down-counting using hardware sources occur at the same time, the GTCNT counter value does not change. The overflow behavior when up-counting using hardware sources is the same as when up-counting by the count clock.

When GTCR.CST bit is set to 1 to count up using hardware sources, the count operation is enabled. After GTCR.CST is set to 1, the counter cannot count up for 1 clock cycle as specified in GTCR.TPCS[3:0] because the count operation is synchronized by the count clock selected in GTCR.TPCS[3:0]. Set GTCR.TPCS[3:0] to 000b to count up with a 1 PCLKD delay after GTCR.CST is set to 1.

Figure 21.5 shows an example of an event count operation in up-counting by a hardware resource (the rising edge of GTETRGA pin input).

(3) 计数时钟递减计数中的周期计数操作

每个通道中的GTCNT计数器可以通过使用GTUPSR设置GTUDDTYC.UD和
GTDNSR寄存器设置为0x00000000。当GTCNT从0变为GTPR值（下溢）时，GTST.TCFPU置1，同时产生下溢中断（GPTn_UDF）。GTCNT计数器下溢后，从GTPR值开始向下计数。

图21.4显示了计数时钟递减计数中周期性计数操作的示例。

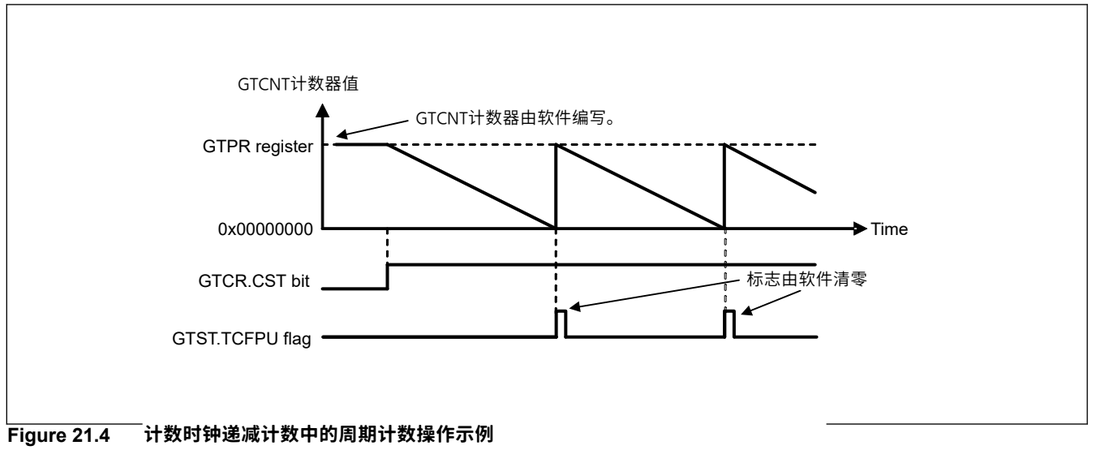

Figure 21.4 计数时钟递减计数中的周期计数操作示例

6	开始计数操作	将GTCR.CST位设置为1以启动计数操作。 在图21.4中，CST位设置为1。

(4) 使用硬件源的递增计数中的事件计数操作

每个通道中的GTCNT计数器可以使用GTUPSR中设置的硬件源执行递增计数。

当GTUPSR设置为使能时，在GTCR.TPCS[3:0]中选择的计数时钟和在
GTUDDTYC.UD被忽略。如果同时使用硬件源进行向上计数和向下计数，则
GTCNT计数器值不会改变。使用硬件源递增计数时的溢出行为与使用计数时钟递增计数时的溢出行为相同。

当GTCR.CST位设置为1以使用硬件源进行计数时，计数操作被启用。GTCR.CST设置为1后，计数器无法按GTCR.TPCS[3:0]中指定的1个时钟周期向上计数，因为计数操作与GTCR.TPCS[3:0]中选择的计数时钟同步。将GTCR.TPCS[3:0]设置为000b以在GTCR.CST设置为1后以1个PCLKD延迟向上计数。

图21.5显示了一个硬件资源递增计数中的事件计数操作示例（上升沿

3	Set initial value for counter	Set the initial value in the GTCNT counter.
4	Start count operation	Set the GTCR.CST bit to 1 to start count operation.

(5) Event count operation in down-counting using hardware sources

The GTCNT counter in each channel can perform down-counting using hardware sources set in the GTDNSR.

When GTDNSR is set to enable, the count clock selected in GTCR.TPCS[3:0] and the count direction selected in GTUDDTYC.UD are ignored. If up-counting and down-counting using hardware sources occur at the same time, the GTCNT counter value does not change. The underflow behavior when down-counting using hardware sources is the same as when down-counting by the count clock.

When GTCR.CST bit is set to 1 to count down using hardware sources, the count operation is enabled. After GTCR.CST is set to 1, the counter cannot count down for 1 clock cycle as specified in GTCR.TPCS[3:0] because the count operation is synchronized with the count clock selected in GTCR.TPCS[3:0]. Set GTCR.TPCS[3:0] to 000b to count down with a 1 PCLKD delay after GTCR.CST is set to 1.

(5) 使用硬件源的递减计数中的事件计数操作

每个通道中的GTCNT计数器可以使用GTDNSR中设置的硬件源进行递减计数。

当GTDNSR设置为使能时，在GTCR.TPCS[3:0]中选择的计数时钟和在GTUDDTYC.UD被忽略。如果同时使用硬件源进行向上计数和向下计数，则GTCNT计数器值不会改变。使用硬件源向下计数时的下溢行为与使用计数时钟向下计数时相同。

当GTCR.CST位设置为1以使用硬件源进行递减计数时，启用计数操作。在GTCR.CST设置为1后，计数器无法按照GTCR.TPCS[3:0]中的规定向下计数1个时钟周期，因为计数操作与GTCR.TPCS[3:0]中选择的计数时钟同步。将GTCR.TPCS[3:0]设置为000b以在GTCR.CST设置为1后以1个PCLKD延迟递减计数。

2	Set cycle	Set the cycle in the GTPR register.
3	Set initial value for counter	Set the initial value in the GTCNT counter.
4	Start count operation	Set the GTCR.CST bit to 1 to start count operation.

(6) Counter clear operation

The counter of each channel is cleared by following sources:

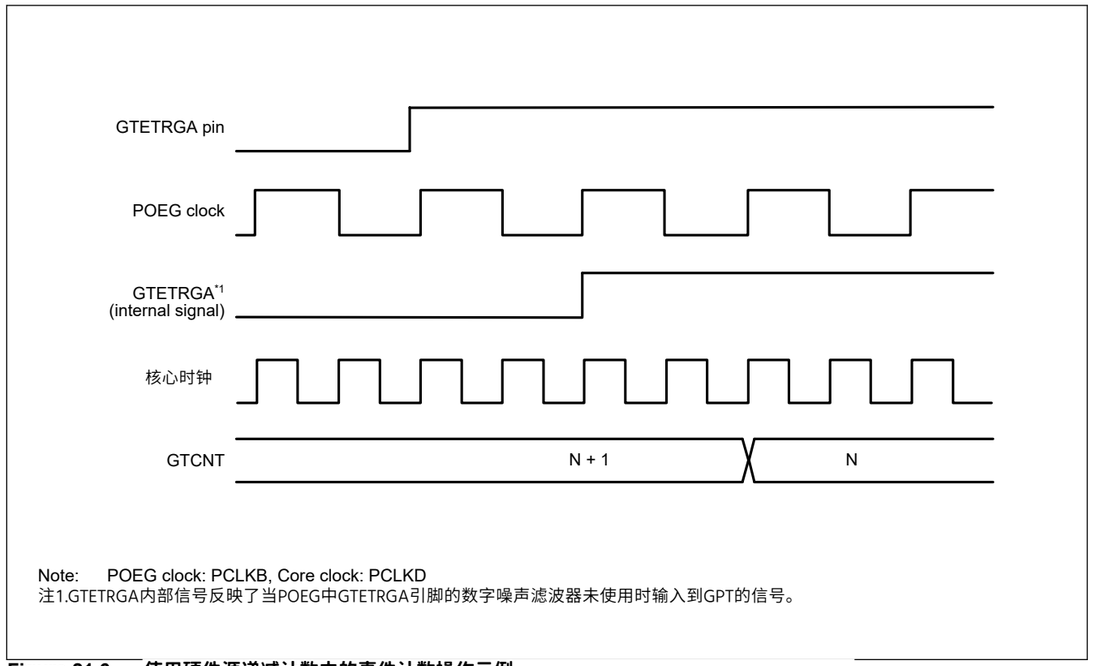
- Writing 0 to GTCNT register
- Writing 1 to the bit in GTCLR associated with the GPT channel number when the GTCSR.CCLR bit set to 1
- The hardware source selected in GTCSR register.

Writing to the GTCNT register is prohibited during count operation. The GTCNT counter can be cleared both by writing 1 to the GTCLR and by the clear request of hardware sources, whether GTCNT is counting (GTCR.CST is 1) or not (GTCR.CST is 0).

When the count direction flag is set as decrement (GTST.TCUF flag = 0) in saw-wave mode selected with GTCR.MD[2:0] bits, the GTCNT register is set to the value of the GTPR register when writing 1 to the GTCLR register and when clearing by hardware sources are performed.

When not in saw-waves mode and down-counting, the GTCNT register is set to 0 when writing 1 to the GTCLR register and when clearing by hardware sources are performed.

In event count operation when at least 1 bit in the GTUPSR or GTDNSR is set to 1, after clear sources occur, both writing to GTCLR register and clearing by hardware sources are performed immediately to synchronize with PCLKD. If other settings are used, clear is synchronized with the counter clock selected in GTCR.TPCS[3:0].



Note: POEG clock: PCLKB, Core clock: PCLKD

2	设置周期	在GTPR寄存器中设置周期。
3	设置计数器的初始值	在GTCNT计数器中设置初始值。
4	开始计数操作	将GTCR.CST位设置为1以启动计数操作。

(6) 计数器清零操作

每个通道的计数器由以下来源清零：

- ●将0写入GTCNT寄存器
- ●当GTCSR.CCLR位设置为1时，将1写入GTCLR中与GPT通道号相关的位
- ●GTCSR寄存器中选择的硬件源。

计数操作期间禁止写入GTCNT寄存器。GTCNT计数器可以通过向GTCLR写入1和硬件源的清除请求来清除，无论GTCNT正在计数（GTCR.CST为1）还是不计数（GTCR.CST为0）。

在使用GTCR.MD[2:0]位选择的锯齿波模式下，当计数方向标志设置为递减（GTST.TCUF标志=0）时，GTCNT寄存器在写入1时设置为GTPR寄存器的值GTCLR寄存器和硬件源清除时执行。

当不处于锯齿波模式和向下计数时，当向GTCLR寄存器写入1和执行硬件源清零时，GTCNT寄存器设置为0。

在GTUPSR或GTDNSR中至少有1位设置为1的事件计数操作中，清除源发生后，立即执行写入GTCLR寄存器和通过硬件源清除以与PCLKD同步。如果使用其他设置，则清除与GTCR.TPCS[3:0]中选择的计数器时钟同步。

21.3.1.2 Waveform output by compare match

Compare match means that the GTCNT counter value matches the value of GTCCRA or GTCCRB. When a compare match occurs, the compare match flag is generated synchronously with the count clock, including the event count. At the same time, the GPT can output low, high, or toggled output from the associated GTIOCnA or GTIOCnB output pin (n = 1, 2, 4, 5). In addition, the GTIOCnA or GTIOCnB pin output can be low, high, or toggled at the cycle end which is determined by GTPR.

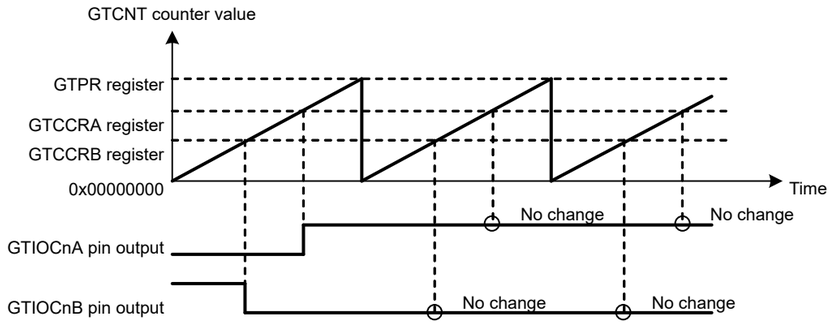
The cycle end is:

- For saw waves in up-counting – when GTCNT changes from the GTPR value to 0 (overflow)
- For saw waves in down-counting – when GTCNT changes from 0 to GTPR value (underflow)
- For saw waves – when the GTCNT counter is cleared
- For triangle waves – when the GTCNT changes from 0 to 1 (trough).

(1) Low output and high output

Figure 21.7 shows an example of low output and high output operation by a compare match of GTCCRA and GTCCRB.

In this example, the GTCNT counter performs up-counting, and settings are made so that high is output from the GTIOCnA pin by a GTCCRA compare match, and low is output from the GTIOCnB pin by a GTCCRB compare match. The pin level does not change when the specified level and pin level match.



[Setting examples]
GTIOR.GTIOA[4:0] bits: Initial output is low, high output at compare match, output retained at cycle end
GTIOR.GTIOB[4:0] bits: Initial output is high, low output at compare match, output retained at cycle end

Note: The base address of registers are the same.

21.3.1.2 比较匹配的波形输出

比较匹配意味着GTCNT计数器值与GTCCRA或GTCCRB的值匹配。当比较匹配发生时，比较匹配标志与计数时钟同步生成，包括事件计数。同时，GPT可以从相关的GTIOCnA或GTIOCnB输出引脚（n=1、2、4、5）输出低电平、高电平或翻转输出。此外，GTIOCnA或GTIOCnB引脚输出可以是低电平、高电平或在由GTPR确定的周期结束时切换。

循环结束为：

●对于递增计数中的锯齿波 当GTCNT从GTPR值变为0时（溢出）

●对于向下计数中的锯齿波 当GTCNT从0变为GTPR值时（下溢）

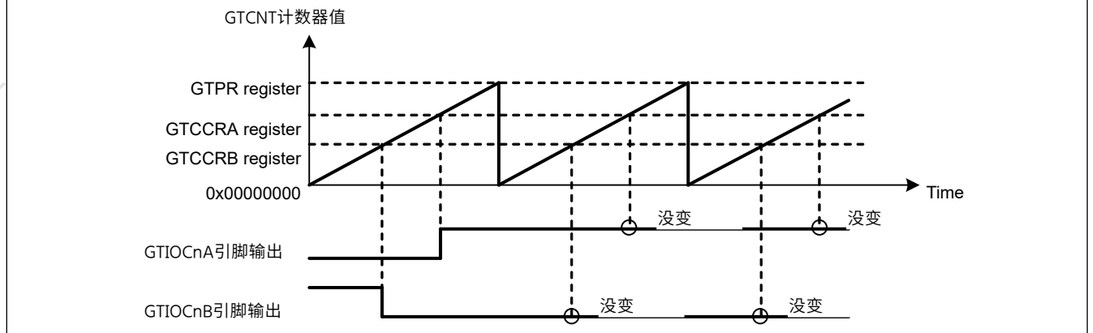
●对于锯齿波 当GTCNT计数器清零时

●对于三角波——当GTCNT从0变为1（波谷）时。

(1) 低输出和高输出

图21.7显示了通过GTCCRA和GTCCRB比较匹配的低输出和高输出操作示例。

在本例中，GTCNT计数器进行递增计数，设定为通过GTCCRA比较匹配从GTIOCnA引脚输出高电平，通过GTCCRB比较匹配从GTIOCnB引脚输出低电平。当指定电平和引脚电平匹配时，引脚电平不会改变。



[Setting examples]

In Figure 21.9, the GTCNT counter performs up-counting, and settings are made so that a GTCCRA compare match toggles the GTIOCnA pin output level and a cycle end toggles the GTIOCnB pin output level.

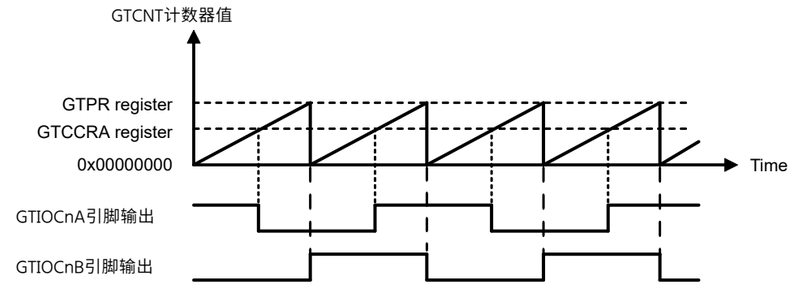
21.3.1.3 Input Capture Function

The GTCNT counter value can be transferred to either GTCCRA or GTCCRB on detection of the hardware source that is set in GTICASR and GTICBSR.

Figure 21.10 shows an example of the input capture function.

In this example, the GTCNT counter performs up-counting by the count clock, and settings are made so that an input capture is performed to GTCCRA at both edges of the GTIOCnA input pin and to GTCCRB on the rising edge of the GTIOCnB input pin.



[Setting examples]

21.3.2 Buffer Operation

- GTPR and GTPBR
- GTCCRA, GTCCRC, and GTCCRD
- GTCCRB, GTCCRE, and GTCCRF

21.3.2.1 GTPR Register Buffer Operation

21.3.2 缓冲操作

可以使用GTBER设置以下缓冲区操作：

- GTPR and GTPBR
- GTCCRA, GTCCRC, and GTCCRD
- GTCCRB, GTCCRE, and GTCCRF

21.3.2.1 GTPR寄存器缓冲区操作

GTPBR可以作为GTPR的缓冲寄存器。

缓冲区传输在锯齿波模式或事件计数中的上溢（向上计数期间）或下溢（向下计数期间）以及三角波模式的波谷处执行。

In saw-wave mode or in event count, the buffer transfer is performed when the following counter clear operations occur during counting:

- Clear by hardware sources (the clear source is selected in GTCSR register)
- Clear by software (when GTCSR.CCLR bit is 1 and GTCLR.CCLRn bit is set to 1, n = 1, 2, 4, 5).

To set GTPR to function as a buffer, set the GTBER.PR bit to 1. To set GTPR not to function as a buffer, set the GTBER.PR bit to 0.

Figure 21.11 to Figure 21.13 show examples of GTPR buffer operation and Table 21.12 shows an example for setting GTPR buffer operation.

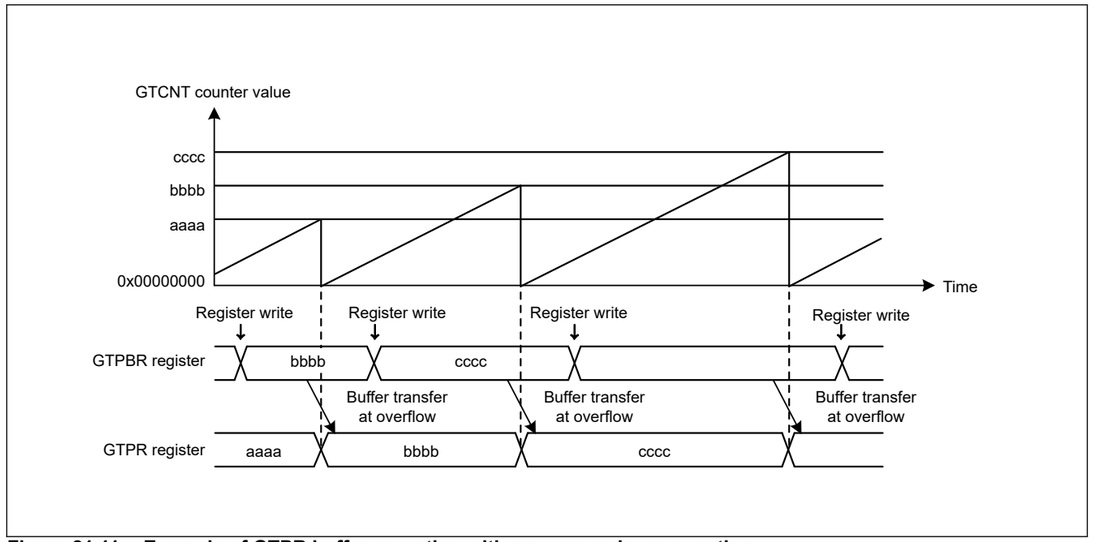

Figure 21.11 Example of GTPR buffer operation with saw waves in up-counting

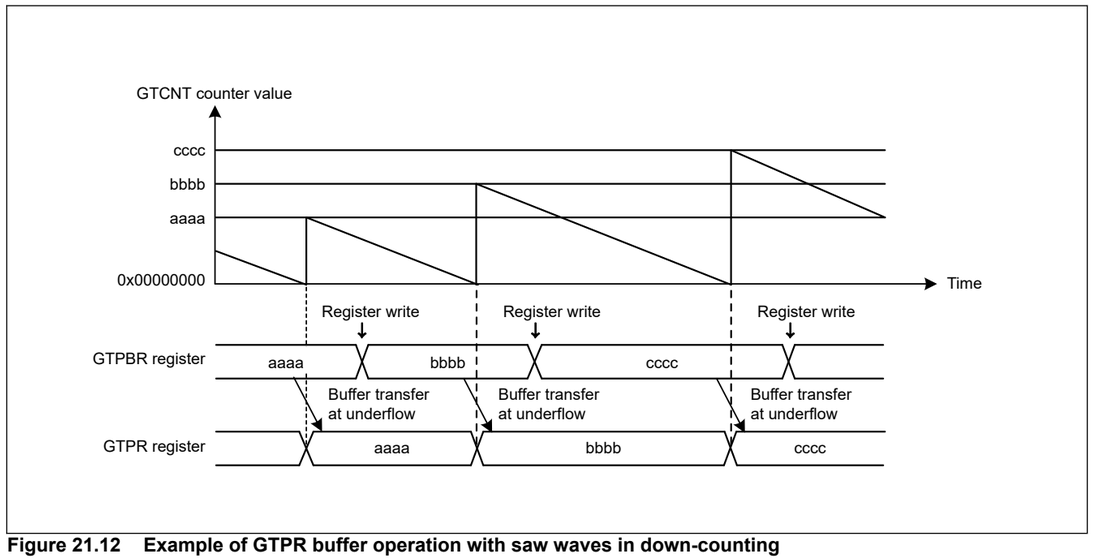

Figure 21.12 Example of GTPR buffer operation with saw waves in down-counting

在锯齿波模式或事件计数中，当计数期间发生以下计数器清零操作时，将执行缓冲区传输：

●通过硬件源清除（清除源在GTCSR寄存器中选择）
●软件清零（当GTCSR.CCLR位为1且GTCLR.CCLRn位设置为1时，n=1 2 4 5）。

要将GTPR设置为缓冲区，请将GTBER.PR位设置为1。要将GTPR设置为不作为缓冲区，请将GTBER.PR位设置为0。

2	Set count direction	Select the count direction (up or down) with the GTUDDTYC register. In Figure 21.11, after 11b is set in the GTUDDTYC[1:0] bits, 01b is set in the GTUDDTYC[1:0] bits (up-counting). In Figure 21.12, after 10b is set in the GTUDDTYC[1:0] bits, 00b is set in the GTUDDTYC[1:0] bits (down-counting).

7	Set buffer value	For buffer operation, set a value in one cycle after the current cycle in the GTPBR register.
8	Start count operation	Set the GTCR.CST bit to 1 to start count operation.
9	Set buffer value for each cycle	For buffer operation, set a value in one cycle after the current cycle in the GTPBR register.

21.3.2.2 Buffer Operation for GTCCRA and GTCCRB Registers

GTCCRC can function as the GTCCRA buffer register and GTCCRD can function as the GTCCRC buffer register (double-buffer register for GTCCRA). Similarly, GTCCRE can function as the GTCCRB buffer register and GTCCRF can function as the GTCCRE buffer register (double-buffer register for GTCCRB).

To set GTCCRA or GTCCRB to function as a double buffer, set GTBER.CCRA[1:0] or GTBER.CCRB[1:0] to 10b or 11b. For single buffer operation, set 01b. To set GTCCRA or GTCCRB to not function as a buffer, set 00b.

(1) When GTCCRA or GTCCRB Functions as Output Compare Register

Buffer transfer occurs in the following situations:

- Buffer transfer by overflow or underflow
  Buffer transfer is performed at an overflow (during up-counting) or an underflow (during down-counting) in saw-wave mode or in event count operation. In triangle-wave mode, buffer transfer is performed at a trough (triangle-wave PWM mode 1) or a crest and trough (triangle-wave PWM mode 2).
- Buffer transfer by counter clear

7	设置缓冲区值	对于缓冲操作，在GTPBR寄存器中的当前周期之后的一个周期内设置一个值。
8	开始计数操作	将GTCR.CST位设置为1以启动计数操作。
9	为每个周期设置缓冲区值	对于缓冲操作，在GTPBR寄存器中的当前周期之后的一个周期内设置一个值。

21.3.2.2 GTCCRA和GTCCRB寄存器的缓冲操作

GTCCRC可以作为GTCCRA缓冲寄存器，GTCCRD可以作为GTCCRC缓冲寄存器（GTCCRA的双缓冲寄存器）。同样，GTCCRE可以作为GTCCRB缓冲寄存器，GTCCRF可以作为GTCCRE缓冲寄存器（GTCCRB的双缓冲寄存器）。

要将GTCCRA或GTCCRB设置为双缓冲区，请将GTBER.CCRA[1:0]或GTBER.CCRB[1:0]设置为10b或11b。对于单缓冲操作，设置01b。要将GTCCRA或GTCCRB设置为不用作缓冲区，请设置00b。

(1) 当GTCCRA或GTCCRB用作输出比较寄存器时

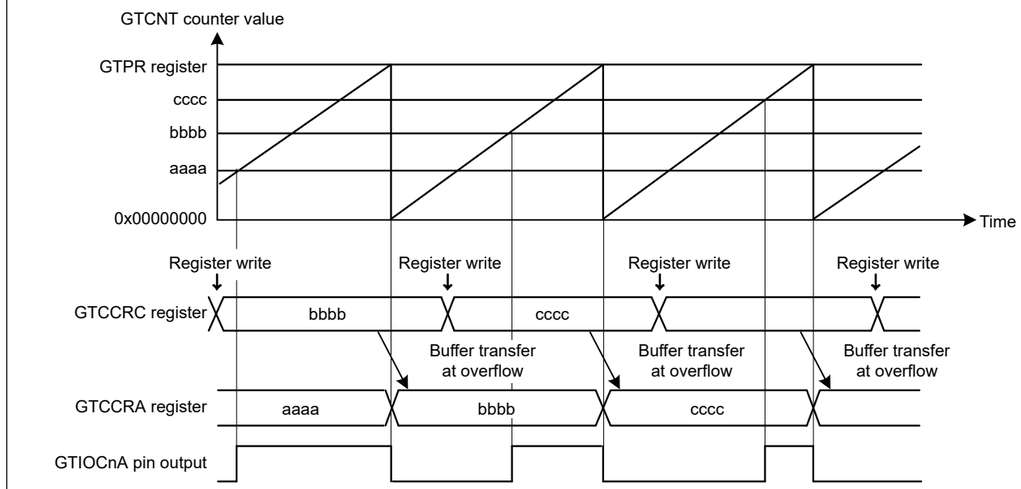
缓冲区传输发生在以下情况：

- 上溢或下溢的缓冲区传输
  在锯齿波模式或事件计数操作中，在溢出（向上计数期间）或下溢（向下计数期间）时执行缓冲区传输。在三角波模式中，缓冲区传输在波谷（三角波PWM模式1）或波峰和波谷（三角波PWM模式2）处执行。
- 通过计数器清除缓冲区传输

In saw-wave mode or in event count operation, during counting, buffer transfer (which is the same as an overflow during up-counting or an underflow during down-counting) is performed by the counter clear sources similar to the case shown in section 21.3.2.1. GTPR Register Buffer Operation.
In triangle-wave mode, buffer transfer is not performed by the counter clear.

- Forcible buffer transfer
When GTBER.CCRSWT bit is set to 1 while the count operation is stopped, the GTCCRA and the GTCCRB register buffer transfer are performed forcibly in saw-wave mode, in event count operation and in triangle-wave mode. Additionally buffer transfer from the GTCCRD register to temporary register A and from the GTCCRF register to temporary register B are performed in saw-wave one-shot pulse mode or triangle-wave PWM mode 3.

Figure 21.14 to Figure 21.16 show examples of GTCCRA and GTCCRB buffer operation and Table 21.13 shows an example for setting GTCCRA and GTCCRB buffer operation.



Note: The base address of registers are the same.

Figure 21.14 Example of GTCCRA and GTCCRB buffer operation with output compare, saw waves in up-counting, high output at GTCCRA compare match, and low output at cycle end

在锯齿波模式或事件计数操作中，在计数期间，缓冲区传输（与向上计数期间的溢出或向下计数期间的下溢相同）由计数器清零源执行，类似于章节中所示的情况21.3.2.1。GTPR寄存器缓冲区操作。在三角波模式下，计数器清零不执行缓冲区传输。

●强制缓冲转移
当GTBER.CCRSWT位在计数操作停止时设置为1时，在锯齿波模式、事件计数操作和三角波模式下强制执行GTCCRA和GTCCRB寄存器缓冲传输。此外，从GTCCRD寄存器到临时寄存器A以及从GTCCRF寄存器到临时寄存器B的缓冲区传输是在锯齿波一次性脉冲模式或三角波PWM模式3中执行的。

(2) When GTCCRA or GTCCRB Functions as Input Capture Register

When an input capture is generated, the GTCNT counter value is transferred to GTCCRA and GTCCRB and the stored GTCCRA and GTCCRB register values are transferred to the buffer registers. In input capture operation, the buffer transfer is not performed by the counter clear.

21.3.3 PWM Output Operating Mode

The GPT can output PWM waveforms to the GTIOCnA or GTIOCnB pin (n = 1, 2, 4, 5) by a compare match between the GTCNT counter and GTCCRA or GTCCRB.

By setting GTDTCR and GTDVU, the compare match value for a negative-phase waveform with dead time can automatically be set to GTCCRB.

21.3.3.1 Saw-Wave PWM Mode

In saw-wave PWM mode, GTCNT performs saw-wave (half-wave) operation by setting the cycle in GTPR and a PWM waveform is output to the GTIOCnA or GTIOCnB pin (n = 1, 2, 4, 5) when a GTCCRA or GTCCRB compare match occurs. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the cycle end according to the GTIOR setting.

21.3.3.2 Saw-Wave One-Shot Pulse Mode

The saw-wave one-shot pulse mode is a mode in which the cycle is set in GTPR, the GTCNT counter performs saw-wave (half-wave) operation and a PWM waveform is output to the GTIOCnA or GTIOCnB pin (n = 1, 2, 4, 5) at a compare match of GTCCRA or GTCCRB with buffer operation fixed.

Buffer operation in saw-wave one-shot pulse mode is different from the usual buffer operation. Buffer transfer is performed from:

- GTCCRC to GTCCRA at the cycle end
- GTCCRE to GTCCRB at the cycle end
- GTCCRD to temporary register A at the cycle end
- GTCCRF to temporary register B at the cycle end
- Temporary register A to GTCCRA at a GTCCRA compare match
- Temporary register B to GTCCRB at a GTCCRB compare match.

The pin output value can be selected from low output, high output, or toggled output separately for a compare match and the cycle end according to the GTIOR setting. When the GTBER.CCRSWT bit is set to 1 while count operation is stopped, the buffer is transferred forcibly from the GTCCRD register to temporary register A and from the GTCCRF register to temporary register B. By setting GTDTCR, GTDVU, a compare match value for a negative-phase waveform with dead time can automatically be set to GTCCRB.

Figure 21.20 shows an example of saw-wave one-shot pulse mode operation, and Table 21.16 shows an example for setting saw-wave one-shot pulse mode.

21.3.3.2 锯波单发脉冲模式

锯齿波单次脉冲模式是在GTPR中设置周期，GTCNT计数器执行锯齿波（半波）操作并将PWM波形输出到GTIOCnA或GTIOCnB引脚（n=1）的模式。 2 4 5)在GTCCRA或GTCCRB的比较匹配中，缓冲区操作已修复。

锯波单次脉冲模式中的缓冲操作不同于通常的缓冲操作。缓冲区传输从以下位置执行：

●GTCCRC到GTCCRA在循环结束
●循环结束时GTCCRE到GTCCRB
●GTCCRD在循环结束时到临时寄存器A
●GTCCRF在循环结束时到临时寄存器B
●GTCCRA比较匹配时到GTCCRA的临时寄存器A
●GTCCRB比较匹配时的临时寄存器B到GTCCRB。

引脚输出值可以根据GTIOR设置分别从低输出、高输出或切换输出中选择，以进行比较匹配和循环结束。当计数操作停止时GTBER.CCRSWT位设置为1，缓冲区被强制从GTCCRD寄存器传送到临时寄存器A，并从GTCCRF寄存器传送到临时寄存器B。通过设置GTDTCR，GTDVU，比较匹配值带有死区时间的负相位波形可以自动设置为GTCCRB。

21.3.3.5 三角波PWM模式3（波谷64位传输）

三角波PWM模式3是在GTPR中设定周期的模式。GTCNT计数器执行三角波（全波）操作，并且在GTCCRA或GTCCRB的比较匹配且缓冲器操作固定时，PWM波形输出到GTIOCnA或GTIOCnB引脚（n=1、2、4、5）。三角波PWM模式3中的缓冲操作与通常的缓冲操作不同。缓冲区传输从以下位置执行：

- ●GTCCRC到GTCCRA处于低谷
- ●GTCCRE至GTCCRB处于低谷
- ●GTCCRD到谷底临时寄存器A
- ●GTCCRF到波谷的临时寄存器B
- ●顶部为GTCCRA的临时寄存器A
- ●在顶部的GTCCRB临时寄存器B。

引脚输出值可以根据GTIOR设置分别从低输出、高输出或切换输出中选择，用于比较匹配和循环结束。

通过设置GTDTCR、GTDVU，可以自动将带死区时间的反相波形的比较匹配值设置为GTCCRB。

图21.23显示了三角波PWM模式3操作的示例，表21.19显示了设置三角波PWM模式3的示例。

21.3.4 Automatic Dead Time Setting Function

By setting GTDTCR, a compare match value for a negative waveform with dead time obtained by a compare match value for a positive waveform (GTCCRA value) and specified dead time value (GTDVU value) can automatically be set to GTCCRB. The automatic dead time setting function can be used in saw-wave one-shot pulse mode and all the triangle PWM modes.

Writing to GTCCRB is prohibited when the automatic dead time setting function is used. Dead time setting beyond the cycle is also prohibited. Values for automatic dead time setting can be read from GTCCRB. In triangle-wave mode, when the dead time is beyond the cycle by setting the value GTCCRA = 0 or GTCCRA ≥ GTPR for GTCCRA, the output protection function keeps the level of output. For details, see section 21.7.3. GTIOCnm Pin Output Negate Control (n = 1, 2, 4, 5, m = A, B). The automatic dead time value setting to GTCCRB is performed at the next clock cycle count when registers that are used for calculating the automatic dead time value are updated.

When a dead time error occurs, the compare match values for positive and negative waveforms are adjusted to generate the waveforms with the dead time as shown in Table 21.20.

The adjusted value for the negative waveform is set for GTCCRB automatically.

The adjusted value for the positive waveform is used as internal signal and not set for GTCCRA.

21.3.4 自动死区时间设置功能

通过设置GTDTCR，可以自动将正波形的比较匹配值（GTCCRA值）和指定死区时间值（GTDVU值）得到的负波形与死区时间的比较匹配值设置为GTCCRB。自动死区时间设置功能可用于锯波单次脉冲模式和所有三角形

PWM modes.

使用自动死区时间设置功能时，禁止写入GTCCRB。超出周期的死区时间设置也被禁止。自动死区时间设置的值可以从GTCCRB中读取。在三角波模式下，当设置GTCCRA=0或GTCCRA≥GTCCRA时，死区时间超出周期时，输出保护功能保持输出电平。详见21.7.3节。GTIOCnm引脚输出负控制(n=1 2 4 5 m=A B)。当用于计算自动死区时间值的寄存器被更新时，在下一个时钟周期计数时执行GTCCRB的自动死区时间值设置。

当出现死区时间错误时，调整正负波形的比较匹配值以生成具有死区时间的波形，如表21.20所示。

负波形的调整值自动为GTCCRB设置。

正波形的调整值用作内部信号，而不是为GTCCRA设置的。

21.3.5 Count Direction Changing Function

The count direction of the GTCNT counter can be changed by modifying the UD bit in GTUDDTYC.

In saw-wave mode, if the UD bit in GTUDDTYC is modified during count operation, the count direction is changed at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the GTUDDTYC.UD bit is modified while the count operation stops and the GTUDDTYC.UDF bit is 0, the GTUDDTYC.UD bit modification is not reflected at the start of counting and the count direction is changed at an overflow or an underflow. If the UDF bit is set to 1 while the count operation stops, the GTUDDTYC.UD bit value at that time is reflected at the start of counting.

In triangle-wave mode, the count direction does not change even though the UD bit in GTUDDTYC is modified during the count operation. Similarly, even though the GTUDDTYC.UD bit is modified while the count operation stops and GTUDDTYC.UDF bit is 0, the GTUDDTYC.UD bit value is not reflected to the count operation. If the GTUDDTYC.UDF bit is set to 1 while the count operation is stopped, the GTUDDTYC.UD bit value at that time is reflected at the start of counting.

If the count direction changes during a saw-wave count operation, the GTPR value after the start of up-counting is reflected in the count cycle during up-counting and the GTPR value after the start of down-counting is reflected in the count cycle during down-counting.

Figure 21.28 shows an example of count direction changing function operation.

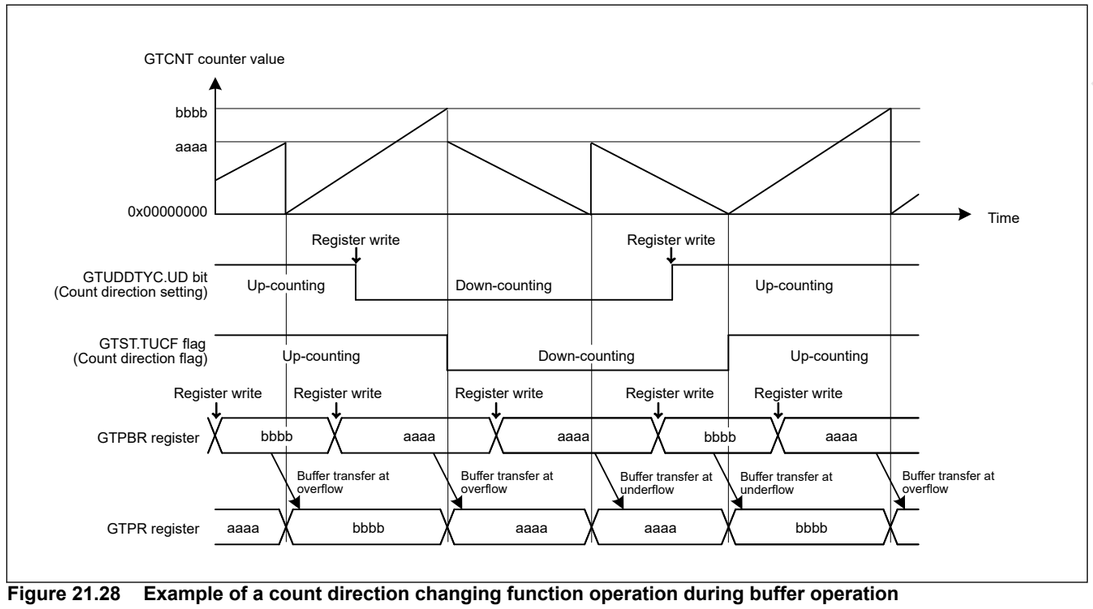

Figure 21.28 Example of a count direction changing function operation during buffer operation

21.3.6 Function of Output Duty 0% and 100%

The output duty of the GTIOCnA pin and the GTIOCnB pin (n = 1, 2, 4, 5) are set to 0% or 100% by changing the GTUDDTYC.OADTY bit or GTUDDTYC.OBDTY bit.

Note: n: 1, 2, 4, 5
m: A, B

21.3.5 计数方向改变功能

GTCNT计数器的计数方向可以通过修改GTUDDTYC中的UD位来改变。

在锯齿波模式下，如果在计数操作期间修改GTUDDTYC中的UD位，则计数方向会在溢出（在向上计数期间修改时）或下溢（在向下计数期间修改时）改变。如果在计数操作停止时修改GTUDDTYC.UD位并且GTUDDTYC.UDF位为0，则GTUDDTYC.UD位的修改不会反映在计数开始时，并且计数方向会在上溢或下溢时改变。如果在计数操作停止时UDF位设置为1，则此时的GTUDDTYC.UD位值将反映在计数开始时。

在三角波模式下，即使在计数操作期间修改GTUDDTYC中的UD位，计数方向也不会改变。同样，即使在计数操作停止且GTUDDTYC.UDF位为0时修改GTUDDTYC.UD位，GTUDDTYC.UD位的值也不会反映到计数操作中。如果在停止计数操作时将GTUDDTYC.UDF位设置为1，则此时的GTUDDTYC.UD位值将反映在计数开始时。

如果在锯齿波计数操作期间计数方向发生变化，则加计数开始后的GTPR值反映在加计数期间的计数周期中，而减计数开始后的GTPR值反映在计数周期中在向下计数期间。

图21.28显示了计数方向改变功能操作的示例。

21.3.6 输出占空比0%和100%的功能

GTIOCnA引脚和GTIOCnB引脚的输出占空比(n=1 2 4 5)通过更改GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位。

In saw-wave mode, if the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified during the count operation, the output duty setting is reflected at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF or the GTUDDTYC.OBDTYF bit is 0, the output duty modification is not reflected at the start of counting. The output duty changes at an overflow or an underflow. If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF or the GTUDDTYC.OBDTYF bit is 1, the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit value at that time is reflected at the start of counting.

In triangle-wave mode, if the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified during the count operation, the output duty setting is reflected an underflow.

If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF or the GTUDDTYC.OBDTYF bit is 0, the output duty modification is not reflected at the start of counting. The output duty changes at an underflow. If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation stops and the GTUDDTYC.OADTYF or the GTUDDTYC.OBDTYF bit is 1, the output duty modification is reflected at the start of counting.

In performing 0% or 100% duty operation, GPT internally continues to:

- Perform compare match operation
- Set compare match flag
- Output interrupt
- Perform buffer operation.

When the control is changed from 0% or 100% duty setting to compare match, the output value of GTIOCnA pin at cycle end is decided by GTIOR.GTIOA[3:2] and GTUDDTYC.OADTYR. The output value of GTIOCnB pin at cycle end is decided by GTIOR.GTIOB[3:2] and GTUDDTYC.OBDTYR.

When GTIOR.GTIOA[3:2] and GTIOR.GTIOB[3:2] are set to 01b, the output pins output low at cycle end. When GTIOR.GTIOA[3:2] and GTIOR.GTIOB[3:2] are set to 10b, the output pins output high at cycle end.

GTUDDTYC.OADTYR selects the value that is the object of output retained/toggled at cycle end, when GTIOR.GTIOm[3:2] are set to 00b (output retained at cycle end) or when GTIOR.GTIOm[3:2] are set to 11b (output toggled at cycle end). Table 21.23 shows the values of GTIOCnA and GTIOCnB pin output at cycle end.

Figure 21.29 shows an example of output duty 0% and 100% function.

在锯齿波模式下，如果在计数操作期间修改GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位，则输出占空比设置反映在溢出（在向上计数期间修改时）或下溢（在向下期间修改时-数数）。如果在计数操作停止且GTUDDTYC.OADTYF或GTUDDTYC.OBDTYF位为0时修改GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位，则在计数开始时不反映输出占空比修改。输出占空比在上溢或下溢时发生变化。如果GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位在计数操作停止并且

GTUDDTYC.OADTYF或GTUDDTYC.OBDTYF位为1，此时的GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位的值反映在计数开始时。

在三角波模式下，如果在计数操作期间修改GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位，则输出占空比设置反映为下溢。

如果在计数操作停止且GTUDDTYC.OADTYF或GTUDDTYC.OBDTYF位为0时修改GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位，则在计数开始时不反映输出占空比修改。输出占空比在下溢时发生变化。如果在计数操作停止且GTUDDTYC.OADTYF或GTUDDTYC.OBDTYF位为1时修改了GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位，则输出占空比修改将反映在计数开始时。

在执行0%或100%占空比操作时，GPT在内部继续：

- ●执行比较匹配操作
- ●设置比较匹配标志
- ●输出中断
- ●执行缓冲操作。

当控制从0%或100%占空比设置更改为比较匹配时，周期结束时GTIOCnA引脚的输出值由GTIOR.GTIOA[3:2]和GTUDDTYC.OADTYR决定。周期结束时GTIOCnB引脚的输出值由GTIOR.GTIOB[3:2]和GTUDDTYC.OBDTYR决定。

当GTIOR.GTIOA[3:2]和GTIOR.GTIOB[3:2]设置为01b时，输出引脚在周期结束时输出低电平。什么时候GTIOR.GTIOA[3:2]和GTIOR.GTIOB[3:2]设置为10b，输出引脚在周期结束时输出高电平。

GTUDDTYC.OADTYR当GTIOR.GTIOm[3:2]设置为00b（在循环结束时保持输出）或GTIOR.GTIOm[3:2]设置时，选择作为在循环结束时切换的输出保留对象的值到11b（输出在循环结束时切换）。表21.23显示了循环结束时GTIOCnA和GTIOCnB引脚输出的值。

21.3.8 Synchronized Operation

Synchronized operation on channels such as a synchronized start, stop, and clear operation can be performed.

21.3.8.1 Synchronized Operation by Software

The GTCNT counters can be started, stopped, and cleared on multiple channels by setting the associated GTSTR, GTSTP, or GTCLR bits simultaneously to 1.

Count start with a phase difference is possible by setting the initial value in the GTCNT counter and setting the associated GTSTR bits simultaneously to 1.

Figure 21.36 shows an example of a simultaneous start, stop, and clear by software. Figure 21.37 shows an example of phase start operation by software.

21.3.8 同步操作

可以对通道进行同步操作，例如同步启动、停止和清除操作。

21.3.8.1 软件同步操作

通过将相关的GTSTR、GTSTP或GTCLR位同时设置为1，可以在多个通道上启动、停止和清除GTCNT计数器。

通过在GTCNT计数器中设置初始值并设置相关的
GTSTR位同时为1。

21.3.8.2 Synchronized Operation by Hardware

The counters for multiple channels can be started, stopped, and cleared simultaneously by the following hardware sources. Hardware sources that can cause a synchronized operation are external trigger input and ELC event input. Synchronized operation through the GTIOCnA and GTIOCnB pin inputs is possible by setting an ELC event due to input capture as a hardware source (n = 1, 2, 4, 5).

Figure 21.38 shows an example of a simultaneous start, stop, and clear operation by a hardware source. Table 21.28 shows the setting example.

21.3.8.2 硬件同步操作

多个通道的计数器可以通过以下硬件源同时启动、停止和清除。
可以导致同步操作的硬件源是外部触发输入和ELC事件输入。通过将输入捕获导致的ELC事件设置为硬件源（n =1、2、4、5），可以通过GTIOCnA和GTIOCnB引脚输入进行同步操作。

图21.38显示了一个硬件源同时启动、停止和清除操作的示例。表21.28显示了设置示例。

The GTIOCnA is set so that it outputs low as the initial value, high at a GTCCRA compare match, and low at the cycle end. The GTIOCnB is set so that it outputs low as the initial value, high at a GTCCRB compare match, and low at the cycle end.

21.3.10 Period Count Function

By setting the GTPC register, the end of period can be counted.

The number of period to be counted should be set into the GTPC.PCNT counter when the GTPC.PCEN bit is 0. When the PCEN bit is 1, the PCNT counter can be read, but writing is disabled. When the PCEN bit is 1, down-counting is performed at the end of period. When the PCNT counter is 1 at the end of period, it becomes 0 and counting is stopped to finish the period count function. At that time, the GTST.PCF flag is set, and the period count function finish interrupt request GPTn_PC is generated. When the GTPC.ASTP bit is 1, the GTCNT counter is also stopped at the same time that the period count function is finished.

When the GTCNT counter is stopped while period count function is enabled, the PCNT counter keeps its value. When the GTCNT counter restarts counting and the PCEN bit is 1, the PCNT counter restarts down-counting from the hold value.

When the PCEN bit is changed from 0 to 1 while the PCNT counter is 0 and the ASTP bit is 1, the GTCNT counter is stopped at the count clock immediately after that.

When either GTSECR.SPCE bit or GTSECR.SPCD bit is set to 1, the PCEN bit in the channels set to 1 by the GTSECSR register is simultaneously set the value to enable or disable the period count function for multiple channels.

Figure 21.45 and Figure 21.46 show examples of PWM cycle count function.

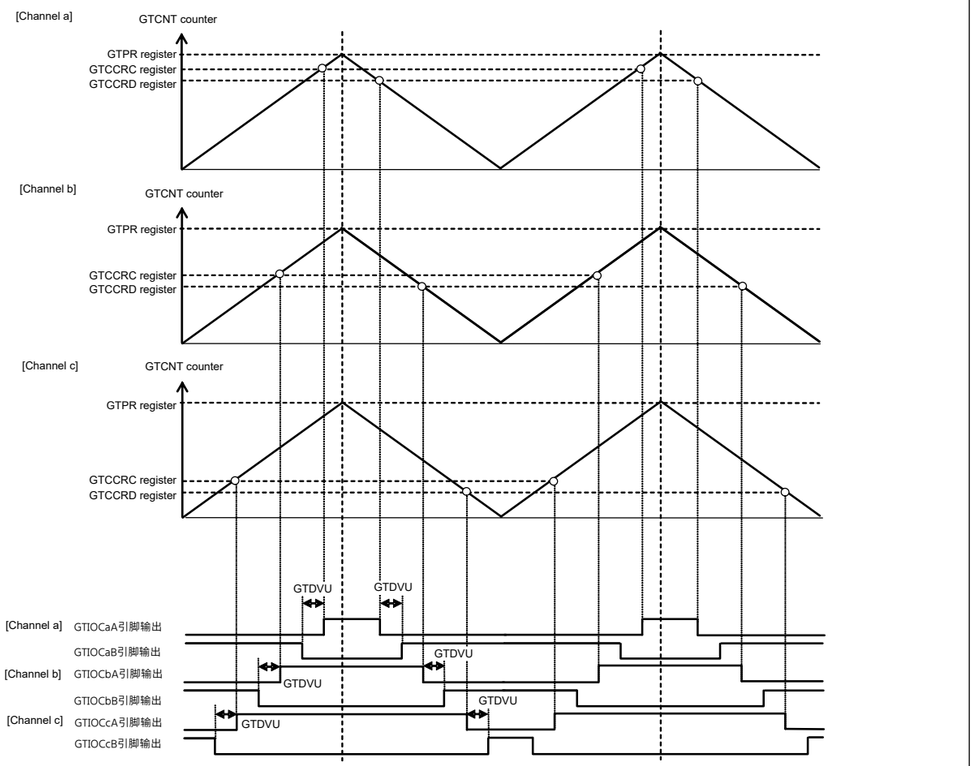

Figure 21.44 具有自动死区时间设置的三相不对称三角波互补PWM输出示例

21.3.10 周期计数功能

通过设置GTPC寄存器，可以计算周期结束。

当GTPC.PCEN位为0时，要计数的周期数应设置到GTPC.PCNT计数器中。当PCEN位为1，可以读取PCNT计数器，但禁止写入。当PCEN位为1时，在周期结束时执行递减计数。当PCNT计数器在周期结束时为1时，它变为0并停止计数以完成周期计数功能。此时，GTST.PCF标志置位，产生周期计数功能完成中断请求GPTn_PC。当GTPC.ASTP位为1时，GTCNT计数器也在周期计数功能完成的同时停止。

当GTCNT计数器停止而周期计数功能使能时，PCNT计数器保持其值。当。。。的时候GTCNT计数器重新开始计数且PCEN位为1，PCNT计数器重新从保持值开始向下计数。

当PCEN位从0变为1且PCNT计数器为0且ASTP位为1时，GTCNT计数器立即在计数时钟处停止。

当GTSECR.SPCE位或GTSECR.SPCD位设置为1时，通过GTSECSR寄存器设置为1的通道中的PCEN位同时设置该值以启用或禁用多个通道的周期计数功能。

图21.45和图21.46显示了PWM周期计数功能的示例。

21.3.11 Phase Counting Function

The phase difference between the GTIOCnA and GTIOCnB pin (n = 1, 2, 4, 5) inputs is detected and the associated GTCNT counts up or counts down. The detectable phase difference is available in any combination with the relationship between the edge and the level of GTIOCnA and GTIOCnB pin inputs being set in the GTUPSR and GTDNSR registers. For details on count operation, see section 21.3.1.1. Counter operation.

21.3.11 相位计数功能

GTIOCnA和GTIOCnB引脚(n=1 2 4 5)输入之间的相位差被检测到并且相关的GTCNT向上计数或向下计数。可检测的相位差可与在GTUPSR和GTDNSR寄存器中设置的GTIOCnA和GTIOCnB引脚输入的边沿和电平之间的关系进行任何组合。有关计数操作的详细信息，请参阅第21.3.1.1节。柜台操作。

21.3.12 Inter Channel Logical Operation Function

The logical operation function between compare match outputs can be performed.

Figure 21.57 shows the block diagram of inter channel logical operation.

To prevent hazard to the GPT output, the signal after logical operation is latched with PCLKD. After latching, the output disable control is performed.

When the logical operation function which causes the delay of 1 PCLKD is selected, the output enable signal is also delayed with 1 PCLKD and input to the output disable control.

When the same signal (C = A or D = B) to operate logical function AND, OR, EXOR and NOR is selected, C or D is treated as 1. In the case of GTIOCnA pin output, when A of same channel is selected for C, the result of AND is A, the result of OR is 1, the result of EXOR is NOT A, and the result of NOR is 0.

21.4 Interrupt Sources

21.4.1 Interrupt Sources

The GPT provides the following interrupt sources:

- GTCCR input capture/compare match
- GTCNT counter overflow (GTPR compare match)/underflow.
- period count function finish

Each interrupt source has its own status flag. When an interrupt source signal is generated, the associated status flag in GTST is set to 1. The associated status flag in GTST can be cleared by writing 0. If flag set and flag clear occur at the same time, flag clear takes priority over flag set. These flags are automatically updated by the internal state. The Interrupt Controller Unit can change the relative channel priorities. However, the priority within a channel is fixed. For details, see section 13, Interrupt Controller Unit (ICU).

Table 21.39 lists the GPT interrupt sources.

21.4 中断源

21.4.1 中断源

GPT提供以下中断源：

●GTCCR输入捕捉比较匹配

●GTCNT计数器上溢（GTPR比较匹配）下溢。

●周期计数功能完成

每个中断源都有自己的状态标志。当一个中断源信号产生时，相关的状态标志在GTST设置为1。GTST中相关的状态标志可以通过写入0来清除。如果标志设置和标志清除同时发生，标志清除优先于标志设置。这些标志由内部状态自动更新。中断控制器单元可以改变相关的通道优先级。但是，通道内的优先级是固定的。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

表21.39列出了GPT中断源。

21.5 由ELC链接的操作

21.5.1 事件信号输出到ELC

21.5.2 来自ELC的事件信号输入

GPT可以执行以下操作以响应来自ELC的最多8个事件：

●开始计数、停止计数、清计数

- Up-counting, down-counting

●输入捕捉。

有关ELC和事件信号输入之间的连接，请参见第18节，事件链接控制器(ELC)。

21.6 噪音过滤功能

用于GPT的输入捕捉和霍尔传感器输入的每个引脚都配备了噪声滤波器。噪声滤波器以采样时钟对输入信号进行采样，并去除长度小于3个采样周期的脉冲。

The noise filter functionality includes enabling and disabling the noise filter for each pin and setting of the sampling clock for each channel.

Figure 21.59 shows the timing of noise filtering.

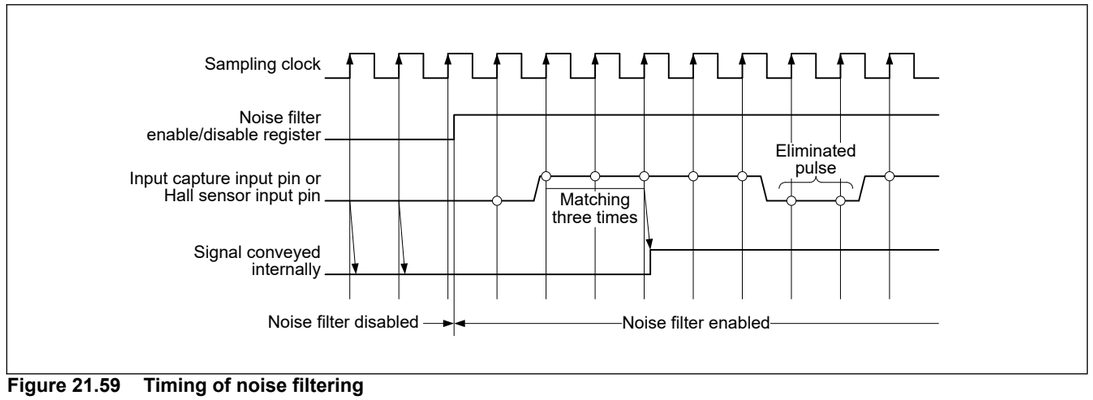

Figure 21.59 Timing of noise filtering

If noise filtering is enabled, the input capture operation or output phase switching operation is performed on the edges of the noise filtered signal after a delay of (sampling interval × 2 + PCLKD) at the shortest. This is due to the noise filtering for the input capture input or hall sensor input.

21.7 Protection Function

21.7.1 Write-Protection for Registers

To prevent registers from being accidentally modified, registers can be write-protected in channel units by setting GTWP.WP. Write-protection can be set for the following registers:

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTDTCR, GTDVU, GTADSMR, GTICLF, GTPC.

Every bit in registers GTSTR, GTSTP and GTCLR which can update the corresponding registers in other channels and can be updated by any of the corresponding registers in other channels conversely, can be protected by setting the GTWP.STRWP, STPWP, and CLRWP bits, respectively, per channel.

Likewise, writing to the GTSECSR and GTSECR registers, which can control all channels by writing to the GTSECSR and GTSECR registers of a given channel, can by enabled or disabled by the setting of the GTWP.CMNWP bit.

Protection using the GTWP register is only for write operations by the CPU. This protection does not cover updates to registers that occur in association with CPU writes.

21.7.2 Disabling of Buffer Operation

If the timing of the buffer register write is delayed relative to the timing for the buffer transfer, buffer operation can be suspended with the GTBER.BD[1] and BD[0] bits settings. Specifically, buffer transfer can be temporarily disabled even though a buffer transfer condition is generated during buffer register write, by setting the BD[1] and BD[0] bits to 1 (buffer operation disabled) before buffer register write, and setting the bits to 0 (buffer operation enabled) after completion of writing to all the buffer registers.

The BD[1] and BD[0] bits can be set on channel basis by writing directly to the GTBER register or it can be set to 0 simultaneously by setting the GTSECR register for multiple channels which were set by the GTSECSR register.

Figure 21.60 shows an example of operation for disabling buffer operation by writing to the GTBER register.

噪声过滤器功能包括为每个引脚启用和禁用噪声过滤器以及为每个通道设置采样时钟。

图21.59显示了噪声过滤的时序。

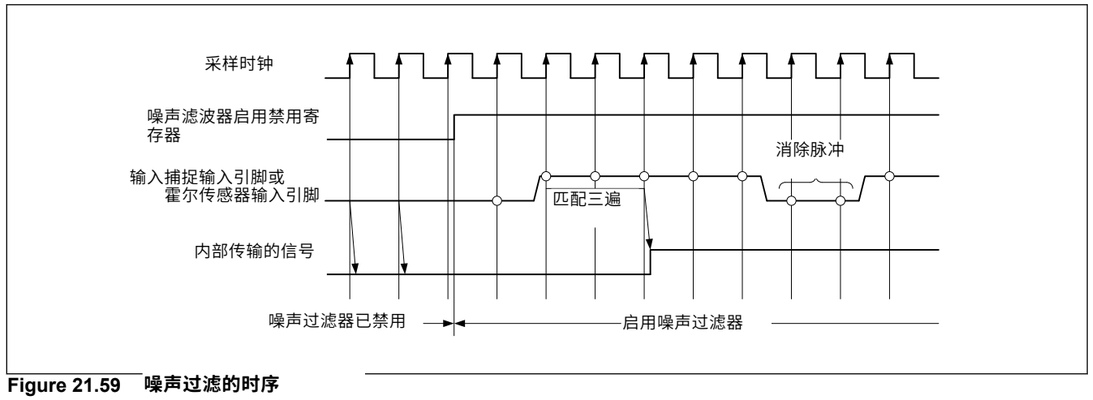

Figure 21.59 噪声过滤的时序

如果噪声过滤使能，输入捕捉操作或输出相位切换操作在最短延迟（采样间隔×2+PCLKD）后在噪声过滤信号的边缘执行。这是由于输入捕捉输入或霍尔传感器输入的噪声过滤。

21.7 保护功能

21.7.1 寄存器的写保护

为了防止寄存器被意外修改，可以通过设置以通道为单位对寄存器进行写保护 GTWP.WP。可以为以下寄存器设置写保护：

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTDTCR, GTDVU, GTADSMR, GTICLF, GTPC.

寄存器GTSTR、GTSTP和GTCLR中的每个位可以更新其他通道中的相应寄存器，反之也可以由其他通道中的任何相应寄存器更新，可以分别通过设置GTWP.STRWP、STPWP和CLRWP位来保护 每个频道。

同样，写入GTSECSR和GTSECR寄存器，它们可以通过写入GTSECSR和给定通道的GTSECR寄存器可以通过设置GTWP.CMNWP位来启用或禁用。

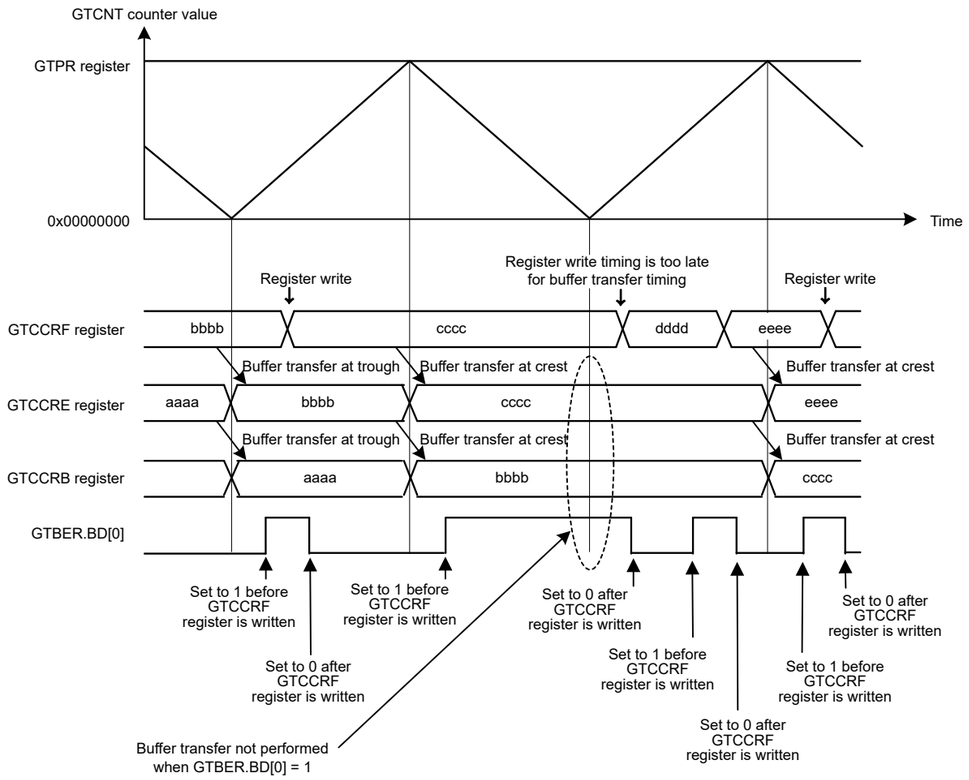
使用GTWP寄存器的保护仅适用于CPU的写操作。此保护不涵盖与CPU写入相关的寄存器更新。

21.7.2 禁用缓冲区操作

如果缓冲寄存器写入的时序相对于缓冲传输的时序延迟，则可以通过GTBER.BD[1]和BD[0]位设置暂停缓冲操作。具体而言，即使在缓冲寄存器写入期间产生缓冲传送条件，通过在缓冲寄存器写入之前将BD[1]和BD[0]位设置为1（禁用缓冲操作），并设置这些位，也可以暂时禁用缓冲传送写入所有缓冲寄存器后变为0（启用缓冲操作）。

BD[1]和BD[0]位可以通过直接写入GTBER寄存器以通道为单位进行设置，也可以通过将GTSECR寄存器设置为由GTSECSR寄存器设置的多个通道同时设置为0。

图21.60显示了通过写入GTBER寄存器来禁用缓冲区操作的操作示例。



Note: The base address of registers are the same.

Figure 21.60 Example of operation for disabling buffer operation with triangle waves, double buffer operation, and buffer transfer at both troughs and crests

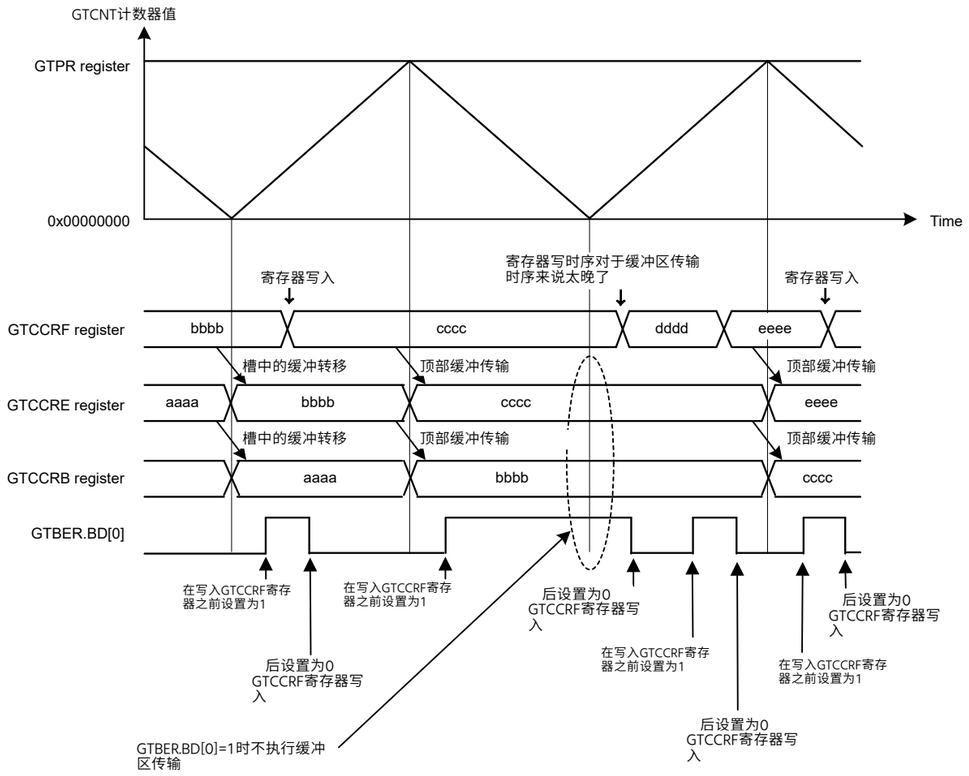
21.7.2.1 Simultaneous Control of Buffer Operations of Multiple Channels

The GTBER.BD bit can be set by writing directly to the GTBER register per channel or by making settings in the GTSECR register for multiple channels that have already set in the GTSECSR register.

Follow the procedure below to simultaneously set the GTBER.BD bits of multiple channels.

1. Select the channels for simultaneously setting by the GTSECSR register
   Set the GTSECSR register so that the values at the bit positions for the corresponding channels for simultaneously setting of the GTBER.BD bits become 1. All GTSECSR registers can be updated by writing to the GTSECSR register of any channel.
2. Simultaneously set the GTBER.BD bits by updating the GTSECR register
   In the GTSECR register, set the operation of the GTBER.BD bits (enabling or disabling of buffer operation) which are to be simultaneously set. Writing to a GTSECR register from any channel updates the GTBER.BD bits in all channels corresponding to the bits set as 1 in the GTSECSR register, in accordance with the value of the GTSECR register.

Figure 21.61 show examples of simultaneously controlling the enabling or disabling of buffer operation for multiple channels.



Note: 寄存器的基地址相同。

Figure 21.60 三角波缓冲操作、双缓冲操作、波谷和波峰缓冲转移的禁用操作示例

21.7.2.1 多通道缓冲操作的同时控制

GTBER.BD位可以通过直接写入每个通道的GTBER寄存器或通过在GTSECR寄存器中为已在GTSECSR寄存器中设置的多个通道进行设置来设置。

按照以下步骤同时设置多个通道的GTBER.BD位。

1.通过GTSECSR寄存器选择同时设置的通道
设置GTSECSR寄存器，使用于同时设置GTBER.BD位的相应通道的位位置的值变为1。通过写入任何通道的GTSECSR寄存器，可以更新所有GTSECSR寄存器。

2.通过更新GTSECR寄存器同时设置GTBER.BD位
在GTSECR寄存器中，设置要同时设置的GTBER.BD位的操作（启用或禁用缓冲区操作）。根据GTSECR寄存器的值，从任何通道写入GTSECR寄存器会更新与GTSECSR寄存器中设置为1的位相对应的所有通道中的GTBER.BD位。

图21.61显示了同时控制多个通道的缓冲区操作的启用或禁用的示例。

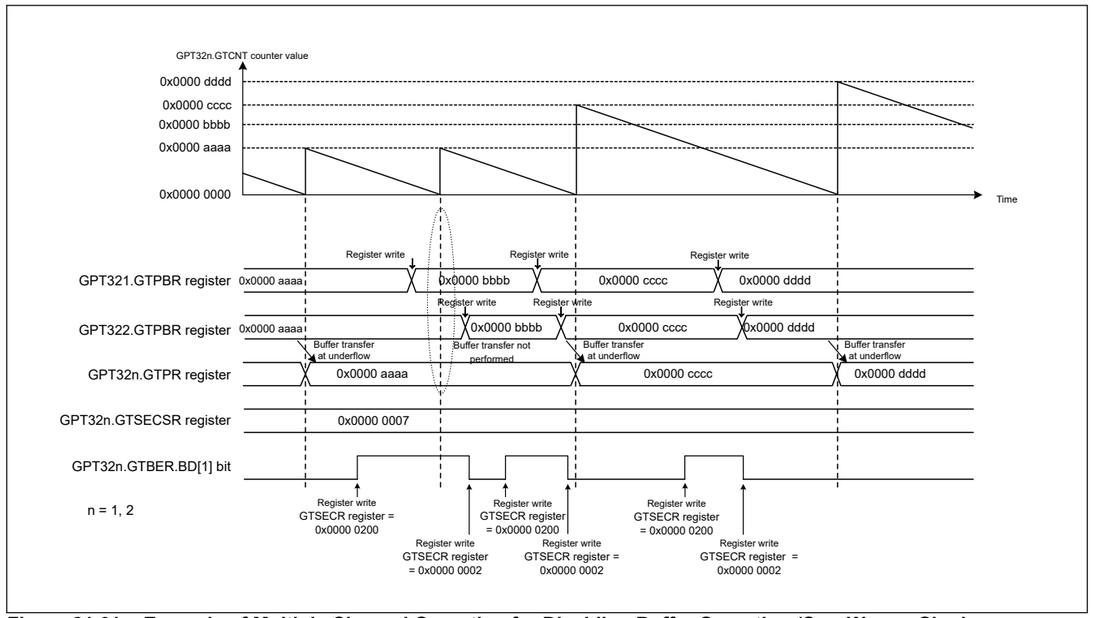


Figure 21.61 Example of Multiple Channel Operation for Disabling Buffer Operation (Saw Waves, Single Buffer Operation)

21.7.3 GTIOCnm Pin Output Negate Control (n = 1, 2, 4, 5, m = A, B)

For protection from system failure, the output disable control that changes the GTIOCnm pin output value forcibly is provided for GTIOCnm pin output by the request of output disable from POEG. Output protection is required when the same output level being on the GTIOCnA and GTIOCnB pins is detected. GPT detects this condition and generates output disable requests to POEG according to the setting of the output disable request permission bits, such as GTINTAD.GRPABH, GTINTAD.GRPABL. After the POEG performs the logical OR of the output disable request from each channel and the output disable request from the external input, the POEG generates output disable requests to GPT.

One output disable signal (representing the shared output disable request signal of the GTIOCnA pin and the GTIOCnB pin) out of 4 output disable requests generated by the POEG is selected by setting GTINTAD.GRP[1:0]. The status of the selected disable output request is monitored by reading the GTST.ODF bit. The output level during output disable is set based on the GTIOR.OADF[1:0] bits for the GTIOCnA pin and the GTIOR.OBDF[1:0] setting for the GTIOCnB pin.

The change to the output disable state is performed asynchronously by generating the output disable request from the POEG. The release of the output disable state is performed at end of cycle by terminating the output disable request. It is after 3 PCLKD at shortest when the output disable condition is released after the output disable request becomes no longer satisfied. To reliably control output disabling, clear the flag of POEG for which the condition for the request to disable the output is no longer satisfied after 4 cycles of PCLKD.

When event count is performed or when the output disable state should be released immediately without waiting for end of cycle, GTIOR.OADF[1:0] should be set to 00b (for GTIOCnA pin) or GTIOR.OBDF[1:0] should be set to 00b (for the GTIOCnB pin).

Figure 21.62 shows an example of the GTIOCnm pin output disable control operation. (n = 1, 2, 4, 5, m = A, B)

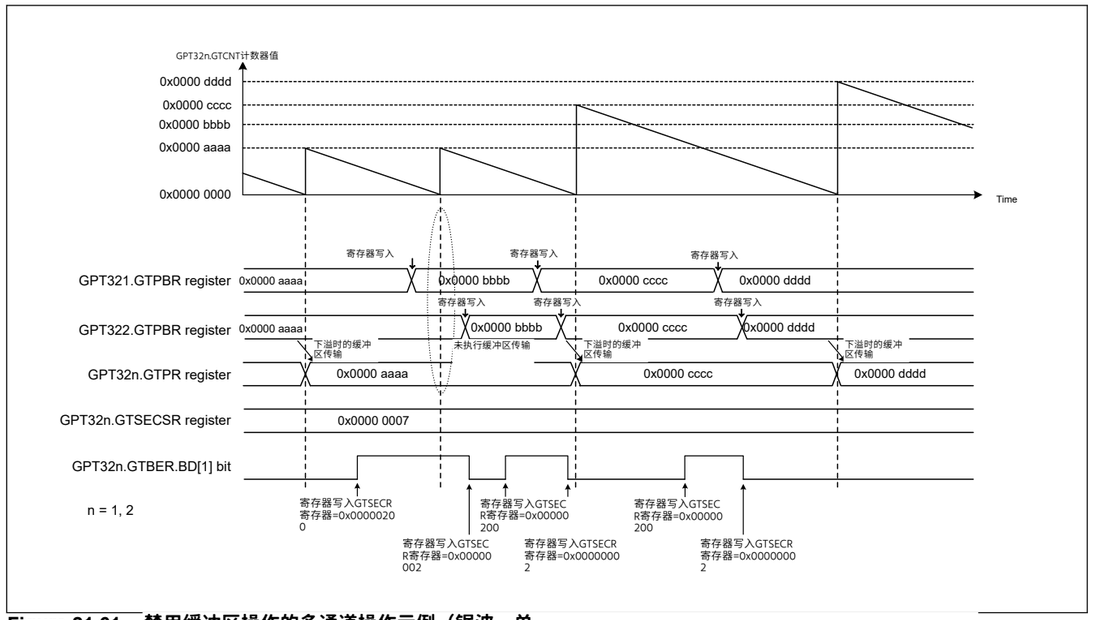

Figure 21.61 禁用缓冲区操作的多通道操作示例（锯波，单 Buffer Operation)

21.7.3 GTIOCnm引脚输出负控制(n=1 2 4 5 m=A B)

为防止系统故障，根据POEG的输出禁用请求，为GTIOCnm引脚输出提供强制改变GTIOCnm引脚输出值的输出禁用控制。当检测到GTIOCnA和GTIOCnB引脚上的输出电平相同时，需要输出保护。GPT检测到这种情况并根据输出禁用请求许可位的设置，如GTINTAD.GRPABH、GTINTAD.GRPABL向POEG生成输出禁用请求。在POEG对来自每个通道的输出禁止请求和来自外部输入的输出禁止请求进行逻辑或运算后，POEG向GPT生成输出禁止请求。

通过设置GTINTAD.GRP[1:0]，在POEG产生的4个输出禁止请求中选择一个输出禁止信号（代表GTIOCnA引脚和GTIOCnB引脚的共享输出禁止请求信号）。通过读取GTST.ODF位来监控所选禁用输出请求的状态。输出禁用期间的输出电平根据GTIOCnA引脚的GTIOR.OADF[1:0]位和GTIOCnB引脚的GTIOR.OBDF[1:0]设置来设置。

对输出禁用状态的更改是通过从
POEG。通过终止输出禁用请求，在循环结束时执行输出禁用状态的释放。输出禁止请求不再满足后，输出禁止条件解除的时间最短为3个PCLKD之后。为了可靠地控制输出禁用，在4个PCLKD周期后，清除不再满足禁用输出请求的条件的POEG标志。

当执行事件计数或应立即释放输出禁用状态而不等待周期结束时，应将GTIOR.OADF[1:0]设置为00b（对于GTIOCnA引脚）或GTIOR.OBDF[1:0]应设置为设置为00b（对于GTIOCnB引脚）。

图21.62显示了GTIOCnm引脚输出禁用控制操作的示例。(n=1 2 4 5 m=A B)

21.8 Initialization Method of Output Pins

21.8.1 Pin Settings after Reset

The GPT registers are initialized at a reset. Start counting after selecting the port pin function with the PmnPFS register, setting GTIOR.OAE and GTIOR.OBE bits, and outputting the GPT function to external pins.

21.8.2 Pin Initialization Due to Error during Operation

If an error occurs during GPT operation, the following four types of pin control can be performed before pin initialization:

- Set the OAHLD and OBHLD bits in GTIOR to 1 and retain the outputs at count stop
- Set the OAHLD and OBHLD bits in GTIOR to 0, specify arbitrary output values at OADFLT and OBDFLT in GTIOR, and output the arbitrary values at count stop
- Set the pin to output an arbitrary value as a general output port by setting the PDR, PODR registers and PmnPFS.PMR bit of the I/O port in advance. Set the OAE and OBE bits in GTIOR to 0, and the control bit associated with the pin in the PMR to 0 to allow arbitrary values to be output from the pin set as a general output port when an error occurs.
- Drive the output to a high impedance state using the POEG function.

If the automatic dead time setting is made, clear the GTDTCR.TDE bit to 0 after counting stops. When counting stops, only the values of registers that are changed by a GPT external source change. If counting is resumed, operation continues from where it stopped. If counting is stopped, the registers must be initialized before counting starts.

21.9 Usage Notes

21.9.1 Module-Stop Function Setting

The Module Stop Control Register can enable or disable GPT operation. The GPT is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

21.9.2 GTCCRn Settings during Compare Match Operation (n = A to F)

(1) When automatic dead time setting is made in triangle-wave PWM mode

The GTCCRA register must satisfy all of the following conditions:

- GTDVU < GTCCRA
- 0 < GTCCRA < GTPR

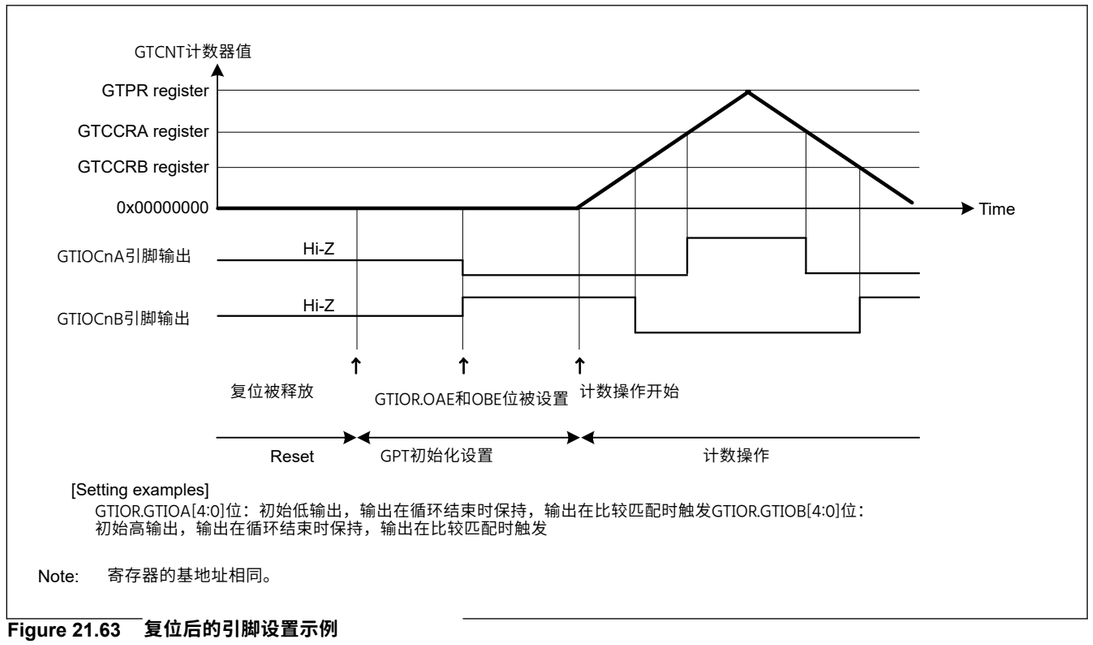

Figure 21.63 复位后的引脚设置示例

21.8.2 由于操作过程中的错误而导致的引脚初始化

如果在GPT操作过程中发生错误，可以在引脚初始化之前进行以下四种引脚控制：

●将GTIOR中的OAHLD和OBHLD位设置为1，并在计数停止时保留输出

●将GTIOR中的OAHLD和OBHLD位设置为0，在GTIOR中的OADFLT和OBDFLT指定任意输出值，并在计数停止时输出任意值

●通过预先设置IO端口的PDR、PODR寄存器和PmnPFS.PMR位，将引脚设置为输出任意值作为通用输出端口。将GTIOR中的OAE和OBE位设置为0，并将与PMR中的引脚相关的控制位设置为0，以允许在发生错误时从设置为通用输出端口的引脚输出任意值。

●使用POEG功能将输出驱动为高阻抗状态。

如果进行了自动死区时间设置，则在计数停止后将GTDTCR.TDE位清零。当计数停止时，只有被GPT外部源改变的寄存器的值会改变。如果重新开始计数，则从停止处继续操作。如果停止计数，则必须在计数开始前初始化寄存器。

21.9 使用说明

21.9.1 模块停止功能设置

模块停止控制寄存器可以启用或禁用GPT操作。GPT在重置后最初停止。
释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

21.9.2 比较匹配操作期间的GTCCRn设置（n=A到F）

(1) 在三角波PWM模式下进行自动死区时间设置时

GTCCRA寄存器必须满足以下所有条件：

- GTDVU < GTCCRA
- 0 < GTCCRA < GTPR

When the setting of GTCCRA = 0 or GTCCRA ≥ GTPR is made for the GTCCRA register during count operation, the output protection function is activated. However, if the following condition is not satisfied, the output protection function does not work normally:

- The value of the GTCCRA register at the start of counting is larger than 0 and less than GTPR.

For details, see section 21.7.3. GTIOCnm Pin Output Negate Control (n = 1, 2, 4, 5, m = A, B).

(2) When automatic dead time setting is not made in triangle-wave PWM mode

The GTCCRA register must be set within the range of 0 < GTCCRA < GTPR. If GTCCRA = 0 or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0 or GTCCRA = GTPR is satisfied. When GTCCRA > GTPR, no compare match occurs.

Similarly, GTCCRB must be set within the range of 0 < GTCCRB < GTPR. If GTCCRB = 0 or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB is 0 or GTCCRB = GTPR is satisfied. When GTCCRB > GTPR, no compare match occurs.

(3) When automatic dead time setting is made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, the correct output waveforms with secured dead time may not be obtained.

- In up-counting: GTCCRC < GTCCRD, GTCCRC > GTDVU, GTCCRD < GTPR - GTDVU
- In down-counting: GTCCRC > GTCCRD, GTCCRC < GTPR - GTDVU, GTCCRD > GTDVU

(4) When automatic dead time setting is not made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRC < GTCCRD < GTPR
- In down-counting: GTPR > GTCCRC > GTCCRD > 0

Similarly, GTCCRE and GTCCRF must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRE < GTCCRF < GTPR
- In down-counting: GTPR > GTCCRE > GTCCRF > 0.

(5) In saw-wave PWM mode

The GTCCRA register must be set with the range of 0 < GTCCRA < GTPR. If GTCCRA = 0 or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0 or GTCCRA = GTPR is satisfied. If GTCCRA > GTPR is set, no compare match occurs.

Similarly, GTCCRB must be set with the range of 0 < GTCCRB < GTPR. If GTCCRB = 0 or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB = 0 or GTCCRB = GTPR is satisfied. If GTCCRB > GTPR is set, no compare match occurs.

21.9.3 Setting Range for GTCNT Counter

The GTCNT counter register must be set with the range of 0 ≤ GTCNT ≤ GTPR.

21.9.4 Starting and Stopping the GTCNT Counter

The control timing of starting and stopping the GTCNT counter by the GTCR.CST bit synchronizes the count clock that is selected in GTCR.TPCS[3:0]. When GTCR.CST is updated, the GTCNT counter starts/stops after a count clock that is selected in GTCR.TPCS[3:0]. Therefore, an event generated before the GTCNT counter actually starts is ignored, resulting in situations in which an event is accepted or an interrupt occurs after GTCR.CST is set to 0.

当在计数操作期间对GTCCRA寄存器设置GTCCRA=0或GTCCRA≥GTPR时，输出保护功能被激活。但是，如果不满足以下条件，则输出保护功能不能正常工作：

●计数开始时GTCCRA寄存器的值大于0小于GTPR。

详见21.7.3节。GTIOCnm引脚输出负控制(n=1 2 4 5 m=A B)。

(2) 在三角波PWM模式下未进行自动死区时间设置时

GTCCRA寄存器必须设置在0<GTCCRA<GTPR的范围内。如果设置了GTCCRA=0或GTCCRA=GTPR，则仅当满足GTCCRA=0或GTCCRA=GTPR时，才会在周期内发生比较匹配。当GTCCRA>GTPR时，不发生比较匹配。

同样，GTCCRB必须设置在0<GTCCRB<GTPR的范围内。如果设置了GTCCRB=0或GTCCRB=GTPR，则仅当GTCCRB为0或GTCCRB=GTPR满足时，才会在周期内发生比较匹配。当GTCCRB>GTPR时，不发生比较匹配。

(3) 在锯波单发脉冲模式下进行自动死区时间设置时

GTCCRC和GTCCRD寄存器必须设置为满足以下限制。如果不满足这些限制，则可能无法获得具有安全死区时间的正确输出波形。

- In up-counting: GTCCRC < GTCCRD, GTCCRC > GTDVU, GTCCRD < GTPR - GTDVU
- In down-counting: GTCCRC > GTCCRD, GTCCRC < GTPR - GTDVU, GTCCRD > GTDVU

(4) 在锯波单发脉冲模式下未进行自动死区时间设置时

GTCCRC和GTCCRD寄存器必须设置为满足以下限制。如果不满足限制，则不会发生两个比较匹配，并且无法执行脉冲输出。

- In up-counting: 0 < GTCCRC < GTCCRD < GTPR
- In down-counting: GTPR > GTCCRC > GTCCRD > 0

同样，必须设置GTCCRE和GTCCRF以满足以下限制。如果不满足限制，则不会发生两个比较匹配，并且无法执行脉冲输出。

- In up-counting: 0 < GTCCRE < GTCCRF < GTPR
- In down-counting: GTPR > GTCCRE > GTCCRF > 0.

(5) 在锯齿波PWM模式下

GTCCRA寄存器必须设置为0<GTCCRA<GTPR。如果设置了GTCCRA=0或GTCCRA=GTPR，则仅当满足GTCCRA=0或GTCCRA=GTPR时，才会在周期内发生比较匹配。如果设置了GTCCRA>GTPR，则不会发生比较匹配。

类似地，GTCCRB必须设置在0<GTCCRB<GTPR的范围内。如果设置了GTCCRB=0或GTCCRB=GTPR，则仅当满足GTCCRB=0或GTCCRB=GTPR时，才会在周期内发生比较匹配。如果设置了GTCCRB>GTPR，则不会发生比较匹配。

21.9.3 GTCNT计数器的设置范围

GTCNT计数器寄存器的设置范围必须为0≤GTCNT≤GTPR。

21.9.4 启动和停止GTCNT计数器

通过GTCR.CST位启动和停止GTCNT计数器的控制时序与在GTCR.TPCS[3:0]中选择的计数时钟同步。当GTCR.CST更新时，GTCNT计数器在GTCR.TPCS[3:0]中选择的计数时钟后开始停止。因此，在GTCNT计数器实际启动之前产生的事件将被忽略，从而导致在GTCR.CST设置为0之后接受事件或发生中断的情况。

21.9.5 Priority Order of Each Event

(1) GTCNT register

Table 21.40 shows a priority order of events updating the GTCNT register.

Table 21.40 Priority order of sources updating GTCNT

Source updating GTCNT	Priority order
Writing by CPU (writing to GTCNT/GTCLR)	High
Clear by hardware sources set in GTCSR	↑
Count up or down by hardware sources set in GTUPSR/GTDNSR	↑
Count operation	Low

If up-counting and down-counting by hardware sources occur at the same time, the GTCNT counter value does not change. When there is a conflict between updating the GTCNT register and reading by the CPU, pre-update data is read.

(2) GTCR.CST bit

When there is a conflict between starting/stopping by hardware sources set in the GTSSR/GTPSR registers and writing by the CPU (writing to GTCR/GTSTR/GTSTP registers), the writing by CPU has priority over the starting/stopping by hardware sources.

In case that stop by the period count function conflicts with start by the CPU writing (GTCR register writing/GTSTR register writing), the period count function is finished with setting the GTST.PCF flag. The CST bit is not changed and the GTCNT continues to count.

When there is a conflict between starting by hardware sources set in the GTSSR register and stopping by hardware sources set in GTPSR register, the GTCR.CST bit value does not change. When there is a conflict between updating the GTCR.CST bit and reading by the CPU (reading from GTCR/GTSTR/GTSTP registers), pre-update data is read.

(3) GTCCRm registers (m = A to F)

When there is a conflict between input capture/buffer transfer operation and writing to the GTCCRm registers, the writing to GTCCRm registers has priority over input capture/buffer transfer operation. When there is a conflict between input capture and writing to the counter register by the CPU or updating the counter register by hardware sources, the pre-update counter value is captured. When there is a conflict between updating the GTCCRm registers and reading by the CPU, pre-update data is read.

(4) GTPR register

When there is a conflict between buffer transfer operation and writing to the GTPR register, writing to GTPR register has priority over buffer transfer operation. When there is a conflict between updating GTPR register and reading by the CPU, pre-update data is read.

21.9.5 每个事件的优先顺序

(1) GTCNT register

表21.40显示了更新GTCNT寄存器的事件的优先顺序。

Table 21.40 更新GTCNT的源的优先顺序

源更新GTCNT	优先顺序
CPU写入（写入GTCNTGTCLR）	High
由GTCSR中设置的硬件源清除	↑
通过GTUPSRGTDNSR中设置的硬件源进行向上或向下计数	↑
计数操作	Low

如果硬件源的递增计数和递减计数同时发生，GTCNT计数器值不会改变。
当更新GTCNT寄存器和CPU读取之间存在冲突时，会读取更新前的数据。

(2) GTCR.CST bit

当GTSSRGTPSR寄存器中设置的硬件源启动停止与CPU写入（写入GTCRGTSTRGTSTP寄存器）发生冲突时，CPU写入优先于硬件源启动停止。

如果周期计数功能停止与CPU写入启动（GTCR寄存器写入GTSTR寄存器写入）发生冲突，则周期计数功能通过设置GTST.PCF标志结束。CST位不变，GTCNT继续计数。

当GTSSR寄存器中设置的硬件源启动和GTPSR寄存器中设置的硬件源停止之间存在冲突时，GTCR.CST位的值不会改变。当更新GTCR.CST位与CPU读取（从GTCRGTSTRGTSTP寄存器读取）之间存在冲突时，将读取更新前数据。

(3) GTCCRm寄存器（m=A到F）

当输入捕捉缓冲区传输操作与写入GTCCRm寄存器之间存在冲突时，写入GTCCRm寄存器优先于输入捕捉缓冲区传输操作。当输入捕获与CPU写入计数器寄存器或硬件源更新计数器寄存器之间存在冲突时，将捕获更新前的计数器值。当更新GTCCRm寄存器和CPU读取之间存在冲突时，会读取更新前的数据。

(4) GTPR register

当缓冲区传输操作与写入GTPR寄存器之间存在冲突时，写入GTPR寄存器优先于缓冲区传输操作。当更新GTPR寄存器与CPU读取发生冲突时，读取更新前的数据。

22. Low Power Asynchronous General Purpose Timer (AGT)

22.1 Overview

The low power Asynchronous General Purpose Timer (AGT) is a 16-bit timer that can be used for pulse output, external pulse width or period measurement, and counting external events. This timer consists of a reload register and a down counter. The reload register and the down counter are allocated to the same address, and can be accessed with the AGT register.

Table 22.1 lists the AGT specifications, Figure 22.1 shows a block diagram, and Table 22.2 lists the I/O pins.

22.2 Register Descriptions

22.2.1 AGT : AGT Counter Register

Base address: AGTn = 0x400E_8000 + 0x0100 × n (n = 0 to 3, 5)

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	n/a	16-bit counter and reload register Setting range : 0x0000 to 0xFFFF	R/W

AGTn.AGT is a 16-bit register. The write value is written to the reload register and the read value is read from the counter.

The states of the reload register and the counter change according to the TSTART bit in the AGTCR register and TCMEA/TCMEB bit in the AGTCMSR register. For details, see section 22.3.1. Reload Register and Counter Rewrite Operation.

When 1 is written to the TSTOP bit in the AGTCR register, AGT counter is forcibly stopped and set to 0xFFFF.

When the TCK[2:0] bits setting in the AGTMR1 register are a value other than 001b (PCLKB/8) or 011b (PCLKB/2), if the AGT register is set to 0x0000, a request signal to the ICU, the DTC, the DMAC, and the ELC is generated once immediately after the count starts. The AGTOn, AGTIOn pin output are toggled.

When the AGT register is set to 0x0000 in event counter mode, regardless of the value of TCK[2:0] bits, a request signal to the ICU, the DTC, the DMAC, and the ELC is generated once immediately after the count starts.

In addition, the AGTOn pin output is toggled even during a period other than the specified count period. When the AGT register is set to 0x0001 or more, a request signal is generated each time AGT underflows.

22.2.2 AGTCMA : AGT Compare Match A Register

Base address: AGTn = 0x400E_8000 + 0x0100 × n (n = 0 to 3, 5)

Offset address: 0x02

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	n/a	16-bit compare match A data is stored.*1 Setting range : 0x0000 to 0xFFFF	R/W

Note 1. Set the AGTCMA register to 0xFFFF when compare match A is not used.

The **AGTCMA** register is a read/write register to set a value for compare match with the AGT counter. The states of the reload register and compare register A change according to the TSTART bit in the AGTCR register. For details, see section 22.3.2. Reload Register and AGT Compare Match A/B Register Rewrite Operation.

22.2 注册说明

22.2.1 AGT:AGT计数器寄存器

Base address: AGTn = 0x400E_8000 + 0x0100 × n (n = 0 to 3, 5)

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
重置后的值:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	n/a	16位计数器和重载寄存器设置范 围：0x0000到0xFFFF	R/W

AGTn.AGT是一个16位寄存器。写入值写入重载寄存器，读取值从计数器中读取。

重载寄存器和计数器的状态根据AGTCR寄存器和TCMEA中的TSTART位改变
AGTCMSR寄存器中的TCMEB位。详见22.3.1节。重载寄存器和计数器重写操作。

当AGTCR寄存器的TSTOP位写入1时，AGT计数器被强制停止并设置为0xFFFF。

当AGTMR1寄存器中的TCK[2:0]位设置为001b(PCLKB8)或011b(PCLKB2)以外的值时，如果
AGT寄存器设置为0x0000，在计数开始后立即生成一次对ICU、DTC、DMAC和ELC的请求信号。AGTO
n、AGTIOn引脚输出被切换。

当AGT寄存器在事件计数器模式下设置为0x0000时，无论TCK[2:0]位的值如何，都会在计数开始后立即生成一次对ICU、DTC、DMAC和ELC的请求信号.

此外，即使在指定计数周期以外的周期内，AGTOn引脚输出也会切换。当AGT寄存器设置为0x0001或更大时，每次AGT下溢时都会产生一个请求信号。

22.2.2 AGTCMA:AGT比较匹配A寄存器

Base address: AGTn = 0x400E_8000 + 0x0100 × n (n = 0 to 3, 5)

注1.不使用比较匹配A时，将AGTCMA寄存器设置为0xFFFF。

AGTCMA寄存器是一个读写寄存器，用于设置与AGT计数器比较匹配的值。重载寄存器和比较寄存器A的状态根据AGTCR寄存器中的TSTART位而改变。详见22.3.2节。重载寄存器和AGT比较匹配AB寄存器重写操作。

22.2.3 AGTCMB : AGT Compare Match B Register

Base address: AGTn = 0x400E_8000 + 0x0100 × n (n = 0 to 3, 5)

Bit field:																
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	n/a	16-bit compare match B data is stored.*1 Setting range : 0x0000 to 0xFFFF	R/W

Note 1. Set the AGTCMB register to 0xFFFF when compare match B is not used.

The AGTCMB register is a read/write register to set a value for compare match with the AGT counter. The states of the reload register and compare register B change according to the TSTART bit in the AGTCR register. For details, see section 22.3.2. Reload Register and AGT Compare Match A/B Register Rewrite Operation.

7	TCMBF	Compare Match B Flag 0: No match 1: Match	R/(W)*3

Note 1. When 1 (count is forcibly stopped) is written to the TSTOP bit, the TSTART bit and TCSTF flag are initialized at the same time. The pulse output level is also initialized. The read value is 0.
Note 2. For information on using the TSTART bit and TCSTF flag, see section 22.4.1. Count Operation Start and Stop Control.
Note 3. Only 0 can be written to clear the flag.

TSTART bit (AGT Count Start)

The count operation is started by writing 1 to the TSTART bit and stopped by writing 0. When the TSTART bit is set to 1 (count starts), the TCSTF flag is set to 1 (count in progress) in synchronization with the count source. Also, after 0 is written to the TSTART bit, the TCSTF flag is set to 0 (count stops) in synchronization with the count source. For details, see section 22.4.1. Count Operation Start and Stop Control.

TCSTF flag (AGT Count Status Flag)

The TCSTF flag indicates the AGT count status.

[Setting condition]

Note 2. When count source is AGTLCLK or AGTSCLK, the switch of CKS[2:0] bits is valid.
Note 3. Do not switch the TCK[2:0] bits in the AGTMR1 register when CKS[2:0] bits are not 000b. Switch the TCK[2:0] bits in the AGTMR1 register after CKS[2:0] bits are set to 000b, and wait for 1 cycle of the count source.

CKS[2:0] bit (AGTLCLK or AGTSCLK Count Source Clock Frequency Division Ratio)

CKS[2:0] bits select the Count Source Clock Frequency Division Ratio for AGTLCLK or AGTSCLK.

LPM bit (Low Power Mode)

The LPM bit sets the low power operation, which impacts access to certain AGT registers. Set this bit to 1 to operate in low power.

When this bit is 1, access to the following registers is prohibited:

- AGT/AGTCMA/AGTCMB/AGTCR.

After this bit is switched from 1 to 0, the first access to the register is constrained as follows:

- When reading from the AGT register, read AGT register twice. Only the second reading of data is valid.
- When writing to the AGT, AGTCMA, AGTCMB, and AGTCR register, allow at least 2 cycles of the count source clock when writing to the register.
- When confirm the value written to the AGT, AGTCMA, AGTCMB, and AGTCR registers.
  - When the count operation is stopped; after writing data, it can be read in the next cycle.
  - When the count operation is operating; after writing data, it can be written 4 cycles after the count source clock.

注1.在计数操作期间不要重写CKS[2:0]位。仅当AGTCR寄存器中的TSTART位和TCSTF标志都设置为0（计数停止）时才重写CKS[2:0]位。

注2.当计数源为AGTLCLK或AGTSCLK时，CKS[2:0]位的切换有效。
注3.当CKS[2:0]位不是000b时，不要切换AGTMR1寄存器中的TCK[2:0]位。在CKS[2:0]位设置为000b后，切换AGTMR1寄存器中的TCK[2:0]位，并等待计数源的1个周期。

CKS[2:0]位（AGTLCLK或AGTSCLK计数源时钟分频比）

CKS[2:0]位选择AGTLCLK或AGTSCLK的计数源时钟分频比。

LPM位（低功耗模式）

LPM位设置低功耗操作，这会影响对某些AGT寄存器的访问。将此位设置为1以在低功耗下运行。

该位为1时，禁止访问以下寄存器：

- AGT/AGTCMA/AGTCMB/AGTCR.

该位由1变为0后，对寄存器的第一次访问受到如下约束：

●读取AGT寄存器时，读取AGT寄存器两次。只有第二次读取数据是有效的。

●写入AGT、AGTCMA、AGTCMB和AGTCR寄存器时，写入寄存器时至少允许计数源时钟的2个周期。

●确认写入AGT、AGTCMA、AGTCMB、AGTCR寄存器的值时。
当计数操作停止时；写入数据后，可以在下一个周期读取。
当计数操作正在运行时；写入数据后，可在计数源时钟后4个周期写入。

22.3 Operation

22.3.1 Reload Register and Counter Rewrite Operation

Regardless of the operating mode, the timing of the rewrite operation to the reload register and the counter differs depending on the value of the TSTART bit in the AGTCR register and of the TCMEA or TCMEB bit in the AGTCMSR register. When the TSTART bit is 0 (count stops), the count value is directly written to the reload register and the counter. When the TSTART bit is 1 (count starts) and the TCMEA bit and TCMEB bit are 0 (AGT compare match A/B register are invalid), the value is written to the reload register in synchronization with the count source, and then to the counter in synchronization with the next count source. When the TSTART bit is 1 (count starts) and the TCMEA bit or the TCMEB bit is 1 (AGT compare match A register or compare match B register is valid), the value is written to the reload register in synchronization with the underflow of the counter.

Figure 22.3 and Figure 22.4 show the timing of rewrite operation with TSTART bit value and TCMEA/TCMEB bit value.

22.3 Operation

22.3.1 重载寄存器和计数器重写操作

无论何种操作模式，对重载寄存器和计数器的重写操作的时序根据AGTCR寄存器中的TSTART位和AGTCMSR寄存器中的TCMEA或TCMEB位的值而有所不同。当TSTART位为0（计数停止）时，计数值直接写入重载寄存器和计数器。当TSTART位为1（计数开始）且TCMEA位和TCMEB位为0（AGT比较匹配AB寄存器无效）时，该值与计数源同步写入重载寄存器，然后写入计数器与下一个计数源同步。当TSTART位为1（计数开始）且TCMEA位或TCMEB位为1（AGT比较匹配A寄存器或比较匹配B寄存器有效）时，值与计数源同步写入重载寄存器，然后与计数器的下溢同步到计数器。

图22.3和图22.4显示了使用TSTART位值和TCMEATCMEB位值进行重写操作的时序。

22.3.2 Reload Register and AGT Compare Match A/B Register Rewrite Operation

Regardless of the operating mode, the timing of the rewrite operation to the reload register and AGT compare register A/B depends on the value of the TSTART bit in the AGTCR register. When the TSTART bit is 0 (count stops), the count value is directly written to the reload register and AGT compare register A/B. When the TSTART bit is 1 (count starts), the value is written to the reload register in synchronization with the count source, and then to the compare register in synchronization with the underflow of the counter.

Figure 22.5 shows the timing of rewrite operation with TSTART bit value for compare register A. AGT Compare register B is of the same timing as AGT compare register A.

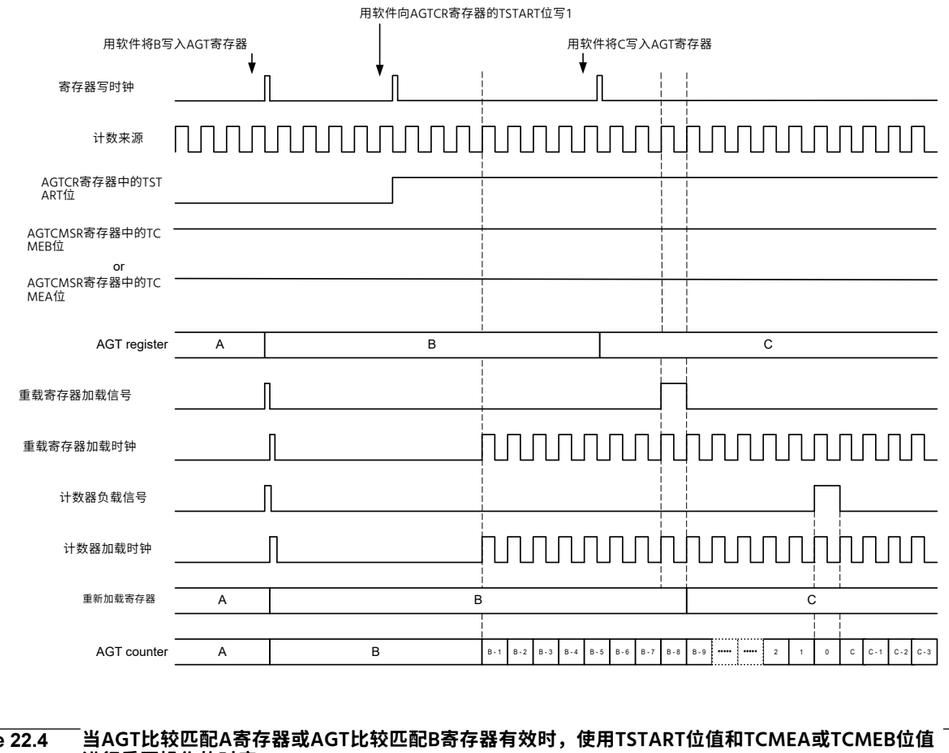

Figure 22.4 当AGT比较匹配A寄存器或AGT比较匹配B寄存器有效时，使用TSTART位值和TCMEA或TCMEB位值进行重写操作的时序

22.3.2 重载寄存器和AGT比较匹配AB寄存器重写操作

不管操作模式如何，对重载寄存器和AGT比较寄存器AB的重写操作的时序取决于AGTCR寄存器中TSTART位的值。当TSTART位为0（计数停止）时，计数值直接写入重载寄存器和AGT比较寄存器AB。当TSTART位为1（计数开始）时，该值同步写入重载寄存器计数源，然后与计数器的下溢同步到比较寄存器。

图22.5显示了比较寄存器A的TSTART位值的重写操作时序。AGT比较寄存器B与AGT比较寄存器A的时序相同。

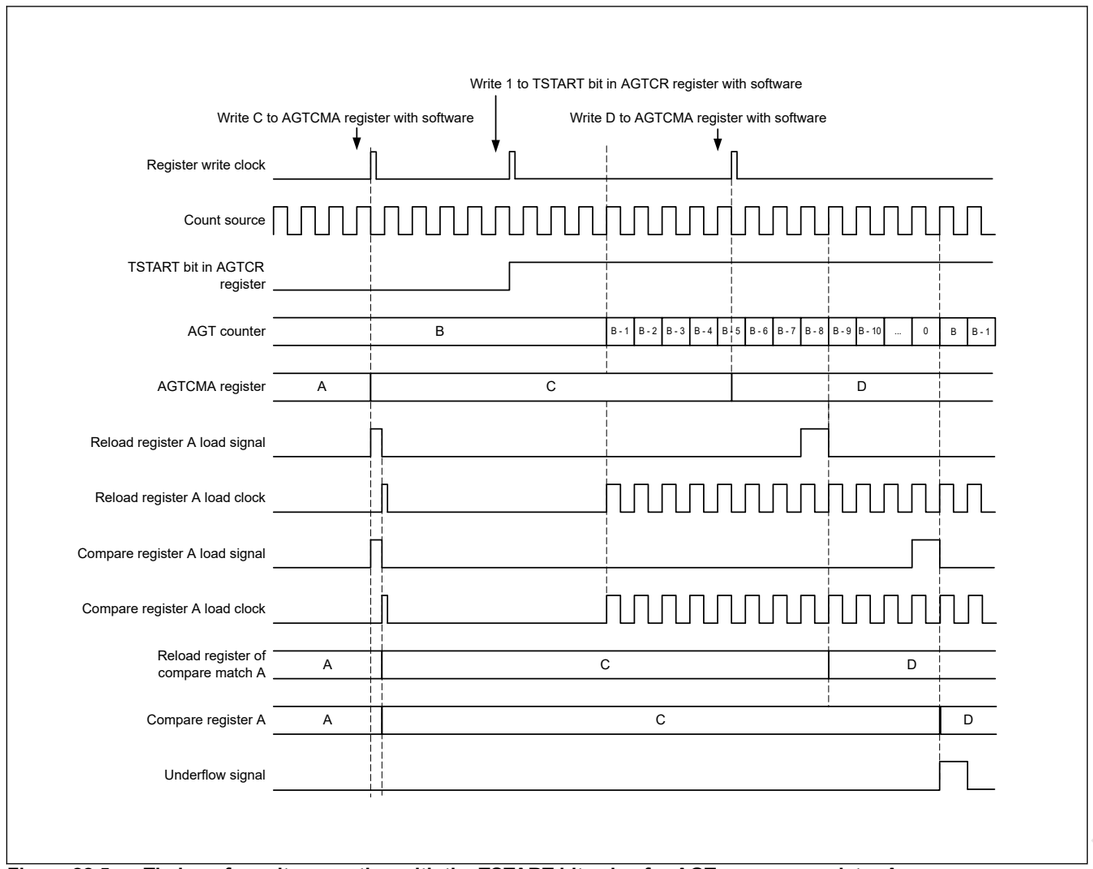

Figure 22.5 Timing of rewrite operation with the TSTART bit value for AGT compare register A

22.3.3 Timer Mode

In this mode, the AGT counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register. In timer mode, the count value is decremented by 1 on each rising edge of the count source. When the count value reaches 0x0000 and the next count source is input, an underflow occurs and an interrupt request is generated.

Figure 22.6 shows the operation example in timer mode.

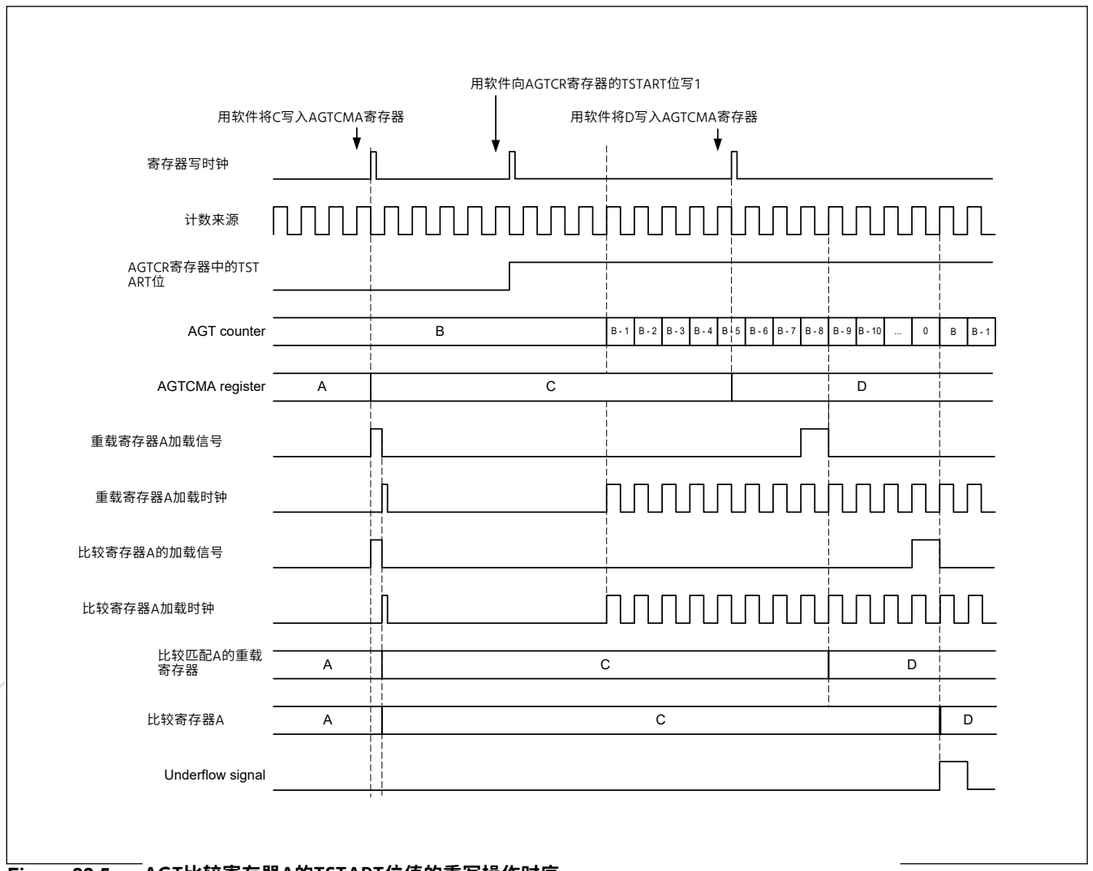

Figure 22.5 AGT比较寄存器A的TSTART位值的重写操作时序

22.3.3 定时器模式

在此模式下，AGT计数器按AGTMR1寄存器中的TCK[2:0]位选择的计数源递减。
在定时器模式下，计数值在计数源的每个上升沿减1。当计数值达到0x0000并输入下一个计数源时，发生下溢并产生中断请求。

图22.6显示了定时器模式下的操作示例。

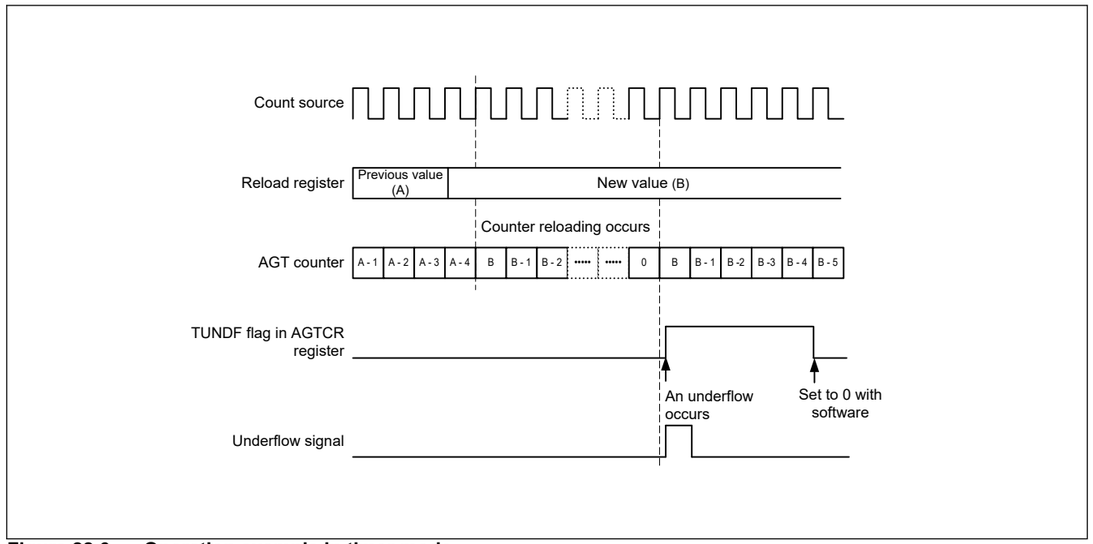

Figure 22.6 Operation example in timer mode

22.3.4 Pulse Output Mode

In pulse output mode, the counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register, and the output level of the AGTIOn and AGTOn pins inverted each time an underflow occurs.

In pulse output mode, the count value is decremented by 1 on each rising edge of the count source. When the count value reaches 0x0000 and the next count source is input, an underflow occurs and an interrupt request is generated. In addition, a pulse can be output from the AGTIOn and AGTOn pins. The output level is inverted each time an underflow occurs. The pulse output from the AGTOn pin can be stopped with the TOE bit in the AGTIOC register. The output level can be selected with the TEDGSEL bit in the AGTIOC register.

Figure 22.7 shows the operation example in pulse output mode.

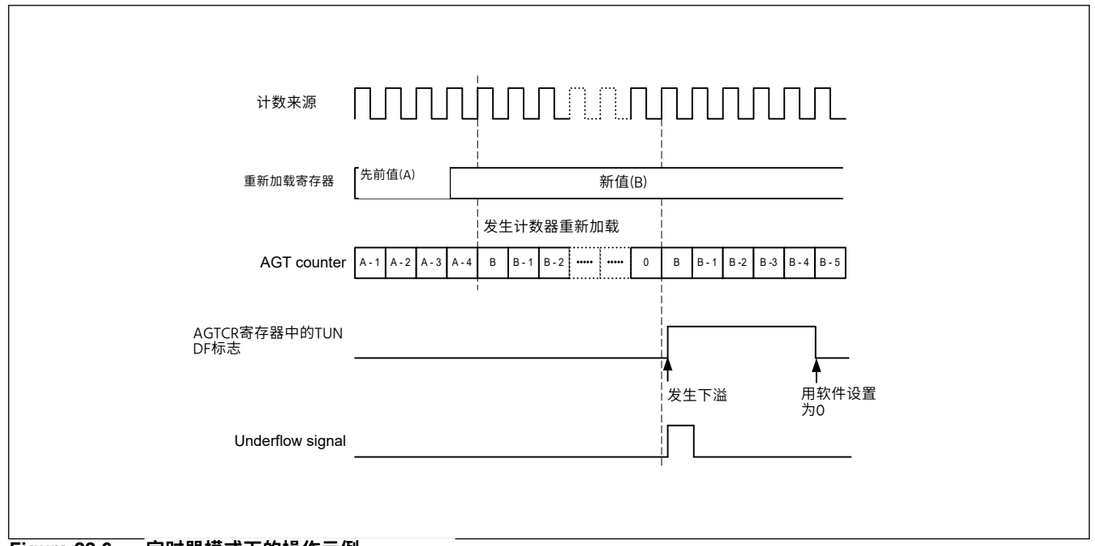

Figure 22.6 定时器模式下的操作示例

22.3.4 脉冲输出方式

在脉冲输出模式下，计数器由AGTMR1寄存器中的TCK[2:0]位选择的计数源递减，并且每次发生下溢时反转AGTIOn和AGTOn引脚的输出电平。

在脉冲输出模式下，计数值在计数源的每个上升沿减1。当计数值达到0x0000并输入下一个计数源时，发生下溢并产生中断请求。此外，可以从AGTIOn和AGTOn引脚输出脉冲。每次发生下溢时，输出电平都会反转。AGTOn引脚的脉冲输出可通过AGTIOC寄存器中的TOE位停止。可以通过AGTIOC寄存器中的TEDGSEL位选择输出电平。

图22.7显示了脉冲输出模式下的操作示例。

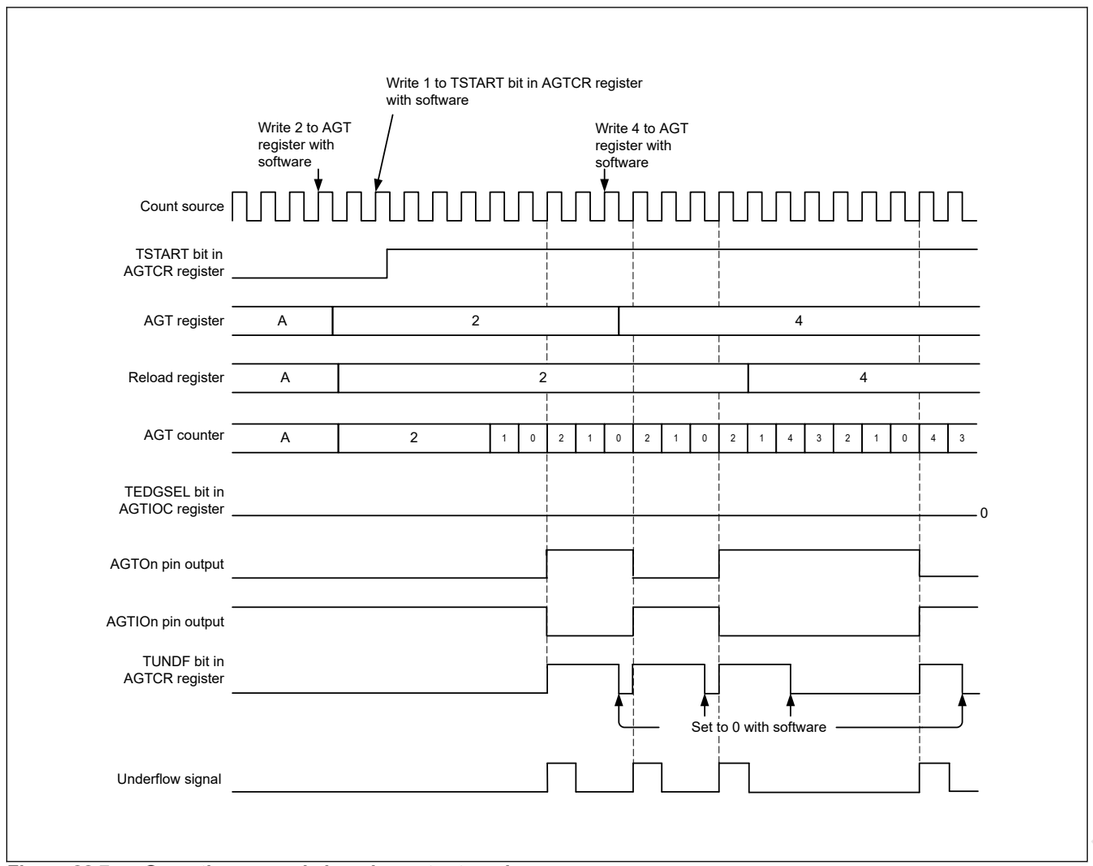

Figure 22.7 Operation example in pulse output mode

22.3.5 Event Counter Mode

In event counter mode, the counter is decremented by an external event signal (count source) input to the AGTIOn pin. Various periods for counting events can be set with the TIOGT[1:0] bits in the AGTIOC register and AGTISR registers. In addition, the filter function for the AGTIOn pin input can be specified with bits TIPF[1:0] in the AGTIOC register. The output from the AGTOn pin can be toggled even in event counter mode.

Figure 22.8 shows the operation example in event counter mode.

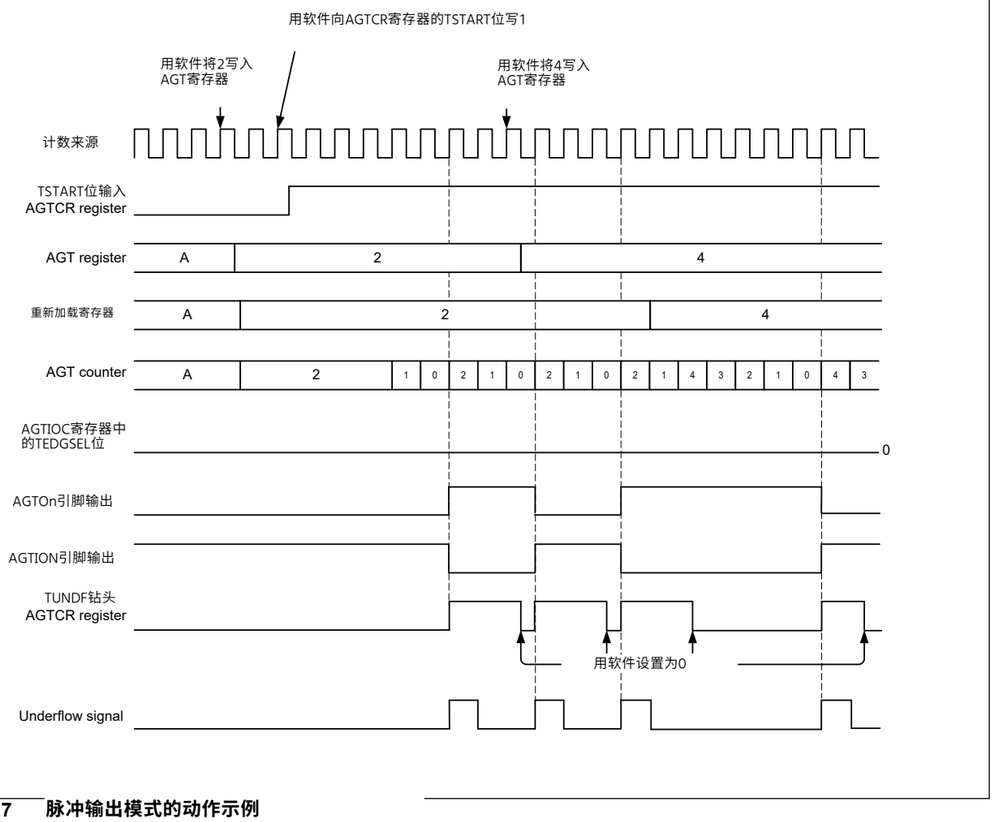

Figure 22.7 脉冲输出模式的动作示例

22.3.5 事件计数器模式

在事件计数器模式下，计数器由输入到AGTIOn引脚的外部事件信号（计数源）递减。可以使用AGTIOC寄存器和AGTISR寄存器中的TIOGT[1:0]位设置计数事件的各种周期。此外，可以通过AGTIOC寄存器中的位TIPF[1:0]指定AGTIOn引脚输入的过滤功能。即使在事件计数器模式下，也可以切换AGTOn引脚的输出。

图22.8显示了事件计数器模式下的操作示例。

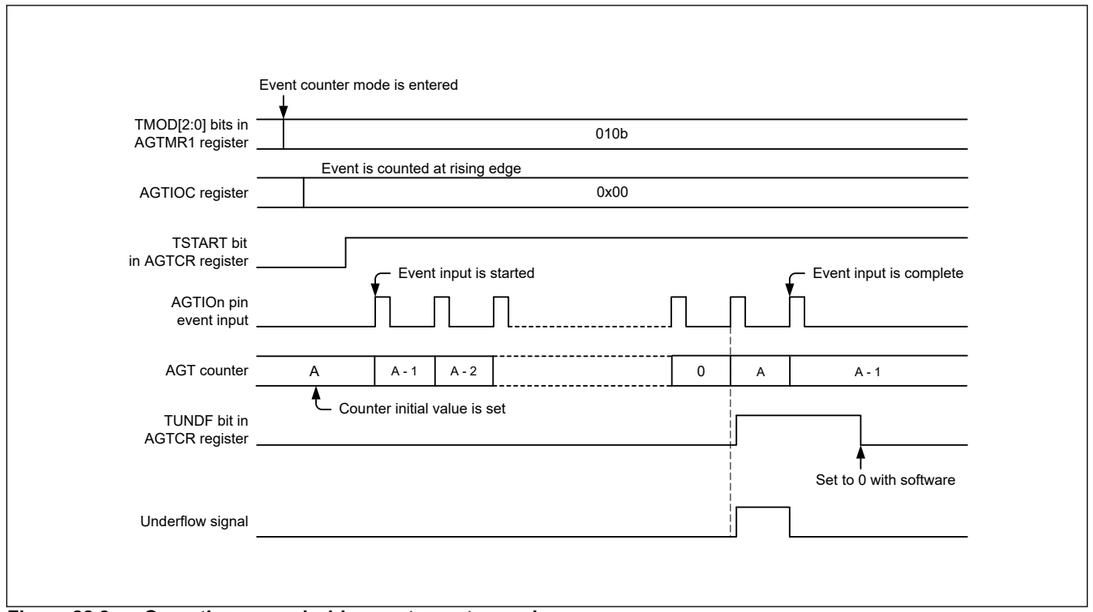

Figure 22.8 Operation example 1 in event counter mode

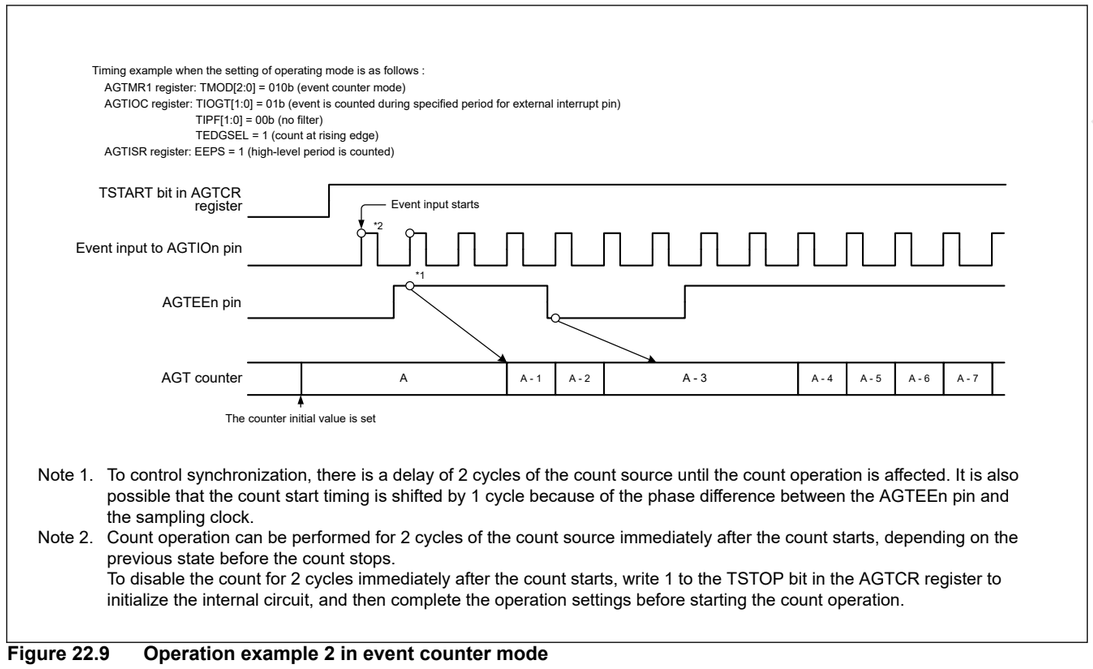
Figure 22.9 shows an operation example for counting during the specified period in event counter mode (TIOGT[1:0] bits in the AGTIOC register are set to 01b).



Note 1. To control synchronization, there is a delay of 2 cycles of the count source until the count operation is affected. It is also possible that the count start timing is shifted by 1 cycle because of the phase difference between the AGTEEn pin and the sampling clock.

Note 2. Count operation can be performed for 2 cycles of the count source immediately after the count starts, depending on the previous state before the count stops.
To disable the count for 2 cycles immediately after the count starts, write 1 to the TSTOP bit in the AGTCR register to initialize the internal circuit, and then complete the operation settings before starting the count operation.

Figure 22.9 Operation example 2 in event counter mode

22.3.6 Pulse Width Measurement Mode

In pulse width measurement mode, the pulse width of an external signal input to the AGTIOn pin is measured. When the level specified by the TEDGSEL bit in the AGTIOC register is input to the AGTIOn pin, the counter is decremented by the

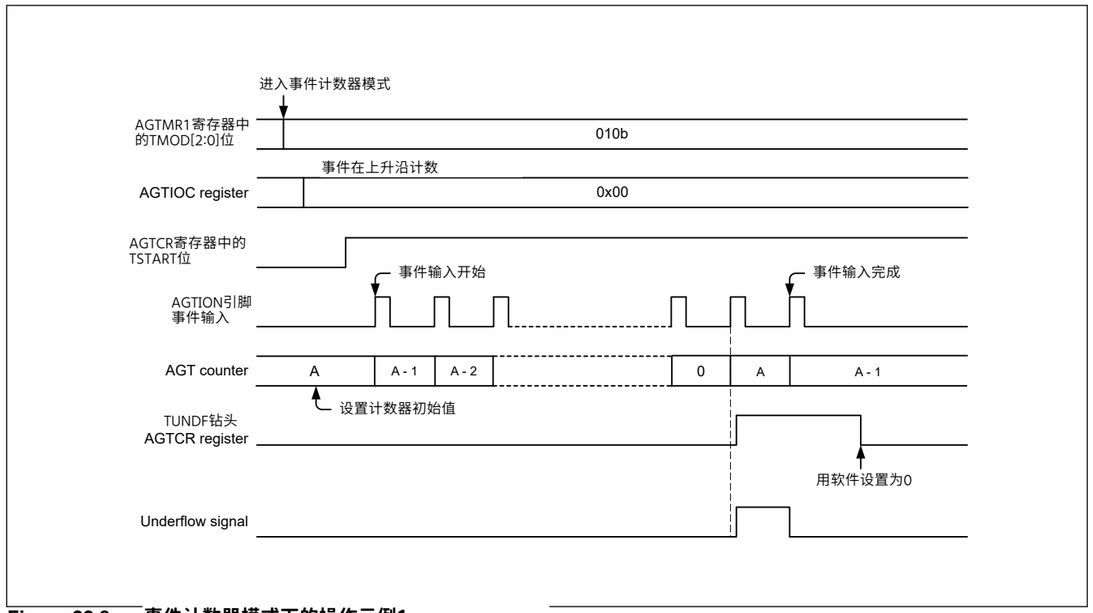


Figure 22.8 事件计数器模式下的操作示例1

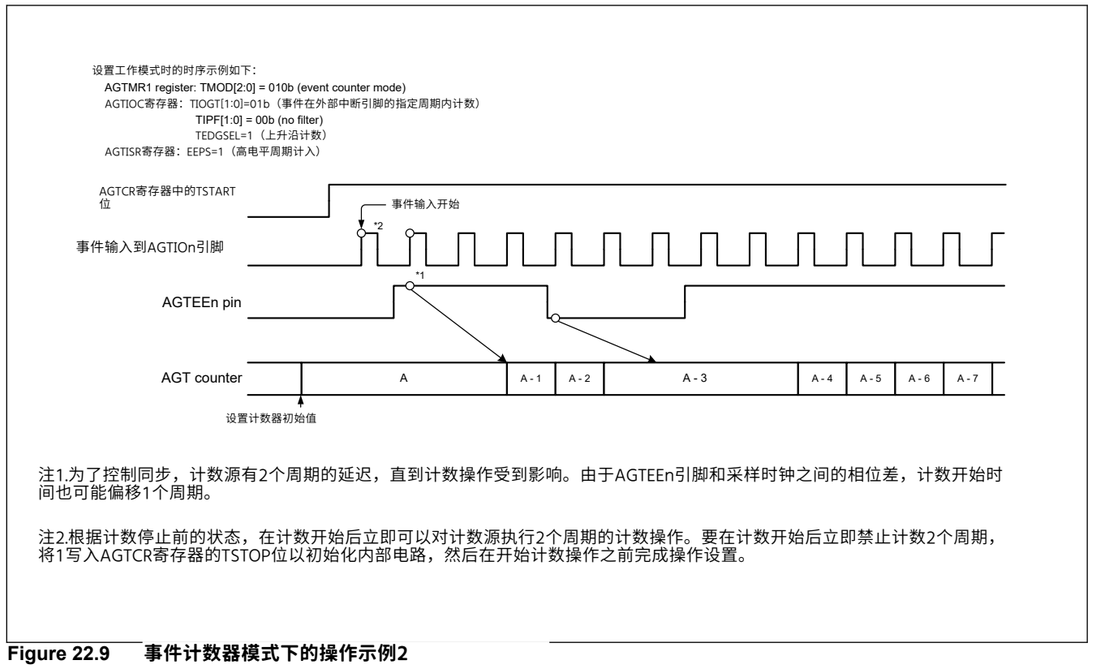
图22.9显示了在事件计数器模式下在指定周期内进行计数的操作示例（AGTIOC寄存器中的TIOGT[1:0]位设置为01b）。



注1.为了控制同步，计数源有2个周期的延迟，直到计数操作受到影响。由于AGTEEn引脚和采样时钟之间的相位差，计数开始时间也可能偏移1个周期。

注2.根据计数停止前的状态，在计数开始后立即可以对计数源执行2个周期的计数操作。要在计数开始后立即禁止计数2个周期，将1写入AGTCR寄存器的TSTOP位以初始化内部电路，然后在开始计数操作之前完成操作设置。

22.3.6 脉冲宽度测量模式

在脉冲宽度测量模式下，测量输入到AGTIOn引脚的外部信号的脉冲宽度。当AGTIOC寄存器中的TEDGSEL位指定的电平输入到AGTIOn引脚时，计数器递减

count source selected with the TCK[2:0] bits in the AGTMR1 register. When the specified level on the AGTIOn pin ends, the counter is stopped, the TEDGF bit in the AGTCR register is set to 1 (active edge received), and an interrupt request is generated. The measurement of pulse width data is performed by reading the count value while the counter is stopped. Also, when the counter underflows during measurement, the TUNDF bit in the AGTCR register is set to 1 and an interrupt request is generated.

Figure 22.10 shows the operation example in pulse width measurement mode.

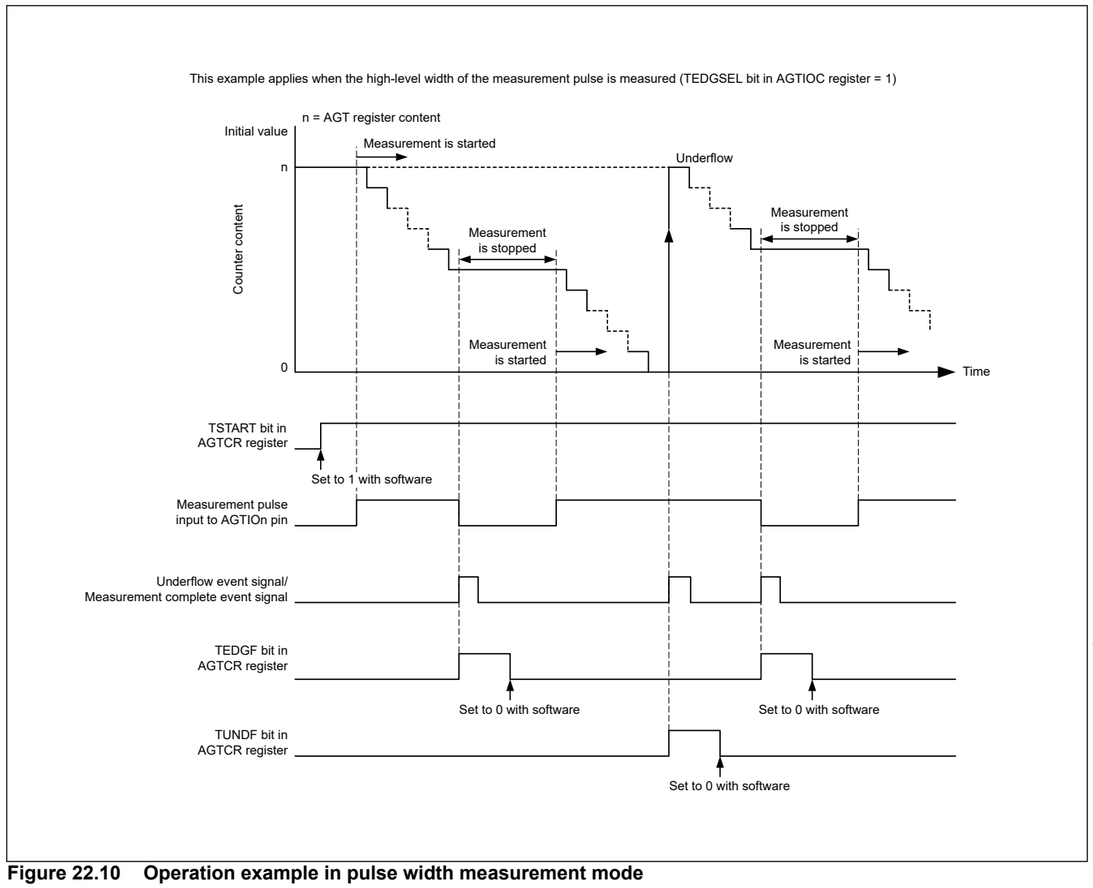

Figure 22.10 Operation example in pulse width measurement mode

22.3.7 Pulse Period Measurement Mode

In pulse period measurement mode, the pulse period of an external signal input to the AGTIOn pin is measured. The counter is decremented by the count source selected with TCK[2:0] bits in the AGTMR1 register. When a pulse with the period specified by the TEDGSEL bit in the AGTIOC register is input to the AGTIOn pin, the count value is transferred to the read-out buffer on the rising edge of the count source. The value in the reload register is loaded to the counter at the next rising edge. Simultaneously, the TEDGF flag in the AGTCR register is set to 1 (active edge received) and an interrupt request is generated. The read-out buffer (AGT register) is read at this time and the difference from the reload value (see section 22.4.6. How to Calculate Event Number, Pulse Width, and Pulse Period) is the period data of the input pulse. The period data is retained until the read-out buffer is read. When the counter underflows, the TUNDF flag in the AGTCR register is set to 1 (underflow) and an interrupt request is generated.

Figure 22.11 shows the operation example in pulse period measurement mode.

Only input pulses with a period longer than twice the period of the count source are measured. Also, the low-level and high-level widths must both be longer than the period of the count source. If a pulse period shorter than these conditions is input, the input might be ignored.

通过AGTMR1寄存器中的TCK[2:0]位选择计数源。当AGTIOn引脚上的指定电平结束时，计数器停止，AGTCR寄存器中的TEDGF位设置为1（接收到有效沿），并产生中断请求。通过在计数器停止时读取计数值来执行脉冲宽度数据的测量。此外，当测量期间计数器下溢时，AGTCR寄存器中的TUNDF位设置为1，并产生中断请求。

图22.10显示了脉宽测量模式下的操作示例。

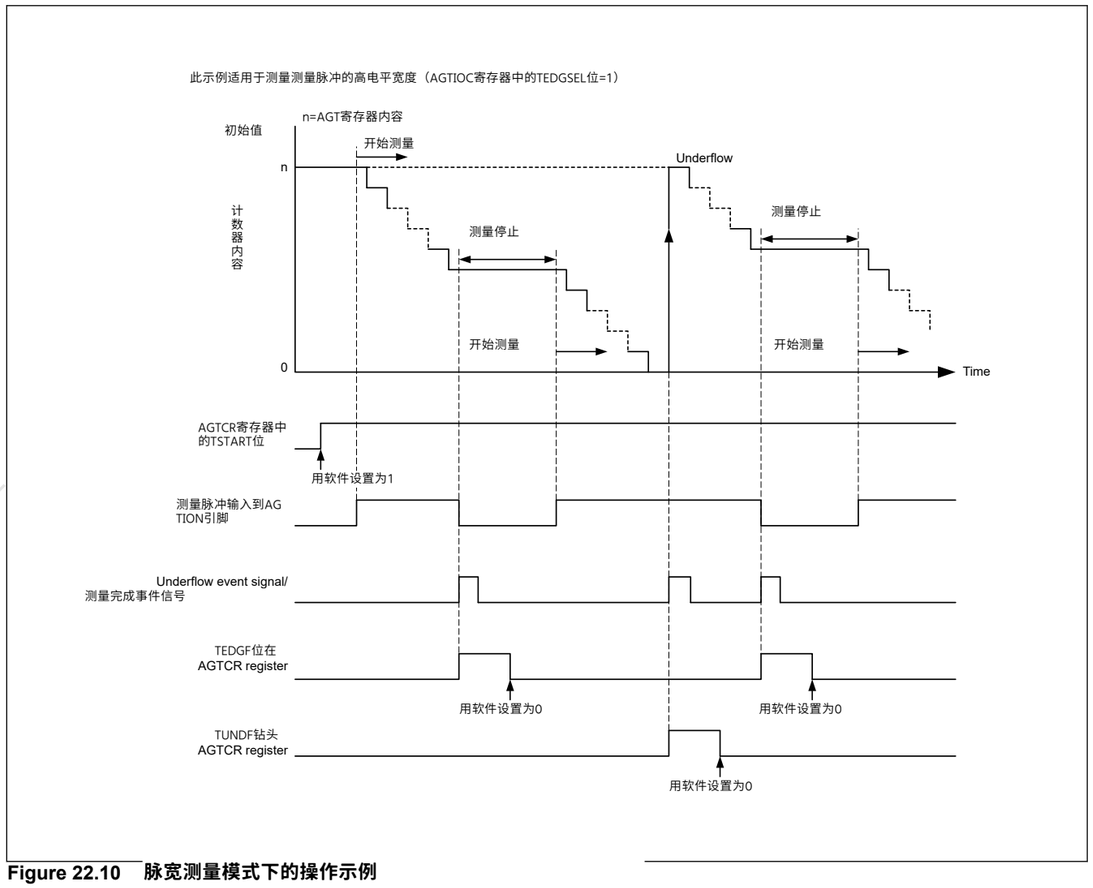

Figure 22.10 脉宽测量模式下的操作示例

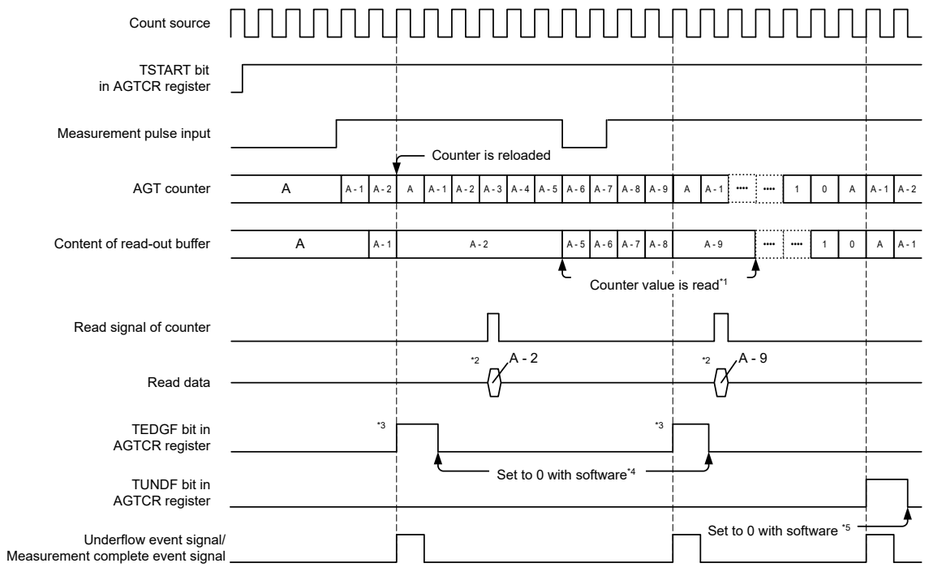
22.3.7 脉冲周期测量模式

在脉冲周期测量模式下，测量输入到AGTIOn引脚的外部信号的脉冲周期。计数器由AGTMR1寄存器中的TCK[2:0]位选择的计数源递减。当AGTIOC寄存器中的TEDGSEL位指定周期的脉冲输入到AGTIOn引脚时，计数值在计数源的上升沿传送到读出缓冲器。重载寄存器中的值在下一个上升沿加载到计数器。同时，AGTCR寄存器中的TEDGF标志设置为1（接收到有效沿）并产生中断请求。此时读取读出缓冲区（AGT寄存器），与重载值的差值（见22.4.6. 如何计算事件数、脉冲宽度和脉冲周期）是输入脉冲的周期数据。周期数据被保留，直到读出缓冲器被读取。当计数器下溢时，AGTCR寄存器中的TUNDF标志设置为1（下溢）并产生中断请求。

图22.11显示了脉冲周期测量模式下的操作示例。

仅测量周期长于计数源周期两倍的输入脉冲。此外，低电平和高电平宽度都必须长于计数源的周期。如果输入比这些条件短的脉冲周期，输入可能会被忽略。



This example applies when the initial value of the AGT register is set to A, the TEDGSEL bit in the AGTIOC register is set to 0, and the period from one rising edge to the next edge of the measurement pulse is measured.

Note 1. Reading from the AGT register must be performed during the period from when the TEDGF flag is set to 1 (active edge received) until the next active edge is input. The content of the read-out buffer is retained until the AGT register is read. If it is not read before the active edge is input, the measurement result of the previous period is retained.
Note 2. When the AGT register is read in pulse period measurement mode, the content of the read-out buffer is read.
Note 3. When the active edge of the measurement pulse is input and then the set edge of an external pulse is input, the TEDGF flag in the AGTCR register is set to 1 (active edge received).
Note 4. To set to 0 with software, write 0 to the TEDGF flag in the AGTCR register with an 8-bit memory manipulation instruction.
Note 5. To set to 0 with software, write 0 to the TUNDF flag in the AGTCR register with an 8-bit memory manipulation instruction.

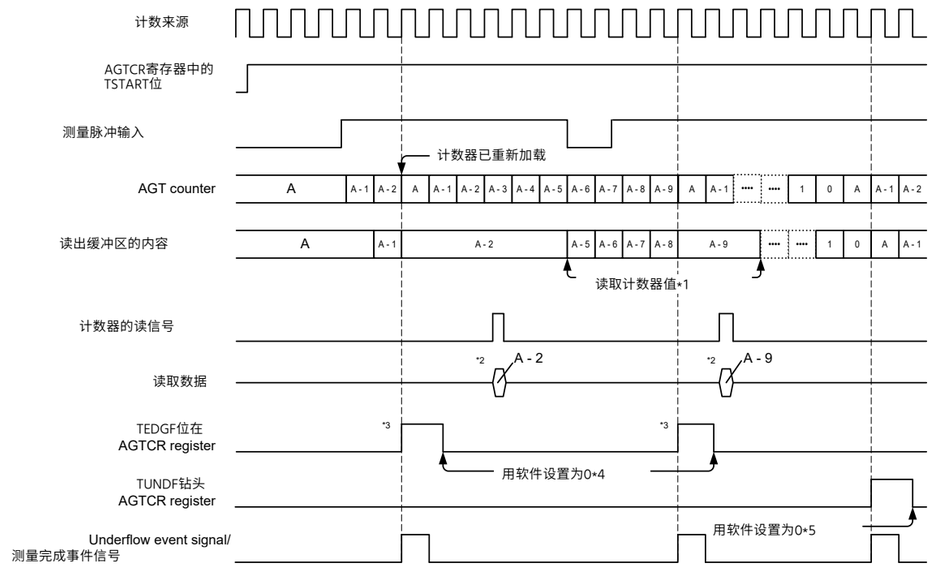
Figure 22.11 Operation example in pulse period measurement mode

22.3.8 Compare Match function

The compare match function detects matches (compare match) between the content of the AGTCMA or AGTCMB register and the content of the AGT register. This function is enabled when the TCMEA or TCMEB bit in the AGTCMSR register is 1 (compare match A register or compare match B register is valid). The counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register, and when the values of AGT and AGTCMA or AGTCMB match, the TCMAF/TCMBF flag in the AGTCR register is set to 1 (match), and an interrupt request is generated.

When the compare match function is enabled, the timing of the rewrite operation to the reload register and the counter differs. See section 22.3.1. Reload Register and Counter Rewrite Operation for details. In addition, the output level of the AGTOAn, AGTOBn pins is inverted by the match and by the underflow. The output level can be selected with the TOPOLA or TOPOLB bit in the AGTCMSR register.

Figure 22.12 shows the operation example in compare match mode.



此示例适用于将AGT寄存器的初始值设置为A，将AGTIOC寄存器中的TEDGSEL位设置为0，并测量从一个上升沿到下一个测量脉冲沿的周期的情况。

注1.从TEDGF标志设置为1（接收到有效边沿）到输入下一个有效边沿期间，必须执行从AGT寄存器的读取。读出缓冲器的内容一直保留到AGT寄存器被读取。如果在输入有效边沿之前未读取，则保留前一周期的测量结果。

注2.在脉冲周期测量模式下读取AGT寄存器时，会读取读出缓冲区的内容。
注3.当输入测量脉冲的有效边沿，然后输入外部脉冲的设置边沿时，AGTCR寄存器中的TEDGF标志设置为1（接收到有效边沿）。

注4.要使用软件设置为0，请使用8位存储器操作指令将0写入AGTCR寄存器中的TEDGF标志。注5.要通过软件设置为0，请使用8位存储器操作指令将0写入AGTCR寄存器中的TUNDF标志。

Figure 22.11 脉冲周期测量模式下的操作示例

22.3.8 比较匹配功能

比较匹配功能检测AGTCMA或AGTCMB寄存器的内容与AGT寄存器的内容之间的匹配（比较匹配）。该功能在AGTCMSR寄存器中的TCMEA或TCMEB位为1时使能（比较匹配A寄存器或比较匹配B寄存器有效）。计数器按AGTMR1寄存器中TCK[2:0]位选择的计数源递减，当AGT和AGTCMA或AGTCMB的值匹配时，AGTCR寄存器中的TCMAFTCMBF标志设置为1（匹配），并产生中断请求。

当比较匹配功能启用时，对重载寄存器和计数器的重写操作的时序不同。请参阅第22.3.1节。重载寄存器和计数器重写操作了解详情。此外，AGTOAn、AGTOBn引脚的输出电平通过匹配和下溢反转。输出电平可以选择与

AGTCMSR寄存器中的TOPOLA或TOPOLB位。

22.3.12 Event Signal Output to ELC

The AGT uses the Event Link Controller (ELC) to perform a link operation to a specified module using the interrupt request signal as the event signal. The AGT outputs compare match A, compare match B, and underflow/measurement complete signals as event signals. For details, see section 18, Event Link Controller (ELC).

22.4 Usage Notes

22.4.1 Count Operation Start and Stop Control

- When the operating mode (see Table 22.1) is set to other than the event counter mode, or the count source is set to other than AGTn underflow event signal (TCK[2:0] = 101b):
  - After 1 (count starts) is written to the TSTART bit in the AGTCR register while the count is stopped, the TCSTF flag in the AGTCR register remains 0 (count stops) for 3 cycles of the count source. Do not access the registers associated with AGT other than the TCSTF flag until this bit is set to 1 (count in progress).
  - After 0 (count stops) is written to the TSTART bit during a count operation, the TCSTF flag remains 1 for 3 cycles of the count source. When the TCSTF flag is set to 0, the count is stopped. Do not access the registers associated with AGT. Other than the TCSTF flag until this bit is set to 0.
- When the operating mode (see Table 22.1) is set to event counter mode, or the count source is set to AGT1 underflow event signal (TCK[2:0] = 101b):
  - After 1 (count starts) is written to the TSTART bit in the AGTCR register while the count is stopped, the TCSTF flag in the AGTCR register remains 0 (count stops) for 2 PCLKB cycles. Do not access the registers associated with AGT other than the TCSTF flag until this bit is set to 1 (count in progress).
  - After 0 (count stops) is written to the TSTART bit during a count operation, the TCSTF flag remains 1 for 2 PCLKB cycles. When the TCSTF flag is set to 0, the count is stopped. Do not access the registers associated with AGT other than the TCSTF flag until this bit is set to 0.

22.4.2 Access to Counter Register

When the TSTART bit and TCSTF flag in the AGTCR register are both 1 (count starts), allow at least 3 cycles of the count source clock between writes when writing to the AGT register successively.

22.4.3 When Changing Mode

The registers associated with AGT operating mode (AGTMR1, AGTMR2, AGTIOC, AGTISR, AGTCMSR and AGTIOC) can be changed only when the count is stopped with both the TSTART bit and TCSTF flag set to 0 (count stops). Do not change these registers during count operation.

When the registers associated with AGT operating mode are changed, the values of TEDGF, TUNDF, TCMAF, and TCMBF flags are undefined. Before starting the count, write 0 to the following flags:

- TEDGF (no active edge received)
- TUNDF (no underflow)
- TCMAF (no match)
- TCMBF (no match).

22.4.4 Output pin setting

When using the AGTOn, AGTIOn, AGTOAn, or AGTOBn as an output pin, set up the Operation and determine the initial output values. Then set an output mode in the port register.

When using the AGTIOn as an input pin in pulse width measurement mode or pulse period measurement mode, set up the Operation and start count operation. Then start to enter external events from the AGTIOn pin. Invalidate the first measurement and validate the second and later completed measurements.

22.4.5 Digital Filter

When using the digital filter, do not start the timer operation for 5 cycles of the digital filter clock after setting TIPF[1:0] bits and when the TEDGSEL bit in the AGTIOC register changes.

22.4.6 How to Calculate Event Number, Pulse Width, and Pulse Period

- In event counter mode, event number is expressed mathematically as follows:
  Event number = initial value of counter [AGT register] - counter value of active event end

22.4 使用说明

22.4.1 计数操作启动和停止控制

●当操作模式（见表22.1）设置为非事件计数器模式，或计数源设置为非AGTn下溢事件信号（TCK[2:0]=101b）时：

在计数停止期间将1（计数开始）写入AGTCR寄存器中的TSTART位后，AGTCR寄存器中的TCSTF标志在计数源的3个周期内保持为0（计数停止）。在此位设置为1（正在进行计数）之前，不要访问与AGT相关的寄存器，而不是TCSTF标志。

在计数操作期间将0（计数停止）写入TSTART位后，TCSTF标志在计数源的3个周期内保持为1。当TCSTF标志设置为0时，停止计数。不要访问与AGT关联的寄存器。除TCSTF标志外，直到该位设置为0。

●当工作模式（见表22.1）设置为事件计数器模式，或计数源设置为AGT1下溢事件信号（TCK[2:0]=101b）时：

在停止计数时将1（计数开始）写入AGTCR寄存器中的TSTART位后，AGTCR寄存器中的TCSTF标志在2个PCLKB周期内保持为0（计数停止）。在此位设置为1（正在进行计数）之前，不要访问与AGT相关的寄存器，而不是TCSTF标志。

在计数操作期间将0（计数停止）写入TSTART位后，TCSTF标志保持1持续2
PCLKB周期。当TCSTF标志设置为0时，停止计数。不要访问与相关的寄存器
AGT不是TCSTF标志，直到该位设置为0。

22.4.2 访问计数器寄存器

当AGTCR寄存器中的TSTART位和TCSTF标志都为1（计数开始）时，连续写入AGT寄存器时，在两次写入之间至少允许计数源时钟的3个周期。

22.4.3 更改模式时

与AGT操作模式相关的寄存器（AGTMR1、AGTMR2、AGTIOC、AGTISR、AGTCMSR和AGTIOC）只有在TSTART位和TCSTF标志都设置为0（计数停止）时停止计数时才能更改。在计数操作期间不要更改这些寄存器。

当与AGT工作模式相关的寄存器发生变化时，TEDGF、TUNDF、TCMAF和
TCMBF标志未定义。在开始计数之前，将0写入以下标志：

●TEDGF（未收到有效边沿）

- TUNDF (no underflow)
- TCMAF (no match)
- TCMBF (no match).

22.4.4 输出引脚设置

当使用AGTOn、AGTIOn、AGTOAn或AGTOBn作为输出引脚时，设置操作并确定初始输出值。然后在端口寄存器中设置一个输出模式。

在脉冲宽度测量模式或脉冲周期测量模式下使用AGTIOn作为输入引脚时，设置
操作并开始计数操作。然后开始从AGTIOn引脚输入外部事件。使第一次测量无效并验证第二次和以后
完成的测量。

22.4.5 数字滤波器

使用数字滤波器时，在设置TIPF[1:0]位后以及AGTIOC寄存器中的TEDGSEL位发生变化时，在数字滤波器时钟的5个周期内不要启动定时器操作。

22.4.6 如何计算事件编号、脉冲宽度和脉冲周期

●在事件计数器模式下，事件编号以数学方式表示如下：
事件编号=计数器的初始值[AGT寄存器]活动事件结束的计数器值

- In pulse width measurement mode, pulse width is expressed mathematically as follows:
  Pulse width = counter value of stopping measurement - counter value of next stopping measurement
- In pulse period measurement mode, input pulse period is expressed mathematically as follows:
  Period of input pulse = (initial value of counter [AGT register] - reading value of the read-out buffer) + 1.

22.4.7 When Count is Forcibly Stopped by TSTOP Bit

After the counter is forcibly stopped by the TSTOP bit in the AGTCR register, do not access the following I/O registers for 1 cycle of the count source:

- AGT
- AGTCMA
- AGTCMB
- AGTCR
- AGTMR1
- AGTMR2.

22.4.8 When Selecting AGTn (n = 0, 2) Underflow as the Count Source

Operate according to the following procedures described in this section when selecting the underflow event signal as the count source.

(1) Procedure for starting operation

1. Set AGT.
2. Start the count operation of AGTn (n = 1, 3, 5).
3. Start the count operation of AGTn (n = 0, 2).

(2) Procedure for stopping operation

1. Stop the count operation of AGTn (n = 0, 2).
2. Stop the count operation of AGTn (n = 1, 3, 5).
3. Stop the count source clock of AGTn (n = 1, 3, 5) (write 000b in the AGTMR1.TCK[2:0] bits).

22.4.9 Module-stop function

AGT operation can be disabled or enabled using Module Stop Control Register D (MSTPCRD) and Module Stop Control Register E (MSTPCRE). The AGT module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes

22.4.10 When Switching Source Clock

When switching a clock source by changing SCKSCR.CKSEL[2:0], the clock output from the selector stops for 4 cycles of the switched clock. Therefore, when using the AGTIO, AGTEE, or both input as external event input, the clock source should not be switched. If switching the clock source while using the external event input, extend the input pulse width by 4 clock cycles of the switched source clock cycles.

●在脉冲宽度测量模式下，脉冲宽度以数学方式表示如下：
脉冲宽度=停止测量的计数器值下一个停止测量的计数器值
●在脉冲周期测量模式下，输入脉冲周期的数学表达式如下：
输入脉冲周期=（计数器初始值[AGT寄存器]读出缓冲器的读取值）+1。

22.4.7 当计数被TSTOP位强制停止时

计数器被AGTCR寄存器中的TSTOP位强制停止后，在计数源的1个周期内不要访问以下IO寄存器：

- AGT
- AGTCMA
- AGTCMB
- AGTCR
- AGTMR1
- AGTMR2.

22.4.8 选择AGTn(n=0 2)下溢作为计数源时

选择下溢事件信号作为计数源时，请按照本节所述的以下步骤进行操作。

(1) 开始运行的步骤

1. Set AGT.
2.启动AGTn(n=1 3 5)的计数操作。
3.启动AGTn(n=0 2)的计数操作。

(2) 停止运行的步骤

1.停止AGTn(n=0 2)的计数操作。
2.停止AGTn(n=1 3 5)的计数操作。
3.停止AGTn(n=1 3 5)的计数源时钟（将000b写入AGTMR1.TCK[2:0]位）。

22.4.9 Module-stop function

可以使用模块停止控制寄存器D(MSTPCRD)和模块停止控制来禁用或启用AGT操作
寄存器E(MSTPCRE)。AGT模块在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式

22.4.10 切换源时钟时

当通过改变SCKSCR.CKSEL[2:0]来切换时钟源时，选择器的时钟输出在切换时钟的4个周期内停止。因此，当使用AGTIO、AGTEE或两者输入作为外部事件输入时，不应切换时钟源。如果在使用外部事件输入时切换时钟源，请将输入脉冲宽度延长4个切换源时钟周期的时钟周期。

23. Realtime Clock (RTC)

23.1 Overview

The realtime clock (RTC) has two counting modes, calendar count mode and binary count mode, that are used by switching register settings. For calendar count mode, the RTC has a 100-year calendar from 2000 to 2099 and automatically adjusts dates for leap years. For binary count mode, the RTC counts seconds and retains the information as a serial value. Binary count mode can be used for calendars other than the Gregorian (Western) calendar.

The sub-clock oscillator or LOCO can be selected as the count source of the time counters. The RTC uses a 128-Hz clock acquired by dividing the count source by a prescaler. Year, month, date, day-of-week, a.m. /p.m. (in 12-hour mode), hour, minute, second, or 32-bit binary is counted by 1/128 second.

Table 23.1 lists the RTC specifications, Figure 23.1 shows a block diagram, and Table 23.2 lists the I/O pins.

Table 23.1 RTC specifications

Parameter	Specifications
Count mode	Calendar count mode/binary count mode

Clock and calendar functions	• Calendar count mode – Year, month, date, day of week, hour, minute, second are counted, BCD display – 12 hours/24 hours mode switching function – 30 seconds adjustment function (a number less than 30 is rounded down to 00 seconds, and 30 seconds or more are rounded up to 1 minute) – Automatic adjustment function for leap years • Binary count mode – Count seconds in 32 bits, binary display • Shared by both modes – Start/stop function – The sub-second digit is displayed in binary units (1 Hz, 2 Hz, 4 Hz, 8 Hz, 16 Hz, 32 Hz, or 64 Hz) – Clock error correction function – Clock (1-Hz/64-Hz) output
Interrupts	• Alarm interrupt (RTC_ALM) – As an alarm interrupt condition, selectable for comparison with the following: – Calendar count mode: Year, month, date, day-of-week, hour, minute, or second can be selected – Binary count mode: Each bit of the 32-bit binary counter • Periodic interrupt (RTC_PRD) – 2 seconds, 1 second, 1/2 second, 1/4 second, 1/8 second, 1/16 second, 1/32 second, 1/64 second, 1/128 second, or 1/256 second can be selected as an interrupt period. • Carry interrupt (RTC_CUP) – An interrupt is generated at either of the following conditions: • When a carry from the 64-Hz counter to the second counter is generated. • When the 64-Hz counter is changed and the R64CNT register is read at the same time. (32-KHz count mode is only for 64-Hz counter reading) • Return from Software Standby or Deep Software Standby mode mode can be performed by an alarm interrupt or periodic interrupt
Time capture function	• Times can be captured when the edge of the time capture event input pin is detected. For every event input, month, date, hour, minute, and second are captured or the 32-bit binary counter value is captured. • Interrupt can be generated when the edge of the time capture event input is detected. The time capture event input pin and IRQ are shared.
Event link function	Periodic event output (RTC_PRD)
TrustZone filter	Security attribution can be set

Note 1. The frequency of the peripheral module clock (PCLKB) ≥ the frequency of the count source should be satisfied.

23. 实时时钟(RTC)

23.1 Overview

实时时钟(RTC)有两种计数模式，日历计数模式和二进制计数模式，通过切换寄存器设置使用。对于日历计数模式，RTC有一个从2000年到2099年的100年日历，并自动调整闰年的日期。对于二进制计数模式，RTC会计算秒数并将信息保留为序列值。二进制计数模式可用于公历（西方）以外的日历。

可以选择子时钟振荡器或LOCO作为时间计数器的计数源。RTC使用一个128-Hz时钟，通过预分频器将计数源分频获得。年、月、日、星期、上午、下午（在12小时模式下）时、分、秒或32位二进制按1128秒计数。

表23.1列出了RTC规格，图23.1显示了框图，表23.2列出了IO引脚。

23.2 Register Descriptions

Write or read from the RTC registers as described in section 23.6.5. Notes on Writing to and Reading from Registers.

If the value in an RTC register after a reset is given as x (undefined bits) in the list, it is not initialized by a reset. When RTC enters the reset state or a low power state during counting operations, for example, while the RCR2.START bit is 1, the year, month, day of the week, date, hours, minutes, seconds, and 64-Hz counters continue to operate.

Note: A reset generated while writing to a register might destroy the register value. In addition, do not allow the MCU to enter Software Standby or Deep Software Standby mode immediately after setting any of these registers. For details, see section 23.6.4. Transitions to Low Power Modes after Setting Registers.

23.2 注册说明

如第23.6.5节所述，从RTC寄存器写入或读取。关于写入和读取寄存器的注意事项。

如果复位后RTC寄存器中的值在列表中以x（未定义位）的形式给出，则它不会被复位初始化。当RTC在计数操作期间进入复位状态或低功耗状态时，例如，当RCR2.START位为1时，年、月、星期、日期、小时、分钟、秒和64-Hz计数器继续经营。

Note: 写入寄存器时产生的复位可能会破坏寄存器值。此外，不要让MCU在设置任何这些寄存器后立即进入软件待机或深度软件待机模式。详见23.6.4节。设置寄存器后转换到低功耗模式。

The R64CNT counter is used in both calendar count mode and binary count mode The 64-Hz counter (R64CNT) generates the period for a second by counting up periods of the 128-Hz clock. The state in the sub-second range can be confirmed by reading this counter.

This counter is set to 0x00 by an RTC software reset or an execution of a 30-second adjustment. To read this counter, follow the procedure in section 23.3.5. Reading 64-Hz Counter and Time.

23.2.2 RSECCNT : Second Counter (in Calendar Count Mode)

Base address: RTC = 0x4008_3000

Offset address: 0x02

R64CNT计数器用于日历计数模式和二进制计数模式。64-Hz计数器(R64CNT)通过向上计数128-Hz时钟的周期来产生一秒的周期。亚秒范围内的状态可以通过读取该计数器来确认。

该计数器通过RTC软件复位或执行30秒调整设置为0x00。要读取此计数器，请按照第23.3.5节中的程序进行。读取64-Hz计数器和时间。

23.2.2 RSECCNT:第二个计数器（在日历计数模式下）

RTCOS bit (RTCOUT Output Select)

The RTCOS bit selects the RTCOUT output period. The RTCOS bit must be rewritten while the count operation is stopped (RCR2.START = 0) and the RTCOUT output is disabled (RCR2.RTCOE = 0). When RTCOUT is output to an external pin, the RCR2.RTCOE bit must be enabled.

PES[3:0] bits (Periodic Interrupt Select)

The RCR2 register is related to hours mode, automatic adjustment function, enabling RTCOUT output, 30-second adjustment, RTC software reset, and controlling count operation.

START bit (Start)

The START bit stops or restarts the prescaler or time counter operation. This bit is updated in synchronization with the next cycle of the count source. When the START bit is modified, check that the bit is updated before proceeding.

RESET bit (RTC Software Reset)

The RESET bit initializes the prescaler and registers to be reset by RTC software. When 1 is written to this bit, initialization starts in synchronization with the count source. When the initialization is complete, the RESET bit is automatically set to 0. Check that this bit is 0 before proceeding.

ADJ30 bit (30-Second Adjustment)

The ADJ30 bit is for 30-second adjustment.

When 1 is written to the ADJ30 bit, the RSECCNT value of 30 seconds or less is rounded down to 00 second and the value of 30 seconds or more is rounded up to 1 minute.

The 30-second adjustment is performed in synchronization with the count source. When 1 is written to this bit, the ADJ30 bit is automatically set to 0 after the 30-second adjustment completes. If 1 is written to the ADJ30 bit, check that the bit is 0 before proceeding. When the 30-second adjustment is performed, the prescaler and R64CNT are also reset. The ADJ30 bit is set to 0 by an RTC software reset.

RTCOE bit (RTCOUT Output Enable)

The RTCOE bit enables output of a 1-Hz/64-Hz clock signal from the RTCOUT pin.

Use the START bit to stop counting before changing the value of the RTCOE bit. Do not stop counting (write 0 to the START bit) and change the value of the RTCOE bit at the same time.

When RTCOUT is to be output from an external pin, enable the RTCOE bit and set up the port control for the pin.

AADJE bit (Automatic Adjustment Enable)

The AADJE bit controls (enables or disables) automatic adjustment.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJE bit.

The AADJE bit is set to 0 by an RTC software reset.

AADJP bit (Automatic Adjustment Period Select)

The AADJP bit selects the automatic-adjustment period.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJP bit.

The AADJP bit is set to 0 by an RTC software reset.

HR24 bit (Hours Mode)

The HR24 bit specifies whether the RTC operates in 12- or 24-hour mode.

Use the START bit to stop counting before changing the value of the HR24 bit. Do not stop counting (write 0 to the START bit) and change the value of the HR24 bit at the same time.

CNTMD bit (Count Mode Select)

The CNTMD bit specifies whether the RTC count mode operates in calendar count mode or in binary count mode.

When setting the count mode, execute an RTC software reset and start again from the initial settings. This bit is updated in synchronization with the count source. However, the count mode switches only after the RTC software reset. (Bit switches before RTC reset, mode switches after RTC reset.)

For details on initial settings, see section 23.3.1. Outline of Initial Settings of Registers after Power On.

RCR2寄存器与小时模式、自动调整功能、启用RTCOUT输出、30秒调整、RTC软件复位和控制计数操作有关。

开始位（开始）

START位停止或重新启动预分频器或时间计数器操作。该位与计数源的下一个周期同步更新。修改START位后，请在继续之前检查该位是否已更新。

RESET位（RTC软件复位）

RESET位初始化预分频器和寄存器以由RTC软件复位。当向该位写入1时，初始化与计数源同步开始。初始化完成后，RESET位自动设置为0。在继续之前检查该位是否为0。

ADJ30 bit (30-Second Adjustment)

ADJ30位用于30秒调整。

向ADJ30位写入1时，30秒以下的RSECCNT值向下舍入为00秒，30秒以上的值向上舍入为1分钟。

30秒调整与计数源同步进行。向该位写入1时，30秒调整完成后ADJ30位自动设置为0。如果将1写入ADJ30位，请在继续之前检查该位是否为0。当执行30秒调整时，预分频器和R64CNT也被复位。RTC软件复位将ADJ30位设置为0。

RTCOE位（RTCOUT输出使能）

RTCOE位使能从RTCOUT引脚输出1-Hz64-Hz时钟信号。

在更改RTCOE位的值之前，使用START位停止计数。不要停止计数（将0写入START位）并同时更改RTCOE位的值。

当RTCOUT要从外部引脚输出时，使能RTCOE位并设置引脚的端口控制。

ADJE位（自动调整使能）

AADJE位控制（启用或禁用）自动调整。

在更改ADJE位的值之前，将正负位(RADJ.PMADJ[1:0])设置为00b（不执行调整）。

RTC软件复位将ADJE位设置为0。

AADJP位（自动调整周期选择）

AADJP位选择自动调整周期。

在更改AADJP位的值之前，将正负位(RADJ.PMADJ[1:0])设置为00b（不执行调整）。

AADJP位通过RTC软件复位设置为0。

HR24 bit (Hours Mode)

HR24位指定RTC是在12小时还是24小时模式下运行。

在更改HR24位的值之前，使用START位停止计数。不要停止计数（将0写入START位）并同时更改HR24位的值。

CNTMD位（计数模式选择）

CNTMD位指定RTC计数模式是在日历计数模式还是二进制计数模式下运行。

设置计数模式时，执行RTC软件复位并从初始设置重新开始。该位与计数源同步更新。但是，计数模式仅在RTC软件复位后切换。（RTC复位前位切换，RTC复位后模式切换。）

有关初始设置的详细信息，请参阅第23.3.1节。上电后寄存器的初始设置概要。

The RESET bit initializes the prescaler and registers to be reset by RTC software. When 1 is written to this bit, initialization starts in synchronization with the count source. When the initialization is complete, the RESET bit is automatically set to 0. When 1 is written to the RESET bit, check that the bit is 0 before proceeding.

RTCOE bit (RTCOUT Output Enable)

The RTCOE bit enables output of a 1-Hz/64-Hz clock signal from the RTCOUT pin.

Use the START bit to stop counting before changing the value of the RTCOE bit. Do not stop counting (write 0 to the START bit) and change the value of the RTCOE bit at the same time. When an RTCOUT signal is to be output from an external pin, enable the port control in addition to setting this bit.

23.2.26 RFRL:频率寄存器L

Base address: RTC = 0x4008_3000

Offset address: 0x2C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Symbol	Function	R/W
15:0	RFC[15:0]	Frequency Comparison Value Write 0x00FF to this register when using the LOCO.	R/W

RFRL is a register for controlling the prescaler when LOCO is selected.

The RTC time counter operates on a 128-Hz clock signal as the base clock. Therefore, when LOCO is selected, LOCO is divided by the prescaler to generate a 128-Hz clock signal. Set the frequency comparison value in the RFC[15:0] bits to generate a 128-Hz clock from the LOCO frequency. Before writing to RFC[15:0] after a cold start, write 0x0000 to the RFRH register.

A value from 0x0007 through 0x01FF can be specified as the frequency comparison value. If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2. The operating frequency of the peripheral module clock and the LOCO should be such that the peripheral module clock is ≥ LOCO.

Calculation method of frequency comparison value:

RFC[15:0] = (LOCO clock frequency) / 128 - 1

When the LOCO frequency is 32.768 kHz, the RFRL register should be set to 0x00FF.

15:0	RFC[15:0]	频率比较值 使用LOCO时将0x00FF写入该寄存器。	R/W

RFRL是一个寄存器，用于在选择LOCO时控制预分频器。

RTC时间计数器以128-Hz时钟信号作为基本时钟运行。Therefore whenLOCOisselected LOCOisdividedbythepr escalertogeneratea128-Hzclocksignal设置RFC[15:0]位中的频率比较值以从LOCO频率生成128-Hz时钟。在冷启动后写入RFC[15:0]之前，将0x0000写入RFRH寄存器。

从0x0007到0x01FF的值可以指定为频率比较值。如果指定的值超出此范围，则RTC将无法正确运行。在写入该寄存器之前，请务必通过设置RCR2中的START位来停止计数操作。外围模块时钟和LOCO的工作频率应使外围模块时钟≥LOCO。

频率比较值的计算方法：

RFC[15:0] = (LOCO clock frequency) / 128 - 1

当LOCO频率为32.768kHz时，RFRL寄存器应设置为0x00FF。

is performed when writing to the RADJ. If the RCR2.AADJE bit is 1, adjustment is performed in the interval specified in the Automatic Adjustment Period Select (RCR2.AADJP) bit.

The current adjustment by software (disabling automatic adjustment) may be invalid if the following adjustment value is specified within 320 cycles of the count source after the register setting. To perform adjustment consecutively, wait for 320 cycles or more of the count source after the register setting, then specify the next adjustment value.

RADJ is updated in synchronization with the count source. When RADJ is modified, check that all the bits are updated before continuing with more processing. This register is set to 0x00 by an RTC software reset. The setting of this register is enabled only when the sub-clock oscillator is selected. When LOCO is selected, adjustment is not performed.

ADJ[5:0] bits (Adjustment Value)

The ADJ[5:0] bits specify the adjustment value (number of sub-clock cycles) from the prescaler.

PMADJ[1:0] bits (Plus-Minus)

The PMADJ[1:0] bits select whether the clock is set ahead or back depending on the error-adjustment value set in the ADJ[5:0] bits.

Note 1. Indicates that an event is detected. Writing 1 to this bit has no effect. Writing 0 sets this bit to 0.

The RTCCR0 register is used both in calendar count mode and in binary count mode.RTCCR0 controls the RTCIC0 pin.

RTCCR0 is updated in synchronization with the count source. When RTCCR0 is modified, check that all the bits except the TCST bit are updated before continuing with additional processing. This register is cleared to 0x00 by an RTC software reset. When RTCIC0 is used as the time capture pin, VBTICTLR.VCHnIEN (n = 0) must be set to 1.

TCCT[1:0] bits (Time Capture Control)

The TCCT[1:0] bits control the edge detection of the time capture event input pin, RTCIC0.The detection edge is selectable. The TCCT[1:0] bits must be set while the VBTICTLR.VCHnIEN bit is 1.

在写入RADJ时执行。如果RCR2.AADJE位为1，则在自动调整周期选择(RCR2.AADJP)位指定的间隔内执行调整。

RADJ与计数源同步更新。修改RADJ后，在继续进行更多处理之前检查所有位是否已更新。该寄存器通过RTC软件复位设置为0x00。该寄存器的设置仅在选择了副时钟振荡器时启用。选择LOCO时，不进行调整。

注1.表示检测到事件。向该位写入1无效。写入0将该位设置为0。

RTCCR0寄存器用于日历计数模式和二进制计数模式。RTCCR0控制RTCIC0引脚。

RTCCR0与计数源同步更新。当RTCCR0被修改时，检查除
TCST位在继续进行附加处理之前被更新。RTC软件复位将该寄存器清零为0x00。当RTCIC0用作时间捕捉引脚时，VBTICTLR.VCHnIEN(n=0)必须设置为1。

TCCT[1:0]位（时间捕捉控制）

TCCT[1:0]位控制时间捕捉事件输入引脚RTCIC0的边沿检测。检测边沿是可选的。
当VBTICTLR.VCHnIEN位为1时，必须设置TCCT[1:0]位。

TCST bit (Time Capture Status)

The TCST bit indicates that an event on the time capture event input pin, RTCIC0,was detected. When the TCST bit is 0, no event is detected. When the TCST bit is 1, this bit indicates that an event was detected on the associated pin and the capture register is valid. When multiple events are detected, the capture time for the first event is retained.

The event is detected only during count operation (RCR2.START bit = 1). Before reading the capture register, make sure that this bit is set to 1.

Set the TCST bit while the TCCT[1:0] bits are 00b (no event is detected). The TCST bit is set to 0 in synchronization with the count source. When the TCST bit is set to 0, check that the bit is updated before continuing with additional processing.

TCNF[1:0] bits (Time Capture Noise Filter Control)

The TCNF[1:0] bits control the noise filter of the time capture event input pin (RTCIC0).

When the noise filter is on, the count source divided by 1 or divided by 32 is selectable. In this case, when the input level on the time capture event input pin matches three consecutive times at the set sampling period, the input level is determined.

Set the TCNF[1:0] bits while the TCCT[1:0] bits are 00b (no event is detected). When the noise filter is used, set the TCNF[1:0] bits, wait for 3 cycles of the specified sampling period, then set the TCCT[1:0] bits. Set the TCNF[1:0] bits when the VBTICTLR.VCHnIEN bit is 1.

TCEN bit (Time Capture Event Input Pin Enable)

The TCEN bit enables or disables the time capture event input pin, RTCIC0. When the functions of the time capture event input pins are multiplexed, set VBTICTLR first. If the TCEN bit is set to 0, also set the TCCT[1:0] bits to 00b.

Before setting this bit to 1, be sure to set the count source setting bit (RCR4.RCKSEL), RTC time capture event enable bit (RCPE.RTCEN), port control setting bits (PmnPFS.PDR, and PmnPFS.PMR). For details on the port control setting bits (PmnPFS.PDR and PmnPFS.PMR), see section 19, I/O Ports.

6:4	SEC10[2:0]	10-Second Capture Capture value for the tens place of seconds.	R
7	—	The read value is undefined.	R

RSECCP0 is a read-only register that captures the RSECCNT value when a time capture event is detected.

The event detection times detected by the RTCIC0 pin is stored in the RSECCP0 register, respectively. This register is cleared to 0x00 by an RTC software reset. Before reading from this register, the time capture event detection should be stopped using the RTCCRn.TCCT[1:0] bits.

TCST位（时间捕捉状态）

TCST位指示检测到时间捕捉事件输入引脚RTCIC0上的事件。当TCST位为0时，未检测到任何事件。当TCST位为1时，该位表示在相关引脚上检测到事件并且捕捉寄存器有效。当检测到多个事件时，将保留第一个事件的捕获时间。

仅在计数操作期间检测到事件（RCR2.START位=1）。在读取捕获寄存器之前，请确保该位设置为1。

当TCCT[1:0]位为00b（未检测到事件）时，设置TCST位。TCST位与计数源同步设置为0。当TCST位设置为0时，在继续进行其他处理之前检查该位是否已更新。

TCNF[1:0]位（时间捕捉噪声滤波器控制）

TCNF[1:0]位控制时间捕捉事件输入引脚(RTCIC0)的噪声滤波器。

当噪声滤波器打开时，计数源除以1或除以32是可选的。在这种情况下，当时间捕捉事件输入引脚上的输入电平在设置的采样周期内连续匹配3次时，确定输入电平。

当TCCT[1:0]位为00b（未检测到事件）时，设置TCNF[1:0]位。使用噪声滤波器时，设置TCNF[1:0]位，等待指定采样周期的3个周期，然后设置TCCT[1:0]位。当VBTICTLR.VCHnIEN位为1时，设置TCNF[1:0]位。

TCEN位（时间捕捉事件输入引脚使能）

TCEN位启用或禁用时间捕捉事件输入引脚RTCIC0。当时间捕捉事件输入引脚的功能复用时，首先设置VBTICTLR。如果TCEN位设置为0，也将TCCT[1:0]位设置为00b。

在将此位设置为1之前，请务必设置计数源设置位(RCR4.RCKSEL)、RTC时间捕捉事件使能位(RCPE.RTCEN)、端口控制设置位(PmnPFS.PDR和PmnPFS.PMR)。有关端口控制设置位（PmnPFS.PDR和PmnPFS.PMR）的详细信息，请参阅第19节，IO端口。

Note 1. Disable interrupts if required.

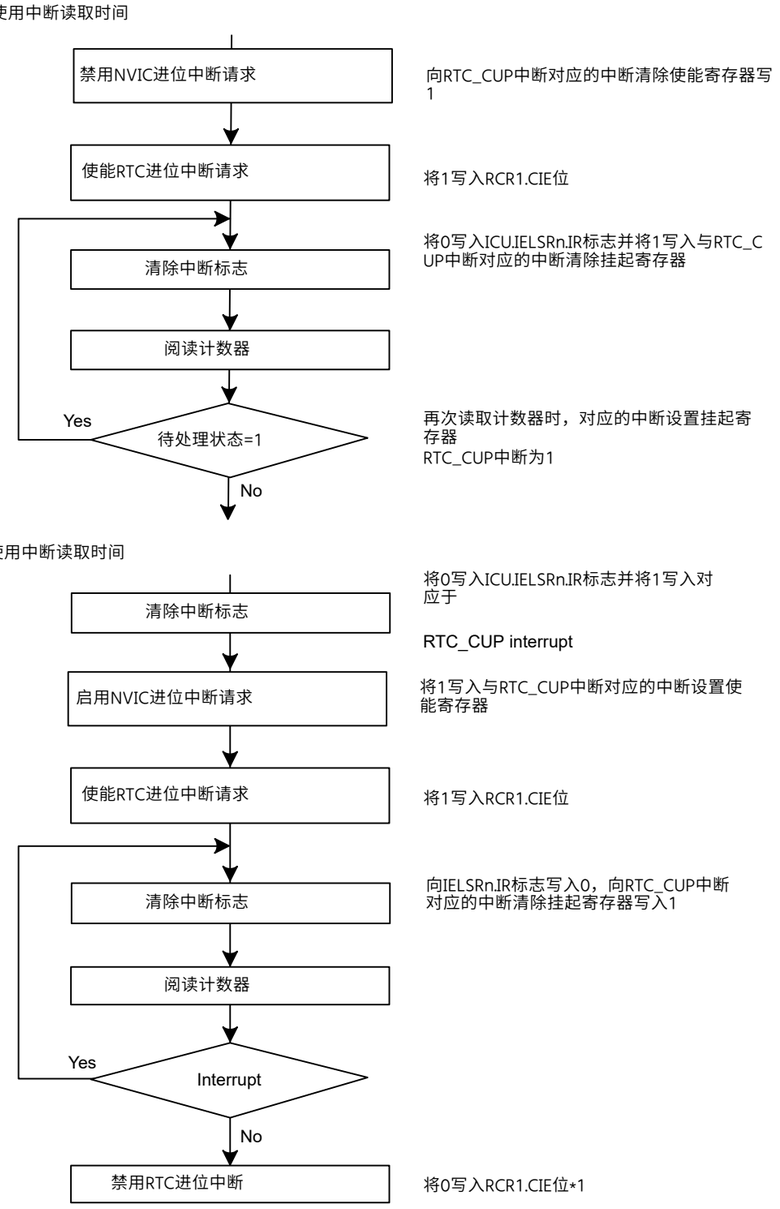
If a carry occurs while the 64-Hz counter and time are read, the correct time is not obtained, therefore they must be read again. The procedure for reading the time without using interrupts is shown in (a) in Figure 23.6, and the procedure using carry interrupts is shown in (b). To keep the program simple, method (a) should be used in most cases.



注1.如果需要，禁用中断。

如果在读取64-Hz计数器和时间时发生进位，则无法获得正确的时间，因此必须再次读取它们。不使用中断读取时间的过程如图23.6(a)所示，使用进位中断的过程如图23.6所示。为保持程序简单，在大多数情况下应使用方法(a)。

23.3.6 Alarm Function

Figure 23.7 shows how to use the alarm function.

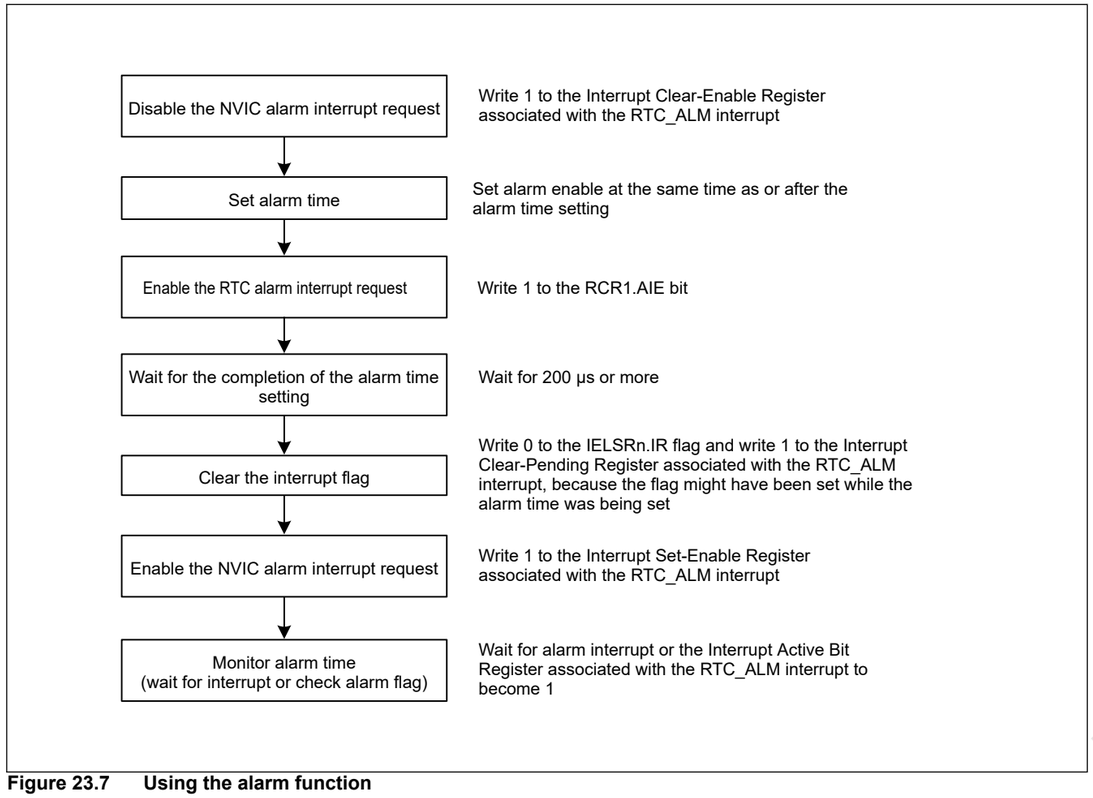

Figure 23.7 Using the alarm function

In calendar count mode, an alarm can be generated by any one of year, month, date, day-of-week, hour, minute or second, or any combination of those. Write 1 to the ENB bit in the alarm registers involved in the alarm setting, and set the alarm time in the lower bits. Write 0 to the ENB bit in registers not involved in the alarm setting.

In binary count mode, an alarm can be generated in any bit combination of 32 bits. Write 1 to the ENB bit of the Alarm Enable register associated with the target bit of the alarm, and set the alarm time in the alarm register. For bits that are not the target of the alarm, write 0 to the ENB bit of the Alarm Enable register.*1

For any of the ENB[31:0] bits that are set to 1, the bits in the corresponding positions in the binary counter (BCNT[31:0]) are compared with the values of the corresponding bits in the binary alarm registers*1. When all such bits match, the IR flag associated with the RTC_ALM interrupt is set to 1 and the corresponding bits in the Interrupt Set-Pending/Clear-Pending Registers are set to 1. Alarm detection can be confirmed by reading the Interrupt Set-Pending Register associated with the RTC_ALM interrupt, but an interrupt should be used in most cases. If 1 is set in the Interrupt Set-Enable Register associated with the RTC_ALM interrupt, an alarm interrupt is generated in the event of the alarm, enabling the alarm to be detected.

Writing 0 sets the IELSRn.IR flag associated with the RTC_ALM interrupt to 0. If interrupt is enabled, the Interrupt Set-Pending/Clear-Pending Register associated with the RTC_ALM interrupt is cleared automatically after exiting the interrupt handler. Otherwise, write 1 to the Interrupt Clear-Pending Register associated with the RTC_ALM interrupt to clear it.

When the counter and the alarm time match in a low power state, the MCU returns from the low power state.

Note 1. For any bits in the ENB bits that are set to 1, the values in the corresponding positions in the alarm registers from the following registers are compared with the corresponding bits of the counted values.

Counter registers: RSECCNT, RMINCNT, RHRCNT, RWKCNT, RDAYCNT, RMONCNT, RYRCNT

Alarm registers: RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, RYRAREN

23.3.6 报警功能

图23.7显示了如何使用报警功能。

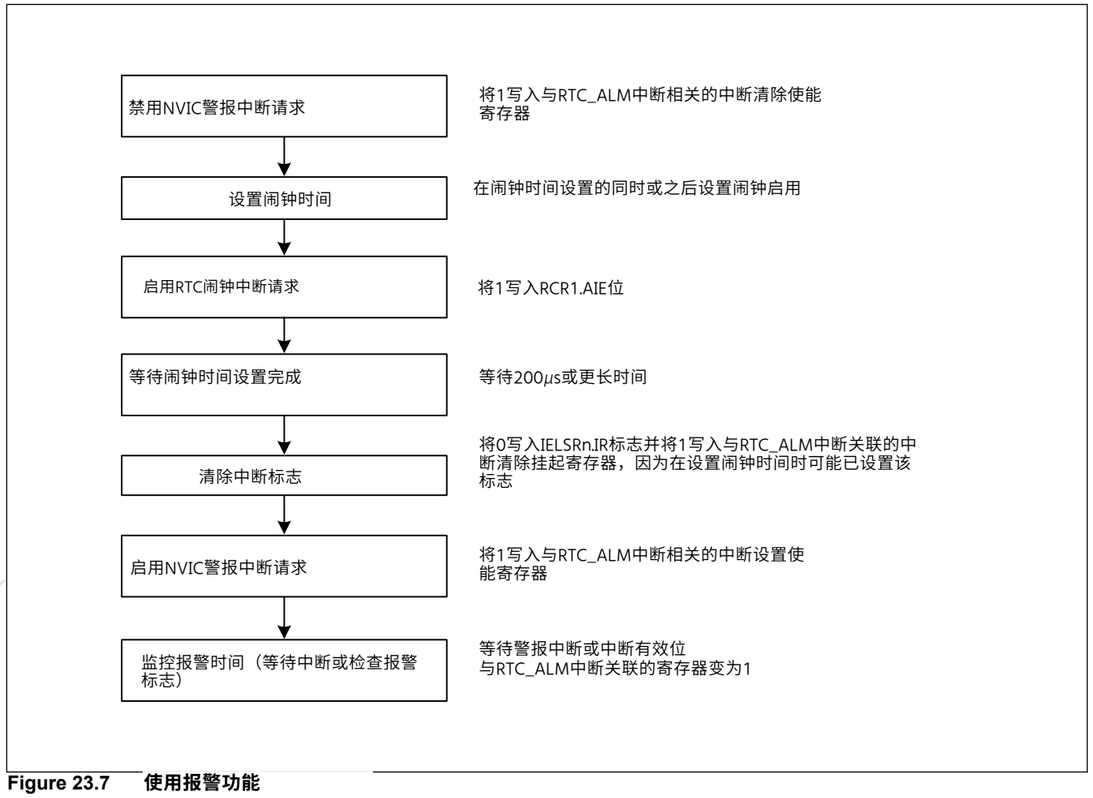

Figure 23.7 使用报警功能

在日历计数模式下，可以通过年、月、日、星期、小时、分钟或秒中的任何一个或它们的任意组合来生成警报。将1写入涉及闹钟设置的闹钟寄存器的ENB位，并在低位设置闹钟时间。将0写入与报警设置无关的寄存器中的ENB位。

在二进制计数模式下，可以以32位的任意位组合产生报警。将1写入闹钟的ENB位与报警的目标位相关联的使能寄存器，并在报警寄存器中设置报警时间。对于不是警报目标的位，将0写入警报启用寄存器的ENB位。*1

对于任何设置为1的ENB[31:0]位，二进制计数器(BCNT[31:0])中相应位置的位与二进制报警寄存器中相应位的值进行比较*1.当所有这些位匹配时，与RTC_ALM中断相关的IR标志设置为1，并且中断设置挂起清除挂起寄存器中的相应位设置为1。可以通过读取中断设置挂起寄存器来确认警报检测与RTC_ALM中断相关联，但在大多数情况下应使用中断。如果在与RTC_ALM中断相关的中断设置使能寄存器中设置为1，则在发生警报时会产生警报中断，从而能够检测到警报。

写入0将与RTC_ALM中断关联的IELSRn.IR标志设置为0。如果启用中断，则中断设置与RTC_ALM中断关联的PendingClear-Pending寄存器在退出中断处理程序后自动清除。否则，将1写入与RTC_ALM中断相关的中断清除挂起寄存器以将其清除。

当计数器和闹钟时间在低功耗状态下匹配时，MCU从低功耗状态返回。

注1.对于设置为1的ENB位中的任何位，将以下寄存器中警报寄存器中相应位置的值与计数值的相应位进行比较。

Counter registers: RSECCNT, RMINCNT, RHRCNT, RWKCNT, RDAYCNT, RMONCNT, RYRCNT

Alarm registers: RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, RYRAREN

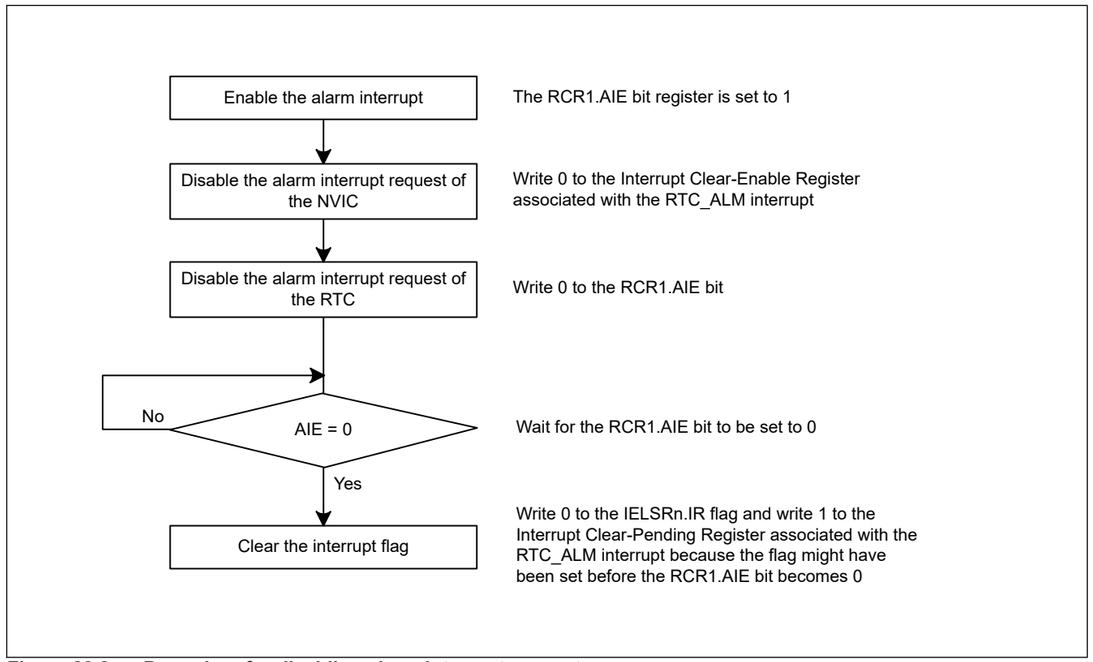

Figure 23.8 Procedure for disabling alarm interrupt request

23.3.8 Time Error Adjustment Function

The time error adjustment function is used to correct errors, running fast or slow, in the time caused by variation in the precision of oscillation by the sub-clock oscillator. Because 32768 cycles of the sub-clock oscillator constitute 1 second of operation when the sub-clock oscillator is selected, the clock runs fast if the sub-clock frequency is high and slow if the sub-clock frequency is low.

The time error adjustment functions include:

- Automatic adjustment
- Adjustment by software

Use the RCR2.AADJE bit to select automatic adjustment or adjustment by software.

23.3.8.1 Automatic adjustment

Enable automatic adjustment by setting the RCR2.AADJE bit to 1.

Automatic adjustment is the addition or subtraction of the value counted by the prescaler to or from the value in the RADJ register every time the adjustment period selected by the RCR2.AADJP bit elapses.

(1) Example 1: Sub-clock oscillator running at 32.769 kHz

Adjustment procedure

When the sub-clock oscillator is running at 32.769 kHz, 1 second elapses every 32769 clock cycles. The RTC is meant to run at 32768 clock cycles, so the clock runs fast by 1 clock cycle every second. The time on the clock is fast by 60 clock cycles per minute, so adjustment can take the form of setting the clock back by 60 cycles every minute.

23.3.7 禁用警报中断的步骤

图23.8显示了禁用启用的警报中断请求的过程。

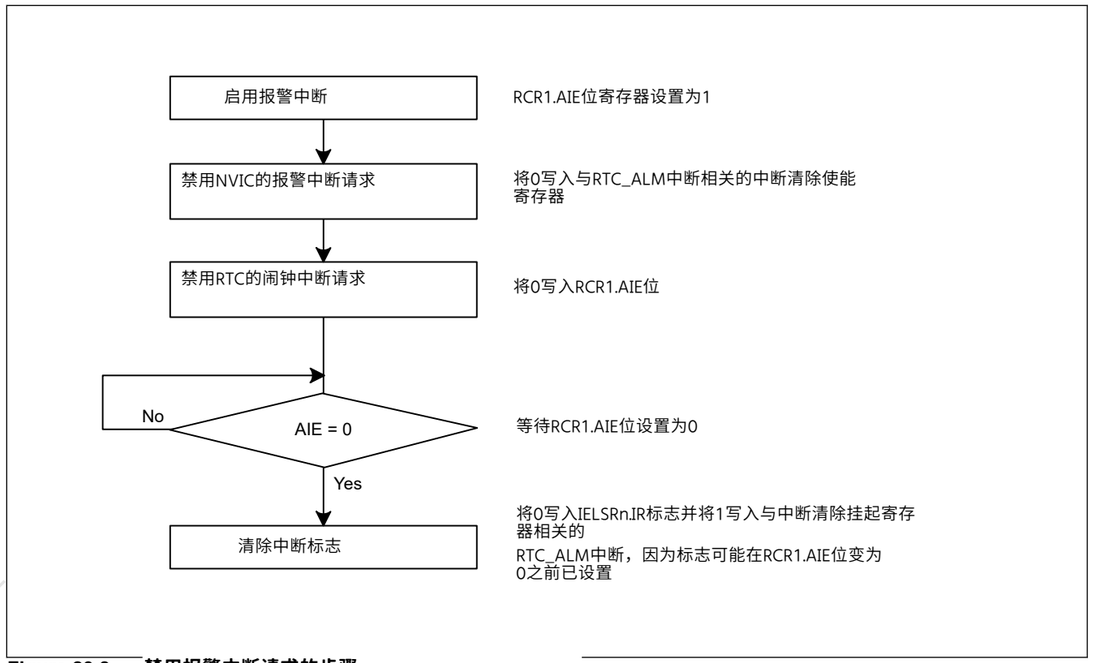

Figure 23.8 禁用报警中断请求的步骤

23.3.8 时间误差调整功能

时间误差调整功能用于校正子时钟振荡器振荡精度变化引起的时间误差，运行速度快或慢。由于在选择子时钟振荡器时，子时钟振荡器的32768个周期构成1秒的操作，因此如果子时钟频率高，则时钟运行快，如果子时钟频率低，则时钟运行慢。

时间误差调整功能包括：

- 自动调整
- 软件调整

使用RCR2.AADJE位选择自动调整或软件调整。

23.3.8.1 自动调整

通过将RCR2.AADJE位设置为1来启用自动调整。

自动调整是每次经过RCR2.AADJP位选择的调整周期后，将预分频器计数的值与RADJ寄存器中的值相加或相减。

(1) 示例1：运行在32.769kHz的子时钟振荡器

调整程序

当副时钟振荡器以32.769kHz运行时，每32769个时钟周期经过1秒。RTC旨在以32768个时钟周期运行，因此时钟以每秒1个时钟周期的速度运行。时钟上的时间每分钟快60个时钟周期，因此调整可以采取将时钟每分钟调回60个周期的形式。

Register settings when RCR2.CNTMD = 0:

- RCR2.AADJP = 0 (adjustment every minute)
- RADJ.PMADJ[1:0] = 10b (adjustment is performed by the subtraction from the prescaler)
- RADJ.ADJ[5:0] = 60 (0x3C)

(2) Example 2: Sub-clock oscillator running at 32.766 kHz

Adjustment procedure

When the sub-clock oscillator is running at 32.766 kHz, 1 second elapses every 32766 clock cycles. The RTC is meant to run at 32768 clock cycles, so the clock runs slow by 2 clock cycles every second. The time on the clock is slow by 20 clock cycles every 10 seconds, so adjustment can take the form of setting the clock forward by 20 cycles every 10 seconds.

Register settings when RCR2.CNTMD = 0:

- RCR2.AADJP = 1 (adjustment every 10 seconds)
- RADJ.PMADJ[1:0] = 01b (adjustment is performed by the addition to the prescaler)
- RADJ.ADJ[5:0] = 20 (0x14)

(3) Example 3: Sub-clock oscillator running at 32.764 kHz

Adjustment procedure

When the sub-clock oscillator is running at 32.764 kHz, 1 second elapses on 32764 clock cycles. Because the RTC operates for 32768 clock cycles as 1 second, the clock is delayed for 4 clock cycles per second. In 8 seconds, the delay is 32 clock cycles, therefore correction can be made by advancing the clock 32 clock cycles every 8 seconds.

Register settings when RCR2.CNTMD = 1:

- RCR2.AADJP = 1 (adjustment every 8 seconds)
- RADJ.PMADJ[1:0] = 01b (adjustment is performed by the addition to the prescaler)
- RADJ.ADJ[5:0] = 32 (0x20)

23.3.8.2 Adjustment by software

Enable adjustment by software by setting the RCR2.AADJE bit to 0. Adjustment by software is the addition or subtraction of the value counted by the prescaler to or from the value in the RADJ register on execution of a write instruction to the RADJ register.

(1) Example 1: Sub-clock oscillator running at 32.769 kHz

Adjustment procedure

When the sub-clock oscillator is running at 32.769 kHz, 1 second elapses every 32769 clock cycles. The RTC is meant to run at 32768 clock cycles, so the clock runs fast by 1 clock cycle every second. The time on the clock is fast by 1 clock cycle per second, so adjustment can take the form of setting the clock back by 1 cycle every second.

Register settings

- RADJ.PMADJ[1:0] = 10b (adjustment is performed by the subtraction from the prescaler)
- RADJ.ADJ[5:0] = 1 (0x10)
  This is written to the RADJ register once per 1-second interrupt.

23.3.8.3 Procedure to change the mode of adjustment

When changing the mode of adjustment, change the value of the AADJE bit in RCR2 after setting the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).

To change adjustment by software to automatic adjustment:

1. Set the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).
2. Set the RCR2.AADJE bit to 1 (automatic adjustment is enabled).

RCR2.CNTMD=0时的寄存器设置：

- RCR2.AADJP = 0 (adjustment every minute)
- ●RADJ.PMADJ[1:0]=10b（通过预分频器的减法进行调整）
- RADJ.ADJ[5:0] = 60 (0x3C)

(2) 示例2：以32.766kHz运行的子时钟振荡器

调整程序

当子时钟振荡器以32.766kHz运行时，每32766个时钟周期经过1秒。RTC旨在以32768个时钟周期运行，因此时钟每秒运行2个时钟周期。时钟上的时间每10秒慢20个时钟周期，因此调整可以采取将时钟每10秒向前20个周期的形式。

RCR2.CNTMD=0时的寄存器设置：

- RCR2.AADJP = 1 (adjustment every 10 seconds)
- ●RADJ.PMADJ[1:0]=01b（通过加到预分频器进行调整）
- RADJ.ADJ[5:0] = 20 (0x14)

(3) 示例3：以32.764kHz运行的子时钟振荡器

调整程序

当副时钟振荡器以32.764kHz运行时，32764个时钟周期经过1秒。由于RTC以1秒为单位运行32768个时钟周期，因此时钟每秒延迟4个时钟周期。在8秒内，延迟为32个时钟周期，因此可以通过每8秒将时钟提前32个时钟周期来进行校正。

RCR2.CNTMD=1时的寄存器设置：

- RCR2.AADJP = 1 (adjustment every 8 seconds)
- ●RADJ.PMADJ[1:0]=01b（通过加到预分频器进行调整）
- RADJ.ADJ[5:0] = 32 (0x20)

23.3.8.2 软件调整

通过将RCR2.AADJE位设置为0来启用软件调整。软件调整是在执行对RADJ寄存器的写指令时，将预分频器计数的值与RADJ寄存器中的值相加或相减。

(1) 示例1：运行在32.769kHz的子时钟振荡器

调整程序

当副时钟振荡器以32.769kHz运行时，每32769个时钟周期经过1秒。RTC旨在以32768个时钟周期运行，因此时钟以每秒1个时钟周期的速度运行。时钟上的时间每秒快1个时钟周期，因此调整可以采取将时钟每秒调回1个周期的形式。

注册设置

- ●RADJ.PMADJ[1:0]=10b（通过预分频器的减法进行调整）
- RADJ.ADJ[5:0] = 1 (0x10)
  每1秒中断一次将其写入RADJ寄存器。

23.3.8.3 更改调整模式的步骤

改变调整模式时，将RADJ.PMADJ[1:0]位设置为00b后改变RCR2中的AADJE位的值（不进行调整）。

将软件调整改为自动调整：

1.将RADJ.PMADJ[1:0]位设置为00b（不进行调整）。

2.将RCR2.AADJE位设置为1（启用自动调整）。

3. Use the RCR2.AADJP bit to select the period of adjustment.
4. In RADJ, set the PMADJ[1:0] bits for addition or subtraction and the ADJ[5:0] bits to the value for use in time error adjustment.

To change automatic adjustment to adjustment by software:

1. Set the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).
2. Set the RCR2.AADJE bit to 0 (adjustment by software is enabled).
3. Proceed with the adjustment by setting the RADJ.PMADJ[1:0] bits for addition or subtraction and the RADJ.ADJ[5:0] bits to the value for use in time error adjustment at the wanted time. After that, the time is adjusted every time a value is written to the RADJ register.

23.3.8.4 Procedure to stop adjustment

Stop the adjustment by setting the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).

23.3.9 Capturing the time

The RTC is capable of storing the month, date, hour, minute and second/binary counters 3 to 0 by detecting an edge of a signal on a time capture event input pin in calendar count mode or binary count mode .

A noise filter can also be used on a time capture event input pin. If the noise filter is enabled, the RTCCRn.TCST bit is set to 1 when the input level on the pin matches three times.

The noise filter can be switched on or off for each of the time capture event input pins.Set VBTICTLR.VCHnIEN (n = 0 to 2) to 1 to enable the RTCICn input. Operation when the noise filter is off is shown in Figure 23.9 and operation when the noise filter is on is shown in Figure 23.10.

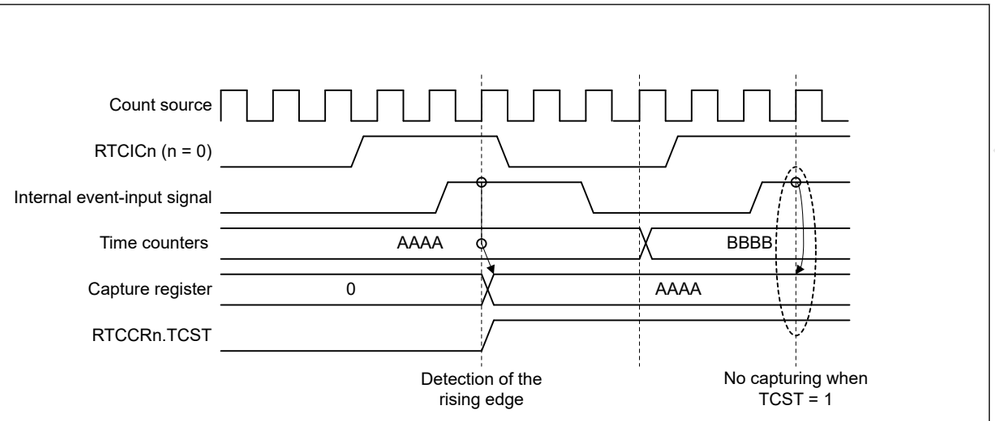

Figure 23.9 Timing of a time capture operation with the noise filter off

3.使用RCR2.AADJP位选择调整周期。

4.在RADJ中，将PMADJ[1:0]位设置为加法或减法，并将ADJ[5:0]位设置为用于时间误差调整的值。

将自动调整更改为软件调整：

1.将RADJ.PMADJ[1:0]位设置为00b（不进行调整）。

2.将RCR2.AADJE位设置为0（启用软件调整）。

3.通过将RADJ.PMADJ[1:0]位设置为加法或减法并将RADJ.ADJ[5:0]位设置为在所需时间用于时间误差调整的值，继续进行调整。之后，每次将值写入RADJ寄存器时都会调整时间。

23.3.8.4 停止调整的步骤

通过将RADJ.PMADJ[1:0]位设置为00b来停止调整（不执行调整）。

23.3.9 捕捉时间

通过在日历计数模式或二进制计数模式下检测时间捕捉事件输入引脚上的信号沿，RTC能够存储月、日、小时、分钟和秒二进制计数器3到0。

噪声滤波器也可用于时间捕捉事件输入引脚。如果启用噪声滤波器，则当引脚上的输入电平匹配3次时，RTCCRn.TCST位设置为1。

可以为每个时间捕捉事件输入引脚打开或关闭噪声滤波器。将VBTICTLR.VCHnIEN（n=0到2）设置为1以启用RTCICn输入。噪声滤波器关闭时的操作如图23.9所示，噪声滤波器打开时的操作如图23.10所示。

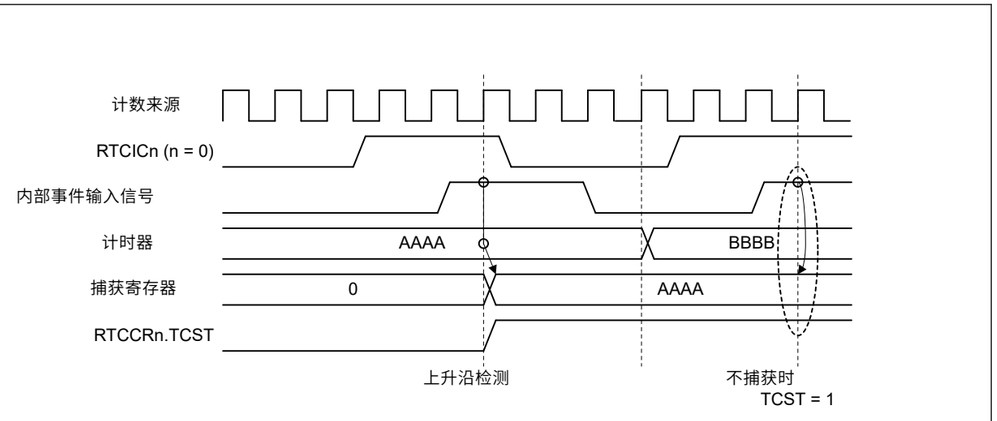

Figure 23.9 关闭噪声过滤器的时间捕获操作的时序

23.4 Interrupt Sources

The RTC has three interrupt sources, as listed in Table 23.3.

Table 23.3 RTC interrupt sources

Name	Interrupt source
RTC_ALM	Alarm interrupt
RTC_PRD	Periodic interrupt
RTC_CUP	Carry interrupt

(1) Alarm interrupt (RTC_ALM)

This interrupt is generated based on the comparison result between the alarm registers and RTC counters. For details, see section 23.3.6. Alarm Function.

Because there is a possibility that the interrupt flag might be set to 1 when the settings of the alarm registers match the clock counters, wait for the alarm time settings to be confirmed and clear the IELSRn.IR flag and the interrupt Set-Pending Register associated with the RTC_ALM interrupt to 0 again after modifying values of the alarm registers. After the interrupt flag for the alarm interrupt is set to 1 and the state is returned to mismatching of the alarm registers and clock counters, the flag is not 1 again until there is another match or the values of the alarm registers are modified again.

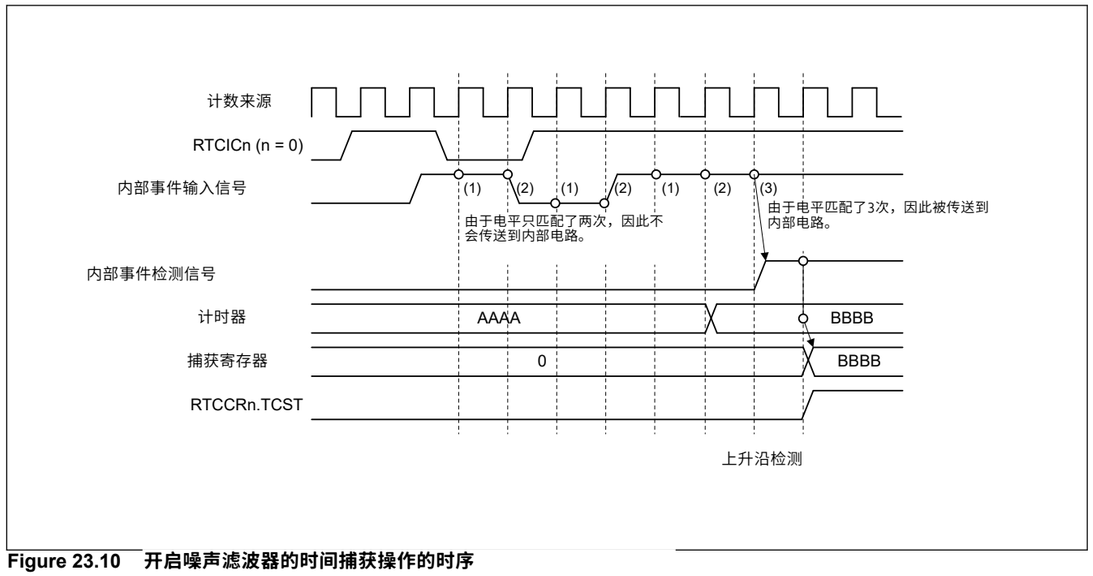

Figure 23.10 开启噪声滤波器的时间捕获操作的时序

23.4 中断源

RTC具有三个中断源，如表23.3中所列。

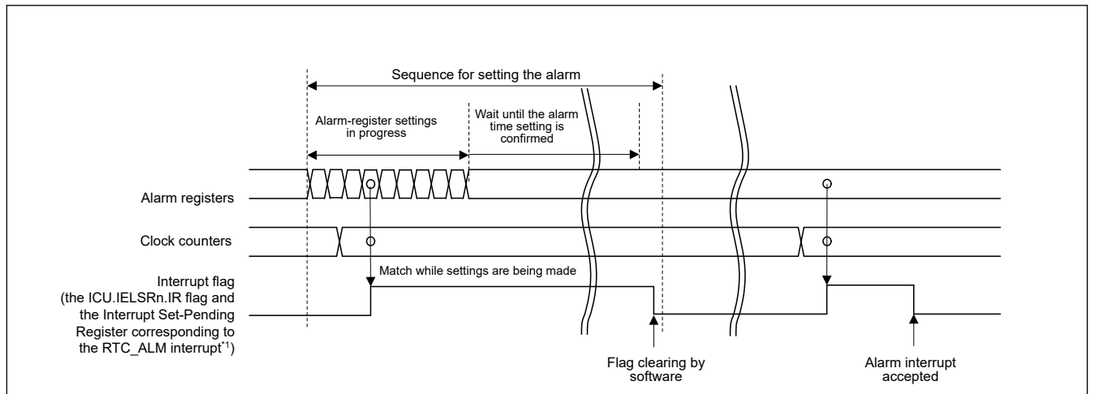
Table 23.3 RTC中断源

Name	中断源
RTC_ALM	报警中断
RTC_PRD	周期性中断
RTC_CUP	进位中断

(1) 闹钟中断(RTC_ALM)

该中断是根据闹钟寄存器和RTC计数器之间的比较结果产生的。详见23.3.6节。报警功能。

因为当闹钟寄存器的设置与时钟计数器匹配时中断标志可能被设置为1，请等待闹钟时间设置被确认并清除IELSRn.IR标志和相关的中断设置挂起寄存器修改闹钟寄存器的值后，RTC_ALM中断再次为0。报警中断的中断标志置1并返回报警寄存器和时钟计数器不匹配状态后，该标志不再为1，直到再次匹配或再次修改报警寄存器的值。



Note 1. See section 13, Interrupt Controller Unit (ICU) for details on the associated interrupt vector number.

Figure 23.11 Timing for the alarm interrupt (RTC_ALM)

(2) Periodic interrupt (RTC_PRD)

This interrupt is generated at intervals of 2 seconds, 1 second, 1/2 second, 1/4 second, 1/8 second, 1/16 second, 1/32 second, 1/64 second, 1/128 second, or 1/256 second. The interrupt interval can be selected in the RCR1.PES[3:0] bits.

(3) Carry interrupt (RTC_CUP)

This interrupt is generated when a carry to the second counter/binary counter 0 occurred or a carry to the R64CNT counter occurred during read access to the 64-Hz counter.

Figure 23.12 shows the timing of the carry interrupt (RTC_CPU).

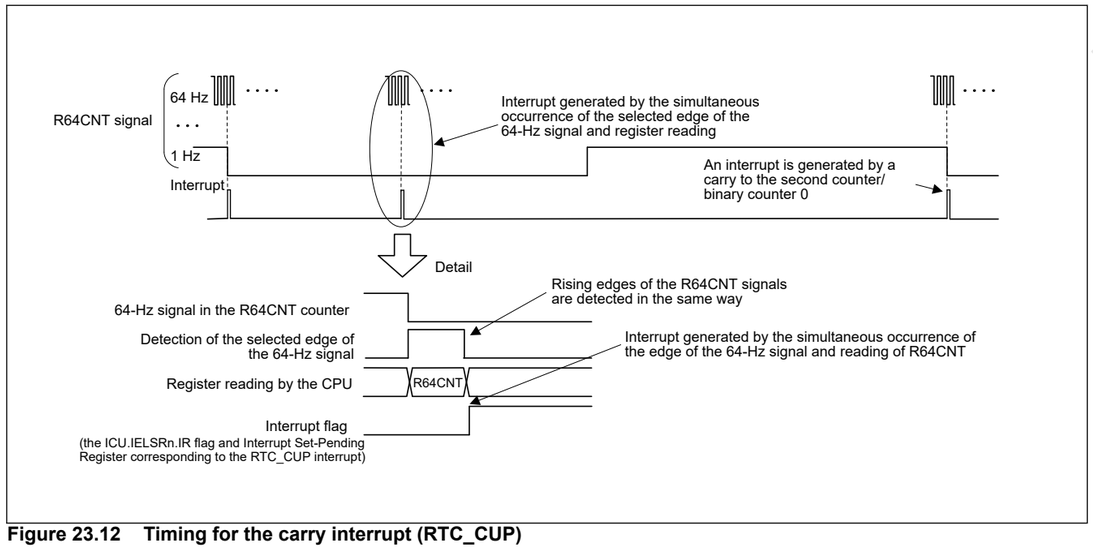


Figure 23.12 Timing for the carry interrupt (RTC_CUP)

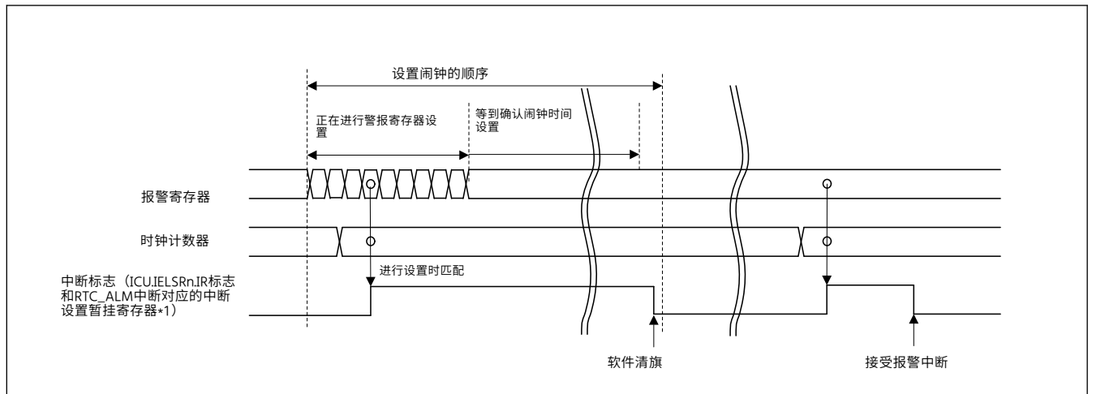
23.5 Event Link Output

The RTC generates periodic event output (RTC_PRD) event signal for the ELC that can be used to initiate operations by other modules selected in advance.



注1.有关相关中断向量编号的详细信息，请参见第13节，中断控制器单元(ICU)。

Figure 23.11 闹钟中断的时序(RTC_ALM)

(2) 周期性中断(RTC_PRD)

此中断以2秒、1秒、12秒、14秒、18秒、116秒、132秒、164秒、1128秒或1256秒的间隔生成。可以在RCR1.PES[3:0]位中选择中断间隔。

(3) 进位中断(RTC_CUP)

当第二个计数器二进制计数器0的进位发生或在对64-Hz计数器的读访问期间发生对R64CNT计数器的进位时，将产生此中断。

图23.12显示了进位中断(RTC_CPU)的时序。

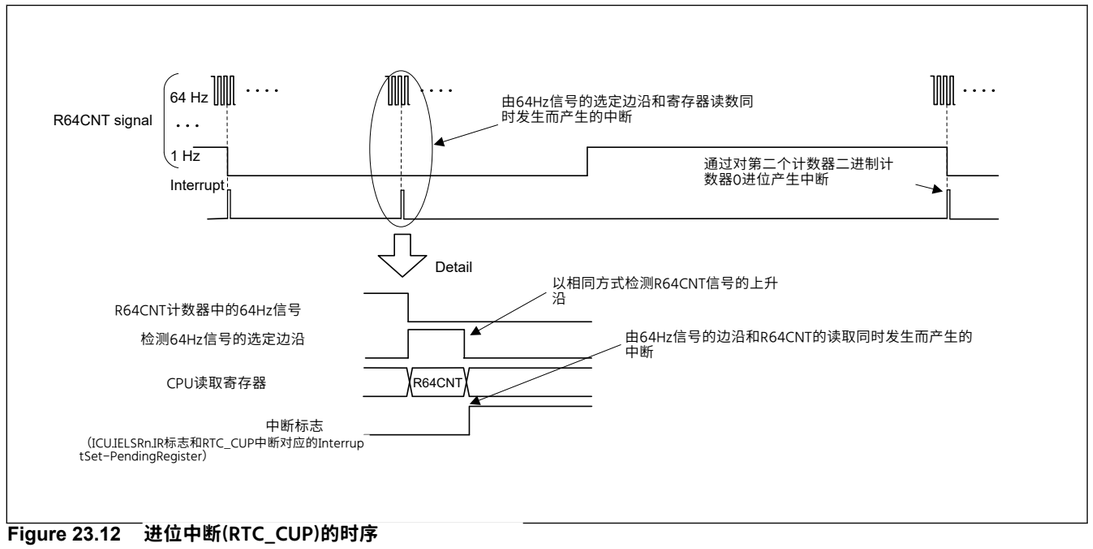


Figure 23.12 进位中断(RTC_CUP)的时序

23.5 事件链接输出

RTC为ELC生成周期性事件输出(RTC_PRD)事件信号，该信号可用于启动预先选择的其他模块的操作。

The periodic event signal is output at the interval selected from 1/256, 1/128, 1/64, 1/32, 1/16, 1/8, 1/4, 1/2, 1, and 2 seconds by setting the RCR1.PES[3:0] bits.

The event generation period immediately after the event generation is selected is not guaranteed.

Note: If event linking from the RTC is used, only set the ELC after setting the RTC, for example initialization and time settings. Setting the RTC after the ELC can lead to output of unexpected event signals.

23.5.1 Interrupt Handling and Event Linking

The RTC has a bit to enable or disable periodic interrupts. An interrupt request signal is output to the CPU when an interrupt source is generated while the associated enable bit is enabled.

In contrast, an event link output signal is sent to other modules as an event signal through the ELC when an interrupt source is generated, regardless of the setting of the associated interrupt enable bit.

Note: Although alarm and periodic interrupts can still be output during Software Standby or Deep Software Standby mode, the periodic event signals for the ELC are not output.

23.6 Usage Notes

23.6.1 Register Writing during Counting

The following registers should not be written to during counting, that is, while the RCR2.START bit is 1:

- RSECCNT/BCNT0
- RMINCNT/BCNT1
- RHRCNT/BCNT2
- RDAYCNT
- RWKCNT/BCNT3
- RMONCNT
- RYRCNT
- RCR1.RTCOS
- RCR2.RTCOE
- RCR2.HR24
- RFRL

The counter should be stopped before writing to any of these registers.

23.6.2 Use of Periodic Interrupts

Figure 23.13 shows the procedure for using periodic interrupts.

The generation and period of the periodic interrupt can be changed by setting the RCR1.PES[3:0] bits. However, because the prescaler R64CNT and RSECCNT/BCNT0 are used to generate interrupts, the interrupt period is not guaranteed immediately after setting the RCR1.PES[3:0] bits.

In addition, any of the following operation can affect the interrupt period:

- Stopping/restarting or resetting counter operation
- Reset by RTC software
- 30-second adjustment by changing the RCR2 value

When the time error adjustment function is used, the interrupt generation period after adjustment is added or subtracted based on the adjustment value.

通过设置RCR1.PES[3:0，以从1256、1128、164、132、116、18、14、12、1和2秒中选择的间隔输出周期性事件信号]位。

不保证选择事件生成后的事件生成周期。

Note: 如果使用来自RTC的事件链接，请仅在设置RTC后设置ELC，例如初始化和时间设置。在ELC之后设置RTC会导致意外事件信号的输出。

23.5.1 中断处理和事件链接

RTC有一个位来启用或禁用周期性中断。当相关使能位使能时产生中断源时，将向CPU输出中断请求信号。

相反，当产生中断源时，事件链接输出信号作为事件信号通过ELC发送到其他模块，而不管相关中断使能位的设置如何。

Note: 尽管在软件待机或深度软件待机模式下仍可输出警报和周期性中断，但不会输出ELC的周期性事件信号。

23.6 使用说明

23.6.1 计数期间的寄存器写入

计数期间不应写入以下寄存器，即RCR2.START位为1时：

- RSECCNT/BCNT0
- RMINCNT/BCNT1
- RHRCNT/BCNT2
- RDAYCNT
- RWKCNT/BCNT3
- RMONCNT
- RYRCNT
- RCR1.RTCOS
- RCR2.RTCOE
- RCR2.HR24
- RFRL

在写入任何这些寄存器之前，应停止计数器。

23.6.2 使用周期性中断

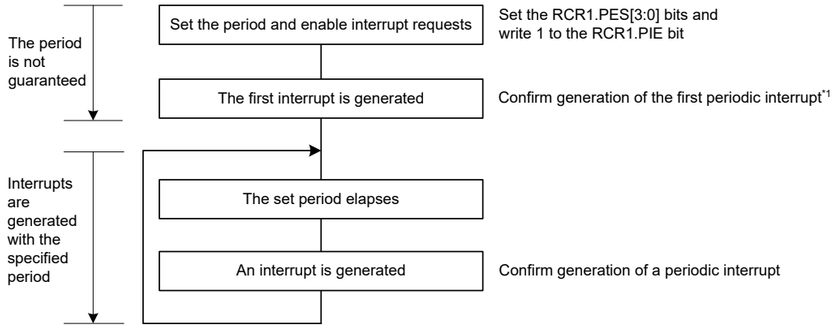
图23.13显示了使用周期性中断的过程。

可以通过设置RCR1.PES[3:0]位来更改周期性中断的产生和周期。但是，因为预分频器R64CNT和RSECCNTBCNT0用于产生中断，所以在设置RCR1.PES[3:0]位后不能立即保证中断周期。

此外，以下任何操作都会影响中断周期：

- ●停止重新启动或重置计数器操作
- ●RTC软件复位
- ●通过改变RCR2值进行30秒调整

使用时间误差调整功能时，根据调整值加减调整后的中断产生周期。



Note 1. When an interrupt generation period changes while the periodic interrupt is used, an interrupt might be generated at the completion of the setting. If the interrupt is generated immediately after the setting, the period is not guaranteed for two interrupts including the current interrupt.

Figure 23.13 Using the periodic interrupt function

23.6.3 RTCOUT (1-Hz/64-Hz) Clock Output

Stopping/restarting or resetting counter operation, reset by RTC software, and the 30-second adjustment by changing the RCR2 value affects the period of RTCOUT (1-Hz/64-Hz) output. When the time error adjustment function is used, the period of RTCOUT (1-Hz/64-Hz) output after adjustment is added or subtracted based on the adjustment value.

23.6.4 Transitions to Low Power Modes after Setting Registers

A transition to a low power state (Software Standby mode, Deep Software Standby mode, or battery backup state) during a write to an RTC register might corrupt the value of the register. After setting the register, confirm that the setting is in place before initiating a transition to a low power state.

23.6.5 Notes on Writing to and Reading from Registers

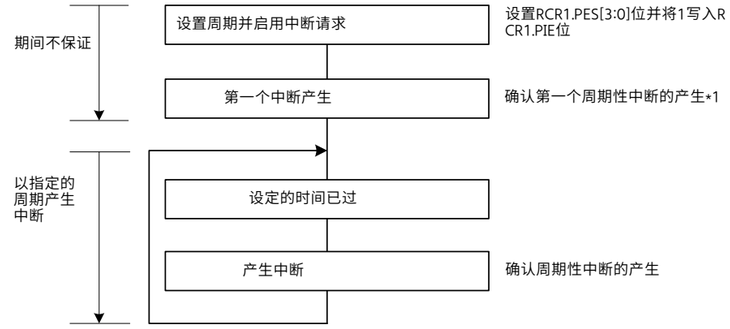
- When reading a counter register such as the second counter after writing to the counter register, follow the procedure in section 23.3.5. Reading 64-Hz Counter and Time.
- The value written to the count registers, alarm registers, year alarm enable register, bits RCR2.AADJE, AADJP, and HR24, RCR4 register, or frequency register is reflected when fourth read operations are performed after writing.
- The values written to the RCR1.CIE, RCR1.RTCOS, and RCR2.RTCOE bits can be read immediately after writing.
- To read the value from the timer counter after returning from a reset or a period in Software Standby mode, Deep Software Standby mode, or battery backup state, wait for 1/128 second while the clock is operating (RCR2.START bit = 1).
- After a reset is generated, write to the RTC register after 6 cycles of the count source clock have elapsed.

23.6.6 Changing the Count Mode

When changing the count mode (calendar count mode/binary count mode), set the RCR2.START bit to 0, stop the counting operation, then start it again from the initial setting. For details on the initial setting, see section 23.3.1. Outline of Initial Settings of Registers after Power On.

23.6.7 Initialization Procedure When the RTC Is Not to Be Used

Registers in the RTC are not initialized by a reset. Depending on the initial state, the generation of an unintentional interrupt request or operation of the counter might lead to increased power consumption.



注1.当使用周期性中断时中断产生周期发生变化时，可能会在设置完成时产生中断。如果设置后立即产生中断，则不能保证包括当前中断在内的两次中断的周期。

Figure 23.13 使用周期性中断功能

23.6.3 RTCOUT(1-Hz64-Hz)时钟输出

停止重新启动或重置计数器操作，通过RTC软件重置，并通过更改30秒调整RCR2值影响RTCOUT(1-Hz64-Hz)输出的周期。使用时间误差调整功能时，调整后的RTCOUT（1-Hz64-Hz）输出的周期根据调整值加减。

23.6.4 设置寄存器后转换到低功耗模式

在写入RTC寄存器期间转换到低功耗状态（软件待机模式、深度软件待机模式或电池备份状态）可能会损坏寄存器的值。设置寄存器后，在开始转换到低功耗状态之前确认设置到位。

23.6.5 关于写入和读取寄存器的注意事项

●在写入计数器寄存器后读取第二个计数器等计数器寄存器时，请按照第23.3.5节。读取64-Hz计数器和时间。

●写入计数寄存器、报警寄存器、年报警使能寄存器、RCR2.AADJE、AADJP位和HR24、RCR4寄存器或频率寄存器的值在写入后执行第四次读操作时反映。

●写入RCR1.CIE、RCR1.RTCOS和RCR2.RTCOE位的值可在写入后立即读取。

●要在软件待机模式下从复位或一段时间返回后从定时器计数器读取值，Deep软件待机模式或电池备份状态在时钟运行时等待1128秒（RCR2.START位=1）。

●产生复位后，经过6个计数源时钟周期后写入RTC寄存器。

23.6.6 更改计数模式

当改变计数模式（日历计数模式二进制计数模式）时，将RCR2.START位设置为0，停止计数操作，然后从初始设置重新开始。有关初始设置的详细信息，请参阅第23.3.1节。上电后寄存器的初始设置概要。

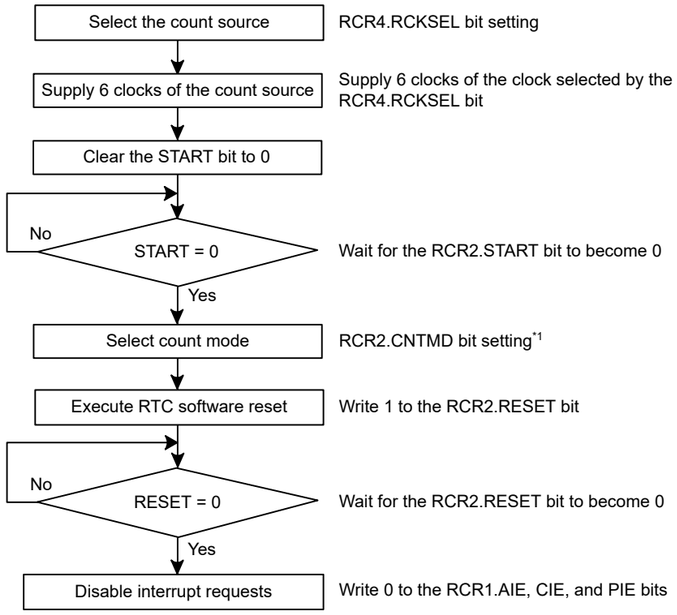
23.6.7 不使用RTC时的初始化程序

RTC中的寄存器不会因复位而初始化。根据初始状态，意外中断请求的生成或计数器的操作可能会导致功耗增加。

For applications that do not require a realtime clock, initialize the registers by following the initialization procedure shown in Figure 23.14.

Alternatively, when the sub-clock oscillator is not used as the system clock or realtime clock, the counter can be stopped by writing 0 (sub-clock oscillator is selected) to the RCR4.RCKSEL bit and stopping the sub-clock oscillator. To stop the sub-clock oscillator, write 1 to the SOSCCR.SOSTP bit.

For details on the setting of the SOSCCR.SOSTP bit, see section 8, Clock Generation Circuit.



Note 1. This step is not necessary if the count mode is concurrently set by setting the START bit to 0.

Figure 23.14 Initialization procedure

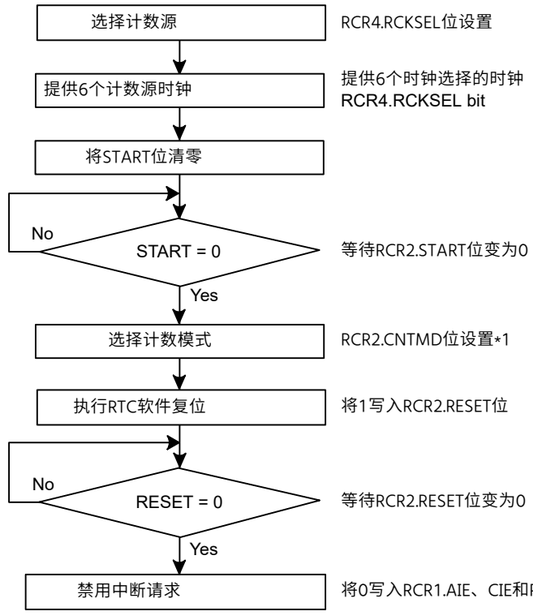
23.6.8 When Switching Source Clock

When switching a clock source by changing SCKSCR.CKSEL[2:0], the clock output from the selector stops for 4 cycles of the switched clock. If the RTC periodical interrupt or RTC periodical event output was generated at this time, the interrupt or event is invalid.

对于不需要实时时钟的应用程序，按照图23.14所示的初始化过程初始化寄存器。

或者，当副时钟振荡器不用作系统时钟或实时时钟时，可以通过向RCR4.RCKSEL位写入0（选择副时钟振荡器）并停止副时钟振荡器来停止计数器。要停止副时钟振荡器，向SOSCCR.SOSTP位写入1。

有关SOSCCR.SOSTP位设置的详细信息，请参见第8节，时钟生成电路。



注1.如果通过将START位设置为0同时设置计数模式，则不需要此步骤。

Figure 23.14 初始化程序

23.6.8 切换源时钟时

当通过改变SCKSCR.CKSEL[2:0]来切换时钟源时，选择器的时钟输出在切换时钟的4个周期内停止。如果此时产生了RTC周期性中断或RTC周期性事件输出，则该中断或事件无效。

24. Watchdog Timer (WDT)

24.2 Register Descriptions

24.2.1 WDTRR : WDT Refresh Register

Base address: WDT = 0x4008_3400

Offset address: 0x00

Bit position:	7							0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

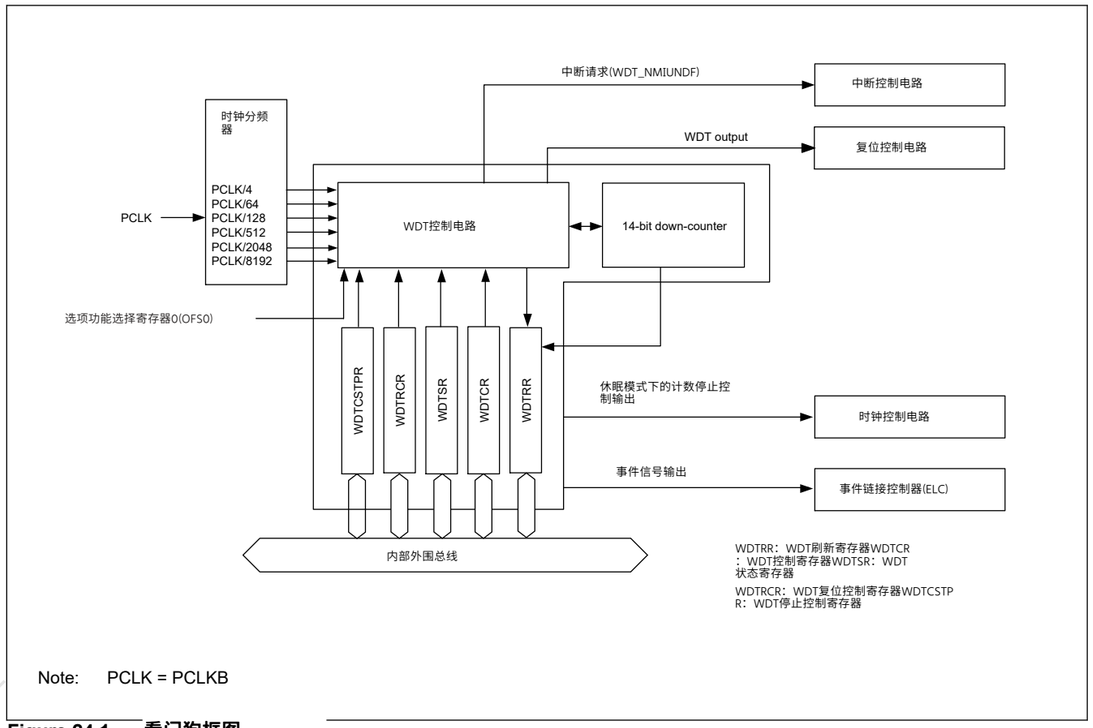
Bit	Symbol	Function	R/W
7:0	n/a	The down-counter is refreshed by writing 0x00 and then writing 0xFF to this register.	R/W

The WDTRR register refreshes the down-counter of the WDT.

The down-counter of the WDT is refreshed by writing 0x00 and then writing 0xFF to WDTRR register (refresh operation) within the refresh-permitted period.

After the down-counter is refreshed, it starts counting down from the value selected by setting the WDT Timeout Period Select bits (OFS0.WDTTOPS[1:0]) in the Option Function Select Register 0 in auto start mode. In register start mode, counting down starts from the value selected by setting the Timeout Period Select bits (WDTCR.TOPS[1:0]) in the WDT Control Register.

When 0x00 is written, the read value is 0x00. When a value other than 0x00 is written, the read value is 0xFF. For details of the refresh operation, see section 24.3.3. Refresh Operation.



Note: PCLK = PCLKB

WDTRR寄存器刷新WDT的递减计数器。

WDT的递减计数器通过在允许刷新期间内写入0x00然后将0xFF写入WDTRR寄存器（刷新操作）来刷新。

递减计数器刷新后，在自动启动模式下，它从通过设置选项功能选择寄存器0中的WDT超时周期选择位(OFS0.WDTTOPS[1:0])选择的值开始递减计数。在寄存器启动模式下，倒计时从通过设置WDT控制寄存器中的超时周期选择位(WDTCR.TOPS[1:0])选择的值开始。

写入0x00时，读取值为0x00。写入0x00以外的值时，读取的值为0xFF。有关刷新操作的详细信息，请参阅第24.3.3节。刷新操作。

The WDTCR register is used to set the clock division ratio, and window start and end positions for refresh, and the timeout period until the down-counter underflows in register start mode.

Some constraints apply to writes to the WDTCR register. For details, see section 24.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the settings in the WDTCR register are disabled, and the settings in the Option Function Select Register 0 (OFS0) are enabled. The settings for the WDTCR register can also be made in the OFS0 register. For details, see section 24.3.8. Association between Option Function Select Register 0 (OFS0) and WDT Registers.

TOPS[1:0] bits (Timeout Period Select)

The TOPS[1:0] bits select the timeout period, the period until the down-counter underflows, from 1024, 4096, 8192, and 16384 cycles, taking the divided clock specified in the CKS[3:0] bits as 1 cycle. After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the number of PCLKB cycles until the counter underflows.

Table 24.2 lists the relationship between the CKS[3:0] and TOPS[1:0] bit settings, the timeout period, and the number of PCLKB cycles.

WDTCR寄存器用于设置时钟分频比、刷新的窗口开始和结束位置，以及在寄存器开始模式下直到递减计数器下溢的超时时间。

一些限制适用于写入WDTCR寄存器。详见24.3.2节。控制对WDTCR的写入，WDTRCR和WDTCSTPR寄存器。

在自动启动模式下，禁用WDTCR寄存器中的设置，启用选项功能选择寄存器0(OFS0)中的设置。WDTCR寄存器的设置也可以在OFS0寄存器中进行。详见24.3.8节。选项功能选择寄存器0(OFS0)和WDT寄存器之间的关联。

TOPS[1:0]位（超时周期选择）

TOPS[1:0]位从1024、4096、8192和16384个周期中选择超时周期，即递减计数器下溢之前的周期，将CKS[3:0]位中指定的分频时钟作为1个周期.向下计数器刷新后，CKS[3:0]和TOPS[1:0]位的组合决定了PCLKB周期数，直到计数器下溢。

表24.2列出了CKS[3:0]和TOPS[1:0]位设置、超时时间和
PCLKB cycles.

	11b		16384	134217728

CKS[3:0] bits (Clock Division Ratio Select)

The CKS[3:0] bits specify the division ratio of the clock used for the down-counter. The division ratio can be selected from the PCLKB divided by 4, 64, 128, 512, 2048, and 8192. Combined with the TOPS[1:0] bit setting, this allows the WDT to be configured to a count period between 4096 and 134217728 PCLKB clock cycles.

RPES[1:0] bits (Window End Position Select)

The RPES[1:0] bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. Set the window end position to a value less than the value for the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.

RPSS[1:0] bits (Window Start Position Select)

The RPSS[1:0] bits specify the window start position that indicates the refresh-permitted period. 100%, 75%, 50%, or 25% of the timeout period can be selected for the window start position. Set the window start position to a value greater than the value for the window end position. If the window start position is set to a value less than or equal to the window end position, the window end position is set to 0%.

Table 24.3 lists the counter values for the window start and end positions, and Figure 24.2 shows the refresh-permitted period set in the RPSS[1:0], RPES[1:0], and TOPS[1:0] bits.

CKS[3:0]位（时钟分频比选择）

CKS[3:0]位指定用于递减计数器的时钟的分频比。分频比可以从PCLKB除以4、64、128、512、2048和8192中选择。结合TOPS[1:0]位设置，这允许将WDT配置为4096和134217728个PCLKB时钟周期。

RPES[1:0]位（窗口结束位置选择）

RPES[1:0]位指定指示刷新允许周期的窗口结束位置。可以为窗口结束位置选择75%、50%、25%或0%的超时时间。将窗口结束位置设置为小于窗口起始位置的值（窗口起始位置>窗口结束位置）。如果窗口结束位置大于窗口起始位置，则仅启用窗口起始位置设置。

RPSS[1:0]位（窗口起始位置选择）

RPSS[1:0]位指定指示允许刷新周期的窗口起始位置。窗口起始位置可选择100%、75%、50%或25%的超时时间。将窗口开始位置设置为大于窗口结束位置的值。如果窗口开始位置设置为小于或等于窗口结束位置的值，则窗口结束位置设置为0%。

表24.3列出了窗口开始和结束位置的计数器值，图24.2显示了在RPSS[1:0]、RPES[1:0]和TOPS[1:0]位中设置的允许刷新周期。

24.2.3 WDTSR:WDT状态寄存器

Base address: WDT = 0x4008_3400

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Symbol	Function	R/W
15	REFEF	Refresh Error Flag 0: No refresh error occurred 1: Refresh error occurred	R/W*1

Note 1. Only 0 can be written to clear the flag.

The WDTSR register indicates the counter value of the down-counter and the status of whether an underflow or refresh error occurred in the down-counter.

CNTVAL[13:0] bits (Down-Counter Value)

Read the CNTVAL[13:0] bits to confirm the value of the down-counter. The read value might differ from the actual count by 1.

UNDFF flag (Underflow Flag)

Read the UNDFF flag to confirm whether an underflow occurred in the counter. A value of 1 indicates that the down counter underflowed. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N+1) PCLKB cycles. In addition, clearing of the flag is ignored for (N+1) PCLKB cycles after an underflow. N is specified in the WDTCR.CKS[3:0] bits as follows:

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

REFEF flag (Refresh Error Flag)

Read the REFEF flag to confirm whether a refresh error occurred, indicating that a refresh operation was performed during a prohibited period. A value of 1 indicates that a refresh error occurred. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the REFEF flag takes (N+1) PCLKB cycles. In addition, clearing of the flag is ignored for (N+1) PCLKB cycles after a refresh error. N is specified in the WDTCR.CKS[3:0] bits as follows:

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64

24.3 Operation

24.3.1 Count Operation in each Start Mode

The WDT has two start modes:

- Auto start mode, in which counting automatically starts after a release from the reset state
- Register start mode, in which counting starts with a refresh by writing to the register.

In auto start mode, counting automatically starts after a release from the reset state according to the settings in the Option Function Select register 0 (OFS0) in the flash.

In register start mode, counting starts with a refresh by writing to the WDTRR register after the respective registers are set after a release from the reset state.

在自动启动模式下，WDTRCR寄存器设置被禁用，而选项功能选择寄存器0(OFS0)中的设置被启用。WDTRCR寄存器的设置也可以对OFS0寄存器进行。详见24.3.8节。选项功能选择寄存器0(OFS0)和WDT寄存器之间的关联。

24.3 Operation

24.3.1 每种启动模式下的计数操作

WDT有两种启动模式：

●自动启动模式，从复位状态释放后自动开始计数

●寄存器启动模式，通过写入寄存器，从刷新开始计数。

在自动启动模式下，根据选项中的设置从复位状态释放后自动开始计数
功能选择闪存中的寄存器0(OFS0)。

在寄存器启动模式下，在从复位状态释放后，在设置各个寄存器后，通过写入WDTRR寄存器，从刷新开始计数。

Select auto start mode or register start mode by setting the WDT Start Mode Select bit (OFS0.WDTSTRT) in the OFS0 register.

When the auto start mode is selected, the settings in the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are disabled while the settings in the OFS0 register are enabled.

When the register start mode is selected, the setting for the OFS0 register is disabled while the settings for the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are enabled.

24.3.1.1 Register start mode

When the WDT Start Mode Select bit (OFS0.WDTSTRT) is 1, register start mode is selected and the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are enabled.

After the reset state is released, set the following to Sleep mode in the WDTCSTPR register:

- Clock division ratio
- Window start and end positions
- Timeout period in the WDTCR register
- Reset output or interrupt request output in the WDTRCR register
- Counter stop control during transitions to Sleep mode in the WDTCSTPR register

Refresh the down-counter to start counting down from the value set in the Timeout Period Selection bits (WDTCR.TOPS[1:0]).

Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and counting down continues. The WDT does not output the reset signal as long as counting continues. However, if the down-counter underflows because the down-counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the WDT outputs the reset signal or a non-maskable interrupt request/interrupt request (WDT_NMIUNDF). Reset output or interrupt request output can be selected in the WDT Reset Interrupt Request Select bit (WDTRCR.RSTIRQS). Non-maskable interrupt requests or interrupt requests can be selected in the WDT Underflow/Refresh Error Interrupt Enable bit (NMIER.WDTEN).

Figure 24.3 shows an example of operation under the following conditions:

- Register start mode (OFS0.WDTSTRT = 1)
- Reset output is enabled (WDTRCR.RSTIRQS = 1)
- The window start position is 75% (WDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (WDTCR.RPES[1:0] = 10b)

通过设置OFS0寄存器中的WDT启动模式选择位(OFS0.WDTSTRT)来选择自动启动模式或寄存器启动模式。

选择自动启动模式后，WDT控制寄存器（WDTCR）中的设置，WDTRESET控制寄存器（WDTRCR）和WDT计数停止控制寄存器（WDTCSTPR）在启用OFS0寄存器中的设置时被禁用。

选择寄存器启动模式时，在WDT控件的设置时禁用OFS0寄存器的设置
使能寄存器(WDTCR)、WDT复位控制寄存器(WDTRCR)和WDT计数停止控制寄存器(WDTCSTPR)。

24.3.1.1 注册启动模式

当WDT启动模式选择位(OFS0.WDTSTRT)为1时，选择寄存器启动模式并启用WDT控制寄存器(WDTCR)、WDT复位控制寄存器(WDTRCR)和WDT计数停止控制寄存器(WDTCSTPR)。

释放复位状态后，在WDTCSTPR寄存器中将以下内容设置为休眠模式：

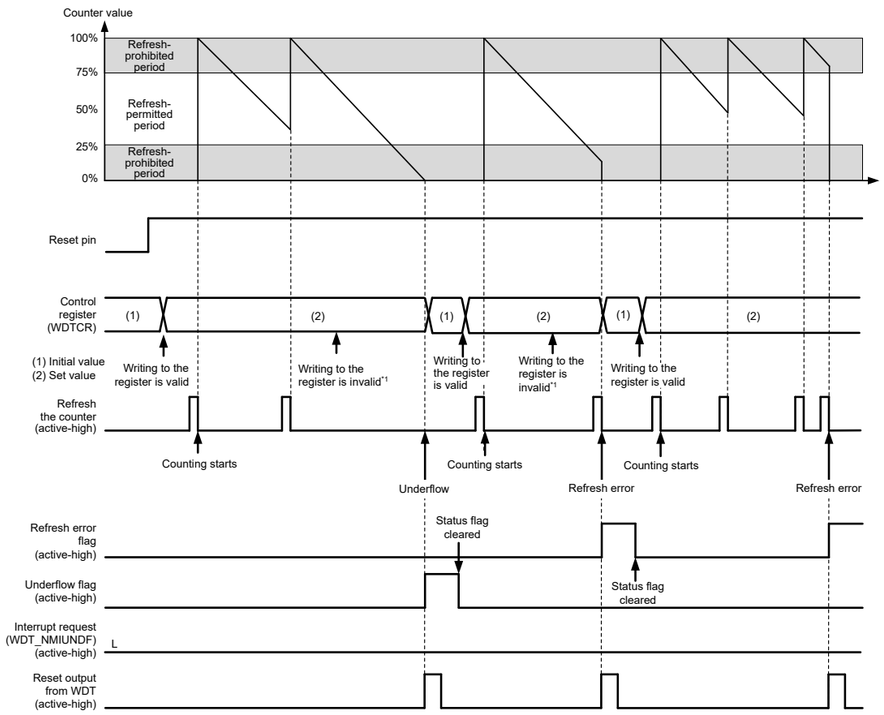
- ●时钟分频比
- ●窗口开始和结束位置
- ●WDTCR寄存器中的超时时间
- ●WDTRCR寄存器中的复位输出或中断请求输出
- ●WDTCSTPR寄存器中转换到休眠模式期间的计数器停止控制

刷新递减计数器以从超时周期选择位(WDTCR.TOPS[1:0])中设置的值开始递减计数。

此后，只要在可刷新期间刷新计数器，每次刷新计数器时，计数器中的值都会被重置，并继续递减计数。只要继续计数，WDT就不会输出复位信号。但是，如果由于程序失控导致递减计数器无法刷新而导致递减计数器下溢，或者由于计数器在刷新允许时间之外刷新而发生刷新错误，则WDT输出复位信号或非可屏蔽中断请求中断请求(WDT_NMIUNDF)。可以在WDT复位中断请求选择位(WDTRCR.RSTIRQS)中选择复位输出或中断请求输出。可以在WDT下溢刷新错误中断 允许位(NMIER.WDTEN)中选择不可屏蔽的中断请求或中断请求。

图24.3显示了以下条件下的操作示例：

- ●寄存器启动模式（OFS0.WDSTSTRT=1）
- ●启用复位输出(WDTRCR.RSTIRQS=1)
- ●窗口起始位置为75%(WDTCR.RPSS[1:0]=10b)
- ●窗口结束位置为25%(WDTCR.RPES[1:0]=10b)



Note: See section 24.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

Figure 24.3 Operation example in register start mode

24.3.1.2 Auto start mode

When the WDT Start Mode Select bit (OFS0.WDTSTRT) in the Option Function Select Register 0 (OFS0) is 0, auto start mode is selected, the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are disabled, and the settings in the OFS0 register are enabled.

Within the reset state, the setting values for the following in the Option Function Select Register 0 (OFS0) are set in the WDT registers:

- Clock division ratio
- Window start and end positions
- Timeout period
- Reset output or interrupt request
- Counter stop control during transition to Sleep mode

When the reset state is released, the down-counter automatically starts counting down from the value set in the WDT Timeout Period Select bits (OFS0.WDTTOPS[1:0]).

Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and counting down continues. The WDT does not output the reset signal as long as the counting continues. However, if the down-counter underflows because refreshing of the down-counter is not possible due to a

Figure 24.3 寄存器启动模式下的操作示例

24.3.1.2 自动启动模式

当WDT启动模式选择位置（OFS0.WDTSTSTRT）中的选项功能选择寄存器0（OFS0）为0时，选择了自动启动模式，WDT控制寄存器（WDTCR）（WDTCR），WDTRESETRESETCONTROMCONTROL寄存器（WDTRCR）和WDTCountCountCountCountCount停止控制寄存器(WDTCSTPR)被禁用，而OFS0寄存器中的设置被启用。

在复位状态下，选项功能选择寄存器0(OFS0)中的以下设置值在
WDT registers:

- ●时钟分频比
- ●窗口开始和结束位置
- ●超时时间
- ●复位输出或中断请求
- ●转换到睡眠模式期间的计数器停止控制

超时周期选择位(OFS0.WDTTOPS[1:0])。

此后，只要在可刷新期间刷新计数器，每次刷新计数器时，计数器中的值都会被重置，并继续递减计数。只要继续计数，WDT就不会输出复位信号。但是，如果递减计数器下溢，因为递减计数器的刷新是不可能的，因为

runaway program or if a refresh error occurs due to refreshing outside the refresh-permitted period, the WDT outputs the reset signal or non-maskable interrupt request/interrupt request (WDT_NMIUNDF).

After the reset signal or non-maskable interrupt request/interrupt request is generated, the counter reloads the timeout period after counting for 1 cycle. The value of the timeout period is set in the down-counter and counting restarts.

Reset output or interrupt request output can be selected by setting the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS). Non-maskable interrupt request or interrupt request can be selected in the WDT Underflow/ Refresh Error Interrupt Enable bit (NMIER.WDTEN).

Figure 24.4 shows an example of operation (non-maskable interrupt) under the following conditions:

- Auto start mode (OFS0.WDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.WDTRSTIRQS = 0)
- The window start position is 75% (OFS0.WDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.WDTRPES[1:0] = 10b)

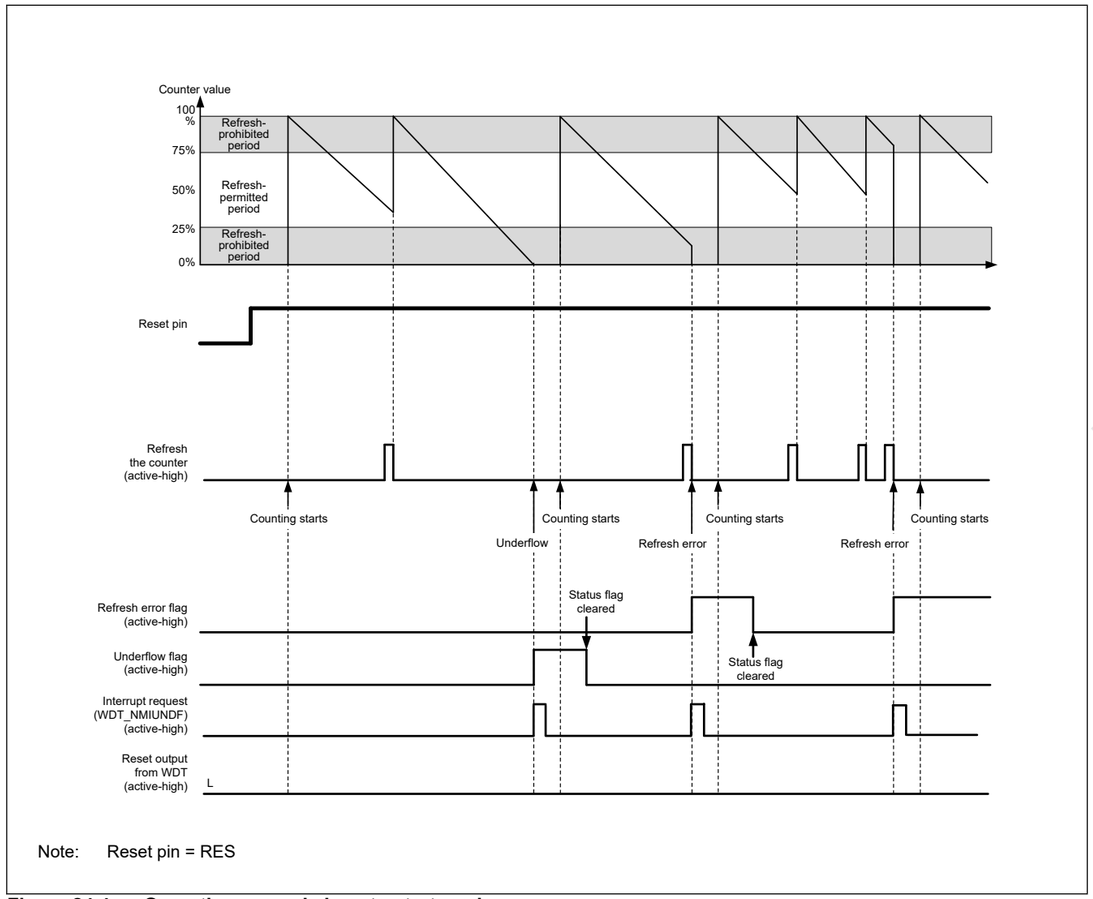

Figure 24.4 Operation example in auto start mode

24.3.2 Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers

Writing to the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), or WDT Count Stop Control Register (WDTCSTPR) is possible once between the release from the reset state and the first refresh operation.

如果程序失控或由于刷新允许刷新期间之外发生刷新错误，则WDT输出复位信号或不可屏蔽中断请求中断请求(WDT_NMIUNDF)。

复位信号或不可屏蔽中断请求中断请求产生后，计数器在计数1个周期后重新加载超时周期。超时时间的值在递减计数器中设置并重新开始计数。

通过设置WDT复位中断请求选择位(OFS0.WDTRSTIRQS)可以选择复位输出或中断请求输出。可以在WDT下溢刷新错误中断 允许位(NMIER.WDTEN)中选择不可屏蔽的中断请求或中断请求。

图24.4显示了以下条件下的操作示例（不可屏蔽中断）：

- ●自动启动模式（OFS0.WDTSTRT=0）
- ●使能不可屏蔽中断请求输出（OFS0.WDTRSTIRQS=0）
- ●窗口起始位置为75%(OFS0.WDTRPSS[1:0]=10b)
- ●窗口结束位置为25%(OFS0.WDTRPES[1:0]=10b)

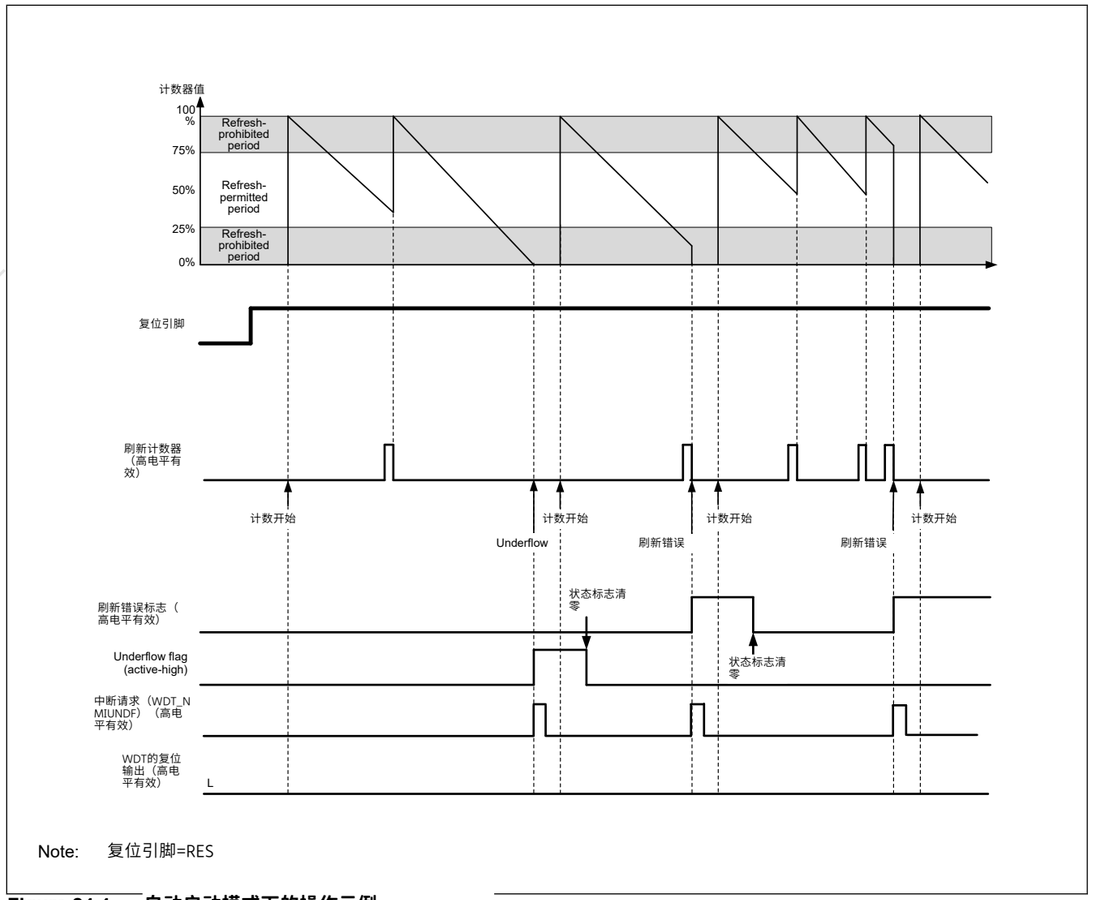

Figure 24.4 自动启动模式下的操作示例

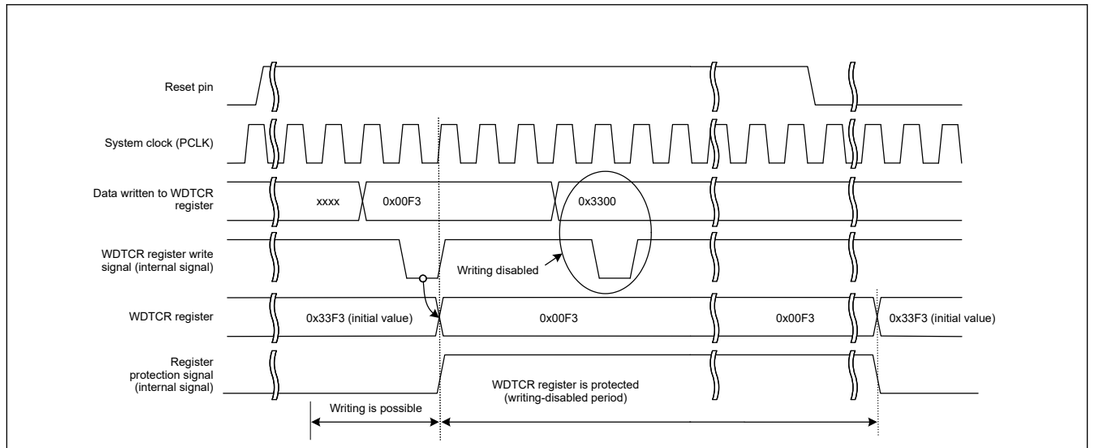
24.3.2 控制对WDTCR、WDTRCR和WDTCSTPR寄存器的写入

写入WDT控制寄存器(WDTCR)、WDT复位控制寄存器(WDTRCR)或WDT计数停止控制在从复位状态释放到第一次刷新操作之间，寄存器(WDTCSTPR)是可能的。

After a refresh (counting starts) or a write to WDTCR, WDTRCR or WDTCSTPR register, the protection signal in the WDT becomes 1 to protect WDTCR, WDTRCR and WDTCSTPR register against subsequent write attempts. This protection is released by the reset source of the WDT. With other reset sources, the protection is not released.

Figure 24.5 shows control waveforms produced in response to writing to the WDTCR.



Note: PCLK = PCLKB
Reset pin = RES

Figure 24.5 Control waveforms produced in response to writes to the WDTCR register

24.3.3 Refresh Operation

The down-counter is refreshed and starts counting operation on a write of the values 0x00 and 0xFF to the WDT Refresh Register (WDTRR). If a value other than 0xFF is written after 0x00, the down-counter is not refreshed. If an invalid value is written, correct refreshing resumes on a write of 0x00 and 0xFF to the WDTRR register.

Correct refreshing is also performed when a register other than WDTRR is accessed or WDTRR is read between writing 0x00 and writing 0xFF to WDTRR. Writes to refresh the counter must be made within the refresh-permitted period, and this is determined by the 0xFF write. For this reason, correct refreshing is performed even when 0x00 is written outside the refresh-permitted period.

[Example write sequences that are valid for refreshing the counter]

- 0x00 → 0xFF
- 0x00 ((n–1)th time) → 0x00 (nth time) → 0xFF
- 0x00 → access to another register or read from WDTRR → 0xFF

[Example write sequences that are invalid for refreshing the counter]

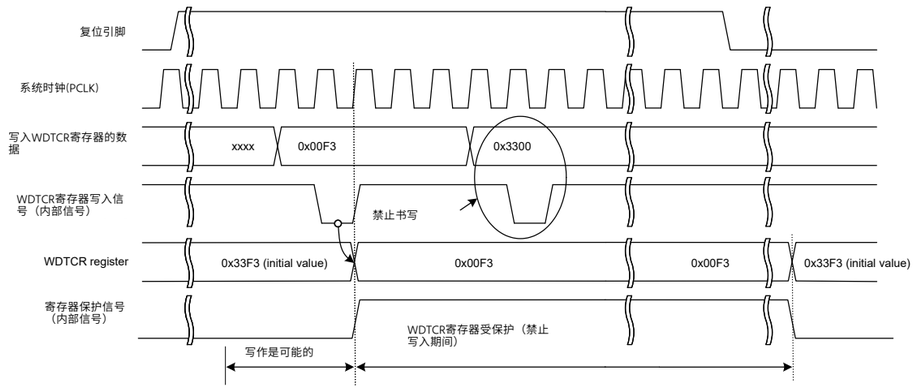
- 0x23 (a value other than 0x00) → 0xFF
- 0x00 → 0x54 (a value other than 0xFF)
- 0x00 → 0xAA (0x00 and a value other than 0xFF) → 0xFF

After 0xFF is written to the WDT Refresh Register (WDTRR), refreshing the down-counter requires up to 4 cycles of the signal for counting. To meet this requirement, complete writing 0xFF to WDTRR 4 count cycles before the down-counter underflows.

Figure 24.6 shows the WDT refresh-operation waveforms when the clock division ratio is PCLKB/64.

在刷新（计数开始）或写入WDTCR、WDTRCR或WDTCSTPR寄存器后，
WDT变为1以保护WDTCR、WDTRCR和WDTCSTPR寄存器免受后续写入尝试。该保护由WDT的复位源解除。使用其他复位源时，不会解除保护。

图24.5显示了响应写入WDTCR产生的控制波形。



Note: PCLK=PCLKB复位引脚=RES

Figure 24.5 响应写入WDTCR寄存器而产生的控制波形

24.3.3 刷新操作

向下计数器刷新并在将值0x00和0xFF写入WDT刷新时开始计数操作
寄存器(WDTRR)。如果在0x00之后写入0xFF以外的值，则不刷新递减计数器。如果写入无效值，则在向WDTRR寄存器写入0x00和0xFF时会恢复正确刷新。

在写入0x00和写入0xFF到WDTRR之间访问WDTRR以外的寄存器或读取WDTRR时，也会执行正确刷新。刷新计数器的写入必须在允许刷新的周期内进行，这由0xFF写入决定。因此，即使在可刷新期间外写入0x00，也会执行正确的刷新。

[对刷新计数器有效的示例写入序列]

- 0x00 → 0xFF
- 0x00 ((n–1)th time) → 0x00 (nth time) → 0xFF
- ●0x00→访问另一个寄存器或从WDTRR读取→0xFF

[对刷新计数器无效的示例写入序列]

- ●0x23（0x00以外的值）→0xFF
- ●0x00→0x54（0xFF以外的值）
- ●0x00→0xAA（0x00和0xFF以外的值）→0xFF

将0xFF写入WDT刷新寄存器(WDTRR)后，刷新递减计数器最多需要4个信号周期进行计数。为满足此要求，请在递减计数器下溢之前的4个计数周期内将0xFF写入WDTRR。

图24.6显示了时钟分频比为PCLKB64时的WDT刷新操作波形。

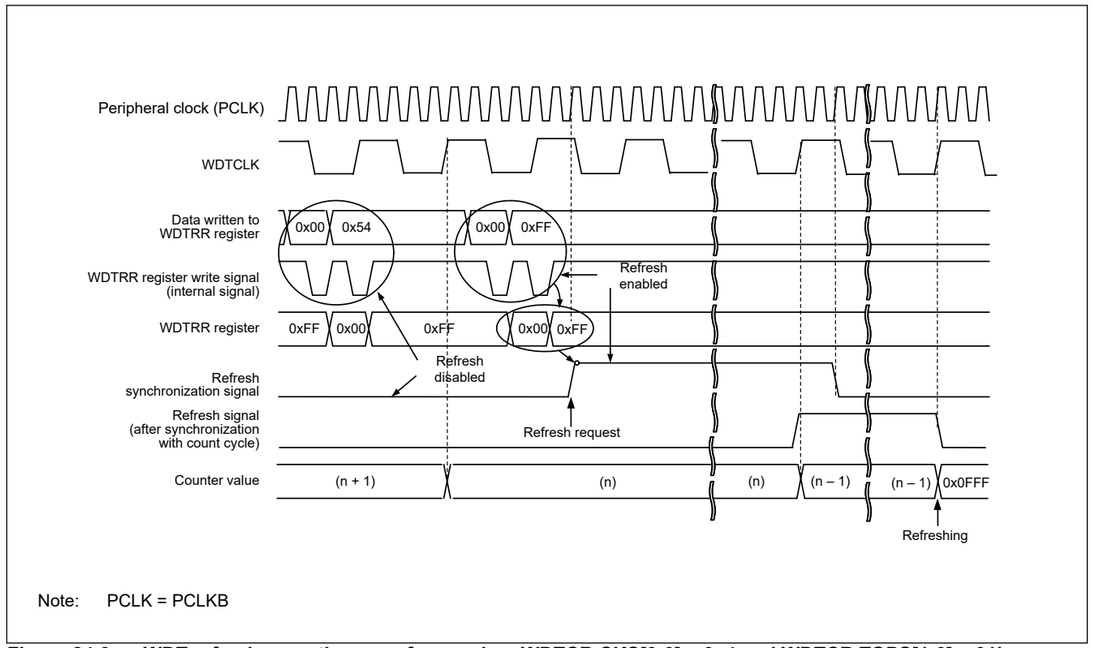


Figure 24.6 WDT refresh operation waveforms when WDTCR.CKS[3:0] = 0x4 and WDTCR.TOPS[1:0] = 01b

Note: When setting the refresh time, consider the oscillation accuracy of the clock sources of the PCLKB and WDTCLK. Set values which ensure that refreshing is possible even when the frequency varies in the range of error of the oscillation accuracy.

24.3.4 Status Flags

The refresh error (WDTSR.REFEF) and underflow (WDTSR.UNDFF) flags retain the source of the interrupt request from the WDT. After a release from the interrupt request generation, read the WDTSR.REFEF and WDTSR.UNDFF flags to check for the interrupt source. For each flag, writing 0 clears the bit. Writing 1 has no effect. Leaving the status flags unchanged does not affect operation. If the flags are not cleared at the next interrupt request from the WDT, the earlier interrupt source is cleared and the new interrupt source is written. For the time period between when 0 is written in each flag and when its value is reflected, see section 24.2.3. WDTSR : WDT Status Register.

24.3.5 Reset Output

When the Reset Interrupt Select bit (WDTRCR.RSTIRQS) is set to 1 in register start mode, or when the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 1 in auto start mode, a reset signal is output for 1 cycle count when an underflow in the down-counter or a refresh error occurs.

In register start mode, the down-counter is initialized (all bits set to 0) and stopped in that state after output of a reset signal. After the reset state is released and the program is restarted, the counter is set up again and counting down starts again with a refresh. In auto start mode, counting down starts automatically after the reset state is released.

24.3.6 Interrupt Sources

When the Reset Interrupt Select bit (WDTRCR.RSTIRQS) is set to 0 in register start mode or when the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 0 in auto start mode, an interrupt (WDT_NMIUNDF) signal is generated when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or an interrupt. For details, see section 13, Interrupt Controller Unit (ICU).

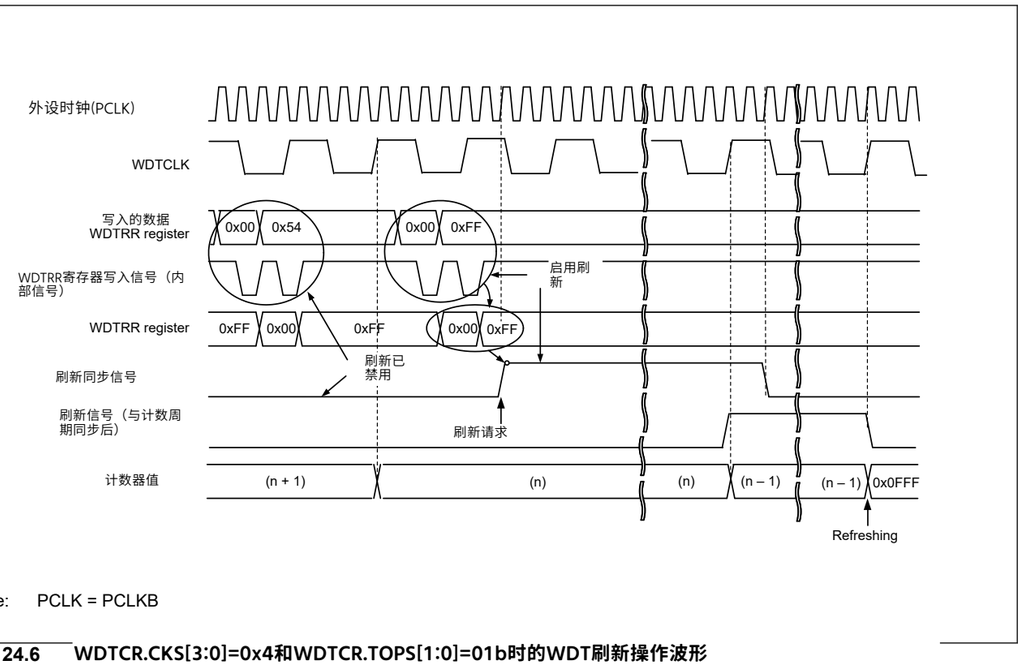

Figure 24.6 WDTCR.CKS[3:0]=0x4和WDTCR.TOPS[1:0]=01b时的WDT刷新操作波形

Note: 设置刷新时间时，要考虑PCLKB和WDTCLK时钟源的振荡精度。
设定即使频率在振荡精度的误差范围内变化也能进行刷新的值。

24.3.4 状态标志

刷新错误(WDTSR.REFEF)和下溢(WDTSR.UNDFF)标志保留来自WDT的中断请求源。释放中断请求生成后，读取WDTSR.REFEF和WDTSR.UNDFF标志以检查中断源。对于每个标志，写入0会清除该位。写1无效。保持状态标志不变不会影响操作。如果在WDT发出下一个中断请求时未清除标志，则清除较早的中断源并写入新的中断源。关于从各标志写入0到反映其值的时间段，请参阅第24.2.3节。WDTSR：WDT状态寄存器。

24.3.5 复位输出

当复位中断选择位(WDTRCR.RSTIRQS)在寄存器启动模式下设置为1时，或当WDT复位时
在自动启动模式下，选项功能选择寄存器0(OFS0)中的中断请求选择位(OFS0.WDTRSTIRQS)设置为1，当递减计数器中的下溢或刷新错误发生时，在1个周期计数内输出复位信号.

在寄存器启动模式下，递减计数器被初始化（所有位设置为0）并在输出复位信号后停止在该状态。复位状态解除并重新启动程序后，再次设置计数器，并通过刷新再次开始倒计时。在自动启动模式下，复位状态解除后自动开始倒计时。

24.3.6 中断源

当在寄存器启动模式下复位中断选择位(WDTRCR.RSTIRQS)设置为0或WDT复位时
在自动启动模式下，选项功能选择寄存器0(OFS0)中的中断请求选择位(OFS0.WDTRSTIRQS)设置为0，当计数器下溢或发生刷新错误时，将产生中断(WDT_NMIUNDF)信号。此中断可用作不可屏蔽中断或中断。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

24.3.7 Reading the Down-Counter Value

The WDT stores the counter value in the down-counter value bits (WDTSR.CNTVAL[13:0]) of the WDT Status Register. Check these bits to obtain the counter value. The read value of the down-counter might differ from the actual count by one.

Figure 24.7 shows the processing for reading the WDT down-counter value when the clock division ratio is PCLKB/64.

24.3.8 Association between Option Function Select Register 0 (OFS0) and WDT Registers

Table 24.5 lists the association between the Option Function Select Register 0 (OFS0) used in auto start mode, and the registers used in register start mode. For details on the Option Function Select Register 0 (OFS0), see section 6.2.1. OFS0 : Option Function Select Register 0.

WDT将计数器值存储在WDT状态寄存器的递减计数器值位(WDTSR.CNTVAL[13:0])中。检查这些位以获得计数器值。递减计数器的读取值可能与实际计数相差1。

图24.7显示了在时钟分频比为PCLKB64时读取WDT递减计数器值的处理。

24.4 Output to the Event Link Controller (ELC)

The WDT is capable of a link operation for the previously specified module when interrupt request signal is used as an event signal by the ELC. The event signal is output by the counter underflow and refresh error. An event signal is output regardless of the setting of the Reset Interrupt Request Select bit (WDTRCR.RSTIRQS) in register start mode or auto start mode. An event signal can also be output when the next interrupt source is generated while the Refresh Error flag (WDTSR.REFEF) or Underflow flag (WDTSR.UNDFF) is 1. For details, see section 18, Event Link Controller (ELC).

24.5 Usage Notes

24.5.1 ICU Event Link Setting Register n (IELSRn) Setting

Setting 0x53 to ICU Event Link Setting Register n (ICU.IELSRn) is prohibited when enabling the WDT reset assertion (OFS0.WDTRSTIRQS = 0 or WDTRCR.RSTIRQS = 0) or when enabling event link operation (ELSRn.ELS[8:0] = 0x53).

24.4 输出到事件链接控制器(ELC)

当ELC将中断请求信号用作事件信号时，WDT能够对先前指定的模块进行链接操作。事件信号由计数器下溢和刷新错误输出。在寄存器启动模式或自动启动模式下，无论复位中断请求选择位(WDTRCR.RSTIRQS)的设置如何，都会输出事件信号。当刷新错误标志(WDTSR.REFEF)或下溢标志(WDTSR.UNDFF)为1时，也可以在产生下一个中断源时输出事件信号。有关详细信息，请参阅第18节，事件链接控制器(ELC)。

24.5 使用说明

24.5.1 ICU事件链接设置寄存器n(IELSRn)设置

当启用WDT复位断言(OFS0.WDTRSTIRQS=0或WDTRCR.RSTIRQS=0)或启用事件链接操作(ELSRn.ELS[8:0])时，禁止将0x53设置为ICU事件链接设置寄存器n(ICU.IELSRn)=0x53)。

25. Independent Watchdog Timer (IWDT)

25.1 Overview

The Independent Watchdog Timer (IWDT) consists of a 14-bit down counter that must be serviced periodically to prevent counter underflow. The IWDT provides functionality to reset the MCU or to generate a non-maskable interrupt or an underflow interrupt. Because the timer operates with an independent, dedicated clock source, it is particularly useful in returning the MCU to a known state as a fail-safe mechanism when the system runs out of control. The IWDT can be triggered automatically by a reset, underflow, refresh error, or a refresh of the count value in the registers.

The IWDT functions differ from those of the WDT in the following respects:

- The divided IWDT-dedicated clock (IWDTCLK) is used as the count source (not affected by PCLKB)
- IWDT does not support register start mode

Table 25.1 lists the IWDT specifications and Figure 25.1 shows a block diagram.

Table 25.1 IWDT specifications

Parameter	Description
Count source*1	IWDT-dedicated clock (IWDTCLK)
Clock division ratio	Division by 1, 16, 32, 64, 128, or 256
Counter operation	Counting down using a 14-bit down-counter
Condition for starting the counter	• Counting automatically starts after a reset • Only secure developer can start the IWDT
Conditions for stopping the counter	• Reset (the down-counter and other registers return to their initial values) • A counter underflows or a refresh error is generated (counting restarts automatically).
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods)
Reset output sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error).
Non-maskable interrupt/interrupt sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error).
Reading the counter value	The down-counter value can be read by the IWDTSR register
Event link function	• Down-counter underflow event output • Refresh error event output.
Output signal (internal signal)	• Reset output • Interrupt request output • Sleep-mode count stop control output.
Auto start mode	Configurable to the following triggers: • Clock frequency division ratio after a reset (OFS0.IWDTCKS[3:0] bits) • Timeout period of the Independent Watchdog Timer (OFS0.IWDTTOPS[1:0] bits) • Window start position in the Independent Watchdog Timer (OFS0.IWDTRPSS[1:0] bits) • Window end position in the Independent Watchdog Timer (OFS0.IWDTRPES[1:0] bits) • Reset output or interrupt request output (OFS0.IWDTRSTIRQS bit) • Down-count stop function at transition to Sleep, Snooze, or Software Standby mode (OFS0.IWDTSTPCTL bit).
TrustZone Filter	Security attribution can be set

Note 1. Satisfy the frequency of the peripheral module clock (PCLKB) ≥ 4 × (the frequency of the count clock source after division).

The bus interface and registers operate with PCLKB, and the 14-bit counter and control circuits operate with IWDTCLK.

25. 独立看门狗定时器(IWDT)

25.1 Overview

独立看门狗定时器(IWDT)包含一个14位递减计数器，必须定期对其进行服务以防止计数器下溢。IWDT提供复位MCU或生成不可屏蔽中断或下溢中断的功能。由于定时器使用独立的专用时钟源运行，因此当系统失控时，它在将MCU作为故障安全机制返回到已知状态时特别有用。IWDT可以通过复位、下溢、刷新错误或寄存器中的计数值的刷新来自动触发。

IWDT的功能与WDT的功能有以下不同：

●分频IWDT专用时钟（IWDTCLK）用作计数源（不受PCLKB影响）

●IWDT不支持寄存器启动方式

表25.1列出了IWDT规范，图25.1显示了框图。

25.2.1 IWDTRR : IWDT Refresh Register

Base address: IWDT = 0x4008_3200

Offset address: 0x00

Bit position:	7							0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	n/a	The down-counter is refreshed by writing 0x00 and then writing 0xFF to this register	R/W

The IWDTRR register refreshes the down-counter of the IWDT. The down-counter of the IWDT is refreshed by writing 0x00 and then writing 0xFF to IWDTRR (refresh operation) within the refresh-permitted period. After the down-counter is refreshed, it starts counting down from the value selected in the IWDT Timeout Period Select bits (OFS0.IWDTTOPS[1:0]) in the Option Function Select Register 0 (OFS0).

When 0x00 is written, the read value is 0x00. When a value other than 0x00 is written, the read value is 0xFF. For details of the refresh operation, see section 25.3.2. Refresh Operation.

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	REFEF	UNDFF	CNTVAL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	CNTVAL[13:0]	Down-counter Value Value counted by the down-counter	R
14	UNDFF	Underflow Flag 0: No underflow occurred 1: Underflow occurred	R/W*1
15	REFEF	Refresh Error Flag 0: No refresh error occurred 1: Refresh error occurred	R/W*1

Note 1. Only 0 can be written to clear the flag.

The IWDTSR register indicates the counter value of the down-counter and whether an underflow or refresh error occurred in the down-counter.

CNTVAL[13:0] bits (Down-counter Value)

Read the CNTVAL[13:0] bits to confirm the value of the down-counter. The read value might differ from the actual count by 1.

UNDFF flag (Underflow Flag)

Read the UNDFF flag to confirm whether an underflow occurred in the down-counter. The value 1 indicates that the down-counter underflowed. Write 0 to the UNDFF flag to set the value to 0. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N + 2) IWDTCLK cycles and 2 PCLKB cycles. In addition, clearing of this flag is ignored for (N + 2) IWDTCLK cycles after an underflow. N is specified in the IWDTCKS[3:0] bits as follows:

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128
- When OFS0.IWDTCKS[3:0] = 0x5, N = 256.

REFEF flag (Refresh Error Flag)

Read the REFEF flag to confirm whether a refresh error occurred. This indicates that a refresh operation was performed during a prohibited period. The value 1 indicates that a refresh error occurred. Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

Clearing of the REFEF flag takes (N + 2) IWDTCLK cycles and 2 PCLKB cycles. In addition, clearing of this flag is ignored for (N + 2) IWDTCLK cycles following a refresh error. N is specified in the IWDTCKS[3:0] bits as follows:

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128

25.2.2 IWDTSR:IWDT状态寄存器

Base address: IWDT = 0x4008_3200

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	REFEF	UNDFF	CNTVAL[13:0]

Bit	Symbol	Function	R/W
13:0	CNTVAL[13:0]	Down-counter Value 递减计数器计数的值	R
14	UNDFF	Underflow Flag 0：未发生下溢1：发生下溢	R/W*1
15	REFEF	刷新错误标志 0：未发生刷新错误1：发生刷新错误	R/W*1

注1.只能写入0来清除标志。

IWDTSR寄存器指示递减计数器的计数值以及递减计数器是否发生下溢或刷新错误。

CNTVAL[13:0] bits (Down-counter Value)

读取CNTVAL[13:0]位以确认递减计数器的值。读取的值可能与实际计数相差1。

UNDFF flag (Underflow Flag)

读取UNDFF标志以确认递减计数器中是否发生下溢。值1表示递减计数器下溢。将0写入UNDFF标志以将值设置为0。写入1无效。

清除UNDFF标志需要(N+2)个IWDTCLK周期和2个PCLKB周期。此外，在下溢后的(N+2)个IWDTCLK周期内，该标志的清除将被忽略。N在IWDTCKS[3:0]位中指定如下：

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128
- When OFS0.IWDTCKS[3:0] = 0x5, N = 256.

REFEF标志（刷新错误标志）

读取REFEF标志以确认是否发生刷新错误。这表示在禁止期间执行了刷新操作。值1表示发生了刷新错误。将0写入REFEF标志以将值设置为0。写入1无效。

清除REFEF标志需要(N+2)个IWDTCLK周期和2个PCLKB周期。此外，在刷新错误后的(N+2)个IWDTCLK周期内，该标志的清除将被忽略。N在IWDTCKS[3:0]位中指定如下：

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128

- When OFS0.IWDTCKS[3:0] = 0x5, N = 256.

25.2.3 OFS0 : Option Function Select Register 0

For information on the Option Function Select Register 0 (OFS0), see section 6.2.1. OFS0 : Option Function Select Register 0.

IWDTTOPS[1:0] bits (IWDT Timeout Period Select)

The IWDTTOPS[1:0] bits select the timeout period, that is, the period until the down-counter underflows, from 128, 512, 1024, or 2048 cycles, taking the divided clock specified in the IWDTCKS[3:0] bits as 1 cycle.

After the down-counter is refreshed, the combination of the IWDTCKS[3:0] and IWDTTOPS[1:0] bits determines the number of IWDTCLK cycles until the counter underflows.

Table 25.2 lists the relationship between the IWDTCKS[3:0] and IWDTTOPS[1:0] bit settings, the timeout period, and the number of IWDTCLK cycles.

Table 25.2 Timeout period settings

IWDTCKS[3:0] bits (IWDT-Dedicated Clock Frequency Division Ratio Select)

The IWDTCKS[3:0] bits specify the division ratio of the clock used for the down-counter. The division ratio can be selected from the IWDT-dedicated clock (IWDTCLK) divided by 1, 16, 32, 64, 128, and 256. Combined with the IWDTTOPS[1:0] bit setting, the IWDT can be configured to a count period between 128 and 524,288 IWDTCLK cycles.

- When OFS0.IWDTCKS[3:0] = 0x5, N = 256.

有关选项功能选择寄存器0(OFS0)的信息，请参见第6.2.1节。OFS0：选项功能选择寄存器0。

IWDTTOPS[1:0]位（IWDT超时周期选择）

IWDTTOPS[1:0]位选择超时周期，即从128、512、1024或2048个周期开始，直到递减计数器下溢的周期，采用IWDTCKS[3:0]位中指定的分频时钟作为1个周期。

向下计数器刷新后，IWDTCKS[3:0]和IWDTTOPS[1:0]位的组合决定了在计数器下溢之前的IWDTCLK周期数。

表25.2列出了IWDTCKS[3:0]和IWDTTOPS[1:0]位设置、超时周期和IWDTCLK周期数之间的关系。

IWDTCKS[3:0]位（IWDT专用时钟分频比选择）

IWDTCKS[3:0]位指定用于递减计数器的时钟分频比。分频比可以从IWDT专用时钟(IWDTCLK)除以1、16、32、64、128和256中选择。结合IWDTTOPS[1:0]位设置，可以将IWDT配置为计数128到524 288个IWDTCLK周期之间的周期。

IWDTRPES[1:0] bits (IWDT Window End Position Select)

The IWDTRPES[1:0] bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. Set the window end position to a value less than the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.

IWDTRPSS[1:0] bits (IWDT Window Start Position Select)

The IWDTRPSS[1:0] bits specify the window start position that indicates the refresh-permitted period. 100%, 75%, 50%, or 25% of the timeout period can be selected for the window start position. Set the window start position to a value greater than the window end position. If the window start position is less than or equal to the window end position, the window end position is set to 0%.

Table 25.3 lists the counter values for the window start and end positions, and Figure 25.2 shows the refresh-permitted period set in the IWDTRPSS[1:0], IWDTRPES[1:0], and IWDTTOPS[1:0] bits.

IWDTRSTIRQS bit (IWDT Reset Interrupt Request Select)

The IWDTRSTIRQS bit specifies the behavior when an underflow or a refresh error occurs. Setting 1 selects reset output. Setting 0 selects non-maskable interrupt or interrupt.

IWDTRPES[1:0]位（IWDT窗口结束位置选择）

IWDTRPES[1:0]位指定指示刷新允许周期的窗口结束位置。可以为窗口结束位置选择75%、50%、25%或0%的超时时间。将窗口结束位置设置为小于窗口开始位置的值（窗口开始位置>窗口结束位置）。如果窗口结束位置大于窗口起始位置，则仅启用窗口起始位置设置。

IWDTRPSS[1:0]位（IWDT窗口起始位置选择）

IWDTRPSS[1:0]位指定指示刷新允许周期的窗口起始位置。窗口起始位置可选择100%、75%、50%或25%的超时时间。将窗口开始位置设置为大于窗口结束位置的值。如果窗口开始位置小于或等于窗口结束位置，则窗口结束位置设置为0%。

表25.3列出了窗口开始和结束位置的计数器值，图25.2显示了在IWDTRPSS[1:0]、IWDTRPES[1:0]和IWDTTOPS[1:0]位中设置的允许刷新周期。

IWDTSTPCTL bit (IWDT Stop Control)

The IWDTSTPCTL bit selects whether to stop counting on transition to Sleep, Snooze, or Software Standby mode.

25.3 Operation

25.3.1 Auto Start Mode

When the IWDT Start Mode Select bit (OFS0.IWDTSTRT) in the Option Function Select Register 0 is 0, auto start mode is selected, otherwise the IWDT is disabled.

Within the reset state, the setting values for the following in the Option Function Select Register 0 (OFS0) are set in the IWDT registers:

- Clock division ratio (OFS0.IWDTCKS[3:0])
- Window start and end positions (OFS0.IWDTRPSS[1:0], OFS0.IWDTRPES[1:0])
- Timeout period (OFS0.IWDTTOPS[1:0])
- Reset output or interrupt request (OFS0.IWDTRSTIRQS)

When the reset state is released, the counter automatically starts counting down from the value selected in the IWDT Timeout Period Select bits (OFS0.IWDTTOPS[1:0]).

After that, as long as the program continues normal operation and the counter is refreshed within the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and down-counting continues. The IWDT does not output the reset signal as long as this procedure continues. However, if the counter underflows because the program crashed or because a refresh error occurred when an attempt is made to refresh outside the refresh-permitted period, the IWDT asserts the reset signal or non-maskable interrupt request/interrupt request (IWDT_NMIUNDF).

After the reset signal or non-maskable interrupt request/interrupt request is generated, the counter reloads the timeout period after counting for 1 cycle, the value of the timeout period is set in the down-counter and counting starts. The reset output or interrupt request output can be selected with the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS). Non-maskable interrupt request or interrupt request can be selected with the IWDT Underflow/Refresh Error Interrupt Enable bit (NMIER.IWDTEN).

Figure 25.3 shows an example of operation under the following conditions:

- Auto start mode (OFS0.IWDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.IWDTRSTIRQS = 0)
- The window start position is 75% (OFS0.IWDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.IWDTRPES[1:0] = 10b).

IWDTSTPCTL位（IWDT停止控制）

IWDTSTPCTL位选择在转换到休眠、贪睡或软件待机模式时是否停止计数。

25.3 Operation

25.3.1 自动启动模式

当IWDT启动模式选择位置（OFS0.IWDTSTRT）中的选项函数选择寄存器0为0时，选择了自动启动模式，否则IWDT将被禁用。

在复位状态下，选项功能选择寄存器0(OFS0)中的以下设置值在
IWDT registers:

- ●时钟分频比（OFS0.IWDTCKS[3:0]）
- ●窗口开始和结束位置（OFS0.IWDTRPSS[1:0]、OFS0.IWDTRPES[1:0]）
- ●超时周期（OFS0.IWDTOPS[1:0]）
- ●复位输出或中断请求（OFS0.IWDTRSTIRQS）

解除复位状态后，计数器自动从IWDT中选择的值开始倒计时
超时周期选择位(OFS0.IWDTOPS[1:0])。

之后，只要程序继续正常运行，并且在允许刷新的时间内刷新计数器，每次刷新计数器并继续递减计数时，计数器中的值都会被复位。只要此过程继续，IWDT就不会输出复位信号。但是，如果由于程序崩溃或在刷新允许周期之外尝试刷新时发生刷新错误而导致计数器下溢，则IWDT将置位复位信号或不可屏蔽中断请求中断请求(IWDT_NMIUNDF)。

在产生复位信号或不可屏蔽中断请求中断请求后，计数器在计数1个周期后重新加载超时周期，超时周期的值设置在递减计数器中并开始计数。可以通过IWDT复位中断请求选择位(OFS0.IWDTRSTIRQS)选择复位输出或中断请求输出。可以使用IWDT下溢刷新错误中断 允许位(NMIER.IWDTEN)选择不可屏蔽的中断请求或中断请求。

图25.3显示了以下条件下的操作示例：

- ●自动启动模式（OFS0.IWDTSTRT=0）
- ●使能不可屏蔽中断请求输出（OFS0.IWDTRSTIRQS=0）
- ●窗口起始位置为75%(OFS0.IWDTRPSS[1:0]=10b)
- ●窗口结束位置为25%(OFS0.IWDTRPES[1:0]=10b)。

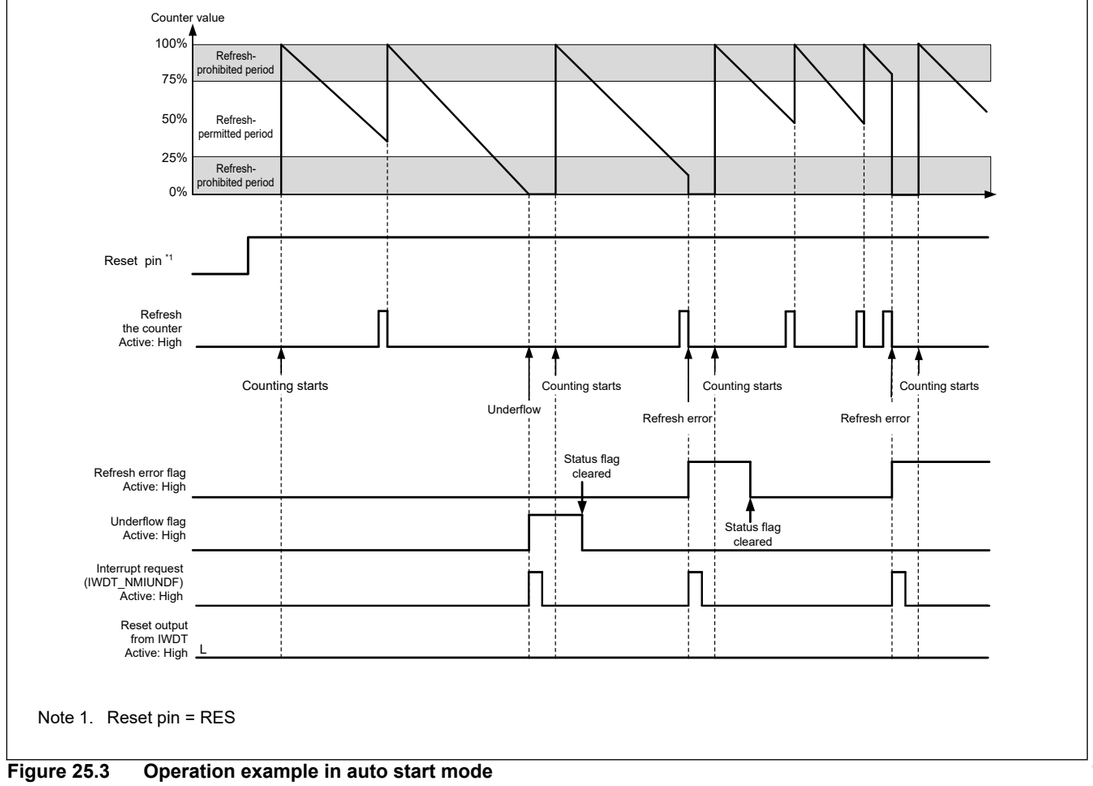

Figure 25.3 Operation example in auto start mode

25.3.2 Refresh Operation

The down-counter is refreshed and operation starts (counting is started by refreshing) by writing the values 0x00 and 0xFF to the IWDT Refresh Register (IWDTRR). If a value other than 0xFF is written after 0x00, the down-counter is not refreshed. If an invalid value is written, correct refreshing resumes on a write of 0x00 and 0xFF to the IWDTRR.

When writes are made in the order of 0x00 (first time) → 0x00 (second time), and if 0xFF is written after that, the writing order 0x00 → 0xFF is satisfied. Writing 0x00 ((n - 1)th time) →0x00 (nth time) → 0xFF is valid, and the refresh is performed correctly. Even when the first value written before 0x00 is not 0x00, correct refreshing is performed as long as the operation contains the write sequence of 0x00 → 0xFF.

Correct refreshing is also performed regardless of whether a register other than IWDTRR is accessed or IWDTRR is read between writing 0x00 and writing 0xFF to IWDTRR. Writes to refresh the counter must be made within the refresh-permitted period. Whether writing is done within the refresh-permitted period is determined when 0xFF is written. For this reason, correct refreshing is performed even when 0x00 is written outside the refresh-permitted period.

[Example write sequences that are valid to refresh the counter]

- 0x00 → 0xFF
- 0x00 ((n - 1)th time) → 0x00 (nth time) → 0xFF
- 0x00 → access to another register or read from IWDTRR → 0xFF.

[Example write sequences that are not valid to refresh the counter]

- 0x23 (a value other than 0x00) → 0xFF
- 0x00 → 0x54 (a value other than 0xFF)

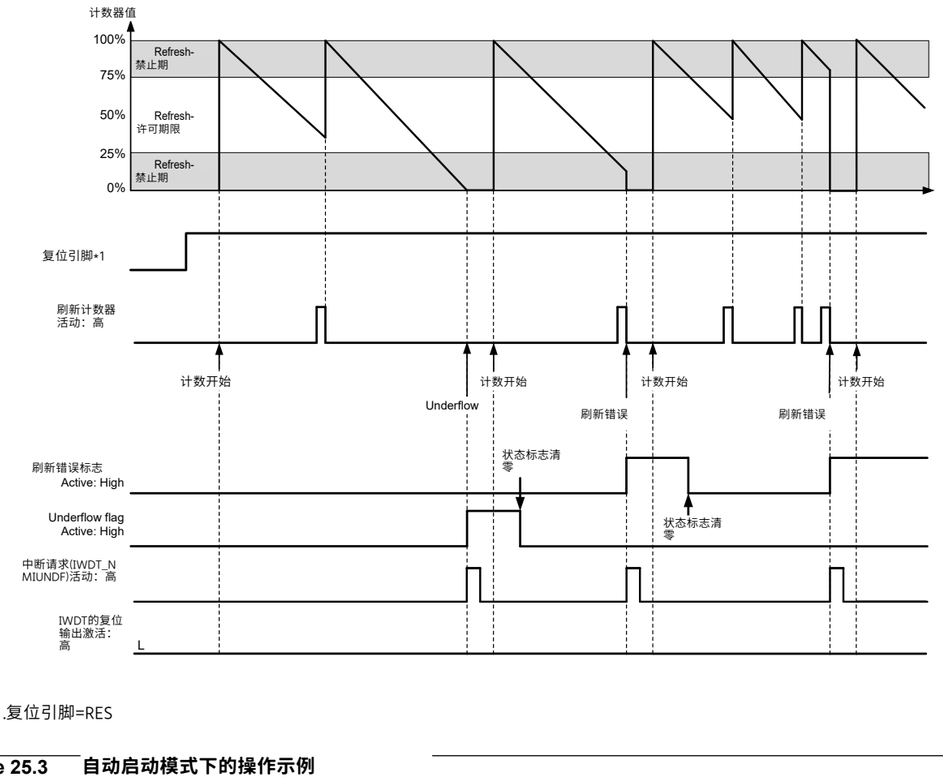

Figure 25.3 自动启动模式下的操作示例

25.3.2 刷新操作

通过将值0x00和0xFF写入IWDT刷新寄存器(IWDTRR)来刷新递减计数器并开始操作（通过刷新开始计数）。如果在0x00之后写入0xFF以外的值，则不刷新递减计数器。如果写入无效值，则在向IWDTRR写入0x00和0xFF时会恢复正确刷新。

当以0x00（第一次）→0x00（第二次）的顺序进行写入时，如果在此之后写入0xFF，则满足写入顺序0x00→0xFF。写入0x00((n1)次)→0x00(n次)→0xFF有效，刷新正确。即使在0x00之前写入的第一个值不是0x00时，只要操作包含0x00→0xFF的写入序列，就会执行正确的刷新。

无论在写入0x00和写入0xFF到IWDTRR之间是否访问IWDTRR以外的寄存器或读取IWDTRR，也会执行正确刷新。刷新计数器的写入必须在允许刷新的期限内进行。在写入0xFF时确定是否在可刷新周期内完成写入。因此，即使在可刷新期间外写入0x00，也会执行正确的刷新。

[对刷新计数器有效的示例写入序列]

- 0x00 → 0xFF
- 0x00 ((n - 1)th time) → 0x00 (nth time) → 0xFF
- ●0x00→访问另一个寄存器或从IWDTRR读取→0xFF。

[对刷新计数器无效的示例写入序列]

- ●0x23（0x00以外的值）→0xFF
- ●0x00→0x54（0xFF以外的值）

- 0x00 → 0xAA (0x00 and a value other than 0xFF) → 0xFF.

After 0xFF is written to the IWDTRR register, refreshing the counter requires up to 4 cycles of the signal for counting (the IWDT-Dedicated Clock Frequency Division Ratio Select bits (OFS0.IWDTCKS[3:0]) to determine how many cycles of the IWDT-dedicated clock (IWDTCLK) make up 1 cycle for counting. To meet this requirement, writing 0xFF to the IWDTRR must be completed 4 count cycles before the end of the refresh-permitted period or a down-counter underflow. The value of the counter can be checked with the counter bits (IWDTSR.CNTVAL[13:0]).

[Example refreshing timings]

- When the window start position is set to 0x1FFF, even if 0x00 is written to IWDTRR before 0x1FFF is reached at (0x2002, for example), refreshing occurs if 0xFF is written to IWDTRR after the value of the IWDTSR.CNTVAL[13:0] bits reaches 0x1FFF
- When the window end position is set to 0x1FFF, refreshing occurs if 0x2003 (4 count cycles before 0x1FFF) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 0x00 → 0xFF to IWDTRR
- When the refresh-permitted period continues until count 0x0000, refreshing can be performed immediately before an underflow. In this case, if 0x0003 (4 count cycles before an underflow) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 0x00 → 0xFF to IWDTRR, no underflow occurs and refreshing is performed.

Figure 25.4 shows the IWDT refresh-operation waveforms when PCLKB > IWDTCLK and the clock division ratio is IWDTCLK.

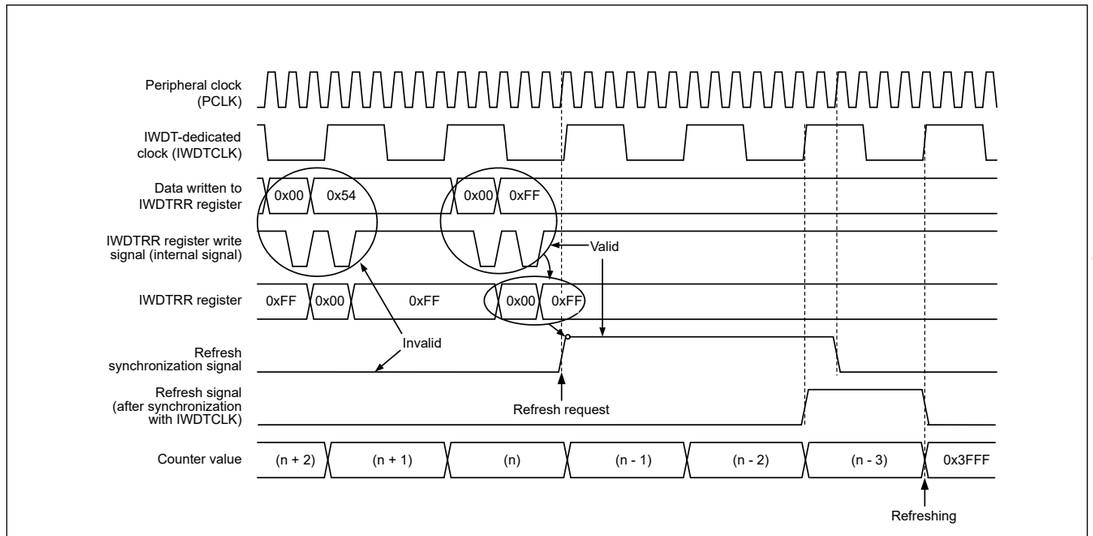

Figure 25.4 IWDT refresh operation waveforms when OFS0.IWDTCKS[3:0] = 0000b, OFS0.IWDTTOPS[1:0] = 11b

25.3.3 Status Flags

The refresh error (IWDTSR.REFEF) and underflow (IWDTSR.UNDFF) flags retain the source of the interrupt request from the IWDT. Therefore, after a release from the interrupt request generation, read the IWDTSR.REFEF and UNDFF flags to check for the interrupt source. For each flag, writing 0 clears the bit and writing 1 has no effect.

Leaving the status flags unchanged does not affect operation. If the flags are not cleared at the time of the next interrupt request from the IWDT, the earlier interrupt source is cleared and the new interrupt source is written. For the time period between when 0 is written in each flag and when its value is reflected, see section 25.2.2. IWDTSR : IWDT Status Register.

●0x00→0xAA（0x00和0xFF以外的值）→0xFF。

将0xFF写入IWDTRR寄存器后，刷新计数器需要最多4个周期的信号用于计数（IWDT专用时钟分频比选择位(OFS0.IWDTCKS[3:0])以确定IWDT专用时钟(IWDTCLK)占1个周期用于计数。为满足此要求，必须在刷新允许周期结束或递减计数器下溢之前4个计数周期完成向IWDTRR写入0xFF。可以使用计数器位(IWDTSR.CNTVAL[13:0])检查计数器。

[Example refreshing timings]

●当窗口起始位置设置为0x1FFF时，即使在到达0x1FFF之前将0x00写入IWDTRR（例如0x2002），如果在IWDTSR.CNTVAL[13:0]位的值达到0x1FFF后将0xFF写入IWDTRR，则会发生刷新

●当窗口结束位置设置为0x1FFF时，如果在将0x00→0xFF写入IWDTRR后立即从IWDTSR.CNTVAL[13:0]位读取0x2003（0x1FFF之前的4个计数周期）或更大的值，则会发生刷新

●当刷新允许周期持续到计数0x0000时，可以在下溢之前立即执行刷新。在这种情况下，如果在将0x00→0xFF写入IWDTRR后立即从IWDTSR.CNTVAL[13:0]位读取0x0003（下溢前的4个计数周期）或更大的值，则不会发生下溢并执行刷新。

图25.4显示了当PCLKB>IWDTCLK且时钟分频比为时的IWDT刷新操作波形
IWDTCLK.

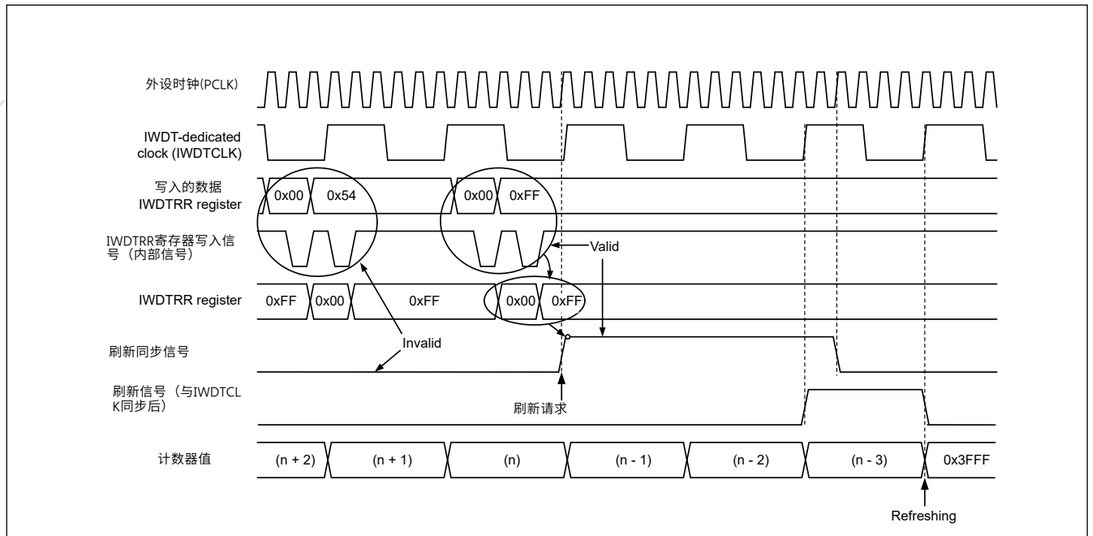

Figure 25.4 OFS0.IWDTCKS[3:0]=0000b OFS0.IWDTCKS[1:0]=11b时的IWDT刷新操作波形

25.3.3 状态标志

刷新错误(IWDTSR.REFEF)和下溢(IWDTSR.UNDFF)标志保留来自IWDT的中断请求源。因此，在中断请求生成释放后，读取IWDTSR.REFEF和UNDFF标志以检查中断源。对于每个标志，写入0清除该位，写入1无效。

保持状态标志不变不会影响操作。如果在IWDT发出下一个中断请求时未清除标志，则清除较早的中断源并写入新的中断源。关于从各标志写入0到反映其值的时间段，请参阅第25.2.2节。IWDTSR：IWDT状态寄存器。

25.3.4 Reset Output

When the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 1, a reset signal is output when an underflow in the counter or a refresh error occurs. Counting down automatically starts after the reset output.

25.3.5 Interrupt Sources

When the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 0, an interrupt (IWDT_NMIUNDF) signal occurs when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or an interrupt. For details, see section 13, Interrupt Controller Unit (ICU).

Table 25.4 IWDT interrupt source

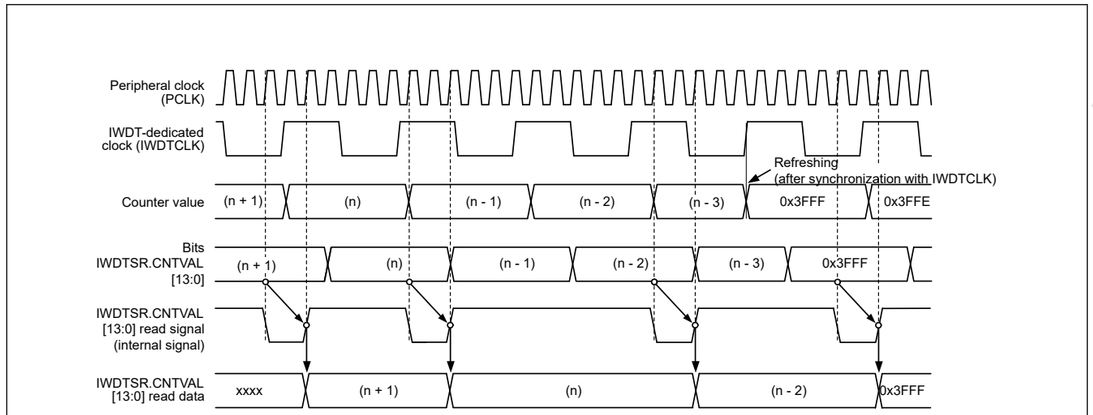
Name	Interrupt source	Interrupt to CPU	Start DMAC or DTC
IWDT_NMIUNDF	• Down-counter underflow • Refresh error	Possible	Not possible

25.3.6 Reading the Down-Counter Value

As the counter is a IWDT-dedicated clock (IWDTCLK), the counter value cannot be read directly. The IWDT synchronizes the counter value with the peripheral clock (PCLKB) and stores it in the down-counter value bits (IWDTSR.CNTVAL[13:0]) of the IWDT Status Register. Check these bits to obtain the counter value indirectly.

Reading the counter value requires multiple PCLKB clock cycles (up to 4 clock cycles), and the read counter value might differ from the actual counter value by a value of one count.

Figure 25.5 shows the processing for reading the IWDT counter value when PCLKB > IWDTCLK and the clock division ratio is IWDTCLK.



Note: PCLK = PCLKB

Figure 25.5 Processing for reading IWDT counter value when OFS0.IWDTCKS[3:0] = 0000b, OFS0.IWDTTOPS[1:0] = 11b

25.4 Output to the Event Link Controller (ELC)

The IWDT is capable of link operation for a specified module when the interrupt request signal is used as an event signal by the event link controller (ELC). The event signal is output by the counter underflow or refresh error.

An event signal is output regardless of the setting of the OFS0.IWDTRSTIRQS bit. An event signal can also be output at generation of the next interrupt source while the Refresh Error flag (IWDTSR.REFEF) or Underflow flag (IWDTSR.UNDFF) is 1. For details, see section 18, Event Link Controller (ELC).

25.3.4 复位输出

当IWDT重置中断请求选择位置（OFS0.IWDTRSTIRQS）中的选项函数选择寄存器0（OFS0）的位置为1时，当计数器中的下流或刷新错误发生时，将输出重置信号。复位输出后自动开始倒计时。

25.3.5 中断源

当IWDT重置中断请求选择位置（OFS0.IWDTRSTIRQS）中的选项函数选择寄存器0（OFS0）设置为0时，当计数器中的下流或刷新错误发生时，会发生中断（IWDT_NMIUNDF）信号。此中断可用作不可屏蔽中断或中断。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

Table 25.4 IWDT中断源

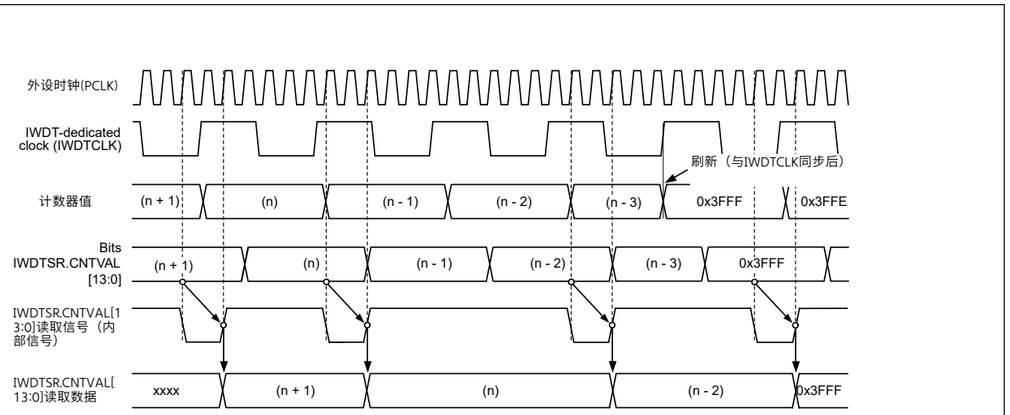
Name	中断源	对CPU的中断	启动DMAC或DTC
IWDT_NMIUNDF	• Down-counter underflow • 刷新错误	Possible	不可能

25.3.6 读取递减计数器值

由于计数器是IWDT专用时钟(IWDTCLK)，因此无法直接读取计数器值。IWDT将计数器值与外设时钟(PCLKB)同步，并将其存储在IWDT状态寄存器的递减计数器值位(IWDTSR.CNTVAL[13:0])中。检查这些位以间接获得计数器值。

读取计数器值需要多个PCLKB时钟周期（最多4个时钟周期），读取的计数器值可能与实际计数器值相差一个计数值。

图25.5显示了当PCLKB>IWDTCLK且时钟分频比为IWDTCLK时读取IWDT计数器值的处理。



Note: PCLK = PCLKB

Figure 25.5 OFS0.IWDTCKS[3:0]=0000b时读取IWDT计数器值的处理，OFS0.IWDTTOPS[1:0] = 11b

25.4 输出到事件链接控制器(ELC)

当中断请求信号被事件链接控制器(ELC)用作事件信号时，IWDT能够对指定模块进行链接操作。事件信号由计数器下溢或刷新错误输出。

无论OFS0.IWDTRSTIRQS位的设置如何，都会输出事件信号。当刷新错误标志(IWDTSR.REFEF)或下溢标志(IWDTSR.UNDFF)为1时，也可以在生成下一个中断源时输出事件信号。有关详细信息，请参阅第18节，事件链接控制器(ELC)。

25.5 Usage Notes

25.5.1 Refresh Operations

While configuring the refresh time, consider variations in the range of errors given the accuracy of PCLKB and IWDTCLK. Set values that ensure refreshing is possible.

25.5.2 Clock Division Ratio Setting

Satisfy the frequency of the peripheral module clock (PCLKB) ≥ 4 × (the frequency of the count clock source after division).

25.5.3 Constraints on the ICU Event Link Setting Register n (IELSRn) Setting

Setting 0x52 to ICU Event Link Setting Register n (IELSRn.IELS[8:0]) is prohibited when enabling the IWDT reset assertion (OFS0.IWDTRSTIRQS = 0) or when enabling event link operation (ELSRn.ELS[8:0] = 0x52).

USBE bit (USBFS Operation Enable)

The USBE bit enables or disables operation of the USBFS.

Changing the USBE bit from 1 to 0 initializes the bits listed in Table 26.3. Only change this bit while the SCKE bit is 1. In host controller mode, this bit must be set to 1 after setting the DRPD bit to 1, eliminating SYSSTS0.LNST[1:0] flags chattering, and confirming that the USB bus state is stable.

DPRPU bit (D+ Line Resistor Control)

The DPRPU bit enables or disables pulling up the D+ line in device controller mode.

When the DPRPU bit is set to 1 in device controller mode, the USBFS pulls up the D+ line to notify the USB host that it attached. Changing the DPRPU bit from 1 to 0 releases the pull-up, thereby notifying the USB host that it detached.

Set this bit to 1 in device controller mode and to 0 in host controller mode.

USBE位（USBFS操作使能）

USBE位启用或禁用USBFS的操作。

将USBE位从1更改为0会初始化表26.3中列出的位。仅在SCKE位为1时更改该位。在主机控制器模式下，必须在将DRPD位设置为1后将该位设置为1，消除SYSSTS0.LNST[1:0]标志抖动，并确认USB总线状态是稳定的。

DPRPU位（D+线路电阻控制）

DPRPU位启用或禁用在设备控制器模式下上拉D+线。

当DPRPU位在设备控制器模式下设置为1时，USBFS拉高D+线以通知USB主机它已连接。将DPRPU位从1更改为0会释放上拉电阻，从而通知USB主机它已分离。

在设备控制器模式下将此位设置为1，在主机控制器模式下设置为0。

DRPD bit (D+/D– Line Resistor Control)

TheDRPD bit enables or disables pulling down D+ and D– lines in host controller mode.

Set this bit to 1 in host controller mode and to 0 in device controller mode.

DCFM bit (Controller Function Select)

The DCFM bit selects the host or device function of the USBFS.

Only change this bit when the DPRPU and DRPD bits are both 0.

SCKE bit (USB Clock Enable)

The SCKE bit stops or enables the 48-MHz clock supply to the USBFS.

When this bit is 0, only SYSCFG is permitted to be read from and written to; the other registers related to the USB should not be read from or written to.

LNST[1:0] bits (USB Data Line Status Monitor)

The LNST[1:0] bits indicate the state of the USB data lines, D+ and D–. For details, see Table 26.4.

In device controller mode, read the LNST[1:0] bits after connection processing (SYSCFG.DPRPU bit = 1). In host controller mode, read them after enabling pull-down of the lines (SYSCFG.DRPD bit = 1).

SOFEA bit (Active Monitor When the Host Controller Is Selected)

The SOFEA bit is used in host controller mode to check whether the output of the last SOF is complete when the USBFS is suspended because of a 0 setting to the DVSTCTR0.UACT bit.

In host controller mode, check that both the HTACT and SOFEA bits are 0 before setting the SYSCFG.USBE bit to 0 to stop the USBFS or setting the SYSCFG.SCKE bit to 0 to stop the clock signal supply during communication.

HTACT bit (USB Host Sequencer Status Monitor)

The HTACT bit is set to 0 when the host sequencer of the USBFS is completely stopped.

In host controller mode, check that the HTACT bit is 0 before setting the DVSTCTR0.UACT bit to 0 to place the USBFS in the suspended state or setting the SCKE bit to 0 to stop the clock signal supply during communication.

OVCMON bits (External USB_OVRCURA Input Pin Monitor)

The OVCMON bits indicate the status of the overcurrent signals from an external power supply IC.

SOFEA位（选择主机控制器时的主动监视器）

SOFEA位在主机控制器模式下用于检查当USBFS因为DVSTCTR0.UACT位设置为0而暂停时最后一个SOF的输出是否完成。

在主机控制器模式下，在将SYSCFG.USBE位设置为0以停止USBFS或将SYSCFG.SCKE位设置为0以在通信期间停止时钟信号供应之前，请检查HTACT和SOFEA位是否都为0。

HTACT位（USB主机定序器状态监视器）

当USBFS的主机定序器完全停止时，HTACT位设置为0。

在主机控制器模式下，在将DVSTCTR0.UACT位设置为0以将USBFS置于挂起状态或将SCKE位设置为0以在通信期间停止时钟信号供应之前，请检查HTACT位是否为0。

OVCMON位（外部USB_OVRCURA输入引脚监视器）

OVCMON位指示来自外部电源IC的过流信号的状态。

11	—	These bits are read as 0. The write value should be 0.	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W

The USBFS controller does not support low-speed connections in device controller mode. When this value is read, abnormal connection processing must be executed in higher level application software.

LNST[1:0] bits (USB Bus Reset Status)

LNST[1:0] bits indicate the status of the USB bus reset.

In host controller mode, writing 1 to the USBRST bit causes the LNST[1:0] bits to set to 100b. When 0 is written to the USBRST bit and the USBFS ends the SE0 state, the LNST[1:0]bits update to a new value.

In device controller mode, if the USBFS detects a USB bus reset, the RHST[2:0] bits indicate 010b if the DPRPU bit is 1, and a DVST interrupt is generated.

UACT bit (USB Bus Enable)

When set to 1 in host controller mode, the UACT bit enables USB bus operation by controlling SOF packet transmission to the USB bus in addition to data and reception. The USBFS starts SOF packet output within one frame period after the UACT bit is set to 1. When UACT is set to 0, the USBFS enters the idle state after the SOF packet output.

The USBFS sets the UACT bit to 0 on any of the following conditions:

- A DTCH interrupt is detected during communication (when UACT = 1)
- An EOFERR interrupt is detected during communication (when UACT = 1)

Always write 1 to the UACT bit at the end of the USB bus reset processing (writing 0 to the USBRST bit) or at the end of resume processing from the suspended state (writing 0 to the RESUME bit).

In device controller mode, always set this bit to 0.

RESUME bit (Resume Output)

The RESUME bit controls the resume signal output in host controller mode.

When this bit is set to 1, the USBFS drives the USB port to the K-state and outputs the resume signal. The USBFS sets the bit to 1 on detection of a remote wakeup signal while the RWUPE bit is 1 and in the USB Suspend state.

The USBFS continues outputting the K-state while the RESUME bit is 1, until the bit is cleared to 0 by software. The RESUME bit must be 1 (resume period) for the time defined in the USB 2.0 specification. Only set this bit to 1 while the interface is in the Suspend state. Write 1 to the UACT bit simultaneously with the end of the resume processing (writing 0 to the RESUME bit).

Always set this bit to 0 in device controller mode.

USBRST bit (USB Bus Reset Output)

The USBRST bit controls the output of the USB bus signal in host controller mode. When this bit set to 1, the USBFS drives the USB port to the SE0 state to reset the USB bus. The USBFS continues outputting SE0 while the USBRST bit is 1, until the bit is cleared to 0 by software. The USBRST bit must be 1 (USB bus reset period) for the time defined in the USB 2.0 specification. Writing 1 to the USBRST bit during communication (UACT = 1) or during resume processing (RESUME = 1) prevents the USBFS from starting USB bus reset processing until both the UACT and RESUME bits become 0. Write 1 to the UACT bit simultaneously with the end of the USB bus reset processing (writing 0 to the USBRST bit).

Always set this bit to 0 in device controller mode.

RWUPE bit (Wakeup Detection Enable)

The RWUPE bit enables or disables remote wakeup signals (resume signals) from downstream peripheral devices in host controller mode. When this bit is set to 1, the USBFS detects a remote wakeup signal (K-state for 2.5 µs) from a downstream peripheral device, and performs resume processing, driving the K-state. When the RWUPE bit is set to 0, the USBFS ignores remote wakeup signals (K-states) from peripheral devices connected to the USB port.

Bit	Symbol	Function	R/W

11	—	这些位被读取为0。写入值应为0。	R/W
15:12	—	这些位被读取为0。写入值应为0。	R/W

USBFS控制器不支持设备控制器模式下的低速连接。当读取此值时，必须在更高级别的应用软件中执行异常连接处理。

LNST[1:0]位（USB总线复位状态）

LNST[1:0]位指示USB总线复位的状态。

在主机控制器模式下，将1写入USBRST位会导致LNST[1:0]位设置为100b。当0被写入USBRST位和USBFS结束SE0状态，LNST[1:0]位更新为新值。

在设备控制器模式下，如果USBFS检测到USB总线复位，如果DPRPU位为1，则RHST[2:0]位指示010b，并产生DVST中断。

UACT位（USB总线使能）

在主机控制器模式下设置为1时，UACT位通过控制向USB总线发送SOF数据包以及数据和接收来启用USB总线操作。USBFS在UACT位设置为1后的一帧周期内开始SOF数据包输出。当UACT设置为0时，USBFS在SOF数据包输出后进入空闲状态。

USBFS在以下任何条件下将UACT位设置为0：

●通信期间检测到DTCH中断（当UACT=1时）

●通信期间检测到EOFERR中断（当UACT=1时）

在USB总线复位处理结束（将0写入USBRST位）或从挂起状态恢复处理结束（将0写入RESUME位）时，始终向UACT位写入1。

在设备控制器模式下，始终将此位设置为0。

RESUME位（恢复输出）

RESUME位控制主机控制器模式下的恢复信号输出。

当该位设置为1时，USBFS将USB端口驱动到K状态并输出恢复信号。当RWUPE位为1且处于USB挂起状态时，USBFS在检测到远程唤醒信号时将该位设置为1。

当RESUME位为1时，USBFS继续输出K状态，直到该位被软件清除为0。这在USB2.0规范中定义的时间内，RESUME位必须为1（恢复周期）。仅当接口处于挂起状态时将此位设置为1。在恢复处理结束的同时向UACT位写入1（向RESUME位写入0）。

在设备控制器模式下始终将此位设置为0。

USBRST位（USB总线复位输出）

USBRST位控制主机控制器模式下USB总线信号的输出。当该位设置为1时，USBFS将USB端口驱动到SE0状态以复位USB总线。当USBRST位为1时，USBFS继续输出SE0，直到该位被软件清零。在USB2.0规范中定义的时间内，USBRST位必须为1（USB总线复位周期）。在通信期间(UACT=1)或恢复处理期间(RESUME=1)向USBRST位写入1可防止USBFS开始USB总线复位处理，直到UACT和RESUME位都变为0。同时向UACT位写入1与USB总线复位处理结束（将0写入USBRST位）。

在设备控制器模式下始终将此位设置为0。

RHUPE位（唤醒检测使能）

在主机控制器模式下，RWUPE位启用或禁用来自下游外围设备的远程唤醒信号（恢复信号）。当该位设置为1时，USBFS检测到来自下游外围设备的远程唤醒信号（K状态持续2.5µs），并执行恢复处理，驱动K状态。当RHUPE位设置为0时，USBFS忽略来自连接到USB端口的外围设备的远程唤醒信号（K状态）。

Do not stop the internal clock when the RWUPE bit is 1, even in the Suspend state (SYSCFG.SCKE bit must be set to 1).

Always set this bit to 0 in device controller mode.

WKUP bit (Wakeup Output)

The WKUP bit enables or disables remote wakeup signals (resume signals) to the USB bus in device controller mode.

The USBFS controls the output timing of the remote wakeup signals. When this bit is set to 1, the USBFS clears it to 0 after outputting the K-state for 10 ms. The USB 2.0 specification specifies that the USB bus idle state must be kept for 5 ms or longer before a remote wakeup signal is sent. If the USBFS writes 1 to the WKUP bit immediately after detecting the Suspend state, the K-state is output after 2 ms.

Only write 1 to the WKUP bit when the device is in the Suspend state (INTSTS0.DVSQ[2:0] = 1xxb) and the USB host enables the remote wakeup signal (RWUPE = 1). Do not stop the internal clock while this bit is 1, even in the Suspend state (SYSCFG.SCKE bit must be set to 1).

Always set this bit to 0 in host controller mode.

26.2.4 CFIFO/CFIFOL : CFIFO Port Register

Base address: USBFS = 0x4009_0000

Offset address: 0x014

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FIFOPORT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	FIFOPORT[15:0]*1	FIFO Port Read receive data from the FIFO buffer or write transmit data to the FIFO buffer by accessing these bits	R/W

Note 1. The valid bits depend on the MBW settings (CFIFOSEL.MBW) and BIGEND settings (CFIFOSEL.BIGEND) in the associated port selection register. See Table 26.5 and Table 26.6.

Three FIFO ports are available:

- CFIFO
- D0FIFO
- D1FIFO

Each FIFO port is configured with:

- A port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer and writing of data to the FIFO buffer
- A port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that selects the pipe assigned to the FIFO port
- A port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR)

Each FIFO port has the following constraints:

- Access to the FIFO buffer for DCP control transfers is through the CFIFO port
- Access to the FIFO buffer for DMA or DTC transfers is through the D0FIO or D1FIFO port
- The D0FIFO and D1FIFO ports can also be accessed by the CPU
- When using functions specific to the FIFO port, such as the DMA or DTC transfer function, you cannot change the pipe number selected in the CURPIPE[3:0] bits of the port selection register
- Registers configuring a FIFO port do not affect other FIFO ports
- The same pipe must not be assigned to two or more FIFO ports

当RHUPE位为1时不要停止内部时钟，即使处于挂起状态（SYSCFG.SCKE位必须设置为1）。

在设备控制器模式下始终将此位设置为0。

WKUP bit (Wakeup Output)

WKUP位在设备控制器模式下启用或禁用到USB总线的远程唤醒信号（恢复信号）。

USBFS控制远程唤醒信号的输出时序。当该位设置为1时，USBFS在输出K状态10ms后将其清除为0。USB2.0规范规定，在发送远程唤醒信号之前，USB总线空闲状态必须保持5ms或更长时间。如果USBFS在检测到Suspend状态后立即向WKUP位写入1，则在2ms后输出K-state。

仅当设备处于挂起状态（INTSTS0.DVSQ[2:0]=1xxb）且USB主机使能远程唤醒信号（RWUPE=1）时向WKUP位写入1。当该位为1时不要停止内部时钟，即使处于挂起状态（SYSCFG.SCKE位必须设置为1）。

在主机控制器模式下始终将此位设置为0。

三个FIFO端口可用：

- CFIFO
- D0FIFO
- D1FIFO

每个FIFO端口配置有：

●一个端口寄存器（CFIFO、D0FIFO或D1FIFO），用于处理从FIFO缓冲区读取数据并将数据写入FIFO缓冲区

●端口选择寄存器（CFIFOSEL、D0FIFOSEL或D1FIFOSEL），用于选择分配给FIFO端口的管道

●一个端口控制寄存器（CFIFOCTR、D0FIFOCTR或D1FIFOCTR）

每个FIFO端口具有以下约束：

●通过CFIFO端口访问DCP控制传输的FIFO缓冲区

●通过D0FIO或D1FIFO端口访问DMA或DTC传输的FIFO缓冲区

●D0FIFO和D1FIFO端口也可以被CPU访问

●当使用特定于FIFO端口的功能时，例如DMA或DTC传输功能，您不能更改在端口选择寄存器的CURPIPE[3:0]位中选择的管道号

●配置FIFO端口的寄存器不会影响其他FIFO端口

●不能将同一管道分配给两个或多个FIFO端口

- There are two FIFO buffer states, one giving access rights to the CPU and the other to the serial interface engine (SIE). When the SIE has access rights, the FIFO buffer cannot be accessed by the CPU

FIFOPORT[15:0] bits (FIFO Port)

When the FIFOPORT[15:0] bit is accessed, the USBFS reads the received data from the FIFO buffer or writes the transmit data to the FIFO buffer. The FIFO port register can be accessed only when the FRDY bit in the associated port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is 1.

The valid bits in the FIFO port register depend on the MBW and BIGEND settings in the port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL). See Table 26.5 and Table 26.6.

Three FIFO ports are available:

- CFIFO
- D0FIFO
- D1FIFO

Each FIFO port is configured with:

- A port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer and writing of data to the FIFO buffer
- A port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that selects the pipe assigned to the FIFO port
- A port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR)

Each FIFO port has the following constraints:

- Access to the FIFO buffer for DCP control transfers is through the CFIFO port

●有两种FIFO缓冲区状态，一种授予CPU访问权限，另一种授予串行接口引擎(SIE)。当SIE有访问权限时，CPU不能访问FIFO缓冲区

FIFOPORT[15:0] bits (FIFO Port)

当访问FIFOPORT[15:0]位时，USBFS从FIFO缓冲区读取接收数据或将发送数据写入FIFO缓冲区。只有当相关端口控制寄存器（CFIFOCTR、D0FIFOCTR或D1FIFOCTR）中的FRDY位为1时，才能访问FIFO端口寄存器。

FIFO端口寄存器中的有效位取决于端口选择寄存器（CFIFOSEL、D0FIFOSEL或D1FIFOSEL）中的MBW和BIGEND设置。请参见表26.5和表26.6。

- CFIFO
- D0FIFO

每个FIFO端口配置有：

●端口选择寄存器（CFIFOSEL、D0FIFOSEL或D1FIFOSEL），用于选择分配给FIFO端口的管道

●一个端口控制寄存器（CFIFOCTR、D0FIFOCTR或D1FIFOCTR）

每个FIFO端口具有以下约束：

●通过CFIFO端口访问DCP控制传输的FIFO缓冲区

- Access to the FIFO buffer for DMA or DTC transfers is through the D0FIO or D1FIFO port
- The D0FIFO and D1FIFO ports can also be accessed by the CPU
- When using functions specific to the FIFO port, such as the DMA or DTC transfer function, you cannot change the pipe number selected in the CURPIPE[3:0] bits of the port selection register

In double buffer mode, the DTLN[8:0] value is cleared when all data is read from only a single plane. 1: The DTLN[8:0] bits are decremented each time the receive data is read from the CFIFO.	R/W

Note 1. Only 0 can be read.

Do not specify the same pipe number in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.

When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

Do not change the pipe number while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (CFIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number to use for reading or writing data through the CFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, even when an attempt is made to change the CURPIPE[3:0] setting, the current access setting is retained until access is complete.

ISEL bit (CFIFO Port Access Direction When DCP Is Selected)

After writing a new value to the ISEL bit with the DCP as the selected pipe, read the ISEL bit to check that the written value agrees with the read value before proceeding to the next process. Set the ISEL and CURPIPE[3:0] bits simultaneously.

MBW bit (CFIFO Port Access Bit Width)

The MBW bit specifies the bit width for accessing the CFIFO port.

When the selected pipe is receiving, set the CURPIPE[3:0] and MBW bits simultaneously. After a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read.

When the selected pipe is transmitting, the bit width cannot be changed from 8-bit to 16-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether to rewind the buffer pointer.

注1.只能读取0。

不要在CFIFOSEL、D0FIFOSEL和D1FIFOSEL寄存器的CURPIPE[3:0]位中指定相同的管道编号。

当D0FIFOSEL和D1FIFOSEL寄存器中的CURPIPE[3:0]位设置为0000b时，不选择管道。

启用DMA或DTC传输时不要更改管道编号。

CURPIPE[3:0]位（CFIFO端口访问管道规范）

CURPIPE[3:0]位指定用于通过CFIFO端口读取或写入数据的管道编号。写入这些位后，读取它们以检查写入的值是否与读取的值一致，然后再进行下一个过程。不要为CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位设置相同的管道编号。

在FIFO缓冲区访问期间，即使尝试更改CURPIPE[3:0]设置，当前访问设置也会保留，直到访问完成。

ISEL位（选择DCP时的CFIFO端口访问方向）

在以DCP作为选定管道的情况下将新值写入ISEL位后，读取ISEL位以检查写入的值是否与读取的值一致，然后再进行下一个过程。同时设置ISEL和CURPIPE[3:0]位。

MBW位（CFIFO端口访问位宽度）

MBW位指定访问CFIFO端口的位宽。

当所选管道正在接收时，同时设置CURPIPE[3:0]和MBW位。在写入这些位开始从FIFO缓冲区读取数据后，在读取所有数据之前不要更改这些位。

当所选管道正在传输时，位宽不能从8位更改为16位，同时数据正在写入FIFO缓冲区。

即使选择了16位宽度，也可以通过字节访问控制写入奇数个字节。

REW位（缓冲区指针倒带）

REW位指定是否倒回缓冲区指针。

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double buffering, this setting enables re-reading of the currently-read FIFO buffer plane from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the REW bit to 1, be sure to check that the FRDY bit is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

当所选管道正在接收时，在读取FIFO缓冲区时将此位设置为1允许从第一个数据重新读取FIFO缓冲区。在双缓冲中，此设置允许从第一个条目重新读取当前读取的FIFO缓冲区平面。

请勿在同时更改CURPIPE[3:0]位时将此位设置为1。在将REW位设置为1之前，请务必检查FRDY位是否为1。

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number to use for reading or writing data through the DnFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, even when an attempt is made to change the CURPIPE[3:0] setting, the current access setting is retained until access is complete.

MBW bit (FIFO Port Access Bit Width)

The MBW bit specifies the bit width for accessing the DnFIFO port.

When the selected pipe is receiving, after a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read. Set the CURPIPE[3:0] and MBW bits simultaneously.

When the selected pipe is transmitting, the bit width cannot be changed from 8-bit to 16-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

DREQE bit (DMA/DTC Transfer Request Enable)

The DREQE bit enables or disables issuing of DMA or DTC transfer requests. To enable DMA or DTC transfer requests, set this bit to 1 after setting the CURPIPE[3:0] bits. To change the CURPIPE[3:0] setting, first set this bit to 0.

DCLRM bit (Auto Buffer Memory Clear Mode Accessed after Specified Pipe Data is Read)

The DCLRM bit enables or disables automatic FIFO buffer clearing after data in the selected pipe is read.

When this bit is set to 1, on receiving a zero-length packet while the FIFO buffer assigned to the selected pipe is empty, or when reading of a received short packet is complete while the PIPECFG.BFRE bit is 1, the USBFS sets the BCLR bit in the FIFO port control register to 1.

When using the USBFS with the SOFCFG.BRDYM bit set to 1, set this bit to 0.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double buffering, this setting enables re-reading of the currently-read FIFO buffer plane from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the bit to 1, be sure to check that the FRDY bit is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

RCNT bit (Read Count Mode)

The RCNT bit specifies the read mode for the value in the CFIFOCTR.DTLN bit. When accessing DnFIFO with the PIPECFG.BFRE bit set to 1, set the RCNT bit to 0.

26.2.8 CFIFOCTR : CFIFO Port Control Register

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CURPIPE[3:0]位（FIFO端口访问管道规范）

CURPIPE[3:0]位指定用于通过DnFIFO端口读取或写入数据的管道编号。写入这些位后，读取它们以检查写入的值是否与读取的值一致，然后再进行下一个过程。不要为CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位设置相同的管道编号。

在FIFO缓冲区访问期间，即使尝试更改CURPIPE[3:0]设置，当前访问设置也会保留，直到访问完成。

MBW位（FIFO端口访问位宽度）

MBW位指定访问DnFIFO端口的位宽。

当所选管道正在接收时，在写入这些位后开始从FIFO缓冲区读取数据，在读取所有数据之前不要更改这些位。同时设置CURPIPE[3:0]和MBW位。

当所选管道正在传输时，位宽不能从8位更改为16位，同时数据正在写入FIFO缓冲区。

即使选择了16位宽度，也可以通过字节访问控制写入奇数个字节。

DREQE位（DMADTC传输请求使能）

DREQE位启用或禁用DMA或DTC传输请求的发出。要启用DMA或DTC传输请求，请在设置CURPIPE[3:0]位后将此位设置为1。要更改CURPIPE[3:0]设置，首先将该位设置为0。

DCLRM位（读取指定管道数据后访问的自动缓冲存储器清除模式）

在读取所选管道中的数据后，DCLRM位启用或禁用自动FIFO缓冲区清除。

当该位设置为1时，在分配给所选管道的FIFO缓冲区为空时接收到零长度数据包，或在PIPECFG.BFRE位为1时完成读取接收到的短数据包时，USBFS设置FIFO端口控制寄存器中的BCLR位为1。

当使用SOFCFG.BRDYM位设置为1的USBFS时，将此位设置为0。

REW位（缓冲区指针倒带）

REW位指定是否倒回缓冲区指针。

当所选管道正在接收时，在读取FIFO缓冲区时将此位设置为1允许从第一个数据重新读取FIFO缓冲区。在双缓冲中，此设置允许从第一个条目重新读取当前读取的FIFO缓冲区平面。

请勿在同时更改CURPIPE[3:0]位时将此位设置为1。在将该位设置为1之前，请务必检查FRDY位是否为1。

要从传输管道的第一个数据重写FIFO缓冲区，请使用BCLR位。

RCNT位（读取计数模式）

RCNT位指定CFIFOCTR.DTLN位中值的读取模式。当使用DnFIFO访问PIPECFG.BFRE位设置为1，将RCNT位设置为0。

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[8:0] bits (Receive Data Length)

The DTLN[8:0] bits indicate the length of the receive data.

While the FIFO buffer is being read, the DTLN[8:0] bits indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1), as follows:

- RCNT = 0

  The USBFS sets the DTLN[8:0] bits to indicate the length of the receive data until the CPU or DMA/DTC has read all of the received data from a single FIFO buffer plane.

  While the PIPECFG.BFRE bit = 1, the USBFS retains the length of the receive data until the BCLR bit is set to 1, even after all the data is read.

- RCNT = 1

  The USBFS decrements the value indicated in the DTLN[8:0] bits each time data is read from the FIFO buffer. The value is decremented by 1 when MBW = 0, and by 2 when MBW = 1.

  The USBFS sets these bits to 0 when all the data is read from one FIFO buffer plane. In double buffer mode, if data is received in one FIFO buffer plane before all of the data is read from the other plane, the USBFS sets these bits to indicate the length of the receive data in the former plane when all of the data is read from the latter plane.

FRDY bit (FIFO Port Ready)

The FRDY bit indicates whether the FIFO port can be accessed by the CPU or DMA/DTC.

In the following cases, the USBFS sets the FRDY bit to 1 but data cannot be read through the FIFO port because there is no data to be read:

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit = 1

In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

BCLR bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU side for the selected pipe.

When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USBFS clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the DCP is the selected pipe, setting the BCLR bit to 1 allows the USBFS to clear the FIFO buffer regardless of whether the CPU or SIE has access rights. To clear the buffer when the SIE has access rights, set the DCPCTR.PID[1:0] bits to 00b (NAK response) before setting the BCLR bit to 1.

When the selected pipe is transmitting, if 1 is written to the BVAL flag and the BCLR bit simultaneously, the USBFS clears the data that is already written, enabling transmission of a zero-length packet.

CFIFOCTR、D0FIFOCTR和D1FIFOCTR寄存器对应于CFIFO、D0FIFO和D1FIFO缓冲区。

DTLN[8:0]位（接收数据长度）

DTLN[8:0]位指示接收数据的长度。

在读取FIFO缓冲区时，DTLN[8:0]位指示不同的值，具体取决于DnFIFOSEL.RCNT位(n=0 1)，如下所示：

- RCNT = 0

  USBFS设置DTLN[8:0]位以指示接收数据的长度，直到CPU或DMADTC从单个FIFO缓冲区平面读取所有接收数据。

  当PIPECFG.BFRE位=1时，USBFS将保留接收数据的长度，直到BCLR位设置为1，即使在读取所有数据之后也是如此。

- RCNT = 1

  每次从FIFO缓冲区读取数据时，USBFS都会递减DTLN[8:0]位中指示的值。当MBW=0时该值减1，当MBW=1时该值减2。

  当从一个FIFO缓冲平面读取所有数据时，USBFS将这些位设置为0。在双缓冲区模式下，如果在一个FIFO缓冲区平面中的所有数据从另一个平面读取之前接收到数据，USBFS设置这些位以指示在读取所有数据时前一个平面中接收数据的长度从后一个平面。

FRDY位（FIFO端口就绪）

FRDY位指示FIFO端口是否可以被CPU或DMADTC访问。

在以下情况下，USBFS将FRDY位设置为1，但由于没有数据可读取，因此无法通过FIFO端口读取数据：

●当分配给所选管道的FIFO缓冲区为空时，接收到一个长度为零的数据包

●PIPECFG.BFRE位=1时接收到一个短数据包并完全读取数据

在这些情况下，将BCLR位设置为1以清除FIFO缓冲区，并启用下一个数据的发送和接收。

BCLR位（CPU缓冲区清除）

将BCLR位设置为1以清除所选管道的CPU端的FIFO缓冲区。

当分配给所选管道的FIFO缓冲区设置为双缓冲区模式时，USBFS仅清除
即使两个平面都已启用读取，也有FIFO缓冲区。

当DCP为选定管道时，将BCLR位设置为1允许USBFS清除FIFO缓冲区，而不管CPU或SIE是否具有访问权限。要在SIE具有访问权限时清除缓冲区，请将DCPCTR.PID[1:0]位设置为00b（NAK响应），然后再将BCLR位设置为1。

当所选管道正在传输时，如果同时向BVAL标志和BCLR位写入1，则USBFS会清除已写入的数据，从而可以传输零长度数据包。

When the selected pipe is not the DCP, only write 1 to the BCLR bit while the FRDY bit in the FIFO port control register is 1 (set by the USBFS).

BVAL flag (Buffer Memory Valid Flag)

Set the BVAL flag to 1 when data is completely written to the FIFO buffer on the CPU side for the pipe selected in CURPIPE[3:0].

When the selected pipe is transmitting, set this flag to 1 in the following cases:

- To transmit a short packet, set this flag to 1 after data is written
- To transmit a zero-length packet, set this flag to 1 before data is written to the FIFO buffer

The USBFS then switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When data of the maximum packet size is written for the pipe in continuous transfer mode, the USBFS sets the BVAL flag to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

Only write 1 to the BVAL flag while the FRDY bit is 1 (set by the USBFS). When the selected pipe is receiving, do not set the BVAL flag to 1.

26.2.9 DnFIFOCTR : DnFIFO Port Control Register (n = 0, 1)

15	BVAL	Buffer Memory Valid Flag 0: Invalid (writing 0 has no effect) 1: Writing ended	R/W

Note 1. Only 0 can be read.

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[8:0] bits (Receive Data Length)

The DTLN[8:0] bits indicate the length of the receive data.

While the FIFO buffer is being read, the DTLN[8:0] bits indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1), as follows:

- RCNT = 0

  The USBFS sets the DTLN[8:0] bits to indicate the length of the receive data until the CPU or DMA/DTC has read all of the received data from a single FIFO buffer plane.

  While the PIPECFG.BFRE bit = 1, the USBFS retains the length of the receive data until the BCLR bit is set to 1, even after all the data is read.

当所选管道不是DCP时，仅在FIFO端口控制寄存器中的frdy位为1（由USBF设置）时，仅将1个写入BCLR位。

BVAL标志（缓冲存储器有效标志）

当数据完全写入CPU端的FIFO缓冲区时，将BVAL标志设置为1，用于在CURPIPE[3:0].

当所选管道正在传输时，在以下情况下将此标志设置为1：

●要发送一个短包，在数据写入后将此标志设置为1

●要发送零长度数据包，请在数据写入FIFO缓冲区之前将此标志设置为1

然后USBFS将FIFO缓冲区从CPU端切换到SIE端，从而启用传输。

当在连续传输模式下为管道写入最大数据包大小的数据时，USBFS将BVAL标志设置为1，并将FIFO缓冲区从CPU侧切换到SIE侧，从而启用传输。

仅在FRDY位为1（由USBFS设置）时将1写入BVAL标志。当所选管道正在接收时，不要将BVAL标志设置为1。

注1.只能读取0。

CFIFOCTR、D0FIFOCTR和D1FIFOCTR寄存器对应于CFIFO、D0FIFO和D1FIFO缓冲区。

DTLN[8:0]位（接收数据长度）

DTLN[8:0]位指示接收数据的长度。

在读取FIFO缓冲区时，DTLN[8:0]位指示不同的值，具体取决于DnFIFOSEL.RCNT位(n=0 1)，如下所示：

- RCNT = 0

  USBFS设置DTLN[8:0]位以指示接收数据的长度，直到CPU或DMADTC从单个FIFO缓冲区平面读取所有接收数据。

  当PIPECFG.BFRE位=1时，USBFS将保留接收数据的长度，直到BCLR位设置为1，即使在读取所有数据之后也是如此。

- RCNT = 1

  The USBFS decrements the value indicated in the DTLN[8:0] bits each time data is read from the FIFO buffer. The value is decremented by 1 when MBW = 0, and by 2 when MBW = 1.

  The USBFS sets these bits to 0 when all the data is read from one FIFO buffer plane. In double buffer mode, if data is received in one FIFO buffer plane before all of the data is read from the other plane, the USBFS sets these bits to indicate the length of the receive data in the former plane when all of the data is read from the latter plane.

FRDY bit (FIFO Port Ready)

The FRDY bit indicates whether the FIFO port can be accessed by the CPU or DMA/DTC.

In the following cases, the USBFS sets the FRDY bit to 1 but data cannot be read through the FIFO port because there is no data to be read:

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit = 1

In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

BCLR bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU side for the selected pipe.

When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USBFS clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the DCP is the selected pipe, setting the BCLR bit to 1 allows the USBFS to clear the FIFO buffer regardless of whether the CPU or SIE has access rights. To clear the buffer when the SIE has access rights, set the DCPCTR.PID[1:0] bits to 00b (NAK response) before setting the BCLR bit to 1.

When the selected pipe is transmitting, if 1 is written to the BVAL flag and the BCLR bit simultaneously, the USBFS clears the data that is already written, enabling transmission of a zero-length packet.

When the selected pipe is not the DCP, only write 1 to the BCLR bit while the FRDY bit in the FIFO port control register is 1 (set by the USBFS).

BVAL flag (Buffer Memory Valid Flag)

Set the BVAL flag to 1 when data is completely written to the FIFO buffer on the CPU side for the pipe selected in CURPIPE[3:0].

When the selected pipe is transmitting, set this flag to 1 in the following cases:

- To transmit a short packet, set this flag to 1 after data is written
- To transmit a zero-length packet, set this flag to 1 before data is written to the FIFO buffer

The USBFS then switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When data of the maximum packet size is written for the pipe in continuous transfer mode, the USBFS sets the BVAL flag to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

Only write 1 to the BVAL flag while the FRDY bit is 1 (set by the USBFS). When the selected pipe is receiving, do not set the BVAL flag to 1.

Note: INTENB1中的位只能在主机控制器模式下设置为1。不要在设备控制器模式下将这些位设置为1。

INTENB1指定主机控制器模式和设置事务的中断掩码。

当INTSTS1寄存器中的状态标志设置为1并且INTENB1寄存器中相关的中断请求使能位设置为1时，USBFS发出USBFS中断请求。

无论INTENB1寄存器设置如何，INTSTS1寄存器中的状态标志都会设置为1，以响应满足相关条件的状态更改。

当INTENB1寄存器中的中断请求使能位从0切换到1时，而相关的状态标志在INTSTS1寄存器设置为1，请求USBFS中断。

不要在设备控制器模式下启用中断。

The BRDYENB register enables or disables the INTSTS0.BRDY bit to be set to 1 when a BRDY interrupt is detected for each pipe.

When a status flag in the BRDYSTS register sets to 1 and the associated PIPEnBRDYE bit (n = 0 to 9) setting in theBRDYENB register is 1, the INTSTS0.BRDY flag sets to 1. In this case, if the BRDYE bit in INTENB0 is 1, the USBFS generates a BRDY interrupt request. While at least one PIPEnBRDY bit indicates 1, the USB generates the BRDY interrupt request when the associated interrupt request enable bit in the BRDYENB register is changed from 0 to 1 by software.

EDGESTS bit (Edge Interrupt Output Status Monitor)

The EDGESTS bit indicates 1 during the edge processing of an edge interrupt output signal. Confirm that this bit is 0 before stopping the clock supply to the USBFS.

BRDYM bit (BRDY Interrupt Status Clear Timing)

The BRDYM bit specifies how the BRDY interrupt status flags for the pipes are cleared.

TRNENSEL bit (Transaction-Enabled Time Select)

When the USB port is in use for full- or low-speed communications, the TRNENSEL bit specifies the timing with which the USBFS issues tokens in a frame (transaction-enabled time).

Set this bit to 1 when a low-speed device is connected. The bit is only valid in host controller mode. Set this bit to 0 in device controller mode.

EDGESTS位（边缘中断输出状态监视器）

在边沿中断输出信号的边沿处理期间，EDGESTS位指示1。在停止向USBFS提供时钟之前，请确认该位为0。

BRDYM位（BRDY中断状态清除时序）

BRDYM位指定如何清除管道的BRDY中断状态标志。

当USB端口用于全速或低速通信时，TRNENSEL位指定
USBFS在一个帧中发布令牌（事务启用时间）。

Note: The value of the DVST bit is 0 when the MCU is reset and 1 after a USB bus reset.
Note: The value of the VBSTS bit is 1 when the USB_VBUS pin is high and 0 when the USB_VBUS pin is low.
Note: The value of the DVSQ[2:0] bits is 000b when the MCU is reset and 001b after a USB bus reset.
Note 1. To clear the VBINT, RESM, SOFR, DVST, CTRT, or VALID bits, write 0 only to the bits to be cleared. Write 1 to the other bits. Do not write 0 to the status bits indicating 0.
Note 2. The status of the RESM, DVST, and CTRT bits are changed only in device controller mode. Set the associated interrupt enable bits to 0 (disabled) in host controller mode.
Note 3. The USBFS detects a change in the status indicated in the VBINT andRESM bits even while the clock supply is stopped (SCKE bit = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply before clearing the status by software.

CTSQ[2:0] bits (Control Transfer Stage)

In host controller mode, the read value of the CTSQ[2:0] bits is invalid.

VALID bit (USB Request Reception)

In host controller mode, the read value of the VALID bit is invalid.

DVSQ[2:0] bits (Device State)

The DVSQ[2:0] bits are initialized by a USB bus reset. In host controller mode, the read value is invalid.

BRDY flag (Buffer Ready Interrupt Status)

The BRDY flag indicates the BRDY interrupt status.

The USBFS sets the BRDY bit to 1 when it detects a BRDY interrupt status (PIPEnBRDY = 1, n = 0 to 9) on at least one pipe for which BRDY interrupts are enabled (BRDYENB.PIPEnBRDYE = 1).

For the conditions that cause the PIPEnBRDY status to be asserted, see section 26.3.3.1. BRDY interrupt.

The USBFS sets the BRDY bit to 0 when the software writes 0 to all of the PIPEnBRDY bits associated with the PIPEnBRDYE bits that are set to 1. Writing 0 to the BRDY flag in the software does not clear the flag.

NRDY flag (Buffer Not Ready Interrupt Status)

The NRDY flag indicates the NRDY interrupt status.

The USBFS sets the NRDY bit to 1 when it detects a NRDY interrupt status (PIPEnNRDY = 1, n = 0 to 9) on at least one pipe for which NRDY interrupts are enabled (NRDYENB.PIPEnNRDYE = 1).

For the conditions that cause the PIPEnNRDY status to be asserted, see section 26.3.3.2. NRDY interrupt.

The USBFS sets the NRDY bit to 0 when the software writes 0 to all of the PIPEnNRDY bits associated with the PIPEnNRDYE bits that are set to 1. Writing 0 to the NRDY flag in the software does not clear the flag.

BEMP flag (Buffer Empty Interrupt Status)

The BEMP flag indicates the BEMP interrupt status.

The USBFS sets the BEMP bit to 1 when it detects a BEMP interrupt status (PIPEnBEMP = 1, n = 0 to 9) on at least one pipe for which BEMP interrupts are enabled (BEMPENB.PIPEnBEMPE = 1).

For the conditions that cause the PIPEnBEMP status to be asserted, see section 26.3.3.3. BEMP interrupt.

注1.要清除VBINT、RESM、SOFR、DVST、CTRT或VALID位，只需将0写入要清除的位。将1写入其他位。不要将0写入指示0的状态位。

注2.RESM、DVST和CTRT位的状态仅在设备控制器模式下更改。在主机控制器模式下，将相关的中断使能位设置为0（禁用）。

注3.即使在时钟供应停止（SCKE位=0）时，USBFS也会检测到VBINT和RESM位指示的状态变化，并在相关中断请求位为1时请求中断。在之前启用时钟供应通过软件清除状态。

CTSQ[2:0]位（控制传输级）

在主机控制器模式下，CTSQ[2:0]位的读取值无效。

有效位（USB请求接收）

在主机控制器模式下，VALID位的读取值无效。

DVSQ[2:0] bits (Device State)

DVSQ[2:0]位由USB总线复位初始化。在主机控制器模式下，读取的值无效。

BRDY标志（缓冲区就绪中断状态）

BRDY标志指示BRDY中断状态。

当USBFS在至少一个启用了BRDY中断(BRDYENB.PIPEnBRDYE=1)的管道上检测到BRDY中断状态(PIPEnBRDY=1 n=0到9)时，将BRDY位设置为1。

有关导致PIPEnBRDY状态被断言的条件，请参见第26.3.3.1节。BRDY中断。

当软件将0写入与设置为1的PIPEnBRDYE位。在软件中将0写入BRDY标志不会清除该标志。

当USBFS在至少一个启用了NRDY中断(NRDYENB.PIPEnNRDYE=1)的管道上检测到NRDY中断状态(PIPEnNRDY=1 n=0到9)时，将NRDY位设置为1。

有关导致PIPEnNRDY状态被断言的条件，请参见第26.3.3.2节。NRDY中断。

USBFS将NRDY位设置为0，当软件将0写入与设置为1的PIPEnNRDYE位。在软件中将0写入NRDY标志不会清除该标志。

BEMP标志（缓冲区空中断状态）

BEMP标志指示BEMP中断状态。

当USBFS在至少一个启用了BEMP中断(BEMPENB.PIPEnBEMPE=1)的管道上检测到BEMP中断状态(PIPEnBEMP=1 n=0到9)时，将BEMP位设置为1。

有关导致PIPEnBEMP状态被断言的条件，请参见第26.3.3.3节。BEMP中断。

The USBFS sets the BEMP bit to 0 when the software writes 0 to all of the PIPEnBEMP bits associated with the PIPEnBEMPE bits that are set to 1. Writing 0 to the BEMP flag in the software does not clear the flag.

CTRT flag (Control Transfer Stage Transition Interrupt Status)

In device controller mode, the USBFS updates the value of the CTSQ[2:0] bits and sets the CTRT flag to 1 on detecting a transition in the control transfer stage. When a control transfer stage transition interrupt occurs, clear the CTRT flag before the USBFS detects the next control transfer stage transition.

Values read from the CTRT flag in host controller mode are invalid.

DVST flag (Device State Transition Interrupt Status)

In device controller mode, the USBFS updates the value of the DVSQ[2:0] bits and sets the DVST flag to 1 on detecting a change in the device state. When a device state transition interrupt occurs, clear theDVST flag before the USBFS detects the next device state transition.

Values read from the DVST flag in host controller mode are invalid.

SOFR flag (Frame Number Refresh Interrupt Status)

In host controller mode, the USBFS sets the SOFR flag to 1 on updating the frame number when the DVSTCTR0.UACT bit is set to 1 by software. A SOFR interrupt is detected every 1 ms.

In device controller mode, the USBFS sets the SOFR flag to 1 on updating the frame number. A frame number refresh interrupt is detected every 1 ms.

The USBFS can detect an SOFR interrupt through the internal interpolation function even when a corrupted SOF packet is received from the USB host.

RESM flag (Resume Interrupt Status)

In device controller mode, the USBFS sets the RESM flag to 1 on detecting the falling edge of the signal on the USB_DP pin in the Suspend state (DVSQ[2:0] = 1xxb). Values read from the RESM flag in host controller mode are invalid.

VBINT flag (VBUS Interrupt Status)

The USBFS sets the VBINT flag to 1 on detecting a level change (high to low or low to high) in the USB_VBUS pin input value. The USBFS sets the VBSTS flag to indicate the USB_VBUS pin input value. When a VBUS interrupt occurs, eliminate transient elements by reading the VBSTS flag at least three times through software processing and check that the values read are the same.

CTRT标志（控制传输阶段转换中断状态）

在设备控制器模式下，USBFS更新CTSQ[2:0]位的值，并在检测到控制传输阶段的转换时将CTRT标志设置为1。当控制传输阶段转换中断发生时，在USBFS检测到下一个控制传输阶段转换之前清除CTRT标志。

在主机控制器模式下从CTRT标志读取的值无效。

DVST标志（设备状态转换中断状态）

在设备控制器模式下，USBFS更新DVSQ[2:0]位的值，并在检测到设备状态发生变化时将DVST标志设置为1。当设备状态转换中断发生时，在USBFS检测到下一个设备状态转换之前清除DVST标志。

在主机控制器模式下从DVST标志读取的值无效。

VBINT标志（VBUS中断状态）

USBFS在检测到USB_VBUS引脚输入值的电平变化（从高到低或从低到高）时将VBINT标志设置为1。USBFS设置VBSTS标志以指示USB_VBUS引脚输入值。当发生VBUS中断时，通过软件处理至少3次读取VBSTS标志来消除瞬态元素，并检查读取的值是否相同。

Note 1. The USBFS detects a change in the status in the PDDETINT, OVRCR or BCHG bit even when the clock supply is stopped (SYSCFG.SCKE = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply (SYSCFG.SCKE = 1) before clearing the status through software. No other interrupts can be detected while the clock supply is stopped (SYSCFG.SCKE bit = 0).
Note 2. To clear the bits in the INTSTS1 register, write 0 only to the bits to be cleared. Write 1 to the other bits.
Note 3. To clear the bits in INTSTS1, write 0 only to the bits to be cleared. Write 1 to the other bits.
Note 4. The USBFS detects a change in the status in the OVRCR or BCHG bit even when the clock supply is stopped (SYSCFG.SCKE = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply (SYSCFG.SCKE = 1) before clearing the status through the software. No other interrupts can be detected while the clock supply is stopped (SYSCFG.SCKE bit = 0).

INTSTS1 is used to confirm the status of each interrupt in host controller mode. Only enable the status change interrupts indicated in the bits in INTSTS1 in host controller mode.

PDDETINT flag (PDDET Detection Interrupt Status Flag)

The USBFS sets the PDDETINT flag to 1 on detecting a level change (high to low or low to high) in the PDDET pin input value. When the PDDETINT interrupt is generated, perform debouncing by reading the BCCTRL1.PDDETSTS flag at least three times through software processing and checking that the values read are the same.

SACK flag (Setup Transaction Normal Response Interrupt Status)

The SACK flag indicates the status of the setup transaction normal response interrupt in host controller mode.

The USBFS detects the SACK interrupt and sets this flag to 1 when an ACK response is returned from a peripheral device during the setup transactions issued by the USBFS. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

Values read from the SACK flag in device controller mode are invalid.

SIGN flag (Setup Transaction Error Interrupt Status)

The SIGN flag indicates the status of setup transaction error interrupts in host controller mode.

The USBFS detects the SIGN interrupt and sets this flag to 1 when an ACK response is not returned from a peripheral device three consecutive times during the setup transactions issued by the USBFS. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS detects the SIGN interrupt when any of the following response conditions occur for three consecutive setup transactions:

- Timeout is detected by the USBFS when the peripheral device has returned no response
- A corrupted ACK packet is received
- A handshake other than ACK (NAK, NYET, or STALL) is received

Values read from the SIGN flag in device controller mode are invalid.

注1.即使停止时钟供应(SYSCFG.SCKE=0)，USBFS也会检测到PDDETINT、OVRCR或BCHG位的状态变化，并在相关中断请求位为1时请求中断。使能在通过软件清除状态之前提供时钟（SYSCFG.SCKE=1）。停止提供时钟（SYSCFG.SCKE位=0）时，不会检测到其他中断。

注2.要清除INTSTS1寄存器中的位，只需将0写入要清除的位。将1写入其他位。
注3.要清除INTSTS1中的位，只需将0写入要清除的位。将1写入其他位。
注4.即使停止时钟供应(SYSCFG.SCKE=0)，USBFS也会检测到OVRCR或BCHG位的状态变化，并在相关中断请求位为1时请求中断。使能时钟供应(SYSCFG.SCKE=1)在通过软件清除状态之前。停止提供时钟（SYSCFG.SCKE位=0）时，不会检测到其他中断。

INTSTS1用于确认主机控制器模式下每个中断的状态。仅在主机控制器模式下启用INTSTS1位中指示的状态更改中断。

PDDETINT标志（PDDET检测中断状态标志）

USBFS在检测到PDDET引脚输入值的电平变化（从高到低或从低到高）时将PDDETINT标志设置为1。当产生PDDETINT中断时，通过软件处理至少3次读取BCCTRL1.PDDETSTS标志并检查读取的值是否相同来执行去抖动。

SACK标志（设置事务正常响应中断状态）

SACK标志指示主机控制器模式下设置事务正常响应中断的状态。

在USBFS发出的设置事务期间，当外围设备返回ACK响应时，USBFS检测到SACK中断并将该标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

在设备控制器模式下从SACK标志读取的值无效。

SIGN标志（设置事务错误中断状态）

SIGN标志指示主机控制器模式下设置事务错误中断的状态。

在USBFS发出的设置事务期间，如果外围设备连续3次没有返回ACK响应，则USBFS检测到SIGN中断并将该标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

当三个连续的设置事务发生以下任何响应条件时，USBFS检测到SIGN中断：

- 当外围设备没有返回响应时，USBFS检测到超时
- 收到损坏的ACK数据包
- 收到ACK（NAK、NYET或STALL）以外的握手

在设备控制器模式下从SIGN标志读取的值无效。

EOFERR flag (EOF Error Detection Interrupt Status)

The EOFERR flag indicates the status of EOF error detection interrupts in host controller mode.

The USBFS detects the EOFERR interrupt and sets this flag to 1 on detecting that communication did not complete at the EOF2 timing defined in the USB 2.0 specification. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

After detecting the EOFERR interrupt, the USBFS controls the hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt was detected to 0
- Puts the port in which the EOFERR interrupt occurred into the idle state

The software must terminate all pipes in which communications are being carried out and re-enumerate the USB port.

Values read from the EOFERR flag in device controller mode are invalid.

ATTCH flag (ATTCH Interrupt Status)

The ATTCH flag indicates the status of USB attach detection interrupts in host controller mode.

The USBFS detects the ATTCH interrupt and sets this flag to 1 on detecting a J- or K-state on the full- or low-speed signal level for 2.5 µs. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS detects the ATTCH interrupt on any of the following conditions.

- K-state, SE0, or SE1 changes to J-state, and J-state continues for 2.5 µs
- J-state, SE0, or SE1 changes to K-state, and K-state continues for 2.5 µs

Values read from the ATTCH flag in device controller mode are invalid.

DTCH flag (USB Disconnection Detection Interrupt Status)

The DTCH flag indicates the status of USB disconnection detection interrupts in host controller mode.

The USBFS detects the DTCH interrupt and sets this flag to 1 on detecting a USB bus detach event. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS detects bus detach events based on the USB 2.0 specification.

After detecting the DTCH interrupt, the USBFS controls hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt was detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state

The software must terminate all pipes in which communications are being carried out and invoke the wait state for attaching to the USB port (waiting for ATTCH interrupt generation).

Values read from the DTCH flag in device controller mode are invalid.

BCHG flag (USB Bus Change Interrupt Status)

The BCHG flag indicates the status of USB bus change interrupts in host controller mode.

The USBFS detects the BCHG interrupt and sets this flag to 1 when a change in the full- or low-speed signal level occurs on the USB port. This includes any change from J-state, K-state, or SE0 to J-state, K-state, or SE0. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS sets the LNST[1:0] flags to indicate the input state of the USB port. When a BCHG interrupt occurs, eliminate transient elements by repeat reading the LNST[1:0] flags by software until the same value is read at least three times.

Change in the USB bus state can be detected while the internal clock is stopped.

Values read from the BCHG flag in device controller mode are invalid.

OVRCR flag (Overcurrent Input Change Interrupt Status)

The OVRCR flag indicates the status of USB_OVRCURA input pin change interrupts.

EOFERR标志（EOF错误检测中断状态）

EOFERR标志指示主机控制器模式下EOF错误检测中断的状态。

USBFS检测到EOFERR中断，并在检测到通信未在USB2.0规范中定义的EOF2时序完成时将该标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

检测到EOFERR中断后，USBFS对硬件进行如下控制，而不考虑相关的中断使能位设置：

- 将检测到EOFERR中断的端口的DVSTCTR0.UACT位设置为0
- 将发生EOFERR中断的端口置于空闲状态

软件必须终止正在执行通信的所有管道并重新枚举USB端口。

在设备控制器模式下从EOFERR标志读取的值无效。

ATTCH标志（ATTCH中断状态）

ATTCH标志指示主机控制器模式下USB连接检测中断的状态。

USBFS检测到ATTCH中断，并在检测到全速或低速信号电平上的JorK状态持续2.5µs时将此标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

USBFS在以下任何条件下检测ATTCH中断。

- K-state、SE0或SE1变为J-state，J-state持续2.5µs
- J-state、SE0或SE1变为K-state，K-state持续2.5µs

在设备控制器模式下从ATTCH标志读取的值无效。

DTCH标志（USB断线检测中断状态）

DTCH标志指示主机控制器模式下USB断开检测中断的状态。

USBFS检测到DTCH中断并在检测到USB总线分离事件时将此标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

USBFS根据USB2.0规范检测总线分离事件。

检测到DTCH中断后，USBFS对硬件进行如下控制，而不管相关的中断使能位设置如何：

- 将检测到DTCH中断的端口的DVSTCTR0.UACT位设置为0
- 将发生DTCH中断的端口置于空闲状态

软件必须终止正在执行通信的所有管道并调用等待状态以连接到USB端口（等待ATTCH中断生成）。

在设备控制器模式下从DTCH标志读取的值无效。

BCHG标志（USB总线更改中断状态）

BCHG标志指示主机控制器模式下USB总线更改中断的状态。

当USB端口上发生全速或低速信号电平变化时，USBFS检测到BCHG中断并将该标志设置为1。这包括从J-state、K-state或SE0到J-state、K-state或SE0的任何更改。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

USBFS设置LNST[1:0]标志以指示USB端口的输入状态。当发生BCHG中断时，通过软件重复读取LNST[1:0]标志来消除瞬态元素，直到至少读取相同的值3次。

当内部时钟停止时，可以检测到USB总线状态的变化。

在设备控制器模式下从BCHG标志读取的值无效。

OVRCR标志（过流输入变化中断状态）

OVRCR标志指示USB_OVRCURA输入引脚变化中断的状态。

The USBFS detects the OVRCR interrupt and sets this flag to 1 when a change (high to low or low to high) occurs in at least one of the input values to the USB_OVRCURA pins. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

FRNM[10:0] flags (Frame Number)

The USBFS sets the FRNM[10:0] flags to indicate the latest frame number, which is updated every 1 ms, when an SOF packet is issued or received.

CRCE flag (Receive Data Error)

The CRCE flag sets to 1 when a CRC error or bit stuffing error occurs during isochronous transfer. On detecting a CRC error in host controller mode, the USBFS generates an internal NRDY interrupt.

To clear the CRCE flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

OVRN flag (Overrun/Underrun Detection Status)

The OVRN flag sets to 1 when an overrun or underrun error occurs during isochronous transfer. To clear the flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

In host controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the time to issue an OUT token comes before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the time to issue an IN token comes when no FIFO buffer planes are empty

In device controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the IN token is received before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the OUT token is received when no FIFO buffer planes are empty

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FRNM[10:0] flags (Frame Number)

USBFS设置FRNM[10:0]标志以指示最新的帧号，该帧号每1ms更新一次，当发出或接收SOF数据包时。

CRCE标志（接收数据错误）

当同步传输期间发生CRC错误或位填充错误时，CRCE标志设置为1。在主机控制器模式下检测到CRC错误时，USBFS会生成内部NRDY中断。

要清除CRCE标志，向其写入0，同时向FRMNUM寄存器中的其他位写入1。

OVRN标志（溢出欠载检测状态）

当同步传输期间发生溢出或欠载错误时，OVRN标志设置为1。要清除该标志，请向其写入0，同时向FRMNUM寄存器中的其他位写入1。

在主机控制器模式下，OVRN标志在以下任何条件下设置为1：

●对于传输同步管道，发出OUT令牌的时间是在所有传输数据写入FIFO缓冲区之前

●对于接收同步管道，在没有FIFO缓冲平面为空时发出IN令牌

在设备控制器模式下，OVRN标志在以下任何条件下设置为1：

●对于传输同步管道，在所有传输数据写入FIFO缓冲区之前接收到IN令牌

●对于接收同步管道，当没有FIFO缓冲平面为空时接收OUT令牌

USBINDX由USB总线复位初始化。

WINDEX[15:0] bits (Index)

WINDEX[15:0]位保存USB请求的wIndex值。

●在主机控制器模式下：

在传输设置事务中将这些位设置为USB请求中的wIndex值。当DCPCTR.SUREQ位为1时，不要更改位的值。

在设备控制器模式下，存储接收到的wLength的值。在主机控制器模式下，设置要传输的wLength的值。

USBLENG由USB总线复位初始化。

WLENTUH[15:0] bits (Length)

WLENTUH[15:0]位保存USB请求的wLength值。

- In host controller mode:

  Set these bits to the wLength value in USB requests in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.

- In device controller mode:

  These bits indicate the wLength value in USB requests received in reception setup transactions. Writing to the bits has no effect.

26.2.28 DCPCFG : DCP Configuration Register

Base address: USBFS = 0x4009_0000

Offset address: 0x05C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15:8	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only set this bit while the PID is NAK. Before setting this bit, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

DIR bit (Transfer Direction)

In host controller mode, the DIR bit sets the transfer direction of the data stage and status stage for control transfers. In device controller mode, set the DIR bit to 0.

SHTNAK bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to change PID to NAK on transfer end when the selected pipe is receiving. It is only valid when the selected pipe is receiving.

When the SHTNAK bit is 1, the USBFS changes the DCPCTR.PID[1:0] bits for the DCP to NAK on determining that a transfer has ended. The USBFS determines transfer end on the following condition:

- A short packet, including a zero-length packet, is successfully received.

注1.仅当PID为NAK时设置该位。在设置该位之前，请检查DCPCTR.PBUSY位是否为0，然后更改DCPCTR.PID[1:0]位用于DCP从BUF到NAK。如果PID[1:0]位被USBFS更改为NAK，则无需通过软件检查PBUSY位。

DIR位（传输方向）

在主机控制器模式下，DIR位设置控制传输的数据阶段和状态阶段的传输方向。在设备控制器模式下，将DIR位设置为0。

SHTNAK位（传输结束时禁用管道）

SHTNAK位指定当所选管道正在接收时，是否在传输结束时将PID更改为NAK。仅在所选管道正在接收时有效。

当SHTNAK位为1时，USBFS在确定传输已结束时将DCPCR.PID[1:0]位更改为DCP为NAK。USBFS在以下条件下确定传输结束：

●成功接收到短报文，包括零长度报文。

26.2.29 DCPMAXP:DCP最大数据包大小寄存器

Base address: USBFS = 0x4009_0000

Offset address: 0x05E

Note 1. Only set the MXPS[6:0] bits while PID is NAK. Before setting these bits, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary. After the MXPS[6:0] bits are set and the DCP is set to the CURPIPE[3:0] bits in a port select register, clear the buffer by setting the BCLR bit in the port control register to 1.

Note 2. Only set the DEVSEL[3:0] bits while PID is NAK and the DCPCTR.SUREQ bit is 0. Before setting these bits, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

MXPS[6:0] bits (Maximum Packet Size)

The MXPS[6:0] bits specify the maximum data payload (maximum packet size) for the DCP. The initial value is 0x40 (64 bytes). Set the bits to a USB 2.0-compliant value. Do not write to the FIFO buffer or set PID = BUF whileMXPS[6:0] is set to 0.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target peripheral device for a control transfer. Set up the device address in the associated DEVADDn (n = 0 to 5) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0010b, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0000b.

注1.仅在PID为NAK时设置MXPS[6:0]位。在设置这些位之前，请检查DCPCTR.PBUSY位是否为0，然后将DCP的DCPCTR.PID[1:0]位从BUF更改为NAK。如果PID[1:0]位被USBFS更改为NAK，则无需通过软件检查PBUSY位。在设置MXPS[6:0]位并将DCP设置为端口选择寄存器中的CURPIPE[3:0]位后，通过将端口控制寄存器中的BCLR位设置为1来清除缓冲区。

注2.仅在PID为NAK且DCPCTR.SUREQ位为0时设置DEVSEL[3:0]位。在设置这些位之前，请检查DCPCTR.PBUSY位为0，然后将DCPCR.PID[1:0]位从BUF更改为NAK。如果PID[1:0]位被USBFS更改为NAK，则无需通过软件检查PBUSY位。

MXPS[6:0]位（最大数据包大小）

MXPS[6:0]位指定DCP的最大数据有效载荷（最大数据包大小）。初始值为0x40（64字节）。将这些位设置为符合USB2.0的值。当MXPS[6:0]设置为0时，不要写入FIFO缓冲区或设置PID=BUF。

DEVSEL[3:0] bits (Device Select)

在主机控制器模式下，DEVSEL[3:0]位指定目标外围设备的地址以进行控制传输。首先在相关的DEVADDn（n=0到5）寄存器中设置设备地址，然后将这些位设置为相应的值。例如，要将DEVSEL[3:0]位设置为0010b，首先要设置DEVADD2寄存器中的地址。

在设备控制器模式下，将这些位设置为0000b。

15	BSTS	Buffer Status 0: Buffer access disabled 1: Buffer access enabled	R

Note 1. This bit is read as 0.

Note 2. Only set the SQSET and SQCLR bits while PID is NAK. Before setting these bits, check that the PBUSY bit is 0, and then change the PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

PID[1:0] bits (Response PID)

The PID[1:0] bits control the USB response type during control transfers.

In host controller mode, to change the PID[1:0] setting from NAK to BUF:

- When the transmitting direction is set:
  a. Write all of the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  b. Set PID[1:0] bits to 01b (BUF).
  The USBFS then executes the OUT transaction.
- When the receiving direction is set:
  a. Check that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  b. Set PID[1:0] bits to 01b (BUF).
  The USBFS then executes the IN transaction.

The USBFS changes the PID[1:0] setting as follows:

- When the PID[1:0] bits are set to BUF (01b) by software and the USBFS has received data exceeding MaxPacketSize, the USBFS sets the PID[1:0] to STALL (11b)
- When a reception error, such as a CRC error, is detected three times consecutively, the USBFS sets thePID[1:0] bits to NAK (00b)
- On receiving the STALL handshake, the USBFS sets PID[1:0] to STALL (11b)

In device controller mode, the USBFS changes the PID[1:0] setting as follows:

Bit	Symbol	Function	R/W
6	SQMON	序列切换位监视器 0: DATA0 1: ATA1	R
7	SQSET	序列切换位设置*2 设置DCP传输中的序列切换位。 该位读为0。 0：无效（写0无效）1：将下一笔交易的期望值设置为DATA1	R/W*1
8	SQCLR	序列切换位清除*2 清除DCP传输中的序列切换位。 该位读为0。 0：无效（写0无效）1：清除下一笔交易的期望值到DATA0	R/W*1

13:12	—	这些位被读取为0。写入值应为0。	R/W
14	SUREQ	设置令牌传输 在主机控制器模式下设置令牌传输。 0：无效（写0无效）1：发送设置包	R/W
15	BSTS	缓冲区状态 0：禁止缓冲区访问1：允许缓冲区访问	R

注1.该位读为0。

注2.仅在PID为NAK时设置SQSET和SQCLR位。在设置这些位之前，请检查PBUSY位是否为0，然后将DCP的PID[1:0]位从BUF更改为NAK。如果PID[1:0]位被USBFS更改为NAK，则无需通过软件检查PBUSY位。

PID[1:0] bits (Response PID)

PID[1:0]位在控制传输期间控制USB响应类型。

在主机控制器模式下，要将PID[1:0]设置从NAK更改为BUF：

●设置传输方向时：

a. 当DVSTCTR0.UACT位为1且PID为NAK时，将所有发送数据写入FIFO缓冲区。

湾。将PID[1:0]位设置为01b(BUF)。

然后USBFS执行OUT事务。

●设置接收方向时：

a. 在DVSTCTR0.UACT位为1且PID为NAK时检查FIFO缓冲区是否为空（或清空缓冲区）。

湾。将PID[1:0]位设置为01b(BUF)。

然后USBFS执行IN事务。

USBFS更改PID[1:0]设置如下：

●当PID[1:0]位被软件设置为BUF(01b)并且USBFS接收到超过MaxPacketSize的数据时，USBFS将PID[1:0]设置为STALL(11b)

●当连续3次检测到接收错误（例如CRC错误）时，USBFS将PID[1:0]位设置为NAK(00b)

●在接收到STALL握手时，USBFS将PID[1:0]设置为STALL(11b)

在设备控制器模式下，USBFS将PID[1:0]设置更改如下：

- On receiving a setup packet, the USBFS sets PID[1:0] to NAK (00b). The USBFS then sets the INTSTS0.VALID flag to 1, and the PID[1:0] setting cannot be changed until the software clears the VALID flag to 0.
- When the PID[1:0] bits are set to BUF (01b) by software and the USBFS has received data exceeding MaxPacketSize, the USBFS sets PID[1:0] to STALL (11b)
- On detecting a control transfer sequence error, the USBFS sets PID[1:0] to STALL (1xb)
- On detecting a USB bus reset, the USBFS sets PID[1:0] to NAK

The USBFS does not check the PID[1:0] setting while processing a SET_ADDRESS request.

The PID[1:0] bits are initialized by a USB bus reset.

CCPL bit (Control Transfer End Enable)

In device controller mode, setting the CCPL bit to 1 enables the status stage of the control transfer to be completed. When the bit is set to 1 by software while the associated PID[1:0] bits are set to BUF, the USBFS completes the control transfer status stage.

During control read transfers, the USBFS transmits the ACK handshake in response to the OUT transaction from the USB host. During control write or no-data control transfers, it transmits the zero-length packet in response to the IN transaction from the USB host. On detecting a SET_ADDRESS request, the USBFS operates in auto response mode from the setup stage up to status stage completion regardless of the CCPL bit setting.

The USBFS changes the CCPL bit from 1 to 0 on receiving a new setup packet. The software cannot write 1 to the bit while the INTSTS0.VALID bit is 1. The bit is initialized by a USB bus reset.

In host controller mode, always write 0 to the CCPL bit.

PBUSY bit (Pipe Busy)

The PBUSY bit indicates whether DCP is used for the transaction when USBFS changes the PID[1:0] bits from BUF to NAK. The USBFS changes the PBUSY bit from 0 to 1 on start of a USB transaction for the selected pipe. It changes the PBUSY bit from 1 to 0 on completion of one transaction.

After PID is set to NAK by software, the value in the PBUSY bit indicates whether changes to pipe settings can proceed.

For details, see section 26.3.4.1. Pipe control register switching procedures.

SQMON bit (Sequence Toggle Bit Monitor)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

The USBFS toggles the bit on normal completion of the transaction. It does not toggle the bit, however, when a DATAPID mismatch occurs during a transfer in the receiving direction.

In device controller mode, the USBFS sets the SQMON bit to 1 (specifies DATA1 as the expected value) on successful reception of the setup packet.

In device controller mode, the USBFS does not reference this bit during IN or OUT transactions at the status stage, and it does not toggle the bit on normal completion.

SQSET bit (Sequence Toggle Bit Set)

The SQSET bit specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SQCLR bit (Sequence Toggle Bit Clear)

The SQCLR bit specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer. It is read as 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SUREQCLR bit (SUREQ Bit Clear)

In host controller mode, setting the SUREQCLR bit to 1 clears the SUREQ bit to 0. The bit is read as 0.

If transfer stops while the SUREQ bit is set to 1 in a setup transaction, set the SUREQCLR bit to 1 by software. This is not necessary at the end of a normal setup transaction, because the USBFS automatically clears the SUREQ bit to 0.

●在接收到设置数据包时，USBFS将PID[1:0]设置为NAK(00b)。然后USBFS将INTSTS0.VALID标志设置为1，并且在软件将VALID标志清除为0之前无法更改PID[1:0]设置。

●当PID[1:0]位被软件设置为BUF(01b)并且USBFS接收到超过MaxPacketSize的数据时，USBFS将PID[1:0]设置为STALL(11b)

●在检测到控制传输序列错误时，USBFS将PID[1:0]设置为STALL(1xb)

●在检测到USB总线复位时，USBFS将PID[1:0]设置为NAK

USBFS在处理SET_ADDRESS请求时不检查PID[1:0]设置。

PID[1:0]位由USB总线复位初始化。

CCPL位（控制传输结束使能）

在设备控制器模式下，将CCPL位设置为1可以完成控制传输的状态阶段。当该位由软件设置为1且相关的PID[1:0]位设置为BUF时，USBFS完成控制传输状态阶段。

在控制读取传输期间，USBFS发送ACK握手以响应来自USB主机的OUT事务。在控制写入或无数据控制传输期间，它传输零长度数据包以响应来自USB主机的IN事务。在检测到SET_ADDRESS请求时，USBFS从设置阶段到状态阶段完成以自动响应模式运行，无论CCPL位设置如何。

USBFS在接收到新的设置数据包时将CCPL位从1更改为0。当INTSTS0.VALID位为1时，软件无法向该位写入1。该位由USB总线复位初始化。

在主机控制器模式下，始终将0写入CCPL位。

PBUSY bit (Pipe Busy)

PBUSY位指示当USBFS将PID[1:0]位从BUF更改为NAK时是否使用DCP进行事务处理。USBFS在所选管道的USB事务开始时将PBUSY位从0更改为1。它改变了

PBUSY位在一个事务完成时从1变为0。

在软件将PID设置为NAK后，PBUSY位中的值指示是否可以继续对管道设置进行更改。

详见26.3.4.1节。管道控制寄存器切换程序。

SQMON位（序列切换位监视器）

SQMON位指示DCP传输期间下一个事务的序列切换位的预期值。

USBFS在事务正常完成时切换该位。但是，当在接收方向的传输过程中发生DATAPID不匹配时，它不会切换该位。

在设备控制器模式下，USBFS在成功接收到设置数据包时将SQMON位设置为1（指定DATA1作为预期值）。

在设备控制器模式下，USBFS在状态阶段的IN或OUT事务期间不引用该位，并且它不会在正常完成时切换该位。

SQSET位（序列切换位设置）

SQSET位将DATA1指定为DCP传输期间下一个事务的序列切换位的预期值。

不要同时将SQCLR和SQSET位设置为1。

SQCLR位（序列翻转位清除）

SQCLR位将DATA0指定为DCP传输期间下一个事务的序列切换位的预期值。读为0。

不要同时将SQCLR和SQSET位设置为1。

SUREQCLR bit (SUREQ Bit Clear)

在主机控制器模式下，将SUREQCLR位设置为1会将SUREQ位清除为0。该位被读取为0。

如果在设置事务中将SUREQ位设置为1时传输停止，则通过软件将SUREQCLR位设置为1。这在正常设置事务结束时不是必需的，因为USBFS会自动将SUREQ位清除为0。

Only control the SUREQ bit through the SUREQCLR bit while the DVSTCTR0.UACT bit is 0. When UACT is 0, communication is halted or no transfer is occurring because a bus disconnection was detected.

In device controller mode, always write 0 to this bit.

SUREQ bit (Setup Token Transmission)

In host controller mode, setting the SUREQ bit to 1 triggers the USBFS to transmit the setup packet. After completing the setup transaction process, the USBFS generates either the SACK or SIGN interrupt and clears the SUREQ bit to 0. The USBFS also clears the SUREQ bit to 0 when the software sets the SUREQCLR bit to 1.

Before setting the SUREQ bit to 1, set the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, and USBLENG appropriately to transmit the target USB request in the setup transaction. Also check that the PID[1:0] bits for the DCP are set to NAK. After setting the SUREQ bit to 1, do not change the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, or USBLENG until the setup transaction is complete (SUREQ bit = 1). Write 1 to the SUREQ bit only when transmitting the setup token. Otherwise, write 0.

In device controller mode, always write 0 to this bit.

BSTS flag (Buffer Status)

The BSTS flag indicates the status of access to the DCP FIFO buffer. The meaning of this flag varies as follows depending on the CFIFOSEL.ISEL setting:

- When ISEL = 0, the bit indicates whether receive data can be read from the buffer
- When ISEL = 1, the bit indicates whether transmit data can be written to the buffer

Set pipes 1 to 9 using the PIPESEL, PIPECFG, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN registers (n = 0 to 9).

After selecting the pipe in the PIPESEL register, pipe functions must be set in the associated PIPECFG, PIPEMAXP, and PIPEPERI registers. PIPEnCTR, PIPEnTRE, and PIPEnTRN can be set independently of the pipe selection in this register.

PIPESEL[3:0] bits (Pipe Window Select)

The PIPESEL[3:0] bits select the pipe number associated with the PIPECFG, PIPEMAXP, and PIPEPERI registers used for data writing and reading. Selecting a pipe number in the PIPESEL[3:0] bits allows writing to and reading from PIPECFG, PIPEMAXP, and PIPEPERI associated with the selected pipe number.

当DVSTCTR0.UACT位为0时，仅通过SUREQCLR位控制SUREQ位。当UACT为0时，由于检测到总线断开，通信停止或没有传输发生。

在设备控制器模式下，始终向该位写入0。

SURESQ位（设置令牌传输）

在主机控制器模式下，将SUREQ位设置为1会触发USBFS发送设置数据包。完成设置事务过程后，USBFS产生SACK或SIGN中断并将SUREQ位清零。当软件将SUREQCLR位设置为1时，USBFS也将SUREQ位清零。

在将SUREQ位设置为1之前，将DCPMAXP.DEVSEL[3:0]位、USBREQ、USBVAL、USBINDX和USBLENG适当地在设置事务中传输目标USB请求。还要检查DCP的PID[1:0]位是否设置为NAK。将SUREQ位设置为1后，在设置事务完成（SUREQ位=1）之前，不要更改DCPMAXP.DEVSEL[3:0]位、USBREQ、USBVAL、USBINDX或USBLENG。仅在发送设置令牌时向SUREQ位写入1。否则，写0。

在设备控制器模式下，始终向该位写入0。

BSTS flag (Buffer Status)

BSTS标志指示访问DCPFIFO缓冲区的状态。根据CFIFOSEL.ISEL设置，该标志的含义如下：

●ISEL=0时，该位指示是否可以从缓冲区读取接收数据

●ISEL=1时，该位指示发送数据是否可以写入缓冲区

使用PIPESEL、PIPECFG、PIPEMAXP、PIPEPERI、PIPEnCTR、PIPEnTRE和PIPEnTRN寄存器（n=0到9）设置管道1到9。

在PIPESEL寄存器中选择管道后，必须在相关的PIPECFG、PIPEMAXP和PIPEPERI寄存器。PIPEnCTR、PIPEnTRE和PIPEnTRN可以独立于该寄存器中的管道选择进行设置。

PIPESEL[3:0]位（管道窗口选择）

PIPESEL[3:0]位选择与用于数据写入和读取的PIPECFG、PIPEMAXP和PIPEPERI寄存器相关的管道编号。在PIPESEL[3:0]位中选择一个管道编号允许写入和读取与所选管道编号相关的PIPECFG、PIPEMAXP和PIPEPERI。

When PIPESEL[3:0] = 0000b, 0 is read from all of the bits in PIPECFG, PIPEMAXP, and PIPEPERI. Writing to these bits has no effect.

Note 1. Only set the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 2. Only set the BFRE, DBLB, and DIR bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 3. To change the BFRE, DBLB, or DIR bits after completing USB communication on the selected pipe, in addition to the constraints described in Note 2, write 1 and 0 to the PIPEnCTR.ACLRM bit continuously through the software and clear the FIFO buffer assigned to the pipe.

PIPECFG specifies the transfer type, FIFO buffer access direction, and endpoint numbers for pipes 1 to 9. It also selects single or double buffer mode, and whether to continue or disable pipe operation at the end of transfer.

EPNUM[3:0] bits (Endpoint Number)

The EPNUM[3:0] bits specify the endpoint number for the selected pipe. Setting 0000b indicates the pipe not used.

当PIPESEL[3:0]=0000b时，从PIPECFG、PIPEMAXP和PIPEPERI中的所有位读取0。写入这些位无效。

注1.PID为NAK时，仅设置TYPE[1:0]、SHTNAK和EPNUM[3:0]位。在设置这些位之前，请检查PIPEnCTR.PBUSY位为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

注2.仅在PID为NAK且在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置BFRE、DBLB和DIR位。在设置这些位之前，请检查PIPEnCTR.PBUSY位是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

注3.要在所选管道上完成USB通信后更改BFRE、DBLB或DIR位，除了注2中描述的约束外，通过软件连续向PIPEnCTR.ACLRM位写入1和0并清除FIFO分配给管道的缓冲区。

PIPECFG指定管道1到9的传输类型、FIFO缓冲区访问方向和端点编号。它还选择单缓冲区或双缓冲区模式，以及在传输结束时是继续还是禁用管道操作。

EPNUM[3:0] bits (Endpoint Number)

EPNUM[3:0]位指定所选管道的端点号。设置0000b表示管道未使用。

Set these bits so that the combination of the DIR and EPNUM[3:0] settings is different from those for other pipes. The EPNUM[3:0] bits can be set to 0000b for all pipes.

DIR bit (Transfer Direction)

The DIR bit specifies the transfer direction for the selected pipe.

When the software sets this bit to 0, the USBFS uses the selected pipe for receiving. When the software sets this bit to 1, the USBFS uses the selected pipe for transmitting.

SHTNAK bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to change the PIPEnCTR.PID[1:0] bits to 00b (NAK) at the end of transfer when the selected pipe is set in the receiving direction. The bit is valid for pipes 1 to 5 in the receiving direction.

When the software sets this bit to 1 for a receiving pipe, the USBFS changes the associated PIPEnCTR.PID[1:0] bits to 00b (NAK) on determining the transfer end. The USBFS determines that the transfer has ended on the following conditions:

- A short packet data (including a zero-length packet) was successfully received
- The transaction counter is used and the number of packets specified for the transaction counter are successfully received

DBLB bit (Double Buffer Mode)

The DBLB bit selects either single or double buffer mode for the FIFO buffer used by the selected pipe. The bit is valid for pipes 1 to 5.

BFRE bit (BRDY Interrupt Operation Specification)

The BFRE bit specifies the BRDY interrupt generation timing from the USBFS to the CPU for the selected pipe.

When the software sets the BFRE bit to 1 and the selected pipe is in the receiving direction, the USBFS detects the transfer completion and generates the BRDY interrupt on reading the packet.

When a BRDY interrupt is generated with this setting, the software must write 1 to the BCLR bit in the port control register. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to the BCLR bit.

When the BFRE bit is set to 1 by software and the selected pipe is in the transmitting direction, the USBFS does not generate the BRDY interrupt. For details, see section 26.3.3.1. BRDY interrupt.

TYPE[1:0] bits (Transfer Type)

The TYPE[1:0] bits specify the transfer type for the pipe selected in the PIPESEL.PIPESEL[3:0] bits. Before setting PID to BUF and starting USB communication on the selected pipe, set the TYPE[1:0] bits to a value other than 00b.

26.2.33 PIPEMAXP : Pipe Maximum Packet Size Register

R/W
11:9	—	These bits are read as 0. The write value should be 0.	R/W

设置这些位，以便DIR和EPNUM[3:0]设置的组合不同于其他管道的设置。这
对于所有管道，EPNUM[3:0]位可以设置为0000b。

DIR位（传输方向）

DIR位指定所选管道的传输方向。

当软件将此位设置为0时，USBFS使用所选管道进行接收。当软件将该位设置为1时，
USBFS使用选定的管道进行传输。

SHTNAK位（传输结束时禁用管道）

SHTNAK位指定当所选管道设置为接收方向时，是否在传输结束时将PIPEnCTR.PID[1:0]位更改为00b(NAK)。该位对接收方向的管道1到5有效。

当软件将该位设置为1用于接收管道时，USBFS在确定传输结束时将相关的PIPEnCTR.PID[1:0]位更改为00b(NAK)。USBFS在以下条件下确定传输已结束：

●成功接收短包数据（包括零长度包）

●使用事务计数器，成功接收事务计数器指定的包数

DBLB位（双缓冲模式）

DBLB位为所选管道使用的FIFO缓冲区选择单缓冲区模式或双缓冲区模式。该位对管道1到5有效。

BFRE位（BRDY中断操作规范）

BFRE位为所选管道指定从USBFS到CPU的BRDY中断生成时序。

当软件将BFRE位设置为1且所选管道处于接收方向时，USBFS检测到传输完成并在读取数据包时产生BRDY中断。

当使用该设置产生BRDY中断时，软件必须将1写入端口控制寄存器中的BCLR位。
在将1写入BCLR位之前，分配给所选管道的FIFO缓冲区不会用于接收。

当BFRE位由软件设置为1且所选管道处于发送方向时，USBFS不会产生BRDY中断。详见26.3.3.1节。BRDY中断。

TYPE[1:0] bits (Transfer Type)

TYPE[1:0]位指定在PIPESEL.PIPESEL[3:0]位中选择的管道的传输类型。设置PID之前
BUF并在所选管道上启动USB通信，将TYPE[1:0]位设置为00b以外的值。

Note: The value of the MXPS[8:0] bits is 0x000 when no pipe is selected in the PIPESEL.PIPESEL[3:0] bits and 0x040 when a pipe is selected.

Note 1. Only set the MXPS[8:0] bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 2. Only set the DEVSEL[3:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00b (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

PIPEMAXP specifies the maximum packet size for pipes 1 to 9.

MXPS[8:0] bits (Maximum Packet Size)

The MXPS[8:0] bits specify the maximum data payload (maximum packet size) for the selected pipe.

Set these bits to the appropriate value for each transfer type based on the USB 2.0 specification. When MXPS[8:0] = 0, do not write to the FIFO buffer or set PID to BUF. These writes have no effect.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target device for USB communication. Set up the device address in the associated DEVADDn (n = 0 to 5) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0x2, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0x0.

PIPEPERI selects whether the buffer is flushed or not when an interval error occurred during isochronous IN transfers, and sets the interval error detection interval for pipes 1 to 9.

在设置这些位之前，请检查PIPEnCTR.PBUSY位是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

注2.仅在PID为NAK时设置DEVSEL[3:0]位。在设置这些位之前，请检查PIPEnCTR.PBUSY位是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00b(NAK)，则无需通过软件检查PBUSY位。

PIPEMAXP指定管道1到9的最大数据包大小。

MXPS[8:0]位（最大数据包大小）

MXPS[8:0]位指定所选管道的最大数据有效负载（最大数据包大小）。

根据USB2.0规范将这些位设置为每种传输类型的适当值。当MXPS[8:0]=0时，不要写入FIFO缓冲区或将PID设置为BUF。这些写入没有效果。

DEVSEL[3:0] bits (Device Select)

在主机控制器模式下，DEVSEL[3:0]位指定USB通信的目标设备的地址。首先在相关的DEVADDn（n=0到5）寄存器中设置设备地址，然后将这些位设置为相应的值。例如，要将DEVSEL[3:0]位设置为0x2，首先设置DEVADD2寄存器中的地址。

在设备控制器模式下，将这些位设置为0x0。

26.2.34 PIPEPERI:管道循环控制寄存器

PIPEPERI选择在同步IN传输期间发生间隔错误时是否刷新缓冲区，并设置管道1到9的间隔错误检测间隔。

IITV[2:0] bits (Interval Error Detection Interval)

To change the IITV[2:0] bits to another value after they are set and USB communication is performed, set the PIPEnCTR.PID[1:0] bits to 00b (NAK) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer.

The IITV[2:0] bits are not provided for pipes 3 to 5. Write 000b to bit positions of the IITV[2:0] bits associated with pipes 3 to 5.

IFIS bit (Isochronous IN Buffer Flush)

The IFIS bit specifies whether to flush the buffer when the pipe selected in the PIPESEL.PIPESEL[3:0] bits is used for isochronous IN transfers.

In device controller mode when the selected pipe is for isochronous IN transfers, the USBFS automatically clears the FIFO buffer if the USBFS fails to receive the IN token from the USB host within the interval set in theIITV[2:0] bits in terms of frames.

When double buffering is specified (PIPECFG.DBLB = 1), the USBFS only clears the data in the previously used plane.

The USBFS clears the FIFO buffer on receiving the SOF packet immediately after the frame in which the USBFS expected to receive the IN token. Even if the SOF packet is corrupted, the FIFO buffer is cleared at the time the SOF packet is expected to be received by using the internal interpolation function.

In host controller mode, set the IITV[2:0] bits to 000b.

Set the IITV[2:0] bits to 000b when the selected pipe is not used for isochronous transfers.

IITV[2:0]位（间隔错误检测间隔）

要在设置IITV[2:0]位并在执行USB通信后将其更改为另一个值，请设置PIPEnCTR.PID[1:0]位为00b(NAK)，然后将PIPEnCTR.ACLRM位设置为1以初始化间隔定时器。

不为管道3到5提供IITV[2:0]位。将000b写入与管道3到5相关联的IITV[2:0]位的位位置。

IFIS位（同步IN缓冲区刷新）

IFIS位指定当在PIPESEL.PIPESEL[3:0]位中选择的管道用于同步IN传输时是否刷新缓冲区。

在设备控制器模式下，当所选管道用于同步IN传输时，如果USBFS在IITV[2:0]位（以帧为单位）设置的间隔内未能从USB主机接收IN令牌，则USBFS自动清除FIFO缓冲区.

当指定双缓冲时（PIPECFG.DBLB=1），USBFS只清除先前使用的平面中的数据。

在USBFS预期接收IN令牌的帧之后，USBFS在接收到SOF数据包后立即清除FIFO缓冲区。即使SOF数据包损坏，FIFO缓冲区也会在预期接收SOF数据包时使用内部插值功能清除。

在主机控制器模式下，将IITV[2:0]位设置为000b。

当所选管道不用于同步传输时，将IITV[2:0]位设置为000b。

Note 1. Only 0 can be read.
Note 2. Only set the ATREPM bit or write 1 to the SQCLR or SQSETbit while PID is NAK. Before setting these bits, check that the PBUSY bit is 0, and then change the PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSYbit through the software is not necessary.
Note 3. Only set the ACLRM bit while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting this bit, check that the PBUSY bit is 0, and then change the PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

PIPEnCTR can be set for any pipe selection in the PIPESEL register.

PID[1:0] bits (Response PID)

The PID[1:0]bits specify the response type for the next transaction on the selected pipe.

The default PID[1:0] setting is NAK. Change the PID[1:0] setting to BUF to use the associated pipe for USB transfer. Table 26.9 and Table 26.10 show the basic operations of the USBFS (when there are no errors in the communication packets) based on the PID[1:0] bit setting.

After changing the PID[1:0] setting from BUF to NAK through the software during USB communication on the selected pipe, check that the PBUSY bit is 1 to see if USB transfer on the pipe has actually entered the NAK state. If the USBFS changes the PID[1:0] bits to NAK, checking the PBUSY bit through the software is not necessary.

The USBFS changes the PIPEnCTR.PID[1:0] setting in the following cases:

- The USBFS sets PID to NAK on recognizing completion of the transfer when the selected pipe is in the receiving direction and the PIPECFG.SHTNAK bit for the selected pipe is set to 1 by software
- The USBFS sets PID to STALL (11b) on receiving a data packet with a payload exceeding the maximum packet size of the selected pipe
- The USBFS sets PID to NAK on detecting a USB bus reset in device controller mode
- The USBFS sets PID to NAK on detecting a reception error, such as a CRC error, three consecutive times in host controller mode
- The USBFS sets PID to STALL (11b) on receiving the STALL handshake in host controller mode

To specify the response type, set the PID[1:0] bits as follows:

- To transition from NAK (00b) to STALL, set 10b
- To transition from BUF (01b) to STALL, set 11b
- To transition from STALL (11b) to NAK, set 10b and then 00b
- To transition from STALL to BUF, set 00b (NAK) and then 01b (BUF)

注1.只能读取0。
注2.PID为NAK时，仅设置ATREPM位或向SQCLR或SQSET位写入1。在设置这些位之前，请检查PBUSY位是否为0，然后将PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

注3.仅在PID为NAK且在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置ACLRM位。在设置该位之前，请检查PBUSY位是否为0，然后将PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

PIPEnCTR可以为PIPESEL寄存器中的任何管道选择设置。

PID[1:0] bits (Response PID)

PID[1:0]位指定所选管道上下一个事务的响应类型。

默认PID[1:0]设置为NAK。将PID[1:0]设置更改为BUF以使用关联的管道进行USB传输。表26.9和表26.10显示了基于PID[1:0]位设置的USBFS的基本操作（当通信数据包中没有错误时）。

在选定管道上进行USB通信期间，通过软件将PID[1:0]设置从BUF更改为NAK后，检查PBUSY位是否为1，以查看管道上的USB传输是否真正进入了NAK状态。如果USBFS将PID[1:0]位更改为NAK，则无需通过软件检查PBUSY位。

USBFS在以下情况下更改PIPEnCTR.PID[1:0]设置：

●当所选管道处于接收方向并且所选管道的PIPECFG.SHTNAK位由软件设置为1时，USBFS在识别到传输完成时将PID设置为NAK

●USBFS在接收到负载超过所选管道的最大数据包大小的数据包时将PID设置为STALL(11b)

●USBFS在设备控制器模式下检测到USB总线复位时将PID设置为NAK

●USBFS在主机控制器模式下连续3次检测到接收错误（例如CRC错误）时将PID设置为NAK

●USBFS在主机控制器模式下接收到STALL握手时将PID设置为STALL(11b)

要指定响应类型，请按如下方式设置PID[1:0]位：

●要从NAK(00b)转换到STALL，设置10b

●要从BUF(01b)转换到STALL，设置11b

●要从STALL(11b)转换为NAK，请设置10b，然后设置00b

●要从STALL转换到BUF，请设置00b(NAK)，然后设置01b(BUF)

	Isochronous	Does not depend on the setting	Returns nothing in response to the token from the USB host

PBUSY bit (Pipe Busy)

The PBUSY bit indicates whether the selected pipe is being used for the current transaction.

The USBFS changes the PBUSY bit from 0 to 1 on start of the USB transaction for the selected pipe, and changes the PBUSY bit from 1 to 0 on completion of one transaction.

Reading the PBUSY bit by software after PID is set to NAK allows you to check whether changing the pipe setting is possible. For details, see section 26.3.4.1. Pipe control register switching procedures.

SQMON bit (Sequence Toggle Bit Confirmation)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.

When the selected pipe is not the isochronous transfer type, the USBFS toggles the SQMON flag on successful completion of the transaction. However, the USBFS does not toggle the SQMON flag when a DATA-PID mismatch occurs during transfer in the receiving direction.

10b (STALL) or 11b (STALL)	批量或中断	不依赖于设置	返回STALL以响应来自USB主机的令牌
	Isochronous	不依赖于设置	响应来自USB主机的令牌，不返回任何内容

PBUSY bit (Pipe Busy)

PBUSY位指示所选管道是否正在用于当前事务。

USBFS在所选管道的USB事务开始时将PBUSY位从0更改为1，并更改
PBUSY位在一个事务完成时从1变为0。

在PID设置为NAK后，通过软件读取PBUSY位可以检查是否可以更改管道设置。详见26.3.4.1节。管道控制寄存器切换程序。

SQMON位（序列切换位确认）

SQMON位指示所选管道的下一个事务的序列切换位的预期值。

当所选管道不是同步传输类型时，USBFS在事务成功完成时切换SQMON标志。但是，当在接收方向的传输过程中发生DATA-PID不匹配时，USBFS不会切换SQMON标志。

SQSET bit (Sequence Toggle Bit Set)

Setting the SQSET bit to 1 through the software causes the USBFS to set DATA1 as the expected value of the sequence toggle bit for the next transaction on the selected pipe. The USBFS clears the SQSET bit to 0.

SQCLR bit (Sequence Toggle Bit Clear)

Setting the SQCLR bit to 1 through the software causes the USBFS to clear the expected value of the sequence toggle bit for the next transaction on the selected pipe to DATA0. The USBFS clears the SQCLR bit to 0.

ACLRM bit (Auto Buffer Clear Mode)

The ACLRM bit enables or disables auto buffer clear mode for the selected pipe. To completely clear the data in the FIFO buffer allocated to the selected pipe, write 1 and then 0 to the ACLRM bit continuously.

Table 26.11 shows the data cleared by writing 1 and 0 to the ACLRM bit continuously and the cases in which this processing is required.

Table 26.11 Data cleared by the USBFS when ACLRM = 1

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear
1	All data in the FIFO buffer allocated to the selected pipe (two FIFO buffers in double buffer mode)	When initializing the selected pipe
2	Interval count value when the selected pipe is the isochronous transfer type	When resetting the interval count value
3	Internal flags related to the PIPECFG.BFRE bit	When changing the PIPECFG.BFRE setting
4	FIFO buffer toggle control	When changing the PIPECFG.DBLB setting
5	Internal flags related to the transaction count	When forcing the transaction count function to terminate

ATREPM bit (Auto Response Mode)

The ATREPM bit enables or disables auto response mode for the selected pipe.

This bit can be set to 1 in device controller mode when the selected pipe is the bulk transfer type. When the bit is set to 1, the USBFS responds to the token from the USB host as follows:

- When the selected pipe is set for bulk IN transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 1):
  a. When the ATREPM bit = 1 and PID = BUF, the USBFS transmits a zero-length packet in response to the IN token.
  b. The USBFS updates (allows toggling of) the sequence toggle bit (DATA-PID) each time the USBFS receives ACK from the USB host. In a single transaction, the IN token is received, a zero-length packet is transmitted, and then ACK is received. The USBFS does not generate the BRDY or BEMP interrupt.
- When the selected pipe is set for bulk OUT transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 0):
  When the ATREPM bit = 1 and PID = BUF, the USBFS returns NAK in response to the OUT token and generates an NRDY interrupt.

For USB communication in auto response mode, set the ATREPM bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode. When the selected pipe uses isochronous transfer, always set this bit to 0.

In host controller mode, always set the ATREPM bit to 0.

INBUFM bit (Transmit Buffer Monitor)

The INBUFM bit indicates the FIFO buffer status for the selected pipe in the transmitting direction.

When the selected pipe is set in the transmitting direction (PIPECFG.DIR = 1), the USBFS sets this bit to 1 when the CPU or DMA/DTC completes writing data to at least one FIFO buffer plane.

The USBFS sets this bit to 0 when the USBFS completes transmission of the data from the FIFO buffer plane to which all the data is written. In double buffer mode (PIPECFG.DBLB = 1), the USBFS sets the INBUFM bit to 0 when the USBFS completes transmission of the data from the two FIFO buffer planes before the CPU or DMA/DTC completes writing data to one FIFO buffer plane.

SQSET位（序列切换位设置）

通过软件将SQSET位设置为1会导致USBFS将DATA1设置为所选管道上下一个事务的序列切换位的预期值。USBFS将SQSET位清0。

SQCLR位（序列翻转位清除）

通过软件将SQCLR位设置为1会导致USBFS将所选管道上下一个事务的序列切换位的预期值清除为DATA0。USBFS将SQCLR位清0。

ACLRM位（自动缓冲区清除模式）

ACLRM位启用或禁用所选管道的自动缓冲区清除模式。要完全清除分配给所选管道的FIFO缓冲区中的数据，请向ACLRM位连续写入1和0。

表26.11显示了通过向ACLRM位连续写入1和0来清除的数据以及需要进行此处理的情况。

Table 26.11 ACLRM=1时USBFS清除的数据

Number	通过设置ACLRM位清除数据	需要数据清楚的情况

2	选择管道为等时传输类型时的间隔计数值	重置间隔计数值时
3	与PIPECFG.BFRE位相关的内部标志	更改PIPECFG.BFRE设置时
4	FIFO缓冲区切换控制	更改PIPECFG.DBLB设置时
5	与事务计数相关的内部标志	强制事务计数函数终止时

ATREPM位（自动响应模式）

ATREPM位启用或禁用所选管道的自动响应模式。

当所选管道为批量传输类型时，该位可以在设备控制器模式下设置为1。当该位设置为1时，USBFS响应来自USB主机的令牌，如下所示：

●Whentheselectedpipeissetforbulk INtransfers(PIPECFG.TYPE[1:0]=01bandPIPECFG.DIR=1):

a. 当ATREPM位=1且PID=BUF时，USBFS发送一个长度为零的数据包以响应IN令牌。

湾。每次USBFS从USB主机接收到ACK时，USBFS都会更新（允许切换）序列切换位(DATA-PID)。在单个事务中，收到IN令牌，发送零长度数据包，然后收到ACK。USBFS不会产生BRDY或BEMP中断。

●当所选管道设置为批量OUT传输时（PIPECFG.TYPE[1:0]=01b和PIPECFG.DIR=0）：

当ATREPM位=1且PID=BUF时，USBFS返回NAK以响应OUT令牌并生成一个
NRDY interrupt.

对于自动响应模式下的USB通信，当FIFO缓冲区为空时，将ATREPM位设置为1。在自动响应模式下的USB通信期间不要写入FIFO缓冲区。当所选管道使用同步传输时，始终将此位设置为0。

在主机控制器模式下，始终将ATREPM位设置为0。

INBUFM位（发送缓冲区监视器）

INBUFM位指示发送方向上所选管道的FIFO缓冲区状态。

当所选管道设置为发送方向(PIPECFG.DIR=1)时，当CPU或DMADTC完成将数据写入至少一个FIFO缓冲区平面时，USBFS将该位设置为1。

当USBFS完成从写入所有数据的FIFO缓冲区平面传输数据时，USBFS将该位设置为0。在双缓冲模式(PIPECFG.DBLB=1)下，当USBFS在CPU或DMADTC完成将数据写入一个FIFO缓冲层之前完成从两个FIFO缓冲层的数据传输时，USBFS将INBUFM位设置为0。

The INBUFM bit indicates the same value as the BSTS bit when the selected pipe is in the receiving direction (PIPECFG.DIR = 0).

BSTS bit (Buffer Status)

The BSTS bit indicates the FIFO buffer status for the selected pipe.

The meaning of the BSTS bit depends on the PIPECFG.DIR, PIPECFG.BFRE, and DnFIFOSEL.DCLRM settings, as shown in Table 26.12.

Table 26.12 BSTS bit operation

DIR value	BFRE value	DCLRM value	BSTS bit function
0	0	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read

	1	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 when the software sets the BCLR bit in the port control register to 1 after the data read is complete
		1	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read
1	0	0	Sets to 1 when transmit data can be written to the FIFO buffer, and clears to 0 on completion of data write

当所选管道处于接收方向时（PIPECFG.DIR=0），INBUFM位指示与BSTS位相同的值。

BSTS bit (Buffer Status)

BSTS位指示所选管道的FIFO缓冲区状态。

BSTS位的含义取决于PIPECFG.DIR、PIPECFG.BFRE和DnFIFOSEL.DCLRM设置，如表26.12所示。

If the PID[1:0] bits are changed to 00b (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 2. Only set the ACLRM bit while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. If the PID[1:0] bits are changed to 00b (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

PID[1:0] bits (Response PID)

The PID[1:0]bits specify the response type for the next transaction of the selected pipe.

The default PID[1:0] setting is NAK. Change the PID[1:0] setting to BUF to use the associated pipe for USB transfer. Table 26.9 and Table 26.10 show the basic operation (when there are no errors in the transmitted and received packets) of the USBFS depending on the PID[1:0] setting.

After changing the PID[1:0] setting from BUF to NAK through the software during USB communication on the selected pipe, check that the PBUSY bit is 1 to see if USB transfer on the selected pipe has actually entered the NAK state. If the USBFS changes the PID[1:0] bits to NAK, checking the PBUSY bit through the software is not necessary.

The USBFS changes the PIPEnCTR.PID[1:0] setting in the following cases:

- The USBFS sets PID to STALL (11b) on receiving a data packet with a payload exceeding the maximum packet size of the selected pipe
- The USBFS sets PID to NAK on detecting a USB bus reset in device controller mode
- The USBFS sets PID to NAK on detecting a reception error, such as a CRC error, three consecutive times in host controller mode
- The USBFS sets PID to STALL (11b) on receiving the STALL handshake in host controller mode

To specify each response type, set the PID[1:0] bits as follows:

- To transition from NAK (00b) to STALL, set 10b
- To transition from BUF (01b) to STALL, set 11b
- To transition from STALL (11b) to NAK, set 10b and then 00b
- To transition from STALL to BUF, set 00b (NAK) and then 01b (BUF)

PBUSY bit (Pipe Busy)

The PBUSY bit indicates whether the selected pipe is being used for the current transaction.

The USBFS changes the PBUSY bit from 0 to 1 on start of the USB transaction for the selected pipe, and changes the PBUSY bit from 1 to 0 on completion of one transaction.

Reading the PBUSY bit by software after PID is set to NAK allows you to check whether changing the pipe setting is possible.

SQMON bit (Sequence Toggle Bit Confirmation)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.

The USBFS toggles the SQMON bit on successful completion of the transaction. However, the USBFS does not toggle the SQMON bit when a DATA-PID mismatch occurs during transfer in the receiving direction.

Bit	Symbol	Function	R/W
8	SQCLR	序列切换位清除*1 清除管道n的序列切换位。 0：无效（写0无效）1：清除下一笔交易的期望值到DATA0	W
9	ACLRM	自动缓冲区清除模式*2 0：禁用1：启用（所有缓冲区已初始化）	R/W
14:10	—	这些位被读取为0。写入值应为0。	R/W
15	BSTS	缓冲区状态 0：禁止缓冲区访问1：允许缓冲区访问	R

注1.PID为NAK时，仅向SQCLR或SQSET位写入1。在设置这些位之前，请检查PBUSY位是否为0，然后将PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00b(NAK)，则无需通过软件检查PBUSY位。

注2.仅在PID为NAK时和在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置ACLRM位。在设置该位之前，请检查PIPEnCTR.PBUSY位是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00b(NAK)，则无需通过软件检查PBUSY位。

PID[1:0] bits (Response PID)

PID[1:0]位指定所选管道的下一个事务的响应类型。

默认PID[1:0]设置为NAK。将PID[1:0]设置更改为BUF以使用关联的管道进行USB传输。表26.9和表26.10显示了取决于PID[1:0]设置的USBFS的基本操作（在发送和接收的数据包中没有错误时）。

在选定管道上进行USB通信期间，通过软件将PID[1:0]设置从BUF更改为NAK后，检查PBUSY位是否为1，以查看选定管道上的USB传输是否真正进入了NAK状态。如果USBFS将PID[1:0]位更改为NAK，则无需通过软件检查PBUSY位。

USBFS在以下情况下更改PIPEnCTR.PID[1:0]设置：

●USBFS在接收到负载超过所选管道的最大数据包大小的数据包时将PID设置为STALL(11b)

●USBFS在设备控制器模式下检测到USB总线复位时将PID设置为NAK

●USBFS在主机控制器模式下连续3次检测到接收错误（例如CRC错误）时将PID设置为NAK

●USBFS在主机控制器模式下接收到STALL握手时将PID设置为STALL(11b)

要指定每种响应类型，请按如下方式设置PID[1:0]位：

●要从NAK(00b)转换到STALL，设置10b

●要从BUF(01b)转换到STALL，设置11b

●要从STALL(11b)转换为NAK，请设置10b，然后设置00b

●要从STALL转换到BUF，请设置00b(NAK)，然后设置01b(BUF)

PBUSY bit (Pipe Busy)

PBUSY位指示所选管道是否正在用于当前事务。

USBFS在所选管道的USB事务开始时将PBUSY位从0更改为1，并更改PBUSY位在一个事务完成时从1变为0。

在PID设置为NAK后，通过软件读取PBUSY位可以检查是否可以更改管道设置。

SQMON位（序列切换位确认）

SQMON位指示所选管道的下一个事务的序列切换位的预期值。

USBFS在事务成功完成时切换SQMON位。但是，USBFS不会切换SQMON位，当在接收方向的传输过程中发生DATA-PID不匹配时。

SQSET bit (Sequence Toggle Bit Set)

Setting the SQSET bit to 1 through the software causes the USBFS to set DATA1 as the expected value of the sequence toggle bit for the next transaction on the selected pipe. The USBFS sets the SQSET bit to 0.

SQCLR bit (Sequence Toggle Bit Clear)

Setting the SQCLR bit to 1 through the software causes the USBFS to clear the expected value of the sequence toggle bit for the next transaction on the selected pipe to DATA0. The USBFS sets the SQCLR bit to 0.

ACLRM bit (Auto Buffer Clear Mode)

The ACLRM bit enables or disables auto buffer clear mode for the selected pipe. To completely clear the data in the FIFO buffer allocated to the selected pipe, write 1 and then 0 to the ACLRM bit continuously.

Table 26.13 shows the data cleared by writing 1 and 0 continuously to the ACLRM bit and the cases in which this processing is required.

Table 26.13 Data cleared by the USBFS when ACLRM = 1

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear
1	All data in the FIFO buffer allocated to the selected pipe	When initializing the selected pipe
2	Interval count value when the selected pipe is the isochronous transfer type	When resetting the interval count value
3	Internal flags related to the PIPECFG.BFRE bit	When changing the PIPECFG.BFRE setting
4	Internal flags related to the transaction count	When forcing the transaction count function to terminate

BSTS bit (Buffer Status)

The BSTS bit indicates the FIFO buffer status for the selected pipe.

The meaning of the BSTS bit depends on the PIPECFG.DIR, PIPECFG.BFRE, and DnFIFOSEL.DCLRM settings, as shown in Table 26.12.

26.2.37 PIPEnTRE : PIPEn Transaction Counter Enable Register (n = 1 to 5)

15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: Set each bit in PIPEnTRE while PID is NAK. Before setting these bits after changing the PIPEnCTR.PID[1:0] bits for the selected pipe from BUF to NAK, check that the PIPEnCTR.PBUSY bit is 0. However, if the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

TRCLR bit (Transaction Counter Clear)

When the TRCLR bit sets to 1, the USBFS clears the value of the transaction counter associated with the selected pipe and then sets the TRCLR bit to 0.

SQSET位（序列切换位设置）

通过软件将SQSET位设置为1会导致USBFS将DATA1设置为所选管道上下一个事务的序列切换位的预期值。USBFS将SQSET位设置为0。

SQCLR位（序列翻转位清除）

通过软件将SQCLR位设置为1会导致USBFS将所选管道上下一个事务的序列切换位的预期值清除为DATA0。USBFS将SQCLR位设置为0。

ACLRM位（自动缓冲区清除模式）

ACLRM位启用或禁用所选管道的自动缓冲区清除模式。要完全清除分配给所选管道的FIFO缓冲区中的数据，请向ACLRM位连续写入1和0。

表26.13显示了通过向ACLRM位连续写入1和0来清除的数据以及需要进行此处理的情况。

Table 26.13 ACLRM=1时USBFS清除的数据

4	与事务计数相关的内部标志	强制事务计数函数终止时

BSTS bit (Buffer Status)

BSTS位指示所选管道的FIFO缓冲区状态。

BSTS位的含义取决于PIPECFG.DIR、PIPECFG.BFRE和DnFIFOSEL.DCLRM设置，如表26.12所示。

26.2.37 PIPEnTRE:PIPEn事务计数器使能寄存器(n=1到5)

Note: 当PID为NAK时，设置PIPEnTRE中的每个位。在将所选管道的PIPEnCTR.PID[1:0]位从BUF更改为NAK之后设置这些位之前，请检查PIPEnCTR.PBUSY位是否为0。但是，如果PID[1:0]位更改为NAK通过USBFS，无需通过软件检查PBUSY位。

TRCLR位（事务计数器清零）

当TRCLR位设置为1时，USBFS清除与所选管道关联的事务计数器的值，然后将TRCLR位设置为0。

TRENB bit (Transaction Counter Enable)

The TRENB bit enables or disables the transaction counter.

For receiving pipes, setting the TRENB bit to 1 after setting the total number of the packets to be received in the PIPEnTRN.TRNCNT[15:0] bits through the software allows the USBFS to control hardware on having received the number of packets equal to the TRNCNT[15:0] setting, as follows:

- When the PIPECFG.SHTNAK bit is 1, the USBFS changes the PID bits to NAK for the associated pipe on having received the number of packets equal to the TRNCNT[15:0] setting
- When the PIPECFG.BFRE bit is 1, the USBFS asserts the BRDY interrupt on having received the number of packets equal to the TRNCNT[15:0] setting and then reading the last received data

For transmitting pipes, set the TRENB bit to 0.

When the transaction counter is not used, set this bit to 0. When the transaction counter is used, set the TRNCNT[15:0] bits before setting this bit to 1. Set this bit to 1 before receiving the first packet to be counted by the transaction counter.

26.2.38 PIPEnTRN : PIPEn Transaction Counter Register (n = 1 to 5)

15:0	TRNCNT[15:0]	Transaction Counter When written to, this bit specifies the total packets (number of transactions) to be received by the selected pipe. When read from, when PIPEnTRE.TRENB is 0, this bit indicates the specified number of transactions. When PIPEnTRE.TRENB is 1, this bit indicates the current transaction count.	R/W

The PIPEnTRN registers retain their settings during a USB bus reset.

TRNCNT[15:0] bits (Transaction Counter)

The USBFS increments the value of the TRNCNT[15:0] bits by 1 when all of the following conditions are satisfied on receiving the packet:

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value ≠ current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[9:0] setting

The USBFS clears the value of the TRNCNT[15:0] bits to 0 when any of the following conditions are satisfied:

All of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value = current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[9:0] setting

Both of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The USBFS received a short packet

Both of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1

TRENB位（事务计数器使能）

TRENB位启用或禁用事务计数器。

对于接收管道，在设置接收管道的总包数后，将TRENB位设置为1 PIPEnTRN.TRNCNT[15:0]位通过软件允许USBFS在接收到等于TRNCNT[15:0]设置的数据包数量时控制硬件，如下所示：

●当PIPECFG.SHTNAK位为1时，USBFS在接收到等于TRNCNT[15:0]设置的数据包数时将关联管道的PID位更改为NAK

●当PIPECFG.BFRE位为1时，USBFS在接收到等于TRNCNT[15:0]设置的数据包数量并读取最后接收到的数据时断言BRDY中断

对于传输管道，将TRENB位设置为0。

不使用事务计数器时，将该位设置为0。使用事务计数器时，将该位设置为1之前设置TRNCNT[15:0]位。在接收第一个要计数的数据包之前将该位设置为1由交易柜台。

26.2.38 PIPEnTRN:PIPEn事务计数器寄存器(n=1到5)

TRNCNT[15:0] bits (Transaction Counter)

●接收数据包的有效载荷与PIPEMAXP.MXPS[9:0]设置一致

当满足以下任一条件时，USBFS将TRNCNT[15:0]位的值清零：

满足以下所有条件：

●PIPEnTRE.TRENB位=1
●(TRNCNT[15:0]setvalue=currentcountervalue+1)收到数据包
●接收数据包的有效载荷与PIPEMAXP.MXPS[9:0]设置一致

满足以下两个条件：

●PIPEnTRE.TRENB位=1
●USBFS收到一个短数据包

满足以下两个条件：

●PIPEnTRE.TRENB位=1

- The PIPEnTRE.TRCLR bit was set to 1 by software

For transmitting pipes, set the TRNCNT[15:0] bits to 0. When the transaction counter is not used, set the TRNCNT[15:0] bits to 0.

Setting the number of transactions to be transferred to the TRNCNT[15:0] bits is only enabled when the PIPEnTRE.TRENB bit is 0. To set the number of transactions to be transferred, set the TRCLR bit to 1 to clear the current counter value before setting the PIPEnTRE.TRENB bit to 1.

26.3 Operation

26.3.1 System Control

This section describes register settings required for initializing the USBFS and controlling power consumption.

26.3.1.1 Setting data to the USBFS registers

Setting the SYSCFG.USBE bit to 1 after starting the clock supply (SYSCFG.SCKE bit = 1) enables and starts USBFS operation.

26.3.1.2 Selecting the controller function

The USBFS can operate as either a host or device controller.

Use the SYSCFG.DCFM bit to select one of these USBFS functions. The DCFM bit must be changed in the initial settings immediately after a reset or in the D+ pull-up-disabled state (SYSCFG.DPRPU bit = 0) and D+ and D– pull-down-disabled state (SYSCFG.DRPD bit = 0).

26.3.1.3 Controlling the USB data bus using resistors

The USBFS provides pull-up and pull-down resistors for the D+ and D– lines. Pull these lines up or down by setting the SYSCFG.DPRPU and DRPD bits.

In device controller mode, confirm that connection to the USB host is made, and then set the SYSCFG.DPRPU bit to 1 and pull up the D+ line (in full-speed communication).

When the SYSCFG.DPRPU bit is set to 0 during communication with a PC, the USBFS disables the pull-up resistor of the USB data line, thereby notifying the USB host of disconnection.

In host controller mode, set the SYSCFG.DRPD bit to 1 to pull down the D+ and D– lines.

26.3.1 系统控制

本节介绍初始化USBFS和控制功耗所需的寄存器设置。

26.3.1.1 将数据设置到USBFS寄存器

启动时钟供应（SYSCFG.SCKE位=1）后将SYSCFG.USBE位设置为1启用并启动USBFS操作。

26.3.1.2 选择控制器功能

USBFS可以作为主机或设备控制器运行。

使用SYSCFG.DCFM位选择这些USBFS功能之一。DCFM位必须在复位后立即更改为初始设置或在D+上拉禁用状态（SYSCFG.DPRPU位=0）和D+和D 下拉禁用状态（SYSCFG.DRPD位=0））。

26.3.1.3 使用电阻控制USB数据总线

USBFS为D+和D−线提供上拉和下拉电阻。通过设置
SYSCFG.DPRPU和DRPD位。

在设备控制器模式下，确认与USB主机的连接已建立，然后将SYSCFG.DPRPU位设置为1并拉高D+线（全速通信）。

当SYSCFG.DPRPU位在与PC通信期间设置为0时，USBFS禁用上拉电阻
USB数据线，从而通知USB主机断开。

在主机控制器模式下，将SYSCFG.DRPD位设置为1以拉低D+和D−线。

26.3.1.5 Release from deep software standby mode because of USB suspend/resume interrupts

Deep Software Standby mode can be canceled by a USB suspend/resume interrupt. USB suspend/resume interrupts are detected by the USB resume detecting unit, which controls and monitors the USB I/O pins to detect the interrupts.

26.3.3 Interrupt Descriptions

26.3.3.1 BRDY interrupt

The BRDY interrupt is generated in both host and device controller modes. This section describes the conditions in which the USBFS sets the associated bit in BRDYSTS to 1. Under these conditions, the USBFS generates a BRDY interrupt if the software has set the bit in BRDYENB associated with the given pipe to 1 and the INTENB0.BRDYE bit to 1.

The conditions for generating and clearing the BRDY interrupt depend on the SOFCFG.BRDYM and PIPECFG.BFRE settings for each pipe as follows:

(1) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.

On any of the following conditions, the USBFS generates an internal BRDY interrupt request trigger and sets the BRDYSTS.PIPEnBRDY bit associated with the selected pipe to 1.

For transmitting pipes

- When the DIR bit is changed from 0 to 1 by software
- When packet transmission is complete for a pipe while write-access from the CPU to the FIFO buffer for the pipe is disabled (when the BSTS bit is read as 0)
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is complete
- When the hardware flushes the buffer of the pipe for isochronous transfers
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to transition from the write-disabled to write-enabled state

No request trigger is generated for the DCP, that is, during data transmission for control transfers.

For receiving pipes

- When packet reception is successfully complete, enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the given pipe is disabled (when the BSTS bit is read as 0). No request trigger is generated for transactions in which a DATA-PID mismatch has occurred.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode. No request trigger is generated until completion of reading data from the currently-read FIFO buffer, even if reception by the other FIFO buffer is complete.

In device controller mode, the BRDY interrupt is not generated in the status stage of control transfers. The PIPEBRDY interrupt status of the selected pipe can be set to 0 by writing 0 to the associated PIPEnBRDY bit through software. In this case, the other PIPEBRDY bit should be set to 1.

26.3.3 中断说明

26.3.3.1 BRDY interrupt

在主机和设备控制器模式下都会产生BRDY中断。本节介绍USBFS将BRDYSTS中的相关位设置为1的条件。在这些条件下，如果软件将BRDYENB中与给定管道相关的位设置为1并且INTENB0.BRDYE位，USBFS将生成BRDY中断为1。

产生和清除BRDY中断的条件取决于每个管道的SOFCFG.BRDYM和PIPECFG.BFRE设置，如下所示：

(1) 当SOFCFG.BRDYM=0且PIPECFG.BFRE=0时

通过这些设置，BRDY中断指示FIFO端口可访问。

在以下任何一种情况下，USBFS都会产生一个内部BRDY中断请求触发器并设置BRDYSTS.PIPEnBRDY位与所选管道相关联为1。

用于传输管道

●DIR位由软件从0变为1时

●当一个管道的数据包传输完成而从CPU到该管道的FIFO缓冲区的写访问被禁用时（当BSTS位被读取为0时）

●双缓冲模式下，当一个FIFO缓冲区完成向另一个FIFO缓冲区写入数据时为空时

●直到向当前写入的FIFO缓冲区写入数据完成，才会产生请求触发，即使传输到另一个FIFO缓冲区已完成

●当硬件刷新管道缓冲区以进行同步传输时

●当PIPEnCTR.ACLRM位写入1时，导致FIFO缓冲区从写禁止状态转变为写使能状态

没有为DCP生成请求触发，即在控制传输的数据传输期间。

用于接收管道

●当数据包接收成功完成时，允许读取FIFO缓冲区，同时禁止CPU对给定管道的FIFO缓冲区的读取访问（当BSTS位被读取为0时）。对于发生DATA-PID不匹配的事务，不会生成请求触发器。

●当一个FIFO缓冲区在双缓冲区模式下从另一个FIFO缓冲区读取数据完成后使能读取。在从当前读取的FIFO缓冲区读取数据完成之前，不会生成请求触发，即使其他FIFO缓冲区的接收已完成。

在设备控制器模式下，在控制传输的状态阶段不会产生BRDY中断。通过软件将0写入相关的PIPEnBRDY位，可以将所选管道的PIPEBRDY中断状态设置为0。在这种情况下，另一个PIPEBRDY位应设置为1。

Clear the BRDY status before accessing the FIFO buffer.

(2) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 1

With these settings, the USBFS generates a BRDY interrupt on completion of reading all data for a single transfer using the receiving pipe, and sets the bit in BRDYSTS associated with the pipe to 1.

On any of the following conditions, the USBFS determines that the last data for a single transfer was received.

- When a short packet including a zero-length packet is received
- When the PIPEn transaction counter register (PIPEnTRN) is used and the number of packets specified in the PIPEnTRN.TRNCNT[15:0] bits are completely received

When the data is completely read after any of these conditions is satisfied, the USBFS determines that all data for a single transfer is completely read.

When a zero-length packet is received while the FIFO buffer is empty, the USBFS determines that all data for a single transfer is completely read when the FRDY bit in the FIFO port control register is 1 and the DTLN[8:0] bits are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the associated port control register through the software. With these settings, the USBFS does not detect a BRDY interrupt for the transmitting pipe.

The PIPEBRDY interrupt status of a pipe can be set to 0 by writing 0 to the associated BRDYSTS.PIPEnBRDY bit through the software. In this case, 1s must be written to the PIPEBRDY bits for the other pipes.

In this mode, do not change the PIPECFG.BFRE bit setting until all data for a single transfer is processed. When it is necessary to change the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pipe must be cleared using the PIPEnCTR.ACLRM bit.

(3) When SOFCFG.BRDYM = 1 and PIPECFG.BFRE = 0

With these settings, the BRDYSTS.PIPEnBRDY values are linked to the BSTS bit setting for each pipe. In other words, the BRDY interrupt status bits (PIPEBRDY) are set to 1 or 0 by the USB depending on the FIFO buffer status.

For transmitting pipes

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for write access, and are set to 0 when it is not ready. The BRDY interrupt is not generated for the DCP in the transmitting direction even when it is ready for write access.

For receiving pipes

The BRDY interrupt status bits set to 1 when the FIFO buffer is ready for read access, and set to 0 when all data is read (not ready for read access).

When a zero-length packet is received while the FIFO buffer is empty, the associated bit is set to 1 and the BRDY interrupt is continuously generated until the software writes 1 to BCLR. With this setting, the PIPEnBRDY bit cannot be set to 0 by software.

When the SOFCFG.BRDYM bit is set to 1, set the PIPECFG.BFRE bit for all pipes to 0.

Figure 26.10 shows the timing of BRDY interrupt generation.

在访问FIFO缓冲区之前清除BRDY状态。

(2) 当SOFCFG.BRDYM=0且PIPECFG.BFRE=1时

使用这些设置，USBFS在完成使用接收管道读取单次传输的所有数据时生成BRDY中断，并将BRDYSTS中与管道关联的位设置为1。

在以下任何一种情况下，USBFS都会确定已接收到单次传输的最后一个数据。

- 收到包含零长度包的短包时
- 当使用PIPEn事务计数器寄存器(PIPEnTRN)并且完全接收到PIPEnTRN.TRNCNT[15:0]位中指定的数据包数量时

当满足其中任何一个条件后数据被完全读取时，USBFS确定单次传输的所有数据都被完全读取。

当FIFO缓冲区为空时接收到零长度数据包时，当FIFO端口控制寄存器中的FRDY位为1且DTLN[8:0]位为0.在这种情况下，要开始下一次传输，通过软件向相关端口控制寄存器中的BCLR位写入1。使用这些设置，USBFS不会检测到传输管道的BRDY中断。

通过软件将0写入相关的BRDYSTS.PIPEnBRDY位，可以将管道的PIPEBRDY中断状态设置为0。在这种情况下，必须将1写入其他管道的PIPEBRDY位。

在此模式下，在处理完单次传输的所有数据之前，不要更改PIPECFG.BFRE位设置。当需要在处理完成之前更改PIPECFG.BFRE位时，必须使用PIPEnCTR.ACLRM位清除管道的所有FIFO缓冲区。

(3) 当SOFCFG.BRDYM=1且PIPECFG.BFRE=0时

通过这些设置，BRDYSTS.PIPEnBRDY值链接到每个管道的BSTS位设置。换句话说，BRDY中断状态位(PIPEBRDY)由USB设置为1或0，具体取决于FIFO缓冲区状态。

用于传输管道

当FIFO缓冲区准备好进行写访问时，BRDY中断状态位设置为1，当它未准备好时设置为0。发送方向上的DCP不会产生BRDY中断，即使它已准备好进行写访问。

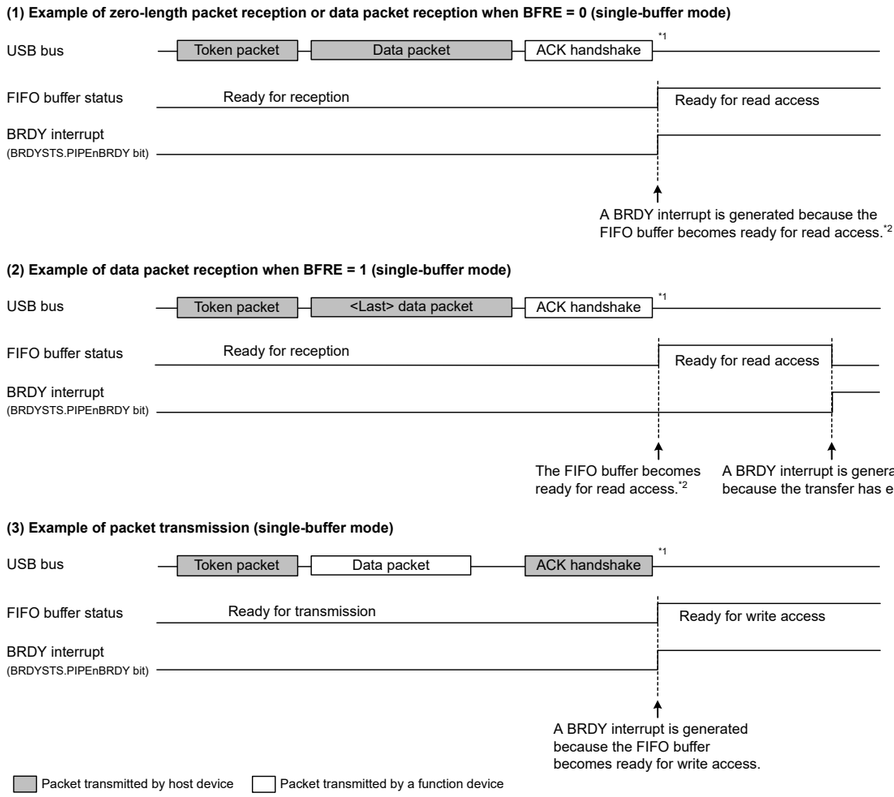
用于接收管道

当FIFO缓冲区准备好进行读取访问时，BRDY中断状态位设置为1，并在读取所有数据（未准备好进行读取访问）时设置为0。

当FIFO缓冲区为空时接收到零长度数据包时，相关位设置为1，并且持续产生BRDY中断，直到软件将1写入BCLR。使用此设置，PIPEnBRDY位不能通过软件设置为0。

当SOFCFG.BRDYM位设置为1时，将所有管道的PIPECFG.BFRE位设置为0。

图26.10显示了BRDY中断产生的时序。



Note 1. The ACK handshake is not used in isochronous transfers.
Note 2. The FIFO buffer becomes ready for read access under the following condition:
When a packet is received while no data remains unread in the FIFO buffer in the CPU.
Note 3. A transfer ends under either of the following conditions:
(1) When a short packet including a zero-length packet is received
(2) When the number of packets specified in the transaction counter are received

Figure 26.10 Timing of BRDY interrupt generation

The condition for clearing the INTSTS0.BRDY bit depends on the SOFCFG.BRDYM bit setting, as shown in Table 26.18.

Table 26.18 Conditions for clearing the BRDY bit

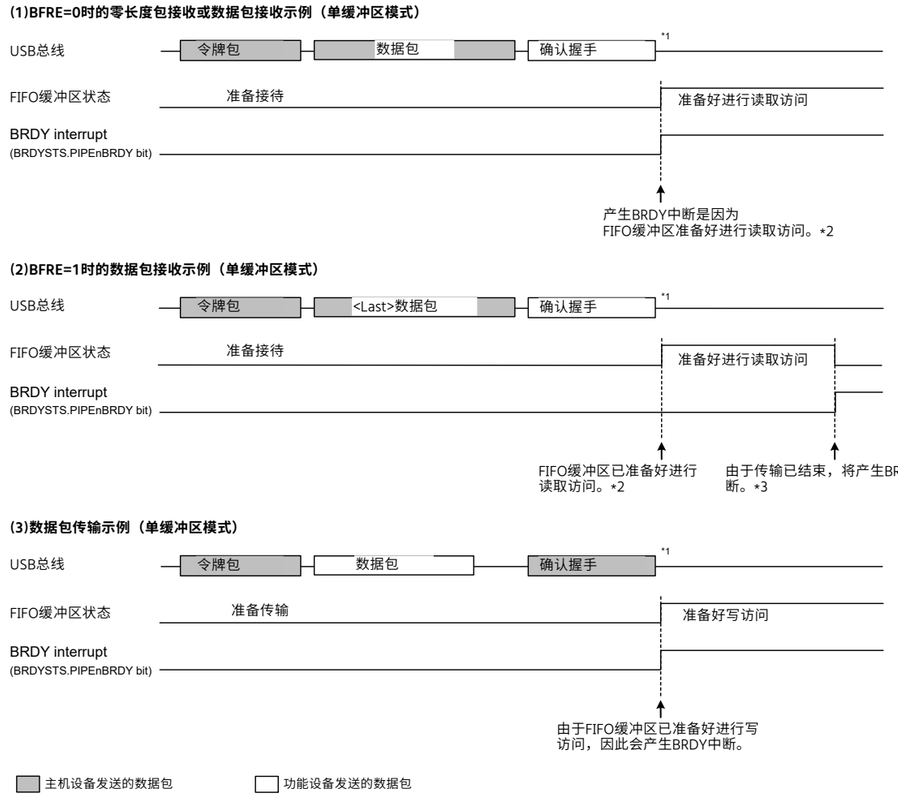
BRDYM bit	Condition for clearing BRDY bit
0	The USBFS clears the BRDY bit to 0 when all bits in BRDYSTS are set to 0 by software.
1	The USBFS clears the BRDY bit to 0 when the BSTS bits for all pipes have cleared to 0.

26.3.3.2 NRDY interrupt

On generating an internal NRDY interrupt request for the pipe whose PID bits are set to BUF by software, the USBFS sets the associated PIPEnNRDY bit in NRDYSTS to 1. If the associated bit in NRDYENB is set to 1 by software, the USBFS sets the INTSTS0.NRDY bit to 1 and generates a USBFS interrupt.

This section describes the conditions in which the USBFS generates the internal NRDY interrupt request for a given pipe.

The internal NRDY interrupt request is not generated during setup transaction execution in host controller mode. During setup transactions in host controller mode, the SACK or SIGN interrupt is detected.



注1.ACK握手不用于同步传输。
注2.FIFO缓冲区在以下条件下准备好进行读取访问：

注3.转会在以下任一情况下结束：
(1)接收到包含零长度数据包的短数据包时(2)接收到事务计数器中指定数量的数据包时

Figure 26.10 BRDY中断产生的时序

清除INTSTS0.BRDY位的条件取决于SOFCFG.BRDYM位设置，如表26.18所示。

Table 26.18 清除BRDY位的条件

BRDYM bit	清除BRDY位的条件
0	当BRDYSTS中的所有位被软件设置为0时，USBFS将BRDY位清零。
1	当所有管道的BSTS位已清零时，USBFS将BRDY位清零。

26.3.3.2 NRDY interrupt

在为PID位由软件设置为BUF的管道生成内部NRDY中断请求时，USBFS将NRDYSTS中的相关PIPEnNRDY位设置为1。如果NRDYENB中的相关位由软件设置为1，则USBFS设置INTSTS0.NRDY位为1并产生USBFS中断。

本节描述USBFS为给定管道生成内部NRDY中断请求的条件。

内部NRDY中断请求在主控制器模式下的设置事务执行期间不会产生。在主机控制器模式下的设置事务期间，检测到SACK或SIGN中断。

The internal NRDY interrupt request is not generated during status stage execution of the control transfer in device controller mode.

(1) In host controller mode

For transmitting pipes

On any of the following conditions, the USBFS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBFS transmits a zero-length packet following the OUT token and sets the associated NRDYSTS.PIPEnNRDY bit and the FRMNUM.OVRN bit to 1.
- During communications other than setup transactions on pipes not used for isochronous transfers, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device
  - An error is detected in the packet from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the associated PID[1:0] setting for the pipe to NAK
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the PID[1:0] setting for the associated pipe to STALL (11b).

For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBFS discards the received data for the IN token and sets the PIPEnNRDY bit associated with the pipe and the OVRN bit to 1. When a packet error is detected in the received data for the IN token, the USBFS also sets the FRMNUM.CRCE bit to 1.
- For non-isochronous transfer pipes, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device for the IN token issued by the USBFS (when timeout is detected before detection of the DATA packet from the peripheral device)
  - An error is detected in the packet from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the associated PID[1:0] setting for the pipe to NAK
- For isochronous transfer pipes, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe to 1. The PID[1:0] setting for the pipe is not changed.
- For isochronous transfer pipes, when a CRC error or a bit stuffing error is detected in the received data packet. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe and the CRCE bit to 1.
- When the STALL handshake is received. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe to 1 and changes the PID[1:0] setting for the associated pipe to STALL.

(2) In device controller mode

For transmitting pipes

- When an IN token is received while there is no data to be transmitted in the FIFO buffer. In this case, the USBFS generates a NRDY interrupt request on reception of the IN token and sets the NRDYSTS.PIPEnNRDY bit to 1. For an isochronous transfer pipe in which an interrupt is generated, the USBFS transmits a zero-length packet and sets the FRMNUM.OVRN bit to 1.

For receiving pipes

- When an OUT token is received but there is no space available in the FIFO buffer. For an isochronous transfer pipe in which an interrupt is generated, the USBFS generates a NRDY interrupt request on reception of the OUT token and sets the PIPEnNRDY bit to 1 and OVRN bit to 1. For a non-isochronous transfer pipe in which an interrupt is generated, the USBFS generates a NRDY interrupt request when a NAK handshake is transferred after the data following the OUT token is received, and sets the PIPEnNRDY bit to 1. The NRDY interrupt request is not generated during retransmission

在设备控制器模式下控制传输的状态阶段执行期间，不会产生内部NRDY中断请求。

(1) 在主机控制器模式下

用于传输管道

在以下任何一种情况下，USBFS都会检测到NRDY中断：

●对于同步传输管道，当FIFO缓冲区中没有要传输的数据时发出OUT令牌的时间到来。在这种情况下，USBFS在OUT令牌之后发送一个长度为零的数据包，并将相关的NRDYSTS.PIPEnNRDY位和FRMNUM.OVRN位设置为1。

●在不用于同步传输的管道上的设置事务以外的通信期间，当以下两种情况的任意组合连续发生3次时：

外围设备没有返回响应（当在检测到来自外围设备的握手包之前检测到超时时

在来自外围设备的数据包中检测到错误。在这种情况下，USBFS将相关的PIPEnNRDY位设置为1，并将管道的相关PID[1:0]设置更改为NAK

●在设置事务以外的通信期间，当从外围设备接收到STALL握手时。在这种情况下，USBFS将相关的PIPEnNRDY位设置为1，并将相关管道的PID[1:0]设置更改为STALL(11b)。

用于接收管道

●对于同步传输管道，当发出IN令牌的时间到来但FIFO中没有可用空间时缓冲。在这种情况下，USBFS丢弃接收到的IN令牌数据，并将与管道关联的PIPEnNRDY位和OVRN位设置为1。当在接收到的IN令牌数据中检测到数据包错误时，USBFS也会设置FRMNUM.CRCE位为1。

●对于非等时传输管道，当以下两种情况的任意组合连续出现3次时：

USBFS发出的IN令牌没有从外围设备返回响应（当在检测到来自外围设备的DATA包之前检测到超时时）

在来自外围设备的数据包中检测到错误。在这种情况下，USBFS将相关的PIPEnNRDY位设置为1，并将管道的相关PID[1:0]设置更改为NAK

●对于同步传输管道，当外围设备没有返回对IN令牌的响应时（当在检测到外围设备的DATA包之前检测到超时时）或在外围设备的数据包中检测到错误。在这种情况下，USBFS将与管道关联的PIPEnNRDY位设置为1。管道的PID[1:0]设置不会更改。

●对于同步传输管道，当在接收到的数据包中检测到CRC错误或比特填充错误时。在这种情况下，USBFS将与管道关联的PIPEnNRDY位和CRCE位设置为1。

●收到STALL握手时。在这种情况下，USBFS将与管道关联的PIPEnNRDY位设置为1，并将关联管道的PID[1:0]设置更改为STALL。

(2) 在设备控制器模式下

用于传输管道

●当接收到一个IN令牌而FIFO缓冲区中没有要传输的数据时。在这种情况下，USBFS在接收到IN令牌时生成NRDY中断请求并将NRDYSTS.PIPEnNRDY位设置为1。对于产生中断的同步传输管道，USBFS发送一个长度为零的数据包并将FRMNUM.OVRN位设置为1.

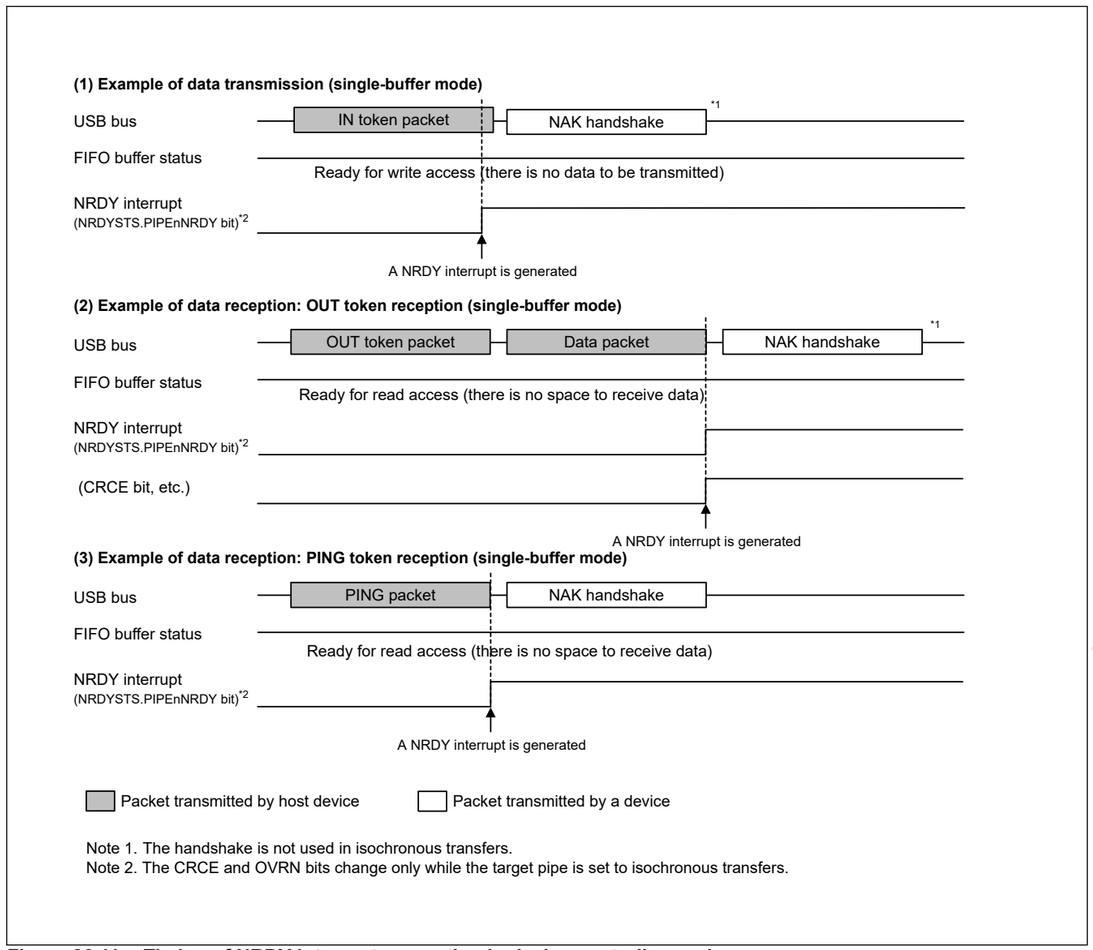
用于接收管道

●当接收到OUT令牌但FIFO缓冲区中没有可用空间时。对于产生中断的同步传输管道，USBFS在接收到OUT令牌时产生一个NRDY中断请求，并将PIPEnNRDY位设置为1，并将OVRN位设置为1。USBFS在接收到OUT令牌之后的数据后，在传输NAK握手时产生NRDY中断请求，并将PIPEnNRDY位设置为1。重传期间不产生NRDY中断请求

because of a DATA-PID mismatch. In addition, the NRDY interrupt request is not generated if an error occurs in the DATA packet.

- For isochronous transfer pipes, when a token is not received successfully within an interval frame. In this case, the USBFS generates an NRDY interrupt request when the SOF is received, and sets the PIPEnNRDY bit to 1.

Figure 26.11 shows the timing of NRDY interrupt generation in device controller mode.



Note 1. The handshake is not used in isochronous transfers.
Note 2. The CRCE and OVRN bits change only while the target pipe is set to isochronous transfers.

Figure 26.11 Timing of NRDY interrupt generation in device controller mode

26.3.3.3 BEMP interrupt

On detecting a BEMP interrupt for the pipe whose PID bits are set to BUF by software, the USBFS sets the associated BEMPSTS.PIPEnBEMP bit to 1. If the associated bit in BEMPENB is set to 1 by software, the USBFS sets the INTSTS0.BEMP bit to 1 and generates a USBFS interrupt. This section describes the conditions in which the USBFS generates an internal BEMP interrupt request.

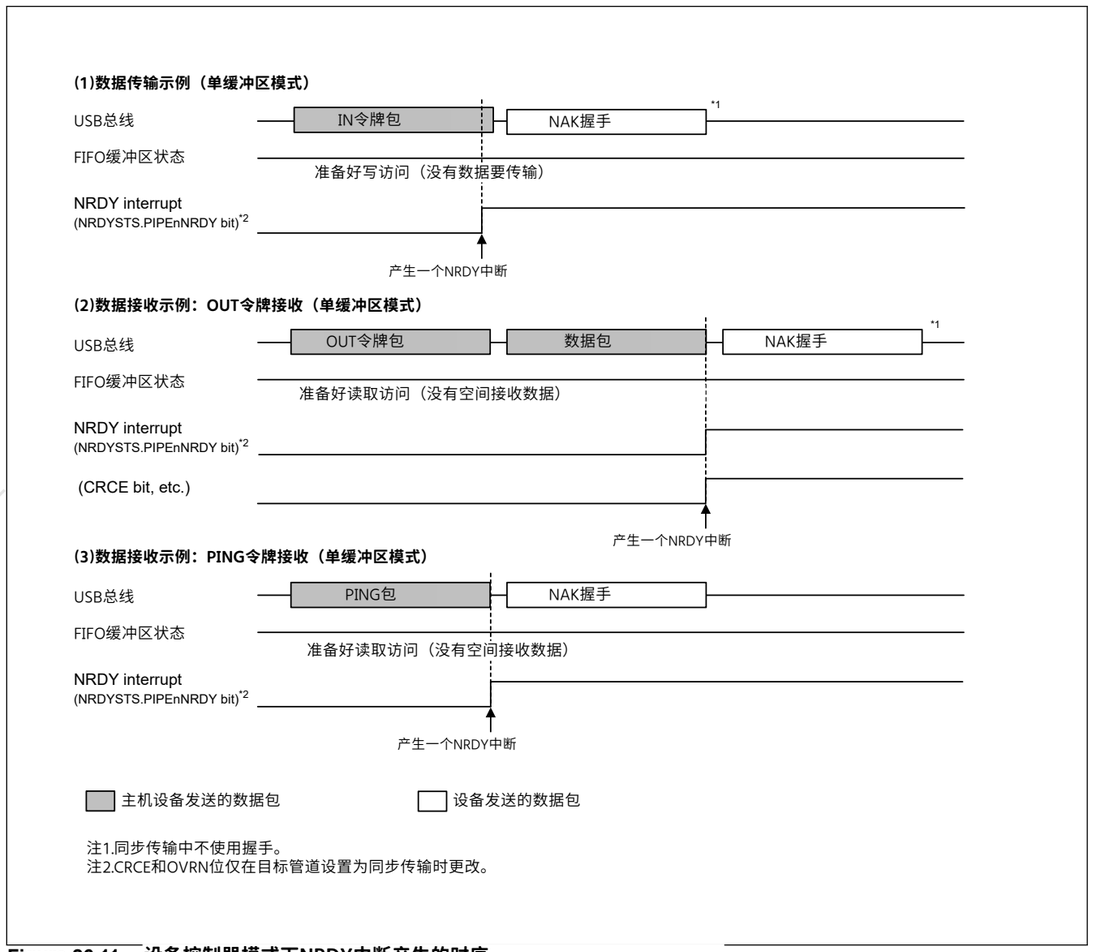
(1) For transmitting pipes

When the FIFO buffer of the associated pipe is empty on completion of transmission, including zero-length packet transmission, and in single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for a non-DCP pipe. The internal BEMP interrupt request is not generated in any of the following conditions:

因为DATA-PID不匹配。此外，如果DATA包发生错误，则不会产生NRDY中断请求。

●对于同步传输管道，当在间隔帧内没有成功接收到令牌时。在这种情况下，USBFS在接收到SOF时产生一个NRDY中断请求，并将PIPEnNRDY位设置为1。

图26.11显示了设备控制器模式下NRDY中断产生的时序。



注1.同步传输中不使用握手。
注2.CRCE和OVRN位仅在目标管道设置为同步传输时更改。

Figure 26.11 设备控制器模式下NRDY中断产生的时序

26.3.3.3 BEMP interrupt

在检测到PID位被软件设置为BUF的管道的BEMP中断时，USBFS将相关的BEMPSTS.PIPEnBEMP位设置为1。如果BEMPENB中的相关位被软件设置为1，USBFS将设置
INTSTS0.BEMP位为1并产生USBFS中断。本节介绍USBFS产生内部BEMP中断请求的条件。

(1) 用于传输管道

当相关管道的FIFO缓冲区在传输完成时为空时，包括零长度数据包传输，并且在单缓冲区模式下，内部BEMP中断请求与非DCP管道的BRDY中断同时生成。在以下任何一种情况下都不会产生内部BEMP中断请求：

- When the CPU or DMA/DTC has already started writing data to the FIFO buffer of the CPU on completion of transmitting data from one FIFO buffer in double buffer mode
- When the buffer is cleared (emptied) by setting the PIPEnCTR.ACLRM or the BCLR bit to 1 in the port control register
- When an IN transfer (zero-length packet transmission) is performed during the control transfer status stage in device controller mode

(2) For receiving pipes

When a successfully-received data packet size exceeds the specified maximum packet size. In this case, the USBFS generates a BEMP interrupt request, sets the associated BEMPSTS.PIPEnBEMP bit to 1, discards the received data, and changes the associated PID[1:0] setting for the pipe to STALL (11b). The USBFS returns no response in host controller mode, and returns STALL response in device controller mode.

The internal BEMP interrupt request is not generated in any of the following conditions:

- When a CRC error or a bit stuffing error is detected in the received data
- When a setup transaction is being performed:
  - Writing 0 to the BEMPSTS.PIPEnBEMP bit clears the status
  - Writing 1 to the BEMPSTS.PIPEnBEMP bit has no effect

Figure 26.12 shows the timing of BEMP interrupt generation in device controller mode.

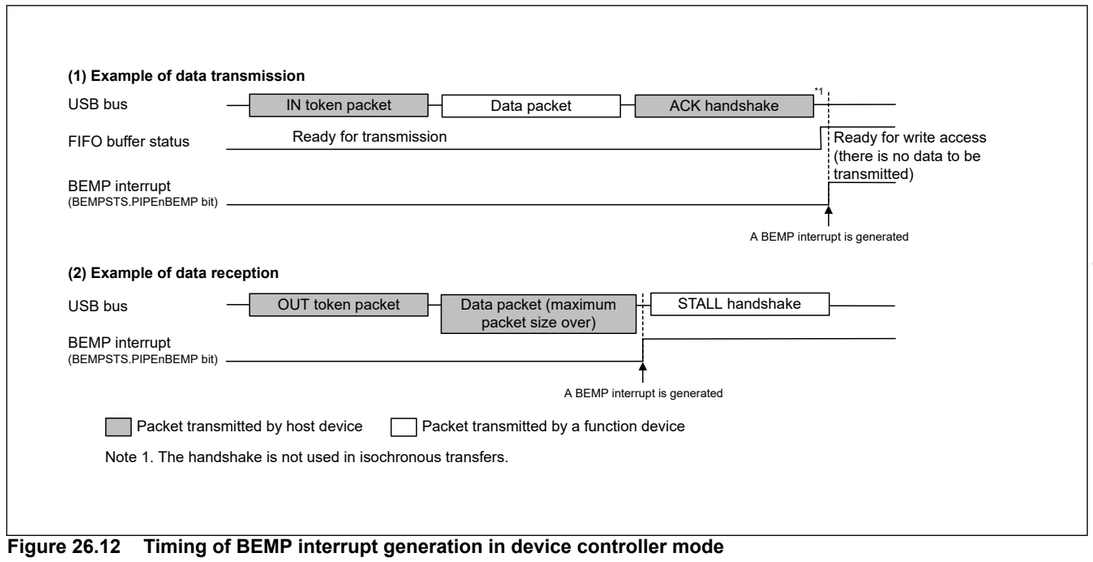


Figure 26.12 Timing of BEMP interrupt generation in device controller mode

26.3.3.4 Device state transition interrupt (device controller mode)

Figure 26.13 shows a diagram of the USBFS device state transitions. The USBFS controls device states and generates device state transition interrupts. However, recovery from the Suspend state (resume signal detection) is detected by means of the resume interrupt. Device state transition interrupts can be enabled or disabled independently in INTENB0. Devices whose states have changed can be checked in the INTSTS0.DVSQ[2:0] bits.

When a transition is made to the default state, a device state transition interrupt is generated after a USB bus reset is detected.

The USBFS controls device states, and device state transition interrupts can be generated, only in device controller mode.

●当CPU或DMADTC在双缓冲模式下从一个FIFO缓冲区完成数据传输后已经开始向CPU的FIFO缓冲区写入数据时

●通过将端口控制寄存器中的PIPEnCTR.ACLRM或BCLR位设置为1来清除（清空）缓冲区时

●在设备控制器模式的控制传输状态阶段进行IN传输（零长度包传输）时

(2) 用于接收管道

当成功接收的数据包大小超过指定的最大包大小时。在这种情况下，USBFS生成一个BEMP中断请求，将相关的BEMPSTS.PIPEnBEMP位设置为1，丢弃接收到的数据，并将管道的相关PID[1:0]设置更改为STALL(11b)。USBFS在主机控制器模式下不返回响应，在设备控制器模式下返回STALL响应。

在以下任何一种情况下都不会产生内部BEMP中断请求：

●在接收到的数据中检测到CRC错误或位填充错误时

●执行设置事务时：

将0写入BEMPSTS.PIPEnBEMP位可清除状态

向BEMPSTS.PIPEnBEMP位写入1无效

图26.12显示了设备控制器模式下BEMP中断产生的时序。

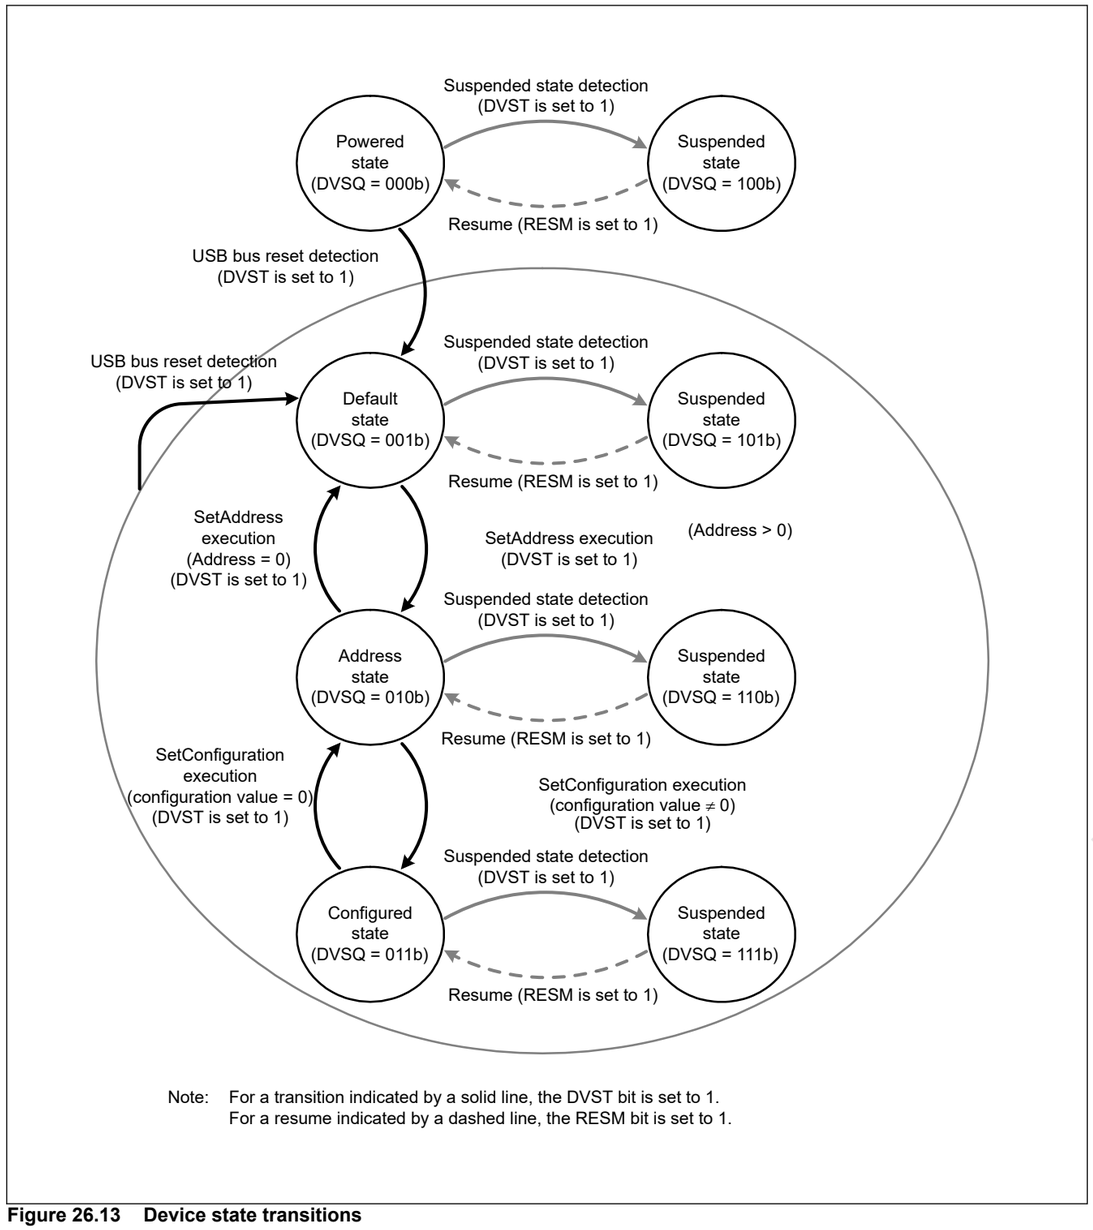
26.3.3.4 设备状态转换中断（设备控制器模式）

图26.13显示了USBFS设备状态转换的示意图。USBFS控制设备状态并产生设备状态转换中断。但是，从挂起状态的恢复（恢复信号检测）是通过恢复中断来检测的。可以在INTENB0中独立启用或禁用设备状态转换中断。可以在INTSTS0.DVSQ[2:0]位中检查状态已更改的设备。

当转换到默认状态时，检测到USB总线复位后会产生设备状态转换中断。

USBFS控制设备状态，并且只能在设备控制器模式下产生设备状态转换中断。



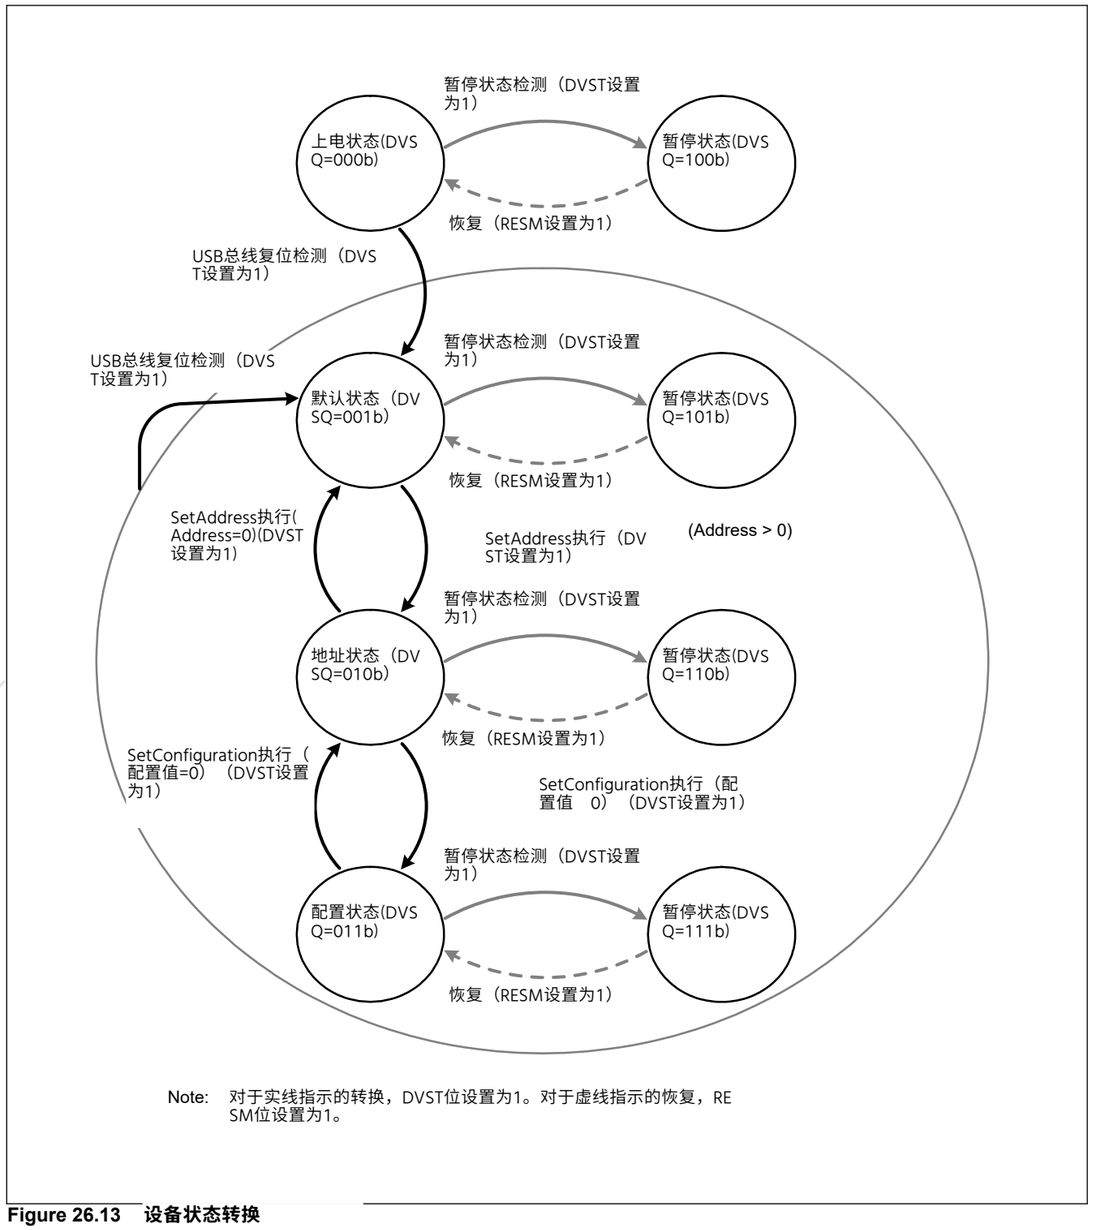
Note: For a transition indicated by a solid line, the DVST bit is set to 1.
For a resume indicated by a dashed line, the RESM bit is set to 1.

Figure 26.13 Device state transitions

26.3.3.5 Control transfer stage transition interrupt (device controller mode)

Figure 26.14 shows a diagram of the control transfer stage transitions of the USBFS. The USBFS controls the control transfer sequence and generates control transfer stage transition interrupts. Control transfer stage transition interrupts can be enabled or disabled independently in INTENB0. Transfer stages that have transitioned can be checked in the INTSTS0.CTSQ[2:0] bits.

Control transfer stage transition interrupts are generated only in device controller mode. This section describes control transfer sequence errors. If an error occurs, the DCPCTR.PID[1:0] bits are set to 1xb (STALL response).



Note: 对于实线指示的转换，DVST位设置为1。对于虚线指示的恢复，RESM位设置为1。

Figure 26.13 设备状态转换

26.3.3.5 控制转移阶段转换中断（设备控制器模式）

图26.14显示了USBFS的控制传输阶段转换图。USBFS控制控制传输序列并产生控制传输阶段转换中断。控制转移阶段转换中断可以在INTENB0中独立启用或禁用。可以在INTSTS0.CTSQ[2:0]位中检查已转换的传输阶段。

控制转移阶段转换中断仅在设备控制器模式下产生。本节描述控制传输序列错误。如果发生错误，则DCPCTR.PID[1:0]位设置为1xb（STALL响应）。

(1) Control read transfer errors

- An OUT token is received but no data is transferred in response to the IN token at the data stage
- An IN token is received at the status stage
- A data packet with DATAPID = DATA0 is received at the status stage

(2) Control write transfer errors

- An IN token is received but no ACK is returned in response to the OUT token at the data stage
- A data packet with DATAPID = DATA0 is received as the first data packet at the data stage
- An OUT token is received at the status stage

(3) Control write no data transfer errors

- An OUT token is received at the status stage

At the control write transfer data stage, if the receive data length exceeds the wLength value of the USB request, it is not recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (INTSTS0.CTRT = 1), the CTSQ[2:0] = 110b value is saved until the CTRT bit is set to 0, clearing the interrupt status. While CTSQ[2:0] = 110b is being saved, no CTRT interrupt for ending the setup stage is generated, even if a new USB request is received. The USBFS saves the setup stage completion status, and it generates a CTRT interrupt after the interrupt status is cleared by software.

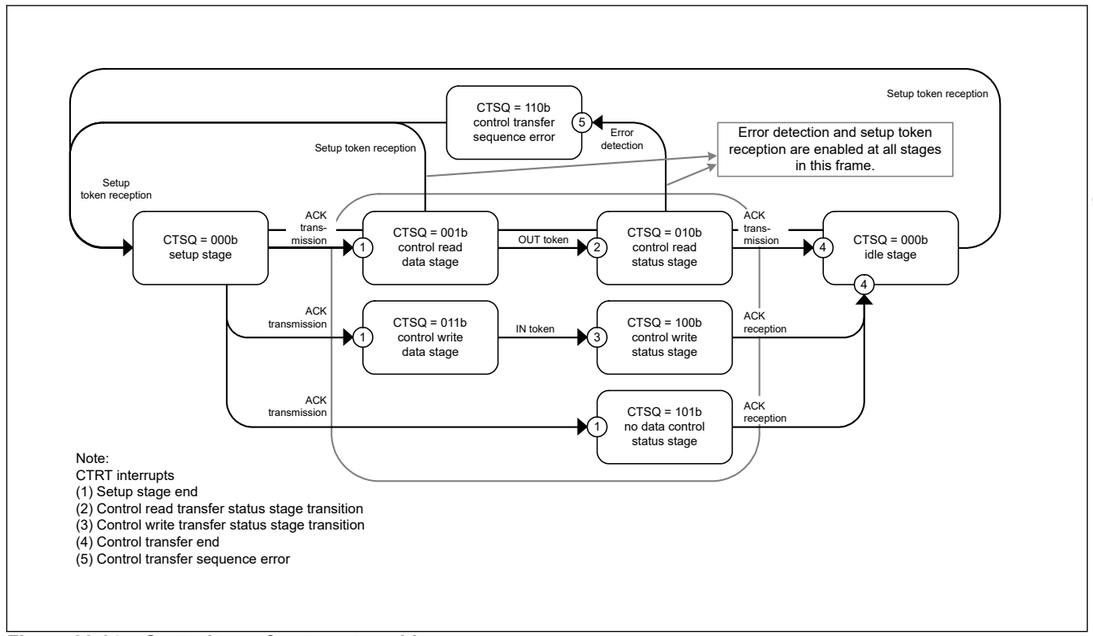


Figure 26.14 Control transfer stage transitions

26.3.3.6 Frame update interrupt

In host controller mode, an interrupt is generated when the frame number is updated.

In device controller mode, an SOFR interrupt is generated when the frame number is updated. The USBFS updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation.

(1) 控制读取传输错误

●在数据阶段收到一个OUT令牌，但没有传输数据以响应IN令牌

●在状态阶段收到一个IN令牌

●在状态阶段接收到DATAPID=DATA0的数据包

(2) 控制写入传输错误

●在数据阶段收到一个IN令牌，但没有返回ACK响应OUT令牌

●DATAPID=DATA0的数据包作为数据阶段的第一个数据包被接收

●在状态阶段收到一个OUT令牌

(3) 控制写入无数据传输错误

●在状态阶段收到一个OUT令牌

在控制写入传输数据阶段，如果接收数据长度超过USB请求的wLength值，则不被识别为控制传输序列错误。
在控制读取传输状态阶段，除了零长度数据包之外的数据包被一个ACK响应接收并且传输正常结束。

当响应序列错误（INTSTS0.CTRT=1）而发生CTRT中断时，将保存CTSQ[2:0]=110b值，直到CTRT位设置为0，清除中断状态。在保存CTSQ[2:0]=110b时，不会产生用于结束设置阶段的CTRT中断，即使收到新的USB请求也是如此。USBFS保存设置阶段完成状态，软件清除中断状态后产生CTRT中断。

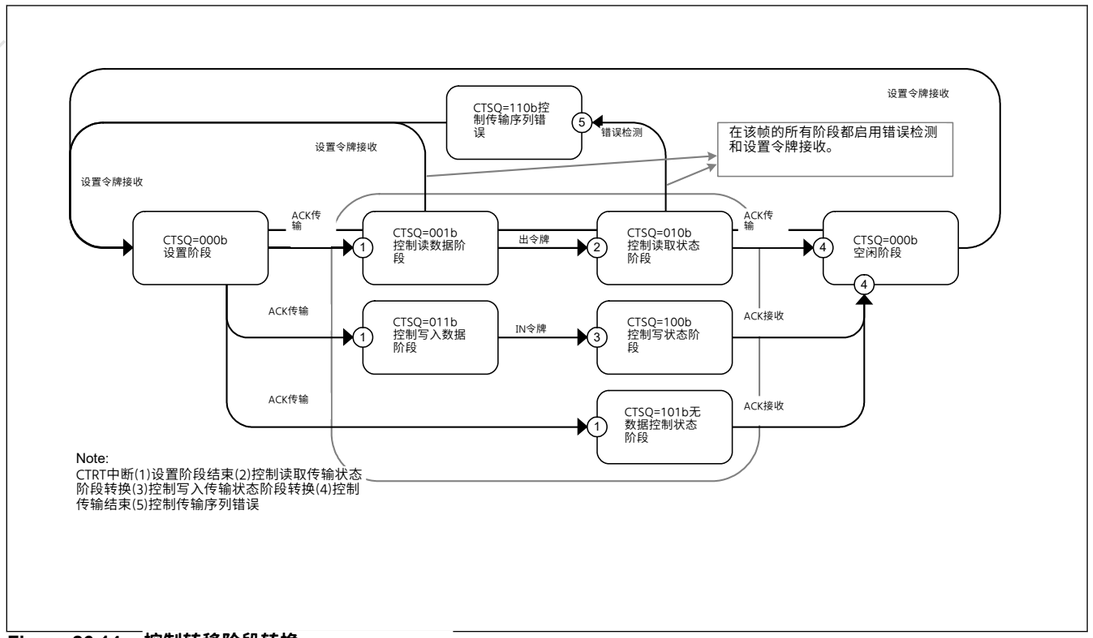

Figure 26.14 控制转移阶段转换

26.3.3.6 帧更新中断

在主机控制器模式下，更新帧号时会产生中断。

在设备控制器模式下，更新帧号时会产生SOFR中断。如果USBFS在全速运行期间检测到新的SOF数据包，则USBFS会更新帧号并生成SOFR中断。

26.3.3.7 VBUS interrupt

When the USB_VBUS pin level changes, a VBUS interrupt is generated. The level of the USB_VBUS pin can be checked with the INTSTS0.VBSTS bit. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. If the system is activated with the host controller connected, the first VBUS interrupt is not generated, because there is no change in the USB_VBUS pin level.

26.3.3.8 Resume interrupt

In device controller mode, a resume interrupt is generated when the device state is the Suspend state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the Suspend state is detected by means of the resume interrupt.

In host controller mode, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

26.3.3.9 OVRCR interrupt

An OVRCR interrupt is generated when the USB_OVRCURA pin level has changed. The levels of the USB_OVRCURA pins can be checked in the SYSSTS0.OVCMON[1:0] flags. The external power supply IC can check whether overcurrent is detected using the OVRCR interrupt.

26.3.3.10 BCHG interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether a peripheral device is connected and can also be used to detect a remote wakeup in host controller mode. The BCHG interrupt is generated in both host and device controller modes.

26.3.3.11 DTCH interrupt

A DTCH interrupt occurs when a USB bus disconnect is detected in host controller mode. The USBFS detects bus disconnects in compliance with the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software. The pipes enter the wait state for a bus connection to the port, waiting for an ATTCH interrupt to occur. Regardless of the value set in the associated interrupt enable bit, the USBFS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt is detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state

26.3.3.12 SACK interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet is received from the peripheral device in host controller mode. The SACK interrupt can be used to confirm that the setup transaction is successfully complete.

26.3.3.13 SIGN interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet is not correctly received from the peripheral device three consecutive times in host controller mode. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

26.3.3.14 ATTCH interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5 µs in host controller mode. To be more specific, an ATTCH interrupt is detected on any of the following conditions:

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5 µs
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5 µs

26.3.3.15 EOFERR interrupt

An EOFERR interrupt occurs when the USBFS detects that communication is not complete at the EOF2 timing defined in the USB 2.0 specification.

26.3.3.7 VBUS interrupt

当USB_VBUS引脚电平改变时，会产生VBUS中断。USB_VBUS引脚的电平可以通过INTSTS0.VBSTS位检查。主控制器是连接还是断开可以使用VBUS中断来确认。如果系统在连接主机控制器的情况下激活，则不会产生第一个VBUS中断，因为USB_VBUS引脚电平没有变化。

26.3.3.8 恢复中断

在设备控制器模式下，当设备状态为Suspend状态且USB总线状态发生变化（从J-state到K-state，或从J-state到SE0）时，会产生恢复中断。通过恢复中断检测从挂起状态的恢复。

在主机控制器模式下，不会产生恢复中断。使用BCHG中断来检测USB总线状态的变化。

26.3.3.9 OVRCR interrupt

当USB_OVRCURA引脚电平发生变化时，会产生OVRCR中断。USB_OVRCURA引脚的电平可以在SYSSTS0.OVCMON[1:0]标志中检查。外部电源IC可以使用OVRCR中断检查是否检测到过电流。

26.3.3.10 BCHG interrupt

当USB总线状态改变时会产生BCHG中断。BCHG中断可用于检测是否连接了外围设备，也可用于检测主机控制器模式下的远程唤醒。BCHG中断在主机和设备控制器模式下产生。

26.3.3.11 DTCH interrupt

当在主机控制器模式下检测到USB总线断开连接时，会发生DTCH中断。USBFS检测符合USB2.0规范的总线断开连接。

在检测到中断时，为相关端口执行通信的所有管道必须由软件终止。管道进入等待状态，等待总线连接到端口，等待ATTCH中断发生。无论相关中断使能位中设置的值如何，USBFS硬件：

●将检测到DTCH中断的端口的DVSTCTR0.UACT位设置为0

●将发生DTCH中断的端口置于空闲状态

26.3.3.12 SACK中断

当在主机控制器模式下从外围设备接收到对发送的设置数据包的ACK响应时，将产生SACK中断。SACK中断可用于确认设置事务成功完成。

26.3.3.13 标志中断

在主机控制器模式下，如果连续三次未从外围设备正确接收到已发送的设置数据包的ACK响应，则会产生SIGN中断。SIGN中断可用于检测没有从外围设备发送的ACK响应或ACK数据包的损坏。

26.3.3.14 ATTCH interrupt

在主机控制器模式下，当在USB端口上检测到全速信号电平的J状态或K状态持续2.5µs时，将产生ATTCH中断。更具体地说，在以下任何条件下都会检测到ATTCH中断：

●当K-state、SE0或SE1变为J-state时，J-state持续2.5µs

●J-state、SE0或SE1变为K-state时，K-state持续2.5µs

26.3.3.15 EOFERR interrupt

当USBFS检测到在USB2.0规范中定义的EOF2时序未完成通信时，将发生EOFERR中断。

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software, and the port must be re-enumerated. Regardless of the value set in the associated interrupt enable bit, the USBFS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt is detected to 0
- Puts the port in which the EOFERR interrupt is generated into the idle state

26.3.3.16 Portable Device Detection Interrupt

The USBFS sets the INTSTS1.PDDETINT flag to 1 on detecting a portable device and generates the portable device detection interrupt. When the portable device detection interrupt is generated, use software to repeat reading the BCCTRL1.PDDETSTS flag until the same value is read three or more times, and perform debounce processing.

26.3.4 Pipe Control

Table 26.19 lists the pipe settings for the USBFS. USB data transfer is performed through logical pipes that the software associates with endpoints. The USBFS provides 10 pipes that are used for data transfer. Set up the pipes based on your system specifications.

- 将检测到EOFERR中断的端口的DVSTCTR0.UACT位设置为0
- 将产生EOFERR中断的端口置于空闲状态

26.3.3.16 便携式设备检测中断

USBFS在检测到便携式设备时将INTSTS1.PDDETINT标志设置为1，并生成便携式设备检测中断。当便携式设备检测中断产生时，使用软件重复读取BCCTRL1.PDDETSTS标志，直到读取相同的值3次或更多次，并进行去抖动处理。

26.3.4 管道控制

26.3.4.1 Pipe control register switching procedures

The following bits in the pipe control registers can be changed only when USB communication is prohibited (PID = NAK).

Do not change the following registers and bits when USB communication is enabled (PID = BUF):

- Bits in DCPCFG and DCPMAXP
- SQCLR and SQSET bits in DCPCTR
- Bits in PIPECFG, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPEnCTR
- Bits in PIPEnTRE and PIPEnTRN

To set these bits when USB communication is enabled (PID = BUF):

1. A request to change the bits in the pipe control register occurs.
2. Set the PID[1:0] bits associated with the pipe to NAK.
3. Wait until the associated PBUSY bit clears to 0.
4. Set the bits in the pipe control register.

The following bits in the pipe control registers can be changed only when the selected pipe information is not set in the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Do not set the following registers when the CURPIPE[3:0] bits are set:

- Bits in DCPCFG and DCPMAXP
- Bits in PIPECFG, PIPEMAXP and PIPEPERI

To change pipe information, you must set the CURPIPE[3:0] bits in the port select registers to a pipe other than the one to be changed. For the DCP, the buffer must be cleared using the BCLR bit in the Port Control Register after the pipe information is changed.

26.3.4.2 Transfer types

The PIPECFG.TYPE[1:0] bits specify the following transfer types for each pipe:

- DCP: No setting is necessary (fixed at control transfer)
- Pipes 1 and 2: Set to bulk or isochronous transfer
- Pipes 3 to 5: Set to bulk transfer
- Pipes 6 to 9: Set to interrupt transfer

26.3.4.3 Endpoint number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to 15.

- DCP: No setting is necessary (fixed at endpoint 0)
- Pipes 1 to 9: Select and set the endpoint numbers from 1 to 15 so that the combination of the PIPECFG.DIR and EPNUM[3:0] bits is unique

26.3.4.4 Maximum packet size setting

Specify the maximum packet size for each pipe in the DCPMAXP.MXPS[6:0] and PIPEMAXP.MXPS[9:0] bits. The DCP and pipes 1 to 5 can be set to any of the maximum pipe sizes defined in the USB 2.0 specification. For pipes 6 to 9, the maximum packet size is 64 bytes. Set the maximum packet size as follows before starting a transfer (PID = BUF):

- DCP: Set to 8, 16, 32, or 64
- Pipes 1 to 5: Set to 8, 16, 32, or 64 for bulk transfers
- Pipes 1 and 2: Set between 1 and 256 for isochronous transfers
- Pipes 6 to 9: Set between 1 and 64

26.3.4.1 管道控制寄存器切换程序

只有当USB通信被禁止(PID=NAK)时，管道控制寄存器中的以下位才能更改。

当启用USB通信(PID=BUF)时，请勿更改以下寄存器和位：

- ●DCPCFG和DCPMAXP中的位
- ●DCPCTR中的SQCLR和SQSET位
- ●PIPECFG、PIPEMAXP和PIPEPERI中的位
- ●PIPEnCTR中的ATREPM、ACLRM、SQCLR和SQSET位
- ●PIPEnTRE和PIPEnTRN中的位

要在启用USB通信(PID=BUF)时设置这些位：

1.发生更改管道控制寄存器中的位的请求。

2.将与管道关联的PID[1:0]位设置为NAK。

3.等到相关的PBUSY位清除为0。

4.设置管道控制寄存器中的位。

管道控制寄存器中的以下位只有在所选管道信息未设置时才能更改CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位。

设置CURPIPE[3:0]位时不要设置以下寄存器：

- ●DCPCFG和DCPMAXP中的位
- ●PIPECFG、PIPEMAXP和PIPEPERI中的位

要更改管道信息，您必须将端口选择寄存器中的CURPIPE[3:0]位设置为要更改的管道以外的管道。对于DCP，必须在管道信息更改后使用端口控制寄存器中的BCLR位清除缓冲区。

26.3.4.2 传输类型

PIPECFG.TYPE[1:0]位为每个管道指定以下传输类型：

- ●DCP：无需设置（控制转移时固定）
- ●管道1和2：设置为批量或同步传输
- ●管道3到5：设置为批量传输
- ●管道6到9：设置为中断传输

26.3.4.3 端点编号

PIPECFG.EPNUM[3:0]位用于设置每个管道的端点号。DCP固定在端点0。其他管道可以设置从端点1到15。

- ●DCP：无需设置（固定在端点0）
- ●管道1到9：从1到15选择和设置端点编号，以便PIPECFG.DIR和EPNUM[3:0]位的组合是唯一的

26.3.4.4 最大数据包大小设置

在DCPMAXP.MXPS[6:0]和PIPEMAXP.MXPS[9:0]位中指定每个管道的最大数据包大小。DCP和管道1到5可以设置为USB2.0规范中定义的任何最大管道尺寸。对于管道6到9，最大数据包大小为64字节。在开始传输之前设置最大数据包大小如下（PID=BUF）：

- ●DCP：设置为8、16、32或64
- ●管道1到5：设置为8、16、32或64以进行批量传输
- ●管道1和2：设置在1和256之间，用于同步传输
- ●管道6到9：设置在1到64之间

26.3.4.5 Transaction counter for pipes 1 to 5 in the receiving direction

When the specified number of transactions is complete in the data packet receiving direction, the USBFS recognizes that the transfer ended. Two transaction counters are provided: one is the PIPEnTRN register, which specifies the number of transactions to be executed, and the other is the current counter, which internally counts the number of executed transactions. If the PIPECFG.SHTNAK bit is set to 1, when the current counter value matches the specified number of transactions, the associated PIPEnCTR.PID[1:0] bits are set to NAK and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The data read from PIPEnTRN differs depending on the PIPEnTRE.TRENB setting as follows:

- The TRENB bit = 0: Specified transaction counter value can be read
- The TRENB bit = 1: Current counter value indicating the internally counted number of executed transactions can be read

The following constraints apply when working with the TRCLR bit:

- If the transactions are being counted and PID = BUF, the current counter cannot be cleared
- If there is any data left in the buffer, the current counter cannot be cleared

26.3.4.6 Response PID

Specify the response PID for each pipe in the PID[1:0] bits in DCPCTR and PIPEnCTR. This section describes the USBFS operation with different response PID settings.

(1) Software response PID settings in host controller mode

Select the response PID to specify the execution of transactions as follows:

- NAK setting: Using pipes is disabled and no transactions are executed
- BUF setting: Transactions are executed based on the FIFO buffer state:
  - OUT direction: An OUT token is issued if the FIFO buffer contains transmit data.
  - IN direction: An IN token is issued if the FIFO buffer is not full and can receive data.
- STALL setting: Using pipes is disabled and no transactions are executed

Note: Use the DCPCTR.SUREQ bit to execute setup transactions for the DCP.

(2) Software response PID settings in device controller mode

Select the response PID to respond as follows to transactions from the host:

- NAK setting: A NAK response is returned to all generated transactions
- BUF setting: A response is returned to transactions based on the FIFO buffer
- STALL setting: A STALL response is returned to all generated transactions

Note: For setup transactions, an ACK response is always returned, regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

Sections (3) and (4) describe situations in which the USBFS writes to the PID[1:0] bits because of specific transaction results.

(3) Hardware response PID settings in host controller mode

- NAK setting: PID = NAK is set in the following cases, and issuing of tokens is automatically stopped:
  - When a non-isochronous transfer is performed and an NRDY interrupt is generated
    (For details, see section 26.3.3.2. NRDY interrupt.)
  - If a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
  - If transaction counting ends when the SHTNAK bit is set to 1 for bulk transfers
- BUF setting: The USBFS does not write this setting.

26.3.4.5 接收方向上管道1到5的事务计数器

当在数据包接收方向完成指定数量的事务时，USBFS识别传输结束。提供了两个事务计数器：一个是PIPEnTRN寄存器，指定要执行的事务数，另一个是当前计数器，内部统计执行的事务数。如果PIPECFG.SHTNAK位设置为1，则当当前计数器值与指定的事务数匹配时，相关的PIPEnCTR.PID[1:0]位将设置为NAK，并禁用后续传输。通过PIPEnTRE.TRCLR位初始化事务计数器功能的当前计数器，事务可以从头开始重新计数。从PIPEnTRN读取的数据因PIPEnTRE.TRENB设置而异，如下所示：

●TRENB位=0：可以读取指定的事务计数器值
●TRENB位=1：表示内部计数的已执行事务数的当前计数器值可被读取

使用TRCLR位时适用以下约束：
●如果正在对事务进行计数且PID=BUF，则无法清除当前计数器
●如果缓冲区中还有数据，则无法清除当前计数器

26.3.4.6 响应PID

在DCPCTR和PIPEnCTR的PID[1:0]位中指定每个管道的响应PID。本节介绍具有不同响应PID设置的USBFS操作。

(1) 主机控制器模式下的软件响应PID设置

选择响应PID来指定事务的执行，如下所示：
●NAK设置：禁用使用管道，不执行任何事务
●BUF设置：根据FIFO缓冲区状态执行事务：
OUT方向：如果FIFO缓冲区包含发送数据，则发出OUT令牌。
IN方向：如果FIFO缓冲区未满并且可以接收数据，则发出IN令牌。
●STALL设置：禁止使用管道，不执行任何事务

Note: 使用DCPCTR.SUREQ位执行DCP的设置事务。

(2) 设备控制器模式下的软件响应PID设置

选择响应PID以对来自主机的事务进行如下响应：
●NAK设置：对所有生成的事务返回NAK响应
●BUF设置：根据FIFO缓冲区向事务返回响应
●STALL设置：向所有生成的事务返回STALL响应

Note: 对于设置事务，无论PID[1:0]位设置如何，始终返回ACK响应，并且USB请求存储在寄存器中。

第(3)和(4)节描述了USBFS由于特定事务结果而写入PID[1:0]位的情况。

(3) 主机控制器模式下的硬件响应PID设置

●NAK设置：PID=NAK在以下情况下设置，令牌自动停止发行：
当执行非同步传输并产生NRDY中断时
（有关详细信息，请参阅第26.3.3.2节。NRDY中断。）
如果在PIPECFG.SHTNAK位设置为1以进行批量传输时接收到短数据包
如果在SHTNAK位设置为1以进行批量传输时事务计数结束
●BUF设置：USBFS不写入此设置。

- STALL setting: PID = STALL is set in the following cases, and issuing of tokens is automatically stopped:
  - When STALL is received in response to a transmitted token
  - When a received data packet exceeds the maximum packet size

(4) Hardware response PID settings in device controller mode

- NAK setting: PID = NAK is set in the following cases, and a NAK response is returned to transactions:
  - When the setup token is received normally (DCP only)
  - If transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
- BUF setting: There is no BUF writing by the USBFS.
- STALL setting: PID = STALL is set in the following cases, and a STALL response is returned to transactions:
  - When a received data packet exceeds the maximum packet size
  - When a control transfer sequence error is detected (DCP only)

26.3.4.7 Data PID sequence bit

The USBFS automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON bit in DCPCTR and PIPEnCTR. When data is transmitted, the sequence bit toggles on ACK handshake reception. When data is received, the sequence bit toggles on ACK handshake transmission. The SQCLR bit in DCPCTR and the SQSET bit in PIPEnCTR can be used to change the data PID sequence bit.

In device controller mode when control transfers are used, the USBFS automatically sets the sequence bit for stage transitions. DATA1 is returned when the setup stage ends. The sequence bit is not referenced and PID = DATA1 is returned in the status stage. Therefore, no software settings are required. However, in host controller mode when control transfers are used, the sequence bit must be set by software for the stage transitions.

For ClearFeature requests for transmission or reception, the data PID sequence bit must be set by software in both host and device controller modes.

26.3.4.8 Response PID = NAK function

The USBFS provides a function for disabling pipe operation (PID response = NAK) when the final data packet of a transaction is received. The USBFS automatically distinguishes this based on reception of a short packet or the transaction counter. Enable this function by setting the PIPECFG.SHTNAK bit to 1.

When the double buffer mode is being used for the FIFO buffer, using this function enables reception of data packets in transfer units. If pipe operation is disabled, the software must enable the pipe again (PID response = BUF).

The response PID = NAK function can be used only for bulk transfers.

26.3.4.9 Auto response mode

For bulk transfer pipes (1 to 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (PIPECFG.DIR = 0), OUT-NAK mode is invoked, and during an IN transfer (DIR = 1), null auto response mode is invoked.

26.3.4.10 OUT-NAK mode

For bulk OUT transfer pipes, NAK is returned in response to an OUT token, and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To transition from normal mode to OUT-NAK mode, specify OUT-NAK mode while pipe operation is disabled (PID[1:0] = 00b for NAK response). Next enable pipe operation (PID[1:0] = 01b for BUF response), on which OUT-NAK mode becomes valid. If an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To transition from OUT-NAK mode to normal mode, cancel OUT-NAK mode while pipe operation is disabled (NAK). Next enable pipe operation (BUF). In normal mode, reception of OUT data is enabled.

●STALL设置：PID=STALL在以下情况下设置，并且自动停止发行令牌：

当接收到STALL以响应传输的令牌时

当接收到的数据包超过最大包大小时

(4) 设备控制器模式下的硬件响应PID设置

●NAK设置：PID=NAK在以下情况下设置，并向事务返回NAK响应：

正常接收到设置令牌时（仅DCP）

当PIPECFG.SHTNAK位设置为1以进行批量传输时，如果事务计数结束或收到短数据包

●BUF设置：USBFS不写入BUF。

●STALL设置：PID=STALL在以下情况下设置，并向事务返回STALL响应：

当接收到的数据包超过最大包大小时

当检测到控制传输序列错误时（仅限DCP）

26.3.4.7 数据PID序列位

当数据在控制传输数据阶段、批量传输和中断传输成功传输时，USBFS会自动切换数据PID中的序列位。下一个要发送的数据PID的序列位可以通过DCPCTR和PIPEnCTR中的SQMON位来确认。发送数据时，序列位在ACK握手接收时切换。当接收到数据时，序列位在ACK握手传输上切换。DCPCTR中的SQCLR位和PIPEnCTR中的SQSET位可用于更改数据PID序列位。

在使用控制传输的设备控制器模式下，USBFS自动设置阶段转换的序列位。DATA1在设置阶段结束时返回。不引用序列位，在状态阶段返回PID=DATA1。因此，不需要任何软件设置。但是，在使用控制传输的主机控制器模式下，必须由软件设置序列位以进行阶段转换。

对于发送或接收的ClearFeature请求，数据PID序列位必须由软件在主机和设备控制器模式下设置。

26.3.4.8 响应PID=NAK功能

USBFS提供了在接收到事务的最终数据包时禁用管道操作（PID响应=NAK）的功能。USBFS根据收到的短数据包或事务计数器自动区分这一点。通过将PIPECFG.SHTNAK位设置为1来启用此功能。

当FIFO缓冲区使用双缓冲区模式时，使用此功能可以接收以传输为单位的数据包。如果管道操作被禁用，软件必须再次启用管道（PID响应=BUF）。

响应PID=NAK函数只能用于批量传输。

26.3.4.9 自动响应模式

对于批量传输管道（1到5），当PIPEnCTR.ATREPM位设置为1时，将转换到自动响应模式。在OUT传输期间(PIPECFG.DIR=0)，将调用OUT-NAK模式，在IN传输期间(DIR=1)，将调用空自动响应模式。

26.3.4.10 OUT-NAK mode

对于批量OUT传输管道，NAK响应OUT令牌返回，并且当PIPEnCTR.ATREPM位设置为1。要从正常模式转换到OUT-NAK模式，请在禁用管道操作时指定OUT-NAK模式（对于NAK响应，PID[1:0]=00b）。接下来启用管道操作（PID[1:0]=01b用于BUF响应），此时OUT-NAK模式变为有效。如果在禁用管道操作之前立即收到OUT令牌，则正常接收令牌数据，并向主机返回ACK。

要从OUT-NAK模式转换到正常模式，请在禁用管道操作(NAK)时取消OUT-NAK模式。接下来启用管道操作(BUF)。在正常模式下，可以接收OUT数据。

26.3.4.11 Null auto response mode

For bulk IN transfer pipes, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To transition from normal mode to null auto response mode, specify null auto response mode while pipe operation is disabled (response PID = NAK). Next enable pipe operation (response PID = BUF) on which null auto response mode becomes valid. Before setting null auto response mode, check that PIPEnCTR.INBUFM = 0, because the mode can be set only when the buffer is empty. If the INBUFM bit is 1, empty the buffer using the PIPEnCTR.ACLRM bit. Do not write data from the FIFO port while a transition to null auto response mode is being made.

To transition from null auto response mode to normal mode, keep pipe operation disabled (response PID = NAK) for the period of the zero-length packet transmission (about 10 µs) before canceling the null auto response mode. In normal mode, data can be written from the FIFO port, so packet transmission to the host is enabled by enabling pipe operation (response PID = BUF).

26.3.5 FIFO Buffer

The USBFS provides a FIFO buffer for data transfers, and it manages the memory area used for each pipe. The FIFO buffer has two states depending on whether the access right is assigned to the system (CPU side) or the USBFS (SIE side).

(1) Buffer status

Table 26.20 and Table 26.21 show the buffer status in the USBFS. The FIFO buffer status can be confirmed using the DCPCTR.BSTS and PIPEnCTR.INBUFM bits. The transfer direction for the FIFO buffer can be specified in either the PIPECFG.DIR or CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM bit is valid for pipes 0 to 5 in the transmitting direction.

When a transmitting pipe uses double buffering, the software can read the BSTS bit to monitor the FIFO buffer status on the CPU side and the INBUFM bit to monitor the FIFO buffer status on the SIE side. When write access to the FIFO port by the CPU or DMA/DTC is slow and the buffer empty status cannot be determined using the BEMP interrupt, the software can use the INBUFM bit to confirm the end of transmission.

Table 26.20 Buffer status indicated in the BSTS bit

ISEL or DIR	BSTS	FIFO buffer status
0 (receiving direction)	0	There is no received data, or data is being received. Reading from the FIFO port is disabled.
0 (receiving direction)	1	There is received data, or a zero-length packet is received. Reading from the FIFO port is allowed. When a zero-length packet is received, reading is not possible and the buffer must be cleared.
1 (transmitting direction)	0	Transmission has not completed. Writing to the FIFO port is disabled.
1 (transmitting direction)	1	Transmission is complete. CPU write is allowed.

Table 26.21 Buffer status indicated in the INBUFM bit

DIR	INBUFM	FIFO buffer status
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	Transmission is complete. There is no data waiting to be transmitted.
1 (transmitting direction)	1	The FIFO port has written data to the buffer. There is data to be transmitted.

26.3.6 FIFO Buffer Clearing

Table 26.22 shows the methods for clearing the FIFO buffer. The FIFO buffer can be cleared using BCLR bit in the port control register, DnFIFOSEL.DCLRM, or the PIPEnCTR.ACLRM bit.

Single or double buffering can be selected for pipes 1 to 5 in the PIPECFG.DBLB bit.

26.3.4.11 空自动响应模式

对于批量IN传输管道，当PIPEnCTR.ATREPM位设置为1时，将连续传输零长度数据包。

要从正常模式转换为空自动响应模式，请在禁用管道操作时指定空自动响应模式（响应PID=NAK）。接下来启用空自动响应模式有效的管道操作（响应PID=BUF）。在设置空自动响应模式之前，请检查PIPEnCTR.INBUFM=0，因为只有在缓冲区为空时才能设置模式。如果INBUFM位为1，则使用PIPEnCTR.ACLRM位清空缓冲区。在转换到空自动响应模式时，不要从FIFO端口写入数据。

要从空值自动响应模式转换到正常模式，在取消空值自动响应模式之前，在零长度数据包传输期间（约10µs）保持管道操作禁用（响应PID=NAK）。在正常模式下，可以从FIFO端口写入数据，因此通过启用管道操作（响应PID=BUF）来启用到主机的数据包传输。

26.3.5 FIFO Buffer

USBFS为数据传输提供FIFO缓冲区，并管理用于每个管道的内存区域。根据访问权限是分配给系统（CPU端）还是USBFS（SIE端），FIFO缓冲区有两种状态。

(1) 缓冲状态

表26.20和表26.21显示了USBFS中的缓冲区状态。FIFO缓冲区状态可以使用确认DCPCTR.BSTS和PIPEnCTR.INBUFM位。FIFO缓冲区的传输方向可以在任一pipecfg.dir或cfifoselisel位（选择DCP时）。

INBUFM位对传输方向的管道0到5有效。

当传输管道使用双缓冲时，软件可以读取BSTS位来监控CPU侧的FIFO缓冲区状态，以及读取INBUFM位来监控SIE侧的FIFO缓冲区状态。当写访问FIFO端口由CPU或DMADTC较慢且无法使用BEMP中断确定缓冲区空状态，软件可以使用INBUFM位确认传输结束。

Table 26.20 BSTS位中指示的缓冲区状态

ISEL或DIR	BSTS	FIFO缓冲区状态
0 (receiving direction)	0	没有接收到数据，或正在接收数据。 禁止从FIFO端口读取。
0 (receiving direction)	1	有接收数据，或接收到零长度数据包。 允许从FIFO端口读取。 当接收到零长度数据包时，无法读取，必须清除缓冲区。
1 (transmitting direction)	0	传输尚未完成。 禁止写入FIFO端口。
1 (transmitting direction)	1	传输完成。 允许CPU写入。

Table 26.21 INBUFM位中指示的缓冲区状态

DIR	INBUFM	FIFO缓冲区状态
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	传输完成。 没有等待传输的数据。
1 (transmitting direction)	1	FIFO端口已将数据写入缓冲区。 有数据要传输。

26.3.6 FIFO缓冲区清除

表26.22显示了清除FIFO缓冲区的方法。可以使用端口控制寄存器中的BCLR位、DnFIFOSEL.DCLRM或PIPEnCTR.ACLRM位清除FIFO缓冲区。

可以在PIPECFG.DBLB位中为管道1到5选择单缓冲或双缓冲。

Table 26.22 Buffer clearing methods

FIFO buffer clearing mode	Clearing FIFO buffer on the CPU side	Mode for automatically clearing the FIFO buffer after reading the specified pipe data	Auto buffer clear mode for discarding all received packets
Register used	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Bit used	BCLR	DCLRM	ACLRM
Clearing condition	Cleared by writing 1	1: Mode valid 0: Mode invalid	1: Mode valid 0: Mode invalid

(1) Auto buffer clear mode function

The USBFS discards all received data packets if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet is received, the ACK response is returned to the host controller. The auto buffer clear mode function can only be set in the FIFO buffer reading direction.

Setting the ACLRM bit to 1 and then to 0 clears the FIFO buffer of the selected pipe regardless of the access direction. An access cycle of at least 100 ns is required for the internal hardware sequence processing between ACLRM = 1 and ACLRM = 0.

26.3.7 FIFO Port Functions

Table 26.23 shows the settings for the FIFO port functions. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, set the BVAL flag in the port control register to end writing. To send a zero-length packet, use the BCLR bit to clear the buffer, and then set the BVAL flag to end writing.

In reading, reception of new packets is automatically enabled when all data is read. Data cannot be read when a zero-length packet is received (DTLN[8:0] = 0), so the buffer must be cleared with the BCLR bit. The length of the receive data can be confirmed in the DTLN[8:0] bits in the port control register.

Table 26.23 FIFO port function settings

Register name	Bit name	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	Selects DTLN[11:0] read mode
	REW	FIFO buffer rewind (re-read, rewrite)
	DCLRM	Automatically clears receive data for a specified pipe after the data is read (only for DnFIFO)
	DREQE	Enables DMA/DTC transfers (only for DnFIFO)
	MBW	FIFO port access bit width
	BIGEND	Selects FIFO port endian
	ISEL	FIFO port access direction (only for DCP)
	CURPIPE	Selects the current pipe
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	Ends writing to the FIFO buffer
	BCLR	Clears the FIFO buffer on the CPU side
	DTLN	Checks the length of receive data

(1) FIFO port selection

Table 26.24 shows the pipes that can be selected with the different FIFO ports. The pipe to be accessed must be selected in the CURPIPE[3:0] bits in the port select register. After the pipe is selected, the software must check whether the written value can be read correctly from the CURPIPE[3:0] bits. (If the previous pipe number is read, it indicates that the USBFS is modifying the pipe.) Next, the software checks that the FRDY bit in the port control register is 1.

In addition, the software must specify the bus width to be accessed in the MBW bit in the port select register. The FIFO buffer access direction conforms to the PIPECFG.DIR setting. For the DCP only, the ISEL bit in the port select register determines the direction.

Table 26.22 缓冲区清除方法

FIFO缓冲区清除模式	清除FIFO缓冲区 CPU端	读取指定管道数据后自动清除FIFO缓冲区的模式	自动缓冲区清除模式，用于丢弃所有接收到的数据包
注册使用	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
使用的位	BCLR	DCLRM	ACLRM
清算条件	通过写1清除	1：模式有效0 ：模式无效	1：模式有效0 ：模式无效

(1) 自动缓冲清除模式功能

如果PIPEnCTR.ACLRM位设置为1，USBFS将丢弃所有接收到的数据包。如果接收到正确的数据包，则向主机控制器返回ACK响应。自动缓冲区清除模式功能只能在FIFO缓冲区读取方向设置。

无论访问方向如何，将ACLRM位设置为1，然后设置为0都会清除所选管道的FIFO缓冲区。ACLRM=1和ACLRM=0之间的内部硬件序列处理需要至少100ns的访问周期。

26.3.7 FIFO端口功能

表26.23显示了FIFO端口功能的设置。在写访问中，在达到最大数据包大小之前写入数据会自动启用数据传输。要在达到最大数据包大小之前启用传输，请设置端口控制寄存器中的BVAL标志以结束写入。要发送零长度数据包，请使用BCLR位清除缓冲区，然后设置BVAL标志以结束写入。

在读取中，当所有数据被读取时，自动启用新数据包的接收。接收到零长度数据包时（DTLN[8:0]=0）无法读取数据，因此必须使用BCLR位清除缓冲区。接收数据的长度可以在端口控制寄存器的DTLN[8:0]位中确认。

Table 26.23 FIFO端口功能设置

注册名称	位名称	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	选择DTLN[11:0]读取模式
	REW	FIFO缓冲区倒带（重新读取、重写）
	DCLRM	读取数据后自动清除指定管道的接收数据（仅适用于DnFIFO）
	DREQE	启用DMADTC传输（仅适用于DnFIFO）
	MBW	FIFO端口访问位宽
	BIGEND	选择FIFO端口字节序
	ISEL	FIFO端口访问方向（仅适用于DCP）
	CURPIPE	选择当前管道
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	结束写入FIFO缓冲区
	BCLR	清除CPU端的FIFO缓冲区
	DTLN	检查接收数据的长度

(1) 先进先出端口选择

表26.24显示了可以使用不同FIFO端口选择的管道。必须在端口选择寄存器的CURPIPE[3:0]位中选择要访问的管道。选择管道后，软件必须检查是否可以从CURPIPE[3:0]位正确读取写入的值。（如果读取了之前的管道号，则表明USBFS正在修改管道。）接下来，软件检查端口控制寄存器中的FRDY位是否为1。

此外，软件必须在端口选择寄存器的MBW位中指定要访问的总线宽度。FIFO缓冲区访问方向符合PIPECFG.DIR设置。仅对于DCP，端口选择寄存器中的ISEL位决定方向。

Table 26.24 FIFO port access by pipe

Pipe	Access method	Ports that can be used
DCP	CPU access	CFIFO port register
Pipes 1 to 9	CPU access	• CFIFO port register • D0FIFO/D1FIFO port register
	DMA/DTC access	D0FIFO/D1FIFO port register

(2) REW bit

It is possible to temporarily stop access to a pipe currently being accessed, access a different pipe, and then continue processing for the first pipe again. The REW bit in the port select register is used for this processing.

If a pipe is selected in the CURPIPE[3:0] bits in the port select register with the REW bit set to 1, the pointer used for reading from and writing to the FIFO buffer is reset, and reading or writing can be carried out from the first byte. If a pipe is selected with 0 set for the REW bit, data can be read and written in continuation from the previous selection, without the pointer being reset.

To access the FIFO port, the software must check that the FRDY bit in the port control register is 1 after selecting a pipe.

26.3.8 DMA Transfers (D0FIFO and D1FIFO Ports)

(1) Overview of DMA transfers

For pipes 1 to 9, the FIFO port can be accessed using the DMAC. When buffer access for a pipe targeted for DMA transfer is enabled, a DMA transfer request is issued.

Select the unit of transfer to the FIFO port in the DnFIFOSEL.MBW bit, and select the pipe targeted for the DMA transfer in the DnFIFOSEL.CURPIPE[3:0] bits. Do not change the selected pipe during the DMA transfer.

(2) DnFIFO auto clear mode (D0FIFO and D1FIFO port reading direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USBFS automatically clears the FIFO buffer of the selected pipe when reading of data from the FIFO buffer is complete.

Table 26.25 shows the packet reception and FIFO buffer clearing processing by software for each of the settings. As shown in the table, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA transfers without involving software.

The DnFIFO auto clear mode can only be set in the FIFO buffer reading direction.

Table 26.25 Packet reception and FIFO buffer clearing processing by software

Buffer status when packet is received	Register setting			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	No clearing required	No clearing required	No clearing required	No clearing required
Zero-length packet reception	Clearing required	Clearing required	No clearing required	No clearing required
Normal short packet reception	No clearing required	Clearing required	No clearing required	No clearing required
Transaction count end	No clearing required	Clearing required	No clearing required	No clearing required

26.3.9 Control Transfers Using the DCP

The DCP is used for data transfers in the control transfer data stage. The FIFO buffer of the DCP is a 64-byte single buffer with a fixed area for both control reads and control writes. The FIFO buffer can be accessed only through the CFIFO port.

Table 26.24 通过管道访问FIFO端口

Pipe	访问方法	可以使用的端口
DCP	CPU访问	CFIFO端口寄存器
管道1至9	CPU访问	• CFIFO端口寄存器 • D0FIFOD1FIFO端口寄存器
	DMA/DTC access	D0FIFOD1FIFO端口寄存器

(2) REW位

可以暂时停止对当前正在访问的管道的访问，访问不同的管道，然后再次继续处理第一个管道。端口选择寄存器中的REW位用于此处理。

如果在端口选择寄存器的CURPIPE[3:0]位中选择了一个管道，并且REW位设置为1，则用于读取和写入FIFO缓冲区的指针复位，可以进行读取或写入从第一个字节开始。如果在REW位设置为0的情况下选择管道，则可以从先前的选择继续读取和写入数据，而无需重置指针。

要访问FIFO端口，软件必须在选择管道后检查端口控制寄存器中的FRDY位是否为1。

26.3.8 DMA传输（D0FIFO和D1FIFO端口）

(1) DMA传输概述

对于管道1到9，可以使用DMAC访问FIFO端口。当启用以DMA传输为目标的管道的缓冲区访问时，将发出DMA传输请求。

在DnFIFOSEL.MBW位中选择传输到FIFO端口的单位，并在DnFIFOSEL.CURPIPE[3:0]位中选择DMA传输的目标管道。在DMA传输期间不要更改选定的管道。

(2) DnFIFO自动清除模式（D0FIFO和D1FIFO端口读取方向）

如果DnFIFOSEL.DCLRM位设置为1，USBFS会在从FIFO缓冲区读取数据完成时自动清除所选管道的FIFO缓冲区。

表26.25显示了软件对每个设置的数据包接收和FIFO缓冲区清除处理。如表所示，缓冲区清除条件取决于PIPECFG.BFRE位中设置的值。使用DnFIFOSEL.DCLRM位无需在任何需要清除缓冲区的情况下通过软件清除缓冲区。这可以在不涉及软件的情况下实现DMA传输。

DnFIFO自动清除模式只能设置在FIFO缓冲区读取方向。

Table 26.25 通过软件进行数据包接收和FIFO缓冲区清除处理

收到数据包时的缓冲区状态	注册设置			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
缓冲区已满	无需清算	无需清算	无需清算	无需清算
零长度数据包接收	需要清算	需要清算	无需清算	无需清算
正常短包接收	无需清算	需要清算	无需清算	无需清算
交易计数结束	无需清算	需要清算	无需清算	无需清算

26.3.9 使用DCP进行控制传输

DCP用于控制传输数据阶段的数据传输。DCP的FIFO缓冲区是一个64字节的单缓冲区，具有用于控制读取和控制写入的固定区域。FIFO缓冲区只能通过CFIFO端口访问。

26.3.9.1 Control transfers in host controller mode

(1) Setup stage

The USQREQ, USBVAL, USBINDX, and USBLENG registers are used to transmit USB requests for setup transactions. Writing the setup packet data to the registers and then writing 1 to the DCPCTR.SUREQ bit transmits the specified data for the setup transaction. On completion of the transaction, the SUREQ bit clears to 0. Do not change these USB request registers while SUREQ = 1.

When an attached function device is detected, the software must issue the first setup transaction for the device using this sequence with the DCPMAXP.DEVSEL[3:0] bits cleared to 0 and the DEVADD0.USBSPD[1:0] bits set appropriately.

When an attached function device is shifted to the Address state, the software must issue setup transactions using this sequence with the assigned USB address set in the DEVSEL[3:0] bits and the bits in DEVADDn corresponding to the specified USB address set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in DEVADD2. When PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in DEVADD5.

When the setup transaction data is sent, an interrupt request is generated based on the response from the peripheral device (SIGN or SACK bit in INTSTS1). This interrupt request allows the software to check the setup transaction result.

A DATA0 data packet (USB request) for the setup transaction is always transmitted regardless of the status of the DCPCTR.SQMON bit.

(2) Data stage

The data stage is used to transfer data using the DCP FIFO buffer.

Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit. Specify the transfer direction in the DCPCFG.DIR bit.

For the first data packet of the data stage, the data PID must be transferred as DATA1. Set data PID = DATA1 in the DCPCTR.SQSET bit and set the PID bits = BUF. Completion of data transfer is detected using the BRDY or BEMP interrupt.

For control write transfers, when the number of data bytes to be sent is an integer multiple of the maximum packet size, the software must send a zero-length packet at the end.

(3) Status stage

The status stage is used for zero-length packet data transfers in the reverse direction of the data stage. As in the data stage, data is transfered using the DCP FIFO buffer. Transactions are executed using the same procedure as the data stage.

Data packets in the status stage must be transmitted and received with the data PID set to DATA1 using the DCPCTR.SQSET bit.

When a zero-length packet is received, check the receive-data length in the CFIFOCTR.DTLN[8:0] bits after a BRDY interrupt is generated, and then clear the FIFO buffer using the BCLR bit.

26.3.9.2 Control transfers in device controller mode

(1) Setup stage

The USBFS sends an ACK response to a normal setup packet for the USBFS. The USBFS operates in the setup stage as follows:

On receiving a new setup packet, the USBFS sets the following bits:

- Sets the INTSTS0.VALID bit to 1
- Sets the DCPCTR.PID[1:0] bits to NAK
- Sets the DCPCTR.CCPL bit to 0

When the USBFS receives a data packet following a setup packet, it stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Before performing the response processing for a control transfer, set the VALID flag to 0. When the VALID bit = 1, PID = BUF cannot be set, and the data stage cannot be terminated.

26.3.9.1 主机控制器模式下的控制传输

(1) 设置阶段

USQREQ、USBVAL、USBINDX和USBLENG寄存器用于传输设置事务的USB请求。
将设置数据包数据写入寄存器，然后向DCPCTR.SUREQ位写入1，以传输设置事务的指定数据。事务完成后，SUREQ位清除为0。在SUREQ=1时不要更改这些USB请求寄存器。

当检测到连接的功能器件时，软件必须使用此序列为器件发出第一个设置事务，并将DCPMAXP.DEVSEL[3:0]位清零，并适当设置DEVADD0.USBSPD[1:0]位。

当连接的功能器件转移到地址状态时，软件必须使用此序列发出设置事务，其中指定的USB地址设置在DEVSEL[3:0]位中，并且DEVADDn中的位对应于指定的USB地址设置适当。例如，当PIPEMAXP.DEVSEL[3:0]=0010b时，在DEVADD2中进行适当的设置。当PIPEMAXP.DEVSEL[3:0]=0101b时，在DEVADD5中进行适当的设置。

发送设置事务数据时，根据外围设备的响应（INTSTS1中的SIGN或SACK位）生成中断请求。该中断请求允许软件检查设置事务结果。

一个DATA0数据包（USB请求）用于设置事务总是被传输，无论状态如何
DCPCTR.SQMON bit.

(2) 数据阶段

数据级用于使用DCPFIFO缓冲区传输数据。

在访问DCPFIFO缓冲区之前，请在CFIFOSEL.ISEL位中指定访问方向。在DCPCFG.DIR位中指定传输方向。

对于数据阶段的第一个数据包，数据PID必须作为DATA1传输。在DCPCTR.SQSET位中设置数据PID=DATA1，并设置PID位=BUF。使用BRDY或BEMP中断检测数据传输的完成。

对于控制写传输，当要发送的数据字节数是最大数据包大小的整数倍时，软件必须在最后发送一个长度为零的数据包。

(3) 状态阶段

状态阶段用于在数据阶段的相反方向上进行零长度分组数据传输。与数据阶段一样，使用DCPFIFO缓冲区传输数据。事务使用与数据阶段相同的过程执行。

状态阶段的数据包必须在数据PID设置为DATA1的情况下使用
DCPCTR.SQSET bit.

当接收到零长度数据包时，在产生BRDY中断后检查CFIFOCTR.DTLN[8:0]位中的接收数据长度，然后使用BCLR位清除FIFO缓冲区。

26.3.9.2 设备控制器模式下的控制传输

(1) 设置阶段

USBFS向USBFS的正常设置数据包发送ACK响应。USBFS在设置阶段运行如下：

在接收到新的设置数据包时，USBFS设置以下位：

- ●将INTSTS0.VALID位设置为1
- ●将DCPCTR.PID[1:0]位设置为NAK
- ●将DCPCTR.CCPL位设置为0

当USBFS在setup数据包之后接收到数据包时，它会将USB请求参数存储在USBREQ中，
USBVAL, USBINDX, and USBLENG.

在执行控制传输的响应处理之前，将VALID标志设置为0。当VALID位=1时，PID=BUF不能设置，数据阶段不能终止。

Using the VALID bit function, the USBFS can suspend a request being processed when it receives a new USB request during a control transfer and return a response to the latest request.

In addition, the USBFS automatically detects the direction bit (bmRequestType bit [8]) and the request data length (wLength) in the received USB request. It distinguishes between control read transfers, control write transfers, and no-data control transfers, and it controls stage transitions. For an incorrect sequence, a sequence error occurs in the control transfer stage transition interrupt, and the interrupt is reported to the software. For a diagram of the stage control by the USBFS, see Figure 26.14.

(2) Data stage

The DCP must be used to execute data transfers for received USB requests. Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit.

If the transfer data is larger than the size of the DCP FIFO buffer, execute the data transfer using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

(3) Status stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to BUF.

After this setting is made, the USBFS automatically executes the status stage based on the data transfer direction determined at the setup stage. The procedure is as follows:

- For control read transfers

  The USBFS receives a zero-length packet from the USB host and transmits an ACK response.
- For control write transfers and no-data control transfers

  The USBFS transmits a zero-length packet and receives an ACK response from the USB host.

(4) Control transfer auto response function

The USBFS automatically responds to a correct SET_ADDRESS request. If any of the following errors occurs in the SET_ADDRESS request, a response from the software is necessary.

- bmRequestType is not 00h: Any transfer other than a control write transfer
- wIndex is not 00h: Request error
- wLength is not 00h: Any transfer other than a no-data control transfer
- wValue is larger than 7Fh: Request error
- INTSTS0.DVSQ[2:0] are 011b (Configured state): Control transfer of a device state error

For all requests other than the SET_ADDRESS request, a response is required from the corresponding software.

26.3.10 Bulk Transfers (Pipes 1 to 5)

The FIFO buffer usage (single/double buffer setting) is configurable for bulk transfers. The USBFS provides the following functions for bulk transfers:

- BRDY interrupt function (PIPECFG.BFRE bit), see section 26.3.3.1. BRDY interrupt
- Transaction count function (PIPEnTRE.TRENB, TRCLR, and PIPEnTRN.TRNCNT[15:0] bits), see section 26.3.4.5. Transaction counter for pipes 1 to 5 in the receiving direction
- Response PID = NAK function (PIPECFG.SHTNAK bit), see section 26.3.4.8. Response PID = NAK function
- Auto response mode (PIPEnCTR.ATREPM bit), see section 26.3.4.9. Auto response mode

26.3.11 Interrupt Transfers (Pipes 6 to 9)

In device controller mode, the USBFS performs interrupt transfers based on the timing dictated by the host controller.

In host controller mode, the software can set the timing for issuing tokens using the interval counter.

使用VALID位功能，USBFS可以在控制传输期间接收到新的USB请求时暂停正在处理的请求，并返回对最新请求的响应。

此外，USBFS会自动检测接收到的USB请求中的方向位（bmRequestTypebit[8]）和请求数据长度（wLength）。它区分控制读取传输、控制写入传输和无数据控制传输，并控制阶段转换。对于不正确的序列，在控制转移阶段转换中断中发生序列错误，并将中断报告给软件。USBFS的阶段控制图见图26.14。

(2) 数据阶段

DCP必须用于执行接收到的USB请求的数据传输。在访问DCPFIFO缓冲区之前，请在CFIFOSEL.ISEL位中指定访问方向。

如果传输数据大于DCPFIFO缓冲区的大小，则使用控制写传输的BRDY中断和控制读传输的BEMP中断执行数据传输。

(3) 状态阶段

通过将DCPCTR.CCPL位设置为1而将DCPCTR.PID[1:0]位设置为BUF来终止控制传输。

完成此设置后，USBFS根据设置阶段确定的数据传输方向自动执行状态阶段。程序如下：

●用于控制读取传输

USBFS从USB主机接收零长度数据包并发送ACK响应。

●用于控制写传输和无数据控制传输

USBFS发送一个长度为零的数据包并接收来自USB主机的ACK响应。

(4) 控制转移自动响应功能

USBFS自动响应正确的SET_ADDRESS请求。如果出现以下任何错误SET_ADDRESS请求，需要软件的响应。

●bmRequestType不是00h：控制写入传输以外的任何传输

●wIndexisnot00h：请求错误

●wLength不是00h：除无数据控制传输之外的任何传输

●wValue大于7Fh：请求错误

●INTSTS0.DVSQ[2:0]为011b（已配置状态）：设备状态错误的控制传输

对于除SET_ADDRESS请求之外的所有请求，都需要相应软件的响应。

26.3.10 批量传输（管道1到5）

FIFO缓冲区使用（单双缓冲区设置）可配置为批量传输。USBFS为批量传输提供以下功能：

●BRDY中断功能（PIPECFG.BFRE位），见26.3.3.1节。BRDY中断

●事务计数函数（PIPEnTRE.TRENB、TRCLR和PIPEnTRN.TRNCNT[15:0]位），参见第26.3.4.5节。接收方向上管道1到5的事务计数器

●响应PID=NAK功能（PIPECFG.SHTNAK位），参见第26.3.4.8节。响应PID=NAK功能

●自动响应模式（PIPEnCTR.ATREPM位），见第26.3.4.9节。自动响应模式

26.3.11 中断传输（管道6到9）

在设备控制器模式下，USBFS根据主机控制器规定的时序执行中断传输。

在主机控制器模式下，软件可以使用间隔计数器设置发布令牌的时间。

26.3.11.1 Interval counter for interrupt transfers in host controller mode

Specify the transaction interval for interrupt transfers in the PIPEPERI.IITV[2:0] bits. The USBFS issues interrupt transfer tokens based on this interval.

(1) Counter initialization

The USBFS initializes the interval counter under the following conditions:

- Power-on reset

  This initializes the IITV[2:0] bits.

- FIFO buffer initialization using the PIPEnCTR.ACLRM bit:

  This does not initialize the IITV[2:0] bits, but does initialize the count value. Setting the PIPEnCTR.ACLRM bit to 0 starts counting from the value set in IITV[2:0].

The interval counter is not initialized in the following case:

- USB bus reset or USB suspended

  The IITV[2:0] bits are not initialized. Setting 1 to the DVSTCTR0.UACT bit starts counting from the value saved before entering the USB bus reset state or USB suspend state.

(2) Operation when tokens cannot be transmitted or received even on token generation

No token is generated in the following cases even at token generation time. In these cases, the USBFS tries to execute the transaction in the next interval.

- When the PID is set to NAK or STALL
- When the FIFO buffer is full at token transmit time in the receiving (IN) direction
- When there is no data to be transmitted in the FIFO buffer at token transmit time in the transmitting (OUT) direction

26.3.12 Isochronous Transfers (Pipes 1 and 2)

The USBFS provides the following functions for isochronous transfers:

- Notification of isochronous transfer error
- Interval counter specified in the PIPEPERI.IITV[2:0] bits
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function specified in the PIPEPERI.IFIS bit

26.3.12.1 Error detection in isochronous transfers

The USBFS provides a function for detecting the errors described in this section, so that when errors occur in isochronous transfers, they can be controlled by software. Table 26.26 and Table 26.27 show the priority order for errors detected by the USBFS and the associated interrupts.

PID errors

- The PID value of the received packet is invalid.

CRC errors and bit stuffing errors

- A CRC error is found in a received packet or the bit stuffing is illegal.

Maximum packet size exceeded

- The data size of the received packet exceeds the specified maximum packet size.

Overrun and underrun errors

In host controller mode:

- The FIFO buffer is full at token transmit time in the IN (receiving) direction
- There is no data to be sent in the FIFO buffer at token transmit time in the OUT (transmitting) direction

26.3.11.1 主机控制器模式下中断传输的间隔计数器

在PIPEPERI.IITV[2:0]位中指定中断传输的事务间隔。USBFS基于此间隔发出中断传输令牌。

(1) 计数器初始化

USBFS在以下条件下初始化间隔计数器：

- Power-on reset

  这将初始化IITV[2:0]位。

●使用PIPEnCTR.ACLRM位初始化FIFO缓冲区：

这不会初始化IITV[2:0]位，但会初始化计数值。将PIPEnCTR.ACLRM位设置为0从IITV[2:0]中设置的值开始计数。

在以下情况下不初始化间隔计数器：

●USB总线复位或USB挂起

IITV[2:0]位未初始化。将DVSTCTR0.UACT位置1从进入USB总线复位状态或USB挂起状态之前保存的值开始计数。

(2) 即使在生成令牌时也无法发送或接收令牌时的操作

在以下情况下，即使在生成令牌时也不会生成令牌。在这些情况下，USBFS会尝试在下一个时间间隔执行事务。

●当PID设置为NAK或STALL时

●接收(IN)方向的令牌发送时FIFO缓冲区已满时

●在发送（OUT）方向的令牌发送时间，FIFO缓冲区中没有要发送的数据时

26.3.12 同步传输（管道1和2）

USBFS为同步传输提供以下功能：

●同步传输错误通知

●PIPEPERI.IITV[2:0]位中指定的间隔计数器

●同步IN传输数据设置控制（IDLY功能）

●PIPEPERI.IFIS位中指定的同步IN传输缓冲区刷新功能

26.3.12.1 同步传输中的错误检测

USBFS提供了检测本节所述的错误的功能，以便在同步传输中发生错误时，可以通过软件进行控制。表26.26和表26.27显示了USBFS检测到的错误和相关中断的优先级顺序。

PID错误

●接收报文的PID值无效。

CRC错误和位填充错误

●收到的报文发现CRC错误或比特填充不合法。

超出最大数据包大小

●接收到的数据包的数据大小超过了指定的最大数据包大小。

溢出和欠载错误

在主机控制器模式下：

●在IN（接收）方向发送令牌时，FIFO缓冲区已满

●在OUT（发送）方向的令牌发送时间，FIFO缓冲区中没有要发送的数据

In device controller mode:

- There is no data to be sent in the FIFO buffer at token receive time in the IN (transmitting) direction
- The FIFO buffer is full at token receive time in the OUT (receiving) direction

Interval errors

In device controller mode, the following cases are treated as an interval error:

- Failure to receive an IN token in the interval frame during an isochronous IN transfer
- Failure to receive an OUT token in the interval frame during an isochronous OUT transfer

Table 26.26 Error detection for token transmission and reception

Detection priority	Error	Generated interrupt and status
1	PID error	No interrupts are generated in either host or device controller mode (ignored as a corrupted packet)
2	CRC or bit stuffing error	No interrupts are generated in either host or device controller mode (ignored as a corrupted packet)
3	Overrun or underrun error	An NRDY interrupt is generated to set the FRMNUM.OVRN bit to 1 in both host and device controller modes. In device controller mode, a zero-length packet is transmitted in response to an IN token. No data packets are received in response to OUT token.
4	Interval error	An NRDY interrupt is generated in device controller mode. No interrupt is generated in host controller mode.

Table 26.27 Error detection for data packet reception

Detection priority	Error	Generated interrupt and status
1	PID error	No interrupts are generated (ignored as a corrupted packet)
2	CRC or bit stuffing error	An NRDY interrupt is generated and the FRMNUM.CRCE bit sets to 1 in both host and device controller modes
3	Maximum packet size exceeded error	A BEMP interrupt is generated and the PID[1:0] bits set to STALL in both host and device controller modes

26.3.12.2 DATA-PID

In device controller mode, the USBFS responds to a received PID as follows:

(1) IN direction

- DATA0: Transmitted as data packet PID
- DATA1: Not transmitted
- DATA2: Not transmitted
- mDATA: Not transmitted

(2) OUT direction

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets ignored
- mDATA: Packets ignored

26.3.12.3 Interval counter

The isochronous transfer interval can be set in the PIPEPERI.IITV[2:0] bits. In device controller mode, the interval counter enables the functions as shown in Table 26.28. In host controller mode, the USBFS generates the token issuance timing, and the interval counter operation is the same as that for interrupt transfers.

在设备控制器模式下：

●在IN（发送）方向的令牌接收时间，FIFO缓冲区中没有要发送的数据

●在OUT（接收）方向的令牌接收时间，FIFO缓冲区已满

间隔错误

在设备控制器模式下，以下情况被视为间隔错误：

●等时IN传输期间在间隔帧中接收IN令牌失败

●在等时OUT传输期间未能在间隔帧中接收到OUT令牌

Table 26.26 令牌发送和接收的错误检测

检测优先级	Error	产生的中断和状态
1	PID错误	在主机或设备控制器模式下都不会产生中断（被忽略为损坏的数据包）
2	CRC或位填充错误	在主机或设备控制器模式下都不会产生中断（被忽略为损坏的数据包）
3	溢出或欠载错误	在主机和设备控制器模式下，都会产生一个NRDY中断来将FRMNUM.OVRN位设置为1。在设备控制器模式下，发送一个零长度数据包以响应IN令牌。 没有接收到响应OUT令牌的数据包。
4	间隔误差	在设备控制器模式下会产生一个NRDY中断。在主机控制器模式下不产生中断。

Table 26.27 数据包接收错误检测

检测优先级	Error	产生的中断和状态
1	PID错误	不产生中断（作为损坏的数据包被忽略）
2	CRC或位填充错误	在主机和设备控制器模式下都会产生一个NRDY中断并且FRMNUM.CRCE位设置为1
3	超出最大数据包大小错误	在主机和设备控制器模式下都会产生BEMP中断并且PID[1:0]位设置为STALL

26.3.12.2 DATA-PID

在设备控制器模式下，USBFS响应接收到的PID如下：

(1) 在方向

●DATA0：作为数据包PID发送

●DATA1：未发送

●DATA2：未传输

●mDATA：不传输

(2) 出方向

●DATA0：作为数据包PID正常接收

●DATA1：作为数据包PID正常接收

●DATA2：忽略的数据包

●mDATA：忽略的数据包

26.3.12.3 间隔计数器

同步传输间隔可以在PIPEPERI.IITV[2:0]位中设置。在设备控制器模式下，间隔计数器启用如表26.28所示的功能。在主机控制器模式下，USBFS产生令牌发布时序，间隔计数器操作与中断传输相同。

Table 26.28 Interval counter functions in device controller mode

Transfer direction	Function	Conditions for detection
IN	Transmit buffer flush	Failure to receive an IN token successfully in the interval frame during an isochronous IN transfer.
OUT	Notification of no reception of token	Failure to receive an OUT token successfully in the interval frame during an isochronous OUT transfer.

The interval count is performed when an SOF is received or for interpolated SOFs, so the isochronism can be maintained even if an SOF is corrupt. The frame interval can be set to 2^{IITV} frames.

(1) Counter initialization in device controller mode

The USBFS initializes the interval counter under the following conditions:

- Power-on reset

  This initializes the PIPEPERI.IITV[2:0] bits.
- FIFO buffer initialization using the ACLRM bit

  This does not initialize the IITV[2:0] bits, but does initialize the count value.

After the interval counter is initialized, the interval count starts under one of the following conditions when a packet is transferred successfully:

- An SOF is received after data is transmitted in response to an IN token when PID = BUF
- An SOF is received after data is received in response to an OUT token when PID = BUF

The interval counter is not initialized in the following conditions:

- When the PID[1:0] bits are set to NAK or STALL

  This does not stop the interval timer. The USBFS attempts the transaction in the next interval.
- When the USB bus is reset or USBFS is suspended

  This does not initialize the IITV[2:0] bits. When an SOF is received, the interval counter starts counting from the value set before SOF was received.

(2) Interval counting and transfer control in host controller mode

The USBFS controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bits settings. Specifically, the USBFS issues a token for a selected pipe once every 2^{IITV} frames.

The USBFS starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits are set to BUF by software.

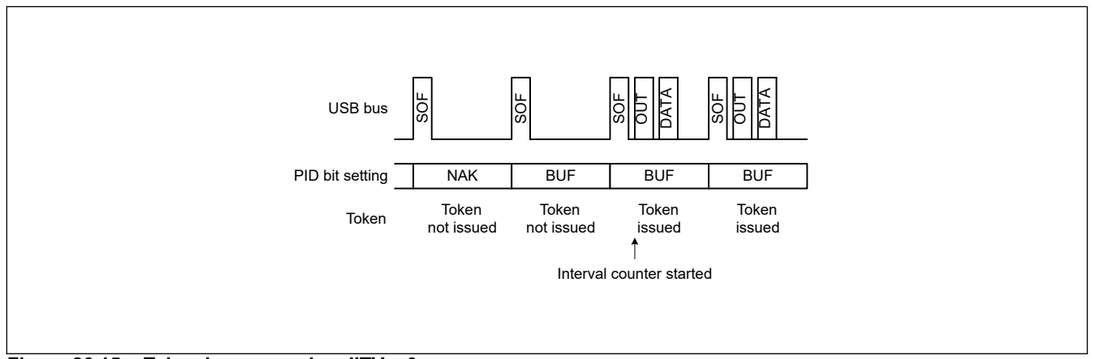

Figure 26.15 Token issuance when IITV = 0

Table 26.28 设备控制器模式下的间隔计数器功能

转移方向	Function	检测条件
IN	发送缓冲区刷新	在同步IN传输期间未能在间隔帧中成功接收IN令牌。
OUT	未收到令牌的通知	在同步OUT传输期间未能在间隔帧中成功接收OUT令牌。

间隔计数在接收到SOF时执行或对插值SOF执行，因此即使SOF损坏也可以保持等时性。帧间隔可以设置为2个IITV帧。

(1) 设备控制器模式下的计数器初始化

USBFS在以下条件下初始化间隔计数器：

- Power-on reset

  这将初始化PIPEPERI.IITV[2:0]位。
- 使用ACLRM位初始化FIFO缓冲区

  这不会初始化IITV[2:0]位，但会初始化计数值。

间隔计数器初始化后，当数据包传输成功时，间隔计数在以下条件之一开始：

- 当PID=BUF时，响应IN令牌传输数据后收到SOF
- 当PID=BUF时，接收到响应OUT令牌的数据后接收到SOF

间隔计数器在以下情况下不会初始化：

- 当PID[1:0]位设置为NAK或STALL时

  这不会停止间隔计时器。USBFS在下一个间隔尝试事务。
- USB总线复位或USBFS挂起时

  这不会初始化IITV[2:0]位。当接收到SOF时，间隔计数器从接收到SOF之前设置的值开始计数。

(2) 主机控制器模式下的间隔计数和传输控制

USBFS根据PIPEPERI.IITV[2:0]位设置控制令牌发布操作之间的间隔。
具体来说，USBFS每2个IITV帧为所选管道发布一次令牌。

USBFS在PID[1:0]位设置为的帧之后的帧开始计算令牌发布间隔
BUF通过软件。

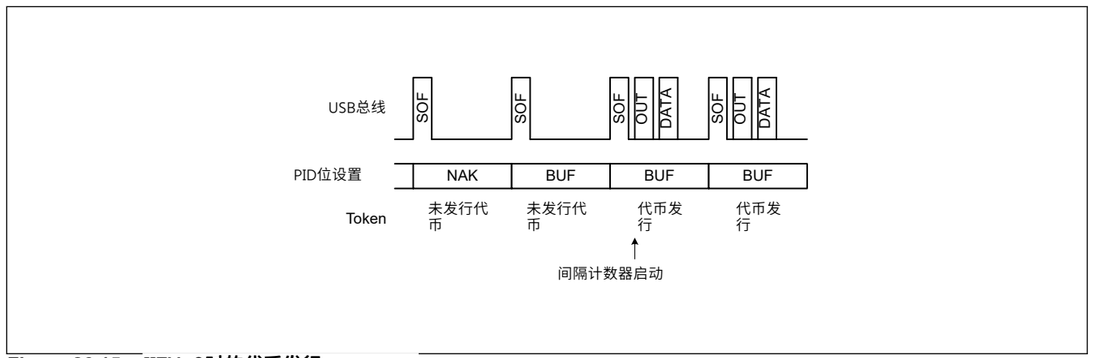

Figure 26.15 IITV=0时的代币发行

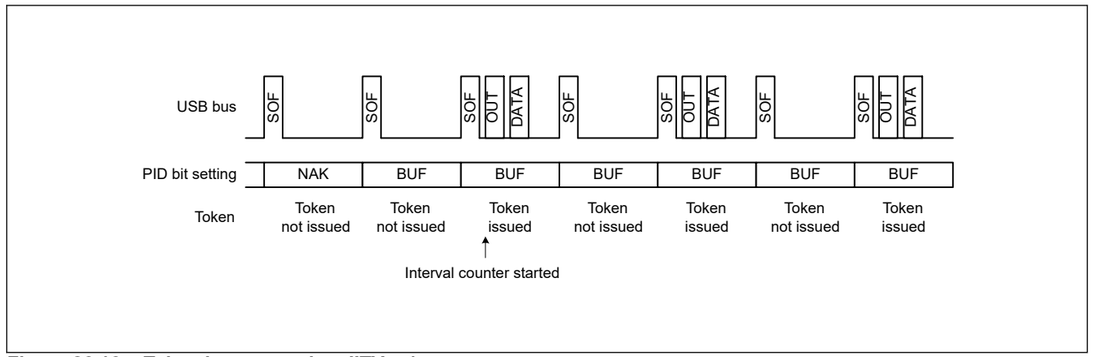

Figure 26.16 Token issuance when IITV = 1

When the selected pipe is set for isochronous transfers, the USBFS performs the following operation in addition to controlling the token issuance interval. The USBFS issues a token even when the NRDY interrupt generation condition is satisfied.

When the selected pipe is for isochronous IN transfers

The USBFS generates an NRDY interrupt when the USBFS issues an IN token but does not successfully receive a packet from a peripheral device (no response or packet error).

The USBFS sets the FRMNUM.OVRN bit to 1, generating an NRDY interrupt, when the time to issue an IN token occurs while the USBFS cannot receive data because the FIFO buffer is full, because the CPU or DMAC/DTC is too slow in reading data from the FIFO buffer.

When the selected pipe is for isochronous OUT transfers

The USBFS sets the OVRN bit to 1, generating an NRDY interrupt and transmitting a zero-length packet, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer, or because the CPU or DMAC/DTC is too slow in writing data to the FIFO buffer.

The token issuance interval is reset on any of the following conditions:

- When the USBFS is reset through a reset pin

  This initializes the IITV[2:0] bits.
- When the PIPEnCTR.ACLRM bit is set to 1 by software

(3) Interval counting and transfer control in device controller mode

When the selected pipe is for isochronous OUT transfers

The USBFS generates an NRDY interrupt when it fails to receive a data packet within the interval set in the PIPEPERI.IITV[2:0] bits.

The USBFS also generates an NRDY interrupt when it fails to receive data because of a CRC error or other errors contained in the data packet or because the FIFO buffer is full.

The NRDY interrupt is generated on SOF packet reception. Even if the SOF packet is corrupted, internal interpolation allows the interrupt to be generated when the SOF packet is received. However, when the IITV bits are set to a value other than 0, the USBFS generates an NRDY interrupt on receiving an SOF packet for every interval after interval counting starts.

When the PID[1:0] bits are set to NAK by software after starting the interval timer, the USBFS does not generate an NRDY interrupt on receiving an SOF packet.

The timing for starting interval counting depend on the IITV[2:0] setting as follows:

- When the IITV[2:0] bits = 0:

  Interval counting starts at the next frame after the software changes the PID[1:0] bits of the selected pipe to BUF.
- When the IITV[2:0] bits ≠ 0:

  Interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe are changed to BUF.

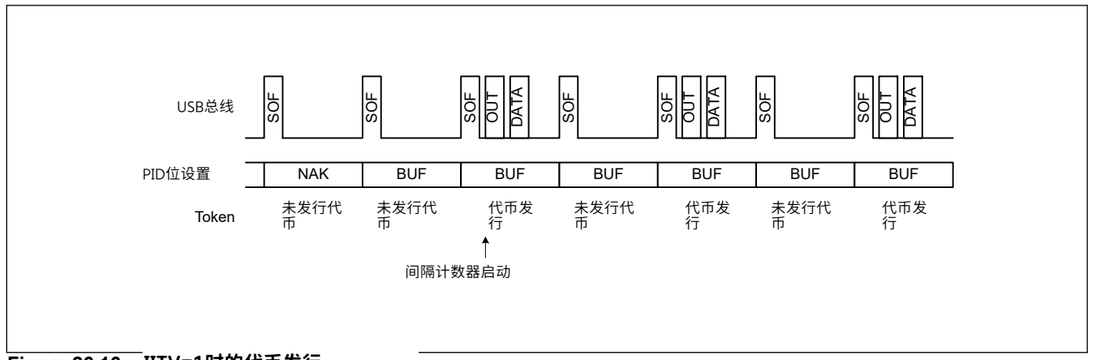

Figure 26.16 IITV=1时的代币发行

当所选管道设置为同步传输时，USBFS除了控制令牌发布间隔外，还执行以下操作。即使满足NRDY中断生成条件，USBFS也会发出令牌。

当所选管道用于同步IN传输时

当USBFS发出IN令牌但未成功接收到来自外围设备的数据包（无响应或数据包错误）时，USBFS会生成NRDY中断。

USBFS将FRMNUM.OVRN位设置为1，产生一个NRDY中断，此时发生发出IN令牌的时间，而USBFS无法接收数据，因为FIFO缓冲区已满，因为CPU或DMACDTC读取数据太慢从FIFO缓冲区。

当所选管道用于同步OUT传输时

USBFS将OVRN位设置为1，产生一个NRDY中断并发送一个长度为零的数据包，当发出OUT令牌的时间到来而FIFO缓冲区中没有要发送的数据时，或者因为CPU或DMACDTC将数据写入FIFO缓冲区太慢。

令牌发行间隔在以下任何条件下重置：

●USBFS通过复位引脚复位时

这将初始化IITV[2:0]位。

●PIPEnCTR.ACLRM位由软件设置为1时

(3) 设备控制器模式下的间隔计数和传输控制

当所选管道用于同步OUT传输时

当USBFS在设置的时间间隔内没有接收到数据包时，会产生一个NRDY中断。
PIPEPERI.IITV[2:0] bits.

当由于数据包中包含的CRC错误或其他错误或FIFO缓冲区已满而无法接收数据时，USBFS也会产生NRDY中断。

NRDY中断在SOF数据包接收时产生。即使SOF数据包损坏，内部插值也允许在接收到SOF数据包时产生中断。但是，当IITV位设置为0以外的值时，USBFS会在间隔计数开始后的每个间隔接收到SOF数据包时产生NRDY中断。

当PID[1:0]位在启动间隔定时器后被软件设置为NAK时，USBFS在接收到SOF数据包时不会产生NRDY中断。

开始间隔计数的时间取决于IITV[2:0]设置，如下所示：

●当IITV[2:0]位=0时：

软件将所选管道的PID[1:0]位更改为BUF后，间隔计数从下一帧开始。

●当IITV[2:0]位≠0时：

在所选管道的PID[1:0]位更改为BUF后，成功接收第一个数据包后，间隔计数开始。

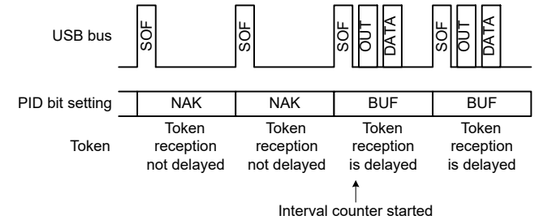

Figure 26.17 Relationship between frames and expected token reception when IITV[2:0] = 0

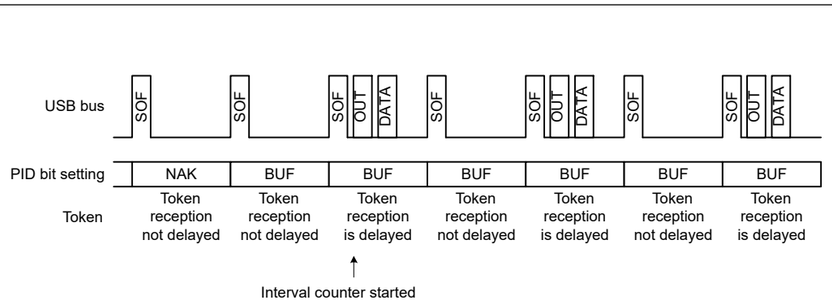

Figure 26.18 Relationship between frames and expected token reception when IITV[2:0] ≠ 0

When the selected pipe is for isochronous IN transfers

The PIPEPERI.IFIS bit must be 1 for this use case. When IFIS = 0, the USBFS transmits a data packet in response to a received IN token regardless of the PIPEPERI.IITV[2:0] setting.

When IFIS is 1 and there is data to be transmitted in the FIFO buffer, the USBFS clears the FIFO buffer when it fails to receive an IN token in the frame at the interval set in the IITV[2:0] bits.

The USBFS also clears the FIFO buffer when it fails to receive an IN token successfully because of a bus error, such as a CRC error, contained in the IN token.

The FIFO buffer is cleared on SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the FIFO buffer to be cleared when the SOF packet is received.

The timing to start interval counting depends on the IITV[2:0] setting, as with OUT transfers.

The interval is counted on any of the following conditions in device controller mode:

- When a hardware reset is applied to the USBFS (which also sets the IITV[2:0] bits to 000b)
- When the PIPEnCTR.ACLRM bit is set to 1 by software
- When the USBFS detects a USB bus reset

(4) Transmit data setup for isochronous transfers in device controller mode

With isochronous data transmission using the USBFS in device controller mode, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the SOF packet is detected. This isochronous transfer transmit data setup function can identify the frame that started transmission.

When the double buffering is used, transmission is only enabled for the buffer where data writing was completed first, even after the data write to both buffers is complete. Accordingly, even if multiple IN tokens are received, only the one packet of FIFO buffer data is transmitted.

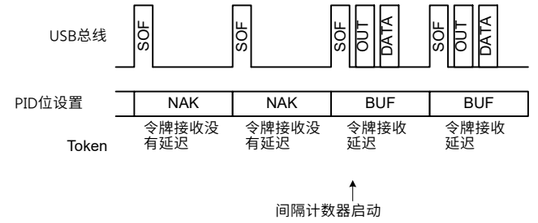

Figure 26.17 IITV[2:0]=0时帧与预期令牌接收之间的关系

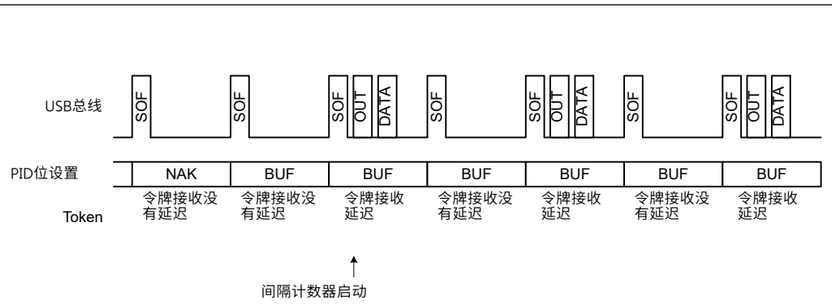

Figure 26.18 IITV[2:0]≠0时帧与预期令牌接收的关系

当所选管道用于同步IN传输时

对于此用例，PIPEPERI.IFIS位必须为1。当IFIS=0时，无论PIPEPERI.IITV[2:0]设置如何，USBFS都会发送一个数据包以响应接收到的IN令牌。

当IFIS为1且FIFO缓冲区中有数据要发送时，如果USBFS在IITV[2:0]位设置的时间间隔内未能接收到帧中的IN令牌，则清除FIFO缓冲区。

当USBFS由于总线错误（例如
CRC错误，包含在IN令牌中。

FIFO缓冲区在SOF数据包接收时被清除。即使SOF数据包损坏，内部插值也允许在接收到SOF数据包时清除FIFO缓冲区。

开始间隔计数的时间取决于IITV[2:0]设置，与OUT传输一样。

在设备控制器模式下，根据以下任何条件计算间隔：

- 当对USBFS应用硬件复位时（也将IITV[2:0]位设置为000b）
- PIPEnCTR.ACLRM位由软件设置为1时
- 当USBFS检测到USB总线复位时

(4) 设备控制器模式下同步传输的传输数据设置

在设备控制器模式下使用USBFS进行同步数据传输，数据写入FIFO缓冲区后，可在检测到SOF包后的第一帧发送数据包。此同步传输传输数据设置功能可以识别开始传输的帧。

使用双缓冲时，仅对先完成数据写入的缓冲区启用传输，即使在两个缓冲区的数据写入完成后也是如此。因此，即使接收到多个IN令牌，也仅发送一包FIFO缓冲器数据。

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transferred and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

Figure 26.19 shows an example transmission using the isochronous transfer transmission data setup function when IITV = 0 (every frame) is set.

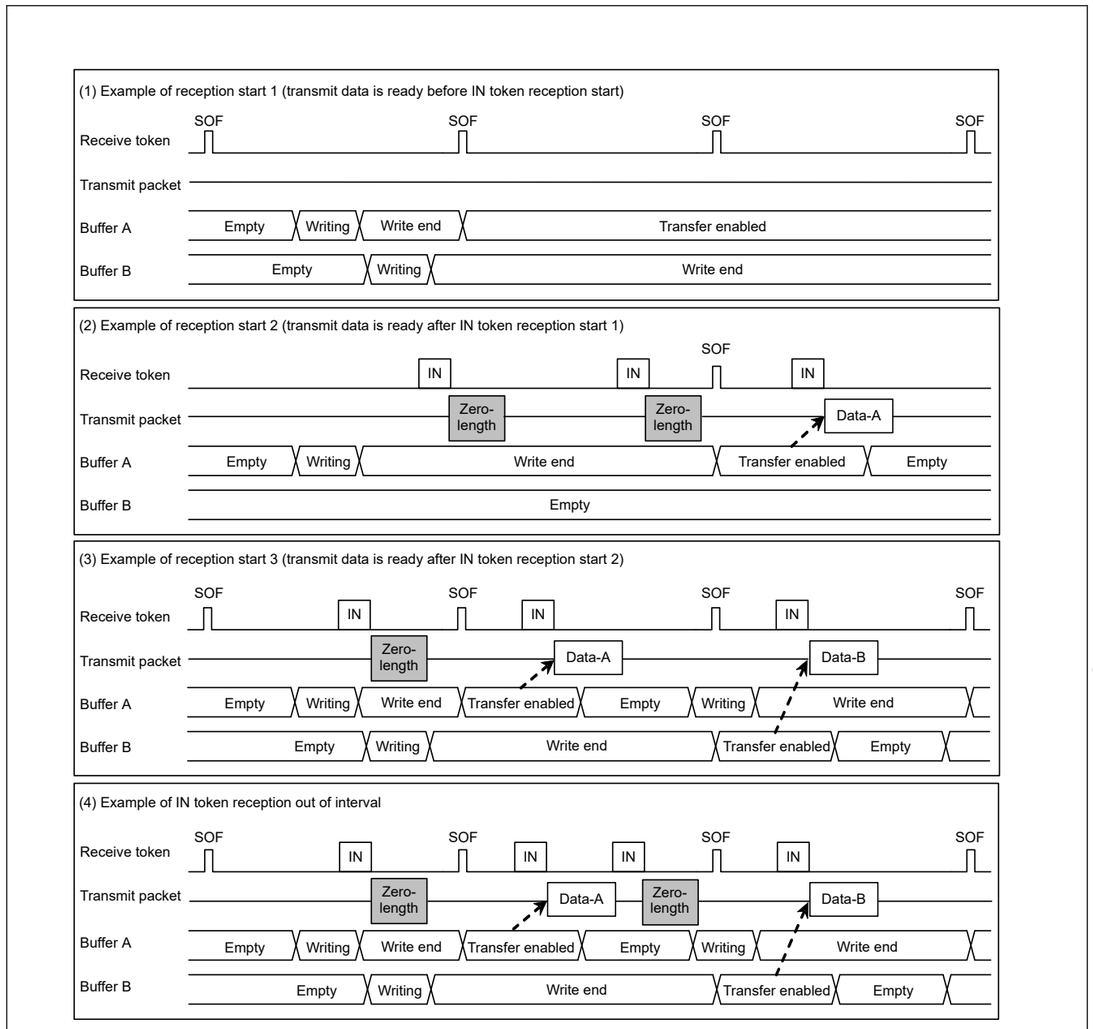

Figure 26.19 Example data setup operation

(5) Transmit buffer flush for isochronous transfers in device controller mode

In device controller mode during isochronous data transmission, if the USBFS receives an SOF packet for the next frame without receiving an IN token in the interval frame, it operates as if the IN token is corrupt and clears the buffer that is enabled for transmission, putting that buffer in the writing enabled state.

When double buffering is used and writing to both buffers is complete, the cleared FIFO buffer is assumed to be the one where the data was transmitted in the interval frame, and transmission is enabled for the FIFO buffer that was not cleared on SOF packet reception.

当接收到IN令牌时，当FIFO缓冲区准备好传输数据时，将传输数据并返回正常响应。但是，如果FIFO缓冲区无法传输数据，则会传输零长度数据包并发生欠载错误。

图26.19显示了在设置IITV=0（每帧）时使用同步传输传输数据设置功能的示例传输。

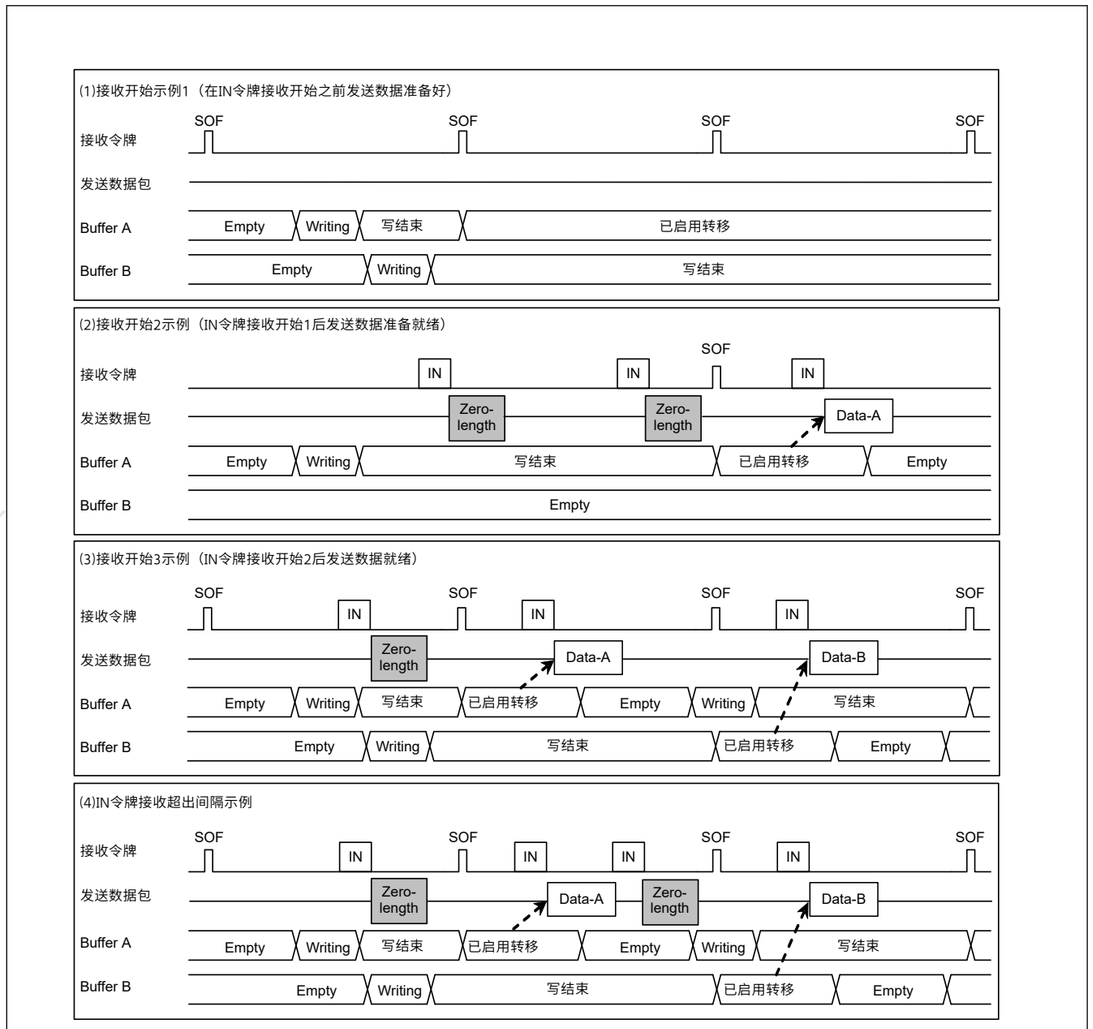

Figure 26.19 示例数据设置操作

(5) 设备控制器模式下同步传输的传输缓冲区刷新

在同步数据传输期间的设备控制器模式下，如果USBFS接收到下一帧的SOF数据包，而在间隔帧中没有接收到IN令牌，则它会像IN令牌损坏一样操作并清除启用传输的缓冲区，将该缓冲区处于写入启用状态。

当使用双缓冲并完成对两个缓冲区的写入时，已清除的FIFO缓冲区被假定为在间隔帧中传输数据的缓冲区，并为接收SOF数据包时未清除的FIFO缓冲区启用传输。

The timing of the buffer flush function depends on the PIPEPERI.IITV[2:0] setting as follows:

- When IITV = 0:

  The buffer flush operation starts from the first frame after the pipe is enabled.
- When IITV ≠ 0:

  The buffer flush operation starts after the first normal transaction.

Figure 26.20 shows an example buffer flush. When an unanticipated token is received before the interval frame, the USBFS sends the write data or a zero-length packet as an underrun error, depending on the data setup status.

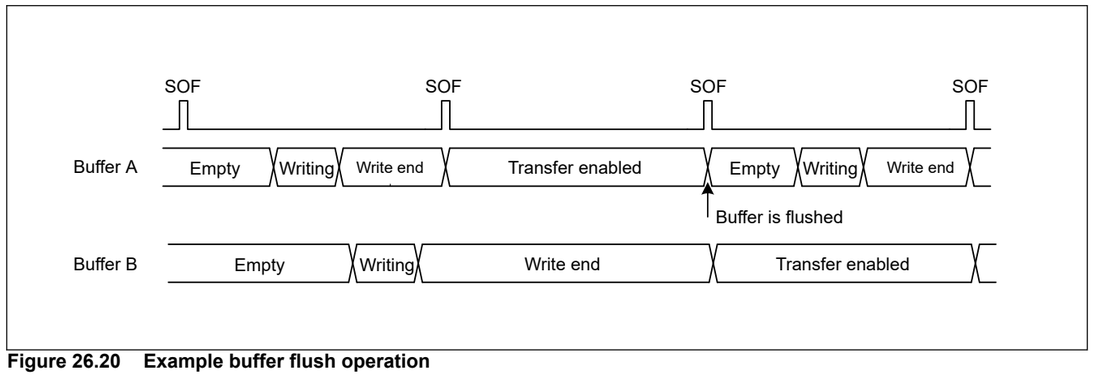

Figure 26.20 Example buffer flush operation

Figure 26.21 shows an example interval error occurrence. There are five types of interval errors, as shown in the figure. An interval error occurs at timing (A), and the buffer flush function is activated.

If an interval error occurs during an IN transfer, the buffer flush function is activated. If it occurs during an OUT transfer, an NRDY interrupt is generated. Use the FRMNUM.OVRN bit to distinguish between this and NRDY interrupts triggered by received packet errors and overrun errors.

For tokens that are shaded in the figure, responses are returned based on the FIFO buffer status.

- IN direction:
  - If the buffer is ready to transfer data, the data is transferred and a normal response is returned
  - If the buffer is not ready to transfer data, a zero-length packet is transmitted and an underrun error occurs
- OUT direction:
  - If the buffer is ready to receive data, the data is received and a normal response is returned
  - If the buffer is not ready to receive data, the received data is discarded and an overrun error occurs

缓冲区刷新功能的时间取决于PIPEPERI.IITV[2:0]设置，如下所示：

- When IITV = 0:

  缓冲区刷新操作从启用管道后的第一帧开始。
- When IITV ≠ 0:

  缓冲区刷新操作在第一个正常事务之后开始。

图26.20显示了一个示例缓冲区刷新。当在间隔帧之前接收到意外令牌时，USBFS将根据数据设置状态发送写数据或零长度数据包作为欠载错误。

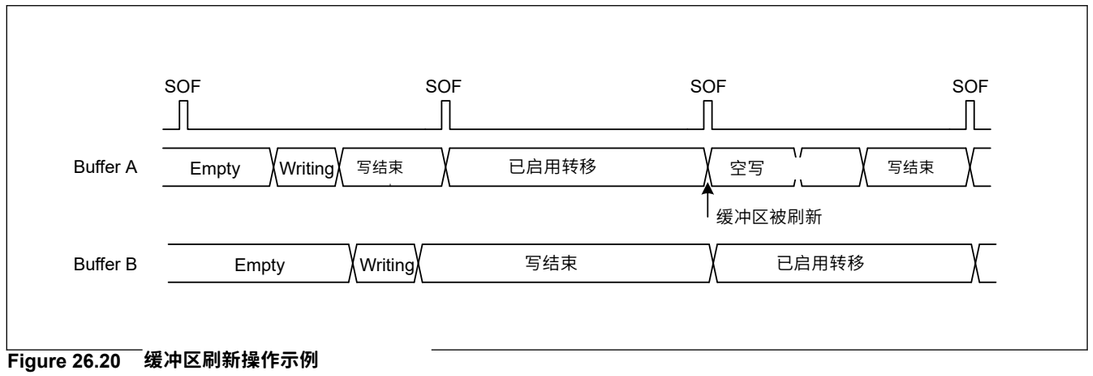

Figure 26.20 缓冲区刷新操作示例

图26.21显示了一个发生间隔错误的示例。如图所示，有五种区间误差。在时间（A）发生间隔错误，缓冲刷新功能被激活。

如果在IN传输期间发生间隔错误，则会激活缓冲区刷新功能。如果它发生在OUT传输期间，则NRDY中断产生。使用FRMNUM.OVRN位来区分此中断和由接收数据包错误和溢出错误触发的NRDY中断。

对于图中带阴影的令牌，根据FIFO缓冲区状态返回响应。

- IN direction:

  如果缓冲区准备好传输数据，则传输数据并返回正常响应

  如果缓冲区未准备好传输数据，则传输零长度数据包并发生欠载错误
- OUT direction:

  如果缓冲区准备好接收数据，则接收数据并返回正常响应

  如果缓冲区没有准备好接收数据，则丢弃接收到的数据并发生溢出错误

26.3.13 SOF Interpolation Function

In device controller mode, if packet reception is disabled at intervals of 1 ms because the SOF packet is corrupted or missing, the USBFS interpolates the SOF. SOF interpolation begins when the USBE and SCKE bits in SYSCFG are set to 1 and an SOF packet is received.

The interpolation function is initialized under the following conditions:

- MCU reset
- USB bus reset
- Suspend state detection

The SOF interpolation operates as follows:

- The interpolation function is not activated until an SOF packet is received
- When the first SOF packet is received, interpolation is performed by counting 1 ms on the 48-MHz internal clock
- When the second and subsequent SOF packets are received, interpolation is performed at the previous reception interval
- Interpolation is not performed in the Suspend state or on reception of a USB bus reset

The USBFS supports the following functions controlled by SOF packet reception. These functions operate normally with SOF interpolation if the SOF packet is missing:

- Updating of the frame number
- SOFR interrupt timing
- Isochronous transfer interval count

If an SOF packet is missing during full-speed operation, the FRMNUM.FRNM[10:0] bits are not updated.

26.3.14 Pipe Schedule

26.3.14.1 Conditions for generating transactions

In host controller mode and when the DVSTCTR0.UACT bit is set to 1, the USBFS generates transactions under the conditions shown in Table 26.29.

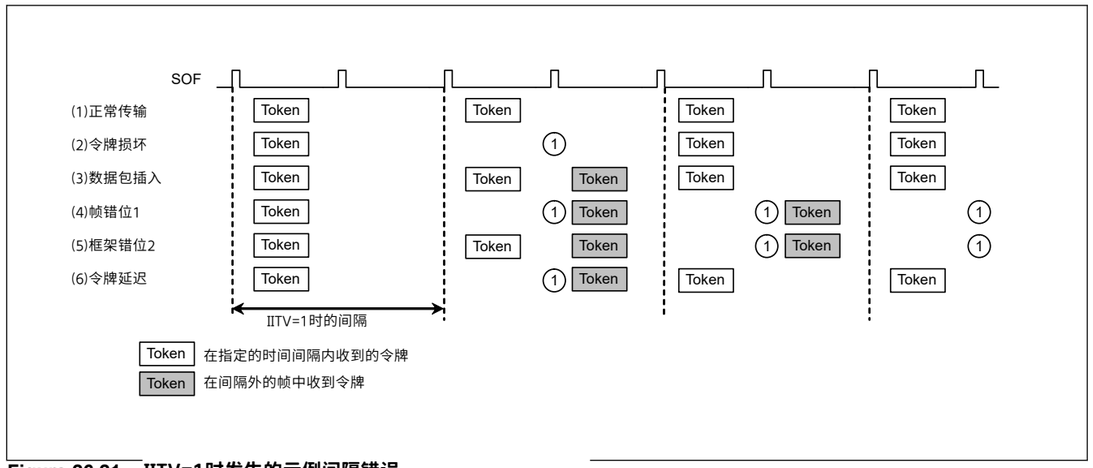

Figure 26.21 IITV=1时发生的示例间隔错误

26.3.13 SOF插值函数

在设备控制器模式下，如果由于SOF数据包损坏或丢失而每隔1ms禁用数据包接收，则USBFS会内插SOF。当SYSCFG中的USBE和SCKE位设置为1并且接收到SOF数据包时，SOF内插开始。

插值函数在以下条件下初始化：

- MCU reset
- ●USB总线复位
- ●暂停状态检测

SOF插值操作如下：

- ●直到收到SOF数据包才激活插值功能
- ●当接收到第一个SOF数据包时，通过在48-MHz内部时钟上计数1ms执行插值
- ●当接收到第二个和后续的SOF数据包时，按照之前的接收间隔进行插值
- ●在挂起状态或接收到USB总线复位时不执行插值

USBFS支持以下由SOF数据包接收控制的功能。这些功能正常运行
如果SOF数据包丢失，则SOF插值：

- ●更新帧号
- ●SOFR中断时序
- ●同步传输间隔计数

如果在全速运行期间丢失SOF数据包，则不会更新FRMNUM.FRNM[10:0]位。

26.3.14 管道计划

26.3.14.1 产生交易的条件

在主机控制器模式下，当DVSTCTR0.UACT位设置为1时，USBFS在表26.29所示的条件下生成事务。

Table 26.29 Conditions for generating transactions

Transaction	Conditions for generation				
	DIR	PID	IITV0	Buffer state	SUREQ
Setup	—*1	—*1	—*1	—*1	1 setting
Control transfer data stage, status stage, bulk transfer	IN	BUF	Invalid	Receive area exists	—*1
	OUT	BUF	Invalid	Transmit data exists	—*1
Interrupt transfer	IN	BUF	Valid	Receive area exists	—*1
	OUT	BUF	Valid	Transmit data exists	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

Note 1. An em dash (—) in the table indicates that the condition is unrelated to the generating of tokens. “Valid” indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter. “Invalid” indicates that a transaction is generated regardless of the interval counter.
Note 2. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.
Note 3. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

26.3.14.2 Transfer schedule

This section describes the transfer scheduling within a frame of the USBFS. After the USBFS sends an SOF, the transfer is carried out in the following sequence:

1. Execution of periodic transfers:

   A pipe is searched for in the order of pipe 1 → pipe 2 → pipe 6 → pipe 7 → pipe 8 → pipe 9, and then if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.

2. Setup transactions for control transfers:

   The DCP is checked, and if a setup transaction is possible, it is sent.

3. Execution of bulk transfers, control transfer data stages, and control transfer status stages:

   A pipe is searched for in the order of DCP → pipe 1 → pipe 2 → pipe 3 → pipe 4 → pipe 5, and then if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.

   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

26.3.14.3 Enabling USB communication

Setting the DVSTCTR0.UACT bit to 1 initiates an SOF transmission, and transaction generation is enabled. Setting the UACT bit to 0 stops SOF transmission and the Suspend state is invoked. If the UACT setting is changed from 1 to 0, processing stops after the next SOF is sent.

26.3.15 Battery Charging Detection Processing

The USBFS provides control over the data contact detection processing (D+ line contact checking), primary detection processing (charger detection processing), and secondary detection processing (charger determination processing) as defined in the Battery Charging Specification.

26.3.15.1 Processing in device controller mode

To operate a function device as a battery charging portable device:

注1.表中的破折号(—)表示该条件与令牌的生成无关。“有效”表示，对于中断传输和同步传输，事务仅在基于间隔计数器的传输帧中生成。“无效”表示无论间隔计数器如何都生成事务。

注2.这表示无论是否有接收区域，都会生成一个事务。但是，如果没有接收区域，则丢弃接收到的数据。

注3.这表示无论是否有任何数据要传输，都会产生交易。然而，如果没有要传输的数据，则传输零长度数据包。

26.3.14.2 转移时间表

本节介绍USBFS帧内的传输调度。USBFS发送SOF后，按以下顺序进行传输：

1.定期转账的执行：

按照管道1→管道2→管道6→管道7→管道8→管道9的顺序查找管道，如果有管道可以生成等时或中断传输事务，则生成事务.

2.为控制转移设置交易：

DCP被检查，如果设置事务是可能的，它被发送。

3、批量传输、控制传输数据阶段、控制传输状态阶段的执行：

按照DCP→管道1→管道2→管道3→管道4→管道5的顺序搜索管道，然后如果有管道需要进行批量传输、控制传输数据阶段或可以生成控制转移状态阶段，生成事务。

生成事务时，无论来自外围设备的响应是ACK还是NAK，处理都会转移到下一个管道事务。如果帧内有时间进行传输，则重复步骤3。

26.3.14.3 启用USB通信

将DVSTCR0.UACT位设置为1启动SOF传输，并启用事务生成。设置
UACT位为0停止SOF传输并调用暂停状态。如果UACT设置从1更改为0，则在发送下一个SOF后处理停止。

26.3.15 电池充电检测处理

USBFS提供对电池充电规范中定义的数据接触检测处理（D+线路接触检查）、一次检测处理（充电器检测处理）和二次检测处理（充电器确定处理）的控制。

26.3.15.1 设备控制器模式下的处理

将功能设备作为电池充电便携式设备操作：

1. Start primary detection processing after detecting contact with the D+ and D- lines. The Battery Charging Specification describes two processing methods for Data Contact Detection. The USBFS supports both methods as follows:
   - Software processing
     After a VBINT interrupt or polling of the VBSTS flag indicates a change in the state of the USBFS_VBUS input pin, software controls a wait from 300 to 900 ms. The BCCTRL1.VDPSRCE and CHGDETE bits are then both set to 1 to start primary detection processing.
   - Hardware Processing
     Apply 7 to 13 µA of current to the D+ line to hold the D+ line at the logical high level. This is done to detect the D+ and D- lines going to the logical low level because of pull-down resistors on the host device side when the D+ and D- lines come in contact with those of the host. Monitor the SYSSTS0.LNST[1:0] flags while the PHYSECTRL.CNEN bit, BCCTRL1.RPDME and IDPSRCE bit are set to 1 to see when the level on the D+ line changes from high to low. After detecting a low level on the D+ line, clear the PHYSECTRL.CNEN bit, BCCTRL1.RPDME and IDPSRCE bit to 0 and set both the BCCTRL1.VDPSRCE and CHGDETE bits to 1 to start primary detection processing. The VDPSRCE and CHGDETE bits must be set to 1 simultaneously.
2. After the start of primary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL1.CHGDETSTS flag. A value of 1 indicates detection of a charger, and secondary detection processing starts.*1
3. To start secondary detection processing, clear the BCCTRL1.VDPSRCE bit to 0, then clear the BCCTRL1.CHGDETE bits to 0 after a software-controlled wait of 20 ms. Next, set both the BCCTRL1.VDMSRCE and PDDETE bits to 1.
4. After the start of secondary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL1.PDDETSTS flag, and determine the result of the secondary detection processing.

Note 1. In primary detection processing, detection of a voltage above the range from 0.25 to 0.4 V and below the range from 0.8 to 2.0 V on the D-Line indicates that the other device is a host device that supports battery charging (charging downstream port). The BCCTRL1.CHGDETSTS flag in the PHY block only indicates whether the voltage on the D-line is higher than the range from 0.25 to 0.4 V, so add processing as required to read the SYSSTS0.LNST[1:0] flags and confirm that the voltage on the D- line is also below the range from 0.8 to 2.0 V.

Figure 26.22 shows the process flow.

1.检测到与D+和Dlines的接触后开始初级检测处理。电池充电规范描述了数据接触检测的两种处理方法。USBFS支持以下两种方法：

●软件处理

在VBINT中断或VBSTS标志的轮询指示USBFS_VBUS输入引脚的状态发生变化后，软件控制从300到900ms的等待。然后将BCCTRL1.VDPSRCE和CHGDETE位都设置为1以启动主要检测处理。

●硬件处理

向D+线施加7到13µA的电流，以将D+线保持在逻辑高电平。这样做是为了检测D+和Dlines进入逻辑低电平，因为当D+和Dlines与主机的那些接触时，由于主机设备侧的下拉电阻器。在PHYSECTRL.CNEN位、BCCTRL1.RPDME和IDPSRCE位设置为1时监控SYSSTS0.LNST[1:0]标志，以查看D+线上的电平何时从高变为低。检测到D+线上的低电平后，将PHYSECTRL.CNEN位、BCCTRL1.RPDME和IDPSRCE位清除为0，并将BCCTRL1.VDPSRCE和CHGDETE位都设置为1，以启动初级检测处理。VDPSRCE和CHGDETE位必须同时设置为1。

2.主要检测处理开始后，软件控制等待40毫秒后，检查
BCCTRL1.CHGDETSTS标志。值为1表示检测到充电器，并开始二次检测处理。*1

3.要启动二次检测处理，将BCCTRL1.VDPSRCE位清零，然后在软件控制的20ms等待后将BCCTRL1.CHGDETE位清零。接下来，将BCCTRL1.VDMSRCE和PDDETE位都设置为1。

4.二次检测处理开始后，软件控制等待40ms，检查BCCTRL1.PDDETSTS标志，确定二次检测处理的结果。

注1.在初级检测处理中，在D-Line上检测到高于0.25至0.4V范围且低于0.8至2.0V范围的电压表示其他设备是支持电池充电的主机设备（充电下游港口）。PHY模块中的BCCTRL1.CHGDETSTS标志位仅指示Dline上的电压是否高于0.25到0.4V的范围，因此根据需要添加处理以读取SYSSTS0.LNST[1:0]标志位并确认电压Dline上的电压也低于0.8至2.0V的范围。

图26.22显示了处理流程。

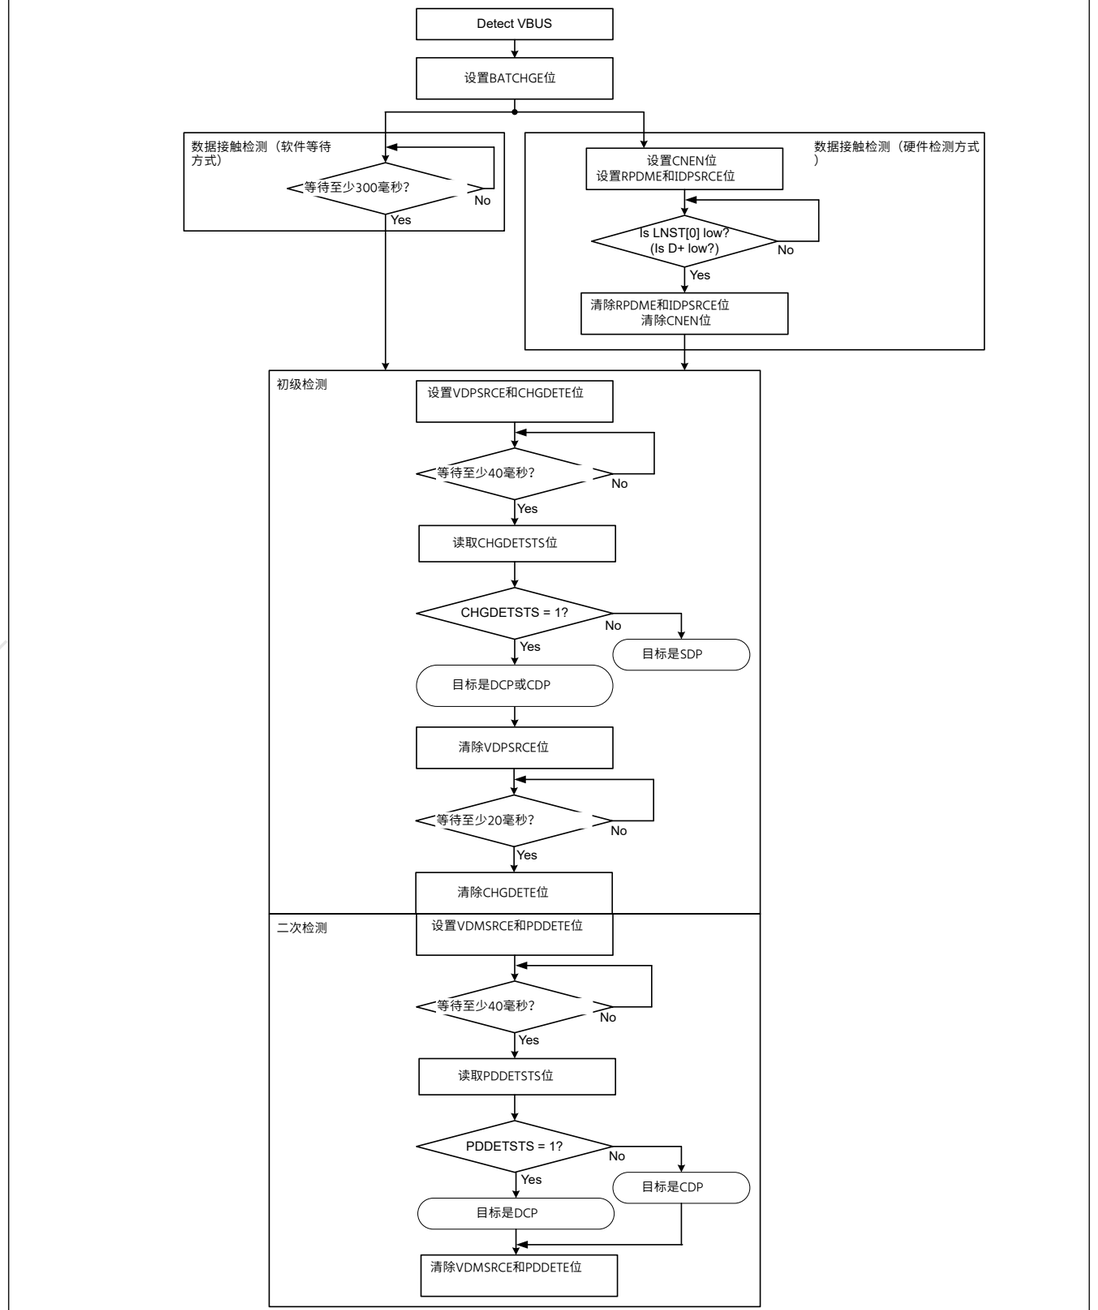

Figure 26.22 作为便携式设备的处理流程

26.3.15.2 Processing in host controller mode

In host controller mode, driving the D- line is required for a portable device to perform primary detection. The USBFS supports the following two primary detection methods:

When using the Portable Device detection function

The D- line is driven when a Portable Device is detected.

1. Start driving the VBUS.
2. Set the BCCTRL1.PDDETE bit to 1 to enable the portable device detection circuit.
3. Monitor the portable device detection signal and start driving the D- line when the level of the portable device detection signal is high.*1
4. Stop driving the D- line when the portable device detection signal is at the low level.*1

Note 1. The PDDETINT interrupt indicates a change in the level of the portable device detection signal, and the current level can be obtained by reading the PDDETSTS flag.

When not using the Portable Device detection function

Regardless of whether or not a Portable Device was detected, drive the D- line after device disconnection is detected, and leave the D- line open after connection is detected. Software handles the timing of a and b.

a. After disconnection is detected, start driving the D- line within 200 ms.

b. After connection is detected, stop driving the D- line within 10 ms.

Figure 26.23 shows the process flow for steps 1. to 4. and Figure 26.24 shows the process flow for steps a. and b., respectively.

26.3.15.2 主机控制器模式下的处理

在主机控制器模式下，便携式设备需要驱动Dline才能执行初级检测。USBFS支持以下两种主要检测方法：

使用便携式设备检测功能时

当检测到便携式设备时驱动Dline。

1.开始驱动VBUS。

2.将BCCTRL1.PDDETE位设置为1以启用便携式设备检测电路。

3.监测便携设备检测信号，当便携设备检测信号为高电平时开始驱动Dline。*1

4、当便携设备检测信号为低电平时，停止驱动Dline。*1

注1.PDDETINT中断表示便携式设备检测信号电平的变化，当前电平可通过读取PDDETSTS标志获得。

不使用便携设备检测功能时

无论是否检测到便携式设备，在检测到设备断开后驱动Dline，在检测到连接后保持Dline处于打开状态。软件处理a和b的时序。

a. 检测到断线后，在200ms内开始驱动Dline。

湾。检测到连接后，请在10ms内停止驱动Dline。

26.4 Usage Notes

26.4.1 Settings for the Module-Stop State

USBFS operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The USBFS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

26.4.2 Clearing the Interrupt Status Register on Exiting Software Standby Mode

Because the input buffer is always enabled in Software Standby mode, an unexpected interrupt might occur under the following conditions:

- When the interrupt is enabled in Normal mode
- When the interrupt is disabled in Software Standby mode
- When the input level of the pin that cancels software standby is changed in Software Standby mode

These conditions might cause the associated interrupt flag in the Interrupt Status Register to set unexpectedly. After the MCU exits the Software Standby mode, the unexpected interrupt might be sent to the interrupt controller. To avoid this, always clear the INTSTS0 and INTSTS1 registers in the canceling sequence.

26.4.3 Clearing the Interrupt Status Register after Setting Up the Port Function

The input buffer is disabled before the PmnPFS.PSEL and PmnPFS.PMR port is set up, so the internal signal is fixed high or low. The input buffer is enabled after the port is set so that the external pin state is propagated to the MCU. An unexpected interrupt might occur at this time, causing the VBINT and OVRCR bits in INTSTS0 and INTSTS1, or other

26.4 使用说明

26.4.1 模块停止状态的设置

可以使用模块停止控制寄存器B(MSTPCRB)禁用或启用USBFS操作。USBFS在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

26.4.2 退出软件待机模式时清除中断状态寄存器

由于在软件待机模式下始终启用输入缓冲区，因此在以下情况下可能会发生意外中断：

- ●在正常模式下使能中断时
- ●在软件待机模式下禁用中断时
- ●在软件待机模式下，取消软件待机的引脚的输入电平发生变化时

这些情况可能会导致中断状态寄存器中的相关中断标志意外设置。MCU退出软件待机模式后，可能会向中断控制器发送意外中断。为避免这种情况，请始终在取消序列中清除INTSTS0和INTSTS1寄存器。

26.4.3 设置端口功能后清除中断状态寄存器

在设置PmnPFS.PSEL和PmnPFS.PMR端口之前，输入缓冲器被禁用，因此内部信号固定为高电平或低电平。设置端口后启用输入缓冲器，以便将外部引脚状态传播到MCU。此时可能会发生意外中断，导致INTSTS0和INTSTS1中的VBINT和OVRCR位，或其他

interrupt status flags to set to 1. To avoid a malfunction, always clear the INTSTS0 and INTSTS1 registers after setting up the port.

中断状态标志设置为1。为避免故障，请在设置端口后始终清除INTSTS0和INTSTS1寄存器。

27. Serial Communications Interface (SCI)

27.1 Overview

The Serial Communications Interface (SCI) × 4 channels have asynchronous and synchronous serial interfaces:

- Asynchronous interfaces (UART and Asynchronous Communications Interface Adapter (ACIA))
- 8-bit clock synchronous interface
- Simple IIC (master-only)

The smart card interface complies with the ISO/IEC 7816-3 standard for electronic signals and transmission protocol. SCIn (n = 0, 3, 4, 9) has FIFO buffers to enable continuous and full-duplex communication, and the data transfer speed can be configured independently using an on-chip baud rate generator.

In this section, PCLK refers to PCLKA.

Table 27.1 lists the SCI specifications, Figure 27.1 shows a block diagram of SCI, and Table 27.3 lists the I/O pins.

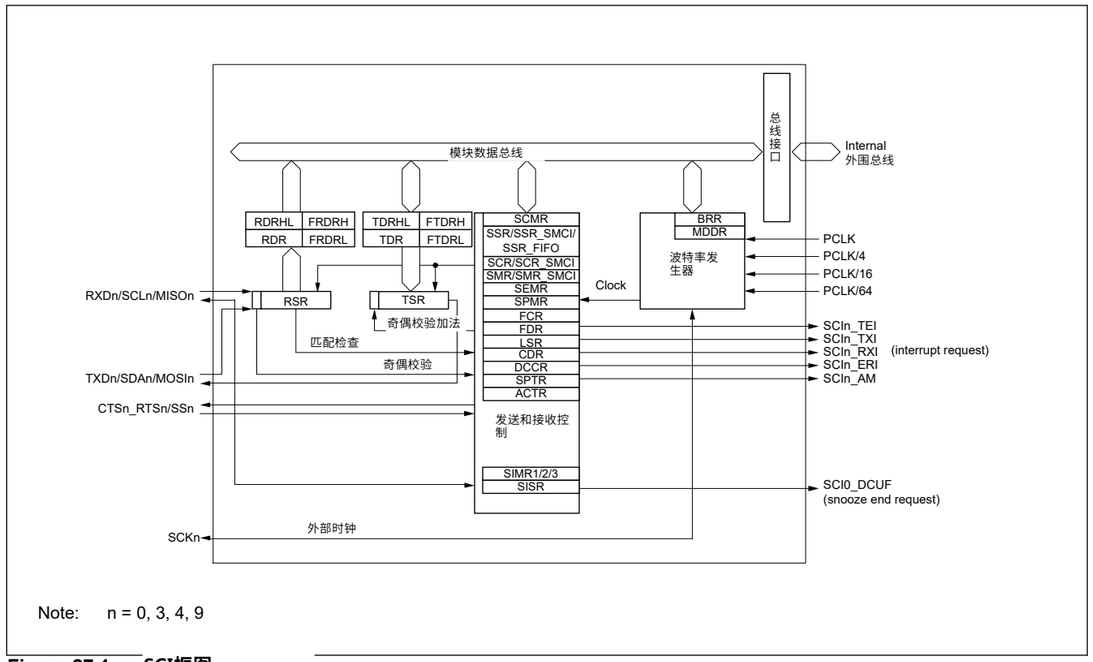
27.2 Register Descriptions

27.2.1 RSR : Receive Shift Register

RSR is a shift register that receives serial data input from the RXDn pin and converts it into parallel data. When one frame of data is received, the data is automatically transferred to the RDR, RDRHL, or the receive FIFO register. The RSR register cannot be directly accessed by the CPU.



Note: n = 0, 3, 4, 9

27.2 注册说明

27.2.1 RSR:接收移位寄存器

RSR是一个移位寄存器，它接收从RXDn引脚输入的串行数据并将其转换为并行数据。当接收到一帧数据时，数据会自动传输到RDR、RDRHL或接收FIFO寄存器。CPU不能直接访问RSR寄存器。

27.2.2 RDR : Receive Data Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

RDR is an 8-bit register that stores received data. When one frame of serial data is received, it is transferred from RSR to RDR, and the RSR register can receive more data. Because RSR and RDR function as a double buffer, continuous received operations can be performed.

Read the RDR only once after a receive data full interrupt (SCIn_RXI) occurs.

Note: If the next frame of data is received before reading the received data from RDR, an overrun error occurs. The CPU cannot write to the RDR.

27.2.3 RDRHL : Receive Data Register for Non-Manchester mode (MMR.MANEN = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x10

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	RDAT[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	RDAT[8:0]	Serial Receive Data	R
15:9	—	These bits are read as 0.	R

RDRHL is a 16-bit register that stores received data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of RDRHL are the shadow register of RDR, so access to RDRHL affects the RDR register. Access to the RDRHL register is prohibited if 7-bit or 8-bit data length is selected.

After one frame of data is received, the received data is transferred from the RSR register to the RDR/RDRHL registers, allowing the RSR register to receive more data.

The RSR and RDRHL registers form a double-buffered structure to enable continuous reception. RDRHL should be read only when a receive data full interrupt (SCIn_RXI) request is issued. An overrun error occurs when the next frame of data is received before the received data is read from RDRHL. The CPU cannot write to the RDRHL register.

27.2.4 RDRHL_MAN : Receive Data Register for Manchester mode (MMR.MANEN = 1)

Base address: SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x10

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	RSYNC	—	—	MPB	RDAT[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

27.2.2 RDR:接收数据寄存器

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
重置后的值:	0	0	0	0	0	0	0	0

RDR是一个8位寄存器，用于存储接收到的数据。当接收到一帧串行数据时，将其从RSR传输到RDR，而RSR寄存器可以接收更多的数据。由于RSR和RDR用作双缓冲器，因此可以执行连续接收操作。

在接收数据完全中断(SCIn_RXI)发生后，仅读取一次RDR。

Note: 如果在从RDR读取接收到的数据之前接收到下一帧数据，则会发生溢出错误。CPU无法写入RDR。

27.2.3 RDRHL:非曼彻斯特模式的接收数据寄存器(MMR.MANEN=0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x10

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Symbol	Function	R/W
8:0	RDAT[8:0]	串行接收数据	R
15:9	—	这些位读为0。	R

RDRHL是一个16位寄存器，用于存储接收到的数据。选择异步模式和9位数据长度时，请使用此寄存器。

RDRHL的低8位是RDR的影子寄存器，因此访问RDRHL会影响RDR寄存器。访问
如果选择7位或8位数据长度，则禁止RDRHL寄存器。

接收到一帧数据后，将接收到的数据从RSR寄存器传送到RDRRDRHL寄存器，使RSR寄存器可以接收更多数据。

RSR和RDRHL寄存器形成一个双缓冲结构以实现连续接收。只有在发出接收数据完全中断(SCIn_RXI)请求时才应读取RDRHL。在从RDRHL读取接收到的数据之前接收到下一帧数据时，会发生溢出错误。CPU无法写入RDRHL寄存器。

27.2.4 RDRHL_MAN：曼彻斯特模式的接收数据寄存器（MMR.MANEN=1）

15:13	—	These bits are read as 0. The write value should be 0.	R

RDRHL_MAN is a 16-bit register that stores received data. Use this register when asynchronous mode and 9-bit data length are selected. The lower 8 bits of RDRHL_MAN are the shadow register of RDR, so access to RDRHL_MAN affects the RDR register. Access to the RDRHL_MAN register is prohibited if 7-bit or 8-bit data length is selected.

After one frame of data is received, the received data is transferred from the RSR register to the RDR/RDRHL_MAN registers, allowing the RSR register to receive more data.

The RSR and RDRHL_MAN registers form a double-buffered structure to enable continuous reception.

RDRHL_MAN should be read only when a receive data full interrupt (SCIn_RXI) request is issued. An overrun error occurs when the next frame of data is received before the received data is read from RDRHL_MAN.

The CPU cannot write to the RDRHL_MAN register.

RDRHL_MAN是一个16位寄存器，用于存储接收到的数据。选择异步模式和9位数据长度时，请使用此寄存器。RDRHL_MAN的低8位是RDR的影子寄存器，因此访问RDRHL_MAN会影响RDR寄存器。如果选择7位或8位数据长度，则禁止访问RDRHL_MAN寄存器。

15	—	This bit is read as 0.	R

Note 1. If this flag is read, it indicates the same value as that read from the SSR_FIFO register. Write 0 to the SSR_FIFO register to clear the flag.

FRDRHL is a 16-bit register that consists of the 8-bit FRDRH and FRDRL registers. FRDRH is assigned to the FRDRHL[15:8] bits, and allocated to the same address as FRDRHL. FRDRL is assigned to the FRDRHL[7:0] bits, and allocated to (the address of FRDRHL + 1) address.

FRDRH and FRDRL constitute a 16-stage FIFO register that stores serial receive data and related status information readable by software. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

The SCI completes reception of one frame of serial data by transferring the received data from the Receive Shift Register (RSR) into FRDRH and FRDRL for storage. Continuous reception is executed until 16 stages are stored. If data is read when there is no received data in FRDRH and FRDRL, the value is undefined. When FRDRH and FRDRL are full, subsequent serial receive data is lost. The CPU can read from the FRDRH and FRDRL registers but cannot write to them.

Reading 1 from the RDF, ORER, or DR flags of the FRDRH register is the same as reading from those bits in the SSR_FIFO register. When writing 0 to clear a flag in the SSR_FIFO register after reading the FRDRH register, write 0 only to the flag that is to be cleared and write 1 to the other flags.

When reading both the FRDRH and FRDRL registers, read in order from FRDRH to FRDRL. The FRDRHL register can be accessed in 16-bit units.

注1.如果读取该标志，则表示与从SSR_FIFO寄存器读取的值相同。将0写入SSR_FIFO寄存器以清除标志。

FRDRHL是一个16位寄存器，由8位FRDRH和FRDRL寄存器组成。FRDRH被分配到FRDRHL[15:8]位，并分配到与FRDRHL相同的地址。FRDRL分配给FRDRHL[7:0]位，并分配给（FRDRHL+1的地址）地址。

FRDRH和FRDRL构成一个16级FIFO寄存器，用于存储串行接收数据和软件可读的相关状态信息。该寄存器仅在异步模式下有效，包括多处理器模式或时钟同步模式。

SCI通过将接收到的数据从接收移位寄存器（RSR）传送到FRDRH和FRDRL中进行存储，从而完成一帧串行数据的接收。执行连续接收，直到存储16个阶段。如果在FRDRH和FRDRL中没有接收到数据时读取数据，则该值未定义。当FRDRH和FRDRL已满时，后续的串行接收数据会丢失。CPU可以读取FRDRH和FRDRL寄存器，但不能写入它们。

从FRDRH寄存器的RDF、ORER或DR标志读取1与从SSR_FIFO寄存器。在读取FRDRH寄存器后写入0以清除SSR_FIFO寄存器中的标志时，仅将0写入要清除的标志，将1写入其他标志。

读取FRDRH和FRDRL寄存器时，按从FRDRH到FRDRL的顺序读取。FRDRHL寄存器可以以16位为单位进行访问。

TDR is an 8-bit register that stores transmit data.

When the SCI detects that the TSR register is empty, it transfers the transmit data written in the TDR register to the TSR register and starts transmission.

The double-buffered structure of the TDR and TSR registers enables continuous serial transmission. If the next transmit data is already written to TDR when one frame of data is transmitted, the SCI transfers the written data to the TSR register to continue transmission.

The CPU can read from or write to TDR at any time. Only write transmit data to TDR once after each instance of the transmit data empty interrupt (SCIn_TXI).

27.2.7 TDRHL : Transmit Data Register for Non-Manchester mode (MMR.MANEN = 0)

TDRHL is a 16-bit register that stores transmit data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of TDRHL are the shadow register of TDR, so access to TDRHL affects the TDR register. Access to the TDRHL register is prohibited if 7-bit or 8-bit data length is selected.

When empty space is detected in the TSR register, the transmit data stored in the TDRHL registers is transferred to TSR and transmission starts.

The TSR and TDRHL registers have a double-buffered structure to support continuous transmission. When the next data to be transmitted is stored in TDRHL after one frame of data is transmitted, the transmitting operation continues by transferring the data to the TSR register.

The CPU can read and write to the TDRHL register. Bits [15:9] in TDRHL are fixed to 1. These bits are read as 1. The write value should be 1.

Write transmit data to theTDRHL register only once when a transmit data empty interrupt (SCIn_TXI) request is issued.

TDRHL的低8位是TDR的影子寄存器，因此访问TDRHL会影响TDR寄存器。访问
如果选择7位或8位数据长度，则禁止TDRHL寄存器。

当在TSR寄存器中检测到空空间时，存储在TDRHL寄存器中的发送数据被传送到TSR并开始发送。

TSR和TDRHL寄存器具有双缓冲结构以支持连续传输。当发送完一帧数据后，下一个要发送的数据存储在TDRHL中时，通过将数据传输到TSR寄存器来继续发送操作。

CPU可以读取和写入TDRHL寄存器。TDRHL中的位[15:9]固定为1。这些位被读取为1。写入值应为1。

TDRHL_MAN is a 16-bit register that stores transmit data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of TDRHL_MAN are the shadow register of TDR, so access to TDRHL_MAN affects the TDR register. Access to the TDRHL_MAN register is prohibited if 7-bit or 8-bit data length is selected.

When empty space is detected in the TSR register, the transmit data stored in the TDRHL_MAN registers is transferred to TSR and transmission starts.

FTDRHL is a 16-bit register that consists of the 8-bit FTDRH and FTDRL registers. FTDRH is assigned to the FTDRHL[15:8] bits, and allocated to the same address as FTDRHL. FTDRL is assigned to the FTDRHL[7:0] bits, and allocated to (the address of FTDRHL + 1) address.

FTDRH and FTDRL constitute a 16-stage FIFO register that stores data for serial transmission and a multi-processor transfer bit. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

When the SCI detects that the Transmit Shift Register (TSR) is empty, it transfers data written in the FTDRH and FTDRL registers to the TSR register and starts serial transmission. Continuous serial transmission is executed until no transmit data is left in FTDRH and FTDRL. When FTDRHL is full of transmit data, no more data can be written. If writing new data is attempted, the data is ignored. The CPU can write to the FTDRH and FTDRL registers but cannot read them.

When writing to both the FTDRH and FTDRL registers, write in order from FTDRH to FTDRL.

TDAT[8:0] bits (Serial transmit data)

The TDAT[8:0] bits set the serial transmission data. This is valid only when FIFO is selected in asynchronous mode (including multiprocessor) or clock synchronous mode.

MPBT flag (Multi-Processor Transfer Bit Flag)

The MPBT flag specifies the value of the multi-processor bit of the transmit frame. When FCR.FM = 1, SSR.MPBT is invalid.

27.2.10 TSR : Transmit Shift Register

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first automatically transfers transmit data from TDR, TDRHL, or transmit FIFO to TSR, then sends the data to the TXDn pin. The CPU cannot directly access the TSR.

27.2.11 SMR : Serial Mode Register for Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

15:10	—	写入值应为1。	W

FTDRHL是一个16位寄存器，由8位FTDRH和FTDRL寄存器组成。FTDRH分配给FTDRHL[15:8]位，并分配到与FTDRHL相同的地址。FTDRL分配给FTDRHL[7:0]位，并分配给（FTDRHL的地址+1）地址。

FTDRH和FTDRL构成一个16级FIFO寄存器，用于存储串行传输的数据和一个多处理器传输位。该寄存器仅在异步模式下有效，包括多处理器模式或时钟同步模式。

当SCI检测到传输移位寄存器(TSR)为空时，它将写入FTDRH和FTDRL寄存器的数据传输到TSR寄存器并开始串行传输。执行连续串行传输，直到在FTDRH和FTDRL中没有剩余传输数据。当FTDRHL充满传输数据时，不能再写入数据。如果尝试写入新数据，则忽略该数据。CPU可以写入FTDRH和FTDRL寄存器，但不能读取它们。

当同时写入FTDRH和FTDRL寄存器时，按照从FTDRH到FTDRL的顺序写入。

TDAT[8:0]位（串行发送数据）

TDAT[8:0]位设置串行传输数据。这仅在异步模式（包括多处理器）或时钟同步模式下选择FIFO时有效。

MPBT标志（多处理器传输位标志）

MPBT标志指定发送帧的多处理器位的值。FCR.FM=1时，SSR.MPBT无效。

27.2.10 TSR：发送移位寄存器

TSR是传送串行数据的移位寄存器。为了进行串行数据传输，SCI首先自动将发送数据从TDR、TDRHL或发送FIFO传输到TSR，然后将数据发送到TXDn引脚。CPU不能直接访问TSR。

27.2.11 SMR：非智能卡接口模式的串行模式寄存器（SCMR.SMIF=0）

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)

7	CM	Communication Mode 0: Asynchronous mode or simple IIC mode 1: Clock synchronous mode or simple SPI mode	R/W*4

Note 1. n is the decimal notation of the value of n in the BRR register. See section 27.2.20. BRR : Bit Rate Register.
Note 2. In any mode other than asynchronous mode, this bit setting is invalid and a fixed data length of 8 bits is used.
Note 3. LSB-first is fixed and the MSB (bit [7]) in the TDR register is not transmitted in transmit mode.
Note 4. Writable only when SCR.TE = 0 and SCR.RE = 0 (both serial transmission and reception are disabled).

The SMR register sets the communication format and clock source for the on-chip baud rate generator.

CKS[1:0] bits (Clock Select)

The CKS[1:0] bits select the clock source for the on-chip baud rate generator. For the relationship between the settings of these bits and the baud rate, see section 27.2.20. BRR : Bit Rate Register.

MP bit (Multi-Processor Mode)

The MP bit disables or enables the multi-processor communications function. The PE and PM bit settings are invalid in multi-processor mode.

STOP bit (Stop Bit Length)

The STOP bit selects the stop bit length in transmission.

In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

PM bit (Parity Mode)

The PM bit selects the parity mode (even or odd) for transmission and reception. The PM bit setting is invalid in multiprocessor mode.

PE bit (Parity Enable)

When the PE bit is set to 1, the parity bit is added to transmit data, and the parity bit is checked in reception. Regardless of the PE bit setting, the parity bit is not added or checked in multi-processor format.

CHR bit (Character Length)

The CHR bit selects the data length for transmission and reception in combination with the SCMR.CHR1 bit. In modes other than asynchronous, a fixed data length of 8 bits is used.

CM bit (Communication Mode)

The CM bit selects the communication mode:

Bit	Symbol	Function	R/W
3	STOP	停止位长度 仅在异步模式下有效。 0：1个停止位1 ：2个停止位	R/W*4

注1.n是BRR寄存器中n值的十进制表示法。请参阅第27.2.20节。BRR：比特率寄存器。
注2.在异步模式以外的任何模式下，该位设置无效，使用8位的固定数据长度。
注3.LSB-first是固定的，并且TDR寄存器中的MSB（位[7]）在发送模式下不发送。
注4.仅当SCR.TE=0且SCR.RE=0时可写（串行发送和接收均禁用）。

SMR寄存器设置片内波特率发生器的通信格式和时钟源。

CKS[1:0] bits (Clock Select)

CKS[1:0]位选择片内波特率发生器的时钟源。关于这些位的设置与波特率之间的关系，请参见第27.2.20节。BRR：比特率寄存器。

PM bit (Parity Mode)

The PM bit selects the parity mode for transmission and reception (even or odd). For details on the usage of this bit in smart card interface mode, see section 27.7.2. Data Format (Except in Block Transfer Mode).

PE bit (Parity Enable)

Set the PE bit to 1. The parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

7	TIE	Transmit Interrupt Enable 0: Disable SCIn_TXI interrupt requests 1: Enable SCIn_TXI interrupt requests	R/W

Note 1. Writable only when TE = 0 and RE = 0.
Note 2. 1 can be written only when TE = 0 and RE = 0, when the SMR.CM bit is 1. After setting TE or RE to 1, only 0 can be written to TE and RE. When the SMR.CM bit is 0 and the SIMR1.IICM bit is 0, writing is enabled under any condition.
Note 3. When writing a new value to a bit other than the MPIE bit of this register in multi-processor mode (SMR.MP bit = 1), write 0 to the MPIE bit using the store instruction to avoid accidentally setting the MPIE bit to 1 by a read-modify-write operation when using a bit manipulation instruction.

The SCR register controls operation and clock source selection for transmission and reception.

CKE[1:0] bits (Clock Enable)

The CKE[1:0] bits select the clock source and the SCKn pin function.

TEIE bit (Transmit End Interrupt Enable)

The TEIE bit enables or disables SCIn_TEI interrupt requests. Set TEIE to 0 to disable an SCIn_TEI interrupt request.

In simple IIC mode, SCIn_TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STIn). In this case, the TEIE bit can be used to enable or disable the STI.

MPIE bit (Multi-Processor Interrupt Enable)

When the MPIE bit is set to 1 and data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags RDRF, ORER, FER, RDF, and DR in SSR/SSR_FIFO to 1 is disabled. When data with the multi-processor bit set to 1 is received, the MPIE bit is automatically set to 0, and normal reception resumes. For details, see section 27.4. Multi-Processor Communication Function.

When the MPB bit in the SSR register is 0, the receive data is not transferred from the RSR register to the RDR register, a receive error is not detected, and setting the flags ORER and FER to 1 is disabled.

When the MPB bit is set to 1, the MPIE bit is automatically set to 0, SCIn_RXI and SCIn_ERI interrupt requests are enabled (if the RIE bit in SCR is set to 1), and setting of the ORER and FER flags to 1 is enabled.

Set MPIE to 0 if the multi-processor communications function is not used.

RE bit (Receive Enable)

The RE bit enables or disables serial reception. When the RE bit is set to 1, serial reception starts by detecting the start bit in asynchronous mode or the synchronous clock input in clock synchronous mode. Set the reception format in the SMR register before setting the RE bit to 1.

In non-FIFO operation, when reception is halted by setting the RE bit to 0, the RDRF, ORER, FER, and PER flags in the SSR register are not affected, and the previous values are retained.

When FIFO operation is selected and reception is halted by setting the RE bit to 0, the RDF, ORER, FER, PER, and DR flags in SSR_FIFO are not affected and the previous values are retained.

注1.仅当TE=0且RE=0时可写。
注2.只有当TE=0且RE=0时，当SMR.CM位为1时，才能写入1。将TE或RE设置为1后，TE和RE只能写入0。当SMR.CM位为0且SIMR1.IICM位为0时，在任何情况下都可以写入。
注3.在多处理器模式下（SMR.MP位=1）向该寄存器的MPIE位以外的位写入新值时，将0写入MPIE位使用存储指令以避免在使用位操作指令时通过读-修改-写操作意外将MPIE位设置为1。

SCR寄存器控制发送和接收的操作和时钟源选择。

CKE[1:0] bits (Clock Enable)

CKE[1:0]位选择时钟源和SCKn引脚功能。

TEIE位（发送结束中断允许）

TEIE位启用或禁用SCIn_TEI中断请求。将TEIE设置为0以禁用SCIn_TEI中断请求。

在简单IIC模式下，SCIn_TEI在完成发出启动、重新启动或停止条件(STIn)时分配给中断。
在这种情况下，TEIE位可用于启用或禁用STI。

MPIE位（多处理器中断允许）

当MPIE位设置为1并且接收到多处理器位设置为0的数据时，不读取数据并且将SSRSSR_FIFO中的状态标志RDRF、ORER、FER、RDF和DR设置为1被禁用。当接收到多处理器位设置为1的数据时，MPIE位自动设置为0，并恢复正常接收。有关详细信息，请参阅第27.4节。多处理器通信功能。

当SSR寄存器的MPB位为0时，接收数据不会从RSR寄存器传送到RDR寄存器，不会检测到接收错误，并且将标志ORER和FER设置为1被禁止。

当MPB位设置为1时，MPIE位自动设置为0，允许SCIn_RXI和SCIn_ERI中断请求（如果SCR中的RIE位设置为1），并且允许设置ORER和FER标志为1.

如果不使用多处理器通信功能，则将MPIE设置为0。

RE位（接收使能）

RE位启用或禁用串行接收。当RE位设置为1时，串行接收通过检测异步模式下的起始位或时钟同步模式下的同步时钟输入来启动。在将RE位设置为1之前，在SMR寄存器中设置接收格式。

在非FIFO操作中，当通过将RE位设置为0来停止接收时，RDRF、ORER、FER和PER标志
SSR寄存器不受影响，保留之前的值。

WhenFIFOoperationisselectedandreceptionishaltedbysettingtheREbitto0 theRDF ORER FER PER andDRflagsin SSR_FIFOarenotaffectedandthepreviousvaluesareretained.

TE bit (Transmit Enable)

The TE bit enables or disables serial transmission.

When the TE bit is set to 1, serial transmission is started by writing transmit data to the TDR register. Set the transmission format in the SMR register before setting the TE bit to 1.

RIE bit (Receive Interrupt Enable)

The RIE bit enables or disables SCIn_RXI and SCIn_ERI interrupt requests.

SCIn_RXI and SCIn_ERI interrupt requests are disabled by setting the RIE bit to 0.

An SCIn_ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in SSR/SSR_FIFO then setting the flag to 0, or by setting the RIE bit to 0.

TIE bit (Transmit Interrupt Enable)

The TIE bit enables or disables SCIn_TXI interrupt requests. SCIn_TXI interrupt requests are disabled by setting the TIE bit to 0.

Note: To switch the TIE bit value from 0 to 1 in FIFO mode, set the TIE and TE bits to 1 simultaneously or set the TIE bit to 1 when TE = 1. When TE = 0 in FIFO mode, setting the TIE bit to 1 is prohibited.

TE位（发送使能）

TE位启用或禁用串行传输。

当TE位设置为1时，通过将发送数据写入TDR寄存器开始串行发送。在将TE位设置为1之前，在SMR寄存器中设置传输格式。

RIE位（接收中断允许）

RIE位启用或禁用SCIn_RXI和SCIn_ERI中断请求。

通过将RIE位设置为0来禁用SCIn_RXI和SCIn_ERI中断请求。

SCIn_ERI中断请求可以通过从SSRSSR_FIFO中的ORER、FER或PER标志读取1然后将该标志设置为0或通过将RIE位设置为0来取消。

TIE位（发送中断允许）

TIE位启用或禁用SCIn_TXI中断请求。通过将TIE位设置为0来禁用SCIn_TXI中断请求。

Note: 要在FIFO模式下将TIE位的值从0切换为1，请将TIE和TE位同时设置为1，或者在TE=1时将TIE位设置为1。在FIFO模式下，当TE=0时，将TIE位设置为1禁止。

The SCR_SMCI register sets transmission and reception control, interrupt control, and clock source selection for transmission and reception.

For details on interrupt requests, see section 27.11. Interrupt Sources.

CKE[1:0] bits (Clock Enable)

The CKE[1:0] bits control the clock output from the SCKn pin. In GSM mode, clock output can be dynamically switched. For details, see section 27.7.8. Clock Output Control.

Set the TEIE bit to 0 in smart card interface mode.

MPIE bit (Multi-Processor Interrupt Enable)

Set the MPIE bit to 0 in smart card interface mode.

有关中断请求的详细信息，请参阅第27.11节。中断源。

CKE[1:0] bits (Clock Enable)

CKE[1:0]位控制SCKn引脚的时钟输出。在GSM模式下，时钟输出可以动态切换。

在智能卡接口模式下将TEIE位设置为0。

MPIE位（多处理器中断允许）

在智能卡接口模式下将MPIE位设置为0。

RE位（接收使能）

RE位启用或禁用串行接收。当RE位设置为1时，串行接收通过检测起始位开始。

RIE位启用或禁用SCIn_RXI和SCIn_ERI中断请求。

通过将RIE位设置为0来禁用SCIn_RXI和SCIn_ERI中断请求。

通过从SSR_SMCI寄存器中的ORER、FER或PER标志读取1，然后将该标志设置为0，或将RIE位设置为0，可以取消SCIn_ERI中断请求。

The SSR register provides SCI status flags and transmission and reception multi-processor bits.

MPBT bit (Multi-Processor Bit Transfer)

The MPBT bit sets the value of the multi-processor bit in the transmit frame.

MPB bit (Multi-Processor)

The MPB bit holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

TEND flag (Transmit End Flag)

The TEND flag indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled) and the FCR.FM bit is set to 0 (non-FIFO selected). When the SCR.TE bit is set to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated on transmission of the tail-end bit of a character being transmitted.

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR.TE bit is 1
- When 0 is written to TDRE after reading TDRE = 1 while the SCR.TE bit is 1

PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

Bit	Symbol	Function	R/W

7	TDRE	传输数据空标志 0：在TDR寄存器中发送数据1：在TDR寄存器中不发送数据	R/(W)*1

注1.读1后只能写0清除标志。

SSR寄存器提供SCI状态标志和发送和接收多处理器位。

MPBT bit (Multi-Processor Bit Transfer)

MPBT位设置发送帧中多处理器位的值。

MPB bit (Multi-Processor)

MPB位保存接收帧中多处理器位的值。当SCR.RE位为0时，该位不变。

TEND标志（发送结束标志）

TEND标志表示传输完成。

[Setting conditions]

●当SCR.TE位设置为0（禁用串行传输）且FCR.FM位设置为0（选择非FIFO）时。当SCR.TE位设置为1时，TEND标志不受影响并保持值1。

●TDR寄存器未在发送字符的尾端位时更新时。

[Clearing conditions]

●当SCR.TE位为1时将发送数据写入TDR寄存器

●当SCR.TE位为1时，读取TDRE=1后向TDRE写入0

PER标志（奇偶校验错误标志）

PER标志表示在异步模式接收过程中发生奇偶校验错误，接收异常结束。

[Setting condition]

●当地址匹配功能被禁用（DCCR.DCME=0）时，在异步模式接收期间检测到奇偶校验错误。

Although receive data is transferred to the RDR register when the parity error occurs, no SCIn_RXI interrupt request occurs. When the PER flag is set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to PER after reading PER = 1. After writing 0 to the PER flag, read the PER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

The FER flag indicates that a framing error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When 0 is sampled as the stop bit during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

  In 2-stop-bit mode, only the first stop bit is checked. The second stop bit is not checked. Although receive data is transferred to the RDR register when the framing error occurs, no SCIn_RXI interrupt request occurs. When the FER flag is to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to FER after reading FER = 1. After writing 0 to the FER flag, read the FER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error and a framing error is read from the RDR register.

  The data received before an overrun error occurred is saved in the RDR register, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register. In clock synchronous mode, serial transmission and reception are stopped.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1. After writing 0 to the ORER flag, read the ORER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing conditions]

- When 0 is written to RDRF after reading RDRF = 1
- When data is forwarded from the RDR register

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates the presence of transmit data in the TDR register.

[Setting conditions]

- When the SCR.TE bit is 0

尽管发生奇偶校验错误时接收数据被传送到RDR寄存器，但不会发生SCIn_RXI中断请求。当PER标志设置为1时，后续接收数据不会传送到RDR寄存器。

[Clearing condition]

●读取PER=1后向PER写入0时。将0写入PER标志后，读取PER标志以检查它是否实际设置为0。

当SCR.RE位设置为0（禁用串行接收）时，PER标志不受影响并保留其先前的值。

FER标志（帧错误标志）

FER标志表示在异步模式下接收过程中发生了帧错误，并且接收异常结束。

[Setting condition]

●当地址匹配功能被禁用（DCCR.DCME=0）时，在异步模式接收期间采样0作为停止位时。

在2停止位模式下，仅检查第一个停止位。不检查第二个停止位。虽然发生帧错误时接收数据被传输到RDR寄存器，但不会发生SCIn_RXI中断请求。当FER标志为1时，后续接收数据不传送到RDR寄存器。

[Clearing condition]

●当读取FER=1后向FER写入0时。将0写入FER标志后，读取FER标志以检查它是否实际设置为0。

当SCR.RE位设置为0（禁用串行接收）时，FER标志不受影响并保留其先前的值。

ORER标志（溢出错误标志）

ORER标志表示接收期间发生溢出错误，接收异常结束。

[Setting condition]

●在接收没有奇偶校验错误和帧错误的数据之前接收下一个数据时，从RDR寄存器中读取。

溢出错误发生前接收到的数据保存在RDR寄存器中，但错误发生后接收到的数据丢失。
当ORER标志设置为1时，接收数据不转发到RDR寄存器。在时钟同步模式下，串行发送和接收停止。

[Clearing condition]

●读取ORER=1后向ORER写入0时。向ORER标志写入0后，读取ORER标志以检查它是否实际设置为0。

当SCR.RE位设置为0（禁用串行接收）时，ORER标志不受影响并保留其先前的值。

RDRF标志（接收数据满标志）

RDRF标志指示RDR寄存器中存在接收数据。

[Setting condition]

●接收正常结束时，接收数据从RSR寄存器转发到RDR寄存器。

[Clearing conditions]

●读取RDRF=1后向RDRF写入0时

●从RDR寄存器转发数据时

TDRE标志（传输数据空标志）

TDRE标志表示TDR寄存器中存在发送数据。

[Setting conditions]

●当SCR.TE位为0时

- When data is transmitted from the TDR register to the TSR register

[Clearing conditions]

- When 0 is written to TDRE after reading TDRE = 1
- When the SCR.TE bit is 1 and data is written to the TDR register

Note 1. Only 0 can be written, to clear the flag after reading 1.

The SSR_FIFO register provides the SCI with FIFO mode status flags.

DR flag (Receive Data Ready Flag)

The DR flag indicates that the amount of data stored in the Receive FIFO Data Register (FRDRHL) falls below the specified receive triggering number, and that no next data is received after 15 ETUs (elementary time units) from the last stop bit in asynchronous mode. This flag is valid only in asynchronous mode, including multi-processor mode, when FIFO operation is selected.

7	TDFE	发送FIFO数据空标志 0：写入FTDRHL的发送数据量超过指定的发送触发数 1：写入FTDRHL的发送数据量等于或小于指定的发送触发数	R/W*1

注1.只能写入0，读取1后清除标志。

SSR_FIFO寄存器为SCI提供FIFO模式状态标志。

DR标志（接收数据就绪标志）

DR标志表示存储在接收FIFO数据寄存器(FRDRHL)中的数据量低于指定的接收触发数，并且在异步模式下从最后一个停止位开始15个ETU（基本时间单位）后没有接收到下一个数据.此标志仅在选择FIFO操作时在异步模式下有效，包括多处理器模式。

In clock synchronous mode, the DR flag is not set to 1.

[Setting condition]

- When FRDRHL contains less data than the specified receive triggering number, and no next data is received after 15 ETUs*1 from the last stop bit, and the SSR_FIFO.FER and SSR_FIFO.PER flags are 0.

[Clearing conditions]

- When 1 is read from DR, after all received data is read
- When the FCR.FM bit is changed from 0 to 1

Note 1. This is equivalent to 1.5 frames in the 8-bit format with one stop bit.
The DR flag is only set to 1 when FIFO is selected in asynchronous mode, including multi-processor mode. It is not set to 1 in other operation modes.

TEND flag (Transmit End Flag)

The TEND flag indicates that FTDRHL does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

- When FTDRHL does not contain transmit data when the last bit of a 1-byte serial character is transmitted.

[Clearing conditions]

- When transmit data is written to FTDRHL*1 while the SCR.TE bit is 1
- When 0 is written to TEND after 1 is read from TEND, when the SCR.TE bit is 1
- When the FCR.FM bit is changed from 0 to 1

Note 1. Do not use the TEND bit as a transmit end flag when the DTC writes data to FTDRHL in response to an SCIn_TXI interrupt request.

PER flag (Parity Error Flag)

The PER flag indicates whether there is a parity error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When data is received and a parity error is detected, when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to PER after reading PER = 1.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a parity error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

The FER flag indicates whether there is a framing error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When 0 is sampled as the stop bit during reception when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to FER after reading FER = 1.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a framing error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

在时钟同步模式下，DR标志不设置为1。

[Setting condition]

●当FRDRHL包含的数据少于指定的接收触发数，并且从最后一个停止位开始15个ETU*1后没有接收到下一个数据，并且SSR_FIFO.FER和SSR_FIFO.PER标志为0。

[Clearing conditions]

●从DR读取1时，在读取所有接收到的数据后

●当FCR.FM位由0变为1时

注1.这相当于8位格式的1.5帧，带有一位停止位。
只有在异步模式（包括多处理器模式）下选择FIFO时，DR标志才设置为1。在其他操作模式下不设置为1。

TEND标志（发送结束标志）

TEND标志表明FTDRHL在发送串行字符的最后一位时不包含有效数据，因此暂停发送。

[Setting condition]

●当FTDRHL不包含发送数据时，发送1字节串行字符的最后一位。

[Clearing conditions]

●当SCR.TE位为1时将发送数据写入FTDRHL*1

●从TEND读取1后，向TEND写入0时，SCR.TE位为1时

●当FCR.FM位由0变为1时

注1.当DTC将数据写入FTDRHL以响应SCIn_TXI中断请求时，请勿使用TEND位作为发送结束标志。

PER标志（奇偶校验错误标志）

PER标志指示在禁用地址匹配功能（DCCR.DCME=0）时，异步模式下从FRDRHL寄存器读取的数据是否存在奇偶校验错误。

[Setting condition]

●当接收到数据并检测到奇偶校验错误时，当地址匹配功能被禁用时（DCCR.DCME=0）。

[Clearing condition]

●读取PER=1后向PER写入0时。

接收操作是连续的，接收数据存储在FRDRHL寄存器中，即使在接收过程中发生奇偶校验错误。

当SCR.RE位设置为0（禁用串行接收）时，PER标志不受影响并保留其先前的值。

FER标志（帧错误标志）

FER标志指示在禁用地址匹配功能（DCCR.DCME=0）时，异步模式下从FRDRHL寄存器读取的数据是否存在帧错误。

[Setting condition]

●当地址匹配功能被禁用（DCCR.DCME=0）时，在接收期间采样0作为停止位时。

[Clearing condition]

●读取FER=1后向FER写入0时。

接收操作是连续的，接收数据存储在FRDRHL寄存器中，即使在接收过程中发生帧错误。

当SCR.RE位设置为0（禁用串行接收）时，FER标志不受影响并保留其先前的值。

ORER flag (Overrun Error Flag)

The ORER flag indicates that the receive operation stopped abnormally because an overrun error occurred.

[Setting condition]

- When the next serial reception completes while the receive FIFO is full with 16-byte receive data.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1.

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.

RDF flag (Receive FIFO Data Full Flag)

The RDF flag indicates that receive data was transferred to the FRDRHL register, and the amount of data in FRDRHL is equal to or exceeds the specified receive triggering number. When RTRG is set to 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0.

[Setting condition]

- When the amount of receive data equal to or greater than the specified receive triggering number is stored in FRDRHL,*1 and the FIFO is not empty.

[Clearing conditions]

- When 0 is written to RDF after reading RDF = 1
- When FRDRHL is read by the DTC, but only when the block transfer is the last transmission
- When the setting and clearing conditions occur at the same time, the RDF bit is set to 0. After that, when the amount of data stored in the FRDRHL register is the same as or greater than the RTRG value, RDF is set to 1 after 1 PCLK.

Note 1. Because FRDRHL is a 16-stage FIFO register, the maximum amount of data that can be read when RDF is 1 is equivalent to the specified receive triggering number. If an attempt is made to read after all the data in FRDRHL is read, the data is undefined.

TDFE flag (Transmit FIFO Data Empty Flag)

The TDFE flag indicates that data is transferred from the FTDRHL register into the TSR register, the amount of data in FTDRHL is below the specified transmit triggering number, and writing of transmit data to FTDRHL is enabled.

[Setting conditions]

- When the TE bit in SCR is 0
- When the amount of transmit data written in FTDRHL is equal to or less than the specified transmit triggering number*1

[Clearing conditions]

- When writing to FTDRHL is executed on the last transmission while the DTC is activated
- When 0 is written to the TDFE flag after reading TDFE = 1.*2
  The setting conditions are given priority when TE = 0. When the setting condition and clearing condition occur at the same time, the TDFE flag is set to 0. After that, when the amount of data stored in the FTDRHL register is equal to or less than the TTRG value, TDFE is set to 1 after 1 PCLK.

Note 1. Because the FTDRHL register is a 16-stage FIFO register, when the TDFE flag is 1, the maximum amount of data that can be written to the FTDRHL register is 16 minus FDR.T[4:0] bytes. If more data is written, data is discarded.
Note 2. Do not clear the TDFE flag during block transfer processing by the DTC.

ORER标志（溢出错误标志）

ORER标志指示接收操作由于发生溢出错误而异常停止。

[Setting condition]

●当接收FIFO已满16字节接收数据时，下一次串行接收完成时。

[Clearing condition]

●读取ORER=1后向ORER写入0时。

当SCR.RE位设置为0（禁用串行接收）时，ORER标志不受影响并保留其先前的值。

RDF标志（接收FIFO数据满标志）

RDF标志表示接收数据已传送到FRDRHL寄存器，并且FRDRHL中的数据量等于或超过指定的接收触发数。当RTRG设置为0时，即使接收FIFO中的数据量等于0，RDF标志也不会设置。

[Setting condition]

●当FRDRHL中存储了等于或大于指定接收触发数的接收数据量时，*1且FIFO不为空。

[Clearing conditions]

●读取RDF=1后向RDF写入0时

●当DTC读取FRDRHL时，但仅当块传输是最后一次传输时

●当设置和清除条件同时发生时，RDF位被设置为0。之后，当FRDRHL寄存器中存储的数据量等于或大于RTRG值时，RDF被设置为1在1个PCLK之后。

注1.因为FRDRHL是16级FIFO寄存器，所以当RDF为1时可以读取的最大数据量等于指定的接收触发数。如果在读取FRDRHL中的所有数据后尝试读取，则数据未定义。

TDFE标志（发送FIFO数据空标志）

TDFE标志表示数据从FTDRHL寄存器传送到TSR寄存器，在FTDRHL低于指定的发送触发数，并且允许将发送数据写入FTDRHL。

[Setting conditions]

●当SCR的TE位为0时

●当写入FTDRHL的发送数据量等于或小于指定的发送触发数时*1

[Clearing conditions]

●当DTC激活时，在最后一次传输上执行写入FTDRHL时

●读取TDFE=1后向TDFE标志写入0时。*2
当TE=0时，设置条件优先。当设置条件和清除条件同时发生时，TDFE标志设置为0。之后，当FTDRHL寄存器中存储的数据量等于或小于比TTRG值，TDFE在1个PCLK后设置为1。

注1.由于FTDRHL寄存器为16级FIFO寄存器，因此当TDFE标志为1时，可写入FTDRHL寄存器的最大数据量为16减去FDR.T[4:0]字节。如果写入更多数据，则丢弃数据。
注2.在DTC的块传输处理过程中，不要清除TDFE标志。

TEND flag (Transmit End Flag)

When there is no error signal from the receiving side, the TEND flag is set to 1 when more data for transfer is ready to be transferred to the TDR register.

[Setting conditions]

  When the SCR_SMCI.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period elapses after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated.

  The set timing is determined by the following register settings:
  - When SMR_SMCI.GM = 0 and SMR_SMCI.BLK = 0, 12.5 ETUs after the start of transmission
  - When SMR_SMCI.GM = 0 and SMR_SMCI.BLK = 1, 11.5 ETUs after the start of transmission

SSR_SMCI寄存器为SCI提供智能卡接口模式状态标志。

TEND标志（发送结束标志）

当接收端没有错误信号时，当更多数据准备好传输到TDR寄存器时，TEND标志设置为1。

当SCR_SMCI.TE位从0变为1时，TEND标志不受影响并保持值1。

●在最后一次发送1个字节后经过指定时间后，ERS标志为0，并且不更新TDR寄存器。

设置时序由以下寄存器设置确定：

当SMR_SMCI.GM=0且SMR_SMCI.BLK=0时，传输开始后12.5ETU

当SMR_SMCI.GM=0和SMR_SMCI.BLK=1时，传输开始后11.5ETU

当SMR_SMCI.GM=1和SMR_SMCI.BLK=0时，传输开始后11.0ETU

当SMR_SMCI.GM=1且SMR_SMCI.BLK=1时，传输开始后11.0ETU

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception. Although receive data is transferred to RDR when a parity error occurs, no SCIn_RXI interrupt request occurs. After the PER flag is set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to PER after reading PER = 1. After writing 0 to the PER flag, read the flag to check that it is actually set to 0.

When the RE bit in SCR_SMCI is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

[Clearing conditions]

- When 0 is written to MER after reading MER = 1 (after writing 0 to it, read the MER bit to check that it has actually been set to 0.)
  Even when the RE bit in SCR is set to 0 (serial reception is disabled), the MER flag is not affected and retains its previous value.

[Clearing condition]

- When 0 is written to PER after reading PER = 1 (after writing 0 to it, read the PER bit to check that it has actually been set to 0.)

Even when the RE bit in SCR is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

BRR is an 8-bit register that adjusts the bit rate.

As each SCI channel has independent baud rate generator control, different bit rates can be set for each channel. Table 27.6 shows the relationship between the setting (N) in the BRR and the bit rate (B) for normal asynchronous mode, multi-processor transfer, clock synchronous mode, smart card interface mode, simple SPI mode, and simple IIC mode.

The initial value of the BRR register is 0xFF. The BRR register can be read by the CPU, but it can be written to only when the TE and RE bits in SCR/SCR_SMCI are 0.

BRR是一个8位寄存器，用于调整比特率。

由于每个SCI通道都有独立的波特率发生器控制，因此可以为每个通道设置不同的比特率。表27.6显示了BRR中的设置(N)与正常异步模式、多处理器传输、时钟同步模式、智能卡接口模式、简单SPI模式和简单IIC模式的比特率(B)之间的关系。

BRR寄存器的初始值为0xFF。BRR寄存器可以被CPU读取，但只有当SCRSCR_SMCI中的TE和RE位为0时才能写入。

Table 27.10 and Table 27.11 list examples of BRR (N) settings in normal asynchronous mode. Table 27.12 lists the maximum bit rate settable for each operating frequency. Table 27.16 lists examples of BRR (N) settings in smart card interface mode.

In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, see section 27.7.4. Receive Data Sampling Timing and Reception Margin. Table 27.13 and Table 27.15 list the maximum bit rates with external clock input.

When either the Asynchronous Mode Base Clock Select bit (ABCS) or the Baud Rate Generator Double-speed Mode Select bit (BGDM) in the Serial Extended Mode Register (SEMR) is set to 1 in asynchronous mode, the bit rate becomes twice the value listed in Table 27.17. When both of those registers are set to 1, the bit rate becomes four times the listed value.

When either the ABCS or BGDM bit is set to 1, the bit rate doubles.
When both ABCS = 1 and BGDM = 1, the bit rate quadruples.

Note: Space: Setting prohibited.
—: Can be set, but an error occurs.

Note 1. Continuous transmission or reception is not possible. After transmitting or receiving one frame of data, a 1-bit period elapses before starting to transmit or receive the next frame of data. The output of the synchronization clock is stopped for a 1-bit period. Therefore, it takes 9 bits worth of time to transfer one frame (8 bits) of data, and the average transfer rate is 8/9 times the bit rate. When the FIFO is selected, this setting (BRR = 00h and SMR.CKS[1:0] = 00b) is not available.

Note: 空格：禁止设置。一：可以设置，
但发生错误。

注1.不能连续发送或接收。发送或接收一帧数据后，经过1位周期后
开始发送或接收下一帧数据。同步时钟的输出停止1位周期。因此，传输一帧（8位）数据需要9位的时间，平均传输速率为89倍的位速率。
选择FIFO时，此设置（BRR=00h且SMR.CKS[1:0]=00b）不可用。

27.2.21 MDDR : Modulation Duty Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

MDDR corrects the bit rate adjusted by the BRR register.

When the BRME bit in SEMR is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected using the settings in MDDR (M/256). Table 27.20 shows the relationship between the MDDR setting (M) and the bit rate (B).

The initial value of MDDR is 0xFF. Bit [7] in this register is fixed to 1.

The CPU can read the MDDR register, but this register is only writable when the TE and RE bits in SCR/SCR_SMCI are 0.

27.2.21 MDDR：调制占空比寄存器

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

MDDR校正由BRR寄存器调整的比特率。

当SEMR中的BRME位设置为1时，片上波特率发生器生成的比特率使用MDDR(M256)中的设置进行均匀校正。表27.20显示了MDDR设置(M)和比特率(B)之间的关系。

MDDR的初始值为0xFF。该寄存器中的位[7]固定为1。

CPU可以读取MDDR寄存器，但该寄存器只有在SCRSCR_SMCI中的TE和RE位为0时才可写。

Note 2. Adjust the bit rate so that the widths at high and low level of the SCLn output in simple IIC mode satisfy the IIC standard.

7	RXDESEL	Asynchronous Start Bit Edge Detection Select Valid only in asynchronous mode. 0: Detect low level on RXDn pin as start bit 1: Detect falling edge of RXDn pin as start bit	R/W*1

Note 1. Writable only when the TE and RE bits in SCR/SCR_SMCI are 0 (both serial transmission and reception are disabled).

The SEMR register selects the clock source for the 1-bit period in asynchronous mode.

PADIS bit (Preamble function Disable)

In asynchronous mode, select enable / disable of preamble function. In Manchester mode, preamble is not output regardless of this bit setting

BRME bit (Bit Rate Modulation Enable)

The BRME bit enables or disables the bit rate modulation function. The bit rate generated by the on-chip baud rate generator is evenly corrected when this function is enabled. Set to 0 in Manchester mode.

ABCSE bit (Asynchronous Mode Extended Base Clock Select 1)

The ABCSE bit sets the pulse number for the base clock in a 1-bit period to 6, and the double-frequency clock is output from the baud rate generator. When the bit rate is set to 6 while dividing the bus clock frequency, use this bit and set SMR.CKS[1:0] = 00b and BRR = 0.

Set it to "0" in modes other than asynchronous mode. Even in asynchronous mode, set it to "0" when using external clock.

ABCS bit (Asynchronous Mode Base Clock Select)

The ABCS bit selects the number of clock cycles for a 1-bit period.

Set it to "0" in modes other than asynchronous mode and Manchester mode.

NFEN bit (Digital Noise Filter Function Enable)

The NFEN bit enables or disables the digital noise filter function.

When the digital noise filter function is enabled:

- Noise cancellation is applied to the RXDn input signal in asynchronous mode
- Noise cancellation is applied to the SDAn and SCLn input signals in simple I^2C mode

In all other modes, set the NFEN bit to 0 to disable the digital noise filter function. When the function is disabled, input signals are transferred as received.

BGDM bit (Baud Rate Generator Double-Speed Mode Select)

The BGDM bit selects whether or not to double the base clock frequency output from the baud rate generator.

The BGDM bit is valid when the on-chip baud rate generator is selected as the clock source (SCR.CKE[1] = 0) in asynchronous mode (SMR.CM = 0) or Manchester mode (MMR.MANEN = 1). When external clock is selected (SCR.CKE[1] = 1), set it to 0. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.

Set this bit to 0 in modes other than asynchronous mode or Manchester mode.

RXDESEL bit (Asynchronous Start Bit Edge Detection Select)

The RXDESEL bit selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data reception operation depends on the setting of this bit. Set this bit to 1 when reception must be stopped while a break occurs or when reception must be started without keeping the RXDn pin input at the high level for the period of one data frame or longer after completion of the break.

Set this bit to 0 in modes other than asynchronous mode.

Bit	Symbol	Function	R/W
7	RXDESEL	异步起始位边沿检测选择 仅在异步模式下有效。 0：检测RXDn引脚的低电平作为起始位1：检测RXDn引脚的下降沿作为起始位	R/W*1

注1.仅当SCRSCR_SMCI中的TE和RE位为0时可写（串行发送和接收均禁用）。

SEMR寄存器选择异步模式下1位周期的时钟源。

PADIS位（前导功能禁用）

在异步模式下，选择enabledisableofpreamble功能。在曼彻斯特模式下，无论该位设置如何，都不会输出前导码

BRME位（比特率调制启用）

BRME位启用或禁用比特率调制功能。该功能使能时，片内波特率发生器产生的比特率得到均匀校正。在曼彻斯特模式下设置为0。

ABCSE位（异步模式扩展基本时钟选择1）

ABCSE位将基本时钟在1位周期内的脉冲数设置为6，并从波特率发生器输出双频时钟。当比特率设置为6并同时分频总线时钟频率时，使用该位并设置SMR.CKS[1:0]=00b和BRR=0。

在异步模式以外的模式下将其设置为“0”。即使在异步模式下，使用外部时钟时也将其设置为“0”。

ABCS位（异步模式基本时钟选择）

ABCS位选择1位周期的时钟周期数。

在异步模式和曼彻斯特模式以外的模式下将其设置为“0”。

NFEN位（数字噪声滤波器功能使能）

NFEN位启用或禁用数字噪声滤波器功能。

启用数字噪声滤波器功能时：

●在异步模式下对RXDn输入信号应用噪声消除

●在简单I2C模式下，对SDAn和SCLn输入信号应用噪声消除

在所有其他模式下，将NFEN位设置为0以禁用数字噪声滤波器功能。禁用该功能时，输入信号按接收到的方式传输。

BGDM位（波特率发生器双速模式选择）

BGDM位选择是否将波特率发生器输出的基本时钟频率加倍。

在异步模式(SMR.CM=0)或曼彻斯特模式(MMR.MANEN=1)选择片内波特率发生器作为时钟源(SCR.CKE[1]=0)时，BGDM位有效。选择外时钟（SCR.CKE[1]=1）时，将其设置为0。基本时钟是由BaudRateGenerator的时钟输出生成的。当BGDM位设置为1时，基本时钟周期减半，比特率加倍。

在异步模式或曼彻斯特模式以外的模式下将此位设置为0。

RXDESEL位（异步起始位边沿检测选择）

RXDESEL位选择异步模式下接收起始位的检测方法。发生中断时，数据接收操作取决于该位的设置。如果在发生中断时必须停止接收，或者在中断完成后，RXDn引脚输入在一个数据帧或更长时间内不保持高电平而必须开始接收时，将该位设置为1。

在异步模式以外的模式下将此位设置为0。

In simple I2C mode, when 32 clocks are selected as one bit period in the basic clock selection bits of the SEMR register, set the NFCS [2: 0] bits in the range from 001b to 100b. IICINTM位（IIC中断模式选择）

IICINTM位选择简单IIC模式下的中断请求源。

IICCSC bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SCLn clock signal is to be synchronized when the SCLn pin is driven low because a wait was inserted by another other device.

The SCLn clock signal is not synchronized if the IICCSC bit is 0. The SCLn clock signal is generated according to the rate selected in the BRR register regardless of the level being input on the SCLn pin.

Set the IICCSC bit to 1 except during debugging.

IICACKT bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set the IICACKT bit to 1 when ACK and NACK bits are received.

Note 1. Only generate a start condition after checking the bus state and confirming that the bus is free.
Note 2. Generate a restart or stop condition after checking the bus state and confirming that the bus is busy.
Note 3. Do not set more than one of the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.
Note 4. Write only 0. When 1 is written, the value is ignored.
Note 5. Execute the generation of a condition after the value of the IICSTIF flag is 0.
Note 6. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

The SIMR3 register is used to control the start, restart, and stop conditions in the simple I^2C mode, and to hold the SSDAn and SSCLn pins at fixed levels.

IICCSC bit (Clock Synchronization)

如果在SCLn引脚被驱动为低电平时内部生成的SCLn时钟信号要同步，则将IICCSC位设置为1，因为另一个其他设备插入了等待。

如果IICCSC位为0，则SCLn时钟信号不同步。SCLn时钟信号根据BRR寄存器中选择的速率生成，与SCLn引脚上输入的电平无关。

除调试期间外，将IICCSC位设置为1。

IICACKT位（ACK传输数据）

传输的数据包含ACK位。当收到ACK和NACK位时，将IICACKT位设置为1。

注5.在IICSTIF标志的值为0后执行条件生成。
注6.当该位为1时，请勿向该位写入0。当该位为1时，通过向该位写入0来暂停条件的产生。

SIMR3寄存器用于控制简单I2C模式下的启动、重启和停止条件，并将SSDAn和SSCLn引脚保持在固定电平。

IICSTAREQ bit (Start Condition Generation)

When a start condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICSTAREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of start condition generation.

IICRSTAREQ bit (Restart Condition Generation)

When a restart condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICRSTAREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of restart condition generation.

IICSTPREQ bit (Stop Condition Generation)

When a stop condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICSTPREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of stop condition generation.

IICSTIF flag (Issuing of Start, Restart, or Stop Condition Completed Flag)

After generating a condition, the IICSTIF flag indicates that the condition generation is complete. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.

When the IICSTIF flag is 1 while an interrupt request is enabled by setting the SCR.TEIE bit, an STI request is output.

[Setting condition]

- On completion of a start, restart, or stop condition generation.

  If the setting condition conflicts with any of the clearing conditions for the flag, the clearing condition takes precedence.

[Clearing conditions]

- On writing 0 to the bit. After writing 0 to the IICSTIF bit, read the bit to check that it is actually set to 0.
- On writing 0 to the SIMR1.IICM bit when operation is not in simple IIC mode.
- On writing 0 to the SCR.TE bit.

IICSDAS[1:0] bits (SDAn Output Select)

The IICSDAS[1:0] bits control output from the SDAn pin. Set IICSDAS[1:0] and IICSCLS[1:0]to the same value during normal operations.

IICSCLS[1:0] bits (SCLn Output Select)

The IICSCLS[1:0] bits control output from the SCLn pin. Set IICSDAS[1:0] and IICSCLS[1:0] to the same value during normal operations.

IICSTAREQ位（开始条件生成）

当要产生一个开始条件时，除了设置IICSDAS[1:0]和IICSCLS[1:0]为01b IICSTAREQ位为1。

[Setting condition]

●向该位写入1。

[Clearing condition]

●完成启动条件生成。

IICRSTAREQ位（重启条件生成）

当要产生重启条件时，除了设置IICSDAS[1:0]和IICSCLS[1:0]为01b IICRSTAREQ位为1。

[Setting condition]

●向该位写入1。

[Clearing condition]

●完成重启条件生成。

IICSTPREQ位（停止条件生成）

当要产生停止条件时，除了设置IICSDAS[1:0]和IICSCLS[1:0]为01b IICSTPREQ位为1。

[Setting condition]

●向该位写入1。

[Clearing condition]

●停止条件生成完成时。

IICSTIF标志（发出启动、重启或停止条件完成标志）

生成条件后，IICSTIF标志指示条件生成完成。使用时IICSTAREQ、IICRSTAREQ或IICSTPREQ位会导致条件生成，请在将IICSTIF标志设置为0后执行此操作。

当IICSTIF标志为1且通过设置SCR.TEIE位使能中断请求时，输出STI请求。

[Setting condition]

●完成启动、重新启动或停止条件生成时。

如果设置条件与标志的任何清除条件冲突，则清除条件优先。

[Clearing conditions]

●向该位写入0。将0写入IICSTIF位后，读取该位以检查它是否实际设置为0。

●在非简单IIC模式下向SIMR1.IICM位写入0。

●将0写入SCR.TE位。

IICSDAS[1:0]位（SDAn输出选择）

IICSDAS[1:0]位控制SDAn引脚的输出。在正常操作期间将IICSDAS[1:0]和IICSCLS[1:0]设置为相同的值。

IICSCLS[1:0]位（SCLn输出选择）

IICSCLS[1:0]位控制SCLn引脚的输出。在正常操作期间将IICSDAS[1:0]和IICSCLS[1:0]设置为相同的值。

7	CKPH	Clock Phase Select 0: Do not delay clock 1: Delay clock	R/W*1

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).
Note 2. Only 0 can be written to this bit, to clear the flag.

SPMR selects the extension settings in asynchronous and clock synchronous modes.

SSE bit (SSn Pin Function Enable)

Set the SSE bit to 1 to use the SSn pin to control transmission and reception in simple SPI mode. Set this bit to 0 in all other modes. In simple SPI mode, when master mode is selected (SCR.CKE[1:0] = 00b and SPMR.MSS = 0) and there is a single master, the SSn pin on the master side is not required to control reception and transmission. In such a case, set the SSE bit to 0. Do not set both the SSE and CTSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

CTSE bit (CTS Enable)

Set the CTSE bit to 1 if the SSn pin is to be used for inputting the CTS control signal to control transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, and simple IIC mode. Do not set both the CTSE and SSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

MSS bit (Master Slave Select)

The MSS bit selects master or slave operation in simple SPI mode. The functions of the TXDn and RXDn pins are reversed when this bit is set to 1, so that data is received through the TXDn pin and transmitted through the RXDn pin.

Set this bit to 0 in modes other than simple SPI mode.

CSTPEN bit (CTS external pin Enable)

Select the terminals usage method when using the CTS and RTS functions.

MFF flag (Mode Fault Flag)

The MFF flag indicates mode fault errors. In a multi-master configuration, determine the mode fault error occurrence by reading this flag.

[Setting condition]

- When input on the SSn pin is low during master operation in simple SPI mode (SSE bit = 1 and MSS bit = 0).

[Clearing condition]

- On writing 0 to the bit after it is read as 1.

CKPOL bit (Clock Polarity Select)

The CKPOL bit selects the polarity of the clock signal output through the SCKn pin. See Figure 27.96 for details. Set the CKPOL bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

CKPH bit (Clock Phase Select)

The CKPH bit selects the phase of the clock signal output through the SCKn pin. See Figure 27.96 for details. Set the CKPH bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

Bit	Symbol	Function	R/W
5	—	该位读取为0。写入值应为0。	R/W
6	CKPOL	时钟极性选择 0：不反转时钟极性1：反转时钟极性	R/W*1
7	CKPH	时钟相位选择 0：不延迟时钟1：延迟时钟	R/W*1

注1.只有当SCR寄存器中的RE和TE位为0（串行发送和接收都被禁止）时，才能写入这些位。

注2.该位只能写入0，以清除标志。

SPMR在异步和时钟同步模式下选择扩展设置。

SSE位（SSn引脚功能使能）

将SSE位设置为1以使用SSn引脚控制简单SPI模式下的发送和接收。在所有其他模式下将此位设置为0。在简单的SPI模式下，选择主模式（SCR.CKE[1：0]=00B和SPMR.MSS=0），并且有一个主人，无需控制主侧的SSNPIN即可控制接收和传输.在这种情况下，请将SSE位设置为0。不要将SSE和CTSE位都设置为1。如果进行此设置，则操作与将这些位设置为0时的操作相同。

CTSE bit (CTS Enable)

如果SSn引脚用于输入CTS控制信号以控制发送和接收，请将CTSE位设置为1。该位设置为0时输出RTS信号。在智能卡接口模式、简单SPI模式和简单模式下设置该位为0
IIC模式。不要将CTSE和SSE位都设置为1。如果进行此设置，则操作与将这些位设置为0时的操作相同。

MSS位（主从选择）

MSS位选择简单SPI模式下的主机或从机操作。当该位设置为1时，TXDn和RXDn引脚的功能相反，因此数据通过TXDn引脚接收并通过RXDn引脚发送。

在简单SPI模式以外的模式下将此位设置为0。

CSTPEN位（CTS外部引脚使能）

使用CTS和RTS功能时选择终端使用方法。

MFF标志（模式故障标志）

MFF标志指示模式故障错误。在多主机配置中，通过读取该标志确定模式故障错误发生。

[Setting condition]

●在简单SPI模式（SSE位=1和MSS位=0）的主机操作期间，SSn引脚上的输入为低电平。

[Clearing condition]

●读为1后向该位写入0。

CKPOL位（时钟极性选择）

CKPOL位选择通过SCKn引脚输出的时钟信号的极性。详见图27.96。设置
在除简单SPI模式和时钟同步模式之外的所有模式中，CKPOL位为0。

CKPH位（时钟相位选择）

CKPH位选择通过SCKn引脚输出的时钟信号的相位。详见图27.96。设置
CKPH位在除简单SPI模式和时钟同步模式之外的所有模式下为0。

Note 1. Writable only when TE = 0 and RE = 0.

FCR selects FIFO mode, resets FTDRHL and FRDRHL, selects the FIFO data trigger number for transmission or reception, and selects the RTS output active trigger number.

FM bit (FIFO Mode Select)

When the FM bit is set to 1, FTDRHL and FRDRHL are selected for communication. When the FM bit is set to 0, TDR and RDR, or TDRHL and RDRHL are selected for communication.

RFRST bit (Receive FIFO Data Register Reset)

When the RFRST bit is set to 1, the FRDRHL register is reset and the received data count resets to 0. When 1 is written to the RFRST bit, it clears to 0 after 1 PCLK.

TFRST bit (Transmit FIFO Data Register Reset)

When the TFRST bit is set to 1, the FTDRHL register is reset and the transmit data count resets to 0. When 1 is written to the TFRST bit, it clears to 0 after 1 PCLK.

DRES bit (Receive Data Ready Error Select)

When detecting a receive data ready error, the selection can be made from an SCIn_RXI interrupt request or an SCIn_ERI interrupt request. When starting DTC or DMAC and reading from the FRDRH and FRDRL registers, set the DRES bit to 1.

TTRG[3:0] bits (Transmit FIFO Data Trigger Number)

The TDFE flag is set to 1 when the amount of transmit data in FTDRHL is equal to or less than the transmit triggering number specified in the TTRG[3:0] bits, and software can write data to FTDRHL. If SCR.TIE = 1, an SCIn_TXI interrupt request occurs.

RTRG[3:0] bits (Receive FIFO Data Trigger Number)

The RDF flag is set to 1 when the amount of receive data in FRDRHL is equal to or greater than the receive triggering number specified in the RTRG[3:0] bits, and software can read data from FRDRHL. If SCR.RIE = 1, an SCIn_RXI interrupt request occurs.

When RTRG[3:0] is 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0, and an SCIn_RXI interrupt does not occur.

RSTRG[3:0] bits (RTS Output Active Trigger Number Select)

When the amount of receive data stored in FRDRHL is equal to or greater than the receive triggering number specified in the RSTRG[3:0] bits, the RTS signal goes high.

When RSTRG[3:0] is 0, the RTS signal does not go high even when the amount of data in FRDRHL is equal to 0.

[Setting condition]

●当DCCR.DCME=1时，比较数据(CDR.CMPD)与接收数据匹配。

[Clearing condition]

●从DCMF读取1后写入0时。

将SCR.RE位清除为0不会影响DCMF标志，它保留其先前的值。

The DPER flag indicates that a parity error occurred on address match detection (receive data match detection).

[Setting condition]

- When a parity error is detected in a frame in which an address match is detected.

The DFER flag indicates that a framing error occurred on address match detection (receive data match detection).

[Setting conditions]

- When a stop bit of a frame in which an address match is detected is 0.

  When in 2-stop-bit mode, only the first bit of the stop bits is checked for a value of 1 (the second stop bit is not checked).

[Clearing conditions]

- When 0 is written after 1 is read from DFER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DFER flag is not affected and retains its previous value.

IDSEL bit (ID Frame Select)

DCME bit (Data Compare Match Enable)

The DCME bit enables or disables the address match function (data compare match function).

If the SCI detects a match to the comparison data (CDR.CMPD) with the receive data, the DCME bit clears automatically, after which SCI operation mode is in normal receive mode. See section 27.3.6. Address Match (Receive Data Match Detection) Function.

The write value must be 0 for all modes other than asynchronous mode.

The SPTR register provides confirmation of the serial reception pin (RXDn pin) status and sets the transmission and receive pin status.

And SPTR register has enable bits for adjust functions of receive sampling timing and transmit timing.

The TXDn pin status is determined by the combination of SCR.TE, SPTR.SPB2IO, and SPTR.SPB2DT settings, as shown in Table 27.24.

The data of RDR is controlled by RINV and SCMR.SINV. And the data from TXDn terminal is controlled by TINV and SCMR.SINV. The control by RINV/TINV are done to communication terminals(RXDn/TXDn), so they can control not only data-bits but also other bits (start bit, stop bit, parity bit). Please refer to Figure 27.2 in detail.

SPTR寄存器提供串行接收引脚（RXDn引脚）状态的确认，并设置发送和接收引脚状态。

SPTR寄存器具有调整接收采样时序和发送时序功能的使能位。

Note: This register is valid only when the Manchester mode is enabled (MMR.MANEN = 1).
Note 1. Only 0 can be written to this bit, to clear the flag. To clear the flag, confirm that the flag is 1 before setting it to 0.

This register indicates an error status when receiving frames in Manchester mode.

A preface error, receive SYNC error or start bit error was detected.

PFER bit (Preface Error flag)

This bit indicates that a preface error was detected when receiving frames in Manchester mode.

[Setting condition]

- When detecting a preface error when receiving frames in Manchester mode
  The following operations are performed when a preface error occurs.
  When MECR.PFEREN = 1
  The received data is not transferred to the RDR register and no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the PFER flag is being set to 1, the subsequently received data is not transferred to the RDR register.
  When MECR.PFEREN = 0
  The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the PFER flag being set to 1.

[Clearing condition]

- When 0 is written to the bit after it was read as 1

Even if the SCR.RE bit is cleared, the PFER flag is not affected, and the previous state is retained.

SYER bit (SYNC Error flag)

This bit indicates that a receive SYNC error was detected when receiving frames in Manchester mode with

MMR.ERTEN = 1 (Manchester edge retiming enabled).

[Setting condition]

- When detecting a receive SYNC error when receiving frames in Manchester mode
  The following operations are performed when a receive SYNC error occurs.
  When MECR.SYEREN = 1

This register is used to specify whether to handle a preface error, receive SYNC error, or a start bit error as an interrupt source in Manchester mode. If those errors are handled as interrupt sources, interrupt requests and event requests are generated at the occurrence of each error, and the next reception is not performed until the corresponding error flag is cleared.

Please set this register when MMR.MANEN = ”0”. And do not change this register during communication.

PFEREN bit (Preface Error Enable)

SYEREN bit (Receive SYNC Error Enable)

This bit specifies whether to handle a receive SYNC error as an interrupt source.

When it is set to 0, a receive SYNC error is not handled as an interrupt source. When it is set to 1, a receive SYNC error is handled as an interrupt source.

SBEREN bit (Start Bit Error Enable)

This bit specifies whether to handle a start bit error as an interrupt source.

When it is set to 0, a start bit error is not handled as an interrupt source. When it is set to 1, a start bit error is handled as an interrupt source.

27.3 Operation in Asynchronous Mode

Figure 27.3 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit or receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communications line is usually held in the mark state (high level).

The SCI monitors the communications line. When the SCI detects a low, it regards that as a start bit and starts serial communication.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and receiver have a double-buffered structure in addition to FIFO mode, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

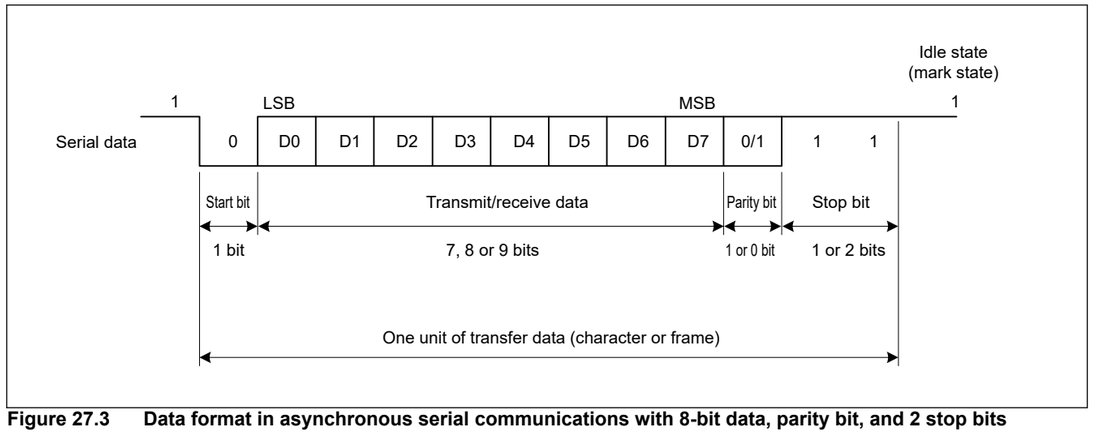

Figure 27.3 Data format in asynchronous serial communications with 8-bit data, parity bit, and 2 stop bits

27.3.1 Serial Data Transfer Format

Table 27.25 lists the serial data transfer formats that can be used in asynchronous mode. Any of 18 transfer formats can be selected with the SMR and SCMR settings. For details on the multi-processor function, see section 27.4. Multi-Processor Communication Function.

27.3 异步模式下的操作

图27.3显示了异步串行通信的一般格式。一帧由起始位（低电平）、发送或接收数据、奇偶校验位和停止位（高电平）组成。在异步串行通信中，通信线路通常保持在标记状态（高电平）。

SCI监控通信线路。当SCI检测到低电平时，将其视为起始位并开始串行通信。

在SCI内部，发射器和接收器是独立的单元，可实现全双工通信。发送器和接收器除了FIFO模式外，都具有双缓冲结构，从而可以在发送或接收过程中读取或写入数据，从而实现数据的连续发送和接收。

27.3.2 异步模式下接收数据采样时序和接收余量

在异步模式下，SCI在频率为16倍*1比特率的基本时钟上运行。

在接收时，SCI使用基本时钟对起始位的下降沿进行采样，并执行内部同步。*2

Because receive data is sampled on the rising edge of the 8th pulse*1 of the base clock, data is latched at the middle of each bit (when sampling timing does not adjust (SPTR.ASEN = 0)), as shown in Figure 27.4 The reception margin in asynchronous mode is determined by the following formula (1):

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%] \quad \ldots \quad \text{Formula (1)}$$

Note: M: Reception margin

N: Ratio of bit rate to clock

(N = 16 when SEMR.ABCSE = 0 and SEMR.ABCS = 0,

N = 8 when SEMR.ABCS = 1,

N = 6 when SEMR.ABCSE = 1)

D: Duty cycle of clock (D = 0.5 to 1.0)

L: Frame length (L = 9 to 13)

F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined using the following formula:
$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\ \%$

This represents the computed value. Renesas recommends a margin of 20% to 30% in system design.

Note 1. In this example, the SEMR.ABCS bit is 0 and the SEMR.ABCSE is 0. When the ABCS bit is 1 and the ABCSE bit is 0, a frequency of 8 times the bit rate is used as a base clock, and receive data is sampled on the rising edge of the 4th pulse of the base clock.

When the ABCSE bit is 1, a sextuple frequency of a bit rate is used as a base clock, and receive data is sampled on the rising edge of the 3rd pulse of the base clock.

Note 2. The determination condition of the start bit is as follows.

The function of adjust sampling timing is OFF (ASEN = 0):

The determination condition of a start bit is that Low beyond half bit length continues. It is same as the sampling timing. In Figure 27.4, Low period should be kept over 8-cycles to detect a start bit. If Low period does not keep over 8-cycles, the IP judges this as a noise. So, the IP does not start reception and wait start bit.

The function of adjust sampling timing is ON (ASEN = 1):

The determination condition of a start bit is that Low keeps up until the sampling timing. Adjusting the sampling timing forward (AJD = 1) increases the possibility of erroneously determin-ing a noise as the start bit.

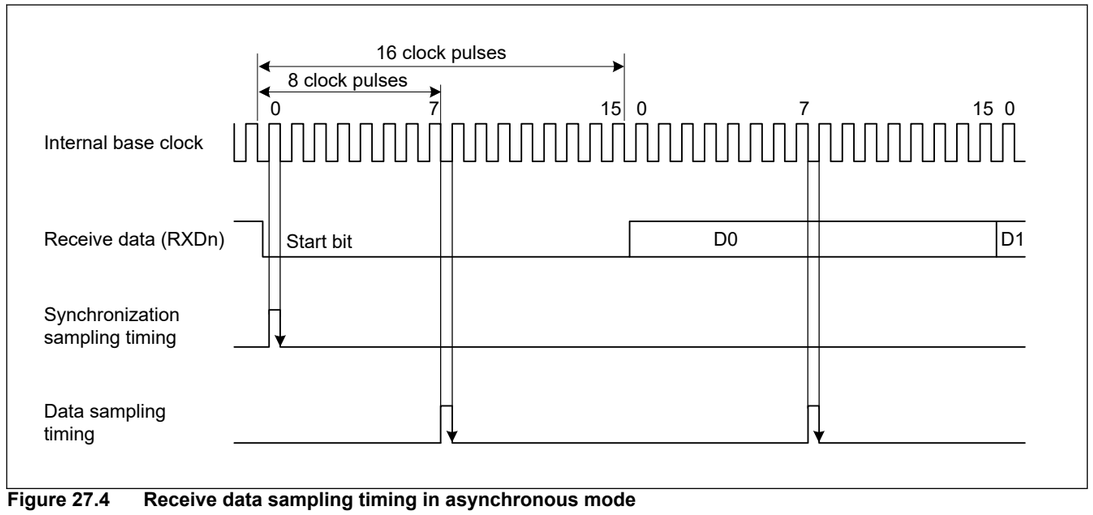

Figure 27.4 Receive data sampling timing in asynchronous mode

由于接收数据在基本时钟的第8个脉冲*1的上升沿进行采样，因此数据在每个位的中间锁存（当采样时序不调整时(SPTR.ASEN=0)），如图27.4所示异步模式下的接收余量由以下公式（1）确定：

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%] \quad \ldots \quad \text{Formula (1)}$$

Note: M：接收余量

N：比特率与时钟的比率

（当SEMR.ABCSE=0和SEMR.ABCS=0时，N=16，

N = 8 when SEMR.ABCS = 1,

N = 6 when SEMR.ABCSE = 1)

D:时钟占空比(D=0.5to1.0)

L：帧长（L=9到13）

F：时钟频率偏差的绝对值

假设公式（1）中的F=0和D=0.5的值，接收裕量使用以下公式确定：
$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\ \%$

这表示计算值。瑞萨建议在系统设计中留出20%到30%的余量。

注1.本例中，SEMR.ABCS位为0，SEMR.ABCSE位为0。当ABCS位为1，ABCSE位为0时，使用8倍比特率的频率作为基准时钟，并在基本时钟的第4个脉冲的上升沿对接收数据进行采样。

当ABCSE位为1时，以比特率的六倍频为基准时钟，在基准时钟的第3个脉冲的上升沿对接收数据进行采样。

注2.起始位的判断条件如下。

调整采样定时功能关闭（ASEN=0）：

起始位的确定条件是超过半位长度的Low继续。与采样时间相同。在图27.4中，低电平周期应保持超过8个周期以检测起始位。如果Low周期未保持超过8个周期，则IP将其判断为噪声。因此，IP不开始接收并等待开始位。

调整采样定时功能开启（ASEN=1）：

起始位的确定条件是Low一直保持到采样定时。向前调整采样时序(AJD=1)会增加错误地将噪声确定为起始位的可能性。

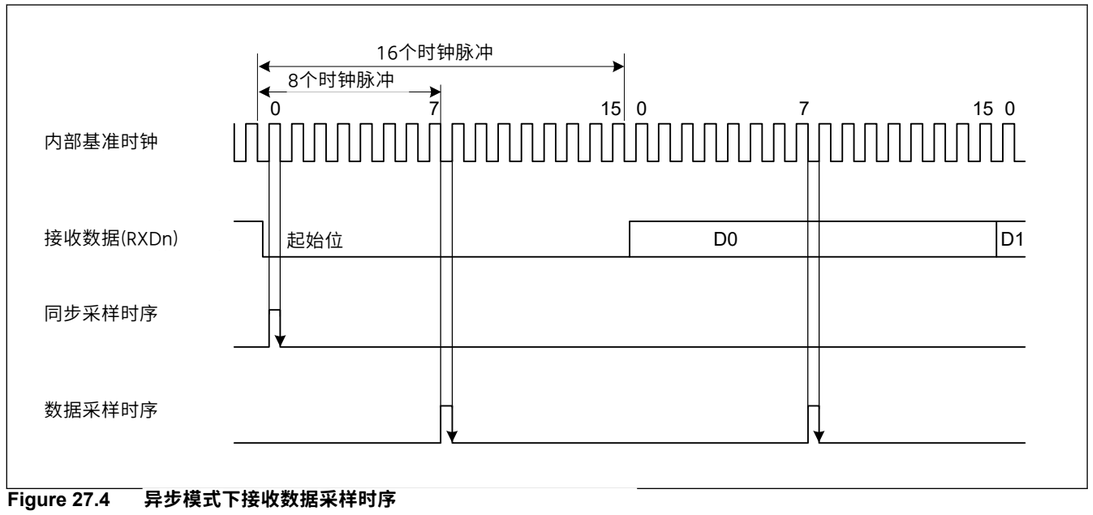

Figure 27.4 异步模式下接收数据采样时序

27.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the transfer clock of the SCI, based on the SMR.CM and SCR.CKE[1:0] settings.

When an external clock is input to the SCKn pin, the clock frequency must be 16 times the bit rate (when SEMR.ABCS = 0) or 8 times the bit rate (when SEMR.ABCS = 1).

When the SCI uses its internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is configured so that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 27.5.

When clock output is enabled, the clock is output after setting the SCR.TE or SCR.RE bit to 1.

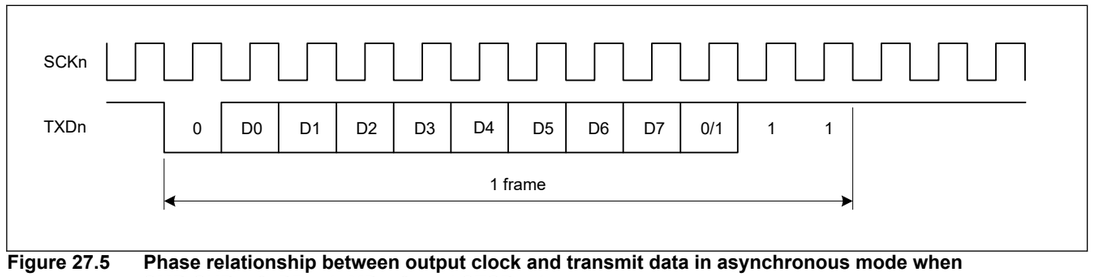

Figure 27.5 Phase relationship between output clock and transmit data in asynchronous mode when SMR.CHR = 0, PE = 1, MP = 0, and STOP = 1

27.3.4 Double-Speed Operation and Frequency of 6 Times the Bit Rate

When the SEMR.ABCS bit is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0. When the SEMR.BGDM bit is set to 1, the cycle of the base clock is half and the bit rate is double that of when BGDM is set to 0. When the SCR.CKE[1] bit is set to 0 and the on-chip baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the SCI to operate at a bit rate four times that when the ABCS and BGDM bits are set to 0.

When the SEMR.ABCSE bit is set to 1, the number of base clock pulses is 6 during a period of 1 bit, and the SCI operates at a bit rate 16/3 times that when SEMR.ABCS = 0, SEMR.BGDM = 0, and SEMR.ABCSE = 0.

As shown by Formula (1) in section 27.3.2. Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, the reception margin decreases when the SEMR.ABCS or SEMR.ABCSE bit is set to 1. Therefore, if the target bit rate can be obtained with ABCS or ABCSE set to 0, it is recommended that you use the SCI with ABCS and ABCSE set to 0.

27.3.5 CTS and RTS Functions

The CTS function uses input on the CTSn_RTSn pin in transmission control. Setting the SPMR.CTSE bit to 1 enables the CTS function. For the functions of CTS and RTS, you can select the alternate setting that uses either function with one terminal and the dedicated setting that uses each function independently with two terminals. This setting is done with the SPMR.CTSPEN bit.

When the CTS function is enabled, placing a low level on the CTSn_RTSn pin causes transmission to start.

Driving the CTSn_RTSn pin high while transmission is in progress does not affect transmission of the current frame.

In the RTS function, which uses output on the CTSn_RTSn pin, a low level is output when reception becomes possible. Conditions for output of the low and high levels are shown in this section.

[Conditions for low level output]

Satisfaction of all conditions are listed in this section.

Non-FIFO selected

- The value of the SCR.RE bit is 1
- Reception is not in progress
- There is no received data yet to be read

27.3.3 Clock

根据SMR.CM和SCR.CKE[1:0]设置，可以选择片内波特率发生器产生的内部时钟或输入到SCKn引脚的外部时钟作为SCI的传输时钟。

当外部时钟输入到SCKn引脚时，时钟频率必须为比特率的16倍（SEMR.ABCS=0时）或比特率的8倍（SEMR.ABCS=1时）。

当SCI使用其内部时钟时，时钟可以从SCKn引脚输出。在这种情况下，时钟输出的频率等于比特率，并配置相位，使时钟的上升沿位于发送数据的中间，如图27.5所示。

时钟输出使能时，将SCR.TE或SCR.RE位设置为1后输出时钟。

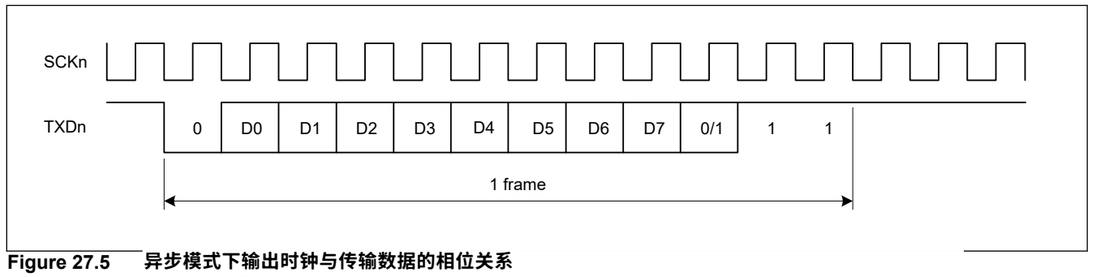

Figure 27.5 异步模式下输出时钟与传输数据的相位关系 SMR.CHR=0，PE=1，MP=0，STOP=1

27.3.4 双倍速操作和6倍比特率的频率

当SEMR.ABCS位设置为1并选择1位周期的8个基本时钟脉冲时，SCI以ABCS设置为0时的两倍比特率运行。当SEMR.BGDM位为设置为1，基本时钟的周期是BGDM设置为0时的一半，比特率是两倍。当SCR.CKE[1]位设置为0并且选择片内波特率发生器时，将ABCS和BGDM位设置为1允许SCI以四倍于ABCS和BGDM位设置为0时的比特率运行。

当SEMR.ABCSE位设置为1时，1位周期内的基本时钟脉冲数为6，SCI以16的比特率运行，是SEMR.ABCS=0时SEMR.BGDM=0时的3倍 和SEMR.ABCSE=0。

如第27.3.2节中的公式（1）所示。异步模式下的接收数据采样时序和接收裕度，当SEMR.ABCS或SEMR.ABCSE位设置为1时，接收裕度减小。因此，如果将ABCS或ABCSE设置为0即可获得目标码率，则为建议您使用SCI，ABCS和ABCSE设置为0。

27.3.5 CTS和RTS函数

CTS功能在传输控制中使用CTSn_RTSn引脚上的输入。将SPMR.CTSE位设置为1可启用CTS功能。对于CTS和RTS的功能，您可以选择在一个端子上使用任一功能的交替设置和在两个端子上独立使用每个功能的专用设置。该设置通过SPMR.CTSPEN位完成。

当CTS功能使能时，将CTSn_RTSn引脚置于低电平会导致传输开始。

在传输过程中将CTSn_RTSn引脚驱动为高电平不会影响当前帧的传输。

在使用CTSn_RTSn引脚输出的RTS功能中，当可以接收时输出低电平。
本节显示了低电平和高电平的输出条件。

【低电平输出的条件】

本节列出了所有条件的满足情况。

- The amount of receive data written in FRDRHL is equal to or less than the setting value of FCRH.RSTRG[3:0]

[Condition for high level output]

- The conditions for low-level output are not satisfied

27.3.6 Address Match (Receive Data Match Detection) Function

The address match function can be used only in asynchronous mode.

If the DCCR.DCME bit is set to 1, when one frame of data is received, the SCI compares that received data with the data set in CDR.CMPD. If the SCI detects a match to the comparison data (CDR.CMPD*1) with the received data, the SCI can issue the SCIn_RXI interrupt request.

If the SMR.MP bit is set to 0, comparison occurs only for valid data in receive format. In multi-processor mode (SMR.MP bit = 1), if the DCCR.IDSEL bit is set to 1, receive data where the MPB bit is 1 is subject to comparison for address match and receive data where the MPB bit is 0 is always treated as a non-match.

If the DCCR.IDSEL bit is set to 0, SCI performs address match detection regardless of the MPB bit value of the received data.

Until SCI detects a match to the comparison data (CDR.CMPD*1) with receive data, received data is skipped (discarded), and the SCI cannot detect a parity error or framing error.

When SCI detects a match, the DCCR.DCME bit is automatically cleared, and the DCCR.DCMF flag is set to 1. If the DCCR.IDSEL bit is set to 1, the SCR.MPIE bit is automatically cleared. If DCCR.IDSEL is set to 0, the value of the SCR.MPIE bit is retained. If the SCR.RIE bit is set to 1, the SCI issues an SCIn_RXI interrupt request.

If the SCI detects a framing error in the receive data for which a match is detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag is set to 1. The compared receive data is not stored in the RDR register, and SSR.RDRF remains 0. When FCR.FM = 1, the RDR register indicates the FRDRHL register, and the SSR.RDRF flag indicates the SSR_FIFO.RDF flag.

After the SCI detects a match, and DCCR.DCME is automatically cleared, the SCI receives the next data continuously based on the current register setting.

When the DCCR.DFER or DCCR.DPER flag is set, the address match is not performed. Before enabling the address match function, set the DCCR.DFER and DCCR.DPER flags to 0.

Examples of the address match function are shown in Figure 27.6 and Figure 27.7.

Note 1. This comparative target can select one length of 3 types: CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.

27.3.6 地址匹配（接收数据匹配检测）功能

地址匹配功能只能在异步模式下使用。

如果DCCR.DCME位设置为1，当接收到一帧数据时，SCI会将接收到的数据与CDR.CMPD中设置的数据进行比较。如果SCI检测到比较数据(CDR.CMPD*1)与接收到的数据匹配，则SCI可以发出SCIn_RXI中断请求。

如果SMR.MP位设置为0，则仅对接收格式的有效数据进行比较。在多处理器模式下（SMR.MP位=1），如果DCCR.IDSEL位设置为1，则接收MPB位为1的数据进行地址匹配比较，接收MPB位为0的数据始终被视为不匹配。

如果DCCR.IDSEL位设置为0，SCI执行地址匹配检测，而不管接收数据的MPB位值。

在SCI检测到与接收数据的比较数据(CDR.CMPD*1)匹配之前，会跳过（丢弃）接收到的数据，并且SCI无法检测奇偶校验错误或帧错误。

当SCI检测到匹配时，自动清除DCCR.DCME位，并将DCCR.DCMF标志设置为1。如果DCCR.IDSEL位设置为1，SCR.MPIE位自动清零。如果DCCR.IDSEL设置为0，则SCR.MPIE位被保留。如果SCR.RIE位设置为1，则SCI发出SCIn_RXI中断请求。

如果SCI在检测到匹配的接收数据中检测到帧错误，则DCCR.DFER标志设置为1，如果SCI在该帧中检测到奇偶校验错误，则DCCR.DPER标志设置为1。比较后的接收数据不存入RDR寄存器，SSR.RDRF保持为0。当FCR.FM=1时，RDR寄存器指示FRDRHL寄存器，而

SSR.RDRF标志表示SSR_FIFO.RDF标志。

SCI检测到匹配后，DCCR.DCME自动清零，SCI根据当前寄存器设置连续接收下一个数据。

当设置DCCR.DFER或DCCR.DPER标志时，不执行地址匹配。在启用地址匹配功能之前，将DCCR.DFER和DCCR.DPER标志设置为0。

地址匹配函数的例子如图27.6和图27.7所示。

注1.此比较目标可以选择3种长度中的一种：7位长度的CMPD[6:0]、8位长度的CMPD[7:0]和9位长度的CMPD[8:0].

27.3.7 SCI Initialization in Asynchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the SCR register, then continue through the SCI initialization procedure (select non-FIFO or FIFO) shown in Table 27.26 and Table 27.27. Whenever the operating mode or transfer format is to be changed, the SCR register must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied during initialization.

27.3.7 异步模式下的SCI初始化

在发送和接收数据之前，首先将初始值0x00写入SCR寄存器，然后继续执行SCI初始化程序（选择非FIFO或FIFO）如表27.26和表27.27所示。每当要更改操作模式或传输格式时，必须在更改之前初始化SCR寄存器。

在异步模式下使用外部时钟时，请确保在初始化期间提供时钟信号。

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, RDRF, RDF, PER, and DR flags in SSR/SSR_FIFO nor RDR and RDRHL. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: In non-FIFO mode, switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of an SCIn_TXI interrupt request.

Note: 在非FIFO模式下，当SCR.TIE位为1时，将SCR.TE位的值从1切换为0或从0切换为1会导致产生SCIn_TXI中断请求。

27.3.8 Serial Data Transmission in Asynchronous Mode

(1) Non-FIFO selected

Figure 27.8, Figure 27.9, and Figure 27.10 show examples of serial transmission in asynchronous mode.

In serial transmission, the SCI operates as described in this section. When the SCR.TE bit is set to 1, the high level is output to TXDn for one frame. However, when SEMR.PADIS is set to "1", this preamble will not be output. An example of operation when preamble is not output is shown in Figure 27.11.

1. The SCI transfers data from the TDR*1 register to the TSR register when data is written to TDR*1 in the SCIn_TXI interrupt handling routine.
   The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the TDR*1 register to the TSR register. If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to the TDR*1 register in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR*1 register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data
   - Parity bit or multi-processor bit (can be omitted depending on the format)
   - Stop bit
4. The SCI checks for update of the TDR register on output of the stop bit.
5. When the TDR register is updated, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from the TDR*1 register to the TSR register and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register is not updated, the SSR.TEND flag is set to 1, the stop bit is sent, and the mark state is entered, in which 1 is output. If the SCR.TEIE bit is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Note 1. The TDRHL register when 9-bit data length is selected.

27.3.8 异步模式下的串行数据传输

(1)选择非FIFO图27.8、图27.9和图27.10显示了异步模式下的串行传输示例。

在串行传输中，SCI的操作如本节所述。当SCR.TE位设置为1时，高电平输出到TXDn一帧。但是，当SEMR.PADIS设置为"1"时，不会输出此前导码。图27.11显示了不输出前导码时的操作示例。

1.当在SCIn_TXI中断处理程序中将数据写入TDR*1时，SCI将数据从TDR*1寄存器传输到TSR寄存器。当一条指令同时将SCR.TE和SCR.TIE位设置为1时，会在传输开始时产生SCIn_TXI中断请求。

2.在SPMR.CTSE位设置为0（禁用CTS功能）或CTSn_RTSn引脚上的低电平导致数据从TDR*1寄存器传输到TSR寄存器后，传输开始。如果SCR.TIE位为1，则产生SCIn_TXI中断请求。通过在当前发送数据的发送完成之前将下一个发送数据写入SCIn_TXI中断处理程序中的TDR*1寄存器，可以进行连续发送。使用SCIn_TEI中断请求时，在写入最后一个要发送的数据后，将SCR.TIE位设置为0（禁止SCIn_TXI中断请求）并将SCR.TEIE位设置为1（启用SCIn_TEI中断请求）从SCIn_TXI请求的处理例程到TDR*1寄存器。

3.数据按以下顺序从TXDn引脚发送：

- ●起始位
- ●传输数据
- ●奇偶校验位或多处理器位（可根据格式省略）
- ●停止位

4.SCI在停止位输出时检查TDR寄存器的更新。

5.当TDR寄存器更新时，将SPMR.CTSE位设置为0（禁用CTS功能）或CTSn_RTSn引脚上的低电平输入会导致下一个发送数据从TDR*1寄存器传输到TSR寄存器，并且传输停止位，然后开始下一帧的串行传输。

6、如果TDR寄存器没有更新，则将SSR.TEND标志置1，发送停止位，进入标记状态，其中输出1。如果SCR.TEIE位为1，则SSR.TEND标志设置为1，并产生SCIn_TEI中断请求。

Figure 27.13 Data format written to FTDRH and FTDRL with FIFO selected

In serial transmission, the SCI operates as described in this section. When the TE bit is set to 1, the high level is output to TXDn for one frame (preamble).

1. The SCI transfers data from the FTDRL*1 register to the TSR register when data is written to FTDRL*1 in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the FTDRL*1 register to the TSR register. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, SSR_FIFO.TDFE is set to 1. If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to FTDRL*1 in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the FTDRL*1*2 register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data
   - Parity bit or multi-processor bit (can be omitted depending on the format)
   - Stop bit
4. On output of the stop bit, the SCI checks whether non-transmitted data remains in the FTDRL*3 register.
5. When data is set to FTDRL*3, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from FTDRL*1 to TSR and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set in FTDRL*3, the TEND flag in SSR_FIFO is set to 1, the stop bit is sent, and the mark state is entered in which 1 is output. If the SCR.TEIE bit is 1, the SSR_FIFO.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Note 1. Write data not to FTDRL but to the FTDRH and FTDRL registers.
Note 2. Write data in order from FTDRH to FTDRL when 9-bit data length is selected.
Note 3. The SCI only checks for update to the FTDRL register and not the FTDRH register when 9-bit data length is selected.

Figure 27.14 shows an example flow of serial transmission in asynchronous mode with FIFO selected.

Figure 27.13 选择FIFO写入FTDRH和FTDRL的数据格式

在串行传输中，SCI的操作如本节所述。当TE位设置为1时，高电平输出到TXDn一帧（前导码）。

1.当数据写入FTDRL*1时，SCI将数据从FTDRL*1寄存器传输到TSR寄存器
SCIn_TXI中断处理程序。可写入FTDRL的数据量为16减去FDR.T[4:0]字节。当一条指令同时将SCR.TE和SCR.TIE位设置为1时，会在传输开始时产生SCIn_TXI中断请求。

2.在SPMR.CTSE位设置为0（禁用CTS功能）或CTSn_RTSn引脚上的低电平导致数据从FTDRL*1寄存器传输到TSR寄存器后，传输开始。当写入FTDRL的发送数据量等于或小于指定的发送触发数时，SSR_FIFO.TDFE设置为1。如果SCR.TIE位为1，则产生SCIn_TXI中断请求。在当前发送数据的发送完成之前，通过在SCIn_TXI中断处理例程中将下一个发送数据写入FTDRL*1，可以进行连续发送。当使用SCIn_TEI中断请求时，将SCR.TIE位设置为0（禁止SCIn_TXI中断请求）并且
将要发送的最后一个数据写入到SCR.TEIE位为1（启用SCIn_TEI中断请求）
FTDRL*1*2寄存器来自SCIn_TXI请求的处理例程。

3.数据按以下顺序从TXDn引脚发送：
- ●起始位
- ●传输数据
- ●奇偶校验位或多处理器位（可根据格式省略）
- ●停止位

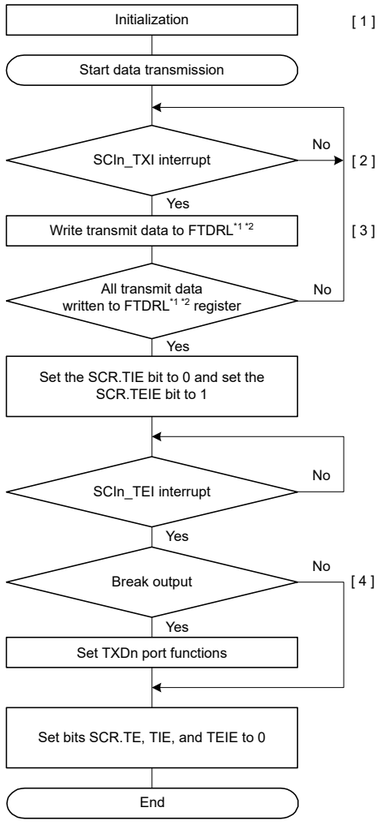
4.在停止位输出时，SCI检查未发送的数据是否保留在FTDRL*3寄存器中。

5.当数据设置为FTDRL*3时，将SPMR.CTSE位设置为0（禁用CTS功能）或CTSn_RTSn引脚上的低电平输入会导致下一个传输数据从FTDRL*1传输到TSR并传输停止位，之后开始下一帧的串行传输。

6.如果FTDRL*3中没有设置数据，则将SSR_FIFO中的TEND标志设置为1，发送停止位，并进入输出1的标记状态。如果SCR.TEIE位为1，则SSR_FIFO.TEND标志设置为1，并产生SCIn_TEI中断请求。

注1.不要将数据写入FTDRL，而是写入FTDRH和FTDRL寄存器。
注2.选择9位数据长度时，按从FTDRH到FTDRL的顺序写入数据。
注意3.SCI仅检查对FTDRL寄存器的更新，而不是选择9位数据长度时的FTDRH寄存器。

图27.14显示了选择FIFO的异步模式下串行传输的示例流程。



[1] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[2] Transmit data write to FTDRL*1 by an SCIn_TXI interrupt request:
When transmit data is transferred from FTDRL to TSR, when the quantity of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL*1 *2 once in the SCIn_TXI interrupt handling routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data to FTDRL using an SCIn_TXI interrupt request and clear the SSR_FIFO.TDFE flag to 0. The number of transmission data it is possible to write in is 16 - (the number of stored transmit FIFO data). Transmit data can also be written to FTDRL by activating the DTC or DMAC. When writing the data to FTDRL by DTC or DMAC, the TDFE flag is cleared automatically, so do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to FTDRL.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXD pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

Note 1. When data length is 9 bits, this refers to FTDRH and FTDRL registers.
Note 2. When data length is 9 bits, write in order from FTDRH to FTDRL.

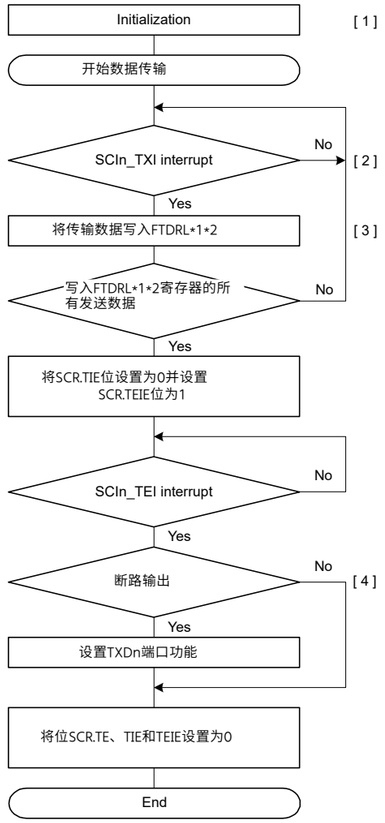
27.3.9 Serial Data Reception in Asynchronous Mode

(1) Non-FIFO selected

Figure 27.15 and Figure 27.16 show an example of the operation for serial data reception in asynchronous mode.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and when it detects a start bit, the SCI performs internal synchronization, stores receive data in RSR.
3. If the multi-processor communication function is enabled (SMR.MP = 1), see section 27.4.2. Multi-Processor Serial Data Reception. If the address match function (data compare match function) is enabled (DCCR.DCME = 1), the SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and comparison data (CDR.CMPD*1).
4. If the SCI detects an address match, the DCCR.DCME bit is automatically cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt*2 request is generated. To enable the generation of an SCIn_RXI interrupt request, set the SCR.RIE bit to 1. The compared receive data are not stored in the RDR register*3. The SSR.RDRF flag remains 0.



[1] SCI initialization:
设置数据传输。
SCR.TE位设置为1后，每帧输出1，并启用传输。

[2] 通过SCIn_TXI中断请求将数据写入FTDRL*1：
当发送数据从FTDRL传输到TSR时，当写入FTDRL的发送数据量等于或小于指定的发送触发数时，将产生发送数据FIFO空中断（SCIn_TXI）请求。在SCIn_TXI中断处理例程中将发送数据写入FTDRL*1*2一次。

[3] 串行传输继续程序：
要继续串行传输，请使用SCIn_TXI中断请求将所有传输数据写入FTDRL，并将SSR_FIFO.TDFE标志清零。可以写入的传输数据数为16（存储的传输FIFO数据数）。也可以通过激活DTC或DMAC将传输数据写入FTDRL。通过DTC或DMAC将数据写入FTDRL时，TDFE标志会自动清除，因此不要写入

TDFE flag.
使用SCIn_TEI中断请求时，将要发送的最后一个数据写入FTDRL后，将SCR.TIE位设置为0，并将SCR.TEIE位设置为1。

[4] 串行传输结束时中断输出：
要在串行传输中输出中断，通过SPTR.SPB2IO和SPTR.SPB2DT位设置TXD引脚的输出状态（低电平输出）后，将SCR.TE位设置为0。

注1.当数据长度为9位时，指的是FTDRH和FTDRL寄存器。
注2.当数据长度为9位时，按照FTDRH到FTDRL的顺序写入。

Figure 27.14 选择FIFO的异步模式下串行传输示例流程

27.3.9 异步模式下的串行数据接收

(1) Non-FIFO selected

图27.15和图27.16显示了异步模式下串行数据接收操作的示例。

在串行数据接收中，SCI操作如下：

1.当SCR.RE位的值变为1时，CTSn_RTSn引脚上的输出信号变为低电平。

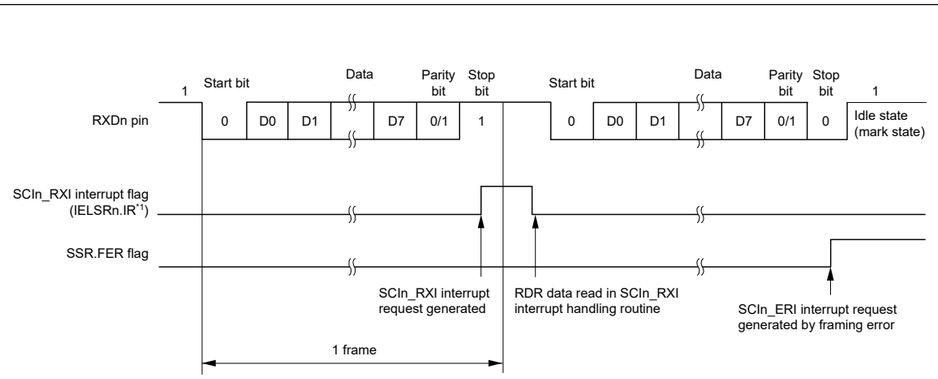
2.SCI监控通信线路，当检测到起始位时，SCI执行内部同步，将接收数据存储在RSR中。

3.如果启用多处理器通信功能（SMR.MP=1），请参见第27.4.2节。多处理器串行数据接收。如果地址匹配功能（数据比较匹配功能）被启用（DCCR.DCME=1），SCI无法检测奇偶校验或帧错误，因为接收数据被跳过（丢弃），直到SCI检测到接收数据和比较之间的匹配数据（CDR.CMPD*1）。

4.如果SCI检测到地址匹配，DCCR.DCME位自动清零，DCCR.DCMF标志变为1，并产生SCIn_AM中断*2请求。要启用SCIn_RXI中断请求的生成，请将SCR.RIE位设置为1。比较的接收数据不存储在RDR寄存器*3中。SSR.RDRF标志保持为0。

5. If the SCI detects a framing error in the receive data for which an address match is detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag becomes 1. To enable the generation of an SCIn_ERI interrupt request, set the SCR.RIE bit to 1.
6. If a framing or a parity error is detected (the DCCR.DFER flag or DCCR.DPER flag is 1) in the SCIn_AM interrupt handling routine, set the DCCR.DFER and DCCR.DPER flags to 0 and set the DCCR.DCME bit to 1 to enable the address match function again. If neither a framing nor a parity error has been detected (the DCCR.DFER and DCCR.DPER flags are both 0), set the DCCR.DCMF flag to 0. See Figure 27.6.
7. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR*3 register.
8. If a parity error is detected, the SSR.PER flag is set to 1 and receive data is transferred to the RDR*3 register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
9. If a framing error is detected, the SSR.FER flag is set to 1 and receive data is transferred to the RDR*3 register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
10. When reception finishes successfully, receive data is transferred to the RDR*3 register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data is complete. Reading the received data that was transferred to the RDR register causes the CTSn_RTSn pin to output low.

Note 1. This scope of comparison is selectable as one of three lengths: CMPD[6:0] is for 7-bit length, CMPD[7:0] is for 8-bit length, and CMPD[8:0] is for 9-bit length.
Note 2. As no interrupt enable bit is assigned to the SCIn_AM interrupt, an interrupt request is generated by setting the DCCR.DCMF to 1.
Note 3. Only read data in the RDRHL register when 9-bit data length is selected.



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 27.15 Example of SCI operation for serial reception in asynchronous mode (1) when the RTS function is not used, and with 8-bit data, parity bit, and 1 stop bit

5.如果SCI在检测到地址匹配的接收数据中检测到帧错误，则DCCR.DFER标志设置为1，如果SCI在该帧中检测到奇偶校验错误，则DCCR.DPER标志变为1.要启用SCIn_ERI中断请求的生成，请将SCR.RIE位设置为1。

6.如果在SCIn_AM中断处理例程中检测到成帧或奇偶校验错误（DCCR.DFER标志或DCCR.DPER标志为1），则将DCCR.DFER和DCCR.DPER标志设置为0，并设置DCCR.DCME位为1以再次启用地址匹配功能。如果既没有检测到成帧错误也没有检测到奇偶校验错误（DCCR.DFER和DCCR.DPER标志都为0），将DCCR.DCMF标志设置为0。参见图27.6。

7.如果发生溢出错误，则SSR.ORER标志设置为1。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。接收数据不传送到RDR*3寄存器。

8.如果检测到奇偶校验错误，则将SSR.PER标志设置为1，并将接收数据传输到RDR*3寄存器。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。

9.如果检测到帧错误，则将SSR.FER标志设置为1，并将接收数据传输到RDR*3寄存器。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。

10.接收成功后，接收数据被传送到RDR*3寄存器。如果SCR.RIE位为1，则
SCIn_RXI中断请求产生。通过读取传输到的接收数据启用连续接收

Figure 27.16 Example of SCI operation for serial reception in asynchronous mode (2) when RTS function is used, and with 8-bit data, parity bit, and 1 stop bit

Table 27.28 lists the states of the flags in the SSR register and receive data handling when a receive error is detected.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER bits to 0 before resuming reception. In addition, be sure to read the RDR or RDRHL register during overrun error processing. When a reception is forced to terminate by setting the SCR.RE bit to 0 during operation, read the RDR or RDRHL register because received data that is not yet read might be left in the RDR or RDRHL.

Figure 27.17 and Figure 27.18 show example flows of serial data reception.

表27.28列出了SSR寄存器中标志的状态以及检测到接收错误时的接收数据处理。

如果检测到接收错误，则会产生SCIn_ERI中断请求，但不会产生SCIn_RXI中断请求。
当接收错误标志为1时，无法恢复数据接收。因此，在恢复接收之前，请将ORER、FER和PER位设置为0。此外，请务必在溢出错误处理期间读取RDR或RDRHL寄存器。如果在操作期间通过将SCR.RE位设置为0来强制终止接收，请读取RDR或RDRHL寄存器，因为尚未读取的已接收数据可能留在RDR或RDRHL中。

[1] SCI initialization:
Set data reception.

[2][3] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. The error type is identified by reading the ORER, PER, and FER flags in SSR. After performing the appropriate error processing, be sure to set the ORER, PER, and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. For a framing error, a break can be detected by reading the value of the input port associated with the RXDn pin.

[4] Read the receive data in RDR once inthe SCIn_RXI interrupt handling routine.

[5] To continue serial reception, before the stop bit of the current frame is received, read data from RDR in the SCIn_RXI interrupt processing routine. The RDR data can also be read by activating the DMAC or DTC.

Note 1. Do not set RE to 0 before reading RDR.
Note 2. The RDR register becomes the RDRHL register when 9-bit data length is selected.

[2][3]接收错误处理和中断检测：如果发生接收错误，则产生SCIn_ERI中断。
错误类型通过读取SSR中的ORER、PER和FER标志来识别。执行适当的错误处理后，请务必将ORER、PER和FER标志设置为0。如果这些标志中的任何一个设置为1，则无法恢复接收。对于 帧错误，可以通过读取值来检测中断与RXDn引脚相关的输入端口。

An error is identified by reading the DFER or DPER flag in DCCR in the SCIn_AM interrupt handling routine.

When a reception error occurs, the SCIn_ERI interrupt is generated.
The error is identified by reading the ORER, PER, and FER flags in the SSR.

To continue serial reception, read the value of the RDR register in the SCIn_RXI interrupt handling routine before the stop bit is received.
The value of the RDR register can also be read by activating the DMAC or DTC.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and, when it detects a start bit, the SCI performs internal synchronization, stores receive data in the RSR register.
3. If the multi-processor communications function is enabled (SMR.MP = 1), see section 27.4.2. Multi-Processor Serial Data Reception. If the address match function (data compare match function) is enabled (DCCR.DCME = 1), the SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and the data for comparison (CDR.CMPD*1).
4. If the SCI detects an address match, the DCCR.DCME bit is automatically cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt*2 request is generated. To enable the generation of an SCIn_RXI interrupt request, set the SCR.RIE bit to 1. The compared receive data are not stored in the RDR register*3. The SSR.RDRF flag remains 0.
5. If the SCI detects a framing error in the receive data for which an address match was detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag becomes 1. To enable the generation of an SCIn_ERI interrupt request, set the SCR.RIE bit to 1.
6. If a framing or a parity error is detected (the DCCR.DFER flag or DCCR.DPER flag is 1) in the SCIn_AM interrupt handling routine, set the DCCR.DFER and DCCR.DPER flags to 0 and set the DCCR.DCME bit to 1 to enable the address match function again. If neither a framing nor a parity error has been detected (the DCCR.DFER and DCCR.DPER flags are 0), set the DCCR.DCMF flag to 0. See Figure 27.6.
7. If an overrun error occurs during normal communications, the SSR_FIFO.ORER flag is set to 1. If the SCR.RIE bit in SCR is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the FRDRL*3 register.
8. If a parity error is detected, the PER flag and receive data are transferred to the FRDRL*3 register. If the SCR.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
9. If a framing error is detected, the FER flag and receive data are transferred to the FRDRL*3 register. If the SCR.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
10. After a framing error is detected and when SCI detects that the continuous receive data is zero for one frame, reception stops.
11. When the amount of data stored in the FRDRL register falls below the specified receive triggering number, and the next data is not received after 15 ETUs from the last stop bit in asynchronous mode, the SSR_FIFO.DR flag is set to 1. When the SCR.RIE bit is 1 and the FCR.DRES bit is 0, the SCI generates an SCIn_RXI interrupt request. When the FCR.DRES bit is 1, SCI generates an SCIn_ERI interrupt request.

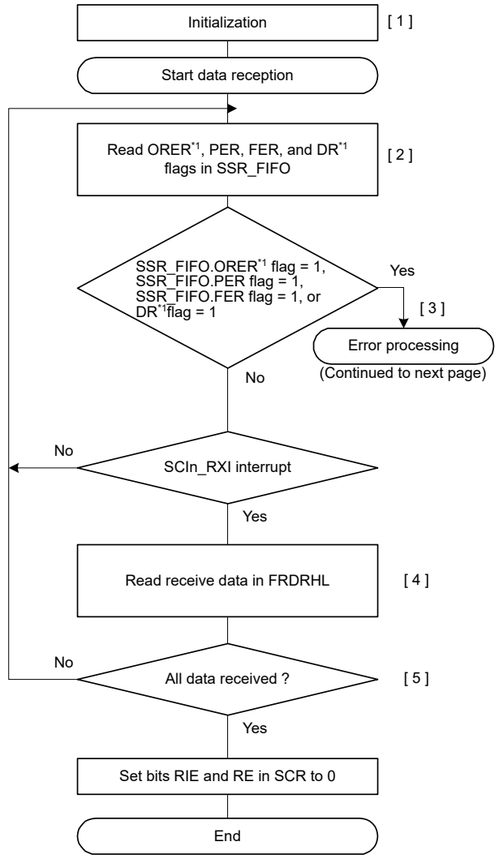
9.如果检测到帧错误，则将FER标志和接收数据传送到FRDRL*3寄存器。如果SCR.RIE位设置为1，则会产生SCIn_ERI中断请求。

10、检测到帧错误后，当SCI检测到连续接收数据一帧为零时，停止接收。

11.当FRDRL寄存器中存储的数据量低于指定的接收触发数，并且在异步模式下从最后一个停止位开始15个ETU后没有接收到下一个数据时，SSR_FIFO.DR标志设置为1。SCR.RIE位为1，FCR.DRES位为0，SCI产生一个SCIn_RXI中断请求。当FCR.DRES位为1时，SCI产生一个SCIn_ERI中断请求。

12. When reception finishes successfully, receive data is transferred to the FRDRL*3 register. The RDF bit is set to 1 when the amount of receive data written to FRDRHL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit in SCR is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the FRDRL*4 register in the SCIn_RXI interrupt handling routine, before an overrun error occurs. If the received data that is transferred to FRDRL*5 is less than the RTS trigger number, the CTSn_RTSn pin outputs low.

Note 1. One of three lengths is selected for the target for comparison: CMPD[6:0] is for 7-bit length, CMPD[7:0] is for 8-bit length, and CMPD[8:0] is for 9-bit length.
Note 2. As no interrupt enable bit is assigned to the SCIn_AM interrupt, an interrupt request is generated by setting the DCCR.DCMF to 1.
Note 3. Only read data in the FRDRH and FRDRL registers when 9-bit data length is selected.
Note 4. Read data in order from FRDRH to FRDRL when 9-bit data length is selected.
Note 5. The SCI only checks for update to the FRDRL register and not to the FRDRH register when 9-bit data length is selected.



[1] SCI initialization:
Set data reception.

[2] [3] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. A break can be detected by reading the SPTR.RXDMON flag. An error is identified by reading the ORER*1, PER, DR*1, and FER flags in SSR_FIFO. After performing the appropriate error processing, be sure to set the ORER*1 flag to 0. Reception cannot be resumed if ORER*1 flag is set to 1. The reception operation is continuous, even if the FER = 1 or PER = 1 or DR*1 = 1.

[4] Read the receive data in FRDRHL in the SCIn_RXI interrupt handling routine. The receive data stored in the FRDRHL register is read until the number of stored data is below the FCR.RTRG value. Confirm the number of the reception data in the FIFO by reading FDR.R.

[5] Serial reception continuation procedure:
To continue serial reception, before an overrun error occurs, read data from FRDRHL in the SCIn_RXI interrupt handling routine and clear RDF flag and DR flag to 0.
The FRDRHL data can also be read by activating the DMA or DTC. The RDF flag is cleared automatically in this case, so do not write to the RDF flag.

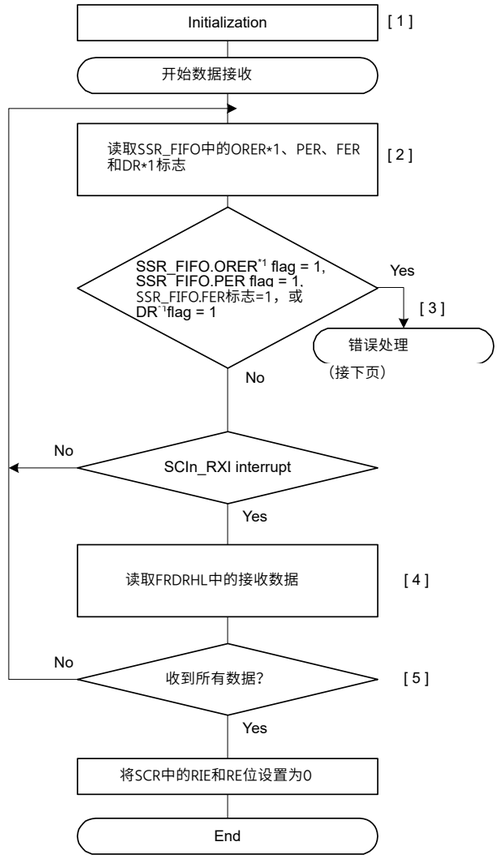
Note 1. Can be read in the FRDRHL.ORER and DR flags.

Figure 27.23 Example flow of serial reception in asynchronous mode with FIFO selected and Address Matching Enabled (1)

12.接收成功后，接收数据被传送到FRRDL*3寄存器。当写入FRDRHL的接收数据量等于或大于指定的接收触发数时，RDF位设置为1。如果SCR中的SCR.RIE位为1，则产生SCIn_RXI中断请求。在发生溢出错误之前，通过在SCIn_RXI中断处理程序中读取传输到FRDRL*4寄存器的接收数据来启用连续接收。如果传送到FRDRL*5的接收数据小于RTS触发数，CTSn_RTSn引脚输出低电平。

注1.选择三个长度之一作为目标进行比较：CMPD[6:0]为7位长度，CMPD[7:0]为8位长度，CMPD[8:0]为9位长度。

注2.由于没有为SCIn_AM中断分配中断使能位，因此通过设置
DCCR.DCMF to 1.
注3.选择9位数据长度时，仅读取FRDRH和FRDRL寄存器中的数据。
注4.选择9位数据长度时，按从FRDRH到FRDRL的顺序读取数据。
Note5.TheSCIonlychecksforupdatetotheFRDRLregisterandnottotheFRDRHregisterwhen9-bitdatalengthisselected.



[1]SCI初始化：设置数据接收。

[2][3]接收错误处理和中断检测：如果发生接收错误，则产生SCIn_ERI中断。可以通过读取SPTR.RXDMON标志来检测中断。通过读取SSR_FIFO中的ORER*1、PER、DR*1和FER标志来识别错误。执行适当的错误处理后，请务必将ORER*1标志设置为0。如果ORER*1标志设置为1，则无法恢复接收。接收操作是连续的，即使FER=1或PER=1或DR*1=1。

[4]在SCIn_RXI中断处理程序中读取FRDRHL中的接收数据。读取存储在FRDRHL寄存器中的接收数据，直到存储的数据数量低于FCR.RTRG值。通过读取FDR.R来确认FIFO中接收数据的数量。

[5]串行接收继续程序：
要继续串行接收，在发生溢出错误之前，在SCIn_RXI中断处理程序中从FRDRHL读取数据，并将RDF标志和DR标志清除为0。也可以通过激活DMA或DTC来读取FRDRHL数据。在这种情况下，RDF标志会自动清除，因此不要写入RDF标志。

注1.可以在FRDRHL.ORER和DR标志中读取。

[1-2] Address match cycle:
Set the DCCR.DCME bit to 1 to enable address matching.

[1-3] Comparing received data and data for comparison (CDR.CMPD):
Compare receive data and comparison data.
The SCI cannot detect a parity or framing error as received data are skipped (discarded) until the SCI detects a match between the received data and data for comparison.
If the SCI detects an address match, the DCCR.DCME bit is cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt request is issued.

[1-4] [1-5] Reception error processing:
An error is identified by reading the DFER or DPER flag in DCCR from within the SCIn_AM interrupt handling routine.
After appropriate handling of the error, set both the DFER and DPER flags to 0.
If either of these flags is set to 1, address matching cannot be resumed.

[2] [3] Reception error processing and break detection:
When a reception error occurs, an SCIn_ERI interrupt is generated.
A break is identified by reading SPTR.RXDMON.
The error is identified by reading each among the SSR_FIFO.ORER*1, PER, FER, and DR*1 flags.
After appropriate handling of the error, set the ORER*1 flag to 0.
If the ORER*1 flag remains 1, reception cannot be resumed.
The reception operation is continuous, even if the FER = 1, PER = 1 or DR*1 = 1.

[4] Reading the received data in the FRDRHL register from within the SCIn_RXI interrupt handling routine:
The received data stored in the FRDRHL register are read until the amount of stored data is less than the value of the FCR.RTRG[3:0] bits.
Confirm the number of received data in the FIFO with the value of the FDR.R[4:0] bits.

[5] Serial reception continuation procedure:
To continue with serial reception, read data from the FRDRHL register from within the SCIn_RXI interrupt handling routine before an overrun error occurs, and set the RDF and DR flags to 0. The data in the FRDRHL register can also be read by activating the DMAC or DTC. In this case, do not write to the RDF flag because the flag is automatically cleared.

Note 1. The FRDRHL.ORER and DR flags can also be read.

27.3.10 调整接收采样定时功能（异步模式）

当通过光电耦合器的上升传输时间和下降传输时间之间存在差异时，位中间的接收采样时间会影响接收裕度。在这种情况下，接收采样时序可以通过使用该功能从比特中间调整到最佳时序。

The receive sampling timing is adjusted from the middle of bit by following formula. And the adjustable direction is set by ACTR.AJD. You can select forward or backward from the middle of bit. When adjusting backward (ACTR.AJD = 0), substitute AJD = +1 and substitute AJD = -1 when adjusting forward (ACTR.AJD = 1).

Adjusted sampling timing = the middle of bit + AJD * (base clock * the setting value of ACTR.AST[2:0])

The setting timing is limited by base clock cycles per 1 bit. Please refer to Table 27.29 in detail.

An overview of reception operation of the communication through a photo coupler with this function is shown in Figure 27.28, Figure 27.29 and Figure 27.30, the explanation of operation with this function is shown in Figure 27.31.

Please don't use this function when there is no difference between the rising transfer time and the falling transfer time, because there is a possibility of deteriorating the reception margin.

27.3.11 The function of adjust transmit timing (Asynchronous Mode)

In communication via a photo coupler or the like, when either the rising or falling transition time of the TXD output signal is long, then a communication partner receive dulled waveform. In this case, the reception margin may be affected.

In these cases, make a communication partner to be sampling at middle of bit using the function of adjust transmit timing.

When SPTR.ATEN is 1, this function can adjust the edge timing at the timing calculated by the following formula for the edge set with ACTR.AET.

The adjustment edge timing = the base clock * ACTR.ATT[2:0]

In addition, the upper limit of the adjustment edge timing is limited by setting the base clock cycles. Refer to Table 27.30 in details.

A transmission movement image figure of the communication through a photo coupler with this function is shown in Figure 27.32, Figure 27.33 and Figure 27.34, the overview of operation with this function is shown in Figure 27.35 and Figure 27.36.

Please don't use this function when there is not the difference between the rising transfer time and the falling transfer time, there is a possibility of deteriorating the reception margin of a communication partner.

27.3.11 调整发送时间的功能（异步模式）

在经由光电耦合器等的通信中，当TXD输出信号的上升或下降过渡时间较长时，通信伙伴接收到钝化的波形。在这种情况下，接收裕量可能会受到影响。

在这些情况下，使用调整发送时间的功能使通信伙伴在位中间进行采样。

当SPTR.ATEN为1时，该功能可以在ACTR.AET设置的边沿通过以下公式计算的时序调整边沿时序。

调整边沿时序=基准时钟*ACTR.ATT[2:0]

另外，调整边沿时序的上限是通过设置基本时钟周期来限制的。详见表27.30。

图27.32、图27.33、图27.34为使用该功能的光电耦合器通信的传输动作图，使用该功能的操作概要如图27.35、图27.36所示。

请不要在上升传输时间和下降传输时间之间没有差异时使用此功能，这可能会降低通信伙伴的接收裕度。

27.4 Multi-Processor Communication Function

The multi-processor communication function enables the SCI to transmit and receive data between multiple processors by sharing an asynchronous serial communication line that has an added multi-processor bit. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station.

The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle:

- When the multi-processor bit is set to 1, the transmission cycle is the ID transmission cycle
- When the multi-processor bit is set to 0, the transmission cycle is the data transmission cycle

Figure 27.37 shows an example of communication between processors using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits communication data in which the multi-processor bit set to 0 is added to the transmit data. After receiving communication data with the multi-processor bit set to 1, the receiving station compares the received ID with the ID of the receiving station itself. If the two match, the receiving station receives communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until it receives data in which the multi-processor bit is set to 1.

(1) Non-FIFO selected

To support this function, the SCI provides the SCR.MPIE bit. When the MPIE bit is set to 1, the following operations are disabled until the reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR register (the RDRHL register when 9-bit data length is selected)
- Detection of a receive error

27.4 多处理器通信功能

多处理器通信功能使SCI能够通过共享一条增加了多处理器位的异步串行通信线路在多个处理器之间发送和接收数据。在多处理器通信中，为每个接收站分配一个唯一的ID代码。串行通信周期由指定接收站的ID传输周期和向指定接收站传输数据的数据传输周期组成。

多处理器位用于区分ID传输周期和数据传输周期：

- 当多处理器位设置为1时，传输周期为ID传输周期
- 当多处理器位设置为0时，传输周期为数据传输周期

图27.37显示了使用多处理器格式的处理器之间的通信示例。首先，发送站发送将设置为1的多处理器位添加到接收站的ID码的通信数据。接着，发送站发送在发送数据中附加了多处理器比特为0的通信数据。接收站接收到多处理器位设置为1的通信数据后，将接收到的ID与接收站自身的ID进行比较。如果两者匹配，则接收站接收随后发送的通信数据。如果接收到的ID与接收站的ID不匹配，则接收站跳过通信数据，直到接收到多处理器位设置为1的数据。

(1) Non-FIFO selected

为了支持这个功能，SCI提供了SCR.MPIE位。当MPIE位设置为1时，以下操作被禁止，直到接收到多处理器位设置为1的数据：

- 将接收数据从RSR寄存器传送到RDR寄存器（选择9位数据长度时的RDRHL寄存器）
- 接收错误检测

- Setting of the respective RDRF, ORER, and FER status flags in the SSR register

When the SCI receives a character in which the multi-processor bit is set to 1, the SSR.MPBT bit is set to 1 and the SCR.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode. The clock used for the multi-processor communication is the same as the clock used in normal asynchronous mode.

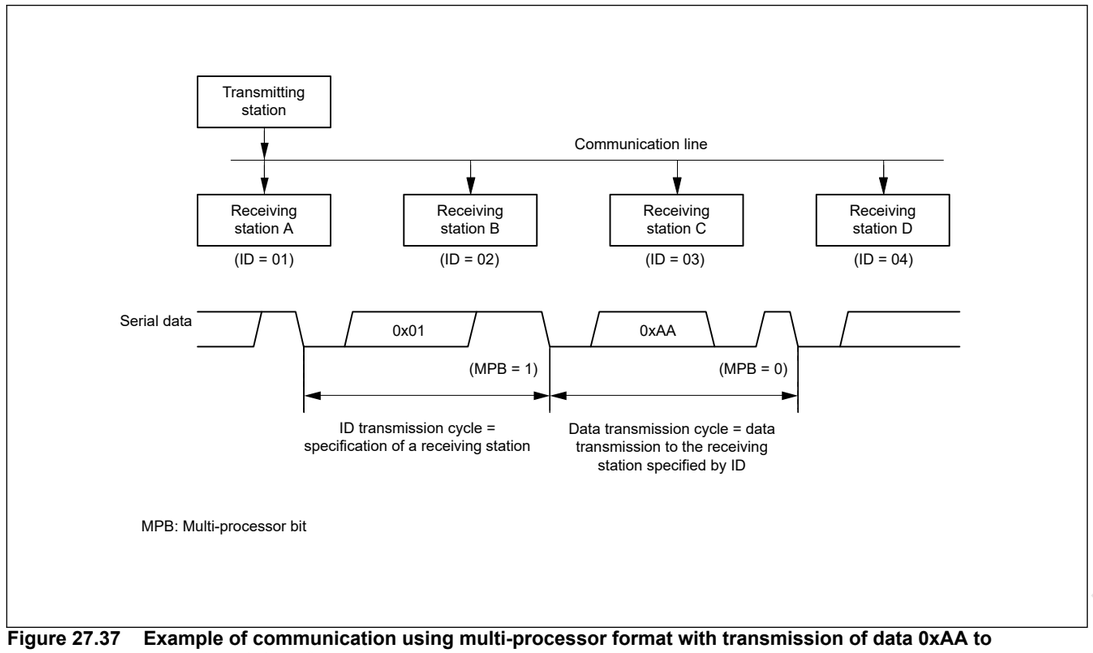

Figure 27.37 Example of communication using multi-processor format with transmission of data 0xAA to receiving station A

(2) FIFO selected

For data transmission, software must write data to FTDRHL.MPBT that corresponds to transmit data in FTDRHL.TDAT. For data reception, the multi-processor bit that is part of the receive data is written to FTDRHL.MPB and receive data is written to FRDRL.

When the MPIE bit is set to 1, the following operations are disabled until reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the FRDRHL register
- Detection of a receive error
- Break
- Setting of the respective RDF, ORER, and FER status flags in the SSR_FIFO register

When the SCI receives an 8-bit character in which the multi-processor bit is set to 1, the FTDRHL.MPB bit is set to 1 and receive data is written to FRDRHL.RDAT. The SCR.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode with FIFO selected.

27.4.1 Multi-Processor Serial Data Transmission

(1) Non-FIFO selected

●在SSR寄存器中设置相应的RDRF、ORER和FER状态标志

当SCI接收到多处理器位设置为1的字符时，SSR.MPBT位设置为1，并且SCR.MPIE位自动清零，使SCI恢复正常接收操作。如果SCR.RIE位设置为1，则SCIn_RXI中断产生。

当指定多处理器格式时，奇偶校验位功能被禁用。除此之外，与正常异步模式下的操作没有区别。用于多处理器通信的时钟与正常异步模式下使用的时钟相同。

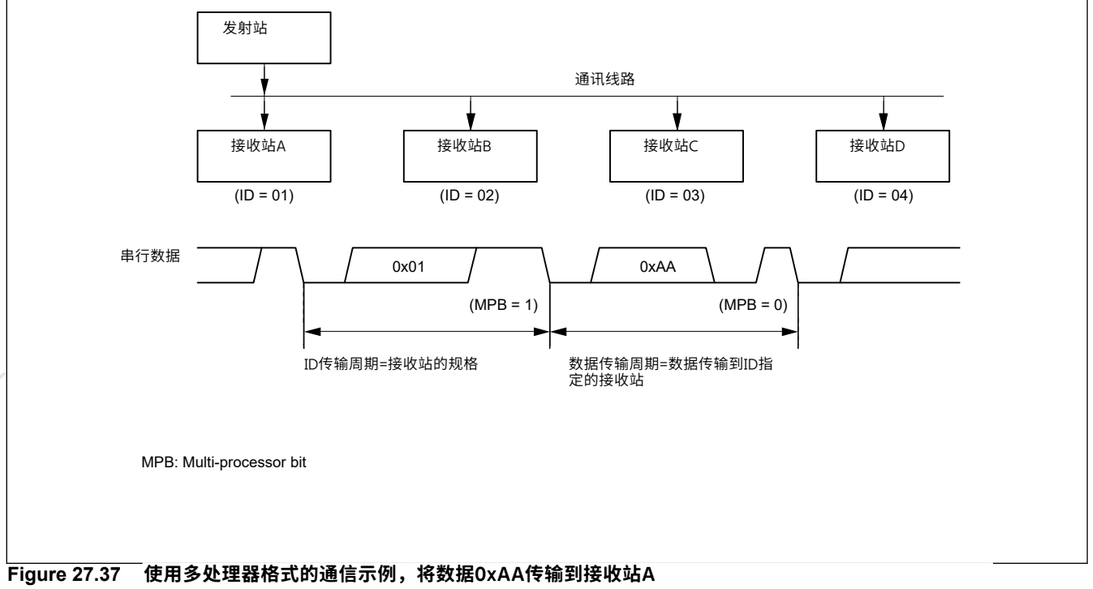

Figure 27.37 使用多处理器格式的通信示例，将数据0xAA传输到接收站A

(2) FIFO selected

对于数据传输，软件必须将数据写入与FTDRHL.TDAT中的传输数据相对应的FTDRHL.MPBT。对于数据接收，作为接收数据一部分的多处理器位被写入FTDRHL.MPB，接收数据被写入FRDRL。

当MPIE位设置为1时，以下操作被禁止，直到接收到多处理器位设置为1的数据：

●将接收数据从RSR寄存器传送到FRDRHL寄存器

●接收错误检测

- Break

●在SSR_FIFO寄存器中设置相应的RDF、ORER和FER状态标志

当SCI接收到多处理器位设置为1的8位字符时，FTDRHL.MPB位设置为1，接收数据写入FRDRHL.RDAT。SCR.MPIE位自动清零，使SCI恢复正常接收操作。如果SCR.RIE位设置为1，则会产生SCIn_RXI中断。

当指定多处理器格式时，奇偶校验位功能被禁用。除此之外，与选择FIFO的正常异步模式下的操作没有区别。

27.4.1 多处理器串行数据传输

(1) Non-FIFO selected

Figure 27.38 shows an example flow of multi-processor data transmission. In the ID transmission cycle, the ID must be transmitted with the SSR.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in asynchronous mode. Write the values in the order of the FTDRH register then the FTDRL register.

Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[2] SCIn_TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated.
Set the MPBT bit in SSR to 0 or 1, and write transmit data to TDR once in the SCIn_TXI interrupt processing routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR once using an SCIn_TXI interrupt request.
Transmit data can also be written to TDR by activating the DMAC or DTC.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXD pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

(2) FIFO selected

Figure 27.44 shows an example of a data format that is written to FRDRH and FRDRL in multi-processor mode.

In multi-processor mode, the MPB value that is a part of the receive data is written to the FRDRH.MPB bit. A value of 0 is written to the FRDRH.PER flag. Data is written to FRDRH and FRDRL with the correct data length. Unused bits are written with 0. Read in order from FRDRH to FRDRL. When software reads the FRDRL register, the SCI updates FER, MPB, and receive data (RDAT[8:0]) in FRDRL with the next data. The RDF, ORER and DR flags in the FRDRH register always reflect the associated flags in the SSR_FIFO register.

图27.44显示了在多处理器模式下写入FRDRH和FRDRL的数据格式示例。

[3] SCI status confirmation and reception and comparison of ID:
SCI stores first data (MPB = 1) and subsequent received data in FRDRHL.
RDF is set to 1 and an SCIn_RXI interrupt request is generated when a quantity of receive data equal to or greater than the specified receive triggering number is stored in FRDRHL. When the quantity of data stored in FRDRHL falls the specified receive triggering number and received data is equal to or greater than 1, and no next data is received after the elapse of 15 ETUs from the last stop bit, SSR_FIFO.DR is set to 1. An SCIn_RXI interrupt request is generated when FCR.DRES bit is 0.
Read data in FRDRHL at the first SCIn_RXI interrupt, and compare it with the ID of the receiving station itself.
If the ID does not match the ID of the receiving station itself, the SCI reads until the data with MPB = 1, and compares next ID. If it is no data with MPB = 1 in FRDRHL, set the MPIE bit to 1 again and wait for another SCIn_RXI interrupt request.

图27.46显示了曼彻斯特编码的概念图。

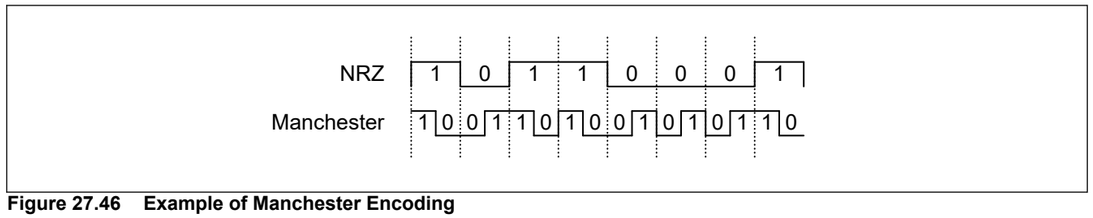

Figure 27.46 Example of Manchester Encoding

In Manchester mode, a preface and a start bit area are added to the transmit data in the register to configure a transmit frame. For transmission, data is encoded in Manchester encoding. When data is received, frames having the same format as transmitted frames are detected and Manchester decoding is performed.

For details on the frame format, see section 27.5.1. Frame Format.

27.5.1 Frame Format

Figure 27.47 shows the frame format in Manchester mode.

In the upper half of the figure, relevant setting registers are shown.

The preface area and the data area are encoded in Manchester encoding.

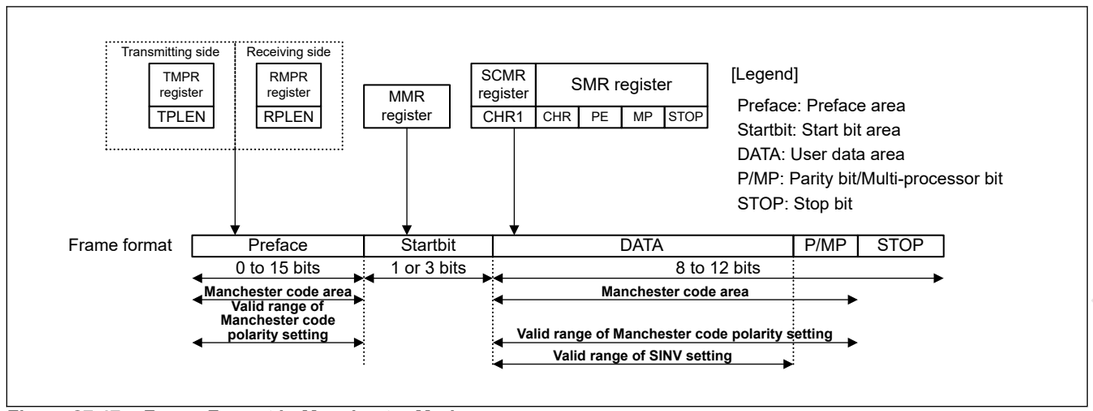

Figure 27.47 Frame Format in Manchester Mode

(1) Preface area

This is a fixed pattern area located at the beginning of each frame.

Different registers are used to set the preface area for transmission and reception. The preface length is determined by setting TMPR.TPLEN[3:0] for transmission. It is determined by setting RMPR.RPLEN[3:0] for reception.

If it is set to 0, the transmit preface is disabled and is not added.

If it is set to 1d to 15d, a preface whose length is determined by this setting is added.

(For example, if it is set to 1d, a 1-bit preface is added. If it is set to 15d, a 15-bit preface is added.)

The preface pattern is set with TMPR.TPPAT[1:0] for transmission and RMPR.RPPAT[1:0] for reception, and is selected from four types of patterns.

Figure 27.48 shows how the preface pattern is set. The preface area and the start bit area are added for each communication frame.

在曼彻斯特模式下，前言和起始位区域被添加到寄存器中的发送数据以配置发送帧。对于传输，数据以曼彻斯特编码进行编码。当接收到数据时，检测与传输帧格式相同的帧并执行曼彻斯特解码。

有关帧格式的详细信息，请参阅第27.5.1节。帧格式。

27.5.1 帧格式

图27.47显示了曼彻斯特模式下的帧格式。

在图的上半部分，显示了相关的设置寄存器。

前言区和数据区采用曼彻斯特编码。

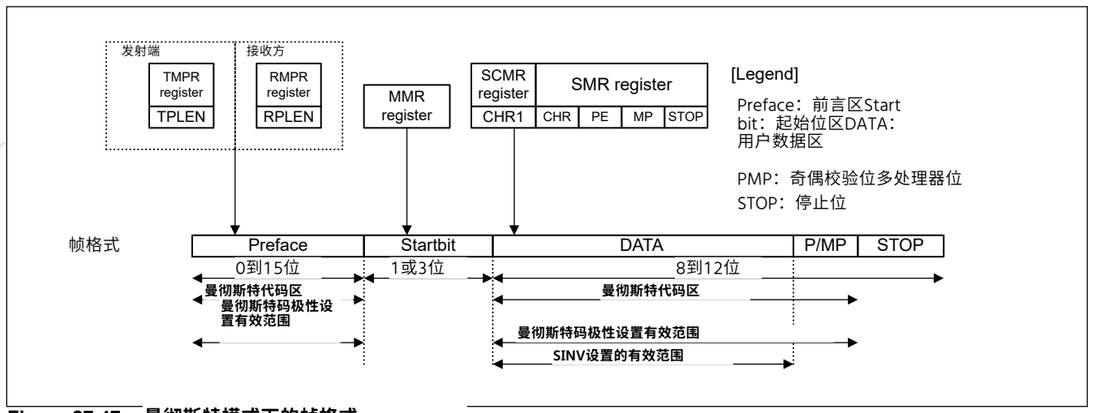

Figure 27.47 曼彻斯特模式下的帧格式

(1) 前言区

这是位于每帧开始处的固定模式区域。

不同的寄存器用于设置发送和接收的前言区域。前言长度通过设置TMPR.TPLEN[3:0]来决定传输。通过设置RMPR.RPLEN[3:0]来确定接收。

如果设置为0，则发送前言被禁用且不添加。

如果设置为1d到15d，则添加一个长度由该设置确定的前言。

（例如，如果设置为1d，则添加1位前言。如果设置为15d，则添加15位前言。）

前言模式设置为发送用TMPR.TPPAT[1:0]，接收用RMPR.RPPAT[1:0]，从四种模式中选择。

(2) Start bit area

This is an area indicating the start of valid data in a frame. It is added after the preface area.

The start bit length is determined by MMR.SBSEL setting. When MMR.SBSEL = “0”, the start bit length is 1 bit.

When MMR.SBSEL = “1”, the start bit length is 3 bits.

When MMR.SBSEL = “1”, the SYNC type can be selected from command SYNC and data SYNC.

Command SYNC means the three start bits are added as a one-to-zero transition.

(2) 起始位区

这是指示帧中有效数据开始的区域。它添加在前言区域之后。

起始位长度由MMR.SBSEL设置决定。当MMR.SBSEL=“0”时，起始位长度为1位。

当MMR.SBSEL=“1”时，起始位长度为3位。

当MMR.SBSEL=“1”时，SYNC类型可以从命令SYNC和数据SYNC中选择。

命令SYNC意味着三个起始位被添加为一个从1到零的转换。

Data SYNC means the three start bits are added as a zero-to-one transition.

The SYNC type is determined by the MMR.SYNSEL, MMR.SYNVAL and TDRH_MAN.TSYNC settings.

(When receiving, the received result is applied to RDRH_MAN.RSYNC.)

When MMR.SBSEL = “0”, the start bit is added as a zero-to-one or one-to-zero transition.

The selection is determined by the MMR.SYNVAL setting.

The MMR.SYNSEL bit specifies the destination to be referred to when setting for transmission.

When the MMR.SYNSEL bit is set to 1, the MMR.SYNVAL setting is referred to. When the MMR.SYNSEL bit is set to 0, the TDRH_MAN.TSYNC setting is referred to.

Figure 27.49 shows the state of the start bit area according to the settings in the MMR.SYNSEL, MMR.SYNVAL and TDRH_MAN.TSYNC registers in the case of transmission. Figure 27.50 shows that in the case of reception.

The start bit(s) is not affected by the MMR.TMPOL or MMR.RMPOL setting.

数据同步意味着三个起始位被添加为一个零到一的转换。

SYNC类型由MMR.SYNSEL、MMR.SYNVAL和TDRH_MAN.TSYNC设置确定。

（接收时，将接收到的结果应用到RDRH_MAN.RSYNC。）

当MMR.SBSEL=“0”时，添加起始位作为零到一或一到零的转换。

选择由MMR.SYNVAL设置决定。

MMR.SYNSEL位指定发送设置时要参考的目标。

当MMR.SYNSEL位设置为1时，参考MMR.SYNVAL设置。当MMR.SYNSEL位设置为0时，参考TDRH_MAN.TSYNC设置。

(3) DATA

由于数据区的格式与异步模式相同，见27.3.1节。串行数据传输 Format.

As shown in Figure 27.46, Frame Format in Manchester Mode, the stop bit is not included in the Manchester encoding range.

27.5.2 Clock

As the transfer clock in Manchester mode, the clock generated by the on-chip baud rate generator is used by setting the SMR.CKS[1:0] bit.

Also it is possible to set the oversampling (transfer rate of one-bit period) by SEMR.ABCS bit.

When the SMER.ABCS bit is set to 0, oversampling x16 is selected with the one-bit period being 16 cycles of the base clock. When the SMER.ABCS bit is set to 1, oversampling x8 is selected with the one-bit period being 8 cycles of the base clock.

27.5.3 Initialization of the SCI in Manchester Mode

Before transferring data, write the initial value (00h) to the SCR register and initialize the SCI following the example of flowchart shown in Figure 27.51.

Whenever the operating mode or transfer format is changed, the SCR register must be initialized before the change is made.

Note that setting the SCR.RE bit to 0 initializes none of: the ORER, FER, PER, MER, and RDRF flags in the SSR_MANC register, the SYER, PFER and SBER flags in the MESR register, and the RDR, RDRHL_MAN registers.

Note also that switching the value of SCR.TE from 0 to 1 when SCR.TIE is 1 generates a SCIn_TXI interrupt request.

如图27.46，曼彻斯特模式下的帧格式，停止位不包含在曼彻斯特编码范围内。

27.5.2 Clock

作为曼彻斯特模式下的传输时钟，片内波特率发生器产生的时钟用于设置
SMR.CKS[1:0] bit.

也可以通过SEMR.ABCS位设置过采样（一位周期的传输率）。

当SMER.ABCS位设置为0时，选择过采样x16，一位周期为基本时钟的16个周期。当SMER.ABCS位设置为1时，选择过采样x8，一位周期为基本时钟的8个周期。

27.5.3 曼彻斯特模式下SCI的初始化

在传输数据之前，将初始值（00h）写入SCR寄存器并按照图27.51所示的流程图示例初始化SCI。

每当改变操作模式或传输格式时，必须在改变之前初始化SCR寄存器。

请注意，将SCR.RE位设置为0不会初始化：SSR_MANC寄存器中的ORER、FER、PER、MER和RDRF标志，MESR寄存器中的SYER、PFER和SBER标志，以及RDR、RDRHL_MAN寄存器。

另请注意，当SCR.TIE为1时，将SCR.TE的值从0切换到1会产生SCIn_TXI中断请求。

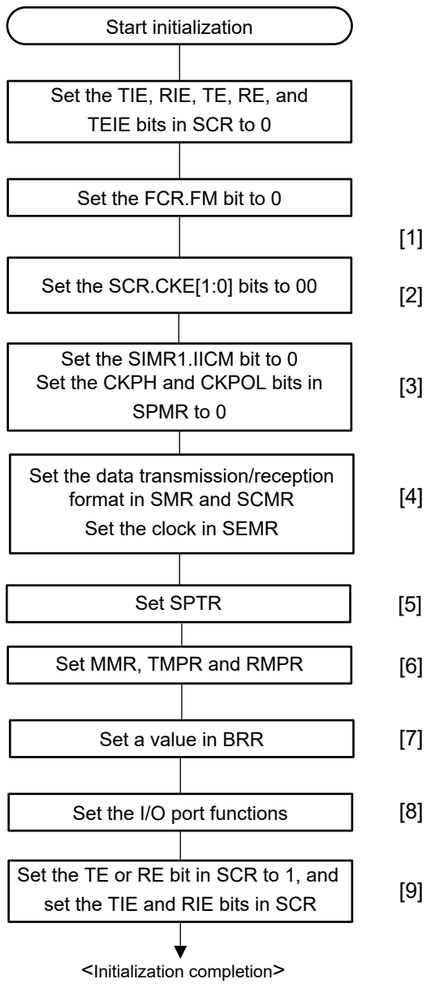

Figure 27.51 SCI Initialization Flow in Manchester Mode

27.5.4 Double-speed operation

When the ABCS bit in SEMR is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the BGDM bit in SEMR is set to 1, the cycle of the base clock is reduced to half and the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the ABCS and the BGDM bits in SEMR are set to 1, the SCI operates on the bit rate four times that of when the ABCS and the BGDM bits in SEMR are set to 0.

27.5.5 CTS and RTS functions

The CTS function uses input on the CTSn_RTSn pin in transmission control. Setting the CTSE bit in SPMR to 1 enables the CTS function. The CTSn_RTSn pin can be set as a multiplexed pin which allows one pin to be used for either function, or as dedicated pins with each pin for a single function. Use the CTSPEN bit in SPMR for this setting.

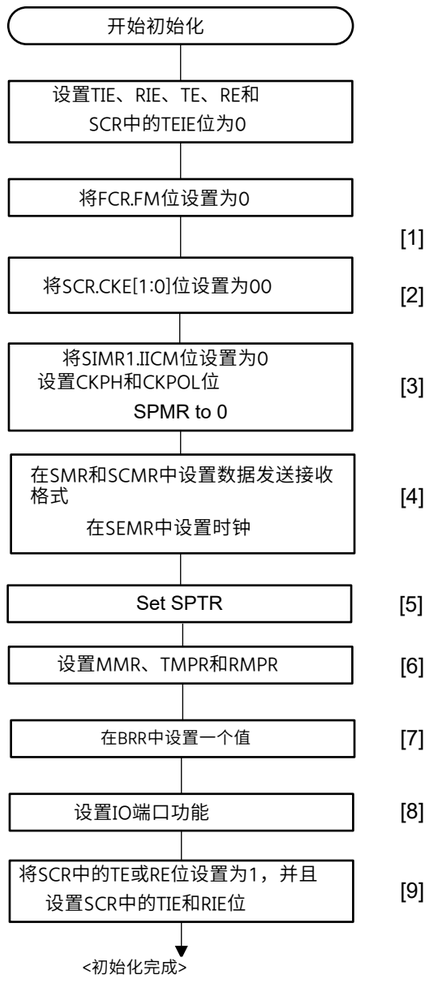

Figure 27.51 曼彻斯特模式下的SCI初始化流程

27.5.4 Double-speed operation

当SEMR中的ABCS位设置为1并选择1位周期的8个基本时钟脉冲时，SCI以ABCS设置为0时的两倍比特率运行。

当SEMR中的BGDM位设置为1时，基本时钟的周期减少到一半，SCI的比特率是ABCS设置为0时的两倍。

当SEMR中的ABCS和BGDM位设置为1时，SCI以四倍的比特率运行。
SEMR中的ABCS和BGDM位设置为0。

27.5.5 CTS和RTS功能

CTS功能在传输控制中使用CTSn_RTSn引脚上的输入。将SPMR中的CTSE位设置为1使能CTS功能。CTSn_RTSn管脚可以设置为多路复用管脚，允许一个管脚用于任一功能，或作为专用管脚，每个管脚用于单一功能。使用SPMR中的CTSPEN位进行此设置。

When the CTS function is enabled, reception starts only when the CTSn_RTSn pin is at the low level.

Applying a high level to the CTSn_RTSn pin after transmission starts does not affect transmission of the current frame, which continues.

The RTS function uses output on the CTSn_RTSn pin to request transmission. When the SCI is ready to receive, it outputs a low level to the CTSn_RTSn pin, Conditions for output of the low level and high level are as follows:

[Conditions for low-level output]

When all conditions listed below are satisfied:

- The value of the RE bit in SCR is 1.
- The SCI is ready to receive.
- There is no received data yet to be read.
- All of the following flags are set to 0: SSR_MANC.ORER, FER, PER and MER flags, and MESR.SYER (when SYEREN = 1), PFER (when PFEREN = 1) and SBER flags (when SBEREN = 1).

[Conditions for high-level output]

- When the conditions for low output are not satisfied

27.5.6 Serial data transmission in Manchester mode

The SCI encodes data in Manchester encoding and sends the resultant data in Manchester mode.

When the polarity setting (MMR.TMPOL) set to 0, logic 0 is coded as a zero-to-one transition in Manchester code and logic 1 is coded as a one-to-zero transition in Manchester code.

When the polarity setting (MMR.TMPOL) set to 1, logic 0 is coded as a one-to-zero transition in Manchester code and logic 1 is coded as a zero-to-one transition in Manchester code.

For this reason, a level transition occurs with the Manchester encoded data in the middle of individual logic data. (See Figure 27.46).

The transmitter constructs transmit frames in a specific format by adding a preface area to data and setting the start bit(s) according to the polarity setting and sends resultant serial data.

For details on the frame format, see section 27.5.1. Frame Format.

Figure 27.52 shows the flowchart in transmission. Figure 27.53, Figure 27.54, and Figure 27.55 show examples of the operation for serial transmission in Manchester mode.

当CTS功能使能时，只有在CTSn_RTSn引脚为低电平时才开始接收。

传输开始后将高电平应用到CTSn_RTSn引脚不会影响当前帧的传输，当前帧会继续传输。

RTS功能使用CTSn_RTSn引脚上的输出来请求传输。当SCI准备好接收时，向CTSn_RTSn管脚输出一个低电平，输出低电平和高电平的条件如下：

[Conditions for low-level output]

当满足下列所有条件时：

●SCR中RE位的值为1。

●SCI已准备好接收。

●没有接收到的数据尚未读取。

●以下所有标志都设置为0：SSR_MANC.ORER、FER、PER和MER标志，以及MESR.SYER（当SYEREN=1时）、PFER（当PFEREN=1时）和SBER标志（当SBEREN=1时）。

[Conditions for high-level output]

●不满足低输出条件时

27.5.6 曼彻斯特模式下的串行数据传输

SCI以曼彻斯特编码对数据进行编码，并以曼彻斯特模式发送结果数据。

当极性设置(MMR.TMPOL)设置为0时，逻辑0被编码为曼彻斯特代码中的零到一转换，逻辑1被编码为曼彻斯特代码中的一到零转换。

当极性设置(MMR.TMPOL)设置为1时，逻辑0被编码为曼彻斯特代码中的一对零转换，逻辑1被编码为曼彻斯特代码中的零到一转换。

出于这个原因，在各个逻辑数据中间的曼彻斯特编码数据会发生电平转换。（看Figure 27.46).

发送器通过向数据添加前言区域并根据极性设置设置起始位来构建特定格式的发送帧，并发送结果串行数据。

有关帧格式的详细信息，请参阅第27.5.1节。帧格式。

图27.52显示了传输的流程图。图27.53、图27.54和图27.55显示了曼彻斯特模式下串行传输的操作示例。

The transmit data can also be written to TDR by activating the DMAC or DTC in the TXI interrupt request.
When TEI interrupt requests are used, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to TDR.

27.5.7 Serial Data Reception in Manchester Mode

In Manchester mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate. Reception starts by sampling the falling edges of received data at the base clock. As shown in Figure 27.56, reception starts at a falling edge of the received data and it continues if the received data keeps low for the duration of 1/4 bit. If the received data goes high within the duration of 1/4 bit, the SCI judges it as an error and waits for a falling edge again.

If a high level is expected in the first half of a bit in the received data, the SCI judges a low level that continues for one base clock cycle as an error and ignores the change to the low level.

Note 1. This is the case when SEMR.ABCS = 0. When SEMR.ABCS = 1, the SCI operates on a base clock with a frequency of 8 times the bit rate.

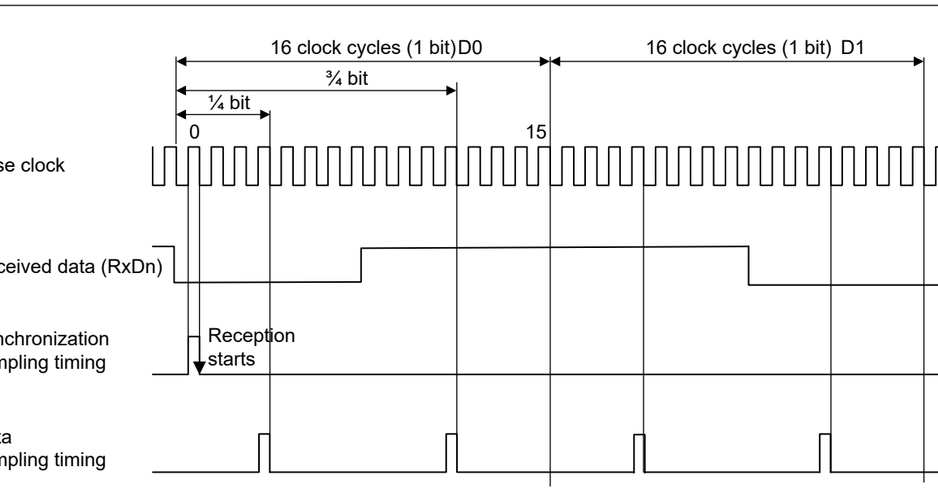

Figure 27.56 Data Reception Sampling Timing in Manchester Mode

In Manchester mode, data reception starts with detection of a preface and start bit area.

The SCI checks the input from the RXDn pin to see whether a preface is added based on the value of RMPR.RPLEN.

Figure 27.55 曼彻斯特模式下串行传输的传输结束操作示例（使用前言但没有CTS功能）

27.5.7 曼彻斯特模式下的串行数据接收

在曼彻斯特模式下，SCI在频率为16倍*1比特率的基本时钟上运行。接收开始于在基本时钟处对接收到的数据的下降沿进行采样。如图27.56所示，接收在接收数据的下降沿开始，如果接收数据保持低电平持续14位，则继续接收。如果接收到的数据在14bit的时间内变高，则SCI判断为错误，再次等待下降沿。

如果在接收数据的前半个比特中预期为高电平，则SCI将持续一个基本时钟周期的低电平判断为错误，并忽略向低电平的变化。

注1.这是SEMR.ABCS=0时的情况。当SEMR.ABCS=1时，SCI在频率为比特率8倍的基本时钟上运行。

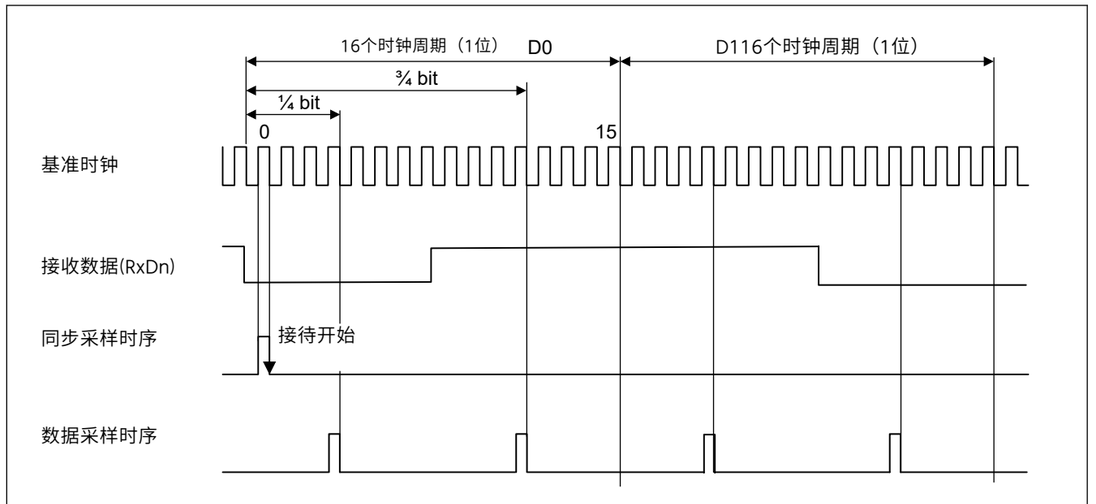

Figure 27.56 曼彻斯特模式下的数据接收采样时序

在曼彻斯特模式下，数据接收从检测前言和起始位区域开始。

SCI检查来自RXDn引脚的输入，以查看是否根据RMPR.RPLEN的值添加了前言。

If the preface is disabled (RMPR.RPLEN = 0), it moves on to the detection of a start bit area without detecting a preface.

When a preface is enabled, it identifies a preface pattern setting according to the set value in RMPR.RPPAT, and compares it with the RXDn input for a pattern match to detect a preface pattern.

Upon detection of a preface pattern match, it judges it as a normal preface and moves on to the detection of a start bit area.

If detecting a preface pattern mismatch or a Manchester code error in the preface area, it judges it as a preface error and asserts a preface error (PFER).

For start bit detection, the SCI selects an expected value based on the register settings (MMR.SBSEL and SYNVAL), compares it with the RXDn input for a pattern match to detect a start bit area. Upon detection of a start bit pattern match, it judges it as a normal start bit area and moves on to the data processing.

Only when a preface and a start bit area are detected normally, it moves on to the next phase of data reception.

Upon detection of a start bit pattern mismatch, it asserts a start bit error flag (SBER).

In data processing, the SCI shifts the data by the expected received data length based on the register settings (SCMR.CHR1 and SMR.CHR) through the RSR register. If two sampling points in a bit of the received data are identical, the SCI judges this as a Manchester code error.

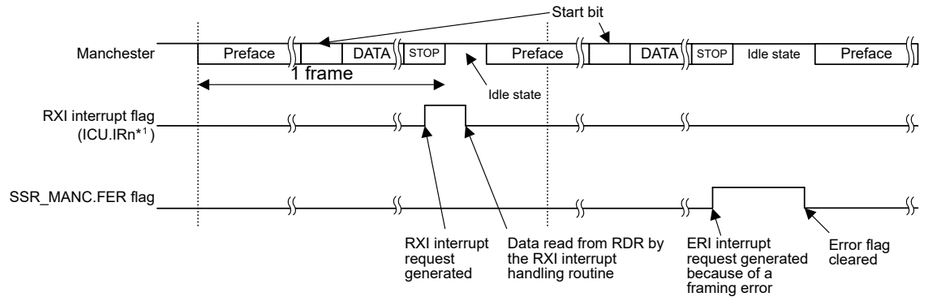
For details, see section 27.5.11. Errors in Manchester Mode (4).

When the parity function is disabled (SMR.PE = 0), the SCI moves on to the next phase of stop bit detection. When the parity function is enabled (SMR.PE = 1), the SCI performs parity checking. If detecting a parity error, it asserts a parity error flag (PER), and then moves on to stop bit detection.

In stop bit detection, the SCI checks the following in the stop bit area of the received frame:

It has two sampling points in a bit. If both points are at the high level, the bit is recognized as a normal stop bit and the data is stored in the RDR register. At least one low-level point is judged as an abnormal stop bit, causing a framing error flag (FER) to be set. Even when an error is detected, the received data is stored in the RDR register as abnormal data.

Figure 27.57 shows an example of the operation for serial data reception in Manchester mode.



Note 1. For corresponding interrupt numbers, see section 13, Interrupt Controller Unit (ICU).

Figure 27.57 Example of Operation for Serial Data Reception in Manchester mode (with a Preface)

For the state of each status flag in the SSR_MANC register and RXDn input processing when a receive error is detected, see section 27.5.11. Errors in Manchester Mode.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated.

Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, PER, MER, SYER*1, PFER*1, and SBER*1 flags to 0 before resuming reception. Also, be sure to read the RDR (or RDRHL_MAN) register during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR (or the RDRHL_MAN) register because received data which has not yet been read may be left in the RDR (or the RDRHL_MAN) register.

Figure 27.58 and Figure 27.59 show examples of serial data reception flowchart in Manchester mode.

如果前言被禁用（RMPR.RPLEN=0），它会继续检测起始位区域而不检测前言。

启用前言时，它根据RMPR.RPPAT中的设置值识别前言模式设置，并将其与模式匹配的RXDn输入进行比较，以检测前言模式。

在检测到前言模式匹配时，将其判断为正常前言并继续检测起始位区域。

如果在前言区域检测到前言模式不匹配或曼彻斯特码错误，则将其判断为前言错误并断言前言错误（PFER）。

对于起始位检测，SCI根据寄存器设置（MMR.SBSEL和SYNVAL）选择预期值，将其与模式匹配的RXDn输入进行比较，以检测起始位区域。在检测到起始位模式匹配时，将其判断为正常起始位区域并继续进行数据处理。

只有在正常检测到前言和起始位区域时，才进入下一个数据接收阶段。

在检测到起始位模式不匹配时，它会断言起始位错误标志(SBER)。

在数据处理中，SCI根据寄存器设置（SCMR.CHR1和SMR.CHR）通过RSR寄存器将数据移位预期的接收数据长度。如果接收到的数据位中的两个采样点相同，则SCI判断为曼彻斯特码错误。

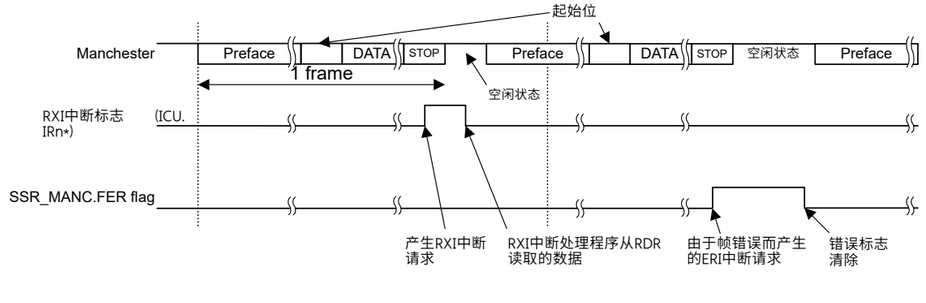
详见27.5.11节。曼彻斯特模式中的错误(4)。

当奇偶校验功能被禁用（SMR.PE=0）时，SCI进入下一个停止位检测阶段。当启用奇偶校验功能时（SMR.PE=1），SCI执行奇偶校验。如果检测到奇偶校验错误，它会置位奇偶校验错误标志(PER)，然后继续进行停止位检测。

在停止位检测中，SCI在接收帧的停止位区域中检查以下内容：

它有两个采样点。如果两个点都处于高电平，则该位被识别为正常停止位，数据存储在RDR寄存器中。至少有一个低电平点被判断为异常停止位，导致设置帧错误标志（FER）。即使检测到错误，接收到的数据也会作为异常数据存储在RDR寄存器中。

图27.57显示了曼彻斯特模式下串行数据接收操作的示例。



注1.有关相应的中断号，请参阅第13节，中断控制器单元(ICU)。

Figure 27.57 曼彻斯特模式下串行数据接收操作示例（附前言）

关于SSR_MANC寄存器中各状态标志的状态以及检测到接收错误时的RXDn输入处理，请参阅第27.5.11节。曼彻斯特模式中的错误。

如果检测到接收错误，则会产生SCIn_ERI中断请求，但不会产生SCIn_RXI中断请求。

接收错误标志为1时无法恢复数据接收。因此，请设置ORER、FER、PER、MER、SYER*1，

PFER*1和SBER*1在恢复接收之前标志为0。此外，请务必在溢出错误处理期间读取RDR（或RDRHL_MAN）寄存器。如果在操作期间通过将SCR.RE位设置为0来强制终止接收，请读取RDR（或RDRHL_MAN）寄存器，因为尚未读取的接收数据可能留在RDR（或RDRHL_MAN）寄存器中。

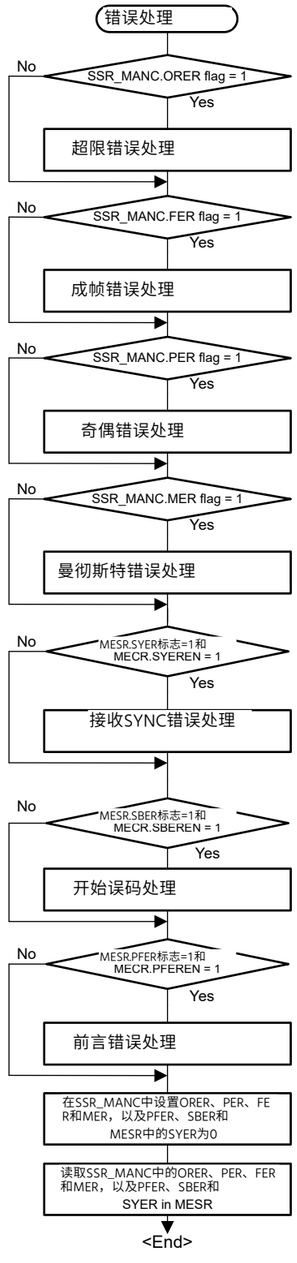

Figure 27.59 曼彻斯特模式下的串行接收流程图示例（错误处理）

27.5.8 使用多处理器位时的操作

See section 27.4. Multi-Processor Communication Function (1) for the operation in Manchester mode when using multi-processor mode because the operation is the same.

A preface and a start bit area are added to the frame format in Manchester mode. See Figure 27.59 for error processing in Manchester mode for the reception flowchart (Figure 27.43). Refer to Table 27.33 for the operation status when detecting various errors.

27.5.9 Receive Retiming

This function corrects the timing for each central edge of the bit, taking advantage of the fact that each bit has an edge in the center in Manchester code.

The receive retiming function can be turned on or off by setting the ERTEN bit in the MMR register.

When the receive retiming function is turned off (MMR.ERTEN = 0), retiming is not performed, causing misalignment between the internal clock and the RXDn input to be accumulated and the receive margin to be reduced.

When the receive retiming function is turned on (MMR.ERTEN = 1), retiming is performed for the preface area, the start bit area*1, and the data area (excluding the stop bit).

Note 1. Retiming is not performed for the start bit area if the preface length is 0 and the start bit length is 3.

As an example, the receive retiming when oversampling x16 is selected is shown below.

When detecting an RXDn input edge two to four cycles before the expected receive cycle, the receive processing is shortened by one sampling CLK cycle.

When detecting a RXDn input edge two to three cycles after the expected receive cycle, the receive processing is extended by one sampling CLK cycle.

(Even if the clock is misaligned with the data by more than two cycles, one cycle is corrected for each bit.)

Figure 27.60 shows the conceptual image of receive retiming range.

When detecting an edge in the tolerance area in the figure, data is received as is without making correction.

When detecting an edge in the SyncJump area in the figure, data is corrected for reception.

When detecting an edge in the SyncError area in the figure, data is received as abnormal data with no correction made.

For a Manchester code error (data matches at the 1/4-phase and 3/4-phase sampling points), the SCI reports a code error.

请参见第27.4节。多处理器通信功能(1)曼彻斯特模式下的操作在使用多处理器模式时因为操作是一样的。

曼彻斯特模式的帧格式中添加了前言和起始位区域。接收流程图（图27.43）在曼彻斯特模式下的错误处理见图27.59。检测各种错误时的动作状态见表27.33。

27.5.9 接收重定时

该函数利用曼彻斯特码中每个位在中心的边缘这一事实，校正位的每个中心边沿的时序。

通过设置MMR寄存器中的ERTEN位可以打开或关闭接收重定时功能。

当接收重定时功能关闭时（MMR.ERTEN=0），不执行重定时，导致内部时钟和RXDn输入之间的错位累积，接收余量减小。

当接收重定时功能打开时（MMR.ERTEN=1），对前言区、起始位区*1和数据区（不包括停止位）执行重定时。

注1.如果序言长度为0且起始位长度为3，则不对起始位区域执行重定时。

例如，选择过采样x16时的接收重定时如下所示。

当在预期接收周期前2到4个周期检测到RXDn输入边沿时，接收处理将缩短1个采样CLK周期。

当在预期接收周期后两到三个周期检测到RXDn输入边沿时，接收处理将延长一个采样CLK周期。

（即使时钟与数据的偏差超过两个周期，也会为每一位校正一个周期。）

图27.60显示了接收重定时范围的概念图。

在图中的公差范围内检测边缘时，直接接收数据而不进行校正。

当在图中的SyncJump区域检测到边缘时，数据被校正以进行接收。

当在图中的SyncError区域检测到边缘时，数据作为异常数据接收，没有进行校正。

对于曼彻斯特编码错误（数据在1个4相和3个4相采样点匹配），SCI报告编码错误。

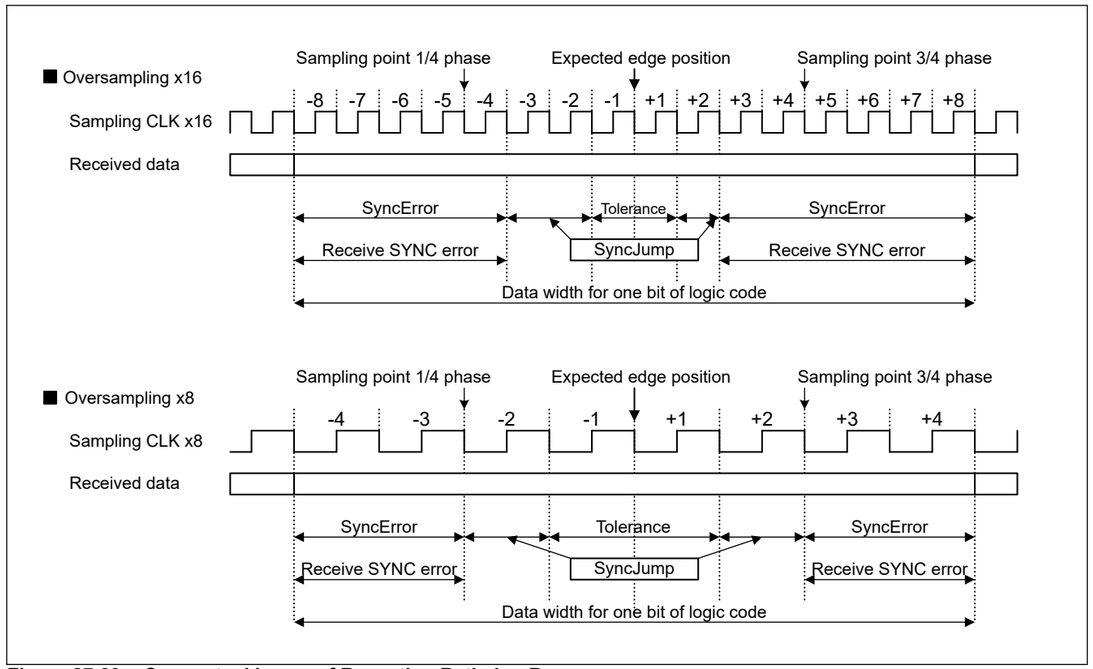

Figure 27.60 Conceptual Image of Reception Retiming Range

27.5.10 Polarity Setting for Manchester Code

The polarity of the Manchester code can be set with the Manchester Mode Register (MMR).

It can be set separately for transmission and reception. Use the MMR.TMPOL bit to set the polarity for transmission and the MMR.RMPOL bit to set the polarity for reception.

The Manchester code polarity setting is valid for the preface area, the data area, and the parity or multi-processor area.

When the initial settings (TMPOL/RMPOL = 0) are used for the polarity of Manchester code, logic 0 is encoded as a zero-to-one transition in Manchester code and logic 1 is encoded as a one-to-zero transition in Manchester code. If the settings are changed to TMPOL/RMPOL = 1, logic 0 is encoded as a one-to-zero transition in Manchester code and logic 1 is encoded as a zero-to-one transition in Manchester code. Figure 27.61 shows the conceptual image of the settings and operation.

Separately from the function above, the transmitted and received data in the data area can be inverted by the transmitted/received data inversion function (SCMR.SINV). Since the polarity of Manchester code (MMR.TMPOL/RMPOL) can be set separately from the transmitted/received data invert function (SCMR.SINV), if both are set to inversion (MMR.TMPOL/RMPOL = 1 and SCMR.SINV = 1), the transmitted and received data are set to initial state (inversion + inversion = normal).

The polarity of the start bit area can be set by a register different from the ones mentioned above.

Since a different register is used, the polarity of the start bit area is not affected by the polarity setting for Manchester code mentioned above.

For details on the setting for the start bit area, see section 27.5.1. Frame Format (2).

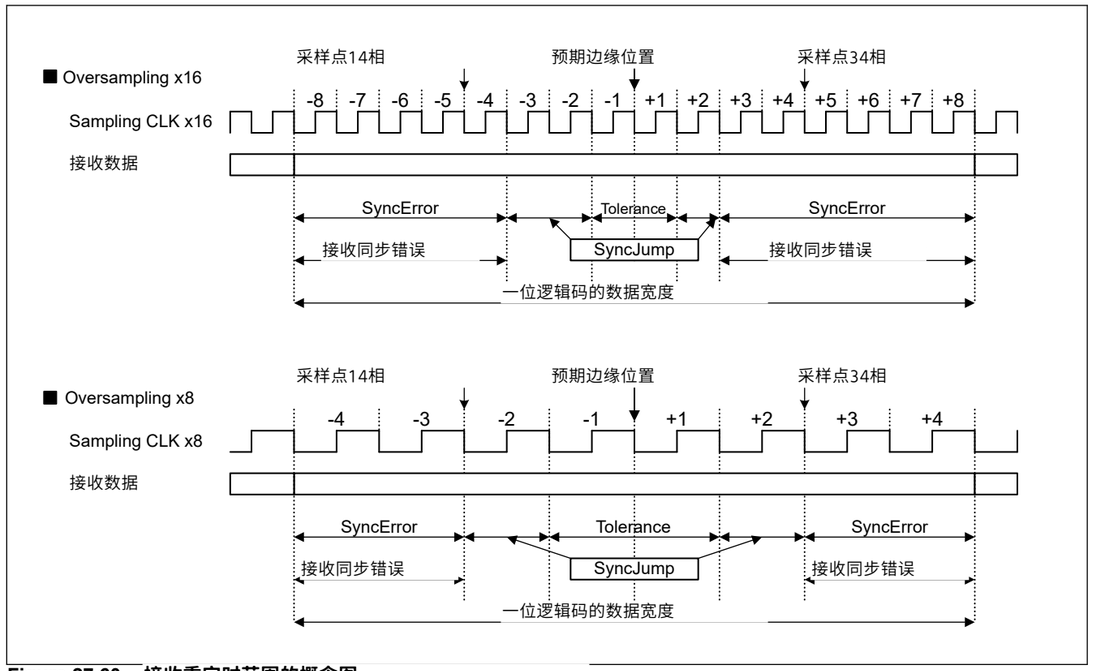

Figure 27.60 接收重定时范围的概念图

27.5.10 曼彻斯特码的极性设置

曼彻斯特码的极性可以通过曼彻斯特模式寄存器(MMR)设置。

可以分别设置发送和接收。使用MMR.TMPOL位设置传输的极性和MMR.RMPOL位设置接收极性。

曼彻斯特码极性设置对前言区、数据区、奇偶校验或多处理器区有效。

当初始设置(TMPOLRMPOL=0)用于曼彻斯特代码的极性时，逻辑0被编码为曼彻斯特代码中的零到一转换，逻辑1被编码为曼彻斯特代码中的一到零转换。如果设置更改为TMPOLRMPOL=1，则逻辑0被编码为曼彻斯特代码中的一对零转换，逻辑1被编码为曼彻斯特代码中的零到一转换。图27.61显示了设置和操作的概念图。

与上述功能不同，数据区中的发送和接收数据可以通过发送接收数据反转功能(SCMR.SINV)反转。由于曼彻斯特码的极性(MMR.TMPOLRMPOL)可以与发送的接收数据反转功能(SCMR.SINV)分开 设置，如果两者都设置为反转(MMR.TMPOLRMPOL=1和SCMR.SINV=1)，发送和接收的数据设置为初始状态（反转+反转=正常）。

起始位区域的极性可以通过与上述不同的寄存器来设置。

由于使用了不同的寄存器，因此起始位区域的极性不受上述曼彻斯特码极性设置的影响。

关于起始位区域的设置，请参阅27.5.1节。帧格式(2)。

27.5.11 Errors in Manchester Mode

There are the following errors in Manchester mode:

1. Parity error
2. Over run error
3. Framing error
4. Manchester error
5. Preface error
6. Start Bit error
7. Receive SYNC error

For errors (1) to (3), see section 27.3.9. Serial Data Reception in Asynchronous Mode (1) because they are the same as in asynchronous mode.

Each errors are judged in each area, but they are reflected on flags and operations at the timing of 3/4-bit sampling of the STOP bit area. If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the previous information.

Table 27.31 lists the states of the serial status register when detecting errors and judgment about whether to store data in the RDR.

Table 27.32 lists the errors that can be detected in each area of a Manchester frame.

If a Preface error or Start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the result of the previous frame reception. Also, if an error is detected in the previous frame, data will not be received, but errors in the pre-face area and start bit area will update that flag. Table 27.33 shows the flags and actions in this case.

27.5.11 曼彻斯特模式中的错误

曼彻斯特模式有以下错误：

1.奇偶校验错误

2.溢出错误

3.构图错误

4.曼彻斯特错误

5.前言错误

6.起始位错误

7.收到SYNC错误

关于错误(1)至(3)，请参阅第27.3.9节。异步模式下的串行数据接收(1)因为它们与异步模式下相同。

在每个区域中判断每个错误，但它们反映在标志和操作上，在3个4位采样的时间
停止位区域。如果检测到前言错误或起始位错误，则不会接收后续数据。因此，不进行其他错误检测，错误标志保存先前的信息。

表27.31列出了串口状态寄存器在检测错误和判断是否存储数据时的状态
RDR.

表27.32列出了在曼彻斯特帧的每个区域中可以检测到的错误。

如果检测到Preface错误或Startbit错误，则不会接收后续数据。因此，不进行其他错误检测，错误标志保存前一帧接收的结果。此外，如果在前一帧中检测到错误，则不会接收数据，但前脸区域和起始位区域中的错误将更新该标志。表27.33显示了这种情况下的标志和操作。

(4) Manchester error

A Manchester error is generated when a Manchester code error is detected.

In Manchester code, there must be an edge (transition) in the center of the bit.

In the data area of a received frame (including the parity/multi-processor bit), the values of the 1/4-bit and 3/4-bit sampling points are checked in each received 1-bit data, and a Manchester code error is determined if these two values match.

If a Manchester code error is detected, the Manchester error flag (SSR_MANC.MER) is asserted.

If a Manchester error occurs, it is handled as an interrupt source and event source. If a Manchester error is detected, the next reception is not performed until the corresponding error flag is cleared.

(5) Preface error

A preface error is generated when the preface pattern does not match or a Manchester code error is detected in the preface area. If a preface error is detected, the preface error flag (SSR_MANC.PFER) is asserted.

It is possible to set whether to use this error flag as an interrupt source with the setting of the MECR register.

When MECR.PFEREN = 1, a preface error is handled as an interrupt source or event source. If a preface error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.PFEREN = 0, a preface error is not handled as an interrupt source or event source, and the next reception is not halted. However, a preface error is notified to MESR.PFER.

(6) Start bit error

A start bit error is generated when a mismatch is detected between the start bit area in the received frame and the preset start bit pattern. Upon detection of a start bit error, a start bit error flag (MESR.SBER) is asserted.

It is possible to set whether to use the start bit error as an interrupt source with the setting of the MECR register.

When MECR.SBEREN = 1, a start bit error is handled as an interrupt source or event source. If a start bit error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.SBEREN = 0, a start bit error is not handled as an interrupt source or event source, and the next reception is not halted. However, a start bit error is notified to MESR.SBER.

(7) Receive SYNC error

When the receive retiming function described in section 27.5.9. Receive Retiming is enabled, the receive retiming operation is performed.

If no edges are detected within the receive retiming range (SyncError area in Figure 27.60) when receive timing operation is being performed, a receive SYNC error is generated. Upon detection of a receive SYNC error, a receive SYNC error flag (MESR.SYER) is asserted. In areas not subject to retiming, receive SYNC errors are not detected.

The preface area*1, the start bit area*1,*2, and the data area (excluding the stop bit) for which receive retiming operation is performed are checked.

It is possible to set whether to use the receive SYNC error as an interrupt source with the setting of the MECR register.

When MECR.SYEREN = 1, a receive SYNC error is handled as an interrupt source or event source. If a receive SYNC error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.SYEREN = 0, a receive SYNC error is not handled as an interrupt source or event source, and the next reception is not halted. However, a receive SYNC error is notified to MESR.SYER.

Note 1. In the case of a frame that starts with a pattern that expects the first half of the bit to be High, it is excluded from retiming.

Note 2. In the start bit area, when there is no preface length and 3 bit start bit is set, it is not subject to retiming.
Also, the 1st bit and the 2nd bit in the start bit area when 3 bit start bit is set are not subject to retiming.

(4)曼彻斯特错误

当检测到曼彻斯特码错误时，就会产生曼彻斯特错误。

在曼彻斯特码中，位的中心必须有一个边（转换）。

在接收帧的数据区（包括奇偶校验多处理器位），在每个接收的1位数据中检查1个4位和3个4位采样点的值，确定曼彻斯特码错误如果这两个值匹配。

如果检测到曼彻斯特代码错误，则会置位曼彻斯特错误标志(SSR_MANC.MER)。

如果发生曼彻斯特错误，则将其作为中断源和事件源进行处理。如果检测到曼彻斯特错误，则在清除相应错误标志之前不会执行下一次接收。

(5)前言错误

当前言模式不匹配或在前言区检测到曼彻斯特码错误时，会产生前言错误。如果检测到前言错误，则会置位前言错误标志(SSR_MANC.PFER)。

可以通过MECR寄存器的设置来设置是否使用该错误标志作为中断源。

当MECR.PFEREN=1时，前言错误作为中断源或事件源处理。如果检测到前言错误，则在相应的错误标志被清除之前不会执行下一次接收。

当MECR.PFEREN=0时，前言错误不会作为中断源或事件源处理，并且不会停止下一次接收。但是，前言错误会通知给MESR.PFER。

(6)起始位错误

当检测到接收帧中的起始位区域与预设的起始位模式不匹配时，会产生起始位错误。在检测到起始位错误时，将置位起始位错误标志(MESR.SBER)。

可以通过MECR寄存器的设置来设置是否使用起始位错误作为中断源。

当MECR.SBEREN=1时，起始位错误作为中断源或事件源处理。如果检测到起始位错误，则在清除相应错误标志之前不会执行下一次接收。

当MECR.SBEREN=0时，不将起始位错误作为中断源或事件源处理，并且不会停止下一次接收。但是，将向MESR.SBER通知起始位错误。

(7)接收同步错误

当接收重定时功能在第27.5.9节中描述。启用接收重定时，执行接收重定时操作。

如果在执行接收定时操作时在接收重定时范围内（图27.60中的SyncError区域）没有检测到边沿，则会产生接收SYNC错误。在检测到接收同步错误时，接收同步错误标志(MESR.SYER)被置位。在不受重定时限制的区域中，不会检测到接收同步错误。

检查执行接收重定时操作的前言区域*1、起始位区域*1、*2和数据区域（不包括停止位）。

可以通过MECR寄存器的设置来设置是否使用接收SYNC错误作为中断源。

当MECR.SYEREN=1时，接收SYNC错误将作为中断源或事件源处理。如果检测到接收SYNC错误，则在清除相应错误标志之前不会执行下一次接收。

当MECR.SYEREN=0时，接收SYNC错误不会作为中断源或事件源处理，并且不会停止下一次接收。但是，接收同步错误会通知给MESR.SYER。

注1.对于以预期位的前半部分为高的模式开始的帧，它被排除在重定时之外。

注2.在起始位区域中，当没有序言长度且设置了3位起始位时，不进行重定时。
此外，当设置3位起始位时，起始位区域中的第1位和第2位不受重定时的影响。

Note 4. Since the SCIn_ERI interrupt request is level output, it remains active due to errors in the previous frame regardless of the presence or absence of error in the relevant frame.
Note 5. Since the error cause is continuously detected, the SCIn_ERI event is not newly output regardless of the presence or absence of errors in the relevant frame.
Note 6. For PFER, SBER, and SYER, when each enable bit is set to disable, it is treated as no error.

27.6 Operation in Clock Synchronous Mode

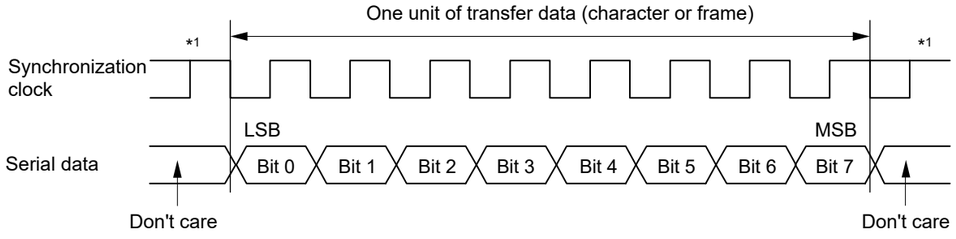
Figure 27.62 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. For single-character data transfer, data consists of 8-bit. In clock synchronous mode, no parity bit can be added.

In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next falling edge. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the last bit as output state. When the SPMR.CKPH bit is 1 in slave mode, the transmission line holds the first bit output state.

Within the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by using a shared clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

However, it is not possible to perform continuous transfer in the fastest bit rate setting (BRR[7:0] = 0x00 and SMR.CKS[1:0] = 00b). Therefore, when the FIFO is selected, this setting (BRR[7:0] = 0x00 and SMR.CKS[1:0] = 00b) is not available.



Note 1. Holds a high level except during continuous transfer.

Figure 27.62 Data format in clock synchronous serial communications with LSB-first order

27.6.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected based on the SCR.CKE[1:0] setting.

When the SCI operates on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character. When no transfer is performed, the clock is held high. However, when only data reception is performed while the CTS function is disabled, the synchronization clock output starts when the SCR.RE bit set to 1. The synchronization clock stops when it goes high*1 and an overrun error occurs or the SCR.RE bit is set to 0.

When only data reception is performed and the CTS function is enabled, the clock output does not start when the SCR.RE bit set to 1 and the CTSn_RTSn pin input is high. The synchronization clock output starts when the SCR.RE bit is set to 1 and the CTSn_RTSn pin input is low. Following that, when the CTSn_RTSn pin input is high on completion of the frame reception, the synchronization clock output stops when it goes high. If the CTSn_RTSn pin input continues to be low, the synchronization clock stops when it goes high*1 and an overrun error occurs or the SCR.RE bit is set to 0.

Note 1. The signal is held high while (SPMR.CKPH = 0 and SPMR.CKPOL = 1) or (SPMR.CKPH = 1 and SPMR.CKPOL = 1). It is held low while (SPMR.CKPH = 0 and SPMR.CKPOL = 1) or (SPMR.CKPH = 1 and SPMR.CKPOL = 0).

注2.如果没有检测到错误，则输出SCIn_RXI中断请求或事件，如果检测到，则输出SCIn_ERI中断请求或事件。

注3.在序言区域或起始位区域中检测到SYER时，根据SYEREN位作为错误处理的行为会发生变化。

27.6 时钟同步模式下的操作

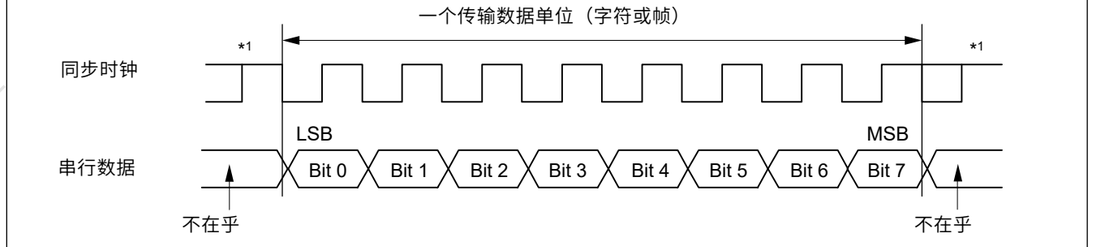
图27.62显示了时钟同步串行数据通信的数据格式。

在时钟同步模式下，数据的发送或接收与时钟脉冲同步。对于单字符数据传输，数据由8位组成。在时钟同步模式下，不能添加奇偶校验位。

在数据传输中，SCI从同步时钟的一个下降沿到下一个下降沿输出数据。在数据接收中，SCI与同步时钟的上升沿同步接收数据。8位数据输出后，传输线保持最后一位作为输出状态。当SPMR.CKPH位在从机模式下为1时，传输线保持第一位输出状态。

在SCI中，发送器和接收器是独立的单元，通过使用共享时钟实现全双工通信。发送端和接收端都具有双缓冲结构，可以在发送时写入下一个发送数据，或者在接收时读取前一个接收数据，实现数据的连续传输。

但是，不可能以最快的比特率设置（BRR[7:0]=0x00和SMR.CKS[1:0]=00b)。Therefore whentheFIFOisselected thissetting(BRR[7:0]=0x00andSMR.CKS[1:0]=00b)isnotavailable.



注1.保持高电平，连续传输期间除外。

Figure 27.62 具有LSB优先顺序的时钟同步串行通信中的数据格式

27.6.1 Clock

可以根据SCR.CKE[1:0]设置选择由片内波特率发生器生成的内部时钟或SCKn引脚上的外部同步时钟输入。

当SCI在内部时钟上运行时，同步时钟从SCKn引脚输出。在一个字符的传输中输出八个同步时钟脉冲。当不执行传输时，时钟保持高电平。但是，当CTS功能禁用时仅执行数据接收时，同步时钟输出会在SCR.RE位设置为1时开始。同步时钟在变为高电平时停止*1并且发生溢出错误或SCR.RE位设置为0。

仅执行数据接收且启用CTS功能时，当SCR.RE位设置为1且CTSn_RTSn引脚输入为高电平时，时钟输出不会启动。当SCR.RE位设置为1且CTSn_RTSn引脚输入为低电平时，同步时钟输出开始。之后，当CTSn_RTSn引脚输入在帧接收完成时为高电平时，同步时钟输出在其变为高电平时停止。如果CTSn_RTSn引脚输入持续为低电平，则同步时钟在变为高电平时停止*1并发生溢出错误或SCR.RE位设置为0。

注1.当(SPMR.CKPH=0且SPMR.CKPOL=1)或(SPMR.CKPH=1且SPMR.CKPOL=1)时，信号保持高电平。它在(SPMR.CKPH=0和SPMR.CKPOL=1)或(SPMR.CKPH=1和SPMR.CKPOL=0)时保持低电平。

27.6.2 CTS and RTS Functions

In the CTS function, the CTSn_RTSn pin input controls the start of data reception or transmission when the clock source is the internal clock. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, setting the CTSn_RTSn pin low causes data reception or transmission to start.

Setting the CTSn_RTSn pin high while the data transmission or reception is in progress does not affect transmission or reception of the current frame.

In the RTS function, the CTSn_RTSn pin output is used to request the start of data reception or transmission when the clock source is an external synchronizing clock. The CTSn_RTSn output goes low when serial communication is enabled. Conditions for output of the CTSn_RTSn low and high are shown as follows:

[Conditions for low output]

Satisfaction of all the following conditions:

Non-FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- Neither transmission nor reception is in progress
- There is no received data available to be read when the SCR.RE bit is 1
- Transmit data is written when the SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR.ORER flag is 0

FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- Neither transmission nor reception is in progress
- The amount of receive data written in FRDRHL is less than the setting value of FCRH.RSTRG[3:0] when SCR.RE = 1
- Data that has not been transmitted is available in FTDRHL when SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR_FIFO.ORER flag is 0

[Condition for high output]

- The conditions for low output are not satisfied

27.6.3 SCI Initialization in Clock Synchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the SCR register, then continue through the SCI initialization procedure given in the sections describing non-FIFO and FIFO selection in section 27.6.2. CTS and RTS Functions. Anytime the operating mode or transfer format is to be changed, the SCR register must be initialized before the change can be made.

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in SSR/SSR_FIFO nor the RDR register. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: In non-FIFO mode, switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 when the SCR.TIE bit is 1 generates an SCIn_TXI interrupt request.

Table 27.35 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (1 of 2)

27.6.2 CTS和RTS函数

在CTS功能中，当时钟源为内部时钟时，CTSn_RTSn引脚输入控制数据接收或发送的开始。将SPMR.CTSE位设置为1可启用CTS功能。当CTS功能使能时，将CTSn_RTSn引脚设置为低电平会导致数据接收或发送开始。

在数据发送或接收过程中将CTSn_RTSn引脚设置为高电平不会影响当前帧的发送或接收。

在RTS功能中，当时钟源为外部同步时钟时，CTSn_RTSn引脚输出用于请求开始数据接收或发送。当串行通信启用时，CTSn_RTSn输出变为低电平。CTSn_RTSn低电平和高电平的输出条件如下所示：

[低输出的条件]

满足以下所有条件：

满足以下所有条件时选择非FIFO

●SCR.RE位或SCR.TE位的值为1

●发送和接收都没有进行

●当SCR.RE位为1时，没有可读取的接收数据

●当SCR.TE位为1且SCR.CKE[1]位为0时写入发送数据

●当SCR.TE位为1且SCR.CKE[1]位为1时，TSR寄存器中的数据可用于传输

●SSR.ORER标志为0

满足以下所有条件时选择FIFO

●SCR.RE位或SCR.TE位的值为1

●发送和接收都没有进行

●SCR.RE=1时，FRDRHL写入的接收数据量小于FCRH.RSTRG[3:0]的设定值

●当SCR.TE位为1且SCR.CKE[1]位为0时，FTDRHL中未发送的数据可用

●当SCR.TE位为1且SCR.CKE[1]位为1时，TSR寄存器中的数据可用于传输

●SSR_FIFO.ORER标志为0

【高输出条件】

●不满足低输出条件

27.6.3 时钟同步模式下的SCI初始化

在发送和接收数据之前，首先将初始值0x00写入SCR寄存器，然后继续执行第27.6.2节中描述非FIFO和FIFO选择的部分中给出的SCI初始化过程。CTS和RTS功能。任何时候要更改操作模式或传输格式，必须先初始化SCR寄存器，然后才能进行更改。

Note: 将SCR.RE位设置为0既不会初始化SSRSSR_FIFO中的ORER、FER和PER标志，也不会初始化RDR寄存器。当TE位设置为0时，所选FIFO缓冲区的TEND标志未初始化。

Note: 在非FIFO模式下，当SCR.TIE位为1时，将SCR.TE位的值从1切换为0或从0切换为1会产生SCIn_TXI中断请求。

27.6.4 Serial Data Transmission in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 27.63, Figure 27.64, and Figure 27.65 show examples of serial transmission in clock synchronous mode.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. The SCIn_TXI interrupt request at the beginning of transmission is generated when the TE bit is set to 1 but only after the TIE bit in the SCR is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data finishes. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks for update to the TDR register on output of the last bit.
5. When the TDR register is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame starts.
6. If TDR is not updated, the SSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Figure 27.63, Figure 27.64, and Figure 27.65 show examples of serial data transmission.

Transmission does not start while a receive error flag (ORER, FER, or PER in SSR) is set to 1. Always set the receive error flags to 0 before starting transmission.

Note: Setting the SCR.RE bit to 0 does not clear the receive error flags.

27.6.4 时钟同步模式下的串行数据传输

(1) Non-FIFO selected

图27.63、图27.64和图27.65显示了时钟同步模式下的串行传输示例。

在串行数据传输中，SCI操作如下：

1.当数据在SCIn_TXI中断处理程序中写入TDR时，SCI将数据从TDR寄存器传输到TSR寄存器。发送开始时的SCIn_TXI中断请求在TE位设置为1时产生，但仅在SCR中的TIE位也设置为1或当这两个位通过一条指令同时设置为1时产生。

2.将数据从TDR传输到TSR后，SCI开始传输。当SCR.TIE位设置为1时，会产生SCIn_TXI中断请求。在当前发送数据发送完成之前，通过在SCIn_TXI中断处理例程中将下一个发送数据写入TDR来启用连续发送。当使用SCIn_TEI中断请求时，在SCIn_TXI请求的处理程序将要发送的最后一个数据写入TDR寄存器后，将SCR.TIE位设置为0，并将SCR.TEIE位设置为1。

3.指定时钟输出模式时，与输出时钟同步，指定使用外部时钟时，与输入时钟同步，从TXDn引脚发送8位数据。当SPMR.CTSE位为1时，时钟信号的输出被暂停，直到输入CTS信号为低电平。

4.SCI在最后一位输出时检查对TDR寄存器的更新。

5.TDR寄存器更新后，下一个发送数据从TDR传送到TSR，开始下一帧的串行发送。

6.如果TDR未更新，则SSR.TEND标志设置为1。TXDn引脚保持最后一位的输出状态。如果SCR.TEIE位为1，则产生SCIn_TEI中断请求并且SCKn引脚保持高电平。

图27.63、图27.64和图27.65显示了串行数据传输的示例。

当接收错误标志（SSR中的ORER、FER或PER）设置为1时，发送不会开始。在开始发送之前，请务必将接收错误标志设置为0。

Note: 将SCR.RE位设置为0不会清除接收错误标志。

[1] [1]SCI initialization:
Set data transmission.

[2] [2]Writing transmit data write to TDR by an SCIn_TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated.
Transmit data is written to TDR once from the handling routine for SCIn_TXI requests.

[3] [3]Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR upon accepting a transmit data empty interrupt (SCIn_TXI) request. Transmit data can also be written to TDR by activating the DMAC or DTC by theSCIn_TXI interrup trequest.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to theTDR

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

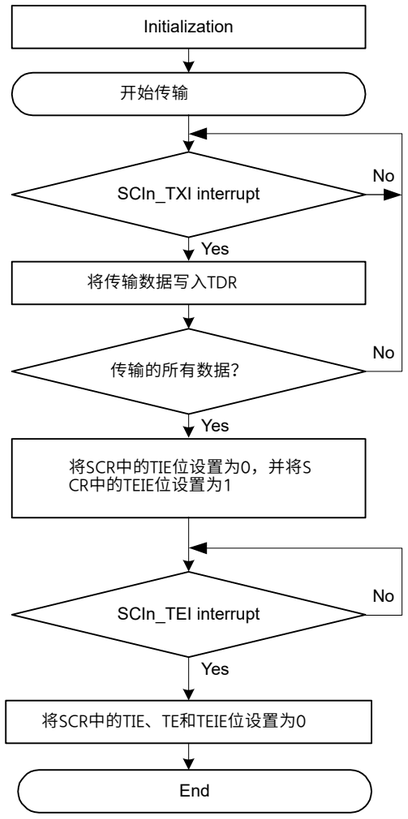
Figure 27.66 Example flow of serial transmission in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 27.67 shows an example of serial transmission in clock synchronous mode with FIFO selected.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the FTDRL*1 register to the TSR register when data is written to FTDRL*1 in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 but only after the SCR.TIE bit is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from FTDRL to TSR, the SCI starts transmission. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, the SSR_FIFO.TDFE is set to 1. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to FTDRL in the SCIn_TXI interrupt handling routine before transmission of the current transmit data has finished. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks whether non-transmitted data remains in FTDRL on output of the stop bit.



[1] [1]SCI初始化：设置数据传输。

[2] [2]通过SCIn_TXI中断请求将发送数据写入TDR：当发送数据从TDR传输到TSR时，会产生发送数据空中断(SCIn_TXI)请求。传输数据从SCIn_TXI请求的处理例程中写入一次TDR。

[3] [3]串行传输继续程序：要继续串行传输，在接受传输数据空中断（SCIn_TXI）请求后将传输数据写入TDR。发送数据也可以通过SCIn_TXI中断请求激活DMAC或DTC写入TDR。当SCIn_TEI中断请求正在使用时，设置

将要传输的最后一个数据写入TDR后，SCR.TIE位为0，SCR.TEIE位为1

Note: 当使用外部时钟时（SCR.CKE[1:0]位的值为10b或11b），SCKn引脚上最后一位的上升沿将SSR.TEND标志设置为1。设置SCR.TE位在这之后立即变为0可能会导致接收端接收数据保持时间不足。

Figure 27.66 选择非FIFO的时钟同步模式下的串行传输示例流程

(2)选择FIFO图27.67显示了在时钟同步模式下选择FIFO的串行传输示例。

在串行数据传输中，SCI操作如下：

1.当数据写入FTDRL*1时，SCI将数据从FTDRL*1寄存器传输到TSR寄存器

SCIn_TXI中断处理程序。可写入FTDRL的数据量为16减去FDR.T[4:0]字节。发送开始时的SCIn_TXI中断请求在SCR.TE位被设置为1时产生，但仅在SCR.TIE位也被设置为1或当这两个位被一条指令同时设置为1时产生。

2.将数据从FTDRL传输到TSR后，SCI开始传输。当写入FTDRL的发送数据量等于或小于指定的发送触发数时，SSR_FIFO.TDFE设置为1。当

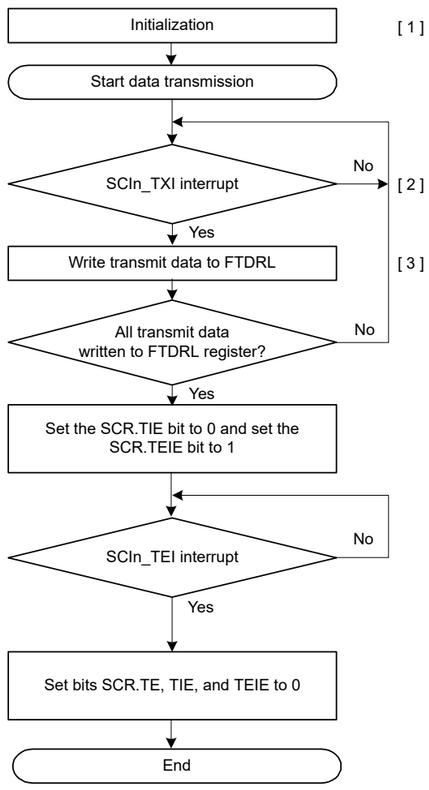
SCR.TIE位设置为1，产生SCIn_TXI中断请求。在当前发送数据的发送完成之前，通过在SCIn_TXI中断处理例程中将下一个发送数据写入FTDRL来启用连续发送。当使用SCIn_TEI中断请求时，在SCIn_TXI请求的处理例程中将要发送的最后一个数据写入FTDRL后，将SCR.TIE位设置为0，并将SCR.TEIE位设置为1。

3.指定时钟输出模式时，与输出时钟同步，指定使用外部时钟时，与输入时钟同步，从TXDn引脚发送8位数据。当SPMR.CTSE位为1时，时钟信号的输出被暂停，直到输入CTS信号为低电平。

4.SCI在停止位输出时检查未传输的数据是否保留在FTDRL中。

5. When FTDRL is updated, the next transmit data is transferred from FTDRL to TSR and serial transmission of the next frame starts.
6. If FTDRL is not updated, the SSR_FIFO.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Note 1. In clock synchronous mode, FTDRH is not used.



[1]SCI initialization:
Set data transmission.
After the TE bit in SCR is set to 1, 1 is output for a frame, and transmission is enabled.

[2]Transmit data write to FTDRL by an SCIn_TXI interrupt request:
For transmission data from FTDRL to TSR, when the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL once in the SCIn_TXI interrupt handling routine.

[3]Serial transmission continuation procedure:
To continue serial transmission, write the next transmit data to FTDRL in this SCIn_TXI interrupt handling routine and clear the SSR_FIFO.TDFE flag to 0 before transmission of the current transmit data finishes.
Transmit data can also be written to FTDRL by activating the DMAC or DTC. The TDFE flag is cleared automatically in this case. Do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL.

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR_FIFO.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

27.6.5 Serial Data Reception in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 27.68 and Figure 27.69 show examples of SCI operation for serial reception in clock synchronous mode.

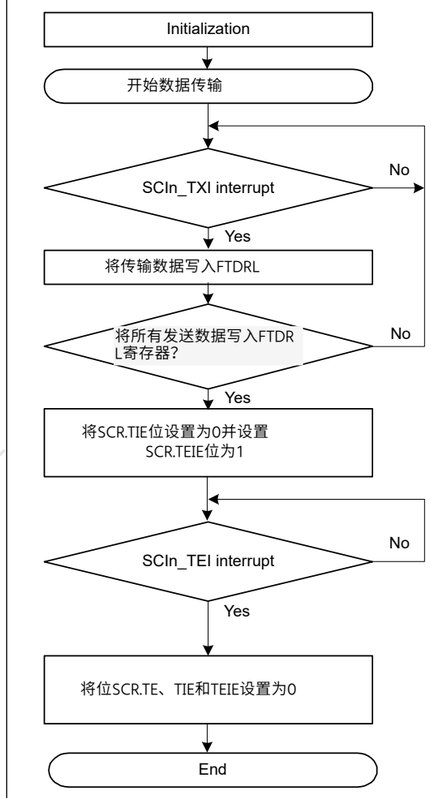
In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.

5.当FTDRL更新时，下一个传输数据从FTDRL传输到TSR并开始下一帧的串行传输。

6.如果FTDRL未更新，则SSR_FIFO.TEND标志设置为1。TXDn引脚保持最后一位的输出状态。如果SCR.TEIE位为1，则产生SCIn_TEI中断请求并且SCKn引脚保持高电平。

注1.在时钟同步模式下，不使用FTDRH。



[1]SCI初始化：设置数据传输。
SCR中的TE位设置为1后，每帧输出1，使能传输。

[2]通过SCIn_TXI中断请求向FTDRL发送数据写入：对于从FTDRL到TSR的发送数据，当写入FTDRL的发送数据量等于或小于指定的发送触发数时，发送数据FIFO空中断（SCIn_TXI)请求被生成。在SCIn_TXI中断处理例程中将发送数据写入FTDRL一次。

[3]串行传输继续程序：要继续串行传输，在这个SCIn_TXI中断处理程序中将下一个传输数据写入FTDRL并清除

在当前传输数据传输完成之前，SSR_FIFO.TDFE标志为0。发送数据也可以通过激活

DMAC或DTC。在这种情况下，TDFE标志会自动清除。
不要写入TDFE标志。
当SCIn_TEI中断请求正在使用时，设置
在将要传输的最后一个数据写入FTDRL后，SCR.TIE位为0，SCR.TEIE位为1。

Note: 当使用外部时钟时（SCR.CKE[1:0]位的值为10b或11b），SCKn引脚上最后一位的上升沿将SSR_FIFO.TEND标志设置为1。设置SCR.TE位在这之后立即变为0可能会导致接收端接收数据保持时间不足。

27.6.5 时钟同步模式下的串行数据接收

(1) Non-FIFO selected

图27.68和图27.69显示了时钟同步模式下串行接收的SCI操作示例。

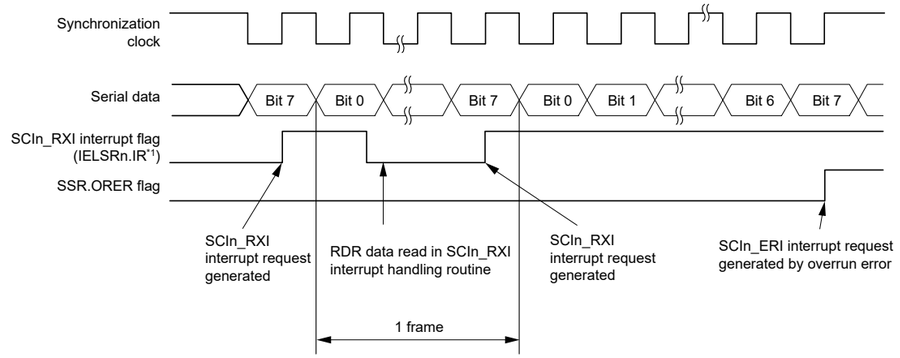
在串行数据接收中，SCI操作如下：

1.当SCR.RE位的值变为1时，CTSn_RTSn引脚变为低电平。

2.SCI执行内部初始化，并与同步时钟输入或输出同步开始接收数据，并将接收数据存储在RSR寄存器中。

3.如果发生溢出错误，则SSR.ORER标志设置为1。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。接收数据不传送到RDR寄存器。

4. When reception completes successfully, receive data is transferred to the RDR register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the received data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that is transferred to RDR causes the CTSn_RTSn pin to output low.



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

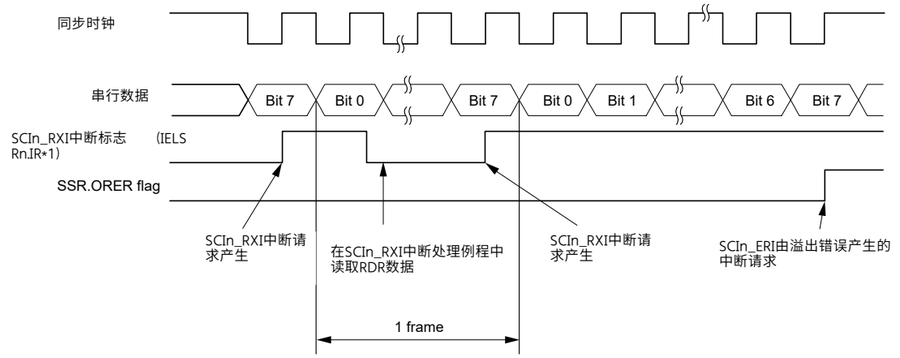
Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 27.69 Example operation for serial reception in clock synchronous mode (2) when RTS function is used

Data transfer cannot resume while the receive error flag is 1. Therefore, clear the ORER, FER, and PER flags in the SSR register to 0 before resuming data reception. Additionally, always read the RDR register during overrun error processing. When a data reception is forced to terminate by a 0 write to the SCR.RE bit during operation, read the RDR register because received data that is not yet read might be left in the RDR register.

4.当接收成功完成时，接收数据被传送到RDR寄存器。如果SCR.RIE位为1，则SCIn_RXI中断请求产生。连续接收是通过读取接收到的数据传输到在接收下一个接收数据完成之前，SCIn_RXI中断处理程序中的RDR寄存器。读取传输到RDR的接收数据会导致CTSn_RTSn引脚输出低电平。



注1.有关相应中断事件编号的信息，请参见第13节，中断控制器单元(ICU)。

注1.有关相应中断事件编号的信息，请参见第13节，中断控制器单元(ICU)。

Figure 27.69 使用RTS功能时时钟同步模式下串行接收的示例操作(2)

接收错误标志为1时无法恢复数据传输。因此，在恢复数据接收之前，将SSR寄存器中的ORER、FER和PER标志清除为0。此外，在溢出错误处理期间始终读取RDR寄存器。如果在操作期间通过向SCR.RE位写入0来强制终止数据接收，请读取RDR寄存器，因为尚未读取的已接收数据可能会留在RDR寄存器中。

(2) FIFO selected

Figure 27.71 shows an example of serial reception in clock synchronous mode with FIFO selected.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.

(2)选择FIFO图27.71显示了在时钟同步模式下选择FIFO的串行接收示例。

在串行数据接收中，SCI操作如下：

1.当SCR.RE位的值变为1时，CTSn_RTSn引脚变为低电平。

2.SCI执行内部初始化，并与同步时钟输入或输出同步开始接收数据，并将接收数据存储在RSR寄存器中。

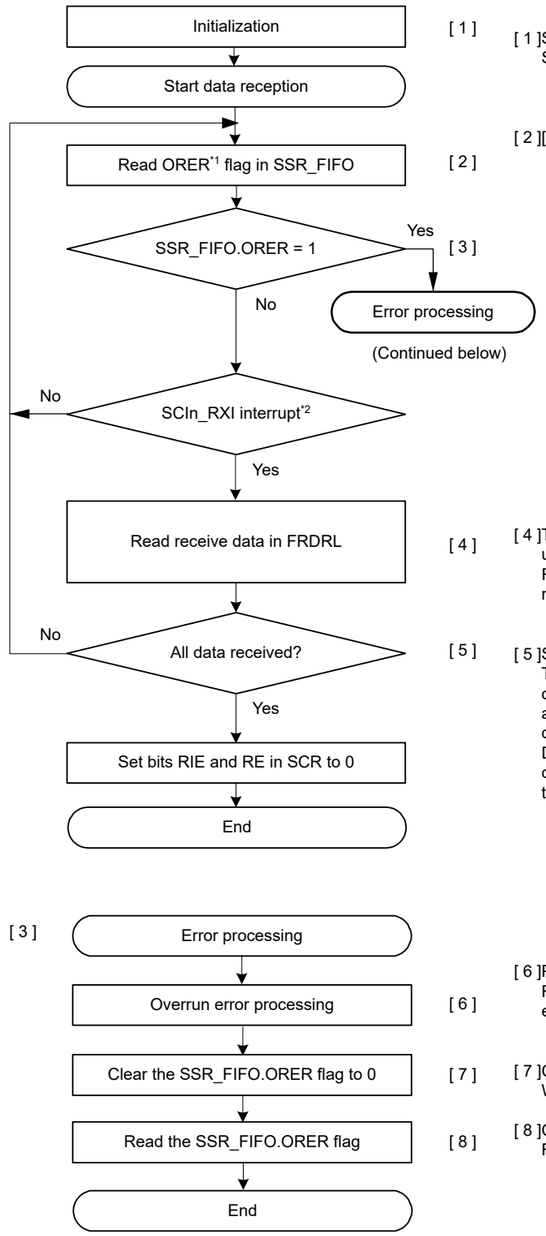
3. If an overrun error occurs, the SSR_FIFO.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Received data is not transferred to the FRDRL[*1] register.
4. When data reception completes successfully, the receive data is transferred to the FRDRL[*1] register. The RDF flag is set to 1 when the amount of the receive data stored in FRDRL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous data reception is enabled by reading the receive data transferred to FRDRL[*2] in the SCIn_RXI interrupt handling routine before an overrun error occurs. If the amount of received data that is transferred to FRDRL is less than the specified receive triggering number, the CTSn_RTSn pin goes low.

Note 1. In clock synchronous mode, FRDRH is not used.
Note 2. Read data in order from FRDRH to FRDRL when RDF and ORER are read with receive data.

3.如果发生溢出错误，则SSR_FIFO.ORER标志设置为1。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。接收到的数据不传送到FRDRL*1寄存器。

4.当数据接收成功完成时，接收数据被传送到FRDRL*1寄存器。当存储在FRDRL中的接收数据量等于或大于指定的接收触发数时，RDF标志设置为1。如果SCR.RIE位为1，则产生SCIn_RXI中断请求。在发生溢出错误之前，通过在SCIn_RXI中断处理程序中读取传输到FRDRL*2的接收数据来启用连续数据接收。如果传输到FRDRL的接收数据量小于指定的接收触发数，则CTSn_RTSn引脚变为低电平。

注1.在时钟同步模式下，不使用FRDRH。
注2.RDF和ORER与接收数据一起读取时，按FRDRH到FRDRL的顺序读取数据。



[1]SCI initialization:
Set the input port for pins to be used as RXDn pins.

[2][3]Receive error processing:
If a receive error occurs, read the ORER flag in SSR_FIFO, perform the relevant error processing, then set the SSR_FIFO.ORER flag to 0. Data reception cannot resume while the ORER flag is 1.

[4]The receive data stored in FRDRL register is read until the amount of stored data is less than the FCR.RTRG[3:0] value. Software can check readable data in FDR.R[4:0].

[5]Serial reception continuation procedure:
To continue serial reception, before overrun error occurs, finish reading the receive data in FRDRL and clear the SSR_FIFO.RDF flag to 0.The FRDRL data can also be read by activating the DMAC or DTC by an SCIn_RXI interrupt request. The RDF flag is cleared automatically in this case. Do not write to the RDF flag.

[6]Processing in response to an overrun error:
Read the FRDRL. In combination with step [7], this enables correct reception of the next frame possible.

[7]Clearing the error flag:
Write 0 to the error flag.

[8]Confirming that the error flag is cleared:
Read the error flag to confirm that its value is 0.

Note 1. It can also be read from FRDRH.ORER. However, to clear the ORER flag, write 0 to the associated bit in the SSR_FIFO register.
Note 2. It should be all receive data and is an integer times the FIFO triggering number.

27.6.6 Simultaneous Serial Data Transmission and Reception in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 27.72 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode. After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.

To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data transmission by verifying that the SSR.TEND flag is set to 1.
2. Initialize the SCR register, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

2. Set the RIE and RE bits to 0, and then check that the receive error flag ORER in the SSR register is 0.
3. Set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

[2] Transmit data write:

[5] Serial transmission/reception continuation procedure:
To continue serial reception, before overrun error occurs, finish reading the receive data in FRDRL and clear the SSR_FIFO.RDF flag to 0. To continue serial transmission, before transmission of the current transmit data is finished, write the next transmit data to FTDRL in the SCIn_TXI interrupthandling routine and clear the SSR_FIFO.TDFE flag to 0.

[2] 发送数据写入：
在SCIn_TXI中断请求处理例程中将发送数据写入FTDRL。可写入的发送数据个数为16位，即FIFO中存储的发送数据个数。

27.7 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

27.7.1 Example Connection

Figure 27.74 shows an example connection between a smart card (IC card) and the MCU. As shown in Figure 27.74, because the MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

Setting the SCR_SMCI.TE and SCR_SMCI.RE bits to 1 with an IC card disconnected enables closed-loop transmission or reception, allowing self-diagnosis. To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.

An output port of the MCU can be used to output a reset signal.

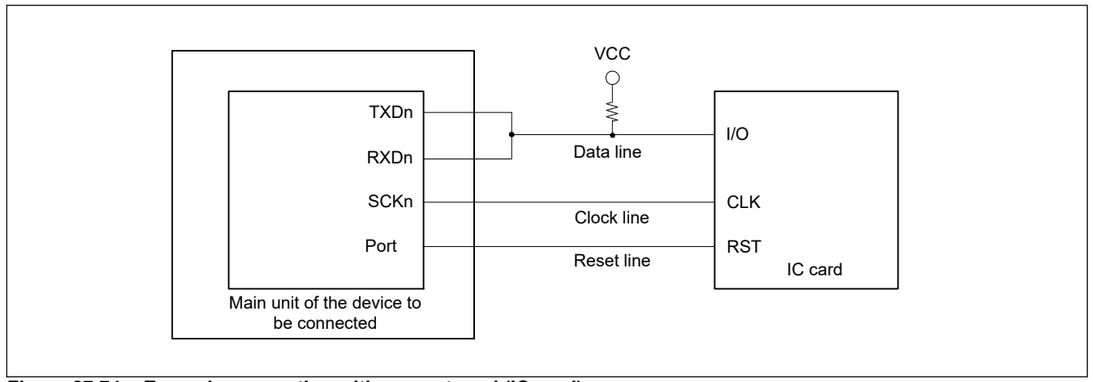

Figure 27.74 Example connection with a smart card (IC card)

27.7.2 Data Format (Except in Block Transfer Mode)

Figure 27.75 shows the data transfer formats in smart card interface mode:

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 ETUs (elementary time unit – the time required for transferring 1 bit) is set as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low error signal is output for 1 ETU after 10.5 ETUs elapse from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 ETUs.

27.7 智能卡接口模式下的操作

SCI支持符合ISOIEC7816-3（识别卡标准）的智能卡（IC卡）接口，作为SCI的扩展功能。

可以使用适当的寄存器选择智能卡接口模式。

27.7.1 示例连接

图27.74显示了智能卡（IC卡）和MCU之间的示例连接。如图27.74所示，由于MCU使用单条传输线与IC卡通信，因此将TXDn和RXDn引脚互连，并使用电阻将数据传输线上拉到VCC。

在断开IC卡的情况下将SCR_SMCI.TE和SCR_SMCI.RE位设置为1可启用闭环发送或接收，从而实现自诊断。要将SCI产生的时钟脉冲提供给IC卡，请将SCKn引脚输出输入到IC卡的CLK引脚。

MCU的输出端口可用于输出复位信号。

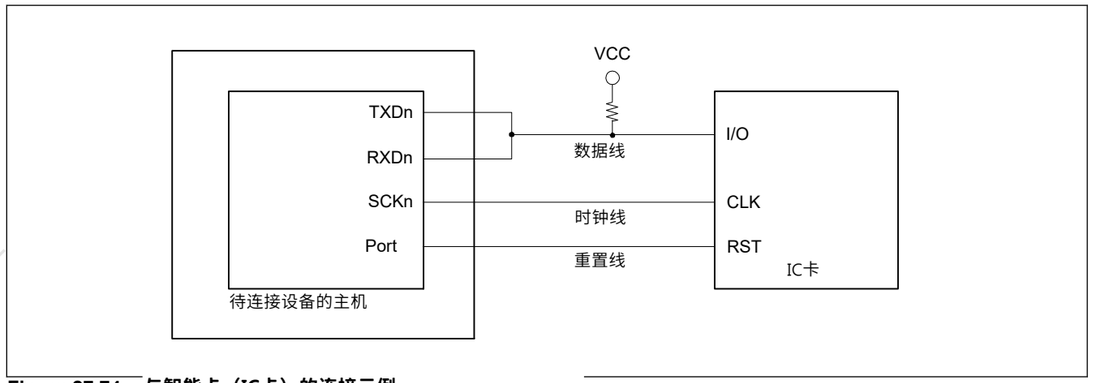

Figure 27.74 与智能卡（IC卡）的连接示例

27.7.2 数据格式（块传输模式除外）

图27.75显示了智能卡接口模式下的数据传输格式：

●一帧由8位数据和一个异步模式的奇偶校验位组成。

●在传输过程中，至少设置2个ETU（基本时间单位——传输1位所需的时间）作为从奇偶校验位结束到下一帧开始的保护时间。

●如果在接收过程中检测到奇偶校验错误，则在从起始位经过10.5ETU后输出1ETU的低错误信号。

●如果在传输过程中对错误信号进行采样，相同的数据会在至少2个ETU后自动重传。

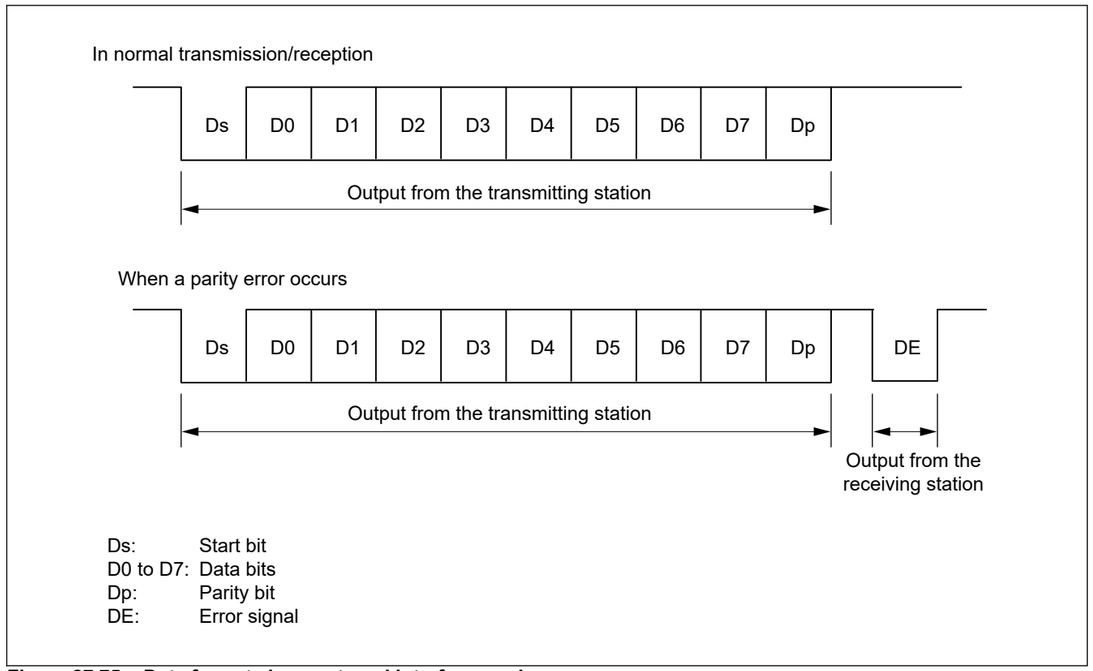

Figure 27.75 Data formats in smart card interface mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedures in this section.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 indicate the Z and A states, respectively, and data is transferred with LSB-first for the start character, as shown in Figure 27.76. Therefore, data in the start character in the figure is 0x3B.

When using the direct convention type, write 0 to both the SCMR.SDIR and SCMR.SINV bits. Write 0 to the SMR_SMCI.PM bit to use even parity, which is prescribed by the smart card standard.

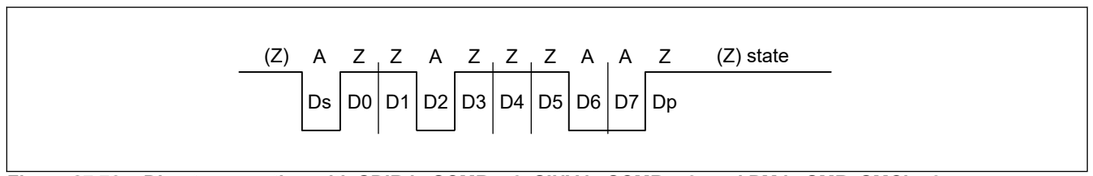

Figure 27.76 Direct convention with SDIR in SCMR = 0, SINV in SCMR = 0, and PM in SMR_SMCI = 0

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 indicate the A and Z states, respectively, and data is transferred with MSB-first for the start character, as shown in Figure 27.77. Therefore, data in the start character in the figure is 0x3F.

When using the inverse convention type, write 1 to both the SCMR.SDIR and SCMR.SINV bits. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to the Z state. Because the SINV bit of the MCU only inverts data bits D7 to D0, write 1 to the PM bit in SMR_SMCI to invert the parity bit for both transmission and reception.

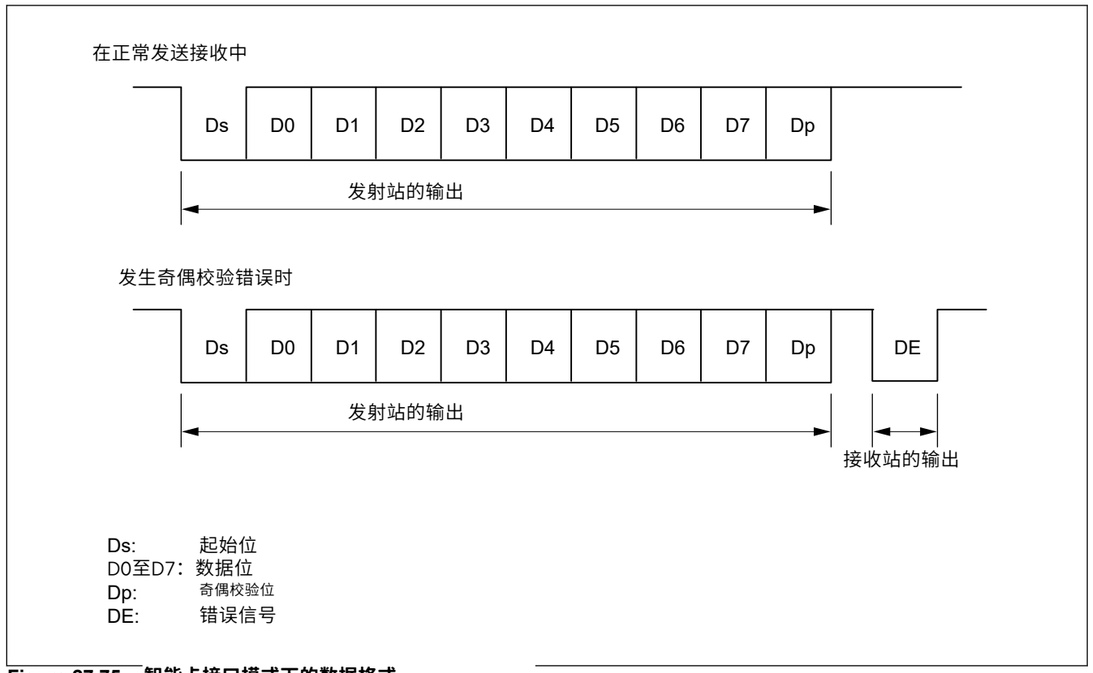

Figure 27.75 智能卡接口模式下的数据格式

与直接约定型和逆约定型IC卡进行通信时，请按照本节的步骤进行。

(1) 直接约定型

对于直接约定类型，逻辑电平1和0分别表示Z和A状态，数据通过LSB-first为起始字符，如图27.76所示。因此，图中起始字符中的数据为0x3B。

使用直接约定类型时，将0写入SCMR.SDIR和SCMR.SINV位。将0写入SMR_SMCI.PM位使用智能卡标准规定的偶校验。

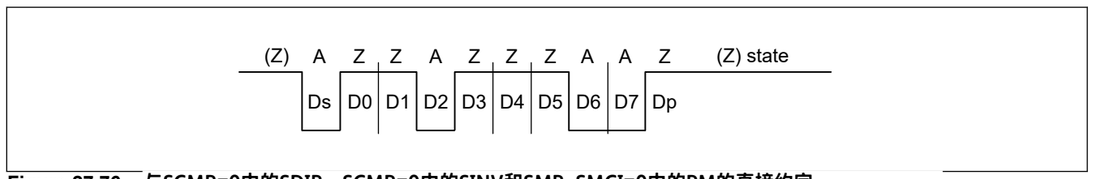

Figure 27.76 与SCMR=0中的SDIR、SCMR=0中的SINV和SMR_SMCI=0中的PM的直接约定

(2) 逆约定型

对于逆约定类型，逻辑电平1和0分别表示A和Z状态，数据通过MSB-first为起始字符，如图27.77所示。因此，图中起始字符中的数据为0x3F。

使用逆约定类型时，将1写入SCMR.SDIR和SCMR.SINV位。奇偶校验位为逻辑电平0，产生偶校验，这是智能卡标准规定的，对应于Z状态。由于MCU的SINV位仅将数据位D7反转为D0，因此向SMR_SMCI中的PM位写入1以反转发送和接收的奇偶校验位。

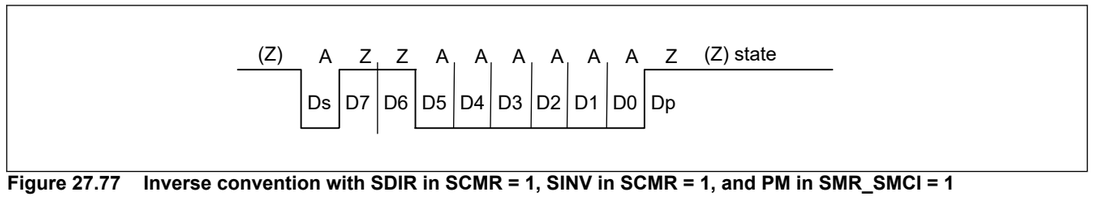

Figure 27.77 Inverse convention with SDIR in SCMR = 1, SINV in SCMR = 1, and PM in SMR_SMCI = 1

27.7.3 Block Transfer Mode

Block transfer mode differs from normal smart card interface mode as follows:

- Even if a parity error is detected during reception, no error signal is output. Because the PER flag in SSR_SMCI is set by error detection, clear the PER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 ETU is set as a guard time from the end of the parity bit until the start of the next frame
- Because the same data is not retransmitted, the TEND flag in SSR_SMCI is set to 11.5 ETUs after transmission starts
- In block transfer mode, the ERS flag in SSR_SMCI indicates the error signal status as in normal smart card interface mode, but the flag is read as 0 because no error signal is transferred

27.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate set up in the SCMR.BCP2 and the SMR_SMCI.BCP[1:0] bits. The frequency is always 16 times the bit rate in normal asynchronous mode.

For data reception, the falling edge of the start bit is sampled with the base clock to perform internal synchronization. Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 27.78. The reception margin is determined by the following formula:

$$M = \left|(0.5 - \frac{1}{2N}) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%]$$

M: Reception margin (%)

N: Ratio of bit rate to clock ($N = 32, 64, 372, 256$)

D: Duty cycle of clock ($D = 0$ to 1.0)

L: Frame length ($L = 10$)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the specified formula, the reception margin is determined using the following formula:

$$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\ \%$$

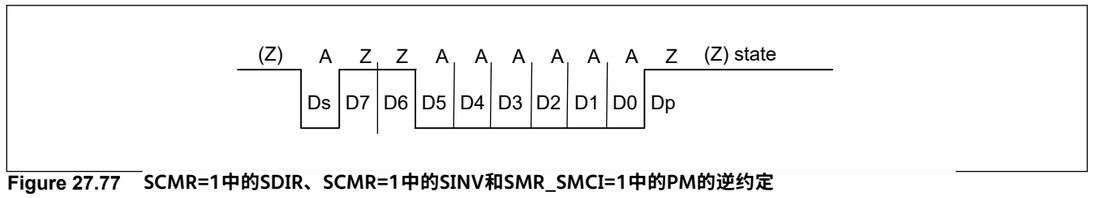

Figure 27.77 SCMR=1中的SDIR、SCMR=1中的SINV和SMR_SMCI=1中的PM的逆约定

27.7.3 块传输模式

块传输模式与普通智能卡接口模式的区别如下：

●即使在接收过程中检测到奇偶校验错误，也不会输出错误信号。因为SSR_SMCI中的PER标志是由错误检测设置的，所以在接收下一帧的奇偶校验位之前清除PER标志。

●在传输过程中，从奇偶校验位结束到下一帧开始至少设置1个ETU作为保护时间

●由于没有重传相同的数据，所以在传输开始后，SSR_SMCI中的TEND标志设置为11.5ETU

●在块传输模式下，SSR_SMCI中的ERS 标志指示错误信号状态，与普通智能卡接口模式一样，但该标志被读取为0，因为没有传输错误信号

27.7.4 接收数据采样时序和接收裕量

只有片内波特率发生器产生的内部时钟可以用作智能卡接口模式下的传输时钟。

在这种模式下，SCI可以在频率为SCMR.BCP2和SMR_SMCI.BCP[1:0]位。在正常异步模式下，频率始终是比特率的16倍。

对于数据接收，起始位的下降沿用基准时钟进行采样，以进行内部同步。接收数据在基本时钟的第16、32、186、128、46、64、93和256个上升沿进行采样，以便在每个位的中间锁存，如图27.78所示。接收余量由以下公式确定：

$$M = \left|(0.5 - \frac{1}{2N}) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%]$$

M：接收余量（%）

N：比特率与时钟的比率（N=32、64、372、256）

D：时钟的占空比（D=0到1.0）

L：帧长（L=10）

F：时钟频率偏差的绝对值

假设指定公式中的F=0、D=0.5和N=372的值，则使用以下公式确定接收余量：

$$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\ \%$$

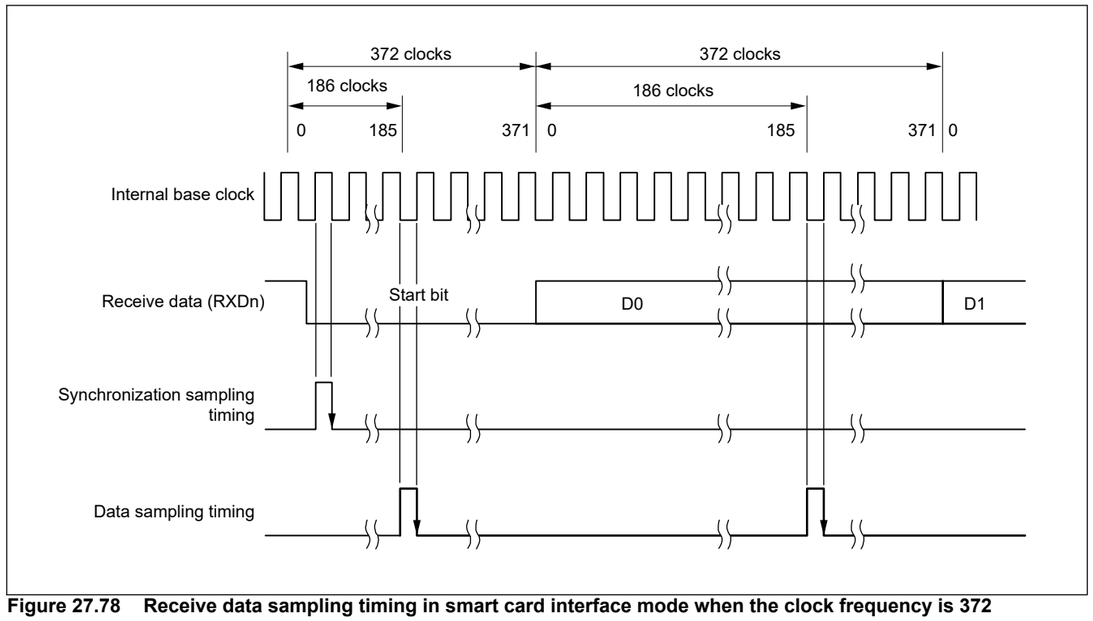

Figure 27.78 Receive data sampling timing in smart card interface mode when the clock frequency is 372 times the bit rate

27.7.5 SCI Initialization (Smart Card Interface Mode)

Before transmitting and receiving data, write the initial value 0x00 in the SCR_SMCI register and initialize the SCI following the example flow shown in Table 27.37.

Always set the initial value in the TIE, RIE, TE, RE, TEIE bits in the SCR_SMCI register before switching from transmission to reception mode or from reception to transmission mode. When SCR_SMCI.RE is set to 0, the RDR register is not initialized.

To change from reception mode to transmission mode, first check that reception has completed, then initialize the SCI. At the end of initialization, set SCR_SMCI.TE = 1 and SCR_SMCI.RE = 0. Reception completion can be verified by reading the SCIn_RXI request, ORER, or PER flag in SSR_SMCI.

To change transmission mode to reception mode, first check that transmission has completed, then initialize the SCI. At the end of initialization, set SCR_SMCI.TE = 0 and SCR_SMCI.RE = 1. Transmission completion can be verified by reading the TEND flag in SSR_SMCI.

27.7.5 SCI初始化（智能卡接口模式）

在发送和接收数据之前，将初始值0x00写入SCR_SMCI寄存器并按照表27.37所示的示例流程初始化SCI。

在从发送模式切换到接收模式或从接收模式切换到发送模式之前，请务必在SCR_SMCI寄存器中的TIE、RIE、TE、RE、TEIE位中设置初始值。当SCR_SMCI.RE设置为0时，RDR寄存器未初始化。

要从接收模式更改为发送模式，首先检查接收是否完成，然后初始化SCI。在初始化结束时，设置SCR_SMCI.TE=1和SCR_SMCI.RE=0。可以通过读取SSR_SMCI中的SCIn_RXI请求、ORER或PER标志来验证接收完成。

要将传输模式更改为接收模式，首先检查传输是否完成，然后初始化SCI。在初始化结束时，设置SCR_SMCI.TE=0和SCR_SMCI.RE=1。可以通过读取SSR_SMCI中的TEND标志来验证传输完成。

27.7.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode) is different from that in non-smart card interface mode, in that an error signal is sampled and data can be re-transmitted in smart card mode. Figure 27.79 shows the data re-transfer operation during transmission.

1. When an error signal from the receiver end is sampled after 1-frame data is transmitted, the SSR_SMCI.ERS flag is set to 1. If the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
2. For a frame in which an error signal is received, the SSR_SMCI.TEND flag is not set. Data is re-transferred from TDR to TSR, allowing automatic data retransmission.
3. If no error signal is returned from the receiver, the ERS flag is not set to 1.
4. In this case, the SCI determines that transmission of 1-frame data, including the re-transfer, is complete, and the TEND flag is set. If the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated. Write transmit data to the TDR to start transmission of the next data.

Figure 27.81 shows an example flow of serial transmission. All the processing steps are automatically performed using an SCIn_TXI interrupt request to activate the DTC or DMAC.

When the SSR_SMCI.TEND flag is set to 1 in transmission and when the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated.

The DTC or DMAC is activated by an SCIn_TXI interrupt request if the SCIn_TXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission when an error occurs. Because the ERS flag is not automatically cleared, set the RIE bit to 1 before enabling an SCIn_ERI interrupt request to be generated if an error occurs, and clear the ERS flag to 0.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings.

For DTC or DMAC settings, see section 17, Data Transfer Controller (DTC), section 16, DMA Controller (DMAC).

27.7.6 串行数据传输（块传输模式除外）

智能卡接口模式下的串行数据传输（块传输模式除外）与非智能卡接口模式下的串行数据传输不同之处在于，在智能卡模式下对错误信号进行采样，数据可以重新传输。图27.79显示了传输过程中的数据重传操作。

1.发送1帧数据后，当从接收端采样到错误信号时，SSR_SMCI.ERS标志置1。如果SCR_SMCI.RIE位为1，则产生SCIn_ERI中断请求。在采样下一个奇偶校验位之前将ERS 标志清零。

2.对于接收到错误信号的帧，不设置SSR_SMCI.TEND标志。数据从TDR重新传输到TSR，允许自动数据重新传输。

3.如果接收器没有返回错误信号，则ERS 标志不设置为1。

4.在这种情况下，SCI确定1帧数据的传输（包括重新传输）已完成，并设置TEND标志。如果SCR_SMCI.TIE位为1，则产生SCIn_TXI中断请求。将传输数据写入TDR以开始传输下一个数据。

图27.81显示了串行传输的示例流程。所有处理步骤都使用一个自动执行SCIn_TXI中断请求以激活DTC或DMAC。

当发送中SSR_SMCI.TEND标志设置为1且SCR_SMCI.TIE位为1时，将产生SCIn_TXI中断请求。

如果SCIn_TXI中断请求先前被指定为DTC或DMAC激活源，则DTC或DMAC由SCIn_TXI中断请求激活，从而允许传输数据。当DTC或DMAC传输数据时，TEND标志自动设置为0。

如果发生错误，SCI会自动重新传输相同的数据。在此重传期间，TEND标志保持为0，并且DTC或DMAC未激活。因此，SCI和DTC或DMAC会自动传输指定的字节数，包括发生错误时的重传。因为ERS 标志不会自动清零，所以如果发生错误，在使能SCIn_ERI中断请求之前将RIE位设置为1，并将ERS 标志清零。

使用DTC或DMAC发送或接收数据时，请务必在进行SCI设置之前启用DTC或DMAC。

对于DTC或DMAC设置，请参阅第17节，数据传输控制器(DTC)，第16节，DMA控制器(DMAC)。

27.7.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 27.82 shows the data re-transfer operation in reception mode.

1. If a parity error is detected in the receive data, the SSR_SMCI.PER flag is set to 1. When the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no SCIn_RXI interrupt is generated.
3. When no parity error is detected, the SCR_SMCI.PER flag is not set to 1.
4. In this case, data is determined to be received successfully. When the SCR_SMCI.RIE bit is 1, an SCIn_RXI interrupt request is generated.

Figure 27.83 shows an example flow of serial data reception. All the processing steps are automatically performed using an SCIn_RXI interrupt request to activate the DTC or DMAC.

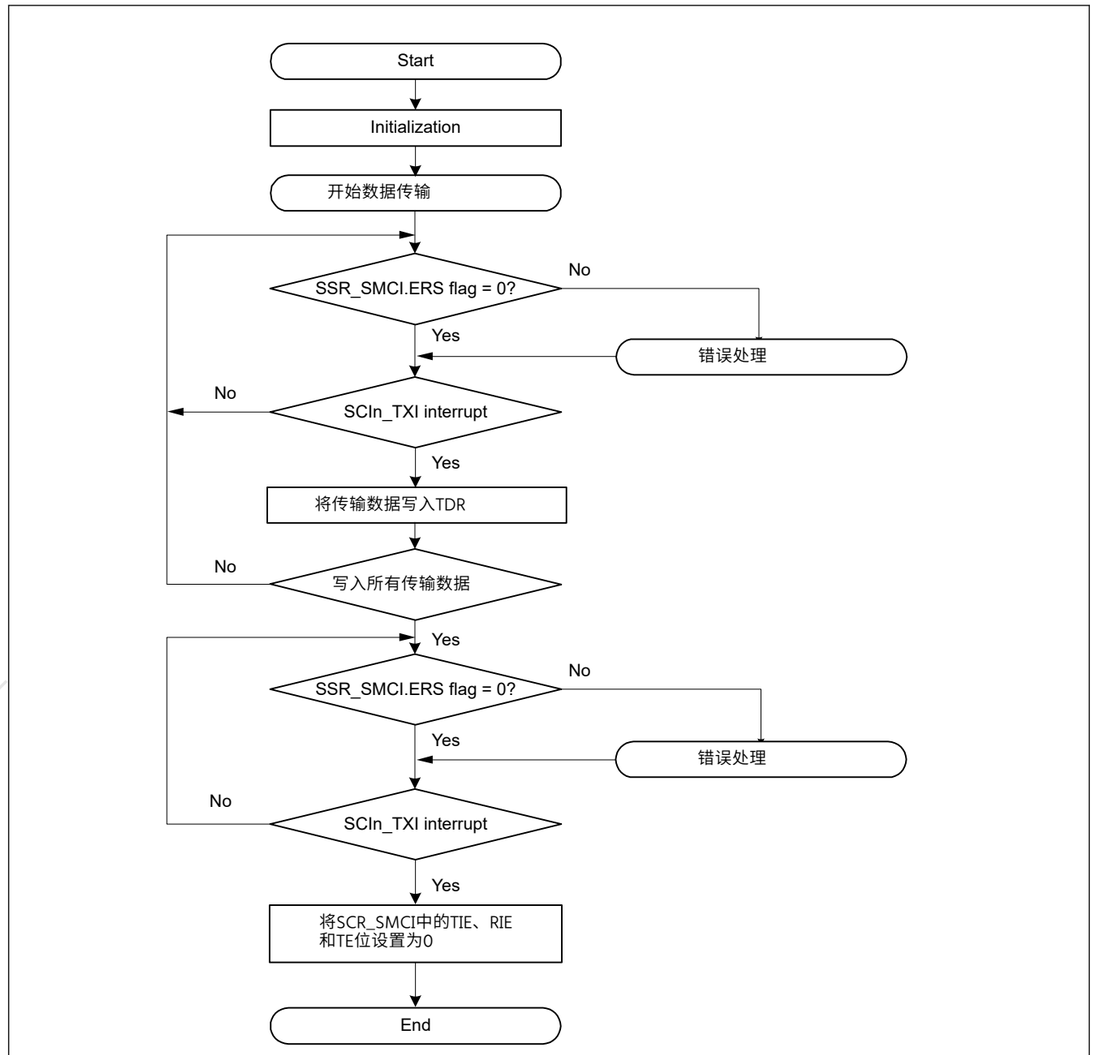

Figure 27.81 智能卡接口传输示例流程

27.7.7 串行数据接收（块传输模式除外）

智能卡接口模式下的串行数据接收与非智能卡接口模式下的串行数据接收类似。图27.82显示了接收模式下的数据重传操作。

1.如果在接收数据中检测到奇偶校验错误，则SSR_SMCI.PER标志设置为1。当SCR_SMCI.RIE位为1时，产生SCIn_ERI中断请求。在采样下一个奇偶校验位之前将PER标志清零。

2.对于检测到奇偶校验错误的帧，不产生SCIn_RXI中断。

3.未检测到奇偶校验错误时，SCR_SMCI.PER标志不设置为1。

4、在这种情况下，确定数据接收成功。当SCR_SMCI.RIE位为1时，产生SCIn_RXI中断请求。

图27.83显示了串行数据接收的示例流程。所有处理步骤都使用一个自动执行SCIn_RXI中断请求以激活DTC或DMAC。

In reception, setting the RIE bit to 1 allows an SCIn_RXI interrupt request to be generated. The DTC or DMAC is activated by an SCIn_RXI interrupt request if the SCIn_RXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in SSR_SMCI is set to 1, a receive error interrupt (SCIn_ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.

If a parity error occurs and the PER flag is set to 1 during reception, the receive data is transferred to RDR, allowing the data to be read.

When a reception is forced to terminate by setting SCR_SMCI.RE to 0 during operation, read the RDR register because the received data that is not yet read might be left in the RDR.

Note: For operations in block transfer mode, see section 27.3.9. Serial Data Reception in Asynchronous Mode.

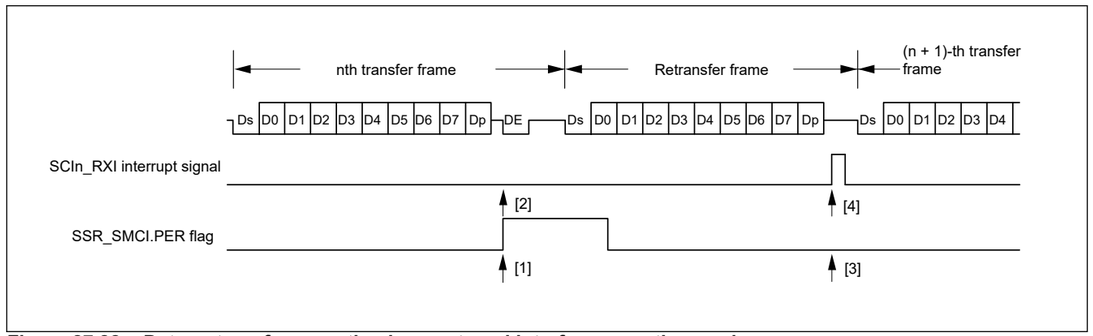

Figure 27.82 Data re-transfer operation in smart card interface reception mode

在接收时，将RIE位设置为1允许产生SCIn_RXI中断请求。如果SCIn_RXI中断请求先前被指定为DTC或DMAC激活源，则DTC或DMAC由SCIn_RXI中断请求激活，从而允许传输接收数据。

如果接收期间发生错误并且SSR_SMCI中的ORER或PER标志设置为1，则会生成接收错误中断(SCIn_ERI)请求。错误发生后清除错误标志。如果发生错误，则不会激活DTC或DMAC并跳过接收数据。因此，将传输DTC或DMAC中指定的接收数据字节数。

如果在接收过程中发生奇偶校验错误并且PER标志设置为1，则接收数据将传输到RDR，从而可以读取数据。

如果在操作期间通过将SCR_SMCI.RE设置为0来强制终止接收，请读取RDR寄存器，因为尚未读取的已接收数据可能留在RDR中。

Note: 关于块传输模式下的操作，请参见第27.3.9节。异步模式下的串行数据接收。

27.7.8 Clock Output Control

When the GM bit in SMR_SMCI is set to 1, the clock output can be controlled by the CKE[1:0] bits in SCR_SMCI. For details on the CKE[1:0] bits, see section 27.2.14. SCR_SMCI : Serial Control Register for Smart Card Interface Mode (SCMR.SMIF = 1). When setting the clock output, the base clock described in section 27.7.4. Receive Data Sampling Timing and Reception Margin is applied.

Figure 27.84 shows an example timing for the clock output control when the CKE[1] bit in SCR_SMCI is set to 0 and the CKE[0] bit in SCR_SMCI is controlled.

When the GM bit in SMR_SMCI is 0, output control by the CKE[0] bit in SCR_SMCI is immediately reflected on the SCKn pin, so there is a possibility that pulses with an unintended width may be output from the SCKn pin.

When the GM bit in SMR_SMCI is 1, the clock with the same pulse width as the base clock is output even if the CKE[0] bit in SCR_SMCI is changed.

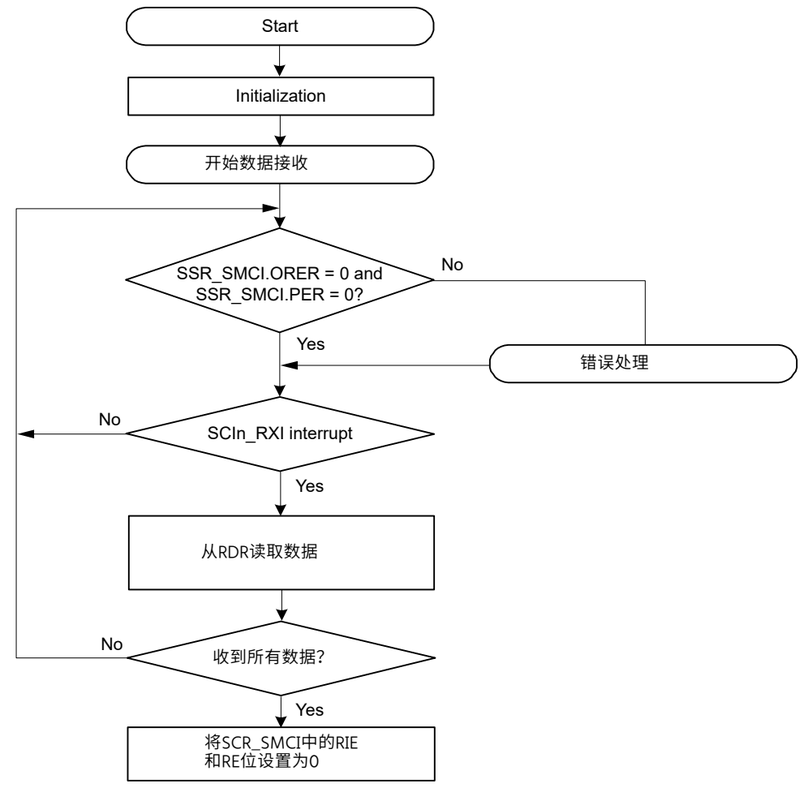

Figure 27.83 智能卡接口接收示例流程

27.7.8 时钟输出控制

当SMR_SMCI中的GM位设置为1时，时钟输出可以由SCR_SMCI中的CKE[1:0]位控制。有关CKE[1:0]位的详细信息，请参见第27.2.14节。SCR_SMCI：智能卡接口模式的串行控制寄存器(SCMR.SMIF=1)。设置时钟输出时，使用第27.7.4节中描述的基本时钟。应用接收数据采样时序和接收裕度。

图27.84显示了当SCR_SMCI中的CKE[1]位设置为0且控制SCR_SMCI中的CKE[0]位。

当SMR_SMCI中的GM位为0时，SCR_SMCI中CKE[0]位的输出控制立即反映在SCKn引脚，因此有可能会从SCKn引脚输出具有意外宽度的脉冲。

当SMR_SMCI中的GM位为1时，即使SCR_SMCI中的CKE[0]位发生变化，也会输出与基本时钟脉冲宽度相同的时钟。

27.8 Operation in Simple IIC Mode

Simple IIC mode format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device can specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8 data bits in all frames are transmitted in order from the MSB.

The I^2C bus format and timing of the I^2C bus are shown in Figure 27.85 and Figure 27.86.

27.8 简单IIC模式下的操作

简单IIC模式格式由8个数据位和一个确认位组成。通过在启动条件或重新启动条件之后继续进入从地址帧，主设备可以指定从设备作为通信伙伴。当前指定的从设备保持有效，直到指定新的从设备或满足停止条件。所有帧中的8个数据位从MSB开始按顺序传输。

I2C总线格式和I2C总线时序如图27.85和图27.86所示。

27.8.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the SIMR3.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept in the released state
- The hold time for the start condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the IICSTAREQ bit in SIMR3 is set to 0, and a start-condition generated interrupt is output

Writing 1 to the IICRSTAREQ bit in SIMR3 causes the generation of a restart condition. The generation of a restart condition proceeds through the following operations:

- The SDAn line is released and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SDAn line falls (from the high level to the low level)
- The hold time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the SIMR3.IICRSTAREQ bit is set to 0, and a restart-condition generated interrupt is output

Writing 1 to the SIMR3.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)

27.8.1 启动、重启和停止条件的生成

将1写入SIMR3.IICSTAREQ位会导致产生启动条件。开始条件的生成通过以下操作进行：

●SDAn线上的电平下降（从高电平到低电平），SCLn线保持在释放状态

●开始条件的保持时间设置为比特周期的一半，比特率由BRR设置确定

●SCLn线上的电平下降（从高电平到低电平），SIMR3中的IICSTAREQ位设置为0，并输出一个起始条件产生的中断

将1写入SIMR3中的IICRSTAREQ位会导致产生重启条件。重新启动条件的生成通过以下操作进行：

●SDAn线释放，SCLn线保持低电平

●SCLn线的低电平周期设置为比特周期的一半，比特率由BRR设置确定

●SCLn线被释放（由低电平转变为高电平）

●当在SCLn线上检测到高电平时，重新启动条件的建立时间设置为BRR设置确定的比特率的半个比特周期

●SDAn线上的电平下降（从高电平到低电平）

●重启条件的保持时间设置为比特周期的一半，比特率由BRR设置确定

●SCLn线上的电平下降（从高电平变为低电平），SIMR3.IICRSTAREQ位设置为0，并输出重启条件产生的中断

将1写入SIMR3.IICSTPREQ位会导致产生停止条件。停止条件的生成通过以下操作进行：

●SDAn线上的电平下降（从高电平到低电平），SCLn线保持在低电平

●SCLn线的低电平周期设置为比特周期的一半，比特率由BRR设置确定

●SCLn线被释放（由低电平转变为高电平）

- When a high level is detected on the SCLn line, the setup time for the stop condition is set as half of a bit period at the bit rate determined by the BRR setting
- The SDAn line is released (transition from the low to the high level), the SIMR3.IICSTPREQ bit is set to 0, and a stop-condition generated interrupt is output

Figure 27.87 shows the timing of operations in the generation of start, restart, and stop conditions.

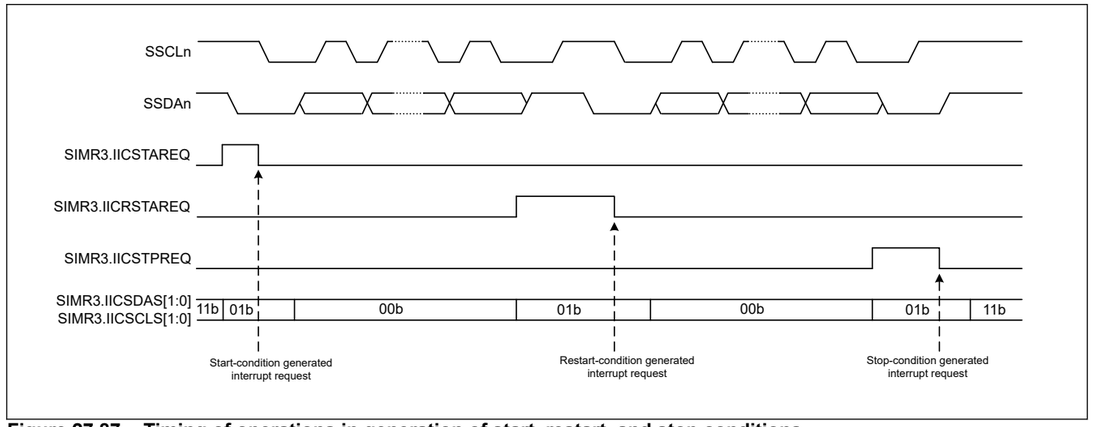

Figure 27.87 Timing of operations in generation of start, restart, and stop conditions

27.8.2 Clock Synchronization

The SCLn line can be driven low if a wait is inserted by a slave device at the other side of the transfer. Setting the SIMR2.IICCSC bit to 1 applies control to obtain synchronization when a difference arises between the levels of the internal SCLn clock signal and the level being input on the SCLn pin.

When the SIMR2.IICCSC bit is set to 1, the level of the internal SCLn clock signal changes from low to high. Counting to determine the period at a high level stops while the low level is being input on the SCLn pin. Counting to determine the period at a high level starts after the transition of the input on the SCLn pin to the high level.

The interval from this time until counting to determine the period at high level starts on the transition of the SCLn pin to the high level, is the total of the delay of SCLn output, delay for noise filtering of the input on the SCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLK). The period at high level of the internal SCLn clock is extended even when other devices do not place the low level on the SCLn line.

If the SIMR2.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SCLn pin and the internal SCLn clock. If the SIMR2.IICCSC bit is 0, synchronization with the internal SCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a wait period into the interval until the transition of the internal SCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a wait period after the transition of the internal SCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the waiting period, generation of the condition itself is not guaranteed.

Figure 27.88 shows an example operation for synchronizing the clocks.

●当在SCLn线上检测到高电平时，停止条件的建立时间设置为比特周期的一半，比特率由BRR设置确定

●SDAn线被释放（从低电平转换为高电平），SIMR3.IICSTPREQ位设置为0，并输出停止条件生成中断

图27.87显示了生成启动、重启和停止条件的操作时序。

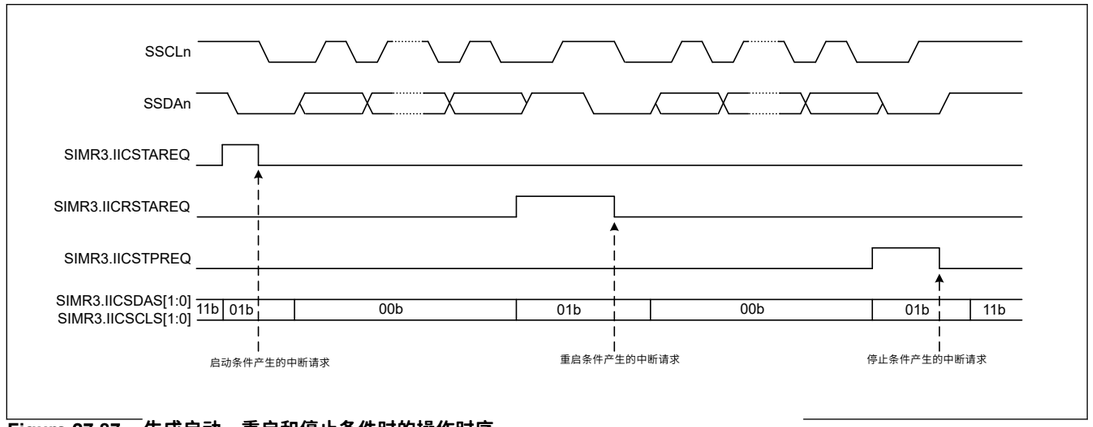

Figure 27.87 生成启动、重启和停止条件时的操作时序

27.8.2 时钟同步

如果从设备在传输的另一侧插入等待，则可以将SCLn线驱动为低电平。设置当内部电平之间出现差异时，SIMR2.IICCSC位为1应用控制以获得同步SCLn时钟信号和输入到SCLn引脚的电平。

当SIMR2.IICCSC位设置为1时，内部SCLn时钟信号的电平由低变为高。当SCLn引脚输入低电平时，停止计数以确定高电平周期。在SCLn引脚上的输入转换为高电平后，开始计数以确定高电平的周期。

从这个时间到从SCLn引脚转换为高电平开始计数确定高电平周期的时间间隔是SCLn输出延迟的总和，SCLn引脚上输入的噪声过滤延迟（2或3个周期的采样时钟用于噪声滤波器），以及延迟用于内部处理（1或2个PCLK周期）。即使其他设备没有将低电平置于SCLn线上，内部SCLn时钟的高电平周期也会延长。

如果SIMR2.IICCSC位为1，则通过取逻辑数据的发送和接收来获得同步
SCLn引脚上的输入与内部SCLn时钟的与。如果SIMR2.IICCSC位为0，则与内部SCLn时钟同步以进行数据的发送和接收。

如果从设备在发出启动、重新启动或停止条件的生成请求后，在内部SCLn时钟信号从低电平转变为高电平之前的间隔中插入一个等待周期，则直到生成的时间为延长了那个时期。

如果从设备在内部SCLn时钟信号从低电平转变为高电平之后插入等待周期，尽管在不停止等待周期的情况下发出生成完成中断，但不能保证条件本身的生成。

图27.88显示了同步时钟的示例操作。

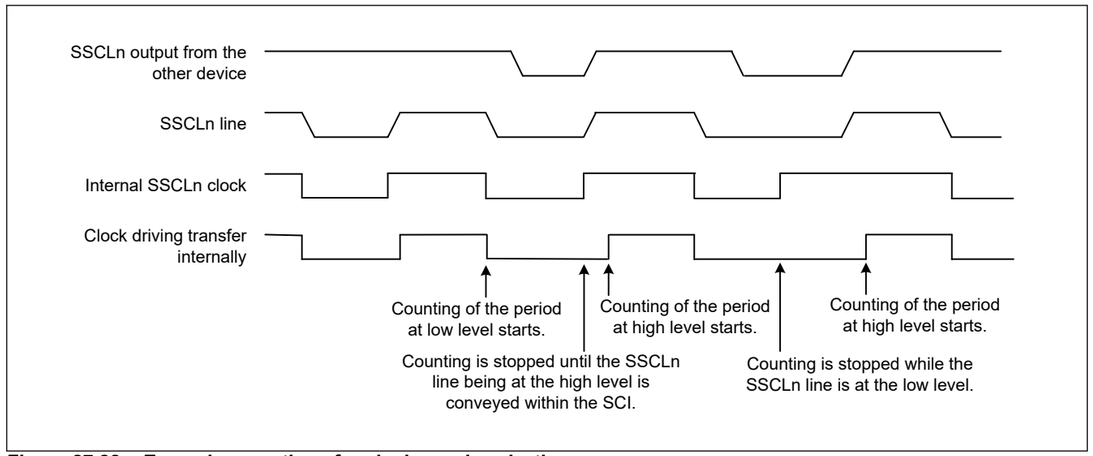

Figure 27.88 Example operations for clock synchronization

27.8.3 SDAn Output Delay

The SIMR1.IICDL[4:0] bits can be used to set a delay for output on the SDAn pin relative to falling edges of output on the SCLn pin. Delay settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, PCLK, by the divisor selected in the SMR.CKS[1:0] bits). A delay for output on the SDAn pin applies to the start condition/restart condition/stop condition signal, 8-bit transmit data, and acknowledge bit.

If the SDAn output delay is shorter than the time for the level on the SCLn pin to fall, the change of the output on the SDAn pin starts while the output level on the SCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SDAn pin specify times greater than the time output on the SCLn pin takes to fall (300 ns for IIC in normal mode and fast mode).

Figure 27.89 shows the timing of delays in SDAn output.

27.8.4 SCI Initialization in Simple IIC Mode

Before transferring data, write the initial value 0x00 to SCR and initialize the interface following the example shown in Table 27.38.

27.8.3 SDAn输出延迟

SIMR1.IICDL[4:0]位可用于设置SDAn引脚输出相对于输出下降沿的延迟。
SCLn引脚。从0到31的延迟设置是可选的，表示来自片上波特率发生器的时钟信号的相应周期数的周期（通过在SMR.CKS中选择的除数对基本时钟PCLK进行分频得出[1:0]位）。SDAn引脚上的输出延迟适用于启动条件重启条件停止条件信号、8位发送数据和确认位。

如果SDAn输出延迟小于SCLn引脚电平下降的时间，则SDAn引脚上的输出变化会在SCLn引脚上的输出电平下降时开始，从而产生从设备错误操作的可能性.确保SDAn引脚上的输出延迟设置指定的时间大于SCLn引脚上输出的下降时间（IIC在正常模式和快速模式下为300ns）。

图27.89显示了SDAn输出中的延迟时间。

Before making any changes to the operating mode or transfer format, be sure to set SCR to its initial value. In simple IIC mode, the open-drain setting for the communication ports should be made on the port side.

Figure 27.90 shows the operation example when SIMR2.IICINTM bit is 1 (use reception and transmission interrupts) and the value of the SCR.RIE bit is assumed to be 0 (SCIn_RXI and SCIn_ERI interrupt requests are disabled).

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.

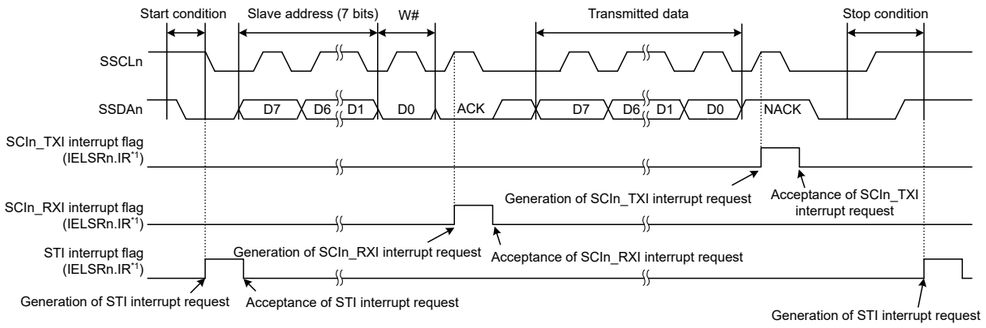
Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 27.90 Example 1 of operations for master transmission in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts

When the SIMR2.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and required number of data bytes are transmitted. When the NACK is received, error processing such as transmission stop and retransmission is performed using the NACK interrupt as the trigger.

To restart communication for some reason after writing data in the TDR register, use the following procedure:

1. Set the TE and RE bits in the SCR register to 0 to stop communication.
2. Set 0xF0 in the SIMR3 register, release the I^2C bus, and clear the generation of a condition.
3. If the RDRF flag in the SSR register is set to 1, clear it.
4. Set the TE and RE bits in the SCR register to 1 and start the next communication.



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

当在主机传输期间SIMR2.IICINTM位设置为0（使用ACKNACK中断）时，DTC或DMAC由ACK中断作为触发器激活并传输所需的数据字节数。接收到NACK时，以NACK中断为触发进行发送停止、重发等错误处理。

要在将数据写入TDR寄存器后出于某种原因重新启动通信，请使用以下过程：

1.将SCR寄存器中的TE和RE位设置为0以停止通信。

2.设置SIMR3寄存器中的0xF0，释放I2C总线，并清除条件的产生。

3.如果SSR寄存器中的RDRF标志设置为1，则清除它。

4.将SCR寄存器中的TE和RE位设置为1，开始下一次通信。

27.9 简单SPI模式下的操作

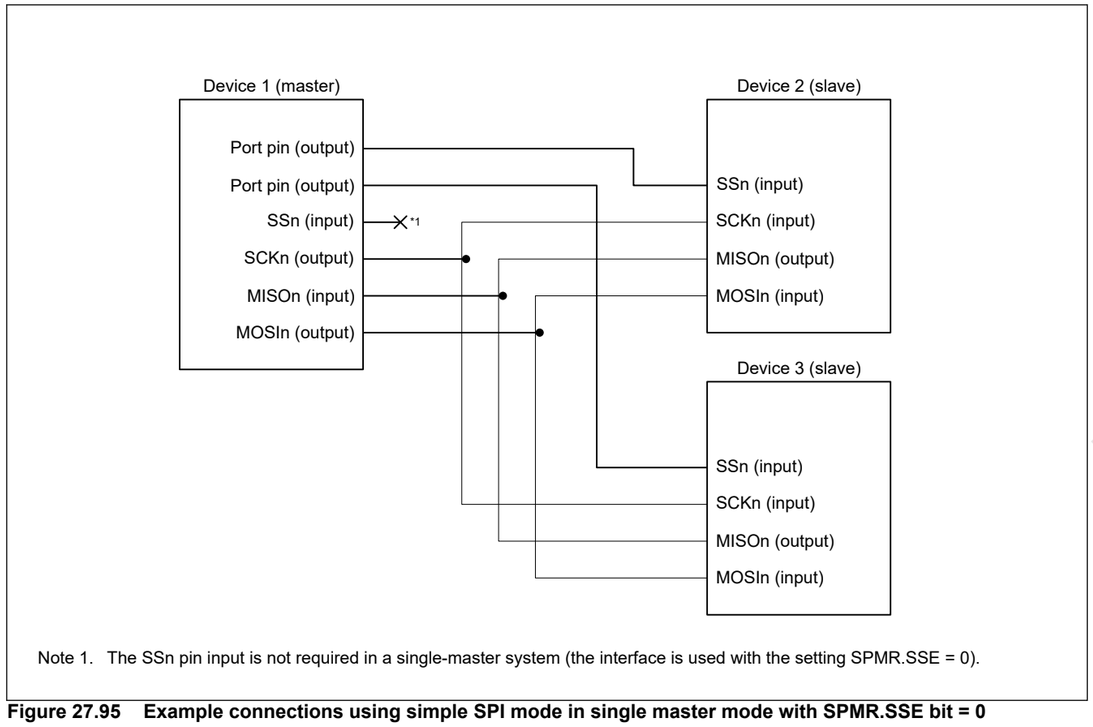
作为一项扩展功能，SCI支持简单的SPI模式，可处理一个或多个主设备与多个从设备之间的传输。

Using the settings for clock synchronous mode (SCMR.SMIF = 0, SIMR1.IICM = 0, SMR.CM = 1) and setting the SPMR.SSE bit to 1 place the SCI in simple SPI mode. However, the SSn pin function on the master side is not required for connection of the device used as the master in simple SPI mode when the configuration only has a single master. Therefore, set the SPMR.SSE bit to 0 in such cases.

Figure 27.95 shows an example of connections for simple SPI mode. Control a general port pin to produce the SSn output signal from the master.

In simple SPI mode, data is transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended. The data can be inverted by setting the SCMR.SINV bit to 1.

Because the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a shared clock signal. Additionally, because both the transmitter and receiver have a buffered structure, writing the next transmit data while transmission is in progress and reading previously received data while reception is in progress are both possible. This enables continuous transfer.



Note 1. The SSn pin input is not required in a single-master system (the interface is used with the setting SPMR.SSE = 0).

Figure 27.95 Example connections using simple SPI mode in single master mode with SPMR.SSE bit = 0

27.9.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (SCR.CKE[1:0] = 00b or 01b and SPMR.MSS = 0) or slave (SCR.CKE[1:0] = 10b or 11b and SPMR.MSS = 1).

Table 27.39 lists the relationship between the pin states, mode, and level on the SSn pin.

Table 27.39 States of pins by mode and input level on SSn pin (1 of 2)

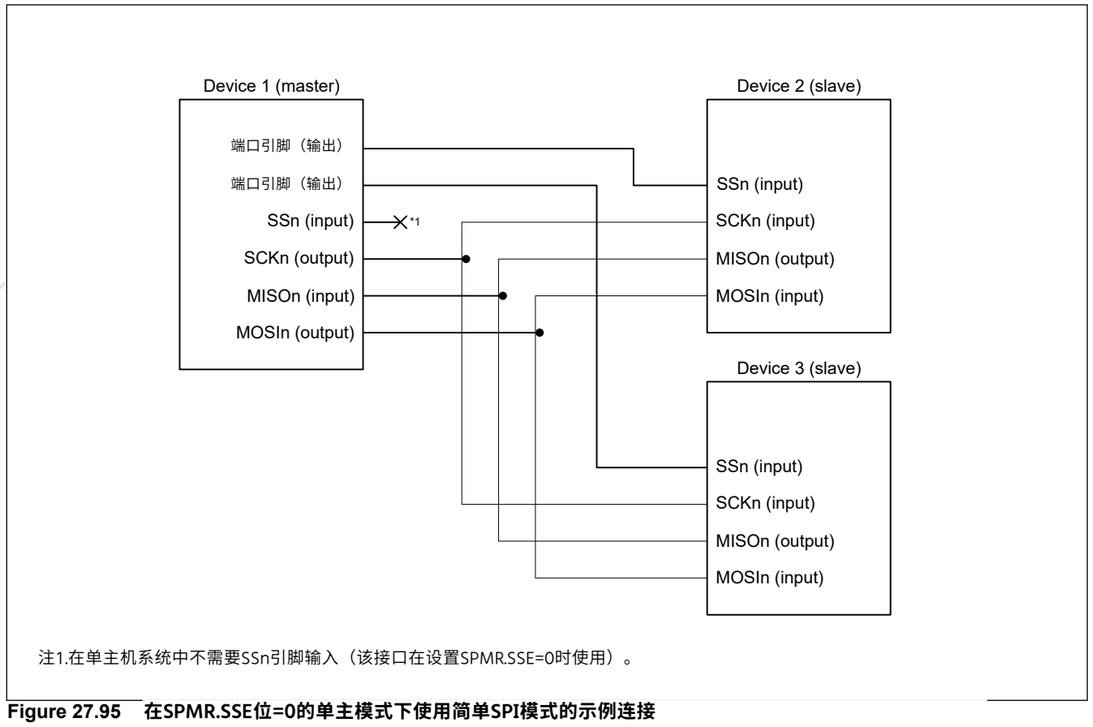
Mode	Input on SSn pin	State of MOSIn pin	State of MISOn pin	State of SCKn pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance

使用时钟同步模式的设置(SCMR.SMIF=0 SIMR1.IICM=0 SMR.CM=1)并设置SPMR.SSE位为1将SCI置于简单SPI模式。但是，当配置只有一个主控时，在简单SPI模式下连接用作主控的设备不需要主控侧的SSn引脚功能。因此，在这种情况下，将SPMR.SSE位设置为0。

图27.95显示了简单SPI模式的连接示例。控制一个通用端口引脚以产生来自主机的SSn输出信号。

在简单SPI模式下，数据与时钟脉冲同步传输，方式与时钟同步模式相同。1个字符的传输数据由8位数据组成，不能附加奇偶校验位。可以通过将SCMR.SINV位设置为1来反转数据。

由于接收器和发送器在SCI模块中彼此独立，因此可以使用共享时钟信号进行全双工通信。此外，由于发送器和接收器都具有缓冲结构，因此在发送过程中写入下一个发送数据和在接收过程中读取先前接收到的数据都是可能的。这使得连续传输成为可能。



注1.在单主机系统中不需要SSn引脚输入（该接口在设置SPMR.SSE=0时使用）。

Figure 27.95 在SPMR.SSE位=0的单主模式下使用简单SPI模式的示例连接

27.9.1 主从模式下的引脚状态

简单SPI模式接口的引脚方向（输入或输出）根据设备是主设备（SCR.CKE[1:0]=00b或01b且SPMR.MSS=0）还是从设备（SCR.CKE）而不同[1:0]=10b或11b且SPMR.MSS=1)。

表27.39列出了SSn引脚上的引脚状态、模式和电平之间的关系。

Table 27.39 SSn引脚上的模式和输入电平的引脚状态（2个中的1个）

Mode	SSn引脚上的输入	MOSIn管脚状态	MISon引脚的状态	SCKn引脚状态
主模式*1	高电平（可以进行转移）	数据传输用输出*2	接收数据的输入	时钟输出*3
	低电平（传输无法进行）	High-impedance	接收数据的输入（但禁用）	High-impedance

Table 27.39 States of pins by mode and input level on SSn pin (2 of 2)

Mode	Input on SSn pin	State of MOSIn pin	State of MISOn pin	State of SCKn pin
Slave mode	High level (transfer cannot proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer can proceed)	Input for received data	Output for data transmission	Clock input

Note 1. When there is only a single master (SPMR.SSE = 0), transfer is possible regardless of the input level on the SSn pin. This is equivalent to input of a high level on the SSn pin.
Note 2. The MOSIn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE bit = 0).
Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE = 0 and SCR.RE = 0) in a multi-master configuration (SPMR.SSE = 1).

27.9.2 SS Function in Master Mode

Setting the CKE[1:0] bits in the SCR to 00b or 01b and the MSS bit in the SPMR to 0 selects master mode operation. The SSn pin is not used in single-master configurations (SPMR.SSE = 0), so transmission or reception can proceed regardless of the value of the SSn pin.

When the level on the SSn pin is high in a multi-master configuration (SPMR.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission.

When the level on the SSn pin is low in a multi-master configuration (SPMR.SSE = 1), there are other masters, and a transmission or reception is in progress. The MOSIn output and SCKn pins are placed in the high-impedance state and starting transmission or reception is not possible. In addition, the value of the SPMR.MFF bit is 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading SPMR.MFF flag. If a mode fault error occurs while transmission or reception is in progress, transmission or reception does not stop, but the MOSIn and SCKn outputs are in the high-impedance state after completion of the transfer.

Use a general port pin to produce the SS output signal from the master.

27.9.3 SS Function in Slave Mode

Setting the SCR.CKE[1:0] bits to 10b or 11b and the SPMR.MSS bit to 1 selects slave operation. When the SSn pin is high, the MISOn output pin is in the high-impedance state and clock input through the SCKn pin is ignored. When the SSn pin is low, clock input through the SCKn pin is valid and transmission or reception can proceed.

If the input on the SSn pin changes from low to high during transmission or reception, the MISOn output pin is placed in the high-impedance state. Meanwhile, the internal processing for transmission or reception continues at the rate of the clock input through the SCKn pin until processing for the character being transmitted or received is complete, after which it stops, and the appropriate interrupt (SCIn_TXI, SCIn_RXI, or SCIn_TEI) is generated.

27.9.4 Relationship between Clock and Transmit/Receive Data

The CKPOL and CKPH bits in the SPMR register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in Figure 27.96. The relation is the same for both master and slave operation. This is the same as when the level on the SSn pin is high.

Table 27.39 SSn引脚上的模式和输入电平的引脚状态（2个中的2个）

Mode	SSn引脚上的输入	MOSIn管脚状态	MISon引脚的状态	SCKn引脚状态
从机模式	高电平（传输无法进行）	接收数据的输入（但禁用）	High-impedance	时钟输入（但禁用）
	低电平（可以继续传输）	接收数据的输入	数据传输输出	时钟输入

注1.当只有一个主机(SPMR.SSE=0)时，无论SSn引脚上的输入电平如何，都可以进行传输。这相当于在SSn引脚上输入高电平。

注2.当串行传输被禁用（SCR.TE位=0）时，MOSIn引脚输出处于高阻抗状态。
注3.在多主机配置(SPMR.SSE=1)中禁用串行传输(SCR.TE=0和SCR.RE=0)时，SCKn引脚输出处于高阻抗状态。

27.9.2 主控模式下的SS功能

将SCR中的CKE[1:0]位设置为00b或01b并将SPMR中的MSS位设置为0选择主机模式操作。这SSn引脚不用于单主机配置(SPMR.SSE=0)，因此无论SSn引脚的值如何，都可以进行发送或接收。

在多主机配置（SPMR.SSE=1）中，当SSn引脚上的电平为高电平时，主机设备在开始发送或接收之前从SCKn引脚输出时钟信号，以指示没有其他主机或另一个主机在进行接收或发送。

在多主机配置（SPMR.SSE=1）中，当SSn引脚上的电平为低电平时，存在其他主机，并且正在进行发送或接收。MOSIn输出和SCKn引脚处于高阻状态，无法开始发送或接收。此外，SPMR.MFF位的值为1，表示模式故障错误。在多主机配置中，通过读取SPMR.MFF标志开始错误处理。如果在发送或接收过程中发生模式故障错误，则发送或接收不会停止，但MOSIn和SCKn输出在传输完成后处于高阻抗状态。

使用通用端口引脚从主机产生SS输出信号。

27.9.3 从模式下的SS功能

将SCR.CKE[1:0]位设置为10b或11b并将SPMR.MSS位设置为1选择从机操作。当SSn引脚为高电平时，MIOn输出引脚处于高阻状态，通过SCKn引脚输入的时钟被忽略。当SSn引脚为低电平时，通过SCKn引脚输入的时钟有效，可以进行发送或接收。

如果SSn引脚上的输入在发送或接收期间从低电平变为高电平，则MISOn输出引脚处于高阻抗状态。同时，发送或接收的内部处理以通过SCKn引脚输入的时钟速率继续进行，直到对正在发送或接收的字符的处理完成，之后它停止，并出现适当的中断（SCIn_TXI、SCIn_RXI或SCIn_TEI）生成。

27.9.4 时钟与发送接收数据的关系

SPMR寄存器中的CKPOL和CKPH位可用于以四种不同的方式设置用于发送和接收的时钟。时钟信号与数据收发的关系如图27.96所示。主从操作的关系是相同的。这与SSn引脚上的电平为高电平时相同。

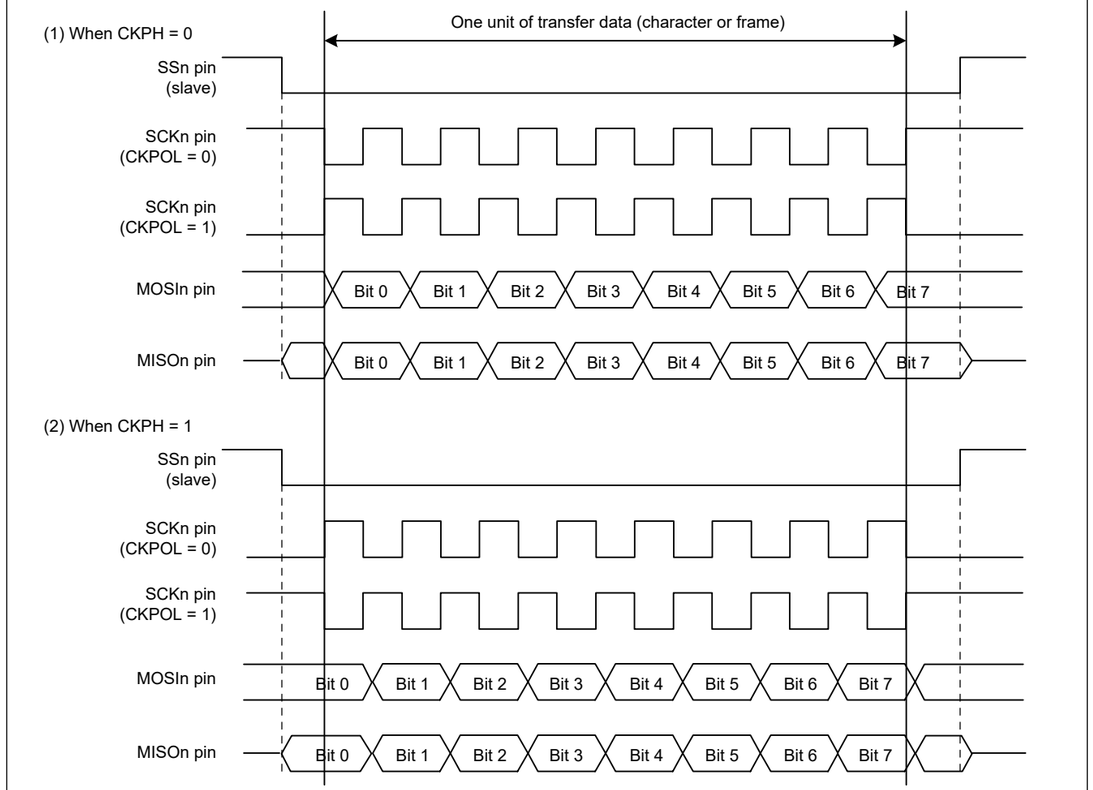


Figure 27.96 Relation between clock signal and transmit or receive data in simple SPI mode

27.9.5 SCI Initialization in Simple SPI Mode

Initialization in simple SPI mode is the same as in clock synchronous mode. See section 27.6.3. SCI Initialization in Clock Synchronous Mode for an example initialization flow. The CKPOL and CKPH bits in the SPMR register must be set to ensure that the clock signal is suitable for both master and slave devices.

Always initialize the SCR register before making any changes to the operating mode or transfer format.

Note: Only the RE bit is set to 0. The SSR.ORER, FER, PER, and RDR flags are not initialized.

Changing the value of the TE bit from 1 to 0 or from 0 to 1 when the TIE bit in the SCR register is 1 at the same time, leads to the generation of a transmit data empty interrupt (SCIn_TXI).

27.9.6 Transmission and Reception of Serial Data in Simple SPI Mode

In master operation, ensure that the SSn pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. Otherwise, the procedures are the same as in clock synchronous mode.

27.10 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be evenly corrected using the number specified in the MDDR register among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in SMR/SMR_SMCI.

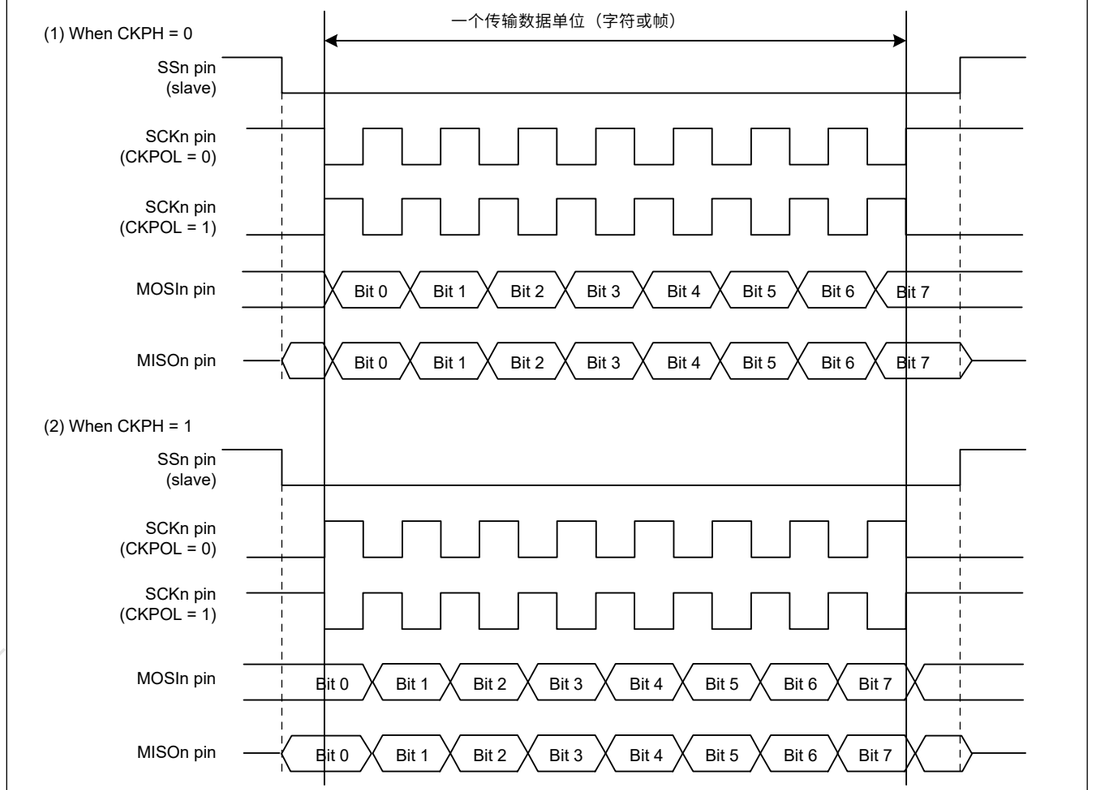

Figure 27.96 简单SPI模式下时钟信号与发送或接收数据的关系

27.9.5 简单SPI模式下的SCI初始化

简单SPI模式的初始化与时钟同步模式相同。请参见第27.6.3节。时钟中的SCI初始化
示例初始化流程的同步模式。必须设置SPMR寄存器中的CKPOL和CKPH位，以确保时钟信号适用于主设备和从设备。

在对操作模式或传输格式进行任何更改之前，始终初始化SCR寄存器。

Note: 只有RE位设置为0。SSR.ORER、FER、PER和RDR标志未初始化。

当SCR寄存器中的TIE位同时为1时，将TE位的值从1更改为0或从0更改为1，会导致产生发送数据空中断（SCIn_TXI）。

27.9.6 简单SPI模式下串行数据的发送和接收

在主机操作中，确保传输另一侧的从设备的SSn管脚在开始传输前为低电平，在传输完成时为高电平。否则，过程与时钟同步模式相同。

27.10 比特率调制功能

使用比特率调制功能，可以在SMRSMR_SMCI中的CKS[1:0]位选择的内部时钟的256个时钟周期中，使用MDDR寄存器中指定的数量均匀地校正比特率。

Figure 27.97 shows an example where the PCLK is selected in the CKS[1:0] bits in SMR/SMR_SMCI, the BRR bit is set to 0, and the MDDR is set to 160 in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256).

Note: Enabling an internal clock causes bias, and expansion and contraction are generated in the pulse width of the internal base clock.

Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

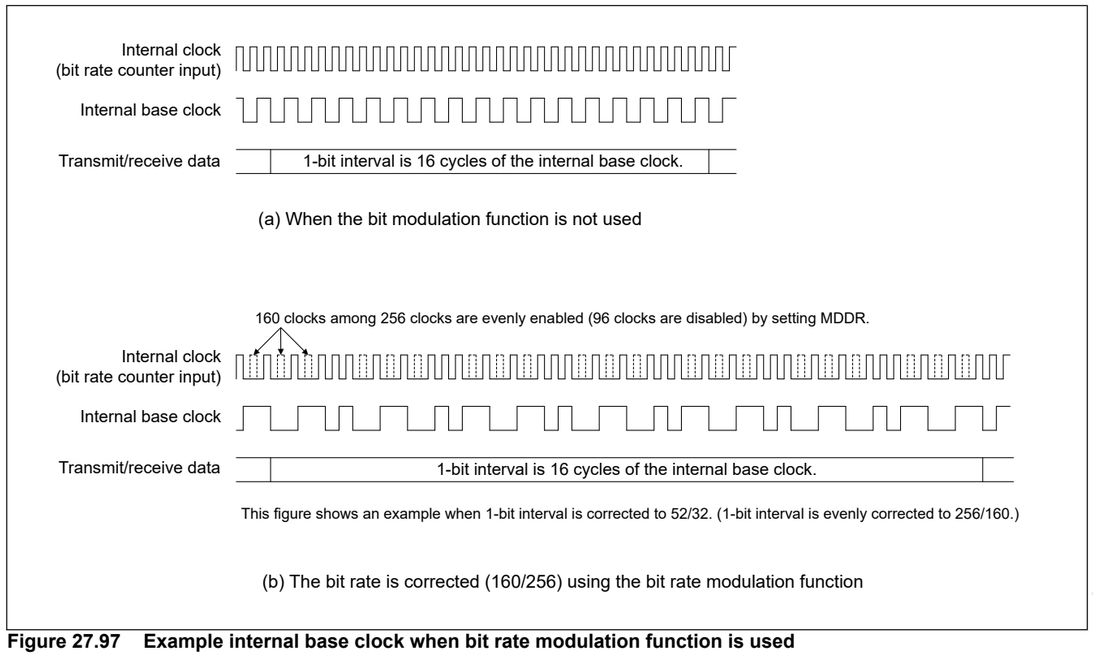

Figure 27.97 Example internal base clock when bit rate modulation function is used

27.11 Interrupt Sources

27.11.1 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (non-FIFO selected)

If the conditions for an SCIn_TXI and SCIn_RXI interrupt are satisfied while the interrupt status flag in the ICU is 1, the ICU does not output the interrupt request but saves it internally with a capacity for retention of one request per source.

When the interrupt status flag in the ICU is set to 0, the interrupt request retained within the ICU is output. The internally retained interrupt request is automatically discarded when the actual interrupt is output. Clearing of the associated interrupt enable bit (the TIE or RIE bit in the SCR/SCR_SMCI) can also be used to discard an internally retained interrupt request.

27.11.2 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (FIFO selected)

When an interrupt status flag in the ICU is set to 1, the SCIn_TXI and SCIn_RXI interrupts do not output interrupt requests to the ICU. When an interrupt status flag of the ICU is set to 0, and if the conditions for an SCIn_TXI and SCIn_RXI interrupts are satisfied, an interrupt request is generated.

27.11.3 Interrupts in Asynchronous, Manchester, Clock Synchronous, and Simple SPI Modes

(1) Non-FIFO selected

Table 27.40 lists interrupt sources in asynchronous mode, Manchester mode, clock synchronous mode, and simple SPI mode.

图27.97显示了一个示例，其中在SMRSMR_SMCI的CKS[1:0]位中选择PCLK，BRR位设置为0，异步模式下MDDR设置为160。在这个例子中，基本时钟的周期被均匀地校正（256160）并且比特率也被校正（160256）。

Note: 启用内部时钟会导致偏差，并且会在内部基本时钟的脉冲宽度中产生扩展和收缩。

不要在时钟同步模式和简单SPI模式的最高速度设置（SMR.CKS[1:0]=00b，SCR.CKE[1]=0和BRR=0）中使用此功能。

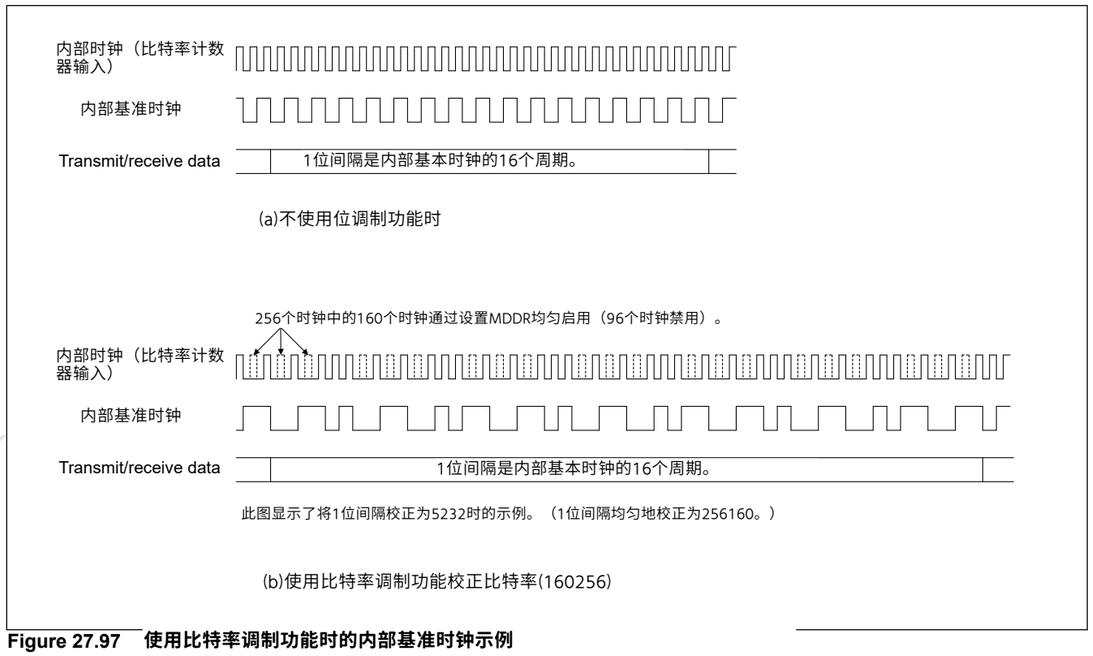

Figure 27.97 使用比特率调制功能时的内部基准时钟示例

27.11 中断源

27.11.1 SCIn_TXI和SCIn_RXI中断的缓冲区操作（选择非FIFO）

如果在ICU中的中断状态标志为1时满足SCIn_TXI和SCIn_RXI中断的条件，则ICU不输出中断请求，而是将其保存在内部，每个源可以保留一个请求。

当ICU中的中断状态标志设置为0时，输出ICU中保留的中断请求。当实际中断输出时，内部保留的中断请求会被自动丢弃。清除相关中断使能位（SCRSCR_SMCI中的TIE或RIE位）也可用于丢弃内部保留的中断请求。

27.11.2 SCIn_TXI和SCIn_RXI中断的缓冲区操作（选择FIFO）

当ICU中的中断状态标志设置为1时，SCIn_TXI和SCIn_RXI中断不会向ICU输出中断请求。当ICU的中断状态标志设置为0，并且满足SCIn_TXI和SCIn_RXI中断的条件时，将产生中断请求。

27.11.3 异步、曼彻斯特、时钟同步和简单SPI中的中断 Modes

(1) Non-FIFO selected

表27.40列出了异步模式、曼彻斯特模式、时钟同步模式和简单SPI模式下的中断源。

A different interrupt vector can be assigned to each interrupt source. Individual interrupt sources can be enabled or disabled with the enable bits in the SCR register.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when transmit data is transferred from the TDR or TDRHL register*1 to the TSR register. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TE and SCR.TIE bits to 1 at the same time. An SCIn_TXI interrupt request can activate the DTC or DMAC to handle data transfer.

An SCIn_TXI interrupt request is not generated by setting the SCR.TE bit to 1 when SCR.TIE is 0 or by setting the SCR.TIE bit to 1 when the SCR.TE is 1.*2

When new data is not written by the time of transmission of the last bit of the current transmit data and SCR.TEIE is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated. Additionally, when SCR.TE is 1, the SSR.TEND flag retains the value 1 until more transmit data is written to the TDR or TDRHL register*1, and setting SCR.TEIE to 1 leads to the generation of an SCIn_TEI interrupt request.

Writing data to the TDR or TDRHL register*1 leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the SCIn_TEI interrupt request.

If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated when received data is stored in the RDR register. An SCIn_RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting any of the SSR.ORER, FER, PER and MER*3 flags to 1 when the SCR.RIE bit is 1 leads to the generation of an SCIn_ERI interrupt request.

An SCIn_RXI interrupt request is not generated in this case. Clearing all these flags (ORER, FER, PER, MER*3, SYER*3, PFER*3 and SBER*3) leads to discarding of the SCIn_ERI interrupt request.

Note 1. When asynchronous mode and 9-bit data length are selected.
Note 2. To temporarily prohibit SCIn_TXI interrupts on transmission of the last of the data when a new round of transmission is to be started, after handling the transmission-completed interrupt, control activation of the interrupt by using the interrupt request enable bit in the ICU rather than using the SCR.TIE bit. This approach can prevent the suppression of SCIn_TXI interrupt requests in the transfer of new data.
Note 3. MER, SYER, PFER, and SBER work as a factor of SCIn_ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECR) are set to "1".

(2) FIFO selected

Table 27.41 lists interrupt sources in FIFO selected mode.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when the stored amount of data in the FTDRL register becomes the threshold value indicated in FCR.TTRG or below. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TIE and SCR.TE bits to 1 simultaneously or by setting SCR.TIE to 1 when SCR.TE is 1.

An SCIn_TXI interrupt request is not generated by setting SCR.TE to 1 when SCR.TIE is 0.

If SCR.TEIE is 1 and if the next data is not written to the FTDRL register by the time the last bit of the transmit data is sent, the SSR_FIFO.TEND flag is set to 1 and the SCIn_TEI interrupt request is generated.

If SCR.RIE is 1, the SCIn_RXI interrupt request is generated when the stored amount of data in the FRDRL register is equal to or greater than the threshold value indicated in FCR.RTRG. When RTRG is 0, an SCIn_RXI interrupt does not occur even when the amount of data in the receive FIFO is equal to 0.

If the SCR.RIE bit is 1, when the SSR_FIFO.ORER flag is set to 1 or data with a framing error or a parity error is stored in the FRDRL register, the SCIn_ERI interrupt request is generated. When the amount of data stored in the FRDRL register is at the threshold value or above, the SCIn_RXI interrupt request is also generated. The SCIn_ERI interrupt request can be canceled, in which case SSR_FIFO.ORER, FER, and PER flags are all cleared.

Table 27.40 SCI interrupt sources with non-FIFO selected (1 of 2)

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0, 3, 4, 9)	Receive error*1	SSR.ORER, SSR.FER, SSR.PER, DCCR.DFER, DCCR.DPER, (SSR.MER, MESR.SYER, MESR.PFER, MESR.SBER)*2	SCR.RIE	Not possible

可以为每个中断源分配不同的中断向量。可以使用SCR寄存器中的启用位启用或禁用各个中断源。

如果SCR.TIE位为1，则当发送数据从TDR传输或
TDRHL寄存器*1到TSR寄存器。也可以使用一条指令同时将SCR.TE和SCR.TIE位设置为1，从而产生SCIn_TXI中断请求。SCIn_TXI中断请求可以激活DTC或DMAC来处理数据传输。

当SCR.TIE为0时将SCR.TE位设置为1或通过设置
当SCR.TE为1时，SCR.TIE位为1。*2

当当前发送数据的最后一位发送时尚未写入新数据且SCR.TEIE为1，则
SSR.TEND标志设置为1并产生SCIn_TEI中断请求。此外，当SCR.TE为1时，SSR.TEND标志保持值1，直到更多发送数据写入TDR或TDRHL寄存器*1，并且将SCR.TEIE设置为1会导致产生SCIn_TEI中断请求。

将数据写入TDR或TDRHL寄存器*1会导致SSR.TEND标志清零，并在一定时间后丢弃SCIn_TEI中断请求。

如果SCR.RIE位为1，则当接收到的数据存储在RDR寄存器中时会产生SCIn_RXI中断请求。一个
SCIn_RXI中断请求可以激活DTC或DMAC来处理数据传输。

当SCR.RIE位为1时，将任何SSR.ORER、FER、PER和MER*3标志设置为1会导致生成
SCIn_ERI中断请求。

在这种情况下不会产生SCIn_RXI中断请求。清除所有这些标志(ORER FER PER MER*3 SYER*3
PFER*3和SBER*3)导致丢弃SCIn_ERI中断请求。

注意1.选择异步模式和9位数据长度时。
注2.为了在新一轮传输开始时，在传输最后一个数据时暂时禁止SCIn_TXI中断，在处理完传输完成中断后，使用ICU中的中断请求使能位控制中断的激活而不是使用SCR.TIE位。这种方法可以防止在传输新数据时抑制SCIn_TXI中断请求。

注3.MER、SYER、PFER和SBER仅在曼彻斯特模式下作为SCIn_ERI中断的一个因素起作用。SYER、PFER和
SBER也仅在其启用位（MECR中的SYEREN、PFEREN、SBEREN）设置为“1”时才起作用。

(2) FIFO selected

表27.41列出了FIFO选择模式下的中断源。

如果SCR.TIE位为1，当FTDRL寄存器中存储的数据量变为FCR.TTRG中指示的阈值或更低时，将产生SCIn_TXI中断请求。SCIn_TXI中断请求也可以通过使用一条指令同时将SCR.TIE和SCR.TE位设置为1或在SCR.TE为1时将SCR.TIE设置为1来生成。

当SCR.TIE为0时，将SCR.TE设置为1不会产生SCIn_TXI中断请求。

如果SCR.TEIE为1，并且如果在发送数据的最后一位发送之前没有将下一个数据写入FTDRL寄存器，则SSR_FIFO.TEND标志设置为1，并产生SCIn_TEI中断请求。

如果SCR.RIE为1，则当FRDRL寄存器中存储的数据量等于或大于FCR.RTRG中指示的阈值时，将产生SCIn_RXI中断请求。当RTRG为0时，即使接收FIFO中的数据量等于0，也不会发生SCIn_RXI中断。

如果SCR.RIE位为1，当SSR_FIFO.ORER标志设置为1或帧错误或奇偶校验错误的数据存储在FRDRL寄存器中时，将产生SCIn_ERI中断请求。当FRDRL寄存器中存储的数据量在阈值或以上时，也会产生SCIn_RXI中断请求。SCIn_ERI中断请求可以被取消，在这种情况下SSR_FIFO.ORER、FER和PER标志都被清除。

27.11.4 Interrupts in Smart Card Interface Mode

Table 27.42 lists interrupt sources in smart card interface mode. A transmit end interrupt (SCIn_TEI) request and an address match (SCIn_AM) request cannot be used in this mode.

Data transmission or reception using the DTC or DMAC is also possible in smart card interface mode, similar to normal SCI mode. In transmission, when the SSR_SMCI.TEND flag is set to 1, an SCIn_TXI interrupt request is generated. This SCIn_TXI interrupt request activates the DTC or DMAC, allowing transfer of transmit data if the SCIn_TXI request is previously specified as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

27.11.4 智能卡接口模式中的中断

表27.42列出了智能卡接口模式下的中断源。在此模式下不能使用发送结束中断(SCIn_TEI)请求和地址匹配(SCIn_AM)请求。

Table 27.42 SCI中断源

Name	中断源	中断标志	中断使能	DTC或DMAC激活

SCIn_TXI (n = 0, 3, 4, 9)	传输数据为空	SSR_SMCI.TEND	SCR_SMCI.TIE	Possible

在智能卡接口模式下也可以使用DTC或DMAC进行数据传输或接收，类似于正常SCI模式。在发送过程中，当SSR_SMCI.TEND标志设置为1时，会产生一个SCIn_TXI中断请求。该SCIn_TXI中断请求激活DTC或DMAC，如果之前将SCIn_TXI请求指定为DTC或DMAC激活源，则允许传输数据。当DTC或DMAC传输数据时，TEND标志自动设置为0。

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission after an error occurrence. However, the SSR_SMCI.ERS flag is not automatically set to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the SCR_SMCI.RIE bit to 1 to enable an SCIn_ERI interrupt request to be generated at error occurrence.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings. For DTC or DMAC settings, see section 17, Data Transfer Controller (DTC), section 16, DMA Controller (DMAC).

In reception, an SCIn_RXI interrupt request is generated when receive data is set to the RDR register. This SCIn_RXI interrupt request activates the DTC or DMAC, allowing transfer of the receive data if the SCIn_RXI request is previously specified as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an SCIn_ERI interrupt request is issued to the CPU instead. The error flag must be cleared.

27.11.5 Interrupts in Simple IIC Mode

Table 27.43 lists the interrupt sources in simple IIC mode. The STI interrupt is allocated to the transmit end interrupt (SCIn_TEI) request. The receive error interrupt (SCIn_ERI) and the address match (SCIn_AM) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple IIC mode.

When the SIMR2.IICINTM bit is 1:

- An SCIn_RXI request is generated on the falling edge of the SCLn signal for the 8th bit. If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.
- An SCIn_TXI request is generated on the falling edge of the SCLn signal for the 9th bit (acknowledge bit). If SCIn_TXI is previously set up as an activation source for the DTC or DMAC, the SCIn_TXI request activates the DTC or DMAC to handle transfer of the transmit data.

When the SIMR2.IICINTM bit is 0:

- An SCIn_RXI request (ACK detection) is generated if the input on the SDAn pin is low on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- An SCIn_TXI request (NACK detection) is generated if the input on the SDAn pin is high on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.

If the DTC or DMAC is used for data transfer in reception or transmission, always set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in SIMR3 are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_RXI (n = 0, 3, 4, 9)	Reception, ACK detection	—	SCMR.RIE	Possible*1
SCIn_TXI (n = 0, 3, 4, 9)	Transmission, NACK detection	—	SCMR.TIE	Possible
SCIn_TEI(STIn) (n = 0, 3, 4, 9)	Completion of generation of a start, restart, or stop condition	SIMR3.IICSTIF	SCMR.TEIE	Not possible

Note 1. Activation of the DTC or DMAC is only possible when the SIMR2.IICINTM bit is 1 (use reception and transmission interrupts)

27.12 Event Linking

By using interrupt request signals as event signals, the SCIn can provide linked operation through the ELC for modules selected in advance.

如果发生错误，SCI会自动重新传输相同的数据。在重传期间，TEND标志保持为0，并且DTC或DMAC不被激活。因此，SCI和DTC或DMAC会自动传输指定的字节数，包括发生错误后的重传。但是，发生错误时，SSR_SMCI.ERS标志不会自动设置为0。因此，必须通过预先将SCR_SMCI.RIE位设置为1来清除ERS 标志，以在发生错误时启用SCIn_ERI中断请求。

使用DTC或DMAC发送或接收数据时，请务必在进行SCI设置之前启用DTC或DMAC。对于DTC或DMAC设置，请参阅第17节，数据传输控制器(DTC)，第16节，DMA控制器(DMAC)。

在接收中，当接收数据设置到RDR寄存器时，会产生SCIn_RXI中断请求。该SCIn_RXI中断请求激活DTC或DMAC，如果先前将SCIn_RXI请求指定为DTC或DMAC激活源，则允许传输接收数据。如果发生错误，则设置错误标志。因此，不会激活DTC或DMAC，而是向CPU发出SCIn_ERI中断请求。必须清除错误标志。

27.11.5 简单IIC模式下的中断

表27.43列出了简单IIC模式下的中断源。STI中断分配给发送结束中断(SCIn_TEI)请求。不能使用接收错误中断(SCIn_ERI)和地址匹配(SCIn_AM)请求。

DTC或DMAC也可用于处理简单IIC模式下的传输。

当SIMR2.IICINTM位为1时：

●SCIn_RXI请求在第8位的SCLn信号下降沿产生。如果SCIn_RXI先前设置为DTC或DMAC的激活源，则SCIn_RXI请求将激活DTC或DMAC以处理接收数据的传输。

●SCIn_TXI请求在第9位（确认位）的SCLn信号的下降沿产生。如果SCIn_TXI先前设置为DTC或DMAC的激活源，则SCIn_TXI请求将激活DTC或DMAC以处理传输数据的传输。

当SIMR2.IICINTM位为0时：

●如果SDAn引脚上的输入在第9位（确认位）的SCLn信号的上升沿为低电平，则生成SCIn_RXI请求（ACK检测）

●如果SDAn引脚上的输入在第9位（确认位）的SCLn信号的上升沿为高电平，则生成SCIn_TXI请求（NACK检测）

●如果先前将SCIn_RXI设置为DTC或DMAC的激活源，则SCIn_RXI请求将激活DTC或DMAC以处理接收数据的传输。

如果DTC或DMAC用于接收或传输中的数据传输，请务必在设置SCI之前设置并启用DTC或DMAC。

当SIMR3中的IICSTAREQ、IICRSTAREQ和IICSTPREQ位用于生成开始条件、重新启动条件或停止条件时，生成完成时会发出STI请求。

Table 27.43 SCI中断源

Name	中断源	中断标志	中断使能	DTC或DMAC激活
SCIn_RXI (n = 0, 3, 4, 9)	接收、ACK检测	—	SCMR.RIE	Possible*1
SCIn_TXI (n = 0, 3, 4, 9)	传输、NACK检测	—	SCMR.TIE	Possible
SCIn_TEI(STIn) (n = 0, 3, 4, 9)	完成启动、重新启动或停止条件的生成	SIMR3.IICSTIF	SCMR.TEIE	不可能

注1.仅当SIMR2.IICINTM位为1时才可能激活DTC或DMAC（使用接收和发送中断）

27.14 Noise Cancellation Function

Figure 27.98 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a 2-stage flip-flop circuit and a match detection circuit. When the input signals of the noise filter and the output signals of the 2- stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. When the same level is retained for 3 cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for 3 cycles or shorter is considered as noise, not as a receive signal.

In asynchronous mode, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The receive level of the RXDn is taken in the flip-flop circuit of the noise filter on the base clock of asynchronous mode.

- When SEMR.ABCS = 0 and SEMR.ABCSE = 0, the cycle is 1/16 of a 1-bit period.
- When SEMR.ABCS = 1 and SEMR.ABCSE = 0, the cycle is 1/8 of a 1-bit period.
- When SEMR.ABCSE = 1, the cycle is 1/6 of a 1-bit period.

In simple IIC mode, this function can be used for each input on SDAn and SCLn. The sampling clock is selected from divided clock of baud rate generator settings SNFR.NFCS[2:0].

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR.TE and SCR.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, the function determines that a level match is detected and the result is conveyed as an internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles.

27.15 Usage Notes

27.15.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable SCI operation. The SCI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

27.14 降噪功能

图27.98显示了用于噪声消除的噪声滤波器的配置。噪声滤波器由一个2级触发器电路和一个匹配检测电路组成。当噪声滤波器的输入信号和2级触发器电路的输出信号完全匹配时，匹配的电平作为内部信号传送。除非另有匹配，否则将保留先前的值。当相同电平在噪声滤波器的采样时钟上保持3个周期或更长时间时，它被认为是有效的接收信号。3个周期或更短的脉冲变化被认为是噪声，而不是接收信号。

在异步模式下，可以对输入到RXDn引脚的接收信号应用噪声消除功能。RXDn的接收电平是在异步模式的基本时钟上的噪声滤波器的触发器电路中获取的。

- 当SEMR.ABCS=0且SEMR.ABCSE=0时，周期为1位周期的116。
- 当SEMR.ABCS=1且SEMR.ABCSE=0时，周期为1位周期的18。
- 当SEMR.ABCSE=1时，周期为1位周期的16。

在简单IIC模式下，该功能可用于SDAn和SCLn上的每个输入。采样时钟从波特率发生器设置SNFR.NFCS[2:0]的分频时钟中选择。

如果在启用噪声滤波器的情况下基准时钟停止一次，然后再次重新启动基准时钟输入，则噪声滤波器操作将从时钟停止的状态恢复。当SCR.TE和SCR.RE在基本时钟输入期间设置为0时，所有噪声滤波器触发器值都被初始化为1。因此，如果在接收操作恢复时输入数据为1，则该函数确定一个电平检测到匹配并将结果作为内部信号传送。当输入的电平对应于0时，保留噪声滤波器的初始输出，直到电平在三个连续的采样周期中匹配。

27.15 使用说明

27.15.1 模块停止功能的设置

模块停止控制寄存器B(MSTPCRB)可以启用或禁用SCI操作。SCI在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

27.15.2 SCI Operation during Low Power State

(1) Transmission

When setting the module to the stopped state or in transitions to Software Standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR/SCR_SMCI to 0) after switching the TXDn pin to the general I/O port pin function. When setting I/O port as an SCI connection, the SPTR register can control the state of the TXDn pin. Setting the TE bit to 0 initializes the TSR register and the TEND bit in the SSR/SSR_SMCI is initialized to 1 with non-FIFO selected, and the value is retained, with FIFO selected. Depending on the port settings and SPTR register settings, output pins might output the level before a transition to the low-power state is made after release from the module-stopped state or Software Standby mode. When transitions to these states are made during transmission, the transmitted data becomes indeterminate.

To transmit data in the same transmission mode after cancellation of the low-power state:

1. Set the TE bit to 1.
2. Read SSR/SSR_FIFO/SSR_SMCI.
3. Write data to TDR sequentially to start data transmission.

To transmit data with a different transmission mode, initialize the SCI first.

Figure 27.99 shows an example flow of transition to Software Standby mode during transmission. Figure 27.100 and Figure 27.101 show the port pin states during transition to Software Standby mode.

Before specifying the module-stop state or making a transition to Software Standby mode from the transmission mode using DTC or DMAC transfer, stop the transmit operations (TE = 0). To start transmission after cancellation using the DTC or DMAC, set the TE bit to 1. The SCIn_TXI interrupt flag is set to 1 and transmission starts using the DTC or DMAC.

(2) Reception

When address match function is not used as wake-up condition

Before specifying the module-stop state or making a transition to Software Standby mode, stop the receive operations (RE = 0 in SCR/SCR_SMCI). If transition is made during data reception, the received data is invalid.

Figure 27.102 shows an example flow of transition to Software Standby mode during reception.

When address match function is used as wake-up condition

Before specifying the module-stop state or making a transition to Software Standby mode:

1. Set the operations after cancellation of the low power state.
2. Set CDR.CMPD and DCCR.DCME to 1.
3. Set the receive operations (RE = 1 in SCR/SCR_SMCI).
4. Set the module-stop state or Software Standby mode.

When SCI transfers to low power mode, if the receive data pin (RXD) is at the low level, set SEMR.RXDESEL = 0.

When setting SEMR.RXDESEL = 1, there is a possibility that a start bit (falling edge of RXD pin) cannot be detected on release of the low power mode.

Figure 27.103 shows an example flow of transition to Software Standby mode during reception with address match.

When using SCI0 in Snooze mode

When using SCI0 in Snooze mode, some restrictions apply, including maximum bit rates. For details, see section 10, Low Power Modes.

27.15.2 低功耗状态下的SCI操作

(1) Transmission

当将模块设置为停止状态或转换为软件待机时，在将TXDn引脚切换为通用IO端口引脚功能后停止操作（通过将SCRSCR_SMCI中的TIE、TE和TEIE位设置为0）。当设置IO端口为SCI连接时，SPTR寄存器可以控制TXDn引脚的状态。将TE位设置为0初始化TSR寄存器，并且SSRSSR_SMCI中的TEND位在选择非FIFO时初始化为1，而在选择FIFO时保持该值。根据端口设置和SPTR寄存器设置，输出引脚可能会在从模块停止状态或软件待机模式释放后转换到低功耗状态之前输出电平。在传输过程中转换到这些状态时，传输的数据变得不确定。

在取消低功耗状态后以相同的传输模式传输数据：

1.将TE位设置为1。

2. Read SSR/SSR_FIFO/SSR_SMCI.

3.将数据依次写入TDR，开始数据传输。

要以不同的传输模式传输数据，请先初始化SCI。

图27.99显示了传输期间转换到软件待机模式的示例流程。图27.100和图27.101显示了转换到软件待机模式期间的端口引脚状态。

在指定模块停止状态或从传输模式转换到软件待机模式之前，使用DTC或DMAC传输，停止传输操作(TE=0)。要在取消后使用DTC或DMAC，将TE位设置为1。SCIn_TXI中断标志 设置为1，并使用DTC或DMAC开始传输。

(2) Reception

地址匹配功能不用作唤醒条件时

在指定模块停止状态或转换到软件待机模式之前，停止接收操作（SCRSCR_SMCI中的RE=0）。如果在数据接收期间进行转换，则接收到的数据无效。

图27.102显示了接收期间转换到软件待机模式的示例流程。

当地址匹配功能用作唤醒条件时

在指定模块停止状态或转换到软件待机模式之前：

1.设置取消低功耗状态后的操作。

2.将CDR.CMPD和DCCR.DCME设置为1。

3.设置接收操作（在SCRSCR_SMCI中RE=1）。

4.设置模块停止状态或软件待机模式。

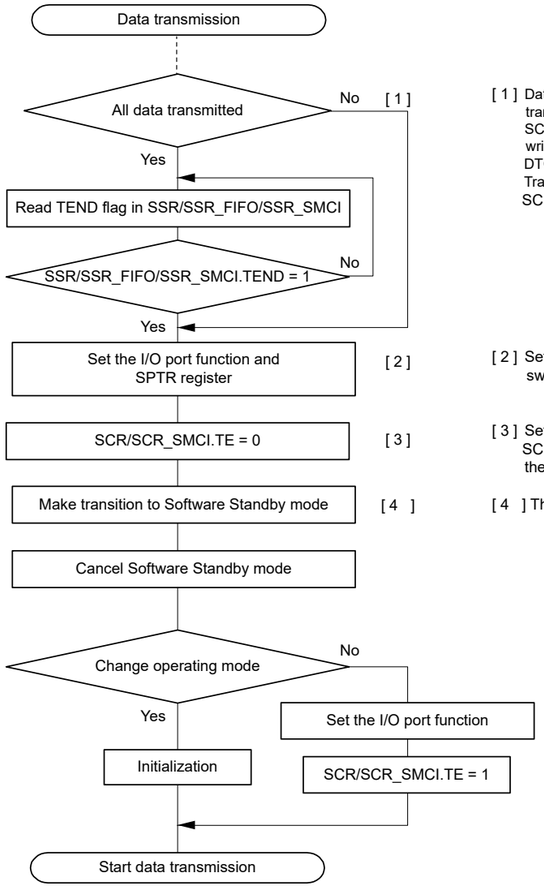
当SCI转移到低功耗模式时，如果接收数据引脚(RXD)为低电平，则设置SEMR.RXDESEL=0。

当设置SEMR.RXDESEL=1时，有可能在解除低功耗模式时无法检测到起始位（RXD引脚的下降沿）。

图27.103显示了在地址匹配的接收期间转换到软件待机模式的示例流程。

在贪睡模式下使用SCI0时

在贪睡模式下使用SCI0时，有一些限制，包括最大比特率。有关详细信息，请参阅第10节，低电源模式。



[1] Data being transmitted is lost. Data can be normally transmitted from the CPU by setting the TE bit in SCR/SCR_SMCI to 1, reading SSR/SSR_FIFO/ SSR_SMCI, and writing in Software Standby mode. However, if the DMAC or DTC is activated, the data remaining in the DMAC or DTC is Transmitted when both the TE and TIE bits in SCR/SCR_SMCI are set to 1.

[2] Set the I/O port function and SPTR register settings to switch the TXDn pin to operate as a general I/O port.

[3] Set SCR/SCR_SMCI.TE bit to 0. If SCR/SCR_SMCI.TIE = 1 and SCR/SCR_SMCI.TEIE = 1, these are set to 0 simultaneously with the SCR.TE bit.

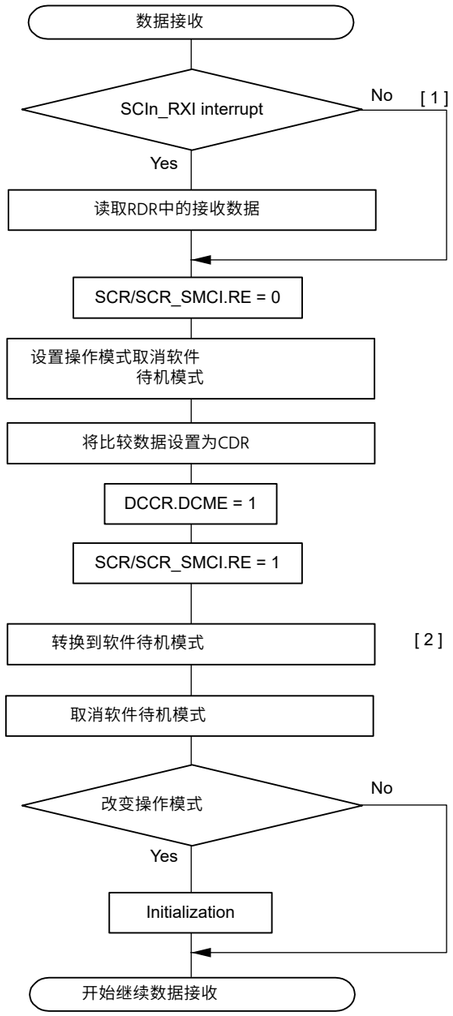
27.15.3 Break Detection and Processing

(1) Non-FIFO selected

When a framing error is detected, a break can be detected by reading the RXDn pin value directly. In a break, the input from the RXDn pin becomes all 0s, and the SSR.FER flag is set to 1 to indicate a framing error, and the SSR.PER flag might also be set to 1 to indicate a parity error. The SCI continues the receive operation even after a break is received. Therefore, even if the FER flag is 0, indicating that no framing error occurred, it is set to 1 again. When the SEMR.RXDESEL bit is 1, the SCI sets the SSR.FER flag to 1 and stops receiving operations until a start bit of the next data frame is detected. If the SSR.FER flag is set to 0, the SSR.FER flag retains 0 during the break.



[1]接收到的数据无效

[2]包括模块停止状态的设置

图27.103在地址匹配的接收期间转换到软件待机模式的示例流程

27.15.3 断裂检测和处理

(1) Non-FIFO selected

当检测到帧错误时，可以通过直接读取RXDn引脚值来检测中断。在中断时，来自RXDn引脚的输入变为全0，并且SSR.FER标志设置为1表示帧错误，SSR.PER标志也可能设置为1表示奇偶校验错误。即使在收到中断后，SCI仍继续接收操作。因此，即使FER标志为0，表示没有发生帧错误，它也会再次设置为1。当SEMR.RXDESEL位为1时，SCI将SSR.FER标志设置为1并停止接收操作，直到检测到下一个数据帧的起始位。如果

SSR.FER标志设置为0，SSR.FER标志在中断期间保持0。

When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit on the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

(2) FIFO selected

After a framing error is detected and when the SCI detects that continuous receive data is 0 for 1 frame, reception stops. When a framing error is detected, a break can be detected by reading the SPTR.RXDMON flag value. After the RXDn signal is in high and the break is finished, data reception to the FRDRHL register resumes.

27.15.4 Mark State and Production of Breaks

When the SCR/SCR_SMCI.TE bit is 0, disabling serial transmission, the state of the TXDn pin can be set using the SPTR.SPB2IO and SPTR.SPB2DT bits. With this approach, a TXDn pin can be placed in the mark state to transmit a break.

Before setting the SCR/SCR_SMCI.TE bit to 1, enabling serial transmission, set the SPB2IO and SPB2DT bits to put the communication line in the mark state (the state of 1), and change the TXDn pin using I/O port function. To output a break on data transmission, after setting the TXDn pin to output 0 by setting the SPB2IO and SPB2DT bits, change the TXDn pin using the I/O port function and set the SCR/SCR_SMCI.TE bit to 0. When the SCR/SCR_SMCI.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

27.15.5 Receive Error Flags and Transmit Operation in Clock Synchronous Mode and Simple SPI Mode

Transmission cannot start when a receive error flag (ORER) in SSR/SSR_FIFO is set to 1, even when data is written to TDR or FTDRL*1. Always set the receive error flags to 0 before starting transmission.

Note: The receive error flags cannot be set to 0 when the RE bit in SCR/SCR_SMCI is set to 0 (serial reception is disabled).

Note 1. Do not use the FTDRH register in simple SPI mode.

27.15.6 Restrictions on Clock Synchronous Transmission in Clock Synchronous Mode and Simple SPI Mode

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

Wait at least the following time from writing transmit data to TDR to the start of the external clock input:

1 PCLK cycle + data output delay time for the slave (t_{DO}) + setup time for the master (t_{SU}). See Figure 27.104.

(2) Continuous transmission

Write the next transmit data to TDR or TDRHL before the falling edge of the transmit clock for bit [7] . See Figure 27.104.

When updating TDR after bit [7] has started to transmit, update TDR while the synchronization clock is in the low-level period, and set the high-level width of the transmit clock (bit [7]) to 4 PCLK cycles or longer. See Figure 27.104.

当RXDn引脚设置为1且中断结束时，在第一个下降沿检测起始位的开始
RXDn引脚允许SCI开始接收操作。

(2) FIFO selected

检测到帧错误后，当SCI检测到1帧连续接收数据为0时，接收停止。当检测到帧错误时，可以通过读取SPTR.RXDMON标志值来检测中断。RXDn信号为高电平且中断完成后，FRDRHL寄存器的数据接收恢复。

27.15.4 标记状态和产生的中断

当SCRSCR_SMCI.TE位为0时，禁用串行传输，TXDn引脚的状态可以使用
SPTR.SPB2IO和SPTR.SPB2DT位。使用这种方法，可以将TXDn引脚置于标记状态以发送中断。

在设置SCRSCR_SMCI.TE位为1，使能串行传输之前，设置SPB2IO和SPB2DT位使通信线处于标记状态（状态为1），并使用IO端口功能改变TXDn引脚。要输出数据传输中断，通过设置SPB2IO和SPB2DT位将TXDn引脚设置为输出0后，使用IO端口功能更改TXDn引脚并将SCRSCR_SMCI.TE位设置为0。当SCRSCR_SMCI.TE位设置为0，无论当前的传输状态如何，都初始化发送器。

27.15.5 在时钟同步模式下接收错误标志和发送操作和简单SPI模式

当SSRSSR_FIFO中的接收错误标志(ORER)设置为1时，传输无法开始，即使数据已写入TDR或FTDRL*1。在开始传输之前，始终将接收错误标志设置为0。

Note: 当SCRSCR_SMCI中的RE位设置为0（禁用串行接收）时，接收错误标志不能设置为0。

注1.不要在简单SPI模式下使用FTDRH寄存器。

27.15.6 时钟同步模式和简单SPI模式下时钟同步传输的限制

当外部时钟源用作同步时钟时，有以下限制。

(1) 传输开始

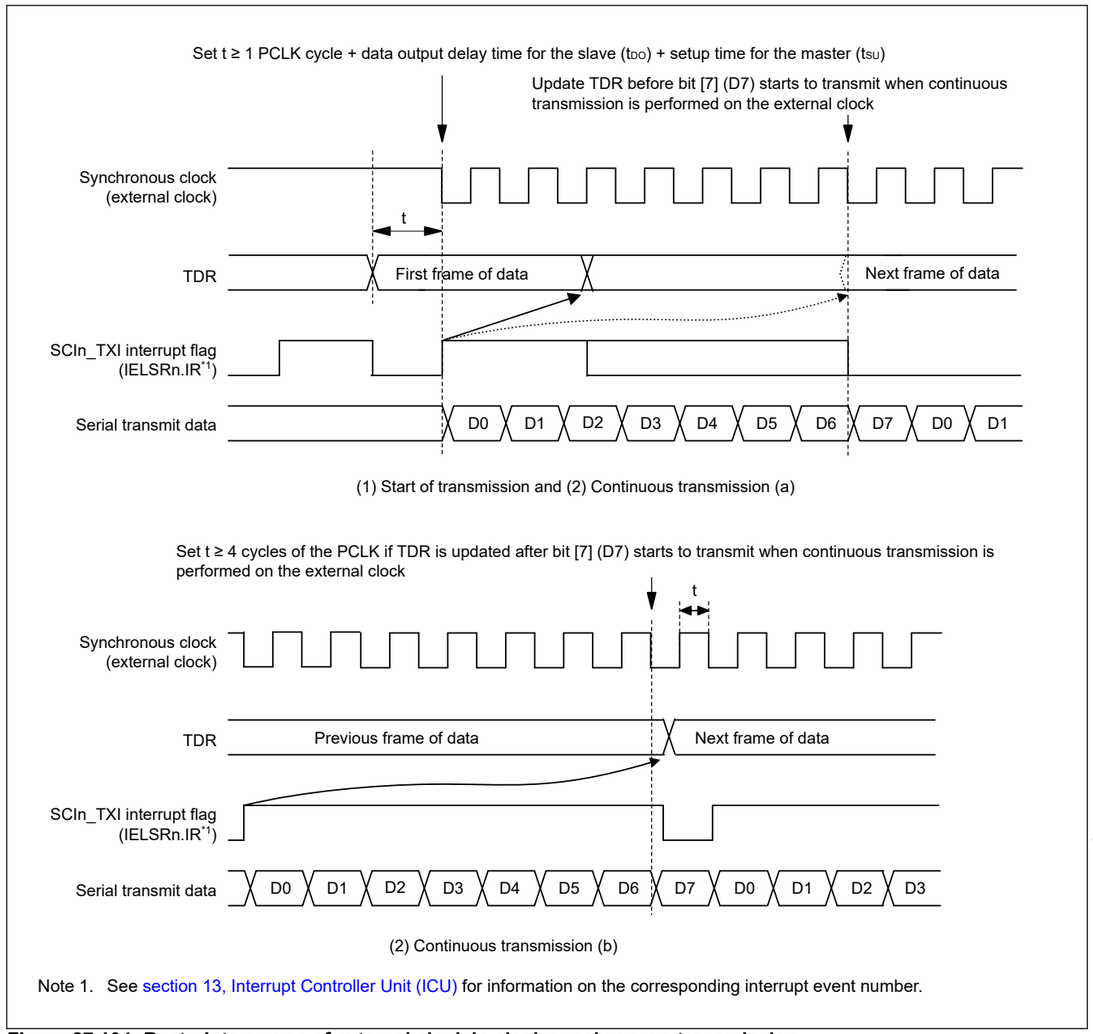
从将发送数据写入TDR到外部时钟输入开始，至少等待以下时间：

1个PCLK周期+从机的数据输出延迟时间(tDO)+主机的建立时间(tSU)。参见图27.104。

(2) 连续传输

在位[7]的发送时钟下降沿之前将下一个发送数据写入TDR或TDRHL。参见图27.104。

在bit[7]开始发送后更新TDR时，在同步时钟处于低电平期间更新TDR，并将发送时钟（bit[7]）的高电平宽度设置为4个PCLK周期或更长.参见图27.104。



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 27.104 Restraints on use of external clock in clock synchronous transmission

27.15.7 Restrictions on Using DTC or DMAC

During transmission or reception operations using the DTC or DMAC, do not set transfer data for the DTC or DMAC.

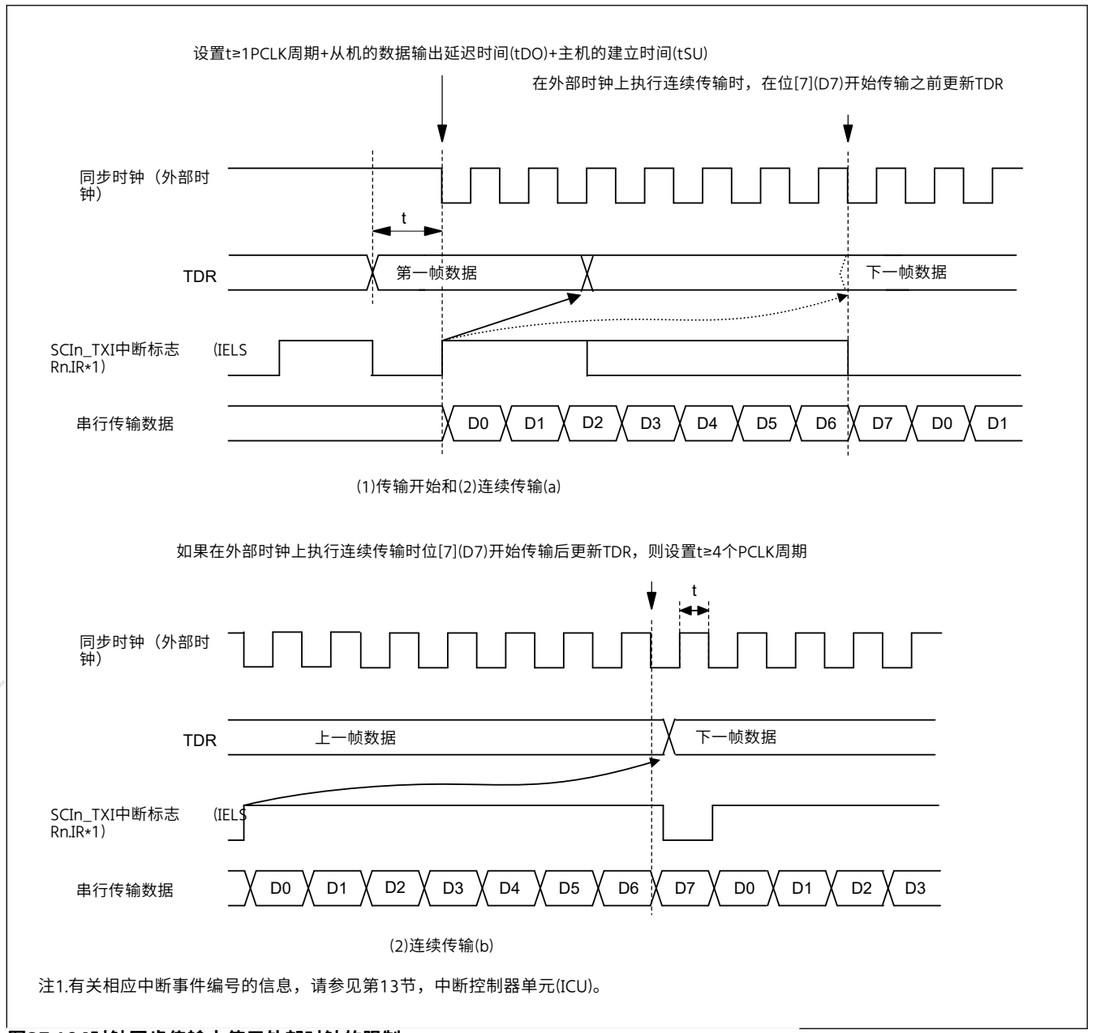
(1) Writing data to TDR (FTDRHL)

Non-FIFO selected

Data can be written to TDR and TDRHL. However, if new data is written to TDR or TDRHL when transmit data remains in TDR or TDRHL, the previous data in TDR and TDRHL is lost because it was not transferred to TSR yet. When using DTC or DMAC, always write transmit data to TDR or TDRHL in the SCIn_TXI interrupt request handling routine.

FIFO selected

It is possible to write data to the FTDRH and FTDRL registers when SCR.TE is 1. Confirm the amount of writable data using the FDR.T[4:0] bits.



注1.有关相应中断事件编号的信息，请参见第13节，中断控制器单元(ICU)。

图27.104时钟同步传输中使用外部时钟的限制

27.15.7 使用DTC或DMAC的限制

在使用DTC或DMAC进行发送或接收操作期间，请勿为DTC或DMAC设置传输数据。

(1) 将数据写入TDR(FTDRHL)

Non-FIFO selected

数据可以写入TDR和TDRHL。但是，如果在发送数据保留在TDR或TDRHL中时将新数据写入TDR或TDRHL，则TDR和TDRHL中的先前数据将丢失，因为它尚未传输到TSR。使用DTC或DMAC时，始终在SCIn_TXI中断请求处理程序中将发送数据写入TDR或TDRHL。

FIFO selected

当SCR.TE为1时，可以将数据写入FTDRH和FTDRL寄存器。使用FDR.T[4:0]位确认可写入的数据量。

(2) Reading data from RDR (FRDRHL)

When using the DTC or DMAC to read RDR and RDRHL, always set the receive data full interrupt (SCIn_RXI) as the activation source of the relevant SCI.

27.15.8 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IELSRn.IR flag) in the ICU is 1, follow the procedure in this section to clear interrupt requests before permitting operations (by setting the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit to 1). For details on the interrupt status flag, see section 13, Interrupt Controller Unit (ICU).

1. Confirm that transfer has stopped (the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit is 0)
2. Set the associated interrupt enable bit (SCR/SCR_SMCI.TIE or SCR/SCR_SMCI.RIE bit) to 0
3. Read the associated interrupt enable bit (SCR/SCR_SMCI.TIE or SCR/SCR_SMCI.RIE bit) to check that it actually becomes 0
4. Set the interrupt status flag, IELSRn.IR, in the ICU to 0

27.15.9 External Clock Input in Clock Synchronous Mode and Simple SPI Mode

In clock synchronous mode and simple SPI mode, the external clock SCKn must be input as follows:

High-pulse period, low-pulse period = 2 PCLK cycles or more, period = 6 PCLK cycles or more.

27.15.10 Limitations on Simple SPI Mode

(1) Master mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set in the SPMR.CKPH and CKPOL bits when the SPMR.SSE bit is 1.

  This prevents the clock line from being placed in the high-impedance state when the SCR.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR.TE bit changes from 0 to 1. When the SPMR.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not required because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.

- For the clock delay setting (SPMR.CKPH bit is 1), the receive data full interrupt (SCIn_RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 27.105. If the TE and RE bits in the SCR register become 0 before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Additionally, an SCIn_RXI interrupt might lead to the input signal on the SSn pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, the SCKn pin output goes to high-impedance while the input on the SSn pin is at the low level if a mode fault error occurs while a character is being transferred, stopping supply of the clock signal to the connected slave. Reset the connected slave to avoid misaligned bits when transfer is restarted.

(2) 从RDR(FRDRHL)读取数据

使用DTC或DMAC读取RDR和RDRHL时，始终将接收数据满中断（SCIn_RXI）设置为相关SCI的激活源。

27.15.8 开始转移注意事项

在ICU中的中断状态标志（IELSRn.IR标志）为1时开始传输的点，按照本节中的程序在允许操作之前清除中断请求（通过设置SCRSCR_SMCI.TE或SCRSCR_SMCI.RE位到1)。有关中断状态标志的详细信息，请参见第13节，中断控制器单元(ICU)。

1.确认传输已停止（SCRSCR_SMCI.TE或SCRSCR_SMCI.RE位为0）

2.将相关的中断使能位（SCRSCR_SMCI.TIE或SCRSCR_SMCI.RIE位）设置为0

3.读取相关的中断使能位（SCRSCR_SMCI.TIE或SCRSCR_SMCI.RIE位），检查它是否实际变为0

4.将ICU中的中断状态标志IELSRn.IR设置为0

27.15.9 时钟同步模式和简单SPI模式下的外部时钟输入

在时钟同步模式和简单SPI模式下，外部时钟SCKn必须输入如下：

高脉冲周期，低脉冲周期=2个PCLK周期或更多，周期=6个PCLK周期或更多。

27.15.10 简单SPI模式的限制

(1) 主模式

●当SPMR.SSE位为1时，使用电阻上拉或下拉与SPMR.CKPH和CKPOL位中设置的传输时钟的初始设置相匹配的时钟线。

这可以防止当SCR.TE位设置为0时时钟线处于高阻抗状态，或者当SCR.TE位从0变为1时在时钟线上产生意外边沿。SSE位在单主机模式下为0，不需要上拉或下拉时钟线，因为即使SCR.TE位设置为0，时钟线也不会处于高阻状态。

●对于时钟延迟设置（SPMR.CKPH位为1），接收数据满中断（SCIn_RXI）在SCKn引脚的最后一个时钟沿之前产生，如图27.105所示。如果SCR寄存器中的TE和RE位在SCKn引脚上的时钟信号的最后一个边沿之前变为0，则SCKn引脚处于高阻状态，因此传输时钟的最后一个时钟脉冲的宽度为缩短。此外，SCIn_RXI中断可能会导致所连接从机的SSn引脚上的输入信号在SCKn引脚上的时钟信号的最后一个边沿之前变为高电平，从而导致从机的错误操作。

●在多主机配置中，如果在传输字符时发生模式故障错误，则SCKn引脚输出变为高阻态，而SSn引脚上的输入处于低电平，从而停止向主机提供时钟信号。连接的奴隶。重新启动传输时，重置连接的从机以避免未对齐的位。

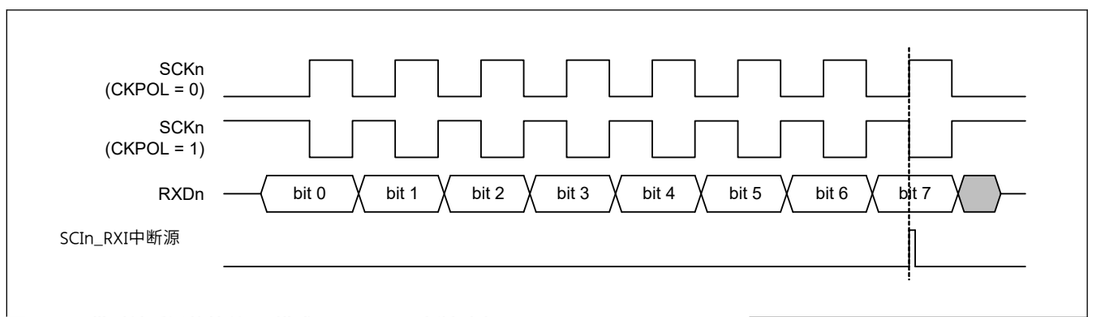

图27.105带时钟延迟的简单SPI模式下SCIn_RXI中断时序

(2) Slave mode

- Wait at least the following time from writing transmit data in the TDR register to the start of the external clock input.
  1 PCLK cycle + data output delay for the slave (t_{DO}) + setup time for the master (t_{SU})
  Also wait at least 5 PCLK cycles from the input of the low level on the SSn pin to the start of the external clock input.
- Provide an external clock signal to the master the same as the data length for transfer
- Control the input on the SSn pin before the start and after the end of data transfer
- When the input level on the SSn pin is to be changed from low to high while a character is being transferred, set the TE and RE bits in the SCR register to 0 and, after restoring the settings, restart transfer of the first byte

27.15.11 Notes on Transmit Enable bit (SCR.TE)

In initial register value, when SCR.TE bit is “0”, the terminal as “TXDn” outputs high impedance.

So please make sure that the TXDn line won’t be high impedance by the following one of ways.

1. The pull-up resistance is connected to the TXDn line.
2. Before SCR.TE bit is “0”, the function of the terminal is changed to general-purpose input port or output port. And after SCR.TE bit is “1”, thr function of the terminal is changed to “TXDn”.
3. In asynchronous mode, you can set SPTR and decided level of TXDn terminal during SCR.TE is “0”.

In the Simple SPI mode slave operation, the RXDn terminal operates in the same way as the above TXDn terminal, so please deal with 1 or 2 in the same way. (3 can not be used.)

27.15.12 Note on Stopping Reception When Using the RTS Function in Asynchronous Mode

One clock cycle of PCLK is required for the time from setting the SCR.RE bit to 0 to stopping the RTS signal generator in asynchronous mode.

When reading the RDR (or RDRL) register after setting the SCR.RE bit to 0, confirm that the RE bit has been set to 0 before reading the RDR (or RDRL) register to prevent these two processes from being performed consecutively.

(2) 从机模式

●从将发送数据写入TDR寄存器到外部时钟输入开始，至少等待以下时间。
1个PCLK周期+从机的数据输出延迟(tDO)+主机的建立时间(tSU)
还要等待至少5个PCLK周期，从SSn引脚上的低电平输入到外部时钟输入开始。

●向主机提供与传输数据长度相同的外部时钟信号

●在数据传输开始前和结束后控制SSn引脚上的输入

●当在字符传输过程中SSn引脚的输入电平由低变为高时，将SCR寄存器中的TE和RE位设置为0，并在恢复设置后重新开始传输第一个字节

27.15.11 发送使能位(SCR.TE)的注意事项

在初始寄存器值中，当SCR.TE位为“0”时，“TXDn”端输出高阻抗。

所以请通过以下方式之一确保TXDn线不会高阻。

1.上拉电阻连接到TXDn线。

2.SCR.TE位为“0”之前，端子功能变为通用输入端口或输出端口。并且在SCR.TE位为“1”后，终端的thr功能变为“TXDn”。

3.在异步模式下，可以设置SPTR和SCR.TE期间TXDn端子的决定电平为“0”。

在SimpleSPI模式从机操作中，RXDn端子与上述TXDn端子的操作方式相同，因此请按相同方式处理1或2。（3个不能用。）

27.15.12 异步使用RTS函数时停止接收的注意事项 Mode

从将SCR.RE位设置为0到在异步模式下停止RTS信号发生器，需要一个PCLK时钟周期。

在将SCR.RE位设置为0后读取RDR（或RDRL）寄存器时，请在读取RDR（或RDRL）寄存器之前确认RE位已设置为0，以防止这两个过程连续执行。

SDAO bit (SDA Output Control/Monitor) and SCLO bit (SCL Output Control/Monitor)

The SDAO and SCLO bits directly control the SDA0 and SCL0 signals output from the IIC. When writing to these bits, also write 0 to the SOWP bit. Setting these bits results in input to the IIC by the input buffer. When slave mode is selected, a start condition might be detected and the bus might be released, depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, transmission, or reception. Operation after rewriting under these conditions is not guaranteed. When reading these bits, the state of signals output from the IIC can be read.

CLO bit (Extra SCL Clock Cycle Output)

The CLO bit allows output of an extra SCL clock cycle for debugging or error processing. Normally, set this bit to 0. Setting the bit to 1 in a normal communication state causes a communication error. For details on this function, see section 28.12.2. Extra SCL Clock Cycle Output Function.

IICRST bit (I^2C Bus Interface Internal Reset)

The IICRST bit initiates an internal state reset of the IIC. Setting this bit to 1 initiates an IIC reset or internal reset. Whether an IIC reset or internal reset is initiated is determined by the settings of this bit in combination with the ICE bit. Table 28.3 lists the IIC resets.

The IIC reset initializes all registers except ICCR1.ICE and ICCR1.IICRST bits and internal states of the IIC. In addition to the internal states of the IIC, the internal reset initializes the following:

- Bit counter (ICMR1.BC[2:0] bits)
- I^2C Bus Shift Register (ICDRS)
- I^2C Bus Status Registers (ICSR1 and ICSR2)
- SDAO and SCLO Output Control/Monitor (ICCR1.SDAO and ICCR1.SCLO bits)

SDAO位（SDA输出控制监视器）和SCLO位（SCL输出控制监视器）

SDAO和SCLO位直接控制IIC输出的SDA0和SCL0信号。写入这些位时，还要向SOWP位写入0。设置这些位会导致输入缓冲器向IIC输入。选择从模式时，可能会检测到启动条件并释放总线，具体取决于位设置。

不要在开始条件、停止条件、重启条件、发送或接收期间重写这些位。不保证在这些条件下重写后的操作。读取这些位时，可以读取IIC输出的信号状态。

CLO位（额外SCL时钟周期输出）

CLO位允许输出额外的SCL时钟周期用于调试或错误处理。通常，将此位设置为0。在正常通信状态下将此位设置为1会导致通信错误。有关此功能的详细信息，请参阅第28.12.2节。额外的SCL时钟周期输出功能。

IICRST位（I2C总线接口内部复位）

IICRST位启动IIC的内部状态复位。将此位设置为1会启动IIC复位或内部复位。是IIC复位还是内部复位由该位的设置和ICE位共同决定。表28.3列出了IIC复位。

IIC复位初始化除ICCR1.ICE和ICCR1.IICRST位和IIC内部状态之外的所有寄存器。除了IIC的内部状态之外，内部复位还会初始化以下内容：

- ●位计数器（ICMR1.BC[2:0]位）
- ●I2C总线移位寄存器(ICDRS)
- ●I2C总线状态寄存器（ICSR1和ICSR2）
- ●SDAO和SCLO输出控制监视器（ICCR1.SDAO和ICCR1.SCLO位）

- I²C Bus Control Register 2 (except ICCR2.BBSY bit)

For the reset conditions for each register, see section 28.15. State of Registers When Issuing Each Condition.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the IIC without initializing the port settings and the control and setting registers of the IIC. If the IIC hangs in a low-level output state, resetting the internal states cancels the low-level output state and releases the bus with the SCL0 pin and SDA0 pin at high impedance.

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up that occurs during communication with the master device in slave mode, the slave and master devices might enter different states, because the bit counter information differs. For this reason, do not initiate an internal reset in slave mode. Initiate recovery processing from the master device. If an internal reset is required because the IIC hangs with the SCL0 line in a low-level output state in slave mode, initiate an internal reset, then issue a restart condition from the master device, or issue a stop condition and resume communication from the start condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start or restart condition from the master device, synchronization is lost because the master and slave devices operate asynchronously.

Table 28.3 IIC resets

IICRST	ICE	State	Specifications
1	0	IIC reset	Resets all registers except ICCR1.IICRST and ICCR1.ICE bits, and the internal states of the IIC
	1	Internal reset	Reset the following: • ICMR1.BC[2:0] bits • ICSR1, ICSR2, ICDRS registers • SDAO and SCLO Output Control/Monitor (ICCR1.SDAO and ICCR1.SCLO bits) • I²C Bus Control Register 2 (except ICCR2.BBSY bit) • Internal states of the IIC

ICE bit (I²C Bus Interface Enable)

The ICE bit selects the active or inactive state of the SCL0 and SDA0 pins. It can also be combined with the IICRST bit to initiate two types of resets. See Table 28.3 for the reset descriptions.

Set the ICE bit to 1 when using the IIC. The SCL0 and SDA0 pins are placed in the active state when the ICE bit is set to 1. Set the ICE bit to 0 when the IIC is not used. The SCL0 and SDA0 pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCL0 or SDA0 pin to the IIC when setting up the pin function control. Slave address comparison is performed if the pins are assigned to the IIC.

●I2C总线控制寄存器2（ICCR2.BBSY位除外）

关于各寄存器的复位条件，请参阅第28.15节。发出每个条件时的寄存器状态。

在操作期间将IICRST位设置为1（ICE位设置为1）启动的内部复位会复位IIC的内部状态，而无需初始化IIC的端口设置以及控制和设置寄存器。如果IIC挂在低电平输出状态，复位内部状态会取消低电平输出状态并释放总线，SCL0引脚和SDA0引脚处于高阻抗状态。

Note: 如果在从模式下与主设备通信期间发生的总线挂断使用IICRST位启动内部复位，则从设备和主设备可能会进入不同的状态，因为位计数器信息不同。因此，不要在从模式下启动内部复位。从主设备启动恢复处理。如果由于IIC在从模式下挂起且SCL0线处于低电平输出状态而需要内部复位，则启动内部复位，然后从主设备发出重新启动条件，或者发出停止条件并从主设备恢复通信开始条件。如果通过仅在从设备中启动复位来重新启动通信，而没有从主设备发出启动或重启条件，则由于主设备和从设备异步操作而失去同步。

ICE位（I2C总线接口使能）

ICE位选择SCL0和SDA0引脚的有效或无效状态。它也可以与IICRST位组合来启动两种类型的复位。复位说明见表28.3。

使用IIC时将ICE位设置为1。当ICE位设置为1时，SCL0和SDA0引脚处于活动状态。不使用IIC时，将ICE位设置为0。当ICE位设置为0时，SCL0和SDA0引脚处于无效状态。在设置引脚功能控制时，不要将SCL0或SDA0引脚分配给IIC。如果引脚分配给IIC，则执行从地址比较。

Note 1. The MST and TRS bits can be written to when the ICMR1.MTWP bit is set to 1.

ST bit (Start Condition Issuance Request)

The ST bit requests transition to master mode and triggers a start condition. When this bit is set to 1, a start condition is issued when the BBSY flag is set to 0 (bus free state). For details on this function, see section 28.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the ST bit.

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Only set the ST bit to 1 (start condition request) when the BBSY flag is set to 0 (bus free state). Arbitration might be lost if the ST bit is set to 1 (start condition request) when the BBSY flag is 1 (bus busy state).

RS bit (Restart Condition Issuance Request)

The RS bit requests that a restart condition be issued in master mode. When this bit is set to 1 to request a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 28.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the RS bit with the BBSY flag in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Do not set the RS bit to 1 while issuing a stop condition.
Note: If 1 (restart condition request) is written to the RS bit in slave mode, the restart condition is not issued, but the RS bit remains set to 1. If the operating mode changes to master mode without the bit being cleared, a restart condition might be issued.

Bit	Symbol	Function	R/W
3	SP	停止条件发出请求 0：不发出停止条件请求1：发出停止条件请求	R/W
4	—	该位读取为0。写入值应为0。	R/W
5	TRS	Transmit/Receive Mode 0：接收模式1：发送模式	R/W*1
6	MST	Master/Slave Mode 0：从模式1：主模式	R/W*1
7	BBSY	总线忙检测标志 0：I2C总线释放（总线空闲状态）1：I2C总线占用（总线忙状态）	R

注1.当ICMR1.MTWP位设置为1时，可以写入MST和TRS位。

ST位（开始条件发布请求）

ST位请求转换到主模式并触发启动条件。当该位设置为1时，当BBSY标志设置为0（总线空闲状态）时发出启动条件。有关此功能的详细信息，请参阅第28.11节。启动、重启和停止条件发布功能。

[Setting condition]

●ST位写入1时。

[Clearing conditions]

●ST位写入0时

●发出启动条件时（检测到启动条件）

●ICSR2中的AL（仲裁失败）标志设置为1时

●当ICCR1的IICRST位写入1时，应用IIC复位或内部复位。

Note: 仅当BBSY标志设置为0（总线空闲状态）时，才将ST位设置为1（启动条件请求）。如果在BBSY标志为1（总线繁忙状态）时将ST位设置为1（开始条件请求），则仲裁可能会丢失。

RS位（重启条件发布请求）

RS位请求在主机模式下发出重启条件。当该位设置为1以请求重新启动条件时，当BBSY标志设置为1（总线繁忙状态）且MST位设置为1（主模式）时，发出重新启动条件。有关此功能的详细信息，请参阅第28.11节。启动、重启和停止条件发布功能。

[Setting condition]

●当ICCR2中的BBSY标志设置为1时，将1写入RS位。

[Clearing conditions]

●向RS位写入0时

●发出重新启动条件时（检测到启动条件）

●ICSR2中的AL（仲裁失败）标志设置为1时

●当ICCR1的IICRST位写入1时，应用IIC复位或内部复位。

Note: 发出停止条件时不要将RS位设置为1。
Note: 如果在从模式下将1（重新启动条件请求）写入RS位，则不会发出重新启动条件，但RS位保持设置为1。如果操作模式更改为主模式而未清除该位，则重新启动条件可能会发出。

SP bit (Stop Condition Issuance Request)

The SP bit requests that a stop condition be issued in master mode. When this bit is set to 1, a stop condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 28.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the MST bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition is issued (a stop condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Writing to the SP bit is not possible while the BBSY flag is 0 (bus free state).
Note: Do not set the SP bit to 1 while a restart condition is being issued.

TRS bit (Transmit/Receive Mode)

The TRS bit indicates transmit or receive mode. The IIC is in receive mode when the TRS bit is 0 and in transmit mode when the bit is 1. The combination of this bit and the MST bit indicates the IIC operating mode.

The value of the TRS bit automatically changes to 1 for transmit mode or 0 for receive mode when a start condition is issued or detected and the R/W# bit is set. Although writing to the TRS bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When a restart condition is issued normally because of a restart condition request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit appended to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in ICSER, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When the R/W# bit appended to the slave address is set to 1 in master mode
- In slave mode, on a match between the received address and the address enabled in ICSER when the value of the received R/W# bit is 0, including when the received address is the general call address
- In slave mode, when a restart condition is detected (a restart condition is detected with ICCR2.BBSY = 1 and ICCR2.MST = 0)
- When 0 is written to the TRS bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

MST bit (Master/Slave Mode)

The MST bit indicates master or slave mode. The IIC is in slave mode when the MST bit is 0 and is in master mode when the bit is 1. The combination of this bit and the TRS bit indicates the IIC operating mode.

The value of the MST bit automatically changes to 1 for master mode or 0 for slave mode when a start condition is issued or a stop condition is issued or detected. Although writing to the MST bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

SP位（停止条件发布请求）

SP位请求在主机模式下发出停止条件。当该位设置为1时，当BBSY标志设置为1（总线繁忙状态）且MST位设置为1（主模式）时，发出停止条件。有关此功能的详细信息，请参阅第28.11节。启动、重启和停止条件发布功能。

[Setting condition]

●当ICCR2中的BBSY标志和MST位都设置为1时，将1写入SP位。

[Clearing conditions]

●SP位写入0时
●发出停止条件时（检测到停止条件）
●ICSR2中的AL（仲裁失败）标志设置为1时
●检测到启动条件和重启条件时
●当ICCR1的IICRST位写入1时，应用IIC复位或内部复位。

Note: 当BBSY标志为0（总线空闲状态）时，不能写入SP位。
Note: 发出重启条件时不要将SP位设置为1。

TRS bit (Transmit/Receive Mode)

TRS位指示发送或接收模式。TRS位为0时IIC处于接收模式，该位为1时IIC处于发送模式。该位和MST位的组合表示IIC工作模式。

当发出或检测到启动条件并且设置RW#位时，TRS位的值自动更改为1（发送模式）或0（接收模式）。虽然当ICMR1的MTWP位设置为1时可以写入TRS位，但在正常使用期间不需要写入该位。

[Setting conditions]

●因启动条件请求而正常发出启动条件时（ST位设置为1时检测到启动条件时）
●因重新启动条件请求而正常发出重新启动条件时（在RS位设置为1的情况下检测到重新启动条件时）
●在主机模式下，附加在从机地址上的RW#位设置为0时
●从机模式接收到的地址与ICSER中使能的地址匹配时，RW#位设置为1
●当ICMR1中的MTWP位设置为1时将1写入TRS位。

[Clearing conditions]

●检测到停止条件时
●ICSR2中的AL（仲裁失败）标志设置为1时
●在主机模式下，附加在从机地址上的RW#位设置为1时
●从机模式下，当接收到的RW#位的值为0时，接收到的地址与ICSER中使能的地址匹配，包括当接收到的地址是广播地址时
●在从模式下，检测到重启条件时（检测到重启条件时ICCR2.BBSY=1和ICCR2.MST=0）
●当ICMR1中的MTWP位设置为1时，将0写入TRS位时
●当ICCR1的IICRST位写入1时，应用IIC复位或内部复位。

MST bit (Master/Slave Mode)

MST位指示主机或从机模式。当MST位为0时，IIC处于从机模式，当该位为1时，IIC处于主机模式。该位和TRS位的组合表示IIC工作模式。

当发出启动条件或发出或检测到停止条件时，MST位的值自动变为1（主机模式）或0（从机模式）。虽然当ICMR1中的MTWP位设置为1时可以写入MST位，但在正常使用期间不需要写入该位。

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 0 is written to the MST bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

BBSY flag (Bus Busy Detection Flag)

The BBSY flag indicates whether the I^2C bus is occupied (bus busy state) or released (bus free state). The flag is set to 1 when the SDA0 line changes from high to low when the SCL0 line is high, assuming that a start condition was issued. The flag is set to 0 if a start condition is not detected for the bus free time (ICBRL setting), assuming that a stop condition was issued.

[Setting condition]

- When a start condition is detected.

[Clearing conditions]

- When a start condition is not detected for the bus free time (ICBRL setting) after detecting a stop condition
- When 1 is written to the IICRST bit in ICCR1 with the ICE bit in ICCR1 set to 0 (IIC reset).

BBSY标志（总线忙检测标志）

BBSY标志指示I2C总线是被占用（总线繁忙状态）还是被释放（总线空闲状态）。当SCL0线为高电平时SDA0线从高电平变为低电平时，该标志设置为1，假设发出了启动条件。如果在总线空闲时间（ICBRL设置）没有检测到启动条件，则该标志设置为0，假设发出了停止条件。

BC[2:0] bits (Bit Counter)

The BC[2:0] bits function as a counter indicating the number of bits remaining to be transferred on detection of a rising edge on the SCL0 line. Although BC[2:0] are read/write bits, it is not required to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one, for an additional acknowledge bit, between transferred frames when the SCL0 line is at a low level. The value in the BC[2:0] bits returns to 000b at the end of a data transfer, including the acknowledge bit, or when a start or restart condition is detected.

Note 1. The setting DLCS = 1 (IICφ/2) is only valid when SCL is low. When SCL is high, the DLCS = 1 setting becomes invalid and the clock source becomes the internal reference clock (IICφ).

TMOS bit (Timeout Detection Time Select)

The TMOS bit selects long or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE = 1). When this bit is set to 0, long mode is selected. When it is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14- bit counter. While the SCL0 line is in the state that enables this counter as specified in the TMOH and TMOL bits, the counter

BC[2:0] bits (Bit Counter)

BC[2:0]位用作计数器，指示在检测到SCL0线上的上升沿时要传输的剩余位数。虽然BC[2:0]是读写位，但在正常情况下不需要访问这些位。

要写入这些位，当SCL0线处于低电平时，指定要传输的位数加1，作为附加的确认位，在传输的帧之间。BC[2:0]位中的值在数据传输结束时返回到000b，包括确认位，或者当检测到启动或重启条件时。

注1.设置DLCS=1(IICφ2)仅在SCL为低电平时有效。当SCL为高电平时，DLCS=1设置无效，时钟源变为内部参考时钟(IICφ)。

TMOS位（超时检测时间选择）

当使能超时功能（ICFER.TMOE=1）时，TMOS位为超时检测时间选择长模式或短模式。当该位设置为0时，选择长模式。当设置为1时，选择短模式。在长模式下，超时检测内部计数器用作16位计数器。在短模式下，计数器用作14位计数器。当SCL0线处于启用TMOH和TMOL位中指定的计数器的状态时，计数器

counts up in synchronization with the internal reference clock (IICφ) as a count source. For details on this function, see section 28.12.1. Timeout Function.

TMOL bit (Timeout L Count Control)

The TMOL bit enables or disables up-counting on the internal counter of the timeout function while the SCL0 line is held low and the timeout function is enabled (ICFER.TMOE = 1).

TMOH bit (Timeout H Count Control)

The TMOH bit enables or disables up-counting on the internal counter of the timeout function while the SCL0 line is held high and the timeout function is enabled (ICFER.TMOE = 1).

SDDL[2:0] bits (SDA Output Delay Counter)

The SDDL[2:0] bits can be used to delay the SDA output. This counter works with the clock source selected in the DLCS bit. This setting can be used for all types of SDA output, including transmission of the acknowledge bit.

Set the SDA output delay to meet the I²C bus standard for the data enable time/acknowledge enable time,*1 or the SMBus standard, within [data hold time (300 ns or more + the SCL clock low-level period) - the data setup time (250 ns)]. If a value outside the standard is set, communication between devices might malfunction or falsely indicate a start or stop condition, depending on the bus state.

For details on this function, see section 28.5. SDA Output Delay Function.

Note 1. Data enable time/acknowledge enable time.
3,450 ns for up to 100 kbps: Standard mode (Sm)
900 ns for up to 400 kbps: Fast mode (Fm)

与作为计数源的内部参考时钟(IICφ)同步计数。有关此功能的详细信息，请参阅第28.12.1节。超时功能。

TMOL位（超时L计数控制）

TMOL位启用或禁用超时功能内部计数器的递增计数，同时SCL0线保持低电平且启用超时功能(ICFER.TMOE=1)。

TMOH位（超时H计数控制）

TMOH位启用或禁用超时功能内部计数器的递增计数，同时SCL0线保持高电平且启用超时功能(ICFER.TMOE=1)。

SDDL[2:0]位（SDA输出延迟计数器）

SDDL[2:0]位可用于延迟SDA输出。该计数器与在DLCS位中选择的时钟源一起工作。该设置可用于所有类型的SDA输出，包括确认位的传输。

将SDA输出延迟设置为满足I2C总线标准的数据使能时间确认使能时间，*1或SMBus标准，在[数据保持时间（300 ns或更长+SCL时钟低电平周期）内的数据建立时间（250ns）]。如果设置了超出标准的值，则设备之间的通信可能会发生故障或错误地指示开始或停止条件，具体取决于总线状态。

有关此功能的详细信息，请参阅第28.5节。SDA输出延迟功能。

7	SMBS	SMBus/I2C Bus Select 0: Select I2C Bus 1: Select SMBus	R/W

Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If the application writes 1 to the ACKWP and ACKBT bits at the same time, the ACKBT bit is not set to 1.
Note 2. The WAIT and RDRFS bits are only valid in receive mode (invalid in transmit mode).

NF[1:0] bits (Noise Filter Stage Select)

The NF[1:0] bits select the number of stages in the digital noise filter. For details on this function, see section 28.6. Digital Noise Filter Circuits

Note: Set the noise range to be filtered within a range less than the SCL0 line high- or low-level period. If the noise range is set to a value of [SCL clock width: high- or low-level period, whichever is shorter] - [1.5 internal reference clock (IICφ) cycles + analog noise filter: 120 ns (reference values)] or more, the SCL clock is regarded as noise, which might prevent the IIC from operating normally.

ACKBR bit (Receive Acknowledge)

The ACKBR bit stores the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKBT bit (Transmit Acknowledge)

The ACKBT bit sets the acknowledge bit to be sent in receive mode

[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1.

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition request is detected with the SP bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKWP bit (ACKBT Write Protect)

The ACKWP bit controls write enabling of the ACKBT bit.

RDRFS bit (RDRF Flag Set Timing Select)

The RDRFS bit selects the RDRF flag set timing in receive mode and also selects whether to hold the SCL0 line low on the falling edge of the 8th SCL clock cycle.

When the RDRFS bit is 0, the SCL0 line is not held low on the falling edge of the 8th SCL clock cycle, and the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 on the rising edge of the 8th SCL clock cycle, and the SCL0 line is held low on the falling edge of the 8th SCL clock cycle. The low-hold of the SCL0 line is released by a write to the ACKBT bit.

After data is received with this setting, the SCL0 line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1), based on the receive data.

Bit	Symbol	Function	R/W
6	WAIT	通过读取ICDRR释放低保持。 0：无等待（在第9个时钟周期和第1个时钟周期之间的时间段内，SCLn线不保持低电平。） 1：等待（SCLn线在第9个时钟周期和第1个时钟周期之间保持低电平。）	R/W*2
7	SMBS	SMBusI2C总线选择 0：选择I2C总线1 ：选择SMBus	R/W

注1.仅当ACKWP位已经为1时才写入ACKBT位。如果应用程序同时向ACKWP和ACKBT位写入1，则ACKBT位不会设置为1。

注2.WAIT和RDRFS位仅在接收模式下有效（在发送模式下无效）。

NF[1:0]位（噪声滤波器级选择）

NF[1:0]位选择数字噪声滤波器的级数。关于此功能的详细信息，请参阅第28.6节。数字的噪声滤波电路

Note: 将要过滤的噪声范围设置在小于SCL0线高电平或低电平周期的范围内。如果噪声范围设置为[SCL时钟宽度：高电平或低电平周期，以较短者为准][1.5内部参考时钟(IICφ)周期+模拟噪声滤波器：120ns（参考值）]或更大的值，则SCL时钟被视为噪声，可能会妨碍IIC正常工作。

ACKBR bit (Receive Acknowledge)

ACKBR位存储在发送模式下从接收设备接收到的确认位信息。

[Setting condition]

●当ICCR2中的TRS位设置为1接收到1作为确认位时。

[Clearing conditions]

●当ICCR2中的TRS位设置为1接收到0作为确认位时

●当ICCR1中的IICRST位写入1而ICCR1中的ICE位为0时（IIC复位）。

ACKBT bit (Transmit Acknowledge)

ACKBT位设置要在接收模式下发送的确认位

[Setting condition]

●当1写入该位且ACKWP位设置为1时。

[Clearing conditions]

●当0写入该位且ACKWP位设置为1时

●ICCR2的SP位设置为1时检测到停止条件请求时

●当ICCR1中的IICRST位写入1而ICCR1中的ICE位为0时（IIC复位）。

ACKWP位（ACKBT写保护）

ACKWP位控制ACKBT位的写使能。

RDRFS位（RDRF标志设置时序选择）

RDRFS位选择接收模式下的RDRF标志设置时序，还选择是否在第8个SCL时钟周期的下降沿将SCL0线保持为低电平。

当RDRFS位为0时，SCL0线在第8个SCL时钟周期的下降沿不保持低电平，并且RDRF标志在第9个SCL时钟周期的上升沿设置为1。

当RDRFS位为1时，RDRF标志在第8个SCL时钟周期的上升沿设置为1，并且SCL0线在第8个SCL时钟周期的下降沿保持低电平。SCL0线的低保持通过写ACKBT位来释放。

使用此设置接收数据后，SCL0线在发送确认位之前自动保持低电平。这使处理能够根据接收数据发送ACK(ACKBT=0)或NACK(ACKBT=1)。

WAIT bit (WAIT)

The WAIT bit controls whether to force a low-hold between the ninth SCL clock cycle and the first SCL clock cycle, until the receive data buffer (ICDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation continues without a low-hold between the ninth and the first SCL clock cycle. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCL0 line is held low from the falling edge of the ninth clock cycle until the ICDRR value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When the value of the WAIT bit is to be read, always read ICDRR first.

SMBS bit (SMBus/I²C Bus Select)

Setting the SMBS bit to 1 selects the SMBus and enables the HOAE bit in ICSER.

Note 1. The Fast-mode Plus enable bit (FMPE) is supported by IIC0 (SCL0_A, SDA0_A). Bit [7] is the reserved bit in the not supported channel.

TMOE bit (Timeout Function Enable)

The TMOE bit enables or disables the timeout function. For details on this function, see section 28.12.1. Timeout Function.

等待位（等待）

WAIT位控制是否在第9个SCL时钟周期和第一个SCL时钟周期之间强制保持低电平，直到每次在接收模式下接收到单字节数据时完全读取接收数据缓冲区(ICDRR)。

当WAIT位为0时，接收操作继续，在第9个和第一个SCL时钟周期之间没有低电平保持。当RDRFS和WAIT位都为0时，双缓冲器使能连续接收操作。

当WAIT位为1时，SCL0线从第9个时钟周期的下降沿保持低电平，直到每次接收到单字节数据时读取ICDRR值。这启用了以字节为单位的接收操作。

Note: 当要读取WAIT位的值时，总是先读取ICDRR。

SMBS位（SMBusI2C总线选择）

将SMBS位设置为1可选择SMBus并启用ICSER中的HOAE位。

TMOE位（超时功能使能）

TMOE位启用或禁用超时功能。有关此功能的详细信息，请参阅第28.12.1节。超时功能。

MALE bit (Master Arbitration-Lost Detection Enable)

The MALE bit specifies whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

The NALE bit specifies whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode, for example when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with a different number of receive bytes.

SALE bit (Slave Arbitration-Lost Detection Enable)

The SALE bit specifies whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode, for example when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs because of noise.

NACKE bit (NACK Reception Transfer Suspension Enable)

The NACKE bit specifies whether to continue or discontinue the transfer operation when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended. When the NACKE bit is 0, the next transfer operation continues regardless of the received acknowledge content.

For details, see section 28.9.2. NACK Reception Transfer Suspension Function.

SCLE bit (SCL Synchronous Circuit Enable)

The SCLE bit specifies whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCLE bit is set to 0 (no SCL synchronous circuit used), the IIC does not synchronize the SCL clock with the SCL input clock. With this setting, the IIC outputs the SCL clock at the transfer rate set in ICBRH and ICBRL, regardless of the SCL0 line state. For this reason, if the bus load of the I^2C bus line is much larger than the specification value, or if the SCL clock output overlaps in multiple masters, a short-cycle SCL clock that does not meet the specification might be output. When no SCL synchronous circuit is used, it also affects the issuing of the start, restart, and stop conditions, and the continuous output of extra SCL clock cycles.

Do not set this bit to 0 except when checking the output of the set transfer rate.

FMPE bit (Fast-Mode Plus Enable)

The FMPE bit specifies whether to use a slope control circuit for Fast-mode Plus (Fm+).

When this bit is set to 1, a slope control circuit conforming to the I^2C bus Fast-mode Plus (Fm+) standard (tof) is selected. When this bit is set to 0, a slope control circuit conforming to the I^2C bus Standard-mode (Sm) and Fast-mode (Fm) standards (tof) is selected.

Set this bit to 1 when using transmission rates up to 1 Mbps (Fast-mode Plus (Fm+) standard). Set it to 0 when using other transmission rates (up to 100 kbps (Sm) or up to 400 kbps (Fm)) or for SMBus (10 to 100 kbps).

MALE位（主仲裁丢失检测使能）

MALE位指定是否在主机模式下使用仲裁丢失检测功能。通常，将此位设置为1。

NALE位（NACK传输仲裁丢失检测使能）

NALE位指定在接收模式下发送NACK期间检测到ACK时是否导致仲裁丢失，例如，当总线上存在具有相同地址的从设备时，或者当两个或多个主设备同时选择相同的从设备时接收字节数。

SALE位（从设备仲裁丢失检测使能）

SALE位指定当在从发送模式下在总线上检测到与正在发送的值不同的值时是否导致仲裁丢失，例如，当总线上存在具有相同地址的从机或与发送数据不匹配时由于噪音而发生。

NACKE位（NACK接收传输暂停使能）

NACKE位指定在发送模式下接收到NACK时是继续还是停止传输操作。通常，将此位设置为1。

当在NACKE位设置为1的情况下接收到NACK时，暂停下一个传输操作。当NACKE位为0时，无论接收到的确认内容如何， 下一次传输操作都会继续进行。

有关详细信息，请参阅第28.9.2节。NACK接收传输暂停功能。

SCLE位（SCL同步电路使能）

SCLE位指定是否将SCL时钟与SCL输入时钟同步。通常，将此位设置为1。

当SCLE位设置为0（不使用SCL同步电路）时，IIC不会将SCL时钟与SCL输入时钟同步。使用此设置，无论SCL0线路状态如何，IIC都以ICBRH和ICBRL中设置的传输速率输出SCL时钟。因此，如果I2C总线的总线负载远大于规格值，或者多个主机的SCL时钟输出重叠，则可能会输出不符合规格的短周期SCL时钟。当不使用SCL同步电路时，也会影响启动、重启和停止条件的发出，以及额外SCL时钟周期的连续输出。

除非检查设置传输速率的输出，否则不要将此位设置为0。

FMPE位（Fast-ModePlusEnable）

FMPE位指定是否对Fast-modePlus(Fm+)使用斜率控制电路。

当该位设置为1时，选择符合I2C总线快速模式加(Fm+)标准(tof)的斜率控制电路。
当该位设置为0时，选择符合I2C总线标准模式(Sm)和快速模式(Fm)标准(tof)的斜率控制电路。

当使用高达1Mbps的传输速率（Fast-modePlus(Fm+)标准）时，将此位设置为1。当使用其他传输速率（最高100kbps(Sm)或最高400kbps(Fm)）或SMBus（10至100kbps）时，将其设置为0。

7	HOAE	Host Address Enable 0: Disable host address detection 1: Enable host address detection	R/W

SARyE bit (Slave Address Register y Enable) (y = 0 to 2)

The SARyE bit enables or disables the received slave address and the slave address set in SARLy and SARUy.

When this bit is set to 1, the slave address set in SARLy and SARUy is enabled and is compared with the received slave address. When this bit is set to 0, the slave address set in SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

GCAE bit (General Call Address Enable)

The GCAE bit specifies whether to ignore the general call address (0000 000b + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the IIC recognizes the received slave address as the general call address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the data receive operation. When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

DIDE bit (Device-ID Address Detection Enable)

The DIDE bit specifies whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first frame after a start or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the IIC recognizes that the device-ID address was received. When the next R/W# bit is 0 (W), the IIC recognizes the second and the subsequent frames as slave addresses and continues the receive operation. When this bit is set to 0, the IIC ignores the received first frame even if it matches the device-ID address, and it recognizes the first frame as a normal slave address.

For details on this function, see section 28.7.3. Device-ID Address Detection.

HOAE bit (Host Address Enable)

The HOAE bit specifies whether to ignore the received host address (0001 000b) when the SMBS bit in ICMR3 is 1.

When this bit is set to 1 while the SMBS bit in ICMR3 is 1, if the received slave address matches the host address, the IIC recognizes the received slave address as the host address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the receive operation.

When the SMBS bit in ICMR3 or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

SARyE位（从地址寄存器y使能）（y=0到2）

SARyE位启用或禁用接收到的从机地址和设置在SARLy和SARUy中的从机地址。

当该位设置为1时，设置在SARLy和SARUy中的从机地址被启用，并与接收到的从机地址进行比较。当该位设置为0时，设置在SARLy和SARUy中的从机地址被禁用并被忽略，即使它与接收到的从机地址匹配。

GCAE位（广播呼叫地址使能）

GCAE位指定接收到的广播调用地址（0000000b+0[W]：全0）是否忽略。

当该位设置为1时，如果接收到的从机地址与广播呼叫地址匹配，则IIC将接收到的从机地址识别为广播呼叫地址，而与在SARLy和SARUy中设置的从机地址（y=0到2）无关，并执行数据接收操作。当该位设置为0时，即使接收到的从机地址与广播呼叫地址匹配，也会忽略它。

DIDE位（设备ID地址检测使能）

DIDE位指定在检测到启动或重新启动条件后的第一帧中接收到设备ID(1111100b)时是否识别和执行设备ID地址。

当该位设置为1时，如果接收到的第一个帧与设备ID匹配，则IIC识别出设备ID地址已被接收。当下一个RW#位为0(W)时，IIC将第二个和后续帧识别为从地址并继续接收操作。当该位设置为0时，IIC忽略接收到的第一帧，即使它与设备ID地址匹配，并将第一帧识别为正常的从地址。

有关此功能的详细信息，请参阅第28.7.3节。设备ID地址检测。

HOAE位（主机地址使能）

HOAE位指定当ICMR3中的SMBS位为1时是否忽略接收到的主机地址（0001000b）。

当该位设置为1且ICMR3中的SMBS位为1时，如果接收到的从机地址与主机地址匹配，则IIC将接收到的从机地址识别为主机地址，而与SARLy和SARUy中设置的从机地址无关（y=0到2)并执行接收操作。

当ICMR3中的SMBS位或HOAE位设置为0时，即使接收到的从机地址与主机地址匹配，也会忽略它。

Note 1. Only 0 can be written, to clear the flag.

TMOF flag (Timeout Detection Flag)

The TMOF flag is set to 1 when the IIC detects a timeout because the SCL0 line state remains unchanged for the set period.

[Setting condition]

- When the SCL0 line state remains unchanged for the period specified in the ICMR2.TMOH, TMOL, and TMOS bits while the ICFER.TMOE bit is 1 (timeout function enabled) in master or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF flag after reading TMOF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

AL flag (Arbitration-Lost Flag)

The AL flag indicates that bus mastership was lost in arbitration because of a bus conflict or some other reason when a start condition was issued or an address and data was transmitted. The IIC monitors the level on the SDA0 line during transmission and, if the level on the line does not match the value of the bit being output, is set the value of the AL flag to 1 to indicate that the bus is occupied by another device.

The IIC can also set the AL flag to indicate the detection of arbitration loss during NACK transmission or during data transmission.

[Setting conditions]

When master arbitration-lost detection is enabled (ICFER.MALE = 1):

- When the internal SDA output state does not match the SDA0 line level on the rising edge of the SCL clock except for the ACK period during data transmission in master transmit mode
- When a start condition is detected while the ST bit in ICCR2 is 1 (start condition requested) or the internal SDA output state does not match the SDA0 line level
- When the ST bit in ICCR2 is 1 (start condition requested), with the BBSY flag in ICCR2 set to 1.

When NACK arbitration-lost detection is enabled (ICFER.NALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICFER.SALE = 1):

- When the internal SDA output state does not match the SDA0 line level on the rising edge of the SCL clock, except for the ACK period during data transmission in slave transmit mode.

[Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

[Setting condition]

●SCL0线状态在ICMR2.TMOH、TMOL和TMOS位指定的时间段内保持不变，而ICFER.TMOE位在主机或从机模式下为1（使能超时功能）且接收到的从机地址匹配。

[Clearing conditions]

●读取TMOF=1后向TMOF标志写入0时

●当ICCR1的IICRST位写入1时，应用IIC复位或内部复位。

AL标志（仲裁失败标志）

AL标志表明在发出启动条件或发送地址和数据时，由于总线冲突或其他原因，总线控制权在仲裁中丢失。IIC在传输过程中监控SDA0线上的电平，如果线上的电平与正在输出的位的值不匹配，则将AL标志的值设置为1，表示总线被另一个设备占用.

IIC还可以设置AL标志以指示在NACK传输或数据传输期间检测到仲裁丢失。

[Setting conditions]

当启用主机仲裁丢失检测时(ICFER.MALE=1)：

●主机发送模式下数据发送期间，除了ACK周期外，当内部SDA输出状态在SCL时钟的上升沿与SDA0线电平不匹配时

●当ICCR2的ST位为1（请求启动条件）或内部SDA输出状态与SDA0线电平不匹配时检测到启动条件

●ICCR2中的ST位为1（请求启动条件）时，ICCR2中的BBSY标志设置为1。

当启用NACK仲裁丢失检测时(ICFER.NALE=1)：

●在接收模式下的NACK传输过程中，当内部SDA输出状态在ACK周期的SCL时钟上升沿与SDAn线电平不匹配时。

当启用从设备仲裁丢失检测时(ICFER.SALE=1)：

●当内部SDA输出状态在SCL时钟的上升沿与SDA0线电平不匹配时，除了在从机传输模式下数据传输期间的ACK周期。

[Clearing conditions]

●读取AL=1后向AL标志写入0时

●当ICCR1的IICRST位写入1时，应用IIC复位或内部复位。

- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1, the IIC suspends data transmission and reception. To restart data transmission or reception, set the NACKF flag to 0.

The TEND flag indicates completion of transmission.

[Setting condition]

- On the rising edge of the ninth SCL clock cycle while the TDRE flag is 1.

[Clearing conditions]

- When 0 is written to the TEND flag after reading TEND = 1
- When data is written to ICDRT
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates whether the ICDRT contains transmit data.

[Setting conditions]

- When data is transferred from ICDRT to ICDRS and ICDRT becomes empty
- When the TRS bit in ICCR2 is set to 1
- When the received slave address matches while the TRS bit is 1.

[Clearing conditions]

- When data is written to ICDRT
- When the TRS bit in ICCR2 is set to 0
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1 while the NACKE bit in ICFER is 1, the IIC suspends data transmission and reception. In this case, if the TDRE flag is 0 (next transmit data written), data is transferred to the ICDRS register and the ICDRT register becomes empty on the rising edge of the 9th clock cycle, but the TDRE flag does not set to 1.

WUSEN bit (Wakeup Function Synchronous Enable)

The WUSEN bit is used in combination with the WUASYF flag (or WUSYF flag) to switch between the PCLKB synchronous and asynchronous operation, when the wakeup effective function is enabled (ICWUR.WUE = 1).

The PCLKB operation switches from synchronous to asynchronous operation:

When the ICCR2.BBSY flag is 0, if 0 is written to the WUSEN bit while the WUASYF flag is 0. The reception occurs independently of the operation of PCLKB (with PCLKB stopped) after it switches to the PCLKB asynchronous operation, on wakeup event detection.

The PCLKB operation switches from asynchronous to synchronous operation:

- When 1 is written to the WUSEN bit, with the WUASYF flag at 1, when a wakeup event is detected. After writing 1, the WUASYF flag immediately becomes 0.
- When the stop condition is detected with a wakeup event undetected.

WUASYF flag (Wakeup Function Asynchronous Operation Status Flag)

The WUASYF flag can place the IIC in PCLKB asynchronous operation when the wakeup effective function is enabled (ICWUR.WUE = 1).

[Setting condition]

- When the ICCR2.BBSY flag is 0, and the WUSEN bit is set to 0 with the ICWUR.WUE bit set to 1.

[Clearing conditions]

- When 1 is written to the WUSEN bit after detecting the wake-up event with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wake-up event with WUASY flag set to 1 with ICWUR.WUE bit set to 1.
- When you write 1 in the WUSEN bit with the WUASYF flag detected 1 and the wake-up event in the state of ICWUR.WUE = 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

WUSYF flag (Wakeup Function Synchronous Operation Status Flag)

It is shown that IIC is in the PCLKB synchronous operation at wake-up effective function (ICWUR.WUE = 1). This flag is a value in which the WUASYF flag is always reserved.

[Setting conditions]

- When 1 is written to the WUSEN bit after detecting the wake-up event with ICWUR.WUE bit set to 1 with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wake-up event with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

[Clearing condition]

- When the ICCR2.BBSY flag is 0 with the ICWUR.WUE bit set to 1 after writing 0 to the WUSEN bit.

7:3	—	这些位被读取为1。写入值应为1。	R/W

WUSEN位（唤醒功能同步使能）

WUSEN位与WUASYF标志（或WUSYF标志）结合使用，在启用唤醒有效功能（ICWUR.WUE=1）时在PCLKB同步和异步操作之间切换。

PCLKB操作从同步操作切换到异步操作：

当ICCR2.BBSY标志为0时，如果在WUASYF标志为0时将0写入WUSEN位。在唤醒事件切换到PCLKB异步操作后，接收发生独立于PCLKB的操作（PCLKB停止）检测。

PCLKB操作从异步操作切换到同步操作：

●当WUSEN位写入1且WUASYF标志为1时，检测到唤醒事件。写入1后，WUASYF标志立即变为0。

●当检测到停止条件且未检测到唤醒事件时。

WUASYF标志（唤醒功能异步操作状态标志）

WUASYF标志可以在启用唤醒有效功能（ICWUR.WUE=1）时将IIC置于PCLKB异步操作中。

[Setting condition]

●ICCR2.BBSY标志为0且WUSEN位设置为0且ICWUR.WUE位设置为1时。

[Clearing conditions]

●当检测到唤醒事件后将1写入WUSEN位，且ICWUR.WUE位设置为1。

●在检测到WUASY标志设置为1且ICWUR.WUE位设置为1的唤醒事件之前检测到WUSEN位设置为1的停止条件时。

●当您在WUSEN位写入1时，检测到WUASYF标志为1，并且唤醒事件处于ICWUR.WUE=1的状态。

- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

WUSYF标志（唤醒功能同步操作状态标志）

表明IIC在唤醒有效功能(ICWUR.WUE=1)时处于PCLKB同步操作。此标志是WUASYF标志始终保留的值。

[Setting conditions]

●当检测到唤醒事件后将1写入WUSEN位时，将ICWUR.WUE位设置为1，将WUSYF标志设置为0，并将ICWUR.WUE位设置为1。

●在检测到WUSYF标志设置为0且ICWUR.WUE位设置为1的唤醒事件之前检测到WUSEN位设置为1的停止条件时。

- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

[Clearing condition]

●当ICCR2.BBSY标志为0且ICWUR.WUE位在WUSEN位写入0后设置为1时。

SVA0 bit (10-bit Address LSB)

When the 10-bit address format is selected (SARUy.FS = 1), the SVA0 bit functions as the LSB of a 10-bit address and is combined with the SVA[6:0] bits to form the lower 8 bits of a 10-bit address.

This bit is valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in this bit is ignored.

SVA[6:0] bits (7-bit Address/10-bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS = 0), the SVA[6:0] bits function as a 7-bit address. When the 10- bit address format is selected (SARUy.FS = 1), these bits combine with the SVA0 bit to form the lower 8 bits of a 10-bit address.

When the SARyE bit in ICSER is 0, the setting in these bits is ignored.

When the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the SVA[1:0] and SARLy settings are valid.

When the SARyE bit in ICSER is 0 (SARLy and SARUy disabled), the SARUy.FS setting is invalid.

BRL[4:0] bits (Bit Rate Low-Level Period)

The BRL[4:0] bits set the low-level period of the SCL clock. ICBRL counts the low-level period with the internal reference clock source (IICφ) specified by the CKS[2:0] bits in ICMR1. ICBRL also generates the data setup time for automatic SCL low-hold operation, see section 28.9. Automatic Low-Hold Function for SCL. When the IIC is used in slave mode, the BRL[4:0] bits must be set to a value longer than the data setup time*1.

If the digital noise filter is enabled (NFE bit in ICFER is 1), set the BRL[4:0] bits to a value at least one greater than the number of stages in the noise filter. For details on the number of stages, see the description of the NF[1:0] bits in section 28.2.5. ICMR3 : I2C Bus Mode Register 3.

如果启用了数字噪声滤波器（ICFER中的NFE位为1），请将BRL[4:0]位设置为至少比噪声滤波器中的级数大1的值。关于阶段数的详细信息，请参见第28.2.5节中对NF[1:0]位的描述。ICMR3：I2C总线模式寄存器3。

ICBRH counts the high-level period with the internal reference clock source (IICφ) specified in the CKS[2:0] bits in ICMR1.

If the digital noise filter is enabled (the NFE bit in ICFER is 1), set these bits to a value at least one greater than the number of stages in the noise filter. For the number of stages in the noise filter, see the description of the NF[1:0] bits in section 28.2.5. ICMR3 : I2C Bus Mode Register 3.

The IIC transfer rate and the SCL clock duty are calculated using the following expressions (1) to (5):

1. ICFER.SCLE = 0
   Transfer rate = 1/[{(BRH + 1) + (BRL + 1)}/IICφ*1 + tr*2 + tf*2]
   Duty cycle = [tr + {(BRH + 1)/IICφ}]/[tr + tf + {(BRH + 1) + (BRL + 1)}/IICφ]
2. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = 1/[{(BRH + 3) + (BRL+ 3)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 3)/IICφ}]/[tr + tf + {(BRH + 3) + (BRL + 3)}/IICφ]
3. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = 1/[{(BRH + 3 + nf*3) + (BRL + 3 + nf)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 3 + nf)/IICφ}]/[tr + tf + {(BRH + 3 + nf) + (BRL + 3 + nf)}/IICφ]

28.2.17 ICDRT : I2C Bus Transmit Data Register

Base address: IIC0 = 0x4009_F000

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

When ICDRT detects a space in the I2C Bus Shift Register (ICDRS), it transfers the transmit data that was written to ICDRT to ICDRS and starts transmitting data in transmit mode. The double-buffer structure of ICDRT and ICDRS allows continuous transmit operation if the next transmit data is written to ICDRT while the ICDRS data is being transmitted.

ICDRT can always be read and written to. Write transmit data to ICDRT once when a transmit data empty interrupt (IIC0_TXI) request is generated.

28.2.18 ICDRR : I2C Bus Receive Data Register

Base address: IIC0 = 0x4009_F000

Offset address: 0x13

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

When 1 byte of data is received, the received data is transferred from the I2C Bus Shift Register (ICDRS) to ICDRR to enable the next data to be received. The double-buffer structure of ICDRS and ICDRR allows continuous receive operation if the received data is read from ICDRR while ICDRS is receiving data. ICDRR cannot be written to. Read data from ICDRR once when a receive data full interrupt (IIC0_RXI) request is generated.

If ICDRR receives the next receive data before the current data is read from ICDRR (while the RDRF flag in ICSR2 is 1), the IIC automatically holds the SCL clock low 1 cycle before the RDRF flag is set to 1 next.

28.2.19 ICDRS : I2C Bus Shift Register

Base address: n/a

Offset address: n/a

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	—	—	—	—	—	—	—	—

ICDRS is an 8-bit shift register for data transmit and receive. During transmission, transmit data is transferred from ICDRT to ICDRS and is transmitted from the SDA0 pin. During reception, data is transferred from ICDRS to ICDRR after 1 byte of data is received. ICDRS cannot be accessed directly.

28.3 Operation

28.3.1 Communication Data Format

The I2C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start or restart condition is an address frame that specifies a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 28.3 shows the I2C bus format, and Figure 28.4 shows the I2C bus timing.

28.2.17 ICDRT：I2C总线发送数据寄存器

Base address: IIC0 = 0x4009_F000

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
重置后的值:	1	1	1	1	1	1	1	1

当ICDRT检测到I2C总线移位寄存器(ICDRS)中有空间时，它将写入ICDRT的发送数据传输到ICDRS，并开始在发送模式下发送数据。ICDRT和ICDRS的双缓冲结构允许在传输ICDRS数据的同时将下一个传输数据写入ICDRT的连续传输操作。

ICDRT始终可以被读取和写入。当产生发送数据空中断（IIC0_TXI）请求时，将发送数据写入ICDRT。

28.2.18 ICDRR:I2C总线接收数据寄存器

Base address: IIC0 = 0x4009_F000

Offset address: 0x13

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
重置后的值:	0	0	0	0	0	0	0	0

当接收到1个字节的数据时，接收到的数据会从I2C总线移位寄存器(ICDRS)传输到ICDRR，以便接收下一个数据。如果在ICDRS正在接收数据时从ICDRR读取接收到的数据，ICDRS和ICDRR的双缓冲结构允许连续接收操作。无法写入ICDRR。当产生接收数据完全中断（IIC0_RXI）请求时，从ICDRR读取数据一次。

如果ICDRR在从ICDRR读取当前数据之前接收到下一个接收数据（此时ICSR2中的RDRF标志为1），则IIC在下一个RDRF标志设置为1之前自动将SCL时钟保持低1个周期。

28.2.19 ICDRS:I2C总线移位寄存器

Base address: n/a

Offset address: n/a

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
重置后的值:	—	—	—	—	—	—	—	—

ICDRS是一个用于数据发送和接收的8位移位寄存器。在传输过程中，传输数据从ICDRT传输到ICDRS，并从SDA0引脚传输。在接收过程中，接收到1个字节的数据后，数据从ICDRS传输到ICDRR。ICDRS不能直接访问。

28.3.2 初始设置

在开始数据发送或接收之前，使用图28.5所示的过程初始化IIC。

1.将ICCR1.ICE位设置为0，将SCLn和SDAn引脚设置为无效状态。

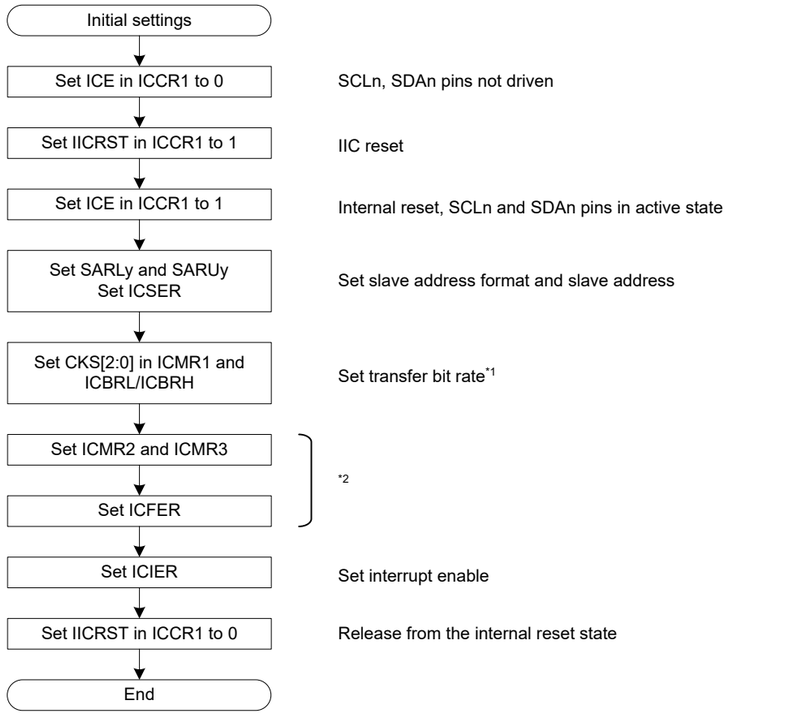
2.将ICCR1.IICRST位设置为1以启动IIC复位。

3.将ICCR1.ICE位设置为1以启动内部复位。

4.设置SARLy、SARUy、ICSER、ICMR1、ICBRH和ICBRL寄存器（y=0到2），并根据需要设置其他寄存器。IIC的初始设置见图28.5。

5. When the required register settings are complete, set the ICCR1.IICRST bit to 0 to release the IIC reset.

This procedure is not required if the IIC initialization is already complete.



Note: n = 0
Note 1. When the IIC is used only in slave mode, set the ICBRL register to a value longer than the data setup time.
Note 2. Set these registers as required.

Figure 28.5 Example IIC initialization flow

28.3.3 Master Transmit Operation

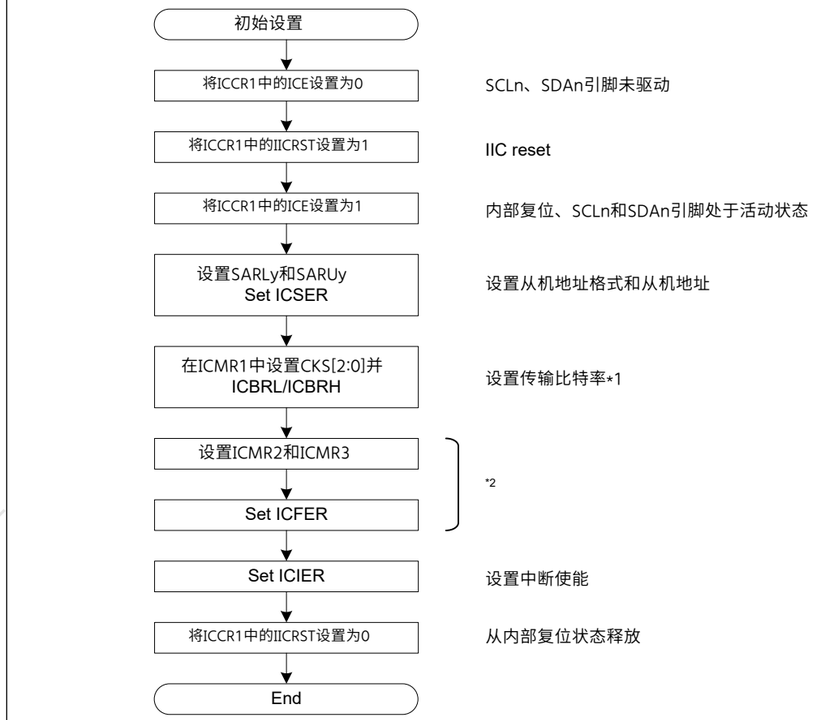
In master transmit operation, the IIC outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 28.6 shows an example of master transmission, and Figure 28.7 to Figure 28.9 show the operation timing in master transmission.

To set up and perform master transmission:

1. Process initial settings. For details, see section 28.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and START flags in ICSR2 automatically set to 1 and the ST bit automatically is set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.

5.完成所需的寄存器设置后，将ICCR1.IICRST位设置为0以释放IIC复位。

如果IIC初始化已经完成，则不需要此过程。



Note: n = 0
注1.当IIC仅用于从模式时，将ICBRL寄存器设置为比数据建立时间更长的值。
注2.根据需要设置这些寄存器。

Figure 28.5 示例IIC初始化流程

28.3.3 主发送操作

在主设备发送操作中，IIC作为主设备输出SCL时钟和发送的数据信号，从设备返回确认。图28.6显示了主传输的示例，图28.7至图28.9显示了主传输中的操作时序。

设置和执行主传输：

1.处理初始设置。详见28.3.2节。初始设置。

2.读取ICCR2中的BBSY标志，检查总线是否空闲，然后将ICCR2中的ST位设置为1（启动条件要求）。收到请求后，IIC发出一个开始条件。同时，ICSR2中的BBSY和START标志位自动置1，ST位自动置0。此时，如果检测到启动条件，内部电平为SDA输出状态和当ST位为1时SDAn线匹配，IIC识别出ST位请求的启动条件的发布已成功完成，并且ICCR2中的MST和TRS位自动设置为1，将IIC置于主机发送模式。ICSR2中的TDRE标志也自动设置为1，以响应TRS位设置为1。

3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. After the byte containing the slave address and R/W# bit is transmitted, the value of the TRS bit automatically updates to select master transmit or master receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the IIC continues in master transmit mode. Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For data transmission with an address in the 10-bit format, start by writing 11110b, the 2 higher-order bits of the slave address, and W to ICDRT as the first address transmission. For the second address transmission, write the 8 lower-order bits of the slave address to ICDRT.
4. Check that the TDRE flag in ICSR2 is 1, and then write the transmit data to the ICDRT register. The IIC automatically holds the SCLn line low until the transmit data is ready or a stop condition is issued.
5. After all bytes of transmit data are written to the ICDRT register, wait until the value in the TEND flag in ICSR2 returns to 1, and then set the SP bit in ICCR2 to 1 (stop condition requested). On receiving a stop condition request, the IIC issues the stop condition. Regarding issuing a stop condition, see section 28.11.3. Issuing a Stop Condition.
6. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, it automatically sets the TDRE and TEND flags to 0, and sets the STOP flag in ICSR2 to 1.
7. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

3.检查ICSR2中的TDRE标志是否为1，然后将要发送的值（从机地址和RW#位）写入ICDRT。当发送数据写入ICDRT时，TDRE标志自动设置为0，数据从ICDRT传输到ICDRS，TDRE标志再次设置为1。在发送包含从机地址和RW#位的字节后，TRS位的值会自动更新，以根据发送的RW#位的值选择主机发送或主机接收模式。如果RW#位的值为0，则IIC继续处于主机发送模式。由于此时ICSR2.NACKF标志为1表示没有从设备识别该地址或通信中存在错误，因此向ICCR2.SP位写入1以发出停止条件。对于地址为10位格式的数据传输，首先将11110b、从机地址的高2位和W写入ICDRT作为第一个地址传输。对于第二次地址传输，将从地址的低8位写入ICDRT。

4.检查ICSR2中的TDRE标志是否为1，然后将发送数据写入ICDRT寄存器。IIC自动将SCLn线保持为低电平，直到发送数据准备好或发出停止条件。

5.将发送数据的所有字节写入ICDRT寄存器后，等待ICSR2中TEND标志的值返回1，然后将ICCR2中的SP位设置为1（请求停止条件）。在收到停止条件请求时，IIC发出停止条件。关于发出停止条件，请参阅第28.11.3节。发出停止条件。

6.在检测到停止条件时，IIC自动将ICCR2中的MST和TRS位设置为00b并进入从机
接收模式。此外，它自动将TDRE和TEND标志设置为0，并将ICSR2中的STOP标志设置为1。

7.检查ICSR2.STOP标志是否为1，然后将ICSR2.NACKF和STOP标志设置为0以进行下一次传输操作。

28.3.4 Master Receive Operation

In master receive operation, the IIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because the IIC must start by sending a slave address to the associated slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 28.10 and Figure 28.11 show examples of master reception (7-bit address format), and Figure 28.12 to Figure 28.14 show the operation timing in master reception.

To set up and perform master reception:

1. Process initial settings. For details, see section 28.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. When the IIC detects the start condition, the BBSY and START flags in ICSR2 automatically set to 1, and the ST bit automatically is set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. When the byte containing the slave address and R/W# bit is transmitted, the value of the ICCR2.TRS bit automatically updates to select transmit or receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit is 1, the TRS bit is set to 0 on the rising edge of the ninth cycle of the SCL clock, placing the IIC in master receive mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag automatically is set to 1.
   Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 11110b, the two higher-order bits of the slave address, and the R bit places the IIC in master receive mode.
4. Dummy read ICDRR after confirming that the RDRF flag in ICSR2 is 1. This makes the IIC start output of the SCL clock and start data reception.

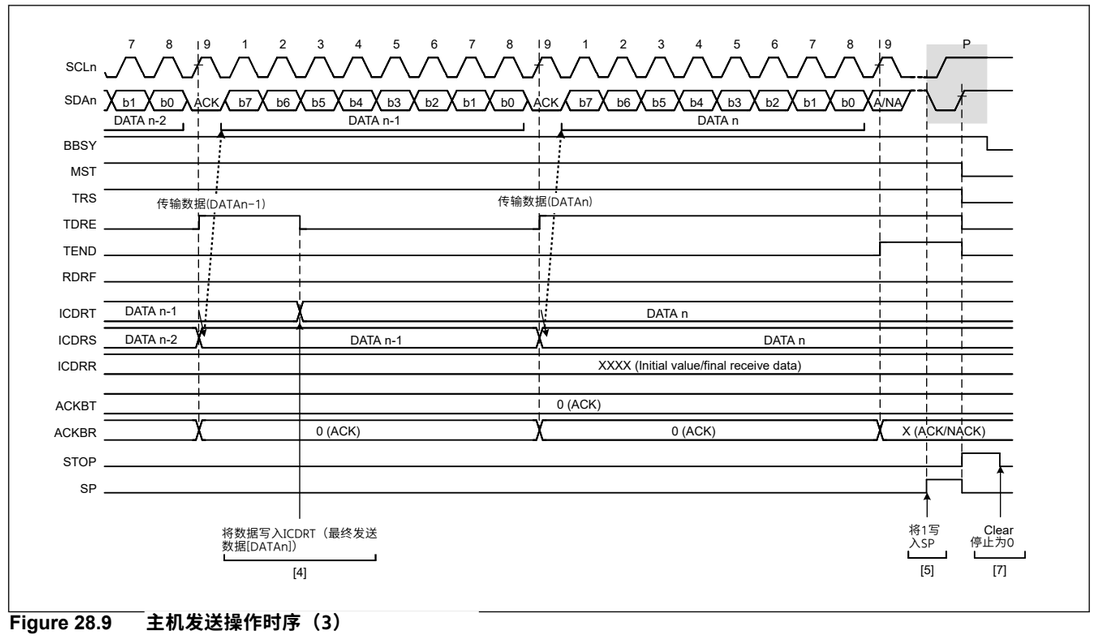

Figure 28.9 主机发送操作时序（3）

28.3.4 主接收操作

在主设备接收操作中，作为主设备的IIC输出SCL时钟，从从设备接收数据，并返回确认。因为IIC必须首先向相关的从设备发送一个从地址，所以这部分过程在主发送模式下执行，但后续步骤在主接收模式下执行。

图28.10和图28.11显示了主机接收示例（7位地址格式），图28.12至图28.14显示了主机接收中的操作时序。

设置和执行主接收：

1.处理初始设置。详见28.3.2节。初始设置。

2.读取ICCR2中的BBSY标志，检查总线是否空闲，然后将ICCR2中的ST位设置为1（启动条件要求）。收到请求后，IIC发出一个开始条件。当IIC检测到启动条件时，ICSR2中的BBSY和START标志位自动置1，ST位自动置0。此时，如果检测到启动条件，则SDA输出的电平和电平在ST位为1时SDAn线匹配时，IIC识别出由ST位请求的启动条件的发布已成功完成，并且MST和

ICCR2中的TRS位自动设置为1，将IIC置于主机发送模式。ICSR2中的TDRE标志也自动设置为1，以响应TRS位设置为1。

3、检查ICSR2中的TDRE标志为1，然后写入值进行发送（第一个字节表示从机RW#位的地址和值）到ICDRT。当发送数据写入ICDRT时，TDRE标志自动设置为0，数据从ICDRT传输到ICDRS，TDRE标志再次设置为1。当发送包含从机地址和RW#位的字节时，ICCR2.TRS位的值自动更新以根据发送的RW#位的值选择发送或接收模式。如果RW#位的值为1，则在SCL时钟的第9个周期的上升沿将TRS位设置为0，将IIC置于主机接收模式。此时TDRE标志置0，ICSR2.RDRF标志自动置1。因为此时ICSR2.NACKF标志为1表示没有从设备识别该地址或通信出现错误，向ICCR2.SP位写入1以发出停止条件。对于来自具有10位地址的设备的主机接收，首先使用主机发送来发出10位地址，然后发出重启条件。之后，发送11110b、从机地址的两个高阶位和R位将IIC置于主机接收模式。

4.确认ICSR2中的RDRF标志为1后伪读ICDRR。这使得IIC开始输出SCL时钟并开始数据接收。

5. After 1 byte of data is received, the RDRF flag in ICSR2 is set to 1 on the rising edge of the 8th or 9th cycle of the SCL clock, as selected in the RDRFS bit in ICMR3. Reading ICDRR at this time produces the received data, and the RDRF flag is automatically set to 0 at the same time. Additionally, the value of the acknowledgment field received during the ninth cycle of the SCL clock is returned as the value set in the ICMR3.ACKBT bit. If the next byte to be received is the second-to-last byte, set the ICMR3.WAIT bit to 1 for wait insertion before reading ICDRR, containing the second-to-last byte. In addition to enabling NACK output, even when interrupts or other operations result in delays in setting the ICMR3.ACKBT bit to 1 (NACK) in step (6), this fixes the SCLn line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, which enables the issuing of a stop condition.
6. When the ICMR3.RDRFS bit is 0, and the slave device must be notified that it is to end transfer for data reception after transfer of the next and final byte, set the ICMR3.ACKBT bit to 1 (NACK).
7. After reading the second-to-last byte from the ICDRR register, if the value of the ICSR2.RDRF flag is 1, write 1 to the SP bit in ICCR2 (stop condition requested), and then read the last byte from ICDRR. When ICDRR is read, the IIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is complete or the SCLn line is released from the low-hold state.
8. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, detection of the stop condition sets the ICSR2.STOP flag to 1.
9. Check that the ICSR2.STOP flag is 1, then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

5.接收到1个字节的数据后，在SCL时钟的第8或第9个周期的上升沿将ICSR2中的RDRF标志设置为1，这由ICMR3中的RDRFS位选择。此时读取ICDRR产生接收数据，同时RDRF标志位自动置0。此外，在SCL时钟的第9个周期内接收到的确认字段的值作为ICMR3.ACKBT位中设置的值返回。如果要接收的下一个字节是倒数第二个字节，则在读取包含倒数第二个字节的ICDRR之前将ICMR3.WAIT位设置为1以等待插入。除了使能NACK输出外，即使在中断或其他操作导致在步骤(6)中将ICMR3.ACKBT位设置为1(NACK)时出现延迟，这也将SCLn线在第9个上升沿固定为低电平接收最后一个字节的时钟周期，它可以发出停止条件。

6.当ICMR3.RDRFS位为0时，必须通知从设备在传输下一个和最后一个字节后结束传输以进行数据接收，将ICMR3.ACKBT位设置为1(NACK)。

7.从ICDRR寄存器中读取倒数第二个字节后，如果ICSR2.RDRF标志的值为1，则将1写入ICCR2中的SP位（请求停止条件），然后从ICDRR中读取最后一个字节.当读取ICDRR时，IIC从等待状态中释放，并在第9个时钟周期的低电平输出完成或SCLn线从低保持状态释放后发出停止条件。

8.在检测到停止条件时，IIC自动将ICCR2中的MST和TRS位设置为00b并进入从机接收模式。此外，检测到停止条件会将ICSR2.STOP标志设置为1。

9.检查ICSR2.STOP标志是否为1，然后将ICSR2.NACKF和STOP标志设置为0以进行下一次传输操作。

28.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL clock, the IIC transmits data as a slave device, and the master device returns acknowledgments.

Figure 28.15 shows an example of slave transmission, and Figure 28.16 and Figure 28.17 show the operation timing in slave transmission.

To set up and perform slave transmission:

1. Initialize the IIC using the procedure in section 28.3.2. Initial Settings.
   After initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit is 1, the IIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.
3. Check that the ICSR2.TDRE flag is 1, then write the transmit data to the ICDRT register. If the IIC receives no acknowledge from the master device (receives an NACK signal) while the ICFER.NACKE bit is 1, the IIC suspends transfer of the next data.
4. Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the IIC drives the SCLn line low on the ninth falling edge of the SCL clock.
5. When the ICSR2.NACKF or ICSR2.TEND flag is 1, dummy read ICDRR to complete the processing. This releases the SCLn line.
6. On detecting the stop condition, the IIC automatically sets the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2), the ICSR2.TDRE and TEND flags, and the ICCR2.TRS bit to 0, and enters slave receive mode.
7. Check that the ICSR2.STOP flag is 1, then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

28.3.5 从机发送操作

在从发送操作中，主设备输出SCL时钟，IIC作为从设备发送数据，主设备返回确认。

图28.15显示了从机传输的示例，图28.16和图28.17显示了从机传输的操作时序。

设置和执行从属传输：

1.使用第28.3.2节中的过程初始化IIC。初始设置。
初始化后，IIC一直处于待机状态，直到收到匹配的从机地址。

2.接收到匹配的从地址后，IIC在SCL时钟的第9个周期的上升沿将相关的ICSR1.HOA、GCA和AASy标志之一（y=0到2）设置为1，并输出该值在SCL时钟的第9个周期将ICMR3.ACKBT位设置为确认位。如果RW#位的值为1，则IIC通过将ICCR2.TRS位和ICSR2.TDRE标志都设置为1自动将自身置于从发送模式。

3.检查ICSR2.TDRE标志是否为1，然后将发送数据写入ICDRT寄存器。如果IIC没有收到
当ICFER.NACKE位为1时，来自主设备的确认（接收NACK信号），IIC暂停下一个数据的传输。

4.等到ICSR2.TEND标志设置为1，而ICSR2.TDRE标志为1，在ICSR2.NACKF标志设置为1或将要发送的最后一个字节写入ICDRT寄存器之后。当ICSR2.NACKF标志或TEND标志为1时，IIC在SCL时钟的第九个下降沿将SCLn线驱动为低电平。

5.当ICSR2.NACKF或ICSR2.TEND标志为1时，假读ICDRR完成处理。这将释放SCLn线。

6.在检测到停止条件时，IIC自动将ICSR1.HOA、GCA和AASy标志（y=0到2）、ICSR2.TDRE和TEND标志以及ICCR2.TRS位设置为0，并进入从机接收模式。

7.检查ICSR2.STOP标志是否为1，然后将ICSR2.NACKF和STOP标志设置为0以进行下一次传输操作。

Figure 28.18 shows an example of slave reception, and Figure 28.19 and Figure 28.20 show the operation timing in slave reception.

To set up and perform slave reception:

1. Initialize the IIC using the procedure in section 28.3.2. Initial Settings.
   After initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit is 0, the IIC continues to place itself in slave receive mode and sets the RDRF flag in ICSR2 to 1.
3. Check that the ICSR2.STOP flag is 0 and the ICSR2.RDRF flag is 1, then dummy read ICDRR. The dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected.
4. When ICDRR is read, the IIC automatically sets the ICSR2.RDRF flag to 0. If reading of ICDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the IIC holds the SCLn line low until 1 SCL cycle before the point where RDRF must be set. In this case, reading ICDRR releases the SCLn line from being held low.
   When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1, read ICDRR until all the data is completely received.
5. On detecting the stop condition, the IIC automatically clears the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 0.
6. Check that the ICSR2.STOP flag is 1, then set the ICSR2.STOP flag to 0 for the next transfer operation.

设置和执行从属接收：

2.接收到匹配的从地址后，IIC在SCL时钟的第9个周期的上升沿将相关的ICSR1.HOA、GCA和AASy标志之一（y=0到2）设置为1，并输出该值在SCL时钟的第9个周期将ICMR3.ACKBT位设置为确认位。如果RW#位的值为0，则IIC继续将自身置于从机接收模式并将ICSR2中的RDRF标志设置为1。

3.检查ICSR2.STOP标志为0且ICSR2.RDRF标志为1，然后虚拟读取ICDRR。虚拟值
选择7位地址格式时由从机地址和RW#位组成，选择10位地址格式时由低8位组成。

4.读取ICDRR时，IIC自动将ICSR2.RDRF标志设置为0。如果ICDRR读取延迟并且在RDRF标志仍设置为1时接收到下一个字节，则IIC将SCLn线保持为低电平直到1SCL在必须设置RDRF的点之前循环。在这种情况下，读取ICDRR会释放SCLn线的低电平。当ICSR2.STOP标志为1且ICSR2.RDRF标志也为1时，读取ICDRR直到完全接收到所有数据。

5.在检测到停止条件时，IIC自动将ICSR1.HOA、GCA和AASy标志（y=0到2）清除为0。

28.4 SCL Synchronization Circuit

For generation of the SCL clock, the IIC starts counting the value for the high-level period specified in ICBRH when it detects a rising edge on the SCLn line, and it drives the SCLn line low when it completes counting. When the IIC detects the falling edge of the SCLn line, it starts counting the value for the low-level period specified in ICBRL, and then it stops

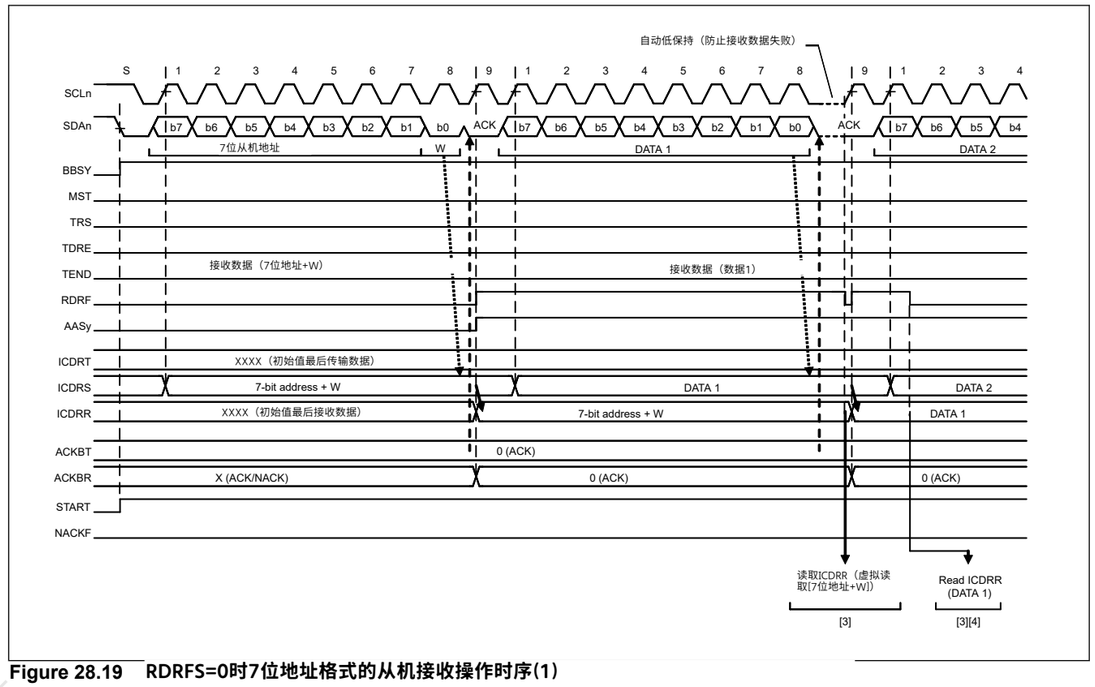

Figure 28.19 RDRFS=0时7位地址格式的从机接收操作时序(1)

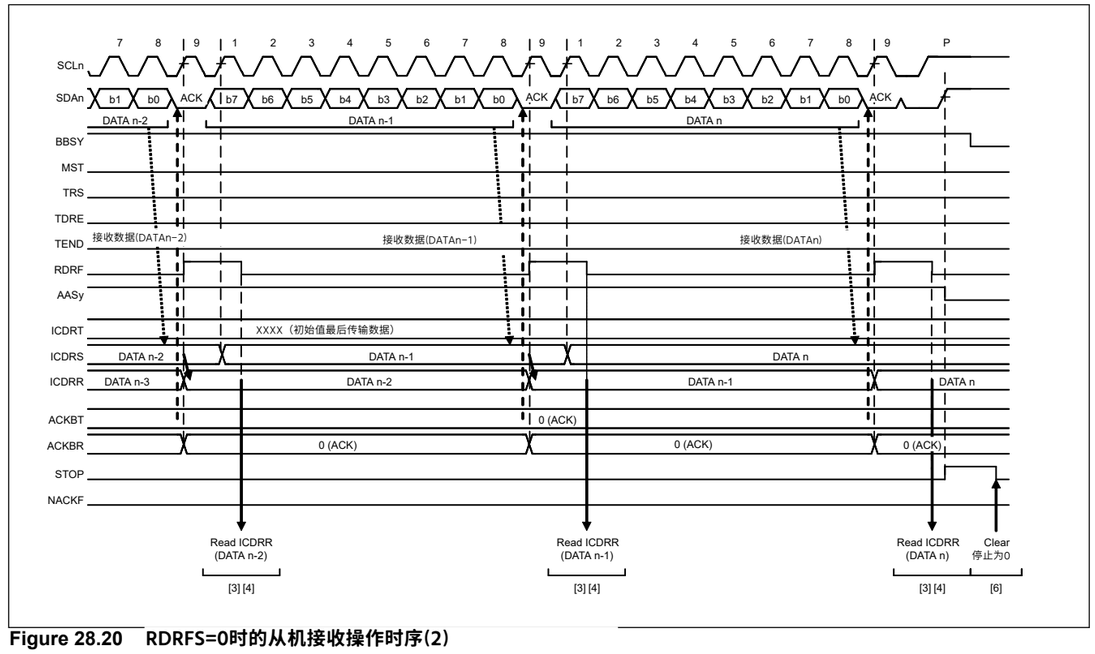

Figure 28.20 RDRFS=0时的从机接收操作时序(2)

28.4 SCL同步电路

为了生成SCL时钟，IIC在检测到SCLn线上的上升沿时开始对ICBRH中指定的高电平周期的值进行计数，并在完成计数时将SCLn线驱动为低电平。当IIC检测到SCLn线的下降沿时，它开始计数ICBRL中指定的低电平周期的值，然后停止

driving the SCLn line, releasing the line, when it completes counting. The IIC repeats this process to generate the SCL clock.

If multiple master devices are connected to the I^2C bus, a collision of SCL signals might arise because of contention with another master device. In such cases, the master devices must synchronize their SCL signals. Because this synchronization of SCL signals must be bit-by-bit, the IIC is equipped with an SCL synchronization circuit to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When the IIC detects a rising edge on the SCLn line and starts counting the high-level period specified in ICBRH.BRH[4:0], and the level on the SCLn line falls because an SCL signal is being generated by another master device, the IIC performs the following:

1. Stops counting when it detects the falling edge.
2. Drives the level on the SCLn line low.
3. Starts counting the low-level period specified in ICBRL.BRL[4:0].

When the IIC finishes counting the low-level period, it stops driving the SCLn line low to release the line. If the low-level period of the SCL clock signal from the other master device is longer than the low-level period set in the IIC, the low-level period of the SCL signal is extended. When the low-level period for the other master device ends, the SCL signal rises because the SCLn line is released.

When the IIC finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, when SCL signals from more than one master are contending, the high-level period of the SCL signal is synchronized with that of the clock with the narrower period, and the low-level period of the SCL signal is synchronized with that of the clock with the broader period. However, such synchronization of the SCL signal is only enabled when the SCLE bit in ICFER is set to 1.

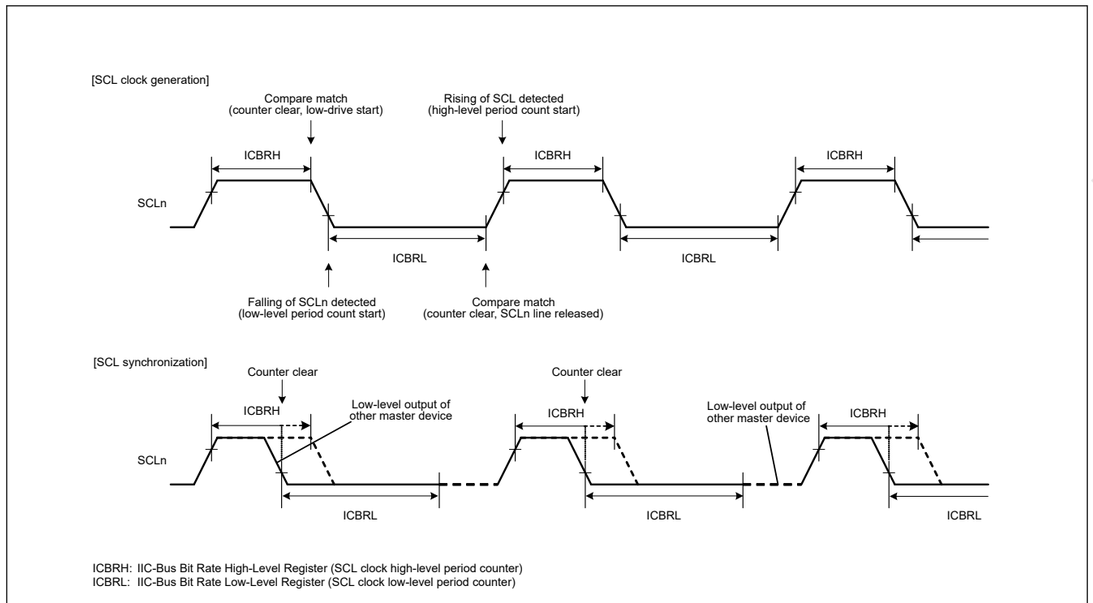

Figure 28.21 Generation and synchronization of SCL signal from IIC

28.5 SDA Output Delay Function

The IIC module incorporates a function for delaying output on the SDA line. The delay can be applied to all output on the SDA line, including issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals.

完成计数后，驱动SCLn线，释放线。IIC重复此过程以生成SCL时钟。

如果多个主设备连接到I2C总线，由于与另一个主设备争用，可能会出现SCL信号冲突。在这种情况下，主设备必须同步它们的SCL信号。因为SCL信号的这种同步必须是逐位的，所以IIC配备了一个SCL同步电路，通过在主机模式下监视SCLn线来获得SCL时钟信号的逐位同步。

当IIC检测到SCLn线上的上升沿并开始计数指定的高电平周期时
ICBRH.BRH[4:0]，并且SCLn线上的电平下降，因为另一个主设备正在生成SCL信号，IIC执行以下操作：

1.检测到下降沿停止计数。

2.将SCLn线上的电平拉低。

3.开始计算ICBRL.BRL[4:0]中指定的低电平周期。

当IIC完成对低电平周期的计数时，它停止将SCLn线驱动为低电平以释放该线。如果来自其他主设备的SCL时钟信号的低电平周期长于IIC中设置的低电平周期，则延长SCL信号的低电平周期。当另一个主设备的低电平周期结束时，SCL信号上升，因为SCLn线被释放。

当IIC输出完SCL时钟的低电平周期后，SCLn线被释放，SCL时钟上升。
即当来自多个主控的SCL信号竞争时，SCL信号的高电平周期与周期较窄的时钟同步，SCL信号的低电平周期与主控的低电平周期同步。具有更广泛周期的时钟。但是，只有当ICFER中的SCLE位设置为1时，才会启用SCL信号的这种同步。

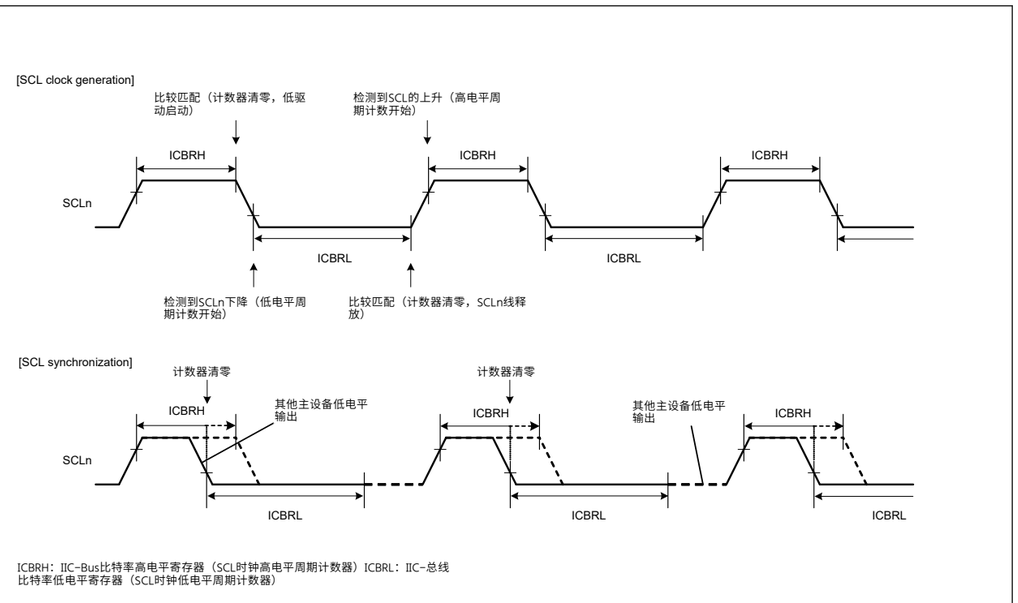

Figure 28.21 从IIC生成和同步SCL信号

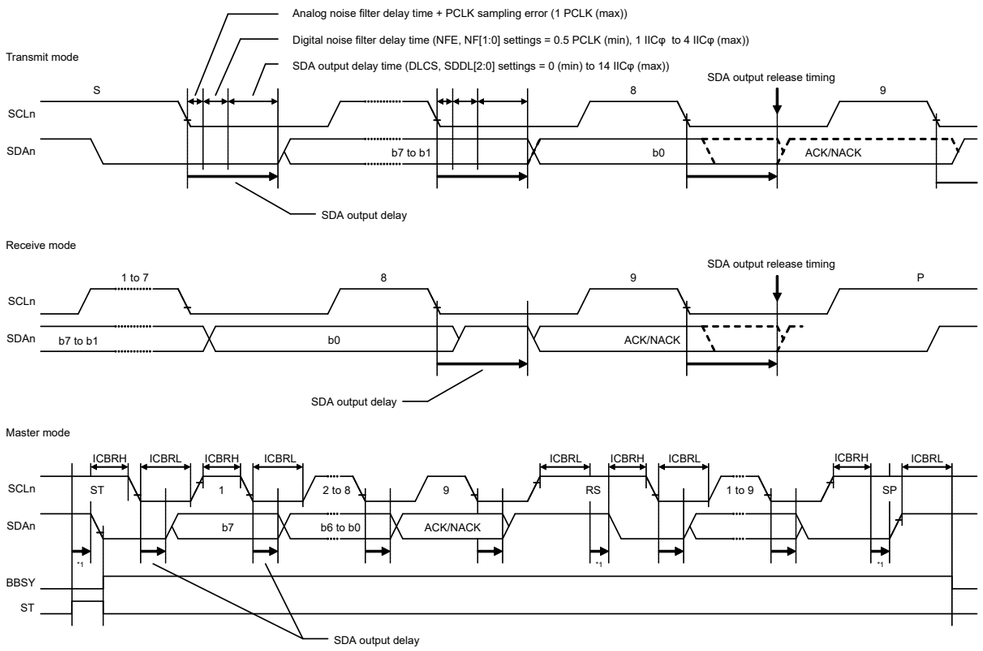
28.5 SDA输出延迟功能

IIC模块包含延迟SDA线上输出的功能。延迟可以应用于所有输出SDA线，包括发出启动、重新启动和停止条件、数据以及ACK和NACK信号。

With this function, SDA output is delayed from the detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval during which the SCL clock is low. This approach helps prevent erroneous operation of communications devices, with the aim of satisfying the 300-ns minimum data-hold time requirement of the SMBus specification. The output delay function is enabled by setting the SDDL[2:0] bits in ICMR2 to a value other than 000b, and disabled by setting the same bits to 000b.

When the SDA output delay function is enabled, for example, the DLCS bit in ICMR2 selects the clock source for the SDA output delay counter, either as the internal base clock (IICφ) for the IIC module or as the internal base clock divided by 2 (IICφ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in ICMR2. When the delay cycles count is reached, the IIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.



Note: PCLK = PCLKB
Note 1. The output delay function is set by the DLCS and SDDL[2:0] bits when a start (ST), restart (RS), or stop (SP) condition is issued.

28.6 Digital Noise Filter Circuits

The internal circuitry sees the states of the SCLn and SDAn pins through analog and digital noise-filter circuits. Figure 28.23 shows a block diagram of the digital noise-filter circuit.

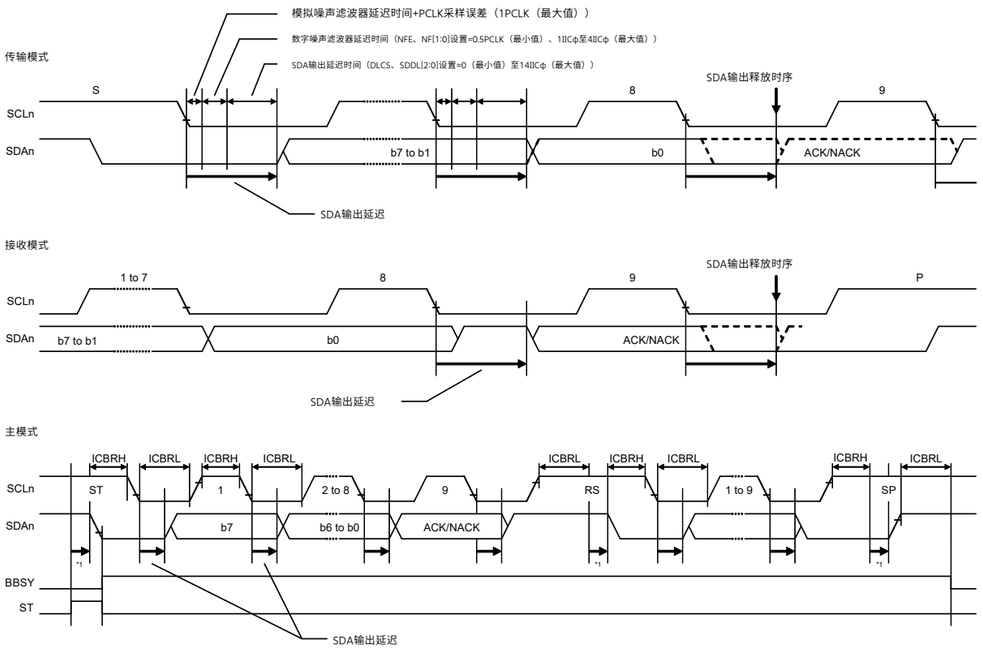
The on-chip digital noise-filter circuit of the IIC consists of four flip-flop circuit stages connected in series and a match-detection circuit. The number of valid stages in the digital noise filter is selected in the NF[1:0] bits in ICMR3. The selected number of valid stages determines the noise-filtering capability as a period from 1 to 4 IICφ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on falling edges of the IICφ signal. When the input signal level matches the output level of the number of valid flip-flop circuit stages as selected in the NF[1:0] bits in ICMR3, the signal level is seen in the the subsequent stage. If the signal levels do not match, the previous value is saved.

If the ratio between the frequency of the internal operating clock (PCLKB) and the transfer rate is small, for example, if data transfer is 400 kbps with PCLKB = 4 MHz, the characteristics of the digital noise filter might lead to the elimination of

使用此功能，SDA输出从检测到SCL信号的下降沿开始延迟，以确保在SCL时钟为低电平的时间间隔内输出SDA信号。这种方法有助于防止通信设备的错误操作，旨在满足SMBus规范的300ns最小数据保持时间要求。通过将ICMR2中的SDDL[2:0]位设置为000b以外的值来启用输出延迟功能，通过将相同位设置为000b来禁用输出延迟功能。

例如，当SDA输出延迟功能使能时，ICMR2中的DLCS位选择SDA输出延迟计数器的时钟源，或者作为IIC模块的内部基准时钟(IICφ)，或者作为内部基准时钟除以2(IICφ2)。计数器计算ICMR2中SDDL[2:0]位中设置的周期数。当达到延迟周期计数时，IIC模块将所需的输出（启动、重启或停止条件、数据或ACK或NACK信号）放在SDA线上。



Note: PCLK = PCLKB
注1.当发出启动(ST)、重启(RS)或停止(SP)条件时，输出延迟功能由DLCS和SDDL[2:0]位设置。

28.6 数字噪声滤波器电路

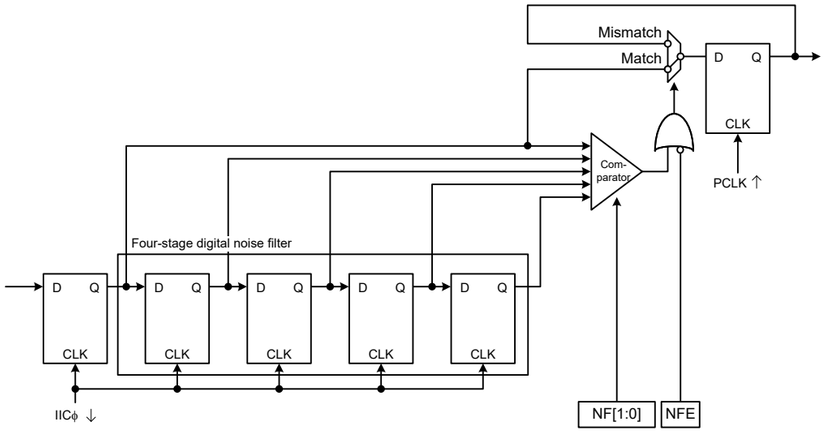
内部电路通过模拟和数字噪声滤波器电路查看SCLn和SDAn引脚的状态。图28.23显示了数字噪声滤波器电路的框图。

IIC的片上数字噪声滤波器电路由四个串联的触发器电路级和一个匹配检测电路组成。数字噪声滤波器的有效级数在ICMR3的NF[1:0]位中选择。选定的有效级数决定了噪声过滤能力，周期为1到4个IICφ周期。

SCLn引脚（或SDAn引脚）的输入信号在IICφ信号的下降沿采样。当输入信号电平与在ICMR3的NF[1:0]位中选择的有效触发器电路级数的输出电平相匹配时，将在后续级中看到信号电平。如果信号电平不匹配，则保存先前的值。

如果内部工作时钟(PCLKB)的频率与传输速率之间的比率很小，例如，如果数据传输为400kbps，PCLKB=4MHz，则数字噪声滤波器的特性可能会导致消除

required signals as noise. In such cases, it is possible to disable the digital noise-filter circuit by setting the ICFER.NFE bit to 0, and use only the analog noise filter circuit.



Note: PCLK = PCLKB

28.7 Address Match Detection

The IIC can set three unique slave addresses in addition to the general call address and host address. The slave addresses can be 7-bit or 10-bit slave addresses.

28.7.1 Slave-Address Match Detection

The IIC can set three unique slave addresses and has a slave address detection function for each unique slave address. When the SARyE bit (y = 0 to 2) in ICSER is set to 1, the slave addresses set in SARUy and SARLy (y = 0 to 2) can be detected.

When the IIC detects a match of the set slave address, the associated AASy flag (y = 0 to 2) in ICSR1 is set to 1 on the rising edge of the ninth SCL clock cycle, and the RDRF flag in ICSR2 or the TDRE flag in ICSR2 is set to 1 by the subsequent R/W# bit. This causes a receive data full interrupt (IICn_RXI) or transmit data empty interrupt (IICn_TXI) to be generated. The AASy flag identifies which slave address is specified.

Figure 28.24 to Figure 28.26 show the AASy flag set timing in three cases.

28.7 地址匹配检测

IIC除了广播地址和主机地址外，还可以设置三个唯一的从机地址。从地址可以是7位或10位从地址。

28.7.1 从地址匹配检测

IIC可以设置三个唯一的从机地址，并对每个唯一的从机地址具有从机地址检测功能。当ICSER中的SARyE位（y=0到2）设置为1时，可以检测到设置在SARUy和SARLy（y=0到2）中的从机地址。

当IIC检测到与设置的从地址匹配时，ICSR1中相关的AASy标志（y=0到2）在第9个SCL时钟周期的上升沿设置为1，并且ICSR2中的RDRF标志或TDRE标志ICSR2中的1由随后的RW#位设置为1。这会导致产生接收数据满中断（IICn_RXI）或发送数据空中断（IICn_TXI）。AASy标志标识指定了哪个从地址。

28.7.2 Detection of General Call Address

The IIC provides detection of the general call address (0000 000b + 0 [W]). This is enabled by setting the GCAE bit in ICSER to 1.

If the address received after a start or restart condition is issued is 0000 000b + 1[R] (start byte), the IIC recognizes this as the address of a slave device with an all-zero address, but not as the general call address.

When the IIC detects the general call address, both the GCA flag in ICSR1 and the RDRF flag in ICSR2 set to 1 on the rising edge of the ninth cycle of the SCL clock. This leads to the generation of a receive data full interrupt (IICn_RXI). The value of the GCA flag can be checked to confirm that the general call address was transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

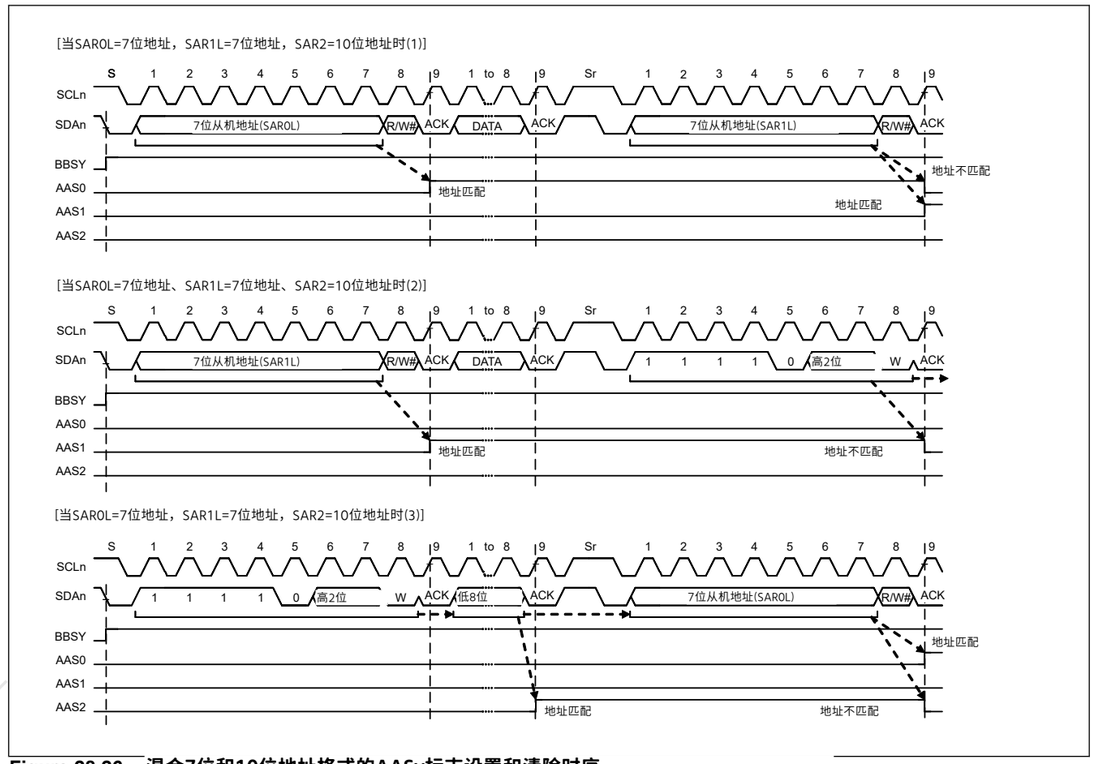

Figure 28.26 混合7位和10位地址格式的AASy标志设置和清除时序

28.7.2 广播呼叫地址检测

IIC提供对广播呼叫地址(0000000b+0[W])的检测。这是通过设置GCAE位启用
ICSER to 1.

如果在发出启动或重启条件后接收到的地址是0000000b+1[R]（起始字节），则IIC将其识别为具有全零地址的从设备的地址，但不是广播地址.

当IIC检测到广播呼叫地址时，ICSR1中的GCA标志和ICSR2中的RDRF标志都在SCL时钟的第9个周期的上升沿设置为1。这会导致接收数据完全中断(IICn_RXI)的产生。可以检查GCA标志的值以确认广播呼叫地址已被传输。

检测到广播呼叫地址后的操作与正常的从机接收操作相同。

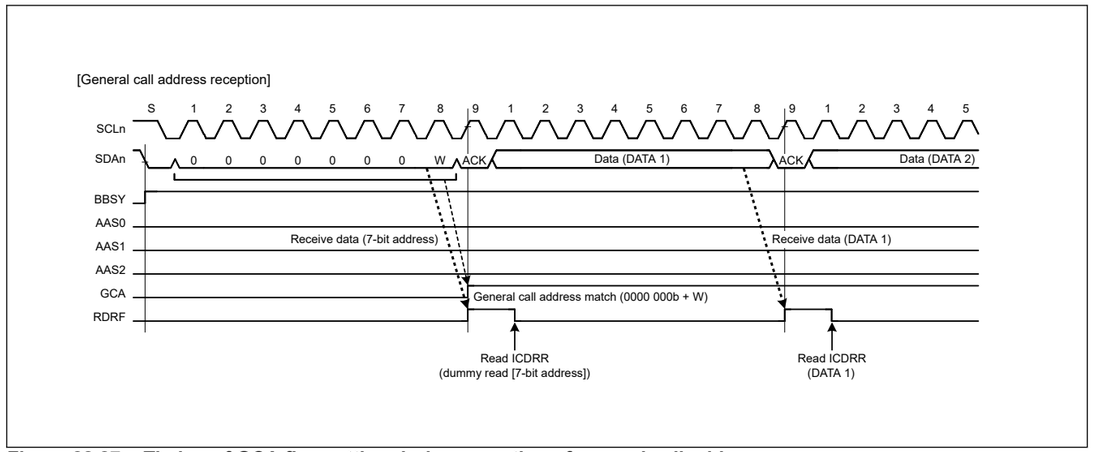

Figure 28.27 Timing of GCA flag setting during reception of general call address

28.7.3 Device-ID Address Detection

The IIC module provides detection of device-ID address compliant with the I^2C bus specification (revision 03). When the IIC receives 1111 100b as the first byte after a start or restart condition is issued with the DIDE bit in ICSER set to 1, it recognizes the address as a device ID, sets the DID flag in ICSR1 to 1 on the rising edge of the ninth SCL clock cycle when the subsequent R/W# bit is 0, then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the IIC sets the associated AASy flag (y = 0 to 2) in ICSR1 to 1.

When the first byte received after the issue of a start or restart condition matches the device ID address (1111 100b) again and the subsequent R/W# bit is 1, the IIC does not compare the second and subsequent bytes and sets the ICSR2.TDRE flag to 1.

In the device ID address detection function, the IIC sets the DID flag to 0 if a match with the IIC slave address is not obtained or a match with the device ID address is not obtained after a match with the IIC slave address and a restart condition is not detected. If the first byte after detection of a start or restart condition matches the device ID address (1111 100b), and the R/W# bit is 0, the IIC sets the DID flag to 1 and compares the second and subsequent bytes with the slave address of the IIC. If the R/W# bit is 1, the DID flag holds the previous value and the IIC does not compare the second and subsequent bytes. Therefore, the reception of a device ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Additionally, prepare the device ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal transmit data. For details on the information that must be included in device ID fields, contact NXP Semiconductors.

28.7.3 设备ID地址检测

IIC模块提供符合I2C总线规范（修订版03）的设备ID地址检测。当。。。的时候

IIC在ICSER中的DIDE位设置为1的情况下，在发出启动或重启条件后接收1111100b作为第一个字节，它将地址识别为设备ID，在第9个上升沿将ICSR1中的DID标志设置为1当后续的RW#位为0时，SCL时钟周期，然后将第二个和后续字节与其自己的从地址进行比较。如果地址与从地址寄存器中的值匹配，则IIC将ICSR1中相关的AASy标志（y=0到2）设置为1。

当发出启动或重启条件后接收到的第一个字节再次与设备ID地址(1111100b)匹配且后续RW#位为1时，IIC不比较第二个和后续字节并设置ICSR2.TDRE标志为1。

在设备ID地址检测功能中，如果没有获得与IIC从机地址匹配或在与IIC从机地址匹配和重启条件后未获得与设备ID地址匹配，则IIC将DID标志设置为0未检测到。如果检测到启动或重启条件后的第一个字节与设备ID地址(1111100b)匹配，并且RW#位为0，则IIC将DID标志设置为1，并将第二个和后续字节与从机地址进行比较IIC。如果RW#位为1，则DID标志保持前一个值，并且IIC不比较第二个和后续字节。因此，在确认TDRE=1后，可以通过读取DID标志来检查设备ID地址的接收。

此外，准备设备ID字段（3个字节：12位表示制造商+9位表示部件+3位表示版本），在接收到连续的设备ID字段作为正常发送数据后必须发送到主机。有关必须包含在设备ID字段中的信息的详细信息，请联系NXPSemiconductors。

28.7.4 Host Address Detection

The IIC provides host address detection when operating in SMBus. When the HOAE bit in ICSER is set to 1 while the SMBS bit in ICMR3 is 1, the IIC can detect the host address (0001 000b) in slave receive mode (MST and TRS bits = 00b in ICCR2).

When the IIC detects the host address, the HOA flag in ICSR1 is set to 1 on the rising edge of the 9th SCL clock cycle, and at the same time, the RDRF flag in ICSR2 is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (IICn_RXI) to be generated. The HOA flag indicates that the host address was sent from another device.

If the bit following the host address (0001 000b) is an Rd bit (R/W# bit = 1), the IIC can also detect the host address. After the host address is detected, the IIC operates in the same manner as in normal slave operation.

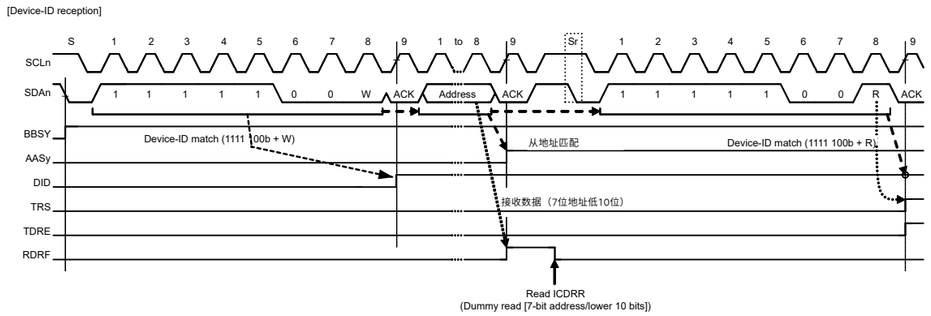

Figure 28.28 在接收设备ID期间设置AASy和DID标志并清除时序

28.7.4 主机地址检测

IIC在SMBus中运行时提供主机地址检测。当ICSER中的HOAE位设置为1而ICMR3中的SMBS位为1，IIC可以在从机接收模式下检测主机地址（0001000b）（ICCR2中的MST和TRS位=00b）。

当IIC检测到主机地址时，ICSR1中的HOA标志在第9个SCL时钟周期的上升沿置1，同时ICSR2中的RDRF标志在RW#位为0时置1（写位）。这会导致产生接收数据完全中断（IICn_RXI）。HOA标志表明主机地址是从另一个设备发送的。

如果主机地址（0001000b）后面的位是Rd位（RW#位=1），则IIC也可以检测主机地址。检测到主机地址后，IIC以与正常从机操作相同的方式运行。

28.8 Wakeup Function

The IIC provides a wakeup function that causes the MCU to transition from Software Standby mode or Snooze mode to normal operation. The wakeup function enables the reception of data when the system clock (PCLKB) is stopped, and generates a wakeup interrupt signal on a match of the slave address of the received data. This wakeup interrupt signal triggers the return to normal operation. After the wakeup interrupt occurs, switch the IIC to PCLKB synchronous operation so that communication can continue.

The wakeup function has four operation modes:

- Normal wakeup mode 1
- Normal wakeup mode 2
- Command recovery mode
- EEP response mode

Table 28.9 describes the behavior in these modes.

Table 28.9 Wakeup operation modes

Operation mode	ACK response timing	ACK response before wakeup to PCLKB synchronous operation	SCL state during wakeup to PCLKB synchronous operation
Normal wakeup mode 1	Before wakeup to PCLKB synchronous operation*1	ACK	Fixed low
Normal wakeup mode 2	After wakeup to PCLKB synchronous operation*2	Before wakeup: no response (NACK level retained) After wakeup: ACK response	Fixed low
Command recovery mode	Before wakeup to PCLKB synchronous operation*1	ACK	Open
EEP response mode	Before recovery to PCLKB synchronous operation*1	NACK	Open

Note 1. Switching timing from PCLKB asynchronous operation to PCLKB synchronous operation is the falling edge of the 9th clock of the SCL.
Note 2. Switching timing from PCLKB asynchronous operation to PCLKB synchronous operation is the falling edge of the 8th clock of the SCL.

The following can be selected as wakeup interrupt sources:

- Host address detection (valid when ICSER.HOAE = 1)
- General call address detection (valid when ICSER.GCAE = 1)
- Slave address 0*1 detection (valid when ICSER.SAR0E = 1)

28.8 唤醒功能

IIC提供唤醒功能，使MCU从软件待机模式或贪睡模式转换到正常操作。唤醒功能在系统时钟（PCLKB）停止时启用数据接收，并在接收到的数据的从地址匹配时产生唤醒中断信号。该唤醒中断信号触发恢复正常操作。唤醒中断发生后，将IIC切换为PCLKB同步操作，以便继续通信。

唤醒功能有四种操作模式：

- ●正常唤醒模式1
- ●正常唤醒模式2
- ●命令恢复模式
- ●EEP响应方式

表28.9描述了这些模式下的行为。

Table 28.9 唤醒操作模式

操作模式	ACK响应时间	唤醒前的ACK响应到PCLKB同步操作	唤醒到PCLKB同步操作期间的SCL状态
正常唤醒模式1	唤醒到PCLKB同步操作之前*1	ACK	固定低
正常唤醒模式2	唤醒到PCLKB同步操作后*2	唤醒前：无响应（保留NACK电平） 唤醒后：ACK响应	固定低
命令恢复模式	唤醒到PCLKB同步操作之前*1	ACK	Open
EEP响应模式	恢复到PCLKB同步操作之前*1	NACK	Open

注1.从PCLKB异步操作切换到PCLKB同步操作的时序是第9个时钟的下降沿SCL.
注2.从PCLKB异步操作切换到PCLKB同步操作的时序是第8个时钟的下降沿SCL.

可以选择以下作为唤醒中断源：

- ●主机地址检测（当ICSER.HOAE=1时有效）
- ●广播地址检测（ICSER.GCAE=1时有效）
- ●从机地址0*1检测（在ICSER.SAR0E=1时有效）

- Slave address 1*1 detection (valid when ICSER.SAR1E = 1)
- Slave address 2*1 detection (valid when ICSER.SAR2E = 1)

Note 1. Only 7-bit address can be set. Set the FS bit in SARUy (y = 0 to 2) to 0.

Precautions on the use of the wakeup function

- Do not change the content of the IIC registers except the WUSEN bit in ICWUR2 while the WUASYF flag in ICWUR2 is 1 (during PCLKB asynchronous operation).
- Set ICWUR.WUE and ICWUR.WUIE to 1, and ICCR2.MST and ICCR2.TRS to 0 (slave reception mode) before switching to PCLKB asynchronous mode.
- The device ID and the 10-bit slave address cannot be selected for the wakeup interrupt source. Set the DIDE bit in ICSER and FS bit in SARUy (y = 0 to 2) to 0.
- Set bits TIE, TEIE, RIE, NAKIE, SPIE, STIE, ALIE, and TMOIE in the ICIER register to 0 (interrupt disabled) before switching to the asynchronous operation.
- When the wakeup function is enabled, do not use the timeout function (ICWUR.WUE = 1)
- Even when a wakeup interrupt is generated during PCLKB asynchronous operation (when ICWUR2.WUASYF = 1), if the slave addresses match in PCLKB synchronous mode (ICWUR2.WUASYF = 0), the wakeup interrupt does not occur and the WUF flag is not set.
- If the timing of writing 0 to the ICWUR2.WUSEN bit and the timing of detecting a start condition conflict, the IIC might start the next reception in PCLKB synchronous operation mode. In this case, ICWUR2.WUASYF flag becomes 1 (switch to PCLKB asynchronous mode) when data communication is complete, a stop condition is detected, and detection of a wakeup event starts.
- After writing 0 to the WUSEN bit in ICWUR2, do not change registers relate to the IIC operation mode setting (ICMR3, ICSER, and SARLy) until the mode is switched to PCLKB asynchronous operation from PCLKB synchronous operation (while the ICWUR2.WUASYF flag is 1). If the register value changes during this period by an interrupt handling or another factor, the IIC might malfunction before switching to the asynchronous operation.

28.8.1 Normal Wakeup Mode 1

This section describes the behavior, the timing, and an example operation of normal wakeup mode 1.

In normal wakeup mode 1, a wakeup interrupt triggered by the match of the slave address initiates the transition to normal operation as follows:

Before wakeup:	ACK is sent in response to the data received with its own slave address of the IIC.
During wakeup:	ACK response is made on the 9th clock cycle of SCL, after which SCL is held low*1.
After wakeup:	Normal operation continues.

Note 1. Between the 9th clock cycle and 1st clock cycle during wakeup, WAIT = 1 is invalid.

If the slave address does not match, the SCL line is not held low after the 9th clock cycle of SCL, and the slave operation continues. Figure 28.30 shows an operation example, and Figure 28.32 shows the detailed timing.

If the transition from Software Standby mode or Snooze mode is triggered by an interrupt other than a wakeup interrupt, for example the IRQn, the WUF flag is not set to 1. Figure 28.31 shows an operation example.

●从机地址1*1检测（当ICSER.SAR1E=1时有效）

●从机地址2*1检测（当ICSER.SAR2E=1时有效）

注1.只能设置7位地址。将SARUy（y=0到2）中的FS位设置为0。

唤醒功能使用注意事项

●当ICWUR2的WUASYF标志为1时（PCLKB异步操作期间），不要改变ICWUR2中除WUSEN位以外的IIC寄存器的内容。

●在切换到PCLKB异步模式之前，将ICWUR.WUE和ICWUR.WUIE设置为1，并将ICCR2.MST和ICCR2.TRS设置为0（从接收模式）。

●唤醒中断源不能选择设备ID和10位从机地址。将ICSER中的DIDE位和SARUy（y=0到2）中的FS位设置为0。

●在切换到异步操作之前，将ICIER寄存器中的TIE、TEIE、RIE、NAKIE、SPIE、STIE、ALIE和TMOIE位设置为0（禁止中断）。

●启用唤醒功能时，不要使用超时功能（ICWUR.WUE=1）

●即使在PCLKB异步操作期间（ICWUR2.WUASYF=1）产生唤醒中断，如果在PCLKB同步模式下从机地址匹配（ICWUR2.WUASYF=0），唤醒中断不会发生并且WUF标志不放。

●如果向ICWUR2.WUSEN位写入0的时序与检测启动条件的时序冲突，则IIC可能会在PCLKB同步操作模式下开始下一次接收。在这种情况下，当数据通信完成时，ICWUR2.WUASYF标志变为1（切换到PCLKB异步模式），检测到停止条件，并开始检测唤醒事件。

●在ICWUR2的WUSEN位写入0后，不要更改与IIC操作模式设置相关的寄存器（ICMR3、ICSER和SARLy），直到模式从PCLKB同步操作切换到PCLKB异步操作（同时ICWUR2.WUASYF标志是1）。如果在此期间寄存器值因中断处理或其他因素而发生变化，则IIC可能会在切换到异步操作之前发生故障。

28.8.1 正常唤醒模式1

本节介绍正常唤醒模式1的行为、时序和示例操作。

在正常唤醒模式1中，由匹配从机地址触发的唤醒中断启动到正常操作的转换，如下所示：

Before wakeup:	ACK是响应接收到的带有IIC从机地址的数据而发送的。
During wakeup:	在SCL的第9个时钟周期做出ACK响应，之后SCL保持低电平*1。
After wakeup:	正常操作继续。

注1.在唤醒期间的第9个时钟周期和第1个时钟周期之间，WAIT=1无效。

如果从机地址不匹配，则SCL线在SCL的第9个时钟周期后不保持低电平，从机操作继续。图28.30显示了一个操作示例，图28.32显示了详细的时序。

如果从软件待机模式或贪睡模式的转换是由唤醒中断以外的中断触发的，例如IRQn，则WUF标志不设置为1。图28.31显示了一个操作示例。

28.8.2 Normal Wakeup Mode 2

This section describes the behavior, the timing, and an example operation of normal wakeup mode 2.

In normal wakeup mode 2, a wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows:

Before wakeup:	No response to data received with its own slave address until the end of the 8th SCL cycle.
During wakeup:	SCL line held low during the 8th and 9th clock cycles.
After wakeup:	ACK returns on the 9th clock cycle of SCL, and normal operation continues.

If the slave address does not match, the SCL line is not held low after the 8 th SCL clock cycle, and the slave operation continues. Figure 28.33 shows an example operation, and Figure 28.34 shows the detailed timing.

If the transition from Software Standby mode or Snooze mode is triggered by an interrupt other than a wakeup interrupt, such as the IRQn, for example, the WUF flag is not set to 1. Figure 28.31 shows an operation example.

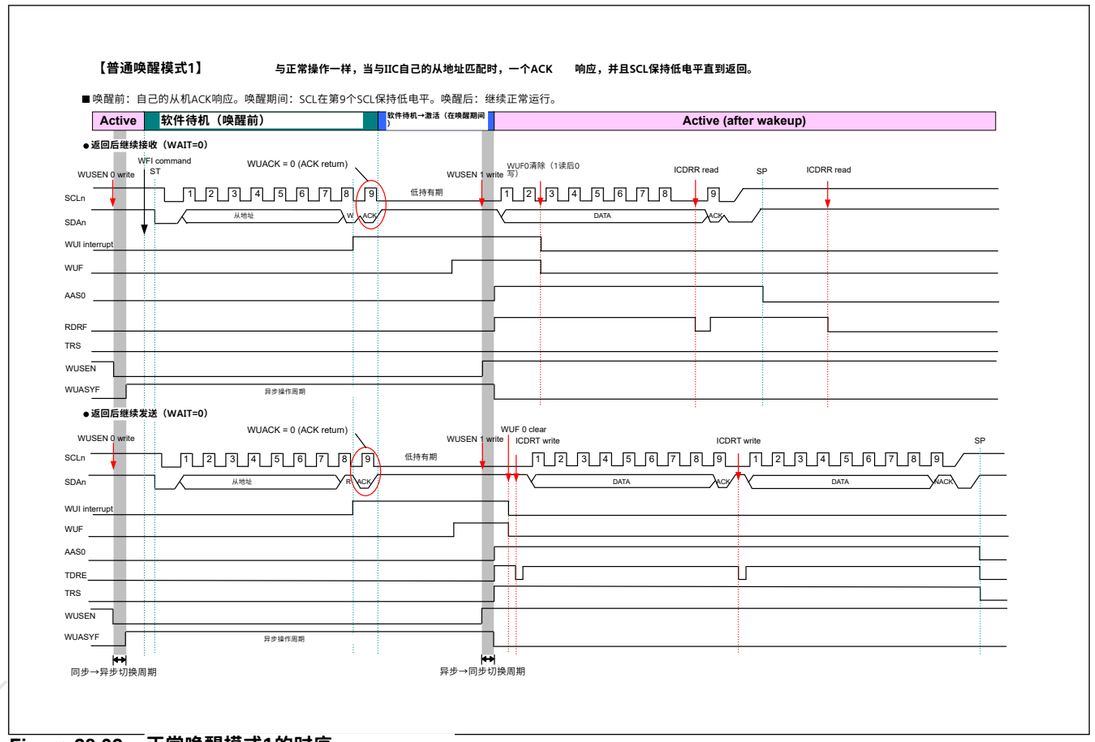

Figure 28.32 正常唤醒模式1的时序

28.8.2 正常唤醒模式2

本节介绍正常唤醒模式2的行为、时序和示例操作。

在正常唤醒模式2中，由匹配从机地址触发的唤醒中断会启动到正常操作的转换，如下所示：

Before wakeup:	直到第8个SCL周期结束，才对接收到的带有自己的从地址的数据作出响应。
During wakeup:	SCL线在第8和第9个时钟周期内保持低电平。
After wakeup:	ACK在SCL的第9个时钟周期返回，并继续正常操作。

如果从机地址不匹配，则SCL线在第8个SCL时钟周期后不会保持低电平，从机操作继续。图28.33显示了一个示例操作，图28.34显示了详细的时序。

如果从软件待机模式或贪睡模式的转换是由唤醒中断以外的中断触发的，例如IRQn，则WUF标志不设置为1。图28.31显示了一个操作示例。

28.8.3 Command Recovery Mode and EEP Response Mode (Special Wakeup Modes)

This section describes the behavior, the timing, and example operations of the command recovery and EEP response modes.

In the command recovery and EEP response modes, the SCL line is not held low during the wakeup period (after the rise of the 9th clock cycle of SCL). Therefore, other IIC devices can use the I^2C bus during this period.

A wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows:

Before wakeup:	In response to the data received with its own slave address, the IIC returns ACK (command recovery mode) or NACK (EEP response mode).
During wakeup:	The SCL line is not held low.
After wakeup:	Normal operation continues after IIC initialization.

If the slave address does not match, the slave operation continues.

Note: Because the SCL line is not held low during wakeup, transmission or reception of the data that follows the slave address is not possible.

Note: The command recovery and EEP response modes are internal reset states (ICE = IICRST = 1). Therefore, the match of the slave address does not set the flags, HOA, GCA, ASS0, ASS1, and ASS2 in the ICSR1 register.

Figure 28.35 shows an example operation in recovery and EEP response modes. Figure 28.37 shows the detailed timing.

If the transition from Software Standby mode or Snooze mode is triggered by an interrupt other than a wakeup interrupt, such as IRQn for example, the WUF flag is not set to 1. Follow the processing shown in Figure 28.36.

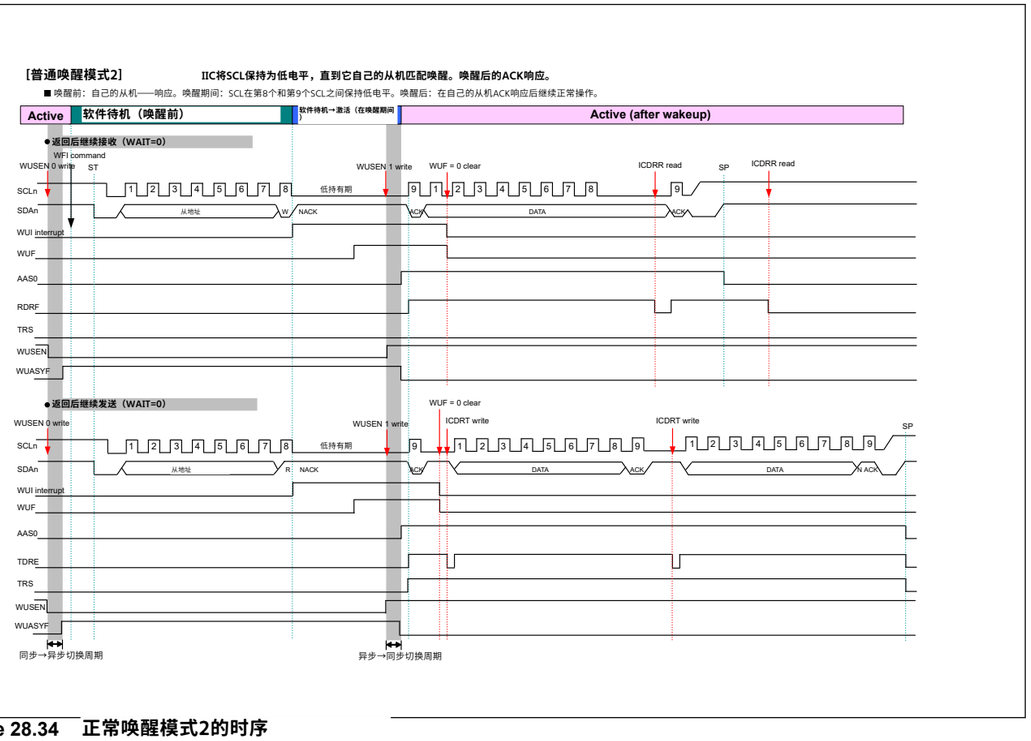

Figure 28.34 正常唤醒模式2的时序

28.8.3 命令恢复模式和EEP响应模式（特殊唤醒模式）

本节介绍命令恢复和EEP响应模式的行为、时序和示例操作。

在命令恢复和EEP响应模式下，SCL线在唤醒期间（在SCL的第9个时钟周期上升之后）不保持低电平。因此，其他IIC设备在此期间可以使用I2C总线。

由匹配从地址触发的唤醒中断会启动到正常操作的转换，如下所示：

Before wakeup:	IIC响应使用自己的从机地址接收到的数据，返回ACK（命令恢复模式）或NACK（EEP响应模式）。
During wakeup:	SCL线没有保持低电平。
After wakeup:	IIC初始化后继续正常操作。

如果从机地址不匹配，从机操作继续。

Note: 因为SCL线在唤醒期间没有保持低电平，所以无法发送或接收跟随从地址的数据。

Note: 命令恢复和EEP响应模式是内部复位状态(ICE=IICRST=1)。因此，从地址的匹配不会设置ICSR1寄存器中的标志位HOA、GCA、ASS0、ASS1和ASS2。

图28.35显示了恢复和EEP响应模式下的示例操作。图28.37显示了详细的时序。

如果从软件待机模式或贪睡模式的转换是由唤醒中断以外的中断触发的，例如IRQn，则WUF标志不设置为1。按照图28.36中所示的处理。

28.9 Automatic Low-Hold Function for SCL

28.9.1 Function to Prevent Wrong Transmission of Transmit Data

If the I²C Bus Shift Register (ICDRS) is empty and data has not been written to the I²C Bus Transmit Data Register (ICDRT) with the IIC in transmission mode (TRS bit = 1 in ICCR2), the SCLn line is automatically held low over the subsequent intervals. This low-hold period is extended until the transmit data is written, which prevents the unintended transmission of erroneous data.

Master transmit mode:

- Low-level interval after a start or restart condition is issued
- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

Slave transmit mode:

- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

28.9 SCL的自动低保持功能

28.9.1 防止传输数据错误传输的功能

如果I2C总线移位寄存器(ICDRS)为空且数据尚未写入I2C总线发送数据寄存器(ICDRT)且IIC处于传输模式（TRS位=ICCR2中的1），则SCLn线为在随后的时间间隔内自动保持低电平。这个低保持期一直延长到发送数据被写入，这样可以防止错误数据的意外传输。

主传输模式：

●发出启动或重启条件后的低电平间隔

●一次传输的第9个时钟周期和下一次传输的第1个时钟周期之间的低电平间隔。

从机发送模式：

●一次传输的第9个时钟周期和下一次传输的第1个时钟周期之间的低电平间隔。

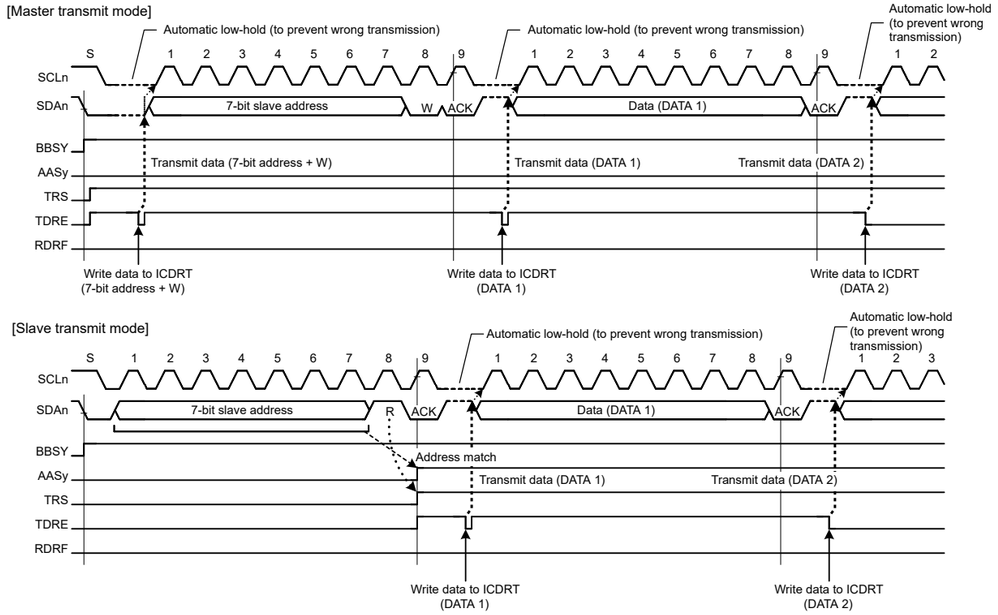

Figure 28.38 Automatic low-hold operation in transmit mode

28.9.2 NACK Reception Transfer Suspension Function

This function suspends transfer operation when NACK is received in transmit mode (TRS bit = 1 in ICCR2). This function is enabled when the NACKE bit in ICFER is set to 1. If the next transmit data is already written (TDRE flag = 0 in ICSR2) when NACK is received, the next data transmission on the falling edge of the 9th SCL clock cycle is automatically suspended. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (NACKF flag = 1 in ICSR2), transmit and receive operations are discontinued. To restore transmit or receive operation, after issuing the restart condition, you need to set the NACKF flag to 0 and try again, or set the NACKF flag to 0 after issuing the stop condition and then start again from issuing the start condition..

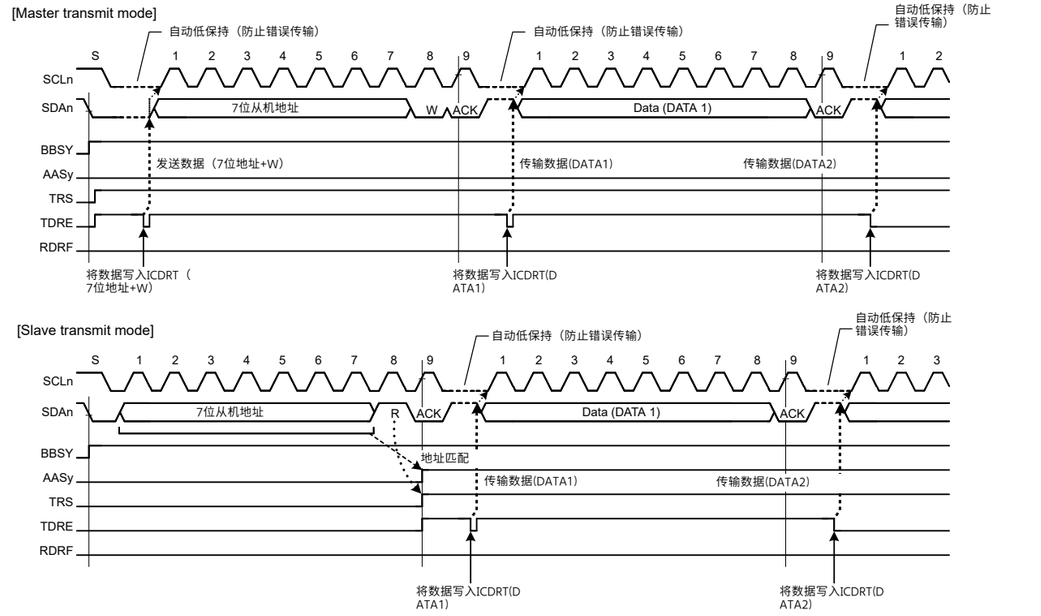

Figure 28.38 发送模式下的自动低保持操作

28.9.2 NACK接收传输暂停功能

当在发送模式下接收到NACK（ICCR2中的TRS位=1）时，该函数暂停传输操作。当ICFER中的NACKE位设置为1时，此功能使能。如果在收到NACK时已经写入下一个发送数据（ICSR2中的TDRE标志=0），则在第9个SCL时钟周期的下降沿进行下一个数据发送被自动挂起。这可以防止SDAn线路输出电平在下一个发送数据的MSB为0时保持低电平。

如果传输操作被该函数挂起（ICSR2中的NACKF标志=1），发送和接收操作将中断。要恢复发送或接收操作，在发出重启条件后，您需要将NACKF标志设置为0并重试，或者在发出停止条件后将NACKF标志设置为0，然后从发出启动条件重新开始。

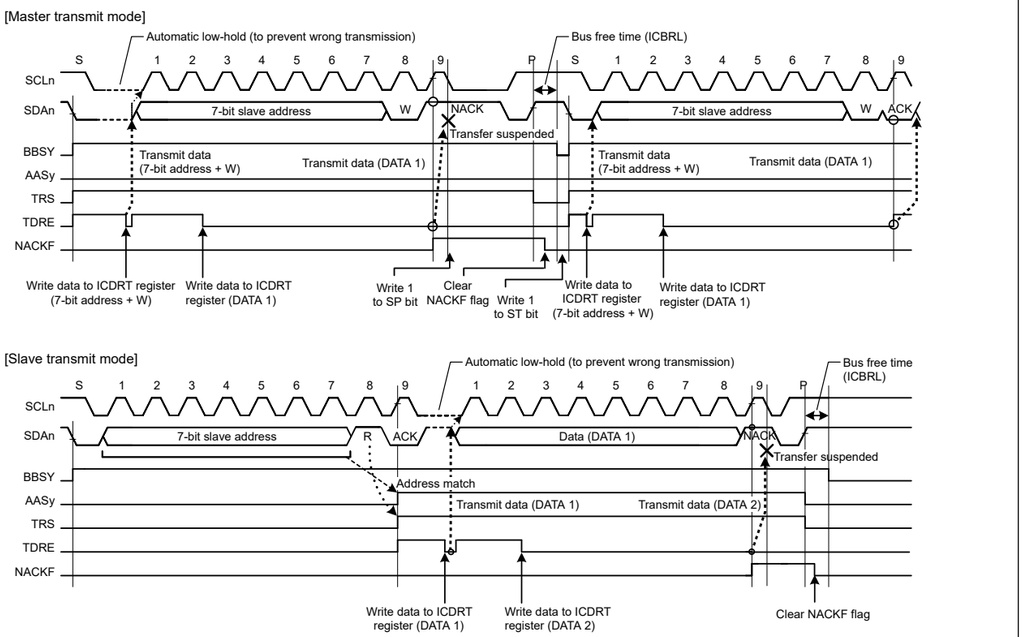

Figure 28.39 Suspension of data transfer when NACK is received, when NACKE = 1

28.9.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer frame or more with receive data full (RDRF flag = 1 in ICSR2) in receive mode (TRS = 0 in ICCR2), the IIC holds the SCLn line low automatically immediately before the next data is received to prevent a failure to receive data.

This function is enabled even if the read processing of the final receive data is delayed and, in the meantime, the IIC slave address is designated after a stop condition is issued. This function does not interfere with other communication because the IIC does not hold the SCLn line low when a mismatch with its own slave address occurs after a stop condition is issued.

Periods in which the SCLn line is held low can be selected with a combination of the WAIT and RDRFS bits in ICMR3.

(1) 1-byte receive operation and automatic low-hold function using the WAIT bit

When the WAIT bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the WAIT bit function. Additionally, when the ICMR3.RDRFS bit is 0, the IIC automatically sends the ACKBT bit value in ICMR3 for the acknowledge bit in the period from the falling edge of the 8th SCL clock cycle to the falling edge of the 9th SCL clock cycle, and automatically holds the SCLn line low on the falling edge of the 9th SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from ICDRR, which enables byte-wise receive operation.

The WAIT bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

(2) 1-byte receive operation (ACK/NACK transmission control) and automatic low-hold function using the RDRFS bit

When the RDRFS bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the RDRFS bit function. When the RDRFS bit is set to 1, the RDRF flag in ICSR2 is set to 1 (receive data full) on the rising edge of the eighth SCL clock cycle, and the SCLn line is automatically held low on the falling edge of the eighth SCL clock cycle. This low-hold is released by writing a value to the ACKBT bit in ICMR3, but cannot be released by reading data from ICDRR, which enables receive operation through the ACK or NACK transmission control based on the data received in byte units.

28.9.3 防止数据接收失败的功能

如果在接收模式（ICCR2中的TRS=0）下接收数据（ICDRR）读取延迟一个传输帧或更长时间且接收数据已满（ICSR2中的RDRF标志=1）时响应处理延迟，则IIC保持在接收到下一个数据之前，SCLn线自动变为低电平，以防止接收数据失败。

即使最终接收数据的读取处理延迟，该功能也有效，同时，在发出停止条件后指定IIC从机地址。此功能不会干扰其他通信，因为在发出停止条件后发生与其自己的从地址不匹配时，IIC不会将SCLn线保持为低电平。

可以通过ICMR3中的WAIT和RDRFS位的组合来选择SCLn线保持低电平的周期。

(1) 使用WAIT位的1字节接收操作和自动低保持功能

当ICMR3中的WAIT位设置为1时，IIC使用WAIT位功能执行1字节接收操作。此外，当ICMR3.RDRFS位为0时，IIC在第8个SCL时钟周期的下降沿到第9个SCL时钟周期的下降沿期间自动发送ICMR3中的ACKBT位值作为确认位，并且使用WAIT位功能在第9个SCL时钟周期的下降沿自动将SCLn线保持为低电平。该低保持通过从ICDRR读取数据来释放，从而启用逐字节接收操作。

在主机或从机接收模式下获得与IIC从机地址（包括广播地址和主机地址）匹配后的接收帧启用WAIT位功能。

(2) 1字节接收操作（ACKNACK传输控制）和使用RDRFS位的自动低保持功能

当ICMR3中的RDRFS位设置为1时，IIC使用RDRFS位功能执行1字节接收操作。当RDRFS位设置为1时，ICSR2中的RDRF标志在第8个SCL时钟周期的上升沿被设置为1（接收数据满），并且SCLn线在第8个SCL的下降沿自动保持为低时钟周期。该低保持通过向ICMR3中的ACKBT位写入值来释放，但不能通过从ICDRR读取数据来释放，ICDRR可以根据以字节为单位接收的数据通过ACK或NACK传输控制进行接收操作。

The RDRFS bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

28.10 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I^2C bus standard, the IIC provides functions to prevent double-issue of a start condition, detect arbitration-lost during transmission of NACK, and detect arbitration-lost in slave transmit mode.

28.10.1 Master Arbitration-Lost Detection (MALE Bit)

The IIC drives the SDAn line low to issue a start condition. However, if the SDAn line was already driven low by another master device issuing a start condition, the IIC regards its own start condition as an error and considers this a loss in arbitration. Priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the ST bit in ICCR2 to 1 while the bus is busy (BBSY flag = 1 in ICCR2), the IIC regards this as a double-issuing-of-start-condition error and considers itself to have lost in arbitration. This prevents a failure of transfer resulting from a start condition being issued while transfer is in progress.

When a start condition is issued successfully, if the transmit data including the address bits (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state) and a low level is detected on the SDAn line, the IIC loses in arbitration.

After a loss in arbitration of mastership, the IIC immediately enters slave receive mode. If a slave address, including the general call address, matches its own address at this time, the IIC continues in slave operation.

在主机或从机接收模式下获得与IIC从机地址（包括广播地址和主机地址）匹配后的接收帧启用RDRFS位功能。

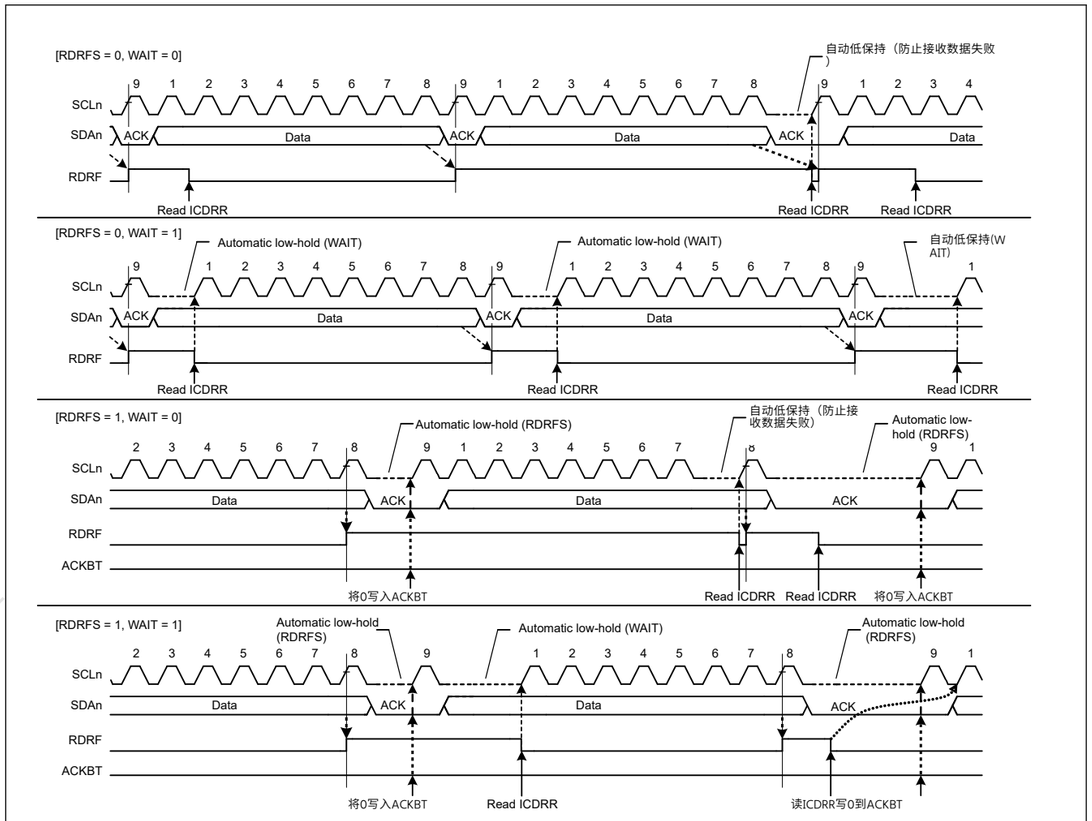

Figure 28.40 使用RDRFS和WAIT位在接收模式下自动保持低电平操作

28.10 仲裁丢失检测功能

除了I2C总线标准定义的正常仲裁丢失检测功能外，IIC还提供防止重复发出启动条件、在NACK传输期间检测仲裁丢失以及在从机发送中检测仲裁丢失的功能模式。

28.10.1 主仲裁丢失检测（MALE位）

IIC将SDAn线驱动为低电平以发出启动条件。但是，如果SDAn线已经被另一个发出启动条件的主设备驱动为低电平，则IIC将其自己的启动条件视为错误，并认为这是仲裁失败。其他主设备优先传输。类似地，如果在总线繁忙时通过将ICCR2中的ST位设置为1来发出启动条件的请求（ICCR2中的BBSY标志=1），则IIC将此视为双重启动条件错误，并且认为自己在仲裁中败诉。这可以防止由于在传输过程中发出启动条件而导致传输失败。

当启动条件成功发出时，如果发送数据包括地址位（内部SDA输出电平）与SDAn线上的电平不匹配（高输出作为内部SDA输出，意味着SDAn引脚处于高阻抗状态)并且在SDAn线上检测到低电平，则IIC在仲裁中失败。

在主控权仲裁失败后，IIC立即进入从机接收模式。如果此时从机地址（包括广播地址）与自己的地址匹配，则IIC继续从机操作。

A loss in arbitration of mastership is detected when the following conditions are met while the MALE bit in ICFER is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Mismatching of the internal level for output on SDA and the level on the SDAn line after a start condition was issued by setting the ST bit in ICCR2 to 1 while the BBSY flag in ICCR2 is set to 0 (erroneous issuing of a start condition)
- Setting of the ST bit in ICCR2 to 1 (start condition double-issue error) while the BBSY flag is 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDAn line in master transmit mode (MST and TRS bits = 11b in ICCR2).

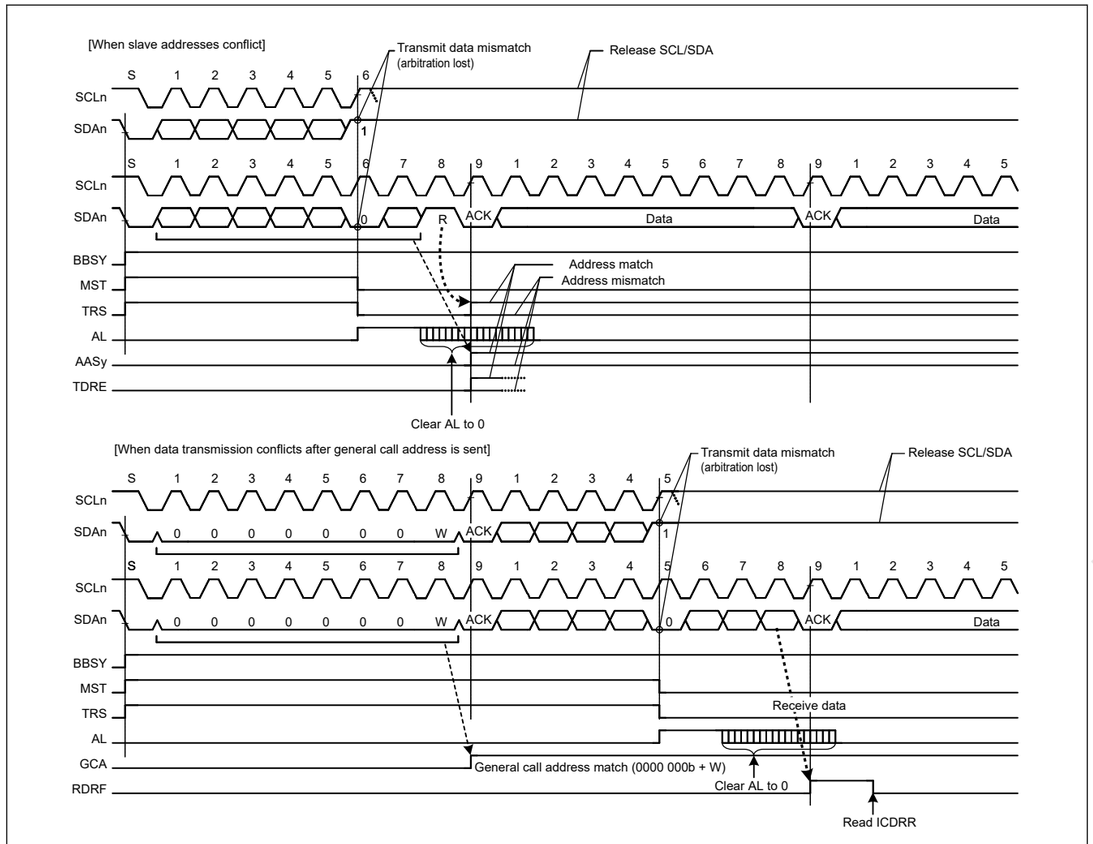

Figure 28.41 Examples of master arbitration-lost detection when MALE = 1

当ICFER中的MALE位为1（启用主仲裁丢失检测）时满足以下条件时，检测到主控仲裁丢失。

[Master arbitration-lost conditions]

●通过将ICCR2中的ST位设置为1，同时将ICCR2中的BBSY标志设置为0，发出启动条件后，SDA输出的内部电平与SDAn线上的电平不匹配（错误发出启动条件）

●在BBSY标志为1时将ICCR2中的ST位设置为1（启动条件双发错误）

●当发送数据不包括确认（内部SDA输出电平）与主发送模式下SDAn线上的电平不匹配时（ICCR2中的MST和TRS位=11b）。

28.10.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

This function causes arbitration to be lost if the internal SDA output level does not match the level on the SDAn line (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state) and the low level is detected on the SDAn line during transmission of NACK in receive mode. Arbitration is lost because of a conflict between NACK and ACK transmissions when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such a conflict occurs when multiple master devices send or receive the same information through a single slave device. Figure 28.43 shows an example of arbitration-lost detection during transmission of NACK.

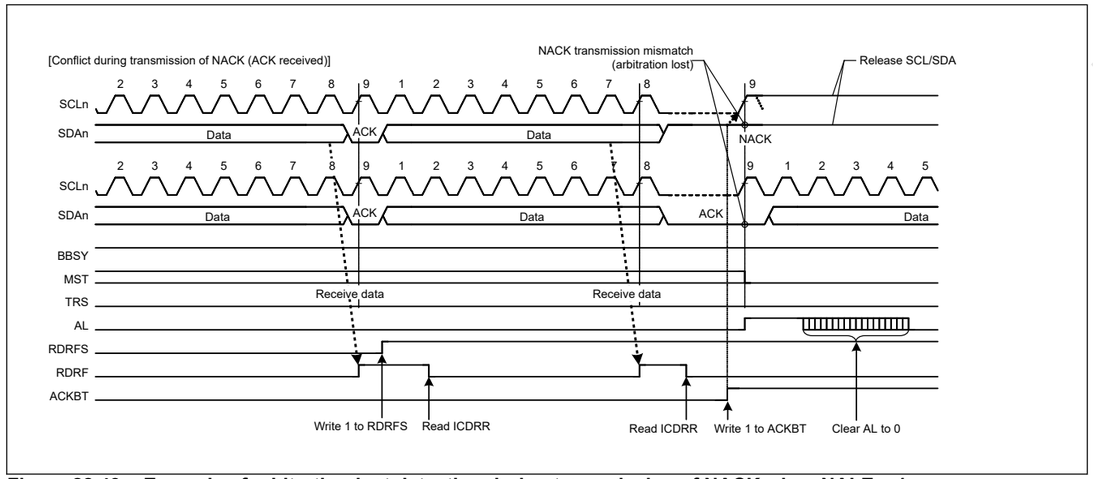

Figure 28.43 Example of arbitration-lost detection during transmission of NACK when NALE = 1

The following explains arbitration-lost detection using an example in which two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in either master A or master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Master A sends NACK when it has received 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the required 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like

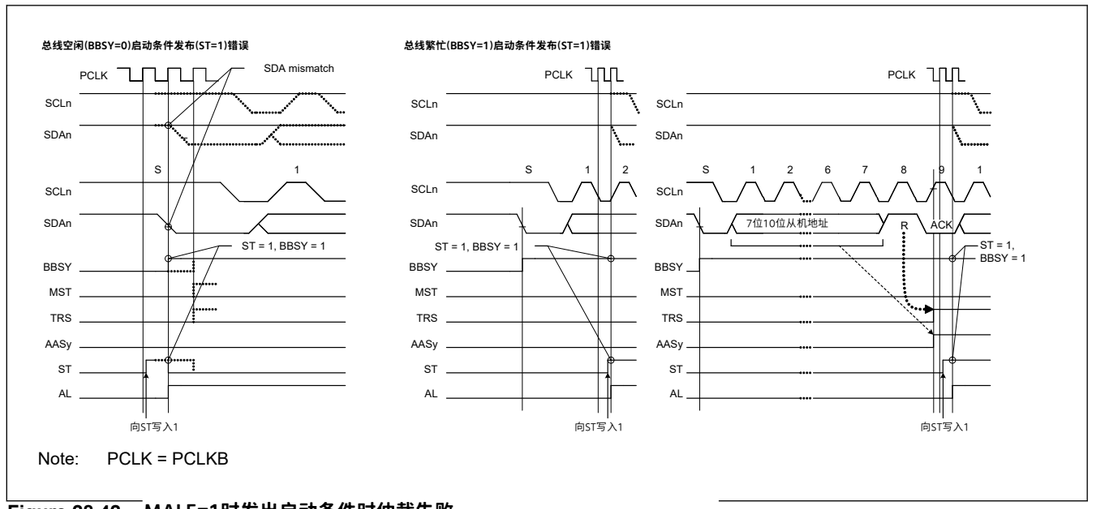

Figure 28.42 MALE=1时发出启动条件时仲裁失败

28.10.2 在NACK传输期间检测仲裁丢失的功能（NALE位）

如果内部SDA输出电平与SDAn线上的电平不匹配（高输出作为内部SDA输出，意味着SDAn引脚处于高阻抗状态）并且在上检测到低电平，此功能会导致仲裁丢失在接收模式下发送NACK期间的SDAn线。当多主控系统中两个或多个主控设备同时从同一从属设备接收数据时，由于NACK和ACK传输之间的冲突，仲裁会丢失。当多个主设备通过单个从设备发送或接收相同的信息时，就会发生这种冲突。图28.43显示了在NACK传输期间检测仲裁丢失的示例。

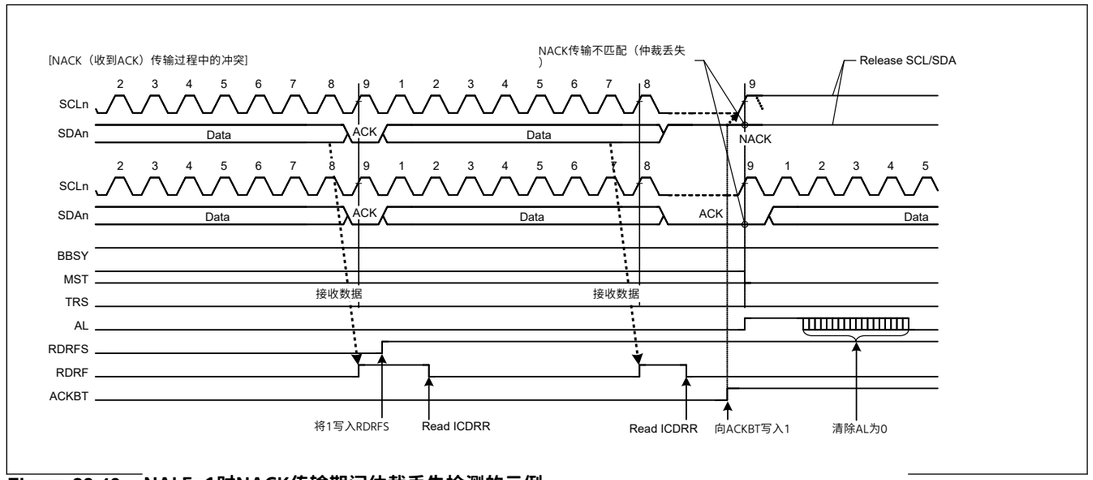

Figure 28.43 NALE=1时NACK传输期间仲裁丢失检测的示例

下面以两个主设备（主设备A和主设备B）和一个从设备通过总线连接的示例来说明仲裁丢失检测。在本例中，主设备A从从设备接收2个字节的数据，主设备B从从设备接收4个字节的数据。

如果主设备A和主设备B同时访问从设备，因为从设备地址相同，在访问从设备期间，主设备A或主设备B都不会丢失仲裁。因此，主机A和主机B都承认他们已经获得了总线控制权并照此运行。主设备A在从从设备接收到2个最终字节的数据时发送NACK。同时，masterB发送ACK，因为它没有收到所需的4字节数据。此时，来自masterA的NACK传输和来自masterB的ACK传输冲突。一般来说，如果像这样的冲突

this occurs, master A cannot detect the ACK transmitted by master B and issues a stop condition. The stop condition issue conflicts with the SCL clock output of master B, which disrupts communication.

When the IIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost. If arbitration is lost during transmission of NACK, the IIC immediately cancels the slave match condition and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing, such as 0xFF transmission processing, which is required if the UDID (Unique Device Identifier) of the assigned address does not match in the Get UDID general processing after the Assign Address command.

The IIC detects arbitration-lost during transmission of NACK when the following condition is met with the NALE bit in ICFER set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDAn line (ACK is received) during transmission of NACK (ACKBT bit = 1 in ICMR3).

28.10.3 Slave Arbitration-Lost Detection (SALE Bit)

This function causes arbitration to be lost if the transmit data (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state), and the low level is detected on the SDAn line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

When the IIC loses slave arbitration, the IIC is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminates subsequent redundant processing for the transmission of 0xFF.

The IIC detects slave arbitration-lost when the following condition is met with the SALE bit in ICFER set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When transmit data excluding acknowledge (internal SDA output level) does not match the SDAn line in slave transmit mode (MST and TRS bits = 01b in ICCR2).

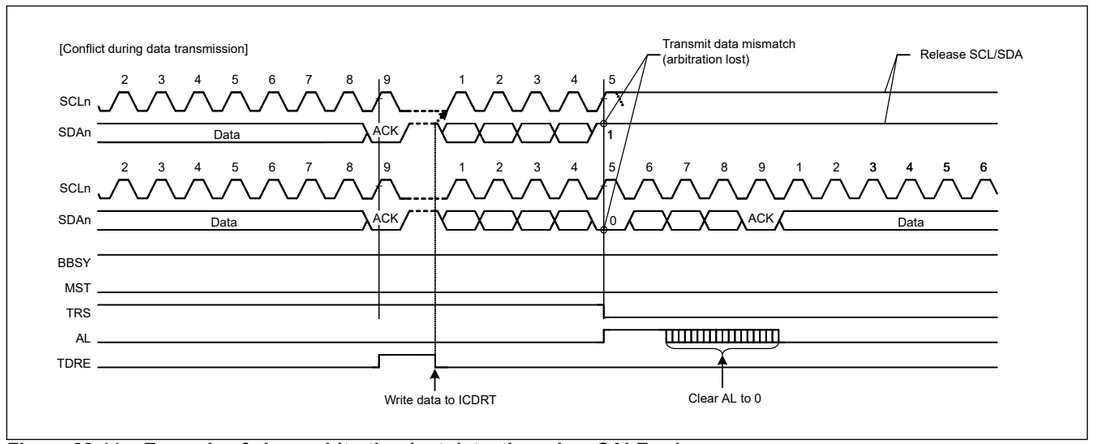

Figure 28.44 Example of slave arbitration-lost detection when SALE = 1

发生这种情况时，主机A无法检测到主机B发送的ACK并发出停止条件。停止条件问题与主B的SCL时钟输出冲突，从而中断通信。

当IIC在NACK传输过程中收到ACK时，它会检测到与其他主设备冲突的失败并导致仲裁丢失。如果在NACK传输过程中仲裁丢失，IIC立即取消从机匹配条件并进入从机接收模式。这可以防止发出停止条件，从而防止总线上的通信故障。

同样，在SMBus的ARP命令处理中，检测传输过程中仲裁丢失的功能
NACK也可用于消除额外的时钟周期处理，例如0xFF传输处理，如果分配地址的UDID（唯一设备标识符）在分配地址命令后的获取UDID常规处理中不匹配，则需要此处理。

IIC在NACK传输期间检测到仲裁丢失，当满足以下条件时
ICFER设置为1（启用NACK传输期间的仲裁丢失检测）。

[在NACK传输期间仲裁丢失的条件]

●在发送NACK（ICMR3中的ACKBT位=1）期间，当内部SDA输出电平与SDAn线不匹配时（接收到ACK）。

28.10.3 从设备仲裁丢失检测（SALE位）

如果发送数据（内部SDA输出电平）与SDAn线上的电平不匹配（高输出作为内部SDA输出，意味着SDAn引脚处于高阻状态），此功能会导致仲裁丢失，并且在从机发送模式下，SDAn线上检测到低电平。这种仲裁丢失检测功能主要用于通过SMBus传输UDID（唯一设备标识符）时。

当IIC失去从机仲裁时，IIC立即从从机匹配状态中释放并进入从机接收模式。该功能可以检测通过SMBus传输UDID期间的数据冲突，并消除后续对0xFF传输的冗余处理。

当ICFER中的SALE位设置为1（启用从设备仲裁丢失检测）满足以下条件时，IIC检测从设备仲裁丢失。

[从机仲裁失败的条件]

●当发送数据不包括确认（内部SDA输出电平）与从发送模式下的SDAn线不匹配时（MST和TRS位=ICCR2中的01b）。

28.11 Start, Restart, and Stop Condition Issuing Function

28.11.1 Issuing a Start Condition

The IIC issues a start condition when the ST bit in ICCR2 is set to 1. When the ST bit is set to 1, a start condition request is made, and the IIC issues a start condition when the BBSY flag in ICCR2 is 0 (bus free state). When a start condition is issued normally, the IIC automatically shifts to the master transmit mode.

To issue a start condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure that the time set in ICBRH and the start condition hold time elapse.
3. Drive the SCLn line low (high level to low level).
4. Detect low level on the SCLn line and ensure the low-level period of the SCLn line set in ICBRL elapses.

28.11.2 Issuing a Restart Condition

The IIC issues a restart condition when the RS bit in ICCR2 is set to 1. When the RS bit is set to 1, a restart condition request is made, and the IIC issues a restart condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a restart condition:

1. Release the SDAn line.
2. Ensure the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure the time set in ICBRL and the restart condition setup time elapse.
5. Drive the SDAn line low (high level to low level).
6. Ensure the time set in ICBRH and the restart condition hold time elapse.
7. Drive the SCLn line low (high level to low level).
8. Detect a low level on the SCLn line and ensure the low-level period of the SCLn line set in ICBRL elapses.

Note: When issuing restart condition requests, write the slave address to ICDRT after confirming that ICCR2.RS = 0. Data written while ICCR2.RS = 1 is not forwarded because of the retransmission condition before the occurrence.

28.11 启动、重启和停止条件发布功能

28.11.1 发出开始条件

当ICCR2中的ST位设置为1时，IIC发出启动条件。 当ST位设置为1时，发出启动条件请求，当ICCR2中的BBSY标志为0时，IIC发出启动条件（总线自由状态）。当启动条件正常发出时，IIC自动切换到主机发送模式。

发出开始条件：

1.将SDAn线拉低（高电平转低电平）。

2.确保ICBRH中设置的时间和启动条件保持时间已过。

3.将SCLn线拉低（高电平转低电平）。

4.检测SCLn线的低电平，确保ICBRL中设置的SCLn线的低电平周期过去。

28.11.2 发出重启条件

当ICCR2中的RS位设置为1时，IIC发出重启条件。当RS位设置为1时，发出重启条件请求，当ICCR2中的BBSY标志为1时，IIC发出重启条件（总线忙状态）并且ICCR2中的MST位为1（主模式）。

发出重启条件：

1.释放SDAn线。

2.确保ICBRL中设置的SCLn线的低电平周期已过。

3.释放SCLn线（低电平到高电平）。

4.检测SCLn线上的高电平并确保ICBRL中设置的时间和重启条件设置时间已过。

5.将SDAn线拉低（高电平转低电平）。

6.确保ICBRH中设置的时间和重启条件保持时间已过。

7.将SCLn线拉低（从高电平到低电平）。

8.检测SCLn线上的低电平，确保ICBRL中设置的SCLn线的低电平周期过去。

Note: 发出重启条件请求时，确认ICCR2.RS=0后，将从机地址写入ICDRT。在ICCR2.RS=1时写入的数据由于发生前的重传条件而不会转发。

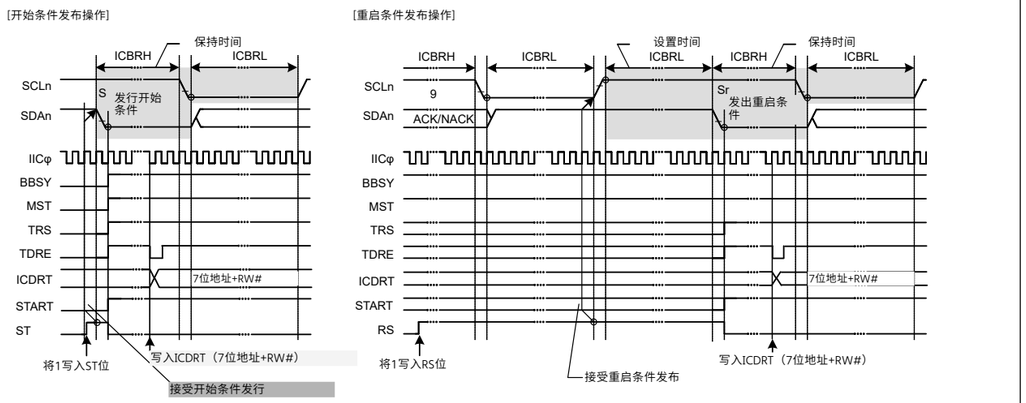

Figure 28.45 使用ST和RS位的启动和重启条件发出时序

Figure 28.46 shows the operation timing when a restart condition is issued after the master transmission.

[To issue a restart condition after the master transmission:]

1. Initialize the IIC using the procedure in section 28.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is open, then set the ST bit in ICCR2 to 1 (start condition issuance request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and the START flags in ICSR2 are automatically set to 1 and the ST bit is automatically set to 0. If the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that a start condition is successfully issued as requested by the ST bit has been successfully completed. The MST and TRS bits in ICCR2 are automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 is also automatically set to 1 when the TRS bit is set to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. After the data for transmission is written to ICDRT, the TDRE flag is automatically set to 0, data is transferred from ICDRT to ICDRS, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode according to the value of the transmitted R/W# bit. If the value of the R/W# bit is 0, the IIC continues in master transmit mode. If the ICSR2.NACKF flag is 1 at this time, indicating that no slave device recognized the address or that there was an error in communications, write 1 to ICCR2.SP bit to issue a stop condition. To transmit data with an address in the 10-bit format, start by writing 1111 0b, the 2 upper bits of the slave address, and W to ICDRT as the first address transmission. Then, as the second address transmission, write the 8 lower bits of the slave address to ICDRT.
4. After confirming that the TDRE flag in ICSR2 is 1, write data for transmission to the ICDRT register. The IIC automatically holds the SCLn line low until data for transmission is ready, a restart condition is issued or a stop condition is issued.
5. After all bytes of data for transmission are written to the ICDRT register, wait until the value of the TEND flag in ICSR2 returns to 1. Then after checking that the START flag in ICSR2 is 1, set the START flag in ICSR2 to 0.
6. Set the RS bit in ICCR2 to 1 (restart condition issue request). On receiving the request, the IIC issues a restart condition.
7. After checking that the START flag in ICSR2 is 1, write the value for transmission (the slave address and the R/W# bit) to ICDRT.

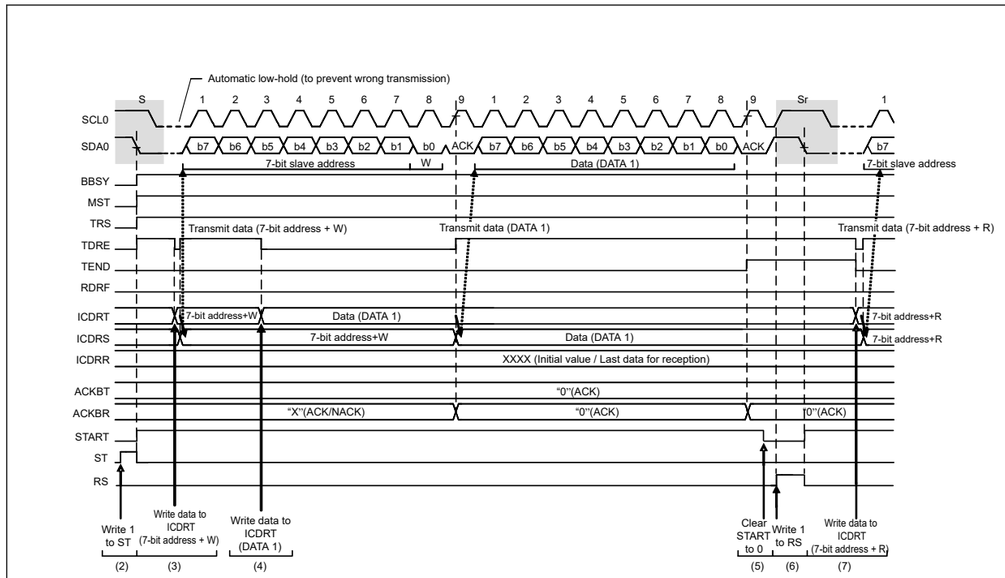

Figure 28.46 Restart condition issue timing after master transmission.

图28.46显示了在主机发送后发出重新启动条件时的操作时序。

[在主传输后发出重启条件：]

1.使用第28.3.2节中的过程初始化IIC。初始设置。

2.读取ICCR2中的BBSY标志以检查总线是否打开，然后将ICCR2中的ST位设置为1（开始条件发出请求）。收到请求后，IIC发出一个开始条件。同时，ICSR2中的BBSY和START标志位自动置1，ST位自动置0。如果检测到启动条件，则内部电平为SDA输出状态和SDAn线上的电平当ST位为1时匹配，IIC识别成功发出启动条件，因为ST位请求已成功完成。ICCR2中的MST和TRS位自动设置为1，将IIC置于主机发送模式。当TRS位设置为1时，ICSR2中的TDRE标志也自动设置为1。

3.检查ICSR2中的TDRE标志是否为1，然后将要发送的值（从机地址和RW#位）写入ICDRT。待发送数据写入ICDRT后，TDRE标志自动置0，数据从ICDRT传输到ICDRS，TDRE标志再次置1。发送时，TRS位的值会根据发送的RW#位的值自动更新以选择主机发送或主机接收模式。如果RW#位的值为0，则IIC继续处于主机发送模式。如果此时ICSR2.NACKF标志位为1，表示没有从设备识别该地址或通信出现错误，向ICCR2.SP位写入1发出停止条件。要使用10位格式的地址传输数据，首先将11110b、从机地址的高2位和W写入ICDRT作为第一个地址传输。然后，作为第二次地址传输，将从地址的低8位写入ICDRT。

4.确认ICSR2中的TDRE标志为1后，将要发送的数据写入ICDRT寄存器。IIC自动将SCLn线保持为低电平，直到传输数据准备好、发出重启条件或发出停止条件。

5.待发送的所有字节数据写入ICDRT寄存器后，等待ICSR2中的TEND标志的值返回1。然后检查ICSR2中的START标志为1后，将ICSR2中的START标志设置为0.

6.将ICCR2中的RS位设置为1（重新启动条件发出请求）。收到请求后，IIC发出重启条件。

7.检查ICSR2中的START标志为1后，将要发送的值（从机地址和RW#位）写入ICDRT。

28.11.3 Issuing a Stop Condition

The IIC issues a stop condition when the SP bit in ICCR2 is set to 1. When the SP bit is set to 1, a stop condition request is made, and the IIC issues a stop condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a stop condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure the time set in ICBRH and the stop condition setup time elapse.
5. Release the SDAn line (low level to high level).
6. Ensure the time set in ICBRL and the bus free time elapse.
7. Clear the BBSY flag to 0 to release the bus mastership.

28.12 Bus Hanging

If the clock signals from the master and slave devices are out of synchronization because of noise or other factors, the I^2C bus might hang with a fixed level on the SCLn line or SDAn line.

To manage bus hanging, the IIC has a timeout function to detect hanging by monitoring the SCLn line, and a function for outputting an extra SCL clock cycle to release the bus from:

- A timeout function to detect hanging by monitoring the SCLn line
- The IIC reset function
- An internal reset function.

By checking the SCLO, SDAO, SCLI, and SDAI bits in ICCR1, it is possible to see whether the IIC or its communicating partner is placing the low level on the SCLn or SDAn line.

28.12.1 Timeout Function

The timeout function can detect when the SCLn line is stuck longer than the predetermined time. The IIC can detect an abnormal bus state by monitoring that the SCLn line is stuck low or high for a predetermined time.

The timeout function monitors the SCLn line state and counts the low- or high-level period using the internal counter. The timeout function resets the internal counter each time the SCLn line changes (rises or falls), but continues to count unless the SCLn line changes. If the internal counter overflows because no SCLn line changes, the IIC can detect the timeout and report the bus hung state.

28.11.3 发出停止条件

当ICCR2中的SP位设置为1时，IIC发出停止条件。当SP位设置为1时，发出停止条件请求，当ICCR2中的BBSY标志为1时，IIC发出停止条件（总线忙状态）并且ICCR2中的MST位为1（主模式）。

发出停止条件：

1.将SDAn线拉低（高电平转低电平）。

2.确保ICBRL中设置的SCLn线的低电平周期已过。

3.释放SCLn线（低电平到高电平）。

4.检测SCLn线上的高电平并确保ICBRH中设置的时间和停止条件设置时间已过。

5.释放SDAn线（低电平到高电平）。

6.确保ICBRL中设置的时间和巴士空闲时间已过。

7.将BBSY标志清为0以释放总线控制权。

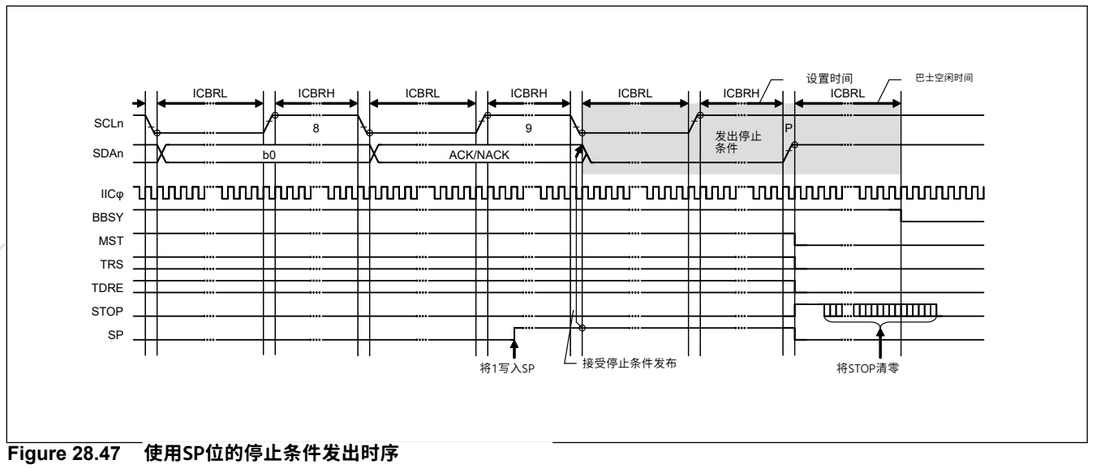

Figure 28.47 使用SP位的停止条件发出时序

28.12 巴士挂

如果来自主从设备的时钟信号由于噪声或其他因素不同步，则I2C总线可能会在SCLn线或SDAn线上以固定电平挂起。

为了管理总线挂起，IIC具有通过监视SCLn线检测挂起的超时功能，以及输出额外SCL时钟周期以释放总线的功能：

●通过监控SCLn线路来检测挂起的超时功能

●IIC复位功能

●内部复位功能。

通过检查ICCR1中的SCLO、SDAO、SCLI和SDAI位，可以查看IIC或其通信伙伴是否将SCLn或SDAn线置于低电平。

28.12.1 超时功能

超时功能可以检测SCLn线路何时卡住超过预定时间。IIC可以通过监视SCLn线在预定时间内保持低电平或高电平来检测异常总线状态。

超时功能监控SCLn线路状态并使用内部计数器计算低电平或高电平周期。每次SCLn线改变（上升或下降）时，超时功能都会复位内部计数器，但除非SCLn线改变，否则会继续计数。如果内部计数器因为SCLn线没有变化而溢出，IIC可以检测到超时并报告总线挂起状态。

This timeout function is enabled when the ICFER.TMOE bit is 1. It detects a hung state when the SCLn line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1) in master mode (ICCR2.MST bit is 1)
- The IIC slave address is detected (ICSR1 register is not 0x00) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0)
- The bus is open (ICCR2.BBSY flag is 0) while a start condition is requested (ICCR2.ST bit is 1).

The internal counter of the timeout function uses the internal reference clock (IICφ) set in the CKS[2:0] bits in ICMR1 as a count source. It functions as a 16-bit counter when long mode is selected (TMOS bit = 0 in ICMR2) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCLn line level (low, high, or both levels) during which this counter is activated can be selected in the TMOH and TMOL bits in ICMR2. If both TMOL and TMOH bits are set to 0, the internal counter is disabled.

28.12.2 Extra SCL Clock Cycle Output Function

In master mode, this function outputs extra SCL clock cycles to release the SDAn line of the slave device from being held low because the master is out of synchronization with the slave device. This function is mainly used in master mode to release the SDAn line of the slave device from being fixed low by including extra cycles of SCL output from the IIC. It uses single cycles of the SCL clock for a bus error where the IIC cannot issue a stop condition because the slave device is holding the SDAn line at the low level. Do not use this function in normal situations. Using it when communications are proceeding correctly leads to malfunctions.

When the CLO bit in ICCR1 is set to 1 in master mode, a single cycle of the SCL clock at the frequency specified in the CKS[2:0] bits in ICMR1, and in the ICBRH and ICBRL registers, is output as an extra clock cycle. After output of this

此超时功能在ICFER.TMOE位为1时启用。在以下情况下，当SCLn线卡在低电平或高电平时，它会检测到挂起状态：

●总线繁忙（ICCR2.BBSY标志为1）在主机模式（ICCR2.MST位为1）

●检测到IIC从机地址（ICSR1寄存器不是0x00）并且在从机模式下总线忙（ICCR2.BBSY标志为1）（ICCR2.MST位为0）

●请求启动条件时（ICCR2.ST位为1），总线打开（ICCR2.BBSY标志为0）。

超时功能的内部计数器使用ICMR1的CKS[2:0]位中设置的内部参考时钟(IICφ)作为计数源。Itfunctionsasa16-bitcounterwhenlongmodeisselected(TMOSbit=0inICMR2)ora14-bitcounterwhenshortmodeisselected(TMOSbit=1).

可以在TMOH和
ICMR2中的TMOL位。如果TMOL和TMOH位都设置为0，则内部计数器被禁用。

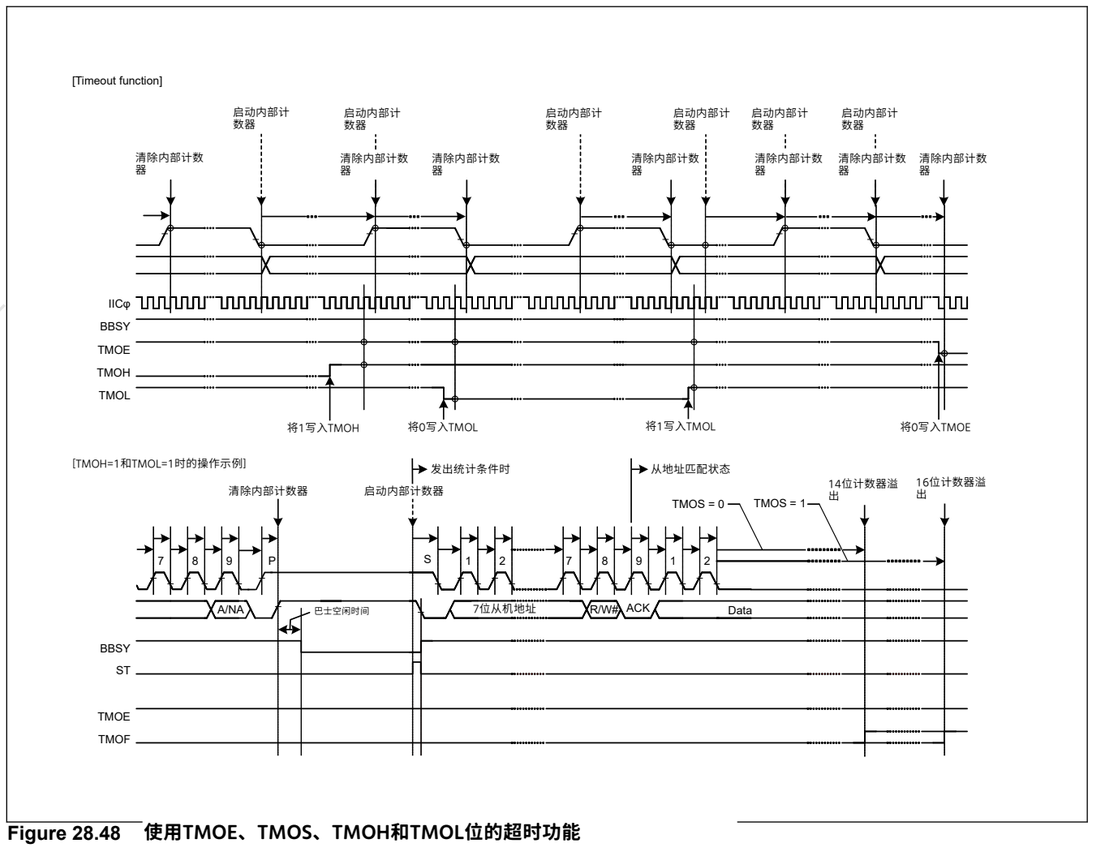

Figure 28.48 使用TMOE、TMOS、TMOH和TMOL位的超时功能

28.12.2 额外的SCL时钟周期输出功能

在主模式下，该函数输出额外的SCL时钟周期，以释放从设备的SDAn线保持低电平，因为主设备与从设备不同步。该功能主要用于主机模式，通过包含IIC的额外SCL输出周期来释放从机设备的SDAn线固定为低电平。它使用SCL时钟的单个周期来处理IIC无法发出停止条件的总线错误，因为从设备将SDAn线保持在低电平。在正常情况下不要使用此功能。在通信正常进行时使用它会导致故障。

当ICCR1中的CLO位在主机模式下设置为1时，以ICMR1中的CKS[2:0]位以及ICBRH和ICBRL寄存器中指定的频率的SCL时钟的单个周期作为额外输出输出时钟周期。这个输出后

single cycle of the SCL clock, the CLO bit is automatically set to 0. At this time, if ICCR2.BBSY = 1, the SCL pin goes low, and when ICCR2.BBSY = 0, the SCL pin goes high. After confirming that the CLO bit is 0 by software, write 1 to the CLO bit to output the additional clock continuously.

When the IIC module is in master mode and the slave device is holding the SDAn line low because synchronization with the slave device is lost because of effects like noise, the output of a stop condition is not possible. This function can be used to output extra cycles of SCL one by one to make the slave device release the SDAn line from being held low, and so recover the bus from an unusable state. Release of the SDAn line by the slave device can be monitored by reading the SDAI bit in ICCR1. After confirming the release of the SDAn line by the slave device, complete communications by reissuing the stop condition.

[Output conditions for using the CLO bit in ICCR1]

- When the bus is open (BBSY flag in ICCR2 = 0) or in master mode (MST bit = 1 and BBSY flag = 1 in ICCR2)
- When the communication device does not hold the SCLn line low.

Figure 28.49 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

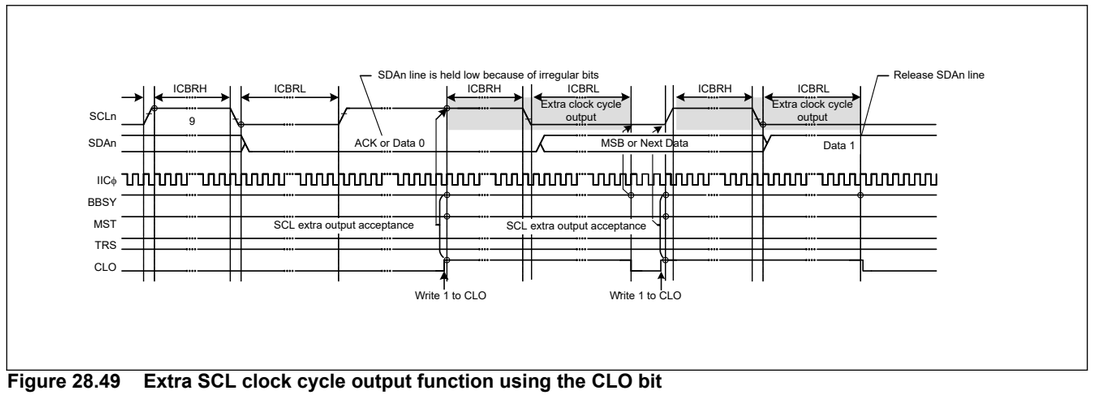

Figure 28.49 Extra SCL clock cycle output function using the CLO bit

28.12.3 IIC Reset and Internal Reset

The IIC module incorporates a function for resetting itself. It uses two types of resets:

- An IIC reset, which initializes all registers, including the BBSY flag in ICCR2.
- An internal reset, which releases the IIC from the slave-address matched state and initializes the internal counter while saving other settings.

After issuing a reset, always set the IICRST bit in ICCR1 to 0. Both types of resets are valid for release from bus-hung states, because both restore the output state of the SCLn and SDAn pins to the high-impedance state.

Issuing a reset during slave operation might lead to a loss of synchronization between the master device clock and the slave device clock, so avoid this when possible. In addition, monitoring of the bus state, such as for the presence of a start condition, is not possible during an IIC reset (ICE and IICRST bits = 01b in ICCR1).

For a detailed description of the IIC and internal resets, see section 28.15. State of Registers When Issuing Each Condition.

28.13 SMBus Operation

The IIC supports data communication conforming to the SMBus Specification (version 2.0). To perform SMBus communication, set the SMBS bit in ICMR3 to 1. To use the transfer rate within a range of 10 to 100 kbps of the SMBus standard, set the CKS[2:0] bits in ICMR1, the ICBRH, and ICBRL registers. In addition, specify the values in the DLCS bit in ICMR2 and the SDDL[2:0] bits in ICMR2 to meet the data hold time specification of 300 ns or more. When the IIC is used only as a slave device, the transfer rate setting is not required, but ICBRL must be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001b), use one of the slave address registers L0 to L2 (SARL0, SARL1, and SARL2), and set the associated FS bit (7- or 10-bit address format select) in SARUy (y = 0 to 2) to 0 (7-bit address format).

在SCL时钟的一个周期内，CLO位自动设置为0。此时，如果ICCR2.BBSY=1，SCL引脚变为低电平，当ICCR2.BBSY=0时，SCL引脚变为高电平。通过软件确认CLO位为0后，向CLO位写入1以连续输出附加时钟。

当IIC模块处于主模式且从设备保持SDAn线为低电平时，由于噪声等影响与从设备失去同步，因此无法输出停止条件。该功能可用于逐个输出额外的SCL周期，使从设备释放SDAn线的低电平状态，从而将总线从不可用状态恢复。从设备释放SDAn线可以通过读取ICCR1中的SDAI位来监控。从设备确认SDAn线的释放后，通过重新发出停止条件完成通信。

[使用ICCR1中CLO位的输出条件]

●当总线打开（ICCR2中的BBSY标志=0）或主机模式（ICCR2中的MST位=1和BBSY标志=1）时

●当通信设备不保持SCLn线为低电平时。

图28.49显示了额外SCL时钟周期输出功能（CLO位）的操作时序。

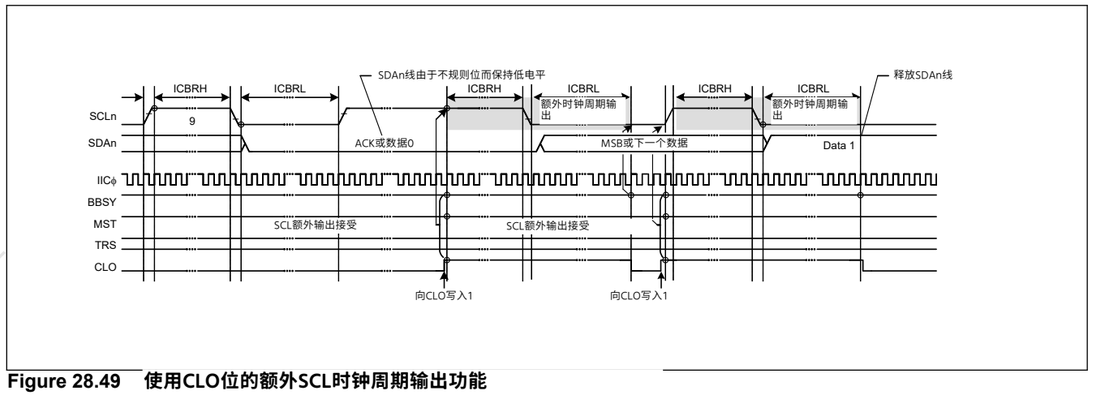

Figure 28.49 使用CLO位的额外SCL时钟周期输出功能

28.12.3 IIC复位和内部复位

IIC模块包含一个自我复位功能。它使用两种类型的重置：

●IIC复位，初始化所有寄存器，包括ICCR2中的BBSY标志。

●内部复位，将IIC从从地址匹配状态释放并初始化内部计数器，同时保存其他设置。

发出复位后，始终将ICCR1中的IICRST位设置为0。两种类型的复位都对从总线挂起状态释放有效，因为两者都将SCLn和SDAn引脚的输出状态恢复为高阻状态。

在从机操作期间发出复位可能会导致主设备时钟和从设备时钟之间失去同步，因此请尽可能避免这种情况。此外，在IIC复位（ICE和IICRST位=ICCR1中的01b）期间无法监控总线状态，例如是否存在启动条件。

有关IIC和内部复位的详细说明，请参见第28.15节。发出每个条件时的寄存器状态。

28.13 SMBus Operation

IIC支持符合SMBus规范（2.0版）的数据通信。要执行SMBus通信，请将ICMR3中的SMBS位设置为1。要使用SMBus标准的10到100kbps范围内的传输速率，请设置ICMR1、ICBRH和ICBRL寄存器中的CKS[2:0]位.此外，请指定ICMR2中的DLCS位和ICMR2中的SDDL[2:0]位中的值，以满足300ns或更长的数据保持时间规范。当IIC仅用作从设备时，不需要设置传输速率，但必须将ICBRL设置为比数据建立时间（250ns）更长的值。

对于SMBus器件默认地址(1100001b)，使用从地址寄存器L0到L2之一（SARL0、SARL1和SARL2），并将SARUy(y=0to2)中相关的FS位（7位或10位地址格式选择）设置为0（7位地址格式）。

When transmitting the UDID (Unique Device Identifier), set the SALE bit in ICFER to 1 to enable the slave arbitration-lost detection function.

28.13.1 SMBus Timeout Measurement

(1) Measuring slave device timeout

The following period (timeout interval: $T_{LOW: SEXT}$) must be measured for slave devices in SMBus communication:

- From start condition to stop condition.

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the GPT using the IIC start condition detection interrupt (STIn) and stop condition detection interrupt (SPIn). The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW: SEXT}$: 25 ms (maximum) of the SMBus standard.

If the time measured with the GPT exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the slave device must release the bus by writing 1 to the IICRST bit in ICCR1 to issue an internal reset of the IIC. When an internal reset is issued, the IIC stops driving the bus for the SCLn and SDAn pins, making them output high-impedance, which releases the bus.

(2) Measuring master device timeout

The following periods (timeout interval: $T_{LOW: MEXT}$) must be measured for master devices in SMBus communication:

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition.

To measure timeout for master devices, measure these periods with the GPT using the IIC start condition detection interrupt (STIn), stop condition detection interrupt (SPIn), transmit end interrupt (IICn_TEI), or receive data full interrupt (IICn_RXI). The measured timeout period must be within the total clock low-level extended period (master device) $T_{LOW: MEXT}$: 10 ms (maximum) of the SMBus standard, and the total of all $T_{LOW: MEXT}$ values from start condition to stop condition must be within $T_{LOW: SEXT}$: 25 ms (maximum).

For the ACK receive timing (rising edge of the 9th SCL clock cycle), monitor the TEND flag in ICSR2 in master transmit mode (master transmitter) and the RDRF flag in ICSR2 in master receive mode (master receiver). Perform byte-wise transmit operations in master transmit mode, and hold the RDRFS bit in ICMR3 at 0 until the byte immediately before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

If the period measured with the GPT exceeds the total clock low-level extended period (master device) $T_{LOW: MEXT}$: 10 ms (maximum) of the SMBus standard or the total of measured periods exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (stop writing data to ICDRT).

发送UDID（UniqueDeviceIdentifier）时，将ICFER中的SALE位设置为1，以使能从机仲裁丢失检测功能。

28.13.1 SMBus超时测量

(1) 测量从设备超时

对于SMBus通信中的从设备，必须测量以下周期（超时间隔：TLOW:SEXT）：

●从开始条件到停止条件。

要测量从设备的超时，请使用GPT使用IIC启动条件检测中断(STIn)和停止条件检测中断(SPIn)测量从启动条件检测到停止条件检测的周期。测得的超时周期必须在总时钟低电平周期[从设备]TLOW:SEXT:SMBus标准的25ms（最大值）内。

如果用GPT测量的时间超过时钟低电平检测超时TTIMEOUT:25ms（最小值）
SMBus标准，从设备必须通过向ICCR1中的IICRST位写入1来释放总线，以发出IIC的内部复位。当发出内部复位时，IIC停止驱动SCLn和SDAn引脚的总线，使它们输出高阻抗，从而释放总线。

(2) 测量主设备超时

对于SMBus通信中的主设备，必须测量以下周期（超时间隔：TLOW:MEXT）：

●从开始条件到确认位
●确认位之间
●从确认位到停止条件。

要测量主设备的超时，请使用GPT使用IIC开始条件检测中断(STIn)、停止条件检测中断(SPIn)、发送结束中断(IICn_TEI)或接收数据完整中断(IICn_RXI)来测量这些周期。测量的超时周期必须在总时钟低电平扩展周期（主设备）TLOW内：
MEXT：SMBus标准的10毫秒（最大值），从开始条件到停止条件的所有TLOW：MEXT值的总和必须在TLOW：SEXT：25毫秒（最大值）内。

对于ACK接收时序（第9个SCL时钟周期的上升沿），在主机发送模式（主机发送器）下监控ICSR2中的TEND标志，在主机接收模式（主机接收器）下监控ICSR2中的RDRF标志。在主机发送模式下执行逐字节发送操作，并将ICMR3中的RDRFS位保持为0，直到在主机接收模式下接收到最后一个字节之前的字节。当RDRFS位为0时，RDRF标志在第9个SCL时钟周期的上升沿设置为1。

如果用GPT测量的周期超过总时钟低电平延长周期（主设备）TLOW:MEXT:SMBus标准的10ms（最大值）或总测量周期超过时钟低电平检测超时TTIMEOUT：SMBus标准的25ms（最小值），主设备必须通过发出停止条件来停止事务。在主机发送模式下，立即停止发送操作（停止向ICDRT写入数据）。

28.13.2 Packet Error Code (PEC)

The MCU provides a CRC calculator that enables transmission of a Packet Error Code (PEC) or allows checking of the received data in SMBus data communication for the IIC. For the CRC-generating polynomials of the CRC calculator, see section 32, Cyclic Redundancy Check (CRC).

In master transmit mode, the PEC data can be generated by writing all transmit data to the CRC Data Input Register (CRCDIR) in the CRC calculator.

In master receive mode, the PEC data can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC Data Output Register (CRCDOR) with the received PEC data.

To send ACK or NACK based on the match or mismatch result when the final byte is received as a result of the PEC code check, set the RDRFS bit in ICMR3 to 1 before the rising edge of the 8th SCL clock cycle during reception of the final byte, and hold the SCLn line low on the falling edge of the 8th clock cycle.

28.13.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communicating over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address, or to request its own slave address from the SMBus host.

For a product using the MCU to operate as an SMBus host or ARP master, the host address (0001 000b) sent from the slave device must be detected as a slave address, and so the IIC provides a function for detecting the host address. To detect the host address as a slave address, set the SMBS bit in ICMR3 and the HOAE bit in ICSER to 1. Operation after the host address is detected is the same as normal slave operation.

28.14 Interrupt Sources

The IIC issues five types of interrupt requests:

- Transfer error or event generation (arbitration-lost, NACK detection, timeout detection, start condition detection, and stop condition detection)
- Receive data full
- Transmit data empty
- Transmit end
- Address match during wakeup function

Table 28.10 lists details about the interrupt requests. The receive data full and transmit data empty interrupts can activate data transfer by the DTC or DMAC.

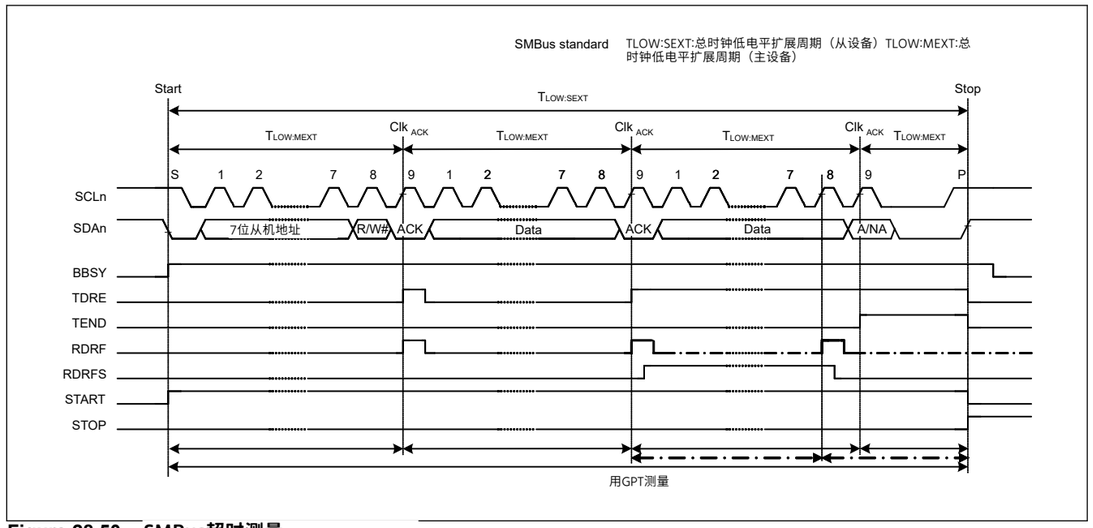

Figure 28.50 SMBus超时测量

28.13.2 数据包错误代码(PEC)

MCU提供了一个CRC计算器，可以传输数据包错误代码(PEC)或检查IIC的SMBus数据通信中接收到的数据。有关CRC计算器的CRC生成多项式，请参阅第32节，循环冗余校验(CRC)。

在主机发送模式下，可以通过将所有发送数据写入CRC计算器中的CRC数据输入寄存器(CRCDIR)来生成PEC数据。

在主机接收模式下，可以通过将所有接收数据写入CRC计算器中的CRCDIR并将CRC数据输出寄存器(CRCDOR)中获得的值与接收到的PEC数据进行比较来检查PEC数据。

当作为PEC代码检查的结果接收到最后一个字节时，要根据匹配或不匹配结果发送ACK或NACK，在接收最后一个字节期间，在第8个SCL时钟周期的上升沿之前将ICMR3中的RDRFS位设置为1字节，并在第8个时钟周期的下降沿保持SCLn线为低电平。

28.13.3 SMBus主机通知协议（通知ARP主机命令）

在通过SMBus进行通信时，从设备可以临时充当主设备来通知SMBus主机（或ARP主机）它自己的从地址，或者从SMBus主机请求它自己的从地址。

对于使用MCU作为SMBus主机或ARP主机的产品，必须将从机发送的主机地址（0001000b）检测为从机地址，因此IIC提供了主机地址检测功能。要将主机地址检测为从机地址，请将ICMR3中的SMBS位和ICSER中的HOAE位设置为1。检测到主机地址后的操作与正常从机操作相同。

28.14 中断源

IIC发出五种类型的中断请求：

- 传输错误或事件发生（仲裁丢失、NACK检测、超时检测、开始条件检测和停止条件检测）
- 接收数据已满
- 传输数据为空
- 发送端
- 唤醒功能期间的地址匹配

表28.10列出了有关中断请求的详细信息。接收数据满和发送数据空中断可以通过DTC或DMAC激活数据传输。

IIC0_WUI*4	Slave address match during wakeup function	WUF	Not possible	Slave address match Slave receive complete RWAK operation ASY0 = 1 WUIE = 1

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and the actual writing to the module. When an interrupt flag is cleared or masked, read the relevant flag again to check whether clearing or masking is complete, then return from interrupt handling. Not doing so creates the possibility of repeated processing of the same interrupt.

Note 1. Because IICn_TXI is edge-detected, it does not require clearing. Additionally, the TDRE flag in ICSR2 (condition for IICn_TXI) is automatically set to 0 when transmit data is written to the ICDRT register or a stop condition is detected (STOP flag = 1 in ICSR2).

Note 2. Because IICn_RXI is edge-detected, it does not require clearing. Additionally, the RDRF flag in ICSR2 (condition for IICn_RXI) is automatically set to 0 when data is read from ICDRR.

Note 3. When using the IICn_TEI interrupt, clear the TEND flag in ICSR2 in the IICn_TEI interrupt handling. The TEND flag in ICSR2 automatically is set to 0 when transmit data is written to the ICDRT register or a stop condition is detected (STOP flag = 1 in ICSR2).

Note 4. Only channel 0 has a wakeup function, so IIC0_WUI is for channel 0 only.

Note 5. Channel number (n = 0).

Clear or mask each flag during interrupt handling.

28.14.1 Buffer Operation for IICn_TXI and IICn_RXI Interrupts

If the conditions for generating an IICn_TXI or IICn_RXI interrupt are satisfied while the associated IR flag is 1, the interrupt request is not output for the ICU but is saved internally. One request per source can be saved internally.

An interrupt request that is saved in the ICU is output when the ICU.IELSRn.IR flag becomes 0. Internally saved interrupt requests are automatically cleared under normal conditions. They can also be cleared by writing 0 to the interrupt enable bit within the associated peripheral module.

28.15 State of Registers When Issuing Each Condition

The IIC has two dedicated resets, IIC reset and Internal reset. Table 28.11 lists the registers states when issuing each condition.

Table 28.11 Register states when issuing each condition (1 of 2)

Note: CPU执行外围模块的写指令与实际写入模块之间存在延迟。当一个中断标志被清除或屏蔽时，再次读取相关标志，检查清除或屏蔽是否完成，然后从中断处理返回。不这样做会产生重复处理同一中断的可能性。

注1.因为IICn_TXI是边沿检测，所以不需要清零。此外，当发送数据写入ICDRT寄存器或检测到停止条件（ICSR2中的STOP标志=1）时，ICSR2中的TDRE标志（IICn_TXI的条件）自动设置为0。

注2.因为IICn_RXI是边沿检测，所以不需要清零。此外，从ICDRR读取数据时，ICSR2中的RDRF标志（IICn_RXI的条件）自动设置为0。

注3.使用IICn_TEI中断时，在IICn_TEI中断处理中清除ICSR2中的TEND标志。当发送数据写入ICDRT寄存器或检测到停止条件（ICSR2中的STOP标志=1）时，ICSR2中的TEND标志自动设置为0。

注4.只有通道0有唤醒功能，所以IIC0_WUI仅适用于通道0。

注5.通道编号(n=0)。

在中断处理期间清除或屏蔽每个标志。

28.14.1 IICn_TXI和IICn_RXI中断的缓冲区操作

如果在相关的IR标志为1时满足产生IICn_TXI或IICn_RXI中断的条件，则中断请求不会输出给ICU，而是在内部保存。每个源的一个请求可以在内部保存。

当ICU.IELSRn.IR标志变为0时，输出ICU中保存的中断请求。在正常情况下，内部保存的中断请求会自动清除。它们也可以通过向相关外围模块中的中断使能位写入0来清除。

28.16 Event Link Output

The IIC0 module handles the event output for the Event Link Controller (ELC) for the following sources:

(1) Transfer error event

When a transfer error event occurs, the associated event signal can be output to another module by the ELC.

(2) Receive data full

When a receive data register becomes full, the associated event signal can be output to another module by the ELC.

(3) Transmit data empty

When a transmit data register becomes empty, the associated event signal can be output to another module by the ELC.

(4) Transmit end

On completion of the transfer, the associated event signal can be output to another module by the ELC.

28.16.1 Interrupt Handling and Event Linking

Each of the IIC interrupt types (see Table 28.10) has an enable bit to control enabling and disabling of the associated interrupt signal. An interrupt request signal is output to the CPU when an interrupt source condition is satisfied while the associated enable bit is set.

(2) 接收数据已满

当接收数据寄存器变满时，ELC可以将相关的事件信号输出到另一个模块。

当发送数据寄存器变为空时，ELC可以将相关的事件信号输出到另一个模块。

(4) 发射端

传输完成后，ELC可以将相关的事件信号输出到另一个模块。

28.16.1 中断处理和事件链接

每种IIC中断类型（见表28.10）都有一个启用位来控制相关中断信号的启用和禁用。当相关的使能位设置时，中断源条件成立时，将向CPU输出中断请求信号。

The associated event link output signals are sent to other modules as event signals by the ELC when the interrupt source conditions are satisfied, regardless of the interrupt enable bit settings. For details on interrupt sources, see Table 28.10.

28.17 Usage Notes

28.17.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable IIC operation. The IIC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

28.17.2 Notes on Starting Transfer

If the IR flag associated with the IIC interrupt is 1 when transfer is started (ICCR1.ICE bit = 1), follow the procedure in this section to clear the interrupts before enabling operations. Starting transfer with the IR flag set to 1 while the ICCR1.ICE bit is 1 leads to an interrupt request being internally saved after transfer starts, and this can lead to unexpected behavior of the IR flag.

To clear interrupts before starting transfer operation:

1. Confirm that the ICCR1.ICE bit is 0.
2. Set the relevant interrupt enable bits, such as ICIER.TIE to 0.
3. Read the relevant interrupt enable bits, such as ICIER.TIE, and confirm that the value is 0.
4. Set the IR flag to 0.

当满足中断源条件时，ELC将关联的事件链接输出信号作为事件信号发送到其他模块，而不管中断使能位设置如何。有关中断源的详细信息，请参见表28.10。

28.17 使用说明

28.17.1 模块停止功能的设置

模块停止控制寄存器B(MSTPCRB)可以启用或禁用IIC操作。IIC在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

28.17.2 开始转移注意事项

如果在传输开始时与IIC中断相关的IR标志为1（ICCR1.ICE位=1），请按照本节中的步骤在使能操作之前清除中断。在ICCR1.ICE位为1时将IR标志设置为1开始传输会导致在传输开始后内部保存中断请求，这可能导致IR标志的意外行为。

在开始传输操作之前清除中断：

1.确认ICCR1.ICE位为0。

2.设置相关的中断使能位，如ICIER.TIE为0。

3、读取相关的中断使能位，如ICIER.TIE，确认值为0。

4.将IR标志设置为0。

Note 2. Set the RBOC bit to 1 in the bus-off state.
Note 3. This bit is automatically set to 0 after being set to 1. It should read as 0.
Note 4. Set the TSRC bit to 1 in CAN operation mode.
Note 5. When the CANM[1:0] and SLPM bits are changed, check STR to ensure that the mode is switched. Do not change the CANM[1:0] bits or SLPM bit until the mode is switched.
Note 6. Write to the SLPM bit in CAN reset mode or CAN halt mode. When changing the SLPM bit, write 0 or 1 only to the SLPM bit.

MBM bit (CAN Mailbox Mode Select)

When the MBM bit is 0 (normal mailbox mode), mailboxes 0 to 31 are configured as transmit or receive mailboxes. When the MBM bit is 1 (FIFO mailbox mode):

- Mailboxes 0 to 23 are configured as transmit or receive mailboxes
- Mailboxes 24 to 27 are configured as transmit FIFO
- Mailboxes 28 to 31 are configured as receive FIFO

Transmit data is written into mailbox 24, a window mailbox for the transmit FIFO. Receive data is read from mailbox 28, a window mailbox for the receive FIFO.

Table 29.3 lists the mailbox configuration.

IDFM[1:0] bits (ID Format Mode Select)

The IDFM[1:0] bits specify the ID format.

MLM bit (Message Lost Mode Select)

The MLM bit specifies the operation when a new message is captured in an unread mailbox. Overwrite mode or overrun mode can be selected. In both cases, the mode applies to all mailboxes, including the receive FIFO.

When the MLM bit is 0, all mailboxes are set to overwrite mode. Any new message received overwrites the pre-existing message.

注1.在CAN复位模式下写入BOM[1:0]、TSPS[1:0]、TPM、MLM、IDFM[1:0]和MBM位。
注2.在总线关闭状态下将RBOC位设置为1。
注3.该位设置为1后自动设置为0，应读为0。
注4.在CAN操作模式下，将TSRC位设置为1。
注5.当CANM[1:0]和SLPM位改变时，检查STR以确保模式切换。在切换模式之前不要更改CANM[1:0]位或SLPM位。

注6.在CAN复位模式或CAN暂停模式下写入SLPM位。更改SLPM位时，仅向SLPM位写入0或1。

MBM位（CAN邮箱模式选择）

当MBM位为0（正常邮箱模式）时，邮箱0到31被配置为发送或接收邮箱。当MBM位为1（FIFO邮箱模式）时：

- 邮箱0到23被配置为发送或接收邮箱
- 邮箱24到27被配置为发送FIFO
- 邮箱28到31配置为接收FIFO

发送数据写入邮箱24，这是发送FIFO的窗口邮箱。接收数据从邮箱28中读取，该邮箱是接收FIFO的窗口邮箱。

表29.3列出了邮箱配置。

IDFM[1:0]位（ID格式模式选择）

IDFM[1:0]位指定ID格式。

MLM位（消息丢失模式选择）

MLM位指定在未读邮箱中捕获新消息时的操作。可以选择覆盖模式或溢出模式。在这两种情况下，该模式都适用于所有邮箱，包括接收FIFO。

当MLM位为0时，所有邮箱都设置为覆盖模式。收到的任何新消息都会覆盖先前存在的消息。

When the MLM bit is 1, all mailboxes are set to overrun mode. Any new message received does not overwrite the preexisting message, and it is discarded.

TPM bit (Transmission Priority Mode Select)

The TPM bit specifies the priority when transmitting messages. ID priority transmit mode or mailbox number transmit mode can be selected. All mailboxes are set for either ID priority transmission or mailbox number priority transmission.

When TPM is 0, ID priority transmit mode is selected and transmission priority is arbitrated as defined in the ISO11898- 1 CAN specification. In ID priority transmit mode, mailboxes 0 to 31 (in normal mailbox mode), and mailboxes 0 to 23 (in FIFO mailbox mode), and the transmit FIFO are compared for the IDs of mailboxes configured for transmission. If two or more mailbox IDs are the same, the mailbox with the smaller number has higher priority.

Only the next message to be transmitted from the transmit FIFO is included in the transmission arbitration. If a FIFO message is being transmitted, the next pending message within the transmit FIFO is included in the transmission arbitration.

When TPM is 1, mailbox number transmit mode is selected and the transmit mailbox with the smallest mailbox number has the highest priority. In FIFO mailbox mode, the transmit FIFO has lower priority than normal mailboxes (0 to 23).

TSRC bit (Time Stamp Counter Reset Command)

The TSRC bit resets the time stamp counter. When it is set to 1, TSR is set to 0x0000. TSRC is set to 0 automatically.

TSPS[1:0] bits (Time Stamp Prescaler Select)

The TSPS[1:0] bits select the prescaler for the time stamp. The reference clock for the time stamp can be selected to 1- bit, 2-bit, 4-bit, or 8-bit time periods.

CANM[1:0] bits (CAN Operating Mode Select)

The CANM[1:0] bits select one of the following modes for the CAN module:

- CAN operation mode
- CAN reset mode
- CAN halt mode

The CAN sleep mode is set in the SLPM bit. For details, see section 29.3. Operation Modes.

When the CAN module enters CAN halt mode based on the BOM[1:0] setting, the CANM[1:0] bits are automatically set to 10b.

SLPM bit (CAN Sleep Mode)

When the SLPM bit is set to 1, the CAN module enters CAN sleep mode. When the SLPM bit is set to 0, the CAN module exits CAN sleep mode. For details, see section 29.3. Operation Modes.

BOM[1:0] bits (Bus-Off Recovery Mode)

The BOM[1:0] bits select bus-off recovery mode for the CAN module.

When the BOM[1:0] bits are 00b, the recovery from bus-off is compliant with the ISO11898-1 CAN specification. The CAN module recovers CAN communication (error-active state) after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request occurs when recovering from bus-off.

When the BOM[1:0] bits are 01b and the CAN module reaches the bus-off state, the CANM[1:0] bits in CTLR are set to 10b to enter CAN halt mode. No bus-off recovery interrupt request occurs when recovering from bus-off, and TECR and RECR are set to 0x00.

When the BOM[1:0] bits are 10b, the CANM[1:0] bits are set to 10b as soon as the CAN module reaches the bus-off state. The CAN module enters CAN halt mode after the recovery from the bus-off state, and after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request occurs when recovering from bus-off, and TECR and RECR are set to 0x00.

When the BOM[1:0] bits are 11b, the CAN module enters CAN halt mode by setting the CANM[1:0] bits to 10b while the CAN module is still in the bus-off state. No bus-off recovery interrupt request occurs when recovering from bus-off, and TECR and RECR are set to 0x00. However, if the CAN module recovers from bus-off after detecting 11 consecutive recessive bits 128 times before the CANM[1:0] bits are set to 10b, a bus-off recovery interrupt request is generated.

当MLM位为1时，所有邮箱都设置为溢出模式。收到的任何新消息都不会覆盖先前存在的消息，并且会被丢弃。

TPM位（传输优先模式选择）

TPM位指定传输消息时的优先级。可选择ID优先传输模式或邮箱号码传输模式。所有信箱都设置为ID优先传输或信箱号码优先传输。

当TPM为0时，选择ID优先传输模式，传输优先级按照ISO118981CAN规范中的定义进行仲裁。在ID优先传输模式下，邮箱0到31（在普通邮箱模式下）和邮箱0到23（在FIFO邮箱模式下）和传输FIFO会针对配置为传输的邮箱ID进行比较。如果两个或多个邮箱ID相同，则编号较小的邮箱优先级较高。

只有从发送FIFO发送的下一条消息包含在发送仲裁中。如果正在发送FIFO消息，则发送FIFO中的下一个待处理消息将包含在发送仲裁中。

当TPM为1时，选择邮箱号发送模式，邮箱号最小的发送邮箱优先级最高。在FIFO邮箱模式下，发送FIFO的优先级低于普通邮箱（0到23）。

TSRC位（时间戳计数器复位命令）

TSRC位复位时间戳计数器。当它设置为1时，TSR设置为0x0000。TSRC自动设置为0。

TSPS[1:0]位（时间戳预分频器选择）

TSPS[1:0]位选择时间戳的预分频器。时间戳的参考时钟可以选择为1位、2位、4位或8位时间段。

CANM[1:0]位（CAN操作模式选择）

CANM[1:0]位为CAN模块选择以下模式之一：

- ●CAN操作模式
- ●CAN复位模式
- ●CAN停机模式

CAN睡眠模式在SLPM位中设置。有关详细信息，请参阅第29.3节。操作模式。

当CAN模块根据BOM[1:0]设置进入CAN暂停模式时，CANM[1:0]位自动设置为10b。

SLPM位（CAN休眠模式）

当SLPM位设置为1时，CAN模块进入CAN睡眠模式。当SLPM位设置为0时，CAN模块退出CAN睡眠模式。有关详细信息，请参阅第29.3节。操作模式。

BOM[1:0]位（总线关闭恢复模式）

BOM[1:0]位选择CAN模块的总线关闭恢复模式。

当BOM[1:0]位为00b时，总线关闭恢复符合ISO11898-1CAN规范。这CAN模块在检测到11个连续隐性位128次后恢复CAN通信（错误激活状态）。从总线关闭中恢复时会出现总线关闭恢复中断请求。

当BOM[1:0]位为01b且CAN模块达到总线关闭状态时，CTLR中的CANM[1:0]位设置为10b以进入CAN停止模式。总线关闭恢复时不产生总线关闭恢复中断请求，TECR和RECR设置为0x00。

当BOM[1:0]位为10b时，CAN模块一到达总线关闭状态，CANM[1:0]位就会设置为10b。CAN模块从总线关闭状态恢复后，并在检测到11个连续的隐性位128次后进入CAN停止模式。从总线关闭恢复时产生总线关闭恢复中断请求，TECR和RECR设置为0x00。

当BOM[1:0]位为11b时，CAN模块通过将CANM[1:0]位设置为10b进入CAN暂停模式，而CAN模块仍处于总线关闭状态。从总线关闭恢复时没有总线关闭恢复中断请求发生，并且TECR和RECR设置为0x00。但是，如果CAN模块在CANM[1:0]位设置为10b之前128次检测到11个连续隐性位后从总线关闭中恢复，则会产生总线关闭恢复中断请求。

If the CPU requests an entry to CAN reset mode at the same time as the CAN module attempts to enter CAN halt mode (at bus-off entry when the BOM[1:0] bits are 01b, or at bus-off end when the BOM[1:0] bits are 10b), then the CPU request has higher priority.

RBOC bit (Forcible Return from Bus-Off)

When the RBOC bit is set to 1 in the bus-off state, the CAN module forcibly exits the bus-off state. It is set to 0 automatically, and the error state changes from bus-off to error-active. When the RBOC bit is set to 1, RECR and TECR are set to 0x00 and the BOST bit in STR is set to 0, indicating that the CAN module is not in bus-off state. The other registers remain unchanged when RBOC is set to 1. No bus-off recovery interrupt request occurs by this recovery from the bus-off state. Use the RBOC bit only when the BOM[1:0] bits are 00b (normal mode).

Table 29.3 Mailbox configuration

Mailbox	MBM bit = 0 (normal mailbox mode)	MBM bit = 1 (FIFO mailbox mode)*1 *2 *3 *4 *5
Mailboxes 0 to 23	Normal mailbox	Normal mailbox
Mailboxes 24 to 27		Transmit FIFO
Mailboxes 28 to 31		Receive FIFO

Note 1. The transmit FIFO is controlled by TFCR. The MCTL_TX[j] registers associated with mailboxes 24 to 27 are disabled. MCTL_TX[24] to MCTL_TX[27] cannot be used by the transmit FIFO.
Note 2. The receive FIFO is controlled by RFCR. The MCTL_RX[j] registers associated with mailboxes 28 to 31 are disabled. MCTL_RX[28] to MCTL_RX[31] cannot be used by the receive FIFO.
Note 3. See the MIER_FIFO description for information on the FIFO interrupts.
Note 4. The bits in MKIVLR associated with mailboxes 24 to 31 are disabled. Set these bits to 0.
Note 5. The transmit and receive FIFOs can be used for both data frames and remote frames.

如果CPU在CAN模块尝试进入CAN暂停模式的同时请求进入CAN复位模式（当BOM[1:0]位为01b时在总线关闭进入，或者当BOM[1:0]位为10b），则CPU请求具有更高的优先级。

RBOC位（从总线关闭强制返回）

当RBOC位在总线关闭状态下设置为1时，CAN模块强制退出总线关闭状态。它自动设置为0，错误状态从总线关闭变为错误激活。当RBOC位设置为1时，RECR和TECR设置为0x00，STR中的BOST位设置为0，表示CAN模块不处于总线关闭状态。当RBOC设置为1时，其他寄存器保持不变。从总线关闭状态恢复不会产生总线关闭恢复中断请求。仅当BOM[1:0]位为00b（正常模式）时才使用RBOC位。

注2.接收FIFO由RFCR控制。与邮箱28到31关联的MCTL_RX[j]寄存器被禁用。MCTL_RX[28]到MCTL_RX[31]不能被接收FIFO使用。

Note: Tq: Time Quantum
Note 1. Do not select a value less than or equal to 1 while the SCKSCR.CKSEL[2:0] bits are 011b (selecting the main clock oscillator).

For details about setting the bit timing, see section 29.4. Data Transfer Rate Configuration. Set BCR before entering CAN halt or CAN operation mode from CAN reset mode. After the setting is made once, this register can be written to in CAN reset or CAN halt mode. A 32-bit read/write accesses must be performed carefully so as not to change bits [7:0].

CCLKS bit (CAN Clock Source Selection)

The CCLKS bit selects CAN clock source. When the CCLKS bit is 0, the peripheral module clock (PCLKB) produced by the PLL frequency synthesizer is used as the CAN clock source (fCAN). When the CCLKS bit is 1, CANMCLK produced externally by the EXTAL pins is used as the CAN clock source (fCAN).

TSEG2[2:0] bits (Time Segment 2 Control)

The TSEG2[2:0] bits specify the length of the phase buffer segment 2 (PHASE_SEG2) with a Tq value. A value from 2 to 8 Tq can be set. Set a value smaller than that in the TSEG1[3:0] bits.

SJW[1:0] bits (Synchronization Jump Width Control)

The SJW[1:0] bits specify the synchronization jump width with a Tq value. A value from 1 to 4 Tq can be set. Set a value smaller than or equal to that in the TSEG2[2:0] bits.

BRP[9:0] bits (Baud Rate Prescaler Select)

The BRP[9:0] bits set the frequency of the CAN communication clock (fCANCLK). The fCANCLK cycle is 1 Tq. If the setting is P (0 to 1023), the baud rate prescaler divides fCAN by P + 1.

TSEG1[3:0] bits (Time Segment 1 Control)

The TSEG1[3:0] bits specify the total length of the propagation time segment (PROP_SEG) and phase buffer segment 1 (PHASE_SEG1) with a time quantum (Tq) value. A value from 4 to 16 Tq can be set.

Note: Tq：时间量子
注1.当SCKSCR.CKSEL[2:0]位为011b（选择主时钟振荡器）时，请勿选择小于或等于1的值。

有关设置位时序的详细信息，请参阅第29.4节。数据传输率配置。在从CAN复位模式进入CAN停止或CAN操作模式之前设置BCR。设置一次后，可在CAN复位或CAN停止模式下写入该寄存器。必须小心执行32位读写访问，以免更改位[7:0]。

CCLKS位（CAN时钟源选择）

CCLKS位选择CAN时钟源。当CCLKS位为0时，PLL频率合成器产生的外设模块时钟（PCLKB）用作CAN时钟源（fCAN）。当CCLKS位为1时，由EXTAL引脚从外部产生的CANMCLK用作CAN时钟源(fCAN)。

TSEG2[2:0]位（时间段2控制）

TSEG2[2:0]位用Tq值指定相位缓冲段2(PHASE_SEG2)的长度。一个从2到8的值可以设置Tq。设置一个小于TSEG1[3:0]位的值。

SJW[1:0]位（同步跳转宽度控制）

SJW[1:0]位用Tq值指定同步跳转宽度。可以设置1到4Tq的值。设置一个小于或等于TSEG2[2:0]位的值。

BRP[9:0]位（波特率预分频器选择）

BRP[9:0]位设置CAN通信时钟(fCANCLK)的频率。fCANCLK周期为1Tq。如果设置为P（0到1023），则波特率预分频器将fCAN除以P+1。

TSEG1[3:0]位（时间段1控制）

TSEG1[3:0]位用时间量(Tq)值指定传播时间段(PROP_SEG)和相位缓冲段1(PHASE_SEG1)的总长度。可以设置4到16Tq的值。

For the mask function in FIFO mailbox mode, see section 29.6. Acceptance Filtering and Masking Functions.

Write to MKR0 to MKR7 in CAN reset mode or CAN halt mode.

EID[17:0] bits (Extended ID)

The EID[17:0] bits are the filter mask bits associated with the CAN extended ID bits. They are used to receive extended ID messages. When an EID[17:0] bit is set to 0, the received ID is not compared with the associated mailbox ID. When an EID[17:0] bit is set to 1, the received ID is compared with the associated mailbox ID.

SID[10:0] bits (Standard ID)

The SID[10:0] bits are the filter mask bits associated with the CAN standard ID bits. They are used to receive both standard ID and extended ID messages. When an SID[10:0] bit is set to 0, the received ID is not compared with the associated mailbox ID. When an SID[10:0] bit is set to 1, the received ID is compared with the associated mailbox ID.

FIDCR0 and FIDCR1 are enabled when the MBM bit in CTLR is set to 1 (FIFO mailbox mode). In this mode, the EID[17:0], SID[10:0], RTR, and IDE bits in mailboxes 28 to 31 are disabled. Write to FIDCR0 and FIDCR1 in CAN reset mode or CAN halt mode. For information on using FIDCR0 and FIDCR1, see section 29.6. Acceptance Filtering and Masking Functions.

EID[17:0] bits (Extended ID of data and remote frames)

SID[10:0] bits (Standard ID of data and remote frames)

The SID[10:0] bits set the standard ID of data frames and remote frames. These bits are used to receive both standard ID and extended ID messages.

RTR bit (Remote Transmission Request)

IDE bit (ID Extension)

The IDE bit sets the ID format to standard ID or extended ID. The IDE bit is enabled when the IDFM[1:0] bits in CTLR are 10b (mixed ID mode):

- When the IDE bits in both FIDCR0 and FIDCR1 registers are set to 0, only standard ID frames are received
- When the IDE bits in both FIDCR0 and FIDCR1 registers are set to 1, only extended ID frames are received
- When the IDE bits in both FIDCR0 and FIDCR1 registers are set to different values, both standard ID and extended ID frames are received

Each bit in MKIVLR is associated with a mailbox of the same number. Bit [0] in MKIVLR corresponds to mailbox 0 (MB0), and bit [31] corresponds to mailbox 31 (MB31).*1

When a bit is set to 1, the associated acceptance mask register becomes invalid for the associated mailbox. When a mask invalid bit is set to 1, a message is received by the associated mailbox only if the receive message ID matches the mailbox ID exactly.

Write to MKIVLR in CAN reset or halt mode.

当CTLR中的MBM位设置为1（FIFO邮箱模式）时，FIDCR0和FIDCR1被使能。在这种模式下，邮箱28到31中的EID[17:0]、SID[10:0]、RTR和IDE位被禁用。在CAN复位模式或CAN暂停模式下写入FIDCR0和FIDCR1。有关使用FIDCR0和FIDCR1的信息，请参阅第29.6节。接受过滤和屏蔽功能。

EID[17:0]位（数据和远程帧的扩展ID）

EID[17:0]位设置数据帧和远程帧的扩展ID。这些位用于接收扩展ID消息。

SID[10:0]位（数据和远程帧的标准ID）

SID[10:0]位设置数据帧和远程帧的标准ID。这些位用于接收标准ID和扩展ID消息。

RTR位（远程传输请求）

RTR位将帧格式设置为数据帧或远程帧：

- ●当FIDCR0和FIDCR1寄存器的RTR位都设置为0时，只接收数据帧
- ●当FIDCR0和FIDCR1寄存器的RTR位都设置为1时，只接收远程帧
- ●当FIDCR0和FIDCR1寄存器的RTR位设置为不同的值时，数据帧和远程帧都被接收

IDE位（ID扩展）

IDE位将ID格式设置为标准ID或扩展ID。当CTLR中的IDFM[1:0]位为10b（混合ID模式）时，IDE位被使能：

- ●当FIDCR0和FIDCR1寄存器中的IDE位都设置为0时，只接收标准ID帧
- ●当FIDCR0和FIDCR1寄存器中的IDE位都设置为1时，只接收扩展ID帧
- ●当FIDCR0和FIDCR1寄存器中的IDE位设置为不同的值时，标准ID和扩展ID帧都被接收

Note 2. The IDE bit is enabled when the CTLR.IDFM[1:0] bits are 10b (mixed ID mode). When the IDFM[1:0] bits are not 10b, only write 0 to IDE. It reads as 0.

EID[17:0] bits (Extended ID of data and remote frames)

The EID[17:0] bits set the extended ID of data frames and remote frames. They are used to transmit or receive extended ID messages.

SID[10:0] bits (Standard ID of data and remote frames)

The SID[10:0] bits set the standard ID of data frames and remote frames. They are used to transmit or receive both standard ID and extended ID messages.

RTR bit (Remote Transmission Request)

The RTR bit sets the frame format of data frames or remote frames.

- The receive mailbox only receives frames with the format specified in the RTR bit
- The transmit mailbox transmits with the frame format specified in the RTR bit
- The receive FIFO mailbox receives the data frame, remote frame, or both frames specified in the RTR bit in FIDCR0 and FIDCR1
- The transmit FIFO mailbox transmits the data frame or remote frame specified in the RTR bit in the transmit message

IDE bit (ID Extension)

The IDE bit sets the ID format to standard IDs or extended IDs. The IDE bit is enabled when the IDFM[1:0] bits in CTLR are 10b (mixed ID mode).

- The receive mailbox only receives the ID format specified in the IDE bit
- The transmit mailbox transmits with the ID format specified in the IDE bit
- The receive FIFO mailbox receives messages with the standard ID and extended ID settings specified in the IDE bit in FIDCR0 and FIDCR1
- The transmit FIFO mailbox transmits messages with the standard ID or extended ID settings specified in the IDE bit in the transmit message

DLC[3:0] bits (Data Length Code)

The DLC[3:0] bits specify the data length to be transmitted in data frames. When a remote frame is used to request data, this field specifies the requested data length.

When a data frame is received, the received data length is stored in this field. When a remote frame is received, this field stores the requested data length.

MIER can enable interrupts for each mailbox independently. This register is available in normal mailbox mode. Do not access this register in FIFO mailbox mode.

Each bit is associated with the mailbox having the same number. These bits enable or disable transmission and reception complete interrupts for the associated mailboxes as follows:

- Bit [0] in MIER corresponds to mailbox 0 (MB0)
- Bit [31] in MIER corresponds to mailbox 31 (MB31)

Write to MIER only when the associated MCTL_TX[j] or MCTL_RX[j] register (j = 0 to 31) is 0x00 and the associated mailbox is not processing a transmission or reception abort request.

31:30	—	The read values are undefined. The write value should be 0.	R/W

Note 1. No interrupt request occurs when the receive FIFO becomes buffer warning because it is full.
Note 2. Buffer warning indicates a state in which the third message is stored in the receive FIFO.

MIER_FIFO can independently enable interrupts for each mailbox and FIFO. This register is available in FIFO mailbox mode. Do not access it in normal mailbox mode.

The MB0 to MB23 bits are associated with the mailbox of the same number. These bits enable or disable transmission and reception complete interrupts for the associated mailboxes:

- Bit [0] in MIER_FIFO is associated with mailbox 0 (MB0)
- Bit [23] in MIER_FIFO is associated with mailbox 23 (MB23)

MB24, MB25, MB28, and MB29 specify whether transmit and receive FIFO interrupts are enabled or disabled, and the timing of interrupt requests.

Write to MIER_FIFO only when the associated MCTL_TX[j] or MCTL_RX[j] register (j = 0 to 31) is 0x00 and the associated mailbox is not processing a transmission or reception abort request. In addition, change the bits in MIER_FIFO for the associated FIFO only when all of the following conditions are true:

- The TFE bit in TFCR is 0 and the TFEST bit is 1.
- The RFE bit in RFCR is 0 and the RFEST bit in RFCR is 1.

29.2.9 MCTL_TX[j] : Message Control Register for Transmit (j = 0 to 31)

注1.当接收FIFO已满而变为缓冲区警告时，不会发生中断请求。
注2.缓冲区警告表示第三条消息存储在接收FIFO中的状态。

MIER_FIFO可以独立启用每个邮箱和FIFO的中断。该寄存器在FIFO邮箱模式下可用。不要在普通邮箱模式下访问它。

MB0到MB23位与相同编号的邮箱相关联。这些位启用或禁用相关邮箱的发送和接收完成中断：

- ●MIER_FIFO中的位[0]与邮箱0(MB0)相关联
- ●MIER_FIFO中的位[23]与邮箱23(MB23)相关联

MB24、MB25、MB28和MB29指定是启用还是禁用发送和接收FIFO中断，以及中断请求的时序。

仅当关联的MCTL_TX[j]或MCTL_RX[j]寄存器（j=0到31）为0x00并且关联的邮箱未处理发送或接收中止请求时才写入MIER_FIFO。此外，仅当以下所有条件都为真时，才更改关联FIFO的MIER_FIFO中的位：

- ●TFCR中的TFE位为0，TFEST位为1。
- ●RFCR中的RFE位为0，RFCR中的RFEST位为1。

7	TRMREQ	Transmit Mailbox Request*2 *4 0: Do not configure for transmission 1: Configure for transmission	R/W

Note 1. Write 0 only. Writing 1 has no effect.
Note 2. When writing to bits of this register, write 1 to SENTDATA and TRMABT flags if these bits are not the write target.
Note 3. To enter one-shot transmit mode, write 1 to the ONESHOT bit at the same time as setting the TRMREQ bit to 1. To exit one-shot transmit mode, write 0 to the ONESHOT bit after the message is transmitted or aborted.
Note 4. Do not set both the RECREQ and TRMREQ bits to 1.
Note 5. When setting the RECREQ bit to 0, set the SENTDATA, TRMACTIVE, and TRMABT flags to 0 simultaneously.

MCTL_TX[j] sets mailbox j to transmit mode or receive mode. In transmit mode, MCTL_TX[j] also controls and indicates the transmission status. Do not access MCTL_TX[j] if mailbox j is in receive mode. Only write to MCTL_TX[j] in CAN operation or halt mode. Do not use MCTL_TX24 to MCTL_TX31 in FIFO mailbox mode.

SENTDATA flag (Transmission Complete Flag)

The SENTDATA flag is set to 1 when data transmission from the associated mailbox is complete. This flag is set to 0 through a software write. To set this flag to 0, first set the TRMREQ bit to 0. The SENTDATA flag and the TRMREQ bit cannot be set to 0 simultaneously. To transmit a new message from the associated mailbox, set the SENTDATA flag to 0.

TRMACTIVE flag (Transmission-in-Progress Status Flag)

The TRMACTIVE flag is set to 1 when the associated mailbox of the CAN module begins to transmit a message. It is set to 0 when the CAN module loses the CAN bus arbitration, when a CAN bus error occurs, or when data transmission completes.

TRMABT flag (Transmission Abort Complete Flag)

The TRMABT flag is set to 1 in the following cases:

- Following a transmission abort request, when the transmission abort is complete before starting transmission
- Following a transmission abort request, when the CAN module detects CAN bus arbitration-lost or a CAN bus error
- In one-shot transmission mode (RECREQ = 0, TRMREQ = 1, and ONESHOT = 1), when the CAN module detects a CAN bus arbitration-lost or a CAN bus error.

The TRMABT flag is not set to 1 when data transmission is complete. The SENTDATA flag is set to 1, and the TRMABT flag is set to 0 through a software write.

ONESHOT bit (One-Shot Enable)

When the ONESHOT bit is set to 1 in transmit mode (RECREQ = 0 and TRMREQ = 1), the CAN module transmits a message only one time. The CAN module does not transmit the message again if a CAN bus error or CAN bus arbitration-lost occurs. When transmission is complete, the SENTDATA flag is set to 1. If transmission does not complete because of a CAN bus error or CAN bus arbitration-lost error, the TRMABT flag is set to 1. Set the ONESHOT bit to 0 after the SENTDATA or TRMABT flag is set to 1.

RECREQ bit (Receive Mailbox Request)

The RECREQ bit selects the receive modes listed in Table 29.10.

Bit	Symbol	Function	R/W
2	TRMABT	传输中止完成标志*1*2 0：传输开始，传输中止失败，因为传输完成，或者没有请求传输中止 1：传输中止完成	R/W
3	—	该位读取为0。写入值应为0。	R/W
4	ONESHOT	One-Shot Enable*2 *3 0：禁止一次性发送1：允许一次性发送	R/W
5	—	该位读取为0。写入值应为0。	R/W
6	RECREQ	接收邮箱请求*2*3*4*5 0：不配置接收1：配置接收	R/W
7	TRMREQ	发送邮箱请求*2*4 0：不配置传输1：配置传输	R/W

注1.只写0。写1无效。
注2.当写入该寄存器的位时，如果这些位不是写入目标，则将1写入SENTDATA和TRMABT标志。
注3.要进入一次性发送模式，请在将TRMREQ位设置为1的同时向ONESHOT位写入1。要退出一次性发送模式，请在发送或中止消息后向ONESHOT位写入0.
注4.不要将RECREQ和TRMREQ位都设置为1。
注5.将RECREQ位设置为0时，同时将SENTDATA、TRMACTIVE和TRMABT标志设置为0。

MCTL_TX[j]将邮箱j设置为发送模式或接收模式。在传输模式下，MCTL_TX[j]也控制和指示传输状态。如果邮箱j处于接收模式，则不要访问MCTL_TX[j]。仅在CAN操作或暂停模式下写入MCTL_TX[j]。不要在FIFO邮箱模式下使用MCTL_TX24到MCTL_TX31。

SENTDATA标志（传输完成标志）

当来自相关邮箱的数据传输完成时，SENTDATA标志设置为1。该标志通过软件写入设置为0。要将此标志设置为0，首先将TRMREQ位设置为0。SENTDATA标志和TRMREQ位不能同时设置为0。要从关联邮箱发送新消息，请将SENTDATA标志设置为0。

TRMACTIVE标志（传输中状态标志）

当CAN模块的相关邮箱开始发送消息时，TRMACTIVE标志设置为1。当CAN模块失去CAN总线仲裁、发生CAN总线错误或数据传输完成时，它设置为0。

TRMABT标志（传输中止完成标志）

在以下情况下，TRMABT标志设置为1：

●在发送中止请求之后，在开始发送前完成发送中止时

●在发送中止请求后，CAN模块检测到CAN总线仲裁丢失或CAN总线错误

●单次传输模式（RECREQ=0，TRMREQ=1，ONESHOT=1），当CAN模块检测到CAN总线仲裁失败或CAN总线错误时。

当数据传输完成时，TRMABT标志不设置为1。SENTDATA标志设置为1，TRMABT标志通过软件写入设置为0。

ONESHOT bit (One-Shot Enable)

在发送模式下（RECREQ=0且TRMREQ=1）将ONESHOT位设置为1时，CAN模块仅发送一次报文。如果发生CAN总线错误或CAN总线仲裁丢失，CAN模块不会再次发送消息。当传输完成时，SENTDATA标志设置为1。如果由于CAN总线错误或CAN总线仲裁丢失错误导致传输未完成，则TRMABT标志设置为1。在发送后将ONESHOT位设置为0

SENTDATA或TRMABT标志设置为1。

RECREQ位（接收邮箱请求）

RECREQ位选择表29.10中列出的接收模式。

When the RECREQ bit is set to 1, the associated mailbox is configured for reception of a data or remote frame.

When the RECREQ bit is set to 0, the associated mailbox is not configured for reception of a data or remote frame.

Due to hardware protection, the RECREQ bit cannot be set to 0 through a software write during the following period:

- Hardware protection is started from the acceptance filter processing (the beginning of the CRC field)
- Hardware protection is released:
  - For the mailbox that is specified to receive the incoming message, after the received data is stored in the mailbox or a CAN bus error occurs. This means that the maximum period of hardware protection is from the beginning of CRC field to the end of the 7th bit of EOF.
  - For the other mailboxes, after acceptance filter processing
  - If no mailbox is specified to receive the message, after acceptance filter processing.

When setting the RECREQ bit to 1, do not set the TRMREQ bit to 1. To change the configuration of a mailbox from transmission to reception, first abort the transmission, then set the SENTDATA and TRMABT flags to 0 before changing to reception.

Note: MCTL_TX[j].RECREQ is the mirror bit of MCTL_RX[j].RECREQ.

TRMREQ bit (Transmit Mailbox Request)

The TRMREQ bit selects the transmit modes listed in Table 29.10.

When the TRMREQ bit is set to 1, the associated mailbox is configured for transmission of a data or remote frame.

When the TRMREQ bit is set to 0, the associated mailbox is not configured for transmission of a data or remote frame.

If the TRMREQ bit is changed from 1 to 0 to cancel the associated transmission request, either the TRMABT or SENTDATA flag is set to 1. When setting the TRMREQ bit to 1, do not set the RECREQ bit to 1. To change the configuration of a mailbox from reception to transmission, first abort the reception, then set the NEWDATA and MSGLOST flags to 0 before changing to transmission.

Note: MCTL_TX[j].TRMREQ is the mirror bit of MCTL_RX[j].TRMREQ.

29.2.10 MCTL_RX[j] : Message Control Register for Receive (j = 0 to 31)

3	—	This bit is read as 0. The write value should be 0.	R/W
4	ONESHOT	One-Shot Enable*2 *3 0: Disable one-shot reception 1: Enable one-shot reception	R/W

当RECREQ位设置为1时，相关邮箱配置为接收数据或远程帧。

当RECREQ位设置为0时，相关邮箱未配置为接收数据或远程帧。

由于硬件保护，RECREQ位在以下期间不能通过软件写入设置为0：

●硬件保护从验收过滤处理开始（CRC字段的开始）

●硬件保护解除：

对于指定接收传入消息的邮箱，在接收到的数据存储在邮箱中或发生CAN总线错误后。这意味着硬件保护的最大周期是从CRC字段的开始到EOF的第7位结束。

对于其他邮箱，接受过滤处理后

如果没有指定邮箱接收消息，则在接受过滤处理之后。

将RECREQ位设置为1时，不要将TRMREQ位设置为1。要将邮箱配置从发送更改为接收，首先中止发送，然后在更改为接收之前将SENTDATA和TRMABT标志设置为0。

Note: MCTL_TX[j].RECREQ是MCTL_RX[j].RECREQ的镜像位。

TRMREQ位（发送邮箱请求）

TRMREQ位选择表29.10中列出的发送模式。

当TRMREQ位设置为1时，相关邮箱配置为传输数据或远程帧。

当TRMREQ位设置为0时，相关邮箱未配置为传输数据或远程帧。

如果TRMREQ位从1更改为0以取消相关的发送请求，则TRMABT或SENTDATA标志设置为1。将TRMREQ位设置为1时，不要将RECREQ位设置为1。要更改邮箱从接收到发送，首先中止接收，然后将NEWDATA和MSGLOST标志设置为0，然后再更改为发送。

Note: MCTL_TX[j].TRMREQ是MCTL_RX[j].TRMREQ的镜像位。

29.2.10 MCTL_RX[j]:接收消息控制寄存器(j=0to31)

Base address: CAN0 = 0x400A_8000

Offset address: 0x820 + 0x01 × j

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TRMREQ	RECREQ	—	热门	—	MSGLOST	INVALDATA	NEWDATA
重置后的值：	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	NEWDATA	接收完成标志*1*2 0：未接收到数据，或标志位已写入01：新消息正在存储或已存储在邮箱中	R/W
1	INVALDATA	接收中状态标志 0：消息有效1：消息正在更新	R
2	MSGLOST	消息丢失标志*1*2 0：信息未被覆盖或溢出1：信息被覆盖或溢出	R/W
3	—	该位读取为0。写入值应为0。	R/W
4	ONESHOT	One-Shot Enable*2 *3 0：关闭一键接收1：打开一键接收	R/W

Bit	Symbol	Function	R/W

6	RECREQ	Receive Mailbox Request*2 *3 *4 *5 0: Do not configure for reception 1: Configure for reception	R/W
7	TRMREQ	Transmit Mailbox Request*2 *4 0: Do not configure for transmission 1: Configure for transmission	R/W

Note 1. Write 0 only. Writing 1 has no effect.
Note 2. When writing to bits of this register, write 1 to the NEWDATA and MSGLOST flags if they are not the write target.
Note 3. To enter one-shot receive mode, write 1 to the ONESHOT bit at the same time as setting the RECREQ bit to 1. To exit one-shot receive mode, write 0 to the ONESHOT bit after writing 0 to the RECREQ bit and confirming that it is 0.
Note 4. Do not set both the RECREQ and TRMREQ bits to 1.
Note 5. When setting the RECREQ bit to 0, set MSGLOST, NEWDATA, and RECREQ to 0 simultaneously.

MCTL_RX[j] sets mailbox j to transmit or receive mode. In receive mode, MCTL_RX[j] also controls and indicates the reception status. Do not access MCTL_RX[j] if mailbox j is in transmit mode. Only write to the MCTL_RX[j] in CAN operation or halt mode. Do not use MCTL_RX24 to MCTL_RX31 in FIFO mailbox mode.

NEWDATA flag (Reception Complete Flag)

The NEWDATA flag is set to 1 when a new message is being stored or was stored in the mailbox. Always set this bit to 1 simultaneously with the INVALDATA flag. The NEWDATA flag is set to 0 through a software write. The NEWDATA flag cannot be set to 0 through a software write while the associated INVALDATA flag is 1.

INVALDATA flag (Reception-in-Progress Status Flag)

After the completion of a message reception, the INVALDATA flag is set to 1 while the received message is updated in the associated mailbox. The INVALDATA flag is set to 0 immediately after the message is stored. If the mailbox is read while the INVALDATA flag is 1, the data is undefined.

MSGLOST flag (Message Lost Flag)

The MSGLOST flag is set to 1 when the mailbox is overwritten or overrun by a new received message while the NEWDATA flag is 1. The MSGLOST flag is set to 1 at the end of the 6th bit of EOF. The MSGLOST flag is set to 0 through a software write.

In both overwrite and overrun modes, the MSGLOST flag cannot be set to 0 through a software write during the 5 PCLKB cycles following the 6th bit of EOF.

ONESHOT bit (One-Shot Enable)

When the ONESHOT bit is set to 1 in receive mode (RECREQ = 1 and TRMREQ = 0), the mailbox receives a message only one time. The mailbox does not behave as a receive mailbox after having received a message one time. The behavior of the NEWDATA and INVALDATA flags is the same as in normal receive mode. In one-shot receive mode, the MSGLOST flag is not set to 1. To set the ONESHOT bit to 0, first write 0 to the RECREQ bit and ensure that it is 0.

RECREQ bit (Receive Mailbox Request)

The RECREQ bit selects receive modes listed in Table 29.10.

When the RECREQ bit is set to 1, the associated mailbox is configured for reception of a data or remote frame.

When the RECREQ bit is set to 0, the associated mailbox is not configured for reception of a data or remote frame.

Due to hardware protection, the RECREQ bit cannot be set to 0 through a software write during the following period:

- Hardware protection is started from the acceptance filter processing (the beginning of the CRC field)
- Hardware protection is released:
  - For the mailbox that is specified to receive the incoming message, after the received data is stored in the mailbox or a CAN bus error occurs. This means that the maximum period of hardware protection is from the beginning of the CRC field to the end of the 7th bit of EOF.
  - For the other mailboxes, after acceptance filter processing
  - If no mailbox is specified to receive the message, after acceptance filter processing.

5	—	该位读取为0。写入值应为0。	R/W
6	RECREQ	接收邮箱请求*2*3*4*5 0：不配置接收1：配置接收	R/W
7	TRMREQ	发送邮箱请求*2*4 0：不配置传输1：配置传输	R/W

注1.只写0。写1无效。
注2.当写入该寄存器的位时，如果NEWDATA和MSGLOST标志不是写入目标，则向它们写入1。
注3.要进入一次性接收模式，请在将RECREQ位设置为1的同时向ONESHOT位写入1。要退出一次性接收模式，请在向RECREQ位写入0后向ONESHOT位写入0并确认它是0。
注4.不要将RECREQ和TRMREQ位都设置为1。
注5.将RECREQ位设置为0时，同时将MSGLOST、NEWDATA和RECREQ设置为0。

MCTL_RX[j]将邮箱j设置为发送或接收模式。在接收模式下，MCTL_RX[j]也控制和指示接收状态。如果邮箱j处于发送模式，则不要访问MCTL_RX[j]。仅在CAN操作或暂停模式下写入MCTL_RX[j]。不要在FIFO邮箱模式下使用MCTL_RX24到MCTL_RX31。

NEWDATA标志（接收完成标志）

当新消息正在存储或已存储在邮箱中时，NEWDATA标志设置为1。始终将此位与INVALDATA标志同时设置为1。NEWDATA标志通过软件写入设置为0。当相关的INVALDATA标志为1时，不能通过软件写入将NEWDATA标志设置为0。

INVALDATA标志（接收进行中状态标志）

消息接收完成后，INVALDATA标志设置为1，同时在相关邮箱中更新接收到的消息。INVALDATA标志在消息存储后立即设置为0。如果在INVALDATA标志为1时读取邮箱，则数据未定义。

MSGLOST标志（消息丢失标志）

当邮箱被新收到的消息覆盖或溢出时，MSGLOST标志设置为1，而
NEWDATA标志为1。MSGLOST标志在EOF的第6位末尾设置为1。MSGLOST标志通过软件写入设置为0。

在覆盖和溢出模式下，MSGLOST标志不能在EOF第6位之后的5个PCLKB周期内通过软件写入设置为0。

ONESHOT bit (One-Shot Enable)

在接收模式下（RECREQ=1和TRMREQ=0）将ONESHOT位设置为1时，邮箱只接收一次消息。邮箱在收到一次消息后不再充当接收邮箱。NEWDATA和INVALDATA标志的行为与正常接收模式相同。在单次接收模式下，MSGLOST标志不设置为1。要将ONESHOT位设置为0，首先将0写入RECREQ位并确保其为0。

RECREQ位（接收邮箱请求）

RECREQ位选择表29.10中列出的接收模式。

当RECREQ位设置为1时，相关邮箱配置为接收数据或远程帧。

当RECREQ位设置为0时，相关邮箱未配置为接收数据或远程帧。

由于硬件保护，RECREQ位在以下期间不能通过软件写入设置为0：

●硬件保护从验收过滤处理开始（CRC字段的开始）

●硬件保护解除：

对于指定接收传入消息的邮箱，在接收到的数据存储在邮箱中或发生CAN总线错误后。这意味着硬件保护的最大周期是从CRC字段的开始到EOF的第7位结束。

对于其他邮箱，接受过滤处理后

如果没有指定邮箱接收消息，则在接受过滤处理之后。

When setting the RECREQ bit to 1, do not set the TRMREQ bit to 1. To change the configuration of a mailbox from transmission to reception, first abort the transmission, then set the SENTDATA and TRMABT flags to 0 before changing to reception.

Note: MCTL_RX[j].RECREQ is the mirror bit of MCTL_TX[j].RECREQ.

TRMREQ bit (Transmit Mailbox Request)

The TRMREQ bit selects the transmit modes listed in Table 29.10.

When the TRMREQ bit is set to 1, the associated mailbox is configured for transmission of a data or remote frame.

When the TRMREQ bit is set to 0, the associated mailbox is not configured for transmission of a data or remote frame.

If the TRMREQ bit is changed from 1 to 0 to cancel the associated transmission request, either the TRMABT or SENTDATA flag is set to 1. When setting the TRMREQ bit to 1, do not set the RECREQ bit to 1. To change the configuration of a mailbox from reception to transmission, first abort the reception, then set the NEWDATA and MSGLOST flags to 0 before changing to transmission.

Note: MCTL_RX[j].TRMREQ is the mirror bit of MCTL_TX[j].TRMREQ.

7	RFEST	Receive FIFO Empty Status Flag 0: Unread message in receive FIFO 1: No unread message in receive FIFO	R

Write to RFCR in CAN operation or halt mode.

RFE bit (Receive FIFO Enable)

When the RFE bit is set to 1, the receive FIFO is enabled.

将RECREQ位设置为1时，不要将TRMREQ位设置为1。要将邮箱配置从发送更改为接收，首先中止发送，然后在更改为接收之前将SENTDATA和TRMABT标志设置为0。

Note: MCTL_RX[j].RECREQ是MCTL_TX[j].RECREQ的镜像位。

TRMREQ位（发送邮箱请求）

TRMREQ位选择表29.10中列出的发送模式。

当TRMREQ位设置为1时，相关邮箱配置为传输数据或远程帧。

当TRMREQ位设置为0时，相关邮箱未配置为传输数据或远程帧。

如果TRMREQ位从1更改为0以取消相关的发送请求，则TRMABT或SENTDATA标志设置为1。将TRMREQ位设置为1时，不要将RECREQ位设置为1。要更改邮箱从接收到发送，首先中止接收，然后将NEWDATA和MSGLOST标志设置为0，然后再更改为发送。

Note: MCTL_RX[j].TRMREQ是MCTL_TX[j].TRMREQ的镜像位。

29.2.11 RFCR：接收FIFO控制寄存器

Base address: CAN0 = 0x400A_8000

7	RFEST	接收FIFO空状态标志 0：接收FIFO中有未读报文1：接收FIFO中没有未读报文	R

在CAN操作或暂停模式下写入RFCR。

RFE bit (Receive FIFO Enable)

当RFE位设置为1时，启用接收FIFO。

When the RFE bit is set to 0, the receive FIFO is disabled for reception and becomes empty (RFEST bit = 1). Write 0 to the RFE bit simultaneously with the RFMLF flag setting.

Do not set this bit to 1 in normal mailbox mode (MBM bit in CTLR = 0). Due to hardware protection, the RFE bit cannot be set to 0 through a software write during the following period:

- Hardware protection is started from acceptance filter processing (the beginning of the CRC field)
- When hardware protection is released:
  - If the receive FIFO is specified to receive the incoming message, after the received data is stored in the receive FIFO or a CAN bus error occurs. This means that the maximum period of hardware protection is from the beginning of the CRC field to the end of the 7th bit of EOF.
  - If the receive FIFO is not specified to receive the message, after acceptance filter processing.

RFUST[2:0] bits (Receive FIFO Unread Message Number Status)

The RFUST[2:0] bits indicate the number of unread messages in the receive FIFO. The value of the RFUST[2:0] bits are initialized to 000b when the RFE bit is set to 0.

RFMLF flag (Receive FIFO Message Lost Flag)

The RFMLF flag is set to 1 (receive FIFO message lost) when the receive FIFO receives a new message and is full. It is set to 1 at the end of the 6th bit of EOF.

The RFMLF flag is set to 0 through a software write. Writing 1 has no effect. In both overwrite and overrun modes, if the receive FIFO is full and determined to have received a message, the RFMLF flag cannot be set to 0 (no receive FIFO message lost) through a software write during the 5 PCLKB cycles following the 6th bit of EOF.

RFFST flag (Receive FIFO Full Status Flag)

The RFFST flag is set to 1 (receive FIFO is full) when the number of unread messages in the receive FIFO is 4. The flag is 0 (receive FIFO is not full) when the number of unread messages in the receive FIFO is less than 4. The flag is set to 0 when the RFE bit is 0.

RFWST flag (Receive FIFO Buffer Warning Status Flag)

The RFWST flag is set to 1 (receive FIFO is a buffer warning) when the number of unread messages in the receive FIFO is 3. The flag is 0 (receive FIFO is not a buffer warning) when the number of unread messages in the receive FIFO is less than 3 or equal to 4. The RFWST flag is set to 0 when the RFE bit is 0.

RFEST flag (Receive FIFO Empty Status Flag)

The RFEST flag is set to 1 (no unread message in receive FIFO) when the number of unread messages in the receive FIFO is 0. The flag is set to 1 when the RFE bit is set to 0. The flag is set to 0 (unread message in receive FIFO) when the number of unread messages in the receive FIFO is one or more.

Figure 29.2 shows the receive FIFO mailbox operation.

当RFE位设置为0时，接收FIFO禁止接收并变为空（RFEST位=1）。将0写入RFE位与RFMLF标志设置同时进行。

在正常邮箱模式下不要将此位设置为1（CTLR中的MBM位=0）。由于硬件保护，RFE位在以下期间不能通过软件写入设置为0：

●硬件保护从验收过滤处理开始（CRC字段的开始）

●硬件保护解除时：

如果指定接收FIFO接收传入报文，则在接收到的数据存储在接收FIFO中或发生CAN总线错误后。这意味着硬件保护的最大周期是从CRC字段的开始到EOF的第7位结束。

如果接收FIFO未指定接收报文，则在接受过滤处理之后。

RFUST[2:0]位（接收FIFO未读消息编号状态）

RFUST[2:0]位指示接收FIFO中未读消息的数量。当RFE位设置为0时，RFUST[2:0]位的值被初始化为000b。

RFMLF标志（接收FIFO消息丢失标志）

当接收FIFO接收到新消息并已满时，RFMLF标志设置为1（接收FIFO消息丢失）。它在EOF的第6位末尾设置为1。

RFMLF标志通过软件写入设置为0。写1无效。在覆盖和溢出模式下，如果接收FIFO已满并确定已接收到消息，则RFMLF标志不能在第6位之后的5个PCLKB周期内通过软件写入设置为0（没有接收FIFO消息丢失）EOF。

RFFST标志（接收FIFO满状态标志）

当接收FIFO中未读消息数为4时，RFFST标志设置为1（接收FIFO已满）。当接收FIFO中未读消息数小于4.当RFE位为0时，标志设置为0。

RFWST标志（接收FIFO缓冲区警告状态标志）

当接收FIFO中的未读报文数为3时，RFWST标志设置为1（接收FIFO为缓冲区警告）。当接收中未读报文数为0时，该标志为0（接收FIFO不是缓冲区警告）FIFO小于3或等于4。当RFE位为0时，RFWST标志设置为0。

RFEST标志（接收FIFO空状态标志）

当接收FIFO中的未读报文数为0时，RFEST标志设置为1（接收FIFO中没有未读报文）。当RFE位设置为0时，该标志设置为1。该标志设置为0（接收FIFO中的未读消息）当接收FIFO中的未读消息数为1或多个时。

When the receive FIFO is not empty, write 0xFF to RFPCR through software to increment the CPU pointer to the next mailbox location. Do not write to RFPCR when the RFE bit in RFCR is 0 (receive FIFO disabled).

Both the CAN and CPU pointers are incremented when a new message is received and the RFFST flag is 1 (receive FIFO is full) in overwrite mode. When the RFMLF flag is 1 in this condition, the CPU pointer does not increment on a software write to RFPCR.

Write to TFCR in CAN operation or halt mode.

TFE bit (Transmit FIFO Enable)

Setting the TFE bit set to 1 enables the transmit FIFO. Setting the TFE bit to 0 empties the transmit FIFO (TFEST bit = 1), and unsent messages in the transmit FIFO are lost in the following ways:

- Immediately if a message from the transmit FIFO is not scheduled for the next transmission or is already in transmission
- On completion of transmission, on a CAN bus error, CAN bus arbitration-lost, or entry to CAN halt mode, if a message from the transmit FIFO is scheduled for the next transmission or is already in transmission.

Before setting the TFE bit to 1 again, ensure that the TFEST bit is set to 1. After setting the TFE bit to 1, write transmit data to mailbox 24.

Do not set the TFE bit to 1 in normal mailbox mode (MBM bit in CTLR = 0).

TFUST[2:0] bits (Transmit FIFO Unsent Message Number Status)

The TFUST[2:0] bits indicate the number of unsent messages in the transmit FIFO. These bits are set to 000b after the TFE bit is set to 0 and transmission is aborted or completes.

TFFST bit (Transmit FIFO Full Status)

The TFFST bit is set to 1 (transmit FIFO is full) when the number of unsent messages in the transmit FIFO is 4. The TFFST bit is set to 0 (transmit FIFO is not full) when the number of unsent messages in the transmit FIFO is less than 4. The TFFST bit is set to 0 when transmission from the transmit FIFO is aborted.

在CAN操作或暂停模式下写入TFCR。

TFE bit (Transmit FIFO Enable)

将TFE位设置为1会启用发送FIFO。将TFE位设置为0会清空发送FIFO（TFEST位=1），发送FIFO中未发送的消息会通过以下方式丢失：

●如果来自发送FIFO的消息未安排下一次发送或已在发送中，则立即发送

●在传输完成、CAN总线错误、CAN总线仲裁丢失或进入CAN暂停模式时，如果来自传输FIFO的消息被安排用于下一次传输或已经在传输中。

在再次将TFE位设置为1之前，请确保将TFEST位设置为1。将TFE位设置为1后，将发送数据写入邮箱24。

不要在正常邮箱模式下将TFE位设置为1（CTLR中的MBM位=0）。

TFUST[2:0]位（发送FIFO未发送消息编号状态）

TFUST[2:0]位指示发送FIFO中未发送消息的数量。在TFE位设置为0并且传输被中止或完成后，这些位设置为000b。

TFFST位（发送FIFO满状态）

当发送FIFO中未发送消息的数量为4时，TFFST位设置为1（发送FIFO已满）。当发送FIFO中的未发送消息数为4时，TFFST位设置为0（发送FIFO未满）小于4。当来自发送FIFO的发送被中止时，TFFST位设置为0。

TFEST bit (Transmit FIFO Empty Status)

The TFEST bit is set to 1 (no message in transmit FIFO) when the number of unsent messages in the transmit FIFO is 0. The TFEST bit is set to 1 when transmission from the transmit FIFO is aborted. The TFEST bit is set to 0 (message in transmit FIFO) when the number of unsent messages in the transmit FIFO is not 0.

Bit	Symbol	Function	R/W
7	SEST	Search Result Status 0: Search result found 1: No search result	R

MBNST[4:0] bits (Search Result Mailbox Number Status)

In all mailbox search modes, the MBNST[4:0] bits output the smallest found mailbox number. In receive mailbox search mode, transmit mailbox search mode, and message lost search mode, the value of the mailbox (the search result to be output) is updated under the following conditions:

- When the associated NEWDATA, SENTDATA, or MSGLOST flag is set to 0 for a mailbox output by MBNST[4:0]
- When the associated NEWDATA, SENTDATA, or MSGLOST flag is set to 1 for a mailbox with a smaller number than that in MBNST[4:0]

If the MBSM[1:0] bits are set to 00b (receive mailbox search mode) or 10b (message lost search mode), the receive FIFO (mailbox 28) is output when it is not empty and there are no unread received messages and no lost messages in any of the normal mailboxes 0 to 23. If the MBSM[1:0] bits are set to 01b (transmit mailbox search mode), the transmit FIFO (mailbox 24) is not output. Table 29.6 lists the behavior of the MBNST[4:0] bits in FIFO mailbox mode.

In channel search mode, the MBNST[4:0] bits output the associated channel number. After MSSR is read by software, the next target channel number is output.

SEST bit (Search Result Status)

The SEST bit is set to 1 (no search result) when no associated mailbox is found after searching all mailboxes. For example, in transmit mailbox search mode, the SEST bit is set to 1 when no SENTDATA flag is 1 for any mailbox. The SEST bit is set to 0 when at least one SENTDATA flag is 1. When the SEST bit is 1, the value of the MBNST[4:0] bits is undefined.

Table 29.6 Behavior of MBNST[4:0] bits in FIFO mailbox mode

MBSM[1:0] bits	Mailbox 24 (transmit FIFO)	Mailbox 28 (receive FIFO)
00b	Mailbox 24 is not output.	Mailbox 28 is output when no MCTL_RX[j].NEWDATA flag for the normal mailboxes is set to 1 (new message is being stored or was stored in the mailbox) and the receive FIFO is not empty.
01b		Mailbox 28 is not output.
10b		Mailbox 28 is output when no MCTL_RX[j].MSGLOST flag for the normal mailboxes is set to 1 (message is overwritten or overrun) and the RFCR.RFMLF flag is set to 1 (receive FIFO message lost) in the receive FIFO.
11b		Mailbox 28 is not output.

7:0	n/a	When the value for the channel search is input, the channel number is output to MSSR.	R/W

The bits that are set to 1 in CSSR, are encoded by an 8/3 encoder (the LSB position has the higher priority) and output to the MBNST[4:0] bits in MSSR. MSSR outputs the updated value whenever it is read by software.

Write to CSSR only when the MSMR.MBSM[1:0] bits are 11b (channel search mode). Write to CSSR in CAN operation mode or CAN halt mode.

Figure 29.4 shows the write and read operations of the CSSR and MSSR registers.

Bit	Symbol	Function	R/W
7	SEST	搜索结果状态 0：找到搜索结果1：没有搜索结果	R

MBNST[4:0]位（搜索结果邮箱号码状态）

在所有邮箱搜索模式中，MBNST[4:0]位输出找到的最小邮箱号。在接收邮箱搜索模式、发送邮箱搜索模式和消息丢失搜索模式下，邮箱的值（要输出的搜索结果）在以下条件下更新：

- 当MBNST[4:0]为邮箱输出的相关NEWDATA、SENTDATA或MSGLOST标志设置为0时
- 当邮箱的相关NEWDATA、SENTDATA或MSGLOST标志设置为1时，邮箱的编号小于MBNST[4:0]中的编号

如果MBSM[1:0]位设置为00b（接收邮箱搜索模式）或10b（邮件丢失搜索模式），则在接收FIFO（邮箱28）不为空且没有未读接收到的消息时输出在任何正常邮箱0到23中都没有丢失消息。如果MBSM[1:0]位设置为01b（发送邮箱搜索模式），则不输出发送FIFO（邮箱24）。表29.6列出了MBNST[4:0]位在FIFO邮箱模式下的行为。

在频道搜索模式下，MBNST[4:0]位输出相关的频道号。软件读取MSSR后，输出下一个目标通道号。

SEST位（搜索结果状态）

当搜索所有邮箱后未找到相关邮箱时，SEST位设置为1（无搜索结果）。例如，在发送邮箱搜索模式中，当没有任何邮箱的SENTDATA标志为1时，SEST位设置为1。当至少一个SENTDATA标志为1时，SEST位设置为0。当SEST位为1时，MBNST[4:0]位的值未定义。

Table 29.6 FIFO邮箱模式下MBNST[4:0]位的行为

MBSM[1:0] bits	Mailbox 24 (transmit FIFO)	Mailbox 28 (receive FIFO)
00b	邮箱24不输出。	当正常邮箱的MCTL_RX[j].NEWDATA标志未设置为1（新消息正在存储或已存储在邮箱中）且接收FIFO不为空时，输出邮箱28。
01b		邮箱28不输出。
10b		当正常邮箱的MCTL_RX[j].MSGLOST标志未设置为1（消息被覆盖或溢出）且接收FIFO中的RFCR.RFMLF标志设置为1（接收FIFO消息丢失）时，输出邮箱28。
11b		邮箱28不输出。

CSSR中设置为1的位由83编码器（LSB位置具有较高优先级）编码并输出到MSSR中的MBNST[4:0]位。每当软件读取时，MSSR就会输出更新的值。

仅当MSMR.MBSM[1:0]位为11b（通道搜索模式）时才写入CSSR。在CAN操作模式或CAN暂停模式下写入CSSR。

图29.4显示了CSSR和MSSR寄存器的写和读操作。

15:0	n/a	After the standard ID of a received message is written, the value converted for data table search can be read.	R/W

Note: Write to AFSR in CAN operation mode or CAN halt mode.

The acceptance filter support unit (ASU) can be used for data table (8 bits × 256) searches. In the data table, all standard IDs that are created are set as valid or invalid in bit units. When AFSR is written with data in 16-bit units including the SID[10:0] bits in MBj_ID (j = 0 to 31), in which a received standard ID is stored, a decoded row (byte offset) position and column (bit) position for data table search can be read. The ASU can be used for standard (11-bit) IDs only.

The ASU is enabled in the following cases:

- When the ID to be received cannot be masked by the acceptance filter. For example, if IDs to be received are 0x078, 0x087, and 0x111.
- When there are too many IDs to receive, and the software filtering time is expected to be shortened.

Note: AFSR cannot be set in CAN reset mode.

Figure 29.5 shows the write and read operations in the AFSR register.

Note: 在CAN操作模式或CAN暂停模式下写入AFSR。

验收滤波器支持单元(ASU)可用于数据表（8位×256）搜索。在数据表中，所有创建的标准ID都以位为单位设置为有效或无效。当AFSR以16位单元写入数据时，包括MBj_ID(j=0到31)中的SID[10:0]位，其中存储了接收到的标准ID，解码的行（字节偏移）位置和列（位）数据表搜索的位置可以被读取。ASU只能用于标准（11位）ID。

ASU在以下情况下启用：

●当接收的ID不能被接受过滤器屏蔽时。例如，如果要接收的ID是0x078、0x087和0x111。

●接收的ID过多，预计软件过滤时间会缩短。

Note: CAN复位模式下不能设置AFSR。

图29.5显示了AFSR寄存器中的写和读操作。

If an event associated with an EIFR flag occurs, the associated bit in EIFR is set to 1, regardless of the setting of EIER.

Clear the bits to 0 through a software write. If a bit is set to 1 at the same time that the software clears it, it becomes 1. When setting a single bit to 0 in software, use the transfer instruction (MOV) to ensure that only the specified bit is set to 0 and the other bits are set to 1. Writing 1 has no effect to these bit values.

BEIF flag (Bus Error Detect Flag)

The BEIF flag is set to 1 when a bus error is detected.

EWIF flag (Error-Warning Detect Flag)

The EWIF flag is set to 1 when the value of the receive error counter (REC) or transmit error counter (TEC) exceeds 95. The EWIF flag is set to 1 only when REC or TEC initially exceeds 95. If software writes 0 to this flag while the REC or TEC value remains greater than 95, the EWIF flag does not set to 1 until the REC or TEC value goes below 95, and then exceeds 95 again.

EPIF flag (Error-Passive Detect Flag)

The EPIF flag is set to 1 when the CAN error state becomes error-passive, when the REC or TEC value exceeds 127. The EPIF flag is set to 1 only when the REC or TEC value initially exceeds 127. If software writes 0 to this flag while REC or TEC remains greater than 127, the EPIF flag is not set to 1 until REC or TEC goes below 127, and then exceeds 127 again.

BOEIF flag (Bus-Off Entry Detect Flag)

The BOEIF flag is set to 1 when the CAN error state becomes bus-off, when the TEC value exceeds 255. The BOEIF flag is also set to 1 when the BOM[1:0] bits in CTLR are 01b (automatic entry to CAN halt mode on bus-off entry) and the CAN module becomes the bus-off state.

BORIF flag (Bus-Off Recovery Detect Flag)

The BORIF flag is set to 1 when the CAN module recovers from the bus-off state normally by detecting 11 consecutive bits 128 times in the following conditions:

- When the BOM[1:0] bits in CTLR are 00b
- When the BOM[1:0] bits in CTLR are 10b
- When the BOM[1:0] bits in CTLR are 11b

The BORIF flag is not set to 1 if the CAN module recovers from the bus-off state in the following conditions:

- When the CANM[1:0] bits in CTLR are set to 01b or 11b (CAN reset mode)
- When the RBOC bit in CTLR is set to 1 (forced return from bus-off)
- When the BOM[1:0] bits in CTLR are set to 01b
- When the BOM[1:0] bits in CTLR are set to 11b and the CANM[1:0] bits in CTLR are set to 10b (CAN halt mode) before normal recovery occurs

Table 29.7 lists the behavior of the BOEIF and BORIF flags for each CTLR.BOM[1:0] bits setting.

Bit	Symbol	Function	R/W
5	ORIF	接收溢出检测标志 0：未检测到接收溢出1：检测到接收溢出	R/W
6	OLIF	过载帧传输检测标志 0：未检测到过载帧传输1：检测到过载帧传输	R/W
7	BLIF	总线锁定检测标志 0：未检测到总线锁定1：检测到总线锁定	R/W

如果发生与EIFR标志相关的事件，则EIFR中的相关位设置为1，而与EIER的设置无关。

通过软件写入将这些位清除为0。如果在软件清零的同时将某个位设置为1，则该位变为1。
在软件中设置单个位为0时，使用传输指令(MOV)确保只有指定位设置为0，其他位设置为1。写1对这些位值没有影响。

BEIF标志（总线错误检测标志）

当检测到总线错误时，BEIF标志设置为1。

EWIF标志（错误警告检测标志）

当接收错误计数器(REC)或发送错误计数器(TEC)的值超过95时，EWIF标志设置为1。仅当REC或TEC最初超过95时，EWIF标志才设置为1。如果软件将0写入此当REC或TEC值保持大于95时，EWIF标志不会设置为1，直到REC或TEC值低于95，然后再次超过95。

EPIF标志（错误被动检测标志）

当CAN错误状态变为被动错误时，当REC或TEC值超过127时，EPIF标志设置为1。仅当REC或TEC值最初超过127时，EPIF标志设置为1。如果软件将0写入此当REC或TEC保持大于127时，EPIF标志不会设置为1，直到REC或TEC低于127，然后再次超过127。

BOEIF标志（总线关闭进入检测标志）

当CAN错误状态变为总线关闭时，当TEC值超过255时，BOEIF标志设置为1。当CTLR中的BOM[1:0]位为01b（自动进入CAN进入总线关闭时的停止模式）并且CAN模块变为总线关闭状态。

BORIF标志（总线关闭恢复检测标志）

当CAN模块通过检测11个连续位128次从总线关闭状态正常恢复时，BORIF标志设置为1，条件如下：

●CTLR的BOM[1:0]位为00b时
●CTLR的BOM[1:0]位为10b时
●CTLR的BOM[1:0]位为11b时

如果CAN模块在以下情况下从总线关闭状态恢复，则BORIF标志不设置为1：

●CTLR中的CANM[1:0]位设置为01b或11b时（CAN复位模式）
●CTLR的RBOC位设置为1时（强制从总线关闭返回）
●当CTLR的BOM[1:0]位设置为01b时
●CTLR中的BOM[1:0]位设置为11b且CTLR中的CANM[1:0]位设置为10b时（CAN停止模式）在正常恢复发生之前

表29.7列出了每个CTLR.BOM[1:0]位设置的BOEIF和BORIF标志的行为。

Table 29.7 Behavior of BOEIF and BORIF flags for each CTLR.BOM[1:0] setting

BOM[1:0] bits	BOEIF flag	BORIF flag
00b	Set to 1 on entry to the bus-off state	Sets to 1 on exit from the bus-off state
01b		Do not set to 1
10b		Set to 1 on exit from the bus-off state
11b		Set to 1 if normal bus-off recovery occurs before the CANM[1:0] bits are set to 10b (CAN halt mode)

ORIF flag (Receive Overrun Detect Flag)

The ORIF flag is set to 1 when a receive overrun occurs. This flag is not set to 1 in overwrite mode.

In overwrite mode, a reception complete interrupt request occurs if an overwrite condition occurs and the ORIF flag is not set to 1.

In overrun mode with normal mailbox mode, if an overrun occurs in any of mailboxes 0 to 31, the ORIF flag is set to 1. In overrun mode with FIFO mailbox mode, if an overrun occurs in any of mailboxes 0 to 23 or the receive FIFO, this flag is set to 1.

OLIF flag (Overload Frame Transmission Detect Flag)

The OLIF flag is set to 1 if the transmitting condition of an overload frame is detected when the CAN module is transmitting or receiving.

BLIF flag (Bus Lock Detect Flag)

The BLIF flag is set to 1 if 32 consecutive dominant bits are detected on the CAN bus while the CAN module is in CAN operation mode. After the BLIF flag is set to 1, 32 consecutive dominant bits are detected again in either of the following conditions:

- Recessive bits are detected after the BLIF flag changes to 0 from 1
- The CAN module enters CAN reset or halt mode and then enters CAN operation mode again after the BLIF flag changes to 0 from 1

01b		不要设置为1
10b		退出总线关闭状态时设置为1
11b		如果在CANM[1:0]位设置为10b（CAN停止模式）之前发生正常的总线关闭恢复，则设置为1

ORIF标志（接收溢出检测标志）

当发生接收溢出时，ORIF标志设置为1。此标志在覆盖模式下不设置为1。

在覆盖模式下，如果出现覆盖条件且ORIF标志未设置为1，则会产生接收完成中断请求。

在具有正常邮箱模式的溢出模式中，如果在任何邮箱0到31中发生溢出，则ORIF标志设置为1。在具有FIFO邮箱模式的溢出模式中，如果在任何邮箱0到23或接收中发生溢出FIFO，此标志设置为1。

OLIF标志（过载帧传输检测标志）

如果在CAN模块发送或接收时检测到过载帧的发送条件，则OLIF标志设置为1。

BLIF标志（总线锁定检测标志）

如果在CAN模块处于CAN操作模式时在CAN总线上检测到32个连续显性位，则BLIF标志设置为1。将BLIF标志设置为1后，在以下任一条件下再次检测到32个连续的显性位：

●BLIF标志由1变为0后检测隐性位

●CAN模块进入CAN复位或停止模式，待BLIF标志位由1变为0后再次进入CAN工作模式

29.2.24 ECSR：错误代码存储寄存器

注1.写1对这些位值没有影响。

Note 2. To write 0 to the SEF, FEF, AEF, CEF, BE1F, BE0F, and ADEF bits, use the transfer (MOV) instruction to ensure that only the specified bit is set to 0 and the other bits are set to 1.
Note 3. Write to the EDPM bit in CAN reset or halt mode.
Note 4. If more than one error condition is detected simultaneously, all related bits are set to 1.

ECSR indicates whether an error occurs on the CAN bus. See the CAN specification (ISO11898-1) for the conditions when each error occurs.

Clear all of the bits, except for the EDPM bit, to 0 through a software write. If the ECSR bit is set to 1 at the same time that software writes 0 to it, the bit becomes 1.

SEF flag (Stuff Error Flag)

The SEF flag is set to 1 when a stuff error is detected.

FEF flag (Form Error Flag)

The FEF flag is set to 1 when a form error is detected.

AEF flag (ACK Error Flag)

The AEF flag is set to 1 when an ACK error is detected.

CEF flag (CRC Error Flag)

The CEF flag is set to 1 when a CRC error is detected.

BE1F flag (Bit Error (recessive) Flag)

The BE1F flag is set to 1 when a recessive bit error is detected.

BE0F flag (Bit Error (dominant) Flag)

The BE0F flag is set to 1 when a dominant bit error is detected.

ADEF flag (ACK Delimiter Error Flag)

The ADEF flag is set to 1 when a form error is detected with the ACK delimiter during transmission.

EDPM bit (Error Display Mode Select)

The EDPM bit selects the output mode of ECSR. When the EDPM bit is set to 0, ECSR outputs the first error code. When the EDPM bit is set to 1, ECSR outputs the accumulated error code.

29.2.25 TSR : Time Stamp Register

Base address: CAN0 = 0x400A_8000
Offset address: 0x854

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	n/a	Free-running counter value for the time stamp function	R

Note: Read TSR in 16-bit units.

Reading the TSR register returns the current value of the 16-bit free-running time stamp counter. The time stamp counter reference clock is configured in the TSPS[1:0] bits in CTLR. The counter stops in CAN sleep mode and CAN halt mode, and is initialized in CAN reset mode. The time stamp counter value is stored in the TSL[7:0] and TSH[7:0] bits in MBj_TS when a received message is stored in a receive mailbox.

注2.要将0写入SEF、FEF、AEF、CEF、BE1F、BE0F和ADEF位，请使用传输(MOV)指令确保只有指定位设置为0，其他位设置为1.

注3.在CAN复位或暂停模式下写入EDPM位。
注4.如果同时检测到多个错误条件，则所有相关位都设置为1。

ECSR指示CAN总线上是否发生错误。有关每个错误发生的条件，请参见CAN规范(ISO11898-1)。

通过软件写入将除EDPM位之外的所有位清零。如果ECSR位在软件写入0的同时设置为1，则该位变为1。

SEF标志（填充错误标志）

当检测到填充错误时，SEF标志设置为1。

FEF标志（表格错误标志）

当检测到表单错误时，FEF标志设置为1。

AEF标志（ACK错误标志）

当检测到ACK错误时，AEF标志设置为1。

CEF标志（CRC错误标志）

当检测到CRC错误时，CEF标志设置为1。

BE1F标志（位错误（隐性）标志）

当检测到隐性位错误时，BE1F标志设置为1。

BE0F标志（位错误（显性）标志）

当检测到显性位错误时，BE0F标志设置为1。

ADEF标志（ACK分隔符错误标志）

当在传输过程中使用ACK定界符检测到格式错误时，ADEF标志设置为1。

EDP M位（错误显示模式选择）

EDP M位选择ECSR的输出模式。当EDPM位设置为0时，ECSR输出第一个错误代码。当EDPM位设置为1时，ECSR输出累积的错误代码。

29.2.25 TSR:时间戳寄存器

Base address: CAN0 = 0x400A_8000

Note: 以16位为单位读取TSR。

读取TSR寄存器返回16位自由运行时间戳计数器的当前值。时间戳计数器参考时钟在CTLR的TSPS[1:0]位中配置。计数器在CAN睡眠模式和CAN暂停模式下停止，并在CAN复位模式下初始化。当收到的消息存储在接收邮箱中时，时间戳计数器值存储在MBj_TS中的TSL[7:0]和TSH[7:0]位中。

29.2.26 TCR : Test Control Register

Base address: CAN0 = 0x400A_8000

Offset address: 0x858

Bit position:	7	6	5	4	3	2	1	0

7:3	—	These bits are read as 0. The write value should be 0.	R/W

TCR controls the CAN test mode. Write to TCR in CAN halt mode only.

(1) Listen-only mode

The CAN specification (ISO11898-1) recommends an optional bus monitoring mode. In listen-only mode, valid data frames and valid remote frames can be received. However, only recessive bits can be sent on the CAN bus. The ACK bit, overload flag, and active error flag cannot be sent.

Listen-only mode can be used for baud rate detection. Do not request transmission from any mailboxes in listen-only mode.

Figure 29.6 shows the connection when listen-only mode is selected.

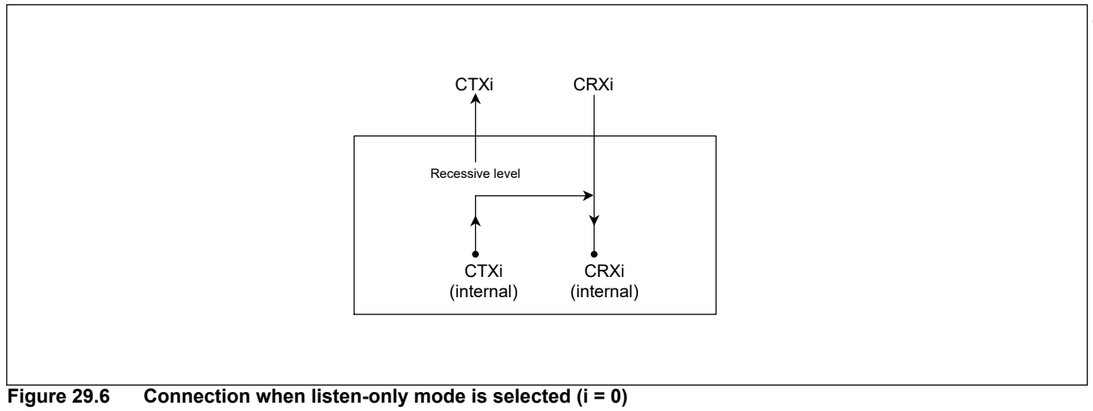

Figure 29.6 Connection when listen-only mode is selected (i = 0)

(2) Self-test mode 0 (external loopback)

Self-test mode 0 is provided for CAN transceiver tests. In this mode, the protocol module treats its own transmitted messages as those received by the CAN transceiver and stores them into the receive mailbox. To be independent from external stimulation, the protocol module generates the ACK bit. Connect the CTXi and CRXi pins to the transceiver.

Figure 29.7 shows the connection when self-test mode 0 is selected.

29.2.26 TCR:测试控制寄存器

TCR控制CAN测试模式。仅在CAN停止模式下写入TCR。

(1) Listen-only mode

CAN规范(ISO11898-1)推荐一种可选的总线监控模式。在只听模式下，可以接收到有效的数据帧和有效的远程帧。但是，只能在CAN总线上发送隐性位。不能发送ACK位、过载标志和活动错误标志。

只听模式可用于波特率检测。不要在只听模式下从任何邮箱请求传输。

图29.6显示了选择只听模式时的连接。

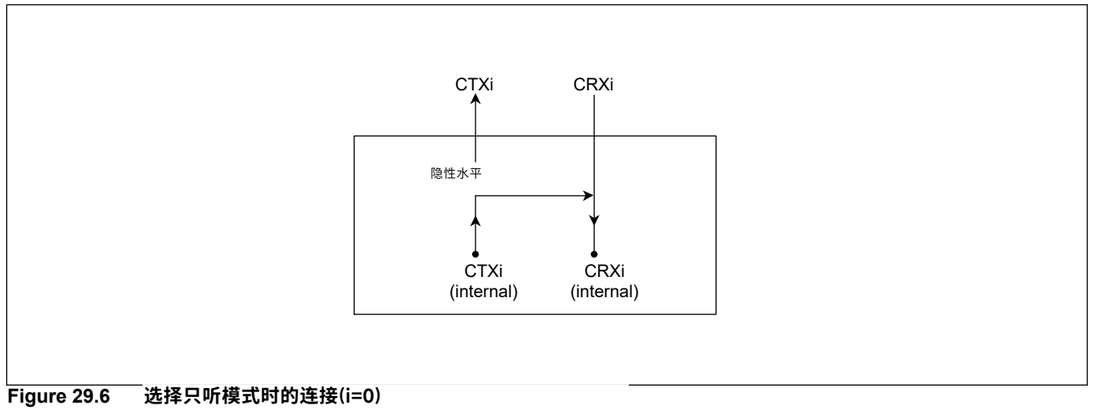

Figure 29.6 选择只听模式时的连接(i=0)

(2) Self-test mode 0 (external loopback)

自测模式0用于CAN收发器测试。在该模式下，协议模块将自己发送的报文视为CAN收发器接收到的报文，并将其存储到接收邮箱中。为独立于外部刺激，协议模块生成ACK位。将CTXi和CRXi引脚连接到收发器。

图29.7显示了选择自检模式0时的连接。

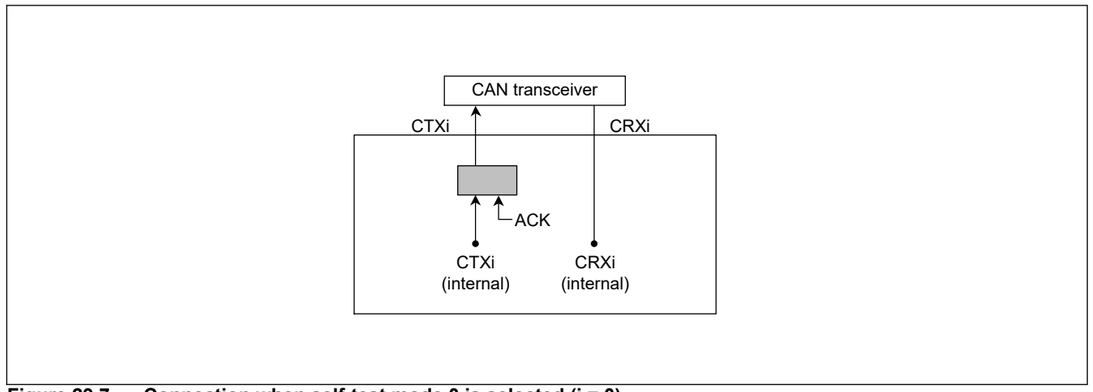

Figure 29.7 Connection when self-test mode 0 is selected (i = 0)

(3) Self-test mode 1 (internal loopback)

Self-test mode 1 is provided for self-test functions. In this mode, the protocol controller treats its transmitted messages as received messages and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.

In self-test mode 1, the protocol controller performs an internal feedback from the internal CTXi pin to the internal CRXi pin. The input value of the external CRXi pin is ignored. The external CTXi pin outputs only recessive bits. The CTXi and CRXi pins are not required to be connected to the CAN bus or any external device.

Figure 29.8 shows the connection when self-test mode 1 is selected.

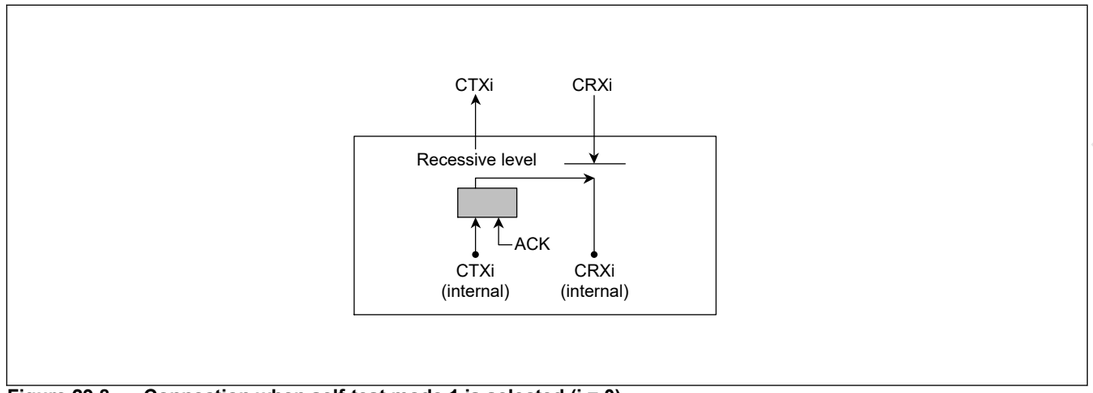

Figure 29.8 Connection when self-test mode 1 is selected (i = 0)

29.3 Operation Modes

The CAN module operation includes the following modes:

- CAN reset mode
- CAN halt mode
- CAN operation mode
- CAN sleep mode

Figure 29.9 shows the transitions between different operation modes.

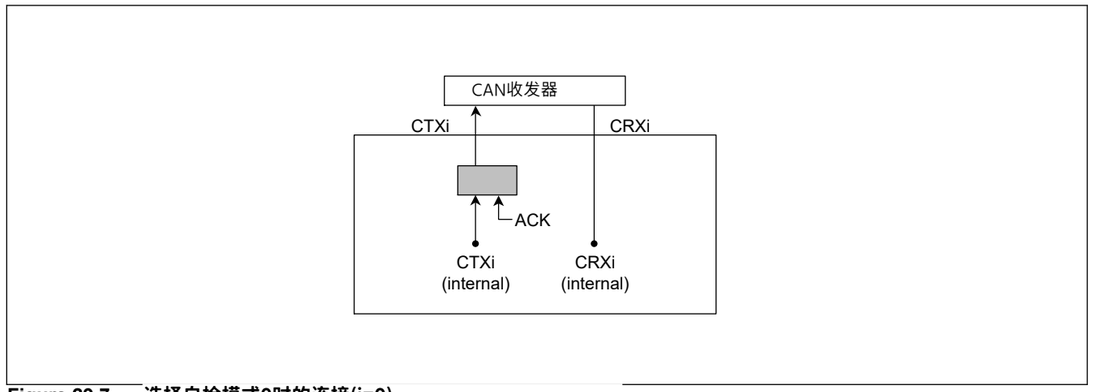

Figure 29.7 选择自检模式0时的连接(i=0)

(3) Self-test mode 1 (internal loopback)

自检模式1用于自检功能。在这种模式下，协议控制器将其发送的消息视为接收的消息，并将它们存储到接收邮箱中。为了独立于外部刺激，协议控制器生成ACK位。

在自检模式1中，协议控制器执行从内部CTXi引脚到内部CRXi引脚的内部反馈。外部CRXi引脚的输入值被忽略。外部CTXI引脚仅输出隐性位。CTXi和CRXi引脚不需要连接到CAN总线或任何外部设备。

图29.8显示了选择自检模式1时的连接。

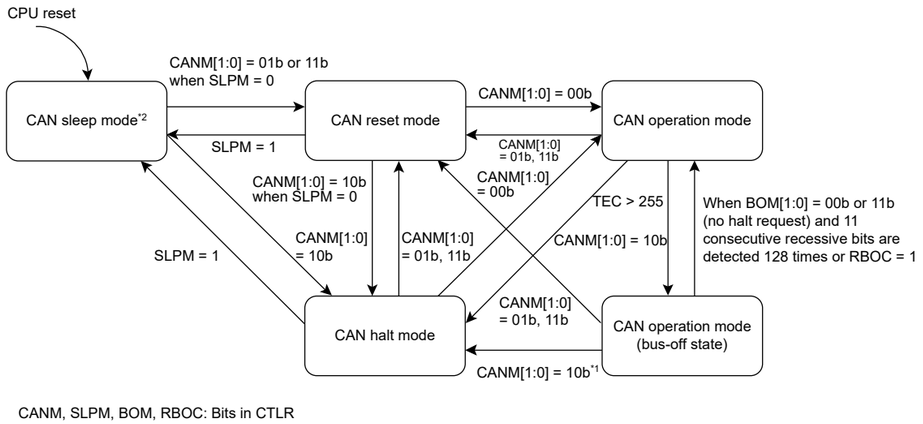
29.3 操作模式

CAN模块操作包括以下模式：

- CAN复位模式
- CAN停机模式
- CAN操作模式
- CAN睡眠模式

图29.9显示了不同操作模式之间的转换。



Note 1. The transition timing from the bus-off state to CAN halt mode depends on the setting of the CTLR.BOM[1:0] bits.
When the CTLR.BOM[1:0] bits are 01b, the state transition occurs immediately after entering the bus-off state.
When the CTLR.BOM[1:0] bits are 10b, the state transition occurs at the end of the bus-off state.
When the CTLR.BOM[1:0] bits are 11b, the state transition occurs at the setting of the CTLR.CANM[1:0] bits to 10b (CAN halt mode).
Note 2. Change the CTLR.SLPM bit to set or cancel CAN sleep mode.

Figure 29.9 Transition between different operation modes

29.3.1 CAN Reset Mode

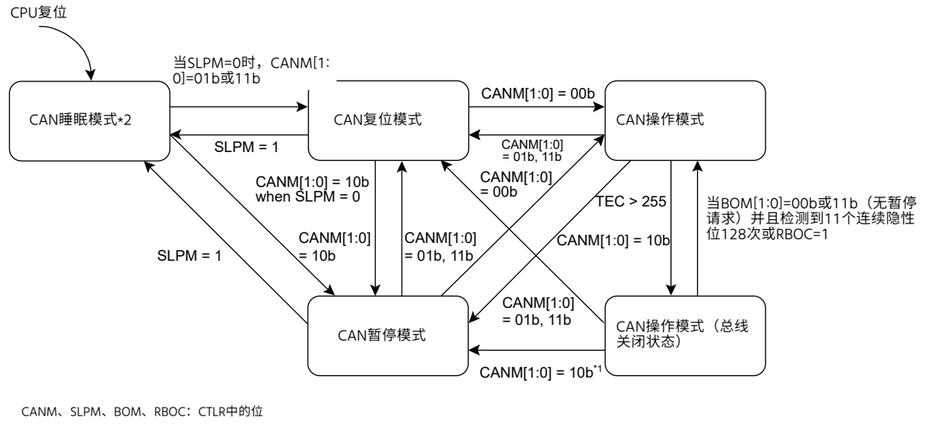
CAN reset mode is provided for CAN communication configuration. When the CTLR.CANM[1:0] bits are set to 01b or 11b, the CAN module enters CAN reset mode. The STR.RSTST bit is then set to 1. Do not change the CTLR.CANM[1:0] bits until the RSTST flag is 1. Set BCR before exiting CAN reset mode to enter any other modes.

The following registers are initialized to their reset values after entering CAN reset mode, and their initial values are saved during CAN reset mode:

- MCTL_TX[j] and MCTL_RX[j]
- STR (except for the SLPST and TFST bits)
- EIFR
- RECR
- TECR
- TSR
- MSSR
- MSMR
- RFCR
- TFCR
- TCR
- ECSR (except for the EDPM bit)

The following registers retain their previous values even after entering CAN reset mode:

- CTLR
- STR (only the SLPST and TFST bits)



注1.从总线关闭状态到CAN停止模式的转换时序取决于CTLR.BOM[1:0]位的设置。
当CTLR.BOM[1:0]位为01b时，状态转换在进入总线关闭状态后立即发生。
当CTLR.BOM[1:0]位为10b时，状态转换发生在总线关闭状态结束时。
当CTLR.BOM[1:0]位为11b时，状态转换发生在CTLR.CANM[1:0]位设置为10b（CAN停止模式）时。

注2.更改CTLR.SLPM位以设置或取消CAN睡眠模式。

Figure 29.9 不同操作模式之间的转换

29.3.1 CAN复位模式

CAN复位模式用于CAN通信配置。当CTLR.CANM[1:0]位设置为01b或11b时，CAN模块进入CAN复位模式。然后将STR.RSTST位设置为1。在RSTST标志为1之前不要更改CTLR.CANM[1:0]位。在退出CAN复位模式以进入任何其他模式之前设置BCR。

以下寄存器在进入CAN复位模式后初始化为其复位值，并在CAN复位模式期间保存其初始值：

- MCTL_TX[j] and MCTL_RX[j]
- STR（SLPST和TFST位除外）
- EIFR
- RECR
- TECR
- TSR
- MSSR
- MSMR
- RFCR
- TFCR
- TCR
- ECSR（EDPM位除外）

即使在进入CAN复位模式后，以下寄存器仍保留其先前的值：

- CTLR
- STR（仅SLPST和TFST位）

- MIER and MIER_FIFO
- EIER
- BCR
- CSSR
- ECSR (only the EDPM bit)
- MBj_ID, MBj_DL, MBj_Dm and MBj_TS
- MKRk
- FIDCR0 and FIDCR1
- MKIVLR
- AFSR
- RFPCR
- TFPCR

29.3.2 CAN Halt Mode

CAN halt mode is used for mailbox configuration and test mode setting.

When the CTLR.CANM[1:0] bits are set to 10b, CAN halt mode is selected, and the STR.HLTST bit is set to 1. Do not change the CTLR.CANM[1:0] bits until the HLTST bit is 1.

See Table 29.8 for the state transition conditions when transmitting or receiving.

All registers except for the RSTST, HLTST, and SLPST bits in STR remain unchanged when the CAN enters CAN halt mode. Do not change CTLR (except for the CANM[1:0] and SLPM bits) and EIER in CAN halt mode. BCR can be changed in CAN halt mode only when listen-only mode is selected for automatic baud rate detection.

Table 29.8 Operation in CAN reset mode and CAN halt mode

Operation mode	Receiver	Transmitter	Bus-off
CAN reset mode (forced transition) CANM[1:0] = 11b	CAN module enters CAN reset mode without waiting for the end of message reception.	CAN module enters CAN reset mode without waiting for the end of message transmission.	CAN module enters CAN reset mode without waiting for the end of bus-off recovery.

Note: BOM[1:0] bits: Bits in CTLR.
Note 1. If transmission of multiple messages is requested, a mode transition occurs on completion of the first transmission. If the CAN reset mode is being requested during suspend transmission, mode transition occurs when the bus is idle, the next transmission ends, or the CAN module becomes a receiver.
Note 2. If the CAN bus is locked at the dominant level, the program can detect this state by monitoring the BLIF flag in EIFR.
Note 3. If a CAN bus error occurs during reception after CAN halt mode is requested, the CAN module transitions to CAN halt mode.

29.3.2 CAN暂停模式

CAN暂停模式用于邮箱配置和测试模式设置。

当CTLR.CANM[1:0]位设置为10b时，选择CAN停止模式，并且STR.HLTST位设置为1。在HLTST位之前不要更改CTLR.CANM[1:0]位是1。

发送或接收时的状态转换条件见表29.8。

当CAN进入CAN暂停模式时，除STR中的RSTST、HLTST和SLPST位之外的所有寄存器都保持不变。不要在CAN暂停模式下更改CTLR（CANM[1:0]和SLPM位除外）和EIER。只有在为自动波特率检测选择只听模式时，才能在CAN暂停模式下更改BCR。

Table 29.8 CAN复位模式和CAN暂停模式下的操作

操作模式	Receiver	Transmitter	Bus-off
CAN复位模式（强制转换）CANM[1:0]=11b	CAN模块无需等待报文接收结束即可进入CAN复位模式。	CAN模块无需等待报文传输结束就进入CAN复位模式。	CAN模块无需等待总线关闭恢复结束即可进入CAN复位模式。
CAN复位模式CANM[1:0]=01b	CAN模块无需等待报文接收结束即可进入CAN复位模式。	CAN模块等待报文传输结束后进入CAN复位模式。*1*4	CAN模块无需等待总线关闭恢复结束即可进入CAN复位模式。
CAN暂停模式	CAN模块在等待报文接收结束后进入CAN停止模式。*2*3	CAN模块在等待报文传输结束后进入CAN停止模式。*1*4	• 当BOM[1:0]位为00b时：仅在总线关闭恢复后才接受来自软件的暂停请求。 • 当BOM[1:0]位为01b时：CAN模块自动进入CAN停止模式，无需等待总线关闭恢复结束，无论来自软件的停止请求如何。 • 当BOM[1:0]位为10b时：CAN模块在等待总线关闭恢复结束后自动进入CAN停止模式，无论软件是否有停止请求。 • 当BOM[1:0]位为11b时：如果在总线关闭期间软件请求停止，CAN模块无需等待总线关闭恢复结束即可进入CAN停止模式。

Note: BOM[1:0]位：CTLR中的位。
注1.如果请求发送多个消息，则在第一次发送完成时发生模式转换。如果在暂停传输期间请求CAN复位模式，则在总线空闲、下一次传输结束或CAN模块成为接收器时发生模式转换。

注2.如果CAN总线被锁定在显性电平，程序可以通过监控EIFR中的BLIF标志来检测该状态。
注3.如果在请求CAN暂停模式后接收期间发生CAN总线错误，CAN模块将转换到CAN暂停模式。

Note 4. If a CAN bus error or arbitration-lost occurs during transmission after CAN reset mode or CAN halt mode is requested, the CAN module transitions to the requested CAN mode.

29.3.3 CAN Sleep Mode

CAN sleep mode reduces power consumption by stopping the clock supply to the CAN module. After a reset from an MCU pin or a software reset, the CAN module starts from CAN sleep mode.

When the SLPM bit in CTLR is set to 1, the CAN module enters CAN sleep mode, and the SLPST bit in STR is set to 1. Do not change the value of the SLPM bit until the SLPST bit is 1. The other registers remain unchanged when the CAN module enters CAN sleep mode.

Write to the SLPM bit in CAN reset mode and CAN halt mode. Do not change any registers (except for the SLPM bit) during CAN sleep mode. Read operation is still allowed.

When the SLPM bit is set to 0, the CAN module is released from CAN sleep mode. When the CAN module exits CAN sleep mode, the other registers remain unchanged.

29.3.4 CAN Operation Mode (Excluding Bus-Off State)

CAN operation mode is used for CAN communication.

When the CANM[1:0] bits in CTLR are set to 00b, the CAN module enters CAN operation mode. The RSTST and HLTST bits in STR are set to 0. Do not change the value of the CANM[1:0] bits until the RSTST and HLTST bits are 0.

If 11 consecutive recessive bits are detected after entering CAN operation mode:

- The CAN module becomes an active node on the network, which enables transmission and reception of CAN messages.
- Error monitoring of the CAN bus, such as receive and transmit error counters, is performed.

During CAN operation mode, the CAN module might be in one of the following three sub-modes, depending on the status of the CAN bus:

- Idle mode: No transmission or reception occurs.
- Receive mode: A CAN message sent by another node is being received.
- Transmit mode: A CAN message is being transmitted. The CAN module receives a message transmitted by the local node simultaneously when self-test mode 0 (TSTM[1:0] bits in TCR = 10b) or self-test mode 1 (TSTM[1:0] bits = 11b) is selected.

Figure 29.10 shows the sub-modes of CAN operation mode.

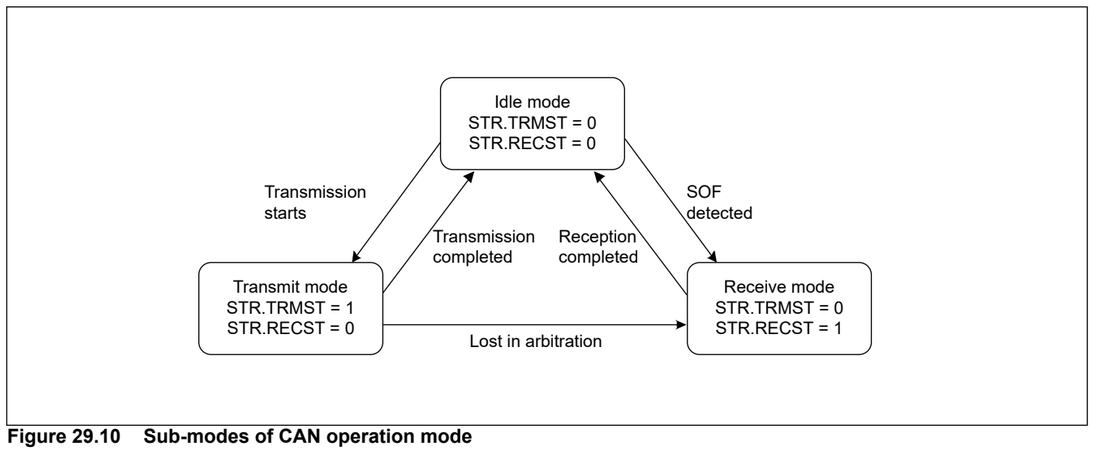

Figure 29.10 Sub-modes of CAN operation mode

注4.如果在请求CAN复位模式或CAN暂停模式后的传输过程中发生CAN总线错误或仲裁丢失，则CAN模块将转换到请求的CAN模式。

29.3.3 CAN睡眠模式

CAN睡眠模式通过停止向CAN模块提供时钟来降低功耗。在从MCU引脚复位或软件复位后，CAN模块从CAN睡眠模式启动。

当CTLR中的SLPM位为1时，CAN模块进入CAN休眠模式，同时STR中的SLPST位为1。在SLPST位为1之前不要改变SLPM位的值。其他寄存器保持不变CAN模块进入CAN休眠模式时不变。

在CAN复位模式和CAN暂停模式下写入SLPM位。在CAN睡眠模式期间不要更改任何寄存器（SLPM位除外）。仍然允许读取操作。

当SLPM位设置为0时，CAN模块从CAN睡眠模式中释放。当CAN模块退出CAN休眠模式时，其他寄存器保持不变。

29.3.4 CAN操作模式（不包括总线关闭状态）

CAN操作模式用于CAN通信。

当CTLR中的CANM[1:0]位设置为00b时，CAN模块进入CAN操作模式。STR中的RSTST和HLTST位设置为0。在RSTST和HLTST位为0之前，不要更改CANM[1:0]位的值。

如果进入CAN操作模式后检测到11个连续的隐性位：

●CAN模块成为网络上的一个活动节点，实现CAN报文的发送和接收。

●执行CAN总线的错误监控，例如接收和发送错误计数器。

在CAN操作模式期间，CAN模块可能处于以下三种子模式之一，具体取决于CAN总线的状态：

●空闲模式：不发送或接收。

●接收模式：正在接收另一个节点发送的CAN报文。

●传输模式：正在传输CAN报文。CAN模块接收本地发送的报文nodesimultaneouslywhenself-testmode0(TSTM[1:0]bitsinTCR=10b)orself-testmode1(TSTM[1:0]bits=11b)isselected.

图29.10显示了CAN操作模式的子模式。

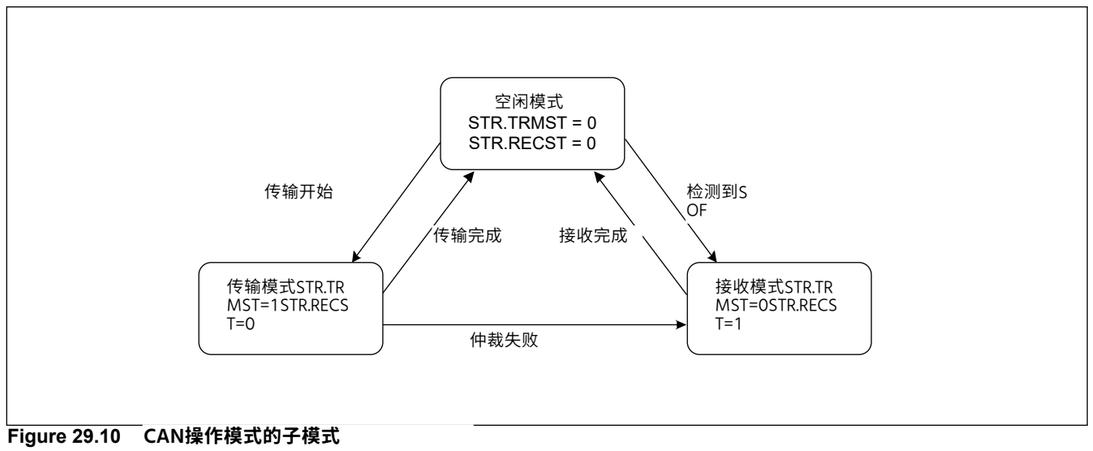

Figure 29.10 CAN操作模式的子模式

29.3.5 CAN Operation Mode (Bus-Off State)

The CAN module enters the bus-off state based on the incrementing or decrementing rules for the transmit and error counters defined in the CAN specifications.

The following cases apply when the CAN module is recovering from the bus-off state. When the CAN module is in the bus-off state, the values of the CAN module registers remain unchanged, except for those in STR, EIFR, RECR, TECR, and TSR.

(1) When CTLR.BOM[1:0] = 00b (normal mode)

The CAN module enters the error-active state after it completes recovery from the bus-off state and CAN communication is enabled. The BORIF flag in EIFR is set to 1 (bus-off recovery detected).

(2) When CTLR.RBOC = 1 (forced return from bus-off)

The CAN module enters the error-active state when it is in the bus-off state and the RBOC bit is 1. CAN communication is enabled again after 11b consecutive recessive bits are detected. The BORIF flag is not set to 1.

(3) When CTLR.BOM[1:0] = 01b (automatic transition to CAN halt mode on bus-off entry)

The CAN module enters CAN halt mode when it reaches the bus-off state. The BORIF flag is not set to 1.

(4) When CTLR.BOM[1:0] = 10b (automatic transition to CAN halt mode on bus-off end)

The CAN module enters CAN halt mode when it completes recovery from bus-off. The BORIF flag is set to 1.

(5) When CTLR.BOM[1:0] = 11b (automatic transition to CAN halt mode through software) and CTLR.CANM[1:0] = 10b (CAN halt mode) during bus-off state

The CAN module enters CAN halt mode when it is in the bus-off state and the CANM[1:0] bits are set to 10b (CAN halt mode). The BORIF flag is not set to 1.

If the CANM[1:0] bits are not set to 10b during bus-off, the same behavior as (1) applies.

29.4 Data Transfer Rate Configuration

This section describes how to configure the data transfer rate.

29.4.1 Clock Setting

The CAN module provides a CAN clock generator. The CAN clock can be set in the CCLKS and BRP[9:0] bits in BCR. Figure 29.11 shows a block diagram of the CAN clock generator.

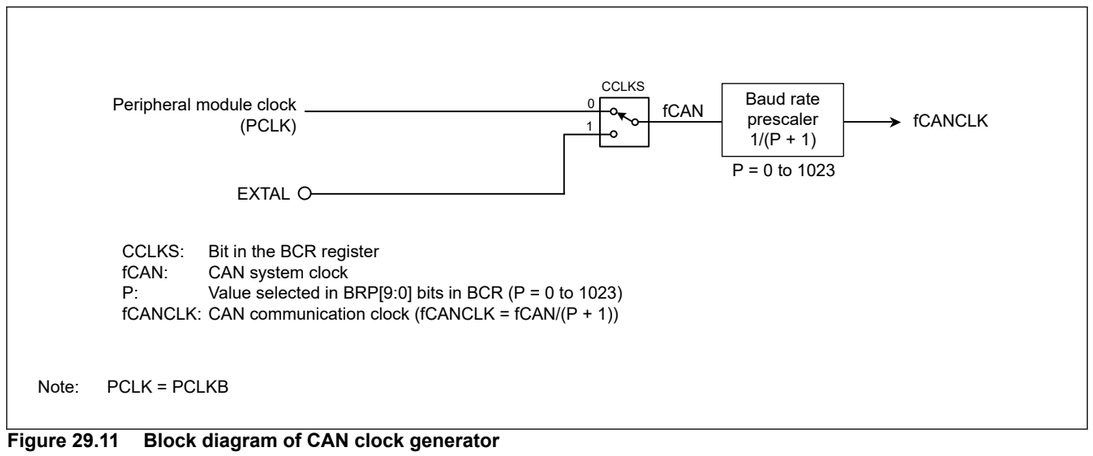

Figure 29.11 Block diagram of CAN clock generator

29.3.5 CAN操作模式（总线关闭状态）

CAN模块根据CAN规范中定义的发送和错误计数器的递增或递减规则进入总线关闭状态。

以下情况适用于CAN模块从总线关闭状态恢复时。当CAN模块处于busoff状态时，CAN模块寄存器的值保持不变，除了STR、EIFR、RECR、TECR和TSR中的值。

(1) When CTLR.BOM[1:0] = 00b (normal mode)

CAN模块在完成从总线关闭状态恢复并启用CAN通信后进入错误激活状态。EIFR中的BORIF标志设置为1（检测到总线关闭恢复）。

(2) 当CTLR.RBOC=1时（从总线关闭强制返回）

当CAN模块处于总线关闭状态且RBOC位为1时，进入错误激活状态。在检测到11b个连续的隐性位后再次启用CAN通信。BORIF标志未设置为1。

(3) 当CTLR.BOM[1:0]=01b时（在总线关闭进入时自动转换到CAN暂停模式）

CAN模块在达到总线关闭状态时进入CAN停止模式。BORIF标志未设置为1。

(4) 当CTLR.BOM[1:0]=10b时（在总线关闭结束时自动转换到CAN暂停模式）

CAN模块在完成总线关闭恢复后进入CAN暂停模式。BORIF标志设置为1。

(5) 当CTLR.BOM[1:0]=11b（通过软件自动转换到CAN暂停模式）并且总线关闭状态期间CTLR.CANM[1:0]=10b（CAN停止模式）

CAN模块在总线关闭状态且CANM[1:0]位设置为10b（CAN停止模式）时进入CAN停止模式。BORIF标志未设置为1。

如果在总线关闭期间CANM[1:0]位未设置为10b，则适用与(1)相同的行为。

29.4 数据传输率配置

本节介绍如何配置数据传输速率。

29.4.1 时钟设置

CAN模块提供一个CAN时钟发生器。CAN时钟可以在BCR的CCLKS和BRP[9:0]位中设置。
图29.11显示了CAN时钟发生器的框图。

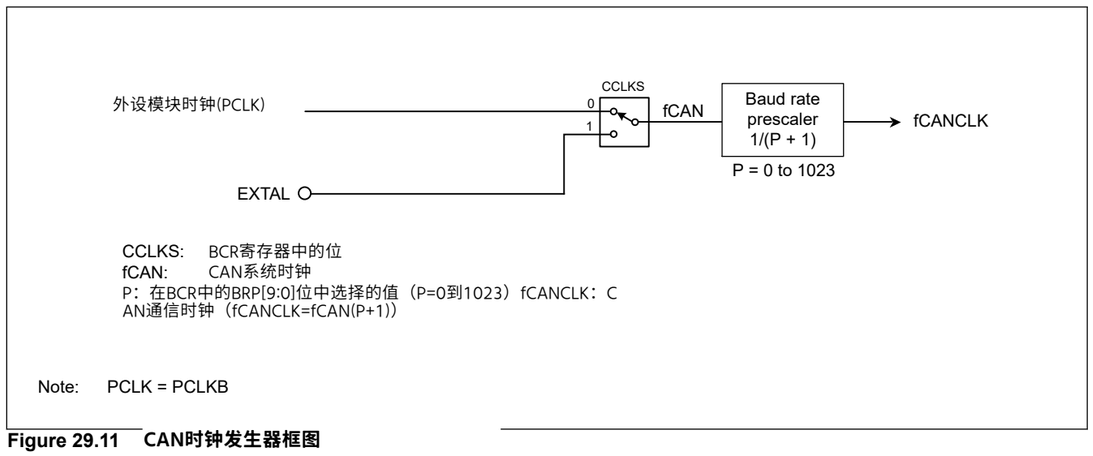

Figure 29.11 CAN时钟发生器框图

29.4.2 Bit Timing Setting

The bit timing consists of three segments as shown in Figure 29.12.

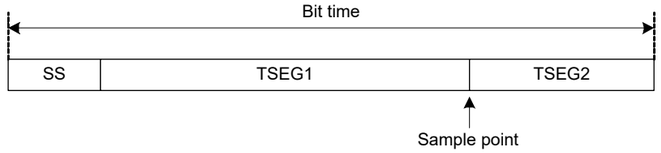

Figure 29.12 Bit timing

29.4.3 Data Transfer Rate

The data transfer rate depends on the division value of fCAN (CAN system clock), the division value of the baud rate prescaler, and the Tq count for 1 bit time.

The division value of baud rate prescaler = P + 1 (P: 0 to 1023), where P is the BRP[9:0] setting in BCR.

$$\text{Data transfer rate (bps)} = \frac{\text{fCAN}}{\text{Baud rate prescaler division value} \times \text{Tq count for 1 bit time}} = \frac{\text{fCANCLK}}{\text{Tq count for 1 bit time}}$$

Table 29.9 lists data transfer rate examples.

29.4.2 位时序设置

位时序由三个部分组成，如图29.12所示。

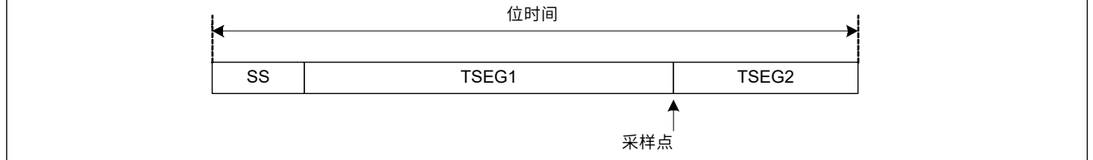

Figure 29.12 位时序

29.4.3 数据传输率

数据传输速率取决于fCAN（CAN系统时钟）的分频值、波特率预分频器的分频值和1位时间的Tq计数。

波特率预分频器的分频值=P+1(P:0to1023)，其中P是BCR中的BRP[9:0]设置。

$$\text{数据传输率(bps)} = \frac{\text{fCAN波特率预分频器分频值} \times \text{1位时间的Tq计数}}{\text{1位时间的fCANCLKTq计数}}$$

表29.9列出了数据传输率示例。

29.6 Acceptance Filtering and Masking Functions

The acceptance filtering and masking functions allow you to select and receive messages with multiple IDs for mailboxes within a specified range.

The MKRk registers can mask the standard ID and the extended ID of 29 bits.

- MKR0 controls mailboxes 0 to 3
- MKR1 controls mailboxes 4 to 7
- MKR2 controls mailboxes 8 to 11
- MKR3 controls mailboxes 12 to 15
- MKR4 controls mailboxes 16 to 19
- MKR5 controls mailboxes 20 to 23
- MKR6 controls mailboxes 24 to 27 in normal mailbox mode and the receive FIFO mailboxes 28 to 31 in FIFO mailbox mode
- MKR7 controls mailboxes 28 to 31 in normal mailbox mode and the receive FIFO mailboxes 28 to 31 in FIFO mailbox mode

MKIVLR disables acceptance filtering independently for each mailbox.

The IDE bit in MBj_ID is valid when the IDFM[1:0] bits in CTLR are 10b (mixed ID mode).

The RTR bit in MBj_ID selects a data or remote frame.

In FIFO mailbox mode, normal mailboxes 0 to 23 use one associated register from MKR0 to MKR5 for acceptance filtering. The receive FIFO mailboxes 28 to 31 use two registers, MKR6 and MKR7, for acceptance filtering.

The receive FIFO also uses two registers, FIDCR0 and FIDCR1, for ID comparison. The EID[17:0], SID[10:0], RTR, and IDE bits in MB28 to MB31 for the receive FIFO are disabled. As acceptance filtering depends on the result of two logic AND operations, two ranges of IDs can be received into the receive FIFO. MKIVLR is disabled for the receive FIFO.

If different standard ID and extended ID values are set in the IDE bits in FIDCR0 and FIDCR1, both ID formats are received.

If different data frame and remote frame values are set in the RTR bits in FIDCR0 and FIDCR1, both data and remote frames are received.

When a combination of two ranges of IDs is not required, set the same mask value and the same ID into both the FIFO ID and mask registers.

Figure 29.16 shows the associations between the mask registers and mailboxes. Figure 29.17 shows the acceptance filtering.

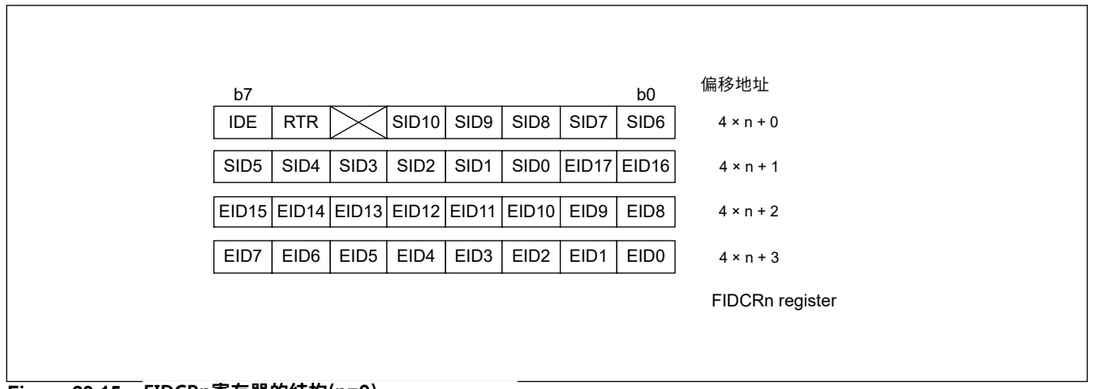

Figure 29.15 FIDCRn寄存器的结构(n=0)

29.6 接受过滤和屏蔽功能

接受过滤和屏蔽功能允许您为指定范围内的邮箱选择和接收具有多个ID的消息。

MKRk寄存器可以屏蔽标准ID和29位扩展ID。

- MKR0控制邮箱0到3
- MKR1控制邮箱4到7
- MKR2控制邮箱8到11
- MKR3控制邮箱12到15
- MKR4控制邮箱16到19
- MKR5控制邮箱20到23
- MKR6在普通邮箱模式下控制邮箱24到27，在FIFO邮箱模式下控制接收FIFO邮箱28到31
- MKR7在普通邮箱模式下控制邮箱28到31，在FIFO邮箱模式下控制接收FIFO邮箱28到31

MKIVLR为每个邮箱单独禁用接受过滤。

当CTLR中的IDFM[1:0]位为10b（混合ID模式）时，MBj_ID中的IDE位有效。

MBj_ID中的RTR位选择数据或远程帧。

在FIFO邮箱模式下，普通邮箱0到23使用一个从MKR0到MKR5的关联寄存器用于接受过滤。接收FIFO邮箱28到31使用两个寄存器，MKR6和MKR7，用于接受过滤。

接收FIFO还使用两个寄存器FIDCR0和FIDCR1进行ID比较。EID[17:0]、SID[10:0]、RTR和MB28到MB31中用于接收FIFO的IDE位被禁用。由于验收过滤取决于两个逻辑的结果AND操作，可以将两个范围的ID接收到接收FIFO中。MKIVLR对接收FIFO禁用。

如果在FIDCR0和FIDCR1的IDE位中设置了不同的标准ID和扩展ID值，则会接收两种ID格式。

如果在FIDCR0和FIDCR1的RTR位中设置了不同的数据帧和远程帧值，则数据帧和远程帧都被接收。

当不需要两个ID范围的组合时，将相同的掩码值和相同的ID设置到FIFOID和掩码寄存器中。

29.7 Reception and Transmission

Table 29.10 lists the CAN communication mode settings.

Table 29.10 Settings for CAN receive and transmit modes

MCTL_TX[j].TRMREQ and MCTL_RX[j].TRMREQ	MCTL_TX[j].RECREQ and MCTL_RX[j].RECREQ	MCTL_TX[j].ONESHOT and MCTL_RX[j].ONESHOT	Mailbox communication mode
0	0	0	Mailbox disabled or transmission being aborted
0	0	1	Can be configured only when transmission or reception from a mailbox programmed in one-shot mode is aborted
0	1	0	Configured as a receive mailbox for a data or remote frame
0	1	1	Configured as a one-shot receive mailbox for a data or remote frame.
1	0	0	Configured as a transmit mailbox for a data or remote frame.
1	0	1	Configured as a one-shot transmit mailbox for a data or remote frame.
1	1	0	Do not set.
1	1	1	Do not set.

Note: j = 0 to 31

When a mailbox is configured as a receive mailbox or a one-shot receive mailbox, the following restrictions apply:

- Before configuring the mailbox, set MCTL_RX[j] to 0x00.
- A received message is stored in the first mailbox that matches the condition resulting from the receive mode settings and acceptance filtering. The matching mailbox with the smallest number takes priority for storing the received message.
- In CAN operation mode, the CAN module does not receive its own transmitted data even when the ID is a match. In self-test mode, however, the CAN module receives its own transmitted data and returns ACK.

When configuring a mailbox as a transmit mailbox or a one-shot transmit mailbox, the following constraint applies:

- Before configuring a mailbox, ensure that MCTL_TX[j] is 0x00 and that there is no pending abort process.

29.7.1 Reception

Figure 29.18 shows an operation example of data frame reception in overwrite mode. The example shows the overwriting of the first message when the CAN module receives two consecutive CAN messages that match the receiving conditions in MCTL_RX[j] (j = 0 to 31).

29.7 接收和传输

表29.10列出了CAN通信模式设置。

Table 29.10 CAN接收和发送模式的设置

MCTL_TX[j].TRMREQ and MCTL_RX[j].TRMREQ	MCTL_TX[j].RECREQ and MCTL_RX[j].RECREQ	MCTL_TX[j].ONESHOT and MCTL_RX[j].ONESHOT	邮箱通讯方式
0	0	0	邮箱禁用或传输被中止
0	0	1	只有在一次性模式中编程的邮箱的发送或接收被中止时才可以配置
0	1	0	配置为数据或远程帧的接收邮箱
0	1	1	配置为数据或远程帧的一次性接收邮箱。
1	0	0	配置为数据或远程帧的传输邮箱。
1	0	1	配置为数据或远程帧的一次性发送邮箱。
1	1	0	不要设置。
1	1	1	不要设置。

Note: j = 0 to 31

当邮箱配置为接收邮箱或一次性接收邮箱时，以下限制适用：

●配置邮箱前，将MCTL_RX[j]设置为0x00。

●收到的消息存储在第一个符合接收模式设置和接受过滤条件的邮箱中。编号最小的匹配邮箱优先存储收到的消息。

●在CAN操作模式下，即使ID匹配，CAN模块也不会接收到自己发送的数据。然而，在自检模式下，CAN模块接收自己发送的数据并返回ACK。

将邮箱配置为传输邮箱或一次性传输邮箱时，适用以下约束：

●在配置邮箱之前，请确保MCTL_TX[j]为0x00，并且没有挂起的中止进程。

29.7.1 Reception

图29.18显示了覆盖模式下数据帧接收的操作示例。该示例显示当CAN模块接收到与MCTL_RX[j]（j=0到31）中的接收条件匹配的两个连续CAN报文时，第一条报文的覆盖。

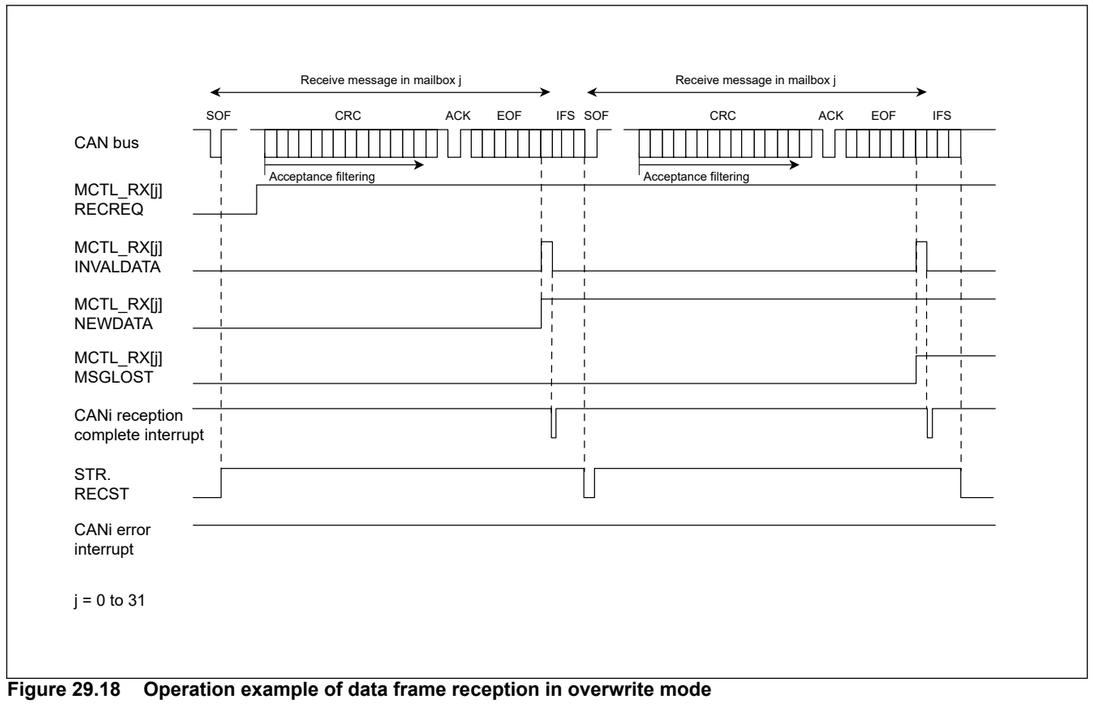

Figure 29.18 Operation example of data frame reception in overwrite mode

1. When an SOF is detected on the CAN bus, the RECST bit in STR is set to 1 (reception in progress) if the CAN module has no message ready to start transmission.
2. Acceptance filtering starts at the beginning of the CRC field to select the receive mailbox.
3. After a message is received, the NEWDATA flag in MCTL_RX[j] for the receive mailbox is set to 1 (new message is being stored or was stored in the mailbox). The INVALDATA flag in MCTL_RX[j] is set to 1 (message is being updated) at the same time, and then the INVALDATA flag is set to 0 (message valid) again after the complete message is transferred to the mailbox.
4. When the interrupt enable bit in MIER for the receive mailbox is 1 (interrupt enabled), the INVALDATA flag is set to 0, which triggers a CAN0 reception complete interrupt request.
5. After reading the message from the mailbox, the NEWDATA flag must be set to 0 by software.
6. In overwrite mode, if the next CAN message is received before the NEWDATA flag in MCTL_RX[j] is set to 1, the MSGLOST flag in MCTL_RX[j] is set to 1 (message was overwritten). The new received message is transferred to the mailbox. The CAN0 reception complete interrupt request occurs the same as in step 4.

Figure 29.19 shows an operation example of data frame reception in overrun mode. The example shows the overrunning of the second message when the CAN module receives two consecutive CAN messages that match the receiving conditions in MCTL_RX[j] (j = 0 to 31).

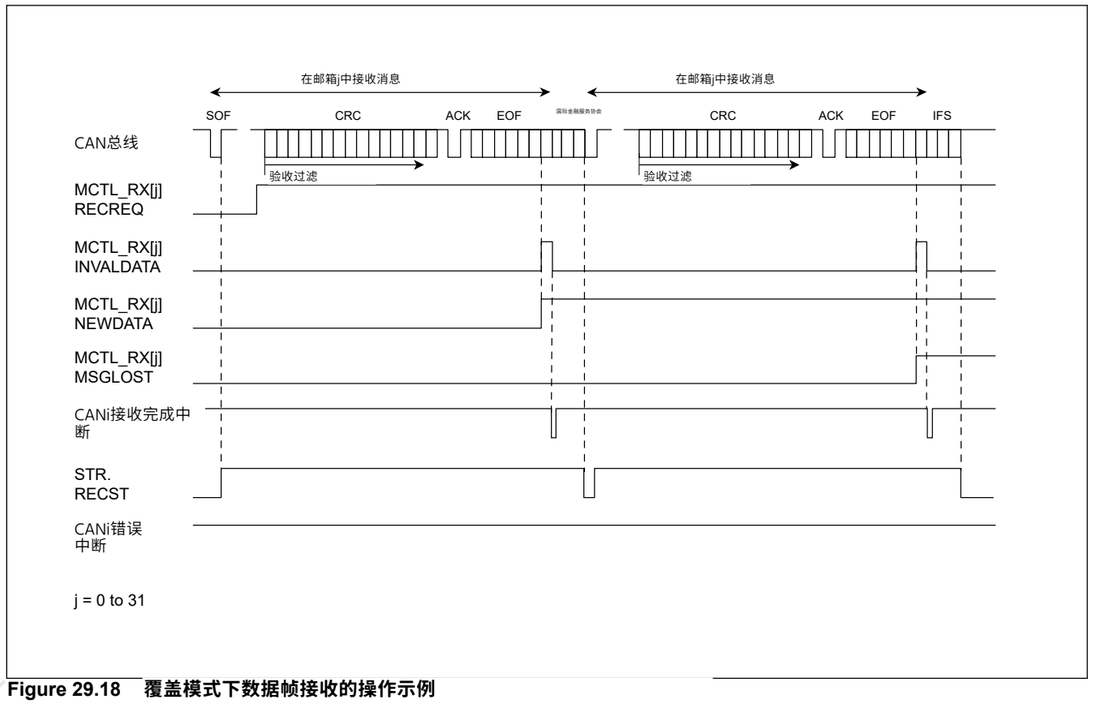

Figure 29.18 覆盖模式下数据帧接收的操作示例

1.当CAN总线上检测到SOF时，如果CAN模块没有准备好开始发送的消息，则STR中的RECST位设置为1（正在接收）。

2.接受过滤从CRC字段的开头开始，以选择接收邮箱。

3.收到消息后，接收邮箱的MCTL_RX[j]中的NEWDATA标志设置为1（新消息正在存储或已存储在邮箱中）。MCTL_RX[j]中的INVALDATA标志同时设置为1（消息正在更新），然后在完整的消息传送到邮箱后再次将INVALDATA标志设置为0（消息有效）。

4.当接收邮箱的MIER中的中断使能位为1（中断使能）时，INVALDATA标志设置为0，触发CAN0接收完成中断请求。

5.从邮箱读取消息后，NEWDATA标志必须由软件设置为0。

6.在覆盖模式下，如果在MCTL_RX[j]中的NEWDATA标志设置为1之前接收到下一个CAN报文，则MCTL_RX[j]中的MSGLOST标志设置为1（消息被覆盖）。新收到的消息被传送到邮箱。CAN0接收完成中断请求的发生与步骤4相同。

图29.19显示了溢出模式下数据帧接收的操作示例。该示例显示当CAN模块接收到与MCTL_RX[j]（j=0到31）中的接收条件匹配的两个连续CAN报文时，第二条报文的溢出。

The new received message is discarded and a CANi error interrupt request occurs if the associated interrupt enable bit in EIER is set to 1 (interrupt enabled).

29.7.2 Transmission

图29.20显示了数据帧传输的操作示例。

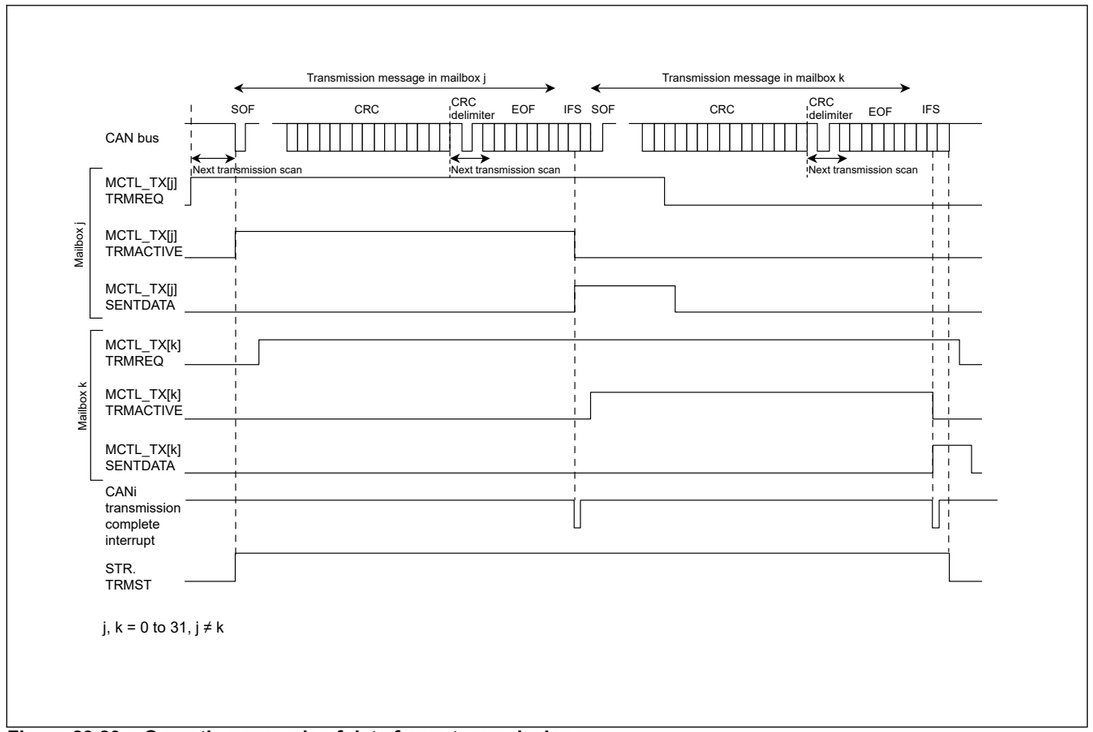

Figure 29.20 Operation example of data frame transmission

1. When a TRMREQ bit in MCTL_TX[j] (j = 0 to 31) is set to 1 (transmit mailbox) in the bus-idle state, mailbox scanning starts to decide the highest-priority mailbox for transmission. When the transmit mailbox is decided, the TRMACTIVE flag in MCTL_TX[j] is set to 1 (from acceptance of transmission request to completion of transmission, or error or arbitration-lost), the TRMST bit in STR is set to 1 (transmission in progress), and the CAN module starts transmission.*1
2. If other TRMREQ bits are set, the transmission scanning starts with the CRC delimiter for the next transmission.
3. If transmission is complete without losing arbitration, the SENTDATA flag in MCTL_TX[j] is set to 1 (transmission complete) and the TRMACTIVE flag is set to 0 (transmission is pending or transmission is not requested). If the interrupt enable bit in MIER is 1 (interrupt enabled), the CANi transmission complete interrupt request is generated.
4. When requesting the next transmission from the same mailbox, set the SENTDATA flag and TRMREQ bit to 0, and then set the TRMREQ bit to 1 after checking that the SENTDATA flag and TRMREQ bit are set to 0.

Note 1. If arbitration is lost after the CAN module starts transmission, the TRMACTIVE flag is set to 0. Transmission scanning is performed again to search for the highest-priority transmit mailbox from the beginning of the CRC delimiter. If an error occurs either during transmission or following arbitration-lost, transmission scanning is performed again to search for the highest-priority transmit mailbox from the start of the error delimiter.

29.8 Interrupts

The CAN module provides the following interrupts for each channel. Table 29.11 lists the CAN interrupts.

- CANi reception complete interrupt for mailboxes 0 to 31 (CANi_RXM)
- CANi transmission complete interrupt for mailboxes 0 to 31 (CANi_TXM)
- CANi receive FIFO interrupt (CANi_RXF)
- CANi transmit FIFO interrupt (CANi_TXF)
- CANi error interrupt (CANi_ERS)

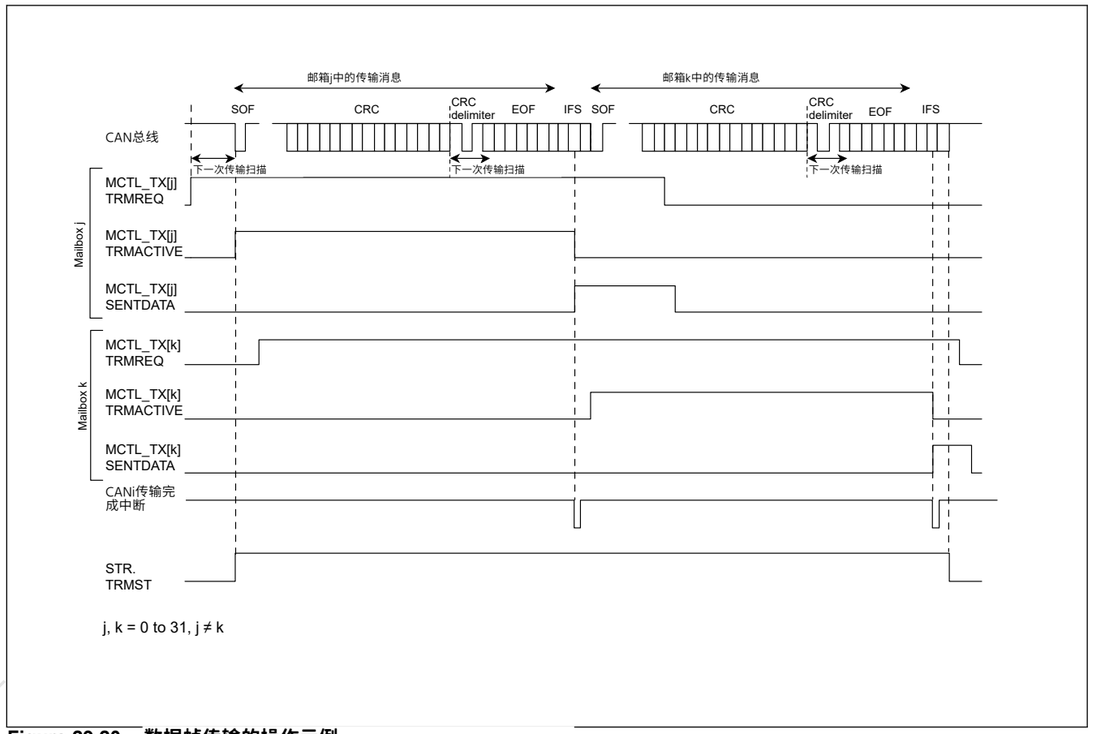

Figure 29.20 数据帧传输的操作示例

1.当MCTL_TX[j]（j=0到31）中的TRMREQ位在总线空闲状态下设置为1（发送邮箱）时，邮箱扫描开始决定发送的最高优先级邮箱。当确定发送邮箱时，MCTL_TX[j]中的TRMACTIVE标志置1（从接受发送请求到发送完成，或错误或仲裁丢失），STR中的TRMST位设置为1（发送进度），CAN模块开始传输。*1

2.如果设置了其他TRMREQ位，则传输扫描以CRC定界符开始，以进行下一次传输。

3.如果传输完成且没有丢失仲裁，则MCTL_TX[j]中的SENTDATA标志设置为1（传输完成），TRMACTIVE标志设置为0（传输未决或未请求传输）。如果MIER中的中断使能位为1（中断使能），则产生CANi传输完成中断请求。

4.从同一邮箱请求下一次发送时，将SENTDATA标志和TRMREQ位设置为0，然后在检查SENTDATA标志和TRMREQ位设置为0后将TRMREQ位设置为1。

注1.如果CAN模块开始发送后仲裁丢失，则TRMACTIVE标志设置为0。再次执行发送扫描以从CRC分隔符的开头搜索优先级最高的发送邮箱。如果在传输过程中或仲裁丢失后发生错误，则再次执行传输扫描以从错误分隔符的开头搜索最高优先级的传输邮箱。

CAN模块为每个通道提供以下中断。表29.11列出了CAN中断。

- ●邮箱0到31(CANi_RXM)的CANi接收完成中断

- ●CANi接收FIFO中断（CANi_RXF）
- ●CANi发送FIFO中断(CANi_TXF)

29.9 Usage Notes

29.9.1 Settings for the Module-Stop State

The MSTPCRB can enable or disable CAN operation. The CAN module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

29.9.2 Settings for the Operating Clock

The settings for the operating clock can be made as follows:

- The following clock constraint must be satisfied for the CAN module:

  $PCLKB \geq CANMCLK$

- The peripheral module clock source must be PLL for the CAN module when the CCLKS bit is 0.

八个中断源可用于CANi错误中断。检查EIFR以确定中断源：

●总线错误

- Error-warning
- Error-passive
- Bus-off entry
- Bus-off recovery

●接收溢出

The SPI automatically switches the I/O direction of the SSLn0 pin. SSLn0 is set as an output when the SPI is a single master, and as an input when the SPI is a multi-master or a slave. The RSPCKn, MOSIn, and MISOn pins are automatically set as inputs or outputs based on the master or slave setting and the level input on the SSLn0 pin. For details, see section 30.3.2. Controlling the SPI Pins.

SPMS bit (SPI Mode Select)

The SPMS bit selects SPI operation (4-wire method) or clock synchronous operation (3-wire method).

The SSLn0 to SSLn3 pins are not used in clock synchronous operation. The RSPCKn, MOSIn, and MISOn pins handle communications. For clock synchronous operation in master mode (MSTR = 1), the SPCMDm.CPHA bit can be set to either 0 or 1. For clock synchronous operation in slave mode (MSTR = 0), always set the CPHA bit to 1. Do not perform operations if the CPHA bit is set to 0 for clock synchronous operation in slave mode (MSTR = 0).

TXMD bit (Communications Operating Mode Select)

The TXMD bit selects full-duplex synchronous serial communications or transmit-only operations. When this bit is set to 1, the SPI only performs transmit operations and not receive operations (see section 30.3.6. Data Transfer Modes), and receive buffer full interrupt requests cannot be used.

TXMD setting is invalid in receive only slave mode.

MODFEN bit (Mode Fault Error Detection Enable)

The MODFEN bit enables or disables the detection of mode fault errors (see section 30.3.9. Error Detection). In addition, the SPI determines the I/O direction of the SSLni pins based on combination of the MODFEN and MSTR bits (see section 30.3.2. Controlling the SPI Pins).

SPMS位（SPI模式选择）

SPMS位选择SPI操作（4线方法）或时钟同步操作（3线方法）。

SSLn0到SSLn3引脚不用于时钟同步操作。RSPCKn、MOSIn和MIOn引脚处理通信。对于主机模式下的时钟同步操作(MSTR=1)，SPCMDm.CPHA位可以设置为0或1。对于从机模式下的时钟同步操作(MSTR=0)，始终将CPHA位设置为1。不要如果CPHA位设置为0以在从机模式下进行时钟同步操作（MSTR=0），则执行操作。

TXMD位（通信操作模式选择）

TXMD位选择全双工同步串行通信或仅发送操作。当该位设置为1时，SPI只执行发送操作而不执行接收操作（参见第30.3.6节。数据传输模式），并且不能使用接收缓冲区满中断请求。

TXMD设置在只接收从机模式下无效。

MODFEN位（模式故障错误检测使能）

MODFEN位启用或禁用模式故障错误检测（请参阅第30.3.9节。错误检测）。此外，SPI根据MODFEN和MSTR位的组合确定SSLni引脚的IO方向（参见第30.3.2节。控制SPI引脚）。

MSTR bit (SPI Master/Slave Mode Select)

The MSTR bit selects master or slave mode for the SPI. Based on the MSTR bit settings, the SPI determines the direction of the RSPCKn, MOSIn, MISOn, and SSLni pins.

SPEIE bit (SPI Error Interrupt Enable)

The SPEIE bit enables or disables the generation of SPI error interrupt requests when one of the following occurs:

- The SPI detects a mode fault error or underrun error and sets the SPSR.MODF flag to 1
- The SPI detects an overrun error and sets the SPSR.OVRF flag to 1
- The SPI detects a parity error and sets the SPSR.PERF flag to 1

For details, see section 30.3.9. Error Detection.

SPTIE bit (Transmit Buffer Empty Interrupt Enable)

The SPTIE bit enables or disables the generation of transmit buffer empty interrupt requests when the SPI detects that the transmit buffer is empty. To generate a transmit buffer empty interrupt request when transmission starts, set the SPE and SPTIE bits to 1 at the same time or set the SPE bit to 1 after setting the SPTIE bit to 1.

When the SPTIE bit is 1, transmit buffer interrupts are generated even when the SPI function is disabled (when the SPE bit is changed to 0).

SPE bit (SPI Function Enable)

The SPE bit enables or disables the SPI function. The SPE bit cannot be set to 1 when the SPSR.MODF flag is 1. For details, see section 30.3.9. Error Detection.

Setting the SPE bit to 0 disables the SPI function and initializes a part of the module function. For details, see section 30.3.10. Initializing the SPI. In addition, a transmit buffer empty interrupt request is generated when the SPE bit is changed from 0 to 1 or from 1 to 0.

SPRIE bit (SPI Receive Buffer Full Interrupt Enable)

The SPRIE bit enables or disables the generation of an SPI receive buffer full interrupt request when the SPI detects a receive buffer full write after completion of a serial transfer.

30.2.2 SSLP : SPI Slave Select Polarity Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x01

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	SSL3P	SSL2P	SSL1P	SSL0P
Value after reset:	0	0	0	0	0	0	0	0

2	SSL2P	SSLn2 Signal Polarity Setting 0: Set SSLn2 signal to active-low 1: Set SSLn2 signal to active-high	R/W
3	SSL3P	SSLn3 Signal Polarity Setting 0: Set SSLn3 signal to active-low 1: Set SSLn3 signal to active-high	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

MSTR位（SPI主从模式选择）

MSTR位选择SPI的主模式或从模式。根据MSTR位设置，SPI确定RSPCKn、MOSIn、MISOn和SSLni引脚的方向。

SPEIE位（SPI错误中断使能）

当发生以下情况之一时，SPEIE位启用或禁用SPI错误中断请求的生成：

- SPI检测到模式故障错误或欠载错误并将SPSR.MODF标志设置为1
- SPI检测到溢出错误并将SPSR.OVRF标志设置为1
- SPI检测到奇偶校验错误并将SPSR.PERF标志设置为1

有关详细信息，请参阅第30.3.9节。错误检测。

SPTIE位（发送缓冲区空中断允许）

当SPI检测到发送缓冲区为空时，SPTIE位使能或禁止生成发送缓冲区空中断请求。要在发送开始时产生发送缓冲区空中断请求，请将SPE和SPTIE位同时设置为1，或在将SPTIE位设置为1后将SPE位设置为1。

当SPTIE位为1时，即使禁用SPI功能（当SPE位变为0时）也会产生发送缓冲区中断。

SPE位（SPI功能使能）

SPE位启用或禁用SPI功能。当SPSR.MODF标志为1时，SPE位不能设置为1。详情请参见30.3.9节。错误检测。

将SPE位设置为0将禁用SPI功能并初始化部分模块功能。有关详细信息，请参阅第30.3.10节。初始化SPI。此外，当SPE位从0变为1或从1变为0时，会产生发送缓冲区空中断请求。

SPRIE位（SPI接收缓冲器满中断使能）

当SPI在串行传输完成后检测到接收缓冲区已满写入时，SPRIE位启用或禁用SPI接收缓冲区已满中断请求的生成。

30.2.2 SSLP：SPI从机选择极性寄存器

30.2.3 SPPCR : SPI Pin Control Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MOIFE	MOIFV	—	—	SPLP2	SPLP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPLP	SPI Loopback 0: Normal mode 1: Loopback mode (receive data = inverted transmit data)	R/W
1	SPLP2	SPI Loopback 2 0: Normal mode 1: Loopback mode (receive data = transmit data)	R/W

4	MOIFV	MOSI Idle Fixed Value 0: Set level output on MOSIn pin during MOSI idling to low 1: Set level output on MOSIn pin during MOSI idling to high	R/W
5	MOIFE	MOSI Idle Value Fixing Enable 0: Set MOSI output value to equal final data from previous transfer 1: Set MOSI output value to equal value set in the MOIFV bit	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

SPLP bit (SPI Loopback)

The SPLP bit selects the mode of the SPI pins. When this bit is set to 1, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0. The SPI then inverts the value of the input path for the shift register and connects it to the output path (loopback mode). For more information, see section 30.3.13. Loopback Mode.

SPLP2 bit (SPI Loopback 2)

The SPLP2 bit selects the mode of the SPI pins. When this bit is set to 1, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0. The SPI then connects the value of the input path for the shift register to the output path (loopback mode) without inverting the value. For more information, see section 30.3.13. Loopback Mode.

MOIFV bit (MOSI Idle Fixed Value)

The MOIFV bit determines the MOSIn pin output value during the SSL negation period (including the SSL retention period during a burst transfer) when the MOIFE bit is 1 in master mode.

MOIFE bit (MOSI Idle Value Fixing Enable)

The MOIFE bit fixes the MOSIn output value when the SPI is in master mode and in an SSL negation period (including the SSL retention period during a burst transfer).When the MOIFE bit is 0, the SPI outputs the last data from the previous serial transfer during the SSL negation period to the MOSIn pin. When the MOIFE bit is 1, the SPI outputs the fixed value set in the MOIFV bit to the MOSIn pin.

30.2.3 SPPCR:SPI引脚控制寄存器

Base address: SPI0 = 0x4011_A000

Offset address: 0x02

5	MOIFE	MOSI空闲值固定启用 0：设置MOSI输出值等于上次传输的最终数据1：设置MOSI输出值等于MOIFV位中设置的值	R/W
7:6	—	这些位被读取为0。写入值应为0。	R/W

SPLP bit (SPI Loopback)

SPLP位选择SPI引脚的模式。当该位设置为1时，如果SPCR.MSTR位为1，则SPI关闭MIOn引脚和移位寄存器之间的路径，如果SPCR.MSTR位为0，则关闭MOSIn引脚和移位寄存器之间的路径。SPI然后反转移位寄存器的输入路径的值并将其连接到输出路径（环回模式）。有关详细信息，请参阅第30.3.13节。环回模式。

SPLP2 bit (SPI Loopback 2)

SPLP2位选择SPI引脚的模式。当该位设置为1时，如果SPCR.MSTR位为1，则SPI关闭MIOn引脚和移位寄存器之间的路径，如果SPCR.MSTR位为0，则关闭MOSIn引脚和移位寄存器之间的路径。然后SPI将移位寄存器的输入路径的值连接到输出路径（环回模式），而不反转该值。有关详细信息，请参阅第30.3.13节。环回模式。

MOIFV位（MOSI空闲固定值）

MOIFV位决定主模式下MOIFE位为1时SSL否定期间（包括突发传输期间的SSL保持期间）的MOSIn引脚输出值。

MOIFE位（MOSI空闲值固定启用）

MOIFE位固定SPI处于主机模式和SSL否定周期（包括突发传输期间的SSL保持周期）时的MOSIn输出值。当MOIFE位为0时，SPI输出上一个串行的最后一个数据在SSL否定期间传输到MOSIn引脚。当MOIFE位为1时，SPI将MOIFV位中设置的固定值输出到MOSIn引脚。

The OVRF flag indicates the occurrence of an overrun error. In master mode (SPCR.MSTR bit = 1) and when the RSPCK clock auto-stop function is enabled (SPCR1.SCKASE bit = 1), overrun errors do not occur. This flag does not set to 1. For details, see section 30.3.9.1. Overrun errors.

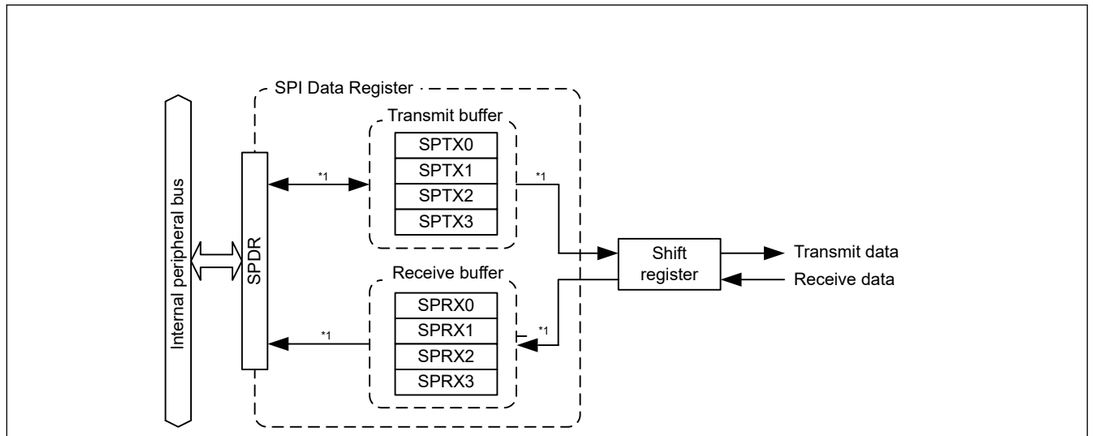
SPDRSPDR_HASPDR_BY是与缓冲区的接口，缓冲区保存数据以供SPI发送和接收。以字访问该寄存器时（SPDCR.SPLW位为1），访问SPDR。当以半字访问它时（

SPLW位为0)，访问SPDR_HA。当按字节访问时（SPDCR.SPBYT位为1），访问SPDR_BY。

The transmit buffer (SPTX) and receive buffer (SPRX) are independent but are both mapped to SPDR/SPDR_HA. Figure 30.2 shows the configuration of the SPDR/SPDR_HA register.



Note: SPDR = SPDR/SPDR_HA/SPDR_BY
Note 1. The destination buffer and stage for access is automatically switched by the hardware.

Figure 30.2 Configuration of SPDR/SPDR_HA/SPDR_BY

The transmit and receive buffers each have one stages. The four stages of the buffer are all mapped to the single address of SPDR/SPDR_HA/SPDR_BY.

Data written to SPDR/SPDR_HA/SPDR_BY is written to a transmit-buffer stage (SPTXn) (n = 0 to 3), and then transmitted from the buffer. The receive buffer holds received data on completion of reception. The receive buffer is not updated if an overrun is generated.

Additionally, if the data length is not 32 bits, bits not referred to in SPTXn (n = 0 to 3) are stored in the associated bits in SPRXn (n = 0 to 3). For example, if the data length is 9 bits, the received data is stored in the SPRXn[8:0] bits, and the SPTXn[31:9] bits are stored in the SPRXn[31:9] bits.

(1) Bus interface

SPDR/SPDR_HA/SPDR_BY is an interface with 32-bit wide transmit and receive buffers, each of which has one stages, for a total of 32 bytes. The 32 bytes are mapped to the 4-byte address space for SPDR/SPDR_HA/SPDR_BY. Additionally, the unit of access for SPDR/SPDR_HA/SPDR_BY is selected by the SPI Word Access/Halfword Access Specification bit in the SPI Data Control Register (SPDCR.SPLW). SPDR can also be accessed with the access size specified by the SPI Byte Access bit in the SPI Data Control Register (SPDCR.SPBYT).

Flush the transmission data at the LSB end of the register, and store the received data at the LSB end.

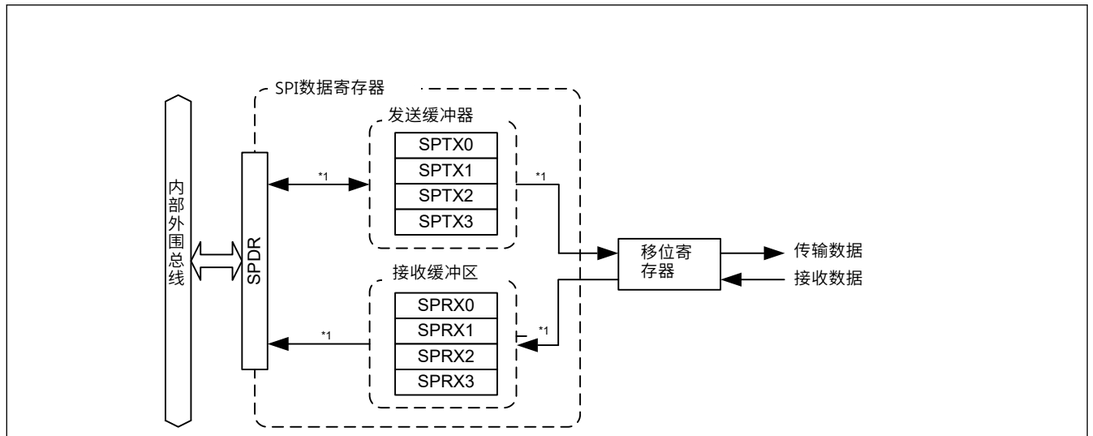
The following sections describe the operations involved in writing to and reading from SPDR/SPDR_HA/SPDR_BY.

Writing

Data written to SPDR/SPDR_HA/SPDR_BY is written to a transmit buffer (SPTXn). This is not affected by the value of the SPDCR.SPRDTD bit, unlike when reading from SPDR/SPDR_HA/SPDR_BY. The transmit buffer includes a transmit buffer write pointer that is automatically updated to reference the next stage each time data is written to SPDR/SPDR_HA/SPDR_BY.

Figure 30.3 shows the configuration of the bus interface with the transmit buffer when writing to SPDR/SPDR_HA/SPDR_BY.

发送缓冲区(SPTX)和接收缓冲区(SPRX)是独立的，但都映射到SPDRSPDR_HA。图30.2显示了SPDRSPDR_HA寄存器的配置。



Note: SPDR = SPDR/SPDR_HA/SPDR_BY
注1.访问的目标缓冲区和阶段由硬件自动切换。

Figure 30.2 SPDRSPDR_HASPDR_BY的配置

发送和接收缓冲器各有一级。缓冲区的四个阶段都映射到单个地址
SPDR/SPDR_HA/SPDR_BY.

写入SPDRSPDR_HASPDR_BY的数据被写入发送缓冲区级(SPTXn)(n=0到3)，然后从缓冲区发送。接收缓冲器在接收完成时保存接收到的数据。如果产生溢出，接收缓冲区不会更新。

此外，如果数据长度不是32位，SPTXn(n=0到3)中未提及的位将存储在
SPRXn（n=0到3）。例如，如果数据长度为9位，则接收到的数据存储在SPRXn[8:0]位中，而
SPTXn[31:9]位存储在SPRXn[31:9]位中。

(1) 总线接口

SPDRSPDR_HASPDR_BY是一个具有32位宽的发送和接收缓冲区的接口，每个缓冲区都有一个阶段，总共32个字节。32个字节映射到SPDRSPDR_HASPDR_BY的4字节地址空间。此外，SPDRSPDR_HASPDR_BY的访问单元由SPI数据控制寄存器(SPDCR.SPLW)中的SPI字访问半字访问规范位选择。SPDR也可以通过SPI字节指定的访问大小进行访问

SPI数据控制寄存器(SPDCR.SPBYT)中的访问位。

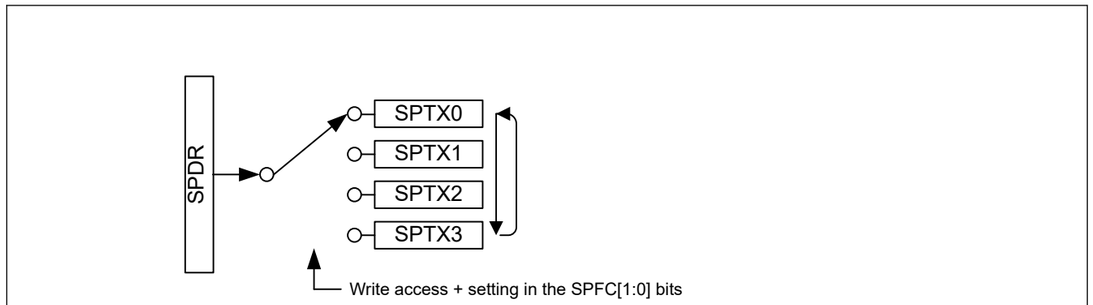
在寄存器的LSB端刷新发送数据，在LSB端存储接收到的数据。

以下部分描述了写入和读取SPDRSPDR_HASPDR_BY所涉及的操作。

Writing

写入SPDRSPDR_HASPDR_BY的数据被写入发送缓冲区(SPTXn)。这不受价值的影响
SPDCR.SPRDTD位，与从SPDRSPDR_HASPDR_BY读取时不同。发送缓冲区包括一个发送缓冲区写指针，每次将数据写入SPDRSPDR_HASPDR_BY时，该指针会自动更新以引用下一阶段。

图30.3显示了写入SPDRSPDR_HA时带有发送缓冲区的总线接口的配置
SPDR_BY.



Note: SPDR = SPDR/SPDR_HA/SPDR_BY

Figure 30.3 Configuration of SPDR/SPDR_HA/SPDR_BY for write access

The sequence for switching the transmit buffer write pointer differs with the setting of the number of frames specification bits in the SPI Data Control Register (SPDCR.SPFC[1:0]). The relationship of the SPFC[1:0] setting and the sequence of pointer switching from SPTX0 to SPTX3 is as follows:

- When SPFC[1:0] = 00b: SPTX0 → SPTX0 → SPTX0 → …
- When SPFC[1:0] = 01b: SPTX0 → SPTX1 → SPTX0 → SPTX1 → …
- When SPFC[1:0] = 10b: SPTX0 → SPTX1 → SPTX2 → SPTX0 → SPTX1 → …
- When SPFC[1:0] = 11b: SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → …

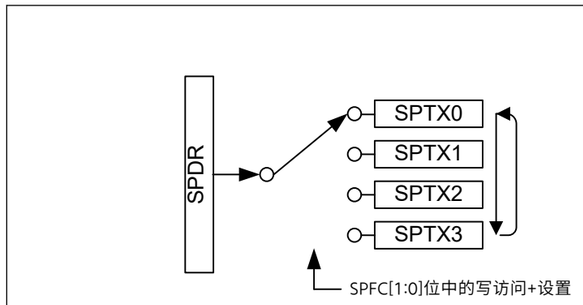
When 1 is written to the SPI Function Enable bit in the SPI Control Register (SPCR.SPE) while the bit is 0, SPTX0 is the destination for the next write.

When writing to the transmit buffer (SPTXn) after generating the transmit buffer empty interrupt (when SPSR.SPTEF is 1), write the number of frames set in SPFC[1:0] in the SPI Data Control Register (SPDCR). Even when the specified number of frames is written to the transmit buffer (SPTXn), the value of the buffer is not updated after completion of the writing and before generation of the next transmit buffer empty interrupt (when SPTEF is 0).

Reading

SPDR/SPDR_HA/SPDR_BY can be accessed to read the value of a receive buffer (SPRXn) or a transmit buffer (SPTXn). The setting in the SPI Receive/Transmit Data Select bit in the SPI Data Control Register (SPDCR.SPRDTD) selects whether reading is of the receive or transmit buffer. The sequence of reading the SPDR/SPDR_HA/SPDR_BY register is controlled by the independent receive buffer and transmit buffer read pointers.

Figure 30.4 shows the configuration of the bus interface with the receive and transmit buffers for reading from SPDR/ SPDR_HA/SPDR_BY.



Note: SPDR = SPDR/SPDR_HA/SPDR_BY

Figure 30.3 为写访问配置SPDRSPDR_HASPDR_BY

发送缓冲区写指针的切换顺序因SPI数据控制寄存器(SPDCR.SPFC[1:0])中帧数规范位的设置而异。SPFC[1:0]设置与指针从SPTX0切换到SPTX3的顺序关系如下：

- When SPFC[1:0] = 00b: SPTX0 → SPTX0 → SPTX0 → …
- When SPFC[1:0] = 01b: SPTX0 → SPTX1 → SPTX0 → SPTX1 → …
- When SPFC[1:0] = 10b: SPTX0 → SPTX1 → SPTX2 → SPTX0 → SPTX1 → …
- When SPFC[1:0] = 11b: SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → …

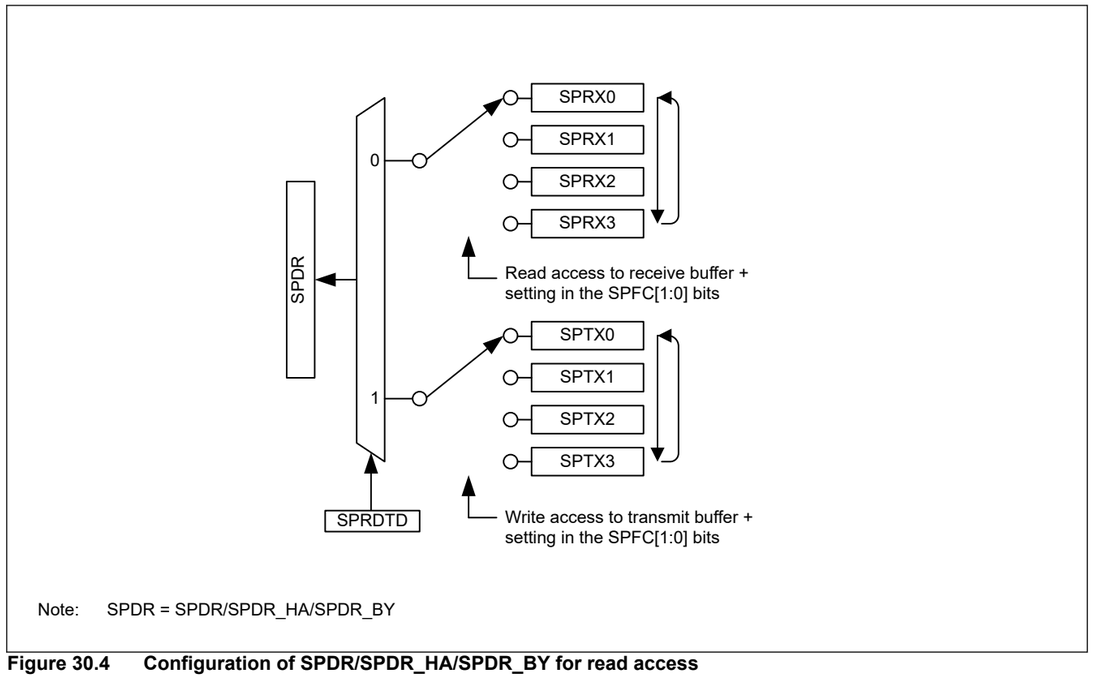
当1写入SPI控制寄存器(SPCR.SPE)中的SPI功能使能位且该位为0时，SPTX0是下一次写入的目标。

在产生发送缓冲区空中断后写入发送缓冲区(SPTXn)时（当SPSR.SPTEF为1时），将SPFC[1:0]中设置的帧数写入SPI数据控制寄存器(SPDCR)。即使指定的帧数被写入发送缓冲区(SPTXn)，缓冲区的值在写入完成后和下一个发送缓冲区空中断发生之前（SPTEF为0时）也不会更新。

Reading

SPDRSPDR_HA可以访问SPDR_BY以读取接收缓冲区(SPRXn)或发送缓冲区(SPTXn)的值。
SPI数据控制寄存器(SPDCR.SPRDTD)的SPI接收发送数据选择位中的设置选择读取接收缓冲区还是发送缓冲区。
读取SPDRSPDR_HASPDR_BY寄存器的顺序由独立的接收缓冲区和发送缓冲区读取指针控制。

图30.4显示了带有用于从SPDR读取的接收和发送缓冲区的总线接口配置
SPDR_HA/SPDR_BY.



Note: SPDR = SPDR/SPDR_HA/SPDR_BY

Figure 30.4 Configuration of SPDR/SPDR_HA/SPDR_BY for read access

Reading the receive buffer switches the receive buffer read pointer to the next buffer automatically. The switching sequence for the receive buffer read pointer is the same as that for the transmit buffer write pointer. However, when 1 is written to the SPI Function Enable bit in the SPI Control Register (SPCR.SPE) while the value of the bit is 1, SPRX0 is referenced by the buffer read pointer for the next read.

The transmit buffer read pointer is updated when writing to SPDR/SPDR_HA/SPDR_BY, but not updated when reading from the transmit buffer. When reading from the transmit buffer, the value most recently written to SPDR/SPDR_HA/SPDR_BY is read.

After a transmit buffer empty interrupt is generated, reading from the transmit buffer returns all 0s after the completion of writing the number of frames of data specified in the SPDCR.SPFC[1:0] bits, until the next buffer empty interrupt is generated (when SPTEF is 0).

读取接收缓冲区会自动将接收缓冲区读取指针切换到下一个缓冲区。接收缓冲区读指针的切换顺序与发送缓冲区写指针的切换顺序相同。但是，当1写入SPI控制寄存器(SPCR.SPE)中的SPI功能使能位且该位的值为1时，缓冲区读取指针将引用SPRX0以进行下一次读取。

发送缓冲区读指针在写入SPDRSPDR_HASPDR_BY时更新，但在从发送缓冲区读取时不更新。从发送缓冲区读取时，会读取最近写入SPDRSPDR_HASPDR_BY的值。

产生发送缓冲区空中断后，在完成写入SPDCR.SPFC[1:0]位中指定的数据帧数后，从发送缓冲区读取返回全0，直到产生下一个缓冲区空中断（当SPTEF为0时）。

SPSLN[2:0] bits (SPI Sequence Length Specification)

The SPSLN[2:0] bits specify the sequence length when the SPI in master mode performs sequential operations. The SPI in master mode changes the SPCMD0 to SPCMD7 registers to be referenced, and the order in which they are referenced is based on this sequence length setting. In slave mode, SPCMD0 is referenced.

SPSLN[2:0]位（SPI序列长度规范）

SPSLN[2:0]位指定SPI在主模式下执行顺序操作时的序列长度。主机模式下的SPI将SPCMD0到SPCMD7寄存器更改为被引用，它们被引用的顺序基于此序列长度设置。在从模式下，以SPMD0为参考。

SPCP[2:0] bits (SPI Command Pointer)

The SPCP[2:0] bits indicate the SPCMDm register that is referenced to by the pointer during sequence control by the SPI. For the SPI sequence control, see section 30.3.11.1. Master mode operation.

SPECM[2:0] bits (SPI Error Command)

The SPECM[2:0] bits indicate the SPCMDm register that is specified in the SPCP[2:0] bits when an error is detected during sequence control by the SPI. The SPI updates the SPECM[2:0] bits only when an error is detected. If both the SPSR.OVRF and SPSR.MODF flags are 0 and there is no error, the values of the SPECM[2:0] bits have no meaning.

For the SPI error detection function, see section 30.3.9. Error Detection. For the SPI sequence control, see section 30.3.11.1. Master mode operation.

30.2.8 SPBR : SPI Bit Rate Register

Base address: SPI0 = 0x4011_A000

Offset address: 0x0A

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	n/a	Bit rate	R/W

SPBR sets the bit rate in master mode.

When the SPI is in slave mode, the bit rate depends on the bit rate of the input clock, regardless of the settings in SPBR and the SPCMDm.BRDV[1:0] bits (bit rate division setting). Use bit rates that satisfy the electrical characteristics of the device.

The bit rate is determined by combinations of the SPBR and SPCMDm.BRDV[1:0] settings in the SPI Command Register. The equation for calculating the bit rate is given as follows:

$$\text{Bit rate} = \frac{f(\text{PCLK})}{2 \times (n+1) \times 2^N}$$

(PCLK = PCLKA)

In the equation, n denotes an SPBR setting (0, 1, 2, …, 255), and N denotes a BRDV[1:0] setting (0, 1, 2, 3).

Table 30.3 lists examples of the relationship between the SPBR settings, the BRDV[1:0] settings, and bit rates.

SPECM[2:0]位（SPI错误命令）

SPECM[2:0]位指示在SPI序列控制期间检测到错误时在SPCP[2:0]位中指定的SPCMDm寄存器。SPI仅在检测到错误时更新SPECM[2:0]位。如果SPSR.OVRF和SPSR.MODF标志均为0且没有错误，则SPECM[2:0]位的值没有意义。

关于SPI错误检测功能，请参见第30.3.9节。错误检测。有关SPI序列控制，请参阅第30.3.11.1节。

SPBR在主模式下设置比特率。

当SPI处于从机模式时，比特率取决于输入时钟的比特率，与SPBR和SPMDm.BRDV[1:0]位（比特率分频设置）的设置无关。使用满足设备电气特性的比特率。

比特率由SPI命令寄存器中的SPBR和SPMDm.BRDV[1:0]设置的组合确定。
计算比特率的公式如下：

$$\text{比特率} = \frac{f(\text{PCLK})}{2 \times (n+1) \times 2^N}$$

(PCLK = PCLKA)

在等式中，n表示SPBR设置(0 1 2 … 255)，N表示BRDV[1:0]设置(0 1 2 3)。

表30.3列出了SPBR设置、BRDV[1:0]设置和比特率之间的关系示例。

The SPI Data Control Register (SPDCR) is used to read the number of frames that can be stored in the SPDR register,read the SPDR register, and to set the access width for the SPDR register to word access, halfword access, or byte access. Up to four frames can be transmitted or received in one round of transmission or reception. The amount of data in each transfer is controlled by the combination of the SPCMDm.SPB[3:0] bits, the SPSCR.SPSLN[2:0] bits, and the SPFC[1:0] bits.

When changing the SPFC[1:0] bits while the SPCR.SPE bit is 1, check that the SPSR.IDLNF flag is 0.

SPFC[1:0] bits (Number of Frames Specification)

The SPFC[1:0] bits specify the number of frames that can be stored in SPDR/SPDR_HA per transfer activation. Up to four frames can be transmitted or received in one round of transmission or reception.

When the number of transmission data frames specified in the SPFC[1:0] bits is written to the SPDR/SPDR_HA register, SPI clears the SPSR.SPTEF flag to 0 and begins transmitting. After that, when the number of transmission data frames specified in the SPFC[1:0] bits is transmitted to the shift register, the SPI generates the transmit buffer empty interrupt (SPSR.SPTEF sets to 1).

When the number of data frames specified in the SPFC[1:0] bits is received, the SPI generates the receive buffer full interrupt (SPSR.SPRF sets to 1).

SPI数据控制寄存器(SPDCR)用于读取SPDR寄存器中可存储的帧数，读取SPDR寄存器，并将SPDR寄存器的访问宽度设置为字访问、半字访问或字节访问.在一轮发送或接收中最多可以发送或接收四帧。每次传输中的数据量由SPCMDm.SPB[3:0]位、SPSCR.SPSLN[2:0]位和SPFC[1:0]位的组合控制。

在SPCR.SPE位为1时更改SPFC[1:0]位时，检查SPSR.IDLNF标志是否为0。

SPFC[1:0]位（帧数规范）

SPFC[1:0]位指定每次传输激活时可以存储在SPDRSPDR_HA中的帧数。在一轮发送或接收中最多可以发送或接收四帧。

当SPFC[1:0]位中指定的传输数据帧数写入SPDRSPDR_HA寄存器时，SPI将SPSR.SPTEF标志清除为0并开始发送。之后，当SPFC[1:0]位中指定的发送数据帧数被发送到移位寄存器时，SPI产生发送缓冲区空中断（SPSR.SPTEF设置为1）。

当接收到SPFC[1:0]位中指定的数据帧数时，SPI产生接收缓冲区满中断（SPSR.SPRF设置为1）。

SPRDTD bit (SPI Receive/Transmit Data Select)

The SPRDTD bit selects whether the SPDR/SPDR_HA reads values from the receive buffer or from the transmit buffer. If reading is from the transmit buffer, the last value written to SPDR/SPDR_HA register is read. Read the transmit buffer after an SPI transmit buffer empty interrupt is generated until data of frames specified by SPFC[1:0] has been written (while the SPSR.SPTEF flag is 1).

For details, see section 30.2.5. SPDR/SPDR_HA/SPDR_BY : SPI Data Register.

SPLW bit (SPI Word Access/Halfword Access Specification)

The SPLW bit specifies the access width for SPDR. Access to SPDR_HA in halfwords is valid when the SPLW bit is 0 and access to SPDR in words is valid when the SPLW bit is 1. Also, when this bit is 0, set the SPI data length setting bits, SPCMDm.SPB[3:0], from 8 to 16 bits. Do not perform any operations when a data length of 20, 24, or 32 bits is specified.

SPBYT bit (SPI Byte Access Specification)

The SPBYT bit is used to set the data width of access to the SPI Data Register (SPDR). When SPBYT = 0, use word or half word access to SPDR/SPDR_HA. When SPBYT = 1 (in that case, SPLW is invalid), use byte access to SPDR_BY.

When SPBYT = 1, set the SPI data length bits (SPB[3:0]) in the SPI Command Register m (SPCMDm) to 8 bits. If SPB[3:0] are set to 9 to 16, 20, 24, or 32 bit, subsequent operation is not guaranteed.

30.2.10 SPCKD : SPI Clock Delay Register

Table 30.4 SPSLN[2:0]和SPFC[1:0]位的可设置组合（2个中的2个）

SPRDTD位（SPI接收发送数据选择）

SPRDTD位选择SPDRSPDR_HA是从接收缓冲区还是从发送缓冲区读取值。如果从发送缓冲区读取，则读取写入SPDRSPDR_HA寄存器的最后一个值。在产生SPI发送缓冲区空中断后读取发送缓冲区，直到SPFC[1:0]指定的帧数据被写入（此时SPSR.SPTEF标志为1）。

有关详细信息，请参阅第30.2.5节。SPDRSPDR_HASPDR_BY：SPI数据寄存器。

SPLW位（SPI字访问半字访问规范）

SPLW位指定SPDR的访问宽度。当SPLW位为0时，以半字访问SPDR_HA有效，当SPLW位为1时，以字访问SPDR有效。此外，当该位为0时，设置SPI数据长度设置位SPMDm.SPB[3：0]，从8到16位。当指定数据长度为20、24或32位时，请勿执行任何操作。

SPBYT位（SPI字节访问规范）

SPBYT位用于设置访问SPI数据寄存器(SPDR)的数据宽度。当SPBYT=0时，使用字或半字访问SPDRSPDR_HA。当SPBYT=1时（在这种情况下，SPLW无效），使用对SPDR_BY的字节访问。

当SPBYT=1时，将SPI命令寄存器m(SPCMDm)中的SPI数据长度位(SPB[3:0])设置为8位。如果SPB[3:0]设置为9至16、20、24或32位，不保证后续操作。

7:5	—	These bits are read as 0. The write value should be 0.	R/W

SPPE bit (Parity Enable)

The SPPE bit enables or disables the parity function.

When the SPCR.TXMD bit is 0 and this bit is 1, the parity bit is added to transmit data and parity checking is performed for receive data.

When the SPCR.TXMD bit is 1 and this bit is 1, the parity bit is added to transmit data but parity checking is not performed for receive data.

SPOE bit (Parity Mode)

The SPOE bit specifies odd or even parity.

When even parity is set, parity bit addition is performed so that the total number of bits whose value is 1 in the transmit or receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit addition is performed so that the total number of bits whose value is 1 in the transmit or receive character plus the parity bit is odd.

The SPOE bit is only valid when the SPPE bit is 1.

SPIIE bit (SPI Idle Interrupt Enable)

The SPIIE bit enables or disables the generation of SPI idle interrupt requests when an idle state is detected in the SPI and the SPSR.IDLNF flag clears is set to 0.

PTE bit (Parity Self-Testing)

The PTE bit enables self-diagnosis of the parity circuit to check whether the parity function is operating correctly.

SPNDL[2:0]位（SPI下一次访问延迟设置）

当SPMDm.SPNDEN位为1时，SPNDL[2:0]位指定下一次访问延迟。在从机模式下使用SPI时，将SPNDL[2:0]位设置为000b。

SPPE bit (Parity Enable)

SPPE位启用或禁用奇偶校验功能。

当SPCR.TXMD位为0且该位为1时，发送数据添加奇偶校验位，接收数据执行奇偶校验。

当SPCR.TXMD位为1且该位为1时，发送数据添加奇偶校验位，但接收数据不执行奇偶校验。

SPOE bit (Parity Mode)

SPOE位指定奇校验或偶校验。

当设置了偶校验时，执行奇偶校验位相加，以使发送或接收字符中值为1的总位数加上奇偶校验位为偶数。类似地，当设置奇校验时，执行校验位相加，使得发送或接收字符中值为1的位加上奇偶校验位的总数为奇数。

SPOE位仅在SPPE位为1时有效。

SPIIE位（SPI空闲中断允许）

当在SPI中检测到空闲状态并且SPSR.IDLNF标志清除设置为0时，SPIIE位启用或禁用SPI空闲中断请求的生成。

PTE bit (Parity Self-Testing)

PTE位启用奇偶校验电路的自诊断，以检查奇偶校验功能是否正常运行。

SCKASE bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit enables or disables the RSPCK auto-stop function. When this function is enabled, the RSPCK clock is stopped before an overrun error occurs, when data is received in master mode. For details, see section 30.3.9.1. Overrun errors.

15	SCKDEN	RSPCK Delay Setting Enable 0: Select RSPCK delay of 1 RSPCK 1: Select RSPCK delay equal to the setting in the SPI Clock Delay Register (SPCKD)	R/W

The SPCMDm registers specify the transfer format for the SPI in master mode. Each channel has eight SPCMDm (m = 0 to 7). Some of the bits in the SPCMD0 registers are used to set the transfer mode for the SPI in slave mode. The SPI in master mode sequentially references the SPCMDm registers based on the settings in the SPSCR.SPSLN[2:0] bits and executes the serial transfer that is set in the referenced SPCMDm registers.

Set the SPCMDm registers while the transmit buffer is empty (SPSR.SPTEF is 1 and data for the next transfer is not set) and before the setting of the data to be transmitted when that SPCMDm registers is referenced.

The SPCMDm registers referenced by the SPI in master mode can be checked by means of the SPSSR.SPCP[2:0] bits.

CPHA bit (RSPCK Phase Setting)

The CPHA bit selects the RSPCK phase of the SPI in master or slave mode. Data communications between SPI modules require the same RSPCK phase setting between the modules.

CPOL bit (RSPCK Polarity Setting)

The CPOL bit selects the RSPCK polarity of the SPI in master or slave mode. Data communications between SPI modules require the same RSPCK polarity setting between the modules.

BRDV[1:0] bits (Bit Rate Division Setting)

The BRDV[1:0] bits determine the bit rate in combination with the settings in the SPBR register. (see section 30.2.8. SPBR : SPI Bit Rate Register). The SPBR settings determine the base bit rate. The BRDV[1:0] setting selects the bit rate obtained by dividing the base bit rate by 1, 2, 4, or 8. Different BRDV[1:0] bit settings can be specified in the SPCMD0 register. This enables execution of serial transfers at different bit rates for each command.

SSLA[2:0] bits (SSL Signal Assertion Setting)

The SSLA[2:0] bits control the SSLni signal assertion when the SPI performs serial transfers in master mode. When an SSLni signal is asserted, its polarity is determined by the value set in the associated SSLP. When the SSLA[2:0] bits are set to 000b in multi-master mode, serial transfers are performed with all the SSL signals in the negated state (as the SSLn0 pin acts as input).

When using the SPI in slave mode, set the SSLA[2:0] bits to 000b.

SSLKP bit (SSL Signal Level Keeping)

When the SPI in master mode performs a serial transfer, the SSLKP bit specifies whether the SSLni signal level for the current command is to be kept or negated between the SSL negation associated with the current command and the SSL assertion associated with the next command. Setting the SSLKP bit to 1 enables a burst transfer. For details, see section 30.3.11.1. Master mode operation. When using the SPI in slave mode, set the SSLKP bit to 0.

SPB[3:0] bits (SPI Data Length Setting)

The SPB[3:0] bits specify the transfer data length for the SPI in master or slave mode.

LSBF bit (SPI LSB First)

The LSBF bit specifies the data format of the SPI in master or slave mode to MSB-first or LSB-first.

SPNDEN bit (SPI Next-Access Delay Enable)

The SPNDEN bit specifies the next-access delay, the period from the time the SPI in master mode terminates a serial transfer and sets the SSLni signal inactive until the SPI enables the SSLni signal assertion for the next access. If the SPNDEN bit is 0, the SPI sets the next-access delay to 1 RSPCK + 2 PCLKA. If the SPNDEN bit is 1, the SPI inserts a next-access delay according to the SPND setting.

Bit	Symbol	Function	R/W
14	SLNDEN	SSL否定延迟设置启用 0：选择SSL否定延迟1RSPCK1：选择SSL否定延迟等于SPI从选择否定延迟寄存器(SSLND)中的设置	R/W
15	SCKDEN	RSPCK延迟设置启用 0：选择RSPCK延迟为1RSPCK1：选择RSPCK延迟等于SPI时钟延迟寄存器(SPCKD)中的设置	R/W

SPCMDm寄存器指定主模式下SPI的传输格式。每个通道有8个SPCMDm（m=0到7）。SPCMD0寄存器中的一些位用于设置SPI在从机模式下的传输模式。主机模式下的SPI根据SPSCR.SPSLN[2:0]位中的设置顺序引用SPCMDm寄存器，并执行在引用的SPCMDm寄存器中设置的串行传输。

在发送缓冲区为空时（SPSR.SPTEF为1且未设置下一次传输的数据）和设置要发送的数据之前，当引用该SPCMDm寄存器时设置SPCMDm寄存器。

SPI在主模式下引用的SPCMDm寄存器可以通过SPSSR.SPCP[2:0]位进行检查。

CPHA位（RSPCK相位设置）

CPHA位在主模式或从模式下选择SPI的RSPCK相位。SPI模块之间的数据通信需要模块之间相同的RSPCK相位设置。

CPOL位（RSPCK极性设置）

CPOL位在主模式或从模式下选择SPI的RSPCK极性。SPI模块之间的数据通信要求模块之间的RSPCK极性设置相同。

BRDV[1:0]位（比特率划分设置）

BRDV[1:0]位结合SPBR寄存器中的设置确定比特率。（参见第30.2.8节。SPBR：SPI比特率寄存器）。SPBR设置决定了基本比特率。BRDV[1:0]设置选择通过将基本比特率除以1、2、4或8获得的比特率。可以在SPCMD0寄存器中指定不同的BRDV[1:0]位设置。这使得每个命令能够以不同的比特率执行串行传输。

SSLA[2:0]位（SSL信号断言设置）

当SPI在主模式下执行串行传输时，SSLA[2:0]位控制SSLni信号断言。当一个SSLni信号被置位，其极性由相关SSLP中设置的值确定。当SSLA[2:0]位在多主机模式下设置为000b时，串行传输在所有SSL信号处于否定状态时执行（因为SSLn0引脚用作输入）。

在从机模式下使用SPI时，将SSLA[2:0]位设置为000b。

SSLKP位（SSL信号电平保持）

当主模式的SPI执行串行传输时，SSLKP位指定当前命令的SSLni信号电平是在与当前命令关联的SSL否定和与下一个命令关联的SSL断言之间保持还是否定。将SSLKP位设置为1可启用突发传输。有关详细信息，请参阅第30.3.11.1节。主模式操作。在从机模式下使用SPI时，将SSLKP位设置为0。

SPB[3:0]位（SPI数据长度设置）

SPB[3:0]位指定SPI在主模式或从模式下的传输数据长度。

LSBF bit (SPI LSB First)

LSBF位指定SPI在主模式或从模式下的数据格式为MSB优先或LSB优先。

SPNDEN位（SPI下一次访问延迟使能）

SPNDEN位指定下一次访问延迟，即从主模式下的SPI终止串行传输并将SSLni信号设置为无效到SPI为下一次访问启用SSLni信号断言的时间段。如果SPNDEN位为0，则SPI将下一次访问延迟设置为1RSPCK+2PCLKA。如果SPNDEN位为1，则SPI根据SPND设置插入下一次访问延迟。

When using the SPI in slave mode, set the SPNDEN bit to 0.

SLNDEN bit (SSL Negation Delay Setting Enable)

The SLNDEN bit specifies the SSL negation delay, the period from the time the SPI in master mode stops RSPCK oscillation until the SPI sets the SSLni signal to inactive. If the SLNDEN bit is 0, the SPI sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, the SPI negates the SSL signal at the SSL negation delay according to the SSLND setting.

When using the SPI in slave mode, set the SLNDEN bit to 0.

SCKDEN bit (RSPCK Delay Setting Enable)

The SCKDEN bit specifies the SPI clock delay, the period from the point when the SPI in master mode asserts the SSLni signal until the RSPCK starts oscillation. If the SCKDEN bit is 0, the SPI sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, the SPI starts the oscillation of RSPCK at an RSPCK delay according to the SPCKD setting.

When using the SPI in slave mode, set the SCKDEN bit to 0.

30.2.15 SPDCR2 : SPI Data Control Register 2

Base address: SPI0 = 0x4011_A000

Offset address: 0x20

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SINV	BYSW
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BYSW	Byte Swap Operating Mode Select 0: Byte Swap OFF 1: Byte Swap ON	R/W
1	SINV	Serial Data Invert Bit 0: Not invert serial data 1: Invert serial data	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

SPI Data Control Register 2 (SPDCR2) is the setting register, that is to swap a transmit/receive data in byte units and to invert serial data. If these bits are modified while the SPI in slave mode is enabled (SPCR.SPE = 1), subsequent operation is not guaranteed.

BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. When byte access is valid (SPDCR.SPBYT = 1), byte swap is invalid. When byte swap is valid, parity function must be invalid (SPCR2.SPPE bit = 0). Setting change of BYSW bit must be SPCR.SPE bit = 0.

A data after byte swap is different by a data length (setting of SPCMD.SPB[3:0]).

When byte swap, A data length (setting of SPB[3:0]) must be set to 32 bit or 16bit. Other case of data length (that is 8 to 15, 20, 24 bit length), byte swap is not guaranteed. Before swap and after swap are shown below (length data (32 bit/16 bit)).

- Length data 32 bits (SPB[3:0] = 0010b or 0011b)

  Before swap: [31:24] [23:16] [15:8] [7:0]

  After swap: [7:0] [15:8] [23:16] [31:24]
- Length data 16 bit (SPB[3:0] = 1111b)

  Before swap: [31:24] [23:16]

  After swap: [23:16] [31:24]

When byte access mode (SPDCR.SPBT = 1), byte swap setting is invalid.

在从机模式下使用SPI时，将SPNDEN位设置为0。

SLNDEN位（SSL否定延迟设置启用）

SLNDEN位指定SSL否定延迟，即从主模式下的SPI停止RSPCK振荡到SPI将SSLni信号设置为无效的时间段。如果SLNDEN位为0，则SPI将SSL否定延迟设置为1RSPCK。如果SLNDEN位为1，则SPI根据SSLND设置在SSL否定延迟时否定SSL信号。

在从机模式下使用SPI时，将SLNDEN位设置为0。

SCKDEN位（RSPCK延迟设置使能）

SCKDEN位指定SPI时钟延迟，即从主模式下的SPI断言SSLni信号到RSPCK开始振荡的周期。如果SCKDEN位为0，则SPI将RSPCK延迟设置为1RSPCK。如果SCKDEN位为1，则SPI根据SPCKD设置以RSPCK延迟启动RSPCK的振荡。

在从机模式下使用SPI时，将SCKDEN位设置为0。

30.2.15 SPDCR2:SPI数据控制寄存器2

Base address: SPI0 = 0x4011_A000

Offset address: 0x20

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SINV	BYSW
重置后的值：	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BYSW	字节交换操作模式选择 0：字节交换关闭1 ：字节交换开启	R/W
1	SINV	串行数据反转位 0：不反转串行数据1： 反转串行数据	R/W
7:2	—	这些位被读取为0。写入值应为0。	R/W

SPI数据控制寄存器2(SPDCR2)是设置寄存器，即以字节为单位交换发送接收数据和反转串行数据。如果在使能从模式下的SPI(SPCR.SPE=1)时修改这些位，则无法保证后续操作。

BYSW位（字节交换操作模式选择）

它是一个设置位，即以字节为单位交换一个发送接收数据。当字节访问有效时（SPDCR.SPBYT=1），字节交换无效。当字节交换有效时，奇偶校验功能必须无效（SPCR2.SPPE位=0）。BYSW位的设置更改必须是SPCR.SPE位=0。

字节交换后的数据因数据长度不同（SPCMD.SPB[3:0]的设置）。

字节交换时，A数据长度（SPB[3:0]的设置）必须设置为32位或16位。其他数据长度情况（即8到15、20、24位长度），不保证字节交换。交换前和交换后如下所示（长度数据（32位16位））。

●长度数据32位(SPB[3:0]=0010b或0011b)

Before swap: [31:24] [23:16] [15:8] [7:0]

After swap: [7:0] [15:8] [23:16] [31:24]

●长度数据16位(SPB[3:0]=1111b)

Before swap: [31:24] [23:16]

After swap: [23:16] [31:24]

当字节访问模式（SPDCR.SPBT=1）时，字节交换设置无效。

When byte swap is valid, set parity function to invalid (SPCR2.SPPE = 0). When the parity function set to valid, the behavior is not guaranteed.

SINV bit (Serial Data Invert Bit)

This bit is used to invert transmit data and receive data.

When the SINV bit is set to 1, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/ reception data.

30.2.16 SPCR3 : SPI Control Register 3

Base address: SPI0 = 0x4011_A000

Offset address: 0x21

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CENDIE	—	—	BFDS	ETXMD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ETXMD	Extended Communication Mode Select 0: Full-duplex synchronous or transmit-only serial communications. [the SPCR.TXMD bit is enabled] 1: Receive-only serial communications in slave mode (SPCR.MSTR bit = 0). [the SPCR.TXMD bit is disabled] Setting is prohibited in master mode (SPCR.MSTR bit = 1).	R/W
1	BFDS	Between Burst Transfer Frames Delay Select 0: Delay (RSPCK delay, SSL negation delay and next-access delay) between frames is inserted in burst transfer. 1: Delay between frames is not inserted in burst transfer.	R/W

4	CENDIE	RSPI Communication End Interrupt Enable 0: Communication end interrupt request is disabled. 1: Communication end interrupt request is enabled.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

SPI control register 3 (SPCR3) is control register for operation mode. If you change the value of ETXMD and BFDS when the SPCR.SPE bit is 1, the SPI operation does not guarantee.

ETXMD bit (Extended Communication Mode Select)

This bit is valid on slave mode only (the SPCR.MSTR bit is 0). This bit select receive only operation. When the ETXMD bit is 1 on slave mode, the communication is only received not transmit (see section 30.3.6. Data Transfer Modes). When the ETXMD is 1, transmit data empty interrupt can not be used.

The communication state by each mode (master mode, slave mode) is shown as below. It is controlled by the ETXMD bit, the SPCR.MSTR bit and the TXMD bit.

Table 30.5 RSPI communication state (master/slave mode)

SPCR.MSTR bit	SPCR3.ETXMD bit	SPCR.TXMD bit	Communication state
1	0	0	Transmit-receive master mode
1	0	1	Transmit master mode
0	0	0	Transmit-receive slave mode (default)
0	0	1	Transmit slave mode
0	1	—	Receive slave mode

当字节交换有效时，将奇偶校验功能设置为无效（SPCR2.SPPE=0）。当奇偶校验函数设置为有效时，行为不被保证。

SINV位（串行数据反转位）

该位用于反转发送数据和接收数据。

当SINV位设置为1时，发送缓冲器(SPTX)数据反转以反转发送数据和接收数据，然后将反转的数据存储在接收缓冲器(SPRX)中。奇偶校验位是对应于反转的发送接收数据的值。

30.2.16 SPCR3：SPI控制寄存器3

Base address: SPI0 = 0x4011_A000

Offset address: 0x21

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CENDIE	—	—	BFDS	ETXMD

4	CENDIE	RSPI通信结束中断使能 0：禁止通讯结束中断请求。1：使能通信结束中断请求。	R/W
7:5	—	这些位被读取为0。写入值应为0。	R/W

SPI控制寄存器3(SPCR3)是操作模式的控制寄存器。如果在SPCR.SPE位为1时更改ETXMD和BFDS的值，则SPI操作不保证。

ETXMD位（扩展通信模式选择）

该位仅在从模式下有效（SPCR.MSTR位为0）。该位选择只接收操作。当ETXMD位在从机模式下为1时，通信只接收不发送（参见第30.3.6节。数据传输模式）。当ETXMD为1时，不能使用发送数据空中断。

各模式（主模式、从模式）的通信状态如下所示。它由ETXMD位、SPCR.MSTR位和TXMD位控制。

Table 30.5 RSPI通信状态（主从模式）

SPCR.MSTR bit	SPCR3.ETXMD bit	SPCR.TXMD bit	通讯状态

BFDS bit (Between Burst Transfer Frames Delay Select)

This bit controls whether insert the delay time between the burst transfer frames.

This bit is valid when the SPCMD.SSLKP bit is 1 in master mode (the SPCR.MSTR bit is 1).

This bit should be set to 0 in slave mode. The usage of SSL delay control between transfer frames is shown as below. See (4)Burst transfers in detail.

Table 30.6 Usage of SSL delay control between transfer frames (Master mode)

Transmit		SPCMD.SSLKP bit	SPCR3.BFDS bit	SSL delay control register*1 (RSPCK clock delay, SSL negation delay, next access delay)
Non-burst transmit		0	0	Any given value. You can control each delay value according to setting for RSPCK clock delay, SSL negation delay and next access delay.
Burst transmit with delay between frames	From the 1st frame to the last previous frame	1	0	
	The last frame	0	0	
Burst transmit with no delay between frames	From the 1st frame to the last previous frame	1	1	Any given value. But delay is inserted only below. ● RSPCK clock delay of the 1st frame ● SSL negation delay and next access delay of the last frame
	The last frame	0	1	

Note 1. Whether the setting value of following bits are valid or not depends on the setting value of the SPCMD.SPNDEN bit (see section 30.2.14. SPCMDm : SPI Command Register m (m = 0 to 7)).
The SPCKD.SCKDL[2:0] bits: RSPCK delay
The SSLND.SLNDL[2:0] bits: SSL negate delay
The SPND.SPNDL[2:0] bits: Next access delay

CENDIE bit (RSPI Communication End Interrupt Enable)

This bit controls generation of a communication end interrupt request.

30.3 Operation

In this section, the serial transfer period refers to the period from the beginning of driving valid data to the fetching of the final valid data.

30.3.1 Overview of SPI Operation

The SPI is capable of synchronous serial transfers in the following modes:

- Slave mode (SPI operation)
- Single master mode (SPI operation)
- Multi-master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation)

The SPI mode can be selected by using the MSTR, MODFEN, and SPMS bits in SPCR. Table 30.7 lists the relationship between SPI modes and SPCR settings, and a description of each mode.

Table 30.7 Relationship between SPCR settings and SPI modes (1 of 2)

Mode	Slave (SPI operation)	Single-master (SPI operation)	Multi-master (SPI operation)	Slave (clock synchronous operation)	Master (clock synchronous operation)
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1

BFDS位（突发传输帧之间延迟选择）

该位控制是否在突发传输帧之间插入延迟时间。

当SPCMD.SSLKP位在主机模式下为1（SPCR.MSTR位为1）时，该位有效。

在从机模式下，该位应设置为0。传输帧之间的SSL延迟控制的使用如下所示。详见(4)突发传输。

Table 30.6 传输帧之间使用SSL延迟控制（主模式）

Transmit		SPCMD.SSLKP bit	SPCR3.BFDS bit	SSL延迟控制寄存器*1（RSPCK时钟延迟、SSL否定延迟、下一次访问延迟）
Non-burst transmit		0	0	任何给定的值。您可以根据对RSPCK时钟延迟、SSL否定延迟和下一次访问延迟的设置来控制每个延迟值。
帧之间有延迟的突发传输	从第一帧到最后一帧	1	0	
	最后一帧	0	0	
帧间无延迟的突发传输	从第一帧到最后一帧	1	1	任何给定的值。但是延迟只在下面插入。● 第一帧的RSPCK时钟延迟 ● 最后一帧的SSL否定延迟和下一次访问延迟
	最后一帧	0	1	

注1.以下位的设置值是否有效取决于SPCMD.SPNDEN位的设置值（参见第30.2.14节。SPCMDm：SPI命令寄存器m（m=0至7））。SPCKD.SCDL[2:0]位：RSPCK延迟

SSLND.SLNDL[2:0]位：SSL否定延迟SPND.SPNDL[2:0]位：下一次访问延迟

CENDIE位（RSPI通信结束中断使能）

该位控制通信结束中断请求的产生。

30.3 Operation

在本节中，串行传输周期是指从开始驱动有效数据到获取最终有效数据的周期。

30.3.1 SPI操作概述

SPI能够在以下模式下进行同步串行传输：

●从机模式（SPI操作）

●单主模式（SPI操作）

- Multi-master mode (SPI operation)

●从机模式（时钟同步操作）

●主模式（时钟同步操作）

可以使用SPCR中的MSTR、MODFEN和SPMS位选择SPI模式。表30.7列出了SPI模式和SPCR设置之间的关系，以及每种模式的说明。

Table 30.7 SPCR设置和SPI模式之间的关系(1of2)

Note 5. When SPI is receive only slave mode, none of transmit buffer empty and underrun error is detected.

30.3.2 Controlling the SPI Pins

Based on the settings of the MSTR, MODFEN, and SPMS bits in SPCR and the PmnPFS.NCODR bit for I/O Ports, the SPI can switch pin states. Table 30.8 lists the relationship between pin states and bit settings. Setting the PmnPFS.NCODR bit for an I/O port to 0 selects the CMOS output. Setting it to 1 selects the open-drain output. The I/O port settings must follow this relationship.

注5.当SPI为仅接收从机模式时，不会检测到发送缓冲区为空和欠载错误。

30.3.2 控制SPI引脚

根据SPCR中的MSTR、MODFEN和SPMS位以及IO端口的PmnPFS.NCODR位的设置，SPI可以切换引脚状态。表30.8列出了引脚状态和位设置之间的关系。将IO端口的PmnPFS.NCODR位设置为0可选择CMOS输出。将其设置为1选择开漏输出。IO端口设置必须遵循这种关系。

Table 30.8 Relationship between pin states and bit settings

	MISOn	CMOS output	Open-drain output

Note 1. This function is not supported in this mode.
Note 2. SPI settings are not reflected in multiplexed pins for which the SPI function is not selected.
Note 3. When SSLn0 is at the active level, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SSLP.SSL0P bit.
Note 4. When SSLn0 is at the non-active level or the SPCR.SPE bit is 0, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SSLP.SSL0P bit.
Note 5. These pins are available for use as I/O port pins.

The SPI in single-master mode (SPI operation) or multi-master mode (SPI operation) determines the MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) based on the MOIFE and MOIFV bit settings in SPPCR, as listed in Table 30.9.

30.3.3 SPI System Configuration Examples

30.3.3.1 Single-master/single-slave with the MCU as a master

Figure 30.5 shows a single-master/single-slave SPI system configuration example where the MCU is used as a master. In the single-master/single-slave configuration, the SSLni outputs of the MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in the selected state.*1

Note 1. In the transfer format configured when the SPCMDm.CPHA bit is 0, the SSL signal for some slave devices cannot be fixed to an active level. In this case, always connect the SSLni output of the MCU to the SSL input of the slave device.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

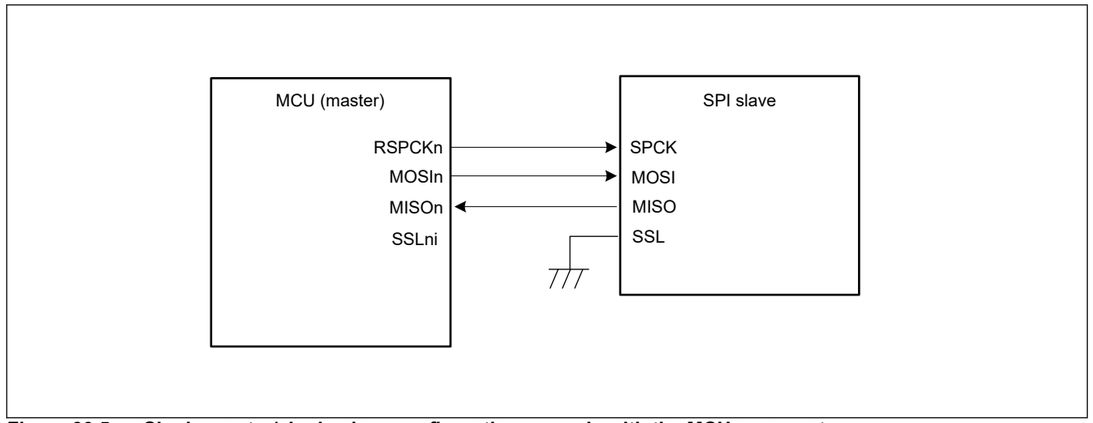

Figure 30.5 Single-master/single-slave configuration example with the MCU as a master

30.3.3.2 Single-master/single-slave with the MCU as a slave

Figure 30.6 shows a single-master/single-slave SPI system configuration example where the MCU is used as a slave. When the MCU operates as a slave, the SSLn0 pin is used as SSL input. The SPI master drives the RSPCK and MOSI signals. The MCU (slave) drives the MISOn signal.*1

Note 1. When SSLn0 is at a non-active level, the pin state is Hi-Z.

In the single-slave configuration when the SPCMDm.CPHA bit is set to 1, the SSLn0 input of the MCU (slave) is fixed to the low level and the MCU (slave) is maintained in the selected state. This enables serial transfer execution (Figure 30.7). However, the communication end interrupt does not output when SSL0 input is fixed as Figure 30.7.

30.3.3.3 Single-master/multi-slave with the MCU as a master

Figure 30.8 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes the MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCKn and MOSIn outputs of the MCU (master) are connected to the RSPCK and MOSI inputs of SPI slaves 0 to 3. The MISO outputs of SPI slaves 0 to 3 are all connected to the MISOn input of the MCU (master). The SSLn0 to SSLn3 outputs of the MCU (master) are connected to the SSL inputs of SPI slaves 0 to 3, respectively.

The MCU (master) drives the RSPCKn, MOSIn, and SSLn0 to SSLn3 signals. Of the SPI slaves 0 to 3, the slave that receives low-level input into the SSL input drives the MISO signal.

30.3.3.4 Single-master/multi-slave with the MCU as a slave

Figure 30.9 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a slave. In this example, the SPI system includes an SPI master and two MCUs (slaves X and Y).

The SPCK and MOSI outputs of the SPI master are connected to the RSPCKn and MOSIn inputs of the MCUs (slaves X and Y). The MISOn outputs of the MCUs (slaves X and Y) are all connected to the MISO input of the SPI master. The SSLX and SSLY outputs of the SPI master are connected to the SSLn0 inputs of the MCUs (slaves X and Y, respectively).

The SPI master drives the SPCK, MOSI, SSLX, and SSLY signals. Of the MCUs (slaves X and Y), the slave that receives low-level input into the SSLn0 input drives the MISOn signal.

30.3.3.5 Multi-master/multi-slave with the MCU as a master

Figure 30.10 shows a multi-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes two MCUs (masters X and Y) and two SPI slaves (SPI slaves 1 and 2).

The RSPCKn and MOSIn outputs of the MCUs (masters X and Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOn inputs of the MCUs (masters X and Y). Any generic port Y output from the MCU (master X) is connected to the SSLn0 input of the MCU (master Y). Any generic port X output of the MCU (master Y) is connected to the SSLn0 input of the MCU (master X). The SSLn1 and SSLn2 outputs of the MCUs (masters X and Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, because the system can be comprised solely of SSLn0 input, and SSLn1 and SSLn2 outputs for slave connections, the SSLn3 output of the MCU is not required.

The MCU drives the RSPCKn, MOSIn, SSLn1, and SSLn2 signals when the SSLn0 input level is high. When the SSLn0 input level is low, the MCU detects a mode fault error, sets RSPCKn, MOSIn, SSLn1, and SSLn2 to Hi-Z, and releases the SPI bus directly to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives the MISO signal.

图30.10显示了一个多主机多从机SPI系统配置示例，其中MCU用作主机。在此示例中，SPI系统包括两个MCU（主X和Y）和两个SPI从机（SPI从机1和2）。

MCU（主机X和Y）的RSPCKn和MOSIn输出连接到SPI从机1和2的RSPCK和MOSI输入。SPI从机1和2的MISO输出连接到MCU（主机X）的MISOn输入和Y)。来自MCU（主X）的任何通用端口Y输出都连接到MCU（主Y）的SSLn0输入。MCU（主设备Y）的任何通用端口X输出都连接到MCU（主设备X）的SSLn0输入。MCU（主机X和Y）的SSLn1和SSLn2输出连接到SPI从机1和2的SSL输入。在此配置示例中，因为系统可以仅由SSLn0输入和SSLn1和SSLn2输出组成从连接，不需要MCU的SSLn3输出。

当SSLn0输入电平为高电平时，MCU驱动RSPCKn、MOSIn、SSLn1和SSLn2信号。当SSLn0输入电平为低时，MCU检测到模式故障错误，将RSPCKn、MOSIn、SSLn1和SSLn2设置为Hi-Z，并将SPI总线直接释放到另一个主控。在SPI从机1和2中，接收到SSL输入的低电平输入的从机驱动MISO信号。

In addition, SSLn0 to SSLn3 of the MCU (slave) are not used.

The MCU (slave) can only execute serial transfers in the single-slave configuration when the SPCMDm.CPHA bit is set to 1.

30.3.4 Data Formats

The data format of the SPI depends on the settings in SPI Command Register m (SPCMDm) and the parity enable bit in SPI Control Register 2 (SPCR2.SPPE). Regardless of whether the MSB or LSB is first, the SPI treats the range from the LSB bit in the SPI Data Register (SPDR/SPDR_HA) to the bit associated with the selected data length, as transfer data.

This section shows the format of one frame of data before or after transfer.

Data format with parity disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[3:0]).

30.3.4 数据格式

SPI的数据格式取决于SPI命令寄存器m(SPCMDm)中的设置和SPI控制寄存器2(SPCR2.SPPE)中的奇偶校验使能位。无论MSB还是LSB在前，SPI都会将SPI数据寄存器(SPDRSPDR_HA)中的LSB位到与所选数据长度相关的位的范围视为传输数据。

本节显示传输前后一帧数据的格式。

禁用奇偶校验的数据格式

当奇偶校验被禁用时，数据的发送或接收将按照在SPI命令寄存器m(SPCMDm.SPB[3:0])的SPI数据长度设置中选择的位长度进行。

Data format with parity enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[3:0]). In this case, however, the last bit is a parity bit.

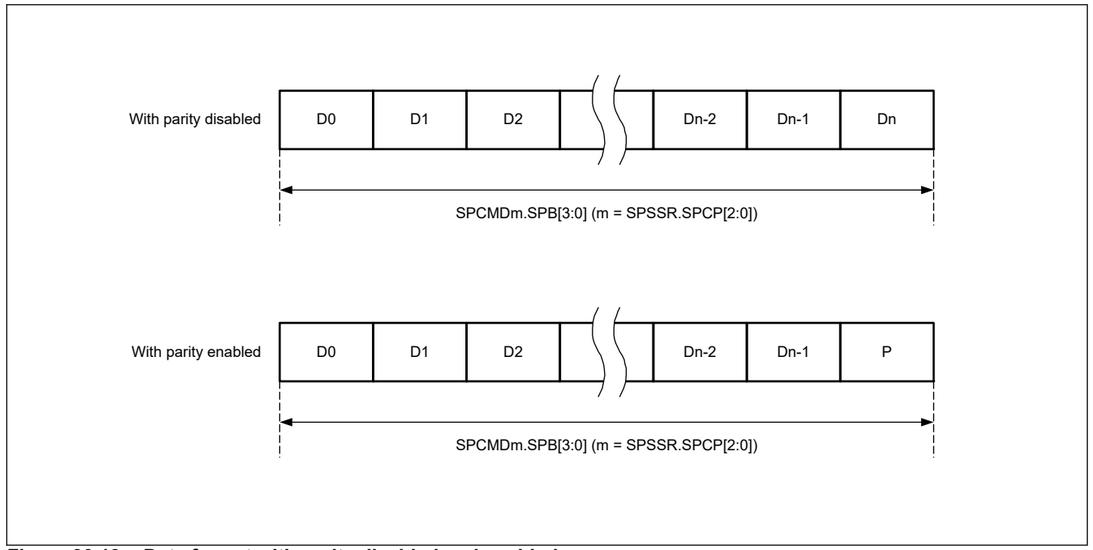

Figure 30.13 Data format with parity disabled and enabled

30.3.4.1 Operation when parity is disabled (SPCR2.SPPE = 0)

When parity is disabled, data for transmission is copied to the shift register with no pre-processing. This section describes the connection between the SPI Data Register (SPDR/SPDR_HA) and the shift register in terms of the combination of MSB- or LSB-first order and data length.

(1) MSB-first transfer with 32-bit data

Figure 30.14 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, a SPI data length of 32 bits, and MSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T31 to T30, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

启用奇偶校验的数据格式

当奇偶校验使能时，数据的发送或接收按照在SPI命令寄存器m(SPCMDm.SPB[3:0])的SPI数据长度设置中选择的位长度进行。然而，在这种情况下，最后一位是奇偶校验位。

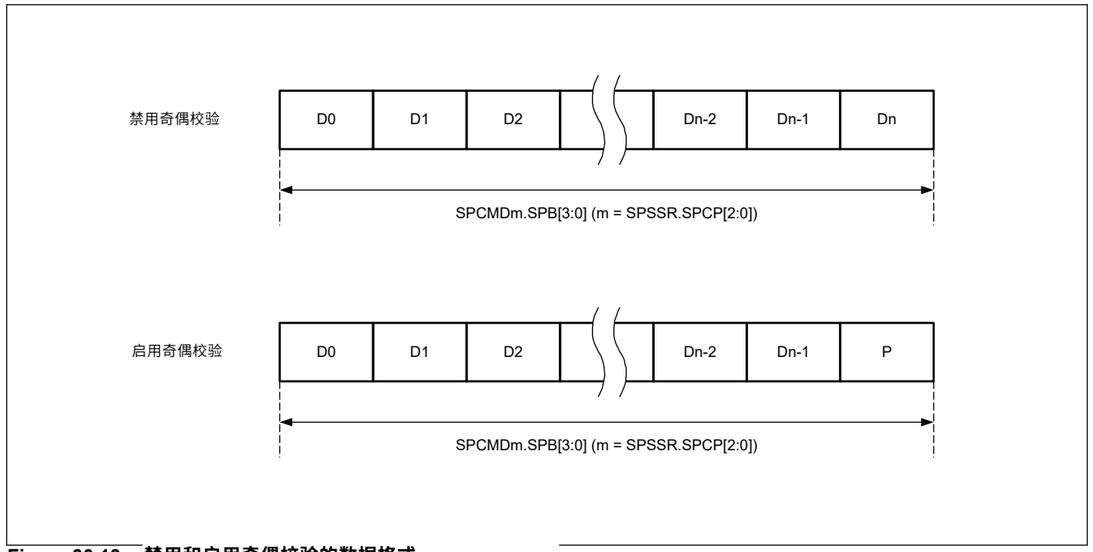

Figure 30.13 禁用和启用奇偶校验的数据格式

30.3.4.1 禁用奇偶校验时的操作(SPCR2.SPPE=0)

当奇偶校验被禁用时，用于传输的数据被复制到移位寄存器而不进行预处理。本节从MSB或LSB-firstorder和数据长度的组合来描述SPI数据寄存器(SPDRSPDR_HA)和移位寄存器之间的连接。

(1) 32位数据的MSB优先传输

图30.14显示了SPI数据寄存器(SPDR)和移位寄存器在奇偶校验禁用的传输中的操作，a SPI数据长度为32位，且MSB优先选择。

在发送过程中，发送缓冲器当前级的T31到T00位被复制到移位寄存器。发送数据从移位寄存器从T31移出到T30，并继续到T00。

在接收中，接收到的数据通过移位寄存器的bit[0]逐位移位。在输入所需的RSPCK周期数后收集R31至R00位时，将移位寄存器中的值复制到接收缓冲区。

(2) MSB-first transfer with 24-bit data

Figure 30.15 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 24 bits for an example that is not 32 bits, and MSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T23 to T22, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to bits T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.

在发送过程中，来自发送缓冲器当前阶段的低24位（T23到T00）被复制到移位寄存器。

30.3.4.2 Operation when parity is enabled (SPCR2.SPPE = 1)

When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB-first transfer with 32-bit data

Figure 30.18 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and MSB-first selected.

30.3.5 Transfer Formats

30.3.5.1 When CPHA = 0

Figure 30.24 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Do not perform clock synchronous operation (SPCR.SPMS = 1) when the SPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 30.24, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0, and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI settings. For details, see section 30.3.2. Controlling the SPI Pins.

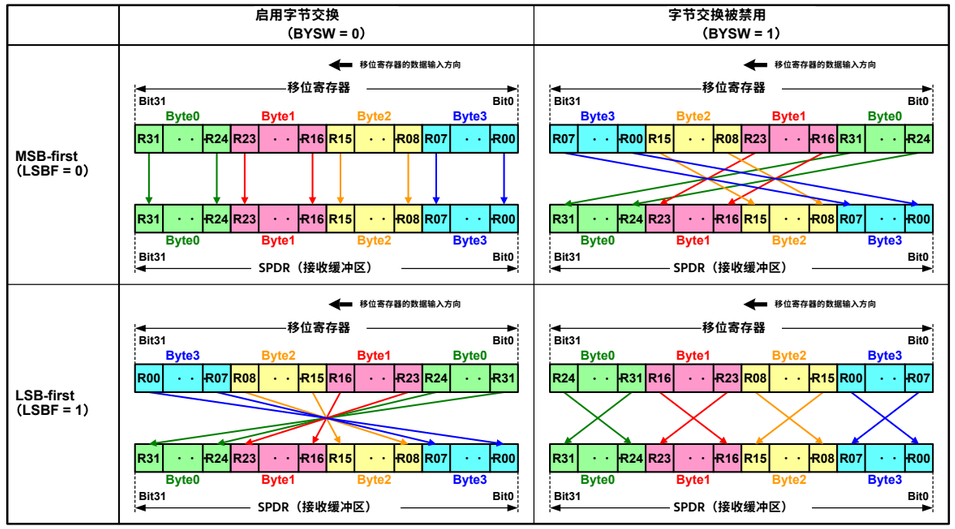
When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIn and MISOn signals begins at an SSLni signal assertion. The first RSPCKn signal change that occurs after the SSLni signal assertion becomes the first transfer data fetch. After this, data is sampled every 1 RSPCK cycle. The change timing for MOSIn and MISOn signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCK signal operation timing as it only affects the signal polarity.

t1 denotes the RSPCK delay, the period from an SSLni signal assertion to RSPCKn oscillation. t2 denotes the SSL negation delay, the period from the termination of RSPCKn oscillation to an SSLni signal negation. t3 denotes the next-access delay,

(4) LSB优先传输。（启用字节交换时。）

第一个接收到的数据（R24）存放在移位寄存器的第0位，接收到的数据按R24→R25→…→R31→R16→R17→…→R23→R08→R09→…→R15→的顺序移位R00→R01→…→R07。

当输入必要的RSPCK周期并将数据从Byte0[R24到R31]到Byte3[R00到R07]存储时，移位寄存器中每个字节的位值以位为单位反转，并按顺序复制到接收缓冲区Byte0[R31到R24]到Byte3[R07到R00]。



Note: 1.使用字节交换时，将数据长度设置为16位或32位（SPCMD.SPB[3:0]设置）。如果设置其他长度（8到15、20、24位），则无法保证行为。2.当字节交换有效时，将奇偶校验功能设置为无效（SPCR2.SPPE位=0）。如果将奇偶校验功能设置为有效（SPPE位=1），则无法保证行为。3.当SPCR.SPE位为0时，设置SPDCR2.BYSW位。如果重写BYSW位，当SPE位为1时，不保证之后的行为。

30.3.5 传输格式

30.3.5.1 When CPHA = 0

图30.24显示了当SPCMDm.CPHA位为0时串行传输8位数据的示例传输格式。当SPI在从机模式下运行时（SPCR.MSTR=0)且CPHA位为0。在图30.24中，RSPCKn(CPOL=0)表示SPCMDm.CPOL位为0时的RSPCKn信号波形，RSPCKn(CPOL=1)表示CPOL位为0时的RSPCKn信号波形1.采样时序表示SPI将串行传输数据取入移位寄存器的时序。信号的IO方向取决于SPI设置。有关详细信息，请参阅第30.3.2节。控制SPI引脚。

当SPCMDm.CPHA位为0时，将有效数据驱动到MOSIn和MISOn信号开始于SSLni信号断言。在SSLni信号断言之后发生的第一个RSPCKn信号变化成为第一次传输数据获取。此后，每1个RSPCK周期对数据进行采样。MOSIn和MISOn信号的变化时序是传输数据获取时序之后的12RSPCK周期。CPOL位设置不影响RSPCK信号操作时序，因为它只影响信号极性。

t1表示RSPCK延迟，即从SSLni信号断言到RSPCKn振荡的周期。t2表示SSL否定延迟，即从RSPCKn振荡终止到SSLni信号否定的周期。t3表示下一次访问延迟，

the period in which SSLni signal assertion is suppressed for the next transfer after the end of serial transfer. t1, t2, and t3 are controlled by a master device running on the SPI system. For a description of t1, t2, and t3 when the SPI is in master mode, see section 30.3.11.1. Master mode operation.

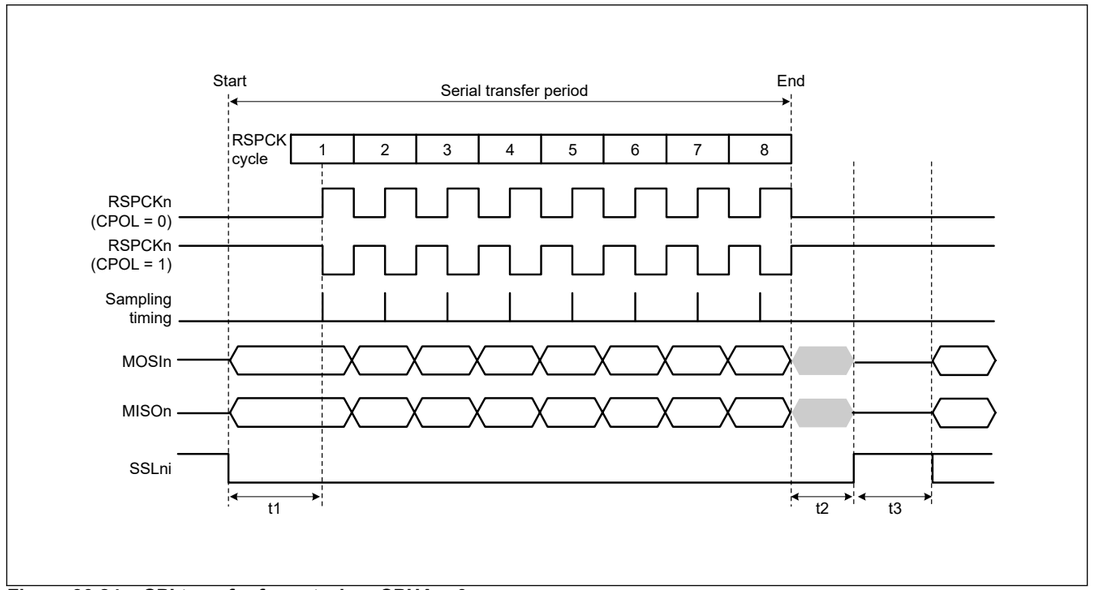

Figure 30.24 SPI transfer format when CPHA = 0

30.3.5.2 When CPHA = 1

Figure 30.25 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLni signals are not used, and only the three signals RSPCKn, MOSIn, and MISOn handle communications. In Figure 30.25, RSPCK (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0 and RSPCK (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI mode (master or slave mode). For details, see section 30.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOn signal begins at an SSLni signal assertion. The output of valid data to the MOSIn and MISOn signals begins at the first RSPCKn signal change that occurs after the SSLni signal assertion. After this, data is updated every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKn signal operation timing. It only affects the signal polarity.

t1, t2, and t3 are the same as those when CPHA = 0. For a description of t1, t2, and t3 when the SPI of the MCU is in master mode, see section 30.3.11.1. Master mode operation.

在串行传输结束后，为下一次传输抑制SSLni信号断言的时间段。t1、t2和t3由在SPI系统上运行的主设备控制。有关SPI处于主模式时的t1、t2和t3的说明，请参见第30.3.11.1节。主模式操作。

30.3.5.2 When CPHA = 1

图30.25显示了当SPMDm.CPHA位为1时串行传输8位数据的示例传输格式。
但是，当SPCR.SPMS位为1时，不使用SSLni信号，只有RSPCKn、MOSIn和MISON处理通信。在图30.25中，RSPCK(CPOL=0)表示SPCMDm.CPOL位为0时的RSPCKn信号波形，RSPCK(CPOL=1)表示CPOL位为1时的RSPCKn信号波形。SPI将串行传输数据提取到移位寄存器中。信号的IO方向取决于SPI模式（主模式或从模式）。有关详细信息，请参阅第30.3.2节。控制SPI引脚。

当SPCMDm.CPHA位为1时，将无效数据驱动到MIOn信号开始于SSLni信号断言。在SSLni信号置位后发生的第一个RSPCKn信号变化时，开始向MOSIn和MISOn信号输出有效数据。此后，每1个RSPCK周期更新一次数据。传输数据获取时序是数据更新时序之后的12个RSPCK周期。SPCMDm.CPOL位设置不影响RSPCKn信号操作时序。它只影响信号极性。

t1、t2、t3与CPHA=0时相同。MCU的SPI为主机模式时t1、t2、t3的说明见30.3.11.1节。主模式操作。

30.3.6 Data Transfer Modes

Full-duplex synchronous serial communications or transmit operations can only be selected in the Communications Operating Mode Select bit (SPCR.TXMD) when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is 0. The SPI operation is receive only in slave mode (SPCR.MSTR = 0) when the SPCR3.ETXMD bit is 1, because SPCR.TXMD bit does not affect the SPI operation. The register accesses shown in Figure 30.26, Figure 30.27, and Figure 30.28 indicate the condition of access to the SPDR/SPDR_HA register, where W denotes a write cycle.

30.3.6.1 Full-duplex synchronous serial communications (SPCR3.ETXMD = 0, SPCR.TXMD = 0)

Figure 30.26 shows an example of operation when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 0 and the Communications Operating Mode Select bit (SPCR.TXMD) is set to 0. In this example, the SPI performs an 8-bit serial transfer when SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

30.3.6 数据传输模式

全双工同步串行通信或传输操作只能在通信中选择
当SPI控制寄存器3(SPCR3)中的扩展通信模式选择位(ETXMD)为0时，工作模式选择位(SPCR.TXMD)。当SPCR3.ETXMD位为1，因为SPCR.TXMD位不影响SPI操作。图30.26、图30.27和图30.28所示的寄存器访问表示访问SPDRSPDR_HA寄存器的条件，其中W表示写周期。

30.3.6.1 全双工同步串行通信（SPCR3.ETXMD=0，SPCR.TXMD = 0)

图30.26显示了当SPI控制寄存器3(SPCR3)中的扩展通信模式选择位(ETXMD)设置为0并且通信操作模式选择位(SPCR.TXMD)设置为0时的操作示例。在此示例中，当SPDCR.SPFC[1:0]位为00b、SPCMDm.CPHA位为1、SPCMDm.CPOL位为0时，SPI执行8位串行传输。波形中为RSPCKn给出的数字表示RSPCK周期数，例如传输的位数。

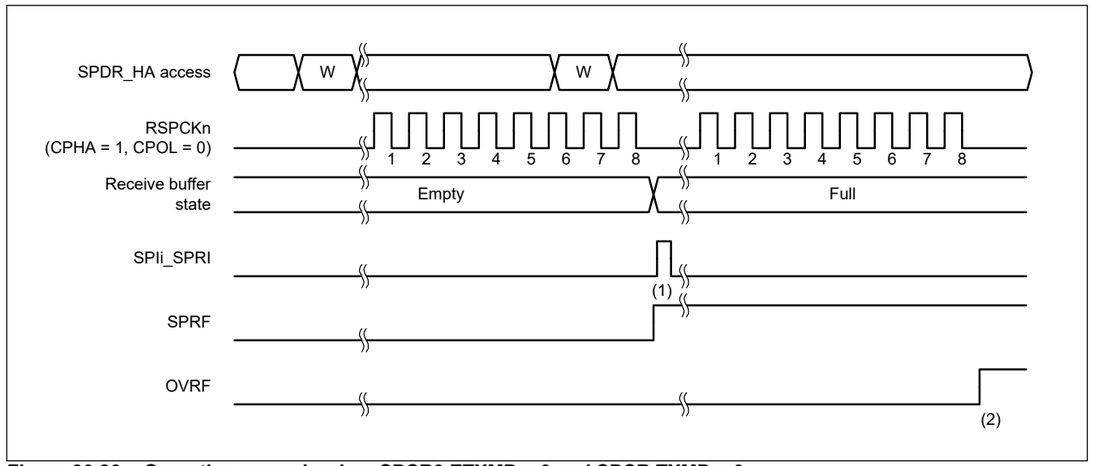

Figure 30.26 Operation example when SPCR3.ETXMD = 0 and SPCR.TXMD = 0

The operation of the flags at timings (1) and (2) in Figure 30.26 is as follows:

1. When a serial transfer ends with the receive buffer of SPDR_HA empty, the SPI generates a receive buffer full interrupt request (SPIi_SPRI), the SPI sets the SPSR.SPRF flag to 1, and copies the received data in the shift register to the receive buffer.
2. When a serial transfer ends with the receive buffer of SPDR_HA holding data that was received in the previous serial transfer, the SPI sets the SPSR.OVRF flag to 1, and discards the received data in the shift register. For details about the operation of the SPSR.OVRF flag, see section 30.3.9.1. Overrun errors.

30.3.6.2 Transmit-Only Serial Communications (SPCR3.ETXMD = 0, SPCR.TXMD = 1)

Figure 30.27 shows an example of operation when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 0 and the Communications Operating Mode Select bit (SPCR.TXMD) is set to 1. In this example, the SPI performs an 8-bit serial transfer when SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

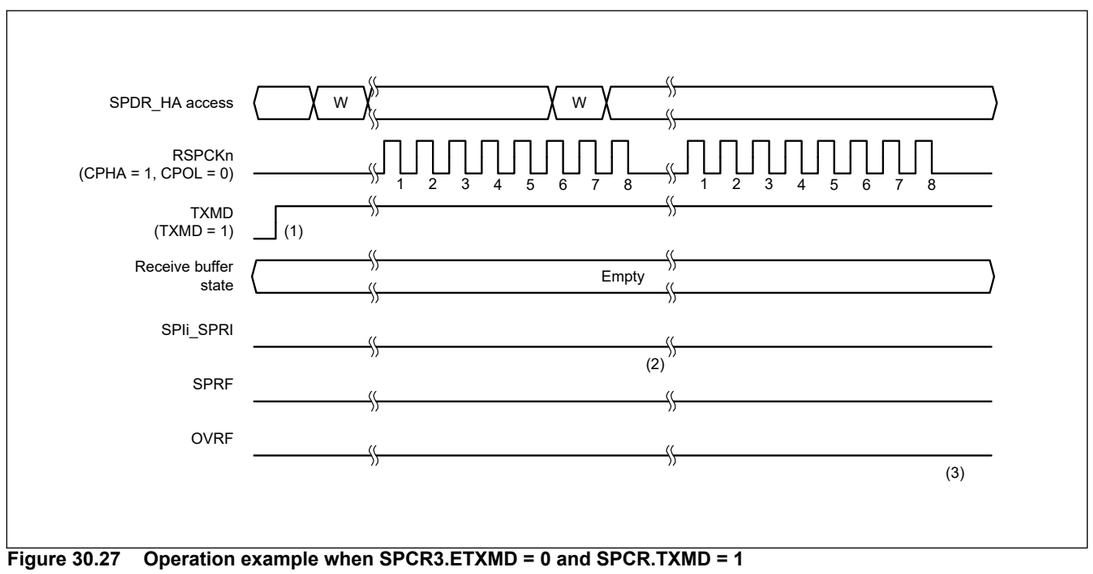

Figure 30.27 Operation example when SPCR3.ETXMD = 0 and SPCR.TXMD = 1

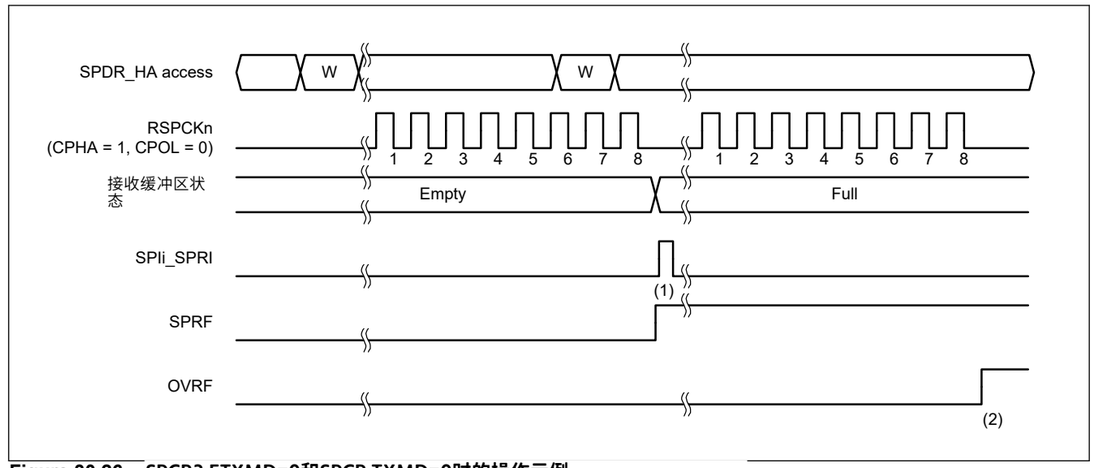

Figure 30.26 SPCR3.ETXMD=0和SPCR.TXMD=0时的操作示例

图30.26中时序(1)和(2)的标志操作如下：

1.当串行传输结束且SPDR_HA的接收缓冲区为空时，SPI产生接收缓冲区满中断请求（SPIi_SPRI），SPI将SPSR.SPRF标志设置为1，并将接收到的移位寄存器中的数据复制到接收缓冲区。

2.当串行传输结束时，SPDR_HA的接收缓冲区保存了前一次串行传输中接收到的数据，SPI将SPSR.OVRF标志设置为1，并丢弃移位寄存器中接收到的数据。有关SPSR.OVRF标志操作的详细信息，请参见第30.3.9.1节。溢出错误。

30.3.6.2 仅发送串行通信（SPCR3.ETXMD=0，SPCR.TXMD=1）

图30.27显示了当SPI控制寄存器3(SPCR3)中的扩展通信模式选择位(ETXMD)设置为0且通信操作模式选择位(SPCR.TXMD)设置为1时的操作示例。在此示例中，当SPDCR.SPFC[1:0]位为00b、SPCMDm.CPHA位为1、SPCMDm.CPOL位为0时，SPI执行8位串行传输。波形中为RSPCKn给出的数字表示RSPCK周期数，例如传输的位数。

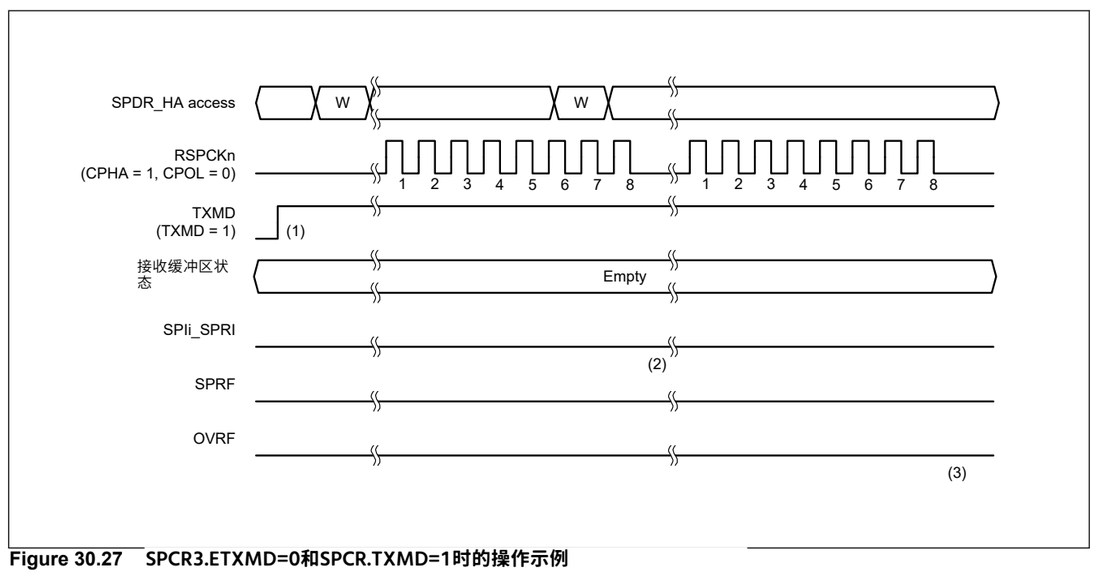

Figure 30.27 SPCR3.ETXMD=0和SPCR.TXMD=1时的操作示例

The operation of the flags at timings (1) to (3) in Figure 30.27 is as follows:

1. Make sure there is no data left in the receive buffer (the SPSR.SPRF flag is 0) and the SPSR.OVRF flag is 0 before entering transmit-only mode (SPCR3.ETXMD = 0, SPCR.TXMD = 1).
2. When a serial transfer ends with the receive buffer of SPDR_HA empty, if the transmit-only mode is selected (SPCR3.ETXMD = 0, SPCR.TXMD = 1), the SPSR.SPRF flag retains the value of 0, and the SPI does not copy the data in the shift register to the receive buffer.
3. Because the receive buffer of SPDR_HA does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

In transmit-only mode (SPCR3.ETXMD = 0, SPCR.TXMD = 1), the SPI transmits data but does not receive data. Therefore, the SPSR.SPRF and SPSR.OVRF flags remain 0 at timings (1) to (3).

30.3.6.3 Receive-Only Serial Communication (MSTR = 0, ETXMD = 1)

Figure 30.28 shows an example of operation when the SPI master/slave mode select bit (MSTR) in the SPI control register (SPCR) is set to 0 and the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 1. In the example in Figure 30.28, the SPI performs 8-bit data serial transfer with the settings of SPFC[1:0] in the SPI data control register (SPDCR) = 00b, CPHA in the SPI command register (SPCMD) = 1, and CPOL in SPCMD = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

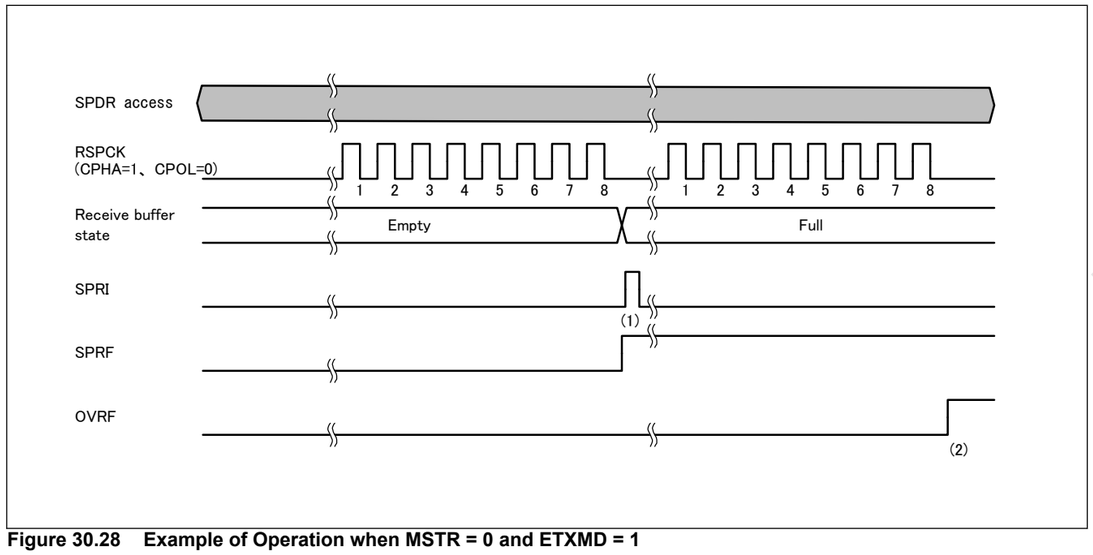

Figure 30.28 Example of Operation when MSTR = 0 and ETXMD = 1

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the SPDR's receive buffer is empty, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer

(2) When serial transfer ends while previously received data is remaining in the SPDR's receive buffer, the SPI sets the OVRF flag in the SPI status register (SPSR) to 1 and discards the received data in the shift register.

30.3.7 Transmit Buffer Empty and Receive Buffer Full Interrupts

Figure 30.29 and Figure 30.30 show examples of operation of the transmit buffer empty interrupt (SPIi_SPTI) and the receive buffer full interrupt (SPIi_SPRI). The SPDR_HA register accesses shown in these figures indicate the conditions of access to the register, where W denotes a write cycle and R a read cycle. In Figure 30.29, the SPI performs an 8-bit serial transfer when SPCR.TXMD bit is 0, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 0, and the SPCMDm.CPOL bit is 0. In Figure 30.30, the SPI performs an 8-bit serial transfer when SPCR.TXMD bit is 0, the

图30.27中时间(1)到(3)的标志操作如下：

1.在进入仅发送模式（SPCR3.ETXMD=0，SPCR.TXMD=1）之前，确保接收缓冲区中没有剩余数据（SPSR.SPRF标志为0）且SPSR.OVRF标志为0。

2.当串行传输结束且SPDR_HA的接收缓冲区为空时，如果选择了仅传输模式（SPCR3.ETXMD=0 SPCR.TXMD=1），SPSR.SPRF标志保持0的值，SPI不将移位寄存器中的数据复制到接收缓冲区。

3、因为SPDR_HA的接收缓冲区中没有保存上一次串行传输接收到的数据，所以即使一次串行传输结束，SPSR.OVRF标志保持值0，移位寄存器中的数据不会被复制到接收缓冲区。

在仅发送模式下（SPCR3.ETXMD=0，SPCR.TXMD=1），SPI发送数据但不接收数据。
因此，SPSR.SPRF和SPSR.OVRF标志在时间(1)到(3)保持0。

30.3.6.3 仅接收串行通信（MSTR=0，ETXMD=1）

图30.28显示了当SPI控制寄存器(SPCR)中的SPI主从模式选择位(MSTR)设置为0并且SPI控制寄存器3(SPCR3)中的扩展通信模式选择位(ETXMD)被设置时的操作示例设置为1。在图30.28的示例中，SPI执行8位数据串行传输，设置SPI数据控制寄存器（SPDCR）中的SPFC[1:0]=00b，SPI命令寄存器中的CPHA（SPCMD)=1，SPCMD中的CPOL=0。RSPCK波形下的数字表示RSPCK周期数（传输位数）。

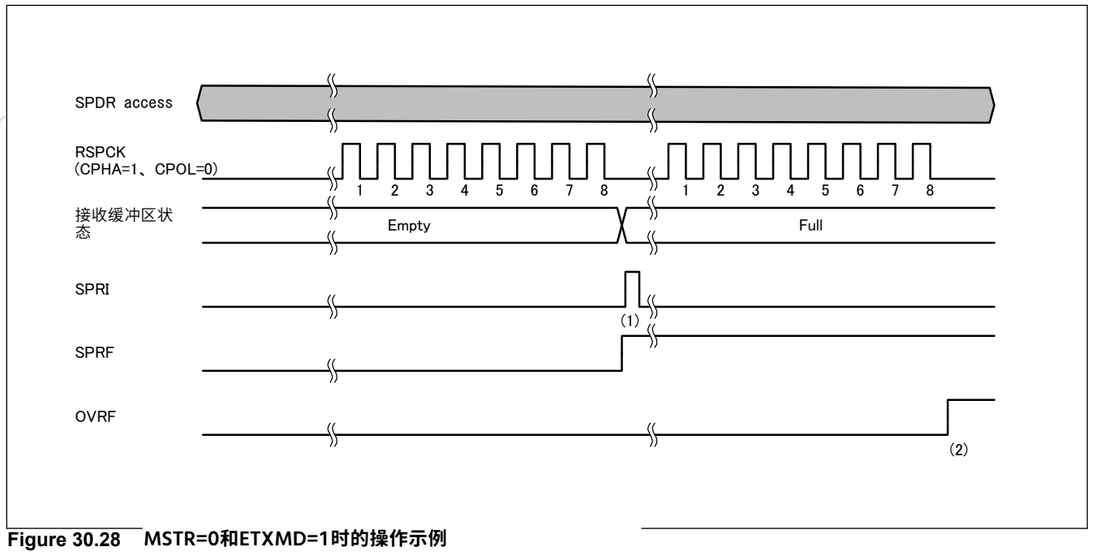

Figure 30.28 MSTR=0和ETXMD=1时的操作示例

下面描述在上图中的时间(1)和(2)的标志的操作。

(1)当串行传输结束而SPDR的接收缓冲区为空时，SPI产生一个接收缓冲区满中断请求SPRI（将SPSR.SPRF标志设置为1）并将接收到的移位寄存器中的数据复制到接收缓冲区

(2)当串行传输结束而先前接收的数据仍留在SPDR的接收缓冲区中时，SPI将SPI状态寄存器(SPSR)中的OVRF标志设置为1，并丢弃移位寄存器中的接收数据。

30.3.7 发送缓冲区空和接收缓冲区满中断

图30.29和图30.30显示了发送缓冲区空中断(SPIi_SPTI)和接收缓冲区满中断(SPIi_SPRI)的操作示例。这些图中显示的SPDR_HA寄存器访问表示访问寄存器的条件，其中W表示写周期，R表示读周期。在图30.29中，当SPCR.TXMD位为0、SPDCR.SPFC[1:0]位为00b、SPCMDm.CPHA位为0、SPCMDm.CPOL位为0时，SPI执行8位串行传输.在图30.30中，当SPCR.TXMD位为0时，SPI执行8位串行传输，

SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

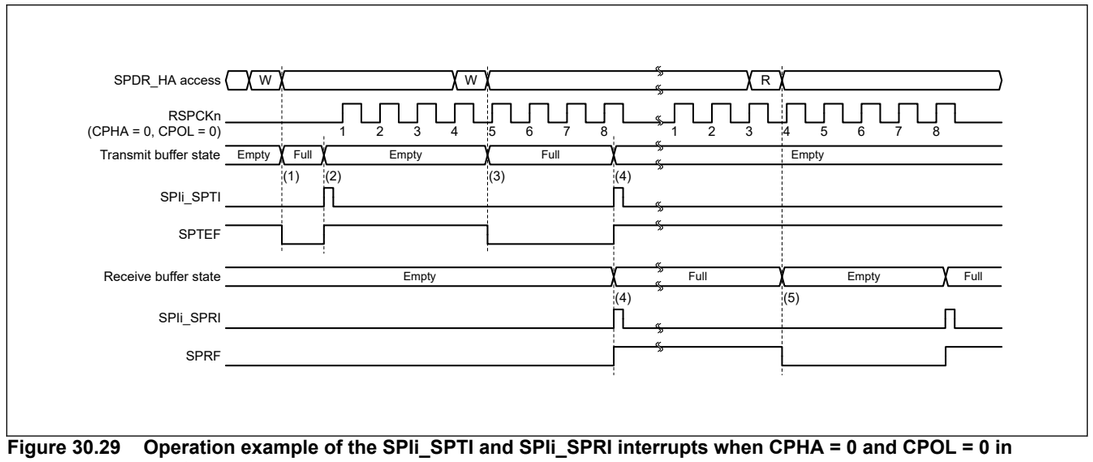

Figure 30.29 Operation example of the SPIi_SPTI and SPIi_SPRI interrupts when CPHA = 0 and CPOL = 0 in master mode

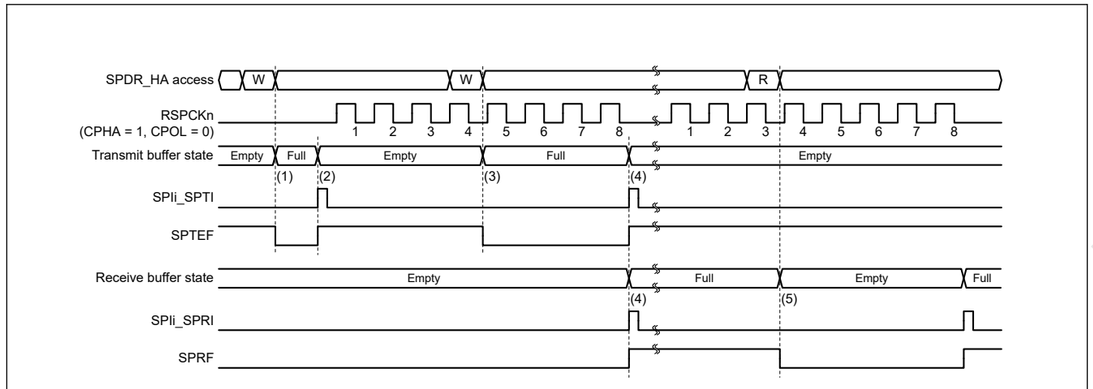

Figure 30.30 Operation example of the SPIi_SPTI and SPIi_SPRI interrupts when CPHA = 1 and CPOL = 0 in master mode

The operation of the SPI at timings (1) to (5) in Figure 30.29 and Figure 30.30 is as follows:

1. When transmit data is written to SPDR_HA with the transmit buffer of SPDR_HA is empty and data for the next transfer is not set, the SPI writes data to the transmit buffer and clears the SPSR.SPTEF flag to 0.
2. If the shift register is empty, the SPI copies the data in the transmit buffer to the shift register, generates a transmit buffer empty interrupt request (SPIi_SPTI), and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the SPI mode. For details, see section 30.3. Operation, and section 30.3.12. Clock Synchronous Operation.
3. When transmit data is written to SPDR_HA either by the transmit buffer empty interrupt routine, or by the processing of the transmit buffer empty using the SPTEF flag, the SPI writes data to the transmit buffer and clears the SPTEF flag to 0. Because the data being transferred serially is stored in the shift register, the SPI does not copy the data in the transmit buffer to the shift register.
4. When the serial transfer ends with the receive buffer of SPDR_HA empty, the SPI copies the receive data in the shift register to the receive buffer, generates a receive buffer full interrupt request (SPIi_SPRI), and sets the SPRF flag to 1. Because the shift register becomes empty on completion of the serial transfer, if the transmit buffer is full before the serial transfer ended, the SPI sets the SPTEF flag to 1 and copies data in the transmit buffer to the shift register. Even

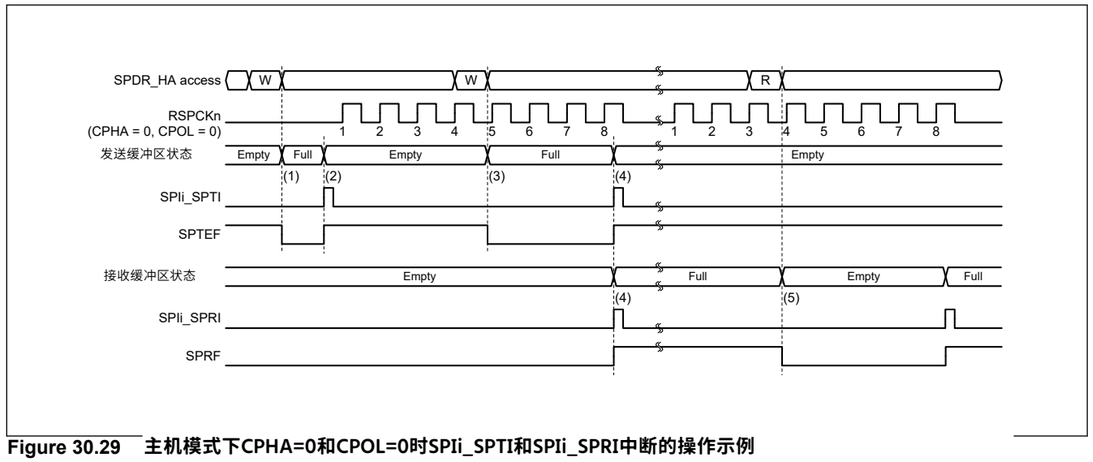

Figure 30.29 主机模式下CPHA=0和CPOL=0时SPIi_SPTI和SPIi_SPRI中断的操作示例

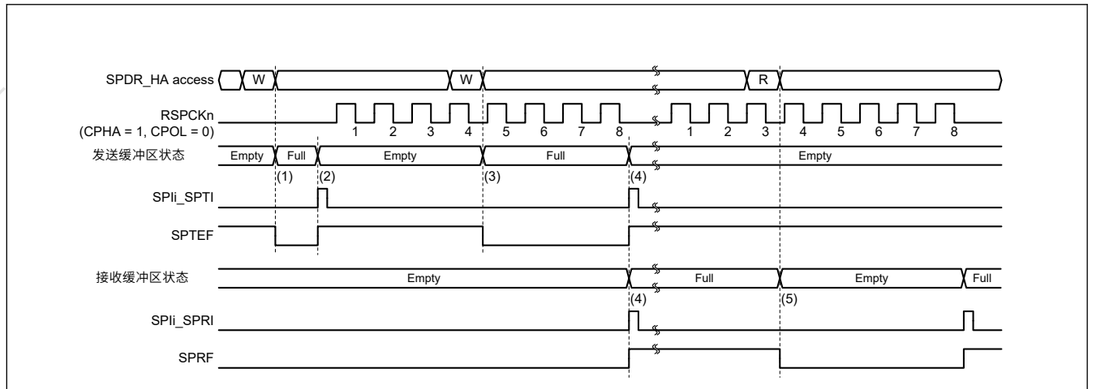

Figure 30.30 主机模式下CPHA=1和CPOL=0时SPIi_SPTI和SPIi_SPRI中断的操作示例

SPI在图30.29和图30.30中时序（1）到（5）的操作如下：

1.当发送数据写入SPDR_HA且SPDR_HA的发送缓冲区为空且未设置下一次传输的数据时，SPI将数据写入发送缓冲区并将SPSR.SPTEF标志清除为0。

2.如果移位寄存器为空，SPI将发送缓冲区中的数据复制到移位寄存器，产生发送缓冲区空中断请求（SPIi_SPTI），并将SPSR.SPTEF标志设置为1。如何启动串行传输取决于SPI模式。有关详细信息，请参阅第30.3节。操作和第30.3.12节。时钟同步操作。

3.当发送数据被发送缓冲区空中断程序写入SPDR_HA时，或者通过使用SPTEF标志处理发送缓冲区空，SPI将数据写入发送缓冲区并将SPTEF标志清除为0。因为串行传输的数据存储在移位寄存器中，SPI不会将发送缓冲区中的数据复制到移位寄存器中。

4、当串口传输结束且SPDR_HA的接收缓冲区为空时，SPI将移位寄存器中的接收数据复制到接收缓冲区，产生接收缓冲区满中断请求（SPIi_SPRI），并将SPRF标志置1。因为串行传输完成后移位寄存器变为空，如果在串行传输结束前发送缓冲区已满，SPI将SPTEF标志设置为1，并将发送缓冲区中的数据复制到移位寄存器。甚至

when received data is not copied from the shift register to the receive buffer in an overrun error status, on completion of the serial transfer, the SPI determines that the shift register is empty, so data transfer from the transmit buffer to the shift register is enabled.

5. When SPDR_HA is read either by the receive buffer full interrupt routine or processing of the receive buffer full interrupt using the SPRF flag, the receive data can be read.

If SPDR_HA is written to when the transmit buffer holds data that is not yet transmitted (the SPTEF flag is 0), the SPI does not update data in the transmit buffer. When writing to SPDR_HA, always use either a transmit buffer empty interrupt request or processing of the transmit buffer empty interrupt using the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1. If the SPI function is disabled (the SPCR.SPE bit is 0), set the SPTIE bit to 0.

When serial transfer ends and the receive buffer is full (the SPRF flag is 1), the SPI does not copy data from the shift register to the receive buffer, and it detects an overrun error (see section 30.3.9. Error Detection). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an SPI receive buffer full interrupt, set the SPCR.SPRIE bit to 1.

Transmission and reception interrupts or the associated IELSRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers.

Similarly, the SPTEF and SPRF flags can be used to confirm the states of the transmit and receive buffers. See section 13, Interrupt Controller Unit (ICU) for the interrupt vector numbers.

30.3.8 Communication End Interrupt

30.3.8.1 Transmit-Receive/Transmit in Master Mode

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1, when following conditions are satisfied in transmit-receive master mode and transmit master mode. The set timing of the CENDF flag is same as IDLNF flag. The communication end interrupt (SPCI) is one PCLKUSCIx width and low active.

- When the value of the SPSSR.SPCP[2:0] bits are same as the SPSCR.SPSLN[2:0] bits.
- When there is no next transmission data.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following tow conditions.

- When the next transmission data is written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 30.31 shows an example of communication end interrupt operation during transmit-receive/transmit master mode.

当接收到的数据在溢出错误状态下没有从移位寄存器复制到接收缓冲区时，在串行传输完成时，SPI确定移位寄存器为空，因此从发送缓冲区到移位寄存器的数据传输被启用.

5.当接收缓冲区满中断程序或使用SPRF标志处理接收缓冲区满中断读取SPDR_HA时，可以读取接收数据。

如果在发送缓冲区保存尚未发送的数据时写入SPDR_HA（SPTEF标志为0），则SPI不会更新发送缓冲区中的数据。写入SPDR_HA时，始终使用发送缓冲区空中断请求或使用SPTEF标志处理发送缓冲区空中断。要使用发送缓冲区空中断，请将SPCR中的SPTIE位设置为1。如果禁用SPI功能（SPCR.SPE位为0），请将SPTIE位设置为0。

当串行传输结束并且接收缓冲区已满（SPRF标志为1）时，SPI不会将数据从移位寄存器复制到接收缓冲区，它会检测到溢出错误（参见第30.3.9节。错误检测）。为防止接收数据溢出错误，请在下一次串行传输结束前使用接收缓冲区满中断请求读取接收数据。要使用SPI接收缓冲区满中断，请将SPCR.SPRIE位设置为1。

ICU中的发送和接收中断或相关的IELSRn.IR标志（其中n是中断向量号）可用于确认发送和接收缓冲区的状态。

类似地，SPTEF和SPRF标志可用于确认发送和接收缓冲区的状态。见第13节，用于中断向量编号的中断控制器单元(ICU)。

30.3.8 通讯结束中断

30.3.8.1 主控模式下的发送-接收发送

在发送-接收主机模式和发送主机模式下满足以下条件时，将产生通信结束中断(SPCI)并将CENDF标志设置为1。CENDF标志的设置时序与IDLNF标志相同。通信结束中断(SPCI)是一个PCLKUSCIx宽度和低电平有效。

●当SPSSR.SPCP[2:0]位的值与SPSCR.SPSLN[2:0]位的值相同时。

●当没有下一个传输数据时。

即使在CENDF=1后清除SPCR.SPE位，CENDF标志也不会被清除。CENDF标志将在以下两种情况之一被清除。

●下一个发送数据写入发送缓冲区（SPTX）时。

●当CENDF标志为1时，读取SPSR后CENDF标志被写入0。

图30.31显示了发送-接收发送主机模式下的通信结束中断操作示例。

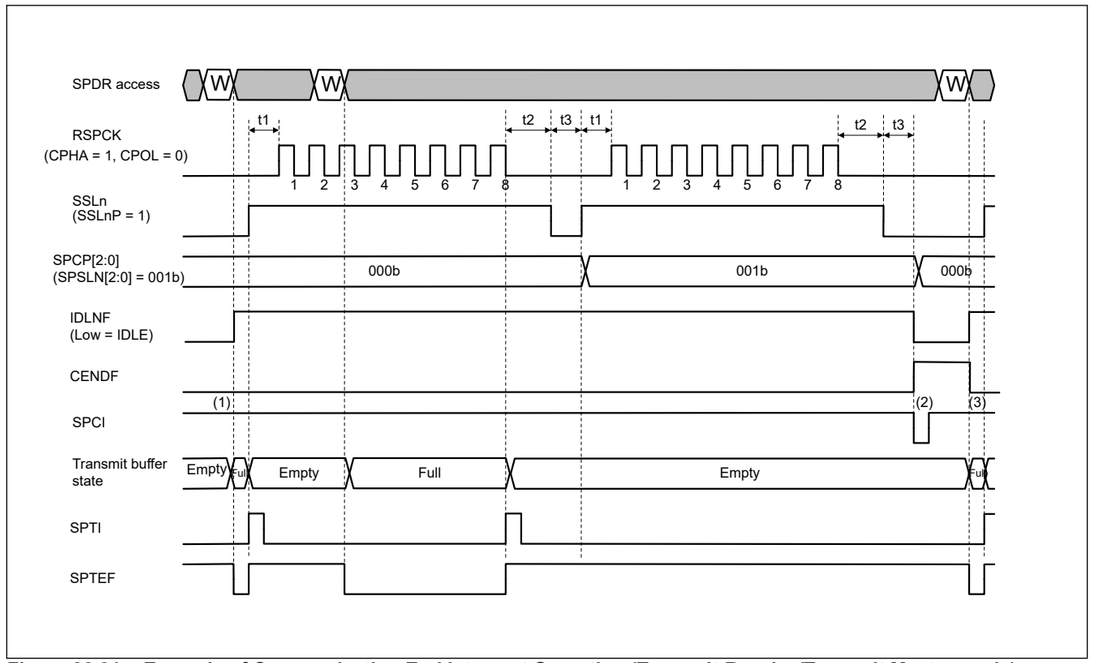

Figure 30.31 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Master mode)

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle, because the next command is 000b and there is no next transmit data, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

In slave mode operation, the output timing of the communication end interrupt is deferent due to the value of the SPCR.SPMS bit (RSPI mode select bit), and the clear timing of the communication end interrupt is deferent due to the communication mode (transmit-receive or transmit-only or receive-only).

30.3.8.2 Transmit-Receive/Transmit in Slave Mode on SPI Operation (4-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1, when both SPTX buffer and transmit shift buffer are empty in transmit-receive/transmit slave mode on SPI Operation (4-wire). The set timing of the CENDF flag is same as SSL0 negate timing. The communication end interrupt (SPCI) is one PCLKUSCIx width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following tow conditions.

- When the next transmission data is written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 30.32 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on SPI operation.

1、通信开始前CNEDF标志为0，SPCI的电平为1，在通信过程中一直保持。

2.CENDF标志在t3周期结束时为1（通讯结束），因为下一条指令为000b，没有下一条发送数据，当CENDIE位为1时SPCI中断输出。

3.CENDF标志在下一个发送数据写入发送缓冲区（SPTX）时被清除。或者，当CENDF标志为1时，如果在读取SPCR后将CENDF标志写入0，则清除CENDF标志。

在从模式操作中，通信结束中断的输出时序是不同的，因为SPCR.SPMS位（RSPI模式选择位），通信结束中断的清除时序因通信模式（发送–接收或仅发送或仅接收）而异。

30.3.8.2 SPI操作（4线）从模式下的发送–接收发送

在SPI操作（4线）的发送–接收发送从模式下，当SPTX缓冲区和发送移位缓冲区都为空时，将产生通信结束中断(SPCI)并将CENDF标志设置为1。CENDF标志的设置时序与SSL0否定时序相同。通信结束中断(SPCI)是一个PCLKUSCIx宽度和低电平有效。

即使在CENDF=1后清除SPCR.SPE位，CENDF标志也不会被清除。CENDF标志将在以下两种情况之一被清除。

- ●下一个发送数据写入发送缓冲区（SPTX）时。
- ●当CENDF标志为1时，读取SPSR后CENDF标志被写入0。

图30.32显示了在发送–接收发送从模式开启期间的通信结束中断操作示例SPI操作。

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the timing of SSL0 negate, when both SPTX buffer and transmit shift buffer are empty, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

30.3.8.3 Receive Only in Slave Mode on SPI Operation (4-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1 at the SSL0 negate timing in receive only slave mode on SPI operation (4-wire). The number of transmission frame is set by the SPDCR.SPFC[1:0]. Then the SSL0 is negated at the last frame transmission end. The communication end interrupt (SPCI) is one PCLKUSCIx width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following tow conditions.

- The SSL0 assert timing of next transmission.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

- SSL0断言下一次传输的时序。

30.3.8.6 Common Operation

In this chapter, the operation common to each mode / area option communication in section 30.3.8.1. Transmit-Receive/ Transmit in Master Mode to section 30.3.8.5. Receive Only in Slave Mode on Clock Synchronous Operation (3-wire) is explained. When the enable of RSPI communication end interrupt (CENDIE) is 0, at the time of communication completion, a flag of communication end (CENDF) is set and an event of communication end (sp_elccend) is output, but no interrupt is output. However, if the enable of communication end interrupt (CENDIE) is set to 1 before clearing the flag of communication end (CENDF) while the enable of RSPI function (SPE) is 1, the communication end interrupt is output.

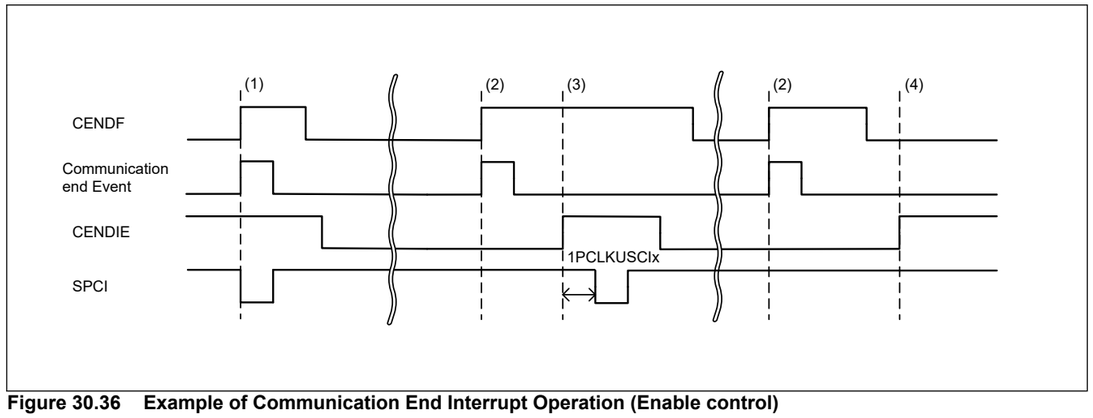

Figure 30.36 Example of Communication End Interrupt Operation (Enable control)

1. When the enable of RSPI communication end interrupt (CENDIE) is 1, at the time of communication completion, the following three are the same timing.
   - A flag of communication end (CENDF)
   - An event of communication end (sp_elccend)
   - The communication end interrupt

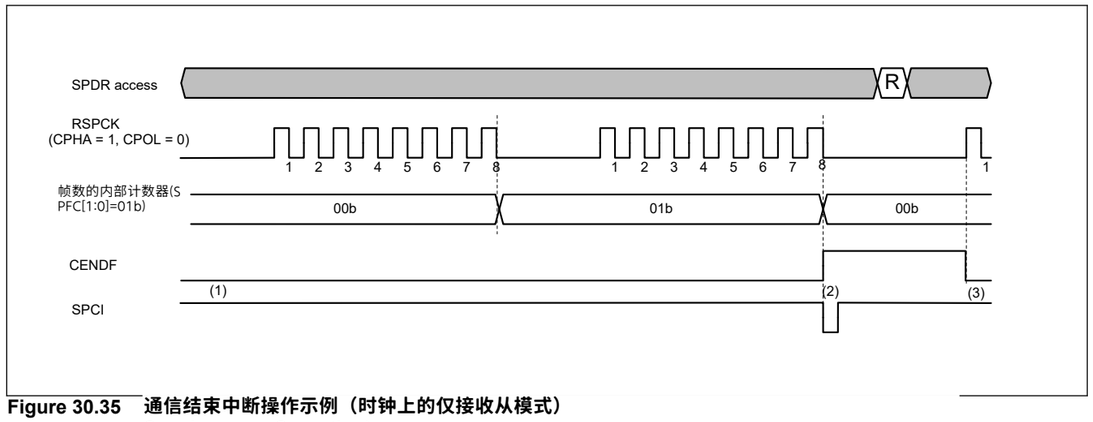

Figure 30.35 通信结束中断操作示例（时钟上的仅接收从模式）

2.CENDF标志位在RSPCK的最后一个数据采样定时为1（通信结束），即最后一帧传输结束。传输帧数由SPDCR.SPFC[1:0]设置。然后在CENDIE位为1时输出SPCI中断。

3.CENDF标志在RSPCK的第一个边沿被清除以进行下一次传输。或者，当CENDF标志为1时，如果在读取SPCR后将CENDF标志写入0，则清除CENDF标志。

30.3.8.6 常用操作

在本章中，30.3.8.1节中的每个模式区域选项通信的通用操作。发送-接收在主模式下发送到第30.3.8.5节。解释了时钟同步操作（3线）时仅在从模式下接收。当RSPI通信结束中断（CENDIE）使能为0时，通信完成时，设置通信结束标志（CENDF）并输出通信结束事件（sp_elccend），但不输出中断。但是，如果在清除通信结束标志（CENDF）之前将通信结束中断（CENDIE）的使能设置为1，而RSPI功能（SPE）的使能为1，则输出通信结束中断。

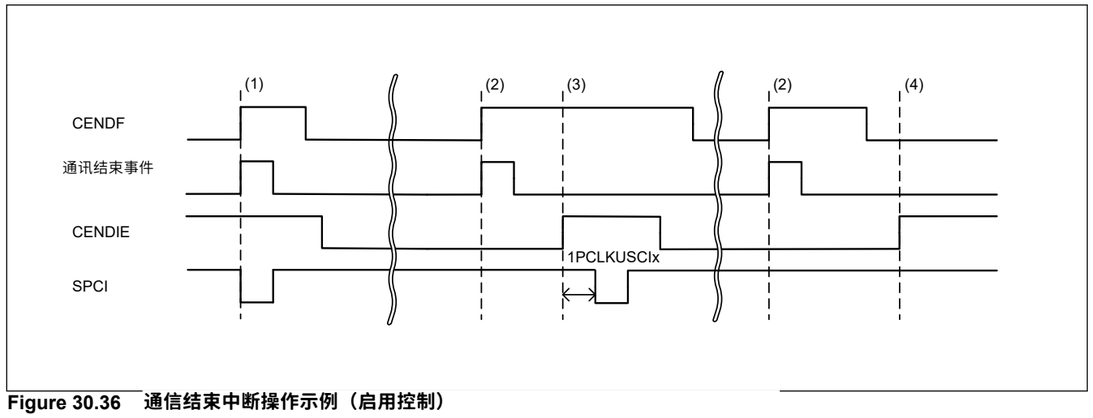

Figure 30.36 通信结束中断操作示例（启用控制）

1、当RSPI通讯结束中断（CENDIE）使能为1时，通讯完成时，以下三个是相同的时序。

- ●通讯结束标志（CENDF）
- ●通信结束事件（sp_elccend）
- ●通讯结束中断

2. When the enable of RSPI communication end interrupt (CENDIE) is 0, at the time of communication completion, the following two are the same timing, but no interrupt.
   - A flag of communication end (CENDF)
   - An event of communication end (sp_elccend)
3. After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of RSPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt is output after 1 PCLKUSCIx.
4. After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of RSPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt is not output.

30.3.9 Error Detection

In normal SPI serial transfers, data written to the transmit buffer of SPDR/SPDR_HA is transmitted, and received data can be read from the receive buffer of SPDR/SPDR_HA. If access is made to SPDR/SPDR_HA, an abnormal transfer might occur, depending on the status of the transmit or receive buffer or the status of the SPI at the beginning or end of serial transfer.

If an abnormal transfer occurs, the SPI detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 30.10 lists the relationship between non-normal transfer operations and the SPI error detection function.

Table 30.10 Relationship between non-normal transfer operations and SPI error detection

Operation	Occurrence condition	SPI operation	Error detection
1	SPDR/SPDR_HA is written when the transmit buffer is full.	• The contents of the transmit buffer are kept • Write data is missing	None
2	SPDR/SPDR_HA is read when the receive buffer is empty.	The contents of the receive buffer and previously received data are output.	None
3	Serial transfer is started in slave mode when the SPI is not able to transmit data.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Underrun error
4	Serial transfer terminates when the receive buffer is full.	• Keeps the contents of the receive buffer • Missing receive data	Overrun error
5	An incorrect parity bit is received during full-duplex synchronous serial communication with the parity function enabled in following mode: • Transmit-receive master mode • Transmit-receive slave mode • Receive-only slave mode	The parity error flag is asserted	Parity error
6	The SSLn0 input signal is asserted when the serial transfer is idle in multi-master mode.	• Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped • SPI function is disabled	Mode fault error
7	The SSLn0 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped • SPI function is disabled	Mode fault error
8	The SSLn0 input signal is negated during serial transfer in slave mode.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Mode fault error

In operation 1 described in Table 30.10, the SPI does not detect an error. To prevent data omission during writes to SPDR/SPDR_HA, the writes to SPDR/SPDR_HA must be executed using a transmit buffer empty interrupt request (when the SPSR.SPTEF flag is 1).

Similarly, the SPI does not detect an error in operation 2. To prevent extraneous data from being read, SPDR/SPDR_HA read must be executed with an SPI receive buffer full interrupt request (when the SPSR.SPRF flag is 1).

For information on the other errors, see the following sections:

2、当RSPI通讯结束中断（CENDIE）使能为0时，通讯完成时，以下两者时序相同，但无中断。

●通讯结束标志（CENDF）

●通信结束事件（sp_elccend）

3.（2）之后，如果在RSPI功能（SPE）使能和通信结束标志（CENDF）为1的情况下设置通信结束中断（CENDIE）使能，则在1个PCLKUSCIx后输出通信结束中断。

4.(2)后，即使在RSPI功能(SPE)使能或通信结束标志(CENDF)为0时设置通信结束中断(CENDIE)使能，也不输出通信结束中断。

30.3.9 错误检测

在正常的SPI串行传输中，写入到SPDRSPDR_HA的发送缓冲区的数据被发送，接收到的数据可以从SPDRSPDR_HA的接收缓冲区中读取。如果访问SPDRSPDR_HA，可能会发生异常传输，具体取决于发送或接收缓冲区的状态或串行传输开始或结束时SPI的状态。

如果发生异常传输，SPI会将事件检测为欠载错误、溢出错误、奇偶校验错误或模式故障错误。
表30.10列出了非正常传输操作和SPI错误检测功能之间的关系。

Table 30.10 非正常传输操作与SPI错误检测的关系

Operation	发生条件	SPI操作	错误检测
1	SPDRSPDR_HA在发送缓冲区已满时写入。	• 发送缓冲区的内容被保留 • 写入数据丢失	None
2	SPDRSPDR_HA在接收缓冲区为空时读取。	输出接收缓冲区的内容和先前接收的数据。	None
3	当SPI无法传输数据时，串行传输在从模式下启动。	• 串行传输被暂停 • 发送或接收数据丢失 • MIOn输出信号的驱动停止 • SPI功能被禁用	Underrun error
4	当接收缓冲区已满时，串行传输终止。	• 保留接收缓冲区的内容 • 缺少接收数据	溢出错误
5	全双工同步串行通信时接收到错误的奇偶校验位，并在以下模式下启用奇偶校验功能：● 收发主模式 • 收发从模式 • 只接收从模式	奇偶错误标志被置位	奇偶校验错误
6	当串行传输在多主模式下空闲时，SSLn0输入信号被置位。	• 将RSPCKn、MOSIn、SSLn1驱动到SSLn3输出信号停止 • SPI功能被禁用	模式故障错误
7	SSLn0输入信号在多主机模式下的串行传输期间被置位。	• 串行传输被暂停 • 发送或接收数据丢失 • 将RSPCKn、MOSIn、SSLn1驱动到SSLn3输出信号停止 • SPI功能被禁用	模式故障错误
8	SSLn0输入信号在从模式下的串行传输期间被否定。	• 串行传输被暂停 • 发送或接收数据丢失 • MIOn输出信号的驱动停止 • SPI功能被禁用	模式故障错误

在表30.10中描述的操作1中，SPI未检测到错误。防止写入SPDR期间的数据遗漏SPDR_HA，对SPDRSPDR_HA的写入必须使用发送缓冲区空中断请求（当SPSR.SPTEF标志为1)。

同样，SPI不会检测到操作2中的错误。为防止读取无关数据，必须使用SPI接收缓冲区满中断请求（当SPSR.SPRF标志为1时）执行SPDRSPDR_HA读取。

30.3.9.1 Overrun errors

If a serial transfer ends when the receive buffer of SPDR/SPDR_HA is full, the SPI detects an overrun error and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the SPI does not copy data from the shift register to the receive buffer, so the data prior to the error occurrence is retained in the receive buffer. To set the OVRF flag to 0, write 0 to the OVRF flag after the CPU reads SPSR with the OVRF flag set to 1.

Figure 30.37 shows an example of operation of the OVRF and SPRF flags. The SPSR and SPDR_HA accesses shown in Figure 30.37 indicate the condition of accesses to the SPSR and SPDR_HA register, where W denotes a write cycle, and R a read cycle. In this example, the SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

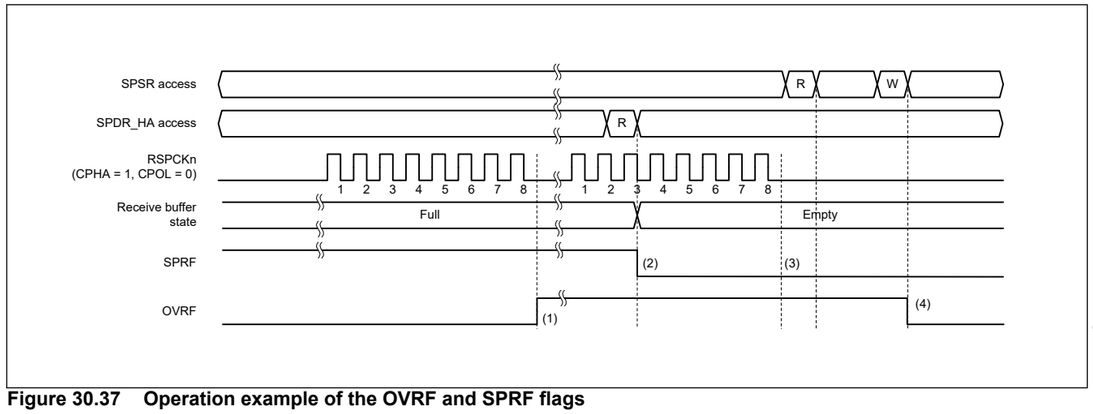

Figure 30.37 Operation example of the OVRF and SPRF flags

The operation of the flags at timings (1) to (4) in Figure 30.37 is as follows:

1. If a serial transfer terminates with the SPRF flag set to 1 (receive buffer full), the SPI detects an overrun error, and sets the OVRF flag to 1. The SPI does not copy the data in the shift register to the receive buffer. Even when the SPPE bit is 1, parity errors are not detected.
2. When SPDR/SPDR_HA is read, the SPI outputs the data in the receive buffer. The SPRF flag is then set to 0. The receive buffer becoming empty does not set the OVRF flag to 0.
3. If the serial transfer ends with the OVRF flag set to 1 (overrun error occurred), the SPI does not copy data in the shift register to the receive buffer (the SPRF flag does not set to 1). A receive buffer full interrupt is not generated. Even when the SPPE bit is 1, parity errors are not detected. In an overrun error state when the SPI does not copy the received data from the shift register to the receive buffer, on termination of the serial transfer, the SPI determines that the shift register is empty. This enables data transfer from the transmit buffer to the shift register.
4. If 0 is written to the OVRF flag after SPSR is read when the OVRF flag is 1, the OVRF flag clears is set to 0.

The occurrence of an overrun can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. When executing a serial transfer, you must ensure that overrun errors are detected early, for example by reading SPSR immediately after SPDR/SPDR_HA/SPDR_BY is read.

If an overrun error occurs and the OVRF flag sets to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

30.3.9.1 溢出错误

如果在SPDRSPDR_HA的接收缓冲区已满时串行传输结束，则SPI检测到溢出错误并设置SPSR.OVRF标志为1。当OVRF标志为1时，SPI不会将数据从移位寄存器复制到接收缓冲区，因此错误发生之前的数据会保留在接收缓冲区中。要将OVRF标志设置为0，请在CPU读取OVRF标志设置为1的SPSR后将0写入OVRF标志。

图30.37显示了OVRF和SPRF标志的操作示例。SPSR和SPDR_HA访问显示在图30.37表示访问SPSR和SPDR_HA寄存器的条件，其中W表示写周期，R表示读周期。在本例中，当SPCMDm.CPHA位为1且SPCMDm.CPOL位为0时，SPI执行8位串行传输。波形中为RSPCKn给出的数字表示RSPCK周期数，例如传输的次数位。

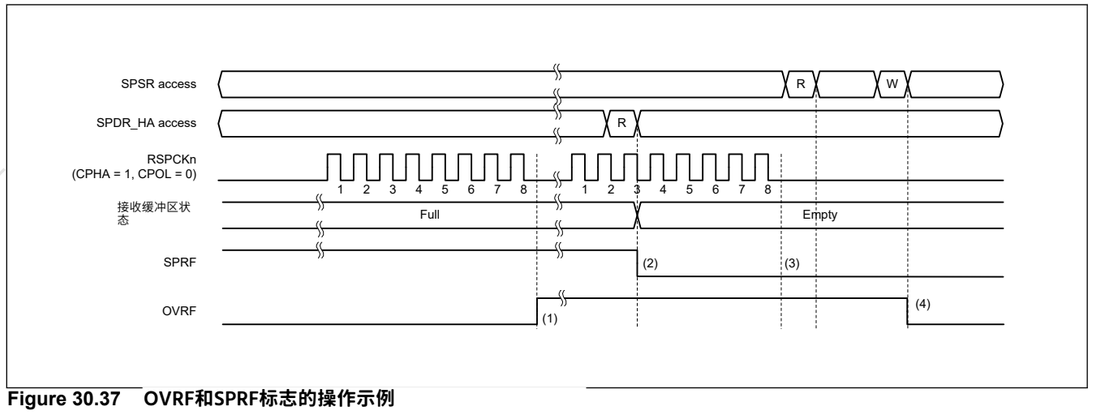

Figure 30.37 OVRF和SPRF标志的操作示例

图30.37中时间(1)到(4)的标志操作如下：

1.如果串行传输终止且SPRF标志设置为1（接收缓冲区已满），则SPI检测到溢出错误，并将OVRF标志设置为1。SPI不会将移位寄存器中的数据复制到接收缓冲区.即使SPPE位为1，也不会检测到奇偶校验错误。

2.读取SPDRSPDR_HA时，SPI输出接收缓冲区中的数据。然后SPRF标志设置为0。接收缓冲区变空不会将OVRF标志设置为0。

3.如果串行传输结束时OVRF标志设置为1（发生溢出错误），则SPI不会将移位寄存器中的数据复制到接收缓冲区（SPRF标志不设置为1）。不产生接收缓冲区满中断。即使SPPE位为1，也不会检测到奇偶校验错误。在SPI未将接收到的数据从移位寄存器复制到接收缓冲区的溢出错误状态下，在串行传输终止时，SPI确定移位寄存器为空。这使数据能够从发送缓冲器传输到移位寄存器。

4.如果在OVRF标志为1时读取SPSR后向OVRF标志写入0，则OVRF标志清除设置为0。

可以通过读取SPSR或使用SPI错误中断并读取SPSR来检查溢出的发生。
执行串行传输时，必须确保及早检测到溢出错误，例如在读取SPDRSPDR_HASPDR_BY后立即读取SPSR。

如果发生溢出错误并且OVRF标志设置为1，则在OVRF标志设置为0之前无法执行正常接收操作。

When the RSPCK auto-stop function is enabled (SPCR2.SCKASE = 1) in master mode, an overrun error does not occur. Figure 30.38 and Figure 30.39 show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

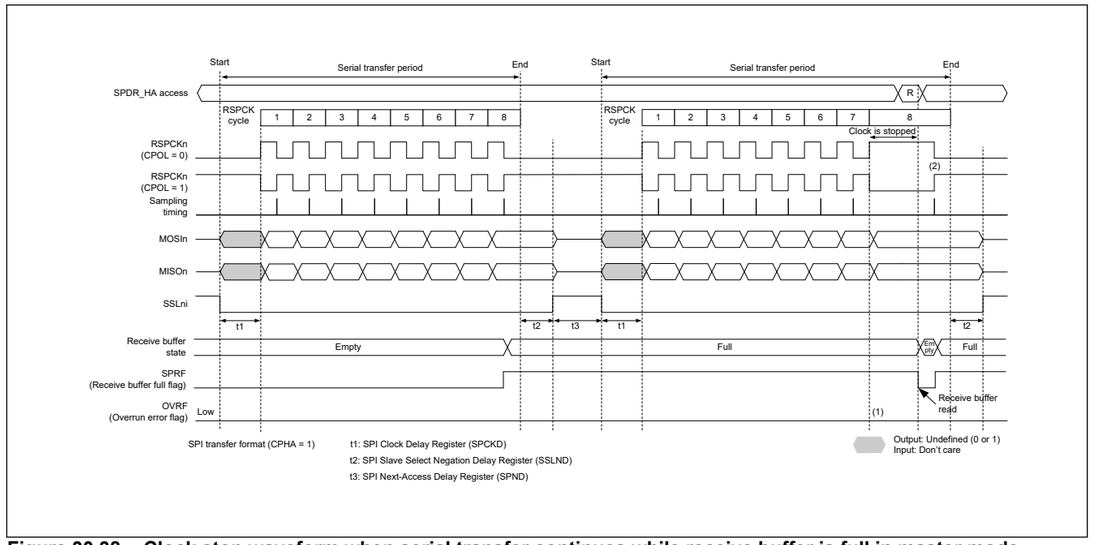

Figure 30.38 Clock stop waveform when serial transfer continues while receive buffer is full in master mode (CPHA = 1)

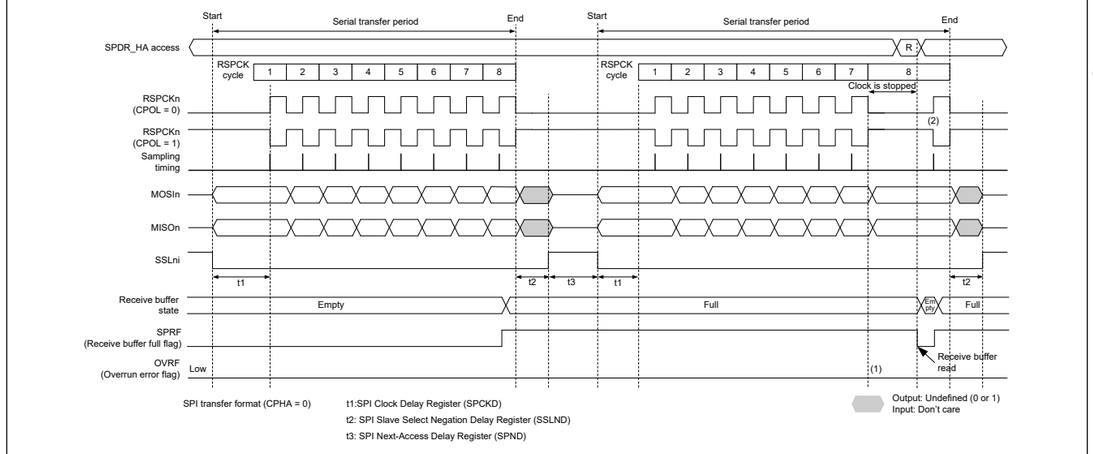

Figure 30.39 Clock stop waveform when serial transfer continues while receive buffer is full in master mode (CPHA = 0)

The operation of the flags at timings (1) and (2) in Figure 30.38 and Figure 30.39 is as follows:

1. When the receive buffer is full, an overrun error does not occur because the RSPCK clock is stopped.
2. If SPDR/SPDR_HA is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts after reading the receive buffer (after the SPSR.SPRF flag is set to 0).

在主机模式下启用RSPCK自动停止功能（SPCR2.SCKASE=1）时，不会发生溢出错误。
图30.38和图30.39显示了在主机模式下接收缓冲器已满时串行传输继续时的时钟停止波形。

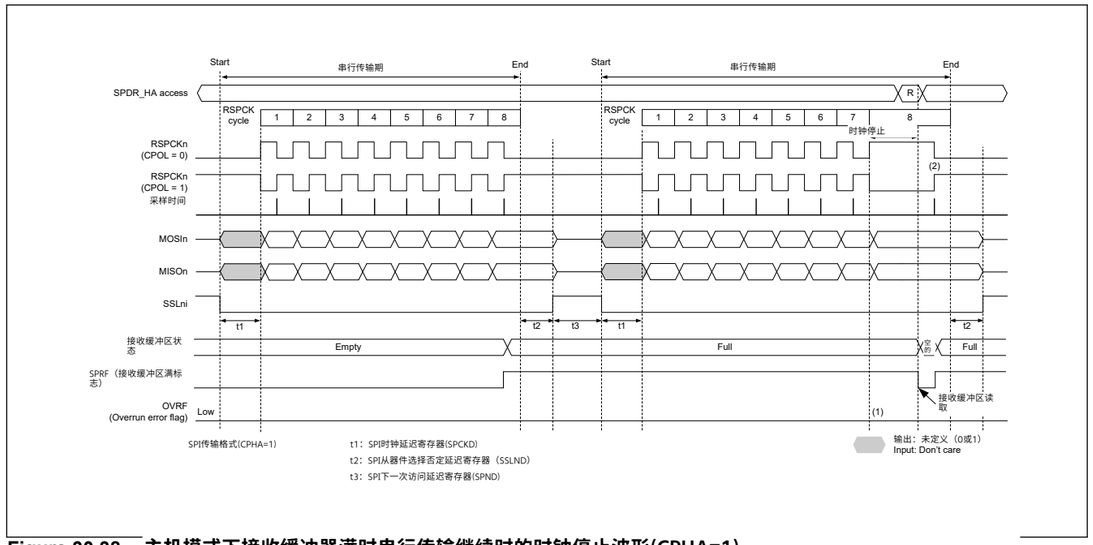

Figure 30.38 主机模式下接收缓冲器满时串行传输继续时的时钟停止波形(CPHA=1)

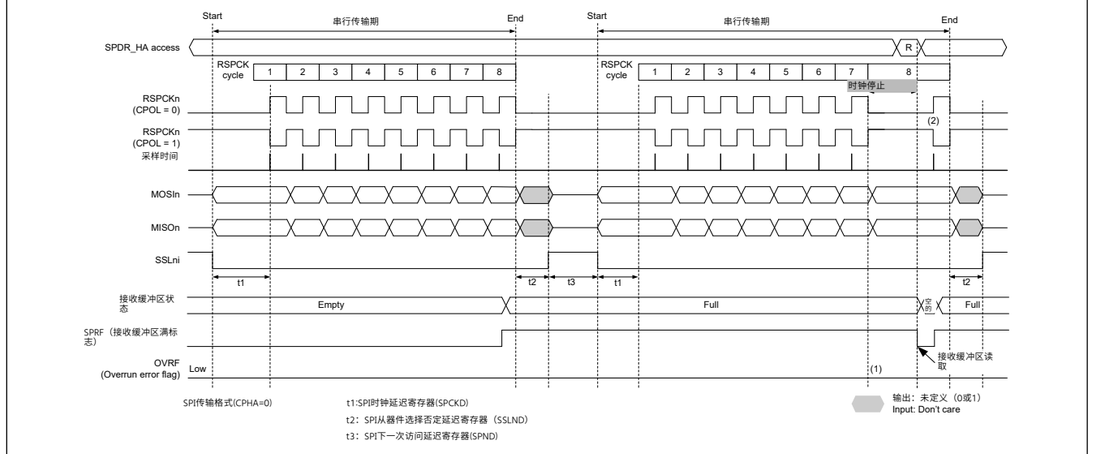

Figure 30.39 主机模式下接收缓冲器满时串行传输继续时的时钟停止波形(CPHA=0)

图30.38和图30.39中时序（1）和（2）的标志操作如下：

1.当接收缓冲区已满时，不会发生溢出错误，因为RSPCK时钟已停止。

2.如果在时钟停止时读取SPDRSPDR_HA，则可以读取接收缓冲区中的数据。RSPCK时钟在读取接收缓冲区后重新启动（在SPSR.SPRF标志设置为0后）。

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. Figure 30.40 and Figure 30.41 show the clock stop waveform, when there is no delay between frames at burst transfer and the serial transfer continues in the reception buffer full state.

The following describes operation of flags at timings (1) and (2) in the figure above.

在主模式下的突发传输期间，如果传输启用RSPCK自动停止功能且帧之间没有延迟，则不会发生溢出错误。图30.40和图30.41显示了时钟停止波形，当突发传输的帧之间没有延迟并且串行传输在接收缓冲器满状态下继续时。

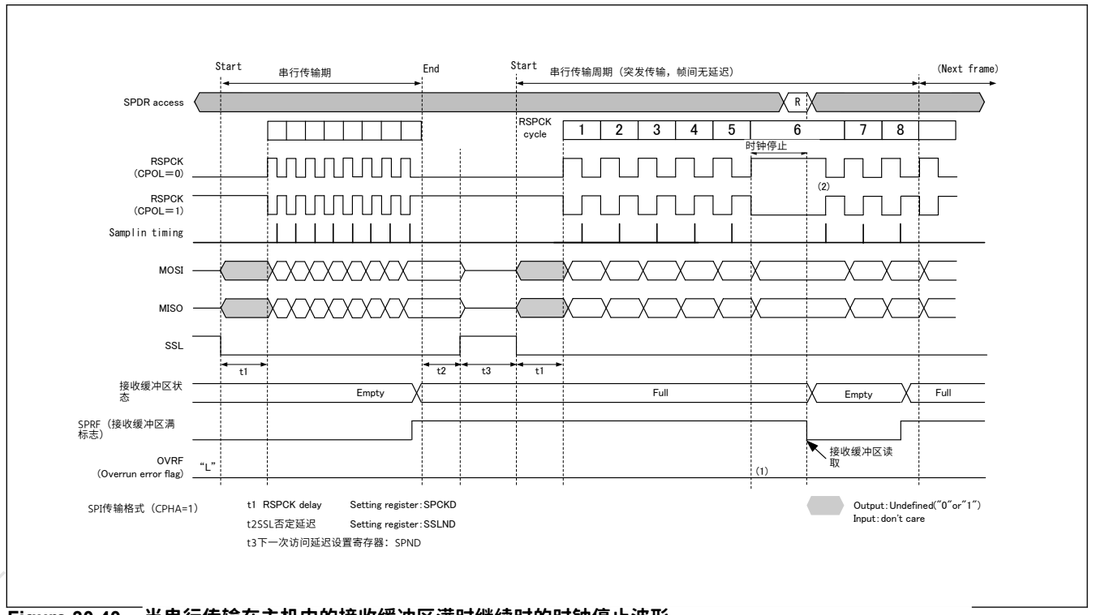

Figure 30.40 当串行传输在主机中的接收缓冲区满时继续时的时钟停止波形模式（突发传输且帧之间无延迟CPHA=1）

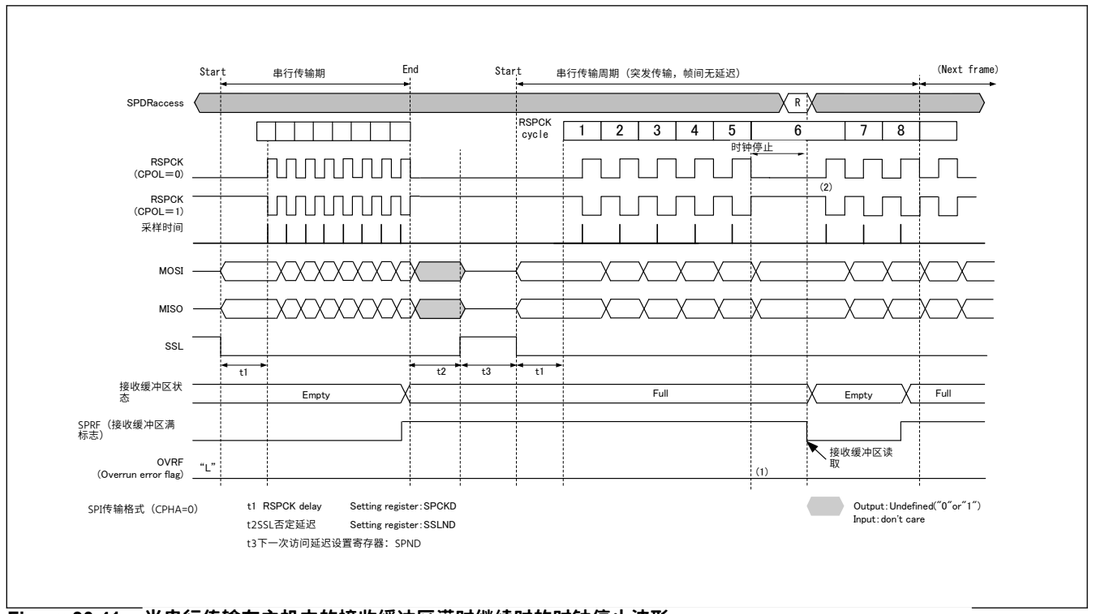

Figure 30.41 当串行传输在主机中的接收缓冲区满时继续时的时钟停止波形模式（突发传输且帧之间无延迟CPHA=0）

下面描述在上图中的时间(1)和(2)的标志的操作。

1. While the receive buffer is full, the RSPCK clock is deactivated and no overrun error occurs.
2. Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read (after the SPSR.SPRF flag has been cleared to 0), the RSPCK clock restarts.

30.3.9.2 Parity errors

When full-duplex synchronous serial communications is performed with the SPCR.TXMD bit set to 0 and the SPCR2.SPPE bit set to 1, when serial transfer ends, the SPI checks whether there are parity errors. On detecting a parity error in the received data, the SPI sets the SPSR.PERF flag to 1. Because the SPI does not copy data in the shift register to the receive buffer when the SPSR.OVRF flag is set to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, write 0 to the PERF flag after the SPSR register is read with the PERF flag set to 1.

Figure 30.42 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 30.42 indicates the condition of access to the register, where W denotes a write cycle, and R a read cycle. In this example, full-duplex serial communication is performed while the SPCR2.SPPE bit is 1. The SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

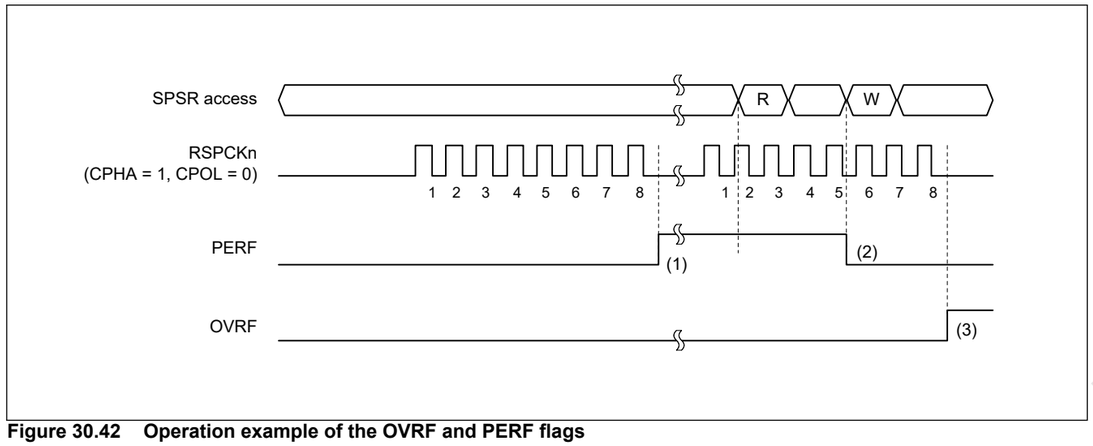

Figure 30.42 Operation example of the OVRF and PERF flags

The operation of the flags at timings (1) to (3) in Figure 30.42 is as follows:

1. If a serial transfer terminates with the SPI not detecting an overrun error, the SPI copies the data in the shift register to the receive buffer. The SPI checks the received data at this time and sets the PERF flag to 1 if a parity error is detected.
2. If 0 is written to the PERF flag after the SPSR register is read when the PERF flag is 1, the PERF flag is set to 0.
3. When the SPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The SPI does not perform parity error detection at this time.

Parity errors can be checked for by either reading the SPSR register or using an SPI error interrupt and reading the SPSR register. When executing a serial transfer, such checks are required to ensure early detection of parity errors. When the SPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits (Only SPI0).

30.3.9.3 Mode fault errors

The SPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input for the SSLn0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of the status of the serial transfer, and sets the SPSR.MODF flag to 1. On detecting the mode fault error, the SPI copies the value of the pointer to SPCMDm to the SPDCR.SPFC[1:0] bits. The active level of the SSLn0 signal is determined by the SSLP.SSL0P bit.

When the MSTR bit is 0, the SPI operates in slave mode. The SPI detects a mode fault error if the MODFEN bit of the SPI in slave mode is 1, and the SPMS bit is 0, and if the SSLn0 input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

1.当接收缓冲器已满时，RSPCK时钟被停用，不会发生溢出错误。

2.在时钟停止时，可以通过读取SPDR来读取接收缓冲数据。读取接收缓冲区数据后（在SPSR.SPRF标志被清除为0后），RSPCK时钟重新启动。

30.3.9.2 奇偶校验错误

当SPCR.TXMD位设置为0且SPCR2.SPPE位设置为1进行全双工同步串行通信时，串行传输结束时，SPI会检查是否有奇偶校验错误。在接收到的数据中检测到奇偶校验错误时，SPI将SPSR.PERF标志设置为1。因为当SPSR.OVRF标志设置为1时，SPI不会将移位寄存器中的数据复制到接收缓冲区，所以奇偶校验错误检测不针对接收到的数据执行。要将PERF标志设置为0，请在读取SPSR寄存器并将PERF标志设置为1后将0写入PERF标志。

图30.42显示了OVRF和PERF标志的操作示例。图30.42所示的SPSR访问表示访问寄存器的条件，其中W表示写周期，R表示读周期。在本例中，当SPCR2.SPPE位为1时执行全双工串行通信。当SPCMDm.CPHA位为1且SPCMDm.CPOL位为0时，SPI执行8位串行传输。波形表示RSPCK周期数，例如传输的位数。

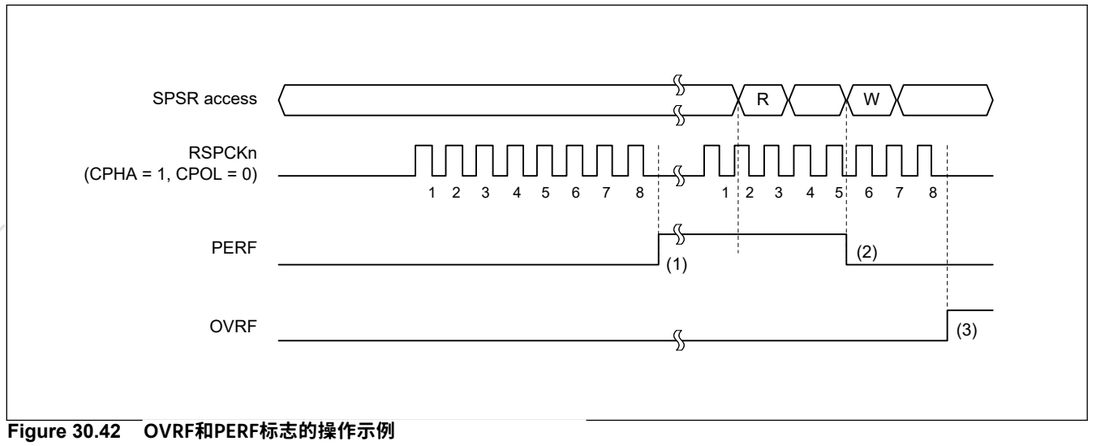

Figure 30.42 OVRF和PERF标志的操作示例

图30.42中时间(1)到(3)的标志操作如下：

1.如果串行传输终止且SPI未检测到溢出错误，则SPI将移位寄存器中的数据复制到接收缓冲区。此时SPI会检查接收到的数据，如果检测到奇偶校验错误，则将PERF标志设置为1。

2.如果在PERF标志为1时读取SPSR寄存器后将0写入PERF标志，则将PERF标志设置为0。

3.当SPI检测到溢出错误并终止串行传输时，移位寄存器中的数据不会复制到接收缓冲区。此时SPI不执行奇偶校验错误检测。

可以通过读取SPSR寄存器或使用SPI错误中断并读取SPSR寄存器来检查奇偶校验错误。在执行串行传输时，需要进行此类检查以确保及早发现奇偶校验错误。当SPI用于主机模式时，可以通过读取SPSSR.SPECM[2:0]位（仅SPI0）来检查发生错误时指向SPCMDm寄存器的指针值。

30.3.9.3 模式故障错误

当SPCR.MSTR位为1、SPCR.SPMS位为0、SPCR.MODFEN位为1时，SPI工作在多主机模式。如果在多主机模式下SPI的SSLn0输入信号输入有效电平-主模式，无论串行传输的状态如何，SPI都会检测到模式故障错误，并将SPSR.MODF标志设置为1。在检测到模式故障错误时，SPI将指向SPCMDm的指针的值复制到SPDCR.SPFC[1:0]位。SSLn0信号的有效电平由SSLP.SSL0P位决定。

当MSTR位为0时，SPI工作在从机模式。如果从机模式下SPI的MODFEN位为1，SPMS位为0，并且在串行传输期间（从驱动有效数据开始开始到获取最终有效数据的时间）。

On detecting a mode fault error, the SPI stops the driving of the output signals and clears the SPCR.SPE bit to 0 (see section 30.3.10. Initializing the SPI). For multi-master configuration, detection of a mode fault error is used to stop the driving of output signals and the SPI function, which allows the master to be released.

The occurrence of a mode fault error can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting mode-fault errors without using the SPI error interrupt requires polling of SPSR. When using the SPI in master mode, the value of the pointer to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of a mode fault error, the MODF flag must be set to 0.

30.3.9.4 Underrun errors

While the SPI is operating in slave mode (SPCR.MSTR bit = 0) and the Extended Communication Mode Select bit (ETXMD) in the SPI Control Register 3 (SPCR3) is set to 0, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1 (SPI function enabled), the SPI detects an underrun error and sets the SPSR.MODF and SPSR.UDRF flags to 1.

On detecting an underrun error, the SPI stops the driving of output signals and clears the SPCR.SPE bit to 0 (see section 30.3.10. Initializing the SPI).

The occurrence of underrun errors can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting underrun errors without using the SPI error interrupt requires polling of SPSR.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of an underrun error, the MODF flag must be set to 0.

30.3.10 Initializing the SPI

If 0 is written to the SPCR.SPE bit or if the SPI sets the SPE bit to 0 because it detected a mode fault error or an underrun error, the SPI disables the SPI function and initializes some of the module functions. When a system reset is generated, the SPI initializes all of the module functions. This section describes initialization by clearing of the SPCR.SPE bit and by a system reset.

30.3.10.1 Initialization by clearing of the SPCR.SPE bit

When the SPCR.SPE bit is set to 0, the SPI initializes by:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the SPI
- Initializing the transmit buffer of the SPI (the SPSR.STEF flag sets to 1)

Initialization by clearing of the SPE bit does not initialize the control bits of the SPI. For this reason, the SPI can be started in the same transfer mode in use prior to initialization when the SPE bit is set to 1 again.

The SPSR.CENDF, SPSR.SPRF, SPSR.OVRF, SPSR.MODF, SPSR.PERF, and SPSR.UDRF flags are not initialized, and the value of the SPI Sequence Status Register (SPSSR) is not initialized. Therefore, even after the SPI is initialized, data from the receive buffer can be read to check the communication completion status and the error status during an SPI transfer.

The transmit buffer is initialized to an empty state (the SPSR.SPTEF flag sets to 1). Therefore, if the SPCR.SPTIE bit is set to 1 after SPI initialization, a transmit buffer empty interrupt is generated. To disable any transmit buffer empty interrupts when the SPI is initialized, write 0 to the SPTIE bit simultaneously while writing 0 to the SPE bit.

30.3.10.2 Initialization by system reset

A system reset completely initializes the SPI by initializing all SPI control bits, status bits, and data registers, in addition to meeting the requirements described in section 30.3.10.1. Initialization by clearing of the SPCR.SPE bit.

在检测到模式故障错误时，SPI停止驱动输出信号并将SPCR.SPE位清零（参见第30.3.10节。初始化SPI）。对于多主机配置，检测到模式故障错误用于停止驱动输出信号和SPI功能，从而释放主机。

可以通过读取SPSR或使用SPI错误中断并读取SPSR来检查模式故障错误的发生。在不使用SPI错误中断的情况下检测模式错误需要轮询SPSR。在主模式下使用SPI时，可以通过读取SPSSR.SPECM[2:0]位来检查发生错误时指向SPCMDm寄存器的指针的值。

当MODF标志为1时，向SPE位写入1会被SPI忽略。要在检测到模式故障错误后启用SPI功能，MODF标志必须设置为0。

30.3.9.4 Underrun errors

当SPI在从机模式下运行（SPCR.MSTR位=0）并且SPI控制寄存器3（SPCR3）中的扩展通信模式选择位（ETXMD）设置为0时，如果串行传输在发送数据输出之前开始准备好将SPCR.SPE位设置为1（启用SPI功能），SPI检测到欠载错误并将SPSR.MODF和SPSR.UDRF标志设置为1。

检测到欠载错误时，SPI停止驱动输出信号并将SPCR.SPE位清零（参见第30.3.10节。初始化SPI）。

可以通过读取SPSR或使用SPI错误中断并读取
SPSR。在不使用SPI错误中断的情况下检测欠载错误需要轮询SPSR。

当MODF标志为1时，向SPE位写入1会被SPI忽略。要在检测到欠载错误后启用SPI功能，MODF标志必须设置为0
。

30.3.10 初始化SPI

如果将0写入SPCR.SPE位，或者如果SPI由于检测到模式故障错误或欠载错误而将SPE位设置为0，则SPI将禁用SPI功能并初始化一些模块功能。当产生系统复位时，SPI初始化所有模块功能。本节介绍通过清除SPCR.SPE位和系统复位进行的初始化。

30.3.10.1 通过清除SPCR.SPE位进行初始化

当SPCR.SPE位设置为0时，SPI通过以下方式初始化：

- 暂停任何正在执行的串行传输
- 从机模式下停止驱动输出信号（Hi-Z）
- 初始化SPI的内部状态
- 初始化SPI的发送缓冲区（SPSR.STEF标志设置为1）

通过清除SPE位进行的初始化不会初始化SPI的控制位。因此，当SPE位再次设置为1时，SPI可以在初始化之前以相同的传输模式启动。

SPSR.CENDF、SPSR.SPRF、SPSR.OVRF、SPSR.MODF、SPSR.PERF和SPSR.UDRF标志未初始化，SPI序列状态寄存器(SPSSR)的值未初始化。因此，即使在SPI初始化之后，也可以从接收缓冲区读取数据，以检查SPI传输期间的通信完成状态和错误状态。

发送缓冲区初始化为空状态（SPSR.SPTEF标志设置为1）。因此，如果SPCR.SPTIE位在SPI初始化后设置为1，则会产生发送缓冲区空中断。要在SPI初始化时禁用任何发送缓冲区空中断，请同时将0写入SPTIE位，同时将0写入SPE位。

30.3.10.2 通过系统复位初始化

除了满足第30.3.10.1节中描述的要求外，系统复位还通过初始化所有SPI控制位、状态位和数据寄存器来完全初始化SPI。通过清除SPCR.SPE位进行初始化。

30.3.11 SPI Operation

30.3.11.1 Master mode operation

The only difference between single- and multi-master mode operation is the use of mode fault error detection (see section 30.3.9. Error Detection). In single-master mode, the SPI does not detect mode fault errors whereas in multi-master mode, it does. This section explains operations that are common to both modes.

(1) Starting a serial transfer

The SPI updates the data in the transmit buffer (SPTX) when data is written to the SPI Data Register (SPDR/SPDR_HA) with the SPI transmit buffer empty, data for the next transfer is not set, and the SPSR.STEF flag is 0. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR/SPDR_HA/SPDR_BY, the SPI copies data from the transmit buffer to the shift register and starts serial transfer. On copying transmit data to the shift register, the SPI changes the status of the shift register to full. On termination of the serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

The polarity of the SSLni output pins depends on the SSLP register settings. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

(2) Terminating a serial transfer

Regardless of the SPCMDm.CPHA bit setting, the SPI terminates the serial transfer after transmitting an RSPCKn edge associated with the final sampling timing. If free space is available in the receive buffer (SPRX) (the SPSR.SPRF flag is 0), on termination of the serial transfer, the SPI copies data from the shift register to the receive buffer of the SPDR/SPDR_HA register.

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[3:0] bit settings. The polarity of the SSLni output pin depends on the SSLP register settings. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

(3) Sequence control

The transfer format used in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers.

The SPSCR register determines the sequence configuration for serial transfers that are executed by the SPI in master mode. The following items are set in the SPCMDm register:

- SSLni pin output signal value
- MSB- or LSB-first
- Data length
- Some of the bit rate settings
- RSPCK polarity and phase
- Whether SPCKD is to be referenced
- Whether SSLND is to be referenced
- Whether SPND is to be referenced

SPBR holds some of the bit rate settings, including SPCKD (SPI clock delay), SSLND (SSL negation delay), and SPND (next-access delay).

Based on the sequence length assigned in SPSCR, the SPI makes up a sequence comprised of a part or all of the SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command in the sequence, the SPI sets the pointer to SPCMD0, and in this way the sequence is executed repeatedly.

30.3.11 SPI操作

30.3.11.1 主模式操作

单主机模式和多主机模式操作之间的唯一区别是使用模式故障错误检测（请参阅第30.3.9节。错误检测）。在单主机模式下，SPI不检测模式故障错误，而在多主机模式下，它可以。本节介绍两种模式共有的操作。

(1) 开始串行传输

当数据写入SPI数据寄存器(SPDRSPDR_HA)且SPI发送缓冲区为空、未设置下一次传输的数据且SPSR.STEF标志为0时，SPI更新发送缓冲区(SPTX)中的数据。当SPDCR.SPFC[1:0]位中设置的帧数写入SPDRSPDR_HASPDR_BY后移位寄存器为空时，SPI将数据从发送缓冲区复制到移位寄存器并开始串行传输。在将发送数据复制到移位寄存器时，SPI将移位寄存器的状态更改为已满。在串行传输终止时，它将移位寄存器的状态更改为空。无法引用移位寄存器的状态。

SSLni输出引脚的极性取决于SSLP寄存器设置。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

(2) 终止串行传输

无论SPMDm.CPHA位设置如何，SPI在发送与最终采样时序相关的RSPCKn边沿后终止串行传输。如果接收缓冲区(SPRX)中有可用空间（SPSR.SPRF标志为0），则在串行传输终止时，SPI将数据从移位寄存器复制到SPDRSPDR_HA寄存器的接收缓冲区。

最终的采样时序根据传输数据的位长而变化。在主模式下，SPI数据长度取决于SPMDm.SPB[3:0]位设置。SSLni输出引脚的极性取决于SSLP寄存器设置。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

(3) 顺序控制

主机模式中使用的传输格式由SPSCR、SPCMDm、SPBR、SPCKD、SSLND和SPND寄存器决定。

SPSCR寄存器确定由SPI在主模式下执行的串行传输的序列配置。
在SPCMDm寄存器中设置以下项目：

●SSLni管脚输出信号值

- MSB- or LSB-first

●数据长度

●一些比特率设置

●RSPCK极性和相位

●是否引用SPCKD

●是否引用SSLND

●是否引用SPND

SPBR保存一些比特率设置，包括SPCKD（SPI时钟延迟）、SSLND（SSL否定延迟）和SPND（下一次访问延迟）。

根据在SPSCR中分配的序列长度，SPI组成一个由部分或全部SPMDm寄存器组成的序列。SPI包含一个指向构成序列的SPCMDm寄存器的指针。该指针的值可以通过读取SPSSR.SPCP[2:0]位来检查。当SPCR.SPE位设置为1且SPI功能使能时，SPI加载指向SPCMD0中命令的指针，并在串行传输开始时将SPCMD0设置合并到传输格式中。每次数据传输的下一个访问延迟周期结束时，SPI都会递增指针。在完成对应于序列中最终命令的串行传输后，SPI将指针设置为

SPCMD0，并以这种方式重复执行序列。

(4) Burst transfers

If the SPCMDm.SSLKP bit that the SPI references during the current serial transfer is 1, the SPI maintains the SSLni signal level during the serial transfer until the beginning of the SSLni signal assertion for the next serial transfer. If the SSLni

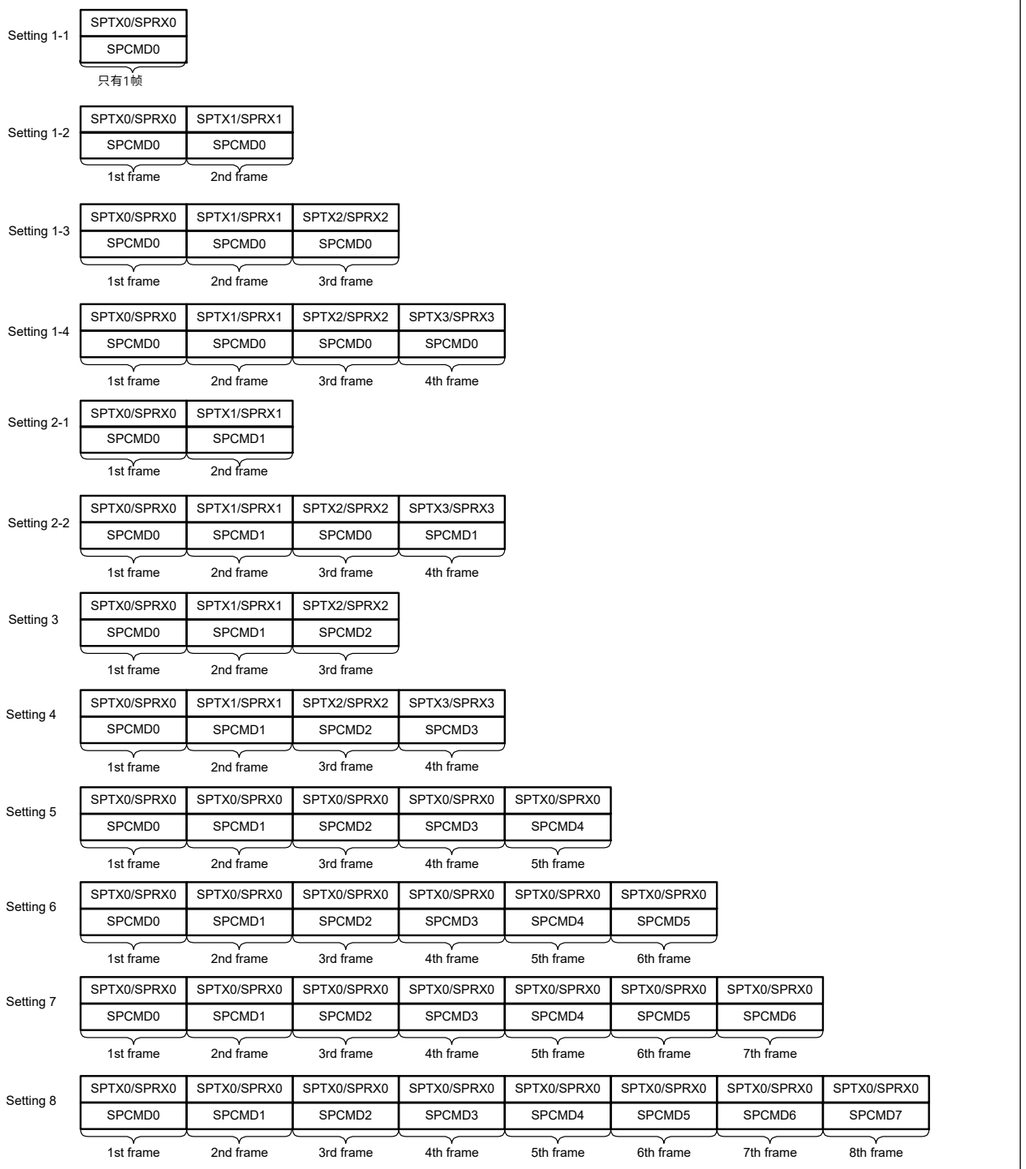

Figure 30.45 顺序操作中SPI命令寄存器与发送接收缓冲区的对应关系

(4) 突发传输

如果SPI在当前串行传输期间引用的SPCMDm.SSLKP位为1，则SPI在串行传输期间保持SSLni信号电平，直到下一次串行传输的SSLni信号断言开始。如果SSLni

signal level for the next serial transfer is the same as the SSLni signal level for the current serial transfer, the SPI can execute continuous serial transfers while keeping the SSLni signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register 3 (SPCR3) is 0.

Figure 30.46 shows an example of an SSLni signal operation for a burst transfer that is implemented using the SPCMD0 and SPCMD1 register settings. This section describes SPI operations (1) to (8) shown in Figure 30.46.

Note: The polarity of the SSLni output signal depends on the SSLP register settings.

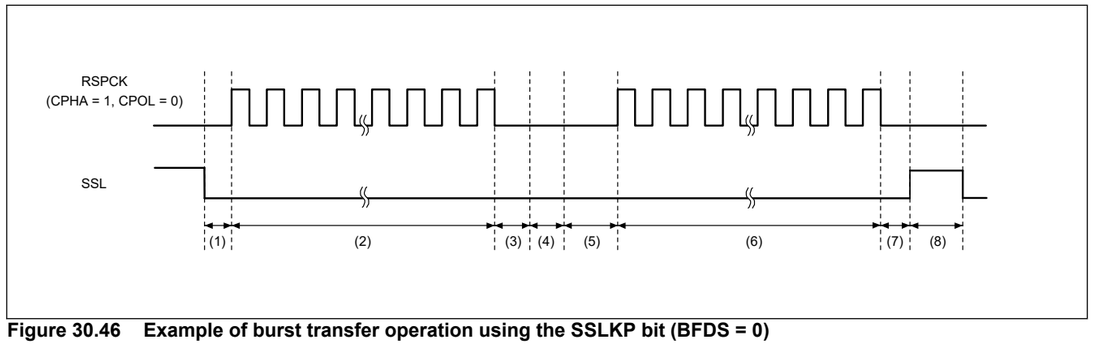

Figure 30.46 Example of burst transfer operation using the SSLKP bit (BFDS = 0)

The SPI operation at times (1) to (8) in the figure is as follows:

1. Based on the SPCMD0 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
2. The SPI executes serial transfers in accordance with the SPCMD0 settings.
3. The SPI inserts an SSL negation delay.
4. Because the SPCMD0.SSLKP bit is 1, the SPI keeps the SSLni signal value specified in SPCMD0. This period is sustained at a minimum for a period equal to the next-access delay in SPCMD0. If the shift register is empty after the passage of the minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
5. Based on the SPCMD1 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
6. The SPI executes serial transfers in accordance with the SPCMD1 settings.
7. Insert SSL negate delay.
8. Because the SPCMD1.SSLKP bit is 0, the SPI negates the SSLni signal. In addition, a next-access delay is inserted in accordance with SPCMD1.

If the SSLni signal output settings in the SPCMDm register where 1 is assigned to the SSLKP bit are different from the SSLni signal output settings in the SPCMDm register to be used in the next transfer, the SPI switches the SSLni signal status to SSLni signal assertion as shown in (5) in Figure 30.46. This corresponds to the command for the next transfer.

Note: If such an SSLni signal switching occurs, the slaves that drive the MISOn signal compete, and collision of signal levels might occur.

The SPI in master mode references the SSLni signal operation within the module when the SSLKP bit is not used. When the SPCMDm.CPHA bit is 0, the SPI can accurately start serial transfers by using the SSLni signal assertion for the next transfer that is detected internally.

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register 3 (SPCR3) is 1.

Figure 30.47 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 30.47. The SSL output signal polarity depends on the set SPI slave select polarity register (SSLP) value.

下一次串行传输的信号电平与当前串行传输的SSLni信号电平相同，SPI可以在保持SSLni信号断言状态（突发传输）的同时执行连续串行传输。

●当SPI控制寄存器3(SPCR3)的突发传输帧之间延迟选择位(BFDS)为0时。

图30.46显示了使用SPCMD0和SPCMD1寄存器设置实现的突发传输的SSLni信号操作示例。本节介绍图30.46所示的SPI操作(1)至(8)。

Note: SSLni输出信号的极性取决于SSLP寄存器设置。

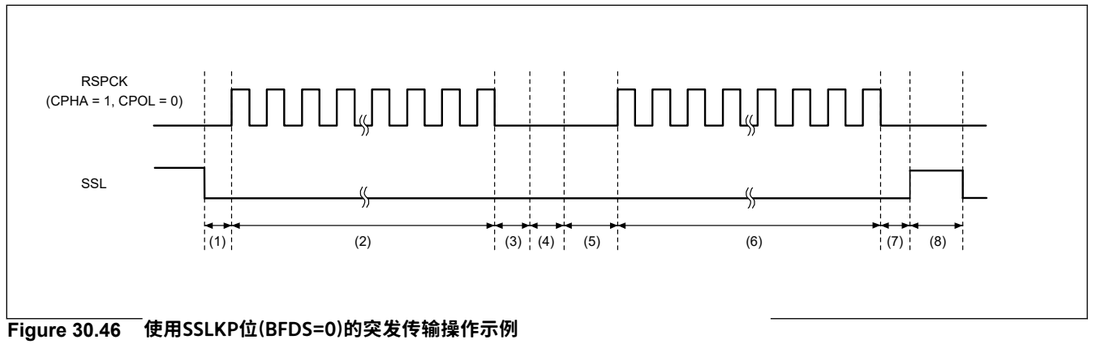

Figure 30.46 使用SSLKP位(BFDS=0)的突发传输操作示例

图中（1）到（8）时刻的SPI操作如下：

1.基于SPCMD0设置，SPI断言SSLni信号并插入RSPCK延迟。

2.SPI根据SPMD0设置执行串行传输。

3.SPI插入SSL否定延迟。

4.由于SPCMD0.SSLKP位为1，SPI保持SPCMD0中指定的SSLni信号值。这个时期是至少持续一段时间等于SPMD0中的下一次访问延迟。如果在经过最小周期后移位寄存器为空，则该周期一直持续到发送数据存储在移位寄存器中以供下一次传输。

5.基于SPCMD1设置，SPI断言SSLni信号并插入RSPCK延迟。

6.SPI根据SPMD1设置执行串行传输。

7.插入SSL否定延迟。

8.由于SPCMD1.SSLKP位为0，SPI否定SSLni信号。此外，根据SPMD1插入下一个访问延迟。

如果SPCMDm寄存器中SSLKP位为1的SSLni信号输出设置与下次传输使用的SPCMDm寄存器中的SSLni信号输出设置不同，则SPI将SSLni信号状态切换为SSLni信号断言，如下所示如图30.46（5）所示。这对应于下一次传输的命令。

Note: 如果发生这种SSLni信号切换，驱动MISon信号的从机竞争，可能会发生信号电平冲突。

当不使用SSLKP位时，主模式下的SPI参考模块内的SSLni信号操作。当。。。的时候SPCMDm.CPHA位为0，SPI可以通过使用SSLni信号断言来准确启动串行传输，以进行内部检测到的下一次传输。

●当SPI控制寄存器3(SPCR3)的突发传输帧之间延迟选择位(BFDS)为1时。

图30.47显示了使用SPCMD0和SPCMD1的设置实现突发传输时SSL信号操作的示例。下面描述图30.47所示的(1)到(6)的SPI操作。SSL输出信号极性取决于设置的SPI从机选择极性寄存器(SSLP)值。

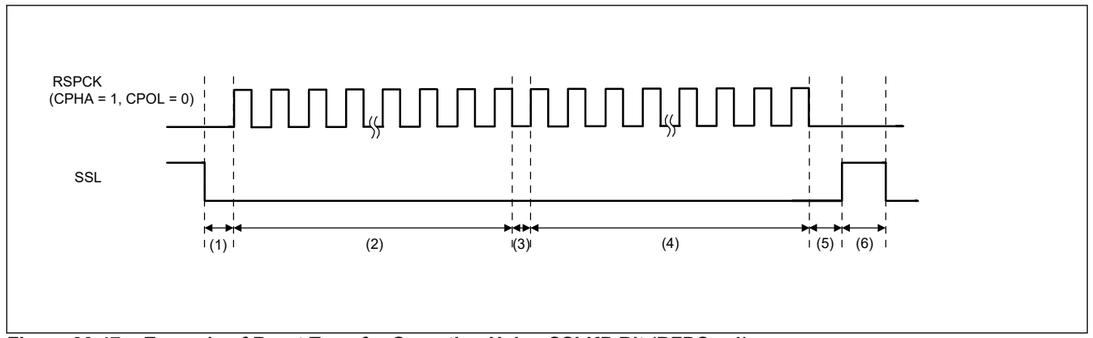

Figure 30.47 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1)

1. Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0. Wait last clock until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
3. The value of SSL signal according to SPCMD0 was hold, because the SPCMD0.SSLKP bit is 1. RSPCK negate period between frames is 0.5RSPCK, if the shift register is not empty.
4. Perform serial transfer according to SPCMD1.
5. Insert SSL negate delay for the last frame.
6. The SSL signal is negated because the SSLKP bit in SPCMD1 is 0. Furthermore, the next-access delay is inserted according to SPCMD1.

(5) RSPCK delay (t1)

The RSPCK delay value of the SPI in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD.SCKDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during a serial transfer by pointer control, and determines an RSPCK delay using the SPCMDm.SCKDEN bit and SPCKD.SCKDL[2:0] bits, as listed in Table 30.11. For a definition of RSPCK delay, see section 30.3.5. Transfer Formats.

RSPCK delay insert to only the first frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay”. (The SPCMD.SSLKP bit is 1 and the SPCR3.BFDS bit is 1.)

Table 30.11 Relationship between the SPCMDm.SCKDEN bit, SPCKD.SCKDL[2:0] bits, and RSPCK delay

SPCMDm.SCKDEN bit	SPCKD.SCKDL[2:0] bits	RSPCK delay
0	000b to 111b	1 RSPCK
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(6) SSL negation delay (t2)

The SSL negation delay value of the SPI in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND.SLNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced by pointer control during a serial transfer, and determines an SSL negation delay using the SPCMDm.SLNDEN bit and SSLND.SLNDL[2:0] bits, as listed in Table 30.12. For a definition of SSL negation delay, see section 30.3.5. Transfer Formats.

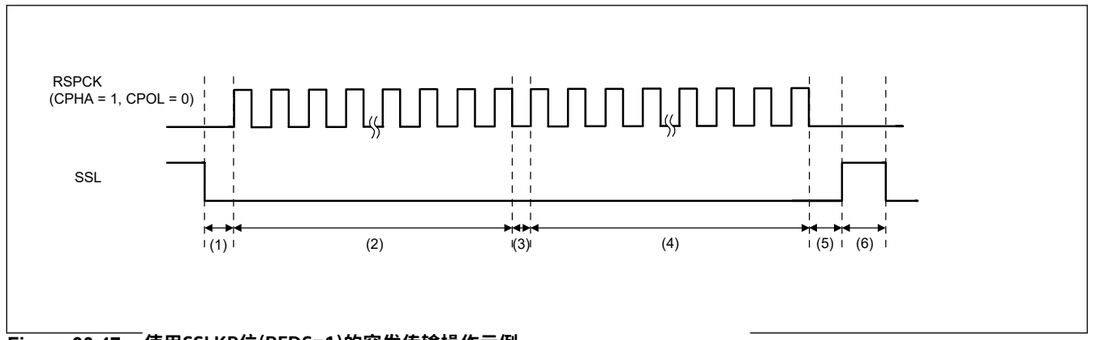

Figure 30.47 使用SSLKP位(BFDS=1)的突发传输操作示例

1.置位SSL信号并根据SPMD0插入一个RSPCK延迟。RSPCK延迟仅插入突发传输的第一帧。

2.根据SPMD0进行串行传输。如果在帧之间的RSPCK否定周期内移位寄存器为空，则等待最后一个时钟，直到下一个发送数据存储在移位寄存器中。

3.SPCMD0的SSL信号值被保持，因为SPCMD0.SSLKP位为1。如果移位寄存器不为空，则帧之间的RSPCK否定周期为0.5RSPCK。

4.根据SPMD1进行串行传输。

5.为最后一帧插入SSL否定延迟。

6.SSL信号被取反，因为SPCMD1中的SSLKP位为0。另外，根据SPCMD1插入下一个访问延迟。

(5) RSPCK delay (t1)

主机模式下SPI的RSPCK延迟值取决于SPMDm.SCKDEN位设置和SPCKD.SCKDL[2:0]位设置。SPI通过指针控制确定串行传输期间要引用的SPCMDm寄存器，并使用SPCMDm.SCKDEN位和SPCKD.SCKDL[2:0]位确定RSPCK延迟，如表30.11中所列。有关RSPCK延迟的定义，请参见第30.3.5节。传输格式。

当没有“BetweenBurstTransferFrames”传输时，RSPCK延迟仅插入到突发传输的第一帧延迟”。（SPCMD.SSLKP位为1，SPCR3.BFDS位为1。）

(6) SSL否定延迟(t2)

主模式下SPI的SSL否定延迟值取决于SPMDm.SLNDEN位设置和SSLND.SLNDL[2:0]位设置。SPI确定串行传输期间指针控制要引用的SPCMDm寄存器，并使用SPCMDm.SLNDEN位和SSLND.SLNDL[2:0]位确定SSL否定延迟，如表30.12中所列。有关SSL否定延迟的定义，请参阅第30.3.5节。传输格式。

(7) Next-access delay (t3)

The next-access delay value of the SPI in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND.SPNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and then determines a next-access delay during serial transfer using the SPCMDm.SPNDEN bit and SPND.SPNDL[2:0] bits, as listed in Table 30.13. For a definition of next-access delay, see section 30.3.5. Transfer Formats.

A next-Access delay is inserted to only the last frame of the burst transmission, that is, transmit without “between burst transfer frames delay”. (SPCMD.SSLKP bit is 1 and SPCR3.BFDS bit is 1).

(7) Next-access delay (t3)

主机模式下SPI的下一次访问延迟值取决于SPMDm.SPNDEN位设置和SPND.SPNDL[2:0]位设置。SPI通过指针控制确定串行传输期间要引用的SPCMDm寄存器，然后使用SPCMDm.SPNDEN位和SPND.SPNDL[2:0]位确定串行传输期间的下一次访问延迟，如表30.13中所列。有关下一次访问延迟的定义，请参见第30.3.5节。传输格式。

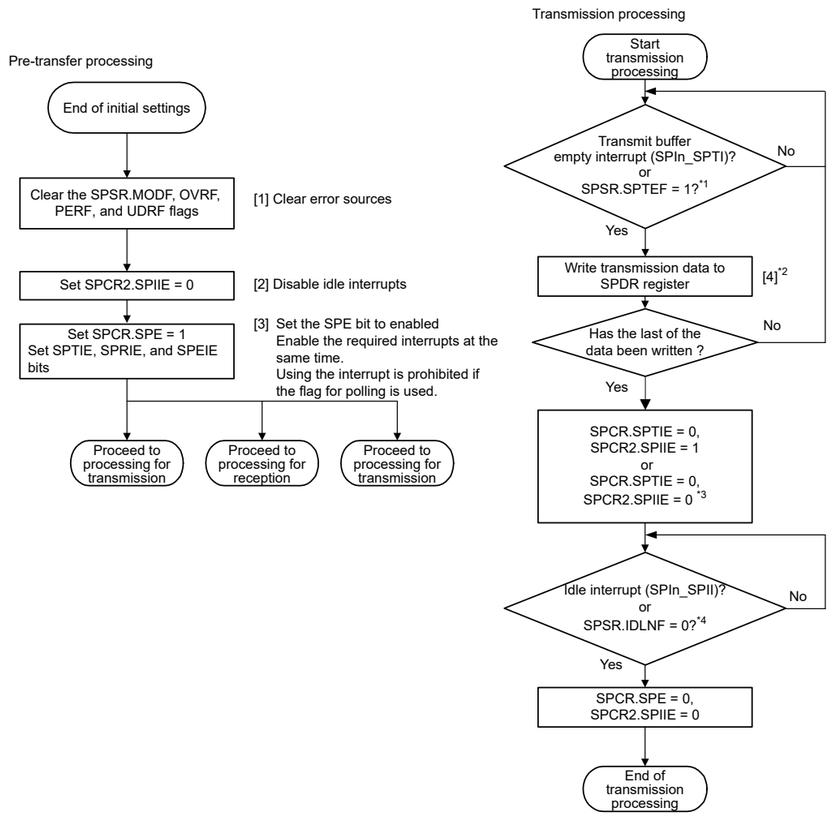
Transmit processing flow

When transmitting data, with the SPIi_SPII interrupt enabled, the CPU is notified of the completion of data transmission after the last data write for transmission.



Note 1. Before writing data for transmission to SPDR/SPDR_HA/SPDR_BY, check that the transmit buffer is empty by reading the SPSR.SPTEF flag, if the flag for polling is used.
Note 2. Setting SPCR2.SPIIE and SPCR3.CENDIE to 0 is prohibited if the flag for polling is used.

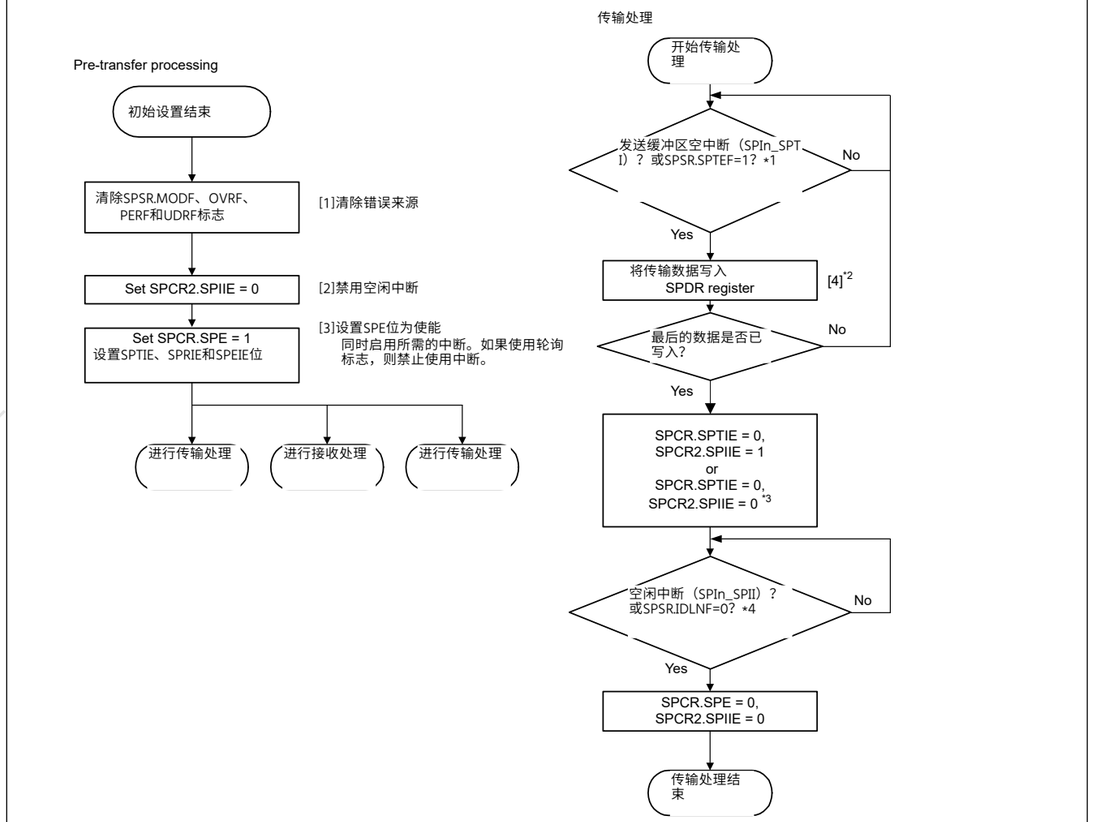
传输处理流程

发送数据时，SPIi_SPII中断使能，在最后一次数据写入发送后通知CPU数据发送完成。



注1.在将数据写入SPDRSPDR_HASPDR_BY之前，如果使用轮询标志，请通过读取SPSR.SPTEF标志检查发送缓冲区是否为空。

注2.如果使用轮询标志，则禁止将SPCR2.SPIIE和SPCR3.CENDIE设置为0。

Figure 30.49 主模式下的传输流

接收处理流程

SPI在从机模式下仅接收操作。

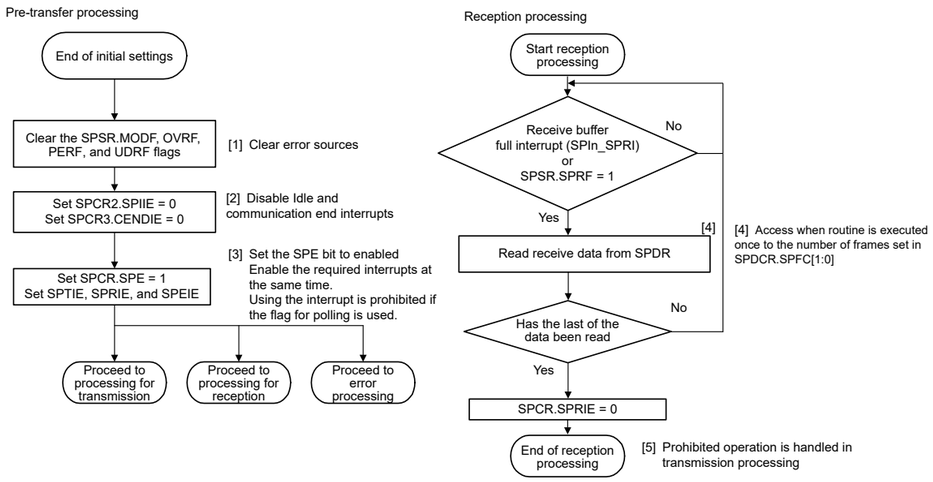

Figure 30.50 Reception flow in master mode

Error processing flow

The SPI detects the following errors:

- Mode fault error
- Underrun error
- Overrun error
- Parity error

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, the SPCR.SPE bit is not cleared and operations for transmission and reception continue. Therefore, Renesas recommends clearing the SPCR.SPE bit to stop operations for errors other than mode fault errors. Not doing so leads to updating of the SPSSR.SPECM[2:0] bits.

When an error is detected using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

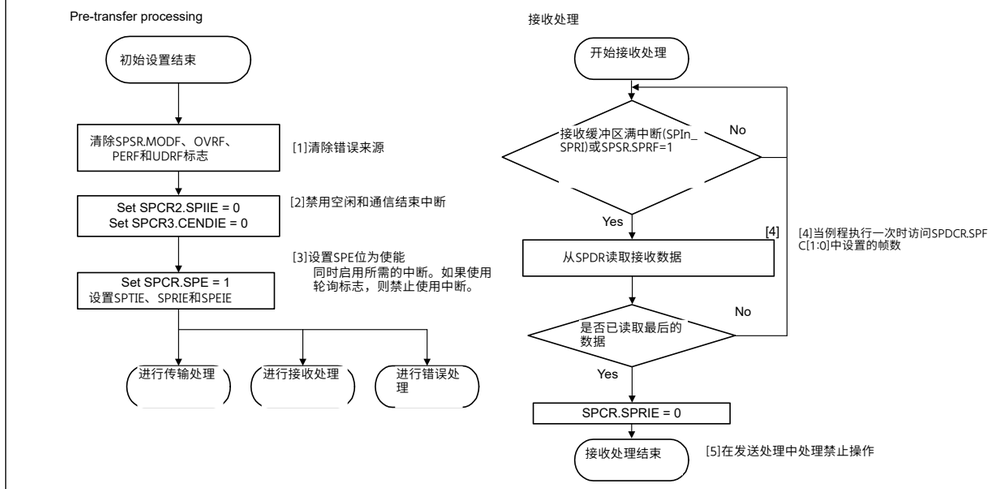

Figure 30.50 主模式下的接收流程

错误处理流程

SPI检测到以下错误：

●模式故障错误

- Underrun error

●超限错误

●奇偶校验错误

当产生模式故障错误时，SPCR.SPE位自动清零，停止发送和接收操作。对于其他来源的错误，SPCR.SPE位不会被清除，发送和接收操作会继续。因此，瑞萨建议清除SPCR.SPE位以停止除模式故障错误以外的错误操作。不这样做会导致更新SPSSR.SPECM[2:0]位。

当使用中断检测到错误时，清除错误处理例程中的ICU.IELSRn.IR标志。如果不这样做，ICU.IELSRn.IR标志可能会继续指示SPIi_SPTI或SPIi_SPRI中断请求。如果指示了SPIi_SPRI中断请求，则读取接收缓冲区并初始化SPI中的定序器。

30.3.11.2 Slave mode operation

(1) Starting a serial transfer

When the SPCMD0.CPHA bit is 0, if the SPI detects an SSLn0 input signal assertion, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLn0 input signal triggers the start of a serial transfer.

When the CPHA bit is 1, if the SPI detects the first RSPCKn edge in an SSLn0 signal asserted condition, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 1, the first RSPCKn edge in an SSLn0 signal asserted condition triggers the start of a serial transfer.

Regardless of the CPHA bit setting, the SPI drives the MISOn output signal on SSLn0 signal assertion. The data that is output by the SPI is either valid or invalid, depending on the CPHA bit setting.

For details on the SPI transfer format, see section 30.3.5. Transfer Formats. The polarity of the SSLn0 input signal depends on the SSLP.SSL0P setting.

(2) Terminating a serial transfer

Regardless of the SPCMD0.CPHA bit setting, the SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR/SPDR_HA register. On termination of a serial transfer, the SPI changes the status of the shift register to empty, regardless of the receive buffer state. A mode fault error occurs if the SPI detects an SSLn0 input signal negation from the beginning of serial transfer to the end of serial transfer (see section 30.3.9. Error Detection).

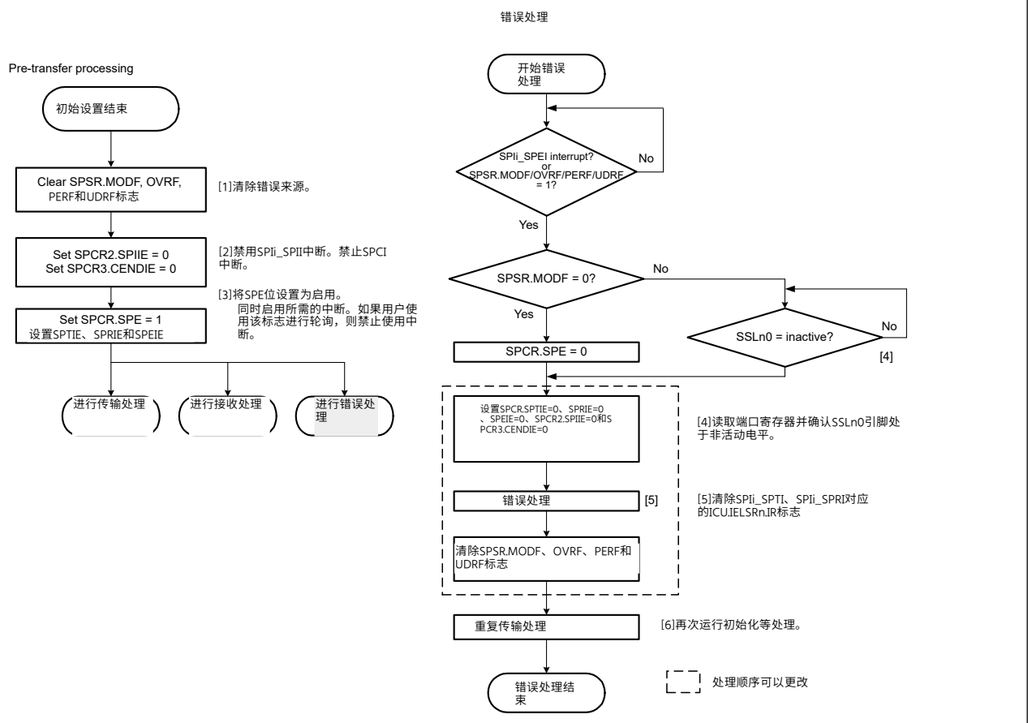

Figure 30.51 主模式下的错误处理流程

30.3.11.2 从模式操作

(1) 开始串行传输

当SPCMD0.CPHA位为0时，如果SPI检测到SSLn0输入信号断言，它必须将有效数据驱动到MISOn输出信号。因此，当CPHA位为0时，SSLn0输入信号的断言触发串行传输的开始。

当CPHA位为1时，如果SPI在SSLn0信号置位条件下检测到第一个RSPCKn边沿，它必须将有效数据驱动到MISOn输出信号。因此，当CPHA位为1时，SSLn0信号断言条件中的第一个RSPCKn边沿触发串行传输的开始。

无论CPHA位设置如何，SPI都会在SSLn0信号置位时驱动MIOn输出信号。SPI输出的数据是有效还是无效，取决于CPHA位设置。

有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。SSLn0输入信号的极性取决于SSLP.SSL0P设置。

(2) 终止串行传输

无论SPCMD0.CPHA位设置如何，SPI在检测到对应于最终采样时序的RSPCKn边沿后终止串行传输。当接收缓冲区中有可用空间（SPSR.SPRF标志为0）时，串行传输终止时，SPI将接收到的数据从移位寄存器复制到SPDRSPDR_HA寄存器的接收缓冲区。在串行传输终止时，SPI将移位寄存器的状态更改为空，而与接收缓冲区状态无关。如果SPI从串行传输开始到串行传输结束检测到SSLn0输入信号取反，则会发生模式故障错误（请参阅第30.3.9节。错误检测）。

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length is determined by the SPCMD0.SPB[3:0] bits setting. The polarity of the SSLn0 input signal is determined by the SSLP.SSL0P bit setting. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

(3) Notes on single-slave operations

If the SPCMD0.CPHA bit is 0, the SPI starts serial transfers when it detects the assertion edge for an SSLn0 input signal. In the configuration shown in Figure 30.7, if the SPI is used in single-slave mode, the SSLn0 signal is fixed at an active state. Therefore, when the CPHA bit is set to 0, the SPI cannot correctly start a serial transfer. For the SPI to correctly execute transmit and receive operations in slave mode when the SSLn0 input signal is fixed at an active state, the CPHA bit must be set to 1. Do not fix the SSLn0 input signal if there is a requirement for setting the CPHA bit to 0.

(4) Burst transfer

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLn0 input signal. When the CPHA bit is 1, the serial transfer period is the period from the first RSPCKn edge to the sampling timing for the reception of the final bit in an SSLn0 signal active state. Even when the SSLn0 input signal remains at the active level, the SPI can accommodate burst transfers, because it can detect the start of an access.

When the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

(5) Initialization flow

Figure 30.52 shows an example of initialization flow for SPI operation when the SPI is in slave mode. For a description of how to set up the ICU, DTC, and I/O ports, see the descriptions given in the individual blocks.

最终的采样时序根据传输数据的位长而变化。在从机模式下，SPI数据长度由SPCMD0.SPB[3:0]位设置决定。SSLn0输入信号的极性由SSLP.SSL0P位设置决定。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

(3) 单从操作注意事项

如果SPCMD0.CPHA位为0，则SPI在检测到SSLn0输入信号的断言边沿时开始串行传输。在图30.7所示的配置中，如果SPI用于单从模式，则SSLn0信号固定在激活状态。因此，当CPHA位设置为0时，SPI无法正确启动串行传输。为使SPI在SSLn0输入信号固定为活动状态时正确执行从模式下的发送和接收操作，CPHA位必须设置为1。如果需要设置CPHA，请不要固定SSLn0输入信号位为0。

(4) 突发传输

如果SPCMD0.CPHA位为1，则可以执行连续串行传输（突发传输），同时保持SSLn0输入信号的断言状态。当CPHA位为1时，串行传输周期是从第一个RSPCKn边沿到SSLn0信号有效状态下接收最后一个位的采样时序的周期。即使SSLn0输入信号保持在有效电平，SPI也可以适应突发传输，因为它可以检测访问的开始。

当CPHA位为0时，突发传输期间的第二次和后续串行传输无法正确执行。

In slave mode operation, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the state of the SSLn0 pin.

If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. 30.3.12 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the SPI. In clock synchronous operation, the SSLni pin is not used, and the RSPCKn, MOSIn, and MISOn pins handle communications. All SSLni pins are available as I/O port pins.

Although clock synchronous operation does not require the use of the SSLni pin, operation of the module is the same as in SPI operation. In both master mode and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected, because the SSLni pin is not used.

Additionally, do not perform operation if clock synchronous operation is enabled when the SPCMDm.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).

30.3.12.1 Master mode operation

(1) Starting serial transfer

The SPI updates the data in the transmit buffer (SPTX) of SPDR/SPDR_HA when data is written to the SPDR/SPDR_HA register with the transmit buffer empty, the data for the next transfer not set and the SPSR.SPTEF flag is 1. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR/SPDR_HA, the SPI copies data from the transmit buffer to the shift register and starts serial transmission. On copying transmit data to the shift register, the SPI changes the status of the shift register to full, and on termination of serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

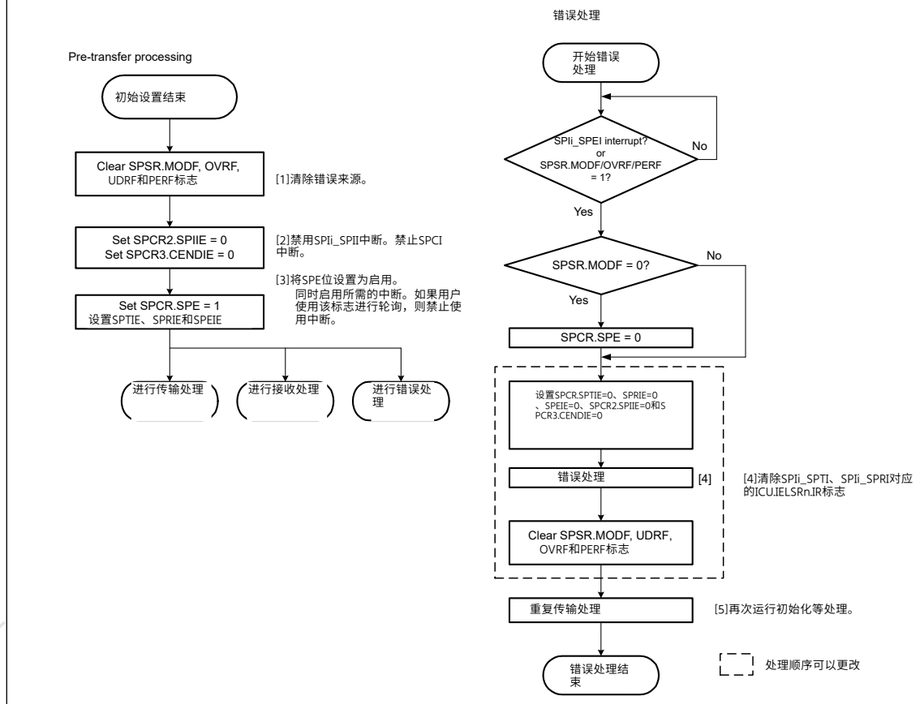

Figure 30.55 从机模式的错误处理流程

30.3.12 时钟同步操作

将SPCR.SPMS位设置为1可选择SPI的时钟同步操作。在时钟同步操作中，不使用SSLni引脚，而RSPCKn、MOSIn和MISOn引脚处理通信。所有SSLni引脚都可用作IO端口引脚。

虽然时钟同步操作不需要使用SSLni引脚，但模块的操作与SPI操作相同。在主模式和从模式操作中，可以使用与在相同的流程中执行通信
SPI操作。但是，未检测到模式故障错误，因为未使用SSLni引脚。

此外，如果在从模式(SPCR.MSTR=0)下SPCMDm.CPHA位设置为0时使能时钟同步操作，则不要执行操作。

30.3.12.1 主模式操作

(1) 开始串行传输

当数据写入SPDRSPDR_HA寄存器且发送缓冲区为空、未设置下一次传输的数据且SPSR.SPTEF标志为1时，SPI更新SPDRSPDR_HA的发送缓冲区(SPTX)中的数据。当移位将SPDCR.SPFC[1:0]位中设置的帧数写入SPDRSPDR_HA后，寄存器为空，SPI将数据从发送缓冲区复制到移位寄存器并开始串行传输。将发送数据复制到移位寄存器时，SPI将移位寄存器的状态更改为满，而在串行传输终止时，它将移位寄存器的状态更改为空。无法引用移位寄存器的状态。

在没有SSLn0输出信号的情况下进行时钟同步操作的传输。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

(2) Terminating serial transfer

The SPI terminates the serial transfer after transmitting an RSPCKn edge corresponding to the sampling timing. If free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies data from the shift register to the receive buffer of the SPI Data Register (SPDR/SPDR_HA).

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[3:0] bits setting. Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

(3) Sequence control

The transfer format used in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers. Although the SSLni signals are not output in clock synchronous operation, these settings are valid.

The SPSCR register determines the sequence configuration for serial transfers that are executed by the SPI in master mode. The following parameters are specified in the SPCMDm register:

- SSLni output signal value
- MSB or LSB first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPCKD is to be referenced
- Whether SSLND is to be referenced
- Whether SPND is to be referenced

SPBR holds some of the bit rate settings such as SPCKD, an SPI clock delay value, SSLND, an SSL negation delay, and SPND, a next-access delay value.

Based on the sequence length that is assigned to SPSCR, the SPI makes up a sequence comprised of a part or all of SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command comprising the sequence, the SPI sets the pointer to the SPCMD0 register, and in this manner the sequence is executed repeatedly.

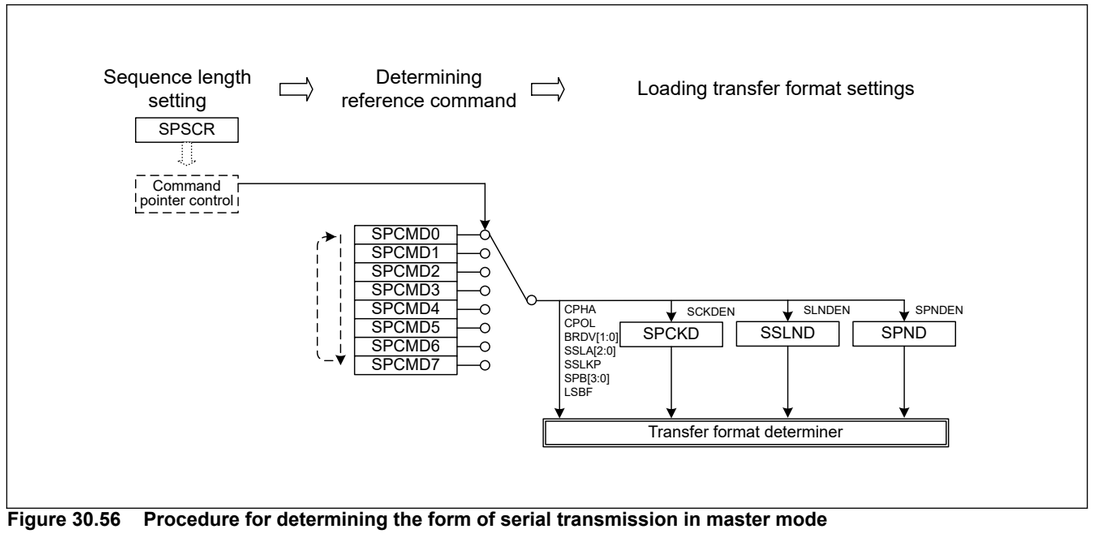

Figure 30.56 Procedure for determining the form of serial transmission in master mode

(2) 终止串行传输

SPI在发送对应于采样时序的RSPCKn边沿后终止串行传输。如果接收缓冲区中有可用空间（SPSR.SPRF标志为0），则在串行传输终止时，SPI将数据从移位寄存器复制到SPI数据寄存器(SPDRSPDR_HA)的接收缓冲区。

最终的采样时序根据传输数据的位长而变化。在主机模式下，SPI数据长度取决于SPMDm.SPB[3:0]位设置。在没有SSLn0输出信号的情况下进行时钟同步操作的传输。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

(3) 顺序控制

主机模式中使用的传输格式由SPSCR、SPCMDm、SPBR、SPCKD、SSLND和SPND寄存器决定。虽然在时钟同步操作中不输出SSLni信号，但这些设置是有效的。

SPSCR寄存器确定由SPI在主模式下执行的串行传输的序列配置。
SPCMDm寄存器中指定了以下参数：

- ●SSLni输出信号值
- ●MSB或LSB在前
- ●数据长度
- ●一些比特率设置
- ●RSPCKn极性和相位
- ●是否引用SPCKD
- ●是否引用SSLND
- ●是否引用SPND

SPBR保存一些比特率设置，例如SPCKD、SPI时钟延迟值、SSLND、SSL否定延迟和SPND，下一次访问延迟值。

根据分配给SPSCR的序列长度，SPI组成一个序列，该序列由部分或全部SPMDm寄存器。SPI包含一个指向构成序列的SPCMDm寄存器的指针。该指针的值可以通过读取SPSSR.SPCP[2:0]位来检查。当SPCR.SPE位设置为1且SPI功能使能时，SPI将指针加载到SPCMD0寄存器中的命令，并在串行传输开始时将SPCMD0寄存器设置合并到传输格式中。每次数据传输的下一个访问延迟周期结束时，SPI都会递增指针。在完成对应于包含序列的最终命令的串行传输后，SPI将指针设置为SPMD0寄存器，并以这种方式重复执行序列。

(5) Software processing flow

Software processing during clock synchronous master operation is the same as that for SPI master operation. For details, see (9) Software processing flow in section 30.3.11.1. Master mode operation. Mode fault errors do not occur in clock synchronous operation.

30.3.12.2 Slave mode operation

(1) Starting serial transfer

When the SPCR.SPMS bit is 1, the first RSPCKn edge triggers the start of a serial transfer in the SPI, and the SPI drives the MISOn output signal. The SSL0 input signal is not used in clock synchronous operation. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

(2) Terminating serial transfer

The SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR/SPDR_HA register. On termination of a serial transfer, the SPI changes the status of the shift register to empty regardless of the receive buffer.

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length depends on the SPCMD0.SPB[3:0] bits setting. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

(3) Initialization flow

Figure 30.60 shows an example of initialization flow for clock synchronous operation when the SPI is used in slave mode. For a description of how to set up the ICU, DTC, and I/O ports, see the descriptions given in the individual blocks.

(5) 软件处理流程

时钟同步主机操作期间的软件处理与SPI主机操作相同。详见30.3.11.1（9）软件处理流程。主模式操作。时钟同步操作中不会发生模式故障错误。

30.3.12.2 从模式操作

(1) 开始串行传输

当SPCR.SPMS位为1时，第一个RSPCKn边沿触发SPI中串行传输的开始，并且SPI驱动MISon输出信号。SSL0输入信号不用于时钟同步操作。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

(2) 终止串行传输

SPI在检测到对应于最终采样时序的RSPCKn边沿后终止串行传输。当接收缓冲区中有可用空间（SPSR.SPRF标志为0）时，串行传输终止时，SPI将接收到的数据从移位寄存器复制到SPDRSPDR_HA寄存器的接收缓冲区。在串行传输终止时，SPI将移位寄存器的状态更改为空，而与接收缓冲区无关。

最终的采样时序根据传输数据的位长而变化。在从机模式下，SPI数据长度取决于SPCMD0.SPB[3:0]位设置。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

(3) 初始化流程

图30.60显示了在从模式下使用SPI时时钟同步操作的初始化流程示例。
有关如何设置ICU、DTC和IO端口的说明，请参见各个块中给出的说明。

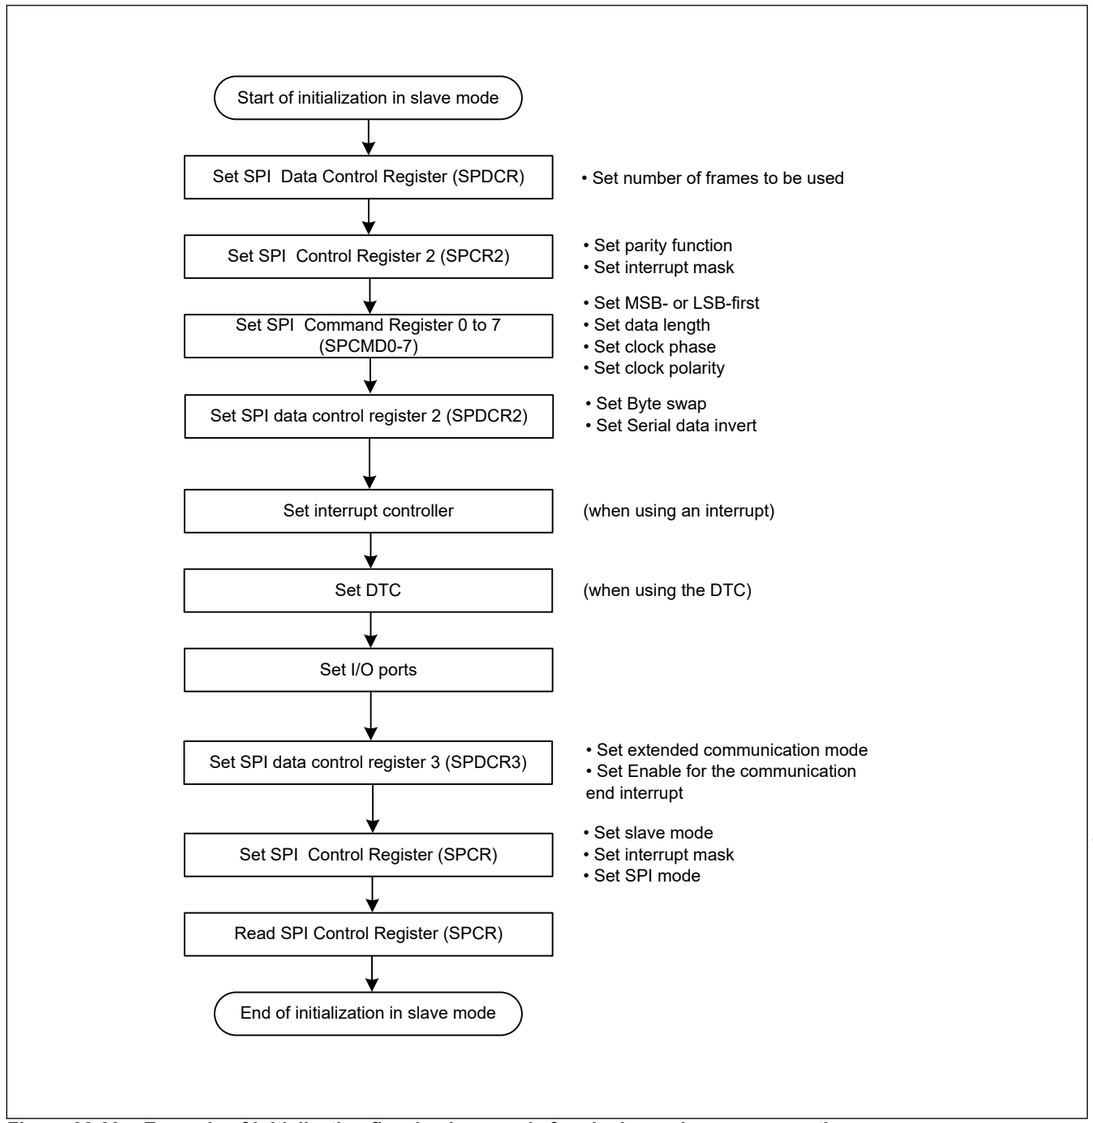

Figure 30.60 Example of initialization flow in slave mode for clock synchronous operation

(4) Software processing flow

Software processing during clock synchronous slave operation is the same as that for SPI slave operation. For details, see (6)Software processing flow. Mode fault errors do not occur in clock synchronous mode.

30.3.13 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, or between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0, and connects the input and output paths of the shift register, establishing a loopback mode. The SPI does not shut off the path between the MOSIn pin and the shift register if the SPCR.MSTR bit is 1, or between the MISOn pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the SPI or the reversed transmit data becomes the received data for the SPI.

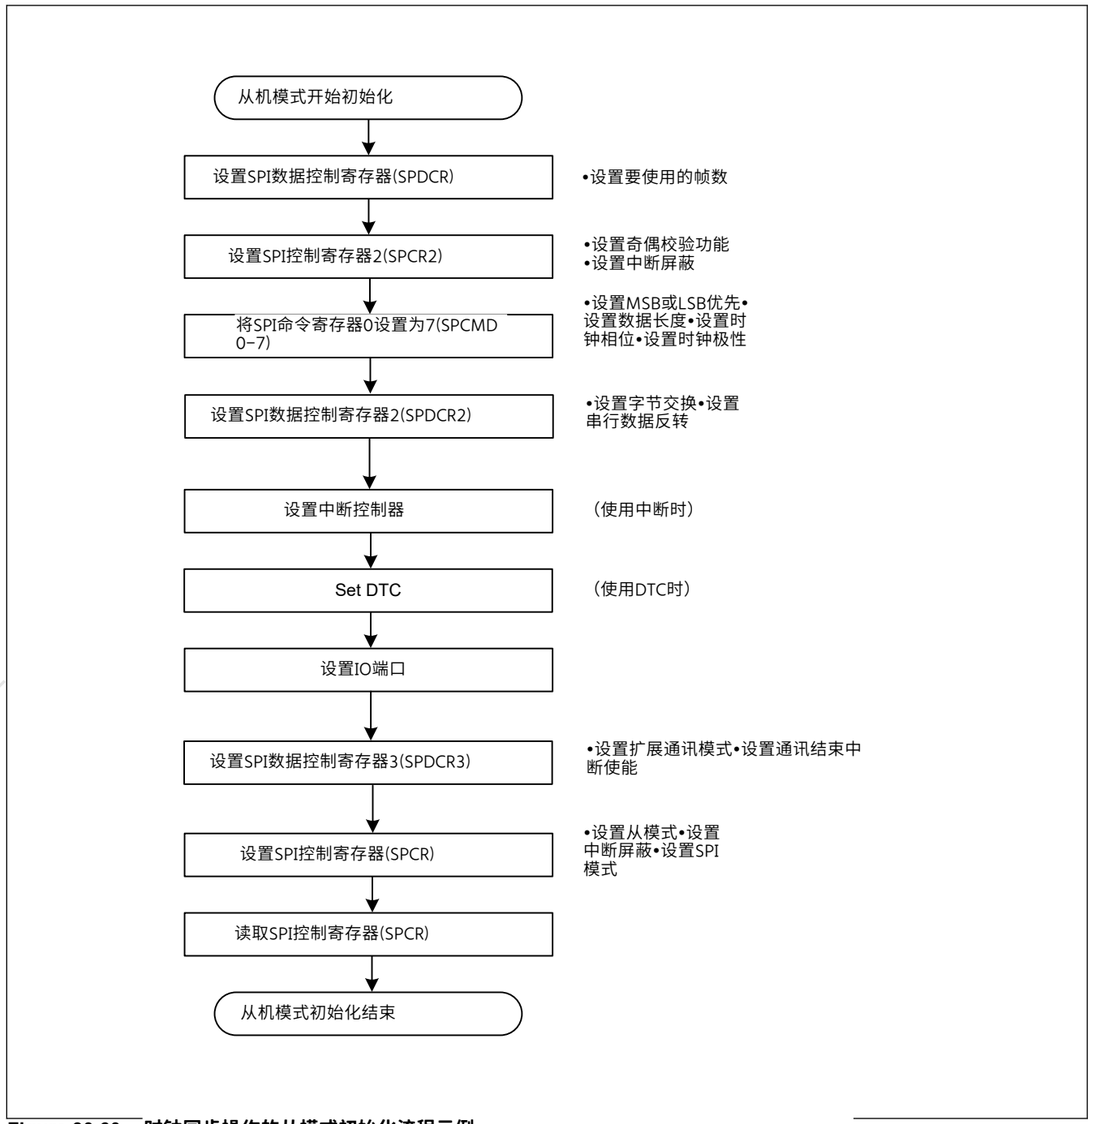

Figure 30.60 时钟同步操作的从模式初始化流程示例

(4) 软件处理流程

时钟同步从机操作期间的软件处理与SPI从机操作相同。详见（6）软件处理流程。时钟同步模式下不会发生模式故障错误。

30.3.13 Loopback Mode

当向SPPCR.SPLP2位或SPPCR.SPLP位写入1时，如果SPCR.MSTR位为1，则SPI关闭MISOn引脚和移位寄存器之间的路径，或者如果SPCR.MSTR位为0，连接移位寄存器的输入和输出路径，建立环回模式。如果SPCR.MSTR位为1，SPI不关闭MOSIn引脚和移位寄存器之间的路径，如果SPCR.MSTR位为0，则SPI不关闭MISOn引脚和移位寄存器之间的路径。这称为环回模式。当在环回模式下执行串行传输时，SPI的发送数据或反向发送数据将成为SPI的接收数据。

Table 30.14 lists the relationship between the SPLP2 and SPLP bits and the received data. Figure 30.61 shows the configuration of the shift register I/O paths when the SPI in master mode is set to loopback mode (SPPCR.SPLP2 = 0, SPPCR.SPLP = 1).

30.3.14 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. To detect defects in the parity bit adding unit and error detecting unit, the parity circuit performs self-diagnosis as shown in Figure 30.62.

表30.14列出了SPLP2和SPLP位与接收数据之间的关系。图30.61显示了当主模式下的SPI设置为环回模式（SPPCR.SPLP2=0，SPPCR.SPLP=1）时移位寄存器IO路径的配置。

1	0	传输数据

30.3.14 奇偶校验位功能自诊断

奇偶校验电路由用于发送数据的奇偶校验位添加单元和用于接收数据的错误检测单元组成。为了检测奇偶校验位添加单元和错误检测单元中的缺陷，奇偶校验电路执行自诊断，如图所示Figure 30.62.

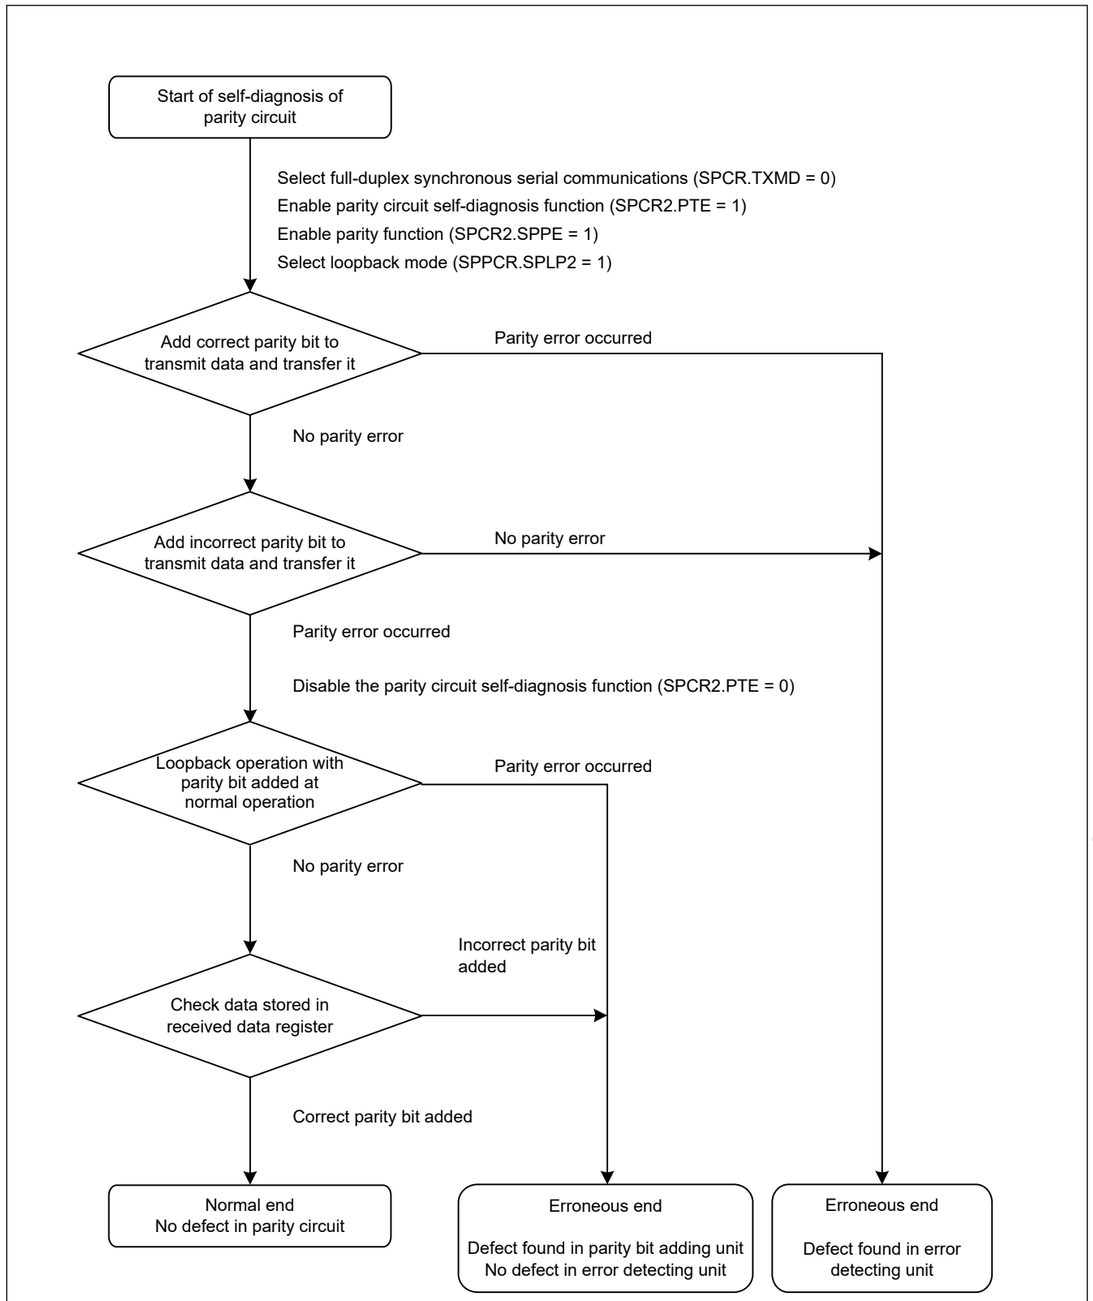

Figure 30.62 Self-diagnosis flow for parity circuit

30.3.15 Interrupt Sources

The SPI has the following interrupt sources:

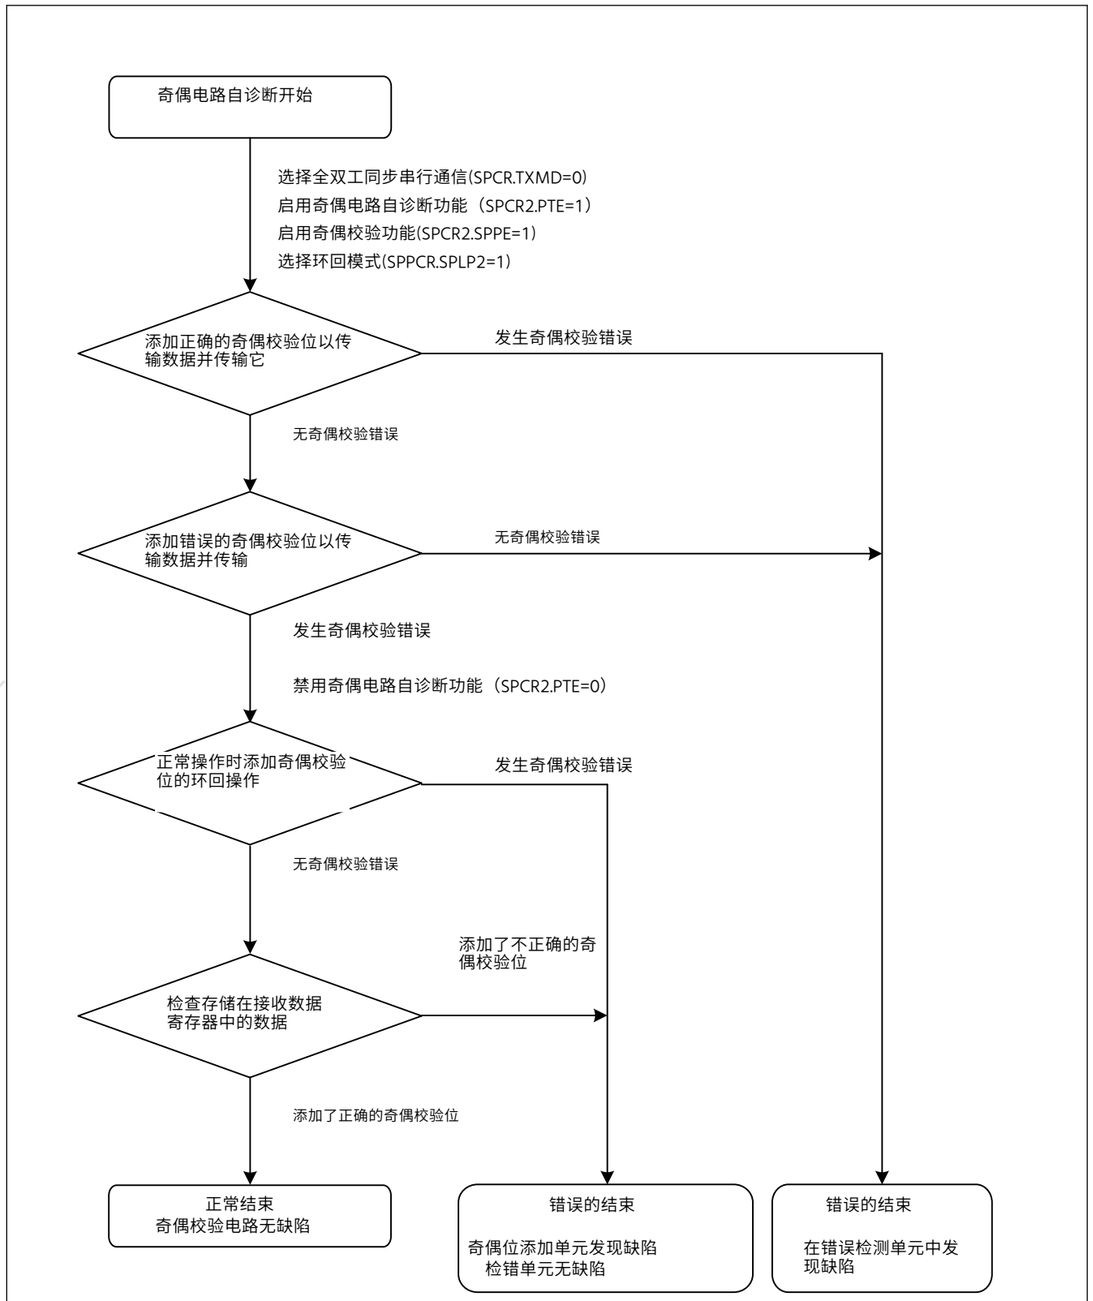

Figure 30.62 奇偶校验电路的自诊断流程

30.3.15 中断源

SPI有以下中断源：

- Receive buffer full
- Transmit buffer empty
- SPI error (mode-fault, underrun, overrun, or parity error)
- SPI idle
- Communication-end

The DMAC or DTC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Because the vector address for the SPIi_SPEI (SPI error interrupt) is allocated to interrupt requests on mode-fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the SPI are listed in Table 30.15. An interrupt is generated on satisfaction of one of the interrupt conditions in Table 30.15. Clear the receive buffer full and transmit buffer empty sources through a data transfer.

When using the DMAC or DTC to perform data transmission and reception, you must first set up the DMAC or DTC to be in a transfer-enabled status before setting the SPI. For information on setting up the DMAC or DTC, see section 16, DMA Controller (DMAC) and section 17, Data Transfer Controller (DTC).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt occur while the ICU.IELSRn.IR flag is 1, the interrupt is not output as a request for the ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IELSRn.IR flag becomes 0. A retained interrupt request is automatically discarded when it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be set to 0.

Table 30.15 SPI interrupt sources

Interrupt source	Symbol	Interrupt condition	DTC/DMAC activation
Receive buffer full	SPIi_SPRI	The receive buffer becomes full (SPSR.SPRF flag is 1) while the SPCR.SPRIE bit is 1	Possible
Transmit buffer empty	SPIi_SPTI	The transmit buffer becomes empty (SPSR.SPTEF flag is 1) while the SPCR.SPTIE bit is 1	Possible
SPI error (mode-fault, underrun, overrun, or parity error)	SPIi_SPEI	The SPSR.MODF, OVRF, UDRF or PERF flag sets to 1 while the SPCR.SPEIE bit is 1	Impossible
SPI idle	SPIi_SPII	The SPSR.IDLNF flag sets to 0 while the SPCR2.SPIIE bit is 1	Impossible
Communication-end	SPIi_SPCI	CENDIE = 1 and CENDF = 1	Impossible

30.4 Event Link Controller Event Output

The Event Link Controller (ELC) can produce the following event output signals:

- Receive buffer full event output
- Transmit buffer empty event output
- Mode-fault, underrun, overrun, or parity error event output
- SPI idle event output
- Transmission-completed event output

The event link output signal is output regardless of the interrupt enable bit setting.

30.4.1 Receive Buffer Full Event Output

This event signal is output when received data is transferred from the shift register to the SPDR/SPDR_HA on completion of serial transfer.

30.4.2 Transmit Buffer Empty Event Output

This event signal is output when data for transmission is transferred from the transmit buffer to the shift register and when the value of the SPE bit changes from 0 to 1.

●接收缓冲区已满

●发送缓冲区空

●SPI错误（模式故障、欠载、溢出或奇偶校验错误）

●SPI空闲

- Communication-end

DMAC或DTC可由接收缓冲区满或发送缓冲区空中断激活以执行数据传输。

由于SPIi_SPEI（SPI错误中断）的向量地址分配给模式错误、欠载、溢出和奇偶校验错误的中断请求，因此必须根据标志确定实际中断源。表30.15列出了SPI的中断源。满足表30.15中的中断条件之一时会产生中断。通过数据传输清除接收缓冲区满和发送缓冲区空源。

使用DMAC或DTC进行数据收发时，必须先将DMAC或DTC设置为传输使能状态，然后再设置SPI。有关设置DMAC或DTC的信息，请参阅第16节，DMA控制器(DMAC)和第17节，数据传输控制器(DTC)。

如果在ICU.IELSRn.IR标志为1时发生发送缓冲区空或接收缓冲区满中断的条件，则该中断不会作为对ICU的请求输出，而是在内部保留（保留容量为每个请求一个请求）资源）。当ICU.IELSRn.IR标志变为0时，输出保留中断请求。当作为实际中断请求输出时，自动丢弃保留中断请求。内部保留中断请求的中断使能位（SPCR.SPTIE或SPCR.SPRIE位）也可以设置为0。

Table 30.15 SPI中断源

中断源	Symbol	中断条件	DTC/DMAC activation
接收缓冲区已满	SPIi_SPRI	当SPCR.SPRIE位为1时，接收缓冲区变满（SPSR.SPRF标志为1）	Possible
发送缓冲区为空	SPIi_SPTI	当SPCR.SPTIE位为1时，发送缓冲区变为空（SPSR.SPTEF标志为1）	Possible
SPI错误（模式错误、欠载、溢出或奇偶校验错误）	SPIi_SPEI	SPSR.MODF、OVRF、UDRF或PERF标志设置为1，而SPCR.SPEIE位为1	Impossible
SPI空闲	SPIi_SPII	SPSR.IDLNF标志设置为0，而SPCR2.SPIIE位为1	Impossible
Communication-end	SPIi_SPCI	CENDIE = 1 and CENDF = 1	Impossible

30.4 事件链接控制器事件输出

事件链接控制器(ELC)可以产生以下事件输出信号：

●接收缓冲区满事件输出

●发送缓冲区空事件输出

●模式故障、欠载、溢出或奇偶校验错误事件输出

●SPI空闲事件输出

●传输完成事件输出

无论中断允许位设置如何，都会输出事件链接输出信号。

30.4.1 接收缓冲区满事件输出

串行传输完成后，当接收到的数据从移位寄存器传输到SPDRSPDR_HA时，输出此事件信号。

30.4.2 发送缓冲区空事件输出

当要发送的数据从发送缓冲器传送到移位寄存器时，以及SPE位的值从0变为1时，输出该事件信号。

30.4.3 Mode-Fault, Underrun, Overrun, or Parity Error Event Output

This event signal is output when mode-fault, underrun, overrun, or parity error is detected. See section 30.5.4. Constraints on Mode-Fault, Underrun, Overrun, or Parity Error Event Output if using this event signal.

(1) Mode-fault

Table 30.16 lists the conditions for occurrence of a mode-fault event.

Table 30.16 Conditions for mode-fault occurrence

SPI mode	SPCR.MODFEN bit	SSLn0 pin	Remarks
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0)	1	Not active	Event is output only when the SSLn0 pin is deactivated during transmission

(2) Underrun

This event signal is output in response to an underrun when a serial transfer starts while the transmission data is not ready, and the value of the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1. Under these conditions, the MODF and UDRF flags are set to 1.

(3) Overrun

This event signal is output in response to an overrun when a serial transfer completes while the receive buffer contains unread data and the value of the SPCR.TXMD bit is 0. Under these conditions, the OVRF flag is set to 1.

(4) Parity error

This event signal is output in response to a parity error detected on completion of a serial transfer while the value of the TXMD bit in SPCR is 0 and the value of the SPPE bit in SPCR2 is 1.

30.4.4 SPI Idle Event Output

(1) In master mode

In master mode, an event is output when the condition for setting the IDLNF flag (SPI idle flag) to 0 is satisfied.

(2) In slave mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (SPI is initialized).

30.4.5 Communication End Event Output

In master mode, an event is output when the IDLNF flag (RSPI idle flag) changes from 1 to 0. In slave mode, an event occurs with conditions shown in Table 30.17 and Table 30.18

Table 30.17 Communication End Event Generating Conditions (transmit-receive/transmit slave mode)

	Transmit Buffer Status	Shift Register Status	Others
SPI operation (SPMS = 0)	Empty	Empty	SSL0 input is negated
Clock synchronous operation (SPMS = 1)	Empty	Empty	The last even edge of RSPCK of last data was detected (CPHA = 1)

Table 30.18 Communication End Event Generating Conditions (receive only slave mode)

	Others
SPI operation (SPMS = 0)	SSL0 input is negated
Clock synchronous operation (SPMS = 1)	The last even edge of RSPCK of last data was detected (CPHA = 1)

Regardless of master mode or slave mode, no event is output when 0 is written to the SPCR.SPE bit during transmission or when the SPCR.SPE bit is cleared due to a mode fault error or an underrun error.

30.4.3 模式故障、欠载、溢出或奇偶校验错误事件输出

当检测到模式故障、欠载、溢出或奇偶校验错误时，输出此事件信号。请参阅第30.5.4节。如果使用此事件信号，则对模式故障、欠载、溢出或奇偶校验错误事件输出的约束。

(1) Mode-fault

表30.16列出了模式故障事件发生的条件。

Table 30.16 模式故障发生的条件

SPI模式	SPCR.MODFEN bit	SSLn0 pin	Remarks
SPI操作(SPMS=0)从机(SPCR.MSTR=0)	1	不活跃	只有在传输过程中禁用SSLn0引脚时才会输出事件

(2) Underrun

当串行传输开始而传输数据尚未准备好，并且SPCR.MSTR位的值为0且SPCR.SPE位为1时，输出此事件信号以响应欠载。在这些条件下，MODF和UDRF标志设置为1。

(3) Overrun

当串行传输完成而接收缓冲区包含未读数据且SPCR.TXMD位的值为0时，输出此事件信号以响应溢出。在这些情况下，OVRF标志设置为1。

(4) 奇偶校验错误

该事件信号是响应在串行传输完成时检测到的奇偶校验错误而输出的，而SPCR中的TXMD位为0，SPCR2中的SPPE位的值为1。

30.4.4 SPI空闲事件输出

(1) 在主模式

在主机模式下，当将IDLNF标志（SPI空闲标志）设置为0的条件成立时输出事件。

(2) 在从模式

在从机模式下，当SPCR.SPE位设置为0（SPI初始化）时，会输出一个事件。

30.4.5 通讯结束事件输出

在主机模式下，当IDLNF标志（RSPI空闲标志）从1变为0时输出事件。在从机模式下，事件发生的条件如表30.17和表30.18所示

Table 30.17 通信结束事件发生条件（发送-接收发送从模式）

	发送缓冲区状态	移位寄存器状态	Others
SPI操作(SPMS=0)	Empty	Empty	SSL0输入被否定

	Others
SPI操作(SPMS=0)	SSL0输入被否定
时钟同步操作(SPMS=1)	检测到最后一个数据的RSPCK的最后一个偶边沿(CPHA=1)

无论主模式还是从模式，在传输过程中向SPCR.SPE位写入0或由于模式故障错误或欠载错误而清除SPCR.SPE位时，不输出任何事件。

A communication end event is output at the following timing. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

30.5 Usage Notes

30.5.1 Settings for the Module-Stop State

The Module Stop Control Register B (MSTPCRB) can enable or disable the SPI operation. The SPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details on the Module Stop Control Register B, see section 10, Low Power Modes.

30.5.2 Constraint on Low-Power Functions

When using the module-stop function and entering a low-power mode other than Sleep mode, set the SPCR.SPE bit to 0 before completing communication.

30.5.3 Constraints on Starting Transfer

If the ICU.IELSRn.IR flag is 1 when transfer starts, the interrupt request is internally retained, which can lead to unanticipated behavior of the ICU.IELSRn.IR flag.

To prevent this, use the following procedure to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1):

1. Confirm that transfer stopped (the SPCR.SPE bit is 0).
2. Set the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.
3. Read the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IELSRn.IR flag to 0.

30.5.4 Constraints on Mode-Fault, Underrun, Overrun, or Parity Error Event Output

Using the mode-fault, underrun, overrun, or parity error event is prohibited if the SPI is in multi-master mode (when the SPCR.SPMS bit is 0, the SPCR.MSTR bit is 1, and the SPCR.MODFEN bit is 1).

30.5.5 Constraints on the SPSR.SPRF and SPSR.SPTEF Flags

If the polling flags, SPRF and SPTEF, are used, using the interrupts is prohibited, and you must set the SPCR.SPRIE and SPCR.SPTIE bits to 0. Either the interrupts or the flags can be used, but not both.

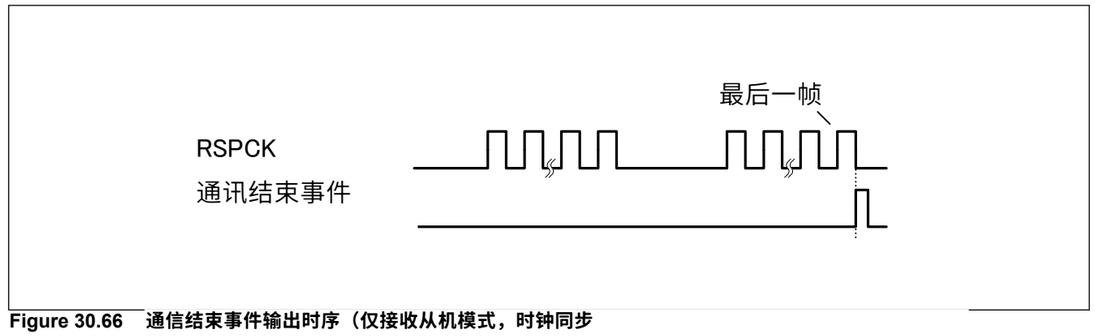

Figure 30.66 通信结束事件输出时序（仅接收从机模式，时钟同步 Operation)

30.5 使用说明

30.5.1 模块停止状态的设置

模块停止控制寄存器B(MSTPCRB)可以启用或禁用SPI操作。SPI在复位后最初停止。释放模块停止状态可以访问寄存器。有关模块停止控制寄存器B的详细信息，请参见第10节，低功耗模式。

30.5.2 对低功耗功能的限制

当使用模块停止功能并进入除睡眠模式以外的低功耗模式时，在完成通信之前将SPCR.SPE位设置为0。

30.5.3 开始传输的限制

如果ICU.IELSRn.IR标志在传输开始时为1，则内部保留中断请求，这可能导致ICU.IELSRn.IR标志的意外行为。

为防止这种情况发生，请使用以下程序在使能操作之前清除中断请求（通过将SPCR.SPE位设置为1）：

1.确认传输停止（SPCR.SPE位为0）。

2.将相关的中断使能位（SPCR.SPTIE位或SPCR.SPRIE位）设置为0。

3.读取相关的中断使能位（SPCR.SPTIE位或SPCR.SPRIE位）并确认其值为0。

4.将ICU.IELSRn.IR标志设置为0。

30.5.4 模式故障、欠载、溢出或奇偶校验错误事件输出的约束

如果SPI处于多主模式（当
SPCR.SPMS位为0，SPCR.MSTR位为1，SPCR.MODFEN位为1)。

30.5.5 SPSR.SPRF和SPSR.SPTEF标志的约束

如果使用轮询标志SPRF和SPTEF，则禁止使用中断，您必须设置SPCR.SPRIE和SPCR.SPTIE位为0。可以使用中断或标志，但不能同时使用。

31.3 内存映射

31.3.1 外部总线空间

串行闪存和控制寄存器在地址空间上的位置由配置中设置的区域的地址范围决定。

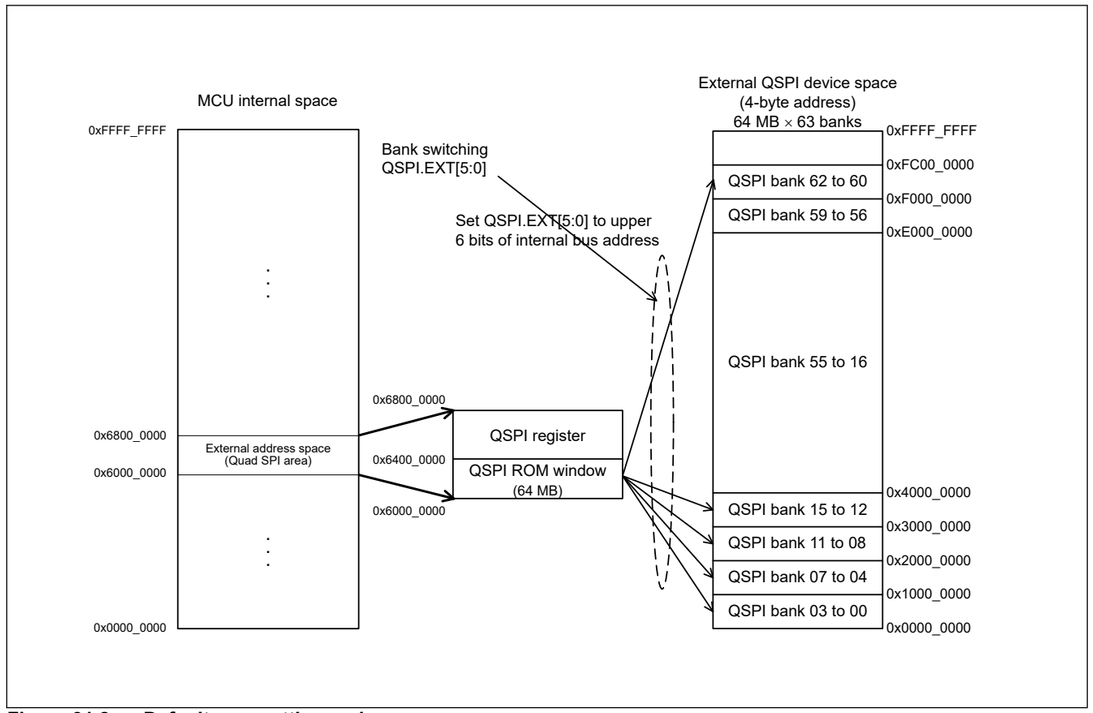

Figure 31.2 Default area setting and memory map

31.3.2 Address Width of the SPI Space and SPI Bus

The SPI space has a 32-bit address width for referencing the serial flash memory. When the SPI space is accessed for a read, an SPI bus cycle starts automatically, and data read from the serial flash is returned.

The address width of the SPI space is fixed at 32 bits. However, the address width of the SPI bus is selectable to 8, 16, 24, or 32 bits in the SFMAS[1:0] bits in the Address Mode Control Register (SFMSAC) register. If 8, 16, or 24 bits is selected as the address width of the SPI bus, only the lower part of the address used to access the SPI space is posted to the serial flash memory through the SPI bus. As a result, the mirror image of the serial flash corresponding to the address width of the SPI bus repeatedly appears in the SPI space.

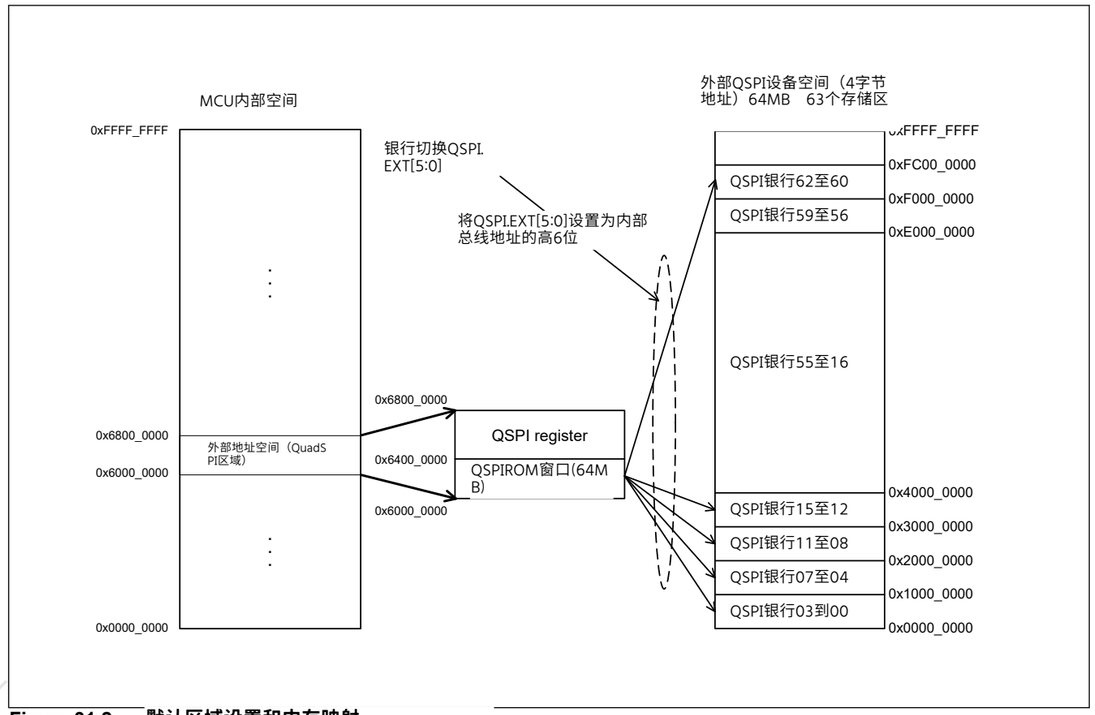

Figure 31.2 默认区域设置和内存映射

31.3.2 SPI空间和SPI总线的地址宽度

SPI空间具有32位地址宽度，用于引用串行闪存。当访问SPI空间进行读取时，会自动启动一个SPI总线周期，并返回从串行闪存读取的数据。

SPI空间的地址宽度固定为32位。但是，SPI总线的地址宽度可选择为地址模式控制寄存器(SFMSAC)寄存器中的SFMAS[1:0]位中的8、16、24或32位。如果选择8位、16位或24位作为SPI总线的地址宽度，则只有用于访问SPI空间的地址的低部分通过SPI总线发布到串行闪存中。结果，对应于SPI总线地址宽度的串行闪存的镜像在SPI空间中反复出现。

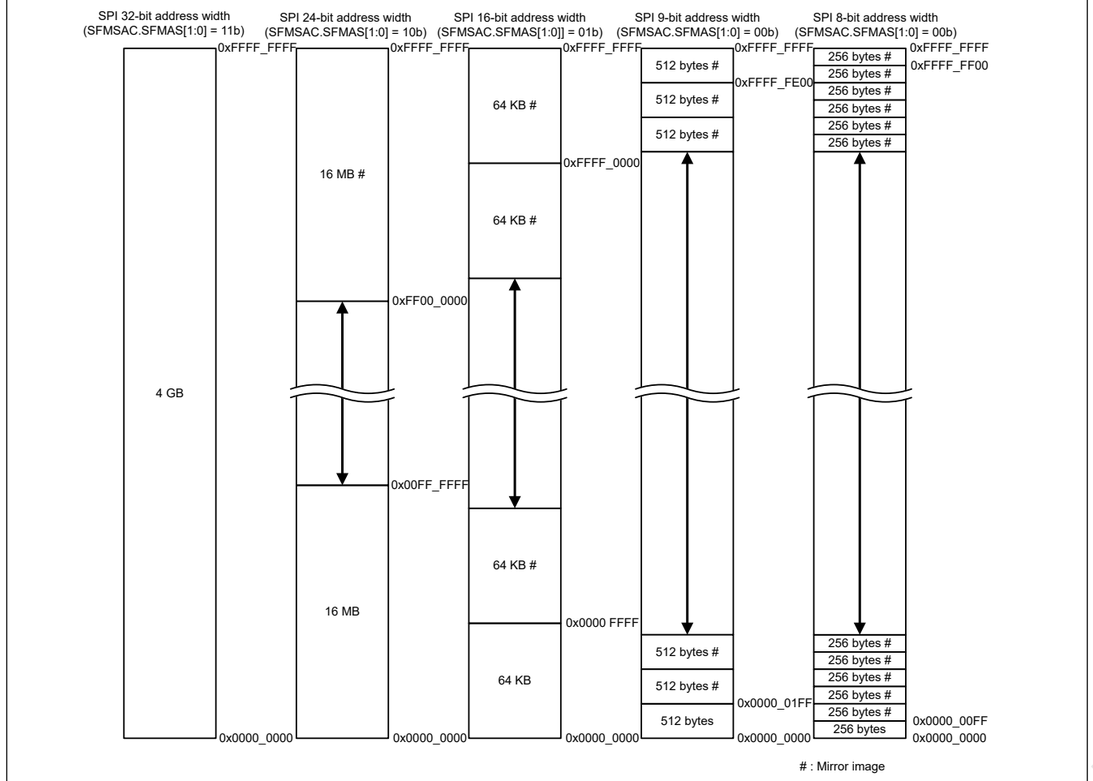

Figure 31.3 Memory map of SPI space

Note: The SPI bus address width is selectable to 8, 16, 24, or 32 bits in the SFMAS[1:0] bits in the SFMSAC register (cases 1 to 3 and 5 in the figure correspond to the respective address widths). When an 8-bit address width is selected, the address information of the ninth bit can be embedded in the Read instruction code. The memory map in case 4 in the figure is for the 9-bit address width. For details on the Read instruction, see section 31.6.2. Standard Read Instruction.

31.4 SPI Bus

31.4.1 SPI Protocol

Single SPI, extended SPI, dual SPI, and quad SPI are supported in addition to the SPI protocol used for serial flash memory connection.

The initial state of the SPI protocol is Single SPI, extended SPI and can be changed with the SFMSPI[1:0] bits in the SPI Protocol Control Register (SFMSPC) register.

The address and data pins used in the Single SPI, extended SPI protocol change depending on the setting of the serial interface read mode select bits SFMRM[2:0] in Transfer Mode Control Register (SFMSMD). Table 31.3 and Table 31.4 list the pins used for instruction code, addresses, and data in each of the SPI protocols.

Note: In read operation, the QSPI outputs additional one clock without accompanying data reception per one SPI bus cycle. For details, see section 31.5.9. Serial Data Receiving Latency.

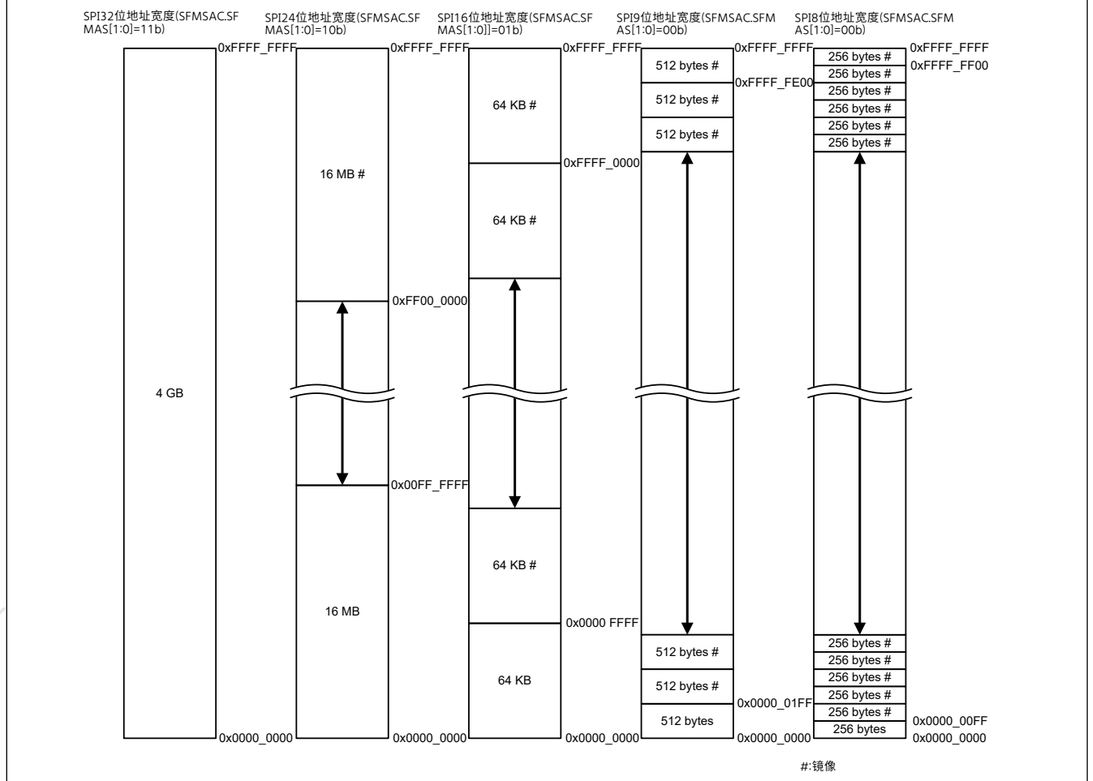

Figure 31.3 SPI空间的内存映射

Note: SPI总线地址宽度在SFMSAC寄存器的SFMAS[1:0]位中可选择为8、16、24或32位（图中的情况1到3和5对应于各自的地址宽度）。Whenan8-bitaddresswidthisselected theaddressinformationoftheninthbitcanbeembeddedintheReadinstructioncode.图中案例4中的内存映射是针对9位地址宽度的。有关读取指令的详细信息，请参阅第31.6.2节。标准阅读说明。

31.4 SPI总线

31.4.1 SPI协议

除了用于串行闪存连接的SPI协议外，还支持单SPI、扩展SPI、双SPI和四SPI。

SPI协议的初始状态是SingleSPI，扩展SPI，可以通过SPI中的SFMSPI[1:0]位改变协议控制寄存器(SFMSPC)寄存器。

单SPI、扩展SPI协议中使用的地址和数据引脚根据传输模式控制寄存器(SFMSMD)中串行接口读取模式选择位SFMRM[2:0]的设置而变化。表31.3和表31.4列出了每个SPI协议中用于指令代码、地址和数据的引脚。

Note: 在读操作中，QSPI会在每个SPI总线周期输出额外的一个时钟，而不会伴随数据接收。有关详细信息，请参阅第31.5.9节。串行数据接收延迟。

31.4.2 SPI Mode

Either SPI mode 0 or SPI mode 3 can be selected as the SPI mode by the SFMSMD.SFMMD3 bit. This can be switched by changing the register setting during operation. The difference between SPI modes 0 and 3 is the state of the QSPCLK signal when it is inactive. The standby level of the QSPCLK signal in SPI mode 0 is low, and high in SPI mode 3.

Serial data is output from the QSPI on a falling edge of the serial clock and is read into the serial flash memory on a rising edge of the serial clock. Serial data is output from the serial flash memory on a falling edge of the serial clock and is read into the QSPI on the next falling edge of the serial clock.

31.4.2 SPI模式

可以通过SFMSMD.SFMMD3位选择SPI模式0或SPI模式3作为SPI模式。这可以通过在操作期间更改寄存器设置来切换。SPI模式0和3之间的区别在于QSPCLK信号处于非活动状态时的状态。QSPCLK信号在SPI模式0中的待机电平为低，在SPI模式3中为高。

串行数据在串行时钟的下降沿从QSPI输出，并在串行时钟的上升沿读入串行闪存。串行数据在串行时钟的下降沿从串行闪存输出，并在串行时钟的下一个下降沿读入QSPI。

31.5 SPI Bus Timing Adjustment

The timing of the SPI bus signal can be adjusted in the registers. The configured timing is applied to all SPI bus accesses, for both ROM access and direct communication.

31.5.1 SPI Bus Reference Cycles

The SPI bus operates on reference cycles obtained by multiplying PCLKA by an integer. The reference cycles are selectable within the range of PCLKA multiplied by 2 to 48 in the SFMDV[4:0] bits in the Transfer Mode Control Register (SFMSKC) register.

31.5.1 SPI总线参考周期

31.5.2 QSPCLK Signal Duty Ratio

When the reference clock is configured as PCLKA divided by an odd number without duty ratio correction, the duty ratio of the QSPCLK signal will not be 50%. When the reference clock is PCLKA divided by an odd number, be sure to enable the duty ratio correction function (SFMSKC.SFMDTY = 1).

When the reference clock is PCLKA divided by an even number, the SFMDTY setting in the SFMSKC register is ignored.

当参考时钟为PCLKA除以偶数时，SFMSKC寄存器中的SFMDTY设置被忽略。

31.5.3 Minimum High-Level Width for the QSSL Signal

Between adjacent SPI bus cycles, the QSSL signal must be held high (inactive) for a sufficient time to satisfy the deselect time required by the serial flash memory. The minimum high-level width of the QSSL output signal is selectable as the reference cycle multiplied by an integer from 1 to 16 in the SFMSW[3:0] bits in the Instruction Code Register (SFMSSC) register.

31.5.4 QSSL Signal Setup Time

The QSSL signal setup time that the serial flash memory requires after the QSSL signal is driven active low until the first rising edge of the QSPCLK signal can be configured. The setup time can be selected as 0.5 or 1.5 cycles of QSPCLK in the SFMSLD bit of the SFMSSC register.

Set a value that meets the most constrained timing condition for your application.

31.5.3 QSSL信号的最小高电平宽度

在相邻的SPI总线周期之间，QSSL信号必须保持高电平（无效）足够长的时间，以满足串行闪存所需的取消选择时间。QSSL输出信号的最小高电平宽度可选择为参考周期乘以指令代码寄存器(SFMSSC)寄存器中SFMSW[3:0]位中的1到16的整数。

31.5.4 QSSL信号建立时间

从QSSL信号被驱动为低电平有效到QSPCLK信号的第一个上升沿可以配置，串行闪存所需的QSSL信号建立时间。设置时间可以在SFMSSC寄存器的SFMSLD位中选择为0.5或1.5个QSPCLK周期。

31.5.6 Hold Time of the Serial Data Output Enable

The buffer output enable of the QIO0, QIO1, QIO2, or QIO3 pin can be extended by 1 QSPCLK using the SFMOEX bit in the SFMSMD register.

For a standard read instruction, it is extended immediately after an address code. For other read instructions, it is extended after two cycles of mode data (XIP mode control) of the serial flash memory in dummy cycles.

31.5.5 QSSL信号保持时间

可以配置在QSPCLK信号的最后一个上升沿之后，直到QSSL信号被驱动为高电平之前，串行闪存所需的QSSL信号保持时间。保持时间可以在SFMSSC寄存器的SFMSHD位中选择为0.5或1.5个QSPCLK周期。

31.5.6 串行数据输出使能的保持时间

可以使用SFMSMD寄存器中的SFMOEX位将QIO0、QIO1、QIO2或QIO3引脚的缓冲器输出使能扩展1个QSPCLK。

对于标准读指令，它在地址码之后立即扩展。对于其他读指令，它在串行闪存的两个模式数据（XIP模式控制）周期后以虚拟周期进行扩展。

31.5.7 Setup Time for Serial Data Output

When a command or address is transmitted to the serial flash memory, the setup time begins on serial data output and ends when the QSPCLK signal rises. If this setup time is insufficient, it can be extended by 1 PCLKA using the SFMOSW bit in the SFMSMD register. When SFMOSW is 1, the low-level width of QSPCLK during serial data transmission is extended by 1 PCLKA while data is being output from the QSPI. This function has no effect on serial data reception.

31.5.8 Hold Time for Serial Data Output

When a command or address is transmitted to the serial flash memory, the hold time begins on the rising edge of QSPCLK and ends when the serial data makes another transmission. If this hold time is insufficient, it can be extended by 1 PCLKA using the SFMOHW bit in the SFMSMD register. When SFMOSW is 1, the high-level width of QSPCLK during serial data transmission is extended by 1 PCLKA while data is being output from the QSPI. This function has no effect on serial data reception.

31.5.7 串行数据输出的建立时间

当命令或地址传输到串行闪存时，设置时间从串行数据输出开始，到QSPCLK信号上升时结束。如果此建立时间不足，可以使用SFMSMD寄存器中的SFMOSW位将其延长1个PCLKA。当SFMOSW为1时，在从QSPI输出数据时，串行数据传输期间QSPCLK的低电平宽度扩展1PCLKA。该功能对串行数据接收没有影响。

31.5.8 串行数据输出的保持时间

当命令或地址传输到串行闪存时，保持时间从QSPCLK的上升沿开始，并在串行数据进行另一次传输时结束。如果该保持时间不足，可以使用SFMSMD寄存器中的SFMOHW位将其延长1个PCLKA。当SFMOSW为1时，在从QSPI输出数据时，串行数据传输期间QSPCLK的高电平宽度扩展1PCLKA。该功能对串行数据接收没有影响。

31.5.9 Serial Data Receiving Latency

The serial flash outputs data in synchronization with the falling edge of the QSPCLK signal. The QSPI receives that data in synchronization with the falling edge of the subsequent QSPCLK signal. The delay from when the serial flash starts outputting data until the QSPI receives that data is called the receiving latency. The QSPI adds a latency adjustment cycle immediately before the first data reception cycle in the SPI bus cycle. From the serial flash side, this is seen as an increase in the number of data reception cycles. This added latency adjustment cycle is not generated in the SPI bus cycle without accompanying data reception.

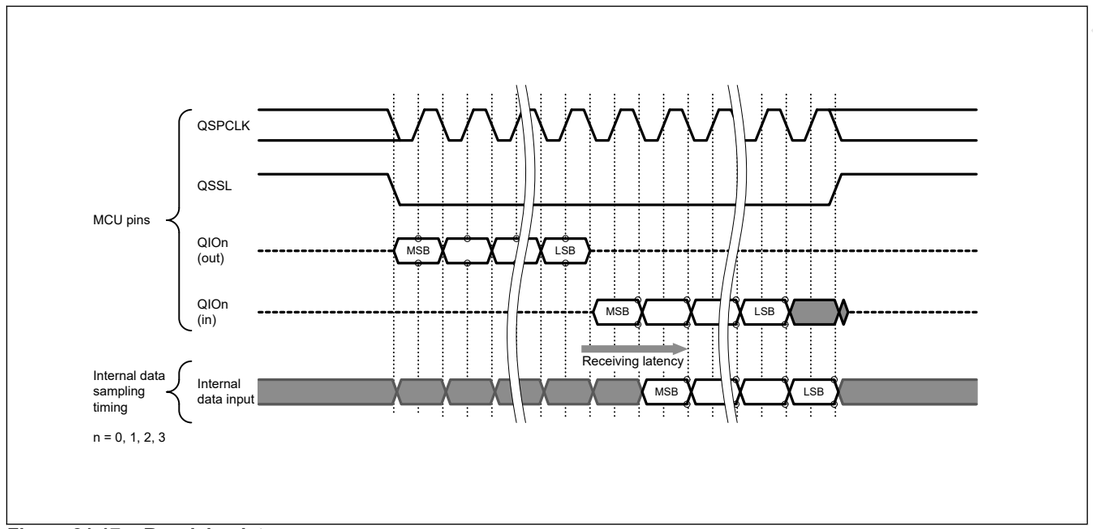

Figure 31.17 Receiving latency

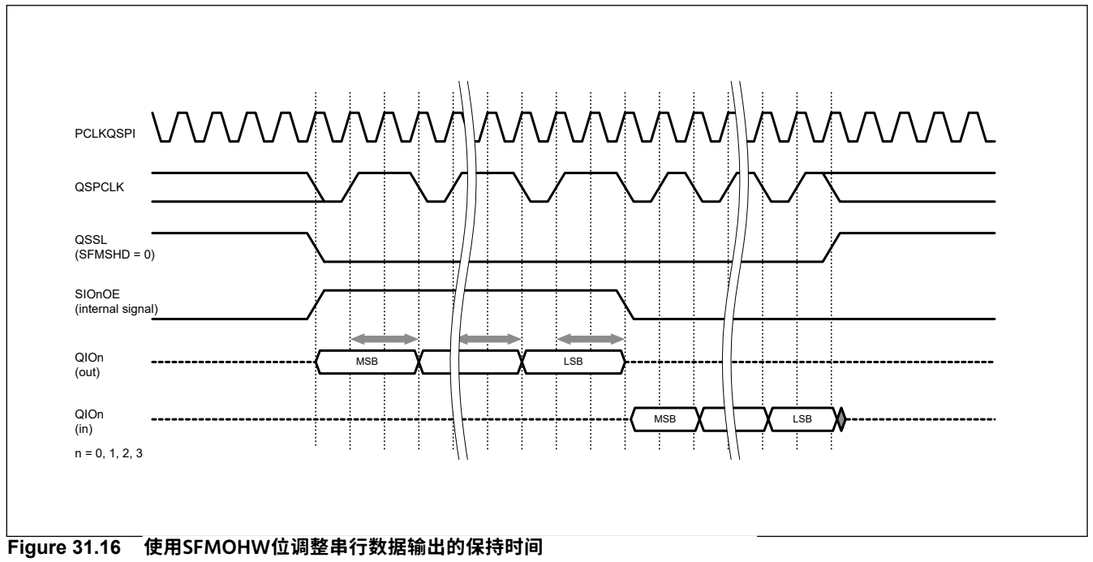

Figure 31.16 使用SFMOHW位调整串行数据输出的保持时间

31.5.9 串行数据接收延迟

串行闪存与QSPCLK信号的下降沿同步输出数据。QSPI与随后的QSPCLK信号的下降沿同步接收该数据。从串行闪存开始输出数据到QSPI接收到该数据的延迟称为接收延迟。QSPI在SPI总线周期的第一个数据接收周期之前添加一个延迟调整周期。从串行闪存方面来看，这被视为数据接收周期数的增加。如果没有伴随的数据接收，则不会在SPI总线周期中生成这个增加的延迟调整周期。

31.6.2 Standard Read Instruction

The standard Read instruction is a common read instruction supported by most serial flash memory. When an SPI bus cycle starts, the QSSL signal (serial flash memory select) is asserted, and the instruction code (0x03 or 0x13)*1 is output. Next, an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted. Data is then received.

This standard Read instruction is selected in the initial QSPI settings.

Note 1. Many 4-KB serial flash memory devices have an address field not larger than 1 byte (A7-A0) to minimize the overhead and to receive A8 information from bit 3 of the Read instruction code. To support these devices, the QSPI only outputs A8 (address bit 8) to bit [3] of the standard Read instruction code when an address width of 1 byte is specified (SFMAS[1:0] = 00). This means that 0x0B might be output instead of 0x03 as the standard Read instruction code. This code duplicates the Fast Read instruction code. However, for most of the 2-KB or smaller serial flash memory, with an address width of 1 byte, bit 3 of a command is designed to be excluded from decoding as a don't-care bit, so such a Read instruction code is recognized correctly as the standard Read instruction code. In rare cases, some serial flash memory allow bit 3 to be decoded. When such a serial flash memory is connected, configure your application to avoid access resulting in A8 = 1.

31.6.3 Fast Read Instruction

The Fast Read instruction is a read instruction that supports a higher communication clock speed than the standard Read instruction. When an SPI bus cycle starts, the QSSL signal is asserted, and the instruction code (0x0B or 0x0C) is output.

31.6.2 标准阅读说明

标准读指令是大多数串行闪存支持的常见读指令。当SPI总线周期开始时，QSSL信号（串行闪存选择）被置位，并输出指令代码（0x03或0x13）*1。接下来，发送宽度为1到4字节的地址，在SFMSAC寄存器的SFMAS[1:0]位中指定。然后接收数据。

在初始QSPI设置中选择此标准读取指令。

注1.许多4KB串行闪存器件的地址字段不大于1字节(A7-A0)，以尽量减少
开销并从读取指令代码的第3位接收A8信息。为了支持这些器件，当指定地址宽度为1字节（SFMAS[1:0]=00）时，QSPI仅将A8（地址位8）输出到标准读指令代码的位[3]。这意味着可能会输出0x0B而不是0x03作为标准读取指令代码。此代码复制了快速读取指令代码。但是，对于大多数2-KB或更小的串行闪存，地址宽度为1字节，命令的第3位被设计为作为无关位从解码中排除，因此这样的读取指令代码被正确识别为标准读取指令代码。在极少数情况下，某些串行闪存允许对第3位进行解码。连接此类串行闪存时，配置您的应用程序以避免访问导致A8=1。

31.7 SPI Bus Cycle Arrangement

31.7.1 Serial Flash Memory Read Based on Individual Conversion

ROM read bus cycles are individually converted to SPI bus cycles on a one-to-one basis. When a ROM read bus cycle is detected, the QSSL signal is asserted, and an SPI bus cycle starts. When the data receiving is finished from the serial flash memory, the QSSL signal is negated and the SPI bus cycle is complete.

When the next ROM read bus cycle is detected, the QSSL signal set by the SFMSSC.SFMSW[3: 0] bits is asserted again, then the next SPI bus cycle starts.

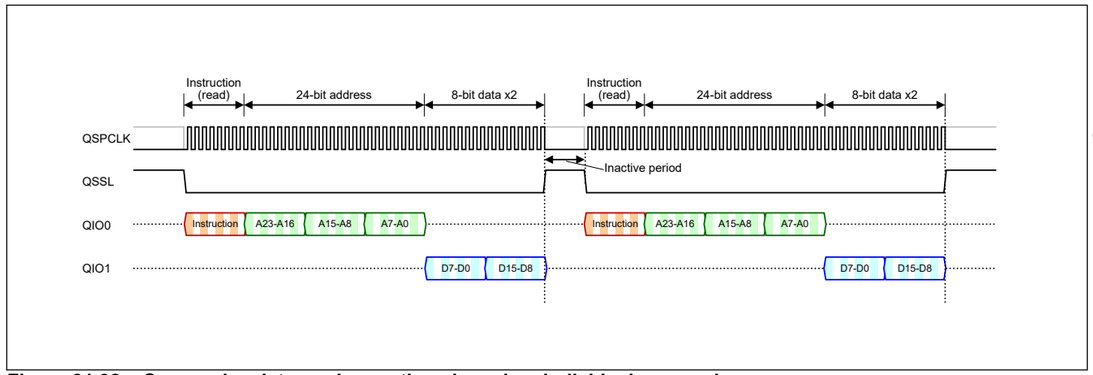

Figure 31.32 Successive data read operations based on individual conversion

31.7.2 Serial Flash Memory Read Using the Prefetch Function

In operations such as CPU instruction execution and block data transfer, data is often read in ascending order from contiguous addresses. Serial flash memory provides the ability to repeat data reception without reissuing an instruction code and address. To work with this function, the QSPI has a prefetch function for continuous data reception. However, if the CPU issues a flash read request for discontinuous flash addresses, SPI bus cycles are separated from each other, disabling the prefetch function.

To enable the prefetch function of the QSPI, set the SFMPFE bit in the SFMSMD register to 1. When the prefetch function is enabled, data is received continuously and stored in the prefetch buffer of the QSPI, without waiting for another flash read request. When the CPU issues a flash read request, an address check is made. If an address match is confirmed, the data in the buffer is passed to the CPU. If an address mismatch is detected, the data in the buffer is discarded and a new SPI bus cycle is issued.

The buffer for prefetching is 18 bytes long. When this buffer is full, the SPI bus cycle is ended. When the buffer data is read to create free space, a new SPI bus cycle is automatically started to resume prefetching.

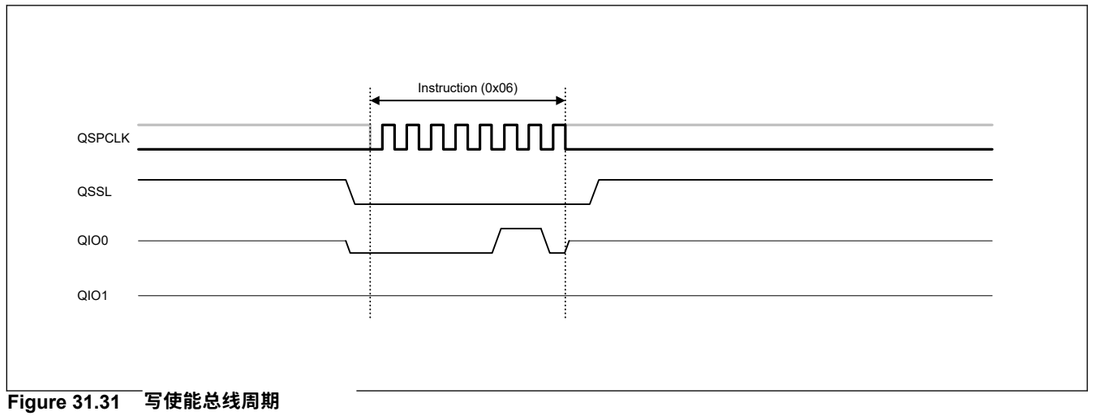

Figure 31.31 写使能总线周期

31.7 SPI总线周期安排

31.7.1 基于单独转换的串行闪存读取

ROM读取总线周期以一对一的方式单独转换为SPI总线周期。当检测到ROM读取总线周期时，QSSL信号被置位，并且SPI总线周期开始。当从串行闪存完成数据接收时，QSSL信号被取反，SPI总线周期完成。

当检测到下一个ROM读取总线周期时，由SFMSSC.SFMSW[3:0]位设置的QSSL信号再次置位，然后下一个SPI总线周期开始。

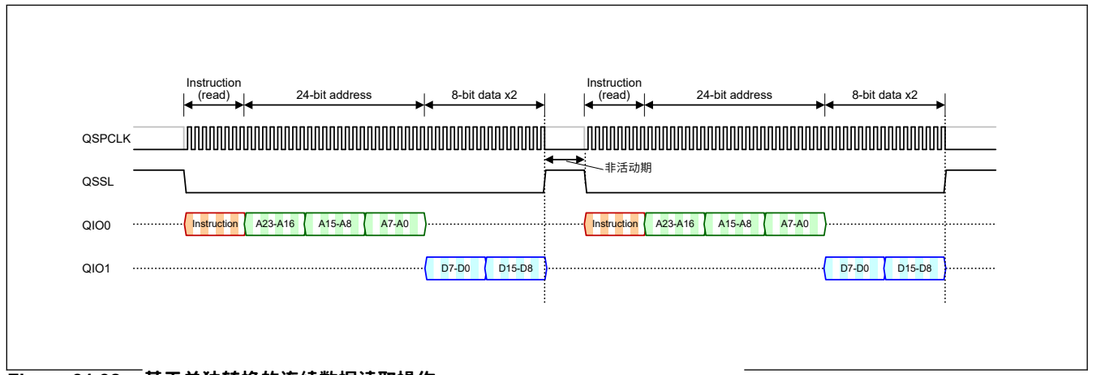

Figure 31.32 基于单独转换的连续数据读取操作

31.7.2 使用预取功能读取串行闪存

在CPU指令执行和块数据传输等操作中，数据通常是从连续地址按升序读取的。串行闪存提供了重复数据接收的能力，而无需重新发出指令代码和地址。为了使用此功能，QSPI具有用于连续数据接收的预取功能。但是，如果CPU对不连续的闪存地址发出闪存读取请求，则SPI总线周期会相互分离，从而禁用预取功能。

要使能QSPI的预取功能，请将SFMSMD寄存器中的SFMPFE位设置为1。当使能预取功能时，会连续接收数据并存储在QSPI的预取缓冲区中，而无需等待另一个闪存读取请求。当CPU发出闪存读取请求时，会进行地址检查。如果确认地址匹配，则将缓冲区中的数据传递给CPU。如果检测到地址不匹配，则丢弃缓冲区中的数据并发出新的SPI总线周期。

用于预取的缓冲区为18字节长。当此缓冲区满时，SPI总线周期结束。当缓冲区数据被读取以创建空闲空间时，会自动启动一个新的SPI总线周期以恢复预取。

The prefetch function allows for efficient transfer operations when data is read in ascending order from contiguous addresses, as in instruction fetch and block data transfer.

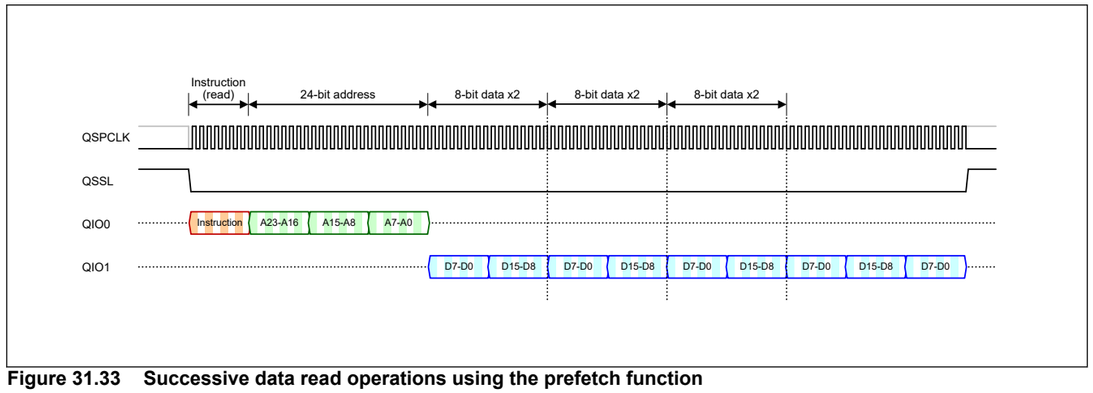

Figure 31.33 Successive data read operations using the prefetch function

31.7.3 Halt of Prefetching

If a serial flash memory read request for discontinuous addresses is issued when continuous data is being received by the prefetch function, the transfer of continuous data being made is halted and a new SPI bus cycle is started. Usually, such a halt of serial transfer occurs on data reception byte boundaries. However, if the SFMPAE bit in the SFMSMD register is set to 1, the halt can occur on locations other than byte boundaries.

31.7.4 Direct Specification of Prefetch Destination

When the prefetch function is enabled (SFMSMD.SFMPFE = 1), when writing to the QSPI window area occurs, after the writing is completed, prefetching starts from the write start address. Writes to serial flash memory cannot be performed. Combining this function with described in section 31.7.5. Prefetch State Polling, can reduce the load on the internal bus when data is read from a low-speed serial flash memory.

Note: Writing to the QSPI window area with a data size of 2 bytes or more causes a hardfault.

31.7.5 Prefetch State Polling

A read by CPU from a low-speed serial flash memory causes the CPU system bus to be occupied until completion of the SPI reception bus cycle. The prefetch state polling function is provided to reduce this load.

The PFOFF bit in the Status Register (SFMSST) register indicates the state of the prefetch function, and the PFCNT[4:0] bits in the SFMSST register indicate the number of data bytes already prefetched. Place the polling program in the SRAM of this device.

```
//
// copy 1K byte (32bit x 256 word) data from serial flash to internal SRAM
//
unsigned long *sptr; // pointer for the serial flash
unsigned long *dptr; // pointer for the destination
int i;

SFMSMD |= 0x0040; // set SFMPFE bit to enable prefetch
*( (volatile unsigned char *) sptr ) = 0; // make the TAG valid to start prefetch

for ( i = 0 ; i < 256 ; i++ ){
while ( ( SFMSST & 0x00FF ) < 0x04 ){}; // waiting for 4-byte data to be received
*(dptr++) = *(sptr++);
}
```

Note: When executing a polling program, place the program outside of the serial flash memory. If the polling program is executed when the program is placed on the serial flash memory, the prefetch target frequently switches to an instruction code. This eliminates the effect of polling, and an infinite loop can result because the prefetch buffer is not filled.

当从连续地址以升序读取数据时，预取功能允许有效的传输操作，如在指令取指和块数据传输中。

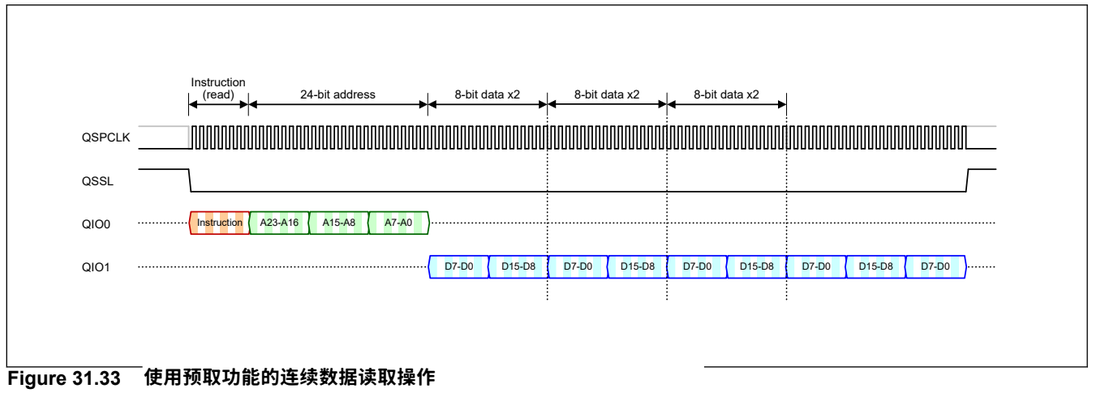

Figure 31.33 使用预取功能的连续数据读取操作

31.7.3 停止预取

如果在预取功能正在接收连续数据时发出对不连续地址的串行闪存读取请求，则正在进行的连续数据的传输将停止并开始新的SPI总线周期。通常，这种串行传输的停止发生在数据接收字节边界上。但是，如果SFMSMD寄存器中的SFMPAE位设置为1，则停止可能发生在字节边界以外的位置。

31.7.4 直接指定预取目的地

当预取功能使能时（SFMSMD.SFMPFE=1），当写入QSPI窗口区域时，写入完成后，从写入起始地址开始预取。无法执行对串行闪存的写入。

将此功能与第31.7.5节中的描述相结合。PrefetchStatePolling，可以减少从低速串行闪存读取数据时内部总线的负载。

Note: 写入数据大小为2字节或更大的QSPI窗口区域会导致硬故障。

31.7.5 预取状态轮询

CPU从低速串行闪存中读取会导致CPU系统总线被占用，直到完成SPI接收总线周期。提供了预取状态轮询功能来减少这种负载。

状态寄存器(SFMSST)寄存器中的PFOFF位指示预取功能的状态，SFMSST寄存器中的PFCNT[4:0]位指示已经预取的数据字节数。将轮询程序放在本设备的SRAM中。

```
将1K字节（32位x256字）数据从      串行闪存复制到内部SRAM无符号长*sptr；串行闪存指针un
signedlong*dptr;目标inti的指针；

SFMSMD=0x0040；设置SFMPFE位以启用预取*((volatileunsignedchar*)sptr)=0;使TAG有效以开始预
取

for(i=0;i<256;i++){而((SFMSST&0x00FF)<0x04){ ;等待接收4字节数据*(dptr++)=*(sptr++);
```

Note: 执行轮询程序时，请将程序置于串行闪存之外。如果轮询程序在程序放在串行闪存上时执行，则预取目标频繁切换到指令代码。这消除了轮询的影响，并且由于未填充预取缓冲区可能导致无限循环。

31.7.6 SPI Bus Cycle Extension Function

If the SFMSE[1:0] bits in the SFMSMD register are set to a value other than 00b, the QSPI waits for the next flash read. At this time, the QSPCLK signal stops, the QSSL signal is kept active low even after data is obtained from the serial flash memory, and the SPI bus cycle is suspended.

If the address of the next flash read is contiguous in ascending order, the toggling of the QSPCLK signal is restarted to continue reception of subsequent data. If the address of the next flash read is not contiguous in ascending order, the QSSL signal is driven high once to end the SPI bus cycle being suspended. A new SPI bus cycle is then started.

When data is read intermittently from ascending order contiguous addresses, this function enables an efficient transfer operation to be performed by reducing the overhead for instruction code and address transmission.

The SPI bus cycle extension time is selectable in the SFMSE[1:0] bits in the SFMSMD register. When the specified extension time elapses, the QSSL signal returns to the high level to automatically end the SPI bus cycle being suspended. If the SFMSE[1:0] bits are set to 11b, QSSL is extended infinitely. This increases the power consumption of the serial flash memory.

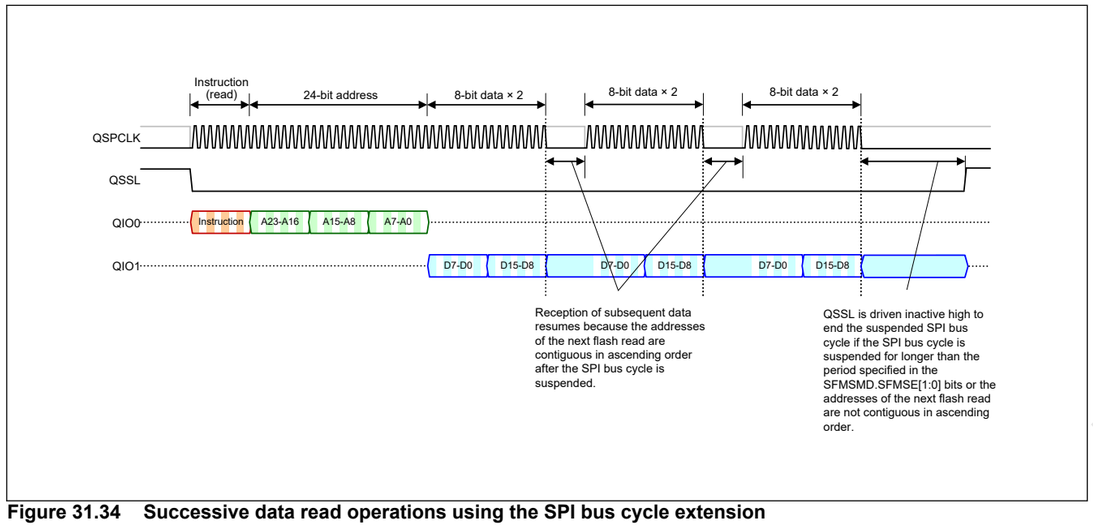

Figure 31.34 Successive data read operations using the SPI bus cycle extension

31.8 XIP Control

Some serial flash memory devices allow latencies to be reduced by skipping instruction code reception for flash reads. This instruction code skip function is selected in mode data received during the dummy cycle period of the previous serial bus cycle.

In the dummy cycle of the Fast Read instructions, the QSPI controls the XIP mode of the serial flash memory by using the serial data signal to send the mode data set in the SFMXD[7:0] bits in the SFMSDC register during the first 2 cycles, as shown in Figure 31.35.

The mode data to enable the XIP mode differs for each serial flash memory. Accordingly, set the appropriate mode data in the SFMXD[7:0] bits.

31.7.6 SPI总线周期扩展功能

如果SFMSMD寄存器中的SFMSE[1:0]位设置为00b以外的值，则QSPI等待下一次闪存读取。此时，QSPCLK信号停止，即使从串行闪存中获取数据后，QSSL信号也保持低电平有效，并且暂停SPI总线周期。

如果下一次闪存读取的地址按升序连续，则重新启动QSPCLK信号的翻转以继续接收后续数据。如果下一次flash读取的地址升序不连续，则QSSL信号被驱动一次高电平以结束暂停的SPI总线周期。然后开始一个新的SPI总线周期。

当从升序连续地址间歇性地读取数据时，该功能通过减少指令代码和地址传输的开销来实现高效的传输操作。

SPI总线周期延长时间可在SFMSMD寄存器的SFMSE[1:0]位中选择。当指定的延长时间过去后，QSSL信号返回高电平，自动结束暂停的SPI总线周期。如果SFMSE[1:0]位设置为11b，QSSL将无限扩展。这增加了串行闪存的功耗。

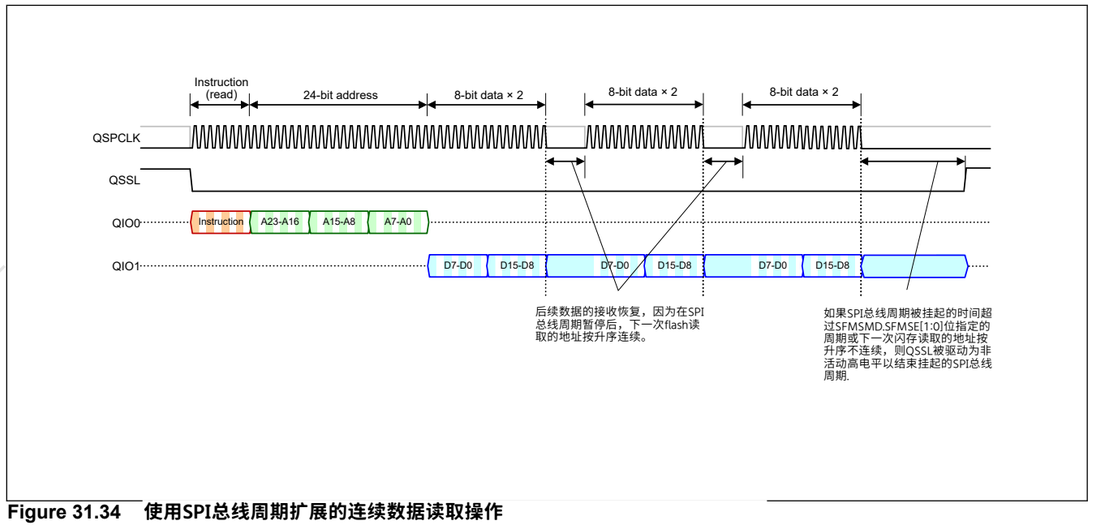

Figure 31.34 使用SPI总线周期扩展的连续数据读取操作

31.8 XIP Control

一些串行闪存设备允许通过跳过用于闪存读取的指令代码接收来减少延迟。在前一个串行总线周期的虚拟周期期间接收到的模式数据中选择此指令代码跳过功能。

在快速读取指令的空周期中，QSPI在前2循环，如图31.35所示。

启用XIP模式的模式数据因串行闪存而异。因此，在SFMXD[7:0]位中设置适当的模式数据。

31.8.1 Setting XIP Mode

To start XIP mode in serial flash memory, perform the following register settings:

- Set a mode data value in the SFMXD[7:0] bits in the SFMSDC register.*1
- Set the SFMXEN bit in the SFMSDC register to 1.

In the dummy cycle of the first fast read cycle after these registers are set, the mode data value set in the register is transferred. From that point, XIP mode is enabled in the serial flash memory. To confirm the current XIP mode status, read the SFMXST flag in the SFMSDC register.

Note 1. In the SFMXD[7:0] bits in the SFMSDC register, set the mode data that follows the specifications for the actual serial flash memory.

The following figure shows an example of the XIP mode setting procedure.

31.8.1 设置XIP模式

要在串行闪存中启动XIP模式，请执行以下寄存器设置：

●在SFMSDC寄存器的SFMXD[7:0]位中设置模式数据值。*1

●将SFMSDC寄存器中的SFMXEN位设置为1。

在设置这些寄存器后的第一个快速读取周期的空周期中，传输寄存器中设置的模式数据值。从那时起，串行闪存中的XIP模式被启用。要确认当前XIP模式状态，请读取SFMSDC寄存器中的SFMXST标志。

31.8.2 Releasing the XIP Mode

To release XIP mode in serial flash memory, perform the following register setting:

- Set the mode data value to disable XIP mode in SFMSDC.SFMXD [7: 0] bits*1
- Set the SFMXEN bit in the SFMSDC register to 0.

31.8.2 释放XIP模式

要在串行闪存中释放XIP模式，请执行以下寄存器设置：

- ●在SFMSDC.SFMXD[7:0]位中设置模式数据值以禁用XIP模式*1
- ●将SFMSDC寄存器中的SFMXEN位设置为0。

In the dummy cycle of the first fast read cycle after this register is set, The mode data value that disables the XIP mode set in the register is transferred. From that point, XIP mode is disabled in the serial flash memory. To confirm the current XIP mode status, read the SFMXST flag in the SFMSDC register.

Note 1. Set the mode data in the SFMSDC.SFMXD [7: 0] bits according to the specifications of the serial flash memory.

Figure 31.37 shows an example of the procedure for releasing XIP mode.

31.9 QIO2 and QIO3 Pin States

The QIO2 and QIO3 pin states depend on the serial interface read mode specified in the SFMRM[2:0] bits in the SFMSMD register.

Note 1. The serial flash memory can also use the QIO2 pin for the write protect (WP) function. The WP function prohibits writes to the status registers. (The function is available in mode other than Quad-SPI mode.)
Note 2. The serial flash memory can also use the QIO3 pin for the HOLD or RESET function.
The hold function places the I/O pin in an inactive state without deselecting the chip. (The function is available in mode other than Quad-SPI mode.)
The reset function resets the serial flash memory. (The function is available when the QSSL pin function is disabled or in a mode in which the QIO3 pin is not used.)

31.10 Direct Communication Mode

31.10.1 About Direct Communication

The QSPI can read the serial flash memory contents by automatically converting from reading the QSPI window area to SPI bus cycles. However, serial flash memory have many different functions in addition to memory data read, including ID information read, erase, programming, and status information read. There is no standardized instruction set for using these functions, and more functions are being added rapidly by different vendors to different devices. Therefore, to support these functions, the software can create any required SPI bus cycle by communicating directly with serial flash memory.

31.10.2 Using Direct Communication Mode

To communicate directly with serial flash memory, transition to direct communication mode by setting the DCOM bit in the Communication Mode Control Register (SFMCMD) register to 1. While direct communications mode is selected, the read operation to the serial flash memory by the QSPI window is invalid.

Note: If the QSPI is set to the XIP mode, you must terminate the XIP mode before starting direct communication mode.

31.10.3 Generating the SPI Bus Cycle during Direct Communication

The SPI bus cycle in direct communications starts on the first access to the SFMCOM register, and after a series of input / output operations are executed via the SFMCOM register, the bus cycle ends when 1 is written to the SFMCMD register. At that point, a write to the SFMCOM port is converted to a one-byte transmission to the SPI bus, and a read from the SFMCOM register is converted to a one-byte reception from the SPI bus.

During the period from the first access to the SFMCOM register to the last write operation to the SFMCMD register, the QSSL signal is held active to notify the serial flash memory that a series of SPI bus cycles is in progress.

Note: In direct communication mode, all writes to registers other than SFMCMD and SFMCOM (including SFMSMD, SFMSSC, SFMSKC, SFMSST, SFMCST, SFMSIC, SFMSAC, SFMSDC, SFMSPC, and SFMPMD) are disabled.

Figure 31.38 to Figure 31.40 show direct communication program examples, and Figure 31.41 shows ID read direct communication timing examples.

注1.串行闪存也可以将QIO2引脚用于写保护(WP)功能。WP功能禁止写入状态寄存器。（该功能在Quad-SPI模式以外的模式下可用。）

注2.串行闪存也可以将QIO3引脚用于HOLD或RESET功能。
保持功能将IO引脚置于非活动状态，而无需取消选择芯片。（该功能在除Quad-SPI mode.)
复位功能复位串行闪存。（当QSSL引脚功能被禁用或处于未使用QIO3引脚的模式时，该功能可用。）

31.10 直接通讯方式

31.10.1 关于直接沟通

QSPI可以通过从读取QSPI窗口区域自动转换为SPI总线周期来读取串行闪存内容。然而，串行闪存除了读取存储器数据外，还有许多不同的功能，包括ID信息读取、擦除、编程和状态信息读取。使用这些功能没有标准化的指令集，更多的功能正在由不同的供应商迅速添加到不同的设备中。因此，为了支持这些功能，软件可以通过直接与串行闪存通信来创建任何所需的SPI总线周期。

31.10.2 使用直接通信模式

要直接与串行闪存通信，通过设置DCOM位转换到直接通信模式CommunicationModeControlRegister(SFMCMD)registerto1.Whiledirectcommunicationsmodeisselected therea doperationtotheserialflashmemorybytheQSPIwindowisinvalid.

Note: 如果QSPI设置为XIP模式，则必须在启动直接通信模式之前终止XIP模式。

31.10.3 在直接通信期间生成SPI总线周期

直接通信中的SPI总线周期从第一次访问SFMCOM寄存器开始，通过SFMCOM寄存器执行一系列输入输出操作后，总线周期在SFMCMD寄存器写入1时结束。此时，对SFMCOM端口的写入转换为向SPI总线发送一个字节，从SFMCOM寄存器读取转换为从SPI总线接收一个字节。

在从第一次访问SFMCOM寄存器到最后一次写入SFMCMD寄存器期间，
QSSL信号保持有效，以通知串行闪存一系列SPI总线周期正在进行中。

Note: 在直接通信模式下，所有写入除SFMCMD和SFMCOM以外的寄存器（包括SFMSMD、SFMSSC、SFMSKC、SFMSST、SFMCST、SFMSIC、SFMSAC、SFMSDC、SFMSPC和SFMPMD）被禁用。

(2) SFMCOM = Instruction_RDID; // Read ID instruction (to open the transaction)

(6) SFMCMD = 0x01; // Close the transaction.
(7) SFMCMD = 0x00; // Disable direct operation.

The timings (1), (6) and (7) for enabling or disabling direct communications mode are omitted in the figure.

Figure 31.41 Example of direct communication timing for ID read

Note: When the Single SPI Protocol, Extended SPI Protocol is used in direct communication mode, the standard Read or Fast Read instruction must be used to reference the contents of the serial flash memory. The QSPI does not support Fast Read Dual Output, Fast Read Dual I/O, Fast Read Quad Output, or Fast Read Quad I/O transfers in this configuration. When these Fast Read operations are required, use ROM access memory.

31.11 Interrupts

When ROM read access is detected in direct communication mode, the SFMCST.EROMR flag is set to 1 and QSPI generates an interrupt request. Interrupt requests are retained until the EROMR flag is cleared by a 0 write. For details, see section 13, Interrupt Controller Unit (ICU).

31.12 Usage Note

31.12.1 Settings for the Module-Stop Function

QSPI operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The QSPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

31.12.2 Procedure for Changing Settings in Multiple Control Registers

The settings of the QSPI control registers can be modified dynamically during system operation. However, when the settings of multiple control registers are changed sequentially, an SPI bus cycle might occur before all of the registers are updated. The register setting sequence must be designed so that the SPI bus timing specifications are satisfied at all stages of register setting modification.

图中省略了启用或禁用直接通信模式的时序(1)、(6)和(7)。

必须使用快速读取指令来引用串行闪存的内容。QSPI不支持
此配置中的快速读取双输出、快速读取双IO、快速读取四输出或快速读取四IO传输。当需要这些快速读取操作时，请使用ROM存取存储器。

31.11 Interrupts

当在直接通信模式下检测到ROM读访问时，SFMCST.EROMR标志设置为1，并且QSPI产生中断请求。中断请求被保留，直到EROMR标志被0写入清除。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

31.12 使用说明

31.12.1 模块停止功能的设置

可以使用模块停止控制寄存器B(MSTPCRB)禁用或启用QSPI操作。QSPI在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

31.12.2 更改多个控制寄存器中的设置的步骤

QSPI控制寄存器的设置可以在系统运行期间动态修改。但是，当多个控制寄存器的设置依次更改时，可能会在所有寄存器更新之前发生一个SPI总线周期。必须设计寄存器设置序列，以便在寄存器设置修改的所有阶段都满足SPI总线时序规范。

32.3 Operation

32.3.1 Basic Operation

The CRC calculator generates CRC codes for use in LSB-first or MSB-first transfer.

The following examples show CRC code generation for input data (0xF0) using the 16-bit CRC-CCITT generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before CRC calculation.

When an 8-bit CRC (with the polynomial $X^8 + X^2 + X + 1$) is in use, the valid bits of the CRC code are obtained in CRCDOR_BY. When a 32-bit CRC is in use, the valid bits of the CRC code are obtained in CRCDOR.

Figure 32.2 and Figure 32.3 show the LSB-first and MSB-first data transmission examples respectively. Figure 32.4 and Figure 32.5 show the LSB-first and MSB-first data reception examples.

32.3 Operation

32.3.1 基本操作

CRC计算器生成用于LSB优先或MSB优先传输的CRC代码。

以下示例显示了使用16位CRC-CCITT生成多项式(X16+X12+X5+1)为输入数据(0xF0)生成CRC码。在这些示例中，CRC数据输出寄存器(CRCDOR_HA)的值在CRC计算之前被清除。

当使用8位CRC（多项式X8+X2+X+1）时，CRC码的有效位在CRCDOR_BY。使用32位CRC时，在CRCDOR中获取CRC码的有效位。

图32.2和图32.3分别显示了LSB-first和MSB-first数据传输示例。图32.4和图32.5显示了LSB优先和MSB优先的数据接收示例。

32.4 Usage Notes

32.4.1 Settings for the Module-Stop State

The Module Stop Control Register C (MSTPCRC) can enable or disable CRC calculator operation. The CRC calculator is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

32.4.2 Note on Transmission

The transmission sequence for the CRC code differs based on whether the transmission is LSB-first or MSB-first. Figure 32.6 shows an LSB-first and MSB-first data transmission.

The JTIDR register data is output from the TDO pin when the IDCODE instruction is executed. After a reset release, the DID[31:0] of JTIDR changes into the Arm® debug code. See the *Arm® CoreSight™ SoC-400 Technical Reference Manual* (ARM DDI 0480F).

33.2.3 JTBPR : Bypass Register

The JTBPR register is a 1-bit register and is connected between the TDI and TDO pins when the JTIR register is set to BYPASS mode. The JTBPR register cannot be read from or written to by the CPU.

33.2.4 JTBSR : Boundary Scan Register

The JTBSR register is a shift register for controlling the external input and output pins of this device, and is distributed across the pads. To apply the JTBSR register in boundary-scan testing, issue the EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ instructions. The BSDL file describes the associations between the JTBSR register bits and the pins of this device. The value after reset is undefined.

33.3 Operation

During a reset, the JTAG ports, TCK, TMS, TDI, and TDO, are assigned as default pin functions. The TCK, TMS, and TDI pins are pulled up by the pull-up resistors. Boundary scan testing can be executed after the setup time elapses when POR is negated and RES is driven low.

33.3.1 TAP Controller

Figure 33.2 shows the state transition diagram of the TAP controller. All transitions are controlled by the TMS signal.

JTIDR的DID[31:0]更改为Arm®调试代码。请参阅Arm®CoreSight SoC-400技术参考手册(ARMDDI0480F)。

33.2.3 JTBPR:旁路寄存器

JTBPR寄存器是一个1位寄存器，当JTIR寄存器设置为
旁路模式。CPU无法读取或写入JTBPR寄存器。

33.2.4 JTBSR:边界扫描寄存器

JTBSR寄存器是一个移位寄存器，用于控制该器件的外部输入和输出引脚，分布在各个焊盘上。要在边界扫描测试中应用JTBSR寄存器，请发出EXTEST、SAMPLEPRELOAD、CLAMP和HIGHZ指令。BSDL文件描述了JTBSR寄存器位和该器件引脚之间的关联。复位后的值未定义。

33.3 Operation

在复位期间，JTAG端口、TCK、TMS、TDI和TDO被分配为默认引脚功能。TCK、TMS和TDI引脚由上拉电阻上拉。
当POR被否定并且RES被驱动为低电平时，可以在设置时间过去后执行边界扫描测试。

图33.2显示了TAP控制器的状态转换图。所有转换都由TMS信号控制。

33.3.2 Commands

(1) BYPASS

The BYPASS instruction drives the Bypass Register (JTBPR). This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed circuit board at higher speeds. While this instruction is being executed, the test circuit has no effect on the system circuits.

The JTBPR register is connected between the TDI and TDO pins. Bypass operation is initiated from the Shift-DR operation. The TDO is low in the first clock cycle in the Shift-DR state. In the subsequent clock cycles, values input to the TDI pin are output from the TDO pin.

(2) EXTEST

The EXTEST instruction is used to test external circuits when this device is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified in the SAMPLE/PRELOAD instruction) from the Boundary Scan Register (JTBSR) to the other devices, and input pins are used to input the test result.

(3) SAMPLE/PRELOAD

The SAMPLE/PRELOAD instruction is used to input data from the internal circuits of this device to the JTBSR register, output data from the scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to this device and output signals are also directly output to the external circuits. This device system circuit is not affected by this instruction.

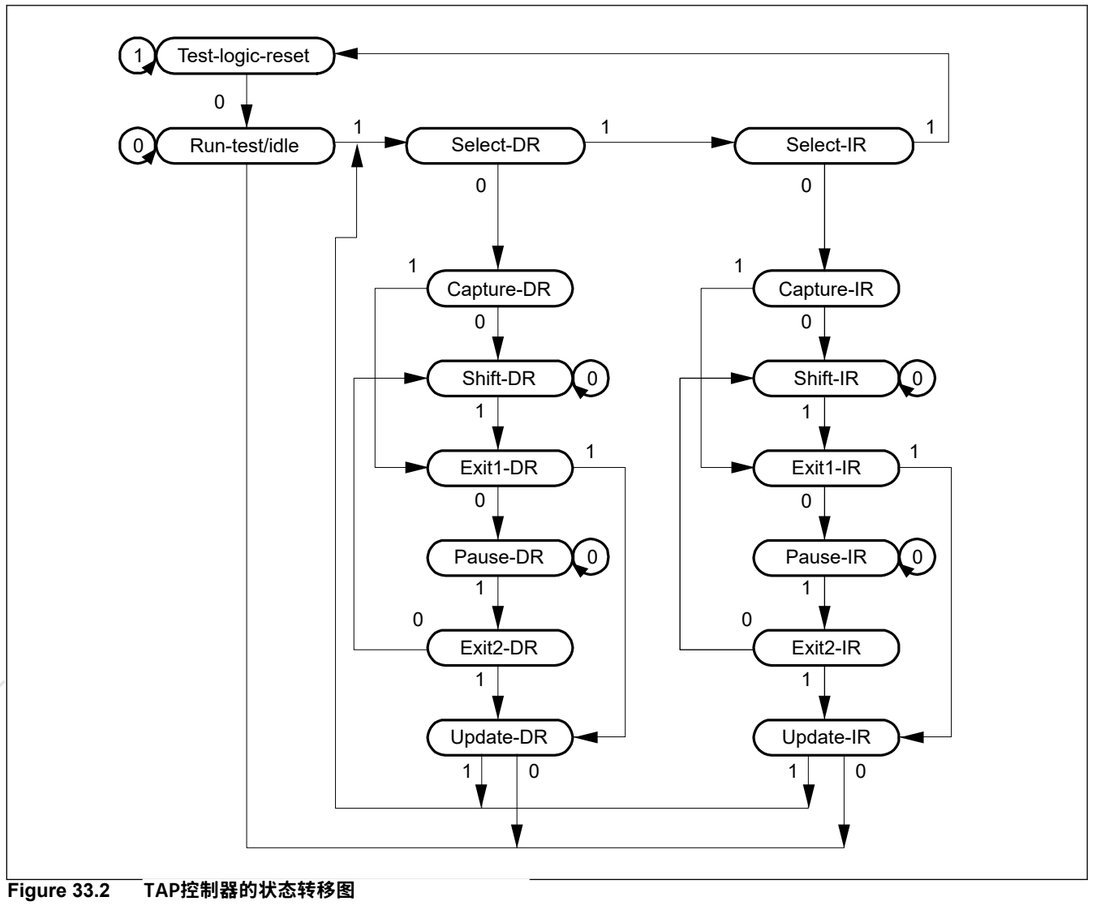

Figure 33.2 TAP控制器的状态转移图

33.3.2 Commands

(1) BYPASS

BYPASS指令驱动旁路寄存器(JTBPR)。该指令缩短了移位路径，便于将串行数据以更高的速度传输到印刷电路板上的其他LSI。在执行该指令时，测试电路对系统电路没有影响。

JTBPR寄存器连接在TDI和TDO引脚之间。旁路操作从Shift-DR操作开始。TDO在Shift-DR状态的第一个时钟周期内为低电平。在随后的时钟周期中，输入到TDI引脚的值从TDO引脚输出。

(2) EXTEST

当本设备安装在印刷电路板上时，EXTEST指令用于测试外部电路。如果执行该指令，输出引脚用于将测试数据（在SAMPLEPRELOAD指令中指定）从边界扫描寄存器(JTBSR)输出到其他设备，输入引脚用于输入测试结果。

(3) SAMPLE/PRELOAD

SAMPLEPRELOAD指令用于将数据从本器件内部电路输入到JTBSR寄存器，从扫描路径输出数据，并将数据重新加载到扫描路径。执行该指令时，输入信号直接输入到本设备，输出信号也直接输出到外部电路。本设备系统电路不受本指令影响。

In SAMPLE operation, the JTBSR register latches a snapshot of the data transferred from the input pins to the internal circuit or data transferred from the internal circuit to the output pins. The latched data is read from the scan path. The JTBSR register latches the data snapshot on the rising edge of the TCK pin in the Capture-DR state. The data snapshot is only transferred from the internal circuit to the output pins during a reset.

In PRELOAD operation, the initial value is written from the scan path to the parallel output latch of the JTBSR register prior to the EXTEST instruction execution. If EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In the EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE

When the IDCODE instruction is selected, the ID Code Register (JTIDR) value is output to the TDO pin in the Shift-DR state of the TAP controller. In this case, the JTIDR register value is output LSB-first. During this instruction execution, the test circuit does not affect the system circuit.

(5) CLAMP

When the CLAMP instruction is selected, output pins output the JTBSR register value that was specified in the SAMPLE/ PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of the JTBSR register is maintained regardless of the TAP controller state.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

(6) HIGHZ

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the JTBSR register is maintained regardless of the state of the TAP controller.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

33.4 Usage Notes

The boundary scan function is subject to the following constraints:

- The boundary scan must be executed when the RES pin is driven low
- Serial data input/output is in LSB order, as shown in Figure 33.3

在SAMPLE操作中，JTBSR寄存器锁存从输入引脚传输到内部电路的数据或从内部电路传输到输出引脚的数据的快照。从扫描路径读取锁存的数据。在Capture-DR状态下，JTBSR寄存器在TCK引脚的上升沿锁存数据快照。数据快照仅在复位期间从内部电路传输到输出引脚。

在PRELOAD操作中，在执行EXTEST指令之前，将初始值从扫描路径写入JTBSR寄存器的并行输出锁存器。如果在不执行此PRELOAD操作的情况下执行EXTEST，则从EXTEST序列的开头到结尾（传输到输出锁存器）输出未定义的值。（在EXTEST指令中，输出并行锁存器始终输出到输出引脚。）

(4) IDCODE

WhentheIDCODEinstructionisselected theIDCodeRegister(JTIDR)valueisoutputtotheTDOpinintheShift-DRstateoftheTAPcontroller.在这种情况下，JTIDR寄存器值首先输出LSB。在该指令执行期间，测试电路不影响系统电路。

(5) CLAMP

选择夹具指令时，输出引脚输出样品中指定的JTBSR寄存器值
预先PRELOAD指令。选择CLAMP指令时，无论TAP控制器状态如何，都将保持JTBSR寄存器的状态。

JTBPR寄存器连接在TDI和TDO引脚之间，导致与选择BYPASS指令时相同的操作。

(6) HIGHZ

选择Highz指令时，所有输出引脚都输入高阻抗状态。选择HIGHZ指令时，无论TAP控制器的状态如何，都会保持JTBSR寄存器。

JTBPR寄存器连接在TDI和TDO引脚之间，导致与选择BYPASS指令时相同的操作。

33.4 使用说明

2. Enter the target data to the SCE9. Plaintext data is converted to ciphertext and ciphertext data to plaintext.
3. Read the converted data.

The encryption engine has input and output buffers, and can perform encryption/decryption in parallel with data input/output. Figure 34.3 shows the encryption engine timing.

34.3 Usage Notes

34.3.1 Software Standby Mode

When the software standby mode is entered while the encryption engine is in process, proper processing cannot be resumed after the software standby mode is exited. The software standby mode should therefore be entered while the encryption engine is not running.

34.3.2 Module-Stop Function Setting

SCE9 operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The SCE9 module is initially stopped after reset. Releasing the module-stop state enables access to the registers.

当加密引擎正在运行时进入软件待机模式时，退出软件待机模式后无法恢复正常处理。因此，应在加密引擎未运行时进入软件待机模式。

34.3.2 模块停止功能设置

可以使用模块停止控制寄存器C(MSTPCRC)禁用或启用SCE9操作。SCE9模块在复位后最初停止。释放模块停止状态可以访问寄存器。

35. 12-Bit A/D Converter (ADC12)

35.1 Overview

The MCU includes 12-bit successive approximation A/D converter (ADC12) unit. Up to 9 analog input channels, internal reference voltage can be selected for conversion.

The A/D conversion accuracy is selectable from 12-bit, 10-bit, 8-bit conversion, making it possible to optimize the trade-off between speed and resolution in generating a digital value.

The ADC12 supports the following operating modes:

- Single scan mode to convert analog inputs of selected channels in ascending order of channel number
- Continuous scan mode to convert analog inputs of selected channels continuously in ascending order of channel number
- Group scan mode to divide analog inputs of channels into two groups (group A and B) and convert the analog inputs of selected channels for each group in ascending order of channel number.

In group scan mode, select two groups (group A and B). You can individually select the scan start conditions for each group (group A, B) and start scanning of each group at different times. In addition, when group A priority control operation is set, the ADC12 accepts group A scan start during group B A/D conversion, suspending group B conversion. This allows you to assign higher priority to A/D conversion start for group A.

In double trigger mode, the analog input of a selected channel is converted in single scan mode or group scan mode (group A), and data converted by the first and second A/D conversion start triggers are stored in different registers, providing duplexing of A/D converted data.

Self-diagnosis is performed once at the beginning of each scan, and one of the three reference voltage values generated in ADC12 is A/D converted.

The internal reference voltage is selectable at the same time as the analog input of the channel. First A/D conversion is performed for the analog input of the channel, and then for the internal reference voltage.

The ADC12 also provides a compare function (window A and window B). The compare function specifies the upper reference value for window A and lower reference value for window B, and outputs an interrupt when the A/D converted value of the selected channel meets the comparison conditions.

The A/D data storage buffer is a ring buffer consisting of 16 buffers to sequentially store A/D converted data.

Table 35.1lists the ADC12 specifications and Table 35.2 list the functions. Figure 35.1 shows a block diagram of ADC12 and Table 35.3 lists the I/O pins.

35. 12-Bit A/D Converter (ADC12)

35.1 Overview

MCU包括12位逐次逼近模数转换器(ADC12)单元。最多9个模拟输入通道，可选择内部参考电压进行转换。

AD转换精度可从12位、10位、8位转换中选择，从而可以在生成数字值时优化速度和分辨率之间的权衡。

ADC12支持以下工作模式：

●单次扫描模式，以通道号升序转换所选通道的模拟输入

●连续扫描模式，以通道号升序连续转换所选通道的模拟输入

●组扫描模式，将通道的模拟输入分为两组（A组和B组），并按通道编号升序对每组所选通道的模拟输入进行转换。

在组扫描模式下，选择两个组（A组和B组）。您可以单独选择每个组（A、B组）的扫描开始条件，并在不同时间开始每个组的扫描。此外，当设置A组优先控制操作时，ADC12在B组AD转换期间接受A组扫描启动，暂停B组转换。这允许您为A组的AD转换启动分配更高的优先级。

在双触发模式下，选定通道的模拟输入转换为单扫描模式或组扫描模式（组A），由第一个和第二个AD转换启动触发器转换的数据存储在不同的寄存器中，提供AD转换数据的双工。

自诊断在每次扫描开始时执行一次，并在生成的三个参考电压值之一ADC12经过AD转换。

内部参考电压可与通道的模拟输入同时选择。首先对通道的模拟输入进行AD转换，然后对内部参考电压进行AD转换。

ADC12还提供比较功能（窗口A和窗口B）。比较函数指定窗口A的上参考值和窗口B的下参考值，并在所选通道的AD转换值满足比较条件时输出中断。

AD数据存储缓冲区是由16个缓冲区组成的环形缓冲区，用于顺序存储AD转换后的数据。

ADDRn registers are 16-bit read-only registers to store A/D conversion results.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 35.4 shows the example of bit assignment for 12-bit accuracy.

Table 35.4 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 35.5 shows example of the bit assignment for 12-bit accuracy.

ADDRn寄存器是16位只读寄存器，用于存储AD转换结果。

以下条件决定了AD数据寄存器中的数据格式：

●AD数据寄存器格式选择位(ADCER.ADRFMT)的设置（左对齐或右对齐）

●AD转换精度选择位(ADCER.ADPRC[1:0])中的设置（可选择12位、10位、8位。）

●加法平均计数选择位(ADADC.ADC[2:0])的设置（1、2、3、4或16次）

●设置平均模式启用位(ADADC.AVEE)（加法或平均）。

本节介绍不同模式下这些条件的数据格式。

对于12位精度，在AD转换值相加模式中也可以选择16倍。在AD转换值相加模式中，这些寄存器指示通过在特定通道上添加AD转换值获得的值。AD转换结果作为指定转换精度的4位扩展值存储在AD数据寄存器中。

ADDBLDR register is a 16-bit read-only register to store A/D conversion results in response to a second trigger in double-trigger mode.

- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 35.6 shows the example of bit assignment for 12-bit accuracy.

(2) When A/D-converted value average mode is selected

Note 1. To start A/D conversion using an external pin (asynchronous trigger):
After a high-level signal is input to the external pin (ADTRG0), write 1 to both the TRGE and EXTRG bits in the ADCSR register and drive the ADTRG0 pin low. With these settings, the scan conversion process starts on detection of the falling edge of ADTRG0. The pulse width of the low-level input must be at least PCLKA 1.5 clock cycles.

The ADCSR register sets double-trigger mode and A/D conversion start trigger, enables or disables scan end interrupt, selects the scan mode, and starts or stops A/D conversion.

DBLANS[4:0] bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one channel for A/D conversion data duplication in double-trigger mode. This can be selected by setting the binary value of the channel number to be duplicated. The A/D conversion results of the analog input of the channel selected in the DBLANS[4:0] bits are stored in A/D Data Register y when conversion is started by the first trigger, and in the A/D Data Duplexing Register when conversion is started by the second trigger.

In double-trigger mode, the channels selected in the ADANSA0 and ADANSA1 registers, are invalid, and the channel selected in the DBLANS[4:0] bits is A/D converted instead.

When double-trigger mode is used in group scan mode, double-trigger control is only applied to group A and not to group B. Therefore, multiple channel analog input can be selected for group B even in double-trigger mode.

Only set the DBLANS[4:0] bits when the ADST bit is 0. Do not set the DBLANS[4:0] bits at the same time that you write 1 to the ADST bit.

To enter A/D-converted value addition/average mode when in double-trigger mode, select the channel using the DBLANS[4:0] bits in the ADANSA0 and ADANSA1 registers.

A/D-converted data from the self-diagnosis function and internal reference voltage cannot be used in double-trigger mode.

GBADIE bit (Group B Scan End Interrupt and ELC Event Enable)

The GBADIE bit enables or disables group B scan end interrupt (ADC120_GBADI) in group scan mode.

15	ADST	AD转换开始 0：停止AD转换过程。1：开始AD转换过程。	R/W

注1.使用外部引脚（异步触发）启动AD转换：
向外部引脚(ADTRG0)输入高电平信号后，向ADCSR寄存器的TRGE和EXTRG位写入1并将ADTRG0引脚驱动为低电平。通过这些设置，扫描转换过程在检测到ADTRG0的下降沿时开始。低电平输入的脉冲宽度必须至少为PCLKA1.5个时钟周期。

ADCSR寄存器设置双触发模式和AD转换启动触发，使能或禁止扫描结束中断，选择扫描模式，启动或停止AD转换。

DBLANS[4:0]位（双触发通道选择）

DBLANS[4:0]位选择一个通道用于双触发模式下的AD转换数据复制。这可以通过设置要复制的通道号的二进制值来选择。在DBLANS[4:0]位中选择的通道的模拟输入的AD转换结果在第一次触发开始转换时存储在AD数据寄存器y中，当转换开始时存储在AD数据双工寄存器中。第二个触发器。

在双触发模式下，ADANSA0和ADANSA1寄存器中选择的通道无效，DBLANS[4:0]位中选择的通道改为AD转换。

在组扫描模式下使用双触发模式时，双触发控制只适用于A组，不适用于组B.因此，即使在双触发模式下，B组也可以选择多路模拟输入。

仅当ADST位为0时设置DBLANS[4:0]位。不要在将1写入ADST位的同时设置DBLANS[4:0]位。

要在双触发模式下进入AD转换值加法平均模式，请使用ADANSA0和ADANSA1寄存器中的DBLANS[4:0]位。

来自自诊断功能和内部参考电压的D转换数据不能用于双触发模式。

GBADIE位（B组扫描结束中断和ELC事件使能）

GBADIE位在组扫描模式下启用或禁用组B扫描结束中断(ADC120_GBADI)。

DBLE bit (Double Trigger Mode Select)

The DBLE bit selects or deselects double-trigger mode. Double-trigger mode can only be operated by the synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits.

Double-trigger operation is as follows:

1. The ADC120_ADI interrupt is not output on completion of the first conversion but on completion of the second conversion.
2. The A/D conversion results from the duplication channel (selected in DBLANS[4:0]) started by the first trigger are stored in A/D Data Register y and those started by the second trigger are stored in the A/D Data Duplexing Register.

When the DBLE bit is set (double-trigger mode is selected), the channels specified in the ADANSA0 and ADANSA1 registers are invalid. Double-trigger mode is deselected by setting DBLE to 0. Setting DBLE to 1 again enables the same double-trigger operation described in 1. and 2. for first time scanning with the first trigger.

Do not select double-trigger mode in continuous scan mode. Software triggering cannot be used in double-trigger mode. Always set the ADST bit to 0 before setting the DBLE bit. Do not set the DBLE bit at that same time as writing 1 to the ADST bit.

EXTRG bit (Trigger Select)

The EXTRG bit selects the synchronous or asynchronous trigger as the trigger for starting A/D conversion.

In group scan mode, the setting of this bit takes effect on the trigger selected for group A. For group B, A/D conversion is started by the selected synchronous trigger regardless of this bit setting.

TRGE bit (Trigger Start Enable)

The TRGE bit enables or disables A/D conversion by the synchronous and asynchronous triggers. In group scan mode, set this bit to 1.

ADCS[1:0] bits (Scan Mode Select)

The ADCS[1:0] bits select the scan mode.

In single scan mode, A/D conversion is performed for the analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, the scan conversion stops.

In continuous scan mode, when the ADCSR.ADST bit is 1, A/D conversion is performed for the analog inputs of the channels selected with the ADANSA0 and ADANSA1 registers , in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion repeats from the first channel. If the ADCSR.ADST bit is set to 0 during continuous scan, A/D conversion stops even if scanning is in progress.

In group scan mode:

- Group A scanning is started by the synchronous trigger (ELC) selected in the TRSA[5:0] bits in the ADSTRGR register. A/D conversion is performed on group A analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.
- Group B scanning is started by the synchronous trigger (ELC) selected in the ADSTRGR.TRSB[5:0] bits. A/D conversion is performed on group B analog inputs of the channels selected in the ADANSB0 and ADANSB1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.

If the conversion processes in group A and group B occur at the same time, those conversions cannot be controlled separately. In this case, set group A Priority Control Setting bit (ADGSPCR.PGS) in the A/D Group Scan Priority Control Register (ADGSPCR) to 1 to assign a priority to group A conversion.

In group scan mode, select different channels and triggers for group A and group B.

Only set the ADCS[1:0] bits when the ADST bit is 0. Do not set the ADCS[1:0] bits at the same time that you write 1 to the ADST bit.

DBLE位（双触发模式选择）

DBLE位选择或取消选择双触发模式。双触发模式只能由在ADSTRGR.TRSA[5:0]位中选择的同步触发(ELC)操作。

双触发操作如下：

1.ADC120_ADI中断不是在第一次转换完成时输出，而是在第二次转换完成时输出。

2.由第一次触发启动的复制通道（在DBLANS[4:0]中选择）的AD转换结果存储在AD数据寄存器y中，由第二次触发启动的数据存储在AD数据双工寄存器中。

当DBLE位置位（选择双触发模式）时，在ADANSA0和ADANSA1寄存器中指定的通道无效。通过将DBLE设置为0可以取消选择双触发模式。再次将DBLE设置为1可以启用与第一次触发第一次扫描时在1.和2.中描述的相同的双触发操作。

不要在连续扫描模式下选择双触发模式。软件触发不能用于双触发模式。在设置DBLE位之前，始终将ADST位设置为0。不要在将DBLE位设置为1的同时
ADST bit.

EXTRG bit (Trigger Select)

EXTRG位选择同步或异步触发作为启动AD转换的触发。

在组扫描模式下，该位的设置对A组选择的触发生效。对于B组，无论该位设置如何，都由选择的同步触发启动AD转换。

TRGE位（触发启动使能）

TRGE位通过同步和异步触发启用或禁用AD转换。在组扫描模式下，将此位设置为1。

ADCS[1:0]位（扫描模式选择）

ADCS[1:0]位选择扫描模式。

在单次扫描模式下，对ADANSA0中选择的通道的模拟输入执行AD转换，并且
ADANSA1寄存器，按通道号升序排列。当所有选定通道的1个AD转换周期完成时，扫描转换停止。

在连续扫描模式下，当ADCSR.ADST位为1时，ADANSA0和ADANSA1寄存器选择的通道的模拟输入按通道编号的升序执行AD转换。当所有选定通道的1个AD转换周期完成时，AD转换从第一个通道开始重复。如果

ADCSR.ADST位在连续扫描期间设置为0，即使在扫描过程中AD转换也会停止。

在组扫描模式下：

●A组扫描由在ADSTRGR寄存器的TRSA[5:0]位中选择的同步触发(ELC)启动。AD转换在ADANSA0和ADANSA1寄存器中选择的通道的A组模拟输入上执行，按通道编号的升序排列。当所有选定通道完成1个AD转换周期时，AD转换停止。

●B组扫描由在ADSTRGR.TRSB[5:0]位中选择的同步触发(ELC)启动。广告
转换是在ADANSB0和ADANSB1寄存器中选择的通道的B组模拟输入上执行的，按通道编号的升序排列。当所有选定通道完成1个AD转换周期时，AD转换停止。

如果A组和B组中的转换过程同时发生，则不能单独控制这些转换。在这种情况下，将AD组扫描优先级控制寄存器(ADGSPCR)中的A组优先级控制设置位(ADGSPCR.PGS)设置为1，以将优先级分配给A组转换。

在组扫描模式下，为A组和B组选择不同的通道和触发。

仅当ADST位为0时才设置ADCS[1:0]位。不要在向寄存器写入1的同时设置ADCS[1:0]位
ADST bit.

ADSn bits (A/D-Converted Value Addition/Average Channel Select n) (n = 0 to 4, 11 to 13)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA0 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB0 register

For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS0 register bits when the ADCSR.ADST bit is 0.

Figure 35.2 shows a scanning operation sequence in which the ADADS0 register bits (channel c and g) are set to 1. In this figure:

- Addition mode is selected (ADADC.AVEE = 0)
- The number of conversions is set to 4 (ADADC.ADC[1:0] = 11b)
- The analog input channels (a to h) are selected by ADANSA0 register in continuous scan mode (ADCSR.ADCS[1:0] = 10b).

The conversion process begins with analog input A (channel a). The analog input C (channel c) conversion is performed successively 4 times and the added value is returned to A/D Data Register c (ADDRc). Next, the analog input D (channel d) conversion process is started. The analog input G (channel g) is performed successively 4 times and the added value is returned to A/D Data Register g (ADDRg). After conversion of analog input H (channel h), the conversion operation repeats in the same sequence starting with analog input A (channel a).

不要选择在ADANSA0和ADANSA1寄存器中选择的A组中指定的通道，或者双触发模式下的ADCSR.DBLANS[4:0]位。

ADSn位（AD转换值加法平均通道选择n）（n=0到4、11到13）

ADSn位确定哪些AD转换通道要进行AD转换值加法平均。当一个与选择用于AD转换的通道相关的ADSn位设置为1，相应通道的模拟输入的AD转换按ADC[2:0]中的规定连续执行1、2、3、4或16次ADADC寄存器中的位。

当ADADC.AVEE位为0时，相加得到的值存储在AD数据寄存器中。当ADADC.AVEE位为1时，加法所得结果的平均值存储在AD数据寄存器中。

ADSn位仅适用于为AD转换选择的通道：

●ADANSA0寄存器中的ANSan位或ADCSR寄存器中的DBLANS[4:0]位

●ADANSB0寄存器中的ANSBn位

对于进行了AD转换且未选择加法平均模式的通道，将执行正常的1次转换，并将转换结果存储在AD数据寄存器中。

仅当ADCSR.ADST位为0时设置ADADS0寄存器位。

图35.2显示了扫描操作序列，其中ADADS0寄存器位（通道c和g）设置为1。在该图中：

●选择加法模式（ADADC.AVEE=0）

●转换次数设置为4(ADADC.ADC[1:0]=11b)

●模拟输入通道（a到h）在连续扫描模式下由ADANSA0寄存器选择（ADCSR.ADCS[1:0]=10b）。

转换过程从模拟输入A（通道a）开始。模拟输入C（通道c）转换连续执行4次，相加后的值返回到AD数据寄存器c（ADDRc）。接下来，开始模拟输入D（通道d）转换过程。模拟输入G（通道g）连续执行4次，相加后的值返回到AD数据寄存器g（ADDRg）。模拟输入H（通道h）转换后，转换操作从模拟输入A（通道a）开始以相同的顺序重复。

ADPRC[1:0] bit (A/D Conversion Accuracy Specify)

The ADPRC[1:0] bits set the A/D conversion accuracy. Changing the A/D conversion accuracy also changes the bit width of valid data stored in the result register and the A/D conversion time. For details, see section 35.3.6. Analog Input Sampling and Scan Conversion Timesection 45.3.6, Analog Input Sampling and Scan Conversion Time. Only set the ADPRC[1:0] bits while the ADCSR.ADST bit is 0.

ACE bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0) of the ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, or ADOCDR register after any of these registers is read by the CPU or DTC. Automatic clearing of the A/D data registers enables detection of failures that are not updated in the A/D data registers. For details, see section 35.3.7. Usage Example of A/D Data Register Automatic Clearing Function.

DIAGVAL[1:0] bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis fixed voltage mode. For details, see the DIAGLD bit description.

Do not execute self-diagnosis by setting the DIAGLD bit to 1 when the DIAGVAL[1:0] bits are set to 00b.

DIAGLD bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated, or the fixed voltage is used in self-diagnosis.

Setting the DIAGLD bit to 0 selects conversion of the voltages in rotation mode, where 0 V, the reference voltage × 1/2, and the reference voltage are converted, in that order. After reset and when self-diagnosis voltage rotation mode is selected, self-diagnosis is executed from 0 V. The self-diagnosis voltage value does not return to 0 V when scan conversion completes. When scan conversion is restarted, rotation starts at the voltage value following the previous value.

Setting the DIAGLD bit to 1 selects fixed voltage, in which the fixed voltage specified in the ADCER.DIAGVAL[1:0] bits is converted. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

ADPRC[1:0]位（AD转换精度指定）

ADPRC[1:0]位设置AD转换精度。更改AD转换精度也会更改存储在结果寄存器中的有效数据的位宽和AD转换时间。有关详细信息，请参阅第35.3.6节。模拟输入采样和扫描转换时间第45.3.6节，模拟输入采样和扫描转换时间。只设置

ADPRC[1:0]位，而ADCSR.ADST位为0。

ACE位启用或禁用ADDRy、ADRD、ADDBLDR、ADDBLDRA、
CPU或DTC读取这些寄存器中的任何一个之后的ADDBLDRB或ADOCDR寄存器。自动清除AD数据寄存器可以检测未在AD数据寄存器中更新的故障。有关详细信息，请参阅第35.3.7节。AD数据寄存器自动清除功能的使用示例。

DIAGVAL[1:0]位（自诊断转换电压选择）

DIAGVAL[1:0]位选择用于自诊断固定电压模式的电压值。有关详细信息，请参见DIAGLD位说明。

当DIAGVAL[1:0]位设置为00b时，不要通过将DIAGLD位设置为1来执行自诊断。

DIAGLD位（自诊断模式选择）

DIAGLD位选择是轮换三个电压值，还是使用固定电压进行自诊断。

将DIAGLD位设置为0选择在旋转模式下转换电压，其中0V、参考电压×12和参考电压按此顺序转换。复位后，选择自诊断电压旋转模式时，从0V开始执行自诊断。扫描转换完成时，自诊断电压值不会返回到0V。重新开始扫描转换时，从前一个值之后的电压值开始旋转。

将DIAGLD位设置为1选择固定电压，其中转换ADCER.DIAGVAL[1:0]位中指定的固定电压。如果将固定模式切换到旋转模式，则从固定电压值开始旋转。

Only set the DIAGLD bit when the ADCSR.ADST bit is 0.

DIAGM bit (Self-Diagnosis Enable)

The DIAGM bit enables or disables self-diagnosis.

Self-diagnosis is used to detect a failure of the ADC12. In self-diagnosis mode, one of the three voltage values (0 V, the reference voltage × 1/2, or the reference voltage) is converted. When conversion completes, information on the converted voltage and the conversion result is stored into the A/D Self-Diagnosis Data Register (ADRD). The ADRD register can be read to determine whether the conversion result falls within the normal or abnormal range.

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. In double trigger mode (ADCSR.DBLE = 1), self-diagnosis (DIAGM = 0) is deselected. When self-diagnosis is selected in group scan mode, self-diagnosis is executed separately for group A and group B.

Only set the DIAGM bit when the ADCSR.ADST bit is 0.

ADRFMT bit (A/D Data Register Format Select)

The ADRFMT bit specifies flush-right or flush-left for data to be stored in the ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADOCDR, ADCMPDR0/1, ADWINLLB, ADWINULB, or ADRD register.

Only set the ADRFMT bit when the ADCSR.ADST bit is 0.

15:14	—	These bits are read as 0. The write value should be 0.	R/W

TRSB[5:0] bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits must only be set in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. In group scan mode, set the TRSB[5:0] bits to a value other than 0x00 and set the ADCSR.TRGE bit to 1.

When group A is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 0x3F. The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than t_{SCAN}, A/D conversion by the trigger might have no effect.

仅当ADCSR.ADST位为0时设置DIAGLD位。

DIAGM bit (Self-Diagnosis Enable)

DIAGM位启用或禁用自诊断。

自诊断用于检测ADC12的故障。在自诊断模式下，转换三个电压值（0V、参考电压×12或参考电压）之一。转换完成后，转换电压和转换结果的信息将存储到AD自诊断数据寄存器(ADRD)中。可以读取ADRD寄存器来确定转换结果是否在正常或异常范围内。

自诊断在每次扫描开始时执行一次，并转换三个电压之一。在双触发模式(ADCSR.DBLE=1)中，自诊断(DIAGM=0)被取消选择。在组扫描模式下选择自诊断时，对A组和B组分别执行自诊断。

仅当ADCSR.ADST位为0时设置DIAGM位。

ADRFMT位（AD数据寄存器格式选择）

ADRFMT位指定要存储在ADDRy、ADDBLDR、ADDBLDRA、ADDBLDRB、ADOCDR、ADCMPDR01、ADWINLLB、ADWINULB或ADRD寄存器。

仅当ADCSR.ADST位为0时才设置ADRFMT位。

15:14	—	这些位被读取为0。写入值应为0。	R/W

TRSB[5:0]位（B组的AD转换开始触发选择）

TRSB[5:0]位选择触发以开始扫描组B中选择的模拟输入。TRSB[5:0]位只能在组扫描模式下设置，不得用于任何其他扫描模式。对于B组的扫描转换开始触发，禁止设置软件触发或异步触发。在组扫描模式下，将TRSB[5:0]位设置为0x00以外的值，并将ADCSR.TRGE位设置为1。

当A组在组扫描模式下具有优先权时，将ADGSPCR.GBRP位设置为1允许B组在单次扫描模式下连续工作。将ADGSPCR.GBRP位设置为1时，将TRSB[5:0]位设置为0x3F。转换触发的发布周期必须大于或等于实际扫描转换时间(tSCAN)。如果发行周期小于tSCAN，触发器的AD转换可能无效。

TRSA[5:0] bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode, or the trigger to start scanning of group A analog inputs in group scan mode. When scanning is executed in group scan mode or double trigger mode, software trigger or asynchronous trigger is prohibited.

- When using a synchronous trigger (ELC), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 0.
- When using the asynchronous trigger (ADTRG0), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, or the TRSA[5:0] bits.

The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by a trigger might have no effect.

●使用同步触发(ELC)时，将ADCSR寄存器中的TRGE位设置为1，并将ADCSR寄存器中的EXTRG位设置为0。

●使用异步触发（ADTRG0）时，将ADCSR寄存器的TRGE位设置为1，并将ADCSR寄存器的EXTRG位设置为1。

OCSAD bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Internal Reference Voltage Data Register (ADOCDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADOCDR.

Only set the OCSAD bit while the ADCSR.ADST bit is 0.

OCSA bit (Internal Reference Voltage A/D Conversion Select)

The OCSA bit selects A/D conversion of the internal reference voltage for group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the internal reference voltage is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the OCSA bit while the ADCSR.ADST bit is 0. In addition, wait for 400 ns or more after the OCSA bit is set to 1 before starting A/D conversion.

OCSB bit (Internal Reference Voltage A/D Conversion Select for Group B)

The OCSB bit selects A/D conversion of the internal reference voltage for group B in group scan mode. Only set the OCSB bit while the ADCSR.ADST bit is 0. Do not set the OCSB bit to 1 while the OCSA bit is 1. Moreover, start the A/D conversion after waiting for 400 ns or more after the OCSB bit is set to 1.

35.2.17 ADSSTRn/ADSSTRL/ADSSTRO : A/D Sampling State Register (n = 0 to 4, 11 to 13)

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SST[7:0]

Bit	Symbol	Function	R/W
7:0	SST[7:0]	Sampling Time Setting These bits set the sampling time in the range from 5 to 255 states.	R/W

The ADSSTRn register sets the sampling time for analog input.

The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow. The set value indicates the time for one ADCLK cycle, and the required sampling time is specified by the voltage conditions. For details, see section 43.5. ADC12 Characteristics.

The lower limit of the sampling time setting depends on the frequency ratio:

- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:1, 2:1, 4:1, or 8:1 the sampling time must be set to a value of more than 5 states

OCSAD位（内部参考电压AD转换值加法平均模式选择）

当OCSAD位设置为1时，选择内部参考电压的AD转换，并按ADADC的ADC[2:0]位指定的次数连续执行。当ADADC.AVEE位为0时，通过加法（积分）获得的值返回到AD内部参考电压数据寄存器（ADocDR）。当ADADC.AVEE位为1时，平均值返回给ADOCDR。

仅在ADCSR.ADST位为0时设置OCSAD位。

OCSA位（内部参考电压AD转换选择）

OCSA位在单次扫描模式、连续扫描模式或组扫描模式下选择A组内部参考电压的AD转换。WhenADconversion oftheinternalreferencevoltageisselectedandperformed settheADCSR.DBLEbitto0.

仅在ADCSR.ADST位为0时设置OCSA位。此外，在OCSA位设置为1后等待400ns或更长时间，然后再开始AD转换。

OCSB位（B组的内部参考电压AD转换选择）

OCSB位选择组扫描模式下B组内部参考电压的AD转换。仅在ADCSR.ADST位为0时设置OCSB位。不要在OCSA位为1时将OCSB位设置为1。此外，在OCSB位设置为1后等待400ns或更长时间后开始AD转换.

Bit	Symbol	Function	R/W
7:0	SST[7:0]	采样时间设置 这些位在5到255个状态范围内设置采样时间。	R/W

ADSSTRn寄存器设置模拟输入的采样时间。

如果模拟输入信号源的阻抗太高而无法保证足够的采样时间，或者如果ADCLK时钟很慢，则可以调整采样时间。设定值表示一个ADCLK周期的时间，所需的采样时间由电压条件指定。有关详细信息，请参阅第43.5节。ADC12特性。

采样时间设置的下限取决于频率比：

●如果PCLKA与PCLKC(ADCLK)的频率比=1:1、2:1、4:1或8:1，则必须将采样时间设置为超过5个状态的值

- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:2 or 1:4, the sampling time must be set to a value of more than 6 states.

Table 35.18 shows the relationship between the A/D Sampling State Register and the associated channels. For details, see section 35.3.6. Analog Input Sampling and Scan Conversion Time.

Only set the SST[7:0] bits when the ADCSR.ADST bit is 0.

4	PCHG	Precharge/discharge select 0: Discharge 1: Precharge	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

The ADDISCR register selects either precharge or discharge, and the period of precharge or discharge for the A/D disconnection detection assist function. Only set the ADDISCR register when the ADCSR.ADST bit is 0. When the internal reference voltage is converted, the A/D converter executes discharge automatically.

Disable the disconnection detection assist function if any of the following functions are used:

- The internal reference voltage
- A/D self-diagnosis

ADNDIS[3:0] bits (Disconnection Detection Assist Setting)

The ADNDIS[3:0] bits specify the period of precharge or discharge. When ADNDIS[3:0] = 0000b, the disconnection detection assist function is disabled. Setting the ADNDIS[3:0] bits to 0001b is prohibited. Except when ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge or discharge. When the ADNDIS[3:0] bits are set to any values other than 0000b or 0001b, the disconnection detection assistance function is enabled.

PCHG bit (Precharge/discharge select)

The PCHG bit selects either precharge or discharge.

●如果PCLKA与PCLKC(ADCLK)的频率比=1:2或1:4，则必须将采样时间设置为6个以上状态的值。

表35.18显示了AD采样状态寄存器和相关通道之间的关系。有关详细信息，请参阅第35.3.6节。模拟输入采样和扫描转换时间。

如果使用以下任何功能，请禁用断线检测辅助功能：

●内部参考电压

- A/D self-diagnosis

ADNDIS[3:0]位（断线检测辅助设置）

ADNDIS[3:0]位指定预充电或放电周期。当ADNDIS[3:0]=0000b时，断线检测辅助功能被禁用。禁止将ADNDIS[3:0]位设置为0001b。除了ADNDIS[3:0]=0000b或0001b时，指定值表示预充电或放电期间的状态数。当ADNDIS[3:0]位设置为0000b或0001b以外的任何值时，将启用断线检测辅助功能。

1	GBRSCN	Lower-Priority Group Restart Setting (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Disable rescanning of the group that was stopped in group priority operation 1: Enable rescanning of the group that was stopped in group priority operation.	R/W
13:2	—	These bits are read as 0. The write value should be 0.	R/W
14	LGRRS	Restart Channel Select Enabled only when PGS = 1 and GBRSCN = 1. 0: Start rescanning from the first channel for scanning 1: Start rescanning from the channel for which A/D conversion is not completed.	R/W
15	GBRP	Single Scan Continuous Start*2 (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Single scan is not continuously activated. 1: Single scan for the group with the lower-priority is continuously activated.	R/W

Note 1. The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting PGS to 1. Operation is not guaranteed if these bits are set to any other value.

Note 2. When the GBRP bit is set to 1, single scan is performed continuously for the group with the lower-priority regardless of the setting in the GBRSCN bit.

PGS bit (Group Priority Operation Setting)

The PGS bit controls group priority operation in group scan mode. Set the PGS bit to 1 to enable group priority operation.

The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting the PGS bit to 1. Operation is not guaranteed if the bits are set to any other value.

When the PGS bit is set to 0, a clear operation must be performed by software as described in section 35.6.3. Constraints on Stopping A/D Conversion. When the PGS bit is set to 1, use the settings described in section 35.3.4.3. Group Priority Operation.

GBRSCN bit (Lower-Priority Group Restart Setting)

The GBRSCN bit controls the restarting of scan operation in group priority operation.

When the GBRSCN bit is set to 1, if the scan operation of a lower-priority group is stopped by a trigger input of a priority group, the lower-priority group scanning is restarted on completion of the priority group scanning. If a trigger of a lower-priority group is input during scanning of the priority group, the lower-priority group scanning is started on completion of the priority group scanning.

When the GBRSCN bit is set to 0, triggers input during scanning are ignored. Set the GBRSCN bit while the ADCSR.ADST bit is 0.

LGRRS bit (Restart Channel Select)

This bit sets the channel from which rescanning is to be started in group priority operation. The setting of the LGRRS bit is valid when the PGS and GBRSCN bits are 1.

If the LGRRS bit is 0, scanning of a lower-priority group that was stopped in group priority operation is restarted from the first channel after scanning of the priority group completes.

注1.ADCSR.ADCS[1:0]位必须在PGS设置为1之前设置为01b（组扫描模式）。如果这些位设置为任何其他值，则无法保证操作。

注2.当GBRP位设置为1时，无论GBRSCN位的设置如何，都会对优先级较低的组连续执行单次扫描。

PGS位（组优先操作设置）

PGS位控制组扫描模式下的组优先级操作。将PGS位设置为1以启用组优先操作。

在将PGS位设置为1之前，必须将ADCSR.ADCS[1:0]位设置为01b（组扫描模式）。如果这些位设置为任何其他值，则无法保证操作。

当PGS位设置为0时，必须通过软件执行清除操作，如第35.6.3节所述。约束停止AD转换。当PGS位设置为1时，使用第35.3.4.3节中描述的设置。团体优先Operation.

GBRSCN位（低优先级组重启设置）

GBRSCN位控制组优先操作中扫描操作的重新启动。

当GBRSCN位被设置为1时，如果低优先级组的扫描操作被优先级组的触发输入停止，则低优先级组扫描在优先级组扫描完成时重新开始。如果在优先级组扫描期间输入了较低优先级组的触发，则在完成优先级组扫描时开始较低优先级组扫描。

当GBRSCN位设置为0时，扫描期间的触发输入将被忽略。设置GBRSCN位，而ADCSR.ADST位为0。

LGRRS位（重启通道选择）

该位设置在组优先操作中要从哪个通道开始重新扫描。当PGS和GBRSCN位为1时，LGRRS位的设置有效。

如果LGRRS位为0，则在优先级组扫描完成后，从第一个通道开始重新开始对在组优先级操作中停止的低优先级组的扫描。

If the LGRRS bit is 1, scanning of a lower-priority group that was stopped in group priority operation is restarted (upon completion of scanning of the priority group) from the channel for which A/D conversion is not complete. If A/D conversion of the addition setting channel was not completed the specified number of times when scanning stopped, A/D conversion of the addition setting channel is performed again the specified number of times when scanning restarts.

Set the LGRRS bit while the ADCSR.ADST bit is 0.

GBRP bit (Single Scan Continuous Start)

The GBRP bit is set when a single scan operation is to be performed continuously on the group with the lower-priority.

Setting the GBRP bit to 1 starts a single scan of the group with the lower-priority. On completion of the scan, another single scan of the group with the lower-priority is started automatically. If scanning has been stopped during group priority operation, single scan of the group with the lower-priority is automatically restarted on completion of the A/D conversion of the priority group.

Before setting the GBRP bit to 1, disable input of a trigger for the lower-priority group. If the GBRP bit is set to 1, rescanning is performed only on the group with the lower-priority even if the GBRSCN bit is set to 0.

如果LGRRS位为1，则从未完成AD转换的通道重新开始（在完成优先级组的扫描时）组优先操作中停止的低优先级组的扫描。如果在扫描停止时加法设置通道的AD转换未完成指定次数，则在扫描重新开始时再次执行加法设置通道的AD转换指定次数。

当ADCSR.ADST位为0时设置LGRRS位。

GBRP位（单次扫描连续启动）

当要对优先级较低的组连续执行单次扫描操作时，设置GBRP位。

将GBRP位设置为1开始对具有较低优先级的组进行单次扫描。扫描完成后，将自动开始对具有较低优先级的组进行另一次单次扫描。如果在组优先操作期间扫描已停止，则在优先组的AD转换完成后，将自动重新开始优先级较低的组的单次扫描。

在将GBRP位设置为1之前，禁用低优先级组的触发器输入。如果GBRP位设置为1，即使GBRSCN位设置为0，也仅对具有较低优先级的组执行重新扫描。

CMPLCHAn bits (Compare Window A Comparison Condition Select n)

The CMPLCHAn bits specify the comparison conditions for channels to which Window A comparison conditions are applied. These bits can be set for each analog input to be compared. When the comparison result of each analog input meets the set condition, the ADCMPSR0.CMPSTCHAn flag sets to 1 and a compare interrupt (ADC120_CMPAI) is generated.

35.2.27 ADCMPDRn : A/D Compare Function Window A Lower-Side/Upper-Side Level Setting Register (n = 0, 1)

The ADCMPDRy (y = 0, 1) register specifies the reference data when the compare window A function is used. ADCMPDR0 sets the lower reference for window A, and ADCMPDR1 sets the upper reference for window A.

ADCMPDRy are read/write registers.

ADCMPDRy are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

Set these registers so that the upper reference is not less than the lower reference (ADCMPDR1 ≥ ADCMPDR0). ADCMPDR1 are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See Figure 35.4. If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

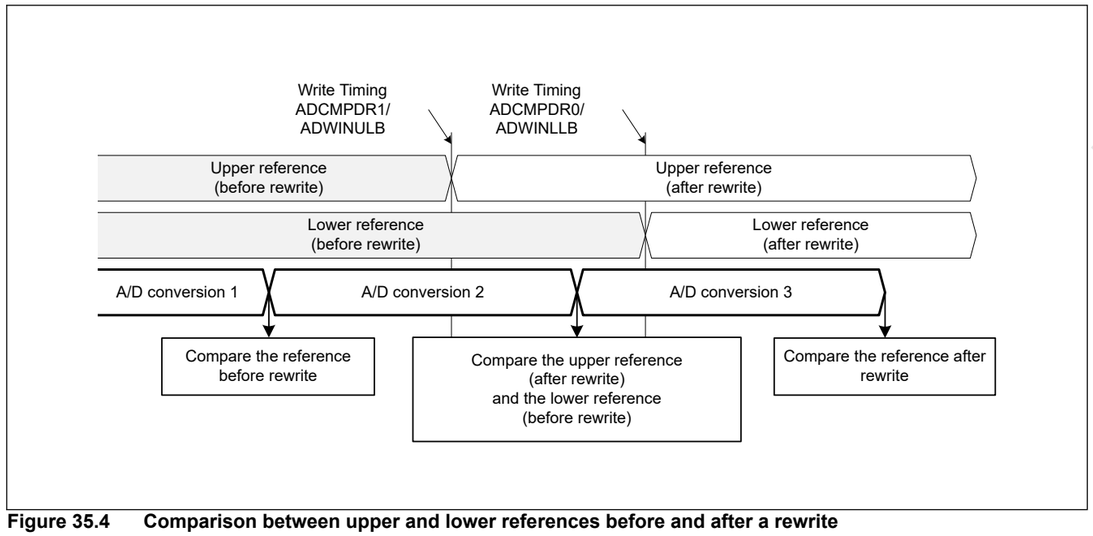

Figure 35.4 Comparison between upper and lower references before and after a rewrite

The ADCMPDRy registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
   - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid

ADCMPDRy(y=0 1)寄存器指定使用比较窗口A功能时的参考数据。ADCMPDDR0设置窗口A的下参考值，而ADCMPDR1设置窗口A的上参考值。

ADCMPDRy是读写寄存器。

ADCMPDRy即使在AD转换期间也是可写的。在AD转换*1期间，可以通过重写寄存器值来动态更改参考数据。

设置这些寄存器，使参考上限不小于参考下限(ADCMPDR1≥ADCMPDR0)。
禁用窗口功能时不使用ACMPDDR1。

注1.写入每个寄存器时，低位和高位参考值会发生变化。例如，当上参考值改变和下参考值改变时，MCU将上参考（重写后）和下参考（重写前）与AD转换结果进行比较。请参见图35.4。如果在重写这两个参考时比较错误，则在ADCSR.ADST和目标比较窗口操作使能位（ADCMPCR.CMPAE或ADCMPCR.CMPBE）都为0时重写这些参考值。

- AD数据寄存器格式选择位的值（flush-rightorflush-left）
- AD转换精度选择位（12位、10位、8位）的值
- AD-ConvertedValueAdditionAverageChannelSelect位的值（选择或不选择AD-convertedvalue添加模式）。

每个条件的数据格式如下所示：

1.未选择AD转换值加法模式时

- 12位精度的右冲洗数据—低12位([11:0])有效

- Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid

- Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid

The ADWINULB and ADWINLLB registers specify the reference data when the compare window B function is used. ADWINLLB sets the lower reference for window B, and ADWINULB sets the upper reference for window B.

ADWINnLB are read/write registers.

ADWINnLB are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

7:2	—	These bits are read as 0. The write value should be 0.	R/W

The ADCMPSER register stores compare results of compare function window A.

CMPSTOCA flag (Compare Window A Internal Reference Voltage Compare Flag)

The CMPSTOCA flag indicates the internal reference voltage comparison result. When the comparison condition set in ADCMPLER.CMPLOCA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC120_CMPAI) is generated when this flag sets to 1.

Writing 1 to the CMPSTOCA flag is invalid.

[Setting condition]

CMPCHB[5:0] bits (Compare Window B Channel Select)

The CMPCHB[5:0] bits specify the channels to be compared with the compare Window B conditions from AN000 to AN004, AN011 to AN013, AN016, the internal reference voltage. The compare Window B function is enabled by specifying the hexadecimal number of the A/D conversion channel selected in the ADANSA0, ADANSA1, ADANSB0, ADANSB1 registers.

Set the CMPCHB[5:0] bits while the ADCSR.ADST bit is 0.

CMPLB bit (Compare Window B Comparison Condition Setting)

The CMPLB bit specifies the comparison conditions for channels for Window B. When the comparison result of an analog input meets the set condition, the associated ADCMPBSR.CMPSTB flag sets to 1 and a compare interrupt request (ADC120_CMPBI) is generated.

7:5	—	These bits are read as 0. The write value should be 0.	R/W

ADBUFPTR is a register that indicates the data buffer pointer and overflow status.

BUFPTR[3:0] bit (Data Buffer Pointer)

These bits indicate the number of data buffer to which the next A/D converted data is transferred.

When data has been transferred to data buffer 15, the pointer value becomes 0000b and the PTROVF bit is set to 1.

When the next data has been transferred, the data in data buffer 0 is overwritten.

Writing 00h to this register clears the value of these bits. Writing a value other than 00h is disabled.

PTROVF bit (Pointer Overflow Flag)

This bit indicates whether the data buffer pointer has overflowed. This bit is set to 1 when the pointer value becomes 0000b (overflow).

Writing 00h to this register clears this bit value. Writing a value other than 00h is disabled.

35.2.37 ADBUFn : A/D Data Buffer Registers n (n = 0 to 15)

Bit	Symbol	Function	R/W
15:0	n/a	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 35.19 and Table 35.20.	R

ADBUFn registers are 16-bit read-only registers that sequentially store all A/D conversion results. The automatic clear function is not applied to these registers.

ADBUFn settings are the same as the A/D data register format settings. about details see section 1.2.1 ADDRn : A/D Data Registers n.

The following conditions determine the formats for data in the ADBUFn registers:

- Setting of the Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

ADBUFPTR是指示数据缓冲区指针和溢出状态的寄存器。

BUFPTR[3:0]位（数据缓冲区指针）

这些位指示下一个AD转换数据传输到的数据缓冲区的编号。

当数据已传输到数据缓冲区15时，指针值变为0000b并且PTROVF位设置为1。

当下一个数据传输完毕后，数据缓冲区0中的数据将被覆盖。

向该寄存器写入00h会清除这些位的值。禁止写入00h以外的值。

PTROVF位（指针溢出标志）

该位指示数据缓冲区指针是否溢出。当指针值变为0000b（溢出）时，该位设置为1。

向该寄存器写入00h会清除该位值。禁止写入00h以外的值。

ADBUFn设置与AD数据寄存器格式设置相同。有关详细信息，请参阅第1.2.1节ADDRn:ADData Registers n.

以下条件决定了ADBUFn寄存器中数据的格式：

●寄存器格式选择位(ADCER.ADRFMT)的设置（左对齐或右对齐）

●加法平均计数选择位(ADADC.ADC[2:0])的设置（1、2、3、4或16次）

●设置平均模式启用位(ADADC.AVEE)（加法或平均）。

本节介绍不同模式下这些条件的数据格式。

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicatesthese registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

35.3 Operation

35.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

Scan conversion is performed in any of the three operating modes:

- Single scan mode
- Continuous scan mode
- Group scan mode

In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until software sets the ADCSR.ADST bit to 0. In group scan mode, the selected channels in group A, B are scanned once after scan starts in response to the respective synchronous trigger.

In single scan mode and continuous scan mode, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n. In group scan mode, A/D conversion is performed for the ANn channels in group A selected in the ADANSA0 and ADANSA1 registers, and for the

35.3 Operation

35.3.1 扫描操作

扫描时，对指定通道的模拟输入依次进行AD转换。

扫描转换在以下三种操作模式中的任何一种中执行：

- ●单次扫描模式
- ●连续扫描模式
- ●组扫描模式

在单次扫描模式下，一个或多个指定通道被扫描一次。在连续扫描模式下，重复扫描一个或多个指定通道，直到软件将ADCSR.ADST位设置为0。在组扫描模式下，在扫描开始后对A、B组中选定的通道进行一次扫描，以响应相应的同步触发.

在单次扫描模式和连续扫描模式下，对选择的ANn通道进行AD转换
ADANSA0和ADANSA1寄存器，从编号n最小的通道开始。在组扫描模式下，对在ADANSA0和ADANSA1寄存器中选择的A组中的ANn通道执行AD转换，并为

ANn channels in group B selected in the ADANSB0 and ADANSB1 registers, starting from the channel with the smallest number n.

When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three reference voltages is converted.

The internal reference voltage can be selected at the same time as the analog input of the channels, and A/D conversion is performed on the analog input of channels, and internal reference voltage, in that order.

Double trigger mode can be used with single scan mode or group scan mode. With double trigger mode enabled (ADCSR.DBLE = 1), A/D conversion data of a channel selected in the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits. In group scan mode, only group A can use double trigger mode.

In the extended operation of double trigger mode, the A/D conversion operation is generated from the synchronous trigger combination selected in the ADSTRGR.TRSA[5:0] bits. In addition to normal double trigger mode operation, A/ D conversion data with odd number trigger (ELC_AD00) is stored in A/D Data Duplexing Register A (ADDBLDRA), and A/D conversion data with even number trigger (ELC_AD01) is stored in A/D Data Duplexing Register B (ADDBLDRB). In the extended operation of double trigger mode, when one of the trigger combinations occurs at the same time, the data duplexing register settings for the specified triggers do not work, and A/D conversion data is stored in A/D Data Duplexing Register B (ADDBLDRB).

The ADC12 ignores a synchronous trigger that occurs during the A/D conversion started by another synchronous trigger.

35.3.2 Single Scan Mode

35.3.2.1 Basic Operation

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (ELC), or an asynchronous trigger input, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC120_ADI interrupt request is generated .
4. The ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.

在ADANSB0和ADANSB1寄存器中选择的B组中的ANn通道，从具有最小编号n的通道开始。

选择自诊断时，在每次扫描开始时执行一次，并转换三个参考电压之一。

内部参考电压可以与通道的模拟输入同时选择，通道的模拟输入和内部参考电压依次进行AD转换。

双触发模式可与单扫描模式或组扫描模式一起使用。启用双触发模式(ADCSR.DBLE=1)时，仅当转换由ADSTRGR中选择的同步触发(ELC)启动时，ADCSR.DBLANS[4:0]位中选择的通道的AD转换数据才会被复制.TRSA[5:0]位。在组扫描模式下，只有A组可以使用双触发模式。

在双触发模式的扩展操作中，ADSTRGR.TRSA[5:0]位中选择的同步触发组合产生AD转换操作。除了正常的双触发模式操作外，奇数触发的AD转换数据(ELC_AD00)存储在AD数据双工寄存器A(ADDBLDRA)中，偶数触发的AD转换数据(ELC_AD01)存储在AD数据双工寄存器B(ADDBLDRB)。在双触发模式的扩展操作中，当其中一种触发组合同时发生时，指定触发的数据双工寄存器设置不起作用，AD转换数据存储在AD数据双工寄存器B（ADDBLDRB）中。

ADC12忽略由另一个同步触发启动的AD转换期间发生的同步触发。

35.3.2 单次扫描模式

35.3.2.1 基本操作

在单扫描模式的基本操作中，对指定通道的模拟输入进行一次AD转换，如下所示：

1.当通过软件触发、同步触发输入(ELC)或异步触发输入将ADCSR.ADST位设置为1（AD转换开始）时，对在ADANSA0和ADANSA1中选择的ANn通道执行AD转换寄存器，从具有最小编号n的通道开始。

2.每次完成单通道的AD转换，AD转换结果存入相关的AD数据寄存器（ADDRy）。

3.当所有选定通道的AD转换完成时，会产生ADC120_ADI中断请求。

4.ADST位在AD转换期间保持1（AD转换开始），并在所有选定通道的AD转换完成时自动设置为0。ADC12然后进入等待状态。

35.3.2.2 Channel Selection and Self-Diagnosis

When channels and self-diagnosis are selected, A/D conversion is first performed for the reference voltage (×0, ×1/2, or ×1) , then A/D conversion is performed once on the analog input of the selected channels as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC120_ADI interrupt request is generated .
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.

35.3.2.2 频道选择和自诊断

选择通道和自诊断时，首先对参考电压（×0、×12或×1）进行AD转换，然后对所选通道的模拟输入进行一次AD转换，如下所示：

1.通过软件触发输入、同步触发输入(ELC)或异步触发输入将ADCSR.ADST位设置为1（AD转换开始）时，首先启动用于自诊断的D转换。

2.自诊断用AD转换完成后，AD转换结果存储在AD自诊断数据寄存器(ADRD)中。然后对ADANSA0中选择的ANn通道执行D转换，并

3.每次完成单通道的AD转换，AD转换结果存储在相关的AD数据寄存器（ADDRy）中。

4.当所有选定通道的AD转换完成后，会产生ADC120_ADI中断请求。

5.ADCSR.ADST位在AD转换期间保持1（AD转换开始），并在所有选定通道的AD转换完成时自动设置为0。ADC12然后进入等待状态。

35.3.2.3 A/D conversion of internal reference voltage

When the channels and internal reference voltage are selected at the same time, A/D conversion is performed first on the analog input of the selected channels, and once on the internal reference voltage. With the channels deselected, selecting only the internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of the internal reference voltage starts.
3. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC120_ADI interrupt request is generated (no register setting).
4. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 on completion of A/D conversion. Then, the ADC12 enters a wait state.

35.3.2.3 内部参考电压的AD转换

当同时选择通道和内部参考电压时，先对所选通道的模拟输入进行AD转换，再对内部参考电压进行一次AD转换。取消选择通道后，也可以只选择内部参考电压。

操作如下：

1.当软件触发、同步触发(ELC)或异步触发将ADCSR.ADST位设置为1（AD转换开始）时，对ADANSA0和ADANSA1寄存器中选择的ANn通道执行AD转换，从通道开始用最小的数n。

2.在通道上完成AD转换后，结果将存储在相关的AD数据寄存器y(ADDRy)中，然后内部参考电压的AD转换开始。

3.内部参考电压的AD转换完成后，结果存储在相关的ADInternal
参考电压数据寄存器(AOCDR)，并产生ADC120_ADI中断请求（无寄存器设置）。

4.ADCSR.ADST位在AD转换期间保持1（AD转换开始），并在AD转换完成时自动清零。然后，ADC12进入等待状态。

35.3.2.4 A/D conversion in double-trigger mode

When double trigger mode is selected in single scan mode, two rounds of single scan operation started by a synchronous trigger (ELC) are performed in sequence.

Deselect self-diagnosis and set the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In double trigger mode, select a synchronous trigger (ELC) with the ADSTRGR.TRSA[5:0] bits. Additionally, set the ADCSR.EXTRG bit to 0 and the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (ELC), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC120_ADI interrupt request is not generated .
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion is completed, the result is stored in the A/D Data Duplexing Register (ADDBLDR), which is exclusively used in double-trigger mode.
6. An ADC120_ADI interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion is completed. Then the ADC12 enters a wait state.

35.3.2.4 双触发模式下的AD转换

在单扫描模式下选择双触发模式时，由同步触发(ELC)启动的两轮单扫描操作将依次执行。

取消选择自诊断并设置内部参考电压AD转换选择位(ADEXICR.OCSA和ADEXICR.OCSB) to 0.

AD转换数据的复制通过在ADCSR.DBLANS[4:0]位并将ADCSR.DBLE位设置为1。当ADCSR.DBLE位设置为1时，使用ADANSA0和ADANSA1寄存器的通道选择无效。

在双触发模式下，使用ADSTRGR.TRSA[5:0]位选择同步触发(ELC)。此外，设置ADCSR.EXTRG位为0，ADCSR.TRGE位为1。不要使用软件触发。

操作如下：

1.当同步触发输入(ELC)将ADCSR.ADST位设置为1（AD转换开始）时，ADCSR.DBLANS[4:0]位中选择的单通道开始AD转换。

2.每次完成单个通道的AD转换，AD转换结果存储在相关的AD数据寄存器y(ADDRy)中。

3.ADCSR.ADST位自动设置为0，ADC12进入等待状态。不会产生ADC120_ADI中断请求。

4.当第二个触发输入将ADCSR.ADST位设置为1（AD转换开始）时，AD转换在ADCSR.DBLANS[4:0]位中选择的单通道上开始。

5.AD转换完成后，结果存入AD数据双工寄存器(ADDBLDR)，该寄存器专用于双触发模式。

6.产生一个ADC120_ADI中断请求。

7.ADCSR.ADST位在AD转换期间保持1（AD转换开始），并在AD转换完成时自动设置为0。然后ADC12进入等待状态。

35.3.2.5 Extended operations when double-trigger mode is selected

When double trigger mode is selected in single scan mode, and a synchronous trigger (ELC_AD00/ELC_AD01) is selected as the trigger for the start of A/D conversion, two rounds of single scan operation are performed.

Deselect self-diagnosis and set the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In extended double trigger mode, select a synchronous trigger combination ELC_AD00/ELC_AD01 by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, set the ADCSR.EXTRG bit to 0, and set the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (ELC_AD00/ ELC_AD01), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. When A/D conversion completes, the A/D conversion result is stored in the associated A/D Data Register (ADDRy) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 0).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC120_ADI interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger (ELC_AD00/ELC_AD01), A/ D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion completes, the A/D conversion result is stored in the A/D Data Duplexing Register (ADDBLDR) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 0).

取消选择自诊断并设置内部参考电压AD转换选择位(ADEXICR.OCSA和ADEXICR.OCSB) to 0.

通过将要复制的通道号设置为ADCSR.DBLANS[4:0]位并将ADCSR.DBLE位设置为1，启用AD转换数据的复制。当ADCSR.DBLE位设置为1时，通道选择使用ADANSA0和ADANSA1寄存器无效。

在扩展双触发模式下，选择同步触发组合ELC_AD00ELC_AD01通过设置ADSTRGR.TRSA[5:0]位为0x0B，将ADCSR.EXTRG位设置为0，并将ADCSR.TRGE位设置为1。不要使用软件触发。

操作如下：

2.当AD转换完成时，当ELC_ADi0或ELC_ADi1触发输入时，AD转换结果分别存储在相关的AD数据寄存器(ADDRy)和AD数据双工寄存器A(ADDBLDRA)或AD数据双工寄存器B(ADDBLDRB)中(i=0)。

35.3.3 Continuous Scan Mode

35.3.3.1 Basic Operation

In continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (ELC), or an asynchronous trigger input, A/D conversion is performed for ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC120_ADI interrupt request is generated. The ADC12 sequentially starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. The ADCSR.ADST bit is not automatically cleared, and steps 2. and 3. are repeated as long as ADCSR.ADST remains 1 (A/ D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
5. When the ADCSR.ADST bit is later set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.

35.3.3 连续扫描模式

35.3.3.1 基本操作

在连续扫描模式下，对指定通道的模拟输入重复进行AD转换。

操作如下：

1.当软件触发、同步触发输入(ELC)或异步触发输入将ADCSR.ADST位设置为1（AD转换开始）时，对在ADANSA0和ADANSA1寄存器中选择的ANn通道执行AD转换，从编号n最小的通道开始。

2.每次完成单个通道的AD转换，AD转换结果存储在相关的AD数据寄存器（ADDRy）中。

3.当所有选定通道的AD转换完成后，会产生ADC120_ADI中断请求。ADC12从编号n最小的通道开始依次启动ADANSA0和ADANSA1寄存器中选择的ANn通道的A/D转换。

4.ADCSR.ADST位不会自动清零，只要ADCSR.ADST保持1（AD转换开始），就会重复步骤2.和3.。当ADCSR.ADST位设置为0（AD转换停止）时，AD转换停止并且ADC12进入等待状态。

5.当ADCSR.ADST位稍后设置为1（AD转换开始）时，AD转换再次开始在ADANSA0和ADANSA1寄存器中选择的ANn通道，从具有最小编号n的通道开始。

35.3.3.2 Channel Selection and Self-Diagnosis

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage (×0, ×1/2, or ×1) supplied to the ADC12, and A/D conversion is performed on the analog input of the selected channels. This sequence is repeated as described in the section that follows.

The operation is as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the corresponding A/D Data Register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC120_ADI interrupt request is generated. At the same time, the ADC12 starts A/D conversion for self-diagnosis and then on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. The ADCSR.ADST bit is not automatically cleared, and steps 2. to 4. are repeated as long as the ADCSR.ADST bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is later set to 1 (A/D conversion start), the A/D conversion for self-diagnosis is started again.

35.3.3.2 频道选择和自诊断

当同时选择通道和自诊断时，首先对提供给ADC12的参考电压（×0、×12或×1）进行AD转换，然后对ADC12的模拟输入进行AD转换。选定的频道。如以下部分所述重复此序列。

操作如下：

1.通过软件触发输入、同步触发输入(ELC)或异步触发输入将ADCSR.ADST位设置为1（AD转换开始）时，首先启动用于自诊断的D转换。

2.自诊断用AD转换完成后，AD转换结果存储在AD自诊断数据寄存器(ADRD)中。然后对ADANSA0中选择的ANn通道执行D转换，并

ADANSA1寄存器，从编号n最小的通道开始。

3、每完成一次单通道的AD转换，AD转换结果存入对应的AD数据寄存器（ADDRy）。

4.当所有选定通道的AD转换完成后，会产生ADC120_ADI中断请求。同时，ADC12启动AD转换进行自诊断，然后在ADANSA0和ADANSA1寄存器中选择的ANn通道上，从编号n最小的通道开始。

5.ADCSR.ADST位不会自动清零，只要ADCSR.ADST位保持为1，就会重复步骤2.到4.。当ADST位设置为0（AD转换停止）时，AD转换停止并且ADC12进入等待状态。

6.当ADST位稍后设置为1（AD转换开始）时，用于自诊断的AD转换再次开始。

35.3.3.3 A/D conversion of internal reference voltage

When the channels and internal reference voltage are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then the A/D conversion of the internal reference voltage is repeated.

With the channels deselected, selecting only the internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of internal reference voltage starts.
3. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC120_ADI interrupt request is generated. In addition, the ADC12 continuously starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.
4. The ADCSR.ADST bit is not cleared automatically, and steps 2 to 4 are repeated as long as this bit remains set to 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
5. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.

35.3.3.3 内部参考电压的AD转换

当同时选择通道和内部参考电压时，首先对所选通道的模拟输入进行AD转换，然后重复内部参考电压的AD转换。

取消选择通道后，也可以只选择内部参考电压。

操作如下：

1.当软件触发、同步触发(ELC)或异步触发将ADCSR.ADST位设置为1（AD转换开始）时，对ADANSA0和ADANSA1寄存器中选择的ANn通道执行AD转换，从通道开始用最小的数n。

2.通道完成AD转换后，结果存储在相关的AD数据寄存器y(ADDRy)中，然后内部参考电压的AD转换开始。

3.内部参考电压的AD转换完成后，结果存储在相关的AD内部参考电压数据寄存器(ADOCDR)中，并产生ADC120_ADI中断请求。除此之外

ADC12连续启动在ADANSA0和ADANSA1寄存器中选择的ANn通道的AD转换，从编号最小的通道n开始。

4.ADCSR.ADST位不会自动清零，只要该位保持设置为1，就会重复步骤2到4。

当ADCSR.ADST位设置为0（AD转换停止）时，AD转换停止并且ADC12进入等待状态。

5.当ADCSR.ADST位被设置为1（AD转换开始）时，AD转换再次开始在ADANSA0和ADANSA1寄存器中选择的ANn通道，从编号最小的通道n开始。

35.3.4 Group Scan Mode

35.3.4.1 Basic operation

In group scan mode, A/D conversion is performed once on the analog input of all the specified channels in group A and B after scanning is started by a synchronous trigger (ELC). The scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A and B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger.

The group A channels to be A/D-converted are selected using the ADANSA0 and ADANSA1 registers and the ADEXICR.OCSA bit. The group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers and the ADEXICR.OCSB bit. Group A and B cannot use the same channels.

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for Group A and B.

The following sequence describes operation in group scan mode using a synchronous trigger from the ELC. In this example, the ELC_AD00 trigger from the ELC is used to start conversion of group A and the ELC_AD01 trigger from the ELC is used to start conversion of group B. In addition, ELC_AD00 and ELC_AD01 are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group A is started by ELC_AD00.
2. When group A scanning completes, an ADC120_ADI interrupt is generated (no register setting).
3. Scanning of group B is started by ELC_AD01.
4. When group B scanning completes, an ADC120_GBADI interrupt is generated if the ADCSR.GBADIE bit is 1 (ADC120_GBADI interrupt when scanning completion is enabled).

35.3.4 组扫描模式

35.3.4.1 基本操作

在组扫描模式下，通过同步触发（ELC）开始扫描后，对A组和B组中所有指定通道的模拟输入进行一次AD转换。每组的扫描操作类似于单次扫描模式下的扫描操作。

可以在A组的ADSTRGR.TRSA[5:0]位和B组的ADSTRGR.TRSB[5:0]位中选择同步触发。对A组和B组使用不同的触发以防止同时进行AD转换两组。不要使用软件触发。

使用ADANSA0和ADANSA1寄存器选择要进行AD转换的A组通道
ADEXCR.OCSA位。使用ADANSB0和ADANSB1寄存器以及ADEXICR.OCSB位选择要进行AD转换的B组通道。
A组和B组不能使用相同的通道。

在组扫描模式下选择自诊断时，对A组和B组分别执行自诊断。

以下序列描述了使用来自ELC的同步触发在组扫描模式下的操作。在此示例中，ELC的ELC_AD00触发器用于启动A组的转换，ELC的ELC_AD01触发器用于启动B组的转换。此外，关联ELC中的GPT事件选择ELC_AD00和ELC_AD01.ELSRn寄存器。

操作如下：

1.A组扫描由ELC_AD00启动。

2.A组扫描完成后，产生ADC120_ADI中断（无寄存器设置）。

3.B组扫描由ELC_AD01启动。

4.B组扫描完成时，如果ADCSR.GBADIE位为1，则产生ADC120_GBADI中断（扫描完成时ADC120_GBADI中断使能）。

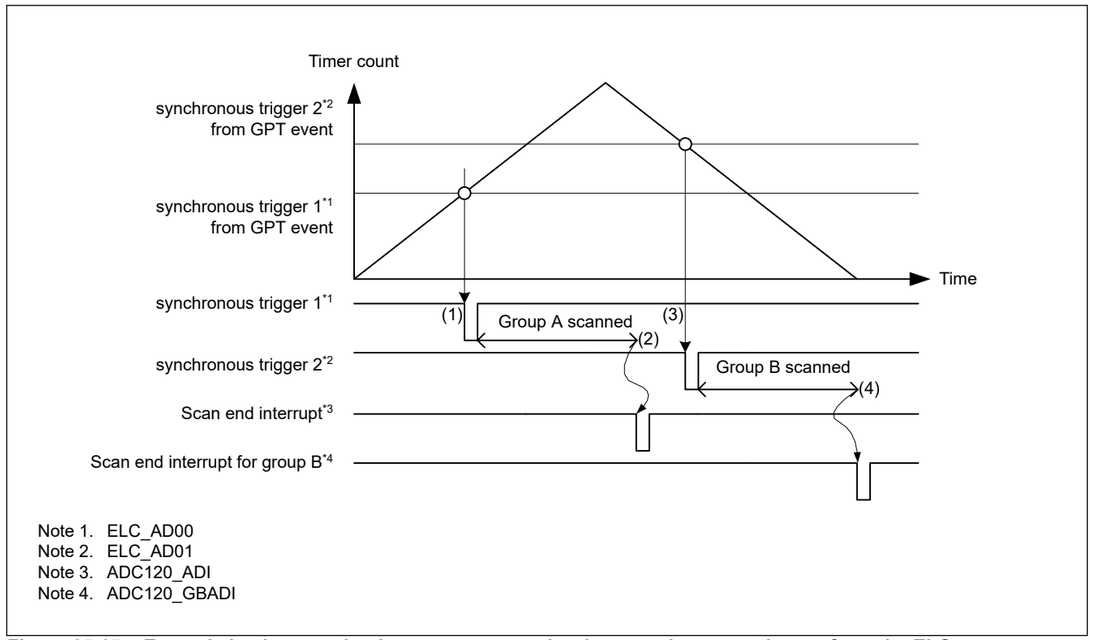

Figure 35.15 Example basic operation in group scan mode when synchronous triggers from the ELC are used

35.3.4.2 A/D conversion in double-trigger mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger (ELC) are performed as a sequence for group A. For group B, single scan operation started by a synchronous trigger (ELC) is performed once.

In group scan mode, the synchronous trigger can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for groupA, B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger or an asynchronous trigger.

When an ELC_AD00/ELC_AD01 is selected as group A synchronous triggers by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, operation proceeds in extended double trigger mode.

The group A channel to be A/D-converted is selected using the DBLANS[4:0] bits in the ADCSR register, while the group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers. Group A, B cannot use the same channels.

When double-trigger mode is selected in group scan mode, set the A/D conversion select bits for the internal reference voltage (ADEXICR.OCSA) to 0 (deselected).

Self-diagnosis cannot be selected when double trigger mode is selected in group scan mode.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following sequence describes operation in group scan mode with double trigger mode selected and using a synchronous trigger from the ELC. In this example, the ELC_AD00 trigger is used to start conversion of group A and the ELC_AD01 trigger is used to start conversion of group B. In addition, ELC_AD00 and ELC_AD01 are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group B is started by the ELC_AD00 trigger from the ELC.
2. When group B scanning completes, an ADC120_GBADI interrupt is generated if the GBADIE bit in ADCSR is 1 (ADC120_GBADI interrupt when scanning completion is enabled).
3. The first scan of group A is started by the first ELC_AD01 trigger.

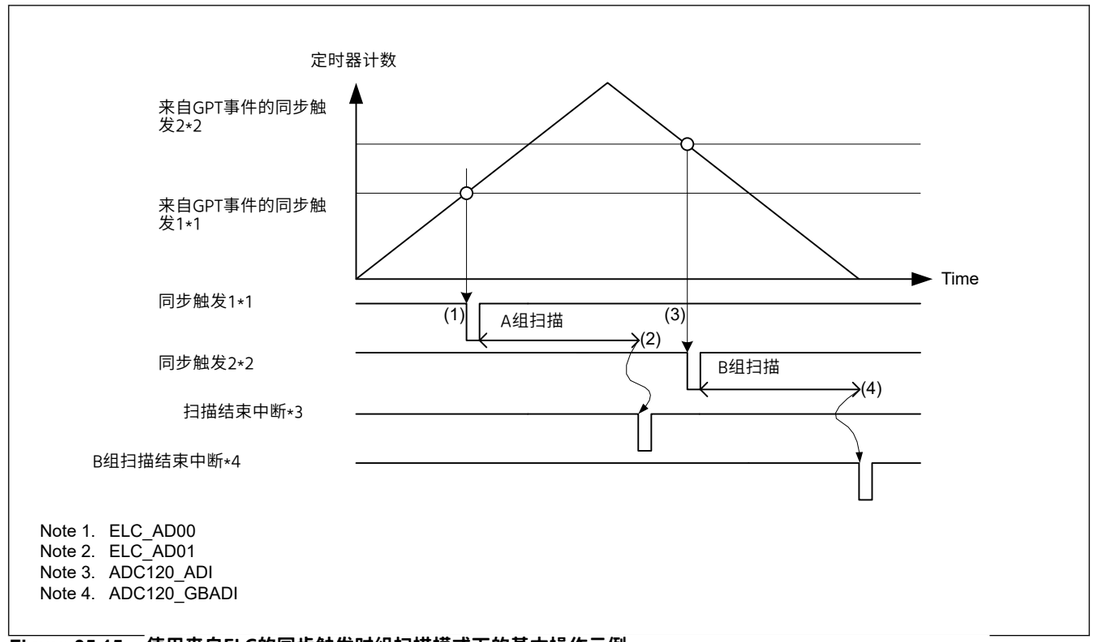

Figure 35.15 使用来自ELC的同步触发时组扫描模式下的基本操作示例

35.3.4.2 双触发模式下的AD转换

在组扫描模式中选择双触发模式时，由同步触发(ELC)启动的两轮单扫描操作作为A组的顺序执行。对于B组，由同步触发(ELC)启动的单扫描操作是执行一次。

在组扫描模式下，可以在ADSTRGR.TRSA[5:0]位中为A组选择同步触发，并在组B的ADSTRGR.TRSB[5:0]位。对组A、B使用不同的触发，以防止两组同时进行AD转换。不要使用软件触发或异步触发。

当通过将ADSTRGR.TRSA[5:0]位设置为0x0B选择ELC_AD00ELC_AD01作为A组同步触发时，操作在扩展双触发模式下进行。

使用ADCSR寄存器中的DBLANS[4:0]位选择要进行AD转换的A组通道，而组使用ADANSB0和ADANSB1寄存器选择要进行AD转换的B通道。A、B组不能使用相同的通道。

在组扫描模式下选择双触发模式时，将内部参考电压的AD转换选择位(ADEXICR.OCSA)设置为0（取消选择）。

在组扫描模式下选择双触发模式时，不能选择自诊断。

AD转换数据的复制通过在ADCSR.DBLANS[4:0]位并将ADCSR.DBLE位设置为1。

以下序列描述了组扫描模式下的操作，其中选择了双触发模式并使用来自ELC的同步触发。在本例中，ELC_AD00触发器用于启动A组转换，ELC_AD01触发器用于启动B组转换。此外，ELC_AD00和ELC_AD01被选择用于相关ELC.ELSRn寄存器中的GPT事件。

操作如下：

1.B组的扫描由来自ELC的ELC_AD00触发器启动。

2.B组扫描完成时，如果ADCSR中的GBADIE位为1则产生ADC120_GBADI中断（扫描完成时ADC120_GBADI中断使能）。

3.A组的第一次扫描由第一个ELC_AD01触发器启动。

4. When the first scan of group A completes, the conversion result is stored in the associated A/D Data Register y (ADDRy); an ADC120_ADI interrupt request is not generated.
5. The second scan of group A is started by the second ELC_AD01 trigger.
6. When the second scan of group A completes, the conversion result is stored in ADDBLDR. An ADC120_ADI interrupt is generated.

35.3.4.3 Group Priority Operation

Group priority operation is performed by setting the ADGSPCR.PGS bit to 1 in group-scan mode. The priority of groups is group A > group B.

When setting the PGS bit in the ADGSPCR register to 1, follow the procedure described in Figure 35.17. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

As the basic operation in group-scan mode, a trigger input generated during A/D conversion of group A, B is ignored, and the A/D conversion operation of each group is similar to the operation in single-scan mode.

In group priority operation, if a trigger for a priority group is input during scanning of a lower-priority group, A/D conversion for the lower-priority group is stopped and A/D conversion for the priority group is performed.

If the setting of the ADGSPCR.GBRSCN bit is 0, the lower-priority group enters a wait state when A/D conversion for the priority group completes. A trigger input of the lower-priority group generated during A/D conversion is ignored.

If the setting of the ADGSPCR.GBRSCN bit is 1, A/D conversion for the lower-priority group automatically restarts upon completion of A/D conversion for the priority group. A trigger input of the lower-priority group generated during A/D conversion on the priority group takes effect, and A/D conversion for the lower-priority group is automatically performed upon completion of A/D conversion on the priority group.

If the ADGSPCR.GBRSCN bit is 1 and the ADGSPCR.LGRRS bit is 0, A/D conversion for the lower-priority group is restarted from the first channel. If the setting of the ADGSPCR.LGRRS bit is 1, A/D conversion for the lower-priority group is restarted from the channel for which the conversion stopped. However, if the self-diagnosis function is used, the A/D conversion is restarted from the channel for which the conversion stopped after self-diagnosis completed.

Table 35.21 summarizes operations in response to the input of a trigger during A/D conversion with the settings of the ADGSPCR.GBRSCN bit.

4、A组第一次扫描完成后，转换结果存入相关的AD数据寄存器y（ADDRy）；不会产生ADC120_ADI中断请求。

5.A组的第二次扫描由第二个ELC_AD01触发器启动。

6.A组第二次扫描完成后，转换结果存入ADDBLDR。产生一个ADC120_ADI中断。

35.3.4.3 集团优先运营

在组扫描模式下，通过将ADGSPCR.PGS位设置为1来执行组优先级操作。组的优先级为A组>B组。

将ADGSPCR寄存器中的PGS位设置为1时，请遵循图35.17中描述的过程。如果不遵循该程序，则无法保证AD转换操作和存储数据。

作为组扫描模式下的基本操作，A、B组A/D转换过程中产生的触发输入被忽略，各组的A/D转换操作与单扫描模式下的操作类似。

在组优先操作中，如果在低优先级组的扫描期间输入了优先级组的触发，则停止低优先级组的AD转换并执行优先级组的AD转换。

如果ADGSPCR.GBRSCN位设置为0，则当优先级组的AD转换完成时，低优先级组进入等待状态。AD转换期间产生的低优先级组的触发输入被忽略。

如果ADGSPCR.GBRSCN位设置为1，则在优先级组的AD转换完成后，低优先级组的AD转换自动重新开始。对优先组进行AD转换时产生的低优先组的触发输入生效，在优先组的AD转换完成后，自动进行低优先组的AD转换。

如果ADGSPCR.GBRSCN位为1，ADGSPCR.LGRRS位为0，则从第一个通道重新开始低优先级组的AD转换。如果ADGSPCR.LGRRS位设置为1，则低优先级组的AD转换从转换停止的通道重新开始。但是，如果使用自诊断功能，则从自诊断完成后停止转换的通道重新开始AD转换。

表35.21总结了在AD转换期间响应触发输入的操作，其中设置为ADGSPCR.GBRSCN bit.

If the setting of the ADGSPCR.GBRP bit is 1, A/D conversion operation for the lowest-priority group is to continuously perform single scans.

For the trigger settings in group-scan mode, select a synchronous trigger for group A by using the ADSTRGR.TRSA[5:0] bits, a synchronous trigger for group B by using the ADSTRGR.TRSB[5:0] bits. Each trigger must be different from each other. Set the ADSTRGR.TRSB[5:0] bits to 0x3F when setting the ADGSPCR.GBRP bit to 1.

The channels to be scanned must be selected in the registers shown in section 35.3.4. Group Scan Mode.

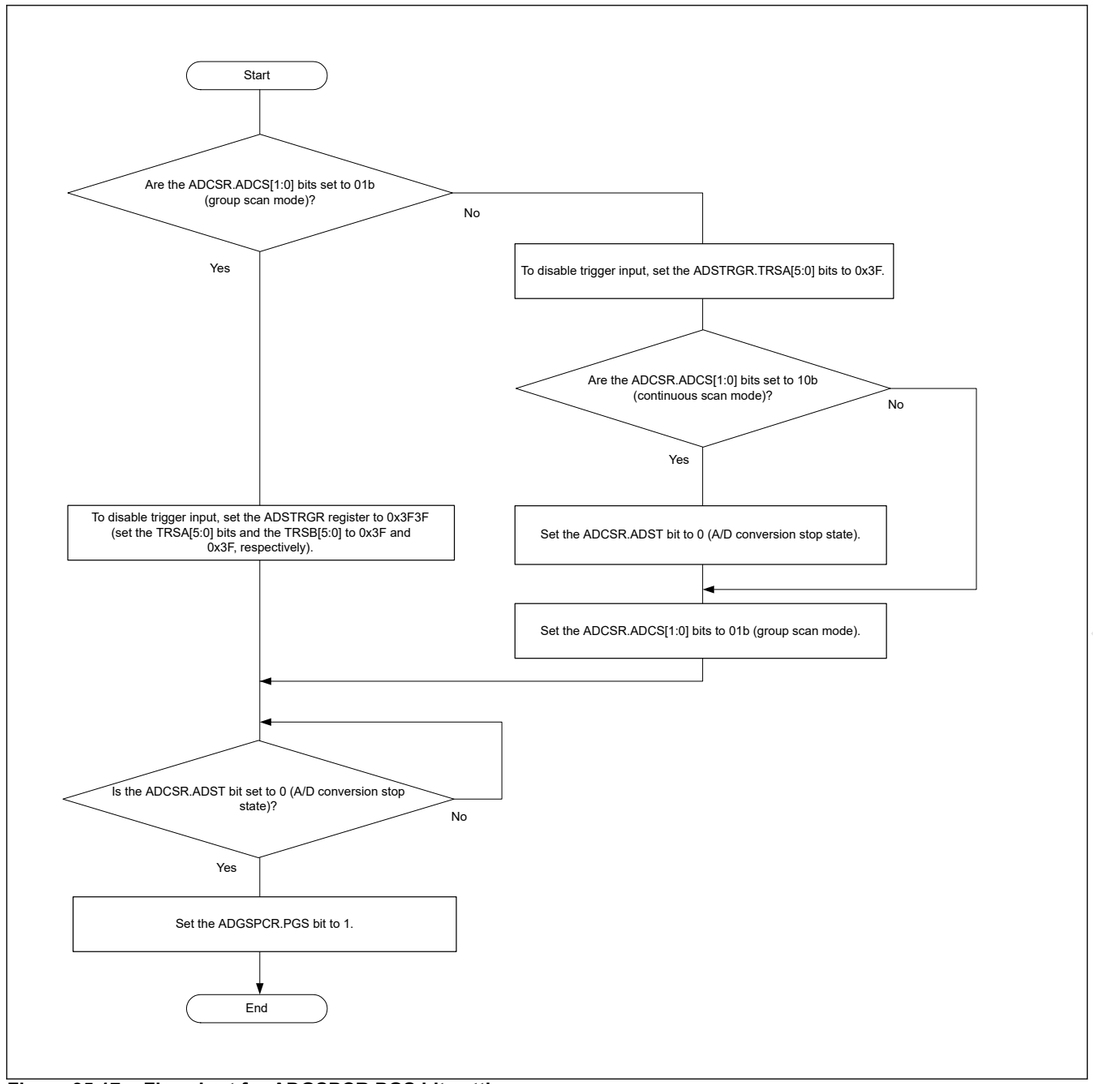

Figure 35.17 Flowchart for ADGSPCR.PGS bit setting

如果ADGSPCR.GBRP位设置为1，则最低优先级组的AD转换操作是连续执行单次扫描。

对于组扫描模式下的触发设置，使用ADSTRGR.TRSA[5:0]位选择A组同步触发，使用ADSTRGR.TRSB[5:0]位选择B组同步触发。每个触发器必须彼此不同。将ADGSPCR.GBRP位设置为1时，将ADSTRGR.TRSB[5:0]位设置为0x3F。

要扫描的通道必须在第35.3.4节所示的寄存器中选择。组扫描模式。

(1) 两个组的组优先操作（当ADGSPCR.PGS=1时）

操作示例1-1到1-5显示了当为组A和通道1选择通道0时，组扫描模式下的组优先操作（当ADGSPCR.GBRSCN=1、ADGSPCR.GBRP=0和ADGSPCR.LGRRS=0时）为B组选择3至3个。

操作示例1-1：启用重新扫描时的"B组扫描期间A组触发输入"

1.当B组的触发输入将ADCSR.ADST位设置为1（开始AD转换）时，ADANSB0和ADANSB1寄存器中选择的模拟输入通道的AD转换按照转换顺序从最小通道开始号码n.

2.B组中每个通道的AD转换完成后，将结果存储在相应的AD数据寄存器y(ADDRy)中。

3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1. Then A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. An ADC120_ADI interrupt request is generated.
6. If the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1.
7. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.

Operation example 1-2: “Group A trigger input during rescanning of group B” when rescanning is enabled

Figure 35.19 shows the operation when a group A trigger is input during rescanning operation for group B.

Even during rescanning operation, when a trigger for group A is input, A/D conversion on group B stops and A/D conversion for group A starts. A/D conversion for group B starts after A/D conversion for group A completes.

Operations for setting the ADCSR.ADST bit, storing the A/D conversion result in the corresponding A/D Data Register y (ADDRy), and generating interrupt requests are the same as those in operation example 1-1.

3.在B组的AD转换期间输入A组的触发信号时，B组的AD转换停止，而ADCSR.ADST位保持为1。然后在ADANSA0和ADANSA1寄存器中选择的A组模拟输入通道的AD转换开始根据编号n最小的通道的转换顺序。如果AD转换在完成之前停止，则转换结果不会存储在AD数据寄存器y(ADDRy)中。

4.在通道上完成AD转换后，结果将存储在相应的AD数据寄存器y(ADDRy)中。

5.产生一个ADC120_ADI中断请求。

6.如果ADGSPCR.GBRSCN位设置为1（允许重新扫描在组优先操作中停止的组），则ADANSB0和ADANSB1寄存器中选择的B组模拟输入通道的AD转换根据转换顺序重新启动当ADCSR.ADST保持为1时，来自编号为n的最小通道。

7.在通道上完成AD转换后，结果将存储在相应的AD数据寄存器y(ADDRy)中。

8.如果ADCSR.GBADIE位设置为1（使能在B组扫描完成时产生中断），则产生B组扫描结束中断请求。

Figure 35.19 Example of group priority operation 1-2: Group A trigger input during rescanning of group B when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-3: “Group B trigger input during group A scan” when rescanning is enabled

The following describes the operation when the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation) and a trigger for group B is input during scanning operation for group A.

If the setting of the ADGSPCR.GBRSCN bit is 0, any trigger for group B that is input during scanning operation for group A is invalid.

1. When input of a trigger for group A sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n.
2. When a trigger for group B is input during A/D conversion for group A, group B is ready for A/D conversion.
3. On completion of A/D conversion for each channel in group A, the result is stored in the corresponding A/D Data Register y (ADDRy).
4. An ADC120_ADI interrupt request is generated.
5. When A/D conversion for group A completes, while the ADCSR.ADST bit remains 1, A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
   (As with the case of operation example 1-1, if a trigger for group A is input during A/D conversion for group B, A/D conversion for group A starts. Then A/D conversion for group B starts upon completion of A/D conversion for group A.)
6. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
7. Upon completion of A/D conversion for group B, a group B scan end interrupt request is generated if the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan).
8. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.

操作示例1-3：启用重新扫描时的“A组扫描期间B组触发输入”

下面介绍当ADGSPCR.GBRSCN位设置为1（允许重新扫描在组优先操作中停止的组）并且在A组扫描操作期间输入B组触发器时的操作。

如果ADGSPCR.GBRSCN位设置为0，则在组扫描操作期间输入的任何组B触发A无效。

1.当A组的触发输入将ADCSR.ADST位设置为1（开始AD转换）时，在ADANSA0和ADANSA1寄存器中选择的A组模拟输入通道的AD转换根据来自通道的转换顺序开始最小的数n。

2.在A组AD转换期间输入B组触发器时，B组准备好进行AD转换。

3.A组中每个通道的AD转换完成后，将结果存储在相应的AD数据寄存器y(ADDRy)中。

4.产生一个ADC120_ADI中断请求。

5.当A组的AD转换完成，而ADCSR.ADST位保持为1时，ADANSB0和ADANSB1寄存器中选择的B组模拟输入通道的AD转换按照编号n最小通道的转换顺序开始。（与操作示例1-1的情况一样，如果在B组的AD转换期间输入了A组的触发信号，则A组的AD转换开始。然后，在A组的AD转换完成后，开始B组的AD转换。）

6.单通道AD转换完成后，结果存入对应的AD数据寄存器y(ADDRy)。

7.B组的AD转换完成后，如果ADCSR.GBADIE位设置为1，则产生B组扫描结束中断请求（在B组扫描完成时允许产生中断）。

8.当所有通道的AD转换完成时，ADCSR.ADST位自动清零，AD转换器进入等待状态。

Operation example 1-4 shows the group priority operation in group-scan mode (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0) when channel 0 is selected for group A and channels 1 to 3 are selected for group B.

Operation example 1-4: “Group A trigger input during group B scan” when rescanning is disabled

1. When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
6. When A/D conversion for group A completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state. A/D conversion for group B is not performed until a trigger for group B is input the next time.

2.B组中每个通道的AD转换完成后，将结果存储在相应的AD数据寄存器y(ADDRy)中。

Operation example 1-5: Continuously activating single-scan operation for group B

1. When ADGSPCR.GBRP = 1 is set, the ADCSR.ADST bit is set to 1 (starting A/D conversion) and A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).

操作示例1−5：B组连续激活单扫描操作

1.当设置ADGSPCR.GBRP=1时，ADCSR.ADST位设置为1（开始AD转换），并且ADANSB0和ADANSB1寄存器中选择的模拟输入通道的AD转换根据通道的转换顺序开始最小的数n。

2.B组中每个通道的AD转换完成后，将结果存储在相应的AD数据寄存器y(ADDRy)中。

3.在B组的AD转换期间输入A组的触发信号时，B组的AD转换停止，而ADCSR.ADST位保持为1，然后在ADANSA0和ADANSA1寄存器中选择的A组模拟输入通道的AD转换开始根据编号为n的通道的转换顺序z。如果AD转换在完成之前停止，则转换结果不会存储在AD数据寄存器y(ADDRy)中。

4.单通道AD转换完成后，结果存入对应的AD数据寄存器y(ADDRy)。

5.A组AD转换完成后，会产生ADC120_ADI中断请求。

7.单通道AD转换完成后，结果存入对应的AD数据寄存器y(ADDRy)。

8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.

35.3.5 Compare Function for Windows A and B

35.3.5.1 Compare function windows A and B

The compare function compares a reference value with the A/D conversion result. The reference value can be set for Window A and Window B independently. When the compare function is in use, the self-diagnosis function and double trigger mode cannot be used. The main differences between Window A and Window B are their different interrupt output signals and the constraint on Window B of only one selectable channel.

This section provides an example operation that combines continuous scan mode and the compare function.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, a synchronous trigger (ELC) or an asynchronous trigger, A/D conversion starts in the order of the selected channels and internal reference voltage.
2. On completion of A/D conversion, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy, or ADOCDR). When ADCMPCR.CMPAE = 1, if bits in the ADCMPANSRy register or the ADCMPANSER register are set for Window A, the A/D conversion result is compared with the set ADCMPDR0/1 register value. When ADCMPCR.CMPBE = 1, if bits in the ADCMPBNSR register are set for Window B, the A/D conversion result is compared with the ADWINULB/ADWINLLB register setting.

8.如果ADCSR.GBADIE位设置为1（使能在B组扫描完成时产生中断），则产生B组扫描结束中断请求。

9.如果设置ADGSPCR.GBRP=1（连续执行单次扫描），B组模拟输入的AD转换
在ADANSB0和ADANSB1寄存器中选择的通道根据转换顺序从具有最小编号n的通道重新启动，而ADCSR.ADST保持为1（开始AD转换）。

只要ADGSPCR.GBRP位保持为1，就重复步骤6到9。不要清除ADCSR.ADST位，只要ADGSPCR.GBRP位为1。要在ADGSPCR.GBRP=1时强制停止AD转换，请按照以下步骤进行操作

35.3.5 比较WindowsA和B的函数

35.3.5.1 比较功能窗口A和B

比较功能将参考值与AD转换结果进行比较。参考值可设置为
窗口A和窗口B独立。使用比较功能时，不能使用自诊断功能和双触发模式。WindowA和WindowB的主要区别在于它们的中断输出信号不同以及WindowB只能选择一个通道的限制。

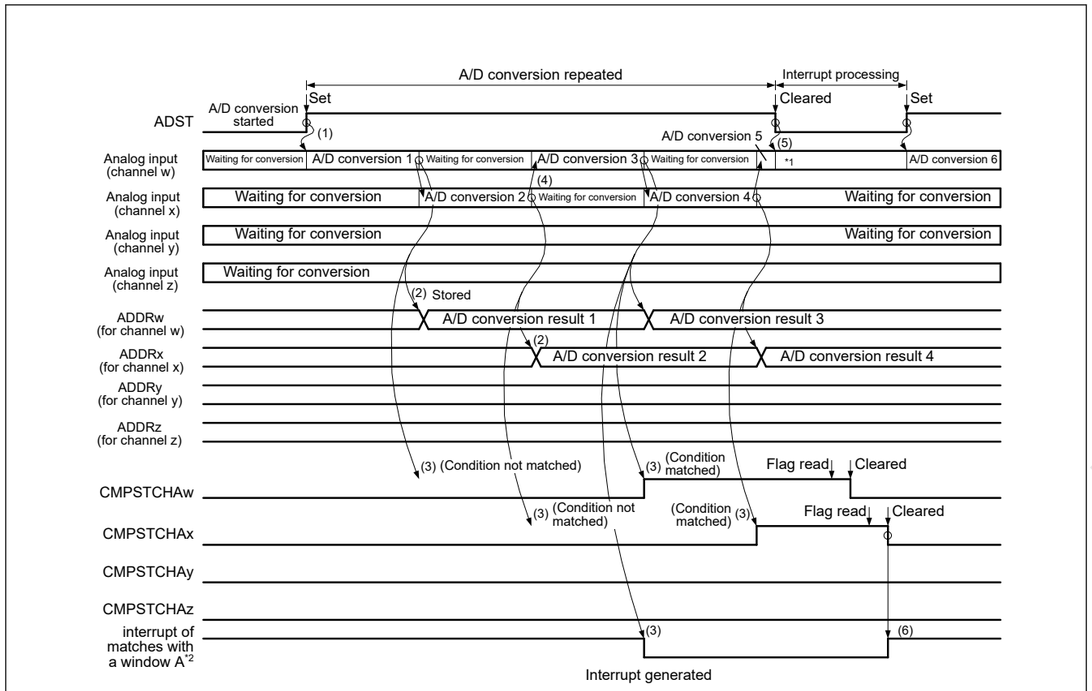
本节提供结合连续扫描模式和比较功能的示例操作。

操作如下：

1.当ADCSR.ADST位通过软件、同步触发(ELC)或异步触发设置为1（AD转换开始）时，AD转换按所选通道和内部参考电压的顺序开始。

2.AD转换完成后，AD转换结果存储在相关的AD数据寄存器y（ADDRy或ADOCDR）中。当ADCMPCR.CMPAE=1时，如果ADCMPANSRy寄存器或ADCMPANSER寄存器中的位为窗口A设置，则AD转换结果将与设置的ADCMPDR01寄存器值进行比较。当ADCMPCR.CMPBE=1时，如果ADCMPBNSR寄存器中的位为窗口B设置，则将AD转换结果与ADWINULBADWINLLB寄存器设置进行比较。

3. As a result of the comparison, when Window A meets the condition set in ADCMPLR0/1 or ADCMPLER, the Compare Window A Flag (ADCMPSR0.CMPSTCHAn, ADCMPSR1.CMPSTCHAn, or ADCMPSER.CMPSTOCA) sets 1. At this time, if the ADCMPCR.CMPAIE bit is 1, an ADC120_CMPAI interrupt request is generated. In the same way, when Window B meets the condition set in ADCMPBNSR.CMPLB, the Compare Window B Flag (ADCMPBSR.CMPSTB) sets to 1. At this time, if the ADCMPCR.CMPBIE bit is 1, an ADC120_CMPBI interrupt request is generated.
4. On completion of all selected A/D conversions and comparisons, scan restarts.
5. After the ADC120_CMPAI and ADC120_CMPBI interrupts are accepted, the ADCSR.ADST bit is set to 0 (A/D conversion stop) and processing is performed for channels for which the compare flag is set to 1.
6. When all compare flags of Window A are cleared, the ADC120_CMPAI interrupt request is canceled. In the same way, when all compare flags of Window B are cleared, the ADC120_CMPBI interrupt request is reset. To perform comparison again, restart the A/D conversion.



Note: w, x, y, and z (w < x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. Data on conversion is ignored.
Note 2. ADC120_CMPAI

Figure 35.23 Example of compare function operation, when the analog inputs (channel w to z) are compared

35.3.5.2 Event output of compare function

The event output of the compare function specifies the upper-side reference voltage value and the lower-side reference voltage value for window A and window B, respectively. The output compares the A/D converted value of the selected channel with the upper and lower side reference voltage value and outputs events (ADC120_WCMPM/ ADC120_WCMPUM) based on event conditions (A or B, A and B, A xor B) and comparison result of window A and window B.

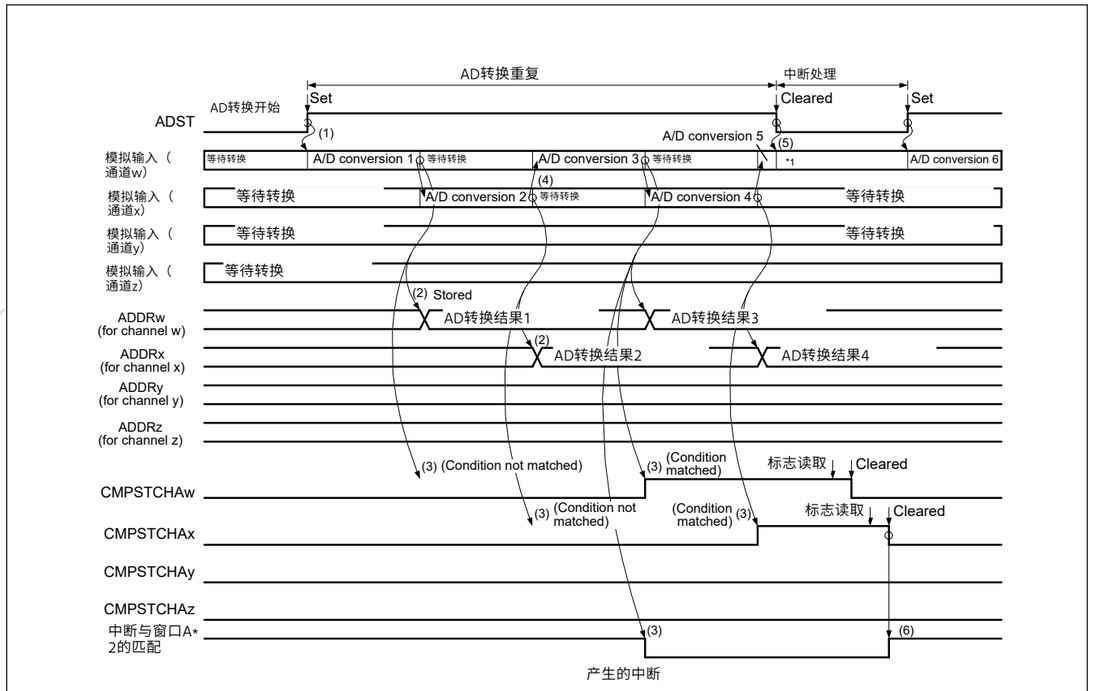
If more than one channel is selected for window A, and even when one channel in window A meets the comparison condition, the comparison result of window A is met. When using this function, perform A/D conversion in single scan mode.

3.作为比较的结果，当窗口A满足ADCMPLR01或ADCMPLER中设置的条件时，比较窗口A标志（ADCMPSR0.CMPSTCHAn、ADCMPSR1.CMPSTCHAn或ADCMPSER.CMPSTOCA）设置为1。此时，如果ADCMPCR.CMPAIE位为1，产生ADC120_CMPAI中断请求。同理，当窗口B满足ADCMPBNSR.CMPLB中设置的条件时，比较窗口B标志（ADCMPBSR.CMPSTB）置1。此时如果ADCMPCR.CMPBIE位为1，则产生ADC120_CMPBI中断请求.

4.完成所有选定的AD转换和比较后，重新开始扫描。

5.接受ADC120_CMPAI和ADC120_CMPBI中断后，ADCSR.ADST位设置为0（AD转换停止），并对比较标志设置为1的通道执行处理。

6.当窗口A的所有比较标志被清除时，ADC120_CMPAI中断请求被取消。同理，当窗口B的所有比较标志清零时，ADC120_CMPBI中断请求被复位。要再次进行比较，请重新开始AD转换。



Note: w、x、y和z(w<x<y<z)是ADANSA01选择的通道号。
注1.转换数据被忽略。
Note 2. ADC120_CMPAI

35.3.5.2 比较函数的事件输出

比较函数的事件输出分别指定窗口A和窗口B的上侧参考电压值和下侧参考电压值。输出将所选通道的AD转换值与上下侧参考电压值进行比较，并根据事件条件（A或B、A和B、AxorB）和窗口A的比较结果输出事件（ADC120_WCMPMADC120_WCMPUM）和窗口B。

如果窗口A选择了多个通道，即使窗口A中的一个通道满足比较条件，也满足窗口A的比较结果。使用此功能时，请在单次扫描模式下进行AD转换。

Any channels from analog input and internal reference voltage are selectable for window A.

One channel from analog input and internal reference voltage is selectable for window B.

The following sequence is an example of how to set up and use the event output of the compare function:

1. Confirm that the value in the ADCSR.ADCS bits is 00b (single scan mode).
2. Select the channel for window A in the ADCMPANSR0/1 and ADCMPANSER registers. Set the window comparison conditions in the ADCMPLR0/1 and ADCMPLER registers. Set the upper-side and lower-side reference values in the ADCMPDR0/1 registers.
3. Select the channel and comparison conditions for Window B in the ADCMPBNSR register, and set the upper and lower reference values in the ADWINULB and ADWINLLB registers.
4. Set the composite conditions for window A/B, window A/B operation enable, and interrupt output enable in the ADCMPCR register.

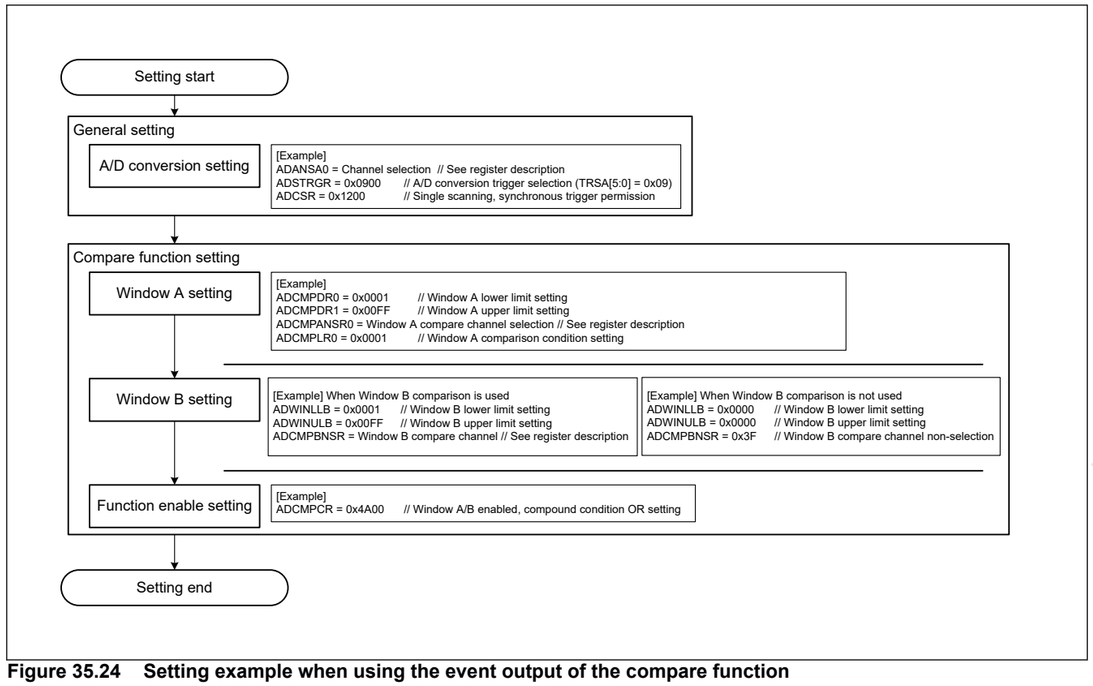

Figure 35.24 Setting example when using the event output of the compare function

For event output usage when using only window A for the compare function, note the following:

- Enable both Window A and Window B (ADCMPCR.CMPAE = 1, ADCMPCR.CMPBE = 1)
- Set the compound condition of Window A and Window B to “OR condition” (ADCMPCR.CMPAB[1:0] = 00b)
- Set the compared channel of Window B to “No selection” (ADCMPBNSR.CMPCHB[5:0] = 0x3F)
- Set the compare condition of Window B to “0 < results < 0 always means mismatch”. (ADCMPCR.WCMPE = 1, ADWINLLB[15:0] = ADWINULB[15:0] = 0x0000, and ADCMPBNSR.CMPLB = 1)

Figure 35.25 shows the event output operation example of compare function.

A scan end event (ADC120_ADI) is output with the same timing as single scan completion. A match or mismatch event (ADC120_WCMPM/ADC120_WCMPUM) is output with 1 PCLKA cycle delay depending on the ADCMPCR.CMPAB[1:0] settings.

Note: The match and mismatch events are exclusive, so both events are never output simultaneously.

窗口A可选择来自模拟输入和内部参考电压的任何通道。

窗口B可选择来自模拟输入和内部参考电压的一个通道。

以下序列是如何设置和使用比较函数的事件输出的示例：

1.确认ADCSR.ADCS位中的值为00b（单次扫描模式）。

2.在ADCMPANSR01和ADCMPANSER寄存器中选择窗口A的通道。在ADCMPLR01和ADCMPLER寄存器中设置窗口比较条件。在ADCMPDR01寄存器中设置上侧和下侧参考值。

3.在ADCMPBNSR寄存器中选择窗口B的通道和比较条件，并在ADWINULB和ADWINLLB寄存器中设置上下参考值。

4.在ADCMPCR寄存器中设置窗口AB、窗口AB操作使能和中断输出使能的复合条件。

Figure 35.24 使用比较功能的事件输出时的设置示例

对于仅将窗口A用于比较功能时的事件输出用法，请注意以下几点：

●启用窗口A和窗口B(ADCMPCR.CMPAE=1 ADCMPCR.CMPBE=1)

●将窗口A和窗口B的复合条件设置为“或条件”（ADCMPCR.CMPAB[1:0]=00b）

●将窗口B的比较通道设置为“无选择”（ADCMPBNSR.CMPCHB[5:0]=0x3F）

●将窗口B的比较条件设置为“0<结果<0总是不匹配”。（ADCMPCR.WCMPE=1，ADWINLLB[15:0]=ADWINULB[15:0]=0x0000，ADCMPBNSR.CMPLB=1）

图35.25显示了比较功能的事件输出操作示例。

扫描结束事件(ADC120_ADI)以与单次扫描完成相同的时序输出。匹配或不匹配事件(ADC120_WCMPMADC120_WCMPUM)以1个PCLKA周期延迟输出，具体取决于ADCMPCR.CMPAB[1:0]设置。

Note: match和mismatch事件是互斥的，因此这两个事件永远不会同时输出。

Note: Event output of compare function outputs match/mismatch from the comparison results of Window A and Window B, based on the ADCMPCR.CMPAB[1:0] settings.
Note: The comparison result of Window A is the logical addition of the comparison results of the comparison target channels of Window A. The comparison results of Window A and Window B are updated by each A/D conversion, and are kept even when single scan ends. Set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0 to clear the comparison results to 0.

35.3.5.3 Restrictions on the compare function

The following constraints apply for the compare function:

- The compare function cannot be used together with the self-diagnosis function or double-trigger mode. (The compare function is not available for ADRD, ADDBLDR, ADDBLDRA, and ADDBLDRB.)
- Specify single scan mode when using match/mismatch event outputs.
- When the internal reference voltage is selected for Window A, Window B operations are disabled.
- When the internal reference voltage is selected for Window B, Window A operations are disabled.
- Setting the same channel for Window A and Window B is prohibited.
- Set the reference voltage values so that the high-potential reference voltage value is equal to or larger than the low potential reference voltage value.

Note: 根据ADCMPCR.CMPAB[1:0]设置，比较函数输出的事件输出与窗口A和窗口B的比较结果匹配不匹配。

Note: 窗口A的比较结果是窗口A的比较目标通道的比较结果的逻辑相加。窗口A和窗口B的比较结果在每次AD转换时更新，即使在单次扫描结束时也会保持。将ADCMPCR.CMPAE和ADCMPCR.CMPBE设置为0，将比较结果清除为0。

35.3.5.3 比较功能的限制

以下约束适用于比较功能：

- 比较功能不能与自诊断功能或双触发模式一起使用。（比较功能不适用于ADRD、ADDBLDR、ADDBLDRA和ADDBLDRB。）
- 使用匹配不匹配事件输出时指定单次扫描模式。
- 当窗口A选择内部参考电压时，窗口B操作被禁用。
- 当窗口B选择内部参考电压时，窗口A操作被禁用。
- 禁止窗口A和窗口B设置相同的通道。
- 设置参考电压值，使高电位参考电压值等于或大于低电位参考电压值。

35.3.6 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated either by a software trigger, a synchronous trigger (ELC), or an asynchronous trigger (ADTRG0). After the start-of-scanning-delay time (t_D) has elapsed, processing for disconnection detection assistance, and processing of conversion for self-diagnosis all proceed, followed by processing for A/D conversion.

Figure 35.26 shows the scan conversion timing, in which scan conversion is activated by a software trigger or a synchronous trigger (ELC). Figure 35.27 shows the scan conversion timing, in which scan conversion is activated by an asynchronous trigger (ADTRG0). The scan conversion time (t_{SCAN}) includes the start-of-scanning-delay time (t_D), disconnection detection assistance processing time (t_{DIS})*1, self-diagnosis A/D conversion processing time (t_{DIAG} and t_{DSD})*2, A/D conversion processing time (t_{CONV}), and end-of-scanning-delay time (t_{ED}).

The A/D conversion processing time (t_{CONV}) consists of input sampling time (t_{SPL}) and time for conversion by successive approximation (t_{SAM}). The sampling time (t_{SPL}) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/ D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTRn register.

The time for conversion by successive approximation (t_{SAM}) is the following

- 13 ADCLK states with 12-bit accuracy selected.
- 11 ADCLK states with 10-bit accuracy selected.
- 9 ADCLK states with 8-bit accuracy selected.

Table 35.23 shows the time for conversion by successive approximation (t_{SAM}).

The scan conversion time (t_{SCAN}) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = t_D + (t_{DIS} \times n) + t_{DIAG} + t_{ED} + (t_{CONV} \times n)$$ *3

The scan conversion time for the first cycle in continuous scan mode is t_{SCAN} for single scan minus t_{ED} . The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed in the following:

$$(t_{DIS} \times n) + t_{DIAG} + t_{DSD} + (t_{CONV} \times n)$$ *3

Note 1. When disconnection detection assistance is not selected, t_{DIS} = 0.

Only when the internal reference voltage is A/D-converted, the auto-discharge period of 15 ADCLK states is inserted.

Note 2. When the self-diagnosis function is not used, t_{DIAG} = 0, t_{DSD} = 0.

Note 3. When input sampling times (t_{SPL}) of all selected channels are the same, this element equals t_{CONV} × n. If each channel has a different sampling time, this element equals that of t_{SPL} and t_{SAM} set to each selected channel.

Table 35.23 shows the times for conversion during scanning.

35.3.6 模拟输入采样和扫描转换时间

扫描转换可以通过软件触发、同步触发(ELC)或异步触发(ADTRG0)来激活。在经过扫描开始延迟时间(tD)之后，断线检测辅助处理和自诊断转换处理全部进行，接着进行AD转换处理。

图35.26显示了扫描转换时序，其中扫描转换由软件触发或同步触发(ELC)激活。图35.27显示了扫描转换时序，其中扫描转换由异步触发(ADTRG0)激活。扫描转换时间(tSCAN)包括扫描开始延迟时间(tD)、断线检测辅助处理时间(tDIS)*1、自诊断AD转换处理时间(tDIAG和tDSD)*如图2所示，AD转换处理时间(tCONV)和扫描结束延迟时间(tED)。

AD转换处理时间(tCONV)由输入采样时间(tSPL)和逐次逼近转换时间(tSAM)组成。采样时间(tSPL)用于为AD转换器中的采样保持电路充电。如果由于模拟输入信号源的高阻抗而没有足够的采样时间，或者如果AD转换时钟(ADCLK)很慢，则可以使用ADSSTRn寄存器调整采样时间。

逐次逼近转换时间(tSAM)如下

- ●13个ADCLK状态，选择12位精度。
- ●11个ADCLK状态，选择精度为10位。
- ●选择8位精度的9个ADCLK状态。

表35.23显示了逐次逼近转换的时间(tSAM)。

选择通道数为n的单次扫描模式下的扫描转换时间(tSCAN)可以确定如下：

tSCAN=tD+tDIS×n+tDIAG+tED+tCONV×n*3

连续扫描模式下第一个周期的扫描转换时间是单次扫描的tSCAN减去tED。连续扫描模式下第二个和后续周期的扫描转换时间固定如下：tDIS×n+tDIAG+tDSD+tCONV×n*3

注1.未选择断线检测辅助时，tDIS=0。

只有当内部参考电压经过AD转换时，才会插入15个ADCLK状态的自动放电周期。

注2.不使用自诊断功能时，tDIAG=0，tDSD=0。

注3.当所有选定通道的输入采样时间(tSPL)相同时，该元素等于tCONV×n。如果每个通道具有不同的采样时间，则该元素等于为每个选定通道设置的tSPL和tSAM。

表35.23显示了扫描期间的转换时间。

35.3.7 Usage Example of A/D Data Register Automatic Clearing Function

Setting the ADCER.ACE bit to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADOCDR) to 0x0000 when the A/D data registers are read by the CPU or DTC or DMAC.

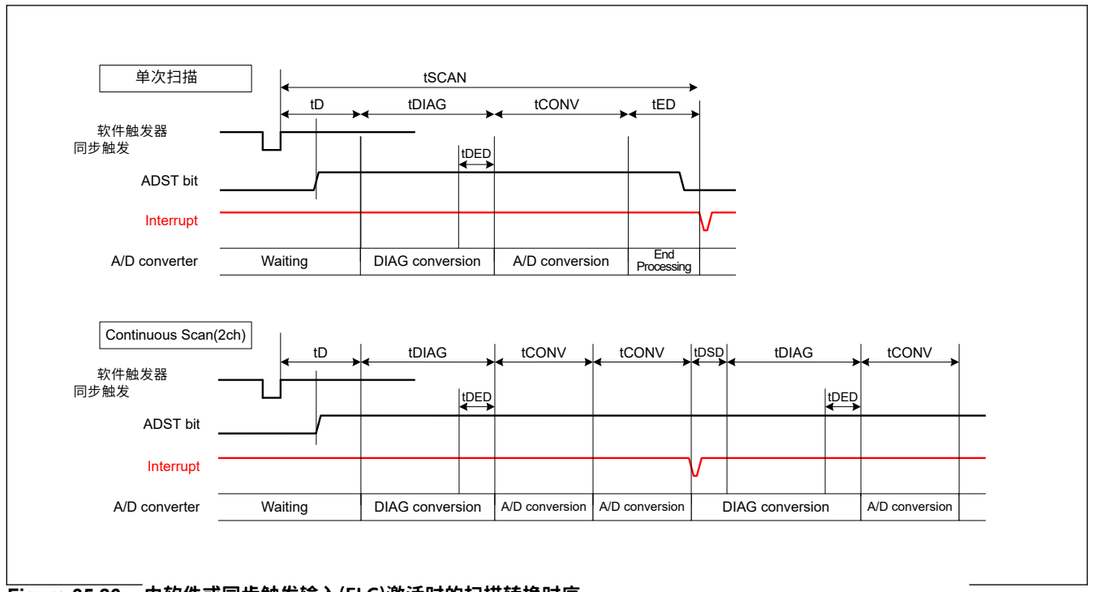

Figure 35.26 由软件或同步触发输入(ELC)激活时的扫描转换时序

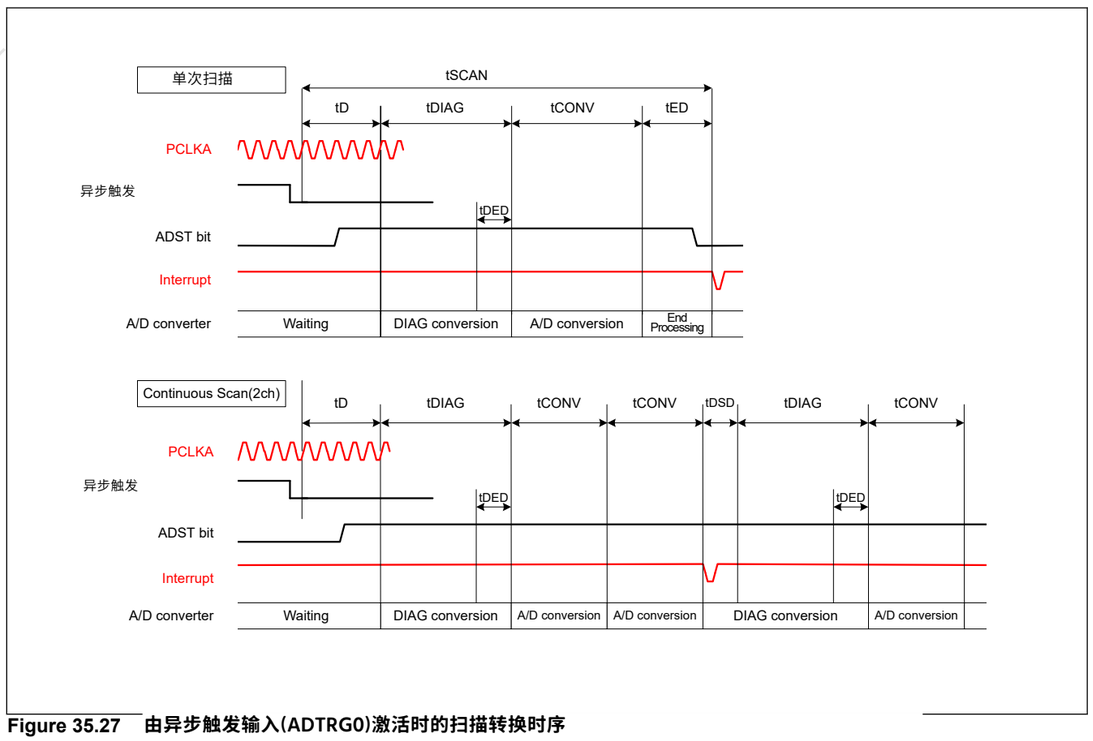

Figure 35.27 由异步触发输入(ADTRG0)激活时的扫描转换时序

35.3.7 AD数据寄存器自动清除功能的使用示例

将ADCER.ACE位设置为1会自动清除AD数据寄存器（ADDRy、ADRD、ADDBLDR、ADDBLDRA、当CPU或DTC或DMAC读取AD数据寄存器时，ADDBLDRB ADOCDR)为0x0000。

This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADOCDR). This section describes examples in which the function to automatically clear the ADDRy register is enabled and disabled.

- If the ADCER.ACE bit is 0 (automatic clearing is disabled) and for some reason, if the A/D conversion result (0x0222) is not written to the ADDRy register, the ADDRy value retains the old data (0x0111). In addition, if this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, the old data (0x0111) can be saved in the general-purpose register. When checking whether there is an update failure, it is necessary to frequently save the old data in SRAM or in a general-purpose register.
- If the ADCER.ACE bit is 1 (automatic clearing is enabled), when ADDRy = 0x0111 is read by the CPU or DTC or DMAC, ADDRy is automatically set to 0x0000. Next, if the A/D conversion result of 0x0222 cannot be transferred to ADDRy for some reason, the cleared data (0x0000) remains as the ADDRy value. If this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, 0x0000 is saved in the general-purpose register. Occurrence of an ADDRy update failure can be determined by checking that the read data value is 0x0000.

35.3.8 A/D-Converted Value Addition/Average Mode

A/D-converted value addition/average mode can be used when A/D conversion of the analog input of the selected channels, the internal reference voltage is selected.

In A/D-converted value addition mode, the same channel is A/D-converted 1, 2, 3, 4, or 16 consecutive times, and the sum of the converted values is stored in the data register. The conversion count of the addition function can be set to 16 only when 12-bit accuracy is selected. In A/D-converted value average mode, the same channel is A/D-converted 1, 2, or 4 consecutive times, and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition/average function can be used when A/D conversion of the analog inputs of the selected channels or A/D conversion of the internal reference voltage is selected. The A/D-converted value addition/average function can also be used for channels for which the double-trigger function is selected.

The addition function for self-diagnosis is not provided.

35.3.9 Disconnection Detection Assist Function

The ADC12 incorporates a function to fix the charge for sampling capacitance to the specified state VREFH0 or VREFL0 before the start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

Figure 35.28 shows the A/D conversion operation when the disconnection detection assist function is used. Figure 35.29 shows an example of disconnection detection when precharge is selected. Figure 35.30 shows an example of disconnection detection when discharge is selected.

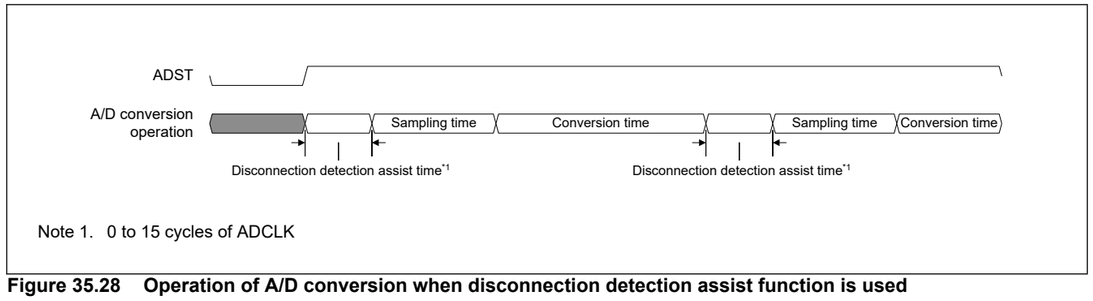

Figure 35.28 Operation of A/D conversion when disconnection detection assist function is used

此功能可以检测AD数据寄存器（ADDRy、ADRD、ADDBLDR、ADDBLDRA、ADDBLDRB、ADOCDR）。本节介绍启用和禁用自动清除ADDRy寄存器的功能的示例。

●如果ADCER.ACE位为0（禁止自动清零）并且由于某种原因，如果AD转换结果（0x0222）没有写入ADDRy寄存器，则ADDRy值保留旧数据（0x0111）。此外，如果使用AD扫描结束中断将该ADDRy值读入通用寄存器，则可以将旧数据（0x0111）保存在通用寄存器中。在检查是否有更新失败时，需要经常将旧数据保存在SRAM或通用寄存器中。

●如果ADCER.ACE位为1（使能自动清除），当ADDRy=0x0111时由CPU或DTC或DMAC ADDRy自动设置为0x0000。接下来，如果0x0222的AD转换结果由于某种原因无法传送到ADDRy，则清除的数据(0x0000)仍保留为ADDRy值。如果使用AD扫描结束中断将该ADDRy值读入通用寄存器，则将0x0000保存在通用寄存器中。ADDRy更新失败的发生可以通过检查读取的数据值为0x0000来确定。

35.3.8 一种D转换的增值平均模式

选择通道的模拟输入进行AD转换，选择内部参考电压时，可以使用D转换值加法平均模式。

在AD转换值加法模式下，同一通道连续1、2、3、4或16次AD转换，转换值的总和存储在数据寄存器中。只有选择12位精度时，才能将加法功能的转换计数设置为16。在AD转换值平均模式下，同一通道连续1、2或4次AD转换，转换值的平均值存储在数据寄存器中。根据存在的噪声成分的类型，使用这些结果的平均值可以提高AD转换的精度。但是，该功能不能始终保证AD转换精度的提高。

选择通道的模拟输入的AD转换或内部参考电压的AD转换时，可以使用AD转换值加法平均功能。AD转换值加法平均功能也可用于选择了双触发功能的通道。

不提供自我诊断的附加功能。

35.3.9 断线检测辅助功能

ADC12具有在开始AD转换之前将用于采样电容的电荷固定到指定状态VREFH0或VREFL0的功能。此功能可在模拟输入接线中进行断线检测。

图35.28显示了使用断线检测辅助功能时的AD转换操作。图35.29显示了选择预充电时的断线检测示例。图35.30显示了选择放电时的断线检测示例。

35.3.10 Starting A/D Conversion with an Asynchronous Trigger

A/D conversion can be started by the input of an asynchronous trigger. To start A/D conversion by an asynchronous trigger, set the pin function in the PmnPFS register, set the A/D Conversion Start Trigger Select bits (ADSTRGR.TRSA[5:0]) to 0x00, then input a high-level signal to the asynchronous trigger (ADTRG0 pin). Finally, set both the ADCSR.TRGE and ADCSR.EXTRG bits to 1. Figure 35.31 shows timing of the asynchronous trigger input.

An asynchronous trigger cannot be selected in the A/D conversion start trigger for group B used in group scan mode. For details on setting the pin function, see section 19, I/O Ports.

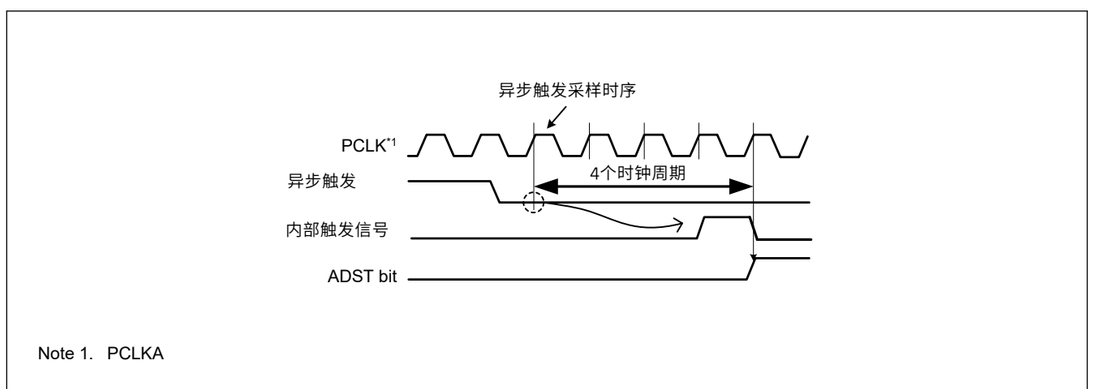
注1.由于断线时的结果数据因外部电路而异，因此应在充分评估后使用转换结果。

Figure 35.30 选择放电时的断线检测示例

35.3.10 使用异步触发启动AD转换

可以通过输入异步触发器来启动D转换。要通过异步触发启动AD转换，请在PmnPFS寄存器中设置引脚功能，将AD转换启动触发选择位(ADSTRGR.TRSA[5:0])设置为0x00，然后向异步触发输入高电平信号（ADTRG0引脚）。最后，将ADCSR.TRGE和ADCSR.EXTRG位都设置为1。图35.31显示了异步触发输入的时序。

在组扫描模式中使用的B组的AD转换开始触发中不能选择异步触发。有关设置引脚功能的详细信息，请参见第19节，IO端口。



Note 1. PCLKA

Figure 35.31 异步触发输入时序

35.3.11 Starting A/D Conversion with a Synchronous Trigger from a Peripheral Module

A/D conversion can be started by a synchronous trigger (ELC). To do this, set the ADCSR.TRGE bit to 1 and the ADCSR.EXTRG bit to 0, and select the relevant sources in the ADSTRGR.TRSA[5:0] bits and ADSTRGR.TRSB[5:0] bits.

35.3.12 Using Data Buffers

This IP is provided with a ring buffer function consisting of 16 A/D data buffers. This function sequentially stores A/D conversion results other than self-diagnosis result (including addition/average results) in data buffers (ADBUFn, n = 0 to 15).

Each conversion result is stored at the timing when the A/D conversion result is stored in the data register, and most recent 16 conversion result data are retained.

The figure-below shows the schematic of data buffers, pointer, and overflow flag operations. When the BUFEN bit is set to 1, the A/D conversion result is transferred at each end of A/D conversion. The pointer indicates the number of data buffer to which the next transferred data is to be written. When data is written to up to buffer 15, the pointer is reset to 0000b and the overflow flag is set to 1. Subsequently transferred data overwrites the previously written data.

The overflow flag is reset to the initial value by writing 00h to the ADBUFPTR register.

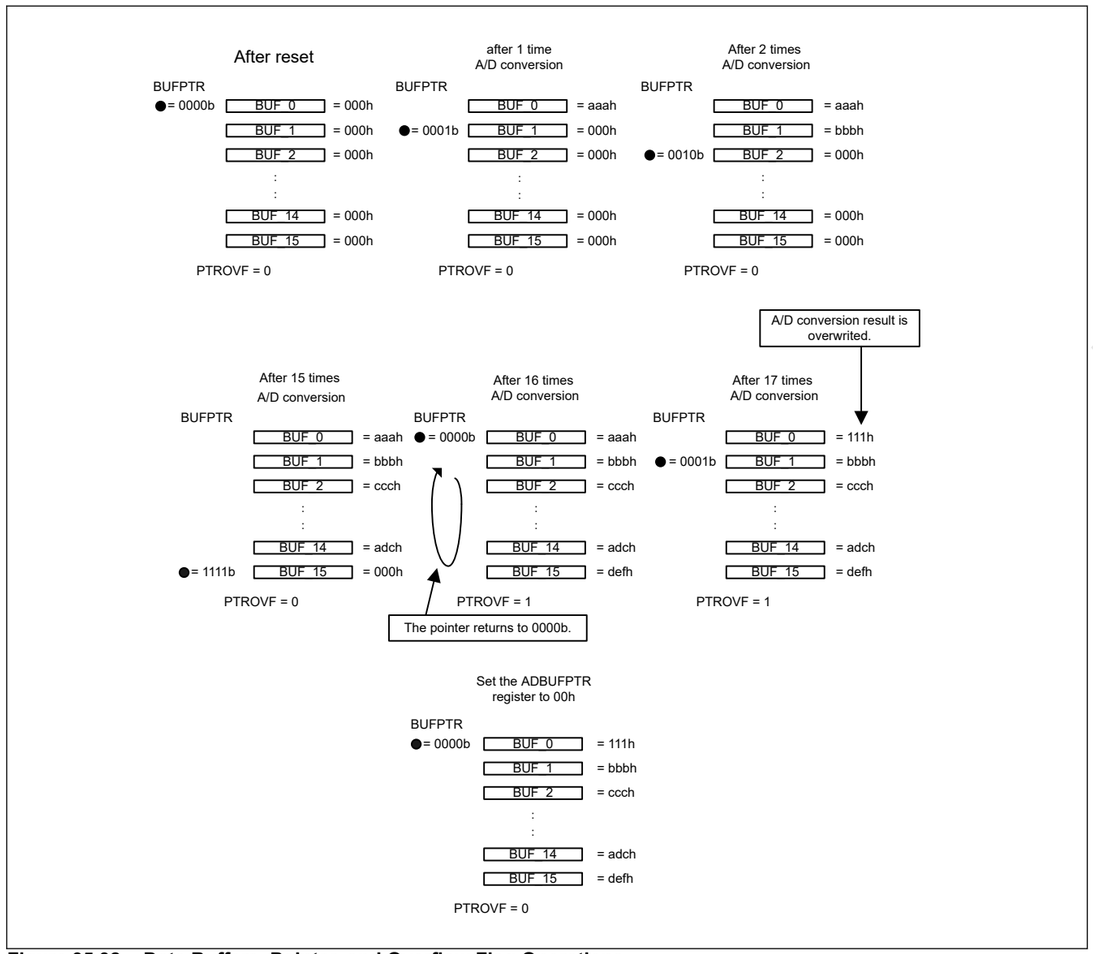


Figure 35.32 Data Buffers, Pointer, and Overflow Flag Operations

35.3.11 使用来自外设模块的同步触发启动AD转换

D转换可以通过同步触发器(ELC)启动。为此，将ADCSR.TRGE位设置为1，并将ADCSR.EXTRG位为0，并在ADSTRGR.TRSA[5:0]位和ADSTRGR.TRSB[5:0]位中选择相关源。

35.3.12 使用数据缓冲区

该IP具有由16个AD数据缓冲区组成的环形缓冲区功能。该功能将除自诊断结果以外的AD转换结果（包括加法平均结果）依次存储在数据缓冲区（ADBUFn，n=0至15）中。

每个转换结果在AD转换结果存储在数据寄存器中时存储，并保留最近的16个转换结果数据。

下图显示了数据缓冲区、指针和溢出标志操作的示意图。当BUFEN位设置为1时，AD转换结果在AD转换的每一端传送。指针指示要写入下一个传输数据的数据缓冲区的编号。当数据写入缓冲区15时，指针复位为0000b，溢出标志设置为1。随后传输的数据将覆盖先前写入的数据。

通过将00h写入ADBUFPTR寄存器，溢出标志复位为初始值。

35.4 Interrupt Sources and DTC, DMAC Transfer Requests

35.4.1 Interrupt Requests

The ADC12 can send scan end interrupt requests ADC120_ADI and ADC120_GBADI to the CPU. The ADC12 also generates the ADC120_CMPAI/ADC120_CMPBI interrupt for the CPU in response to matches with a condition for comparison.

An ADC120_ADI interrupt is always generated. An ADC120_GBADI interrupt can be generated by setting the ADCSR.GBADIE bit to 1. Similarly, ADC120_CMPAI and ADC120_CMPBI interrupts can be generated by setting the ADCMPCR.CMPAIE and ADCMPCR.CMPBIE bit to 1.

In addition, the DTC or DMAC can be started when an ADC120_ADI or an ADC120_GBADI interrupt is generated. Using an ADC120_ADI or ADC120_GBADI interrupt to activate the DTC or DMAC to read the converted data enables continuous conversion without a burden on software.

Table 35.24 describes the interrupt sources and ELC events available for the ADC12.

35.4 中断源和DTC、DMAC传输请求

35.4.1 中断请求

ADC12可以向CPU发送扫描结束中断请求ADC120_ADI和ADC120_GBADI。ADC12还为CPU生成ADC120_CMPAIADC120_CMPBI中断，以响应与比较条件的匹配。

始终会产生ADC120_ADI中断。一个ADC120_GBADI中断可以通过设置产生ADCSR.GBADIE位为1。类似地，ADC120_CMPAI和ADC120_CMPBI中断可以通过设置ADCMPCR.CMPAIE和ADCMPCR.CMPBIE位为1。

此外，当ADC120_ADI或ADC120_GBADI中断产生时，可以启动DTC或DMAC。使用ADC120_ADI或ADC120_GBADI中断来激活DTC或DMAC以读取转换后的数据可实现连续转换，而无需软件负担。

35.5 Event Link Function

35.5.1 Event Output to the ELC

The ELC uses the ADC120_ADI interrupt request signal as an event signal ADC120_ADI, enabling link operation for the preset module. The ADC120_GBADI interrupt and ADC120_CMPAI/ADC120_CMPBI interrupts cannot be used as an event signal. For details, see Table 35.24.

An event signal can be output regardless of the settings of the corresponding interrupt request enable bits. For the scan end event(ADC120_ADI), a high-level pulse for one PCLKA cycle is output at the same output timing as the interrupt output (ADC120_ADI) shown in Table 35.24. For a compare match (ADC120_WCMPM) and mismatch event (ADC120_WCMPUM) to the ELC, a high-level pulse for one PCLKA cycle is output at the timing delayed by one cycle (PCLKA) from the interrupt output (ADC120_ADI) shown in Table 35.24.

To use compare match (ADC120_WCMPM) or mismatch event (ADC120_WCMPUM) to the ELC, specify single-scan mode.

35.5.2 ADC12 Operation through an Event from the ELC

The ADC12 can start A/D conversion by the preset event specified in the ELSRn settings for the ELC as follows:

- Select the ELC_AD00 signal in the ELC.ELSR8 register
- Select the ELC_AD01 signal in the ELC.ELSR9 register

35.5 事件链接功能

35.5.1 事件输出到ELC

ELC使用ADC120_ADI中断请求信号作为事件信号ADC120_ADI，为预设模块启用链接操作。ADC120_GBADI中断和ADC120_CMPAIADC120_CMPBI中断不能用作事件信号。详见表35.24。

无论相应中断请求使能位的设置如何，都可以输出事件信号。对于扫描结束事件（ADC120_ADI），1个PCLKA周期的高电平脉冲以与表35.24所示的中断输出（ADC120_ADI）相同的输出时序输出。对于到ELC的比较匹配(ADC120_WCMPM)和失配事件(ADC120_WCMPUM)，在表35.24所示的中断输出(ADC120_ADI)延迟一个周期(PCLKA)的时序上输出一个PCLKA周期的高电平脉冲。

要将比较匹配(ADC120_WCMPM)或不匹配事件(ADC120_WCMPUM)用于ELC，请指定单扫描模式。

35.5.2 ADC12通过来自ELC的事件进行操作

ADC12可以通过ELC的ELSRn设置中指定的预设事件启动AD转换，如下所示：

●选择ELC.ELSR8寄存器中的ELC_AD00信号

●选择ELC.ELSR9寄存器中的ELC_AD01信号

If an ELC event occurs during A/D conversion, the event is disabled.

35.6 Usage Notes

35.6.1 Constraints on Setting the Registers

Set each register while the ADCSR.ADST bit is 0.

35.6.2 Constraints on Reading the Data Registers

The following registers must be read in halfword units:

- A/D Data Registers
- A/D Data Duplexing Register
- A/D Data Duplexing Register A
- A/D Data Duplexing Register B
- A/D Internal Reference Voltage Register
- A/D Self-Diagnosis Data Register
- A/D Data Buffer Registers n (N = 0 to 15)

If a register is read twice in byte units, that is, the upper byte and lower byte are read separately, the A/D-converted value read initially might disagree with the A/D-converted value read subsequently. To prevent this, never read the data registers in byte units.

35.6.3 Constraints on Stopping A/D Conversion

(1) A/D Conversion Stop Procedure

To stop A/D conversion when an asynchronous trigger or a synchronous trigger is selected as the condition for starting A/D conversion, follow the procedure shown in Figure 35.33.

如果在AD转换期间发生ELC事件，则该事件被禁用。

35.6 使用说明

35.6.1 设置寄存器的限制

当ADCSR.ADST位为0时设置每个寄存器。

35.6.2 读取数据寄存器的限制

以下寄存器必须以半字为单位读取：

- AD数据寄存器
- AD数据双工寄存器
- AD数据双工寄存器A
- AD数据双工寄存器B
- AD内部参考电压寄存器
- AD自诊断数据寄存器
- AD数据缓冲寄存器n(N=0to15)

如果以字节为单位读取寄存器两次，即分别读取高字节和低字节，则最初读取的AD转换值可能与随后读取的AD转换值不一致。为防止这种情况，切勿以字节为单位读取数据寄存器。

35.6.3 停止AD转换的约束

(1) AD转换停止程序

TostopADconversionwhenanasynchronoustriggerorasynchronoustriggerisselectedastheconditionforstartingADconversion followtheprocedureshowninFigure35.33.

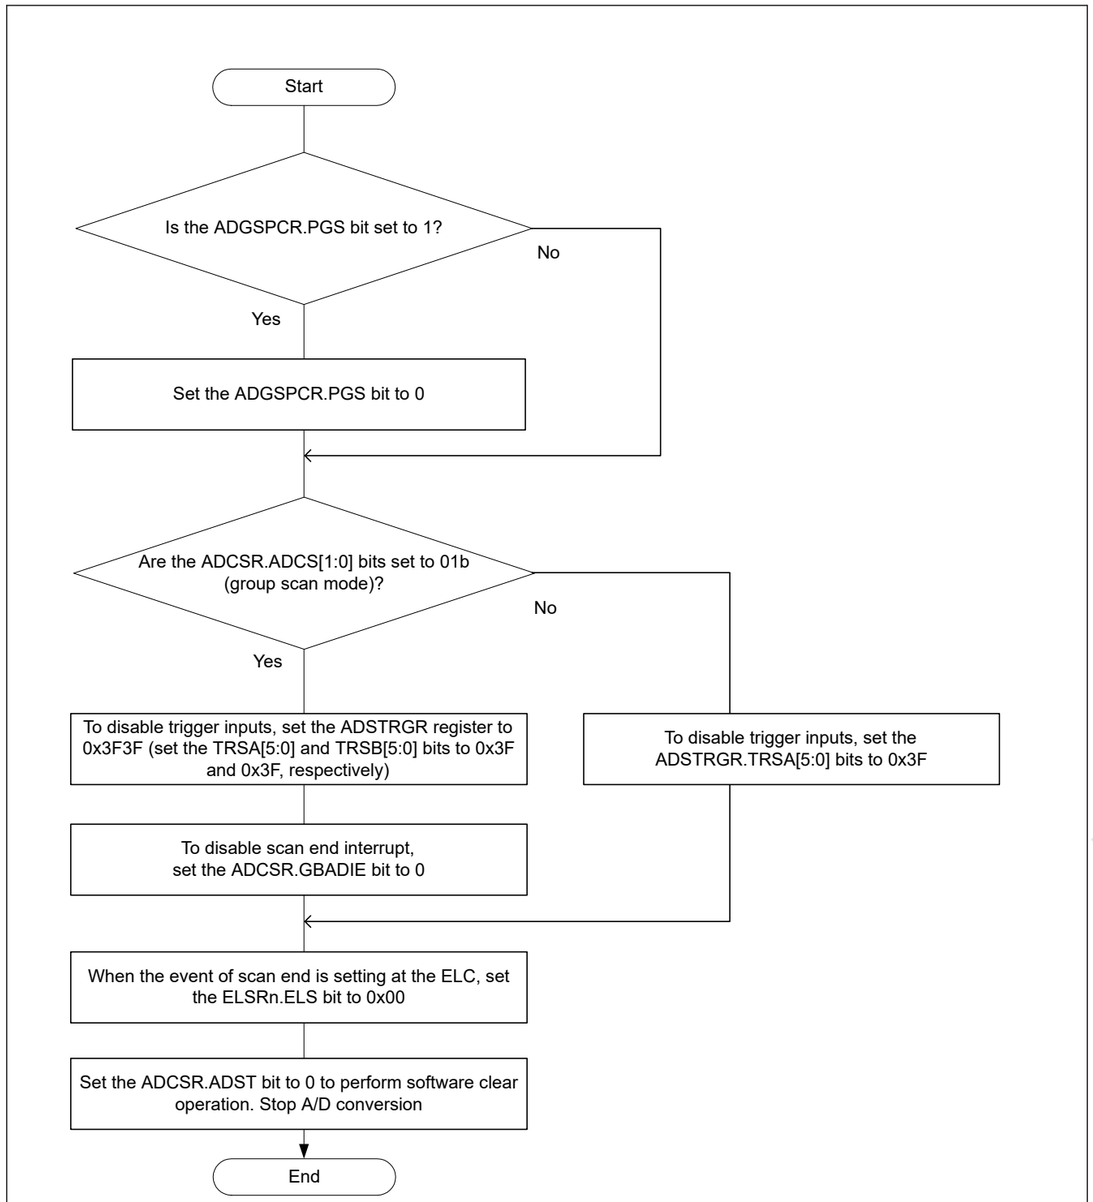

Figure 35.33 Procedures for clearing the ADCSR.ADST bit by software

To specify the following settings after performing the clear operation by software, provide a wait period for at least two ADCLK cycles.

- Enabling scan end interrupts
- Enabling scan end events for the event link controller
- Starting A/D conversion by software
- Enabling trigger input

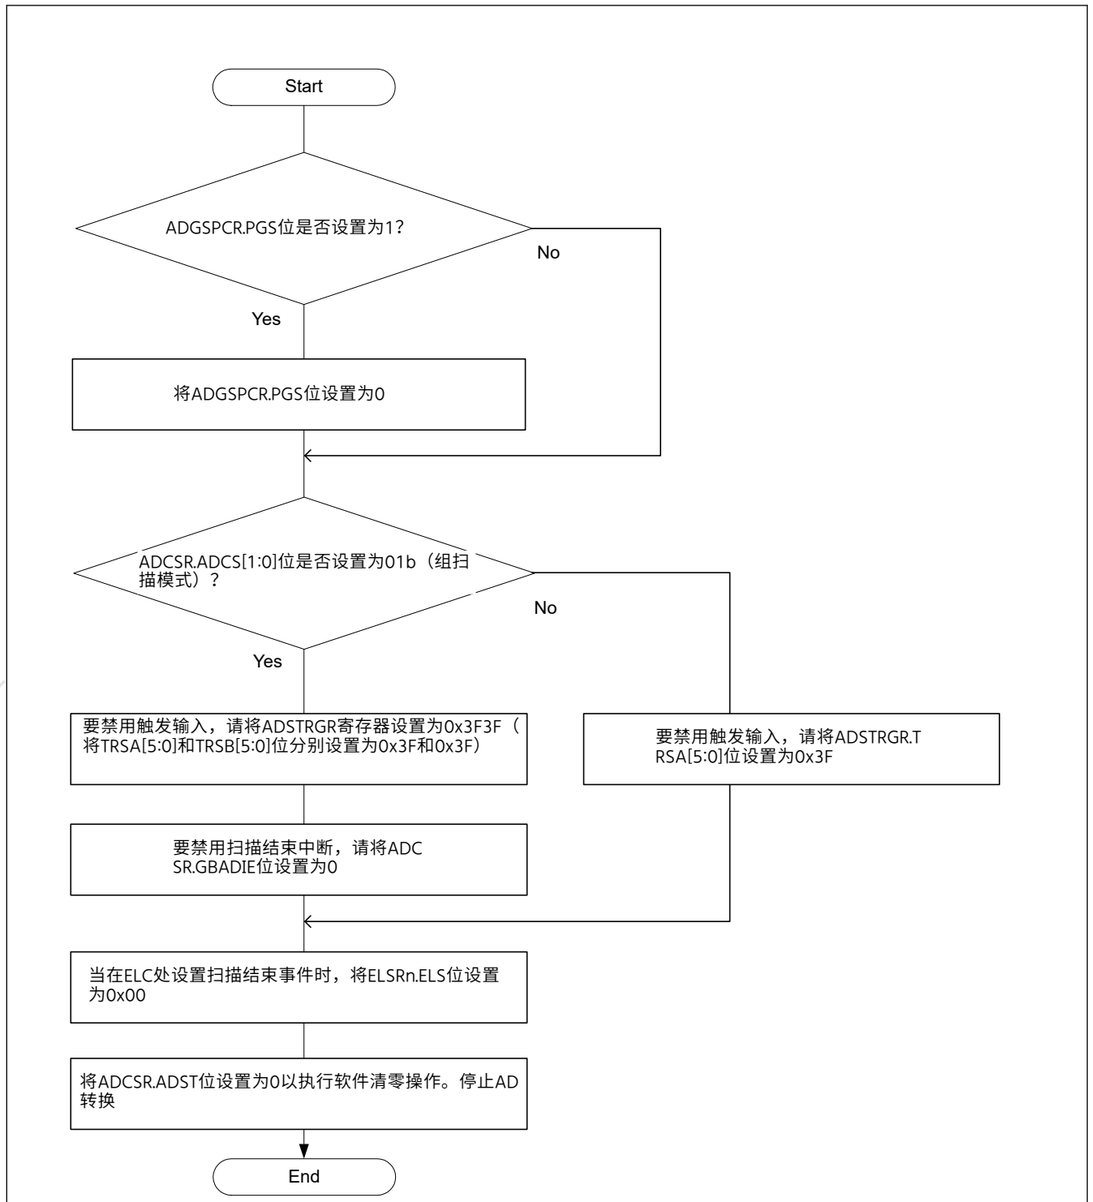

Figure 35.33 通过软件清除ADCSR.ADST位的程序

要在通过软件执行清除操作后指定以下设置，请提供至少两个等待时间ADCLK cycles.

- ●启用扫描结束中断
- ●为事件链接控制器启用扫描结束事件
- ●通过软件启动AD转换
- ●启用触发输入

(2) Notes on Modes and Status Bits

If necessary, individually initialize or set again the voltage status for self-diagnosis, the judgment of the even number or odd number specified for double-trigger mode, and the monitor flags of the compare function.

- To set again the voltage status for self-diagnosis, set the ADCER.DIAGLD bit to 1 and then set a desired value in the ADCER.DIAGVAL[1:0] bits.
- If the setting of the ADCSR.DBLE bit is changed from 0 to 1, the double-trigger mode operation starts from the first scanning.
- To initialize the monitor flags of the compare function (MONCMPA, MONCMPB, and MONCOMB), set the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits to 0.

35.6.4 A/D Conversion Restart and Termination Timing

A maximum of 6 ADCLK cycles is required for the idle analog unit of the ADC12 to restart on setting the ADCSR.ADST bit to 1. A maximum of 2 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0.

35.6.5 Constraints on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data. This occurs when the CPU does not complete the reading of the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

35.6.6 Settings for the Module-Stop Function

The Module Stop Control Register can enable or disable ADC12 operation. The ADC12 is initially stopped after a reset. The registers become accessible on release from the module-stop state. After release from the module-stop state, wait for at least 1 µs before starting A/D conversion. For details, see section 10, Low Power Modes.

35.6.7 Notes on Entering the Low-Power States

Before entering the module-stop state or Software Standby mode, be sure to stop A/D conversion. Set the ADCSR.ADST bit in ADCSR to 0 and secure certain period until the analog unit of the ADC12 stops. Follow the procedure shown in Figure 35.33 to clear the ADCSR.ADST bit with software. Then, wait for 2 clock cycles of ADCLK before entering the module-stop state or Software Standby mode.

35.6.8 Error in Absolute Accuracy When Disconnection Detection Assistance Is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the ADC12. This error arises because an erroneous voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull- down resistor (Rp) and the resistance of the signal source (Rs). This error in absolute accuracy is calculated from the following formula:

$$\text{Maximum error in absolute accuracy (LSB)} = \left(2^{\text{Resolution}} - 1\right) \times \text{Rs} / \left(\text{Rs} + \text{Rp}\right)$$

Only use disconnection detection assistance after thorough evaluation.

35.6.9 Constraints on Operating Modes and Status Bits

Initialize or set again individually, if necessary, the voltage values in self-diagnosis, the value of the first scan or second scan in double trigger mode, the data buffer pointer, and status monitor in the compare function.

- Select the voltage values in self-diagnosis (ADCER.DIAGVAL[1:0]) after setting ADCER.DIAGLD to 1.
- Double-trigger mode operates as the first scan after setting ADCSR.DBLE from 0 to 1.
- The status monitor bits (MONCMPA, MONCMPB, MONCOMB) in the compare function are initialized after setting ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

(2) 模式和状态位注意事项

如有必要，单独初始化或重新设置电压状态以进行自诊断、双触发模式指定的偶数或奇数判断以及比较功能的监视标志。

●要再次设置自诊断的电压状态，请将ADCER.DIAGLD位设置为1，然后在ADCER.DIAGVAL[1:0]位中设置所需的值。

●如果ADCSR.DBLE位的设置从0变为1，则双触发模式操作从第一次扫描开始。

●要初始化比较函数的监控标志（MONCMPA、MONCMPB和MONCOMB），请将ADCMPCR.CMPAE和ADCMPCR.CMPBE位设置为0。

35.6.4 AD转换重启和终止时序

ADC12的空闲模拟单元最多需要6个ADCLK周期才能在将ADCSR.ADST位设置为1时重新启动。ADC12的操作模拟单元需要最多2个ADCLK周期才能在设置ADCSR时终止.ADST位为0。

35.6.5 扫描结束中断处理的约束

当使用任何触发器扫描相同的模拟输入两次时，第一个AD转换数据将被第二个AD转换数据覆盖。当CPU在

在产生第一次扫描结束中断后，第二次扫描的第一个模拟输入的D转换结束。

35.6.6 模块停止功能的设置

模块停止控制寄存器可以启用或禁用ADC12操作。ADC12在复位后最初停止。
寄存器在从模块停止状态释放时变得可访问。从模块停止状态释放后，至少等待1µs再开始AD转换。有关详细信息，请参阅第10节，低功耗模式。

35.6.7 进入低功耗状态的注意事项

在进入模块停止状态或软件待机模式之前，请务必停止AD转换。将ADCSR中的ADCSR.ADST位设置为0并确保一定的时间，直到ADC12的模拟单元停止。按照图35.33所示的过程用软件清零ADCSR.ADST位。然后，在进入模块停止状态或软件待机模式之前等待ADCLK的2个时钟周期。

35.6.8 使用断线检测辅助时的绝对精度误差

使用断开检测辅助会导致ADC12的绝对精度出现误差。由于上拉或下拉电阻(Rp)与信号源电阻(Rs)之间的电阻分压，导致错误电压输入到模拟输入引脚，因此会出现此错误。该绝对精度误差由以下公式计算得出：

绝对精度的最大误差(LSB)=2分辨率 1×RsRs+Rp)

仅在全面评估后使用断线检测辅助。

35.6.9 操作模式和状态位的限制

必要时单独初始化或重新设置自诊断中的电压值、双触发模式下的第一次扫描或第二次扫描的值、数据缓冲区指针和比较功能中的状态监视器。

●设置ADCER.DIAGLD为1后，选择自诊断中的电压值（ADCER.DIAGVAL[1:0]）。

●双触发模式在将ADCSR.DBLE从0设置为1后作为第一次扫描运行。

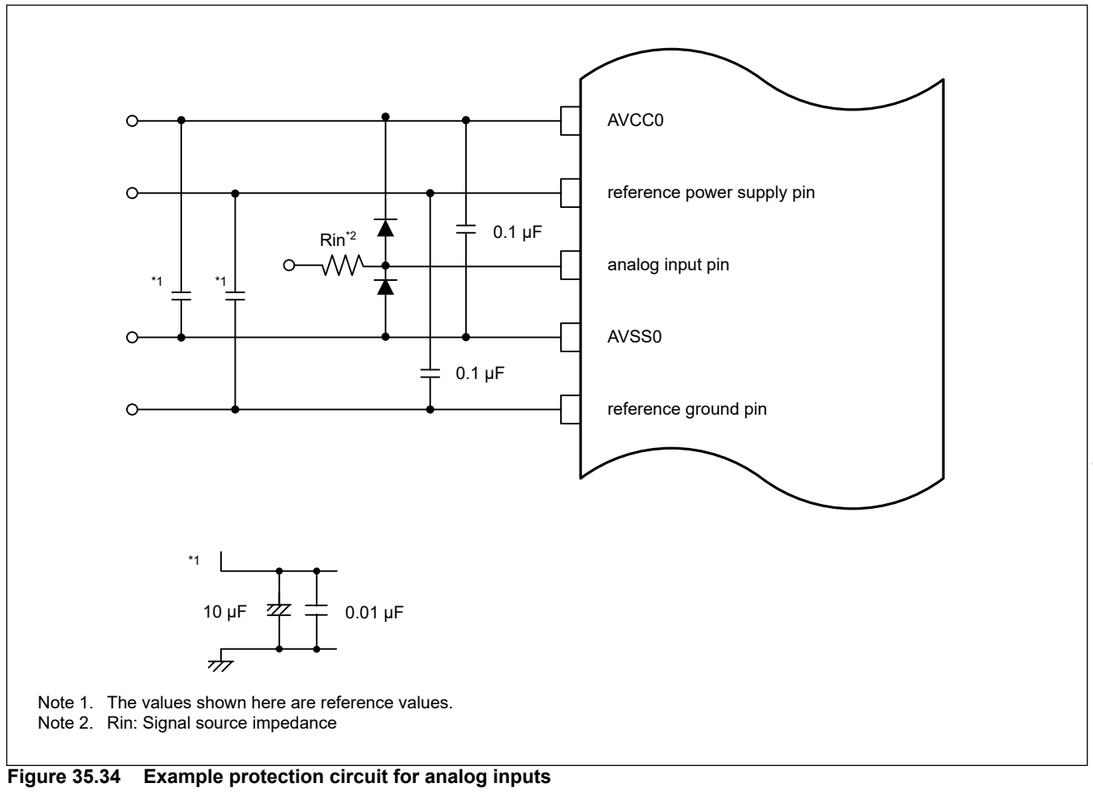
●比较功能中的状态监控位（MONCMPA、MONCMPB、MONCOMB）在设置ADCMPCR.CMPAE和ADCMPCR.CMPBE为0后被初始化。

35.6.10 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible. In addition, digital circuit signal lines and analog circuit signal lines should not intersect or be placed near each other. If these rules are not followed, noise can occur on analog signals and A/D conversion accuracy is affected. The analog input pins, reference power supply pin (VREFH0), reference ground pin (VREFL0), and analog power supply (AVCC0) should be separated from digital circuits using the analog ground (AVSS0). The analog ground (AVSS0) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

35.6.11 Constraints on Noise Prevention

To prevent the analog input pins from being destroyed by abnormal voltage such as excessive surge, insert a capacitor between AVCC0 and AVSS0 and between VREFH0 and VREFL0. Additionally, connect a protection circuit to protect the analog input pins as shown in Figure 35.34.



Note 1. The values shown here are reference values.
Note 2. Rin: Signal source impedance

Figure 35.34 Example protection circuit for analog inputs

35.6.12 Port Settings When Using the ADC12 Input

When using the high-precision channels, do not use PORT0 as general I/O. Renesas recommends that you do not use the digital output that is also used as the AD analog input if normal-precision channel is used. If the digital output that is also used as the AD analog input is used for output signals, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

35.6.13 Notes on Canceling Software Standby Mode

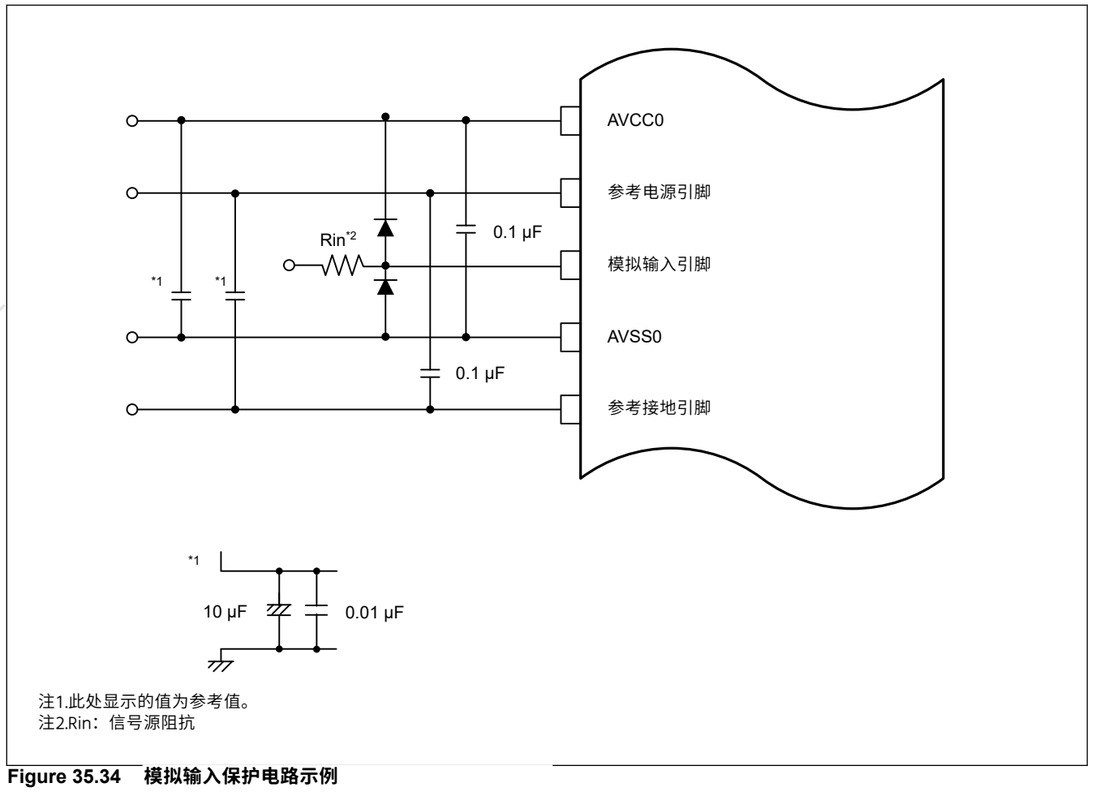
After software standby mode is canceled, wait at least 1 µs after the stabilization time for the oscillator elapses and before starting A/D conversion. For details, see section 10, Low Power Modes

35.6.10 电路板设计注意事项

电路板的设计应使数字电路和模拟电路尽可能分开。此外，数字电路信号线和模拟电路信号线不应交叉或靠近。如果不遵守这些规则，模拟信号上可能会出现噪声，影响AD转换精度。模拟输入引脚、参考电源引脚(VREFH0)、参考接地引脚(VREFL0)和模拟电源(AVCC0)应与使用模拟接地(AVSS0)的数字电路分开。模拟接地(AVSS0)应连接到板上的稳定数字接地(VSS)（单点接地层连接）。

35.6.11 防止噪音的限制

为防止模拟输入引脚被过大浪涌等异常电压损坏，请在AVCC0和AVSS0之间以及VREFH0和VREFL0之间插入一个电容器。此外，连接保护电路以保护模拟输入引脚，如图35.34所示。



注1.此处显示的值为参考值。
注2.Rin：信号源阻抗

Figure 35.34 模拟输入保护电路示例

35.6.12 使用ADC12输入时的端口设置

使用高精度通道时，请勿将PORT0用作通用IO。如果使用普通精度通道，瑞萨建议您不要使用同时用作AD模拟输入的数字输出。如果同时用作AD模拟输入的数字输出用于输出信号，则进行数次A/D转换，消除最大值和最小值，取其他结果的平均值。

35.6.13 关于取消软件待机模式的注意事项

取消软件待机模式后，在振荡器的稳定时间过去后至少等待1µs，然后再开始AD转换。有关详细信息，请参阅第10节，低功耗模式

35.6.14 Calculation for sampling time

The sampling time can be easily estimated by the following figure and formula. This is the time to reach the voltage within 1/4 LSB.

$t_{SPL} = (R_{EXT} + R_{AD}) \times (C_{EXT} + C_{AD}) \times \ln (C_{AD} / (C_{EXT} + C_{AD}) \times 2^{N+2})$

R_{EXT} shows external signal source impedance
C_{EXT} shows external capacitance (pin capacitance*1 + PCB parasitic capacitance)
N = 12, 10 or 8 (conversion resolution)
C_{AD} = 5 pF (internal capacitance)
R_{AD} = 1.0 kΩ (internal resistance, case of high-speed channels)
R_{AD} = 2.0 kΩ (internal resistance, case of normal-speed channels)

Note 1. Typical value of analog input pin is 5 pF

For example, if R_{EXT} is 1 kΩ, C_{EXT} is 10 pF and N is 12 bits, t_{SPL} of high-speed channel is 258 ns.

This formula simplifies the general use case. This formula is not guaranteed and should be used only for estimation.

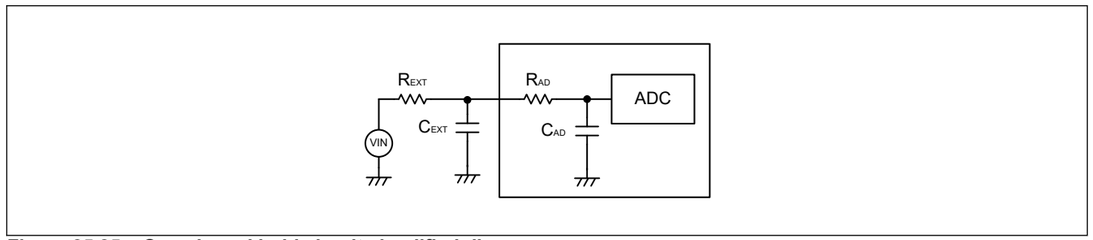


Figure 35.35 Sample and hold circuit simplified diagram

35.6.14 采样时间计算

采样时间可以通过下图和公式轻松估算。这是在14LSB内达到电压的时间。

tSPL=(REXT+RAD)×(CEXT+CAD)×ln(CAD(CEXT+CAD)×2N+2)

REXT显示外部信号源阻抗
CEXT表示外部电容（引脚电容*1+PCB寄生电容）
N = 12, 10 or 8 (conversion resolution)
C_{AD} = 5 pF (internal capacitance)
RAD=1.0kΩ（内部电阻，高速通道的情况）
RAD=2.0kΩ（内部电阻，正常速度通道的情况）

注1.模拟输入引脚的典型值为5pF

例如，如果REXT为1kΩ，CEXT为10pF，N为12位，则高速通道的tSPL为258ns。

此公式简化了一般用例。这个公式不能保证，只能用于估计。

DADRn寄存器是16位读写寄存器，用于存储用于DA转换的数据。当模拟输出使能时，DADRn中的值被转换并输出到模拟输出引脚。

在DADPR.DPSEL位设置中，12位数据可以被格式化为左对齐或右对齐。在右对齐格式(DADPR.DPSEL=0)中，低12位[11:0]有效。在左对齐格式(DADPR.DPSEL=1)中，高12位[15:4]有效。

Only set this register while the ADC12 is halted when the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled). Only set DACR while the ADCSR.ADST bit is 0 and after selecting the software trigger, for the ADC12 trigger to securely stop the ADC12.

DAE bit (D/A Enable)

The DAE bit controls D/A conversion, amplifier operation, and analog output in combination with the DAOEi bit (i = 0) and the DAAMPCR.DAAMPi bit (i = 0). See Table 36.4.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the ADCSR.ADST bit of the ADC12 to 0. Then, select the software trigger for the ADC12 trigger to securely stop the ADC12.

DAOE0 bit (D/A Output Enable 0)

The DAOE0 bit controls D/A conversion, amplifier operation, and analog output in combination with the DAE bit and DAAMPCR.DAAMPi bit (i = 0). See Table 36.4.

When both the DAOE0 bit and DAE bit are 0, D/A conversion of channel i (i = 0) is not processed, and no conversion result is output.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAOE0 bit while the ADCSR.ADST bit of the ADC12 is set to 0. Then, select the software trigger for the ADC12 trigger to securely stop the ADC12.

The event link function can be used to set the DAOE0 bit to 1. The DAOE0 bit is set to 1 when the event specified in the ELSR12 register of the ELC (ELC_DA0 event) occurs, and output of the D/A conversion results starts.

仅当DAADSCR.DAADST位为1时ADC12停止时才设置此寄存器（之间的干扰减少DA和AD转换已启用）。只有在ADCSR.ADST位为0且选择软件触发后设置DACR，ADC12触发才能安全停止ADC12。

DAE位（DA启用）

DAE位与DAOEi位(i=0)和DAAMPCR.DAAMPi位(i=0)一起控制DA转换、放大器操作和模拟输出。见表36.4。

当启用DA和AD转换之间的干扰减少(DAADSCR.DAADST=1)时，设置ADC12的ADCSR.ADST位为0。然后，选择ADC12触发的软件触发以安全停止ADC12。

DAOE0位（DA输出使能0）

DAOE0位与DAE位一起控制DA转换、放大器操作和模拟输出，以及DAAMPCR.DAAMPi位(i=0)。见表36.4。

当DAOE0位和DAE位均为0时，通道i(i=0)的DA转换不进行处理，不输出转换结果。

当启用DA和AD转换之间的干扰降低时（DAADSCR.DAADST=1），在ADC12的ADCSR.ADST位设置为0的同时设置DAOE0位。然后，选择ADC12触发的软件触发以安全停止ADC12。

事件链接功能可用于将DAOE0位设置为1。当在发生ELC（ELC_DA0事件）的ELSR12寄存器，开始输出DA转换结果。

To minimize interference between D/A and A/D conversion, the DAADSCR register enables synchronization of the start timing of D/A conversion with the ADC12 synchronous D/A conversion enable input signal.

Only set this register while the ADC12 is halted, that is, while the ADCSR.ADST bit is 0 after selecting the software trigger as the ADC12 trigger.

Select the target ADC12 unit before setting the DAADST bit to 1. Set DAADUSR[0] bit to 1 to select unit 0.

DAADST bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the register value to be converted into analog data at any time. Setting the DAADST bit to 1 allows synchronization of D/A conversion with the synchronous D/A conversion enable input signal from the ADC12. With this bit set, D/A conversion does not start until the ADC12 completes A/D conversion, even when the register is changed.

Set this bit while the ADCSR.ADST bit is set to 0. Then, select the software trigger for the ADC12 trigger to securely stop the ADC12. Set the DAADUSR.AMADSEL0 bit to 1 before setting the DAADST bit to 1.

The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR12 register of the ELC.

36.2.4 DAADSCR:DAAD同步启动控制寄存器

Offset address: 0x06

7	DAADST	DAAD同步转换 0：DAC12不与ADC12操作同步（禁用DA和AD转换之间的干扰降低）。 1：DAC12与ADC12操作同步（使能DA和AD转换之间的干扰降低）。	R/W

为了尽量减少DA和AD转换之间的干扰，DAADSCR寄存器使DA转换的开始时序与ADC12同步DA转换使能输入信号同步。

仅在ADC12停止时设置该寄存器，即选择软件触发作为ADC12触发后ADCSR.ADST位为0。

在将DAADST位设置为1之前选择目标ADC12单元。将DAADUSR[0]位设置为1以选择单元0。

DAADST位（DAAD同步转换）

将DAADST位设置为0可以随时将寄存器值转换为模拟数据。将DAADST位设置为1允许DA转换与来自ADC12的同步DA转换使能输入信号同步。设置该位后，ADC12完成AD转换后才开始DA转换，即使更改了寄存器也是如此。

在ADCSR.ADST位设置为0时设置该位。然后，选择ADC12触发的软件触发以安全地停止ADC12。在将DAADST位设置为1之前，将DAADUSR.AMADSEL0位设置为1。

当DAADST位设置为1时，不能使用事件链接功能。通过设置ELC的ELSR12寄存器。

36.2.5 DAAMPCR:DA输出放大器控制寄存器

DAAMPCR寄存器选择使用或不使用放大器的DA输出。

DAAMP0 bit (Amplifier Control 0)

When the DAAMP0 bit is 0, analog values are output for D/A output of channel 0 without using the amplifier. When the DAAMP0 bit is 1, analog values are output for D/A output of channel 0 through the amplifier.

When both the DACR.DAE and DACR.DAOE0 bits are 0, the amplifier is not used regardless of the setting of the DAAMP0 bit. See Table 36.4 for details.

36.2.6 DAASWCR : D/A Amplifier Stabilization Wait Control Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x1C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	DAASW0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

7	—	These bits are read as 0. The write value should be 0.	R/W

The DAASWCR register controls D/A output with the output amplifier. This register is used in the initialization procedure to wait for stabilization of the D/A output amplifier. Each bit in DAASWCR should be set to 1 when both the DACR.DAE bit and the DACR.DAOEi (i = 0) bit are 0. See section 36.6.5. Initialization Procedure with the Output Amplifier.

DAASW0 bit (D/A Amplifier Stabilization Wait 0)

Set the DAASW0 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 0 output amplifier. When DAASW0 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 0. When the DAASW0 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 0 is output through the output amplifier.

36.2.7 DAADUSR : D/A A/D Synchronous Unit Select Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x10C0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	AMADSEL0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AMADSEL0	A/D Unit 0 Select 0: Do not select unit 0 1: Select unit 0	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

The DAADUSR register selects the target ADC12 unit for D/A and A/D synchronous conversions. Set the AMADSEL0 bit to 1 to select unit 0 as the target synchronous unit for the MCU. When setting the DAADSCR.DAADST bit to 1 for synchronous conversions, select the target unit in this register in advance.

Only set the DAADUSR register while the ADCSR.ADST bit of the ADC12 is set to 0 and the DAADSCR.DAADST bit is set to 0.

DAAMP0位（放大器控制0）

当DAAMP0位为0时，模拟值输出通道0的DA输出，而不使用放大器。当。。。的时候DAAMP0位为1，模拟值通过放大器输出通道0的DA输出。

当DACR.DAE和DACR.DAOE0位都为0时，无论设置如何都不会使用放大器DAAMP0位。详见表36.4。

36.2.6 DAASWCR:DA放大器稳定等待控制寄存器

Base address: DAC12 = 0x4017_1000

Offset address: 0x1C

Bit position:	7	6	5	4	3	2	1	0

7	—	这些位被读取为0。写入值应为0。	R/W

DAASWCR寄存器通过输出放大器控制DA输出。该寄存器在初始化过程中用于等待DA输出放大器的稳定。当DACR.DAE位和DACR.DAOEi(i=0)位均为0时，DAASWCR中的每个位都应设置为1。请参见第36.6.5节。输出放大器的初始化程序。

DAASW0位（DA放大器稳定等待0）

在初始化过程中将DAASW0位设置为1，以等待DA通道0输出放大器稳定。当DAASW0设置为1时，DA转换进行，但DA的转换结果不从通道0输出。当DAASW0位为0时，稳定等待时间停止，通过输出输出通道0的DA转换结果放大器。

36.2.7 DAADUSR:DAAD同步单元选择寄存器

Base address: DAC12 = 0x4017_1000

Offset address: 0x10C0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	AMADSEL0
重置后的值:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W

1	—	该位读取为0。写入值应为0。	R/W
7:2	—	这些位被读取为0。写入值应为0。	R/W

DAADUSR寄存器为DA和AD同步转换选择目标ADC12单元。将AMADSEL0位设置为1以选择单元0作为MCU的目标同步单元。将DAADSCR.DAADST位设置为1以进行同步转换时，请预先在该寄存器中选择目标单位。

仅在ADC12的ADCSR.ADST位设置为0且DAADSCR.DAADST位设置为0时设置DAADUSR寄存器。

36.3 Operation

The DAC12 includes D/A conversion circuits for one channel. When the DAOEn bit (n = 0) in DACR is set to 1, DAC12 is enabled and the conversion result is output.

This following example shows D/A conversion on channel 0. Figure 36.2 shows the timing of this operation.

To process D/A conversion on channel 0:

1. Set the data for D/A conversion in the DADR0 register and the data format in the DADPR.DPSEL bit.
2. Set the DACR.DAOE0 bit to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time t_{DCONV} elapses. The conversion result continues to be output until DADR0 is written to again or the DAOE0 bit is set to 0. The output value (reference) is expressed by the following formula:

$$\frac{\text{Setting in DADR0}}{4096} \times \text{VREFH}$$

3. To start conversion again, write another value to DADR0. The conversion result is output after the conversion time t_{DCONV} elapses.
   When the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled), a maximum of one A/D conversion time is required for D/A conversion to start. When ADCLK is faster than the peripheral clock, a longer time might be required.
4. To disable analog output, set the DAOE0 bit to 0.

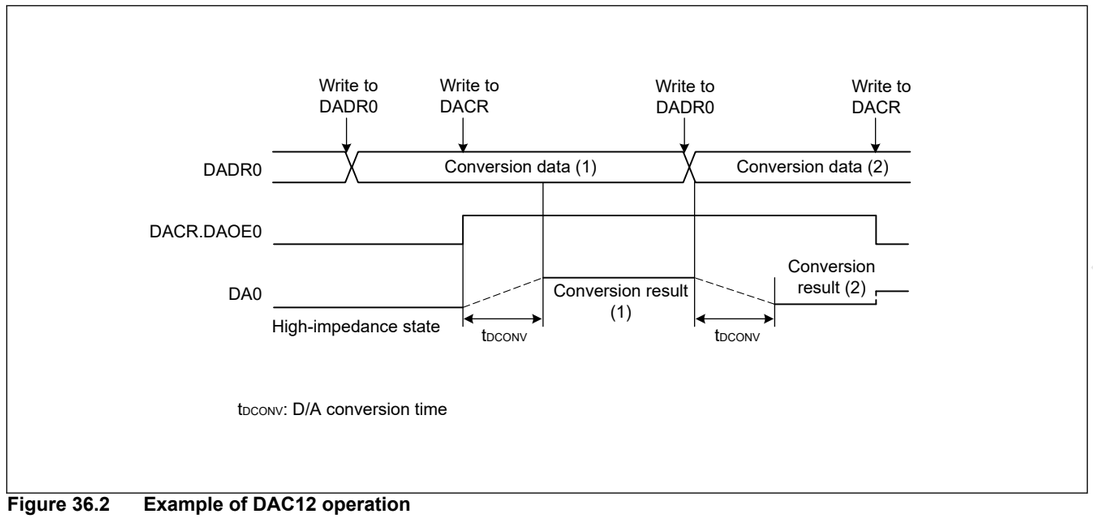

Figure 36.2 Example of DAC12 operation

36.3.1 Reducing Interference between D/A and A/D Conversion

When D/A conversion starts, the DAC12 generates inrush current. Because the DAC12 and ADC12 share the same analog power supply, the generated inrush current can interfere with ADC12 operation.

While the DAADSCR.DAADST bit is 1, D/A conversion does not start immediately on updating the DADRm register. Instead:

- If the DADRm register data is modified while the ADC12 is halted, D/A conversion starts in 1 PCLKA cycle.
- If the DADRm register data is modified while the ADC12 is performing a 12-bit A/D conversion, D/A conversion starts on A/D conversion completion. Therefore, it takes up to one A/D conversion time period for the DADRm register data update to be reflected as the D/A conversion circuit output. Until the D/A conversion completes, the DADRm register value does not correspond to the analog output value.

When the DAADSCR.DAADST bit is 1, it is not possible to check through software whether the register value was D/A-converted.

36.3 Operation

DAC12包括一个通道的DA转换电路。当DACR中的DAOEn位(n=0)设置为1时，DAC12使能并输出转换结果。

以下示例显示通道0上的DA转换。图36.2显示了此操作的时序。

在通道0上处理DA转换：

1.在DADR0寄存器中设置用于DA转换的数据，在DADPR.DPSEL位中设置数据格式。

2.将DACR.DAOE0位设置为1以启动DA转换。经过转换时间tDCONV后，转换结果从模拟输出引脚DA0输出。转换结果继续输出，直到再次写入DADR0或将DAOE0位设置为0。输出值（参考值）由以下公式表示：

$$\frac{\text{DADR04096中的设置}}{} \times \text{VREFH}$$

3.要再次开始转换，向DADR0写入另一个值。在经过转换时间tDCONV后输出转换结果。当DAADSCR.DAADST位为1时（启用DA和AD转换之间的干扰降低），最多需要一个AD转换时间才能启动DA转换。当ADCLK比外设时钟快时，可能需要更长的时间。

4.要禁用模拟输出，请将DAOE0位设置为0。

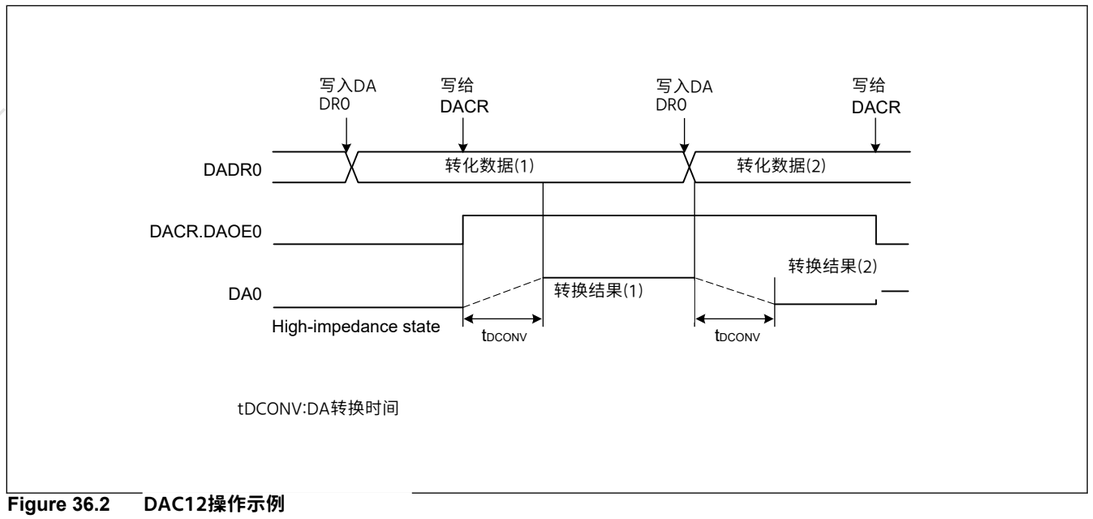

Figure 36.2 DAC12操作示例

36.3.1 减少DA和AD转换之间的干扰

当DA转换开始时，DAC12会产生浪涌电流。由于DAC12和ADC12共用同一个模拟电源，产生的浪涌电流会干扰ADC12的运行。

当DAADSCR.DAADST位为1时，DA转换不会在更新DADRm寄存器时立即开始。
Instead:

●如果在ADC12停止时修改了DADRm寄存器数据，则DA转换在1个PCLKA周期内开始。

●如果在ADC12执行12位AD转换时修改了DADRm寄存器数据，则DA转换在AD转换完成时开始。因此，DADRm寄存器数据更新最多需要一个AD转换时间周期才能反映为DA转换电路输出。在DA转换完成之前，DADRm寄存器的值与模拟输出值不对应。

当DAADSCR.DAADST位为1时，无法通过软件检查寄存器值是否经过DA转换。

The following sequence provides an example of D/A conversion, in which the DAC12 is synchronized with the ADC12. Figure 36.3 shows the timing of this operation.

To perform D/A conversion in synchronization with the ADC12:

1. Confirm that the ADC12 is halted and set the DAADUSR.AMADSEL0 bit to 1.
2. Confirm that the ADC12 is halted and set the DAADSCR.DAADST bit to 1.
3. Confirm that the ADC12 is halted and set the DACR.DAOE0 bit to 1.
4. Set the DADR0 register. If ADCLK is faster than the peripheral clock, D/A conversion might be delayed for longer than one A/D conversion time.
   - If the ADC12 is halted (ADCSR.ADST = 0) when the DADR0 register is modified, D/A conversion starts in 1 PCLKA cycle.
   - If the 12-bit A/D conversion is in progress (ADCSR.ADST = 1) when the DADR0 register is modified, D/A conversion starts on A/D conversion completion. If the DADR0 register is modified twice during A/D conversion, the first update might not be converted.

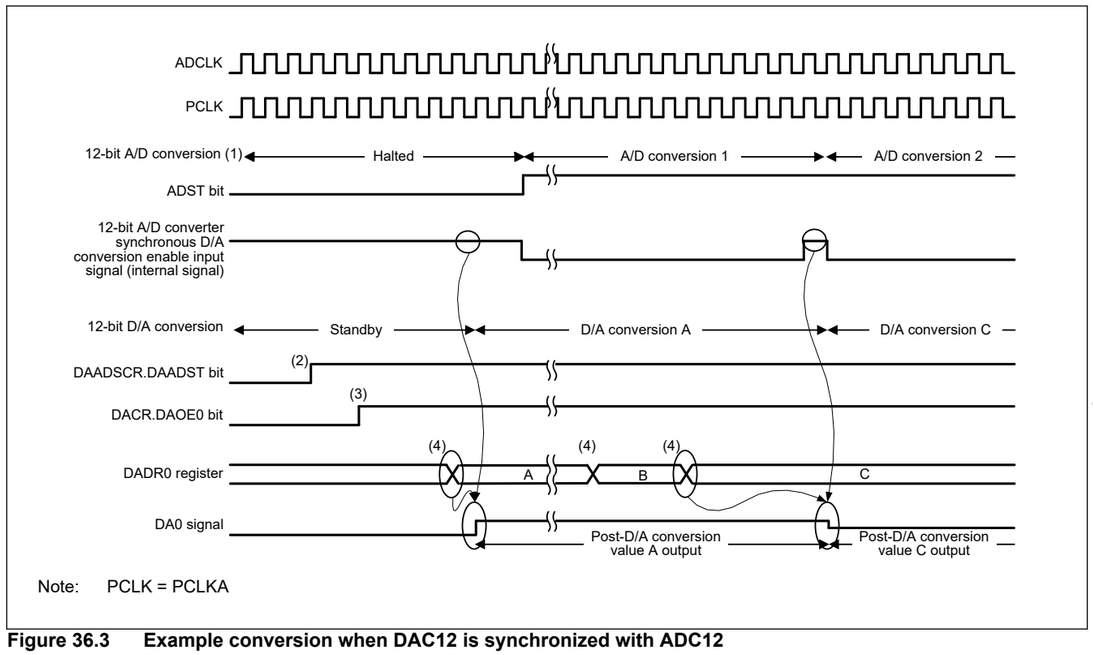

Figure 36.3 Example conversion when DAC12 is synchronized with ADC12

When ADCLK is faster than PCLKA, the DAC12 might not be able to capture the synchronous D/A conversion enable input signal from the ADC12 during the 1 ADCLK cycle that is output between A/D conversion 1 and A/D conversion 2, as shown in Figure 36.4. In this case, post-D/A conversion value A is continuously output as the DA0 signal.

以下序列提供了一个DA转换示例，其中DAC12与ADC12同步。
图36.3显示了此操作的时序。

与ADC12同步执行DA转换：

1.确认ADC12已停止并将DAADUSR.AMADSEL0位设置为1。

2.确认ADC12已停止并将DAADSCR.DAADST位设置为1。

3.确认ADC12已停止并将DACR.DAOE0位设置为1。

4.设置DADR0寄存器。如果ADCLK比外设时钟快，则DA转换可能会延迟超过一次AD转换时间。

- 如果在修改DADR0寄存器时ADC12停止（ADCSR.ADST=0），则DA转换在1个PCLKA周期内开始。
- 如果在修改DADR0寄存器时正在进行12位AD转换（ADCSR.ADST=1），则DA转换在AD转换完成时开始。如果在AD转换期间DADR0寄存器被修改两次，第一次更新可能不会被转换。

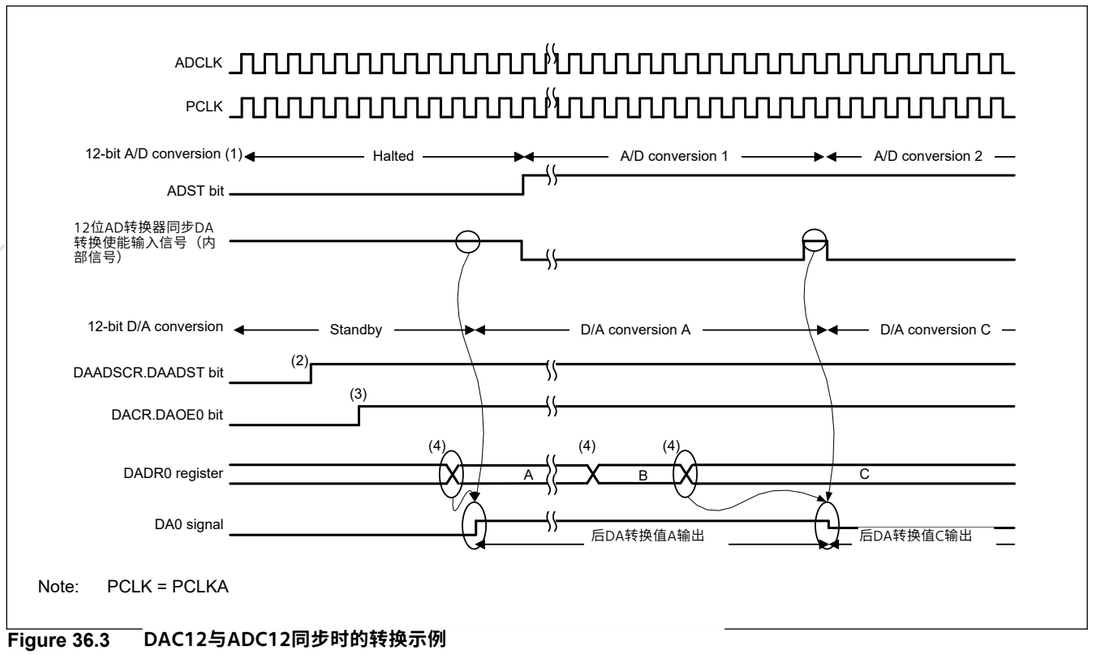

Figure 36.3 DAC12与ADC12同步时的转换示例

当ADCLK快于PCLKA时，DAC12可能无法在AD转换1和AD转换2之间输出的1个ADCLK周期内捕获来自ADC12的同步DA转换使能输入信号，如图36.4所示。在这种情况下，后DA转换值A作为DA0信号连续输出。

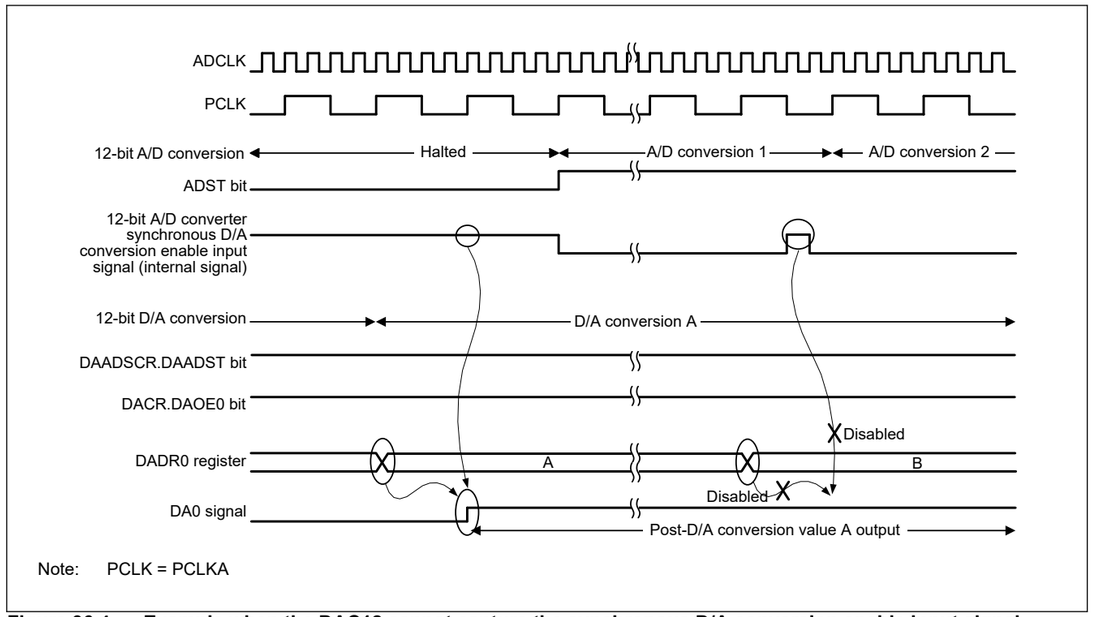

Figure 36.4 Example when the DAC12 cannot capture the synchronous D/A conversion enable input signal from the ADC12

36.4 Event Link Operation Setting Procedure

This section describes the procedures used in event link operation.

36.4.1 DA0 Event Link Operation Setting Procedure

To set up DA0 event link operation:

1. Set the DADPR.DPSEL bit and the data for D/A conversion in the DADR0 register.
2. Set the ELC_DA0 event signal to be linked to each peripheral module in the ELSR12 register.
3. Set the ELCR.ELCON bit to 1. This enables event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit becomes 1, and D/A conversion starts on channel 0.
5. Set the ELSR12 register to 0x0000 to stop event link operation of DAC12 channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

36.5 Usage Notes on Event Link Operation

- When the event link function is used, do not use the amplifier output function.
- When the event link function is used, set the DACR.DAE bit to 0.
- When the event specified for the ELC_DA0 event signal is generated while a write to the DACR.DAOE0 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 to reduce interference between D/A and A/D conversions.

36.6 Usage Notes

36.6.1 Settings for the Module-Stop Function

DAC12 operation can be disabled or enabled using the Module Stop Control Register. The DAC12 is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

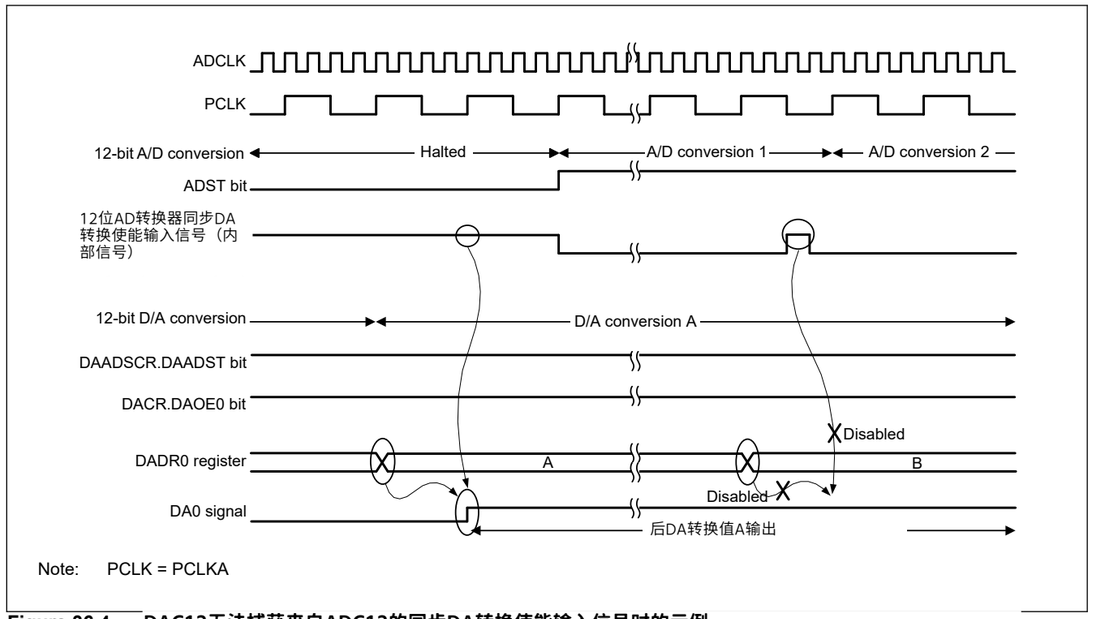

Figure 36.4 DAC12无法捕获来自ADC12的同步DA转换使能输入信号时的示例

36.4 事件链接操作设置步骤

本节介绍事件链接操作中使用的过程。

36.4.1 DA0事件链接操作设置步骤

设置DA0事件链接操作：

1.设置DADPR.DPSEL位和DADR0寄存器中用于DA转换的数据。

2.在ELSR12寄存器中设置ELC_DA0事件信号链接到每个外围模块。

3.将ELCR.ELCON位设置为1。这将为所有选择了事件链接功能的模块启用事件链接操作。

4.设置事件输出源模块，激活事件链接。模块输出事件后，DACR.DAOE0位变为1，通道0开始DA转换。

5.将ELSR12寄存器设置为0x0000以停止DAC12通道0的事件链接操作。所有事件链接操作在ELCR.ELCON位设置为0时停止。

36.5 事件链接操作使用说明

●使用事件链接功能时，请勿使用放大器输出功能。

●使用事件链接功能时，将DACR.DAE位设置为0。

●如果在执行对DACR.DAOE0位的写入时产生了为ELC_DA0事件信号指定的事件，则写入周期停止，并且产生的事件优先将该位设置为1。

●DAADSCR.DAADST位设置为1时禁止使用事件链接功能，以减少DA和AD转换之间的干扰。

36.6 使用说明

36.6.1 模块停止功能的设置

可以使用模块停止控制寄存器禁用或启用DAC12操作。DAC12在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

36.6.2 DAC12 Operation in the Module-Stop State

When the MCU enters the module-stop state with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in the module-stop state, disable D/A conversion by setting the DACR.DAOE0, and DAE bits to 0.

36.6.3 DAC12 Operation in Software Standby Mode

When the MCU enters Software Standby mode with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in Software Standby mode, disable D/A conversion by setting the DACR.DAOE0, and DAE bits to 0.

36.6.4 Constraint on Entering Deep Software Standby Mode

When the MCU enters Deep Software Standby mode with D/A conversion enabled, the outputs of the DAC12 are placed in a high impedance state.

36.6.5 Initialization Procedure with the Output Amplifier

Use the following initialization procedures with the output amplifier.

To initialize the DAC12 with the output amplifier:

1. Write 0x0000 to the DADR0 register.
2. Set the DAASWCR.DAASW0 bit to 1.
3. Set the DAAMPCR.DAAMP0 bit to 1.
4. Set the DACR.DAE bit or the DACR.DAOE0 bit to 1 to start operation of the amplifier.
5. Clear the DAASWCR.DAASW0 bit to 0 after waiting for the duration of D/A conversion time t_{DCONV}.
6. Write the value to be converted in the DADR0 register.

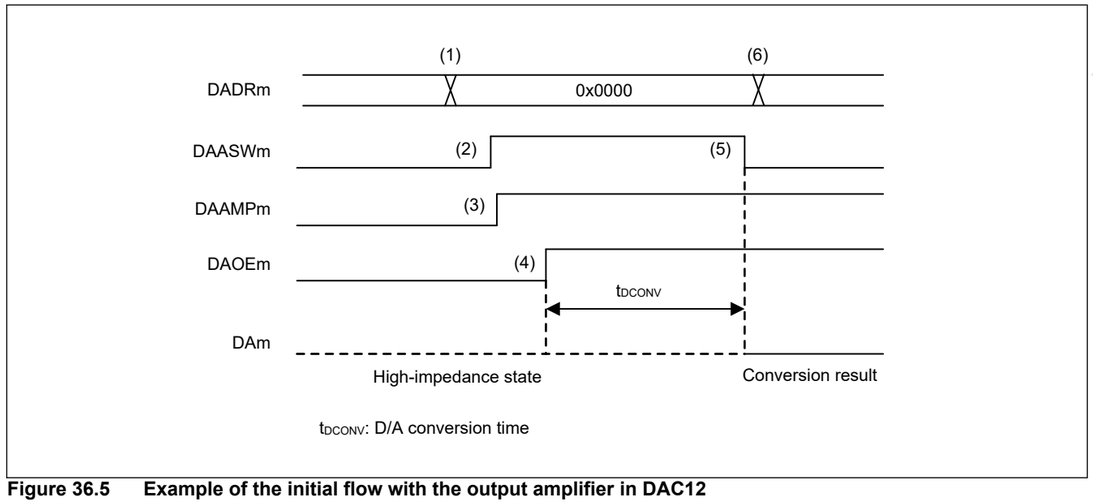

Figure 36.5 Example of the initial flow with the output amplifier in DAC12

While the amplifier is running, clearing the DACR.DAE and DACR.DAOE0 bits to 0 allows the amplifier to stop operation. To use the amplifier again, repeat steps 1 to 6.

36.6.6 Constraint on Usage When Interference Reduction between D/A and A/D Conversion Is Enabled

When the DAADSCR.DAADST bit is 1, enabling interference reduction between D/A and A/D conversion, do not place the ADC12 in the module-stop state. Doing so can halt D/A conversion in addition to A/D conversion.

36.6.2 DAC12在模块停止状态下的操作

当MCU进入模块停止状态并启用DA转换时，DA输出保持不变，模拟电源电流与DA转换时相同。如果必须在模块停止状态下降低模拟电源电流，则通过将DACR.DAOE0和DAE位设置为0来禁用DA转换。

36.6.3 DAC12在软件待机模式下的操作

当MCU进入软件待机模式并启用DA转换时，DA输出保持不变，模拟电源电流与DA转换期间相同。如果在软件待机模式下必须降低模拟电源电流，则通过将DACR.DAOE0和DAE位设置为0来禁用DA转换。

36.6.4 进入深度软件待机模式的限制

当MCU在启用DA转换的情况下进入深度软件待机模式时，DAC12的输出置于高阻抗状态。

36.6.5 输出放大器的初始化程序

对输出放大器使用以下初始化程序。

使用输出放大器初始化DAC12：

1.将0x0000写入DADR0寄存器。

2.将DAASWCR.DAASW0位设置为1。

3.将DAAMPCR.DAAMP0位设置为1。

4.将DACR.DAE位或DACR.DAOE0位设置为1以启动放大器的操作。

5.等待DA转换时间tDCONV后，将DAASWCR.DAASW0位清零。

6.将要转换的值写入DADR0寄存器。

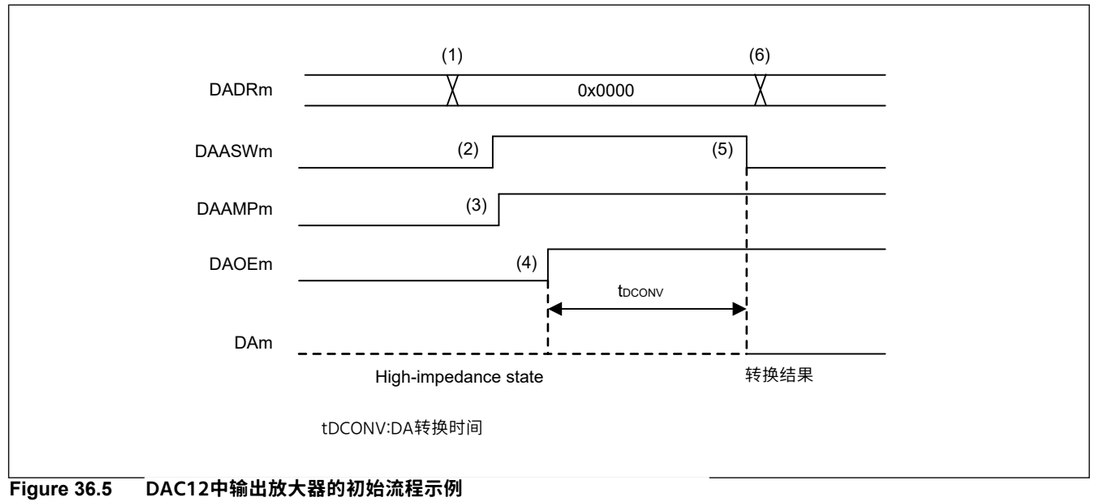

Figure 36.5 DAC12中输出放大器的初始流程示例

在放大器运行时，将DACR.DAE和DACR.DAOE0位清零可让放大器停止运行。要再次使用放大器，请重复步骤1至6。

36.6.6 DA和AD之间减少干扰时的使用限制转换已启用

当DAADSCR.DAADST位为1时，启用DA和AD转换之间的干扰减少，不要放置ADC12处于模块停止状态。除了AD转换之外，这样做还可以停止DA转换。

37.3 Operation

37.3.1 Data Comparison Mode

Figure 37.2 shows an example operation in data comparison mode operation by the DOC. The following sequence is an example operation when DCSEL is set to 0 (data mismatch is detected as a result of data comparison):

1. Write 00b to the DOCR.OMS[1:0] bits to select data comparison mode.
2. Set 16-bit reference data in DODSR.
3. Write the 16-bit data for comparison to DODIR.
4. Continue writing the 16-bit data until all data for comparison is written to DODIR.
5. If a value written to DODIR does not match that in DODSR, the DOCR.DOPCF flag is set to 1.

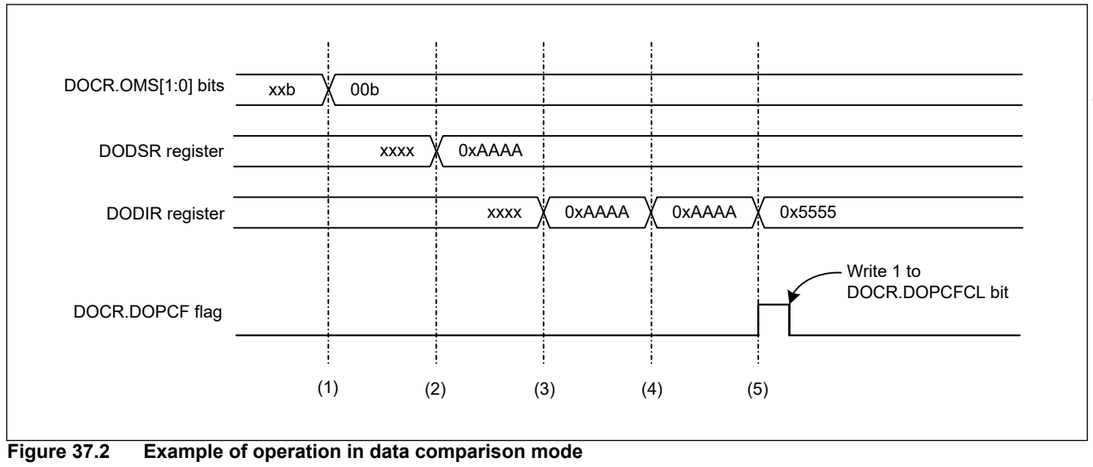

Figure 37.2 Example of operation in data comparison mode

37.3.2 Data Addition Mode

Figure 37.3 shows an example operation in data addition mode. The steps are as follows:

1. Write 01b to the DOCR.OMS[1:0] bits to select data addition mode.
2. Set 16-bit data as the initial value in the DODSR register.
3. Write the 16-bit data to be added to the DODIR register. The result of the operation is stored in the DODSR register.
4. Continue writing the 16-bit data until all data to be added is written to the DODIR.
5. If the result of an operation is greater than 0xFFFF, the DOCR.DOPCF flag is set to 1.

1.将00b写入DOCR.OMS[1:0]位以选择数据比较模式。

2.在DODSR中设置16位参考数据。

3.将16位数据写入DODIR进行比较。

3.将要添加的16位数据写入DODIR寄存器。运算结果存储在DODSR寄存器中。

4.继续写入16位数据，直到所有要添加的数据都写入DODIR。

5.如果运算结果大于0xFFFF，则DOCR.DOPCF标志设置为1。

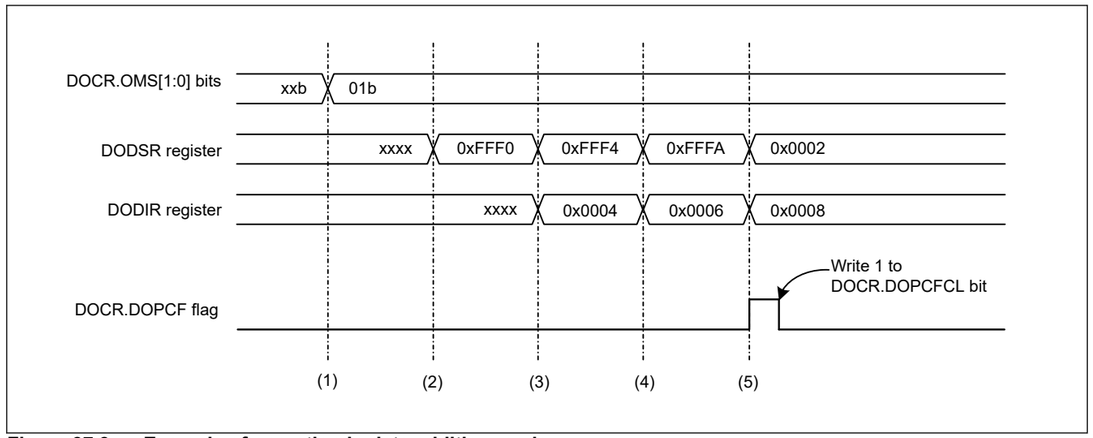

Figure 37.3 Example of operation in data addition mode

37.3.3 Data Subtraction Mode

Figure 37.4 shows an example operation in data subtraction mode. The steps are as follows:

37.4 Interrupt Source

The DOC generates the DOC interrupt (DOC_DOPCI) as an interrupt request. Table 37.2 describes the DOC interrupt request.

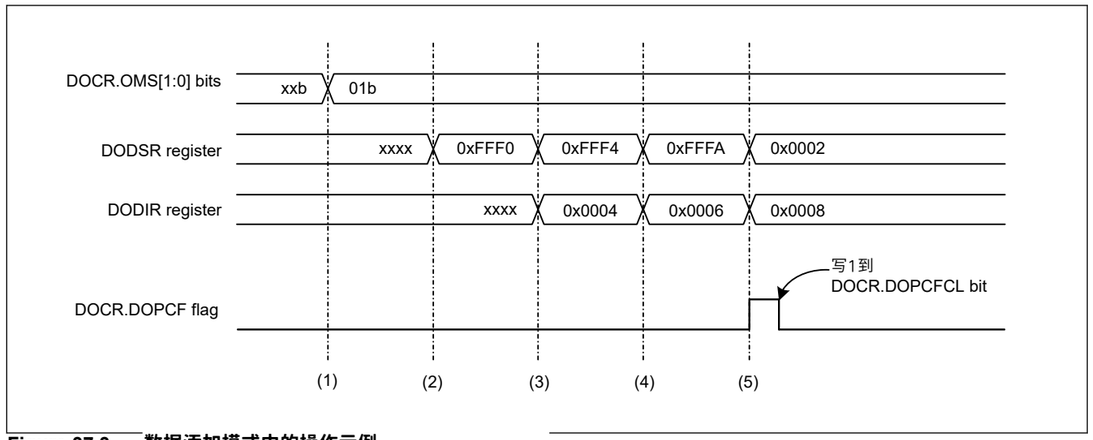

Figure 37.3 数据添加模式中的操作示例

37.3.3 数据减法模式

图37.4显示了数据减法模式下的示例操作。步骤如下：

1.将10b写入DOCR.OMS[1:0]位以选择数据减法模式。

3.将要减去的16位数据写入DODIR寄存器。操作结果存储在DODSR中。

4.继续将16位数据写入DODIR寄存器，直到写入所有要减去的数据。

5.如果运算结果小于0x0000，则DOCR.DOPCF标志设置为1。

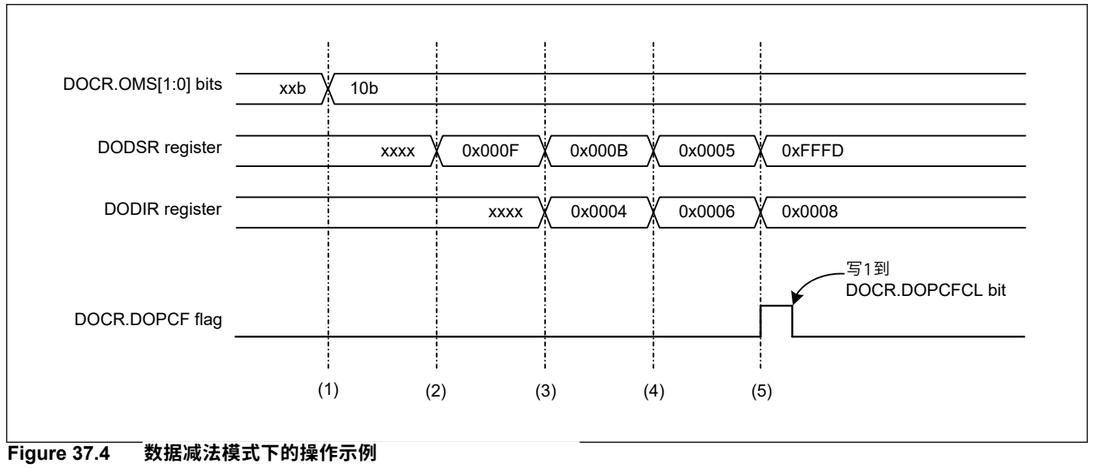

Figure 37.4 数据减法模式下的操作示例

37.4 中断源

DOC生成DOC中断(DOC_DOPCI)作为中断请求。表37.2描述了DOC中断请求。

Table 37.2 Interrupt request from DOC

Interrupt request	Status flag	Interrupt source
DOC interrupt	DOPCF	• The result of data comparison matches the condition selected in the DOCR.DCSEL bit. • The result of data addition is greater than 0xFFFF. • The result of data subtraction is less than 0x0000.

37.5 Output of an Event Signal to the Event Link Controller (ELC)

The DOC outputs an event signal for the ELC under the following conditions:

- The compared values either match or mismatch
- The data addition result is greater than 0xFFFF
- The data subtraction result is less than 0x0000

This signal can be used to initiate operations by other modules selected in advance and can also be used as an interrupt request. When an event signal is generated, the DOC Flag (DOCR.DOPCF) is set to 1.

37.6 Usage Notes

37.6.1 Settings for the Module-Stop State

The module Stop Control Register C (MSTPCRC) can enable or disable DOC operation. The DOC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

Table 37.2 来自DOC的中断请求

中断请求	状态标志	中断源
文档中断	DOPCF	• 数据比较的结果与DOCR.DCSEL位中选择的条件相匹配。 • 数据相加的结果大于0xFFFF。 • 数据减法的结果小于0x0000。

37.5 将事件信号输出到事件链接控制器(ELC)

DOC在以下条件下为ELC输出事件信号：

- ●比较值匹配或不匹配
- ●数据相加结果大于0xFFFF
- ●数据减法结果小于0x0000

该信号可用于启动其他预先选择的模块的操作，也可用作中断请求。生成事件信号时，DOC标志(DOCR.DOPCF)设置为1。

37.6 使用说明

37.6.1 模块停止状态的设置

模块停止控制寄存器C(MSTPCRC)可以启用或禁用DOC操作。DOC在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

38.2.2 PARIOAD : SRAM Parity Error Operation After Detection Register

Base address: SRAM = 0x4000_2000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The PARIOAD register controls the operation on detection of a parity error. The SRAM Protection Register (SRAMPRCR) protects this register against writes. Always set the SRAMPRCR bit in SRAMPRCR to enabled before writing to this bit. Do not write to the PARIOAD register while accessing the SRAM.

OAD bit (Operation After Detection)

The OAD bit specifies either a reset or non-maskable interrupt when a parity error is detected. The OAD bit is used for SRAM0(with Parity)/Standby SRAM.

38.2.3 SRAMPRCR : SRAM Protection Register

38.2.2 PARIOAD：检测寄存器后的SRAM奇偶校验错误操作

Base address: SRAM = 0x4000_2000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD
重置后的值：	0	0	0	0	0	0	0	0

Note: 如果安全属性配置为安全：●
- 允许安全访问和非安全读取访问
- 忽略非安全写入访问，不会生成TrustZone访问错误。

如果安全属性配置为非安全：●
- 允许安全和非安全访问。

PARIOAD寄存器控制检测奇偶校验错误时的操作。SRAM保护寄存器(SRAMPRCR)保护该寄存器不被写入。在写入该位之前，始终将SRAMPRCR中的SRAMPRCR位设置为启用。访问SRAM时不要写入PARIOAD寄存器。

OAD位（检测后操作）

当检测到奇偶校验错误时，OAD位指定复位或不可屏蔽中断。OAD位用于SRAM0(with Parity)/Standby SRAM.

38.2.3 SRAMPRCR:SRAM保护寄存器

Base address: SRAM = 0x4000_2000

Offset address: 0x04

Bit position:	7						1	0
Bit field:	KW[6:0]							SRAMPRCR
重置后的值：	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRAMPRCR	寄存器写控制 0：禁止写入受保护寄存器1：允许写入受保护寄存器	R/W

Bit	Symbol	Function	R/W
7:1	KW[6:0]	Write Key Code These bits enable or disable writes to the SRAMPRCR bit	W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

SRAMPRCR bit (Register Write Control)

The SRAMPRCR bit controls the write mode of the PARIOAD register. Setting the bit to 1 enables writes to the PARIOAD register. When you write to this bit, always write 0x78 to KW[6:0] bits simultaneously.

KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the SRAMPRCR bit. When you write to the SRAMPRCR bit, always write 0x78 to these bits simultaneously. When a value other than 0x78 is written to KW[6:0], the SRAMPRCR bit is not updated. The KW[6:0] bits are always read as 0x00.

38.2.4 SRAMWTSC : SRAM Wait State Control Register

Base address: SRAM = 0x4000_2000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SRAM0WTEN
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	SRAM0WTEN	SRAM0 wait enable 0: No wait 1: Add wait state in read access cycle to SRAM0	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

This register can be rewritten only when the SRAMPRCR2 bit in the SRAMPRCR2 register is 1.

The protection register (SRAMPRCR2) protects this register against writing. Change the effective bit in the protection register (SRAMPRCR2) to write in this register.

Do not write to SRAMWTSC while access to SRAM is in progress.

SRAM0WTEN bit (SRAM0 wait enable)

This bit sets the wait cycle to the operation region in SRAM0. When it is set 1 in the SRAM0WTEN bit, 1 wait cycle is inserted into the read cycle of operation region in SRAM0. And 1 wait cycle is also inserted between the “write to read/write” sequential cycle in the same region of SRAM0.

Bit	Symbol	Function	R/W
7:1	KW[6:0]	编写关键代码 这些位启用或禁用对SRAMPRCR位的写入	W

Note: 如果安全属性配置为安全：●
允许安全访问和非安全读取访问
- 忽略非安全写入访问，不会生成TrustZone访问错误。

如果安全属性配置为非安全：●
允许安全和非安全访问。

SRAMPRCR位（寄存器写控制）

SRAMPRCR位控制PARIOAD寄存器的写模式。将该位设置为1可以写入PARIOAD寄存器。写入该位时，始终同时将0x78写入KW[6:0]位。

KW[6:0]位（写入密钥代码）

KW[6:0]位启用或禁用对SRAMPRCR位的写入。当您写入SRAMPRCR位时，请始终同时将0x78写入这些位。当向KW[6:0]写入0x78以外的值时，SRAMPRCR位不会更新。KW[6:0]位总是被读取为0x00。

38.2.4 SRAMWTSC:SRAM等待状态控制寄存器

Base address: SRAM = 0x4000_2000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SRAM0WTEN
重置后的值：	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	SRAM0WTEN	SRAM0等待使能 0：无等待1：在SRAM0读访问周期中添加等待状态	R/W
7:1	—	这些位被读取为0。写入值应为0。	R/W

Note: 如果安全属性配置为安全：●
允许安全访问和非安全读取访问
- 忽略非安全写入访问，不会生成TrustZone访问错误。

如果安全属性配置为非安全：●
允许安全和非安全访问。

只有当SRAMPRCR2寄存器中的SRAMPRCR2位为1时，才能重写该寄存器。

保护寄存器(SRAMPRCR2)保护该寄存器不被写入。更改保护寄存器(SRAMPRCR2)中的有效位以写入该寄存器。

在访问SRAM的过程中不要写入SRAMWTSC。

SRAM0WTEN位（SRAM0等待使能）

该位将等待周期设置为SRAM0中的操作区域。当SRAM0WTEN位设置为1时，将1个等待周期插入SRAM0中操作区域的读取周期。并且在SRAM0的同一区域中的“写到读”顺序周期之间也插入了1个等待周期。

38.2.5 SRAMPRCR2 : SRAM Protection Register 2

Base address: SRAM = 0x4000_2000

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

SRAMPRCR2 bit (Register Write Control)

The SRAMPRCR2 bit controls the write mode of the SRAMWTSC register. Setting the bit to 1 enables writes to the SRAMWTSC register. When you write to this bit, always write 0x78 to KW[6:0] at the same time.

KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the SRAMPRCR2 bit. When you write to SRAMPRCR2 bit, always write 0x78 to these bits at the same time. When a value other than 0x78 is written to KW[6:0], the SRAMPRCR2 bit is not updated. The KW[6:0] bits are always read as 0x00.

38.3 Operation

38.3.1 Module Stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

SRAM0 is controlled by SRAM0 bit in MSTPCRA register and, in the case of 1, SRAM0 becomes the clock stop state.

The SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The SRAM operates after a reset.

SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to SRAM is in progress.

Access to the SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see section 10, Low Power Modes.

38.3.2 Parity Calculation Function

The IEC60730 standard requires the checking of SRAM data. When data is written, a parity bit is added to every 8-bit data in the SRAM which has 32-bit data width, and when data is read, the parity is checked. When a parity error occurs, a parity-error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the PARIOAD register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

Parity errors often occur because of noise. To confirm whether the cause of the parity error is noise or corruption, follow the parity check flows shown in Figure 38.1 and Figure 38.2.

Note: 如果安全属性配置为安全：●
允许安全访问和非安全读取访问
- 忽略非安全写入访问，不会生成TrustZone访问错误。

如果安全属性配置为非安全：●

SRAMPRCR2位（寄存器写控制）

SRAMPRCR2位控制SRAMWTSC寄存器的写模式。将该位设置为1可以写入SRAMWTSC寄存器。写入该位时，始终同时将0x78写入KW[6:0]。

KW[6:0]位（写入密钥代码）

KW[6:0]位启用或禁用对SRAMPRCR2位的写入。当您写入SRAMPRCR2位时，请始终同时向这些位写入0x78。当向KW[6:0]写入0x78以外的值时，SRAMPRCR2位不会更新。KW[6:0]位总是被读取为0x00。

38.3 Operation

38.3.1 模块停止功能

通过设置模块停止控制寄存器A(MSTPCRA)停止向SRAM提供时钟信号，可以降低功耗。

SRAM0由MSTPCRA寄存器中的SRAM0位控制，在为1的情况下，SRAM0变为时钟停止状态。

因此，通过停止提供时钟信号，SRAM被置于模块停止状态。SRAM在复位后运行。

如果SRAM处于模块停止状态，则无法访问。在访问SRAM的过程中，不应转换到模块停止状态。

禁止在模块停止状态下访问SRAM。如果尝试访问，则无法保证正确操作。

有关MSTPCRA寄存器的详细信息，请参见第10节，低功耗模式。

38.3.2 奇偶校验计算功能

IEC60730标准要求检查SRAM数据。写入数据时，对32位数据宽度的SRAM中的每8位数据添加一个奇偶校验位，读取数据时检查奇偶校验位。发生奇偶校验错误时，会生成奇偶校验错误通知。此功能也可用于触发复位。

奇偶校验错误通知可以指定为不可屏蔽中断或PARIOAD寄存器的OAD位中的复位。当OAD位设置为1时，奇偶校验错误输出到复位功能。当OAD位设置为0时，奇偶校验错误作为不可屏蔽中断输出到ICU。

奇偶校验错误经常因噪声而发生。要确认奇偶校验错误的原因是噪声还是损坏，请遵循图38.1和图38.2所示的奇偶校验流程。

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.

38.3.3 TrustZone Filter function

There are two types of TrustZone Filter function for SRAM.

- TrustZone Filter for SRAM register protection
- TrustZone Filter for SRAM memory protection

38.3.3.1 TrustZone Filter for SRAM register protection

SRAM registers can be protected with a Security Attribution (SA) from Non-secure access. When SA indicates that SRAM registers are secure status, non-secure access can not overwrite them because TrustZone Filter detects finds an error and protects the write access. SA for SRAM registers is just one to be used commonly among SRAM registers.

SA	Access status	Write access	Read access
Secure	Secure	Permit	Permit
	Non-secure	TrustZone Filter error Protected	Permit

38.3.3 TrustZone过滤器功能

SRAM有两种TrustZoneFilter功能。

- 用于SRAM寄存器保护的TrustZone过滤器
- 用于SRAM内存保护的TrustZone过滤器

38.3.3.1 用于SRAM寄存器保护的TrustZone过滤器

可以使用安全属性(SA)保护SRAM寄存器免受非安全访问。当SA指示SRAM寄存器处于安全状态时，非安全访问无法覆盖它们，因为TrustZoneFilter检测到发现错误并保护写访问。SRAM寄存器的SA只是SRAM寄存器中常用的一种。

Table 38.2 寄存器保护(1of2)

SA	访问状态	写访问	读取权限
Secure	Secure	Permit	Permit
	Non-secure	TrustZone过滤器错误受保护	Permit

SA	Access status	Write access	Read access
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

When TrustZone Filter error for SRAM register access occurs, no error notification and no error response occurs.

38.3.3.2 TrustZone Filter for SRAM memory protection

SRAM memory, e.g. SRAM0 include Non-parity region and Parity can be divided into Secure/Non secure callable/Non secure status with Memory Security Attribution (MSA) and can be protected from Non-secure access. When MSA indicates that SRAM memory region are Secure or Non secure callable status, Non-secure access can't overwrite them.

Table 38.3 Memory protection

SA	Access status	Write access	Read access
Secure / Non secure callable	Secure	Permit	Permit
	Non-secure	TrustZone Filter error • Protected • Error response occurs	TrustZone Filter error • Read data is 0 • Error response occurs
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

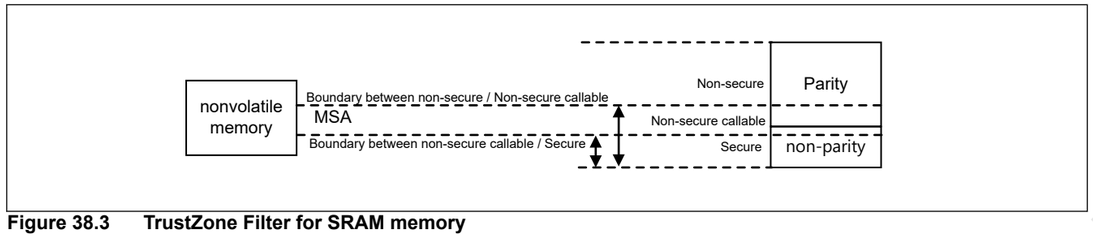

Figure 38.3 TrustZone Filter for SRAM memory

When TrustZone Filter error for SRAM memory access occurs, an error notification which become Reset request or NMI request occurs. See section 42.2. Arm TrustZone Security .

38.3.4 Interrupt Source

The SRAM interrupt source includes a Parity error and TrustZone filter error. Parity error can choose non-maskable interrupt or reset by OAD bit. When the debugger is connected, reset and non-maskable interrupt are maskable. For details on the debug mode, see section 2, CPU.

Table 38.4 SRAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
PARITYERR	Parity error	Not possible	Not possible
TZFLT	TrustZone filter error	Not possible	Not possible

38.3.5 Wait state

Depending on the operating frequency of ICLK, the WAIT setting for SRAM access has the following conditions.

[ICLK frequency] (SRAM0):

- 100 MHz ≥ ICLK = No-wait

38.3.6 Access Cycle

■ Number of cycles from the CPU

Table 38.2 注册保护(2of2)

SA	访问状态	写访问	读取权限
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

当发生SRAM寄存器访问的TrustZoneFilter错误时，不会发生错误通知和错误响应。

38.3.3.2 用于SRAM内存保护的TrustZone过滤器

SRAM存储器，例如SRAM0包括非奇偶校验区域，奇偶校验可分为安全非安全可调用非安全状态和内存安全属性(MSA)，并可防止非安全访问。当MSA指示SRAM内存区域为安全或非安全可调用状态时，非安全访问无法覆盖它们。

Table 38.3 内存保护

SA	访问状态	写访问	读取权限

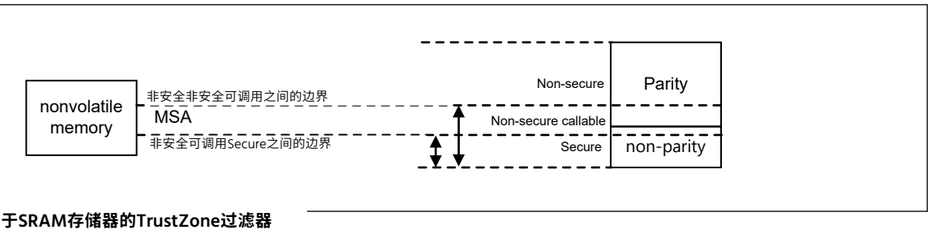

Figure 38.3 用于SRAM存储器的TrustZone过滤器

当发生SRAM内存访问的TrustZoneFilter错误时，会发生错误通知，成为Resetrequest或NMIrequest。见第42.2节。ArmTrustZone安全。

38.3.4 中断源

SRAM中断源包括奇偶校验错误和TrustZone过滤器错误。奇偶校验错误可以选择不可屏蔽中断或通过OAD位复位。当调试器连接时，复位和不可屏蔽中断都是可屏蔽的。有关调试模式的详细信息，请参见第2节CPU。

Table 38.4 SRAM中断源

Name	中断源	DTC Activation	DMAC Activation

38.3.5 等待状态

根据ICLK的工作频率，SRAM访问的WAIT设置具有以下条件。

[ICLK frequency] (SRAM0):

- 100 MHz ≥ ICLK = No-wait

38.3.6 访问周期

■CPU的周期数

Table 38.5 SRAM0

Register Setting	Read (cycles)		Write (cycles)	
	Word access	Half-word/Byte access	Word access	Half-word/Byte access
SRAM0WTEN = 0	1		1*1	
SRAM0WTEN = 1	2		1*1	

Note 1. For efficiency of the access, when read access occurs to the same memory after write, memory write by the precedent write command delays it until for the next idle cycle or the next write access. When read continues, it is given priority to read.

Table 38.5 SRAM0

注1.为提高访问效率，当写入后对同一内存进行读取访问时，先行写入命令的内存写入会将其延迟到下一个空闲周期或下一次写入访问。继续读取时，优先读取。

NSBSTBR[3:0] bit (Security attributes of each region for Standby RAM)

Standby RAM is divided into 8 regions. Each region can be set as Secure or Non-secure state with NSBSTBR[3:0]

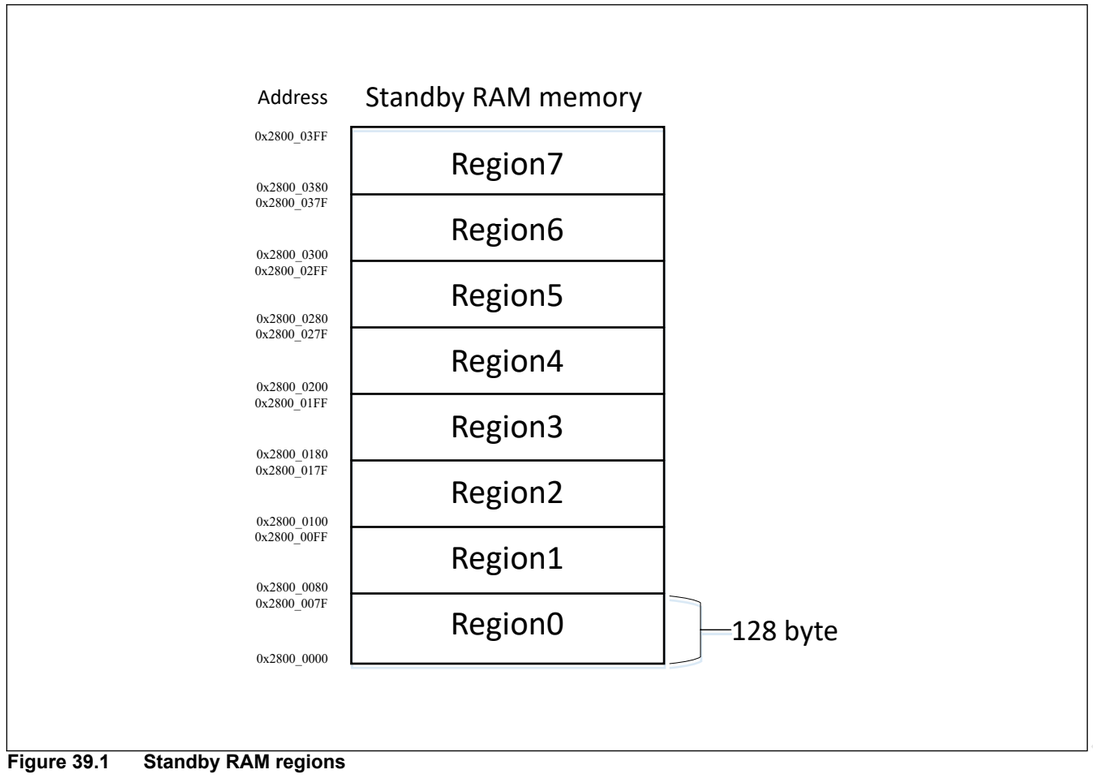

Figure 39.1 Standby RAM regions

39.3 Operation

39.3.1 Data Retention

The power supply to the Standby SRAM in Deep Software Standby mode is enabled by the DPSBYCR.DEEPCUT[1:0] bits. If the DPSBYCR.DEEPCUT[1:0] bits are set to 00b, data in the Standby SRAM is retained in Deep Software Standby mode. See section 10, Low Power Modes, for details on the DPSBYCR.DEEPCUT[1:0] bits.

39.3.2 Setting for the Module-stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

If the Standby SRAM bit in MSTPCRA is set to 1, supply of the clock signal to the Standby SRAM is stopped.

The Standby SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The Standby SRAM operates after a reset.

The Standby SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to the standby SRAM is in progress.

For details on the MSTPCRA register, see section 10, Low Power Modes.

39.3.3 Parity Calculation Function

The parity calculation Function for Standby SRAM is as same as SRAM with Parity.

NSBSTBR[3:0]位（StandbyRAM每个区域的安全属性）

备用RAM分为8个区域。每个区域都可以通过NSBSTBR[3:0]设置为安全或非安全状态

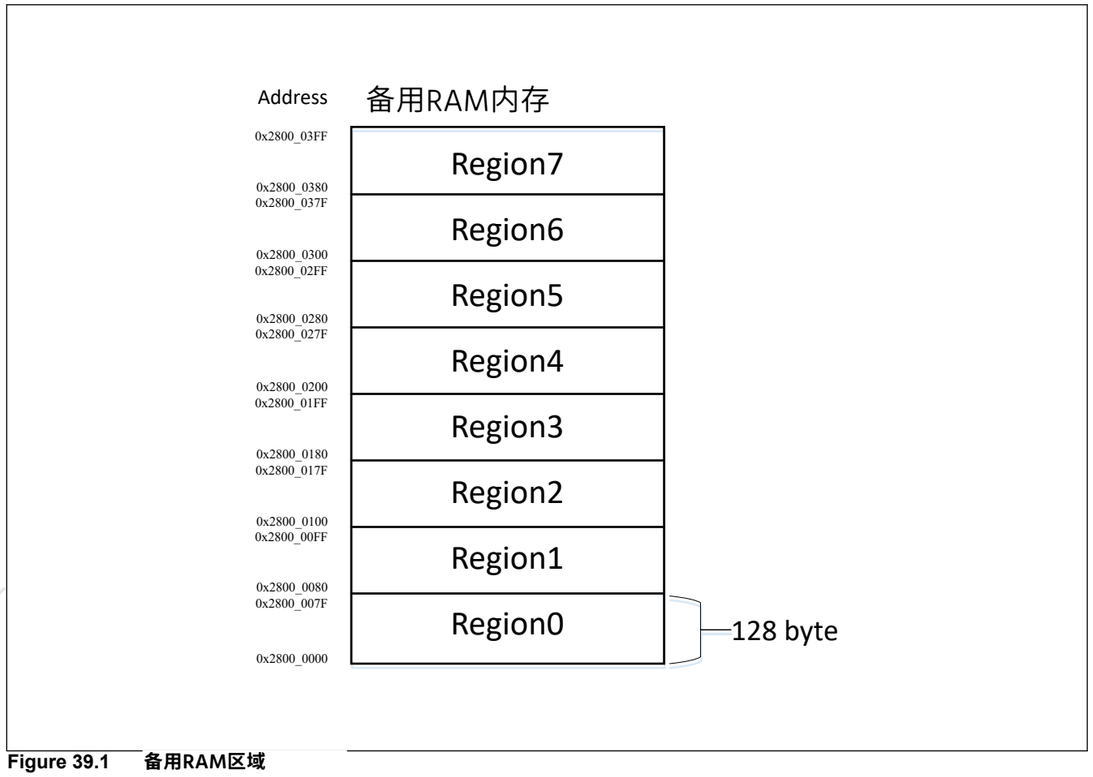

Figure 39.1 备用RAM区域

39.3 Operation

39.3.1 数据保留

深度软件待机模式下的待机SRAM电源由DPSBYCR.DEEPCUT[1:0]位启用。如果DPSBYCR.DEEPCUT[1:0]位设置为00b，则待机SRAM中的数据将保留在深度软件待机模式中。有关DPSBYCR.DEEPCUT[1:0]位的详细信息，请参见第10节，低功耗模式。

39.3.2 模块停止功能的设置

通过设置模块停止控制寄存器A(MSTPCRA)停止向SRAM提供时钟信号，可以降低功耗。

如果MSPCRA中的StandbySRAM位设置为1，则停止向StandbySRAM提供时钟信号。
因此，通过停止提供时钟信号，备用SRAM进入模块停止状态。待机SRAM在复位后运行。

如果处于模块停止状态，则无法访问备用SRAM。在访问备用SRAM的过程中，不应转换到模块停止状态。

有关MSTPCRA寄存器的详细信息，请参见第10节，低功耗模式。

39.3.3 奇偶校验计算功能

StandbySRAM的奇偶校验计算功能与带奇偶校验的SRAM相同。

See section 38.3.2. Parity Calculation Function and section 38.3.4. Interrupt Source.

OAD bit in PARIOAD register is commonly used for SRAM0 (with Parity) / Standby SRAM.

39.3.4 TrustZone Filter function

There is only one type of TrustZone Filter function for Standby SRAM and that is, TrustZone Filter for SRAM memory protection

39.3.4.1 TrustZone Filter for Standby SRAM Memory Protection

Standby SRAM memory can be divided into 8 regions, 128 bytes each with a Security Attribution (SA) to be protected from Non-secure access. When SA indicates that the region in Standby SRAM is secure status, non-secure access can not overwrite them because TrustZone Filter detects finds an error and protects the write access.

Table 39.2 Security Attribution and Access status

SA	Access status	Write access	Read access
Secure	Secure	Permit	Permit
	Non-secure	TrustZone Filter error - Protected	TrustZone Filter error - Read data is 0
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

When TrustZone Filter error for Standby SRAM access occurs, no error notification and no error response occurs.

39.3.5 Access Cycle

Number of cycles from the CPU.

Table 39.3 Standby SRAM (Parity Area 0x2800_0000 to 0x2800_03FF)

	Read cycle		Write cycle	
	Word access	Half-word/Byte access	Word access	Half-word/Byte access
ICLK ≥ PCLKB	Min.: 2 PCLKB Max.: (n -1) ICLK + 2 PCLKB		Min.: 1 PCLKB Max.: (n -1) ICLK + 1 PCLKB	

Note: When the frequency ratio of ICLK : PCLKB is n : 1

39.4 Usage Notes

39.4.1 Instruction Fetch from the Standby SRAM Area

When using Standby SRAM to operate a program, initialize the Standby SRAM area so that the CPU can correctly prefetch data. A parity error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 4-byte boundary. Renesas recommends using the NOP instruction for data initialization.

请参阅第38.3.2节。奇偶校验计算函数和第38.3.4节。中断源。

PARIOAD寄存器中的OAD位常用于SRAM0（带奇偶校验）备用SRAM。

39.3.4 TrustZone过滤器功能

StandbySRAM只有一种TrustZoneFilter功能，即用于SRAM内存保护的TrustZoneFilter

39.3.4.1 用于备用SRAM内存保护的TrustZone过滤器

备用SRAM存储器可分为8个区域，每个128字节具有安全属性(SA)
非安全访问。当SA指示StandbySRAM中的区域为安全状态时，非安全访问无法覆盖它们，因为TrustZone Filter检测发现错误并保护写访问。

Table 39.2 安全属性和访问状态

SA	访问状态	写访问	读取权限
Secure	Secure	Permit	Permit
	Non-secure	TrustZone过滤器错 误受保护	TrustZone过滤器错 误读取数据为0
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

当StandbySRAM访问的TrustZoneFilter错误发生时，不会发生错误通知和错误响应。

39.3.5 访问周期

CPU的周期数。

Note: 当ICLK:PCLKB的频率比为n:1时

39.4 使用说明

39.4.1 从备用SRAM区域取指令

使用StandbySRAM操作程序时，初始化StandbySRAM区域，以便CPU可以正确预取数据。如果CPU从未初始化的区域预取，则可能发生奇偶校验错误。用4字节边界从程序的结束地址初始化额外的12字节区域。瑞萨推荐使用NOP指令进行数据初始化。

7	CFAE	Code Flash Memory Access Violation Flag 0: No code flash memory access violation has occurred 1: A code flash memory access violation has occurred.	R/W*1

Note 1. Only 0 can be written to clear the flag after 1 is read.

The FASTAT register indicates whether a code flash or data flash memory access violation has occurred. If any of the CFAE, CMDLK, and DFAE bits is set to 1, the flash sequencer enters the command-locked state (see section 40.11.2. Error Protection). To release it from the command-locked state, issue a status clear command or Forced Stop command to the flash sequencer.

DFAE bit (Data Flash Memory Access Violation Flag)

The DFAE bit indicates whether a data flash memory access violation occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the data flash P/E mode are as follows:

- The setting of the FSADDR or FEADDR register is the reserved portion of the data area
- FACI commands of non-secure access are issued while the setting of the FSADDR or FEADDR register is the secure region address.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1
- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CMDLK bit (Command Lock Flag)

The CMDLK bit indicates that the flash sequencer is in the command-locked state.

[Setting conditions]

- The flash sequencer detects an error and enters the command-locked state.

[Clearing conditions]

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CFAE bit (Code Flash Memory Access Violation Flag)

The CFAE bit indicates whether a code flash memory access violation has occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

Conversely, the address in the FSADDR register should be equal to or larger than the address in the FEADDR register when decremental mode is selected as the addressing mode for Blank Check (i.e. when FBCCNT.BCDIR = 1). If the BCDIR, FSADDR, and FEADDR bit settings are inconsistent with the specified rules, the flash sequencer enters the command-locked state (see section 40.11.2. Error Protection).

40.4.26 FPCKAR : Flash Sequencer Processing Clock Notification Register

Base address: FACI = 0x407F_E000

Offset address: 0xE4

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								PCKA[7:0]

Bit	Symbol	Function	R/W
7:0	PCKA[7:0]	Flash Sequencer Operating Clock Notification These bits are used to set the operating frequency of the flash sequencer while processing FACI commands.	R/W*1*2
15:8	KEY[7:0]	Key Code	W*3

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x1E.
Note 3. Written values are not retained by these bits (always read 0x00).

FPCKAR specifies the operating frequency of the flash sequencer while processing FACI commands. The highest operating frequency for the given product is set as the initial value.

PCKA[7:0] bits (Flash Sequencer Operating Clock Notification)

The PCKA[7:0] bits specify the operating frequency of the flash sequencer while processing FACI commands. Set the desired frequency for these bits before issuing an FACI command. Specifically, convert the frequency in MHz to a binary number and set it for these bits.

Example:

Frequency is 35.9 MHz (PCKA = 0x24)

Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics cannot be guaranteed. If the value set in these bits is greater than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics can be guaranteed but the FACI command processing time such as the time programming/erasure takes will increase. The minimum FACI command processing time is obtained when the operating frequency of the flash sequencer is the same as the PCKA value.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the PCKA bit.

40.4.27 FSUACR : Flash Startup Area Control Register

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESUSPMD位（擦除挂起模式）

当闪存定序器正在执行擦除处理时发出PE暂停命令时，ESUSPMD位选择擦除暂停模式（请参阅第40.9.3.10节。PE暂停命令）。该位应在发出块擦除或多块擦除命令之前设置。

40.4.26 FPCKAR:闪存定序器处理时钟通知寄存器

Base address: FACI = 0x407F_E000

Offset address: 0xE4

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								PCKA[7:0]

Bit	Symbol	Function	R/W
7:0	PCKA[7:0]	闪存定序器工作时钟通知 这些位用于在处理时设置闪存定序器的工作频率 FACI命令。	R/W*1*2
15:8	KEY[7:0]	关键代码	W*3

注1.当FSTATR寄存器中的FRDY位为1时可以写入该位。当FRDY位为0时忽略写入该位。
注2.仅当写入16位且写入KEY[7:0]位的值为0x1E时，才能写入这些位。
注3.这些位不保留写入的值（始终读取0x00）。

FPCKAR在处理FACI命令时指定闪存定序器的工作频率。将给定产品的最高工作频率设置为初始值。

PCKA[7:0]位（闪存定序器工作时钟通知）

PCKA[7:0]位指定闪存定序器在处理FACI命令时的工作频率。在发出FACI命令之前为这些位设置所需的频率。具体来说，将以MHz为单位的频率转换为二进制数并为这些位设置它。

Example:

频率为35.9MHz(PCKA=0x24)

将35.9MHz的第一个小数位四舍五入为整数(=36)并将其转换为二进制数。

如果这些位中设置的值小于闪存定序器的实际工作频率，则无法保证闪存编程擦除特性。如果这些位中设置的值大于闪存定序器的实际工作频率，则可以保证闪存编程擦除特性，但FACI命令处理时间（例如编程擦除所花费的时间）会增加。当闪存定序器的工作频率与PCKA值相同时，得到最小FACI命令处理时间。

KEY[7:0] bits (Key Code)

KEY[7:0]位控制对PCKA位的写入权限。

Note 1. Following described the write condition of thisese bits (these conditions are required at the same time).
1. Access size to this register is 16 bits
2. The value of KEY[7:0] is 0x66
3. The FSPR bit is 1.

Note 2. Written values are not retained by these bits (always read 0x00).

Note 3. Only secure access can write to this register. Both secure access and non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is note generated.

FSUACR sets the startup area for the boot swap function.

SAS[1:0] bits (Startup Area Select)

The SAS[1:0] bits select the startup area. Three methods are available for changing the startup area.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SAS [1:0] bits.

40.4.28 FCKMHZ : Data Flash Access Frequency Register

Base address: FLAD = 0x407F_C000

Offset address: 0x40

Bit position:	7	6	5	4	3	2	1	0
Bit field:	FCKMHZ[7:0]							
Value after reset:	0	0	1	1	1	1	0	0

Bit	Symbol	Function	R/W
7:0	FCKMHZ[7:0]	Data Flash Access Frequency Register These bits optimize the speed of reading the data flash memory.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

This register optimizes the speed of reading the data flash memory.

Set the frequency of the peripheral module clock (FCLK) of internal peripheral bus which is the clock for access to the data flash memory, in MHz units. For example, 35.9 MHz should be rounded up and set the frequency to 36. Number of cycles required for access to the data flash memory are inserted according to the frequency. When changing the frequency of the FCLK, follow the procedure below to modify the value of the data flash access frequency register (FCKMHZ) in either of the following ways according to whether operation is at a lower frequency before or after the change.

- When changing the speed from low to high: Modify FCKMHZ. After confirming the change by reading FCKMHZ, change the frequency.
- When changing the speed from high to low: Change the frequency. After the frequency is changed, modify FCKMHZ.

●转速由低变高时：修改FCKMHZ。通过读取FCKMHZ确认更改后，更改频率。

●速度由高变低时：改变频率。频率改变后，修改FCKMHZ。

40.7 Overview of Functions

By using a dedicated flash-memory programmer to program the flash memory through a serial interface (serial programming) or JTAG/SWD interface (on-chip debug mode), the device can be rewritten regardless of whether this is before or after it is mounted on the target system.

Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties.

Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations. Table 40.10 lists the overview of the methods of programming and the corresponding operating modes.

Table 40.10 Programming methods

Programming method	Functional overview	Operating mode
Serial programming	A dedicated flash-memory programmer through the SCI or USBFS interface enables on-board programming of the flash memory after the device is mounted on the target system.	Serial programming mode
	A dedicated flash-memory programmer through the SCI or USBFS interface and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	
Self-programming	A user program written to memory in advance of serial programming execution can also program the flash memory. The background operation capability makes it possible to fetch instructions or otherwise read data from the code flash memory while the data flash memory is programmed. As a result, a program resident in the code flash memory is able to program the data flash memory. For background operations that are not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while the code flash memory is being programmed by self-programming. In such cases, a program for programming from the internal SRAM must be transferred in advance and executed.	Normal operating mode
JTAG or SWD programming	A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD enables on-board programming of the flash memory after the device is mounted on the target system. A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system. Table 40.11 lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FACI command or the user program realizes each function of self-programming.

40.7 功能概述

通过使用专用闪存编程器通过串行接口（串行编程）或JTAGSWD接口（片上调试模式）对闪存进行编程，无论是在安装之前还是之后，都可以重写设备目标系统。

此外，内置了禁止重写或读取写入闪存的用户程序的安全功能，这可以防止第三方篡改和非法读取程序。

用户程序编程（自编程）适用于目标系统上的应用程序在制造或发货后可能需要更新的应用程序。还集成了用于安全重写闪存的保护功能。此外，支持自编程期间的中断处理，因此可以与外部通信处理等同时进行编程，这在各种情况下都是如此。表40.10列出了编程方法和相应操作模式的概述。

40.8 Operating Modes of the Flash Sequencer

The flash sequencer has three operating modes as shown in Figure 40.6. Transitions between modes are initiated by changing the value of the FENTRYR register.

When the value of the FENTRYR register is 0x0000, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. The code flash memory and data flash memory are both readable.

When the value of the FENTRYR register is 0x0001, the flash sequencer is in code flash P/E mode where the code flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is readable.

When the value of the FENTRYR register is 0x0080, the flash sequencer is in data flash P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

40.8 FlashSequencer的操作模式

闪存定序器具有三种工作模式，如图40.6所示。通过更改FENTRYR寄存器的值来启动模式之间的转换。

当FENTRYR寄存器的值为0x0000时，闪存定序器处于读取模式。在这种模式下，它不接收FACI命令。代码闪存和数据闪存都是可读的。

当FENTRYR寄存器的值为0x0001时，闪存定序器处于代码闪存PE模式，代码闪存可以通过FACI命令进行编程或擦除。在这种模式下，数据闪存是可读的。

当FENTRYR寄存器的值为0x0080时，闪存定序器处于数据闪存PE模式，可以通过FACI命令对数据闪存进行编程或擦除。在这种模式下，数据闪存是不可读的。但是，代码闪存是可读的。

The FACI commands are issued by writing to the FACI command-issuing area (see Table 40.3). When write access as shown in Table 40.14 proceeds in the specified state, the flash sequencer executes the processing associated with the given command (see section 40.9.2. Relationship between the Flash Sequencer State and FACI Commands).

Table 40.14 FACI command formats

Note: WDN (N = 1, 2, …): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY bit to 0 at the start of a command processing other than the Status Clear command, and sets this bit to 1 on completion.

If the FRDYIE.FRDYIE bit setting is 1, a flash ready (FRDY) interrupt is generated when the FSTATR.FRDY bit is set to 1.

40.9.2 Relationship between the Flash Sequencer State and FACI Commands

The FACI commands are accepted according to the mode/state of the flash sequencer. FACI commands should be issued after transitioning of the flash sequencer to the code flash P/E mode or data flash P/E mode and after checking the state of the flash sequencer.

Use the FSTATR and FASTAT registers to check the state of the flash sequencer. In addition, the occurrence of errors in general can be checked by reading the CMDLK bit in the FASTAT register. The value of the CMDLK bit is the logical OR of the following bits in the FSTATR register:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR
- FLWEERR.

Table 40.15 lists the available FACI commands in each operating mode.

FACI命令通过写入FACI命令发布区域来发布（参见表40.3）。当表40.14所示的写访问在指定状态下进行时，闪存定序器执行与给定命令相关的处理（请参阅第40.9.2节。闪存定序器状态和FACI命令之间的关系）。

Table 40.14 FACI命令格式

FACI命令	写访问次数	将数据写入FACI命令发布区			
		1st access	2nd access	第3次到第(N+2)次访问	(N+3)th access

配置集 N = 8	11	0x40	0x08 (=N)	WD1 to WD8	0xD0

Note: WDN(N=1 2 …)：要编程的第N个16位数据。

闪存定序器在除状态清除命令之外的命令处理开始时将FSTATR.FRDY位清除为0，并在完成时将此位设置为1。

如果FRDYIE.FRDYIE位设置为1，则当FSTATR.FRDY位设置为1时会产生闪存就绪(FRDY)中断。

40.9.2 FlashSequencerState和FACI命令之间的关系

根据闪存定序器的模式状态接受FACI命令。FACI命令应在闪存定序器转换到代码闪存PE模式或数据闪存PE模式并检查闪存定序器的状态之后发出。

使用FSTATR和FASTAT寄存器检查闪存序列器的状态。此外，一般可以通过读取FASTAT寄存器中的CMDLK位来检查错误的发生。CMDLK位的值是FSTATR寄存器中以下位的逻辑或：

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR
- FLWEERR.

Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (see section 43, Electrical Characteristics)

Figure 40.11 Procedure to transition to read mode

40.9.3.6 Recovery from the Command-Locked State

When the flash sequencer enters the command-locked state, FACI commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, forced stop command, or FASTAT register.

When the command-locked state is detected by checking for an error before issuing the P/E suspend command, the FRDY bit in the FSTATR register might be 0 even though command processing has not completed. If processing is not complete by the maximum programming/erasure time specified in the electrical characteristics, this is a timeout and the flash sequencer must be stopped with the forced stop command.

The FLWEERR bit in the FSTATR register does not change from 1 to 0 with the status clear command. When these bits are set to 1, use the forced stop command to release from the command-locked state. Bits other than FRDY and FLWEERR in FSTATR register that indicate the command-locked state can be changed from 1 to 0 with the status clear or forced stop command.

Figure 40.12 shows the recovery flow from the command-locked state.

40.9.3.6 从命令锁定状态恢复

当闪存定序器进入命令锁定状态时，无法接受FACI命令。要从命令锁定状态释放定序器，请使用状态清除命令、强制停止命令或FASTAT寄存器。

当通过在发出PE挂起命令之前检查错误来检测命令锁定状态时，即使命令处理尚未完成，FSTATR寄存器中的FRDY位也可能为0。如果在电气特性中指定的最大编程擦除时间未完成处理，则这是一个超时，并且必须使用强制停止命令停止闪存定序器。

FSTATR寄存器中的FLWEERR位不会随着状态清除命令从1变为0。当这些位设置为1时，使用强制停止命令从命令锁定状态中释放。FSTATR寄存器中除FRDY和FLWEERR以外的位指示命令锁定状态可以通过状态清除或强制停止命令从1更改为0。

图40.12显示了从命令锁定状态的恢复流程。

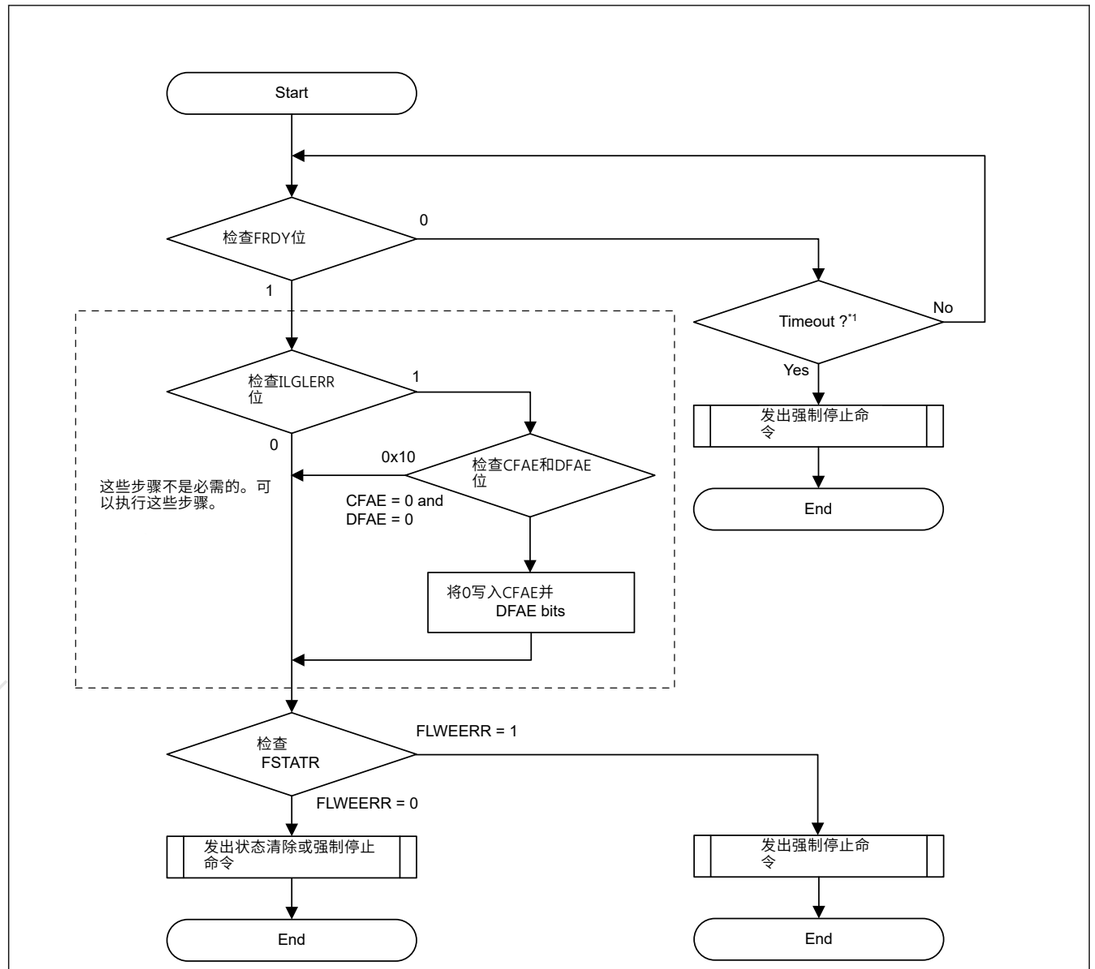
40.9.3.7 Program Command

The program command is used for writing to the user area and data area. Before issuing the FACI program command, set the first address of the target block in the FSADDR register. Writing 0xD0 at the final access of the FACI command-issuing area starts the program command processing. If the target area of program command processing contains area that are not for writing, write 0xFFFF to the corresponding area.

Issuing the program command while the FACI internal data buffer is full leads to a wait on the peripheral bus that might affect communications performance of other peripheral modules. To avoid a wait, set the DBFULL bit in the FSTATR register to 0 when issuing the FACI command. Writing to the data area does not lead to the data buffer becoming full.

Figure 40.13 shows the usage of the program command.



注1.超时的判断是基于1.1倍的FACI命令处理正在进行的最长时间（见第43节，电气特性）

Figure 40.12 从命令锁定状态恢复流程

40.9.3.7 程序命令

程序命令用于写入用户区和数据区。在发出FACI程序命令之前，在FSADDR寄存器中设置目标块的首地址。在最终访问FACI命令发布区域时写入0xD0开始程序命令处理。如果程序命令处理的目标区域包含非写入区域，则将0xFFFF写入相应区域。

在FACI内部数据缓冲区已满时发出程序命令会导致外围总线等待，这可能会影响其他外围模块的通信性能。为避免等待，请在发出FACI命令时将FSTATR寄存器中的DBFULL位设置为0。写入数据区不会导致数据缓冲区变满。

图40.13显示了程序命令的用法。

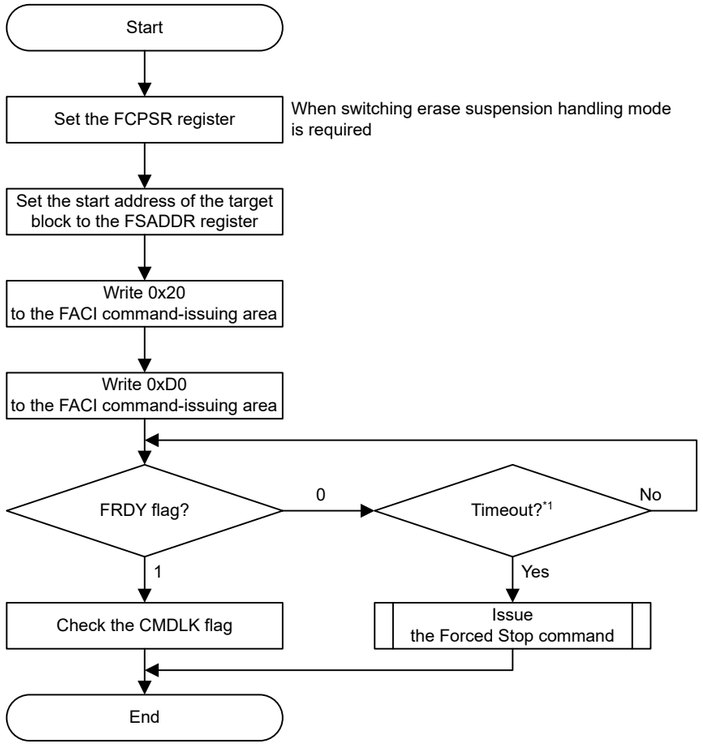
40.9.3.8 Block Erase Command

The block erase command is used for erasing user area or data area. The erase unit is one block. Before issuing a block erase command, set the first address of the target block to FSADRR register. Writing 0xD0 at the second write access of the FACI command triggers the FACI to start the block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

Figure 40.14 shows the usage of the block erase command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of erasure.
See section 43, Electrical Characteristics.

Figure 40.14 Usage flow of the block erase command

40.9.3.9 Multi Block Erase Command

The multi block erase command is used for erasing data area. The erase unit is 64, 128, or 256 bytes. Before issuing the multi block erase command, set the start address to FSADRR register and the end address to FEADDR register. Writing 0xD0 at the second write access of the FACI command triggers FACI to start the multi block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the multi block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

40.9.3.8 块擦除命令

块擦除命令用于擦除用户区或数据区。擦除单位是一个块。在发出块擦除命令之前，将目标块的首地址设置为FSADRR寄存器。在FACI命令的第二次写访问时写入0xD0会触发FACI开始块擦除命令处理。命令处理的完成可以通过FSTATR寄存器的FRDY位来确认。

在发出块擦除命令之前设置FCPSR寄存器。此外，当要切换擦除暂停模式时，必须设置FCPSR。

图40.14显示了块擦除命令的用法。

参见第43节，电气特性。

Figure 40.14 块擦除命令的使用流程

40.9.3.9 多块擦除命令

多块擦除命令用于擦除数据区域。擦除单元为64、128或256字节。在发出多块擦除命令之前，将起始地址设置为FSADRR寄存器，将结束地址设置为FEADDR寄存器。在FACI命令的第二次写访问时写入0xD0会触发FACI开始多块擦除命令处理。命令处理的完成可以通过FSTATR寄存器的FRDY位来确认。

在发出多块擦除命令之前设置FCPSR寄存器。此外，当要切换擦除暂停模式时，必须设置FCPSR。

The erase size is specified by both the FSADDR and FEADDR settings. Table 40.17 describes how to set the FSADDR and FEADDR.

40.9.3.10 P/E Suspend Command

The P/E suspend command is used to suspend programming/erasure. Before issuing a P/E suspend command, check that the CMDLK bit in the FASTAT register is 0, and that the execution of programming/erasure is performed normally. To confirm that the P/E suspend command can be received, check that the SUSRDY bit in the FSTATR register is 1. After issuing a P/E suspend command, read the CMDLK bit to confirm that no error occurs.

If an error occurs during programming/erasure, the CMDLK bit is set to 1. When programming/erasure processing has finished from the time when the SUSRDY bit is 1 to when the P/E suspend command is received, no error occurs and the

40.9.3.10 PE挂起命令

PE暂停命令用于暂停编程擦除。在发出PE挂起命令之前，请检查FASTAT寄存器中的CMDLK位是否为0，并且编程擦除的执行是否正常执行。要确认可以接收到PE挂起命令，请检查FSTATR寄存器中的SUSRDY位是否为1。发出PE挂起命令后，读取CMDLK位以确认没有错误发生。

如果在编程擦除过程中发生错误，则将CMDLK位设置为1。从SUSRDY位为1到接收到PE暂停命令时，当编程擦除处理完成时，不会发生错误，并且

suspended state is not entered (the FRDY bit in the FSTATR register is 1 and the ERSSPD and PRGSPD bits in FSTATR are 0).

When a P/E suspend command is received and the programming/erasure suspend processing finishes normally, the flash sequencer enters the suspended state, the FRDY bit is set to 1, and the ERSSPD or PRGSPD bit is 1. After issuing a P/E suspend command, check that the ERSSPD or PRGSPD bit is 1 and the suspended state is entered, then proceed with the subsequent flow. If a P/E resume command is issued in the subsequent flow even when the suspended state is not entered, an illegal command error occurs and the flash sequencer shifts to the command-locked state (see section 40.11.2. Error Protection).

If the erasure suspended state is entered, programming to blocks other than an erasure target block can be performed. Additionally, the programming and erasure suspended states can shift to read mode by clearing the FENTRYR register.

Figure 40.16 shows the usage of the P/E suspend command.

未进入挂起状态（FSTATR寄存器中的FRDY位为1，FSTATR中的ERSSPD和PRGSPD位为0）。

当接收到PE挂起命令并且编程擦除挂起处理正常完成时，闪存定序器进入挂起状态，FRDY位设置为1，ERSSPD或PRGSPD位为1。发出PE挂起命令后，检查是否ERSSPD或PRGSPD位为1，进入挂起状态，然后进行后续流程。如果在后续流程中发出PEresume命令，即使未进入挂起状态，也会发生非法命令错误，并且闪存定序器会切换到命令锁定状态（请参阅第40.11.2节。错误保护）。

如果进入擦除暂停状态，则可以执行对擦除目标块以外的块的编程。
此外，通过清除FENTRYR寄存器，编程和擦除暂停状态可以转换为读取模式。

When issuing a P/E suspend command during flash memory programming, the flash sequencer suspends programming processing. Figure 40.17 shows the suspend programming operation. Figure 40.16 PE挂起命令的使用流程

(1) 编程期间暂停

在闪存编程期间发出PE暂停命令时，闪存定序器暂停编程处理。图40.17显示了挂起编程操作。当接收到编程相关命令时，flashsequencer将FSTATR寄存器中的FRDY位清0以开始编程。如果闪存定序器进入状态

in which the P/E suspend command can be received after programming starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0. If the flash sequencer receives a P/E suspend command while a programming pulse is applied, the flash sequencer continues with the pulse. After the specified pulse application time, the flash sequencer finishes pulse application, starts the programming suspend processing, and sets the PRGSPD bit in the FSTATR register to 1.

When a suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the programming suspended state. When receiving a P/E resume command in the programming suspended state, the flash sequencer clears the FRDY and PRGSPD bits to 0 and resumes programming.

Figure 40.17 shows the timing for suspension during programming.

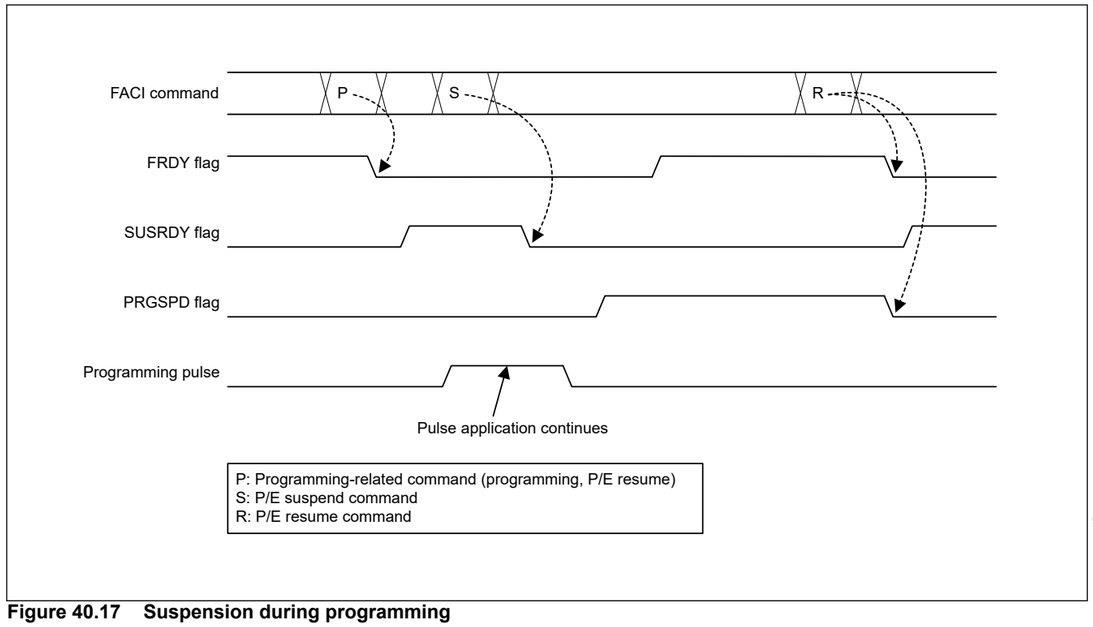

Figure 40.17 Suspension during programming

(2) Suspension during Erasure (Suspension Priority Mode)

The flash sequencer has a suspension priority mode for the suspension of erasure. Figure 40.18 shows the suspend operation of erasure when the erasure suspend mode is set to the suspension priority mode (the ESUSPMD bit in the FCPSR register is 0).

When receiving an erasure-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start erasure. If the flash sequencer enters the state in which the P/E suspend command can be received after erasure starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0.

When receiving a suspend command during erasure, the flash sequencer starts the suspend processing and sets the ERSSPD bit in the FSTATR register to 1 even when it is applying an erasure pulse. When the suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the erasure suspended state. When receiving a P/E resume command in the erasure suspended state, the flash sequencer clears the FRDY and ERSSPD bits to 0 and resumes erasure. Operations of the FRDY, SUSRDY, and ERSSPD bits at the suspension and resumption of erasure are the same, regardless of the erasure suspend mode.

The setting of the erasure suspend mode affects the control method of erasure pulses. In suspension priority mode, when receiving a P/E suspend command while erasure pulse A that has not been previously suspended is being applied, the flash sequencer suspends the application of erasure pulse A and enters the erasure suspended state. When receiving a P/E suspend command while reapplying erasure pulse A after erasure is resumed with a P/E resume command, the flash sequencer

在编程开始后可以接收PE挂起命令的情况下，它将FSTATR寄存器中的SUSRDY位设置为1。

当发出PE暂停命令时，闪存定序器接收该命令并将SUSRDY位清除为0。如果在施加编程脉冲时闪存定序器接收到PE暂停命令，则闪存定序器继续执行该脉冲。在指定的脉冲施加时间之后，闪存序列器完成脉冲施加，开始编程暂停处理，并将FSTATR寄存器中的PRGSPD位设置为1。

当暂停处理完成时，闪存定序器将FRDY位设置为1以进入编程暂停状态。当在编程暂停状态下接收到PEresume命令时，闪存定序器将FRDY和PRGSPD位清除为0并恢复编程。

图40.17显示了编程期间暂停的时序。

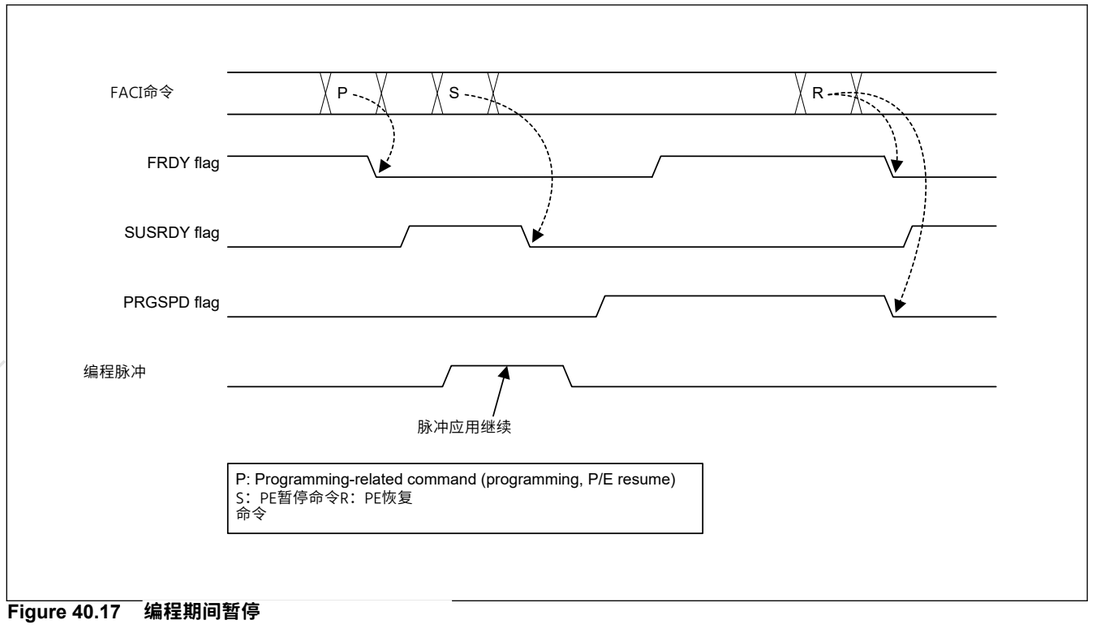

Figure 40.17 编程期间暂停

(2) 擦除期间暂停（暂停优先模式）

闪存定序器具有用于暂停擦除的暂停优先模式。图40.18显示了擦除挂起模式设置为挂起优先模式（FCPSR寄存器中的ESUSPMD位为0）时的擦除挂起操作。

当接收到擦除相关命令时，闪存定序器将FSTATR寄存器中的FRDY位清零以开始擦除。如果闪存序列器在擦除开始后进入可以接收PE挂起命令的状态，它会将FSTATR寄存器中的SUSRDY位设置为1。

当发出PE挂起命令时，闪存定序器接收该命令并将SUSRDY位清除为0。

在擦除期间接收到挂起命令时，闪存定序器启动挂起处理并将FSTATR寄存器中的ERSSPD位设置为1，即使它正在施加擦除脉冲。当挂起处理完成时，闪存定序器将FRDY位设置为1以进入擦除挂起状态。当在擦除暂停状态下接收到PE恢复命令时，闪存定序器将FRDY和ERSSPD位清除为0并恢复擦除。无论擦除暂停模式如何，FRDY、SUSRDY和ERSSPD位在擦除暂停和恢复时的操作都是相同的。

擦除暂停模式的设置会影响擦除脉冲的控制方法。在挂起优先模式下，当在施加先前未被挂起的擦除脉冲A的同时接收到PE挂起命令时，闪存定序器挂起擦除脉冲A的施加并进入擦除挂起状态。在使用PE恢复命令恢复擦除后，在重新应用擦除脉冲A的同时接收到PE暂停命令时，闪存定序器

continues to apply erasure pulse A. After the specified pulse application time, the flash sequencer finishes erasure pulse application and enters the erasure suspended state.

When the flash sequencer receives a P/E resume command next and erasure pulse B is being applied, the flash sequencer receives a P/E suspend command again, and the application of erasure pulse B is then suspended. In suspension priority mode, delays due to suspension can be minimized because the application of an erasure pulse is suspended once per pulse, and priority is given to the suspend processing.

If the interval of suspension after resume is longer than t_{REST1} (Resume time: priority on suspension, resume after the 1st suspend for the same pulse), suspend delay will be always t_{SESD1} (Suspend delay: priority on suspension, the 1st suspend for the same pulse).

If the interval of suspension after resume is shorter than t_{REST1}, suspend delay becomes either t_{SESD1} or t_{SESD2} (Suspend delay: priority on suspension, the 2nd suspend for the same pulse).

(The value of t_{REST1} / t_{SESD1} / t_{SESD2}, see section 43, Electrical Characteristics.)

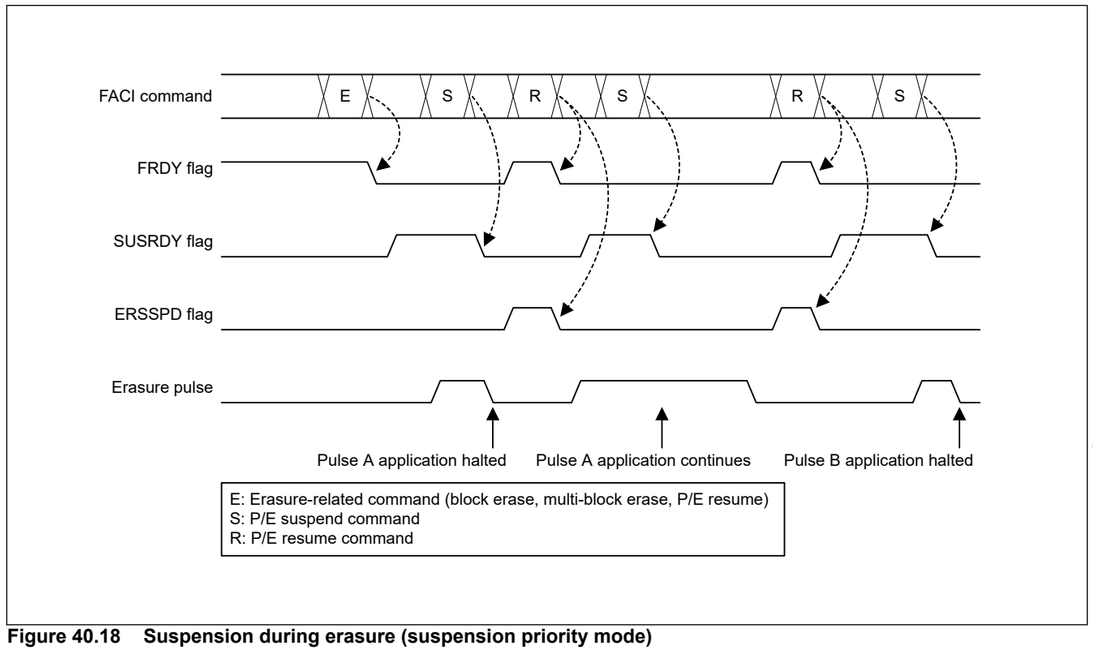

Figure 40.18 Suspension during erasure (suspension priority mode)

(3) Suspension during Erasure (Erasure Priority Mode)

The flash sequencer has an erasure priority mode for the suspension of erasure. Figure 40.19 shows the suspend operation of erasure when the erasure suspend mode is set to the erasure priority mode (the ESUSPMD bit in the FCPSR register is 1). The control method of erasure pulses in erasure priority mode is the same as that of programming pulses for the programming suspend processing.

If the flash sequencer receives a P/E suspend command while an erasure pulse is applied, the flash sequencer continues to apply the pulse. In this mode, the required time for the erasure processing can be reduced compared to the suspension priority mode because the re-application of erasure pulses does not occur when a P/E resume command is issued.

继续施加擦除脉冲A。在指定的脉冲施加时间之后，闪存定序器完成擦除脉冲施加并进入擦除暂停状态。

当闪存定序器接下来接收到PE恢复命令并且正在施加擦除脉冲B时，闪存定序器再次接收到PE暂停命令，然后暂停擦除脉冲B的施加。在挂起优先模式中，由于擦除脉冲的施加在每个脉冲中挂起一次，因此挂起引起的延迟可以被最小化，并且挂起处理具有优先权。

如果恢复后挂起的时间间隔大于tREST1（恢复时间：挂起优先，相同脉冲第一次挂起后恢复），挂起延迟将始终为tSESD1（挂起延迟：挂起优先，第一次挂起相同的脉冲）。

如果恢复后的暂停间隔小于tREST1，则暂停延迟变为tSESD1或tSESD2（暂停延迟：暂停优先，相同脉冲的第2次暂停）。

（tREST1tSESD1tSESD2的值，请参见第43节，电气特性。）

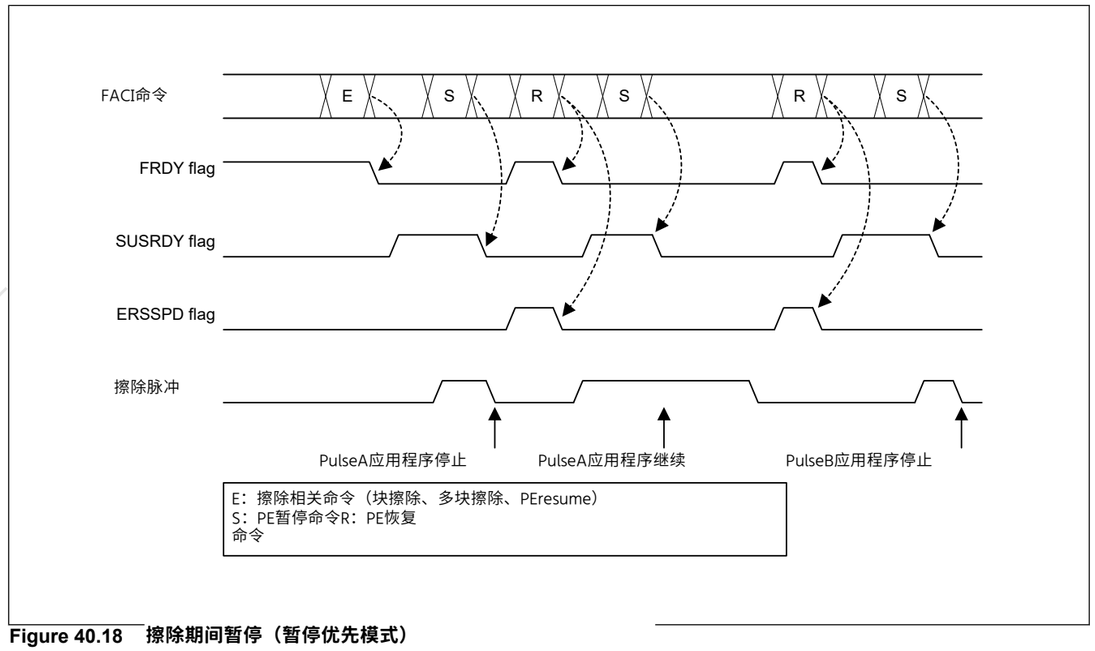

Figure 40.18 擦除期间暂停（暂停优先模式）

(3) 擦除期间暂停（擦除优先模式）

闪存定序器具有用于暂停擦除的擦除优先模式。图40.19显示了擦除挂起模式设置为擦除优先模式时的擦除挂起操作（FCPSR寄存器中的ESUSPMD位为1）。擦除优先模式中擦除脉冲的控制方法与用于编程暂停处理的编程脉冲的控制方法相同。

如果在施加擦除脉冲时闪存定序器接收到PE暂停命令，则闪存定序器继续施加脉冲。在这种模式下，与暂停优先模式相比，擦除处理所需的时间可以减少，因为当发出PE恢复命令时不会发生擦除脉冲的重新施加。

40.9.3.11 P/E Resume Command

The P/E resume command is used to resume suspended programming or erasure. If the FENTRYR setting has been modified during suspension, issue a P/E resume command only after resetting FENTRYR to the previous value that was held before the P/E suspend command was issued. Figure 40.20 shows usage of the P/E resume command.

40.9.3.12 Status Clear Command

The status clear command is used to clear the command-locked state (see section 40.9.3.6. Recovery from the Command-Locked State).

You can use the status clear command to clear the following bits in the FSTATR register in the command-locked state:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR

Figure 40.21 shows usage of the status clear command.

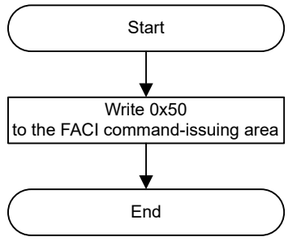

Figure 40.21 Usage flow of the status clear command

40.9.3.13 Forced Stop Command

The forced stop command is used to forcibly end command processing by the flash sequencer. Although this command halts command processing more quickly than the P/E suspension command, values from the programming or erasure that are in progress are not guaranteed. Additionally, resumption of processing is not possible. Processing of programming or erasure that is halted by the forced stop command is also defined as one programming round.

Executing the forced stop command also initializes part of the FACI, the whole FCU, the FSTATR and FASTAT registers. This command can be used in the procedure for recovery from the command-locked state and for processing in response to a timeout of the flash sequencer (see section 40.9.3.6. Recovery from the Command-Locked State).

Figure 40.22 shows usage of the forced stop command.

40.9.3.12 状态清除命令

statusclear命令用于清除命令锁定状态（参见第40.9.3.6节。从命令恢复锁定状态）。

在命令锁定状态下，您可以使用statusclear命令清除FSTATR寄存器中的以下位：

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR

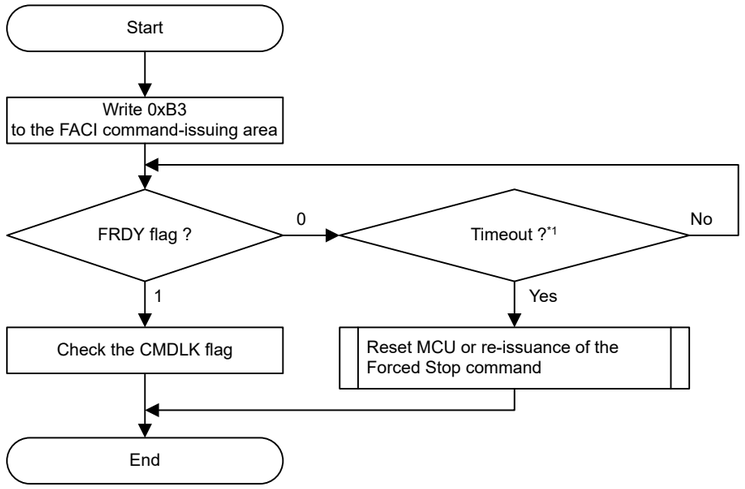
40.9.3.13 强制停止命令

强制停止命令用于强制结束闪存定序器的命令处理。尽管此命令比PE暂停命令更快地停止命令处理，但不能保证正在进行的编程或擦除的值。此外，无法恢复处理。由强制停止命令停止的编程或擦除的处理也被定义为一轮编程。

执行强制停止命令还会初始化部分FACI、整个FCU、FSTATR和FASTAT寄存器。
此命令可用于从命令锁定状态恢复的过程中以及用于响应闪存定序器超时的处理（请参阅第40.9.3.6节。从命令锁定状态恢复）。

图40.22显示了强制停止命令的用法。



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of the Forced Stop command latency.
See section 43, Electrical Characteristics.

Figure 40.22 Usage flow of the forced stop command

(1) Notes on Using the Forced Stop Command during Command Issue

When using the forced stop command at the timeout occurrence by DBFULL bit of the program command, writing in the FACI command-issuing area is sometimes processed as writing in data of the program command. See Table 40.3 in section 40.3. Address Space for information on the FACI command-issuing area to force a command lock. Then issue a forced stop command with return method from the command lock status (see Figure 40.13). Locking commands is possible in any case where the unit for reading the FACI command issuing area is 8, 16, or 32 bits.

40.9.3.14 Blank Check Command

The blank check command is used to confirm that an area is in the non-programmed state. Values read from the data flash memory that have been erased but not yet programmed again that is in the non-programmed state, are undefined.

Before issuing the Blank Check command, set addressing mode, start address, and end address of the target area for Blank Check to the FBCCNT, FSADDR, and FEADDR registers. When Blank Check addressing mode is set to decremental mode (i.e. FBCCNT.BCDIR = 1), address specified in FSADDR should be equal to or larger than address in FEADDR.

On the other hand, the address in FSADDR should be equal to or smaller than address in FEADDR when Blank Check addressing mode is set to incremental mode (i.e. FBCCNT.BCDIR = 0).

If the settings of the BCDIR bit, FSADDR, and FEADDR are inconsistent, the flash sequencer enters the command-locked state. The size of the target area for Blank Check is in the range from 4 bytes to the data flash memory capacity and is set in units of 4 bytes.

Write 0x71 and 0xD0 to the FACI command-issuing area to start Blank Check. Completion of processing can be confirmed by the FRDY bit of the FSTATR register. At the end of processing, the result of Blank Check is stored in the BCST bit in the FBCSTAT register. If non-programmed data exists within the target area for Blank Check, flash sequencer stops Blank Check command operation. In this case, address of non-programmed data is indicated to FPSADDR register.

Figure 40.23 shows usage of the blank check command.

(1) 命令发出期间使用强制停止命令的注意事项

通过程序命令的DBFULL位在超时发生时使用强制停止命令时，写入
FACI命令发布区域有时被处理为写入程序命令的数据。请参见第40.3节中的表40.3。FACI命令发布区域信息的地址空间以强制命令锁定。然后从命令锁定状态发出带返回方法的强制停止命令（见图40.13）。在读取FACI命令发布区域的单位为8、16或32位的任何情况下，锁定命令都是可能的。

40.9.3.14 空白检查命令

空白检查命令用于确认某个区域处于非编程状态。从处于未编程状态的已擦除但尚未再次编程的数据闪存读取的值未定义。

在发出空白检查命令之前，设置空白目标区域的寻址方式、起始地址和结束地址
检查FBCCNT、FSADDR和FEADDR寄存器。当空白检查寻址模式设置为递减模式（即FBCCNT.BCDIR=1）时，FSADDR中指定的地址应等于或大于FEADDR中的地址。

另一方面，当空白检查寻址模式设置为增量模式（即FBCCNT.BCDIR=0）时，FSADDR中的地址应等于或小于FEADDR中的地址。

如果BCDIR位、FSADDR和FEADDR的设置不一致，则flashsequencer进入command-locked状态。BlankCheck的目标区域大小在4字节到数据闪存容量的范围内，以4字节为单位设置。

将0x71和0xD0写入FACI命令发出区域以启动空白检查。可通过FSTATR寄存器的FRDY位确认处理完成。处理结束时，空白检查的结果存储在FBCSTAT寄存器的BCST位中。如果空白检查的目标区域内存在未编程的数据，闪存定序器将停止空白

检查命令操作。在这种情况下，非编程数据的地址被指示到FPSADDR寄存器。

40.9.3.15 Configuration Set Command

The Configuration set command is used to set option-setting memory. Before issuing the Configuration set command, set the specified address (shown in Table 40.18) in the FSADDR register. Writing 0xD0 to the FACI command-issuing area in the final access for issuing the FACI command starts FACI processing of the Configuration set command.

40.9.3.15 配置集命令

Configurationset命令用于设置选项设置内存。在发出配置设置命令之前，在FSADDR寄存器中设置指定的地址（如表40.18所示）。在发出FACI命令的最终访问中将0xD0写入FACI命令发出区域，开始配置设置命令的FACI处理。

Note 1. The SAS.FSPR bit cannot be restored to 1 by using the Configuration set command once it is set to 0. Therefore, setting the start-up area select flags again becomes impossible. (when the Configuration set command is issued to the address of 0x0100A134, the command is locked.) Exercise extra caution when handling the SAS.FSPRbit.
Note 2. Once PBPS[n] bit is set to 0, the BPS[n] bit cannot be restored to 1 by using the Configuration set command.
Note 3. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS[n] bit can not be set to 0 by using the Configuration set command when the BPS[n] bit is 1.
Note 4. Once PBPS_SEC[n] bit is set to 0, the BPS_SEC[n] bit cannot be restored to 1 by using the Configuration set command.
Note 5. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS_SEC[n] bit cannot be set to 0 by using the Configuration set command when the BPS_SEC[n] bit is 1.

40.10 Suspend Operation

Reading from the flash memory is not possible during programming or erasure if the conditions for background operation given in Table 40.29 are not satisfied. When a P/E suspend command is issued to suspend the programming or erasure of the flash memory, reading from the flash memory is enabled. Regarding P/E suspend commands, there are one suspend command mode for programming and two suspend command modes for erasure (suspension priority mode and erasure priority mode). To resume suspended programming or erasure, the P/E resume command is available. See details on the suspend operation, refer to Figure 40.16.

40.11 Protection Function

40.11.1 Software Protection

Software protection disables programming and erasure of the code flash memory through the settings of control registers and block protect setting in the user area. If an attempt is made to issue an FACI command against software protection, the flash sequencer enters the command-locked state.

40.11.1.1 Protection through FWEPROR

Unless the FWEPROR.FLWE[1:0] bits are set to 01b, programming cannot proceed in any mode.

配置设置可能的目标数据与FSADDR寄存器中设置的地址值的对应关系如表40.18所示。有关详细信息，请参阅第40.4.12节。FSADDR：FACI命令起始地址寄存器。

注1.SAS.FSPR位一旦设置为0，就无法通过Configurationset命令恢复为1。因此，再次设置启动区域选择标志变得不可能。（当向0x0100A134地址发出Configurationset命令时，该命令被锁定。）处理SAS.FSPRbit时要格外小心。
注2.一旦PBPS[n]位设置为0，BPS[n]位不能通过使用配置设置命令恢复为1。
注3.一旦这些位设置为0，就不能使用配置设置命令将这些位恢复为1。当BPS[n]位为1时，不能使用配置设置命令将PBPS[n]位设置为0。
注4.一旦PBPS_SEC[n]位设置为0，则BPS_SEC[n]位无法通过使用配置设置命令恢复为1。
注5.一旦这些位设置为0，就不能使用配置设置命令将这些位恢复为1。当BPS_SEC[n]位为1时，无法使用配置设置命令将PBPS_SEC[n]位设置为0。

40.10 暂停操作

如果不满足表40.29中给出的后台操作条件，则在编程或擦除期间无法从闪存读取。当发出PE暂停命令以暂停闪存的编程或擦除时，将启用从闪存读取。关于PE挂起命令，有一种用于编程的挂起命令模式和两种用于擦除的挂起命令模式（挂起优先模式和擦除优先模式）。要恢复暂停的编程或擦除，可以使用PEresume命令。有关挂起操作的详细信息，请参见图40.16。

40.11 保护功能

40.11.1 软件保护

软件保护通过控制寄存器的设置和用户区的块保护设置禁用代码闪存的编程和擦除。如果尝试针对软件保护发出FACI命令，则闪存定序器进入命令锁定状态。

40.11.1.1 通过FWEPROR进行保护

除非FWEPROR.FLWE[1:0]位设置为01b，否则无法在任何模式下进行编程。

40.11.1.2 Protection by FENTRYR

When the FENTRYR register is set to 0x0000, the flash sequencer enters read mode. In read mode, FACI commands cannot be accepted. If an attempt is made to issue an FACI command in read mode, the flash sequencer enters the command-locked state.

40.11.1.3 Protection by Block Protect Setting

Each block in user area has the block protect setting (BPS or BPS_SEC). When the FBPROT0 or FBPROT1 register is 0x0000 and the block protect bit is 0, issuing the Program or Block Erase command to user area of the code flash causes the command-locked state. To program or erase the block whose block protect bit is 0, set the FBPROT0 or FBPROT1 register to 0x0001.

The block protect setting can be locked by the permanent block protect setting (PBPS or PBPS_SEC). When the permanent block protect setting and the block protect setting are 0, issuing a Program or Block erase command to user area of the code flash causes the flash sequencer to enter the command-locked state regardless of the FBPROT0 and FBPROT1 register settings.

Valid block protect setting (BPS or BPS_SEC) depends on the Block Protect Select bit (BPS_SEL).

See section 40.12.2. Permanent Block Protect Setting for details of the block protect setting and permanent block protect setting. See section 40.4.15. FBPROT0 : Flash Block Protection Register and section 40.4.16. FBPROT1 : Flash Block Protection for Secure Register for more information.

For details of block protect setting (BPS or BPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

The protected area by the block protect setting is always determined by the address of the FSADDR register setting regardless of the address swapping function setting (the startup area select). Table 40.19 to Table 40.20 show the relation of user area and the block protect setting in each function setting.

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of user area (for example, address is 0x00_0000 to the last block address).
- BPS[0]/BPS_SEC[0] and BPS[1]/BPS_SEC[1] are assigned to the block of user area depending on the startup area select setting (SAS.BTFLG bit). (See section 40.11.3. Start-Up Program Protection).

Table 40.19 shows the block protect setting when the startup area select is disabled (not swapping).

Table 40.20 show example of the block protect setting when the address conversion function is used.

40.11.1.2 FENTRYR的保护

当FENTRYR寄存器设置为0x0000时，闪存定序器进入读取模式。在读取模式下，无法接受FACI命令。如果尝试在读取模式下发出FACI命令，则闪存定序器进入命令锁定状态。

40.11.1.3 通过块保护设置进行保护

用户区的每个块都有块保护设置（BPS或BPS_SEC）。当FBPROT0或FBPROT1寄存器为0x0000且块保护位为0时，向代码闪存的用户区发出Program或BlockErase命令会导致命令锁定状态。要编程或擦除块保护位为0的块，请将FBPROT0或FBPROT1寄存器设置为0x0001。

块保护设置可以通过永久块保护设置（PBPS或PBPS_SEC）锁定。当永久块保护设置和块保护设置为0时，无论FBPROT0和FBPROT1寄存器设置如何，向代码闪存的用户区发出程序或块擦除命令都会使闪存定序器进入命令锁定状态。

有效的块保护设置（BPS或BPS_SEC）取决于块保护选择位（BPS_SEL）。

请参阅第40.12.2节。永久块保护设置有关块保护设置和永久块保护设置的详细信息。请参阅第40.4.15节。FBPROT0：闪存块保护寄存器和第40.4.16节。FBPROT1：安全寄存器的闪存块保护了解更多信息。

有关块保护设置（BPS或BPS_SEC）和块保护选择（BPS_SEL）的详细信息，请参阅第6节，选项设置Memory.

块保护设置的保护区域始终由FSADDR寄存器设置的地址决定，与地址交换功能设置（启动区域选择）无关。表40.19至表40.20显示了每个功能设置中用户区和块保护设置的关系。

●BPS[0]到BPS[n]或BPS_SEC[0]到BPS_SEC[n]分配给用户区的块（例如，地址是0x00_0000到最后一个块地址）。

●BPS[0]BPS_SEC[0]和BPS[1]BPS_SEC[1]根据启动区选择设置（SAS.BTFLG位）分配给用户区块。（参见第40.11.3节。启动程序保护）。

表40.19显示了禁用启动区域选择（不交换）时的块保护设置。

表40.20显示了使用地址转换功能时的块保护设置示例。

40.11.2 Error Protection

Error protection detects the issuing of illegal FACI commands, illegal access, and flash sequencer malfunction. FACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue the Status Clear or Forced Stop command. The Status Clear command can only be used while the FRDY bit in the FSTATR register is 1. The Forced Stop command can be used regardless of the value of the FRDY bit. While the CMDLKIE bit in the FAEINT register is 1, a flash access error (FIFERR) interrupt is generated if the flash sequencer enters the command-locked state (the CMDLK bit in the FASTAT register is set to 1).

If the flash sequencer enters the command-locked state in response to a command other than the P/E suspend command during programming or erasure processing, the flash sequencer continues the processing for programming or erasure. In this state, the P/E suspend command cannot be used to suspend the processing for programming or erasure. If a command is issued in the command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set from previous error detection.

Table 40.21 shows the error protection types and status bit values after error detections.

40.11.2 错误保护

错误保护检测非法FACI命令的发出、非法访问和闪存定序器故障。FACI命令接受被禁用（命令锁定状态）以响应检测到这些错误。闪存定序器处于命令锁定状态时，无法对闪存进行编程或擦除。要从命令锁定状态释放，请发出状态清除或强制停止命令。状态清除命令只能在FSTATR寄存器中的FRDY位为1时使用。无论FRDY位的值如何，都可以使用强制停止命令。当FAEINT寄存器中的CMDLKIE位为1时，如果闪存定序器进入命令锁定状态（FASTAT寄存器中的CMDLK位设置为1），则会产生闪存访问错误(FIFERR)中断。

如果闪存定序器在编程或擦除处理期间响应于除了PE暂停命令之外的命令而进入命令锁定状态，则闪存定序器继续进行编程或擦除处理。在这种状态下，PE挂起命令不能用于挂起编程或擦除处理。如果在命令锁定状态下发出命令，则ILGLERR位变为1，其他位保留先前错误检测设置的值。

表40.21显示了错误检测后的错误保护类型和状态位值。

40.11.3 Start-Up Program Protection

Protection of the startup program is for protection of the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.

The startup area is 8 Kbytes in size and is assigned to the user area in the code flash memory. This function uses the values of the SAS.BTFLG bit and the FSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see Figure 40.25 to Figure 40.28).

In protection of the startup program, the state of the selection of the startup area can be fixed by the FSPR bit. However, the SAS.FSPR bit never be restored to 1 once the flag is set to 0. Exercise extra caution when handling the SAS.FSPR bit.

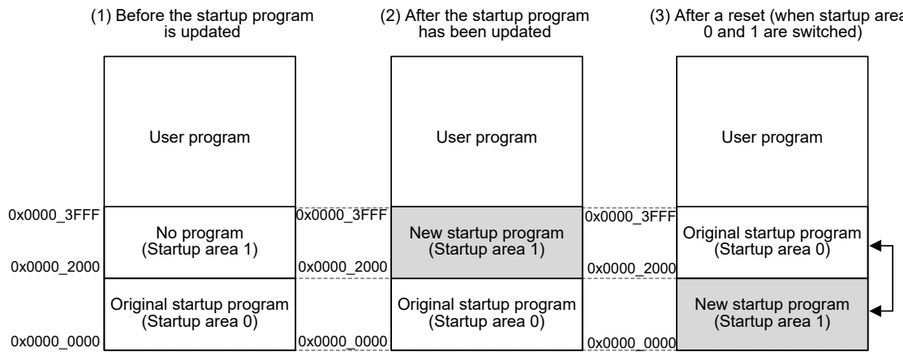
40.11.3 启动程序保护

启动程序的保护是为了保护复位后要启动的程序（启动程序）。此功能提供了一种在复位期间暂停重写时安全更新启动程序的方法。

启动区大小为8KB，分配给代码闪存中的用户区。该函数使用SAS.BTFLG位和FSUACR.SAS[1:0]位的值来改变以块为单位存储启动程序的区域（见图40.25至图40.28）。

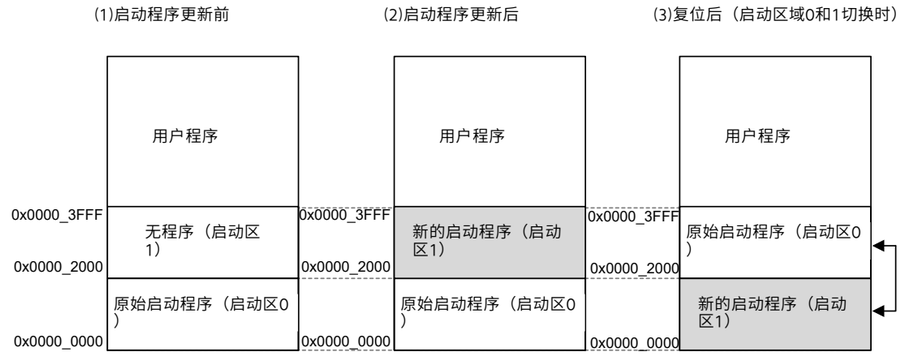
在启动程序的保护中，启动区域的选择状态可以通过FSPR位来固定。但是，那一旦标志设置为0，SAS.FSPR位永远不会恢复为1。处理SAS.FSPR位时要格外小心。



Note: The addresses are used for reading, programming, and erasure. Startup area 0 is erased when Block Erase command is issued for the address 0x00000000 with allocation shown under 3.

1. Before the startup program is updated
   When the SAS.BTFLG bit is 1 and the FSUACR.SAS[1:0] bits are 0xb, the address range from 0x00002000 to 0x00003FFF is selected as startup area 1 and the address range from 0x00000000 to 0x00001FFF is selected as startup area 0.
2. After the startup program has been updated
   A new startup program can be written to startup area 1. At this time, startup area 0 will still contain the previous startup program, so rewriting by starting up from startup area 0 remains possible if rewriting to the startup area 1 fails.
3. After a reset (when startup areas 0 and 1 are switched)
   When rewriting startup area 1 is successfully completed, switch the assignment of startup areas 0 and 1 by rewriting the startup area selection bit (the SAS.BTFLG bit) with Configuration set command. Afterwards, the program is started up from startup area 1 after a reset.

Figure 40.25 Concept of Protection of the Startup Program



Note: 这些地址用于读取、编程和擦除。当对地址0x00000000发出块擦除命令时，启动区域0被擦除，分配如下3所示。1.更新启动程序之前

当SAS.BTFLG位为1且FSUACR.SAS[1:0]位为0xb时，选择0x00002000到0x00003FFF的地址范围作为启动区1，选择从0x00000000到0x00001FFF的地址范围作为启动区0。2.启动程序更新后

可以将新的启动程序写入启动区1。此时启动区0仍会包含之前的启动程序，因此如果对启动区1的重写失败，仍然可以从启动区0启动进行重写。3.复位后（启动区域0和1切换时）

当重写启动区1成功完成时，通过使用Configurationset命令重写启动区选择位（SAS.BTFLG位）来切换启动区0和1的分配。之后，程序在复位后从启动区1启动。

40.12 Security Function

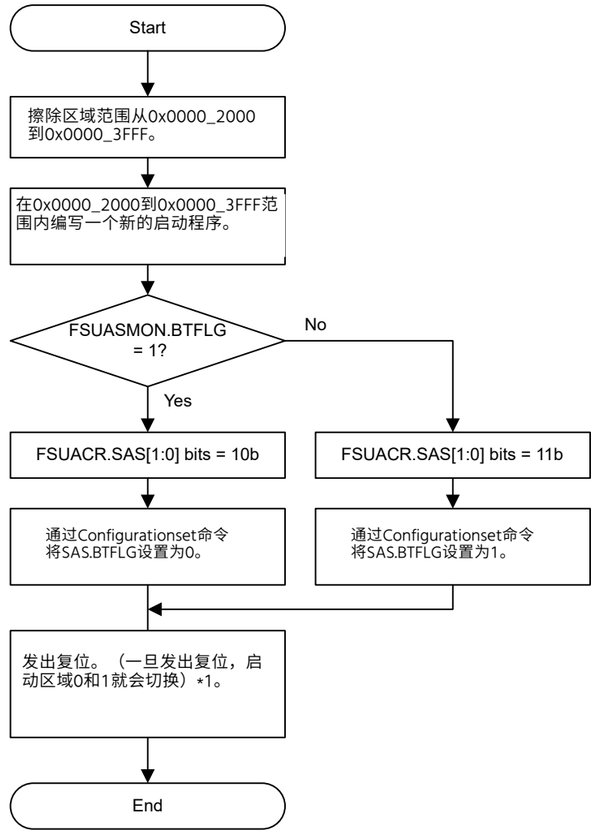
The flash sequencer supports the following security functions:

- Security flag for startup area
- Permanent block protect setting
- Flash memory protection for TrustZone

40.12.1 Security Flag for Startup Area Select

The security flag (SAS.FSPR) for the startup area is located in the option-setting memory.

When the SAS.FSPR bit is 0, issuing the configuration set command to change the SAS.BTFLG bit causes the flash sequencer to be in the command-locked state. Also, when the SAS.FSPR bit is 0, it is invalid to write to the Startup Area Select bits SAS[1:0] in the FSUACR register. The SAS.FSPR bit enables protection.



注1.详见图40.26和图40.27。

Figure 40.28 保护启动程序的概念

40.12 安全功能

闪存定序器支持以下安全功能：

- 启动区安全标志
- 永久封锁保护设置
- TrustZone的闪存保护

40.12.1 启动区域选择的安全标志

启动区域的安全标志(SAS.FSPR)位于选项设置内存中。

当SAS.FSPR位为0时，发出配置设置命令来更改SAS.BTFLG位会导致闪存定序器处于命令锁定状态。此外，当SAS.FSPR位为0时，写入FSUACR寄存器中的启动区域选择位SAS[1:0]无效。SAS.FSPR位启用保护。

40.12.2 Permanent Block Protect Setting

The permanent block protect setting is the clear protection for the block protection setting. User area cannot be permanently updated by the FACI command when the permanent block protect setting is enabled. See section 40.11.1.3. Protection by Block Protect Setting for more details.

The block protect setting and the permanent block protect setting have the write/clear protection against the configuration set command. The flash sequencer does not detect an error when the configuration set command is issued to the write/clear protected settings.

Figure 40.29 and Table 40.22 show the write/clear protection against the block protect setting (BPS[n]) and the permanent protect setting (PBPS[n]). Figure 40.30 and Table 40.23 show the write/clear protection against the block protect setting for secure (BPS_SEC[n]) and permanent protect setting for secure (PBPS_SEC[n]).

Effective permanent block protect setting (PBPS or PBPS_SEC) depends on block protect select (BPS_SEL). For details of permanent block protect setting (PBPS or PBPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

40.12.2 永久块保护设置

永久块保护设置是对块保护设置的明确保护。启用永久块保护设置后，FACI命令无法永久更新用户区域。请参阅第40.11.1.3节。通过块保护设置进行保护以获取更多详细信息。

块保护设置和永久块保护设置具有针对配置集命令的写清除保护。向写清除保护设置发出配置设置命令时，闪存定序器不会检测到错误。

图40.29和表40.22显示了针对块保护设置(BPS[n])和永久保护设置(PBPS[n])的写清除保护。图40.30和表40.23显示了针对安全的块保护设置(BPS_SEC[n])和安全的永久保护设置(PBPS_SEC[n])的写清除保护。

有效的永久块保护设置（PBPS或PBPS_SEC）取决于块保护选择（BPS_SEL）。有关永久块保护设置（PBPS或PBPS_SEC）和块保护选择（BPS_SEL）的详细信息，请参见第6节，选项设置存储器。

40.12.3 Flash Memory Protection for TrustZone

Information in this section focuses on the flash sequencer operation.

The flash memory provides the following types of protect function against non-secure access:

- Protection for flash memory area (P/E)
- Protection for flash memory area (read)
- Protection for registers
- Protection during FACI command operation
- Code flash P/E mode entry protection

40.12.3.1 Protection for Flash Memory Area (P/E)

This function protects the secure region of the code flash and data flash from FACI commands of non-secure access. The condition of protection depends on the FACI command, the access attribution, and the memory boundary setting.

For details of secure region, see section 42, Security Features .

See Table 40.24 for information on protection of the flash memory area (P/E).

40.12.3 TrustZone的闪存保护

本节中的信息侧重于闪存定序器的操作。

闪存提供以下类型的保护功能以防止非安全访问：

- ●保护闪存区（PE）
- ●保护闪存区域（读取）
- ●寄存器保护
- ●FACI命令操作期间的保护
- ●CodeflashPE模式进入保护

40.12.3.1 对闪存区域(PE)的保护

此功能保护代码闪存和数据闪存的安全区域免受非安全访问的FACI命令的影响。保护条件取决于FACI命令、访问属性和内存边界设置。

有关安全区域的详细信息，请参阅第42节，安全功能。

有关保护闪存区域(PE)的信息，请参见表40.24。

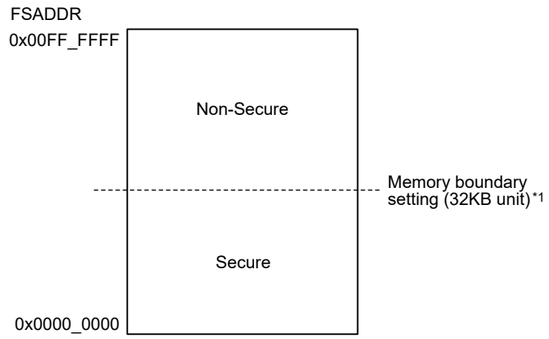
When the target area of FACI command is the user area of code flash, the flash sequencer compares the FSADDR register setting with the memory boundary setting of the code flash and determines whether the target area is in the secure region.

The memory boundary can be set to 0x0000_0000 to 0x00FF_8000 in 32 KB unit.

Figure 40.31 shows details of the non-secure/secure attribute of user area in the code flash.



Note 1. Comparing FSADDR with memory boundary setting of user area and judges whether the target area is in secure area.

Figure 40.31 Secure/non-secure region in user area

When the target area of the issuing FACI command is the data area of data flash, the flash sequencer compares the FSADDR/FEADDR register setting with the memory boundary setting of the data flash and determines whether the target area is in secure region. The memory boundary can be set to 0x0800_0000 to 0x0800_FC00 in 1 KB unit. Figure 40.32 shows details of the non-secure/secure attribute of data area in the data flash.

- X indicates read/write access is not possible by the non-secure access. Write data is ignored and read data is always 0.

Note 1. The FACI command issued by the non-secure access is not allowed.

Code flash programming/erasure can be protected by the FMEPROT register of secure function. Therefore, it does not assume that secure function issues P/E suspend command during code flash programming/erasure of non-secure function.

Data flash programming/erasure of non-secure can be suspended by secure function. If secure function issues P/E suspend command during data flash programming/erasure of non-secure function, secure function should issue P/E resume command. When secure function issues P/E resume command, secure function should notify non-secure function that data flash programming/erasure is complete and return to non-secure function. See Figure 40.35 and Figure 40.36 in example of issuing P/E suspend of secure function during programming/erasure of non-secure function.

注1.非安全访问发出的FACI命令是不允许的。

代码闪存编程擦除可以通过安全功能的FMEPROT寄存器进行保护。因此，不假设安全功能在非安全功能的代码闪存编程擦除期间发出PE挂起命令。

非安全的数据闪存编程擦除可以通过安全功能暂停。如果在非安全功能的数据闪存编程擦除期间安全功能发出PE暂停命令，安全功能应发出PE恢复命令。当安全功能发出PEresume命令时，安全功能应通知非安全功能数据闪存编程擦除完成并返回到非安全功能。在对非安全功能进行编程擦除时发出PE暂停安全功能的示例，请参见图40.35和图40.36。

40.12.3.5 Code Flash P/E Mode Entry Protection

The flash sequencer has protection function of code flash P/E by the FMEPROT register for the secure developer. Secure function can prevent disturbance of reading code flash memory by this protection function. See section 40.4.14. FMEPROT : Flash P/E Mode Entry Protection Register.

For applications that do not require non-secure region programming/erasure other than from secure function, it is recommended to always disable non-secure function of code flash programming/erasure by enabling the protection function of FMEPROT register.

See Figure 40.37 in details of the code flash P/E sequence example by non-secure function.

40.12.3.5 CodeFlashPE模式进入保护

闪存定序器通过FMEPROT寄存器为安全开发人员提供代码闪存PE的保护功能。安全功能可以通过此保护功能防止读取代码闪存的干扰。请参阅第40.4.14节。FMEPROT：FlashPE模式进入保护寄存器。

对于除安全功能外不需要非安全区域编程擦除的应用，建议始终通过启用FMEPROT寄存器的保护功能来禁用代码闪存编程擦除的非安全功能。

有关非安全功能的代码闪存PE序列示例的详细信息，请参见图40.37。

Note 1. The drive capability of the sub clock oscillator is set to standard by SOMCR.SODRV bit. Note that if you use the crystal corresponding the low drive capability on your board, the crystal may not oscillate in the boot mode.
Note 2. See the boot firmware manual for the detail connection time.

40.13.1 Boot Mode (for the SCI Interface)

In boot mode (for the SCI interface), the host sends control commands and data for programming, and the flash memory is programmed or erased accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When this MCU is activated in boot mode (for the SCI interface), the program on the dedicated area the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.

Figure 40.38 shows the system configuration for operations in boot mode (for the SCI interface).

注2.详细连接时间请参见启动固件手册。

40.13.1 引导模式（用于SCI接口）

在引导模式下（针对SCI接口），主机发送控制命令和数据进行编程，相应地对闪存进行编程或擦除。片上SCI以异步模式处理主机和该MCU之间的传输。主机中必须准备好用于传输控制命令和编程数据的工具。

当这个MCU在启动模式下被激活时（对于SCI接口），在MCU的专用区域上的程序被执行。引导程序通过接收来自主机的控制命令自动调整SCI的比特率并控制编程擦除。

图40.38显示了引导模式下操作的系统配置（对于SCI接口）。

40.13.2 Boot Mode (for the USB Interface)

In boot mode (with the USB interface), the flash memory can be programmed or erased by sending control commands and program data from the host. An on-chip USB is used for communications between the host and this MCU. The host requires tools for sending control commands and data for programming. Figure 40.39 shows the configuration of a system for use in boot mode (for the USB interface). The USB cable must be connected on reset release.

40.14 Using the Serial Programmer for Rewriting

A serial programmer can be used to rewrite flash memory in boot mode.

(1) Serial Programming

This MCU is mounted on the system board at the time of serial programming. Providing a connector to the board enables rewriting of this MCU by the serial programmer to proceed.

40.14.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU with data are described below.

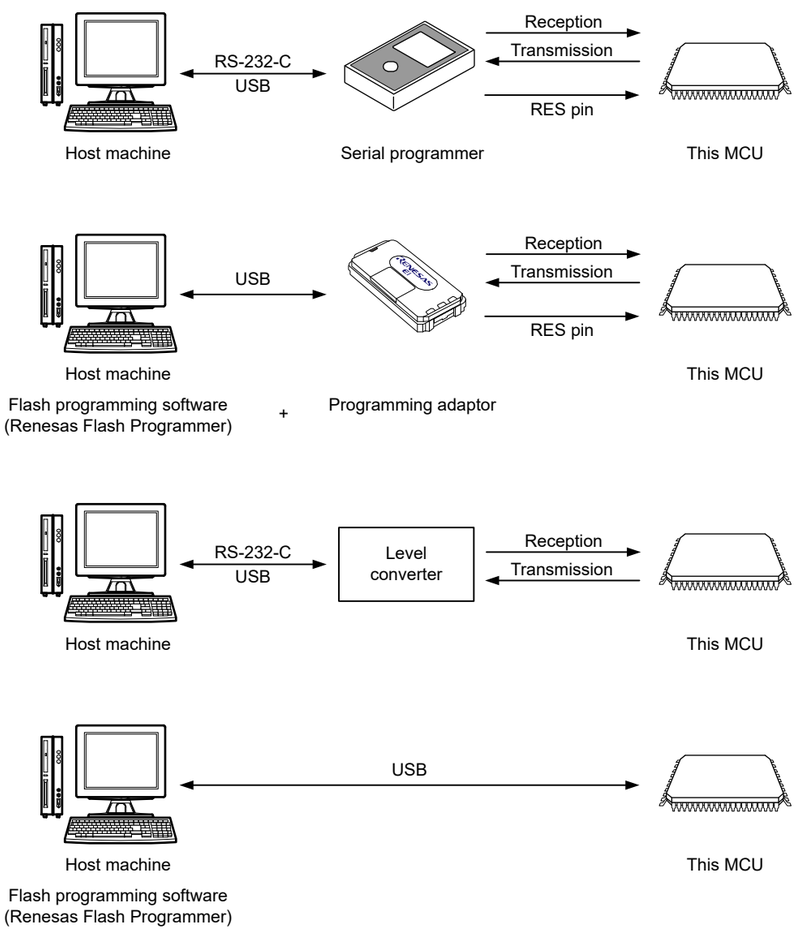

Figure 40.40 Environments for Rewriting the Flash Memory

40.14 使用串行编程器进行重写

串行编程器可用于在引导模式下重写闪存。

(1) 串行编程

该MCU在串行编程时安装在系统板上。为电路板提供连接器可以让串行编程器重写该MCU以继续进行。

40.14.1 串行编程环境

使用数据重写MCU的闪存的推荐环境如下所述。

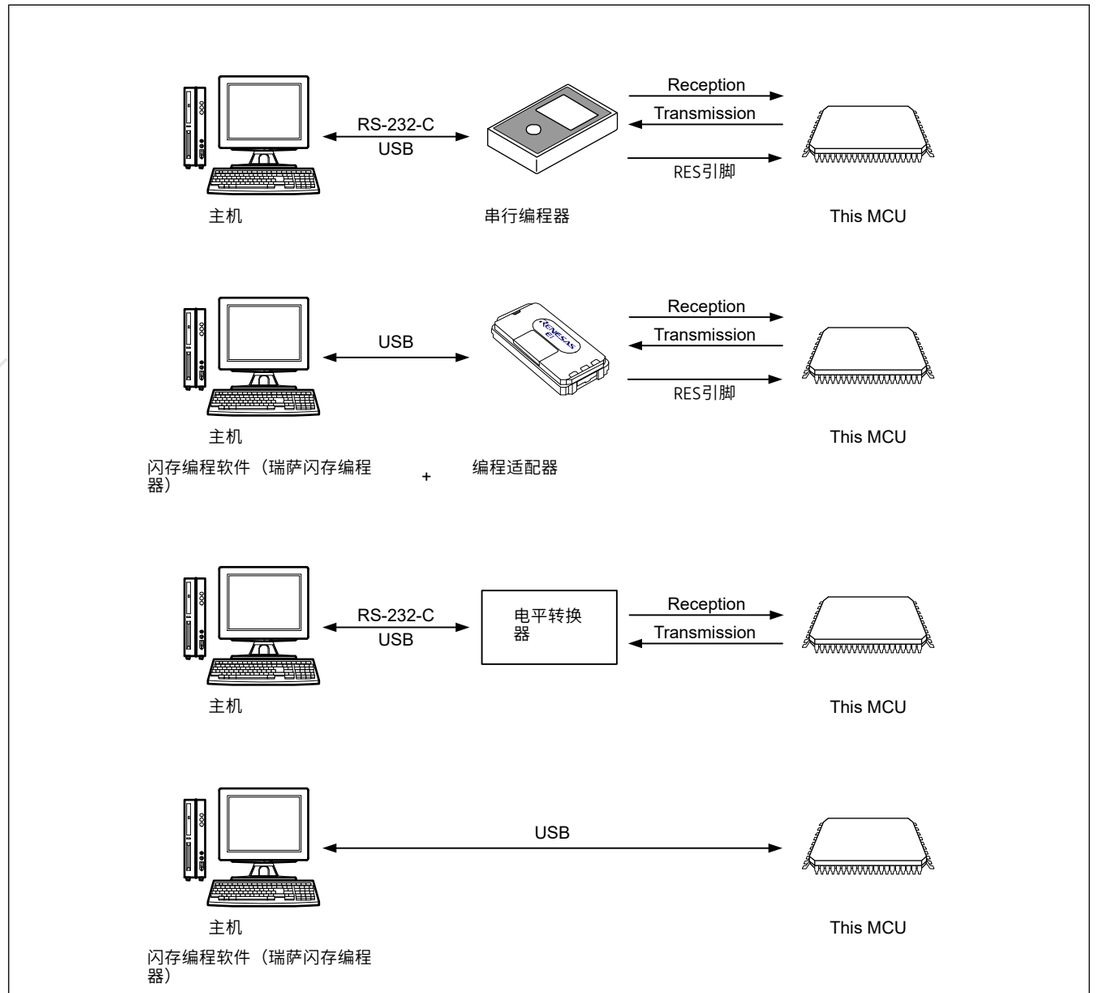

Figure 40.40 重写闪存的环境

40.15 Programming through Self-Programming

40.15.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACI commands can be used with user programs for writing to the flash memory. This allows upgrading of user programs and rewriting of constant data fields.

The program for rewriting must be transferred to the internal RAM in advance when the BGO is not available or when rewriting the option-setting memory.

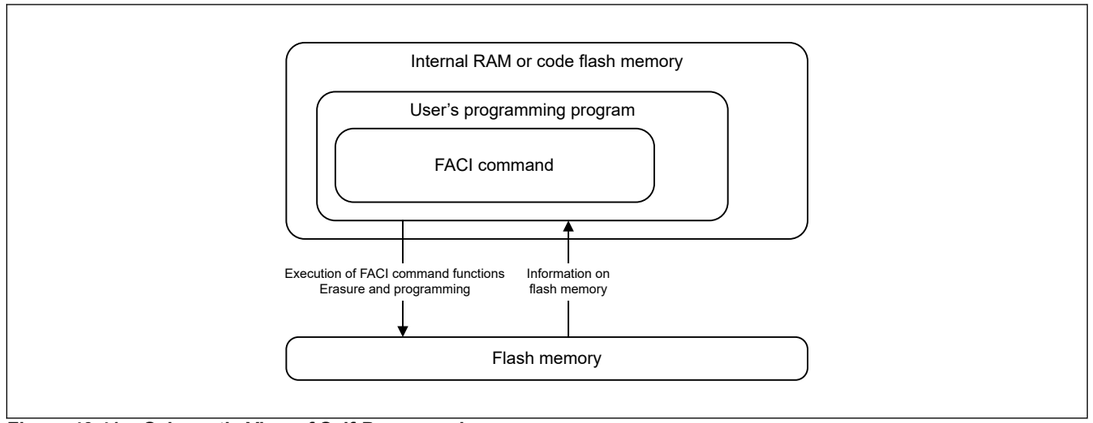

Figure 40.41 Schematic View of Self-Programming

For comprehensive information on the self-programming, refer to section 40.9. FACI Commands

40.15.2 Background Operation

The background operation (BGO) can be used to execute the flash rewrite routine on the code flash memory when the data flash memory is rewritten.

Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed below.

Table 40.29 Conditions under which Background Operation is Usable

	Range for rewriting	Range for reading
Common	Code flash memory	Data flash memory
	Data flash memory	Code flash memory

40.16 Reading Flash Memory

40.16.1 Reading Code Flash Memory

Special settings are not required to read code flash memory after release from the reset state. Data can simply be read out through access to addresses in the code flash memory.

When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

40.16.2 Reading Data Flash Memory

Special settings are not required to read data flash memory after release from the reset state. Data can simply be read out through access to addresses in the data flash memory.

40.15 通过自编程进行编程

40.15.1 Overview

该MCU支持用户程序本身对闪存进行编程。FACI命令可与用户程序一起用于写入闪存。这允许升级用户程序和重写常量数据字段。

当BGO不可用或重写选项设置存储器时，必须提前将重写程序传送到内部RAM。

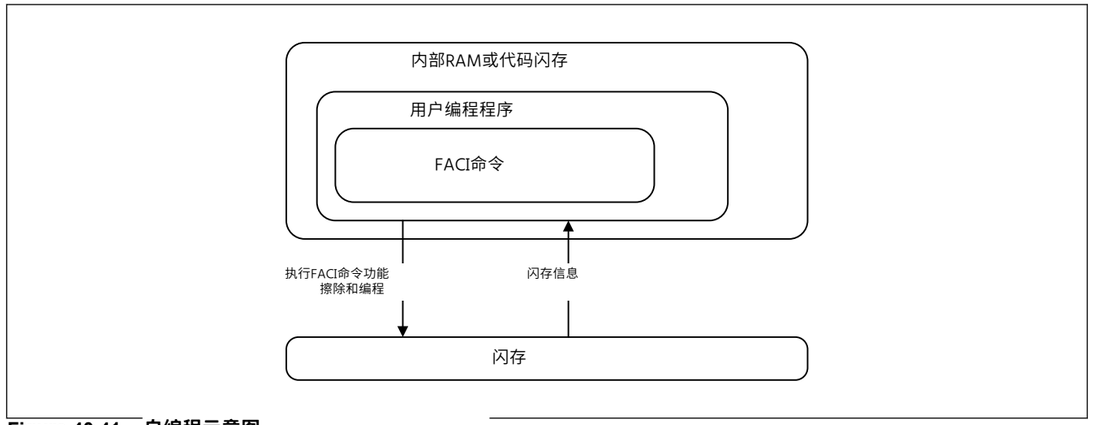

Figure 40.41 自编程示意图

有关自编程的全面信息，请参阅第40.9节。FACI命令

40.15.2 后台操作

当数据闪存被重写时，后台操作（BGO）可用于在代码闪存上执行闪存重写例程。

当用于重写的闪存和用于读取的闪存的组合为下列任何一种时，可以使用后台操作。

Table 40.29 后台操作可用的条件

	重写范围	读取范围
Common	代码闪存	数据闪存
	数据闪存	代码闪存

40.16 读取闪存

40.16.1 读码闪存

从复位状态释放后，读取代码闪存不需要特殊设置。可以通过访问代码闪存中的地址来简单地读取数据。

当读取已擦除但尚未再次编程的代码闪存时（即处于未编程状态），所有位都被读取为1。

40.16.2 读取数据闪存

从复位状态释放后读取数据闪存不需要特殊设置。通过访问数据闪存中的地址可以简单地读取数据。

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

40.17 Usage Notes

(1) Reading Area Where Programming/Erasure was Interrupted and Area Targeted for Suspension

The data stored in the area where programming or erasure has been suspended or the area where programming or erasure has been suspended by using the suspend command are undefined. To avoid faulty operation caused by reading undefined data, take care not to fetch instructions or read data from areas where programming or erasure was suspended and where programming or erasure was suspended by using the suspend command.

(2) Suspension During Programming/Erasure

When processing of programming/erasure is stopped by issuing the P/E suspend command, the programming/erasure processing can be resumed by issuing the P/E resume command. If the flash sequencer enters the command-locked state for any reason and issues the forced stop command after the suspended processing is normally completed and the ERSSPD flag or PRGSPD flag is set to 1, the suspended processing cannot be resumed. In addition, the values in the area where the processing was suspended are not guaranteed. Erase that area

(3) Prohibition of Additional Programming

Programming a given area of the code flash memory or data flash memory twice is not possible. To program the code flash memory or data flash memory where has been programed, erase the target area. Programming can be added to the option-setting memory.

(4) Resets During Programming/Erasure, or Blank Checking

In the case of a reset due to the signal on the RES pin during programming/erasure, or blank checking of the flash memory, wait for at least t_{RESW} (see section 43, Electrical Characteristics) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics, then release the device from the reset state.

从已擦除但尚未再次编程（即处于未编程状态）的数据闪存中读取的值未定义。当您需要确认某个区域处于非编程状态时，请使用空白检查。

40.17 使用说明

(1) 编程擦除被中断的阅读区域和暂停的目标区域

存储在已暂停编程或擦除的区域或已使用suspend命令暂停编程或擦除的区域中的数据是未定义的。为避免因读取未定义数据而导致错误操作，请注意不要从暂停编程或擦除的区域以及使用暂停命令暂停编程或擦除的区域获取指令或读取数据。

(2) 编程擦除期间的暂停

当通过发出PE暂停命令停止编程擦除处理时，可以通过发出PE恢复命令来恢复编程擦除处理。如果闪存定序器由于任何原因进入命令锁定状态并在挂起处理正常完成并且ERSSPD标志或PRGSPD标志设置为1后发出强制停止命令，则无法恢复挂起的处理。此外，不能保证处理暂停的区域中的值。擦除该区域

(3) 禁止额外编程

不能对代码闪存或数据闪存的给定区域进行两次编程。要对已编程的代码闪存或数据闪存进行编程，请擦除目标区域。可以将编程添加到选项设置存储器中。

(4) 在编程擦除或空白检查期间复位

如果在编程擦除期间由于RES引脚上的信号导致复位，或者闪存的空白检查，一旦工作电压达到在电气特性规定的范围内，然后将设备从复位状态释放。

(5) Allocation of Vectors for Interrupts and Other Exceptions During Programming/Erasure

Generation of an interrupt or other exception during programming/erasure may lead to fetching of the vector from the code flash memory. Under conditions where BGO cannot be used, set the address of the vector to an address that is not in the code flash memory. Alternatively, make sure that no handling of interrupts or exceptions proceeds during programming/erasure.

(6) Items Prohibited During Programming/Erasure, or Blank Checking

High voltage is applied to the flash memory during programming/erasure, or blank checking. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0]bits.
- Change the OPCCR.OPCM[2:0] and SOPCCR.SOPCM bits.
- Change the SCKDIVCR.FCK[2:0]bits.
- Change the SCKSCR.CKSEL[2:0]bits.
- Transition to the software standby mode, or deep software standby mode.

(7) Programming/Erasure in Low-Speed Modes and Subosc-Speed Mode

Do not programming/erasure the flash memory when low-speed mode or subosc-speed mode is selected with the operating power control register (OPCCR or SOPCCR).

(8) Emulator Connection

Renesas provides the emulator which supports both debugging using SWD or JTAG communication and serial programming using SCI communication. This emulator makes it easy to switch between debugging and serial programming.

Table 40.32 shows the pinout of 10 pin or 20 pin socket pinouts when using this emulator. The pinout of SWD and JTAG is ARM standard, and MD, TXD, RXD pins are added for the serial programming using SCI communication.

The serial programming interface must be used to program the TrustZone IDAU boundary register settings.

It is recommended to connect P300/SWCLK/TCK and P201/MD pins using wired OR circuit on the board to use both debugging and serial programming

Table 40.32 Pin assign for emulator

7	NC	NC	NC

(5) 在编程擦除期间为中断和其他异常分配向量

在编程擦除期间产生中断或其他异常可能会导致从代码闪存中获取向量。在无法使用BGO的情况下，将向量的地址设置为不在代码闪存中的地址。或者，确保在编程擦除期间不处理中断或异常。

(6) 编程擦除或空白检查期间禁止的项目

在编程擦除或空白检查期间向闪存施加高电压。为防止损坏闪存，请勿执行以下操作。

- ●电源的工作电压是否超出允许范围。
- ●改变FWEPROR.FLWE[1:0]位。
- ●更改OPCCR.OPCM[2:0]和SOPCCR.SOPCM位。
- ●更改SCKDIVCR.FCK[2:0]位。
- ●更改SCKSCR.CKSEL[2:0]位。
- ●转换到软件待机模式或深度软件待机模式。

(7) 低速模式和Subosc-Speed模式下的编程擦除

当使用工作电源控制寄存器（OPCCR或SOPCCR）选择低速模式或subosc-speed模式时，不要对闪存进行编程擦除。

(8) 仿真器连接

瑞萨电子提供的仿真器支持使用SWD或JTAG通信进行调试和使用SCI通信进行串行编程。该仿真器可以轻松地在调试和串行编程之间切换。

表40.32显示了使用该仿真器时10针或20针插座的引脚排列。SWD和JTAG的管脚是ARM标准，并增加了MD、TXD、RXD引脚用于使用SCI通信的串行编程。

必须使用串行编程接口对TrustZoneIDAU边界寄存器设置进行编程。

建议使用板上的有线OR电路连接P300SWCLKTCK和P201MD引脚，以同时使用调试和串行编程

42.2 Arm TrustZone Security

42.2.1 Arm TrustZone Technology

Arm TrustZone technology divides the system and the application into Secure and Non-secure domains. Secure application can access both Secure and Non-secure memory and resources. Non-secure application can only access Non-secure memory and resources.

The system starts up in Secure state by default. The security state of CPU can be either Secure or Non-secure.

42.2.2 Memory Security Attribution

The code flash, the data flash, and the SRAM are divided into Secure (S), Non-secure (NS) and Non-secure callable (NSC) regions. These memory security attributions are set into the nonvolatile memory by the serial programming command when the device lifecycle is SSD state. These memory security attributions are loaded into the IDAU and the memory controller before application execution. These memory security attributions cannot be updated by application but can be through the dedicated registers.

The code flash can be divided in up to three regions. The data flash can be divided in up to two regions. The SRAM can be divided in up to three regions. Figure 42.1 shows the memory mapping. Table 42.1 shows the size of memory region.

42.2.1 ArmTrustZone技术

ArmTrustZone技术将系统和应用程序划分为安全和非安全域。安全应用程序可以访问安全和非安全内存和资源。非安全应用程序只能访问非安全内存和资源。

系统默认以安全状态启动。CPU的安全状态可以是Secure或Non-secure。

42.2.2 内存安全归属

代码闪存、数据闪存和SRAM分为安全(S)、非安全(NS)和非安全可调用(NSC)区域。当设备生命周期为SSD状态时，这些内存安全属性由串行编程命令设置到非易失性内存中。这些内存安全属性在应用程序执行之前被加载到IDAU和内存控制器中。这些内存安全属性不能由应用程序更新，但可以通过专用寄存器来更新。

代码闪存最多可分为三个区域。数据闪存最多可分为两个区域。SRAM最多可分为三个区域。图42.1显示了内存映射。表42.1显示了内存区域的大小。

42.2.3 Peripheral Security Attribution

Each peripheral can be configured to be Secure or Non-secure.

Peripherals are divided into two types.

Type-1 peripherals has the one security attribution. Access to all registers is controlled by one security attribution. Type-1 peripheral security attribution is set to the PSARx (x = B to E) register by the secure application.

Type-2 peripherals has the security attribution for each register or for each bit. Access to each register or bit field is controlled according to these security attributions. Type-2 peripheral security attribution is set to the Security Attribution register in each module by the secure application. For the Security Attribution register, see sections in the user manual for each peripheral.

Table 42.3 shows the classification of peripheral type.

42.2.3 外围安全属性

每个外围设备都可以配置为安全或非安全。

外设分为两种。

Type-1外围设备具有唯一的安全属性。对所有寄存器的访问由一个安全属性控制。类型1外设安全属性由安全应用程序设置到PSARx（x=B到E）寄存器。

Type-2外设对每个寄存器或每个位都有安全属性。根据这些安全属性控制对每个寄存器或位字段的访问。类型2外围安全属性由安全应用程序设置到每个模块中的安全属性寄存器。对于安全属性寄存器，请参阅每个外设的用户手册中的部分。

表42.3显示了外围类型的分类。

42.3.1 Changing the Lifecycle State

Use the serial programming commands to change the device lifecycle state. See the boot firmware application note for the detail of command. The lifecycle cannot be updated by application but can read through the dedicated registers.

As shown in Figure 42.2, there are three types lifecycle transition.

The first one is to change to lower debug access level or restrict the serial programming mode. This change can be done with no restriction.

Note: The debug interface is permanently disabled in LCK_DBG. After changed to LCK_DBG, the debug interface cannot be used forever.

Note: The debug interface and serial programming interface are permanently disabled in LCK_BOOT. After changed to LCK_BOOT, the debug interface and the serial programming interface cannot be used forever.

The second one is to change to higher debug access level or request for RMA. This change needs key authentication. The key length is 128 bits. The secure developer needs to inject two keys when the lifecycle is SSD state. One is “SECDBG_KEY” which is used to authentication to change the lifecycle from NSECSD to SSD. Other one is “RMA_KEY” which is used to authentication to change the lifecycle from SSD or DPL to RMA_REQ. The non-secure developer needs to inject one key when the lifecycle is NSECSD state. This is “NONSECDBG_KEY” which is used to authentication to change the lifecycle from DPL to NSECSD. See section 42.4. Key Injection for the detail of how to inject the key. The key authentication uses a challenge and response authentication or authentication using the unique ID. The authentication using the unique ID is available only transition to RMA_REQ. The following is the process of how to calculate the response, challenge and response authentication, or the authentication code using unique ID.

Response = HMAC-SHA256 (KEY, 128bits challenge || fixed value (256bits))

Authentication code = HMAC-SHA256 (KEY, 128bits unique ID || fixed value (256 bits))

fixed value = 9e56dc41 cf0c9648 1b811141 f8f9ba1e 4dd77746 6d403593 17f46d64 fe64fdf6

Note: That "||" represents concatenation, not logical or.

Note: In case the key is not injected, these lifecycle changes cannot be done.

Note: In the lifecycle transition from NSECSD to SSD or form DPL to NSECSD, the contents on the flash memory are not erased.

Note: MCU does not respond after changing to higher debug access level or RMA_REQ. If you continue to use the serial programming commands, need to re-enter the boot mode after a reset. See the boot firmware application note for the detail.

Note: In the lifecycle transition to RMA_REQ, the contents on the flash memory except permanently locked block or setting or BPS_SEL register are erased. The contents in the permanently locked block or register can be read by Renesas at failure analysis. Permanently locked block means the block which programming and erasure is disabled permanently by PBPS, PBPS_SEC and BPS_SEL register. Permanently locked register means SAS register which programming and erasure is disabled permanently by FSPR bit.

The third one is all erase. This is done by an initialize command unless an initialize command itself is disabled. The lifecycle is back to SSD and the contents on the flash memory is erased. If there is permanently locked block or register, an initialize command does not execute. In case of the all bits of PBPS and PBPS_SEC register are 1 and FSPR bit is1, an initialize command is executable.

Note: The initialize command can be issued by everyone, so contents on the flash memory are easily erased. Developers who do not want this can invalidate the initialize command permanently by parameter setting command.

Note: MCU does not respond after executing the initialize command. If you continue to use the serial programming commands, need to re-enter the boot mode after a reset. See the boot firmware application note for the detail.

Lifecycle	Definition	调试级别	串行编程	瑞萨测试模式

42.3.1 更改生命周期状态

使用串行编程命令更改设备生命周期状态。有关命令的详细信息，请参见启动固件应用说明。生命周期不能由应用程序更新，但可以通过专用寄存器读取。

如图42.2所示，生命周期转换分为三种。

第一个是更改为降低调试访问级别或限制串行编程模式。这种改变可以不受限制地进行。

Note: 调试接口在LCK_DBG中被永久禁用。改成LCK_DBG后，调试接口就不能一直使用了。

Note: 调试接口和串行编程接口在LCK_BOOT中永久禁用。改成之后
LCK_BOOT、调试接口和串行编程接口不能永远使用。

第二个是更改为更高的调试访问级别或请求RMA。此更改需要密钥身份验证。密钥长度为128位。当生命周期为SSD状态时，安全开发人员需要注入两个密钥。一种是“SECDBG_KEY”，用于身份验证以将生命周期从NSECSD更改为SSD。另一种是“RMA_KEY”，用于身份验证以将生命周期从SSD或DPL更改为RMA_REQ。当生命周期为NSECSD状态时，非安全开发者需要注入一个密钥。这是“NONSECDBG_KEY”，用于身份验证以将生命周期从DPL更改为NSECSD。见第42.4节。KeyInjection有关如何注入密钥的详细信息。密钥身份验证使用质询和响应身份验证或使用唯一ID的身份验证。使用唯一ID的身份验证只能转换到RMA_REQ。以下是如何计算响应、挑战和响应身份验证或使用唯一ID的身份验证码的过程。

响应=HMAC-SHA256(KEY 128bitschallengeFixedvalue(256bits))

认证码=HMAC-SHA256（KEY，128bits唯一ID固定值（256bits））

固定值=9e56dc41cf0c96481b811141f8f9ba1e4dd777466d40359317f46d64fe64fdf6

Note: 那“”代表连接，不是逻辑或。

Note: 如果未注入密钥，则无法完成这些生命周期更改。

Note: 在从NSECSD到SSD或从DPL到NSECSD的生命周期转换中，闪存上的内容不会被擦除。

Note: 更改为更高的调试访问级别或RMA_REQ后，MCU没有响应。如果继续使用串口编程命令，需要复位后重新进入开机模式。有关详细信息，请参阅启动固件应用说明。

Note: 在到RMA_REQ的生命周期转换中，闪存上的内容除了永久锁定的块或设置或BPS_SEL寄存器外被擦除。瑞萨在故障分析时可以读取永久锁定的块或寄存器中的内容。永久锁定块是指被PBPS、PBPS_SEC和BPS_SEL寄存器永久禁用编程和擦除的块。永久锁定寄存器是指通过FSPR位永久禁用编程和擦除的SAS寄存器。

第三个是全部擦除。这由初始化命令完成，除非初始化命令本身被禁用。生命周期回到SSD，闪存上的内容被擦除。如果存在永久锁定的块或寄存器，则不会执行初始化命令。如果PBPS和PBPS_SEC寄存器的所有位为1，FSPR位为1，则可执行初始化命令。

Note: 每个人都可以发出初始化命令，因此闪存上的内容很容易被擦除。不希望这样的开发者可以通过参数设置命令使初始化命令永久无效。

Note: 执行初始化命令后MCU没有响应。如果继续使用串口编程命令，需要复位后重新进入开机模式。有关详细信息，请参阅启动固件应用说明。

42.3.2 Debug access level

There are three debug access levels, and the debug access level changes according to the lifecycle state.

- DBG2: The debugger connection is allowed, and no restriction to access memories and peripherals
- DBG1: The debugger connection is allowed, and restricted to access only non-secure memory regions and peripherals
- DBG0: The debugger connection is not allowed

42.3.3 Serial Programming

Whether a serial programmer can be connected and the range of flash memory that can be accessed depends on the lifecycle state as shown in Table 42.8. And the accepted serial programming command differs depending on the lifecycle state. See the boot firmware application note for the detail of command.

42.3.4 Lifecycle changing example

The following is a typical lifecycle changing example.

Secure developer

- Change the lifecycle from CM to SSD by using the serial programming command.
- Set the memory security attribution of the code flash, data flash and SRAM by using the serial programming command.
- Program the secure application by using the serial programming interface and debug the secure application. Debug is possible if the lifecycle is CM, but it is impossible to set the memory security attribution in CM state. If the memory security attribution is not set, all area of the code flash, data flash and SRAM is Secure.

Note: Need to configure the registers listed in Table 42.10 as Non-secure only in NSECSD state. See section 42.6.1. Restrictions on setting the security attribution for details.

- Inject “SECDBG_KEY” and “RMA_KEY” by using the serial programming command (if need).
- Inject AES, RSA, ECC, HMAC keys listed in Table 42.9 (if need).
- Disable the all erase by using the serial programming command (if need).
- Change the lifecycle from SSD to NSECSD by using the serial programming command.

Non-secure developer

- Program the Non-secure application by using the serial programming interface and debug the Non-secure application.
- Inject “NONSECDBG_KEY” by using the serial programming command (if need).
- Inject AES, RSA, ECC, HMAC keys listed in Table 42.9 (if need).
- Disable the all erase by using the serial programming command (if need).
- Change the lifecycle to DPL by using the serial programming command.

42.3.5 Failure analysis

If the customer requests the failure analysis to Renesas, it is necessary to send the device after changing the lifecycle to RMA_REQ. If the lifecycle is not RMA_REQ, Renesas can not do the failure analysis. Because RMA_REQ is permanent state, it can not back to the another state after changing to RMA_REQ. It is assumed to change to SSD or NSECSD and analyze before changing to RMA_REQ.

Devices sent to Renesas will not be returned to customers. The device will be discarded.

Note: As described in the section 42.3.1. Changing the Lifecycle State, RMA_KEY is needed to change the lifecycle to RMA_REQ. If the customer forgets the RMA_KEY, Renesas can not do the failure analysis.

42.4 Key Injection

There are three steps required to inject a user key into the MCU.

42.3.2 调试访问级别

共有三个调试访问级别，调试访问级别根据生命周期状态而变化。

●DBG2：允许调试器连接，不限制访问内存和外设

●DBG1：允许调试器连接，但仅限于访问非安全内存区域和外围设备

●DBG0：不允许调试器连接

42.3.3 串行编程

是否可以连接串行编程器以及可以访问的闪存范围取决于生命周期状态，如表42.8所示。并且接受的串行编程命令根据生命周期状态而有所不同。有关命令的详细信息，请参见启动固件应用说明。

42.3.4 生命周期更改示例

以下是一个典型的生命周期更改示例。

安全开发人员

●使用串行编程命令将生命周期从CM更改为SSD。

●使用串行编程命令设置codeflash、dataflash和SRAM的内存安全属性。

●使用串行编程接口对安全应用程序进行编程并调试安全应用程序。如果生命周期是CM，则可以调试，但无法在CM状态下设置内存安全属性。如果未设置内存安全属性，则代码闪存、数据闪存和SRAM的所有区域都是安全的。

Note: 仅在NSECSD状态下需要将表42.10中列出的寄存器配置为非安全。请参见第42.6.1节。
设置安全属性的限制以获取详细信息。

●使用串行编程命令（如果需要）注入“SECDBG_KEY”和“RMA_KEY”。

●注入表42.9中列出的AES、RSA、ECC、HMAC密钥（如果需要）。

●使用串行编程命令禁用全部擦除（如果需要）。

●使用串行编程命令将生命周期从SSD更改为NSECSD。

Non-secure developer

●使用串行编程接口对非安全应用程序进行编程并调试非安全应用程序。

●使用串行编程命令（如果需要）注入“NONSECDBG_KEY”。

●注入表42.9中列出的AES、RSA、ECC、HMAC密钥（如果需要）。

●使用串行编程命令禁用全部擦除（如果需要）。

●使用串行编程命令将生命周期更改为DPL。

42.3.5 故障分析

如果客户要求对瑞萨进行故障分析，则需要在将生命周期更改为RMA_REQ后发送设备。如果生命周期不是RMA_REQ，瑞萨将无法进行故障分析。因为RMA_REQ是永久状态，所以在更改为RMA_REQ后不能回到另一个状态。假设更改为SSD或NSECSD并在更改为RMA_REQ之前进行分析。

发送给瑞萨的设备将不会退还给客户。该设备将被丢弃。

Note: 如第42.3.1节所述。更改LifecycleState，需要RMA_KEY才能将生命周期更改为RMA_REQ。如果客户忘记了RMA_KEY，瑞萨将无法进行故障分析。

42.4 密钥注入

将用户密钥注入MCU需要三个步骤。

First, the customer needs to create the 128 bits installation key. This key is called User Factory Programming Key (UFPK) and used to encrypt a user key. The customer gets the key of the wrapped version (W-UFPK) through the Renesas Key Wrapping Service.

Second the customer encrypts the user key using UFPK as the AES key.

Last the customer sends W-UFPK and the encrypted user key to the MCU by using serial programming interface. The sent user key is decrypted, wrapped with the hardware unique key, and then stored in the nonvolatile memory.

Figure 42.3 is the illustration of key injection. Table 42.9 shows the keys that can be injected by serial programming interface.

User Key is also used for authentication during the life cycle transition.

首先，客户需要创建128位安装密钥。此密钥称为用户工厂编程密钥(UFPK)，用于加密用户密钥。客户通过RenesasKeyWrappingService获得打包版本(W-UFPK)的密钥。

其次，客户使用UFPK作为AES密钥对用户密钥进行加密。

最后客户通过串行编程接口将W-UFPK和加密的用户密钥发送给MCU。发送的用户密钥被解密，用硬件唯一密钥包装，然后存储在非易失性存储器中。

图42.3是密钥注入的示意图。表42.9显示了串行编程接口可以注入的密钥。

用户密钥还用于生命周期转换期间的身份验证。

When the PROTECT bit is set, write 0xA5 in the KEY[7:0] bits at the same time.

42.6 Usage Notes

42.6.1 Restrictions on setting the security attribution

To set the software breakpoint, the debugger need to re-program the flash. Table 42.10 shows the registers that the debugger sets to re-program the flash. If the security attribution of the register listed in Table 42.10 is configured as secure, the debugger can not set the software breakpoint in NSECSD state because the debugger can not change the register setting. Secure developper need to configure the registers listed in Table 42.10 as non-secure only in NSECSD state.

Table 42.10 The registers that the debugger sets to re-program the flash

Function name	Register name
Clock Generation Circuit	SCKDIVCR, SCKCR, PLLCCR, PLLCR, HOCOCR, MOCOCR
Low-Power modes	OPCCR, SOPCCR

42.6.2 SAU setting

After reset, all of address space is marked as Secure by SAU default setting. SAU_CTRL register should be set to 0x2 to enable the IDAU security attribution. That is, after setting SAU_CTRL register to 0x2, the address space security attribution becomes as shown in Table 42.6.

42.6.3 Non-secure exception during the setting of FACI registers

As shown in Table 42.5, the registers related to FACI are protected from non-secure access only during programming/erasure or during suspend programming/erasure. Outside of this state, the access from non-secure region is not protected. For example, when programming by the secure user, the non-secure user can rewrite the FSADDR if a non-secure exception occurs immediately after “Set the start address of the target block to the FSADDR register” flow in Figure 40.13. If the FACI command is issued after the non-secure exception processing is completed and the CPU state returns to the secure state, data will be programmed to an address not intended by the secure user.

To prevent such a things, secure user needs to set not to accept the non-secure exception during the following period.

- Set not to accept the non-secure exeption before setting FWEPROR to 01h or setting FENTRYR to other than 0000h, that is before lereasing the protection of FWEPROR or FENTRYR.
- Set to accept the non-secure exception after all write access to the FACI command-issuing area is completed.

42.6.4 FCU interrupt usage

It is recommended that secure users do not use the FCU interrupts, but rather use the register polling. Because non-secure users can program/erase the data flash without calling the secure gateway, if secure user uses FCU interrupts, the unintentional exception handliing may be exeuted when data flash is programmed/erased by a non-secure user.

- 允许安全和非安全访问。

PROTECT位（寄存器保护）

PROTECT位控制启用或禁用对受保护的相应寄存器的写入。TZFOAD寄存器受PROTECT保护。

当PROTECT位置位时，同时向KEY[7:0]位写入0xA5。

KEY[7:0] bits (KeyCode)

KEY[7:0]位用于启用或禁用PROTECT位的写入。写入PROTECT位时，同时向KEY[7:0]位写入0xA5。

写入除0xA5以外的KEY[7:0]位值时，PROTECT位不更新。

KEY[7:0]位总是被读取为0x00。

42.6 使用说明

42.6.1 设置安全属性的限制

要设置软件断点，调试器需要重新编程闪存。表42.10显示了调试器为重新编程闪存而设置的寄存器。如果将表42.10中列出的寄存器的安全属性配置为安全，则调试器无法在NSECSD状态下设置软件断点，因为调试器无法更改寄存器设置。仅在NSECSD状态下，安全开发人员需要将表42.10中列出的寄存器配置为非安全。

Table 42.10 调试器设置的用于重新编程闪存的寄存器

函数名称	注册名称
时钟产生电路	SCKDIVCR, SCKCR, PLLCCR, PLLCR, HOCOCR, MOCOCR
Low-Power modes	OPCCR, SOPCCR

42.6.2 SAU设置

复位后，SAU默认设置将所有地址空间标记为安全。SAU_CTRL寄存器应设置为0x2以启用IDAU安全属性。即设置SAU_CTRL寄存器为0x2后，地址空间安全属性变为如表42.6所示。

42.6.3 FACI寄存器设置期间的非安全异常

如表42.5所示，与FACI相关的寄存器仅在编程擦除或挂起编程擦除期间受到保护，不会受到非安全访问。在此状态之外，来自非安全区域的访问不受保护。例如，当由安全用户编程时，如果在图40.13中的“将目标块的起始地址设置为FSADDR寄存器”流程之后立即发生非安全异常，非安全用户可以重写FSADDR。如果在非安全异常处理完成后发出FACI命令并且CPU状态返回到安全状态，则数据将被编程到安全用户不打算使用的地址。

为了防止这样的事情发生，安全用户需要在接下来的时间段内设置不接受非安全异常。

●在将FWEPROR设置为01h或将FENTRYR设置为0000h以外的值之前，即在解除对FWEPROR或FENTRYR的保护之前，设置不接受非安全例外。

●设置为在对FACI命令发布区域的所有写访问完成后接受非安全异常。

42.6.4 FCU中断使用

建议安全用户不要使用FCU中断，而是使用寄存器轮询。由于非安全用户可以在不调用安全网关的情况下对数据闪存进行编程擦除，因此如果安全用户使用FCU中断，则在数据闪存被非安全用户编程擦除时可能会执行意外异常处理。

43. Electrical Characteristics

Supported peripheral functions and pins differ from one product name to another.

Unless otherwise specified, the electrical characteristics of the MCU are defined under the following conditions:

- VCC = AVCC0 = VCC_USB = VBATT = 2.7 to 3.6 V
- 2.7 ≤ VREFH0/VREFH ≤ AVCC0
- VSS = AVSS0 = VREFL0/VREFL = VSS_USB = 0 V
- $T_a = T_{opr}$

Figure 43.1 shows the timing conditions.

The recommended measurement conditions for the timing specification of each peripheral provided are for the best peripheral operation. Make sure to adjust the driving abilities of each pin to meet your conditions.

- 2.7 ≤ VREFH0/VREFH ≤ AVCC0
- VSS = AVSS0 = VREFL0/VREFL = VSS_USB = 0 V
- $T_a = T_{opr}$

43.2.7 Thermal Characteristics

Maximum value of junction temperature (Tj) must not exceed the value of "section 43.2.1. Tj/Ta Definition".

Tj is calculated by either of the following equations.

- Tj = Ta + θja × Total power consumption
- Tj = Tt + Ψjt × Total power consumption
  - Tj : Junction Temperature (°C)
  - Ta : Ambient Temperature (°C)
  - Tt : Top Center Case Temperature (°C)
  - θja : Thermal Resistance of "Junction"-to-"Ambient" (°C/W)
  - Ψjt : Thermal Resistance of "Junction"-to-"Top Center Case" (°C/W)
- Total power consumption = Voltage × (Leakage current + Dynamic current)
- Leakage current of IO = Σ (I_{OL} × V_{OL}) /Voltage + Σ ($|I_{OH}|$ × $|VCC - V_{OH}|$) /Voltage
- Dynamic current of IO = Σ IO (C_{in} + C_{load}) × IO switching frequency × Voltage
  - C_{in}: Input capacitance
  - C_{load}: Output capacitance

Regarding θja and Ψjt, refer to Table 43.11.

43.2.7 热特性

结温（Tj）的最大值不得超过"第43.2.1节的值。TjTa定义"。

Tj通过以下任一公式计算。

- Tj=Ta+θja×总功耗
- Tj=Tt+Ψjt×总功耗
  - Tj：结温(°C)
  - Ta：环境温度（°C）
  - Tt：顶部中心外壳温度(°C)
  - θja："结"到"环境"的热阻(°CW)
  - Ψjt："结"到"顶部中心外壳"的热阻(°CW)
- 总功耗=电压×（漏电流+动态电流）
- IO漏电流=Σ(IOL×VOL)电压+Σ(IOH×VCC VOH)电压
- IO的动态电流=ΣIO(Cin+Cload)×IO开关频率×电压
  - Cin:输入电容
  - C负载：输出电容

Assumption :

- Package 64-pin LQFP : θja = 54.6 °C/W
- Ta = 80 °C

●ICC最大值=40mA

- VCC = 3.5 V (VCC = AVCC = VCC_USB)

●IOH=1mA，VOH=VCC 0.5V，12个输出

●IOL=20mA，VOL=1.0V，8个输出

●IOL=1mA，VOL=0.5V，12路输出

●Cin=8pF，16个引脚，输入频率=10MHz

- C_{load} = 30 pF, 16 pins, Output frequency = 10 MHz

Leakage current of IO = Σ (V_{OL} × I_{OL}) / Voltage + Σ ((VCC - V_{OH}) × I_{OH}) / Voltage
= (20 mA × 1 V) × 8 / 3.5 V + (1 mA × 0.5 V) × 12 / 3.5 V + ((VCC - (VCC - 0.5 V)) × 1 mA) × 12 / 3.5 V
= 45.7 mA + 1.71 mA + 1.71 mA
= 49.1 mA

Dynamic current of IO = Σ IO (C_{in} + C_{load}) × IO switching frequency × Voltage
= ((8 pF × 16) × 10 MHz + (30 pF × 16) × 10 MHz) × 3.5 V

Total power consumption = (I_{CC}max × Voltage) + (Leakage current of IO + Dynamic current of IO) × Voltage

= 386 mW (0.386 W)

Tj = Ta + θja × Total power consumption

Note 1. When setting up the main clock oscillator, ask the oscillator manufacturer for an oscillation evaluation, and use the results as the recommended oscillation stabilization time. Set the MOSCWTCR register to a value equal to or greater than the recommended value.
After changing the setting in the MOSCCR.MOSTP bit to start main clock operation, read the OSCSF.MOSCSF flag to confirm that it is 1, and then start using the main clock oscillator.

Note 2. This is the time from release from reset state until the HOCO oscillation frequency (f_{HOCO}) reaches the range for guaranteed operation.

Note 1. When setting up the sub-clock oscillator, ask the oscillator manufacturer for an oscillation evaluation and use the results as the recommended oscillation stabilization time.
After changing the setting in the SOSCCR.SOSTP bit to start sub-clock operation, only start using the sub-clock oscillator after the sub-clock oscillation stabilization time elapses with an adequate margin. A value that is two times the value shown is recommended.

Note 1. The recovery time is determined by the system clock source. When multiple oscillators are active, the recovery time can be determined with the following equation:
Total recovery time = recovery time for an oscillator as the system clock source + the longest tSBYOSCWT in the active oscillators - tSBYOSCWT for the system clock + 2 LOCO cycles (when LOCO is operating) + Subosc is oscillating and MSTPC0 = 0 (CAC module stop))
Note 2. When the frequency of the crystal is 24 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 1.
Note 3. When the frequency of PLL is 200 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 4.

Note 8. The HOCO frequency is 20 MHz and the greatest value of the internal clock division setting is 1.
Note 9. The PLL frequency is 200 MHz and the greatest value of the internal clock division setting is 4.
Note 10. The MOCO frequency is 8 MHz and the greatest value of the internal clock division setting is 1.
Note 11. In Subosc-speed mode, the sub-clock oscillator or LOCO continues oscillating in Software Standby mode.
Note 12. When the SNZCR.RXDREQEN bit is set to 0, the following time is added as the power supply recovery time: 16 µs (typical), 48 µs (maximum).
Note 13. The recovery time can be calculated with the equation of tSBYOSCWT + tSBYSEQ. And they can be determined with the following value and equation. For n, the greatest value is selected from among the internal clock division settings.

Wakeup time	TYP		MAX		Unit

Absolute accuracy

Absolute accuracy is the difference between output code based on the theoretical A/D conversion characteristics, and the actual A/D conversion result. When measuring absolute accuracy, the voltage at the midpoint of the width of the analog input voltage (1-LSB width), which can meet the expectation of outputting an equal code based on the theoretical A/D conversion characteristics, is used as an analog input voltage. For example, if 12-bit resolution is used and the reference voltage VREFH0 = 3.072 V, then the 1-LSB width becomes 0.75 mV, and 0 mV, 0.75 mV, and 1.5 mV are used as the analog input voltages. If the analog input voltage is 6 mV, an absolute accuracy of ±5 LSB means that the actual A/D conversion result is in the range of 0x003 to 0x00D, though an output code of 0x008 can be expected from the theoretical A/D conversion characteristics.

Integral nonlinearity error (INL)

Integral nonlinearity error is the maximum deviation between the ideal line when the measured offset and full-scale errors are zeroed, and the actual output code.

Differential nonlinearity error (DNL)

Differential nonlinearity error is the difference between the 1-LSB width based on the ideal A/D conversion characteristics and the width of the actual output code.

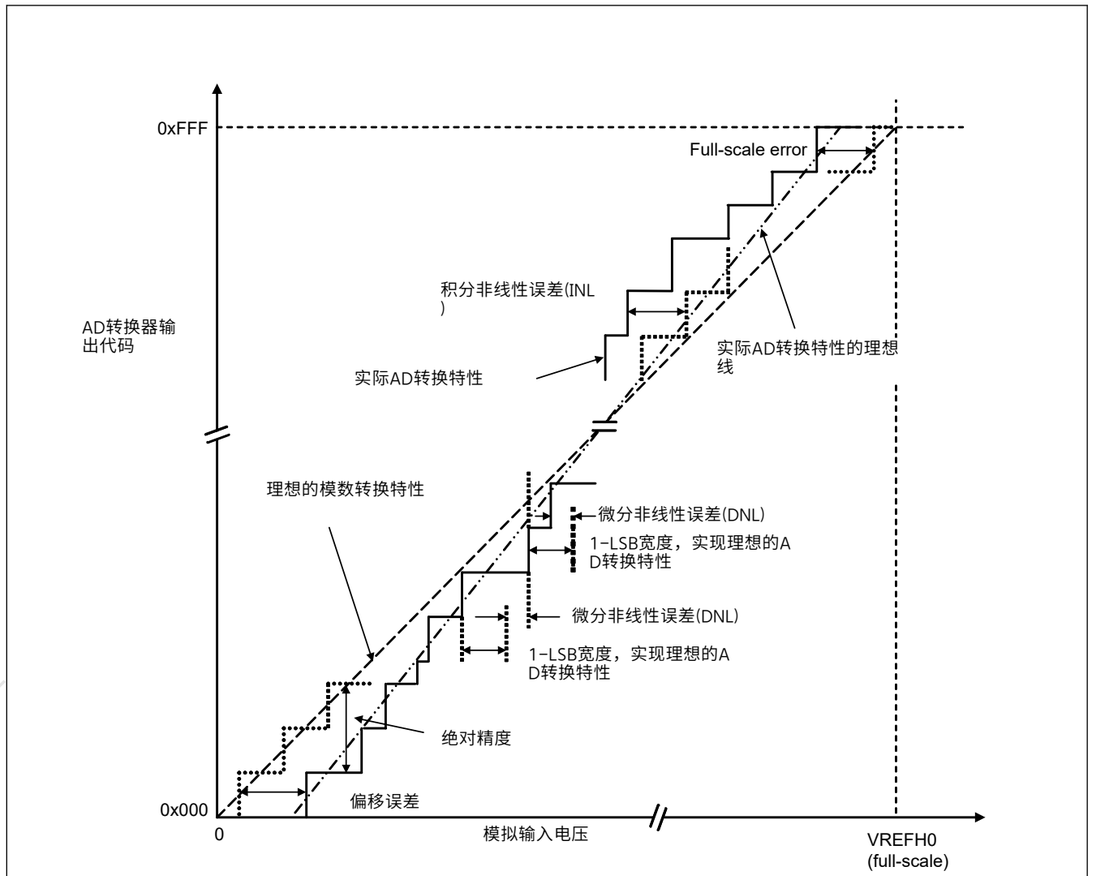

Figure 43.47 ADC12特征项说明

绝对精度

绝对精度是基于理论AD转换特性的输出代码与实际AD转换结果之间的差异。测量绝对精度时，将模拟输入电压宽度（1-LSB宽度）的中点电压作为模拟输入电压，该电压可以满足基于理论模数转换特性输出等码的预期.例如，如果使用12位分辨率并且参考电压VREFH0=3.072V，则1-LSB宽度变为0.75mV，并且使用0mV、0.75mV和1.5mV作为模拟输入电压。如果模拟输入电压为6mV，±5LSB的绝对精度意味着实际的AD转换结果在0x003到0x00D的范围内，尽管从理论上的AD转换特性可以预期输出代码为0x008。

积分非线性误差(INL)

积分非线性误差是测量的偏移和满量程误差为零时的理想线与实际输出代码之间的最大偏差。

微分非线性误差(DNL)

微分非线性误差是基于理想AD转换特性的1-LSB宽度与实际输出码的宽度之差。

Offset error

Offset error is the difference between the transition point of the ideal first output code and the actual first output code.

Full-scale error

Full-scale error is the difference between the transition point of the ideal last output code and the actual last output code.

Note 4. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 10,000), erasing can be performed n times for each block. For example, when 128-byte programming is performed 64 times for different addresses in 8-KB blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. Overwriting is prohibited.
Note 5. Time for resumption includes time for reapplying the erasing pulse (up to one full pulse) that was cut off at the time of suspension.
Note 6. The reference value at VCC = 3.3V and room temperature.

3.2 Access Cycles

This section provides access cycle information for the I/O registers described in this manual.

- Registers are grouped by associated module.
- The number of access cycles indicates the number of cycles based on the specified reference clock.
- In the internal I/O area, reserved addresses that are not allocated to registers must not be accessed, otherwise operations cannot be guaranteed.
- The number of I/O access cycles depends on bus cycles of the internal peripheral bus, divided clock synchronization cycles, and wait cycles of each module. Divided clock synchronization cycles differ depending on the frequency ratio between ICLK and PCLK.
- When the frequency of ICLK is equal to that of PCLK, the number of divided clock synchronization cycles is always constant.
- When the frequency of ICLK is greater than that of PCLK, at least 1 PCLK cycle is added to the number of divided clock synchronization cycles.
- The number of write access cycles indicates the number of cycles obtained by non-bufferable write access.

3.2 访问周期

本节提供本手册中描述的IO寄存器的访问周期信息。

●寄存器按相关模块分组。

●访问周期数是指基于指定参考时钟的周期数。

●在内部IO区，不能访问未分配给寄存器的保留地址，否则无法保证操作。

●IO访问周期数取决于内部外设总线的总线周期、分频时钟同步周期和每个模块的等待周期。分频时钟同步周期取决于ICLK和PCLK之间的频率比。

●当ICLK的频率等于PCLK的频率时，分频的时钟同步周期数始终是恒定的。

●当ICLK频率大于PCLK频率时，分频时钟同步周期数至少增加1个PCLK周期。

●写访问周期数是指非缓冲写访问所获得的周期数。

Note: This applies to the number of cycles when access from the CPU does not conflict with the instruction fetching to the external memory or bus access from other bus masters such as DTC or DMAC.

Table 3.2 Access cycles (3 of 3)

Peripherals	Address		Number of access cycles				Cycle Unit	Related function
			ICLK = FCLK		ICLK > FCLK*1			
	From	To	Read	Write	Read	Write		
FLAD, FACI	0x407F_C000	0x407F_EFFF	3	3	2 to 3	2 to 3	FCLK	Data Flash, Flash Application Command Interface

Note 1. If the number of PCLK or FCLK cycles is non-integer (for example 1.5), the minimum value is without the decimal point, and the maximum value is rounded up to the decimal point. For example, 1.5 to 2. 5 is 1 to 3.
Note 2. When accessing a 16-bit register (FTDRHL, FRDRHL, FCR, FDR, LSR, and CDR), access is 2 cycles more than the value shown in Table 3.2. When accessing an 8-bit register (including FTDRH, FTDRL, FRDRH, and FRDRL), the access cycles are as shown in Table 3.2.
Note 3. When accessing the 32-bit register (SPDR), access is 2 cycles more than the value in Table 3.2. When accessing an 8-bit or 16-bit register (SPDR_HA), the access cycles are as shown in Table 3.2.
Note 4. The access cycles depend on the QSPI bus cycles.

Table 3.2 访问周期（2个，共3个）

Peripherals	Address		访问周期数				Cycle Unit	相关功能
			ICLK = PCLK		ICLK > PCLK*1

Table 3.2 访问周期（3个，共3个）

Peripherals	Address		访问周期数				Cycle Unit	相关功能
			ICLK = FCLK		ICLK > FCLK*1			
	From	To	Read	Write	Read	Write		
FLAD, FACI	0x407F_C000	0x407F_EFFF	3	3	2 to 3	2 to 3	FCLK	数据闪存、闪存应用命令 Interface

注1.如果PCLK或FCLK周期数为非整数（例如1.5），则最小值不带小数点，最大值四舍五入到小数点。例如，1.5到2。5是1到3。

注2.访问16位寄存器（FTDRHL、FRDRHL、FCR、FDR、LSR和CDR）时，访问时间比中所示的值多2个周期
表3.2。访问8位寄存器（包括FTDRH、FTDRL、FRRDH和FRDRL）时，访问周期如下图所示：
Table 3.2.
注3.访问32位寄存器(SPDR)时，访问比表3.2中的值多2个周期。访问8位或16位寄存器（SPDR_HA）时，访问周期如表3.2所示。

注4.访问周期取决于QSPI总线周期。
