General Precautions in the Handling of Microprocessing Unit and Microcontroller Unit Products

The following usage notes are applicable to all Microprocessing unit and Microcontroller unit products from Renesas. For detailed usage notes on the products covered by this document, refer to the relevant sections of the document as well as any technical updates that have been issued for the products.

1. Precaution against Electrostatic Discharge (ESD)
   A strong electrical field, when exposed to a CMOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop the generation of static electricity as much as possible, and quickly dissipate it when it occurs. Environmental control must be adequate. When it is dry, a humidifier should be used. This is recommended to avoid using insulators that can easily build up static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors must be grounded. The operator must also be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions must be taken for printed circuit boards with mounted semiconductor devices.
2. Processing at power-on
   The state of the product is undefined at the time when power is supplied. The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the time when power is supplied. In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the time when power is supplied until the reset process is completed. In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the time when power is supplied until the power reaches the level at which resetting is specified.
3. Input of signal during power-off state
   Do not input signals or an I/O pull-up power supply while the device is powered off. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements. Follow the guideline for input signal during power-off state as described in your product documentation.
4. Handling of unused pins
   Handle unused pins in accordance with the directions given under handling of unused pins in the manual. The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of the LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible.
5. Clock signals
   After applying a reset, only release the reset line after the operating clock signal becomes stable. When switching the clock signal during program execution, wait until the target clock signal is stabilized. When the clock signal is generated with an external resonator or from an external oscillator during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Additionally, when switching to a clock signal produced with an external resonator or by an external oscillator while program execution is in progress, wait until the target clock signal is stable.
6. Voltage application waveform at input pin
   Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between V_{IL} (Max.) and V_{IH} (Min.) due to noise, for example, the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between V_{IL} (Max.) and V_{IH} (Min.).
7. Prohibition of access to reserved addresses
   Access to reserved addresses is prohibited. The reserved addresses are provided for possible future expansion of functions. Do not access these addresses as the correct operation of the LSI is not guaranteed.
8. Differences between products
   Before changing from one product to another, for example to a product with a different part number, confirm that the change will not lead to problems. The characteristics of a microprocessing unit or microcontroller unit products in the same group but having a different part number might differ in terms of internal memory capacity, layout pattern, and other factors, which can affect the ranges of electrical characteristics, such as characteristic values, operating margins, immunity to noise, and amount of radiated noise. When changing to a product with a different part number, implement a system-evaluation test for the given product.

微处理单元和微控制器单元产品处理的一般注意事项

以下使用说明适用于瑞萨的所有微处理单元和微控制器单元产品。有关本文件所涵盖产品的详细使用说明,请参阅文件的相关部分以及为产品发布的任何技术更新。

1。防止静电放电（ESD）

当暴露于 CMOS 器件时,强电场会导致栅极氧化物破坏并最终降低器件操作。必须采取措施尽可能停止静电的产生,并在静电发生时迅速消散。环境控制必须充分。干燥时应使用加湿器。建议避免使用容易积聚静电的绝缘体。

半导体器件必须在防静电容器、静电屏蔽袋或导电材料中储存和运输。所有测试和测量工具,包括工作台和地板,都必须接地。操作员还必须使用腕带接地。半导体器件不得徒手触摸。对于安装有半导体器件的印刷电路板,必须采取类似的预防措施。

2锛姣涓涓。通电处理

供电时产品的状态未定义。LSI 中内部电路的状态是不确定的,寄存器设置和引脚的状态在供电时是不确定的。在将复位信号施加到外部复位引脚的成品中,从供电到复位过程完成,引脚的状态无法得到保证。以类似的方式,从供电到功率达到指定重置的水平,不保证由片上开机重置函数重置的产品中的引脚的状态。

3锛　　娴　　。断电状态下信号的输入

设备断电时请勿输入信号或 I/O 上拉电源。由输入这样的信号或I/O上拉电源引起的电流注入可能会导致故障,并且此时通过设备中的异常电流可能导致内部元件的退化。遵循产品文档中所述的断电状态下输入信号的指南。

4锛姣涓。未使用的销钉的处理

根据手册中未使用销钉处理时给出的说明处理未使用销钉。CMOS产品的输入引脚一般处于高阻抗状态。在未使用的引脚处于开路状态的操作中,在 LSI 附近感应出额外的电磁噪声,相关的穿透电流在内部流动,并且由于错误地识别引脚状态作为输入信号而发生故障成为可能。

5锛姣涓。时钟信号

应用复位后,仅在工作时钟信号稳定后释放复位线。在程序执行过程中切换时钟信号时,等待目标时钟信号稳定。当在复位期间用外部谐振器或从外部振荡器生成时钟信号时,确保仅在时钟信号完全稳定后才释放复位线。另外,当在程序执行进行时切换到由外部谐振器或由外部振荡器产生的时钟信号时,等待直到目标时钟信号稳定。

6锛　　涓€涓。输入引脚处的电压施加波形

由于输入噪声或反射波而导致的波形失真可能会导致故障。CMOS设备的输入由于噪声而停留在 V_{IL} （最大）和 V_{IH}（最小）之间的区域,例如,设备可能会发生故障。注意防止输入电平固定时以及输入电平通过 V_{IL}（Max。）和 V_{IH}（Min。）之间的区域的过渡期内进入设备时出现颤动噪声。

7锛　　娴　　。禁止访问保留地址

禁止访问保留地址。为未来可能的功能扩展提供了保留地址。不要访问这些地址,因为无法保证 LSI 的正确操作。

8锛　　娴　　。产品之间的差异

在从一种产品更换为另一种产品（例如更换为具有不同零件号的产品）之前,请确认更改不会导致问题。同一组中但具有不同零件号的微处理单元或微控制器单元产品的特性在内部存储器容量、布局模式和其他因素方面可能有所不同,这会影响电气特性的范围,例如特性值、工作边距、对噪声的抗扰度和辐射噪声量。当更改为具有不同零件号的产品时,对给定产品实施系统评估测试。

Clock Frequency Accuracy Measurement Circuit (CAC)	The Clock Frequency Accuracy Measurement Circuit (CAC) counts pulses of the clock to be measured (measurement target clock) within the time generated by the clock selected as the measurement reference (measurement reference clock), and determines the accuracy depending on whether the number of pulses is within the allowable range. When measurement is complete or the number of pulses within the time generated by the measurement reference clock is not within the allowable range, an interrupt request is generated. See section 9, Clock Frequency Accuracy Measurement Circuit (CAC).

Table 1.6 Timers (2 of 2)

Feature	Functional description
Low Power Asynchronous General Purpose Timer (AGT)	The low power Asynchronous General Purpose Timer (AGT) is a 32-bit timer that can be used for pulse output, external pulse width or period measurement, and counting external events. This timer consists of a reload register and a down counter. The reload register and the down counter are allocated to the same address, and can be accessed with the AGT register. See section 21, Low Power Asynchronous General Purpose Timer (AGTW).
Watchdog Timer (WDT)	The Watchdog Timer (WDT) is a 14-bit down counter that can be used to reset the MCU when the counter underflows because the system has run out of control and is unable to refresh the WDT. In addition, the WDT can be used to generate a non-maskable interrupt or an underflow interrupt. See section 22, Watchdog Timer (WDT).
Independent Watchdog Timer (IWDT)	The Independent Watchdog Timer (IWDT) consists of a 14-bit down counter that must be serviced periodically to prevent counter underflow. The IWDT provides functionality to reset the MCU or to generate a non-maskable interrupt or an underflow interrupt. Because the timer operates with an independent, dedicated clock source, it is particularly useful in returning the MCU to a known state as a fail-safe mechanism when the system runs out of control. The IWDT can be triggered automatically by a reset, underflow, refresh error, or a refresh of the count value in the registers. See section 23, Independent Watchdog Timer (IWDT).

Table 1.7 Communication interfaces

SCIn (n = 0, 9) has FIFO buffers to enable continuous and full-duplex communication, and the data transfer speed can be configured independently using an on-chip baud rate generator. See section 24, Serial Communications Interface (SCI).
I3C bus interface (I3C)	The I3C bus interface (I3C) has one channel. The I3C module conforms with and provides a subset of the NXP I2C (Inter-Integrated Circuit) bus interface functions and a subset of the MIPI I3C. See section 25, I3C Bus Interface (I3C).

Table 1.8 Analog (2 of 2)

Feature	Functional description
High-Speed Analog Comparator (ACMPHS)	The High-Speed Analog Comparator (ACMPHS) compares a test voltage with a reference voltage and provides a digital output based on the conversion result. Both the test and reference voltages can be provided to the comparator from internal sources such as the DAC12 output and internal reference voltage, and an external source with or without an internal PGA. Such flexibility is useful in applications that require go/no-go comparisons to be performed between analog signals without necessarily requiring A/D conversion. See section 35, High-Speed Analog Comparator (ACMPHS).
Temperature Sensor (TSN)	The on-chip Temperature Sensor (TSN) determines and monitors the die temperature for reliable operation of the device. The sensor outputs a voltage directly proportional to the die temperature, and the relationship between the die temperature and the output voltage is fairly linear. The output voltage is provided to the ADC12 for conversion and can be further used by the end application. See section 34, Temperature Sensor (TSN).

Table 1.9 Data processing

Feature	Functional description
Cyclic Redundancy Check (CRC) calculator	The Cyclic Redundancy Check (CRC) generates CRC codes to detect errors in the data. The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication. Additionally, various CRC-generation polynomials are available. See section 29, Cyclic Redundancy Check (CRC).
Data Operation Circuit (DOC)	The Data Operation Circuit (DOC) compares, adds, and subtracts 16-bit data. When a selected condition applies, 16-bit data is compared and an interrupt can be generated. See section 36, Data Operation Circuit (DOC).

温度传感器（TSN）	片上温度传感器（TSN）确定并监控模具温度,以实现设备的可靠运行。传感器输出与模具温度成正比的电压,并且模具温度与输出电压之间的关系是相当线性的。输出电压提供给ADC12进行转换,最终应用可以进一步使用。 请参阅第 34 节,温度传感器（TSN）。

Note 1. OCD connect is determined by the CDBGPWRUPREQ bit output in the SWJ-DP register. The bit can only be written by the OCD. However, the level of the bit can be confirmed by reading the DBGSTR.CDBGPWRUPREQ bit.

2.5.2 Emulator Connection

Renesas provides the emulator which supports both debugging using SWD communication and serial programming using SCI or SWD communication.

Table 2.5 shows the pinout of 10 pin or 20 pin socket pinouts when using this emulator.

2.5.3 Effect of Debug Function

The debug function effects inside and outside of CPU.

2.5.3.1 Low power mode

All CoreSight debug components can store the register settings even when the CPU enters Software Standby, Snooze or Deep Software Standby mode. However, AHB-AP cannot respond to On-Chip Debug (OCD) access in these low power modes. The OCD must wait for cancellation of the low power mode to access the CoreSight debug components. To request low power mode cancellation, the OCD can set the DBIRQ bit in the MCUCTRL register. For details, see section 2.6.5.3. MCUCTRL : MCU Control Register.

2.5.3.2 Reset

In OCD mode, some resets depend on the CPU status and the DBGSTOPCR register setting.

注1。OCD 连接由 SWJ-DP 寄存器中的 CDBGPWRUPREQ 位输出确定。该位只能由 OCD 编写。
然而,可以通过读取DBGSTR。CDBGPWRUPREQ位来确认该位的电平。

2.5.2 模拟器连接

Renesas 提供模拟器,支持使用 SWD 通信进行调试和使用 SCI 或 SWD 通信进行串行编程。

表 2。5 显示了使用此模拟器时 10 个引脚或 20 个引脚插座引脚的引脚排列。

2。5。3 调试功能的影响

CPU内部和外部的调试功能效果。

2。5。3。1 低功率模式

即使 CPU 进入软件待机、打瞌睡或深度软件待机模式,所有 CoreSight 调试组件也可以存储寄存器设置。然而,在这些低功耗模式下,AHB-AP 无法响应片上调试（OCD）访问。OCD 必须等待取消低功耗模式才能访问 CoreSight 调试组件。要请求低功耗模式消除,OCD 可以设置 MCUCTRL 寄存器中的 DBIRQ 位。详情请参见第 2。6。5。3 节。

MCUCTRL:MCU 控制寄存器 .

2。5。3。2 重置

在 OCD 模式下,某些重置取决于 CPU 状态和 DBGSTOPCR 寄存器设置。

2.6 Programmers Model

2.6.1 Address Spaces

The MCU debug system includes two CoreSight Access Ports (AP):

- AHB-AP, which is connected to the CPU bus matrix and has the same access to the system address space as the CPU
- APB-AP, which has a dedicated address space (OCD address space) and is connected to the OCDREG registers.

Figure 2.3 shows a block diagram of the AP connection and address spaces.

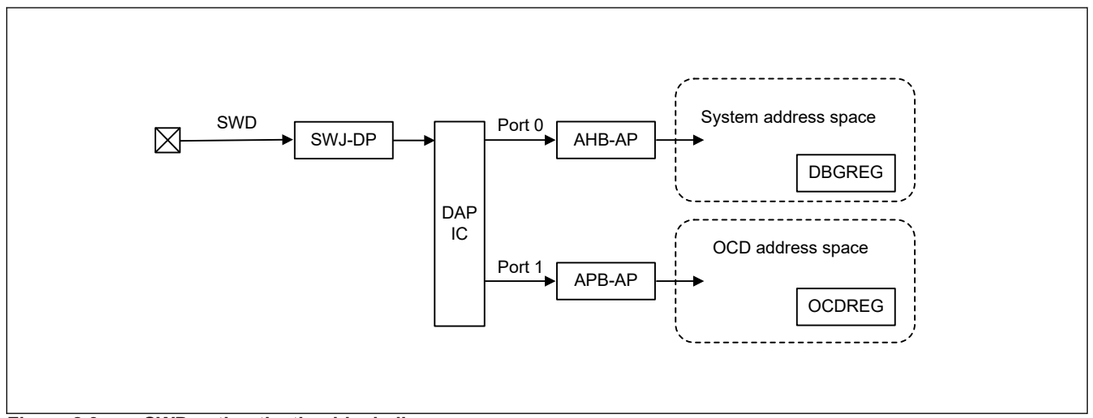

Figure 2.3 SWD authentication block diagram

For debugging purposes, there are two register modules, DBGREG and OCDREG. DBGREG is located in the system address space and can be accessed from the OCD emulator, the CPU, and other bus masters in the MCU. OCDREG is located in the OCD address space and can only be accessed from the OCD tool. The CPU and other bus masters cannot access OCDREG.

2。6。1 地址空间

MCU调试系统包括两个CoreSight访问端口（AP）：

- AHB-AP,它连接到CPU总线矩阵,并且与CPU具有相同的系统地址空间访问权限
- APB-AP,它具有专用地址空间（OCD地址空间）,并连接到OCDREG寄存器。

图 2。3 显示了 AP 连接和地址空间的框图。

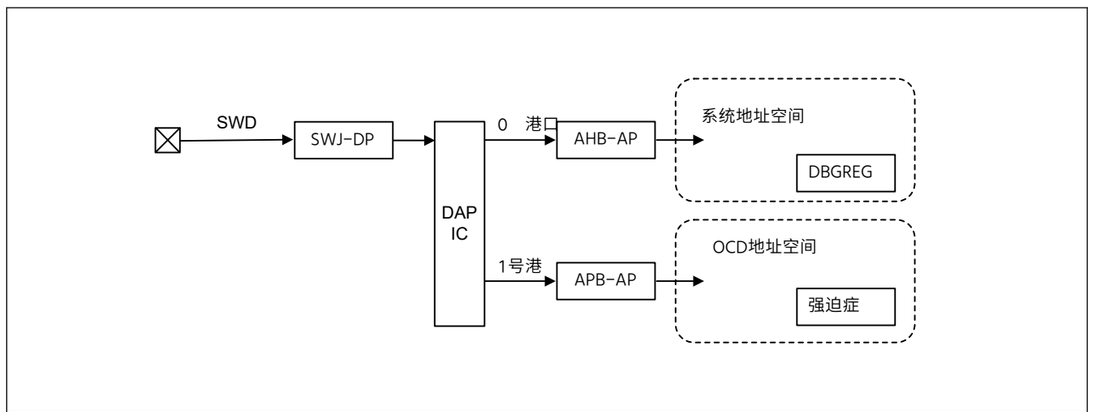

图2。3 SWD 身份验证框图

DBGREG和OCDREG两个寄存器模块进行调试,DBGREG位于系统地址空间内,可以从MCU中的OCD仿真器、CPU、等总线母线访问。OCDREG 位于 OCD 地址空间中,只能从 OCD 工具访问。CPU 和其他总线主机无法访问 OCDREG。

2.6.2 Peripheral Address Map

In system address space, the Cortex-M33 core has a Private Peripheral Bus (PPB) which can be accessed only from CPU and OCD emulator. The PPB is expanded from the original implementation of the Cortex-M33 core for this MCU. Table 2.7 shows the address map of the MCU.

2.6.3.1 ROM entries

ROM entries hold a list of components in the system. OCD emulator can use the ROM entries to determine which components are implemented in a system.

Table 2.8 and Table 2.9 show the System ROM entries and Processor ROM entries. See reference 5. in section 2.13. References for details.

2.6.5.1 IAUTHn : ID Authentication Code Register (n = 0 to 3)

Base address: CPU_OCD = 0x8000_0000

Offset address: 0x000 + 0x100 × n

Bit position:	31																												0
Bit field:	IAUTHn: AID (32+32×n -1) to (32×n) bits																												
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
31:0	IAUTHn	AID (32+32×n -1) to (32×n) bits	W

There are authentication registers for writing 128 bit key. These 4 registers must be written by sequential order from IAUTH0 to IAUTH3. If set of register writes is not compliant with this order, the result is unpredictable.

Only 32 bits write is permitted. Initial value of the registers is all 1. It means that SWD access is initially permitted when ID code in OSIS register has the initial value. See section 2.12.3.4. Connecting sequence and SWD authentication.

Note: Only secure access can write to this register. Both secure access and non-secure read access are allowed. Non-secure write access is denied, and no TrustZone access error is generated.

Note: This register is write-protected by PRCR register.

By guarding entire EPPB bus, the non-secure access from CPU to debug related components is completely controlled by the current value of the CPUDSA0 bit. Since this bit is modifiable only when CPU is in secure state, user must be aware of the CPUDSAR register before using CoreSight debug components.

CPUDSA0 bit (CPU Debug Security Attribution 0)

Security attributes of register for accessing the debug component of the CPU.

0: Debug component can only be accessed with secure access.

1: There is no restriction on accessing the debug component.

2.6.7 Processing on Error response generated by CPU access

In addition to the specific-error detection specification of the Arm Cortex-M33 processor, this MCU also provides additional error information which is described in section 13, Buses.

This section describes how to handle the additional error information with no conflict to that of the Arm Cortex-M33 processor.

注: 只有安全访问才能写入此寄存器。允许安全访问和非安全读取访问。非安全写访问被拒绝,并且不会生成 TrustZone 访问错误。

注: 该寄存器受 PRCR 寄存器写保护。

通过保护整个EPPB总线,CPU对调试相关组件的非安全访问完全由CPUDSA0位的当前值控制。由于此位仅在 CPU 处于安全状态时才可修改,因此用户在使用 CoreSight 调试组件之前必须了解 CPUDSAR 寄存器。

CPUDSA0 位（CPU 调试安全属性 0）

用于访问 CPU 调试组件的寄存器的安全属性。

0:调试组件只能通过安全访问来访问。1:访问调试组件没有限制。

2。6。7 CPU 访问生成的错误响应处理

除了 Arm Cortex-M33 处理器的特定错误检测规范之外,该 MCU 还提供了第 13 节"总线 ."中描述的附加错误信息

本节介绍如何处理与 Arm Cortex-M33 处理器不冲突的附加错误信息。

Table 2.15 shows error detection modules, which are also described in section 13, Buses. These error detection modules not only provide error information on the bus module, but also notify the processor to trigger the exception handler.

Table 2.15 Error detection modules

	NMI/RESET request	Interrupt	Bus error status register	Error address register Error RW register
Slave TZF	NMISR.TZFST	Bus Fault*1 (Hard Fault)	BUS.BUSnERRSTAT.STERRSTAT	BUS.BTZFnERRADD BUS.BTZFnERRRW
Slave bus error	—	Bus Fault*1 (Hard Fault)	BUS.BUSnERRSTAT.SLERRSTAT	BUS.BUSnERRADD BUS.BUSnERRRW
Illegal address access error	—	Bus Fault*1 (Hard Fault)	BUS.BUSnERRSTAT.ILERRSTAT	BUS.BUSnERRADD BUS.BUSnERRRW

Note 1. A Bus Fault can be treated as HardFault. For details, see *ARM® Cortex®-M33 Device Generic User Guide* in the section 2.13. References.

To prevent unexpected operation, when handling the exception, additional operation should be added into exception routing.

BusFault when occurred by error detected as shown in Table 2.15:

- See section 13, Buses for the error information in the corresponding register
- Clear the data in cache for the error address
- Clear the Error Status register in the bus module
- Service exception handling with Arm-guided operation

For a Bus Fault that is not detected in the Renesas-specific error detection module (occurred inside the Arm Cortex-M33 core), see the *ARM® Cortex®-M33 Device Generic User Guide* to handle this case.

In the system bus specification, there is a specific case for Slave TrustZone Filter, that is, if an error is selected to generate an NMI, then before the processor handles the Bus Fault exception, NMI with higher priority takes the exception first. Therefore, use the BusFault handler and not NMI handler to handle this error. In other words, the NMI status should be cleared but the error status bit should not be cleared to ensure that BusFault captures all the error information.

Figure 2.4 and Figure 2.5 show the recommended flows for NMI handler and BusFault handler for the errors described in Table 2.15.

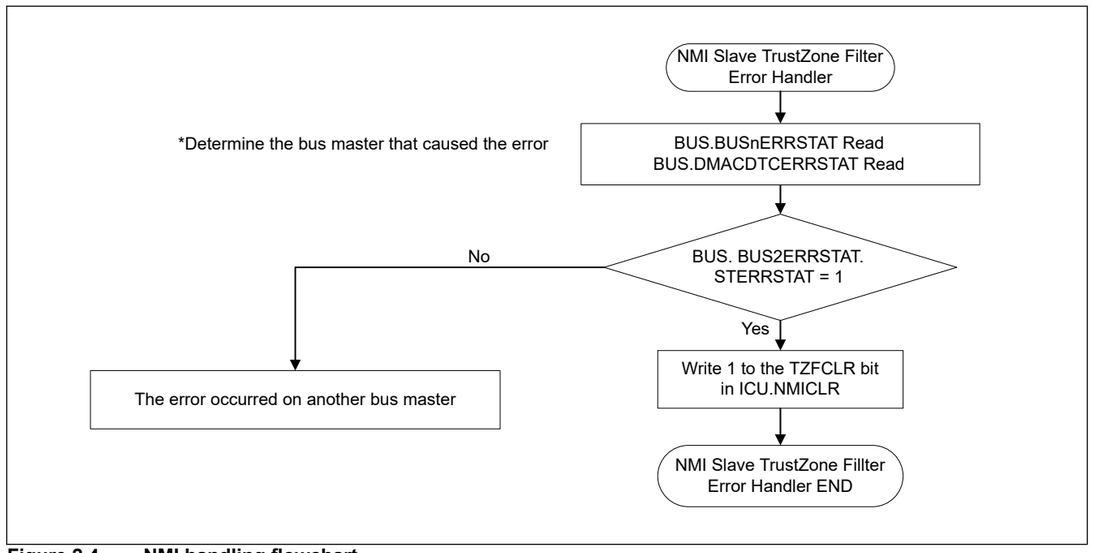

Figure 2.4 NMI handling flowchart

表 2。15 显示了错误检测模块,这些模块也在第 13 节"总线"中进行了描述。这些错误检测模块不仅提供总线模块上的错误信息,还通知处理器触发异常处理程序。

表 2。15 错误检测模块

	NMI/重置请求	中断	总线错误状态寄存器	地址寄存器错误 RW寄存器出错

注1。总线故障可以被视为 HardFault。有关详细信息,请参阅第 2。13 节中的 ARM ® Cortex ® -M33 设备通用用户指南。参考文献 .

为了防止意外操作,在处理异常时,应在异常路由中添加附加操作。

BusFault 发生时检测到错误,如表 2.15: 所示

- See 第 13 节,对应寄存器中错误信息的总线
- 清除缓存中的数据以获取错误地址
- 清除总线模块中的错误状态寄存器
- 使用臂引导操作进行服务异常处理

Renesas 特定错误检测模块中未检测到的总线故障（发生在 Arm Cortex-M33 核心内部）,请参阅 ARM ® Cortex ® -M33 设备通用用户指南来处理此情况。

在系统总线规范中,Slave TrustZone Filter有一种特定的情况,即如果选择错误来生成NMI,那么在处理器处理总线故障异常之前,优先级较高的NMI首先采用异常。因此,使用 BusFault 处理程序而不是 NMI 处理程序来处理此错误。换句话说,应该清除 NMI 状态,但不应清除错误状态位,以确保 BusFault 捕获所有错误信息。

2。8 CoreSight ATB 漏斗

MCU 中有一个 CoreSight ATB 漏斗。漏斗有两个 ATB 从站和一个 ATB 主站,它选择从 ETM 和 ITM 到 ETB 的调试跟踪源。图 2。7 显示了 MCU 中的 CoreSight ATB 连接。

See reference 4. in section 2.13. References for details of the ATB and funnel.

2.9 Break Point Unit

The MCU has Break Point Unit. See BreakPoint unit chapter of reference 1. in section 2.13. References for details about register description of this module.

2.10 CoreSight Time Stamp Generator

A CoreSight Time Stamp Generator provides a CPU clock-based timestamp to ITM and ETM.The timestamp is generated by a 64-bit counter. See reference 4. in section 2.13. References for details.

2.11 SysTick Timer

The MCU has SysTick timer that provides two 24-bit down counters, non-secure and secure counters. The timer can select SysTick timer clock (SYSTICCLK) or System clock (ICLK).

See section 8, Clock Generation Circuit and reference 1. in section 2.13. References for details.

Note: SysTick timer counter operation is enabled by signal synchronized with CPU clock. Therefore, the counter might not operate correctly if the CPU clock is slower than the SysTick timer clock. In other words, clock setting must satisfy the following: CPU clock ≥ SysTick timer clock (LOCO: 32.768 kHz).

2.12 OCD Emulator Connection

The MCU has a SWD authentication mechanism to check access permission for debug and chip resources. To obtain full debug functionality, pass result of the authentication mechanism is required.

Figure 2.8 shows the block diagram of authentication mechanism.

2。9 断点单元

MCU 有断点单元。请参阅第 2。13 节中参考文献 1 的 BreakPoint 单元章节。有关此模块的寄存器描述的详细信息参考。

2。10 CoreSight 时间戳生成器

CoreSight 时间戳生成器为 ITM 和 ETM 提供基于 CPU 时钟的时间戳。时间戳由 64 位计数器生成。参见第 2。13 节中的参考文献 4。详情参考。

2。11 SysTick 定时器

MCU 具有 SysTick 定时器,可提供两个 24 位下计数器、非安全计数器和安全计数器。定时器可以选择SysTick定时器时钟（SYSTICCLK）或系统时钟（ICLK）。

请参阅第 8 节"时钟生成电路"和第 2。13 节中的参考文献 1。详情参考。

注意:SysTick 定时器计数器操作是通过与 CPU 时钟同步的信号来启用的。因此,如果 CPU 时钟比 SysTick 定时器时钟慢,计数器可能无法正常运行。换句话说,时钟设置必须满足以下条件: CPU 时钟 ≥ SysTick 定时器时钟（LOCO:32。768 kHz）。

2。12 强迫症模拟器连接

MCU 有一个 SWD 认证机制来检查调试和芯片资源的访问权限。要获得完整的调试功能,需要通过身份验证机制的结果。

图2。8显示了认证机制的框图。

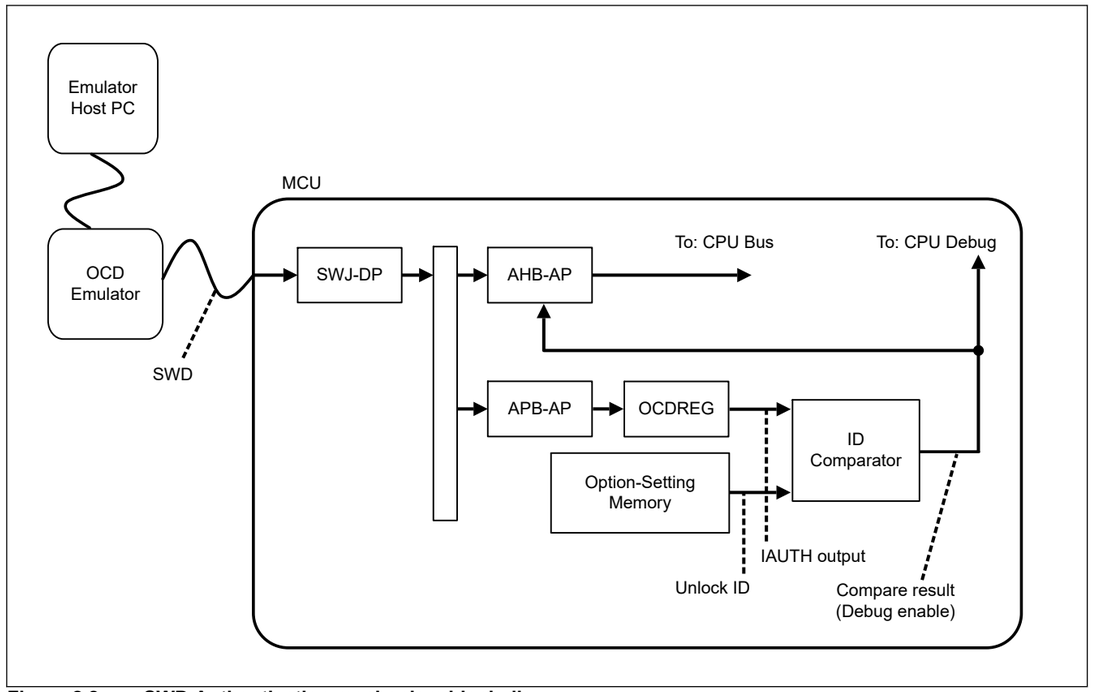

Figure 2.8 SWD Authentication mechanism block diagram

An ID comparator is available in the MCU for authentication. The comparator is comparing 128 bit IAUTH output from OCDREG and 128 bit Unlock ID code from Option-Setting Memory. When the two outputs are identical, the CPU debug functions and system bus access from the OCD emulator are permitted.

2.12.1 DBGEN

After the OCD emulator gets access permission, the OCD emulator must set the DBGEN bit in the System Control OCD Control Register (SYOCDCR). In addition, the OCD emulator must clear the DBGEN bit before disconnecting it. See section 10, Low Power Modes for details.

2.12.2 Unlock ID Code

Unlock ID code is used for checking permission for debug and access to on-chip resources. If the Unlock ID code is matched with 128 bits data written in IAUTH0-3, SWD debugger obtains the access permission. Unlock ID code is written in OCD/Serial Programmer ID Setting Register (OSIS) in Option Setting Memory. The initial value of the unlock ID code is all 1 (0xFFFFFFFF_FFFFFFFF_FFFFFFFF_FFFFFFFF). See section 6, Option-Setting Memory and section 38, Flash Memory for the detail of OSIS.

2.12.3 Restrictions on Connecting an OCD emulator

This section describes the restrictions on emulator access.

2.12.3.1 Starting connection while in low power mode

When starting a SWD connection from an OCD emulator, the MCU must be in Normal or Sleep mode. If the MCU is in Software Standby, Snooze, or Deep Software Standby mode, the OCD emulator can cause the MCU to hang.

2.12.3.2 Changing low power mode while in OCD mode

When the MCU is in OCD mode, the low power mode can be changed. However, system bus access from AHB-AP is prohibited in Software Standby, Snooze or Deep Software Standby mode. Only SWJ-DP, APB-AP, and OCDREG can be accessed from the OCD emulator in these modes. Table 2.18 shows the restrictions.

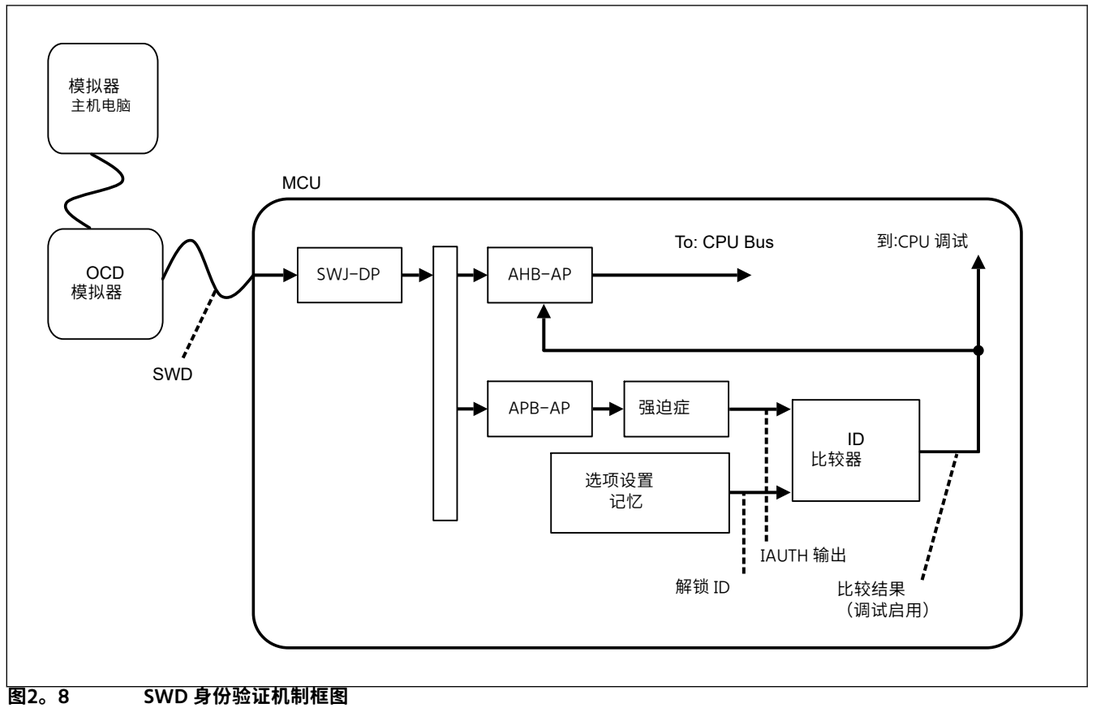

图2。8 SWD 身份验证机制框图

MCU 中有一个 ID 比较器可用于身份验证。比较器正在比较来自 OCDREG 的 128 位 IAUTH 输出和来自选项设置内存的 128 位解锁 ID 代码。当两个输出相同时,允许从OCD模拟器访问CPU调试功能和系统总线。

2。12。1 DBGEN

OCD仿真器获得访问权限后,OCD仿真器必须在系统控制OCD控制寄存器（SYOCDCR）中设置DBGEN位。此外,OCD 模拟器必须在断开 DBGEN 位之前清除它。有关详细信息,请参阅第 10 节"低功耗模式"。

2。12。2 解锁 ID 代码

解锁 ID 代码用于检查调试权限和访问片上资源。Unlock ID 代码与 IAUTH0-3 中编写的 128 位数据匹配,则 SWD 调试器将获得访问权限。解锁 ID 代码写在选项设置内存中的 OCD/串行程序员 ID 设置寄存器（OSIS）中。解锁ID码的初始值都是1(0xFFFFFFF_FFFFFFF_FFFFFFF_FFFFFFF）。有关 OSIS 的详细信息,请参阅第 6 节"选项设置内存"和第 38 节"闪存"。

2。12。3 连接强迫症模拟器的限制

本节介绍模拟器访问的限制。

2.12.3.1 低功耗模式下启动连接

OCD模拟器启动SWD连接时,MCU必须处于正常或睡眠模式。MCU 处于软件待机、打瞌睡或深度软件待机模式,则 OCD 模拟器可导致 MCU 挂起。

2。12。3。2 在强迫症模式下改变低功率模式

MCU处于OCD模式时,可以改变低功耗模式。但是,在软件待机、Snooze 或深度软件待机模式下,禁止从 AHB-AP 访问系统总线。在这些模式下,只能从 OCD 模拟器访问 SWJ-DP、APB-AP 和 OCDREG。表 2。18 显示了限制。

Table 2.18 Restrictions by mode

Active mode	Start OCD emulator connection	Change low power mode	Access AHB-AP and system bus	Access APB-AP and OCDREG
Normal	Yes	Yes	Yes	Yes
Sleep	Yes	Yes	Yes	Yes
Software Standby	No	Yes	No	Yes
Snooze	No	Yes	No	Yes
Deep Software Standby	No	Yes	No	Yes

If system bus access is required in Software Standby, Snooze, or Deep Software Standby mode, set the MCUCTRL.DBIRQ bit in OCDREG to wake up the MCU from the low power modes. Simultaneously, by asserting the MCUCTRL.DBIRQ bit in OCDREG, the OCD emulator can wake up the MCU without starting CPU execution by using a CPU break.

2.12.3.3 Modify unlock ID code in OSIS

After modifying the unlock ID code in OSIS, OCD emulator must reset the MCU by asserting RES pin or setting SYSRESETREQ bit of Application Interrupt and Reset Control Register in the System Control block to 1. The modified unlock ID code is reflected after the reset.

2.12.3.4 Connecting sequence and SWD authentication

Because the OCD emulator is protected by the SWD authentication mechanism, the OCD might be required to input the ID code to the authentication registers. The OSIS value in the option-setting memory determines whether the code is required.

After the negation of the reset, a 5 µs wait time is required before comparing the OSIS value at cold start.

(1) When MSB of OSIS is 0 (bit [127] = 0)

The ID code is always mismatching and connection to the OCD is prohibited.

(2) When OSIS is all 1s (default)

OCD authentication is not required and the OCD can use the AHB-AP without authentication.

1. Connect the OCD emulator to the MCU through the SWD interface.
2. Set up SWJ-DP to access the DAP bus. In the setup, the OCD emulator must assert CDBGPWRUPREQ in the SWJDP Control Status Register, then wait until CDBGPWRUPACK in the same register is asserted.
3. Set MCUCTRL.CPUWAIT = 1.
4. Read if MCUSTAT.DBGFUNCEN = 1, set the Debug related-register, then clear MCUCTRL.CPUWAIT to 0.
5. Set up the AHB-AP to access the system address space. The AHB-AP is connected to the DAP bus port 0.
6. Set SYOCDCR.DBGEN to 1.
7. Start accessing the CPU debug resources using the AHB-AP.

(3) When OSIS[127:126] = 10b

OCD authentication is required, the OCD must write the Unlock ID code to IAUTH registers 0 to 3 in OCDREG before using the AHB-AP.

1. Connect the OCD debugger to the MCU through the SWD interface.
2. Set up SWJ-DP to access the DAP bus. In the setup, the OCD emulator must assert CDBGPWRUPREQ in the SWJDP Control Status Register, and wait until CDBGPWRUPACK in the same register is asserted.
3. Set up the APB-AP to access OCDREG. The APB-AP is connected to the DAP bus port 1.
4. Write the 128-bit ID code to IAUTH registers 0 to 3 in the OCDREG using the APB-AP.
5. Set MCUCTRL.CPUWAIT = 1.
6. If the 128-bit ID code matches the OSIS value, the AHB-AP is authorized to issue an AHB transaction. The authorization result can be confirmed by the DbgStatus bit in the AHB-AP Control Status Word Register.

表 2。18 按模式限制

活动模式	启动强迫症模拟器 连接	更改低功耗 模式	访问 AHB-AP 和 系统总线	访问 APB-AP 和 强迫症
正常	Yes	Yes	Yes	Yes
睡觉	Yes	Yes	Yes	Yes
软件备用	No	Yes	No	Yes
贪睡	No	Yes	No	Yes
深度软件待机	No	Yes	No	Yes

如果在软件待机、Snooze 或深度软件待机模式中需要系统总线访问,请在 OCDREG 中设置 MCUCTRL。DBIRQ 位以从低功耗模式唤醒 MCU。同时,通过断言 OCDREG 中的 MCUCTRL。DBIRQ 位,OCD 模拟器可以使用 CPU 中断来唤醒 MCU,而无需启动 CPU 执行。

2。12。3。3 修改OSIS中的解锁ID代码

OSIS中修改解锁ID代码后,OCD模拟器必须通过断言RES引脚或将系统控制块中的应用程序中断和重置控制寄存器的SYSRESETREQ位设置为1来重置MCU。修改后的解锁 ID 代码在重置后被反映。

2.12.3.4 连接序列和 SWD 身份验证

由于OCD模拟器受到SWD认证机制的保护,因此可能需要OCD将ID码输入到认证寄存器。OSIS 值在选项设置内存中决定是否需要代码。

Reset的否定后,需要5 µs的等待时间,然后才能比较冷启动时的OSIS值。

(1)当 OSIS 的 MSB 为 0 时 （位 [127] = 0),ID 代码总是不匹配,并且禁止与 OCD 连接。

(2)当 OSIS 是所有 1 时 （默认）

不需要 OCD 身份验证,并且 OCD 无需身份验证即可使用 AHB-AP。

1。OCD模拟器通过SWD接口连接到MCU。

2锛姣涓。设置 SWJ-DP 以访问 DAP 总线。在设置中,OCD 模拟器必须在 SWJDP 控制状态寄存器中断言 CDBGPWRUPREQ,然后等待同一寄存器中的 CDBGPWRUPACK 断言。

3锛 娴 。设置 MCUCTRL。CPUWAIT = 1。

4锛姣涓。如果 MCUSTAT。DBGFUNCEN = 1,请读取,设置 Debug 相关寄存器,然后将 MCUCTRL。CPUWAIT 清除为 0。

5锛姣涓。置AHB-AP来访问系统地址空间。AHB-AP连接到DAP总线端口0。

6锛 涓€涓。将 SYOCDCR。DBGEN 设置为 1。

7锛 娴 。使用 AHB-AP 开始访问 CPU 调试资源。

(3)当OSIS[127:126] = 10b

需要 OCD 身份验证,OCD 在使用 AHB-AP 之前必须将 Unlock ID 代码写入 OCDREG 中的 IAUTH 寄存器 0 至 3。

1。OCD调试器通过SWD接口连接到MCU。

2锛姣涓。设置 SWJ-DP 以访问 DAP 总线。在设置中,OCD 模拟器必须在 SWJDP 控制状态寄存器中断言 CDBGPWRUPREQ,并等待同一寄存器中的 CDBGPWRUPACK 断言。

3锛 娴 。设置APB-AP以访问OCDREG。APB-AP连接到DAP总线端口1。

4锛姣涓。使用 APB-AP 将 128 位 ID 代码写入 OCDREG 中的 IAUTH 寄存器 0 至 3。

5锛姣涓。设置 MCUCTRL。CPUWAIT = 1。

6锛 涓€涓。如果 128 位 ID 代码与 OSIS 值匹配,则 AHB-AP 有权发出 AHB 事务。授权结果可以通过AHB-AP控制状态字寄存器中的DbgStatus位来确认。

- When the DbgStatus bit is 1, the 128-bit ID code is a match with the OSIS value. AHB transfers are permitted.
- When the DbgStatus bit is 0, the 128-bit ID code is not a match with the OSIS value. AHB transfers are not permitted.

7. Read if MCUSTAT.DBGFUNCEN = 1 set Debug related register then clear MCUCTRL.CPUWAIT = 0.
8. Set up the AHB-AP to access the system address space. The AHB-AP is connected to the DAP bus port 0.
9. Set SYOCDCR.DBGEN to 1.
10. Start accessing the CPU debug resources using the AHB-AP.

(4) When OSIS[127:126] is 11b

OCD authentication is required and the OCD must write the unlock ID code to IAUTH registers 0 to 3 in the OCDREG. The connection sequence is the same when OSIS[127:126] is 10b except for “ALeRASE” capability.

When IATUH registers 0 to 3 are written with “ALeRASE” in ASCII code (0x414C_6552_4153_45FF_FFFF_FFFF_FFFF_FFFF), the contents of the code flash, data flash, and configuration area are erased at once. See section 38, Flash Memory for details.

The ALeRASE sequence is as follows:

1. Connect the OCD debugger to the MCU through the SWD interface.
2. Set up SWJ-DP to access DAP bus. In the setup, the OCD emulator must assert CDBGPWRUPREQ in the SWJDP Control Status Register, then wait until CDBGPWRUPACK in the same register is asserted.
3. Set the APB-AP to access OCDREG. The APB-AP is connected to the DAP bus port 1.
4. Write the 128-bit ID code to IAUTH registers 0 to 3 in the OCDREG using the APB-AP.
5. If the 128-bit ID code is “ALeRASE” in ASCII code, the contents of the code flash, data flash, and configuration area are erased. Thereafter, the MCU transitions to Sleep mode.

7锛 娴 。读取如果 MCUSTAT。DBGFUNCEN = 1 集 Debug 相关寄存器,则清除 MCUCTRL。CPUWAIT = 0。

8锛 娴 。置AHB-AP来访问系统地址空间。AHB-AP连接到DAP总线端口0。

9锛 涓€涓。将 SYOCDCR。DBGEN 设置为 1。

10 瀹跺涵涓杞权。使用 AHB-AP 开始访问 CPU 调试资源。

(4)当 OSIS[127:126] 为 11b 时

需要 OCD 身份验证,并且 OCD 必须将解锁 ID 代码写入 OCDREG 中的 IAUTH 寄存器 0 至 3。OSIS[127:126] 为 10b 时连接序列相同,除了 “ALeRASE” 能力。

当 IATUH 寄存器 0 到 3 用 ASCII 代码中的 “AleRASE” 写入时（0x414C_6552_4153_45FF_FFFF_FFFF_FFFF）时, 代码闪存、数据闪存、配置区域的内容会一次性擦除。有关详细信息,请参阅第 38 节"闪存"。

ALeRASE 序列如下:

1。OCD调试器通过SWD接口连接到MCU。

2锛姣涓涓。设置 SWJ-DP 以访问 DAP 总线。在设置中,OCD 模拟器必须在 SWJDP 控制状态寄存器中断言 CDBGPWRUPREQ,然后等待同一寄存器中的 CDBGPWRUPACK 断言。

3锛 娴 。设置APB-AP以访问OCDREG。APB-AP连接到DAP总线端口1。

4锛姣涓。使用 APB-AP 将 128 位 ID 代码写入 OCDREG 中的 IAUTH 寄存器 0 至 3。

5锛姣涓。如果 ASCII 代码中的 128 位 ID 代码为 “ALeRASE”,则代码闪存、数据闪存和配置区域的内容将被删除。此后,MCU 过渡到睡眠模式。

3. Operating Modes

3.1 Overview

Table 3.1 shows the selection of operating modes by the mode-setting pin. For details, see section 3.2. Details of Operating Modes. Operation starts with the on-chip flash memory enabled, regardless of the mode in which operation started.

Table 3.1 Selection of operating modes by the mode-setting pin

Mode-setting pin (MD)	Operating mode	On-chip Flash
1	Single chip mode/SWD boot mode	Enable
0	SCI boot mode	Enable

3.2 Details of Operating Modes

3.2.1 Single-Chip Mode

In single-chip mode, all I/O pins are available for use as input or output port, inputs or outputs for peripheral functions, or as interrupt inputs.

When a reset is released while the MD pin is high, the MCU starts in single-chip mode and the on-chip flash is enabled.

3.2.2 SCI Boot Mode

In this mode, the on-chip flash memory programming routine (SCI boot program), stored in the boot area within the MCU, is used. The on-chip flash, including code flash memory and data flash memory, can be modified from outside the MCU by using a universal asynchronous receiver/transmitter (UART) SCI. For details, see section 38, Flash Memory. The MCU starts in SCI boot mode if the MD pin is held low on release from the reset state.

3.2.3 SWD Boot Mode

In this mode, the on-chip flash memory programming routine (SWD boot program), stored in the boot area within the MCU, is used. The on-chip flash, including code flash memory and data flash memory, can be modified from outside the MCU by using the SWD interface. For details, see section 38, Flash Memory. To enter this mode, it is necessary to input the request from the SWD-I/F during RES pin reset.

3.3 Operating Modes Transitions

3.3.1 Operating Mode Transitions as Determined by the Mode-Setting Pin

在单芯片模式下,所有 I/O 引脚均可用作输入或输出端口、外围功能的输入或输出或中断输入。

MD引脚高时释放复位,MCU以单芯片模式启动,并启用片上闪光灯。

3。2。2 SCI 启动模式

在此模式下,使用存储在MCU内引导区域的片上闪存编程例程（SCI引导程序）。片上闪存,包括代码闪存和数据闪存,可以通过使用通用异步接收器/发射器（UART）SCI从MCU外部进行修改。有关详细信息,请参阅第 38 节"闪存"。 如果 MD 引脚在从复位状态释放时保持较低位置,则 MCU 以 SCI 启动模式启动。

3。2。3 SWD 启动模式

在此模式下,使用存储在MCU内引导区域的片上闪存编程例程（SWD引导程序）。片上闪存,包括代码闪存和数据闪存,可以通过使用SWD接口从MCU外部进行修改。有关详细信息,请参阅第 38 节"闪存"。 要进入此模式,需要在 RES 引脚重置期间输入来自 SWD-I/F 的请求。

5.3 Operation

5.3.1 RES Pin Reset

The RES pin generates this reset. When the RES pin is driven low, all the processing in progress is aborted and the MCU enters a reset state. To successfully reset the MCU, the RES pin must be held low for the power supply stabilization time specified at power-on.

When the RES pin is driven high from low, the internal reset is canceled after the post-RES cancellation wait time (t_{RESWT}) elapses. The CPU then starts the reset exception handling.

For details, see section 41, Electrical Characteristics.

5.3.2 Power-On Reset

The power-on reset (POR) is an internal reset generated by the power-on reset circuit. A power-on reset is generated under the following conditions.

1. If the RES pin is in a high level state when power is supplied

5.3 操作

5。3。1 RES 引脚重置

RES引脚生成这个复位。RES引脚被低驱动时,所有正在进行的处理中止,MCU进入复位状态。要成功重置 MCU,RES 引脚必须在开机时指定的电源稳定时间保持较低。

RES 引脚从低到高被驱动时,在 RES 取消后等待时间（t RESWT）过后,内部复位被取消。CPU 然后开始重置异常处理。详情请参阅第 41 节"电气特性"。

5.3.2 通电复位

上电复位（POR）是由上电复位电路生成的内部复位。在以下条件下生成通电复位。

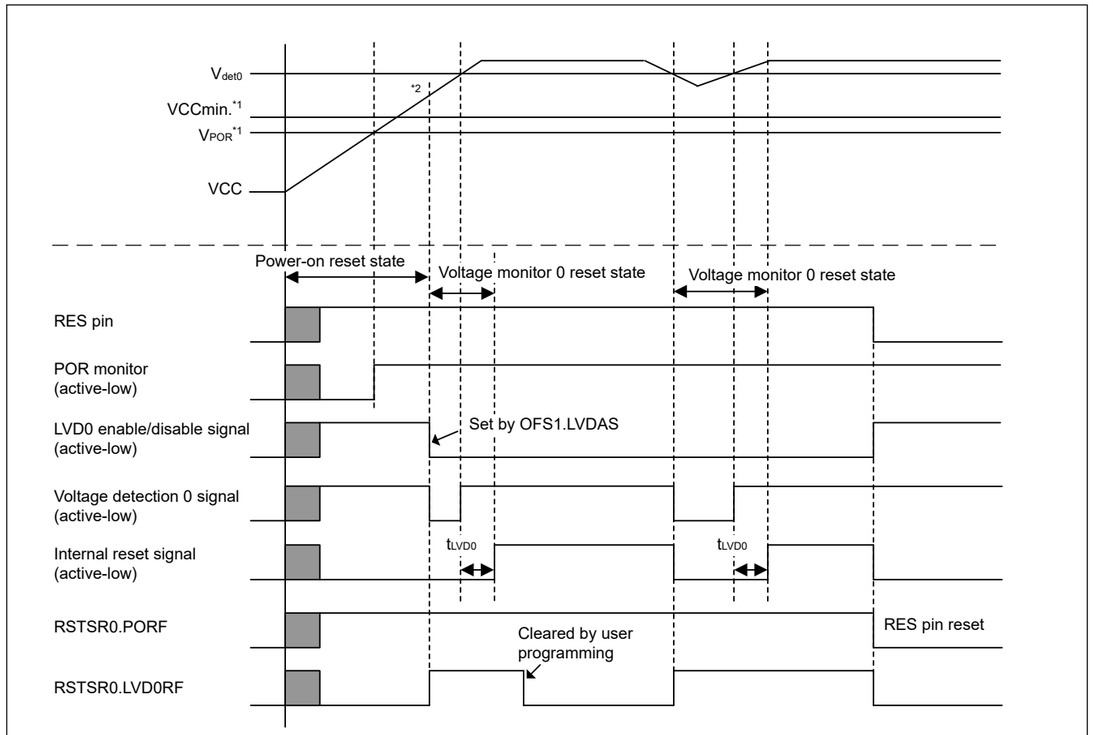
1。如果供电时 RES 引脚处于高电平状态

2. If the RES pin is in a high level state when VCC is below V_{POR}

After VCC exceeds V_{POR} and the specified power-on reset time (t_{POR}) elapses, the CPU starts the reset exception handling. The power-on reset time is a stabilization period of the external power supply and the MCU circuit.

After a power-on reset is generated, the PORF flag in the RSTSR0 is set to 1. The PORF flag is initialized by the RES pin reset. When VCC falls below V_{POR}, a power-on reset state is occurred.

Figure 5.1 shows example of operations during a power-on reset.



Note: For details on the electrical characteristics, see section 41, Electrical Characteristics.
Note 1. V_{POR} shows a power-on reset detection level, and VCCmin shows the minimum guaranteed voltage of MCU.
Note 2. At power-on, VCC should rise to the minimum guaranteed voltage before the power-on reset is released.

Figure 5.1 Example of operations during a power-on reset

5.3.3 Voltage Monitor Reset

The voltage monitor i (i = 0, 1, 2) reset is an internal reset generated by the voltage monitor i circuit. If the Voltage Detection 0 Circuit Start (LVDAS) bit in the Option Function Select Register 1 (OFS1) is 0 (voltage monitor 0 reset is enabled after a reset) and VCC falls below V_{det0}, the RSTSR0.LVD0RF flag becomes 1 and the voltage detection circuit generates voltage monitor 0 reset. Clear the OFS1.LVDAS bit to 0 if the voltage monitor 0 reset is to be used. After VCC exceeds V_{det0} and the voltage monitor 0 reset time (t_{LVD0}) elapses, the internal reset is canceled and the CPU starts the reset exception handling.

When the Voltage Monitor 1 Interrupt/Reset Enable bit (RIE) is set to 1 (enabling generation of a reset or interrupt by the voltage detection circuit) and the Voltage Monitor 1 Circuit Mode Select bit (RI) is set to 1 (selecting generation of a reset in response to detection of a low voltage) in Voltage Monitor 1 Circuit Control Register 0 (LVD1CR0), the RSTSR0.LVD1RF flag is set to 1 and the voltage detection circuit generates a voltage monitor 1 reset if VCC falls to or below V_{det1}.

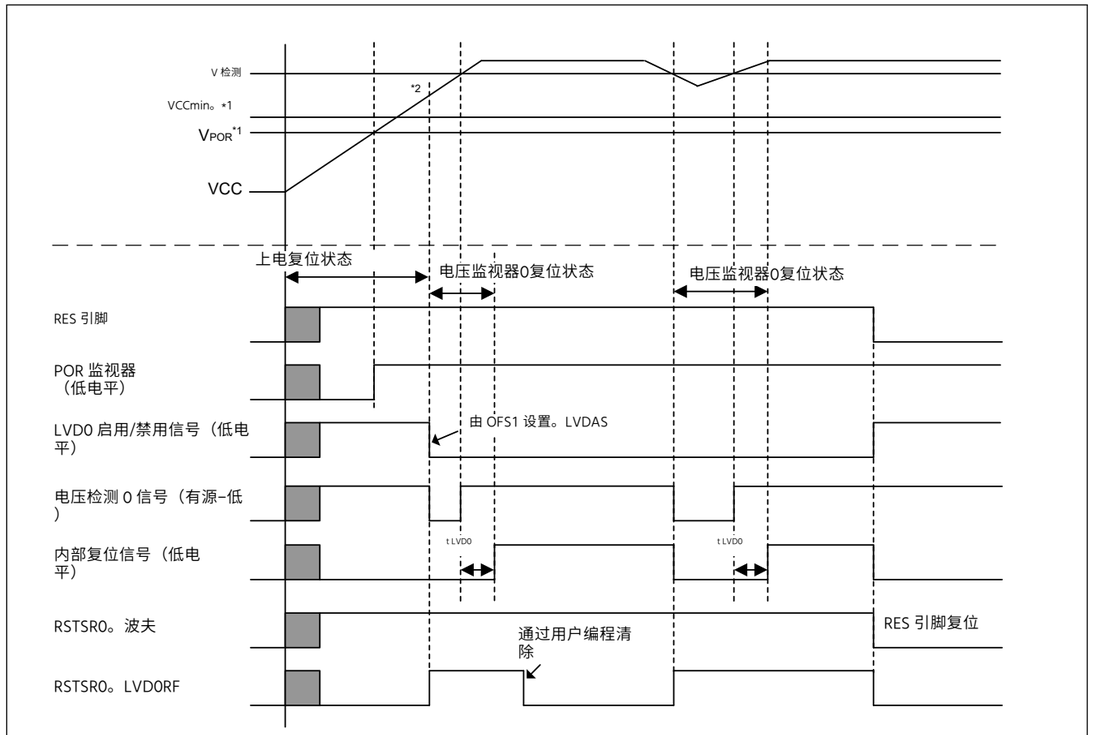
Likewise, when the Voltage Monitor 2 Interrupt/Reset Enable bit (RIE) is set to 1 (enabling generation of a reset or interrupt by the voltage detection circuit) and the Voltage Monitor 2 Circuit Mode Select bit (RI) is set to 1 (selecting generation of a

2锛姣涓。如果当 VCC 低于 VPOR 时 RES 引脚处于高电平状态

VCC 超过 VPOR 并且经过指定的上电复位时间（tPOR）后, CPU 开始复位异常处理。
上电复位时间是外部电源和MCU电路的稳定期。

产生通电复位后,RSTSR0中的PORF标志被设置为1。PORF 标志由 RES 引脚重置初始化。VCC 低于 VPOR 时,会发生通电复位状态。

图 5。1 显示了通电复位期间的操作示例。



注: 有关电气特性的详细信息,请参阅第 41 节"电气特性"。
注1。V POR 显示上电复位检测电平,VCCmin 显示 MCU 的最小保证电压。
注2。上电时,VCC 应在释放上电复位之前升至最低保证电压。

图5。1 上电复位期间的操作示例

5。3。3 电压监视器复位

器（i = 0,1,2)复位是电压监视器i电路产生的内部复位。如果选项功能选择寄存器 1（OFS1）中的电压检测 0 电路启动（LVDAS）位为 0（复位后启用电压监视器 0 重置）并且 VCC 低于 Vdet0,则 RSTSR0。LVD0RF标志变为1,电压检测电路产生电压监视器0复位。清除 OFS1。如果要使用电压监视器0复位,则LVDAS比特为0。VCC 超过 Vdet 0 且电压监视器 0 复位时间（tLVD0）后, 取消内部复位, CPU 开始复位异常处理。

当电压监视器1中断/重置使能位（RIE）设置为 1（使能由电压检测电路生成重置或中断）,电压监视器 1 电路模式选择位（RI）设置为 1（响应于检测而选择重置的生成）电压监视器 1 电路控制寄存器 0（LVD1CR0）中的低电压）,即 RSTSR0。LVD1RF标志被设置为1并且电压检测电路产生电压监视器1复位,如果VCC下降到或低于Vdet1 .

同样,当电压监视器 2 中断/复位启用位（RIE）设置为 1（允许电压检测电路生成复位或中断）并且电压监视器 2 电路模式选择位（RI）设置为 1（选择生成一个

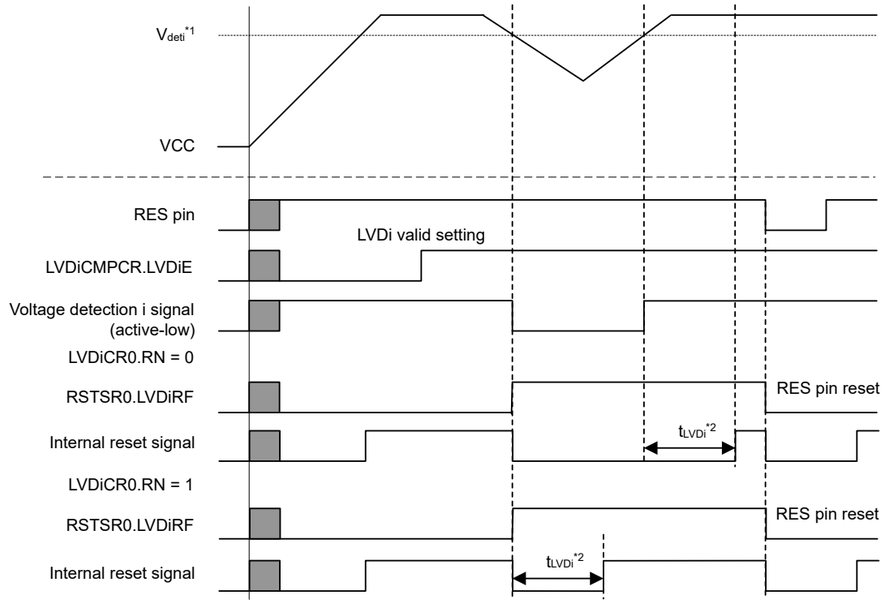
reset in response to detection of a low voltage) in Voltage Monitor 2 Circuit Control Register 0 (LVD2CR0), the RSTSR0.LVD2RF flag is set to 1 and the voltage detection circuit generates a voltage monitor 2 reset if VCC falls to or below V_{det2}.

Similarly, timing for release from the voltage monitor 1 reset state is selectable with the Voltage Monitor 1 Reset Negate Select bit (RN) in the LVD1CR0. When the LVD1CR0.RN bit is 0 and VCC falls to or below V_{det1}, the CPU is released from the internal reset state and starts reset exception handling when the LVD1 reset time (t_{LVD1}) elapses after VCC rises above V_{det1}. When the LVD1CR0.RN bit is 1 and VCC falls to or below V_{det1}, the CPU is released from the internal reset state and starts reset exception handling when the LVD1 reset time (t_{LVD1}) elapses.

Likewise, timing for release from the voltage monitor 2 reset state is selectable by setting the Voltage Monitor 2 Reset Negate Select bit (RN) in the LDV2CR0 register.

Detection levels V_{det1} and V_{det2} can be changed in the Voltage Monitoring Comparator Control Register (LVD1CMPCR/ LVD2CMPCR).

Figure 5.2 shows example of operations during voltage monitor 1 and 2 resets. For details on the voltage monitor 1 reset and voltage monitor 2 reset, see section 7, Low Voltage Detection (LVD).



Note: For details on the electrical characteristics, see section 41, Electrical Characteristics.
Note 1. V_{deti} indicates the detection level of a voltage monitor 1 reset and a voltage monitor 2 reset (i = 1, 2).
Note 2. t_{LVDi} indicates the time for a voltage monitor 1 reset and a voltage monitor 2 reset (i = 1, 2).

Figure 5.2 Example of operations during voltage monitor 1 and voltage monitor 2 resets

5.3.4 Deep Software Standby Reset

This is an internal reset generated when Deep Software Standby mode is canceled by an interrupt.

When a Deep Software Standby mode cancelation source is generated, a Deep Software Standby reset is generated. The Deep Software Standby reset is canceled after t_{DSBY} (return time after Deep Software Standby mode cancelation) has elapsed. At the same time, Deep Software Standby mode is also canceled.

响应于检测到低电压而复位）在电压监视器 2 电路控制寄存器 0（LVD2CR0）（RSTSR0)中。LVD2RF标志被设置为1并且电压检测电路产生电压监视器2复位,如果VCC下降到或低于Vdet2 .

类似地,通过LVD1CR0中的电压监视器1复位否定选择位（RN）,可以选择从电压监视器1复位状态释放的定时。当LVD1CR0。RN位为0且VCC下降到或低于Vdet1,CPU从内部复位状态释放,并在VCC上升到Vdet1以上后经过LVD1复位时间（tLVD1)时开始复位异常处理。当LVD1CR0。RN位为1且VCC降至或低于Vdet1,CPU从内部复位状态释放,并在LVD1复位时间（tLVD1)过去时开始复位异常处理。

同样,通过在LDV2CR0寄存器中设置电压监视器2复位否定选择位（RN）,可以选择从电压监视器2复位状态释放的定时。

检测级别 Vdet1 和 Vdet2 可以在电压监测比较器控制寄存器（LVD1CMPCR/LVD2CMPCR）中更改。

图5。2示出了电压监视器1和2复位期间的操作示例。1复位和电压监视器2复位的细节,参见第7节,低压检测（LVD）。

5。3。4 深度软件待机重置

这是当深度软件待机模式因中断而取消时生成的内部重置。

当生成深度软件待机模式取消源时,生成深度软件待机重置。深度软件待机重置在tDSBY（深度软件待机模式取消后的返回时间）过后取消。同时,深度软件待机模式也被取消。

When t_{DSBYWT} (wait time after Deep Software Standby mode cancelation) has elapsed after Deep Software Standby mode has been canceled, the internal reset is canceled and the CPU starts the reset exception handling.

For details of the Deep Software Standby reset, see section 10, Low Power Modes.

5.3.5 Independent Watchdog Timer Reset

The independent watchdog timer reset is an internal reset generated from the Independent Watchdog Timer (IWDT). Output of the reset from the IWDT can be selected in the Option Function Select Register 0 (OFS0).

When output of the independent watchdog timer reset is selected, the reset is generated if the IWDT underflows, or if data is written when refresh operation is disabled. When the internal reset time (t_{RESW2}) elapses after the independent watchdog timer reset is generated, the internal reset is canceled and the CPU starts the reset exception handling.

For details on the independent watchdog timer reset, see section 23, Independent Watchdog Timer (IWDT).

5.3.6 Watchdog Timer Reset

The watchdog timer reset is an internal reset generated from the Watchdog Timer (WDT). Output of the reset from the WDT can be selected in the WDT Reset Control Register (WDTRCR) or Option Function Select register 0 (OFS0).

When output of the watchdog timer reset is selected, a watchdog timer reset is generated if the WDT underflows, or if data is written when refresh operation is disabled. When the internal reset time (t_{RESW2}) elapses after the watchdog timer reset is generated, the internal reset is canceled and the CPU starts the reset exception handling.

For details on the watchdog timer reset, see section 22, Watchdog Timer (WDT).

5.3.7 Software Reset

The software reset is an internal reset generated by a software setting of the SYSRESETREQ bit in the AIRCR register in the Arm core. When the SYSRESETREQ bit is set to 1, a software reset is generated. When the internal reset time (t_{RESW2}) elapses after the software reset is generated, the internal reset is canceled and the CPU starts the reset exception handling.

For details on the SYSRESETREQ bit, see the *ARM® Cortex®-M33 Technical Reference Manual*.

5.3.8 Determination of Cold/Warm Start

Read the CWSF flag in RSTSR2 to determine the cause of reset processing. This flag indicates whether a power-on reset caused the reset processing (cold start) or a reset signal input during operation caused the reset processing (warm start).

The CWSF flag is set to 0 when a power-on reset occurs (cold start), otherwise the flag is not set to 0. The flag is set to 1 when 1 is written to it through software. It is not set to 0 even on writing 0 to it.

Figure 5.3 shows an example of cold/warm start determination operation.

当tDSBYWT（深度软件待机模式取消后的等待时间）在深度软件待机模式取消后过去时,内部重置被取消,CPU开始重置异常处理。

Deep 软件待机重置的详细信息, 请参阅第 10 节, 低功耗模式 .

5。3。5 独立看门狗定时器重置

独立看门狗定时器重置是由独立看门狗定时器（IWDT）生成的内部重置。IWDT 的重置输出可以在选项函数选择寄存器 0（OFS0) 中选择。

当选择独立看门狗定时器重置的输出时,如果 IWDT 下溢,或者在禁用刷新操作时写入数据,则生成重置。当产生独立看门狗定时器重置后经过内部重置时间（tRESW2)时,内部重置被取消,CPU开始重置异常处理。

有关独立看门狗定时器重置的详细信息,请参阅第 23 节"独立看门狗定时器（IWDT）."

5。3。6 看门狗定时器重置

看门狗定时器重置是从看门狗定时器（WDT）生成的内部重置。WDT 的重置输出可以在 WDT 重置控制寄存器（WDTRCR）或选项功能选择寄存器 0（OFS0) 中选择。

当选择看门狗定时器重置的输出时,如果WDT下溢,或者如果在禁用刷新操作时写入数据,则生成看门狗定时器重置。当生成看门狗定时器重置后经过内部重置时间（tRESW2)时,内部重置被取消,CPU开始重置异常处理。

有关看门狗定时器重置的详细信息,请参阅第 22 节"看门狗定时器（WDT）."

5。3。7 软件重置

软件重置是由Arm核心AIRCR寄存器中的SYSRESETREQ位进行软件设置生成的内部重置。当SYSRESETREQ位设置为1时,生成软件重置。当内部重置时间（软件重置生成后经过tRESW2))时,内部重置被取消,CPU开始重置异常处理。

有关 SYSRESETREQ 位的详细信息,请参阅 ARM ®Cortex ®-M33 技术参考手册 .

5。3。8 冷/暖启动的测定

RSTSR2 中读取 CWSF 标志来确定重置处理的原因。该标志指示通电复位是否引起复位处理（冷启动）,或者操作期间的复位信号输入是否引起复位处理（暖启动）。CWSF 标志设置为 0 当发生开机复位（冷启动）,否则标志不设置为 0。1通过软件写入时,标志被设置为1。即使在写入 0 时,它也不会设置为 0。

图 5。3 显示了冷/热启动确定操作的示例。

5.3.9 Determination of Reset Generation Source

Read RSTSR0 and RSTSR1 to determine which reset executes the reset exception handling.

Figure 5.4 shows an example of the flow to identify a reset generation source. The reset flag must be written with 0 after it is read as 1.

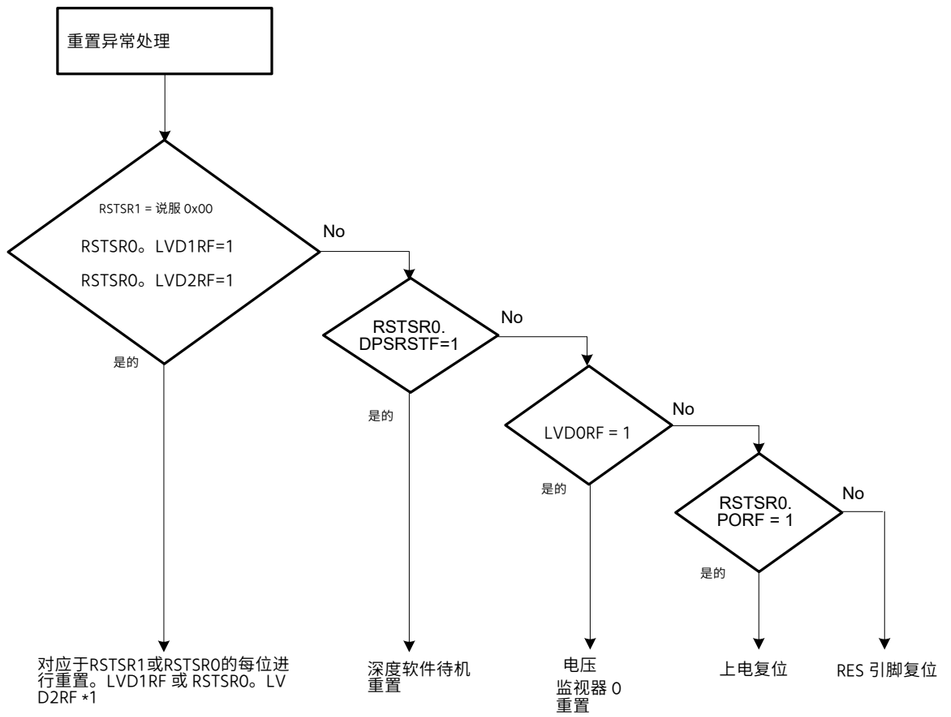
5.4 Initialization Procedure Required after Reset

The MCU has registers that are not initialized after reset. In some cases, an unintended interrupt request may cause an increase in power consumption or malfunction. Therefore, initialize these register after reset according to one of the procedures described in Figure 5.5 and Figure 5.6.

Figure 5.5 shows the initialization procedure in all cases and Figure 5.6 shows the initialization procedure that can be applied when the sub-clock oscillator is not used.



注1。当两个或多个源同时生成重置时,将设置两个或多个相应的重置标志 to 1.

5。4 重置后所需的初始化程序

6.2.2 OSIS : OCD/Serial Programmer ID Setting Register

The OSIS register stores the ID for ID code protection of the OCD/serial programmer. When connecting the OCD/serial programmer, write values so that the MCU can determine whether to permit the connection. Use this register to check whether a code transmitted from the OCD/serial programmer matches the ID code in the option-setting memory.

When the ID codes match, connection of the OCD/serial programmer is permitted, if not, connection with the OCD/serial programmer is not possible. The OSIS register must be set in 32-bit words.

Address: 0x0100_A120, 0x0100_A124, 0x0100_A128, 0x0100_A12C

Bit position:	31	0
Bit field:		
Value after reset:	User setting	

Note: Only secure access can write to this register.

These fields hold the ID for use in ID authentication for the OCD/serial programmer.

ID code bits [127] and [126] determine whether ID code protection is enabled and the method of authentication to use with the host. Table 6.2 shows how the ID code determines the method of authentication.

Setting bit [127] = 0 or bit [126] = 0 prevents Renesas from accessing the test mode. Therefore, Renesas cannot perform failure analysis unless bit [127] = 1 and bit [126] = 1 are set. To process any warranty claim, Renesas must be able to perform failure analysis.

WDTRPSS[1:0] 位（WDT 窗口开始位置选择）

WDTRPSS[1:0] 位指定下计数器窗口开始的位置为计数值的 25%、50%、75% 或 100%。 计数开始的点是 100% ,发生下溢的点是 0%。 窗口开始和结束的位置之间的间隔成为可以刷新的周期。

在此期限之外无法刷新。

有关详细信息,请参阅第 22 节"看门狗定时器（WDT）."

WDTRSTIRQS 位（WDT 重置中断请求选择）

WDTRSTIRQS 位选择下计数器下溢或刷新错误生成的操作。该操作可选择看门狗定时器重置、不可屏蔽的中断请求或中断请求。

有关详细信息,请参阅第 22 节"看门狗定时器（WDT）."

WDTSTPCTL 位（WDT 停止控制）

WDTSTPCTL 位指定进入睡眠模式时是否停止计数。

有关详细信息,请参阅第 22 节"看门狗定时器（WDT）."

6。2。2 OSIS:OCD/串行程序员 ID 设置寄存器

OSIS 寄存器存储用于保护 OCD/串行程序员的 ID 码的 ID。OCD/串行程序员连接时,写入值,以便MCU可以确定是否允许连接。使用此寄存器检查从 OCD/串行程序员传输的代码是否与选项设置内存中的 ID 代码匹配。

当ID码匹配时,允许连接OCD/串行程序员,如果不允许,则不可能连接OCD/串行程序员。OSIS 寄存器必须设置为 32 位字。

地址: 0x0100_A120、0x0100_A124、0x0100_A128、0x0100_A12C

位位置:	31	0
位字段:		
重置后的值:	用户设置	

注: 只有安全访问才能写入此寄存器。

这些字段保存用于 OCD/串行程序员 ID 身份验证的 ID。

ID码位[127]和[126]确定是否启用ID码保护以及认证方法与主机一起使用。表 6。2 显示了 ID 代码如何确定身份验证方法。

置[127] = 0或位[126] = 0,则会阻止瑞萨访问测试模式。因此,除非设置位 [127] = 1 和位 [126] = 1,否则瑞萨无法执行故障分析。要处理任何保修索赔,瑞萨必须能够执行故障分析。

Serial programming mode (SCI/SWD boot mode) On-chip debug mode (SWD boot mode)	0xFF, …, 0xFF (all bytes are 0xFF)	Protection disabled	Connection to programmer or on-chip debugger is permitted. The connection to the programmer does not check the ID code, the ID code always matches, and the connection to the programmer is permitted. The on-chip debugger needs to send 0xFF, …, 0xFF (All bytes = 0xFF) on connection.

When the ID code sent from the programmer or the on-chip debugger is ALeRASE in ASCII code (0x414C_6552_4153_45FF_FFFF_FFFF_FFFF_FFFF), the content of the user flash area is erased. However, forced erasure is not executed when the FSPR bit is 0 or there is a block with permanent block protection.
	Bit [127] = 1 and bit [126] = 0	Protection enabled	Matching ID code = authentication is complete and connection to the programmer or the on-chip debugger is permitted. Mismatching ID code = transition to the ID code protection wait state. Renesas cannot access the test mode.
	Bit [127] = 0	Protection enabled	The ID code is not checked, the ID code is always mismatching, the connection to the programmer or the on-chip debugger is prohibited, and Renesas cannot access the test mode.

LVDAS bits (Voltage Detection 0 Circuit Start)

The LVDAS bit selects whether the voltage monitor 0 reset is enabled or disabled after a reset.

HOCOEN bit (HOCO Oscillation Enable)

The HOCOEN bit selects whether the HOCO oscillation is enabled or disabled after a reset. Setting this bit to 0 allows the HOCO oscillation to start before the CPU starts operation, which reduces the wait time for oscillation stabilization.

Note: When the HOCOEN bit is set to 0, the system clock source is not switched to HOCO. The system clock source is only switched to HOCO by setting the Clock Source Select bits (SCKSCR.CKSEL[2:0]). To use the HOCO clock,

VDSEL[1:0] 位（电压检测 0 级选择）

VDSEL[1:0]位选择电压检测0电路的电压检测电平。

LVDAS 位（电压检测 0 电路启动）

LVDAS位选择在复位之后是否启用或禁用电压监视器0复位。

HOCOEN 位（HOCO 振荡启用）

HOCOEN 位选择重置后 HOCO 振荡是启用还是禁用。将此位设置为 0 允许 HOCO 振荡在 CPU 开始运行之前开始,从而减少了振荡稳定的等待时间。

注意:当HOCOEN位设置为0时,系统时钟源不切换为HOCO。仅通过设置时钟源选择位（SCKSCR。CKSEL[2:0])将系统时钟源切换为HOCO。要使用 HOCO 时钟,

you must set the OFS1.HOCOFRQ0 bit to an optimum value. The value of OFS1.HOCOFRQ0[1:0] bits is automatically transferred to HOCOCR2.HCFRQ0[1:0] bits after reset, therefore it can also be specified by HOCOCR2.HCFRQ0[1:0] bits.

HOCOFRQ0[1:0] bits (HOCO Frequency Setting 0)

The HOCOFRQ0[1:0] bits specify the HOCO frequency after a reset as 16, 18, or 20 MHz.

The PBPS register invalidates writes to bits of BPS. The bit of this register can be set to 0 when corresponding bit of BPS is set to 0. When the bit of this register is set to 0, writing the corresponding bit of BPS register is invalid. Once the bit of this register is set to 0, it is impossible to change the bit to 1. Table 6.3 shows the relationship between the bit of applied PBPS and bit of applied BPS.

The relationship between the bit of this register and the block number is the same as BPS register (Figure 6.3). Unused bits are reserved and should be set to 1.

Table 6.3 Relationship between bit PBPS and bit BPS

The bit of applied PBPS	The bit of applied BPS	Content
1	1	Programming and erasure to the corresponding block is valid.
1	0	Programming and erasure to the corresponding block is invalid. This protection can be canceled by FBPROT1 register.
0	1	Condition cannot be set.
0	0	Programming and erasure to the corresponding block is permanently invalid.

6.3 Setting Option-Setting Memory

6.3.1 Allocation of Data in Option-Setting Memory

Programming data is allocated to the addresses in the option-setting memory shown in Figure 6.1. The allocated data is used by tools such as a flash programming software or an on-chip debugger.

Note: Programming formats vary depending on the compiler. See the compiler manual for details.

6.3.2 Setting Data for Programming Option-Setting Memory

Allocating data according to the procedure described in section 6.3.1. Allocation of Data in Option-Setting Memory, alone does not actually write the data to the option-setting memory. You must also follow one of the actions described in this section.

(1) Changing the option-setting memory by self-programming

Use the configuration setting command to write data to the option-setting memory in the configuration setting area.

The option-setting memory does not support background operations (BGO). When write the option-setting memory, jump to SRAM after copying writing softwere to SRAM.

For details of the configuration setting command, see section 38, Flash Memory.

(2) Debugging through an OCD or programming by a flash writer

This procedure depends on the tool in use, see the tool manual for details.

The MCU provides two setting procedures:

- Read the data allocated as described in section 6.3.1. Allocation of Data in Option-Setting Memory, from an object file or Motorola S-format file generated by the compiler, and write the data to the MCU
- Use the GUI interface of the tool to program the same data as allocated in section 6.3.1. Allocation of Data in Option-Setting Memory.

6.3.3 Timing of the Setting Value

For SAS, BPS, and PBPS registers, the setting value of the related startup area and block protection is applied immediately after programming. For other registers, the setting value is applied after the MCU is reset.

For programming using the serial programming mode in customer's factory, ensure that the block protection is applied after the MCU is reset.

PBPS 寄存器使对 BPS 位的写入无效。BPS的相应位设置为0时,该寄存器的位可以设置为0。当该寄存器的位设置为0时,写入BPS寄存器的相应位无效。一旦该寄存器的位设置为 0,就不可能将该位更改为 1。表6。3显示了所应用的PBPS位与所应用的BPS位之间的关系。

该寄存器的位与块号之间的关系与BPS寄存器相同（图6。3)。未使用的位被保留并且应设置为 1。

表 6。3 位 PBPS 和位 BPS 之间的关系

应用 PBPS 的位	应用 BPS 的位	内容
1	1	对相应块进行编程和擦除是有效的。
1	0	对相应块进行编程和擦除无效。FBPROT1 寄存器可以取消此保护。
0	1	无法设置条件。
0	0	对相应块进行编程和擦除永久无效。

6。3 设置选项-设置内存

6.3.1 选项设置内存中的数据分配

编程数据被分配给图 6。1 所示的选项设置存储器中的地址。分配的数据由 Flash 编程软件或片上调试器等工具使用。

注: 编程格式根据编译器的不同而有所不同。详细信息请参阅编译器手册。

6。3。2 编程的设置数据 选项设置 内存

根据第 6。3。1 节中描述的程序分配数据。选项设置内存中的数据分配本身并不能将数据实际写入选项设置内存。您还必须遵循本节中描述的操作之一。

(1)通过自编程改变选项设置内存

使用配置设置命令将数据写入配置设置区域中的选项设置内存。

选项设置内存不支持后台操作（BGO）。写入选项设置内存时,将写入软写入SRAM后跳转到SRAM。

有关配置设置命令的详细信息,请参阅第 38 节"闪存 ."

(2)通过OCD进行调试或由闪存写入器进行编程 此过程取决于所使用的工具,详情请参阅工具手册。

MCU提供了两种设置过程:

- 读取按照第 6。3。1 节所述分配的数据。选项设置内存中的数据分配,来自编译器生成的对象文件或摩托罗拉 S 格式文件,并将数据写入 MCU
- 使用工具的 GUI 接口对与第 6。3。1 节中分配的数据相同的数据进行编程。OptionSeting 内存 . 中的数据分配

6。3。3 设定值的时序

SAS、BPS、PBPS 寄存器,编程后立即应用相关启动区域和块保护的设置值。对于其他寄存器,设置值在 MCU 重置后应用。

MCU复位后,使用客户工厂中的串行编程模式进行编程,确保块保护。

6.4 Usage Notes

6.4.1 Data for Programming Reserved Areas and Reserved Bits in the Option-Setting Memory

When reserved areas and reserved bits in the option-setting memory are within the scope of programming, write 1 to all bits of reserved areas and all reserved bits. If 0 is written to these bits, normal operation cannot be guaranteed.

6。4 使用说明

6.4.1 用于对选项设置存储器中的保留区域和保留位进行编程的数据

当选项设置内存中的保留区域和保留位在编程范围内时,将 1 写入保留区域的所有位和所有保留位。0写入这些位,则无法保证正常操作。

7. Low Voltage Detection (LVD)

7.1 Overview

The Low Voltage Detection (LVD) module monitors the voltage level input to the VCC pin. The detection level can be selected by register settings. The LVD module consists of three separate voltage level detectors (LVD0, LVD1, LVD2). LVD0, LVD1, and LVD2 measure the voltage level input to the VCC pin. LVD registers allow your application to configure detection of VCC changes at various voltage thresholds.

Voltage monitor registers are used to configure the LVD to trigger an interrupt, event link output, or reset when the thresholds are crossed.

Table 7.1 lists the LVD specifications. Figure 7.1 shows a block diagram of the voltage monitor 0 reset generation circuit. Figure 7.2 shows a block diagram of the voltage monitor 1 interrupt and reset circuit, and Figure 7.3 shows a block diagram of the voltage monitor 2 interrupt and reset circuit.

7. 低压检测（LVD）

7。1 概述

低压检测（LVD）模块监控输入到 VCC 引脚的电压电平。检测级别可以通过寄存器设置来选择。LVD 模块由三个独立的电压电平检测器（LVD0、LVD1、LVD2)组成。

LVD0、LVD1 和 LVD2 测量输入到 VCC 引脚的电压电平。LVD 寄存器允许您的应用程序配置各种电压阈值下 VCC 变化的检测。

电压监视器寄存器用于配置 LVD 以在跨越阈值时触发中断、事件链路输出或重置。

如果安全属性配置为非安全:

注: 在重写此寄存器之前,将 PRCR。PRC3 位设置为 1（启用写入）。

RIE 位（电压监视器 1 中断/重置启用）

RIE 位启用或禁用电压监视器 1 中断/重置。确保在闪存的编程或擦除期间既不会产生电压监视器1中断,也不会产生电压监视器1复位。

DFDIS 位（电压监视器 1 数字滤波器禁用模式选择）

DFDIS 位禁用数字滤波电路。当该位为 0（启用）时,将 LOCOCR。LCSTP 位设置为 0（LOCO 运行）。在软件待机模式或深度软件待机模式下使用电压监视器1电路时,将该位设置为1（禁用）。

CMPE 位（电压监视器 1 电路比较结果输出启用）

CMPE 位启用或禁用电压监视器 1 电路比较结果输出。在电压检测1电路启用并且稳定时间（td（EA））过去之后将CMPE位设置为1。当停止电压检测1电路时,在将CMPE位设置为0之后禁用电压检测1电路。

FSAMP[1:0] 位（采样时钟选择）

FSAMP[1:0] 位只能在 LVD1CR0 时重写。DFDIS 位为 1（禁用数字滤波电路）。如果是 LVD1CR0,请勿重写这些位。DFDIS 位为 0（启用数字滤波电路）。

RI bit (Voltage Monitor 1 Circuit Mode Select)

When the RI bit is 1 (voltage monitor 1 reset selected), transition to Deep Software Standby mode cannot be made. In this case, transition to Software Standby mode is made. To enter Deep Software Standby mode, set the RI bit to 0 (voltage monitor 1 interrupt selected).

RN bit (Voltage Monitor 1 Reset Negate Select)

If the RN bit is set to 1 (negation follows a stabilization time on assertion of the LVD1 reset signal), set the LOCOCR.LCSTP bit to 0 (the LOCO operates). In addition, for a transition to Software Standby or Deep Software Standby mode, the only possible value for the RN bit is 0 (negation follows stabilization time when VCC > V_{det1} is detected). Do not set the RN bit to 1 when this is the case.

7.2.5 LVD2CR0 : Voltage Monitor 2 Circuit Control Register 0

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: Set the PRCR.PRC3 bit to 1 (write enabled) before rewriting this register.

RIE bit (Voltage Monitor 2 Interrupt/Reset Enable)

The RIE bit enables or disables the voltage monitor 2 interrupt/reset. Ensure that neither a voltage monitor 2 interrupt nor a voltage monitor 2 reset is generated during programming or erasure of the flash memory.

RI 位（电压监视器 1 电路模式选择）

RI 位为 1（选择电压监视器 1 重置）时,无法过渡到深度软件待机模式。在这种情况下,将转换为软件待机模式。要进入深度软件待机模式,请将 RI 位设置为 0（选择电压监视器 1 中断）。

RN 位（电压监视器 1 重置否定选择）

如果 RN 位设置为 1（在断言 LVD1 重置信号时出现稳定时间后出现否定）,则将 LOCOCR。LCSTP 位设置为 0（LOCO 运行）。此外,对于向软件待机或深度软件待机模式的过渡,RN 位唯一可能的值是 0（当检测到 VCC > Vdet1 时,稳定时间会出现否定）。RN位不设置为1当这种情况。

When stopping the voltage detection 2 circuit, disable the voltage detection 2 circuit after setting the CMPE bit is 0.

FSAMP[1:0] bits (Sampling Clock Select)

The FSAMP[1:0] bits can be rewritten only when the LVD2CR0.DFDIS bit is 1 (digital filter circuit disabled). Do not rewrite these bits if the LVD2CR0.DFDIS bit is 0 (digital filter circuit enabled).

RI bit (Voltage Monitor 2 Circuit Mode Select)

When the RI bit is 1 (voltage monitor 2 reset selected), transition to Deep Software Standby mode cannot be made. In this case, transition to Software Standby mode is made. To enter Deep Software Standby mode, set the RI bit to 0 (voltage monitor 2 interrupt selected).

RN bit (Voltage Monitor 2 Reset Negate Select)

If the RN bit is set to 1 (negating LVD2 reset in a specified time after its assertion), set the LOCOCR.LCSTP bit to 0 (the LOCO operates). Additionally, for a transition to Software Standby or Deep Software Standby mode, the only possible value for the RN bit is 0 (negation follows a stabilization time when VCC > V_{det2} is detected). Do not set the RN bit to 1 (negation follows a stabilization time after assertion of the LVD2 reset signal) when this is the case.

DFDIS 位（电压监视器 2 数字滤波器禁用模式选择）

DFDIS 位禁用数字滤波电路。当该位为 0（启用数字滤波器）时,将 LOCOCR。LCSTP 位设置为 0（LOCO 运行）。在软件待机模式或深度软件待机模式下使用电压监视器2电路时,将该位设置为1（禁用数字滤波器）。

CMPE 位（电压监视器 2 电路比较结果输出启用）

CMPE 位启用或禁用电压监视器 2 电路比较结果输出。在电压检测2电路启用并且稳定时间（td（EA））过去之后将CMPE位设置为1。当停止电压检测2电路时,在将CMPE位设置为0之后禁用电压检测2电路。

FSAMP[1:0] 位（采样时钟选择）

FSAMP[1:0] 位只能在 LVD2CR0 时重写。DFDIS 位为 1（禁用数字滤波电路）。如果是 LVD2CR0,请勿重写这些位。DFDIS 位为 0（启用数字滤波电路）。

RI 位（电压监视器 2 电路模式选择）

RI 位为 1（选择电压监视器 2 重置）时,无法过渡到深度软件待机模式。在这种情况下,将转换为软件待机模式。要进入深度软件待机模式,请将 RI 位设置为 0（选择电压监视器 2 中断）。

RN 位（电压监视器 2 重置否定选择）

如果 RN 位设置为 1（在其断言后的指定时间内否定 LVD2 重置）,则将 LOCOCR。LCSTP 位设置为 0（LOCO 运行）。此外,对于向软件待机或深度软件待机模式的过渡,RN 位唯一可能的值是 0（当检测到 VCC > Vdet2 时,稳定时间会出现否定）。在这种情况下,请勿将 RN 位设置为 1（在断言 LVD2 重置信号后的稳定时间后进行否定）。

7.5 Interrupt and Reset from Voltage Monitor 1

An interrupt or reset can be generated in response to the comparison results from the voltage monitor 1 circuit.

Table 7.4 shows the procedures for setting bits related to the voltage monitor 1 interrupt/reset so that voltage monitoring occurs. Table 7.5 shows the procedures for setting bits related to the voltage monitor 1 interrupt/reset so that voltage monitoring stops. - When VCC > V_{det1} is detected, negate the voltage monitor 1 reset signal (LVD1CR0.RN = 0) following a stabilization time.

(2) Settings in Deep Software Standby mode

- Disable the digital filter (LVD1CR0.DFDIS = 1).

在软件待机模式或深度软件待机模式下使用电压监视器1电路时,使用本节中的过程设置电路。

- 当检测到 VCC > V det1 时,否定电压监视器 1 重置信号（LVD1CR0)。稳定时间后 RN = 0)。

(2) 深度软件待机模式下的设置

- 禁用数字滤波器（LVD1CR0)。DFDIS = 1)。

- Enable the voltage monitor 1 interrupt (LVD1CR0.RI = 0). If the voltage monitor 1 reset is enabled (LVD1CR0.RI = 1), a transition to Deep Software Standby mode is not possible, and the operation transitions to Software Standby mode instead.
- When the DPSBYCR.DEEPCUT[1:0] bits are 11b, the voltage monitor 1 circuit stops. To use the voltage monitor 1 circuit in Deep Software Standby mode, set the DPSBYCR.DEEPCUT[1:0] bits to a value other than 11b.

Table 7.7 shows the procedures for setting bits related to the voltage monitor 2 interrupt/reset so that voltage monitoring stops. Figure 7.6 shows an example of operations for a voltage monitor 2 interrupt. For the operation of the voltage monitor 2 reset, see Figure 5.2 in section 5, Resets.

When using the voltage monitor 2 circuit in Software Standby mode or Deep Software Standby mode, set up the circuit with the following procedures.

(1) Setting in Software Standby mode

- Disable the digital filter (LVD2CR0.DFDIS = 1)
- When VCC > V_{det2} is detected, negate the voltage monitor 2 reset signal (LVD2CR0.RN = 0) following a LVD2 stabilization time.

(2) Settings in Deep Software Standby mode

- Disable the digital filter (LVD2CR0.DFDIS = 1).
- Enable the voltage monitor 2 interrupt (LVD2CR0.RI = 0). If the voltage monitor 2 reset is enabled (LVD2CR0.RI = 1), a transition to Deep Software Standby mode is not possible, and the operation transitions to Software Standby mode instead.
- When the DPSBYCR.DEEPCUT[1:0] bits are 11b, the voltage monitor 2 circuit stops. To use the voltage monitor 2 circuit in Deep Software Standby mode, set the DPSBYCR.DEEPCUT[1:0] bits to a value other than 11b.

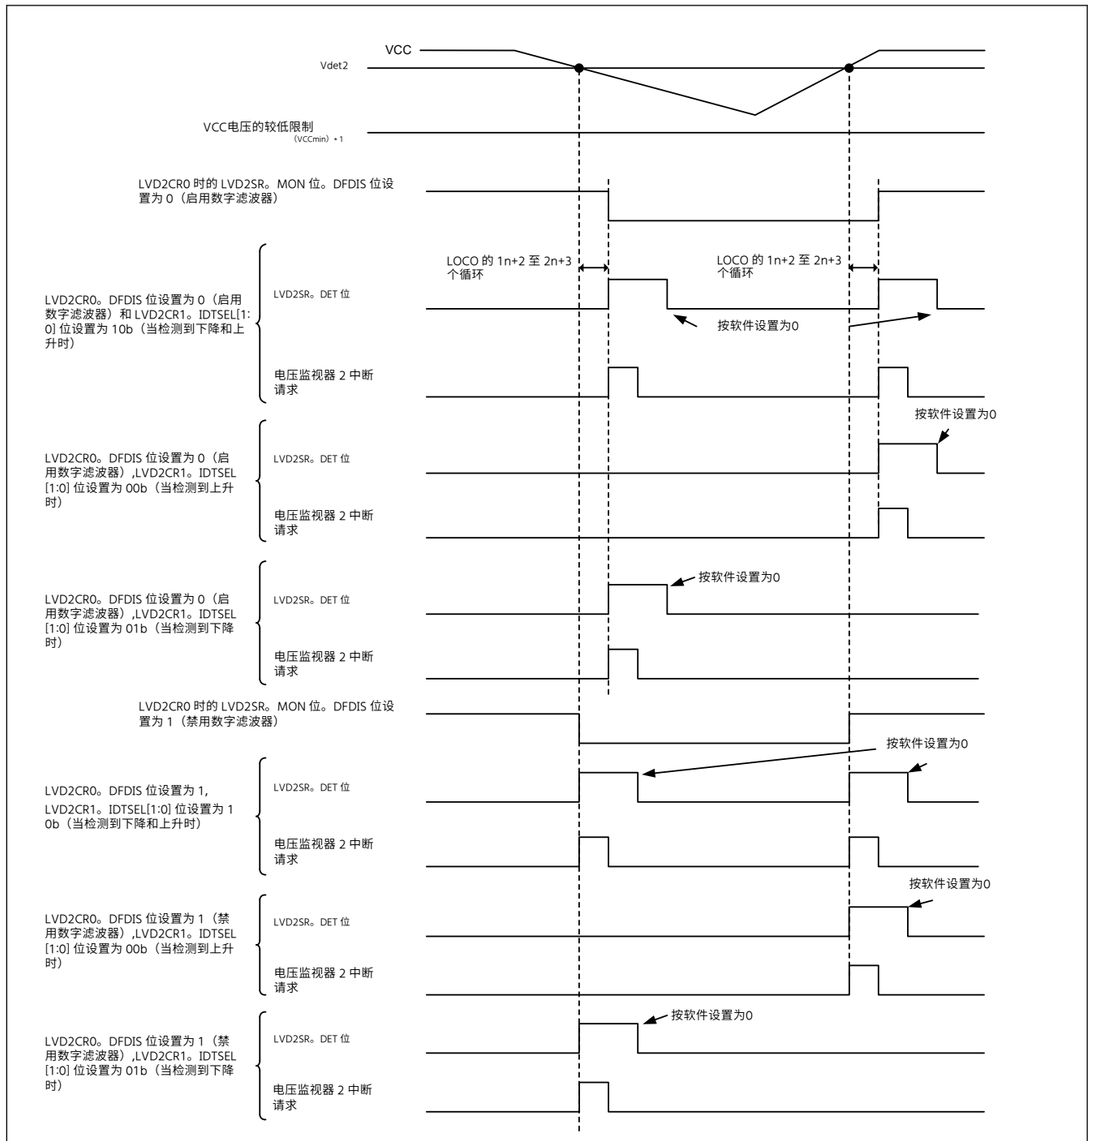
7.7 Event Link Controller (ELC) Output

The LVD can output the event signals to the Event Link Controller (ELC).

(1) V_{det1} Crossing Detection Event

The LVD outputs the event signal when it detects that the voltage has passed the V_{det1} voltage while both the voltage detection 1 circuit and the voltage monitor 1 circuit comparison result output are enabled.



n:数字滤波器的采样时钟的频率是loco频率除以n注1。当电压监视器0复位不使用时,在VCC ≥ VCCmi
n下使用。

7.7 事件链路控制器（ELC）输出

LVD 可以将事件信号输出到事件链路控制器（ELC）。

(1) V det1 交叉检测事件

当LVD检测到电压已通过V det1电压时,LVD输出事件信号,同时启用电压检测1电路和电压监视器1电路比较结果输出。

(2) V_{det2} Crossing Detection Event

The LVD outputs the event signal when it detects that the voltage has passed the V_{det2} voltage while both the voltage detection 2 circuit and the voltage monitor 2 circuit comparison result output are enabled.

When enabling the event link output function of the LVD, you must enable the LVD before enabling the LVD event link function of the ELC. To stop the event link output function of the LVD, you must stop the LVD before disabling the LVD event link function of the ELC.

7.7.1 Interrupt Handling and Event Linking

The LVD provides bits to separately enable or disable the voltage monitor 1 and 2 interrupts. When an interrupt source is generated and the interrupt is enabled by the interrupt enable bit, the interrupt signal is output to the CPU.

In contrast, as soon as an interrupt source is generated, an event link signal is output as the event signal to the other module through the ELC, regardless of the state of the interrupt enable bit.

It is possible to output voltage monitor 1 and 2 interrupts in Software Standby and Deep Software Standby modes. The event signals for the ELC in Software Standby and Deep Software Standby modes are output as follows:

- When a V_{det1} or V_{det2} passage events is detected in Software Standby mode, event signals are not generated for the ELC because the clock is not supplied in Software Standby mode. Because the V_{det1} and V_{det2} passage detection flags are saved, when the clock supply resumes after returning from Software Standby mode, the event signals for the ELC are output based on the state of the V_{det1} and V_{det2} detection flags.
- When a Vdet1 or Vdet2 passage events are detected in Deep Software Standby mode, event signals are not generated for the ELC.

(2)V det2 交叉检测事件

当LVD检测到电压已通过Vdet2电压时,LVD输出事件信号,同时启用电压检测2电路和电压监视器2电路比较结果输出。

LVD 的事件链路输出功能时,在启用 ELC 的 LVD 事件链路功能之前,必须先启用 LVD。LVD 的事件链路输出功能,则必须在禁用 ELC 的 LVD 事件链路功能之前停止 LVD。

7.7.1 中断处理和事件链接

LVD 提供位以单独启用或禁用电压监视器 1 和 2 中断。当产生中断源并且中断使能位使能中断时,中断信号被输出到CPU。

相反,一旦生成中断源,事件链路信号就通过ELC作为事件信号输出到另一个模块,而不管中断使能位的状态如何。

在软件待机和深度软件待机模式下可以输出电压监视器1和2中断。ELC在软件待机和深度软件待机模式下的事件信号输出如下:

- 当在软件待机模式下检测到 Vdet1 或 Vdet2 通道事件时,不会为 ELC 生成事件信号,因为时钟不在软件待机模式下提供。由于保存了Vdet1和Vdet2通道检测标志,因此当从软件待机模式返回后恢复时钟电源时,根据Vdet1和Vdet2检测标志的状态输出ELC的事件信号。
- 当在深度软件待机模式下检测到 Vdet1 或 Vdet2 通道事件时,不会为 ELC 生成事件信号。

CAC Sub clock (CACSCLK)	SOSC	CAC	32.768 kHz

IWDT clock (IWDTCLK)	IWDTLOCO	IWDT	15 kHz
SysTick timer clock (SYSTICCLK)	LOCO	SysTick timer	32.768 kHz
Serial wire clock (SWCLK)	SWCLK	OCD	Up to 25 MHz
Clock/buzzer output (CLKOUT)	MOSC/SOSC/LOCO/MOCO/ HOCO	CLKOUT pin	Up to 60 MHz Division ratios: 1/2/4/8/16/32/64/128

Note: Restrictions on setting clock frequency: ICLK ≥ PCLKA ≥ PCLKB, PCLKD ≥ PCLKA ≥ PCLKB
ICLK ≥ FCLK
Restrictions on clock frequency ratio: (N: integer, and up to 64)
ICLK:FCLK = N:1, ICLK:PCLKA = N:1, ICLK:PCLKB = N:1, ICLK:PCLKC = N:1 or 1:N , ICLK:PCLKD= N:1 or 1:N, ICLK:TRCLK= N:1 or 1:N
If the A/D converter is enabled, the clock frequency ratio is constrained as follows:
PCLKA:PCLKC = 1:1 or 2:1 or 4:1 or 8:1 or 1:2 or 1:4
If the CAN-FD is used, clock frequency ratio is constrained to be PCLKA:PCLKB = 2:1.

Note: Restrictions on the minimum FCLK frequency 4MHz when P/E.

Note: The multiplication of PLL should be set to be within the output frequency range of PLL, taking the frequency of HOCO into consideration when not using the FLL function.

Note: Clocks have a permissible frequency range (See Table 8.2).
Flash memory and SRAM also have a permissible operating frequency range in each wait cycle setting. (See section 37, SRAM, section 38, Flash Memory)
Those clock frequency ranges must be satisfied even if the HOCO has its maximum or minimum frequency when not using FLL function. (See section 41, Electrical Characteristics).

注: 设置时钟频率的限制:ICLK ≥ PCLKA ≥ PCLKB、PCLKD ≥ PCLKA ≥ PCLKB
ICLK ≥ FCLK
时钟频率比的限制:（N:整数,最多 64）
ICLK:FCLK = N:1,ICLK:PCLKA = N:1,ICLK:PCLKB = N:1,ICLK:PCLKC = N:1 或 1:N,ICLK:PCLKD= N:1 或 1:N,ICLK:TRCLK= N:1或1:N
A/D 转换器启用, 则时钟频率比受约束如下:
PCLKA:PCLKC = 1:1 或 2:1 或 4:1 或 8:1 或 1:2 或 1:4
如果使用CAN-FD,则时钟频率比被限制为PCLKA:PCLKB = 2:1。

注: P/E时对最小FCLK频率4MHz的限制。

注: PLL的乘法应设置在PLL的输出频率范围内,在不使用FLL函数时考虑HOCO的频率。

注: 时钟具有允许的频率范围（见表 8。2)。
闪存和 SRAM 在每个等待周期设置中还具有允许的工作频率范围。（参见第37节, SRAM,第38节, 闪存）

即使 HOCO 在不使用 FLL 函数时有其最大或最小频率,也必须满足这些时钟频率范围。（见第41节, 电气特性）。

Note 1. The following relation is required between the frequencies of the system clock (ICLK) and the FlashIF clock (FCLK).
ICLK:FCLK=N:1 (N: integer)

Note 2. The following relation is required between the frequencies of the system clock (ICLK) and the peripheral module clocks (PCLKA, PCLKB)

Note 3. The following relation is required between the frequencies of the system clock (ICLK) and the peripheral module clocks (PCLKC, PCLKD):
ICLK:PCLKC,PCLKD = N:1or1:N (N: integer)

Note 4. The frequency of the system clock (ICLK) is limited to the flash wait cycle register (FLWT). See section 38, Flash Memory.

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

Note 1. SOSC does not exist in 32-pin products. Setting SOSC for the clock source is prohibited in 32-pin products.

The SCKSCR register selects the clock source for the system clock.

CKSEL[2:0] bits (Clock Source Select)

The CKSEL[2:0] bits select the source for the following modules:

- System clock (ICLK)
- Peripheral module clocks (PCLKA, PCLKB, PCLKC, and PCLKD)
- FlashIF clock (FCLK)

The bits select from one of the following sources:

- Low-speed on-chip oscillator (LOCO)
- Middle-speed on-chip oscillator (MOCO)
- High-speed on-chip oscillator (HOCO)
- Main clock oscillator (MOSC)
- Sub-clock oscillator (SOSC)
- PLL

The operating state of each clock source is controlled not only by the clock oscillation enable settings but also by the operating modes of the product. Some clock sources might be forcibly stopped depending on the product operating mode being used.

Check the operation state of clock sources in each product operating mode, and do not select the clock source to be stopped in SCKSCR. The clock sources should be switched when there are no occurring internal asynchronous interrupt. For details, see section 10, Low Power Modes.

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before rewriting this register.

The PLLCR register controls the operation of the PLL circuit.

PLLSTP bit (PLL Stop Control)

This bit runs or stops the PLL circuit.

If the main clock oscillator is to be selected as the clock source for the PLL by the PLLCCR.PLSRCSEL bit, the Main Clock Oscillator Wait Control Register (MOSCWTCR) must be set.

After the PLLSTP bit setting is changed to run the PLL, only use the PLL clock after confirming that the OSCSF.PLLSF bit is set to 1. That is, a fixed time for stabilization is required after starting the PLL operation. A fixed time is also required for oscillation to stop after stopping the PLL operation. Additionally, apply the following limitations when starting and stopping the PLL operation by the PLLSTP bit:

- After stopping the PLL, confirm that the OSCSF.PLLSF bit is 0 before restarting the PLL.
- Confirm that the PLL is operating and that the OSCSF.PLLSF bit is 1 before stopping the PLL.
- Regardless of whether the PLL clock is selected as the system clock, confirm that the OSCSF.PLLSF is set to 1 before executing a WFI instruction to place the MCU in Software Standby or Deep Software Standby mode after operating the PLL.
- When transitioning to Software Standby or Deep Software Standby mode after stopping the PLL, confirm that the OSCSF.PLLSF bit is cleared to 0 before executing a WFI instruction.

Writing 1 to the PLLSTP bit is prohibited when SCKSCR.CKSEL[2:0] = 101 (system clock source = PLL).

Confirm the following conditions before writing 0 to PLLSTP:

- When PLL source clock = MOSC: MOSCCR.MOSTP = 0 (MOSC is enabled)
- When PLL source clock = HOCO: HOCOCR.HCSTP = 0 (HOCO is enabled).

PLLCR 寄存器控制 PLL 电路的操作。

PLLSTP 位（PLL 停止控制）

该位运行或停止 PLL 电路。

如果要通过PLLCCR。PLSRCSEL位选择主时钟振荡器作为PLL的时钟源,则必须设置主时钟振荡器等待控制寄存器（MOSCWTCR）。

PLLSTP位设置改为运行PLL后,只在确认OSCSF。PLLSF位设置为1后才使用PLL时钟。也就是说,开始PLL操作后需要固定的稳定时间。停止 PLL 操作后振荡停止也需要固定的时间。另外,在通过 PLLSTP 位启动和停止 PLL 操作时应用以下限制:

- 停止PLL后,在重新启动PLL之前确认OSCSF。PLLSF位为0。
- 在停止 PLL 之前确认 PLL 正在运行并且 OSCSF。PLLSF 位为 1。
- 不管是否选择PLL时钟作为系统时钟,在执行WFI指令以将MCU在操作PLL后置于软件待机或深度软件待机模式之前,确认OSCSF。PLLSF设置为1。
- 停止PLL后过渡到软件待机或深度软件待机模式时,在执行WFI指令前确认OSCSF。PLLSF位被清除为0。

当 SCKSCR。CKSEL[2:0] = 101（系统时钟源 = PLL）时,禁止将 1 写入 PLLSTP 位。

0 写入 PLLSTP 之前确认以下条件:

- 当 PLL 源时钟 = MOSC:MOSCCR。MOSTP = 0（启用 MOSC）
- 当 PLL 源时钟 = HOCO: HOCOCR。HCSTP = 0（启用 HOCO）。

注1。MOMCR 寄存器必须在将 MOSTP 设置为 0 之前进行设置。

MOSCCR 寄存器控制主时钟振荡器。

MOSTP bit (Main Clock Oscillator Stop)

The MOSTP bit starts or stops the main clock oscillator.

When changing the value of the MOSTP bit, execute subsequent instructions only after reading the bit to check that the value is updated.

When using the main clock, the Main Clock Oscillator Mode Oscillation Control Register (MOMCR) and the Main Clock Oscillator Wait Control Register (MOSCWTCR) must be set before setting MOSTP to 0. After setting the MOSTP bit to 0, confirm that the OSCSF.MOSCSF bit is set to 1 before using the main clock oscillator.

A fixed stabilization wait time is required after setting the main clock oscillator to start operation. A fixed wait time is also required for oscillation to stop after stopping the main clock oscillator.

The following restrictions apply when starting and stopping operation:

- After stopping the main clock oscillator, confirm that the OSCSF.MOSCSF bit is 0 before restarting the main clock oscillator
- Confirm that the main clock oscillator operates and that the OSCSF.MOSCSF bit is 1 before stopping the main clock oscillator
- Regardless of whether the main clock oscillator is selected as the system clock, confirm that the OSCSF.MOSCSF bit is set to 1 before executing a WFI instruction to place the MCU in Software standby after operating the main clock oscillator or Deep Software Standby mode.
- When a transition to Software Standby or Deep Software Standby mode is to follow the setting to stop the main clock oscillator, confirm that the OSCSF.MOSCSF bit is set to 0 before executing the WFI instruction.

Writing 1 to MOSTP is prohibited under the following condition:

- SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC).
- PLLCCR.PLSRCSEL = 0 (PLL source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL)
- PLLCCR.PLSRCSEL = 0 (PLL source clock = MOSC) and PLLCR.PLLSTP = 0 (PLL is operating)

MOSTP 位（主时钟振荡器停止）

MOSTP位启动或停止主时钟振荡器。

MOSTP 位的值时,只有读取该位后才执行后续指令,以检查该值是否更新。

MOSTP设置为0之前,必须先设置主时钟振荡器模式振荡控制寄存器（MOMCR）和主时钟振荡器等待控制寄存器（MOSCWTCR）。MOSTP 位设置为 0 后,在使用主时钟振荡器之前确认 OSCSF。MOSCSF 位设置为 1。

设置主时钟振荡器开始运行后需要固定的稳定等待时间。停止主时钟振荡器后振荡停止还需要固定的等待时间。启动和停止操作时适用以下限制:

- 停止主时钟振荡器后,在重新启动主时钟振荡器之前,确认OSCSF。MOSCSF位为0
- 在停止主时钟振荡器之前确认主时钟振荡器工作并且OSCSF。MOSCSF位为1
- 不管是否选择主时钟振荡器作为系统时钟,在执行 WFI 指令操作主时钟振荡器或深度软件待机模式后将 MCU 置于软件待机状态之前,确认 OSCSF。MOSCSF 位设置为 1。
- 当向软件待机或深度软件待机模式的过渡是按照设置停止主时钟振荡器时,在执行WFI指令之前确认OSCSF。MOSCSF位设置为0。

1写到MOSTP是禁止在以下条件下:

- SCKSCR。CKSEL[2:0] = 011b（系统时钟源 = MOSC）。
- PLLCCR。PLSRCSEL = 0（PLL 源时钟 = MOSC）和 SCKSCR。CKSEL[2:0] = 101b（系统时钟源 = PLL）

注1。SOSTP 设置为 0 之前必须设置 SOMCR 寄存器。

SOSCCR 寄存器控制子时钟振荡器。

SOSTP bit (Sub Clock Oscillator Stop)

The SOSTP bit starts or stops the sub-clock oscillator. When changing the value of the SOSTP bit, only execute subsequent instructions after reading the bit to check that the value is updated. Use the SOSTP bit when using the sub-clock oscillator as the source for a peripheral module, for example the AGT. When using the sub-clock oscillator, set the Sub-Clock Oscillator Mode Control Register (SOMCR) before setting SOSTP to 0.

The following restrictions apply when starting and stopping the operation:

- After stopping the sub-clock oscillator, allow a stop interval of at least 5 SOSC clock cycles before restarting it
- After setting the SOSTP bit to 0, use the sub-clock only after the sub-clock oscillation stabilization time ($t_{SUBOSCWT}$) has elapsed.
- Regardless of whether the sub-clock oscillator is selected as the system clock, confirm that the sub-clock oscillation is stable before executing a WFI instruction to place the MCU in Software Standby or Deep Software Standby mode
- When a transition to Software Standby or Deep Software Standby mode is to follow the setting to stop the sub-clock oscillator, wait for at least 3 SOSC clock cycles before executing the WFI instruction.

Writing 1 to SOSTP is prohibited under the following condition:

- SCKSCR.CKSEL[2:0] = 100b (system clock source = SOSC).

If the security attribution is configured as Non-secure:

The LOCOCR register controls the LOCO clock.

LCSTP bit (LOCO Stop)

The LCSTP bit starts or stops the LOCO clock.

After setting the LCSTP bit to 0 to start the LOCO clock, only use the clock after the LOCO clock-oscillation stabilization wait time (t_{LOCOWT}) elapses. A fixed stabilization wait time is required after setting the LOCO clock to start operation. A fixed wait time is also required after setting the LOCO clock to stop.

The following restrictions apply when starting and stopping operation:

- After stopping the LOCO clock, allow a stop interval of at least 5 LOCO clock cycles before restarting it
- Confirm that LOCO oscillation is stable before stopping the LOCO clock
- Regardless of whether the LOCO is selected as the system clock, confirm that LOCO oscillation is stable before executing a WFI instruction to place the MCU in Software Standby or Deep Software Standby mode
- When a transition to Software Standby or Deep Software Standby mode is to follow the setting to stop the LOCO clock, wait for at least 3 LOCO cycles before executing the WFI instruction.

SOSTP 位启动或停止子时钟振荡器。SOSTP 位的值时,只在读取该位后执行后续指令,检查该值是否更新。SOSTP 位,当使用子时钟振荡器作为外围模块的源时,例如AGT。当使用子时钟振荡器时,在将SOSTP设置为0之前,设置子时钟振荡器模式控制寄存器（SOMCR）。

启动和停止操作时适用以下限制:

- 停止子时钟振荡器后,允许至少 5 个 SOSC 时钟周期的停止间隔,然后再重新启动
- 将 SOSTP 位设置为 0 后,仅在子时钟振荡稳定时间（tSUBOSCWT) 已经过去）之后才使用子时钟。

- 停止 LOCO 时钟后,在重新启动之前允许至少 5 个 LOCO 时钟周期的停止间隔
- 在停止 LOCO 时钟之前确认 LOCO 振荡稳定
- 无论是否选择 LOCO 作为系统时钟,在执行 WFI 指令将 MCU 置于软件待机或深度软件待机模式之前,请确认 LOCO 振荡稳定
- 当向软件待机或深度软件待机模式的转换是按照设置停止 LOCO 时钟时,在执行 WFI 指令之前等待至少 3 个 LOCO 周期。

Writing 1 to LCSTP is prohibited under the following condition:

- SCKSCR.CKSEL[2:0] = 010b (system clock source = LOCO).

Because the LOCO clock measures the wait time for other oscillators, it continues to oscillate while measuring this time, regardless of the setting in LOCOCR.LCSTP. As a result, the LOCO clock might be unintentionally supplied even when the LCSTP is set to stop.

8.2.9 HOCOCR : High-Speed On-Chip Oscillator Control Register

Base address: SYSC = 0x4001_E000

Offset address: 0x036

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	HCSTP
Value after reset:	0	0	0	0	0	0	0	0/1*1

Bit	Symbol	Function	R/W
0	HCSTP	HOCO Stop 0: Operate the HOCO clock *2 1: Stop the HOCO clock	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before rewriting this register.

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. The HCSTP bit value after a reset is 0 when the OFS1.HOCOEN bit is 0. It is 1 when the OFS1.HOCOEN bit is 1.

Note 2. If you are using the HOCO (HCSTP = 0), set the OFS1.HOCOFRQ0[1:0] bit to an optimum value. The value of OFS1.HOCOFRQ0[1:0] bits is automatically transferred to HOCOCR2.HCFRQ0[1:0] bits after reset, therefore it can also be specified by HOCOCR2.HCFRQ0[1:0] bits.

The HOCOCR register controls the HOCO clock.

HCSTP bit (HOCO Stop)

The HCSTP bit starts or stops the HOCO clock.

After setting the HCSTP bit to 0 to start the HOCO clock, confirm that the OSCSF.HOCOSF is set to 1 before using the clock. When OFS1.HOCOEN is set to 0, confirm that OSCSF.HOCOSF is also set to 1 before using the HOCO clock. A fixed stabilization wait time is required after setting the HOCO clock to start operation. A fixed wait time is also required after setting the HOCO clock to stop.

The following limitations apply when starting and stopping operation:

- After stopping the HOCO clock, confirm that the OSCSF.HOCOSF is 0 before restarting the HOCO clock.
- Confirm that the HOCO clock operates and that the OSCSF.HOCOSF is 1 before stopping the HOCO clock.
- Regardless of whether the HOCO clock is selected as the system clock, confirm that the OSCSF.HOCOSF is set to 1 before executing a WFI instruction to place the MCU in Software Standby or Deep Software Standby mode after setting HOCO operation with the HCSTP bit.
- When a transition to Software Standby or Deep Software Standby mode is to follow the setting of the HOCO clock to stop, confirm that the OSCSF.HOCOSF is set to 0 after setting the HOCO clock and before executing the WFI instruction.

Writing 1 to HCSTP is prohibited under the following conditions:

- SCKSCR.CKSEL[2:0] = 000b (system clock source = HOCO).
- PLLCCR.PLSRCSEL = 1 (PLL source clock = HOCO) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL)

LCSTP写入1是禁止在以下条件下:

- SCKSCR。CKSEL[2:0] = 010b（系统时钟源 = LOCO）。

由于 LOCO 时钟测量其他振荡器的等待时间,因此无论 LOCOCR。LCSTP 中的设置如何,它都会在测量该时间时继续振荡。因此,即使 LCSTP 设置为停止,LOCO 时钟也可能无意中被提供。

MOCOCR 寄存器控制 MOCO 时钟。

MCSTP 位（MOCO 停止）

MCSTP 位启动或停止 MOCO 时钟。

After setting MCSTP to 0, use the MOCO clock only after the MOCO clock oscillation stabilization time (t_{MOCOWT}) elapses. A fixed stabilization wait time is required after setting the MOCO clock to start operation. A fixed wait time is also required for oscillation to stop after setting the MOCO clock to stop operation.

The following restrictions apply when starting and stopping the oscillator:

- After stopping the MOCO clock, allow a stop interval of at least 5 MOCO clock cycles before restarting it
- Confirm that MOCO clock oscillation is stable before stopping the MOCO clock
- Regardless of whether the MOCO clock is selected as the system clock, confirm that MOCO clock oscillation is stable before executing a WFI instruction to place the MCU in Software Standby or Deep Software Standby mode
- When a transition to Software Standby or Deep Software Standby mode is to follow the setting to stop the MOCO clock, wait for at least 3 MOCO clock cycles before executing the WFI instruction.

Writing 1 to MCSTP is prohibited under the following condition:

- SCKSCR.CKSEL[2:0] = 001b (system clock source = MOCO).

Writing 1 to the MCSTP bit (stopping the MOCO) is prohibited if oscillation stop detection is enabled in the Oscillation Stop Detection Control Register (OSTDCR.OSTDE).

If the security attribution is configured as Non-secure:

Note: HOCO must be stopped (HOCOCR.HCSTP = 1) before FLLCR1.FLLEN is modified.
Note: SOSC must be operating with stabilization while FLL is enabled (FLLCR1.FLLEN = 1).
Note: Set the PRCR.PRC0 bit to 1 (write enabled) before rewriting this register.
Note: SOSC does not exist in 32-pin products. Setting FLLEN bit to 1 is prohibited in 32-pin products.

The FLLCR1 register controls the FLL function of the HOCO.

FLLEN bit (FLL Enable)

This bit enables or disables the FLL function of the HOCO.

If FLL is enabled, the frequency accuracy is guaranteed after FLL is stabilized. The FLL stabilization can be checked by the CAC frequency measurement, but it must be executed after HOCO stabilization.

In addition, you must disable FLL by setting the FLLEN bit to 0 before transitioning to Software Standby mode.

Table 8.4 show an example flow of the FLL setting for each case.

MCSTP设置为0后,仅在MOCO时钟振荡稳定时间（tMOCOWT)过去后）后才使用MOCO时钟。MOCO 时钟设置开始运行后需要固定的稳定等待时间。MOCO 时钟设置为停止运行后,振荡停止也需要固定的等待时间。

启动和停止振荡器时适用以下限制:

- 停止 MOCO 时钟后,允许至少 5 个 MOCO 时钟周期的停止间隔,然后再重新启动
- 在停止 MOCO 时钟之前确认 MOCO 时钟振荡是稳定的
- 无论是否选择MOCO时钟作为系统时钟,在执行WFI指令将MCU置于软件待机或深度软件待机模式之前,确认MOCO时钟振荡是稳定的
- 当向软件待机或深度软件待机模式的过渡是按照设置停止 MOCO 时钟时,在执行 WFI 指令之前至少等待 3 个 MOCO 时钟周期。

- SCKSCR。CKSEL[2:0] = 001b（系统时钟源 = MOCO）。

如果在振荡停止检测控制寄存器（OSTDCR。OSTDE）中启用振荡停止检测,则禁止将 1 写入 MCSTP 位（停止 MOCO）。

Base address: SYSC = 0x4001_E000

Offset address: 0x03C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	PLLSF	—	MOSCSF	—	—	HOCOSF
Value after reset:	0	0	0	0	0	0	0	0/1*1

Bit	Symbol	Function	R/W
0	HOCOSF	HOCO Clock Oscillation Stabilization Flag 0: The HOCO clock is stopped or is not yet stable 1: The HOCO clock is stable, so is available for use as the system clock	R
2:1	—	These bits are read as 0.	R
3	MOSCSF	Main Clock Oscillation Stabilization Flag 0: The main clock oscillator is stopped (MOSTP = 1) or is not yet stable*2 1: The main clock oscillator is stable, so is available for use as the system clock	R
4	—	This bit is read as 0.	R
5	PLLSF	PLL Clock Oscillation Stabilization Flag 0: The PLL clock is stopped, or oscillation of the PLL clock is not stable yet 1: The PLL clock is stable, so is available for use as the system clock	R
7:6	—	These bits are read as 0.	R

Note 1. The value after reset depends on the OFS1.HOCOEN setting.
When OFS1.HOCOEN = 1 (disable HOCO), the value after reset of HOCOSF is 0.
When OFS1.HOCOEN = 0 (enable HOCO), the HOCOSF value is set to 0 immediately after reset is released, and the HOCOSF value is set to 1 after the HOCO oscillation stabilization wait time elapses.

Note 2. This is true when an appropriate value is set in the Wait Control register for the main clock oscillator. If the wait time value is not sufficient, the oscillation stabilization flag is set to 1 and supply of the clock signal to the internal circuits starts before oscillation is stable.

This register is not controlled by CGFSAR register.

The OSCSF register contains flags to indicate the operating status of the counters in the oscillation stabilization wait circuits for the individual oscillators. After oscillation starts, these counters measure the wait time until each oscillator output clock is supplied to the internal circuits. An overflow of a counter indicates that the clock supply is stable and available for the associated circuit.

HOCOSF flag (HOCO Clock Oscillation Stabilization Flag)

The HOCOSF flag indicates the operating status of the counter that measures the wait time for the high-speed clock oscillator (HOCO). When OFS1.HOCOEN is set to 0, confirm that OSCSF.HOCOSF is set to 1 before using the HOCO clock.

[Setting condition]

- When the HOCO clock is stopped and the HOCOCR.HCSTP bit is set to 0, and then the HOCO oscillation stabilization time is counted by the LOCO clock and supply of the HOCO clock within the MCU is started. For the HOCO oscillation stabilization time, see section 41, Electrical Characteristics.

[Clearing condition]

- When the HOCO clock is operating and then is deactivated because the HOCOCR.HCSTP bit is set to 1.

MOSCSF flag (Main Clock Oscillation Stabilization Flag)

The MOSCSF flag indicates the operating status of the counter that measures the wait time for the main clock oscillator.

OFS1 X 1 时,将要在 2019 年 1 月 1 日之前完成,在 2019 年 1 月 1 日之前完成。HOCOEN = 0（启用HOCO）,重置释放后立即将HOCOSF值设置为0,HOCO振荡稳定等待时间过后将HOCOSF值设置为1。

注2。当主时钟振荡器的等待控制寄存器中设置适当的值时,情况就是如此。如果等待时间值不够,则将振荡稳定标志设置为1,并在振荡稳定之前开始向内部电路提供时钟信号。

该寄存器不受 CGFSAR 寄存器控制。

OSCSF 寄存器包含标志,用于指示各个振荡器的振荡稳定等待电路中计数器的运行状态。振荡开始后,这些计数器测量每个振荡器输出时钟提供给内部电路的等待时间。计数器的溢出表明时钟电源稳定并且可用于相关电路。

HOCOSF 标志（HOCO 时钟振荡稳定标志）

HOCOSF标志指示测量高速时钟振荡器（HOCO）等待时间的计数器的运行状态。OFS1 X 1 时,将要在 2019 年 1 月 1 日之前完成,在 2019 年 1 月 1 日之前完成。HOCOEN 设置为 0,在使用 HOCO 时钟之前确认 OSCSF。HOCOSF 设置为 1。

的【设置条件】

● 当HOCO时钟停止,将HOCOCR。HCSTP位设置为0,然后HOCO振荡稳定时间由LOCO时钟计数,并开始MCU内HOCO时钟的供电。HOCO振荡稳定时间见第41节,电气特性.

的【清零条件】

● 当 HOCO 时钟运行时,然后因 HOCOCR。HCSTP 位设置为 1 而停用。

MOSCSF 标志（主时钟振荡稳定标志）

MOSCSF标志指示测量主时钟振荡器等待时间的计数器的运行状态。

[Setting condition]

- When the main clock oscillator is stopped and the MOSCCR.MOSTP bit is set to 0, and then the number of LOCO clock cycles corresponding to the setting of the MOSCWTCR register is counted and supply of the main clock within the MCU is started.

[Clearing condition]

- When the main clock oscillator is operating and then is deactivated because the MOSCCR.MOSTP bit is set to 1.

PLLSF flag (PLL Clock Oscillation Stabilization Flag)

The PLLSF flag indicates the operating state of the counter that measures the wait time of the PLL.

[Setting condition]

- When the PLL is stopped and the PLLCR.PLLSTP bit is set to 0, and then the PLL oscillation stabilization time is counted by the LOCO clock and supply of the PLL clock within the MCU is started. If oscillation by the PLL clock source is not stable when the PLLCR.PLLSTP bit is set to 0, counting of the LOCO cycles continues even after the PLL clock source oscillation is stabilized. For the PLL oscillation stabilization time, see section 41, Electrical Characteristics.

[Clearing condition]

- When the PLL is operating and then is deactivated because the PLLCR.PLLSTP bit is set to 1.

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The OSTDCR register controls the oscillation stop detection function.

OSTDIE bit (Oscillation Stop Detection Interrupt Enable)

The OSTDIE bit enables the oscillation stop detection function interrupt. It also controls whether oscillation stop detection is reported to the POEG.

If the Oscillation Stop Detection flag in the Oscillation Stop Detection Status Register (OSTDSR.OSTDF) requires clearing, set the OSTDIE bit to 0 before clearing OSTDF. Wait for at least 2 PCLKB cycles before setting the OSTDIE bit to 1. By reading the I/O register whose access cycle number is defined by PCLKB, it is possible to secure waiting time of 2 or more cycles of PCLKB.

的【设置条件】

● 当主时钟振荡器停止, MOSCCR。MOSTP位设置为0, 然后对MOSCWTCR寄存器的设置对应的LOCO时钟周期数进行计数, 启动MCU内主时钟的供电。

● 当主时钟振荡器工作时,然后被停用,因为 MOSCCR。MOSTP 位设置为 1。

PLLSF 标志（PLL 时钟振荡稳定标志）

PLLSF标志指示测量PLL的等待时间的计数器的操作状态。

的【设置条件】

● 当 PLL 停止且 PLLCR。PLLSTP 位设置为 0 时, 然后 PLL 振荡稳定时间由 LOCO 时钟计数, 并启动 MCU 内 PLL 时钟的供电。如果当PLLCR。PLLSTP位设置为0时PLL时钟源的振荡不稳定,则即使在PLL时钟源振荡稳定之后,LOCO循环的计数仍在继续。PLL振荡稳定时间,请参见第41节,电气特性.

的【清零条件】

● 当 PLL 运行时,然后被停用,因为 PLLCR。PLLSTP 位被设置为 1。

- 非安全写访问被忽略,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全访问。

OSTDCR寄存器控制振荡停止检测功能。

OSTDIE 位（振荡停止检测中断启用）

OSTDIE 位启用振荡停止检测功能中断。它还控制是否向 POEG 报告振荡停止检测。

如果振荡停止检测状态寄存器（OSTDSR。OSTDF）中的振荡停止检测标志需要清除,则在清除OSTDF之前将OSTDIE位设置为0。在将OSTDIE位设置为1之前至少等待2个PCLKB周期。通过读取其接入周期号由PCLKB定义的I/O寄存器,可以确保PCLKB的2个或更多周期的等待时间。

OSTDE bit (Oscillation Stop Detection Function Enable)

The OSTDE bit enables the oscillation stop detection function.

When the OSTDE bit is 1 (enabled), the MOCO stop bit (MOCOCR.MCSTP) is set to 0 and the MOCO operation starts. The MOCO clock cannot be stopped while the oscillation stop detection function is enabled. Writing 1 to the MOCOCR.MCSTP bit (MOCO stopped) is invalid.

When the Oscillation Stop Detection flag in the Oscillation Stop Detection Status Register (OSTDSR.OSTDF) is 1 (main clock oscillation stop detected), writing 0 to the OSTDE bit is invalid.

The OSTDE bit must be set to 0 before transitioning to Software Standby or Deep Software Standby mode. To transition to Software Standby or Deep Software Standby mode, first set the OSTDE bit to 0, then execute the WFI instruction.

The following restrictions apply when using the oscillation stop detection function:
In low-speed mode, selecting division by 1, 2, 4, 8 for ICLK, FCLK, PCLKA, PCLKB, PCLKC, and PCLKD is prohibited.

8.2.16 OSTDSR : Oscillation Stop Detection Status Register

Base address: SYSC = 0x4001_E000

Offset address: 0x041

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OSTDF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OSTDF	Oscillation Stop Detection Flag 0: Main clock oscillation stop not detected 1: Main clock oscillation stop detected	R/W*1
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: Set the PRCR.PRC0 bit to 1 (write enabled) before rewriting this register.
Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. This bit can only be set to 0. This bit is cleared to 0 by writing 0 after reading it as 1.

The OSTDSR register indicates the stop detection status of the main clock oscillator.

OSTDF flag (Oscillation Stop Detection Flag)

The OSTDF flag indicates the main clock oscillator status. When this flag is 1, it indicates that the main clock oscillation stop was detected. After this stop is detected, the OSTDF flag is not set to 0 even when the main clock oscillation is restarted. The OSTDF bit is cleared to 0 by writing 0 after reading it as 1.

At least 3 ICLK cycles of wait time are required between writing 0 to OSTDF and reading it as 0. If the OSTDF flag is set to 0 when the main clock oscillation is stopped, the OSTDF flag becomes 0 then returns to 1.

The OSTDF flag cannot be set to 0 under the following conditions:

- SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC).
- PLLCCR.PLSRCSEL = 0 (PLL source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (System clock source = PLL)

The OSTDF flag must be set to 0 after switching the clock source to sources other than the main clock oscillator and PLL.

[Setting condition]

- The main clock oscillator is stopped when OSTDCR.OSTDE = 1 (oscillation stop detection function enabled).

[Clearing condition]

OSTDE 位（振荡停止检测功能启用）

OSTDE 位启用振荡停止检测功能。

当OSTDE位为1（启用）时,MOCO停止位（MOCOCR。MCSTP）设置为0并且MOCO操作开始。
MOCO时钟无法停止,同时启用了振荡停止检测功能。将 1 写入 MOCOCR。MCSTP 位（MOCO 停止）无效。

当振荡停止检测状态寄存器（OSTDSR。OSTDF）中的振荡停止检测标志为1（检测到主时钟振荡停止）时,向OSTDE位写入0无效。

OSTDE 位必须设置为 0,然后才能过渡到软件待机或深度软件待机模式。要过渡到软件待机或深度软件待机模式,请首先将 OSTDE 位设置为 0,然后执行 WFI 指令。

使用振荡停止检测功能时适用以下限制:
在低速模式下,禁止对 ICLK、FCLK、PCLKA、PCLKB、PCLKC 和 PCLKD 选择除以 1、2、4、8。

如果安全属性配置为非安全:

注1。该位只能设置为0。将此位读为 1 后写入 0,将其清除为 0。

OSTDSR寄存器指示主时钟振荡器的停止检测状态。

OSTDF 标志（振荡停止检测标志）

OSTDF标志指示主时钟振荡器状态。当该标志为 1 时,表明检测到主时钟振荡停止。检测到此停止后,即使主时钟振荡重新启动,OSTDF 标志也不会设置为 0。OSTDF 位读取为 1 后写入 0 将其清除为 0。

0写入OSTDF和读取为0之间至少需要3个ICLK周期的等待时间。如果主时钟振荡停止时 OSTDF 标志设置为 0,则 OSTDF 标志变为 0,然后返回到 1。OSTDF标志在以下条件下不能设置为0:

- SCKSCR。CKSEL[2:0] = 011b（系统时钟源 = MOSC）。
- PLLCCR。PLSRCSEL = 0（PLL 源时钟 = MOSC）和 SCKSCR。CKSEL[2:0] = 101b（系统时钟源 = PLL）

OSTDF 标志在将时钟源切换到主时钟振荡器和 PLL 以外的源后必须设置为 0。的【设置条件】

- OSTDCR。OSTDE = 1 时主时钟振荡器停止（启用振荡停止检测功能）。

的【清零条件】

MSTS[3:0] bits (Main Clock Oscillator Wait Time Setting)

The MSTS[3:0] bits specify the oscillation stabilization wait time for the main clock oscillator.

Set the main clock oscillation stabilization time to a period longer than or equal to the stabilization time recommended by the oscillator manufacturer. When the main clock is input externally, set these bits to 0x0 because the oscillation stabilization time is not required.

The wait time set in these bits is counted using: 1 cycle (µs) = 1/(fLOCO[MHz] × 8) = 1/(0.032768 × 8) = 3.81 (µs) (min.) The LOCO clock automatically oscillates when necessary, regardless of the value of the LOCO.LCSTP bit. After the specified wait time elapses, supply of the main clock starts internally in the MCU, and the OSCSF.MOSCSF flag is set to 1. If the specified wait time is short, supply of the main clock starts before oscillation of the clock becomes stable.

Only rewrite the MOSCWTCR register when the MOSCCR.MOSTP bit is 1 and the OSCSF.MOSCSF flag is 0. Do not rewrite this register under any other conditions.

MSTS[3:0] 位（主时钟振荡器等待时间设置）

MSTS[3:0]位指定主时钟振荡器的振荡稳定等待时间。

将主时钟振荡稳定时间设置为长于或等于振荡器制造商推荐的稳定时间的时间段。当主时钟外部输入时,将这些位设置为 0x0,因为不需要振荡稳定时间。

使用以下方式计算这些位中设置的等待时间: 1 周期（µs）= 1/（fLOCO[MHz] × 8) = 1/(0。032768 × 8) = 3。81（µs）（min。) LOCO 时钟在必要时自动振荡,无论 LOCO。LCSTP 位的值如何。指定的等待时间过后,MCU内部开始供应主时钟,OSCSF。MOSCSF标志设置为1。
如果指定的等待时间较短,则在时钟振荡稳定之前开始供应主时钟。

仅当 MOSCCR。MOSTP 位为 1 且 OSCSF。MOSCSF 标志为 0 时才重写 MOSCWTCR 寄存器。请勿在任何其他条件下重写此寄存器。

Note 1. SOSC does not exist in 32-pin products. Setting SOSC for the clock out source is prohibited in 32-pin products.

CKOSEL[2:0] bits (Clock Out Source Select)

The CKOSEL[2:0] bits select the source of the clock to be output from the CLKOUT pin. When changing the clock source, set the CKOEN bit to 0.

CKODIV[2:0] bits (Clock Output Frequency Division Ratio)

The CKODIV[2:0] bits specify the clock division ratio. Set the CKOEN bit to 0 when changing the division ratio.

CKOEN bit (Clock Out Enable)

The CKOEN bit enables output from the CLKOUT pin.

When this bit is set to 1, the selected clock is output. When this bit is set to 0, low is output. When changing this bit, confirm that the clock out source clock selected in the CKOSEL[2:0] bits is stable. Otherwise, a glitch might be generated in the output.

Clear this bit before entering Software Standby or Deep Software Standby mode if the selecting clock out source clock is stopped in that mode.

The CANFDCKCR register controls the CANFD clock (CANFDCLK).

When switching the clock source, ensure that the clock before the switch and the clock after the switch generate stable output. To change the set value of CANFDCKDIVCR.CANFDCKDIV[2:0] and CANFDCKSEL[2:0], use the following procedure:

1. Write 1 to CANFDCKSREQ.
2. Poll until CANFDCKSRDY is read as 1. While CANFDCKSRDY = 1, no clock is output to CANFDCLK.
3. Write to CANFDCKDIVCR.CANFDCKDIV[2:0] and CANFDCKSEL[2:0].
4. Write 0 to CANFDCKSREQ.
5. Poll until CANFDCKSRDY is read as 0.
6. When CANFDCKSRDY becomes 0, CANFDCLK starts to output. Clock switching is complete.

When transitioning to Software Standby or Deep Software Standby mode, do not execute the WFI instruction while performing clock switching. That is, do not execute the WFI instruction when CANFDCKSREQ = 1 and CANFDCKSRDY = 0, or when CANFDCKSREQ = 0 and CANFDCKSRDY = 1.

CANFDCKSEL[2:0] bits (CANFD clock (CANFDCLK) Source Select)

These bits select the clock source of the CANFD clock (CANFDCLK) and must be modified when CANFDCKCR.CANFDCKSRDY = 1.

This bit selects the CANFDCLK switching request.

CANFDCKCR 寄存器控制 CANFD 时钟（CANFDCLK）。

Che关时钟源时,要保证开关前的时钟和开关后的时钟产生稳定De输出。要更改 CANFDCKDIVCR。CANFDCKDIV[2:0] 和 CANFDCKSEL[2:0] 的设置值,请使用以下过程:

1。将 1 写入 CANFDCKSREQ。

2锛姣涓涓。民意调查直到 CANFDCKSRDY 读为 1。虽然 CANFDCKSRDY = 1,但没有时钟输出到 CANFDCLK。

CANFDCKSEL[2:0]位（CANFD时钟（CANFDCLK）源选择）这些位选择CANFD时钟（CANFDCLK）的时钟源,并且必须在CANFDCKCR。CANFDCKSRDY = 1时进行修改。

I3CCKCR controls the I3C clock.

To change the set value of I3CCKDIVCR.I3CCKDIV[2:0] and I3CCKSEL[2:0], follow the procedure below.

When switching the clock source, it is necessary that the clock before switching and the clock after switching are stably output.

Clock selection switching procedure:

1. Write 1 to I3CCKSREQ.
2. Polling until I3CCKSRDY is read as 1.
   While I3CCKSRDY = 1, no clock is output to I3CCLK.
3. Write the setting value to I3CCKDIVCR.I3CCKDIV[2:0] and I3CCKSEL[2:0].
4. Write 0 to I3CCKSREQ.
5. Polling until I3CCKSRDY is read as 0.
   When I3CCKSRDY becomes 0, I3CCLK starts outputting.
6. Clock switching complete.

要更改 I3CCKDIFCR。I3CCKDIV[2:0] 和 I3CCKSEL[2:0] 的设定值,请按照以下程序操作。

切换时钟源时,需要稳定输出切换前的时钟和切换后的时钟。

When a transition to software standby or deep software standby, do not execute the WFI instruction while performing clock selection switching. In other words, do not execute the WFI instruction with I3CCKSREQ = 1 and I3CCKSRDY = 0, or I3CCKSREQ = 0 and I3CCKSRDY = 1.

I3CCKSEL[2:0] bits (I3C clock (I3CCLK) source select)

These bits select the clock source of the I3C clock (I3CCLK).

These bits must change when I3CCKCR. I3CCKSRDY = 1.

I3CCKSREQ bit (I3C clock (I3CCLK) switching request)

This bit selects the I3CCLK switching request.

I3CCKSRDY bit (I3C clock (I3CCLK) switching ready state flag)

This flag indicates the state of switching ready for the I3CCLK.

While I3CCKSRDY = 1, no clock is output to I3CCLK.

8.3 Main Clock Oscillator

To supply the clock signal to the main clock oscillator, use one of the following ways:

- Connect an oscillator
- Connect the input of an external clock signal.

8.3.1 Connecting a Crystal Resonator

Figure 8.2 shows an example of connecting a crystal resonator. A damping resistor (Rd) can be added, if required.

Because the resistor values vary according to the resonator and the oscillation drive capability, use values recommended by the resonator manufacturer. If the manufacturer recommends using an external feedback resistor (Rf), insert an Rf between EXTAL and XTAL by following the instructions.

When connecting a resonator to supply the clock, the frequency of the resonator must be in the frequency range of the resonator for the main clock oscillator as described in Table 8.1.

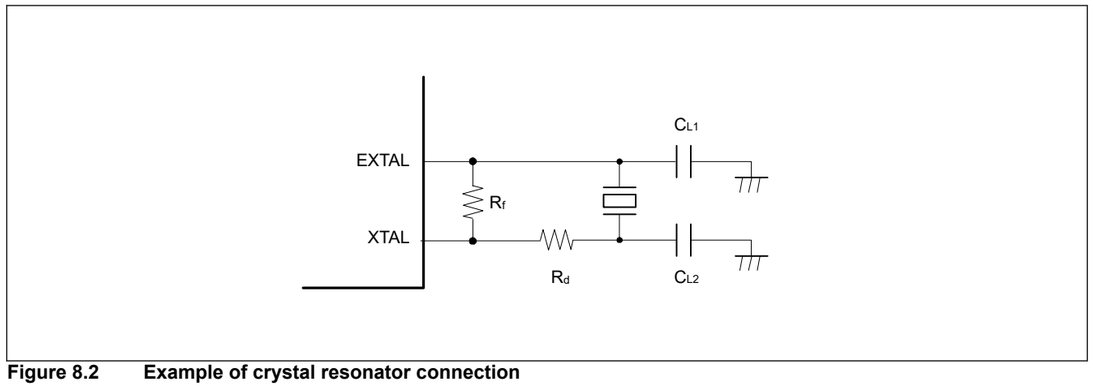

Figure 8.2 Example of crystal resonator connection

Figure 8.3 shows an equivalent circuit of the crystal resonator.

当过渡到软件待机或深度软件待机时,在执行时钟选择切换时请勿执行 WFI 指令。换句话说,不要以I3CCKSREQ = 1和I3CCKSRDY = 0,或者I3CCKSREQ = 0和I3CCKSRDY = 1执行WFI指令。

I3CCKSEL[2:0]位（I3C时钟（I3CCLK）源选择）这些位选择I3C时钟（I3CCLK）的时钟源。I3CCKCR 时,这些位必须发生变化。I3CCKSRDY = 1。

I3CCKSREQ位（I3C时钟（I3CCLK）切换请求）该位选择I3CCLK切换请求。

I3CCKSRDY位（I3C时钟（I3CCLK）切换就绪状态标志）该标志指示为I3CCLK切换就绪状态。

虽然 I3CCKSRDY = 1,但没有时钟输出到 I3CCLK。

8.3 主时钟振荡器

要向主时钟振荡器提供时钟信号,请使用以下方式之一:

- 连接一个振荡器
- 连接外部时钟信号的输入。

8.3.1 连接晶体谐振器

图8。2显示了连接晶体谐振器的示例。如果需要,可以添加阻尼电阻（Rd）。

由于电阻器值根据谐振器和振荡驱动能力而变化,因此使用谐振器制造商推荐的值。如果制造商建议使用外部反馈电阻器（Rf）,请按照说明在 EXTAL 和 XTAL 之间插入 Rf。

当连接谐振器以供应时钟时,谐振器的频率必须在主时钟振荡器的谐振器的频率范围内,如表8。1 .中所述

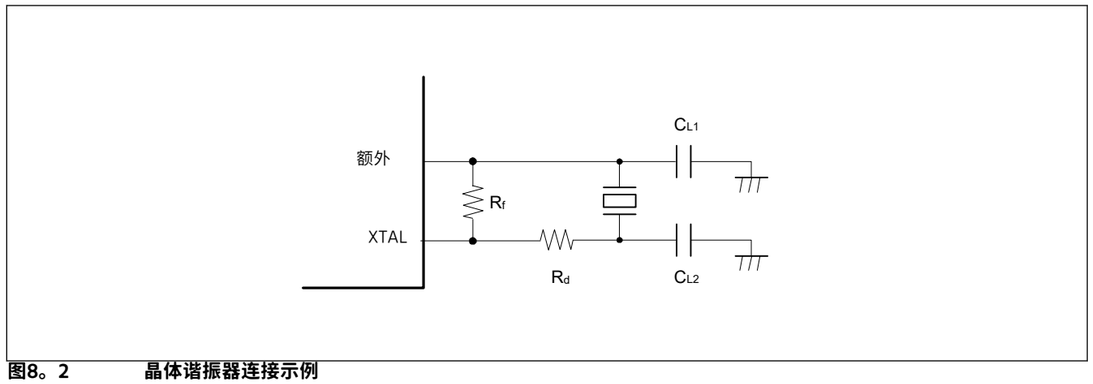

图8。2 晶体谐振器连接示例

图 8。3 显示了晶体谐振器的等效电路。

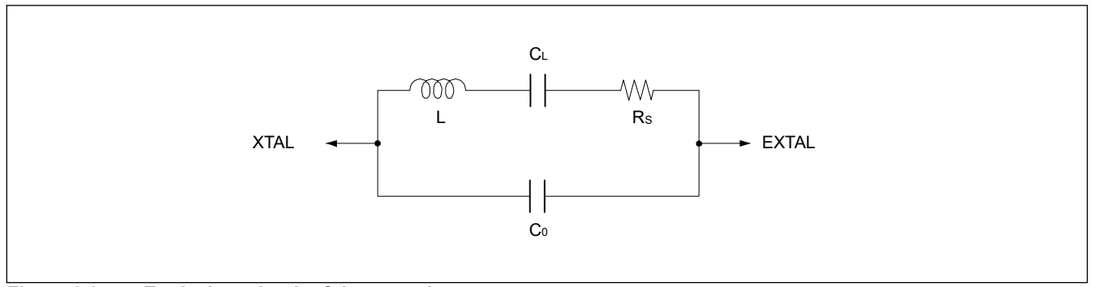

Figure 8.3 Equivalent circuit of the crystal resonator

8.3.2 External Clock Input

Figure 8.4 shows an example of connecting an external clock input. To operate the oscillator with an external clock signal, set the MOMCR.MOSEL bit to 1. The XTAL pin becomes high impedance.

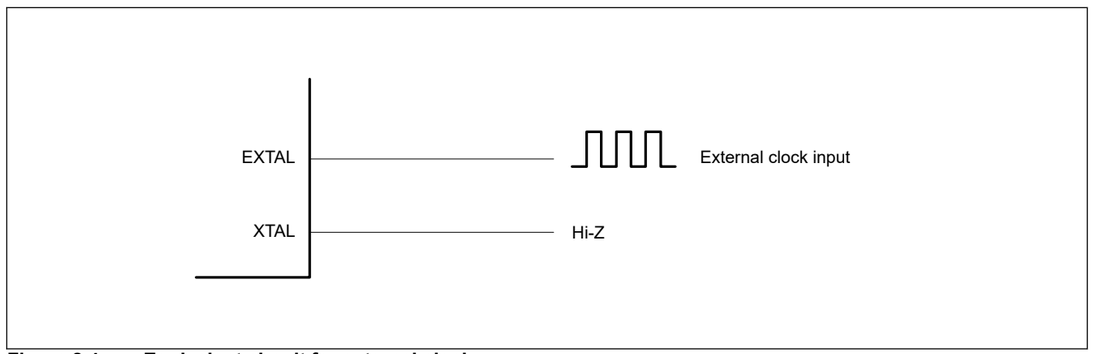

Figure 8.4 Equivalent circuit for external clock

8.3.3 Notes on External Clock Input

The frequency of the external clock input can only be changed when the main clock oscillator is stopped. Do not change the frequency of the external clock input when the setting of the Main Clock Oscillator Stop bit (MOSCCR.MOSTP) is 0.

8.4 Sub-Clock Oscillator

The only way of supplying a clock signal to the sub-clock oscillator is by connecting a crystal oscillator.

8.4.1 Connecting a 32.768-kHz Crystal Resonator

To supply a clock to the sub-clock oscillator, connect a 32.768-kHz crystal resonator as shown in Figure 8.5. A damping resistor (Rd) can be added, if necessary. Because the resistor values vary according to the resonator and the oscillation drive capability, use values recommended by the resonator manufacturer. If the resonator manufacturer recommends the use of an external feedback resistor (Rf), insert an Rf between XCIN and XCOUT by following the instructions. When connecting a resonator to supply the clock, the frequency of the resonator must be in the frequency range of the resonator for the sub-clock oscillator as described in Table 8.1.

8。3。2 外部时钟输入

图 8。4 显示了连接外部时钟输入的示例。要使用外部时钟信号操作振荡器,请将 MOMCR。MOSEL 位设置为 1 。XTAL引脚变为高阻抗。

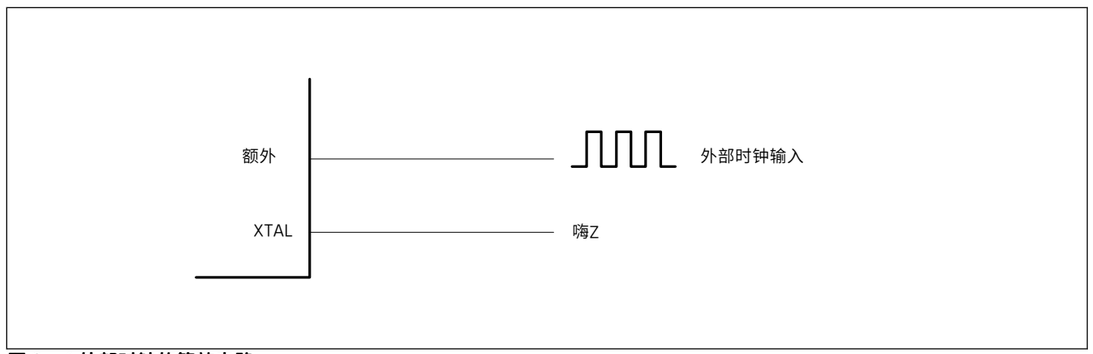

图 8。4 外部时钟的等效电路

8.3.3 外部时钟输入注释

只有当主时钟振荡器停止时,外部时钟输入的频率才能改变。当主时钟振荡器停止位（MOSCCR。MOSTP）的设置为0时,请勿更改外部时钟输入的频率。

8。4 子时钟振荡器

向子时钟振荡器提供时钟信号的唯一方法是连接晶体振荡器。

8。4。1 连接 32。768 kHz 水晶谐振器

要向子时钟振荡器提供时钟,请连接 32。768 kHz 晶体谐振器,如图 8。5 所示。如有必要,可以添加阻尼电阻（Rd ）。由于电阻器值根据谐振器和振荡驱动能力而变化,因此使用谐振器制造商推荐的值。如果谐振器制造商建议使用外部反馈电阻器（Rf）,请按照说明在 XCIN 和 XCOUT 之间插入 Rf。当连接谐振器以供应时钟时,谐振器的频率必须在子时钟振荡器的谐振器的频率范围内,如表8。1 .中所述

8.4.2 Pin Handling When the Sub-Clock Oscillator Is Not Used

When the sub-clock oscillator is not in use, connect the XCIN pin to VSS through a resistor (to pull VSS down) and leave the XCOUT pin open as shown in Figure 8.7. In addition, if an oscillator is not connected, set the Sub-Clock Oscillator Stop bit (SOSCCR.SOSTP) to 1 to stop the oscillator.

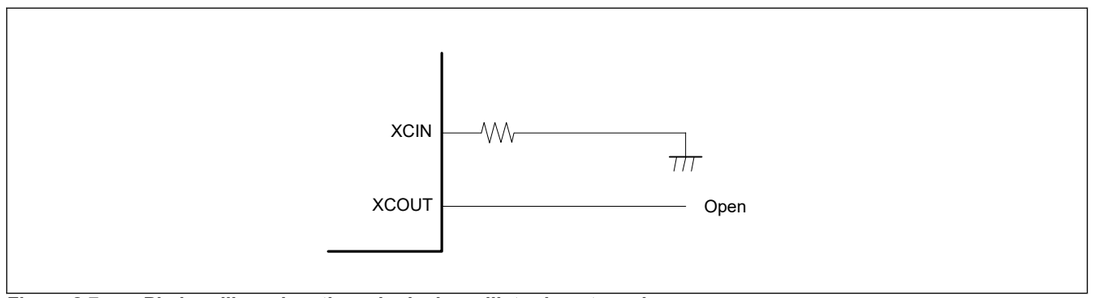

Figure 8.7 Pin handling when the sub-clock oscillator is not used

8.5 Oscillation Stop Detection Function

8.5.1 Oscillation Stop Detection and Operation after Detection

The oscillation stop detection function detects the main clock oscillator stop. When oscillation stop is detected, the system clock switches as follows:

- If an oscillation stop is detected with SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC), the system clock source switches to the MOCO clock.

图8。6 32。768-kHz晶体谐振器的等效电路

8。4。2 子时钟振荡器不使用时的引脚处理

当子时钟振荡器不使用时,通过电阻器将 XCIN 引脚连接到 VSS（以向下拉 VSS）并使 XCOUT 引脚打开,如图 8。7 所示。另外,如果振荡器未连接,则将子时钟振荡器停止位（SOSCCR。SOSTP）设置为1以停止振荡器。

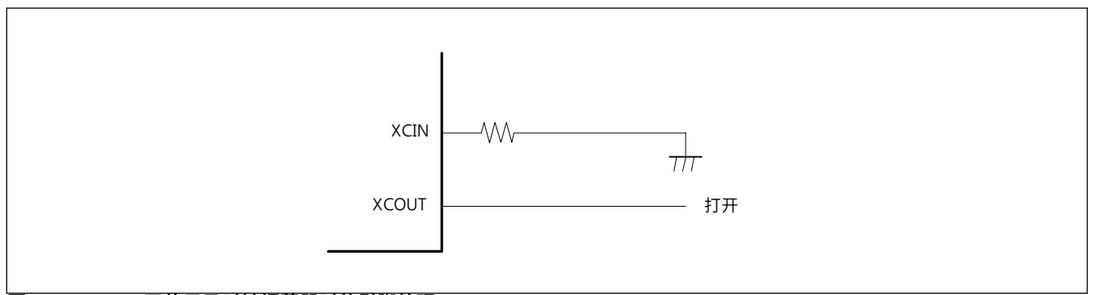

图8。7 不使用子时钟振荡器时的引脚处理

8。5 振荡停止检测功能

8。5。1 振荡停止检测及检测后的操作

振荡停止检测功能检测主时钟振荡器停止。当检测到振荡停止时,系统时钟切换如下:

- 如果用SCKSCR。CKSEL[2:0] = 011b（系统时钟源 = MOSC）检测到振荡停止,则系统时钟源切换到MOCO时钟。

- If an oscillation stop is detected with PLLCCR.PLSRCSEL = 0 (PLL source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL), PLL clock remains the system clock source. However, the frequency becomes a free-running oscillation frequency.

An oscillation stop detection interrupt request can be generated when an oscillation stop is detected. In addition, the General PWM Timer (GPT) output can be forced to a high-impedance state on detection.

The main clock oscillation stop is detected when the input clock remains at 0 or 1 for a certain period, for example, when a malfunction occurs in the main clock oscillator. See section 41, Electrical Characteristics.

Switching between the main clock oscillator and the MOCO clock or between the PLL clock and PLL free-running clock is controlled by the Oscillation Stop Detection Flag (OSTDSR.OSTDF).

OSTDF controls the switched clock as follows:

- When SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC):
  - When OSTDF changes from 0 to 1, the clock source switches to the MOCO clock.
  - When OSTDF changes from 1 to 0, the clock source switches back to MOSC.
- When PLLCCR.PLSRCSEL = 0 (PLL source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (System clock source = PLL):
  - When OSTDF changes 0 to 1, the clock source switches to the PLL free-running oscillation clock.
  - When OSTDF changes 1 to 0, the clock source switches back to PLL.

To switch the clock source to the main clock or PLL clock again after the oscillation stop detection, set the CKSEL[2:0] bits to a clock source other than the main clock or PLL clock and clear the OSTDF flag to 0. Also, check that the OSTDF flag is not 1, then set the CKSEL[2:0] bits to the main clock or PLL clock after the specified oscillation stabilization time elapses.

After a reset release, the main clock oscillator is stopped and the oscillation stop detection function is disabled. To enable the oscillation stop detection function, activate the main clock oscillator and write 1 to the oscillation stop detection function enable bit (OSTDCR.OSTDE) after a specified oscillation stabilization time elapses.

The oscillation stop detection function detects when the main clock is stopped by an external cause. Therefore, the oscillation stop detection function must be disabled before the main clock oscillator is stopped by software or a transition is made to Software Standby or Deep Software Standby mode.

The oscillation stop detection function switches all clocks that can be selected as the MOSC clock except CLKOUT to the MOCO (when system clock is MOSC) or PLL free-running (when system clock is PLL).

The system clock (ICLK) frequency during the MOCO(when system clock is MOSC) or PLL free-running (when system clock is PLL) operation is specified by the MOCO oscillation frequency and the division ratio set by the system clock select bits (SCKDIVCR.ICK[2:0])

● 如果用 PLLCCR。PLSRCSEL = 0（PLL 源时钟 = MOSC）和 SCKSCR。CKSEL[2:0] = 101b（系统时钟源 = PLL）检测到振荡停止,则 PLL 时钟仍然是系统时钟源。然而,该频率成为自由运行的振荡频率。

当检测到振荡停止时,可以生成振荡停止检测中断请求。此外,通用 PWM 定时器（GPT）输出在检测时可以强制达到高阻抗状态。

当输入时钟在一定时间内保持在0或1时,例如当主时钟振荡器发生故障时,检测主时钟振荡停止。参见第 41 节,电气特性 .

主时钟振荡器和MOCO时钟之间或PLL时钟和PLL自由运行时钟之间的切换由振荡停止检测标志（OSTDSR。OSTDF）控制。

OSTDF 对开关时钟的控制如下:

● 当 SCKSCR。CKSEL[2:0] = 011b（系统时钟源 = MOSC）:
  — 当OSTDF从0变为1时,时钟源切换到MOCO时钟。
  — 当 OSTDF 从 1 变为 0 时,时钟源会切换回 MOSC。
● 当 PLLCCR。PLSRCSEL = 0（PLL 源时钟 = MOSC）和 SCKSCR。CKSEL[2:0] = 101b（系统时钟源 = PLL）时:
  — 当OSTDF改变0到1时,时钟源切换到PLL自由运行的振荡时钟。
  — 当 OSTDF 将 1 更改为 0 时,时钟源会切换回 PLL。

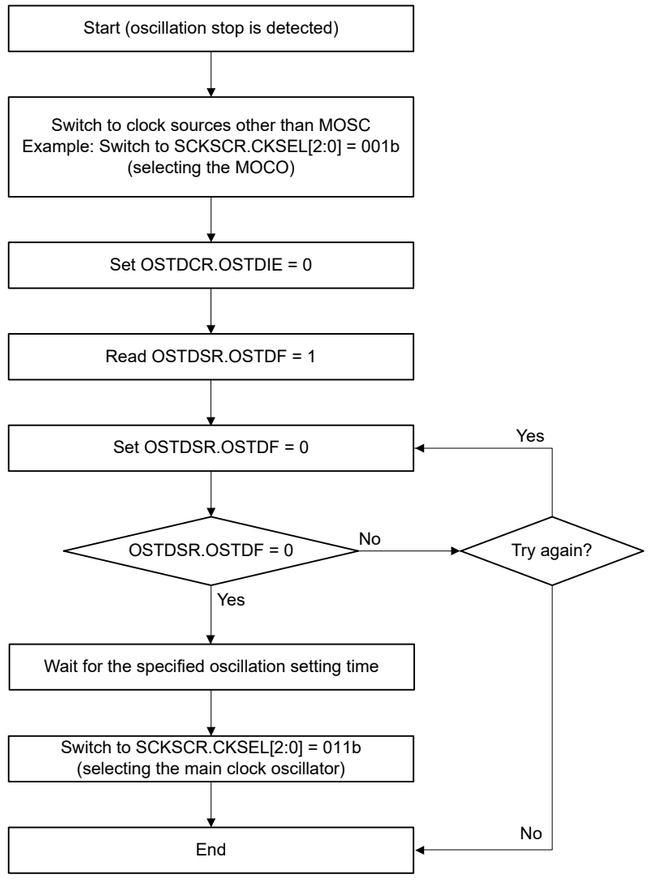
要在振荡停止检测后再次将时钟源切换到主时钟或 PLL 时钟,请将 CKSEL[2:0] 位设置为主时钟或 PLL 时钟以外的时钟源,并将 OSTDF 标志清除为 0。另外,检查OSTDF标志是否为1,然后在指定的振荡稳定时间过后将CKSEL[2:0]位设置为主时钟或PLL时钟。重置释放后,主时钟振荡器停止,振荡停止检测功能被禁用。要启用振荡停止检测功能,请激活主时钟振荡器,并在指定的振荡稳定时间过后将 1 写入振荡停止检测功能使能位（OSTDCR。OSTDE）。

振荡停止检测功能检测主时钟何时因外部原因停止。因此,在软件停止主时钟振荡器或过渡到软件待机或深度软件待机模式之前,必须禁用振荡停止检测功能。

振荡停止检测功能将除CLKOUT之外的所有可以选择为MOSC时钟的时钟切换为MOCO（当系统时钟为MOSC时）或PLL自由运行（当系统时钟为PLL时）。

MOCO（当系统时钟为MOSC时）或PLL自由运行（当系统时钟为PLL时）操作期间的系统时钟（ICLK）频率由MOCO振荡频率和系统时钟选择的位设置的分频比（SCKDIVCR。ICK[2:0]）指定

Example of returning when CKSEL[2:0] = 011b (selecting the main clock oscillator) after an oscillation stop is detected



Note: On return from the oscillation-stopped state, the factor responsible for stopping the main clock oscillation circuit must be removed from the system to allow oscillation to resume.

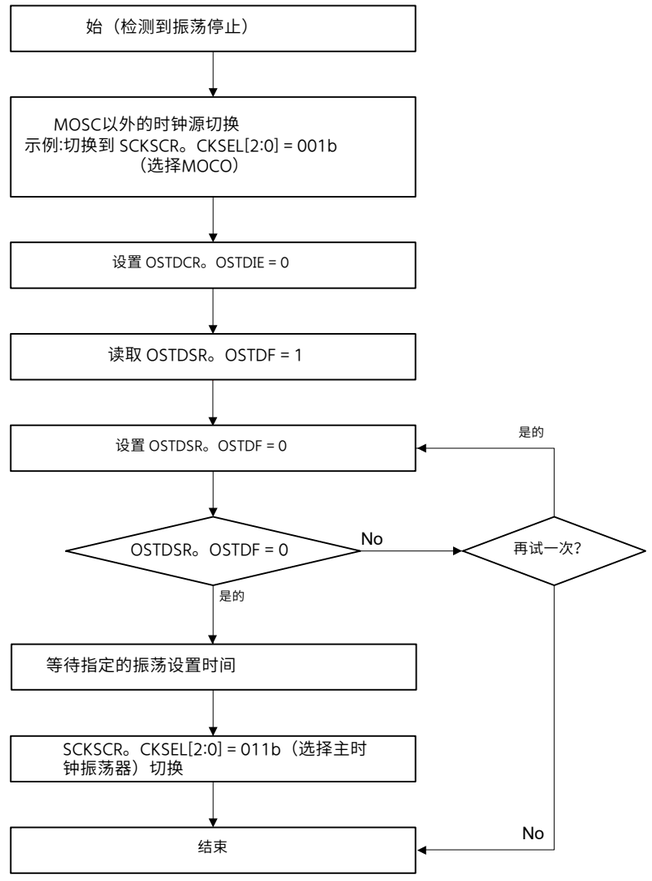
Figure 8.8 Flow of recovery on detection of oscillator stop

8.5.2 Oscillation Stop Detection Interrupts

An oscillation stop detection interrupt (MOSC_STOP) is generated when the Oscillation Stop Detection Flag (OSTDSR.OSTDF) is 1 and the Oscillation Stop Detection Interrupt Enable bit in the Oscillation Stop Detection Control Register (OSTDCR.OSTDIE) is 1 (enabled). The Port Output Enable for GPT (POEG) is notified of the main clock oscillator stop. On receiving the notification, the POEG sets the Oscillation Stop Detection Flag in the POEG Group n Setting Register (POEGGn.OSTPF) to 1 (n = A, B, C, D).

After the oscillation stop is detected, wait at least 10 PCLKB clock cycles before writing to the POEGGn.OSTPF flag. When the OSTDSR.OSTDF flag requires clearing, do so after clearing the Oscillation Stop Detection Interrupt Enable bit in the Oscillation Stop Detection Control Register (OSTDCR.OSTDIE). Wait at least 2 PCLKB clock cycles before setting the OSTDCR.OSTDIE bit to 1 again. A longer PCLKB wait time might be required, depending on the number of cycles required to read a given I/O register.

CKSEL[2:0] = 011b（选择主时钟振荡器）检测到振荡停止后返回的示例



注: 从振荡停止状态返回时,必须从系统中删除负责停止主时钟振荡电路的因素,以允许振荡恢复。

图8。8 检测振荡器停止时的恢复流

8。5。2 振荡停止检测中断

当振荡停止检测标志（OSTDSR。OSTDF）为1并且振荡停止检测控制寄存器（OSTDCR。OSTDIE）中的振荡停止检测中断启用位为1（启用）时,生成振荡停止检测中断（MOSC_STOP）。GPT 端口输出启用（POEG）会收到主时钟振荡器停止的通知。收到通知后,POEG 将 POEG 组 n 设置寄存器（POEGGn。OSTPF）中的振荡停止检测标志设置为 1（n = A、B、C、D）。

检测到振荡停止后,等待至少 10 个 PCLKB 时钟周期,然后再写入 POEGGn。OSTPF 标志。
OSTDSR。OSTDF标志需要清除时,在清除振荡停止检测控制寄存器（OSTDCR。OSTDIE）中的振荡停止检测中断启用位后进行。等待至少 2 个 PCLKB 时钟周期,然后再次将 OSTDCR。OSTDIE 位设置为 1。可能需要更长的 PCLKB 等待时间,具体取决于读取给定 I/O 寄存器所需的周期数。

The oscillation stop detection interrupt is a non-maskable interrupt. Because non-maskable interrupts are disabled in the initial state after a reset release, enable non-maskable interrupts through software before using oscillation stop detection interrupts. For details, see section 12, Interrupt Controller Unit (ICU).

When the ICLK clock source is switched, the duration of the ICLK clock cycle becomes longer during the clock source transition period. See Figure 8.9 and Figure 8.10.

SysTick 定时器专用时钟 SYSTICCLK 是 SysTick 定时器的操作时钟。SYSTICCLK 由 LOCO 时钟生成。

8.7.9 外部引脚输出时钟（CLKOUT）

CLKOUT 从时钟或蜂鸣器输出的 CLKOUT 引脚向外部输出。当 CKOCR。CKOEN 位设置为 1 时,CLKOUT 被输出到 CLKOUT 引脚。仅当 CKOCR。CKOEN 位为 0 时,更改 CKOCR 中的 CKODIV[2:0] 位或 CKOSEL[2:0] 位中的值。

CLKOUT 时钟频率在以下位中指定:

● CKODIV[2:0] 位或 CKOCR 中的 CKOSEL[2:0] 位

OFS1 中的 ● HOCOFRQ0[1:0] 位
。X数学X_2

Note 1. The value of OFS1.HOCOFRQ0[1:0] bits is automatically transferred to HOCOCR2.HCFRQ0[1:0] bits after reset, therefore it can also be specified by HOCOCR2.HCFRQ0[1:0] bits.

8.8 Usage Notes

8.8.1 Notes on Clock Generation Circuit

The frequency of the following clocks supplied to each module changes according to the setting of the SCKDIVCR register:

- System clock (ICLK)
- Peripheral module clocks (PCLKA, PCLKB, PCLKC, and PCLKD)
- FlashIF clock (FCLK)

Each frequency must meet the following conditions:

- Each frequency must be selected within the operation-guaranteed range of the operating frequency (f) specified in the AC characteristics. See section 41, Electrical Characteristics.
- The system clock, peripheral module clock must be set according to Table 8.2.

To ensure correct processing after the clock frequency changes, first write to the relevant Clock Control register to change the frequency, then read the value from the register, and finally perform the subsequent processing.

8.8.2 Notes on Resonator

Because various resonator characteristics relate closely to your board design, adequate evaluation is required before use. See the resonator connection example in Figure 8.5. The circuit constants for the resonator depend on the resonator to be used and the stray capacitance of the mounting circuit. Therefore, consult the resonator manufacturer when determining the circuit constants. The voltage to be applied between the resonator pins must be within the absolute maximum rating.

8.8.3 Notes on Board Design

When using a crystal resonator, place the resonator and its load capacitors as close to the XTAL and EXTAL pins as possible. Other signal lines should be routed away from the oscillation circuit as shown in Figure 8.11 to prevent electromagnetic induction from interfering with correct oscillation. Figure 8.11 shows the case which the main clock oscillator is used. In case of sub-clock oscillator, it is also same as Figure 8.11.

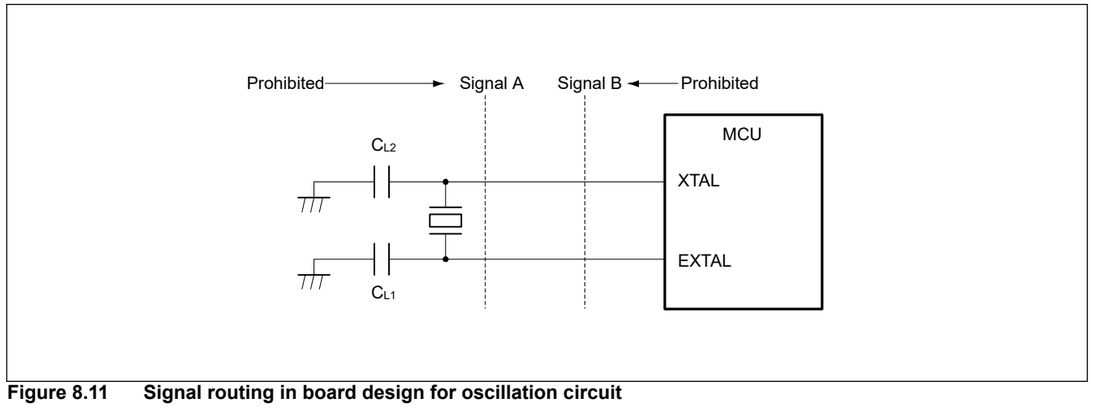

Figure 8.11 Signal routing in board design for oscillation circuit

8.8.4 Notes on Resonator Connect Pin

When the main clock is not used, the EXTAL and XTAL pins can be used as general ports. When these pins are used as general ports, the main clock must be stopped (MOSCCR.MOSTP bit should be set to 1).

注1。OFS1 的值。HOCOFRQ0[1:0] 位会自动传输到 HOCOCR2。HCFRQ0[1:0]位重置后,因此也可以由HOCOCR2指定。HCFRQ0[1:0] 位。

8。8 使用说明

8。8。1 时钟生成电路的注意事项

根据 SCKDIVCR 寄存器的设置, 提供给每个模块的以下时钟的频率发生变化:

- 系统时钟（ICLK）
- 外设模块时钟（PCLKA、PCLKB、PCLKC 和 PCLKD）
- 闪存时钟（FCLK）

每个频率必须满足以下条件:

- 每个频率必须在交流特性中规定的工作频率（f）的运行保证范围内选择。参见第 41 节,电气特性 .
- 系统时钟,外设模块时钟必须按表8。2 .进行设置

Clock频率变化后保证正确的处理,首先写入相关的Clock Control寄存器改变频率,然后从寄存器中读取值,最后进行后续处理。

8。8。2 谐振器注释

由于各种谐振器特性与您的电路板设计密切相关,因此在使用前需要进行充分的评估。请参阅图 8。5 中的谐振器连接示例。谐振器的电路常数取决于要使用的谐振器和安装电路的杂散电容。因此,在确定电路常数时请咨询谐振器制造商。谐振器引脚之间施加的电压必须在绝对最大额定值内。

8。8。3 板材设计注释

使用晶体谐振器时,将谐振器及其负载电容器尽可能靠近 XTAL 和 EXTAL 引脚。其他信号线应远离振荡电路,如图 8。11 所示,以防止电磁感应干扰正确的振荡。图8。11显示了使用主时钟振荡器的情况。子时钟振荡器的情况下,也与图8。11 .相同

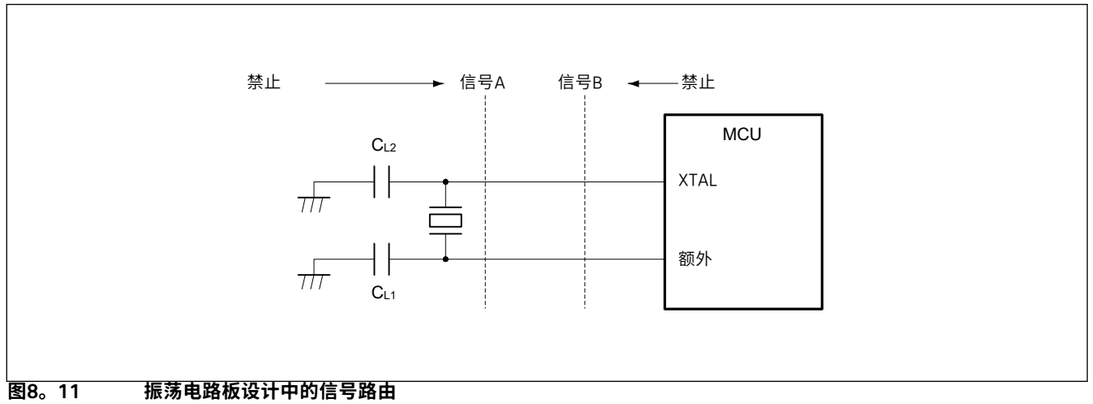

图8。11 振荡电路板设计中的信号路由

8。8。4 谐振器连接引脚注释

当不使用主时钟时,EXTAL 和 XTAL 引脚可用作通用端口。当这些引脚用作通用端口时,必须停止主时钟（MOSCCR。MOSTP 位应设置为 1)。

8.8.5 Notes on Using Sub-Clock Oscillator

The output of the P212 (EXTAL), P213 (XTAL), and P403 pins may affect the oscillation by the sub-clock oscillator.

If the sub-clock oscillator is used, implement board design so as not to affect the oscillation. Renesas strongly recommends setting the PmnPFS.DSCR[1:0] bits to 00b or 01b when using the P212 (EXTAL), P213 (XTAL), and P403 as output pins and using the sub-clock oscillator.

In addition, when using the sub-clock oscillator in low drive capability (SOMCR.SODRV1 = 1), Renesas recommecds setting the PmnPFS.DSCR[1:0] bits to 00b when using the P212 (EXTAL), P213 (XTAL), and P403 as output pins and using the sub-clock oscillator.

8.8.5 使用子时钟振荡器的注意事项

P212（EXTAL）、P213（XTAL）和 P403 引脚的输出可能会影响子时钟振荡器的振荡。

如果使用子时钟振荡器,请实施板设计,以免影响振荡。Renesas 强烈建议在使用 P212（EXTAL）、P213（XTAL）和 P403 作为输出引脚并使用子时钟振荡器时,将 PmnPFS。DSCR[1:0] 位设置为 00b 或 01b。

此外,当使用低驱动能力的子时钟振荡器（SOMCR。SODRV1 = 1)时,当使用 P212（EXTAL）、P213（XTAL）和 P403 作为输出引脚并使用子时钟振荡器。

9. Clock Frequency Accuracy Measurement Circuit (CAC)

9.1 Overview

The Clock Frequency Accuracy Measurement Circuit (CAC) counts pulses of the clock to be measured (measurement target clock) within the time generated by the clock selected as the measurement reference (measurement reference clock), and determines the accuracy depending on whether the number of pulses is within the allowable range. When measurement is complete or the number of pulses within the time generated by the measurement reference clock is not within the allowable range, an interrupt request is generated.

Table 9.1 lists the CAC specifications, Figure 9.1 shows the CAC block diagram, and Table 9.2 lists the CAC I/O pin.

When the counter value falls below the value specified in this register, a frequency error is detected. Write to this register when the CACR0.CFME bit is 0. The counter value stored in CACNTBR can vary depending on the difference between the phases of the digital filter and edge-detection circuit, and the signal on the CACREF pin. Ensure that this setting allows an adequate margin.	R/W

9.3 操作

9.3.1 测量时钟频率

CAC 使用 CACREF 引脚输入或内部时钟作为参考来测量时钟频率。图 9。2 显示了 CAC 的操作示例。

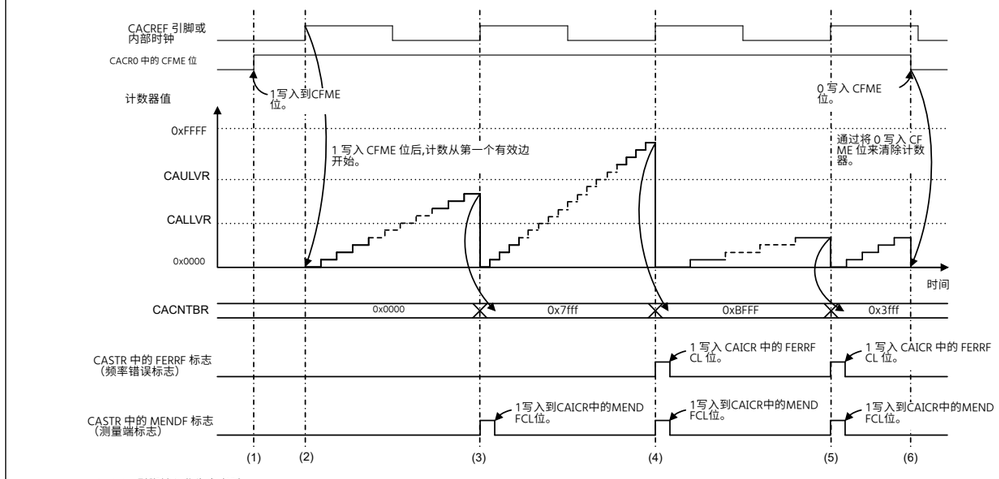

图9。2 CAC 操作示例

The events in Figure 9.2 are:

1. When the CACREF pin input is used as reference (CACR1.CACREFE = 1), frequency measurement is enabled by writing 1 to the CACR0.CFME bit while the CACR2.RPS bit is set to 0 and the CACR1.CACREFE bit is set to 1. When the internal clock is used as reference (CACR1.CACREFE = 0), frequency measurement is enabled by writing 1 to the CACR0.CFME bit while the CACR2.RPS bit is set to 1.
2. When the CACREF pin input is used as reference, after 1 is written to the CFME bit, the timer starts up-counting if the valid edge selected by the CACR1.EDGES[1:0] bits (rising edge (CACR1.EDGES[1:0] = 00b) in Figure 9.2) is input from the CACREF pin. When the internal clock is used as reference, after 1 is written to the CFME bit, the timer starts up-counting if the valid edge selected by the CACR1.EDGES[1:0] bits (rising edge (CACR1.EDGES[1:0] = 00b) in Figure 9.2) is input based on the clock source selected by the CACR2.RSCS[2:0] bits.
3. When the next valid edge is input, the counter value is transferred to CACNTBR and compared with the values in CAULVR and CALLVR. If both CACNTBR ≤ CAULVR and CACNTBR ≥ CALLVR are true, only the MENDF flag in CASTR is set to 1, because the clock frequency is correct. If the MENDIE bit in CAICR is 1, a measurement end interrupt is generated.
4. When the next valid edge is input, the counter value is transferred to CACNTBR and compared with the values in CAULVR and CALLVR. If CACNTBR > CAULVR, the FERRF flag in CASTR is set to 1, because the clock frequency is erroneous. If the FERRIE bit in CAICR is 1, a frequency error interrupt is generated. The MENDF flag in CASTR is set to 1 at the end of measurement. If the MENDIE bit in CAICR is 1, a measurement end interrupt is generated.
5. When the next valid edge is input, the counter value is transferred to CACNTBR and compared with the values in CAULVR and CALLVR. If CACNTBR < CALLVR, the FERRF flag in CASTR is set to 1, because the clock frequency is erroneous. If the FERRIE bit in CAICR is 1, a frequency error interrupt is generated. The MENDF flag in CASTR is set to 1 at the end of measurement. If the MENDIE bit in CAICR is 1, a measurement end interrupt is generated.
6. When the CFME bit in CACR0 is 1, the counter value is transferred to CACNTBR and compared with the values in CAULVR and CALLVR every time a valid edge is input. Writing 0 to the CFME bit in CACR0 clears the counter and stops up-counting.

9.3.2 Digital Filtering of Signals on CACREF Pin

The CACREF pin has a digital filter, and levels on the CACREF pin are transmitted to the internal circuitry after three consecutive matches in the selected sampling interval. The same level continues to be transmitted internally until the level on the pin has three consecutive matches again. Enabling or disabling of the digital filter and its sampling clock are selectable.

The counter value transferred to CACNTBR might be in error by up to 1 cycle of the sampling clock because of the difference between the phases of the digital filter and the signal input to the CACREF pin. When a frequency dividing clock is selected as a count source clock, the counter value error is obtained using the following formula:

Counter value error = (1 cycle of the count source clock)/ (1 cycle of the sampling clock)

9.4 Interrupt Requests

The CAC generates three types of interrupt requests:

- Frequency error interrupt
- Measurement end interrupt
- Overflow interrupt

When an interrupt source is generated, the associated status flag is set to 1. Table 9.3 provides information on the CAC interrupt requests.

Table 9.3 CAC interrupt requests (1 of 2)

Interrupt request	Interrupt enable bit	Status flag	Interrupt sources
Frequency error interrupt	CAICR.FERRIE	CASTR.FERRF	The result of comparing CACNTBR with CAULVR and CALLVR is either CACNTBR > CAULVR or CACNTBR < CALLVR

9。2 中的事件是:

1。当使用 CACREF 引脚输入作为参考时（CACR1)。CACREFE = 1),通过将 1 写入 CACR0 来启用频率测量。CACR 2 时的 CFME 位。RPS 位设置为 0,CACR1。CACREFE 位设置为 1。当内部时钟用作参考时（CACR1)。CACREFE = 0),通过将 1 写入 CACR0 来启用频率测量。CACR2 时的 CFME 位。RPS 位设置为 1。

2锛姣涓。当使用CACREF引脚输入作为参考时,在将1写入CFME位之后,如果CACR1选择的有效边,则定时器开始上计数。边[1:0]位（上升边（CACR1))。EDGES[1:0] = 00b（图9。2)是从CACREF引脚输入的。当使用内部时钟作为参考时,在将1写入CFME位之后,如果CACR1选择的有效边,则定时器开始上计数。边[1:0]位（上升边（CACR1))。EDGES[1:0] = 00b）在图9。2中是根据CACR2选择的时钟源输入的。RSCS[2:0] 位。

3锛 娴 。当输入下一个有效边时,计数器值被传输到 CACNTBR 并与 CAULVR 和 CALLVR 中的值进行比较。如果 CACNTBR ≤ CAULVR 和 CACNTBR ≥ CALLVR 均为真,则 CASTR 中只有 MENDF 标志设置为 1,因为时钟频率正确。如果 CAICR 中的 MENDIE 位为 1,则会生成测量端中断。

4锛姣涓。当输入下一个有效边时,计数器值被传输到 CACNTBR 并与 CAULVR 和 CALLVR 中的值进行比较。如果 CACNTBR > CAULVR,则 CASTR 中的 FERRF 标志设置为 1,因为时钟频率是错误的。CAICR中的FERRIE位为1,则会产生频率错误中断。CASTR 中的 MENDF 标志在测量结束时设置为 1。如果 CAICR 中的 MENDIE 位为 1,则会生成测量端中断。

5锛姣涓。当输入下一个有效边时,计数器值被传输到 CACNTBR 并与 CAULVR 和 CALLVR 中的值进行比较。如果 CACNTBR < CALLVR,则 CASTR 中的 FERRF 标志设置为 1,因为时钟频率是错误的。CAICR中的FERRIE位为1,则会产生频率错误中断。CASTR 中的 MENDF 标志在测量结束时设置为 1。如果 CAICR 中的 MENDIE 位为 1,则会生成测量端中断。

6锛 涓€涓。当CACR0中的CFME位为1时,计数器值被传送到CACNTBR,并在每次输入有效边时与CAULVR和CALLVR中的值进行比较。CACR0 中写入 CFME 位 0 可以清除计数器并停止上计数。

9。3。2 CACREF 引脚上的信号数字滤波

CACREF引脚具有数字滤波器,CACREF引脚上的电平在选定的采样间隔中连续匹配三次后传输到内部电路。相同的关卡继续在内部传输,直到引脚上的关卡再次连续三次匹配。启用或禁用数字滤波器及其采样时钟是可选择的。

由于数字滤波器的相位与输入到 CACREF 引脚的信号之间的差异,传输到 CACNTBR 的计数器值可能会在采样时钟的最多 1 个周期内出错。1个分频时钟选择为计数源时钟时, 使用以下公式得到计数器值误差:

计数器值误差=（计数源时钟的1个周期）/（采样时钟的1个周期）

9。4 中断请求

CAC 生成三种类型的中断请求:

- 频率错误中断
- 测量结束中断
- 溢出中断

当生成中断源时,关联状态标志设置为 1。表 9。3 提供了有关 CAC 中断请求的信息。

Note: Selectable means that operating or not operating can be selected by the control registers.
Stop (Retained) means that the contents of the internal registers are retained but the operations are suspended.
Operation prohibited means that the function must be stopped before entering Software Standby mode.
Stop (Undefined) means that the contents of the internal registers are undefined and power to the internal circuit is cut off.
All modules whose module-stop bits are 0 start as soon as PCLKs are supplied after entering Snooze mode. To avoid increase in power consumption in Snooze mode, module-stop bit of modules that are unnecessary in Snooze mode must be set to 1 before entering Software Standby mode.

Note 1. In IWDT-dedicated on-chip oscillator and IWDT, operating or stopping is selected by setting the IWDT Stop Control bit (IWDTSTPCTL) in Option Function Select register 0 (OFS0) in IWDT auto start mode. In WDT, operating or stopping is selected by setting the WDT Stop Control bit (WDTSTPCTL) in Option Function Select Register 0 (OFS0) in WDT auto start mode. Power consumption can be reduced in Normal and Sleep modes by selecting an appropriate operating power control mode according to the operating frequency.

Note 2. Stopped when the clock output source select bits (CKOCR.CKOSEL[2:0]) are set to a value other than 010b (LOCO) and 100b (SOSC).

Note 3. AGT0 operation is possible when 100b (AGTLCLK) or 110b (AGTSCLK) is selected by the AGT0.AGTMR1.TCK[2:0] bits.
AGT1 operation is possible when 100b (AGTLCLK), 110b (AGTSCLK) or 101b (Underflow event signal from AGT0) is selected by the AGT1.AGTMR1.TCK[2:0] bits.
When 100b (AGTLCLK) is selected by AGTn.AGTMR1.TCK[2:0] bits (n = 0, 1), the DPSBYCR.DEEPCUT[1:0] bits must set to 00b before entering Deep Software Standby mode.

Note 4. I3C wakeup interrupt is available.

Note 5. When using SCI0 in Snooze mode, MOSCCR.MOSTP and PLLCR.PLLSTP bits must be 1.

Note 6. Serial communication modes of SCI0 is only in asynchronous mode.

Note 7. Event lists the restrictions described in section 10.10.13. ELC Events in Snooze Mode.

止（Retained）,表示保留内部寄存器的内容,但暂停操作。
禁止操作是指在进入软件待机模式之前必须停止该功能。
止（未定义）,表示内部寄存器的内容未定义,内部电路的电源被切断。
进入 Snooze 模式后,一旦提供 PCLK,模块停止位为 0 的所有模块都会开始。为了避免 Snooze 模式下功耗增加,在 Snooze 模式下不需要的模块的模块停止位必须在进入软件待机模式之前设置为 1。

注1。在 IWDT 专用片上振荡器和 IWDT 中,通过在 IWDT 自动启动模式下在选项功能选择寄存器 0（OFS0) 中设置 IWDT 停止控制位（IWDTSTPCTL）来选择操作或停止。在WDT中,通过在WDT自动启动模式下在选项功能选择寄存器0（OFS0)中设置WDT停止控制位（WDTSTPCTL）来选择操作或停止。通过根据工作频率选择合适的操作功率控制模式,可以降低正常模式和睡眠模式下的功耗。

Note 8. If the DPSBYCR.DEEPCUT[1:0] bits are 00b, the oscillator status is the same as before entering Deep Software Standby mode. When the DPSBYCR.DEEPCUT[1:0] bits are not 00b, the oscillator stops when the MCU enters Deep Software Standby mode.
Note 9. When using LVD in Deep Software Standby mode, DPSBYCR.DEEPCUT[1:0] bits must be 00b or 01b before entering Deep Software Standby mode.
Note 10. When the MCU enters Deep Software Standby mode with the DPSBYCR.DEEPCUT[1:0] bits set to 11b, the LVD circuit stops and the low-power function of the power-on reset circuit is enabled.
Note 11. When using the 12-bit A/D Converter in Snooze mode, the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits must be 1.
Note 12. When CMPCTL0.CSTEN bit is 1, canceling Software Standby mode or entering Snooze mode by the comparator detection is available.
Note 13. Only VCOUT function is permitted. The VCOUT pin operates when ACMPHS uses no digital filter. For details on digital filter, see section 35, High-Speed Analog Comparator (ACMPHS).
Note 14. When using the Programmable Gain Amplifiers, MSTPDn (n = 16) must be set to 0. For details, see section 32.3.13. Programmable Gain Amplifiers.

Note 1. To use the interrupt request as a trigger for exiting the Snooze mode, the request must be selected in SELSR0. See section 12, Interrupt Controller Unit (ICU) for the setting of SELSR0. When a trigger selected in SELSR0 occurs after executing WFI instruction and during the transition from Normal mode to Software Standby mode, the request might or might not be accepted, depending on the timing of the occurrence.
Note 2. Only one of either SCI0_AM or SCI0_RXI_OR_ERI can be set.
Note 3. The event which is enabled by the SNZEDCRn must not be used.

注8。DPSBYCR。DEEPCUT[1:0]位为00b,则振荡器状态与进入深度软件待机模式之前相同。
DPSBYCR。DEEPCUT[1:0]位不为00b时,当MCU进入深度软件待机模式时,振荡器停止。
注9。Deep 软件待机模式下使用 LVD 时,DPSBYCR。DEEPCUT[1:0] 位必须为 00b 或 01b 才能进入 Deep 软件待机模式。
注10。MCU 进入深度软件待机模式时,DPSBYCR。DEEPCUT[1:0] 位设置为 11b,LVD 电路停止,并启用开机复位电路的低功耗功能。

注11。在 Snooze 模式下使用 12 位 A/D 转换器时,ADCMPCR。CMPAE 和 ADCMPCR。CMPBE 位必须为 1。
注12。当CMPCTL0。CSTEN位为1,取消软件待机模式或通过比较器检测进入Snooze模式是可用的。

注13。仅允许使用 VCOUT 功能。当 ACMPHS 不使用数字滤波器时,VCOUT 引脚会运行。有关数字滤波器的详细信息,请参阅第 35 节"高速模拟比较器（ACMPHS）"。
注14。使用可编程增益放大器时,MSTPDn（n = 16) 必须设置为 0。详情请参见第 32。3。13 节。可编程增益放大器。

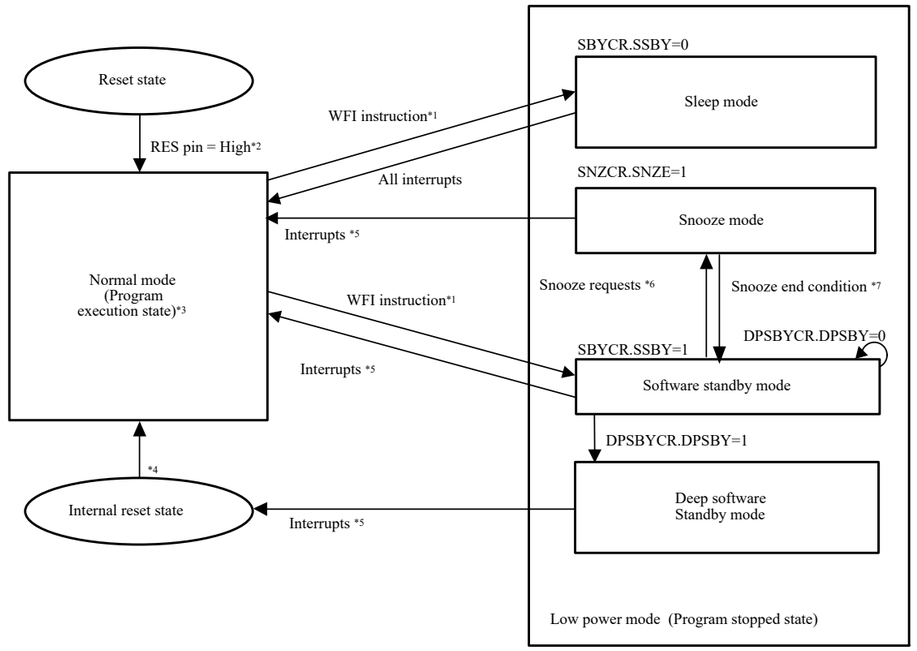
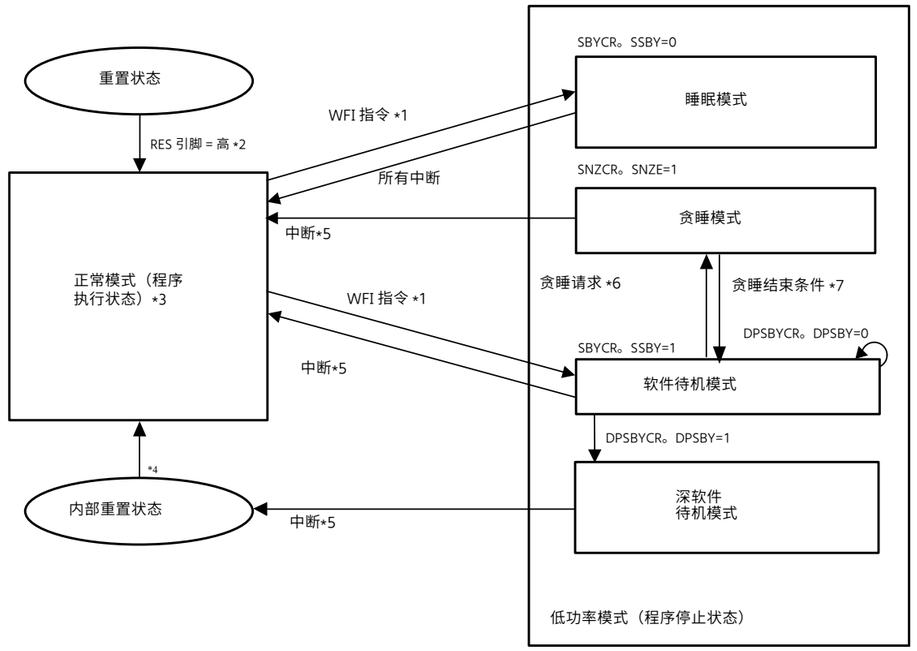
注1。要使用中断请求作为退出 Snooze 模式的触发器,必须在 SELSR0 中选择请求。有关 SELSR0 的设置,请参阅第 12 节"中断控制器单元（ICU）"。 SELSR0 中选择的触发器在执行 WFI 指令之后以及从正常模式到软件待机模式的过渡期间发生时,请求可能会被接受,也可能不会被接受,具体取决于发生的时间。

注2。SCI0_AM 或 SCI0_RXI_OR_ERI 中只能设置一个。
注3。不得使用 SNZEDCRn 启用的事件。



Note 1. When an interrupt that acts as a trigger for cancel is received during a transition to the program-stopped state after the execution of a WFI instruction, the MCU executes interrupt exception handling instead of transitioning to low power mode.
Note 2. The MOCO clock is the source of the operating clock following a transition from the reset state to Normal mode.
Note 3. The transition to Normal mode is made because of an interrupt from Sleep mode, Snooze mode, or Software Standby mode. The clock source is the same as before entering the low power mode.
Note 4. When an available interrupt request is generated, an internal reset (Deep Software Standby reset) is generated over a fixed period. Canceling of Deep Software Standby mode accompanies release from the internal reset state, and then the MCU transitions to Normal mode and executes reset exception processing with the MOCO clock as the source of the operating clock.
Note 5. See Table 10.3
Note 6. See Table 10.7
Note 7. See Table 10.9

Figure 10.1 Mode transitions



注1。当在执行WFI指令之后过渡到程序停止状态期间接收到充当取消触发器的中断时,MCU执行中断异常处理而不是过渡到低功率模式。

注2。MOCO 时钟是从复位状态转换到正常模式后操作时钟的源。
注3。向正常模式的过渡是由于睡眠模式、贪睡模式或软件待机模式的中断而进行的。时钟源与进入低功耗模式之前相同。

注4。当生成可用的中断请求时,会在固定期限内生成内部重置（深度软件待机重置）。取消深度软件待机模式伴随着从内部复位状态的释放,然后MCU过渡到正常模式并执行复位异常处理,MOCO时钟作为操作时钟的源。

If the security attribution is configured as Non-secure:

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

SSBY bit (Software Standby Mode Select)

The SSBY bit specifies the transition destination after a WFI instruction is executed.

When the SSBY bit is set to 1, the MCU enters Software Standby mode after execution of a WFI instruction. When the MCU returns to Normal mode from Software Standby mode by an interrupt, the SSBY bit remains 1. The SSBY bit can be cleared by writing 0 to it.

While the OSTDCR.OSTDE bit is 1, setting of the SSBY bit is ignored. Even if SSBY bit is 1, the MCU enters Sleep mode on execution of a WFI instruction.

While the FENTRYR.FENTRYC bit is 1 setting of the SSBY bit is ignored. Even if SSBY bit is 1, the MCU enters Sleep mode on execution of a WFI instruction.

如果安全属性配置为非安全:

注: 在重写此寄存器之前,将 PRCR。PRC1 位设置为 1（启用写入）。

SSBY 位（软件待机模式选择）

SSBY 位指定执行 WFI 指令后的过渡目的地。

当SSBY位设置为1时,MCU在执行WFI指令后进入软件待机模式。MCU 从软件待机模式中中断返回到正常模式时,SSBY 位保持为 1。SSBY 位可以通过写入 0 来清除它。

虽然 OSTDCR。OSTDE 位为 1,但 SSBY 位的设置被忽略。即使 SSBY 位为 1,MCU 在执行 WFI 指令时也会进入睡眠模式。

虽然 FENTRYR。FENTRYC 位是 SSBY 位的 1 设置,但被忽略。即使 SSBY 位为 1,MCU 在执行 WFI 指令时也会进入睡眠模式。

如果安全属性配置为非安全:
- 允许安全和非安全访问。

注: 在重写此寄存器之前,将 PRCR。PRC1 位设置为 1（启用写入）。

OPCCR 寄存器用于通过指定较低的工作频率来降低正常模式和睡眠模式下的功耗。有关更改操作功率控制模式的过程,请参阅第 10。5 节。降低工作功耗的功能。

当从软件待机模式转换为正常或打瞌睡模式时,OPCCR。OPCM[1:0] 中的设置和 SOPCCR。SOPCM 位如下, 不管在进入软件待机模式之前其设置如何:

- OPCCR。OPCM[1:0] = 00b（高速模式）
- SOPCCR。SOPCM = 0b（不是 Subosc 速度模式）。

If Software Standby mode is canceled before the transition to Software Standby completes, the OPCCR.OPCM[1:0] and SOPCCR.SOPCM bits retain their settings from before the WFI instruction is executed. If this causes any problem, set the MCU to High-speed mode during the exception handling procedure when canceling Software Standby mode.

OPCM[1:0] bits (Operating Power Control Mode Select)

The OPCM[1:0] bits select the operating power control mode in Normal and Sleep modes. Table 10.4 shows the relationship between the operating power control modes and the OPCM[1:0] and SOPCM settings.

OPCMTSF flag (Operating Power Control Mode Transition Status Flag)

The OPCMTSF flag indicates the switching control state when the operating power control mode is switched. This flag becomes 1 when the OPCM bit is written, and 0 when mode transition completes. Read this flag and confirm that it is 0 before proceeding.

10.2.10 SOPCCR : Sub Operating Power Control Register

Base address: SYSC = 0x4001_E000

Offset address: 0x0AA

Bit position:	7	6	5	4	3	2	1	0

4	SOPCMTSF	Operating Power Control Mode Transition Status Flag 0: Transition completed 1: During transition	R
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

The SOPCCR register is used to reduce power consumption in Normal mode and Sleep mode. Setting this register initiates entry to and exit from Subosc-speed mode. Subosc-speed mode is available only when using the sub-clock oscillator or LOCO without dividing the frequency.

For the procedure to change operating power control modes, see section 10.5. Function for Lower Operating Power Consumption.

SOPCM bit (Sub Operating Power Control Mode Select)

The SOPCM bit selects the operating power control mode in Normal and Sleep modes. Setting this bit to 1 allows transition to Subosc-speed mode. Setting this bit to 0 allows a return to the operating mode (operating mode set by OPCCR.OPCM[1:0]) that was active before the transition to Subosc-speed mode.

When transitioning from Software Standby mode to Normal mode or Snooze mode, the OPCCR.OPCM[1:0] and SOPCCR.SOPCM settings are as follows, regardless of their settings before entering Software Standby mode:

- OPCCR.OPCM[1:0] = 00b (High-speed mode)
- SOPCCR.SOPCM = 0b (not Subosc-speed mode)

如果在过渡到软件待机完成之前取消了软件待机模式,则 OPCCR。OPCM[1:0] 和 SOPCCR。SOPCM 位将保留其在执行 WFI 指令之前的设置。如果这导致任何问题,请在取消软件待机模式时的异常处理过程中将 MCU 设置为高速模式。

OPCM[1:0] 位（操作电源控制模式选择）

OPCM[1:0]位选择正常和睡眠模式下的操作功率控制模式。表10。4显示了操作功率控制模式与OPCM[1:0]和SOPCM设置之间的关系。

OPCMTSF 标志（工作电源控制模式转换状态标志）

OPCMTSF标志指示工作电源控制模式切换时的开关控制状态。OPCM 位写入时,此标志变为 1,模式转换完成时变为 0。阅读此标志并确认其为 0,然后再继续。

10。2。10 SOPCCR:子操作电源控制寄存器

基本地址: SYSC = 0x4001_E000

偏移地址: 0x0aa

位位置:	7	6	5	4	3	2	1	0

4	SOPCMTSF	操作电源控制模式转换状态标志 0:过渡完成 1:过渡期间	R
7:5	—	这些位读作 0。写入值应为 0。	R/W

注: 如果安全属性配置为安全:
- 允许安全访问和非安全读取访问
- 非安全写访问被忽略,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全访问。

注: 在重写此寄存器之前,将 PRCR。PRC1 位设置为 1（启用写入）。

SOPCCR 寄存器用于降低正常模式和睡眠模式下的功耗。设置此寄存器会启动 Subosc 速度模式的进入和退出。Subosc 速度模式仅在使用子时钟振荡器或 LOCO 时才可用,而无需划分频率。

有关更改操作功率控制模式的程序,请参阅第 10。5 节。较低工作功率的功能消费。

SOPCM 位（子操作电源控制模式选择）

SOPCM 位选择正常模式和睡眠模式下的操作功率控制模式。将此位设置为 1 允许过渡到 Subosc 速度模式。将此位设置为 0 允许返回到转换为 Subosc 速度模式之前处于活动的操作模式（由 OPCCR。OPCM 设置的操作模式[1:0])。

从"软件待机模式过渡到"正常模式或"打瞌睡模式时, OPCCR。OPCM[1:0] 和 SOPCCR。SOPCM 设置如下, 不管在进入"软件待机模式之前其设置如何:

- OPCCR。OPCM[1:0] = 00b（高速模式）
- SOPCCR。SOPCM = 0b（不是 Subosc 速度模式）

If Software Standby mode is canceled before the transition to Software Standby completes, the OPCCR.OPCM[1:0] and SOPCCR.SOPCM bits retain their settings from before the WFI instruction is executed. If this causes any problem, set the MCU to High-speed mode during the exception handling procedure when canceling Software Standby mode.

Table 10.4 shows the relationship between the operating power control modes, the OPCM[1:0], and SOPCM bits settings.

SOPCMTSF flag (Operating Power Control Mode Transition Status Flag)

The SOPCMTSF flag indicates the switching control state when the operating power control mode is switched to or from Subosc-speed mode. This flag becomes 1 when the SOPCM bit is written, and 0 when mode transition completes. Read this flag and confirm that it is 0 before proceeding.

Table 10.4 shows each operating power control mode.

Table 10.4 Operating power control mode

Operating power control mode	OPCM[1:0] bits	SOPCM bit	Power consumption
High-speed mode	00b	0	High
Low-speed mode	11b	0	↓
Subosc-speed mode	xxb	1	Low

For details about the operating frequency range, see section 41, Electrical Characteristics.

Each operating power control mode is described below.

- High-speed mode
  After a reset cancellation, the MCU is activated in this mode.
- Low-speed mode
  The following constraints apply in low-speed mode:
  - Programming and erasure operations for the flash memory are prohibited
  - Using the PLL is prohibited. See section 10.10.1. Register Access

  In this mode, lower power consumption is possible than in High-speed mode when the same operation is performed under the same conditions, such as operating frequency.
- Subosc-speed mode
  The following constraints apply in Subosc-speed mode:
  - Programming and erasure operations for the flash memory are prohibited
  - Reading of the data flash is prohibited
  - Using MOSC, PLL, MOCO, or HOCO is prohibited. See section 10.10.1. Register Access
  - Using the divided clock for ICK or FCK is prohibited. See section 10.10.1. Register Access
  - Using the oscillation stop detection function of the main clock oscillator is prohibited.

  In this mode, lower power consumption is possible than in low-speed mode when the same operation is performed under the same conditions, such as operating frequency.

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

RXDREQEN bit (RXD0 Snooze Request Enable)

The RXDREQEN bit specifies whether to detect a falling edge of the RXD0 pin in Software Standby mode. This bit can be used only when SCI0 is operating in asynchronous mode. To detect a falling edge of the RXD0 pin, set this bit before entering Software Standby mode. When this bit is set to 1, a falling edge of the RXD0 pin in Software Standby mode causes the MCU to enter Snooze mode.

SNZDTCEN bit (DTC Enable in Snooze mode)

The SNZDTCEN bit specifies whether to use the DTC and SRAM in Snooze mode. To use the DTC and SRAM in Snooze mode, set this bit to 1 before entering Software Standby mode. When this bit is set to 1, the DTC can be activated by setting IELSRn register.

SNZE bit (Snooze mode Enable)

The SNZE bit specifies whether to enable a transition from Software Standby mode to Snooze mode. To use Snooze mode, set this bit to 1 before entering Software Standby mode. When this bit is set to 1, a trigger as shown in Table 10.7 in Software Standby mode causes the MCU to enter Snooze mode. After the MCU transitions from Software Standby mode or Snooze mode to Normal mode, set 0 to the SNZE bit once then set it before re-entering Software Standby mode. For details, see section 10.8. Snooze Mode.

The SNZREQCR0 register controls which trigger causes the MCU to switch from Software Standby mode to Snooze mode. If a trigger is selected as a request to cancel Software Standby mode by setting the WUPENn register, see section 12, Interrupt Controller Unit (ICU), the MCU enters Normal mode when the trigger is generated while the associated bit of the SNZREQCR0 is 1. The setting of the WUPENn register always has higher priority than the setting of the SNZREQCR0 register. For details, see section 10.8. Snooze Mode and section 12, Interrupt Controller Unit (ICU).

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

The DPSBYCR register controls the Deep Software Standby mode.

DPSBYCR is not initialized by the internal reset signal that is the source to cancel the Deep Software Standby mode. For details, see section 5, Resets.

DEEPCUT[1:0] bits (Power-Supply Control)

The DEEPCUT[1:0] bits control the internal power supply to the Low-speed on-chip oscillator, and AGT in Deep Software Standby mode. In addition, these bits control the state of LVD and power-on reset circuit in Deep Software Standby mode.

When an LVD interrupt is used in Deep Software Standby mode, the DEEPCUT[1:0] bits must be set to 00b or 01b.

For lower power consumption, set the DEEPCUT[1:0] bits to 11b so that the LVD is stopped and the low power consumption function of the power-on reset circuit is enabled.

Regardless of the DEEPCUT [1: 0] bit setting, during deep software standby mode, internal power supply to SRAM is stopped.

When a Deep Software Standby mode is used, set DPSWCR.WTSTS bits depending on the value of DEEPCUT[1] before entering Deep Software Standby mode.

IOKEEP bit (I/O Port Rentention)

In Deep Software Standby mode, I/O ports keep the same states as in the Software Standby mode. The IOKEEP bit specifies whether to reset the state of the I/O ports or not when the Deep Software Standby mode is canceled.

DPSBY bit (Deep Software Standby)

The DPSBY bit controls transitions to Deep Software Standby mode.

When the WFI instruction is executed while SBYCR.SSBY bit and DPSBYCR.DPSBY bit are both 1, the MCU enters Deep Software Standby mode through Software Standby mode.

The DPSBY bit remains 1 when Deep Software Standby mode is canceled by certain pins which are sources of external pin interrupts (NMI, IRQn-DS (n = 0, 1, 4 to 12, 14)) or a peripheral interrupt (voltage monitor 1, or voltage monitor 2). Write 0 to this bit to clear it.

The DPSBY bit setting is invalid when OFS0.IWDTSTPCTL bit is 0 (counting continues) regardless of the setting in OFS0.IWDTSTRT bit. In that case, even when SBYCR.SSBY bit is 1 and the DPSBY bit is 1, the transition after the execution of a WFI instruction is to Software Standby mode.

DPSBYCR 寄存器控制深度软件待机模式。

DPSBYCR 不是由作为取消深度软件待机模式源的内部复位信号初始化的。有关详细信息,请参阅第 5 节"重置"第 5 节。

DEEPCUT[1:0] 位（电源控制）

DEEPCUT[1:0]位控制低速片上振荡器的内部电源,以及深度软件待机模式下的AGT。此外,这些位在深度软件待机模式下控制 LVD 和开机复位电路的状态。

Deep 软件待机模式下使用 LVD 中断时, DEEPCUT[1:0] 位必须设置为 00b 或 01b。

DEEPCUT[1:0]位设置为11b,这样LVD就停止了,并启用了上电复位电路的低功耗功能。

DEEPCUT [1: 0] 位设置如何,在深度软件待机模式下,SRAM 的内部电源均停止。

用深度软件待机模式时,在进入深度软件待机模式之前,根据DEEPCUT[1]的值设置DPSWCR。WTSTS位。

IOKEEP 位（I/O 端口租赁）

在深度软件待机模式下,I/O 端口保持与软件待机模式相同的状态。IOKEEP 位指定在取消深度软件待机模式时是否重置 I/O 端口的状态。

DPSBY 位（深度软件待机）

DPSBY 位控制向深度软件待机模式的转换。

当SBYCR。SSBY位和DPSBYCR。DPSBY位均为1时执行WFI指令时,MCU通过软件待机模式进入深度软件待机模式。

当 Deep Software Standby 模式被某些引脚取消时,DPSBY 位保持为 1,这些引脚是外部引脚中断（NMI、IRQn-DS（n = 0、1、4 至 12、14))或外围中断（电压监视器 1)的源,或电压监视器 2)。0写到这个位来清除它。

OFS0时DPSBY位设置无效。无论 OFS0 中的设置如何,IWDTSTPCTL 位都是 0（计数继续）。IWDTSTRT 位。在这种情况下,即使当SBYCR。SSBY位为1并且DPSBY位为1时,WFI指令执行后的转换也是到软件待机模式。

The setting of the DPSBY bit is invalid when voltage monitor 1 reset is enabled (LVD1CR0.RI = 1) or when a voltage monitor 2 reset is enabled (LVD2CR0.RI = 1). In this case, even when the SBYCR.SSBY bit is 1 and the DPSBY bit is 1, the transition after the execution of a WFI instruction is to Software Standby mode.

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.

The DPSWCR register sets the wait stabilization time when a Deep Software Standby mode is canceled by certain pins that are the sources of external pin interrupts.

During a wait stabilization period set in this register, a Deep Software Standby reset occurs, and the MCU is initialized.

The DPSWCR register is not initialized with the internal reset signal by the cancellation of the Deep Software Standby mode. For details, see section 5, Resets.

When a Deep Software Standby mode is used, set DPSWCR.WTSTS bits according to the value of DPSBYCR.DEEPCUT[1] before entering Deep Software Standby mode.

When DPSBYCR.DEEPCUT[1]=0, you can set DPSWCR.WTSTS to the wait cycle for fast recovery.

When DPSBYCR.DEEPCUT[1]=1, you must set DPSWCR.WTSTS to the wait cycle for slow recovery.

DPSWCR 寄存器设置深度软件待机模式被某些引脚取消时的等待稳定时间,这些引脚是外部引脚中断的来源。

在此寄存器中设置的等待稳定期间,会发生深度软件待机重置,并且 MCU 被初始化。

通过取消深度软件待机模式,DPSWCR 寄存器不会用内部重置信号初始化。有关详细信息,请参阅第 5 节"重置"第 5 节。

当使用深度软件待机模式时,根据 的值设置 DPSWCR。WTSTS 位 DPSBYCR。DEEPCUT[1],然后再进入深度软件待机模式。

DPSBYCR。DEEPCUT[1]=0 时,您可以将 DPSWCR。WTSTS 设置为快速恢复的等待周期。

DPSBYCR。DEEPCUT[1]=1 时,您必须将 DPSWCR。WTSTS 设置为等待缓慢恢复的周期。

DPSIER0 is not initialized by the internal reset signal used as Deep Software Standby mode Cancelling source. For details, see section 5, Resets.

After the setting of DPSIER0 is modified, an edge may be internally generated depending on the state of the pin, resulting in DPSIFR0 being set to 1. Therefore, DPSIFR0 should be cleared to 0 before entering Deep Software Standby mode.

当生成相应的取消请求时,每个标志设置为 1。

式（不仅在深度软件待机模式下）生成取消请求或者修改DPSIER3的设置时,每个标志可以设置为1。因此,应在 DPSIFR3 清除至 0x00 后过渡到深度软件待机模式。

DPSIER3 修改后要清除 DPSIFR3 到 0x00,至少要等待 6 个 PCLKB 周期,读取 DPSIFR3,然后写入 0 到 DPSIFR3。例如,可以通过读取 DPSIER3 来保护六个或更多个 PCLKB 周期。

DPSIFR3 不会被用作深度软件待机模式取消源的内部复位信号初始化。有关详细信息,请参阅第 5 节"重置"第 5 节。

Note: Set the PRCR.PRC1 bit to 1 (write enabled) before rewriting this register.
Note 1. Writing 0 clears the flag. Writing 1 is ignored

This register is not controlled by any security attribute register (eg. LPMSAR, DPFSAR).

SYOCDCR can be written when DBGSTR.CDBGPWRUPREQ = 1 (the debugger is connected).

SYOCDCR is not initialized by the internal reset signal that is the source to cancel the Deep Software Standby mode.

DOCDF flag (Deep Software Standby OCD flag)

DOCDF flag indicates that a cancel request of Deep Software Standby mode by the MCUCTRL.DBIRQ bit has been generated. DOCDF flag is set to 1 when a cancel request is generated. This flag may be set to 1 when a cancel request is generated in any mode (not only in Deep Software Standby mode). Therefore, a transition to Deep Software Standby mode must be made after DOCDF flag is cleared to 0.

[Setting condition]

- A cancel request by the MCUCTRL.DBIRQ is generated

[Clearing condition]

- Writing 0 to the flag after reading the bit as 1
- When DBGEN bit is 0

DBGEN bit (Debugger Enable bit)

The DBGEN bit enables the on-chip debug mode. This bit must be set to 1 first in the on-chip debugger mode.

[Setting condition]

- Writing 1 to the bit when the debugger is connected.

[Clearing condition]

- Power-on reset is generated
- Writing 0 to the bit.

Note: Certain restrictions apply in terms of the MCU states in which the DBGEN bit can be set to 1. For details, see section 2.12.3. Restrictions on Connecting an OCD emulator.

注: 在重写此寄存器之前,将 PRCR。PRC1 位设置为 1（启用写入）。
注1。写0可以清除旗帜。写入 1 被忽略

该寄存器不受任何安全属性寄存器的控制（例如。LPMSAR、DPFSAR）。

DBGSTR。CDBGPWRUPREQ = 1（调试器已连接）时可以写入 SYOCDCR。

SYOCDCR 不是由作为取消深度软件待机模式源的内部重置信号初始化的。

DOCDF 标志（深度软件备用 OCD 标志）

DOCDF 标志指示已生成 MCUCTRL。DBIRQ 位对深度软件待机模式的取消请求。DOCDF 标志在生成取消请求时设置为 1。当在任何模式下（不仅在深度软件待机模式下）生成取消请求时,该标志可以设置为 1。因此,在 DOCDF 标志清除到 0 后,必须过渡到深度软件待机模式。

的【设置条件】

- 生成 MCUCTRL。DBIRQ 的取消请求 [清除条件]

- 将位读取为 1 后将 0 写入标志

- **当 DBGEN 位为 0 DBGEN 位（调试器启用位）时**

DBGEN 位启用片上调试模式。在片上调试器模式下,该位必须首先设置为 1。

的【设置条件】

- 调试器连接时将 1 写入位。

的【清零条件】

- 生成开机复位
- 将 0 写入位。

注意:某些限制适用于 DBGEN 位可以设置为 1 的 MCU 状态。详情请参见第 2。12。3 节。连接 OCD 模拟器 . 的限制

10.3 Reducing Power Consumption by Switching Clock Signals

The clock frequency changes when the SCKDIVCR register is set.

For information on module and clock associations, see section 8.2.2. SCKDIVCR : System Clock Division Control Register.

10.4 Module-Stop Function

The module stop function can stop the clock supply set for each peripheral module.

When the MSTPmi bit (m = A to E, i = 31 to 0) in MSTPCRn (n = A to E) is set to 1, the specified module stops operating and enters the module-stop state, but the CPU continues to operate independently. Setting the MSTPmi bit to 0 cancels the module-stop state, allowing the module to resume operation at the end of the bus cycle.

After a reset is canceled, all modules other than the DMAC, DTC and SRAMn modules are placed in the module-stop state. Do not access the module while the corresponding MSTPmi bit is 1. Additionally, do not set 1 to the MSTPmi bit while the corresponding module is accessed.

10.5 Function for Lower Operating Power Consumption

By selecting an appropriate operating power consumption control mode according to the operating frequency, power consumption can be reduced in Normal mode, Sleep mode, and Snooze mode.

10.5.1 Setting Operating Power Control Mode

Ensure the operating condition such as the frequency range is always within the specified range before and after switching the operating power control modes.

This section provides example procedures for switching operating power control modes.

Table 10.5 Available oscillators in each mode

Mode	Oscillator						
	PLL	High-speed on-chip oscillator	Middle-speed on-chip oscillator	Low-speed on-chip oscillator	Main clock oscillator	Sub-clock oscillator	IWDT-dedicated on-chip oscillator
High-speed	Available	Available	Available	Available	Available	Available	Available
Low-speed	N/A	Available	Available	Available	Available	Available	Available
Subosc-speed	N/A	N/A	N/A	Available	N/A	Available	Available

(1) Switching from a higher power mode to a lower power mode

Example 1: From High-speed mode to Low-speed mode:

(Operation begins in High-speed mode)

1. Change the oscillator to what is used in Low-speed mode. Set the frequency of each clock lower than or equal to the maximum operating frequency in Low-speed mode.
2. Turn off the oscillator that is not required in Low-speed mode.
3. Confirm that the OPCCR.OPCMTSF flag is 0 (indicates transition completed).
4. Set the OPCCR.OPCM[1:0] bits to 11b (Low-speed mode).
5. Confirm that OPCCR.OPCMTSF flag is 0 (indicates transition completed).

(Operation is now in Low-speed mode)

Example 2: From High-speed mode to Subosc-speed mode

(Operation begins in High-speed mode)

1. Switch the clock source to sub-clock oscillator. Turn off PLL, HOCO, MOCO, LOCO and main oscillator.
2. Confirm that all clock sources other than the sub-clock oscillator are stopped.

10。3 通过切换时钟信号降低功耗

SCKDIVCR 寄存器设置时,时钟频率会发生变化。

有关模块和时钟关联的信息,请参阅第 8。2。2 节。SCKDIVCR:系统时钟划分控制寄存器 .

10。4 模块停止功能

模块停止功能可以停止每个外围模块的时钟电源设置。

MSTPCRn（n = A to E）中的MSTPmi位（m = A to E,i = 31 to 0)设置为1时,指定的模块停止运行,进入模块停止状态,但CPU继续独立运行。MSTPmi 位设置为 0 取消了模块停止状态,允许模块在总线周期结束时恢复运行。

取消重置后,除DMAC、DTC和SRAMn模块外的所有模块均处于模块停止状态。当相应的 MSTPmi 位为 1 时,请勿访问该模块。另外,在访问相应模块时,请勿将 1 设置为 MSTPmi 位。

10。5 较低工作功耗的功能

通过根据工作频率选择合适的操作功耗控制模式,可以减少正常模式、睡眠模式和贪睡模式下的功耗。

10.5.1 设置操作电源控制模式

断（如频率范围）等工作条件,在切换工作功率控制模式前后始终在规定范围内。

本节提供了切换操作功率控制模式的示例程序。

5. Set the frequency of each clock lower than or equal to the maximum operating frequency for High-speed mode.

(Operation is now in High-speed mode)

10.6 Sleep Mode

10.6.1 Transitioning to Sleep Mode

When a WFI instruction is executed while SBYCR.SSBY bit is 0, the MCU enters Sleep mode. In this mode, the CPU stops operating but the contents of its internal registers are retained. Other peripheral functions do not stop. Available resets or interrupts in Sleep mode cause the MCU to cancel Sleep mode. All interrupt sources are available. If using an interrupt to cancel Sleep mode, you must set the associated IELSRn register before executing a WFI instruction. For details, see section 12, Interrupt Controller Unit (ICU).

Counting by IWDT stops when the MCU enters Sleep mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 1 (IWDT stops in Sleep mode, Software Standby mode, or Snooze mode).

Counting by IWDT continues when the MCU enters Sleep mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 0 (IWDT does not stop in Sleep mode, Software Standby mode, or Snooze mode).

Counting by WDT stops when the MCU enters Sleep mode while the WDT is in auto start mode and the OFS0.WDTSTPCTL bit is 1 (WDT stops in Sleep mode). Similarly, counting by WDT stops when the MCU enters Sleep mode while the WDT is in register start mode and the WDTCSTPR.SLCSTP bit is 1 (WDT stops in Sleep mode).

Counting by WDT continues when the MCU enters Sleep mode while the WDT is in auto start mode and the OFS0.WDTSTPCTL bit is 0 (WDT does not stop in Sleep mode). Similarly, counting by WDT continues when the MCU enters Sleep mode while the WDT is in register start mode and the WDTCSTPR.SLCSTP bit is 0 (WDT does not stop in Sleep mode).

10.6.2 Canceling Sleep Mode

Sleep mode is canceled by:

3锛 娴 。确认 SOPCCR。SOPCMTSF 标志为 0（表示过渡完成）。

4锛姣涓。将 SOPCCR。SOPCM 位设置为 1（子速度模式）。

5锛姣涓。确认 SOPCCR。SOPCMTSF 标志为 0（表示过渡完成）。

（操作现在处于 Subosc 速度模式）

(2)从较低功率模式切换到较高功率模式

示例1:从Subosc速度模式到高速模式（操作从Subosc
速度模式开始）

1。确认 SOPCCR。SOPCMTSF 标志为 0（表示过渡完成）。

2锛姣涓。将 SOPCCR。SOPCM 位设置为 0（高速模式）。

3锛 娴 。确认 SOPCCR。SOPCMTSF 标志为 0（表示过渡完成）。

4锛姣涓。在高速模式下打开所需的振荡器。

5锛姣涓。将每个时钟的频率设置为低于或等于高速模式的最大工作频率。

（操作现在处于高速模式）

示例2:从低速模式到高速模式（操作从低速模式开
始）

1。确认 OPCCR。OPCMTSF 标志为 0（表示过渡完成）。

2锛姣涓。将 OPCCR。OPCM[1:0] 位设置为 00b（高速模式）。

3锛 娴 。确认 OPCCR。OPCMTSF 标志为 0（表示过渡完成）。

4锛姣涓。在高速模式下打开任何所需的振荡器。

5锛姣涓。将每个时钟的频率设置为低于或等于高速模式的最大工作频率。

（操作现在处于高速模式）

10。6 睡眠模式

10。6。1 过渡到睡眠模式

当SBYCR。SSBY位为0时执行WFI指令时,MCU进入睡眠模式。在此模式下,CPU 停止运行,但保留其内部寄存器的内容。其他外围功能不会停止。睡眠模式下的可用重置或中断会导致 MCU 取消睡眠模式。所有中断源均可用。如果使用中断取消睡眠模式,则必须在执行 WFI 指令之前设置关联的 IELSRn 寄存器。有关详细信息,请参阅第 12 节"中断控制器单元（ICU）."

当 MCU 进入睡眠模式时,IWDT 计数停止,而 IWDT 处于自动启动模式和 OFS0。IWDTSTPCTL 位为 1（IWDT 在睡眠模式、软件待机模式或贪睡模式下停止）。

当 MCU 进入睡眠模式且 IWDT 处于自动启动模式且 OFS0 时,按 IWDT 计数将继续。IWDTSTPCTL 位为 0（IWDT 在睡眠模式、软件待机模式或贪睡模式下不会停止）。

当 MCU 进入睡眠模式时,当 WDT 处于自动启动模式且 OFS0 时,WDT 计数停止。WDTSTPCTL 位为 1（WDT 在睡眠模式下停止）。类似地,当MCU进入睡眠模式时,当WDT处于寄存器启动模式并且WDTCSTPR。SLCSTP位为1时,通过WDT计数停止（WDT在睡眠模式下停止）。

当 MCU 进入睡眠模式且 WDT 处于自动启动模式且 OFS0 时,继续按 WDT 计数。WDTSTPCTL 位为 0（WDT 在睡眠模式下不会停止）。类似地,当MCU进入睡眠模式时,当WDT处于寄存器启动模式并且WDTCSTPR。SLCSTP位为0时,WDT计数继续（WDT在睡眠模式下不停止）。

10。6。2 取消睡眠模式

睡眠模式被以下取消:

- An interrupt
- A RES pin reset
- A power-on reset
- A voltage monitor reset
- An SRAM parity error reset
- An SRAM ECC error reset
- A bus master MPU error reset
- A TrustZone error reset
- A reset caused by an IWDT or a WDT underflow

The operations are as follows:

1. Canceling by an interrupt
   When an interrupt request is generated, Sleep mode is canceled and the MCU starts the interrupt handling.
2. Canceling by RES pin reset
   When the RES pin is driven low, the MCU enters the reset state. Be sure to keep the RES pin low for the time period specified in section 41, Electrical Characteristics. When the RES pin is driven high after the specified time period, the CPU starts the reset exception handling.
3. Canceling by IWDT reset
   - Sleep mode is canceled by an internal reset generated by an IWDT underflow and the MCU starts the reset exception handling. However, IWDT stops in Sleep mode and an internal reset for canceling Sleep mode is not generated in the following conditions:
   - OFS0.IWDTSTRT = 0 and OFS0.IWDTSTPCTL = 1.
4. Canceling by WDT reset
   Sleep mode is canceled by an internal reset generated by a WDT underflow and the MCU starts the reset exception handling. However, WDT stops in Sleep mode even when counting in Normal mode and an internal reset for canceling Sleep mode is not generated in the following conditions:
   - OFS0.WDTSTRT = 0 (auto start mode) and OFS0.WDTSTPCTL = 1
   - OFS0.WDTSTRT = 1 (register start mode) and WDTCSTPR.SLCSTP = 1.
5. Canceling by other resets available in Sleep mode
   Sleep mode is canceled by other resets and the MCU starts the reset exception handling.

Note: For details on proper setting of the interrupts, see section 12, Interrupt Controller Unit (ICU).

10.7 Software Standby Mode

10.7.1 Transitioning to Software Standby Mode

When a WFI instruction is executed while SBYCR.SSBY bit is 1 and DPSBYCR.DPSBY bit is 0, the MCU enters Software Standby mode. In this mode, the CPU, most of the on-chip peripheral functions and the oscillators stop. However, the contents of the CPU internal registers and SRAM data, the states of on-chip peripheral functions and the I/O ports are retained. Software Standby mode allows significant reduction in power consumption because most of the oscillators stops in this mode. Table 10.2 shows the status of each on-chip peripheral functions and oscillators. Available resets or interrupts in Software Standby mode make the MCU to cancel Software Standby mode. See Table 10.3 for available interrupt sources and section 12.2.18. WUPEN0 : Wake Up Interrupt Enable Register 0, section 12.2.19. WUPEN1 : Wake Up Interrupt Enable Register 1 for information on waking up the MCU from Software Standby mode. If using an interrupt to cancel an interrupt, you must set the associated IELSRn register before executing a WFI instruction. For details, see section 12, Interrupt Controller Unit (ICU).

Clear DMAST.DMST bit and DTCST.DTCST bit to 0 before executing WFI instruction except when using DTC in Snooze mode. If DTC is required in Snooze mode, set DTCST.DTCST bit to 1 before executing a WFI instruction.

Counting by the IWDT stops if the MCU enters Software Standby mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 1 (IWDT stops in Sleep, Software Standby or Snooze mode).

- 一个中断
- A RES 引脚重置
- 上电复位
- A 电压监视器复位
- SRAM 奇偶校验错误重置
- SRAM ECC 错误重置
- 总线主 MPU 错误重置
- TrustZone 错误重置
- 由 IWDT 或 WDT 底流引起的复位

操作如下:

1。通过中断取消
当生成中断请求时,Sleep 模式将被取消,MCU 开始中断处理。

2锛姣涓涓。RES引脚复位来取消
RES引脚被低驱动时,MCU进入复位状态。在第 41 节"电气特性"中规定的时间段内,请务必保持 RES 引脚较低。RES引脚在指定时间段后被高驱动时,CPU开始重置异常处理。

3锛　　娴　　。通过 IWDT 重置取消

- 睡眠模式被 IWDT 底流生成的内部复位取消,MCU 开始复位异常处理。但是,IWDT 在睡眠模式下停止,并且在以下条件下不会生成用于取消睡眠模式的内部重置:
- OFS0。IWDTSTRT = 0 和 OFS0。IWDTSTPCTL = 1

4锛姣涓。通过 WDT 重置取消
WDT 底流生成的内部复位取消了睡眠模式,MCU 开始复位异常处理。但是,即使在正常模式下计数,WDT 也会在睡眠模式下停止,并且在以下条件下不会生成用于取消睡眠模式的内部重置:

- OFS0。WDTSTRT = 0（自动启动模式）和 OFS0。WDTSTPCTL
- OFS0。WDTSTRT = 1（寄存器启动模式）和 WDTCSTPR。SLCSTP =

5锛姣涓。通过睡眠模式下可用的其他重置来取消
其他重置取消睡眠模式,MCU 启动重置异常处理。

注: 有关正确设置中断的详细信息,请参阅第 12 节"中断控制器单元（ICU）"。

10。7 软件待机模式

10.7.1 过渡到软件待机模式

当SBYCR。SSBY位为1且DPSBYCR。DPSBY位为0时执行WFI指令时,MCU进入软件待机模式。在此模式下,CPU、大部分片上外设功能和振荡器停止。然而,CPU内部寄存器和SRAM数据的内容、片上外围功能的状态和I/O端口被保留。软件待机模式可以显着降低功耗,因为大多数振荡器在此模式下停止。表 10。2 显示了每个片上外围功能和振荡器的状态。软件待机模式下的可用重置或中断使 MCU 取消软件待机模式。有关可用的中断源,请参阅表 10。3 和第 12。2。18 节。WUPEN0:唤醒中断启用寄存器 0,第 12。2。19 节。WUPEN1:唤醒中断 启用寄存器 1 以获取有关从软件待机模式唤醒 MCU 的信息。如果使用中断来取消中断,则必须在执行 WFI 指令之前设置关联的 IELSRn 寄存器。有关详细信息,请参阅第 12 节"中断控制器单元（ICU）."

在执行 WFI 指令之前将 DMAST。DMST 位和 DTCST。DTCST 位清除为 0,但在 Snooze 模式下使用 DTC 时除外。如果 Snooze 模式下需要 DTC,请在执行 WFI 指令之前将 DTCST。DTCST 位设置为 1。

如果 MCU 进入软件待机模式,而 IWDT 处于自动启动模式且 OFS0,则 IWDT 计数将停止。IWDTSTPCTL 位为 1（IWDT 在睡眠、软件待机或贪睡模式下停止）。

Counting by the IWDT continues if the MCU enters Software Standby mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 0 (IWDT does not stop in Sleep, Software Standby or Snooze mode).

WDT stops counting when the MCU enters Software Standby mode because the PCLKB stops.

Do not enter Software Standby mode while OSTDCR.OSTDE = 1 (oscillation stop detection function is enabled). To enter Software Standby mode, execute a WFI instruction after disabling the oscillation stop detection function (OSTDCR.OSTDE = 0). In case of executing WFI instruction while OSTDCR.OSTDE = 1, the MCU enters Sleep mode even if SBYCR.SSBY = 1.

Do not enter Software Standby mode while the flash memory is programming or erasing. To enter Software Standby mode, execute a WFI instruction after programming or erasing procedure completes.

Table 10.6 shows the setting of the related control bits and the modes to enter after executing WFI instruction.

Table 10.6 Bit settings that affect modes when executing a WFI instruction

		SBYCR.SSBY and PSBYCR.DPSBY bit settings

LVD2CR0.RI	0	Sleep	Sleep	Software Standby	Deep Software Standby
	1				Software Standby

10.7.2 Canceling Software Standby Mode

Software Standby mode is canceled by:

- An available interrupt shown in Table 10.3
- A RES pin reset
- A power-on reset
- A voltage monitor reset
- A reset caused by an IWDT underflow.

On exiting Software Standby mode, the oscillators that operate before the transition to the mode restart. After all the oscillators are stabilized, the MCU returns to Normal mode from Software Standby mode. See section 12.2.18. WUPEN0 : Wake Up Interrupt Enable Register 0, section 12.2.19. WUPEN1 : Wake Up Interrupt Enable Register 1 for information on how to wake up the MCU from Software Standby mode.

You can cancel Software Standby mode in any of the following ways:

1. Canceling by an interrupt
   When an available interrupt request (see Table 10.3) is generated, an oscillator that operates before the transition to Software Standby mode restarts. After all the oscillators are stabilized, the MCU returns to Normal mode from Software Standby mode and starts the interrupt handling.
2. Canceling by a RES pin reset
   When the RES pin is driven low, the MCU enters the reset state, and the oscillators whose default status is operating, start the oscillation. Be sure to keep the RES pin low for the time period specified in section 41, Electrical Characteristics. When the RES pin is driven high after the specified time period, the CPU starts the reset exception handling.
3. Canceling by a power-on reset

如果 MCU 进入软件待机模式,而 IWDT 处于自动启动模式且 OFS0,则继续按 IWDT 计数。IWDTSTPCTL 位为 0（IWDT 在睡眠、软件待机或贪睡模式下不会停止）。MCU进入软件待机模式时,WDT停止计数,因为PCLKB停止。

OSTDCR。OSTDE = 1 时请勿进入软件待机模式（启用振荡停止检测功能）。入软件待机模式,禁用振荡停止检测功能后执行WFI指令（OSTDCR。OSTDE = 0)。如果在 OSTDCR。OSTDE = 1 时执行 WFI 指令,则即使 SBYCR。SSBY = 1,MCU 也会进入睡眠模式。

当闪存正在编程或擦除时,请勿进入软件待机模式。要进入软件待机模式,请在编程或擦除过程完成后执行 WFI 指令。

表10。6显示了相关控制位的设置以及执行WFI指令后要输入的模式。

10。7。2 取消软件待机模式

软件待机模式取消方式为:

- 表 10。3 所示的可用中断
- A RES 引脚重
- 上电复位
- 电压监视器复位
- 由内河运输下溢引起的复位。

退出软件待机模式后,在过渡到模式之前运行的振荡器将重新启动。所有振荡器稳定后,MCU 从软件待机模式返回到正常模式。参见第 12。2。18 节。WUPEN0:唤醒中断启用寄存器 0,第 12。2。19 节。WUPEN1:唤醒中断启用寄存器1,以获取有关如何从软件待机模式唤醒MCU的信息。

您可以通过以下任何方式取消软件待机模式:

1。通过中断取消
   当生成可用的中断请求（见表 10。3)时,在过渡到软件待机模式之前运行的振荡器将重新启动。当所有振荡器稳定后,MCU从软件待机模式返回到正常模式并开始中断处理。

2锛姣涓涓。通过 RES 引脚复位来取消
   RES引脚被低驱动时,MCU进入复位状态,默认状态为工作的振荡器开始振荡。在第 41 节"电气特性"中规定的时间段内,请务必保持 RES 引脚较低。RES引脚在指定时间段后被高驱动时,CPU开始重置异常处理。

3锛　　娴　　。通过开机复位取消

Software Standby mode is canceled by a power-on reset and the MCU starts the reset exception handling.

4. Canceling by a voltage monitor reset
   Software Standby mode is canceled by a voltage monitor reset from the voltage detection circuit and the MCU starts the reset exception handling.
5. Canceling by IWDT reset
   Software Standby mode is canceled by an internal reset generated by an IWDT underflow and the MCU starts the reset exception handling. However, IWDT stops in Software Standby mode and an internal reset for canceling Software Standby mode is not generated in the following condition:
   - OFS0.IWDTSTRT = 0 and OFS0.IWDTSTPCTL = 1.

10.7.3 Example of Software Standby Mode Application

Figure 10.2 shows an example of entry to Software Standby mode on detection of a falling edge of the IRQn pin, and exit from Software Standby mode by a rising edge of the IRQn pin.

In this example, an IRQn pin interrupt is accepted with the IRQCRi.IRQMD[1:0] bits of the ICU set to 00b (falling edge) in Normal mode, and the IRQCRi.IRQMD[1:0] bits are set to 01b (rising edge). After that, the SBYCR.SSBY bit is set to 1 and a WFI instruction is executed. As a result, entry to Software Standby mode completes and exit from Software Standby mode is initiated by a rising edge of the IRQn pin.

Setting the ICU is also required to exit Software Standby mode. For details, see section 12, Interrupt Controller Unit (ICU). The oscillation stabilization time in Figure 10.2 is specified in section 41, Electrical Characteristics.

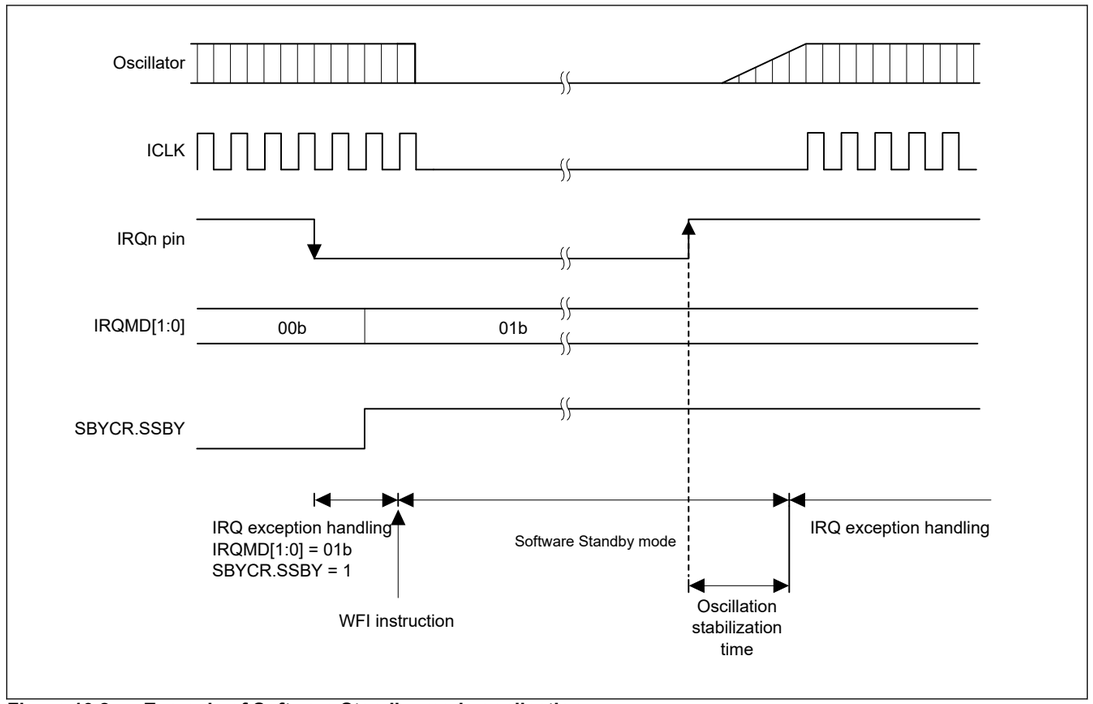

Figure 10.2 Example of Software Standby mode application

软件待机模式通过上电复位取消,MCU 开始复位异常处理。

4锛姣涓。通过电压监视器复位来消除

软件待机模式由电压检测电路的电压监视器复位取消,MCU 开始复位异常处理。

5锛姣涓。通过 IWDT 重置取消

IWDT底流生成的内部复位取消了软件待机模式,MCU开始复位异常处理。但是,IWDT 在软件待机模式下停止,并且在以下条件下不会生成用于取消软件待机模式的内部重置:

- OFS0。IWDTSTRT = 0 和 OFS0。IWDTSTPCTL = 1

。

10。7。3 软件待机模式应用示例

图10。2示出了在检测IRQn引脚的下降边缘时进入软件待机模式并通过IRQn引脚的上升边缘退出软件待机模式的示例。

在此示例中,ICU 的 IRQCRi。IRQMD[1:0] 位在正常模式下设置为 00b（下降沿）时接受 IRQn 引脚中断,并且 IRQCRi。IRQMD[1:0] 位设置为 01b（上升沿）。之后,将SBYCR。SSBY位设置为1并执行WFI指令。结果,进入软件待机模式完成,并且从软件待机模式退出由IRQn引脚的上升沿启动。

退出软件待机模式还需要设置 ICU。有关详细信息,请参阅第 12 节"中断控制器单元（ICU）."
41节电气特性.中规定了图10。2中的振荡稳定时间

10.8 Snooze Mode

10.8.1 Transition to Snooze Mode

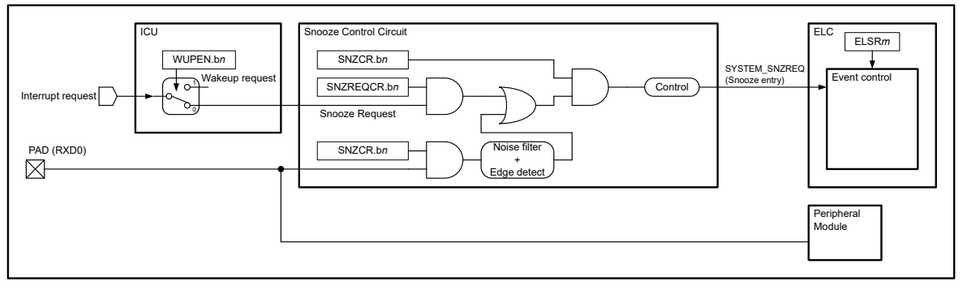

Figure 10.3 Snooze mode entry configuration

When the snooze control circuit accepts an available snooze request in Software Standby mode, the MCU transfers to Snooze mode. In this mode, some peripheral modules operates without waking the CPU. The peripheral modules that can operate in Snooze mode are shown in Table 10.2. Also, DTC operation in Snooze mode can be selected by the setting of SNZCR.SNZDTCEN bit.

Table 10.7 shows the Snooze requests that switch the MCU from Software Standby mode to Snooze mode. To use the listed Snooze requests as a trigger to switch to Snooze mode, the corresponding SNZREQENn bit of the SNZREQCRn register or RXDREQEN bit of SNZCR register must be set before entering Software Standby mode.

Table 10.7 Available snooze requests to switch to Snooze mode

Snooze request	Control Register	
	Register	Bit*1
PORT_IRQn (n = 0 to 14)	SNZREQCR0	SNZREQENn (n = 0 to 14)
ACMP_HS0	SNZREQCR0	SNZREQEN22
AGT1_AGTI	SNZREQCR0	SNZREQEN28
AGT1_AGTCMAI	SNZREQCR0	SNZREQEN29
AGT1_AGTCMBI	SNZREQCR0	SNZREQEN30
RXD0 falling edge	SNZCR	RXDREQEN*2

Note 1. Do not enable multiple snooze requests at the same time.
Note 2. Do not set the RXDREQEN bit to 1 except in asynchronous mode.

Clear the DMAST.DMST and DTCST.DTCST bits to 0 before executing a WFI instruction, except when using the DTC in Snooze mode. If the DTC is required in Snooze mode, set the DTCST.DTCST bit to 1 before executing a WFI instruction.

10.8.2 Canceling Snooze Mode

Snooze mode is canceled by an interrupt request that is available in Software Standby mode or a reset. Table 10.3 shows the requests that can be used to exit each mode. After canceling the Snooze mode, the MCU enters Normal mode and proceeds with exception processing for the given interrupt or reset. The action triggered by the interrupt requests, selected in SELSR0, cancels Snooze mode. Interrupt canceling Snooze mode must be selected in IELSRn to link to the NVIC for the corresponding interrupt handling. See section 12, Interrupt Controller Unit (ICU) for information on SELSR0 and IELSRn registers.

10.8 贪睡模式

10.8.1 过渡到贪睡模式

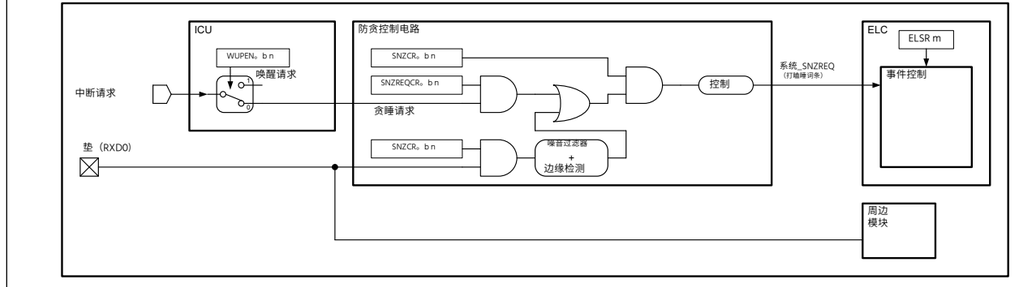

图10。3 贪睡模式进入配置

当贪睡控制电路在软件待机模式下接受可用的贪睡请求时,MCU 转移到贪睡模式。在此模式下,某些外围模块无需唤醒 CPU 即可运行。可在Snooze模式下运行的外围模块如表10。2所示。此外,可以通过设置SNZCR。SNZDTCEN位来选择Snooze模式下的DTC操作。

表 10。7 显示了将 MCU 从软件待机模式切换到 Snooze 模式的 Snooze 请求。要使用列出的 Snooze 请求作为切换到 Snooze 模式的触发器,必须在进入软件待机模式之前设置 SNZREQCRn 寄存器的相应 SNZREQENn 位或 SNZCR 寄存器的 RXDREQEN 位。

表 10。7 切换到贪睡模式的可用贪睡请求

贪睡请求	控制寄存器	
	注册	Bit*1

AGT1_AGTCMAI	SNZREQCR0	SNZREQEN29
AGT1_AGTCMBI	SNZREQCR0	SNZREQEN30
RXD0 下降边缘	SNZCR	RXDREQEN *2

注1。不要同时启用多个打瞌睡请求。
注2。除非处于异步模式,否则请勿将 RXDREQEN 位设置为 1。

在执行 WFI 指令之前将 DMAST。DMST 和 DTCST。DTCST 位清除为 0,但在 Snooze 模式下使用 DTC 时除外。如果 Snooze 模式下需要 DTC,请在执行 WFI 指令之前将 DTCST。DTCST 位设置为 1。

10。8。2 取消贪睡模式

Snooze 模式由软件待机模式或重置中可用的中断请求取消。表 10。3 显示了可用于退出每种模式的请求。取消 Snooze 模式后,MCU 进入正常模式,并对给定的中断或重置进行异常处理。在 SELSR0 中选择的中断请求触发的操作取消了 Snooze 模式。IELSRn 中必须选择中断取消 Snooze 模式才能链接到 NVIC 进行相应的中断处理。有关 SELSR0 和 IELSRn 寄存器的信息,请参阅第 12 节"中断控制器单元（ICU）"。

Note 2. Transition time from Snooze mode to Normal mode.
Note 3. Enable Snooze mode (SNZCR.SNZE = 1) immediately before switching to Software Standby mode.
Note 4. Disable Snooze mode (SNZCR.SNZE = 0) immediately after returning to Normal mode.

Figure 10.4 Canceling of Snooze mode when an interrupt request signal is generated

10.8.3 Returning from Snooze Mode to Software Standby Mode

Table 10.8 shows the snooze end request that can be used as triggers to return to Software Standby mode. The snooze end requests are available only in Snooze mode. If the requests are generated when the MCU is not in Snooze mode, they are ignored. When multiple requests are selected, each of the requests invokes transition to Software Standby mode from Snooze mode.

Table 10.9 shows the snooze end conditions that consist of the snooze end requests and the conditions of the peripheral modules. The SCI0, ADC12n (n = 0), and DTC modules can keep the MCU in Snooze mode until they complete the operation. However, an AGTn (n = 1) underflow as a trigger to return to Software Standby mode cancels Snooze mode without waiting for the completion of SCI0 operation.

Figure 10.5 shows the timing diagram for the transition from Snooze mode to Software Standby mode. This mode transition occurs according to which snooze end requests are set in the SNZEDCR0 register. A snooze request is cleared automatically after returning to Software Standby mode.

10。8。3 从贪睡模式返回到软件待机模式

表 10。8 显示了贪睡结束请求,可用作返回软件待机模式的触发器。Snooze 结束请求仅在 Snooze 模式下可用。如果请求是在 MCU 不处于 Snooze 模式时生成的,则它们将被忽略。当选择多个请求时,每个请求都会调用从 Snooze 模式到软件待机模式的转换。

表10。9显示了由贪睡端请求和外围模块的条件组成的贪睡端条件。SCI0、ADC12n（n = 0) 和 DTC 模块可以使 MCU 保持在贪睡模式,直到它们完成操作。然而,AGTn（n = 1) 底流作为返回软件待机模式的触发器会取消 Snooze 模式,而无需等待 SCI0 操作完成。

图 10。5 显示了从 Snooze 模式到软件待机模式过渡的时序图。发生这种模式转换,根据该模式转换,在 SNZEDCR0 寄存器中设置贪睡结束请求。返回软件待机模式后,贪睡请求会自动清除。

Snooze模式下使用SCI0时,使用以下设置:BGDM = 0,ABCS = 0,ABCSE = 0。有关这些位的信息,请参阅第 24 节" 串行通信接口（SCI）"。

10.9 Deep Software Standby Mode

10.9.1 Transitioning to Deep Software Standby Mode

When a WFI instruction is executed with the SBYCR.SSBY and DPSBYCR.DPSBY bits set to 1, the MCU enters Deep Software Standby mode. See Table 10.6 for the setting of the related control bits. In this mode, the CPU, on-chip peripheral functions, SRAM, and all oscillators (except for Sub-clock oscillator and Low-speed on-chip oscillator) are stopped. Also because the internal power supply to these modules is stopped, power consumption is remarkably reduced. The contents of all CPU registers and internal peripheral modules become undefined.

If the setting in the DEEPCUT[1:0] bits is 11b, the internal power supply to the LVD is stopped, and the low power mode function of the power-on reset circuit is enabled. Therefore, power consumption is further reduced. For details, see section 41, Electrical Characteristics.

When the MCU enters Deep Software Standby mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 1, power supply to the IWDT-dedicated clock and the IWDT is cut off, and counting by the IWDT stops.

When OFS0.IWDTSTPCTL bit is 0, the MCU enters Software Standby mode instead of Deep Software Standby mode, regardless of the setting of OFS0.IWDTSTRT bit or DPSBYCR.DPSBY bit. If OFS0.IWDTSTPCTL bit is 0 while OFS0.IWDTSTRT bit is 0 (auto start mode), IWDT-dedicated clock and IWDT continues the operation.

When LVD1CR0.RI = 1 (voltage monitor 1 reset selected) or LVD2CR0.RI = 1 (voltage monitor 2 reset selected), the MCU enters Software Standby mode instead of Deep Software Standby mode. The I/O port states are the same as in Software Standby mode.

Note: Conditions on the DTC, DMAC, and IWDT for transitioning to Software Standby mode should be met before the WFI instruction is executed. For details, see section 10.7. Software Standby Mode.

10.9.2 Cancelling Deep Software Standby Mode

Deep Software Standby mode is canceled by:

- An interrupt shown in Table 10.3
- A RES pin reset
- A power-on reset
- A voltage monitor 0 reset.

(1) Cancelling by an interrupt

Cancelling by interrupts is controlled by DPSIERn (n = 0 to 3) and DPSIFRn (n = 0 to 3). When a Deep Software Standby Cancelling interrupt is generated, the corresponding flag in DPSIFRn is set to 1. If the interrupt is enabled in DPSIERn, Deep Software Standby mode is canceled. Rising edge or falling edge can be selected by DPSIEGRn (n = 0 to 2). The interrupts for which an edge can be selected are the NMI, IRQn-DS (n = 0, 1, 4 to 12, 14), voltage monitor 1, and voltage monitor 2 interrupts. When a Deep Software Standby mode canceling request occurs, the internal power is supplied and MOCO starts oscillating, and an internal reset (Deep Software Standby reset) is generated for the entire MCU.

The stable MOCO clock is supplied to the entire MCU and Deep Software Standby reset is canceled. The MCU starts reset exception handling.

When Deep Software Standby mode is canceled by an external interrupt pin or internal interrupt signal, the RSTSR0.DPSRSTF flag is set to 1.

(2) Cancelling by RES pin reset

When the RES pin is driven low, the MCU cancels Deep Software Standby mode and enters the reset state. Keep the RES pin low for the time specified in section 41, Electrical Characteristics. When RES pin is driven high after the specified time period, the CPU starts the reset exception handling.

(3) Cancelling by a power-on reset

Deep Software Standby mode is canceled by a power-on reset and the MCU starts the reset exception handling.

10。9 深度软件待机模式

10。9。1 过渡到深度软件待机模式

当使用设置为 1 的 SBYCR。SSBY 和 DPSBYCR。DPSBY 位执行 WFI 指令时,MCU 进入深度软件待机模式。有关相关控制位的设置,请参阅表 10。6。在此模式下,CPU、片内外设功能、SRAM以及所有振荡器（子时钟振荡器和低速片内振荡器除外）停止运行。另外,由于这些模块的内部电源停止,功耗显着降低。CPU所有寄存器和内部外围模块的内容变得未定义。

DEEPCUT[1:0]位中的设置为11b,则停止LVD内部供电,并启用上电复位电路的低功耗模式功能。因此,功耗进一步降低。有关详细信息,请参阅第 41 节"电气特性 ."

当 MCU 进入深度软件待机模式而 IWDT 处于自动启动模式且 OFS0 时。IWDTSTPCTL 位为 1,IWDT 专用时钟的电源和 IWDT 被切断,IWDT 计数停止。

OFS0 X 1000 时,将要在 2000 年代的 IWDTSTPCTL 位为 0,MCU 进入软件待机模式而不是深度软件待机模式,无论 OFS0 的设置如何。IWDTSTRT 位或 DPSBYCR。DPSBY 位。如果 OFS0。IWDTSTPCTL 位为 0,而 OFS0。IWDTSTRT 位为 0（自动启动模式）,IWDT 专用时钟和 IWDT 继续操作。

当LVD1CR0。RI = 1（电压监视器1复位选择）或LVD2CR0。RI = 1（电压监视器2复位选择）,MCU进入软件待机模式而不是深度软件待机模式。I/O 端口状态与软件待机模式相同。

注意:在执行 WFI 指令之前,应满足 DTC、DMAC 和 IWDT 上过渡到软件待机模式的条件。详情请参见第 10。7 节。软件待机模式 .

10.9.2 取消深度软件待机模式

深度软件待机模式被以下取消:

- 表 10。3 所示的中断
- A RES 引脚重
- 上电复位
- 电压监视器 0 重置。

(1)以中断方式取消

中断消除由 DPSIERn（n = 0 至 3) 和 DPSIFRn（n = 0 至 3) 控制。当生成深度软件待机取消中断时,DPSIFRn 中的相应标志设置为 1。如果在 DPSIERn 中启用中断,则取消深度软件待机模式。上升沿或下降沿可由 DPSIEGRn 选择（n = 0 至 2)。可以选择边缘的中断是NMI、IRQn-DS（n=0、1、4至12、14)、电压监视器1和电压监视器2中断。Deep 软件待机模式取消请求时,内部供电,MOCO 开始振荡,为整个 MCU 生成内部复位（深度软件待机复位）。

稳定MOCO时钟提供给整个MCU,并取消深度软件待机重置。MCU 开始重置异常处理。

Deep 软件待机模式被外部中断引脚或内部中断信号取消时,RSTSR0。DPSRSTF 标志设置为 1。

(2)通过RES引脚复位取消

RES引脚低驱动时,MCU取消深度软件待机模式,进入复位状态。在第 41 节"电气特性"中规定的时间内保持 RES 引脚较低。RES引脚在指定时间段后被高驱动时,CPU开始重置异常处理。

(3)通电复位取消

深度软件待机模式通过开机重置取消,MCU 启动重置异常处理。

(4) Cancelling by a voltage monitor 0 reset

Deep Software Standby mode is canceled by a voltage monitor 0 reset from the voltage detection circuit and the MCU starts the reset exception handling.

10.9.3 Pin States when Deep Software Standby mode is Canceled

In Deep Software Standby mode, the I/O ports retain the same states from Software Standby mode. The MCU is initialized by an internal reset generated when Deep Software Standby mode is canceled, and reset exception handling starts immediately. The DPSBYCR.IOKEEP bit setting determines whether to initialize the I/O ports or to retain the I/O ports states for Software Standby mode. The following is the state of the I/O ports for each bit setting:

- When the DPSBYCR.IOKEEP bit = 0
  I/O ports are initialized by an internal reset generated when Deep Software Standby mode is canceled.
- When the DPSBYCR.IOKEEP bit = 1
  Although the MCU is initialized by an internal reset generated when Deep Software Standby mode is canceled, the I/O ports retain their states from Software Standby mode regardless of the MCU internal state. The I/O ports states remain unchanged from Software Standby mode even when settings are made to the I/O ports or peripheral modules. The retained I/O ports states are released by clearing the DPSBYCR.IOKEEP bit to 0, and the MCU operates according to the internal state. The DPSBYCR.IOKEEP bit is not initialized by any internal reset generated when Deep Software Standby mode is canceled.

10.9.4 Example of Deep Software Standby Mode Application

(1) Entering and exiting Deep Software Standby mode

Figure 10.8 shows an example where a transition to Deep Software Standby mode is made at the falling edge of the IRQn-DS pin, and exiting Deep Software Standby mode is made at the rising edge of the IRQn-DS pin. In this example, an IRQn interrupt is accepted with the IRQCRi.IRQMD[1:0] bits of the ICU set to 00b (falling edge). After the DPSIEGRy.DIRQnEG (y = 0 or 1, n = 0, 1, 4 to 12, 14) bit is set to 1 (rising edge) and the SBYCR.SSBY bit and DPSBYCR.DPSBY bit are both set to 1, the WFI instruction is executed. As a result, the MCU transitions to Deep Software Standby mode. Deep Software Standby mode is then canceled on the rising edge of the IRQn-DS pin.

(4)由电压监视器取消0复位

深度软件待机模式被电压监视器0从电压检测电路复位取消,并且MCU开始复位异常处理。

10。9。3 取消深度软件待机模式时的引脚状态

在深度软件待机模式下,I/O 端口保留与软件待机模式相同的状态。MCU 由取消深度软件待机模式时生成的内部复位初始化,复位异常处理立即开始。DPSBYCR。IOKEEP 位设置决定是初始化 I/O 端口还是保留软件待机模式的 I/O 端口状态。I/O 端口的状态, 以下是每个位设置的状态:

- 当 DPSBYCR。IOKEEP 位 = 0 时
  I/O 端口通过取消深度软件待机模式时生成的内部重置来初始化。
- 当 DPSBYCR。IOKEEP 位 = 1 时
  尽管 MCU 是通过取消深度软件待机模式时生成的内部重置来初始化的,但无论 MCU 内部状态如何,I/O 端口都会保留其来自软件待机模式的状态。I/O 端口状态从软件待机模式保持不变, 即使对 I/O 端口或外围模块进行设置。保留的I/O端口状态通过将DPSBYCR。IOKEEP位清除为0来释放,MCU根据内部状态运行。DPSBYCR。IOKEEP 位不会通过取消深度软件待机模式时生成的任何内部重置来初始化。

10。9。4 深度软件待机模式应用示例

(1)进出深度软件待机模式

图10。8示出了在IRQnDS引脚的下降边缘处过渡到深度软件待机模式并且在IRQn-DS引脚的上升边缘处进行退出深度软件待机模式的示例。在此示例中,ICU 的 IRQCRi。IRQMD[1:0] 位设置为 00b（下降沿）时接受 IRQn 中断。DPSIEGRy。DIRQnEG（y = 0 或 1,n = 0, 1, 4 至 12, 14)位设置为 1（上升沿）并且 SBYCR。SSBY 位和 DPSBYCR。DPSBY 位都设置为1后,执行WFI指令。结果,MCU 过渡到深度软件待机模式。IRQn-DS引脚的上升沿上取消深度软件待机模式。

10.9.5 Usage Flow for Deep Software Standby Mode

Figure 10.9 shows an example flow for using Deep Software Standby mode.

In this example, the RSTSR0.DPSRSTF flag of the reset function is read after the reset exception handling to determine whether a reset was generated by the RES pin or by the cancellation of Deep Software Standby mode.

For a reset by the RES pin, the MCU transitions to Deep Software Standby mode after the required register settings are made.

For a reset by cancellation of Deep Software Standby mode, the DPSBYCR.IOKEEP bit is cleared to 0 after the I/O port settings are made.

10.9.5 深度软件待机模式的使用流程

图 10。9 显示了使用深度软件待机模式的示例流程。

在此示例中,RSTSR0。在重置异常处理之后读取重置函数的DPSRSTF标志,以确定重置是由RES引脚生成的还是通过取消深度软件待机模式生成的。

对于 RES 引脚的重置,在进行所需的寄存器设置后,MCU 会转换为深度软件待机模式。

对于通过取消深度软件待机模式进行重置,在进行 I/O 端口设置后,DPSBYCR。IOKEEP 位被清除为 0。

(8) Invalid write access when when PRCR.PRC4 bit is 0

Do not write to registers listed in this section when the PRCR.PRC4 bit is 0.

[Registers]

10.10.2 I/O Port pin states

The I/O port pin states in Software Standby mode, Deep Software Standby and Snooze mode, unless modifying in Snooze mode, are the same before entering the modes. Therefore, power consumption is not reduced while the output signals are held high.

10.10.3 Module-Stop State of DTC, DMAC

Before writing 1 to MSTPCRA.MSTPA22, clear the DMAST.DMST bit of the DMAC and the DTCST.DTCST bit of the DTC to 0. For details, see section 15, DMA Controller (DMAC) and section 16, Data Transfer Controller (DTC).

10.10.4 Internal Interrupt Sources

Interrupts do not operate in the module-stop state. If setting the module-stop bit while an interrupt request is generated, a CPU interrupt source or a DTC or DMAC startup source cannot be cleared. Always disable the associated interrupts before setting the module-stop bits.

10.10.5 Input Buffer Control by DIRQnE Bit

Setting the DPSIERy.DIRQnE (y = 0 or 1, n = 0, 1, 4 to 12, 14) bit to 1 enables the associated input buffer of the IRQn-DS (n = 0, 1, 4 to 12, 14) pins. Although inputs to these pins are sent to the DPSIFRy.DIRQnF (y = 0 or 1, n = 0, 1, 4 to 12, 14) bits, they are not sent to the interrupt controller (ICU), peripheral modules, and I/O ports.

10.10.6 Transitioning to Low Power Modes

Because the MCU does not support wakeup by events, do not enter the low power modes such as Sleep mode, Software Standby mode or Deep Software Standby Mode by executing a WFE instruction. Also, do not set the SLEEPDEEP bit of the System Control Register in the Cortex-M33 core because the MCU does not support low power modes by SLEEPDEEP.

10.10.7 Timing of WFI Instruction

It is possible for the WFI instruction to be executed before I/O register area writes are completed, in which case operation might not be as intended. This can happen if the WFI is placed immediately after a write to an I/O register. To avoid this problem, read back the register that was written to confirm that the write completed.

(6)对FLWT。FLWT的写访问无效[2:0]

000b 以外的任何值,请勿在列出的条件下写入 FLWT。FLWT[2:0] 位。

的【条件】

- SOPCCR。SOPCM = 1（亚音速模式）

(7) PRCR。PRC1 为 0 时写入访问无效

当 PRCR。PRC1 位为 0 时,请勿写入本节中列出的寄存器。

的【注册】

- SBYCR、SNZCR、SNZEDCRn、SNZREQCRn、OPCCR、SOPCCR、DPSBYCR、DPSWCR、DPSIERn、DPSIFRn、DPSIGRn、SYOCDCR

当 PRCR。PRC4 位为 0 时,请勿写入本节中列出的寄存器。

的【注册】

- LPMSAR、DPFSAR

10。10。2 I/O 端口引脚状态

I/O端口引脚在软件待机模式、深度软件待机和Snooze模式下状态,除非在Snooze模式下进行修改,否则在进入模式之前是相同的。因此,当输出信号保持较高时,功耗不会降低。

10。10。3 DTC、DMAC 的模块停止状态

在将 1 写入 MSTPCRA。MSTPA22 之前,将 DMAC 的 DMAST。DMST 位和 DTC 的 DTCST。DTCST 位清除为 0。有关详细信息,请参阅第 15 节 DMA 控制器（DMAC）和第 16 节数据传输控制器（DTC）。

10。10。4 内部中断源

中断在模块停止状态下不起作用。如果在生成中断请求时设置模块停止位,则无法清除 CPU 中断源或 DTC 或 DMAC 启动源。在设置模块停止位之前,请务必禁用关联的中断。

10.10.5 DIRQnE 位输入缓冲区控制

将 DPSIERy。DIRQnE（y = 0 或 1,n = 0,1,4 至 12,14)位设置为 1 可以启用 IRQn-DS（n = 0,1,4 至 12,14)的关联输入缓冲区引脚。尽管这些引脚的输入被发送到 DPSIFRy。DIRQnF（y = 0 或 1,n = 0、1、4 至 12、14)位,但它们不会发送到中断控制器（ICU）、外围模块和I/O 端口。

10.10.6 过渡到低功耗模式

由于MCU不支持事件唤醒,因此请勿通过执行WFE指令进入睡眠模式、软件待机模式或深度软件待机模式等低功耗模式。此外,请勿在 Cortex-M33 内核中设置系统控制寄存器的 SLEEPDEEP 位,因为 MCU 不支持 SLEEPDEEP 的低功耗模式。

10。10。7 WFI 指令的时机

I/O 寄存器区域写入完成之前,WFI 指令有可能被执行,在这种情况下,操作可能不符合预期。如果在写入 I/O 寄存器后立即放置 WFI,则可能会发生这种情况。为了避免这个问题,请读回写入的寄存器以确认写入已完成。

10.10.8 Writing to the WDT/IWDT Registers by DTC or DMAC in Sleep Mode or Snooze Mode

Do not write to the WDT or IWDT registers by the DTC or DMAC while WDT or IWDT is stopped after entering Sleep mode or Snooze mode.

10.10.9 Oscillators in Snooze Mode

Oscillators that stop on entering Software Standby mode automatically restart when a trigger for switching to Snooze mode is generated. The MCU does not enter Snooze mode until all the oscillators stabilize. If in Snooze mode, you must disable oscillators that are not required in Snooze mode before entering Software Standby mode. Otherwise, the transition from Software Standby mode to Snooze mode takes longer.

10.10.10 Snooze Mode Entry by RXD0 Falling Edge

When the SNZCR.RXDREQEN bit is 1, the falling edge of RXD0 pin is used to switch MCU from Software Standby mode to Snooze mode when using UART of SCI0 in Snooze mode. In this case an interrupt such as SCI0_ERI, SCI0_RXI or an address mismatch event is used as the source for canceling Snooze mode. However noise on the RXD0 pin might cause the MCU to transfer from Software Standby mode to Snooze mode unexpectedly. In this case if the MCU does not receive RXD0 data after the noise, an interrupt such as SCI0_ERI or SCI0_RXI, or an address mismatch event is not generated and the MCU stays in Snooze mode. This can be avoided by using AGTn (n = 1) underflow interrupt to return to Software Standby mode or Normal mode unless otherwise UART receive data is completed before AGTn (n = 1) underflow. However, do not use the AGTn (n = 1) underflow as a source to return to Software Standby mode during an UART communication. This causes the UART to stop the operation in a half-finished state.

10.10.11 Using UART of SCI0 in Snooze Mode

When using UART in Snooze mode, ensure that the snooze request (RXD0 falling edge) does not conflict with the wakeup requests set by the WUPEN register, otherwise UART cannot be guaranteed.

When using UART in Snooze mode, the following conditions must be satisfied:

- The clock source must be HOCO
- MOCO, PLL, and the main clock oscillator must be stopped before entering Software Standby mode
- The RXD0 pin must be kept high before entering Software Standby mode
- A transition to Software Standby mode must not occur during an SCI0 communication
- The MSTPCRC.MSTPC0 bit must be 1 before entering Software Standby mode.

10.10.12 Conditions of A/D Conversion Start in Snooze Mode

ADC120 can only be triggered by the ELC in Snooze mode. Do not use software trigger or ADTRGn (n = 0) pin.

10.10.13 ELC Events in Snooze Mode

This section lists available ELC events in Snooze mode. Do not use any other events. If starting peripheral modules for the first time after entering Snooze mode, the Event Link Setting Register (ELSRn) must set a Snooze mode entry event (SYSTEM_SNZREQ) as the trigger.

- Snooze mode entry (SYSTEM_SNZREQ)
- DTC transfer end (DTC_DTCEND)
- ADC120 window A/B compare match (ADC120_WCMPM)
- ADC120 window A/B compare mismatch (ADC120_WCMPUM)
- Data operation circuit interrupt (DOC_DOPCI).

10.10.14 Module-Stop Bit Write Timing

It is possible that access to I/O register may be executed before the corresponding module-stop bit write completed. In this case, access to I/O register may not proceed as intended. To avoid this issue, before accessing I/O register, read back the module-stop bit that was written to confirm that the write completed.

10。10。8 在睡眠模式或贪睡模式下 由 DTC 或 DMAC 写入 WDT/IWDT 寄存器

当进入睡眠模式或贪睡模式后停止 WDT 或 IWDT 时,请勿通过 DTC 或 DMAC 写入 WDT 或 IWDT 寄存器。

10。10。9 贪睡模式下的振荡器

当生成切换到 Snooze 模式的触发器时,停止进入软件待机模式的振荡器会自动重新启动。在所有振荡器稳定之前,MCU 不会进入 Snooze 模式。如果处于 Snooze 模式,则在进入软件待机模式之前,必须禁用 Snooze 模式中不需要的振荡器。否则,从软件待机模式到贪睡模式的过渡需要更长的时间。

10。10。10 RXD0 Falling Edge 的贪睡模式输入

当SNZCR。RXDREQEN位为1时,当在Snooze模式下使用SCI0的UART时,使用RXD0引脚的下落边缘将MCU从软件待机模式切换到Snooze模式。在这种情况下,使用诸如SCI0_ERI、SCI0_RXI之类的中断或地址不匹配事件作为取消Snooze模式的源。然而,RXD0 引脚上的噪声可能会导致 MCU 意外地从软件待机模式转移到 Snooze 模式。在这种情况下,如果MCU在噪声之后没有接收到RXD0数据,则不会生成诸如SCI0_ERI或SCI0_RXI之类的中断,或者地址不匹配事件并且MCU保持在Snooze模式。通过使用 AGTn（n = 1）底流中断返回到软件待机模式或正常模式可以避免这种情况,除非在 AGTn（n = 1）底流之前完成 UART 接收数据。但是,在 UART 通信期间,请勿使用 AGTn（n = 1）底流作为源返回到软件待机模式。这导致 UART 在半完成状态下停止操作。

10。10。11 在贪睡模式下使用 SCI0 的 UART

Snooze 模式下使用 UART 时,确保 snooze 请求（RXD0 下降沿）不会与 WUPEN 寄存器设置的唤醒请求发生冲突,否则无法保证 UART。

Snooze 模式下使用 UART 时, 必须满足以下条件:

- 时钟源必须是 HOCO
- MOCO、PLL 和主时钟振荡器在进入软件待机模式之前必须停止
- 在进入软件待机模式之前,必须将 RXD0 引脚保持在较高位置
- 在 SCI0 通信期间不得发生向软件待机模式的转换
- 在进入软件待机模式之前,MSTPCRC。MSTPC0 位必须为 1。

10.10.12 Snooze 模式下 A/D 转换开始的条件

ADC120 只能在贪睡模式下由 ELC 触发。请勿使用软件触发器或 ADTRGn（n = 0）引脚。

10。10。13 贪睡模式下的 ELC 事件

本节列出了 Snooze 模式下的可用 ELC 事件。请勿使用任何其他事件。Snooze模式后第一次启动外围模块,则事件链接设置寄存器（ELSRn）必须设置一个Snooze模式进入事件（SYSTEM_SNZREQ）作为触发器。

- 贪睡模式条目（SYSTEM_SNZREQ）
- DTC 传输端（DTC_DTCEND）
- ADC120 窗口 A/B 比较匹配（ADC120_WCMPM）
- ADC120 窗口 A/B 比较不匹配（ADC120_WCMPUM）
- 数据操作电路中断（DOC_DOPCI）。

10。10。14 模块停止位写入定时

可以在相应的模块停止位写入完成之前执行对I/O寄存器的访问。在这种情况下,对 I/O 寄存器的访问可能无法按预期进行。为了避免此问题,在访问 I/O 寄存器之前,读回已写入的模块停止位以确认写入已完成。

Low power modes		• Sleep mode: return is initiated by non-maskable interrupts or any other interrupt source • Software Standby mode: return is initiated by non-maskable interrupts. Interrupt can be selected in the WUPEN register. • Snooze mode: return is initiated by non-maskable interrupts. Interrupt can be selected in the SELSR0 and WUPEN registers. See section 12.2.17. SELSR0 : SYS Event Link Setting Register and section 12.2.18. WUPEN0 : Wake Up Interrupt Enable Register 0, section 12.2.19. WUPEN1 : Wake Up Interrupt Enable Register 1.
TrustZone Filter		Available

Note 1. For the DMAC and DTC activation sources, see Table 12.4.
Note 2. Non-maskable interrupts can be enabled only once after a reset release.
Note 3. These non-maskable interrupts can also be used as maskable interrupts. When used as maskable interrupts, do not change the value of the NMIER register from the reset state. To enable voltage monitor 1 and voltage monitor 2 interrupts, set the LVD1CR1.IRQSEL and LVD2CR1.IRQSEL bits to 1.
Note 4. Low level: interrupt detection is not canceled if you do not clear it after a detection.

The value of AIRCR.BFHFNMINS bit [13] in Application Interrupt and Reset Control Register of ARM CPU should be the same as the value of security attribution. The initial values of AIRCR.BFHFNMINS and the SANMI bits are different. AIRCR.BFHFNMINS is secure and SANMI is non-secure. Polarity has the same meaning so program these to match.

Note: Only one of Secure and Non-Secure can set security attribution for non-maskable interrupt-related registers. If you program the Secure attribute as secure, it always goes to the Secure interrupt handler. To release any of the non-maskable interrupt sources to the non-secure user, write a function to execute a nonsecure program from the interrupt handler for Secure.

ARM CPU 的应用程序中断和重置控制寄存器中的 AIRCR。BFHFNMINS 位 [13] 的值应与安全归因的值相同。AIRCR。BFHFNMINS 和 SANMI 位的初始值不同。AIRCR。BFHFNMINS 是安全的,SANMI 是非安全的。极性具有相同的含义,因此对这些进行编程以匹配。

注意:只有 Secure 和 Non-Secure 之一可以为不可屏蔽的中断相关寄存器设置安全归属。如果您将 Secure 属性编程为 secure,它总是会转到 Secure 中断处理程序。要向非安全用户释放任何不可屏蔽的中断源,请编写一个函数从安全中断处理程序执行非安全程序。

注: 该寄存器受 PRCR 寄存器写保护。

SAIELSRn 位（IELSR95 至 IELSR64 寄存器的安全属性）

ARM CPU NVIC 内管理的安全属性必须匹配 IELSEn 的安全属性（n = 64 至 95）。
NVIC 内部寄存器位于 NVIC_ITNS2[31:0]。NVIC_ITNS2 和 ICUSARI 的初始值不同。
NVIC_ITNS2 是安全的,ICUSARI 是非安全的。极性具有相同的含义,因此对这些进行编程以匹配。

如果安全属性配置为非安全:

- Secure and Non-secure access are allowed.

IRQCRi register changes must satisfy the following conditions:

- For a CPU interrupt or DTC trigger:
  Change the IRQCRi register value before setting the target IELSRn register (n = 0 to 95).
  The register value should be changed only when the value of the target IELSRn register is 0x0000.
- For a DMAC trigger:
  Change the IRQCRi register value before setting the target DELSRn register (n = 0 to 7).
  The register value should be changed only when the value of the target DELSRn register is 0x0000.
- For a wakeup enable signal:
  Change the IRQCRi register setting before setting the target WUPEN0.IRQWUPEN[n] (n = 0 to 14). The register value should be changed when the target WUPEN0.IRQWUPEN[n] is 0.

IRQMD[1:0] bits (IRQi Detection Sense Select)

The IRQMD[1:0] bits set the detection sensing method for the IRQi external pin interrupt sources. For setting method when using external pin interrupt, see section 12.5.6. External Pin Interrupts.

FCLKSEL[1:0] bits (IRQi Digital Filter Sampling Clock Select)

The FCLKSEL[1:0] bits select the digital filter sampling clock for the IRQi external pin interrupt request pins, selectable to:

- PCLKB (every cycle)
- PCLKB/8 (once every 8 cycles)
- PCLKB/32 (once every 32 cycles)
- PCLKB/64 (once every 64 cycles)

For details of the digital filter, see section 12.5.5. Digital Filter.

FLTEN bit (IRQi Digital Filter Enable)

The FLTEN bit enables the digital filter used for the IRQi external pin interrupt sources. The digital filter is enabled when the IRQCRi.FLTEN bit is 1 and disabled when the IRQCRi.FLTEN bit is 0. The IRQi pin level is sampled at the clock cycle specified in the IRQCRi.FCLKSEL[1:0] bits. When the sampled level matches three times, the output level from the digital filter changes. For details of the digital filter, see section 12.5.5. Digital Filter.

  在设置目标 IELSRn 寄存器之前更改 IRQCRi 寄存器值（n = 0 到 95）。
  仅当目标 IELSRn 寄存器的值为 0x0000 时才应更改寄存器值。

NMIMD bit (NMI Detection Set)

The NMIMD bit selects the detection sensing method for the NMI pin interrupts.

NFCLKSEL[1:0] bits (NMI Digital Filter Sampling Clock Select)

The NFCLKSEL[1:0] bits select the digital filter sampling clock for the NMI pin interrupts, selectable to:

- PCLKB (every cycle)
- PCLKB/8 (once every 8 cycles)
- PCLKB/32 (once every 32 cycles)

NFLTEN bit (NMI Digital Filter Enable)

The NFLTEN bit enables the digital filter used for NMI pin interrupts. The filter is enabled when NFLTEN is 1, and disabled when NFLTEN is 0. The NMI pin level is sampled at the clock cycle specified in NFCLKSEL[1:0]. When the sampled level matches three times, the output level from the digital filter changes. For details of the digital filter, see section 12.5.5. Digital Filter.

Note 1. Writing 1 to the IR flag is prohibited.

The IELSRn register selects the IRQi source used by the NVIC. For details, see Table 12.3. IELSRn corresponds to the NVIC IRQ input source number, where n = 0 to 95.

IELS[8:0] bits (ICU Event Link Select)

The IELS[8:0] bits link an event signal to the associated NVIC or DTC module. Event options are classified into 8 groups (groups 0 to 7). For details, see Table 12.3 and Table 12.4.

IR flag (Interrupt Status Flag)

The IR status flag indicates an individual interrupt request from the event specified in IELS[8:0].

[Setting condition]

When an interrupt request is received from the associated peripheral module or IRQi pin.

[Clearing condition]

- The IR flag is cleared to 0 by writing 0.
- At the time other than the final transfer transfer end in DTC transfer during DTCE = 1, IR flag repeat set and cleared by Hardware.

When DTC transfer except last transfer is completed (DTCE bit is changed from 1 to 0).

During DTCE = 1, write 0 to IR register is prohibited.

In the case of level detection, clear of the IR flag should follow the steps below.

1. Negate the input interrupt signal.
2. Read access the peripheral once and wait for 2 clock cycles of the target module clock.
3. Clear the IR flag by writing 0.

DTCE bit (DTC Activation Enable)

When the DTCE bit is set to 1, the associated event is selected as the source for DTC activation.

[Setting condition]

- When 1 is written to the DTCE bit.

[Clearing condition]

- When the specified number of transfers is complete. For chain transfers, when the specified number of transfers for the last chain transfer is complete.
- When 0 is written to the DTCE bit.

Note: Error during DTC transfer

If an error response occurs during DTC transfer, the DTC notifies the ICU that an error has occurred. ICU clears all bits of the target IELSRn (n = 0 to 95). IELSRn that is not the target is not cleared.

Note: DTC transfer error in snooze mode

When an error occurs in DTC transfer in Snooze mode, ICU issues a wakeup request. However, interrupt requests are not issued automatically. See section 16, Data Transfer Controller (DTC) for how to set the interrupt when a DTC error occurs.

注1。禁止将 1 写入 IR 标志。

IELSRn 寄存器选择 NVIC 使用的 IRQi 源。详情见表12。3。IELSRn 对应于 NVIC IRQ 输入源编号,其中 n = 0 到 95。

IELS[8:0] 位（ICU 事件链接选择）

IELS[8:0] 位将事件信号链接到关联的 NVIC 或 DTC 模块。活动选项分为 8 组(0 至 7 组）。有关详细信息,请参阅表 12。3 和表 12。4 .

IR 标志（中断状态标志）

IR状态标志指示来自IELS[8:0]中指定的事件的个人中断请求。

的【设置条件】

当从相关联的外围模块或 IRQi 引脚接收到中断请求时。

的【清零条件】

- 通过写入 0 将 IR 标志清除为 0。
- 在 DTCE = 1 期间 DTC 传输中的最终传输传输端之外的时间,IR 标志重复设置并由硬件清除。

DTC 传输时,除了最后一个传输之外（DTCE 位从 1 更改为 0)。

DTCE = 1期间,禁止将0写入IR寄存器。

在电平检测的情况下,清除 IR 标志应遵循以下步骤。

1。否定输入中断信号。

2锛姣涓涓。1次读取访问外设,并等待目标模块时钟的2个时钟周期。

3锛　　娴　　。写入 0 清除 IR 标志。

DTCE 位（启用 DTC 激活）

DTCE 位设置为 1 时,相关事件被选择为 DTC 激活的源。

的【设置条件】

- 当 1 写入 DTCE 位时。

的【清零条件】

- 当指定的传输次数完成时。对于链式转移,当最后一次链式转移的指定转移次数完成时。
- 当 0 写入 DTCE 位时。

注意:DTC 传输期间出错

DTC 传输过程中发生错误响应,则 DTC 通知 ICU 发生错误。ICU 清除目标 IELSRn 的所有位（n = 0 到 95)。不是目标的 IELSRn 不会被清除。

注意:贪睡模式下的 DTC 传输错误

Snooze 模式下 DTC 传输发生错误时,ICU 会发出唤醒请求。但是,中断请求不会自动发出。DTC 错误发生时如何设置中断,请参阅第 16 节"数据传输控制器（DTC）"。

If the security attribution is configured as Non-secure:

Note 1. Writing 1 to the IR flag is prohibited.

DELS[8:0] bit (DMAC Event Link Select)

The DELS[8:0] bits link an event signal to the associated DMAC module. Do not set the same event number in multiple DELSRn registers.

IR flag (DMAC Activation Request Status Flag)

The IR flag is the status flag of a DMAC activation request. This flag is associated with the DELS[8:0] bits of this register.

[Setting condition]

The flag is set to 1 when a DMAC activation request is generated from the associated peripheral module or IRQi pin.

[Clearing conditions]

- When 0 is written to the IR flag.
- At the start of a DMA transfer after the DMAC activation request is issued.

Note: The IR flag is automatically cleared after completion of a DMA transfer. Therefore, do not write 0 unless an abort occurs. When 0 is written, DMA transfer operation cannot be guaranteed.

Note: Error during DMAC transfer

If an error response occurs during a DMAC transfer, the DMAC notifies the ICU that an error has occurred.

The ICU clears all bits of the target channel of DELSRn (n = 0 to 7). DELSRn that is not the target channel is not cleared.

DELS[8:0] 位（DMAC 事件链接选择）

DELS[8:0] 位将事件信号链接到关联的 DMAC 模块。不要在多个事件中设置相同的事件编号 DELSRn 寄存器。

IR 标志（DMAC 激活请求状态标志）

IR 标志是 DMAC 激活请求的状态标志。该标志与该寄存器的 DELS[8:0] 位相关联。

的【设置条件】

当从相关联的外围模块或IRQi引脚生成DMAC激活请求时,标志被设置为1。

的【清算条件】

- 当 0 写入 IR 标志时。
- 在发出 DMAC 激活请求后的 DMA 传输开始时。

注意:完成 DMA 传输后,IR 标志将自动清除。因此,除非发生中止,否则请勿写入 0。0 写入时,无法保证 DMA 传输操作。

注意:DMAC 传输期间出错

如果在 DMAC 传输期间发生错误响应,DMAC 会通知 ICU 已发生错误。

The SELSR0 register selects the events that wake up the CPU from Snooze mode. You can use only the events listed in Table 12.4 checked as “Canceling Snooze mode”. When ICU_SNZCANCEL is selected in the IELSRn.IELS[8:0] bits, an interrupt is generated that cancels snooze mode.

Caution: For security attribution added to parts related to a series of actions, make sure to match all security attribution so that security holes cannot be created.

I3CWUPEN bit (I3C Address Match Interrupt Software Standby/Snooze Mode Returns Enable bit)

I3CWUPEN is the enable bit to control the use of the I3C interrupt as a Software standby return factor.

Note: The security attribution of this register is set for each wakeup event.
To avoid the occurrence of a security hole, the target event of a wakeup and the security attribution added to this bit must match.

12.3 Vector Table

The ICU detects maskable and non-maskable interrupts. Interrupt priorities are set up in the Arm NVIC. For information about these registers, see section 12.9. Reference.

12.3.1 Interrupt Vector Table

Note 2. Only interrupts after DTC transfer are supported.
Note 3. Using SELSR0.
Note 4. Only supported when CMPCTL.CSTEN = 1.

12.4 Interrupt Operation

The ICU performs the following functions:

- Detecting interrupts
- Enabling and disabling interrupts
- Selecting interrupt request destinations such as CPU interrupt, DTC activation, or DMAC activation.

12.4.1 Detecting Interrupts

The ICU selects an event source input from a peripheral function interrupt or an external pin interrupt with IELSRn.IELS [8:0].

The accepted interrupt source sets the IELSRn.IR to 1 and sends an interrupt request to the NVIC.

External pin interrupt requests are detected by either:

- Edges (falling edge, rising edge, or rising and falling edges)
- Level (low level) of the interrupt signal.

Set the IRQCRi.IRQMD[1:0] bits to select the detection mode for the IRQi pins. For interrupt sources associated with peripheral modules, see Table 12.3 and Table 12.4. Events must be accepted by the NVIC before an interrupt occurs and is accepted by the CPU.

12。4 中断操作

ICU执行以下功能:

- 检测中断
- 启用和禁用中断
- 选择中断请求目的地,例如 CPU 中断、DTC 激活或 DMAC 激活。

12.4.1 检测中断

ICU 使用 IELSRn。IELS [8:0] 从外围功能中断或外部引脚中断中选择事件源输入。

接受的中断源将 IELSRn。IR 设置为 1 并向 NVIC 发送中断请求。

外部引脚中断请求由以下任一方式检测:

- 边（下降边、上升边或上升和下降边）
- 中断信号的电平（低电平）。

设置 IRQCRi。IRQMD[1:0] 位以选择 IRQi 引脚的检测模式。有关与外围模块关联的中断源,请参见表 12。3 和表 12。4。事件必须在中断发生之前被 NVIC 接受并被 CPU 接受。

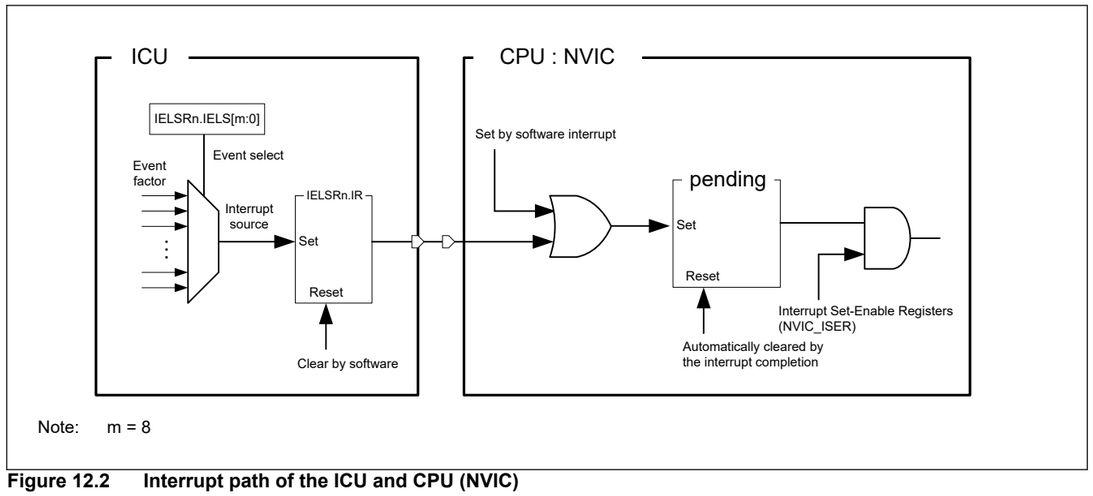

Figure 12.2 Interrupt path of the ICU and CPU (NVIC)

12.5 Interrupt setting procedure

12.5.1 Enabling Interrupt Requests

The procedure for enabling an interrupt request is as follows:

1. Set the Interrupt Set-Enable register (NVIC_ISER).
2. Set the IELSRn.IELS[8:0] bits as the interrupt source.
3. Specify the operation settings for the event source, such as DMAC activation (DELSRn.DELS[8:0]), snooze mode cancellation (SELSR0.SELS[8:0]), software standby mode cancellation (WUPEN register setting).

12.5.2 Disabling Interrupt Requests

The procedure to disable the interrupt request is as follows:

1. Disable the operation settings for the event source, such as DMAC activation (DELSRn.DELS[8:0]), snooze mode cancellation (SELSR0.SELS[8:0]), software standby mode cancellation (WUPEN register setting).
2. Clear the interrupt source setting (IELSRn.IELS[8:0] = 0x00).
3. Clear the interrupt status flag (IELSRn.IR = 0).
4. Clear the interrupt Clear-Enable register (NVIC_ICER) and interrupt Clear-Pending register (NVIC_ICPR).

12.5.3 Polling for interrupts

The procedure for polling for interrupt requests is as follows:

1. Set the Interrupt Clear-Enable register (NVIC_ICER).
2. Set the IELSRn.IELS[8:0] bits as the interrupt source.
3. Specify the operation settings for the event source, such as DMAC activation (DELSRn.DELS[8:0]), snooze mode cancellation (SELSR0.SELS[8:0]), software standby mode cancellation (WUPEN register setting).
4. Poll the interrupt Set-Pending register (NVIC_ISPR).

12.5.4 Selecting Interrupt Request Destinations

The available destinations are fixed for each interrupt, as described in Table 12.3, Table 12.4.

The interrupt output destination, CPU, DMAC, or DTC can be independently selected for each interrupt source.

Use an interrupt request destination setting that is indicated by a "✓" in the event list (see section 12.3.2. Event Number).

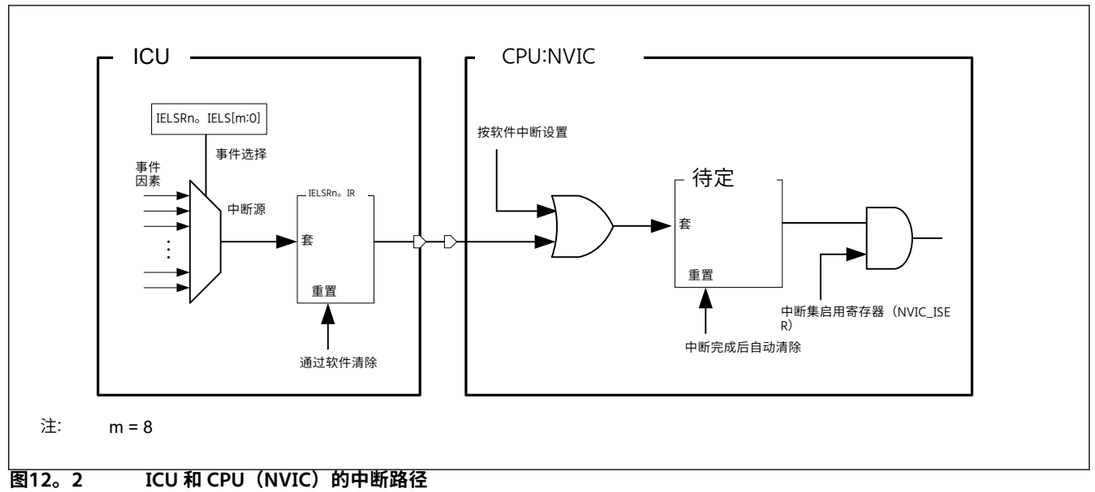

图12。2 ICU 和 CPU（NVIC）的中断路径

12.5 中断设置过程

12。5。1 启用中断请求

启用中断请求的程序如下:

1。设置中断集启用寄存器（NVIC_ISER）。

2锛姣涓涓。将 IELSRn。IELS[8:0] 位设置为中断源。

3锛 娴 。指定事件源的操作设置,例如 DMAC 激活（DELSRn。DELS[8:0]）、贪睡模式取消（SELSR0）。SELS[8:0]),软件待机模式取消（WUPEN寄存器设置）。

12。5。2 禁用中断请求

禁用中断请求的过程如下:

1。禁用事件源的操作设置,例如 DMAC 激活（DELSRn。DELS[8:0]）、贪睡模式取消（SELSR0）。SELS[8:0]),软件待机模式取消（WUPEN寄存器设置）。

2锛姣涓涓。清除中断源设置（IELSRn。IELS[8:0] = 0x00)。

3锛 娴 。清除中断状态标志（IELSRn。IR = 0)。

4锛姣涓。清除中断清除启用寄存器（NVIC_ICER）和中断清除待处理寄存器（NVIC_ICPR）。

12。5。3 中断投票

中断请求的轮询程序如下:

1。设置中断清除启用寄存器（NVIC_ICER）。

2锛姣涓涓。将 IELSRn。IELS[8:0] 位设置为中断源。

3锛 娴 。指定事件源的操作设置,例如 DMAC 激活（DELSRn。DELS[8:0]）、贪睡模式取消（SELSR0）。SELS[8:0]),软件待机模式取消（WUPEN寄存器设置）。

4锛姣涓。轮询中断设置待处理寄存器（NVIC_ISPR）。

12。5。4 选择中断请求目的地

每个中断的可用目的地都是固定的,如表 12。3、表 12。4 . 中所述
可以为每个中断源独立选择中断输出目的地、CPU、DMAC或DTC。

在事件列表中使用由 " ✓ " 指示的中断请求目标设置（参见第 12。3。2 节）。事件编号).

Note: Setting the same interrupt source for IELSRn and DELSRn is prohibited.

If the DMAC or DTC is selected as the destination for requests from an IRQi pin, you must set the IRQCRi.IRQMD[1:0] bits for that interrupt to select edge detection.

12.5.4.1 CPU interrupt request

When IELSRn.DTCE = 0, the event specified in the IELSRn register is output to the NVIC. Set the IELSRn.IELS[8:0] bits to the target event and set the IELSRn.DTCE bit to 0.

12.5.4.2 DTC activation

When IELSRn.DTCE = 1, the event specified in the IELSRn register is output to the DTC. Use the following procedure:

1. Set the IELSRn.IELS[8:0] bits to the target event and set the IELSRn.DTCE bit to 1.
2. Set the DTC Module Start bit (DTCST.DTCST) to 1.

Table 12.5 shows operation when the DTC is the interrupt request destination.

Table 12.5 Operation when DTC becomes interrupt request destination

Interrupt request destination	DISEL*1	Remaining transfer operations	Operation per request	IR*2	Interrupt request destination after transfer
DTC*3	1	≠ 0	DTC transfer → CPU interrupt	Cleared on interrupt acceptance by the CPU	DTC
		= 0	DTC transfer → CPU interrupt	Cleared on interrupt acceptance by the CPU	CPU (IELSRn.DTCE bit is automatically cleared)
	0	≠ 0	DTC transfer	Cleared at the start of DTC data transfer after reading DTC transfer data	DTC
		= 0	DTC transfer → CPU interrupt	Cleared on interrupt acceptance by the CPU	CPU (IELSRn.DTCE bit is automatically cleared)

Note 1. DTC.MRB.DISEL bit controles the interrupt generates timing from DTC to CPU.
Note 2. When the IELSRn.IR flag is 1, an interrupt request (DTC activation request) that occurs again is ignored.
Note 3. For chain transfers, DTC transfer continues until the last chain transfer ends. The DISEL bit state and the remaining transfer count determine whether a CPU interrupt occurs, the IELSRn.IR flag clear timing, and the interrupt request destination after transfer. See Table 16.2 in section 16, Data Transfer Controller (DTC).

Note: Error during DTC transfer

If an error response occurs during DTC transfer, the DTC notifies the ICU that an error has occurred. ICU clears all bits of the target IELSRn (n = 0 to 95). IELSRn that is not the target is not cleared.

Note: DTC transfer error in snooze mode

When an error occurs in DTC transfer in Snooze mode, ICU issues a Wake Up request. However, interrupt requests are not issued automatically. See section 16, Data Transfer Controller (DTC) chapter for information on how to set the interrupt when a DTC error occurs.

12.5.4.3 DMAC Activation

Events specified in the DELSRn registers are output to the DMAC.

To set the interrupt source for DMAC, use the following procedure:

1. Set the DELSRn.DELS[8:0] bits to the event to activate the DMAC.
2. When using interrupts to CPU, set the IELSRn.IELS bit to factor of DMAC interrupt and IELSRn.DTCE bit to 0.
3. Set the activation source for the target DMAC channel (DMACm.DMTMD.DCTG[1:0]) to 01b (interrupt module detection).
4. Set the DMAC transfer enable bit for the target DMAC channel (DMACm.DMCNT.DTE) to 1.
5. Set the DMAC operation enable bit (DMAST.DMST) to 1.

注意:禁止为 IELSRn 和 DELSRn 设置相同的中断源。

如果选择 DMAC 或 DTC 作为 IRQi 引脚请求的目的地,则必须为该中断设置 IRQCRi。IRQMD[1:0] 位以选择边缘检测。

12。5。4。1 CPU 中断请求

当IELSRn。DTCE = 0时,IELSRn寄存器中指定的事件被输出到NVIC。将 IELSRn。IELS[8:0] 位设置为目标事件,并将 IELSRn。DTCE 位设置为 0。

12。5。4。2 DTC 激活

当IELSRn。DTCE = 1时,IELSRn寄存器中指定的事件被输出到DTC。使用以下程序:

1。将 IELSRn。IELS[8:0] 位设置为目标事件,并将 IELSRn。DTCE 位设置为 1。

2锛姣涓涓。将 DTC 模块开始位（DTCST。DTCST）设置为 1。

表 12。5 显示了 DTC 是中断请求目的地时的操作。表 12。5 DTC 成为中断请求目的地时的操作

中断请求目的地	DISEL*1	剩余的转移操作	根据请求进行操作	IR*2	传输后中断请求目的地
DTC*3	1	≠ 0	DTC 传输 → CPU 中断	CPU 中断接受时清除	DTC
		= 0	DTC 传输 → CPU 中断	CPU 中断接受时清除	CPU（IELSRn。DTCE 位自动清除）
	0	≠ 0	DTC 传输	DTC 数据传输开始时读取 DTC 传输数据后清除	DTC
		= 0	DTC 传输 → CPU 中断	CPU 中断接受时清除	CPU（IELSRn。DTCE 位自动清除）

注1。DTC。MRB。DISEL 位控制中断生成从 DTC 到 CPU 的定时。
注2。IELSRn。IR标志为1时,再次发生的中断请求（DTC激活请求）被忽略。
注3。对于链式传输,DTC 传输持续到最后一个链式传输结束。DISEL 位状态和剩余的传输计数来确定是否发生 CPU 中断、IELSRn。IR 标志清除定时以及传输后的中断请求目的地。16节中见表16。2,数据传输控制器（DTC）。

注意:DTC 传输期间出错

DTC 传输过程中发生错误响应,则 DTC 通知 ICU 发生错误。ICU 清除目标 IELSRn 的所有位（n = 0 到 95)。不是目标的 IELSRn 不会被清除。

注意:贪睡模式下的 DTC 传输错误

当 Snooze 模式下的 DTC 传输发生错误时,ICU 会发出唤醒请求。但是,中断请求不会自动发出。有关 DTC 错误发生时如何设置中断的信息,请参阅第 16 节"数据传输控制器（DTC）"章节。

12。5。4。3 DMAC 激活

DELSRn 寄存器中指定的事件被输出到 DMAC。DMAC 的中断源进行设置, 请使用以下过程:

1。将 DELSRn。DELS[8:0] 位设置为事件以激活 DMAC。

2锛姣涓涓。当使用 CPU 中断时,将 IELSRn。IELS 位设置为 DMAC 中断因子,将 IELSRn。DTCE 位设置为 0。

3锛 娴 。将目标DMAC通道（DMACm。DMTMD。DCTG[1:0])的激活源设置为01b（中断模块检测）。

4锛姣涓。将目标DMAC信道（DMACm。DMCNT。DTE）的DMAC传输使能位设置为1。

5锛姣涓涓。将 DMAC 操作使能位（DMAST。DMST）设置为 1。

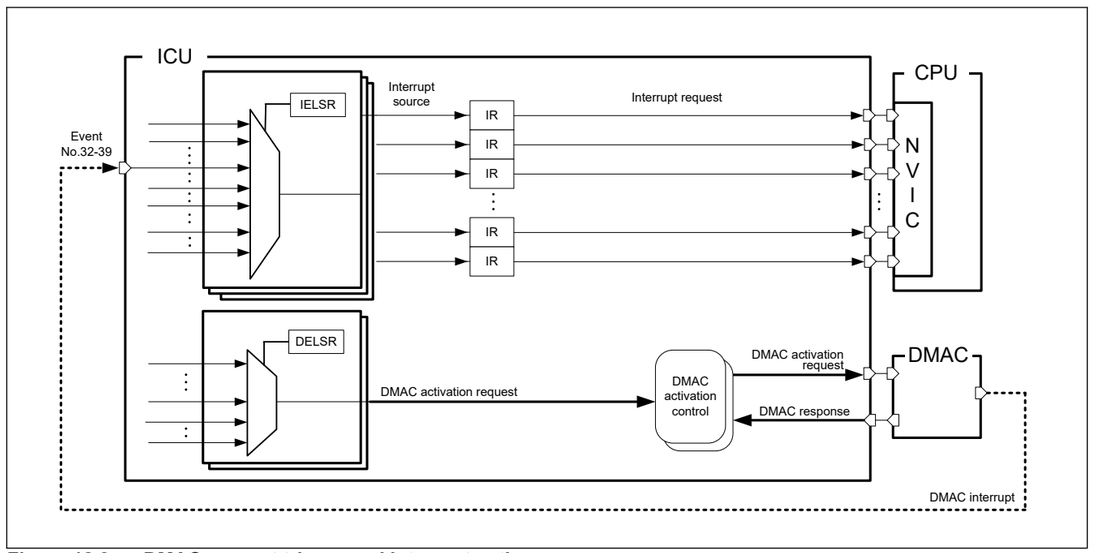

Figure 12.3 DMAC request trigger and interrupt path

Note: Error during DMAC transfer

If an error response occurs during DMAC transfer, the DMAC notifies the ICU that an error has occurred.

The ICU clears all bits of the target channel of DELSRn (n = 0 to 7). DELSRn that is not the target channel is not cleared.

12.5.5 Digital Filter

A digital filter function is provided for the external interrupt request pins IRQi, (i = 0 to 14) and the NMI pin interrupt. It samples input signals on the filter PCLKB sampling clock and removes any signal with a pulse width less than 3 sampling cycles.

To use the digital filter for an IRQi pin:

1. Set the sampling clock cycle to PCLKB, PCLKB/8, PCLKB/32, or PCLKB/64 in the IRQCRi.FCLKSEL[1:0] bits (i = 0 to 14).
2. Set the IRQCRi.FLTEN bit (i = 0 to 14) to 1 (digital filter enabled).

To use the digital filter for an NMI pin:

1. Set the sampling clock cycle to PCLKB, PCLKB/8, PCLKB/32, or PCLKB/64 in the NMICR.NFCLKSEL[1:0] bits.
2. Set the NMICR.NFLTEN bit to 1 (digital filter enabled).

Figure 12.4 shows an example of digital filter operation.

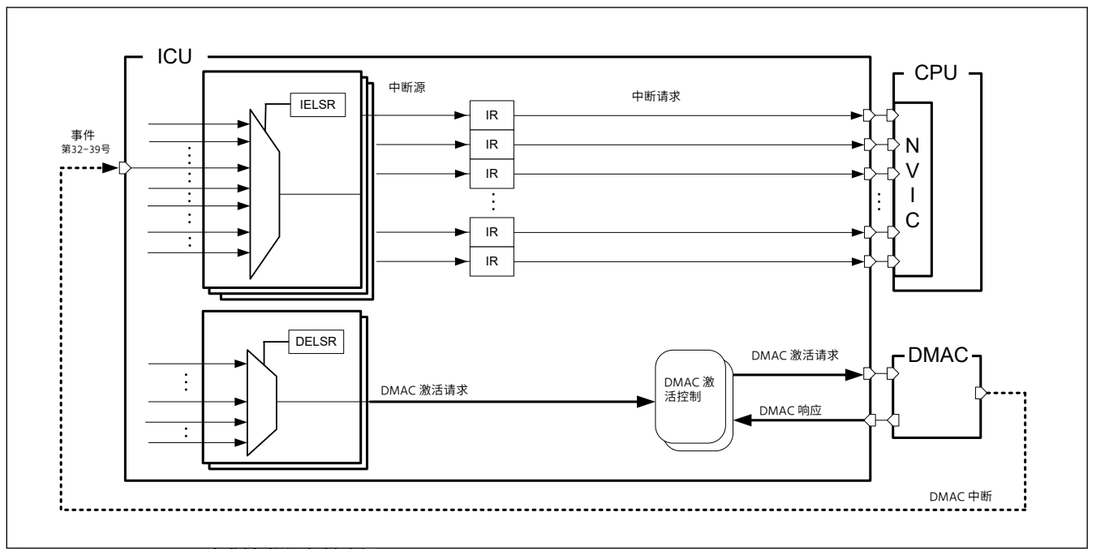

图12。3 DMAC请求触发和中断路径

注意:DMAC 传输期间出错

DMAC 传输过程中发生错误响应,则 DMAC 通知 ICU 发生错误。

ICU 清除 DELSRn 目标通道的所有位（n = 0 到 7)。不是目标通道的 DELSRn 不会被清除。

12。5。5 数字滤波器

为外部中断请求引脚 IRQi（i = 0 至 14)和 NMI 引脚中断提供数字滤波器功能。它对滤波器 PCLKB 采样时钟上的输入信号进行采样,并删除脉冲宽度小于 3 个采样周期的任何信号。

IRQi 引脚使用数字滤波器:

1。将采样时钟周期设置为 IRQCRi。FCLKSEL[1:0] 位中的 PCLKB、PCLKB/8、PCLKB/32 或 PCLKB/64（i = 0 至 14)。

2锛姣涓。将 IRQCRi。FLTEN 位（i = 0 到 14)设置为 1（启用数字滤波器）。

NMI引脚使用数字滤波器:

1。将采样时钟周期设置为 NMICR。NFCLKSEL[1:0] 位中的 PCLKB、PCLKB/8、PCLKB/32 或 PCLKB/64。

2锛姣涓。将 NMICR。NFLTEN 位设置为 1（启用数字滤波器）。

图 12。4 显示了数字滤波器操作的示例。

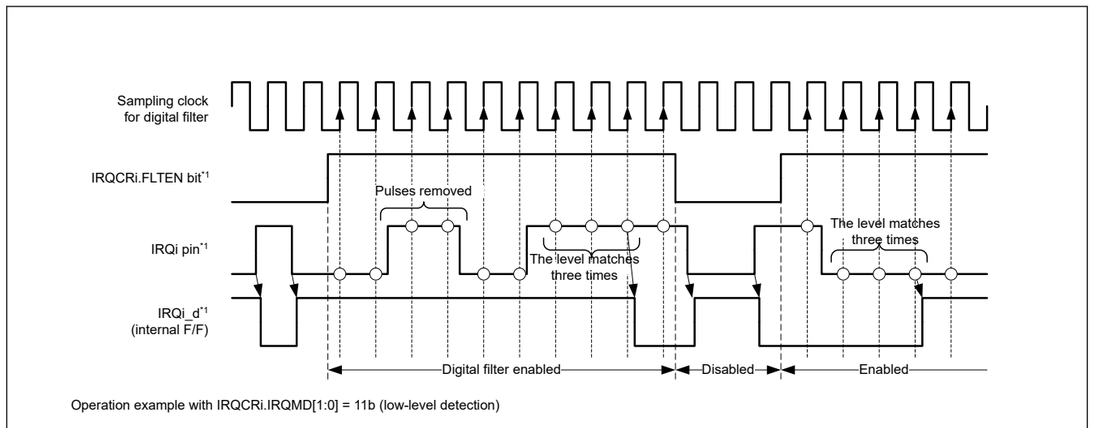

Figure 12.4 Digital filter operation example

Before entering Software Standby mode, disable the digital filters by clearing the IRQCRi.FLTEN and NMICR.NFLTEN bits. The ICU clock stops in Software Standby mode.

On exiting Software Standby mode, the circuit detects the edge by comparing the state before standby to the state after standby release. If the input changes during Software Standby mode, an incorrect edge might be detected. The digital filters can be enabled again after exiting Software Standby mode.

12.5.6 External Pin Interrupts

To use external pin interrupts:

1. Configure I/O ports settings.
2. Clear the IRQCRi.FLTEN bit (i = 0 to 14) to 0 (digital filter disabled).
3. Set the IRQMD[1:0] bits of the given IRQCRi register (i = 0 to 14) to select the senses of detection.
4. Set the FCLKSEL[1:0] bits, and the FLTEN bit of the IRQCRi register.
5. Select the IRQ pin as follows:
   - If the IRQ pin is to be used for CPU interrupt requests, set the IELSRn.IELS[8:0] bits and the IELSRn.DTCE bit to 0.
   - If the IRQ pin is to be used for DTC activation, set the IELSRn.IELS[8:0] bits and the IELSRn.DTCE bit to 1.
   - If the IRQ pin is to be used for DMAC activation, set the DELSRn.DELS[8:0] bits.

12.6 Non-Maskable Interrupt Operation

The following sources can trigger a non-maskable interrupt:

- NMI pin interrupt
- Oscillation stop detection interrupt
- WDT underflow/refresh error interrupt
- IWDT underflow/refresh error interrupt
- Voltage monitor 1 interrupt
- Voltage monitor 2 interrupt
- SRAM parity error interrupt
- SRAM ECC error interrupt

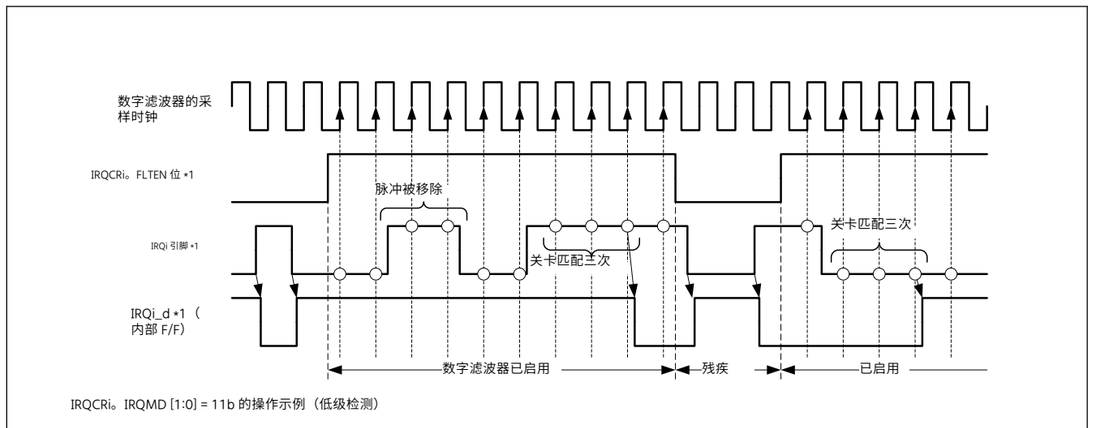

图12。4 数字滤波器操作示例

在进入软件待机模式之前,通过清除 IRQCRi。FLTEN 和 NMICR。NFLTEN 位来禁用数字滤波器。ICU 时钟在软件待机模式下停止。

退出软件待机模式时,电路通过将待机前的状态与待机释放后的状态进行比较来检测边缘。如果输入在软件待机模式期间发生变化,则可能会检测到不正确的边缘。退出软件待机模式后可以再次启用数字滤波器。

12。5。6 外部引脚中断

使用外部引脚中断:

1。配置 I/O 端口设置。

2锛姣涓涓。清除 IRQCRi。FLTEN 位（i = 0 至 14)至 0（禁用数字滤波器）。

3锛　　娴　　。设置给定 IRQCRi 寄存器的 IRQMD[1:0] 位 （i = 0 至 14)以选择检测感官。

4锛姣涓。设置 FCLKSEL[1:0] 位和 IRQCRi 寄存器的 FLTEN 位。

5锛姣涓。IRQ引脚选择如下:

- 如果 IRQ 引脚要用于 CPU 中断请求,请将 IELSRn。IELS[8:0] 位和 IELSRn。DTCE 位设置为 0.
- 如果 IRQ 引脚要用于 DTC 激活,请将 IELSRn。IELS[8:0] 位和 IELSRn。DTCE 位设置为 1。
- 如果 IRQ 引脚要用于 DMAC 激活,请设置 DELSRn。DELS[8:0] 位。

12.6 不可屏蔽的中断操作

以下来源可以触发不可屏蔽的中断:

- NMI 引脚中断
- 振荡停止检测中断
- WDT 底流/刷新错误中断
- IWDT 底流/刷新错误中断
- 电压监视器 1 中断
- 电压监视器2中断
- SRAM 奇偶校验错误中断
- SRAM ECC 错误中断

- Bus master MPU error interrupt
- TrustZone filter error interrupt
- Cache RAM parity error interrupt.

Non-maskable interrupts can only be used with the CPU, not to activate the DTC or DMAC. Non-maskable interrupts take precedence over all other interrupts. The non-maskable interrupt states can be verified in the Non-Maskable Interrupt Status Register (NMISR). Confirm that all bits in the NMISR are 0 before returning from the NMI handler.

Non-maskable interrupts are disabled by default. To use non-maskable interrupts:

1. Clear the NMICR.NFLTEN bit to 0 (digital filter disabled).
2. Set the NMIMD bit, NFCLKSEL[1:0] bits, and NFLTEN bit of NMICR register.
3. Write 1 to the NMICLR.NMICLR bit to clear the NMISR.NMIST flag to 0.
4. Enable the non-maskable interrupt by writing 1 to the associated bit in the Non-Maskable Interrupt Enable Register (NMIER).

After 1 is written to the NMIER register, subsequent write access to the NMIEN bit in NMIER is ignored. An NMI cannot be disabled when enabled, except by a reset.

The secure attribution managed within the Application Interrupt and Reset Control Register (AIRCR) of the Arm CPU must match the security attribution of NMI.

The NMI secure of the CPU is changed by AIRCR.BFHFNMINS. It is managed by software developers who manage Secure program.

12.6.1 Correspondence to TrustZone-M by NMI

Although there is only one NMI per CPU, multiple factors can be set. This section describes the procedure for mixing Secure and NonSecure programs of NMI. When doing so, the NMI-related registers of the ICU are set to Secure.

NMI-related registers:

- NMIER
- NMICLR
- NMICR

Set the ICUSARB.SANMI bit to 0.

The value of AIRCR.BFHFNMINS[13] in the Application Interrupt and Reset Control Register of the ARM CPU must be the same as the value of security attribution. The initial values of AIRCR.BFHFNMINS and ICUSARB.SANMI are different.

AIRCR.BFHFNMINS is for secure and ICUSARB.SANMI is for non-secure. Polarity has the same meaning so program these to match.

If NMI is issued, jump to the NMI handler. When mixing secure and non-secure program, the NMI handler must branch according to the TrustZone-M rule. Figure 12.5 shows the flow.

- 总线主 MPU 错误中断
- TrustZone 过滤器错误中断
- 缓存 RAM 奇偶校验错误中断。

不可屏蔽中断只能与 CPU 一起使用,不能激活 DTC 或 DMAC。不可屏蔽中断优先于所有其他中断。不可屏蔽中断状态可以在不可屏蔽中断状态寄存器（NMISR）中验证。NMI处理程序返回之前确认NMISR中的所有位都是0。

默认情况下禁用不可屏蔽的中断。使用不可屏蔽的中断:

1。将 NMICR。NFLTEN 位清除为 0（禁用数字滤波器）。

2锛姣涓涓。设置 NMICR 寄存器的 NMIMD 位、NFCLKSEL[1:0] 位和 NFLTEN 位。

3锛　　娴　　。将 1 写入 NMICLR。NMICLR 位以将 NMISR。NMIST 标志清除为 0。

4锛姣涓。通过将 1 写入不可屏蔽中断启用寄存器（NMIER）中的关联位来启用不可屏蔽中断。

1写入NMIER寄存器后,随后对NMIER中的NMIEN位的写访问被忽略。启用后,除非通过重置,否则无法禁用 NMI。

Arm CPU 的应用程序中断和重置控制寄存器（AIRCR）中管理的安全归因必须与 NMI 的安全归因相匹配。

CPU 的 NMI 安全性由 AIRCR。BFHFNMINS 更改。它由管理安全程序的软件开发人员管理。

12。6。1 NMI 与 TrustZone-M 的对应关系

尽管每个 CPU 只有一个 NMI,但可以设置多个因素。本节介绍 NMI 的安全程序和非安全程序的混合过程。这样做时,ICU 的 NMI 相关寄存器将设置为安全。

NMI 相关寄存器:

- NMIER
- NMICLR
- NMICR

将 ICUSARB。SANMI 位设置为 0。

ARM CPU的应用程序中断和重置控制寄存器中的AIRCR。BFHFNMINS[13]的值必须与安全归因的值相同。AIRCR。BFHFNMINS 和 ICUSARB。SANMI 的初始值不同。

AIRCR。BFHFNMINS 用于安全,ICUSARB。SANMI 用于非安全。极性具有相同的含义,因此对这些进行编程以匹配。

如果发出 NMI,请跳转到 NMI 处理程序。当混合安全和非安全程序时,NMI 处理程序必须根据 TrustZone-M 规则进行分支。图 12。5 显示了流程。

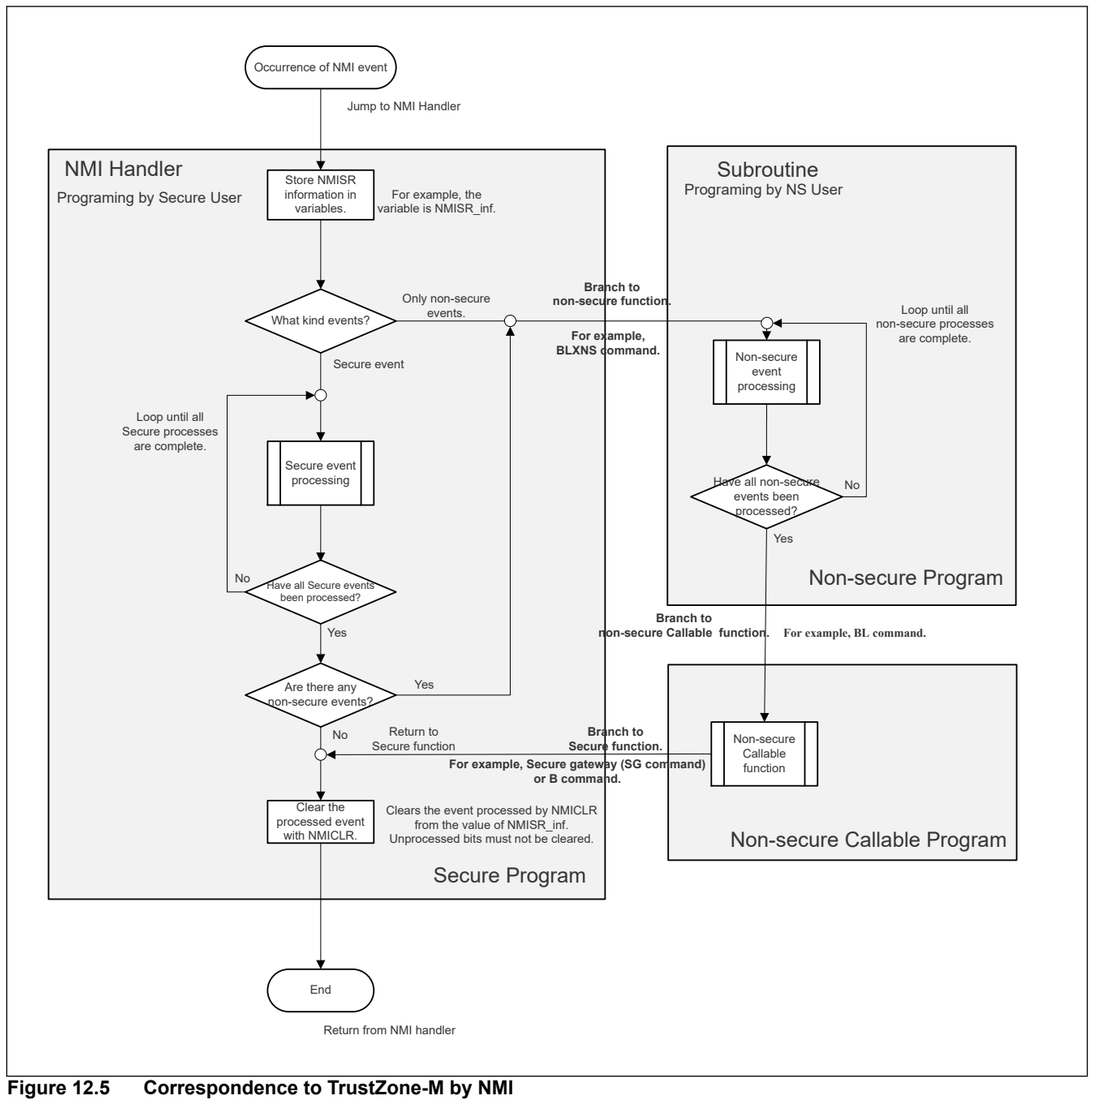

Figure 12.5 Correspondence to TrustZone-M by NMI

See the Arm documentation for details on how to move between secure and non-secure programs.

12.7 Return from Low Power Modes

Table 12.4 lists the interrupt sources that can be used to exit Sleep, Snooze, or Software Standby mode. For more information, see section 10, Low Power Modes.

12.7.1 Return from Sleep Mode

To return from Sleep mode in response to an interrupt:

non-maskable interrupt

- Use the NMIER register to enable the target interrupt request.

maskable interrupt

- Select the CPU as the interrupt request destination.

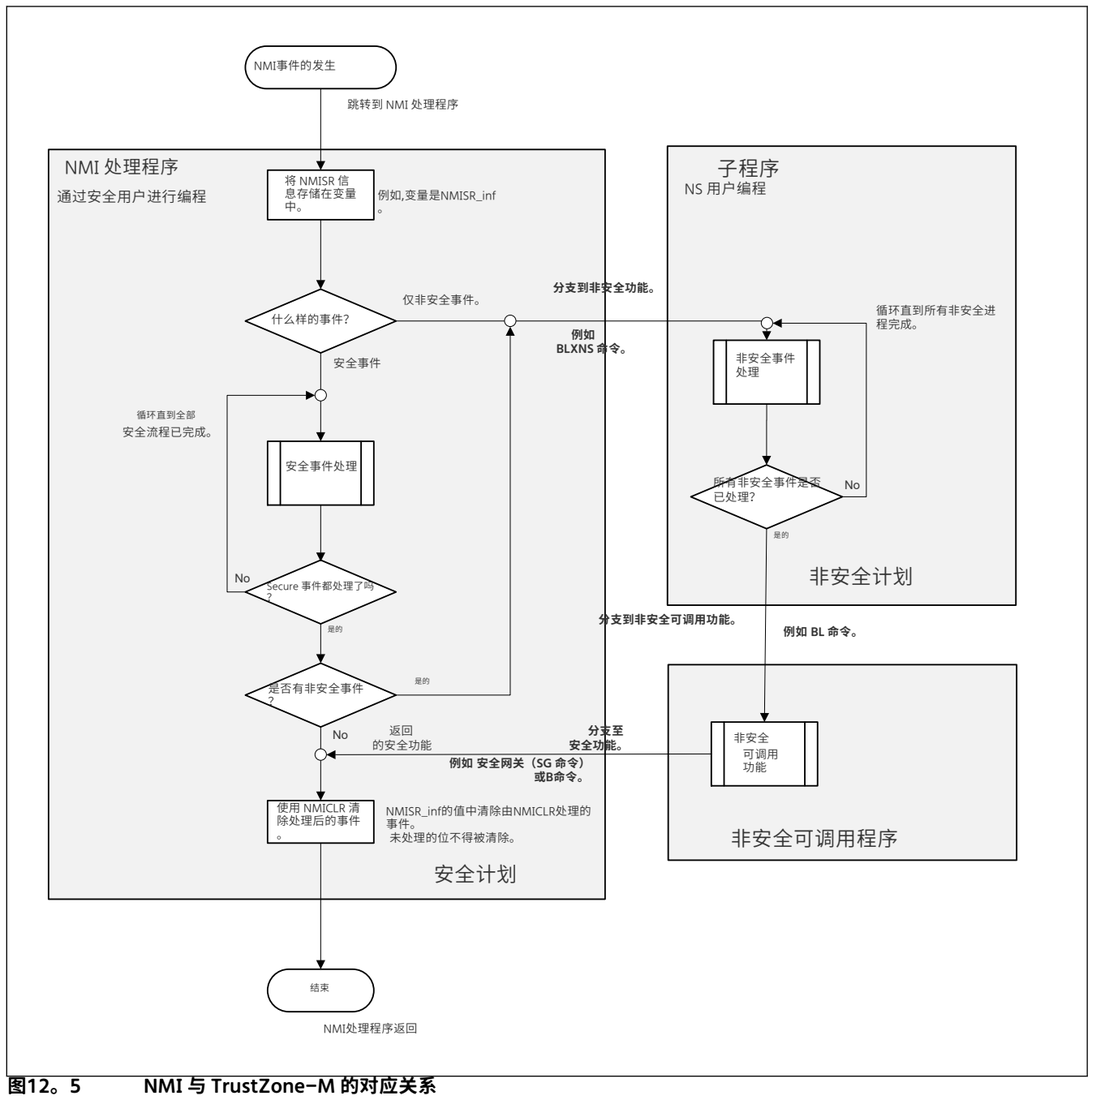

图12。5 NMI 与 TrustZone−M 的对应关系

有关如何在安全程序和非安全程序之间移动的详细信息,请参阅 Arm 文档。

12.7 从低功耗模式返回

表 12。4 列出了可用于退出睡眠、打瞌睡或软件待机模式的中断源。欲了解更多信息,请参阅第 10 节"低功耗模式"。

12.7.1 从睡眠模式返回

响应于中断从睡眠模式返回:

不可屏蔽的中断

- 使用 NMIER 寄存器启用目标中断请求。

可屏蔽中断

- 选择 CPU 作为中断请求目的地。

- Enable the interrupt in the NVIC.

12.7.2 Return from Software Standby Mode

The ICU returns from Software Standby mode using a non-maskable interrupt or a maskable interrupt. For maskable interrupt of canceling source, see Table 12.4.

To return from Software Standby mode:

1. Select the interrupt source that enables return from Software Standby:
   - For non-maskable interrupts, use the NMIER register to enable the target interrupt request
   - For maskable interrupts, use the WUPEN register to enable the target interrupt request.
2. Select the CPU as the interrupt request destination
3. Enable the interrupt in the NVIC.

Interrupt requests through the IRQn pins that do not satisfy these conditions are not detected while the clock is stopped in Software Standby mode.

Similarly, request for a non-maskable interrupt from a request source whose clock is stopped in Software Standby mode cannot be detected.

Transition to/from Software Standby mode

1. Before Software Standby mode is entered, disable the digital filter for the interrupt source as a return target (IRQCRi.FLTEN = 0, NMICR.NFLTEN = 0).
2. To use the digital filter again after returning from Software Standby mode, enable the digital filter (IRQCRi.FLTEN = 1, NMICR.NFLTEN = 1).

12.7.3 Return from Snooze Mode

The ICU can return to Normal mode from Snooze mode using the interrupts provided for this mode.

To return to Normal mode from Snooze mode:

1. Set the number of the required interrupt request in SELSR0.SELS[8:0]
2. Set the value 0x02D (ICU_SNZCANCEL) in IELSRn.IELS[8:0] (n = 0 to 95).
3. Select the CPU as the interrupt request destination.
4. Enable the interrupt in the NVIC.

Interrupt requests through the non-maskable that do not satisfy the above conditions are not detected while the clock is stopped in snooze mode.

Note: In Snooze mode, a clock is supplied to the ICU. If an event selected in IELSRn is detected, the CPU acknowledges the interrupt after returning to Normal mode from Software Standby mode. If an event selected in DELSRn is detected, the DMAC can acknowledge the interrupt after returning to Normal mode from Software Standby mode.

12.8 Using the WFI Instruction with Non-Maskable Interrupts

Whenever a WFI instruction is executed, confirm that all status flags in the NMISR register are 0.

12。7。2 从软件待机模式返回

ICU 使用不可屏蔽中断或可屏蔽中断从软件待机模式返回。于取消源的可屏蔽中断,请参见表 12。4 .

要从软件待机模式返回:

1。选择启用从软件备用返回的中断源:

- 对于不可屏蔽的中断,使用 NMIER 寄存器来启用目标中断请求
- 对于可屏蔽中断, 使用 WUPEN 寄存器启用目标中断请求。

2锛姣涓涓。CPU 选择为中断请求目标

3锛 娴 。启用 NVIC 中的中断。

当时钟停止时,不会检测到通过不满足这些条件的 IRQn 引脚的中断请求
软件待机模式。

类似地,无法检测到来自在软件待机模式下时钟停止的请求源对不可屏蔽中断的请求。

过渡到/从软件待机模式

1。在进入软件待机模式之前,禁用中断源的数字滤波器作为返回目标（IRQCRi。FLTEN = 0,NMICR。N FLTEN = 0)。

2锛姣涓涓。从软件待机模式返回后再次使用数字滤波器,请启用数字滤波器（IRQCRi。FLTEN = 1,NMICR。NFLTE N = 1)。

12。7。3 从贪睡模式返回

ICU 可以使用为此模式提供的中断从 Snooze 模式返回到正常模式。

要从贪睡模式返回正常模式:

1。SELSR0 中设置所需中断请求的编号。SELS[8:0]

2锛姣涓涓。在 IELSRn。IELS[8:0] 中设置值 0x02D（ICU_SNZCANCEL）（n = 0 到 95)。

3锛 娴 。CPU 选择为中断请求目标。

4锛姣涓涓。启用 NVIC 中的中断。

当时钟在贪睡模式下停止时,不会检测到通过不屏蔽的不满足上述条件的中断请求。

注意:在贪睡模式下,时钟被提供给 ICU。IELSRn 中选择的事件被检测到,则 CPU 在从软件待机模式返回到正常模式后确认中断。DELSRn中选择的事件被检测到,则DMAC可以在从软件待机模式返回到正常模式之后确认中断。

12.8 使用具有不可屏蔽中断的 WFI 指令

WFI指令时 确认NMISR寄存器中的所有状态标志都是0。

13.2 Description of Buses

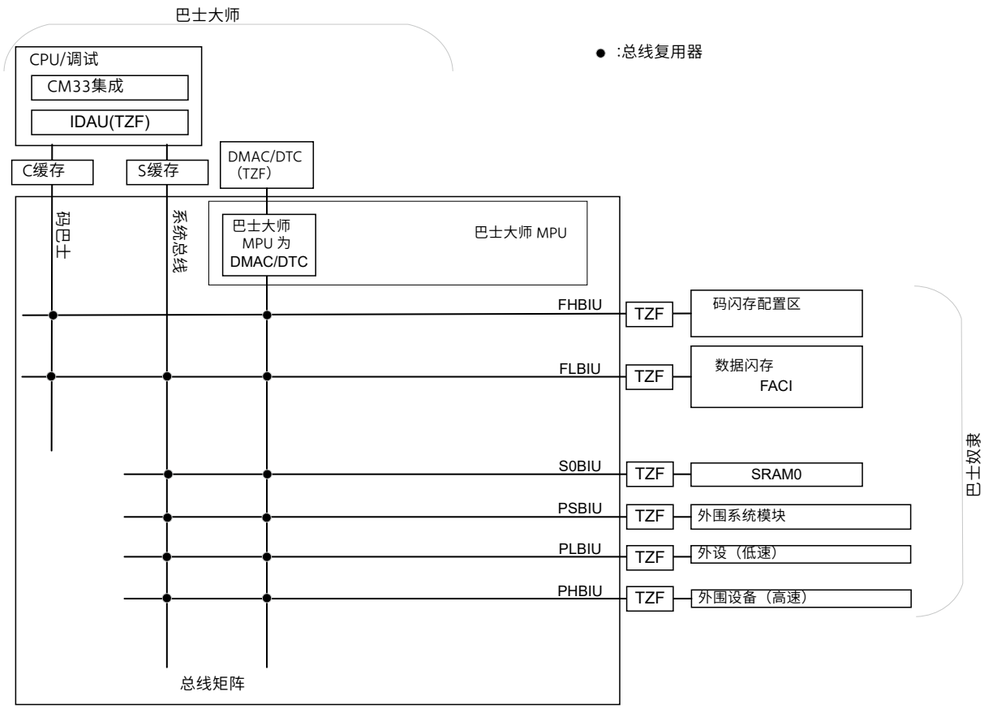
13.2.1 Arbitration

For arbitration between masters in each slave, fixed-priority and round-robin methods can be selected for each master. For details, see section 13.3.3. BUSSCNT<slave> : Slave Bus Control Register (<slave> = FHBIU, FLBIU, S0BIU), section 13.3.4. BUSSCNT<slave> : Slave Bus Control Register (<slave> = PSBIU, PLBIU, PHBIU).

13.2.2 Parallel Operation

Parallel operation is possible when different bus-master modules are requesting access to different slave modules. For example, if the CPU is fetching an instruction from Code Flash and an operand from SRAM0, the DMAC can handle transfer between a peripheral module at the same time.

Figure 13.2 shows an example of parallel operations. In this example, the CPU uses code bus and system bus for simultaneous access to FHBIU and S0BIU, respectively. Furthermore, the DMAC/DTC simultaneously accesses the peripheral bus during access to FHBIU and S0BIU by the CPU.



注: TZF 是 TrustZone 过滤器。C缓存是指令缓存。S缓存就是数据缓存。
FLBIU,代码总线通过FLBIU访问数据闪存和配置区域（代码区域）。系统总线通过 FLBIU 访问 FACI（外围区域）。

13。2 公共汽车的描述

13。2。1 仲裁

对于每个从属主人之间的仲裁,可以为每个主人选择固定优先级和循环赛方法。详情请参见第 13。3。3 节。BUSSCNT<从>:从总线控制寄存器 (<从> = FHBIU, FLBIU, S0BIU），第 13。3。4 节。BUSSCNT<从>:从总线控制寄存器 (<从> = PSBIU, PLBIU, PHBIU）。

13。2。2 并行操作

当不同的总线主模块请求访问不同的从模块时,并行操作是可能的。例如,如果CPU从Code Flash获取指令,从SRAM0获取操作数,则DMAC可以同时处理外围模块之间的传输。

图 13。2 显示了并行操作的示例。在此示例中,CPU 使用代码总线和系统总线分别同时访问 FHBIU 和 S0BIU。此外,在CPU访问FHBIU和S0BIU期间,DMAC/DTC同时访问外围总线。

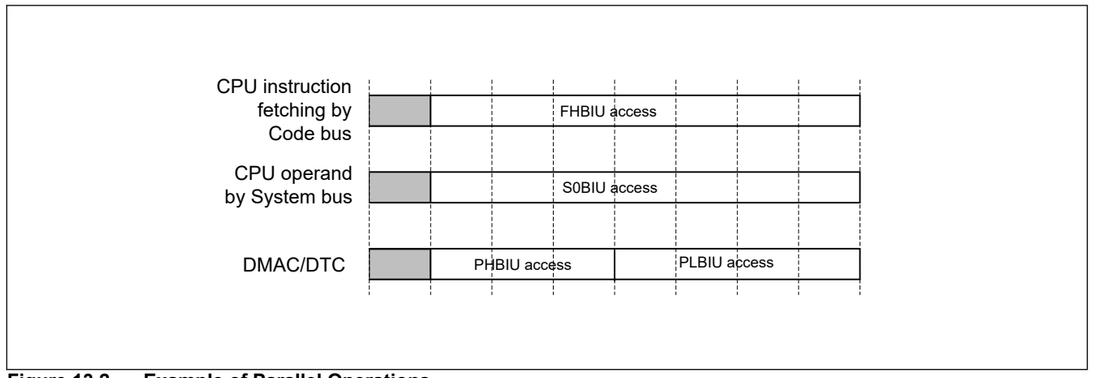

Figure 13.2 Example of Parallel Operations

13.2.3 Restrictions

(1) Restriction on Endian

Memory space must be little-endian in order to execute Cortex code.

(2) Bufferable write access

When CPU or DMAC perform Bufferable Write access to PLBIU or PHBIU, if an STZF error occurs then the error response is invalidated. So there is no error flag will be set and no NMI / RESET request is generated.

When CPU or DMAC perform Bufferable Write access to PHBIU, if a Slave BUS error occurs then the error response will become invalid and the error flag will not be set.

If error response is required, set the bus master to non-bufferable access.

(3) Access to reserved area of FLBIU and S0BIU

Access to the reserved area of FLBIU and S0BIU is prohibited. Operation is not guaranteed if accessed.

(4) Clock setting

The clock division ratio prohibits setting changes during bus access.

13。2。3 限制

(1)对恩典的限制

内存空间必须是小端的才能执行 Cortex 代码。

(2)可缓冲写访问

当 CPU 或 DMAC 对 PLBIU 或 PHBIU 执行可缓冲写入访问时,如果发生 STZF 错误,则错误响应将失效。因此不会设置错误标志,也不会生成 NMI/RESET 请求。

CPU 或 DMAC 对 PHBIU 执行可缓冲写入访问时,如果发生从属 BUS 错误,则错误响应将失效,并且错误标志将不会被设置。

如果需要错误响应,请将总线主站设置为不可缓冲访问。

(3)进入FLBIU和S0BIU的保留区域

禁止进入 FLBIU 和 S0BIU 的保留区域。如果访问,则无法保证操作。

(4)时钟设置

时钟分频比禁止在总线访问期间进行设置更改。

The following bus errors correspond to the master bus:

BUS1ERRSTAT : Code bus

BUS2ERRSTAT : System bus

BUS3ERRSTAT : DMAC/DTC

See Figure 13.1 for connection of each BUS

When an illegal access error, master MPU error, and slave bus error all occurred at the same time, the STAT bit is only valid in the following order of priority. The left side has higher priority.

Master MPU Error > Illegal access error, slave bus error

Note: Illegal access error and slave bus error do not occur at the same time.

If one of ILERRSTAT, MMERRSTAT or SLERRSTAT is set, these bits are not renewed until it is cleared.

SLERRSTAT bit (Slave bus Error Status)

When slave error occurs by bus, BUSnERRSTAT.SLERRSTAT (n = 1 to 3) is set to 1. Clear condition is reset or set BUSnERRCLR.SLERRCLR (n = 1 to 3) to 1. Slave error is an error that occurs on a slave such as a timeout. For detail of slave error that occurs by bus, see section 13.4. Bus Error Monitoring Section.

STERRSTAT bit (Slave TrustZone filter Error Status)

When slave TrustZone filter error occurs by bus, BUSnERRSTAT.STERRSTAT (n = 1 to 3) is set to 1. Clear condition is reset or set BUSnERRCLR.STERRCLR (n = 1 to 3) to 1. The STERRSTAT bit is not set when the debugger accesses the security area. For detail of slave TrustZone filter error that occurs by bus, see section 40, Security Features .

MMERRSTAT bit (Master MPU Error Status)

When master MPU error occurs by bus, BUSnERRSTAT.MMERRSTAT (n = 1 to 3) is set to 1. Clear condition is reset or set BUSnERRCLR.MMERRCLR (n = 1 to 3) to 1. For detail of master MPU error that occurs by bus, see section 14, Memory Protection Unit (MPU).

Note: At master MPU error is occur in DMAC or DTC access, if error address value is not as master MPU area, Illegal address access error or slave error is occurring before DMAC or DTC access. Decide the what error was happened by referring the error address value.

ILERRSTAT bit (Illegal address access Error Status)

When illegal address access error occurs by bus, BUSnERRSTAT.ILERRSTAT (n = 1 to 3) is set to 1. Clear condition is reset or set BUSnERRCLR.ILERRCLR (n = 1 to 3) to 1. For detail of illegal address access error that occurs by bus, see section 13.4. Bus Error Monitoring Section.

13.4 Bus Error Monitoring Section

The bus error monitoring system monitors each individual area, and when an error is detected, an error is returned to the requesting master IP using the AHB-Lite error response protocol.

13.4.1 Bus Error Types

The following types of errors can occur on each bus:

- Illegal address access
- Bus master MPU error
- TrustZone Filter error
- Bus error transmitted from each slave IP

Table 13.2 lists the address ranges where access leads to illegal address access errors. The reserved area in the slave does not trigger an illegal address access error. For more information on the bus master MPU, see section 14, Memory Protection Unit (MPU).

13.4.2 Operations When a Bus Error Occurs

When a bus error occurs, operation is not guaranteed and the error is returned to the requesting master IP.

13。4 总线错误监控部分

总线错误监控系统监控每个单独的区域,当检测到错误时,使用AHB-Lite错误响应协议将错误返回到请求的主IP。

13。4。1 总线错误类型

每条总线上可能会出现以下类型的错误:

- 非法地址访问
- 总线主 MPU 错误
- TrustZone 过滤器错
- 从每个从属 IP 传输的总线错误

表13。2列出了访问导致非法地址访问错误的地址范围。从站中的保留区域不会触发非法地址访问错误。有关总线主 MPU 的更多信息,请参阅第 14 节"内存保护单元（MPU）."

13.4.2 总线错误发生时的操作

当发生总线错误时,无法保证操作并将错误返回到请求的主IP。

图 13。3 显示了从每次错误检测到总线上的用户通知的操作。

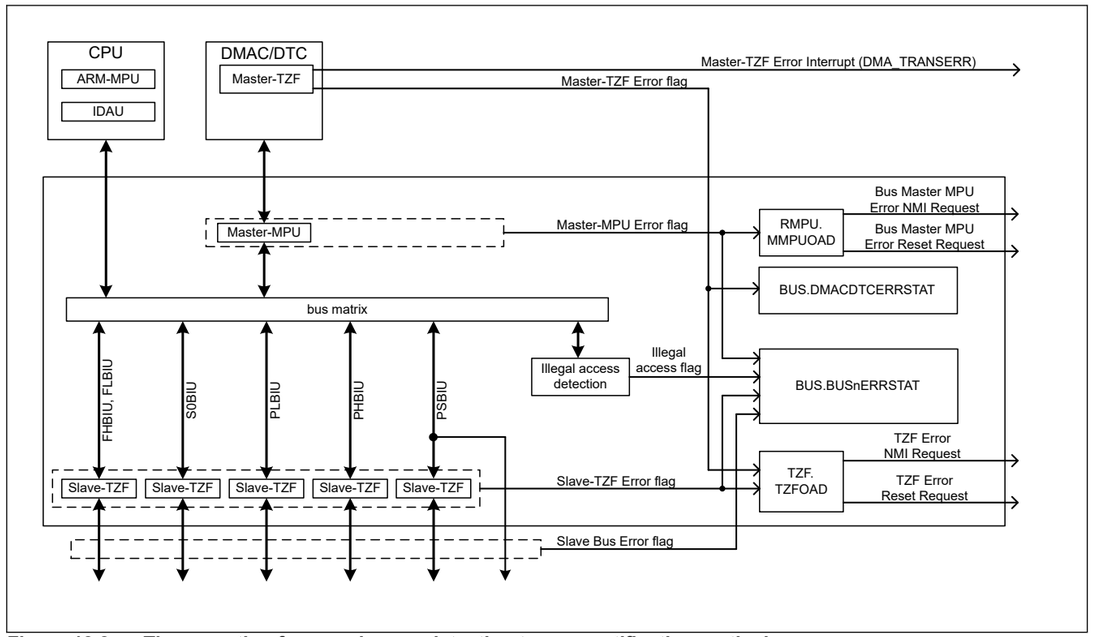

Figure 13.3 The operation from each error detection to user notification on the bus

(1) Bus Master MPU Error

The bus master of DMAC/DTC has a master MPU for access control of the set address area. The CPU does not have a master MPU because it has an Arm MPU. When a bus master MPU error is detected, an Error response is returned to the master. At the same time, perform the following steps:

1. Store the address of the error in BUSnERRADD (n = 3).
2. Store the read/write information of the error in BUSnERRRW (n = 3).
3. Set 1 to MMERRSTAT bit of BUSnERRSTAT (n = 3).

An NMI request or a reset request is generated according to the MMPUOAD.OAD setting (see section 14, Memory Protection Unit (MPU)). Since BUSnERRADD (n = 3), BUSnERRRW (n = 3), and BUSnERRSTAT (n = 3) are held until reset other than MPU- and TZF-related resets or cleared by BUSnERRCLR (n = 3), they can be verified in the NMI handler or after reset.

An NMI request is generated only on the first bus master MPU error after a reset or clearing of BUSnERRSTAT.MMERRSTAT (n = 3) bit by BUSnERRCLR (n = 3).

(2) Illegal Access Error

section 13.4.3. Conditions Leading to Illegal Address Access Errors, describes illegal access errors. When an illegal access error is detected, an Error response is returned to the master. At the same time, perform the following steps:

1. Store the address of the error in BUSnERRADD (n = 1 to 3).
2. Store the read/write information of the error in BUSnERRRW (n = 1 to 3).
3. Set 1 to ILERRSTAT bit of BUSnERRSTAT (n = 1 to 3).

NMI request and reset request are not generated. Since BUSnERRADD (n = 1 to 3), BUSnERRRW (n = 1 to 3), BUSnERRSTAT (n = 1 to 3) are held until reset other than MPU- and TZF-related resets or cleared by BUSnERRCLR (n = 1 to 3), they can be confirmed in the Bus Fault handler or the interrupt handler.

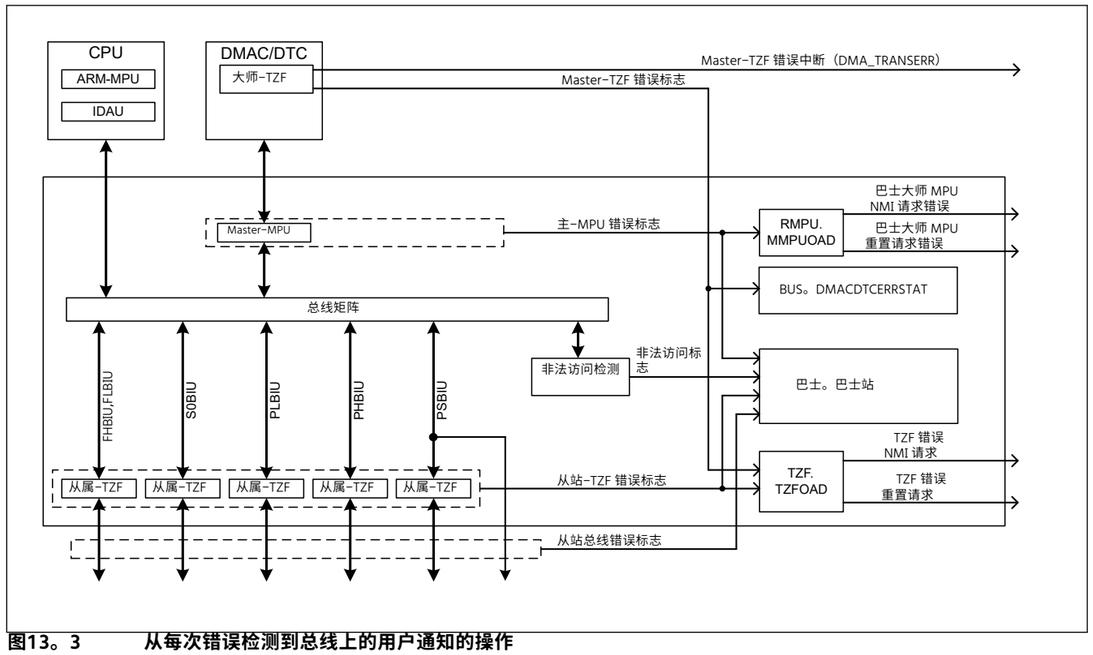

图13。3 从每次错误检测到总线上的用户通知的操作

(1) 总线主 MPU 错误

DMAC/DTC 的总线主站有一个主 MPU,用于对设置的地址区域进行访问控制。CPU 没有主 MPU,因为它有一个 Arm MPU。当检测到总线主 MPU 错误时,错误响应将返回给主。同时,执行以下步骤:

1。将错误地址存储在 BUSnERRADD（n = 3) 中。

2锛姣涓。将错误的读/写信息存储在 BUSnERRRW（n = 3) 中。

3锛 娴 。将 1 设置为 BUSnERRSTAT 的 MMERRSTAT 位（n = 3)。

根据 MMPUOAD。OAD 设置生成 NMI 请求或重置请求（参见第 14 节"内存保护单元（MPU）")。由于 BUSnERRADD（n = 3)、BUSnERRRW（n = 3) 和 BUSnERRSTAT（n = 3) 保持到除 MPU 和 TZF 相关重置之外的重置或由 BUSnERRCLR（n = 3) 清除为止,因此可以在 NMI 处理程序或重置后。

仅在 BUSnERRSTAT（n = 3) 重置或清除 BUSnERRSTAT。MMERRSTAT（n = 3) 位后的第一个总线主 MPU 错误上生成 NMI 请求。

(2)非法访问错误

第 13。4。3 节。导致非法地址访问错误的条件描述了非法访问错误。当检测到非法访问错误时,错误响应将返回给主机。同时,执行以下步骤:

1。将错误地址存储在 BUSnERRADD 中（n = 1 至 3)。

2锛姣涓。将错误的读/写信息存储在 BUSnERRRW 中（n = 1 至 3)。

3锛 娴 。将 1 设置为 BUSnERRSTAT 的 ILERRSTAT 位（n = 1 到 3)。

NMI 请求和重置请求不会生成。由于 BUSnERRADD（n = 1 至 3)、BUSnERRRW（n = 1 至 3)、BUSnERRSTAT（n = 1 至 3) 保持到除 MPU 和 TZF 相关重置之外的重置或由 BUSnERRCLR 清除（n = 1 至 3),它们可以在总线故障处理程序或中断处理程序中确认。

(3) Master-TZF Error

As described in section 40, Security Features , DMAC/DTC has Master-TZF errors. When a Master-TZF error is detected, 1 is set to MTERRSTAT bit of DMACDTCERRSTAT, and because the DMAC/DTC does not perform bus access, no bus error information is stored in BTZF3ERRADD and BTZF3ERRRW.

An NMI request or reset request is generated according to the setting of TZFOAD.OAD. See section 15, DMA Controller (DMAC), section 16, Data Transfer Controller (DTC) for details on Master-TZF errors. Because DMACDTCERRSTAT is held until reset other than MPU- and TZF-related resets or cleared by DMACDTCERRCLR, they can be verified in the NMI handler or after reset.

An NMI request is generated only on the first Master-TZF error after reset or clearing of the DMACDTCERRSTAT.MTERRSTAT bit by DMACDTCERRCLR.

(4) Slave-TZF Error

As described in section 40, Security Features , FHBIU (code flash), FLBIU (data flash), S0BIU (SRAM), PHBIU, PLBIU and peripherals of PSBIU have Slave-TZF errors. When a Slave-TZF error is detected, perform the following steps:

1. Store the address of the error in BTZFnERRADD (n = 1 to 3).
2. Store the read/write information of the error in BTZFnERRRW (n = 1 to 3).
3. Set 1 to STERRSTAT bit of BUSnERRSTAT (n = 1 to 3).

NMI request or reset request is generated according to the setting in TZFOAD.OAD. Since BTZFnERRADD (n = 1 to 3), BTZFnERRRW (n = 1 to 3), and BUSnERRSTAT (n = 1 to 3) are held until reset other than MPU- and TZF-related resets or cleared by BUSnERRCLR (n = 1 to 3), they can be verified in the NMI handler or after reset.

An NMI request is generated only on the first Slave-TZF error after a reset or clearing of the BUSnERRSTAT.STERRSTAT (n = 1 to 3) bit by BUSnERRCLR (n = 1 to 3).

(5) Slave Bus Error

Slave Bus Error occurs in the slave. When Slave Bus Error is detected, an Error response is returned to the master. At the same time, perform the following steps:

1. Store the address of the error in BUSnERRADD (n = 1 to 3)
2. Store the read/write information of the error in BUSnERRRW (n = 1 to 3)
3. Set 1 to SLERRSTAT bit of BUSnERRSTAT (n = 1 to 3).

An NMI request and reset request are not generated. Since BUSnERRADD (n = 1 to 3), BUSnERRRW (n = 1 to 3), and BUSnERRSTAT (n = 1 to 3) are held until reset other than MPU- and TZF-related resets or cleared by BUSnERRCLR (n = 1 to 3), they can be verified in the Bus Fault handler or interrupt handler. When a bus slave MPU error occurs, the error is returned to the requesting master IP and operation is not guaranteed.

13.4.3 Conditions Leading to Illegal Address Access Errors

Table 13.2 lists the address spaces for each bus that trigger illegal address access errors.

Table 13.2 Conditions leading to illegal address access errors (1 of 2)

Address	Slave bus	Master bus		
		CPU		DMA
		Code	System	
0x0000_0000 to 0x01FF_FFFF	FHBIU	—		—
0x0200_0000 to 0x07FF_FFFF	Reserved	E		E
0x0800_0000 to 0x0803_FFFF	FLBIU	—		—

0x1000_0000 to 0x100F_FFFF	Reserved	—		E
0x1010_0000 to 0x1FFF_FFFF	Reserved	E		E

(3)主-TZF错误

如第 40 节"安全功能"中所述,DMAC/DTC 具有 Master-TZF 错误。当检测到Master-TZF错误时,1被设置为DMACDTCERRSTAT的MTERRSTAT位,并且由于DMAC/DTC不执行总线访问,所以BTZF3ERRADD和BTZF3ERRRW中不存储总线错误信息。

TZFOAD。OAD 的设置生成 NMI 请求或重置请求, 有关主 TZF 错误的详细信息, 请参阅第 15 节 DMA 控制器（DMAC），第 16 节数据传输控制器（DTC）。由于 DMACDTCERRSTAT 被保留到除 MPU 和 TZF 相关重置之外的重置或由 DMACDTCERRCLR 清除之前,因此可以在 NMI 处理程序中或重置后对其进行验证。

仅在 DMACDTCERRCLR 重置或清除 DMACDTCERRSTAT。MTERRSTAT 位后的第一个 Master-TZF 错误时生成 NMI 请求。

(4)从-TZF错误

如第 40 节所述,安全功能、FHBIU（代码闪存）、FLBIU（数据闪存）、S0BIU（SRAM）、PHBIU、PLBIU 和 PSBIU 的外围设备存在从属 TZF 错误。Slave-TZF 错误时, 请执行以下步骤:

1。将错误地址存储在 BTZFnERRADD 中（n = 1 至 3)。

2锛姣涓涓。将错误的读/写信息存储在 BTZFnERRRW 中（n = 1 至 3)。

3锛　　娴　　。将 1 设置为 BUSnERRSTAT 的 STERRSTAT 位（n = 1 到 3)。

NMI 请求或重置请求是根据 TZFOAD。OAD 中的设置生成的。由于 BTZFnERRADD（n = 1 至 3)、BTZFnERRRW（n = 1 至 3)和 BUSnERRSTAT（n = 1 至 3)被保留,直到除 MPU 和 TZF 相关重置之外的重置或被 BUSnERRCLR 清除（n = 1 至 3), NMI 处理程序中或重置后可以验证它们。

仅在 BUSnERRSTAT。STERRSTAT（n = 1 至 3) 位重置或清除 BUSnERRCLR（n = 1 至 3) 后的第一个 Slave-TZF 错误时生成 NMI 请求。

(5)从总线错误

从属总线错误发生在从属中。当检测到从属总线错误时,错误响应将返回给主站。同时,执行以下步骤:

1。将错误地址存储在 BUSnERRADD 中（n = 1 至 3)

2锛姣涓涓。将错误的读/写信息存储在 BUSnERRRW 中（n = 1 至 3)

3锛　　娴　　。将 1 设置为 BUSnERRSTAT 的 SLERRSTAT 位（n = 1 到 3)。

NMI 请求和重置请求不会生成。由于 BUSnERRADD（n = 1 至 3)、BUSnERRRW（n = 1 至 3) 和 BUSnERRSTAT（n = 1 至 3) 保持到除 MPU 和 TZF 相关重置之外的重置或由 BUSnERRCLR 清除（n = 1 至 3),它们可以在总线故障处理程序或中断处理程序中进行验证。当发生总线从机MPU错误时,错误会返回到请求的主机IP,无法保证操作。

13.4.4 Time-out

For some peripheral modules, a timeout error occurs with the module-stop function. When there is no response from the slave for a certain period of time, a timeout error is detected. A timeout error is returned to the requesting master IP using the AHB-Lite error response protocol.

- C-cache on code bus
- S-cache on system bus.

Table 13.3 lists the specifications of the cache, Figure 13.4 shows a block diagram of the cache, and Figure 13.5 shows the cache structure.

PRCR bit (Register Write Control)

The PRCR bit controls the write mode of the CAPOAD register. When this bit is set to 1, writing to the CAPOAD register is enabled. When writing to this bit, write 0x78 to the KW[6:0] bits simultaneously.

KW[6:0] bits (Write key code)

The KW[6:0] bits enable or disable writes to the PRCR bit. When writing to the PRCR bit, write 0x78 to the KW[6:0] bits simultaneously. When a value other than 0x78 is written to KW[6:0] bits, the PRCR bit is not updated. The KW[6:0] bits are always read as 0x00.

13.6.3 Operation

13.6.3.1 S-Cache

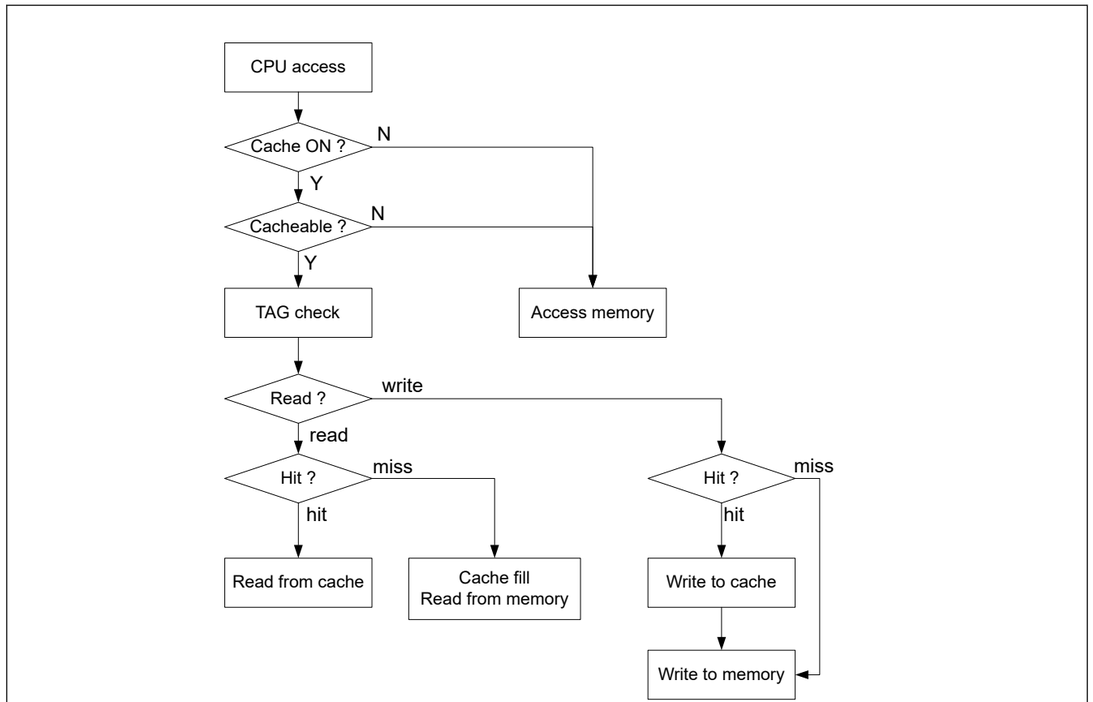

Figure 13.6 Access flow from CPU to S-cache

The cache function works when cache is enabled (CACTL.ENS = 1) and cacheable access is from CPU. The cache checks the address of CPU access request and request in cache tag, then determines whether the CPU access is a hit or a miss-hit.

PRCR 位（注册写入控制）

PRCR 位控制 CAPOAD 寄存器的写入模式。当该位设置为 1 时,将启用写入 CAPOAD 寄存器。写入此位时,同时将 0x78 写入 KW[6:0] 位。

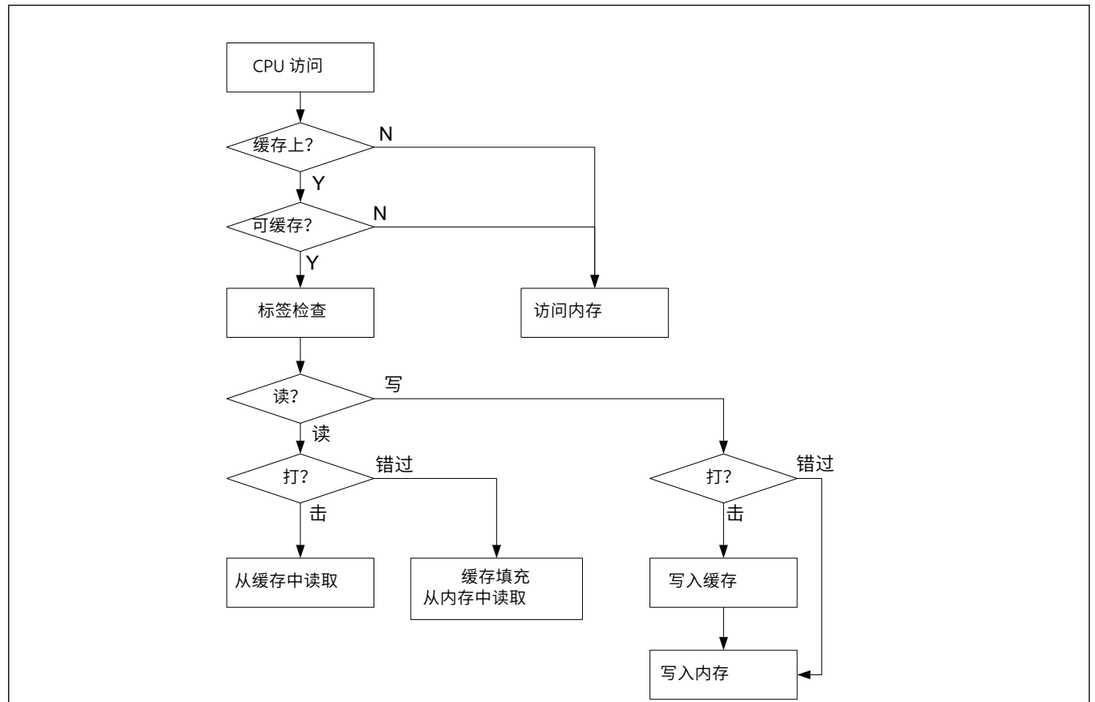
KW[6:0] 位（编写密钥代码）

KW[6:0] 位启用或禁用对 PRCR 位的写入。PRCR位时,同时将0x78写入KW[6:0]位。0x78 以外的值写入 KW[6:0] 位时, PRCR 位不会更新。KW[6:0] 位始终读作 0x00。

13。6。3 操作

13。6。3。1 S-缓存

图 13。6 显示了从 CPU 到 S 缓存的访问流程。



从 CPU 到 S 缓存的访问流程 缓存功能在启用缓存时起作用（CACTL。ENS = 1),并且可缓存访问来自 CPU。缓存检查缓存标签中CPU访问请求和请求的地址,然后确定CPU访问是命中还是未命中。

Read miss

The cache reads one cache line data from memory and stores it into the cache data. The cache then returns the required data to CPU.

Read hit

The cache reads required data from the cache data and returns it to CPU. Access cycle then determines it is a hit because of the 0 wait cycle.

Write miss

The cache processes only a write cycle to memory. No affect to cache data.

Write hit

The cache processes both a write cycle to cache data and a write cycle to memory.

13.6.3.2 C-Cache

Figure 13.7 shows the access flow from CPU to C-cache.

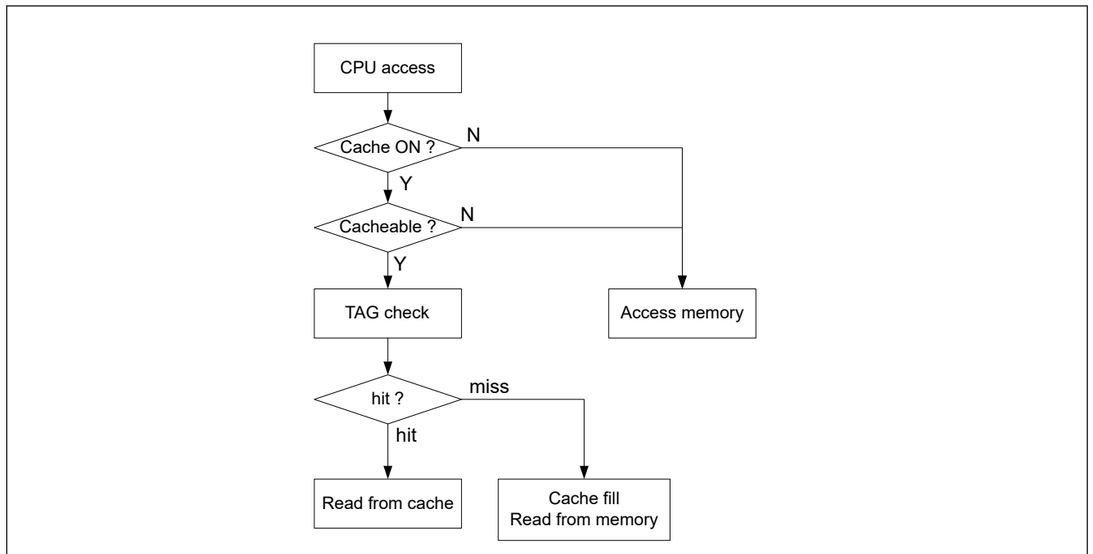


Figure 13.7 Access flow from CPU to C-cache

The cache function works when cache is enabled (CACTL.ENC = 1) and cacheable access is from CPU. The cache checks the address of CPU access request and request in cache tag, then determines whether the CPU access is a hit or a miss-hit.

Read miss

The cache reads one cache line data from memory and stores it into the cache data. The cache then returns the required data to CPU.

Read hit

The cache reads required data from the cache data and returns it to CPU. Access cycle then determines it is a hit because of the 0 wait cycle.

Because C-cache does not function in the ROM area of C-cache, therefore it operates in read-only access.

13.6.3.3 Cache Flush

The Valid bit is cleared with the CAFCT register. However, tag and cache data are not affected by the CAFCT register.

读命中

缓存从缓存数据中读取所需数据并将其返回到 CPU。然后,访问周期确定它是命中,因为等待周期为 0。

由于 C 缓存在 C 缓存的 ROM 区域中不起作用,因此它在只读访问中运行。

13.6.3.3 缓存刷新

使用 CAFCT 寄存器清除有效位。但是,标签和缓存数据不受 CAFCT 寄存器的影响。

The valid bit is also cleared when CACTL is set from 0 to 1.

Note: After changing the cacheable attribute by the Arm MPU, clear the valid bit using the CAFCT register.

13.6.3.4 LRU and Replace

The cache uses LRU (Least Recently Used) mechanism as the cache replacement algorithm. If a CPU access is determined as a hit or a miss-hit, the cache replaces cache data that is not the last restored. Additionally, the cache is tagged as the latest data in LRU of the cache data. Therefore even when the cache line in cache ways are full, the cache can replace cache data using LRU which shows older data.

The algorithm for a 2-way LRU shows which way, for example way 0 or way 1, is the latest stored.

13.6.3.5 Parity Check

The cache has a parity check function for cache RAM that is stored as cache fill data. The cache has 4-bit parities for 32-bit data, that is when data is read, a parity bit is added to every 8-bit data of 32-bit data width. When the cache reads data with a hit status, it checks for parity errors. When a parity error occurs, a parity error notification is generated.

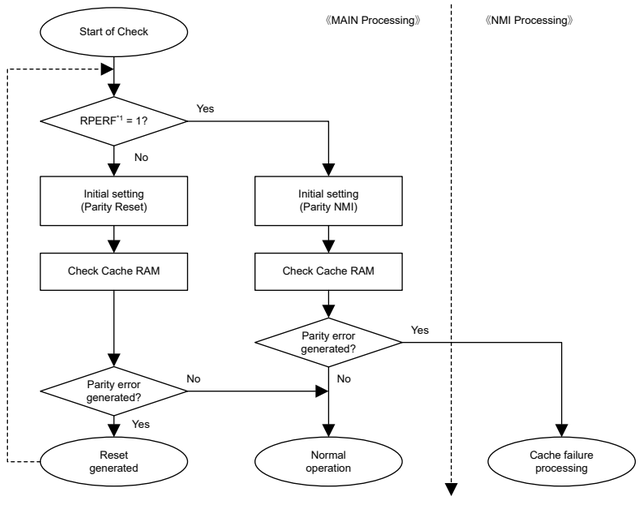
The cache reads 32-bit data even when the CPU requests a byte read or half-word read.

Note: A parity error might occur even though it is caused by a non validated-data byte of which the CPU does not request.

Parity error notification can be specified as a non-maskable interrupt or a reset request in the CAPOAD register. However, if the debug mode requests to suppress the parity error notification, then notification is not generated.

When a parity error occurs, the cache does not perform a cache flush and does not respond to the CPU with a bus error.

Parity errors often occur due to noise. To confirm whether the cause of the parity error is noise or corruption, see the flows for cache parity check in Figure 13.8 and Figure 13.9.



Note 1. RPERF: Cache Parity Error Reset Detect Flag (RSTSR1.RPERF)

Figure 13.8 Flow of cache parity check when parity reset is enabled

当 CACTL 从 0 设置为 1 时,有效位也被清除。

注意:Arm MPU 更改可缓存属性后,使用 CAFCT 寄存器清除有效位。

13。6。3。4 LRU 和替换

缓存使用 LRU（最近最少使用的）机制作为缓存替换算法。CPU 访问被确定为命中或未命中,则缓存将替换不是最后恢复的缓存数据。此外,缓存被标记为缓存数据的LRU中的最新数据。因此,即使高速缓存方式中的高速缓存行已满,高速缓存也可以使用显示旧数据的 LRU 来替换高速缓存数据。

2 路 LRU 的算法显示哪个路（例如路 0 或路 1)是最新存储的。

13。6。3。5 奇偶校验

该缓存具有作为缓存填充数据存储的缓存 RAM 的奇偶校验功能。32位数据缓存有4位奇偶校验,即读取数据时,每8位数据中添加一个32位数据宽度的奇偶校验位。当缓存读取具有命中状态的数据时,它会检查奇偶校验错误。当发生奇偶校验错误时,会生成奇偶校验错误通知。

即使 CPU 请求字节读取或半字读取,缓存也会读取 32 位数据。

注意:即使奇偶校验错误是由 CPU 不请求的未经验证的数据字节引起的,也可能发生奇偶校验错误。

奇偶校验错误通知可以指定为不可屏蔽中断或 CAPOAD 寄存器中的重置请求。但是,如果调试模式请求抑制奇偶校验错误通知,则不会生成通知。

当发生奇偶校验错误时,缓存不会执行缓存刷新,也不会响应具有总线错误的 CPU。

奇偶校验错误经常因噪声而发生。要确认奇偶校验错误的原因是噪声还是损坏,请参阅图 13。8 和图 13。9 。中的缓存奇偶校验流程

Note 1. RPEST: Cache Parity Error Interrupt Detect Flag (NMISR.RPEST)

Figure 13.9 Flow of cache parity check when parity interrupt is enabled

13.6.3.5.1 Cache RAM Check

Parity error of cache RAM occurs at a read access by CPU with a cache status of read-hit. With a read-hit status, some conditions are required before performing a cache RAM check. For S-cache check, execute the check program in flash memory. For C-cache check, execute the check program in SRAM.

(1) Cache RAM check flow

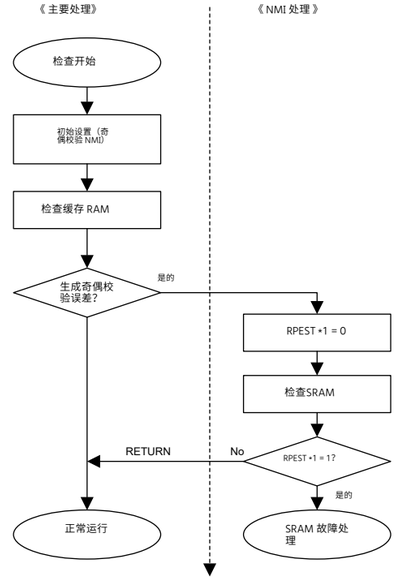
1. Flush all valid bits in cache to clear the cache enable bit.
2. Reserve a 1-KB work memory such as SRAM for S-cache. Because each cache in the MCU is a 2-way set associative with 0.5 KB RAM per way, a total of 1 KB is required for S-cache. The target address should not be used as reserved area.
3. Set the cache enable to 1.
4. Read data from the target word address of 1 KB using the CPU. The status of cache should be a read-miss with the result stored as cache fill data.
5. Read data in another cache way whose address is calculated by adding the address in step 4. with 0.5 KB address. The status of cache should be a read-miss with the result stored as cache fill data in another way. Cache RAM check for a write/read-hit status is now complete.
6. Write test data to the target word address in steps 4. and 5.. The status of cache in steps 4. and 5. should be a write-hit with the results written to the cache RAM.
7. Read from the target word address in steps 4. and 5. again. The status of cache in steps 4. and 5. should be a read-hit. Parity check for a word data is now complete.
8. Go to step 1. to continue parity check for different target addresses.

13.6.3.6 Bus Error

The association from a bus slave to a bus error is described in the sections that follow.

In cache off

The cache returns a bus error to the CPU.



注1。RPEST:缓存奇偶校验错误中断检测标志（NMISR。RPEST）

13。6。3。5。1 缓存 RAM 检查

缓存 RAM 的奇偶校验错误发生在具有读取命中缓存状态的 CPU 的读取访问处。对于读击状态,在执行缓存 RAM 检查之前需要满足一些条件。S缓存检查,在闪存中执行检查程序。C缓存检查,在SRAM中执行检查程序。

(1) 缓存 RAM 检查流程

1。刷新缓存中的所有有效位以清除缓存启用位。

2锛姣涓涓。为 S 缓存保留 1-KB 工作内存,例如 SRAM。由于 MCU 中的每个缓存都是与每路 0。5 KB RAM 关联的 2 路集合,因此 S 缓存总共需要 1 KB。目标地址不应用作保留区域。

3锛 娴 。将缓存启用设置为 1。

4锛姣涓。1 KB 的目标字地址使用 CPU 读取数据。缓存的状态应该是读取遗漏,结果存储为缓存填充数据。

5锛姣涓。以另一种缓存方式读取数据,其地址是通过将步骤 4 中的地址与 0。5 KB 地址相加来计算的。缓存的状态应该是读取遗漏,结果以另一种方式存储为缓存填充数据。缓存 RAM 检查写入/读取命中状态现已完成。

6锛 涓€涓。将测试数据写入步骤 4 和 5 中的目标单词地址。。 步骤 4。和 5。中缓存的状态应该是结果写入缓存 RAM 的写入命中。

7锛 娴 。再次从步骤 4 和 5 中的目标单词地址中读取。步骤 4。和 5。中的缓存状态应该是读取命中。单词数据的奇偶校验现已完成。

8锛 娴 。转到步骤 1。继续检查不同目标地址的奇偶校验。

13。6。3。6 总线错误

从总线从站到总线错误的关联将在下面的部分中描述。

在缓存关闭

缓存向 CPU 返回总线错误。

For non-cacheable access

The cache returns a bus error to the CPU.

During read accesses for cache fill

For the first data that corresponds to a CPU access request, the cache returns a bus error to the CPU. For other read data while filling the cache line, the cache cannot return a bus error to the CPU except for read data with early forwarding. The cache enable bit clears the cache line if the cache accepts a bus error response from the slave.

For write-hit status

The cache cannot return a bus error to the CPU because the cache enable bit does not clear the cache line.

For write-miss status

The cache cannot return a bus error to the CPU.

13.6.3.7 Early Forwarding Function

While filling data in the cache, if the address of the CPU read request and the address of the cache fill request are the same, the cache returns the data to CPU. Table 13.4 shows an example.

Table 13.4 Example of early forwarding

Operation	Access sequence								
Address of CPU read request	0x04	0x08	0x0C	0x14	→	0x10	→	→	→
Address of cache fill	0x04	0x08	0x0C	0x10	0x14	0x18	0x1C	0x00	—
CPU access status	Read (0x04)	Read (0x08)	Read (0x0C)	—	Read (0x14)	—	—	—	Read (0x10)

When the CPU requests read accesses and the addresses are 0x04, 0x08, 0x0C, 0x14 and 0x10 sequentially, the first read access to address 0x04 is of a miss-hit status and the cache starts to fill data into cache. The early forwarding function allows a return of read data to CPU when accesses are to addresses 0x08, 0x0C and 0x14 while the cache is filling the cache line. On the other hand, access to address 0x10 must wait for the completion of filling the cache line. The cache then returns data for address 0x10 when it finished filling the cache line.

13.6.4 Usage Notes

13.6.4.1 Cache Line Configuration Register

Writes to the Cache Line Configuration Register are allowed when the status is cache off (CACTL.ENS = 0 for S-cache, CACTL.ENC = 0 for C-cache).

13.6.4.2 Coherency

The coherency between the cache and the internal SRAM must be guaranteed by software.

When allocating shared memory between the CPU and a bus master such as DMAC in the cache support area, invalidate the cache data as necessary.

为不可缓存访问

缓存向 CPU 返回总线错误。

在读取高速缓存填充访问期间

CPU 访问请求对应的第一数据,缓存会向 CPU 返回总线错误。对于填充缓存行时的其他读取数据,除了早期转发的读取数据之外,缓存无法向 CPU 返回总线错误。如果高速缓存接受从站发出的总线错误响应,则高速缓存启用位清除高速缓存行。

为写入命中状态

缓存无法向 CPU 返回总线错误,因为缓存启用位无法清除缓存行。

为写漏状态

缓存无法将总线错误返回到 CPU。

13.6.3.7 早期转发功能

在高速缓存中填充数据的同时,如果CPU读取请求的地址和高速缓存填充请求的地址相同,则高速缓存将数据返回给CPU。表 13。4 显示了一个示例。

表 13。4 早期转发示例

操作	访问序列								
CPU读取请求的地址	0x04	0x08	0x0c	0x14	→	0x10	→	→	→
缓存填充地址	0x04	0x08	0x0c	0x10	0x14	0x18	0x1c	0x00	—
CPU 访问状态	读 (0x04)	读 (0x08)	读 (0x0c)	—	读 (0x14)	—	—	—	读 (0x10)

CPU 请求读取访问并且地址依次为 0x04、0x08、0x0C、0x14 和 0x10 时,对地址 0x04 的第一次读取访问处于未命中状态,缓存开始将数据填充到缓存中。当高速缓存填充高速缓存行时,当访问地址 0x08、0x0C 和 0x14 时,早期转发功能允许将读取的数据返回到 CPU。另一方面,对地址 0x10 的访问必须等待填充缓存行的完成。然后,缓存在填写完缓存行后返回地址 0x10 的数据。

13。6。4 使用说明

13。6。4。1 缓存行配置寄存器

当状态已缓存关闭时,允许写入缓存行配置寄存器（S 缓存的 CACTL。ENS = 0,C 缓存的 CACTL。ENC = 0)。

13。6。4。2 一致性

缓存和内部 SRAM 之间的一致性必须由软件保证。

CPU和缓存支持区DMAC等总线主机之间分配共享内存时,根据需要使缓存数据失效。

14. Memory Protection Unit (MPU)

14.1 Overview

The MCU has one Memory Protection Unit (MPU).

Table 14.1 lists the MPU specifications, and Table 14.2 shows the behavior on detection of each MPU error.

Table 14.1 MPU specifications

Classification	Module/Function	Specifications
Illegal memory access	Arm® Cortex®-M33 CPU	• Arm CPU has a default memory map. If the CPU makes an illegal access, an exception interrupt occurs • The MPU can change a default memory map.
Memory protection	Arm MPU	Memory protection function for the CPU: • (8+8) region MPU with sub regions and background region for secure and non-secure.
	Bus master MPU	Memory protection function for each bus master except for the CPU: • DMAC/DTC: 8 regions

Table 14.2 Behavior on MPU error detection

MPU type	Notification type	Error Response by HRESP signal of AHB I/F	Bus Access on error detection	Storing of error access information
Arm MPU	• Hard fault	Not supported	• Does not correctly write access • Does not correctly read access	Stored in the Cortex-M33 processor
Bus Master MPU	• Reset or Non-maskable interrupts • Hard fault	Supported	• Write access ignore • Read access is read as 0	Stored

For information on error access for the Arm MPU, see section 14.4. References. For information on error access for other MPUs, see section 13.3. Register Descriptions and section 13.4. Bus Error Monitoring Section in section 13, Buses.

14.2 Arm MPU

The Arm MPU monitors the addresses accessed by the CPU across the entire address space (0x0000_0000 to 0xFFFF_FFFF) and provides support for:

- (8 + 8) protected regions
- When memory regions overlap, the processor generates a fault if a core access hits the overlapping regions
- Setting access permissions to protected region (Read, Write, Execution)
- Export of memory attributes to the system.

Arm MPU mismatches and permission violations invoke the programmable-priority MemManage fault (Hard Fault) handler. For details, see section 14.4. References.

14.3 Bus Master MPU

The bus master MPU monitors the addresses accessed by the bus masters in the entire address space (0x0000_0000 to 0xFFFF_FFFF). Access-control information can be set up to 8 regions in DMAC/DTC and monitor for access to each region is in accord with this information.

If access to a protected region is detected, the bus master MPU generates an internal reset or a non-maskable interrupt. For information on error access, see section 13.3. Register Descriptions and section 13.4. Bus Error Monitoring Section in section 13, Buses.

The access control information for each area consists of protected/not-protected to read or write.

Table 14.3 lists the specifications of the bus master MPU.

14。2 臂 MPU

Arm MPU 监控 CPU 在整个地址空间(0x0000_0000 到）访问的地址 0xFFFF_FFFF）并提供以下方面的支持:

- (8 + 8) 保护区
- 当内存区域重叠时, 如果核心访问击中重叠区域, 处理器会产生故障
- 对受保护区域设置访问权限（读取、写入、执行）
- 将内存属性导出到系统。

Arm MPU 不匹配和权限违规会调用可编程优先级 MemManage 故障（硬故障）处理程序。详情请参见第 14。4 节。参考文献 .

14。3 总线主 MPU

总线主 MPU 监控总线主在整个地址空间 (0x0000_0000 to）中访问的地址 0xffff_ffff）。DMAC/DTC 中最多可设置 8 个区域的访问控制信息,并且每个区域的访问监控与此信息一致。

如果检测到对受保护区域的访问,总线主 MPU 会生成内部重置或不可屏蔽中断。有关错误访问的信息,请参阅第 13。3 节。注册说明和第 13。4 节。13节 公交车错误监控段, 公交车 1。

每个区域的访问控制信息由受保护/未受保护的读取或写入组成。

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The MMPUSDMACn (n = 0 to 7) register specifies the start address where the region starts.

Region n unit sets the ENABLE bit, the RP bit, and the WP bit each.

ENABLE bit (Region enable)

The ENABLE bit controls the enable or disable of DMAC/DTC region n (n = 0 to 7) unit.

When the ENABLE bit is set to 1, the RP bit and the WP bit control access permission for read and write protection to MMPUSDMACn (n = 0 to 7) and MMPUEDMACn (n = 0 to 7).

When the ENABLE bit is set to 0, access to DMAC region n (n = 0 to 7) is the outside region.

RP bit (Read protection)

The RP bit enables or disables read protection of DMAC/DTC region n (n = 0 to 7).

When the ENABLE bit is set to 1, the RP bit is available.

WP bit (Write protection)

The WP bit enables or disables write protection of DMAC/DTC region n (n = 0 to 7).

When the ENABLE bit is set to 1, the WP bit is available.

ENABLE 位控制 DMAC/DTC 区域 n（n = 0 至 7) 单元的启用或禁用。

当ENABLE位设置为1时,RP位和WP位控制对MMPUSDMACn（n=0至7)和MMPUEDMACn（n=0至7)的读写保护的访问权限。

ENABLE 位设置为 0 时,对 DMAC 区域 n（n = 0 到 7)的访问是外部区域。

RP 位（读保护）

RP 位启用或禁用 DMAC/DTC 区域 n 的读保护（n = 0 到 7)。

ENABLE 位设置为 1 时,RP 位可用。

WP 位（写保护）

WP 位启用或禁用 DMAC/DTC 区域 n 的写保护（n = 0 到 7)。

ENABLE 位设置为 1 时,WP 位可用。

A master MPU error occurs on the following conditions:

1. MMPUENDMAC.ENABLE = 1, and output of one or more Region n unit is protected region.
2. MMPUENDMAC.ENABLE = 1, and output of all Region n unit are outside region.

Other cases are handled as permitted region.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note: It is necessary to write by half word access.
Byte write access is prohibited. When byte write access is executed, operation is not guaranteed.

ENABLE bit (Bus Master MPU of DMAC enable)

The ENABLE bit controls enable or disable of the bus master MPU function of each master group.

When the ENABLE bit is set to 1, MMPUACDMACn (n = 0 to 7) is valid. When the ENABLE bit is set to 0, MMPUACDMACn (n = 0 to 7) is invalid for all regions. The bus master MPU function sets the ENABLE bit of each master group. When the ENABLE bit is set, write 0xA5 in KEY[7:0] at the same time.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writing to the ENABLE bit. When writing to the ENABLE bit, write 0xA5 in KEY[7:0] bits at the same time. When values other than 0xA5 are written to KEY[7:0] bits, the ENABLE bit is not updated. The KEY[7:0] bits are always read as 0x00.

14.3.2 Operation

14.3.2.1 Memory protection

The bus master MPU monitors memory access using control settings made individually for the access control regions. If access to a protected region is detected, the bus master MPU generates a memory protection error.

Bus Master MPU can be set for up to 8 protection regions. It is protection region when set up of permission region and protection region overlaps. It is protection region when set up of two protection region overlaps.

Bus Master MPU has master groups of DMAC/DTC.

Memory protection checks the address of the bus which the master group unified. Therefore, all the access of a master group is detected by memory protection.

The region setting registers of the Bus Master MPU for DMAC/DTC can be set for secure access and Non-Secure access using the MMPUSARA register. Make secure access and Non-Secure access settings the same for each DMAC/DTC channel and the corresponding region setting registers of the Bus Master MPU.

Bus Master MPU is permission of all regions after reset. All region is protected by setting MMPUENDMAC.ENABLE = 1.

Each region sets up a permission region on the protection region. If access to the protected region is detected, Bus Master MPU will generate an error.

Figure 14.1 shows the use case of a bus master MPU.

- MMPUOAD

PROTECT 位同时设置时,使用半字访问将 0xA5 写入 KEY[7:0] 位。

KEY[7:0] 位启用或禁用对 PROTECT 位的写入。同时写入 PROTECT 位时,写入
0xA5 到 KEY[7:0] 位。KEY[7:0] 位写入其他值时,保护位不会更新。KEY[7:0] 位始终读作 0x00。

14。3。2 操作

14。3。2。1 内存保护

总线主MPU使用针对访问控制区域单独进行的控制设置来监视存储器访问。如果检测到对受保护区域的访问,则总线主 MPU 会生成内存保护错误。

Bus Master MPU 最多可设置为 8 个保护区域。当许可区域和保护区域的设置重叠时,它是保护区域。当两个保护区域重叠时,它是保护区域。

总线主 MPU 具有 DMAC/DTC 主组。

内存保护检查主组统一的总线地址。因此,主群组的所有访问都是通过内存保护来检测的。

可以使用 MMPUSARA 寄存器设置用于安全访问和非安全访问的 DMAC/DTC 总线主 MPU 的区域设置寄存器。对每个 DMAC/DTC 信道以及总线主 MPU 的相应区域设置寄存器进行安全访问和非安全访问设置相同。

总线主 MPU 是重置后所有区域的权限。所有区域均通过设置 MMPUENDMAC。ENABLE = 1 进行保护。每个区域在保护区域上设置一个许可区域。如果检测到对受保护区域的访问,总线主 MPU 将生成错误。

图 14。1 显示了总线主 MPU 的用例。

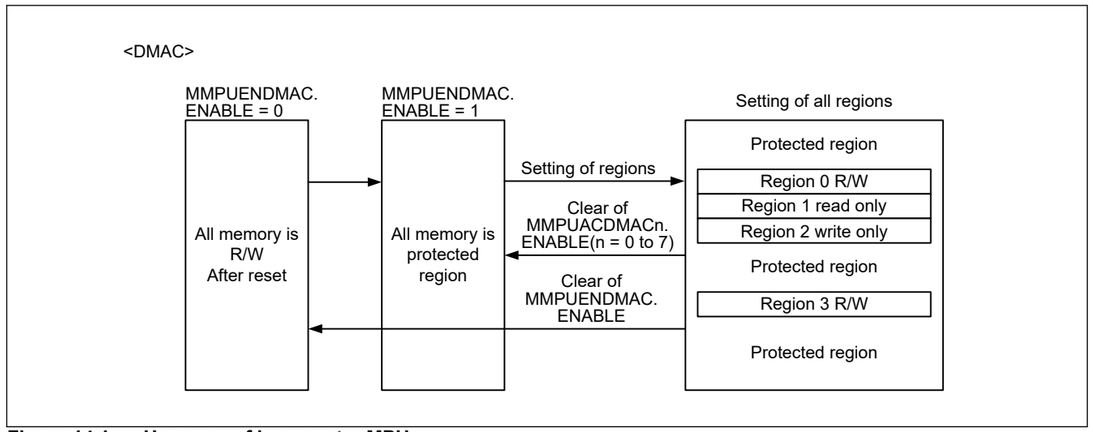

Figure 14.1 Use case of bus master MPU

Figure 14.2 shows the access permission or protection by the overlapping bus master MPU regions.

Access control for the overlapping regions is as follows:

- The region is handled as a protected region when output of one or more region units is a protected region
- The region is handled as a protected region when output of all region units is outside of the regions
- Other cases are handled as permitted regions.

图14。1 总线主 MPU 的用例

图 14。2 显示了重叠总线主 MPU 区域的访问权限或保护。

重叠区域的访问控制如下:

- 当所有区域单元的输出都在区域之外时, 该区域作为受保护区域进行处理
- 其他案件作为允许的区域处理。

15. DMA Controller (DMAC)

15.1 Overview

The MCU includes an 8-channel direct memory access controller (DMAC) that can transfer data without intervention from the CPU. When a DMA transfer request is generated, the DMAC transfers data stored at the transfer source address to the transfer destination address.

Table 15.1 lists the DMAC specifications, and Figure 15.1 shows a block diagram of the DMAC.

Set DMDRR while DMAC activation is disabled (DMAST.DMST = 0) or DMA transfer is disabled (DMCNT.DTE = 0).

DMDRR is the initial value of DMDAR. In repeat-block transfer mode, DMDAR reloads the value of DMDRR after the specified transfer is finished.

In normal transfer mode, repeat transfer mode and block transfer mode, DMDRR is not used. The setting is invalid.

Base address: DMACn = 0x4000_5000 + 0x0040 × n (n = 0 to 7)

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15:0	DMCRAL[15:0]	Lower bits of transfer count Specifies the number of transfer operations.	R/W
25:16	DMCRAH[9:0]	Upper bits of transfer count Specifies the number of transfer operations.	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Set the same value for DMCRAH and DMCRAL in repeat transfer mode, block transfer mode, and repeat-block transfer mode. Bits 15 to 10 are fixed to 0 in repeat transfer mode, block transfer mode, and repeat-block transfer mode.

(1) Normal Transfer Mode (DMTMD.MD[1:0] = 00b)

DMCRAL functions as a 16-bit transfer counter.

The number of transfer operations is one when the setting is 0x0001, and 65,535 when it is 0xFFFF. The value is decremented by one each time data is transferred.

When the setting is 0x0000, no specific number of transfer operations is set; data transfer is performed with the transfer counter stopped (free running function).

Free running function is not selected by DMTMD.TKP bit in normal transfer mode.

DMCRAH is not used in normal transfer mode. Write 0x0000 to DMCRAH.

(2) Repeat Transfer Mode (DMTMD.MD[1:0] = 01b)

DMCRAH specifies the repeat size and DMCRAL functions as a 10-bit transfer counter.

位	符号	功能	R/W
31:0	不适用	指定传输目的地重新加载地址 设置范围为 0x0000_0000 至 0xFFFF_FFFF(4 GB）。	R/W

注: 如果安全属性配置为安全:
- 允许安全访问和非安全读取访问
- 非安全写访问被忽略,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全访问。

禁用 DMAC 激活（DMAST。DMST = 0) 或禁用 DMA 传输（DMCNT。DTE = 0) 时设置 DMDRR。

DMDRR 是 DMDAR 的初始值。在重复块传输模式下,DMDAR 在指定传输完成后重新加载 DMDRR 的值。

在正常传输模式、重复传输模式和块传输模式下,不使用DMDRR。设置无效。

注: 该寄存器中的地址对齐必须与 DMTMD。SZ 位中选择的传输数据大小值匹配。

15.2.6 DMCRA:DMA 传输计数寄存器

基本地址: DMACn = 0x4000_5000 + 0x0040 × n（n = 0 到 7)

偏移地址: 0x08

位位置:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

重置后的值:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
位位置:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
位字段:	DMCRAL[15:0]

位	符号	功能	R/W
15:0	DMCRAL[15:0]	传输计数的较低位 指定传输操作的数量。	R/W
25:16	DMCRAH[9:0]	传输计数的上限位 指定传输操作的数量。	R/W
31:26	—	这些位读作 0。写入值应为 0。	R/W

注: 如果安全属性配置为安全:
- 允许安全访问和非安全读取访问
- 非安全写访问被忽略,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全访问。

在重复传输模式、块传输模式和重复块传输模式下为 DMCRAH 和 DMCRAL 设置相同的值。15至10位在重复传送模式、块传送模式、重复块传送模式下固定为0。

(1)正常转移模式（DMTMD。MD[1:0] = 00b）

DMCRAL 充当 16 位传输计数器。

0x0001 时传输操作次数为 1 次,0xFFFF 时为 65,535 次,每次传输数据时值递减一次。

0x0000 时,不设置具体的传输操作次数;数据传输是在传输计数器停止的情况下进行的（自由运行功能）。

在正常传输模式下,DMTMD。TKP 位不会选择自由运行功能。

DMCRAH 不在正常传输模式下使用。将 0x0000 写入 DMCRAH。

(2) 重复传输模式（DMTMD。MD[1:0] = 01b）

DMCRAH 指定重复大小和 DMCRAL 功能作为 10 位传输计数器。

The number of transfer operations is one when the setting is 0x001, 1023 when it is 0x3FF, and 1024 when it is 0x000. In repeat transfer mode, a value in the range of 0x000 to 0x3FF (1 to 1024) can be set for DMCRAH and DMCRAL.

Setting bits 15 to 10 in DMCRAL is invalid. Write 0 to these bits.

The value in DMCRAL is decremented by one each time data is transferred until it reaches 0x000, at which the value in DMCRAH is loaded into DMCRAL.

(3) Block Transfer Mode (DMTMD.MD[1:0] = 10b)

DMCRAH specifies the block size and DMCRAL functions as a 10-bit block size counter.

The block size is one when the setting is 0x001, 1023 when it is 0x3FF, and 1024 when it is 0x000. In block transfer mode, a value in the range of 0x000 to 0x3FF can be set for DMCRAH and DMCRAL.

Setting bits 15 to 10 in DMCRAL is invalid. Write 0 to these bits.

The value in DMCRAL is decremented by one each time data is transferred until it reaches 0x000, at which the value in DMCRAH is loaded into DMCRAL.

(4) Repeat-Block Transfer Mode (DMTMD.MD[1:0] = 11b)

DMCRAH specifies the block size and DMCRAL functions as a 10-bit block size counter.

The block size is one when the setting is 0x001, 1023 when it is 0x3FF, and 1024 when it is 0x000. In repeat-block transfer mode, a value in the range of 0x000 to 0x3FF can be set for DMCRAH and DMCRAL.

Setting bits 15 to 10 in DMCRAL is invalid. Write 0 to these bits.

The value in DMCRAL is decremented by one each time data is transferred until it reaches 0x000, at which the value in DMCRAH is loaded into DMCRAL.

15.2.7 DMCRB : DMA Block Transfer Count Register

Base address: DMACn = 0x4000_5000 + 0x0040 × n (n = 0 to 7)

Offset address: 0x0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DMCRBH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DMCRBL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DMCRBL[15:0]	Functions as a number of block, repeat or repeat-block transfer counter. 0x0001 to 0xFFFF (1 to 65535) 0x0000 (65536)	R/W
31:16	DMCRBH[15:0]	Specifies the number of block, repeat or repeat-block transfer operations. 0x0001 to 0xFFFF (1 to 65535) 0x0000 (65536)	R/W

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Set the same value for DMCRBH and DMCRBL in repeat transfer mode, block transfer mode and repeat-block transfer mode.

DMCRBH specifies the number of block, repeat and repeat-block transfer operations, and DMCRBL functions as a 16-bit the number of block counter in block, repeat, and repeat-block transfer mode, respectively.

0x001 时传输操作次数为 1 次,0x3FF 时为 1023 次,0x000 时为 1024 次。在重复传输模式下,可以为DMCRAH和DMCRAL设置0x000至0x3FF(1至1024)范围内的值。

DMCRAL 中设置位 15 到 10 是无效的。0 写入这些位。

每次传输数据时,DMCRAL 中的值都会减少 1,直到达到 0x000,此时 DMCRAH 中的值将加载到 DMCRAL 中。

(3)块传输模式（DMTMD。MD[1:0] = 10b）

DMCRAH 指定块大小,DMCRAL 功能作为 10 位块大小计数器。

0x001 时块大小为 1,0x3FF 时为 1023,0x000 时为 1024。在块传输模式下,可以为DMCRAH和DMCRAL设置0x000至0x3FF范围内的值。

DMCRAL 中设置位 15 到 10 是无效的。0 写入这些位。

每次传输数据时,DMCRAL 中的值都会减少 1,直到达到 0x000,此时 DMCRAH 中的值将加载到 DMCRAL 中。

(4)重复块传输模式（DMTMD。MD[1:0] = 11b）DMCRAH 指定块大小和 DMCRAL 函数作为 10 位块大小计数器。

0x001 时块大小为 1,0x3FF 时为 1023,0x000 时为 1024。在重复块传输模式下,可以为DMCRAH和DMCRAL设置0x000至0x3FF范围内的值。

DMCRAL 中设置位 15 到 10 是无效的。0 写入这些位。

每次传输数据时,DMCRAL 中的值都会减少 1,直到达到 0x000,此时 DMCRAH 中的值将加载到 DMCRAL 中。

The number of transfer operations is one when the setting is 0x0001, 65535 when it is 0xFFFF, and 65536 when it is 0x0000.

In repeat transfer mode, the value is decremented by one when the final data of one repeat size is transferred.

In block transfer mode and repeat-block transfer mode, the value is decremented by one when the final data of one block size is transferred.

In normal transfer mode, DMCRB is not used. The setting is invalid.

When DMTMD.TKP is 1 and the final data of one repeat size or one block size is transferred, DMCRBL reloads the value of DMCRBH automatically.

DARIE bit (Destination Address Extended Repeat Area Overflow Interrupt Enable)

When an extended repeat area overflow on the destination address occurs while DARIE bit is set to 1, the DMCNT.DTE bit is cleared to 0. At the same time, the DMSTS.ESIF flag is set to 1 to indicate that an interrupt by an extended repeat area overflow on the destination address is requested.

When block transfer mode is used with the extended repeat area function, an interrupt is requested after completion of a 1-block size transfer. When setting 1 in the DMCNT.DTE bit of the channel for which a transfer has been stopped, the transfer is resumed from the state when the transfer is stopped.

When the extended repeat area is not specified for the destination address, this bit is ignored.

When set to repeat-block transfer mode, do not use this bit.

SARIE bit (Source Address Extended Repeat Area Overflow Interrupt Enable)

When an extended repeat area overflow on the source address occurs while SARIE bit is set to 1, the DMCNT.DTE bit is cleared to 0. At the same time, the DMSTS.ESIF flag is set to 1 to indicate that an interrupt by an extended repeat area overflow on the source address is requested.

DARIE 位（目标地址扩展重复区域溢出中断启用）

当 DARIE 位设置为 1 时,目标地址上出现扩展重复区域溢出时,DMCNT。DTE 位被清除为 0。同时,DMSTS。ESIF标志被设置为1以指示请求目的地地址上的扩展重复区域溢出的中断。

当块传输模式与扩展重复区域函数一起使用时,在完成 1 块大小传输后请求中断。当在已停止传输的信道的DMCNT。DTE位中设置1时,从停止传输时的状态恢复传输。

当未为目标地址指定扩展重复区域时,该位将被忽略。

当设置为重复块传输模式时,请勿使用此位。

SARIE 位（源地址扩展重复区溢出中断启用）

当 SARIE 位设置为 1 时源地址上出现扩展重复区域溢出时,DMCNT。DTE 位被清除为 0。同时,DMSTS。ESIF标志被设置为1以指示请求源地址上的扩展重复区域溢出的中断。

When block transfer mode is used with the extended repeat area function, an interrupt is requested after completion of a 1-block size transfer. When setting 1 in the DMCNT.DTE bit of the channel for which a transfer has been stopped, the transfer is resumed from the state when the transfer is stopped.

When the extended repeat area is not specified for the source address, this bit is ignored.

When set to repeat-block transfer mode, do not use this bit.

RPTIE bit (Repeat Size End Interrupt Enable)

When RPTIE bit is set to 1 in repeat transfer mode, the DMCNT.DTE bit is cleared to 0 after completion of a 1-repeat size data transfer. At the same time, the DMSTS.ESIF flag is set to 1 to indicate that the repeat size end interrupt request has been generated. The repeat size end interrupt request can be generated even when the DMTMD.DTS[1:0] bits are 10b (= repeat area or block area is not specified).

When this bit is set to 1 in block transfer mode, the DMCNT.DTE bit is cleared to 0 after completion of a 1-block data transfer in the same way as repeat transfer mode. At the same time, the DMSTS.ESIF flag is set to 1 to indicate that the repeat size end interrupt request has been generated. The repeat size end interrupt request can be generated even when the DMTMD.DTS[1:0] bits are 10b (= repeat area or block area is not specified).

When set to repeat-block transfer mode, do not use this bit.

ESIE bit (Transfer Escape End Interrupt Enable)

ESIE bit enables or disables the transfer escape end interrupt requests (repeat size end interrupt request and extended repeat area overflow interrupt request) that are generated during DMA transfer.

The transfer escape end interrupt is generated when the DMSTS.ESIF flag is set to 1 with this bit set to 1. The transfer escape end interrupt is cleared by clearing this bit or the DMSTS.ESIF flag to 0.

DTIE bit (Transfer End Interrupt Enable)

DTIE bit enables or disables the transfer end interrupt request to be generated on completion of a specified number of data transfers.

The transfer end interrupt is generated when the DMSTS.DTIF flag is set to 1 with this bit set to 1. The transfer end interrupt is cleared by clearing this bit or the DMSTS.DTIF flag to 0.

15.2.10 DMAMD : DMA Address Mode Register

当未为源地址指定扩展重复区域时,该位将被忽略。

当设置为重复块传输模式时,请勿使用此位。

RPTIE 位（重复大小结束中断启用）

当重复传输模式下RPTIE位设置为1时,完成1重复大小的数据传输后,DMCNT。DTE位被清除为0。同时,DMSTS。ESIF标志被设置为1以指示重复大小结束中断请求已经生成。DMTMD。DTS[1:0]位为10b(=未指定重复区域或块区域）时,也可以生成重复大小结束中断请求。

当该比特在块传输模式下设置为1时,以与重复传输模式相同的方式完成1块数据传输后,DMCNT。DTE比特被清除为0。同时,DMSTS。ESIF标志被设置为1以指示重复大小结束中断请求已经生成。DMTMD。DTS[1:0]位为10b(=未指定重复区域或块区域）时,也可以生成重复大小结束中断请求。

当设置为重复块传输模式时,请勿使用此位。

ESIE 位（传输转义结束中断启用）

DARA[4:0] bits (Destination Address Extended Repeat Area)

DARA[4:0] bits specify the extended repeat area on the destination address. The extended repeat area function is realized by updating the specified lower address bits with the remaining upper address bits fixed. The size of the extended repeat area can be any power of two between 2 bytes and 128 Mbytes.

When the lower address overflows the extended repeat area by address increment, the start address of the extended repeat area is set. Similarly, when the lower address underflows the extended repeat area by address decrement, the end address of the extended repeat area is set.

When the repeat area or block area is specified as a transfer destination, do not specify the extended repeat area on the destination address. When repeat transfer or block transfer is selected, and when DMTMD.DTS[1:0] = 00b (the transfer destination is specified as the repeat area or block area), write 00000b in the DARA[4:0] bits.

In repeat-block transfer mode, write 00000b in the DARA[4:0] bits.

An interrupt can be requested when an overflow or underflow occurs in the extended repeat area with the DMINT.DARIE bit set to 1. Table 15.2 lists the settings and the corresponding extended repeat areas.

DADR bits (Destination Address Update Select After Reload)

In repeat-block transfer mode, this bit specifies the behavior of DMDAR after reloading DMDRR.

When this bit is set to 1, an index value ((DMDBSH-DMDBSL) × DataSize) is added to DMDAR after reloading DMDRR.

When this bit is set to 0, DMDAR only reloads DMDRR. This behavior is described in Table 15.13.

In normal, repeat or block transfer mode, this bit is ignored.

DM[1:0] bits (Destination Address Update Mode)

DM[1:0] bits select the mode of updating the destination address.

When increment is selected and the DMTMD.SZ[1:0] bits are set to 00b, 01b, or 10b, the destination address is incremented by 1, 2, or 4, respectively.

When decrement is selected and the DMTMD.SZ[1:0] bits are set to 00b, 01b, or 10b, the destination address is decremented by 1, 2, or 4, respectively.

When offset addition is selected, the offset specified by the DMOFR register is added to the address.

SARA[4:0] bits (Source Address Extended Repeat Area)

SARA[4:0] bits specify the extended repeat area on the source address. The extended repeat area function is realized by updating the specified lower address bits with the remaining upper address bits fixed. The size of the extended repeat area can be any power of two between 2 bytes and 128 Mbytes.

When the lower address overflows the extended repeat area by address increment, the start address of the extended repeat area is set. Similarly, when the lower address underflows the extended repeat area by address decrement, the end address of the extended repeat area is set.

When the repeat area or block area is specified as a transfer source, do not specify the extended repeat area on the source address. When repeat transfer or block transfer is selected, and when DMTMD.DTS[1:0] = 01b (the transfer source is specified as the repeat area or block area), write 00000b in the SARA[4:0] bits.

注: 如果安全属性配置为安全:
- 允许安全访问和非安全读取访问
- 非安全写访问被忽略,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:

DARA[4:0] 位（目标地址扩展重复区）

DARA[4:0] 位指定目标地址上的扩展重复区域。通过更新指定的下地址位并固定剩余的上地址位来实现扩展重复区域函数。扩展重复区域的大小可以是 2 个字节到 128 Mbytes 之间的任意 2 次方。

当下地址通过地址增量溢出扩展重复区域时,设置扩展重复区域的起始地址。类似地,当下地址通过地址递减使扩展重复区域下溢时,设置扩展重复区域的结束地址。

当重复区域或块区域被指定为传输目的地时,不要在目的地地址上指定扩展的重复区域。选择重复传输或块传输时,当DMTMD。DTS[1:0]=00b时（传输目的地指定为重复区域或块区域）,在DARA[4:0]位中写入00000b。

在重复块传输模式下,在 DARA[4:0] 位中写入 00000b。

当 DMINT。DARIE 位设置为 1 的扩展重复区域发生溢出或下溢时,可以请求中断。表 15。2 列出了设置和相应的扩展重复区域。

DADR 位（重新加载后选择目标地址更新）

在重复块传输模式下,该位指定重新加载 DMDRR 后 DMDAR 的行为。

当该位设置为 1 时,重新加载 DMDRR 后,将索引值（（DMDBSH−DMDBSL）× DataSize）添加到 DMDAR。

当该位设置为 0 时,DMDAR 仅重新加载 DMDRR。此行为如表 15。13 . 所示
在正常、重复或块传输模式下,该位被忽略。

DM[1:0] 位（目标地址更新模式）

DM[1:0] 位选择更新目的地址的模式。

当选择增量并将DMTMD。SZ[1:0]位设置为00b、01b或10b时,目标地址分别增加1、2或4。

当选择递减并将DMTMD。SZ[1:0]位设置为00b、01b或10b时,目标地址分别递减1、2或4。

当选择偏移添加时,DMOFR寄存器指定的偏移将添加到地址。

SARA[4:0] 位（源地址扩展重复区）

SARA[4:0] 位指定源地址上的扩展重复区域。通过更新指定的下地址位并固定剩余的上地址位来实现扩展重复区域函数。扩展重复区域的大小可以是 2 个字节到 128 Mbytes 之间的任意 2 次方。

当下地址通过地址增量溢出扩展重复区域时,设置扩展重复区域的起始地址。类似地,当下地址通过地址递减使扩展重复区域下溢时,设置扩展重复区域的结束地址。

当重复区域或块区域被指定为传输源时,不要在源地址上指定扩展的重复区域。选择重复传输或块传输时,当DMTMD。DTS[1:0]=01b时（传输源指定为重复区域或块区域）,在SARA[4:0]位中写入00000b。

In repeat-block transfer mode, write 00000b in the SARA[4:0] bits.

An interrupt can be requested when an overflow or underflow occurs in the extended repeat area with the DMINT.SARIE bit set to 1. Table 15.2 lists the settings and the corresponding extended repeat areas.

SADR bits (Source Address Update Select After Reload)

In repeat-block transfer mode, this bit specifies the behavior of DMSAR after reloading DMSRR.

When this bit is set to 1, an index value ((DMSBSH-DMSBSL) × DataSize) is added to DMSAR after reloading DMSRR.

When this bit is set to 0, DMSAR only reloads DMSRR. This behavior is described in Table 15.12.

In normal, repeat or block transfer mode, this bit is ignored.

SM[1:0] bits (Source Address Update Mode)

SM[1:0] bits select the mode of updating the source address.

When increment is selected and the DMTMD.SZ[1:0] bits are set to 00b, 01b, or 10b, the source address is incremented by 1, 2, or 4, respectively.

When decrement is selected and the DMTMD.SZ[1:0] bits are set to 00b, 01b, or 10b, the source address is decremented by 1, 2, or 4, respectively.

When offset addition is selected, the offset specified by the DMOFR register is added to the address.

在重复块传输模式下,在 SARA[4:0] 位中写入 00000b。

当 DMINT。SARIE 位设置为 1 的扩展重复区域发生溢出或下溢时,可以请求中断。表 15。2 列出了设置和相应的扩展重复区域。

SADR 位（重新加载后选择源地址更新）

在重复块传输模式下,该位指定重新加载 DMSRR 后 DMSAR 的行为。

当该位设置为 1 时,在重新加载 DMSRR 后将索引值（（DMSBSH-DMSBSL）× DataSize）添加到 DMSAR。

当该位设置为 0 时,DMSAR 仅重新加载 DMSRR。此行为如表 15。12 . 所示
在正常、重复或块传输模式下,该位被忽略。

SM[1:0] 位（源地址更新模式）

SM[1:0]位选择更新源地址的模式。

当选择增量并将DMTMD。SZ[1:0]位设置为00b、01b或10b时,源地址分别增加1、2或4。

当选择递减并将DMTMD。SZ[1:0]位设置为00b、01b或10b时,源地址分别递减1、2或4。

当选择偏移添加时,DMOFR寄存器指定的偏移将添加到地址。

15.2.11 DMOFR : DMA Offset Register

Base address: DMACn = 0x4000_5000 + 0x0040 × n (n = 0 to 7)

Offset address: 0x18

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Specifies the offset when offset addition is selected as the address update mode for transfer source or destination. 0x00000000 to 0x00FFFFFF (0 bytes to (16 M – 1) bytes) 0xFF000000 to 0xFFFFFFFF (–16 Mbytes to –1 byte)	R/W

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Write to this register while the DMAC operation is stopped or DMA transfer is disabled (not during data transfer).

Setting bits 31 to 25 is invalid; a value of bit 24 is extended to bits 31 to 25. Reading DMOFR returns the extended value.

In repeat-block transfer mode, the offset is not specified by DMOFR when offset addition is selected, write 0 to DMOFR.

15.2.12 DMCNT : DMA Transfer Enable Register

Base address: DMACn = 0x4000_5000 + 0x0040 × n (n = 0 to 7)

Offset address: 0x1C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DTE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DTE	DMA Transfer Enable 0: Disables DMA transfer. 1: Enables DMA transfer.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

DTE bit (DMA Transfer Enable)

When the DMAST.DMST bit is set to 1 (DMAC activation is enabled) and this bit is set to 1 (DMA transfer is enabled), DMA transfer can be started for the corresponding channel.

[Setting condition]

31:0	不适用	选择偏移添加作为传输源或目的地的地址更新模式时指定偏移。 0x00000000 到 0x00FFFFFF(0 字节到 (16 M – 1) 字节) 0xFF000000 到 0xFFFFFFFF(–16 Mbytes 到 –1 字节)	R/W

注: 如果安全属性配置为安全:
- 允许安全访问和非安全读取访问
- 非安全写访问被忽略,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全访问。

DMAC 操作停止或 DMA 传输被禁用时（不是在数据传输期间）写入此寄存器。

31至25位设置无效;位24的值扩展到位31至25。读取 DMOFR 返回扩展值。

在重复块传输模式下,当选择偏移相加时,DMOFR 未指定偏移,将 0 写入 DMOFR。

15.2.12 DMCNT:DMA 传输启用寄存器

基本地址: DMACn = 0x4000_5000 + 0x0040 × n（n = 0 到 7）

DTE 位（启用 DMA 传输）

DMAST。DMST 位设置为 1（启用 DMAC 激活）且该位设置为 1（启用 DMA 传输）时,DMA 传输可以为相应的信道启动。的【设置条件】

- When 1 is written to this bit.

[Clearing conditions]

- When 0 is written to this bit.
- When the specified total volume of data transfer is completed.
- When DMA transfer is stopped by the repeat size end interrupt.
- When DMA transfer is stopped by the extended repeat area overflow interrupt.
- When DMA transfer is stopped by the access error occurs. See section 15.5. Processing on DMA Transfer Error.

15.2.13 DMREQ : DMA Software Start Register

Base address: DMACn = 0x4000_5000 + 0x0040 × n (n = 0 to 7)

Offset address: 0x1D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CLRS	—	—	—	SWREQ
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SWREQ	DMA Software Start 0: DMA transfer is not requested. 1: DMA transfer is requested.	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	CLRS	DMA Software Start Bit Auto Clear Select 0: SWREQ bit is cleared after DMA transfer is started by software. 1: SWREQ bit is not cleared after DMA transfer is started by software.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

SWREQ bit (DMA Software Start)

When 1 is written to SWREQ bit, a DMA transfer request is generated. After DMA transfer is started in response to the request, this bit is cleared to 0 if the CLRS bit is set to 0. This bit is not cleared to 0 while the CLRS bit is set to 1. In this case, a DMA transfer request can be issued again after completion of a transfer.

Note that, however, setting this bit is valid and DMA transfer by software is enabled only when the DMTMD.DCTG[1:0] bits are set to 00b (DMAC activation source is software).

Setting this bit is invalid when the DMTMD.DCTG[1:0] bits are set to a value other than 00b.

To start DMA transfer by software with the CLRS bit being 0, ensure that the SWREQ bit is 0, and then write 1 to the SWREQ bit.

[Setting condition]

- When 1 is written to this bit.

[Clearing conditions]

- When a DMA transfer request by software is accepted and DMA transfer is started while the CLRS bit is set to 0 (the SWREQ bit is cleared after DMA transfer is started by software).
- When 0 is written to this bit.

- 当 1 写入到该位时。

的【清算条件】

- 当 0 写入到该位时。
- 当指定的数据传输总量完成时。
- 当 DMA 传输被重复大小结束中断停止时。
- 当 DMA 传输被扩展的重复区域溢出中断停止时。
- 当 DMA 传输因访问错误而停止时。参见第 15。5 节。DMA 传输错误 . 上的处理

15。2。13 DMREQ:DMA 软件启动注册

基本地址:DMACn = 0x4000_5000 + 0x0040 × n（n = 0 到 7）

偏移地址: 0x1d

位位置:	7	6	5	4	3	2	1	0
位字段:	—	—	—	CLRS	—	—	—	SWREQ
重置后的值:	0	0	0	0	0	0	0	0

位	符号	功能	R/W
0	SWREQ	DMA 软件启动 0:不要求DMA传输。1:请求DMA传输。	R/W
3:1	—	这些位读作 0。写入值应为 0。	R/W
4	CLRS	DMA 软件 开始 位 自动 清除 选择 0:软件启动DMA传输后SWREQ位被清除。 1:软件启动DMA传输后,SWREQ位未被清除。	R/W
7:5	—	这些位读作 0。写入值应为 0。	R/W

注: 如果安全属性配置为安全:
- 允许安全访问和非安全读取访问
- 非安全写访问被忽略,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全访问。

SWREQ 位（DMA 软件启动）

1写入到SWREQ位时,生成一个DMA传输请求。DMA 传输响应请求启动后,如果 CLRS 位设置为 0,则该位被清除为 0。当 CLRS 位设置为 1 时,该位未清除为 0。在这种情况下,可以在传输完成后再次发出DMA传输请求。

但请注意,设置此位是有效的,并且只有当 DMTMD。DCTG[1:0] 位设置为 00b 时才启用软件的 DMA 传输（DMAC 激活源是软件）。

DMTMD。DCTG[1:0]位设置为00b以外的值时,设置该位无效。

CLRS位为0的软件开始DMA传输,保证SWREQ位为0,然后写入1到SWREQ位。

的【设置条件】

- 当 1 写入到该位时。

的【清算条件】

- 当软件的 DMA 传输请求被接受并启动 DMA 传输而 CLRS 位被设置为 0 时（软件启动 DMA 传输后 SWREQ 位被清除）。
- 当 0 写入到该位时。

CLRS bit (DMA Software Start Bit Auto Clear Select)

CLRS bit specifies whether to clear the SWREQ bit to 0 after DMA transfer is started in response to the DMA transfer request generated by setting the SWREQ bit to 1. With this bit set to 0, the SWREQ bit is cleared to 0 after DMA transfer is started. With this bit set to 1, the SWREQ bit is not cleared to 0. In this case, a DMA transfer request can be issued again after completion of a transfer.

15.2.14 DMSTS : DMA Status Register

Base address: DMACn = 0x4000_5000 + 0x0040 × n (n = 0 to 7)

Offset address: 0x1E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ACT	—	—	DTIF	—	—	—	ESIF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ESIF	Transfer Escape End Interrupt Flag 0: A transfer escape end interrupt has not been generated. 1: A transfer escape end interrupt has been generated.	R/W*1
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	DTIF	Transfer End Interrupt Flag 0: A transfer end interrupt has not been generated. 1: A transfer end interrupt has been generated.	R/W*1
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	ACT	DMAC Active Flag 0: DMAC is in the idle state. 1: DMAC is operating.	R

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. Only 0 can be written to clear the flag.

ESIF flag (Transfer Escape End Interrupt Flag)

This flag indicates that the transfer escape end interrupt has been generated.

[Setting conditions]

- When 1-repeat size data transfer is completed in repeat transfer mode with the DMINT.RPTIE bit set to 1.

- When an extended repeat area overflow on the source address occurs while the DMINT.SARIE bit is set to 1 and the DMAMD.SARA[4:0] bits are set to a value other than 00000b (extended repeat area is specified on the transfer source address).
- When an extended repeat area overflow on the destination address occurs while the DMINT.DARIE bit is set to 1 and the DMAMD.DARA[4:0] bits are set to a value other than 00000b (extended repeat area is specified on the transfer destination address).

[Clearing conditions]

- When 0 is written to this bit.
- When 1 is written to the DMCNT.DTE bit.

DTIF flag (Transfer End Interrupt Flag)

This flag indicates that the transfer end interrupt has been generated.

[Setting conditions]

CLRS 位（DMA 软件启动位自动清除选择）

CLRS位, 响应于通过将SWREQ位设置为1而生成的DMA传输请求, 指定在DMA传输开始后是否将SWREQ位清除为0。当该位设置为 0 时,DMA 传输开始后,SWREQ 位被清除为 0。当该位设置为 1 时,SWREQ 位不会被清除为 0。在这种情况下,可以在传输完成后再次发出DMA传输请求。

Bit	Symbol	Function	R/W
15:0	DMSBSL[15:0]	Functions as data transfer counter in repeat-block transfer mode See Table 15.3 for available settings.	R/W
31:16	DMSBSH[15:0]	Specifies the repeat-area size in repeat-block transfer mode See Table 15.3 for available settings.	R/W

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Set the same value for DMSBSH and DMSBSL in repeat-block transfer mode. Write 0x00000000 to DMSBS in normal, repeat and block transfer mode.

DMSBSH specifies buffer size and DMSBSL functions as a 16-bit buffer size counter in repeat-block transfer mode. In repeat-block transfer mode, source repeat area is specified by DMSBSH.

When address update mode is incremented address or decremented address, this register means the numbers of data of whole buffer. When address update mode is offset addition, this register means the numbers of data of an individual buffer. In offset addition, setting DMSBSH and DMSBSL to 0x0000 is prohibited. When final data of one buffer size is transferred, DMSBSL reloads value of DMSBSH. When address update mode is fixed address, this register is ignored. Table 15.3 shows

Set the same value for DMDBSH and DMDBSL in repeat-block transfer mode. Write 0x00000000 to DMDBS in normal, repeat and block transfer mode.

DMDBSH specifies buffer size and DMDBSL functions as a 16-bit buffer size counter in repeat-block transfer mode. In repeat-block transfer mode, destination repeat area is specified by DMDBSH.

When address update mode is incremented address or decremented address, this register means the numbers of data of whole buffer. When address update mode is offset addition, this register means the numbers of data of an individual buffer. In offset addition, setting DMDBSH and DMDBSL to 0x0000 is prohibited. When final data of one buffer size is transferred, DMDBSL reloads value of DMDBSH. When address update mode is fixed address, this register is ignored. DMST bit (DMAC Operation Enable)

Setting the DMAST.DMST to 1 enables DMAC activation for all channels. When the DMST bit is set to 1 (DMAC activation is enabled), and 1 is written to the DMCNT.DTE bit (DMA transfer is enabled) for multiple channels, all associated channels can be placed in the transfer request ready state at the same time.

When the DMST bit clears to 0 during DMA transfer, DMA transfer is suspended after the current data transfer associated with a single transfer request completes. To resume DMA transfer, set the DMST bit to 1 again.

15.3 Operation

15.3.1 Transfer Mode

15.3.1.1 Normal Transfer Mode

In normal transfer mode, one data is transferred by one transfer request. A maximum of 65535 can be set as the number of transfer operations using the DMCRAL register. When these bits are set to 0x0000, no specific number of transfer operations is set; data transfer is performed with the transfer counter stopped (free-running function). Setting DMCRB register is invalid in normal transfer mode. Except in free-running function, a transfer end interrupt request can be generated after completion of the specified number of transfer operations.

Table 15.5 summarizes the register update operation in normal transfer mode, and Figure 15.2 shows the operation in normal transfer mode.

Table 15.5 Register update operation in normal transfer mode

Register	Function	Update operation after completion of a transfer by one transfer request
DMSAR	Transfer source address	Increment/decrement/fixed/offset addition
DMDAR	Transfer destination address	Increment/decrement/fixed/offset addition
DMCRAL	Transfer count	Decremented by one/not updated (in free running function)
DMCRAH	—	Not updated (Not used in normal transfer mode)
DMCRB	—	Not updated (Not used in normal transfer mode)

DMESTA 位（DMAC 错误状态）

DMESTA 位指示是否发生 DMA 传输错误。

- 当 DMAC 传输错误发生时。

的【清零条件】

- 当 1 写入 DMESTA 时。

注意:当DMECHSAM = 1时,可以在安全状态和非安全状态下清除。DMECHSAM = 0,在非安全状态下无法清除。

15。3 操作

15。3。1 传输模式

15。3。1。1 正常传输模式

在正常传输模式下,一个数据通过一个传输请求进行传输。最多 65535 可以设置为使用 DMCRAL 寄存器的传输操作次数。0x0000 设置这些位时,不设置特定数量的传输操作;数据传输是在传输计数器停止的情况下执行的（自由运行函数）。设置DMCRB寄存器在正常传输模式下无效。除自由运行功能外,在完成指定数量的传输操作后可以生成传输端中断请求。

表15。5总结了正常传输模式下的寄存器更新操作,图15。2显示了正常传输模式下的操作。

15.3.1.2 Repeat Transfer Mode

In repeat transfer mode, one data is transferred by one transfer request.

A maximum of 1K data can be set as a total repeat transfer size using DMCRA register.

A maximum of 64K can be set as the number of repeat transfer operations using DMCRB register; therefore, a maximum of 64M data (1K data × 64K counts of repeat transfer operations) can be set as a total data transfer size.

Either the transfer source or transfer destination can be specified as a repeat area. When transfer of the repeat size data is completed, the address of the specified repeat area (DMSAR or DMDAR) returns to the transfer start address. When data of the specified repeat size has all been transferred in repeat transfer mode, DMA transfer can be stopped, and the repeat size end interrupt can be requested. DMA transfer can be resumed by writing 1 to the DMCNT.DTE bit in the repeat size end interrupt handling.

A transfer end interrupt request can be generated after completion of the specified number of repeat transfer operations.

Table 15.6 summarizes the register update operation in repeat transfer mode, and Figure 15.3 shows the operation in repeat transfer mode.

15。3。1。2 重复传输模式

在重复传输模式下,一个数据通过一个传输请求进行传输。

DMCRA 寄存器, 最多可将 1K 数据设置为总重复传输大小。

DMCRB 寄存器可将最大 64K 设置为重复传输操作次数;因此,可将最大 64M 数据(1K 数据 × 重复传输操作的 64K 计数）设置为总数据传输大小。

传输源或传输目的地可以指定为重复区域。当重复大小数据的传输完成时,指定重复区域（DMSAR或DMDAR）的地址返回到传输开始地址。当指定重复大小的数据已全部以重复传输模式传输时,可以停止DMA传输,并且可以请求重复大小结束中断。DMA 传输可以通过在重复大小结束中断处理中将 1 写入 DMCNT。DTE 位来恢复。

完成指定数量的重复传输操作后可以生成传输端中断请求。

15.3.1.3 Block Transfer Mode

In block transfer mode, a single block data is transferred by one transfer request.

A maximum of 1K data can be set as a total block transfer size using DMCRA register.

A maximum of 64K can be set as the number of block transfer operations using DMCRB register; therefore, a maximum of 64M data (1K data × 64K counts of block transfer operations) can be set as a total data transfer size.

15。3。1。3 块传输模式

在块传输模式下,单个块数据通过一个传输请求进行传输。

DMCRA 寄存器, 最多可将 1K 数据设置为总块传输大小。

DMCRB 寄存器, 最大可设置 64K 为块传输操作次数;因此, 最大可设置 64M 数据(1K 数据 × 64K 块传输操作计数）为总数据传输大小。

传输源或传输目的地可以指定为块区域。当单个块数据的传输完成时,指定块区域（DMSAR 或 DMDAR）的地址返回到传输开始地址。当单个块数据已全部以块传输模式传输时,可以停止DMA传输,并且可以请求重复大小结束中断。DMA 传输可以通过在重复大小结束中断处理中将 1 写入 DMCNT。DTE 位来恢复。

可以在完成指定数量的块传输操作之后生成传输端中断请求。

表 15。7 总结了块传输模式下的寄存器更新操作,图 15。4 显示了块传输模式下的操作。

15.3.1.4 Repeat-Block Transfer Mode

Repeat-block transfer is the operation mode with the following functions added to the block transfer function.

Repeat function: Added function (ring buffer) to repeat specified address area.

Offset function: Multiple areas with offset can be specified within one block transfer.

The repeat function and the offset function can be used for both the transfer source and the transfer destination of repeat-block transfer.

Figure 15.5 shows an example of adding a repeat function to the transfer destination.

Figure 15.6 shows repeat-block transfer with an offset to the transfer destination.

In repeat-block transfer mode, a single block data is transferred by one transfer request.

A maximum of 1K data can be set as a total block transfer size using DMCRA of the DMACn.

A maximum of 64K can be set as the number of block transfer operations using DMCRB of the DMACn; therefore, a maximum of 64M data (1K data × 64K counts of block transfer operations) can be set as a total data transfer size.

15。3。1。4 重复块传输模式

重复块传输是将以下功能添加到块传输功能的操作模式。

重复功能:添加重复指定地址区域的功能（环缓冲区）。

偏移功能:可以在一次块传输中指定多个具有偏移的区域。

重复函数和偏移函数可用于重复块传输的传输源和传输目的地。

图 15。5 显示了向传输目的地添加重复函数的示例。

图 15。6 显示了带有偏移到传输目的地的重复块传输。

在重复块传输模式中,单个块数据通过一个传输请求进行传输。

DMACn的DMCRA,最多可以设置1K个数据作为总块传输大小。

DMACn的DMCRB,最大64K可以设置为块传输操作的数量;因此,最大64M数据(1K数据×块传输操作的64K计数）可以设置为总数据传输大小。

15.3.2 Extended Repeat Area Function

The DMAC supports a function to specify the extended repeat areas on the transfer source and destination addresses. With the extended repeat areas set, the address registers repeatedly indicate the addresses of the specified extended repeat areas.

The extended repeat areas can be specified separately to the transfer source address register (DMSAR) and transfer destination address register (DMDAR).

The extended repeat area on the source address is specified by the DMAMD.SARA[4:0] bits. The extended repeat area on the destination address is specified by the DMAMD.DARA[4:0] bits. The size can be specified separately for the source and destination sides.

However, the area (of transfer source or transfer destination) which is specified as the repeat area or block area should not be specified as the extended repeat area.

When the address register value reaches the end address of the extended repeat area and the extended repeat area overflows, DMA transfer is stopped and an interrupt by an extended repeat area overflow can be requested. When an overflow occurs in the extended repeat area on the transfer source while the DMINT.SARIE bit is set to 1, the DMSTS.ESIF flag is set to 1 and the DMCNT.DTE bit is cleared to 0 to stop DMA transfer. At this time, if the DMINT.ESIE bit is set to 1, an interrupt by an extended repeat area overflow is requested. When the DMINT.DARIE bit is set to 1, the destination address register becomes a target to apply the function. DMA transfer can be resumed by writing 1 to the DMCNT.DTE bit in the interrupt handling.

Figure 15.7 shows an example of the extended repeat area operation.

15。3。2 扩展重复区函数

DMAC 支持指定传输源和目标地址上的扩展重复区域的函数。通过设置扩展重复区域,地址寄存器重复指示指定的扩展重复区域的地址。

扩展的重复区域可以分别指定为传输源地址寄存器（DMSAR）和传输目的地地址寄存器（DMDAR）。

源地址上的扩展重复区域由 DMAMD。SARA[4:0] 位指定。目标地址上的扩展重复区域由 DMAMD。DARA[4:0] 位指定。尺寸可以针对源侧和目标侧分别指定。

但是,指定为重复区域或块区域的区域（传输源或传输目的地）不应指定为扩展重复区域。

当地址寄存器值到达扩展重复区域的结束地址并且扩展重复区域溢出时,DMA传输停止并且可以请求扩展重复区域溢出的中断。当DMINT。SARIE位设置为1时传输源上的扩展重复区域发生溢出时,DMSTS。ESIF标志设置为1并且DMCNT。DTE位被清除为0以停止DMA传输。此时,如果DMINT。ESIE位设置为1,则请求扩展重复区域溢出的中断。当DMINT。DARIE位设置为1时,目标地址寄存器成为应用该函数的目标。DMA 传输可以通过在中断处理中将 1 写入 DMCNT。DTE 位来恢复。

图 15。7 显示了扩展重复区域操作的示例。

Eight bytes are specified as an extended repeat area by the lower three bits of DMSAR (DMAMD.SARA[4:0] bits = 00011b). The data size is eight bits (DMTMD.SZ[1:0] = 00b).

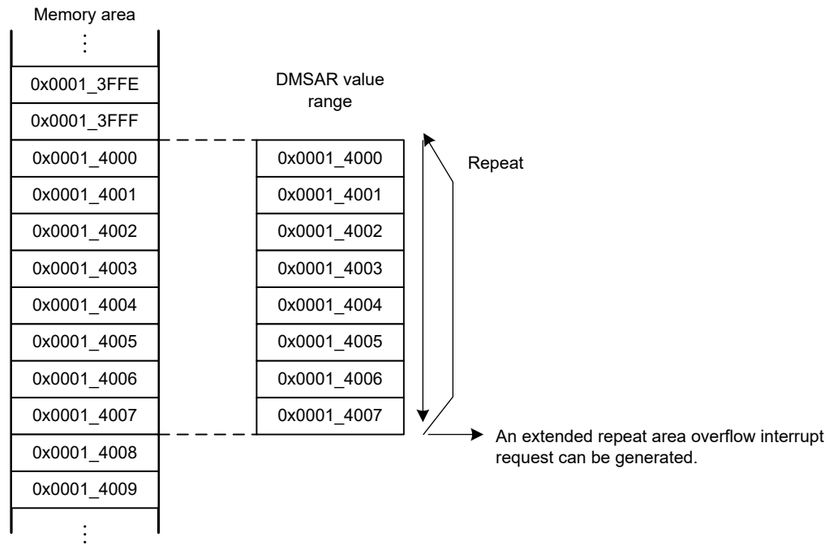

Figure 15.7 Example of extended repeat area operation

When an interrupt by an extended repeat area overflow is used in block transfer mode, the following should be taken into consideration.

When a transfer is stopped by an interrupt by an extended repeat area overflow, the address register must be set so that the block size is a power of 2 or the block size boundary is aligned with the extended repeat area boundary. When an overflow on the extended repeat area occurs during a transfer of one block, the interrupt by the overflow is suspended until transfer of the block is completed, and the transfer overruns.

Figure 15.8 shows an example when the extended repeat area function is used in block transfer mode.

8个字节被DMSAR的较低三位指定为扩展重复区域（DMAMD。SARA[4:0]位 = 00011b）。数据大小为八位（DMTMD。SZ[1:0] = 00b）。

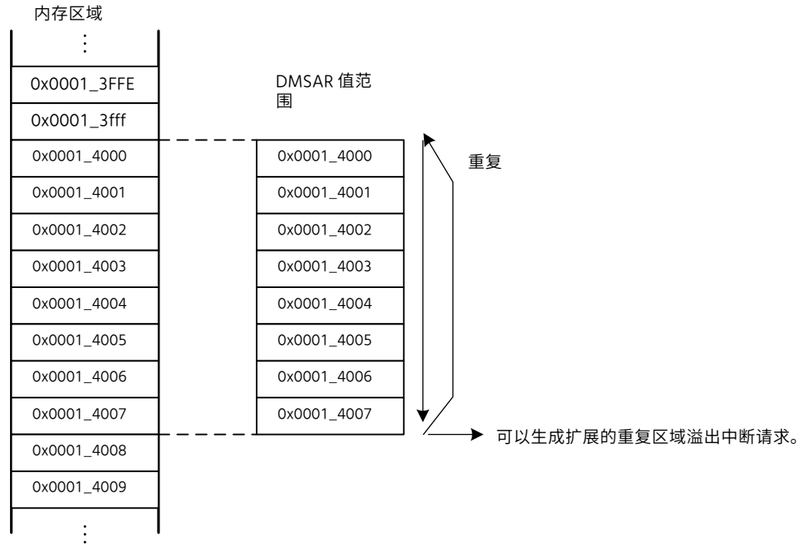

图15。7 扩展重复区域操作示例

当在块传输模式下使用扩展重复区域溢出的中断时,应考虑以下因素。

当传输因扩展重复区域溢出的中断而停止时,必须设置地址寄存器,使得块大小为 2 的幂或者块大小边界与扩展重复区域边界对齐。当在一个块的传送期间发生扩展重复区域上的溢出时,溢出的中断被暂停,直到块的传送完成,并且传送超支。

图15。8示出了在块传输模式下使用扩展重复区域函数的示例。

Eight bytes are specified as an extended repeat area by the lower three bits of DMSAR (DMAMD.SARA[4:0] bits = 00011b), block transfer mode with block size 5 is set (DMCRA = 0x0005_0005), and transfer source address is not specified as a block area. Data size is eight bits (DMTMD.SZ[1:0] bits = 00b).

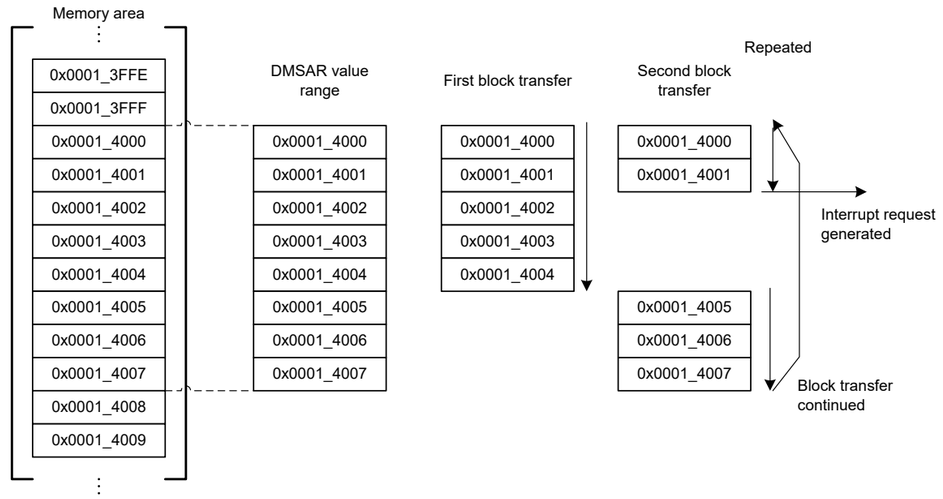

Figure 15.8 Example of extended repeat area function in block transfer mode

15.3.3 Free-running Function

The DMAC supports free-running function. This function allows to transfer repeatedly without reconfiguring in interrupt handler.

15.3.3.1 In Normal Transfer Mode

In normal transfer mode, when DMCRA.DMCRAL bits are set to 0x0000, no specific number of transfer operations is set; data transfer is performed with the transfer counter stopped.

For more information, see section 15.3.1.1. Normal Transfer Mode.

15.3.3.2 In Other Transfer Modes

In repeat, block and repeat-block transfer mode, the DMAC supports free-running function using the DMTMD.TKP bit. If the DMTMD.TKP bit is to be set to 1, the transfer is not stopped by completion of specified total number of transfer operations and reloads DMCRBH repeatedly.

Figure 15.9 show an example of block transfer operation without free-running function.

8个字节被DMSAR的较低三位指定为扩展重复区域（DMAMD。SARA[4:0]位 = 00011b）,块大小为5的块传输模式被设置（DMCRA = 0x0005_0005),传输源地址不被指定为块区域。数据大小为八位（DMTMD。SZ[1:0] 位 = 00b）。

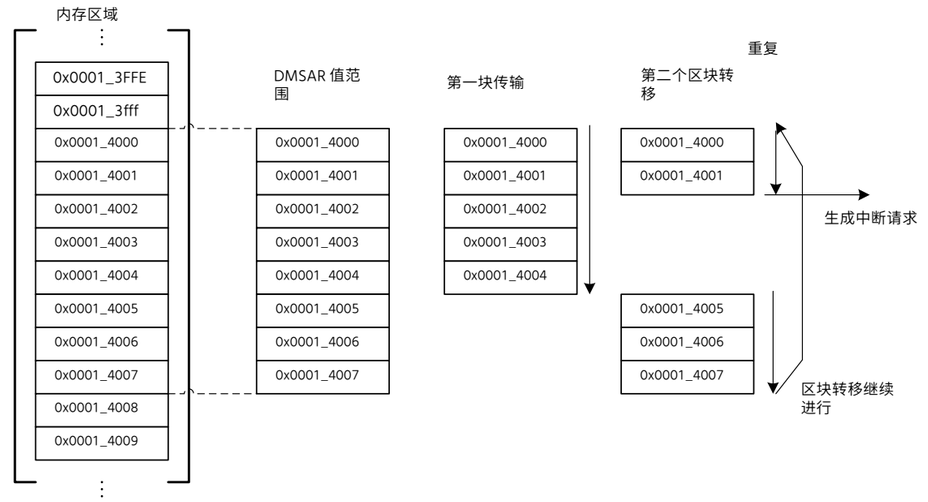

图15。8 块传输模式下的扩展重复区域函数示例

15。3。3 自由运行功能

DMAC支持自由运行功能。此功能允许重复传输,而无需在中断处理程序中重新配置。

15。3。3。1 在正常传输模式下

在正常传输模式下,当DMCRA。DMCRAL位设置为0x0000时,不设置特定数量的传输操作;数据传输是在传输计数器停止的情况下进行的。

欲了解更多信息,请参阅第 15。3。1。1 节。正常传输模式 .

15。3。3。2 在其他传输模式下

在重复、块和重复块传输模式下,DMAC支持使用DMTMD。TKP位的自由运行功能。如果要将 DMTMD。TKP 位设置为 1,则不会通过完成指定的传输操作总数来停止传输并重复重新加载 DMCRBH。

图15。9示出了没有自由运行功能的块传输操作的示例。

15.3.4 Address Update Function using Offset

The source and destination addresses can be updated by fixing, increment, decrement, or offset addition. In normal, repeat and block transfer mode, when the offset addition is selected, the offset specified by the DMA offset register (DMOFR) is added to the address every time the DMAC performs one data transfer. This function realizes a data transfer where addresses are allocated to separated areas.

Offset subtraction can also be realized by setting a negative value in DMOFR. In this case, the negative value must be 2's complement.

图15。10示出了具有自由运行功能的块传输操作的示例。

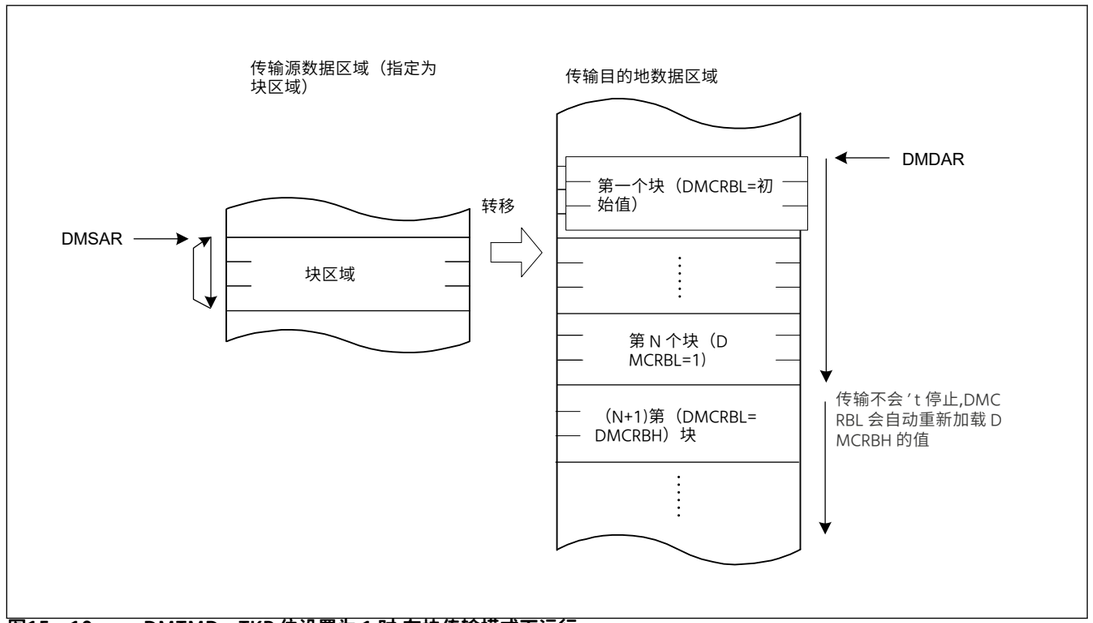

图15。10 DMTMD。TKP 位设置为 1 时 在块传输模式下运行

15.3.4 使用偏移量的地址更新功能

源地址和目标地址可以通过固定、增量、减量或偏移量相加来更新。在正常、重复和分组传输模式下,当选择偏移相加时,每次DMAC执行一次数据传输时,DMA偏移寄存器（DMOFR）指定的偏移量都会添加到地址。该函数实现数据传输,其中地址被分配到单独的区域。

DMOFR中设置负值也可以实现偏移减法。在这种情况下,负值必须是 2's 补码。

DMSBS or DMDBS are used instead of DMOFR in repeat-block transfer mode. For more information section 15.3.1.4. Repeat-Block Transfer Mode

Address update mode	Settings of DMAMD.SM[1:0] and DMAMD.DM[1:0] for address update modes	Address update method (for different SZ[1:0] settings in DMTMD)		
		SZ[1:0] = 00b	SZ[1:0] = 01b	SZ[1:0] = 10b
Address fixed	00b	Fixed		
Offset addition	01b	+DMOFR*1		
Increment	10b	+1	+2	+4
Decrement	11b	–1	–2	–4

Note 1. When setting a negative value in the DMA Offset Register, the value must be in two's complement, obtained by the following formula:
two's complement of a negative offset value = ~ (offset) + 1 (~ = bit inversion)

two的负偏移值的补码 = ~（偏移）+1(~ =位反转）

15.3.4.1 使用偏移加法的基本传输

图 15。11 显示了以下设置。

- 传输数据长 32 位。
- 偏移加法设置为传输源地址更新模式。

- Increment is set as the transfer destination address update mode.

The second and subsequent data is each read from the transfer source address obtained by adding the offset value to the previous address. The data read from the addresses at the specified intervals is written to the continuous locations on the destination.

15.3.4.2 Example of XY Conversion Using Offset Addition

Figure 15.12 shows the XY conversion using offset addition in repeat transfer mode.

Settings are as follows:

- DMAMD.SM — Transfer source address update mode: Offset addition.
- DMAMD.DM — Transfer destination address update mode: Destination address is incremented.
- DMTMD.SZ — Transfer data size select: 32 bits.
- DMTMD.MD — Transfer mode select: Repeat transfer.
- DMTMD.DTS — Repeat area select: The source is specified as the repeat area.
- DMOFR — Offset address: 0x10.
- DMCRA — Repeat size: 0x4.
- DMINT.RPTIE — The repeat size end interrupt is enabled.

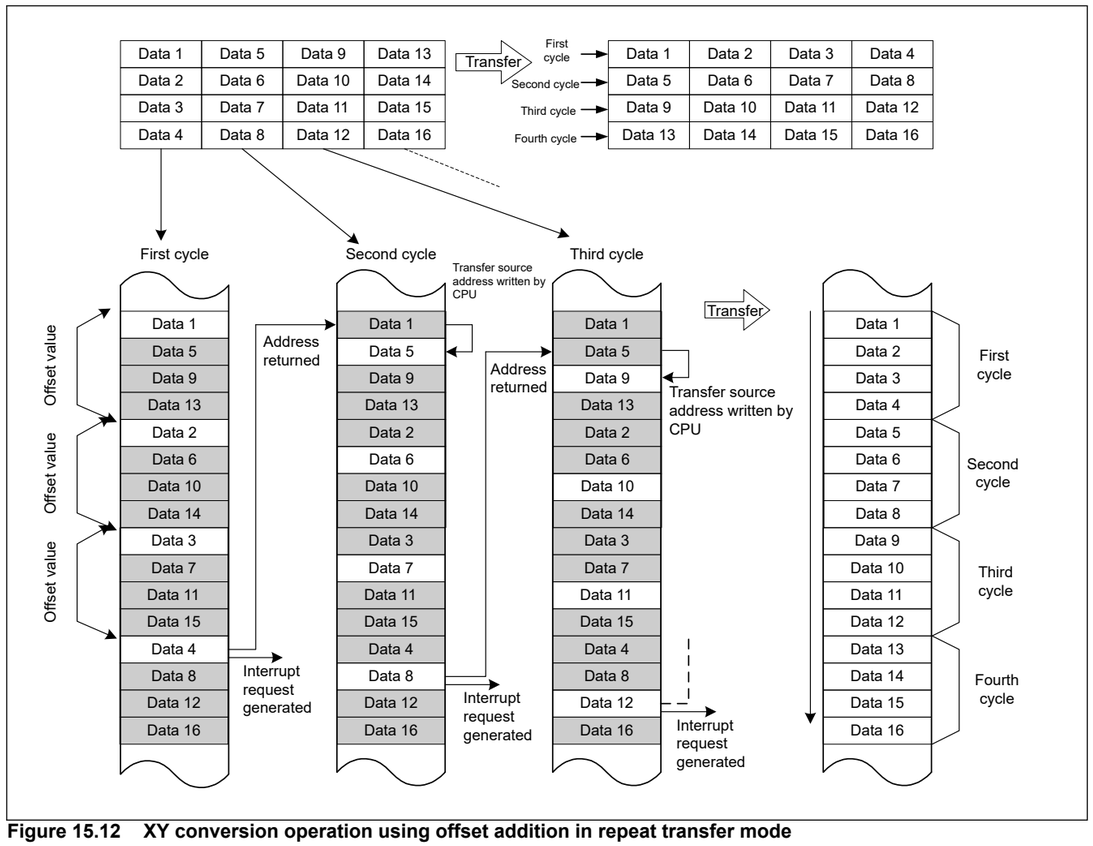

Figure 15.12 XY conversion operation using offset addition in repeat transfer mode

When a transfer starts, the offset value is added to the transfer source address every time data is transferred. The transfer data is written to continuous transfer destination addresses. When data 4 is transferred:

- The repeat size of data transfer is complete.

- 增量设置为传输目的地址更新模式。

第二个及后续数据分别从通过将偏移值添加到先前地址而获得的传输源地址读取。以指定间隔从地址读取的数据被写入目的地的连续位置。

15。3。4。2 使用偏移加法的 XY 转换示例

图 15。12 显示了在重复传输模式下使用偏移相加的 XY 转换。

设置如下:

- DMAMD。SM — 传输源地址更新模式:偏移添加。
- DMAMD。DM — 传输目标地址更新模式:目标地址递增。
- DMTMD。SZ — 传输数据大小选择:32 位。
- DMTMD。MD — 传输模式选择:重复传输。
- DMTMD。DTS — 重复区域选择:源指定为重复区域。
- DMOFR — 偏移地址:0x10。
- DMCRA — 重复大小:0x4。
- DMINT。RPTIE — 启用重复大小结束中断。

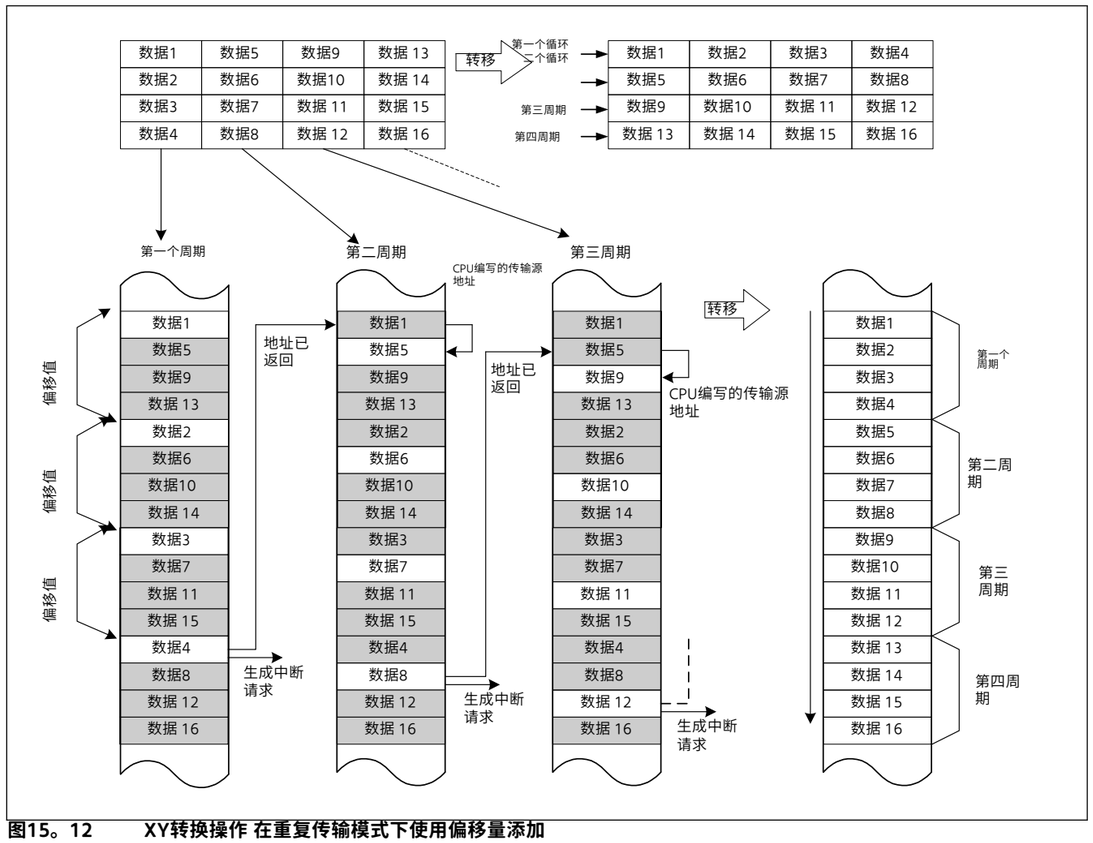

图15。12 XY转换操作 在重复传输模式下使用偏移量添加

当传输开始时,每次传输数据时,偏移值都会添加到传输源地址。传输数据被写入连续传输目标地址。4的数据传输时:

- 数据传输的重复大小是完整的。

- The transfer source address returns to the transfer start address (the address of data 1 on the transfer source).
- A repeat size end interrupt is requested.

During the time this interrupt pauses the transfer, the following operations are performed.

- DMSAR — Rewrite the DMA transfer source address to the address of data 5 (with the above example, the data 1 address + 4).
- DMCNT — Set the DTE bit to 1.

The DMA transfer is resumed from the state when the DMA transfer is stopped. After that, the operations described above are repeated until the transfer source data is transposed to the destination area (XY conversion).

Figure 15.13 shows a flowchart of the XY conversion.

- 传输源地址返回到传输起始地址（传输源上的数据 1 的地址）。
- 请求重复大小结束中断。

在该中断暂停传输期间,执行以下操作。

- DMSAR — 将 DMA 传输源地址重写为数据 5 的地址（以上示例为数据 1 地址 + 4)。
- DMCNT — 将 DTE 位设置为 1 。

DMA 传输停止时从状态恢复 DMA 传输。之后,重复上述操作,直到传输源数据被转换到目标区域（XY转换）。

15.3.5 Address Update Function in Repeat-Block Transfer Mode

Repeat-block transfer mode is an extension of repeat transfer mode and block transfer mode. However, the detailed behavior of the address update is different from these two modes. Here are the details of the address update function in repeat-block transfer mode.

15.3.5.1 Fixed Address Mode

When DMAMD.SM[1:0] is set to 00b, the address update mode of the source is fixed address. And when DMAMD.DM[1:0] is set to 00b, the address update mode of the destination is fixed address.

In fixed address, the address is not updated from the initial value of DMSAR and DMDAR. If the block size (DMCRA) is larger than 1, the same data will be transferred multiple times for one request.

Figure 15.14 shows address update in fixed address.

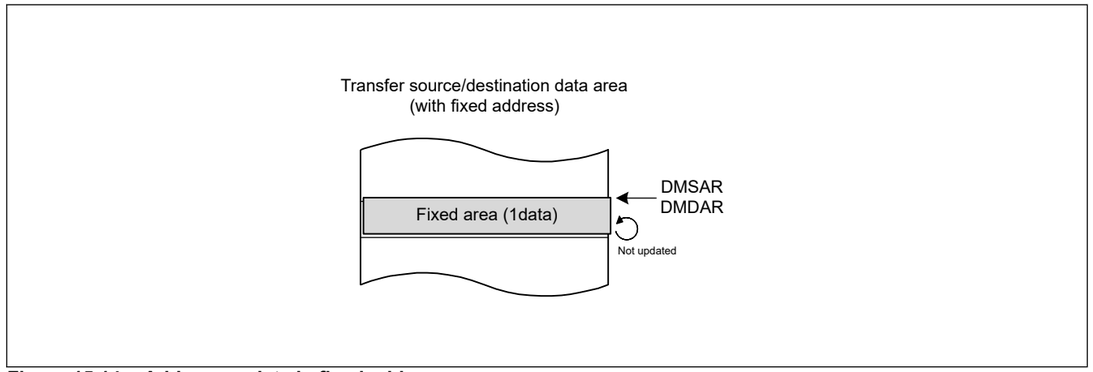

Figure 15.14 Address update in fixed address

15.3.5.2 Incremental and Decremental Address Mode

When DMAMD.SM[1:0] is set to 10b, the address update mode of the source is incremental address. And when DMAMD.DM[1:0] is set to 10b, the address update mode of the destination is incremental address. When DMAMD.SM[1:0] is set to 11b, the address update mode of the source is decremental address. And when DMAMD.DM[1:0] is set to 11b, the address update mode of the destination is decremental address.

In these update modes, the address is incremented or decremented according to the setting of DMTMD.SZ[1:0].

In these update modes DMSBS and DMDBS indicates a reload area. The unit of DMSBS and DMDBS is "number of data". At the start of transfer, DMSBSL and DMDBSL, which is the lower 16 bits of DMSBS and DMDBS, operates as a down counter and decrements each time one data transfer is performed. When the value becomes 1, DMSAR and DMDAR reloads the value of DMSRR and DMDRR.

Figure 15.15 shows address update in incremental address.

15。3。5 重复块传输模式下的地址更新功能

重复块传输模式是重复传输模式和块传输模式的扩展。然而,地址更新的详细行为与这两种模式不同。以下是重复块传输模式下地址更新功能的详细信息。

15。3。5。1 固定地址模式

DMAMD。SM[1:0]设置为00b时,源的地址更新模式为固定地址。并且当DMAMD。DM[1:0]设置为00b时,目的地的地址更新模式是固定地址。

在固定地址中,地址不会从 DMSAR 和 DMDAR 的初始值更新。块（DMCRA）大于1,则对于一个请求,相同的数据将被多次传输。

图 15。14 显示了固定地址中的地址更新。

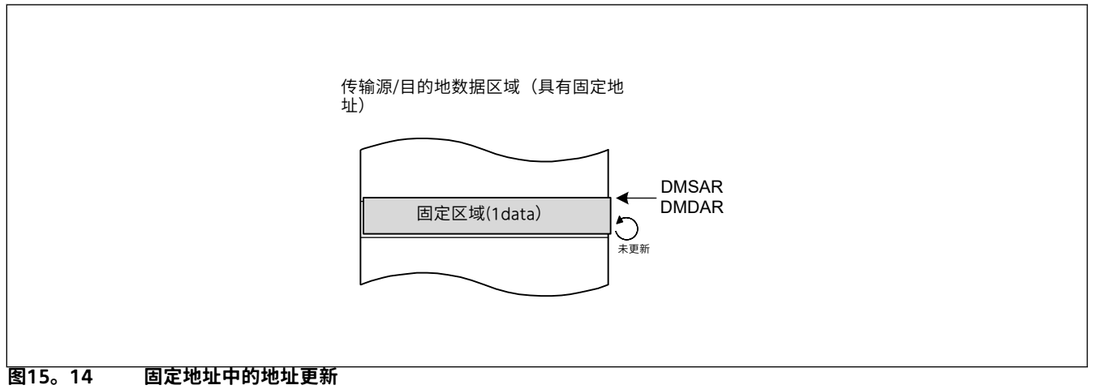

图15。14 固定地址中的地址更新

15。3。5。2 递增和递减地址模式

DMAMD。SM[1:0]设置为10b时,源的地址更新模式为增量地址。且DMAMD。DM[1:0]设置为10b时,目的地的地址更新模式为增量地址。DMAMD。SM[1:0]设置为11b时,源的地址更新模式为递减地址。且DMAMD。DM[1:0]设置为11b时,目的地的地址更新模式为递减地址。

在这些更新模式中,地址根据DMTMD。SZ的设置递增或递减[1:0]。

在这些更新模式中,DMSBS 和 DMDBS 表示重新加载区域。DMSBS 和 DMDBS 的单位是"数据数量"。

在传输开始时,DMSBSL 和 DMDBSL（DMSBS 和 DMDBS 的较低 16 位）作为下计数器运行,并在每次执行一次数据传输时递减。当值变为1时,DMSAR和DMDAR重新加载DMSRR和DMDRR的值。

图 15。15 显示了增量地址中的地址更新。

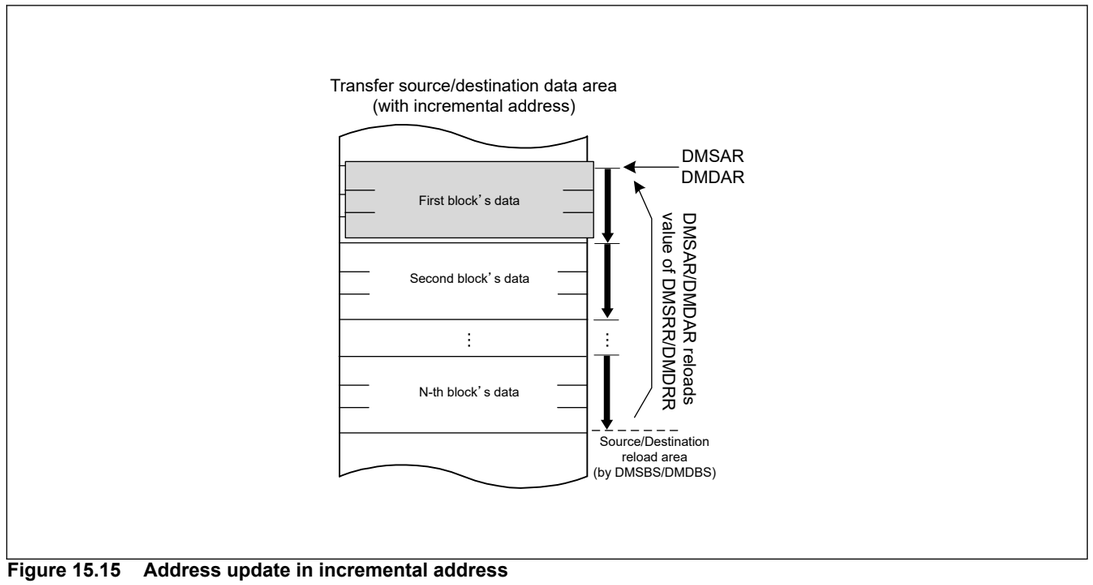

Figure 15.15 Address update in incremental address

15.3.5.3 Offset Addition Mode

When DMAMD.SM[1:0] is set to 01b, the address update mode of the source is offset addition. And when DMAMD.DM[1:0] is set to 01b, the address update mode of the destination is offset addition.

In offset addition, DMSBS and DMDBS indicates reload area and also works as an access offset value. Unlike other transfer modes, DMOFR register is not used in repeat-block transfer mode. In offset addition, the unit of DMSBS and DMDBS is the number of blocks. When the transfer starts, DMCRAL operates as a down counter, DMSAR and DMDAR reloads the value of DMSRR and DMDRR every time one block is transferred. In addition, DMSBSL and DMDBSL, which is the lower 16 bits of DMSBS and DMDBS, also operates as a down counter and decrements every time one block is transferred. When the DMSBS and DMDBS value becomes 1, DMSAR and DMDAR reloads the value of DMSRR and DMDRR.

When DMAMD.SADR and DMAMD.DADR is set to 0, offset addition operation of the same area is repeated. DMDAR only reloads DMDRR. Figure 15.16 shows address update in offset addition with DMAMD.SADR and DMAMD.DADR=0.

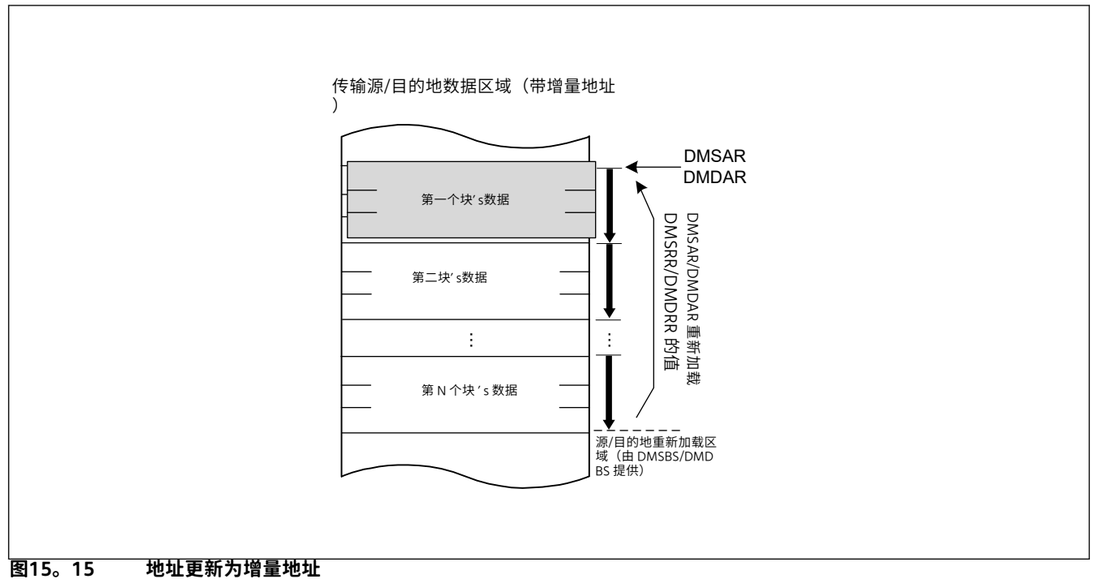

图15。15 地址更新为增量地址

15。3。5。3 偏移添加模式

DMAMD。SM[1:0]设置为01b时,源的地址更新模式为偏移加法。并且当DMAMD。DM[1:0]设置为01b时,目的地的地址更新模式是偏移相加。

在偏移添加中,DMSBS 和 DMDBS 表示重新加载区域,并且还用作访问偏移值。与其他传输模式不同,DMOFR 寄存器不用于重复块传输模式。在偏移加法中,DMSBS 和 DMDBS 的单位是块的数量。当传输开始时,DMCRAL 作为下计数器运行,每次传输一个块时,DMSAR 和 DMDAR 都会重新加载 DMSRR 和 DMDRR 的值。此外,DMSBSL和DMDBSL（DMSBS和DMDBS的较低16位）也作为下计数器运行,并且每次传输一个块时都会递减。

当DMSBS和DMDBS值变为1时,DMSAR和DMDAR重新加载DMSRR和DMDRR的值。

当DMAMD。SADR和DMAMD。DADR设置为0时,重复相同区域的偏移相加操作。DMDAR 仅重新加载 DMDRR。图 15。16 显示了 DMAMD。SADR 和 DMAMD。DADR=0 的偏移添加地址更新。

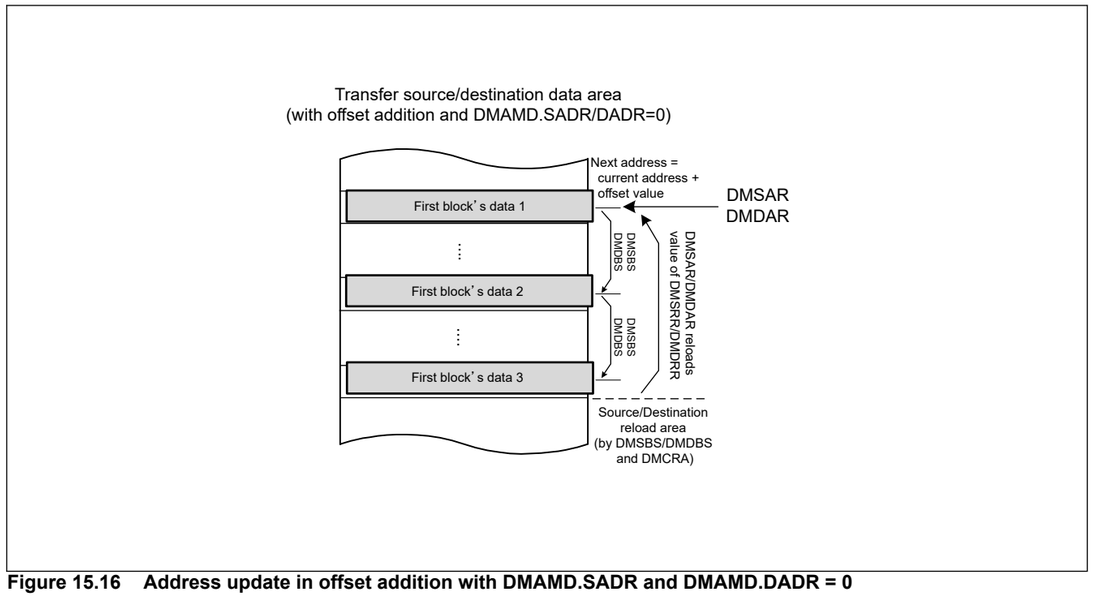

Figure 15.16 Address update in offset addition with DMAMD.SADR and DMAMD.DADR = 0

When DMAMD.SADR and DMAMD.DADR is set to 1, the address is incremented by one data unit after DMSRR and DMDRR is reloaded by DMCRAL=1. In other words, an index value ((DMDBSH-DMDBSL) × DataSize) is added to DMDAR after DMDRR is reloaded. This behavior is used to implement multiple ring buffers. Figure 15.17 shows address update in offset addition with DMAMD.SADR and DMAMD.DADR=1.

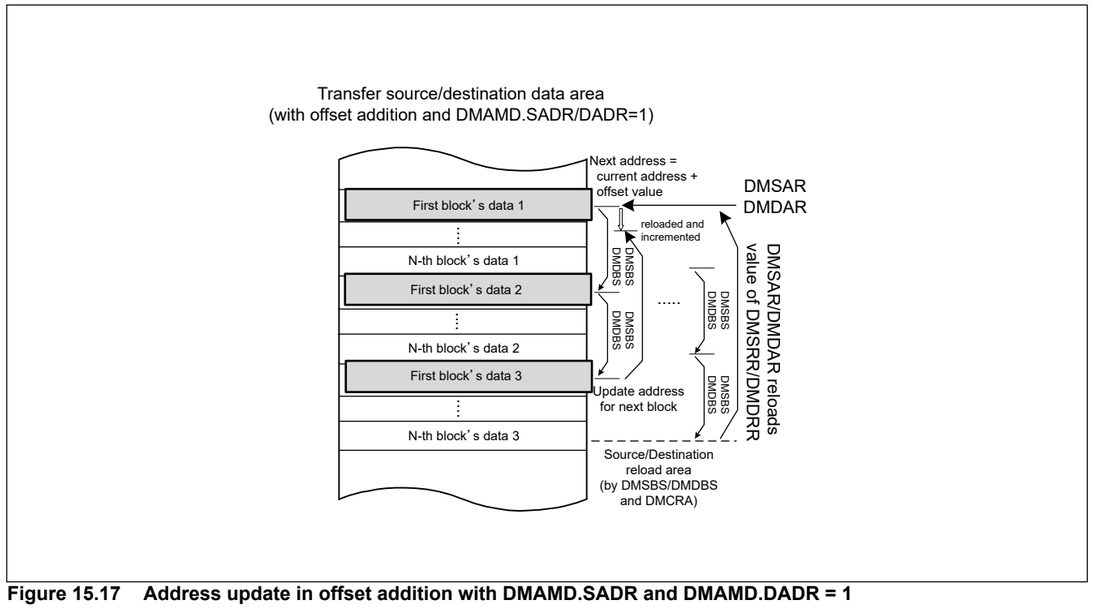

Figure 15.17 Address update in offset addition with DMAMD.SADR and DMAMD.DADR = 1

15.3.6 Example of Using Repeat-Block Transfer Mode

In repeat-block transfer mode, it is possible to realize repeated access to interval data and single or multiple ring buffers by combining the above address update modes. Following sections shows some usage examples.

15.3.6 使用重复块传输模式的示例

在重复块传输模式下,可以通过组合上述地址更新模式来实现对间隔数据和单环或多环缓冲区的重复访问。以下部分显示了一些使用示例。

15.3.6.1 Interval Address to Single Ring Buffer

Figure 15.18 shows an example of reading interval ADDRn registers (data register) of ADC12 module and storing it in single ring buffer. It transfers 2 data every 4 halfwords per 1 request. DMSAR is incremented by one data every one request. This can be achieved by setting the transfer source to offset addition and DMAMD.SADR=1, the block size (DMCRA) to 2, and the transfer source offset (DMSBS) to 4. Table 15.15 shows setting of this example.

Table 15.15 Setting of use case: from interval address to single ring buffer

DMAMD.SADR	1	Incremental source address after reloading
DMAMD.SM[1:0]	01b	Source update mode is offset addition
DMAMD.DM[1:0]	10b	Destination update mode is incremental address
DMCRAH, DMCRAL	2	Transfer block size

DMDBSH, DMDBSL	N × 2 (DMCRA)	Destination buffer size (unit is 'data')

15.3.6.2 Unaligned Ring Buffer to Single Ring Buffer

Figure 15.19 shows an example of reading ADBUFn registers of ADC12 module (conversion result storage ring buffer) incrementally and storing it in single ring buffer. In this example, wrapping occurs because ADBUFn overflows in the fourth scan, but transfer source address of DMAC is also updated accordingly. This can be realized by setting the transfer source to incremental address and setting the DMSBS register to 16 which is the length of ADBUFn. This makes it possible to continue transfer without performing CPU processing using interrupts. Table 15.16 shows setting of this example.

Table 15.16 Setting of use case: from unaligned ring buffer to single ring buffer (1 of 2)

Register	Value	Description
DMSAR, DMSRR	0x4017_00B0	Initial source address
DMDAR, DMDRR	0x2000_0000	Initial destination address
DMTMD.SZ[1:0]	01b	Data size is halfword

图15。18示出了读取ADC12模块的间隔ADDRn寄存器（数据寄存器）并将其存储在单环缓冲器中的示例。它每 1 个请求每 4 个半字传输 2 个数据。DMSAR 每一个请求都会增加一个数据。这可以通过将传输源设置为偏移加法和DMAMD。SADR=1、块大小（DMCRA）设置为2、传输源偏移（DMSBS）设置为4来实现。表 15。15 显示了此示例的设置。

图15。19示出了增量读取ADC12模块的ADBUFn寄存器（转换结果存储环缓冲器）并将其存储在单环缓冲器中的示例。在此示例中,由于 ADBUFn 在第四次扫描中溢出,因此会发生包裹,但 DMAC 的传输源地址也会相应更新。ADBUFn 的长度,通过将传输源设置为增量地址,将 DMSBS 寄存器设置为 16,就可以实现这一点,这样就可以在不使用中断进行 CPU 处理的情况下继续传输。表 15。16 显示了此示例的设置。

15.3.6.3 Single Block to Multi Ring Buffer

Figure 15.20 shows an example of storing the continuous ADDRn registers (data register) of ADC12 module individually in multiple ring buffers. In this example, a ring buffer in which only the first element (ADDR0) in a single block is arranged in transfer order is created at the destination. Also, in the next area, create a ring buffer in which only the second element (ADDR1) is arranged in transfer order. In the following case, create a ring buffer of length N, which is defined by DMDBS. And the number of data elements in the block is 3, which is defined by DMCRA. Table 15.17 shows setting of this example.

15.3.7 Activation Sources

Software, interrupt requests from the peripheral modules, and external interrupt requests can all be specified as DMAC activation sources. Set the DMTMD.DCTG[1:0] bits to select the activation source.

15.3.7.1 DMAC Activation by Software

When DMA transfer is started by software, follow below procedure.

1. Set the DMTMD.DCTG[1:0] bits to 00b.
2. Set the DMCNT.DTE bit to 1 (DMA transfer is enabled).
3. Set the DMAST.DMST bit set to 1 (DMAC activation enabled).
4. Set the DMREQ.SWREQ bit to 1 (DMA requested).

When the DMAC is activated by software while the DMREQ.CLRS bit is 0, the DMREQ.SWREQ bit is cleared to 0 after data transfer is started in response to a DMA transfer request.

When the DMAC is activated by software while the CLRS bit is 1, the SWREQ bit is not cleared to 0 after data transfer is started. In this case, a DMA transfer request is issued again after completion of a transfer.

15.3.7.2 DMAC Activation through Interrupt Requests from On-Chip Peripheral Modules or External Interrupt Requests

You can specify interrupt requests from on-chip peripheral modules and external interrupt requests as DMAC activation sources. The activation sources can be selected individually for each channel in ICU.DELSRn.DELS[8:0] (n = 0 to 7).

To start DMA transfer through an interrupt request from an on-chip peripheral module or an external interrupt request, follow the procedures as indicated below.

1. Set ICU.DELSRn.DELS[8:0] (n = 0 to 7) to the event number (select the DMAC event link).
2. Set the DMTMD.DCTG[1:0] bits to 01b (interrupts from the peripheral modules and the external interrupt pins).
3. Set the DMCNT.DTE bit to 1 (enable DMA transfer).
4. Set the DMAST.DMST bit set to 1 (DMAC activation enabled).

For interrupt requests specified as DMAC activation sources, see Table 12.3, in section 12, Interrupt Controller Unit (ICU).

15.3.8 Operation Timing

The following timing charts show the minimum number of execution cycles.

Figure 15.21 and Figure 15.22 show DMAC operation timing examples.

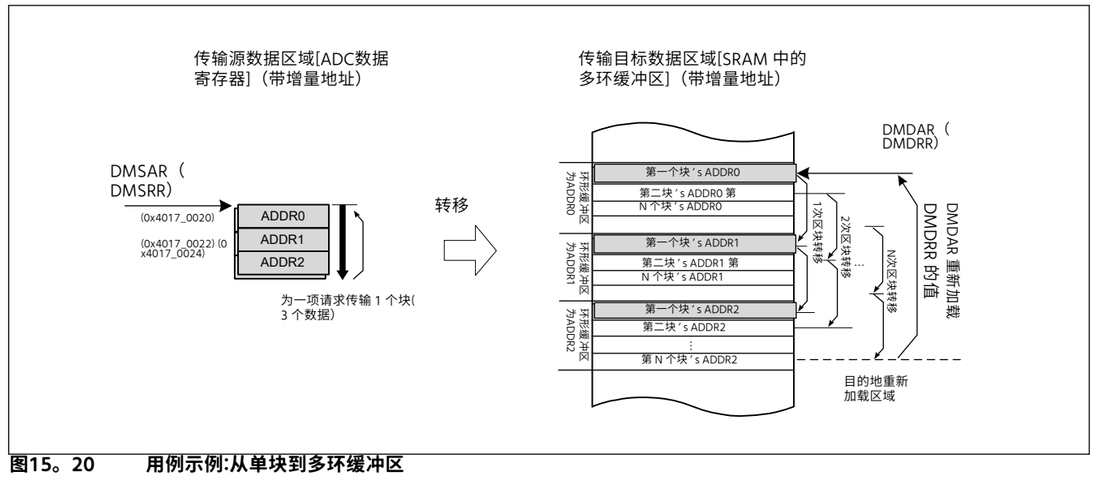

图15。20 用例示例:从单块到多环缓冲区

15。3。7 激活源

软件、外围模块的中断请求和外部中断请求都可以指定为DMAC激活源。设置 DMTMD。DCTG[1:0] 位以选择激活源。

软件激活 DMAC 当软件启动 DMA 传输时,请遵循以下程序。

1。将 DMTMD。DCTG[1:0] 位设置为 00b。

2锛姣涓涓。将 DMCNT。DTE 位设置为 1（启用 DMA 传输）。

3锛 娴 。将 DMAST。DMST 位设置为 1（启用 DMAC 激活）。

4锛姣涓。将 DMREQ。SWREQ 位设置为 1（请求 DMA）。

当DMAC被软件激活而DMREQ。CLRS位为0时,响应于DMA传输请求而开始数据传输后,DMREQ。SWREQ位被清除为0。

CLRS位为1时由软件激活DMAC时,数据传输开始后SWREQ位未清除为0。在这种情况下,在传输完成后再次发出DMA传输请求。

15。3。7。2 通过片上外设模块的中断请求或外部中断请求激活 DMAC

您可以将片上外围模块的中断请求和外部中断请求指定为 DMAC 激活源。ICU。DELSRn。DELS[8:0]（n = 0 至 7)中的每个通道可以单独选择激活源。要通过来自片上外围模块的中断请求或外部中断请求启动 DMA 传输,请按照如下所示的程序进行操作。

1。将 ICU。DELSRn。DELS[8:0]（n = 0 至 7) 设置为事件编号（选择 DMAC 事件链接）。

2锛姣涓涓。将 DMTMD。DCTG[1:0] 位设置为 01b（来自外围模块和外部中断引脚的中断）。

3锛 娴 。将 DMCNT。DTE 位设置为 1（启用 DMA 传输）。

4锛姣涓。将 DMAST。DMST 位设置为 1（启用 DMAC 激活）。

DMAC 激活源指定的中断请求, 请参见第 12 节"中断控制器单元（ICU）."中的表 12。3

Cr and Cw depend on the access destination. For the number of cycles for each access destination, see section 37, SRAM, section 38, Flash Memory, and section 13, Buses. The frequency ratio of the system clock and the peripheral clock is also taken into consideration.

The unit for +1 in “Data Transfer (Read)” column is one system clock cycle (ICLK). For the operation example, see section 15.3.8. Operation Timing.

Table 15.20 Register setting procedure of repeat-block transfer mode (2 of 2)

No.	Step name	Description
17	End of initial settings.	For activation by software. On completion of the initial settings, writing 1 to the DMA software start bit (DMREQ.SWREQ) starts DMA transfer.

Note: n: DMAC channel (n = 0 to 7)
Note 1. The DMAST.DMST bit setting does not necessarily have to follow the settings for the individual activation sources.

15.3.11 Starting DMA Transfer

To enable the DMA transfer, set the DMCNT.DTE bit to 1 (enable the DMA transfer), and then set the DMAST.DMST bit to 1 (enable the DMAC activation).

New activation requests are not accepted during the transfer of another DMAC channel or DTC. When the preceding transfer is complete, channel arbitration selects the DMA transfer request of the highest priority channel, and the DMA transfer of that channel starts. When the DMA transfer starts, the DMSTS.ACT flag is set to 1 (the DMAC is in the active state).

15.3.12 Registers during DMA Transfer

The DMAC registers are updated by a DMA transfer. The value to be updated differs according to the other settings and the transfer state. The registers to be updated are DMSAR, DMDAR, DMCRA, DMCRB, DMSBS, DMDBS, DMCNT, and DMSTS.

DMA Source Address Register (DMSAR)

When data has been transferred in response to one transfer request, the contents of DMSAR are updated to the address to be accessed by the next transfer request.

For details on register update operation in each transfer mode, see Table 15.5 to Table 15.13.

DMA Destination Address Register (DMDAR)

When data has been transferred in response to one transfer request, the contents of DMDAR are updated to the address to be accessed by the next transfer request.

For details on register update operation in each transfer mode, see Table 15.5 to Table 15.13.

DMA Transfer Count Register (DMCRA)

When data has been transferred in response to one transfer request, the count value is updated. The update operation depends on the transfer mode selected.

For details on register update operation in each transfer mode, see Table 15.5 to Table 15.13.

DMA Block Transfer Count Register (DMCRB)

When data has been transferred in response to one transfer request, the count value is updated. The update operation depends on the transfer mode selected.

For details on register update operation in each transfer mode, see Table 15.5 to Table 15.13.

DMA Source Buffer Size Register (DMSBS)

When data has been transferred in response to one transfer request, the count value is updated. The update operation depends on the transfer mode selected.

For details on register update operation in each transfer mode, see Table 15.8 to Table 15.13.

DMA Destination Buffer Size Register (DMDBS)

When data has been transferred in response to one transfer request, the count value is updated. The update operation depends on the transfer mode selected.

For details on register update operation in each transfer mode, see Table 15.8 to Table 15.13.

DMA Transfer Enable Bit (DMCNT.DTE)

Although the DMCNT.DTE bit enables or disables data transfer by the register write access, it is automatically cleared to 0 by the DMAC according to the DMA transfer state.

The conditions for clearing this bit by the DMAC are as follows:

- When the specified total volume of data transfer is completed
- When DMA transfer is stopped by the repeat size end interrupt
- When DMA transfer is stopped by the extended repeat area overflow interrupt
- When DMA transfer error occurs

Writing to the registers for the channels when the corresponding DMCNT.DTE bit is set to 1 is prohibited (except for DMCNT). In this case, writing must be performed after the bit is cleared to 0.

DMAC Active Flag (DMSTS.ACT)

The DMSTS.ACT flag indicates whether the DMACn is in the idle or active state.

This flag is set to 1 when the DMAC starts data transfer, and is cleared to 0 when data transfer in response to one transfer request is completed.

Even when DMA transfer is stopped by writing 0 to the DMCNT.DTE bit during DMA transfer, this flag remains 1 until DMA transfer is completed.

Transfer End Interrupt Flag (DMSTS.DTIF)

The DMSTS.DTIF flag is set to 1 after DMA transfer of the total transfer size of data is completed.

When both this flag and the DMINT.DTIE bit are set to 1, a transfer end interrupt is requested.

This flag is set to 1 when the DMA transfer bus cycle is completed and the DMSTS.ACT flag is cleared to 0 indicating the DMA transfer end.

This flag is automatically cleared to 0 when the DMCNT.DTE bit is set to 1 during the interrupt handling.

Transfer Escape End Interrupt Flag (DMSTS.ESIF)

The DMSTS.ESIF flag is set to 1 when a repeat size end interrupt or extended repeat area overflow interrupt is requested. When this bit and the DMINT.ESIE bit are set to 1, a transfer escape end interrupt is requested.

This flag is set to 1 when the bus cycle of the DMA transfer having caused the interrupt request is completed and the DMSTS.ACT flag is cleared to 0 indicating the DMA transfer end.

This flag is automatically cleared to 0 when the DMCNT.DTE bit is set to 1 during an interrupt handling.

Before sending an interrupt request from the DMAC to the CPU or the DTC, the interrupt control register must be set.

For details, see section 12, Interrupt Controller Unit (ICU).

15.3.13 Channel Priority

When multiple DMA transfer requests are present, the DMAC determines the priority of channels that have DMA transfer requests.

- The channel priority is fixed as follows: Channel 0 > Channel 1 > Channel 2 > Channel 3… > Channel 7 (Channel 0: Highest).

When a DMA transfer request is generated during data transfer, channel arbitration is started after the final data has been transferred, and DMA transfer of the higher-priority channel starts.

15.3.14 Channel Security

The security attribute of transfer access of DMACn, security attribute of access to register of DMACn, security attribute of access to the ICU.DELSRn register are controlled by ICUSARC.SADMACn bit. For details on the ICUSARC register, see section 12, Interrupt Controller Unit (ICU).

When the ICUSARC.SADMACn bit is 0, transfer of DMACn is secure access for both read and write. At the same time, the registers of channel n and the DELSRn register are protected from a non-secure access.

DMA 传输启用位（DMCNT。DTE）

尽管DMCNT。DTE位启用或禁用寄存器写访问的数据传输,但DMAC根据DMA传输状态自动将其清除为0。

DMAC 清除该位的条件如下:

- 当指定的数据传输总量完成时
- 当 DMA 传输被重复大小结束中断停止时
- 当 DMA 传输被扩展的重复区域溢出中断停止时
- 当 DMA 传输错误发生时

当相应的 DMCNT。DTE 位设置为 1 时,禁止写入通道寄存器（DMCNT 除外）。在这种情况下,必须在位清除到 0 后执行写入。

DMAC 活动标志（DMSTS。ACT）

DMSTS。ACT 标志指示 DMACn 是处于空闲状态还是活动状态。

DMAC 开始数据传输时,该标志设置为 1,响应于一个传输请求的数据传输完成时,该标志被清除为 0。

即使在 DMA 传输期间通过将 0 写入 DMCNT。DTE 位来停止 DMA 传输,该标志仍保持为 1,直到 DMA 传输完成。

传输端中断标志（DMSTS。DTIF）

数据总传输大小的DMA传输完成后,DMSTS。DTIF标志被设置为1。

当该标志和DMINT。DTIE位都设置为1时,请求传输端中断。

当DMA传输总线周期完成并且DMSTS。ACT标志被清除到指示DMA传输端的0时,该标志被设置为1。

当中断处理期间 DMCNT。DTE 位设置为 1 时,该标志将自动清除为 0。

传输逃逸端中断标志（DMSTS。ESIF）

当请求重复大小结束中断或扩展重复区域溢出中断时,DMSTS。ESIF 标志被设置为 1。
当该位和DMINT。ESIE位设置为1时,请求传输转义端中断。

当引起中断请求的DMA传输的总线周期完成并且DMSTS。ACT标志被清除到指示DMA传输端的0时,该标志被设置为1。

当中断处理期间 DMCNT。DTE 位设置为 1 时,该标志将自动清除为 0。

DMAC向CPU或DTC发送中断请求之前,必须设置中断控制寄存器。

有关详细信息,请参阅第 12 节"中断控制器单元（ICU）"。

15。3。13 通道优先级

当存在多个DMA传输请求时,DMAC确定具有DMA传输请求的信道的优先级。

- 通道优先级固定如下: 通道 0 > 通道 1 > 通道 2 > 通道 3… > 第 7 频道（第 0 频道: 的（最高）。

当数据传输过程中生成DMA传输请求时,最终数据传输后开始信道仲裁,更高优先级信道的DMA传输开始。

15。3。14 频道安全

DMACn的传输访问的安全属性、DMACn的寄存器访问的安全属性、ICU。DELSRn寄存器访问的安全属性由ICUSARC。SADMACn位控制。ICUSARC寄存器的详细信息,请参见第12节,中断控制器单元（ICU）。

当 ICUSARC。SADMACn 位为 0 时,DMACn 的传输对于读取和写入都是安全的访问。同时,通道n和DELSRn寄存器的寄存器受到保护,免受非安全访问。

When the ICUSARC.SADMACn bit is 1, transfer of DMACn is non-secure access for both read and write. At the same time, the registers of channel n and the DELSRn register are non-secure attributes.

Do not write to the ICUSARC.SADMACn bit while DMA transfer of same channel is enabled or a bus master is writing to the DMA registers of same channel.

15.3.15 Master TrustZone Filter in DMAC

DMAC has the Master TrustZone Filter. The MasterTrustZone Filter in DMAC can detect the security areas of Flash area(code Flash and data Flash) and SRAM area(ECC / Parity RAM) defined by IDAU. When set No-secure channel

当 ICUSARC。SADMACn 位为 1 时,DMACn 的传输对于读取和写入都是非安全的访问。同时,通道n和DELSRn寄存器的寄存器是非安全属性。

当启用同一信道的 DMA 传输或总线主机正在写入同一信道的 DMA 寄存器时,请勿写入 ICUSARC。SADMACn 位。

15.3.15 DMAC 中的 Master TrustZone 过滤器

15.4 Ending DMA Transfer

The operation for ending DMA transfer depends on the transfer end conditions. When DMA transfer ends, the DMCNT.DTE bit and the DMSTS.ACT flag are changed from 1 to 0, indicating that DMA transfer has ended.

15.4.1 Transfer End by Completion of Specified Total Number of Transfer Operations

(1) In Normal Transfer Mode (DMTMD.MD[1:0] = 00b)

When the value of DMCRAL changes from 1 to 0, DMA transfer ends on the corresponding channel, and the DMCNT.DTE bit is cleared to 0 and the DMSTS.DTIF flag is set to 1 at the same time. If the DMINT.DTIE bit is 1 at this time, a transfer end interrupt request is issued to the CPU or the DTC.

(2) In Repeat Transfer Mode (DMTMD.MD[1:0] = 01b)

When the value of DMCRBL changes from 1 to 0, DMA transfer ends on the corresponding channel, and the DMCNT.DTE bit is cleared to 0 and the DMSTS.DTIF flag is set to 1 at the same time. If the DMINT.DTIE bit is 1 at this time, an interrupt request is issued to the CPU or the DTC.

If the DMTMD.TKP bit is 1 (in free-running function), the DMSTS.DTIF bit is set to 1, but the DMCNT.DTE bit is not cleared to 0.

(3) In Block Transfer Mode (DMTMD.MD[1:0] = 10b)

When the value of DMCRBL changes from 1 to 0, DMA transfer ends on the corresponding channel, and the DMCNT.DTE bit is cleared to 0 and the DMSTS.DTIF flag is set to 1 at the same time. If the DMINT.DTIE bit is 1 at this time, an interrupt request is issued to the CPU or the DTC.

Before sending an interrupt request from the DMAC to the CPU or the DTC, the interrupt control register must be set. For details, see section 12, Interrupt Controller Unit (ICU).

If the DMTMD.TKP bit is 1 (in free-running function),the DMSTS.DTIF bit is set to 1, but the DMCNT.DTE bit is not cleared to 0.

(4) In Repeat-Block Transfer Mode (DMTMD.MD[1:0] = 11b)

When the value of DMCRBL changes from 1 to 0, DMA transfer ends on the corresponding channel, and the DMCNT.DTE bit is cleared to 0 and the DMSTS.DTIF flag is set to 1 at the same time. If the DMINT.DTIE bit is 1 at this time, an interrupt request is issued to the CPU or the DTC.

Before sending an interrupt request from the DMAC to the CPU or the DTC, the interrupt control register must be set. For details, see section 12, Interrupt Controller Unit (ICU).

If the DMTMD.TKP bit is 1 (in free-running function),the DMSTS.DTIF bit is set to 1, but the DMCNT.DTE bit is not cleared to 0.

15.4.2 Transfer End by Repeat Size End Interrupt

In repeat transfer mode, a repeat size end interrupt is requested when transfer of a 1-repeat size of data is completed while the DMINT.RPTIE bit is set to 1. When the interrupt is requested to complete DMA transfer, the DMCNT.DTE bit is cleared to 0 and the DMSTS.ESIF flag is set to 1 even if the DMTMD.TKP bit is 1 (in free-running function). If the DMINT.ESIE bit is 1 at this time, an interrupt request is issued to the CPU or the DTC. Here, the transfer can be resumed by writing 1 to the DMCNT.DTE bit.

A repeat size end interrupt can be requested also in block transfer mode. In block transfer mode, the interrupt is requested in the same way as in repeat transfer mode when transfer of a 1-block size data is completed.

Repeat size end interrupt cannot be requested in repeat-block transfer mode.

Before sending an interrupt request from the DMAC to the CPU or the DTC, the interrupt control register must be set. For details, see section 12, Interrupt Controller Unit (ICU).

访问这些地址,它会检测到安全违规行为。不执行违规地址的访问。检测到的错误将作为主信任区过滤器错误进行处理。

15。4 结束 DMA 转移

DMA 转账结束的操作取决于转账结束条件。DMA 传输结束时,DMCNT。DTE 位和 DMSTS。ACT 标志从 1 更改为 0,表明 DMA 传输已结束。

15.4 通过完成正常传输模式下的指定传输操作总数来结束传输（DMTMD。MD[1:0] = 00b）

(1)

DMCRAL的值从1变为0时,DMA传输在相应的信道上结束,同时DMCNT。DTE位被清除为0并且DMSTS。DTIF标志被设置为1。如果此时DMINT。DTIE位为1,则向CPU或DTC发出传输端中断请求。

(2) 在重复传输模式（DMTMD。MD[1:0] = 01b）

DMCRBL的值从1变为0时,DMA传输在相应的信道上结束,同时DMCNT。DTE位被清除为0并且DMSTS。DTIF标志被设置为1。如果此时DMINT。DTIE位为1,则向CPU或DTC发出中断请求。

如果DMTMD。TKP位为1（在自由运行函数中）,则DMSTS。DTIF位被设置为1,但DMCNT。DTE位未被清除为0。

(3) 在块传输模式下（DMTMD。MD[1:0] = 10b）

DMCRBL的值从1变为0时,DMA传输在相应的信道上结束,同时DMCNT。DTE位被清除为0并且DMSTS。DTIF标志被设置为1。如果此时DMINT。DTIE位为1,则向CPU或DTC发出中断请求。

DMAC向CPU或DTC发送中断请求之前,必须设置中断控制寄存器。有关详细信息,请参阅第 12 节"中断控制器单元（ICU）."

如果DMTMD。TKP位为1（在自由运行函数中）,则DMSTS。DTIF位被设置为1,但DMCNT。DTE位未被清除为0。

(4) 在重复块传输模式（DMTMD。MD[1:0] = 11b）

DMCRBL的值从1变为0时,DMA传输在相应的信道上结束,同时DMCNT。DTE位被清除为0并且DMSTS。DTIF标志被设置为1。如果此时DMINT。DTIE位为1,则向CPU或DTC发出中断请求。

DMAC向CPU或DTC发送中断请求之前,必须设置中断控制寄存器。有关详细信息,请参阅第 12 节"中断控制器单元（ICU）."

如果DMTMD。TKP位为1（在自由运行函数中）,则DMSTS。DTIF位被设置为1,但DMCNT。DTE位未被清除为0。

15.4.2 按重复大小传输结束结束中断

在重复传输模式中,当 DMINT。RPTIE 位设置为 1 时,1 重复大小的数据传输完成时,请求重复大小结束中断。当请求中断以完成DMA传输时,即使DMTMD。TKP位为1（在自由运行函数中）,DMCNT。DTE位也被清除为0并且DMSTS。ESIF标志被设置为1。如果此时DMINT。ESIE位为1,则向CPU或DTC发出中断请求。在这里,可以通过将 1 写入 DMCNT。DTE 位来恢复传输。

也可以在块传输模式下请求重复大小的结束中断。在块传输模式下,以与完成1块大小数据的传输时在重复传输模式下相同的方式请求中断。

在重复块传输模式下无法请求重复大小结束中断。

DMAC向CPU或DTC发送中断请求之前,必须设置中断控制寄存器。有关详细信息,请参阅第 12 节"中断控制器单元（ICU）."

15.4.3 Transfer End by Interrupt on Extended Repeat Area Overflow

When an overflow on the extended repeat area occurs while the extended repeat area is specified and the DMINT.SARIE or DMINT.DARIE bit is set to 1 even if the DMTMD.TKP bit is 1 (in free-running function), an interrupt by an extended repeat area overflow is requested. When the interrupt is requested, the DMA transfer is terminated, the DMCNT.DTE bit is cleared to 0, and the ESIF flag in DMSTS is set to 1. If the DMINT.ESIE bit is 1 at this time, an interrupt request is issued to the CPU or the DTC.

Even if an interrupt by an extended repeat area overflow is requested during a read cycle, the following write cycle is performed.

In block transfer mode, even if an interrupt by an extended repeat area overflow is requested during a 1-block transfer, the remaining data in the block is transferred; transfer is terminated after a block transfer.

An interrupt by an extended repeat area overflow cannot be requested in repeat-block transfer mode.

Before sending an interrupt request from the DMAC to the CPU or the DTC, the interrupt control register must be set. For details, see section 12, Interrupt Controller Unit (ICU).

15.5 Processing on DMA Transfer Error

DMA transfer error occurs with the Master TrustZone Filter error in DMAC, the Slave TrustZone Filter error, the Master MPU error, the Slave Bus Error or the Illegal Access Error. If the access error occurs during the DMA transfer, the DMAC immediately stops the transfer of error occurred channel. At this time, the ICU setting of the corresponding channel is also cleared. If there is a request other than the channel which caused the error, it will be re-arbitration as it is.

When the transfer error occurs, DMCNT.DTE of the error causing channel is set to 0. Also, the error response is informed to the ICU.DELSRn of the corresponding channel is cleared. Write back to each register is not performed. Furthermore, it generates the error response detection interrupt request (DMA_TRANSERR) to notify that an error has occurred by DMAC/DTC transfer.

When the Master TrustZone Filter error occurs, the Slave TrustZone error occurs or the Master MPU error occurs, it is possible to confirm the error information of DMAC by selecting NMI. The DMAC error channel register is cleared by selecting reset. Under the conditions where NMI is generated due to transfer error in DMAC, two interrupts(NMI and DMA_TRANSERR) are generated. In this case, NMI always responds first.

The error response detection interrupt request (DMA_TRANSERR) occurs when the Slave Bus error or the Illegal Access error occurs. Furthermore, it occurs after NMI when the error response detection interrupt request (DMA_TRANSERR) is not cleared in NMI handler.

section 15.5.1. Processing on NMI handler describes how to confirm the error information of the DMAC in the NMI handler.

section 15.5.2. Processing on Error response detection interrupt request (DMA_TRANSERR) handler describes how to confirm the error information of the DMAC in the DMA_TRANSERR handler.

Interrupts and the error information generated due to transfer errors are shown in section 15.6.2. Transfer Error Interrupt.

15.5.1 Processing on NMI handler

The cause of NMI due to the DMA transfer error is the Master TrustZone Filter error, the Slave TrustZone Filter error or the Master MPU error. When NMI occurs due to the DMAC transfer error, the error response detection interrupt request (DMA_TRANSERR) will occur after the end of NMI handler. It is possible to confirm the cause of the error and the DMAC channel in which the error occurred. When NMI occurs, perform the necessary processing according to the flow described in the ICU chapter.

Figure 15.24 shows the flow for confirm the channel that caused the Master TrustZone Filter Error in DMAC

Figure 15.25 shows the flow for confirm the channel that caused the Slave TrustZone Filter Error in DMAC

Figure 15.26 shows the flow for confirm the channel and Security Attribute that caused the Master MPU error in DMAC.

If completing all processing in NMI handler, it is possible to clear the error response detection interrupt request (DMA_TRANSERR) that occurs subsequently.

15。4。3 扩展重复区域溢出时通过中断结束传输

当在指定扩展重复区域并且即使 DMTMD。TKP 位为 1（在自由运行函数中）,扩展重复区域也发生溢出并且 DMINT。SARIE 或 DMINT。DARIE 位设置为 1 时,中断请求扩展重复区域溢出。当请求中断时,DMA传输终止,DMCNT。DTE位被清除为0,DMSTS中的ESIF标志被设置为1。如果此时DMINT。ESIE位为1,则向CPU或DTC发出中断请求。

即使在读取周期期间请求扩展重复区域溢出的中断,也执行以下写入周期。

在块传输模式下,即使在1块传输期间请求扩展重复区域溢出的中断,块中的剩余数据也会被传输;传输在块传输后终止。

在重复块传输模式下不能请求扩展重复区域溢出的中断。

DMAC向CPU或DTC发送中断请求之前,必须设置中断控制寄存器。有关详细信息,请参阅第 12 节"中断控制器单元（ICU）."

15.5 DMA 传输错误上进行处理

DMAC 中的主信任区过滤器错误、从信任区过滤器错误、主 MPU 错误、从总线错误或非法访问错误会发生 DMA 传输错误。DMA 传输过程中发生访问错误,则 DMAC 立即停止错误发生信道的传输。此时,相应通道的ICU设置也被清除。如果除了导致错误的渠道之外还有其他请求,则将按原样重新仲裁。

当发生传输错误时,错误导致信道的DMCNT。DTE设置为0。另外,错误响应被通知给相应信道的ICU。DELSRn被清除。未执行写回每个寄存器的操作。此外,它还生成错误响应检测中断请求（DMA_TRANSERR）以通知DMAC/DTC传输已发生错误。

Master TrustZone Filter 错误、Slave TrustZone 错误或 Master MPU 错误发生时,可以通过选择 NMI 来确认 DMAC 的错误信息。DMAC 错误通道寄存器通过选择重置来清除。DMAC中由于传输错误而产生NMI的条件下,产生两个中断（NMI和DMA_TRANSERR）。在这种情况下,NMI 总是首先响应。

Slave Bus 错误或非法访问错误时,会发生错误响应检测中断请求（DMA_TRANSERR）。此外,当 NMI 处理程序中错误响应检测中断请求（DMA_TRANSERR）未被清除时,它会发生在 NMI 之后。

第 15。5。1 节。NMI 处理程序上的处理描述了如何确认 NMI 处理程序中 DMAC 的错误信息。

第 15。5。2 节。处理错误响应检测中断请求（DMA_TRANSERR）处理程序描述了如何确认DMA_TRANSERR处理程序中DMAC的错误信息。

中断和由于传输错误而生成的错误信息显示在第 15。6。2 节中。传输错误中断 .

15。5。1 NMI 处理程序上的处理

DMA 传输错误导致 NMI 的原因是主信任区过滤器错误、从信任区过滤器错误或主 MPU 错误。DMAC传输错误而发生NMI时,错误响应检测中断请求（DMA_TRANSERR）将在NMI处理程序结束后发生。可以确认错误的原因以及发生错误的DMAC信道。NMI发生时,根据ICU章节中描述的流程进行必要的处理。

NMI处理程序中完成所有处理,则可以清除随后发生的错误响应检测中断请求（DMA_TRANSERR）。

15.5.2 Processing on Error response detection interrupt request (DMA_TRANSERR) handler

The cause of error response detection interrupt request (DMA_TRANSERR) due to DMA transfer error is the Slave Bus Error or Illegal Access Error. Also, it occurs after the NMI handler error response detection interrupt request (DMA_TRANSERR) is not cleared by the NMI handler.

It is possible to confirm the cause of the error and the DMAC channel in which the error occurred.

15.6 Interrupts

15.6.1 Transfer End Interrupt

Each DMAC channel can output an interrupt request (DMACn_INT) to the CPU or the DTC after transfer in response to one request is completed.

In repeat-block transfer mode, do not enable escape transfer end interrupt.

Table 15.21 lists the relation among the interrupt sources, the interrupt status flags, and the interrupt enable bits. Figure 15.33 shows the schematic logic diagram of interrupt outputs (DMACn (n = 0 to 7)). Figure 15.34 shows the DMAC interrupt handling routine to resume/terminate DMA transfer.

15。6。1 传输端中断

每个DMAC通道在响应一个请求完成传输后可以向CPU或DTC输出中断请求（DMACn_INT）。

在重复块传输模式下,请勿启用转义传输端中断。

表15。21列出了中断源、中断状态标志和中断使能位之间的关系。图15。33显示了中断输出（DMACn（n=0至7))的示意性逻辑图。图15。34显示了恢复/终止DMA传输的DMAC中断处理例程。

Specifically, the different procedures are used for canceling an interrupt to restart DMA transfer in the following two cases:

- When terminating a DMA transfer
- When continuing a DMA transfer

15.6.1.1 When Terminating a DMA Transfer

Write 0 to the DMSTS.DTIF flag to clear a transfer end interrupt, and to the DMSTS.ESIF flag to clear a repeat size interrupt and an extended repeat area overflow interrupt. The DMACn remains in the stop state. When starting another DMA transfer after that, set the appropriate registers, and set the DMCNT.DTE bit to 1 (DMA transfer enabled).

15.6.1.2 When Continuing a DMA Transfer

Write 1 to the DMCNT.DTE bit. The DMSTS.ESIF flag is automatically cleared to 0 (interrupt source cleared), and DMA transfer is resumed.

具体来说,在以下两种情况下,使用不同的程序来取消中断以重新启动 DMA 传输:

- 终止 DMA 传输时
- 继续 DMA 传输时

15.6.1.1 终止 DMA 传输时

将 0 写入 DMSTS。DTIF 标志以清除传输端中断,并写入 DMSTS。ESIF 标志以清除重复大小中断和扩展重复区域溢出中断。DMACn 仍处于停止状态。之后开始另一次 DMA 传输时,设置适当的寄存器,并将 DMCNT。DTE 位设置为 1（启用 DMA 传输）。

15.6.1.2 继续 DMA 传输时

将 1 写入 DMCNT。DTE 位。DMSTS。ESIF 标志自动清除到 0（中断源清除）,并恢复 DMA 传输。

15.6.2 Transfer Error Interrupt

Error response detection interrupt request (DMA_TRANSERR) is generated from the DMAC/DTC when the transfer error is detected during DMAC transfer. The types of interrupts that occur when a DMAC transfer error occurs are listed in the Table 15.22. The Table 15.22 also shows error information stored when a transfer error occurs.

Table 15.22 Interrupt and error information due to DMAC transfer error cause

15。6。2 传输错误中断

DMAC 传输期间检测到传输错误时, 从 DMAC/DTC 生成错误响应检测中断请求（DMA_TRANSERR）。DMAC 传输错误时发生的中断类型列于表 15。22 中。表15。22还显示了发生传输错误时存储的错误信息。

注1。当检测到主 MPU 错误和 TrustZone 过滤器错误后选择 NMI 请求作为操作时,会生成中断。通过确认 BUS。BUS3ERRSTAT 和 BUS。DMACDTCERRSTAT,判断它是主人还是从人。
注2。如果发生错误响应检测中断（DMA_TRANSERR）并且 Master MPU 或 TrustZone Filter 的 NMI 未发生,请将其视为非法地址访问错误或从站总线错误。也可以通过 BUS。BUS3ERRSTAT 和 BUS 进行判断。DMACDTCERRSTAT。

Note that if the bus error occurs when writing the last data of transfer, the transfer end event and the error response detection interrupt (DMA_TRANSERR) occurs.

15.7 Event Link

Each DMAC channel outputs an event link request signal (DMACn_INT) every time it completes a data transfer, or a block transfer in block transfer mode.

For details, see section 17, Event Link Controller (ELC).

If a bus error occurs when writing the last data of transfer, a transfer end event and error response detection interrupt (DMA_TRANSERR) occurs.

15.8 Low-Power Consumption Function

Before entering the module-stop state or Software Standby mode, or Deep Software Standby mode, you must first set the DMAST.DMST bit to 0 (the DMAC module suspended) and use the settings in the sections that follow.

(1) Module-stop function

Writing 1 to the MSTPCRA.MSTPA22 bit enables the module-stop function of the DMAC. If a DMA transfer is in progress when 1 is written to the MSTPA22 bit, the transition to the module-stop state proceeds after the DMA transfer ends. Access to the DMAC registers is prohibited while the MSTPA22 bit is 1. Writing 0 to the MSTPA22 bit releases the DMAC from the module-stop state.

(2) Software Standby mode and Deep Software Standby mode

Use the settings described in section 10.7.1. Transitioning to Software Standby Mode, or in section 10.9.1. Transitioning to Deep Software Standby Mode .

If DMA transfer operations are in progress when the WFI instruction is executed, the DMA transfer completes before the transition to Software Standby mode or Deep Software Standby mode.

(3) Notes on low power consumption function

For information on the WFI instruction and register settings, see section 10.10.7. Timing of WFI Instruction.

To perform a DMA transfer after returning from a low power mode, set the DMAST.DMST bit to 1 again. To use a request that is generated in Software Standby mode as an interrupt request to the CPU but not as a DMAC startup request, specify the CPU as the interrupt request destination, as described in section 12.4.1. Detecting Interrupts, and then execute the WFI instruction.

15.9 Usage Notes

15.9.1 Access to the Registers during DMA Transfer

Do not write to the following registers while the DMSTS.ACT flag of the same channel is set to 1 (DMAC active state) or the DMCNT.DTE bit of the same channel is set to 1 (DMA transfer enabled):

- DMSAR
- DMDAR
- DMCRA
- DMCRB
- DMTMD
- DMINT
- DMAMD
- DMOFR
- DMSBS
- DMDBS
- DMSRR

请注意,如果在写入传输的最后一个数据时发生总线错误,则会发生传输结束事件和错误响应检测中断（DMA_TRANSERR）。

15。7 活动链接

DMAC信道每次完成数据传输时输出一个事件链路请求信号（DMACn_INT）,或者在块传输模式下输出一个块传输。

有关详细信息,请参阅第 17 节"事件链接控制器（EL

如果在写入传输的最后一个数据时发生总线错误,则会发生传输结束事件和错误响应检测中断（DMA_TRANSERR）。

15。8 低功耗功能

在进入模块停止状态或软件待机模式或深度软件待机模式之前,您必须首先将 DMAST。DMST 位设置为 0（DMAC 模块已暂停）并使用以下部分中的设置。

(1)模块–停止功能

将 1 写入 MSTPCRA。MSTPA22 位可实现 DMAC 的模块停止功能。如果当1写入MSTPA22位时DMA传输正在进行中,则在DMA传输结束后继续向模块停止状态的转换。当 MSTPA22 位为 1 时,禁止访问 DMAC 寄存器。将 0 写入 MSTPA22 位可将 DMAC 从模块停止状态释放。

(2)软件待机模式和深度软件待机模式

使用第 10。7。1 节中描述的设置。过渡到软件待机模式,或第 10。9。1 节。过渡到深度软件待机模式 .

WFI指令执行时正在进行DMA传输操作,则DMA传输在过渡到软件待机模式或深度软件待机模式之前完成。

(3)低功耗功能注意事项

有关 WFI 指令和寄存器设置的信息,请参阅第 10。10。7 节。WFI指令.的时序

要在从低功耗模式返回后执行DMA传输,请再次将DMAST。DMST位设置为1。要使用在软件待机模式下生成的请求作为对 CPU 的中断请求而不是 DMAC 启动请求,请指定 CPU 作为中断请求目的地,如第 12。4。1 节所述。检测中断,然后执行WFI指令。

15。9 使用说明

15。9。1 DMA 传输期间对寄存器的访问

当同一信道的 DMSTS。ACT 标志设置为 1（DMAC 活动状态）或同一信道的 DMCNT。DTE 位设置为 1（启用 DMA 传输）时,请勿写入以下寄存器:

- DMSAR
- DMDAR
- DMCRA
- DMCRB
- DMTMD
- DMINT
- DMAMD
- DMOFR
- DMSBS
- DMDBS
- DMSRR

- DMDRR
- ICUSARC
- DMACSAR

15.9.2 DMA Transfer to Reserved Areas

DMA transfer to the reserved areas is prohibited. If such an access is made, transfer results are not guaranteed. For details on the reserved areas, see section 4, Address Space.

15.9.3 Setting of DMAC Event Link Setting Register of the Interrupt Controller Unit (ICU.DELSRn n = 0 to 7)

The DMAC event link setting register (ICU.DELSRn) should be set while the DMA transfer enable bit (DMCNT.DTE) is cleared to 0 (DMA transfer is disabled). Moreover, the DTC activation enable register (ICU.IELSRn.DTCE (n = 0 to 95)) that corresponds to the same event number that has been set by the ICU.DELSRn register should not be set to 1. For details on the ICU.IELSRn.DTCE and ICU.DELSRn, see section 12, Interrupt Controller Unit (ICU).

15.9.4 Suspending or Restarting DMAC Activation

To suspend a DMAC activation request, write 0x00 to the DMAC Event Link select bits (ICU.DELSRn.DELS[8:0]). To restart the DMA transfer, write the event number to the ICU.DELSRn.DELS[8:0] bits following the settings shown in section 15.3.10. Activating the DMAC.

15.9.5 Precautions for Resuming DMA Transfer

A DMAC activation request might occur in the next request after a DMA transfer completes. If this happens, the DMA transfer starts and the DMAC activation request is held in the DMAC. To prevent this, stop the DMAC activation requests by setting the DELSRn.DELS[8:0] bits in the ICU to 0.

When a DMAC activation request occurs after the last round of the DMA transfer is generated, clear the DMAC activation request with either of the following approaches.

- Clear the DMAC activation request with a DMA dummy transfer.
- Set the DMCNT.DTE bit to 0 and then set the ICU.DELSRn.IR flag to 0.

See Figure 15.35.

- DMDRR
- ICUSARC
- DMACSAR

15.9.2 DMA 转移到保护区

DMA转乘到保留区是被禁止的。如果进行这样的访问,则无法保证传输结果。有关保留区域的详细信息,请参阅第 4 节"地址空间 ."

15.9.3 中断控制器单元的 DMAC 事件链路设置寄存器的设置（ICU。DELSRn n = 0 至 7）

DMAC 事件链路设置寄存器（ICU。DELSRn）应在 DMA 传输使能位（DMCNT。DTE）清除为 0（DMA 传输被禁用）时进行设置。此外,对应于ICU。DELSRn寄存器设置的相同事件编号的DTC激活使能寄存器（ICU。IELSRn。DTCE（n=0至95））不应设置为1。有关 ICU。IELSRn。DTCE 和 ICU。DELSRn 的详细信息,请参阅第 12 节"中断控制器单元（ICU）."

15。9。4 暂停或重新启动 DMAC 激活

要暂停 DMAC 激活请求,请将 0x00 写入 DMAC 事件链接选择位（ICU。DELSRn。DELS[8:0]）。要重新启动 DMA 传输,请按照第 15。3。10 节中所示的设置将事件编号写入 ICU。DELSRn。DELS[8:0] 位。激活 DMAC .

15。9。5 恢复 DMA 转移的注意事项

DMA 传输完成后的下一个请求中可能会出现 DMAC 激活请求。如果发生这种情况,DMA 传输将开始,DMAC 激活请求将保存在 DMAC 中。为了防止这种情况发生,请将 ICU 中的 DELSRn。DELS[8:0] 位设置为 0,从而停止 DMAC 激活请求。

当在生成最后一轮 DMA 传输后发生 DMAC 激活请求时,请使用以下任一方法清除 DMAC 激活请求。

- 使用 DMA 虚拟传输清除 DMAC 激活请求。
- 将DMCNT。DTE位设置为0,然后将ICU。DELSRn。IR标志设置为0。

See section 12.1. Overview in section 12, Interrupt Controller Unit (ICU) for the connections between the DTC and NVIC in the CPU.

16.2 Register Descriptions

MRA, MRB, SAR, DAR, CRA, and CRB are all DTC internal registers that cannot be directly accessed from the CPU. Values to be set in these DTC internal registers are placed in the SRAM area as transfer information. When an activation request is generated, the DTC reads the transfer information from the SRAM area and sets it in its internal registers. After the data transfer ends, the internal register contents are written back to the SRAM area as transfer information.

参见第 12。1 节。第 12 节"中断控制器单元（ICU）"中概述了 DTC 和 NVIC 之间的连接

16。2 寄存器说明

MRA、MRB、SAR、DAR、CRA 和 CRB 都是无法从 CPU 直接访问的 DTC 内部寄存器。这些 DTC 内部寄存器中要设置的值作为传输信息放置在 SRAM 区域中。当生成激活请求时,DTC 从 SRAM 区域读取传输信息并将其设置在其内部寄存器中。数据传输结束后,内部寄存器内容作为传输信息写回SRAM区域。

DM[1:0] bits (Transfer Destination Address Addressing Mode)

The DM[1:0] bits are to fix the address of the DAR register or specify increment / decrement of the DAR register after transfer.

DTS bit (DTC Transfer Mode Select)

The DTS bit specifies whether the transfer source or destination is the repeat or block area in repeat or block transfer mode.

DISEL bit (DTC Interrupt Select)

The DISEL bit specifies the condition for generating an interrupt request to the CPU.

CHNS bit (DTC Chain Transfer Select)

The CHNS bit selects the chain transfer condition. When CHNE is 0, the CHNS setting is ignored. For details on the conditions for chain transfer, see Table 16.3.

When the next transfer is chain transfer, completion of the specified number of transfers is not determined, the activation source flag is not cleared, and an interrupt request to the CPU is not generated.

CHNE bit (DTC Chain Transfer Enable)

The CHNE bit enables chain transfer. The chain transfer condition is selected by the CHNS bit. For details on chain transfer, see section 16.4.6. Chain Transfer.

16.2.4 SAR : DTC Transfer Source Register

Base address: DTCVBR

Offset address: 0x04 + 0x4 × Vector number
(Inaccessible directly from the CPU. See section 16.3.1. Allocating Transfer Information and DTC Vector Table)

Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

The SAR sets the transfer source start address and cannot be accessed directly from the CPU. However, the CPU can access the SRAM area (transfer information (n) start address + 0x04) and DTC transfers it automatically to and from the SAR register. See section 16.3.1. Bit field:																													
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

The DAR sets the transfer destination start address and cannot be accessed directly from the CPU. However, the CPU can access the SRAM area (transfer information (n) start address + 0x08) and DTC transfers it automatically to and from the DAR register. See section 16.3.1. Allocating Transfer Information and DTC Vector Table.

Misalignment is prohibited for DTC transfers. Bit[0] must be 0 when MRA.SZ[1:0] = 01b, and bit[1] and bit[0] must be 0 when MRA.SZ[1:0] = 10b.

当下一次传输是链传输时,未确定指定传输次数的完成,激活源标志未被清除,并且未生成对CPU的中断请求。

CHNE 位（启用 DTC 链传输）

CHNE 位可实现链式传输。链转移条件由CHNS位选择。有关链转移的详细信息,请参阅第 16。4。6 节。链传输 .

Base address: DTCVBR

Offset address: 0x0E + 0x4 × Vector number
(Inaccessible directly from the CPU. See section 16.3.1. Allocating Transfer Information and DTC Vector Table)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
7:0	CRAL	Transfer Counter A Lower Register Specify the transfer count.	—
15:8	CRAH	Transfer Counter A Upper Register Specify the transfer count.	—

Note: The function depends on the transfer mode.
Note: Set CRAH and CRAL to the same value in repeat transfer mode and block transfer mode.

The CRA register consists of 16 bits. CRAL is the lower 8 bits and CRAH is the upper 8 bits. CRA is used in normal mode.

CRAL and CRAH are used in repeat transfer mode and block transfer mode.

The CRA register cannot be accessed directly from the CPU. However, the CPU can access the SRAM area (transfer information (n) start address + 0x0E) and DTC transfers it automatically to and from the CRA register. See section 16.3.1. Allocating Transfer Information and DTC Vector Table.

(1) Normal transfer mode (MRA.MD[1:0] = 00b)

In normal transfer mode, CRA functions as a 16-bit transfer counter. The transfer count is 1, 65535, and 65536 when the set value is 0x0001, 0xFFFF, and 0x0000, respectively. The CRA value is decremented (-1) on each data transfer.

(2) Repeat transfer mode (MRA.MD[1:0] = 01b)

In repeat transfer mode, the CRAH register holds the transfer count and the CRAL register functions as an 8-bit transfer counter. The transfer count is 1, 255, and 256 when the set value is 0x01, 0xFF, and 0x00, respectively. The CRAL value is decremented (-1) on each data transfer. When it reaches 0x00, the CRAH value is transferred to CRAL.

(3) Block transfer mode (MRA.MD[1:0] = 10b)

In block transfer mode, the CRAH register holds the block size and the CRAL register functions as an 8-bit block size counter. The transfer count is 1, 255, and 256 when the set value is 0x01, 0xFF, and 0x00, respectively. The CRAL value is decremented (-1) on each data transfer. When it reaches 0x00, the CRAH value is transferred to CRAL.

Bit field:																
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

The CRB sets the block transfer count for block transfer mode. The transfer count is 1, 65535, and 65536 when the set value is 0x0001, 0xFFFF, and 0x0000, respectively. The CRB value is decremented (-1) when the final data of a single block size is transferred. When normal transfer mode or repeat transfer mode is selected, this register is not used, and the set value is ignored.

RRS bit (DTC Transfer Information Read Skip Enable)

The RRS bit enables skipping of transfer information reads when vector numbers match. The DTC vector number is compared with the vector number in the previous activation process. When these vector numbers match and the RRS bit is set to 1, DTC data transfer is performed without reading the transfer information. However, when the previous transfer is a chain transfer, the transfer information is read regardless of the RRS bit.

When the transfer counter (CRA register) becomes 0 during the previous normal transfer and when the transfer counter (CRB register) becomes 0 during the previous block transfer, the transfer information is read regardless of the RRS bit value.

DTCST bit (DTC Module Start)

Set the DTCST bit to 1 to enable the DTC to accept transfer requests. When this bit is set to 0, transfer requests are no longer accepted. If this bit is set to 0 during a data transfer, the accepted transfer request is active until processing completes.

DTCST must be set to 0 before transitioning to one of the following state or mode:

ACT flag (DTC Active Flag)

The ACT flag indicates the state of the DTC transfer operation.

[Setting condition]

- When the DTC is activated by a transfer request.

[Clearing condition]

- When transfer by the DTC, in response to a transfer request, is complete.

DTCST 位（DTC 模块启动）

将 DTCST 位设置为 1 以使 DTC 能够接受传输请求。当该位设置为 0 时,不再接受传输请求。如果在数据传输期间将该位设置为 0,则接受的传输请求处于活动状态,直到处理完成。

DTCST 必须设置为 0, 才能过渡到以下状态或模式之一:

- 软件待机模式,无需 Snooze 模式转换
- 深度软件待机模式

16.3 Activation Sources

The DTC is activated by an interrupt request. Setting the ICU.IELSRn.DTCE bit to 1 enables activation of the DTC by the associated interrupt. The selector output *n* number set in ICU.IELSRn is defined as the interrupt vector number, where n = 0 to 95. For an enabled interrupt, the specific DTC interrupt source associated with each interrupt vector number *n* is selected in ICU.IELSRn.IELS[8:0] where n = 0 to 95, as listed in section 12.3.2. Event Number in section 12, Interrupt Controller Unit (ICU). For activation by software, see section 17.2.2. ELSEGRn : Event Link Software Event Generation Register n (n = 0, 1).

The interrupt vector number is equivalent to the DTC vector table number. After the DTC accepted an activation request, it does not accept another activation request until the transfer for that single request is complete, regardless of the priority of the requests. When multiple activation requests are generated during a DTC transfer, the highest priority request is accepted on completion of the transfer. When multiple activation requests are generated while the DTC Module Start bit (DTCST.DTCST) is 0, the DTC accepts the highest priority request when DTCST.DTCST is subsequently set to 1. The smaller interrupt vector number has higher priority.

The DTC performs the following operations at the start of a single data transfer or for a chain transfer, after the last of the consecutive transfers:

- On completion of a specified round of data transfer, the ICU.IELSRn.DTCE bit is set to 0, and an interrupt request is sent to the CPU.
- If the MRB.DISEL bit is 1, an interrupt request is sent to the CPU on completion of a data transfer.
- For other transfers, the ICU.IELSRn.IR flag of the activation source is set to 0 at the start of the data transfer.

16.3.1 Allocating Transfer Information and DTC Vector Table

The DTC reads the start address of the transfer information associated with each activation source from the vector table and reads the transfer information starting at that address.

DTC has two vector tables, non-secure side or secure side. Because the interrupt vector number that serves as a trigger for DTC is divided into non-secure or secure. Place the vector table of the interrupt vector number of SA = 1 in DTCVBR which is the non-secure side. Place the vector table of interrupt number SA = 0 in DTCVBR_SEC which is the secure side.

The vector table must be located so that the lower 10 bits of the base address (start address) are 0. Use the DTC Vector Base Register (DTCVBR) to set the base address of the DTC vector table. Transfer information is allocated in the SRAM area. In the SRAM area, the start address of the transfer information *n* with vector number *n* must be 4n added to the base address in the vector table.

Figure 16.2 shows the relationship between the DTC vector table and transfer information. Figure 16.3 shows the allocation of transfer information in the SRAM area.

当在 MPU。MMPUOAD。OAD 和 TZF。TZFOAD。OAD 中选择重置时,该寄存器也会重置。当您想要调试程序时选择 NMI。

的【设置条件】

- 当 DMAC 传输错误发生时。

的【清零条件】

- 当 1 写入 DTEVR。DTESTA 时。

注: DTEVSAM = 1时,可以在安全状态和非安全状态下进行清除。DTEVSAM = 0,在非安全状态下无法清除。

16。3 激活源

DTC 由中断请求激活。将 ICU。IELSRn。DTCE 位设置为 1 可以通过关联的中断激活 DTC。ICU。IELSRn 中设置的选择器输出 *n* 号码定义为中断向量号,其中 n = 0 到 95。对于启用的中断,在 ICU。IELSRn。IELS[8:0] 中选择与每个中断向量号 *n* 关联的特定 DTC 中断源,其中 n = 0 至 95,如第 12。3。2 节中列出。12 节中中断控制器单元（ICU）中的事件编号。有关软件激活,请参阅第 17。2。2 节。ELSEGRn:事件链接软件 事件生成寄存器 n（n = 0, 1）。

中断向量数相当于 DTC 向量表数。DTC 接受激活请求后,在单个请求的传输完成之前,无论请求的优先级如何,它都不会接受另一个激活请求。DTC 传输期间生成多个激活请求时, 传输完成后接受最高优先级请求。当DTC模块开始位（DTCST。DTCST）为0时生成多个激活请求时,当DTCST。DTCST随后设置为1时,DTC接受最高优先级请求。较小的中断向量具有更高的优先级。

DTC 在单个数据传输开始时或链式传输时, 在最后一次连续传输之后执行以下操作:

- 完成指定一轮数据传输后,ICU。IELSRn。DTCE 位设置为 0,并向 CPU 发送中断请求。
- 如果MRB。DISEL位为1,则在数据传输完成时向CPU发送中断请求。
- 对于其他传输,在数据传输开始时将激活源的ICU。IELSRn。IR标志设置为0。

16。3。1 分配传输信息和 DTC 矢量表

DTC从向量表中读取与每个激活源相关联的传输信息的开始地址,并从该地址开始读取传输信息。

DTC 有两个向量表,非安全侧或安全侧。因为作为 DTC 触发器的中断向量数分为非安全或安全。SA = 1的中断向量数的向量表放在作为非安全边的DTCVBR中。DTCVBR_SEC中放置中断数SA = 0的向量表,该向量表是安全侧。向量表的位置必须使基本地址（起始地址）的下 10 位为 0。DTC向量基寄存器（DTCVBR）来设置DTC向量表的基地址。SRAM 区域中分配传输信息。SRAM 区域中,向量编号为 *n* 的传递信息 *n* 的起始地址必须是 4n 添加到向量表中的基地址。

图16。2显示了DTC矢量表与传输信息之间的关系。图16。3显示了SRAM区域中传输信息的分配。

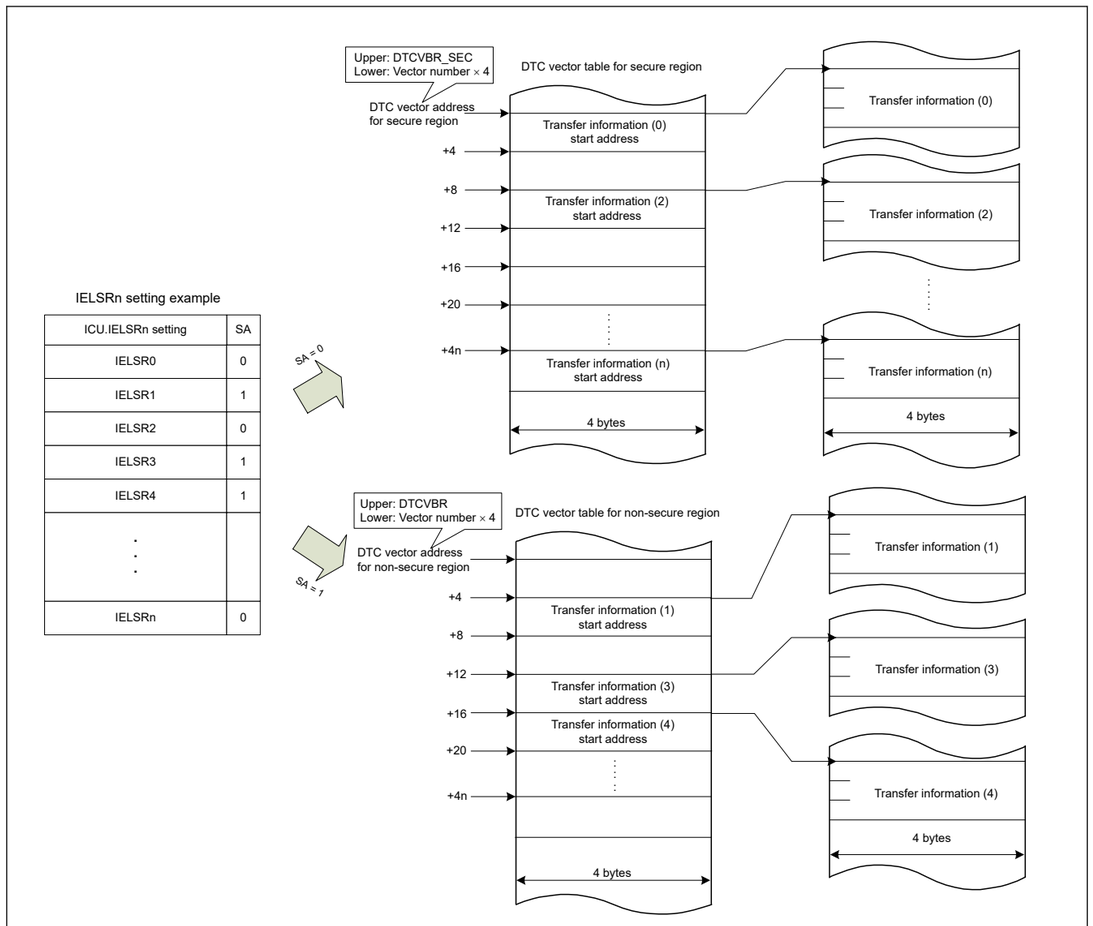

Figure 16.2 DTC vector table and transfer information

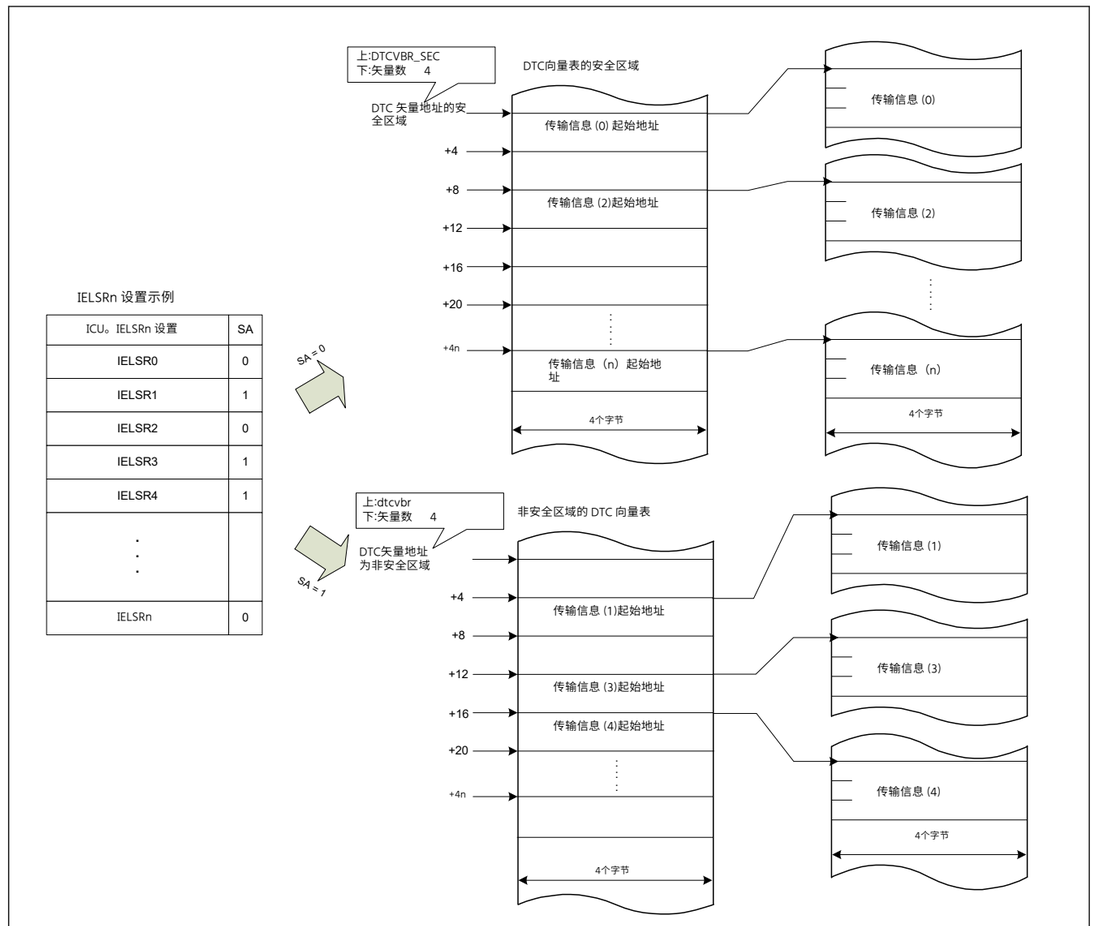

图16。2 DTC矢量表和传输信息

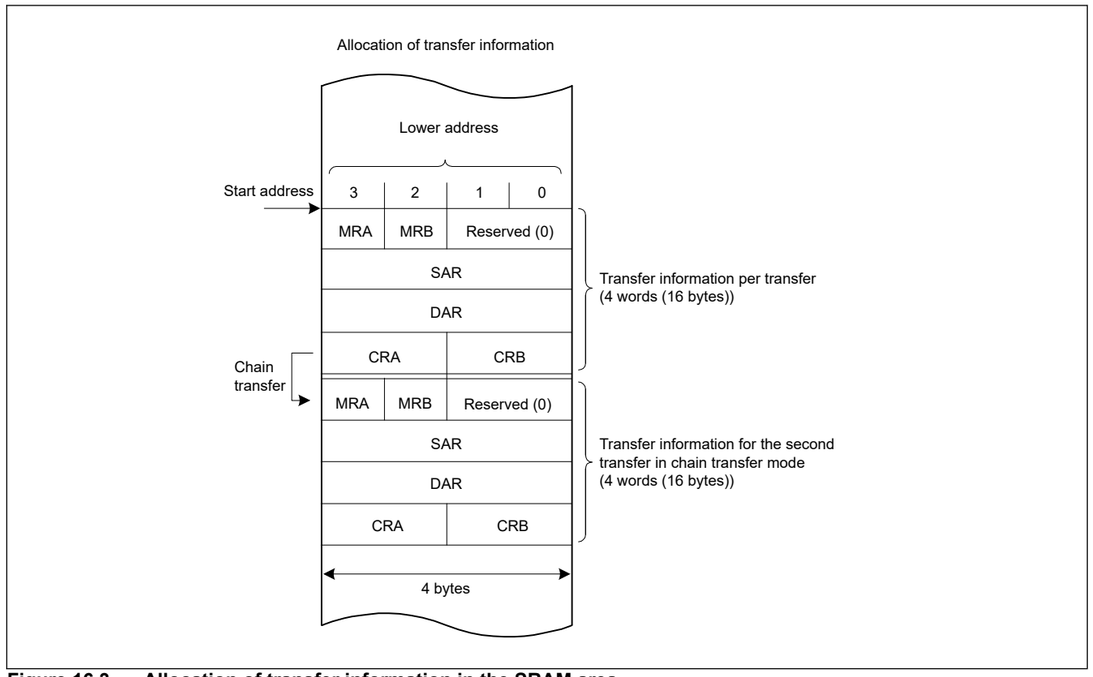

Figure 16.3 Allocation of transfer information in the SRAM area

16.4 Operation

The DTC transfers data according to the transfer information. Storage of the transfer information in the SRAM area is required before a DTC operation. When the DTC is activated, it reads the DTC vector associated with the vector number. The DTC reads the transfer information from the transfer information store address referenced by the DTC vector and transfers the data. After the data transfer, the DTC writes back the transfer information. Storing the transfer information in the SRAM area allows data transfer of any number of channels.

The transfer modes include:

- Normal transfer mode
- Repeat transfer mode
- Block transfer mode.

The DTC specifies a transfer source address in the SAR register and a transfer destination address in the DAR register. The values of these registers are incremented, decremented, or address-fixed independently after the data transfer.

Table 16.2 describes the DTC transfer modes.

Table 16.2 DTC transfer modes

Transfer mode	Data size transferred on single transfer request	Increment or decrement of memory address	Settable transfer count
Normal transfer mode	1 byte (8 bit), 1 halfword (16 bit), 1 word (32 bit)	Incremented or decremented by 1, 2, or 4 or address-fixed	1 to 65536
Repeat transfer mode*1	1 byte (8 bit), 1 halfword (16 bit), 1 word (32 bit)	Incremented or decremented by 1, 2, or 4 or address-fixed	1 to 256*3
Block transfer mode*2	Block size specified in CRAH (1 to 256 bytes, 1 to 256 halfwords (2 to 512 bytes), or 1 to 256 words (4 to 1024 bytes))	Incremented or decremented by 1, 2, or 4 or address-fixed	1 to 65536

Note 1. Set the transfer source or transfer destination as the repeat area.
Note 2. Set the transfer source or transfer destination as the block area.
Note 3. After a data transfer of the specified count, the initial state is restored and operation restarts.

16。4 操作

DTC 根据传输信息传输数据。DTC 操作之前需要将传输信息存储在 SRAM 区域。DTC被激活时,它会读取与向量编号相关联的DTC向量。

DTC从DTC向量引用的传输信息存储地址中读取传输信息并传输数据。数据传输后,DTC 写回传输信息。将传输信息存储在SRAM区域允许任意数量的信道的数据传输。

传输模式包括:

- 正常传输模式
- 重复传输模式
- 块传输模式。

DTC 在 SAR 寄存器中指定传输源地址,在 DAR 寄存器中指定传输目的地地址。这些寄存器的值在数据传输后独立地递增、递减或地址固定。

表 16。2 描述了 DTC 传输模式。

表 16。2 DTC 传输模式

传输模式	数据大小根据单次传输请求传输	内存地址的增加或减少	可结算转账计数
正常传输模式	1个字节(8位），1个半字(16位），1个字(32位)	递增或递减 1、2 或 4 或地址固定	1 至 65536
重复传输模式*1	1个字节(8位），1个半字(16位），1个字(32位)	递增或递减 1、2 或 4 或地址固定	1 to 256*3
块传输模式*2	CRAH中指定的块大小(1到256字节,1到256个半字节(2到512字节），或1到256个字(4到1024字节）)	递增或递减 1、2 或 4 或地址固定	1 至 65536

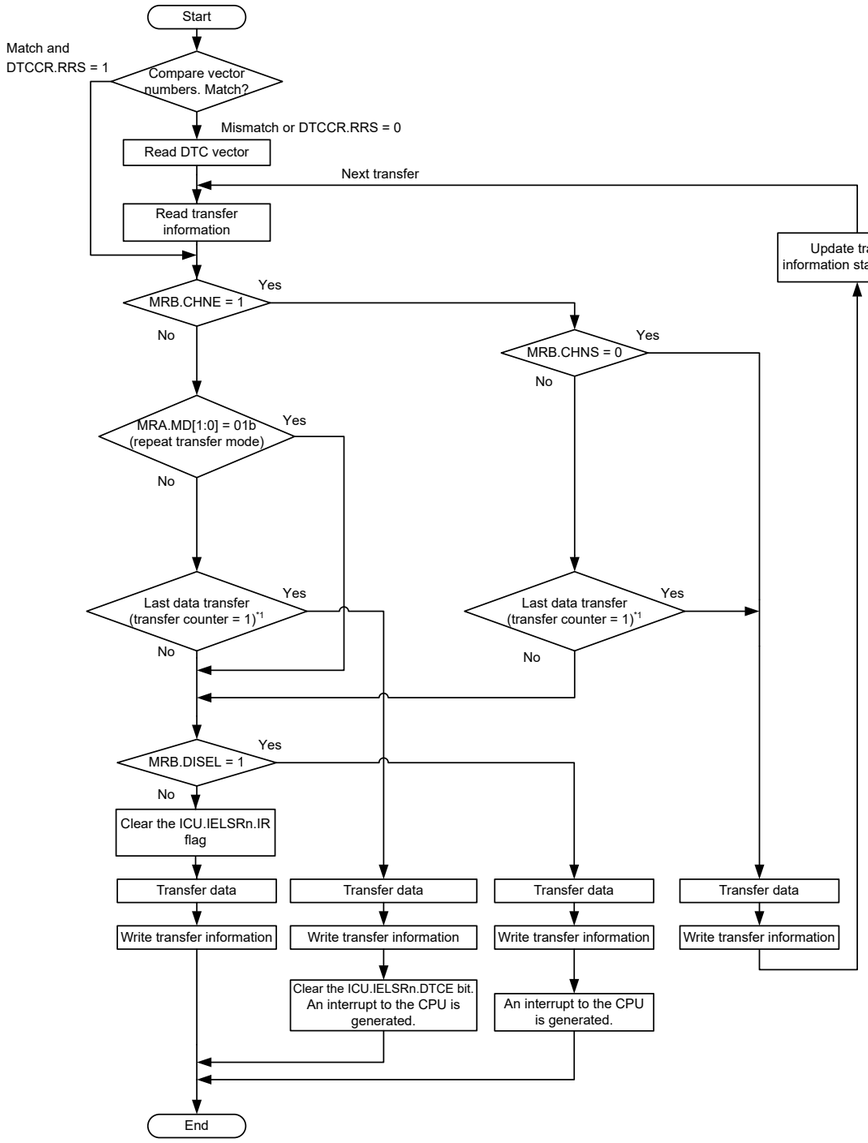
Setting the MRB.CHNE bit to 1 allows multiple transfers or chain transfer on a single activation source. It also enables a chain transfer when the specified data transfer is complete.

Figure 16.4 shows the operation flow of the DTC. Table 16.3 lists the chain transfer conditions. The combination of control information for the second and subsequent transfers are omitted in this table.



Note 1. Counter value before starting data transfer.

将 MRB。CHNE 位设置为 1 允许在单个激活源上进行多次传输或链式传输。当指定的数据传输完成时,它还可以实现链式传输。

Note 1. The transfer counter used depends on the transfer modes as follows:
Normal transfer mode — CRA register
Repeat transfer mode — CRAL register
Block transfer mode — CRB register

Note 2. On completion of a data transfer, the counters operate as follows:
1 → 0 in normal and block transfer modes
1 → CRAH in repeat transfer mode
(1 → *) in the table indicates both of these two operations, depending on the mode.

Note 3. Chain transfer can be selected for the second or subsequent transfers. The conditions for the combination of the second transfer and CHNE = 1 is omitted.

16.4.1 Transfer Information Read Skip Function

Reading of vector addresses and transfer information can be skipped by setting the DTCCR.RRS bit. When a DTC activation request is generated, the current DTC vector number is compared with the DTC vector number in the previous activation process. When these vector numbers match and the RRS bit is set to 1, the DTC data transfer is performed without reading the vector address and transfer information. However, when the previous transfer is a chain transfer, the vector address and transfer information are read. Additionally, when the transfer counter (CRA register) becomes 0 during the previous normal transfer, and when the transfer counter (CRB register) becomes 0 during the previous block transfer, transfer information is read regardless of the RRS bit. Figure 16.12 shows an example when reading the transfer information is skipped.

To update the vector table and transfer information, set the RRS bit to 0, update the vector table and transfer information, then set the RRS bit to 1. The stored vector number is discarded by setting the RRS bit to 0. The updated DTC vector table and transfer information are read in the next activation process.

16.4.2 Transfer Information Write-Back Skip Function

When the MRA.SM[1:0] bits or the MRB.DM[1:0] bits are set to address fixed, a part of the transfer information is not written back. Table 16.4 lists the transfer information write-back skip conditions and the associated registers. The CRA and CRB registers are written back, and the write-back of the MRA and MRB registers is skipped.

重复传输模式 — CRAL 寄存器
块传输模式 — CRB 寄存器

注2。数据传输完成后,计数器的操作如下:
正常和块传输模式下的 1 → 0 重复传输模式下的 1 → CRAH
表中的 (1 → *) 表示这两个操作,具体取决于模式。

注3。可以选择链传输进行第二次或后续传输。省略了第二次转移和 CHNE = 1 组合的条件。

16。4。1 传输信息读取跳过功能

可以通过设置 DTCCR。RRS 位来跳过向量地址和传输信息的读取。DTC激活请求时,将当前DTC向量编号与前一个激活过程中的DTC向量编号进行比较。当这些向量数匹配并且RRS位设置为1时,在不读取向量地址和传输信息的情况下执行DTC数据传输。然而,当先前的传输是链传输时,向量地址和传输信息被读取。另外,当传输计数器（CRA寄存器）在上一次正常传输期间变为0时,并且当传输计数器（CRB寄存器）在上一次块传输期间变为0时,无论RRS位如何,都读取传输信息。图 16。12 显示了跳过读取传输信息时的示例。

要更新向量表和传输信息,请将 RRS 位设置为 0,更新向量表和传输信息,然后将 RRS 位设置为 1。通过将 RRS 位设置为 0 来丢弃存储的向量号。更新的 DTC 向量表和传输信息将在下一个激活过程中读取。

16。4。2 传输信息回写跳过功能

当MRA。SM[1:0]位或MRB。DM[1:0]位被设置为地址固定时,部分传输信息不会被写回。表 16。4 列出了传输信息回写跳过条件和相关寄存器。CRA 和 CRB 寄存器被写回,并且 MRA 和 MRB 寄存器的写回被跳过。

16.4.3 Normal Transfer Mode

The normal transfer mode allows a 1-byte (8 bit), 1-halfword (16 bit), 1-word (32 bit) data transfer on a single activation source. The transfer count can be set from 1 to 65536. Transfer source and destination addresses can be independently set to increment, decrement, or fixed. This mode enables an interrupt request to the CPU to be generated at the end of a specified-count transfer.

Table 16.5 lists register functions in normal transfer mode, and Figure 16.5 shows the memory map of normal transfer mode.

正常传输模式允许在单个激活源上传输 1 字节(8 位）、1 半字(16 位）、1 字(32 位）数据。传输计数可设置为 1 至 65536。传输源地址和目标地址可以独立设置为增量、递减或固定。此模式允许在指定计数传输结束时生成对 CPU 的中断请求。

16.4.4 Repeat Transfer Mode

The repeat transfer mode allows a 1-byte (8-bit), 1-halfword (16-bit), or 1-word (32-bit) data transfer on a single activation source. Transfer source or transfer destination for the repeat area must be specified in the MRB.DTS bit. The transfer count can be set from 1 to 256. When the specified transfer count is complete, the initial value of the address register specified in the repeat area is restored, the initial value of the transfer counter is restored, and transfer is repeated. The other address register is incremented or decremented continuously or remains unchanged.

When the transfer counter CRAL decrements to 0x00 in repeat transfer mode, the CRAL value is updated to the value set in the CRAH register. As a result, the transfer counter does not clear to 0x00, which disables interrupt requests to the CPU when the MRB.DISEL bit is set to 0. An interrupt request to the CPU is generated when the specified data transfer completes.

Table 16.6 lists the register functions in repeat transfer mode, and Figure 16.6 shows the memory map of repeat transfer mode.

16。4。4 重复传输模式

重复传输模式允许在单个激活源上传输 1 字节(8 位）、1 半字(16 位）或 1 字(32 位）数据。重复区域的传输源或传输目的地必须在 MRB。DTS 位中指定。传输计数可设置为 1 至 256。当指定的传输计数完成时,恢复重复区域中指定的地址寄存器的初始值,恢复传输计数器的初始值,并重复传输。另一个地址寄存器连续递增或递减或保持不变。

当传输计数器 CRAL 在重复传输模式下减少到 0x00 时,CRAL 值更新为 CRAH 寄存器中设置的值。因此,传输计数器无法清除到 0x00,当 MRB。DISEL 位设置为 0 时,这会禁用对 CPU 的中断请求。当指定的数据传输完成时,会生成对 CPU 的中断请求。

表16。6列出了重复传输模式下的寄存器函数,图16。6显示了重复传输模式的内存图。

16.4.5 Block Transfer Mode

The block transfer mode allows single-block data transfer on a single activation source. Transfer source or transfer destination for the block area must be specified in the MRB.DTS bit. The block size can be set from 1 to 256 bytes, 1 to 256 halfwords (2 to 512 bytes), or 1 to 256 words (4 to 1024 bytes). When transfer of the specified block completes, the initial values of the block size counter CRAL and the address register (the SAR register when the MRB.DTS = 1 or the DAR register when the DTS = 0) specified in the block area are restored. The other address register is incremented or decremented continuously or remains unchanged.

The transfer count (block count) can be set from 1 to 65536. This mode enables an interrupt request to the CPU to be generated at the end of the specified-count block transfer.

Table 16.7 lists the register functions in block transfer mode, and Figure 16.7 shows the memory map for block transfer mode.

SAR	Transfer source address	• When MRB.DTS bit is 0 Increment, decrement, or fixed*1 • When MRB.DTS bit is 1 SAR register initial value.

16。4。5 块传输模式

块传输模式允许在单个激活源上进行单块数据传输。块区域的传输源或传输目的地必须在 MRB。DTS 位中指定。块大小可以设置为 1 到 256 字节、1 到 256 个半字节(2 到 512 字节）或 1 到 256 个字节(4 到 1024 字节）。当指定块的传输完成时,恢复块区域中指定的块大小计数器CRAL和地址寄存器（MRB。DTS = 1时的SAR寄存器或DTS = 0时的DAR寄存器）的初始值。另一个地址寄存器连续递增或递减或保持不变。

传输计数（块计数）可以从 1 设置为 65536。此模式使得能够在指定的计数块传输结束时生成对 CPU 的中断请求。

表16。7列出了块传输模式下的寄存器函数,图16。7显示了块传输模式的内存图。

16.4.6 Chain Transfer

Setting the MRB.CHNE bit to 1 allows chain transfer to be performed continuously on a single activation source. If the MRB.CHNE is set to 1 and CHNS to 0, an interrupt request to the CPU is not generated on completion of the specified number of rounds of transfer or by setting the MRB.DISEL bit to 1. An interrupt request is sent to the CPU each time DTC data transfer is performed. Data transfer has no effect on the ICU.IELSRn.IR flag of the activation source.

The SAR, DAR, CRA, CRB, MRA, and MRB registers can be set independently of each other to define the data transfer. Figure 16.8 shows a chain transfer operation.

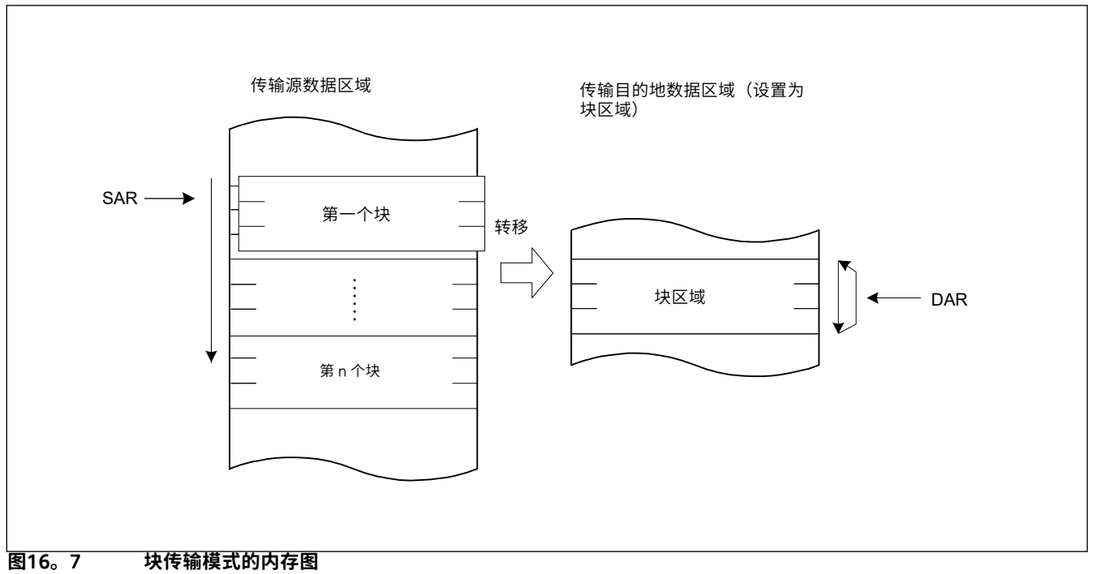

图16。7 块传输模式的内存图

16。4。6 链式转移

将 MRB。CHNE 位设置为 1 允许在单个激活源上连续执行链传输。如果MRB。CHNE被设置为1并且CHNS被设置为0,则在完成指定轮数的传输或通过将MRB。DISEL位设置为1时不会生成对CPU的中断请求。DTC数据传输时,每次都会向CPU发送中断请求。数据传输对激活源的ICU。IELSRn。IR标志没有影响。

SAR、DAR、CRA、CRB、MRA 和 MRB 寄存器可以彼此独立设置以定义数据传输。

Writing 1 to the MRB.CHNE and CHNS bits enables chain transfer to be performed only after completion of the specified data transfer. In repeat transfer mode, chain transfer is performed after completion of the specified data transfer. For details on chain transfer conditions, see Table 16.3.

The unit is for system clocks (ICLK) + 1 in the Vector read, Transfer information read, and Data transfer read columns and 2 in the Internal operation column.
Cv, Ci, Cr, and Cw vary depending on the corresponding access destination. For the number of cycles for respective access destinations, see section 37, SRAM, section 38, Flash Memory, and section 13, Buses.
The frequency ratio of the system clock and peripheral clock is also taken into consideration.
The DTC response time is the time from when the DTC activation source is detected until DTC transfer starts.
Table 16.8 does not include the time until DTC data transfer starts after the DTC activation source becomes active.

16.4.9 DTC Bus Mastership Release Timing

The DTC does not release the bus mastership during transfer information reads. Before the transfer information is read or written, the bus is arbitrated according to the priority determined by the bus master arbitrator. For bus arbitration, see section 13, Buses.

16.4.10 Vector Security

The security attribute of transfer access of DTC vector n and security attribute of access to the IELSRn(n = 0 to 95) register of ICU are controlled by SAIELSRn bit of ICUSARx(x = G,H or I) registers in CPSCU. For details on the CPSCU.ICUSARx registers, see section 12, Interrupt Controller Unit (ICU).

When the CPSCU.ICUSARx.SAIELSRn bit is 0, transfer of DTC vector n is secure access for both read and write. At the same time, the IELSRn register are protected from a non-secure access.

When the CPSCU.ICUSARx.SAIELSRn bit is 1, transfer of DTC vector n is non-secure access for both read and write. At the same time, the IELSRn register are non-secure attributes.

Do not write to the CPSCU.ICUSARx.SAIELSRn bit while DTC transfer is enabled or a bus master is writing to the DTC registers of same channel.

section 16.3.1. Allocating Transfer Information and DTC Vector Table shows security attribute about each DTC vectors.

16.4.11 Master TrustZone Filter in DTC

DTC has the Master TrustZone Filter. The Master TrustZone Filter in DTC can detect the security areas of Flash area(code Flash and data Flash) and SRAM area(ECC / Parity RAM) defined by IDAU. When no-secure accesses those addresses, it detects the security violation. Access of violation address is not performed. Detected the error is handled as the Master TrustZone Filter error.

16.5 DTC Setting Procedure

Before using the DTC, set the DTC Vector Base Register (DTCVBR). Set the ICU.IELSRn.IELS[8:0] bits to 0 to disable the interrupt in the NVIC and follow the procedure in Table 16.9 to set the DTC.

Cv、Ci、Cr 和 Cw 根据相应的访问目的地而有所不同。有关各个访问目的地的周期数,请参阅第 37 节、SRAM、第 38 节、闪存和第 13 节、总线。
系统时钟和外设时钟的频率比也被考虑在内。

16。4。9 DTC 总线主机发布时机

DTC 在传输信息读取期间不会释放总线主控。在读取或写入传输信息之前,总线将根据总线主仲裁员确定的优先级进行仲裁。有关总线仲裁,请参阅第 13 节"总线 ."

16。4。10 矢量安全

DTC向量n的传输访问的安全属性以及对ICU的IELSRn（n = 0至95)寄存器的访问的安全属性由CPSCU中的ICUSARx（x = G,H或I）寄存器的SAIELSRn位控制。CPSCU。ICUSARx 寄存器的详细信息,请参阅第 12 节"中断控制器单元（ICU）."

当 CPSCU。ICUSARx。SAIELSRn 位为 0 时,DTC 向量 n 的传输对于读取和写入都是安全的访问。同时,IELSRn 寄存器受到保护,免受非安全访问。

当 CPSCU。ICUSARx。SAIELSRn 位为 1 时,DTC 向量 n 的传输对于读取和写入都是非安全的访问。同时,IELSRn 寄存器是非安全属性。

在启用 DTC 传输或总线主控器写入同一信道的 DTC 寄存器时,请勿写入 CPSCU。ICUSARx。SAIELSRn 位。

第 16。3。1 节。分配传输信息和 DTC 向量表显示了每个 DTC 向量的安全属性。

16.4.11 DTC 中的主信任区过滤器

DTC 拥有 Master TrustZone 过滤器。DTC中的Master TrustZone Filter可以检测IDAU定义的Flash区域（代码Flash和数据Flash）和SRAM区域（ECC/奇偶校验RAM）的安全区域。当 no-secure 访问这些地址时,它会检测到安全违规行为。不执行违规地址的访问。检测到的错误将作为主信任区过滤器错误进行处理。

16.5 DTC 设置程序

在使用 DTC 之前,设置 DTC 矢量基本寄存器（DTCVBR）。将 ICU。IELSRn。IELS[8:0] 位设置为 0 以禁用 NVIC 中的中断,并按照表 16。9 中的程序设置 DTC。

Table 16.9 DTC setting procedure

2	Set transfer information (MRA, MRB, SAR, DAR, CRA, and CRB)	Allocate transfer information (MRA, MRB, SAR, DAR, CRA, and CRB) in the data area. To set transfer information, see section 16.2. Register Descriptions. To allocate transfer information, see section 16.3.1. Allocating Transfer Information and DTC Vector Table.

The RRS bit can be set to 1, but if this is set during DTC transfer, it becomes valid from the next transfer.

Set ICU.IELSRn.IELS[8:0] as interrupt sources that trigger DTC. The interrupt must be enabled in the NVIC. See section 12.3.2. Event Number in section 12, Interrupt Controller Unit (ICU).
6	Set the enable bit for an activation source interrupt	Set the enable bit for the activation source interrupts to 1. When a source interrupt is generated, the DTC is activated. To set the interrupt source enable bit, see the settings for the modules that are to be the activation sources.
7	Set the DTCST.DTCST bit to 1	Set the DTC Module Start bit (DTCST.DTCST) to 1.

Note: The DTCST.DTCST bit can be set even if the setting for each activation source is not completed.
Note: When used in non-secure state, DTCSAR.DTCSTSA = 1 or DTCST.DTCST = 1 must be set.
Note 1. When used in secure state, access DTCCR_SEC instead of DTCCR.

16.6 Examples of DTC Usage

16.6.1 Normal Transfer

This section provides an example of DTC usage and its application when receiving 128 bytes of data from an SCI.

(1) Transfer information settings

In the MRA register, select a fixed source address (MRA.SM[1:0] = 00b), normal transfer mode (MRA.MD[1:0] = 00b), and byte-sized transfer (MRA.SZ[1:0] = 00b). In the MRB register, specify incrementation of the destination address (MRB.DM[1:0] = 10b) and single data transfer by a single interrupt (MRB.CHNE = 0 and MRB.DISEL = 0). The MRB.DTS bit can be set to any value. Set the RDR register address of the SCI in the SAR register, the start address of the SRAM area for data storage in the DAR register, and 128 (0x0080) in the CRA register. The CRB register can be set to any value.

(2) DTC vector table settings

The start address of the transfer information for the RXI interrupt is set in the vector table for the DTC.

(3) ICU settings and DTC module activation

Set the ICU.IELSRn.DTCE bit to 1 and set ICU.IELSRn.IELS[8:0] as the SCI interrupt. The interrupt must be enabled in the NVIC. Set the DTCST.DTCST bit to 1.

(4) SCI settings

Enable the SCIn_RXI (n = 0, 9) interrupt by setting the SCR.RIE bit in the SCI to 1. If a reception error occurs during the SCI receive operation, reception stops. To manage this, use settings that allow the CPU to accept receive error interrupts.

(5) DTC transfer

Each time a reception of 1 byte by the SCI is complete, an SCIn_RXI interrupt is generated to activate the DTC. The DTC transfers the received byte from the RDR of the SCI to the SRAM, after which the DAR register is incremented and the CRA register is decremented.

1	设置 DTCCR *1。RRS 位到 0	设置 DTCCR *1。RRS 位到 0 来重置传输信息读取跳过标志。之后,在激活DTC时不会跳过传输信息读取。更新传输信息时请务必指定此设置。
2	设置传输信息（MRA, MRB、SAR、DAR、CRA 和 CRB)	在数据区域分配传输信息（MRA、MRB、SAR、DAR、CRA 和 CRB）。要设置传输信息,请参阅第 16。2 节。注册说明。要分配传输信息,请参阅第 16。3。1 节。分配传输信息和 DTC 矢量表。

5	设置 ICU。IELSRn。DTCE 位 to 1. 将 ICU。IELSRn。IELS[8:0] 设置为中断源。应在 NVIC 中启用中断。	将 ICU。IELSRn。DTCE 位设置为 1。将 ICU。IELSRn。IELS[8:0] 设置为触发的中断源 DTC。NVIC 中必须启用中断。参见第 12。3。2 节。12节中的事件编号, 中断控制器单元（ICU）。
6	将启用位设置为激活源中断	将激活源中断的使能位设置为 1。当生成源中断时,DTC 被激活。要设置中断源启用位,请参阅要作为激活源的模块的设置。
7	将 DTCST。DTCST 位设置为 1	将 DTC 模块开始位（DTCST。DTCST）设置为 1。

注: 即使每个激活源的设置未完成,也可以设置 DTCST。DTCST 位。
注: 当以非安全状态使用时,必须设置 DTCSAR。DTCSTSA = 1 或 DTCST。DTCST = 1。
注1。在安全状态下使用时,访问 DTCCR_SEC 而不是 DTCCR。

16。6 DTC 使用示例

16。6。1 正常转移

本节提供了从 SCI 接收 128 字节数据时 DTC 使用情况及其应用的示例。

(1)传输信息设置

MRA寄存器中,选择一个固定源地址（MRA。SM[1:0] = 00b）,正常传输模式（MRA。MD[1:0] = 00b）,以及字节大小的传输（MRA。SZ[1:0] = 00b）。MRB寄存器中,指定目标地址的增量（MRB。DM[1:0] = 10b）和单个中断的单个数据传输（MRB。CHNE = 0和MRB。DISEL = 0)。MRB。DTS 位可以设置为任何值。SAR寄存器中设置SCI的RDR寄存器地址,DAR寄存器中设置数据存储的SRAM区域的起始地址,CRA寄存器中设置128(0x0080)。CRB寄存器可以设置为任何值。

(2)DTC向量表设置

RXI 中断的传输信息的起始地址设置在 DTC 的向量表中。

(3)ICU设置和DTC模块激活

将ICU。IELSRn。DTCE位设置为1并将ICU。IELSRn。IELS[8:0]设置为SCI中断。NVIC 中必须启用中断。将 DTCST。DTCST 位设置为 1。

（四）科学设置

SCI 中的 SCR。RIE 位设置为 1,从而启用 SCIn_RXI（n = 0, 9) 中断。SCI 接收操作期间发生接收错误, 则接收停止。要管理此操作,请使用允许 CPU 接受接收错误中断的设置。

（五）DTC转让

SCI 的 1 个字节的接收每次完成时,都会生成一个 SCIn_RXI 中断来激活 DTC。DTC 将接收到的字节从 SCI 的 RDR 传输到 SRAM,之后递增 DAR 寄存器并递减 CRA 寄存器。

(6) Interrupt handling

After 128 rounds of data transfer are complete and the value in the CRA register becomes 0, an SCIn_RXI interrupt request is generated for the CPU. Complete the process in the handling routine for this interrupt.

16.6.2 Chain transfer

This section provides an example of chain transfer by the DTC and describes its use in the output of pulses by the General PWM Timer (GPT). You can use chain transfer to transfer PWM timer compare data and change the period of the PWM timer for the GPT.

For the first of the chain transfers, normal transfer mode is specified for transfer to the GPTm.GTCCRC register (m = 160 to 165). For the second transfer, normal transfer mode is specified for transfer to the GPTm.GTCCRE register (m = 160 to 165). For the third transfer of the chained transfer, normal transfer mode for transfer to the GPTm.GTPBR register (m = 160 to 165) is specified. This is because clearing of the activation source and generation of an interrupt on completion of the specified number of transfers are restricted to the third of the chain transfers, that is, transfer while MRB.CHNE = 0.

The following example shows how to use the counter overflow interrupt with the GPT160.GTPR register as an activating source for the DTC.

(1) First transfer information setting

Set up transfer to the GTP160.GTCCRC register.

1. In the MRA register, select incrementation of the source address (MRA.SM[1:0] = 10b).
2. Set the transfer to normal transfer mode (MRA.MD[1:0] = 00b) and word-sized transfer (MRA.SZ[1:0] = 10b).
3. In the MRB register, select the destination address as fixed (MRB.DM[1:0] = 00b) and set up chain transfer (MRB.CHNE = 1 and MRB.CHNS = 0).
4. Set the SAR register to the first address of the data table.
5. Set the DAR register to the address of the GPT160.GTCCRC register.
6. Set the CRAH and CRAL registers to the size of the data table. The CRB register can be set to any value.

(2) Second transfer information setting

Set up for transfer to the GPT160.GTCCRE register.

1. In the MRA register, select incrementation of the source address (MRA.SM[1:0] = 10b).
2. Set the transfer to normal transfer mode (MRA.MD[1:0] = 00b) and word-sized transfer (MRA.SZ[1:0] = 10b).
3. In the MRB register, select the destination address as fixed (MRB.DM[1:0] = 00b) and set up chain transfer (MRB.CHNE = 1, MRB.CHNS = 0).
4. Set the SAR register to the first address of the data table.
5. Set the DAR register to the address of the GPT160.GTCCRE register.
6. Set the CRAH and CRAL registers to the size of the data table. The CRB register can be set to any value.

(3) Third transfer information set

Set up transfer to the GPT160.GTPBR register.

1. In the MRA register, select incrementation of the source address (MRA.SM[1:0] = 10b).
2. Set the transfer to normal transfer mode (MRA.MD[1:0] = 00b) and word-sized transfer (MRA.SZ[1:0] = 10b).
3. In the MRB register, select the destination address as fixed (MRB.DM[1:0] = 00b) and set up single data transfer per interrupt (MRB.CHNE = 0, MRB.DISEL = 0). The MRB.DTS bit can be set to any value.
4. Set the SAR register to the first address of the data table.
5. Set the DAR register to the address of the GPT160.GTPBR register.
6. Set the CRA register to the size of the data table. The CRB register can be set to any value.

（六）中断处理

128轮数据传输完成,CRA寄存器中的值变为0后,为CPU生成SCIn_RXI中断请求。完成此中断的处理例程中的过程。

16。6。2 链式转移

本节提供了 DTC 链传输的示例,并描述了其在通用 PWM 定时器（GPT）脉冲输出中的使用。您可以使用链式传输来传输 PWM 定时器比较数据并更改 GPT 的 PWM 定时器的周期。

对于链式传输中的第一个,指定正常传输模式以传输到 GPTm。GTCCRC 寄存器（m = 160 至 165)。对于第二次传输,指定正常传输模式以传输到 GPTm。GTCCRE 寄存器（m = 160 至 165)。对于链式传输的第三次传输,指定了传输到 GPTm。GTPBR 寄存器（m = 160 至 165)的正常传输模式。这是因为激活源的清除和指定传输次数完成后中断的生成仅限于链传输的第三个,即传输,而 MRB。CHNE = 0。

以下示例展示了如何使用 GPT160 的计数器溢出中断。GTPR 注册为 DTC 的激活源。

（一）首次传递信息设置

设置传输到 GTP160。GTCCRC 注册。

1。MRA寄存器中,选择源地址的增量（MRA。SM[1:0] = 10b）。

(4) Transfer information assignment

Place the transfer information for use in the transfer to the GPT160.GTPBR immediately after the transfer control information for use in the GPT160.GTCCRC and GPT160.GTCCRE registers.

(5) DTC vector table

In the DTC vector table, set the address where the transfer control information for use in transfer to the GPT160.GTCCRC and GPT160.GTCCRE registers starts.

(6) ICU setting and DTC module activation

1. Set the ICU.IELSRn.DTCE bit associated with the GPT160 counter overflow interrupt.
2. Set the ICU.IELSRn.IELS[8:0] bits and specify the GPT160 counter overflow.
3. Set the DTCST.DTCST bit to 1.

(7) GPT settings

1. Set the GPT160.GTIOR register so that the GTCCRA and GTCCRB registers operate as output compare registers.
2. Set the default PWM timer compare values in the GPT160.GTCCRA and GPT160.GTCCRB registers and the next PWM timer compare values in the GPT160.GTCCRC and GPT160.GTCCRE registers.
3. Set the default PWM timer period values in the GPT160.GTPR register and the next PWM timer period values in the GPT160.GTPBR register.
4. Set 1 to the output bit in PmnPFS.PDR, and set 00011b to the Peripheral Select bits in PmnPFS.PSEL[4:0].

(8) GPT activation

Set the GPT160.GTSTR.CSTRT bits to 1 to start the GPT160.GTCNT counter.

(9) DTC transfer

Each time a GPT160 counter overflow is generated with the GPT160.GTPR register, the next PWM timer compare values are transferred to the GPT160.GTCCRC and GPT160.GTCCRE registers. The setting for the next PWM timer period is transferred to the GPT160.GTPBR register.

(10) Interrupt handling

After the specified rounds of data transfer are complete, for example when the value in the CRA register for GPT transfer becomes 0, a GPT160 counter overflow interrupt request is issued for the CPU. Complete the process for this interrupt in the handling routine.

16.6.3 Chain Transfer when Counter = 0

The second data transfer is performed only when the transfer counter is set to 0 in the first data transfer, and the first data transfer information is repeatedly changed in the second transfer. Chain transfer enables transfers to be repeated 256 times or more.

The following procedure shows an example of configuring a 1-KB input buffer, where the input buffer is set so that its lower address starts with 0x00. Figure 16.13 shows a chain transfer when the counter = 0.

1. Set the normal transfer mode to input data for the first data transfer. Set the following:
   (a) Transfer source address = fixed.
   (b) CRA register = 0x0200 (512) times.
   (c) MRB.CHNE bit = 1 (chain transfer is enabled).
   (d) MRB.CHNS bit = 1 (chain transfer is performed only when the transfer counter is 0).
   (e) MRB.DISEL bit = 0 (an interrupt request to the CPU is generated when the specified data transfer completes).
2. Prepare the upper 8-bit address of the start address at every 512 times of the transfer destination address for the first data transfer in different area such as the flash. For example, when setting the input buffer to 0x8000 to 0x83FF, prepare 0x82 and 0x80.

（四）转移信息分配

将传输信息放置到 GPT160 中以供传输使用。GTPBR 紧接在传输控制信息之后用于 GPT160。GTCCRC 和 GPT160。GTCCRE 寄存器。

(5)DTC向量表

DTC向量表中,设置传输控制信息用于传输到GPT160的地址。GTCCRC 和 GPT160。GTCCRE 寄存器启动。

(6)ICU设置和DTC模块激活

1。设置与 GPT160 计数器溢出中断关联的 ICU。IELSRn。DTCE 位。

2锛姣涓涓。设置 ICU。IELSRn。IELS[8:0] 位并指定 GPT160 计数器溢出。

3锛　　娴　　。将 DTCST。DTCST 位设置为 1。

（七）GPT设置

4锛姣涓。1 设置为 PmnPFS。PDR 中的输出位,并将 00011b 设置为 PmnPFS。PSEL 中的外围选择位[4:0]。

（八）GPT激活

设置 GPT160。GTSTR。CSTRT 位到 1 以启动 GPT160。GTCNT 计数器。

（九）DTC转让

每次使用 GPT160 生成 GPT160 计数器溢出。GTPR 寄存器,则下一个 PWM 定时器比较值将传输到 GPT160。GTCCRC 和 GPT160。GTCCRE 寄存器。下一个 PWM 定时器周期的设置将传输到 GPT160。GTPBR 注册。

（十）中断处理

指定轮次的数据传输完成后,例如当GPT传输的CRA寄存器中的值变为0时,针对CPU发出GPT160计数器溢出中断请求。完成处理例程中此中断的过程。

16。6。3 计数器 = 0 时链传输

仅当在第一数据传输中将传输计数器设置为0时才执行第二数据传输,并且在第二传输中重复改变第一数据传输信息。链式传输使传输能够重复 256 次或更多次。

以下过程显示了配置 1-KB 输入缓冲区的示例,其中输入缓冲区被设置为其下地址以 0x00 开头。图 16。13 显示了计数器 = 0 时的链转移。

1。将正常传输模式设置为输入数据以进行第一次数据传输。设置以下内容:
)(a 传输源地址 = 固定。
)(b CRA 寄存器 = 0x0200 (512) 次。
)(c MRB。CHNE 位 = 1（启用链传输）。
)(d MRB。CHNS 位 = 1（仅当传输计数器为 0 时才执行链传输）。
   (e) MRB。DISEL 位 = 0（指定数据传输完成时会生成对 CPU 的中断请求）。

2锛姣涓。512次传输目的地址处准备起始地址的上部8位地址,用于闪存等不同区域中的第一次数据传输。例如,当将输入缓冲区设置为 0x8000 至 0x83FF 时,请准备
   0x82 和 0x80。

3. For the second data transfer:
   (a) Set the repeat transfer mode (with transfer source and destination address = fixed.) to reset the transfer counter of the first data transfer.
   (b) Specify the CRA register in the first transfer information area for the transfer destination.
   (c) Set the MRB.CHNE bit = 1 (chain transfer is enabled).
   (d) Set the MRB.CHNS bit = 0 (select continuous chain transfer).
   (e) Set the MRB.DISEL bit = 0 (an interrupt request to the CPU is generated when the specified data transfer completes).
   (f) CRA register = 0x0101 (The transfer count is 1).
4. For the third data transfer:
   (a) Set the repeat transfer mode (with the source as the repeat area) to reset the transfer destination address of the first data transfer.
   (b) Specify the upper 8 bits of the DAR register in the first transfer information area for the transfer destination.
   (c) Set the MRB.CHNE bit = 0 (chain transfer is disabled).
   (d) Set the MRB.DISEL bit = 0 (an interrupt request to the CPU is generated when the specified data transfer completes).
   (e) When setting the input buffer to 0x8000 to 0x83FF, also set the transfer counter to 2.
5. The first data transfer is performed by an interrupt 512 times. When the transfer counter of the first data transfer becomes 0, the second data transfer starts. Set the transfer counter of the first data transfer to 0x0200. The lower 8 bits of the transfer destination address and the transfer counter of the first data transfer becomes 0x0200.
6. The second data transfer is performed by an interrupt 1 times. When the transfer counter of the first data transfer becomes 0, the third data transfer starts. Set the upper 8 bits of the transfer destination address of the first data transfer to 0x82. The lower 8 bits of the transfer destination address becomes 0x00 and the transfer counter of the first data transfer becomes 0x0200.
7. In succession, the first data transfer is performed by an interrupt 512 times as specified for the first data transfer. When the transfer counter of the first data transfer becomes 0, the second data transfer starts. Set the transfer counter of the first data transfer to 0x0200. The lower 8 bits of the transfer destination address and the transfer counter of the first data transfer becomes 0x0200.
8. The second data transfer is performed by an interrupt 1 times. When the transfer counter of the first data transfer becomes 0, the third data transfer starts. Set the upper 8 bits of the transfer destination address of the first data transfer to 0x80. The lower 8 bits of the transfer destination address becomes 0x00 and the transfer counter of the first data transfer becomes 0x0200.
9. Steps 5 to 8 are repeated indefinitely. Because the second data transfer is in repeat transfer mode, no interrupt request to the CPU is generated.

3锛 娴 。对于第二次数据传输:
（a）设置重复传输模式（传输源和目的地址 = 固定。),以重置第一次数据传输的传输计数器。
（b）为转运目的地在第一转运信息区指定CRA登记册。
（c）设置 MRB。CHNE 位 = 1（启用链传输）。
（d）设置 MRB。CHNS 位 = 0（选择连续链传输）。
（e）设置 MRB。DISEL 位 = 0（当指定的数据传输完成时,会生成对 CPU 的中断请求）。
（f）CRA 寄存器 = 0x0101（转移计数为 1)。
4锛姣涓。对于第三次数据传输:
（a）设置重复传输模式（以源为重复区域）,重置第一次数据传输的传输目的地址。
（b）为转移目的地指定第一转移信息区DAR寄存器的上部8位。
（c）设置 MRB。CHNE 位 = 0（链传输被禁用）。
（d）设置 MRB。DISEL 位 = 0（当指定的数据传输完成时,会生成对 CPU 的中断请求）。
（e）在将输入缓冲区设置为0x8000至0x83FF时,也将传输计数器设置为2。
5锛姣涓。第一次数据传输由中断执行512次。当第一数据传输的传输计数器变为0时,第二数据传输开始。将第一次数据传输的传输计数器设置为0x0200。传输目的地址和第一数据传输的传输计数器的下部8位变为0x0200。
6锛 涓€涓。第二次数据传输由中断执行1次。当第一数据传输的传输计数器变为0时,第三数据传输开始。将第一数据传输的传输目的地址的上部8位设置为0x82。传输目的地址的下部8位变为0x00并且第一数据传输的传输计数器变为0x0200。
7锛 娴 。连续地,按照第一数据传输的规定,通过中断512次来执行第一数据传输。当第一数据传输的传输计数器变为0时,第二数据传输开始。将第一次数据传输的传输计数器设置为0x0200。传输目的地址和第一数据传输的传输计数器的下部8位变为0x0200。
8锛 娴 。第二次数据传输由中断执行1次。当第一数据传输的传输计数器变为0时,第三数据传输开始。将第一数据传输的传输目的地址的上部8位设置为0x80。传输目的地址的下部8位变为0x00并且第一数据传输的传输计数器变为0x0200。
9锛 涓€涓。步骤5至8无限期重复。由于第二数据传输处于重复传输模式,因此不会生成对CPU的中断请求。

16.7 Processing on DTC Transfer Error

If the access error occurs during DTC transfer, the DTC immediately stops access during transfer. To stop only the vector number that caused the error, inform the vector number that caused the error to the ICU and clear the corresponding ICU setting. After that, if there is a request other than the vector number which caused the error, it will be re-arbitration as it is. The condition under which the transfer error occurs is indicated when TrustZone Filter in DTC detects a violation.

The error response is informed to ICU when the transfer error occurs. ICU clears the ICU.IELSRn of the corresponding vector number which caused the transfer error. Furthermore, it generates an error response detection interrupt to notify that an error has occurred by DMAC/DTC transfer. (section 16.8.2. Interrupt Request of Transfer Error). Write back to SRAM is not performed.

When the Master TrustZone Filter error occurs, the Slave TrustZone error occurs or the Master MPU error occurs, it is possible to confirm the error information of DTC by selecting NMI. The DTC error vector register is cleared by selecting reset. Under the conditions where NMI is generated due to transfer error in DTC, two interrupts(NMI and DMA_TRANSERR) are generated. In this case, NMI always responds first.

The error response detection interrupt request (DMA_TRANSERR) occurs when the Slave Bus error or the Illegal Access error occurs. Furthermore, it occurs after NMI when the error response detection interrupt request (DMA_TRANSERR) is not cleared in NMI handler.

section 16.7.1. Processing on NMI handler describes how to confirm the error information of the DTC in the NMI handler.
section 16.7.2. Processing on Error response detection interrupt request (DMA_TRANSERR) handler describes how to confirm the error information of the DTC in the DMA_TRANSERR handler.

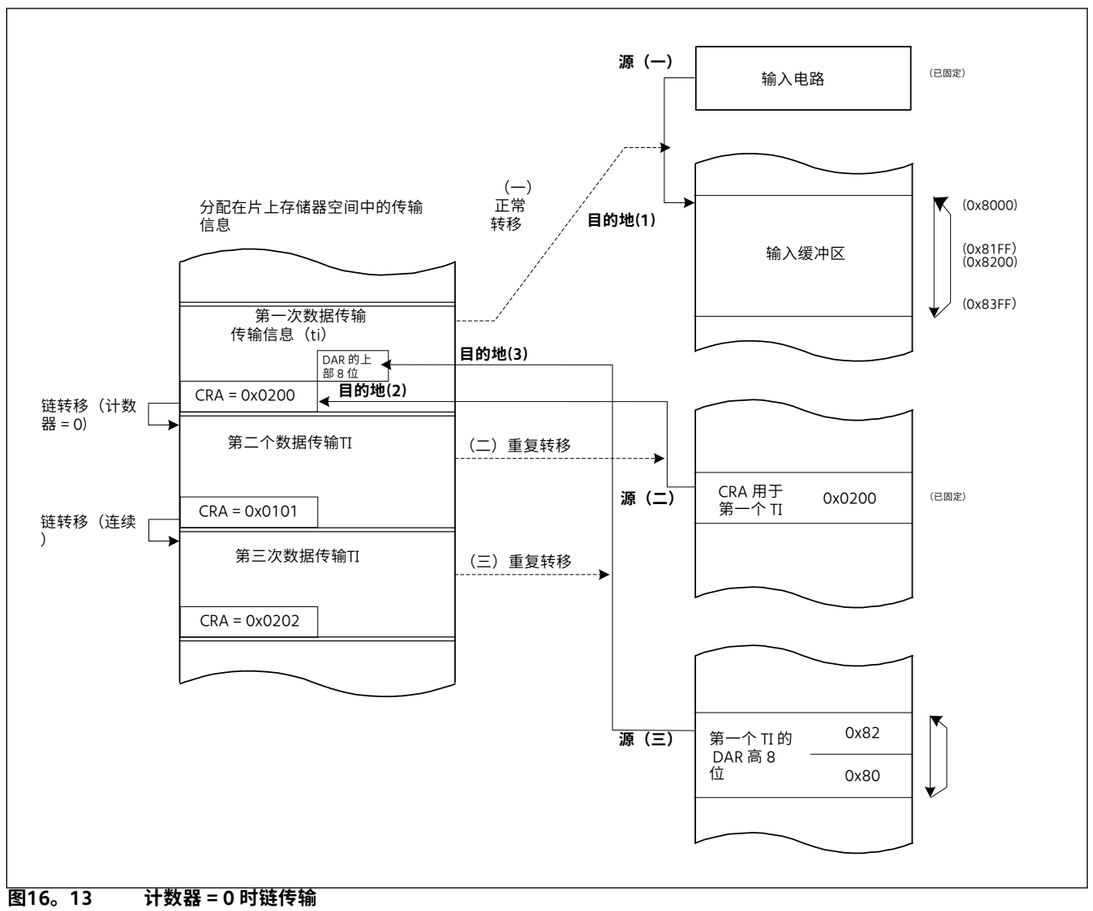

图16。13 计数器 = 0 时链传输

16。7 DTC 传输错误处理

DTC 传输过程中出现访问错误,则 DTC 在传输过程中立即停止访问。要仅停止导致错误的向量号,请将导致错误的向量号通知 ICU 并清除相应的 ICU 设置。之后,如果存在除向量号之外的请求而导致错误,则将按原样重新仲裁。

当 DTC 中的 TrustZone Filter 检测到违规行为时,会指示发生传输错误的条件。

当发生传输错误时,错误响应会通知 ICU。ICU 清除 ICU。IELSRn 中导致传输错误的相应矢量编号。此外,它还会生成错误响应检测中断,以通知 DMAC/DTC 传输已发生错误。（第 16。8。2 节。中断传输请求错误）。不执行写回 SRAM。

Master TrustZone Filter 错误、Slave TrustZone 错误或 Master MPU 错误发生时,可以通过选择 NMI 来确认 DTC 的错误信息。DTC 错误向量寄存器通过选择复位来清除。DTC中由于传输错误而产生NMI的条件下,产生两个中断（NMI和DMA_TRANSERR）。在这种情况下,NMI 总是首先响应。

Slave Bus 错误或非法访问错误时,会发生错误响应检测中断请求（DMA_TRANSERR）。此外,当 NMI 处理程序中错误响应检测中断请求（DMA_TRANSERR）未被清除时,它会发生在 NMI 之后。

第 16。7。1 节。NMI 处理程序上的处理描述了如何确认 NMI 处理程序中 DTC 的错误信息。
第 16。7。2 节。处理错误响应检测中断请求（DMA_TRANSERR）处理程序描述了如何确认DMA_TRANSER R处理程序中DTC的错误信息。

Interrupts and the error information generated due to transfer errors are shown in section 16.8.2. Interrupt Request of Transfer Error.

16.7.1 Processing on NMI handler

The cause of NMI due to the DMA transfer error is the Master TrustZone Filter error, the Slave TrustZone Filter error or the Master MPU error. When NMI occurs due to the DTC transfer error, the error response detection interrupt request (DMA_TRANSERR) will occur after the end of NMI handler. It is possible to confirm the cause of the error and the DTC vector number in which the error occurred. When NMI occurs, perform the necessary processing according to the flow described in the ICU chapter.

Figure 16.15 shows the flow for confirm the vector number that caused the Slave TrustZone Filter Error in DTC

Figure 16.16 shows the flow for confirm the vector number and Security Attribute that caused the Master MPU error in DTC

If completing all processing in NMI handler, it is possible to clear the error response detection interrupt request (DMA_TRANSERR) that occurs subsequently.

16。7。1 NMI 处理程序上的处理

DMA 传输错误导致 NMI 的原因是主信任区过滤器错误、从信任区过滤器错误或主 MPU 错误。DTC 传输错误导致 NMI 发生时,错误响应检测中断请求（DMA_TRANSERR）将在 NMI 处理程序结束后发生。可以确认错误的原因以及发生错误的 DTC 向量号。NMI发生时,根据ICU章节中描述的流程进行必要的处理。

NMI处理程序中完成所有处理,则可以清除随后发生的错误响应检测中断请求（DMA_TRANSERR）。

16.7.2 Processing on Error response detection interrupt request (DMA_TRANSERR) handler

16.8 Interrupt

16.8.1 Interrupt Request of Transfer End

When the DTC completes data transfer of the specified count or when data transfer with MRB.DISEL set to 1 is complete, a DTC activation source generates an interrupt to the CPU. Two types of interrupt are available: interrupts triggered by a DTC activation (per channel) and an interrupt triggered by the event signal DTC_COMPLETE (common to all channels). Interrupts to the CPU are controlled according to the settings in the NVIC and the ICU.IELSRn.IELS[8:0] bits. See section 12, Interrupt Controller Unit (ICU). The DTC prioritizes activation sources by granting the smaller interrupt vector numbers higher priority. The priority of interrupts to the CPU is determined by the NVIC priority.

16.8.2 Interrupt Request of Transfer Error

The error response detection interrupt request (DMA_TRANSERR) is generated from the DMAC/DTC when the transfer error is detected during DTC transfer. The types of interrupts that occur when the DTC transfer error occurs are listed in the Table 16.10. The Table 16.10 also shows error information stored when a transfer error occurs.

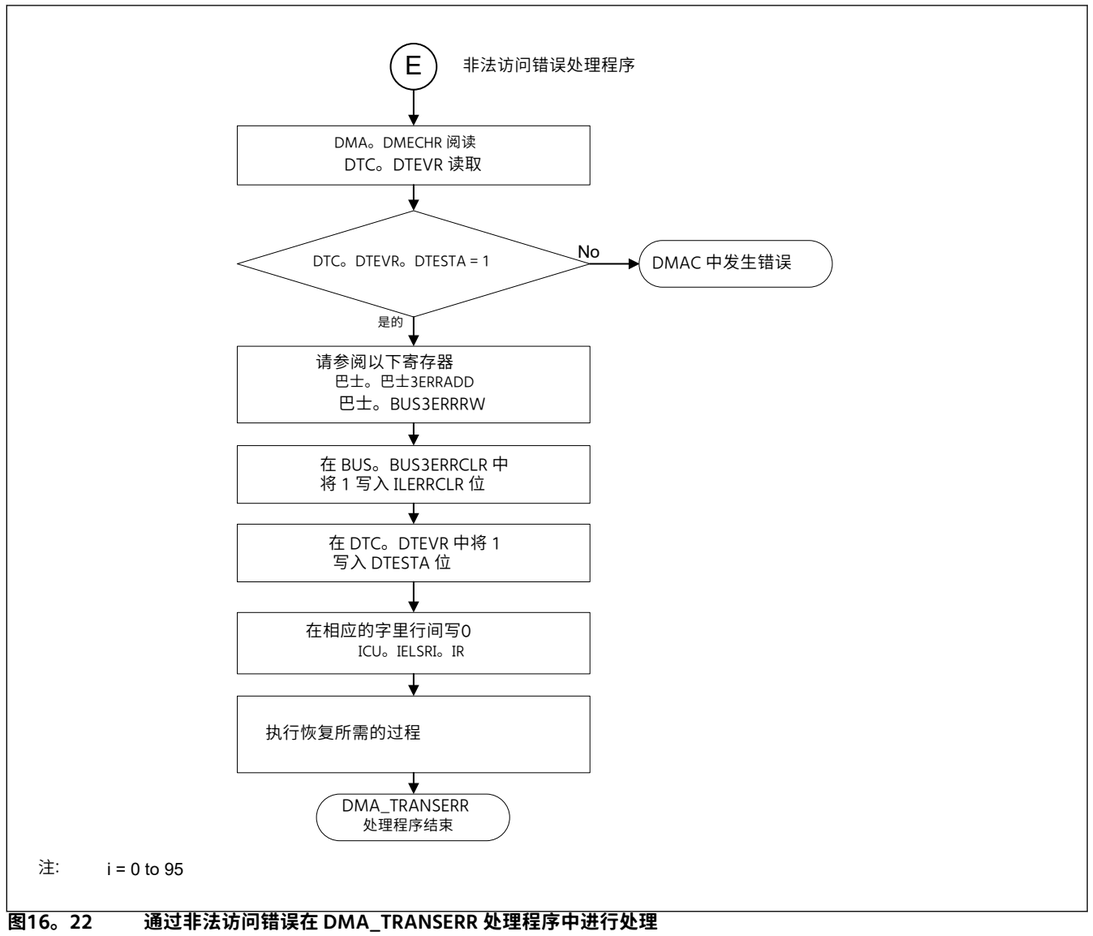

图16。22 通过非法访问错误在 DMA_TRANSERR 处理程序中进行处理

16.8 中断

16.8.1 传输结束的中断请求

当DTC完成指定计数的数据传输或者当设置为1的MRB。DISEL的数据传输完成时,DTC激活源对CPU产生中断。DTC 激活（每个通道）触发的中断和事件信号 DTC_COMPLETE（所有通道通用）触发的中断两种。

CPU 的中断根据 NVIC 和 ICU。IELSRn。IELS[8:0] 位中的设置进行控制。请参阅第 12 节"中断控制器单元（ICU）"。 DTC 通过授予较小的中断向量编号更高的优先级来优先级激活源。CPU 中断的优先级由 NVIC 优先级决定。

16。8。2 传输错误的中断请求

DTC 传输期间检测到传输错误时, 从 DMAC/DTC 生成错误响应检测中断请求（DMA_TRANSERR）。DTC 传输错误时发生的中断类型列于表 16。10。表16。10还显示了发生传输错误时存储的错误信息。

Note 1. Interrupt generated, when NMI request selected as the operation after detection of the Master MPU error and The TrustZone Filter error. By confirming BUS.BUS3ERRSTAT and BUS.DMACDTCERRSTAT, judge whether it is the Master or the Slave.
Note 2. If the error response detection interrupt (DMA_TRANSERR) occurs and NMI of the Master MPU or NMI of the TrustZone Filter has not occurred, treat it as the Illegal address access error or the Slave Bus Error. It can be judged also by BUS.BUS3ERRSTAT and BUS. DMACDTCERRSTAT.

Note that if the bus error occurs when writing the last data of transfer, the transfer end event and the error response detection interrupt (DMA_TRANSERR) occurs.

16.9 Event Link

The DTC can produce an event link request on completion of one transfer request.

16.10 Low Power Consumption Function

Before transitioning to the module-stop state, Software Standby mode without Snooze mode transition, Deep Software Standby mode, set the DTCST.DTCST bit to 0, and then perform the operations described in the following sections. The DTC is available in Snooze mode by setting the SYSTEM.SNZCR.SNZDTCEN bit to 1. See section 10, Low Power Modes.

(1) Module-Stop Function

Writing 1 to the MSTPCRA.MSTPA22 bit enables the module-stop function of the DTC. If a DTC transfer is in progress when 1 is written to the MSTPCRA.MSTPA22 bit, the transition to the module-stop state proceeds after the DTC transfer ends. While the MSTPCRA.MSTPA22 bit is 1, accessing the DTC registers is prohibited. Writing 0 to the MSTPCRA.MSTPA22 bit releases the DTC from the module-stop state.

(2) Software Standby Mode and Deep Software Standby Mode

Use the settings described in section 10.7.1. Transitioning to Software Standby Mode or section 10.9.1. Transitioning to Deep Software Standby Mode.

If DTC transfer operations are in progress when the WFI instruction is executed, the transition to Software Standby mode or Deep Software Standby mode is executed after the completion of the DTC transfer.

(3) Snooze Mode

When the snooze control circuit receives a snooze request in Software Standby mode, the MCU transitions to Snooze mode. See section 10.8.1. Transition to Snooze Mode. DTC operation in Snooze mode can be selected in the SYSTEM.SNZCR.SNZDTCEN bit. If DTC operation is enabled in Snooze mode, before transitioning to Software Standby mode, set the DTCST.DTCST bit to 1. To return to Software Standby mode through DTC, set SYSTEM.SNZEDCR0.DTCZRED or SYSTEM.SNZEDCR0.DTCNZRED to 1. See section 10.8.3. Returning from Snooze Mode to Software Standby Mode. SYSTEM.SNZEDCR0.DTCZRED enables or disables a snooze end request on completion of the last DTC transmission, detected on DTC transmission completion when CRA and CRB are 0. SYSTEM.SNZEDCR0.DTCNZRED enables or disables a snooze end request on a not last DTC transmission completion (CRA and CRB are not 0), detected on DTC transmission completion when CRA and CRB are not 0. The DTC activation request from the ICU is stopped during Software Standby mode but not stopped during Snooze mode.

注1。当检测到主 MPU 错误和 TrustZone 过滤器错误后选择 NMI 请求作为操作时,会生成中断。通过确认 BUS。BUS3ERRSTAT 和 BUS。DMACDTCERRSTAT,判断它是主人还是从人。
注2。如果发生错误响应检测中断（DMA_TRANSERR）并且 Master MPU 或 TrustZone Filter 的 NMI 未发生,请将其视为非法地址访问错误或从站总线错误。也可以通过 BUS。BUS3ERRSTAT 和 BUS 进行判断。DMACDTCERRSTAT。

请注意,如果在写入传输的最后一个数据时发生总线错误,则会发生传输结束事件和错误响应检测中断（DMA_TRANSERR）。

16。9 活动链接

DTC可以在完成一个传输请求后产生一个事件链接请求。

16。10 低功耗功能

在过渡到模块停止状态之前,软件待机模式无Snooze模式过渡,深度软件待机模式,将DTCST。DTCST位设置为0,然后执行以下各节中描述的操作。通过将 SYSTEM。SNZCR。SNZDTCEN 位设置为 1,DTC 可在 Snooze 模式下使用。请参阅第 10 节"低功耗模式 ."

(1)模块–停止功能

将 1 写入 MSTPCRA。MSTPA22 位可实现 DTC 的模块停止功能。如果当1写入MSTPCRA。MSTPA22位时DTC传输正在进行中,则在DTC传输结束后继续向模块停止状态的转换。虽然 MSTPCRA。MSTPA22 位为 1,但禁止访问 DTC 寄存器。将 0 写入 MSTPCRA。MSTPA22 位可将 DTC 从模块停止状态释放。

(2) 软件待机模式和深度软件待机模式

使用第 10。7。1 节中描述的设置。过渡到软件待机模式或第 10。9。1 节。过渡到深度软件待机模式 .

WFI指令执行时正在进行DTC传输操作,则在DTC传输完成后执行向软件待机模式或深度软件待机模式的过渡。

(3)贪睡模式

当Snooze控制电路在软件待机模式下接收到Snooze请求时,MCU转换为Snooze模式。

参见第 10。8。1 节。过渡到贪睡模式。Snooze 模式下的 DTC 操作可以在 SYSTEM。SNZCR。SNZDTCEN 位中选择。如果在 Snooze 模式下启用 DTC 操作,则在转换为软件待机模式之前,将 DTCST。DTCST 位设置为 1。要通过 DTC 返回软件待机模式,请设置

系统。SNZEDCR0。DTCZRED 或 SYSTEM。SNZEDCR0。DTCNZRED 为 1。参见第 10。8。3 节。从贪睡模式返回到软件待机模式。系统。SNZEDCR0。DTCZRED 在完成最后一次 DTC 传输时启用或禁用打瞌睡结束请求,当 CRA 和 CRB 为 0 时,在 DTC 传输完成时检测到该请求。

系统。SNZEDCR0。DTCNZRED 在非最后 DTC 传输完成（CRA 和 CRB 不是 0)上启用或禁用打瞌睡结束请求,当 CRA 和 CRB 不是 0 时,在 DTC 传输完成时检测到该请求。ICU 的 DTC 激活请求在软件待机模式期间停止,但在 Snooze 模式期间不会停止。

(4) Notes on Low Power Consumption Function

For the WFI instruction and the register setting procedure, see section 10, Low Power Modes.

To perform a DTC transfer after returning from a low power mode without a Snooze mode transition, set the DTCST.DTCST bit to 1 again.

To use a request that is generated in Software Standby mode as an interrupt request to the CPU but not as a DTC activation request, specify the CPU as the interrupt request destination as described in section 12.4.1. Detecting Interrupts, then execute the WFI instruction. If DTC operation is enabled in Snooze mode, do not use the module-stop function of the DTC.

16.11 Usage Notes

16.11.1 Transfer Information Start Address

You must set multiples of 4 for the transfer information start addresses in the vector table. Otherwise, such addresses are accessed with their lowest 2 bits regarded as 00b.

(4)低功耗功能注意事项

WFI 指令和寄存器设置过程, 请参见第 10 节低功耗模式 .

要在从低功耗模式返回后执行 DTC 传输而不进行 Snooze 模式转换,请再次将 DTCST。DTCST 位设置为 1。

要使用在软件待机模式下生成的请求作为对 CPU 的中断请求而不是 DTC 激活请求,请将 CPU 指定为中断请求目的地,如第 12。4。1 节中所述。检测中断,然后执行 WFI 指令。如果在 Snooze 模式下启用 DTC 操作,请勿使用 DTC 的模块停止功能。

16。11 使用说明

16.11.1 传输信息起始地址

您必须为向量表中的传输信息起始地址设置 4 的倍数。否则,访问此类地址时,其最低 2 位被视为 00b。

17. Event Link Controller (ELC)

17.1 Overview

The Event Link Controller (ELC) uses the event requests generated by various peripheral modules as source signals to connect them to different modules, allowing direct link between the modules without CPU intervention.

Table 17.1 lists the ELC specifications, and Figure 17.1 shows a block diagram.

Module-stop function	Module-stop state can be set.
TrustZone Filter	Security attribution can be set for each registers

SEG bit (Software Event Generation)

When 1 is written to the SEG bit while the WE bit is 1, a software event is generated. This bit is read as 0. Even when 1 is written to this bit, data is not stored. The WE bit must be set to 1 before writing to this bit.

A software event can trigger a linked DTC event.

WE bit (SEG Bit Write Enable)

The SEG bit can only be written to when the WE bit is 1. Clear the WI bit to 0 before writing to this bit.

[Setting condition]

- If 1 is written to this bit while the WI bit is 0, this bit becomes 1.

[Clearing condition]

- If 0 is written to this bit while the WI bit is 0, this bit becomes 0.

WI bit (ELSEGR Register Write Disable)

The ELSEGR register can only be written to when the write value to the WI bit is 0. This bit is read as 1. Before setting the WE or SEG bit, the WI bit must be set to 0.

17.3 Operation

17.3.1 Relation between Interrupt Handling and Event Linking

Event number for an event link is the same as that for the associated interrupt source. For information on generating event signals, see the explanation in the chapter for each event source module.

17.3.2 Linking Events

When an event occurs and that event is already set as a trigger in the Event Link Setting Register (ELSRn), the associated module is activated. The operation of the module must be set up in advance. Table 17.4 lists the operations of modules when an event occurs.

Table 17.4 Module operations when event occurs

Module	Operations When Event is Input
GPT	• Start counting • Stop counting • Clear counting • Up counting • Down counting • Input capture
DAC12	Start D/A conversion
I/O Ports	• Change pin output based on the EORR (reset) or EOSR (set) • Latch pin state to EIDR • The following ports can be used for the ELC: Port 1 Port 2 Port 3 Port 4
I3C	Start operation
ADC12	Start A/D conversion
DTC	Start DTC data transfer

17.3.3 Example of Procedure for Linking Events

To link events:

1. Set the operation of the module for which an event is to be linked.
2. Set the appropriate ELSRn.ELS[8:0] bits for the module to be linked.
3. Set the ELCR.ELCON bit to 1 to enable linkage of all events.
4. Configure the module from which an event is output and activate the module. The link between the two modules is now active.
5. To stop event linkage of modules individually, set 0 to the ELSRn.ELS[8:0] bit associated with the modules. To stop linkage of all the events, set the ELCR.ELCON bit to 0.

位	符号	功能	R/W
7:0	ELSR[23:16]	事件链接设置寄存器 n 个安全属性（n = 16 至 23） 目标寄存器:ELSRn（n = 16 至 23） 0:安全 1:非安全	R/W

注: 只有安全访问才能写入此寄存器。允许安全访问和非安全读取访问,但不允许非安全写入访问,并且不会生成 TrustZone 访问错误。

注: 该寄存器受 PRCR 寄存器写保护。

该寄存器指定寄存器 ELSRn 的安全属性（n = 16 至 23）

17。3 操作

17。3。1 中断处理与事件链接的关系

事件链接的事件编号与关联的中断源的事件编号相同。有关生成事件信号的信息,请参阅各事件源模块章节中的说明。

17。3。2 链接事件

当事件发生并且该事件已在事件链接设置寄存器（ELSRn）中设置为触发器时,关联模块将被激活。模块的操作必须提前设置。表 17。4 列出了事件发生时模块的操作。

表 17。4 事件发生时的模块操作

模块	事件输入时的操作
GPT	• 开始计数 • 停止计数 • 清零计数 • 计数起来 • 倒计时 • 输入捕获
DAC12	开始 D/A 转换
I/O 端口	• EORR（重置）或EOSR（设置）的基础上更改引脚输出 • EIDR 的锁销状态 • ELC可以使用以下端口: 1号港 2号港 3号口 4号口
I3C	开始操作
ADC12	开始 A/D 转换
DTC	开始 DTC 数据传输

17。3。3 链接事件的程序示例

链接事件:

1。设置要链接事件的模块的操作。

2锛姣涓。为要链接的模块设置适当的 ELSRn。ELS[8:0] 位。

3锛 娴 。将 ELCR。ELCON 位设置为 1 以启用所有事件的链接。

4锛姣涓。配置输出事件的模块并激活该模块。两个模块之间的链接现已处于活动状态。

5锛姣涓。要单独停止模块的事件链接,请将 0 设置为与模块关联的 ELSRn。ELS[8:0] 位。要停止所有事件的链接,请将 ELCR。ELCON 位设置为 0。

If event link output from the LVD is to be used, set the ELC after setting the LVD. To disable the LVD, do so after setting 0x00 to the associated ELSRn register.

17.4 Usage Notes

17.4.1 Linking DMAC/DTC Transfer End Signals as Events

When linking the DMAC/DTC transfer end signals as events, do not set the same peripheral module as the DMAC/DTC transfer destination and event link destination. If set, the peripheral module might be started before DMAC/DTC transfer to the peripheral module is complete.

17.4.2 Setting Clocks

To link events, you must enable the ELC and the related modules. The modules cannot operate if the related modules are in the module-stop state or in low power mode in which the module is stopped (Software Standby mode or Deep Software Standby mode).

Some modules can perform in Snooze mode. For more information, see Table 17.3 and section 10, Low Power Modes.

17.4.3 Module-Stop Function Setting

The Module Stop Control Register C (MSTPCRC) can enable or disable ELC operation. The ELC is initially stopped after reset. Releasing the module-stop state enables access to the registers. The ELCON bit must be set to 0 before disabling ELC operation using the Module Stop Control Register. For more information, see Table 17.3 and section 10, Low Power Modes.

17.4.4 ELC Delay Time

In Figure 17.2, module A accesses module B through the ELC. There is a delay time in the ELC between module A and module B. Table 17.5 shows the ELC delay time.

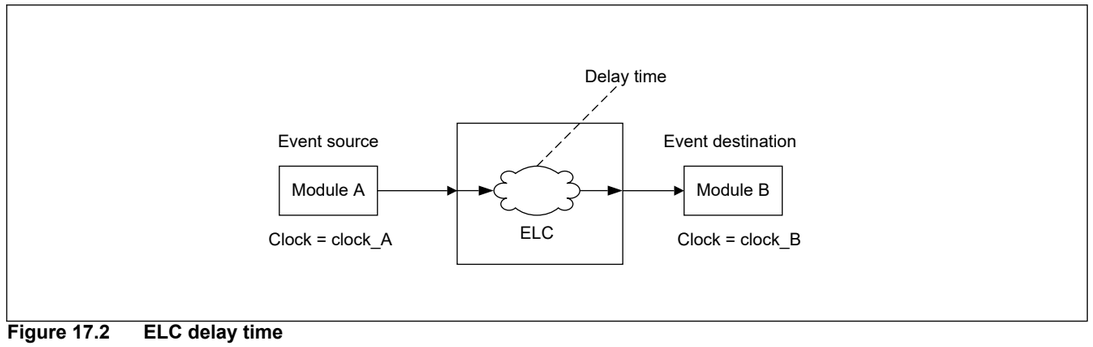

Figure 17.2 ELC delay time

Table 17.5 ELC delay time

Clock domain	Clock frequency	ELC delay time
clock_A = clock_B	clock_A = clock_B	0 cycle
clock_A ≠ clock_B	clock_A = clock_B	1 cycle to 2 cycles
	clock_A > clock_B	1 cycle to 2 cycles of clock_B
	clock_A < clock_B	1 cycle to 2 cycles of clock_A

如果要使用 LVD 输出的事件链路,请在设置 LVD 后设置 ELC。要禁用 LVD,请在设置后禁用 0x00 到关联的 ELSRn 寄存器。

17。4 使用说明

17。4。1 将 DMAC/DTC 传输端信号链接为事件

DMAC/DTC传输端信号作为事件链接时,不要设置与DMAC/DTC传输目的地和事件链路目的地相同的外围模块。如果设置,则可以在 DMAC/DTC 传输到外围模块完成之前启动外围模块。

17。4。2 设置时钟

要链接事件,您必须启用 ELC 和相关模块。如果相关模块处于模块停止状态或处于模块停止的低功耗模式（软件待机模式或深度软件待机模式）,则模块无法运行。

某些模块可以在贪睡模式下执行。欲了解更多信息,请参阅表 17。3 和第 10 节"低功耗模式"。

17。4。3 模块停止功能设置

模块停止控制寄存器 C（MSTPCRC）可以启用或禁用 ELC 操作。ELC在复位后最初停止。释放模块停止状态可以访问寄存器。ELCON 位必须设置为 0,然后才能使用模块停止控制寄存器禁用 ELC 操作。欲了解更多信息,请参阅表 17。3 和第 10 节"低功耗模式 ."

17。4。4 ELC 延迟时间

在图17。2中,模块A通过ELC访问模块B。ELC 中模块 A 和模块 B 之间存在延迟时间, 表 17。5 显示了 ELC 延迟时间。

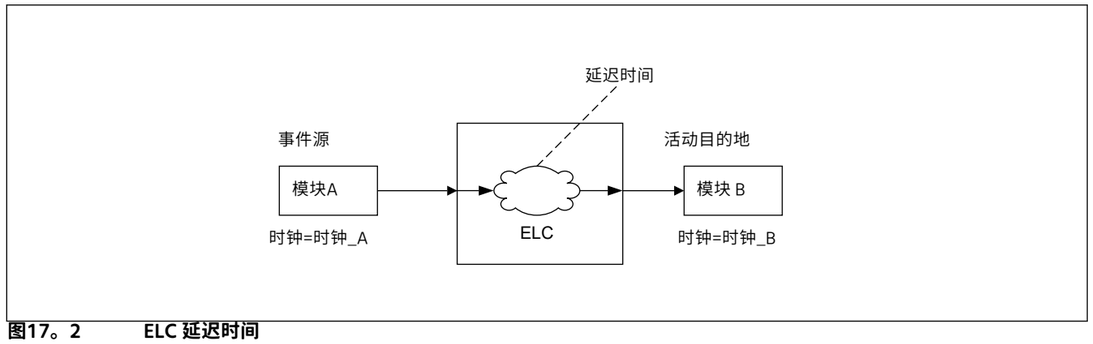

图17。2 ELC 延迟时间

表 17。5 ELC 延迟时间

时钟域	时钟频率	ELC 延迟时间
时钟_A = 时钟_B	时钟_A = 时钟_B	0周期

	时钟_A > 时钟_B	1个周期到2个周期的时钟_B
	时钟_A <时钟_B	1个周期到2个周期的时钟_A

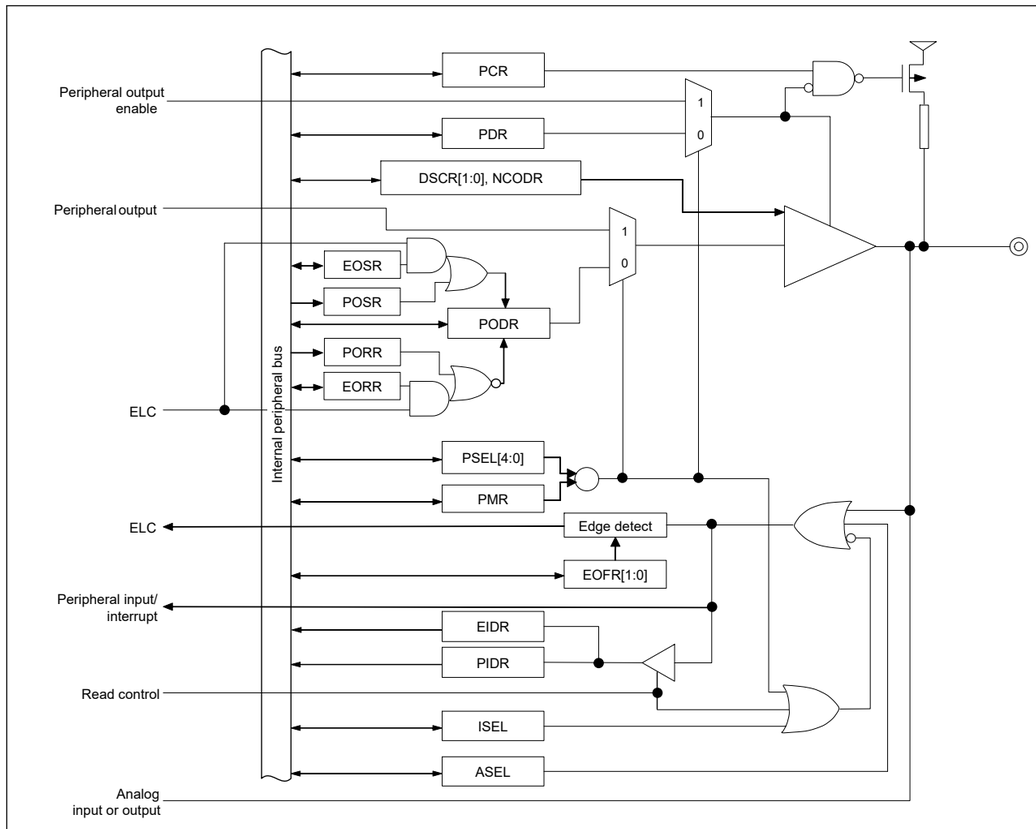
18. I/O Ports

18.1 Overview

The I/O port pins operate as general I/O port pins, I/O pins for peripheral modules, interrupt input pins, analog I/O, port group function for the ELC.

All pins operate as input pins immediately after a reset, and pin functions are switched by register settings. The I/O ports and peripheral modules for each pin are specified in the associated registers.

Figure 18.1 shows a connection diagram for the I/O port registers. The configuration of the I/O ports differs for different packages. Table 18.1 lists the I/O port specifications by package, and Table 18.2 lists the port functions.



Note: This figure shows a basic port configuration. The configuration differs depending on the ports.

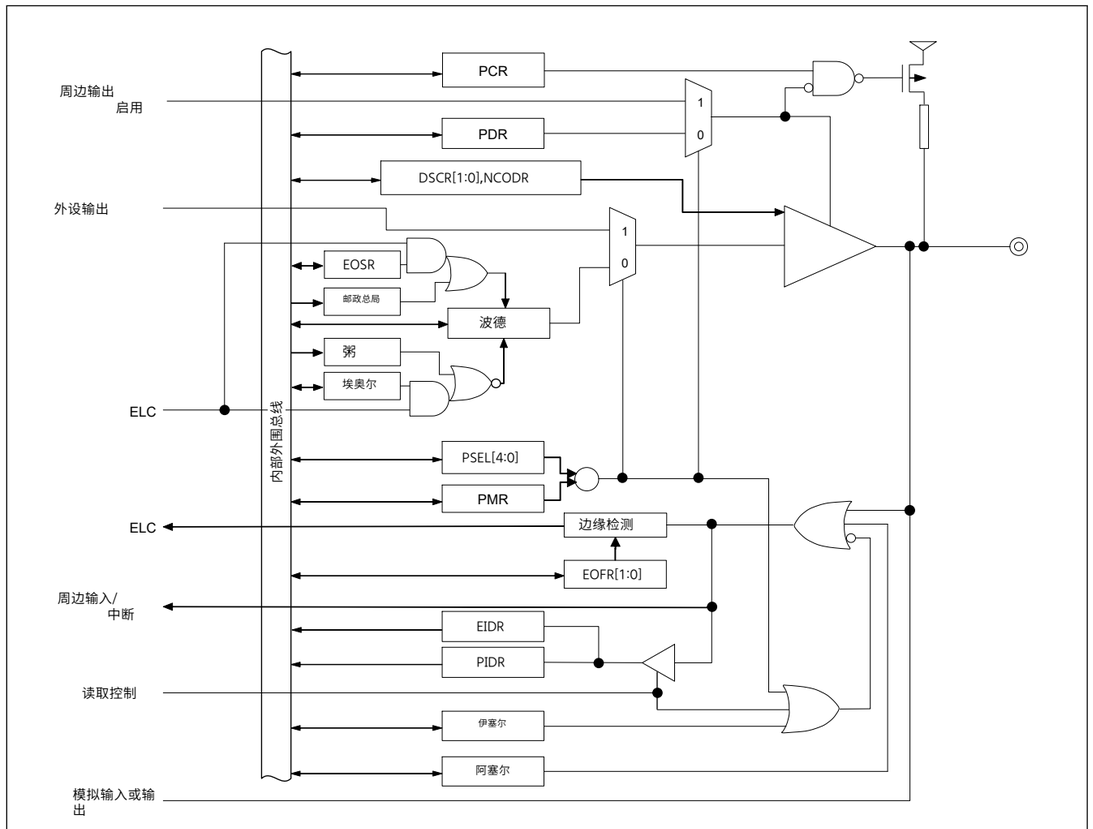
18。1 概述

I/O 端口引脚作为通用 I/O 端口引脚、外设模块的 I/O 引脚、中断输入引脚、模拟 I/O、ELC 端口组功能运行。

所有引脚在重置后立即作为输入引脚运行,并且引脚功能通过寄存器设置进行切换。每个引脚的 I/O 端口和外围模块在相关寄存器中指定。

图 18。1 显示了 I/O 端口寄存器的连接图。I/O 端口的配置因不同的封装而异。表 18。1 按封装列出了 I/O 端口规范,表 18。2 列出了端口功能。



注: 该图显示了基本的端口配置。配置因端口而异。

The Port Control Register 1 (PCNTR1/PODR/PDR) is a 32-bit or 16-bit read/write register that controls port direction and port output data. The PCNTR1 specifies the port direction and output data, and is accessed in 32-bit units. The PDRn (bits [15:0] in PCNTR1) and PODRn (bits [31:16] in PCNTR1) respectively, are accessed in 16-bit units.

PDRn bits (Pmn Direction)

The PDRn bits select the input or output direction for individual pins on the associated port when the pins are configured as general I/O pins. Each pin on port m is associated with a PORTm.PCNTR1.PDRn bit. The I/O direction can be specified in 1-bit unit. Bits associated with non-existent pins are reserved. Reserved bits are read as 0. The write value should be 0. In the case of input only ports, PDRn bits are reserved. See Table 18.2. The PDRn bit in the PORTm.PCNTR1 register serves the same function as the PDR bit in the PFS.PmnPFS register.

PODRn bits (Pmn Output Data)

The PODRn bits hold data to be output from the general I/O pins. Bits of non-existent port m are reserved. Reserved bits are read as 0. The write value should be 0. In the case of input only ports, PODRn bits are reserved. See Table 18.2. The PODRn bit in the PORTm.PCNTR1 register serves the same function as the PODR bit in the PFS.PmnPFS register.

端口控制寄存器 1（PCNTR1/PODR/PDR）是一个 32 位或 16 位读/写寄存器,用于控制端口方向和端口输出数据。PCNTR1 指定端口方向和输出数据,并以 32 位单元访问。PDRn（PCNTR1 中的位 [15:0])和 PODRn（PCNTR1 中的位 [31:16])分别以 16 位单元访问。

PDRn 位（Pmn 方向）

PDRn 位在引脚配置为一般 I/O 引脚时,为关联端口上的各个引脚选择输入或输出方向。端口 m 上的每个引脚都与 PORTM。PCNTR1 相关联。PDRn 位。I/O 方向可以用 1 位单元来指定。与不存在的引脚相关联的位被保留。保留位读作 0。写入值应为 0。在仅输入端口的情况下,保留 PDRn 位。参见表18。2。PORTm。PCNTR1寄存器中的PDRn位与PFS。PmnPFS寄存器中的PDR位具有相同的功能。

PODRn 位（Pmn 输出数据）

PODRn 位保存要从一般 I/O 引脚输出的数据。保留不存在的端口 m 的位。保留位读作 0。写入值应为 0。在仅输入端口的情况下,保留 PODRn 位。参见表18。2。PORTm。PCNTR1寄存器中的PODRn位与PFS。PmnPFS寄存器中的PODR位具有相同的功能。

Note: If the security attribution is configured as Secure:
- Secure read access is allowed
- Non-secure read value is 0 and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure read access are allowed.

Note: m = 0 to 5, 8, n = 00 to 15
Note 1. x = 1, 2, 3 or 4 for EIDR only
Note 2. Supported by ports 1, 2, 3 or 4.

The Port Control Register 2 (PCNTR2/EIDR/PIDR) allows read access to the Pmn state and the port event input data using 32-bit or 16-bit access.

The PCNTR2 represents the Pmn state and the port event input data, and is accessed in 32-bit units.

The PIDRn (bits [15:0] in PCNTR2) and EIDRn (bits [31:16] in PCNTR2) respectively, are accessed in 16-bit units. Bits associated with non-existent pins are reserved. Reserved bits are read as undefined.

PIDRn bits (Pmn State)

The PIDRn bits reflect the individual pin states of the port, regardless of the values set in PmnPFS.PMR and PORTm.PCNTR1.PDRn. The PIDRn bit in the PORTm.PCNTR2 register serves the same function as the PIDR bit in the PFS.PmnPFS register.

A pin state cannot be reflected in PIDRn when one of the following functions is enabled:

- Analog function (ASEL = 1)

EIDRn bits (Port Event Input Data)

The EIDRn bits latch a pin state when an ELC_PORTx signal occurs. Pin states can only be input to EIDRn when PmnPFS.PMR and PORTm.PCNTR1.PDRn are 0. When the PmnPFS.ASEL bit is set to 1, the associated pin state is not reflected in EIDRn.

18.2.3 PCNTR3/PORR/POSR : Port Control Register 3

Base address: PORTm = 0x4008_0000 + 0x0020 × m (m = 0 to 5, 8)

Offset address: 0x008 (PCNTR3/PORR)
0x00A (POSR)

31:16	PORR15 to PORR00	Pmn Output Reset 0: No effect on output 1: Low output	W

Note: If the security attribution is configured as Secure:
- Secure write access is allowed
- Non-secure write access is ignored and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure write access are allowed.

Note: m = 0 to 5, 8, n = 00 to 15

The Port Control Register 3 (PCNTR3/PORR/POSR) is a 32-bit or 16-bit write register that controls the setting or resetting of the port output data.

The PCNTR3 controls the setting or resetting of the port output data, and is accessed in 32-bit units.

注意:如果安全属性配置为 Secure:
- 允许安全读取访问
- 非安全读取值为 0 且未生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全读取访问。

注:m = 0 至 5、8、n = 00 至 15 注 1。x = 1、2、3 或 4 仅适用于 EIDR 注 2。1、2、3或4端口的支持。

端口控制寄存器 2（PCNTR2/EIDR/PIDR）允许使用 32 位或 16 位访问读取对 Pmn 状态和端口事件输入数据的访问。

PCNTR2 表示 Pmn 状态和端口事件输入数据,并以 32 位单元访问。

PIDRn（PCNTR2 中的位 [15:0])和 EIDRn（PCNTR2 中的位 [31:16])分别以 16 位单元访问。与不存在的引脚相关联的位被保留。保留位读作未定义。

PIDRn 位（Pmn 状态）

无论 PmnPFS。PMR 和 PORTM。PCNTR1 中设置的值如何,PIDRn 位都会反映端口的各个引脚状态。PDRn。PORTm。PCNTR2寄存器中的PIDRn位与PFS。PmnPFS寄存器中的PIDR位具有相同的功能。

PIDRn 中启用以下函数之一时, 无法反映一个引脚状态:

- 模拟函数（ASEL = 1）

EIDRn 位（端口事件输入数据）

EIDRn 位在发生 ELC_PORTx 信号时锁存引脚状态。Pin 状态只能在 PmnPFS。PMR 和 PORTM。PCNTR1 时输入到 EIDRn。PDRn 为 0。当PmnPFS。ASEL位设置为1时,关联的引脚状态不会反映在EIDRn中。

18.2.3 PCNTR3/PORR/POSR:端口控制寄存器 3

基本地址: PORTM = 0x4008_0000 + 0x0020 × m（m = 0 to 5, 8)

注: 如果安全属性配置为安全:
- 允许安全写访问
- 非安全写访问被忽略,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全写入访问。

注: m = 0 to 5, 8, n = 00 to 15

端口控制寄存器3（PCNTR3/PORR/POSR）是控制端口输出数据的设置或重置的32位或16位写入寄存器。

PCNTR3控制端口输出数据的设置或重置,并以32位单元访问。

The POSRn (bits [15:0] in PCNTR3) and the PORRn (bits [31:16] in PCNTR3) respectively, are accessed in 16-bit units.

POSRn bits (Pmn Output Set)

POSR changes PODR when set by a software write. For example, for P100, when PORT1.PCNTR3.POSR00 = 1, PORT1.PCNTR1.PODR00 outputs 1. Bits associated with non-existent pins are reserved. The write value should always be 0. In the case of input only ports, POSRn bits are reserved. See Table 18.2.

PORRn bits (Pmn Output Reset)

PORR changes PODR when reset by a software write. For example, for P100, when PORT1.PCNTR3.PORR00 = 1, PORT1.PCNTR1.PODR00 outputs 0. Bits associated with non-existent pins are reserved. The write value should always be 0. In the case of input only ports, PORRn bits are reserved. See Table 18.2.

Note: When EORRn or EOSRn is set, writing is prohibited to PODRn, PORRn, and POSRn.
Note: PORRn and POSRn should not be set at the same time.

The Port Control Register 4 (PCNTR4/EORR/EOSR) is a 32-bit or 16-bit read/write register that controls the setting or resetting of the port output data by an event input from the ELC.

The PCNTR4 controls the setting or resetting of the port output data by an event input from the ELC, and is accessed in 32-bit units.

The EOSRn (bits [15:0] in PCNTR4) and EORRn (bits [31:16] in PCNTR4) respectively, are accessed in 16-bit units.

EOSRn bits (Pmn Event Output Set)

EOSR changes PODR when set because an ELC_PORTx signal occurs. For example, for P100 if PORT1.PCNTR4.EOSR00 is set to 1 when the ELC_PORTx occurs, PORT1.PCNTR1.PODR00 outputs 1. Bits associated with non-existent pins are reserved. The write value should always be 0. For input only ports, EOSRn bits are reserved. See Table 18.2.

POSRn（PCNTR3 中的位 [15:0])和 PORRn（PCNTR3 中的位 [31:16])分别以 16 位单元访问。

POSRn 位（Pmn 输出集）

POSR 在软件写入设置时会更改 PODR。例如,对于 P100,当 PORT1。PCNTR3。POSR00 = 1,端口 1。PCNTR1。PODR00 输出 1。与不存在的引脚相关联的位被保留。写入值应始终为 0。在仅输入端口的情况下,保留 POSRn 位。参见表 18。2 .

PORRn 位（Pmn 输出重置）

当软件写入重置时,PORR 会更改 PODR。例如,对于 P100,当 PORT1。PCNTR3。PORR00 = 1,端口 1。PCNTR1。PODR00 输出 0。与不存在的引脚相关联的位被保留。写入值应始终为 0。在仅输入端口的情况下,保留 PORRn 位。参见表 18。2 .

注:设置 EORRn 或 EOSRn 时,禁止写入 PODRn、PORRn 和 POSRn。
注:PORRn 和 POSRn 不应同时设置。

端口控制寄存器 4（PCNTR4/EORR/EOSR）是一个 32 位或 16 位读/写寄存器,通过 ELC 输入的事件控制端口输出数据的设置或重置。

PCNTR4通过来自ELC的事件输入来控制端口输出数据的设置或重置,并且以32bit为单位进行访问。

EOSRn（PCNTR4 中的位 [15:0])和 EORRn（PCNTR4 中的位 [31:16])分别以 16 位单元访问。

EOSRn 位（Pmn 事件输出集）

EOSR 在设置时会更改 PODR,因为会发生 ELC_PORTx 信号。例如,对于 P100 if PORT1。PCNTR4。EOSR00 在 ELC_PORTx 发生时设置为 1,即 PORT1。PCNTR1。PODR00 输出 1。与不存在的引脚相关联的位被保留。写入值应始终为 0。对于仅输入端口,保留 EOSRn 位。参见表 18。2 .

EORRn bits (Pmn Event Output Reset)

EORR changes PODR when reset because an ELC_PORTx signal occurs. For example, for P100 if PORT1.PCNTR4.EORR00 = 1 when the ELC_PORTx occurs, PORT1.PCNTR1.PODR00 outputs 0. Bits associated with non-existent pins are reserved. The write value should always be 0. For input only ports, EORRn bits are reserved. See Table 18.2.

Note: When EORRn or EOSRn is set, writing is prohibited to PODRn, PORRn, and POSRn.

Note: EORRn and EOSRn should not be set at the same time.

Port mn Pin Function Select Register (PmnPFS/PmnPFS_HA/PmnPFS_BY) is a 32-bit, 16-bit, or 8-bit read/write control register that selects the port mn pin function, and is accessed in 32-bit units. PmnPFS_HA (PmnPFS [15:0] bits) is accessed in 16-bit units. PmnPFS_BY (PmnPFS[7:0] bits) is accessed in 8-bit units.

The available Port mn pin depends on the product. For details, see Table 18.1

PODR bit (Port Output Data), PIDR bit (Port State), PDR bit (Port Direction)

The PDR, PIDR, and PODR bits serve the same function as the PCNTR. When these bits are read, the PCNTR value is read.

PCR bit (Pull-up Control)

The PCR bit enables or disables an input pull-up resistor on the individual port pins. When a pin is in the input state with the associated bit in PmnPFS.PCR set to 1, the pull-up resistor connected to the pin is enabled. When a pin is set as a general port output pin, or a peripheral function output pin, the pull-up resistor for the pin is disabled regardless of the PCR setting. The pull-up resistor is also disabled in the reset state. Bits associated with non-existent pins are reserved. Reserved bits are read as 0. The write value should be 0.

NCODR bit (N-Channel Open-Drain Control)

The NCODR bit specifies the output type for the port pins. Bits associated with non-existent pins are reserved. Reserved bits are read as 0. The write value should be 0.

DSCR[1:0] bits (Port Drive Capability)

The DSCR[1:0] bits switches the drive capacity of the port. If the drive capacity of a pin is fixed, the associated bit is a read/write bit, but the drive capacity cannot be changed. Bits associated with non-existent pins are reserved. Reserved bits are read as 0. The write value should be 0.

端口 mn 引脚函数选择寄存器（PmnPFS/PmnPFS_HA/PmnPFS_BY）是一个 32 位、16 位或 8 位读/写控制寄存器,选择端口 mn 引脚函数,并以 32 位单元访问。PmnPFS_HA（PmnPFS [15:0] 位）以 16 位单元访问。PmnPFS_BY（PmnPFS[7:0] 位）以 8 位单位访问。

可用的端口 mn 引脚取决于产品。详情见表18。1

PODR 位（端口输出数据）、PIDR 位（端口状态）、PDR 位（端口方向）

PDR、PIDR 和 PODR 位具有与 PCNTR 相同的功能。当读取这些位时,读取 PCNTR 值。

PCR 位（上拉控制）

PCR 位启用或禁用各个端口引脚上的输入上拉电阻。PmnPFS。PCR 中关联位设置为 1 的引脚处于输入状态时, 与引脚相连的上拉电阻被启用。当引脚设置为通用端口输出引脚或外围功能输出引脚时,无论 PCR 设置如何,引脚的上拉电阻都会被禁用。上拉电阻在复位状态下也被禁用。与不存在的引脚相关联的位被保留。保留位读作 0。写入值应为 0。

NCODR 位（N 通道开漏控制）

NCODR 位指定端口引脚的输出类型。与不存在的引脚相关联的位被保留。保留位读作 0。写入值应为 0。

DSCR[1:0] 位（端口驱动功能）

DSCR[1:0]位切换端口的驱动容量。Pin的驱动容量固定,则关联位为读/写位,但驱动容量不能改变。与不存在的引脚相关联的位被保留。保留位读作 0。写入值应为 0。

EOFR[1:0] bits (Event on Falling/Event on Rising)

The EOFR[1:0] bits select the edge detection method for the port group input signal. These bits support rising, falling, or both edge detections. When the EOFR[1:0] bits are set to 01b, 10b, or 11b, the input enable of the I/O cell is asserted. Following that, the event pulse is input from the external pin, and the GPIO outputs the event pulse to the ELC. Bits associated with non-existent pins are reserved. Reserved bits are read as 0. The write value should be 0.

ISEL bit (IRQ Input Enable)

The ISEL bit specifies IRQ input pins. This setting can be used in combination with the peripheral functions, although an IRQn (external pin interrupt) of the same number must only be enabled for one pin. The ISEL bit for an unspecified IRQn is reserved.

ASEL bit (Analog Input Enable)

The ASEL bit specifies analog pins. When a pin is set as an analog pin by this bit:

1. Specify it as a general I/O port in the Port Mode Control bit (PmnPFS.PMR).
2. Disable the pull-up resistor in the Pull-up Control bit (PmnPFS.PCR).
3. Specify the input in the Port Direction bit (PmnPFS.PDR). The pin state cannot be read at this point. The PmnPFS register is protected by the Write-Protect Register (PWPR). Release write-protect before modifying the register.

The ASEL bit for an unspecified analog I/O pin is reserved.

PMR bit (Port Mode Control)

The PMR bit specifies the port pin function. Bits associated with non-existent pins are reserved. The write value should be 0.

PSEL[4:0] bits (Peripheral Select)

The PSEL[4:0] bits assign the peripheral function.

EOFR[1:0] 位（坠落事件/上升事件）

EOFR[1:0]位选择端口组输入信号的边缘检测方法。这些位支持上升、下降或两者边缘检测。EOFR[1:0]位设置为01b、10b或11b时,断言I/O小区的输入使能。接下来,事件脉冲从外部引脚输入,GPIO将事件脉冲输出到ELC。与不存在的引脚相关联的位被保留。保留位读作 0。写入值应为 0。

ISEL 位（IRQ 输入启用）

ISEL 位指定 IRQ 输入引脚。此设置可以与外围功能结合使用,尽管必须仅对一个引脚启用相同数量的 IRQn（外部引脚中断）。未指定 IRQn 的 ISEL 位被保留。

ASEL 位（模拟输入启用）

3锛　　娴　　。指定端口方向位（PmnPFS。PDR）中的输入。此时无法读取引脚状态。PmnPFS 寄存器受写保护寄存器（PWPR）保护。修改寄存器之前发布写保护。

保留未指定模拟 I/O 引脚的 ASEL 位。

PMR 位（端口模式控制）

PMR 位指定端口引脚函数。与不存在的引脚相关联的位被保留。写入值应该是 0.

PSEL[4:0] 位（外围选择）

18.3 Operation

18.3.1 General I/O Ports

All pins except P000 to P003, P108, and P300 operate as general I/O ports after reset. General I/O ports are organized as 16 bits per port and can be accessed by port with the Port Control Registers (PCNTRn, where n = 1 to 4), or by individual pins with the Port mn Pin Function Select register. For details on these registers, see section 18.2. Register Descriptions.

Each port has the following bits:

- Port Security Attribution register (PmSAR)(m = 0 to 5, 8), which indicates the security attribution.
- Port Direction bit (PDRn), which selects input or output direction
- Port Output Data bit (PODRn), which holds data for output
- Port Input Data bit (PIDRn), which indicates the pin states
- Event Input Data bit (EIDRn), which indicates the pin state when an ELC_PORTn (n = 1, 2, 3 or 4) signal occurs
- Port Output Set bit (POSRn), which indicates the output value when a software write occurs
- Port Output Reset bit (PORRn), which indicates the output value when a software write occurs
- Event Output Set bit (EOSRn), which indicates the output value when an ELC_PORTn (n = 1, 2, 3 or 4) signal occurs
- Event Output Reset bit (EORRn), which indicates the output value when an ELC_PORTn (n = 1, 2, 3 or 4) signal occurs.

18.3.2 Port Function Select

The following port functions are available for configuring each pin:

- Security function: Security attribution for each pins
- I/O configuration: CMOS output or NMOS open-drain output, pull-up control, and drive capacity
- General I/O port: Port direction, output data setting, and read input data
- Alternate function: Configured function mapping to the pin.

18。3 操作

18。3。1 一般 I/O 端口

除 P000 至 P003、P108 和 P300 之外的所有引脚在重置后均作为通用 I/O 端口运行。一般 I/O 端口按每个端口 16 位组织,可以通过具有端口控制寄存器（PCNTRn,其中 n = 1 至 4)的端口或具有端口 mn 引脚功能的单独引脚访问选择寄存器。有关这些寄存器的详细信息,请参阅第 18。2 节。注册说明 .

每个端口都有以下位:

- 端口安全归属寄存器（PmSAR） （m = 0 到 5, 8),它指示安全归属。
- 端口方向位（PDRn）,它选择输入或输出方向
- 端口输出数据位（PODRn）,它保存用于输出的数据
- 端口输入数据位（PIDRn）,它指示引脚状态
- 事件输入数据位（EIDRn）,它指示 ELC_PORTn（n = 1、2、3 或 4)信号发生时的引脚状态
- 端口输出集位（POSRn）,它指示软件写入发生时的输出值
- 端口输出复位（PORRn）,它指示软件写入发生时的输出值
- 事件输出集位（EOSRn）,它指示发生 ELC_PORTn（n = 1、2、3 或 4)信号时的输出值
- 事件输出复位（EORRn）,它指示发生 ELC_PORTn（n = 1、2、3 或 4)信号时的输出值。

18。3。2 端口功能选择

以下端口功能可用于配置每个引脚:

- 安全功能:每个引脚的安全归属
- I/O 配置:CMOS 输出或 NMOS 开漏输出、上拉控制和驱动容量
- 通用I/O端口:端口方向,输出数据设置,读取输入数据
- 替代函数:配置函数映射到引脚。

Each pin is associated with a Port mn Pin Function Select register (PmnPFS), which includes the associated PODR, PIDR, and PDR bits. In addition, the PmnPFS register includes the following:

- PCR: Pull-up resistor control bit that turns the input pull-up MOS on or off
- NCODR: N-channel open-drain control bit that selects the output type for each pin
- DSCR[1:0]: Drive capacity control bit that selects the drive capacity
- EOFR[1:0]: For selecting the edge of the event that input from the port group
- ISEL: IRQ input enable bit to specify an IRQ input pin
- ASEL: Analog input enable bit to specify an analog pin
- PMR: Port mode bit to specify the pin function of each port
- PSEL[4:0]: Port function select bits to select the associated peripheral function.

These configurations can be made by a single-register access to the Port mn Pin Function Select register. For details, see section 18.2.5. PmnPFS/PmnPFS_HA/PmnPFS_BY : Port mn Pin Function Select Register (m = 0 to 5, 8, n = 00 to 15).

18.3.3 Port Group Function for ELC

In the MCU, Port 1 to Port 4 are assigned for the ELC port group function.

18.3.3.1 Behavior When ELC_PORTn (n = 1, 2, 3 or 4) is Input from ELC

The MCU supports the two functions described in this section when an ELC_PORTn (n = 1, 2, 3 or 4) signal comes from the ELC.

(1) Input to EIDR

For the GPI function (PDR = 0 and PMR = 0 in the PmnPFS register), when an ELC_PORTn (n = 1, 2, 3 or 4) signal comes from the ELC, the input enable of the I/O cell is asserted, and data from the external pins is read into the EIDR bit. See Figure 18.2

For the GPO function (PDR = 1) or the peripheral mode (PMR = 1), 0 is input into the EIDR bit from the external pins.

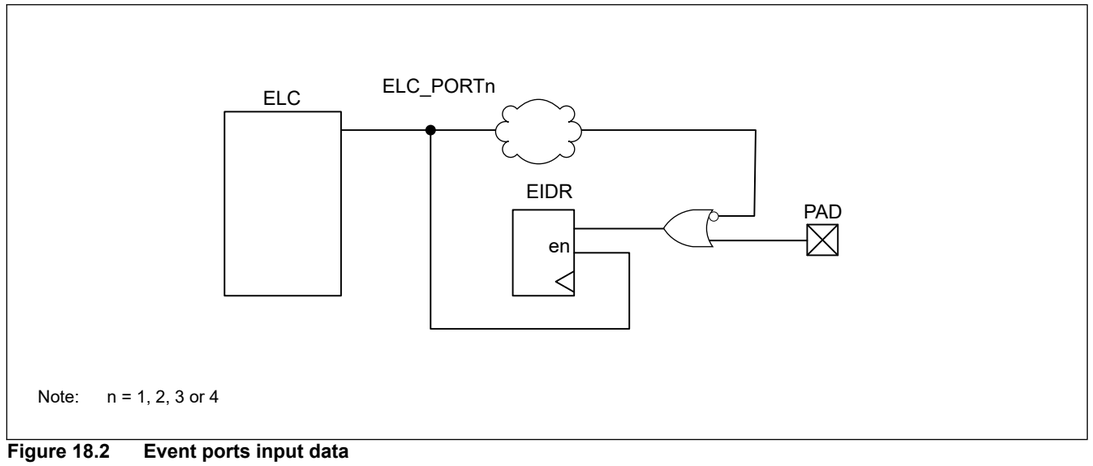

Figure 18.2 Event ports input data

(2) Output from PODR by EOSR and EORR

When an ELC_PORTn (n = 1, 2, 3 or 4) signal occurs, the data is output from the PODR to the external pin based on the settings in the EOSR and EORR registers.

- If EOSR is set to 1, when an ELC_PORTn (n = 1, 2, 3 or 4) signal occurs, the PODR register outputs 1 to the external pin. Otherwise, when EOSR = 0, the PODR value is retained.

每个引脚都与端口 mn 引脚函数选择寄存器（PmnPFS）关联,其中包括关联的 PODR、PIDR 和 PDR 位。此外,PmnPFS 寄存器还包括以下内容:

- PCR:上拉电阻控制位,打开或关闭输入上拉 MOS
- NCODR:为每个引脚选择输出类型的 N 通道开漏控制位
- DSCR[1:0]:选择驱动容量的驱动容量控制位
- EOFR[1:0]:用于选择从端口组输入的事件的边缘
- ISEL:IRQ 输入使能位能够指定 IRQ 输入引脚
- ASEL:模拟输入使能位能够指定模拟引脚
- PMR:端口模式位指定每个端口的引脚函数
- PSEL[4:0]:端口函数选择位来选择关联的外围函数。

这些配置可以通过对端口 mn 引脚函数选择寄存器的单寄存器访问来进行。详情请参见第 18。2。5 节。PmnPFS/PmnPFS_HA/PmnPFS_BY:端口 mn 引脚函数选择寄存器（m = 0 到 5、8、n = 00 到 15）。

18。3。3 ELC 的端口组功能

MCU 中,端口 1 到端口 4 被分配用于 ELC 端口组功能。

行为 当 ELC_PORTn（n = 1、2、3 或 4)从 ELC 输入时,当 ELC_PORTn（n = 1、2、3 或 4)信号来自 ELC 时,MCU 支持本节中描述的两个功能。

(1)输入EIDR

GPI函数（PmnPFS寄存器中PDR = 0和PMR = 0),当一个ELC_PORTn（n = 1,2,3或4)信号来自ELC时,I/O小区的输入使能被断言,来自外部引脚的数据被读入EIDR位。参见图18。2

GPO函数（PDR = 1)或外围模式（PMR = 1),则从外部引脚输入到EIDR位中0。

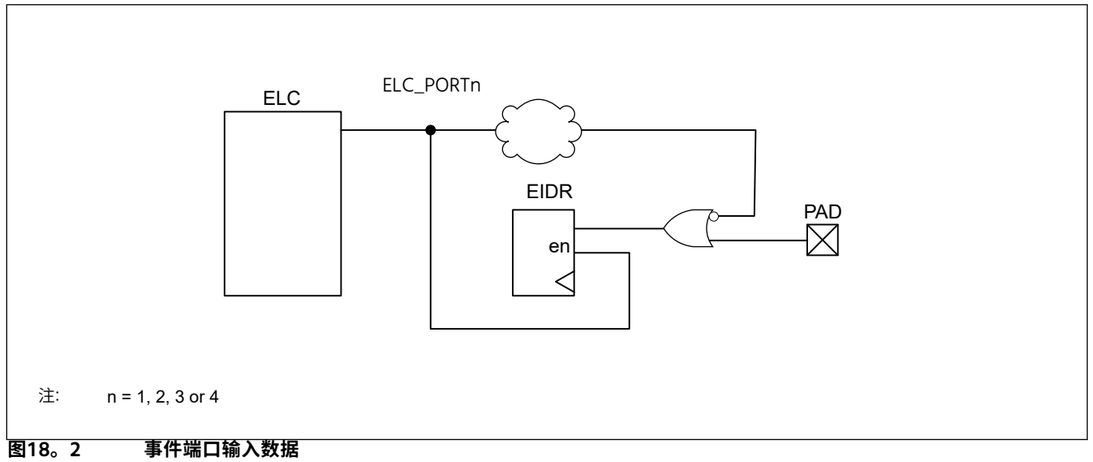

图18。2 事件端口输入数据

(2) EOSR 和 EORR 从 PODR 输出

ELC_PORTn（n = 1,2,3或4)信号时,根据EOSR和EORR寄存器中的设置,将数据从PODR输出到外部引脚。

- 如果 EOSR 设置为 1,当出现 ELC_PORTn（n = 1、2、3 或 4)信号时,PODR 寄存器将 1 输出到外部引脚。否则,当EOSR = 0时,保留PODR值。

- If EORR is set to 1, when ELC_PORTn (n = 1, 2, 3 or 4) signal occurs, the PODR register outputs 0 to the external pin. Otherwise, when EORR = 0, the PODR value is retained.

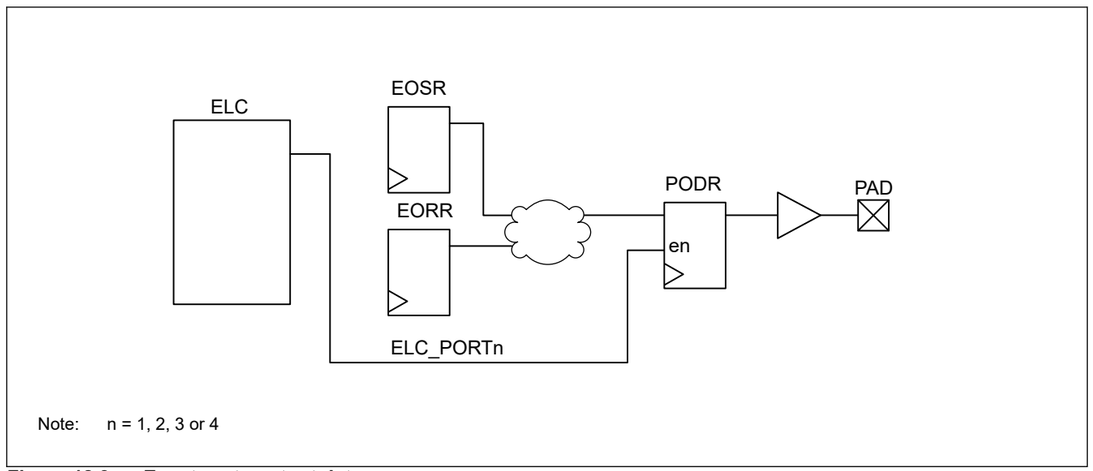

Figure 18.3 Event ports output data

18.3.3.2 Behavior When an Event Pulse is Output to ELC

To output the event pulse from the external pins to the ELC, set the EOFR[1:0] bits in the PmnPFS register. For details, see section 18.2.5. PmnPFS/PmnPFS_HA/PmnPFS_BY : Port mn Pin Function Select Register (m = 0 to 5, 8, n = 00 to 15). When the EOFR[1:0] bits are set, the input enable of the I/O cell is asserted.

Data from the external pin is the input. For example, for Port 1, when the data is input from P100 to P113, the data of those 14 pins is organized by OR logic. This data is formed into a one-shot pulse that goes to the ELC. The operation of Port n (n = 2 to 4) is also the same as Port 1. See Figure 18.4.

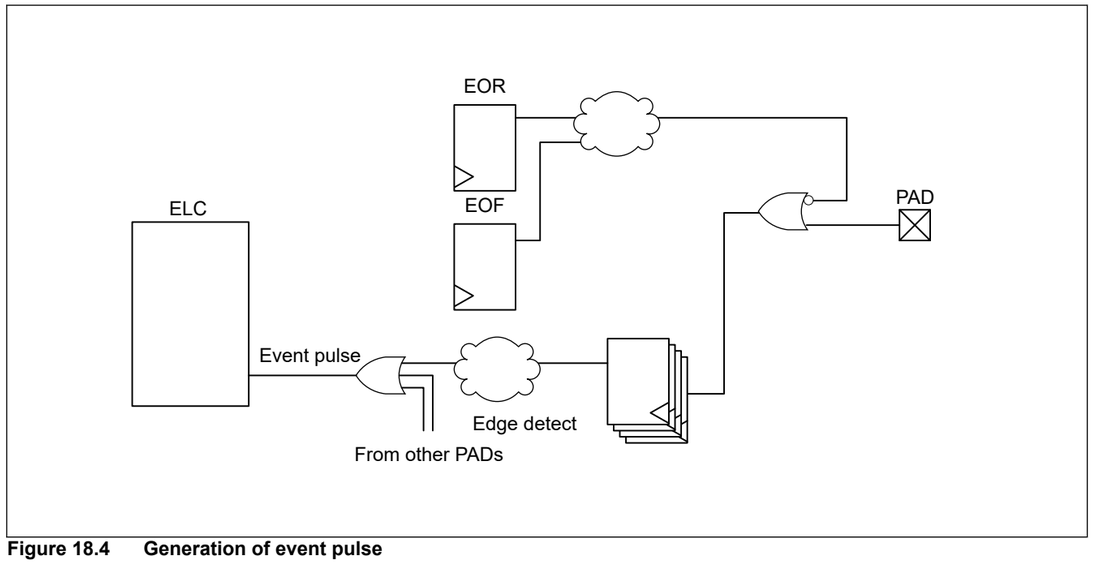

Figure 18.4 Generation of event pulse

18.4 Handling of Unused Pins

Table 18.3 shows how to handle unused pins.

● 如果 EORR 设置为 1,当 ELC_PORTn（n = 1、2、3 或 4)信号发生时,PODR 寄存器将 0 输出到外部引脚。否则,当 EORR = 0 时,保留 PODR 值。

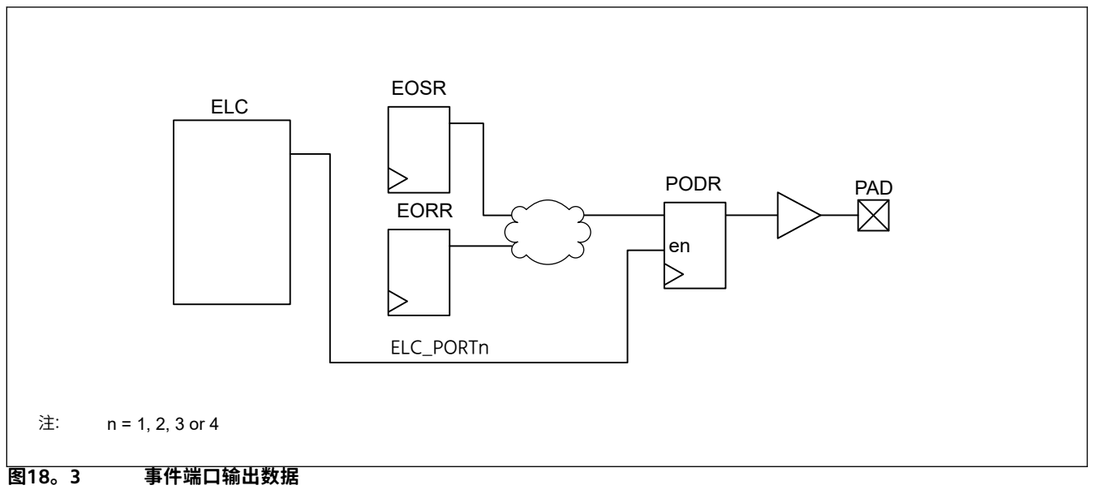

图18。3 事件端口输出数据

18.3.3.2 当事件脉冲输出到 ELC 时的行为

要将事件脉冲从外部引脚输出到 ELC,请在 PmnPFS 寄存器中设置 EOFR[1:0] 位。详情请参见第 18。2。5 节。PmnPFS/PmnPFS_HA/PmnPFS_BY:端口 mn 引脚函数选择寄存器（m = 0 到 5、8、n = 00 到 15)。EOFR[1:0]位被设置时,I/O小区的输入使能被断言。

来自外部引脚的数据是输入。例如,对于端口 1,当数据从 P100 输入到 P113 时,这 14 个引脚的数据由 OR 逻辑组织。该数据形成一个单次脉冲,进入 ELC。口（n = 2至4)的操作也和端口1相同。参见图 18。4。

Note 3. To reduce input leakage current of P003, set the P003PFS.ASEL bits to 0.

18.5 Usage Notes

18.5.1 Procedure for Specifying the Pin Functions

To specify the I/O pin functions:

1. Clear the B0WI bit in the PWPR register. This enables writing to the PFSWE bit in the PWPR register.*1
2. Set 1 to the PFSWE bit in the PWPR register. This enables writing to the PmnPFS register.*1
3. Clear the Port Mode Control bit in the PMR to 0 for the target pin to select the general I/O port.
4. Specify the I/O function for the pin through the PSEL[4:0] bits settings in the PmnPFS register.
5. Set the PMR bit to 1 as required to switch to the selected I/O function for the pin.
6. Clear the PFSWE bit in the PWPR register. This disables writing to the PmnPFS register.*1
7. Set 1 to the B0WI bit in the PWPR register. This disables writing to the PFSWE bit in the PWPR register.*1

Note 1. When the security attribution of Pmn is set to 0, set the PWPRS register to write to the PmnPFS register.

18.5.2 Procedure for Using Port Group Input

To use the port group input (port n (n = 1 to 4)):

1. Set the ELSRx.ELS[8:0] bits to all 0 to ignore unexpected pulses. For more information, see section 17, Event Link Controller (ELC).
2. Set the EOFR[1:0] bits of the PmnPFS register to specify the rising, falling, or both edge detections.
3. Execute a dummy read or wait for a short time, for example 100 ns. Ignoring of unexpected pulses depends on the initial value of the external pin.
4. Set the ELSRx.ELS[8:0] bits to enable the event signals.

18。5 使用说明

18.5.1 指定引脚函数的程序

I/O引脚函数来指定:

1。清除 PWPR 寄存器中的 B0WI 位。这使得能够写入 PWPR 寄存器中的 PFSWE 位。X数学X_1

2锛姣涓。将 1 设置为 PWPR 寄存器中的 PFSWE 位。这使得能够写入 PmnPFS 寄存器。X数学X_1

3锛 娴 。PMR 中的端口模式控制位清除到 0, 以便目标引脚选择一般的 I/O 端口。

4锛姣涓。PmnPFS 寄存器中的 PSEL[4:0] 位设置来指定引脚的 I/O 函数。

5锛姣涓。根据需要将 PMR 位设置为 1,以切换到引脚所选的 I/O 函数。

6锛 涓€涓。清除 PWPR 寄存器中的 PFSWE 位。这会禁用写入 PmnPFS 寄存器。X数学X_1

7锛 娴 。1 设置为 PWPR 寄存器中的 B0WI 位。这会禁用写入 PWPR 寄存器中的 PFSWE 位。*1 注 1。Pmn的安全属性设置为0时,将PWPRS寄存器设置为写入到PmnPFS寄存器。

18.5.2 使用端口组输入的程序

要使用端口组输入（端口 n（n = 1 至 4)):

1。将 ELSRx。ELS[8:0] 位设置为所有 0 以忽略意外的脉冲。有关详细信息,请参阅第 17 节"事件链接控制器（ELC）."

2锛姣涓。PmnPFS 寄存器的 EOFR[1:0] 位来指定上升、下降或两者的边缘检测。

3锛 娴 。执行虚拟读取或等待短时间,例如 100 ns。忽略意外脉冲取决于外部引脚的初始值。

4锛姣涓。设置 ELSRx。ELS[8:0] 位以启用事件信号。

18.5.3 Port Output Data Register (PODR) Summary

This register outputs data as follows:

1. Outputs 0 if PCNTR4.EORR is set to 1 when ELC_PORTn (n = 1, 2, 3 or 4) signal occurs.
2. Outputs 1 if PCNTR4.EOSR is set to 1 when ELC_PORTn (n = 1, 2, 3 or 4) signal occurs.
3. Outputs 0 if PCNTR3.PORR is set to 1.
4. Outputs 1 if PCNTR3.POSR is set to 1.
5. Outputs 0 or 1 because PCNTR1.PODRn is set.
6. Outputs 0 or 1 because PmnPFS.PODRn is set.

Numbers in this list correspond to the priority for writing to the PODRn. For example, if 1. and 3. from the list occur at the same time, the higher priority event 1. is executed.

18.5.4 Notes on Using Analog Functions

To use an analog function, set the Port Mode Control bit (PMR) and the Port Direction bit (PDRn) to 0 so that the pin acts as a general input port. Next, set the Analog Input Enable bit (ASEL) in the Port mn Pin Function Select Register (PmnPFS.ASEL) to 1.

18.5.5 I/O Buffer Specification

The P402 and P403 can be used as the AGT input and other peripheral functions. Table 18.4 lists the P402 and P403 specifications.

Table 18.4 P402 and P403 specifications

I/O port	AGT		Other peripheral	
	AGT input enable register	AGT	other peripheral enable register	CAC, GPT, CANFD, and interrupt
P402	RTCCR0.TCEN	AGTIO0 AGTIO1	P402PFS.PSEL and PMR	For details, see section 18.6. Peripheral Select Settings for Each Product.
P403	RTCCR1.TCEN	AGTIO0 AGTIO1	P403PFS.PSEL and PMR	

These AGT inputs are controlled by the RTCCRn register.

P402 and P403 can be used as IRQn-DS (n = 4, 14) whether AGT inputs are selected or not. See Figure 18.5.

The RTCCRn register is not initialized on reset. Therefore, when not using the AGT inputs, the associated bit of RTCCRn register must be set to 0 after reset.

It is prohibited to set the PMR and PDR bits of P402 to 1 when RTCCR0.TCEN is set to 1. It is prohibited to set the PMR and PDR bits of P403 to 1 when RTCCR1.TCEN is set to 1.

18。5。3 端口输出数据寄存器（PODR）摘要

该寄存器输出数据如下:

1。如果 PCNTR4,输出为 0。ELC_PORTn（n = 1,2,3或4)信号发生时,EORR被设置为1。

2锛姣涓涓。如果 PCNTR4,则输出 1。ELC_PORTn（n = 1,2,3或4)信号发生时,EOSR被设置为1。

3锛　　娴　　。如果 PCNTR3,输出为 0。PORR 设置为 1。

4锛姣涓。如果 PCNTR3,则输出 1。POSR 设置为 1。

5锛姣涓。输出 0 或 1,因为 PCNTR1。PODRn 已设置。

6锛　　涓€涓。输出 0 或 1,因为设置了 PmnPFS。PODRn。

此列表中的数字对应于写入 PODRn 的优先级。例如,如果列表中的 1。和 3。同时发生,则执行更高优先级的事件 1。

18.5.4 使用模拟函数的注意事项

要使用模拟功能,请将端口模式控制位（PMR）和端口方向位（PDRn）设置为 0,以便引脚充当通用输入端口。接下来,将端口 mn 引脚函数选择寄存器（PmnPFS。ASEL）中的模拟输入启用位（ASEL）设置为 1。

18。5。5 I/O 缓冲区规范

P402和P403可以用作AGT输入和其他外围功能。表 18。4 列出了 P402 和 P403 规格。

表 18。4 P402 和 P403 规格

I/O 端口	AGT		其他周边	
	AGT 输入启用寄存器	AGT	其他外围设备启用寄存器 CAC、GPT、CANFD 和中断	
P402	RTCCR0。TCEN	AGTIO0 AGTIO1	P402PFS。PSEL 和 PMR	详情请参见第 18。6 节。外设选择设置 每个产品。
P403	RTCCR1。TCEN	AGTIO0 AGTIO1	P403PFS。PSEL 和 PMR	

这些 AGT 输入由 RTCCRn 寄存器控制。

无论是否选择 AGT 输入,P402 和 P403 都可以用作 IRQn-DS（n = 4, 14)。参见图 18。5 .

RTCCRn 寄存器在重置时未初始化。因此,当不使用AGT输入时,重置后必须将RTCCRn寄存器的关联位设置为0。

RTCCR0时禁止将P402的PMR和PDR位设置为1。TCEN 设置为 1。RTCCR1时禁止将P403的PMR和PDR位设置为 1。TCEN 设置为 1。

18.6 Peripheral Select Settings for Each Product

This section describes the pin function select configuration using the PmnPFS register. Some pin names have added _A, _B, _C, or _D suffixes. When assigning I3C and SPI functionality, select the functional pins having the same suffix. The other pins can be selected regardless of the suffix. Assigning the same function to two or more pins simultaneously is prohibited.

1. In Pmn pin function select register(PmnPFS), the PSEL bits have to be set when the PMR bit of the target pin is 0. If the PSEL bits are set when the PMR bit is 1, the unexpected edges may be input at the input function or the unexpected pulses may be output to the external pin at the output function.
2. Only the allowed values (functions) should be specified in the PSEL bits of PmnPFS register. If a value which is not allowed for the register is specified, the correct operation is not guaranteed.
3. The single function should not be assigned to the multiple pins by PmnPFS register. When the GPT1, GPT5, I3C or SPI0 are configured as secure and these pin function is being assigned to the pin which security attribution is set as secure by the PmSAR register, the write access to the PSEL bits for setting same function as secure pin in other pins is ignored when the security attribution of that pin is non-secure. For example, if the PSARE.PSARE30 bit is 0 (GPT1 is secure) and the P109PFS.PSEL bits is 00011b (pin function is GTIOC1A) and the P1SAR.109SA bit is 0 (P109 is secure), the write 00011b to the P409PFS.PSEL bits is ignored when the P4SAR.409SA bit is 1 (P405 is non-secure).

18。6 每个产品的外围选择设置

本节描述使用 PmnPFS 寄存器的引脚函数选择配置。一些引脚名添加了_A、_B、_C或_D后缀。I3C和SPI功能时,选择具有相同后缀的功能引脚。无论后缀如何,都可以选择其他引脚。禁止同时将相同的功能分配给两个或多个引脚。

1。在Pmn引脚函数选择寄存器（PmnPFS）中,当目标引脚的PMR位为0时,必须设置PSEL位。PMR 位为 1 时设置 PSEL 位, 则可以在输入函数处输入意外边缘或者可以在输出函数处将意外脉冲输出到外部引脚。

2锛姣涓涓。PmnPFS 寄存器的 PSEL 位中仅应指定允许的值（函数）。如果指定了寄存器不允许的值,则不能保证正确的操作。

3锛　　娴　　。PmnPFS 寄存器不应将单个函数分配给多个引脚。当GPT1、GPT5、I3C或SPI0被配置为安全并且这些引脚函数被分配给PmSAR寄存器设置为安全的引脚时,用于设置与其他引脚中的安全引脚相同的功能的PSEL比特的写入访问当该引脚的安全归属不安全时,该引脚被忽略。例如,如果 PSARE。PSARE30 位为 0（GPT1 是安全的）并且 P109PFS。PSEL 位为 00011b（引脚函数为 GTIOC1A）并且 P1SAR。109SA 位为 0（P109 是安全的）,则写入 00011b P409PFS。PSEL 位在 P4SAR。409SA 位为 1（P405 是非安全的）时将被忽略。

4. The PORT0 and 5 have the analog functions such as A/D converter. When these pins are used as an analog function, for avoiding the loss of resolution, the PMR bit should be set to 0 and PDR bit should be set to 0. After that, ASEL bit should be set to 1

The initial value of the ASEL bit for P003 is 1. When this pin is not used as an analog function, the ASEL bit should be set to 0 to reduce the input leakage current.

4锛姣涓。PORT0和5具有A/D转换器等模拟功能。当这些引脚用作模拟函数时,为了避免分辨率损失,PMR位应设置为0,PDR位应设置为0。之后,ASEL 位应设置为 1

P003 的 ASEL 位的初始值为 1。ASEL 位不作为模拟功能时,应设置为 0,以减少输入漏电流。

Note 1. To use this pin function, set the associated pin as a general input (set the PmnPFS.PDR and PmnPFS.PMR bits to 0).
Note 2. Recommend using pins that have a letter appended to their names, for instance "_A" or "_B", to indicate group membership. For the interface, the AC portion of the electrical characteristics is measured for each group.
Note 3. There are 2 types output buffer which are middle drive and high drive. Recommend using same drive buffer for output skew spec (t_{GTISK})

19. Port Output Enable for GPT (POEG)

19.1 Overview

The Port Output Enable (POEG) function can place the General PWM Timer (GPT) output pins in the output disable state in one of the following ways:

- Input level detection of the GTETRGn (n = A to D) pins
- Output-disable request from the GPT
- Comparator interrupt request detection
- Oscillation stop detection of the clock generation circuit
- Register settings

The GTETRGn (n = A to D) pins can be used as GPT external trigger input pins.

Table 19.1 lists the POEG specifications, Figure 19.1 shows a block diagram, and Table 19.2 lists the input pins.

Table 19.1 POEG specifications

Parameter	Specifications
Output-disable control through input level detection	• The GPT output pins can be disabled when a GTETRGn rising edge or high level is sampled after polarity and filter selection.
Output-disable request from the GPT	• When the GTIOCxA pin and the GTIOCxB pin are driven to an active level simultaneously, the GPT generates an output-disable request to the POEG. Through reception of these requests, the POEG can control whether the GTIOCxA and GTIOCxB pins are output-disabled.
Output-disable control through comparator (ACMPHS) interrupt detection	The GPT output pins can be disabled when an interrupt request is generated by a change in the output results of any of the comparators
Output-disable control through oscillation stop detection	• The GPT output pins can be disabled when oscillation of the clock generation circuit stops.
Output-disable control by software (registers)	• The GPT output pins can be disabled by modifying the register settings.
Interrupt	• Interrupts can be generated by detecting the input level of external trigger input pins (GTETRGn pins). • Interrupts can be generated when all GPT output pins are driven to an active level simultaneously. • Interrupts can be generated by the change in the output results of any of the comparators.
External trigger output to the GPT	• The GTETRGn signals can be output to the GPT after polarity and filter selection. (count start, count stop, count clear, up-count, down-count, or input capture function)
Noise filtering	• For input from the GTETRGn pins, PCLKB/1, PCLKB/8, PCLKB/32, or PCLKB/128 can be selected as the noise filtering clock. (Filtering is performed by sampling the input signals three times using the selected clock.) • Positive or negative polarity can be selected for any of the GTETRGn input pins. • Signal state after polarity and filter selection can be monitored.
TrustZone Filter	• Security attribution can be set for each groups.

Note: n = A to D, x = 0 to 5

19. 端口输出支持 GPT（POEG）

19。1 概述

端口输出启用（POEG）功能可以通过以下方式之一将通用 PWM 定时器（GPT）输出引脚置于输出禁用状态:

● GTETRGn（n = A 至 D）引脚的输入电平检测
来自 GPT 的 ● 输出禁用请求
● 比较器中断请求检测
● 时钟生成电路的振荡停止检测
● 注册设置

GTETRGn（n = A 到 D）引脚可用作 GPT 外部触发输入引脚。

表 19。1 列出了 POEG 规范,图 19。1 显示了框图,表 19。2 列出了输入引脚。

表 19。1 POEG 规格

参数	规格
通过输入电平检测进行输出禁用控制	• 当在极性和滤波器选择后对 GTETRGn 上升沿或高电平进行采样时,可以禁用 GPT 输出引脚。
GPT 的输出禁用请求	• 当 GTIOCxA 引脚和 GTIOCxB 引脚同时驱动至活动水平时,GPT向POEG生成一个输出禁用请求,通过接收这些请求,POEG可以控制GTIOCxA和GTIOCxB引脚是否被输出禁用。
通过比较器（ACMPHS）中断检测进行输出禁用控制	当任何比较器的输出结果发生变化而生成中断请求时,可以禁用 GPT 输出引脚
通过振荡停止检测进行输出禁用控制	• 当时钟生成电路振荡停止时,可以禁用 GPT 输出引脚。
软件（寄存器）的输出禁用控制	• GPT 输出引脚可以通过修改寄存器设置来禁用。
中断	• 可以通过检测外部触发输入引脚（GTETRGn 引脚）的输入电平来生成中断。 • 当所有 GPT 输出引脚同时驱动到活动电平时,可以生成中断。 • 任何比较器的输出结果的变化都会产生中断。
GPT 的外部触发器输出	• GTETRGn 信号经过极性和滤波器选择后可以输出到 GPT。（计数开始、计数停止、计数清除、上计数、下计数或输入捕获功能）
噪音过滤	• 对于来自GTETRGn引脚的输入,可以选择PCLKB/1、PCLKB/8、PCLKB/32或PCLKB/128作为噪声滤波时钟。（过滤是通过使用所选时钟对输入信号进行三次采样来进行的。） • 可以为任何 GTETRGn 输入引脚选择正极性或负极性。 • 可以监测极性和滤波器选择后的信号状态。
TrustZone 过滤器	• 可以为每个组设置安全属性。

The POEGGn (n = A to D) registers control the output-disable state of the GPT pins, interrupts, and the external trigger input to the GPT.

In the descriptions, POEGGn represents the POEGGn (n = A to D) registers.

19.3 Output-Disable Control Operation

If any of the following conditions is satisfied, the GTIOCxA, GTIOCxB, and the 3-phase PWM output for BLDC motor control pins can be set to output-disable:

- Input level or edge detection of the GTETRGn pins
  When POEGGn.PIDE is 1, the POEGGn.PIDF flag is set to 1.
- Output-disable request from the GPT
  When POEGGn.IOCE is 1, the POEGGn.IOCF flag is set to 1 if the disable request is enabled by GTINTAD. The GTINTAD.GRPABH and GTINTAD.GRPABL settings apply to the group selected by the GPT register GTINTAD.GRP[1:0] or OPSCR.GRP[1:0].
- Comparator (ACMPHS) interrupt request detection
  Comparator interrupt detection is activated when any of the POEGGn.CDRE[5:0] registers is 1. When the associated comparator interrupt is generated, the GPT output pins are disabled. POEGGn.IOCF indicates the detection status.
- Oscillation stop detection for the clock generation circuit
  While POEGGn.OSTPE is 1, the halt status of the main clock oscillator is detected and the POEGGn. OSTPF flag is set to 1.
- SSF bit setting
  When POEGGn.SSF is set to 1, the GPT and PWM output are disabled.

The output-disable state is controlled in the GPT module. The output-disable of the GTIOCxA and GTIOCxB pins is set in the GTINTAD.GRP[1:0], GTIOR.OADF[1:0], and GTIOR.OBDF[1:0] bits in GPTx. The output-disable of the 3-phase PWM output for BLDC motor control pins is set in the OPSCR.GRP[1:0] bits and OPSCR.GODF bit in GPT_OPS.

19.3.1 Pin Input Level Detection Operation

If the input conditions set in POEGGn.PIDE, POEGGn.NFCS[1:0], POEGGn.NFEN, and POEGGn.INV occur on the GTETRGn pins, the GPT output pins are output-disabled.

19.3.1.1 Digital Filter

Figure 19.2 shows high-level detection by the digital filter. When a high level associated with the POEGGn.INV polarity setting is detected three times consecutively with the sampling clock selected in POEGGn.NFCS[1:0], the detected level is recognized as high, and the GPT output pins are output-disabled. If even one low level is detected during this interval, the detected level is not recognized as high. In addition, in an interval where the sampling clock is not output, changes of the levels on the GTETRGn pins are ignored.

。

POEGGn（n = A 到 D）寄存器控制 GPT 引脚、中断和 GPT 外部触发器输入的输出禁用状态。

在描述中,POEGGn 表示 POEGGn（n = A 至 D）寄存器。

19。3 输出−禁用控制操作

如果满足以下任何条件,GTIOCxA、GTIOCxB 和 BLDC 电机控制引脚的三相 PWM 输出可设置为禁用输出:

● GTETRGn引脚的输入电平或边缘检测 当POEGGn。PIDE为
1时,POEGGn。PIDF标志被设置为1。

来自 GPT 的 ● 输出禁用请求
POEGGn。IOCE 为 1 时,如果禁用请求由 GTINTAD 启用,则 POEGGn。IOCF 标志设置为 1。GTINTAD。G
RPABH 和 GTINTAD。GRPABL 设置适用于 GPT 寄存器 GTINTAD。GRP[1:0] 或 OPSCR。GRP[1:0] 选择的
组。

● 比较器（ACMPHS）中断请求检测
当任何 POEGGn。CDRE[5:0] 寄存器为 1 时,比较器中断检测将被激活。当生成关联的比较器中断时,GPT 输
出引脚将被禁用。POEGGn。IOCF 指示检测状态。

● 时钟生成电路的振荡停止检测
虽然 POEGGn。OSTPE 为 1,但检测到主时钟振荡器的停止状态,并且检测到 POEGGn。OSTPF 标志设置为 1。

● SSF 位设置
当POEGGn。SSF设置为1时,GPT和PWM输出被禁用。

GPT模块中控制输出禁用状态。GTIOCxA 和 GTIOCxB 引脚的输出禁用设置在 GPTx 中的 GTINTAD。GRP[1:0]、G
TIOR。OADF[1:0] 和 GTIOR。OBDF[1:0] 位中。BLDC 电机控制引脚的 3 相 PWM 输出的输出禁用设置在 GPT_OP
S 中的 OPSCR。GRP[1:0] 位和 OPSCR。GODF 位。

19.3.1 Pin输入电平检测操作

如果在GTETRGn引脚上出现POEGGn。PIDE、POEGGn。NFCS[1:0]、POEGGn。NFEN和POEGGn。INV中设
置的输入条件,则GPT输出引脚被输出禁用。

19。3。1。1 数字滤波器

图 19。2 显示了数字滤波器的高级检测。当与POEGGn。INV极性设置相关联的高电平与POEGGn。NFCS[1:0]中
选择的采样时钟连续检测三次时,检测到的电平被识别为高电平,并且GPT输出引脚被输出禁用。如果在此间隔期
间甚至检测到一个低电平,则检测到的电平不会被识别为高电平。另外,在不输出采样时钟的间隔中,GTETRGn引脚
上的电平的变化被忽略。

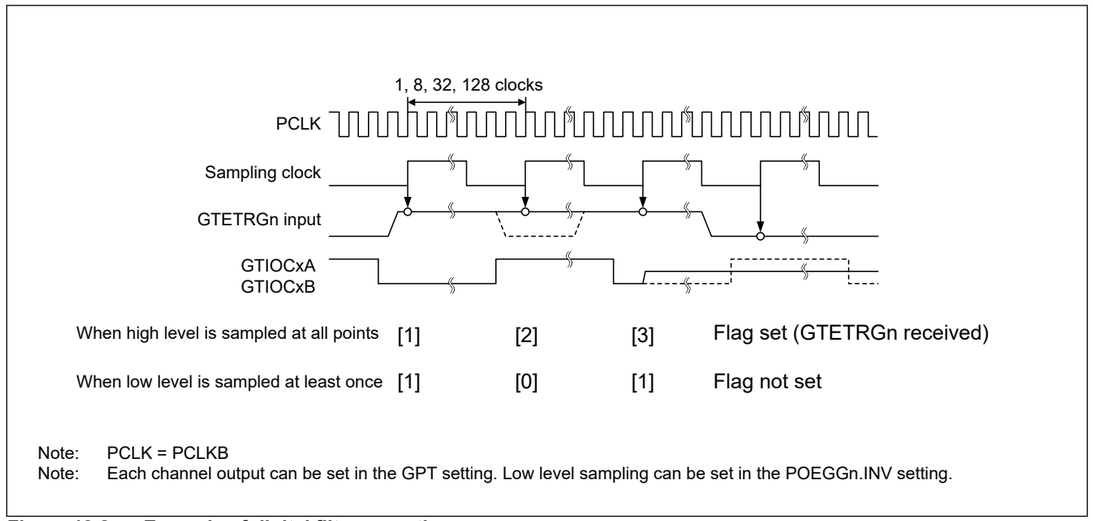

Figure 19.2 Example of digital filter operation

19.3.2 Output-Disable Requests from the GPT

For details on the operation, see the description for GTIOC Pin Output Negate Control in section 20, General PWM Timer (GPT).

19.3.3 Comparator Interrupt Detection

If POEGGn.CDRE[2:0] is 1 when the associated comparator interrupt request is generated, the GPT output pins are output-disabled for each group. The status flag is POEGGn.IOCF, which is shared with GPT output-disable detection.

19.3.4 Output-Disable Control Using Detection of Stopped Oscillation

When the oscillation stop detection function in the clock generation circuit detects stopped oscillation while POEGGn.OSTPE is 1, the GPT output pins are output-disabled for each group.

19.3.5 Output-Disable Control Using Registers

The GPT output pins can be directly controlled by writing 1 to the Software Stop flag, POEGGn.SSF.

19.3.6 Release from Output-Disable

To release the GPT output pins placed in the output-disable state, either return them to their initial state with a reset or clear all of the following flags:

- POEGGn.PIDF
- POEGGn.IOCF
- POEGGn.OSTPF
- POEGGn.SSF

Writing 0 to the POEGGn.PIDF flag is ignored (the flag is not cleared) if the external input pins, GTETRGn are not disabled and the POEGGn.ST bit is not set to 0.

Writing 0 to the POEGGn.IOCF flag is valid (the flag is cleared) only if all of the GTST.OABHF and GTST.OABLF flags in the GPT are set to 0.

Writing 0 to the POEGGn.OSTPF flag is ignored (the flag is not cleared) if the OSTDSR.OSTDF flag in the clock generation circuit is not set to 0. In addition, when the flag set and release occur at the same time, the flag set takes precedence.

19。3。2 GPT 的输出禁用请求

有关操作的详细信息,请参阅第 20 节"通用 PWM 定时器（GPT）."中有关 GTIOC 引脚输出负控件的描述

19。3。3 比较器中断检测

如果生成关联的比较器中断请求时 POEGGn。CDRE[2:0] 为 1,则每个组的 GPT 输出引脚将被禁用。状态标志是 POEGGn。IOCF,与 GPT 输出禁用检测共享。

19。3。4 使用停止振荡检测的输出禁用控制

当时钟生成电路中的振荡停止检测功能检测到POEGGn。OSTPE为1时停止振荡时,每组GPT输出引脚都被禁用。

19.3.5 使用寄存器的输出禁用控制

GPT 输出引脚可以通过将 1 写入 Software Stop 标志 POEGGn。SSF 来直接控制。

19。3。6 输出禁用释放

要释放放置在输出禁用状态的 GPT 输出引脚,请通过重置将它们返回到初始状态或清除以下所有标志:

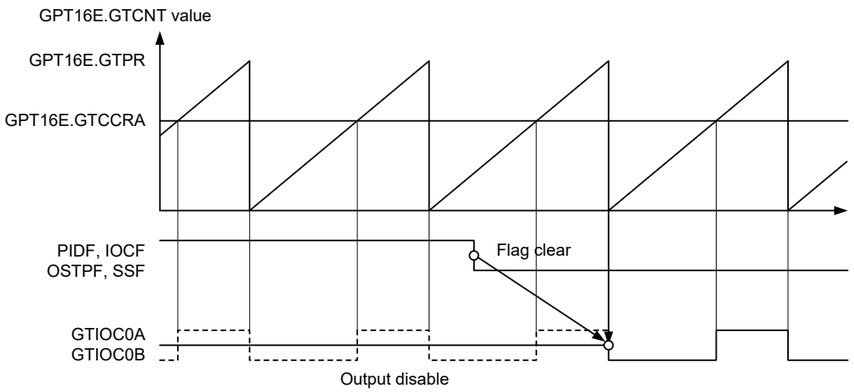
- POEGGn。PIDF
- POEGGn。IOCF
- POEGGn。OSTPF
- POEGGn。SSF

如果外部输入引脚、GTETRGn 未禁用且 POEGGn。ST 位未设置为 0,则忽略将 0 写入 POEGGn。PIDF 标志（标志未清除）。

仅当 GPT 中的所有 GTST。OABHF 和 GTST。OABLF 标志设置为 0 时,将 0 写入 POEGGn。IOCF 标志才有效（标志已清除）。

如果时钟生成电路中的 OSTDSR。OSTDF 标志未设置为 0,则将 0 写入 POEGGn。OSTPF 标志将被忽略（该标志未清除）。另外,当标志设置和释放同时发生时,标志设置优先。

Figure 19.3 shows the release timing for output-disable. The output-disable is released at the beginning of the next count cycle of the GPT after the flag is cleared.



Note: The base address of the registers are the same.

Figure 19.3 Output-disable release timing for GPT pin outputs

19.4 Interrupt Sources

The POEG generates an interrupt request for the following factors:

- Output-disable control by the input level detection
- Output-disable request from the GPT
- Output-disable request from the comparator interrupt request detection.

Table 19.3 lists the conditions for interrupt requests.

Table 19.3 Interrupt sources and conditions

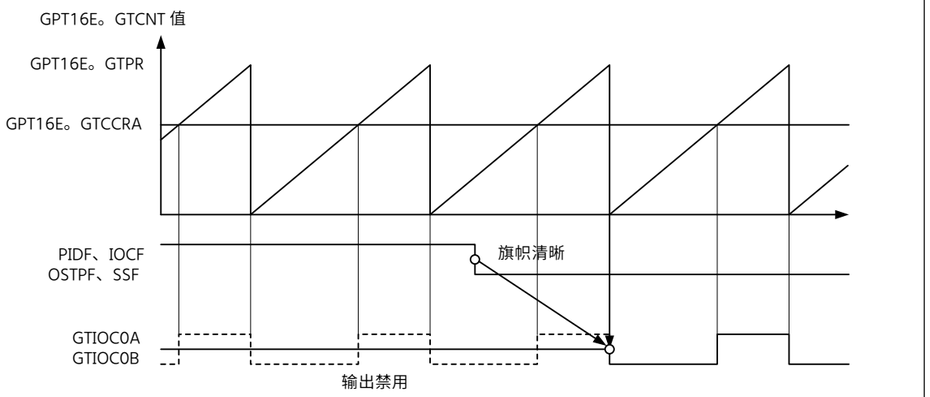
19.5 External Trigger Output to the GPT

The POEG outputs signals generated by filtering and level detection of GTETRGn pins input signals as the GPT operation trigger signal for the following:

- Count start

图 19。3 显示了禁用输出的释放时间。清除标志后,输出禁用将在 GPT 下一个计数周期开始时释放。



注: 寄存器的基本地址是相同的。

19。4 中断源

POEG 对以下因素生成中断请求:

- 输出–通过输入电平检测进行禁用控制

来自 GPT 的
- 输出禁用请求
- 输出–禁用来自比较器中断请求检测的请求。

表 19。3 列出了中断请求的条件。

表 19。3 中断来源和条件

19.5 GPT 的外部触发器输出

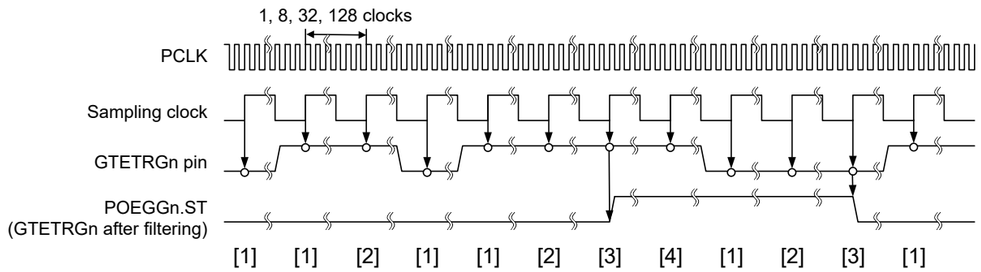
POEG 输出通过对 GTETRGn 引脚输入信号进行滤波和电平检测而生成的信号, 作为以下的 GPT 操作触发信号:

- 计数开始

- Count stop
- Count clear
- Up-count
- Down-count
- Input capture

For the POEGGn.INV polarity setting signal, when the same level is input three times continuously with the sampling clock selected in POEGGn.NFCS[1:0], that value is output. Set the control registers the same as for the input level detection operation described in section 19.3.1. Pin Input Level Detection Operation The state after filtering can be monitored in POEGGn.ST.

Figure 19.4 shows the output timing of an external trigger to the GPT.



Note: PCLK = PCLKB
Note: Each channel output can be set in the GPT settings. Polarity can be reversed in POEGGn.INV.

19.6 Usage Notes

19.6.1 Transition to Software Standby Mode

When using the POEG, do not invoke Software Standby mode. In this mode, the POEG stops and therefore output disable of the pins cannot be controlled.

19.6.2 Specifying Pins Associated with the GPT

The POEG controls output-disable only when a pin is associated with the GPT in the PmnPFS.PMR and PmnPFS.PSEL settings. When the pin is specified as a general I/O pin, the POEG does not perform output-disable control.

19.6 使用说明

19。6。1 过渡到软件待机模式

使用 POEG 时,请勿调用软件待机模式。在此模式下,POEG 停止,因此无法控制引脚的输出禁用。

19。6。2 指定与 GPT 关联的引脚

仅当 PmnPFS。PMR 和 PmnPFS。PSEL 设置中的引脚与 GPT 关联时,POEG 才控制输出禁用。当引脚被指定为通用I/O引脚时,POEG不执行输出禁用控制。

GTWP enables or disables writing to registers to prevent accidental modification. Protection by the GTWP register is only for the writes by the CPU. GTWP does not protect registers from updates that occur in association with CPU writes.

WP bit (Register Write Disable)

The following is a list of write enabled or disabled registers:

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTITC, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTPDBR, GTADTRA, GTADTBRA, GTADTDBRA, GTADTRB, GTADTBRB, GTADTDBRB, GTDTCR, GTDVU, GTDVD, GTDBU, GTDBD, GTSOS, GTSOTR, GTADSMR, GTICLF, GTPC.

STRWP bit (GTSTR.CSTRT Bit Write Disable)

The STRWP bit enables or disables starting the updating of counter values by writing to the CSTRTn bit (n = 0 to 5) corresponding to a channel number in the GTSTR register.

The bit position of each CSTRTn bit in the GTSTR register is allocated to the channel with the corresponding number, and writing to the GTSTR register for any channel results in writing to the registers of all channels. The STRWP bit for each channel does not control writing but only controls updating of the CSTRT bit for the corresponding channel when simultaneously writing to all channels.

Therefore, when writing to the CSTRT bits of a channel for which the setting of the STRWP bit is 1 (disabling writing), the CSTRT bit for the given channel is not updated, but the CSTRT bits corresponding to channel for which the setting of the STRWP bit is 0 (enabling writing) are updated. For example, when the setting of the GPT16E0.GTWP.STRWP bit is 0 (enabling writing), writing 1 to the GPT16E1.GTSTR.CSTRT0 bit when its current setting is 0 causes the value to be updated, and the GPT16E0.GTCNT counter starts to run. When the setting of the GPT16E0.GTWP.STRWP bit is 1 (disabling writing), writing 1 to the GPT16E1.GTSTR.CSTRT0 bit when its current setting is 0 leaves the bit with the value 0, and the GPT16E0.GTCNT counter does not run.

If you want to protect all bits in the GTSTR register from being updated, set the STRWP bits of all channels to 1.

STPWP bit (GTSTP.CSTOP Bit Write Disable)

The STPWP bit enables or disables starting the updating of counter values by writing to the CSTOPn bit (n = 0 to 5) corresponding to a channel number in the GTSTP register.

The bit position of each CSTOPn bit in the GTSTP registers is allocated to the channel with the corresponding number, and the writing to the GTSTP register for any channel results in writing to the registers of all channels. The STPWP bit for each channel does not control writing but only controls updating of the CSTOP bit for the corresponding channel when simultaneously writing to all channels.

Therefore, when writing to the CSTOP bits of a channel for which the setting of the STPWP bit is 1 (disabling writing), the CSTOP bit for the given channel is not updated, but the CSTOP bits corresponding to channel for which the setting of the STPWP bit is 0 (enabling writing) are updated. For example, when the setting of the GPT16E0.GTWP.STPWP bit is 0 (enabling writing), writing 1 to the GPT16E1.GTSTP.CSTOP0 bit when its current setting is 0 causes the value to be updated, and the GPT16E0.GTCNT counter is stopped. When the setting of the GPT16E0.GTWP.STPWP bit is 1 (disabling writing), writing 1 to the GPT16E1.GTSTP.CSTOP0 bit when its current setting is 0 leaves the bit with the value 0, and the GPT16E0.GTCNT counter is not stopped.

If you want to protect all bits in the GTSTP register from being updated, set the STPWP bits of all channels to 1.

CLRWP bit (GTCLR.CCLR Bit Write Disable)

CLRWP bit enables or disables starting the updating of counter values by writing to the CCLRn bit (n = 0 to 5) corresponding to a channel number in the GTCLR register.

The bit position of each CCLRn bit in the GTCLR registers is allocated to the channel with the corresponding number, and the writing to the GTCLR register for any channel results in writing to the registers of all channels. The CLRWP bit for each channel does not control writing but only controls updating of the CCLR bit for the corresponding channel when simultaneously writing to all channels.

Therefore, when writing to the CCLR bits of a channel for which the setting of the CLRWP bit is 1 (disabling writing), the CCLR bit for the given channel is not updated, but the CCLR bits corresponding to channel for which the setting of the CLRWP bit is 0 (enabling writing) are updated. For example, when the setting of the GPT16E0.GTWP.CLRWP bit is 0 (enabling writing), writing 1 to the GPT16E1.GTCLR.CCLR0 bit when its current setting is 0 causes the value to be updated, and the GPT16E0.GTCNT counter is cleared. When the setting of the GPT16E0.GTWP.CLRWP bit is 1 (disabling

GTWP 启用或禁用写入寄存器以防止意外修改。GTWP 寄存器的保护仅适用于 CPU 的写入。GTWP 不会保护寄存器免受与 CPU 写入相关的更新的影响。

WP 位（注册写禁用）

以下是已启用或禁用的写入寄存器的列表:

GTSSR、GTPSR、GTCSR、GTUPSR、GTDNSR、GTICASR、GTICBSR、GTCR、GTUDTYC、GTIOR、GTINTAD、GTST、GTBER、GTITC、GTCNT、GTCCRA、GTCCRB、GTCCRC、GTCCRD、GTCCRE、GTCCRF、GTPR、GTPBR、GTPDBR、GTADTRA、GTADTBRA、GTADTDBRA、GTADTRB、GTADTBRB、GTDTCR、GTDVU、GTDVD、GTDBU、GTDBD、GTSOS、GTSOTR、GTADSMR、GTICLF、GTPC。

STRWP 位（GTSTR。CSTRT 位写入禁用）

STRWP 位通过写入与 GTSTR 寄存器中的信道号相对应的 CSTRTn 位（n = 0 至 5)来启用或禁用开始计数器值的更新。

GTSTR寄存器中每个CSTRTn位的位位置被分配到具有相应编号的信道,并且写入GTSTR寄存器对于任何信道结果以写入到所有信道的寄存器。每个通道的STRWP比特不控制写入,而仅当同时写入所有通道时控制相应通道的CSTRT比特的更新。

因此,当写入STRWP位设置为1的信道的CSTRT位时（禁用写入）,给定信道的CSTRT位不更新,而是与STRWP位设置为1的信道对应的CSTRT位。STRWP位为0（启用写入）被更新。例如,当设置GPT16E0时。GTWP。STRWP 位为 0（启用写入）,将 1 写入 GPT16E1。GTSTR。CSTRT0 位当其当前设置为 0 时会导致值更新,并且 GPT16E0。GTCNT 计数器开始运行。GPT16E0的设置时。GTWP。STRWP 位为 1（禁用写入）,将 1 写入 GPT16E1。当当前设置为 0 时,GTSTR。CSTRT0 位会留下值为 0 的位,以及 GPT16E0。GTCNT 计数器不运行。

如果您想保护 GTSTR 寄存器中的所有位不被更新,请将所有通道的 STRWP 位设置为 1。

STPWP 位（GTSTP。CSTOP 位写入禁用）

STPWP 位通过写入与 GTSTP 寄存器中的信道号相对应的 CSTOPn 位（n = 0 到 5)来启用或禁用开始计数器值的更新。

GTSTP寄存器中每个CSTOPn位的位位置被分配给具有相应编号的信道,并且对任何信道的GTSTP寄存器的写入导致对所有信道的寄存器的写入。每个通道的STPWP比特不控制写入,而仅当同时写入所有通道时控制相应通道的CSTOP比特的更新。

因此,当写入STPWP位设置为1的信道的CSTOP位时（禁用写入）,给定信道的CSTOP位不更新,而是与STPWP位设置为1的信道对应的CSTOP位。STPWP位为0（启用写入）被更新。例如,当设置GPT16E0时。GTWP。STPWP 位为 0（启用写入）,将 1 写入 GPT16E1。GTSTP。CSTOP0 位当前设置为 0 时会导致值更新,并且 GPT16E0。GTCNT 计数器已停止。GPT16E0的设置时。GTWP。STPWP 位为 1（禁用写入）,将 1 写入 GPT16E1。当当前设置为 0 时,GTSTP。CSTOP0 位会留下值为 0 的位,以及 GPT16E0。GTCNT 计数器不会停止。

如果您想保护 GTSTP 寄存器中的所有位不被更新,请将所有通道的 STPWP 位设置为 1。

CLRWP 位（GTCLR。CCLR 位写禁用）

CLRWP 位通过写入与 GTCLR 寄存器中的信道号相对应的 CCLRn 位（n = 0 到 5)来启用或禁用开始计数器值的更新。

GTCLR寄存器中每个CCLRn位的位位置被分配给具有相应编号的信道,并且对任何信道的GTCLR寄存器的写入导致对所有信道的寄存器的写入。每个通道的CLRWP比特不控制写入,而仅控制同时写入所有通道时相应通道的CCLR比特的更新。

因此,当写入CLRWP位设置为1的信道的CCLR位时（禁用写入）,给定信道的CCLR位不更新,而是与CLRWP位设置为1的信道对应的CCLR位更新。CLRWP位为0（启用写入）。例如,当设置GPT16E0时。GTWP。CLRWP 位为 0（启用写入）,将 1 写入 GPT16E1。GTCLR。CCLR0 位当其当前设置为 0 时会导致值更新,并且 GPT16E0。GTCNT 计数器已清除。GPT16E0的设置时。GTWP。CLRWP 位为 1（禁用）

writing), writing 1 to the GPT16E1.GTCLR.CCLR0 bit when its current setting is 0 leaves the bit with the value 0, and the GPT16E0.GTCNT counter is not cleared.

If you want to protect all bits in the GTCLR register from being updated, set the CLRWP bits of all channels to 1.

CMNWP bit (Common Register Write Disabled)

CMNWP bit enables or disables starting the updating of counter values by writing to the SECSELn bit (n = 0 to 5) corresponding to a channel number in the GTSECSR register or to the GTSECR register.

The bit position of each SECSEL bit in the GTSECSR registers is allocated to the channel with the corresponding number, and the writing to the GTSECSR register for any channel results in writing to the registers of all channels. Writing to the GTSECR register of any channel leads to writing to the registers of all channels. The CMNWP bit for each channel does not control writing but only controls updating of the SECSEL bit and the GTSECR register value for the corresponding channel when simultaneously writing to all channels.

Therefore, when writing to the SECSEL bit and the GTSECR register value of a channel for which the setting of the CMNWP bit is 1(disabling writing), the SECSEL bit and the GTSECR register value for the given channel is not updated, but the SECSEL bit and the GTSECR register value corresponding to channel for which the setting of the CMNWP bit is 0 (enabling writing) are updated.

For example, when the setting of the GPT16E0.GTWP.CMNWP bit is 0 (enabling writing), writing to the GPT16E1.GTSECSR.SECSEL0 bit causes the value of the GPT16E0.GTSECSR.SECSEL0 bit to be updated. In the same way, writing to the GPT16E1.GTSECR register updates the value of the GPT16E0.GTSECR register. When the setting of the GPT16E0.GTWP.CMNWP bit is 1 (disabling writing), writing to the GPT16E1.GTSECSR.SECSEL0 bit does not cause the value of the GPT16E0.GTSECSR.SECSEL0 bit to be updated. In the same way, writing to the GPT16E1.GTSECR register does not update the value of the GPT16E0.GTSECR register.

If you want to protect all bits in the GTSECSR and GTSECR registers from being updated, set the CMNWP bits of all channels to 1.

PRKEY[7:0] bit (GTWP Key Code)

This bit controls whether the WP, STRWP, STPWP, CLRWP, and CMNWP bits can be overwritten.

20.2.2 GTSTR : General PWM Timer Software Start Register

Base address: GPT16Em = 0x4016_9000 + 0x0100 × m (m = 0 to 5)

Offset address: 0x04

Bit position:	31																												0
Bit field:	CSTRT31 to CSTRT0																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CSTRT0 to CSTRT31*1	Channel n GTCNT Count Start (n is the same as the bit position value) 0: GTCNT counter is not started 1: GTCNT counter is started	R/W

Note 1. The bits that can be used vary depending on the product. The n in CSTRTn is the same as the GPT channel number. For this product, n is 0 to 5.

The GTSTR starts the GTCNT counter operation for each channel n, where n = 0 to 5.

The GTSTR bit number represents the channel number. The GTSTR register of each channel is shared by all of the channels. The GTCNT counter starts for the channel associated with the GTSTR bit number where 1 is written. Writing 0 has no effect on the status of GTCNT counter and the value of GTSTR register.

The bit corresponding to channel which security attribution is configured as secure can be read by non-secure access but cannot be written by non-secure access. For example, if GPT channel 0 is configured as secure and other GPTs are configured as non-secure, the CSTRT0 bit cannot be written by non-secure access to GTSTP in GPT channel 1, and the GTCNT counter operation status of GPT channel 0 is not changed. When the GTSTR register in GPT channel 1 is read by non-secure access in the same security configuratin as the previous example, the GTCNT counter operation status of GPT channel 0 (CSTRT0 bit) can be read.

写入）,将 1 写入 GPT16E1。当当前设置为 0 时,GTCLR。CCLR0 位留下值为 0 的位,以及 GPT16E0。GTCNT 计数器未清除。

如果您想保护 GTCLR 寄存器中的所有位不被更新,请将所有通道的 CLRWP 位设置为 1。

CMNWP 位（禁用常用寄存器写入）

CMNWP 位通过写入与 GTSECSR 寄存器或 GTSECR 寄存器中的信道号相对应的 SECSELn 位（n = 0 至 5）来启用或禁用开始计数器值的更新。

GTSECSR寄存器中每个SECSEL位的位位置被分配给具有相应编号的信道,并且对任何信道的GTSECSR寄存器的写入导致对所有信道的寄存器的写入。写入任何通道的 GTSECR 寄存器会导致写入所有通道的寄存器。每个通道的CMNWP比特不控制写入,而仅控制同时写入所有通道时相应通道的SECSEL比特和GTSECR寄存器值的更新。

因此,当写入CMNWP位的设置为1的信道的SECSEL位和GTSECR寄存器值（禁用写入）时,给定信道的SECSEL位和GTSECR寄存器值不更新, 但更新了 CMNWP 位设置为 0（启用写入）的信道对应的 SECSEL 位和 GTSECR 寄存器值。

例如,当设置GPT16E0时。GTWP。CMNWP 位为 0（启用写入）,写入 GPT16E1。GTSECSR。SECSEL0 位导致 GPT16E0 的值。GTSECSR。SECSEL0 位待更新。同样,写信给 GPT16E1。GTSECR 寄存器更新 GPT16E0 的值。GTSECR 注册。GPT16E0的设置时。GTWP。CMNWP 位为 1（禁用写入）,写入 GPT16E1。GTSECSR。SECSEL0 位不会导致 GPT16E0 的值。GTSECSR。SECSEL0 位待更新。同样,写信给 GPT16E1。GTSECR 寄存器不更新 GPT16E0 的值。GTSECR 注册。

如果您想保护 GTSECSR 和 GTSECR 寄存器中的所有位不被更新,请将所有通道的 CMNWP 位设置为 1。

GTSTR 开始每个通道 n 的 GTCNT 计数器操作,其中 n = 0 到 5。

与安全属性配置为安全的信道相对应的位可以通过非安全访问读取,但不能通过非安全访问写入。例如,如果GPT信道0被配置为安全并且其他GPT被配置为非安全,则不能通过GPT信道1中对GTSTP的非安全访问来写入CSTRT0位,并且GPT信道0的GTCNT计数器操作状态不改变。当通过与前面的示例相同的安全配置中的非安全访问读取GPT通道1中的GTSTR寄存器时,可以读取GPT通道0的GTCNT计数器操作状态（CSTRT0位）。

CSTRTn bits (Channel n GTCNT Count Start (n = 0 to 5))

The CSTRTn bits start channel n of the GTCNT counter operation. Writing to the GTSTR.CSTRTn bit (n = 0 to 5) has no effect unless the GTSSR.CSTRT bit is set to 1.

The read data shows the counter status of each channel (GTCR.CST bit). A value of 0 means the counter is stopped and 1 means the counter is running.

Note 1. The bits that can be used vary depending on the product. The n in CSTOPn is the same as the GPT channel number. For this product, n is 0 to 5.

The GTSTP stops the GTCNT counter operation for each channel n, where n = 0 to 5.

The GTSTP bit number represents the channel number. The GTSTP register of each channel is shared by all the channels. The GTCNT counter stops for the channel associated with the GTSTP bit number where 1 is written. Writing 0 has no effect on the status of the GTCNT counter and the value of GTSTP register.

The bit corresponding to channel which security attribution is configured as secure can be read by non-secure access but cannot be written by non-secure access. For example, if GPT channel 0 is configured as secure and other GPTs are configured as non-secure, the CSTOP0 bit cannot be written by non-secure access to GTSTP register in GPT channel 1, and the GTCNT counter operation status of GPT channel 0 is not changed. When the GTSTP register in GPT channel 1 is read by non-secure access in the same security configuratin as the previous example, the GTCNT counter operation status of GPT channel 0 (CSTOP0 bit) can be read.

For the association between module names and channel numbers, see Figure 20.2.

CSTOPn bits (Channel n GTCNT Count Stop (n = 0 to 5))

The CSTOPn bits stop channel n of the GTCNT counter operation. Writing to the GTSTP.CSTOPn bit (n = 0 to 5) has no effect unless the GTPSR.CSTOP bit is set to 1. The read data shows the counter status of each channel (invert of GTCR.CST bit). A value of 0 means the counter is running and 1 means the counter is stopped.

31:0	CCLR0 至 CCLR31 *1	通道 n GTCNT 计数清除（n:与位位置值相同） 0:GTCNT计数器未清除 1:GTCNT计数器已清除	W

Note 1. The bits that can be used vary depending on the product. The n of CCLRn is the same as the GPT channel number. For this product, n is 0 to 5.

The GTCLR is a write-only register that clears the GTCNT counter operation for each channel n, where n = 0 to 5.

The GTCLR bit number represents the channel number. The GTCLR register of each channel is shared by all the channels. The GTCNT counter is cleared for the channel associated with the GTCLR bit number where 1 is written. Writing 0 has no effect on the status of GTCNT counter.

The bit corresponding to channel which security attribution is configured as secure can not be written by non-secure access. For example, if GPT channel 0 is configured as secure and other GPTs are configured as non-secure, the CCLR0 bit cannot be written by non-secure access to GTCLR register in GPT channel 1, and the GTCNT counter of GPT channel 0 is not cleared.

For the association between module names and channel numbers, see Figure 20.2.

The value of the counter becomes 0x0000 0000 with other settings. These bits are read as 0.

Note: n = 0 to 5

The GTUPSR sets the source to count up the GTCNT counter.

When at least one bit in the GTUPSR register is set to 1, the GTCNT counter is counted up by the source that is set to 1 in this register. In this case, GTCR.TPCS has no effect.

Number of increment in counting is one even when multiple sources are generated simultaneously.

GTUPSR 设置源来计数 GTCNT 计数器。

GTUPSR 寄存器中的至少一位设置为 1 时,GTCNT 计数器由在此寄存器中设置为 1 的源进行计数。在这种情况下,GTCR。TPCS 没有效果。

即使同时生成多个源,计数增量也为 1。

Note: n = 0 to 5

The GTDNSR sets the source to count down the GTCNT counter.

When at least one bit in the GTDNSR register is set to 1, the GTCNT counter is counted down by the source that is set to 1 in this register. In this case, GTCR.TPCS has no effect.

Number of decrement in counting is one even when multiple sources are generated simultaneously.

Inputs from GTETRGn (n = A to D) pins are input to the GPT through the POEG. Set the polarity of these signals with the POEG.

注: n = 0 to 5

GTDNSR 将源设置为倒计时 GTCNT 计数器。

当 GTDNSR 寄存器中的至少一位设置为 1 时,GTCNT 计数器由该寄存器中设置为 1 的源进行倒计时。在这种情况下,GTCR。TPCS 没有效果。

即使同时生成多个源,计数的减少次数也是 1。

The GTCR controls GTCNT.

CST bit (Count Start)

The CST bit controls the GTCNT counter start and stop.

[Setting conditions]

- The GTSTR value where the channel number associated with the bit number is set to 1 with the GTSSR.CSTRT bit at 1
- The ELC event input, the external trigger, or the GTIOCnA/GTIOCnB input that are enabled by GTSSR for the starting counter source, occurs (n = 0 to 5)
- 1 is written by software directly.

[Clearing conditions]

- The GTSTP value where the channel number associated with the bit number is set to 1 with the GTPSR.CSTOP bit at 1
- The ELC event input, the external trigger, or the GTIOCnA/GTIOCnB input enabled by GTPSR as the counter stop source, occurs (n = 0 to 5)
- 0 is written by software directly.
- When the period count function is finished while the GTPC.ASTP bit is 1.

MD[2:0] bits (Mode Select)

The MD[2:0] bits select the GPT operating mode.

Only the MD[2] bit is valid at input capture. Counting in saw-wave mode is performed with the MD[2] bit set to 0, and counting in triangle-wave mode is performed with the MD[2] bit set to 1.

The MD[2:0] bits must be set while the GTCNT operation is stopped.

During the event count operation (when at least one bit among the bits for the GTUPSR and GTDNSR registers is set to 1), setting of the MD[2:0] bits are ignored, where counting in saw-wave or triangle-wave modes is not performed. Instead, up-counting or down-counting by a source set by the GTUPSR and GTDNSR registers is performed.

TPCS[3:0] bits (Timer Prescaler Select)

The TPCS[3:0] bits select the clock for GTCNT. A clock prescaler can be selected independently for each channel. The TPCS[3:0] bits must be set while the GTCNT operation is stopped.

GTCR 控制 GTCNT。

CST 位（计数开始）

CST 位控制 GTCNT 计数器开始和停止。

的【设置条件】

- 将与位号相关联的信道号设置为 1 的 GTSTR 值,其中 GTSSR。CSTRT 位位于 1
- GTSSR 为起始计数器源启用的 ELC 事件输入、外部触发器或 GTIOCnA/GTIOCnB 输入发生（n = 0 到 5）
- 1 是由软件直接编写的。

的【清算条件】

- 将与位号相关联的信道号设置为 1 的 GTSTP 值,GTPSR。CSTOP 位为 1
- 发生由GTPSR作为计数器停止源启用的ELC事件输入、外部触发器或GTIOCnA/GTIOCnB输入（n = 0至5）
- 0 是由软件直接编写的。
- 当周期计数函数完成时,而 GTPC。ASTP 位为 1。

MD[2:0] 位（模式选择）

MD[2:0] 位选择 GPT 操作模式。

MD[2]位在输入捕获时才有效。MD[2]位设置为0时进行锯波模式计数,MD[2]位设置为1时进行三角波模式计数。

GTCNT 操作停止时必须设置 MD[2:0] 位。

在事件计数操作期间（当GTUPSR和GTDNSR寄存器的位中的至少一位被设置为1时）,忽略MD[2:0]位的设置,其中在锯波或三角波模式中计数不执行。相反,由 GTUPSR 和 GTDNSR 寄存器设置的源执行上计数或下计数。

TPCS[3:0] 位（定时器预分频器选择）

TPCS[3:0]位为GTCNT选择时钟,每个通道可以独立选择时钟预分频器。GTCNT 操作停止时必须设置 TPCS[3:0]位。

GTUDDTYC 设定了 GTCNT 计数的方向（上计数或下计数）,并设定了职责 GTIOCNA/GTIOCNB 引脚输出。

在事件计数操作期间设置无效。

计数方向:

- In saw-wave mode.
  When the UD value is set to 0 during up-counting, the count direction changes at an overflow (the timing synchronous with count clock after the GTCNT value becomes the GTPR value). When the UD value is set to 1 during down-counting, the count direction changes at an underflow (the timing synchronous with count clock after the GTCNT value becomes 0).
  When the UD value changes from 1 to 0 with the UDF bit being 0 and while counting stops, the counter starts up-counting and the count direction changes at an overflow (the timing synchronous with count clock after the GTCNT value becomes the GTPR value). When the UD value changes from 0 to 1 with the UDF bit being 0 and while counting stops, the counter starts down-counting and the count direction changes at an underflow (the timing synchronous with count clock after the GTCNT value becomes 0).
  When the UDF bit is set to 1 while counting stops, the UD bit value is reflected in the count direction when counting starts.
- In triangle-wave mode.
  When the UD value changes during counting, the count direction does not change. When the UD value changes while the UDF bit is 0 and counting stops, the change is not reflected in the count direction when counting starts.
  When the UDF bit is set to 1 while counting is stopped, the UD value is reflected in the count direction when counting starts.

UD bit (Count Direction Setting)

The UD bit sets the count direction (up-counting or down-counting) for GTCNT.

UDF bit (Forcible Count Direction Setting)

The UDF bit forcibly sets the count direction when GTCNT starts operation as the UD value. Only 0 should be written to this bit during counter operation. When 1 is written to this bit while counting stops, return this bit to 0 before counting starts.

Output duty

- In saw-wave mode.
  When the OADTY/OBDTY value changes during up-counting, the duty is reflected at an overflow (GTCNT = GTPR).
  When the OADTY/OBDTY value is changed during down-counting, the duty is reflected at an underflow (GTCNT = 0).
  When the OADTY/OBDTY value is changed with the OADTYF/OBDTYF bit being 0 and while counting stops the output duty is not reflected at the starting counter operation. When the count direction is up, the output duty is reflected at an overflow (GTCNT = GTPR). When the count direction is down, the output duty is reflected at an underflow (GTCNT = 0).
  When the OADTY/OBDTY value is changed with the OADTYF/OBDTYF bit being 1 and while counting stops, the output duty is reflected at starting counter operation.
- In triangle-wave mode.
  When the OADTY/OBDTY value changes during counting, the duty is reflected at an underflow.
  When the OADTY/OBDTY value is changed with the OADTYF/OBDTYF bit being 0 and while counting stops, the output duty is not reflected at the starting counter operation. The output duty is reflected at an underflow.
  When the OADTY/OBDTY value is changed with the OADTYF/OBDTYF bit being 1 and while counting stops, the output duty is reflected at starting counter operation.

In both saw-wave mode and triangle-wave mode, when the OADTYF/OBDTYF bit is set back to 0 and the OADTY[1:0]/OBDTY[1:0] bits are set after setting the OADTYF/OBDTYF bit to 1 and setting the OADTY[1:0]/OBDTY[1:0] bits for the duty of first cycle while count operation is stopped, these duty-cycle set during stopping count operation are reflected in the first cycle and the second cycle after starting count operation.

OmDTY[1:0] bits (GTIOCnm Output Duty Setting) (m = A, B)

The OmDTY[1:0] bits set the output duty (0%, 100% or compare match control) of the GTIOCnm pin.

OmDTYF bit (Forcible GTIOCnm Output Duty Setting) (m = A, B)

The OmDTYF bit forcibly sets the output duty cycle to the OmDTY setting. Set this bit to 0 during counter operation.

- 在锯波模式下。
  UD值在上计数时设置为0时,计数方向在溢出时发生变化（GTCNT值后与计数时钟同步的计时变为GTPR值）。
  UD 值在下计数时设置为 1 时,计数方向在下流处发生变化（GTCNT 值变为 0 后与计数时钟同步的计时）。

  UD 值从 1 变为 0 时,UDF 位为 0,在计数停止时,计数器开始计数,计数方向在溢出时发生变化（GTCNT 值后与计数时钟同步的计时变为 GTPR 值）。当 UD 值从 0 变为 1 时,UDF 位为 0,计数停止时,计数器开始下计数,计数方向在下溢时发生变化（GTCNT 值变为 0 后与计数时钟同步的计时）。

  UDF 位设置为 1 计数停止时,计数开始时 UD 位值在计数方向上反映。

- 在三角波模式下。
  UD值在计数过程中发生变化时,计数方向不发生变化。UD 值在 UDF 位为 0 且计数停止的情况下发生变化时,计数开始时该变化不会反映在计数方向上。
  UDF位设置为1而停止计数时,计数开始时UD值在计数方向上反映。

UD 位（计数方向设置）

UD 位设置 GTCNT 的计数方向（上计数或下计数）。

UDF 位（强制计数方向设置）

UDF位在GTCNT开始操作时强行将计数方向设置为UD值。计数器操作时应仅将 0 写入该位。1 写入到这个位,同时计数停止,在计数开始之前将这个位返回到 0。

输出值

- 在锯波模式下。
  当 OADTY/OBDTY 值在上计数期间发生变化时,占空比反映为溢出（GTCNT = GTPR）。当 OADTY/OBDTY 值在下计数期间发生变化时,占空比反映在下溢处（GTCNT = 0)。

  当 OADTY/OBDTY 值在 OADTYF/OBDTYF 位为 0 且计数停止时发生变化时,输出占空比不会反映在开始计数器操作处。当计数方向向上时,输出占空比反映为溢出（GTCNT = GTPR）。当计数方向向下时,输出占空比反映在下溢（GTCNT = 0)。

  当 OADTY/OBDTY 值在 OADTYF/OBDTYF 位为 1 且计数停止时发生变化时,输出占空比反映在开始计数器操作时。

- 在三角波模式下。
  当 OADTY/OBDTY 值在计数过程中发生变化时,关税会反映在下溢处。
  当 OADTY/OBDTY 值在 OADTYF/OBDTYF 位为 0 且计数停止时发生变化时,输出占空比不会反映在起始计数器操作处。产出税反映在下溢处。
  当 OADTY/OBDTY 值在 OADTYF/OBDTYF 位为 1 且计数停止时发生变化时,输出占空比反映在开始计数器操作时。

在锯波模式和三角波模式下,当将OADTYF/OBDTYF位设置为0并在将OADTYF/OBDTYF位设置为1之后设置OADTY[1:0]/OBDTY[1:0]位并设置 OADTY[1:0]/OBDTY[1:0]位用于停止计数操作时第一周期的占空比, 在停止计数操作期间设置的这些占空比反映在开始计数操作之后的第一周期和第二周期中。

OmDTY[1:0] 位（GTIOCNM 输出占空比设置）（m = A、B）

OmDTY[1:0] 位设置 GTIOCNm 引脚的输出占空比(0%、100% 或比较匹配控制）。

OmDTYF 位（强制 GTIOCNM 输出占空比设置）（m = A、B）

OmDTYF 位将输出占空比强制设置为 OmDTY 设置。在计数器操作期间将此位设置为 0。

OmDTYR bit (GTIOCnm Output Value Selecting after Releasing 0%/100% Duty Setting) (m = A, B)

The OmDTYR bit selects the value that is the object of output retained or toggled at cycle end, when the control changes from 0% or 100% duty setting to compare match for the GTIOCnm pin and GTIOR.GTIOm[3:2] bits are set to 00b (output retained at cycle end) or the GTIOR.GTIOm[3:2] bits are set to 11b (output toggled at cycle end).

The GPT internally continues to perform compare match operation during duty-cycle 0% or 100% operation. When the OmDTYR bit is 1, the value after the period has elapsed due this compare match operation is target for the GTIOm[3:2] bits.

NFAEN bit (Noise Filter A Enable)

The NFAEN bit disables or enables the noise filter for input from the GTIOCnA pin. Because changing the value of the bit might lead to the internal generation of an unexpected edge, select the output compare function for the relevant pin in the GTIOR register before doing so.

NFCSA[1:0] bits (Noise Filter A Sampling Clock Select)

The NFCSA[1:0] bits set the sampling interval for the noise filter of the GTIOCnA pin. When setting these bits, wait for 2 cycles of the selected sampling interval before setting the input capture function.

GRP[1:0] bits (Output Disable Source Select)

These bits select the group of output disable request from GPT to POEG and the group of output disable for GTIOCnA pin and GTIOCnB pin from POEG to GPT.

The output disable request to POEG is output to the group selected in the GRP[1:0] bit, with dead-time errors, simultaneous high output, and simultaneous low output factors following their respective disable request enable bits.

GTST.ODF shows the request of the output disable source group that is selected with the GRP[1:0] bits. Set the GRP[1:0] bits when both GTIOR.OAE and GTIOR.OBE bits are 0.

When the GPTn_OVF/GPTn_UDF interrupt skipping function is used (the GTITC.IVTC[1:0] bits are set to a value other than 00b), the counter is incremented by 1 every time the GPTn_OVF/GPTn_UDF interrupt source selected in GTITC.IVTC[1:0] is generated. These bits are operated independently from the extended interrupt skipping by the GTEITC register.

ODF flag (Output Disable Flag)

The ODF flag shows the request of the output disable source group that is selected in the GRP[1:0] bits.

This flag indicates that the timer output toggle point after the automatic addition of dead time has exceeded the count period.

This flag returns to 0 when the timer output toggle point after the automatic addition of dead time is back within the period.

This flag can only be read from (writing 0 to clear the flag is not allowed).

When the output disable request by the DTEF flag is enabled (when GTINTAD.GRPDTE bit is 1), the DTEF flag is output as the output disable request to the POEG. The GPT does not have a dead time error interrupt. Use the interrupt function in the POEG if this is necessary.

[Setting condition]

- When a change point of the waveform after the automatic setting of dead time has exceeded the count period, in the following cases:

When the output disable request by the OABHF flag is enabled (GTINTAD.GRPABH = 1), the OABHF flag is output to POEG as an output disable request. The GPT does not have an interrupt to indicate that outputs have been simultaneous driven to the high level. Use the interrupt function in the POEG if this is necessary.

[Setting condition]

- The GTIOCnA and GTIOCnB pins output 1 at the same time when both OAE and OBE bits are set to 1.

[Clearing conditions]

该标志表示自动添加死区时间后的定时器输出切换点已超过计数周期。

当自动添加死区时间后的定时器输出切换点返回到周期内时,该标志返回到 0。

该标志只能从（不允许写入 0 来清除标志）读取。

DTEF标志的输出禁用请求时（当GTINTAD。GRPDTE位为1时）,将DTEF标志作为输出禁用请求输出给POEG,GPT没有死区时间错误中断。如果有必要,请在 POEG 中使用中断函数。

的【设置条件】

- 自动设定死区时间后波形的变化点已超过计数周期时, 在下列情况下:
  - 三角波模式下的上计数:
    GTCCRA 寄存器 – GTDVU 寄存器 ≤ 0
  - 三角波模式下的下计数:
    GTCCRA 注册 – GTDVD 注册 < 0

GTCCRA 寄存器 + GTDVU 寄存器 > GTPR 寄存器,或 GTCCRA 寄存器 GTDVD 寄存器 < 0 [清除条件]

- 自动添加死区时间后的定时器输出切换点在计数周期内。

OABHF 标志（相同时间输出级别高标志）

OABHF标志指示GTIOCnA引脚和GTIOCnB引脚同时输出1。

GTIOCnA 或 GTIOCnB 引脚输出 0 时,此标志返回到 0。此标志仅读取。禁止写0清除旗帜。

当启用 OABHF 标志的中断时（GTINTAD。GRPABH = 1),OABHF 标志将作为输出禁用请求输出到 POEG。

当启用 OABHF 标志的输出禁用请求时（GTINTAD。GRPABH = 1),OABHF 标志作为输出禁用请求输出到 POEG。GPT 没有中断来指示输出已同时驱动到高电平。如果有必要,请在 POEG 中使用中断函数。

的【设置条件】

- 当 OAE 和 OBE 位都设置为 1 时,GTIOCnA 和 GTIOCnB 引脚同时输出 1。

的【清算条件】

- The GTIOCnA pin output value is different from the GTIOCnB pin output value when both OAE and OBE bits are set to 1
- The GTIOCnA and GTIOCnB pins output 0 at the same time when both OAE and OBE bits are set to 1
- Either the OAE bit or OBE bit is set to 0.

OABLF flag (Same Time Output Level Low Flag)

The OABLF flag indicates that the GTIOCnA and GTIOCnB pins output 0 at the same time.

When the GTIOCnA pin or GTIOCnB pin outputs 1, this flag returns to 0. This flag is read only. Writing 0 to clear the flag is prohibited.

When an interrupt by the OABLF flag is enabled (GTINTAD.GRPABL = 1), the OABLF flag is output to POEG as an output disable request.

When the output disable request by the OABLF flag is enabled (GTINTAD.GRPABL = 1), the OABLF flag is output to POEG as an output disable request. The GPT does not have an interrupt to indicate that outputs have been simultaneous driven to the low level. Use the interrupt function in the POEG if this is necessary.

[Setting condition]

- The GTIOCnA and GTIOCnB pins output 0 at the same time when both OAE and OBE bits are set to 1.

[Clearing conditions]

- The GTIOCnA pin output value is different from the GTIOCnB pin output value when both OAE and OBE bits are set to 1
- The GTIOCnA and GTIOCnB pins output 1 at the same time when both OAE and OBE bits are set to 1
- Either the OAE bit or the OBE bit is set to 0.

The compare-target signals to generate the OABHF/OABLF flag are the compare match outputs (PWM outputs) signals before they are masked by the output disable function. Even during the output disable condition, compare match operation continues internally, where the OABHF or OABLF flag is updated based on the operation results.

PCF flag (Period Count Function Finish Flag)

[Setting condition]

[Clearing condition]

- 0 is written to this bit.

31	—	This bit is read as 0. The write value should be 0.	R/W

The GTBER register provides settings for the buffer operation. Set the GTBER register except the BDx (x = 0 to 3) bits while the GTCNT counter is stopped.

BD0 bit (GTCCR Buffer Operation Disable)

The BD0 bit disables the buffer operation using GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, and GTCCRF combined.

When GTDTCR.TDE is 1 and when BD0 is set to 0, GTCCRB does not perform buffer operation. The GTCCRB register is automatically set to a compare match value for negative-phase waveform with dead time.

A value for the BD0 bit in the channel related to the position of the bit written with 1 by the GTSECSR register can be set when 1 is written to the GTSECR.SBDCE or GTSECR.SBDCD.

BD1 bit (GTPR Buffer Operation Disable)

The BD1 bit disables the buffer operation using GTPR, GTPBR, and GTPDBR combined.

A value for the BD1 bit in the channel related to the position of the bit written with 1 by the GTSECSR register can be set when 1 is written to the GTSECR.SBDPE or GTSECR.SBDPD.

BD2 bit (GTADTRA/GTADTRB Registers Buffer Operation Disable)

The BD2 bit disables buffer operation using the GTADTRA, GTADTBRA, and GTADTDBRA registers together and buffer operation using the GTADTRB, GTADTBRB, and GTADTDBRB registers together.

The setting is invalid during the event count operation, and the buffer operation using the GTADTRA and GTADTRB registers is not performed.

A value for the BD2 bit in the channel related to the position of the bit written with 1 by the GTSECSR register can be set when 1 is written to the SBDAE or SBDAD bit in the GTSECR register.

BD3 bit (GTDVU/GTDVD Registers Buffer Operation Disable)

The BD3 bit disables buffer operation using the GTDVU and GTDBU registers together and buffer operation using the GTDVD and GTDBD registers together.

Even though the BD3 bit is set to 0, buffer operation in the GTDVD register is not performed if the GTDTCR.TDFER bit is set to 1. Instead, the value in the GTDVU register is set automatically.

The setting is invalid during the event count operation, and the buffer operation using the GTDVU and GTDVD registers is not performed.

A value for the BD3 bit in the channel related to the position of the bit written with 1 by the GTSECSR register can be set when 1 is written to the SBDDE or SBDDD bit in the GTSECR register.

CCRA[1:0] bits (GTCCRA Buffer Operation)

The CCRA[1:0] bits set the buffer operation with GTCCRA, GTCCRC, and GTCCRD combined. When the buffer operation is restricted by the operating mode set in GTCR, the GTCR setting is given priority.

The buffer operation mode is fixed in saw-wave one-shot pulse mode or triangle-wave PWM mode 3 (64-bit transfer at trough), or compementary PWM mode.

CCRB[1:0] bits (GTCCRB Buffer Operation)

The CCRB[1:0] bits set the buffer operation using GTCCRB, GTCCRE, and GTCCRF combined. When the buffer operation is restricted by the operating mode set in GTCR, the GTCR setting is given priority.

The buffer operation mode is fixed in saw-wave one-shot pulse mode or triangle-wave PWM mode 3 (64-bit transfer at trough), or compementary PWM mode.

GTDTCR enables automatic setting of a compare match value for negative-phase waveform with dead time. GPT has a dead time control function and DTDVU and GTDVD registers are used for setting dead time value.

The setting is invalid during the event count operation.

TDE bit (Negative-Phase Waveform Setting)

The TDE bit specifies whether to use DTDVU and GTDVD. When DTDVU and GTDVD are used, the compare match value for a negative-phase waveform with dead time obtained by the compare match value of a positive-phase waveform (GTCCRA) and the dead time value (DTDVU and GTDVD) is automatically set in GTCCRB.

The TDE bit setting is ignored in saw-wave PWM mode, and the GTCCRB is not automatic setting.

The GTCCRB value is automatically set and has the following upper and lower limit values. If the obtained GTCCRB value is not within the upper or lower limit, the following limit value is set in GTCCRB, and the GTST.DTEF flag becomes 1. However, if the obtained GTCCRB value exceeds the upper limit in triangle-wave PWM mode, the DTEF flag becomes 0.

  Lower limit value: 1 in up-counting, 0 in down-counting

GTDTCR 能够自动设置负相波形与死区的比较匹配值。GPT 具有死区时间控制功能,DTDVU 和 GTDVD 寄存器用于设置死区时间值。

在事件计数操作期间设置无效。

TDE 位（负相位波形设置）

TDE 位指定是否使用 DTDVU 和 GTDVD。当使用DTDVU和GTDVD时,通过正相波形（GTCCRA）的比较匹配值和死区时间值（DTDVU和GTDVD）获得的负相波形与死区的比较匹配值在GTCCRB中自动设置。

TDE 位设置在锯波 PWM 模式下被忽略,GTCCRB 不是自动设置。

GTCCRB值自动设置,具有以下上下限值。如果获得的GTCCRB值不在上限或下限内,则在GTCCRB中设置以下限值,并且GTST。DTEF标志变为1。
然而,如果获得的GTCCRB值超过三角波PWM模式的上限,则DTEF标志变为0。

- 三角波:
  上限值:GTPR −1
  下限值:上计数为1,下计数为0

- Saw-wave one-shot pulse mode:

TDBUE bit (GTDVU Register Buffer Operation Enable)

This bit enables buffer operation with the GTDVU and GTDBU registers combined.

The timing of buffer transfer is at troughs in triangle-wave mode, and at overflows or underflows in saw-wave mode.

TDBDE bit (GTDVD Register Buffer Operation Enable)

This bit enables buffer operation with the GTDVD and GTDBD registers combined.

The timing of buffer transfer is at troughs in triangle-wave mode, and at overflows or underflows in saw-wave mode.

When this bit and the TDFER bit are set to 1 simultaneously, the TDFER bit setting is given priority.

TDFER bit (GTDVD Register Setting)

This bit sets whether the value written to the GTDVU register is also set to the GTDVD register automatically.

Bit	Symbol	Function	R/W
31:0	n/a	GTDVk is a read/write register that sets the dead time for generating PWM waveforms with dead time. The effective size of GTDVk is the same as GTCNT (16 bits). The upper 16 bits for access in a 32-bit unit are always read as 0x0000, and writing to these bits is ignored. In triangle-waves, the GTDVU register is used for up-counting. The GTDVD register is used for down-counting. In saw-waves, the GTDVU register controls the front dead time and the GTDVD register controls the rear dead time, regardless of whether the count is up or down. Setting a GTDVk value greater than or equal to GTPR is prohibited. When using the automatic dead time setting function, do not set a value that makes a change point of the waveform exceeds the count period. The change point of the negative-phase waveform, which is automatically calculated, is obtained by reading the GTCCRB register. When GTDVk is used, writing to GTCCRB is prohibited. When this register is set to 0, waveforms without dead time are output. When the GTDTCR.TDFER bit is 1, writing to the GTDVD register has no effect. At this time, when the GTDVD register is read, the value for the GTDVU register is read. While GPT is running, changing the GTDVk values is prohibited. To change GTDVk to a new value, stop the GPT with the CST bit in the GTCR register.	R/W

31:1	—	These bits are read as 0. The write value should be 0.	R/W

The GTSOTR register temporarily releases the protected state of GTIOCnB (n = 0 to 5) pin output when output protection is set. The protected state can be released only when GTSOS.SOS[1:0] bits are 10b (protected state in which GTCCRA register ≥ GTPR register occurred during transfer at trough). The protected state cannot be released for any other case.

SOTR bit (Output Protection Function Temporary Release)

The SOTR bit sets whether to temporarily release the protected state of the GTIOCnB pin output in an output protected state. After the SOTR bit is set to 1, the output protection function is canceled from the first trough. After the SOTR bit is set to 0, output protection is resumed from the first trough.

The GTADSMR register is used to control monitors for the A/D conversion start request signal that is synchronized with a frame period.

ADSMSk[1:0] bits (A/D Conversion Start Request Signal Monitor k Selection) (k = 0, 1)

These bits are used to select A/D conversion start request signal synchronized with a frame period which is monitored by the GTASMk pin. In triangle-wave PWM mode, the following settings are prohibited:

- Set ADSMSk[1:0] bits to 00b (A/D conversion start request during up-counting) when GTADTRA = 0
- Set ADSMSk[1:0] bits to 10b (A/D conversion start request during up-counting) when GTADTRB = 0
- Set ADSMSk[1:0] bits to 01b (A/D conversion start request during down-counting) when GTADTRA = GTPR
- Set ADSMSk[1:0] bits to 11b (A/D conversion start request during down-counting) when GTADTRB = GTPR

ADSMENk bit (A/D Conversion Start Request Signal Monitor k Output Enabling) (k = 0, 1)

This bit enables or disables the monitor output to the GTADSMk pin.

When the output is disabled, the GTADSMk pin goes to the low level.

When the bit is 1, the signal on the GTADSMk pin goes to the high level on assertion of the signal to request the start of A/D conversion selected by the ADSMSk[1:0] bits. The signal then returns to the low level at the end of the current cycle of the timer for the channel that generated the given signal to request the start of A/D conversion. When the counter stops, the value is retained for output. Set the ADSMENk bit to 0 to output the low level.

When a signal to request the start of A/D conversion is generated at the end of a timer period, the generation of this signal has priority in terms of monitoring output and the output remains at the high level until the end of the next period.

When the output of the same A/D conversion start request signal monitoring output is enabled for multiple channels, ORed signals are output from the GPT.

GTADSMR 寄存器用于控制与帧周期同步的 A/D 转换开始请求信号的监视器。

ADSMSk[1:0] 位（A/D 转换开始请求信号监视器 k 选择）（k = 0 1）

这些比特用于选择与由GTASMk引脚监视的帧周期同步的A/D转换开始请求信号。在三角波 PWM 模式下,禁止以下设置:

- 将 ADSMSk[1:0] 位设置为 00b（上计数时的 A/D 转换开始请求）,当 GTADTRA = 0
- 将 ADSMSk[1:0] 位设置为 10b（上计数时的 A/D 转换开始请求）,当 GTADTRB = 0
- 在 GTADTRA = GTPR 时将 ADSMSk[1:0] 位设置为 01b（下计数期间的 A/D 转换开始请求）
- 在 GTADTRB = GTPR 时将 ADSMSk[1:0] 位设置为 11b（下计数期间的 A/D 转换开始请求）

ADSMENk 位（A/D 转换开始请求信号监视器 k 输出启用）（k = 0 1）

该位启用或禁用到 GTADSMk 引脚的监视器输出。

当输出被禁用时,GTADSMk 引脚会进入低电平。

1时,GTADSMk引脚上的信号在断言信号时进入高电平,请求ADSMSk[1:0]位选择的A/D转换的开始。然后,信号在生成给定信号的信道的定时器当前周期结束时返回到低电平,以请求开始 A/D 转换。当计数器停止时,保留该值以进行输出。将 ADSMENk 位设置为 0 以输出低电平。

当在定时器周期结束时生成请求开始A/D转换的信号时,该信号的生成在监视输出方面具有优先级,并且输出保持在高电平直到下一个周期结束。

当针对多个通道启用相同的A/D转换开始请求信号监视输出的输出时,从GPT输出ORed信号。

ICLFm[2:0] bit (GTIOCnm Output Logical Operation Function Select) (m = A, B)

These bits select the logical operation function between signals before performing output disable control for GTIOCnm. To prevent hazard to the GPT output, the signal after logical operation is latched with PCLKD. After latching, the output disable control is performed. When the logical operation function which causes the delay of 1 PCLKD is selected, the output enable signal is also delayed with 1 PCLKD and input to the output disable control.

When the same signal to operate logical function AND, OR, EXOR and NOR is selected, one signal is treated as “1”.

ICLFSELk[5:0] bit (Inter Channel Signal k Select) (k = C, D)

These bits select the signal k that the logical operation is performed with the signal before performing output disable control for GTIOCnm.

27:16	PCNT[11:0]	Period Counter Counter for the number of period	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

The GTPC register counts the number of period.

PCEN bit (Period Count Function Enable)

This bit enables or disables period count function.

Writing is available when counting is both in progress and stopped.

When 1 is written to either the GTSECR.SPCE bit or the GTSECR.SPCD bit, the value is simultaneously set to the PCEN bit in the channels set to 1 by the GTSECSR register.

ASTP bit (Automatic Stop Function Enable)

This bit enables or disables the GTCNT counter automatic stopping after finishing counting the number of period.

When the PCEN bis is 0, writing is available.

When the PCEN bit is 1, writing is disabled.

When the PCEN bit is 1, the ASTP bit is 1, and the PCNT counter is stopped at PCNT = 0, the GTCNT counter is also stopped. When the ASTP bit is 0, the GTCNT counter continues to count.

ICLFm[2:0] 位（GTIOCNm 输出逻辑操作函数选择）（m = A B）

这些位在执行 GTIOCNm 的输出禁用控制之前在信号之间选择逻辑操作函数。GPT 输出的危害,逻辑运算后的信号用 PCLKD 锁存。锁存后,执行输出禁用控制。当选择导致1PCLKD延迟的逻辑操作功能时,输出使能信号也以1PCLKD延迟并输入到输出禁用控制。

当选择操作逻辑函数 AND、OR、EXOR 和 NOR 的相同信号时,一个信号被视为 “1”。

ICLFSELk[5:0] 位（信道间信号 k 选择）（k = C、D）

这些比特在对GTIOCNm执行输出禁用控制之前选择用信号执行逻辑操作的信号k。

This counter counts the number of period.

When the PCEN bis is 0, writing the number of period is available.

When the PCEN bit is 1, writing is disabled, and down-counting is performed at the end of period. In saw-wave mode, the end of period refers to overflow, underflow, or counter clearing. In triangle-wave mode, it refers to trough.

When the PCNT counter is 1 at the end of period, it becomes 0 and counting is stopped.

When the GTCNT counter is stopped while period count function is enabled, the PCNT counter keeps its value. When the GTCNT counter restarts counting and the PCEN bit is 1, the PCNT counter restarts down-counting from the hold value.

When the PCEN bit is changed from 0 to 1 while the PCNT counter is 0 and the ASTP bit is 1, the GTCNT counter is stopped at the count clock immediately after that.

The GTSECSR register selects an intended channel n (n = 0 to 5) for updating an operation enable bit by the GTSECR register. A bit position for the GTSECSR register indicates a channel number. The GTSECSR register of each channel is a common register, and writing 1 to a bit in the GTSECSR register in any channel and updating it changes a channel, related to the position of the bit written with 1 by the GTSECSR register, to be simultaneously controlled of the operation enable bit by the GTSECR register.

The bit corresponding to channel which security attribution is configured as secure can be read by non-secure access but cannot be written by non-secure access. For example, if GPT channel 0 is configured as secure and other GPTs are

PCNT[11:0] 位（周期计数器）

该计数器计算周期数。

PCEN之二为0时,写出周期数是可用的。

PCEN 位为 1 时, 禁用写入, 期末进行下计数。在锯波模式下,周期结束是指溢出、下溢或计数器清除。在三角波模式下,它指的是波谷。

PCNT计数器在周期结束时为1时,变为0,停止计数。

当启用周期计数功能时停止 GTCNT 计数器时,PCNT 计数器保留其值。当GTCNT计数器重新开始计数且PCEN位为1时,PCNT计数器从保持值重新开始下计数。当PCEN位从0变为1而PCNT计数器为0且ASTP位为1时,GTCNT计数器在此之后立即停止在计数时钟处。

GTSECSR 寄存器选择预期信道 n（n = 0 到 5),用于更新 GTSECR 寄存器的操作使能位。GTSECSR 寄存器的位位置指示信道号。每个通道的GTSECSR寄存器是公共寄存器,并且在任何通道中将1写入GTSECSR寄存器中的比特并更新它会改变与GTSECSR寄存器用1写入的比特的位置相关的通道,以同时控制GTSECR寄存器对操作使能比特的控制。

与安全属性配置为安全的信道相对应的位可以通过非安全访问读取,但不能通过非安全访问写入。例如,如果 GPT 通道 0 被配置为安全,则其他 GPT 被配置为安全

The GTSECR register simultaneously updates the value for operation enable bits of a channel set by the GTSECSR register.

Writing 1 to a bit in the GTSECR register in any channel and updating it updates an operation enable bit for all channels, related to the position of the bit written with 1 by all GTSECSR registers.

The GTSECR register of channel which security attribution is configured as secure cannot be written by non-secure access. For example, if GPT channel 0 is configured as secure and other GPTs are configured as non-secure, the GPT16E0.GTSECR register cannot be written by non-secure access to GPT16E1.GTSECR register even if the simultaneous control of GPT channel 0 is enabled, and the simultaneous control status of GPT channel 0 is not changed.

Setting enable and disable bits for the same operation enable bit to 1 in the GTSECR is prohibited.

A bit written to 1 is automatically cleared. When the GTSECR is read, 0 is read.

Access in 8-bit or 16-bit units to the GTSECR register is prohibited, and it should be accessed in 32-bit units.

Note 1. When OPSCR.GODF = 1 and the signal value selected by the OPSCR.GRP[1:0] bit is high, the OPSCR.EN bit is set to 0.

The OPSCR register sets the output of the signal waveform required for brushless DC motor control.

UF , VF , WF bits (Input Phase Soft Setting)

The UF , VF , WF bits set the input phase from the software settings. When OPSCR.FB bit is 1, these bits are valid. The set value of the UF /VF /WF takes the place of the U/V/W external input.

U, V, W bits (Input Phase Monitor)

When the OPSCR.FB bit is 0, external inputs that are synchronized by PCLKD are monitored by these bits. When the OPSCR.FB bit is 1, the OPSCR.U, OPSCR.V, and OPSCR.W bits can read the OPSCR.UF , OPSCR.VF , and OPSCR.WF bits.

注1。OPSCR。GODF = 1 且 OPSCR。GRP[1:0] 位选择的信号值较高时,OPSCR。EN 位设置为 0。

OPSCR寄存器设置无刷直流电机控制所需的信号波形的输出。

UF、VF、WF 位（输入相位软设置）

UF、VF、WF 位从软件设置中设置输入相位。OPSCR。FB 位为 1 时,这些位是有效的。UF/VF/WF 的设定值代替 U/V/W 外部输入。

U、V、W 位（输入相位监视器）

OPSCR。FB 位为 0 时,由 PCLKD 同步的外部输入由这些位监控。当OPSCR。FB位为1时,OPSCR。U、OPSCR。V 和OPSCR。W位可以读取OPSCR。UF、OPSCR。VF和OPSCR。WF位。

EN bit (Output Phase Enable)

The EN bit controls the output enable signal of output phase (positive phase/negative phase).

When the OPSCR.EN bit is 1, the signal waveform is output.

When the OPSCR.EN bit is 0, first set OPSCR.FB, OPSCR.UF /VF /WF (software setting is selected), OPSCR.P/N, OPSCR.INV, OPSCR.RV, OPSCR.ALIGN, OPSCR.GRP[1:0], OPSCR.GODF, OPSCR.NFEN, OPSCR.NFCS. Then, set the EN bit to 1. The EN bit should be set when output disable request does not occur from POEG. Also when OPSCR.GODF is 1 and the signal value selected in the OPSCR.GRP[1:0] bit is high, the OPSCR.EN bit is set to 0. Even if 1 is written by software, the EN bit remains at 0.

For the return, after clearing the Output Disable Request by software, set the EN bit to 1.

Priority order of the EN bit is as follows (when the conflict occurs).

When writing 1 by software and clearing to 0 by the Output Disable Request conflict for the EN bit, clearing to 0 by the Output Disable Request is enabled.

FB bit (External Feedback Signal Enable)

The FB bit selects the input phase from the software settings (OPSCR.UF, VF, WF) and external input such as a Hall element.

P bit (Positive-Phase Output (P) Control)

The P bit selects one of the level signal output or PWM signal output for the positive-phase output (GTOUUP, GTOVUP and GTOWUP pins).

N bit (Negative-Phase Output (N) Control)

The N bit selects one of the level signal output or PWM signal output for the negative-phase output (GTOULO, GTOVLO and GTOWLO pins).

INV bit (Output Phase Invert Control)

The INV bit selects one of the positive logic (active-high) output or negative logic (active-low) output for the output phase.

RV bit (Output Phase Rotation Direction Reversal Control)

The RV bit reverses the direction of rotation of the motor by inverting the input phase.

ALIGN bit (Input Phase Alignment)

The ALIGN bit selects the PCLKD or PWM for the sampling of the input phase (input phase is specified in the OPSCR.FB bit).

When OPSCR.ALIGN bit is 0, input phase is aligned to PCLKD.

Note: When the chopping is performed, there are cases where the PWM width of output is shorter than the width of the PWM used to chop just before or after switching of output phase, depending on the phase difference between the phase output switch timing and the phase of PWM.

When OPSCR.ALIGN bit is 1, input phase is aligned with the falling edge of PWM.

GRP[1:0] bit (Output Disabled Source Selection)

The GRP[1:0] bit selects the output disable source.

The GRP bits should be set when GODF bit is 0. If GRP bits select a POEG except for the connected groups, the status of output pin never change to disable.

GODF bit (Group Output Disable Function)

When OPSCR.GODF is 1 and the signal value selected by the OPSCR.GRP[1:0] bit is high, the OPSCR.EN bit is set to 0.

When OPSCR.GODF bit is 0, this bit is ignored.

The GODF bit should be set when output disable request does not occur from POEG.

EN 位（输出相位启用）

EN位控制输出相位（正相位/负相位）的输出使能信号。

OPSCR。EN位为1时,信号波形输出。

当 OPSCR。EN 位为 0 时,首先设置 OPSCR。FB、OPSCR。UF/VF/WF（选择软件设置）、OPSCR。P/N、OPSCR。INV、OPSCR。RV、OPSCR。ALIGN、OPSCR。GRP[1:0]、OPSCR。GODF、OPSCR。NFEN、OPSCR。NFCS。然后,将 EN 位设置为 1。EN位应该在不从POEG发生输出禁用请求时进行设置,同样当OPSCR。GODF为1并且在OPSCR。GRP[1:0]位中选择的信号值为高时,OPSCR。EN位被设置为0。1 是由软件编写的, EN 位也保持在 0。

对于返回,通过软件清除输出禁用请求后,将 EN 位设置为 1。

EN位的优先顺序如下（冲突发生时）。

当通过软件写入 1 并通过 EN 位的输出禁用请求冲突清除到 0 时,将启用通过输出禁用请求清除到 0。

FB 位（启用外部反馈信号）

FB 位从软件设置（OPSCR。UF、VF、WF）和外部输入（例如霍尔元素）中选择输入相位。

P 位（正相位输出（P）控制）

P 位选择电平信号输出或 PWM 信号输出之一用于正相位输出（GTOUUP、GTOVUP 和 GTOWUP 引脚）。

N 位（负相位输出（N）控制）

N 位选择负相位输出（GTOULO、GTOVLO 和 GTOWLO 引脚）的电平信号输出或 PWM 信号输出之一。

INV 位（输出相位反转控制）

INV位为输出相位选择正逻辑（主动-高）输出或负逻辑（主动-低）输出之一。

RV位（输出相位旋转方向反转控制）RV位通过反转输入相位来反转电机的旋转方向。

ALIGN 位（输入相位对齐）

ALIGN 位选择 PCLKD 或 PWM 进行输入相位采样（输入相位在 OPSCR。FB 位中指定）。

当 OPSCR。ALIGN 位为 0 时,输入相位与 PCLKD 对齐。

注:当执行斩波时,在某些情况下,输出的 PWM 宽度短于输出相位切换之前或之后用于斩波的 PWM 宽度,具体取决于相位输出开关定时和相位之间的相位差PWM 的。

当 OPSCR。ALIGN 位为 1 时,输入相位与 PWM 的下降沿对齐。

GRP[1:0]位（输出禁用源选择）GRP[1:0]位选择输出禁用源。

GRP 位应该在 GODF 位为 0 时进行设置。如果 GRP 位选择除连接组之外的 POEG,则输出引脚的状态永远不会更改为禁用。

GODF 位（组输出禁用函数）

当OPSCR。GODF为1并且OPSCR。GRP[1:0]位选择的信号值为高时,OPSCR。EN位被设置为0。

OPSCR。GODF 位为 0 时,该位将被忽略。

当 POEG 未发生输出禁用请求时,应设置 GODF 位。

NFEN bit (External Input Noise Filter Enable)

The NFEN bit selects the noise filter for external input. When OPSCR.NFEN bit is 0, a noise filter for the external input is not used.

Note: Set this bit during the EN bit is 0 to avoid generation of unintentional internal edge caused by switching this bit.

NFCS[1:0] bits (External Input Noise Filter Clock Selection)

The NFCS[1:0] bits select the clock for the external input noise filter. When the OPSCR.NFEN bit is 1, noise filter sampling clock setting of the external input is enabled.

1. Set the NFCS[1:0].
2. Wait for 2 cycles.
3. Set the OPSCR.EN bit to 1.

20.3 Operation

20.3.1 Basic Operation

Each channel has a 16-bit timer that performs a periodic count operation using the count clock and hardware sources. The count function provides both up-counting and down-counting. The GTPR controls the count cycle.

When the GTCNT counter value matches the value in GTCCRA or GTCCRB, the output from the associated GTIOCnA or GTIOCnB can be changed (n = 0 to 5). GTCCRA or GTCCRB can be used as an input capture register with hardware resources.

GTCCRC and GTCCRD can function as buffer registers for GTCCRA. GTCCRE and GTCCRF can function as buffer registers for GTCCRB.

20.3.1.1 Counter operation

(1) Counter start and stop

The counter of each channel starts the count operation when GTCR.CST is set to 1, and stops counting when the bit is set to 0. The GTCR.CST bit value is changed by the following sources:

- Writing to GTCR register
- Writing 1 to the bit in GTSTR associated with the GPT channel number when the GTSSR.CSTRT bit set to 1
- Writing 1 to the bit in GTSTP associated with the GPT channel number when the GTPSR.CSTOP bit set to 1
- The hardware source selected in the GTSSR register
- The hardware source selected in the GTPSR register
- Completion of the period count function while the GTPC.ASTP bit is 1

(2) Periodic count operation in up-counting by count clock

The GTCNT counter in each channel starts up-counting when the associated GTCR.CST bit is set to 1 with GTUPSR and GTDNSR registers set to 0x00000000. When the GTCNT value changes from the GTPR value to 0 (overflow), the GTST.TCFPO flag is set to 1, and the overflow interrupt(GPTn_OVF) is also generated. After GTCNT overflows, up-counting resumes from 0x00000000.

Figure 20.3 shows an example of a periodic count operation in up-counting by the count clock.

NFEN 位（启用外部输入噪声滤波器）

NFEN 位选择噪声滤波器进行外部输入。当OPSCR。NFEN位为0时,不使用外部输入的噪声滤波器。

Note:在 EN 位期间设置此位为 0,以避免因切换此位而产生无意内部边缘。

NFCS[1:0] 位（外部输入噪声滤波器时钟选择）

NFCS[1:0] 位为外部输入噪声滤波器选择时钟。OPSCR。NFEN 位为 1 时,启用外部输入的噪声滤波采样时钟设置。

1。设置 NFCS[1:0]。

3锌　　娴　　。将 OPSCR。EN 位设置为 1。

20。3 操作

20。3。1 基本操作

每个通道都有一个 16 位定时器,使用计数时钟和硬件源执行周期性计数操作。计数功能提供上计数和下计数。GTPR 控制计数周期。

当GTCNT计数器值与GTCCRA或GTCCRB中的值匹配时,关联的GTIOCnA或GTIOCnB的输出可以改变（n=0至5)。GTCCRA 或 GTCCRB 可用作具有硬件资源的输入捕获寄存器。

GTCCRC 和 GTCCRD 可以充当 GTCCRA 的缓冲寄存器。GTCCRE 和 GTCCRF 可以充当 GTCCRB 的缓冲寄存器。

20。3。1。1 柜台操作

(1)计数器启动和停止

当GTCR。CST设置为1时,每个通道的计数器开始计数操作,当位设置为0时停止计数。GTCR。CST 位值由以下来源更改:

- 写入 GTCR 寄存器
- 当 GTSSR。CSTRT 位设置为 1 时,将 1 写入与 GPT 信道号关联的 GTSTR 中的位
- 当 GTPSR。CSTOP 位设置为 1 时,将 1 写入与 GPT 信道号关联的 GTSTP 中的位
- GTSSR 寄存器中选择的硬件源
- GTPSR 寄存器中选择的硬件源
- 完成周期计数函数,而 GTPC。ASTP 位为 1

(2) 按计数时钟上计数的周期性计数操作

当关联的GTCR。CST位设置为1且GTUPSR和GTDNSR寄存器设置为0x00000000时,每个通道中的GTCNT计数器开始上计数。GTCNT值从GTPR值变为0（溢出）时,GTST。TCFPO标志被设置为1,溢出中断（GPTn_OVF）也生成。GTCNT溢出后,从0x00000000恢复上计数。

图20。3示出了计数时钟上计数中的周期性计数操作的示例。

6	Start count operation	Set the GTCR.CST bit to 1 to start count operation.

(3) Periodic count operation in down-counting by count clock

The GTCNT counter in each channel can perform down-counting by setting GTUDDTYC.UD with GTUPSR and GTDNSR registers set to 0x00000000. When GTCNT changes from 0 to the GTPR value (underflow), GTST.TCFPU is set to 1, and the underflow interrupt(GPTn_UDF) is also generated. After the GTCNT counter underflows, down-counting resumes from the GTPR value.

(3) 按计数时钟下计数的周期性计数操作

每个通道中的 GTCNT 计数器可以通过将 GTUDDTYC。UD 设置为 GTUPSR 和 GTDNSR 寄存器设置为 0x00000000 来执行下计数。GTCNT 从 0 变为 GTPR 值（下溢）时,GTST。TCFPU 设置为 1,同时还生成下溢中断（GPTn_UDF）。GTCNT 计数器下溢后,从 GTPR 值恢复下计数。

5	Set initial value for counter	Set the initial value in the GTCNT counter. In Figure 20.4, the GTPR register value is set.
6	Start count operation	Set the GTCR.CST bit to 1 to start count operation. In Figure 20.4, 1 is set in the CST bit.

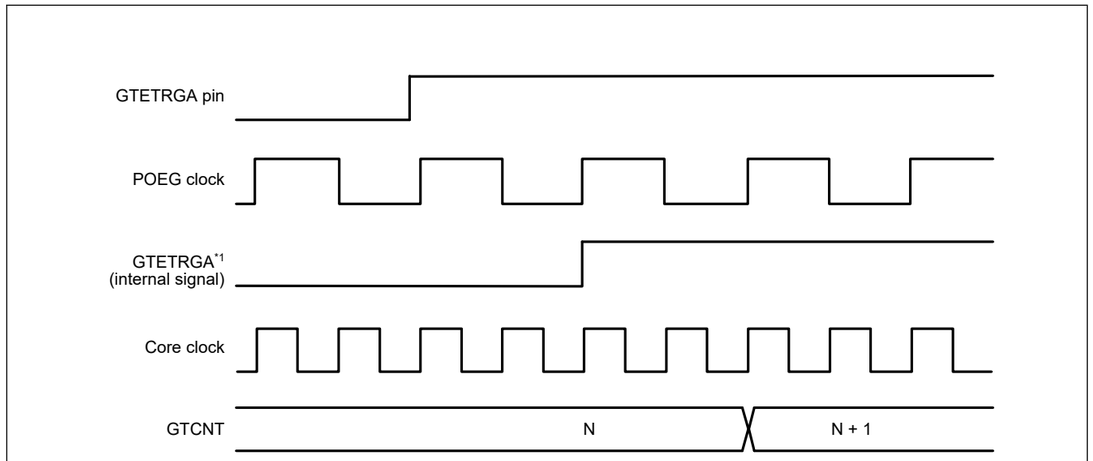
(4) Event count operation in up-counting using hardware sources

The GTCNT counter in each channel can perform up-counting using hardware sources as set in GTUPSR.

When GTUPSR is set to enable, the count clock selected in GTCR.TPCS[3:0] and the count direction selected in GTUDDTYC.UD are ignored. If up-counting and down-counting using hardware sources occur at the same time, the GTCNT counter value does not change. The overflow behavior when up-counting using hardware sources is the same as when up-counting by the count clock.

If you are using a hardware source to count up, set the GTCR.CST bit to 1 to enable the counting operation. After GTCR.CST is set to 1, the counter cannot count up for 1 clock cycle as specified in GTCR.TPCS[3:0] because the count operation is synchronized by the count clock selected in GTCR.TPCS[3:0]. Set GTCR.TPCS[3:0] to 000b to count up with a 1 PCLKD delay after GTCR.CST is set to 1.

Figure 20.5 shows an example of an event count operation in up-counting by a hardware resource (the rising edge of GTETRGA pin input).



Note: POEG clock :PCLKB, Core clock : PCLKD
Note 1. The GTETRGA internal signal reflects the signal being input to the GPT when the digital noise filter for the GTETRGA pin in the POEG is not in use.

6	开始计数操作	将GTCR。CST位设置为1以开始计数操作。 在图20。4中,1设置在CST位中。

(4)使用硬件源上计数中的事件计数操作

每个通道中的 GTCNT 计数器可以使用 GTUPSR 中设置的硬件源执行上计数。

GTUPSR设置为启用时,GTCR。TPCS[3:0]中选择的计数时钟和GTUDDTYC。UD中选择的计数方向被忽略。如果同时使用硬件源进行上计数和下计数,则GTCNT计数器值不会改变。使用硬件源上计数时的溢出行为与计数时钟上计数时的溢出行为相同。

如果您使用硬件源进行计数,请将 GTCR。CST 位设置为 1 以启用计数操作。GTCR。CST 设置为 1 后,计数器无法按照 GTCR。TPCS[3:0] 中指定的 1 个时钟周期进行计数,因为计数操作是由 GTCR。TPCS[3:0] 中选择的计数时钟同步的。将 GTCR。TPCS[3:0] 设置为 000b,以便在 GTCR。CST 设置为 1 后以 1 PCLKD 延迟计数。

注1。当 POEG 中 GTETRGA 引脚的数字噪声滤波器不使用时,GTETRGA 内部信号反映了输入到 GPT 的信号。

2	Set cycle	Set the cycle in the GTPR register.
3	Set initial value for counter	Set the initial value in the GTCNT counter.
4	Start count operation	Set the GTCR.CST bit to 1 to start count operation.

(5) Event count operation in down-counting using hardware sources

The GTCNT counter in each channel can perform down-counting using hardware sources set in the GTDNSR.

When GTDNSR is set to enable, the count clock selected in GTCR.TPCS[3:0] and the count direction selected in GTUDDTYC.UD are ignored. If up-counting and down-counting using hardware sources occur at the same time, the GTCNT counter value does not change. The underflow behavior when down-counting using hardware sources is the same as when down-counting by the count clock.

When GTCR.CST bit is set to 1 to count down using hardware sources, the count operation is enabled. After GTCR.CST is set to 1, the counter cannot count down for 1 clock cycle as specified in GTCR.TPCS[3:0] because the count operation is synchronized with the count clock selected in GTCR.TPCS[3:0]. Set GTCR.TPCS[3:0] to 000b to count down with a 1 PCLKD delay after GTCR.CST is set to 1.

(5) 硬件源下计数中的事件计数操作

每个通道中的GTCNT计数器可以使用GTDNSR中设置的硬件源执行下计数。

GTDNSR设置为启用时,GTCR。TPCS[3:0]中选择的计数时钟和GTUDDTYC。UD中选择的计数方向被忽略。如果同时使用硬件源进行上计数和下计数,则GTCNT计数器值不会改变。使用硬件源下计数时的下溢行为与计数时钟下计数时的下溢行为相同。

当GTCR。CST位设置为1以使用硬件源倒计时时,启用计数操作。GTCR。CST 设置为 1 后,计数器无法按照 GTCR。TPCS[3:0] 中指定的 1 个时钟周期进行倒计时,因为计数操作与 GTCR。TPCS[3:0] 中选择的计数时钟同步。将GTCR。TPCS[3:0]设置为000b,以便在GTCR。CST设置为1之后以1 PCLKD延迟倒计时。

No.	Step Name	Description
3	Set initial value for counter	Set the initial value in the GTCNT counter.

(6) Counter clear operation

The counter of each channel is cleared by following sources:

- Writing 0 to GTCNT register
- Writing 1 to the bit in GTCLR associated with the GPT channel number when the GTCSR.CCLR bit set to 1
- The hardware source selected in GTCSR register.

Writing to the GTCNT register is prohibited during count operation. The GTCNT counter can be cleared both by writing 1 to the GTCLR and by the clear request of hardware sources, whether GTCNT is counting (GTCR.CST is 1) or not (GTCR.CST is 0).

When the count direction flag is set as decrement (GTST.TCUF flag = 0) in saw-wave mode selected with GTCR.MD[2:0] bits, the GTCNT register is set to the value of the GTPR register when writing 1 to the GTCLR register and when clearing by hardware sources are performed.

When not in saw-waves mode and down-counting, the GTCNT register is set to 0 when writing 1 to the GTCLR register and when clearing by hardware sources are performed.

In event count operation when at least 1 bit in the GTUPSR or GTDNSR is set to 1, after clear sources occur, both writing to GTCLR register and clearing by hardware sources are performed immediately to synchronize with PCLKD. If other settings are used, clear is synchronized with the counter clock selected in GTCR.TPCS[3:0].

20.3.1.2 Waveform output by compare match

Compare match means that the GTCNT counter value matches the value of GTCCRA or GTCCRB. When a compare match occurs, the compare match flag is generated synchronously with the count clock, including the event count. At the same time, the GPT can output low, high, or toggled output from the associated GTIOCnA or GTIOCnB output pin (n = 0 to 5). In addition, the GTIOCnA or GTIOCnB pin output can be low, high, or toggled at the cycle end which is determined by GTPR.

The cycle end is:

- For saw waves in up-counting – when GTCNT changes from the GTPR value to 0 (overflow)
- For saw waves in down-counting – when GTCNT changes from 0 to GTPR value (underflow)
- For saw waves – when the GTCNT counter is cleared
- For triangle waves – when the GTCNT changes from 0 to 1 (trough).

(1) Low output and high output

Figure 20.7 shows an example of low output and high output operation by a compare match of GTCCRA and GTCCRB.

In this example, the GTCNT counter performs up-counting, and settings are made so that high is output from the GTIOCnA pin by a GTCCRA compare match, and low is output from the GTIOCnB pin by a GTCCRB compare match. The pin level does not change when the specified level and pin level match.

不。	步骤名称	描述
3	设置计数器的初始值	GTCNT 计数器中设置初始值。
4	开始计数操作	将GTCR。CST位设置为1以开始计数操作。

（六）反清操作

每个通道的计数器由以下来源清除:

- 将 0 写入 GTCNT 寄存器
- 当 GTCSR。CCLR 位设置为 1 时,将 1 写入与 GPT 信道号关联的 GTCLR 中的位
- GTCSR 寄存器中选择的硬件源。

计数操作期间禁止写入 GTCNT 寄存器。无论 GTCNT 是否计数（GTCR。CST 为 1）（GTCR。CST 为 0),都可以通过向 GTCLR 写入 1 以及硬件源的明确请求来清除 GTCNT 计数器。

当在使用GTCR。MD[2:0]位选择的锯波模式下将计数方向标志设置为递减（GTST。TCUF标志=0)时,当写入1时,GTCNT寄存器被设置为GTPR寄存器的值。GTCLR 寄存器以及执行硬件源清除时。

当不处于锯波模式和下计数时,当向GTCLR寄存器写入1以及执行硬件源清除时,GTCNT寄存器被设置为0。

当GTUPSR或GTDNSR中的至少1位设置为1时,在事件计数操作中,在发生清除源之后,立即执行写入GTCLR寄存器和硬件源清除以与PCLKD同步。如果使用其他设置,则 clear 与 GTCR。TPCS[3:0] 中选择的计数器时钟同步。

20.3.1.2 通过比较匹配输出波形

比较匹配是指GTCNT计数器值与GTCCRA或GTCCRB的值匹配。当发生比较匹配时,比较匹配标志与计数时钟（包括事件计数）同步生成。同时,GPT 可以从相关的 GTIOCnA 或 GTIOCnB 输出引脚输出低、高或切换输出（n = 0 至 5)。此外,GTIOCnA或GTIOCnB引脚输出可以在由GTPR确定的循环端低、高或切换。

循环结束时间为:

- 对于 GTCNT 从 GTPR 值变为 0（溢出）时上计数 – 中的锯波
- 对于 GTCNT 从 0 变为 GTPR 值（下流）时下计数 – 中的锯波
- 对于 GTCNT 计数器清除时的锯波 –
- 对于 GTCNT 从 0 变为 1（波谷）时的三角波 –。

(1)低产量高产量

图20。7显示了GTCCRA和GTCCRB的比较匹配的低输出和高输出操作的示例。

在此示例中,GTCNT计数器执行上计数,并且进行设置使得GTCCRA比较匹配从GTIOCNA引脚输出高,并且GTCCRB比较匹配从GTIOCNB引脚输出低。当指定的级别和引脚级别匹配时,引脚级别不会改变。

20.3.1.3 Input Capture Function

The GTCNT counter value can be transferred to either GTCCRA or GTCCRB on detection of the hardware source that is set in GTICASR and GTICBSR.

In this example, the GTCNT counter performs up-counting by the count clock, and settings are made so that an input capture is performed to GTCCRA at both edges of the GTIOCnA input pin and to GTCCRB on the rising edge of the GTIOCnB input pin.

20.3.2 Buffer Operation

The following buffer operations can be set with GTBER:

- GTPR, GTPBR, and GTPDBR
- GTCCRA, GTCCRC, and GTCCRD
- GTCCRB, GTCCRE, and GTCCRF
- GTADTRA, GTADTBRA, and GTADTDBRA
- GTADTRB, GTADTBRB, and GTADTDBRB

The following buffer operation is enabled by setting GTDTCR:

- GTDVU and GTDBU
- GTDVD and GTDBD

20.3.2.1 GTPR Register Buffer Operation

GTPBR can function as a buffer register for GTPR.

GTPDBR register can function as a buffer register for the GTPBR register (double-buffer register for the GTPR register).

The buffer transfer is performed at an overflow (during up-counting) or an underflow (during down-counting) in saw-wave mode or in event count, and at a trough in triangle-wave mode.

In saw-wave mode or in event count, the buffer transfer is performed when the following counter clear operations occur during counting:

- Clear by hardware sources (the clear source is selected in GTCSR register)
- Clear by software (when GTCSR.CCLR bit is 1 and GTCLR.CCLRn bit is set to 1, n = 0 to 5).

To set the GTPR register to function as double buffer, set the GTBER.PR[1:0] bits to 10b or 11b. For single buffer operation, set the bits to 01b. To set the GTPR register to not function as buffer, set the bits to 00b.

Figure 20.11 to Figure 20.13 show examples of GTPR buffer operation and Table 20.12 shows an example for setting GTPR buffer operation.

20。3。2 缓冲区操作

GTBER 可以设置以下缓冲区操作:

- GTPR、GTPBR 和 GTPDBR
- GTCCRA、GTCCRC 和 GTCCRD
- GTCCRB、GTCCRE 和 GTCCRF
- GTADTRA、GTADTBRA 和 GTADTDBRA
- GTADTRB、GTADTBRB 和 GTADTDBRB

通过设置 GTDTCR 启用以下缓冲区操作:

- GTDVU 和 GTDBU
- GTDVD 和 GTDBD

20。3。2。1 GTPR 注册缓冲区操作

GTPBR 可以充当 GTPR 的缓冲寄存器。

GTPDBR寄存器可以用作GTPBR寄存器的缓冲寄存器（GTPR寄存器的双缓冲寄存器）。缓冲器传输在锯波模式或事件计数中的溢出（在上计数期间）或下溢（在下计数期间）以及三角波模式中的波谷处执行。

在锯波模式或事件计数中,当计数过程中发生以下计数器清除操作时,执行缓冲区传输:

- 按硬件源清除（清除源在GTCSR寄存器中选择）
- 通过软件清除（当 GTCSR。CCLR 位为 1 且 GTCLR。CCLRn 位设置为 1 时,n = 0 到 5)。

GTPR寄存器设置为双缓冲区功能,请将GTBER。PR[1:0]位设置为10b或11b。对于单个缓冲区操作,将位设置为 01b。GTPR 寄存器设置为不用作缓冲区,请将位设置为 00b。

9	Set buffer value for each cycle	For buffer operation, set a value in one cycle after the current cycle in the GTPBR register. For double buffer operation, also set a period value for the cycle after the next cycle in the GTPDBR register.

20.3.2.2 Buffer Operation for GTCCRA and GTCCRB Registers

GTCCRC can function as the GTCCRA buffer register and GTCCRD can function as the GTCCRC buffer register (double-buffer register for GTCCRA). Similarly, GTCCRE can function as the GTCCRB buffer register and GTCCRF can function as the GTCCRE buffer register (double-buffer register for GTCCRB).

To set GTCCRA or GTCCRB to function as a double buffer, set GTBER.CCRA[1:0] or GTBER.CCRB[1:0] to 10b or 11b. For single buffer operation, set 01b. To set GTCCRA or GTCCRB to not function as a buffer, set 00b.

In saw-wave one-shot pulse mode and triangle-wave PWM mode 3, the buffer operations that each specific PWM output operation mode are performed regardless of the setting of GTBER.CCRA [1:0] bits and GTBER.CCRB [1:0] bits.

9	设置每个周期的缓冲区值	对于缓冲区操作,在 GTPBR 寄存器中当前周期后的一个周期内设置一个值。 对于双缓冲区操作,还为下一个周期之后的周期设置周期值 GTPDBR 注册。

20。3。2。2 GTCCRA 和 GTCCRB 寄存器的缓冲器操作

GTCCRC 可以充当 GTCCRA 缓冲寄存器,GTCCRD 可以充当 GTCCRC 缓冲寄存器（GTCCRA 的双缓冲寄存器）。类似地,GTCCRE 可以充当 GTCCRB 缓冲寄存器,GTCCRF 可以充当 GTCCRE 缓冲寄存器（GTCCRB 的双缓冲寄存器）。

要将 GTCCRA 或 GTCCRB 设置为双缓冲区,请将 GTBER。CCRA[1:0] 或 GTBER。CCRB[1:0] 设置为 10b 或 11b。对于单个缓冲区操作,设置 01b。要将 GTCCRA 或 GTCCRB 设置为不用作缓冲区,请设置 00b。

在锯波一次脉冲模式和三角波PWM模式3中,无论GTBER。CCRA[1:0]位和GTBER。CCRB[1:0]位。

(1) When GTCCRA or GTCCRB Functions as Output Compare Register

In saw-wave one-shot pulse mode, triangle-wave PWM mode 3, the buffer operations that each specific PWM output operation mode are performed regardless of the setting of GTBER.CCRA [1:0] bits and GTBER.CCRB [1:0] bits. For details, see section 20.3.3. PWM Output Operating Mode. Other than the specified PWM output operation modes, buffer transfer occurs in the following situations:

- Buffer transfer by overflow or underflow
  Buffer transfer is performed at an overflow (during up-counting) or an underflow (during down-counting) in saw-wave mode or in event count operation. In triangle-wave mode, buffer transfer is performed at a trough (triangle-wave PWM mode 1) or a crest and trough (triangle-wave PWM mode 2).
- Buffer transfer by counter clear
  In saw-wave mode or in event count operation, during counting, buffer transfer (which is the same as an overflow during up-counting or an underflow during down-counting) is performed by the counter clear sources similar to the case shown in section 20.3.2.1. GTPR Register Buffer Operation.
  In triangle-wave mode, buffer transfer is not performed by the counter clear.
- Forcible buffer transfer
  When GTBER.CCRSWT bit is set to 1 while the count operation is stopped, the GTCCRA and the GTCCRB register buffer transfer are performed forcibly in saw-wave mode, in event count operation and in triangle-wave mode.
  Additionally buffer transfer from the GTCCRD register to temporary register A and from the GTCCRF register to temporary register B are performed in saw-wave one-shot pulse mode or triangle-wave PWM mode 3.

Figure 20.14 to Figure 20.16 show examples of GTCCRA and GTCCRB buffer operation and Table 20.13 shows an example for setting GTCCRA and GTCCRB buffer operation.

- 通过溢出或底流进行缓冲区传输
  在锯波模式或事件计数操作中,在溢出（上计数期间）或下溢（下计数期间）处执行缓冲区传输。在三角波模式下,缓冲器传输在波谷（三角波 PWM 模式 1)或波峰和波谷（三角波 PWM 模式 2)处执行。
- 通过计数器清除的缓冲区传输
  在锯波模式或事件计数操作中,在计数期间,缓冲区传输（与上计数期间的溢出或下计数期间的下溢相同）由计数器清除源执行,类似于第 20。3 节中所示的情况。2。1。GTPR 注册缓冲区操作 .
  在三角波模式下,计数器清除不会执行缓冲区传输。
- 强行缓冲区传输
  当在计数操作停止时将GTBER。CCRSWT位设置为1时,在锯波模式、事件计数操作和三角波模式下强制执行GTCCRA和GTCCRB寄存器缓冲器传输。
  另外,在锯波一次脉冲模式或三角波PWM模式3中执行从GTCCRD寄存器到临时寄存器A以及从GTCCRF寄存器到临时寄存器B的缓冲器传输。

20.3.2.3 Buffer Operation for GTADTRA and GTADTRB Registers

The GTADTBRA register can function as the GTADTRA buffer register and the GTADTDBRA register can function as the GTADTBRA buffer register (double buffer register for the GTADTRA register). Similarly, the GTADTBRB register can function as the GTADTRB buffer register and the GTADTDBRB register can function as the GTADTBRB buffer register (double buffer register for the GTADTRB register).

To set the GTADTRA or GTADTRB register to function as a double buffer, set the GTBER.ADTDA or ADTDB bit to 1. For single buffer operation, set the bit to 0. To set the GTADTRA or GTADTRB register not to function as buffer, set the GTBER.ADTTA[1:0] or ADTTB[1:0] bits to 00b.

The buffer transfer timing can be set with the ADTTA[1:0] and ADTTB[1:0] bits to an overflow (in up-counting) or an underflow (in down-counting) in saw-wave mode, with ADTTA[1:0] and ADTTB[1:0] bits set to 01b for a crest, to 10b for a trough, or to 11b for both crest and trough in triangle-wave mode.

In saw-wave mode, when the ADTTA[1:0] and ADTTB[1:0] bits are set to value other than 00b and in count operation, the buffer transfer, by similar counter clearing sources in section 20.3.2.1. GTPR Register Buffer Operation, is performed in the same way at an overflow (in up-counting) or an underflow (in down-counting).

Figure 20.19 to Figure 20.21 show examples of buffer operation for the GTADTRA and GTADTRB registers, and Table 20.15 shows an example of setting buffer operation for the GTADTRA and GTADTRB registers.

20。3。2。3 GTADTRA 和 GTADTRB 寄存器的缓冲区操作

GTADTBRA寄存器可以用作GTADTRA缓冲寄存器,GTADTDBRA寄存器可以用作GTADTBRA缓冲寄存器（GTADTRA寄存器的双缓冲寄存器）。类似地,GTADTBRB寄存器可以用作GTADTRB缓冲寄存器,并且GTADTDBRB寄存器可以用作GTADTBRB缓冲寄存器（GTADTRB寄存器的双缓冲寄存器）。

要将 GTADTRA 或 GTADTRB 寄存器设置为双缓冲区,请将 GTBER。ADTDA 或 ADTDB 位设置为 1。对于单个缓冲区操作,将位设置为 0。要将 GTADTRA 或 GTADTRB 寄存器设置为不用作缓冲区,请将 GTBER。ADTTA[1:0] 或 ADTTB[1:0] 位设置为 00b。

ADTTA[1:0]和ADTTB[1:0]位可以设置缓冲区传输定时为锯波模式下的溢出（在上计数中）或下溢（在下计数中）,其中ADTTA[1:0]和ADTTB[1:0]位设置为波峰为01b,波谷为10b, 或三角波模式下波峰和波谷均为 11b。

在锯波模式下,当 ADTTA[1:0] 和 ADTTB[1:0] 位被设置为 00b 以外的值并且在计数操作中,缓冲区由第 20。3。2。1 节中的类似计数器清除源传输。GTPR 寄存器缓冲区操作,在溢出（上计数）或下溢（下计数）时以相同的方式执行。

For double buffer operation, also set the A/D conversion start request point in two cycles after the current cycle (in saw-wave mode or triangle-wave mode with buffer transfer at trough or crest) or one cycle after the current cycle (in triangle-wave mode with buffer transfer at both trough and crest) in the GTADTDBRA and GTADTDBRB registers.

20.3.3 PWM Output Operating Mode

The GPT can output PWM waveforms to the GTIOCnA or GTIOCnB pin (n = 0 to 5) by a compare match between the GTCNT counter and GTCCRA or GTCCRB.

By setting GTDTCR, GTDVU, and GTDVD, the compare match value for a negative-phase waveform with dead time can automatically be set to GTCCRB.

20.3.3.1 Saw-Wave PWM Mode

In saw-wave PWM mode, GTCNT performs saw-wave (half-wave) operation by setting the cycle in GTPR and a PWM waveform is output to the GTIOCnA or GTIOCnB pin (n = 0 to 5) when a GTCCRA or GTCCRB compare match occurs. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the cycle end according to the GTIOR setting.

The timing of the cycle end and the timing of GTCCRx (x = A, B) register compare match are of the same time and the output pin together with the PWM output setting for the cycle end are set by the GTIOR.GTIOx[3:2] bits.

Figure 20.22 shows an example of saw-wave PWM mode operation, and Table 20.16 shows an example for setting saw-wave PWM mode.

表 20。15 GTADTRA 和 GTADTRB 寄存器的设置缓冲区操作示例(2 中的 2)

11	设置每个周期的缓冲区值	对于缓冲区操作,在当前周期（在锯波模式或三角波模式下,缓冲区在槽或波峰传输）之后的一个周期或当前周期（在三角波模式下）之后的半周期中设置 A/D 转换开始请求点GTADTBRA 和 GTADTBRB 寄存器中,缓冲区在槽和波峰传输模式）。 对于双缓冲区操作,还可以在当前周期之后的两个周期（在锯波模式或三角波模式下,缓冲区在波谷或波峰处传输）或当前周期之后的一个周期（在三角波模式下）设置 A/D 转换开始请求点。GTADTDBRA 和 GTADTDBRB 寄存器中的波谷和波峰均有缓冲区传输。

20。3。3 PWM 输出操作模式

GPT 可以通过 GTCNT 计数器与 GTCCRA 或 GTCCRB 之间的比较匹配将 PWM 波形输出到 GTIOCnA 或 GTIOCnB 引脚（n = 0 至 5)。

通过设置GTDTCR、GTDVU和GTDVD,可以将具有死区的负相位波形的比较匹配值自动设置为GTCCRB。

20。3。3。1 锯波 PWM 模式

在锯波 PWM 模式下,GTCNT 通过在 GTPR 中设置周期来执行锯波（半波）操作,并且当 GTCCRA 或 GTCCRB 比较时,PWM 波形被输出到 GTIOCnA 或 GTIOCnB 引脚（n = 0 至 5)发生匹配。引脚输出值可以从低输出、高输出或切换输出中单独选择,以便根据 GTIOR 设置进行比较匹配和循环结束。

循环结束的定时和GTCCRx（x=A,B）寄存器比较匹配的定时是相同的,并且输出引脚与循环结束的PWM输出设置一起由GTIOR。GTIOx[3:2]位设置。

20.3.3.2 Saw-Wave One-Shot Pulse Mode

The saw-wave one-shot pulse mode is a mode in which the cycle is set in GTPR, the GTCNT counter performs saw-wave (half-wave) operation and a PWM waveform is output to the GTIOCnA or GTIOCnB pin (n = 0 to 5) at a compare match of GTCCRA or GTCCRB with buffer operation fixed.

Buffer operation in saw-wave one-shot pulse mode is different from the usual buffer operation. Buffer transfer is performed from:

- GTCCRC to GTCCRA at the cycle end
- GTCCRE to GTCCRB at the cycle end
- GTCCRD to temporary register A at the cycle end
- GTCCRF to temporary register B at the cycle end
- Temporary register A to GTCCRA at a GTCCRA compare match
- Temporary register B to GTCCRB at a GTCCRB compare match.

The pin output value can be selected from low output, high output, or toggled output separately for a compare match and the cycle end according to the GTIOR setting. When the GTBER.CCRSWT bit is set to 1 while count operation is stopped, the buffer is transferred forcibly from the GTCCRD register to temporary register A and from the GTCCRF register to temporary register B. By setting GTDTCR, GTDVU, and GTDVD, a compare match value for a negative-phase waveform with dead time can automatically be set to GTCCRB.

Figure 20.23 shows an example of saw-wave one-shot pulse mode operation, and Table 20.17 shows an example for setting saw-wave one-shot pulse mode.

20。3。3。2 锯波一击脉冲模式

锯波单次脉冲模式是在 GTPR 中设置周期的模式,GTCNT 计数器执行锯波（半波）操作,并将 PWM 波形输出到 GTIOCnA 或 GTIOCnB 引脚（n = 0 至 5) 在 GTCCRA 或 GTCCRB 的比较匹配下,缓冲区操作固定。

锯波一次脉冲模式下的缓冲区操作与通常的缓冲区操作不同。缓冲区传输从以下位置执行:

- GTCCRC 在循环结束时转为 GTCCRA
- GTCCRE 在循环结束时转换为 GTCC
- GTCCRD 在循环结束时临时寄存器 A
- GTCCRF 在循环结束时临时寄存器 B
- 在 GTCCRA 比较比赛中将 A 临时寄存器寄存到 GTCCRA
- 在 GTCCRB 比较匹配中将 B 临时寄存器寄存到 GTCCRB。

引脚输出值可以根据GTIOR设置从低输出、高输出或切换输出中单独选择,以进行比较匹配和循环结束。当停止计数操作时将 GTBER。CCRSWT 位设置为 1 时,缓冲区将从 GTCCRD 寄存器强制传输到临时寄存器 A,从 GTCCRF 寄存器强制传输到临时寄存器 B。通过设置 GTDTCR、GTDVU 和 GTDVD,可以自动将具有死区的负相波形的比较匹配值设置为 GTCCRB。

20.3.3.3 Triangle-Wave PWM Mode 1 (32-Bit Transfer at Trough)

The triangle-wave PWM mode 1 is a mode in which the cycle is set in GTPR. The GTCNT counter performs triangle-wave (full-wave) operation, and a PWM waveform is output to the GTIOCnA or GTIOCnB pin (n = 0 to 5) when a GTCCRA or GTCCRB compare match occurs. Buffer transfer is performed at the trough. The pin output value can be selected from low output, high output, or toggled output separately for a compare match and for the cycle end according to the GTIOR setting.

By setting GTDTCR, GTDVU, and GTDVD, a compare match value for a negative-phase waveform with dead time can automatically be set to GTCCRB.

Figure 20.24 shows an example of a triangle-wave PWM mode 1 operation, and Table 20.18 shows an example for setting a triangle-wave PWM mode 1.

20.3.3.4 Triangle-Wave PWM Mode 2 (32-Bit Transfer at Crest and Trough)

Similarly to triangle-wave PWM mode 1, in triangle-wave PWM mode 2 the cycle is set in GTPR. The GTCNT counter performs triangle-wave (full-wave) operation, and a PWM waveform is output to the GTIOCnA or GTIOCnB pin (n = 0 to 5) when a GTCCRA or GTCCRB compare match occurs. The buffer transfer is performed at both crests and troughs. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the cycle end according to the GTIOR setting.

By setting GTDTCR, GTDVU, and GTDVD, a compare match value for a negative-phase waveform with dead time can automatically be set to GTCCRB.

20.3.3.5 Triangle-Wave PWM Mode 3 (64-Bit Transfer at Trough)

The triangle-wave PWM mode 3 is a mode in which the cycle is set in GTPR. The GTCNT counter performs triangle-wave (full-wave) operation and a PWM waveform is output to the GTIOCnA or GTIOCnB pin (n = 0 to 5) at a compare match of GTCCRA or GTCCRB with buffer operation fixed. Buffer operation in triangle-wave PWM mode 3 is different from the usual buffer operation. Buffer transfer is performed from the following:

- GTCCRC to GTCCRA at the trough
- GTCCRE to GTCCRB at the trough
- GTCCRD to temporary register A at the trough
- GTCCRF to temporary register B at the trough
- Temporary register A to GTCCRA at the crest
- Temporary register B to GTCCRB at the crest.

The pin output value can be selected from low output, high output, or toggled output separately for a compare match and for the cycle end according to the GTIOR setting.

By setting GTDTCR, GTDVU, and GTDVD, a compare match value for a negative-phase waveform with dead time can automatically be set to GTCCRB.

20.3.3.5 三角波 PWM 模式 3（波谷 64 位传输）

三角波PWM模式3是在GTPR中设置周期的模式。GTCNT 计数器执行三角波（全波）操作,并且在 GTCCRA 或 GTCCRB 与缓冲区操作固定的比较匹配下,PWM 波形被输出到 GTIOCnA 或 GTIOCnB 引脚（n = 0 至 5)。三角波 PWM 模式 3 中的缓冲区操作与通常的缓冲区操作不同。缓冲区传输由以下内容执行:

- GTCCRC 到 GTCCRA 的低谷

- GTCCRF 在槽处临时寄存器 B
- 在波峰处将临时寄存器 A 寄存到 GTCCRA

20.3.4 Automatic Dead Time Setting Function

By setting GTDTCR, a compare match value for a negative waveform with dead time obtained by a compare match value for a positive waveform (GTCCRA value) and specified dead time value (GTDVU and GTDVD value) can automatically be set to GTCCRB. The automatic dead time setting function can be used in saw-wave one-shot pulse mode and all the triangle PWM modes.

Dead time can be separately set for the first half and second half of a waveform. Dead time for the changing point in the first half of a negative waveform is set in the GTDVU register and that in the second half is set in GTDVD register. The same dead time can also be set for the first and second halves by setting the GTDTCR.TDFER bit to 1.

The GTDBU register can be used as a buffer register of the GTDVU register, and the GTDBD register can be used as a buffer register of the GTDVD register. Buffer transfer is performed at the end of the cycle (in saw-wave mode, either an overflow of the GTCNT counter (up-counting), an underflow (down-counting), the GTCNT counter clearing or in triangle wave mode, a trough).

The change point of the negative-phase waveform, which is automatically calculated, is obtained by reading the GTCCRB register. Writing to GTCCRB is prohibited when the automatic dead time setting function is used.

Do not set the dead time that makes the change point of the waveform exceeds the count period. When any dead-time setting that can generate a dead-time error is made, adjust the change points of the positive- and negative-phase waveforms to generate waveforms with secured dead-time as shown in Table 20.21. The adjusted change point of the negative-phase waveform is automatically set in the GTCCRB register. An internal signal determines the change point of the positive-phase waveform, therefore the value of the GTCCRA register is not updated by the adjusted value.

In saw-wave one-shot pulse mode, if the order of the change point becomes inconsistent by adjustment of the waveform change point due to occurrence of dead time errors, or if the change point exceeds the count period even after the adjustment, the complementary relation between the positive- and negative-phases cannot be guaranteed.

In triangle-wave PWM mode, if dead time exceeds the count period by setting 0x0000 0000 or a value greater than or equal to the setting value of the GTPR register is set in the GTCCRA register, output change is controlled by the output protection function (see section 20.8.4. Output Protection Function for GTIOCnm Pin Output). When the GTCCRA register is greater than or equal to [GTPR register + GTDVm (m = U, D) register], [GTPR register - 1] is set in the GTCCRB register as the upper limit.

Automatic setting for a dead time value to the GTCCRB register is performed at the next count clock after the register value for calculating the automatic setting value is updated. In triangle-wave mode, it can also be done at the next count clock from the current crest.

20.3.4 自动死区时间设置功能

通过设置GTDTCR,可以将负波形与死区时间的比较匹配值与正波形的比较匹配值（GTCCRA值）和指定的死区时间值（GTDVU和GTDVD值）自动设置为GTCCRB。自动死区时间设置功能可用于锯波一次脉冲模式和所有三角形PWM模式。

波形的前半部分和后半部分可以单独设置死区时间。负波形前半部分变化点的死区时间设置在 GTDVU 寄存器中,后半部分设置在 GTDVD 寄存器中。还可以通过将 GTDTCR。TDFER 位设置为 1 来为第一半和第二半设置相同的死区时间。

GTDBU寄存器可以用作GTDVU寄存器的缓冲寄存器,GTDBD寄存器可以用作GTDVD寄存器的缓冲寄存器。缓冲区传输在周期结束时执行（在锯波模式下,GTCNT 计数器溢出（上计数）、下溢（下计数）、GTCNT 计数器清除或在三角波模式下,槽）。

自动计算的负相波形的变化点是通过读取GTCCRB寄存器获得的。使用自动死区时间设置功能时禁止写入GTCCRB。

请勿设置使波形变化点超过计数周期的死区时间。当做出任何可能产生死区时间误差的死区时间设置时,调整正负相位波形的变化点以生成具有安全死区的波形,如表20。21所示。GTCCRB寄存器中自动设置负相波形的调整后的变化点。内部信号决定正相波形的变化点,因此GTCCRA寄存器的值不会通过调整后的值来更新。

在锯波一次脉冲模式下,如果由于死区时间误差的发生,通过调整波形变化点,变化点的顺序变得不一致,或者即使在调整后,变化点也超过计数周期,则正负相之间的互补关系无法保证。

在三角波PWM模式下,如果死区时间通过设置0x0000 0000超过计数周期,或者在GTCCRA寄存器中设置大于或等于GTPR寄存器设置值的值,则输出变化由输出保护功能控制（参见第 20。8。4 节。GTIOCNm引脚输出的输出保护功能）。GTCCRA寄存器大于或等于[GTPR寄存器 + GTDVm（m = U,D）寄存器]时,在GTCCRB寄存器中设置[GTPR寄存器1]作为上限。

在更新用于计算自动设置值的寄存器值之后,在下一个计数时钟执行对GTCCRB寄存器的死区时间值的自动设置。在三角波模式下,也可以在当前波峰的下一个计数时钟完成。

20.3.5 Count Direction Changing Function

The count direction of the GTCNT counter can be changed by modifying the UD bit in GTUDDTYC.

In saw-wave mode, if the UD bit in GTUDDTYC is modified during count operation, the count direction is changed at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the GTUDDTYC.UD bit is modified while the count operation stops and the GTUDDTYC.UDF bit is 0, the GTUDDTYC.UD

20。3。5 计数方向改变功能

GTCNT计数器的计数方向可以通过修改GTUDDTYC中的UD位来改变。

在锯波模式下,如果在计数操作期间修改了GTUDDTYC中的UD位,则在溢出（在上计数期间修改时）或下溢（在下计数期间修改时）时改变计数方向。如果在计数操作停止且GTUDDTYC。UDF位为0时修改GTUDDTYC。UD位,则 GTUDDTYC。UD

bit modification is not reflected at the start of counting and the count direction is changed at an overflow or an underflow. If the UDF bit is set to 1 while the count operation stops, the GTUDDTYC.UD bit value at that time is reflected at the start of counting.

In triangle-wave mode, the count direction does not change even though the UD bit in GTUDDTYC is modified during the count operation. Similarly, even though the GTUDDTYC.UD bit is modified while the count operation stops and GTUDDTYC.UDF bit is 0, the GTUDDTYC.UD bit value is not reflected to the count operation. If the GTUDDTYC.UDF bit is set to 1 while the count operation is stopped, the GTUDDTYC.UD bit value at that time is reflected at the start of counting.

If the count direction changes during a saw-wave count operation, the GTPR value after the start of up-counting is reflected in the count cycle during up-counting and the GTPR value after the start of down-counting is reflected in the count cycle during down-counting.

Figure 20.31 shows an example of count direction changing function operation.

20.3.6 Function of Output Duty 0% and 100%

The output duty of the GTIOCnA pin and the GTIOCnB pin (n = 0 to 5) are set to 0% or 100% by changing the GTUDDTYC.OADTY bit or GTUDDTYC.OBDTY bit.

In saw-wave mode, if the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified during the count operation, the output duty setting is reflected at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF bit or the GTUDDTYC.OBDTYF bit is 0, the output duty modification is not reflected at the start of counting. The output duty changes at an overflow or an underflow. If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF bit or the GTUDDTYC.OBDTYF bit is 1, the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit value at that time is reflected at the start of counting.

In triangle-wave mode, if the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified during the count operation, the output duty setting is reflected an underflow.

If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF bit or the GTUDDTYC.OBDTYF bit is 0, the output duty modification is not reflected at the start of counting. The output duty changes at an underflow. If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is

位修改在计数开始时不会反映,并且在溢出或下溢时计数方向会改变。如果在计数操作停止时将UDF位设置为1,则在计数开始时反映当时的GTUDDTYC。UD位值。

在三角波模式下,即使在计数操作期间修改了GTUDDTYC中的UD位,计数方向也不会改变。类似地,即使在计数操作停止且GTUDDTYC。UDF位为0时修改GTUDDTYC。UD位,GTUDDTYC。UD位值也不会反映到计数操作中。如果在计数操作停止时将GTUDDTYC。UDF位设置为1,则在计数开始时反映当时的GTUDDTYC。UD位值。

如果在锯波计数操作期间计数方向发生变化,则上计数开始后的GTPR值反映在上计数期间的计数周期中,下计数开始后的GTPR值反映在计数周期中在下计数期间。

图20。31示出了计数方向改变函数操作的示例。

20.3.6 输出占空比 0% 和 100% 的函数

通过改变GTUDDTYC。OADTY位或GTUDDTYC。OBDTY位,将GTIOCnA引脚和GTIOCnB引脚（n=0至5）的输出占空比设置为0%或100%。

在锯波模式下,如果在计数操作期间修改了 GTUDDTYC。OADTY 位或 GTUDDTYC。OBDTY 位,则输出占空比设置会反映在溢出（在上计数期间修改时）或下溢（在下计数期间修改时）。如果在停止计数操作并且GTUDDTYC。OADTYF位或GTUDDTYC。OBDTYF位为0的同时修改GTUDDTYC。OADTYF位或GTUDDTYC。OBDTYF位,则在计数开始时不反映输出占空比修改。输出占空比在溢出或下溢时发生变化。如果 GTUDDTYC。OADTY 位或 GTUDDTYC。OBDTY 位在计数操作停止且 GTUDDTYC。OADTYF 位或 GTUDDTYC。OBDTYF 位为 1 时被修改,则 GTUDDTYC。OADTY 位或 GTUDDTYC。OBDTY 位值在计数开始时反映该时间。

在三角波模式下,如果在计数操作期间修改GTUDDTYC。OADTY位或GTUDDTYC。OBDTY位,则输出占空比设置被反映为下溢。

如果在停止计数操作并且GTUDDTYC。OADTYF位或GTUDDTYC。OBDTYF位为0的同时修改GTUDDTYC。OADTYF位或GTUDDTYC。OBDTYF位,则在计数开始时不反映输出占空比修改。输出占空比在下溢时发生变化。如果 GTUDDTYC。OADTY 位或 GTUDDTYC。OBDTY 位是

modified while the count operation stops and the GTUDDTYC.OADTYF bit or the GTUDDTYC.OBDTYF bit is 1, the output duty modification is reflected at the start of counting.

In performing 0% or 100% duty operation, GPT internally continues to:

- Perform compare match operation
- Set compare match flag
- Output interrupt
- Perform buffer operation.

When the control is changed from 0% or 100% duty setting to compare match, the output value of GTIOCnA pin at cycle end is decided by GTIOR.GTIOA[3:2] and GTUDDTYC.OADTYR. The output value of GTIOCnB pin at cycle end is decided by GTIOR.GTIOB[3:2] and GTUDDTYC.OBDTYR.

When GTIOR.GTIOA[3:2] and GTIOR.GTIOB[3:2] are set to 01b, the output pins output low at cycle end. When GTIOR.GTIOA[3:2] and GTIOR.GTIOB[3:2] are set to 10b, the output pins output high at cycle end.

GTUDDTYC.OADTYR selects the value that is the object of output retained/toggled at cycle end, when GTIOR.GTIOm[3:2] are set to 00b (output retained at cycle end) or when GTIOR.GTIOm[3:2] are set to 11b (output toggled at cycle end). Table 20.24 shows the values of GTIOCnA and GTIOCnB pin output at cycle end.

当计数操作停止并且GTUDDTYC。OADTYF位或GTUDDTYC。OBDTYF位为1时修改,输出占空比修改反映在计数开始时。

0% 或 100% 关税操作时, GPT 内部继续:

- 执行比较匹配操作
- 设置比较匹配标志
- 输出中断
- 执行缓冲区操作。

0% 或 100% 占空比设置控制进行对比匹配时, 循环结束时 GTIOCnA 引脚的输出值由 GTIOR。GTIOA[3:2] 和 GTUDDTYC。OADTYR 决定。GTIOCNB 引脚在循环结束时的输出值由 GTIOR。GTIOB[3:2] 和 GTUDDTYC。OBDTYR 决定。

GTIOR。GTIOA[3:2] 和 GTIOR。GTIOB[3:2] 设置为 01b 时,输出引脚在循环结束时输出较低。GTIOR。GTIOA[3:2] 和 GTIOR。GTIOB[3:2] 设置为 10b 时,输出引脚在循环结束时输出高电平。

GTUDDTYC。OADTYR 选择作为循环结束时保留/切换的输出对象的值,当 GTIOR。GTIOm[3:2] 设置为 00b（循环结束时保留输出）或当 GTIOR。GTIOm[3:2] 设置为 11b（循环结束时切换输出）。表 20。24 显示了循环结束时 GTIOCnA 和 GTIOCnB 引脚输出的值。

20.3.8 Synchronized Operation

Synchronized operation on channels such as a synchronized start, stop, and clear operation can be performed.

20.3.8.1 Synchronized Operation by Software

The GTCNT counters can be started, stopped, and cleared on multiple channels by setting the associated GTSTR, GTSTP, or GTCLR bits simultaneously to 1.

Count start with a phase difference is possible by setting the initial value in the GTCNT counter and setting the associated GTSTR bits simultaneously to 1.

GPTn_OVF/GPTn_UDF（n = 0 到 5) 中断（溢出/下溢中断）不会在计数器被硬件源或软件清除时产生。

图 20。38 显示了硬件源的计数器清除与 GPTn_OVF（n = 0 至 5)中断之间的关系。

20。3。8 同步操作

可以对诸如同步开始、停止和清除操作之类的通道进行同步操作。

20.3.8.1 通过软件同步操作

GTCNT 计数器可以通过同时将关联的 GTSTR、GTSTP 或 GTCLR 位设置为 1 来在多个通道上启动、停止和清除。

通过在 GTCNT 计数器中设置初始值并将关联的 GTSTR 位同时设置为 1,可以以相位差开始计数。

Because the clock of count operation is selected by GTCR.TPCS[3:0] bits in respective channels, if the clock period of each channel that performs synchronous operation (count start/stop/clear) is different from others, the synchronous operation timings of every channels are not exactly the same.

Figure 20.39 shows an example of a simultaneous start, stop, and clear by software. Figure 20.40 shows an example of phase start operation by software.

Figure 20.41, Figure 20.42, and Figure 20.43 show an example of simultaneous start/stop/clearing with different count period.

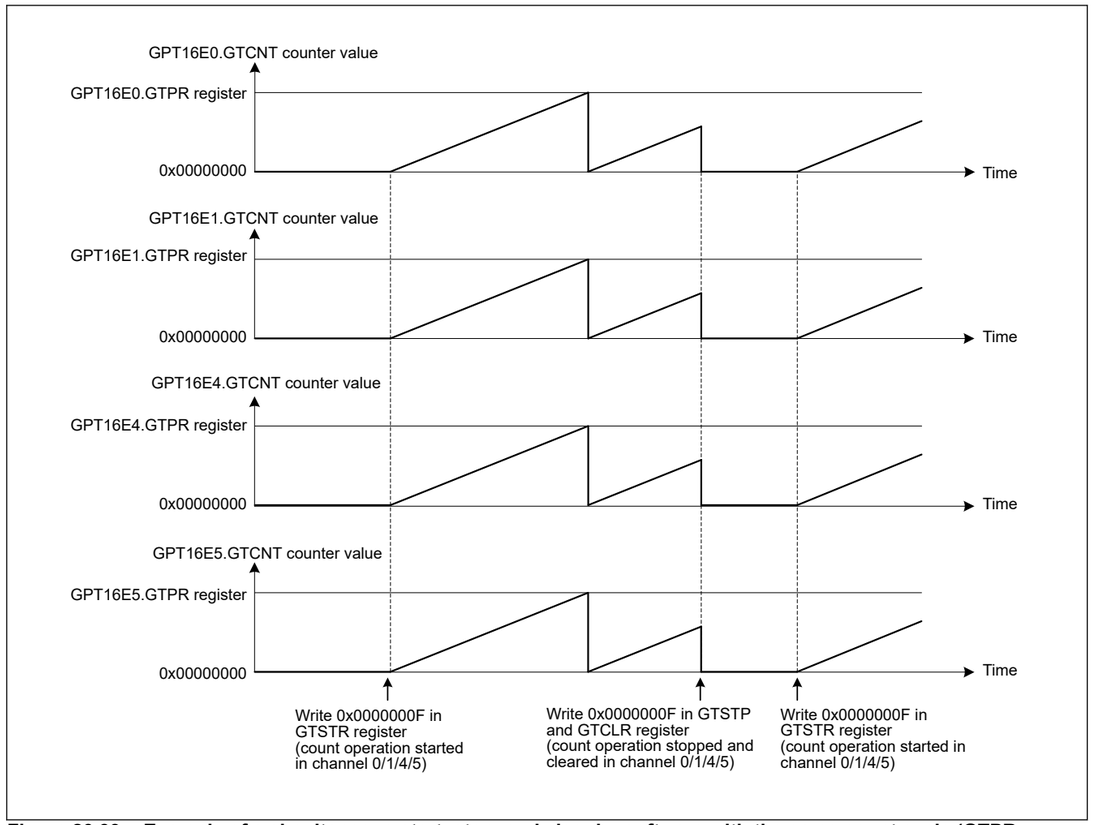

Figure 20.39 Example of a simultaneous start, stop, and clear by software with the same count cycle (GTPR register value)

由于计数时钟操作是由GTCR。TPCS[3:0]位在各个信道中选择的,因此如果执行同步操作（计数开始/停止/清除）的每个信道的时钟周期与其他信道不同,则每个信道的同步操作时序并不完全相同。

图 20。39 显示了通过软件同时启动、停止和清除的示例。图 20。40 显示了软件相位启动操作的示例。

20.3.8.2 Synchronized Operation by Hardware

The counters for multiple channels can be started, stopped, and cleared simultaneously by the following hardware sources. Hardware sources that can cause a synchronized operation are external trigger input and ELC event input. Synchronized operation through the GTIOCnA and GTIOCnB pin inputs is possible by setting an ELC event due to input capture as a hardware source (n = 0 to 5).

Figure 20.44 shows an example of a simultaneous start, stop, and clear operation by a hardware source. Table 20.29 shows the setting example.

20.3.8.2 硬件同步操作

以下硬件源可以同时启动、停止和清除多个通道的计数器。可能导致同步操作的硬件源是外部触发输入和 ELC 事件输入。通过将输入捕获导致的 ELC 事件设置为硬件源（n = 0 到 5),可以通过 GTIOCnA 和 GTIOCnB 引脚输入进行同步操作。

20.3.10 Period Count Function

By setting the GTPC register, the end of period can be counted.

The number of period to be counted should be set into the GTPC.PCNT counter when the GTPC.PCEN bit is 0. When the PCEN bit is 1, the PCNT counter can be read, but writing is disabled. When the PCEN bit is 1, down-counting is performed at the end of period. When the PCNT counter is 1 at the end of period, it becomes 0 and counting is stopped to finish the period count function. At that time, the GTST.PCF flag is set, and the period count function finish interrupt request GPTn_PC is generated. When the GTPC.ASTP bit is 1, the GTCNT counter is also stopped at the same time that the period count function is finished.

When the GTCNT counter is stopped while period count function is enabled, the PCNT counter keeps its value. When the GTCNT counter restarts counting and the PCEN bit is 1, the PCNT counter restarts down-counting from the hold value.

When the PCEN bit is changed from 0 to 1 while the PCNT counter is 0 and the ASTP bit is 1, the GTCNT counter is stopped at the count clock immediately after that.

When either GTSECR.SPCE bit or GTSECR.SPCD bit is set to 1, the PCEN bit in the channels set to 1 by the GTSECSR register is simultaneously set the value to enable or disable the period count function for multiple channels.

Figure 20.51 and Figure 20.52 show examples of PWM cycle count function.

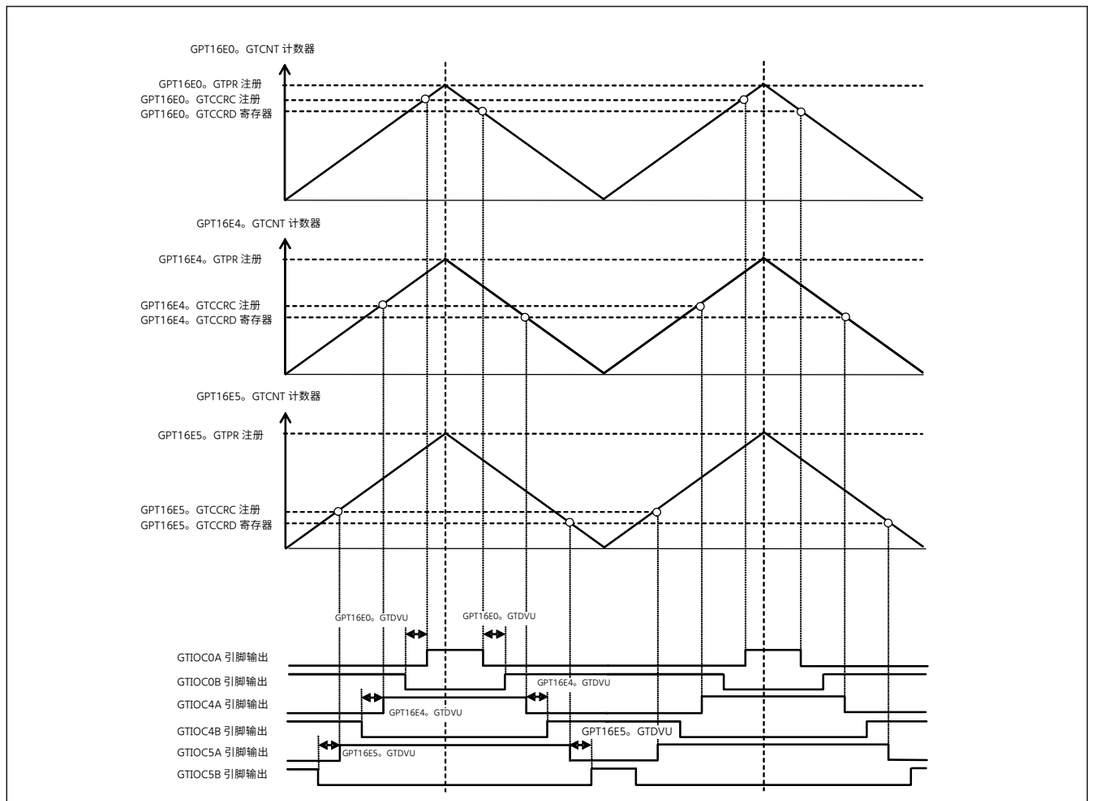

图20。50 具有自动死区时间设置的 3 相非对称三角波互补 PWM 输出示例

20。3。10 周期计数函数

通过设置 GTPC 寄存器,可以计算周期结束时间。

当GTPC。PCEN位为0时,应将要计数的周期数设置到GTPC。PCNT计数器中。PCEN位为1时,可以读取PCNT计数器,但禁止写入。PCEN位为1时,在周期结束时进行下计数。PCNT计数器在周期结束时为1时,变为0,停止计数,完成周期计数功能。时GTST。PCF标志被设置,并生成周期计数函数完成中断请求GPTn_PC。GTPC。ASTP位为1时,GTCNT计数器也在周期计数功能结束的同时停止。

当启用周期计数功能时停止 GTCNT 计数器时,PCNT 计数器保留其值。当GTCNT计数器重新开始计数且PCEN位为1时,PCNT计数器从保持值重新开始下计数。当PCEN位从0变为1而PCNT计数器为0且ASTP位为1时,GTCNT计数器在此之后立即停止在计数时钟处。

当GTSECR。SPCE位或GTSECR。SPCD位被设置为1时,GTSECSR寄存器设置为1的信道中的PCEN位同时被设置值以启用或禁用多个信道的周期计数功能。

20.3.11 Phase Counting Function

The phase difference between the GTIOCnA and GTIOCnB pin (n = 0 to 5) inputs is detected and the associated GTCNT counts up or counts down. The detectable phase difference is available in any combination with the relationship between the edge and the level of GTIOCnA and GTIOCnB pin inputs being set in the GTUPSR and GTDNSR registers. For details on count operation, see section 20.3.1.1. Counter operation.

Figure 20.53 to Figure 20.62 show an example of phase counting modes 1 to 5 operation when the GTIOCnA, GTIOCnB pins are used. Table 20.30 to Table 20.39 show conditions of up-counting or down-counting and list settings for the GTUPSR and GTDNSR registers which is corresponding to Figure 20.53 to Figure 20.62.

20。3。11 相位计数功能

检测 GTIOCNA 和 GTIOCNB 引脚（n = 0 至 5)输入之间的相位差,相关 GTCNT 向上计数或向下计数。可检测的相位差可与 GTUPSR 和 GTDNSR 寄存器中设置的 GTIOCNA 和 GTIOCNB 引脚输入的边缘和电平之间的关系任意组合。有关计数操作的详细信息,请参阅第 20。3。1。1 节。计数器操作 .

20.3.12 Output Phase Switching (GPT_OPS)

GPT_OPS provides a function for easy control of brushless DC motor operation using the Output Phase Switching Control Register (OPSCR).

GPT_OPS outputs a PWM signal to be used for chopper control or level signal for each phase (U-positive phase/negative phase, V-positive phase/negative phase, W-positive phase/negative phase) of the 6-phase motor control. This function uses a soft setting value (OPSCR.UF, VF, WF) set by software or external signals detected by the Hall element, a PWM waveform of GPT16E0.GTIOC0A.

Figure 20.63 shows the conceptual diagram of GPT_OPS control flow.

20.3.12 输出相位切换（GPT_OPS）

GPT_OPS 提供了一种使用输出相位开关控制寄存器（OPSCR）轻松控制无刷直流电机运行的功能。

GPT_OPS 输出一个 PWM 信号,用于 6 相电机控制的每相（U 阳相/阴相、V 阳相/阴相、W 阳相/阴相）的斩波器控制或电平信号。该功能使用软件设置的软设置值（OPSCR。UF、VF、WF）或霍尔元件检测到的外部信号（GPT16E0 的 PWM 波形）。GTIOC0A。

20.3.12.1 Input Selection and Synchronization of External Input Signal

In the GPT_OPS control flow conceptual diagram shown in Figure 20.63, (1) is a selection of input phase from the software settings and external input by the OPSCR.FB bit.

When OPSCR.FB bit is 0, select the external input. Enable the input signal after synchronization with the GPT core clock (PCLKD). After carrying out noise filtering (optional), set the external input to the input phase of PWM (PWM of GPT16E0.GTIOC0A) using falling edge sampling with OPSCR.ALIGN bit set to 1.

When OPSCR.FB bit is 1, select the soft setting (OPSCR.UF, VF, WF) with the value of the input phase of PWM (PWM of GPT16E0.GTIOC0A) using falling edge sampling with OPSCR.ALIGN bit set to 1.

When OPSCR.ALIGN bit is 0, GPT_OPS operates with the input phase of PCLKD synchronization with either OPSCR.FB bit set to 0 or OPSCR.FB bit set to 1. However, there are cases where the PWM pulse width of the output U/V/W phases (PWM output mode) of switch timing (just before/just after) is shortened.

Table 20.40 shows the input selection process and setting of associated OPSCR bits.

20。3。12。1 外部输入信号的输入选择与同步

20。63所示的GPT_OPS控制流概念图中,(1)是从软件设置中选择输入相位,由OPSCR。FB位外部输入。

OPSCR。FB 位为 0 时,选择外部输入。GPT核心时钟（PCLKD）同步后启用输入信号。进行噪声滤波（可选）后,将外部输入设置为PWM的输入相位（GPT16E0的PWM）。GTIOC0A）使用 OPSCR。ALIGN 位设置为 1 的下降沿采样。

当OPSCR。FB位为1时,选择具有PWM输入相位值（GPT16E0的PWM）的软设置（OPSCR。UF、VF、WF）。GTIOC0A）使用 OPSCR。ALIGN 位设置为 1 的下降沿采样。

当 OPSCR。ALIGN 位为 0 时,GPT_OPS 使用 PCLKD 同步的输入相位进行操作,OPSCR。FB 位设置为 0 或 OPSCR。FB 位设置为 1。然而,在某些情况下,开关定时（就在之前/之后）的输出U/V/W相位（PWM输出模式）的PWM脉冲宽度被缩短。

表 20。40 显示了相关 OPSCR 位的输入选择过程和设置。

20.3.12.2 Input Sampling

The OPSCR.U, V, W bits indicate the PCLKD sampling results of the input selected in the OPSCR.FB bit.

When OPSCR.FB bit is 0 and after synchronization with the GPT core clock (PCLKD) and noise filtering (optional), OPSCR.U, V, W bits indicate the sampling results of the external input. When OPSCR.FB bit is 1, OPSCR.U, V, W bits are the value (OPSCR.UF, VF, WF) of the soft setting.

20.3.12.3 Input Phase Decode

In the GPT_OPS control flow conceptual diagram shown in Figure 20.63, (3) enables the 6-phase signals by decoding the input phase selected in the OPSCR.FB bit.

20.3.12.4 Rotation Direction Control

In the GPT_OPS control flow conceptual diagram shown in Figure 20.63, (2) controls the direction of rotation of a 3-phase motor using the OPSCR.RV bit.

When the rotation direction is reverse (RV bit = 1), the input phase is inverted.

20.3.12.5 Output Selection Control

In the GPT_OPS control flow conceptual diagram in Figure 20.63, (4) represents the selection of the output waveform by setting the OPSCR register bit.

For output selection, the following bits are relevant:

- The OPSCR.EN bit controls whether to output the 6-phase output, or to stop
- The OPSCR.P and OPSCR.N bits can select from the level signal or PWM signal (chopper output) for the output phase
- The polarity of the output phase can be set to a positive logic or negative logic by the OPSCR. INV bit.

对于输出选择,以下位相关:

- OPSCR。EN 位控制是输出 6 相输出,还是停止
- OPSCR。P 和 OPSCR。N 位可以从输出相位的电平信号或 PWM 信号（斩波器输出）中进行选择
- 输出相位的极性可由 OPSCR 设置为正逻辑或负逻辑。INV 位。

20.3.12.6 Output Selection Control (Group Output Disable Function)

When OPSCR.GODF is 1 and the signal value selected by the OPSCR.GRP bit is high (output disable request), the group output-disable function asynchronously sets the output to Hi-Z. When an output-disable request is generated, the OPSCR.EN bit is cleared to 0. For the return, set the OPSCR.EN bit to 1 after clearing the output disable request by software.

To ensure output-disable control, use the POEG_GROUPn (n = A to D) interrupt to clear the flag in the POE or check that the OPSCR.EN bit is 0 and then clear the flag. For an example of the operation for group output disable control, see Figure 20.66.

OPSCR。GODF为1且OPSCR。GRP位选择的信号值高时（输出禁用请求）,组输出禁用函数异步将输出设置为Hi-Z,当产生输出禁用请求时,OPSCR。EN位被清除为0。对于返回,在清除软件的输出禁用请求后,将 OPSCR。EN 位设置为 1。

为了确保输出禁用控制,请使用 POEG_GROUPn（n = A 到 D）中断清除 POE 中的标志或检查 OPSCR。EN 位为 0,然后清除标志。组输出禁用控制的操作示例,请参见图 20。66 .

20.3.12.7 Event Link Controller (ELC) Output

In the GPT_OPS control flow conceptual diagram shown in Figure 20.63, (5) outputs the Hall sensor input signal edge to the ELC.

The Hall sensor input edge signal is the logical OR of the rising and falling edge signals of each U-phase/V-phase/W-phase input sampled at PCLKD. That is, if the high period of each of the U-phase/V-phase/W-phase of the input phase is short in duration, the Hall sensor edge input signal is not output at that time.

When the OPSCR.FB bit is 0, the Hall sensor input edge signal is the logical OR of the edge signals of the external input phase sampled at PCLKD.

When OPSCR.FB bit is 1, the Hall sensor input edge signal is the logical OR of the edge of the soft setting (OPSCR.UF, VF, WF) sampled at PCLKD.

See Figure 20.64 to Figure 20.66 for examples of the output signal to the ELC.

20.3.13 Inter-Channel Logical Operation Function

The logical operation function between compare match outputs can be performed.

Figure 20.67 shows the block diagram of inter-channel logical operation.

To prevent hazard to the GPT output, the signal after logical operation is latched with PCLKD. After latching, the output disable control is performed.

When the logical operation function which causes the delay of 1 PCLKD is selected, the output enable signal is also delayed with 1 PCLKD and input to the output disable control.

When the same signal (C = A or D = B) to operate logical function AND, OR, EXOR and NOR is selected, C or D is treated as 1. For GTIOCnA pin output, when A of the same channel is selected for C, the result of AND is A, the result of OR is 1, the result of EXOR is NOT A, and the result of NOR is 0.

20。3。12。7 事件链路控制器（ELC）输出

20。63所示的GPT_OPS控制流概念图中,(5)将霍尔传感器输入信号边输出到ELC。

Hall传感器输入边缘信号是在PCLKD处采样的每个U相/V相/W相输入的上升和下降边缘信号的逻辑OR。即,如果输入相的U相/V相/W相中的每一个的高周期持续时间短,则此时霍尔传感器边缘输入信号不输出。

OPSCR。FB 位为 0 时,霍尔传感器输入边缘信号是在 PCLKD 处采样的外部输入相位边缘信号的逻辑 OR。

当OPSCR。FB位为1时,霍尔传感器输入边缘信号是在PCLKD采样的软设置（OPSCR。UF、VF、WF）边缘的逻辑OR。

20.3.13 通道间逻辑操作功能

可以执行比较匹配输出之间的逻辑运算函数。

图20。67示出了信道间逻辑操作的框图。

GPT 输出的危害,逻辑运算后的信号用 PCLKD 锁存。锁存后,执行输出禁用控制。

当选择导致1PCLKD延迟的逻辑操作功能时,输出使能信号也以1PCLKD延迟并输入到输出禁用控制。

当选择操作逻辑函数 AND、OR、EXOR 和 NOR 的相同信号（C = A 或 D = B）时,C 或 D 被视为 1。GTIOCnA引脚输出,当对C选择同一通道的A时,AND的结果为A,OR的结果为1,EXOR的结果不是A,NOR的结果为0。

20.4 Interrupt Sources

20.4.1 Interrupt Sources

The GPT provides the following interrupt sources:

- GTCCR input capture/compare match
- GTADTR compare match
- GTCNT counter overflow (GTPR compare match)/underflow
- period count function finish

Each interrupt source has its own status flag. When an interrupt source signal is generated, the associated status flag in GTST is set to 1. The associated status flag in GTST can be cleared by writing 0. If flag set and flag clear occur at the same time, flag clear takes priority over flag set. These flags are automatically updated by the internal state. The Interrupt Controller Unit can change the relative channel priorities. However, the priority within a channel is fixed. For details, see section 12, Interrupt Controller Unit (ICU).

Table 20.47 lists the GPT interrupt sources.

Table 20.47 Interrupt sources

20。4 中断源

中断源 GPT 提供以下中断源:

- GTCCR 输入捕获/比较匹配
- GTADTR 比较匹配
- GTCNT 计数器溢出（GTPR 比较匹配）/下溢
- 周期计数函数完成

每个中断源都有自己的状态标志。当生成中断源信号时,GTST中的关联状态标志被设置为1。GTST 中的关联状态标志可以通过写入 0 来清除。如果标志设置和标志清除同时发生,则标志清除优先于标志设置。这些标志由内部状态自动更新。中断控制器单元可以更改相对信道优先级。然而,通道内的优先级是固定的。有关详细信息,请参阅第 12 节"中断控制器单元（ICU）. 表 20。47 列出了 GPT 中断源"。

不执行比较匹配,因此在以下条件下不请求中断:

- GTCR。MD[2:0] = 001b（锯波一次脉冲模式）
- GTCR。MD[2:0] = 110b（三角波 PWM 模式 3）
- GTBER。CCRB[1:0] = 01b、10b、11b（使用 GTCCRE 寄存器的缓冲区操作）

(11) GPTn_PC Interrupt (n = 0, 1, 4, 5)

20.4.2 DMAC and DTC Activation

The DMAC and DTC can be activated by the interrupt in each channel. For details, see section 12, Interrupt Controller Unit (ICU), section 15, DMA Controller (DMAC), and section 16, Data Transfer Controller (DTC).

20.4.3 Interrupt and A/D Conversion Start Request Skipping Function

By setting the GTITC register, the GTCNT counter overflow (GTPR register compare match) interrupt (GPTn_OVF) and underflow interrupt (GPTn_UDF) can be skipped. Other interrupts and A/D conversion start request signals can be skipped in coordination with the GPTn_OVF/GPTn_UDF skipping function. When the interrupt is skipped, the updating of relevant status flag is also skipped. The interrupt skipping continues even if the status flag is set to 1.

The interrupt skipping function is related only to the GTITC register setting, and is not related to setting of the GTINTAD register interrupt enable bit. The interrupt skipping continues even if the interrupt is disabled with GTINTAD register setting.

When both troughs and crests are counted and skipped in triangle-wave mode, if the number of times of skipping is odd, GPTn_OVF/GPTn_UDF interrupt requests cannot be generated at troughs only or at crests only depending on the skipping counter start timing. Therefore, in order to count both troughs and crests and generate the GPTn_OVF/GPTn_UDF interrupts at troughs only or crests only in triangle-wave mode, the number of times of skipping should be even.

Similarly, in saw-wave mode, when both overflows and underflows are counted and skipped with the count direction changed, GPTn_OVF/GPTn_UDF interrupt requests are sometimes not generated at overflows only or at underflows only. Therefore, in order to count both overflows and underflows with the count direction changed and generate the GPTn_OVF/

(8) GPTn_UDF 中断（n = 0 到 5）

在以下条件下生成中断请求:

● 在锯波模式下,在下溢时启用中断请求（当 GTCNT 计数器值在下计数时从 0 变为 GTPR 时）

● 在三角波模式下,在波谷处启用中断请求（GTCNT 从 0 变为 1）

● 在按硬件源计数中,发生了下溢（GTCNT 在下计数中从 0 更改为 GTPR）关于中断信号和中断状态标志,请参见第 20。2。16 节。GTST:通用 PWM 定时器状态寄存器 .

(9)GPTn_ADTRGA 中断（n = 0 到 5）

GTCNT 计数器值与 GTADTRA 匹配时, 在以下条件下生成中断请求:

● 在上计数中,GTINTAD 中的中断使能位（ADTRAUEN）为 1

● 在下计数中,GTINTAD 中的中断使能位（ADTRADEN）为 1 在执行事件计数操作时,不生成该中断请求。

(10) GPTn_ADTRGB 中断（n = 0 到 5）

GTCNT 计数器值与 GTADTRB 匹配时, 在以下条件下生成中断:

● 在上计数中,GTINTAD 中的中断使能位（ADTRBUEN）为 1

● 在下计数中,GTINTAD 中的中断使能位（ADTRBDEN）为 1 在执行事件计数操作时,不生成该中断请求。

(11) GPTn_PC 中断（n = 0, 1, 4, 5）

当GTPC。PCEN位为1且GTPC。PCNT计数器为1时,在周期结束时生成中断请求。

GTCNT 计数器值与 GTADTRA 匹配时, 在以下条件下生成中断请求:

● 在上计数中,GTINTAD 中的中断使能位（ADTRAUEN）为 1

● 在下计数中,GTINTAD 中的中断使能位（ADTRADEN）为 1 在执行事件计数操作时,不生成该中断请求。

20。4。2 DMAC 和 DTC 激活

DMAC 和 DTC 可以通过每个通道中的中断来激活。有关详细信息,请参阅第 12 节"中断控制器单元（ICU）,"第 15 节"DMA 控制器（DMAC）"和第 16 节"数据传输控制器（DTC）."

20。4。3 中断和 A/D 转换开始请求跳过功能

通过设置GTITC寄存器,可以跳过GTCNT计数器溢出（GTPR寄存器比较匹配）中断（GPTn_OVF）和下溢中断（GPTn_UDF）。可以与GPTn_OVF/GPTn_UDF跳过功能协调跳过其他中断和A/D转换开始请求信号。跳过中断时,也会跳过相关状态标志的更新。即使状态标志设置为 1,中断跳跃也会继续。

中断跳过功能仅与GTITC寄存器设置相关,与GTINTAD寄存器中断使能位的设置无关。即使使用 GTINTAD 寄存器设置禁用中断,中断跳跃也会继续。

当在三角波模式下对波谷和波峰进行计数和跳跃时,如果跳跃次数为奇数,则不能仅在波谷或波峰处生成GPTn_OVF/GPTn_UDF中断请求,具体取决于跳跃计数器开始时间。因此,为了同时计算波谷和波峰并生成仅在波谷或仅在三角波模式下的波峰处的GPTn_OVF/GPTn_UDF中断,跳跃次数应该是偶数。

类似地,在锯波模式下,当溢出和下溢都被计数并在计数方向改变的情况下跳过时,GPTn_OVF/GPTn_UDF中断请求有时不会仅在溢出或仅在下溢时生成。因此,为了对计数方向改变的溢出和溢出进行计数并生成GPTn_OVF/

GPTn_UDF interrupts at overflows only or underflows only in saw-wave mode, the skipping state should be carefully checked before use.

When changing the skipping count, be sure to release the skipping count setting (GTITC.IVTC[1:0] bits = 00b).

更改跳过计数时,请务必释放跳过计数设置（GTITC。IVTC[1:0] bits = 00b）。

20.5 A/D Conversion Start Request

The A/D conversion start request can be issued at a compare match between the GTCNT counter and the GTADTRA or GTADTRB register. Up-counting only, down-counting only, or both up-counting and down-counting can be specified by setting the GTINTAD register.

During event count operation, the A/D conversion start request cannot be generated.

The A/D conversion start request is output as event signals to ELC.

The GTADTRA and GTADTRB registers each has two buffer registers. Buffer operation with the GTADTRA register used together with the GTADTBRA and GTADTDBRA registers, and buffer operation with the GTADTRB register used together with the GTADTBRB and GTADTDBRB registers can be performed.

The timing of the generation of requests to start A/D conversion can be monitored by an external pin. When the A/D conversion start request signal to be monitored is selected in the GTADSMR.ADSMSk bit (k = 0, 1) and when the output is enabled in the ADSMENk bit, a signal is output synchronized with a cycle frame of the timer used to generate the A/D conversion start request signal, of which the output is driven high at the generation of the A/D conversion start request signal by the GTADSMk pin, or at the end of the cycle of which the output is driven low. When a signal to request the start of A/D conversion is generated at the end of the cycle, the generation of this signal has priority in terms of monitoring output and the output remains at the high level until the end of the next cycle. GTADTRA and GTADTRB registers that are the sources for generating the A/D conversion start request signals and their counting directions can be checked by the A/D conversion start request flags (ADTRAUF, ADTRADF, ADTRBUF, and ADTRBDF) in the GTST register. When the output of the same A/D conversion start request signal monitoring output is enabled for multiple channels, ORed signals are output from the GPT16E.

Figure 20.75 shows an example of A/D conversion start request operation and Table 20.48 shows example for setting A/D conversion start request operation.

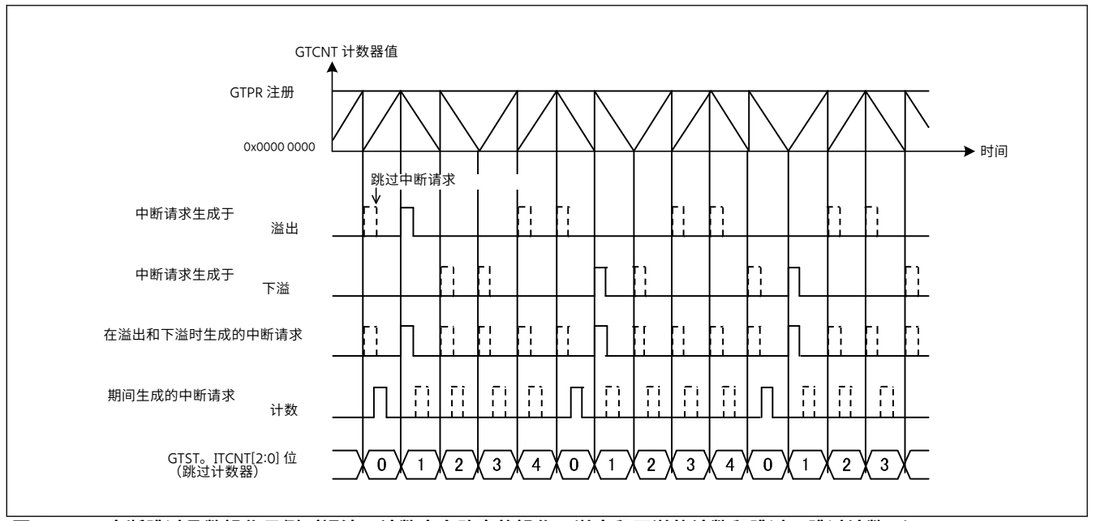

图 20。74 中断跳过函数操作示例（锯波、计数方向改变的操作、溢出和下溢的计数和跳过、跳过计数:4）

20。5 A/D 转换开始请求

A/D 转换开始请求可以在 GTCNT 计数器与 GTADTRA 或 GTADTRB 寄存器之间的比较匹配处发出。仅上计数、仅下计数或同时上计数和下计数可以通过设置 GTINTAD 寄存器来指定。

在事件计数操作期间,无法生成A/D转换开始请求。

A/D转换开始请求作为事件信号输出到ELC。

GTADTRA 和 GTADTRB 寄存器各有两个缓冲寄存器。可以执行与GTADTBRA和GTADTDBRA寄存器一起使用的GTADTRA寄存器的缓冲器操作以及与GTADTBRB和GTADTDBRB寄存器一起使用的GTADTRB寄存器的缓冲器操作。

启动 A/D 转换请求的生成时间可以通过外部引脚监控。当在GTADSMR。ADSMSk位（k=0,1)中选择要监视的A/D转换开始请求信号并且当在ADSMENk位中启用输出时,输出与定时器的周期帧同步的信号用于生成A/D转换开始请求信号,其中输出在生成A/时被驱动为高电平D转换开始请求信号由GTADSMk引脚,或在输出被驱动为低的循环结束时。当在周期结束时生成请求开始A/D转换的信号时,该信号的生成在监视输出方面具有优先级,并且输出保持在高电平直到下一个周期结束。作为生成A/D转换开始请求信号的源的GTADTRA和GTADTRB寄存器及其计数方向可以由GTST寄存器中的A/D转换开始请求标志（ADTRAUF、ADTRADF、ADTRBUF和ADTRBDF）检查。当多个通道启用相同A/D转换开始请求信号监视输出的输出时,从GPT16E输出ORed信号。

The A/D conversion start request A signal is output by the ELC in response to a match in comparison with the GTADTRA register. A/D conversion start request A is passed to ELC on the next rising edge of PCLKA.

20.6 Operations Linked by ELC

20.6.1 Event Signal Output to ELC

The GPT can perform operation linked with another module set in advance when its interrupt request signal is used as an event signal by the Event Link Controller (ELC).

A/D conversion start requests can be enabled and disabled individually with each up-counting and down-counting for both interrupts and event outputs to ELC by enable bits of the interrupt request.

The GPT has the following ELC event signals:

- Generation of compare match and input capture A interrupt (GPTn_CCMPA)
- Generation of compare match and input capture B interrupt (GPTn_CCMPB)
- Generation of compare match C interrupt (GPTn_CMPC)
- Generation of compare match D interrupt (GPTn_CMPD)
- Generation of compare match E interrupt (GPTn_CMPE)
- Generation of compare match F interrupt (GPTn_CMPF)
- Generation of overflow interrupt (GPTn_OVF)
- Generation of underflow interrupt (GPTn_UDF)
- Generation of A/D conversion start request A (GPTn_ADTRGA)
- Generation of A/D conversion start request B (GPTn_ADTRGB)
- Finish of period count function (GPTm_PC)

Note: n = 0 to 5
m = 0, 1, 4, 5

20.6.2 Event Signal Inputs from ELC

The GPT can perform the following operations in response to a maximum of 8 events from the ELC:

- Start counting, stop counting, clear counting
- Up-counting, down-counting
- Input capture.

See section 17, Event Link Controller (ELC) for the connection between the ELC and the event signal input.

20。6 操作 由 ELC 链接

20。6。1 事件信号输出到 ELC

GPT可以执行与另一模块提前设置的链接的操作,当其中断请求信号被事件链路控制器（ELC）用作事件信号时。

通过中断请求的使能位,可以通过中断请求的使能位对中断和事件输出到 ELC 的每次上计数和下计数来单独启用和禁用 A/D 转换启动请求。

GPT 具有以下 ELC 事件信号:

- 比较匹配和输入捕获的生成 A 中断（GPTn_CCMPA）
- 比较匹配和输入捕获 B 中断的生成（GPTn_CCMPB）
- 比较匹配 C 中断的生成（GPTn_CMPC）
- 比较匹配 D 中断的生成（GPTn_CMPD）
- 比较匹配 E 中断的生成（GPTn_CMPE）
- 比较匹配 F 中断的生成（GPTn_CMPF）
- 溢出中断（GPTn_OVF）的生成
- 底流中断（GPTn_UDF）的生成
- A/D 转换开始请求 A（GPTn_ADTRGA）的生成
- A/D 转换开始请求 B（GPTn_ADTRGB）的生成
- 周期计数函数（GPTM_PC）的完成

注:n = 0 到 5
m = 0, 1, 4, 5

20.6.2 ELC 的事件信号输入

GPT 可以响应来自 ELC 的最多 8 个事件执行以下操作:

- 开始计数,停止计数,清除计数
- 上计数、下计数
- 输入捕获。

有关 ELC 和事件信号输入之间的连接,请参阅事件链路控制器（ELC）第 17 节。

20.7 Noise Filter Function

Each pin for use in input capture and Hall sensor input to the GPT is equipped with a noise filter. The noise filter samples input signals at the sampling clock and removes the pulses whose length is less than 3 sampling cycles.

The noise filter functionality includes enabling and disabling the noise filter for each pin and setting of the sampling clock for each channel.

Figure 20.77 shows the timing of noise filtering.

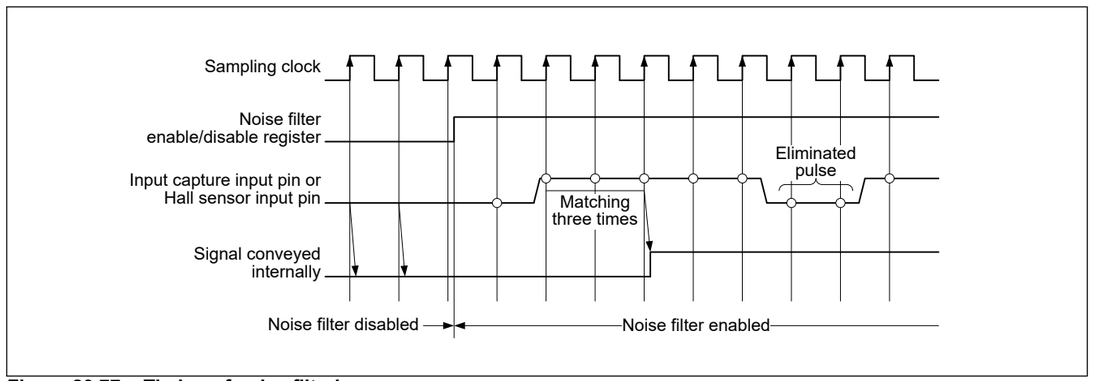

Figure 20.77 Timing of noise filtering

If noise filtering is enabled, the input capture operation or hall sensor input operation is performed on the edges of the noise filtered signal after a delay of (sampling interval × 2 + PCLKD) at the shortest. This is due to the noise filtering for the input capture input or hall sensor input.

20.8 Protection Function

20.8.1 Write-Protection for Registers

To prevent registers from being accidentally modified, registers can be write-protected in channel units by setting GTWP.WP. Write-protection can be set for the following registers:

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTITC, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTPDBR, GTADTRA, GTADTBRA, GTADTDBRA, GTADTRB, GTADTBRB, GTADTDBRB, GTDTCR, GTDVU, GTDVD, GTDBU, GTDBD, GTSOS, GTSOTR, GTADSMR, GTICLF, GTPC.

Every bit in registers GTSTR, GTSTP and GTCLR which can update the corresponding registers in other channels and can be updated by any of the corresponding registers in other channels conversely, can be protected by setting the GTWP.STRWP, STPWP, and CLRWP bits, respectively, per channel.

Likewise, writing to the GTSECSR and GTSECR registers, which can control all channels by writing to the GTSECSR and GTSECR registers of a given channel, can by enabled or disabled by the setting of the GTWP.CMNWP bit.

Protection using the GTWP register is only for write operations by the CPU. This protection does not cover updates to registers that occur in association with CPU writes.

20.8.2 Disabling of Buffer Operation

If the timing of the buffer register write is delayed relative to the timing for the buffer transfer, buffer operation can be suspended with the GTBER.BD[3], BD[2], BD[1] and BD[0] bits settings. Specifically, buffer transfer can be temporarily disabled even though a buffer transfer condition is generated during buffer register write, by setting the BD[3], BD[2], BD[1] and BD[0] bits to 1 (buffer operation disabled) before buffer register write, and setting the bits to 0 (buffer operation enabled) after completion of writing to all the buffer registers.

The BD[3], BD[2], BD[1] and BD[0] bits can be set on channel basis by writing directly to the GTBER register or it can be set to 0 simultaneously by setting the GTSECR register for multiple channels which were set by the GTSECSR register.

Figure 20.78 shows an example of operation for disabling buffer operation by writing to the GTBER register.

20。7 噪声滤波器功能

用于输入捕获和输入 GPT 的霍尔传感器的每个引脚都配备了噪声滤波器。噪声滤波器对采样时钟处的输入信号进行采样,并去除长度小于 3 个采样周期的脉冲。

噪声滤波器功能包括启用和禁用每个引脚的噪声滤波器以及为每个通道设置采样时钟。

图 20。77 显示了噪声滤波的时序。

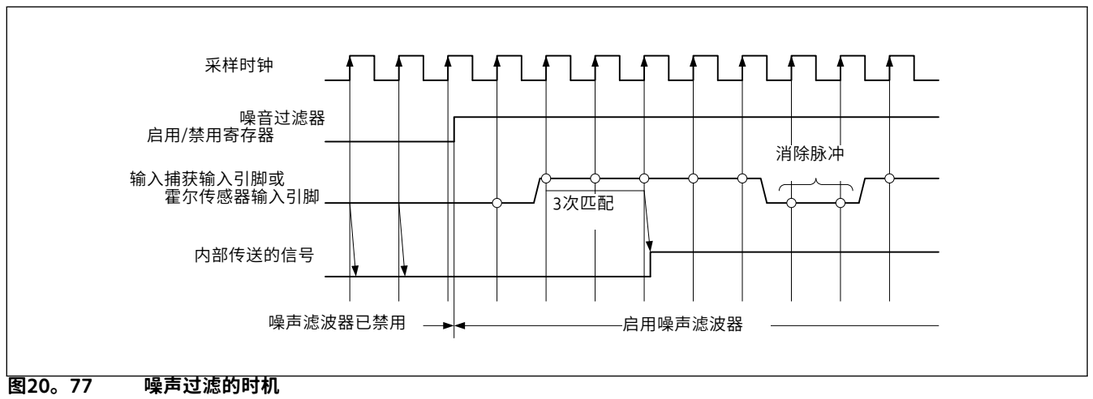

图20。77 噪声过滤的时机

如果启用噪声滤波,则在最短延迟（采样间隔× 2 + PCLKD）后,对噪声滤波信号的边缘执行输入捕获操作或霍尔传感器输入操作。这是由于输入捕获输入或霍尔传感器输入的噪声滤波造成的。

20。8 保护功能

20。8。1 寄存器的写保护

为了防止寄存器被意外修改,可以通过设置GTWP。WP来对信道单元中的寄存器进行写保护。可以为以下寄存器设置写保护:

GTSSR、GTPSR、GTCSR、GTUPSR、GTDNSR、GTICASR、GTICBSR、GTCR、GTUDTYC、GTIOR、GTINTAD、GTST、GTBER、GTITC、GTCNT、GTCCRA、GTCCRB、GTCCRC、GTCCRD、GTCCRE、GTCCRF、GTPR、GTPBR、GTPDBR、GTADTRA、GTADTBRA、GTADTDBRA、GTADTRB、GTADTBRB、GTDTCR、GTDVU、GTDVD、GTDBU、GTDBD、GTSOS、GTSOTR、GTADSMR、GTICLF、GTPC。

寄存器GTSTR、GTSTP和GTCLR中可以更新其他信道中的相应寄存器并且可以相反地由其他信道中的任何相应寄存器更新的每一位都可以通过设置GTWP来保护。STRWP、STPWP和CLRWP位,分别,每个通道。

同样,写入GTSECSR和GTSECR寄存器可以通过设置GTWP。CMNWP位来启用或禁用,GTSECSR和GTSECR寄存器可以通过写入给定信道的GTSECSR和GTSECR寄存器来控制所有信道。

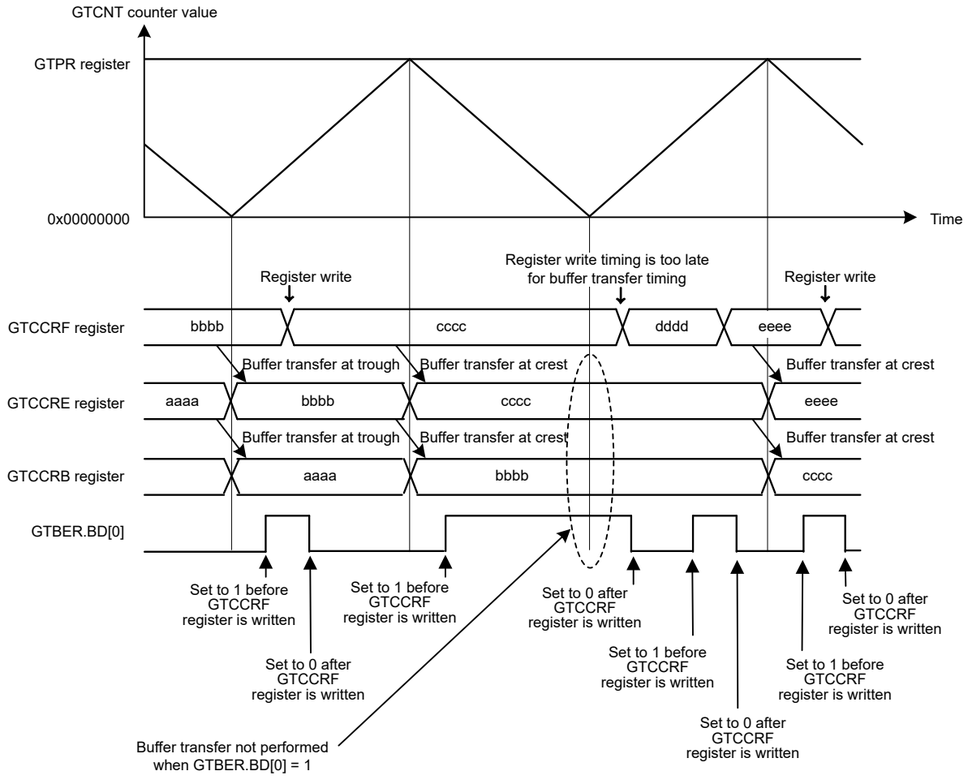
使用 GTWP 寄存器的保护仅适用于 CPU 的写操作。此保护不涵盖与 CPU 写入相关的寄存器更新。

20。8。2 缓冲器操作的禁用

如果缓冲寄存器写入的定时相对于缓冲器传输的定时延迟,则可以通过GTBER。BD[3]、BD[2]、BD[1]和BD[0]位设置来暂停缓冲器操作。具体地,即使在缓冲器寄存器写入期间生成缓冲器传送条件,也可以通过在缓冲器之前将BD[3]、BD[2]、BD[1]和BD[0]位设置为1（缓冲器操作禁用）来暂时禁用缓冲器传送。寄存器写入, 写入所有缓冲区寄存器后,将位设置为 0（启用缓冲区操作）。

BD[3]、BD[2]、BD[1]和BD[0]位可以通过直接写入GTBER寄存器来基于信道设置,或者可以通过为多个信道设置GTSECR寄存器来同时设置为0。由 GTSECSR 寄存器设置。

图 20。78 显示了通过写入 GTBER 寄存器来禁用缓冲区操作的操作示例。



Note: The base address of registers are the same.

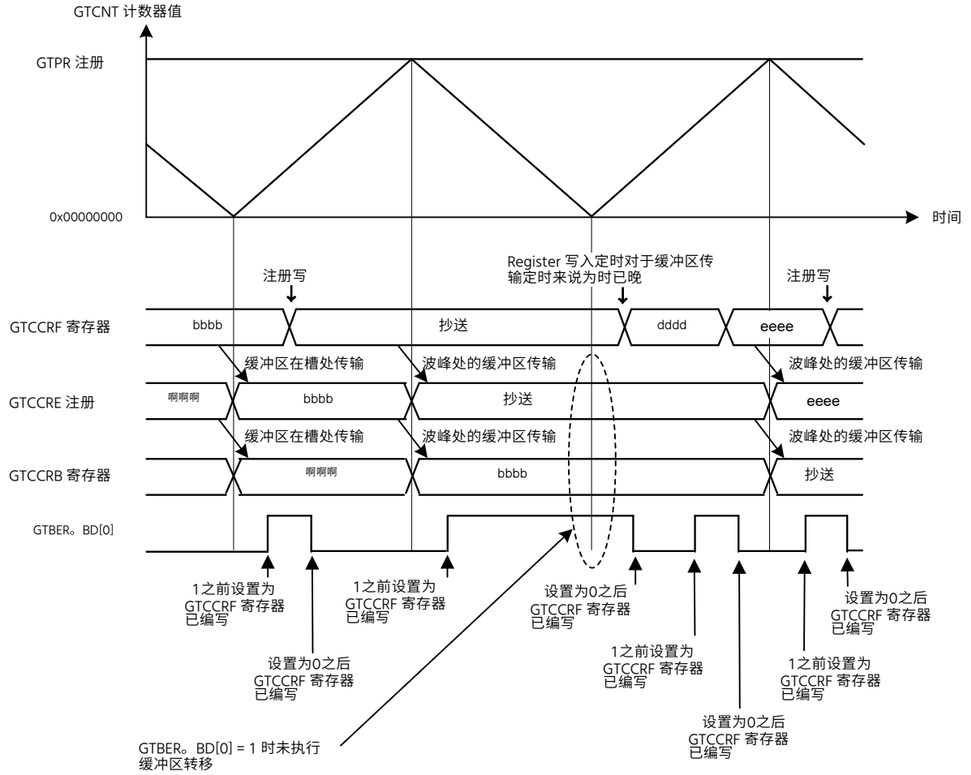
20.8.2.1 Simultaneous Control of Buffer Operations of Multiple Channels

The GTBER.BD bit can be set by writing directly to the GTBER register per channel or by making settings in the GTSECR register for multiple channels that have already set in the GTSECSR register.

Follow the procedure below to simultaneously set the GTBER.BD bits of multiple channels.

1. Select the channels for simultaneously setting by the GTSECSR register
   Set the GTSECSR register so that the values at the bit positions for the corresponding channels for simultaneously setting of the GTBER.BD bits become 1. All GTSECSR registers can be updated by writing to the GTSECSR register of any channel.
2. Simultaneously set the GTBER.BD bits by updating the GTSECR register
   In the GTSECR register, set the operation of the GTBER.BD bits (enabling or disabling of buffer operation) which are to be simultaneously set. Writing to a GTSECR register from any channel updates the GTBER.BD bits in all channels corresponding to the bits set as 1 in the GTSECSR register, in accordance with the value of the GTSECR register.

Figure 20.79 and Figure 20.80 show examples of simultaneously controlling the enabling or disabling of buffer operation for multiple channels.



注: 寄存器的基本地址是相同的。

图 20。78 用于禁用三角波缓冲器操作、双缓冲器操作以及波谷和波峰处的缓冲器传输的操作示例

20.8.2.1 同时控制多个通道的缓冲区操作

GTBER。BD位可以通过直接写入每个通道的GTBER寄存器或通过在GTSECR寄存器中对已经在GTSECSR寄存器中设置的多个通道进行设置来设置。

按照以下程序同时设置多个通道的 GTBER。BD 位。

1。选择 GTSECSR 寄存器同时设置的通道
设置 GTSECSR 寄存器,以便同时设置 GTBER。BD 位的相应通道的位位置值变为 1。所有 GTSECSR 寄存器都可以通过写入任何通道的 GTSECSR 寄存器来更新。

2锛姣涓。通过更新 GTSECR 寄存器同时设置 GTBER。BD 位
在 GTSECR 寄存器中,设置要同时设置的 GTBER。BD 位的操作（启用或禁用缓冲区操作）。根据GTSECR寄存器的值,从任何信道写入GTSECR寄存器更新与GTSECSR寄存器中设置为1的位相对应的所有信道中的GTBER。BD位。

20.8.3 GTIOCnm Pin Output Negate Control (n = 0 to 5, m = A, B)

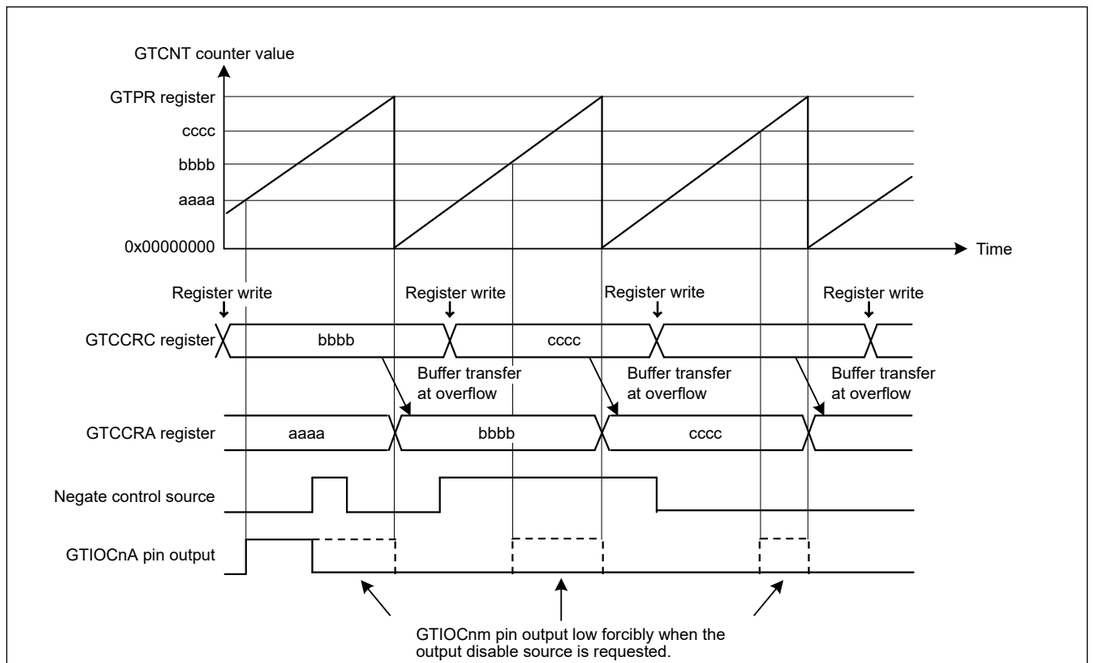
For protection from system failure, the output disable control that changes the GTIOCnm pin output value forcibly is provided for GTIOCnm pin output by the request of output disable from POEG. Output protection is required when a dead time error or the same output level being on the GTIOCnA and GTIOCnB pins is detected. GPT detects this condition and generates output disable requests to POEG according to the setting of the output disable request permission bits, such as GTINTAD.GRPDTE, GTINTAD.GRPABH, GTINTAD.GRPABL. After the POEG performs the logical OR of the output disable request from each channel and the output disable request from the external input, the POEG generates output disable requests to GPT.

One output disable signal (representing the shared output disable request signal of the GTIOCnA pin and the GTIOCnB pin) out of 4 output disable requests generated by the POEG is selected by setting GTINTAD.GRP[1:0]. The status of the selected disable output request is monitored by reading the GTST.ODF bit. The output level during output disable is set based on the GTIOR.OADF[1:0] bits for the GTIOCnA pin and the GTIOR.OBDF[1:0] setting for the GTIOCnB pin.

The change to the output disable state is performed asynchronously by generating the output disable request from the POEG. The release of the output disable state is performed at end of cycle by terminating the output disable request. It is after 3 PCLKD at shortest when the output disable condition is released after the output disable request becomes no longer satisfied. To reliably control output disabling, clear the flag of POEG for which the condition for the request to disable the output is no longer satisfied after 4 cycles of PCLKD.

When event count is performed or when the output disable state should be released immediately without waiting for end of cycle, GTIOR.OADF[1:0] should be set to 00b (for GTIOCnA pin) or GTIOR.OBDF[1:0] should be set to 00b (for the GTIOCnB pin).

Figure 20.81 shows an example of the GTIOCnm pin output disable control operation. (n = 0 to 5, m = A, B)



Note: The base address of registers are the same.

Figure 20.81 Example of GTIOCnm pin output disable control operation in saw-wave up-counting, buffer operation, active level 1, high output at GTCCRA compare match, low output at cycle end, and low output at output disable (n = 0 to 5, m = A, B)

20。8。3 GTIOCNm 引脚输出负控制（n = 0 到 5 m = A B）

为了防止系统故障,通过POEG的输出禁用请求,为GTIOCNm引脚输出提供强制改变GTIOCNm引脚输出值的输出禁用控制。当检测到GTIOCNA和GTIOCNB引脚上的死区时间错误或相同输出电平时,需要输出保护。GPT 检测到此情况,并根据输出禁用请求权限位的设置向 POEG 生成输出禁用请求,例如 GTINTAD。GRPDTE、GTINTAD。GRPABH、GTINTAD。GRPABL。POEG执行来自每个通道的输出禁用请求和来自外部输入的输出禁用请求的逻辑OR之后,POEG向GPT生成输出禁用请求。

POEG生成的4个输出禁用请求中选择一个输出禁用信号（表示GTIOCnA引脚和GTIOCnB引脚的共享输出禁用请求信号）,通过设置GTINTAD。GRP[1:0]。通过读取 GTST。ODF 位来监控所选禁用输出请求的状态。输出禁用期间的输出电平是根据 GTIOCnA 引脚的 GTIOR。OADF[1:0] 位和 GTIOCnB 引脚的 GTIOR。OBDF[1:0] 设置来设置的。POEG生成输出禁用请求异步执行输出禁用状态的改变,通过终止输出禁用请求在周期结束时执行输出禁用状态的释放。当输出禁用请求不再满足后,输出禁用条件被释放时,在最短3 PCLKD之后。为了可靠地控制输出禁用,请清除 POEG 标志,对于该标志,在 PCLKD 4 个周期后不再满足请求禁用输出的条件。

当执行事件计数或应立即释放输出禁用状态而无需等待周期结束时,GTIOR。OADF[1:0]应设置为00b（对于GTIOCnA引脚）或GTIOR。OBDF[1:0]应设置为00b（对于GTIOCnB引脚）。

20.8.4 Output Protection Function for GTIOCnm Pin Output

To prepare for a case when an incorrect value (0 or a value greater than or equal to the GTPR register value) is set in the GTCCRA register, the output protection function for the GTIOCnm pin output (disabling function) is activated when the automatic dead time is set (GTDTCR.TDE bit = 1) in triangle-wave PWM mode.

The status of the output protection function can be read from the GTSOS.SOS[1:0] bits.

Figure 20.82 shows the output protection function state transition.

为了应对GTCCRA寄存器中设置不正确值(0或大于或等于GTPR寄存器值的值）的情况,当自动死区时激活GTIOCNm引脚输出的输出保护功能（禁用功能）在三角波 PWM 模式下设置时间（GTDTCR。TDE 位 = 1)。

(4) 输出保护功能的限制规范

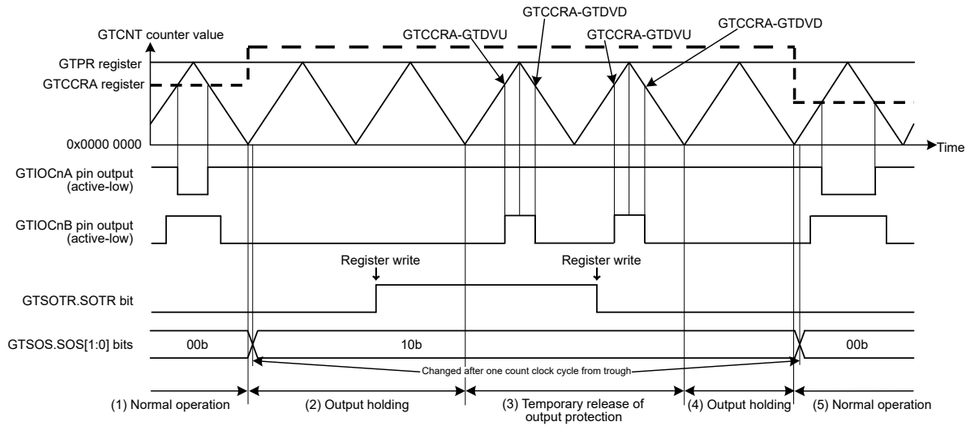
即使在计数操作期间在GTCCRA寄存器中设置了不正确的值(0或大于或等于GTPR寄存器值的值）,输出保护也以特定方式起作用,使得正相和负相之一

outputs becomes non-active. However, if the following condition is not satisfied, the output protection does not operate normally:

- When the GTCCRA register value at the start of count operation is greater than 0, and less than the setting value of the GTPR register

(5) Temporary Release of Output Protection Function

When the GTSOS.SOS[1:0] bits = 10b (protected state in which GTCCRA register ≥ GTPR register occurred during transfer at trough), the protected state of the GTIOCnB pin output can be temporarily released by setting the GTSOTR.SOTR bit to 1. The SOS[1:0] bits retain 10b even if the output protection function is released. When the SOTR bit is set to 0, the GTIOCnB pin output protection can be restarted. Figure 20.91 shows examples of the operation of temporary release of output protection when the setting of the GTCCRA register ≥ GTPR register during buffer transfer at troughs.



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA ≥ GTPR is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 10b, and the output is held while GTCCRA ≥ GTPR.
Even when the GTSOTR.SOTR bit is set to 1 during the output holding period, the GTIOCnB pin output is held until the first trough after the setting.
(3) Output protection temporary release period: After GTSOTR.SOTR bit is set to 1, the GTIOCnB pin output is performed normally from the first trough after the setting.
Even when the GTSOTR.SOTR bit is set to 0 during the output protection releasing period, the GTIOCnB pin output is held until the first trough after the setting.
(4) Output holding period: The output is held until 0 < GTCCRA < GTPR is detected in the trough.
(5) Normal operation period: When 0 < GTCCRA < GTPR is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and toggle output due to a compare match is performed normally.

20.9 Initialization Method of Output Pins

20.9.1 Pin Settings after Reset

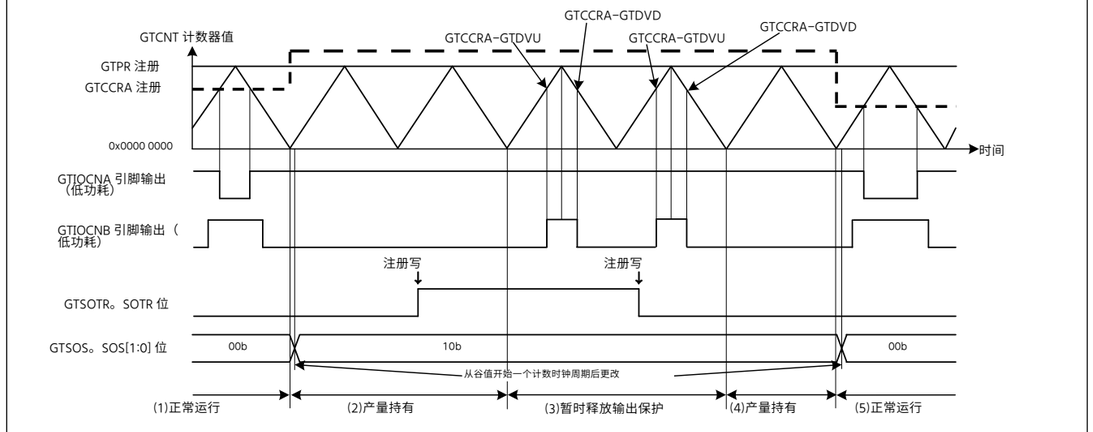
The GPT registers are initialized at a reset. Start counting after selecting the port pin function with the PmnPFS register, setting GTIOR.OAE and GTIOR.OBE bits, and outputting the GPT function to external pins.

输出变得非活动。但是,如果不满足以下条件,则输出保护无法正常运行:

- 当计数操作开始时的GTCCRA寄存器值大于0,且小于GTPR寄存器的设定值时

(5)输出保护功能的临时释放

GTSOS。SOS[1:0]位 = 10b时（在槽转移时发生GTCCRA寄存器≥ GTPR寄存器的保护状态）,可以通过将GTSOTR。SOTR位设置为1来暂时释放GTIOCNB引脚输出的保护状态。SOS[1:0] 位即使释放输出保护功能也保留 10b。SOTR 位设置为 0 时, 可以重新启动 GTIOCNB 引脚输出保护。图 20。91 显示了在槽缓冲器传输期间设置 GTCCRA 寄存器 ≥ GTPR 寄存器时暂时释放输出保护的操作示例。



(1)正常运行期: 由于比较匹配而产生的切换输出是正常执行的。
(2)产量持有期: GTCCRA GTPR在槽中检测到时,输出保护状态变为GTSOS。SOS[1:0]位 = 10b,输出保持而GTCCRA GTPR。
即使当GTSOTR。SOTR位在输出保持期间被设置为1时,GTIOCNB引脚输出也被保持直到设置后的第一槽。
(3)输出保护临时释放期:GTSOTR。SOTR位设置为1后,GTIOCNB引脚输出从设置后的第一槽开始正常进行。
即使当GTSOTR。SOTR位在输出保护释放期间被设置为0时,GTIOCNB引脚输出也保持到设置后的第一槽。
(4)产量持有期: 保持输出直到在槽中检测到 0 < GTCCRA < GTPR。
(5)正常运行期: 0 < GTCCRA < GTPR 在槽中检测到时,输出保护状态变为 GTSOS。SOS[1:0] 位 = 00b,正常执行由于比较匹配而导致的切换输出。

20。9 输出引脚的初始化方法

20。9。1 重置后的引脚设置

GPT 寄存器在重置时初始化。PmnPFS寄存器选择端口引脚功能后开始计数,设置GTIOR。OAE和GTIOR。OBE位,并将GPT功能输出到外部引脚。

20.9.2 Pin Initialization Due to Error during Operation

If an error occurs during GPT operation, the following four types of pin control can be performed before pin initialization:

- Set the OAHLD and OBHLD bits in GTIOR to 1 and retain the outputs at count stop
- Set the OAHLD and OBHLD bits in GTIOR to 0, specify arbitrary output values at OADFLT and OBDFLT in GTIOR, and output the arbitrary values at count stop
- Set the pin to output an arbitrary value as a general output port by setting the PDR, PODR registers and PmnPFS.PMR bit of the I/O port in advance. Set the OAE and OBE bits in GTIOR to 0, and the control bit associated with the pin in the PMR to 0 to allow arbitrary values to be output from the pin set as a general output port when an error occurs.
- Drive the output to a high impedance state using the POEG function.

If the automatic dead time setting is made, clear the GTDTCR.TDE bit to 0 after counting stops. When counting stops, only the values of registers that are changed by a GPT external source change. If counting is resumed, operation continues from where it stopped. If counting is stopped, the registers must be initialized before counting starts.

20.10 Usage Notes

20.10.1 Module-Stop Function Setting

The Module Stop Control Register can enable or disable GPT operation. The GPT is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

20.10.2 GTCCRn Settings during Compare Match Operation (n = A to F)

(1) When automatic dead time setting is made in triangle-wave PWM mode

The GTCCRA register must satisfy all of the following conditions:

- GTDVU < GTCCRA
- GTCCRA > GTDVD
- 0 < GTCCRA < GTPR

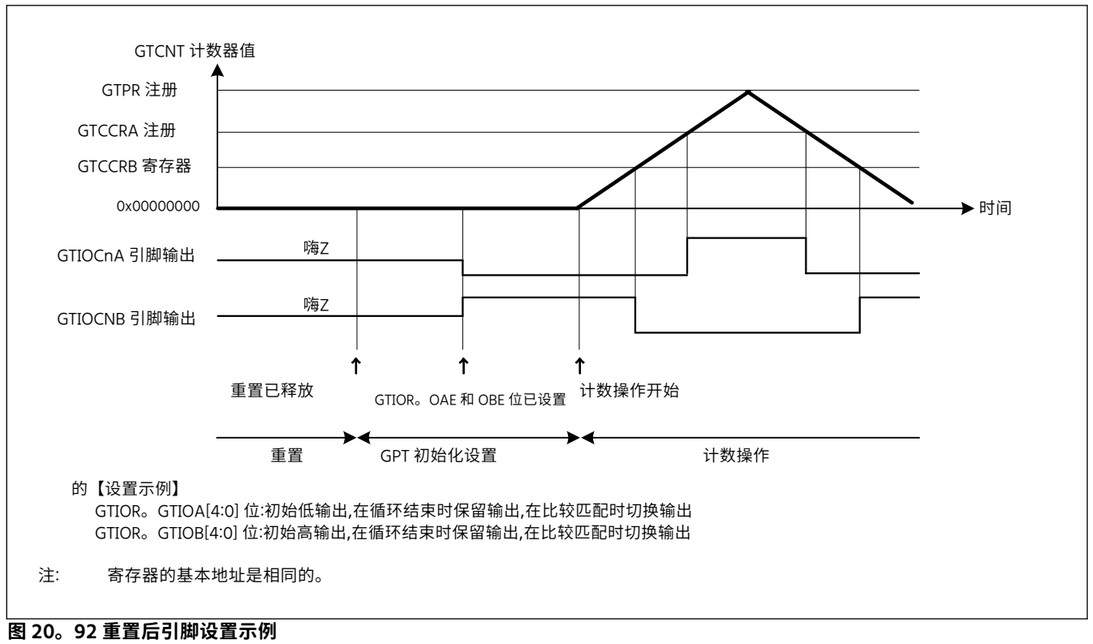

图 20。92 重置后引脚设置示例

20。9。2 由于操作过程中的错误而导致的引脚初始化

GPT 操作时出现错误, 则可以在引脚初始化之前执行以下四种类型的引脚控制:

- 将 GTIOR 中的 OAHLD 和 OBHLD 位设置为 1,并在计数停止时保留输出
- 将 GTIOR 中的 OAHLD 和 OBHLD 位设置为 0,在 GTIOR 中的 OADFLT 和 OBDFLT 处指定任意输出值,并在计数停止处输出任意值
- 通过提前设置 I/O 端口的 PDR、PODR 寄存器和 PmnPFS。PMR 位,将引脚设置为输出任意值作为通用输出端口。GTIOR 中的 OAE 和 OBE 位设置为 0, PMR 中与引脚关联的控制位设置为 0, 以允许在发生错误时从引脚设置为通用输出端口输出任意值。
- 使用 POEG 函数将输出驱动到高阻抗状态。

如果自动死区时间设置,则在计数停止后将 GTDTCR。TDE 位清除为 0。计数停止时,仅 GPT 外部源更改的寄存器的值发生变化。如果恢复计数,则从停止处继续操作。如果停止计数,则必须在计数开始之前初始化寄存器。

20。10 使用说明

20.10.1 模块停止功能设置

模块停止控制寄存器可以启用或禁用 GPT 操作。GPT 在重置后最初停止。
释放模块停止状态可以访问寄存器。有关详细信息,请参阅第 10 节"低功耗模式 ."

20。10。2 比较匹配操作期间的 GTCCRn 设置（n = A 到 F）

(1)在三角波PWM模式下进行自动死区时间设置时

GTCCRA 寄存器必须满足以下所有条件:

- GTDVU < GTCCRA
- GTCCRA > GTDVD
- 0 < GTCCRA < GTPR

When the setting of GTCCRA = 0 or GTCCRA ≥ GTPR is made for the GTCCRA register during count operation, the output protection function is activated. However, if the following condition is not satisfied, the output protection function does not function normally:

- The value of the GTCCRA register at the start of counting is larger than 0 and less than GTPR.

(2) When automatic dead time setting is not made in triangle-wave PWM mode

The GTCCRA register must be set within the range of 0 < GTCCRA < GTPR. If GTCCRA = 0 or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0 or GTCCRA = GTPR is satisfied. When GTCCRA > GTPR, no compare match occurs.

Similarly, GTCCRB must be set within the range of 0 < GTCCRB < GTPR. If GTCCRB = 0 or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB is 0 or GTCCRB = GTPR is satisfied. When GTCCRB > GTPR, no compare match occurs.

(3) When automatic dead time setting is made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, the correct output waveforms with secured dead time may not be obtained.

- In up-counting: GTCCRC < GTCCRD, GTCCRC > GTDVU, GTCCRD < GTPR - GTDVD
- In down-counting: GTCCRC > GTCCRD, GTCCRC < GTPR - GTDVU, GTCCRD > GTDVD

(4) When automatic dead time setting is not made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRC < GTCCRD < GTPR
- In down-counting: GTPR > GTCCRC > GTCCRD > 0

Similarly, GTCCRE and GTCCRF must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRE < GTCCRF < GTPR
- In down-counting: GTPR > GTCCRE > GTCCRF > 0.

(5) In saw-wave PWM mode

The GTCCRA register must be set with the range of 0 < GTCCRA < GTPR. If GTCCRA = 0 or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0 or GTCCRA = GTPR is satisfied. If GTCCRA > GTPR is set, no compare match occurs.

Similarly, GTCCRB must be set with the range of 0 < GTCCRB < GTPR. If GTCCRB = 0 or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB = 0 or GTCCRB = GTPR is satisfied. If GTCCRB > GTPR is set, no compare match occurs.

20.10.3 Setting Range for GTCNT Counter

The GTCNT counter register must be set with the range of 0 ≤ GTCNT ≤ GTPR.

20.10.4 Starting and Stopping the GTCNT Counter

The control timing of starting and stopping the GTCNT counter by the GTCR.CST bit synchronizes the count clock that is selected in GTCR.TPCS[3:0]. When GTCR.CST is updated, the GTCNT counter starts/stops after a count clock that is selected in GTCR.TPCS[3:0]. Therefore, an event generated before the GTCNT counter actually starts is ignored, resulting in situations in which an event is accepted or an interrupt occurs after GTCR.CST is set to 0.

20.10.5 Priority Order of Each Event

(1) GTCNT register

Table 20.49 shows a priority order of events updating the GTCNT register.

当在计数操作期间对GTCCRA寄存器进行GTCCRA = 0或GTCCRA ≥ GTPR的设置时,输出保护功能被激活。但是,如果不满足以下条件,则输出保护功能无法正常运行:

● 计数开始时GTCCRA寄存器的值大于0且小于GTPR。

(2)在三角波PWM模式下不作自动死区时间设定时

GTCCRA 寄存器必须设置在 0 < GTCCRA < GTPR 范围内。如果设置 GTCCRA = 0 或 GTCCRA = GTPR,则仅在满足 GTCCRA = 0 或 GTCCRA = GTPR 时才在周期内发生比较匹配。当 GTCCRA > GTPR 时,不会发生比较匹配。

同样,GTCCRB 必须设置在 0 < GTCCRB < GTPR 范围内。如果设置 GTCCRB = 0 或 GTCCRB = GTPR,则仅在满足 GTCCRB 为 0 或 GTCCRB = GTPR 时才在周期内发生比较匹配。当 GTCCRB > GTPR 时,不会发生比较匹配。

(3)在锯波一次性脉冲模式下进行自动死区时间设置时,必须设置GTCCRC和GTCCRD寄存器以满足以下限制。如果不满足限制,则可能无法获得具有安全死区的正确输出波形。

● 在上计数中:GTCCRC < GTCCRD、GTCCRC > GTDVU、GTCCRD < GTPR GTDVD
● 在下计数中:GTCCRC > GTCCRD、GTCCRC < GTPR GTDVU、GTCCRD > GTDVD

(4)在锯波一次性脉冲模式下未进行自动死区时间设置时,必须设置GTCCRC和GTCCRD寄存器以满足以下限制。如果不满足限制,则不会发生两次比较匹配,并且无法执行脉冲输出。

● 在上计数中:0 < GTCCRC < GTCCRD < GTPR
● 下计数:GTPR > GTCCRC > GTCCRD > 0

同样,GTCCRE 和 GTCCRF 必须设置为满足以下限制。如果不满足限制,则不会发生两次比较匹配,并且无法执行脉冲输出。

● 在上计数中:0 < GTCCRE < GTCCRF < GTPR
● 在下计数中:GTPR > GTCCRE > GTCCRF > 0。

(5)在锯波PWM模式下

GTCCRA 寄存器的设置范围必须为 0 < GTCCRA < GTPR。如果设置 GTCCRA = 0 或 GTCCRA = GTPR,则仅在满足 GTCCRA = 0 或 GTCCRA = GTPR 时才在周期内发生比较匹配。如果设置 GTCCRA > GTPR,则不会发生比较匹配。

同样,GTCCRB 的设置范围必须为 0 < GTCCRB < GTPR。如果设置 GTCCRB = 0 或 GTCCRB = GTPR,则仅在满足 GTCCRB = 0 或 GTCCRB = GTPR 时才在该周期内发生比较匹配。如果设置 GTCCRB > GTPR,则不会发生比较匹配。

20。10。3 GTCNT 计数器的设置范围

GTCNT 计数器寄存器的设置范围必须为 0 ≤ GTCNT ≤ GTPR。

20.10.4 启动和停止 GTCNT 计数器

GTCR。CST 位启动和停止 GTCNT 计数器的控制时序使 GTCR。TPCS 中选择的计数时钟同步[3:0]。当GTCR。CST更新时,GTCNT计数器在GTCR。TPCS[3:0]中选择的计数时钟之后开始/停止。因此,GTCNT计数器实际启动之前生成的事件被忽略,导致事件被接受或在GTCR。CST设置为0之后发生中断的情况。

20。10。5 每个事件的优先顺序

(1)GTCNT 登记册

表 20。49 显示了更新 GTCNT 寄存器的事件的优先顺序。

Table 20.49 Priority order of sources updating GTCNT

Source updating GTCNT	Priority order
Writing by CPU (writing to GTCNT/GTCLR)	High
Clear by hardware sources set in GTCSR	↑
Count up or down by hardware sources set in GTUPSR/GTDNSR	↑
Count operation	Low

If up-counting and down-counting by hardware sources occur at the same time, the GTCNT counter value does not change. When there is a conflict between updating the GTCNT register and reading by the CPU, pre-update data is read.

(2) GTCR.CST bit

When there is a conflict between starting/stopping by hardware sources set in the GTSSR/GTPSR registers and writing by the CPU (writing to GTCR/GTSTR/GTSTP registers), the writing by CPU has priority over the starting/stopping by hardware sources.

In case that stop by the period count function conflicts with start by the CPU writing (GTCR register writing/GTSTR register writing), the period count function is finished with setting the GTST.PCF flag. The CST bit is not changed and the GTCNT continues to count.

When there is a conflict between starting by hardware sources set in the GTSSR register and stopping by hardware sources set in GTPSR register, the GTCR.CST bit value does not change. When there is a conflict between updating the GTCR.CST bit and reading by the CPU (reading from GTCR/GTSTR/GTSTP registers), pre-update data is read.

(3) GTCCRm registers (m = A to F)

When there is a conflict between input capture/buffer transfer operation and writing to the GTCCRm registers, the writing to GTCCRm registers has priority over input capture/buffer transfer operation. When there is a conflict between input capture and writing to the counter register by the CPU or updating the counter register by hardware sources, the pre-update counter value is captured. When there is a conflict between updating the GTCCRm registers and reading by the CPU, pre-update data is read.

(4) GTPR register

When there is a conflict between buffer transfer operation and writing to the GTPR register, writing to GTPR register has priority over buffer transfer operation. When there is a conflict between updating GTPR register and reading by the CPU, pre-update data is read.

(5) GTADTRm registers (m = A, B)

When there is a conflict between buffer transfer operation and writing to GTADTRm register, writing to GTADTRm register has priority over buffer transfer operation.

When there is a conflict between updating the GTADTRm register and reading by the CPU, pre-update data is read.

(6) GTDVm registers (m = U, D)

When there is a conflict between buffer transfer operation and writing to GTDVm register, writing to GTDVm register has priority over buffer transfer operation.

When there is a conflict between updating the GTDVm register and reading by the CPU, pre-update data is read.

(7) GTIOR.GTIOm registers (m = A, B)

When there is a conflict between buffer transfer operation and writing to GTIOR.GTIOm register, writing to GTIOR.GTIOm register has priority over buffer transfer operation.

When there is a conflict between updating the GTIOR.GTIOm and reading by the CPU, pre-update data is read.

表 20。49 更新 GTCNT 的源的优先顺序

源更新 GTCNT	优先顺序
由 CPU 写入（写入 GTCNT/GTCLR）	高
按 GTCSR 中设置的硬件源清除	↑
按 GTUPSR/GTDNSR 中设置的硬件源向上或向下计数	↑
计数操作	Low

如果同时发生硬件源的上计数和下计数,则GTCNT计数器值不会改变。
当更新GTCNT寄存器与CPU读取之间存在冲突时,会读取预更新数据。

(2)GTCR。CST 位

当GTSSR/GTPSR寄存器中设置的硬件源启动/停止与CPU写入（写入GTCR/GTSTR/GTSTP寄存器）之间存在冲突时,CPU写入优先于硬件源启动/停止。

如果周期计数函数停止与 CPU 写入开始冲突（GTCR 寄存器写入/GTSTR 寄存器写入）,则周期计数函数将通过设置 GTST。PCF 标志来完成。CST 位没有改变,GTCNT 继续计数。

当GTSSR寄存器中设置的硬件源开始与GTPSR寄存器中设置的硬件源停止之间存在冲突时,GTCR。CST位值不会改变。当更新GTCR。CST位与CPU读取（从GTCR/GTSTR/GTSTP寄存器读取）之间存在冲突时,读取预更新数据。

(3) GTCCRm 寄存器（m = A 至 F）

当输入捕获/缓冲区传输操作与写入GTCCRm寄存器之间存在冲突时,写入GTCCRm寄存器优先于输入捕获/缓冲区传输操作。CPU 输入捕获与写入计数器寄存器或硬件源更新计数器寄存器发生冲突时, 捕获预更新计数器值。当更新GTCCRm寄存器和CPU读取之间存在冲突时,会读取预更新数据。

（四）GTPR 寄存器

当缓冲区传输操作与写入GTPR寄存器之间存在冲突时,写入GTPR寄存器优先于缓冲区传输操作。当更新GTPR寄存器和CPU读取之间存在冲突时,会读取预更新数据。

(5) GTADTRm 寄存器（m = A B）

当缓冲区传输操作与写入GTADTRm寄存器之间存在冲突时,写入GTADTRm寄存器优先于缓冲区传输操作。

GTADTRm 寄存器更新与 CPU 读取之间存在冲突时, 读取预更新数据。

(6)GTDVm 寄存器（m = U, D）

当缓冲区传输操作与写入GTDVm寄存器之间存在冲突时,写入GTDVm寄存器优先于缓冲区传输操作。

当更新 GTDVm 寄存器与 CPU 读取之间存在冲突时,会读取预更新数据。

(7)GTIOR。GTIOm 寄存器（m = A, B）

当缓冲区传输操作与写入GTIOR。GTIOm寄存器之间存在冲突时,写入GTIOR。GTIOm寄存器优先于缓冲区传输操作。

当更新 GTIOR。GTIOm 与 CPU 读取之间存在冲突时,会读取预更新数据。

21. Low Power Asynchronous General Purpose Timer (AGTW)

This is the AGTW_B version of the AGTW peripheral module.

AGTW_B is referred to as AGT in this chapter.

21.1 Overview

The low power Asynchronous General Purpose Timer (AGT) is a 32-bit timer that can be used for pulse output, external pulse width or period measurement, and counting external events. This timer consists of a reload register and a down counter. The reload register and the down counter are allocated to the same address, and can be accessed with the AGT register.

Table 21.1 lists the AGT specifications, Figure 21.1 shows a block diagram, and Table 21.2 lists the I/O pins.

21.2 注册说明

21.2.1 AGT:AGT 计数器寄存器

基本地址: AGTWn = 0x400E_8000 + 0x0100 × n（n = 0, 1）
偏移地址: 0x00

位位置:	31																												0
位字段:																													
重置后的值:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
31:0	n/a	32-bit counter and reload register Setting range : 0x00000000 to 0xFFFFFFFF	R/W

AGTWn.AGT is a 32-bit register. The write value is written to the reload register and the read value is read from the counter.

The states of the reload register and the counter change according to the TSTART bit in the AGTCR register and TCMEA/TCMEB bit in the AGTCMSR register. For details, see section 21.3.1. Reload Register and Counter Rewrite Operation.

When 1 is written to the TSTOP bit in the AGTCR register, AGT counter is forcibly stopped and set to 0xFFFFFFFF.

When the TCK[2:0] bits setting in the AGTMR1 register are a value other than 001b (PCLKB/8) or 011b (PCLKB/2), if the AGT register is set to 0x00000000, a request signal to the ICU, the DTC, the DMAC, and the ELC is generated once immediately after the count starts. The AGTOn and AGTIOn pin output are toggled.

When the AGT register is set to 0x00000000 in event counter mode, regardless of the value of TCK[2:0] bits, a request signal to the ICU, the DTC, the DMAC, and the ELC is generated once immediately after the count starts.

In addition, the AGTOn pin output is toggled even during a period other than the specified count period. When the AGT register is set to 0x00000001 or more, a request signal is generated each time AGT underflows.

21.2.2 AGTCMA : AGT Compare Match A Register

Base address: AGTWn = 0x400E_8000 + 0x0100 × n (n = 0, 1)

Note 1. Set the AGTCMA register to 0xFFFFFFFF when compare match A is not used.

The AGTCMA register is a read/write register to set a value for compare match with the AGT counter. The states of the reload register and compare register A change according to the TSTART bit in the AGTCR register. For details, see section 21.3.2. Reload Register and AGT Compare Match A/B Register Rewrite Operation.

21.2.3 AGTCMB : AGT Compare Match B Register

Bit	Symbol	Function	R/W
31:0	n/a	32-bit compare match B data is stored.*1 Setting range : 0x00000000 to 0xFFFFFFFF	R/W

Note 1. Set the AGTCMB register to 0xFFFFFFFF when compare match B is not used.

The AGTCMB register is a read/write register to set a value for compare match with the AGT counter. The states of the reload register and compare register B change according to the TSTART bit in the AGTCR register. For details, see section 21.3.2. Reload Register and AGT Compare Match A/B Register Rewrite Operation.

位	符号	功能	R/W
31:0	不适用	32位计数器和重加载寄存器 设置范围:0x000 00000 到 0xFFFFFFFF	R/W

AGTWn。AGT 是一个 32 位寄存器。将写入值写入重加载寄存器,并从计数器读取读取值。

重新加载寄存器的状态和计数器的状态根据AGTCR寄存器和TCMEA/中的TSTART位发生变化
AGTCMSR 寄存器中的 TCMEB 位。详情请参见第 21。3。1 节。重新加载寄存器和计数器重写操作。

1写入到AGTCR寄存器中的TSTOP位时,AGT计数器被强制停止并设置为0xFFFFFFFF。

AGTMR1寄存器中的TCK[2:0]位设置为001b（PCLKB/8)或011b（PCLKB/2)以外的值时,如果
AGT寄存器设置为0x00000000,计数开始后立即生成向ICU、DTC、DMAC和ELC发出的请求信号一次。AGT On 和 AGTIOn 引脚输出已切换。

当AGT寄存器在事件计数器模式下设置为0x00000000时,无论TCK[2:0]位的值如何,计数开始后立即生成一次向ICU、DTC、DMAC和ELC的请求信号。

此外,即使在指定计数周期之外的周期内,AGTOn 引脚输出也会切换。AGT寄存器设置为0x00000001或更多时,每次AGT下溢时都会生成请求信号。

Also, after 0 is written to the TSTART bit, the TCSTF flag is set to 0 (count stops) in synchronization with the count source. For details, see section 21.4.1. Count Operation Start and Stop Control.

TCSTF flag (AGT Count Status Flag)

The TCSTF flag indicates the AGT count status.

LPM bit (Low Power Mode)

The LPM bit sets the low power operation, which impacts access to certain AGT registers. Set this bit to 1 to operate in low power.

When this bit is 1, access to the following registers is prohibited:

- AGT/AGTCMA/AGTCMB/AGTCR.

After this bit is switched from 1 to 0, the first access to the register is constrained as follows:

- When reading from the AGT register, read AGT register twice. Only the second reading of data is valid.
- When writing to the AGT, AGTCMA, AGTCMB, and AGTCR register, allow at least 2 cycles of the count source clock when writing to the register.
- When confirm the value written to the AGT, AGTCMA, AGTCMB, and AGTCR registers.
  - When the count operation is stopped; after writing data, it can be read in the next cycle.
  - When the count operation is operating; after writing data, it can be read 4 cycles after the count source clock.

LPM 位（低功耗模式）

LPM 位设置低功耗操作,这会影响对某些 AGT 寄存器的访问。将此位设置为 1 以低功耗运行。

1 位时, 禁止访问以下寄存器:

- AGT/AGTCMA/AGTCMB/AGTCR。

1 切换到 0 该位后, 对寄存器的第一次访问被约束如下:

- 从 AGT 寄存器读取时,读取 AGT 寄存器两次。只有二读数据才有效。
- 写入 AGT、AGTCMA、AGTCMB 和 AGTCR 寄存器时,写入寄存器时至少允许计数源时钟的 2 个周期。
- 当确认写入 AGT、AGTCMA、AGTCMB 和 AGTCR 寄存器的值时。
  - 停止计数操作时;写入数据后,可以在下一个周期读取。
  - 计数运算正在运算时;写入数据后,计数源时钟后可读取 4 个周期。

TEDGSEL bit (I/O Polarity Switch)

The TEDGSEL bit switches the AGTOn pin output polarity and the AGTIOn pin input/output edge and polarity.

In pulse output mode, it only controls polarity of the AGTOn pin output and AGTIOn pin output. AGTOn pin output and AGTIOn pin output are initialized when the AGTMR1 register is written or the TSTOP bit in the AGTCR register is written with 1.

TOE bit (AGTOn pin Output Enable)

The TOE bit selects whether the AGTOn pin output is disabled or enabled.

TIPF[1:0] bits (Input Filter)

The TIPF[1:0] bits specify the sampling frequency of the AGTIOn pin input filter. When the input to the AGTIOn pin is sampled and the values match three times in succession, the value is regarded as the input value.

TIOGT[1:0] bits (Count Control)

The TIOGT[1:0] bits control the event count.

21.3 Operation

21.3.1 Reload Register and Counter Rewrite Operation

Regardless of the operating mode, the timing of the rewrite operation to the reload register and the counter differs depending on the value of the TSTART bit in the AGTCR register and of the TCMEA or TCMEB bit in the AGTCMSR register. When the TSTART bit is 0 (count stops), the count value is directly written to the reload register and the counter. When the TSTART bit is 1 (count starts) and the TCMEA bit and TCMEB bit are 0 (AGT compare match A/B register are invalid), the value is written to the reload register in synchronization with the count source, and then to the counter in synchronization with the next count source. When the TSTART bit is 1 (count starts) and the TCMEA bit or the TCMEB bit is 1 (AGT compare match A register or compare match B register is valid), the value is written to the reload register in synchronization with the count source, and then to the counter in synchronization with the underflow of the counter.

Figure 21.4 and Figure 21.5 show the timing of rewrite operation with TSTART bit value and TCMEA/TCMEB bit value.

RTCCR1时禁止将P403的PMR和PDR位设置为1。TCEN 设置为 1。

当不使用AGT输入时,将RTCCRn。TCEN设置为0。RTCCRn。TCEN 在重置时未初始化。因此,当不使用AGT输入时,重置后必须将RTCCRn。TCEN设置为0。

在将此位设置为 1 之前,请务必设置计数源设置位（RCR4)。RCKSEL）、端口控制设置位（PmnPFS。PDR 和 PmnPFS。PMR）。有关端口控制设置位（PmnPFS。PDR 和 PmnPFS。PMR）的详细信息,请参阅第 18 节"I/O 端口 ."

21。3 操作

21。3。1 重新加载寄存器和计数器重写操作

无论操作模式如何,重写操作到重加载寄存器和计数器的时序根据AGTCR寄存器中的TSTART位和AGTCMSR寄存器中的TCMEA或TCMEB位的值而不同。TSTART位为0（计数停止）时,计数值直接写入重加载寄存器和计数器。TSTART位为1（计数开始）且TCMEA位和TCMEB位为0（AGT比较匹配A/B寄存器无效）时,与计数源同步将值写入重加载寄存器,然后与下一个计数源同步写入计数器。TSTART位为1（计数开始）且TCMEA位或TCMEB位为1（AGT比较匹配A寄存器或比较匹配B寄存器有效）时,与计数源同步将值写入重加载寄存器,然后与计数器的下溢同步写入计数器。

图21。4和图21。5示出了使用TSTART位值和TCMEA/TCMEB位值的重写操作的时序。

21.3.2 Reload Register and AGT Compare Match A/B Register Rewrite Operation

Regardless of the operating mode, the timing of the rewrite operation to the reload register and AGT compare register A/B depends on the value of the TSTART bit in the AGTCR register. When the TSTART bit is 0 (count stops), the count value is directly written to the reload register and AGT compare register A/B. When the TSTART bit is 1 (count starts), the value is written to the reload register in synchronization with the count source, and then to the compare register in synchronization with the underflow of the counter.

Figure 21.6 shows the timing of rewrite operation with TSTART bit value for compare register A. AGT Compare register B is of the same timing as AGT compare register A.

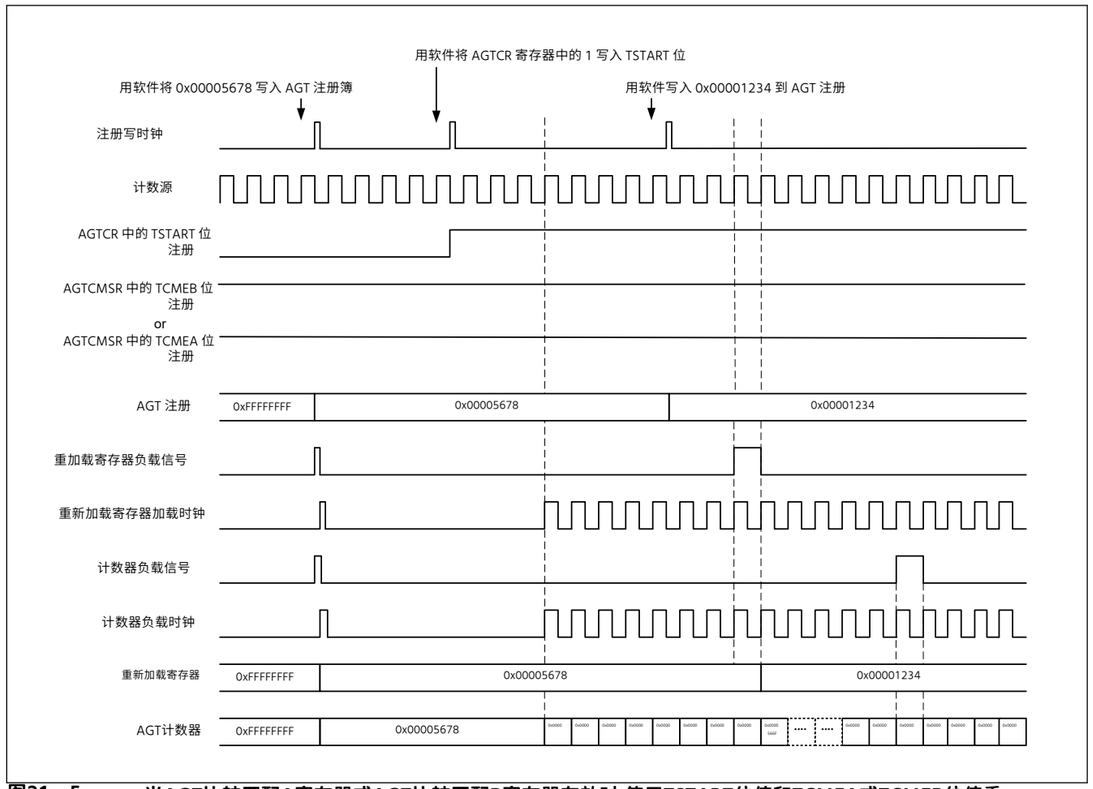

图21。5 当AGT比较匹配A寄存器或AGT比较匹配B寄存器有效时 使用TSTART位值和TCMEA或TCMEB位值重写操作的时序

21。3。2 重新加载寄存器和 AGT 比较匹配 A/B 寄存器重写操作

无论操作模式如何,重写操作到重加载寄存器和AGT比较寄存器A/B的定时取决于AGTCR寄存器中的TSTART位的值。TSTART位为0（计数停止）时,计数值直接写入重加载寄存器,AGT比较寄存器A/B。TSTART位为1（计数开始）时,该值与计数源同步写入重加载寄存器,然后与计数器的下溢同步写入比较寄存器。

图21。6显示了比较寄存器A的TSTART位值的重写操作的定时。AGT比较寄存器B与AGT比较寄存器A具有相同的定时。

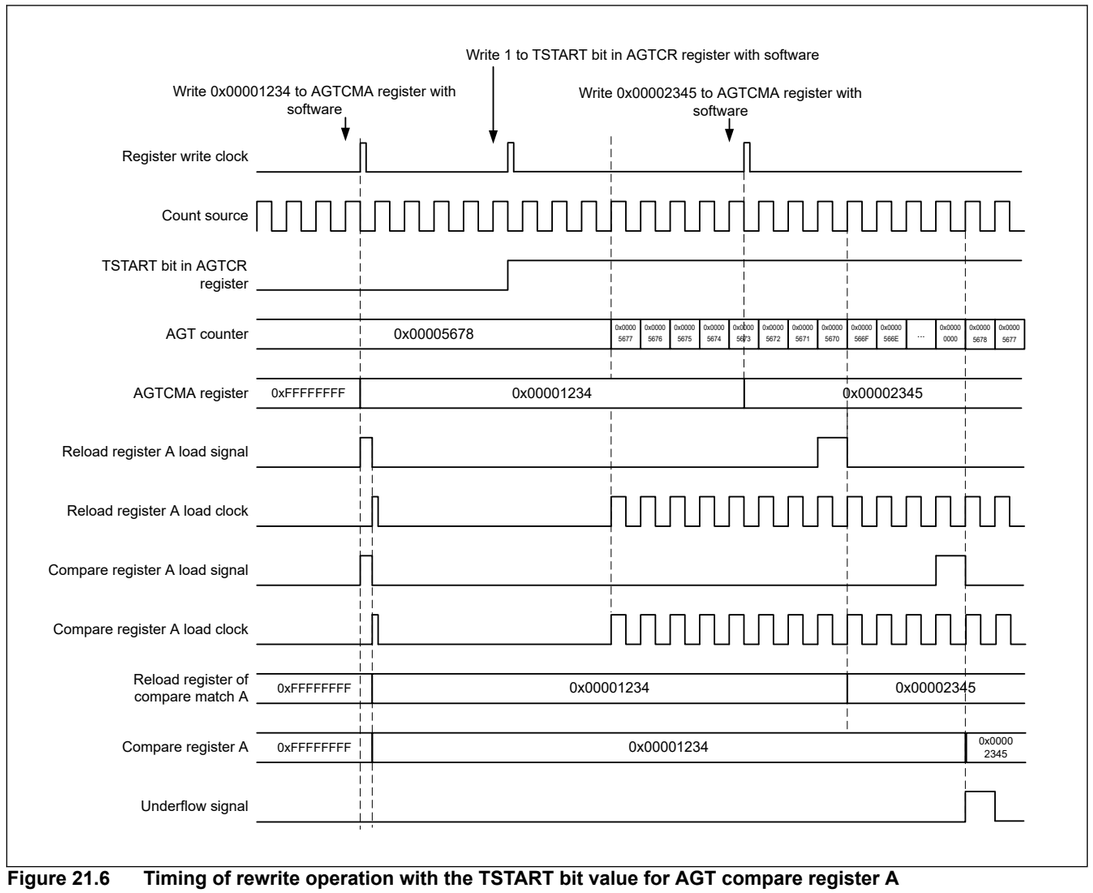

Figure 21.6 Timing of rewrite operation with the TSTART bit value for AGT compare register A

21.3.3 Timer Mode

In this mode, the AGT counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register. In timer mode, the count value is decremented by 1 on each rising edge of the count source. When the count value reaches 0x00000000 and the next count source is input, an underflow occurs and an interrupt request is generated.

Figure 21.7 shows the operation example in timer mode.

21.3.3 定时器模式

在此模式下,AGT 计数器由 AGTMR1 寄存器中 TCK[2:0] 位选择的计数源递减。在定时器模式下,计数源的每个上升沿上的计数值减小 1。当计数值达到时
0x00000000 并且输入下一个计数源,则发生下溢并生成中断请求。

图21。7显示了定时器模式下的操作示例。

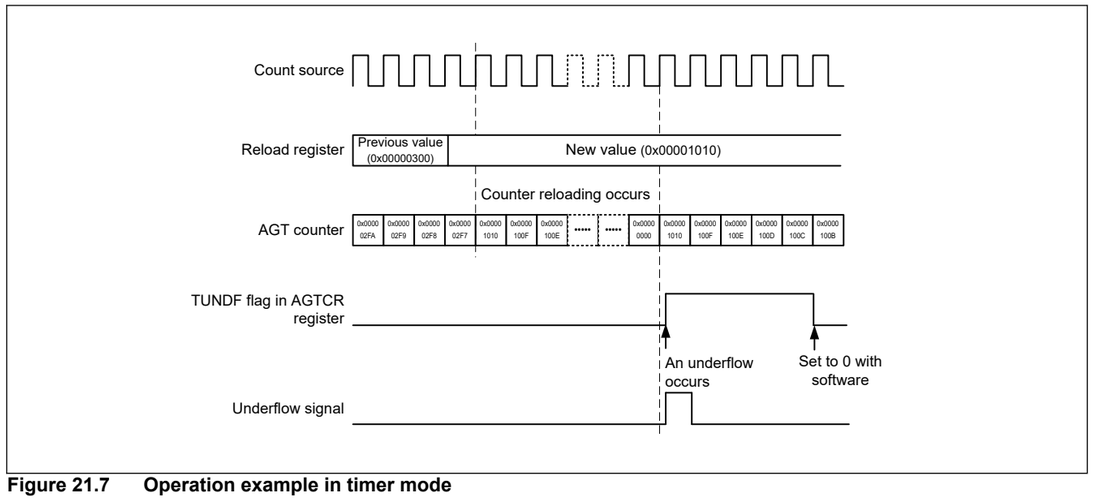

Figure 21.7 Operation example in timer mode

21.3.4 Pulse Output Mode

In pulse output mode, the counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register, and the output level of the AGTIOn and AGTOn pins inverted each time an underflow occurs.

In pulse output mode, the count value is decremented by 1 on each rising edge of the count source. When the count value reaches 0x00000000 and the next count source is input, an underflow occurs and an interrupt request is generated. In addition, a pulse can be output from the AGTIOn and AGTOn pins. The output level is inverted each time an underflow occurs. The pulse output from the AGTOn pin can be stopped with the TOE bit in the AGTIOC register. The output level can be selected with the TEDGSEL bit in the AGTIOC register.

Figure 21.8 shows the operation example in pulse output mode.

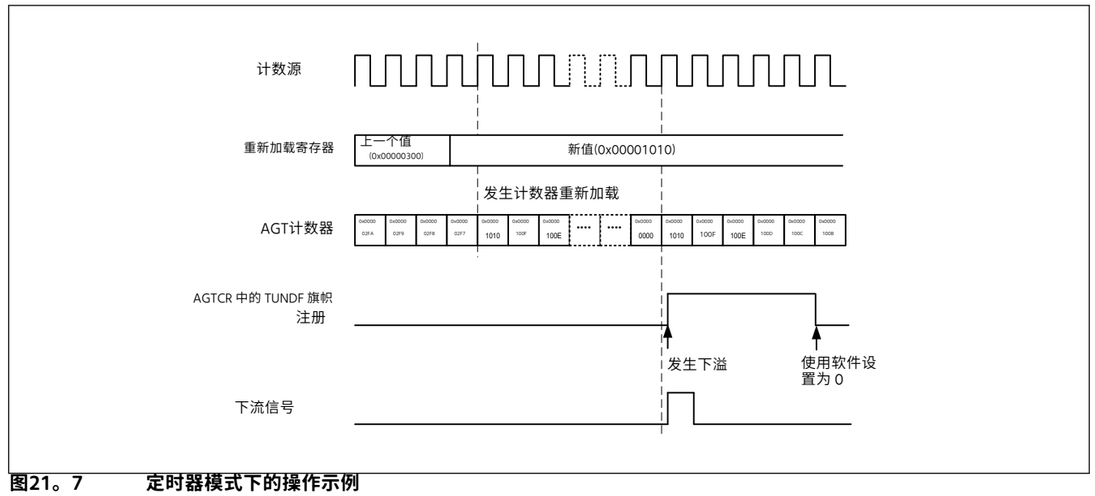

图21。7 定时器模式下的操作示例

21。3。4 脉冲输出模式

在脉冲输出模式下,计数器由 AGTMR1 寄存器中 TCK[2:0] 位选择的计数源递减,并且每次发生下溢时 AGTIOn 和 AGTOn 引脚的输出电平反转。

在脉冲输出模式下,计数源的每个上升沿上的计数值减少1。当计数值达到0x00000000并且输入下一个计数源时,发生下溢并生成中断请求。此外,还可以从 AGTIOn 和 AGTOn 引脚输出脉冲。每次发生下溢时,输出电平都会反转。AGTIOC 寄存器中的 TOE 位可以停止从 AGTOn 引脚输出的脉冲。可以使用 AGTIOC 寄存器中的 TEDGSEL 位来选择输出电平。图21。8示出了脉冲输出模式下的操作示例。

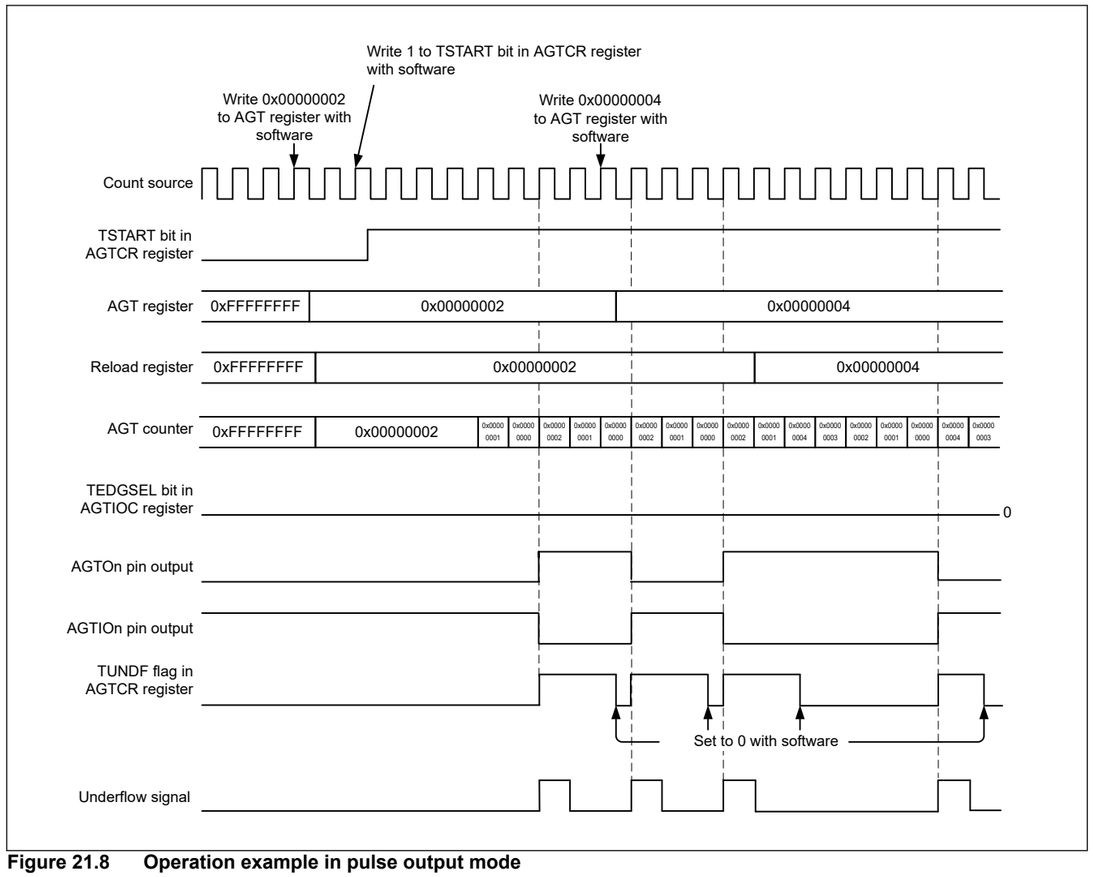

Figure 21.8 Operation example in pulse output mode

21.3.5 Event Counter Mode

In event counter mode, the counter is decremented by an external event signal (count source) input to the AGTIOn pin. Various periods for counting events can be set with the TIOGT[1:0] bits in the AGTIOC register and AGTISR registers. In addition, the filter function for the AGTIOn pin input can be specified with bits TIPF[1:0] in the AGTIOC register. The output from the AGTOn pin can be toggled even in event counter mode.

Figure 21.9 shows the operation example in event counter mode.

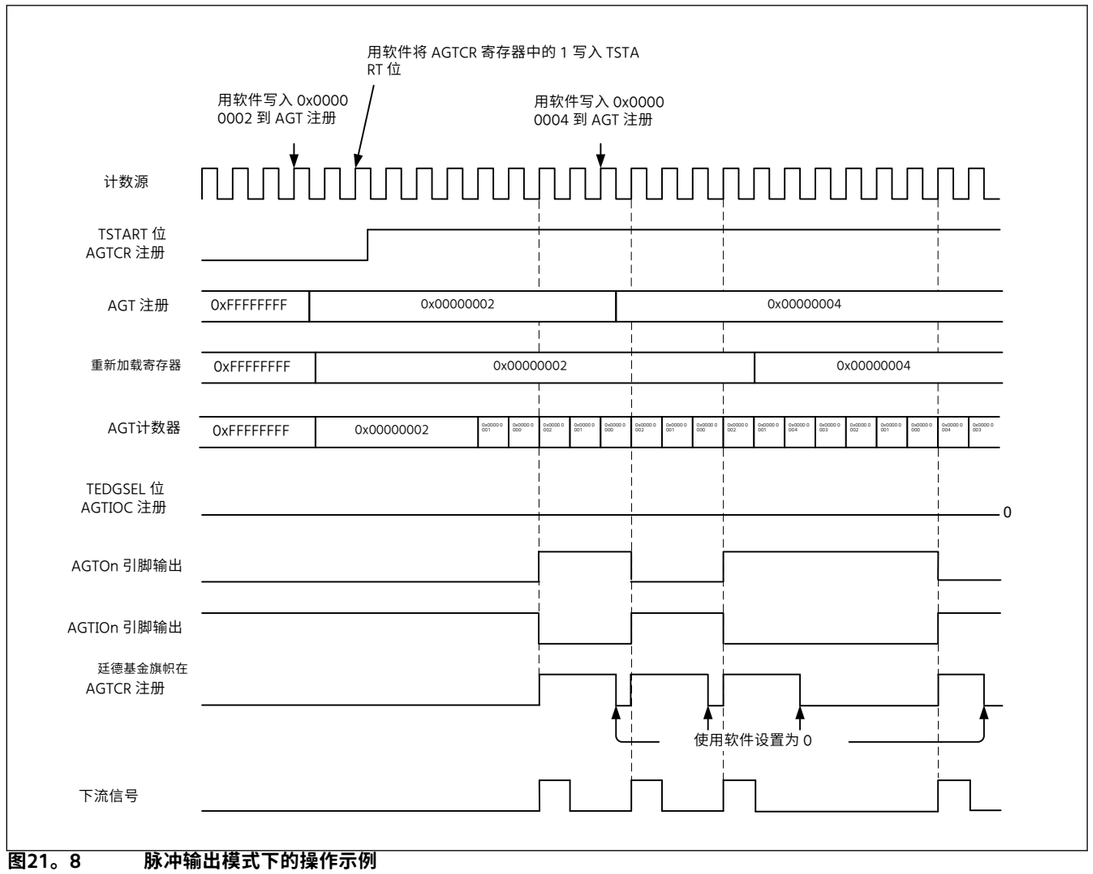

图21。8 脉冲输出模式下的操作示例

21.3.5 事件计数器模式

在事件计数器模式下,计数器由输入到 AGTIOn 引脚的外部事件信号（计数源）递减。

可以使用 AGTIOC 寄存器和 AGTISR 寄存器中的 TIOGT[1:0] 位设置用于计数事件的各种周期。此外,AGTIOn引脚输入的滤波器功能可以在AGTIOC寄存器中用位TIPF[1:0]指定。即使在事件计数器模式下,也可以切换 AGTOn 引脚的输出。图 21。9 显示了事件计数器模式下的操作示例。

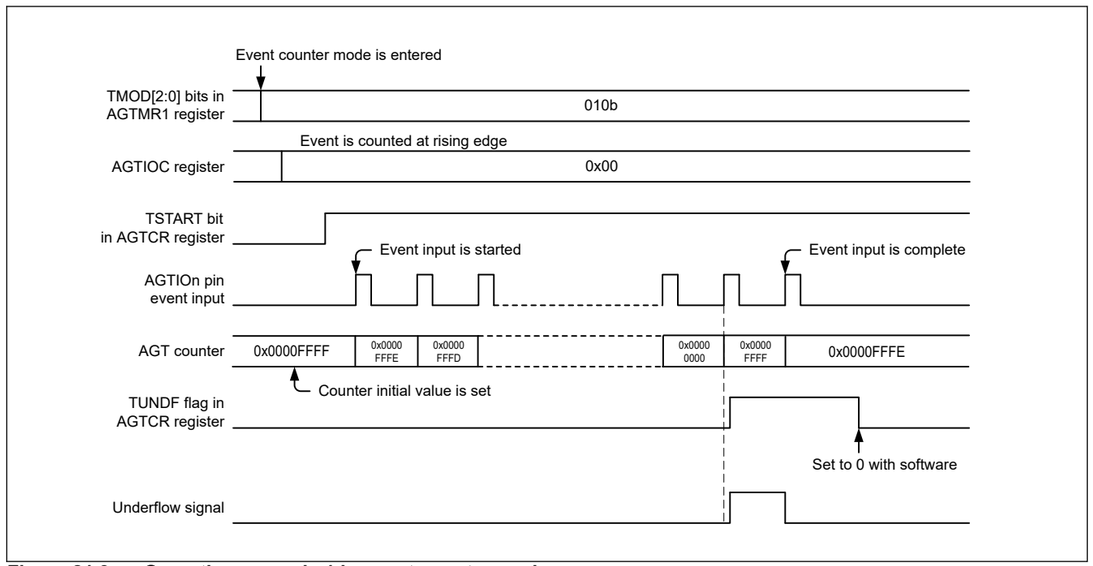

Figure 21.9 Operation example 1 in event counter mode

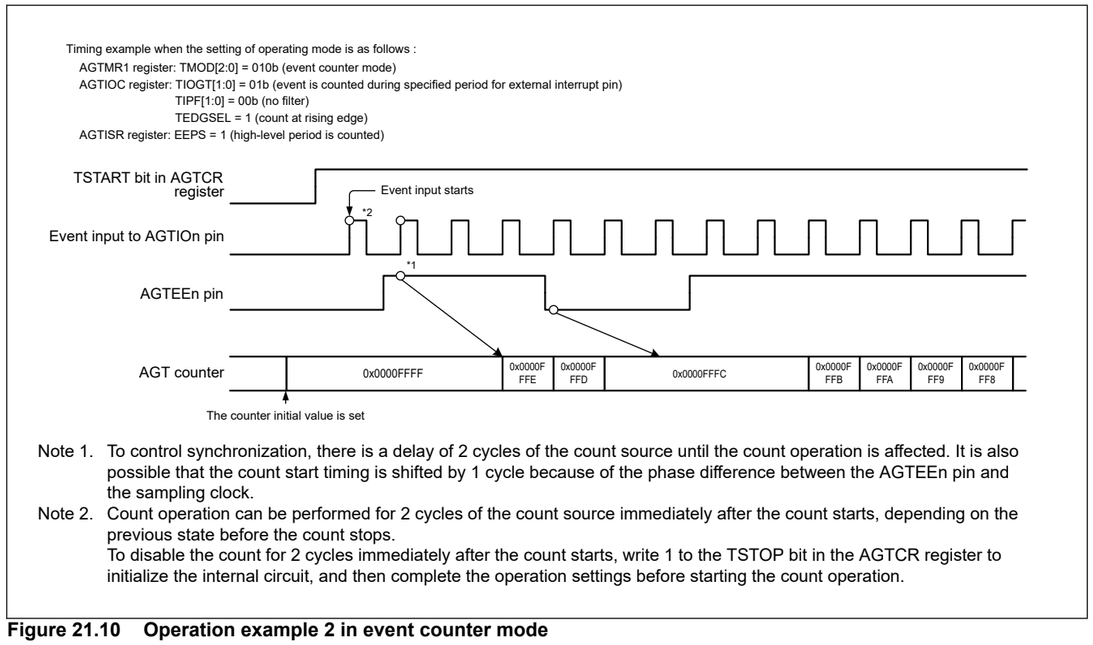
Figure 21.10 shows an operation example for counting during the specified period in event counter mode (TIOGT[1:0] bits in the AGTIOC register are set to 01b).



Note 1. To control synchronization, there is a delay of 2 cycles of the count source until the count operation is affected. It is also possible that the count start timing is shifted by 1 cycle because of the phase difference between the AGTEEn pin and the sampling clock.

Note 2. Count operation can be performed for 2 cycles of the count source immediately after the count starts, depending on the previous state before the count stops.
To disable the count for 2 cycles immediately after the count starts, write 1 to the TSTOP bit in the AGTCR register to initialize the internal circuit, and then complete the operation settings before starting the count operation.

Figure 21.10 Operation example 2 in event counter mode

21.3.6 Pulse Width Measurement Mode

In pulse width measurement mode, the pulse width of an external signal input to the AGTIOn pin is measured. When the level specified by the TEDGSEL bit in the AGTIOC register is input to the AGTIOn pin, the counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register. When the specified level on the AGTIOn pin ends, the counter is stopped, the TEDGF flag in the AGTCR register is set to 1 (active edge received), and an interrupt request is generated. The measurement of pulse width data is performed by reading the count value while the counter is stopped. Also,

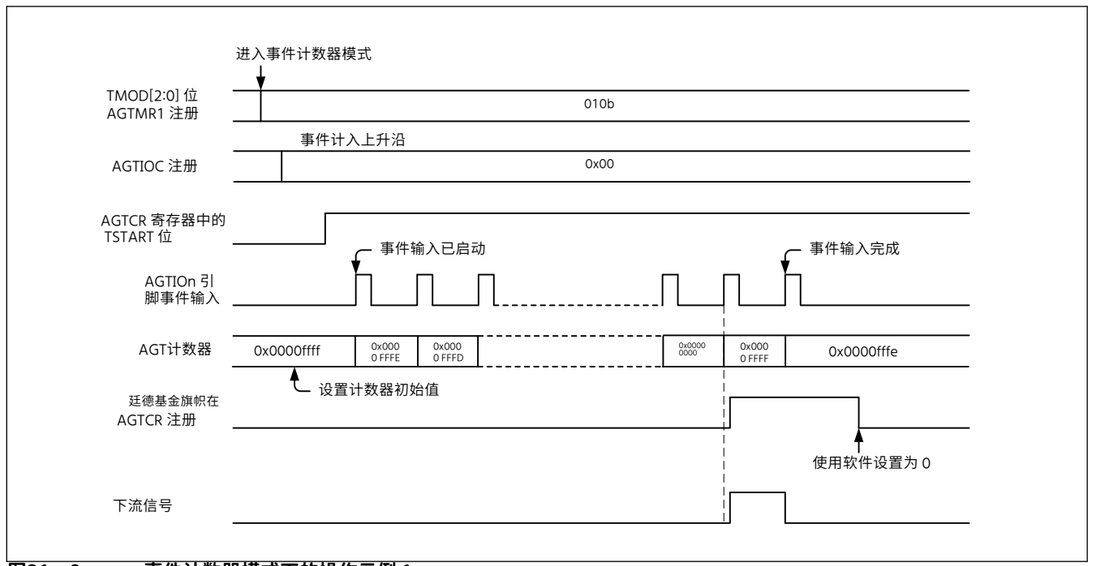


图21。9 事件计数器模式下的操作示例 1

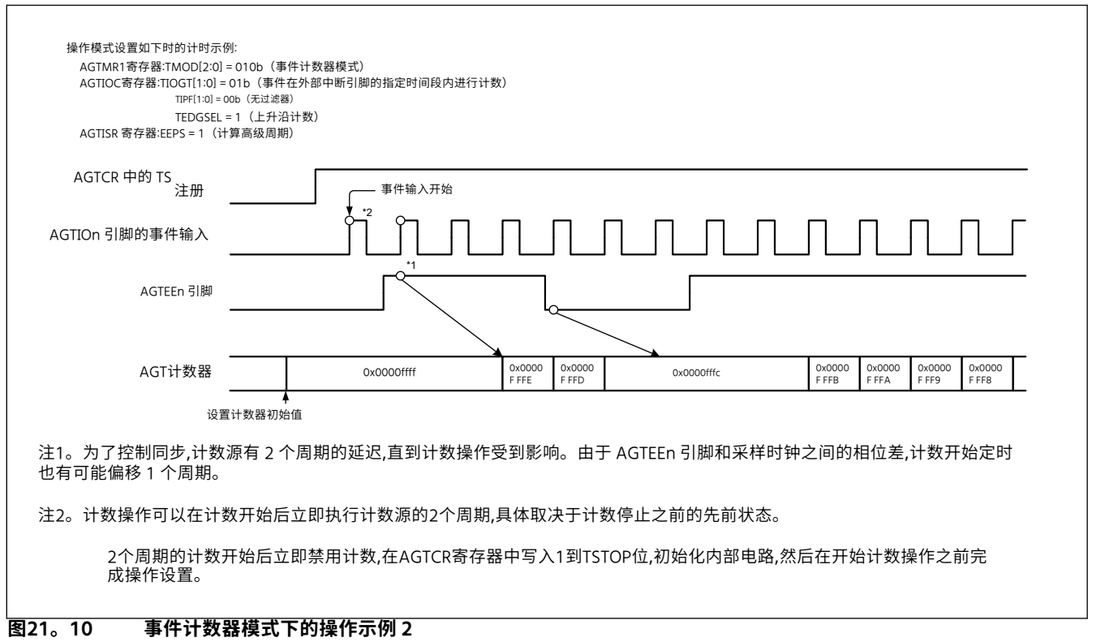
图21。10示出了在事件计数器模式下在指定时间段内计数的操作示例（AGTIOC寄存器中的TIOGT[1:0]位设置为01b）。



注1。为了控制同步,计数源有 2 个周期的延迟,直到计数操作受到影响。由于 AGTEEn 引脚和采样时钟之间的相位差,计数开始定时也有可能偏移 1 个周期。

注2。计数操作可以在计数开始后立即执行计数源的2个周期,具体取决于计数停止之前的先前状态。

2个周期的计数开始后立即禁用计数,在AGTCR寄存器中写入1到TSTOP位,初始化内部电路,然后在开始计数操作之前完成操作设置。

图21。10 事件计数器模式下的操作示例 2

21。3。6 脉冲宽度测量模式

在脉冲宽度测量模式下,测量输入到AGTIOn引脚的外部信号的脉冲宽度。AGTIOC寄存器中的TEDGSEL位指定的电平输入到AGTIOn引脚时,计数器由AGTMR1寄存器中的TCK[2:0]位选择的计数源递减。AGTIOn 引脚上的指定电平结束时,计数器停止,AGTCR 寄存器中的 TEDGF 标志设置为 1（接收到的活动边）,并生成中断请求。通过在计数器停止时读取计数值来执行脉冲宽度数据的测量。也,

when the counter underflows during measurement, the TUNDF flag in the AGTCR register is set to 1 and an interrupt request is generated.

Figure 21.11 shows the operation example in pulse width measurement mode.

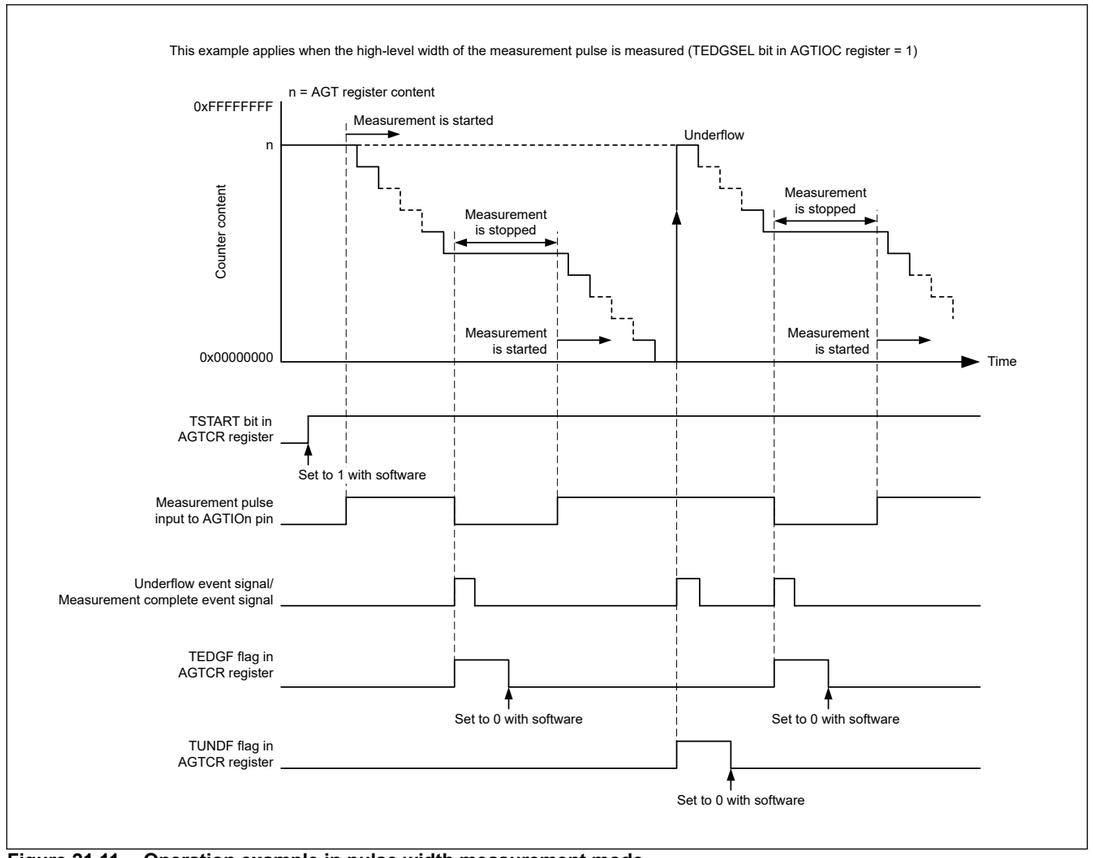


Figure 21.11 Operation example in pulse width measurement mode

21.3.7 Pulse Period Measurement Mode

In pulse period measurement mode, the pulse period of an external signal input to the AGTIOn pin is measured. The counter is decremented by the count source selected with TCK[2:0] bits in the AGTMR1 register. When a pulse with the period specified by the TEDGSEL bit in the AGTIOC register is input to the AGTIOn pin, the count value is transferred to the read-out buffer on the rising edge of the count source. The value in the reload register is loaded to the counter at the next rising edge. Simultaneously, the TEDGF flag in the AGTCR register is set to 1 (active edge received) and an interrupt request is generated. The read-out buffer (AGT register) is read at this time and the difference from the reload value (see section 21.4.6. How to Calculate Event Number, Pulse Width, and Pulse Period) is the period data of the input pulse. The period data is retained until the read-out buffer is read. When the counter underflows, the TUNDF flag in the AGTCR register is set to 1 (underflow) and an interrupt request is generated.

Figure 21.12 shows the operation example in pulse period measurement mode.

Only input pulses with a period longer than twice the period of the count source are measured. Also, the low-level and high-level widths must both be longer than the period of the count source. If a pulse period shorter than these conditions is input, the input might be ignored.

当计数器在测量期间下溢时,AGTCR寄存器中的TUNDF标志被设置为1并生成中断请求。

图21。11示出了脉冲宽度测量模式下的操作示例。

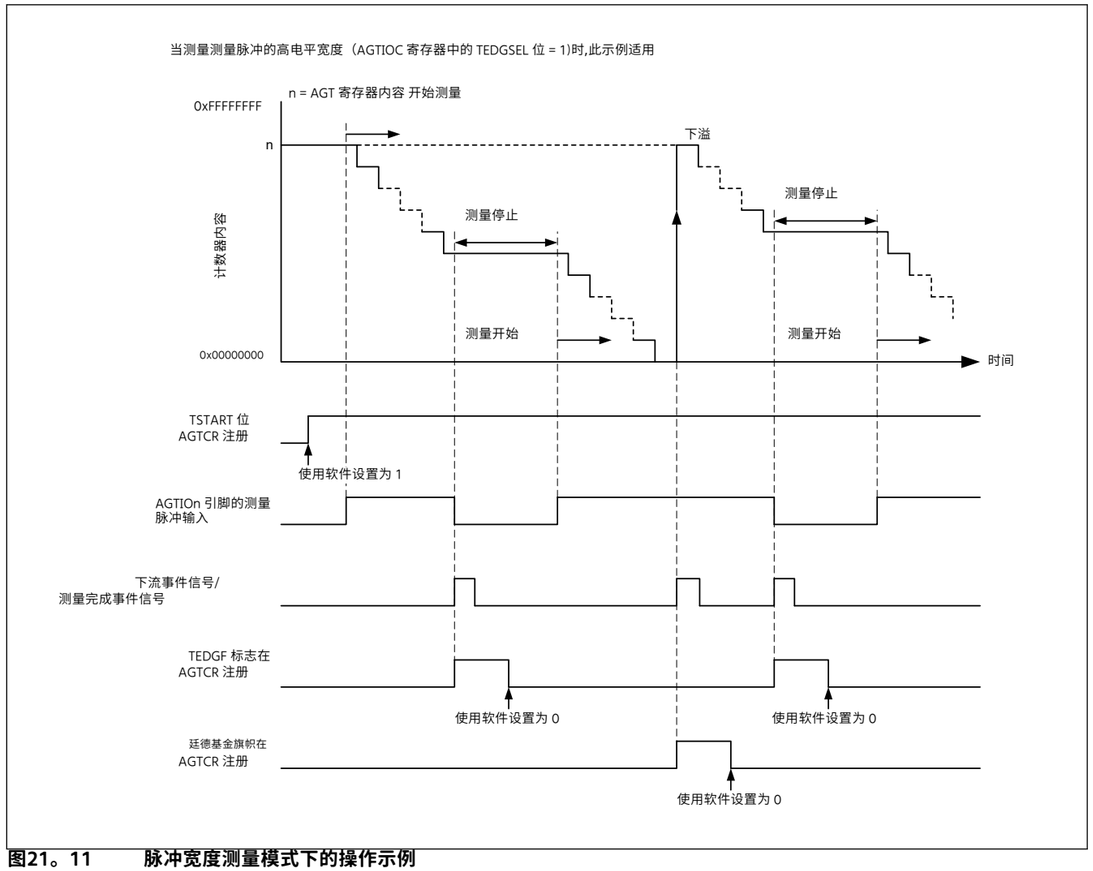

图21。11 脉冲宽度测量模式下的操作示例

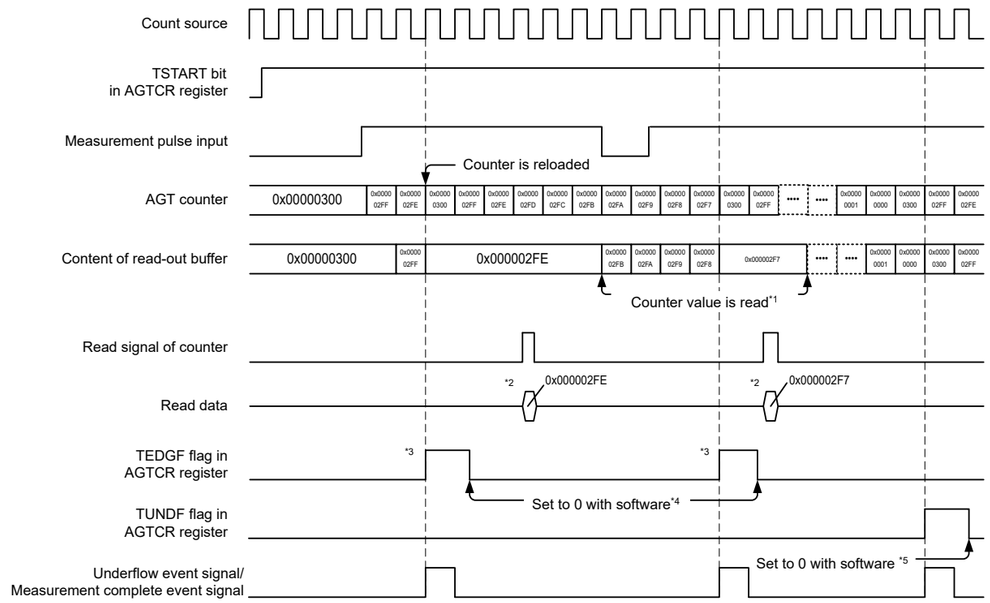
21。3。7 脉冲周期测量模式

在脉冲周期测量模式下,测量输入到AGTIOn引脚的外部信号的脉冲周期。计数器由 AGTMR1 寄存器中 TCK[2:0] 位选择的计数源递减。AGTIOC寄存器中TEDGSEL位指定的周期的脉冲输入到AGTIOn引脚时,计数值被传送到计数源上升沿上的读出缓冲区。重新加载寄存器中的值在下一个上升沿加载到计数器。同时,AGTCR寄存器中的TEDGF标志被设置为1（接收有源边缘）并生成中断请求。此时读出缓冲区（AGT 寄存器）以及与重新加载值的差异（参见第 21。4。6 节）。如何计算事件数、脉冲宽度和脉冲周期）是输入脉冲的周期数据。保留周期数据直到读出缓冲区被读取。当计数器下溢时,AGTCR寄存器中的TUNDF标志被设置为1（下溢）并生成中断请求。

图21。12示出了脉冲周期测量模式下的操作示例。

仅测量周期长于计数源周期两倍的输入脉冲。此外,低电平和高电平宽度必须都长于计数源的周期。如果输入比这些条件短的脉冲周期,则输入可能会被忽略。



This example applies when the initial value of the AGT register is set to A, the TEDGSEL bit in the AGTIOC register is set to 0, and the period from one rising edge to the next edge of the measurement pulse is measured.

Note 1. Reading from the AGT register must be performed during the period from when the TEDGF flag is set to 1 (active edge received) until the next active edge is input. The content of the read-out buffer is retained until the AGT register is read. If it is not read before the active edge is input, the measurement result of the previous period is retained.
Note 2. When the AGT register is read in pulse period measurement mode, the content of the read-out buffer is read.
Note 3. When the active edge of the measurement pulse is input and then the set edge of an external pulse is input, the TEDGF flag in the AGTCR register is set to 1 (active edge received).
Note 4. To set to 0 with software, write 0 to the TEDGF flag in the AGTCR register with an 8-bit memory manipulation instruction.
Note 5. To set to 0 with software, write 0 to the TUNDF flag in the AGTCR register with an 8-bit memory manipulation instruction.

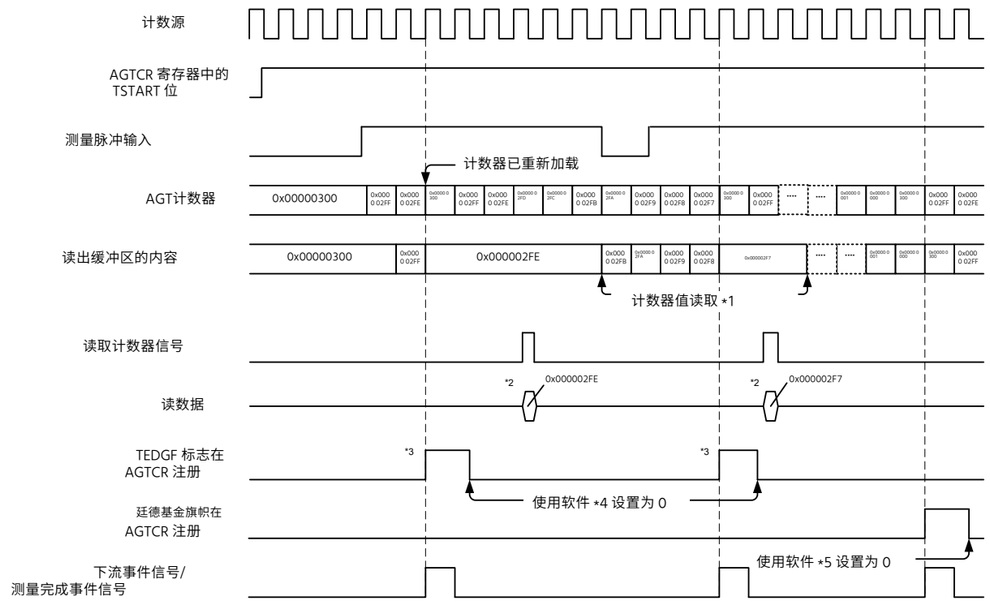
Figure 21.12 Operation example in pulse period measurement mode

21.3.8 Compare Match function

The compare match function detects matches (compare match) between the content of the AGTCMA or AGTCMB register and the content of the AGT register. This function is enabled when the TCMEA or TCMEB bit in the AGTCMSR register is 1 (compare match A register or compare match B register is valid). The counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register, and when the values of AGT and AGTCMA or AGTCMB match, the TCMAF/TCMBF flag in the AGTCR register is set to 1 (match), and an interrupt request is generated.

When the compare match function is enabled, the timing of the rewrite operation to the reload register and the counter differs. See section 21.3.1. Reload Register and Counter Rewrite Operation for details. In addition, the output level of the AGTOAn, AGTOBn pins is inverted by the match and by the underflow. The output level can be selected with the TOPOLA or TOPOLB bit in the AGTCMSR register.

Figure 21.13 shows the operation example in compare match function.



AGT寄存器的初始值设置为A,AGTIOC寄存器中的TEDGSEL位设置为0,测量测量脉冲从一个上升沿到下一个沿的周期时,该示例适用。

注1。从 AGT 寄存器读取必须在从 TEDGF 标志设置为 1（接收活动边）到输入下一个活动边期间执行。读出缓冲区的内容被保留,直到读取 AGT 寄存器。如果在输入活动边之前未读取,则保留上一时段的测量结果。

注2。AGT寄存器在脉冲周期测量模式下读取时,读出缓冲区的内容。
注3。当输入测量脉冲的有源边缘,然后输入外部脉冲的设定边缘时,AGTCR寄存器中的TEDGF标志被设置为1（接收有源边缘）。

注4。要使用软件设置为 0,请使用 8 位内存操作指令将 0 写入 AGTCR 寄存器中的 TEDGF 标志。
注5。要使用软件设置为 0,请使用 8 位内存操作指令将 0 写入 AGTCR 寄存器中的 TUNDF 标志。

图 21。12 脉冲周期测量模式下的操作示例

21。3。8 比较匹配功能

比较匹配函数检测AGTCMA或AGTCMB寄存器的内容与AGT寄存器的内容之间的匹配（比较匹配）。当 AGTCMSR 寄存器中的 TCMEA 或 TCMEB 位为 1（比较匹配 A 寄存器或比较匹配 B 寄存器有效）时,此功能启用。计数器由AGTMR1寄存器中TCK[2:0]位选择的计数源递减,当AGT和AGTCMA或AGTCMB的值匹配时,AGTCR寄存器中的TCMAF/TCMBF标志被设置为1（匹配）,并生成中断请求。

当启用比较匹配函数时,重写操作到重新加载寄存器和计数器的时序不同。参见第 21。3。1 节。重新加载寄存器和计数器重写操作以了解详细信息。此外,AGTOAn、AGTOBn 引脚的输出电平会被匹配和下溢反转。可以使用 AGTCMSR 寄存器中的 TOPOLA 或 TOPOLB 位来选择输出电平。

21.3.12 Event Signal Output to ELC

The AGTn (n = 0, 1) uses the Event Link Controller (ELC) to perform a link operation to a specified module using the interrupt request signal as the event signal. The AGTn (n = 0, 1) outputs compare match A, compare match B, and underflow/measurement complete signals as event signals. For details, see section 17, Event Link Controller (ELC).

21.4 Usage Notes

21.4.1 Count Operation Start and Stop Control

- When the operating mode (see Table 21.1) is set to other than the event counter mode, or the count source is set to other than AGTn underflow event signal (TCK[2:0] = 101b):
  - After 1 (count starts) is written to the TSTART bit in the AGTCR register while the count is stopped, the TCSTF flag in the AGTCR register remains 0 (count stops) for 3 cycles of the count source. Do not access the registers associated with AGT other than the TCSTF flag until this flag is set to 1 (count in progress).
  - After 0 (count stops) is written to the TSTART bit during a count operation, the TCSTF flag remains 1 for 3 cycles of the count source. When the TCSTF flag is set to 0, the count is stopped. Do not access the registers associated with AGT other than the TCSTF flag until this flag is set to 0.

- When the operating mode (see Table 21.1) is set to event counter mode, or the count source is set to AGT1 underflow event signal (TCK[2:0] = 101b):
  - After 1 (count starts) is written to the TSTART bit in the AGTCR register while the count is stopped, the TCSTF flag in the AGTCR register remains 0 (count stops) for 2 PCLKB cycles. Do not access the registers associated with AGT other than the TCSTF flag until this flag is set to 1 (count in progress).
  - After 0 (count stops) is written to the TSTART bit during a count operation, the TCSTF flag remains 1 for 2 PCLKB cycles. When the TCSTF flag is set to 0, the count is stopped. Do not access the registers associated with AGT other than the TCSTF flag until this flag is set to 0.

21.4.2 Access to Counter Register

When the TSTART bit and TCSTF flag in the AGTCR register are both 1 (count starts), allow at least 3 cycles of the count source clock between writes when writing to the AGT register successively.

21.4.3 When Changing Mode

The registers associated with AGT operating mode (AGTMR1, AGTMR2, AGTIOC, AGTISR, and AGTCMSR) can be changed only when the count is stopped with both the TSTART bit and TCSTF flag set to 0 (count stops). Do not change these registers during count operation.

When the registers associated with AGT operating mode are changed, the values of TEDGF, TUNDF, TCMAF, and TCMBF flags are undefined. Before starting the count, write 0 to the following flags:

- TEDGF (no active edge received)
- TUNDF (no underflow)
- TCMAF (no match)
- TCMBF (no match).

21.4.4 Output pin setting

When using the AGTOn, AGTIOn, AGTOAn, or AGTOBn as an output pin, set up the Operation and determine the initial output values. Then set an output mode in the port register.

When using the AGTIOn as an input pin in pulse width measurement mode or pulse period measurement mode, set up the Operation and start count operation. Then start to enter external events from the AGTIOn pin. Invalidate the first measurement and validate the second and later completed measurements.

21.3.12 事件信号输出到 ELC

AGTn（n = 0, 1）使用事件链路控制器（ELC）使用中断请求信号作为事件信号对指定模块执行链路操作。AGTn（n = 0, 1）输出比较匹配 A、比较匹配 B 和底流/测量完整信号作为事件信号。有关详细信息,请参阅第 17 节"事件链接控制器（ELC）."

21。4 使用说明

21。4。1 计数操作开始和停止控制

● 当操作模式（见表 21。1)设置为事件计数器模式以外, 或计数源设置为 AGTn 底流事件信号以外（TCK[2:0] = 101b）：

— 停止计数时将 1（计数开始）写入 AGTCR 寄存器中的 TSTART 位后,AGTCR 寄存器中的 TCSTF 标志在计数源的 3 个周期内保持 0（计数停止）。在将此标志设置为 1（计数进行中）之前,请勿访问与 TCSTF 标志以外的 AGT 关联的寄存器。

— 在计数操作期间将 0（计数停止）写入 TSTART 位后,TCSTF 标志在计数源的 3 个周期内保持 1。TCSTF 标志设置为 0 时, 停止计数。TCSTF 标志以外的其他 AGT 关联的寄存器, 直至该标志设置为 0。

● 当操作模式（见表 21。1)设置为事件计数器模式, 或计数源设置为 AGT1 底流事件信号（TCK[2:0] = 101b）：

— 在停止计数时将 1（计数开始）写入 AGTCR 寄存器中的 TSTART 位后,AGTCR 寄存器中的 TCSTF 标志在 2 个 PCLKB 周期内保持为 0（计数停止）。在将此标志设置为 1（计数进行中）之前,请勿访问与 TCSTF 标志以外的 AGT 关联的寄存器。

— 在计数操作期间将 0（计数停止）写入 TSTART 位后,TCSTF 标志在 2 个 PCLKB 周期内保持为 1。TCSTF 标志设置为 0 时, 停止计数。TCSTF 标志以外的其他 AGT 关联的寄存器, 直至该标志设置为 0。

21。4。2 访问计数器寄存器

AGTCR寄存器中的TSTART位和TCSTF标志都是1（计数开始）时,在连续写入AGT寄存器时,允许计数源时钟在写入之间至少3个周期。

21.4.3 更改模式时

仅当计数停止且 TSTART 位和 TCSTF 标志均设置为 0（计数停止）时,才能更改与 AGT 操作模式（AGTMR1、AGTMR2、AGTIOC、AGTISR 和 AGTCMSR）关联的寄存器。在计数操作期间请勿更改这些寄存器。

当与AGT操作模式相关联的寄存器改变时,TEDGF、TUNDF、TCMAF和TCMBF标志的值未定义。在开始计数之前,将 0 写入以下标志:

- TEDGF（未接收活动边缘）
- TUNDF（无下溢）
- TCMAF（无匹配
- TCMBF（无匹配）

。

21。4。4 输出引脚设置

当使用 AGTOn、AGTIOn、AGTOAn 或 AGTOBn 作为输出引脚时,设置操作并确定初始输出值。然后在端口寄存器中设置输出模式。

AGTIOn作为脉冲宽度测量模式或脉冲周期测量模式的输入引脚时, 设置操作并开始计数操作。然后开始从 AGTIOn 引脚输入外部事件。使第一次测量无效并验证第二次和稍后完成的测量。

21.4.5 Digital Filter

When using the digital filter, do not start the timer operation for 5 cycles of the digital filter clock after setting TIPF[1:0] bits and when the TEDGSEL bit in the AGTIOC register changes.

21.4.6 How to Calculate Event Number, Pulse Width, and Pulse Period

- In event counter mode, event number is expressed mathematically as follows:
  Event number = initial value of counter [AGT register] - counter value of active event end
- In pulse width measurement mode, pulse width is expressed mathematically as follows:
  Pulse width = counter value of stopping measurement - counter value of next stopping measurement
- In pulse period measurement mode, input pulse period is expressed mathematically as follows:
  Period of input pulse = (initial value of counter [AGT register] - reading value of the read-out buffer) + 1.

21.4.7 When Count is Forcibly Stopped by TSTOP Bit

After the counter is forcibly stopped by the TSTOP bit in the AGTCR register, do not access the following I/O registers for 1 cycle of the count source:

- AGT
- AGTCMA
- AGTCMB
- AGTCR
- AGTMR1
- AGTMR2.

21.4.8 When Selecting AGT0 Underflow as the Count Source

Operate according to the following procedures described in this section when selecting the underflow event signal as the count source.

(1) Procedure for starting operation

1. Set AGT.
2. Start the count operation of AGT1.
3. Start the count operation of AGT0.

(2) Procedure for stopping operation

1. Stop the count operation of AGT0.
2. Stop the count operation of AGT1.
3. Stop the count source clock of AGT1 (write 000b in the AGTMR1.TCK[2:0] bits).

21.4.9 Module-stop function

AGT operation can be disabled or enabled using Module Stop Control Register D (MSTPCRD). The AGT module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes

21.4.10 When Switching Source Clock

When switching a clock source by changing SCKSCR.CKSEL[2:0], the clock output from the selector stops for 4 cycles of the switched clock. Therefore, when using the AGTIOn, AGTEEn, or both input as external event input, the clock source should not be switched. If switching the clock source while using the external event input, extend the input pulse width by 4 clock cycles of the switched source clock cycles.

21。4。5 数字滤波器

TIPF[1:0]位设置后以及AGTIOC寄存器中的TEDGSEL位发生变化时,请勿启动数字滤波器时钟5个周期的定时器操作。

21。4。6 如何计算事件数、脉冲宽度、脉冲周期

- 在事件计数器模式下, 事件编号用数学表示如下:
  事件编号 = 计数器初始值 [AGT 寄存器] 活动事件结束计数器值
- 在脉冲宽度测量模式下, 脉冲宽度在数学上表示如下:
  脉冲宽度=停止测量的计数器值 下一次停止测量的计数器值
- 在脉冲周期测量模式下, 输入脉冲周期用数学表示如下:
  输入脉冲周期=（读出缓冲区的计数器[AGT寄存器]读取值的初始值）+1。

21。4。7 当 Count 被 TSTOP Bit 强行停止时

AGTCR 寄存器中的 TSTOP 位强制停止计数器后, 在计数源的 1 个周期内不要访问以下 I/O 寄存器:

- AGT
- AGTCMA
- AGTCMB
- AGTCR
- AGTMR1
- AGTMR2

。

21.4.8 当选择 AGT0 底流作为计数源时

当选择下溢事件信号作为计数源时,根据本节中描述的以下过程进行操作。

(1)开始操作的程序

1。设置 AGT。

2锛姣涓涓。AGT1的计数操作开始。

3锛 娴 。AGT0的计数操作开始。

(2)停止运行的程序

1。AGT0停止计数操作。

2锛姣涓涓。AGT1停止计数操作。

3锛 娴 。AGT1的计数源时钟停止（在AGTMR1中写入000b）。TCK[2:0] 位）。

21。4。9 模块停止功能

可以使用模块停止控制寄存器 D（MSTPCRD）禁用或启用 AGT 操作。AGT模块在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息,请参阅第 10 节"低功耗模式"

21。4。10 切换源时钟时

SCKSCR。CKSEL[2:0] 改变时钟源时,从选择器输出的时钟停止切换时钟的 4 个周期。因此,当使用AGTIOn、AGTEEn或两个输入作为外部事件输入时,不应切换时钟源。如果在使用外部事件输入的同时切换时钟源,则将输入脉冲宽度延长切换源时钟周期的 4 个时钟周期。

22.2 Register Descriptions

22.2.1 WDTRR : WDT Refresh Register

Base address: WDT = 0x4008_3400

Offset address: 0x00

Bit position:	7							0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	n/a	The down-counter is refreshed by writing 0x00 and then writing 0xFF to this register.	R/W

The WDTRR register refreshes the down-counter of the WDT.

The down-counter of the WDT is refreshed by writing 0x00 and then writing 0xFF to WDTRR register (refresh operation) within the refresh-permitted period.

After the down-counter is refreshed, it starts counting down from the value selected by setting the WDT Timeout Period Select bits (OFS0.WDTTOPS[1:0]) in the Option Function Select Register 0 in auto start mode. In register start mode, counting down starts from the value selected by setting the Timeout Period Select bits (WDTCR.TOPS[1:0]) in the WDT Control Register.

When 0x00 is written, the read value is 0x00. When a value other than 0x00 is written, the read value is 0xFF. For details of the refresh operation, see section 22.3.3. Refresh Operation.

The WDTCR register is used to set the clock division ratio, and window start and end positions for refresh, and the timeout period until the down-counter underflows in register start mode.

Some constraints apply to writes to the WDTCR register. For details, see section 22.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the settings in the WDTCR register are disabled, and the settings in the Option Function Select Register 0 (OFS0) are enabled. The settings for the WDTCR register can also be made in the OFS0 register. For details, see section 22.3.8. Association between Option Function Select Register 0 (OFS0) and WDT Registers.

TOPS[1:0] bits (Timeout Period Select)

The TOPS[1:0] bits select the timeout period, the period until the down-counter underflows, from 1024, 4096, 8192, and 16384 cycles, taking the divided clock specified in the CKS[3:0] bits as 1 cycle. After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the number of PCLKB cycles until the counter underflows.

Table 22.2 lists the relationship between the CKS[3:0] and TOPS[1:0] bit settings, the timeout period, and the number of PCLKB cycles.

WDTCR寄存器用于设置时钟分频比,以及用于刷新的窗口起始和结束位置,以及在寄存器启动模式下直到下计数器下溢的超时周期。

一些约束适用于对 WDTCR 寄存器的写入。详情请参见第 22。3。2 节。控制 WDTCR、WDTRCR 和 WDTCSTPR 寄存器 . 的写入

在自动启动模式下,WDTCR寄存器中的设置被禁用,并且选项功能选择寄存器0（OFS0)中的设置被启用。WDTCR寄存器的设置也可以在OFS0寄存器中进行。详情请参见第 22。3。8 节。Option 函数选择寄存器 0（OFS0) 和 WDT 寄存器 . 之间的关联

TOPS[1:0] 位（超时周期选择）

TOPS[1:0] 位从 1024、4096、8192 和 16384 个周期中选择超时周期,即直到下计数器下溢的周期,将 CKS[3:0] 位中指定的分频时钟作为 1 个周期。下计数器刷新后,CKS[3:0]和TOPS[1:0]位的组合确定PCLKB循环的数量,直到计数器下溢。表 22。2 列出了 CKS[3:0] 和 TOPS[1:0] 位设置之间的关系、超时周期以及 PCLKB 周期数。

CKS[3:0] bits (Clock Division Ratio Select)

The CKS[3:0] bits specify the division ratio of the clock used for the down-counter. The division ratio can be selected from the PCLKB divided by 4, 64, 128, 512, 2048, and 8192. Combined with the TOPS[1:0] bit setting, this allows the WDT to be configured to a count period between 4096 and 134217728 PCLKB clock cycles.

RPES[1:0] bits (Window End Position Select)

The RPES[1:0] bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. Set the window end position to a value less than the value for the window start position (window start position > window end position). If the window start position is set to a value less than or equal to the window end position, the window start position setting is enabled and the window end position is set to 0%.

RPSS[1:0] bits (Window Start Position Select)

The RPSS[1:0] bits specify the window start position that indicates the refresh-permitted period. 100%, 75%, 50%, or 25% of the timeout period can be selected for the window start position. Set the window start position to a value greater than the value for the window end position. If the window start position is set to a value less than or equal to the window end position, the window start position setting is enabled and the window end position is set to 0%.

Table 22.3 lists the counter values for the window start and end positions, and Figure 22.2 shows the refresh-permitted period set in the RPSS[1:0], RPES[1:0], and TOPS[1:0] bits.

CKS[3:0] 位（时钟划分比例选择）

CKS[3:0] 位指定用于下计数器的时钟的分频比。分配比可以选自PCLKB除以4、64、128、512、2048和8192。TOPS[1:0]位设置相结合,这允许WDT被配置为4096和134217728PCLKB时钟周期之间的计数周期。

RPES[1:0] 位（窗口结束位置选择）

RPES[1:0]位指定指示刷新允许周期的窗口结束位置,可以为窗口结束位置选择75%、50%、25%或0%的超时周期。将窗口结束位置设置为小于窗口开始位置的值（窗口开始位置>窗口结束位置）。如果窗口开始位置被设置为小于或等于窗口结束位置的值,则窗口开始位置设置被启用并且窗口结束位置被设置为0%。

RPSS[1:0] 位（窗口开始位置选择）

RPSS[1:0]位指定指示刷新允许周期的窗口开始位置,可以为窗口开始位置选择100%、75%、50%或25%的超时周期。将窗口开始位置设置为大于窗口结束位置的值的值。如果窗口开始位置被设置为小于或等于窗口结束位置的值,则窗口开始位置设置被启用并且窗口结束位置被设置为0%。

表 22。3 列出了窗口开始和结束位置的计数器值,图 22。2 显示了 RPSS[1:0]、RPES[1:0] 和 TOPS[1:0] 位中设置的刷新允许周期。

14	UNDFF	下溢标志 0:未发生下溢 1:发生下溢	R/W*1

Bit	Symbol	Function	R/W
15	REFEF	Refresh Error Flag 0: No refresh error occurred 1: Refresh error occurred	R/W*1

Note 1. Only 0 can be written to clear the flag.

The WDTSR register indicates the counter value of the down-counter and the status of whether an underflow or refresh error occurred in the down-counter.

CNTVAL[13:0] bits (Down-Counter Value)

Read the CNTVAL[13:0] bits to confirm the value of the down-counter. The read value might differ from the actual count by 1.

UNDFF flag (Underflow Flag)

Read the UNDFF flag to confirm whether an underflow occurred in the counter. A value of 1 indicates that the down counter underflowed. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N+1) PCLKB cycles. In addition, clearing of the flag is ignored for (N+1) PCLKB cycles after an underflow. N is specified in the WDTCR.CKS[3:0] bits as follows:

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

REFEF flag (Refresh Error Flag)

Read the REFEF flag to confirm whether a refresh error occurred, indicating that a refresh operation was performed during a prohibited period. A value of 1 indicates that a refresh error occurred. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the REFEF flag takes (N+1) PCLKB cycles. In addition, clearing of the flag is ignored for (N+1) PCLKB cycles after a refresh error. N is specified in the WDTCR.CKS[3:0] bits as follows:

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

注1。0才能写清旗。

WDTSR寄存器指示下计数器的计数器值以及下计数器中是否发生下溢或刷新错误的状态。

CNTVAL[13:0] 位（下计数器值）

读取 CNTVAL[13:0] 位以确认下计数器的值。读取值可能与实际计数相差 1。

UNDFF 标志（下流标志）

读取 UNDFF 标志以确认计数器中是否发生下溢。1 的值表示下计数器下溢。0 写入标志,将值设置为 0。1 的书写没有效果。

UNDFF 标志的清除采用（N+1）PCLKB 周期。此外,对于下溢后的（N+1）PCLKB 循环,标志的清除将被忽略。N在WDTCR。CKS[3:0]位中指定如下:

- 当 WDTCR。CKS[3:0] = 0x1 时,N = 4
- 当 WDTCR。CKS[3:0] = 0x4 时,N = 6
- 当 WDTCR。CKS[3:0] = 0xF 时,N = 12
- 当 WDTCR。CKS[3:0] = 0x6 时,N = 51
- 当 WDTCR。CKS[3:0] = 0x7 时,N = 204
- 当 WDTCR。CKS[3:0] = 0x8、N = 8192 时

REFEF 标志（刷新错误标志）

REFEF标志读取,确认是否发生刷新错误,表明在禁止期间执行刷新操作。1 的值表示发生了刷新错误。0 写入标志,将值设置为 0。1的书写没有效果。

REFEF 标志的清除需要（N+1）PCLKB 周期。此外,刷新错误后,对于（N+1）PCLKB 周期,标志的清除将被忽略。N在WDTCR。CKS[3:0]位中指定如下:

- 当 WDTCR。CKS[3:0] = 0x1 时,N = 4
- 当 WDTCR。CKS[3:0] = 0x4 时,N = 6
- 当 WDTCR。CKS[3:0] = 0xF 时,N = 12
- 当 WDTCR。CKS[3:0] = 0x6 时,N = 51
- 当 WDTCR。CKS[3:0] = 0x7 时,N = 204
- 当 WDTCR。CKS[3:0] = 0x8、N = 8192 时

For information on the OFS0 register, see section 22.3.8. Association between Option Function Select Register 0 (OFS0) and WDT Registers.

22.3 Operation

22.3.1 Count Operation in each Start Mode

The WDT has two start modes:

- Auto start mode, in which counting automatically starts after a release from the reset state
- Register start mode, in which counting starts with a refresh by writing to the register.

In auto start mode, counting automatically starts after a release from the reset state according to the settings in the Option Function Select register 0 (OFS0) in the flash.

In register start mode, counting starts with a refresh by writing to the WDTRR register after the respective registers are set after a release from the reset state.

在自动启动模式下,WDTRCR寄存器设置被禁用,并且选项功能选择寄存器0（OFS0)中的设置被启用。WDTRCR 寄存器的设置也可以为 OFS0 寄存器进行。详情请参见第 22。3。8 节。Option 函数选择寄存器 0（OFS0) 和 WDT 寄存器 . 之间的关联

22。3 操作

22。3。1 每个开始模式下的计数操作

WDT 有两种启动模式:

- 自动启动模式,其中从复位状态释放后自动开始计数
- 寄存器开始模式,其中通过写入寄存器以刷新开始计数。

在自动启动模式下,根据闪存中选项功能选择寄存器0（OFS0)中的设置,在从复位状态释放后自动开始计数。

在寄存器启动模式下,计数从刷新开始,在从重置状态释放后设置各个寄存器后写入WDTRR寄存器。

Select auto start mode or register start mode by setting the WDT Start Mode Select bit (OFS0.WDTSTRT) in the OFS0 register.

When the auto start mode is selected, the settings in the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are disabled while the settings in the OFS0 register are enabled.

When the register start mode is selected, the setting for the OFS0 register is disabled while the settings for the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are enabled.

22.3.1.1 Register start mode

When the WDT Start Mode Select bit (OFS0.WDTSTRT) is 1, register start mode is selected, the OFS0 register setting is invalid, and the WDT control register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are enabled.

After the reset state is released, set the following:

- Clock division ratio in the WDTCR register
- Window start and end positions in the WDTCR register
- Timeout period in the WDTCR register
- Reset output or interrupt request output in the WDTRCR register
- Counter stop control during transitions to Sleep mode in the WDTCSTPR register

The WDT refresh register (WDTRR) refreshes the down counter. As a result, the downcount starts at the value set by the timeout period selection bit (WDTCR.TOPS[1:0]).

Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and counting down continues. The WDT does not output the reset signal or non-maskable interrupt request/interrupt request as long as counting continues. However, if the down-counter underflows because the down-counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the WDT outputs the reset signal or a non-maskable interrupt request/interrupt request (WDT_NMIUNDF). Reset output or interrupt request output can be selected in the WDT Reset Interrupt Request Select bit (WDTRCR.RSTIRQS). The interrupt enabled for operating the NMI can be selected in the WDT Underflow/Refresh Error Interrupt Enable bit (NMIER.WDTEN).

Figure 22.3 shows an example of operation under the following conditions:

- Register start mode (OFS0.WDTSTRT = 1)
- WDT reset interrupt request selection (WDTRCR.RSTIRQS = 1)
- The window start position is 75% (WDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (WDTCR.RPES[1:0] = 10b)

通过设置WDT开始模式选择位（OFS0)来选择自动开始模式或寄存器开始模式。WDTSTRT）在 OFS0 寄存器中。

当选择自动启动模式时,WDT控制寄存器（WDTCR）、WDT复位控制寄存器（WDTRCR）和WDT计数停止控制寄存器（WDTCSTPR）中的设置被禁用,同时OFS0寄存器中的设置被启用。

当选择寄存器启动模式时,禁用OFS0寄存器的设置,同时启用WDT控制寄存器（WDTCR）、WDT复位控制寄存器（WDTRCR）和WDT计数停止控制寄存器（WDTCSTPR）的设置。

22。3。1。1 注册启动模式

当WDT开始模式选择位时（OFS0。WDTSTRT）为1,选择寄存器启动模式,OFS0寄存器设置无效,启用WDT控制寄存器（WDTCR）、WDT复位控制寄存器（WDTRCR）、WDT计数停止控制寄存器（WDTCSTPR）。

Reset 状态被释放后, 设置如下:

WDTCR 寄存器中的 ● 时钟分频比

● WDTCR 寄存器中的窗口起始位置和结束位置

WDTCR寄存器中的●超时周期

● 在 WDTRCR 寄存器中重置输出或中断请求输出

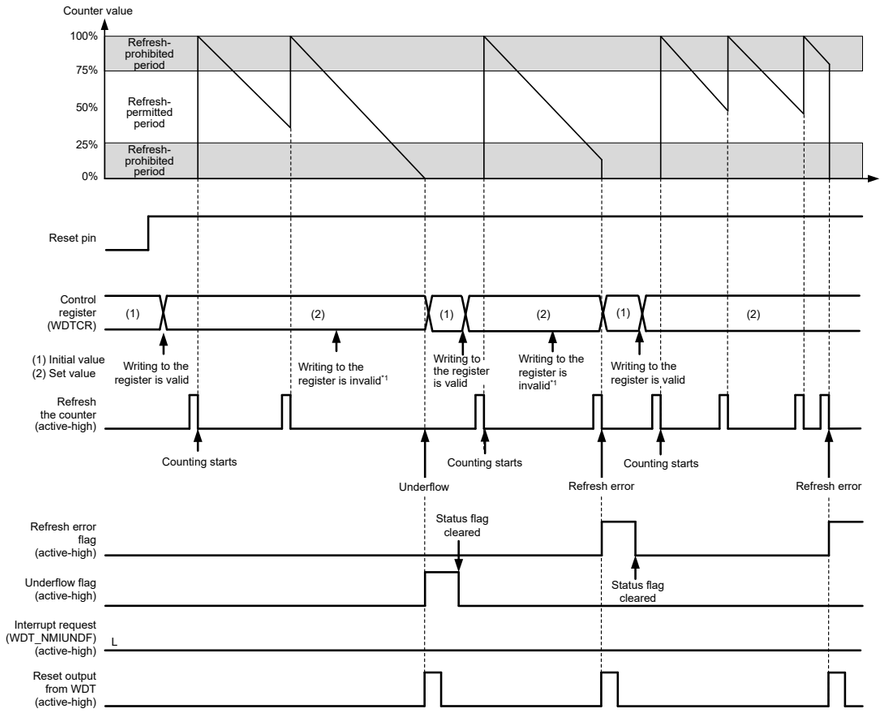
● 在 WDTCSTPR 寄存器中转换为睡眠模式期间进行计数器停止控制

WDT 刷新寄存器（WDTRR）刷新下计数器。结果,下计数从超时周期选择位（WDTCR。TOPS[1:0])设置的值开始。

此后,只要计数器在刷新允许的时间段内刷新,每次刷新计数器并继续倒计时时,计数器中的值都会被重置。WDT不输出复位信号或不可屏蔽的中断请求/中断请求,只要继续计数即可。但是,如果下计数器由于程序失控而无法刷新下计数器而下溢,或者如果由于计数器在刷新允许的周期之外刷新而发生刷新错误,则WDT输出复位信号或不可屏蔽中断请求/中断请求（WDT_NMIUNDF）。可以在WDT重置中断请求选择位（WDTRCR。RSTIRQS）中选择重置输出或中断请求输出。可以在 WDT 下溢/刷新错误中断启用位（NMIER。WDTEN）中选择为操作 NMI 启用的中断。

图 22。3 显示了以下条件下的操作示例:

- 注册启动模式（OFS0。WDTSTRT = 1）
- WDT 重置中断请求选择（WDTRCR。RSTIRQS = 1）
- 窗口起始位置为 75%（WDTCR。RPSS[1:0] = 10b）
- 窗口末端位置为 25%（WDTCR。RPES[1:0] = 10b）



Note: Refreshing the counter requires up to 4 count signal cycles from refresh request to execution.
Note 1. See section 22.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.
Reset pin = RES

Figure 22.3 Operation example in register start mode

22.3.1.2 Auto start mode

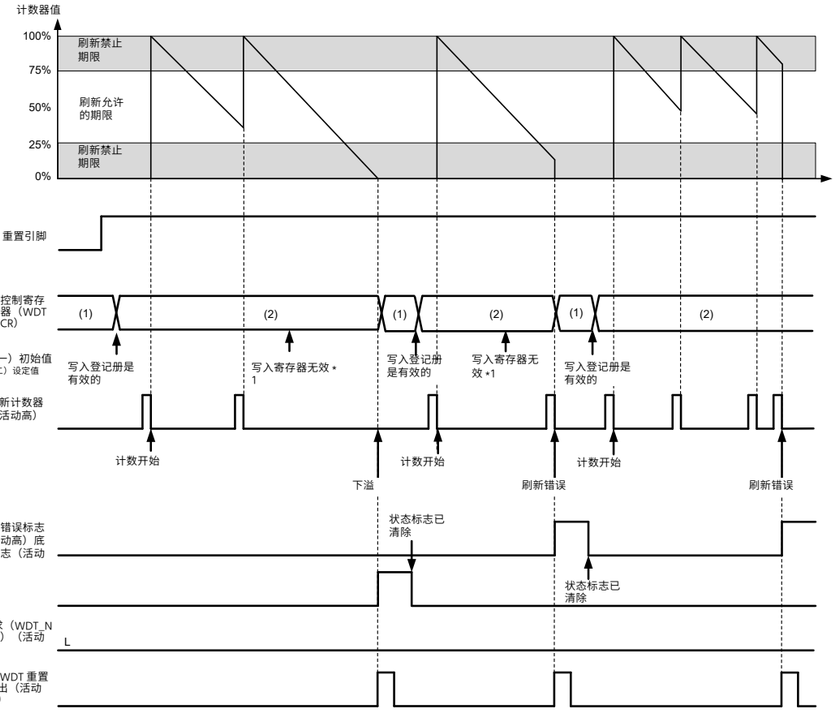
When the WDT Start Mode Select bit (OFS0.WDTSTRT) in the Option Function Select Register 0 (OFS0) is 0, auto start mode is selected, the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are disabled, and the settings in the OFS0 register are enabled.

Within the reset state, the setting values for the following in the Option Function Select Register 0 (OFS0) are set in the WDT registers:

- Clock division ratio
- Window start and end positions
- Timeout period
- Reset output or interrupt request
- Counter stop control during transition to Sleep mode

When the reset state is released, the down-counter automatically starts counting down from the value set in the WDT Timeout Period Select bits (OFS0.WDTTOPS[1:0]).

Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and counting down continues. The WDT does not output the reset signal or non-maskable interrupt request/interrupt request (WDT_NMIUNDF) as long as the counting continues. However, if the down-counter underflows



注: 刷新计数器需要从刷新请求到执行最多 4 个计数信号周期。

图 22。3 寄存器启动模式下的操作示例

22.3.1.2 自动启动模式

当WDT开始模式选择位时（OFS0。选项功能中的WDTSTRT选择寄存器0（OFS0)为0,选择自动启动模式,禁用WDT控制寄存器（WDTCR）、WDT复位控制寄存器（WDTRCR）和WDT计数停止控制寄存器（WDTCSTPR）,并且OFS0寄存器中的设置已启用。

在重置状态下,选项函数选择寄存器0（OFS0)中以下的设置值被设置在
WDT 寄存器:

- 时钟分时比
- 窗口起始位置和结束位置
- 超时期
- 重置输出或中断请求
- 转换到睡眠模式期间的计数器停止控制

当释放复位状态时,下计数器自动开始从 WDT 中设置的值倒计时
超时周期 选择位（OFS0。WDTTOPS[1:0])。

此后,只要计数器在刷新允许的时间段内刷新,每次刷新计数器并继续倒计时时,计数器中的值都会被重置。WDT不输出复位信号或不可屏蔽的中断请求/中断请求（WDT_NMIUNDF）,只要计数继续。但是,如果下计数器下溢

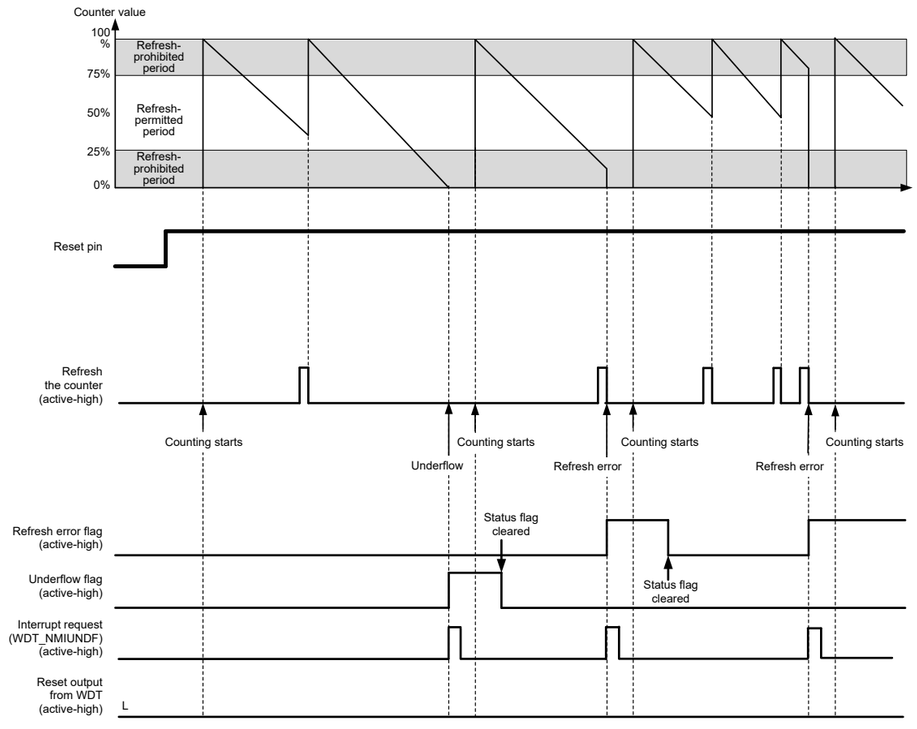
because refreshing of the down-counter is not possible due to a runaway program or if a refresh error occurs due to refreshing outside the refresh-permitted period, the WDT outputs the reset signal or non-maskable interrupt request/interrupt request (WDT_NMIUNDF).

After the reset signal or non-maskable interrupt request/interrupt request is generated, the counter reloads the timeout period after counting for 1 cycle. The value of the timeout period is set in the down-counter and counting restarts.

Reset output or interrupt request output can be selected by setting the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS). Non-maskable interrupt request or interrupt request can be selected in the WDT Underflow/ Refresh Error Interrupt Enable bit (NMIER.WDTEN).

Figure 22.4 shows an example of operation (non-maskable interrupt) under the following conditions:

- Auto start mode (OFS0.WDTSTRT = 0)
- WDT behavior selection: interrupt (OFS0.WDTRSTIRQS = 0)
- Non-maskable Interrupt: IWDT Underflow/Refresh Error Interrupt Enabled (NMIER.WDTEN = 1)
- The window start position is 75% (OFS0.WDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.WDTRPES[1:0] = 10b)



Note: Refreshing the counter requires up to 4 count signal cycles from refresh request to execution.
Note: Reset pin = RES

Figure 22.4 Operation example in auto start mode

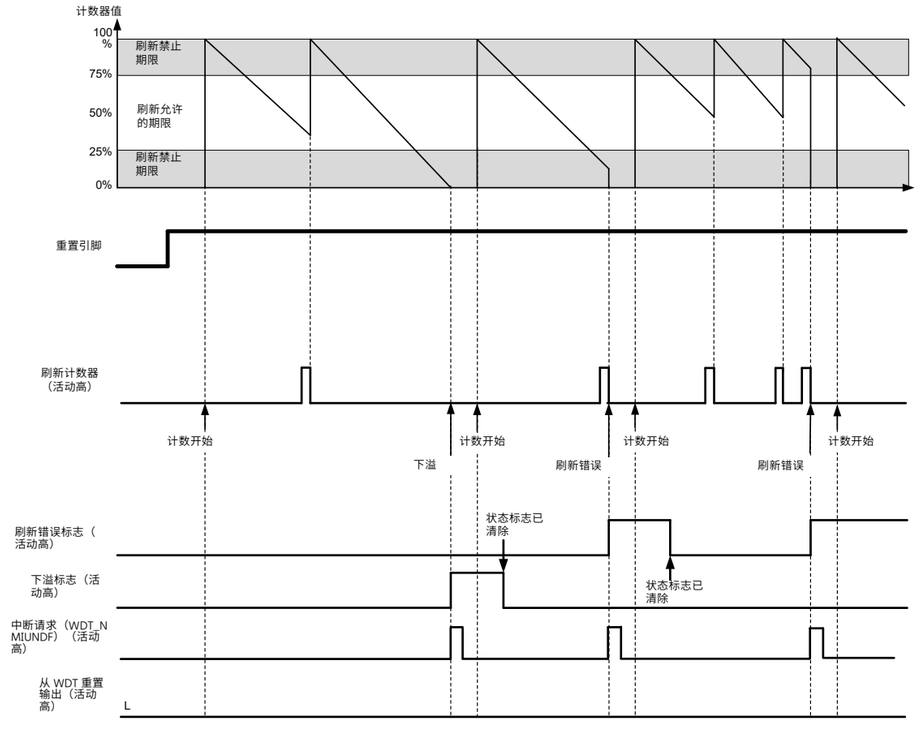
由于失控程序导致下计数器无法刷新,或者如果在刷新允许的周期之外由于刷新而发生刷新错误,则WDT输出重置信号或不可屏蔽的中断请求/中断请求（WDT_NMIUNDF）。

Reset信号或不可屏蔽的中断请求/中断请求生成后,计数器在计数1个周期后重新加载超时周期。超时段的值设置在下计数器和计数重新启动中。

可以通过设置WDT重置中断请求选择位（OFS0)来选择重置输出或中断请求输出。WDTRSTIRQS）。可以在WDT 底流/刷新错误中断启用位（NMIER。WDTEN）中选择不可屏蔽的中断请求或中断请求。

图 22。4 显示了在以下条件下操作（不可屏蔽中断）的示例:

- 自动启动模式（OFS0。WDTSTRT = 0)
- WDT 行为选择:中断（OFS0。WDTRSTIRQS = 0)
- 不可屏蔽中断:启用 IWDT 下溢/刷新错误中断（NMIER。WDTEN = 1）
- 窗口起始位置为 75%（OFS0)。WDTRPSS[1:0] = 10b）
- 窗口末端位置为 25%（OFS0)。WDTRPES[1:0] = 10b）



注: 刷新计数器需要从刷新请求到执行最多 4 个计数信号周期。
注: 重置引脚 = RES

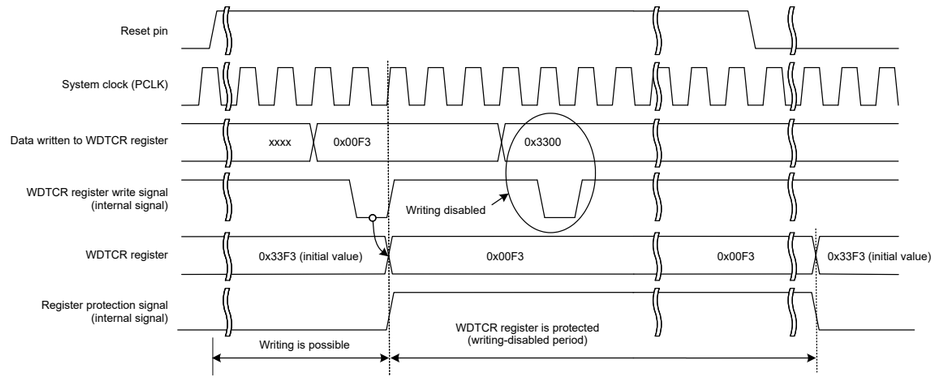
22.3.2 Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers

Writing to the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), or WDT Count Stop Control Register (WDTCSTPR) is possible once each between the release from the reset state and the first refresh operation.

After a refresh (counting starts) or a write to WDTCR, WDTRCR or WDTCSTPR register, the protection signal in the WDT becomes 1 to protect WDTCR, WDTRCR and WDTCSTPR register against subsequent write attempts. This protection is released by the reset source of the WDT. With other reset sources, the protection is not released.

Figure 22.5 shows control waveforms produced in response to writing to the WDTCR.



Note: PCLK = PCLKB
Reset pin = RES

22.3.3 Refresh Operation

To refresh the down counter and start the counting operation, write to the WDT Refresh Register (WDTRR) in the order of values from 0x00 to 0xFF. If a value other than 0xFF is written after 0x00, the down-counter is not refreshed. If an invalid value is written, refreshing is performed normally by writing to the WDTRR register in the order of values from 0x00 to 0xFF.

Correct refreshing is also performed when a register other than WDTRR is accessed or WDTRR is read between writing 0x00 and writing 0xFF to WDTRR. Writes to refresh the counter must be made within the refresh-permitted period, and this is determined by the 0xFF write. For this reason, correct refreshing is performed even when 0x00 is written outside the refresh-permitted period.

[Example write sequences that are valid for refreshing the counter]

- 0x00 → 0xFF
- 0x00 ((n–1)th time) → 0x00 (nth time) → 0xFF
- 0x00 → access to another register or read from WDTRR → 0xFF

[Example write sequences that are invalid for refreshing the counter]

- 0x23 (a value other than 0x00) → 0xFF
- 0x00 → 0x54 (a value other than 0xFF)
- 0x00 → 0xAA (0x00 and a value other than 0xFF) → 0xFF

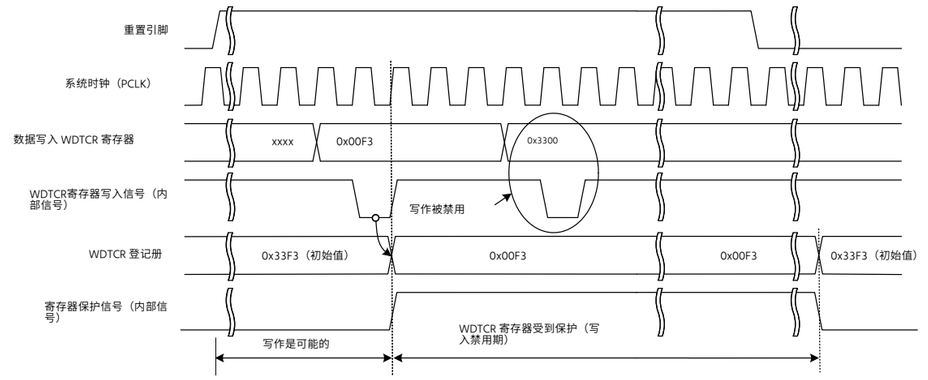
After 0xFF is written to the WDT Refresh Register (WDTRR), refreshing the down-counter requires up to 4 cycles of the signal for counting. To meet this requirement, complete writing 0xFF to WDTRR 4 count cycles before the down-counter underflows.

22。3。2 控制对 WDTCR、WDTRCR 和 WDTCSTPR 寄存器的写入

在从重置状态释放和第一次刷新操作之间,每次可以写入WDT控制寄存器（WDTCR）、WDT重置控制寄存器（WDTRCR）或WDT计数停止控制寄存器（WDTCSTPR）。

刷新（计数开始）或写入 WDTCR、WDTRCR 或 WDTCSTPR 寄存器后,WDT 中的保护信号变为 1,以保护 WDTCR、WDTRCR 和 WDTCSTPR 寄存器免受后续写入尝试的影响。WDT的复位源释放该保护,其他复位源则不释放该保护。

图 22。5 显示了响应 WDTCR 写入而产生的控制波形。



注: PCLK = PCLKB
重置引脚 = RES

图22。5 响应于对 WDTCR 寄存器的写入而产生的控制波形

22。3。3 刷新操作

0x00 到 0xFF 的值顺序,刷新下计数器并开始计数操作,写入 WDT 刷新寄存器（WDTRR）,如果在 0x00 后写入 0xFF 以外的值,则不刷新下计数器。如果写入无效值,则通常通过按照从 0x00 到 的值顺序写入 WDTRR 寄存器来执行刷新
0xFF。

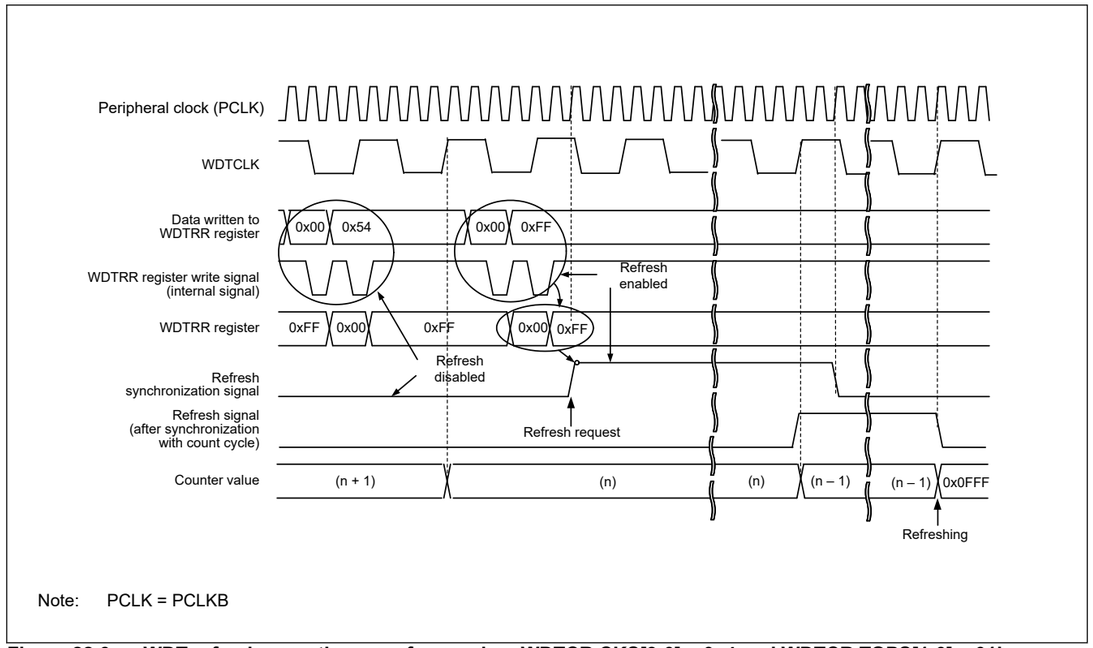
当访问 WDTRR 以外的寄存器或在写入之间读取 WDTRR 时,也会执行正确的刷新
0x00 并将 0xFF 写入 WDTRR。刷新计数器的写入必须在刷新允许的期限内进行,这由 0xFF 写入确定。因此,即使在刷新允许的周期之外写入 0x00,也会执行正确的刷新。

【例写出对刷新计数器有效的序列】

- 0x00 → 0xF
- 0x00 (（n-1)th time）→ 0x00（nth time）
- 0x00 → 访问另一个寄存器或从 WDTRR → 0xFF 读取 [示例写入对刷新计数器无效的序列]
- 0x23(0x00 以外的值）→ 0xFF
- 0x00 → 0x54(0xFF 以外的值）
- 0x00 → 0xAA(0x00 和 0xFF 以外的值）→ 0xFF

0xFF 写入 WDT 刷新寄存器（WDTRR）后,刷新下计数器需要最多 4 个周期的信号进行计数。为了满足此要求,请在下计数器下溢之前完成 0xFF 写入 WDTRR 4 个计数周期。

Figure 22.6 shows the WDT refresh-operation waveforms when the clock division ratio is PCLKB/64.



Note: PCLK = PCLKB

Figure 22.6 WDT refresh operation waveforms when WDTCR.CKS[3:0] = 0x4 and WDTCR.TOPS[1:0] = 01b

Note: When setting the refresh time, consider the oscillation accuracy of the clock sources of the PCLKB and WDTCLK. Set values which ensure that refreshing is possible even when the frequency varies in the range of error of the oscillation accuracy.

22.3.4 Status Flags

The refresh error (WDTSR.REFEF) and underflow (WDTSR.UNDFF) flags retain the source of the interrupt request from the WDT. After a release from the interrupt request generation, read the WDTSR.REFEF and WDTSR.UNDFF flags to check for the interrupt source. For each flag, writing 0 clears the bit. Writing 1 has no effect. Leaving the status flags unchanged does not affect operation. If the flags are not cleared at the next interrupt request from the WDT, the earlier interrupt source is cleared and the new interrupt source is written. For the time period between when 0 is written in each flag and when its value is reflected, see section 22.2.3. WDTSR : WDT Status Register.

22.3.5 Reset Output

When the Reset Interrupt Select bit (WDTRCR.RSTIRQS) is set to 1 in register start mode, or when the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 1 in auto start mode, a reset signal is output for 1 cycle count when an underflow in the down-counter or a refresh error occurs.

In register start mode, the down-counter is initialized (all bits set to 0) and stopped in that state after output of a reset signal. After the reset state is released and the program is restarted, the counter is set up again and counting down starts again with a refresh. In auto start mode, counting down starts automatically after the reset state is released.

22.3.6 Interrupt Sources

When the Reset Interrupt Select bit (WDTRCR.RSTIRQS) is set to 0 in register start mode or when the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 0 in auto start mode, an interrupt (WDT_NMIUNDF) signal is generated when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or an interrupt. For details, see section 12, Interrupt Controller Unit (ICU).

注意:设置刷新时间时,请考虑PCLKB和WDTCLK时钟源的振荡精度。
设置值,确保即使频率在振荡精度的误差范围内变化,刷新也是可能的。

22。3。4 状态标志

刷新错误（WDTSR。REFEF）和下溢（WDTSR。UNDFF）标志保留来自 WDT 的中断请求源。从中断请求生成中释放后,读取 WDTSR。REFEF 和 WDTSR。UNDFF 标志以检查中断源。对于每个标志,写入 0 可以清除该位。1的书写没有效果。状态标志保持不变不会影响操作。如果在 WDT 的下一个中断请求中未清除标志,则清除较早的中断源并写入新的中断源。对于每个标志中写入 0 到反映其值之间的时间段,请参见第 22。2。3 节。WDTSR:WDT 状态寄存器 .

22。3。5 重置输出

当复位中断选择位（WDTRCR。RSTIRQS）在寄存器启动模式下设置为1时,或者当WDT复位中断请求选择位（OFS0)时。WDTRSTIRQS）在选项功能选择寄存器 0（OFS0) 中在自动启动模式下设置为 1,当下计数器出现下溢或出现刷新错误时,会输出复位信号进行 1 个周期计数。

在寄存器启动模式下,下计数器被初始化（所有位设置为 0)并在输出复位信号后停止在该状态。释放复位状态并重新启动程序后,再次设置计数器并重新开始倒计时。在自动启动模式下,复位状态释放后自动开始倒计时。

22。3。6 中断源

当复位中断选择位（WDTRCR。RSTIRQS）在寄存器启动模式下设置为 0 或当 WDT 复位中断请求选择位（OFS0)时。WDTRSTIRQS）在选项功能选择寄存器 0（OFS0) 中设置为 0 在自动启动模式下,当计数器出现下溢或出现刷新错误时,会生成中断（WDT_NMIUNDF）信号。该中断可用作不可屏蔽的中断或中断。有关详细信息,请参阅第 12 节"中断控制器单元（ICU）."

22.3.7 Reading the Down-Counter Value

The WDT stores the counter value in the down-counter value bits (WDTSR.CNTVAL[13:0]) of the WDT Status Register. Check these bits to obtain the counter value. The read value of the down-counter might differ from the actual count by one.

Figure 22.7 shows the processing for reading the WDT down-counter value when the clock division ratio is PCLKB/64.

22.4 Output to the Event Link Controller (ELC)

The WDT is capable of a link operation for the previously specified module when interrupt request signal is used as an event signal by the ELC. The event signal is output by the counter underflow and refresh error. An event signal is output regardless of the setting of the Reset Interrupt Request Select bit (WDTRCR.RSTIRQS) in register start mode or auto start mode. An event signal can also be output when the next interrupt source is generated while the Refresh Error flag (WDTSR.REFEF) or Underflow flag (WDTSR.UNDFF) is 1. For details, see section 17, Event Link Controller (ELC).

22.5 Usage Notes

22.5.1 ICU Event Link Setting Register n (IELSRn) Setting

Setting 0x53 to ICU Event Link Setting Register n (ICU.IELSRn) is prohibited when WDT reset interrupt request selection resets (OFS0.WDTRSTIRQS = 0 or WDTRCR.RSTIRQS = 0) or when enabling event link operation (ELSRn.ELS[8:0] = 0x53).

22。4 输出到事件链路控制器（ELC）

当ELC使用中断请求信号作为事件信号时,WDT能够对先前指定的模块进行链路操作。事件信号由计数器下溢和刷新误差输出。无论寄存器启动模式或自动启动模式下重置中断请求选择位（WDTRCR。RSTIRQS）的设置如何,都会输出事件信号。当刷新错误标志（WDTSR。REFEF）或下溢标志（WDTSR。UNDFF）为 1 时,生成下一个中断源时也可以输出事件信号。有关详细信息,请参阅第 17 节"事件链接控制器（ELC）."

22。5 使用说明

22.5.1 ICU 事件链接设置 注册 n（IELSRn）设置

WDT 重置中断请求选择重置时（OFS0) 禁止将 0x53 设置为 ICU 事件链接设置寄存器 n（ICU。IELSRn）。WDTRSTIRQS = 0 或 WDTRCR。RSTIRQS = 0) 或启用事件链路操作时（ELSRn。ELS[8:0] = 0x53)。

23. Independent Watchdog Timer (IWDT)

23.1 Overview

The Independent Watchdog Timer (IWDT) consists of a 14-bit down counter that must be serviced periodically to prevent counter underflow. The IWDT provides functionality to reset the MCU or to generate a non-maskable interrupt or an underflow interrupt. Because the timer operates with an independent, dedicated clock source, it is particularly useful in returning the MCU to a known state as a fail-safe mechanism when the system runs out of control. The IWDT can be triggered automatically by a reset, underflow, refresh error, or a refresh of the count value in the registers.

The IWDT functions differ from those of the WDT in the following respects:

- The divided IWDT-dedicated clock (IWDTCLK) is used as the count source (not affected by PCLKB)
- IWDT does not support register start mode

Table 23.1 lists the IWDT specifications and Figure 23.1 shows a block diagram.

Table 23.1 IWDT specifications

Parameter	Description
Count source*1	IWDT-dedicated clock (IWDTCLK)
Clock division ratio	Division by 1, 16, 32, 64, 128, or 256

Conditions for stopping the counter	• Reset (the down-counter and other registers return to their initial values) • A counter underflows or a refresh error is generated (counting restarts automatically).
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods)
Reset output sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error).
Non-maskable interrupt/interrupt sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error).
Reading the counter value	The down-counter value can be read by the IWDTSR register
Event link function	• Down-counter underflow event output • Refresh error event output.
Output signal (internal signal)	• Reset output • Interrupt request output • Sleep-mode count stop control output.

Note 1. Satisfy the frequency of the peripheral module clock (PCLKB) ≥ 4 × (the frequency of the count clock source after division).

The bus interface and registers operate with PCLKB, and the 14-bit counter and control circuits operate with IWDTCLK.

23. 独立看门狗计时器（IWDT）

23。1 概述

独立看门狗定时器（IWDT）由 14 位向下计数器组成,必须定期维修以防止计数器下溢。IWDT 提供重置 MCU 或生成不可屏蔽中断或下溢中断的功能。由于定时器使用独立的专用时钟源运行,因此当系统失控时,它对于将 MCU 返回到作为故障安全机制的已知状态特别有用。IWDT 可以通过重置、下溢、刷新错误或寄存器中计数值的刷新自动触发。

IWDT 功能在以下方面与 WDT 不同:

- 分割后的 IWDT 专用时钟（IWDTCLK）作为计数源（不受 PCLKB 的影响）
- IWDT 不支持寄存器启动模式

表 23。1 列出了 IWDT 规范,图 23。1 显示了框图。

7:0	n/a	The down-counter is refreshed by writing 0x00 and then writing 0xFF to this register	R/W

The IWDTRR register refreshes the down-counter of the IWDT. The down-counter of the IWDT is refreshed by writing 0x00 and then writing 0xFF to IWDTRR (refresh operation) within the refresh-permitted period. After the down-counter is refreshed, it starts counting down from the value selected in the IWDT Timeout Period Select bits (OFS0.IWDTTOPS[1:0]) in the Option Function Select Register 0 (OFS0).

When 0x00 is written, the read value is 0x00. When a value other than 0x00 is written, the read value is 0xFF. For details of the refresh operation, see section 23.3.2. Refresh Operation.

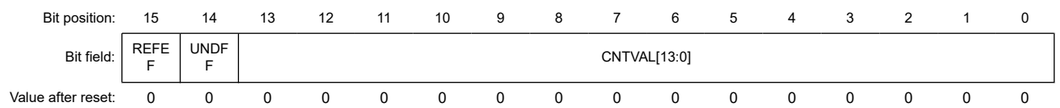
23.2.2 IWDTSR : IWDT Status Register

Base address: IWDT = 0x4008_3200

Offset address: 0x04



Bit	Symbol	Function	R/W
13:0	CNTVAL[13:0]	Down-counter Value Value counted by the down-counter	R
14	UNDFF	Underflow Flag 0: No underflow occurred 1: Underflow occurred	R/W*1
15	REFEF	Refresh Error Flag 0: No refresh error occurred 1: Refresh error occurred	R/W*1

Note 1. Only 0 can be written to clear the flag.

The IWDTSR register indicates the counter value of the down-counter and whether an underflow or refresh error occurred in the down-counter.

CNTVAL[13:0] bits (Down-counter Value)

Read the CNTVAL[13:0] bits to confirm the value of the down-counter. The read value might differ from the actual count by 1.

UNDFF flag (Underflow Flag)

Read the UNDFF flag to confirm whether an underflow occurred in the down-counter. The value 1 indicates that the down-counter underflowed. Write 0 to the UNDFF flag to set the value to 0. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N + 2) IWDTCLK cycles and 2 PCLKB cycles. In addition, clearing of this flag is ignored for (N + 2) IWDTCLK cycles after an underflow. N is specified in the IWDTCKS[3:0] bits as follows:

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128
- When OFS0.IWDTCKS[3:0] = 0x5, N = 256.

REFEF flag (Refresh Error Flag)

Read the REFEF flag to confirm whether a refresh error occurred. This indicates that a refresh operation was performed during a prohibited period. The value 1 indicates that a refresh error occurred. Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

Clearing of the REFEF flag takes (N + 2) IWDTCLK cycles and 2 PCLKB cycles. In addition, clearing of this flag is ignored for (N + 2) IWDTCLK cycles following a refresh error. N is specified in the IWDTCKS[3:0] bits as follows:

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128
- When OFS0.IWDTCKS[3:0] = 0x5, N = 256.

IWDTSR寄存器指示下计数器的计数器值以及下计数器中是否发生下溢或刷新错误。

CNTVAL[13:0] 位（下计数器值）

读取 CNTVAL[13:0] 位以确认下计数器的值。读取值可能与实际计数相差 1。

UNDFF 标志（下流标志）

读取 UNDFF 标志以确认下行计数器中是否发生下溢。值 1 表示下降计数器下溢。0 写入 UNDFF 标志以将值设置为 0。1的书写没有效果。

UNDFF 标志的清除需要（N + 2) 个 IWDTCLK 周期和 2 个 PCLKB 周期。此外,对于下溢后的（N + 2) IWDTCLK 周期,该标志的清除将被忽略。N在IWDTCKS[3:0]位中指定如下:

- 当 OFS0 时。IWDTCKS[3:0] = 0x0,N =
- 当 OFS0 时。IWDTCKS[3:0] = 0x2,N = 1
- 当 OFS0 时。IWDTCKS[3:0] = 0x3,N = 3

- 当 OFS0 时。IWDTCKS[3:0] = 0xF,N = 12
- 当 OFS0 时。IWDTCKS[3:0] = 0x5,N = 256

REFEF 标志（刷新错误标志）

读取 REFEF 标志以确认是否发生刷新错误。这表明刷新操作是在禁止期间进行的。值 1 表示出现刷新错误。0 写入 REFEF 标志以将该值设置为 0。1的书写没有效果。

REFEF 标志的清除需要（N + 2) 个 IWDTCLK 周期和 2 个 PCLKB 周期。此外,刷新错误后的（N + 2) IWDTCLK 周期将忽略该标志的清除。N在IWDTCKS[3:0]位中指定如下:

- 当 OFS0。IWDTCKS[3:0] = 0x0,N = 1
- 当 OFS0。IWDTCKS[3:0] = 0x2,N = 16
- 当 OFS0。IWDTCKS[3:0] = 0x3,N = 32
- 当 OFS0。IWDTCKS[3:0] = 0x4,N = 64
- 当 OFS0。IWDTCKS[3:0] = 0xF,N = 128
- 当 OFS0。IWDTCKS[3:0] = 0x5,N = 256。

23.2.3 OFS0 : Option Function Select Register 0

For information on the Option Function Select Register 0 (OFS0), see section 6.2.1. OFS0 : Option Function Select Register 0.

IWDTTOPS[1:0] bits (IWDT Timeout Period Select)

The IWDTTOPS[1:0] bits select the timeout period, that is, the period until the down-counter underflows, from 128, 512, 1024, or 2048 cycles, taking the divided clock specified in the IWDTCKS[3:0] bits as 1 cycle.

After the down-counter is refreshed, the combination of the IWDTCKS[3:0] and IWDTTOPS[1:0] bits determines the number of IWDTCLK cycles until the counter underflows.

Table 23.2 lists the relationship between the IWDTCKS[3:0] and IWDTTOPS[1:0] bit settings, the timeout period, and the number of IWDTCLK cycles.

IWDTCKS[3:0] bits (IWDT-Dedicated Clock Frequency Division Ratio Select)

The IWDTCKS[3:0] bits specify the division ratio of the clock used for the down-counter. The division ratio can be selected from the IWDT-dedicated clock (IWDTCLK) divided by 1, 16, 32, 64, 128, and 256. Combined with the IWDTTOPS[1:0] bit setting, the IWDT can be configured to a count period between 128 and 524,288 IWDTCLK cycles.

下计数器刷新后,IWDTCKS[3:0]和IWDTTOPS[1:0]位的组合确定IWDTCLK循环的数量,直到计数器下溢。

IWDTRPES[1:0] bits (IWDT Window End Position Select)

The IWDTRPES[1:0] bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. Set the window end position to a value less than the window start position (window start position > window end position). Set the window start position to a value greater than the window end position. If the window start position is set to a value less than or equal to the window end position, the window start position setting is enabled and the window end position is set to 0%.

IWDTSTPCTL bit (IWDT Stop Control)

The IWDTSTPCTL bit selects whether to stop counting on transition to Sleep, Snooze, or Software Standby mode.

23.3 Operation

23.3.1 Auto Start Mode

When the IWDT Start Mode Select bit (OFS0.IWDTSTRT) in the Option Function Select Register 0 is 0, auto start mode is selected, otherwise the IWDT is disabled.

Within the reset state, the setting values for the following in the Option Function Select Register 0 (OFS0) are set in the IWDT registers:

- Clock division ratio (OFS0.IWDTCKS[3:0])
- Window start and end positions (OFS0.IWDTRPSS[1:0], OFS0.IWDTRPES[1:0])
- Timeout period (OFS0.IWDTTOPS[1:0])
- Reset output or interrupt request (OFS0.IWDTRSTIRQS)

When the reset state is released, the counter automatically starts counting down from the value selected in the IWDT Timeout Period Select bits (OFS0.IWDTTOPS[1:0]).

After that, as long as the program continues normal operation and the counter is refreshed within the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and down-counting continues. The IWDT does not output the reset signal as long as this procedure continues. However, if the counter underflows because the program crashed or because a refresh error occurred when an attempt is made to refresh outside the refresh-permitted period, the IWDT asserts the reset signal or non-maskable interrupt request/interrupt request (IWDT_NMIUNDF).

After the reset signal or non-maskable interrupt request/interrupt request is generated, the counter reloads the timeout period after counting for 1 cycle, the value of the timeout period is set in the down-counter and counting starts. The reset output or interrupt request output can be selected with the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS). The interrupt enabled for operating the NMI can be selected with the IWDT Underflow/Refresh Error Interrupt Enable bit (NMIER.IWDTEN).

Figure 23.3 shows an example of operation under the following conditions:

- Auto start mode (OFS0.IWDTSTRT = 0)
- IWDT behavior selection: interrupt (OFS0.IWDTRSTIRQS = 0)
- Non-maskable Interrupt: IWDT Underflow/Refresh Error Interrupt Enabled (NMIER.IWDTEN = 1)
- The window start position is 75% (OFS0.IWDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.IWDTRPES[1:0] = 10b).

23。3 操作

23。3。1 自动启动模式

当 IWDT 开始模式选择位时（OFS0。IWDTSTRT）在选项功能选择寄存器0为0,选择自动启动模式,否则禁用IWDT。

在复位状态下,选项功能选择寄存器0（OFS0)中以下内容的设置值在IWDT寄存器中设置:

- 时钟分频比（OFS0。IWDTCKS[3:0])
- 窗口起始位置和结束位置（OFS0)。IWDTRPSS[1:0],OFS0。内河运输[1:0])
- 超时周期（OFS0。IWDTTOPS[1:0])
- 重置输出或中断请求（OFS0)。IWDTRSTIRQS）

当重置状态被释放时,计数器自动开始从IWDT超时周期选择位（OFS0)中选择的值倒计时。IWDTTOPS[1:0])。

之后,只要程序继续正常操作并且在刷新允许的周期内刷新计数器,每次刷新计数器并继续下计数时都会重置计数器中的值。只要该过程继续,IWDT 就不会输出复位信号。但是,如果计数器由于程序崩溃或由于在刷新允许的周期之外尝试刷新时发生刷新错误而下溢,则IWDT断言重置信号或不可屏蔽的中断请求/中断请求（IWDT_NMIUNDF）。

生成复位信号或不可屏蔽的中断请求/中断请求后,计数器重新加载计数1个周期后的超时周期,在下计数器中设置超时周期值并开始计数。可以使用IWDT重置中断请求选择位（OFS0)来选择重置输出或中断请求输出。IWDTRSTIRQS）。可以使用 IWDT 底流/刷新错误中断启用位（NMIER。IWDTEN）选择启用用于操作 NMI 的中断。

图 23。3 显示了以下条件下的操作示例:

- 自动启动模式（OFS0。IWDTSTRT = 0
- IWDT 行为选择:中断（OFS0)。IWDTRSTIRQS = 0）
- 不可屏蔽中断:启用 IWDT 下溢/刷新错误中断（NMIER。IWDTEN = 1）
- 窗口起始位置为 75%（OFS0)。IWDTRPSS[1:0] = 10b）
- 窗口末端位置为 25%（OFS0)。IWDTRPES[1:0] = 10b）。

23.3.2 Refresh Operation

To refresh the down counter and start the counting operation, write to the IWDT Refresh Register (IWDTRR) in the order of values from 0x00 to 0xFF. If a value other than 0xFF is written after 0x00, the down-counter is not refreshed. If an invalid value is written, refreshing is performed normally by writing to the IWDTRR register in the order of values from 0x00 to 0xFF.

When writes are made in the order of 0x00 (first time) → 0x00 (second time), and if 0xFF is written after that, the writing order 0x00 → 0xFF is satisfied. Writing 0x00 ((n - 1)th time) →0x00 (nth time) → 0xFF is valid, and the refresh is performed correctly. Even when the first value written before 0x00 is not 0x00, correct refreshing is performed as long as the operation contains the write sequence of 0x00 → 0xFF.

Correct refreshing is also performed regardless of whether a register other than IWDTRR is accessed or IWDTRR is read between writing 0x00 and writing 0xFF to IWDTRR. Writes to refresh the counter must be made within the refresh-permitted period. Whether writing is done within the refresh-permitted period is determined when 0xFF is written. For this reason, correct refreshing is performed even when 0x00 is written outside the refresh-permitted period.

[Example write sequences that are valid to refresh the counter]

- 0x00 → 0xFF
- 0x00 ((n - 1)th time) → 0x00 (nth time) → 0xFF
- 0x00 → access to another register or read from IWDTRR → 0xFF.

[Example write sequences that are not valid to refresh the counter]

- 0x23 (a value other than 0x00) → 0xFF

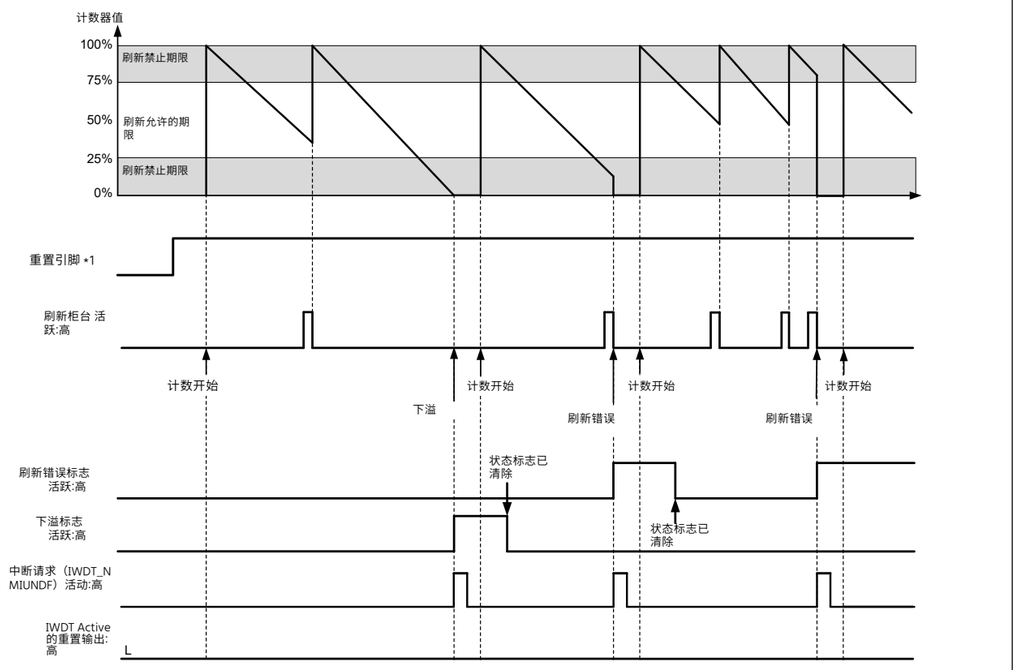

图23。3 自动启动模式下的操作示例

23。3。2 刷新操作

0x00 到 0xFF 的值顺序,刷新下计数器并开始计数操作,写入 IWDT 刷新寄存器（IWDTRR）,如果在 0x00 后写入 0xFF 以外的值,则下计数器不刷新。如果写入无效值,则通常通过按照从 0x00 到 的值顺序写入 IWDTRR 寄存器来执行刷新
0xFF。

0x00（第一次）→ 0x00（第二次）的顺序写入时,如果在此之后写入0xFF,则满足写入顺序0x00 → 0xFF。写入 0x00(（n 第 1 次）→0x00（第 n 次）→ 0xFF 有效,并且正确执行刷新。0x00 之前写入的第一个值不是 0x00 时,只要操作包含 0x00 → 0xFF 的写入序列,就执行正确的刷新。

无论是否访问 IWDTRR 之外的寄存器或在写入 0x00 和写入 0xFF 到 IWDTRR 之间读取 IWDTRR,也会执行正确的刷新。刷新计数器的写入必须在刷新允许的期限内进行。0xFF 写入时确定是否在刷新允许的期间内写入。因此,即使在刷新允许的周期之外写入 0x00,也会执行正确的刷新。[示例写入有效刷新计数器的序列]

- 0x00 → 0xFF
- 0x00(（n 第 1 次）) → 0x00（第 n 次）→ 0xFF
- 0x00 → 访问另一个寄存器或从 IWDTRR → 0xFF 读取。

[示例写入无效的序列以刷新计数器]

- 0x23(0x00 以外的值）→ 0xFF

- 0x00 → 0x54 (a value other than 0xFF)
- 0x00 → 0xAA (0x00 and a value other than 0xFF) → 0xFF.

After 0xFF is written to the IWDTRR register, refreshing the counter requires up to 4 cycles of the signal for counting (the IWDT-Dedicated Clock Frequency Division Ratio Select bits (OFS0.IWDTCKS[3:0]) to determine how many cycles of the IWDT-dedicated clock (IWDTCLK) make up 1 cycle for counting. To meet this requirement, writing 0xFF to the IWDTRR must be completed 4 count cycles before the end of the refresh-permitted period or a down-counter underflow. The value of the counter can be checked with the counter bits (IWDTSR.CNTVAL[13:0]).

[Example refreshing timings]

- When the window start position is set to 0x1FFF, even if 0x00 is written to IWDTRR before 0x1FFF is reached at (0x2002, for example), refreshing occurs if 0xFF is written to IWDTRR after the value of the IWDTSR.CNTVAL[13:0] bits reaches 0x1FFF
- When the window end position is set to 0x1FFF, refreshing occurs if 0x2003 (4 count cycles before 0x1FFF) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 0x00 → 0xFF to IWDTRR
- When the refresh-permitted period continues until count 0x0000, refreshing can be performed immediately before an underflow. In this case, if 0x0003 (4 count cycles before an underflow) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 0x00 → 0xFF to IWDTRR, no underflow occurs and refreshing is performed.

Figure 23.4 shows the IWDT refresh-operation waveforms when PCLKB > IWDTCLK and the clock division ratio is IWDTCLK.

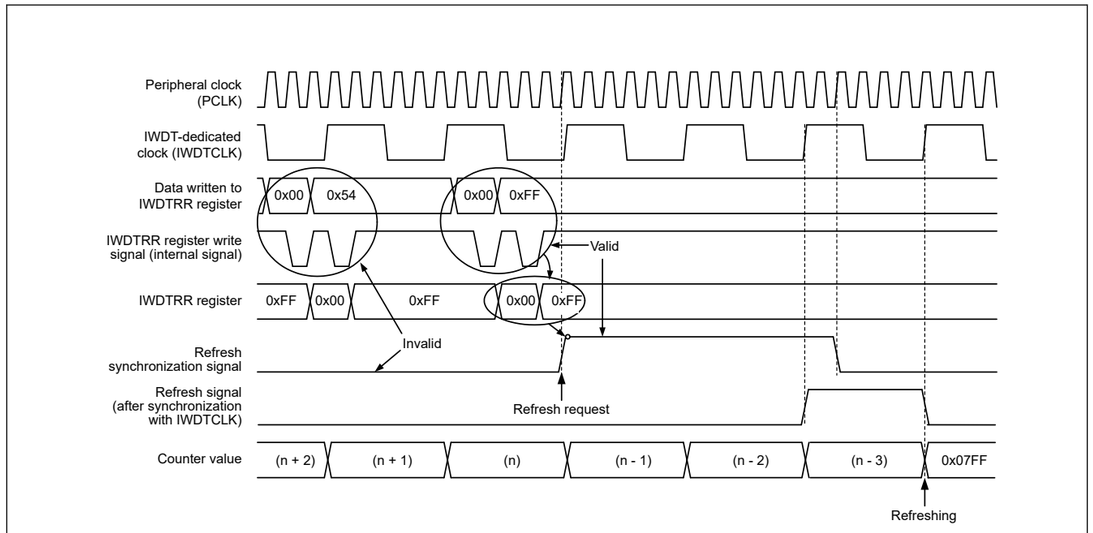

Figure 23.4 IWDT refresh operation waveforms when OFS0.IWDTCKS[3:0] = 0000b, OFS0.IWDTTOPS[1:0] = 11b

23.3.3 Status Flags

The refresh error (IWDTSR.REFEF) and underflow (IWDTSR.UNDFF) flags retain the source of the interrupt request from the IWDT. Therefore, after a release from the interrupt request generation, read the IWDTSR.REFEF and UNDFF flags to check for the interrupt source. For each flag, writing 0 clears the bit and writing 1 has no effect.

● 0x00 → 0x54(0xFF 以外的值）

● 0x00 → 0xAA(0x00 和 0xFF 以外的值）→ 0xFF。

0xFF写入IWDTRR寄存器后,刷新计数器需要最多4个周期的信号进行计数（IWDT专用时钟频分比选择位（OFS0)）。IWDTCKS[3:0])来确定IWDT专用时钟（IWDTCLK）的多少个周期组成1个周期进行计数。为了满足此要求,必须在刷新允许的周期结束或下计数器下溢之前完成 4 个计数周期向 IWDTRR 写入 0xFF。可以使用计数器位检查计数器的值（IWDTSR。CNTVAL[13:0])。

的【刷新时机范例】

● 当窗口起始位置设置为 0x1FFF 时,即使在 0x1FFF 达到（例如 0x2002) 之前将 0x00 写入 IWDTRR,如果在 IWDTSR。CNTVAL[13:0] 位的值达到 0x1FFF 后将 0xFF 写入 IWDTRR,也会发生刷新

● 当窗口结束位置设置为 0x1FFF 时,如果在将 0x00 → 0xFF 写入 IWDTRR 后立即从 IWDTSR。CNTVAL[13:0] 位读取 0x2003(0x1FFF 之前的 4 个计数周期）或更大的值,则会发生刷新

● 当刷新允许的周期持续到计数 0x0000 时,可以在下溢之前立即进行刷新。在这种情况下,如果在将 0x00 → 0xFF 写入 IWDTRR 后立即从 IWDTSR。CNTVAL[13:0] 位读取 0x0003（下溢之前的 4 个计数周期）或更大的值,则不会发生下溢并执行刷新。

图 23。4 显示了 PCLKB > IWDTCLK 且时钟分频比为 IWDTCLK 时的 IWDT 刷新操作波形。

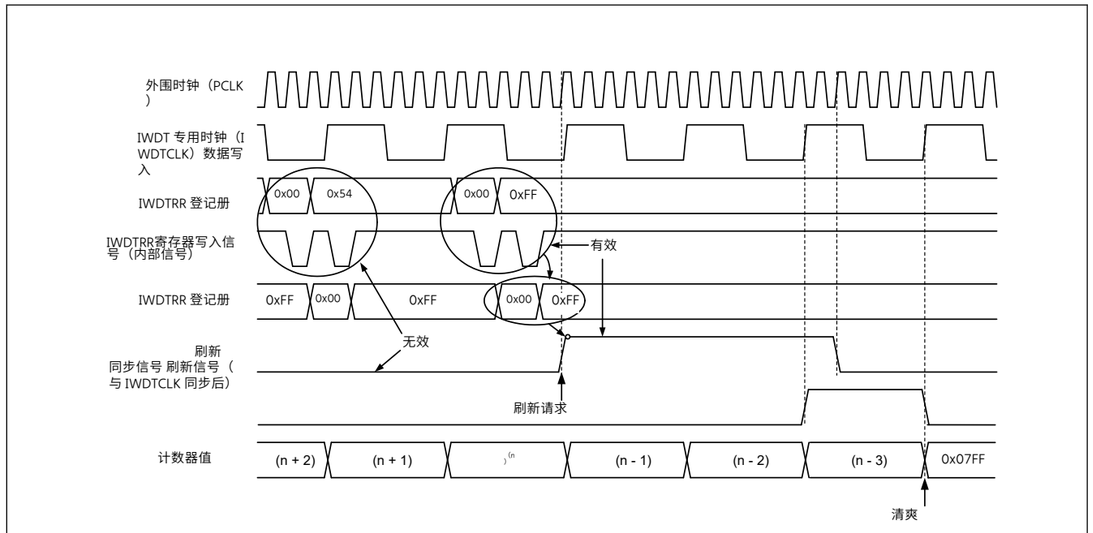

图23。4 OFS0 时 IWDT 刷新操作波形。IWDTCKS[3:0] = 0000b OFS0。IWDTTOPS[1:0] = 11b

23。3。3 状态标志

刷新错误（IWDTSR。REFEF）和下溢（IWDTSR。UNDFF）标志保留了来自IWDT的中断请求源。因此,在从中断请求生成中释放后,读取IWDTSR。REFEF和UNDFF标志以检查中断源。对于每个标志,写入 0 可以清除该位,而写入 1 则没有效果。

Leaving the status flags unchanged does not affect operation. If the flags are not cleared at the time of the next interrupt request from the IWDT, the earlier interrupt source is cleared and the new interrupt source is written. For the time period between when 0 is written in each flag and when its value is reflected, see section 23.2.2. IWDTSR : IWDT Status Register.

23.3.4 Reset Output

When the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 1, a reset signal is output when an underflow in the counter or a refresh error occurs. Counting down automatically starts after the reset output.

23.3.5 Interrupt Sources

When the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 0, an interrupt (IWDT_NMIUNDF) signal occurs when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or an interrupt. For details, see section 12, Interrupt Controller Unit (ICU).

Table 23.4 IWDT interrupt source

Name	Interrupt source	Interrupt to CPU	Start DMAC or DTC
IWDT_NMIUNDF	• Down-counter underflow • Refresh error	Possible	Not possible

23.3.6 Reading the Down-Counter Value

As the counter is a IWDT-dedicated clock (IWDTCLK), the counter value cannot be read directly. The IWDT synchronizes the counter value with the peripheral clock (PCLKB) and stores it in the down-counter value bits (IWDTSR.CNTVAL[13:0]) of the IWDT Status Register. Check these bits to obtain the counter value indirectly.

Reading the counter value requires multiple PCLKB clock cycles (up to 4 clock cycles), and the read counter value might differ from the actual counter value by a value of one count.

Figure 23.5 shows the processing for reading the IWDT counter value when PCLKB > IWDTCLK and the clock division ratio is IWDTCLK.

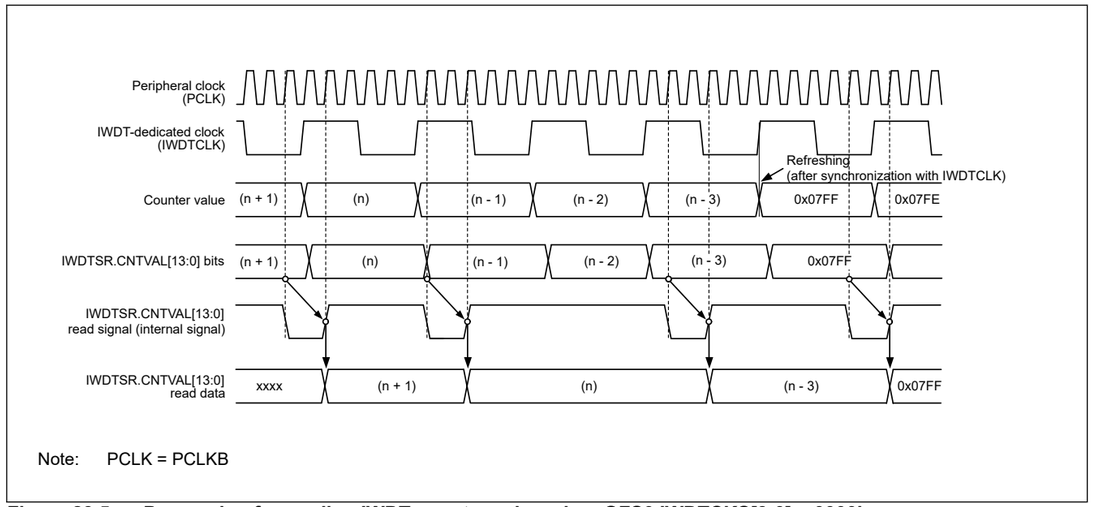

Figure 23.5 Processing for reading IWDT counter value when OFS0.IWDTCKS[3:0] = 0000b, OFS0.IWDTTOPS[1:0] = 11b

23.4 Output to the Event Link Controller (ELC)

The IWDT is capable of link operation for a specified module when the interrupt request signal is used as an event signal by the event link controller (ELC). The event signal is output by the counter underflow or refresh error.

状态标志保持不变不会影响操作。如果在 IWDT 发出的下一个中断请求时未清除标志,则清除较早的中断源并写入新的中断源。0 写入每个标志和反映其值之间的时间段,请参见第 23。2。2 节。IWDTSR:IWDT 状态寄存器 .

23。3。4 重置输出

当 IWDT 重置中断请求选择位（OFS0) 时。IWDTRSTIRQS）在选项功能选择寄存器 0（OFS0) 中设置为 1, 当计数器出现下溢或出现刷新错误时, 输出复位信号。重置输出后自动开始倒计时。

23。3。5 中断源

当 IWDT 重置中断请求选择位（OFS0) 时。IWDTRSTIRQS）在选项函数选择寄存器 0（OFS0) 中设置为 0, 当计数器出现下溢或出现刷新错误时, 会出现中断（IWDT_NMIUNDF）信号。该中断可用作不可屏蔽的中断或中断。有关详细信息,请参阅第 12 节"中断控制器单元（ICU）."

表 23。4 IWDT 中断源

名字	中断源	CPU 中断	启动 DMAC 或 DTC
IWDT_NMIUNDF	• 下柜台下溢 • 刷新错误	可能	不可能

23。3。6 读取下计数器值

由于计数器是 IWDT 专用时钟（IWDTCLK）,因此无法直接读取计数器值。IWDT将计数器值与外围时钟（PCLKB）同步,并将其存储在IWDT状态寄存器的下计数器值位（IWDTSR。CNTVAL[13:0])中。检查这些位以间接获得计数器值。

读取计数器值需要多个PCLKB时钟周期（最多4个时钟周期）,并且读取的计数器值可能与实际计数器值相差一个计数值。

图23。5示出了当PCLKB>IWDTCLK并且时钟分频比为IWDTCLK时读取IWDT计数器值的处理。

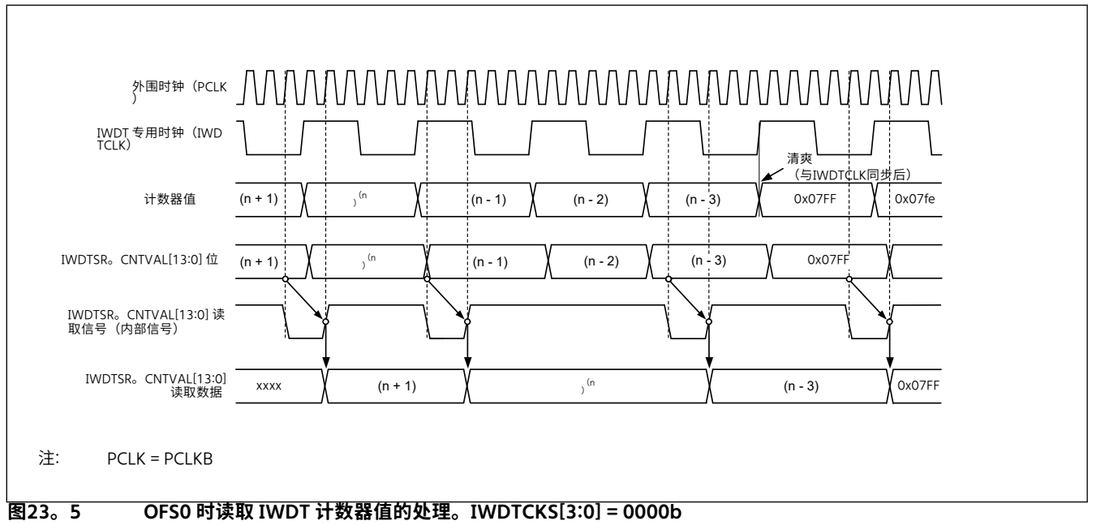

图23。5 OFS0 时读取 IWDT 计数器值的处理。IWDTCKS[3:0] = 0000b OFS0。IWDTTOPS[1:0] = 11b

23.4 输出到事件链路控制器（ELC）

当中断请求信号被事件链路控制器（ELC）用作事件信号时,IWDT能够对指定模块进行链路操作。事件信号由计数器下溢或刷新误差输出。

An event signal is output regardless of the setting of the OFS0.IWDTRSTIRQS bit. An event signal can also be output at generation of the next interrupt source while the Refresh Error flag (IWDTSR.REFEF) or Underflow flag (IWDTSR.UNDFF) is 1. For details, see section 17, Event Link Controller (ELC).

23.5 Usage Notes

23.5.1 Refresh Operations

While configuring the refresh time, consider variations in the range of errors given the accuracy of PCLKB and IWDTCLK. Set values that ensure refreshing is possible.

23.5.2 Clock Division Ratio Setting

Satisfy the frequency of the peripheral module clock (PCLKB) ≥ 4 × (the frequency of the count clock source after division).

23.5.3 Constraints on the ICU Event Link Setting Register n (IELSRn) Setting

Setting 0x52 to ICU Event Link Setting Register n (IELSRn.IELS[8:0]) is prohibited when enabling the IWDT reset assertion (OFS0.IWDTRSTIRQS = 0) or when enabling event link operation (ELSRn.ELS[8:0] = 0x52).

OFS0 的设置无关, 输出事件信号。IWDTRSTIRQS 位。当刷新错误标志（IWDTSR。REFEF）或下溢标志（IWDTSR。UNDFF）为 1 时,还可以在生成下一个中断源时输出事件信号。有关详细信息,请参阅第 17 节"事件链接控制器（ELC）."

23。5 使用说明

23。5。1 刷新操作

在配置刷新时间时,考虑到 PCLKB 和 IWDTCLK 的准确性,请考虑错误范围的变化。
设置确保刷新可能的值。

23。5。2 时钟划分比例设置

满足外围模块时钟（PCLKB）≥ 4 ×（除法后计数时钟源的频率）的频率。

23.5.3 ICU 事件链接设置寄存器 n（IELSRn）设置上的约束

0x52 设置为 ICU 事件链接设置寄存器 n（IELSRn。IELS[8:0]) 在启用 IWDT 重置断言（OFS0) 时被禁止。IWDTRSTIRQS = 0) 或启用事件链接操作时（ELSRn。ELS[8:0] = 0x52)。

24. Serial Communications Interface (SCI)

24.1 Overview

The Serial Communications Interface (SCI) × 2 channels have asynchronous and synchronous serial interfaces:

- Asynchronous interfaces (UART and Asynchronous Communications Interface Adapter (ACIA))
- 8-bit clock synchronous interface
- Simple IIC (master-only)
- Simple SPI
- Smart card interface
- Manchester interface

The smart card interface complies with the ISO/IEC 7816-3 standard for electronic signals and transmission protocol. SCIn (n = 0, 9) has FIFO buffers to enable continuous and full-duplex communication, and the data transfer speed can be configured independently using an on-chip baud rate generator.

In this section, PCLK refers to PCLKA.

Table 24.1 lists the SCI specifications, Figure 24.1 shows a block diagram of SCI, and Table 24.3 lists the I/O pins.

24.2 Register Descriptions

24.2.1 RSR : Receive Shift Register

RSR is a shift register that receives serial data input from the RXDn pin and converts it into parallel data. When one frame of data is received, the data is automatically transferred to the RDR, RDRHL, or the receive FIFO register. The RSR register cannot be directly accessed by the CPU.

24。2 寄存器说明

24。2。1 RSR:接收轮班寄存器

RSR是一个移位寄存器,它接收从RXDn引脚输入的串行数据并将其转换为并行数据。当接收到一帧数据时,数据会自动传输到 RDR、RDRHL 或接收 FIFO 寄存器。CPU无法直接访问RSR寄存器。

24.2.2 RDR : Receive Data Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

RDR is an 8-bit register that stores received data. When one frame of serial data is received, it is transferred from RSR to RDR, and the RSR register can receive more data. Because RSR and RDR function as a double buffer, continuous received operations can be performed.

Read the RDR only once after a receive data full interrupt (SCIn_RXI) occurs.

Note: If the next frame of data is received before reading the received data from RDR, an overrun error occurs. The CPU cannot write to the RDR.

24.2.3 RDRHL : Receive Data Register for Non-Manchester mode (MMR.MANEN = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)

Offset address: 0x10

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	RDAT[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	RDAT[8:0]	Serial Receive Data	R
15:9	—	These bits are read as 0.	R

RDRHL is a 16-bit register that stores received data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of RDRHL are the shadow register of RDR, so access to RDRHL affects the RDR register. Access to the RDRHL register is prohibited if 7-bit or 8-bit data length is selected.

After one frame of data is received, the received data is transferred from the RSR register to the RDR/RDRHL registers, allowing the RSR register to receive more data.

The RSR and RDRHL registers form a double-buffered structure to enable continuous reception. RDRHL should be read only when a receive data full interrupt (SCIn_RXI) request is issued. An overrun error occurs when the next frame of data is received before the received data is read from RDRHL. The CPU cannot write to the RDRHL register.

24.2.4 RDRHL_MAN : Receive Data Register for Manchester mode (MMR.MANEN = 1)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)

Offset address: 0x10

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	RSYNC	—	—	MPB	RDAT[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

24。2。2 RDR:接收数据寄存器

基本地址: SCIn = 0x4011_8000 + 0x0100 × n（n = 0, 9）

偏移地址: 0x05

位位置:	7	6	5	4	3	2	1	0
位字段:								
重置后的值:	0	0	0	0	0	0	0	0

RDR是一个存储接收数据的8位寄存器。1 帧串行数据时,从 RSR 传输到 RDR,RSR 寄存器可以接收更多数据。由于 RSR 和 RDR 充当双缓冲区,因此可以执行连续接收操作。

接收数据发生完全中断（SCIn_RXI）后仅读取 RDR 一次。

注意:如果在从 RDR 读取接收到的数据之前接收到下一帧数据,则会发生溢出错误。CPU 无法写入 RDR。

24。2。3 RDRHL:接收非曼彻斯特模式的数据寄存器（MMR。MANEN = 0）

基本地址: SCIn = 0x4011_8000 + 0x0100 × n（n = 0, 9）

偏移地址: 0x10

位位置:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
位字段:	—	—	—	—	—	—	—	RDAT[8:0]								
重置后的值:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

位	符号	功能	R/W
8:0	RDAT[8:0]	串行接收数据	R
15:9	—	这些位读作 0。	R

RDRHL 是一个 16 位寄存器,用于存储接收到的数据。选择异步模式和 9 位数据长度时使用此寄存器。

RDRHL 的较低 8 位是 RDR 的阴影寄存器,因此对 RDRHL 的访问会影响 RDR 寄存器。如果选择 7 位或 8 位数据长度,则禁止访问 RDRHL 寄存器。

接收一帧数据后,接收到的数据从RSR寄存器传输到RDR/RDRHL寄存器,从而允许RSR寄存器接收更多数据。

RSR 和 RDRHL 寄存器形成双缓冲结构以实现连续接收。仅当发出接收数据完全中断（SCIn_RXI）请求时才应读取 RDRHL。RDRHL 读取接收到的数据之前接收下一帧数据时, 会发生溢出错误。CPU 无法写入 RDRHL 寄存器。

24。2。4 RDRHL_MAN:接收曼彻斯特模式的数据寄存器（MMR。MANEN = 1）基本地址:

SCIn = 0x4011_8000 + 0x0100 × n（n = 0 9）

偏移地址:0x10

位位置:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

重置后的值:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W

9	MPB	Multi-processor bit It can read multi-processor bit corresponded to serial receive data (RDATA[8:0]) 0: Data transmission cycles 1: ID transmission cycles	R
11:10	—	These bits are read as 0. The write value should be 0.	R
12	RSYNC	Receive SYNC data bit It is valid when MMR.SBSEL = 1 in Manchester mode, 0 is read otherwise. 0: The received the Start Bit is DATA SYNC 1: The received the Start Bit is COMMAND SYNC	R
15:13	—	These bits are read as 0. The write value should be 0.	R

RDRHL_MAN is a 16-bit register that stores received data. Use this register when asynchronous mode and 9-bit data length are selected. The lower 8 bits of RDRHL_MAN are the shadow register of RDR, so access to RDRHL_MAN affects the RDR register. Access to the RDRHL_MAN register is prohibited if 7-bit or 8-bit data length is selected.

After one frame of data is received, the received data is transferred from the RSR register to the RDR/RDRHL_MAN registers, allowing the RSR register to receive more data.

The RSR and RDRHL_MAN registers form a double-buffered structure to enable continuous reception.

RDRHL_MAN should be read only when a receive data full interrupt (SCIn_RXI) request is issued. An overrun error occurs when the next frame of data is received before the received data is read from RDRHL_MAN.

The CPU cannot write to the RDRHL_MAN register.

RDAT[8:0] bit (Serial receive data)

It can read serial receive data.

MPB bit (Multi-processor bit)

Holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

RSYNC bit (Receive SYNC data bit)

When Manchester mode and MMR.SBSEL = 1, this bit indicates the type of SYNC of the received the Start Bit. For other settings, it is fixed to 0.

24.2.5 FRDRHL/FRDRH/FRDRL : Receive FIFO Data Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)

15:13	—	这些位读作 0。写入值应为 0。	R

RDRHL_MAN 是一个存储接收数据的 16 位寄存器。选择异步模式和 9 位数据长度时使用此寄存器。RDRHL_MAN 的较低 8 位是 RDR 的阴影寄存器,因此对 RDRHL_MAN 的访问会影响 RDR 寄存器。7 位或 8 位数据长度,则禁止访问 RDRHL_MAN 寄存器。

1帧数据后,接收到的数据从RSR寄存器传送到RDR/RDRHL_MAN寄存器,使得RSR寄存器接收更多的数据。

RSR和RDRHL_MAN寄存器形成双缓冲结构,以实现连续接收。

仅当发出接收数据完全中断（SCIn_RXI）请求时才应读取 RDRHL_MAN。RDRHL_MAN读取接收到的数据之前,接收到下一帧数据时,会发生溢出错误。

CPU 无法写入 RDRHL_MAN 寄存器。

14	RDF	Receive FIFO Data Full Flag This flag is the same as SSR_FIFO.RDF. 0: The amount of receive data written in FRDRH and FRDRL is less than the specified receive triggering number 1: The amount of receive data written in FRDRH and FRDRL is equal to or greater than the specified receive triggering number	R*1
15	—	This bit is read as 0.	R

Note 1. If this flag is read, it indicates the same value as that read from the SSR_FIFO register. Write 0 to the SSR_FIFO register to clear the flag.

FRDRHL is a 16-bit register that consists of the 8-bit FRDRH and FRDRL registers. FRDRH is assigned to the FRDRHL[15:8] bits, and allocated to the same address as FRDRHL. FRDRL is assigned to the FRDRHL[7:0] bits, and allocated to (the address of FRDRHL + 1) address.

FRDRH and FRDRL constitute a 16-stage FIFO register that stores serial receive data and related status information readable by software. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

The SCI completes reception of one frame of serial data by transferring the received data from the Receive Shift Register (RSR) into FRDRH and FRDRL for storage. Continuous reception is executed until 16 stages are stored. If data is read when there is no received data in FRDRH and FRDRL, the value is undefined. When FRDRH and FRDRL are full, subsequent serial receive data is lost. The CPU can read from the FRDRH and FRDRL registers but cannot write to them.

Reading 1 from the RDF, ORER, or DR flags of the FRDRH register is the same as reading from those bits in the SSR_FIFO register. When writing 0 to clear a flag in the SSR_FIFO register after reading the FRDRH register, write 0 only to the flag that is to be cleared and write 1 to the other flags.

When reading both the FRDRH and FRDRL registers, read in order from FRDRH to FRDRL. The FRDRHL register can be accessed in 16-bit units.

15	—	该位读作 0。	R

注1。如果读取此标志,则它表示与从 SSR_FIFO 寄存器读取的值相同的值。SSR_FIFO 寄存器写入 0 来清除标志。

FRDRHL 是一个 16 位寄存器,由 8 位 FRDRH 和 FRDRL 寄存器组成。FRDRH 被分配给 FRDRHL[15:8] 位,并分配给与 FRDRHL 相同的地址。FRDRL 被分配给 FRDRHL[7:0] 位,并分配给（FRDRHL + 1 的地址）地址。

FRDRH 和 FRDRL 构成一个 16 阶段 FIFO 寄存器,用于存储可通过软件读取的串行接收数据和相关状态信息。该寄存器仅在异步模式下有效,包括多处理器模式或时钟同步模式。

SCI 通过将接收到的数据从接收移位寄存器（RSR）传输到 FRDRH 和 FRDRL 进行存储来完成一帧串行数据的接收。执行连续接收直到存储 16 个阶段。如果在 FRDRH 和 FRDRL 中没有接收到的数据时读取数据,则该值未定义。FRDRH 和 FRDRL 满时,后续的串行接收数据会丢失。CPU 可以从 FRDRH 和 FRDRL 寄存器读取,但不能写入它们。

FRDRH 寄存器的 RDF、ORER 或 DR 标志读取 1 与从 SSR_FIFO 寄存器中的这些位读取相同。SSR_FIFO寄存器读取FRDRH寄存器后写入0清除一个标志时,只对要清除的标志写入0,对其他标志写入1。

读取 FRDRH 和 FRDRL 寄存器时,按从 FRDRH 到 FRDRL 的顺序读取。FRDRHL 寄存器可以 16 位单元访问。

TDR 是一个存储传输数据的 8 位寄存器。

When the SCI detects that the TSR register is empty, it transfers the transmit data written in the TDR register to the TSR register and starts transmission.

The double-buffered structure of the TDR and TSR registers enables continuous serial transmission. If the next transmit data is already written to TDR when one frame of data is transmitted, the SCI transfers the written data to the TSR register to continue transmission.

The CPU can read from or write to TDR at any time. Only write transmit data to TDR once after each instance of the transmit data empty interrupt (SCIn_TXI).

24.2.7 TDRHL : Transmit Data Register for Non-Manchester mode (MMR.MANEN = 0)

TDRHL is a 16-bit register that stores transmit data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of TDRHL are the shadow register of TDR, so access to TDRHL affects the TDR register. Access to the TDRHL register is prohibited if 7-bit or 8-bit data length is selected.

When empty space is detected in the TSR register, the transmit data stored in the TDRHL registers is transferred to TSR and transmission starts.

The TSR and TDRHL registers have a double-buffered structure to support continuous transmission. When the next data to be transmitted is stored in TDRHL after one frame of data is transmitted, the transmitting operation continues by transferring the data to the TSR register.

The CPU can read and write to the TDRHL register. Bits [15:9] in TDRHL are fixed to 1. These bits are read as 1. The write value should be 1.

Write transmit data to theTDRHL register only once when a transmit data empty interrupt (SCIn_TXI) request is issued.

24.2.8 TDRHL_MAN : Transmit Data Register for Manchester mode (MMR.MANEN = 1)

SCI 检测到 TSR 寄存器为空时,将 TDR 寄存器中写入的发送数据传输到 TSR 寄存器并开始传输。

TDR 和 TSR 寄存器的双缓冲结构可实现连续串行传输。如果下一传输数据在传输一帧数据时已经写入TDR,则SCI将写入的数据传输到TSR寄存器以继续传输。

CPU可以随时从TDR读取或写入到TDR。在发送数据空中断（SCIn_TXI）的每个实例之后,仅将发送数据写入TDR一次。

24.2.7 TDRHL:非曼彻斯特模式传输数据寄存器（MMR。MANEN = 0）

TDRHL是一个存储传输数据的16位寄存器。选择异步模式和 9 位数据长度时使用此寄存器。

TDRHL 的较低 8 位是 TDR 的阴影寄存器,因此对 TDRHL 的访问会影响 TDR 寄存器。如果选择 7 位或 8 位数据长度,则禁止访问 TDRHL 寄存器。

TSR寄存器中检测到空白时,存储在TDRHL寄存器中的发送数据被传送到TSR并开始传输。

TSR 和 TDRHL 寄存器具有双缓冲结构以支持连续传输。当下一帧数据被发送后被存储在TDRHL中时,通过将数据传输到TSR寄存器来继续发送操作。

CPU可以读写到TDRHL寄存器上。TDRHL中的位[15:9]固定为1。这些位读作 1。写入值应为 1。

发送数据空中断（SCIn_TXI）请求时,仅将传输数据写入 TDRHL 寄存器一次。

FTDRHL 是一个 16 位寄存器,由 8 位 FTDRH 和 FTDRL 寄存器组成。FTDRH 被分配给 FTDRHL[15:8] 位,并分配给与 FTDRHL 相同的地址。FTDRL分配给FTDRHL[7:0]位,并分配给（FTDRHL + 1的地址）地址。

FTDRH and FTDRL constitute a 16-stage FIFO register that stores data for serial transmission and a multi-processor transfer bit. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

When the SCI detects that the Transmit Shift Register (TSR) is empty, it transfers data written in the FTDRH and FTDRL registers to the TSR register and starts serial transmission. Continuous serial transmission is executed until no transmit data is left in FTDRH and FTDRL. When FTDRHL is full of transmit data, no more data can be written. If writing new data is attempted, the data is ignored. The CPU can write to the FTDRH and FTDRL registers but cannot read them.

When writing to both the FTDRH and FTDRL registers, write in order from FTDRH to FTDRL.

TDAT[8:0] bits (Serial transmit data)

The TDAT[8:0] bits set the serial transmission data. This is valid only when FIFO is selected in asynchronous mode (including multiprocessor) or clock synchronous mode.

MPBT flag (Multi-Processor Transfer Bit Flag)

The MPBT flag specifies the value of the multi-processor bit of the transmit frame. When FCR.FM = 1, SSR.MPBT is invalid.

24.2.10 TSR : Transmit Shift Register

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first automatically transfers transmit data from TDR, TDRHL, or transmit FIFO to TSR, then sends the data to the TXDn pin. The CPU cannot directly access the TSR.

24.2.11 SMR : Serial Mode Register for Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)

Offset address: 0x00

FTDRH 和 FTDRL 构成一个 16 级 FIFO 寄存器,用于存储串行传输的数据和多处理器传输位。该寄存器仅在异步模式下有效,包括多处理器模式或时钟同步模式。SCI检测到发送移位寄存器（TSR）为空时,它将写入FTDRH和FTDRL寄存器中的数据传输到TSR寄存器并开始串行传输。执行连续串行传输直到FTDRH和FTDRL中没有留下传输数据。FTDRHL充满传输数据时,就无法再写入数据。如果尝试写入新数据,则数据将被忽略。CPU可以写入FTDRH和FTDRL寄存器,但不能读取它们。

当写入 FTDRH 和 FTDRL 寄存器时,按从 FTDRH 到 FTDRL 的顺序写入。

TDAT[8:0] 位（串行传输数据）

TDAT[8:0]位设置串行传输数据。FIFO在异步模式（包括多处理器）或时钟同步模式下选择时,这才有效。

MPBT标志（多处理器传输位标志）

MPBT标志指定了发送帧的多处理器位的值。当FCR。FM = 1时,SSR。MPBT无效。

24。2。10 TSR:传输移位寄存器

TSR是传输串行数据的移位寄存器。SCI进行串行数据传输,首先自动从TDR、TDRHL传输传输数据,或者将FIFO传输到TSR,然后将数据发送到TXDn引脚。CPU 无法直接访问 TSR。

7	CM	Communication Mode 0: Asynchronous mode or simple IIC mode 1: Clock synchronous mode or simple SPI mode	R/W*4

Note 1. n is the decimal notation of the value of n in the BRR register. See section 24.2.20. BRR : Bit Rate Register.
Note 2. In any mode other than asynchronous mode, this bit setting is invalid and a fixed data length of 8 bits is used.
Note 3. LSB-first is fixed and the MSB (bit [7]) in the TDR register is not transmitted in transmit mode.
Note 4. Writable only when SCR.TE = 0 and SCR.RE = 0 (both serial transmission and reception are disabled).

The SMR register sets the communication format and clock source for the on-chip baud rate generator.

CKS[1:0] bits (Clock Select)

The CKS[1:0] bits select the clock source for the on-chip baud rate generator. For the relationship between the settings of these bits and the baud rate, see section 24.2.20. BRR : Bit Rate Register.

MP bit (Multi-Processor Mode)

The MP bit disables or enables the multi-processor communications function. The PE and PM bit settings are invalid in multi-processor mode.

STOP bit (Stop Bit Length)

The STOP bit selects the stop bit length in transmission.

In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

PM bit (Parity Mode)

The PM bit selects the parity mode (even or odd) for transmission and reception. The PM bit setting is invalid in multiprocessor mode.

PE bit (Parity Enable)

When the PE bit is set to 1, the parity bit is added to transmit data, and the parity bit is checked in reception. Regardless of the PE bit setting, the parity bit is not added or checked in multi-processor format.

CHR bit (Character Length)

The CHR bit selects the data length for transmission and reception in combination with the SCMR.CHR1 bit. In modes other than asynchronous, a fixed data length of 8 bits is used.

CM bit (Communication Mode)

The CM bit selects the communication mode:

- Asynchronous mode or simple IIC mode
- Clock synchronous mode or simple SPI mode

PM bit (Parity Mode)

The PM bit selects the parity mode for transmission and reception (even or odd). For details on the usage of this bit in smart card interface mode, see section 24.7.2. Data Format (Except in Block Transfer Mode).

PE bit (Parity Enable)

Set the PE bit to 1. The parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

BLK bit (Block Transfer Mode)

Setting the BLK bit to 1 enables block transfer mode operation. For details, see section 24.7.3. Block Transfer Mode.

GM bit (GSM Mode)

Setting the GM bit to 1 enables GSM mode operation. In GSM mode, the SSR_SMCI.TEND flag set timing is moved forward to 11.0 ETUs (elementary time unit = 1-bit transfer time) from the start bit, and clock output control is added. For details, see section 24.7.6. Serial Data Transmission (Except in Block Transfer Mode) and section 24.7.8. Clock Output Control.

24.2.13 SCR:非智能卡接口模式的串行控制寄存器（SCMR。SMIF = 0)

7	TIE	Transmit Interrupt Enable 0: Disable SCIn_TXI interrupt requests 1: Enable SCIn_TXI interrupt requests	R/W

Note 1. Writable only when TE = 0 and RE = 0.
Note 2. 1 can be written only when TE = 0 and RE = 0, when the SMR.CM bit is 1. After setting TE or RE to 1, only 0 can be written to TE and RE. When the SMR.CM bit is 0 and the SIMR1.IICM bit is 0, writing is enabled under any condition.
Note 3. When writing a new value to a bit other than the MPIE bit of this register in multi-processor mode (SMR.MP bit = 1), write 0 to the MPIE bit using the store instruction to avoid accidentally setting the MPIE bit to 1 by a read-modify-write operation when using a bit manipulation instruction.

The SCR register controls operation and clock source selection for transmission and reception.

CKE[1:0] bits (Clock Enable)

The CKE[1:0] bits select the clock source and the SCKn pin function.

TEIE bit (Transmit End Interrupt Enable)

The TEIE bit enables or disables SCIn_TEI interrupt requests. Set TEIE to 0 to disable an SCIn_TEI interrupt request.

In simple IIC mode, SCIn_TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STIn). In this case, the TEIE bit can be used to enable or disable the STI.

MPIE bit (Multi-Processor Interrupt Enable)

When the MPIE bit is set to 1 and data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags RDRF, ORER, FER, RDF, and DR in SSR/SSR_FIFO to 1 is disabled. When data with the multi-processor bit set to 1 is received, the MPIE bit is automatically set to 0, and normal reception resumes. For details, see section 24.4. Multi-Processor Communication Function.

When the MPB bit in the SSR register is 0, the receive data is not transferred from the RSR register to the RDR register, a receive error is not detected, and setting the flags ORER and FER to 1 is disabled.

When the MPB bit is set to 1, the MPIE bit is automatically set to 0, SCIn_RXI and SCIn_ERI interrupt requests are enabled (if the RIE bit in SCR is set to 1), and setting of the ORER and FER flags to 1 is enabled.

Set MPIE to 0 if the multi-processor communications function is not used.

RE bit (Receive Enable)

The RE bit enables or disables serial reception. When the RE bit is set to 1, serial reception starts by detecting the start bit in asynchronous mode or the synchronous clock input in clock synchronous mode. Set the reception format in the SMR register before setting the RE bit to 1.

In non-FIFO operation, when reception is halted by setting the RE bit to 0, the RDRF, ORER, FER, and PER flags in the SSR register are not affected, and the previous values are retained.

When FIFO operation is selected and reception is halted by setting the RE bit to 0, the RDF, ORER, FER, PER, and DR flags in SSR_FIFO are not affected and the previous values are retained.

TE bit (Transmit Enable)

The TE bit enables or disables serial transmission.

When the TE bit is set to 1, serial transmission is started by writing transmit data to the TDR register. Set the transmission format in the SMR register before setting the TE bit to 1.

Bit	符号	功能	R/W
4	RE	接收启用 0:禁用串行接收 1:启用串行接收	R/W*2
5	TE	传输启用 0:禁用串行传输 1:启用串行传输	R/W*2
6	RIE	接收中断启用 0:禁用SCIn_RXI和SCIn_ERI中断请求 1:启用SCIn_RXI和SCIn_ERI中断请求	R/W
7	TIE	传输中断启用 0:禁用SCIn_TXI中断请求 1:启用SCIn_TXI中断请求	R/W

注1。仅当 TE = 0 和 RE = 0 时可写。
注 2。只有当 TE = 0 和 RE = 0 时,SMR。CM 位为 1 时,才能写出 1。TE 或 RE 设置为 1 后,只能将 0 写入 TE 和 RE。当SMR。CM位为0且SIMR 1时。IICM位为0,在任何条件下都启用写入。
注3。在多处理器模式下将新值写入该寄存器的 MPIE 位以外的位时（SMR。MP 位 = 1),使用存储指令将 0 写入 MPIE 位,以避免意外地将 MPI E 位设置为 1使用位操作指令时的读-修改-写操作。

SCR 寄存器控制传输和接收的操作和时钟源选择。

CKE[1:0] 位（时钟启用）

CKE[1:0] 位选择时钟源和 SCKn 引脚函数。

TEIE 位（发送端中断启用）

TEIE 位启用或禁用 SCIn_TEI 中断请求。将 TEIE 设置为 0 以禁用 SCIn_TEI 中断请求。

在简单的 IIC 模式下,SCIn_TEI 被分配给发出开始、重新启动或停止条件（STIn）完成后的中断。
在这种情况下,TEIE 位可用于启用或禁用 STI。

MPIE 位（启用多处理器中断）

MPIE 位设置为 1 并且接收到多处理器位设置为 0 的数据时,不读取数据,并禁用 SSR/SSR_FIFO 至 1 中的状态标志 RDRF、ORER、FER、RDF 和 DR。当接收到多处理器位设置为1的数据时,MPIE位自动设置为0,恢复正常接收。详情请参见第 24。4 节。

多处理器通信功能.

SSR寄存器中的MPB位为0时,接收数据没有从RSR寄存器传输到RDR寄存器,没有检测到接收错误,并且禁用将标志ORER和FER设置为1。

MPB 位设置为 1 时,MPIE 位自动设置为 0,启用 SCIn_RXI 和 SCIn_ERI 中断请求（如果 SCR 中的 RIE 位设置为 1),并将 ORER 和 FER 标志设置为 1启用。

MPIE设置为0,如果不使用多处理器通信功能。

RE 位（接收启用）

RE 位启用或禁用串行接收。RE位设置为1时,通过检测异步模式下的起始位或时钟同步模式下的同步时钟输入,开始串行接收。RE 位设置为 1 之前,先在 SMR 寄存器中设置接收格式。

在非FIFO操作中,当通过将RE位设置为0来停止接收时,SSR寄存器中的RDRF、ORER、FER和PER标志不受影响,并且保留先前的值。

FIFO 操作被选择并且通过将 RE 位设置为 0 停止接收时, SSR_FIFO 中的 RDF、ORER、FER、PER 和 DR 标志不受影响, 并保留前面的值。

TE 位（传输启用）

TE 位启用或禁用串行传输。

TE 位设置为 1 时,通过将传输数据写入 TDR 寄存器来开始串行传输。TE 位设置为 1 之前,先在 SMR 寄存器中设置传输格式。

RIE bit (Receive Interrupt Enable)

The RIE bit enables or disables SCIn_RXI and SCIn_ERI interrupt requests.

SCIn_RXI and SCIn_ERI interrupt requests are disabled by setting the RIE bit to 0.

An SCIn_ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in SSR/SSR_FIFO then setting the flag to 0, or by setting the RIE bit to 0.

TIE bit (Transmit Interrupt Enable)

The TIE bit enables or disables SCIn_TXI interrupt requests. SCIn_TXI interrupt requests are disabled by setting the TIE bit to 0.

Note: To switch the TIE bit value from 0 to 1 in FIFO mode, set the TIE and TE bits to 1 simultaneously or set the TIE bit to 1 when TE = 1. When TE = 0 in FIFO mode, setting the TIE bit to 1 is prohibited.

7	TIE	Transmit Interrupt Enable 0: Disable SCIn_TXI interrupt requests 1: Enable SCIn_TXI interrupt requests	R/W

Note 1. Writable only when TE = 0 and RE = 0.
Note 2. 1 can be written only when TE = 0 and RE = 0. After setting TE or RE to 1, only 0 can be written to TE and RE.

The SCR_SMCI register sets transmission and reception control, interrupt control, and clock source selection for transmission and reception.

For details on interrupt requests, see section 24.11. Interrupt Sources.

RIE 位（接收中断启用）

RIE 位启用或禁用 SCIn_RXI 和 SCIn_ERI 中断请求。

SCIn_RXI 和 SCIn_ERI 中断请求通过将 RIE 位设置为 0 来禁用。

TIE 位（传输中断启用）

TIE 位启用或禁用 SCIn_TXI 中断请求。SCIn_TXI 中断请求通过将 TIE 位设置为 0 来禁用。

注: FIFO 模式下将 TIE 位值从 0 切换到 1,同时将 TIE 和 TE 位设置为 1 或在 TE = 1 时将 TIE 位设置为 1。FIFO模式下TE = 0 时,禁止将TIE位设置为1。

SCIn_RXI 和 SCIn_ERI 中断请求通过将 RIE 位设置为 0 来禁用。

SSR_SMCI 寄存器中的 ORER、FER 或 PER 标志读取 1,然后将标志设置为 0,或者将 RIE 位设置为 0,就可以取消 SCIn_ERI 中断请求。

The SSR register provides SCI status flags and transmission and reception multi-processor bits.

MPBT bit (Multi-Processor Bit Transfer)

The MPBT bit sets the value of the multi-processor bit in the transmit frame.

MPB bit (Multi-Processor)

The MPB bit holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

TEND flag (Transmit End Flag)

The TEND flag indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled) and the FCR.FM bit is set to 0 (non-FIFO selected). When the SCR.TE bit is set to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated on transmission of the tail-end bit of a character being transmitted.

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR.TE bit is 1
- When 0 is written to TDRE after reading TDRE = 1 while the SCR.TE bit is 1

PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

  Although receive data is transferred to the RDR register when the parity error occurs, no SCIn_RXI interrupt request occurs. When the PER flag is set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to PER after reading PER = 1. After writing 0 to the PER flag, read the PER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

的【设置条件】

- 当 SCR。TE 位被设置为 0（串行传输被禁用）并且 FCR。FM 位被设置为 0（选择非 FIFO）。SCR。TE 位设置为 1 时,TEND 标志不受影响并保留值 1。
- 当 TDR 寄存器在传输正在传输的字符的尾端位时未更新。

的【设置条件】

- 当地址匹配函数被禁用时在异步模式下接收时检测到奇偶校验错误时（DCCR。DCME = 0)。

  尽管当奇偶校验错误发生时接收数据被传输到 RDR 寄存器,但不会发生 SCIn_RXI 中断请求。PER 标志设置为 1 时,后续接收数据不会传输到 RDR 寄存器。

的【清零条件】

- 当读取 PER = 1 后将 0 写入 PER 时。PER 标志写入 0 后,读取 PER 标志,检查它是否实际设置为 0。

[Setting condition]

- When 0 is sampled as the stop bit during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

  In 2-stop-bit mode, only the first stop bit is checked. The second stop bit is not checked. Although receive data is transferred to the RDR register when the framing error occurs, no SCIn_RXI interrupt request occurs. When the FER flag is to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to FER after reading FER = 1. After writing 0 to the FER flag, read the FER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error and a framing error is read from the RDR register.

  The data received before an overrun error occurred is saved in the RDR register, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register. In clock synchronous mode, serial transmission and reception are stopped.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1. After writing 0 to the ORER flag, read the ORER flag to check that it is actually set to 0.

- When data is forwarded from the RDR register

TDRE flag (Transmit Data Empty Flag)

[Setting conditions]

- When the SCR.TE bit is 0
- When data is transmitted from the TDR register to the TSR register

[Clearing conditions]

- When 0 is written to TDRE after reading TDRE = 1
- When the SCR.TE bit is 1 and data is written to the TDR register

ORER标志,表示在接收过程中发生超限错误,接收异常结束。

的【设置条件】

- 在接收没有奇偶校验误差的数据之前接收到下一个数据时,从 RDR 寄存器读取成帧误差。

  RDR寄存器中保存发生超限错误之前接收的数据,但错误丢失后接收的数据。ORER标志设置为1时,接收数据不会转发到RDR寄存器。在时钟同步模式下,停止串行发送和接收。

的【清零条件】

- 当读取 ORER = 1 后将 0 写入 ORER 时。ORER 标志写入 0 后,读取 ORER 标志,检查它是否实际设置为 0。

SCR。RE 位设置为 0 时（串行接收被禁用）,ORER 标志不受影响并保留其前值。

This flag is valid only in asynchronous mode, including multi-processor mode, when FIFO operation is selected.

In clock synchronous mode, the DR flag is not set to 1.

[Setting condition]

- When FRDRHL contains less data than the specified receive triggering number, and no next data is received after 15 ETUs*1 from the last stop bit, and the SSR_FIFO.FER and SSR_FIFO.PER flags are 0.

注1。0才能写,读完1就把旗子清了。

SSR_FIFO寄存器为SCI提供了FIFO模式状态标志。

DR 标志（接收数据就绪标志）

DR标志指示接收FIFO数据寄存器（FRDRHL）中存储的数据量低于指定的接收触发号码,并且在异步模式下从最后一个停止位15个ETU（基本时间单位）之后没有接收到下一个数据。FIFO操作时,此标志仅在异步模式下有效,包括多处理器模式。

在时钟同步模式下,DR标志不设置为1。的【设置条件】

● 当 FRDRHL 包含的数据少于指定的接收触发号码,并且从最后一个停止位 15 个 ETU *1 后没有接收到下一个数据,并且 SSR_FIFO。FER 和 SSR_FIFO。PER 标志为 0。

的【清算条件】

● 当从 DR 读取 1 时,读取所有接收到的数据后

- When the FCR.FM bit is changed from 0 to 1

Note 1. This is equivalent to 1.5 frames in the 8-bit format with one stop bit.
The DR flag is only set to 1 when FIFO is selected in asynchronous mode, including multi-processor mode. It is not set to 1 in other operation modes.

TEND flag (Transmit End Flag)

The TEND flag indicates that FTDRHL does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

- When FTDRHL does not contain transmit data when the last bit of a 1-byte serial character is transmitted.

[Clearing conditions]

- When transmit data is written to FTDRHL*1 while the SCR.TE bit is 1
- When 0 is written to TEND after 1 is read from TEND, when the SCR.TE bit is 1
- When the FCR.FM bit is changed from 0 to 1

Note 1. Do not use the TEND bit as a transmit end flag when the DTC writes data to FTDRHL in response to an SCIn_TXI interrupt request.

PER flag (Parity Error Flag)

The PER flag indicates whether there is a parity error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When data is received and a parity error is detected, when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to PER after reading PER = 1.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a parity error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

The FER flag indicates whether there is a framing error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When 0 is sampled as the stop bit during reception when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to FER after reading FER = 1.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a framing error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

The ORER flag indicates that the receive operation stopped abnormally because an overrun error occurred.

[Setting condition]

- When the next serial reception completes while the receive FIFO is full with 16-byte receive data.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1.

- 当 FCR。FM 位从 0 更改为 1 时

注1。这相当于 8 位格式的 1。5 帧,有一个停止位。
DR标志仅在异步模式下选择FIFO时设置为1,包括多处理器模式。在其他操作模式下不设置为1。

TEND 标志（发射端标志）

TEND标志表示FTDRHL在传输串行字符的最后一位时不包含有效数据,因此停止传输。

的【设置条件】

- 当 FTDRHL 在传输 1 字节串行字符的最后一位时不包含传输数据。

的【清算条件】

- 当传输数据写入 FTDRHL *1 时,而 SCR。TE 位为 1
- 当从 TEND 中读取 1 后的 0 写入 TEND 时,当 SCR。TE 位为 1 时
- 当 FCR。FM 位从 0 更改为 1 时

注1。DTC 响应 SCIn_TXI 中断请求向 FTDRHL 写入数据时, 请勿使用 TEND 位作为发送端标志。

每个标志（奇偶校验错误标志）

PER标志指示当地址匹配函数被禁用时,在异步模式下从FRDRHL寄存器读取的数据是否存在奇偶校验错误（DCCR。DCME = 0)。

的【设置条件】

- 接收数据并检测到奇偶校验错误时, 禁用地址匹配函数时（DCCR。DCME = 0)。

的【清零条件】

SCR。RE 位设置为 0（串行接收被禁用）时,PER 标志不受影响并保留其前值。

FER 标志（框架错误标志）

FER标志指示当地址匹配函数被禁用时,在异步模式下从FRDRHL寄存器读取的数据是否存在帧错误（DCCR。DCME = 0)。

的【设置条件】

- 当地址匹配函数被禁用时,在接收过程中采样0作为停止位时（DCCR。DCME = 0)。

ORER 标志指示接收操作因发生超限错误而异常停止。

的【设置条件】

- 当下一个串行接收完成时,接收 FIFO 已满 16 字节的接收数据。

的【清零条件】

- 当读取 ORER = 1 后将 0 写入 ORER 时。

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.
