The RDF flag indicates that receive data was transferred to the FRDRHL register, and the amount of data in FRDRHL is equal to or exceeds the specified receive triggering number. When RTRG is set to 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0.

[Setting condition]

- When the amount of receive data equal to or greater than the specified receive triggering number is stored in FRDRHL,*1 and the FIFO is not empty.

[Clearing conditions]

- When 0 is written to RDF after reading RDF = 1
- When FRDRHL is read by the DTC, but only when the block transfer is the last transmission
- When the setting and clearing conditions occur at the same time, the RDF bit is set to 0. After that, when the amount of data stored in the FRDRHL register is the same as or greater than the RTRG value, RDF is set to 1 after 1 PCLK.

Note 1. Because FRDRHL is a 16-stage FIFO register, the maximum amount of data that can be read when RDF is 1 is equivalent to the specified receive triggering number. If an attempt is made to read after all the data in FRDRHL is read, the data is undefined.

TDFE flag (Transmit FIFO Data Empty Flag)

The TDFE flag indicates that data is transferred from the FTDRHL register into the TSR register, the amount of data in FTDRHL is below the specified transmit triggering number, and writing of transmit data to FTDRHL is enabled.

[Setting conditions]

- When the TE bit in SCR is 0
- When the amount of transmit data written in FTDRHL is equal to or less than the specified transmit triggering number*1

[Clearing conditions]

- When writing to FTDRHL is executed on the last transmission while the DTC is activated
- When 0 is written to the TDFE flag after reading TDFE = 1.*2
  The setting conditions are given priority when TE = 0. When the setting condition and clearing condition occur at the same time, the TDFE flag is set to 0. After that, when the amount of data stored in the FTDRHL register is equal to or less than the TTRG value, TDFE is set to 1 after 1 PCLK.

Note 1. Because the FTDRHL register is a 16-stage FIFO register, when the TDFE flag is 1, the maximum amount of data that can be written to the FTDRHL register is 16 minus FDR.T[4:0] bytes. If more data is written, data is discarded.
Note 2. Do not clear the TDFE flag during block transfer processing by the DTC.

24.2.17 SSR_SMCI : Serial Status Register for Smart Card Interface Mode (SCMR.SMIF = 1, and MMR.MANEN = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)
Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TDRE	RDRF	ORER	ERS	PER	TEND	MPB	MPBT
Value after reset:	1	0	0	0	0	1	0	0

Bit	Symbol	Function	R/W
0	MPBT	Multi-Processor Bit Transfer Set this bit to 0 in smart card interface mode	R/W

SCR。RE 位设置为 0 时（串行接收被禁用）,ORER 标志不受影响并保留其前值。

RDF 标志（接收 FIFO 数据完整标志）

RDF标志表示接收数据被传送到FRDRHL寄存器,并且FRDRHL中的数据量等于或超过指定的接收触发数。RTRG 设置为 0 时,即使接收 FIFO 中的数据量等于 0,也不会设置 RDF 标志。

的【设置条件】

- 当接收数据量等于或大于指定的接收触发数存储在FRDRHL中时,*1且FIFO不为空。

的【清算条件】

- 当读取 RDF = 1 后将 0 写入 RDF 时
- 当 FRDRHL 被 DTC 读取时,但仅当块传输是最后一次传输时
- 当设置和清除条件同时发生时,RDF位被设置为0。此后,当FRDRHL寄存器中存储的数据量与RTRG值相同或大于RTRG值时,1PCLK后将RDF设置为1。

注1。由于 FRDRHL 是 16 阶段 FIFO 寄存器,因此 RDF 为 1 时可读取的最大数据量相当于指定的接收触发号。如果在读取 FRDRHL 中的所有数据后尝试读取,则数据未定义。

TDFE 标志（传输 FIFO 数据空标志）

TDFE标志指示数据从FTDRHL寄存器传输到TSR寄存器中,FTDRHL中的数据量低于指定的发送触发号,并且启用向FTDRHL写入发送数据。

的【设置条件】

- 当SCR中的TE位为0时
- 当以 FTDRHL 写入的传输数据量等于或小于指定的传输触发数 *1 时

的【清算条件】

- 当写入 FTDRHL 时,在 DTC 激活时在最后一个传输上执行
- 当读取 TDFE = 1.*2 后将 0 写入 TDFE 标志时
  TE = 0 时优先考虑设置条件。当设置条件和清除条件同时发生时,TDFE标志设置为0。此后,当FTDRHL寄存器中存储的数据量等于或小于TTRG值时,TDFE在1PCLK之后设置为1。

注1。由于 FTDRHL 寄存器是 16 阶段 FIFO 寄存器,因此当 TDFE 标志为 1 时,可以写入 FTDRHL 寄存器的最大数据量为 16 减去 FDR。T[4:0] 字节。如果写入更多数据,则数据将被丢弃。
注2。DTC 进行块传输处理时, 请勿清除 TDFE 标志。

7	TDRE	Transmit Data Empty Flag 0: Transmit data in TDR register 1: No transmit data in TDR register	R/W*1

Note 1. Only 0 can be written, to clear the flag after reading 1.

The SSR_SMCI register provides the SCI with smart card interface mode status flags.

TEND flag (Transmit End Flag)

When there is no error signal from the receiving side, the TEND flag is set to 1 when more data for transfer is ready to be transferred to the TDR register.

[Setting conditions]

- When the SCR_SMCI.TE bit = 0 (serial transmission is disabled).
  When the SCR_SMCI.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period elapses after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated.

  The set timing is determined by the following register settings:

  – When SMR_SMCI.GM = 0 and SMR_SMCI.BLK = 0, 12.5 ETUs after the start of transmission
  – When SMR_SMCI.GM = 0 and SMR_SMCI.BLK = 1, 11.5 ETUs after the start of transmission
  – When SMR_SMCI.GM = 1 and SMR_SMCI.BLK = 0, 11.0 ETUs after the start of transmission
  – When SMR_SMCI.GM = 1 and SMR_SMCI.BLK = 1, 11.0 ETUs after the start of transmission

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR_SMCI.TE bit is 1
- When 0 is written to TDRE after reading TDRE = 1 while the SCR_SMCI.TE bit is 1

PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception. Although receive data is transferred to RDR when a parity error occurs, no SCIn_RXI interrupt request occurs. After the PER flag is set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

注1。0才能写,读完1就把旗子清了。

SSR_SMCI寄存器为SCI提供了智能卡接口模式状态标志。

TEND 标志（发射端标志）

当接收侧没有错误信号时,当更多用于传输的数据准备传输到 TDR 寄存器时,TEND 标志被设置为 1。

的【设置条件】

- 当 SCR_SMCI。TE 位 = 0 时（串行传输被禁用）。
  SCR_SMCI。TE 位从 0 变为 1 时,TEND 标志不受影响并保留值 1。
- 在最近一次传输 1 字节后经过指定周期时,ERS 标志为 0,TDR 寄存器不更新。

  设置的定时由以下寄存器设置确定:

  – 当 SMR_SMCI。GM = 0 且 SMR_SMCI。BLK = 0 时,传输开始后有 12。5 个 ETU
  – 当 SMR_SMCI。GM = 0 且 SMR_SMCI。BLK = 1 时,传输开始后有 11。5 个 ETU
  – 当 SMR_SMCI。GM = 1 且 SMR_SMCI。BLK = 0 时,传输开始后 ETU 为 11。0
  – 当 SMR_SMCI。GM = 1 且 SMR_SMCI。BLK = 1 时,传输开始后 ETU 为 11。0

的【清算条件】

- 当传输数据写入 TDR 寄存器时,而 SCR_SMCI。TE 位为 1
- 当读取 TDRE = 1 后将 0 写入 TDRE 时,而 SCR_SMCI。TE 位为 1

每个标志（奇偶校验错误标志）

PER标志表示异步模式接收时发生奇偶校验错误,接收异常结束。

的【设置条件】

- 在接收过程中检测到奇偶校验错误时。尽管当发生奇偶校验错误时接收数据被传输到 RDR,但不会发生 SCIn_RXI 中断请求。PER标志设置为1后,后续接收数据不传输到RDR。

的【清零条件】

- When 0 is written to PER after reading PER = 1. After writing 0 to the PER flag, read the flag to check that it is actually set to 0.

When the RE bit in SCR_SMCI is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

ERS flag (Error Signal Status Flag)

[Setting condition]

- When a low error signal is sampled.

[Clearing condition]

- When 0 is written to ERS after reading ERS = 1.

ORER flag (Overrun Error Flag)

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error is read from the RDR register. The data received before an overrun error occurred is saved in the RDR, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1. After writing 0 to the ORER flag, read the flag to check that it is actually set to 0.

When the RE bit in SCR_SMCI is set to 0, the ORER flag is not affected and retains its previous value.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing conditions]

- When 0 is written to RDRF after reading RDRF = 1
- When data is forwarded from the RDR register

的【清零条件】

- 当读取 ERS = 1 后将 0 写入 ERS 时。

ORER 标志（超润错误标志）

的【设置条件】

- 在接收没有奇偶校验错误的数据之前接收到下一个数据时,从 RDR 寄存器中读取。RDR 中保存发生超限错误之前接收的数据,但错误丢失后接收的数据。ORER标志设置为1时,接收数据不会转发到RDR寄存器。

的【清零条件】

- 当读取 ORER = 1 后将 0 写入 ORER 时。ORER 标志写入 0 后,读取该标志,检查其是否实际设置为 0。

SCR_SMCI 中的 RE 位设置为 0 时,ORER 标志不受影响并保留其前值。

RDRF 标志（接收数据完整标志）

RDRF 标志指示 RDR 寄存器中存在接收数据。

When data is received in Manchester mode, Manchester error is detected and it is displayed.

[Setting conditions]

- When receiving in Manchester mode and detecting Manchester code error in data area of received frame.
  Received data when an error occurs is transferred to the RDR register, but the RXI interrupt request is not generatedand the ERI interrupt request is generated.
  When the Manchester error flag is set to “1”, subsequent receive data is not transferred to the RDR register.
  For details on Manchester error, see section 24.5.11. Errors in Manchester Mode.

[Clearing conditions]

TEND flag (Transmit End Flag)

Indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled) and FCR.FM bit is set to 0 (non-FIFO selected).
  When the SCR.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at the time of transmission of the tail-end bit of a character being transmitted

[Clearing conditions]

- When transmit data are written to the TDR register while the SCR.TE bit is 1.
- When 0 is written to TDRE after reading TDRE = 1 while the SCR.TE bit is 1.

  Although receive data when the parity error occurs is transferred to RDR, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to PER after reading PER = 1 (after writing 0 to it, read the PER bit to check that it has actually been set to 0.)

Even when the RE bit in SCR is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

[Setting condition]

- When “0” is sampled as the stop bit during reception in Asynchronous Mode and the state of Address Match function invalidity (DCCR.DCME = 0).
  In 2-stop-bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked. Note that although receive data when the framing error occurs is transferred to RDR, no RXI interrupt request occurs. In addition, when the FER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to FER after reading FER = 1 (after writing 0 to it, read the FER bit to check that it has actually been set to 0.)
  .

Even when the RE bit in SCR is set to 0, the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

[Setting condition]

- When the next data is received before receive data is read from RDR which don’t have any valid reception error.
  In RDR, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, reception data isn’t forwarded to RDR register. Note that, in clock synchronous mode, serial transmission and reception will be stop.

的【清零条件】

- 当读取 PER = 1 后将 0 写入 PER 时（写入 0 后,读取 PER 位以检查其实际设置为 0。）

的【清零条件】

- 读取 FER = 1 后将 0 写入 FER 时（写入 0 后,读取 FER 位以检查其是否实际设置为 0。）

Bit	Symbol	Function	R/W
2	SINV	Transmitted/Received Data Invert Set the SINV bit to 0 for operation in simple IIC mode. The level of communication terminals (RXD, TXD) are controlled by combination of this bit and SPTR.TINV/RINV. For details, see Figure 24.2. The SINV bit can be used in the following modes: ● Smart card interface mode ● Asynchronous mode (including multi-processor mode) ● Clock synchronous mode ● Simple SPI mode 0: TDR contents are transmitted as they are. Received data is stored as received in the RDR register. 1: TDR register contents are inverted before transmission. Receive data is stored in inverted form in the RDR register.	R/W*1
3	SDIR	Transmitted/Received Data Transfer Direction Set the SDIR bit to 1 for operation in simple IIC mode. The SDIR bit can be used in the following modes: ● Smart card interface mode ● Asynchronous mode (including multi-processor mode) ● Clock synchronous mode ● Simple SPI mode 0: Transfer LSB-first 1: Transfer MSB-first	R/W*1
4	CHR1	Character Length 1 Valid only in asynchronous mode.*2 Selects the transmit/receive character length in combination with the SMR.CHR bit. 0: SMR.CHR = 0: Transmit/receive in 9-bit data length SMR.CHR = 1: Transmit/receive in 9-bit data length 1: SMR.CHR = 0: Transmit/receive in 8-bit data length (initial value) SMR.CHR = 1: Transmit/receive in 7-bit data length*3	R/W*1
6:5	—	These bits are read as 1. The write value should be 1.	R/W
7	BCP2	Base Clock Pulse 2 Selects the number of base clock cycles in combination with the SMR_SMCI.BCP[1:0] bits. Table 24.5 lists the combinations of the SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits.	R/W*1

Note 1. Writable only when the TE and RE bits in SCR/SCR_SMCI are 0 (both serial transmission and reception are disabled).
Note 2. The setting is invalid and a fixed data length of 8 bits is used in modes other than asynchronous mode.
Note 3. LSB-first must be selected and the value of the MSB (bit [7]) in TDR cannot be transmitted.

The SCMR register selects the smart card interface and communication format.

SMIF bit (Smart Card Interface Mode Select)

Setting the SMIF bit to 1 selects smart card interface mode. Setting it to 0 selects all other modes:

- Asynchronous mode, including multi-processor mode
- Clock synchronous mode
- Simple SPI mode
- Simple IIC mode

SINV bit (Transmitted/Received Data Invert)

The SINV bit inverts the transmit and receive data logic level. It does not affect the logic level of the parity bit. To invert the parity bit, invert the PM bit in SMR or SMR_SMCI.

CHR1 bit (Character Length 1)

The CHR1 bit selects the data length of transmit and receive data in combination with the CHR bit in the SMR register. A fixed data length of 8 bits is used in modes other than asynchronous mode.

BCP2 bit (Base Clock Pulse 2)

The BCP2 bit selects the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set this bit in combination with the SMR_SMCI.BCP[1:0] bits.

24.2.20 BRR : Bit Rate Register

BRR is an 8-bit register that adjusts the bit rate.

As each SCI channel has independent baud rate generator control, different bit rates can be set for each channel. Table 24.6 shows the relationship between the setting (N) in the BRR and the bit rate (B) for normal asynchronous mode, multi-processor transfer, clock synchronous mode, smart card interface mode, simple SPI mode, and simple IIC mode.

The initial value of the BRR register is 0xFF. The BRR register can be read by the CPU, but it can be written to only when the TE and RE bits in SCR/SCR_SMCI are 0.

BRR是一个8位寄存器,可以调整比特率。

由于每个SCI信道具有独立的波特率发生器控制,因此可以为每个信道设置不同的比特率。表24。6显示了正常异步模式、多处理器传输、时钟同步模式、智能卡接口模式、简单SPI模式和简单IIC模式的BRR中的设置（N）与比特率（B）之间的关系。

BRR寄存器的初始值为0xFF,BRR寄存器可以被CPU读取,但只有当SCR/SCR_SMCI中的TE和RE位为0时才能写入。

Table 24.10 and Table 24.11 list examples of BRR (N) settings in normal asynchronous mode. Table 24.12 lists the maximum bit rate settable for each operating frequency. Table 24.16 lists examples of BRR (N) settings in smart card interface mode.

In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, see section 24.7.4. Receive Data Sampling Timing and Reception Margin. Table 24.13 and Table 24.15 list the maximum bit rates with external clock input.

When either the Asynchronous Mode Base Clock Select bit (ABCS) or the Baud Rate Generator Double-speed Mode Select bit (BGDM) in the Serial Extended Mode Register (SEMR) is set to 1 in asynchronous mode, the bit rate becomes twice the value listed in Table 24.17. When both of those registers are set to 1, the bit rate becomes four times the listed value.

Note: Space: Setting prohibited.
—: Can be set, but an error occurs.

Note 1. Continuous transmission or reception is not possible. After transmitting or receiving one frame of data, a 1-bit period elapses before starting to transmit or receive the next frame of data. The output of the synchronization clock is stopped for a 1-bit period. Therefore, it takes 9 bits worth of time to transfer one frame (8 bits) of data, and the average transfer rate is 8/9 times the bit rate. When the FIFO is selected, this setting (BRR = 0x00 and SMR.CKS[1:0] = 00b) is not available.

注: 空间:禁止设置。
—:可以设置,但发生错误。

注1。不可能连续传输或接收。发送或接收一帧数据后,在开始发送或接收下一帧数据之前经过1位周期。同步时钟的输出停止 1 位周期。

因此,传输一帧(8 位）数据需要 9 位时间,平均传输率为比特率的 8/9 倍。
FIFO时,此设置 （BRR = 0x00和SMR。CKS[1:0] = 00b） 不可用。

24.2.21 MDDR : Modulation Duty Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 9)

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

MDDR corrects the bit rate adjusted by the BRR register.

When the BRME bit in SEMR is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected using the settings in MDDR (M/256). Table 24.20 shows the relationship between the MDDR setting (M) and the bit rate (B).

The initial value of MDDR is 0xFF. Bit [7] in this register is fixed to 1.

The CPU can read the MDDR register, but this register is only writable when the TE and RE bits in SCR/SCR_SMCI are 0.

24。2。21 MDDR:调制任务寄存器

基本地址: SCIn = 0x4011_8000 + 0x0100 × n（n = 0, 9）

偏移地址: 0x12

位位置:	7	6	5	4	3	2	1	0
位字段:								
重置后的值:	1	1	1	1	1	1	1	1

MDDR 校正 BRR 寄存器调整的比特率。

SEMR 中的 BRME 位设置为 1 时, 片上波特率发生器生成的比特率使用 MDDR（M/256) 中的设置进行均匀校正。

表24。20显示了MDDR设置（M）和比特率（B）之间的关系。

MDDR 的初始值为 0xFF。此寄存器中的位 [7] 固定为 1。

CPU 可以读取 MDDR 寄存器,但只有当 SCR/SCR_SMCI 中的 TE 和 RE 位为 0 时,该寄存器才可写入。

Note 1. Writable only when the TE and RE bits in SCR/SCR_SMCI are 0 (both serial transmission and reception are disabled).

The SEMR register selects the clock source for the 1-bit period in asynchronous mode.

PADIS bit (Preamble function Disable)

In asynchronous mode, select enable / disable of preamble function. In Manchester mode, preamble is not output regardless of this bit setting

BRME bit (Bit Rate Modulation Enable)

The BRME bit enables or disables the bit rate modulation function. The bit rate generated by the on-chip baud rate generator is evenly corrected when this function is enabled. Set to 0 in Manchester mode.

ABCSE bit (Asynchronous Mode Extended Base Clock Select 1)

The ABCSE bit sets the pulse number for the base clock in a 1-bit period to 6, and the double-frequency clock is output from the baud rate generator. When the bit rate is set to 6 while dividing the bus clock frequency, use this bit and set SMR.CKS[1:0] = 00b and BRR = 0.

Set it to "0" in modes other than asynchronous mode. Even in asynchronous mode, set it to "0" when using external clock.

ABCS bit (Asynchronous Mode Base Clock Select)

The ABCS bit selects the number of clock cycles for a 1-bit period.

Set it to "0" in modes other than asynchronous mode and Manchester mode.

NFEN bit (Digital Noise Filter Function Enable)

The NFEN bit enables or disables the digital noise filter function.

When the digital noise filter function is enabled:

- Noise cancellation is applied to the RXDn input signal in asynchronous mode
- Noise cancellation is applied to the SDAn and SCLn input signals in simple I^2C mode

In all other modes, set the NFEN bit to 0 to disable the digital noise filter function. When the function is disabled, input signals are transferred as received.

BGDM bit (Baud Rate Generator Double-Speed Mode Select)

The BGDM bit selects whether or not to double the base clock frequency output from the baud rate generator.

The BGDM bit is valid when the on-chip baud rate generator is selected as the clock source (SCR.CKE[1] = 0) in asynchronous mode (SMR.CM = 0) or Manchester mode (MMR.MANEN = 1). When external clock is selected (SCR.CKE[1] = 1), set it to 0. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.

Set this bit to 0 in modes other than asynchronous mode or Manchester mode.

RXDESEL bit (Asynchronous Start Bit Edge Detection Select)

The RXDESEL bit selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data reception operation depends on the setting of this bit. Set this bit to 1 when reception must be stopped while a break occurs or when reception must be started without keeping the RXDn pin input at the high level for the period of one data frame or longer after completion of the break.

Set this bit to 0 in modes other than asynchronous mode.

注1。SCR/SCR_SMCI中的TE和RE位为0时才可写入（串行发送和接收均被禁用）。

SEMR寄存器在异步模式下选择1位周期的时钟源。

PADIS 位（前言功能禁用）

在异步模式下,选择启用/禁用前导功能。在曼彻斯特模式下,无论此位设置如何,前导码都不会输出

BRME 位（启用比特率调制）

BRME 位启用或禁用比特率调制功能。当启用此功能时,片上波特率发生器生成的比特率会被均匀校正。在曼彻斯特模式下设置为 0。

ABCSE 位（异步模式扩展基时钟选择 1）

ABCSE位将基时钟在1位周期内的脉冲数设置为6,双频时钟从波特率发生器输出。Bit率在划分总线时钟频率的同时设置为6时,使用该位,将SMR。CKS[1:0] = 00b和BRR = 0。

在异步模式以外的模式下将其设置为"0"。 即使在异步模式下,使用外部时钟时也将其设置为"0"。

ABCS 位（异步模式基时钟选择）

ABCS 位选择 1 位周期的时钟周期数。

在异步模式和曼彻斯特模式以外的模式下将其设置为"0"。

NFEN 位（启用数字噪声滤波器功能）

NFEN 位启用或禁用数字噪声滤波器功能。

当数字噪声滤波器功能启用时:

- 异步模式下将噪声消除应用于 RXDn 输入信号
- 噪声消除以简单的I2C 模式应用于 SDAn 和 SCLn 输入信号

在所有其他模式下,将 NFEN 位设置为 0 以禁用数字噪声滤波器功能。当功能被禁用时,输入信号会按接收到的方式传输。

BGDM 位（波特率发生器双速模式选择）

BGDM 位选择是否将波特率发生器输出的基时钟频率加倍。

BGDM位在异步模式（SMR。CM = 0)或曼彻斯特模式（MMR。MANEN = 1)中选择片上波特率发生器作为时钟源（SCR。CKE[1] = 0)时有效。择（SCR。CKE[1] = 1)外部时钟时,将其设置为0。基时钟由波特率发生器输出的时钟生成。BGDM位设置为1时,基时钟周期减半,比特率加倍。在异步模式或曼彻斯特模式以外的模式下将此位设置为 0。

RXDESEL 位（异步启动位边缘检测选择）

RXDESEL位选择起始位的检测方法,以便在异步模式下接收。当发生中断时,数据接收操作取决于该位的设置。当必须在中断发生时停止接收或必须在中断完成后一个数据帧或更长时间内将 RXDn 引脚输入保持在高电平的情况下开始接收时,将此位设置为 1。

在异步模式以外的模式下将此位设置为 0。

Note 1. Writing to these bits is only possible when the RE and TE bits in SCR/SCR_SMCI are 0 (serial reception and transmission disabled).

The SNFR register sets the digital noise filter clock.

NFCS[2:0] bits (Noise Filter Clock Select)

The NFCS[2:0] bits select the sampling clock for the digital noise filter. To use the noise filter in asynchronous mode, set these bits to 000b. In simple I2C mode, when 32 clocks are selected as one bit period in the basic clock selection bits of the SEMR register, set the NFCS [2: 0] bits in the range from 001b to 100b. IICCSC bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SCLn clock signal is to be synchronized when the SCLn pin is driven low because a wait was inserted by another other device.

The SCLn clock signal is not synchronized if the IICCSC bit is 0. The SCLn clock signal is generated according to the rate selected in the BRR register regardless of the level being input on the SCLn pin.

Set the IICCSC bit to 1 except during debugging.

IICACKT bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set the IICACKT bit to 1 when ACK and NACK bits are received.

The SIMR3 register is used to control the start, restart, and stop conditions in the simple I^2C mode, and to hold the SSDAn and SSCLn pins at fixed levels.

IICCSC 位（时钟同步）

如果当 SCLn 引脚被驱动为低电平时内部生成的 SCLn 时钟信号要同步,则将 IICCSC 位设置为 1,因为另一个其他设备插入了等待。

IICCSC 位为 0 时,则 SCLn 时钟信号未同步。SCLn 时钟信号是根据 BRR 寄存器中选择的速率生成的,而不管 SCLn 引脚上输入的电平如何。

除调试期间外,将 IICCSC 位设置为 1。

IICACKT 位（ACK 传输数据）

传输的数据包含 ACK 位。当接收到 ACK 和 NACK 位时,将 IICACKT 位设置为 1。

IICSTAREQ bit (Start Condition Generation)

When a start condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICSTAREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of start condition generation.

IICRSTAREQ bit (Restart Condition Generation)

When a restart condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICRSTAREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of restart condition generation.

IICSTPREQ bit (Stop Condition Generation)

When a stop condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICSTPREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of stop condition generation.

IICSTIF flag (Issuing of Start, Restart, or Stop Condition Completed Flag)

After generating a condition, the IICSTIF flag indicates that the condition generation is complete. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.

When the IICSTIF flag is 1 while an interrupt request is enabled by setting the SCR.TEIE bit, an STI request is output.

[Setting condition]

- On completion of a start, restart, or stop condition generation.

  If the setting condition conflicts with any of the clearing conditions for the flag, the clearing condition takes precedence.

[Clearing conditions]

- On writing 0 to the bit. After writing 0 to the IICSTIF bit, read the bit to check that it is actually set to 0.
- On writing 0 to the SIMR1.IICM bit when operation is not in simple IIC mode.
- On writing 0 to the SCR.TE bit.

IICSDAS[1:0] bits (SDAn Output Select)

The IICSDAS[1:0] bits control output from the SDAn pin. Set IICSDAS[1:0] and IICSCLS[1:0]to the same value during normal operations.

IICSCLS[1:0] bits (SCLn Output Select)

The IICSCLS[1:0] bits control output from the SCLn pin. Set IICSDAS[1:0] and IICSCLS[1:0] to the same value during normal operations.

的【设置条件】

- 将 1 写入位。

的【清零条件】

- 重启条件生成完成后。

IICSTPREQ 位（停止条件生成）

当要生成停止条件时,除了将 IICSTPREQ 位设置为 1 之外,还将 IICSDAS[1:0] 和 IICSCLS[1:0] 设置为 01b。
的【设置条件】

- 将 1 写入位。

的【清零条件】

- 停止条件生成完成后。

IICSTIF 标志（发出开始、重新启动或停止条件已完成标志）

生成条件后,IICSTIF标志表示条件生成完成。当使用 IICSTAREQ、IICRSTAREQ 或 IICSTPREQ 位导致条件生成时,请在将 IICSTIF 标志设置为 0 后执行此操作。

当 IICSTIF 标志为 1 时,通过设置 SCR。TEIE 位启用中断请求,则输出 STI 请求。

的【设置条件】

- 完成启动、重新启动或停止条件生成后。
  如果设置条件与标志的任何清除条件冲突,则以清除条件为准。

的【清算条件】

- 将 0 写入位。IICSTIF 位写入 0 后,读取该位以检查其是否实际设置为 0。
- 将 0 写入 SIMR1。IICM 位,当操作不处于简单的 IIC 模式时。
- 将 0 写入 SCR。TE 位。

IICSDAS[1:0] 位（SDAn 输出选择）

IICSDAS[1:0] 位控制从 SDAn 引脚的输出。在正常操作期间将 IICSDAS[1:0] 和 IICSCLS[1:0] 设置为相同的值。

IICSCLS[1:0] 位（SCLn 输出选择）

IICSCLS[1:0] 位控制 SCLn 引脚的输出。将 IICSDAS[1:0] 和 IICSCLS[1:0] 在正常操作期间设置为相同的值。

7	CKPH	Clock Phase Select 0: Do not delay clock 1: Delay clock	R/W*1

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).
Note 2. Only 0 can be written to this bit, to clear the flag.

SPMR selects the extension settings in asynchronous and clock synchronous modes.

SSE bit (SSn Pin Function Enable)

Set the SSE bit to 1 to use the SSn pin to control transmission and reception in simple SPI mode. Set this bit to 0 in all other modes. In simple SPI mode, when master mode is selected (SCR.CKE[1:0] = 00b and SPMR.MSS = 0) and there is a single master, the SSn pin on the master side is not required to control reception and transmission. In such a case, set the SSE bit to 0. Do not set both the SSE and CTSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

CTSE bit (CTS Enable)

Set the CTSE bit to 1 if the SSn pin is to be used for inputting the CTS control signal to control transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, and simple IIC mode. Do not set both the CTSE and SSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

MSS bit (Master Slave Select)

The MSS bit selects master or slave operation in simple SPI mode. The functions of the TXDn and RXDn pins are reversed when this bit is set to 1, so that data is received through the TXDn pin and transmitted through the RXDn pin.

Set this bit to 0 in modes other than simple SPI mode.

CTSPEN bit (CTS external pin Enable)

Select the terminals usage method when using the CTS and RTS functions.

MFF flag (Mode Fault Flag)

The MFF flag indicates mode fault errors. In a multi-master configuration, determine the mode fault error occurrence by reading this flag.

[Setting condition]

- When input on the SSn pin is low during master operation in simple SPI mode (SSE bit = 1 and MSS bit = 0).

[Clearing condition]

- On writing 0 to the bit after it is read as 1.

CKPOL bit (Clock Polarity Select)

The CKPOL bit selects the polarity of the clock signal output through the SCKn pin. See Figure 24.96 for details. Set the CKPOL bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

CKPH bit (Clock Phase Select)

The CKPH bit selects the phase of the clock signal output through the SCKn pin. See Figure 24.96 for details. Set the CKPH bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

位	符号	功能	R/W
6	CKPOL	时钟极性选择 0:不要反转时钟极性 1:反转时钟极性	R/W*1
7	CKPH	时钟阶段选择 0: 不要延迟时钟 1: 延迟时钟	R/W*1

注1。SCR寄存器中的RE和TE位为0（串行发送和接收均被禁用）时,才有可能写入这些位。

注2。0才能写到这个位,清除标志。

SPMR选择异步和时钟同步模式下的扩展设置。

SSE 位（启用 SSn 引脚功能）

SSE 位设置为 1,以使用 SSn 引脚在简单的 SPI 模式下控制传输和接收。在所有其他模式下将此位设置为 0。SPI 简易模式下,当选择主模式（SCR。CKE[1:0] = 00b 和 SPMR。MSS = 0)且存在单个主模式时,主端的 SSn 引脚不需要控制接收和传输。在这种情况下,将 SSE 位设置为 0。请勿将 SSE 和 CTSE 位设置为 1。如果进行此设置,则操作与设置这些位时的操作相同

0.

CTSE 位（启用 CTS）

如果要使用SSn引脚输入CTS控制信号来控制发送和接收,则将CTSE位设置为1。RTS信号,当该位设置为0时输出。在智能卡接口模式、简单SPI模式、简单IIC模式下将此位设置为0。请勿将 CTSE 和 SSE 位设置为 1。如果进行此设置,则操作与将这些位设置为 0 时的操作相同。

MSS 位（主从选择）

MSS 位在简单的 SPI 模式下选择主操作或从操作。TXDn 和 RXDn 引脚的功能在将该位设置为 1 时反转,从而通过 TXDn 引脚接收数据并通过 RXDn 引脚传输。

SPI 模式以外的模式下将此位设置为 0。

CTSPEN 位（启用 CTS 外部引脚）

CTS 和 RTS 函数时选择终端使用方法。

MFF标志（模式故障标志）

MFF标志指示模式故障错误。在多主配置中,通过读取此标志来确定模式故障错误的发生。

的【设置条件】

- 在简单 SPI 模式下主操作时 SSn 引脚上的输入较低时（SSE 位 = 1,MSS 位 = 0)。

的【清零条件】

- 在将 0 写入读作 1 后的位时。

CKPOL 位（时钟极性选择）

CKPOL 位选择通过 SCKn 引脚输出的时钟信号的极性。详情见图24。96。CKPOL 位设置为除简单 SPI 模式和时钟同步模式之外的所有模式下的 0。

CKPH 位（时钟相位选择）

CKPH位选择通过SCKn引脚输出的时钟信号的相位。详情见图24。96。CKPH 位设置为 0 在除简单 SPI 模式和时钟同步模式之外的所有模式。

When the FM bit is set to 1, FTDRHL and FRDRHL are selected for communication. When the FM bit is set to 0, TDR and RDR, or TDRHL and RDRHL are selected for communication.

RFRST bit (Receive FIFO Data Register Reset)

TFRST bit (Transmit FIFO Data Register Reset)

When the TFRST bit is set to 1, the FTDRHL register is reset and the transmit data count resets to 0. When 1 is written to the TFRST bit, it clears to 0 after 1 PCLK.

DRES bit (Receive Data Ready Error Select)

When detecting a receive data ready error, the selection can be made from an SCIn_RXI interrupt request or an SCIn_ERI interrupt request. When starting DTC or DMAC and reading from the FRDRH and FRDRL registers, set the DRES bit to 1.

TTRG[3:0] bits (Transmit FIFO Data Trigger Number)

The TDFE flag is set to 1 when the amount of transmit data in FTDRHL is equal to or less than the transmit triggering number specified in the TTRG[3:0] bits, and software can write data to FTDRHL. If SCR.TIE = 1, an SCIn_TXI interrupt request occurs.

The RDF flag is set to 1 when the amount of receive data in FRDRHL is equal to or greater than the receive triggering number specified in the RTRG[3:0] bits, and software can read data from FRDRHL. If SCR.RIE = 1, an SCIn_RXI interrupt request occurs.

RSTRG[3:0] bits (RTS Output Active Trigger Number Select)

When the amount of receive data stored in FRDRHL is equal to or greater than the receive triggering number specified in the RSTRG[3:0] bits, the RTS signal goes high.

DCMF 标志（数据比较匹配标志）

DCMF标志指示SCI检测到接收数据与比较数据（CDR。CMPD）匹配。的【设置条件】

● 当 DCCR。DCME = 1 时,比较数据（CDR。CMPD）与接收数据匹配。

的【清零条件】

● 当从 DCMF 读取 1 之后写入 0 时。

将 SCR。RE 位清除到 0 不会影响 DCMF 标志,DCMF 标志保留其先前值。

DPER标志（数据比较匹配奇偶校验错误标志）

DPER标志指示地址匹配检测（接收数据匹配检测）发生奇偶校验错误。的【设置条件】

● 当在检测到地址匹配的帧中检测到奇偶校验错误时。

的【清算条件】

- When 0 is written after 1 is read from DPER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DPER flag is not affected and retains its previous value.

DFER flag (Data Compare Match Framing Error Flag)

The DFER flag indicates that a framing error occurred on address match detection (receive data match detection).

[Setting conditions]

- When a stop bit of a frame in which an address match is detected is 0.

  When in 2-stop-bit mode, only the first bit of the stop bits is checked for a value of 1 (the second stop bit is not checked).

[Clearing conditions]

- When 0 is written after 1 is read from DFER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DFER flag is not affected and retains its previous value.

The IDSEL bit selects whether to compare data regardless of the MPB bit value or to compare data only when MPB = 1 (ID frame), when the address match function is enabled.

DCME bit (Data Compare Match Enable)

The DCME bit enables or disables the address match function (data compare match function).

If the SCI detects a match to the comparison data (CDR.CMPD) with the receive data, the DCME bit clears automatically, after which SCI operation mode is in normal receive mode. See section 24.3.6. Address Match (Receive Data Match Detection) Function.

The write value must be 0 for all modes other than asynchronous mode.

The SPTR register provides confirmation of the serial reception pin (RXDn pin) status and sets the transmission and receive pin status.

And SPTR register has enable bits for adjust functions of receive sampling timing and transmit timing.

The TXDn pin status is determined by the combination of SCR.TE, SPTR.SPB2IO, and SPTR.SPB2DT settings, as shown in Table 24.24.

The data of RDR is controlled by RINV and SCMR.SINV. And the data from TXDn terminal is controlled by TINV and SCMR.SINV. The control by RINV/TINV are done to communication terminals(RXDn/TXDn), so they can control not only data-bits but also other bits (start bit, stop bit, parity bit). Please refer to Figure 24.2 in detail.

Note: This register is valid only when the Manchester mode is enabled (MMR.MANEN = 1).
Note 1. Only 0 can be written to this bit, to clear the flag. To clear the flag, confirm that the flag is 1 before setting it to 0.

This register indicates an error status when receiving frames in Manchester mode.
A preface error, receive SYNC error or start bit error was detected.

PFER bit (Preface Error flag)

This bit indicates that a preface error was detected when receiving frames in Manchester mode.

[Setting condition]

- When detecting a preface error when receiving frames in Manchester mode
  The following operations are performed when a preface error occurs.
  When MECR.PFEREN = 1
  The received data is not transferred to the RDR register and no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the PFER flag is being set to 1, the subsequently received data is not transferred to the RDR register.
  When MECR.PFEREN = 0
  The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the PFER flag being set to 1.

[Clearing condition]

- When 0 is written to the bit after it was read as 1

Even if the SCR.RE bit is cleared, the PFER flag is not affected, and the previous state is retained.

SYER bit (SYNC Error flag)

This bit indicates that a receive SYNC error was detected when receiving frames in Manchester mode with
MMR.ERTEN = 1 (Manchester edge retiming enabled).

[Setting condition]

- When detecting a receive SYNC error when receiving frames in Manchester mode
  The following operations are performed when a receive SYNC error occurs.
  When MECR.SYEREN = 1

This register is used to specify whether to handle a preface error, receive SYNC error, or a start bit error as an interrupt source in Manchester mode. If those errors are handled as interrupt sources, interrupt requests and event requests are generated at the occurrence of each error, and the next reception is not performed until the corresponding error flag is cleared.

Please set this register when MMR.MANEN = ”0”. And do not change this register during communication.

PFEREN bit (Preface Error Enable)

This bit specifies whether to handle a preface error as an interrupt source.

When it is set to 0, a preface error is not handled as an interrupt source. When it is set to 1, a preface error is handled as an interrupt source.

SYEREN bit (Receive SYNC Error Enable)

This bit specifies whether to handle a receive SYNC error as an interrupt source.

When it is set to 0, a receive SYNC error is not handled as an interrupt source. When it is set to 1, a receive SYNC error is handled as an interrupt source.

SBEREN bit (Start Bit Error Enable)

This bit specifies whether to handle a start bit error as an interrupt source.

When it is set to 0, a start bit error is not handled as an interrupt source. When it is set to 1, a start bit error is handled as an interrupt source.

24.3 Operation in Asynchronous Mode

Figure 24.3 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit or receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communications line is usually held in the mark state (high level).

The SCI monitors the communications line. When the SCI detects a low, it regards that as a start bit and starts serial communication.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and receiver have a double-buffered structure in addition to FIFO mode, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

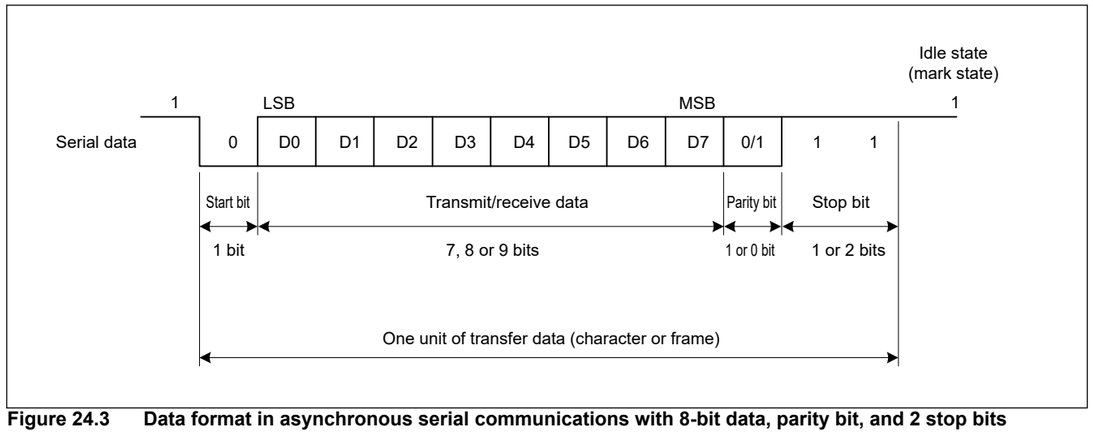

Figure 24.3 Data format in asynchronous serial communications with 8-bit data, parity bit, and 2 stop bits

24.3.1 Serial Data Transfer Format

Table 24.25 lists the serial data transfer formats that can be used in asynchronous mode. Any of 18 transfer formats can be selected with the SMR and SCMR settings. For details on the multi-processor function, see section 24.4. Multi-Processor Communication Function.

当 MMR。MANEN = ”0” 时,请设置此寄存器。并且在通信过程中不要更改此寄存器。

当设置为0时,接收SYNC错误不作为中断源处理。1 时,接收 SYNC 错误作为中断源处理。

SBEREN 位（启用启动位错误）

当它设置为0时,起始位错误不作为中断源处理。1 时,作为中断源处理起始位错误。

24。3 异步模式下操作

图 24。3 显示了异步串行通信的一般格式。一帧由起始位（低电平）、发送或接收数据、奇偶校验位和停止位（高电平）组成。在异步串行通信中,通信线路通常保持在标记状态（高电平）。

SCI 监控通信线路。SCI检测到低时,它将其视为起始位并开始串行通信。

SCI内部,发射器和接收器是独立的单元,可实现全双工通信。除了FIFO模式之外,发射机和接收机都具有双缓冲结构,因此可以在传输或接收期间读取或写入数据,从而实现连续的数据传输和接收。

24.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times[*1] the bit rate.

In reception, the SCI samples the falling edge of the start bit using the base clock, and performs internal synchronization.[*2]

24.3.2 在异步模式下接收数据采样时序和接收裕度

在异步模式下,SCI 在频率为比特率 16 倍 *1 的基时钟上运行。在接收中,SCI使用基时钟对起始位的下降沿进行采样,并执行内部同步。*2

Because receive data is sampled on the rising edge of the 8th pulse*1 of the base clock, data is latched at the middle of each bit (when sampling timing does not adjust (SPTR.ASEN = 0)), as shown in Figure 24.4 The reception margin in asynchronous mode is determined by the following formula (1):

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%] \quad \ldots \quad \text{Formula (1)}$$

Note: M: Reception margin

N: Ratio of bit rate to clock

(N = 16 when SEMR.ABCSE = 0 and SEMR.ABCS = 0,

N = 8 when SEMR.ABCS = 1,

N = 6 when SEMR.ABCSE = 1)

D: Duty cycle of clock (D = 0.5 to 1.0)

L: Frame length (L = 9 to 13)

F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined using the following formula:
$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\ \%$

This represents the computed value. Renesas recommends a margin of 20% to 30% in system design.

Note 1. In this example, the SEMR.ABCS bit is 0 and the SEMR.ABCSE is 0. When the ABCS bit is 1 and the ABCSE bit is 0, a frequency of 8 times the bit rate is used as a base clock, and receive data is sampled on the rising edge of the 4th pulse of the base clock.

When the ABCSE bit is 1, a sextuple frequency of a bit rate is used as a base clock, and receive data is sampled on the rising edge of the 3rd pulse of the base clock.

Note 2. The determination condition of the start bit is as follows.

The function of adjust sampling timing is OFF (ASEN = 0):

The determination condition of a start bit is that Low beyond half bit length continues. It is same as the sampling timing. In Figure 24.4, Low period should be kept over 8-cycles to detect a start bit. If Low period does not keep over 8-cycles, the IP judges this as a noise. So, the IP does not start reception and wait start bit.

The function of adjust sampling timing is ON (ASEN = 1):

The determination condition of a start bit is that Low keeps up until the sampling timing. Adjusting the sampling timing forward (AJD = 1) increases the possibility of erroneously determining a noise as the start bit.

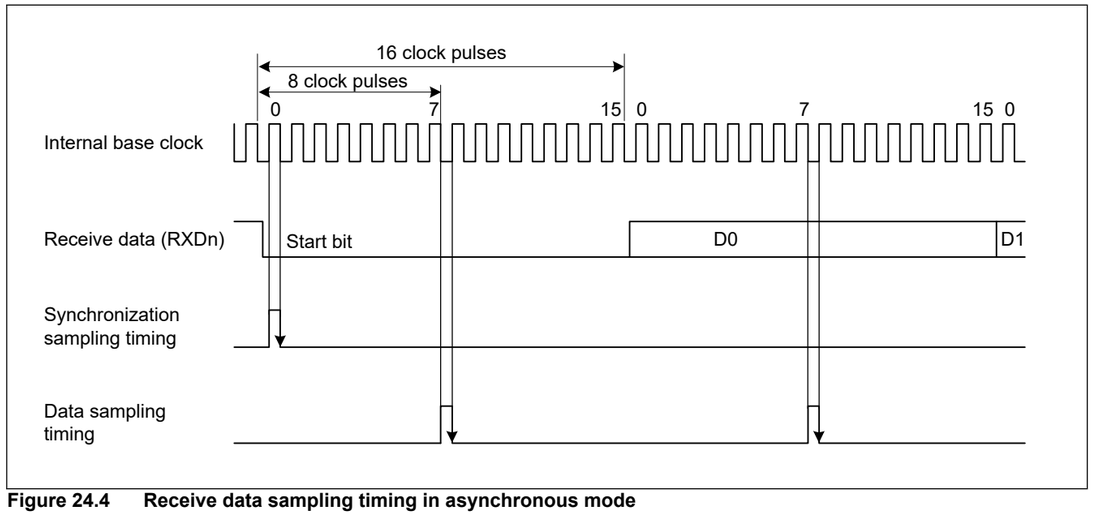

Figure 24.4 Receive data sampling timing in asynchronous mode

为接收数据是在基时钟的第8个脉冲＊1的上升沿上采样的,所以数据被锁存于每个位的中部（当采样时序不调整时（SPTR。ASEN = 0)),如图24。4所示,异步模式下的接收余量由下式(1)确定:

$$M = \left|\left(0。5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%] \quad \ldots \quad 式（一）$$

注: M:接待裕度

N:比特率与时钟的比率

（SEMR。ABCSE = 0 时 N = 16,SEMR。ABCS = 0 时 N = 8,SEMR。ABCS = 1 时,

当 SEMR。ABCSE = 1 时,N = 6

D:时钟的占空比（D = 0。5 至 1。0）

L:帧长度（L = 9 至 13）

F:时钟频率偏差的绝对值

设(1)式中F = 0和D = 0。5的值,则使用以下公式确定接收裕度:
$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\ \%$

这表示计算值。Renesas建议在系统设计中保证金为20%至30%。

注1。在此示例中,SEMR。ABCS 位为 0,SEMR。ABCSE 为 0。ABCS位为1,ABCSE位为0时,以8倍比特率的频率作为基时钟,在基时钟第4个脉冲的上升沿采样接收数据。

ABCSE位为1时,以一个比特率的六倍频作为基时钟,在基时钟第3个脉冲的上升沿采样接收数据。

注2。起始位的确定条件如下。

调整采样定时的功能为 OFF（ASEN = 0):

起始位的确定条件是超过半位长度的 Low 继续。它与采样时间相同。在图 24。4 中,低周期应保持超过 8 个周期以检测起始位。如果低周期不保持超过 8 个周期,IP 会将其判断为噪声。因此,IP 不会开始接收并等待开始位。调整采样定时的功能为ON（ASEN = 1):

起始位的确定条件是 Low 保持直到采样定时。向前调整采样时序（AJD = 1) 会增加错误地确定噪声作为起始位的可能性。

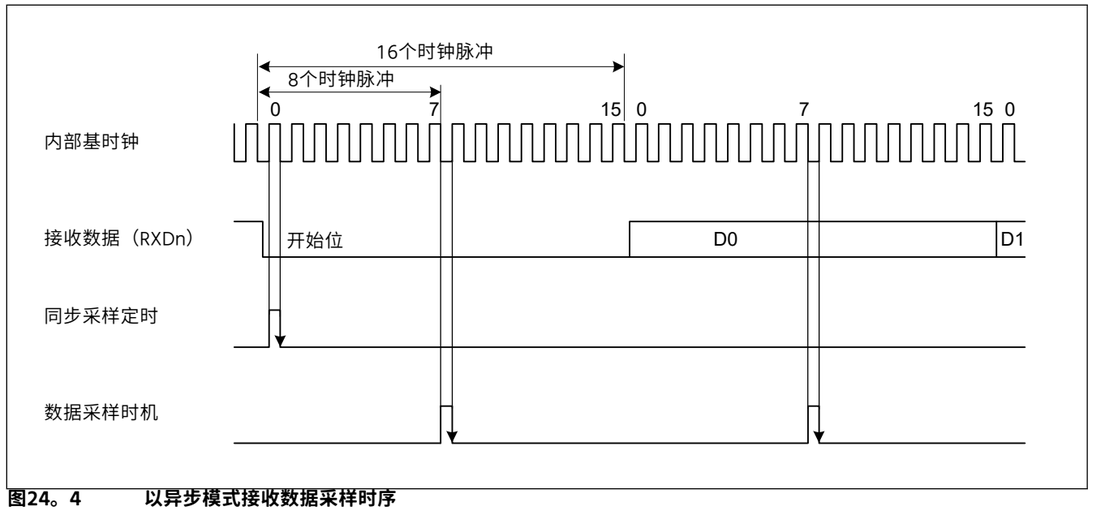

图24。4 以异步模式接收数据采样时序

24.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the transfer clock of the SCI, based on the SMR.CM and SCR.CKE[1:0] settings.

When an external clock is input to the SCKn pin, the clock frequency must be 16 times the bit rate (when SEMR.ABCS = 0) or 8 times the bit rate (when SEMR.ABCS = 1).

When the SCI uses its internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is configured so that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 24.5.

When clock output is enabled, the clock is output after setting the SCR.TE or SCR.RE bit to 1.

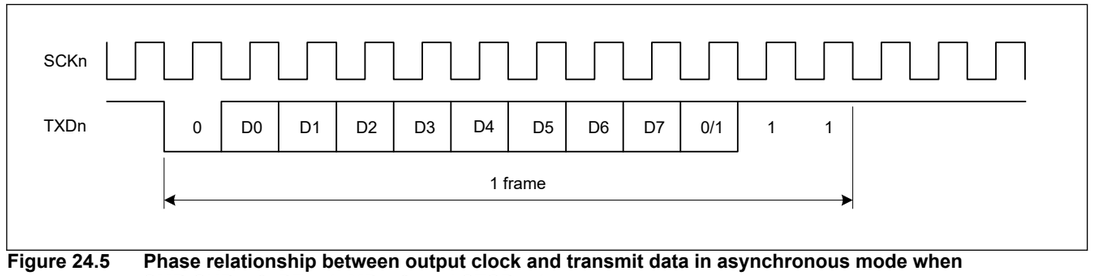

Figure 24.5 Phase relationship between output clock and transmit data in asynchronous mode when SMR.CHR = 0, PE = 1, MP = 0, and STOP = 1

24.3.4 Double-Speed Operation and Frequency of 6 Times the Bit Rate

When the SEMR.ABCS bit is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0. When the SEMR.BGDM bit is set to 1, the cycle of the base clock is half and the bit rate is double that of when BGDM is set to 0. When the SCR.CKE[1] bit is set to 0 and the on-chip baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the SCI to operate at a bit rate four times that when the ABCS and BGDM bits are set to 0.

When the SEMR.ABCSE bit is set to 1, the number of base clock pulses is 6 during a period of 1 bit, and the SCI operates at a bit rate 16/3 times that when SEMR.ABCS = 0, SEMR.BGDM = 0, and SEMR.ABCSE = 0.

As shown by Formula (1) in section 24.3.2. Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, the reception margin decreases when the SEMR.ABCS or SEMR.ABCSE bit is set to 1. Therefore, if the target bit rate can be obtained with ABCS or ABCSE set to 0, it is recommended that you use the SCI with ABCS and ABCSE set to 0.

24.3.5 CTS and RTS Functions

The CTS function uses input on the CTSn_RTSn pin in transmission control. Setting the SPMR.CTSE bit to 1 enables the CTS function. For the functions of CTS and RTS, you can select the alternate setting that uses either function with one terminal and the dedicated setting that uses each function independently with two terminals. This setting is done with the SPMR.CTSPEN bit.

When the CTS function is enabled, placing a low level on the CTSn_RTSn pin causes transmission to start.

Driving the CTSn_RTSn pin high while transmission is in progress does not affect transmission of the current frame.

In the RTS function, which uses output on the CTSn_RTSn pin, a low level is output when reception becomes possible. Conditions for output of the low and high levels are shown in this section.

[Conditions for low level output]

Satisfaction of all conditions are listed in this section.

Non-FIFO selected

- The value of the SCR.RE bit is 1
- Reception is not in progress
- There is no received data yet to be read

24。3。3 时钟

基于SMR。CM和SCR。CKE[1:0]设置,可以选择由片上波特率发生器生成的内部时钟或输入到SCKn引脚的外部时钟作为SCI的传输时钟。

SCKn引脚输入外部时钟时,时钟频率必须是比特率的16倍（当SEMR。ABCS = 0时）或比特率的8倍（当SEMR。ABCS = 1时）。

SCI 使用其内部时钟时,可以从 SCKn 引脚输出时钟。在这种情况下,时钟输出的频率等于比特率,并且相位被配置为时钟的上升沿位于发送数据的中间,如图24。5.所示

当启用时钟输出时,将SCR。TE或SCR。RE位设置为1后输出时钟。

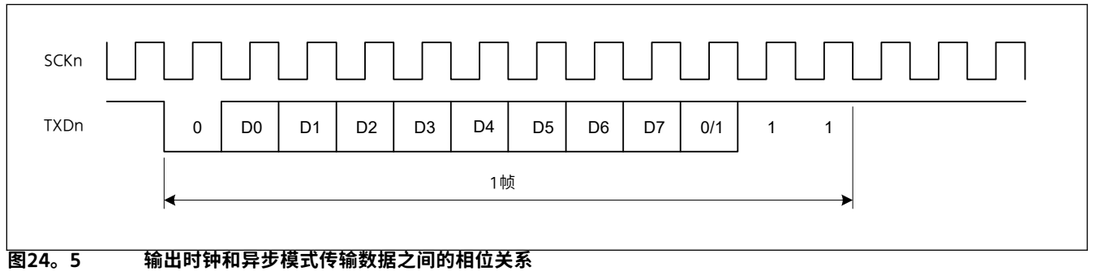

图24。5 输出时钟和异步模式传输数据之间的相位关系 SMR。CHR = 0 PE = 1 MP = 0 STOP = 1

24.3.4 6倍比特率的双速运转和频率

当SEMR。ABCS位被设置为1并且选择基时钟的1位周期的八个脉冲时,SCI的操作比特率是ABCS被设置为0时的两倍。SEMR。BGDM位设置为1时,基时钟的周期为一半,比特率是BGDM设置为0时的两倍。SCR。CKE[1]位设置为0并且选择片上波特率发生器时,将ABCS和BGDM位设置为1允许SCI以比ABCS和BGDM位设置为0时四倍的比特率运行。

当SEMR。ABCSE比特设置为1时,1比特期间基时钟脉冲数为6,SCI的比特率是SEMR。ABCS = 0、SEMR。BGDM时的16/3倍= 0,SEMR。ABCSE = 0。

如第 24。3。2 节中的公式 (1) 所示。在异步模式 , 中接收数据采样定时和接收裕度 当 SEMR。ABCS 或 SEMR。ABCSE 位设置为 1 时,接收裕度会降低。因此,如果 ABCS 或 ABCSE 设置为 0 可以获得目标比特率,建议您在 ABCS 和 ABCSE 设置为 0 的情况下使用 SCI。

24。3。5 CTS 和 RTS 功能

CTS 函数在传输控制中使用 CTSn_RTSn 引脚上的输入。将 SPMR。CTSE 位设置为 1 可以启用 CTS 功能。CTS和RTS的功能,可以选择一个终端使用任一功能的备用设置和两个终端独立使用每个功能的专用设置。此设置是使用 SPMR。CTSPEN 位完成的。

CTS 功能启用时,在 CTSn_RTSn 引脚上放置一个低电平会导致传输启动。

CTSn_RTSn引脚在传输进行时驱动高电平不影响当前帧的传输。

RTS 函数中,该函数在 CTSn_RTSn 引脚上使用输出,当接收成为可能时,会输出低电平。
本节显示了低电平和高电平输出的条件。

[低水平输出的条件] 本节列出了所有条件的满意

24.3.6 Address Match (Receive Data Match Detection) Function

The address match function can be used only in asynchronous mode.

If the DCCR.DCME bit is set to 1, when one frame of data is received, the SCI compares that received data with the data set in CDR.CMPD. If the SCI detects a match to the comparison data (CDR.CMPD[*1]) with the received data, the SCI can issue the SCIn_RXI interrupt request.

If the SMR.MP bit is set to 0, comparison occurs only for valid data in receive format. In multi-processor mode (SMR.MP bit = 1), if the DCCR.IDSEL bit is set to 1, receive data where the MPB bit is 1 is subject to comparison for address match and receive data where the MPB bit is 0 is always treated as a non-match.

If the DCCR.IDSEL bit is set to 0, SCI performs address match detection regardless of the MPB bit value of the received data.

Until SCI detects a match to the comparison data (CDR.CMPD[*1]) with receive data, received data is skipped (discarded), and the SCI cannot detect a parity error or framing error.

When SCI detects a match, the DCCR.DCME bit is automatically cleared, and the DCCR.DCMF flag is set to 1. If the DCCR.IDSEL bit is set to 1, the SCR.MPIE bit is automatically cleared. If DCCR.IDSEL is set to 0, the value of the SCR.MPIE bit is retained. If the SCR.RIE bit is set to 1, the SCI issues an SCIn_RXI interrupt request.

If the SCI detects a framing error in the receive data for which a match is detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag is set to 1. The compared receive data is not stored in the RDR register, and SSR.RDRF remains 0. When FCR.FM = 1, the RDR register indicates the FRDRHL register, and the SSR.RDRF flag indicates the SSR_FIFO.RDF flag.

After the SCI detects a match, and DCCR.DCME is automatically cleared, the SCI receives the next data continuously based on the current register setting.

When the DCCR.DFER or DCCR.DPER flag is set, the address match is not performed. Before enabling the address match function, set the DCCR.DFER and DCCR.DPER flags to 0.

Examples of the address match function are shown in Figure 24.6 and Figure 24.7.

Note 1. This comparative target can select one length of 3 types: CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.

24。3。6 地址匹配（接收数据匹配检测）功能

地址匹配功能只能在异步模式下使用。

如果DCCR。DCME位被设置为1,则当接收到一帧数据时,SCI将接收到的数据与CDR。CMPD中的数据集进行比较。SCI 检测到与比较数据（CDR。CMPD [*1]) 与接收到的数据）匹配,则 SCI 可以发出 SCIn_RXI 中断请求。

如果 SMR。MP 位设置为 0,则仅对接收格式的有效数据进行比较。在多处理器模式下（SMR。MP 位 = 1),如果 DCCR。IDSEL 位设置为 1,则接收 MPB 位为 1 的数据将进行地址匹配比较,并接收 MPB 位为 0 的数据始终被视为不匹配。

如果DCCR。IDSEL位设置为0,则无论接收到的数据的MPB位值如何,SCI都执行地址匹配检测。

SCI检测到与比较数据的匹配（CDR。CMPD [*1])与接收数据,接收数据被跳过（丢弃）,并且SCI无法检测到奇偶校验错误或成帧错误。

SCI检测到匹配时,DCCR。DCME位被自动清除,DCCR。DCMF标志被设置为1。如果DCCR。IDSEL位设置为1,则SCR。MPIE位被自动清除。如果DCCR。IDSEL设置为0,则保留SCR。MPIE位的值。SCR。RIE 位设置为 1,则 SCI 会发出 SCIn_RXI 中断请求。

如果SCI检测到检测到匹配的接收数据中的成帧错误,则DCCR。DFER标志被设置为1,并且如果SCI检测到该帧中的奇偶校验错误,则DCCR。DPER标志被设置为1。比较的接收数据不存储在 RDR 寄存器中,并且 SSR。RDRF 保持 0。FCR。FM = 1 时,RDR 寄存器指示 FRDRHL 寄存器,SSR。RDRF 标志指示 SSR_FIFO。RDF 标志。

SCI 检测到匹配,并且 DCCR。DCME 自动清除后,SCI 根据当前寄存器设置连续接收下一个数据。

当设置DCCR。DFER或DCCR。DPER标志时,不执行地址匹配。在启用地址匹配功能之前,将 DCCR。DFER 和 DCCR。DPER 标志设置为 0。

地址匹配函数的示例如图24。6和图24。7 .所示

24.3.7 SCI Initialization in Asynchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the SCR register, then continue through the SCI initialization procedure (select non-FIFO or FIFO) shown in Table 24.26 and Table 24.27. Whenever the operating mode or transfer format is to be changed, the SCR register must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied during initialization.

24.3.7 SCI 异步模式初始化

在发送和接收数据之前,首先将初始值 0x00 写入 SCR 寄存器,然后继续通过表 24。26 和表 24。27 中所示的 SCI 初始化过程（选择非 FIFO 或 FIFO）。每当要更改操作模式或传输格式时,必须在更改之前初始化 SCR 寄存器。

当外部时钟以异步模式使用时,确保在初始化期间提供时钟信号。

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, RDRF, RDF, PER, and DR flags in SSR/SSR_FIFO nor RDR and RDRHL. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: In non-FIFO mode, switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of an SCIn_TXI interrupt request.

注意:将 SCR。RE 位设置为 0 既不会初始化 SSR/SSR_FIFO 中的 ORER、FER、RDRF、RDF、PER 和 DR 标志,也不会初始化 RDR 和 RDRHL。TE 位设置为 0 时, 所选 FIFO 缓冲区的 TEND 标志未初始化。

注意:在非 FIFO 模式下,当 SCR。TIE 位为 1 时,将 SCR。TE 位的值从 1 切换到 0 或 0 切换到 1 会生成 SCR。TXI 中断请求。

24.3.8 Serial Data Transmission in Asynchronous Mode

(1) Non-FIFO selected

Figure 24.8, Figure 24.9, and Figure 24.10 show examples of serial transmission in asynchronous mode.

In serial transmission, the SCI operates as described in this section. When the SCR.TE bit is set to 1, the high level is output to TXDn for one frame. However, when SEMR.PADIS is set to "1", this preamble will not be output. An example of operation when preamble is not output is shown in Figure 24.11.

1. The SCI transfers data from the TDR*1 register to the TSR register when data is written to TDR*1 in the SCIn_TXI interrupt handling routine.
   The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the TDR*1 register to the TSR register. If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to the TDR*1 register in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR*1 register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data
   - Parity bit or multi-processor bit (can be omitted depending on the format)
   - Stop bit
4. The SCI checks for update of the TDR register on output of the stop bit.
5. When the TDR register is updated, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from the TDR*1 register to the TSR register and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register is not updated, the SSR.TEND flag is set to 1, the stop bit is sent, and the mark state is entered, in which 1 is output. If the SCR.TEIE bit is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Note 1. The TDRHL register when 9-bit data length is selected.

24。3。8 异步模式下的串行数据传输

（一）非FIFO入选

图24。8、图24。9和图24。10示出了异步模式下的串行传输的示例。

在串行传输中,SCI 按照本节所述运行。当 SCR。TE 位设置为 1 时,一帧的高电平将输出到 TXDn。但是,当 SEMR。PADIS 设置为"1"时,该前导码将不会输出。24。11 .中示出了前导码不输出时的操作示例

1。SCI 将数据从 TDR *1 寄存器传输到 TSR 寄存器, 当数据在 SCIn_TXI 中断处理例程中写入到 TDR *1 时。

SCR。TE和SCR。TIE位通过单个指令同时设置为1时,生成传输开始时的SCIn_TXI中断请求。

2锛姣涓涓。SPMR。CTSE 位设置为 0（CTS 函数被禁用）或 CTSn_RTSn 引脚上的低电平导致数据从 TDR *1 寄存器传输到 TSR 寄存器后开始传输。SCR。TIE 位为 1,则生成 SCIn_TXI 中断请求。SCIn_TXI 中断处理例程中写入下一个发送数据到 TDR *1 寄存器, 在当前发送数据的传输完成之前, 可以实现连续传输。当使用 SCIn_TEI 中断请求时,在最后一个数据之后将 SCR。TIE 位设置为 0（禁用 SCIn_TXI 中断请求）,将 SCR。TEIE 位设置为 1（启用 SCIn_TEI 中断请求）将要传输的数据从 SCIn_TXI 请求的处理例程写入 TDR *1 寄存器。

3锛　　娴　　。TXDn 引脚按以下顺序发送数据:

- 启动位
- 传输数据
- 奇偶校验位或多处理器位（根据格式不同可省略）
- 停止位

4锛姣涓。SCI 检查停止位输出的 TDR 寄存器的更新。

5锛姣涓。TDR 寄存器更新时,将 SPMR。CTSE 位设置为 0（CTS 功能被禁用）或 CTSn_RTSn 引脚上的低电平输入会导致下一次传输数据从 TDR *1 寄存器传输到 TSR 寄存器并传输停止位,之后下帧的串行传输开始。

6锛　　涓€涓。如果TDR寄存器不更新,则SSR。TEND标志被设置为1,发送停止位,并输入标记状态,其中输出1。SCR。TEIE 位为 1,则 SSR。TEND 标志设置为 1,并生成 SCIn_TEI 中断请求。

Figure 24.13 Data format written to FTDRH and FTDRL with FIFO selected

In serial transmission, the SCI operates as described in this section. When the TE bit is set to 1, the high level is output to TXDn for one frame (preamble).

1. The SCI transfers data from the FTDRL*1 register to the TSR register when data is written to FTDRL*1 in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the FTDRL*1 register to the TSR register. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, SSR_FIFO.TDFE is set to 1. If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to FTDRL*1 in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the FTDRL*1*2 register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data
   - Parity bit or multi-processor bit (can be omitted depending on the format)
   - Stop bit
4. On output of the stop bit, the SCI checks whether non-transmitted data remains in the FTDRL*3 register.
5. When data is set to FTDRL*3, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from FTDRL*1 to TSR and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set in FTDRL*3, the TEND flag in SSR_FIFO is set to 1, the stop bit is sent, and the mark state is entered in which 1 is output. If the SCR.TEIE bit is 1, the SSR_FIFO.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Note 1. Write data not to FTDRL but to the FTDRH and FTDRL registers.
Note 2. Write data in order from FTDRH to FTDRL when 9-bit data length is selected.
Note 3. The SCI only checks for update to the FTDRL register and not the FTDRH register when 9-bit data length is selected.

图24。13 数据格式写入 FTDRH 和 FTDRL 并选择 FIFO

在串行传输中,SCI 按照本节所述运行。TE 位设置为 1 时,高电平被输出到 TXDn 为一帧（前言）。

1。SCI 将数据从 FTDRL *1 寄存器传输到 TSR 寄存器, 当数据在 SCIn_TXI 中断处理例程中写入 FTDRL *1 时。可写入 FTDRL 的数据量为 16 减去 FDR。T[4:0] 字节。SCR。TE和SCR。TIE位通过单个指令同时设置为1时,生成传输开始时的SCIn_TXI中断请求。

2锌姣涓涓。SPMR。CTSE 位设置为 0（CTS 函数被禁用）或 CTSn_RTSn 引脚上的低电平导致数据从 FTDRL *1 寄存器传输到 TSR 寄存器后开始传输。FTDRL写入的发送数据量等于或小于指定的发送触发数时,SSR_FIFO。TDFE被设置为1。SCR。TIE 位为 1,则生成 SCIn_TXI 中断请求。SCIn_TXI 中断处理例程中写入下一个发送数据到 FTDRL *1 在当前发送数据的传输完成之前, 可以进行连续传输。当使用 SCIn_TEI 中断请求时,将 SCR。TIE 位设置为 0（禁用 SCIn_TXI 中断请求）,并在最后一个数据后将 SCR。TEIE 位设置为 1（启用 SCIn_TEI 中断请求）从 SCIn_TXI 请求的处理例程写入 FTDRL*1*2 寄存器。

3锌 娴 。TXDn 引脚按以下顺序发送数据:

- 启动位
- 传输数据
- 奇偶校验位或多处理器位（根据格式不同可省略）
- 停止位

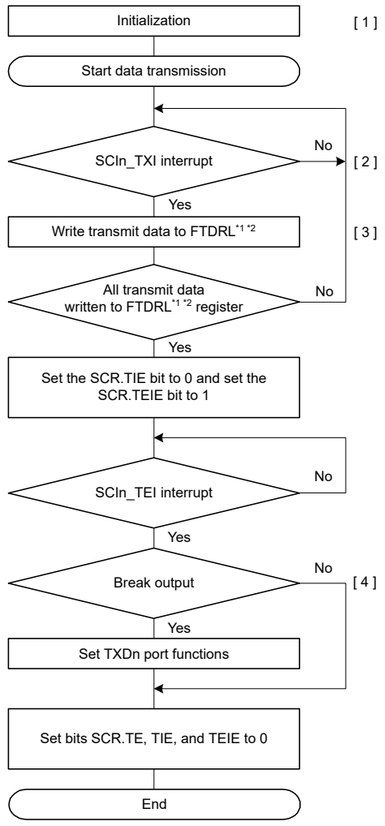
4锌姣涓。在停止位的输出上,SCI检查未传输的数据是否保留在FTDRL *3寄存器中。

5锌姣涓。当数据被设置为FTDRL *3时,将SPMR。CTSE位设置为0（CTS功能被禁用）或CTSn_RTSn引脚上的低电平输入导致下一个发送数据从FTDRL *1传输到TSR并传输停止位,之后下一帧的串行传输开始。

6锌 涓€涓。FTDRL *3 中没有设置数据,则将 SSR_FIFO 中的 TEND 标志设置为 1,发送停止位,并输入输出为 1 的标记状态。SCR。TEIE 位为 1,则 SSR_FIFO。TEND 标志设置为 1,并生成 SCIn_TEI 中断请求。

注1。不将数据写入 FTDRL,而是写入 FTDRH 和 FTDRL 寄存器。
注2。9位数据长度时按从FTDRH到FTDRL的顺序写入数据。
注3。当选择 9 位数据长度时,SCI 仅检查 FTDRL 寄存器的更新,而不检查 FTDRH 寄存器的更新。

图 24。14 显示了选择 FIFO 的异步模式串行传输的示例流程。



[1] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[2] Transmit data write to FTDRL*1 by an SCIn_TXI interrupt request:
When transmit data is transferred from FTDRL to TSR, when the quantity of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL*1 *2 once in the SCIn_TXI interrupt handling routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data to FTDRL using an SCIn_TXI interrupt request and clear the SSR_FIFO.TDFE flag to 0. The number of transmission data it is possible to write in is 16 - (the number of stored transmit FIFO data). Transmit data can also be written to FTDRL by activating the DTC or DMAC. When writing the data to FTDRL by DTC or DMAC, the TDFE flag is cleared automatically, so do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to FTDRL.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXD pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

Note 1. When data length is 9 bits, this refers to FTDRH and FTDRL registers.
Note 2. When data length is 9 bits, write in order from FTDRH to FTDRL.

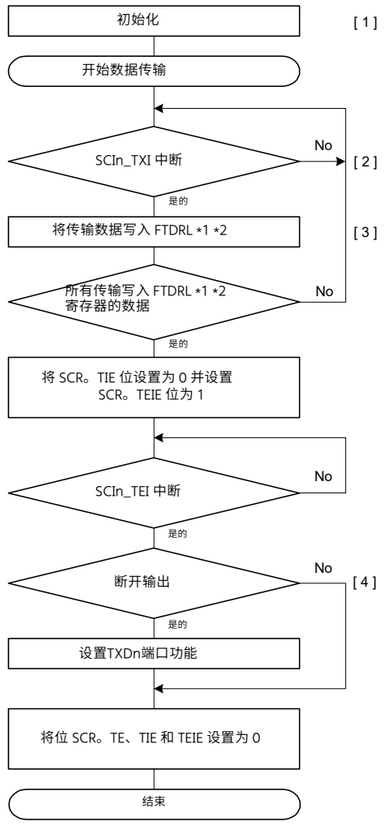
24.3.9 Serial Data Reception in Asynchronous Mode

(1) Non-FIFO selected

Figure 24.15 and Figure 24.16 show an example of the operation for serial data reception in asynchronous mode.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and when it detects a start bit, the SCI performs internal synchronization, stores receive data in RSR.
3. If the multi-processor communication function is enabled (SMR.MP = 1), see section 24.4.2. Multi-Processor Serial Data Reception. If the address match function (data compare match function) is enabled (DCCR.DCME = 1), the SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and comparison data (CDR.CMPD*1).
4. If the SCI detects an address match, the DCCR.DCME bit is automatically cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt*2 request is generated. To enable the generation of an SCIn_RXI interrupt request, set the SCR.RIE bit to 1. The compared receive data are not stored in the RDR register*3. The SSR.RDRF flag remains 0.



[1] SCI 初始化:
设置数据传输。
SCR。TE 位设置为 1 后,为帧输出 1,并启用传输。

[2] 通过 SCIn_TXI 中断请求将数据写入 FTDRL *1:
FTDRL传输数据到TSR时,当以FTDRL写入的传输数据量等于或小于指定的传输触发数时,生成传输数据FIFO空中断（SCIn_TXI）请求。SCIn_TXI 中断处理例程中一次将传输数据写入 FTDRL *1 *2。

[3] 串行传输继续过程:
要继续串行传输,请使用 a 将所有传输数据写入 FTDRL
SCIn_TXI 中断请求,并将 SSR_FIFO。TDFE 标志清除为 0。可以写入的传输数据数量为 16（存储的传输 FIFO 数据数量）。还可以通过激活 DTC 或 DMA C 将数据发送到 FTDRL。DTC 或 DMAC 将数据写入 FTDRL 时,TDFE 标志会自动清除,因此请勿写入

TDFE 标志。
SCIn_TEI 中断请求时,在将要传输的最后一段数据写入 FTDRL 后,将 SCR。TIE 位设置为 0,将 SCR。TEIE 位设置为 1。

[4] 串行传输结束时中断输出:
要输出串行传输中断,请通过SPTR。SPB2IO和SPTR。SPB2DT位设置TXD引脚的输出状态（低电平输出）后,将SCR。TE位设置为0。

注1。当数据长度为 9 位时,这是指 FTDRH 和 FTDRL 寄存器。
注2。当数据长度为 9 位时,按从 FTDRH 到 FTDRL 的顺序写入。

图 24。14 选择 FIFO 的异步模式串行传输的示例流程

24.3.9 异步模式下的串行数据接收

（一）非FIFO入选

图24。15和图24。16示出了异步模式下串行数据接收的操作的示例。

SCI 在串行数据接收中, 操作如下:

1。SCR。RE 位的值变为 1 时,CTSn_RTSn 引脚上的输出信号变低。

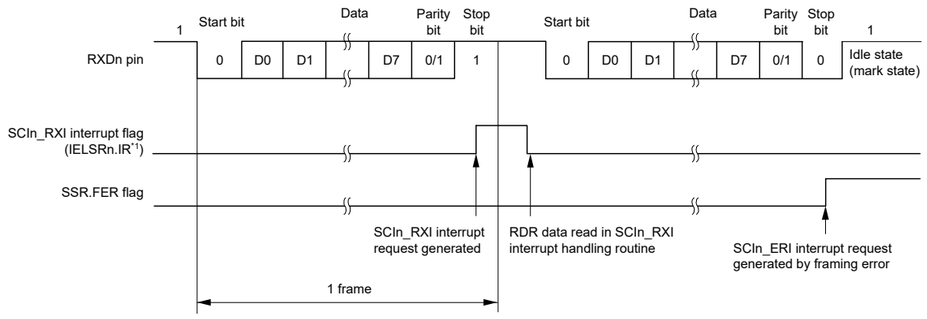
2锛姣涓涓。SCI监控通信线路,当检测到启动位时,SCI执行内部同步,将接收数据存储在RSR中。

3锛　　娴　　。如果启用多处理器通信功能（SMR。MP = 1),请参见第 24。4。2 节。多处理器串行数据接收。如果启用地址匹配函数（数据比较匹配函数）（DCCR。DCME = 1),则 SCI 无法检测到奇偶校验或帧错误,因为接收数据被跳过（丢弃）,直到 SCI 检测到接收数据和数据之间的匹配。比较数据（CDR。CMPD *1)。

4锛姣涓。SCI 检测到地址匹配,则自动清除 DCCR。DCME 位,DCCR。DCMF 标志变为 1,并生成 SCIn_AM 中断 *2 请求。要启用 SCIn_RXI 中断请求的生成,请将 SCR。RIE 位设置为 1。比较的接收数据不存储在 RDR 寄存器中 *3。SSR。RDRF 标志保持为 0。

5. If the SCI detects a framing error in the receive data for which an address match is detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag becomes 1. To enable the generation of an SCIn_ERI interrupt request, set the SCR.RIE bit to 1.
6. If a framing or a parity error is detected (the DCCR.DFER flag or DCCR.DPER flag is 1) in the SCIn_AM interrupt handling routine, set the DCCR.DFER and DCCR.DPER flags to 0 and set the DCCR.DCME bit to 1 to enable the address match function again. If neither a framing nor a parity error has been detected (the DCCR.DFER and DCCR.DPER flags are both 0), set the DCCR.DCMF flag to 0. See Figure 24.6.
7. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR*3 register.
8. If a parity error is detected, the SSR.PER flag is set to 1 and receive data is transferred to the RDR*3 register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
9. If a framing error is detected, the SSR.FER flag is set to 1 and receive data is transferred to the RDR*3 register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
10. When reception finishes successfully, receive data is transferred to the RDR*3 register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data is complete. Reading the received data that was transferred to the RDR register causes the CTSn_RTSn pin to output low.

Note 1. This scope of comparison is selectable as one of three lengths: CMPD[6:0] is for 7-bit length, CMPD[7:0] is for 8-bit length, and CMPD[8:0] is for 9-bit length.
Note 2. As no interrupt enable bit is assigned to the SCIn_AM interrupt, an interrupt request is generated by setting the DCCR.DCMF to 1.
Note 3. Only read data in the RDRHL register when 9-bit data length is selected.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 24.15 Example of SCI operation for serial reception in asynchronous mode (1) when the RTS function is not used, and with 8-bit data, parity bit, and 1 stop bit

5锝姣涓。如果SCI检测到检测到地址匹配的接收数据中的成帧错误,则DCCR。DFER标志被设置为1,并且如果SCI检测到该帧中的奇偶校验错误,则DCCR。DPER标志变为1。要启用 SCIn_ERI 中断请求的生成,请将 SCR。RIE 位设置为 1。

6锝　　涓€涓。SCIn_AM中断处理例程中检测到帧或奇偶校验错误（DCCR。DFER标志或DCCR。DPER标志为1),则将DCCR。DFER和DCCR。DPER标志设置为0,并将DCCR。DCME位设置为1以再次启用地址匹配函数。如果既没有检测到帧错误也没有检测到奇偶校验错误（DCCR。DFER 和 DCCR。DPER 标志均为 0),则将 DCCR。DCMF 标志设置为 0。参见图 24。6 .

7锝　　娴　　。如果发生溢出错误,SSR。ORER 标志将设置为 1。SCR。RIE 位为 1,则生成 SCIn_ERI 中断请求。接收数据不会传输到 RDR *3 寄存器。

8锝　　娴　　。如果检测到奇偶校验错误,则将 SSR。PER 标志设置为 1,并将接收数据传输到 RDR *3 寄存器。SCR。RIE 位为 1,则生成 SCIn_ERI 中断请求。

9锝　　涓€涓。如果检测到成帧错误,则将 SSR。FER 标志设置为 1,并将接收数据传输到 RDR *3 寄存器。SCR。RIE 位为 1,则生成 SCIn_ERI 中断请求。

10 瀹跺涵涓杞杈。当接收成功完成时,接收数据被传输到 RDR *3 寄存器。SCR。RIE 位为 1,则生成 SCIn_RXI 中断请求。SCIn_RXI 中断处理例程中读取传输到 RDR 寄存器的接收数据, 在接收到下一个接收数据完成之前, 可以启用连续接收。读取传输到 RDR 寄存器的接收数据会导致 CTSn_RTSn 引脚输出低电平。

注1。此比较范围可选择为三个长度之一:CMPD[6:0] 代表 7 位长度,CMPD[7:0] 代表 8 位长度,CMPD[8:0] 代表 9 位长度。

注2。SCIn_AM中断没有分配中断使能位,则通过将DCCR。DCMF设置为1来生成中断请求。

注3。9位数据长度时才读取RDRHL寄存器中的数据。

Figure 24.16 Example of SCI operation for serial reception in asynchronous mode (2) when RTS function is used, and with 8-bit data, parity bit, and 1 stop bit

Table 24.28 lists the states of the flags in the SSR register and receive data handling when a receive error is detected.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER bits to 0 before resuming reception. In addition, be sure to read the RDR or RDRHL register during overrun error processing. When a reception is forced to terminate by setting the SCR.RE bit to 0 during operation, read the RDR or RDRHL register because received data that is not yet read might be left in the RDR or RDRHL.

Figure 24.17 and Figure 24.18 show example flows of serial data reception.

Flags in the SSR Status Register			Receive data	Receive error type

表 24。28 列出了检测到接收错误时 SSR 寄存器和接收数据处理中标志的状态。

如果检测到接收错误,则会生成 SCIn_ERI 中断请求,但不会生成 SCIn_RXI 中断请求。

当接收错误标志为 1 时,无法恢复数据接收。因此,在恢复接收之前将ORER、FER和PER比特设置为0。此外,在超限错误处理期间,请务必读取 RDR 或 RDRHL 寄存器。当在操作期间通过将SCR。RE位设置为0来强制终止接收时,读取RDR或RDRHL寄存器,因为接收到的尚未读取的数据可能留在RDR或RDRHL中。

[1] SCI initialization:
Set data reception.

[2][3] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. The error type is identified by reading the ORER, PER, and FER flags in SSR. After performing the appropriate error processing, be sure to set the ORER, PER, and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. For a framing error, a break can be detected by reading the value of the input port associated with the RXDn pin.

[4] Read the receive data in RDR once inthe SCIn_RXI interrupt handling routine.

[5] To continue serial reception, before the stop bit of the current frame is received, read data from RDR in the SCIn_RXI interrupt processing routine. The RDR data can also be read by activating the DMAC or DTC.

Note 1. Do not set RE to 0 before reading RDR.
Note 2. The RDR register becomes the RDRHL register when 9-bit data length is selected.

[1] SCI 初始化:
设置数据接收。

[2][3] 接收错误处理和断裂检测:
如果发生接收错误,则会生成 SCIn_ERI 中断。
通过读取 SSR 中的 ORER、PER 和 FER 标志来识别错误类型。执行适当的错误处理后,请务必将 ORER、PER 和 FER 标志设置为 0。如果这些标志中的任何一个设置为 1,则无法恢复接收。对于成帧错误,可以通过读取与 RXDn 引脚关联的输入端口的值来检测中断。

[4] 在 SCIn_RXI 中断处理例程中读取 RDR 中的接收数据一次。

[5] 继续串行接收,在接收到当前帧的停止位之前,在SCIn_RXI中断处理例程中从RDR读取数据。还可以通过激活 DMAC 或 DTC 来读取 RDR 数据。

[1] SCI initialization:
Set data reception.

[1-2] Address match cycle:
Set the DCCR.DCME bit to 1 to enable address matching.

[1-3] Comparing receive data and data for comparison (CDR.CMPD):
Compare receive data and data for comparison (CDR.CMPD).
The SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and data for comparison.
If the SCI detects an address match, the DCCR.DCME bit is cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt request is issued.

[1-4] [1-5] Reception error processing:
An error is identified by reading the DFER or DPER flag in DCCR in the SCIn_AM interrupt handling routine.
After appropriate handling of the error, set both the DFER and DPER flags to 0.
If either of these flags is set to 1, address matching cannot be resumed.

[2] [3] Reception error processing and break detection:
When a reception error occurs, the SCIn_ERI interrupt is generated.
The error is identified by reading the ORER, PER, and FER flags in the SSR.
After appropriate handling of the error, set all of the ORER, PER, and FER flags to 0. If any of these flags is set to 1, reception cannot be resumed.
If a framing error occurs, a break can be detected by reading the value of the input port bit corresponding to the RXDn pin.

[4] Read the receive data in the RDR register from within the SCIn_RXI interrupt handling routine.

[5] Procedure for continuing serial reception:
To continue serial reception, read the value of the RDR register in the SCIn_RXI interrupt handling routine before the stop bit is received.
The value of the RDR register can also be read by activating the DMAC or DTC.

Note 1. Be sure to set the RE bit to 0 before reading the RDR register.
Note 2. The RDRHL register is used instead of the RDR register when the 9-bit data length is selected.

SCIn_AM 中断处理例程。
适当处理错误后,设置 DFER 和 DPER 标志
to 0.
如果这些标志中的任何一个设置为 1,则无法恢复地址匹配。

[2] [3] 接收错误处理和断裂检测:
当发生接收错误时,会生成 SCIn_ERI 中断。
通过读取 SSR 中的 ORER、PER 和 FER 标志来识别错误。
适当处理错误后,将所有 ORER、PER 和 FER 标志设置为 0。如果这些标志中的任何一个设置为 1,则无法恢复接收。
如果发生成帧错误,则可以通过读取与RXDn引脚相对应的输入端口位的值来检测中断。

[5] 持续串行接收的程序:
要继续串行接收,请在接收到停止位之前读取 SCIn_RXI 中断处理例程中 RDR 寄存器的值。
RDR 寄存器的值也可以通过激活 DMAC 或 DTC 来读取。

Figure 24.22 shows an example of a data format that is written to FRDRH register and FRDRL register in asynchronous mode.

In asynchronous mode, 0 is written to the MPB bit in the FRDRH register. Data that corresponds to the data length is written to FRDRH and FRDRL. Unused bits are written as 0. Read in order from FRDRH to FRDRL. If software reads FRDRL, the

SCI updates FER, PER, and receive data (RDAT[8:0]) in the FRDRL register with the next data. The flags RDF, ORER, and DR in the FRDRH register always reflect the associated flags in the SSR_FIFO register.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and, when it detects a start bit, the SCI performs internal synchronization, stores receive data in the RSR register.
3. If the multi-processor communications function is enabled (SMR.MP = 1), see section 24.4.2. Multi-Processor Serial Data Reception. If the address match function (data compare match function) is enabled (DCCR.DCME = 1), the SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and the data for comparison (CDR.CMPD*1).
4. If the SCI detects an address match, the DCCR.DCME bit is automatically cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt*2 request is generated. To enable the generation of an SCIn_RXI interrupt request, set the SCR.RIE bit to 1. The compared receive data are not stored in the RDR register*3. The SSR.RDRF flag remains 0.
5. If the SCI detects a framing error in the receive data for which an address match was detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag becomes 1. To enable the generation of an SCIn_ERI interrupt request, set the SCR.RIE bit to 1.
6. If a framing or a parity error is detected (the DCCR.DFER flag or DCCR.DPER flag is 1) in the SCIn_AM interrupt handling routine, set the DCCR.DFER and DCCR.DPER flags to 0 and set the DCCR.DCME bit to 1 to enable the address match function again. If neither a framing nor a parity error has been detected (the DCCR.DFER and DCCR.DPER flags are 0), set the DCCR.DCMF flag to 0. See Figure 24.6.
7. If an overrun error occurs during normal communications, the SSR_FIFO.ORER flag is set to 1. If the SCR.RIE bit in SCR is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the FRDRL*3 register.
8. If a parity error is detected, the PER flag and receive data are transferred to the FRDRL*3 register. If the SCR.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
9. If a framing error is detected, the FER flag and receive data are transferred to the FRDRL*3 register. If the SCR.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
10. After a framing error is detected and when SCI detects that the continuous receive data is zero for one frame, reception stops.
11. When the amount of data stored in the FRDRL register falls below the specified receive triggering number, and the next data is not received after 15 etus from the last stop bit in asynchronous mode, the SSR_FIFO.DR flag is set to 1. When the SCR.RIE bit is 1 and the FCR.DRES bit is 0, the SCI generates an SCIn_RXI interrupt request. When the FCR.DRES bit is 1, SCI generates an SCIn_ERI interrupt request.

SCI 更新 FER、PER,并通过下一个数据接收 FRDRL 寄存器中的数据（RDAT[8:0]）。FRDRH 寄存器中的标志 RDF、ORER 和 DR 始终反映 SSR_FIFO 寄存器中的关联标志。

SCI 在串行数据接收中, 操作如下:

1。SCR。RE 位的值变为 1 时,CTSn_RTSn 引脚上的输出信号变低。

2锛姣涓涓。SCI 监控通信线路,当检测到起始位时,SCI 执行内部同步,将接收数据存储在 RSR 寄存器中。

3锛 娴 。如果启用多处理器通信功能（SMR。MP = 1),请参见第 24。4。2 节。多处理器串行数据接收。如果启用地址匹配函数（数据比较匹配函数） （DCCR。DCME = 1),则 SCI 无法检测到奇偶校验或帧错误,因为接收数据被跳过（丢弃）,直到 SCI 检测到接收数据与数据之间的匹配。用于比较的数据（CDR。CMPD *1)。

4锛姣涓。SCI 检测到地址匹配,则自动清除 DCCR。DCME 位,DCCR。DCMF 标志变为 1,并生成 SCIn_AM 中断 *2 请求。要启用 SCIn_RXI 中断请求的生成,请将 SCR。RIE 位设置为 1。比较的接收数据不存储在 RDR 寄存器中 *3 。SSR。RDRF 标志保持为 0。

5锛姣涓。如果SCI检测到检测到地址匹配的接收数据中的成帧错误,则DCCR。DFER标志被设置为1,并且如果SCI检测到该帧中的奇偶校验错误,则DCCR。DPER标志变为1。要启用 SCIn_ERI 中断请求的生成,请将 SCR。RIE 位设置为 1。

6锛 涓€涓。SCIn_AM中断处理例程中检测到帧或奇偶校验错误（DCCR。DFER标志或DCCR。DPER标志为1),则将DCCR。DFER和DCCR。DPER标志设置为0,并将DCCR。DCME位设置为1以再次启用地址匹配函数。如果既没有检测到帧错误也没有检测到奇偶校验错误（DCCR。DFER 和 DCCR。DPER 标志为 0),则将 DCCR。DCMF 标志设置为 0。参见图 24。6。

7锛 娴 。SSR_FIFO。ORER 标志设置为 1,如果在正常通信过程中出现超限错误。SCR 中的 SCR。RIE 位为 1,则生成 SCIn_ERI 中断请求。接收数据不会传输到 FRDRL *3 寄存器。

8锛 娴 。如果检测到奇偶校验错误,则 PER 标志和接收数据将被传输到 FRDRL *3 寄存器。SCR。RIE 位设置为 1,则生成 SCIn_ERI 中断请求。

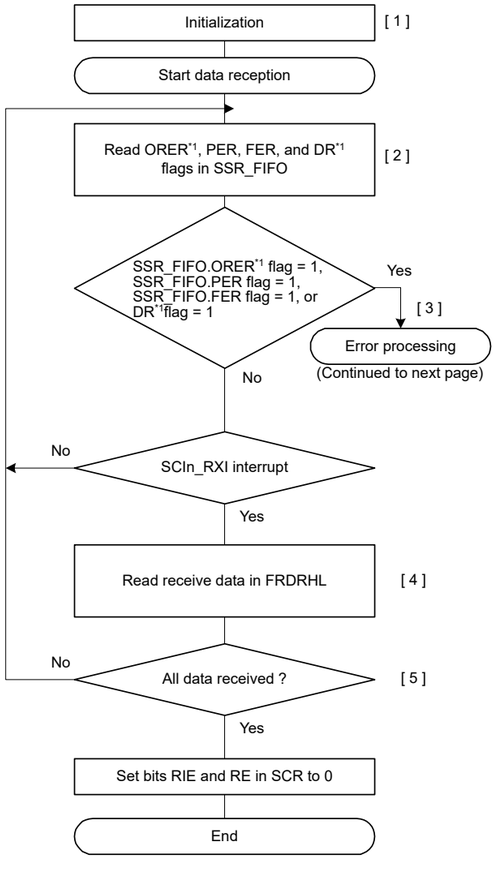
9锛 涓€涓。如果检测到成帧错误,FER 标志和接收数据将被传输到 FRDRL *3 寄存器。SCR。RIE 位设置为 1,则生成 SCIn_ERI 中断请求。

10 瀹跺涵涓杞权。检测到成帧错误后,当 SCI 检测到一帧的连续接收数据为零时,接收停止。

11。FRDRL寄存器中存储的数据量低于指定的接收触发数时,在异步模式下从最后一个停止位15 etus后没有接收到下一个数据时,SSR_FIFO。DR标志被设置为1。SCR。RIE 位为 1,FCR。DRES 位为 0 时,SCI 生成 SCIn_RXI 中断请求。FCR。DRES 位为 1 时,SCI 生成 SCIn_ERI 中断请求。

12. When reception finishes successfully, receive data is transferred to the FRDRL*3 register. The RDF bit is set to 1 when the amount of receive data written to FRDRHL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit in SCR is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the FRDRL*4 register in the SCIn_RXI interrupt handling routine, before an overrun error occurs. If the received data that is transferred to FRDRL*5 is less than the RTS trigger number, the CTSn_RTSn pin outputs low.

Note 1. One of three lengths is selected for the target for comparison: CMPD[6:0] is for 7-bit length, CMPD[7:0] is for 8-bit length, and CMPD[8:0] is for 9-bit length.
Note 2. As no interrupt enable bit is assigned to the SCIn_AM interrupt, an interrupt request is generated by setting the DCCR.DCMF to 1.
Note 3. Only read data in the FRDRH and FRDRL registers when 9-bit data length is selected.
Note 4. Read data in order from FRDRH to FRDRL when 9-bit data length is selected.
Note 5. The SCI only checks for update to the FRDRL register and not to the FRDRH register when 9-bit data length is selected.



[1] SCI initialization:
Set data reception.

[2] [3] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. A break can be detected by reading the SPTR.RXDMON flag. An error is identified by reading the ORER*1, PER, DR*1, and FER flags in SSR_FIFO. After performing the appropriate error processing, be sure to set the ORER*1 flag to 0. Reception cannot be resumed if ORER*1 flag is set to 1. The reception operation is continuous, even if the FER = 1 or PER = 1 or DR*1 = 1.

[4] Read the receive data in FRDRHL in the SCIn_RXI interrupt handling routine. The receive data stored in the FRDRHL register is read until the number of stored data is below the FCR.RTRG value. Confirm the number of the reception data in the FIFO by reading FDR.R.

[5] Serial reception continuation procedure:
To continue serial reception, before an overrun error occurs, read data from FRDRHL in the SCIn_RXI interrupt handling routine and clear RDF flag and DR flag to 0.
The FRDRHL data can also be read by activating the DMA or DTC. The RDF flag is cleared automatically in this case, so do not write to the RDF flag.

Note 1. Can be read in the FRDRHL.ORER and DR flags.

12绔 涔诲芥澶澧。当接收成功完成时,接收数据将被传输到 FRDRL *3 寄存器。RDF 位设置为 1, 当写入 FRDRHL 的接收数据量等于或大于指定的接收触发数。SCR 中的 SCR。RIE 位为 1,则生成 SCIn_RXI 中断请求。SCIn_RXI 中断处理例程中读取传输到 FRDRL *4 寄存器的接收数据来启用连续接收, 之后会出现超限错误。如果接收到的传输到 FRDRL *5的数据小于RTS触发数,则CTSn_RTSn引脚输出较低。

注1。选择三个长度之一用于比较目标:CMPD[6:0]用于7位长度,CMPD[7:0]用于8位长度,CMPD[8:0]用于9位长度。

注2。由于没有向 SCIn_AM 中断分配中断使能位,因此通过设置来生成中断请求

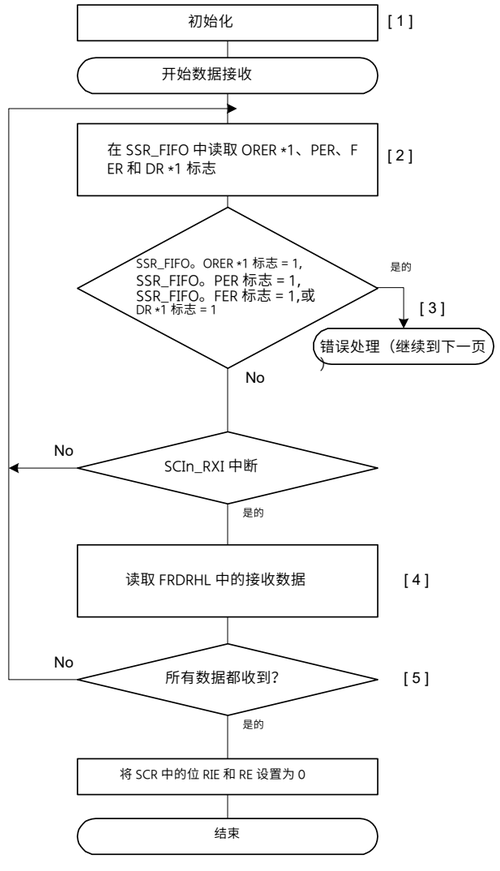
注3。仅在选择 9 位数据长度时读取 FRDRH 和 FRDRL 寄存器中的数据。
注4。9位数据长度时按从FRDRH到FRDRL的顺序读取数据。
注5。SCI 仅在选择 9 位数据长度时检查 FRDRL 寄存器的更新,而不检查 FRDRH 寄存器的更新。



[1] SCI 初始化:
设置数据接收。

[2] [3] 接收错误处理和断裂检测:
如果发生接收错误,则会生成 SCIn_ERI 中断。可以通过读取 SPTR。RXDMON 标志来检测中断。SSR_FIFO 中读取 ORER *1、PER、DR *1、FER 标志识别出错误,进行适当的错误处理后,务必将 ORER *1 标志设置为 0。ORER *1标志设置为1,则无法恢复接收。即使接收操作是连续的

the FER = 1 or PER = 1 or DR*1 = 1.

[4]读取SCIn_RXI中断处理例程中FRDRHL中的接收数据。
读取存储在FRDRHL寄存器中的接收数据,直到存储的数据数量低于FCR。RTRG值。通过读取 FDR。R 确认 FIFO 中的接收数据数量。

[5] 串行接收继续程序:
要继续串行接收,在发生溢出错误之前,请从 SCIn_RXI 中断处理例程中的 FRDRHL 读取数据,并将 RDF 标志和 DR 标志清除为 0。

还可以通过激活 DMA 或 DTC 来读取 FRDRHL 数据。在这种情况下,RDF 标志会自动清除,因此请勿写入 RDF 标志。

注1。可以在 FRDRHL。ORER 和 DR 标志中读取。

[1] SCI initialization:

[1-2] Address match cycle:
Set the DCCR.DCME bit to 1 to enable address matching.

[1-3] Comparing received data and data for comparison (CDR.CMPD):
Compare receive data and comparison data.
The SCI cannot detect a parity or framing error as received data are skipped (discarded) until the SCI detects a match between the received data and data for comparison.
If the SCI detects an address match, the DCCR.DCME bit is cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt request is issued.

[1-4] [1-5] Reception error processing:
An error is identified by reading the DFER or DPER flag in DCCR from within the SCIn_AM interrupt handling routine.
After appropriate handling of the error, set both the DFER and DPER flags to 0.
If either of these flags is set to 1, address matching cannot be resumed.

[2] [3] Reception error processing and break detection:
When a reception error occurs, an SCIn_ERI interrupt is generated.
A break is identified by reading SPTR.RXDMON.
The error is identified by reading each among the SSR_FIFO.ORER*1, PER, FER, and DR*1 flags.
After appropriate handling of the error, set the ORER*1 flag to 0.
If the ORER*1 flag remains 1, reception cannot be resumed.
The reception operation is continuous, even if the FER = 1, PER = 1 or DR*1 = 1.

[4] Reading the received data in the FRDRHL register from within the SCIn_RXI interrupt handling routine:
The received data stored in the FRDRHL register are read until the amount of stored data is less than the value of the FCR.RTRG[3:0] bits.
Confirm the number of received data in the FIFO with the value of the FDR.R[4:0] bits.

[5] Serial reception continuation procedure:
To continue with serial reception, read data from the FRDRHL register from within the SCIn_RXI interrupt handling routine before an overrun error occurs, and set the RDF and DR flags to 0. The data in the FRDRHL register can also be read by activating the DMAC or DTC. In this case, do not write to the RDF flag because the flag is automatically cleared.

Note 1. The FRDRHL.ORER and DR flags can also be read.

24.3.10 调整接收采样定时的功能（异步模式）

当通过光耦合器的上升传输时间和下降传输时间之间存在差异时,位中间的接收采样定时会影响接收裕度。在这种情况下,接收采样定时能够通过使用该功能从位中间调整到最佳定时。

The receive sampling timing is adjusted from the middle of bit by following formula. The adjustable direction is set by ACTR.AJD. When adjusting backward (ACTR.AJD = 0), substitute AJD = +1 and substitute AJD = −1 when adjusting forward (ACTR.AJD = 1).

Adjusted sampling timing = the middle of bit + AJD × (base clock × the setting value of ACTR.AST[2:0])

The setting timing is limited by base clock cycles per 1 bit. For details, see Table 24.29.

An overview of reception operation of the communication through a photo coupler with this function is shown in Figure 24.28, Figure 24.29 and Figure 24.30, the explanation of operation with this function is shown in Figure 24.31.

Do not use this function when there is no difference between the rising transfer time and the falling transfer time, because there is a possibility of deteriorating the reception margin.

24.3.11 The function of adjust transmit timing (Asynchronous Mode)

In communication via a photo coupler or the like, when either the rising or falling transition time of the TXDn output signal is long, then a communication partner receive dulled waveform. In this case, the reception margin may be affected.

In these cases, make a communication partner to be sampling at middle of bit using the function of adjust transmit timing.

When SPTR.ATEN is 1, this function can adjust the edge timing at the timing calculated by the following formula for the edge set with ACTR.AET.

The adjustment edge timing = the base clock × ACTR.ATT[2:0]

In addition, the upper limit of the adjustment edge timing is limited by setting the base clock cycles. For details, see Table 24.30.

A transmission movement image figure of the communication through a photo coupler with this function is shown in Figure 24.32, Figure 24.33 and Figure 24.34, the overview of operation with this function is shown in Figure 24.35 and Figure 24.36.

Do not use this function when there is not the difference between the rising transfer time and the falling transfer time, there is a possibility of deteriorating the reception margin of a communication partner.

24。3。11 调整发射定时的功能（异步模式）

在通过光耦合器等进行通信时,当TXDn输出信号的上升或下降过渡时间较长时,则通信伙伴接收钝化波形。在这种情况下,接收裕度可能会受到影响。

在这些情况下,使用调整传输定时的功能使通信伙伴在位中间采样。当 SPTR。ATEN 为 1 时,该函数可以在以下公式计算的 ACTR。AET 边集的时序处调整边时序。

调整边缘定时 = 基时钟 × ACTR。ATT[2:0]

另外,通过设置基时钟周期来限制调节边缘定时的上限。有关详细信息,请参阅表 24。30 .

当传输时间上升与传输时间下降没有差异时,请勿使用此功能,通信伙伴的接收裕度可能会恶化。

24.4 Multi-Processor Communication Function

The multi-processor communication function enables the SCI to transmit and receive data between multiple processors by sharing an asynchronous serial communication line that has an added multi-processor bit. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station.

The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle:

- When the multi-processor bit is set to 1, the transmission cycle is the ID transmission cycle
- When the multi-processor bit is set to 0, the transmission cycle is the data transmission cycle

Figure 24.37 shows an example of communication between processors using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits communication data in which the multi-processor bit set to 0 is added to the transmit data. After receiving communication data with the multi-processor bit set to 1, the receiving station compares the received ID with the ID of the receiving station itself. If the two match, the receiving station receives communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until it receives data in which the multi-processor bit is set to 1.

(1) Non-FIFO selected

To support this function, the SCI provides the SCR.MPIE bit. When the MPIE bit is set to 1, the following operations are disabled until the reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR register (the RDRHL register when 9-bit data length is selected)
- Detection of a receive error
- Setting of the respective RDRF, ORER, and FER status flags in the SSR register

When the SCI receives a character in which the multi-processor bit is set to 1, the SSR.MPBT bit is set to 1 and the SCR.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode. The clock used for the multi-processor communication is the same as the clock used in normal asynchronous mode.

24。4 多处理器通信功能

多处理器通信功能使SCI能够通过共享具有附加多处理器位的异步串行通信线路来在多个处理器之间传输和接收数据。在多处理器通信中,唯一的ID码被分配给每个接收站。串行通信周期包括用于指定接收站的ID发送周期和用于将数据发送到指定接收站的数据发送周期。

ID 传输周期和数据传输周期的区别采用多处理器位:

- 当多处理器位设置为1时,传输周期为ID传输周期
- 当多处理器位设置为0时,传输周期为数据传输周期

图 24。37 显示了使用多处理器格式的处理器之间通信的示例。首先,发送站发送通信数据,其中将设置为1的多处理器比特添加到接收站的ID码中。接下来,发送站发送将设置为0的多处理器比特添加到发送数据的通信数据。接收站接收多处理器位设置为1的通信数据后,将接收到的ID与接收站本身的ID进行比较。如果两者匹配,则接收站接收随后发送的通信数据。如果接收到的ID与接收站的ID不匹配,则接收站跳过通信数据,直到接收多处理器比特被设置为1的数据。

（一）非FIFO入选

为了支持此功能,SCI 提供 SCR。MPIE 位。MPIE 位设置为 1 时, 禁用以下操作, 直到接收多处理器位设置为 1 的数据:

- 将接收数据从 RSR 寄存器传输到 RDR 寄存器（选择 9 位数据长度时的 RDRHL 寄存器）
- 检测接收错误
- 在 SSR 寄存器中设置相应的 RDRF、ORER 和 FER 状态标志

当SCI接收到多处理器位设置为1的字符时,SSR。MPBT位设置为1并且SCR。MPIE位被自动清除,使SCI恢复到正常接收操作。SCR。RIE 位设置为 1,则会生成 SCIn_RXI 中断。

当指定多处理器格式时,奇偶校验位函数被禁用。除此之外,与正常异步模式下的操作没有区别。用于多处理器通信的时钟与正常异步模式下使用的时钟相同。

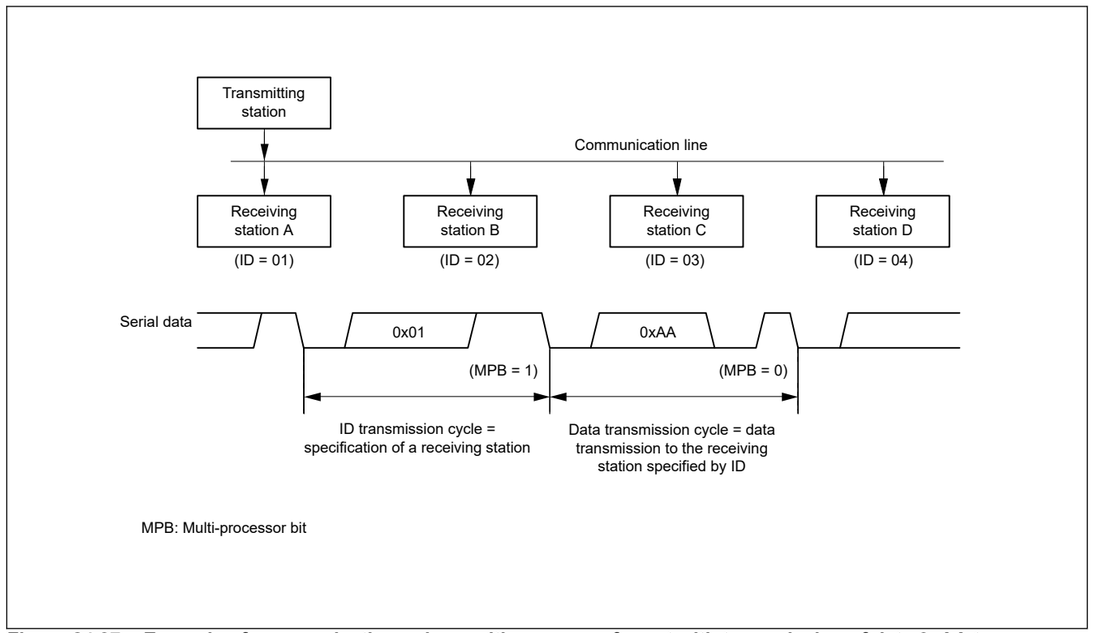

Figure 24.37 Example of communication using multi-processor format with transmission of data 0xAA to receiving station A

(2) FIFO selected

For data transmission, software must write data to FTDRHL.MPBT that corresponds to transmit data in FTDRHL.TDAT. For data reception, the multi-processor bit that is part of the receive data is written to FTDRHL.MPB and receive data is written to FRDRL.

When the MPIE bit is set to 1, the following operations are disabled until reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the FRDRHL register
- Detection of a receive error
- Break
- Setting of the respective RDF, ORER, and FER status flags in the SSR_FIFO register

When the SCI receives an 8-bit character in which the multi-processor bit is set to 1, the FTDRHL.MPB bit is set to 1 and receive data is written to FRDRHL.RDAT. The SCR.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode with FIFO selected.

24.4.1 Multi-Processor Serial Data Transmission

(1) Non-FIFO selected

Figure 24.38 shows an example flow of multi-processor data transmission. In the ID transmission cycle, the ID must be transmitted with the SSR.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in asynchronous mode. Write the values in the order of the FTDRH register then the FTDRL register.

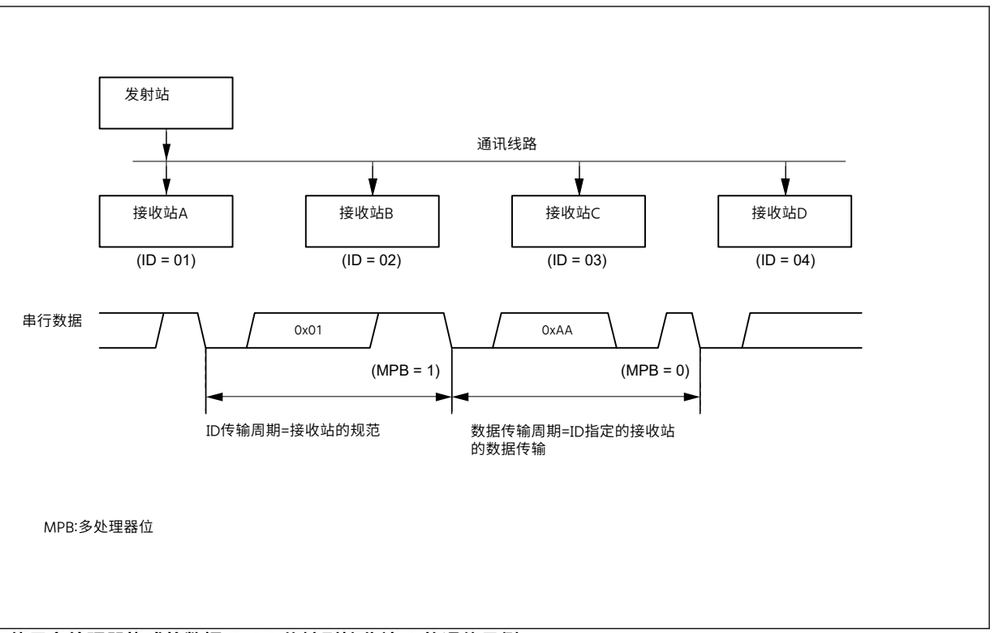

图 24。37 使用多处理器格式将数据 0xAA 传输到接收站 A 的通信示例

(2)选定的FIFO

对于数据传输,软件必须将数据写入 FTDRHL。MPBT,该数据对应于 FTDRHL。TDAT 中的数据传输。对于数据接收,作为接收数据一部分的多处理器比特写入 FTDRHL。MPB,接收数据写入 FRDRL。

当MPIE位设置为1时,禁用以下操作,直到接收到多处理器位的数据
is set to 1:

- 将接收数据从 RSR 寄存器传输到 FRDRHL 寄存器
- 检测接收错误
- 休息
- 在 SSR_FIFO 寄存器中设置相应的 RDF、ORER 和 FER 状态标志

SCI 接收多处理器位设置为 1 的 8 位字符时,FTDRHL。MPB 位设置为 1,接收数据写入 FRDRHL。RDAT。SCR。MPIE 位自动清除,使 SCI 恢复正常接收操作。SCR。RIE 位设置为 1,则会生成 SCIn_RXI 中断。

当指定多处理器格式时,奇偶校验位函数被禁用。除此之外,与选择FIFO的正常异步模式下的操作没有区别。

24。4。1 多处理器串行数据传输

（一）非FIFO入选

图24。38示出了多处理器数据传输的示例流程。ID传输周期中,ID必须以设置为1的SSR。MPBT位进行传输。在数据传输周期中,数据必须在MPBT位设置为0的情况下传输。其余操作与异步模式下的操作相同。按照 FTDRH 寄存器和 FTDRL 寄存器的顺序写入值。

(2) FIFO selected

Figure 24.44 shows an example of a data format that is written to FRDRH and FRDRL in multi-processor mode.

In multi-processor mode, the MPB value that is a part of the receive data is written to the FRDRH.MPB bit. A value of 0 is written to the FRDRH.PER flag. Data is written to FRDRH and FRDRL with the correct data length. Unused bits are written with 0. Read in order from FRDRH to FRDRL. When software reads the FRDRL register, the SCI updates FER, MPB, and receive data (RDAT[8:0]) in FRDRL with the next data. The RDF, ORER and DR flags in the FRDRH register always reflect the associated flags in the SSR_FIFO register.

[1] SCI initialization:
Set data reception.

[2] ID reception cycle:
Set the SCR.MPIE bit to 1 and wait for ID reception.

[3] SCI status confirmation and reception and comparison of ID:
SCI stores first data (MPB = 1) and subsequent received data in FRDRHL.
RDF is set to 1 and an SCIn_RXI interrupt request is generated when a quantity of receive data equal to or greater than the specified receive triggering number is stored in FRDRHL. When the quantity of data stored in FRDRHL falls the specified receive triggering number and received data is equal to or greater than 1, and no next data is received after the elapse of 15 etus from the last stop bit, SSR_FIFO.DR is set to 1. An SCIn_RXI interrupt request is generated when FCR.DRES bit is 0.
Read data in FRDRHL at the first SCIn_RXI interrupt, and compare it with the ID of the receiving station itself.
If the ID does not match the ID of the receiving station itself, the SCI reads until the data with MPB = 1, and compares next ID. If it is no data with MPB = 1 in FRDRHL, set the MPIE bit to 1 again and wait for another SCIn_RXI interrupt request.

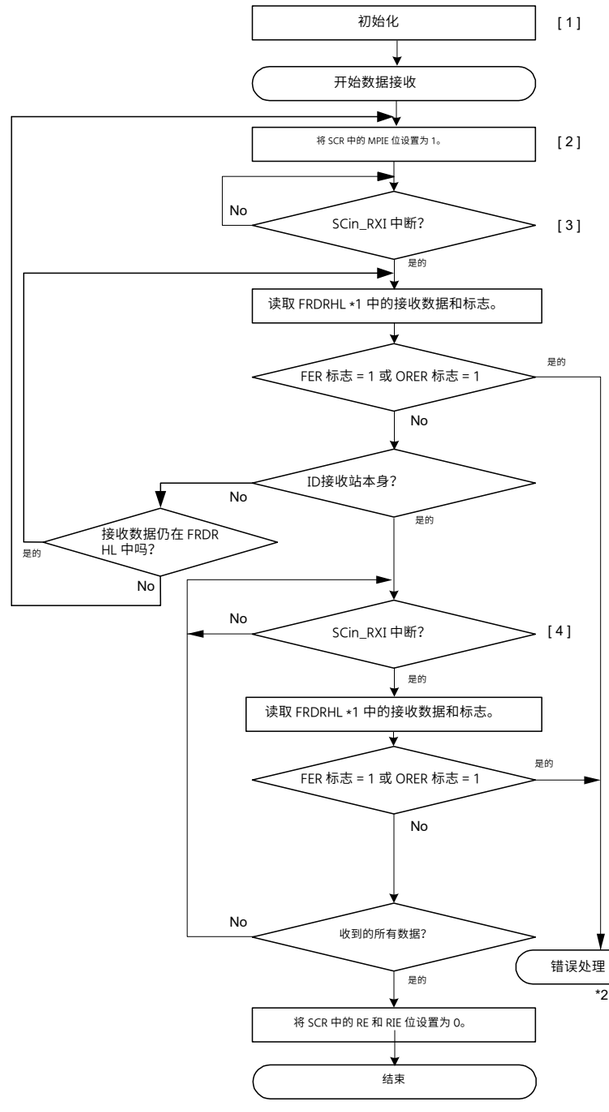
24.5 Operation in Manchester mode

In Manchester mode, the transmit or receive serial data is coded in Manchester encoding.

Figure 24.46 shows the conceptual image of Manchester encoding.



[1] SCI 初始化:

[2] ID 接收周期:
将 SCR。MPIE 位设置为 1 并等待 ID 接收。

[3] SCI状态确认及ID的接收与比较:

SCI 将第一个数据（MPB = 1）和后续接收到的数据存储在 FRDRHL 中。

RDF 设置为 1,当等于或大于指定接收触发数的接收数据量存储在 FRDRHL 中时,生成 SCIn_RXI 中断请求。FRDRHL中存储的数据量下降指定的接收触发数,接收到的数据等于或大于1,并且从最后一个停止位经过15 etus后没有接收到下一个数据时,SSR_FIFO。DR被设置为1。FCR。DRES 位为 0 时生成 SCIn_RXI 中断请求。

FRDRHL中读取第一个SCIn_RXI中断的数据,并将其与接收站本身的ID进行比较。

ID 与接收站本身的 ID 不匹配,则 SCI 读取直到 MPB = 1 的数据,并比较下一个 ID。FRDRHL 中没有 MPB = 1 的数据,则再次将 MPIE 位设置为 1 并等待另一个 SCIn_RXI 中断请求。

[4] 在 SCIn_RXI 中断处的数据接收:

SCIn_RXI 中断例程中读取 FRDRHL 中的数据一次。

[5] 接收错误处理和断裂检测:

SSR_FIFO 中若出现接收错误,通过读取 ORER 和 FER 标志识别出错误,在进行适当的错误处理后,务必将 SSR_FIFO。ORER 和 SSR_FIFO。FER 标志设置为 0。SSR_FIFO。ORER 标志设置为 1,则无法恢复接收。当检测到成帧错误时,可以通过读取 SPTR。RXDMON 标志来检测中断。

24。5 曼彻斯特模式下操作

在曼彻斯特模式下,发送或接收串行数据以曼彻斯特编码进行编码。

图24。46显示了曼彻斯特编码的概念图像。

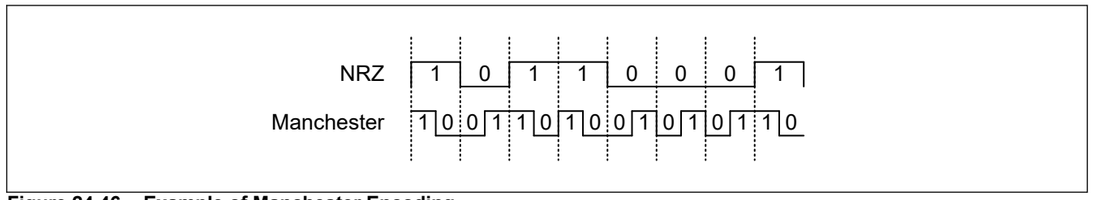

Figure 24.46 Example of Manchester Encoding

In Manchester mode, a preface and a start bit area are added to the transmit data in the register to configure a transmit frame. For transmission, data is encoded in Manchester encoding. When data is received, frames having the same format as transmitted frames are detected and Manchester decoding is performed.

For details on the frame format, see section 24.5.1. Frame Format.

24.5.1 Frame Format

Figure 24.47 shows the frame format in Manchester mode.

In the upper half of the figure, relevant setting registers are shown.

The preface area and the data area are encoded in Manchester encoding.

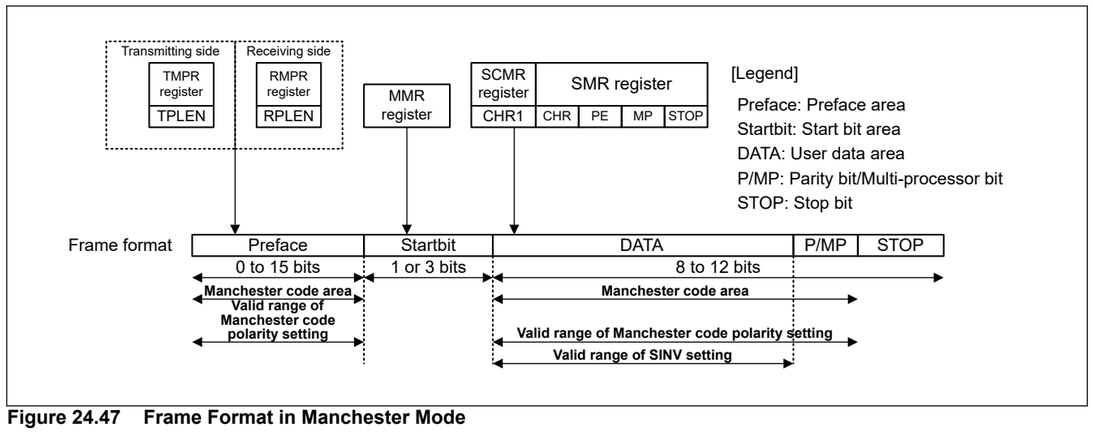

Figure 24.47 Frame Format in Manchester Mode

(1) Preface area

This is a fixed pattern area located at the beginning of each frame.

Different registers are used to set the preface area for transmission and reception. The preface length is determined by setting TMPR.TPLEN[3:0] for transmission. It is determined by setting RMPR.RPLEN[3:0] for reception.

If it is set to 0, the transmit preface is disabled and is not added.

If it is set to 1d to 15d, a preface whose length is determined by this setting is added.

(For example, if it is set to 1d, a 1-bit preface is added. If it is set to 15d, a 15-bit preface is added.)

The preface pattern is set with TMPR.TPPAT[1:0] for transmission and RMPR.RPPAT[1:0] for reception, and is selected from four types of patterns.

Figure 24.48 shows how the preface pattern is set. The preface area and the start bit area are added for each communication frame.

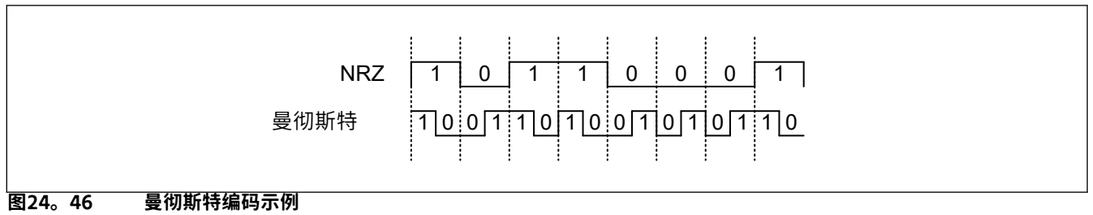

图24。46 曼彻斯特编码示例

在曼彻斯特模式下,前言和起始位区域被添加到寄存器中的发送数据以配置发送帧。为了传输,数据以曼彻斯特编码进行编码。当接收到数据时,检测具有与发送帧相同格式的帧并执行曼彻斯特解码。

有关帧格式的详细信息,请参阅第 24。5。1 节。帧格式 .

24.5.1 框架格式

图 24。47 显示了曼彻斯特模式下的帧格式。

图的上半部分显示了相关的设置寄存器。

（一）前言专区

这是位于每个帧开头的固定模式区域。

使用不同的寄存器来设置传输和接收的前言区域。前言长度通过设置TMPR。TPLEN[3:0]进行传输来确定。它是通过设置 RMPR。RPLEN[3:0] 进行接收来确定的。

如果设置为0,则禁用传输前言并且不添加。

1d 设置为 15d,则添加由该设置确定长度的序言。

（例如, 如果设置为 1d, 则添加 1 位前言。15d 设置的话,就加上一个 15 位的前言。）前言模式设置为用于传输的TMPR。TPPAT[1:0]和用于接收的RMPR。RPPAT[1:0],并从四种类型的模式中选择。

图 24。48 显示了前言模式的设置方式。为每个通信帧添加前言区域和起始位区域。

(2) Start bit area

This is an area indicating the start of valid data in a frame. It is added after the preface area.

The start bit length is determined by MMR.SBSEL setting. When MMR.SBSEL = 0, the start bit length is 1 bit.

When MMR.SBSEL = 1, the start bit length is 3 bits.

When MMR.SBSEL = 1, the SYNC type can be selected from command SYNC and data SYNC.

Command SYNC means the three start bits are added as a one-to-zero transition.

■ TMPR/RMPR = 10:一零模式

■ TMPR/RMPR = 01:零一模式

(2)起始位区域

这是指示帧中有效数据开始的区域。它是在序言区域之后添加的。

起始位长度由 MMR。SBSEL 设置确定。MMR。SBSEL = 0 时,起始位长度为 1 位。

MMR。SBSEL = 1 时,起始位长度为 3 位。

当MMR。SBSEL = 1时,可以从命令SYNC和数据SYNC中选择SYNC类型。

Command SYNC 意味着将三个起始位添加为一到零的转换。

Data SYNC means the three start bits are added as a zero-to-one transition.

The SYNC type is determined by the MMR.SYNSEL, MMR.SYNVAL and TDRH_MAN.TSYNC settings.

(When receiving, the received result is applied to RDRH_MAN.RSYNC.)

When MMR.SBSEL = 0, the start bit is added as a zero-to-one or one-to-zero transition.

The selection is determined by the MMR.SYNVAL setting.

The MMR.SYNSEL bit specifies the destination to be referred to when setting for transmission.

When the MMR.SYNSEL bit is set to 1, the MMR.SYNVAL setting is referred to. When the MMR.SYNSEL bit is set to 0, the TDRH_MAN.TSYNC setting is referred to.

Figure 24.49 shows the state of the start bit area according to the settings in the MMR.SYNSEL, MMR.SYNVAL and TDRH_MAN.TSYNC registers in the case of transmission. Figure 24.50 shows that in the case of reception.

The start bit(s) is not affected by the MMR.TMPOL or MMR.RMPOL setting.

Data SYNC 意味着三个起始位作为零到一的转换添加。

SYNC 类型由 MMR。SYNSEL、MMR。SYNVAL 和 TDRH_MAN。TSYNC 设置确定。（在接收时，接收到的结果被应用于RDRH_MAN。RSYNC。）MMR。SBSEL = 0 时,将起始位添加为零到一或一到零转换。

选择由 MMR。SYNVAL 设置确定。

MMR。SYNSEL 位指定设置传输时要引用的目的地。

当MMR。SYNSEL位设置为1时,参考MMR。SYNVAL设置。当MMR。SYNSEL位设置为0时,参考TDRH_MAN。TSYNC设置。

(3) DATA

由于数据区域的格式与异步模式的格式相同,请参见第 24。3。1 节。串行数据传输格式。

As shown in Figure 24.46, Frame Format in Manchester Mode, the stop bit is not included in the Manchester encoding range.

24.5.2 Clock

As the transfer clock in Manchester mode, the clock generated by the on-chip baud rate generator is used by setting the SMR.CKS[1:0] bit.

Also it is possible to set the oversampling (transfer rate of one-bit period) by SEMR.ABCS bit.

When the SMER.ABCS bit is set to 0, oversampling x16 is selected with the one-bit period being 16 cycles of the base clock. When the SMER.ABCS bit is set to 1, oversampling x8 is selected with the one-bit period being 8 cycles of the base clock.

24.5.3 Initialization of the SCI in Manchester Mode

Before transferring data, write the initial value (0x00) to the SCR register and initialize the SCI following the example of flowchart shown in Figure 24.51.

Whenever the operating mode or transfer format is changed, the SCR register must be initialized before the change is made.

Note that setting the SCR.RE bit to 0 initializes none of the ORER, FER, PER, MER, and RDRF flags in the SSR_MANC register, the SYER, PFER and SBER flags in the MESR register, and the RDR, RDRHL_MAN registers.

Note also that switching the value of SCR.TE from 0 to 1 when SCR.TIE is 1 generates a SCIn_TXI interrupt request.

如图24。46所示,曼彻斯特模式下的帧格式,停止位不包括在曼彻斯特编码范围内。

24。5。2 时钟

作为曼彻斯特模式下的传输时钟,通过设置SMR。CKS[1:0]位来使用片上波特率发生器生成的时钟。

还可以通过 SEMR。ABCS 位设置过采样（一位周期的传输速率）。

SMER。ABCS 位设置为 0 时,选择超采样 x16,其中一位周期为基时钟的 16 个周期。当SMER。ABCS位设置为1时,选择超采样x8,其中一位周期为基时钟的8个周期。

24。5。3 在曼彻斯特模式下初始化 SCI

在传输数据之前,将初始值 (0x00) 写入 SCR 寄存器,并按照图 24。51 . 所示的流程图示例初始化 SCI

每当更改操作模式或传输格式时,必须在更改之前初始化 SCR 寄存器。请注意,将 SCR。RE 位设置为 0 不会初始化 SSR_MANC 寄存器中的 ORER、FER、PER、MER 和 RDRF 标志、MESR 寄存器中的 SYER、PFER 和 SBER 标志以及 RDR、RDRHL_MAN寄存器。

另请注意,当 SCR。TIE 为 1 时,将 SCR。TE 的值从 0 切换到 1 会生成 SCRIn_TXI 中断请求。

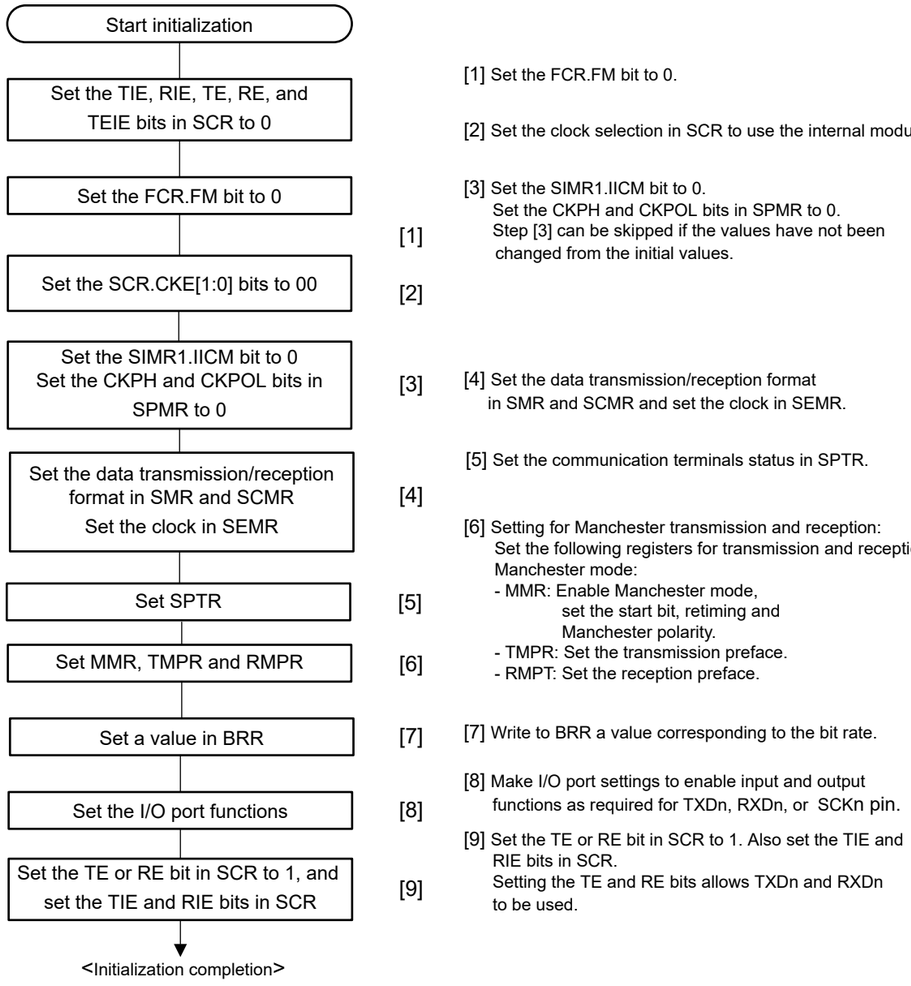

Figure 24.51 SCI Initialization Flow in Manchester Mode

24.5.4 Double-speed operation

When the ABCS bit in SEMR is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the BGDM bit in SEMR is set to 1, the cycle of the base clock is reduced to half and the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the ABCS and the BGDM bits in SEMR are set to 1, the SCI operates on the bit rate four times that of when the ABCS and the BGDM bits in SEMR are set to 0.

24.5.5 CTS and RTS functions

The CTS function uses input on the CTSn_RTSn pin in transmission control. Setting the CTSE bit in SPMR to 1 enables the CTS function. The CTSn_RTSn pin can be set as a multiplexed pin which allows one pin to be used for either function, or as dedicated pins with each pin for a single function. Use the CTSPEN bit in SPMR for this setting.

When the CTS function is enabled, reception starts only when the CTSn_RTSn pin is at the low level.

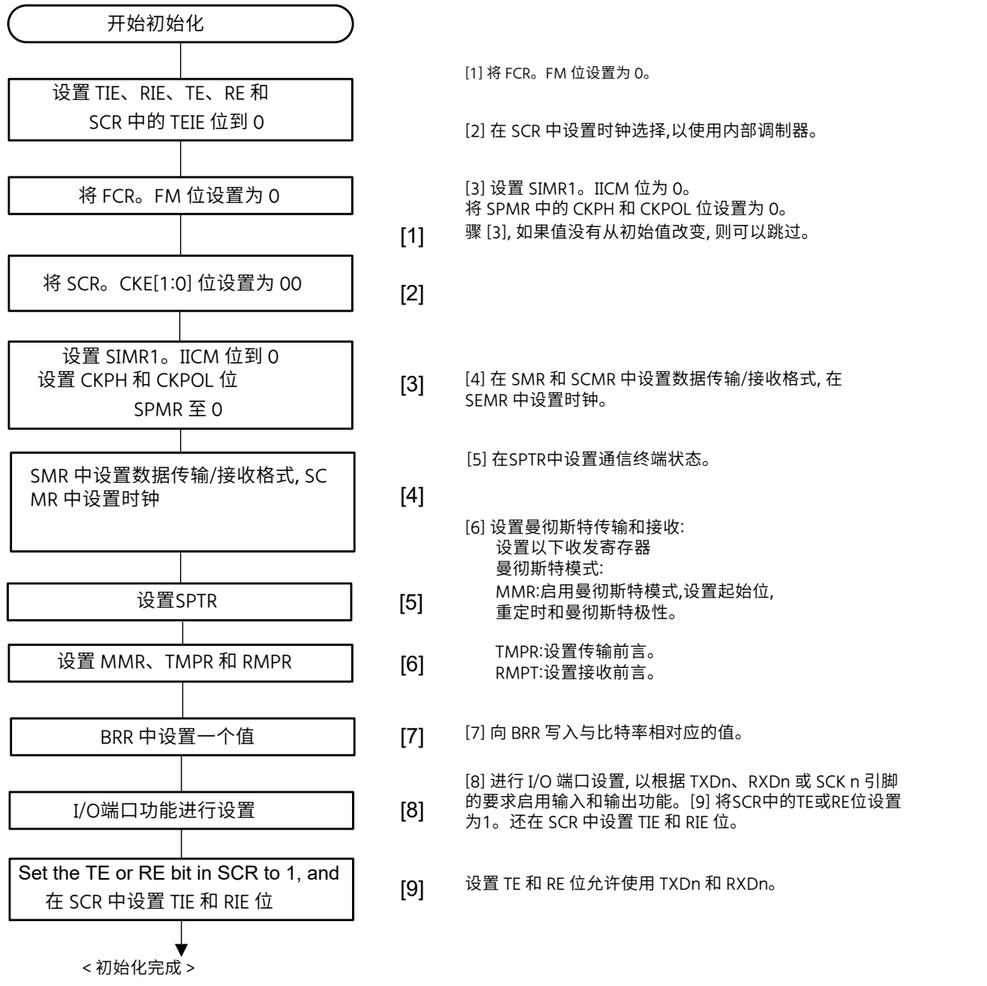

图24。51 曼彻斯特模式下的 SCI 初始化流程

24。5。4 双速运行

SEMR中的ABCS位被设置为1并且选择了1位周期的基时钟的八个脉冲时,SCI的操作比特率是ABCS被设置为0时的两倍。

当SEMR中的BGDM位设置为1时,基时钟的周期减少一半,SCI的比特率是ABCS设置为0时的两倍。

当SEMR中的ABCS和BGDM比特被设置为1时,SCI的比特率是SEMR中的ABCS和BGDM比特被设置为0时的四倍。

24。5。5 CTS 和 RTS 功能

CTS 函数在传输控制中使用 CTSn_RTSn 引脚上的输入。将 SPMR 中的 CTSE 位设置为 1 可以启用 CTS 功能。CTSn_RTSn 引脚可以设置为多路复用引脚,允许一个引脚用于任一功能,也可以设置为每个引脚用于单个功能的专用引脚。在此设置中使用 SPMR 中的 CTSPEN 位。

CTS 功能时,只有当 CTSn_RTSn 引脚处于低电平时,接收才开始。

Applying a high level to the CTSn_RTSn pin after transmission starts does not affect transmission of the current frame, which continues.

The RTS function uses output on the CTSn_RTSn pin to request transmission. When the SCI is ready to receive, it outputs a low level to the CTSn_RTSn pin, Conditions for output of the low level and high level are as follows:

[Conditions for low-level output]

When all conditions listed below are satisfied:

- The value of the RE bit in SCR is 1.
- The SCI is ready to receive.
- There is no received data yet to be read.
- All of the following flags are set to 0: SSR_MANC.ORER, FER, PER and MER flags, and MESR.SYER (when SYEREN = 1), PFER (when PFEREN = 1) and SBER flags (when SBEREN = 1).

[Conditions for high-level output]

- When the conditions for low output are not satisfied

24.5.6 Serial data transmission in Manchester mode

The SCI encodes data in Manchester encoding and sends the resultant data in Manchester mode.

When the polarity setting (MMR.TMPOL) set to 0, logic 0 is coded as a zero-to-one transition in Manchester code and logic 1 is coded as a one-to-zero transition in Manchester code.

When the polarity setting (MMR.TMPOL) set to 1, logic 0 is coded as a one-to-zero transition in Manchester code and logic 1 is coded as a zero-to-one transition in Manchester code.

For this reason, a level transition occurs with the Manchester encoded data in the middle of individual logic data. (See Figure 24.46).

The transmitter constructs transmit frames in a specific format by adding a preface area to data and setting the start bit(s) according to the polarity setting and sends resultant serial data.

For details on the frame format, see section 24.5.1. Frame Format.

Figure 24.52 shows the flowchart in transmission. Figure 24.53, Figure 24.54, and Figure 24.55 show examples of the operation for serial transmission in Manchester mode.

CTSn_RTSn引脚在传输开始后应用高电平不会影响当前帧的传输,当前帧会继续。

RTS 函数使用 CTSn_RTSn 引脚上的输出来请求传输。SCI 准备接收时, 它向 CTSn_RTSn 引脚输出一个低电平, 低电平和高电平输出的条件如下:

[低水平输出的条件] 当满足下列所有条件
时:

- SCR 中 RE 位的值为 1。
- SCI 已准备好接收。
- 尚未读取接收到的数据。
- 以下所有标志均设置为 0:SSR_MANC。ORER、FER、PER 和 MER 标志,以及 MESR。SYER（当 SYEREN = 1 时）、PFER（当 PFEREN = 1 时）和 SBER 标志（当 SBEREN = 1 时）1)。

的【高水平产出条件】

- 当不满足低输出的条件时

24。5。6 曼彻斯特模式下的串行数据传输

SCI 在曼彻斯特编码中对数据进行编码,并以曼彻斯特模式发送结果数据。

当极性设置（MMR。TMPOL）设置为 0 时,逻辑 0 在曼彻斯特代码中被编码为零到一跃迁,逻辑 1 在曼彻斯特代码中被编码为一到零跃迁。

当极性设置（MMR。TMPOL）设置为 1 时,逻辑 0 在曼彻斯特代码中被编码为一到零过渡,逻辑 1 在曼彻斯特代码中被编码为零到一过渡。

因此,曼彻斯特编码数据在单个逻辑数据中间发生电平转换。（见图24。46)。

发射机通过向数据添加前言区域并根据极性设置设置起始位来构建特定格式的发射帧并发送结果串行数据。

有关帧格式的详细信息,请参阅第 24。5。1 节。帧格式 .

24.5.7 Serial Data Reception in Manchester Mode

In Manchester mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate. Reception starts by sampling the falling edges of received data at the base clock. As shown in Figure 24.56, reception starts at a falling edge of the received data and it continues if the received data keeps low for the duration of 1/4 bit. If the received data goes high within the duration of 1/4 bit, the SCI judges it as an error and waits for a falling edge again.

If a high level is expected in the first half of a bit in the received data, the SCI judges a low level that continues for one base clock cycle as an error and ignores the change to the low level.

Note 1. This is the case when SEMR.ABCS = 0. When SEMR.ABCS = 1, the SCI operates on a base clock with a frequency of 8 times the bit rate.

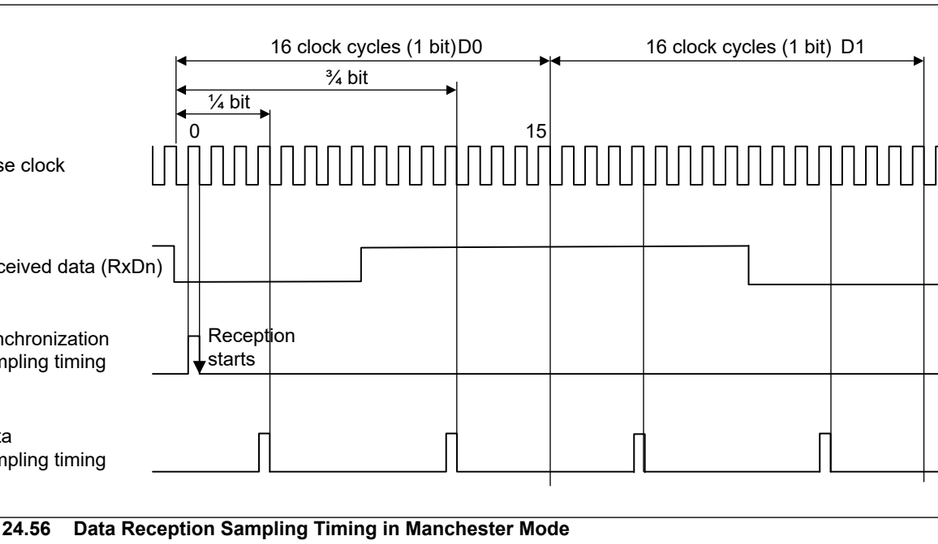

Figure 24.56 Data Reception Sampling Timing in Manchester Mode

In Manchester mode, data reception starts with detection of a preface and start bit area.

The SCI checks the input from the RXDn pin to see whether a preface is added based on the value of RMPR.RPLEN.

24。5。7 曼彻斯特模式下的串行数据接收

在曼彻斯特模式下,SCI 在基时钟上运行,频率为 *1 比特率的 16 倍。接收首先对基时钟处接收到的数据的下降边缘进行采样。如图 24。56 所示,接收从接收到的数据的下降边缘开始,如果接收到的数据在 1/4 位的持续时间内保持在较低位置,则接收继续。如果接收到的数据在 1/4 位的持续时间内变高,SCI 会将其判断为错误并再次等待下降边缘。

注1。当 SEMR。ABCS = 0 时就是这种情况。SEMR。ABCS = 1 时,SCI 在频率为比特率 8 倍的基时钟上运行。

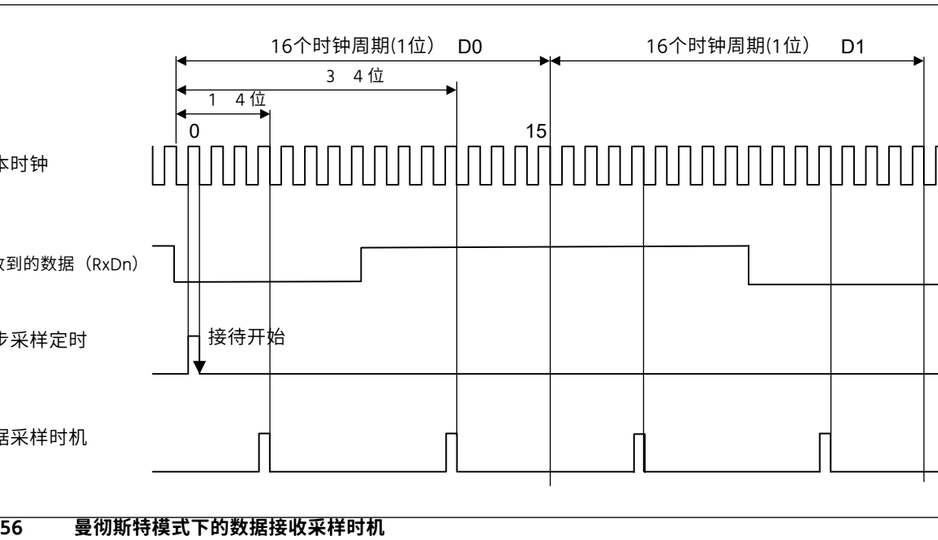

图24。56 曼彻斯特模式下的数据接收采样时机

在曼彻斯特模式下,数据接收从检测前言和启动位区域开始。

SCI 检查来自 RXDn 引脚的输入,看看是否根据 RMPR。RPLEN 的值添加了前言。

If the preface is disabled (RMPR.RPLEN = 0), it moves on to the detection of a start bit area without detecting a preface.

When a preface is enabled, it identifies a preface pattern setting according to the set value in RMPR.RPPAT, and compares it with the RXDn input for a pattern match to detect a preface pattern.

Upon detection of a preface pattern match, it judges it as a normal preface and moves on to the detection of a start bit area.

If detecting a preface pattern mismatch or a Manchester code error in the preface area, it judges it as a preface error and asserts a preface error (PFER).

For start bit detection, the SCI selects an expected value based on the register settings (MMR.SBSEL and SYNVAL), compares it with the RXDn input for a pattern match to detect a start bit area. Upon detection of a start bit pattern match, it judges it as a normal start bit area and moves on to the data processing.

Only when a preface and a start bit area are detected normally, it moves on to the next phase of data reception.

Upon detection of a start bit pattern mismatch, it asserts a start bit error flag (SBER).

In data processing, the SCI shifts the data by the expected received data length based on the register settings (SCMR.CHR1 and SMR.CHR) through the RSR register. If two sampling points in a bit of the received data are identical, the SCI judges this as a Manchester code error.

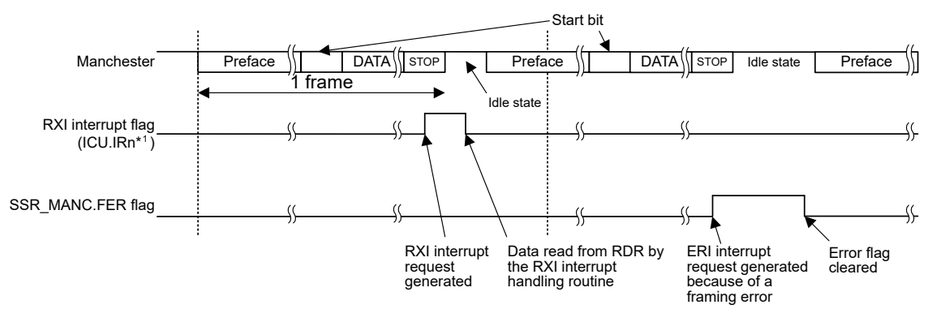
For details, see section 24.5.11. Errors in Manchester Mode (4).

When the parity function is disabled (SMR.PE = 0), the SCI moves on to the next phase of stop bit detection. When the parity function is enabled (SMR.PE = 1), the SCI performs parity checking. If detecting a parity error, it asserts a parity error flag (PER), and then moves on to stop bit detection.

In stop bit detection, the SCI checks the following in the stop bit area of the received frame:

It has two sampling points in a bit. If both points are at the high level, the bit is recognized as a normal stop bit and the data is stored in the RDR register. At least one low-level point is judged as an abnormal stop bit, causing a framing error flag (FER) to be set. Even when an error is detected, the received data is stored in the RDR register as abnormal data.

Figure 24.57 shows an example of the operation for serial data reception in Manchester mode.



Note 1. For corresponding interrupt numbers, see section 12, Interrupt Controller Unit (ICU).

Figure 24.57 Example of Operation for Serial Data Reception in Manchester mode (with a Preface)

For the state of each status flag in the SSR_MANC register and RXDn input processing when a receive error is detected, see section 24.5.11. Errors in Manchester Mode.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated.

Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, PER, MER, SYER*1, PFER*1, and SBER*1 flags to 0 before resuming reception. Also, be sure to read the RDR (or RDRHL_MAN) register during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR (or the RDRHL_MAN) register because received data which has not yet been read may be left in the RDR (or the RDRHL_MAN) register.

Figure 24.58 and Figure 24.59 show examples of serial data reception flowchart in Manchester mode.

如果禁用前言（RMPR。RPLEN = 0),它将继续检测起始位区域,而无需检测前言。

启用前言后,根据RMPR。RPPAT中的设定值识别前言模式设置,并与RXDn输入进行模式匹配比较,检测前言模式。

在检测到前言模式匹配后,它将其判断为普通前言并继续检测起始位区域。

如果在前言区域检测到前言模式不匹配或曼彻斯特代码错误,则将其判断为前言错误并断言前言错误（PFER）。

对于开始位检测,SCI根据寄存器设置（MMR。SBSEL和SYNVAL）选择期望值,将其与RXDn输入进行比较以进行模式匹配以检测开始位区域。在检测到起始位模式匹配后,它将其判断为正常起始位区域并继续进行数据处理。

只有当正常检测到前言和起始位区域时,它才会进入数据接收的下一阶段。

在检测到起始位模式不匹配时,它断言起始位错误标志（SBER）。

在数据处理中,SCI 根据寄存器设置（SCMR。CHR1 和 SMR。CHR）通过 RSR 寄存器将数据移动预期接收到的数据长度。如果接收到的数据中的两个采样点相同,SCI 会将其判断为曼彻斯特代码错误。

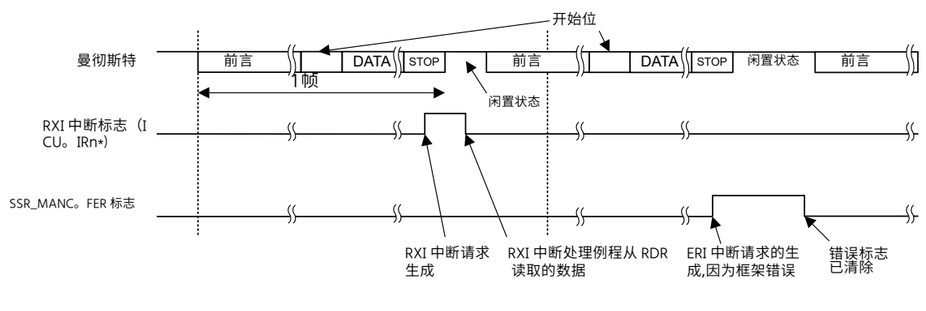
详情请参见第 24。5。11 节。曼彻斯特模式中的错误 (4)。

当奇偶校验函数被禁用（SMR。PE = 0)时,SCI 进入下一阶段的停止位检测。启用奇偶校验函数（SMR。PE = 1)时,SCI 执行奇偶校验。如果检测到奇偶校验错误,它会断言奇偶校验错误标志（PER）,然后继续停止位检测。

在停止位检测中,SCI 在接收帧的停止位区域中检查以下内容:

它有一点有两个采样点。如果两个点都处于高电平,则该位被识别为正常停止位,并且数据存储在 RDR 寄存器中。至少一个低电平点被判断为异常停止位,导致设置成帧错误标志（FER）。即使检测到错误,接收到的数据也会作为异常数据存储在 RDR 寄存器中。

图24。57示出了曼彻斯特模式下串行数据接收操作的示例。



注1。有关相应的中断号码,请参阅第 12 节"中断控制器单元（ICU）."

图24。57 曼彻斯特模式下串行数据接收操作示例（附前言）

SSR_MANC寄存器和RXDn输入处理中检测到接收错误时每个状态标志的状态,请参见第24。5。11节。曼彻斯特模式中的错误。

如果检测到接收错误,则会生成 SCIn_ERI 中断请求,但不会生成 SCIn_RXI 中断请求。

当接收错误标志为 1 时,无法恢复数据接收。因此,设置ORER、FER、PER、MER、SYER *1、PFER *1,和 SBER *1 标志到 0,然后才恢复接收。另外,在溢出错误处理过程中,请务必读取 RDR（或 RDRHL_MAN）寄存器。当在操作期间通过将SCR。RE位设置为0来强制终止接收时,读取RDR（或RDRHL_MAN）寄存器,因为接收到的尚未读取的数据可以留在RDR（或RDRHL_MAN）寄存器中。

图24。58和图24。59示出了曼彻斯特模式下的串行数据接收流程图的示例。

24.5.8 Operation When Multi-Processor Bit Is Used

See section 24.4. Multi-Processor Communication Function (1) for the operation in Manchester mode when using multi-processor mode because the operation is the same.

A preface and a start bit area are added to the frame format in Manchester mode. See Figure 24.59 for error processing in Manchester mode for the reception flowchart (Figure 24.43). See Table 24.33 for the operation status when detecting various errors.

24.5.9 Receive Retiming

This function corrects the timing for each central edge of the bit, taking advantage of the fact that each bit has an edge in the center in Manchester code.

The receive retiming function can be turned on or off by setting the ERTEN bit in the MMR register.

When the receive retiming function is turned off (MMR.ERTEN = 0), retiming is not performed, causing misalignment between the internal clock and the RXDn input to be accumulated and the receive margin to be reduced.

When the receive retiming function is turned on (MMR.ERTEN = 1), retiming is performed for the preface area, the start bit area*1, and the data area (excluding the stop bit).

Note 1. Retiming is not performed for the start bit area if the preface length is 0 and the start bit length is 3.

As an example, the receive retiming when oversampling x16 is selected is shown below.

When detecting an RXDn input edge two to four cycles before the expected receive cycle, the receive processing is shortened by one sampling CLK cycle.

When detecting a RXDn input edge two to three cycles after the expected receive cycle, the receive processing is extended by one sampling CLK cycle.

(Even if the clock is misaligned with the data by more than two cycles, one cycle is corrected for each bit.)

Figure 24.60 shows the conceptual image of receive retiming range.

When detecting an edge in the tolerance area in the figure, data is received as is without making correction.

When detecting an edge in the SyncJump area in the figure, data is corrected for reception.

When detecting an edge in the SyncError area in the figure, data is received as abnormal data with no correction made.

For a Manchester code error (data matches at the 1/4-phase and 3/4-phase sampling points), the SCI reports a code error.

24。5。8 使用多处理器位时的操作

参见第 24。4 节。多处理器通信功能 (1) 用于使用多处理器模式时曼彻斯特模式下的操作,因为操作相同。

在曼彻斯特模式下,帧格式中添加了前言和起始位区域。有关接收流程图的曼彻斯特模式下的错误处理,请参见图 24。59（图 24。43)。检测各种错误时的操作状态见表24。33。

24。5。9 接收重定时

该函数利用曼彻斯特代码中每个位在中心都有一个边的事实来校正该位的每个中心边的时间。

通过设置MMR寄存器中的ERTEN位,可以打开或关闭接收重定时功能。

关（MMR。ERTEN = 0)接收重定时功能时,不执行重定时,导致内部时钟与RXDn输入之间的错位被累积,接收余量被降低。

启（MMR。ERTEN = 1)接收重定时功能时,对前言区域、起始位区域*1、数据区域（不包括停止位）进行重定时。

注1。如果前言长度为 0 且起始位长度为 3,则不会对起始位区域执行重定时。

作为示例,选择过采样x16时的接收重定时如下所示。

当在预期接收周期之前检测到两到四个周期的RXDn输入边缘时,接收处理被缩短一个采样CLK周期。

当在预期接收周期之后检测到两到三个周期的RXDn输入边缘时,接收处理延长一个采样CLK周期。

（即使时钟与数据错位超过两个周期,每个位也会校正一个周期。) 图24。60显示了接收重定时范围的概念图像。

当检测到图中公差区域中的边缘时,数据将按原样接收,而无需进行校正。

当检测到图中 SyncJump 区域中的边缘时,数据将被校正以供接收。

当检测到图中 SyncError 区域中的边缘时,数据将作为异常数据接收,无需进行校正。对于曼彻斯特代码错误（数据在 1/4 相和 3/4 相采样点匹配）,SCI 报告代码错误。

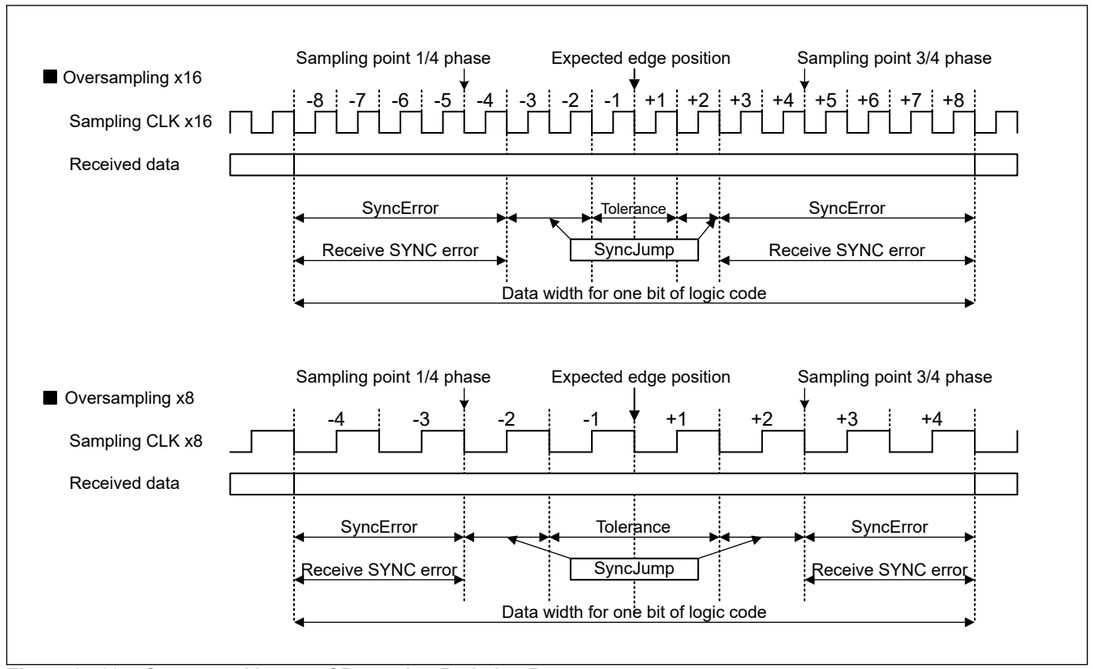

Figure 24.60 Conceptual Image of Reception Retiming Range

24.5.10 Polarity Setting for Manchester Code

The polarity of the Manchester code can be set with the Manchester Mode Register (MMR).

It can be set separately for transmission and reception. Use the MMR.TMPOL bit to set the polarity for transmission and the MMR.RMPOL bit to set the polarity for reception.

The Manchester code polarity setting is valid for the preface area, the data area, and the parity or multi-processor area.

When the initial settings (TMPOL/RMPOL = 0) are used for the polarity of Manchester code, logic 0 is encoded as a zero-to-one transition in Manchester code and logic 1 is encoded as a one-to-zero transition in Manchester code. If the settings are changed to TMPOL/RMPOL = 1, logic 0 is encoded as a one-to-zero transition in Manchester code and logic 1 is encoded as a zero-to-one transition in Manchester code. Figure 24.61 shows the conceptual image of the settings and operation.

Separately from the function above, the transmitted and received data in the data area can be inverted by the transmitted/received data inversion function (SCMR.SINV). Since the polarity of Manchester code (MMR.TMPOL/RMPOL) can be set separately from the transmitted/received data invert function (SCMR.SINV), if both are set to inversion (MMR.TMPOL/RMPOL = 1 and SCMR.SINV = 1), the transmitted and received data are set to initial state (inversion + inversion = normal).

The polarity of the start bit area can be set by a register different from the ones mentioned above.

Since a different register is used, the polarity of the start bit area is not affected by the polarity setting for Manchester code mentioned above.

For details on the setting for the start bit area, see section 24.5.1. Frame Format (2).

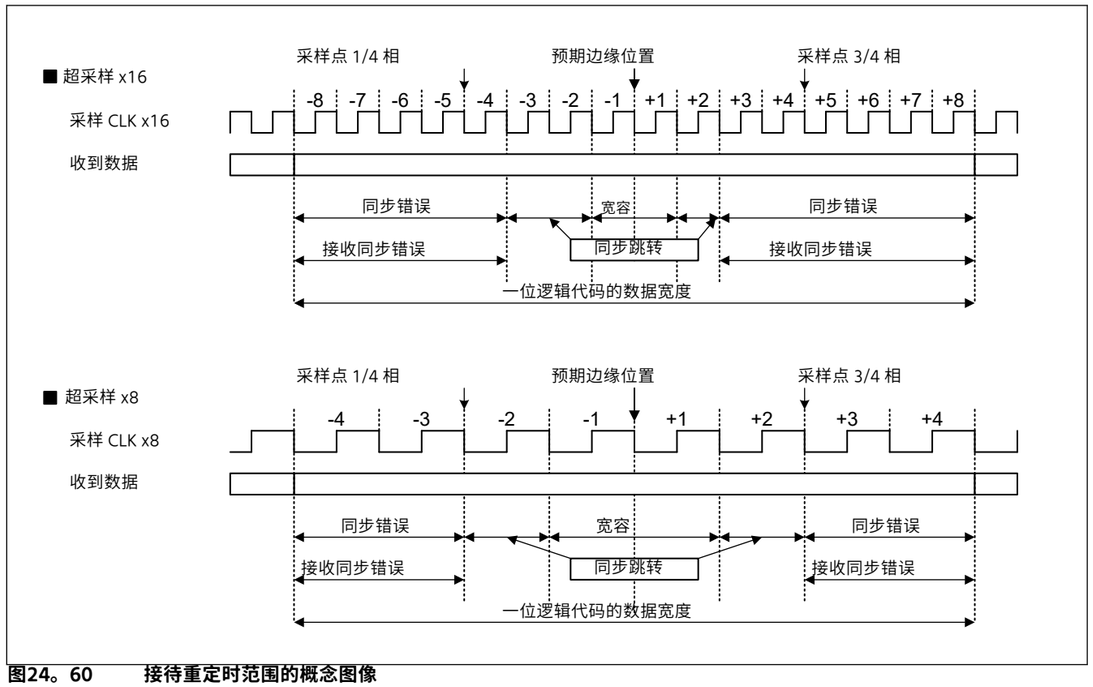

图24。60 接待重定时范围的概念图像

24.5.10 曼彻斯特代码的极性设置

曼彻斯特代码的极性可以使用曼彻斯特模式寄存器（MMR）设置。

可以单独设置用于发送和接收。使用MMR。TMPOL位设置传输极性,使用MMR。RMPOL位设置接收极性。

曼彻斯特代码极性设置对于前言区域、数据区域以及奇偶校验或多处理器区域有效。

当初始设置（TMPOL/RMPOL = 0)用于曼彻斯特代码的极性时,逻辑 0 在曼彻斯特代码中被编码为零一跃迁,逻辑 1 在曼彻斯特代码中被编码为一到零跃迁。如果设置更改为 TMPOL/RMPOL = 1,则逻辑 0 在曼彻斯特代码中被编码为一到零转换,逻辑 1 在曼彻斯特代码中被编码为零到一转换。图 24。61 显示了设置和操作的概念图像。

与上述功能不同,数据区域中的发送和接收数据可以由发送/接收数据反转功能（SCMR。SINV）反转。由于曼彻斯特码（MMR。TMPOL/RMPOL）的极性可以与发送/接收的数据反转函数（SCMR。SINV）分开设置,因此如果两者都设置为反转（MMR。TMPOL/RMPOL = 1 和 SCMR。SINV = 1)),发送和接收的数据设置为初始状态（反转+反转=正常）。

起始位区域的极性可以通过与上述不同的寄存器来设置。

由于使用不同的寄存器,因此起始位区域的极性不受上述曼彻斯特代码的极性设置的影响。

有关起始位区域设置的详细信息,请参阅第 24。5。1 节。框架格式 (2)。

24.5.11 Errors in Manchester Mode

There are the following errors in Manchester mode:

1. Parity error
2. Over run error
3. Framing error
4. Manchester error
5. Preface error
6. Start Bit error
7. Receive SYNC error

For errors (1) to (3), see section 24.3.9. Serial Data Reception in Asynchronous Mode (1) because they are the same as in asynchronous mode.

Each errors are judged in each area, but they are reflected on flags and operations at the timing of 3/4-bit sampling of the STOP bit area. If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the previous information.

Table 24.31 lists the states of the serial status register when detecting errors and judgment about whether to store data in the RDR.

Table 24.32 lists the errors that can be detected in each area of a Manchester frame.

If a Preface error or Start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the result of the previous frame reception. Also, if an error is detected in the previous frame, data will not be received, but errors in the pre-face area and start bit area will update that flag. Table 24.33 shows the flags and actions in this case.

24。5。11 曼彻斯特模式中的错误

曼彻斯特模式存在以下错误:

1。奇偶校验错误

2锛姣涓。超过运行错误

3锛 娴 。框架错误

4锛姣涓。曼彻斯特错误

5锛姣涓。前言错误

6锛 涓€涓。开始位错误

7锛 娴 。接收同步错误

对于错误 (1) 至 (3),请参见第 24。3。9 节。异步模式下的串行数据接收 (1),因为它们与异步模式下相同。

每个错误都会在每个区域中进行判断,但它们会反映在 STOP 位区域 3/4 位采样的时序处的标志和操作上。如果检测到前言错误或启动位错误,则不会接收后续数据。因此,不执行其他错误检测,并且错误标志保存先前的信息。

表24。31列出了在检测错误时串行状态寄存器的状态以及是否在RDR中存储数据的判断。

表 24。32 列出了在曼彻斯特帧的每个区域中可以检测到的错误。

如果检测到前言错误或开始位错误,则不会收到后续数据。因此,不执行其他错误检测,并且错误标志保存前一帧接收的结果。另外,如果在上一帧中检测到错误,则不会接收到数据,但前面区域和开始位区域中的错误将更新该标志。表 24。33 显示了本例中的标志和操作。

(4) Manchester error

A Manchester error is generated when a Manchester code error is detected.

In Manchester code, there must be an edge (transition) in the center of the bit.

In the data area of a received frame (including the parity/multi-processor bit), the values of the 1/4-bit and 3/4-bit sampling points are checked in each received 1-bit data, and a Manchester code error is determined if these two values match.

If a Manchester code error is detected, the Manchester error flag (SSR_MANC.MER) is asserted.

If a Manchester error occurs, it is handled as an interrupt source and event source. If a Manchester error is detected, the next reception is not performed until the corresponding error flag is cleared.

(5) Preface error

A preface error is generated when the preface pattern does not match or a Manchester code error is detected in the preface area. If a preface error is detected, the preface error flag (SSR_MANC.PFER) is asserted.

It is possible to set whether to use this error flag as an interrupt source with the setting of the MECR register.

When MECR.PFEREN = 1, a preface error is handled as an interrupt source or event source. If a preface error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.PFEREN = 0, a preface error is not handled as an interrupt source or event source, and the next reception is not halted. However, a preface error is notified to MESR.PFER.

(6) Start bit error

A start bit error is generated when a mismatch is detected between the start bit area in the received frame and the preset start bit pattern. Upon detection of a start bit error, a start bit error flag (MESR.SBER) is asserted.

It is possible to set whether to use the start bit error as an interrupt source with the setting of the MECR register.

When MECR.SBEREN = 1, a start bit error is handled as an interrupt source or event source. If a start bit error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.SBEREN = 0, a start bit error is not handled as an interrupt source or event source, and the next reception is not halted. However, a start bit error is notified to MESR.SBER.

(7) Receive SYNC error

When the receive retiming function described in section 24.5.9. Receive Retiming is enabled, the receive retiming operation is performed.

If no edges are detected within the receive retiming range (SyncError area in Figure 24.60) when receive timing operation is being performed, a receive SYNC error is generated. Upon detection of a receive SYNC error, a receive SYNC error flag (MESR.SYER) is asserted. In areas not subject to retiming, receive SYNC errors are not detected.

The preface area*1, the start bit area*1,*2, and the data area (excluding the stop bit) for which receive retiming operation is performed are checked.

It is possible to set whether to use the receive SYNC error as an interrupt source with the setting of the MECR register.

When MECR.SYEREN = 1, a receive SYNC error is handled as an interrupt source or event source. If a receive SYNC error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.SYEREN = 0, a receive SYNC error is not handled as an interrupt source or event source, and the next reception is not halted. However, a receive SYNC error is notified to MESR.SYER.

Note 1. In the case of a frame that starts with a pattern that expects the first half of the bit to be High, it is excluded from retiming.

Note 2. In the start bit area, when there is no preface length and 3 bit start bit is set, it is not subject to retiming.
Also, the 1st bit and the 2nd bit in the start bit area when 3 bit start bit is set are not subject to retiming.

(4)曼彻斯特错误

当检测到曼彻斯特代码错误时,会生成曼彻斯特错误。

在曼彻斯特代码中,位中心必须有一个边（转换）。

在接收帧的数据区域（包括奇偶校验/多处理器位）中,在每个接收到的 1 位数据中检查 1/4 位和 3/4 位采样点的值,并且如果这两个值匹配,则确定曼彻斯特代码错误。

如果检测到曼彻斯特代码错误,则断言曼彻斯特错误标志（SSR_MANC。MER）。

如果发生曼彻斯特错误,则将其作为中断源和事件源进行处理。如果检测到曼彻斯特错误,则在清除相应的错误标志之前不会执行下一次接收。

(5)前言错误

当前言模式不匹配或在前言区域检测到曼彻斯特代码错误时,会生成前言错误。如果检测到前言错误,则断言前言错误标志（SSR_MANC。PFER）。

MECR寄存器的设置,可以设置是否使用该错误标志作为中断源。

当 MECR。PFEREN = 1 时,前言错误将作为中断源或事件源处理。如果检测到前言错误,则在清除相应的错误标志之前不会执行下一次接收。

MECR。PFEREN = 0 时,前言错误不作为中断源或事件源处理,并且下一次接收不会停止。但是,前言错误会通知 MESR。PFER。

(6)开始位错误

当检测到接收帧中的起始位区域与预设的起始位模式之间的不匹配时,生成起始位错误。检测到开始比特错误后,断言开始比特错误标志（MESR。SBER）。

MECR寄存器的设置,可以设置是否使用起始位错误作为中断源。

当MECR。SBEREN = 1时,起始位错误被处理为中断源或事件源。如果检测到启动位错误,则在清除相应的错误标志之前不会执行下一次接收。

MECR。SBEREN = 0 时,启动位错误不作为中断源或事件源处理,并且下一个接收不会停止。但是,启动位错误会通知 MESR。SBER。

(7)接收同步错误

24。5。9 节中描述的接收重定时功能时。启用接收重定时,执行接收重定时操作。

如果在执行接收定时操作时在接收重定时范围内（图24。60中的SyncError区域）没有检测到边缘,则会生成接收SYNC错误。当检测到接收同步错误时,断言接收同步错误标志（MESR。SYER）。在不受重定时限制的区域中,不会检测到接收同步错误。

检查执行接收重定时操作的前言区域*1、起始位区域*1,*2和数据区域（不包括停止位）。

可以设置是否使用接收SYNC错误作为MECR寄存器的设置的中断源。MECR。SYEREN = 1 时,接收同步错误作为中断源或事件源处理。如果检测到接收SYNC错误,则在清除相应的错误标志之前不会执行下一次接收。

MECR。SYEREN = 0 时,接收 SYNC 错误不作为中断源或事件源处理,并且下一个接收不会停止。但是,接收同步错误会通知 MESR。SYER。

注1。如果帧以预期位的前半部分为 High 的模式开头,则它被排除在重定时之外。

注2。在起始位区域中,当没有前言长度并且设置了3位起始位时,它不受重定时的影响。
另外,设置3位起始位时起始位区域中的第1位和第2位不受重定时的影响。

24.6 Operation in Clock Synchronous Mode

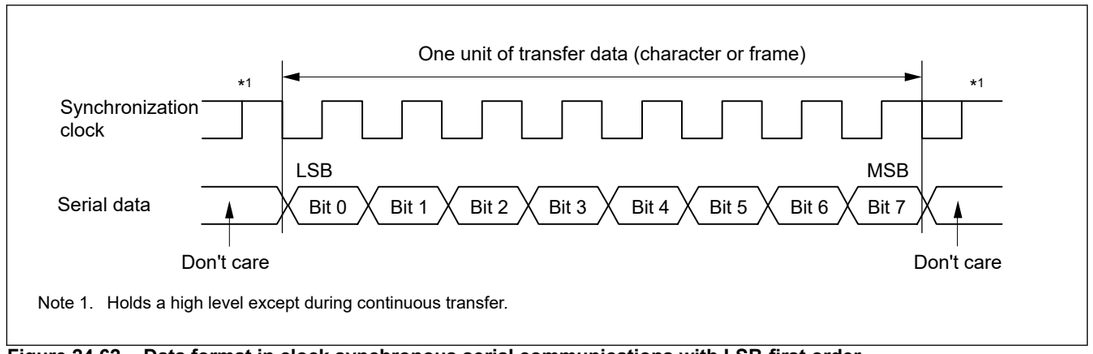
Figure 24.62 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. For single-character data transfer, data consists of 8-bit. In clock synchronous mode, no parity bit can be added.

In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next falling edge. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the last bit as output state. When the SPMR.CKPH bit is 1 in slave mode, the transmission line holds the first bit output state.

Within the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by using a shared clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

However, it is not possible to perform continuous transfer in the fastest bit rate setting (BRR[7:0] = 0x00 and SMR.CKS[1:0] = 00b). Therefore, when the FIFO is selected, this setting (BRR[7:0] = 0x00 and SMR.CKS[1:0] = 00b) is not available.



Note 1. Holds a high level except during continuous transfer.

Figure 24.62 Data format in clock synchronous serial communications with LSB-first order

24.6.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected based on the SCR.CKE[1:0] setting.

When the SCI operates on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character. When no transfer is performed, the clock is held high. However, when only data reception is performed while the CTS function is disabled, the synchronization clock output starts when the SCR.RE bit set to 1. The synchronization clock stops when it goes high*1 and an overrun error occurs or the SCR.RE bit is set to 0.

When only data reception is performed and the CTS function is enabled, the clock output does not start when the SCR.RE bit set to 1 and the CTSn_RTSn pin input is high. The synchronization clock output starts when the SCR.RE bit is set to 1 and the CTSn_RTSn pin input is low. Following that, when the CTSn_RTSn pin input is high on completion of the frame reception, the synchronization clock output stops when it goes high. If the CTSn_RTSn pin input continues to be low, the synchronization clock stops when it goes high*1 and an overrun error occurs or the SCR.RE bit is set to 0.

Note 1. The signal is held high while (SPMR.CKPH = 0 and SPMR.CKPOL = 1) or (SPMR.CKPH = 1 and SPMR.CKPOL = 1). It is held low while (SPMR.CKPH = 0 and SPMR.CKPOL = 1) or (SPMR.CKPH = 1 and SPMR.CKPOL = 0).

24.6.2 CTS and RTS Functions

In the CTS function, the CTSn_RTSn pin input controls the start of data reception or transmission when the clock source is the internal clock. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, setting the CTSn_RTSn pin low causes data reception or transmission to start.

注3。当在前言区域或起始位区域中检测到SYER时,根据SYEREN位而作为错误处理的行为发生变化。

24.6 时钟同步模式下操作

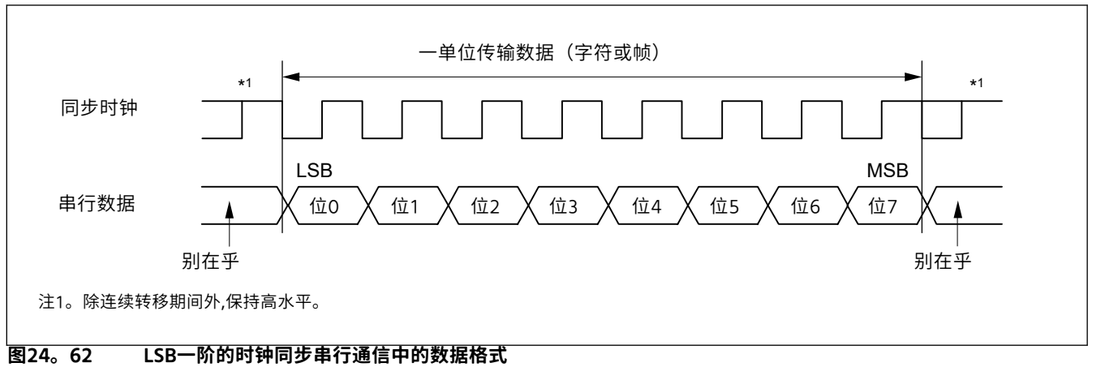
图24。62显示了时钟同步串行数据通信的数据格式。

在时钟同步模式下,数据与时钟脉冲同步发送或接收。对于单字符数据传输,数据由 8 位组成。在时钟同步模式下,不能添加奇偶校验位。

在数据传输中,SCI将数据从同步时钟的一个下降沿输出到下一个下降沿。在数据接收中,SCI与同步时钟的上升沿同步接收数据。8位数据输出后,传输线将最后一位作为输出状态。当从模式下SPMR。CKPH位为1时,传输线保持第一位输出状态。

在 SCI 内,发射机和接收机是独立的单元,通过使用共享时钟实现全双工通信。发射机和接收机还具有双缓冲结构,使得可以在传输期间写入下一个发射数据或在接收期间读取上一个接收数据,从而实现连续的数据传输。

然而,不可能在最快比特率设置中执行连续传输（BRR[7:0] = 0x00 和 SMR。CKS[1:0] = 00b）。因此,当选择 FIFO 时,此设置（BRR[7:0] = 0x00 和 SMR。CKS[1:0] = 00b）不可用。



注1。除连续转移期间外,保持高水平。

图24。62 LSB一阶的时钟同步串行通信中的数据格式

24。6。1 时钟

SCR。CKE[1:0] 设置的基础上, 可以选择由片上波特率发生器生成的内部时钟或SCKn引脚处的外部同步时钟输入。

SCI 在内部时钟上工作时,同步时钟从 SCKn 引脚输出。在一个字符的传输中输出八个同步时钟脉冲。当不执行传输时,时钟会保持高电平。然而,当在禁用CTS功能时仅执行数据接收时,当SCR。RE位设置为1时,同步时钟输出开始。*1 高时同步时钟停止,发生超限错误或 SCR。RE 位设置为 0。

仅执行数据接收并启用CTS功能时,当SCR。RE位设置为1且CTSn_RTSn引脚输入较高时,时钟输出不会开始。SCR。RE 位设置为 1 且 CTSn_RTSn 引脚输入较低时,同步时钟输出开始。接下来,当帧接收完成时CTSn_RTSn引脚输入较高时,同步时钟输出在较高时停止。CTSn_RTSn引脚输入持续低电平,则同步时钟在走高*1时停止,出现超限错误或将SCR。RE位设置为0。

注1。当（SPMR。CKPH = 0 和 SPMR。CKPOL = 1)或（SPMR。CKPH = 1 和 SPMR。CKPOL = 1)。当（SPMR。CKPH = 0 和 SPMR。CKPOL = 1)或（SPMR。CKPH = 1 和 SPMR。CKPOL = 0)时,它保持在较低水平。

24。6。2 CTS 和 RTS 功能

CTS功能中,CTSn_RTSn引脚输入控制时钟源为内部时钟时数据接收或传输的开始。将 SPMR。CTSE 位设置为 1 可以启用 CTS 功能。CTS 功能启用时,将 CTSn_RTSn 引脚设置为低会导致数据接收或传输启动。

Setting the CTSn_RTSn pin high while the data transmission or reception is in progress does not affect transmission or reception of the current frame.

In the RTS function, the CTSn_RTSn pin output is used to request the start of data reception or transmission when the clock source is an external synchronizing clock. The CTSn_RTSn output goes low when serial communication is enabled. Conditions for output of the CTSn_RTSn low and high are shown as follows:

[Conditions for low output]

Satisfaction of all the following conditions:

Non-FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- Neither transmission nor reception is in progress
- There is no received data available to be read when the SCR.RE bit is 1
- Transmit data is written when the SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR.ORER flag is 0

FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- Neither transmission nor reception is in progress
- The amount of receive data written in FRDRHL is less than the setting value of FCRH.RSTRG[3:0] when SCR.RE = 1
- Data that has not been transmitted is available in FTDRHL when SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR_FIFO.ORER flag is 0

[Condition for high output]

- The conditions for low output are not satisfied

24.6.3 SCI Initialization in Clock Synchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the SCR register, then continue through the SCI initialization procedure given in the sections describing non-FIFO and FIFO selection in section 24.6.2. CTS and RTS Functions. Anytime the operating mode or transfer format is to be changed, the SCR register must be initialized before the change can be made.

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in SSR/SSR_FIFO nor the RDR register. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: In non-FIFO mode, switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 when the SCR.TIE bit is 1 generates an SCIn_TXI interrupt request.

Table 24.35 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (1 of 2)

CTSn_RTSn引脚在数据传输或接收进行时设置为高,不影响当前帧的传输或接收。

RTS功能中,CTSn_RTSn引脚输出用于请求当时钟源为外部同步时钟时开始数据接收或传输。当启用串行通信时,CTSn_RTSn 输出会变低。
CTSn_RTSn低和高输出的条件如下所示:

[产量低的条件] 以下所有条件的满意度:

当满足以下所有条件时选择非 FIFO

- SCR。RE 位或 SCR。TE 位的值为 1
- 传输和接收均未进行中
- 当 SCR。RE 位为 1 时,没有接收到的数据可供读取
- 传输数据是在 SCR。TE 位为 1、SCR。CKE[1] 位为 0 时写入的
- 当 SCR。TE 位为 1 且 SCR。CKE[1] 位为 1 时,数据可用于在 TSR 寄存器中传输
- SSR。ORER 标志是 0

当满足以下所有条件时选择 FIFO

- SCR。RE 位或 SCR。TE 位的值为 1
- 传输和接收均未进行中
- 当 SCR。RE = 1 时,用 FRDRHL 编写的接收数据量小于 FCRH。RSTRG[3:0] 的设置值
- 未传送的数据在 SCR。TE 位为 1 且 SCR。CKE[1] 位为 0 时可在 FTDRHL 中获取
- 当 SCR。TE 位为 1 且 SCR。CKE[1] 位为 1 时,数据可用于在 TSR 寄存器中传输
- SSR_FIFO。ORER 标志为 0

件 【高产出条件】

- 不满足低输出的条件

24.6.3 时钟同步模式下的SCI初始化

在传输和接收数据之前,首先将初始值 0x00 写入 SCR 寄存器,然后继续通过第 24。6。2 节中描述非 FIFO 和 FIFO 选择的部分中给出的 SCI 初始化过程。CTS 和 RTS 功能。每当要更改操作模式或传输格式时,必须初始化 SCR 寄存器才能进行更改。

注意:将 SCR。RE 位设置为 0 既不会初始化 SSR/SSR_FIFO 中的 ORER、FER 和 PER 标志,也不会初始化 RDR 寄存器。TE 位设置为 0 时, 所选 FIFO 缓冲区的 TEND 标志未初始化。

注意:在非 FIFO 模式下,当 SCR。TIE 位为 1 时,将 SCR。TE 位的值从 1 切换到 0 或 0 切换到 1 会生成 SCRIn_TXI 中断请求。

24.6.4 时钟同步模式下的串行数据传输

（一）非FIFO入选

图24。63、图24。64和图24。65示出了时钟同步模式下的串行传输的示例。

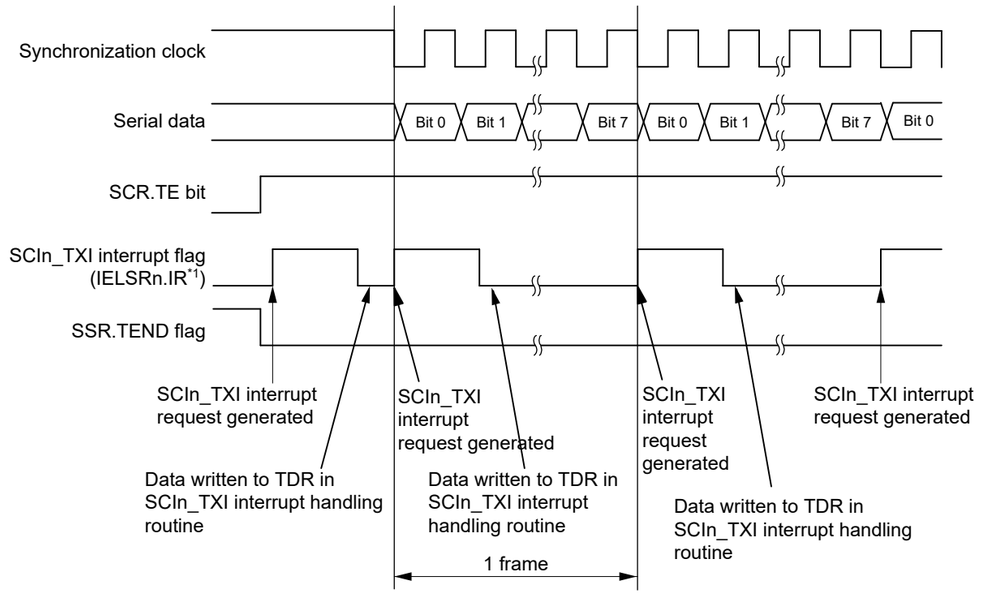
In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. The SCIn_TXI interrupt request at the beginning of transmission is generated when the TE bit is set to 1 but only after the TIE bit in the SCR is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data finishes. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks for update to the TDR register on output of the last bit.
5. When the TDR register is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame starts.
6. If TDR is not updated, the SSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Figure 24.63, Figure 24.64, and Figure 24.65 show examples of serial data transmission.

Transmission does not start while a receive error flag (ORER, FER, or PER in SSR) is set to 1. Always set the receive error flags to 0 before starting transmission.

Note: Setting the SCR.RE bit to 0 does not clear the receive error flags.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

SCI 在串行数据传输中, 操作如下:

1。SCI 在 SCIn_TXI 中断处理例程中将数据写入 TDR 时, 会将数据从 TDR 寄存器传输到 TSR 寄存器。TE 位设置为 1 时,但仅在 SCR 中的 TIE 位也设置为 1 后或通过单个指令同时将这两个位设置为 1 时,才会生成传输开始时的 SCIn_TXI 中断请求。

2锛姣涓。将数据从TDR传输到TSR后,SCI开始传输。SCR。TIE 位设置为 1 时,会生成一个 SCIn_TXI 中断请求。SCIn_TXI中断处理例程中写入下一个发送数据到TDR, 在当前发送数据传输结束之前, 能够实现连续传输。SCIn_TEI 中断请求时,在将要传输的最后一数据从 SCIn_TXI 请求的处理例程写入 TDR 寄存器之后,将 SCR。TIE 位设置为 0,将 SCR。TEIE 位设置为 1。

3、指定时钟输出模式时与输出时钟同步,指定使用外部时钟时与输入时钟同步,从TXDn引脚发送8位数据。当SPMR。CTSE位为1时,时钟信号的输出被暂停,直到输入CTS信号较低。

4锛姣涓。SCI 检查最后一位输出的 TDR 寄存器的更新。

5锛姣涓。TDR 寄存器更新时, 下一个传输数据从 TDR 传输到 TSR, 下一个帧的串行传输开始。

6锛　　涓€涓。如果 TDR 未更新,则 SSR。TEND 标志将设置为 1。TXDn引脚保留最后一位的输出状态。SCR。TEIE 位为 1,则会生成 SCIn_TEI 中断请求,并且 SCKn 引脚保持高电平。

图24。63、图24。64和图24。65示出了串行数据传输的示例。

当接收错误标志（SSR 中的 ORER、FER 或 PER）设置为 1 时,传输不会启动。在开始传输之前始终将接收错误标志设置为 0。

注意:将 SCR。RE 位设置为 0 不会清除接收错误标志。

[1] [1]SCI initialization:
Set data transmission.

[2] [2]Writing transmit data write to TDR by an SCIn_TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated.
Transmit data is written to TDR once from the handling routine for SCIn_TXI requests.

[3] [3]Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR upon accepting a transmit data empty interrupt (SCIn_TXI) request. Transmit data can also be written to TDR by activating the DMAC or DTC by theSCIn_TXI interrup trequest.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to theTDR

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

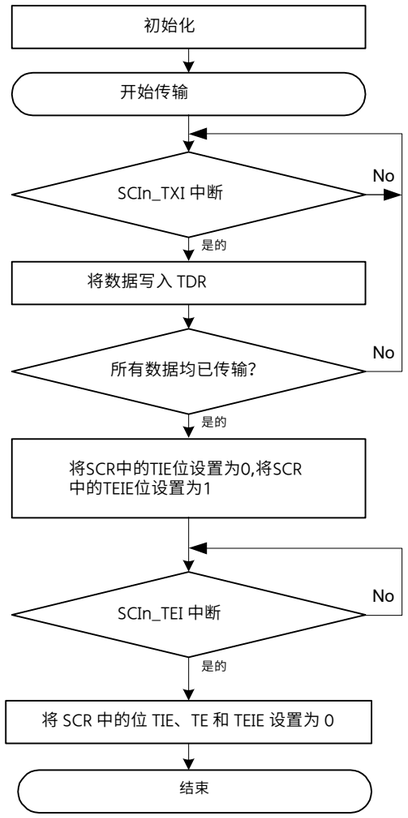
Figure 24.66 Example flow of serial transmission in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 24.67 shows an example of serial transmission in clock synchronous mode with FIFO selected.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the FTDRL*1 register to the TSR register when data is written to FTDRL*1 in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 but only after the SCR.TIE bit is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from FTDRL to TSR, the SCI starts transmission. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, the SSR_FIFO.TDFE is set to 1. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to FTDRL in the SCIn_TXI interrupt handling routine before transmission of the current transmit data has finished. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks whether non-transmitted data remains in FTDRL on output of the stop bit.



[1] [1]SCI 初始化:
设置数据传输。

[2] [2]写入传输数据通过SCIn_TXI中断请求写入TDR:

TDR传输数据到TSR时,会产生一个传输数据空中断（SCIn_TXI）请求。

SCIn_TXI请求的处理例程中发送数据写入TDR一次。

[3] [3]串行传输继续过程:
要继续串行传输,请在接受传输数据空中断（SCIn_TXI）请求时将传输数据写入 TDR。还可以通过 SCIn_TXI 中断 trequest 激活 DMAC 或 DTC 将传输数据写入 TDR。当使用 SCIn_TEI 中断请求时,设置

在将最后要传输的数据写入TDR之后,SCR。TIE比特写入0并且SCR。TEIE比特写入1

注: 用（SCR。CKE[1:0]位的值为10b或11b）时,最后一位的SCKn引脚上的上升沿将SSR。TEND标志设置为1。在此之后立即将 SCR。TE 位设置为 0 可能会导致接收方接收数据保持时间不足。

图24。66 与非 FIFO 选择的时钟同步模式下的串行传输的示例流程

(2)选定的FIFO

图24。67示出了选择了FIFO的时钟同步模式下的串行传输的示例。

SCI 在串行数据传输中, 操作如下:

1。SCI 将数据从 FTDRL *1 寄存器传输到 TSR 寄存器, 当数据在 SCIn_TXI 中断处理例程中写入 FTDRL *1 时。可写入 FTDRL 的数据量为 16 减去 FDR。T[4:0] 字节。SCR。TE位被设置为1时,但只有在SCR。TIE位也被设置为1之后或者当这两个位被单个指令同时设置为1时,才会生成传输开始时的SCIn_TXI中断请求。

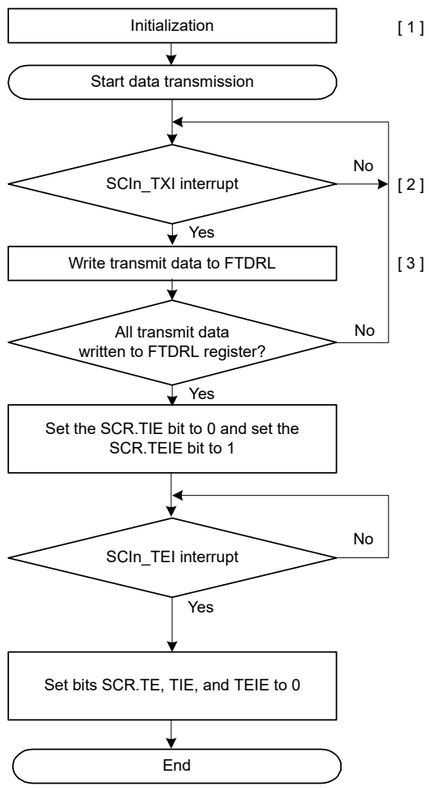
2锛姣涓。将数据从 FTDRL 传输到 TSR 后,SCI 开始传输。FTDRL写入的发送数据量等于或小于指定的发送触发数时,将SSR_FIFO。TDFE设置为1。SCR。TIE 位设置为 1 时,会生成一个 SCIn_TXI 中断请求。SCIn_TXI中断处理例程中在当前发送数据的传输完成之前将下一个发送数据写入FTDRL,从而实现连续传输。SCIn_TEI 中断请求时,在将要传输的最后一数据从 SCIn_TXI 请求的处理例程写入 FTDRL 后,将 SCR。TIE 位设置为 0,将 SCR。TEIE 位设置为 1。

3、指定时钟输出模式时与输出时钟同步,指定使用外部时钟时与输入时钟同步,从TXDn引脚发送8位数据。当SPMR。CTSE位为1时,时钟信号的输出被暂停,直到输入CTS信号较低。

4锛姣涓。SCI 检查停止位输出时未传输的数据是否保留在 FTDRL 中。

5. When FTDRL is updated, the next transmit data is transferred from FTDRL to TSR and serial transmission of the next frame starts.
6. If FTDRL is not updated, the SSR_FIFO.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Note 1. In clock synchronous mode, FTDRH is not used.



[1]SCI initialization:
Set data transmission.
After the TE bit in SCR is set to 1, 1 is output for a frame, and transmission is enabled.

[2]Transmit data write to FTDRL by an SCIn_TXI interrupt request:
For transmission data from FTDRL to TSR, when the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL once in the SCIn_TXI interrupt handling routine.

[3]Serial transmission continuation procedure:
To continue serial transmission, write the next transmit data to FTDRL in this SCIn_TXI interrupt handling routine and clear the SSR_FIFO.TDFE flag to 0 before transmission of the current transmit data finishes.
Transmit data can also be written to FTDRL by activating the DMAC or DTC. The TDFE flag is cleared automatically in this case. Do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL.

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR_FIFO.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

24.6.5 Serial Data Reception in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 24.68 and Figure 24.69 show examples of SCI operation for serial reception in clock synchronous mode.

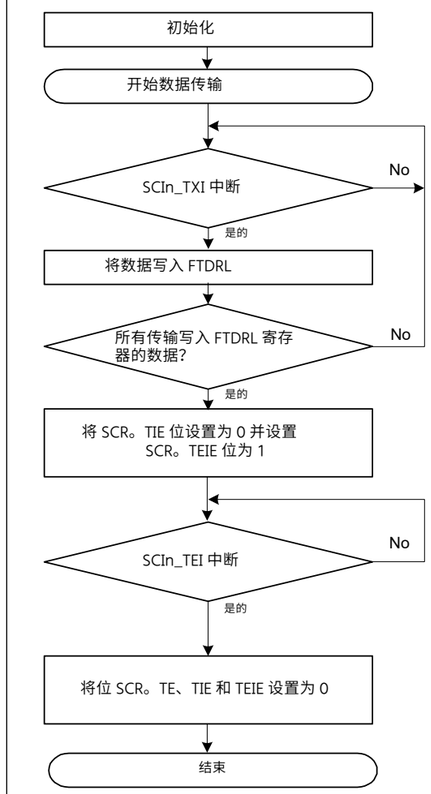
In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.

5锛姣涓。当FTDRL更新时,下一个传输数据从FTDRL传输到TSR并且下一个帧的串行传输开始。

6锛 涓€涓。FTDRL 未更新,则将 SSR_FIFO。TEND 标志设置为 1。TXDn引脚保留最后一位的输出状态。SCR。TEIE 位为 1,则会生成 SCIn_TEI 中断请求,并且 SCKn 引脚保持高电平。

注1。在时钟同步模式下,不使用 FTDRH。



[1]SCI 初始化:
设置数据传输。
SCR中的TE位设置为1后,为一帧输出1,并启用传输。

[2]通过SCIn_TXI中断请求将数据写入FTDRL:对于从FTDRL到TSR的传输数据,当以FTDRL写入的传输数据量等于或小于指定的传输触发数时,生成传输数据FIFO空中断（SCIn_TXI）请求。SCIn_TXI 中断处理例程中将传输数据写入 FTDRL 一次。

[3]串行传输继续过程:
要继续串行传输,请将下一个传输数据写入
FTDRL 在此 SCIn_TXI 中断处理例程并清除
SSR_FIFO。TDFE 标志到当前传输数据的传输结束之前的 0。

还可以通过激活将数据写入 FTDRL
DMAC 或 DTC。在这种情况下,TDFE 标志会自动清除。
请勿写入 TDFE 标志。
当使用 SCIn_TEI 中断请求时,设置
在将要传输的最后一个数据写入FTDRL之后,SCR。TIE比特写入0并且SCR。TEIE比特写入1。

注: 用（SCR。CKE[1:0]位的值为10b或11b）时,最后一位的SCKn引脚上的上升沿将SSR_FIFO。TEND标志设置为1。在此之后立即将 SCR。TE 位设置为 0 可能会导致接收方接收数据保持时间不足。

24。6。5 时钟同步模式下的串行数据接收

（一）非FIFO入选

图24。68和图24。69示出了用于时钟同步模式下的串行接收的SCI操作的示例。

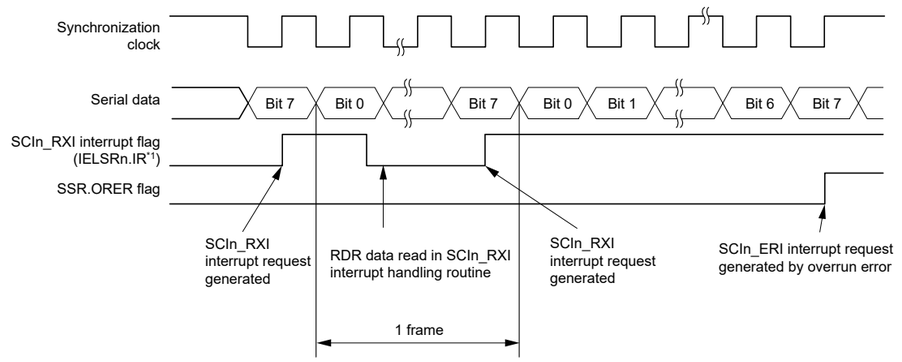
SCI 在串行数据接收中, 操作如下:

1。SCR。RE 位的值变为 1 时,CTSn_RTSn 引脚变低。

2锛姣涓。SCI进行内部初始化,并开始与同步时钟输入或输出同步接收数据,并将接收数据存储在RSR寄存器中。

3锛 娴 。如果发生溢出错误,SSR。ORER 标志将设置为 1。SCR。RIE 位为 1,则生成 SCIn_ERI 中断请求。接收数据不会传输到 RDR 寄存器。

4. When reception completes successfully, receive data is transferred to the RDR register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the received data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that is transferred to RDR causes the CTSn_RTSn pin to output low.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

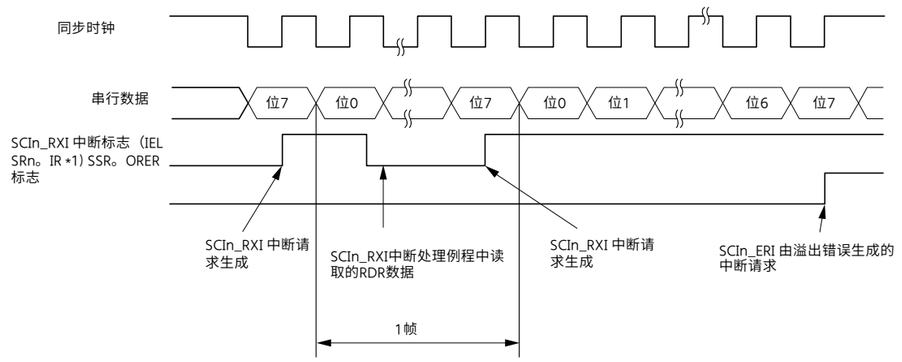
Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 24.69 Example operation for serial reception in clock synchronous mode (2) when RTS function is used

Data transfer cannot resume while the receive error flag is 1. Therefore, clear the ORER, FER, and PER flags in the SSR register to 0 before resuming data reception. Additionally, always read the RDR register during overrun error processing. When a data reception is forced to terminate by a 0 write to the SCR.RE bit during operation, read the RDR register because received data that is not yet read might be left in the RDR register.

4锛姣涓。当接收成功完成时,接收数据将被传输到 RDR 寄存器。SCR。RIE 位为 1,则生成 SCIn_RXI 中断请求。SCIn_RXI 中断处理例程中读取传输到 RDR 寄存器的接收数据, 在下一个接收数据的接收完成之前, 能够实现连续接收。读取传输到 RDR 的接收数据会导致 CTSn_RTSn 引脚输出低电平。



注1。有关相应中断事件编号的信息,请参阅第 12 节"中断控制器单元（ICU）"。

图24。69当使用RTS功能时 时钟同步模式(2)下的串行接收的示例操作

当接收错误标志为 1 时,数据传输无法恢复。因此,在恢复数据接收之前,将 SSR 寄存器中的 ORER、FER 和 PER 标志清除为 0。此外,在溢出错误处理期间始终读取 RDR 寄存器。

当数据接收在操作期间被0写入SCR。RE位强制终止时,读取RDR寄存器,因为接收到的尚未读取的数据可能留在RDR寄存器中。

1。SCR。RE 位的值变为 1 时,CTSn_RTSn 引脚变低。

2锛姣涓涓。SCI进行内部初始化,并开始与同步时钟输入或输出同步接收数据,并将接收数据存储在RSR寄存器中。

3. If an overrun error occurs, the SSR_FIFO.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Received data is not transferred to the FRDRL*1 register.
4. When data reception completes successfully, the receive data is transferred to the FRDRL*1 register. The RDF flag is set to 1 when the amount of the receive data stored in FRDRL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous data reception is enabled by reading the receive data transferred to FRDRL*2 in the SCIn_RXI interrupt handling routine before an overrun error occurs. If the amount of received data that is transferred to FRDRL is less than the specified receive triggering number, the CTSn_RTSn pin goes low.

Note 1. In clock synchronous mode, FRDRH is not used.
Note 2. Read data in order from FRDRH to FRDRL when RDF and ORER are read with receive data.

3锛 娴 。SSR_FIFO。ORER 标志如果发生超限错误,则该标志设置为 1。SCR。RIE 位为 1,则生成 SCIn_ERI 中断请求。接收到的数据不会传输到 FRDRL *1 寄存器。

4锛姣涓。当数据接收成功完成时,接收数据被传送到FRDRL *1寄存器。RDF标志设置为1,当存储在FRDRL中的接收数据的量等于或大于指定的接收触发数。SCR。RIE 位为 1,则生成 SCIn_RXI 中断请求。SCIn_RXI 中断处理例程中读取传输到 FRDRL *2 的接收数据, 在发生溢出错误之前, 能够实现连续数据接收。如果传输到 FRDRL 的接收数据量小于指定的接收触发号码,则 CTSn_RTSn 引脚变低。

2. Initialize the SCR register, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

在 RDR 中读取接收数据一次
SCIn_RXI 中断请求处理例程。

[5] 串行发送/接收继续过程: 要继续串行发送和接收, 在接收到当前帧的MSB位7之前, 完成SCIn_RXI中断对RDR中的接收数据的读取。另外,在当前帧的MSB位7被发送之前,通过SCIn_TXI中断将数据写入TDR。

还可以通过发送数据空中断（SCIn_TXI）请求激活DMAC或DTC来将发送数据写入TDR。类似地,还可以通过接收数据完全中断（SCIn_RXI）请求激活DMAC或DTC来读取RDR数据。

注: 从发送或接收操作切换到同时发送和接收操作时,首先设置TIE、RIE、SCR 中的 TE、RE 和 TEIE 位设置为 0,然后同时将 TIE、RIE、TE 和 RE 位设置为 1。

图24。72 与非 FIFO 选择的时钟同步模式下同时串行发送和接收的示例流程

(2)选定的FIFO

图24。73示出了选择有FIFO的时钟同步模式下的同时串行发送和接收操作的示例流程。

SCI 初始化后,使用以下过程同时进行串行数据发送和接收操作。

要从发送模式切换到同时发送和接收模式:

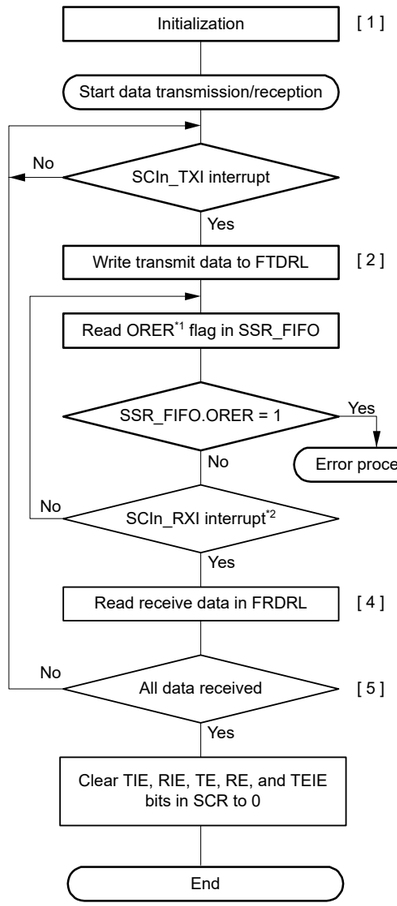
1。SSR_FIFO。TEND标志设置为1的验证来检查SCI是否完成了传输。

2锛姣涓涓。SCR寄存器初始化,然后通过单条指令将SCR寄存器中的TIE、RIE、TE、RE位同时设置为1。

要从接收模式切换到同时发送和接收模式:

1。检查 SCI 是否完成接收。

2. Set the RIE and RE bits to 0.
3. Check that the receive error flags ORER in the SSR_FIFO register are 0, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.



[1] SCI initialization:
The TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[2] Transmit data write:
Write transmit data to FTDRL in the SCIn_TXI interrupt request handling routine. The number of transmission data that can be written is 16 bits, which is the number of stored transmit data in the FIFO.

[3] Receive error processing:
If a receive error occurs, read the ORER flag in SSR_FIFO, performthe relevant error processing, and then set the ORER flag to 0. Data reception cannot resume while the ORER flag is 1.

[4] Reading receive data:
The reception data stored in FRDRL register is read until the number of stored data is less than the FCR.RTRG value. Software can check readable data in FDR.R[4:0].

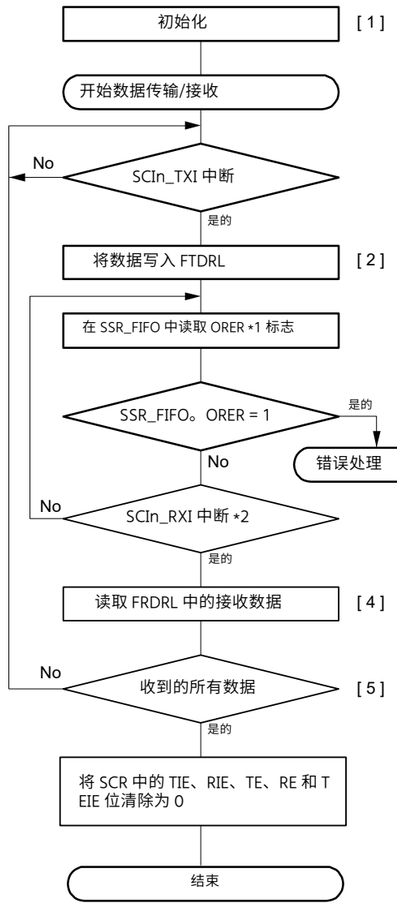
[5] Serial transmission/reception continuation procedure:
To continue serial reception, before overrun error occurs, finish reading the receive data in FRDRL and clear the SSR_FIFO.RDF flag to 0. To continue serial transmission, before transmission of the current transmit data is finished, write the next transmit data to FTDRL in the SCIn_TXI interrupthandling routine and clear the SSR_FIFO.TDFE flag to 0.
Transmit data can also be written to FTDRL by activating the DMAC or DTC by a transmit FIFO data empty interrupt (SCIn_TXI) request. Similarly, the FRDRL data can also be read by activating the DMAC or DTC by a receive FIFO data full interrupt (SCIn_RXI) request.
The RDF and TDFE flags are cleared automatically in this case. Do not write to the RDF and TDFE flags.

Note 1. It can also be read from FRDRH.ORER. To clear the ORER flag, write 0 to the associated bit in the SSR_FIFO register.
Note 2. It should be all receive data with amount an integer times FIFO triggering number.

Figure 24.73 Example flow of simultaneous serial transmission and reception in clock synchronous mode with FIFO selected

2锛姣涓涓。将 RIE 和 RE 位设置为 0。

3锛 娴 。SSR_FIFO寄存器中的接收错误标志ORER是否为0,然后通过单条指令同时将SCR寄存器中的TIE、RIE、TE、RE位设置为1。



[1] SCI 初始化:
TXDn引脚可以作为传输数据的输出引脚,RXDn引脚可以同时作为接收数据的输入引脚。

[2] 传输数据写入:
SCIn_TXI 中断请求处理例程中将传输数据写入 FTDRL。可以写入的传输数据数量为16位,即FIFO中存储的传输数据数量。

[3] 接收错误处理:
如果发生接收错误,请读取 ORER 标志
SSR_FIFO,进行相关的错误处理,然后将ORER标志设置为0。当 ORER 标志为 1 时,数据接收无法恢复。

[4] 读取接收数据:
读取存储在FRDRL寄存器中的接收数据,直到存储的数据数量小于FCR。RTRG值。软件可以在 FDR。R[4:0] 中检查可读数据。

[5] 串行传输/接收继续过程:
要继续串行接收,请在发生溢出错误之前,完成读取 FRDRL 中的接收数据并将 SSR_FIFO。RDF 标志清除为 0。要继续串行传输,在当前传输数据的传输完成之前,将SCIn_TXI中断处理例程中的下一个传输数据写入FTDRL,并将SSR_FIFO。TDFE标志清除为0。

还可以通过发送FIFO数据空中断（SCIn_TXI）请求激活DMAC或DTC来将发送数据写入FTDRL。类似地,还可以通过接收FIFO数据完全中断（SCIn_RXI）请求激活DMAC或DTC来读取FRDRL数据。

在这种情况下,RDF 和 TDFE 标志会自动清除。请勿写入 RDF 和 TDFE 标志。

注1。它也可以从 FRDRH。ORER 读取。ORER 标志清除,请将 0 写入 SSR_FIFO 寄存器中的关联位。
注2。它应该全部接收金额为 FIFO 触发号整数倍的数据。

24.7 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

24.7.1 Example Connection

Figure 24.74 shows an example connection between a smart card (IC card) and the MCU. As shown in Figure 24.74, because the MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

Setting the SCR_SMCI.TE and SCR_SMCI.RE bits to 1 with an IC card disconnected enables closed-loop transmission or reception, allowing self-diagnosis. To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.

An output port of the MCU can be used to output a reset signal.

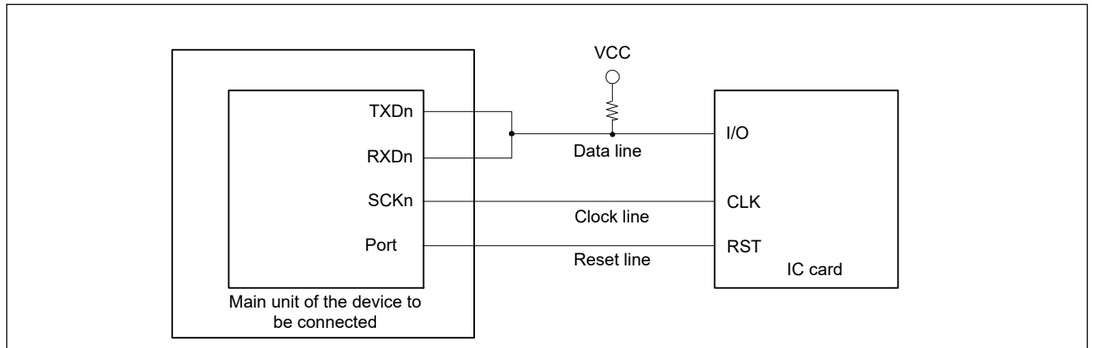

Figure 24.74 Example connection with a smart card (IC card)

24.7.2 Data Format (Except in Block Transfer Mode)

Figure 24.75 shows the data transfer formats in smart card interface mode:

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etus (elementary time unit – the time required for transferring 1 bit) is set as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low error signal is output for 1 etu after 10.5 etus elapse from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etus.

24。7 在智能卡接口模式下操作

SCI支持符合ISO/IEC 7816-3（身份证标准）的智能卡（IC卡）接口,作为SCI的扩展功能。

可以使用适当的寄存器选择智能卡接口模式。

24。7。1 示例连接

图24。74示出了智能卡（IC卡）和MCU之间的示例连接。24。74所示,由于MCU使用单传输线与IC卡通信,因此将TXDn和RXDn引脚互连,并使用电阻将数据传输线拉上VCC。

IC卡断开的情况下将SCR_SMCI。TE和SCR_SMCI。RE位设置为1,可实现闭环传输或接收,从而实现自我诊断。为了向IC卡提供SCI生成的时钟脉冲,请将SCKn引脚输出输入到IC卡的CLK引脚。

MCU的输出端口可以用来输出复位信号。

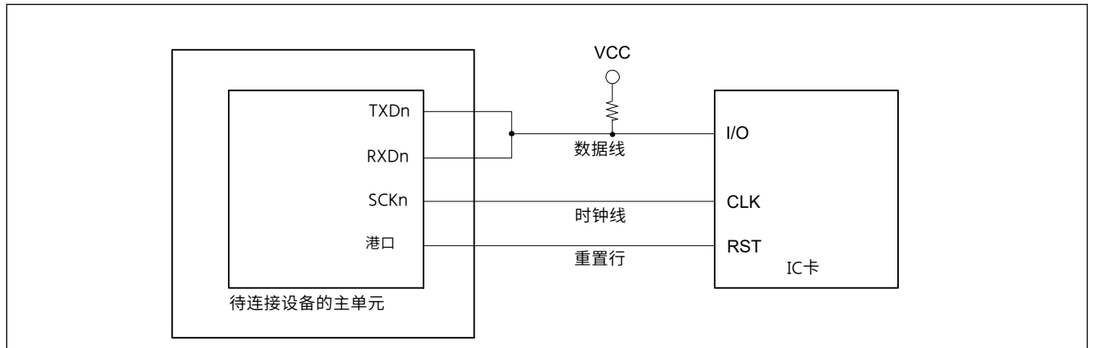

图24。74 与智能卡（IC 卡）的连接示例

24。7。2 数据格式（块传输模式除外）

图 24。75 显示了智能卡接口模式下的数据传输格式:

- 一帧由 8 位数据和异步模式下的奇偶校验位组成。
- 传输过程中,至少 2 etus（基本时间单位 – 传输 1 位所需的时间）被设置为从奇偶校验位结束到下一帧开始的守护时间。
- 如果在接收期间检测到奇偶校验误差,则在从开始位经过10。5 etu之后,输出1 etu的低误差信号。
- 如果在传输过程中对错误信号进行采样,则在至少 2 etus 后自动重传相同的数据。

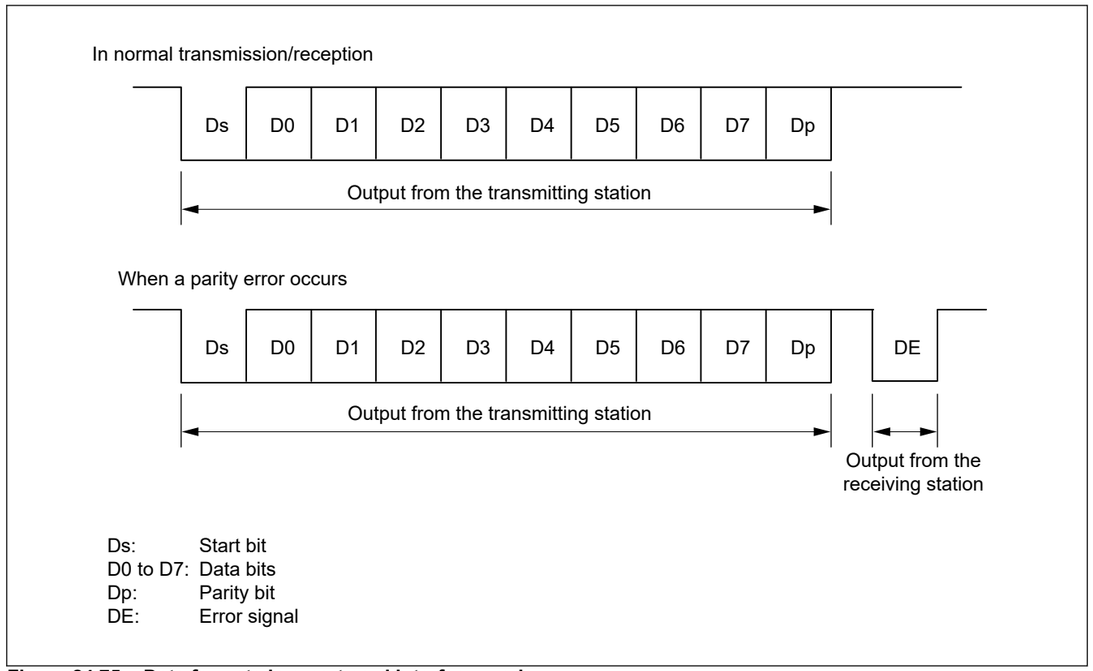

Figure 24.75 Data formats in smart card interface mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedures in this section.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 indicate the Z and A states, respectively, and data is transferred with LSB-first for the start character, as shown in Figure 24.76. Therefore, data in the start character in the figure is 0x3B.

When using the direct convention type, write 0 to both the SCMR.SDIR and SCMR.SINV bits. Write 0 to the SMR_SMCI.PM bit to use even parity, which is prescribed by the smart card standard.

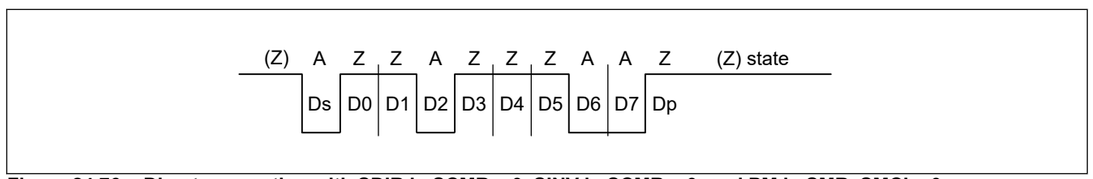

Figure 24.76 Direct convention with SDIR in SCMR = 0, SINV in SCMR = 0, and PM in SMR_SMCI = 0

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 indicate the A and Z states, respectively, and data is transferred with MSB-first for the start character, as shown in Figure 24.77. Therefore, data in the start character in the figure is 0x3F.

When using the inverse convention type, write 1 to both the SCMR.SDIR and SCMR.SINV bits. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to the Z state. Because the SINV bit of the MCU only inverts data bits D7 to D0, write 1 to the PM bit in SMR_SMCI to invert the parity bit for both transmission and reception.

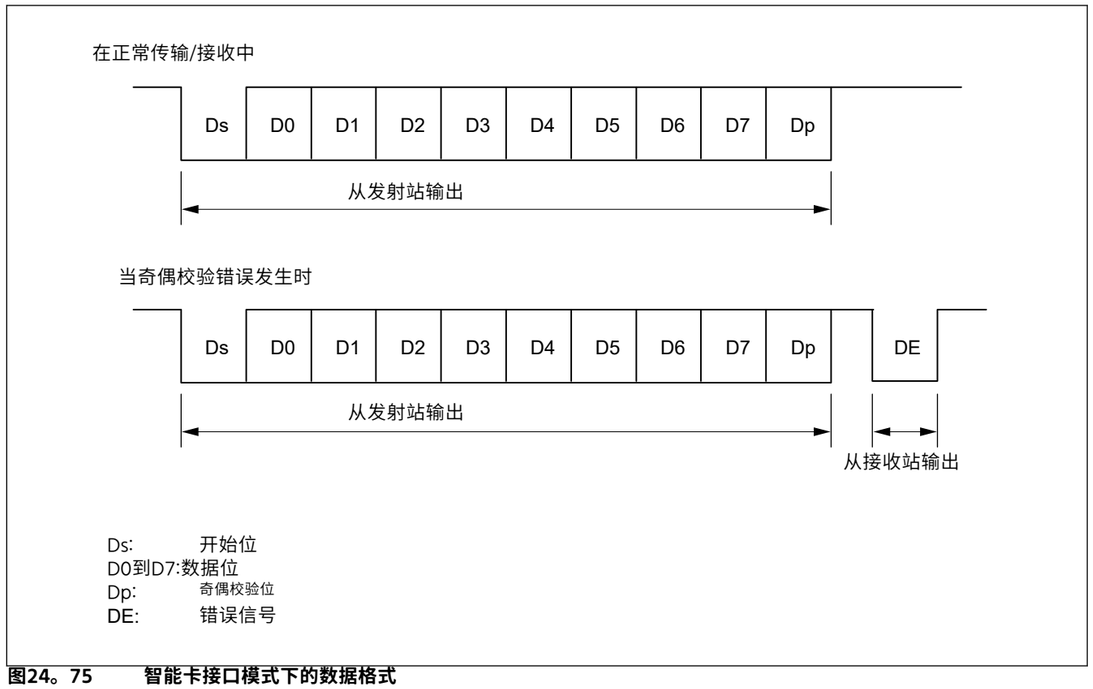

图24。75 智能卡接口模式下的数据格式

IC卡直接约定型和反约定型的通信,请按照本节中的程序操作。

(1) 直接公约类型

对于直接约定类型,逻辑级别 1 和 0 分别指示 Z 和 A 状态,并传输数据
LSB- 首先用于开始字符,如图 24。76 所示。因此,图中起始字符中的数据为 0x3B。

当使用直接约定类型时,将 0 写入 SCMR。SDIR 和 SCMR。SINV 位。将 0 写入
SMR_SMCI。PM位来使用偶奇偶校验,这是由智能卡标准规定的。

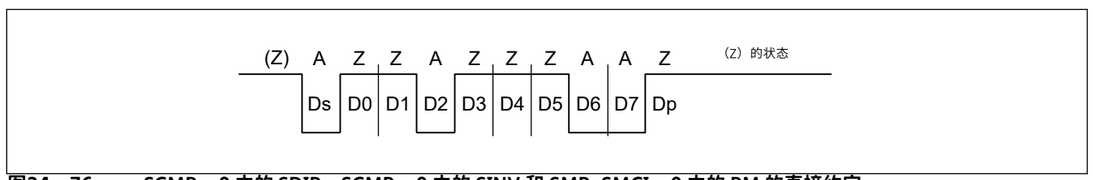

图24。76 SCMR = 0 中的 SDIR、SCMR = 0 中的 SINV 和 SMR_SMCI = 0 中的 PM 的直接约定

(2) 反约定类型

对于逆约定类型,逻辑级别 1 和 0 分别指示 A 和 Z 状态,并传输数据
MSB- 首先用于开始字符,如图 24。77 所示。因此,图中起始字符中的数据为 0x3F。

使用逆约定类型时,将 1 写入 SCMR。SDIR 和 SCMR。SINV 位。奇偶校验位为逻辑电平0,产生偶校验,由智能卡标准规定,对应Z状态。由于MCU的SINV位仅将数据位D7反转为D0,因此在SMR_SMCI中将1写入PM位以反转传输和接收的奇偶校验位。

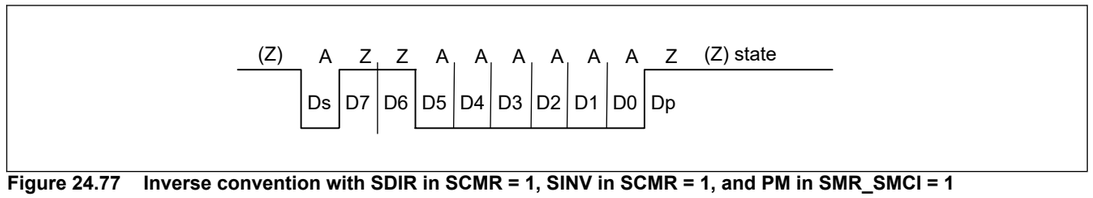

Figure 24.77 Inverse convention with SDIR in SCMR = 1, SINV in SCMR = 1, and PM in SMR_SMCI = 1

24.7.3 Block Transfer Mode

Block transfer mode differs from normal smart card interface mode as follows:

- Even if a parity error is detected during reception, no error signal is output. Because the PER flag in SSR_SMCI is set by error detection, clear the PER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is set as a guard time from the end of the parity bit until the start of the next frame
- Because the same data is not retransmitted, the TEND flag in SSR_SMCI is set to 11.5 etus after transmission starts
- In block transfer mode, the ERS flag in SSR_SMCI indicates the error signal status as in normal smart card interface mode, but the flag is read as 0 because no error signal is transferred

24.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate set up in the SCMR.BCP2 and the SMR_SMCI.BCP[1:0] bits. The frequency is always 16 times the bit rate in normal asynchronous mode.

For data reception, the falling edge of the start bit is sampled with the base clock to perform internal synchronization. Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 24.78. The reception margin is determined by the following formula:

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%]$$

M: Reception margin (%)

N: Ratio of bit rate to clock ($N = 32, 64, 372, 256$)

D: Duty cycle of clock ($D = 0$ to 1.0)

L: Frame length ($L = 10$)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the specified formula, the reception margin is determined using the following formula:

$$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\ \%$$

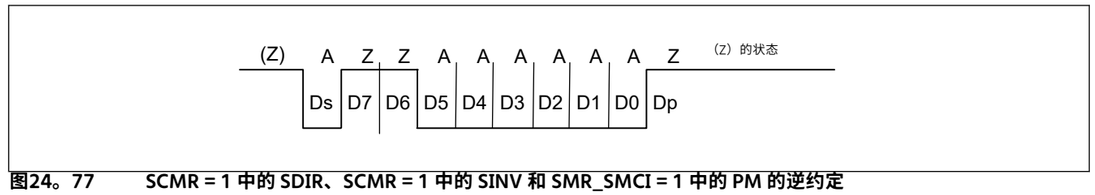

图24。77 SCMR = 1 中的 SDIR、SCMR = 1 中的 SINV 和 SMR_SMCI = 1 中的 PM 的逆约定

24。7。3 块传输模式

块传输模式与普通智能卡接口模式不同如下:

● 即使在接收过程中检测到奇偶校验错误, 也不会输出错误信号。SSR_SMCI 中因为 PER 标志是通过错误检测来设置的,所以在接收到下一帧的奇偶校验位之前清除 PER 标志。

● 在传输过程中,至少 1 etu 被设置为从奇偶校验位结束到下一帧开始的保护时间

● 因为相同的数据没有重传,所以在传输开始后,SSR_SMCI 中的 TEND 标志被设置为 11。5 etus

● 在块传输模式下,SSR_SMCI 中的 ERS 标志指示错误信号状态与正常智能卡接口模式下一样,但由于没有传输错误信号,因此该标志读作 0

24。7。4 接收数据采样时序和接收裕度

只有片上波特率发生器生成的内部时钟才能在智能卡接口模式下用作传输时钟。

在这种模式下,SCI可以在频率为SCMR。BCP2和SMR_SMCI。BCP[1:0]中设置的比特率的32、64、372、256、93、128、186或512倍的基时钟上操作。] 位。在正常异步模式下,频率始终是比特率的 16 倍。

对于数据接收,使用基时钟对起始位的下降沿进行采样以执行内部同步。16、32、186、128、46、64、93、256个基时钟的上升沿对接收数据进行采样,以便可以如图24。78所示在每个位的中部进行锁存。接收裕度由以下公式确定:

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%]$$

M:接待裕度(%)

N:比特率与时钟的比率 （N = 32,64,372,256) D:
时钟的占空比 （D = 0至1。0) L:帧长度 （L = 10）
F:时钟频率偏差的绝对值

F = 0、D = 0。5、N = 372的值在指定的公式中假设, 接收裕度使用以下公式确定:

X数学X_0 ( )}

24.7.5 SCI Initialization (Smart Card Interface Mode)

Before transmitting and receiving data, write the initial value 0x00 in the SCR_SMCI register and initialize the SCI following the example flow shown in Table 24.37.

Always set the initial value in the TIE, RIE, TE, RE, TEIE bits in the SCR_SMCI register before switching from transmission to reception mode or from reception to transmission mode. When SCR_SMCI.RE is set to 0, the RDR register is not initialized.

To change from reception mode to transmission mode, first check that reception has completed, then initialize the SCI. At the end of initialization, set SCR_SMCI.TE = 1 and SCR_SMCI.RE = 0. Reception completion can be verified by reading the SCIn_RXI request, ORER, or PER flag in SSR_SMCI.

To change transmission mode to reception mode, first check that transmission has completed, then initialize the SCI. At the end of initialization, set SCR_SMCI.TE = 0 and SCR_SMCI.RE = 1. Transmission completion can be verified by reading the TEND flag in SSR_SMCI.

24。7。5 SCI 初始化（智能卡接口模式）

在发送和接收数据之前,将初始值 0x00 写入 SCR_SMCI 寄存器中,并按照表 24。37 . 所示的示例流程初始化 SCI

SCR_SMCI寄存器中的TIE、RIE、TE、RE、TEIE位中始终设置初始值,然后再从发送切换到接收模式或从接收切换到发送模式。SCR_SMCI。RE 设置为 0 时,RDR 寄存器不会初始化。

要从接收模式更改为传输模式,首先检查接收是否已完成,然后初始化SCI。初始化结束时,设置 SCR_SMCI。TE = 1,SCR_SMCI。RE = 0。SSR_SMCI 中读取 SCIn_RXI 请求、ORER 或 PER 标志即可验证接收完成。

要将传输模式更改为接收模式,首先检查传输是否已完成,然后初始化SCI。初始化结束时,设置 SCR_SMCI。TE = 0,SCR_SMCI。RE = 1。SSR_SMCI 中读取 TEND 标志即可验证传输完成情况。

24.7.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode) is different from that in non-smart card interface mode, in that an error signal is sampled and data can be re-transmitted in smart card mode. Figure 24.79 shows the data re-transfer operation during transmission.

1. When an error signal from the receiver end is sampled after 1-frame data is transmitted, the SSR_SMCI.ERS flag is set to 1. If the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
2. For a frame in which an error signal is received, the SSR_SMCI.TEND flag is not set. Data is re-transferred from TDR to TSR, allowing automatic data retransmission.
3. If no error signal is returned from the receiver, the ERS flag is not set to 1.
4. In this case, the SCI determines that transmission of 1-frame data, including the re-transfer, is complete, and the TEND flag is set. If the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated. Write transmit data to the TDR to start transmission of the next data.

Figure 24.81 shows an example flow of serial transmission. All the processing steps are automatically performed using an SCIn_TXI interrupt request to activate the DTC or DMAC.

When the SSR_SMCI.TEND flag is set to 1 in transmission and when the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated.

The DTC or DMAC is activated by an SCIn_TXI interrupt request if the SCIn_TXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission when an error occurs. Because the ERS flag is not automatically cleared, set the RIE bit to 1 before enabling an SCIn_ERI interrupt request to be generated if an error occurs, and clear the ERS flag to 0.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings.

For DTC or DMAC settings, see section 16, Data Transfer Controller (DTC), section 15, DMA Controller (DMAC).

24。7。6 串行数据传输（块传输模式除外）

智能卡接口模式下的串行数据传输（块传输模式除外）与非智能卡接口模式下的串行数据传输不同,因为在智能卡模式下可以采样错误信号并重新传输数据。图24。79显示了传输过程中的数据重新传输操作。

1。1帧数据传送后从接收端采样误差信号时,SSR_SMCI。ERS标志被设置为1。如果SCR_SMCI。RIE位为1,则生成SCIn_ERI中断请求。在采样下一个奇偶校验位之前将 ERS 标志清除为 0。

2锛姣涓涓。对于接收到错误信号的帧,不设置SSR_SMCI。TEND标志。数据从 TDR 重新传输到 TSR,从而允许自动数据重传。

3锛　　娴　　。如果没有从接收器返回错误信号,则 ERS 标志不会设置为 1。

4锛姣涓。在这种情况下,SCI确定包括重新传输在内的一帧数据的传输是完整的,并且设置了TEND标志。如果SCR_SMCI。TIE位为1,则生成SCIn_TXI中断请求。将传输数据写入 TDR 以开始传输下一个数据。

图24。81示出了串行传输的示例流程。SCIn_TXI 中断请求来激活 DTC 或 DMAC 自动执行所有处理步骤。

SSR_SMCI。TEND 标志在传输中被设置为 1 并且当 SCR_SMCI。TIE 位为 1 时,会生成 SCIn_TXI 中断请求。

DTC或DMAC由SCIn_TXI中断请求激活,如果SCIn_TXI中断请求先前被指定为DTC或DMAC激活的源,则允许传输数据。DTC或DMAC传输数据时,TEND标志会自动设置为0。

如果发生错误,SCI 会自动重传相同的数据。在此重传期间,TEND 标志保持在 0,并且 DTC 或 DMAC 未激活。因此,SCI 和 DTC 或 DMAC 自动传输指定数量的字节,包括发生错误时的重传。ERS 标志未被自动清除,所以在出现错误时启用 SCIn_ERI 中断请求之前,将 RIE 位设置为 1,并将 ERS 标志清除为 0。DTC 或 DMAC 传输或接收数据时,在进行 SCI 设置之前,始终启用 DTC 或 DMAC。

DTC 或 DMAC 设置, 请参阅第 16 节, 数据传输控制器（DTC）, 第 15 节, DMA 控制器（DMAC）.

24.7.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 24.82 shows the data re-transfer operation in reception mode.

1. If a parity error is detected in the receive data, the SSR_SMCI.PER flag is set to 1. When the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no SCIn_RXI interrupt is generated.
3. When no parity error is detected, the SCR_SMCI.PER flag is not set to 1.
4. In this case, data is determined to be received successfully. When the SCR_SMCI.RIE bit is 1, an SCIn_RXI interrupt request is generated.

Figure 24.83 shows an example flow of serial data reception. All the processing steps are automatically performed using an SCIn_RXI interrupt request to activate the DTC or DMAC.

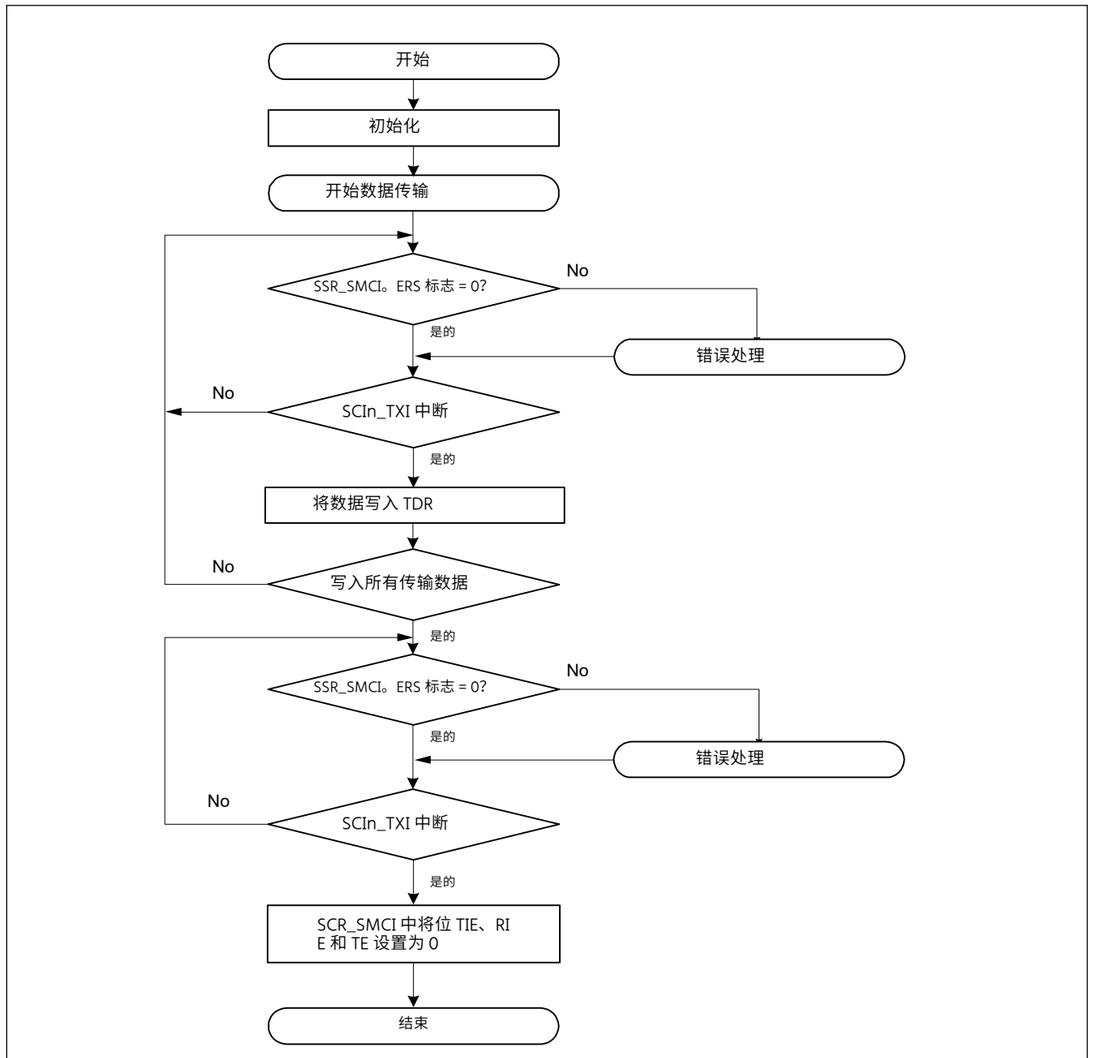

图24。81 智能卡接口传输示例流程

24.7.7 串行数据接收（块传输模式除外）

智能卡接口模式下的串行数据接收与非智能卡接口模式下的串行数据接收类似。图24。82示出了接收模式下的数据重新传输操作。

1。如果在接收数据中检测到奇偶校验错误,则 SSR_SMCI。PER 标志设置为 1。SCR_SMCI。RIE位为1时,生成SCIn_ERI中断请求。PER标志清除到0,然后再对下一个奇偶校验位进行采样。

2锛姣涓涓。对于检测到奇偶校验错误的帧,不会生成 SCIn_RXI 中断。

3锛　　娴　　。当未检测到奇偶校验错误时,SCR_SMCI。PER 标志未设置为 1。

4锛姣涓。在这种情况下,确定数据被成功接收。SCR_SMCI。RIE 位为 1 时,会生成 SCIn_RXI 中断请求。

图24。83示出了串行数据接收的示例流程。所有处理步骤均使用
SCIn_RXI 中断请求以激活 DTC 或 DMAC。

In reception, setting the RIE bit to 1 allows an SCIn_RXI interrupt request to be generated. The DTC or DMAC is activated by an SCIn_RXI interrupt request if the SCIn_RXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in SSR_SMCI is set to 1, a receive error interrupt (SCIn_ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.

If a parity error occurs and the PER flag is set to 1 during reception, the receive data is transferred to RDR, allowing the data to be read.

When a reception is forced to terminate by setting SCR_SMCI.RE to 0 during operation, read the RDR register because the received data that is not yet read might be left in the RDR.

Note: For operations in block transfer mode, see section 24.3.9. Serial Data Reception in Asynchronous Mode.

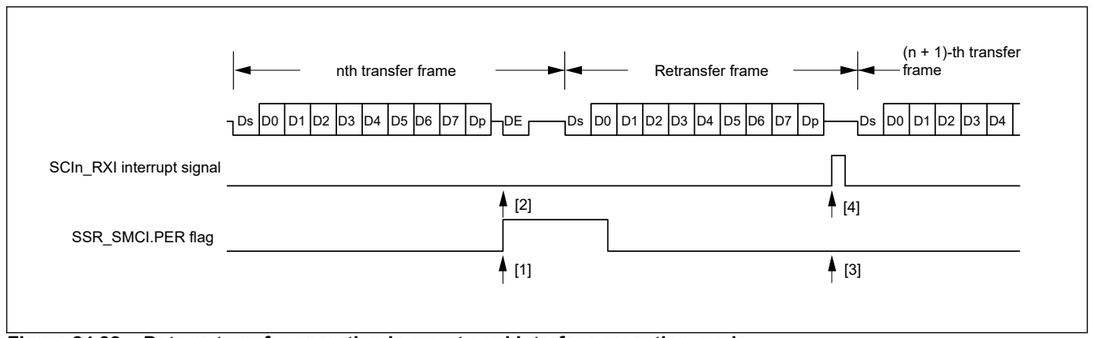

Figure 24.82 Data re-transfer operation in smart card interface reception mode

在接收中,将 RIE 位设置为 1 允许生成 SCIn_RXI 中断请求。DTC或DMAC由SCIn_RXI中断请求激活,如果SCIn_RXI中断请求先前被指定为DTC或DMAC激活的源,则允许接收数据的传输。

如果在接收期间发生错误并且SSR_SMCI中的ORER或PER标志被设置为1,则生成接收错误中断（SCIn_ERI）请求。错误发生后清除错误标志。如果发生错误,DTC 或 DMAC 不会被激活,并且会跳过接收数据。因此,传输DTC或DMAC中指定的接收数据字节数。

如果发生奇偶校验错误并且在接收期间将PER标志设置为1,则接收数据被传输到RDR,从而允许读取数据。

SCR_SMCI。RE 设置为 0 在操作期间强制终止接收时, 读取 RDR 寄存器, 因为接收到的尚未读取的数据可能留在 RDR 中。

注: 对于块传输模式下的操作,请参见第 24。3。9 节。异步模式下的串行数据接收。

24.7.8 Clock Output Control

When the GM bit in SMR_SMCI is set to 1, the clock output can be controlled by the CKE[1:0] bits in SCR_SMCI. For details on the CKE[1:0] bits, see section 24.2.14. SCR_SMCI : Serial Control Register for Smart Card Interface Mode (SCMR.SMIF = 1). When setting the clock output, the base clock described in section 24.7.4. Receive Data Sampling Timing and Reception Margin is applied.

Figure 24.84 shows an example timing for the clock output control when the CKE[1] bit in SCR_SMCI is set to 0 and the CKE[0] bit in SCR_SMCI is controlled.

When the GM bit in SMR_SMCI is 0, output control by the CKE[0] bit in SCR_SMCI is immediately reflected on the SCKn pin, so there is a possibility that pulses with an unintended width may be output from the SCKn pin.

When the GM bit in SMR_SMCI is 1, the clock with the same pulse width as the base clock is output even if the CKE[0] bit in SCR_SMCI is changed.

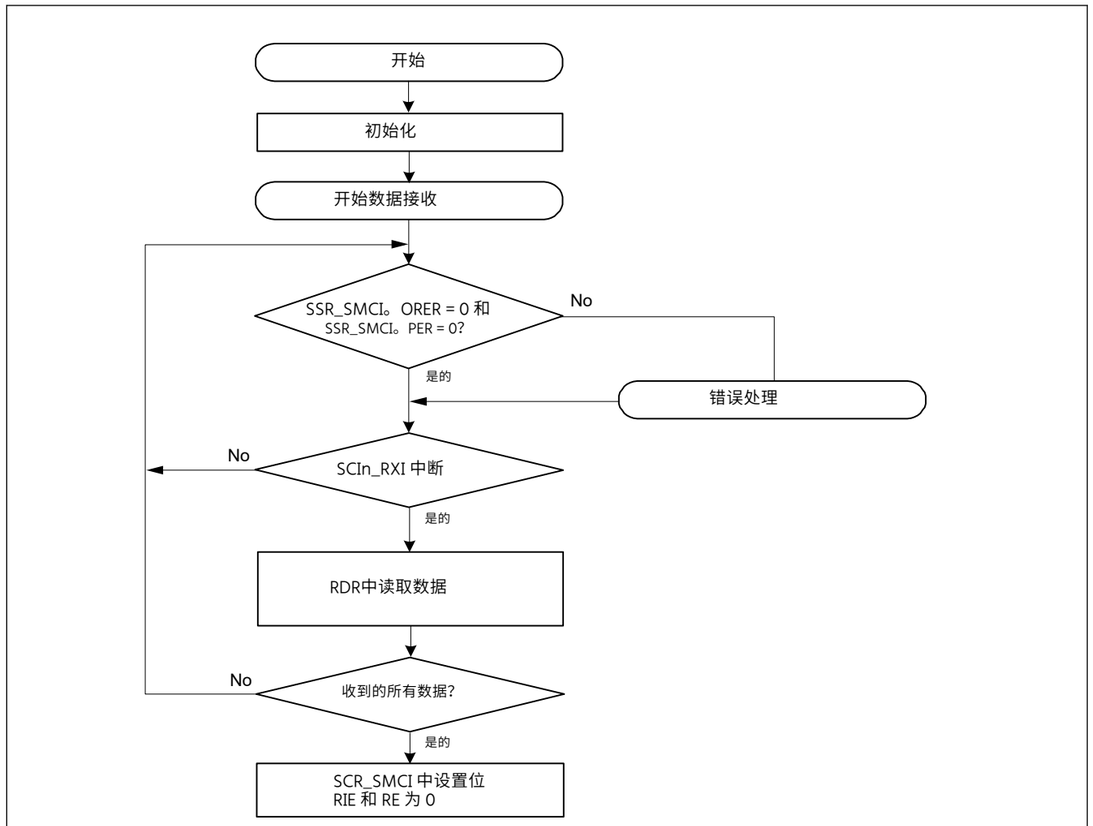

图24。83 智能卡接口接收示例流程

24.7.8 时钟输出控制

SMR_SMCI中的GM位设置为1时,时钟输出可以由SCR_SMCI中的CKE[1:0]位控制。CKE[1:0] 位的详细信息,请参见第 24。2。14 节。SCR_SMCI:智能卡接口模式的串行控制寄存器（SCMR。SMIF = 1)。设置时钟输出时,基时钟在第 24。7。4 节中描述。应用接收数据采样时序和接收裕度。

SCR_SMCI中的CKE[1]位设置为0并且控制SCR_SMCI中的CKE[0]位时,图24。84示出了时钟输出控制的示例定时。

SMR_SMCI 中的 GM 位为 0 时, SCR_SMCI 中 CKE[0] 位的输出控制立即反映在 SCKn 引脚上, 因此有可能从 SCKn 引脚输出具有意外宽度的脉冲。

SMR_SMCI 中的 GM 位为 1 时,即使 SCR_SMCI 中的 CKE[0] 位发生变化,也会输出与基时钟具有相同脉冲宽度的时钟。

24.8 Operation in Simple IIC Mode

Simple IIC mode format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device can specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8 data bits in all frames are transmitted in order from the MSB.

The I^2C bus format and timing of the I^2C bus are shown in Figure 24.85 and Figure 24.86.

24.8 在简单的 IIC 模式下操作

简单的IIC模式格式由8个数据位和一个确认位组成。通过在开始条件或重新启动条件之后继续进入从属地址帧,主设备可以指定从属设备作为通信伙伴。当前指定的从设备在指定新的从设备或满足停止条件之前仍然有效。所有帧中的 8 个数据位均按顺序从 MSB 传输。

24.8.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the SIMR3.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept in the released state
- The hold time for the start condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the IICSTAREQ bit in SIMR3 is set to 0, and a start-condition generated interrupt is output

Writing 1 to the IICRSTAREQ bit in SIMR3 causes the generation of a restart condition. The generation of a restart condition proceeds through the following operations:

- The SDAn line is released and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SDAn line falls (from the high level to the low level)
- The hold time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the SIMR3.IICRSTAREQ bit is set to 0, and a restart-condition generated interrupt is output

Writing 1 to the SIMR3.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)

- S: 表示启动条件,当主设备在 SCLn 线为高时,将 SDAn 线上的电平从高变为低
- SLA:表示从属地址,主设备通过该地址选择从属设备
- R/W#:表示传输（接收或传输）的方向。值1表示从设备到主设备的转移,0表示从主设备到从设备的转移。
- A/A#:表示确认位。由用于主传输的从设备和用于主接收的主设备返回。返回低表示 ACK,返回高表示 NACK。
- Sr:表示重启条件,当主设备在 SCLn 线为高时,在 SDAn 线上的电平从高变为低时以及设置时间过后
- DATA:表示正在接收或传输的数据

24.8.1 生成开始、重新启动和停止条件

将 1 写入 SIMR3。IICSTAREQ 位导致启动条件的生成。开始条件的生成通过以下操作进行:

- SDAn线上的电平下降（从高电平到低电平）,SCLn线保持在释放状态
- 开始条件的保持时间设置为 BRR 设置确定的比特率的比特周期的一半
- SCLn线上的电平下降（从高电平到低电平）,SIMR3中的IICSTAREQ位设置为0,并输出一个启动条件生成的中断

将 1 写入 SIMR3 中的 IICRSTAREQ 位会导致重新启动条件的生成。重新启动条件的生成通过以下操作进行:

- SDAn 线被释放,SCLn 线保持在低电平
- SCLn 线的低电平周期被设置为 BRR 设置确定的比特率的比特周期的一半
- SCLn 线路被释放（从低电平过渡到高电平）
- 当在 SCLn 线上检测到高电平时,重启条件的设置时间被设置为 BRR 设置确定的比特率的比特周期的一半
- SDAn线上的电平下降（从高电平到低电平）
- 重启条件的保持时间设置为 BRR 设置确定的比特率下比特周期的一半
- SCLn线上的电平下降（从高电平到低电平）,SIMR3。IICRSTAREQ 位设置为 0,并输出重启条件生成的中断

将 1 写入 SIMR3。IICSTPREQ 位导致停止条件的生成。停止条件的生成通过以下操作进行:

- SDAn线上的电平下降（从高电平到低电平）,SCLn线保持在低电平
- SCLn 线的低电平周期被设置为 BRR 设置确定的比特率的比特周期的一半
- SCLn 线路被释放（从低电平过渡到高电平）

- When a high level is detected on the SCLn line, the setup time for the stop condition is set as half of a bit period at the bit rate determined by the BRR setting
- The SDAn line is released (transition from the low to the high level), the SIMR3.IICSTPREQ bit is set to 0, and a stop-condition generated interrupt is output

Figure 24.87 shows the timing of operations in the generation of start, restart, and stop conditions.

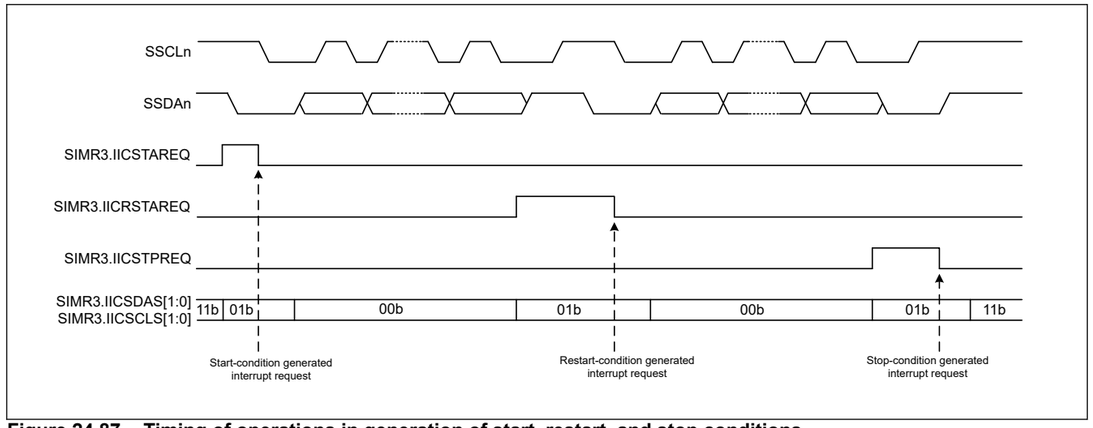

Figure 24.87 Timing of operations in generation of start, restart, and stop conditions

24.8.2 Clock Synchronization

The SCLn line can be driven low if a wait is inserted by a slave device at the other side of the transfer. Setting the SIMR2.IICCSC bit to 1 applies control to obtain synchronization when a difference arises between the levels of the internal SCLn clock signal and the level being input on the SCLn pin.

When the SIMR2.IICCSC bit is set to 1, the level of the internal SCLn clock signal changes from low to high. Counting to determine the period at a high level stops while the low level is being input on the SCLn pin. Counting to determine the period at a high level starts after the transition of the input on the SCLn pin to the high level.

The interval from this time until counting to determine the period at high level starts on the transition of the SCLn pin to the high level, is the total of the delay of SCLn output, delay for noise filtering of the input on the SCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLK). The period at high level of the internal SCLn clock is extended even when other devices do not place the low level on the SCLn line.

If the SIMR2.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SCLn pin and the internal SCLn clock. If the SIMR2.IICCSC bit is 0, synchronization with the internal SCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a wait period into the interval until the transition of the internal SCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a wait period after the transition of the internal SCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the waiting period, generation of the condition itself is not guaranteed.

Figure 24.88 shows an example operation for synchronizing the clocks.

● 当在 SCLn 线上检测到高电平时, 停止条件的设置时间被设置为 BRR 设置确定的比特率的比特周期的一半

● SDAn 线路被释放（从低电平过渡到高电平）,即 SIMR3。IICSTPREQ 位设置为 0,并输出停止条件生成的中断

图 24。87 显示了生成启动、重新启动和停止条件时的操作时序。

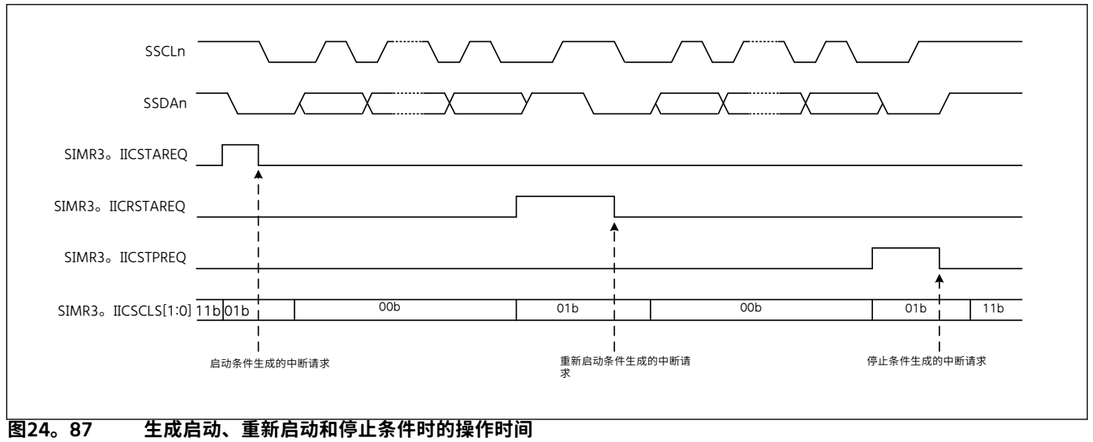

图24。87 生成启动、重新启动和停止条件时的操作时间

24。8。2 时钟同步

SCLn线可以被驱动低,如果等待被从设备插入到转移的另一侧。设置 SIMR2。当内部SCLn时钟信号的电平与SCLn引脚上输入的电平之间出现差异时,IICCSC比特至1应用控制来获得同步。

当SIMR2。IICCSC位设置为1,内部SCLn时钟信号的电平由低变为高。SCLn 引脚上输入低电平时, 计数以确定高电平处的周期停止。SCLn引脚上的输入过渡到高电平后开始计数以确定高电平的周期。

SCLn引脚向高电平过渡时开始计算以确定高电平周期的这段时间,是SCLn输出的延迟总和,SCLn引脚上的输入的噪声滤波延迟（噪声滤波器的采样时钟的2或3个周期）, 以及内部处理的延迟(1 或 2 个 PCLK 周期）。即使其他设备没有将低电平放置在 SCLn 线上,内部 SCLn 时钟的高电平周期也会延长。

如果SIMR2。IICCSC位为1,通过获取SCLn引脚和内部SCLn时钟上的输入的逻辑AND来获得用于数据传输和接收的同步。如果SIMR2。IICCSC位为0,获得与内部SCLn时钟的同步,用于数据的传输和接收。

如果从设备在发出生成开始、重新启动或停止条件的请求后将等待周期插入到该间隔中,直到内部 SCLn 时钟信号从低电平过渡到高电平,则生成之前的时间为延长该周期。

如果从设备在内部SCLn时钟信号从低电平过渡到高电平之后插入等待周期,尽管在不停止等待周期的情况下发出生成完成的中断,但是不能保证条件本身的生成。

图24。88示出了用于同步时钟的示例操作。

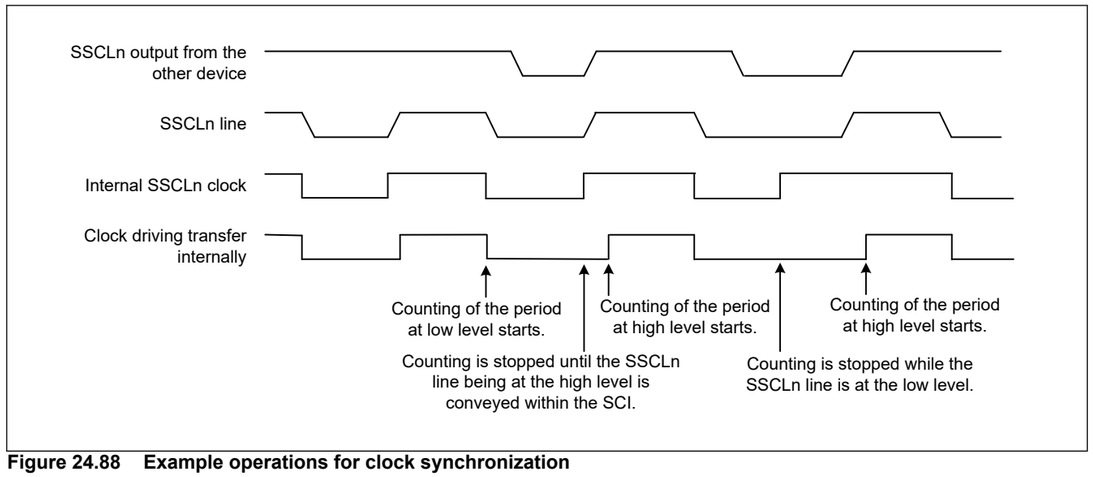

Figure 24.88 Example operations for clock synchronization

24.8.3 SDAn Output Delay

The SIMR1.IICDL[4:0] bits can be used to set a delay for output on the SDAn pin relative to falling edges of output on the SCLn pin. Delay settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, PCLK, by the divisor selected in the SMR.CKS[1:0] bits). A delay for output on the SDAn pin applies to the start condition/restart condition/stop condition signal, 8-bit transmit data, and acknowledge bit.

If the SDAn output delay is shorter than the time for the level on the SCLn pin to fall, the change of the output on the SDAn pin starts while the output level on the SCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SDAn pin specify times greater than the time output on the SCLn pin takes to fall (300 ns for IIC in normal mode and fast mode).

Figure 24.89 shows the timing of delays in SDAn output.

24.8.4 SCI Initialization in Simple IIC Mode

Before transferring data, write the initial value 0x00 to SCR and initialize the interface following the example shown in Table 24.38.

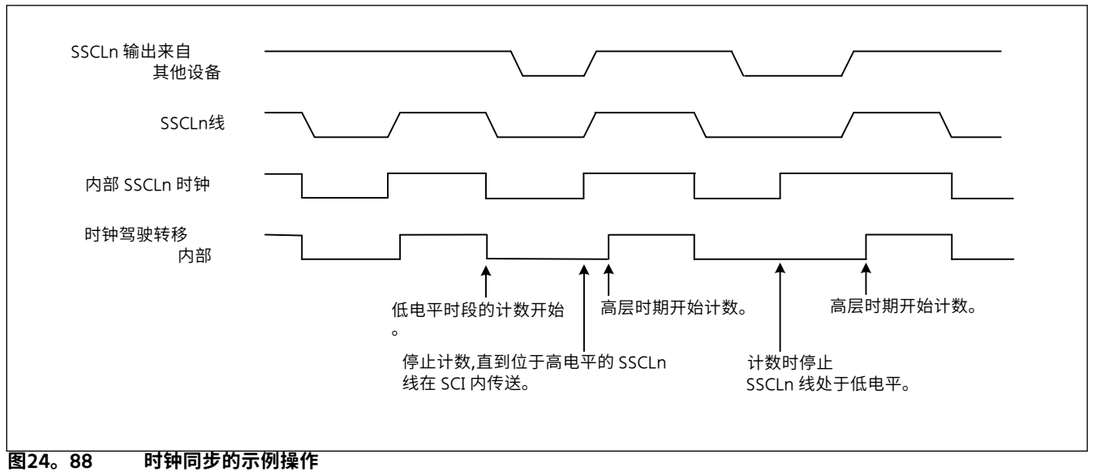

图24。88 时钟同步的示例操作

24。8。3 SDAn 输出延迟

SIMR1。IICDL[4:0] 位可用于设置 SDAn 引脚上的输出相对于 SCLn 引脚上的输出下降边的延迟。从 0 到 31 的延迟设置是可选择的,表示来自片上波特率发生器的时钟信号的相应周期数的周期（通过将基时钟 PCLK 除以 SMR。CKS 中选择的除数来导出[1:0] 位）。SDAn 引脚上的输出延迟适用于启动条件/重新启动条件/停止条件信号、8 位传输数据和确认位。

如果 SDAn 输出延迟短于 SCLn 引脚上的电平下降的时间,则在 SCLn 引脚上的输出电平下降时开始改变 SDAn 引脚上的输出,从而导致从设备操作错误的可能性。确保 SDAn 引脚上输出的延迟设置指定大于 SCLn 引脚上输出下降所需时间的时间（正常模式和快速模式下 IIC 为 300 ns）。图 24。89 显示了 SDAn 输出的延迟时间。

表 24。38 。

Before making any changes to the operating mode or transfer format, be sure to set SCR to its initial value. In simple IIC mode, the open-drain setting for the communication ports should be made on the port side.

24.8.5 Operation in Master Transmission in Simple IIC Mode

Figure 24.90 and Figure 24.91 show examples of master transmission and Figure 24.92 shows an example flow of data transmission.

Figure 24.90 shows the operation example when SIMR2.IICINTM bit is 1 (use reception and transmission interrupts) and the value of the SCR.RIE bit is assumed to be 0 (SCIn_RXI and SCIn_ERI interrupt requests are disabled).

See Table 24.43 for more information on the STI interrupt.

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.

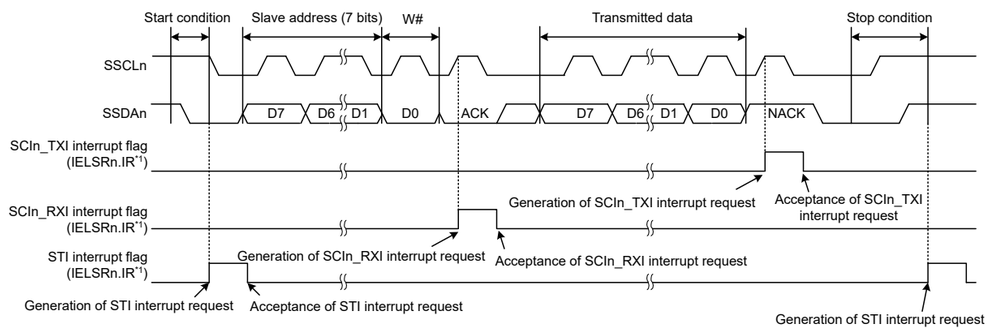
Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 24.90 Example 1 of operations for master transmission in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts

When the SIMR2.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and required number of data bytes are transmitted. When the NACK is received, error processing such as transmission stop and retransmission is performed using the NACK interrupt as the trigger.

To restart communication for some reason after writing data in the TDR register, use the following procedure:

1. Set the TE and RE bits in the SCR register to 0 to stop communication.
2. Set 0xF0 in the SIMR3 register, release the I^2C bus, and clear the generation of a condition.
3. If the RDRF flag in the SSR register is set to 1, clear it.
4. Set the TE and RE bits in the SCR register to 1 and start the next communication.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

[1] [1] Initialization in simple IIC mode:
For transmission, set the SCR.RIE to 0 to disable the SCIn_RXI and ERI interrupts.

[2] [2] Generate a start condition.

[3] [3] Writing to TDR:
Write the slave address and value for the R/W bit to TDR.

[4] [4] Confirming ACK response from the slave device:
Check the SISR.IICACKR bit. If SISR.IICACKR is 0, it indicates that the slave device responded with ACK and operations proceed. If SISR.IICACKR is 1, it indicates that there was no response from the slave device so the next transition is to generate a stop condition.

If 10-bit slave addresses are in use, processing of [3] and [4] is repeated twice.

[5] [5] Continuing with serial transmission:
When transmission is to continue, write additional transmit data to TDR. Except for the first data to be transmitted, a SCIn_TXI interrupt request can activate the DMAC or DTC to handle writing of data to TDR. But it cannot be confirmed status of ACK or NACK.

[6] [6] Generate a stop condition.

Note: In simple IIC mode, the SCIn_TXI interrupt is generated when communication completes.

[2] [2] 生成开始条件。

[3] [3] 写信给 TDR:

[4] [4] 从设备确认 ACK 响应:

IIC 简易模式下,当一帧通信完成时生成发送数据空中断（SCIn_TXI）,与时钟同步传输时的 SCIn_TXI 中断请求生成定时不同。

Set the RIE bit in SCR to 0.

[2] Generation of a start condition.

[3] Writing to TDR:
Write the slave address and value for the R/W bit to TDR.

[4] Confirming ACK response from the slave device:
Check the SISR.IICACKR bit. If SISR.IICACKR is 0, it indicates that the slave device responded with ACK and operations proceed. If SISR.IICACKR is 1, it indicates that there was no response from the slave device so the next transition is to generate the stop condition.

[5] Continuing with reception:
To continue with reception, write 0xFF as dummy transit data to TDR. Other than in the first and last rounds of transmission, a SCIn_TXI request can activate DMAC or DTC to handle writing of data to TDR. Also, for data other than the last data to be received , an SCI_nRXI request can activate DMAC or DTC to handle reading of data from RDR.

[6] NACK is transmitted in response to the last data.

[7] Generation of a stop condition.

Note: In simple IIC mode, the SCIn_TXI interrupt request is generated when communication is complete.

24.9 Operation in Simple SPI Mode

As an extended function, the SCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

[2] 开始条件的生成。

[3] 写信给 TDR:
将 R/W 位的从地址和值写入 TDR.

[4] 从设备确认 ACK 响应:
检查 SISR。IICACKR 位。如果SISR。IICACKR为0,则表明从设备用ACK响应并且操作继续。如果 SISR。IICACKR 为 1,则表明从设备没有响应,因此下一个转换是生成停止条件。

[5] 继续接收:
要继续接收,请将 0xFF 写为 TDR 的虚拟传输数据。SCIn_TXI请求除了在第一轮和最后一轮传输中,可以激活DMAC或DTC来处理数据写入TDR。另外,对于除了要接收的最后数据之外的数据,SCI_nRXI请求可以激活DMAC或DTC来处理从RDR读取数据。

[6] NACK 是响应最后的数据而传输的。

[7] 停止条件的生成。

注: IIC 简易模式下,通信完成时会产生 SCIn_TXI 中断请求。

24。9 在简单 SPI 模式下操作

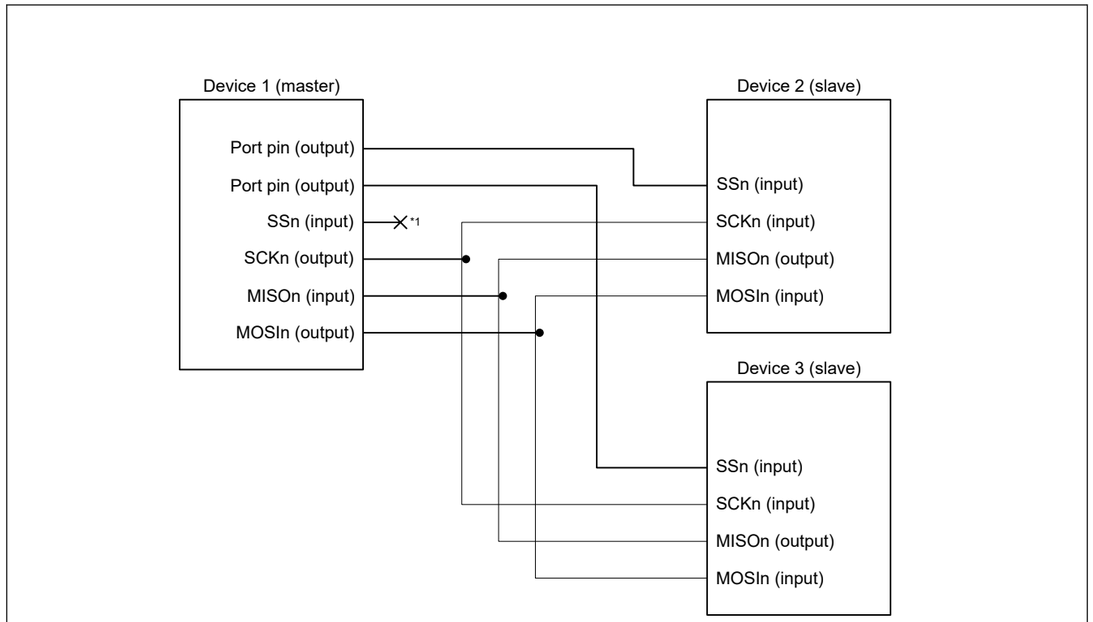
作为扩展功能,SCI支持简单的SPI模式,处理一个或多个主设备和多个从设备之间的传输。

Using the settings for clock synchronous mode (SCMR.SMIF = 0, SIMR1.IICM = 0, SMR.CM = 1) and setting the SPMR.SSE bit to 1 place the SCI in simple SPI mode. However, the SSn pin function on the master side is not required for connection of the device used as the master in simple SPI mode when the configuration only has a single master. Therefore, set the SPMR.SSE bit to 0 in such cases.

Figure 24.95 shows an example of connections for simple SPI mode. Control a general port pin to produce the SSn output signal from the master.

In simple SPI mode, data is transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended. The data can be inverted by setting the SCMR.SINV bit to 1.

Because the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a shared clock signal. Additionally, because both the transmitter and receiver have a buffered structure, writing the next transmit data while transmission is in progress and reading previously received data while reception is in progress are both possible. This enables continuous transfer.



Note 1. The SSn pin input is not required in a single-master system (the interface is used with the setting SPMR.SSE = 0).

Figure 24.95 Example connections using simple SPI mode in single master mode with SPMR.SSE bit = 0

24.9.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (SCR.CKE[1:0] = 00b or 01b and SPMR.MSS = 0) or slave (SCR.CKE[1:0] = 10b or 11b and SPMR.MSS = 1).

Table 24.39 lists the relationship between the pin states, mode, and level on the SSn pin.

Table 24.39 States of pins by mode and input level on SSn pin (1 of 2)

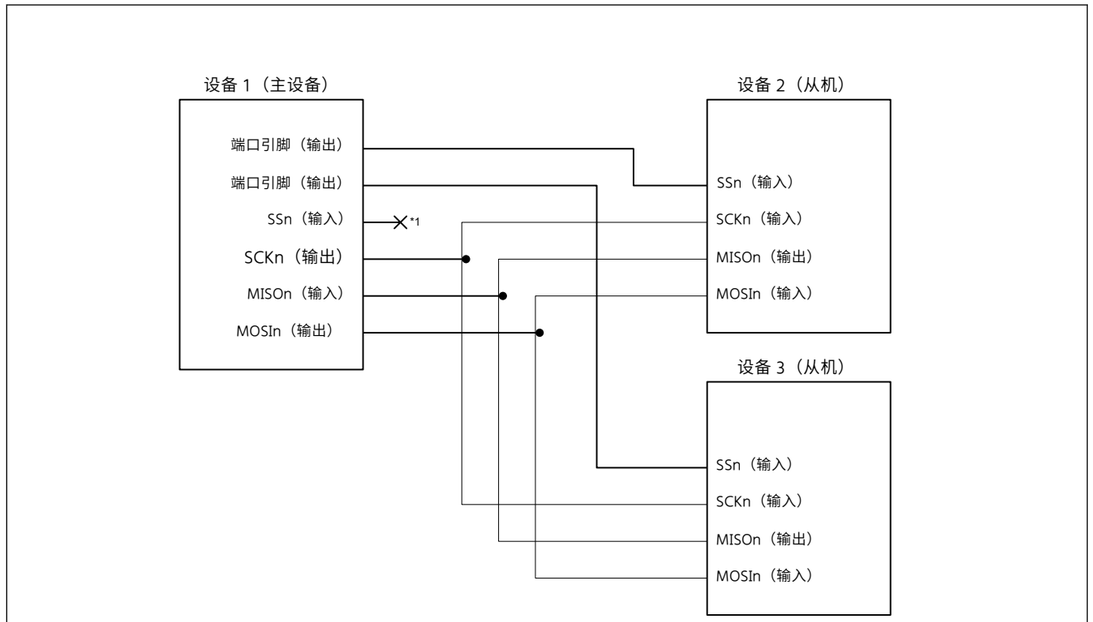
Mode	Input on SSn pin	State of MOSIn pin	State of MISOn pin	State of SCKn pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance

使用时钟同步模式的设置（SCMR。SMIF = 0,SIMR1。IICM = 0,SMR。CM = 1)并将 SPMR。SSE 位设置为 1 将 SCI 置于简单的 SPI 模式。然而,当配置只有单个主设备时,在简单的 SPI 模式下,作为主设备的连接不需要主侧的 SSn 引脚功能。因此,在这种情况下将 SPMR。SSE 位设置为 0。

图 24。95 显示了简单 SPI 模式的连接示例。控制通用端口引脚从主端口产生 SSn 输出信号。

在简单的 SPI 模式下,数据以与时钟同步模式相同的方式与时钟脉冲同步传输。用于传输的数据的一个字符由 8 位数据组成,并且不能附加奇偶校验位。可以通过将 SCMR。SINV 位设置为 1 来反转数据。

由于接收器和发射器在 SCI 模块内彼此独立,因此可以使用共享时钟信号进行全双工通信。另外,由于发射机和接收机都具有缓冲结构,因此在传输进行时写入下一个发射数据以及在接收进行时读取先前接收到的数据都是可能的。这使得能够连续传输。



注1。单主系统中不需要 SSn 引脚输入（该接口与设置 SPMR。SSE = 0 一起使用）。

图24。95 使用单主模式中的简单 SPI 模式的示例连接 SPMR。SSE 位 = 0

24。9。1 主从模式下的引脚状态

SPI 模式简单接口的引脚方向（输入或输出）根据设备是主设备（SCR。CKE[1:0] = 00b 或 01b 且 SPMR。MSS = 0)还是从设备（SCR。CKE[1:0] = 10b 或 11b 且 SPMR。MSS = 1)而有所不同。

表24。39列出了SSn引脚上的引脚状态、模式和电平之间的关系。

表 24。39 SSn 引脚上按模式和输入电平划分的引脚状态(2 中的 1)

模式	SSn引脚上输入	MOSIn 针的状态	MISOn 引脚的状态	SCKn 引脚的状态
主模式*1	高（转账可以进行）	数据传输输出*2	接收数据的输入	时钟输出 *3
	低（转账无法进行）	高阻抗	接收数据的输入（但已禁用）	高阻抗

Table 24.39 States of pins by mode and input level on SSn pin (2 of 2)

Mode	Input on SSn pin	State of MOSIn pin	State of MISOn pin	State of SCKn pin
Slave mode	High level (transfer cannot proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer can proceed)	Input for received data	Output for data transmission	Clock input

Note 1. When there is only a single master (SPMR.SSE = 0), transfer is possible regardless of the input level on the SSn pin. This is equivalent to input of a high level on the SSn pin.
Note 2. The MOSIn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE bit = 0).
Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE = 0 and SCR.RE = 0) in a multi-master configuration (SPMR.SSE = 1).

24.9.2 SS Function in Master Mode

Setting the CKE[1:0] bits in the SCR to 00b or 01b and the MSS bit in the SPMR to 0 selects master mode operation. The SSn pin is not used in single-master configurations (SPMR.SSE = 0), so transmission or reception can proceed regardless of the value of the SSn pin.

When the level on the SSn pin is high in a multi-master configuration (SPMR.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission.

When the level on the SSn pin is low in a multi-master configuration (SPMR.SSE = 1), there are other masters, and a transmission or reception is in progress. The MOSIn output and SCKn pins are placed in the high-impedance state and starting transmission or reception is not possible. In addition, the value of the SPMR.MFF bit is 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading SPMR.MFF flag. If a mode fault error occurs while transmission or reception is in progress, transmission or reception does not stop, but the MOSIn and SCKn outputs are in the high-impedance state after completion of the transfer.

Use a general port pin to produce the SS output signal from the master.

24.9.3 SS Function in Slave Mode

Setting the SCR.CKE[1:0] bits to 10b or 11b and the SPMR.MSS bit to 1 selects slave operation. When the SSn pin is high, the MISOn output pin is in the high-impedance state and clock input through the SCKn pin is ignored. When the SSn pin is low, clock input through the SCKn pin is valid and transmission or reception can proceed.

If the input on the SSn pin changes from low to high during transmission or reception, the MISOn output pin is placed in the high-impedance state. Meanwhile, the internal processing for transmission or reception continues at the rate of the clock input through the SCKn pin until processing for the character being transmitted or received is complete, after which it stops, and the appropriate interrupt (SCIn_TXI, SCIn_RXI, or SCIn_TEI) is generated.

24.9.4 Relationship between Clock and Transmit/Receive Data

The CKPOL and CKPH bits in the SPMR register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in Figure 24.96. The relation is the same for both master and slave operation. This is the same as when the level on the SSn pin is high.

表 24。39 SSn引脚上按模式和输入电平划分的引脚状态(2 of 2)

模式	SSn引脚上输入	MOSIn 针的状态	MISOn 引脚的状态	SCKn 引脚的状态
从模式	高（转账无法进行）	接收数据的输入（但已禁用）	高阻抗	时钟输入（但已禁用）
	低（转移可以继续进行）	接收数据的输入	用于数据传输的输出	时钟输入

注1。当只有一个主站时（SPMR。SSE = 0),无论 SSn 引脚上的输入电平如何,都可以传输。这相当于 SSn 引脚上高电平的输入。

注2。MOSIn引脚输出在串行传输被禁用时处于高阻抗状态（SCR。TE位 = 0)。
注3。SCKn引脚输出处于多主机配置（SPMR。SSE = 1)中串行传输被禁用时（SCR。TE = 0和SCR。RE = 0)的高阻抗状态。

24。9。2 主模式下的SS功能

SCR 中的 CKE[1:0] 位设置为 00b 或 01b, SPMR 中的 MSS 位设置为 0 选择主模式操作。SSn引脚不用于单主配置（SPMR。SSE = 0),因此无论SSn引脚的值如何,传输或接收都可以进行。

SSn引脚上的电平在多主配置中为高电平时（SPMR。SSE = 1),主设备在开始发送或接收之前从SCKn引脚输出时钟信号,以指示没有其他主设备或另一个主设备正在执行接收或传输。

当多主配置中 SSn 引脚上的电平较低时（SPMR。SSE = 1),还有其他主配置,并且正在进行传输或接收。MOSIn输出和SCKn引脚置于高阻抗状态,无法启动传输或接收。另外,SPMR。MFF位的值为1,表示模式故障错误。在多主配置中,通过读取 SPMR。MFF 标志来启动错误处理。如果在传输或接收进行时发生模式故障错误,则传输或接收不会停止,但传输完成后MOSIn和SCKn输出处于高阻抗状态。

使用通用端口引脚从主站产生 SS 输出信号。

24。9。3 从模式下的SS功能

SCR。CKE[1:0] 位设置为 10b 或 11b,SPMR。MSS 位设置为 1 选择从操作。SSn引脚时,MISOn输出引脚处于高阻态,通过SCKn引脚输入的时钟被忽略。SSn引脚较低时,通过SCKn引脚的时钟输入有效,传输或接收可以进行。

SSn引脚上的输入在传输或接收过程中由低变为高,则MISOn输出引脚置于高阻态。同时,用于发送或接收的内部处理以通过SCKn引脚输入时钟的速率继续,直到对正在发送或接收的字符的处理完成,之后它停止,并且适当的中断（SCIn_TXI、SCIn_RXI、或 SCIn_TEI）被生成。

24。9。4 时钟与发送/接收数据之间的关系

SPMR寄存器中的CKPOL和CKPH位可用于以四种不同的方式设置用于发送和接收的时钟。时钟信号与数据发送和接收之间的关系如图24。96所示。主操作和从操作的关系都是相同的。SSn引脚上的电平高时一样。

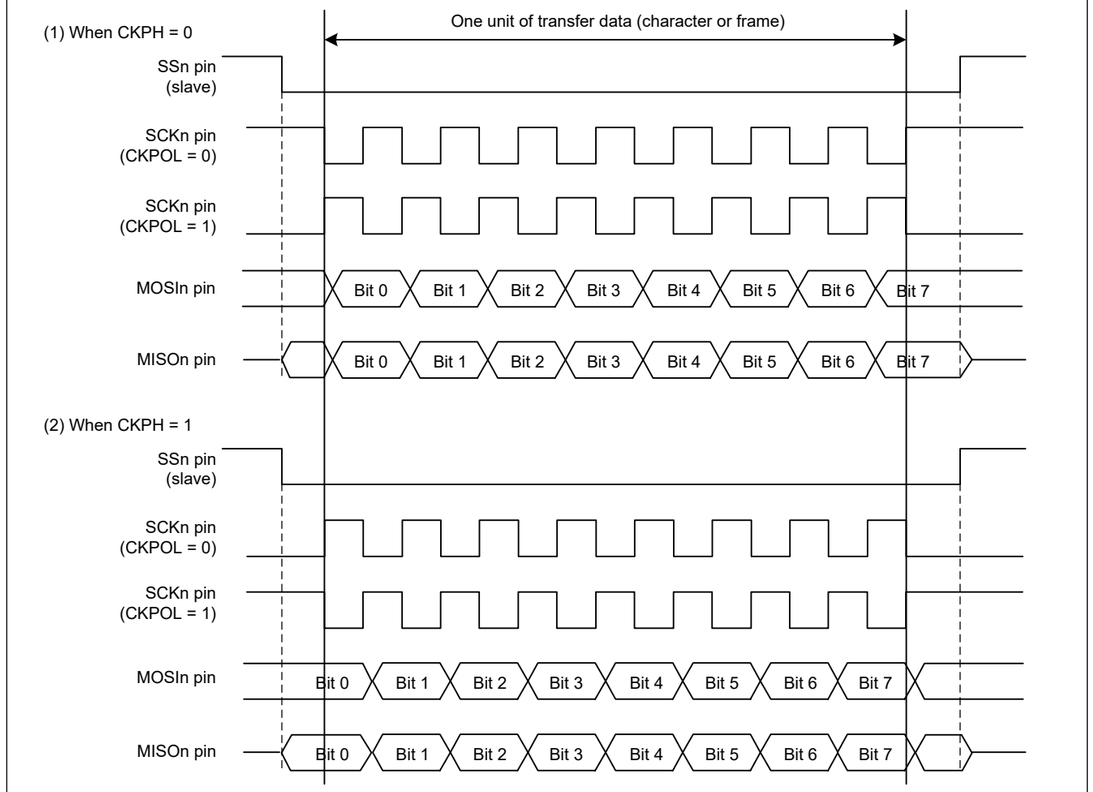


Figure 24.96 Relation between clock signal and transmit or receive data in simple SPI mode

24.9.5 SCI Initialization in Simple SPI Mode

Initialization in simple SPI mode is the same as in clock synchronous mode. See section 24.6.3. SCI Initialization in Clock Synchronous Mode for an example initialization flow. The CKPOL and CKPH bits in the SPMR register must be set to ensure that the clock signal is suitable for both master and slave devices.

Always initialize the SCR register before making any changes to the operating mode or transfer format.

Note: Only the RE bit is set to 0. The SSR.ORER, FER, PER, and RDR flags are not initialized.

Changing the value of the TE bit from 1 to 0 or from 0 to 1 when the TIE bit in the SCR register is 1 at the same time, leads to the generation of a transmit data empty interrupt (SCIn_TXI).

24.9.6 Transmission and Reception of Serial Data in Simple SPI Mode

In master operation, ensure that the SSn pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. Otherwise, the procedures are the same as in clock synchronous mode.

24.10 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be evenly corrected using the number specified in the MDDR register among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in SMR/SMR_SMCI.

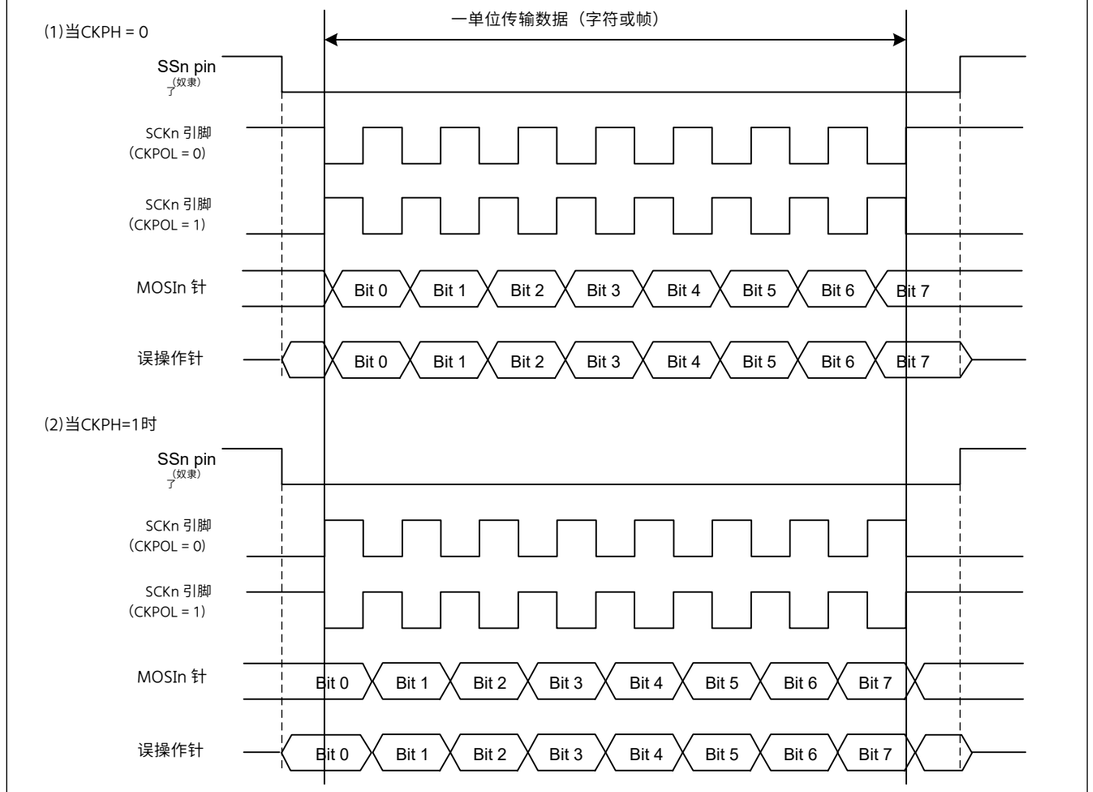

图24。96 时钟信号与简单 SPI 模式下发送或接收数据之间的关系

24。9。5 简单 SPI 模式下的 SCI 初始化

简单 SPI 模式下的初始化与时钟同步模式相同。参见第 24。6。3 节。时钟同步模式下的 SCI 初始化示例初始化流程。SPMR寄存器中的CKPOL和CKPH位必须设置,以确保时钟信号既适用于主设备,也适用于从设备。

在对操作模式或传输格式进行任何更改之前,请务必初始化 SCR 寄存器。

注意:仅将 RE 位设置为 0。SSR。ORER、FER、PER 和 RDR 标志未初始化。

SCR寄存器中的TIE位同时为1时,将TE位的值从1更改为0或从0更改为1,导致生成传输数据空中断（SCIn_TXI）。

24。9。6 简单 SPI 模式下串行数据的传输和接收

在主操作中,确保传送另一侧从设备的SSn引脚在开始传送之前处于低电平,在传送完成时处于高电平。否则,过程与时钟同步模式相同。

24。10比特率调制功能

使用比特率调制功能,可以使用由SMR/SMR_SMCI中的CKS[1:0]位选择的256个内部时钟的时钟周期中的MDDR寄存器中指定的数字来均匀地校正比特率。

Figure 24.97 shows an example where the PCLK is selected in the CKS[1:0] bits in SMR/SMR_SMCI, the BRR bit is set to 0, and the MDDR is set to 160 in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256).

Note: Enabling an internal clock causes bias, and expansion and contraction are generated in the pulse width of the internal base clock.

Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

This figure shows an example when 1-bit interval is corrected to 52/32. (1-bit interval is evenly corrected to 256/160.)

24.11 Interrupt Sources

24.11.1 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (Non-FIFO Selected)

If the conditions for an SCIn_TXI and SCIn_RXI interrupt are satisfied while the interrupt status flag in the ICU is 1, the ICU does not output the interrupt request but saves it internally with a capacity for retention of one request per source.

When the interrupt status flag in the ICU is set to 0, the interrupt request retained within the ICU is output. The internally retained interrupt request is automatically discarded when the actual interrupt is output. Clearing of the associated interrupt enable bit (the TIE or RIE bit in the SCR/SCR_SMCI) can also be used to discard an internally retained interrupt request.

24.11.2 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (FIFO Selected)

When an interrupt status flag in the ICU is set to 1, the SCIn_TXI and SCIn_RXI interrupts do not output interrupt requests to the ICU. When an interrupt status flag of the ICU is set to 0, and if the conditions for an SCIn_TXI and SCIn_RXI interrupts are satisfied, an interrupt request is generated.

24.11.3 Interrupts in Asynchronous, Manchester, Clock Synchronous, and Simple SPI Modes

(1) Non-FIFO selected

Table 24.40 lists interrupt sources in asynchronous mode, Manchester mode, clock synchronous mode, and simple SPI mode.

图24。97示出了在SMR/SMR_SMCI中的CKS[1:0]位中选择PCLK、在异步模式下将BRR位设置为0、将MDDR设置为160的示例。在此示例中,基本时钟的周期被均匀校正(256/160)并且比特率也被校正(160/256)。

注: 启用内部时钟会导致偏差,并且内部基时钟的脉冲宽度会产生膨胀和收缩。

请勿在时钟同步模式和简单 SPI 模式下的最高速度设置中使用此功能（SMR。CKS[1:0] = 00b、SCR。CKE[1] = 0 和 BRR = 0)。

24。11 中断源

24.11.1 SCIn_TXI 和 SCIn_RXI 中断的缓冲区操作（非 FIFO 选择）

如果在ICU中的中断状态标志为1时满足SCIn_TXI和SCIn_RXI中断的条件,则ICU不会输出中断请求,而是在内部保存中断请求,并且每个源保留一个请求的能力。

ICU中的中断状态标志设置为0时,输出ICU内保留的中断请求。当输出实际中断时,内部保留的中断请求将自动丢弃。相关中断使能位（SCR/SCR_SMCI 中的 TIE 或 RIE 位）的清除也可用于丢弃内部保留的中断请求。

24。11。2 SCIn_TXI 和 SCIn_RXI 中断的缓冲区操作（选定 FIFO）

ICU中的中断状态标志设置为1时,SCIn_TXI和SCIn_RXI中断不会向ICU输出中断请求。ICU 的中断状态标志设置为 0 时, 若满足 SCIn_TXI 和 SCIn_RXI 中断的条件, 则生成中断请求。

24。11。3 异步、曼彻斯特、时钟同步和简单 SPI 模式下的中断

（一）非FIFO入选

表 24。40 列出了异步模式、曼彻斯特模式、时钟同步模式和简单 SPI 中的中断源
模式。

A different interrupt vector can be assigned to each interrupt source. Individual interrupt sources can be enabled or disabled with the enable bits in the SCR register.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when transmit data is transferred from the TDR or TDRHL register*1 to the TSR register. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TE and SCR.TIE bits to 1 at the same time. An SCIn_TXI interrupt request can activate the DTC or DMAC to handle data transfer.

An SCIn_TXI interrupt request is not generated by setting the SCR.TE bit to 1 when SCR.TIE is 0 or by setting the SCR.TIE bit to 1 when the SCR.TE is 1.*2

When new data is not written by the time of transmission of the last bit of the current transmit data and SCR.TEIE is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated. Additionally, when SCR.TE is 1, the SSR.TEND flag retains the value 1 until more transmit data is written to the TDR or TDRHL register*1, and setting SCR.TEIE to 1 leads to the generation of an SCIn_TEI interrupt request.

Writing data to the TDR or TDRHL register*1 leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the SCIn_TEI interrupt request.

If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated when received data is stored in the RDR register. An SCIn_RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting any of the SSR.ORER, FER, PER and MER*3 flags to 1 when the SCR.RIE bit is 1 leads to the generation of an SCIn_ERI interrupt request.

An SCIn_RXI interrupt request is not generated in this case. Clearing all these flags (ORER, FER, PER, MER*3, SYER*3, PFER*3 and SBER*3) leads to discarding of the SCIn_ERI interrupt request.

Note 1. When asynchronous mode and 9-bit data length are selected.
Note 2. To temporarily prohibit SCIn_TXI interrupts on transmission of the last of the data when a new round of transmission is to be started, after handling the transmission-completed interrupt, control activation of the interrupt by using the interrupt request enable bit in the ICU rather than using the SCR.TIE bit. This approach can prevent the suppression of SCIn_TXI interrupt requests in the transfer of new data.
Note 3. MER, SYER, PFER, and SBER work as a factor of SCIn_ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECR) are set to "1".

(2) FIFO selected

Table 24.41 lists interrupt sources in FIFO selected mode.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when the stored amount of data in the FTDRL register becomes the threshold value indicated in FCR.TTRG or below. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TIE and SCR.TE bits to 1 simultaneously or by setting SCR.TIE to 1 when SCR.TE is 1.

An SCIn_TXI interrupt request is not generated by setting SCR.TE to 1 when SCR.TIE is 0.

If SCR.TEIE is 1 and if the next data is not written to the FTDRL register by the time the last bit of the transmit data is sent, the SSR_FIFO.TEND flag is set to 1 and the SCIn_TEI interrupt request is generated.

If SCR.RIE is 1, the SCIn_RXI interrupt request is generated when the stored amount of data in the FRDRL register is equal to or greater than the threshold value indicated in FCR.RTRG. When RTRG is 0, an SCIn_RXI interrupt does not occur even when the amount of data in the receive FIFO is equal to 0.

If the SCR.RIE bit is 1, when the SSR_FIFO.ORER flag is set to 1 or data with a framing error or a parity error is stored in the FRDRL register, the SCIn_ERI interrupt request is generated. When the amount of data stored in the FRDRL register is at the threshold value or above, the SCIn_RXI interrupt request is also generated. The SCIn_ERI interrupt request can be canceled, in which case SSR_FIFO.ORER, FER, and PER flags are all cleared.

Table 24.40 SCI interrupt sources with non-FIFO selected (1 of 2)

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0, 9)	Receive error*1	SSR.ORER, SSR.FER, SSR.PER, DCCR.DFER, DCCR.DPER, (SSR.MER, MESR.SYER, MESR.PFER, MESR.SBER)*2	SCR.RIE	Not possible

可以为每个中断源分配不同的中断向量。SCR 寄存器中的使能位可以启用或禁用各个中断源。

如果SCR。TIE位为1,则当发送数据从TDR或TDRHL寄存器*1传输到TSR寄存器时,生成SCIn_TXI中断请求。SCR。TE和SCR。TIE位同时设置为1,也可以使用单个指令生成SCIn_TXI中断请求。SCIn_TXI 中断请求可以激活 DTC 或 DMAC 来处理数据传输。

SCR。TE 为 0 时将 SCR。TE 位设置为 1,或者当 SCR。TE 为 1.*2 时将 SCR。TIE 位设置为 1,不会生成 SCIn_TXI 中断请求

当当前发送数据的最后一位的传输时没有写入新数据并且SCR。TEIE为1时,SSR。TEND标志被设置为1并且生成SCIn_TEI中断请求。此外,当 SCR。TE 为 1 时,SSR。TEND 标志保留值 1,直到更多传输数据写入 TDR 或 TDRHL 寄存器*1,并将 SCR。TEIE 设置为 1 会导致生成 SCIn_TEI中断请求。

将数据写入 TDR 或 TDRHL 寄存器 *1 会导致 SSR。TEND 标志的清除,并在一段时间后丢弃 SCIn_TEI 中断请求。

SCR。RIE位为1,则当接收到的数据存储在RDR寄存器中时,会生成SCIn_RXI中断请求。SCIn_RXI 中断请求可以激活 DTC 或 DMAC 来处理数据传输。

SCR。RIE 位为 1 时,将 SSR。ORER、FER、PER 和 MER *3 标志中的任何一个设置为 1 会导致生成 SCIn_ERI 中断请求。

在这种情况下不会生成 SCIn_RXI 中断请求。清除所有这些标志（ORER、FER、PER、MER *3、SYER *3, PFER *3 和 SBER *3))会导致丢弃 SCIn_ERI 中断请求。

注1。当选择异步模式和9位数据长度时。
注2。为了暂时禁止新一轮传输开始时最后一个数据的传输发生SCIn_TXI中断,在处理传输完成的中断后,通过使用ICU中的中断请求使能位来控制中断的激活,而不是使用SCR。TIE位。SCIn_TXI中断请求的抑制,这种方法可以防止新数据传输中的抑制。
注3。MER、SYER、PFER 和 SBER 仅在曼彻斯特模式下作为 SCIn_ERI 中断的一个因素发挥作用。仅当 SYER、PFER 和 SBER 的使能位（MECR 中的 SYEREN、PFEREN、SBEREN）设置为"1"时,SYER、PFER 和 SBER 才起作用。

(2)选定的FIFO

表 24。41 列出了 FIFO 选择模式下的中断源。

如果SCR。TIE位为1,则当FTDRL寄存器中存储的数据量成为FCR。TTRG或更低版本中指示的阈值时,生成SCIn_TXI中断请求。SCR。TE 为 1 时,也可以通过使用单个指令同时将 SCR。TIE 和 SCR。TE 位设置为 1 或通过将 SCR。TIE 设置为 1 来生成 SCIn_TXI 中断请求。

SCR。TIE 为 0 时,将 SCR。TE 设置为 1 不会生成 SCR_TXI 中断请求。

SCR。TEIE 为 1 并且如果在发送数据的最后一位时下一个数据没有写入 FTDRL 寄存器,则 SSR_FIFO。TEND 标志被设置为 1 并且生成 SCIn_TEI 中断请求。

SCR。RIE为1,则当FRDRL寄存器中存储的数据量等于或大于FCR。RTRG中指示的阈值时,生成SCIn_RXI中断请求。当RTRG为0时,即使接收FIFO中的数据量等于0,也不会发生SCIn_RXI中断。

SCR。RIE位为1,则当SSR_FIFO。ORER标志被设置为1或者在FRDRL寄存器中存储有成帧错误或奇偶校验错误的数据时,生成SCIn_ERI中断请求。FRDRL寄存器中存储的数据量处于阈值或以上时,还生成SCIn_RXI中断请求。SCIn_ERI 中断请求可以被取消,在这种情况下,SSR_FIFO。ORER、FER 和 PER 标志都被清除。

SCIn_TEI (n = 0, 9)	Transmit end	SSR.TEND	SCR.TEIE	Not possible

Note 1. The interrupt flag is only ORER when in clock synchronous and simple SPI mode.
Note 2. MER, SYER, PFER, and SBER work as a factor of ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECR) are set to 1.

Table 24.41 SCI interrupt sources with FIFO selected

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0, 9)	Receive error*1	SSR_FIFO.ORER, SSR_FIFO.FER, SSR_FIFO.PER, DCCR.DFER, DCCR.DPER	SCR.RIE	Not possible
		SSR_FIFO.DR (when FCR.DRES = 1)	SCR.RIE	Not possible
SCIn_RXI (n = 0, 9)	Receive data full	SSR_FIFO.RDF	SCR.RIE	Possible
	Receive data ready	SSR_FIFO.DR (when FCR.DRES = 0)	SCR.RIE	Possible
	Address match	DCCR.DCMF	SCR.RIE	Possible
SCIn_AM (n = 0, 9)	Address match	DCCR.DCMF	—	Not possible
SCIn_TXI (n = 0, 9)	Transmit data empty	SSR_FIFO.TDFE	SCR.TIE	Possible
SCIn_TEI (n = 0, 9)	Transmit end	SSR_FIFO.TEND	SCR.TEIE	Not possible

Note 1. The interrupt flag is only ORER when in clock synchronous and simple SPI mode.

24.11.4 Interrupts in Smart Card Interface Mode

Table 24.42 lists interrupt sources in smart card interface mode. A transmit end interrupt (SCIn_TEI) request and an address match (SCIn_AM) request cannot be used in this mode.

Table 24.42 SCI Interrupt sources

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0, 9)	Receive error or error signal detection	SSR_SMCI.ORER, SSR_SMCI.PER, SSR_SMCI.ERS	SCR_SMCI.RIE	Not possible
SCIn_RXI (n = 0, 9)	Receive data full	SSR_SMCI.RDRF	SCR_SMCI.RIE	Possible
SCIn_TXI (n = 0, 9)	Transmit data empty	SSR_SMCI.TEND	SCR_SMCI.TIE	Possible

Data transmission or reception using the DTC or DMAC is also possible in smart card interface mode, similar to normal SCI mode. In transmission, when the SSR_SMCI.TEND flag is set to 1, an SCIn_TXI interrupt request is generated. This SCIn_TXI interrupt request activates the DTC or DMAC, allowing transfer of transmit data if the SCIn_TXI request is previously specified as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

24。11。4 智能卡接口模式下的中断

表 24。42 列出了智能卡接口模式下的中断源。在此模式下不能使用发射端中断（SCIn_TEI）请求和地址匹配（SCIn_AM）请求。

表 24。42 SCI 中断源

名字	中断源	中断标志	中断启用	DTC 或 DMAC 激活
SCIn_ERI（n = 0, 9)	接收错误或错误信号检测	SSR_SMCI。ORER, SSR_SMCI。PER, SSR_SMCI。ERS	SCR_SMCI。RIE	不可能
SCIn_RXI（n = 0, 9)	接收完整的数据	SSR_SMCI。RDRF	SCR_SMCI。RIE	可能
SCIn_TXI（n = 0, 9)	传输数据为空	SSR_SMCI。TEND	SCR_SMCI。TIE	可能

在智能卡接口模式下也可以使用 DTC 或 DMAC 进行数据传输或接收,类似于普通 SCI 模式。在传输中,当SSR_SMCI。TEND标志设置为1时,生成SCIn_TXI中断请求。此 SCIn_TXI 中断请求激活 DTC 或 DMAC,如果 SCIn_TXI 请求先前指定为 DTC 或 DMAC 激活源,则允许传输传输数据。DTC或DMAC传输数据时,TEND标志会自动设置为0。

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission after an error occurrence. However, the SSR_SMCI.ERS flag is not automatically set to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the SCR_SMCI.RIE bit to 1 to enable an SCIn_ERI interrupt request to be generated at error occurrence.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings. For DTC or DMAC settings, see section 16, Data Transfer Controller (DTC), section 15, DMA Controller (DMAC).

In reception, an SCIn_RXI interrupt request is generated when receive data is set to the RDR register. This SCIn_RXI interrupt request activates the DTC or DMAC, allowing transfer of the receive data if the SCIn_RXI request is previously specified as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an SCIn_ERI interrupt request is issued to the CPU instead. The error flag must be cleared.

24.11.5 Interrupts in Simple IIC Mode

Table 24.43 lists the interrupt sources in simple IIC mode. The STI interrupt is allocated to the transmit end interrupt (SCIn_TEI) request. The receive error interrupt (SCIn_ERI) and the address match (SCIn_AM) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple IIC mode.

When the SIMR2.IICINTM bit is 1:

- An SCIn_RXI request is generated on the falling edge of the SCLn signal for the 8th bit. If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.
- An SCIn_TXI request is generated on the falling edge of the SCLn signal for the 9th bit (acknowledge bit). If SCIn_TXI is previously set up as an activation source for the DTC or DMAC, the SCIn_TXI request activates the DTC or DMAC to handle transfer of the transmit data.

When the SIMR2.IICINTM bit is 0:

- An SCIn_RXI request (ACK detection) is generated if the input on the SDAn pin is low on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- An SCIn_TXI request (NACK detection) is generated if the input on the SDAn pin is high on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.

If the DTC or DMAC is used for data transfer in reception or transmission, always set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in SIMR3 are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Table 24.43 SCI interrupt sources

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_RXI (n = 0, 9)	Reception, ACK detection	—	SCMR.RIE	Possible*1
SCIn_TXI (n = 0, 9)	Transmission, NACK detection	—	SCMR.TIE	Possible
SCIn_TEI(STIn) (n = 0, 9)	Completion of generation of a start, restart, or stop condition	SIMR3.IICSTIF	SCMR.TEIE	Not possible

Note 1. Activation of the DTC or DMAC is only possible when the SIMR2.IICINTM bit is 1 (use reception and transmission interrupts)

24.12 Event Linking

By using interrupt request signals as event signals, the SCIn can provide linked operation through the ELC for modules selected in advance.

如果发生错误,SCI 会自动重传相同的数据。重传期间,TEND 标志保持在 0,并且 DTC 或 DMAC 未激活。因此,SCI和DTC或DMAC自动传输指定数量的字节,包括在发生错误后重传。但是,发生错误时,SSR_SMCI。ERS 标志不会自动设置为 0。因此,必须通过预先将 SCR_SMCI。RIE 位设置为 1 来清除 ERS 标志,以便在发生错误时生成 SCIn_ERI 中断请求。

DTC 或 DMAC 传输或接收数据时,在进行 SCI 设置之前,始终启用 DTC 或 DMAC。DTC 或 DMAC 设置, 请参阅第 16 节, 数据传输控制器（DTC）, 第 15 节, DMA 控制器（DMAC）.

在接收中,当接收数据被设置为 RDR 寄存器时,会生成 SCIn_RXI 中断请求。该SCIn_RXI中断请求激活DTC或DMAC,如果SCIn_RXI请求先前被指定为DTC或DMAC激活源,则允许传输接收数据。如果发生错误,则设置错误标志。因此,DTC或DMAC没有被激活,而是向CPU发出SCIn_ERI中断请求。必须清除错误标志。

24。11。5 简单 IIC 模式下的中断

表 24。43 列出了简单 IIC 模式下的中断源。STI中断分配给发送端中断（SCIn_TEI）请求。无法使用接收错误中断（SCIn_ERI）和地址匹配（SCIn_AM）请求。

DTC 或 DMAC 还可用于处理简单 IIC 模式下的传输。

当SIMR2。IICINTM 位为 1:

● 在 8th 位的 SCLn 信号的下降沿上生成 SCIn_RXI 请求。如果SCIn_RXI先前被设置为DTC或DMAC的激活源,则SCIn_RXI请求激活DTC或DMAC以处理接收到的数据的传输。

● 在 9th 位（确认位）的 SCLn 信号的下降沿上生成 SCIn_TXI 请求。如果SCIn_TXI先前被设置为DTC或DMAC的激活源,则SCIn_TXI请求激活DTC或DMAC以处理发送数据的传输。

当SIMR2。IICINTM 位为 0:

● 如果 SDAn 引脚上的输入在 9th 位（确认位）的 SCLn 信号的上升沿较低,则会生成 SCIn_RXI 请求（ACK 检测）

● 如果 SDAn 引脚上的输入在 9th 位（确认位）的 SCLn 信号的上升沿上较高,则会生成 SCIn_TXI 请求（NACK 检测）

● 如果 SCIn_RXI 先前被设置为 DTC 或 DMAC 的激活源,则 SCIn_RXI 请求激活 DTC 或 DMAC 以处理接收到的数据的传输。

如果 DTC 或 DMAC 用于接收或传输中的数据传输,请在设置 SCI 之前始终设置并启用 DTC 或 DMAC。

当SIMR3中的IICSTAREQ、IICRSTAREQ和IICSTPREQ位用于生成开始条件、重启条件或停止条件时,当生成完成时发出STI请求。

表 24。43 SCI 中断源

名字	中断源	中断标志	中断启用	DTC 或 DMAC 激活
SCIn_RXI（n = 0, 9）	接待处,ACK检测	—	SCMR.RIE	可能*1
SCIn_TXI（n = 0, 9）	传输、NACK检测	—	SCMR.TIE	可能
SCIn_TEI（STIn）（n = 0, 9）	完成启动、重新启动或停止条件的生成	SIMR3。IICSTIF	SCMR.TEIE	不可能

注1。仅当 SIMR2 时才可以激活 DTC 或 DMAC。IICINTM 位为 1（使用接收和传输中断）24。12

24.14 Noise Cancellation Function

Figure 24.98 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a 2-stage flip-flop circuit and a match detection circuit. When the input signals of the noise filter and the output signals of the 2- stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. When the same level is retained for 3 cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for 3 cycles or shorter is considered as noise, not as a receive signal.

In asynchronous mode, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The receive level of the RXDn is taken in the flip-flop circuit of the noise filter on the base clock of asynchronous mode.

- When SEMR.ABCS = 0 and SEMR.ABCSE = 0, the cycle is 1/16 of a 1-bit period.
- When SEMR.ABCS = 1 and SEMR.ABCSE = 0, the cycle is 1/8 of a 1-bit period.
- When SEMR.ABCSE = 1, the cycle is 1/6 of a 1-bit period.

In simple IIC mode, this function can be used for each input on SDAn and SCLn. The sampling clock is selected from divided clock of baud rate generator settings SNFR.NFCS[2:0].

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR.TE and SCR.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, the function determines that a level match is detected and the result is conveyed as an internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles.

24.15 Usage Notes

24.15.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable SCI operation. The SCI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

24。14 噪音消除功能

图 24。98 显示了用于噪声消除的噪声滤波器的配置。噪声滤波器由两级触发器电路和匹配检测电路组成。当噪声滤波器的输入信号与2级触发电路的输出信号完全匹配时,匹配的电平作为内部信号传送。除非另有匹配,否则保留先前的值。当噪声滤波器的采样时钟上相同电平保留 3 个周期或更长时间时,它被视为有效的接收信号。3个周期或更短的脉冲变化被视为噪声,而不是接收信号。

在异步模式下,噪声消除功能可以应用于输入到RXDn引脚的接收信号。RXDn的接收电平在异步模式的基时钟上的噪声滤波器的触发器电路中取。

- 当 SEMR。ABCS = 0 和 SEMR。ABCSE = 0 时,周期为 1 位周期的 1/16。
- 当 SEMR。ABCS = 1 和 SEMR。ABCSE = 0 时,周期为 1 位周期的 1/8。
- 当 SEMR。ABCSE = 1 时,周期为 1 位周期的 1/6。

在简单的 IIC 模式下,该功能可用于 SDAn 和 SCLn 上的每个输入。采样时钟选自波特率发生器设置的分时钟SNFR。NFCS[2:0]。

如果在启用噪声滤波器的情况下停止基时钟一次,然后再次重新启动基时钟输入,则噪声滤波器操作从停止时钟的状态恢复。当基时钟输入期间 SCR。TE 和 SCR。RE 设置为 0 时,所有噪声滤波器触发器值都初始化为 1。因此,如果当接收操作恢复时输入数据为1,则该函数确定检测到电平匹配并且将结果作为内部信号传送。当输入的电平对应于0时,噪声滤波器的初始输出被保留,直到电平在三个连续的采样周期中匹配。

24.15.1 模块停止功能的设置

模块停止控制寄存器 B（MSTPCRB）可以启用或禁用 SCI 操作。SCI在重置后最初停止。释放模块停止状态可以访问寄存器。有关详细信息,请参阅第 10 节"低功耗模式 ."

24.15.2 SCI Operation during Low Power State

(1) Transmission

When setting the module to the stopped state or in transitions to Software Standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR/SCR_SMCI to 0) after switching the TXDn pin to the general I/O port pin function. When setting I/O port as an SCI connection, the SPTR register can control the state of the TXDn pin. Setting the TE bit to 0 initializes the TSR register and the TEND bit in the SSR/SSR_SMCI is initialized to 1 with non-FIFO selected, and the value is retained, with FIFO selected. Depending on the port settings and SPTR register settings, output pins might output the level before a transition to the low-power state is made after release from the module-stopped state or Software Standby mode. When transitions to these states are made during transmission, the transmitted data becomes indeterminate.

To transmit data in the same transmission mode after cancellation of the low-power state:

1. Set the TE bit to 1.
2. Read SSR/SSR_FIFO/SSR_SMCI.
3. Write data to TDR sequentially to start data transmission.

To transmit data with a different transmission mode, initialize the SCI first.

Figure 24.99 shows an example flow of transition to Software Standby mode during transmission. Figure 24.100 and Figure 24.101 show the port pin states during transition to Software Standby mode.

Before specifying the module-stop state or transitioning to Software Standby mode from the transmission mode using DTC or DMAC transfer, stop the transmit operations (TE = 0). To start transmission after cancellation using the DTC or DMAC, set the TE bit to 1. The SCIn_TXI interrupt flag is set to 1 and transmission starts using the DTC or DMAC.

(2) Reception

When address match function is not used as wakeup condition

Before specifying the module-stop state or transitioning to Software Standby mode, stop the receive operations (RE = 0 in SCR/SCR_SMCI). If transition is made during data reception, the received data is invalid.

Figure 24.102 shows an example flow of transition to Software Standby mode during reception.

When address match function is used as wakeup condition

Before specifying the module-stop state or transitioning to Software Standby mode:

1. Set the operations after cancellation of the low power state.
2. Set CDR.CMPD and DCCR.DCME to 1.
3. Set the receive operations (RE = 1 in SCR/SCR_SMCI).
4. Set the module-stop state or Software Standby mode.

When SCI transfers to low power mode, if the receive data pin (RXD) is at the low level, set SEMR.RXDESEL = 0.

When setting SEMR.RXDESEL = 1, there is a possibility that a start bit (falling edge of RXD pin) cannot be detected on release of the low power mode.

Figure 24.103 shows an example flow of transition to Software Standby mode during reception with address match.

When using SCI0 in Snooze mode

When using SCI0 in Snooze mode, some restrictions apply, including maximum bit rates. For details, see section 10, Low Power Modes.

24.15.2 低功率状态下的 SCI 操作

（一）传动

TXDn引脚切换到一般I/O端口引脚功能后,将模块设置为停止状态或转换为软件待机时,停止操作（通过将SCR/SCR_SMCI中的TIE、TE、TEIE位设置为0)。I/O端口设置为SCI连接时,SPTR寄存器可以控制TXDn引脚的状态。TE 位设置为 0 初始化 TSR 寄存器, SSR/SSR_SMCI 中的 TEND 位初始化为 1, 选择非 FIFO, 并保留该值, 选择 FIFO。根据端口设置和 SPTR 寄存器设置,输出引脚可能会在从模块停止状态或软件待机模式释放后过渡到低功耗状态之前输出电平。当在传输过程中转换到这些状态时,传输的数据变得不确定。

要在取消低功耗状态后以相同的传输模式传输数据:

1. Set the TE bit to 1.

2锛姣涓涓。读取 SSR/SSR_FIFO/SSR_SMCI。

3锛 娴 。依次将数据写入TDR以开始数据传输。

要以不同的传输模式传输数据,请首先初始化 SCI。

图 24。99 显示了传输期间过渡到软件待机模式的示例流程。图 24。100 和图 24。101 显示了过渡到软件待机模式期间的端口引脚状态。

在使用 DTC 或 DMAC 传输指定模块停止状态或从传输模式转换为软件待机模式之前,停止传输操作（TE = 0)。要使用 DTC 或 DMAC 取消后开始传输,请将 TE 位设置为 1。SCIn_TXI中断标志设置为1,并使用DTC或DMAC开始传输。

（二）接待

当地址匹配功能不用作唤醒条件时

在指定模块停止状态或过渡到软件待机模式之前,停止接收操作（SCR/SCR_SMCI 中的 RE = 0)。如果在数据接收期间进行转换,则接收到的数据无效。

图 24。102 显示了接收期间过渡到软件待机模式的示例流程。

当地址匹配功能用作唤醒条件时

在指定模块停止状态或过渡到软件待机模式之前:

1。设置取消低功率状态后的操作。

2锛姣涓涓。将 CDR。CMPD 和 DCCR。DCME 设置为 1。

3锛 娴 。设置接收操作（SCR/SCR_SMCI 中的 RE = 1)。

4锛姣涓。设置模块停止状态或软件待机模式。

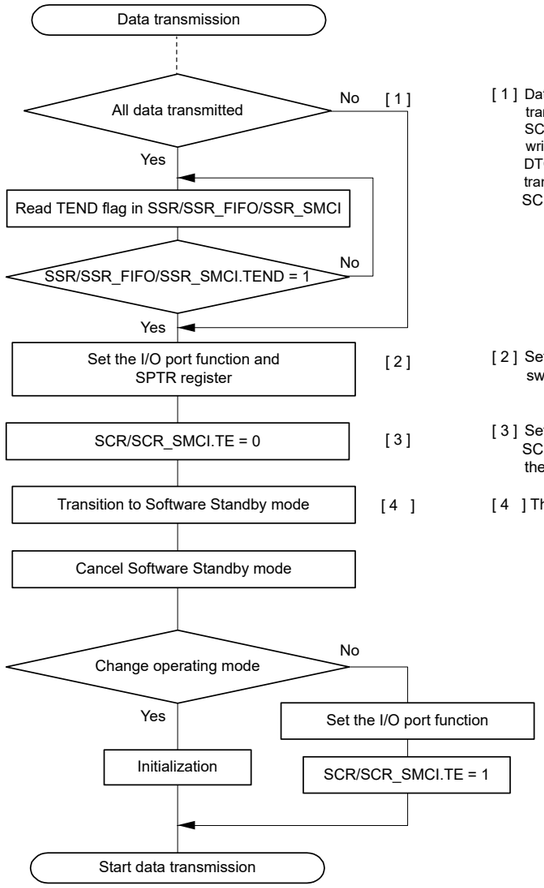
SCI传输到低功耗模式时,如果接收数据引脚（RXD）处于低电平,则设置SEMR。RXDESEL = 0。

当设置 SEMR。RXDESEL = 1 时,有可能在释放低功耗模式时无法检测到启动位（RXD 引脚的下落边）。

图 24。103 显示了接收期间与地址匹配的软件待机模式过渡的示例流程。

在贪睡模式下使用 SCI0 时

Snooze 模式下使用 SCI0 时,会应用一些限制,包括最大比特率。详情请参阅第 10 节"低"电源模式。



[1] Data being transmitted is lost. Data can be normally transmitted from the CPU by setting the TE bit in SCR/SCR_SMCI to 1, reading SSR/SSR_FIFO/ SSR_SMCI, and writing in Software Standby mode. However, if the DMAC or DTC is activated, the data remaining in the DMAC or DTC is transmitted when both the TE and TIE bits in SCR/SCR_SMCI are set to 1.

[2] Set the I/O port function and SPTR register settings to switch the TXDn pin to operate as a general I/O port.

[3] Set SCR/SCR_SMCI.TE bit to 0. If SCR/SCR_SMCI.TIE = 1 and SCR/SCR_SMCI.TEIE = 1, these are set to 0 simultaneously with the SCR.TE bit.

[4] This includes the setting for the module-stop state.

[1] 正在传输的数据丢失。SCR/SCR_SMCI中的TE位设置为1,读取SSR/SSR_FIFO/SSR_SMCI,以软件待机模式写入,就可以正常地从CPU传输数据。但是,如果DMAC或DTC被激活,则当SCR/SCR_SMCI中的TE和TIE位都被设置为1时,DMAC或DTC中剩余的数据被发送。

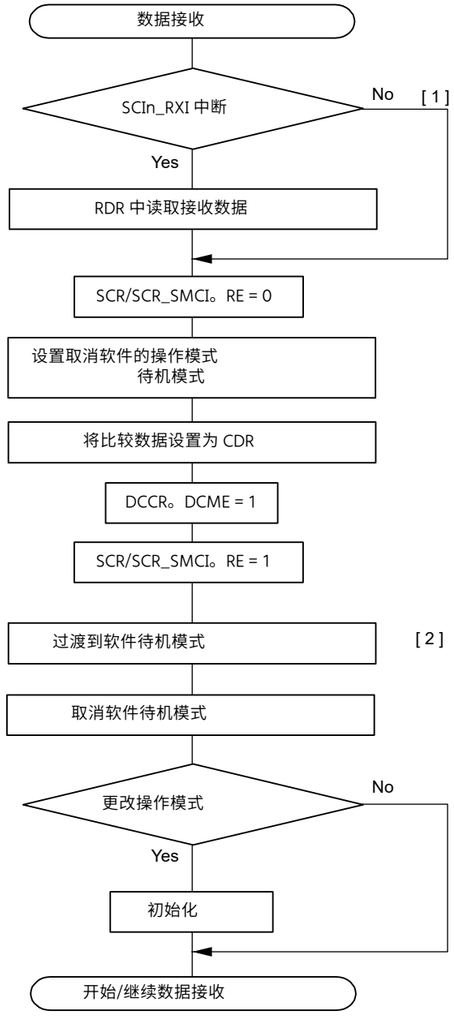
24.15.3 Break Detection and Processing

(1) Non-FIFO selected

When a framing error is detected, a break can be detected by reading the RXDn pin value directly. In a break, the input from the RXDn pin becomes all 0s, and the SSR.FER flag is set to 1 to indicate a framing error, and the SSR.PER flag might also be set to 1 to indicate a parity error. The SCI continues the receive operation even after a break is received. Therefore, even if the FER flag is 0, indicating that no framing error occurred, it is set to 1 again. When the SEMR.RXDESEL bit is 1, the SCI sets the SSR.FER flag to 1 and stops receiving operations until a start bit of the next data frame is detected. If the SSR.FER flag is set to 0, the SSR.FER flag retains 0 during the break.



[1] 接收到的数据无效

[2] 包括模块停止状态的设置

图 24。103 在接收期间通过地址匹配过渡到软件待机模式的示例流程

24。15。3 断裂检测和处理

（一）非FIFO入选

当检测到成帧错误时,可以通过直接读取 RXDn 引脚值来检测中断。休息时,来自 RXDn 引脚的输入变为所有 0,并且 SSR。FER 标志设置为 1 以指示成帧错误,并且 SSR。PER 标志也可能设置为 1 以指示奇偶校验错误。即使在收到中断后,SCI 仍继续接收操作。因此,即使FER标志为0,表明没有发生成帧错误,也再次设置为1。当SEMR。RXDESEL位为1时,SCI将SSR。FER标志设置为1并停止接收操作,直到检测到下一个数据帧的起始位。如果 SSR。FER 标志设置为 0,则 SSR。FER 标志在中断期间保留 0。

When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit on the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

(2) FIFO selected

After a framing error is detected and when the SCI detects that continuous receive data is 0 for 1 frame, reception stops. When a framing error is detected, a break can be detected by reading the SPTR.RXDMON flag value. After the RXDn signal is in high and the break is finished, data reception to the FRDRHL register resumes.

24.15.4 Mark State and Production of Breaks

When the SCR/SCR_SMCI.TE bit is 0, disabling serial transmission, the state of the TXDn pin can be set using the SPTR.SPB2IO and SPTR.SPB2DT bits. With this approach, a TXDn pin can be placed in the mark state to transmit a break.

Before setting the SCR/SCR_SMCI.TE bit to 1, enabling serial transmission, set the SPB2IO and SPB2DT bits to put the communication line in the mark state (the state of 1), and change the TXDn pin using I/O port function. To output a break on data transmission, after setting the TXDn pin to output 0 by setting the SPB2IO and SPB2DT bits, change the TXDn pin using the I/O port function and set the SCR/SCR_SMCI.TE bit to 0. When the SCR/SCR_SMCI.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

24.15.5 Receive Error Flags and Transmit Operation in Clock Synchronous Mode and Simple SPI Mode

Transmission cannot start when a receive error flag (ORER) in SSR/SSR_FIFO is set to 1, even when data is written to TDR or FTDRL*1. Always set the receive error flags to 0 before starting transmission.

Note: The receive error flags cannot be set to 0 when the RE bit in SCR/SCR_SMCI is set to 0 (serial reception is disabled).

Note 1. Do not use the FTDRH register in simple SPI mode.

24.15.6 Restrictions on Clock Synchronous Transmission in Clock Synchronous Mode and Simple SPI Mode

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

Wait at least the following time from writing transmit data to TDR to the start of the external clock input:

1 PCLK cycle + data output delay time for the slave (t_{DO}) + setup time for the master (t_{SU}). See Figure 24.104.

(2) Continuous transmission

Write the next transmit data to TDR or TDRHL before the falling edge of the transmit clock for bit [7] . See Figure 24.104.

When updating TDR after bit [7] has started to transmit, update TDR while the synchronization clock is in the low-level period, and set the high-level width of the transmit clock (bit [7]) to 4 PCLK cycles or longer. See Figure 24.104.

RXDn引脚设置为1且断裂结束时,检测RXDn引脚第一下降沿上的起始位开始,SCI即可开始接收操作。

(2)选定的FIFO

检测到成帧错误后,当 SCI 检测到 1 帧的连续接收数据为 0 时,接收停止。当检测到成帧错误时,可以通过读取SPTR。RXDMON标志值来检测中断。RXDn信号处于高电平并且中断结束后,恢复对FRDRHL寄存器的数据接收。

24。15。4 标记状态和中断的产生

当SCR/SCR_SMCI。TE位为0时,禁用串行传输,可以使用SPTR。SPB2IO和SPTR。SPB2DT位来设置TXDn引脚的状态。通过这种方法,可以将 TXDn 引脚放置在标记状态以传输中断。

SCR/SCR_SMCI。TE位设置为1之前,启用串行传输,将SPB2IO和SPB2DT位设置为将通信线路置于标记状态(1的状态）,并使用I/O端口功能更改TXDn引脚。要输出数据传输中断,通过设置SPB2IO和SPB2DT位将TXDn引脚设置为输出0后,使用I/O端口功能更改TXDn引脚并将SCR/SCR_SMCI。TE位设置为0。SCR/SCR_SMCI。TE 位设置为 0 时,无论传输的当前状态如何,发射机都会被初始化。

24。15。5 在时钟同步模式和简单 SPI 模式下接收错误标志并传输操作

SSR/SSR_FIFO 中的接收错误标志（ORER）设置为 1 时, 即使数据写入到 TDR 或 FTDRL *1 时, 传输也无法启动。在开始传输之前始终将接收错误标志设置为 0。

注意:当SCR/SCR_SMCI中的RE位设置为0时,接收错误标志不能设置为0（禁用串行接收）。

注1。请勿在简单的 SPI 模式下使用 FTDRH 寄存器。

24.15.6 时钟同步模式和简单SPI模式下时钟同步传输的限制

当外部时钟源用作同步时钟时,适用以下限制。

(1)传送的开始

TDR 写入传输数据到外部时钟输入开始, 至少等待以下时间:

1 PCLK 周期 + 从站的数据输出延迟时间（t_{DO}) + 主站的设置时间（t_{SU}). 参见图 24。104 .）

(2)连续传输

位[7]的发送时钟下降沿之前将下一个发送数据写入TDR或TDRHL。参见图 24。104 .

位[7]已经开始发送之后更新TDR时,在同步时钟处于低电平周期时更新TDR,并将发送时钟的高电平宽度（位[7]）设置为4个PCLK周期或更长。参见图 24。104 .

(2) Continuous transmission (b)

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 24.104 Restraints on use of external clock in clock synchronous transmission

24.15.7 Restrictions on Using DTC or DMAC

During transmission or reception operations using the DTC or DMAC, do not set transfer data for the DTC or DMAC.

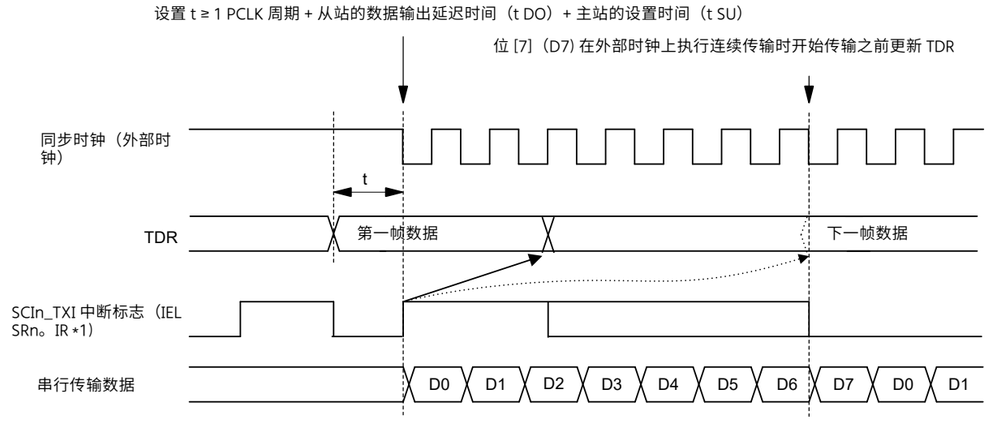
(1) Writing data to TDR (FTDRHL)

Non-FIFO selected

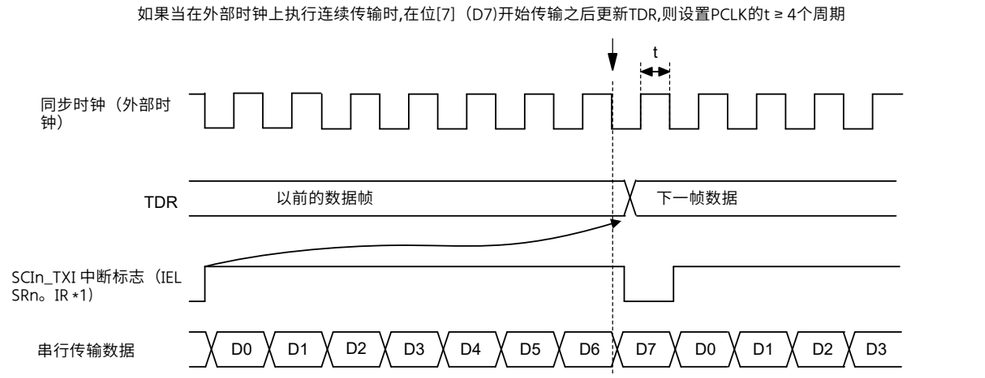
Data can be written to TDR and TDRHL. However, if new data is written to TDR or TDRHL when transmit data remains in TDR or TDRHL, the previous data in TDR and TDRHL is lost because it was not transferred to TSR yet. When using DTC or DMAC, always write transmit data to TDR or TDRHL in the SCIn_TXI interrupt request handling routine.

FIFO selected

It is possible to write data to the FTDRH and FTDRL registers when SCR.TE is 1. Confirm the amount of writable data using the FDR.T[4:0] bits.



(1)传输的开始和(2)连续传输（a）



（二）连续传输（b）

注1。有关相应中断事件编号的信息,请参阅第 12 节"中断控制器单元（ICU）"。

图 24。104 在时钟同步传输中使用外部时钟的限制

24。15。7 使用 DTC 或 DMAC 的限制

DTC 或 DMAC 进行传输或接收操作期间, 请勿为 DTC 或 DMAC 设置传输数据。

(1)向TDR（FTDRHL）编写数据

选择非 FIFO

数据可以写入 TDR 和 TDRHL。但是,如果传输数据时新数据写入 TDR 或 TDRHL 仍保留在 TDR 或 TDRHL 中,则 TDR 和 TDRHL 中的先前数据将丢失,因为它尚未传输到 TSR。DTC 或 DMAC 时, 始终在 SCIn_TXI 中断请求处理例程中将传输数据写入 TDR 或 TDRHL。

FIFO 已选择

当 SCR。TE 为 1 时,可以将数据写入 FTDRH 和 FTDRL 寄存器。FDR。T[4:0]位确认可写数据量。

(2) Reading data from RDR (FRDRHL)

When using the DTC or DMAC to read RDR and RDRHL, always set the receive data full interrupt (SCIn_RXI) as the activation source of the relevant SCI.

24.15.8 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IELSRn.IR flag) in the ICU is 1, follow the procedure in this section to clear interrupt requests before permitting operations (by setting the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit to 1). For details on the interrupt status flag, see section 12, Interrupt Controller Unit (ICU).

1. Confirm that transfer has stopped (the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit is 0)
2. Set the associated interrupt enable bit (SCR/SCR_SMCI.TIE or SCR/SCR_SMCI.RIE bit) to 0
3. Read the associated interrupt enable bit (SCR/SCR_SMCI.TIE or SCR/SCR_SMCI.RIE bit) to check that it actually becomes 0
4. Set the interrupt status flag, IELSRn.IR, in the ICU to 0

24.15.9 External Clock Input in Clock Synchronous Mode and Simple SPI Mode

In clock synchronous mode and simple SPI mode, the external clock SCKn must be input as follows:

High-pulse period, low-pulse period = 2 PCLK cycles or more, period = 6 PCLK cycles or more.

24.15.10 Limitations on Simple SPI Mode

(1) Master mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set in the SPMR.CKPH and CKPOL bits when the SPMR.SSE bit is 1.

  This prevents the clock line from being placed in the high-impedance state when the SCR.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR.TE bit changes from 0 to 1. When the SPMR.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not required because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.

- For the clock delay setting (SPMR.CKPH bit is 1), the receive data full interrupt (SCIn_RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 24.105. If the TE and RE bits in the SCR register become 0 before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Additionally, an SCIn_RXI interrupt might lead to the input signal on the SSn pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, the SCKn pin output goes to high-impedance while the input on the SSn pin is at the low level if a mode fault error occurs while a character is being transferred, stopping supply of the clock signal to the connected slave. Reset the connected slave to avoid misaligned bits when transfer is restarted.

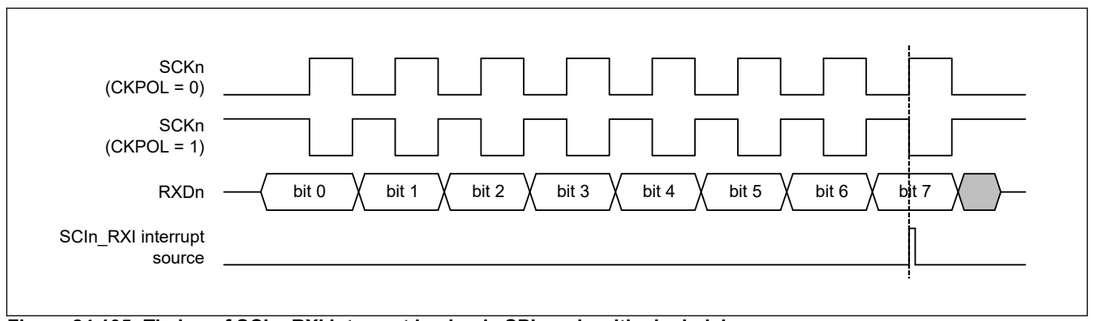


Figure 24.105 Timing of SCIn_RXI interrupt in simple SPI mode with clock delay

(2) 从 RDR（FRDRHL）读取数据

DTC 或 DMAC 读取 RDR 和 RDRHL 时,始终将接收数据完全中断（SCIn_RXI）设置为相关 SCI 的激活源。

24。15。8 关于开始转移的说明

ICU 中中断状态标志（IELSRn。IR 标志）为 1 时开始传输的点, 请按照本节中的程序清除中断请求, 然后再允许操作（通过设置 SCR/SCR_SMCI。TE 或 SCR/SCR_SMCI。RE 位至 1)。中断状态标志的详细信息,请参见第 12 节"中断控制器单元（ICU）."

1。确认传输已停止（SCR/SCR_SMCI。TE 或 SCR/SCR_SMCI。RE 位为 0）

2锛姣涓涓。将关联的中断使能位（SCR/SCR_SMCI。TIE 或 SCR/SCR_SMCI。RIE 位）设置为 0

3锛　　娴　　。读取关联的中断使能位（SCR/SCR_SMCI。TIE 或 SCR/SCR_SMCI。RIE 位）以检查它是否实际变为 0

4锛姣涓。ICU 中设置中断状态标志 IELSRn。IR 为 0

24。15。9 时钟同步模式和简单 SPI 模式下的外部时钟输入

在时钟同步模式和简单SPI模式下,必须按如下方式输入外部时钟SCKn:

高脉冲周期,低脉冲周期 = 2 个 PCLK 周期或更多,周期 = 6 个 PCLK 周期或更多。

24。15。10 简单 SPI 模式的限制

（一）主模式

● 在 SPMR。SSE 位为 1 时,使用电阻向上或向下拉与 SPMR。CKPH 和 CKPOL 位中设置的传输时钟的初始设置相匹配的时钟线。

这可以防止 SCR。TE 位设置为 0 时时钟线处于高阻抗状态,或者当 SCR。TE 位从 0 更改为 1 时时钟线上产生意外边缘。SPMR。SSE位在单主模式下为0时,不需要向上拉或向下拉时钟线,因为即使SCR。TE位设置为0时,时钟线也不处于高阻抗状态。

● 对于时钟延迟设置（SPMR。CKPH 位为 1),在 SCKn 引脚上的最终时钟边沿之前生成接收数据完全中断（SCIn_RXI）,如图 24。105 所示。SCR寄存器中的TE和RE位在SCKn引脚上的时钟信号的最终边缘之前变为0,则SCKn引脚置于高阻抗状态,因此传输时钟的最后一个时钟脉冲的宽度被缩短。此外,SCIn_RXI中断可能会导致连接的从站的SSn引脚上的输入信号在SCKn引脚上的时钟信号的最终边缘之前进入高电平,从而导致从站的错误操作。

● 在多主配置中,如果在传输字符时发生模式故障错误,则 SCKn 引脚输出进入高阻抗,而 SSn 引脚上的输入处于低电平,从而停止向连接的从站提供时钟信号。重置连接的从站,以避免重新启动传输时位错位。

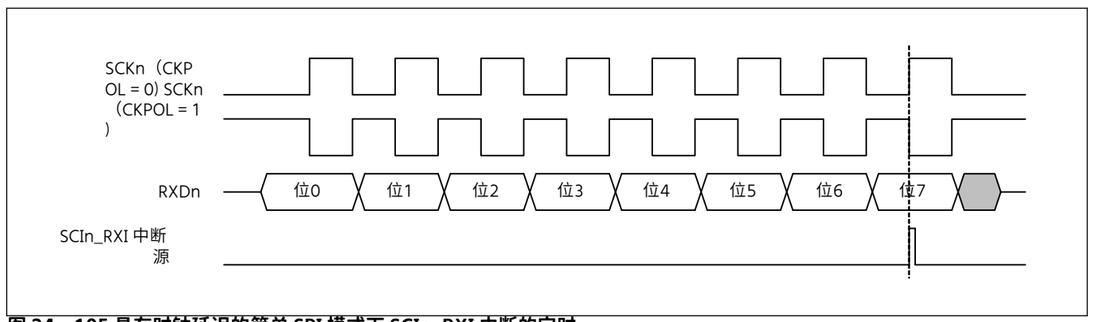

图 24。105 具有时钟延迟的简单 SPI 模式下 SCIn_RXI 中断的定时

(2) Slave mode

- Wait at least the following time from writing transmit data in the TDR register to the start of the external clock input.

  1 PCLK cycle + data output delay for the slave (t_{DO}) + setup time for the master (t_{SU})

  Also wait at least 5 PCLK cycles from the input of the low level on the SSn pin to the start of the external clock input.
- Provide an external clock signal to the master the same as the data length for transfer
- Control the input on the SSn pin before the start and after the end of data transfer
- When the input level on the SSn pin is to be changed from low to high while a character is being transferred, set the TE and RE bits in the SCR register to 0 and, after restoring the settings, restart transfer of the first byte

24.15.11 Notes on Transmit Enable Bit (SCR.TE)

In initial register value, when SCR.TE = 0, the state of the TXDn pin is high impedance. The TXDn line should not be high impedance by the following one of ways.

1. The pull-up resistance is connected to the TXDn line.
2. Before setting the SCR.TE bit to 0, the function of the pin should be changed to a general-purpose output port. After that, set the SCR.TE bit to 1, and then change the function of the pin to TXDn.
3. In asynchronous mode, set SPTR and decided level of TXDn pin during SCR.TE = 0.

In the Simple SPI mode slave operation, the MISOn pin operates in the same way as the above TXDn pin. The MISOn pin, the same as TXDn pin, should not be high impedance by the above list number 1 or list number 2.

24.15.12 Note on Stopping Reception When Using the RTS Function in Asynchronous Mode

One clock cycle of PCLK is required for the time from setting the SCR.RE bit to 0 to stopping the RTS signal generator in asynchronous mode.

When reading the RDR (or RDRL) register after setting the SCR.RE bit to 0, confirm that the RE bit has been set to 0 before reading the RDR (or RDRL) register to prevent these two processes from being performed consecutively.

(2)从模式

- 从在 TDR 寄存器中写入传输数据到外部时钟输入开始,至少等待以下时间。

  1 PCLK 周期 + 从站的数据输出延迟（t_{DO}) + 主站的设置时间（t_{SU}))

  SSn引脚上的低电平的输入到外部时钟输入的开始,也要等待至少5个PCLK周期。
- 向主机提供与数据长度相同的外部时钟信号进行传输
- 控制数据传输开始前和结束后的 SSn 引脚上的输入
- 当要在传输字符时将 SSn 引脚上的输入电平从低变为高时,将 SCR 寄存器中的 TE 和 RE 位设置为 0,并在恢复设置后重新启动第一个字节的传输

24。15。11 关于传输启用位（SCR。TE）的注释

在初始寄存器值中,当SCR。TE = 0时,TXDn引脚的状态为高阻抗。TXDn 线不应通过以下一种方式产生高阻抗。

1。上拉电阻连接到 TXDn 线。

2锛姣涓涓。SCR。TE 位设置为 0 之前,引脚的功能应改为通用输出端口。之后,将SCR。TE位设置为1,然后将引脚的功能更改为TXDn。

3锛　　娴　　。在异步模式下,在 SCR。TE = 0 期间设置 SPTR 并确定 TXDn 引脚的电平。

在简单 SPI 模式从操作中,MISOn 引脚的操作方式与上述 TXDn 引脚相同。MISOn引脚与TXDn引脚相同,不应被上述列表编号1或列表编号2高阻抗。

24。15。12 关于在异步模式下使用 RTS 功能时停止接收的说明

从将 SCR。RE 位设置为 0 到以异步模式停止 RTS 信号发生器的时间需要 PCLK 的一个时钟周期。

SCR。RE 位设置为 0 后读取 RDR（或 RDRL）寄存器时,在读取 RDR（或 RDRL）寄存器之前确认 RE 位已设置为 0,以防止这两个进程连续执行。

Note 1. This bit supports I3C master mode and I3C secondary master mode.
Note 2. This bit supports all I3C mode.

INCBA bit (Include I3C Broadcast Address)

This bit controls whether the I3C broadcast address (0x7E) is included for private transfers.

If the I3C broadcast address is not included for private transfers, then IBIs driven from Slaves might not win the arbitration, potentially delaying acceptance of the IBIs.

ABT bit (Abort)

When set to 1, this bit allows I3C to relinquish control of the I3C Bus before completing the currently issued transfer.

In response to an ABORT request, I3C issues the STOP condition on the I3C Bus after the complete data byte is transferred or received.

The Driver shall clear the ABT bit to allow operation on the Bus.

If BCTL.ABT is set and ABORT processing is performed, please ignore ERR_STATUS of Response Descriptor.

RSM bit (Resume)

This bit is used to resume I3C operation following the Halt state.

I3C enters the Halt state (as indicated in register PRSTDBG) as a result of any type of error occurring in a transfer.

The error type is indicated by the field ERR_STATUS in register NRSPQP, HRSPQP, NRSQP and NIBIQP).

PRTMD 位（协议模式）

PRTMD = 0:I3C FIFO 缓冲区转移（相当于 HCI）

PRTMD = 1:I 2 C 单缓冲区传输

25.2.2 BCTL:总线控制寄存器

基本地址: I3C = 0x4011_F000

偏移地址: 0x014

注1。该位支持I3C主模式和I3C辅助主模式。
注2。该位支持所有 I3C 模式。

INCBA 位（包括 I3C 广播地址）

I3C 广播地址 (0x7E）是否包含用于私有传输, 该位控制。

I3C广播地址不包含用于私人转账,那么从Slaves驱动的IBI可能无法赢得仲裁,可能会延迟接受IBI。

ABT 位（中止）

1 时,该位允许 I3C 在完成当前发布的传输之前放弃对 I3C 总线的控制。

ABORT请求,I3C在传输或接收完整的数据字节后,在I3C总线上发出STOP条件。

驾驶员应清除 ABT 位以允许在总线上运行。

如果设置了 BCTL。ABT 并执行了 ABORT 处理,请忽略响应描述符的 ERR_STATUS。

RSM 位（简历）

该位用于在停止状态之后恢复 I3C 操作。

I3C由于传输中发生任何类型的错误而进入停止状态（如寄存器PRSTDBG中所示）。

误差类型由寄存器 NRSPQP、HRSPQP、NRSQP 和 NIBIQP 中的字段 ERR_STATUS 指示。

After I3C has entered the Halt state, the application must write the value 1 to the RSM bit to resume I3C operation. I3C shall auto-clear the RSM bit once it has resumed making transfers (it has initiated the next Command).

BUSE bit (Bus Enable)

Enables or disables the operation on the I3C Bus by I3C.

Set the BUSE bit to 1 when using I3C. The SCL and SDA pins are placed in the active state when the BUSE bit is set to 1. Set the BUSE bit to 0 when I3C is not to be used. The SCL and SDA pins are placed in the inactive state when the BUSE bit is set to 0.

If the software sets this bit, then it also confirms that initialization is done, and that I3C can use the programmed register values (For example, generation of SCL on IBI detection, etc.). If this bit is not set, then I3C shall not generate SCL for incoming IBI.

Software may disable I3C bus operation while it is active, However:

- If a disable request occurs while receiving IBI, the actual disabling will not occur until reception of the IBI is complete.
- When the software reads the value 0 from this field, this indicates that I3C bus operation disable operation has completed.
  If commands remain in the command queue, do not set BUSE = 0.

25.2.3 MSDVAD : Master Device Address Register

Base address: I3C = 0x4011_F000

Offset address: 0x018

Bit position:	31	30	29	28	27	26	25	24	23	22						16

22:16	MDYAD[6:0]	Master Dynamic Address	R/W

31	MDYADV	Master Dynamic Address Valid 0: The master dynamic address field is not valid. 1: The master dynamic address field is valid.	R/W

Note: This register supports I3C master mode.

MDYAD[6:0] bits (Master Dynamic Address)

This field is used to program I3C master dynamic address. I3C uses this address to respond to master transactions in I3C interface mode (slave or secondary master role).

In I3C main master mode, the software shall program the dynamic address as it self-assigns its dynamic address.

MDYADV bit (Master Dynamic Address Valid)

This bit indicates whether or not the value in the MDYAD field is valid.

In I3C main master mode, the user sets this bit to 1 as it self-assigns its dynamic address.

Note: After setting MSDVAD, and setting BCTL. BUSE = 1, the device will act as main master.
Without setting MSDVAD, setting SVDCT.TBCR76[1:0] = 00b (Device Role Slave), and setting BCTL.BUSE = 1, the device will act as slave.

I3C 已进入停止状态后,应用程序必须将值 1 写入 RSM 位才能恢复 I3C 操作。I3C 恢复进行传输后（它已启动下一个命令）应自动清除 RSM 位。

BUSE 位（启用总线）

I3C 在 I3C 总线上启用或禁用操作。

I3C 时将 BUSE 位设置为 1。BUSE 位设置为 1 时,SCL 和 SDA 引脚处于活动状态。
I3C 不要使用时将 BUSE 位设置为 0。BUSE 位时,SCL 和 SDA 引脚处于非活动状态
is set to 0.

如果软件设置了该位,则它还确认初始化已完成,并且 I3C 可以使用编程的寄存器值（例如,在 IBI 检测上生成 SCL 等）。如果未设置该位,则 I3C 不应为传入 IBI 生成 SCL。

I3C 总线操作处于活动状态时, 软件可能会禁用该操作, 但是:

- 如果在接收 IBI 的同时发生禁用请求,则在 IBI 的接收完成之前不会发生实际的禁用。
- 当软件从该字段读取值 0 时, 这表明 I3C 总线操作禁用操作已经完成。

  如果命令保留在命令队列中,请勿设置 BUSE = 0。

25。2。3 MSDVAD:主设备地址注册

基本地址:I3C = 0x4011_F000

30:23	—	这些位读作 0。写入值应为 0。	R/W
31	MDYADV	主动态地址有效 0:主动态地址字段无效。1:主动态地址字段有效。	R/W

注: 该寄存器支持I3C主模式。

MDYAD[6:0] 位（主动态地址）

I3C主动态地址的程序使用该字段。I3C 使用此地址以 I3C 接口模式（从机或辅助主机角色）响应主机事务。

I3C主主模式下,软件应在自分配动态地址时对动态地址进行编程。

MDYADV 位（主动态地址有效）

该位指示 MDYAD 字段中的值是否有效。

I3C主主模式下,用户在自分配其动态地址时将该位设置为1。

注: 设置 MSDVAD 和设置 BCTL 后。BUSE = 1,设备将充当主主。
MSDVAD、设置SVDCT。TBCR76[1:0] = 00b（设备角色从属）和设置BCTL。BUSE = 1的情况下,设备将充当从属。

Without setting MSDVAD, setting MSDCTm.RBCR76[1:0] = 01b (Device Role Master), and setting BCTL.BUSE = 1, the device will act as slave.

- When 0 written to the MSDVAD.MDYADV by the software.
- When GETACCMST transmission is successfully completed by issuing STOP, after responding ACK to the Mastership-Request received from the Secondary Master.

[Setting conditions]

- When 1 written to the MSDVAD.MDYADV by the software.

The PRSST register returns I3C current state.

State has two parts: this register which is mandatory, and an additional optional PRSST_DEBUG register intended for debug purposes (see the Debug Capability registers in the Extended Capabilities list).

TRMD bit (Transmit/Receive Mode)

This bit indicates transmit or receive mode.

I3C is in receive mode when the TRMD bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the CRMS bit indicates the operating mode of I3C.

The value of TRMD bit is automatically changed to 1 for transmit mode or 0 for receive mode by issuing or detection of a START condition and setting of the R/W# bit.

[Setting conditions]

- When a START condition is issued normally according to the START condition issuance request (when a START condition is detected with the CNDCTL.STCND bit set to 1).
- When a Repeated START condition is issued normally according to the Repeated START condition issuance request (when a Repeated START condition is detected with the CNDCTL.SRCND bit set to 1).
- When the R/W# bit added to the slave address is set to 0 in master mode.
- When the address received in slave mode matches the address enabled in SVCTL, with the R/W# bit set to 1.

[Clearing conditions]

- When a STOP condition is detected.
- The ALF (arbitration-lost) flag in BST being set to 1.
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended.

的【设置条件】

- 当通过发出 STOP 成功完成 GETACCMST 接收时,在 ACK 响应传输到当前主站的主站请求之后。

PRSST 寄存器返回 I3C 当前状态。

State 有两部分:此寄存器是强制性的,以及用于调试目的的附加可选 PRSST_DEBUG 寄存器（请参阅扩展功能列表中的调试功能寄存器）。

TRMD 位（发送/接收模式）

该位指示发送或接收模式。

TRMD位设置为0时I3C处于接收模式,当该位设置为1时处于发送模式。该位和CRMS位的组合指示I3C的操作模式。

TRMD 位的值通过发出或检测 START 条件和 R/W# 位的设置,自动更改为 1 表示发送模式或 0 表示接收模式。

的【设置条件】

- 当根据START条件发出请求正常发出START条件时（当用设置为1的CNDCTL。STCND位检测到START条件时）。
- 根据重复 START 条件发出请求正常发出重复 START 条件时（当用设置为 1 的 CNDCTL。SRCND 位检测到重复 START 条件时）。
- 当添加到从地址的 R/W# 位在主模式下设置为 0。
- 当从模式下接收到的地址与 SVCTL 中启用的地址匹配时,R/W# 位设置为 1。

的【清算条件】

- 当检测到停止情况时。
- BST 中的 ALF（仲裁丢失）标志设置为 1。
- 在主模式下,接收一个从地址,该从地址附加一个具有值1的R/W#位。

- In slave mode, a match between the received address and the address enabled in SVCTL when the value of the received R/W# bit is 0 (including cases where the received address is the general call address).
- In slave mode, a Repeated START condition is detected (a Repeated START condition is detected with BCST.BFREF = 0 and CRMS = 0).

MALE bit (Master Arbitration-Lost Detection Enable)

This bit is used to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

MALE 位（主仲裁- 丢失检测启用）

该位用于指定是否在主模式下使用仲裁丢失检测功能。通常,将此位设置为 1。

NALE 位（NACK 传输仲裁丢失检测启用）

该位用于指定在接收模式下NACK传输期间检测到ACK时（例如总线上存在相同地址的从站时或两个或多个主站同时选择相同的从站设备时）是否导致仲裁丢失。接收字节数不同）。

SALE bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

SCSYNE bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCSYNE bit set to 0 (no SCL synchronous circuit used), I3C does not synchronize the SCL clock with the SCL input clock. In this setting, I3C outputs the SCL clock with the transfer rate set in STDBR and EXTBR regardless of the I3C_SCL line state. For this reason, if the bus load of the I^2C bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output. When no SCL synchronous circuit uses, it also affects the issuance of a START condition, Repeated START condition, and STOP condition, and the continuous output of extra SCL clock cycles.

This bit must not be set to 0 except for checking the output of the set transfer rate.

FMPE bit (Fast-mode Plus Enable)

This bit is used to specify whether to use a slope control circuit for Fast-mode Plus [Fm+].

When this bit is set to 1, a slope control circuit conforming to the Fast-mode Plus [Fm+] slope control specification (tof) of the I3C-bus is selected. When this bit is set to 0, a slope control circuit conforming to the Standard-mode [Sm] and Fast-mode [fm] slope control specification (tof) of the I3C-bus is selected.

Set this bit to 1 when using the transmission rate within a range up to 1 Mbps (Fast-mode Plus [Fm+]) of the I3C-bus specification. Set this bit to 0 when using the transmission rate at other rates (up to 100 kbps [Sm], up to 400 kbps [Fm]) or for SMBus (10 to 100 kbps).

Note: When communicating in Hs-mode, set as follows.
- Set FMPE to 0 when sending Hs-mode master code (0000 1XXXb) with Fast-mode.
- Set FMPE to 1 when sending Hs-mode master code (0000 1XXXb) with Fast-mode Plus.

HSME bit (High Speed Mode Enable)

This bit is used for communicating in Hs-mode.

When this bit is set to 1, the Hs-mode master code is recognized and Hs-mode communication is possible.

After the START condition is detected, if Hs-mode master code (0000 1XXXb) transmission is recognized, Hs-mode communication starts from Repeated START after receiving the NACK response.

It communicates at the bit rate set in STDBR until the NACK response, and automatically switches from Repeated START condition issuance after receiving the NACK response to the bit rate set in EXTBR.

Hs-mode continues until a STOP condition is detected.

When the STOP condition is detected, the bit rate is automatically switched to the bit rate set in STDBR.

Note: When this bit is set to 1, the BST.NACKDF bit will not be set even if a NACK response is received after sending the Hs-mode master code.

SALE 位（从属仲裁– 丢失检测启用）

该位用于指定当在从发送模式下在总线上检测到与正在发送的值不同的值时（例如当总线上存在具有相同地址的从站或当与发送数据由于噪声而发生）。

SCSYNE 位（启用 SCL 同步电路）

该位用于指定是否将SCL时钟与SCL输入时钟同步。通常,将此位设置为 1。

SCSYNE位设置为0时（不使用SCL同步电路）,I3C不将SCL时钟与SCL输入时钟同步。I3C在此设置中,无论I3C_SCL线路状态如何,都以STDBR和EXTBR设置传输速率输出SCL时钟。因此,如果I２C总线线路的总线负载远大于规范值,或者SCL时钟输出在多个主站中重叠,则可以输出不符合规范的短周期SCL时钟。当不使用SCL同步电路时,还会影响START条件、Repeated START条件和STOP条件的发出,以及额外SCL时钟周期的连续输出。

除了检查设置的传输速率的输出之外,该位不得设置为 0。

FMPE 位（快速模式加启用）

该位用于指定是否使用快速模式 Plus [Fm+] 的斜率控制电路。

1设置该位时,选择符合I3C总线的快速模式加[Fm+]斜率控制规范（tof）的斜率控制电路。当该位设置为0时,选择符合I3C总线的标准模式[Sm]和快速模式[fm]斜率控制规范（tof）的斜率控制电路。

I3C总线规范的1 Mbps（快速模式加[Fm+])范围内使用传输速率时,将该位设置为1。当使用其他速率（高达 100 kbps [Sm]、高达 400 kbps [Fm])或 SMBus(10 至 100 kbps）的传输速率时,将此位设置为 0。

注意:以Hs模式通信时,设置如下。
- 使用快速模式发送 Hs 模式主代码 (0000 1XXXb）时,将 FMPE 设置为 0。
- 使用 Fast-mode Plus 发送 Hs 模式主代码 (0000 1XXXb）时,将 FMPE 设置为 1。

HSME 位（高速模式启用）

该位用于以 Hs 模式进行通信。

当该位设置为1时,Hs模式主码被识别并且Hs模式通信是可能的。

START条件检测出来后,如果识别出Hs模式主码(0000 1XXXb）传输,则Hs模式通信在接收到NACK响应后从Repeated START开始。

STDBR中设置的比特率进行通信,直到NACK响应,并在接收到NACK响应后自动从重复START条件发出切换到EXTBR中设置的比特率。

Hs 模式持续,直到检测到 STOP 条件。

STOP条件时, 自动切换比特率至STDBR中设置的比特率。

注意:当该位设置为1时,即使在发送Hs模式主码后接收到NACK响应,也不会设置BST。NACKDF位。

Note 1. This bit supports I2C mode.

Note 2. These bits support I2C, I3C secondary master, and I3C slave mode.

GCAE bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address (0000 000 + 0 (write): All 0) when it is received. When this bit is set to 1, if the received slave address matches the general call address, I3C recognizes the received slave address as the general call address independently of the slave addresses set in the SVDVADn.SVAD[9:0] bits (n = 0 to 2) and performs data receive operation.

When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

HSMCE bit (Hs-mode Master Code Enable)

This bit is used to specify whether to recognize and execute the Hs-mode master code (00001xxxb) is received in the first byte after a START condition is detected.

When this bit is set to 1, if the received first byte matches the Hs-mode master code, I2C recognizes that the Hs-mode master code has been received.

The first byte after Repeated START after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set by SVDVADn.SVAD[9:0]bits (n = 0 to 2).

If the addresses match, the transmission / reception operation continues according to the R/W# bit value.

Hs-mode continues until a STOP condition is detected.

注1。该位支持 I 2 C 模式。

注2。这些位支持 I 2 C、I3C 二级主模式和 I3C 从模式。

GCAE 位（启用通用呼叫地址）

该位用于指定接收时是否忽略一般呼叫地址(0000 000 + 0（写）:全部 0)。1 时,如果接收到的从地址与通用调用地址匹配,则 I3C 独立于 SVDVADn。SVAD[9:0] 位中设置的从地址,将接收到的从地址识别为通用调用地址（n = 0 到 2),并执行数据接收操作。

当该位设置为 0 时,即使与通用调用地址匹配,接收到的从地址也会被忽略。

HSMCE 位（启用 Hs 模式主代码）

该位用于指定在检测到START条件后是否在第一字节中识别并执行Hs模式主代码(00001xxxb）。

当该位设置为1时,如果接收到的第一字节与Hs模式主码匹配,则I 2C识别出Hs模式主码已被接收。

NACK 响应 Hs 模式主代码后重复开始后的第一个字节被识别为从地址,并与 SVDVADn。SVAD 设置的从地址进行比较[9:0]bits（n = 0 到 2)。

如果地址匹配,则根据R/W#位值继续发送/接收操作。

Hs 模式持续,直到检测到 STOP 条件。

When this bit is set to 0, I3C will ignore the pattern until a STOP condition is detected, even if it matches the Hs-mode master code.

Note: When this bit is set to 1, SCSTRCTL.ACKTWE bit must be set to 0 and SCSTRCTL.RWE bit must be set to 1.

DVIDE bit (Device-ID Address Enable)

This bit is used to specify whether to recognize and execute the Device-ID address when a device ID (1111 100) is received in the first byte after a START condition or Repeated START condition is detected.

When this bit is set to 1, if the received first byte matches the Device-ID, I3C recognizes that the Device-ID address has been received. When the following R/W# bit is 0 (write), I3C recognizes the second and the following bytes as slave addresses and continues the receive operation.

When this bit is set to 0, I3C ignores the received first byte even if it matches the Device ID address and recognizes the first byte as a normal slave address.

For details on the Device-ID address detection, see (3)Device-ID Address Detection [I^2C mode].

HOAE bit (Host Address Enable)

This bit is used to specify whether to ignore received host address (0001 000) when the BFCTL.SMBS bit = 1.

When this bit is set to 1 while the SMBS bit = 1, if the received slave address matches the host address, I3C recognizes the received slave address as the host address independently of the slave addresses set in the SVDVADn.SVAD[9:0] bits (n = 0 to 2) and performs the receive operation.

When the SMBS bit or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

SVAE[2:0] bits (Slave Address Enable n (n = 0 to 2))

This bit is used to enable or disable the slave address set in the SVDVADn.SVAD[9:0] bits.

When this bit is set to 1, the slave address set in the SVAD[9:0] bits is enabled and is compared with the received slave address.

When this bit is set to 0, the slave address set in the SVAD[9:0] bits is disabled and is ignored even if it matches the received slave address.

0 时,I3C 将忽略模式,直到检测到 STOP 条件,即使它与 Hs 模式主代码匹配。

注意:当该位设置为 1 时,SCSTRCTL。ACKTWE 位必须设置为 0,SCSTRCTL。RWE 位必须设置为 1。

DVIDE 位（启用设备 ID 地址）

该比特用于在检测到START条件或重复START条件之后在第一字节中接收到设备ID(1111 100)时指定是否识别和执行Device-ID地址。

1 设置该位时, 如果接收到的第一字节与 Device-ID 匹配, I3C 识别出已接收到 Device-ID 地址。0（写入） 时,I3C将第二个和以下字节识别为从地址,并继续接收操作。

I3C 将此位设置为 0 时,即使它与 Device ID 地址匹配,也会忽略接收到的第一字节,并将第一字节识别为普通从地址。

Device-ID 地址检测的详细信息,请参见 (3)Device-ID 地址检测 [I 2 C 模式] .

HOAE 位（启用主机地址）

该位用于指定当 BFCTL。SMBS 位 = 1 时是否忽略接收到的主机地址 (0001 000)。

SMBS 位 = 1 时将该位设置为 1,如果接收到的从地址与主机地址匹配,则 I3C 独立于 SVDVADn。SVAD[9:0] 位中设置的从地址识别接收到的从地址为主机地址（n = 0 到 2)并执行接收操作。

SMBS 位或 HOAE 位设置为 0 时,即使与主机地址匹配,也忽略接收到的从地址。

SVAE[2:0] 位（从地址启用 n（n = 0 到 2））

Note 1. These bits support I2C, I3C master, and I3C secondary master mode.
Note 2. These bits support I3C master mode and I3C secondary master mode.
Note 3. These bits support all I3C mode.
Note 4. This bit supports I2C, I3C master, and I3C secondary master mode.

The STDBR register sets the bit rate according to the operating speed.

- I2C mode: Bit rate setting when communicating with Standard-mode / Fast-mode / Fast-mode plus
- I3C master mode: Bit rate setting selected by mode bit of command descriptor
- I3C slave mode: I3C bit rate setting

The I2C transfer rate and the SCL clock duty are calculated using the following expression.

Transfer rate = 1 / {[(High-level Period + α*1) + (Low-level Period + α)] / I3Cφ*2 + I3C_SCL line rising time [tr]*3 + I3C_SCL line falling time [tf]*3}

Duty cycle = {I3C_SCL line rising time [tr] + (High-level Period + α) / I3Cφ} / {I3C_SCL line falling time [tf] + (Low- level Period + α) / I3Cφ}

Note 1. α depend on the number of stages in the noise filter.
Note 2. I3Cφ = TCLK × Division ratio
Note 3. The I3C_SCL line rising time [tr] and I3C_SCL line falling time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, see the I2C-bus specification from NXP Semiconductors.

The I3C transfer rate and the SCL clock duty are calculated using the following expression.

STDBR寄存器根据运行速度设置比特率。

- I 2 C 模式:与标准模式/快速模式/快速模式 plus 通信时的比特率设置
- I3C 主模式:由命令描述符的模式位选择的比特率设置
- I3C 从模式:I3C 比特率设置

I 2 C 传输速率和 SCL 时钟占空比使用以下表达式计算。

转移率 = 1/{[（高层周期 + α *1)+（低层周期 + α）]/I3Cφ *2 + I3C_SCL 线路上升时间 [tr] *3 + I3C_SCL 线路下降时间 [tf] *3}

占空比 = {I3C_SCL 线上升时间 [tr] +（高层周期 + α）/I3Cφ}/{I3C_SCL 线下降时间 [tf] +（低层周期 + α）/I3Cφ}

注1。α取决于噪声滤波器中的级数。
注2。I3Cφ = TCLK × 除法比
注3。I3C_SCL线路上升时间[tr]和I3C_SCL线路下降时间[tf]取决于总总线线路电容[Cb]和上拉电阻[Rp]。有关详细信息,请参阅恩智浦半导体的I 2 C 总线规范。

I3C 传输速率和 SCL 时钟占空比使用以下表达式计算。

Transfer rate = 1 / [(High-level Period + Low-level Period) / I3Cφ + I3C_SCL line rising time [tr] + I3C_SCL line falling time [tf]]

Duty cycle = [I3C_SCL line rising time [tr] + High-level Period / I3Cφ] / [I3C_SCL line falling time [tf] + Low-level Period / I3Cφ]

SBRLO[7:0] bits (Standard Bit Rate Low-level Period Open-Drain)

The SBRLO[7:0] bits are used to set the low-level period of SCL clock in Open-Drain mode.

I3C counts the low-level period with the internal reference clock source (I3Cφ) specified by the REFCKCTL.IREFCKS[2:0] bits. It also works to generate the data setup time for automatic SCL low-hold operation (see section 25.3.2.3.6. Clock Stretching [I2C mode]); when I3C is used in I2C slave mode, these bits need to be set to a value longer than the data setup time*1.

If the digital noise filter is enabled (INCTL.DNFE = 1), set the SBRLO[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

Note 1. Data setup time (tSU: DAT)
250 ns (up to 100 kbps: Standard-mode [Sm])
100 ns (up to 400 kbps: Fast-mode [Fm])
50 ns (up to 1 Mbps: Fast-mode plus [Fm+])
10 ns (up to 3.4 Mbps: Hs-mode [HS])

SBRHO[7:0] bits (Standard Bit Rate High-level Period Open-Drain)

The SBRHO[7:0] bits use to set the high-level period of SCL clock in Open-Drain mode. SBRHO[7:0] bits are valid in master mode. If I3C is used only in I2C slave mode, these bits need not to set the high-level period.

I3C counts the high-level period with the internal reference clock source (I3Cφ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRHO[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

SBRLP[5:0] bits (Standard Bit Rate Low-level Period Push-Pull)

SBRLP[5:0] bits are used to set the low-level period of SCL clock in Push-Pull.

I3C counts the low-level period with the internal reference clock source (I3Cφ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRLP[5:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

SBRHP[5:0] bits (Standard Bit Rate High-level Period Push-Pull)

SBRHP[5:0] bits is used to set the high-level period of SCL clock in Push-Pull mode.

SBRHP[5:0] bits are valid in master mode. If I3C is used only in I2C slave mode, these bits need not to set the high-level period.

I3C counts the high-level period with the internal reference clock source (I3Cφ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRHP[5:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

DSBRPO bit (Double the Standard Bit Rate Period for Open-Drain)

When DSBRPO = 1, double the high-level period that is set in SBRHO[7:0] and double the low-level period that is set in SBRLO[7:0].

Transfer rate = 1 /[（高层期 + 低层期）/I3Cϕ + I3C_SCL 线路上升时间 [tr] + I3C_SCL 线路下降时间 [tf]]

占空比 = [I3C_SCL 线路上升时间 [tr] + 高电平周期/I3Cϕ] /[I3C_SCL 线路下降时间 [tf] + 低电平周期/I3Cϕ]

SBRLO[7:0] 位（标准位速率低级周期开漏）

如果启用数字噪声滤波器（INCTL。DNFE = 1),则将 SBRLO[7:0] 位设置为比噪声滤波器中的级数至少大一个的值。关于噪声滤波器中的级数,请参阅INCTL。DNFS[3:0]位的描述。

注1。数据设置时间（tSU: DAT）250 ns（高达 100 kbps:标准模式 [Sm]) 100 ns（高达 400 kbps:快速模式 [Fm]) 50 ns（高达 1 Mbps:快速模式加 [Fm+]) 10 ns（高达 3。4 Mbps:Hs 模式 [HS])

SBRHO[7:0] 位（标准比特率高电平周期开漏）

SBRHO[7:0] 位用于在开漏模式下设置 SCL 时钟的高电平周期。SBRHO[7:0] 位在主模式下是有效的。I3C 仅在 I２C 从模式下使用,则这些位无需设置高级周期。

I3C用由REFCKCTL。IREFCKS[2:0]位指定的内部参考时钟源（I3Cϕ）对高级周期进行计数。

如果启用数字噪声滤波器（INCTL。DNFE 位 = 1),则将 SBRHO[7:0] 位设置为比噪声滤波器中的级数至少大一个的值。关于噪声滤波器中的级数,请参阅INCTL。DNFS[3:0]位的描述。

SBRLP[5:0] 位（标准位速率低级周期推挽）

SBRLP[5:0]位用于设置推挽中SCL时钟的低级周期。

I3C用由REFCKCTL。IREFCKS[2:0]位指定的内部参考时钟源（I3Cϕ）对低电平周期进行计数。

如果启用数字噪声滤波器（INCTL。DNFE 位 = 1),则将 SBRLP[5:0] 位设置为比噪声滤波器中的级数至少大一个的值。关于噪声滤波器中的级数,请参阅INCTL。DNFS[3:0]位的描述。

SBRHP[5:0] 位（标准比特率高电平周期推挽）

SBRHP[5:0]位用于在推挽模式下设置SCL时钟的高电平周期。

SBRHP[5:0] 位在主模式下有效。I3C 仅在 I２C 从模式下使用,则这些位无需设置高级周期。

I3C用由REFCKCTL。IREFCKS[2:0]位指定的内部参考时钟源（I3Cϕ）对高级周期进行计数。

如果启用数字噪声滤波器（INCTL。DNFE 位 = 1),则将 SBRHP[5:0] 位设置为比噪声滤波器中的级数至少大一个的值。关于噪声滤波器中的级数,请参阅INCTL。DNFS[3:0]位的描述。

DSBRPO 位（开放排水标准比特率周期的两倍）

DSBRPO = 1 时,将 SBRHO 中设置的高电平周期加倍[7:0],将设置的低电平周期加倍 SBRLO[7:0]。

Note 1. This bit supports I2C, I3C master, and I3C secondary master mode.
Note 2. These bits support I2C mode.
Note 3. This bit supports I2C mode.
Note 4. The setting SDODCS = 1 (I3Cφ/2) only becomes valid when SCL is at the low level. When SCL is at the high level, the setting SDODCS = 1 becomes invalid and the clock source becomes the internal reference clock (I3Cφ).

SDOC bit (SDA Output Control) and SCOC bit (SCL Output Control)

These bits are used to directly control the I3C_SDA and I3C_SCL signals output from this I3C.

When writing to these bits, also write 1 to the SOCWP bit at the same time.

The result of setting these bits is input to I3C via the input buffer. When slave mode is selected, a START condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a START condition, STOP condition, Repeated START condition, or during transmission or reception. Operation after rewriting under the above conditions is not guaranteed.

EXCYC bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.

Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.

For details on this function, see section 25.3.2.3.10. Port Control , (1)Extra SCL Clock Cycle Output Function.

注1。该位支持I 2 C、I3C主控和I3C辅助主控模式。
注2。这些位支持 I 2 C 模式。
注3。该位支持 I 2 C 模式。
注4。SCDODCS = 1（I3Cφ/2) 的设置只有在 SCL 处于低电平时才变得有效。SCL处于高电平时,设置SDODCS = 1 变为无效,时钟源变为内部参考时钟（I3Cφ）。

SDOC 位（SDA 输出控制）和 SCOC 位（SCL 输出控制）

这些位用于直接控制从该I3C输出的I3C_SDA和I3C_SCL信号。

写入这些位时,也同时写入 SOCWP 位 1。

设置这些位的结果通过输入缓冲区输入到 I3C。当选择从模式时,可以检测START条件并且可以根据位设置释放总线。

START 条件、STOP 条件、Repeated START 条件或传输或接收期间,请勿重写这些位。不保证在上述条件下重写后的操作。

EXCYC 位（额外的 SCL 时钟周期输出）

该位用于输出额外的 SCL 时钟周期以进行调试或错误处理。

通常,将位设置为 0。将位设置为 1 处于正常通信状态会导致通信错误。有关此功能的详细信息,请参阅第 25。3。2。3。10 节。端口控制，(1)Extra SCL 时钟周期输出函数 .

DNFS[3:0] bits (Digital Noise Filter Stage Selection)

These bits are used to select the number of stages in the digital noise filter.

For details on the digital noise filter function, see section 25.3.2.6.3. Digital Noise-Filter Circuits [I2C mode].

In I2C High Speed mode, I3C changes the number of noise filter stage to a quarter of the number of noise filter stage automatically.

Note:
- Set the noise range to be filtered out by the noise filter within a range less than the I3C_SCL line high-level period or low-level period. If the noise range is set to a value of (SCL clock width: high-level period or lowlevel period, whichever is shorter) - [1.5 internal reference clock (I3Cφ) cycles] or more, the SCL clock is regarded as noise by the noise filter function of I3C, which may prevent I3C from operating normally.
- In I2C High Speed mode, the lower 2 bits of the DNFS [3:0] bits are ignored, and the number of filter stages for 1 to 4 stages is selected by the upper 2 bits.

这些位用于选择数字噪声滤波器中的级数。

有关数字噪声滤波器功能的详细信息,请参阅第 25。3。2。6。3 节。数字噪声滤波器电路 [I 2 C 模

I 2 C 高速模式下,I3C 将噪声滤波级数自动更改为噪声滤波级数的四分之一。

Note:● 将噪声滤波器滤除的噪声范围设置在小于 I3C_SCL 线高电平周期或低电平周期的范围内。（SCL时钟宽度:高电平周期或低电平周期,以较短者为准）[1。5个内部参考时钟（I3Cφ）周期]或更多的值,则SCL时钟被I3C的噪声滤波器功能视为噪声,这可能会阻止I3C正常工作。

31:8	—	These bits are read as 0. The write value should be 0.	R/W

TODTS[1:0] bits (Timeout Detection Time Selection)

These bits are used to select for the timeout detection time when the timeout function is enabled (BSTE.TODE bit = 1).

When these bits are set to 00b, the timeout detection internal counter functions as a 16-bit counter.

When these bits are set to 01b, the counter functions as a 14-bit counter.

When these bits are set to 10b, the counter functions as a 8-bit counter.

When these bits are set to 11b, the counter functions as a 6-bit counter.

While the I3C_SCL line is in the state that enables this counter as specified by bits TOHCTL and TOLCTL, the counter counts up in synchronization with the internal reference clock (I3Cφ) as a count source.

For details on the timeout function, see section 25.3.2.4.3. Timeout Error Detection .

TOLCTL bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the I3C_SCL line is held low when the timeout function is enabled (BSTE.TODE = 1).

TOHCTL bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the I3C_SCL line is held high when the timeout function is enabled (BSTE.TODE = 1).

TODTS[1:0] 位（超时检测时间选择）

TOLCTL 位（超时 L 计数控制）

该位用于启用或禁用超时函数的内部计数器以进行计数,而当启用超时函数时 I3C_SCL 线保持在较低位置（BSTE。TODE = 1)。

TOHCTL 位（超时 H 计数控制）

I3C_SCL 线在启用超时函数时保持高电平时,该位用于启用或禁用超时函数的内部计数器进行计数（BSTE。TODE = 1)。

TOMDS[1:0] bits (Timeout Operation Mode Selection)

These bits are used to select the detection condition for timeout when the timeout function is enabled.

I3C operation changes into the PCLK synchronous operation at the following conditions. (At the same timing when WUFSYNE flag becomes 0)

In the case Wake-Up event detects : right after WUFSYNE bit is set to 1.

In the case Wake-Up event does not detect : when STOP condition is detected after WUFSYNE bit is set to 1.

31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: This register supports I²C mode.

ACKTWE bit (Acknowledge Transmission Wait Enable)

This bit is used to select the NTST.RDBFF0 flag set timing in receive mode and also to select whether to hold the I3C_SCL line low at the falling edge of the eighth SCL clock cycle.

When ACKTWE = 0, the I3C_SCL line is not held low at the falling edge of the eighth SCL clock cycle, and the NTST.RDBFF0 flag is set to 1 at the rising edge of the ninth SCL clock cycle.

When ACKTWE = 1, the NTST.RDBFF0 flag is set to 1 at the rising edge of the eighth SCL clock cycle and the I3C_SCL line is held low at the falling edge of the eighth SCL clock cycle. The low-hold of the I3C_SCL line is released by writing a value to the ACKCTL.ACKT bit.

After data is received with this setting, the I3C_SCL line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKCTL.ACKT = 0) or NACK (ACKCTL.ACKT = 1) according to receive data.

- 当 1 写入 ACKT 位并且 1 同时写入 ACKTWP 位时。

ACKTWP 位（ACKT 写保护）该位用于控制 ACKT 位的修改。

ACKT 位时,同时将该位设置为 1 可以改变 ACKT 位。

31:2	—	这些位读作 0。写入值应为 0。	R/W

注: 该寄存器支持 I２C 模式。

ACKTWE 位（确认传输等待启用）

该位用于在接收模式下选择NTST。RDBFF0标志设置定时,并且还用于选择是否在第八SCL时钟周期的下降沿处将I3C_SCL线保持在较低位置。

ACKTWE = 0 时,I3C_SCL 线在第八个 SCL 时钟周期的下降沿处不保持低电平,且NTST。RDBFF0 标志在第九个 SCL 时钟周期的上升沿设置为 1。

ACKTWE = 1时,在第八个SCL时钟周期的上升沿将NTST。RDBFF0标志设置为1,并且在第八个SCL时钟周期的下降沿将I3C_SCL线保持在较低位置。I3C_SCL线的低保持是通过写入一个值到ACKCTL。ACKT位来释放的。

用此设置接收数据后,在发送确认位之前,I3C_SCL 行会自动保持在较低位置。这使得处理能够根据接收数据发送ACK（ACKCTL。ACKT=0)或NACK（ACKCTL。ACKT=1)。

RWE bit (Receive Wait Enable)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the receive data buffer (NTDTBP0) is completely read each time single-byte data is received in receive mode.

When RWE = 0, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the ACKTWE and RWE bits = 0, continuous receive operation is enabled with the double buffer.

When RWE = 1, the I3C_SCL line is held low from the falling edge of the ninth clock cycle until the NTDTBP0 value is read each time single-byte data is received.

This enables receive operation in byte units.

Note: When the value of the RWE bit is to be read, be sure to read the NTDTBP0 beforehand.

31	ACKPE	ACK phase Enable Stall enable bit during ACK/NACK phase 0: Does not stall the SCL clock during the ACK/NACK phase. 1: Stall the SCL clock during the ACK/NACK phase.	R/W

Note: This register supports I3C master mode and I3C secondary master mode.

When setting this register, follow Chapter 5.1.2.5 Master Clock Stalling of MIPI I3C Spec V1.0, and use it only when necessary because of its negative impacts on bus performance.

STLCYC[15:0] bits (Stalling Cycle)

These bits set the SCL stall period. The SCL stall period is counted by the internal reference clock (I3Cφ). This is a counter common to the enable bits of each phase.

AAPE bit (Assigned Address Phase Enable)

The master can stall SCL during the low period of the first bit of the assigned address phase of the Enter Dynamic Address Assignment CCC command. It can gain time in assigning dynamic address to the device based on the BCR and DCR of the slave. However, because the Dynamic Address Assignment procedure sends the dynamic address set in the DATBASm (m = 0 to 7) register in sequence, it is not necessary to set this bit and it is prohibited.

RWE 位（接收等待启用）

该位用于控制是否将第九SCL时钟周期和第一SCL时钟周期之间的周期保持在较低位置,直到每次在接收模式下接收单字节数据时完全读取接收数据缓冲器（NTDTBP0)。

RWE = 0 时, 接收操作继续进行, 而不将第九和第一个 SCL 时钟周期之间的周期保持在低电平。当 ACKTWE 和 RWE 位 = 0 时,使用双缓冲区启用连续接收操作。RWE = 1时,I3C_SCL线从第九个时钟周期的下降沿保持在较低位置,直到每次接收到单字节数据时读取NTDTBP0值。这使得能够以字节为单位进行接收操作。

注意:当要读取 RWE 位的值时,请务必提前读取 NTDTBP0。

设置此寄存器时,请按照 MIPI I3C Spec V1。0 第 5。1。2。5 章主时钟失速进行操作,并且仅在必要时使用它,因为它会对总线性能产生负面影响。

这些位设置 SCL 停机周期。SCL失速周期由内部参考时钟（I3Cφ）计数。这是每个相位的使能位共有的计数器。

AAPE 位（已分配地址相位启用）

主设备可以在输入动态地址分配 CCC 命令的分配地址阶段的第一位的低周期内停止 SCL。它可以获得基于从属设备的 BCR 和 DCR 为设备分配动态地址的时间。但是,由于动态地址分配过程依次发送DATBASm（m = 0～7)寄存器中设置的动态地址,因此不需要设置该位,因此被禁止。

PARPE bit (Parity Phase Enable)

The parity bit of the transmission data of I3C write transfer can be used for SCL stalling to avoid underrun of the transmission data FIFO. However, when the transmission data FIFO of the I3C master becomes empty, SCL stalling is performed regardless of the setting of this bit, it is not necessary to set this bit and it is prohibited. It is necessary to set this bit when the I3C slave requires preparation time to receive data.

ACKPE bit (ACK phase Enable)

Determine the need to perform SCL stalling in the ACK/NACK phase based on the following criteria:

- It is necessary to set this bit when the I3C and I2C slaves connected to the bus require preparation time to receive or transmit data.
- In legacy I^2C communication, if there is a possibility that the data FIFO of the I3C master might underrun or overflow, it is not necessary to set this bit because SCL Stalling is performed by FIFO Empty or Full regardless of the setting of this bit.
- Other than legacy I^2C communication, the data FIFO of I3C master might underrun or overflow, and if SCL stalling is required in ACK phase, this bit can be set. However, it is necessary to build the software so that the FIFO does not underrun or overflow due to the interrupt generated according to the FIFO threshold setting (NQTHCTL, NTBTHCTL0, NRQTHCTL, HQTHCTL, HTBTHCTL).
- When I3C master responds ACK/NACK to IBI, it is not necessary to set this bit because ACK/NACK response can be set in advance by DATBASm.DVMRRJ and DATBASm.DVSIRRJ (m = 0 to 7).
- It is necessary to set this bit when the I3C slave connected to the bus requires preparation time to transmit data for Direct GET CCC.

PARPE 位（启用奇偶校验相位）

I3C 写入传输的传输数据的奇偶校验位可用于 SCL 停顿,以避免传输数据 FIFO 欠载,但当 I3C 主机的传输数据 FIFO 变为空时,无论该位的设置如何,都执行 SCL 停顿,不必设置该位,禁止。I3C 从站需要准备时间来接收数据时,有必要设置这个位。

ACKPE 位（启用 ACC 相位）

ACK/NACK 阶段确定是否需要执行 SCL 失速, 依据以下标准:

- 当连接到总线的 I3C 和 I2C 从站需要准备时间来接收或传输数据时,需要设置此位。
- 在遗留 I 2 C 通信中,如果存在 I3C 主数据 FIFO 可能欠载或溢出的可能性,则无需设置此位,因为 SCL 失速由 FIFO Empty 或 Full 执行,而不管此位的设置如何。
- 除了遗留 I 2 C 通信之外,I3C master 的数据 FIFO 可能会不足或溢出,并且如果 ACK 阶段需要 SCL 停止,则可以设置该位。但是,有必要构建软件,以便 FIFO 不会因根据 FIFO 阈值设置（NQTHCTL、NTBTHCTL0、NRQTHCTL、HQTHCTL、HTBTHCTL）生成的中断而发生不足或溢出。
- 当I3C主机响应ACK/NACK到IBI时,没有必要设置这个位,因为ACK/NACK响应可以由DATBASm。DVMRRJ和DATBASm。DVSIRRJ提前设置（m = 0到7)。
- 当连接到总线的 I3C 从站需要准备时间来传输 Direct GET CCC 的数据时,需要设置此位。

STCND bit (START (S) Condition Issuance)

This bit is used to request transition to master mode and issuance of a START condition.

For details on the START condition issuance, see section 25.3.2.3.3. START Condition / Repeated START Condition / STOP Condition Issuing Function .

[Setting condition]

- When 1 is written to the STCND bit

[Clearing conditions]

- When 0 is written to the STCND bit
- When a START condition has been issued (A START condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1

Note: Set the STCND bit to 1 (START condition issuance request) when the BCST.BFREF flag is set to 1 (bus free state).
Note that arbitration may be lost due to a START condition issuance error if the STCND bit is set to 1 (START condition issuance request) when the BFREF flag is set to 0 (bus busy state).

SRCND bit (Repeated START (Sr) Condition Issuance)

This bit is used to request that a Repeated START condition be issued in master mode.

When this bit is set to 1 to request to issue a Repeated START condition, a Repeated START condition is issued when the BFREF flag is set to 0 (bus busy state) and the PRSST.CRMS bit is set to 1 (master mode).

For details on the Repeated START condition issuance, see section 25.3.2.3.3. START Condition / Repeated START Condition / STOP Condition Issuing Function .

[Setting condition]

- When 1 is written to the SRCND bit with the BCST.BFREF flag set to 0

[Clearing conditions]

- When 0 is written to the SRCND bit
- When a Repeated START condition has been issued (A Repeated START condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1

Note: Do not set the SRCND bit to 1 while issuing a STOP condition.

Note: If 1 (requests to issue a Repeated START condition) is written to the SRCND bit in slave mode, the Repeated START condition is not issued but the SRCND bit remains set to 1.
If the operating mode changes to master mode with the bit not being cleared, note that the Repeated START condition may be issued.

SPCND bit (STOP (P) Condition Issuance)

This bit is used to request that a STOP condition be issued in master mode.

When this bit is set to 1 to request to issue a STOP condition, a STOP condition is issued when the BCST.BFREF flag is set to 0 (bus busy state) and the PRSST.CRMS bit is set to 1 (master mode).

For details on the STOP condition issuance, see section 25.3.2.3.3. START Condition / Repeated START Condition / STOP Condition Issuing Function .

[Setting condition]

- When 1 is written to the SPCND bit with the BCST.BFREF flag set to 0 and the PRSST.CRMS bit set to 1

[Clearing conditions]

- When 0 is written to the SPCND bit
- When a STOP condition has been issued (A STOP condition is detected)

注意:此寄存器支持 I 2 C 模式。

STCND 位（START（S）条件发布）

该位用于请求过渡到主模式并发出 START 条件。

有关 START 条件签发的详细信息,请参阅第 25。3。2。3。3 节。START 条件/重复 START 条件/STOP 条件发布功能 .

- 当0写入STCND位时
- 当 START 条件已发出时（检测到 START 条件）
- 当 BST。ALF（仲裁丢失）标志设置为 1 时

注: 当 BCST。BFREF 标志设置为 1（无总线状态）时,将 STCND 位设置为 1（START 条件发出请求）。
请注意,当 BFREF 标志设置为 0（总线忙状态）时,如果 STCND 位设置为 1（START 条件发出请求）,则仲裁可能会因 START 条件发出错误而丢失。

SRCND 位（重复启动（Sr）条件发布）

该位用于请求在主模式下发出重复开始条件。

当该位被设置为1以请求发出重复START条件时,当BFREF标志被设置为0（总线忙状态）并且PRSST。CRMS位被设置为1（主模式）时,发出重复START条件。

有关重复启动条件签发的详细信息,请参阅第 25。3。2。3。3 节。START 条件/重复 START 条件/STOP 条件 发布功能 .

的【设置条件】

- 当 1 写入 SRCND 位时,BCST。BFREF 标志设置为 0

的【清算条件】

- 当0写入SRCND位时
- 当已发出重复启动条件时（检测到重复启动条件）
- 当 BST。ALF（仲裁丢失）标志设置为 1 时

注意:在发出 STOP 条件时不要将 SRCND 位设置为 1。

注意:如果从模式下将 1（请求发出重复 START 条件）写入 SRCND 位,则不会发出重复 START 条件,但 SRCND 位仍设置为 1。
如果操作模式在位未被清除的情况下更改为主模式,请注意,可能会发出重复开始条件。

有关 STOP 条件签发的详细信息,请参阅第 25。3。2。3。3 节。START 条件/重复 START 条件/STOP 条件 发布功能 .

的【设置条件】

- 当 1 写入 SPCND 位时,BCST。BFREF 标志设置为 0,PRSST。CRMS 位设置为 1

的【清算条件】

- 当 0 写入 SPCND 位时
- 当 STOP 条件已发出时（检测到 STOP 条件）

- When the BST.ALF (arbitration-lost) flag is set to 1

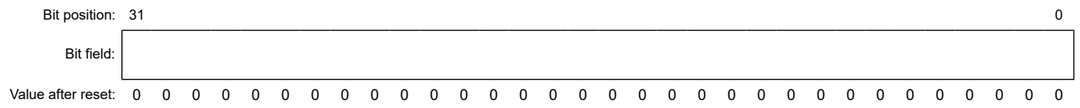
25.2.35 NTDTBP0/NTDTBP0_BY : Normal Transfer Data Buffer Port Register 0

Base address: I3C = 0x4011_F000

Offset address: 0x158



Bit	Symbol	Function	R/W
31:0	n/a	Normal Transfer Data Buffer Port NTDTBP0 is a 32-bit read/write register. NTDTBP0_BY (NTDTBP0[7:0]) is a 8-bit read/write register.	R/W

Note: NTDTBP0 is 32-bit access in I3C mode.

NTDTBP0_BY is 8-bit access in I^2C mode.

32-bit mailbox register NTDTBP0 is a 32-bit bi-directional data transfer register which is used both to read from the Normal Receive Data Buffer, and to write to the Normal Transmit Data Buffer.

In other words, the Normal Receive Data Buffer and the Normal Transmit Data Buffer have the same offset, forming a single bidirectional port for transmitting or receiving I3C data.

Read Operations:

[I3C protocol mode]

Data Read from the Normal Receive Data Buffer. Its should be read based on Normal Queue Status Level indications. The Receive data is always aligned to a 4-byte boundary, and stored in the Normal Receive Data Buffer. If the length of the data transfer is not aligned to a 4-byte boundary, then there will be extra (unused) bytes at the end of the transferred data. The valid data must be identified using the DATA_LENGTH field in the Response Descriptor.

[I2C protocol mode]

When 1 byte of data has been received, the received data is transferred from the internal shift register to NTDTBP0 to enable the next data to be received. The double-buffer structure of the internal shift register and NTDTBP0 allows continuous receive operation if the received data has been read from NTDTBP0 while the internal shift register is receiving data. Read data from NTDTBP0 once when a receive data full interrupt (I3C_RX) request is generated. If NTDTBP0 receives the next receive data before the current data is read from NTDTBP0 (while the RDBFF0 flag in NTST is 1), this module automatically holds the SCL clock low one cycle before the RDBFF0 flag is set to 1 next. The lower 8 bits of the read 32-bit data are valid as received data.

Write Operations:

[I3C protocol mode]

Data Written to the Normal Tx Data Buffer. Data DWORDs written to the Normal Transmit Data Buffer are placed onto the I3C bus one byte at a time, with the DWORD LSB first. Within each byte, bits are placed onto the I3C bus in big-endian order, with bit 7 going out first on the bus. The transmit data should always start aligned to a 4-byte boundary, and written to the NTDTBP0 register. If the length of the transfer is not aligned to a 4-byte boundary, then there will be extra (unused) bytes at the end of the transferred data. I3C shall only send the valid number of bytes indicated in the DATA_LENGTH field of the Command Descriptor.

[I2C protocol mode]

When NTDTBP0 detects a space in the internal shift register, it transfers the transmit data that has been written to NTDTBP0 to the internal shift register and starts transmitting data in transmit mode. The double-buffer structure of NTDTBP0 and the internal shift register allows continuous transmit operation if the next transmit data has been written to NTDTBP0 while the the internal shift register data is being transmitted. Write transmit data to NTDTBP0 once when a transmit data empty interrupt (I3C_TX) request is generated. The lower 8 bits of the written 32-bit data are valid as transmission data.

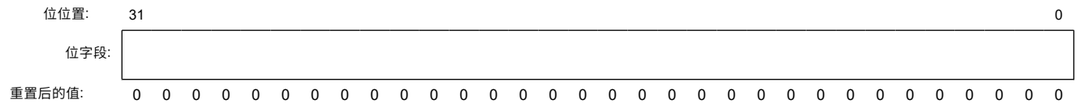
基本地址: I3C = 0x4011_F000

偏移地址: 0x158



位	符号	功能	R/W
31:0	不适用	正常传输数据缓冲端口 NTDTBP0 是一个 32 位读/写寄存器。 NTDTBP0_BY（NTDTBP0[7:0]）是一个 8 位读/写寄存器。	R/W

注: NTDTBP0 是 I3C 模式下的 32 位访问。

NTDTBP0_BY 是 I 2 C 模式下的 8 位访问。

32 位邮箱寄存器 NTDTBP0 是一个 32 位双向数据传输寄存器,既用于从正常接收数据缓冲区读取,也用于写入正常传输数据缓冲区。

换句话说,正常接收数据缓冲器和正常发送数据缓冲器具有相同的偏移量,形成用于发送或接收I3C数据的单个双向端口。

阅读操作:

的【I3C协议模式】

从正常接收数据缓冲区读取数据。应根据正常队列状态级别指示来读取它。接收数据始终与 4 字节边界对齐,并存储在正常接收数据缓冲区中。如果数据传输的长度未与 4 字节边界对齐,则传输数据末尾将存在额外的（未使用的）字节。必须使用响应描述符中的 DATA_LENGTH 字段来识别有效数据。

的【I2C协议模式】

1个字节的数据时,接收到的数据从内部移位寄存器传输到NTDTBP0,以便能够接收下一个数据。如果在内部移位寄存器接收数据时已从NTDTBP0读取接收到的数据,则内部移位寄存器和NTDTBP0的双缓冲区结构允许连续接收操作。NTDTBP0中读取一次数据,当生成接收数据完全中断（I3C_RX）请求时。如果NTDTBP0在从NTDTBP0读取当前数据之前接收到下一个接收数据（而NTST中的RDBFF0标志是1),则该模块在RDBFF0标志下一个周期设置为1之前自动将SCL时钟保持在较低位置。读取的 32 位数据的下 8 位作为接收到的数据有效。

编写操作:

的【I3C协议模式】

数据写入正常 Tx 数据缓冲区。写入正常传输数据缓冲区的数据 DWORD 一次一个字节放置到 I3C 总线上,首先使用 DWORD LSB。在每个字节内,位以大端顺序放置到 I3C 总线上,第 7 位首先在总线上发出。发送数据应始终开始对齐到 4 字节边界,并写入 NTDTBP0 寄存器。如果传输的长度未对齐到 4 字节边界,则传输数据末尾将有额外的（未使用的）字节。I3C 只应发送命令描述符的 DATA_LENGTH 字段中指示的有效字节数。

的【I2C协议模式】

NTDTBP0检测到内部移位寄存器中的空间时,将已经写入NTDTBP0的发送数据传送到内部移位寄存器,并开始以发送模式发送数据。NTDTBP0和内部移位寄存器的双缓冲器结构允许在内部移位寄存器数据被传输时,如果下一个传输数据已经写入NTDTBP0,则连续传输操作。1次生成发送数据空中断（I3C_TX）请求时,将发送数据写入NTDTBP0。写入的 32 位数据的较低 8 位作为传输数据有效。

When receiving an IBI, 32-bit mailbox register NIBIQP is used for both:

- Read the IBI status descriptor (see section 25.3.1.3. IBI Status Descriptor)
- Read the IBI data (which is raw/opaque data).

The IBI status descriptor is a read-only structure describing an IBI event received from a Slave device on the I3C bus.

Note: If the I3C HCI auto-read feature is used, then the IBI data includes the data received from the auto-generated private read operation.

Even if LAST_STATUS is set to 0, the driver software still evaluates the data payload length by examining the CHUNKS field.

The HTDTBP register is a 32-bit bi-directional data transfer register which is used both to read from the high priority receive data, and to write to the high priority transmit data.

For Read Operation:

To receive data from the High Priority RX Buffer, read from the HTDTBP register. It should be read based on queue status indication.

The Queue Threshold Control register controls the interrupt trigger thresholds for the Command Queue, the Response Queue, and the IBI Queue.

The specific reset values are indicative, and could be hardware implementation specific.

CMDQTH[7:0] bits (Normal Command Ready Queue Threshold)

If this field is greater than (Command Queue size*1 – 1), then only the number of bits required to address the full buffer depth will be considered.

RSPQTH[7:0] bits (Normal Response Queue Threshold)

Controls the minimum number of Response Queue entries needed to trigger the I3C_RESP interrupt.

If this field is greater than (Response Status Queue size*2 – 1), then only the number of bits required to address the full buffer depth will be considered.

注1。这些位支持所有 I3C 模式。
注2。这些位支持I3C主模式和I3C辅助主模式。

队列阈值控制寄存器控制命令队列、响应队列和 IBI 队列的中断触发阈值。

具体的重置值是指示性的,并且可以是特定于硬件实现的。

CMDQTH[7:0] 位（正常命令就绪队列阈值）

控制触发 I3C_CMD 中断所需的最小命令队列清空次数。

大（命令队列大小*1 – 1),则只考虑寻址全缓冲区深度所需的位数。

RSPQTH[7:0] 位（正常响应队列阈值）

控制触发 I3C_RESP 中断所需的最小响应队列条目数量。

大（响应状态队列大小*2 – 1),则仅考虑寻址全缓冲区深度所需的位数。

IBIDSSZ[7:0] bits (Normal IBI Data Segment Size)

This is the IBI data segment size, in DWORDs (4 bytes).

In PIO mode, this field allows the incoming IBI data to be sliced into multiple segments generating status individually, to support cutthrough readout of a long IBI payload data.

When Asynchronous Timing Control mode is supported, this field should be set to a value other than 1 or 3 to allow the single data segment to contain the entire Master time-stamp value (for example, both MREF and MC2).

IBIQTH[7:0] bits (Normal IBI Queue Threshold)

For I3C protocol mode (Master): PRTS.PRTMD = 0 and PRSST.CRMS = 1.

Controls generation of the I3C_IBI interrupt, based on the value of the IBI Queue's Outstanding IBI status count.

Each IBI status entry can represent either the complete IBI payload (if the IBI payload byte size is 4×IBIDSSZ or less), or a segment of the IBI payload (if the IBI payload byte size is more than 4×IBIDSSZ).

For I3C protocol mode (Slave) : PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.

Controls the minimum number of IBI Data Buffer empties needed to trigger the I3C_IBII interrupt.

If this field is greater than (IBI Data Buffer size*3 - 1), then only the number of bits required to address the full buffer depth will be considered.

Note 1. Command Queue size is 4.
Note 2. Response Status Queue size is 4.
Note 3. IBI Data Buffer size is 8.

Note: It is assumed that I3C has exactly one Command Queue, exactly one Response Queue, and exactly one IBI Queue.

IBIDSSZ[7:0] 位（正常 IBI 数据段大小）

这是 IBI 数据段大小,单位为 DWORD(4 字节）。

在 PIO 模式下,该字段允许将传入的 IBI 数据切成多个段,单独生成状态,以支持长 IBI 有效负载数据的切入读出。

当支持异步定时控制模式时,该字段应设置为 1 或 3 以外的值,以允许单个数据段包含整个主时间戳值（例如,MREF 和 MC2)。

IBIQTH[7:0] 位（普通 IBI 队列阈值）对于 I3C 协议模式（主）:PRTS。
PRTMD = 0 和 PRSST。CRMS = 1。

I3C_IBI中断的生成进行控制,基于IBI队列的突出IBI状态计数的值。

每个 IBI 状态条目可以表示完整的 IBI 有效负载（如果 IBI 有效负载字节大小为 4×IBIDSSZ 或更小）,也可以表示 IBI 有效负载的一部分（如果 IBI 有效负载字节大小大于 4×IBIDSSZ）。

对于I3C协议模式（从机）:PRTS。PRTMD位=0,PRSST。CRMS位=0。

控制触发 I3C_IBII 中断所需的 IBI 数据缓冲区清空的最小数量。

大（IBI 数据缓冲区大小 *3 - 1),则仅考虑寻址完整缓冲区深度所需的位数。

注1。命令队列大小为 4。
注2。响应状态队列大小为 4。
注3。IBI 数据缓冲区大小为 8。

注: I3C 假定恰好有一个命令队列,恰好有一个响应队列,恰好有一个 IBI 队列。

The Data Buffer Control register controls the interrupt trigger thresholds for the Receive Data Buffer Queue and the Transmit Data Buffer Queue.

TXDBTH[2:0] bits (Normal Transmit Data Buffer Threshold)

Minimum number of Transmit FIFO empties, in DWORDs, that will trigger the I3C_TX interrupt.

The software must program a value less than Transmit Data Buffer size in this register.

RXDBTH[2:0] bits (Normal Receive Data Buffer Threshold)

Minimum number of Receive FIFO entries in DWORDs that will trigger the I3C_RX interrupt.

The software must program a value less than Receive Data Buffer size in this register.

TXSTTH[2:0] bits (Normal Tx Start Threshold)

When preparing to initiate a Write Transfer on the I3C Bus, I3C shall wait until the Transmit Buffer has at least the indicated number of locations available.

Two optional configurable Modes are available:

1. Store and Forward Mode
   If the TXSTTH[2:0] field is set to the Transmit Buffer size, then I3C shall delay initiation of the Write Command as follows:
   - If the data length to be transferred is more than the Transmit Buffer size, then this module shall wait until the Transmit FIFO is completely full.
   - If the data length to be transferred is less than the Transmit Buffer size, then I3C shall wait until enough Transmit FIFO locations are available to store the data to be transferred.
2. Threshold Mode
   If the TXSTTH[2:0] field value is less than the Transmit Buffer size, then I3C shall initiate the Write Command as soon as the indicated number of Transmit FIFO locations are entries.

RXSTTH[2:0] bits (Normal Rx Start Threshold)

When preparing to initiate a Read Transfer on the I3C bus, I3C shall wait until the Receive Buffer has at least the indicated number of empty locations in DWORDs.

Two optional configurable Modes are available:

1. Store and Forward Mode
   If the RXSTTH[2:0] field is set to the Receive Buffer size, then I3C shall delay initiation of the Read Command as follows:
   - If the data length to be transferred is more than the Receive Buffer size, then this module shall wait until the Receive FIFO is completely empty.

数据缓冲区控制寄存器控制接收数据缓冲区队列和发送数据缓冲区队列的中断触发阈值。

TXDBTH[2:0] 位（正常传输数据缓冲区阈值）

最小传输 FIFO 空次数（以 DWORD 为单位）将触发 I3C_TX 中断。

软件必须在此寄存器中对小于传输数据缓冲区大小的值进行编程。

RXDBTH[2:0] 位（正常接收数据缓冲区阈值）

DWORD 中接收将触发 I3C_RX 中断的 FIFO 条目的最小数量。

软件必须在此寄存器中对小于接收数据缓冲区大小的值进行编程。

TXSTTH[2:0] 位（普通 Tx 开始阈值）

I3C总线上准备启动写入传输时,I3C应等到传输缓冲区至少有指定的可用位置数量。

提供两种可选的可配置模式:

1。存储和转发模式
TXSTTH[2:0] 字段设置为传输缓冲区大小, 那么 I3C 应延迟写入命令的启动, 如下:

- 如果要传输的数据长度大于传输缓冲区大小,则该模块应等到传输 FIFO 完全满时才进行。
- 如果要传输的数据长度小于传输缓冲区大小,则 I3C 应等到有足够的传输 FIFO 位置可用来存储要传输的数据。

2锛姣涓涓。阈值模式
TXSTTH[2:0] 字段值小于传输缓冲区大小,则一旦指示的传输 FIFO 位置数量为条目,I3C 应立即启动写入命令。

RXSTTH[2:0] 位（普通 Rx 起始阈值）

- 如果要传送的数据长度大于接收缓冲区大小,则该模块应等到接收 FIFO 完全为空。

- If the data length to be transferred is less than the Receive Buffer size, then I3C shall wait until enough Receive FIFO locations are available to store the data to be transferred.

2. Threshold Mode
If the RXSTTH[2:0] field value is less than the Receive Buffer size, then I3C shall initiate the Read Command as soon as the indicated number of Receive FIFO locations are empty.

TDBEF0 位（正常传输数据缓冲区空标志 0）

的【设置条件】

对于I 2 C协议模式:PRTS。PRTMD位=1。

满足以下条件 1 并且满足以下条件 2 至 4 中的任何一个:

1。NTSTE。TDBEE0 位 = 1（启用 Tx0 数据缓冲区空中断状态日志记录）。

2锛姣涓涓。当数据已从正常传输数据缓冲器0传输到移位寄存器并且正常传输数据缓冲器0变为空时*1。

3锛　　娴　　。当PRSST。TRMD位设置为1时。

4锛姣涓。当接收到的从地址匹配时,TRMD 位 = 1。

对于I3C协议模式:PRTS。PRTMD位=0。

满足以下条件1和2:

1。NTSTE。TDBEE0 位 = 1（启用 Tx0 数据缓冲区空中断状态日志记录）。

2锛姣涓涓。当正常传输数据缓冲器0中的空数为NTBTHCTL0时。TXDBTH[2:0] 阈值或更高（参见 NTBTHCTL0 寄存器）。

的【清算条件】

对于 I 2 C 协议模式:PRTS。PRTMD 位 = 1
。

- When data is written to NTDTBP0.
- When the TRMD bit in PRSST is set to 0.

For I3C protocol mode: PRTS.PRTMD bit = 0.

- Write 0 to this bit after 1 is read.
- On completion of the last write access to Normal Transmit Data by DMAC/DTC.

Note 1. When the BST.NACKDF flag is set to 1 while the BSTE.NACKDE bit = 1, I3C aborts data transmission/reception. If the TDBEF0 flag = 0 (next transmit data has been written), data is transferred to the Shift Register and the Normal Transmit Data Buffer 0 register becomes empty at the rising edge of the 9th clock cycle, but the TDBEF0 flag is not set to 1.

RDBFF0 bit (Normal Receive Data Buffer Full Flag 0)

[Setting conditions]

For I^2C Protocol mode: PRTS.PRTMD bit = 1.

The following condition 1 is satisfied and any of the following condition 2 or 3 is satisfied:

1. The NTSTE.RDBFE0 bit = 1 (enables Rx0 Data Buffer Full Interrupt Status logging).
2. When receive data is transferred from Shift Register to Normal Receive Data Buffer 0.
   The RDBFF0 flag is set to 1 on the rising edge of the 8th or 9th SCL clock cycle (selected in the ACKTWE bit in SCSTRCTL).
3. When the received slave address matches after a START (or Repeated START) condition is detected with the TRMD bit in PRSST set to 0.

For I3C Protocol mode: PRTS.PRTMD bit = 0.

The following conditions 1 and 2 are satisfied:

1. The NTSTE.RDBFE0 bit = 1 (enables Rx0 Data Buffer Full Interrupt Status logging).
2. When the number of Normal Receive Data Buffer 0 entries is the NTBTHCTL0.RXDBTH[2:0] threshold or more (see NTBTHCTL0 register).

[Clearing conditions]

For I^2C Protocol mode: PRTS.PRTMD bit = 1.

- When data is read from NTDTBP0.

For I3C Protocol mode: PRTS.PRTMD bit = 0.

- Write 0 to this bit after 1 is read.
- On completion of the last read access to Normal Receive Data by DMAC/DTC.

IBIQEFF bit (Normal IBI Queue Empty/Full Flag)

[Setting conditions]

The following 2 conditions are satisfied:

1. The NTSTE.IBIQEFE bit = 1 (enables IBI Status Buffer Empty/Full Interrupt Status logging)
2. For I3C protocol mode (master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1.
   - When the number of IBI Status Queue entries is more than the NQTHCTL.IBIQTH threshold (see NQTHCTL register).

   For I3C protocol mode (slave) : PRTS.PRTMD bit = 0, PRSST.CRMS bit = 0.
   If the NQTHCTL.IBIQTH = 0:
   - When IBI Data Buffer is completely empty.

DVIBIPL 位（设备 IBI 有效负载）

指示该设备的 IBI 是否具有数据有效负载。该字段反映了设备总线中的 IBI 有效负载位特征寄存器（BCR）。

在本设备的 IBI 处理过程中,主设备应使用此字段来确定是否驱动 IBI 的接收数据有效负载。数据延续由 T 位指示。

DVSIRRJ 位（设备带内从中断请求拒绝）

控制该设备在执行主角色时是否会接受而不是拒绝其他设备的从属中断请求设备。

DVMRRJ 位（设备带内主请求拒绝）

控制该设备在执行主控角色时是否会接受而不是拒绝其他设备的主控请求。

I3C 声明非当前主功能时,此位才有效。

DVIBITS bit (Device IBI Time-stamp)

Enables or disables IBI time-stamping for a specific Device.

Note: The IBI Status Descriptor for each IBI event indicates whether or not the individual IBI event was actually time-stamped. Set to 0 except for Async mode 0 and Async mode 1 of timing control.

DVNACK[1:0] bits (Device NACK Retry Count)

These bits set the number of retries when a NACK response is received from the slave for the transaction set in the Command Descriptor.

Note: When ENTDAA is executed by Address Assign Command, the setting of this bit is ignored and the transaction ends when NACK is received once.

Note: I3C will retry according to the setting of DVNACK[1:0] bit, even if it receives a NACK for the broadcast address.

Note: If DVNACK[1:0] bits are 0x0, I3C will not retry even for Direct CCCs.

DVIBITS 位（设备 IBI 时间戳）

启用或禁用特定设备的 IBI 时间戳。

注意:每个 IBI 事件的 IBI 状态描述符指示单个 IBI 事件是否实际上已加时间戳。设置为 0,但定时控制的 Async 模式 0 和 Async 模式 1 除外。

DVNACK[1:0] 位（设备 NACK 重试计数）

当从命令描述符中的事务集的从站接收到 NACK 响应时,这些位设置重试次数。

注意:当 ENTDAA 由地址分配命令执行时,该位的设置将被忽略,并且当收到一次 NACK 时事务结束。

Note:I3C会根据DVNACK[1:0]位的设置重试,即使它接收到广播地址的NACK。

SVIRQE bit (Slave Interrupt Requests Enable)

This bit allows the Master to control when Slave-initiated Interrupts are allowed on the I3C Bus.

These four Direct (ENEC/DISEC Format 1) or Broadcast (ENEC/DISEC Format 2) CCCs allows the Master to control when Slave-initiated traffic is (Enable) vs. is not (Disable) allowed on the I3C Bus. This control governs a Slave's attempts to request an Interrupt (ENI) or to request Mastership (ENMR).

MWLG[15:0] bits (Max Write Length)

These bits use for the I3C Master to set or get a maximum data write length in bytes for one Slave Device.

This Max Write Length does not affect data write lengths for Broadcast CCCs. The Set/Get Max Write Length value is transmitted over two bytes, with the most significant byte (MSB) transmitted first. The minimum value that Max Write Length can be set to is 8.

[Update conditions]

- When writing Max Write Length value.

Note: This register supports I3C secondary master mode and I3C slave mode.

MRLG[15:0] bits (Max Read Length)

These bits use for the I3C Master to set or get a maximum data read length for one Slave Device.

The Set/Get Max Read Length value is transmitted over the first two bytes, with most significant byte (MSB) transmitted first. The minimum value to which Max Read Length can be set is 16.

[Update conditions]

- When writing Max Read Length value.
- When receiving SETMRL CCC (Broadcast), these bits are updated to MRL value.*1
- When Slave Address value is its own Slave Address in receiving SETMRL CCC (Direct), these bits are updated to MRL value.*1

IBIPSZ[7:0] bits (IBI Payload Size)

These bits use for the I3C Master to set or get optionally a maximum IBI payload size.

For devices with BCR bit 2 set to 1, the Max IBI payload size value is added as a third-byte, where a value of 0 indicates an unlimited payload size. If Timing Control is used, then the minimum IBI payload size is either four bytes or five bytes. If Timing Control is not used, then the minimum IBI payload size is 1 (one byte).

This CCC is optional for the Slave, with two exceptions:

注: 该寄存器支持I3C辅助主模式和I3C从模式。

MWLG[15:0] 位（最大写入长度）

这些位用于 I3C Master 为一个从属设备设置或获取以字节为单位的最大数据写入长度。

此最大写入长度不会影响广播 CCC 的数据写入长度。Set/Get Max Write Length 值通过两个字节传输,其中最高有效字节（MSB）首先传输。Max Write Length 可以设置的最小值为 8。

- 写入最大写入长度值时。

注: 该寄存器支持I3C辅助主模式和I3C从模式。

MRLG[15:0] 位（最大读长）

I3C Master 使用这些位来设置或获取一个从属设备的最大数据读取长度。

Set/Get Max Read Length 值在前两个字节上传输,其中最高有效字节（MSB）首先传输。最大读长可以设置的最小值是 16。

件 【更新条件】

- 写入最大读取长度值时。
- 接收 SETMRL CCC（广播）时,这些位更新为 MRL 值。X数学X_2
- 当从地址值是其接收 SETMRL CCC（直接）时自己的从地址时,这些位更新为 MRL 值。X数学X_2

IBIPSZ[7:0] 位（IBI 有效负载大小）

这些位用于 I3C Master 设置或可选地获得最大 IBI 有效负载大小。

BCR 位 2 设置为 1 的设备, 最大 IBI 有效负载大小值作为第三字节添加, 其中值为 0 表示无限有效负载大小。如果使用定时控制,则最小 IBI 有效负载大小为四个字节或五个字节。如果不使用定时控制,则最小 IBI 有效负载大小为 1（一个字节）。

此 CCC 对于奴隶来说是可选的,但有两个例外:

1. This CCC is required if both (a) any private Read Request Message (s) and/or any extended Read Request CCC (s) implemented by the Slave support a variable limit on the maximum number of data bytes that the Slave may return per Message, and (b) this limit is greater than 16 bytes.
2. This CCC is required if the Slave both (a) supports an IBI Payload (as indicated with BCR bit 1), and (b) will transmit more than one byte of private payload (not counting Timing Control bytes, when Timing Control used).

[Update conditions]

- When writing Max IBI payload size value.
- When receiving SETMRL CCC (Broadcast), these bits are updated to IBI payload size value.*1
- When Slave Address value is its own Slave Address in receiving SETMRL CCC (Direct), these bits are updated to IBI payload size value.*1

PRTE bit (Protocol Error)

If this bit set to 1, then the Slave detects a protocol error since the last Status read.

The Slave checks for such errors. Note that this value self-clears by the hardware upon every successful completion of a Master read of the Slave's Status.

The Direct CCC is a Get request for one I3C Slave Device to return its current Status, in the two-byte format detailed. Note that byte 0 is the LSB, and byte 1 is the MSB.

[Setting condition]

- When the Slave detected a protocol error.*1

[Clearing condition]

- When transmission by own Slave Address is completed without error after receiving GETSTATUS CCC (Direct).*1

ACTMD[1:0] bits (Slave Device's current Activity Mode)

Contains the two-bit ID of the Slave Device's current Activity Mode (readiness to support data read of sensor or related information).

SC1C[15:0] 位（SC1 捕获）

- 异步模式 0（异步基本模式）
  启用 ATCCNTE。ATCE 后,SC1C[15:0] 计数器从 SC1C[15:0] 计数触发器 *1 向上计数到 IBI 的 ACK 旁边的 SCL 上升沿,并将其捕获为 SC1C[15:0]。

After enabling ATCCNTE.ATCE, SC1C[15:0] Counter counts up from SC1C[15:0] count trigger*1 to the first aME, and capture it as SC1C[15:0].

Note: As the timing control specification, the SC1C[15:0] counter value is included in the IBI frame as IBI data and is sent to I3C Master, therefore it is not necessary for the I3C Slave to read this register. If the I3C Slave needs to read this register, read it after completing the IBI frame.

Note 1. SW or external trigger can be selected by selection bits.

25.3 Operation

25.3.1 Data Structures

25.3.1.1 Command Descriptor

The write-only Command Descriptor structure is 64 bits in length. The Command Descriptor is put to the Command Queue with writes to the Command Queue Port (High Priority or Normal).

Write to the Command Queue Port (High Priority or Normal) in the following order:

1. First write : The least significant DWORD (Command Descriptor Structure Low).
2. Second write : The most significant DWORD (Command Descriptor Structure High).

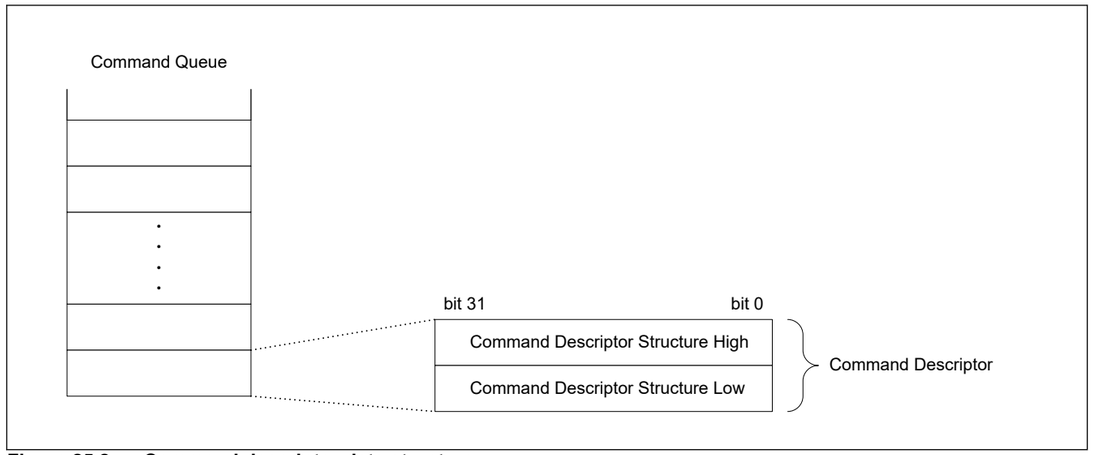

Figure 25.2 Command descriptor data structure

I3C provides a Command Descriptor structure for each command type as follows:

- Address Assign Command
- Immediate Transfer Command
- Regular Transfer Command
- Combo Transfer Command
- Internal Control Command

Details are explained in the following sections.

25.3.1.1.1 Address Assign Command

This command is used for address assignment (ENTDAA, SETDASA).

Note: When issuing SETAASA CCC, use the Immediate Transfer command.

25.3 操作

25.3.1 数据结构

25.3.1.1 命令描述符

仅写命令描述符结构长度为 64 位。命令描述符通过写入命令队列端口（高优先级或普通）被放入命令队列。

按以下顺序写入命令队列端口（高优先级或普通）：

1。首先写:最低有效 DWORD（命令描述符结构低）。

2锛姣涓涓。第二写:最重要的 DWORD（命令描述符结构高）。

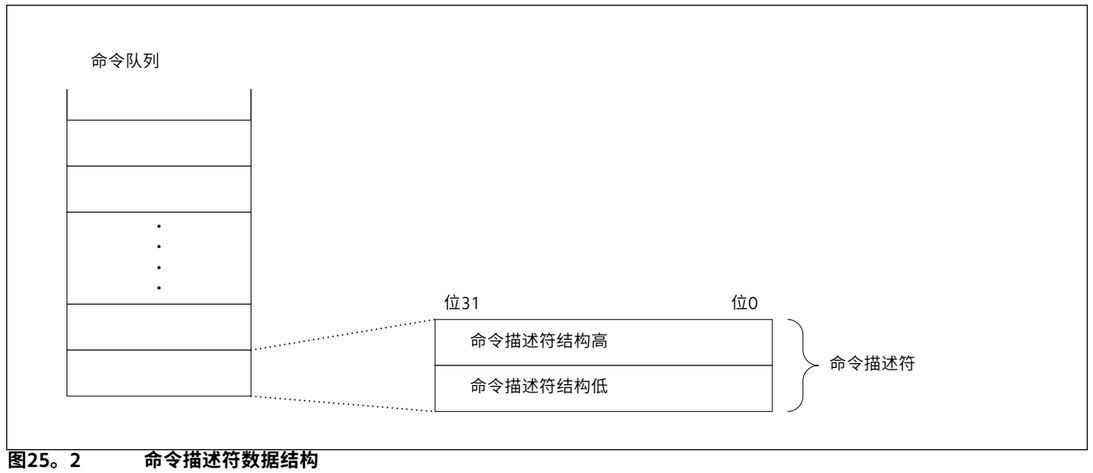

图25。2 命令描述符数据结构

I3C 为每种命令类型提供命令描述符结构如下:

● 地址分配命令
● 立即转移命令
● 常规转移命令
● 组合传输命令
● 内部控制命令

详细信息将在以下部分中解释。

25.3.1.1.1 地址分配命令

该命令用于地址分配（ENTDAA、SETDASA）。

注: 发出 SETAASA CCC 时,请使用"立即传输"命令。

CMD_ATTR[2:0] 位（命令属性）

命令类型,定义其他字段的格式。

TID[3:0] bits (Transaction ID)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

CMD[7:0] bits (Transfer Command CCC Value)

Specifies CCC code indicating whether Address Assignment uses ENTDAA or SETDASA commands. The field comprises the entire command code (ENTDAA or SETDASA).

DEV_INDEX[4:0] bits (Device Index)

Indicates the DATBASm table index for the Slave device being addressed with the transfer. Static and device addressing related information are stored to this index in the DATBASm.

DEV_COUNT[3:0] bits (Device Count)

Indicates the number of devices that a dynamic address is assigned to.

ROC bit (Response on Completion)

Controls whether Response Status is sent after successful completion of the Transfer command. The successful completion is read from register NRSPQP. Upon unsuccessful transfer the Response Status is sent.

TOC bit (Terminate on Completion)

Controls what bus condition to issue after the Transfer command completes.

For ENTDAA, a STOP condition is issued regardless of the setting value of TOC. It is meaningful for SETDASA transfers.

When sending SETDASA CCC by TOC = 0 (RESTART), the next command must be set to SETDASA CCC with the Address Assign Command.

When the next command is not the same SETDASA CCC flame, it must be set to TOC = 1 (STOP).

25.3.1.1.2 Immediate Transfer Command

This structure directly contains data (max 4 bytes) to be transferred, and as a result is only useful for Transfers/CCCs that write data. This structure shall not be used for Read operations (for example, to receive data).

When transmitting data of 4 bytes or less, use this Immediate Transfer Command to communicate.

When transmitting data of 5 bytes or more, use the Regular Transfer Command to communicate.

For the Regular Transfer Command, see section 25.3.1.1.3. Regular Transfer Command.

I3C provides an Immediate Transfer Command for the following mode:

- I3C Master Mode

Details of the Immediate Transfer Command Structure of each mode are shown in this section.

Bit position:	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field:	DATA_BYTE_4[7:0]								DATA_BYTE_3[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bit field:	DATA_BYTE_2[7:0]								DATA_BYTE_1[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TID[3:0] 位（事务 ID）

用作此命令的识别标签。该字段应由软件驱动程序填充,并且相同的值应反映在响应描述符中。

CMD[7:0] 位（传输命令 CCC 值）

指定 CCC 代码,指示地址分配是否使用 ENTDAA 或 SETDASA 命令。该字段包含整个命令代码（ENTDAA 或 SETDASA）。

DEV_INDEX[4:0] 位（设备索引）

指示正在通过传输寻址的从设备的 DATBASm 表索引。静态和设备寻址相关信息存储到 DATBASm 中的此索引中。

DEV_COUNT[3:0] 位（设备计数）

指示分配给动态地址的设备数量。

ROC 位（完成响应）

控制在成功完成传输命令后是否发送响应状态。成功完成是从寄存器 NRSPQP 中读取的。传输不成功后,将发送响应状态。

TOC 位（完成时终止）

Transfer 命令完成后控制要发出什么总线条件。

对于 ENTDAA,无论 TOC 的设置值如何,都会发出 STOP 条件。SETDASA 传输来说是有意义的。

当通过 TOC = 0（RESTART）发送 SETDASA CCC 时,下一个命令必须使用地址分配命令设置为 SETDASA CCC。

当下一个命令与 SETDASA CCC 火焰不同时,必须将其设置为 TOC = 1（STOP）。

25。3。1。1。2 立即转移命令

该结构直接包含要传输的数据（最多 4 字节）,因此仅对写入数据的传输/CCC 有用。该结构不得用于读取操作（例如,接收数据）。

4字节或更少的数据时,使用此立即传输命令进行通信。5个字节或更多的数据时,使用常规传输命令进行通信。

有关常规转移命令,请参阅第 25。3。1。1。3 节。常规传输命令 .

I3C 为以下模式提供即时传输命令:

Number of valid data bytes to use in this Immediate Data Transfer Descriptor.

This field must be set to non-zero value, except for CCCs that does not have payload defined.

MODE[2:0] bits (Immediate Data Transfer Mode and Speed Values)

Sets the mode and speed for the I3C or I^2C transfer.

Interpretation of this field depends on whether the Device is in I3C Mode vs. I^2C Mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

RNW bit (Immediate Data Transfer R/W)

Identifies direction of the transfer.

This field shall always be set to 0, because Immediate transfers are valid for Write transactions only.

ROC bit (Immediate Data Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the data transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

TOC bit (Immediate Data Transfer Terminate on Completion)

Controls what Bus condition is issued after completion of the data transfer.

When sending Direct CCC by TOC = 0 (RESTART), next command must be set to same Direct CCC.

When the next command is not the same Direct CCC, must be set to TOC = 1 (STOP).

25.3.1.1.3 Regular Transfer Command

This structure does not contain data to be transferred.

For Master Mode, the data buffer is available through Transfer Data Queue Port (Receive Data Queue Port and Transmit Data Queue Port).

When transmitting data of 5 bytes or more, use this Regular Transfer Command to communicate.

When transmitting data of 4 bytes or less, use the Immediate Transfer Command to communicate.

For the Immediate Transfer Command, see section 25.3.1.1.2. Immediate Transfer Command.

For I3C Slave Mode, the IBI Payload buffer is available through IBI Status Queue Port.

CMD_ATTR[2:0] 位（组合传输命令属性）

命令类型,定义其他字段的格式。

TID[3:0] 位（组合传输事务）

用作此命令的识别标签。该字段应由软件驱动程序填充,并且相同的值应反映在响应描述符中。

CP bit (Combo Transfer Command Present)

Indicates whether the contents of the CMD field is valid for a HDR Transfer.

DEV_INDEX[4:0] bits (Combo Transfer Device Index)

Indicates the DATBASm table index for the Slave Device being addressed with the transfer. Static and Device addressing related information will be stored to this index in the DATBASm.

FIRST_PHASE_MODE bits (Combo Transfer First Phase Mode)

Indicates whether the first phase of the Combo Transfer is executed in SDR Mode, vs. the Mode indicated by the MODE field.

MODE[2:0] bits (Combo Transfer Speed and Mode Values for I3C Mode)

Sets the mode and speed for the I3C or I^2C transfer.

Interpretation of this field depends on whether the Device is in I3C Mode vs. I^2C Mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

RNW bit (Combo Transfer R/W Identifies direction of the transfer)

Identifies direction of the transfer.

ROC bit (Combo Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the data transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

TOC bit (Combo Transfer Terminate on Completion)

Controls what Bus condition is issued after completion of the data transfer.

When the next command is SDR mode, must be set to TOC = 1 (STOP).

DATA_LENGTH[15:0] bit (Combo Transfer Data Length)

Number of valid data bytes to use in this Combo Transfer Descriptor.

This field must be set to non-zero value.

25.3.1.1.5 Internal Control Command

This structure is used for controlling I3C itself (not for transfer commands).

I3C provides an Internal Control Command for the following mode:

- I3C Master mode

Details of the Internal Control Command Structure are as follows:

Bit position:	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

指示正在通过传输寻址的从设备的 DATBASm 表索引。静态和设备寻址相关信息将存储到 DATBASm 中的此索引中。

FIRST_PHASE_MODE 位（组合传输第一阶段模式）

指示组合传输的第一阶段是否在 SDR 模式下执行,与 MODE 字段指示的模式相比。

MODE[2:0] 位（I3C 模式的组合传输速度和模式值）设置 I3C 或 I 2 C 传输的模式和速度。

In master transmit operation, I3C outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 25.116 shows an example of usage of master transmission and Figure 25.6 to Figure 25.8 show the timing of operations in master transmission.

The following describes the procedure and operations for master transmission.

1. Initial settings. For details, see section 25.3.3.1. Initial Setting Flow.
2. Read the BCST.BFREF flag to check that the bus is open, and then set the CNDCTL.STCND bit to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. At the same time, the BFREF flag bit is

25。3。2。1。1 主模式操作

(1) I 2 C 主操作

（a）数据写入传输（单缓冲区传输）

I3C在主发送操作中,输出SCL时钟和发送的数据信号作为主设备,从设备返回确认。图25。116示出了主传输的使用示例,图25。6至图25。8示出了主传输中的操作定时。

下面描述主传输的过程和操作。

1。初始设置。详情请参见第 25。3。3。1 节。初始设置流程 .

2锛姣涓涓。读取 BCST。BFREF 标志以检查总线是否打开,然后将 CNDCTL。STCND 位设置为 1（START 条件发出请求）。I3C在收到请求后,会发出START条件。同时,BFREF标志位为

automatically set to 0, the BST.STCNDDF flag is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the I3C_SDA line have matched while the STCND bit = 1, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and bits CRMS and TRMD in the PRSST register are automatically set to 1, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.

3. Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the slave address and the R/W# bit) to the NTDTBP0 register. Once the data for transmission are written to the NTDTBP0 register, the TDBEF0 flag is automatically set to 0, the data are transferred from the Normal Transmit Data Buffer 0 to the Shift Register, and the TDBEF0 flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRMD bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, I3C continues in master transmit mode. Because the BST.NACKDF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the CNDCTL.SPCND bit to issue a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1111 0, the 2 higher-order bits of the slave address, and W to the NTDTBP0 register as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to the NTDTBP0 register.
4. After confirming that the NTST.TDBEF0 flag = 1, write the data for transmission to the NTDTBP0 register. I3C automatically holds the I3C_SCL line low until the data for transmission are ready or a STOP condition is issued.
5. After all bytes of data for transmission have been written to the NTDTBP0 register, wait until the value of the BST.TENDF flag returns to 1, and then set the CNDCTL.SPCND bit to 1 (STOP condition issuance request). Upon receiving a STOP condition issuance request, I3C issues the STOP condition.
6. Upon detecting the STOP condition, I3C automatically sets bits CRMS and TRMD in the PRSST register to 00 and enters slave receive mode. Furthermore, it automatically sets the TDBEF0 and TENDF flags to 0, and sets the BST.SPCNDDF flag to 1.
7. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

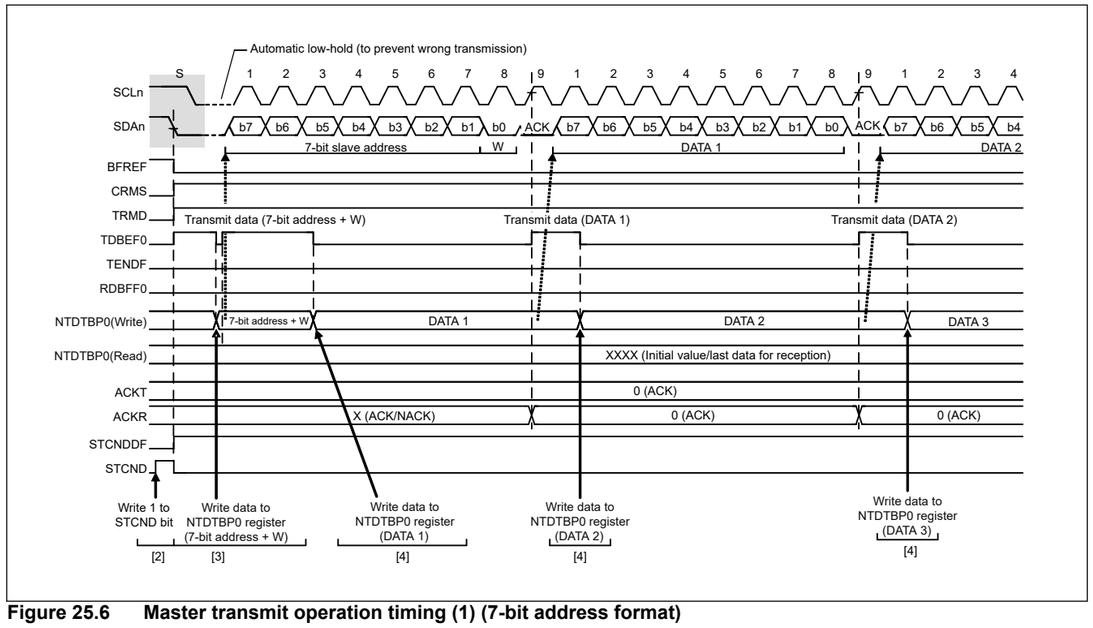

Figure 25.6 Master transmit operation timing (1) (7-bit address format)

自动设置为0,BST。STCNDDF标志自动设置为1,STCND位自动设置为0。START 条件被检测到,并且 SDA 输出状态的内部电平和 I3C_SDA 线路上的电平已经匹配而 STCND 位 = 1,则 I3C 识别出 STCND 位请求的 START 条件的发出已经成功完成,并且 PRSST 寄存器中的位 CRMS 和 TRMD 自动设置为 1, I3C置于主发射模式。NTST。TDBEF0 标志还响应于 TRMD 位的设置而自动设置为 1。

3锛 娴 。检查 NTST。TDBEF0 标志 = 1,然后将传输值（从地址和 R/W# 位）写入 NTDTBP0 寄存器。一旦用于传输的数据被写入NTDTBP0寄存器,TDBEF0标志自动设置为0,数据从正常传输数据缓冲器0传输到移位寄存器,并且TDBEF0标志再次设置为1。在发送包含从地址和R/W#位的字节之后,自动更新TRMD位的值以根据发送的R/W#位的值选择主发送或主接收模式。R/W#位的值为0,则I3C在主传输模式下继续。由于此时 BST。NACKDF 标志为 1 表示从属设备未识别该地址或通信中存在错误,因此将 1 写入 CNDCTL。SPCND 位以发出停止条件。10位格式的地址进行数据传输,首先将从地址的2个高阶位1111 0,W写入NTDTBP0寄存器作为第一地址传输。然后,作为第二地址传输,将从地址的8个低阶位写入NTDTBP0寄存器。

4锛姣涓。确认NTST。TDBEF0标志=1后,将数据写入NTDTBP0寄存器传输。I3C 自动将 I3C_SCL 线路保持在较低位置,直到用于传输的数据准备好或发出 STOP 条件。

5锛姣涓。将所有用于传输的数据字节写入NTDTBP0寄存器后,等待BST。TENDF标志的值返回到1,然后将CNDCTL。SPCND位设置为1（停止条件发出请求）。I3C在收到停止条件发出请求后,发出停止条件。

6锛 涓€涓。I3C 检测到 STOP 条件后,自动将 PRSST 寄存器中的位 CRMS 和 TRMD 设置为 00,进入从接收模式。此外,它自动将TDBEF0和TENDF标志设置为0,并将BST。SPCNDDF标志设置为1。

7锛 娴 。检查BST。SPCNDDF标志=1后,将BST。NACKDF和SPCNDDF标志设置为0以进行下一次传输操作。

(b) Data Read Transfer (Single Buffer transfer)

In master receive operation, I3C as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because I3C must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 25.117 and Figure 25.118 show examples of usage of master reception (7-bit address format) and Figure 25.9 to Figure 25.11 show the timing of operations in master reception.

The following describes the procedure and operations for master reception.

1. Initial settings. For details, see section 25.3.3.1. Initial Setting Flow.

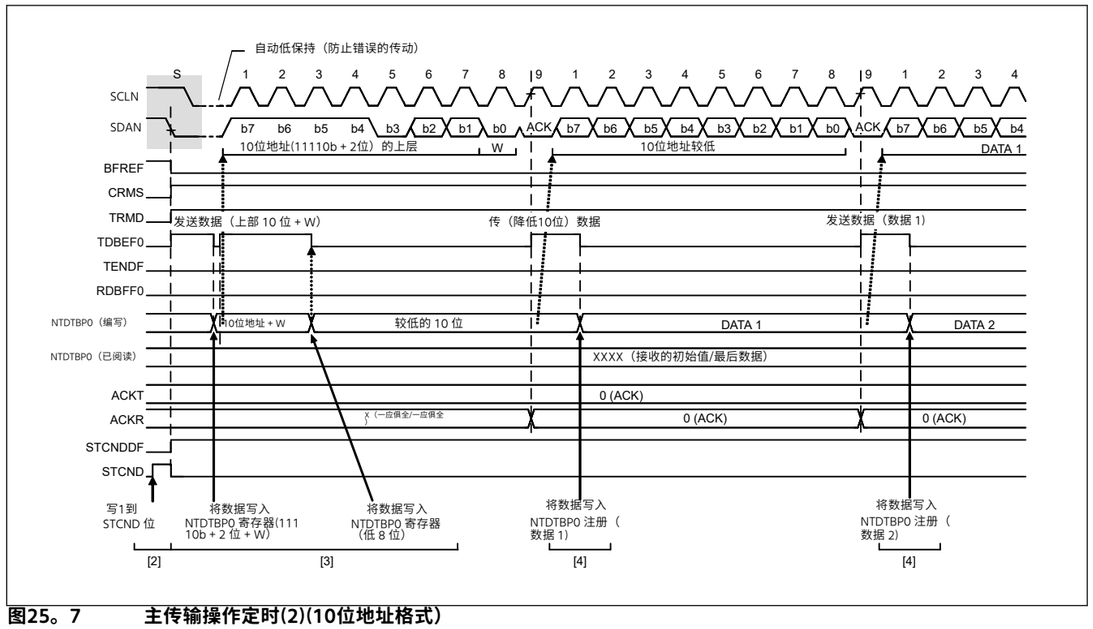

图25。7 主传输操作定时(2)(10位地址格式）

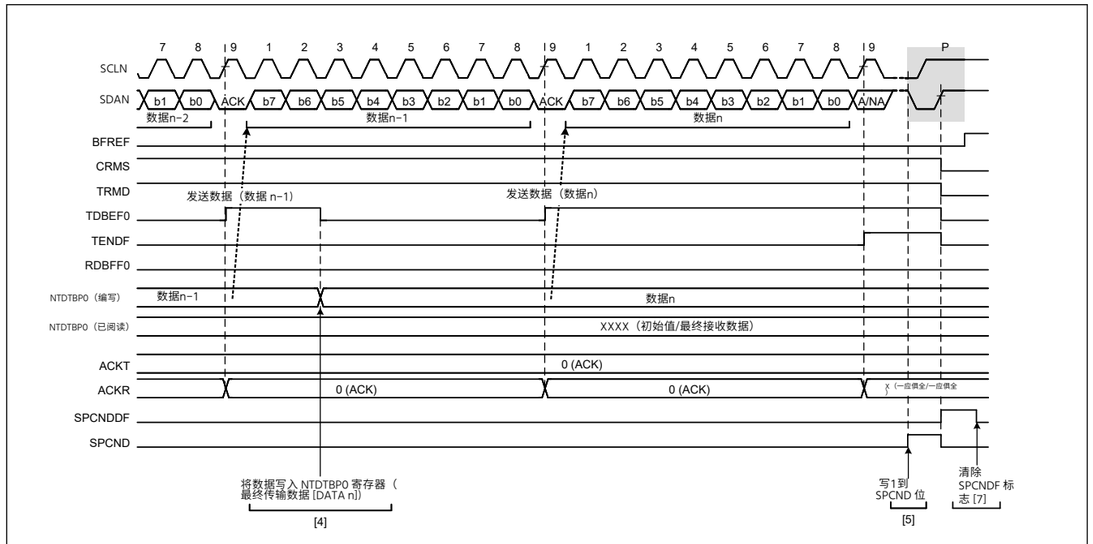

图25。8 主发射操作时序 (3)

（b）数据读取传输（单缓冲区传输）

在主接收操作中,I3C作为主设备输出SCL时钟,从从设备接收数据,并返回确认。I3C因为必须从向对应的从设备发送从地址开始,所以这部分过程是在主发送模式下执行的,但是后续步骤是在主接收模式下。

图25。117和图25。118示出了主接收(7位地址格式）和图25。9的使用示例
图 25。11 显示了主接收中的操作时间。

以下描述了主接收的程序和操作。

1。初始设置。详情请参见第 25。3。3。1 节。初始设置流程。

2. Read the BCST.BFREF flag to check that the bus is open, and then set the CNDCTL.STCND bit to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. When I3C detects the START condition, the BFREF flag is automatically set to 0 and the BST.STCNDDF flag is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the levels for the SDA output and the levels on the I3C_SDA line have matched while the STCND bit = 1, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and bits CRMS and TRMD in the PRSST register are automatically set to 1, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
3. Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to the NTDTBP0 register. Once the data for transmission are written to the NTDTBP0 register, the TDBEF0 flag is automatically set to 0, the data are transferred from the Normal Transmit Data Buffer 0 to the Shift Register, and the TDBEF0 flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the PRSST.TRMD bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the TRMD bit is set to 0 on the rising edge of the ninth cycle of SCL clock, placing I3C in master receive mode. At this time, the TDBEF0 flag is set to 0. The NTST.RDBFF0 flag is automatically set to 1 when ACK response is received from the slave device. If the slave device is not recognized or a communication failure occurs, the BST.NACKDF flag will be set to 1. At this time, set 1 to the CNDCTL.SPCND bit to issue a STOP condition. For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a Repeated START condition. After that, transmitting 1111 0, the two higher-order bits of the slave address, and the R bit places I3C in master receive mode.
4. Dummy read the NTDTBP0 register after confirming that the NTST.RDBFF0 flag = 1; this makes I3C start output of the SCL clock and start data reception.
5. After 1 byte of data has been received, the NTST.RDBFF0 flag is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the SCSTRCTL.ACKTWE bit. Reading the NTDTBP0 register at this time will produce the received data, and the RDBFF0 flag is automatically set to 0 at the same time. Furthermore, the value of the acknowledgment field received during the ninth cycle of SCL clock is returned as the value set in the ACKCTL.ACKT bit. Furthermore, if the next byte to be received is the next to last byte, set the SCSTRCTL.RWE bit to 1 (for wait insertion) before reading the NTDTBP0 register (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the ACKCTL.ACKT bit to 1 (NACK) in step 6, due to other interrupts, etc., this fixes the I3C_SCL line to the low level on the falling edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a STOP condition is possible.
6. When the SCSTRCTL.ACKTWE bit = 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the ACKCTL.ACKT bit to 1 (NACK).
7. After reading the byte before last from the NTDTBP0 register, if the value of the NTST.RDBFF0 flag is confirmed to be 1, write 1 to the CNDCTL.SPCND bit (STOP condition issuance request) and then read the last byte from the NTDTBP0 register. When 1 is written to the CNDCTL.SPCND bit, I3C is released from the wait state and issues the STOP condition after low-level output in the ninth clock cycle is completed or the I3C_SCL line is released from the low-hold state.
8. Upon detecting the STOP condition, I3C automatically sets bits CRMS and TRMD in the PRSST register to 00 and enters slave receive mode. Furthermore, detection of the STOP condition leads to setting of the BST.SPCNDDF flag to 1.
9. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

2锛姣涓涓。读取 BCST。BFREF 标志以检查总线是否打开,然后将 CNDCTL。STCND 位设置为 1（START 条件发出请求）。I3C在收到请求后,会发出START条件。I3C 检测到 START 条件时,BFREF 标志自动设置为 0,BST。STCNDDF 标志自动设置为 1,STCND 位自动设置为 0。START 条件, 此时, 如果检测到 START 条件, 并且 SDA 输出的电平和 I3C_SDA 线路上的电平已经匹配, 而 STCND 位 = 1, I3C 识别出 STCND 位请求的 START 条件的发出已成功完成, PRSST 寄存器中的位 CRMS 和 TRMD 自动设置为 1, 将 I3C 置于主发送模式。NTST。TDBEF0 标志还响应于 TRMD 位的设置而自动设置为 1。

3锛　　娴　　。检查NTST。TDBEF0标志=1,然后将传输值（第一个字节表示R/W#位的从地址和值）写入NTDTBP0寄存器。一旦用于传输的数据被写入NTDTBP0寄存器,TDBEF0标志自动设置为0,数据从正常传输数据缓冲器0传输到移位寄存器,并且TDBEF0标志再次设置为1。一旦发送了包含从地址和R/W#位的字节,PRSST。TRMD位的值就会自动更新,以根据发送的R/W#位的值选择发送或接收模式。R/W#位的值为1,则TRMD位在SCL时钟的第九周期上升沿上设置为0,将I3C置于主接收模式。此时,TDBEF0标志设置为0。当从从设备接收到ACK响应时,NTST。RDBFF0标志自动设置为1。如果未识别从设备或发生通信故障,则 BST。NACKDF 标志将设置为 1。此时,将 1 设置为 CNDCTL。SPCND 位以发出停止条件。10 位地址的设备的主接收,从使用主传输发出 10 位地址开始,然后发出重复 START 条件。之后,发送1111 0,从地址的两个高阶位,R位将I3C置于主接收模式。

4锛姣涓。Dummy在确认NTST。RDBFF0标志 = 1后读取NTDTBP0寄存器;这使得I3C开始输出SCL时钟并开始数据接收。

5锛姣涓。接收到1字节数据后,由SCSTRCTL。ACKTWE位选择的SCL时钟（时钟信号）的第八或第九周期的上升沿将NTST。RDBFF0标志设置为1。此时读取NTDTBP0寄存器将产生接收到的数据,同时自动将RDBFF0标志设置为0。此外,在SCL时钟的第九周期期间接收到的确认字段的值作为ACKCTL。ACKT位中设置的值返回。此外,如果要接收的下一个字节是倒数第二个字节,则在读取 NTDTBP0 寄存器（包含倒数第二个字节）之前,将 SCSTRCTL。RWE 位设置为 1（等待插入）。即使在处理延迟的情况下也启用 NACK 输出,以在步骤 6 中将 ACKCTL。ACKT 位设置为 1（NACK）,由于其他中断等原因,这也会将 I3C_SCL 线固定到下落的低电平接收最后一个字节的第九个时钟周期的边缘,因此状态使得可以发出停止条件。

6锛　　涓€涓。当 SCSTRCTL。ACKTWE 位 = 0 并且必须通知从设备在传输下一个（最终）字节后结束数据接收传输时,将 ACKCTL。ACKT 位设置为 1（NACK）。

7锛　　娴　　。从 NTDTBP0 寄存器读取最后一个字节后,如果确认 NTST。RDBFF0 标志的值为 1,则将 1 写入 CNDCTL。SPCND 位（停止条件发出请求）,然后从 NTDTBP0 寄存器读取最后一个字节。1写入到CNDCTL。SPCND位时,I3C从等待状态释放,并在第九个时钟周期的低电平输出完成或I3C_SCL线从低保持状态释放后发出STOP条件。

8锛　　娴　　。I3C 检测到 STOP 条件后,自动将 PRSST 寄存器中的位 CRMS 和 TRMD 设置为 00,进入从接收模式。此外,STOP 条件的检测导致将 BST。SPCNDDF 标志设置为
1.

9锛　　涓€涓。检查BST。SPCNDDF标志=1后,将BST。NACKDF和SPCNDDF标志设置为0以进行下一次传输操作。

(d) IBI Transfer

1. Write Command Descriptor to the Command Buffer and issue Transaction on I3C Bus.
   If START Request (SDA Low Drive) is issued from the slave device, I3C drives SCL to Low and completes START condition.
   Thereafter, the SCL is supplied and In-Band Interrupt Request is received.
2. In Slave Address with RnW of the Address Header, if losing Arbitration by issuing In-Band Interrupt from I3C Slave, stop issuing Transaction.
3. According to section 25.3.2.3.8. In-Band Interrupt [I3C mode], detect In-Band Interrupt and process.
4. In the interrupt with IBIQEFF = 1, read the IBI Status Descriptor from the IBI Status Buffer via the NIBIQP register and check the status.
   When detected a Slave Interrupt Request and responded with ACK, Read the IBI Data for the Data Length indicated by the DATA_LENGTH[15:0] bits of the IBI Status Descriptor from the IBI Data Buffer via the NIBIQP register.
5. Restart issuing Transaction of Command of Step1.

An example of the processing procedure after detection of In-Band Interrupt is shown below.

Processing procedure for detecting Mastership Request and transferring master right to Secondary Master

1. If the I3C Secondary Master wins the Arbitration, issue a DEFSLVS CCC and notify Slave information to Secondary Master.
2. Issue a GETACCMST CCC and complete CCC by a STOP condition.

The Mastership processing flow is shown in Figure 25.26.

Note:
- After transferring master right to Secondary Master, to get master right again, issue a Mastership Request according to (f) IBI Transfer of (2)I3C Slave Operation.

25.3.2.1.2 Slave Mode Operation

(1) I²C Slave Operation

(a) Data Write Transfer (Single Buffer transfer)

In slave receive operation, the master device outputs the SCL clock and transmit data, and I3C returns acknowledgments as a slave device.

Figure 25.126 shows an example of usage of slave reception and Figure 25.27 and Figure 25.28 show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

1. Initial settings. For details, see section 25.3.3.1. Initial Setting Flow. After initial settings, I3C will stay in the standby state until it receives a slave address that it matches.
2. After receiving a matching slave address, I3C sets one of the corresponding bits SVST.HOAF, GCAF, and SVAF[n] (n = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the acknowledge bit (ACK) on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0, I3C continues to place itself in slave receive mode and sets the NTST.RDBFF0 flag to 1.

25.3.2.1.2 从模式操作

(1) I 2 C 奴隶行动

（a）数据写入传输（单缓冲区传输）

从接收操作中,主设备输出SCL时钟并发送数据,I3C作为从设备返回确认。

图25。126示出了从属接收的使用示例,图25。27和图25。28示出了从属接收中的操作时序。

以下描述了从属接收的程序和操作。

1。初始设置。详情请参见第 25。3。3。1 节。初始设置流程。I3C在初始设置后将保持待机状态,直到收到与其匹配的从站地址。

2锛姣涓涓。I3C接收到匹配的从地址后,在SCL时钟的第九周期上升沿（时钟信号）上将对应位SVST。HOAF、GCAF、SVAF[n]（n = 0～2)中的一个设置为1,输出SCL时钟的第九周期上的确认位（ACK）。如果此时也接收到的R/W#位的值为0,则I3C继续将自身置于从接收模式并将NTST。RDBFF0标志设置为1。

3. After the BST.SPCNDDF flag is confirmed to be 0 and the NTST.RDBFF0 flag to be 1, dummy read the NTDTBP0 register (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected).
4. When the NTDTBP0 register is read, I3C automatically sets the NTST.RDBFF0 flag to 0. If reading of the NTDTBP0 register is delayed and a next byte is received while the RDBFF0 flag is still set to 1, I3C holds the I3C_SCL line low from one SCL cycle before the timing with which RDBFF0 should be set. In this case, reading the NTDTBP0 register releases the I3C_SCL line from being held at the low level. When the BST.SPCNDDF flag = 1 and the NTST.RDBFF0 flag is also 1, read the NTDTBP0 register until all the data is completely received.
5. Upon detecting the STOP condition, I3C automatically clears bits SVST.HOAF, GCAF, and SVAF[n] (n = 0 to 2) to 0.
6. After checking that the BST.SPCNDDF flag = 1, set the BST.SPCNDDF flag to 0 for the next transfer operation.

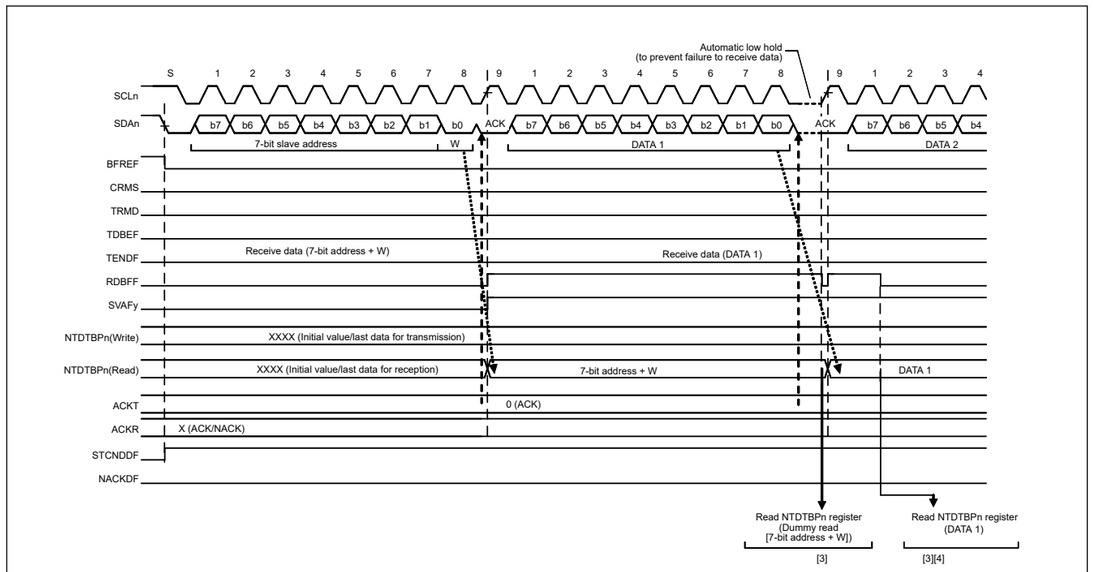

Figure 25.27 Slave receive operation timing (1) (7-bit address format, when ACKTWE = 0)

3锛 娴 。BST。SPCNDDF 标志确认为 0,NTST。RDBFF0 标志确认为 1 后,虚拟读取 NTDTBP0 寄存器（虚拟值由选择 7 位地址格式时的从地址和 R/W# 位组成,或选择 10 位地址格式时的较低 8 位）。

4锛姣涓。NTDTBP0寄存器读取时,I3C自动将NTST。RDBFF0标志设置为0。NTDTBP0寄存器的读取被延迟,并且在RDBFF0标志仍被设置为1时接收到下一个字节,则I3C在应该设置RDBFF0的定时之前从一个SCL周期将I3C_SCL行保持为低。在这种情况下,读取 NTDTBP0 寄存器可以释放 I3C_SCL 线路免于保持在低电平。当BST。SPCNDDF标志=1并且NTST。RDBFF0标志也是1时,读取NTDTBP0寄存器直到完全接收所有数据。

5锛姣涓。STOP 条件后,I3C 会自动清除位 SVST。HOAF、GCAF 和 SVAF[n]（n = 0 到 2）到 0。

6锛 涓€涓。检查BST。SPCNDDF标志=1后,将BST。SPCNDDF标志设置为0以进行下一次传输操作。

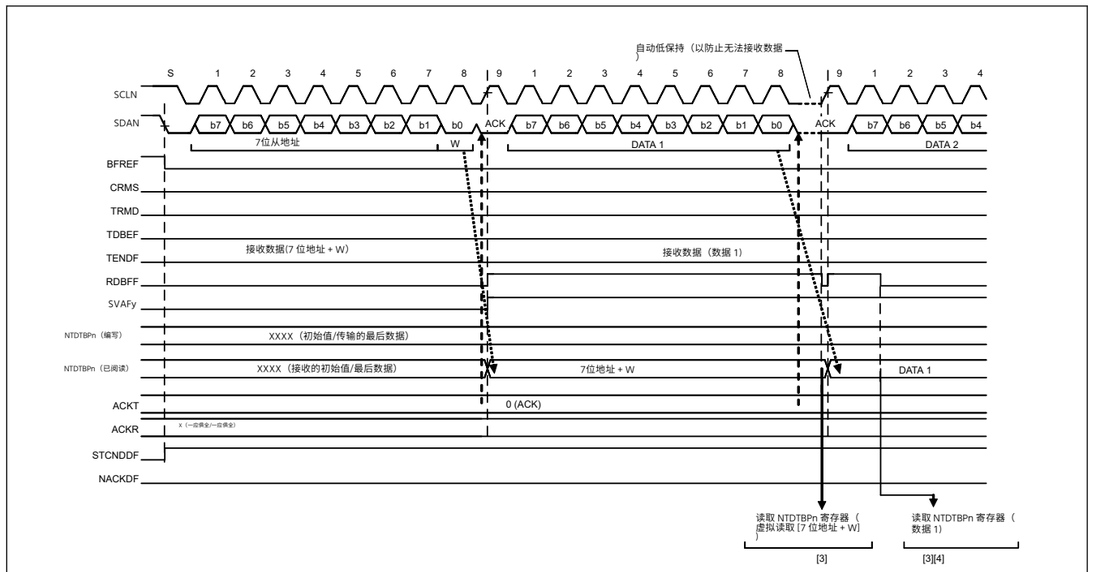

图25。27 从接收操作定时 (1)(7 位地址格式 当 ACKTWE = 0 时）

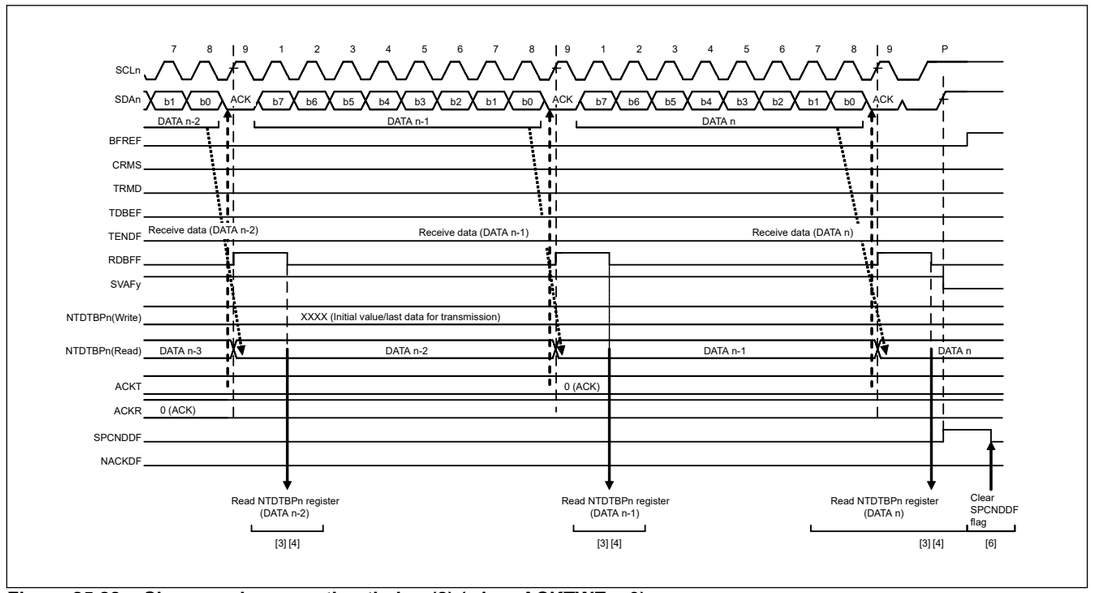

Figure 25.28 Slave receive operation timing (2) (when ACKTWE = 0)

(b) Data Read Transfer (Single Buffer transfer)

In slave transmit operation, the master device outputs the SCL clock, I3C transmits data as a slave device, and the master device returns acknowledgments.

Figure 25.125 shows an example of usage of slave transmission and Figure 25.29 and Figure 25.30 show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

1. Initial settings. For details, see section 25.3.3.1. Initial Setting Flow.
   After initial settings, I3C will stay in the standby state until it receives a slave address that it matches.
2. After receiving a matching slave address, I3C sets one of the corresponding bits SVST.HOAF, GCAF, and SVAF[n] (n = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the acknowledge bit (ACK) on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 1, I3C automatically places itself in slave transmit mode by setting both the PRSST.TRMD bit and the NTST.TDBEF0 flag to 1.
3. After the NTST.TDBEF0 flag is confirmed to be 1, write the data for transmission to the NTDTBP0 register. At this time, if I3C does not receive acknowledge from the master device (receives an NACK signal) while the BSTE.NACKDE bit = 1, I3C aborts transfer of the next data.
4. Wait until the following (a) or (b) condition.
   (a) The BST.NACKDF flag is set to 1.
   (b) The BST.TENDF flag is set to 1 while the NTST.TDBEF0 flag = 1, after the last byte for transmission is written to the NTDTBP0 register.
5. When the BST.NACKDF flag or the BST.TENDF flag = 1, dummy read the NTDTBP0 register to complete the processing. This releases the I3C_SCL line.
6. Upon detecting the STOP condition, I3C automatically sets bits SVST.HOAF, GCAF, and SVAF[n] (n = 0 to 2), flags NTST.TDBEF0 and BST.TENDF, and the PRSST.TRMD bit to 0, and enters slave receive mode.
7. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

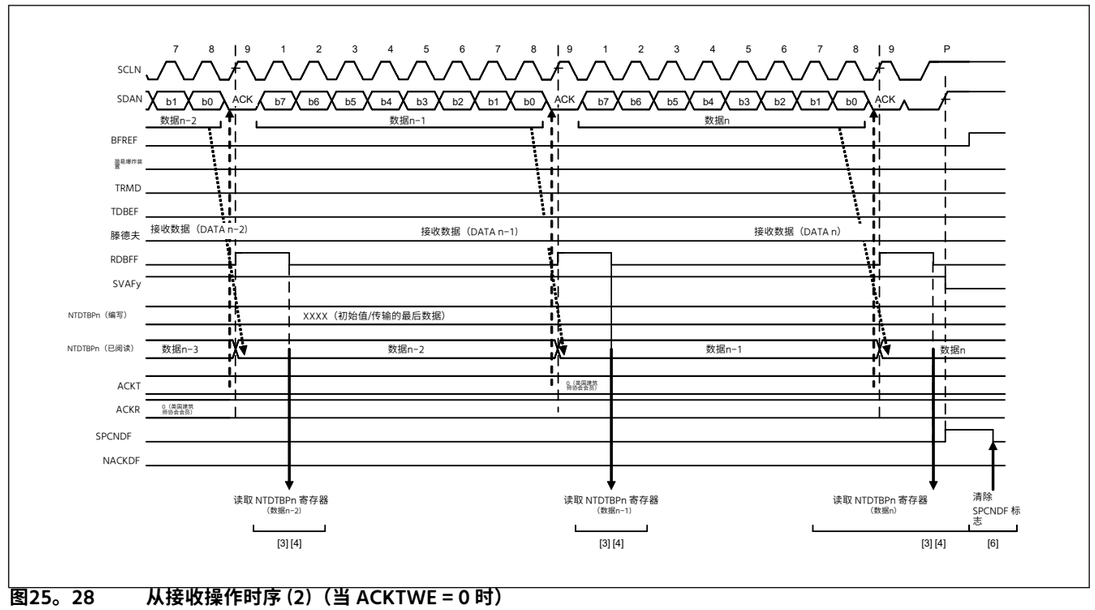

图25。28 从接收操作时序 (2)（当 ACKTWE = 0 时）

（b）数据读取传输（单缓冲区传输）

从发送操作中,主设备输出SCL时钟,I3C作为从设备发送数据,主设备返回确认。

图25。125示出了从传输的使用示例,图25。29和图25。30示出了从传输中的操作时序。

以下描述了从传输的过程和操作。

1。初始设置。详情请参见第 25。3。3。1 节。初始设置流程 .
I3C在初始设置后将保持待机状态,直到收到与其匹配的从站地址。

2锛姣涓涓。I3C接收到匹配的从地址后,在SCL时钟的第九周期上升沿（时钟信号）上将对应位SVST。HOAF、GCAF、SVAF[n]（n = 0～2)中的一个设置为1,输出SCL时钟的第九周期上的确认位（ACK）。如果此时也接收到的R/W#位的值为1,则I3C通过将PRSST。TRMD位和NTST。TDBEF0标志同时设置为1,自动将自身置于从发送模式。

3锛 娴 。在NTST。TDBEF0标志被确认为1之后,写入数据以传输到NTDTBP0寄存器。此时,如果I3C在BSTE。NACKDE位=1时没有从主设备接收确认（接收NACK信号）,则I3C中止下一个数据的传输。

4锛姣涓。等到以下（a）或（b）条件。
（a）BST。NACKDF 标志设置为 1。
（b）BST。TENDF 标志设置为 1,而 NTST。TDBEF0 标志 = 1,最后一个传输字节写入 NTDTBP0 寄存器后。

5锛姣涓。当 BST。NACKDF 标志或 BST。TENDF 标志 = 1 时,dummy 读取 NTDTBP0 寄存器以完成处理。
这释放了 I3C_SCL 线。

6锛 涓€涓。STOP 条件后,I3C 自动设置位 SVST。HOAF、GCAF 和 SVAF[n]（n = 0 到 2),标记 NTST。TDBEF0 和 BST。TENDF,以及 PRSST。TRMD 位到 0,并进入从接收模式。

7锛 娴 。检查BST。SPCNDDF标志=1后,将BST。NACKDF和SPCNDDF标志设置为0以进行下一次传输操作。

ENTDAA CCC 动态地址分配过程期间 R-I3 的操作如下所述。

1。初始设置（详情请参见第 25。3。3。1。2 节。I3C 初始设置流程)

2. When ENTDAA CCC is received, I3C transmits Provisional ID (SDCTPIDH[31:0], SDCTPIDL[15:0]), BCR (SVDCT.TBCRn), DCR (SVDCT.TDCR[7:0]) until a dynamic address is assigned. (For details, see "In case of Broadcast CCC (ENTDAA)" of (6)CCC detection function [I3C mode].)
3. When ENTDAA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in Receive Status Buffer.
4. Read Receive Status Descriptor via NRSQP register and check the status.
5. Read the data for the Data Length indicated by the DATA_LENGTH[15:0] bits of the Receive Status Descriptor from the Receive Data Buffer via the NTDTBP0 register.

If the I3C Slave has a Static Address and the I3C Master executes the Dynamic Address Assign Procedure, it is possible to assign a Dynamic Address with SETDASA CCC.

The operation of I3C during SETDASA CCC Dynamic Address Assign Procedure is described below.

1. Initial setting (For details, see section 25.3.3.1.2. I3C Initial Setting Flow)
2. When SETDASA CCC which agrees with its own Static Address is received, the SDDYAD [7:0] bit of DAT (SDATBAS0 register) is renewed and SDYADV bit of SVDVAD0 register is set in 1. (For details, see "In case of Direct Write CCC" of (6)CCC detection function [I3C mode].)

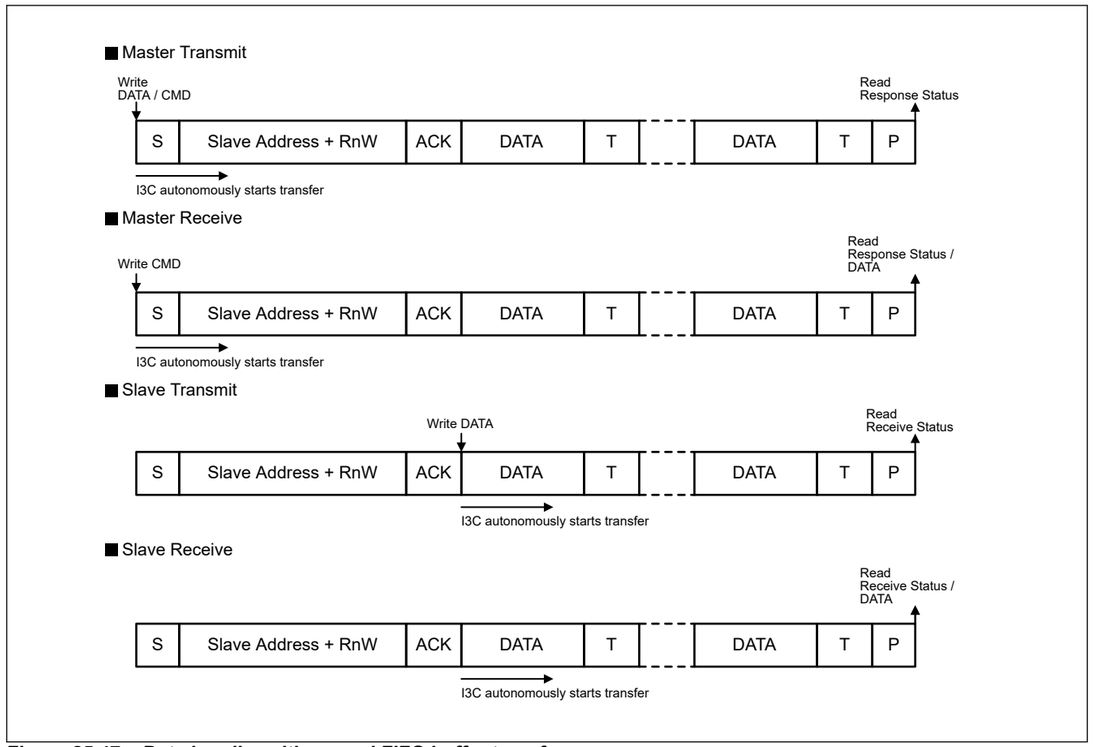

Figure 25.47 Data handler with normal FIFO buffer transfer

(2) High Priority FIFO Buffer Transfer

I3C handles the command of the High Priority FIFO buffer transfer higher priority than the command of the normal FIFO buffer transfer.

If data and commands are written to the High Priority FIFO buffer during normal FIFO buffer transfer, I3C waits for the STOP condition and then processes the command in the High Priority FIFO buffer.

After the command processing in the High Priority FIFO buffer is completed, if the command remains in the normal FIFO buffer, the I3C resumes processing the command in the normal FIFO buffer.

图25。47 具有正常 FIFO 缓冲区传输的数据处理程序

(2)高优先级 FIFO 缓冲区传输

I3C 处理高优先级 FIFO 缓冲区传输的命令的优先级高于普通 FIFO 缓冲区传输的命令。

如果在正常 FIFO 缓冲区传输期间将数据和命令写入高优先级 FIFO 缓冲区,则 I3C 等待 STOP 条件,然后处理高优先级 FIFO 缓冲区中的命令。

High Priority FIFO 缓冲区中的命令处理完成后,如果命令保持在正常的 FIFO 缓冲区中,则 I3C 恢复处理正常的 FIFO 缓冲区中的命令。

25.3.2.3.1 Communication Protocol

(1) I²C Communication Data Format

The I²C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a START condition or Repeated START condition is an address frame used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a STOP condition is issued.

Figure 25.49 shows the I²C bus format, and Figure 25.50 shows the I²C bus timing.

S: START condition. The master device drives the I3C_SDA line low from high level while the I3C_SCL line is at a high level.

SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W = 1, or from the master device to the slave device when R/W = 0.

A: Acknowledge. The receive device drives the I3C_SDA line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)

A#: Not Acknowledge. The receive device drives the I3C_SDA line high.

Sr: Repeated START condition. The master device drives the I3C_SDA line low from the high level after the setup time has elapsed with the I3C_SCL line at the high level.

(2) I3C Communication Data Format

Figure 25.51 through illustrate a typical communication for each of the six I3C Protocols. While these diagrams do not exhaustively illustrate all possible I3C communications, they do serve as useful introductions to the signaling and transmission formatting used in each I3C Protocol.

Figure 25.51 illustrates example communication using I3C Single Data Rate (SDR) coding with Broadcast (0x7E). It shows the Master reading a byte of data from the Slave at Address 0x2B in SDR Mode. From the Bus Free Condition, the Master issues a START by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain.

All Slaves ACK by pulling the SDA line Low (in the Figure, pink fill means the Slave is in control of the SDA line at this time). The Master then issues a Repeated START, then the Address of the Slave (0x2B) it wants to read followed by RnW (1 for Read). The Master then turns on a pull-up resistor and goes to Open Drain, allowing the Slave to acknowledge by pulling the SDA line Low. At this point, the Master continues to toggle the SCL line and release the SDA line, allowing the Slave to drive SDA to send one byte of data (0x4A) followed by T. T = 1 informs the Master that there is additional data, whereas T = 0 signals the end. Here there is additional data, so the Slave drives SDA High until SCL goes High, at which time it releases SDA. The Master has the option of holding SDA High with a weak pullup, which signals to the Slave that the Master allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a Repeated START), which would signal to the Slave that the Master has terminated the Read and is taking over.

SDR Mode is backwards compatible with Legacy I2C Devices, because the High time of an SCL pulse is always less than 50ns and therefore SCL will always appear to be Low because of the I2C 50ns Spike Filter.

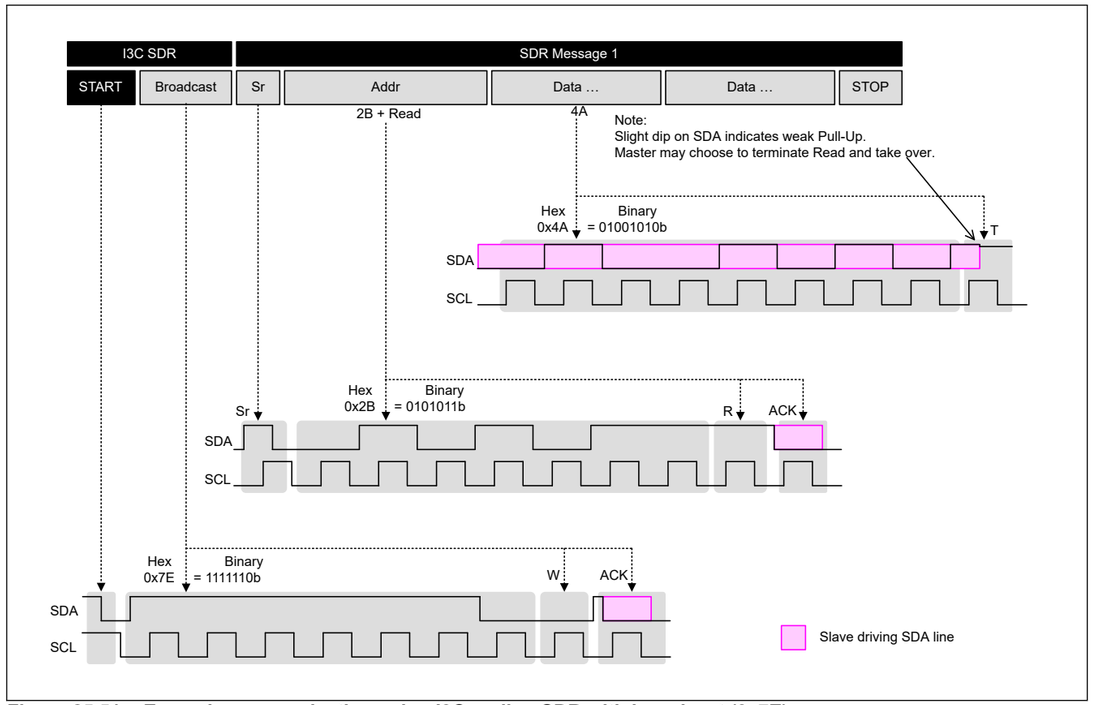

Figure 25.51 Example communication using I3C coding SDR with broadcast (0x7E)

Figure 25.52 illustrates example communication using I3C Single Data Rate (SDR) coding without Broadcast (0x7E). It shows the Master reading a byte of data from the Slave at Address 0x2B in SDR Mode. From the Bus Free Condition, The Master then issues a START, then the Address of the Slave (0x2B) it wants to read followed by RnW (1 for Read).

The Master then turns on a pull-up resistor and goes to Open Drain, allowing the Slave to acknowledge by pulling the SDA line Low. At this point, the Master continues to toggle the SCL line and release the SDA line, allowing the Slave to drive

(2)I3C通信数据格式

图 25。51 至图说明了六种 I3C 协议中每种协议的典型通信。虽然这些图表并未详尽说明所有可能的 I3C 通信,但它们确实可以作为每个 I3C 协议中使用的信令和传输格式的有用介绍。

图 25。51 说明了使用 I3C 单数据速率（SDR）编码与广播 (0x7E）的示例通信。它显示主在 SDR 模式下从地址 0x2B 的从站读取数据字节。从免费巴士状态开始,Master 通过驾驶 SDA 线路 Low 来启动 START,同时保持 SCL 线路 High。然后它发出广播地址 (0x7E）,然后发出 RnW (0 for Write）。然后 Master 打开上拉电阻并转到 Open Drain。

所有奴隶通过拉动 SDA 线 Low 进行 ACK（在图中,粉红色填充意味着此时奴隶控制着 SDA 线）。Master然后发出重复的START,然后是它想要读取的从属地址(0x2B）,然后是RnW(1用于读取）。然后,Master 打开上拉电阻器并转到 Open Drain,允许 Slave 通过拉动 SDA 线路 Low 来确认。此时,Master 继续切换 SCL 线并释放 SDA 线,允许 Slave 驱动 SDA 发送一个字节的数据 (0x4A）,后跟 T。T = 1 通知 Master 有其他数据,而 T = 0 信号结束。这里有额外的数据,因此从驱动 SDA High,直到 SCL 变为 High,此时它会释放 SDA。Master 可以选择以弱上拉方式保持 SDA 高,这向 Slave 发出 Master 允许传输另一个字节的信号,或者拉 SDA 低（而 SCL 为 High –,因此是重复 START）,这将向 Slave 发出信号Master 已终止 Read 并正在接管。

SDR 模式向后兼容 Legacy I2C 设备,因为 SCL 脉冲的高时间始终小于 50ns,因此由于 I2C 50ns 尖峰滤波器,SCL 将始终显示为低。

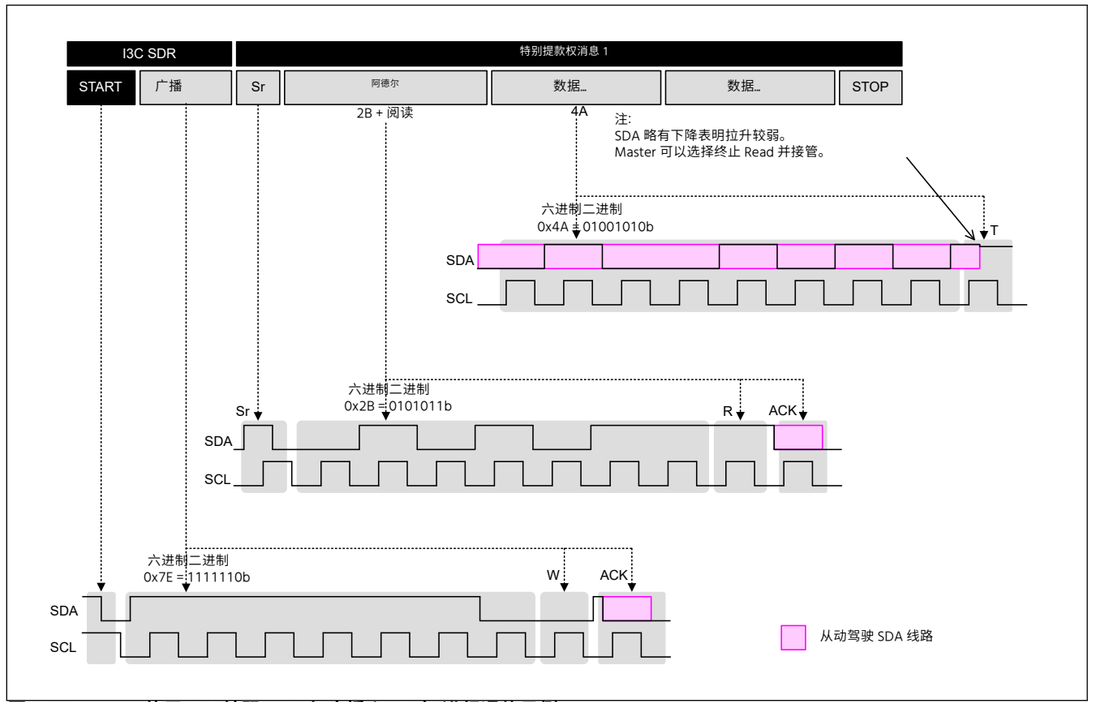

图25。51 使用 I3C 编码 SDR 与广播 (0x7E）进行通信示例

图 25。52 说明了使用 I3C 单数据速率（SDR）编码（不带广播）的示例通信 (0x7E）。它显示主在 SDR 模式下从地址 0x2B 的从站读取数据字节。从公交车免费条件,主人然后发出一个START,然后是它想要读取的从站地址(0x2B）,然后是RnW(1用于读取）。

然后,Master 打开上拉电阻器并转到 Open Drain,允许 Slave 通过拉动 SDA 线路 Low 来确认。此时,Master 继续切换 SCL 线并释放 SDA 线,从而允许 Slave 驱动

SDA to send one byte of data (0x4A) followed by T. T = 1 informs the Master that there is additional data, whereas T = 0 signals the end. Here there is additional data, so the Slave drives SDA High until SCL goes High, at which time it releases SDA. The Master has the option of holding SDA High with a weak pull-up, which signals to the Slave that the Master allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a Repeated START), which would signal to the Slave that the Master has terminated the Read and is taking over.

SDR Mode is backwards compatible with Legacy I2C Devices, because the High time of an SCL pulse is always less than 50ns and therefore SCL will always appear to be Low because of the I2C 50ns Spike Filter.

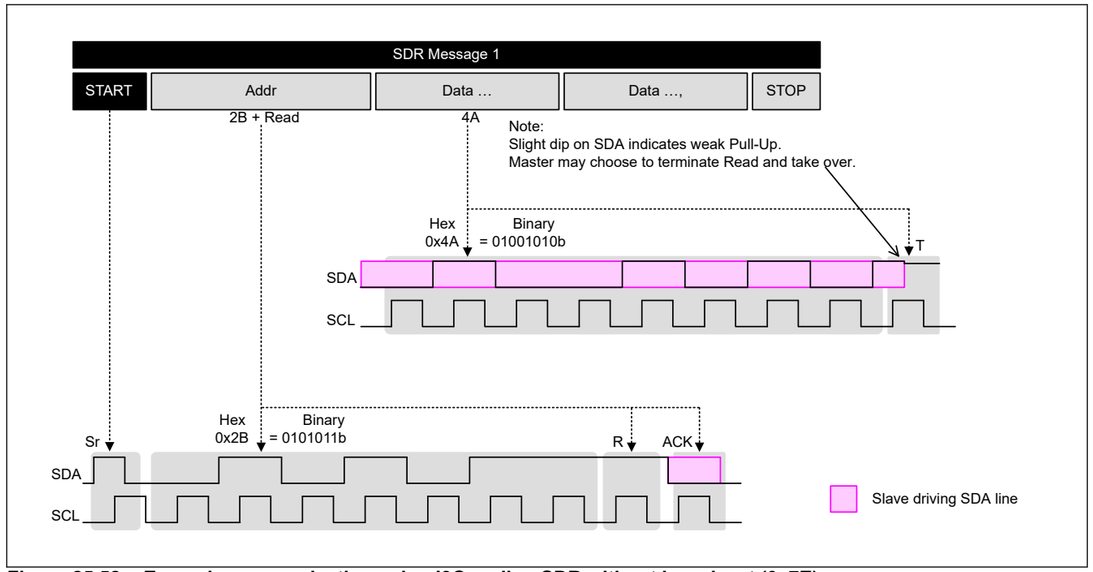

Figure 25.52 Example communication using I3C coding SDR without broadcast (0x7E)

Figure 25.53 shows the Master issuing a CCC Direct Command to a single Slave. This particular command (GETPID) reads the Provisional ID of a Slave.

From the Bus Free Condition, the Master issues a START by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves ACK by pulling SDA Low (in the Figure, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Direct Common Command Code for GETPID (0x8C) followed by parity bit T (odd parity = 0 for 0x8C) then the 7-bit Dynamic Address of the Slave (chosen arbitrarily here to be 0x2B) followed by a RnW bit (1 for Read). Then the Master turns on a pull-up resistor and goes to Open Drain, allowing the Slave at Address 0x2B to ACK by pulling SDA Low, which tells the Master that the Slave Acknowledges the command and will comply. (Alternatively, the Slave may NACK by not pulling SDA Low, which would inform the Master that the Slave will not comply – in this case, that an error occurred.) Following the ACK the Slave outputs its 48-bit PID one byte at a time, and then the Master issues a Repeated START (this part of the waveform sequence is not shown in the Figure).

SDA来发送一个字节的数据(0x4A）后跟T。T = 1通知主有额外的数据,而T = 0信号结束。这里有额外的数据,因此从驱动 SDA High,直到 SCL 变为 High,此时它会释放 SDA。Master 可以选择以弱上拉方式保持 SDA High,这向 Slave 发出 Master 允许传输另一个字节的信号,或者拉 SDA Low（而 SCL 为 High –,因此是重复 START）,这将向从站发出信号,表明主站已终止读取并正在接管。

SDR 模式向后兼容 Legacy I2C 设备,因为 SCL 脉冲的高时间始终小于 50ns,因此由于 I2C 50ns 尖峰滤波器,SCL 将始终显示为低。

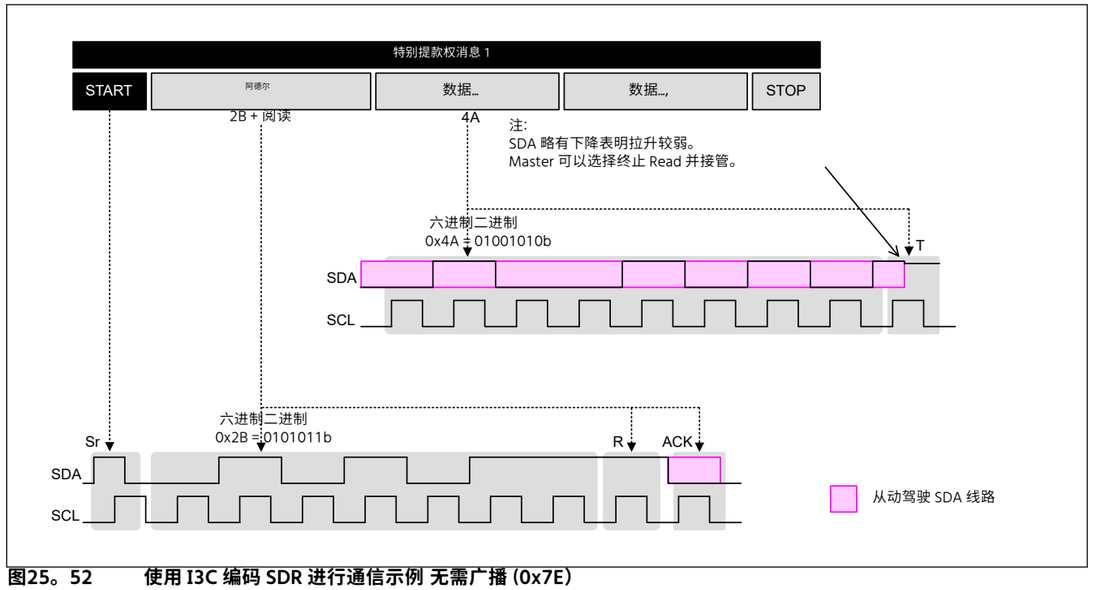

图25。52 使用 I3C 编码 SDR 进行通信示例 无需广播 (0x7E)

图 25。53 显示主向单个从属设备发出 CCC 直接命令。该特定命令（GETPID）读取从属程序的临时 ID。

从免费巴士状态开始,Master 通过驾驶 SDA 线路 Low 来启动 START,同时保持 SCL 线路 High。然后它发出广播地址 (0x7E）,然后发出 RnW (0 for Write）。然后 Master 打开上拉电阻并转到 Open Drain。所有奴隶通过拉动 SDA Low 进行 ACK（在图中,粉红色填充意味着此时奴隶控制着 SDA）。然后,主机发出 GETPID (0x8C）的直接通用命令代码,后跟奇偶校验位 T(0x8C 的奇偶校验 = 0),然后发出从机的 7 位动态地址（此处任意选择为 0x2B）,后跟 RnW 位(1 为读取）。然后,Master 打开上拉电阻并转到 Open Drain,通过拉动 SDA Low 将地址 0x2B 的 Slave 允许 ACK,这告诉 Master,Slave 承认该命令并将遵守。

（或者,Slave 可以通过不拉动 SDA Low 来 NACK,这会通知 Master,在这种情况下,Slave 将不遵守 –,从而发生错误。）ACK 后,从机一次输出一个字节的 48 位 PID,然后主机发出重复 START（图中未显示这部分波形序列）。

Figure 25.54 illustrates example SDR communication with a CCC Broadcast command. The command used in this example sets the Maximum Read Length of all Slaves to 43 bytes (0x002B).

From the Bus Free Condition, the Master issues a START by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (0x7E) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves ACK by pulling SDA Low (in the Figure, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Broadcast Common Command Code for SETMRL (0x09) followed by parity bit T (odd parity = 1 for 0x09), and then 2 data bytes (MSB first) to define the maximum number of bytes which can be read from a Slave in a single read operation. Each data byte is followed by a T bit (parity bit – odd parity). After this the Master issues a Repeated START.

图25。54示出了与CCC广播命令的示例SDR通信。本示例中使用的命令将所有从属设备的最大读取长度设置为 43 字节 (0x002B）。

从免费巴士状态开始,Master 通过驾驶 SDA 线路 Low 来启动 START,同时保持 SCL 线路 High。然后它发出广播地址 (0x7E）,然后发出 RnW (0 for Write）。然后 Master 打开上拉电阻并转到 Open Drain。所有奴隶通过拉动 SDA Low 进行 ACK（在图中,粉红色填充意味着此时奴隶控制着 SDA）。然后,Master 发布 SETMRL 广播通用命令代码 (0x09),后跟奇偶校验位 T(0x09 的奇偶校验 = 1),然后发布 2 个数据字节（首先是 MSB）来定义可以从 SETMRL 读取的最大字节数。单次读取操作中的从站。每个数据字节后面都跟着一个 T 位（奇偶校验位 – 奇偶校验）。此后,大师会发布重复开始。

25.3.2.3.2 Bus Conditions

I3C defines three distinct conditions in which the I3C Bus shall be considered inactive: Bus Free, Bus Available, and Bus Idle (see Figure 25.55).

(1) Bus Free Condition

State on the I3C Bus where both the SCL line and the SDA line are High for at least the period set by BFRECDT.FRECYC[8:0] bit.

(2) Bus Available Condition [I3C mode]

State on the I3C Bus where both the SCL line and the SDA line are High for at least the period set by BAVLCDT.AVLCYC[8:0] bit.

A Slave may only issue a START Request (For example, for an In-Band Interrupt, or for a Master Handoff Request) after a Bus Available Condition.

(3) Bus Idle Condition [I3C mode]

State on the I3C Bus where both the SCL line and the SDA line are High for at least the period set by BIDLCDT.IDLCYC[17:0] bit.

A Slave may only issue a START Request after a Bus Idle Condition.

Specifications are as follows. IDLE needs to be the largest.

BFRECDT.FRECYC[8:0] < BAVLCDT.AVLCYC[8:0] < BIDLCDT.IDLCYC[17:0]

25.3.2.3.3 START Condition / Repeated START Condition / STOP Condition Issuing Function

(1) Issuing a START Condition

I3C issues a START condition when the CNDCTL.STCND bit is set to 1.

Set the STCND bit to 1 (START condition issuance request) when the BCST.BFREF flag is set to 1 (bus free state).

I3C issues a START condition.

When a START condition is issued normally, I3C automatically shifts to the master transmit mode. A START condition is issued in the following sequence.

[START condition issuance]

- Drive the I3C_SDA line low (high level to low level).
- Ensure the time set in STDBR.SBRHO[7:0] and the START condition hold time.
- Drive the I3C_SCL line low (high level to low level).
- Detect low level of the I3C_SCL line and ensure the low-level period of I3C_SCL line set in STDBR.SBRLO[7:0].

(2) Issuing a Repeated START Condition

I3C issues a Repeated START condition when the CNDCTL.SRCND bit is set to 1.

When the SRCND bit is set to 1, a Repeated START condition issuance request is made and I3C issues a Repeated START condition when the BCST.BFREF flag = 0 (bus busy state) and the PRSST.CRMS bit = 1 (master mode).

A Repeated START condition is issued in the following sequence.

[Repeated START condition issuance]

- Release the I3C_SDA line.
- Ensure the low-level period of I3C_SCL line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0] .
- Release the I3C_SCL line (low level to high level).
- Detect a high level of the I3C_SCL line and ensure the time set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0] and the Repeated START condition setup time.
- Drive the I3C_SDA line low (high level to low level).
- Ensure the time set in STDBR.SBRHO[7:0] or EXTBR.EBRHO[7:0] or EXTBR.EBRHO[7:0] and the Repeated START condition hold time.
- Drive the I3C_SCL line low (high level to low level).

25。3。2。3。3 启动条件/重复启动条件/停止条件发出功能

(1) 发布启动条件

I3C 在 CNDCTL。STCND 位设置为 1 时发出 START 条件。

当 BCST。BFREF 标志设置为 1（无总线状态）时,将 STCND 位设置为 1（START 条件发出请求）。

I3C 出一 START 件。

START 条件正常发出时,I3C 会自动切换到主传输模式。START 条件按以下顺序发布。

的【启动条件发放】

- 将 I3C_SDA 线路驱动至低电平（高电平至低电平
- 确保在 STDBR。SBRHO[7:0] 中设置的时间和 START 条件保持时间。
- 将 I3C_SCL 线路驱动至低电平（高电平至低电平
- 检测 I3C_SCL 线的低电平,并保证 STDBR。SBRLO 中设置的 I3C_SCL 线的低电平周期 [7:0]。

(2)签发重复开始条件

I3C 在 CNDCTL。SRCND 位设置为 1 时发出重复 START 条件。

SRCND 位设置为 1 时,会发出重复 START 条件发出请求,当 BCST。BFREF 标志 = 0（总线忙状态）和 PRSST。CRMS 位 = 1（主模式）时,I3C 发出重复 START 条件。

重复开始条件按以下顺序发出。

件 【重复START条件发放】

- 发布 I3C_SDA 系列。
- 确保在 STDBR。SBRLO[7:0] 或 EXTR。EBRLO[7:0] 中设置的 I3C_SCL 线的低电平周期。
- 发布 I3C_SCL 线路（低电平到高电平）。
- 检测 I3C_SCL 线路的高电平,并确保 STDBR。SBRLO[7:0] 或 EXTBR。EBRLO[7:0] 中设置的时间以及重复 START 条件设置时间。
- 将 I3C_SDA 线路驱动至低电平（高电平至低电平
- 确保 STDBR。SBRHO[7:0] 或 EXTBR。EBRHO[7:0] 或 EXTBR。EBRHO[7:0] 中设置的时间以及重复 START 条件保持时间。
- 将 I3C_SCL 线路驱动至低电平（高电平至低电平）。

- Detect a low level of the I3C_SCL line and ensure the low-level period of I3C_SCL line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0] .

Note: When issuing Repeated START conditions request, write the slave address to NTDTBP0 after confirming CNDCTL.SRCND = 0. Data written in the period of CNDCTL.SRCND = 1 is not forwarded because retransmission condition before the occurrence.

To issue a Repeated START condition in Hs-mode, use the following steps.

1. Wait for PRSTDBG.SCOLV=0.
2. Set EXTBR.EBRHO[7:0] to satisfy the hold time of the Repeated START condition.
3. Set the CNDCTL.SRCND bit to 1.
4. After confirming CNDCTL.SRCND=0, wait for PRSTDBG.SCOLV=0.
5. Set EXTBR.EBRHO [7: 0] according to the High period of the SCL clock in Hs-mode.
6. Write the slave address to NTDTBP0.

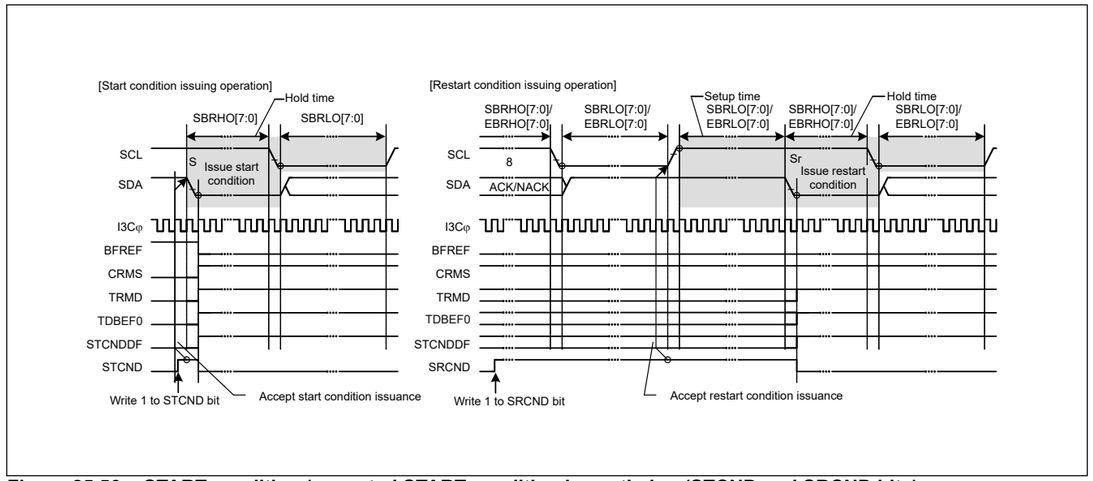

Figure 25.56 START condition / repeated START condition issue timing (STCND and SRCND bits)

Figure 25.57 shows the operation to issue a Repeated START condition after the master transmission.

[Repeated START condition issuance after the master transmission]

- Initial setting. For details, see section 25.3.3.1. Initial Setting Flow.
- Read the BFREF flag in BCST to check that the bus is open, and then set the STCND bit in CNDCTL to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. At the same time, the BFREF flag is automatically set to 0 and the STCNDDF flag in BST is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the I3C_SDA line have matched while the STCND bit = 1, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and CRMS and TRMD bits in PRSST is automatically set to 1, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
- Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the slave address and the R/W# bit) to NTDTBP0. Once the data for transmission are written to NTDTBP0, the TDBEF0 flag is automatically set to 0, the data are transferred from NTDTBP0, and the TDBEF0 flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRMD bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, I3C continues in master transmit mode. Since the BST.NACKDF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to CNDCTL.SPCND bit to issue a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1111 0, the 2 higher-order bits of the slave address, and W to NTDTBP0 as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to NTDTBP0.

● 检测 I3C_SCL 线的低电平,并确保 STDBR。SBRLO[7:0] 或 EXTBR。EBRLO[7:0] 中设置的 I3C_SCL 线的低电平周期。

注: 发重复START条件请求时,确认后将从地址写入NTDTBP0
CNDCTL。SRCND = 0。CNDCTL。SRCND = 1 期间写入的数据不会转发,因为重传条件在发生之前。

要在 Hs 模式下发出重复 START 条件,请使用以下步骤。

1。等待 PRSTDBG。SCOLV=0。

2锛姣涓涓。设置 EXTBR。EBRHO[7:0] 以满足重复 START 条件的保持时间。

3锛 娴 。将 CNDCTL。SRCND 位设置为 1。

4锛姣涓。确认CNDCTL。SRCND=0后,等待PRSTDBG。SCOLV=0。

5锛姣涓。根据 Hs 模式下 SCL 时钟的高周期设置 EXTBR。EBRHO [7: 0]。

6锛 涓€涓。将从站地址写入 NTDTBP0。

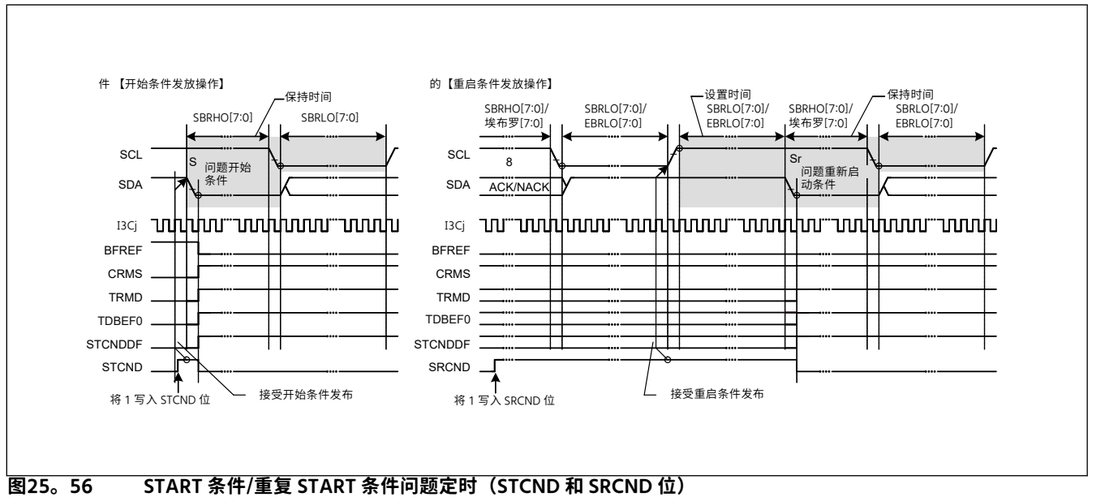

图25。56 START 条件/重复 START 条件问题定时（STCND 和 SRCND 位）

图25。57示出了在主传输之后发出重复开始条件的操作。

的【主传后重复START条件发放】

● 初始设置。详情请参见第 25。3。3。1 节。初始设置流程 .

● 读取 BCST 中的 BFREF 标志检查总线是否打开,然后将 CNDCTL 中的 STCND 位设置为 1（START 条件发出请求）。I3C在收到请求后,会发出START条件。同时,BFREF标志自动设置为0,BST中的STCNDDF标志自动设置为1,STCND位自动设置为0。START 条件被检测到,并且 SDA 输出状态的内部电平和 I3C_SDA 线路上的电平已经匹配而 STCND 位 = 1,则 I3C 识别出 STCND 位请求的 START 条件的发出已经成功完成,并且 PRSST 中的 CRMS 和 TRMD 位被自动设置为 1,将 I3C 置于主发送模式。NTST。TDBEF0 标志还响应于 TRMD 位的设置而自动设置为 1。

● 检查 NTST。TDBEF0 标志 = 1,然后将用于传输的值（从地址和 R/W# 位）写入 NTDTBP0。一旦用于传输的数据写入NTDTBP0,TDBEF0标志自动设置为0,数据从NTDTBP0传输,TDBEF0标志再次设置为1。在发送包含从地址和R/W#位的字节之后,自动更新TRMD位的值以根据发送的R/W#位的值选择主发送或主接收模式。R/W#位的值为0,则I3C在主传输模式下继续。由于此时 BST。NACKDF 标志为 1 表示从属设备未识别该地址或通信中存在错误,因此将 1 写入 CNDCTL。SPCND 位以发出停止条件。10位格式的地址进行数据传输,首先写入1111 0,从地址的2个高阶位,W到NTDTBP0作为第一地址传输。然后,作为第二地址传输,将从地址的8个低阶位写入NTDTBP0。

- After confirming that the NTST.TDBEF0 flag = 1, write the data for transmission to the NTDTBP0 register. I3C automatically holds the I3C_SCL line low until the data for transmission are ready, a Repeated START condition is issued or a STOP condition is issued.
- After all bytes of data for transmission have been written to the NTDTBP0 register, wait until the value of the BST.TENDF flag returns to 1, and then, after check that the BST.STCNDDF flag = 1, set the BST.STCNDDF flag to 0.
- Set the SRCND bit in CNDCTL to 1 (Repeated START condition issuance request). Upon receiving the request, I3C issues a Repeated START condition.
- After check that the BST.STCNDDF flag = 1, write the value for transmission (the slave address and the R/W# bit) to NTDTBP0.

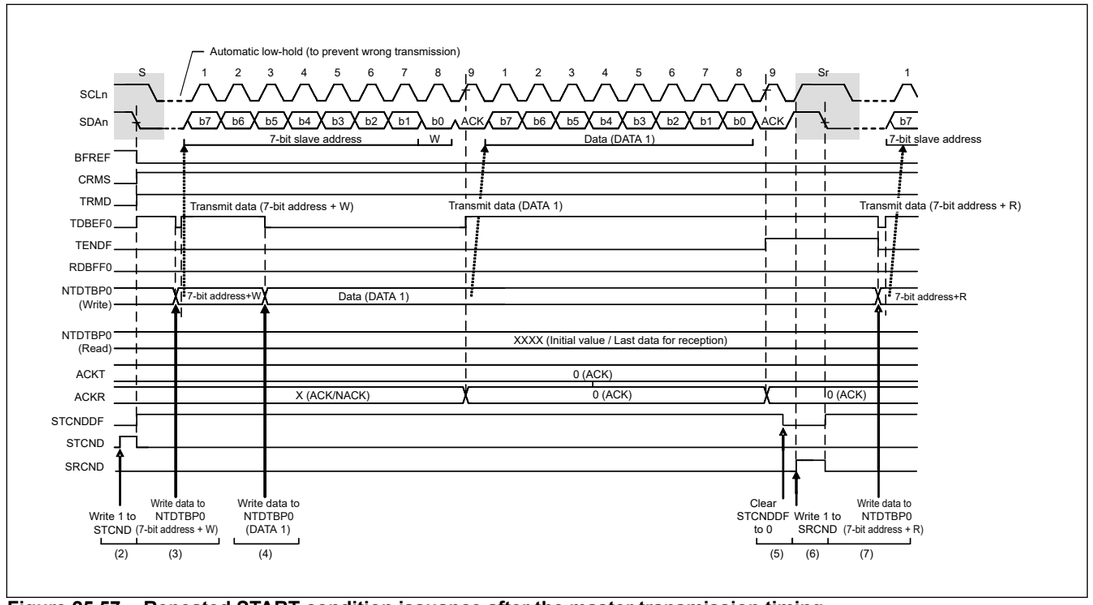

Figure 25.57 Repeated START condition issuance after the master transmission timing

(3) Issuing a STOP Condition

I3C issues a STOP condition when the SPCND bit in CNDCTL is set to 1.

When the SPCND bit is set to 1, a STOP condition issuance request is made and I3C issues a STOP condition when the BCST.BFREF flag = 0 (bus busy state) and the PRSST.MST bit = 1 (master mode).

A STOP condition is issued in the following sequence.

[STOP condition issuance]

- Drive the I3C_SDA line low (high level to low level).
- Ensure the low-level period of I3C_SCL line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0] .
- Release the I3C_SCL line (low level to high level).
- Detect a high level of the I3C_SCL line and ensure the time set in STDBR.SBRHO[7:0] or EXTBR.EBRHO[7:0] and the STOP condition setup time.
- Release the I3C_SDA line (low level to high level).
- Ensure the time set in BFRECDT.FRECYC[8:0] and the bus free time.
- Set the BFREF flag to 1 (to release the bus mastership).

Note: To issue a STOP condition in Hs-mode, use the following steps.

1. Wait for PRSTDBG.SCOLV=0.

● 确认 NTST。TDBEF0 标志 = 1 后,写入数据以传输到 NTDTBP0 寄存器。I3C 自动将 I3C_SCL 线路保持在较低位置,直到用于传输的数据准备就绪、发出重复 START 条件或发出 STOP 条件。

● 当所有用于传输的数据字节都写入 NTDTBP0 寄存器后,等待 BST。TENDF 标志的值返回到 1,然后在检查 BST。STCNDDF 标志 = 1 后,设置 BST。STCNDDF 标志为 0。

● 将 CNDCTL 中的 SRCND 位设置为 1（重复 START 条件发出请求）。I3C 收到请求后会发出重复启动条件。

● 检查 BST。STCNDDF 标志 = 1 后,将传输值（从地址和 R/W# 位）写入 NTDTBP0。

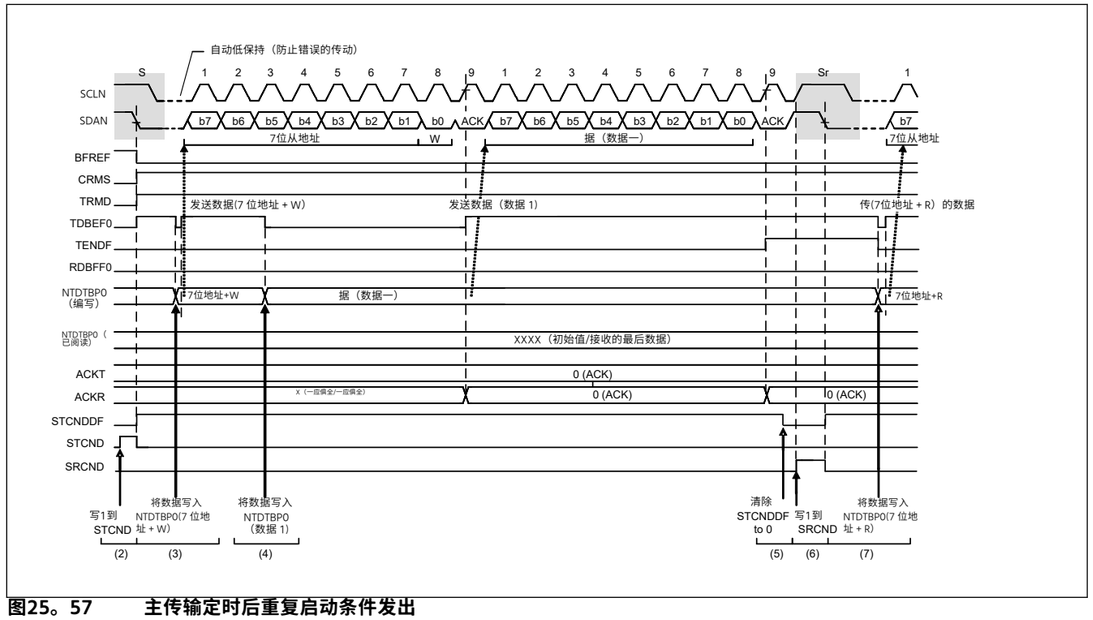

图25。57 主传输定时后重复启动条件发出

(3) 发布停止条件

I3C在CNDCTL中的SPCND位设置为1时发出停止条件。

SPCND 位设置为 1 时,发出 STOP 条件发出请求,I3C 发出 STOP 条件时,
BCST。BFREF 标志 = 0（总线繁忙状态）,PRSST。MST 位 = 1（主模式）。

STOP 条件按以下顺序发出。的【停止条件发放】

● 驱动 I3C_SDA 线低电平（高电平到低电平）。

● 确保 STDBR。SBRLO[7:0] 或 EXTBR。EBRLO[7:0] 中设置的 I3C_SCL 线的低电平周期。

● 释放 I3C_SCL 线（低电平到高电平）。

● 检测 I3C_SCL 线路的高电平,并确保 STDBR。SBRHO[7:0] 或 EXTBR。EBRHO[7:0] 中设置的时间以及 STOP 条件设置时间。

● 释放I3C_SDA线（低电平到高电平）。

● 确保 BFRECDT。FRECYC[8:0] 中设置的时间和总线空闲时间。

● 将 BFREF 标志设置为 1（以释放总线主控）。

注: Hs 模式下发出 STOP 条件, 请使用以下步骤。

1。等待 PRSTDBG。SCOLV=0。

2. Set EXTBR.EBRHO[7:0] to satisfy the setup time for the STOP condition.
3. Set the CNDCTL.SPCND bit to 1.
4. Wait for CNDCTL.SPCND=0.
5. Set EXTBR.EBRHO [7:0] according to the High period of the SCL clock in Hs-mode.

25.3.2.3.4 Address Match Detection

I3C can set three unique slave addresses in addition to the general call address and host address, and also can set 7- bit or 10- bit slave addresses.

(1) Slave-Address Match Detection [I^2C mode]

I3C can set three unique slave addresses, and has a slave address detection function for each unique slave address.

When the SVCTL.SVAEy bit (y = 0 to 2) is set to 1, the slave addresses set in the SVDVAD[y] register (y = 0 to 2) can be detected.

When I3C detects a match of the set slave address, the corresponding SVST.SVAF[y] flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the NTST.RDBFF0 flag or the NTST.TDBEF0 flag is set to 1 by the following R/W# bit. This causes a receive data full interrupt (I3C_RX) or transmit data empty interrupt (I3C_TX) to be generated. The SVAF[y] flag is used to identify which slave address has been specified.

Figure 25.59 to Figure 25.61 show the SVAF[y] flag set timing in three cases.

25。3。2。3。4 地址匹配检测

I3C可以设置通用调用地址和主机地址之外的三个唯一的从地址,也可以设置7bit或10bit从站地址。

(1) 从站地址匹配检测[I 2 C 模式]

I3C可以设置三个唯一的从地址,并且对每个唯一的从地址都有一个从地址检测功能。

SVCTL。SVAEy 位（y = 0 到 2)设置为 1 时,SVDVAD[y] 寄存器中设置的从地址（y = 0 到 2)可以是检测到。

I3C检测到集合从地址的匹配时,在第九个SCL时钟周期的上升沿处将对应的SVST。SVAF[y]标志（y = 0至2)设置为1,NTST。RDBFF0标志或NTST。TDBEF0标志通过以下R/W#位设置为1。这导致生成接收数据完全中断（I3C_RX）或发送数据空中断（I3C_TX）。SVAF[y] 标志用于识别已指定哪个从地址。

(2) Detection of the General Call Address [I²C mode]

I3C has a facility for detecting the general call address (0000 000 + 0 (write)). This is enabled by setting the SVCTL.GCAE bit to 1.

If the address received after a START or Repeated START condition is issued is 0000 000 + 1 (read) (start byte), I3C recognizes this as the address of a slave device with an all-zero address but not as the general call address.

When I3C detects the general call address, both the SVST.GCAF flag and the NTST.RDBFF0 flag are set to 1 on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a receive data full interrupt (I3Cn_RX). The value of the GCAF flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

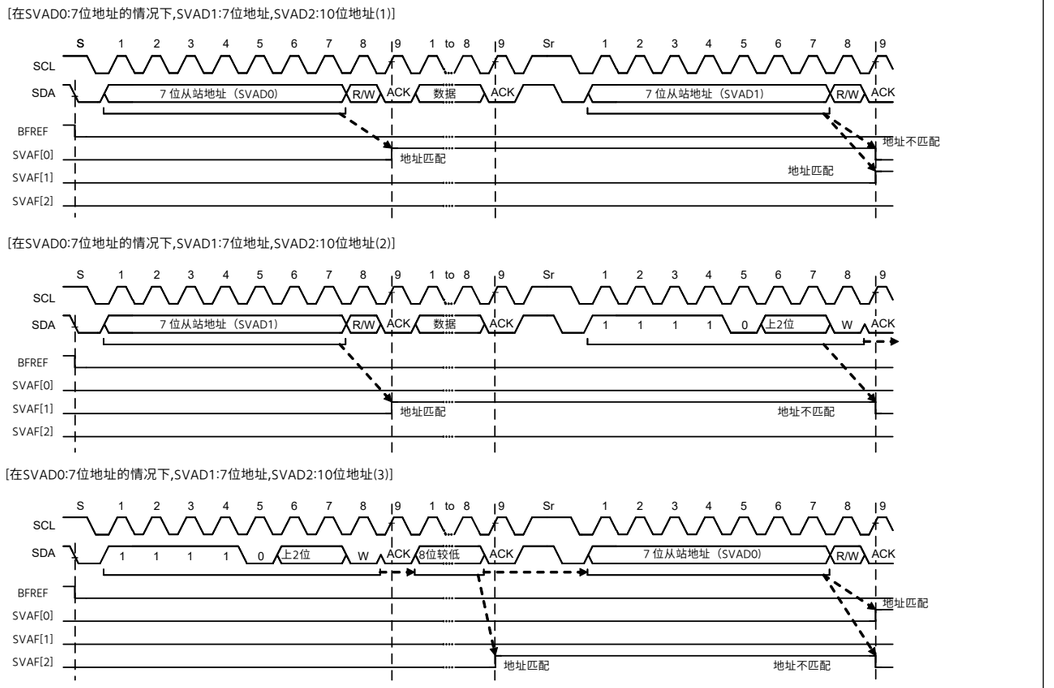

图25。61 SVAF[y]标志集/清除定时与7位/10位地址格式混合

(2) 一般呼叫地址的检测[I 2 C 模式]

I3C 有一个用于检测通用呼叫地址(0000 000 + 0（写入）)的设施。这是通过将 SVCTL。GCAE 位设置为 1 来实现的。

START 或 Repeated START 条件发出后接收到的地址为 0000 000 + 1（读取）（开始字节）,则 I3C 将其识别为具有全零地址但不是通用调用地址的从设备的地址。

I3C检测到通用呼叫地址时,SVST。GCAF标志和NTST。RDBFF0标志都设置为SCL时钟第九周期上升沿上的1。这导致生成接收数据完全中断（I3Cn_RX）。GCAF标志的值可以被确认以识别通用呼叫地址已经被传输。

检测到通用呼叫地址后的操作与正常的从接收操作相同。

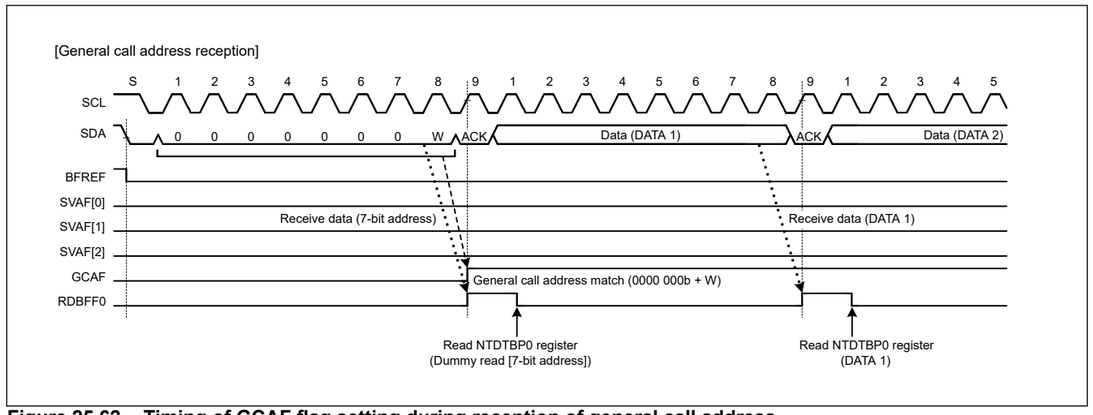

Figure 25.62 Timing of GCAF flag setting during reception of general call address

(3) Device-ID Address Detection [I²C mode]

I3C module has a facility for detecting device-ID addresses conformant with the I²C-bus specification (Rev.03). When I3C receives 1111 100 as the first byte after a START condition or Repeated START condition was issued with the SVCTL.DVIDE bit set to 1, I3C recognizes the address as a device ID, sets the SVST.DVIDF flag to 1 on the rising edge of the ninth SCL clock cycle when the following R/W# bit = 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, I3C sets the corresponding SVST.SVAF[y] flag (y = 0 to 2) to 1.

After that, when the first byte received after a START or Repeated START condition is issued matches the device ID address (1111 100) again and the following R/W# bit = 1, I3C does not compare the second and subsequent bytes and sets the NTST.TDBEF0 flag to 1.

In the device-ID address detection function, I3C sets the DVIDF flag to 0 if a match with I3C's own slave address is not obtained or a match with the device ID address is not obtained after a match with I3C's own slave address and the detection of a Repeated START condition. If the first byte after detection of a START or Repeated START condition matches the device ID address (1111 100) and the R/W# bit = 0, I3C sets the DVIDF flag to 1 and compares the second and subsequent bytes with I3C's slave address. If the R/W# bit = 1, the DVIDF flag holds the previous value and I3C does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DVIDF flag after confirming that TDBEF0 flag = 1.

Furthermore, prepare the device-ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details of the information that must be included in device-ID fields, contact NXP Semiconductors.

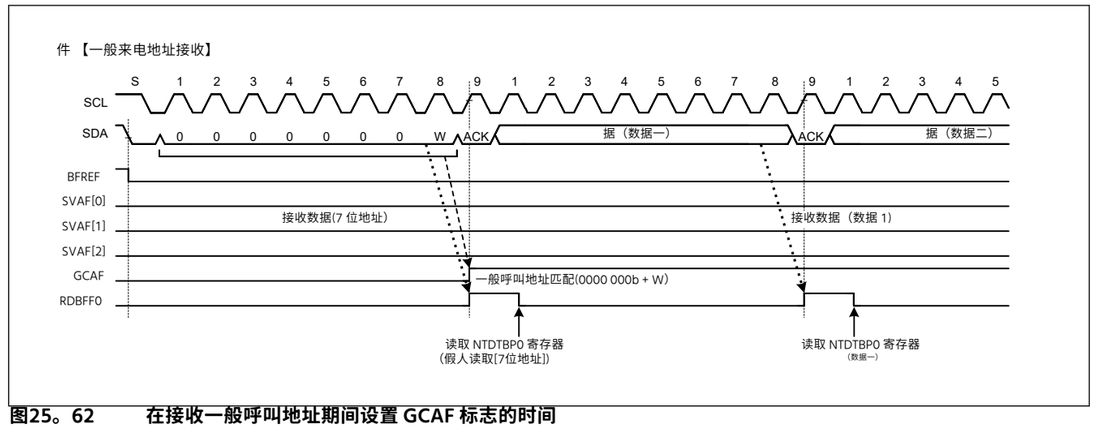

图25。62 在接收一般呼叫地址期间设置 GCAF 标志的时间

(3) 设备 ID 地址检测 [I 2 C 模式]

I3C 模块具有用于检测符合 I 2 C 总线规范（Rev。03）的设备 ID 地址的设施。I3C接收到1111 100作为START条件或Repeated START条件被发出后的第一个字节SVCTL。DVIDE位设置为1时,I3C将地址识别为设备ID,将SVST。DVIDF标志设置为第九个SCL时钟周期上升沿上的1当下面的R/W#位 = 0, 然后将第二个及后续字节与其自己的从站地址进行比较。I3C如果地址与从地址寄存器中的值匹配,则将相应的SVST。SVAF[y]标志 （y = 0到2)设置为1。

之后,当发出START或Repeated START条件后接收到的第一个字节再次匹配设备ID地址(1111 100)并且下面的R/W#位=1时,I3C不比较第二个及后续字节,并将NTST。TDBEF0标志设置为1。

I3C在设备-ID地址检测功能中,如果未获得与I3C自身从地址的匹配或者在与I3C自身从地址匹配并且检测到重复START条件后未获得与设备ID地址的匹配,则I3C将DVIDF标志设置为0。START 或 Repeated START 条件检测后的第一个字节与设备 ID 地址 (1111 100) 匹配且 R/W# 位 = 0,则 I3C 将 DVIDF 标志设置为 1,并将第二个及后续字节与 I3C 的从地址进行比较。R/W# 位 = 1,则 DVIDF 标志保留前一个值,I3C 不比较第二个和后续字节。因此,在确认TDBEF0标志=1后,可以通过读取DVIDF标志来检查设备ID地址的接收。

此外,准备设备 ID 字段(3 个字节:12 位指示制造商 + 9 位识别零件 + 3 位指示修订版）,这些字段必须在接收连续设备 ID 字段作为正常数据后发送到主机进行传输。有关器件 ID 字段中必须包含的信息的详细信息,请联系恩智浦半导体。

[When address before the device-ID + R does not match the slave address]

(4) Host Address Detection [I²C mode]

I3C has a function to detect the host address while the SMBus is operating. When the SVCTL.HOAE bit is set to 1 while the BFCTL.SMBS bit = 1, I3C can detect the host address (0001 000) in slave receive mode (bits CRMS and TRMD in the PRSST register = 00).

When I3C detects the host address, the SVST.HOAF flag is set to 1 at the rising edge of the ninth SCL clock cycle, and at the same time, the NTST.RDBFF0 flag is set to 1 when the R/W# bit = 0 (Wr bit). This causes a receive data full interrupt (I3C_RX) to be generated. The HOAF flag is used to recognize that the host address was sent from the smart battery or other devices.

If the bit following the host address (0001 000) is an Rd bit (R/W# bit = 1), I3C can also detect the host address. After the host address is detected, I3C operates in the same manner as normal slave operation.

(4) 主机地址检测[I 2 C 模式]

I3C具有在SMBus运行时检测主机地址的功能。SVCTL。HOAE位设置为1而BFCTL。SMBS位 = 1时,I3C可以在从接收模式下检测主机地址(0001 000)（PRSST寄存器中的位CRMS和TRMD = 00)。

I3C检测到主机地址时,SVST。HOAF标志在第九个SCL时钟周期的上升沿被设置为1,同时,当R/W#位=0（Wr位）时,NTST。RDBFF0标志被设置为1。这导致生成接收数据完全中断（I3C_RX）。HOAF标志用于识别主机地址是从智能电池或其他设备发送的。

址(0001 000)后面的位是Rd位（R/W#位 = 1),I3C也可以检测主机地址。I3C在检测到主机地址后,以与正常从机操作相同的方式运行。

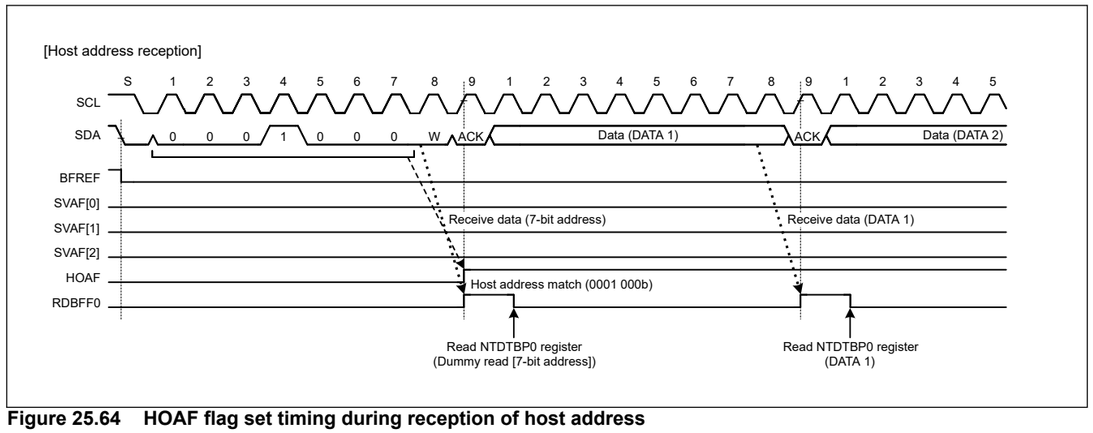

Figure 25.64 HOAF flag set timing during reception of host address

(5) Hs-mode master code Detection [I²C mode]

IIC has a facility for detecting the Hs-mode master code (0000 1XXXb). When IIC receives the Hs-mode master code (0000 1XXXb) as the first byte after a START condition was issued with the SVCTL.HSMCE bit set to 1, this module recognizes the address as the Hs-mode master code, sets the SVST.HSMCF flag to 1 on the rising edge of the ninth SCL clock cycle. The first byte after Repeated START after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set by SVDVADy.SVAD[9:0] (y = 0 to 2). When IIC detects a match of the set slave address, the corresponding SVST.SVAF[y] flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the NTST.RDBFF0 flag or the NTST.TDBEF0 flag is set to 1 by the following R/W# bit. This causes a receive data full interrupt (I3C_RX) or transmit data empty interrupt (I3C_TX) to be generated. The SVAF[y] flag is used to identify which slave address has been specified. The SVST.HSMCF flag is cleared to 0 when the STOP condition is detected.

Note: If the Hs-mode master code (0000 1XXXb) is received with the SVCTL.HSMCE bit set to 0, other patterns are ignored until the STOP condition is detected.

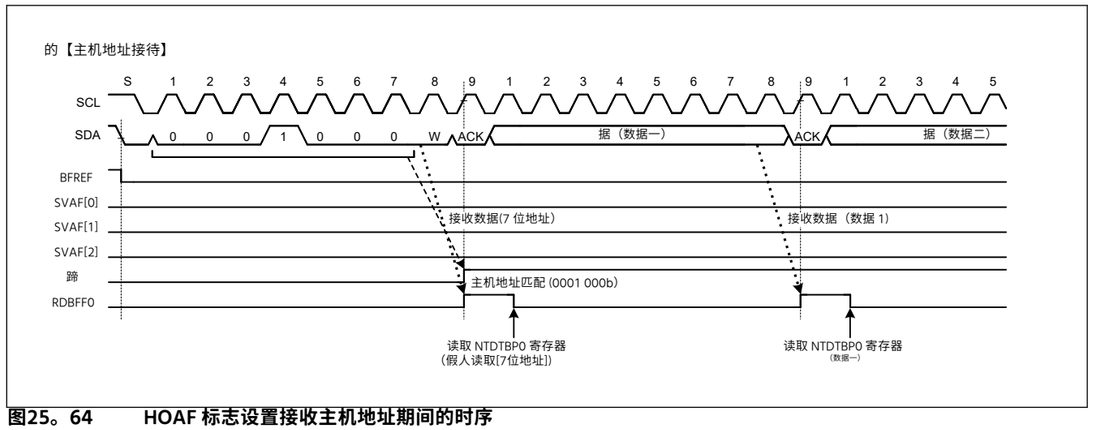

图25。64 HOAF 标志设置接收主机地址期间的时序

(5) Hs模式主码检测【I 2 C模式】

IIC 有一个用于检测 Hs 模式主代码 (0000 1XXXb）的设施。当 IIC 在 SVCTL。HSMCE 位设置为 1 时发出 START 条件后接收 Hs 模式主代码 (0000 1XXXb）作为第一个字节时,该模块将地址识别为 Hs 模式主代码,设置 SVST。HSMCF 第九个 SCL 时钟周期上升沿上的标志为 1。NACK响应Hs模式主代码后重复开始后的第一个字节被识别为从地址,并与SVDVADy。SVAD设置的从地址进行比较[9:0]（y = 0到2)。IIC检测到集合从地址的匹配时,在第九个SCL时钟周期的上升沿处将对应的SVST。SVAF[y]标志（y = 0至2)设置为1,NTST。RDBFF0标志或NTST。TDBEF0标志通过以下R/W#位设置为1。这导致生成接收数据完全中断（I3C_RX）或发送数据空中断（I3C_TX）。SVAF[y] 标志用于识别已指定哪个从地址。当检测到 STOP 条件时,SVST。HSMCF 标志被清除为 0。

注意:如果接收 SVCTL。HSMCE 位设置为 0 的 Hs 模式主代码 (0000 1XXXb）,则忽略其他模式,直到检测到 STOP 条件。

25.3.2.3.5 Arbitration-Lost Detection [I²C mode]

In addition to the normal arbitration-lost detection function defined by the I²C-bus specification, the I3C has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmit mode.

(1) Master Arbitration-Lost Detection (MALE Bit)

The I3C drives the I3C_SDA line low to issue a start condition. However, if the I3C_SDA line has already been driven low by another master device issuing a start condition, this module causes arbitration to be lost, so priority is given to transfer by the other master device. Similarly, if the CNDCTL.STCND bit is set to 1 while the BCST.BFREF flag is 0 (bus busy state), arbitration is lost, so priority is given to transfer by the other master device. No start condition is issued in this case.

When a start condition is issued successfully, if the data for transmission including the address bits (the internal SDA output level) and the level on the I3C_SDA line do not match (the high output as the internal SDA output, that is, the SDA0 pin is in the high-impedance state) and the low level is detected on the I3C_SDA line, the I3C loses in arbitration.

I3C detects master arbitration-lost when the following conditions are met while the BSTE.ALE bit = 1 and the BFCTL.MALE bit = 1 (master arbitration-lost detection enabled).

If arbitration of mastership is lost, I3C immediately enters slave receive mode.

If a slave address (including the general call address) matches its own address at this time, I3C continues in slave operation.

[Conditions for master arbitration-lost]

- Non-matching of the internal level for output on SDA and the level on the I3C_SDA line after a START condition was issued by setting the CNDCTL.STCND bit to 1 while the BCST.BFREF flag was set to 1 (erroneous issuing of a START condition)
- Setting of the CNDCTL.STCND bit to 1 (START condition double-issue error) while the BFREF flag is set to 0

  Note: I3C does not issue a START condition.
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the I3C_SDA line in master transmit mode (bits CRMS and TRMD in the PRSST register = 11)

仲裁丢失检测 [I 2 C 模式] 25。3。2。3。5

I 2 C-bus规范定义的正常仲裁丢失检测功能外,I3C还具有防止双重发出启动条件、检测NACK传输过程中的仲裁丢失以及检测从传输模式下的仲裁丢失的功能。

(1) 主仲裁-丢失检测（男性位）

I3C 驱动 I3C_SDA 线路低电平以发出启动条件。I3C_SDA线路,但是如果已经被另一个主设备发出启动条件的低位驱动,则该模块导致仲裁丢失,因此优先由另一个主设备进行传输。同样,如果CNDCTL。STCND位设置为1,而BCST。BFREF标志为0（总线忙状态）,则仲裁丢失,因此优先由其他主设备传输。在这种情况下,不会发出启动条件。

I3C_SDA 线路上包含地址位（内部 SDA 输出电平）和电平的传输数据不匹配（作为内部 SDA 输出的高输出,即 SDA0 引脚处于高阻抗状态）且在 I3C_SDA 线路上检测到低电平时, I3C在仲裁中败诉。

I3C 检测主仲裁-丢失时满足以下条件,而 BSTE。ALE 位 = 1 和 BFCTL。MALE 位 = 1（启用主仲裁-丢失检测）。

I3C如果主权的仲裁丢失,立即进入从属接收模式。

址（包括一般呼叫地址）此时与自己的地址匹配,则I3C继续进行从操作。

【主仲裁条件-遗失】

● 通过将 CNDCTL。STCND 位设置为 1 而将 BCST。BFREF 标志设置为 1（错误地发出 START 条件）

● 将 CNDCTL。STCND 位设置为 1（START 条件双问题错误）,而 BFREF 标志设置为 0 注:I3C 不发出 START 条件。

● 当不包含确认（内部 SDA 输出电平）的发送数据与主发送模式下 I3C_SDA 线路上的电平不匹配时（PRSST 寄存器中的位 CRMS 和 TRMD = 11）

(2) Arbitration-Lost Detection during NACK Transmission (NALE Bit)

The I3C has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the I3C_SDA line (the high output as the internal SDA output; i.e. the I3C_SDA pin is in the high-impedance state) and the low level is detected on the I3C_SDA line during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device.

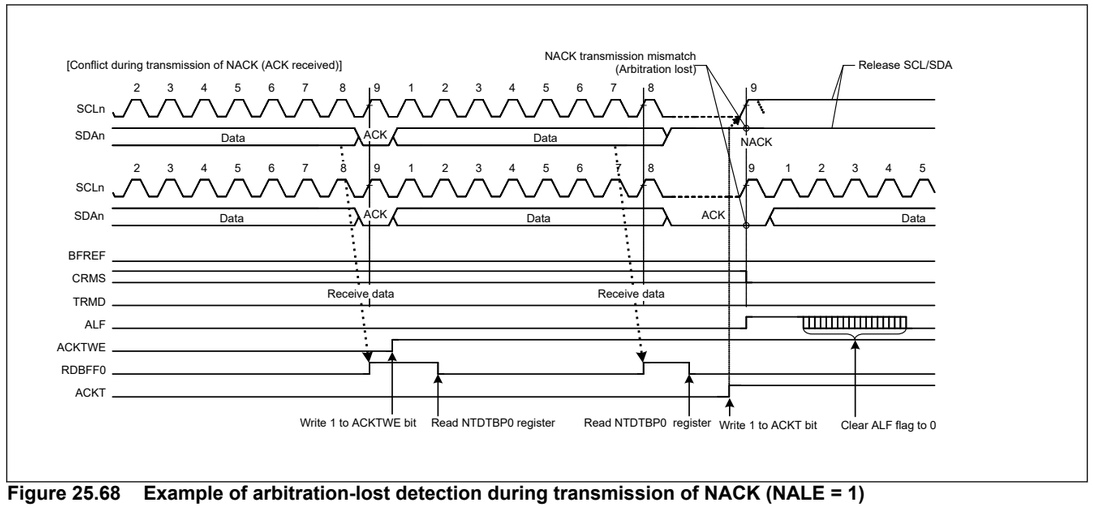

Figure 25.68 Example of arbitration-lost detection during transmission of NACK (NALE = 1)

The following section explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. In this example,, master A sends NACK when it has received 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the necessary 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition. Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When this module receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, this module is immediately released from the slave-matched state and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing (such as 0xFF transmission processing) necessary if the UDID (Unique Device Identifier) of assign address does not match in the Get UDID (general) processing after the Assign Address command.

The I3C detects arbitration-lost during transmission of NACK when the following condition is met while the BSTE.ALE bit = 1 and the BFCTL.NALE bit = 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the I3C_SDA line (ACK is received) during transmission of NACK (ACKCTL.ACKT bit = 1)

(2) NACK 传输过程中的仲裁–丢失检测（NALE 位）

I3C具有如果内部SDA输出电平与I3C_SDA线路上的电平不匹配（作为内部SDA输出的高输出;即I3C_SDA引脚处于高阻抗状态）并且在接收模式下NACK的传输过程中在I3C_SDA线路上检测到低电平,则导致仲裁丢失的功能。当两个或多个主设备在多主系统中同时从同一从设备接收数据时,由于 NACK 传输和 ACK 传输的冲突,仲裁失败。当多个主设备通过单个从设备发送/接收相同的信息时,就会发生这种冲突。

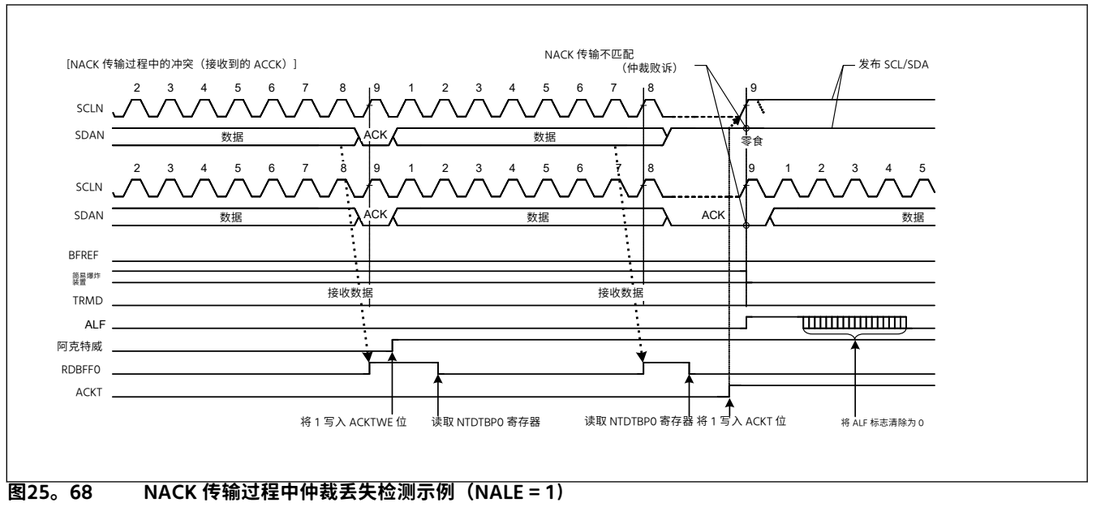

图25。68 NACK 传输过程中仲裁丢失检测示例（NALE = 1）

以下部分使用两个主设备（主 A 和主 B）和一个从设备通过总线连接的示例解释仲裁丢失检测。在此示例中,主A从从设备接收2字节数据,主B从从设备接收4字节数据。

如果主A和主B同时访问从设备,则由于从地址相同,因此在访问从设备期间主A和主B都没有丢失仲裁。因此,A大师和B大师都认识到他们已经获得了公交车的掌握并按此操作。在此示例中,当主 A 从从设备接收到 2 个最终字节的数据时,主 A 会发送 NACK。同时,主 B 发送 ACK 是因为它没有收到必要的 4 字节数据。此时,来自主A的NACK传输和来自主B的ACK传输发生冲突。一般来说,如果发生这样的冲突,主机A无法检测到主机B传输的ACK并发出停止条件。因此,停止条件的发出与主B的SCL时钟输出冲突,从而扰乱通信。

当该模块在NACK传输过程中接收到ACK时,它会检测到与其他主设备冲突中的失败并导致仲裁失败。

NACK的传输过程中丢失仲裁,则该模块立即从从属匹配状态释放,进入从属接收模式。这可以防止发出停止条件,从而防止公交车上的通信故障。

类似地,在SMBus的ARP命令处理中,如果分配地址的UDID（唯一设备标识符）不匹配,则检测NACK传输过程中仲裁丢失的功能也可用于消除必要的额外时钟周期处理（例如0xFF传输处理）在分配地址命令之后的 Get UDID（通用）处理中。

I3C在满足以下条件时检测NACK传输过程中的仲裁丢失,而BSTE。ALE位 = 1和BFCTL。NALE位 = 1（启用NACK传输过程中的仲裁丢失检测）。

【仲裁条件–NACK传输中丢失】

- 当内部的 SDA 输出电平与 NACK 传输过程中的 I3C_SDA 线路不匹配时（接收 ACCT）（ACKCTL。ACKT 位 = 1）

(3) Slave Arbitration-Lost Detection (SALE Bit)

The I3C has a function to cause arbitration to be lost if the data for transmission (the internal SDA output level) and the level on the I3C_SDA line do not match (the high output as the internal SDA output, that is, the I3C_SDA pin is in the high impedance state) and the low level is detected on the I3C_SDA line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

If arbitration is lost during transmission of DATA, this module is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminate subsequent redundant processing (processing for the transmission of 0xFF).

The I3C detects slave arbitration-lost when the following condition is met while the BSTE.ALE bit = 1 and the BFCTL.SALE bit = 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the I3C_SDA line in slave transmit mode (bits CRMS and TRMD in the PRSST register = 01).

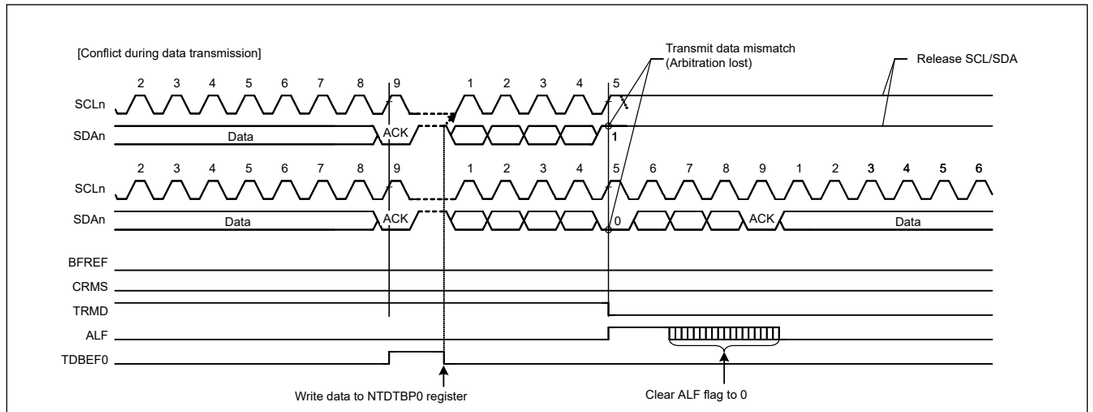

Figure 25.69 Example of slave arbitration-lost detection (SALE = 1)

25.3.2.3.6 Clock Stretching [I²C mode]

(1) Function to Prevent Wrong Transmission of Transmit Data

When data have not been written to the I²C bus transmit data register (NTDTBP0) with I3C in transmission mode (PRSST.TRMD = 1), the I3C_SCL line is automatically held at the low level over the intervals shown below. This low-hold period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

Master transmit mode

- Low-level interval after a START condition or Repeated START condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

Slave transmit mode

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

(3)从属仲裁-丢失检测（销售位）

I3C具有使仲裁丢失的功能,如果用于传输的数据（内部SDA输出电平）与I3C_SDA线路上的电平不匹配（作为内部SDA输出的高输出,即I3C_SDA引脚处于高阻抗状态）,并且在从发送模式下在I3C_SDA线路上检测到低电平。这种仲裁丢失的检测功能主要用于通过SMBus传输UDID（唯一设备标识符）时。

DATA 的传输过程中丢失仲裁,则该模块立即从从属匹配状态释放,进入从属接收模式。该功能可以检测 SMBus 上 UDID 传输过程中的数据冲突,并消除后续冗余处理(0xFF 传输的处理）。

I3C在满足以下条件时检测从仲裁-丢失,而BSTE。ALE位 = 1和BFCTL。SALE位 = 1（启用从仲裁-丢失检测）。

【奴隶仲裁的条件-遗失】

● 当不包含确认的发送数据（内部 SDA 输出电平）与从发送模式下 I3C_SDA 线路上的电平不匹配时（PRSST 寄存器中的位 CRMS 和 TRMD = 01)。

(1)防止错误传输传输数据的功能

当数据尚未写入处于传输模式（PRSST。TRMD = 1)且具有 I3C 的 I 2 C 总线传输数据寄存器（NTDTBP0) 时,I3C_SCL 线路在如下所示的间隔内自动保持在低电平。该低保留期被延长,直到传输数据被写入为止,这防止了错误数据的意外传输。

主传输模式

● 发出 START 条件或重复 START 条件后的低级间隔

● 一个传输的第九个时钟周期与下一个传输的第一个时钟周期之间的低级间隔

从发射模式

● 一个传输的第九个时钟周期与下一个传输的第一个时钟周期之间的低级间隔

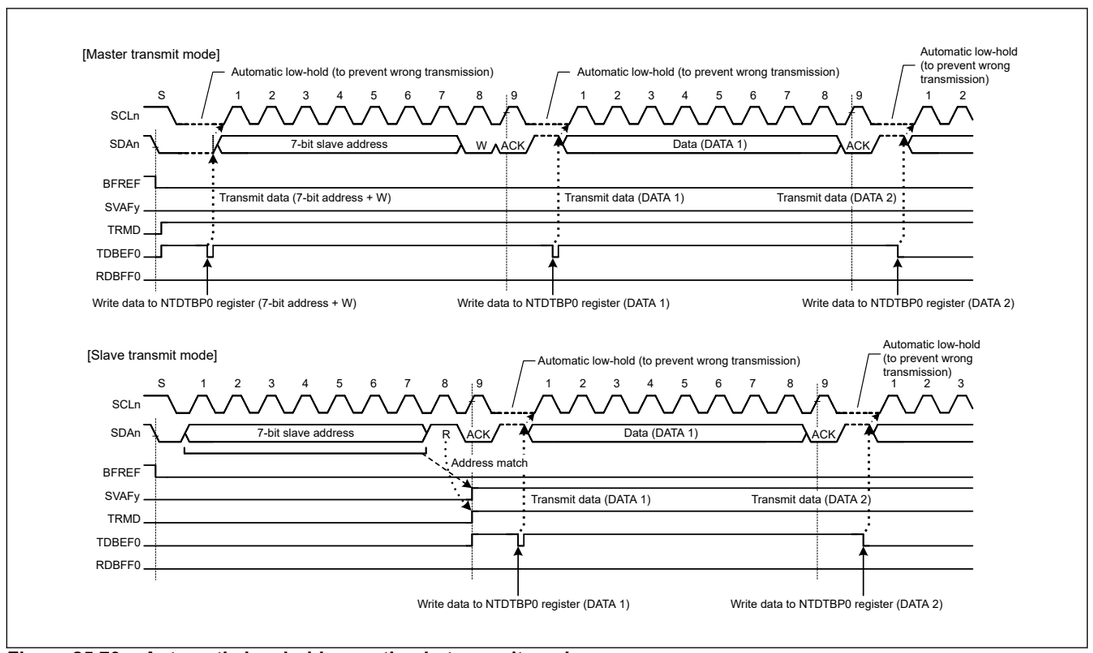

Figure 25.70 Automatic low-hold operation in transmit mode

(2) NACK Reception Transfer Abort Function

I3C has a function to abort transfer operation when NACK is received in transmit mode (PRSST.TRMD = 1). This function is enabled when the BSTE.NACKDE bit is set to 1 (transfer abort enabled). If the next transmit data has already been written (NTST.TDBEF0 = 0) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically aborted. This prevents the I3C_SDA line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is aborted by this function (BST.NACKDF = 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to set the NACKDF flag to 0. In master transmit mode, restore operation using either of the methods below:

- After issuing a Repeated START condition, set the NACKDF flag to 0
- After issuing a STOP condition, set the NACKDF flag to 0 and then issue a START condition

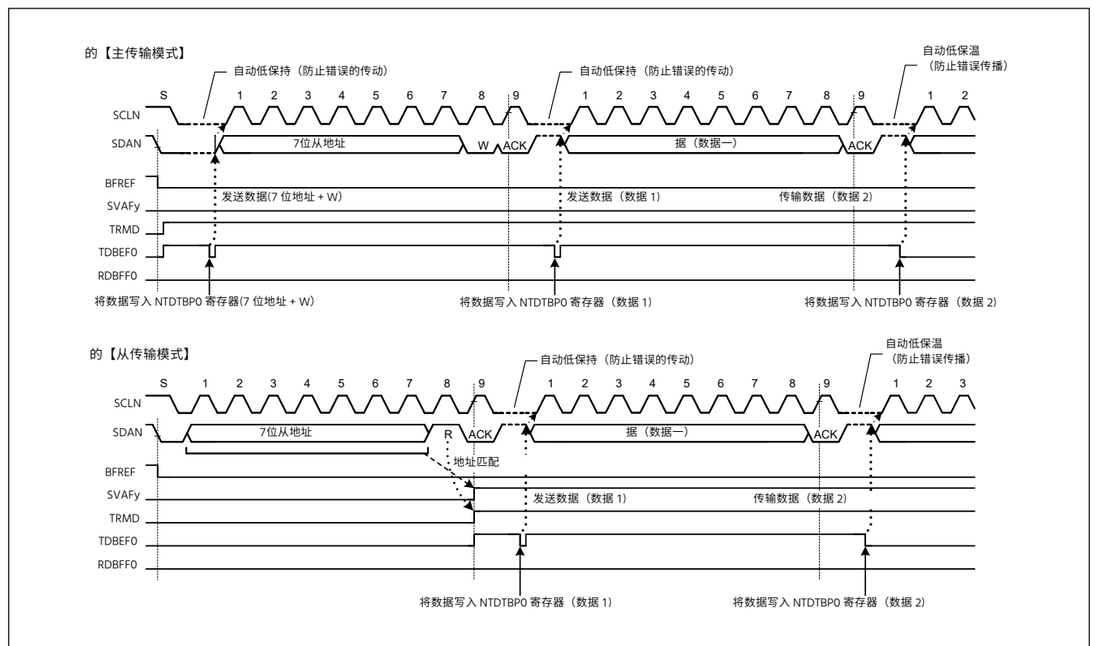

图25。70 发射模式下自动低保持运行

(2) NACK 接待转移中止功能

I3C具有在发送模式下接收NACK时中止传输操作的功能（PRSST。TRMD = 1)。当 BSTE。NACKDE 位设置为 1（启用传输中止）时,此功能将启用。如果接收到 NACK 时下一个传输数据已经写入（NTST。TDBEF0 = 0),则第九个 SCL 时钟周期下降边缘的下一个数据传输将自动中止。I3C_SDA 线路输出电平,这样可以防止在下一个传输数据的 MSB 为 0 时,I3C_SDA 线路输出电平保持在较低水平。

如果传输操作因该功能而中止（BST。NACKDF = 1),则传输操作和接收操作将停止。要恢复发送/接收操作,请务必将 NACKDF 标志设置为 0。在主传输模式下,使用以下任一方法恢复操作:

- 发出重复启动条件后,将 NACKDF 标志设置为 0
- 发出 STOP 条件后,将 NACKDF 标志设置为 0,然后发出 START 条件

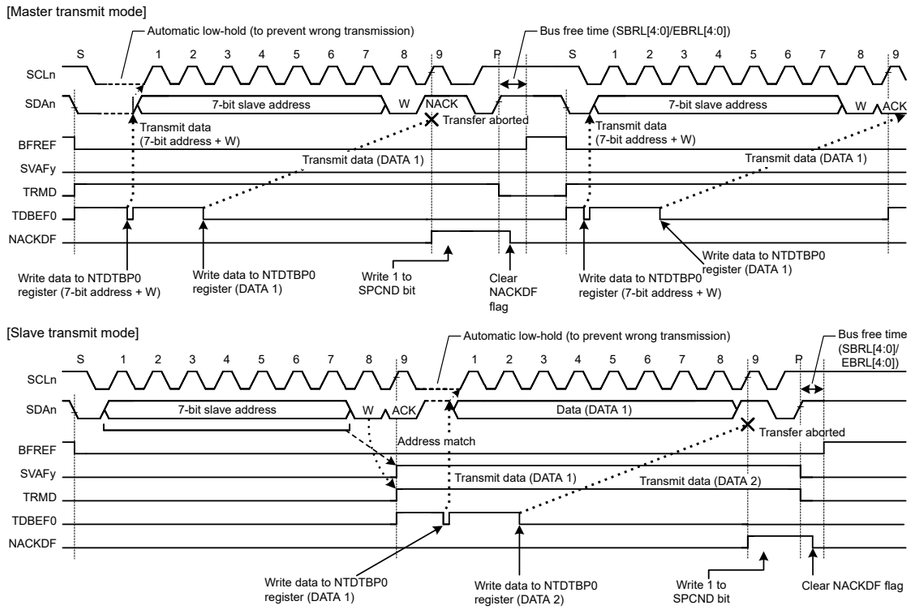

Figure 25.71 Abort of data transfer when NACK is received (NACKE = 1)

(3) Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (NTDTBP0) read is delayed for a period of one transfer frame or more with receive data full (NTST.RDBFF0 = 1) in receive mode (PRSST.TRMD = 0), I3C holds the I3C_SCL line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, I3C's own slave address or another slave address is received after a STOP condition is issued.

Sections in which the I3C_SCL line is held low can be selected with a combination of the RWE and ACKTWE bits in SCSTRCTL.

(a) 1-Byte Receive Operation and Automatic Low-Hold Function Using the RWE Bit

When the SCSTRCTL.RWE bit is set to 1, I3C performs 1-byte receive operation using the RWE bit function.

Furthermore, when the SCSTRCTL.ACKTWE bit = 0, I3C automatically sends the ACKCTL.ACKT bit value for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the I3C_SCL line low at the falling edge of the ninth SCL clock cycle using the RWE bit function. This low-hold is released by reading data from NTDTBP0, which enables bytewise receive operation.

The RWE bit function is enabled for receive frames after a match with I3C's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

(b) 1-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the ACKTWE Bit

When the SCSTRCTL.ACKTWE bit is set to 1, I3C performs 1-byte receive operation using the ACKTWE bit function.

When the ACKTWE bit is set to 1, the NTST.RDBFF0 flag (receive data full) is set to 1 at the rising edge of the eighth SCL clock cycle, and the I3C_SCL line is automatically held low at the falling edge of the eighth SCL clock cycle. This lowhold

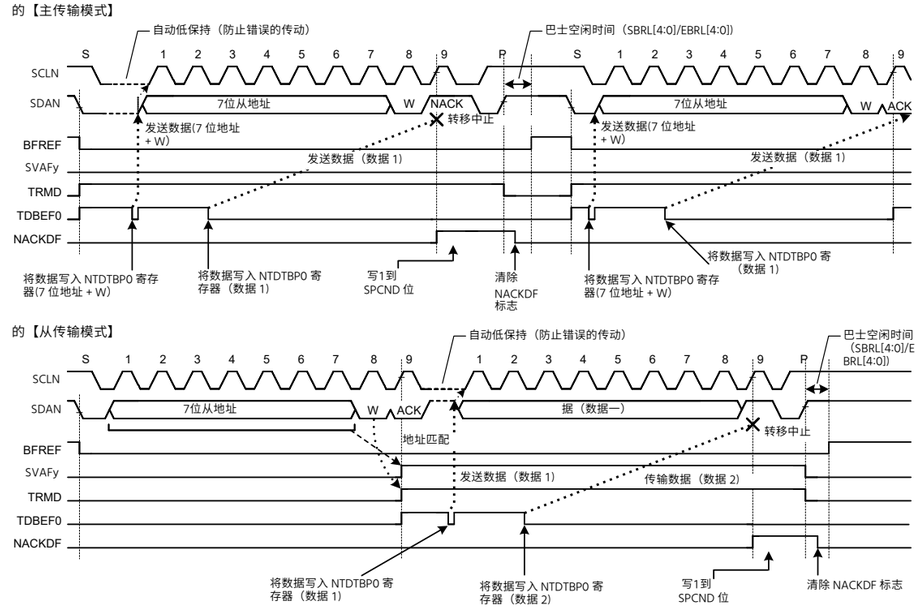

图25。71 收到 NACK 时中止数据传输（NACKE = 1）

(3)防止数据接收失败的功能

据（NTDTBP0)读取在接收模式（PRSST。TRMD = 0)下接收数据满（NTST。RDBFF0 = 1)时延迟一个或多个传输帧的周期时,如果响应处理被延迟,I3C在接收到下一个数据之前立即自动保持I3C_SCL线低,以防止无法接收数据。

即使最终接收数据的读取处理被延迟并且同时在发出STOP条件之后接收到I3C自己的从地址或其他从地址,也启用该功能以防止使用自动低保持功能接收数据失败。

I3C_SCL线保持较低的部分可以用SCSTRCTL中的RWE和ACKTWE比特的组合来选择。

（a）1−Byte 接收操作和使用 RWE 位的自动低保持功能

SCSTRCTL。RWE 位设置为 1 时,I3C 使用 RWE 位函数执行 1 字节接收操作。

此外,当SCSTRCTL。ACKTWE位=0时,I3C自动发送从第八SCL时钟周期的下降沿到第九SCL时钟周期的下降沿期间的确认位的ACKCTL。ACKT位值,并自动保持I3C_SCL线使用RWE位函数在第九SCL时钟周期的下降沿处较低。这种低保持是通过从 NTDTBP0 读取数据来释放的,这使得能够逐字接收操作。

RWE位功能,用于在主接收模式或从接收模式下获得与I3C自身的从地址（包括通用调用地址和主机地址）匹配后的接收帧。

（b）1−字节接收操作（ACK/NACK传输控制）和使用ACKTWE比特的自动低保持功能

SCSTRCTL。ACKTWE 位设置为 1 时,I3C 使用 ACKTWE 位函数执行 1 字节接收操作。

ACKTWE位设置为1时,在第八SCL时钟周期的上升沿将NTST。RDBFF0标志（接收数据满）设置为1,在第八SCL时钟周期的下降沿自动将I3C_SCL线保持在低位。这个低谷

is released by writing a value to the ACKCTL.ACKT bit, but cannot be released by reading data from NTDTBP0, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The ACKTWE bit function is enabled for receive frames after a match with I3C's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

25.3.2.3.7 Clock Stalling [I3C mode]

I3C has the function of stalling the SCL during the SCL Low period.

The SCL stall control is described in the table below.

Table 25.12 I3C clock stalling

25.3.2.3.8 In-Band Interrupt [I3C mode]

I3C detects In-Band Interrupt in the arbitrated Address Header following a START condition (but not following a Repeated START). If START Request (SDA Low Drive) is issued from Slave Device, I3C drives SCL low and completes START condition. After that, it supplies SCL and receives In-Band Interrupt Request.

The In-Band Interrupt to be detected is classified into the following three types:

- Slave Interrupt Request
- Mastership Request

The operation when detecting each In-Band Interrupt is described in the following section.

25.3.2.3.8 带内中断 [I3C 模式]

I3C 检测到在 START 条件（但不遵循重复 START）之后仲裁地址标头的带内中断。如果从从设备发出 START 请求（SDA 低驱动器）,I3C 会低驱动 SCL 并完成 START 条件。之后,它提供 SCL 并接收带内中断请求。

待检测的带内中断分为以下三种类型:

- 从机中断请求
- 主控请求

下一节描述了检测每个带内中断时的操作。

(1) Slave Interrupt Request

2. Compare the detected Slave Address with the DVDYAD[7:0] in each DAT (DATBASm register).
3. When it does not match DAT.DVDYAD[7:0]:
   Responds NACK, then issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and the DAT.DVSIRRJ bit = 1:
   It operates in the following order:
   (a) Responds NACK.
   (b) Issues Repeated START condition, then automatically issues Direct DISEC CCC to the detected slave.
   (c) Issues the STOP condition.

   When it matches the DAT.DVDYAD[7:0] bits and the DAT.DVSIRRJ bit = 0:
   Responds ACK.
4. When DAT.DVIBIPL = 0:
   Issues the STOP condition.
   When DAT.DVIBIPL = 1:
   Drives the SCL to receive the IBI data from the slave following the ACK response and receives IBI data.
   It stores the received IBI data into the IBI Data Queue.
   Each time IBI data of the size set by the NQTHCTL.IBIDSSZ[7:0] bits is received, the IBI Status Descriptor is stored in the IBI Status Queue.
5. After detection of low from T-bit following IBI data, issues STOP condition.
6. After issues of STOP condition
   NACK response:
   - If IBINCTL.NRSIRCTL = 0, the IBI Status Descriptor is not stored into the IBI Status Queue.
   - If IBINCTL.NRSIRCTL = 1, the IBI Status Descriptor is stored into the IBI Status Queue.

25.3.2.3.9 Timing Control

Timing Control is a function that enables Master to efficiently read data from Slave by controlling and grasping the timing at which the Slave Device samples the sensor value.

For details, refer to 5.1.8 Timing Control of MIPI I3C Specificaton v1.0.

In I3C, timing Control supports the following three modes.

- Sync mode
- Async mode 0 (Asynchronous Basic mode)
- Async mode 1 (Asynchronous Advanced mode)

The resources for realizing Timing Control in each mode are described in the following sections.

(1) Sync Mode

1. I3C Master
   - When STCTL.STOE is set to 1, when the master sends an ST message (SETXTIME CCC with ST subcommand), there is a function to issue the synchronous timing event under the START condition of the ST message.
     While measuring the T_ph period with an external timer, the start of T_ph and the Delay Time [DT] of the ST message can be measured by capturing the count value with the synchronous timing event.
     The measured value of Delay Time is sent as a DT message (SETXTIME CCC with DT subcommand) following the ST message.
2. I3C Slave
   - When STCTL.STOE is set to 1, there is a function to issue the synchronous timing event for each START condition.
     STCTL.STOE is cleared when an ST message is received (SETXTIME CCC using the ST subcommand).
     Check the reception of the ST message with the Receive Status Descriptor, and use an external timer to correct the T_ph period based on the count value captured in the synchronous timing event and the Delay Time obtained from the DT message.
     While measuring the T_ph period with an external timer, the start of T_ph and the Delay Time [DT] of the ST message can be measured by capturing the count value with the synchronous timing event.
     The sampling timing is recalculated by the corrected T_ph.

(2) Async Mode 0 (Asynchronous Basic Mode)

For timing control in Async Mode 0, set the ATCTL register if necessary.

25。3。2。3。9 定时控制

定时控制是一种功能,使主设备能够通过控制和掌握从设备采样传感器值的定时来有效地从从设备读取数据。

详情请参阅 5。1。8 MIPI I3C Specificaton v1。0 的时序控制。

I3C中,定时控制支持以下三种模式。

- 同步模式
- 异步模式 0（异步基本模式）
- 异步模式 1（异步高级模式）

以下各节描述了用于实现每种模式下的定时控制的资源。

(1)同步模式

1。I3C大师赛

- 当STCTL。STOE设置为1时,当主发送ST消息（带有ST子命令的SETXTIME CCC）时,有在ST消息的START条件下发出同步定时事件的功能。
  T_ph周期用外部定时器测量的同时,可以通过用同步定时事件捕获计数值来测量T_ph的开始和ST消息的延迟时间[DT]。
  延迟时间的测量值作为 DT 消息（带有 DT 子命令的 SETXTIME CCC）在 ST 消息之后发送。

2锛姣涓涓。I3C的奴隶

- 当STCTL。STOE设置为1时,有一个函数可以为每个START条件发出同步定时事件。
  当接收到 ST 消息时,STCTL。STOE 被清除（SETXTIME CCC 使用 ST 子命令）。
  用接收状态描述符检查ST消息的接收情况,并使用外部定时器根据同步定时事件中捕获的计数值和从DT消息中获得的延迟时间来校正T_ph周期。

  T_ph周期用外部定时器测量的同时,可以通过用同步定时事件捕获计数值来测量T_ph的开始和ST消息的延迟时间[DT]。
  采样时序通过校正后的 T_ph 重新计算。

(2)异步模式0（异步基本模式）

Async模式0中的定时控制,如有必要,设置ATCTL寄存器。

I3C has counters of MREFMREF(32bit) and MC2(16bit) for Async mode 0.

- MREF Counter
  When ATCCNTE.ATCE is enabled, it starts counting.
  It captures as MREF on the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave.
- MC2 Counter
  After enabling ATCCNTE.ATCE, it counts up from the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave to the SCL rise edge next to the Tbit after Mandatory Byte, and capture it as MC2.

The MREF and MC2 capture values are stored next to the IBI Status Descriptor when IBI is received from the I3C Slave with the DATBASm.DVIBITS bit set to 1.

The MREF counter implemented in I3C is 32-bit counter.

However, if the 32-bit counter is insufficient due to system requirements, I3C has MREF counter overflow and MREF capture event for expansion. These events are enabled by setting ATCTL.MREFOE to 1.

MREF counter overflow is output when the internal MREF counter overflows.

The MREF counter can be extended by using it as a count event for an external timer. MREF capture event is output at the same timing as the capture timing of the internal MREF counter. By using it as the capture timing of the external timer, it can be used as an MREF counter concatenated with the value stored in the IBI Data buffer.

Note: Please evaluate the Sensor Event time of I3C Slave according to the calculation formula of the MIPI I3C specification v1.0 document.

2. I3C Slave

I3C has counters of SC1(16bit) and SC2(8bit) for Async mode 0.

- SC1 Counter
  After enabling ATCCNTE.ATCE, it counts up from SC1 count trigger*1 to SCL rise edge next to ACK for the IBI, and capture it as SC1.

I3C具有用于异步模式0的计数器MREFMREF(32bit）和MC2(16bit）。

- MREF 计数器
  当启用 ATCCNTE。ATCE 时,它开始计数。
  对于从 I3C 从属设备传输的 IBI,它在 ACK 旁边的 SCL 上升沿上捕获为 MREF。
- MC2 计数器
  启用 ATCCNTE。ATCE 后,对于从 I3C 从站传输的 IBI,它从 ACK 旁边的 SCL 上升边向上计数到强制字节后 Tbit 旁边的 SCL 上升边,并将其捕获为 MC2。

当从 I3C Slave 接收 IBI 时,MREF 和 MC2 捕获值存储在 IBI 状态描述符旁边,DATBASm。DVIBITS 位设置为 1。

I3C 中实现的 MREF 计数器是 32 位计数器。

32位计数器,但是如果由于系统要求而不足,则I3C有MREF计数器溢出和MREF捕获事件进行扩展。这些事件是通过将 ATCTL。MREFOE 设置为 1 来启用的。

MREF 计数器溢出是在内部 MREF 计数器溢出时输出的。

MREF计数器可以通过将其用作外部定时器的计数事件来扩展。MREF 捕获事件与内部 MREF 计数器的捕获定时相同的时间输出。通过将其用作外部定时器的捕获定时,它可以用作与 IBI 数据缓冲区中存储的值连接的 MREF 计数器。

(3) Async Mode 1 (Asynchronous Advanced Mode)

For timing control in Async Mode 1, set the ATCTL register if necessary.

1. I3C Master
   I3C has counters of MREF(32bit), MSyncCNT(32bit) and MC2(16bit) for Async mode 1.
   - MREF Counter
     When ATCCNTE.ATCE is enabled, it starts counting.
     It captures as MREF at the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave.
   - MSyncCNT Counter
     When ATCCNTE.ATCE is enabled, it starts counting.
     It captures as MSyncCNT for each aME (SDA falling edge of START condition), and store it in the capture register.
   - MC2 Counter
     After enabling ATCCNTE.ATCE, it counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and capture it as MC2.

   The MREF and MC2 capture values are stored next to the IBI Status Descriptor when the IBI is received from the I3C Slave with the DATBASm.DVIBITS bit set to 1 (same as Async mode 0).
   When ATCTL.AMEOE is enabled, an aME Event is issued for each aME. Use that event as a trigger to read the MSyncCNT capture value from the MRCCPT register and hold it in an external memory.
2. I3C Slave
   I3C has counters of SC1(16bit), SC2(8bit) and aME_TICK(8bit) for Async mode 1.
   - SC1 Counter
     After enabling ATCCNTE.ATCE, it counts up from SC1 count trigger *1 to the first aME, and capture it as SC1.

     Note 1. SW or external trigger can be selected by selection bits.
   - SC2 Counter
     After enabling ATCCNTE.ATCE, it counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and capture it as SC2.
   - aME_TICK Counter
     After enabling ATCCNTE.ATCE, it counts every aME, and capture it as aME_TICK at the SCL rise edge next to ACK for the IBI.
     The aME_TICK counter is cleared on the first aME after the SC1 count trigger.

When the CETSS.ASYNE[1] bit = 1 and the ITS bit in Command Descriptor for issuing IBI is 1, the SC1, SC2 and aME_TICK capture values are transmitted following the IBI Mandatory Byte as shown in the following figure.

If the SC1 and SC2 counters overflow, 0xFFFF and 0xFF are captured and CETSS.ICOVF is set 1.

- SC2 计数器
  启用 ATCCNTE。ATCE 后,它从 ACK 旁边的 SCL 上升沿对强制字节后从 I3C 从属传输到 Tbit 旁边的 SCL 上升沿的 IBI 进行计数,并将其捕获为 SC2。

CETSS。ASYNE [0] 位 = 1 且用于发出 IBI 的命令描述符中的 ITS 位为 1 时,SC1 和 SC2 捕获值按照 IBI 强制字节传输,如下图所示。

25.3.2.3.10 Port Control

(1) Extra SCL Clock Cycle Output Function

In master mode, I3C module has a facility for the output of extra SCL clock cycles to release the I3C_SDA line of the slave device from being held at the low level due to the master being out of synchronization with the slave device.

This function is mainly used in master mode to release the I3C_SDA line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from I3C with single cycles of the SCL clock as the unit in the case of a bus error where I3C cannot issue a Repeated START condition or a STOP condition because the slave device is holding the I3C_SDA line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the OUTCTL.EXCYC bit is set to 1, an additional clock pulse at the frequency set by the REFCKCTL.IREFCKS[2:0] bits and the STDBR.SBRHO[7:0] and STDBR.SBRLO[7:0] registers is output from the I3C_SCL pin. After output of this clock pulse, the EXCYC bit automatically becomes 0. After confirming that the EXCYC bit is 0, wait for the setup time of the Repeated START condition or STOP condition, and then confirm the detection of the Repeated START condition or STOP condition. If the Repeated START condition or STOP condition is not detected, consecutive additional clock pulses can be output by writing 1 to the EXCYC bit again.

When I3C module is in master mode and the slave device is holding the I3C_SDA line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a Repeated START condition or a STOP condition is not possible. The facility for output of an extra cycle of the SCL clock can be used to output extra cycles of SCL one by one to make the slave device release the I3C_SDA line from being held at the low level, thus recovering the bus from an unusable state. Release of the I3C_SDA line by the slave device can be monitored by reading the SDILV bit in PRSTDBG. After the I3C_SDA line has been released by the slave device, the preset of a Repeated START condition or a STOP condition is issued.

Use this function with the BFCTL.MALE bit set to 0 (master arbitration-lost detection is disabled).

[Output conditions for using the EXCYC bit in OUTCTL]

- When the bus is free (BFREF flag in BCST = 1) or in master mode (CRMS bit = 1 in PRSST and BFREF flag = 0 in BCST)
- When the communication device does not hold the I3C_SCL line low

(1)额外的SCL时钟周期输出功能

I3C模块在主模式下,具有用于输出额外SCL时钟周期的设施,以释放从设备的I3C_SDA线,使其不会由于主设备与从设备不同步而保持在低电平。

该功能主要用于主模式,通过在以下情况下将来自I3C的SCL输出的额外周期以SCL时钟的单个周期为单位,将从属设备的I3C_SDA线从固定到低电平的状态释放出来:总线错误,其中 I3C 无法发出重复 START 条件或 STOP 条件,因为从属设备是 I3C_SDA线保持在较低水平。请勿在正常情况下使用此设施。当通信正常进行时使用它将导致故障。

OUTCTL。EXCYC 位设置为 1 时,将 REFCKCTL。IREFCKS[2:0] 位以及 STDBR。SBRHO[7:0] 和 STDBR。SBRLO[7:0] 寄存器设置的频率下的附加时钟脉冲从 I3C_SCL 引脚输出。该时钟脉冲输出后,EXCYC 位自动变为 0。EXCYC 位为 0 后,等待重复 START 条件或 STOP 条件的设置时间,然后确认检测到重复 START 条件或 STOP 条件。如果未检测到重复开始条件或停止条件,则可以通过再次将1写入EXCYC位来输出连续的附加时钟脉冲。

I3C 模块处于主模式且从设备由于噪声等影响已经失去与从设备的同步而将 I3C_SDA 线路保持在低电平时, 无法输出重复 START 条件或 STOP 条件。SCL时钟的额外周期输出的设施,可以用来逐个输出SCL的额外周期,使从设备释放I3C_SDA线路被保持在低电平,从而使总线从无法使用的状态恢复。PRSTDBG 中读取 SDILV 位即可监控从设备释放 I3C_SDA 线,当从设备已释放 I3C_SDA 线后,会发出重复 START 条件或 STOP 条件的预设。

将此功能与设置为 0 的 BFCTL。MALE 位一起使用（主仲裁丢失检测被禁用）。

[在 OUTCTL 中使用 EXCYC 位的输出条件]

- 当总线是空闲的（BCST = 1 中的 BFREF 标志）或主模式（PRSST 中的 CRMS 位 = 1,BCST 中的 BFREF 标志 = 0）
- 当通信设备未将 I3C_SCL 线路保持在较低位置时

图25。90显示了额外的SCL时钟周期输出函数（EXCYC位）的操作定时。

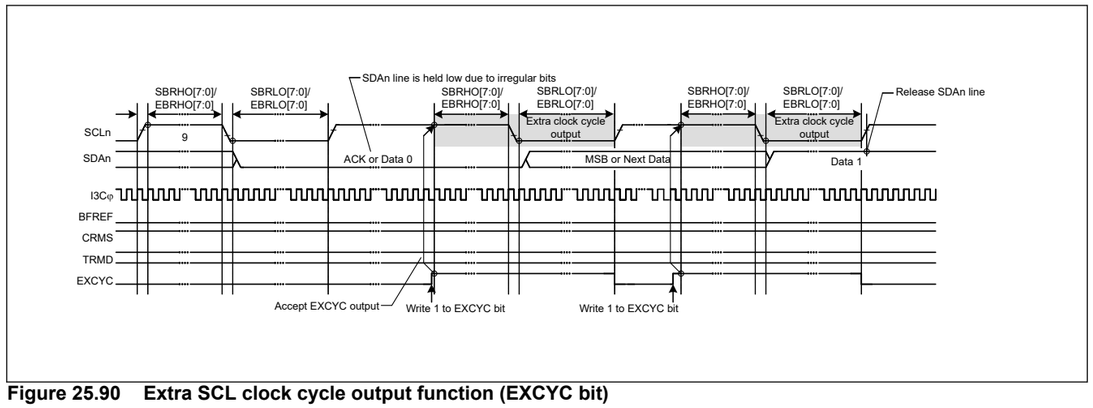

Figure 25.90 Extra SCL clock cycle output function (EXCYC bit)

25.3.2.3.11 SMBus Operation [I²C mode]

I3C is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the BFCTL.SMBS bit to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus specification, set the REFCKCTL.IREFCKS[2:0] bits, the STDBR.SBRHO[7:0] bits, and the STDBR.SBRLO[7:0] bits. In addition, determine the values of the OUTCTL.SDODCS bit and the OUTCTL.SDOD[2:0] bits to meet the data hold time specification of 300 ns or more. If I3C is used only as an I²C slave device, the transfer rate setting is not necessary, whereas the STDBR.SBRLO[7:0] bits needs to be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001), use one of the slave device address table basic registers 0 to 2 (SDATBASn .SDSTAD[6:0] bits (y = 0 to 2), and set the corresponding SDATBASn .SDADLS bit (7-bit/10-bit address format select) (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the BFCTL.SALE bit to 1 to enable the slave arbitrationlost detection function.

(1) SMBus Timeout Measurement

(a) Measuring timeout of slave device

The following period (timeout interval: $T_{LOW:SEXT}$) must be measured for slave devices in SMBus communication.

- From START condition to STOP condition

To measure timeout for slave devices, measure the period from START condition detection to STOP condition detection with the GPT timer using a START condition detection interrupt (I3C_EEI) and STOP condition detection interrupt (I3C_EEI) of I3C. The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:SEXT}$: 25 ms (max.) of the SMBus specification.

If the time measured with the GPT exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (min.) of the SMBus specification, the slave device must release the bus by writing 1 to the RSTCTL.INTLRST bit to issue an internal reset of I3C. When an internal reset is issued, I3C stops driving the bus for the I3C_SCL pin and I3C_SDA pin and make the I3C_SCL/I3C_SDA pin outputs high-impedance, which releases the bus.

(b) Measuring timeout of master device

The following periods (timeout interval: $T_{LOW:MEXT}$) must be measured for master devices in SMBus communication.

- From START condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to STOP condition

To measure timeout for master devices, measure these periods with the GPT timer using a START condition detection interrupt (I3C_EEI), STOP condition detection interrupt (I3C_EEI), and transmit end interrupt (I3C_TEND) or receive data buffer full interrupt (I3C_RX) of I3C. The measured timeout period must be within the total clock lowlevel extended period

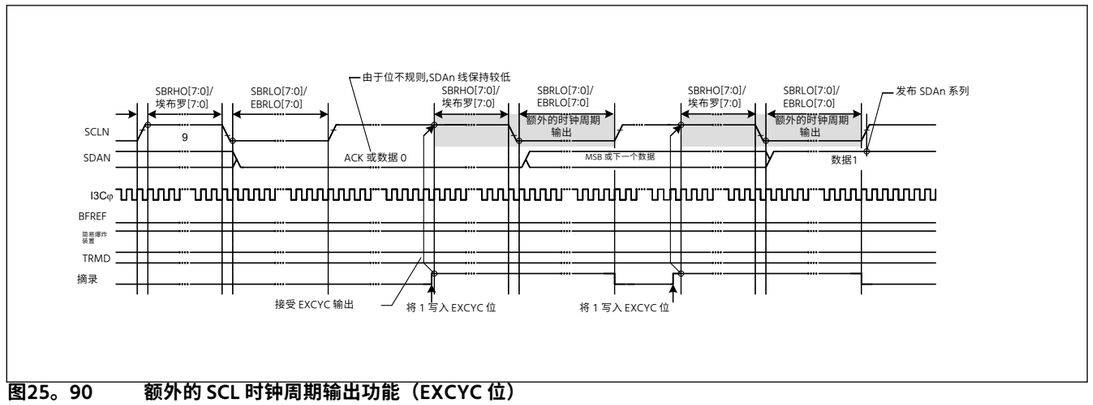

图25。90 额外的 SCL 时钟周期输出功能（EXCYC 位）

SMBus 操作 [I 2 C 模式] 25。3。2。3。11

I3C 可用于符合 SMBus 的数据通信（版本 2。0)。要执行SMBus通信,请将BFCTL。SMBS位设置为1。要使用 SMBus 规范 10 kbps 至 100 kbps 范围内的传输速率,请设置 REFCKCTL。IREFCKS[2:0] 位、STDBR。SBRHO[7:0] 位和 STDBR。SBRLO[7:0] 位。另外,确定OUTCTL。SDODCS位和OUTCTL。SDOD[2:0]位的值以满足300ns或更多的数据保持时间规范。I3C仅用作I 2 C从设备,则传输速率设置不是必需的,而STDBR。SBRLO[7:0]位需要设置为长于数据设置时间(250 ns）的值。

SMBus 设备默认地址 (1100 001),请使用从设备地址表基本寄存器 0 到 2 之一（SDATBASn）。SDSTAD[6:0] 位（y = 0 到 2),并设置相应的 SDATBASn。SDADLS 位(7 位/10 位地址格式选择）（y = 0 到 2)到 0(7 位地址格式）。

UDID（唯一设备标识符）时,将 BFCTL。SALE 位设置为 1,以启用从机仲裁丢失检测功能。

(1) SMBus 超时测量

（a）测量从属装置的超时

SMBus 通信中的从设备必须测量以下周期（超时间隔:TLOW:SEXT）。

- 从 START 条件到 STOP 条件

I3C 的一个 START 条件检测中断（I3C_EEI）和 STOP 条件检测中断（I3C_EEI）来测量从设备超时, 使用 GPT 定时器测量从 START 条件检测到 STOP 条件检测的周期。测量的超时周期必须在总时钟低电平周期内 [从设备] TLOW:SEXT：
SMBus 规范的 25 毫秒（最大）。

GPT 测量的时间超过时钟低电平检测超时 TTIMEOUT:SMBus 规范的 25 ms（min。),则从设备必须通过写入 1 到 RSTCTL。INTLRST 位来释放总线,以发出 I3C 的内部重置。I3C发出内部复位时,停止驱动I3C_SCL引脚和I3C_SDA引脚的总线,并使I3C_SCL/I3C_SDA引脚输出高阻抗,从而释放总线。

（b）测量主设备的超时

SMBus 通信中的主设备必须测量以下周期（超时间隔:TLOW:MEXT）。

- 从 START 条件到确认位
- 确认位之间
- 从确认位到停止条件

要测量主设备的超时,请使用 GPT 定时器使用 START 条件检测中断（I3C_EEI）、STOP 条件检测中断（I3C_EEI）测量这些时段,并发送结束中断（I3C_TEND）或接收数据缓冲区 I3C 的完全中断（I3C_RX）。测量的超时周期必须在总时钟低电平延长周期内

(master device) $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus specification, and the total of all $T_{LOW:MEXT}$ from START condition to STOP condition must be within $T_{LOW:SEXT}$: 25 ms (max.).

For the ACK receive timing (rising edge of the ninth SCL clock cycle), monitor the BST.TENDF flag in master transmit mode (master transmitter) and the NTST.RDBFF0 flag in master receive mode (master receiver). For this reason, perform bytewise transmit operation in master transmit mode, and hold the SCSTRCTL.ACKTWE bit 0 until the byte just before reception of the final byte in master receive mode. While the ACKTWE bit = 0, the RDBFF0 flag is set to 1 at the rising edge of the ninth SCL clock cycle.

If the period measured with the GPT exceeds the total clock low-level extended period (master device) $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus specification or the total of measured periods exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (min.) of the SMBus specification, the master device must stop the transaction by issuing a STOP condition. In master transmit mode, immediately stop the transmit operation (writing data to NTDTBP0).

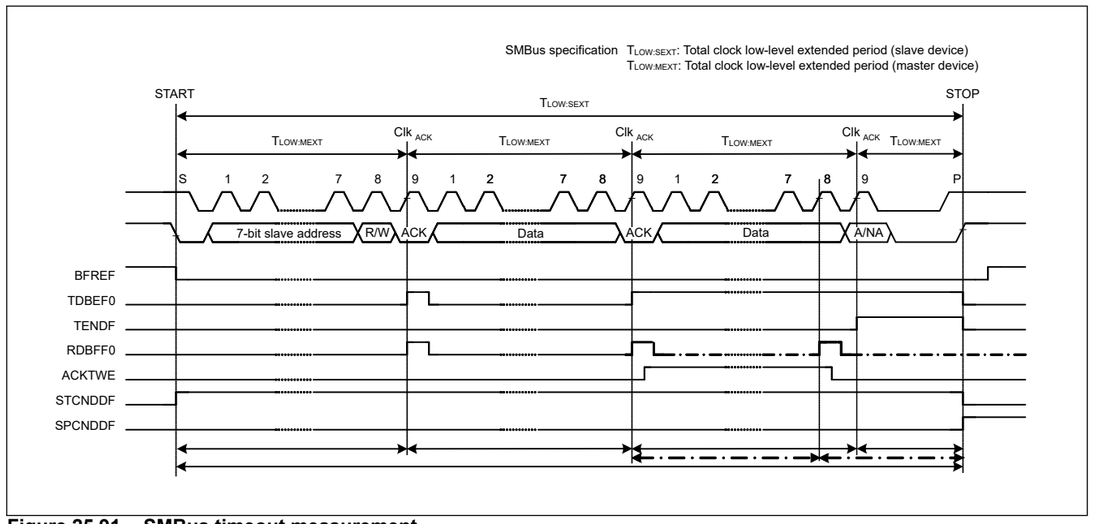

Figure 25.91 SMBus timeout measurement

(2) Packet Error Code (PEC)

This MCU incorporates a CRC calculator. The CRC calculator enables transmission of a packet error code (PEC) or checking the received data of the SMBus in data communication of I3C. For the CRC generating polynomials of the CRC calculator, see section 29, Cyclic Redundancy Check (CRC).

The PEC data in master transmit mode can be generated by writing all transmit data to the CRC data input register (CRCDIR) in the CRC calculator.

The PEC data in master receive mode can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC data output register (CRCDOR) with the received PEC data.

To send ACK or NACK according to the match or mismatch result when the final byte is received as a result of the PEC code check, set the SCSTRCTL.ACKTWE bit to 1 before the rising edge of the eighth SCL clock cycle during reception of the final byte, and hold the I3C_SCL line low at the falling edge of the eighth clock cycle.

(3) SMBus Host Notification Protocol (Notify ARP Master Command)

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address or to request its own slave address from the SMBus host.

For a product of this MCU to operate as an SMBus host (or ARP master), the host address (0001 000) sent from the slave device must be detected as a slave address, so I3C has a function for detecting the host address. To detect the host address as a slave address, set the BFCTL.SMBS bit and the SVCTL.HOAE bit to 1. Operation after the host address has been detected is the same as normal slave operation.

（主设备）TLOW:MEXT: SMBus 规范的 10 毫秒（最大）,并且从 START 条件到 STOP 条件的所有 TLOW:MEXT 总数必须在 TLOW:SEXT: 25 毫秒（最大）内。

对于ACK接收定时（第九SCL时钟周期的上升沿）,监视主发送模式下的BST。TENDF标志（主发送器）和主接收模式下的NTST。RDBFF0标志（主接收器）。因此,在主发送模式下执行字节式发送操作,并保持SCSTRCTL。ACKTWE位0,直到在主接收模式下接收最终字节之前的字节。虽然 ACKTWE 位 = 0,但在第九个 SCL 时钟周期的上升沿,RDBFF0 标志被设置为 1。

GPT 测量的周期超过时钟低电平延长总周期（主设备）TLOW:MEXT: SMBus 规范的 10 ms（max。）或测量的周期总和超过时钟低电平检测超时 T TIMEOUT: SMBus 规范的 25 ms（min。),则主设备必须通过发出 STOP 条件来停止交易。在主发送模式下,立即停止发送操作（将数据写入NTDTBP0)。

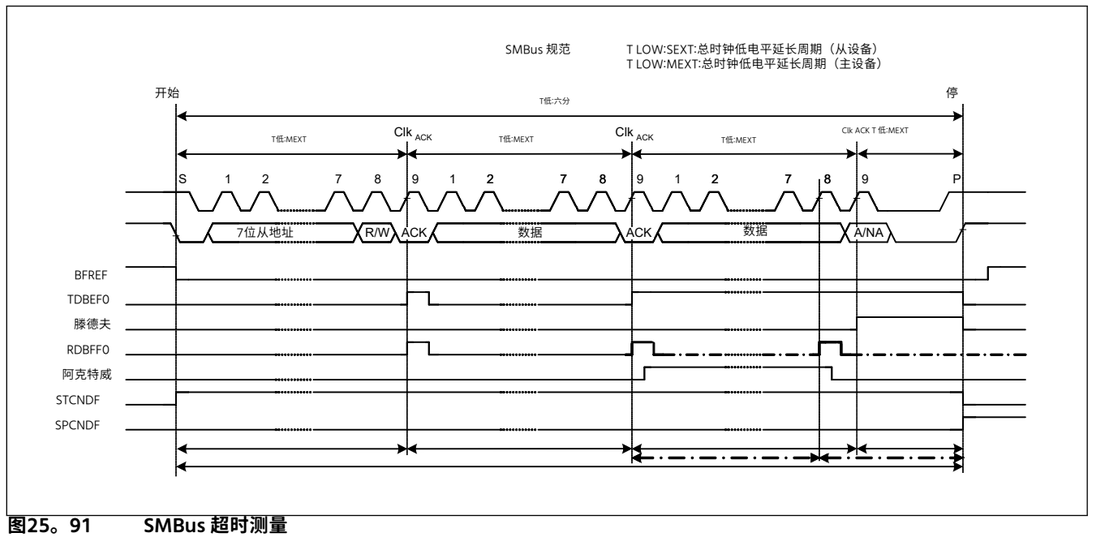

图25。91 SMBus 超时测量

(2) 数据包错误代码（PEC）

该 MCU 包含一个 CRC 计算器。CRC 计算器能够在 I3C 的数据通信中传输数据包错误代码（PEC）或检查接收到的 SMBus 数据。CRC计算器的CRC生成多项式,请参见第29节循环冗余校验（CRC）.

主发送模式下的PEC数据可以通过将所有发送数据写入CRC计算器中的CRC数据输入寄存器（CRCDIR）来生成。

通过将所有接收数据写入CRC计算器中的CRCDIR并将CRC数据输出寄存器（CRCDOR）中获得的值与接收到的PEC数据进行比较,可以检查主接收模式下的PEC数据。

PEC码校验的结果而接收到最终字节时根据匹配或不匹配结果发送ACK或NACK,在接收最终字节期间将SCSTRCTL。ACKTWE位设置为第八SCL时钟周期上升沿之前的1,并在第八时钟周期下降沿将I3C_SCL线保持在较低位置。

(3) SMBus 主机通知协议（通知 ARP 主命令）

SMBus 的通信中,从设备可以暂时充当主设备,以通知 SMBus 主机（或 ARP 主机）自己的从地址,或者向 SMBus 主机请求自己的从地址。

MCU 的一个产品来作为 SMBus 主机（或 ARP 主机）运行,从从设备发送的主机地址 (0001 000) 必须被检测为从机地址,因此 I3C 具有检测主机地址的功能。要将主机地址检测为从站地址,请将 BFCTL。SMBS 位和 SVCTL。HOAE 位设置为 1。检测到主机地址后的操作与正常从机操作相同。

25.3.2.4.3 Timeout Error Detection

I3C includes a timeout function for detecting when the I3C_SCL line has been stuck longer than the predetermined time. I3C can detect an abnormal bus state by monitoring that the I3C_SCL line is stuck low or high for a predetermined time.

The timeout function monitors the I3C_SCL line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the I3C_SCL line changes (rising or falling), but continues to count unless the I3C_SCL line changes. If the internal counter overflows due to no I3C_SCL line change, I3C can detect the timeout and report the bus hung state.

This timeout function is enabled when BSTE.TODE = 1. It detects a hung state that the I3C_SCL line is stuck low or high during the following conditions: (When TMOCTL.TOMDS[1:0] = 00b)

- The bus is busy (BCST.BFREF = 0) in master mode (PRSST.CRMS = 1).
- I3C's own slave address is detected (SVST register is not 0x0000) and the bus is busy (BCST.BFREF = 0) in slave mode (PRSST.CRMS = 0).
- The bus is free (BCST.BFREF = 1) while generation of a START condition is requested (CNDCTL.STCND = 1).

表 25。14 SDR 主错误类型

错误类型	描述	错误检测方法	错误恢复方法
M0	发送 CCC 后进行交易	检测非法格式的 CCC	停止传输,然后发送停止并重试传输。
M1（可选）	监控错误	Master 检测（通过监控）传输的数据与其要传输的数据不同（动态地址仲裁期间不适用）	停止传输,然后发送停止并重试传输。
M2	对广播地址 (0x7E）没有响应	主控在之后检测到 NACK 广播地址(0x7E）传输	检测到 NACK 后,主站会传输 HDR 退出模式,然后发送 STOP

25。3。2。4。3 超时错误检测

I3C包括一个超时功能,用于检测I3C_SCL线路何时被卡住的时间超过预定时间。I3C可以通过监测I3C_SCL线路在预定时间内卡在低或高位置来检测异常总线状态。

Timeout 函数监控 I3C_SCL 线路状态,并使用内部计数器对低电平周期或高电平周期进行计数。I3C_SCL 线每次改变（上升或下降）时,超时函数会重置内部计数器,但除非 I3C_SCL 线改变,否则会继续计数。I3C_SCL 线路没有变化导致内部计数器溢出,I3C 可以检测超时并报告总线挂起状态。

当 BSTE。TODE = 1 时启用此超时函数。I3C_SCL线在以下条件下卡在低或高的悬挂状态下检测到:（当TMOCTL。TOMDS[1:0] = 00b时）

- 总线在主模式（PRSST。CRMS = 1)下忙碌（BCST。BFREF = 0)。
- I3C 自己的从站地址被检测（SVST 寄存器不是 0x0000),总线在从站模式（PRSST。CRMS = 0)下忙碌（BCST。BFREF = 0)。
- 总线是免费的（BCST。BFREF = 1),同时请求生成 START 条件（CNDCTL。STCND = 1)。

25.3.2.4.4 Resume Operation [I3C mode]

I3C enters the Halt state as a result of any type of error occurring in a transfer.

The error type is indicated by the field ERR_STATUS in Response Descriptor or Receive Status Descriptor. After I3C has entered the Halt state, the user must write the value 1 to the RSM bit to resume operation. I3C shall auto-clear the RSM bit once it has initiated the next Command transfer or detected the START condition.

25.3.2.4.5 Abort Operation [I3C mode]

When the BCTL.ABT bit is set to 1, I3C relinquish control of the bus before completing the currently issued transfer. In response to an abort request, I3C issues the STOP condition on the bus after the complete data byte is transferred or received. After I3C has aborted, the user shall clear the BCTL.ABT bit to allow operation on the bus.

Note: For Read transaction, when BCTL.ABT is set to 1, that receive data is stored in Receive data buffer.

25.3.2.4.4 恢复操作[I3C模式]

I3C由于传输中发生任何类型的错误而进入停止状态。

错误类型由响应描述符或接收状态描述符中的字段 ERR_STATUS 指示。I3C 已进入停止状态后,用户必须将值 1 写入 RSM 位才能恢复运行。I3C 在启动下一次命令传输或检测到 START 条件后,应自动清除 RSM 位。

25。3。2。4。5 中止操作[I3C模式]

BCTL。ABT 位设置为 1 时,I3C 在完成当前发布的传输之前放弃对总线的控制。I3C响应中止请求,在传输或接收完整的数据字节后,在总线上发出STOP条件。I3C 中止后,用户应清除 BCTL。ABT 位以允许在总线上运行。

注意:对于读取事务,当BCTL。ABT设置为1时,接收数据存储在接收数据缓冲区中。

25.3.2.4.6 Error Recovery Operation

(1) Error Recovery Operation

When an error occurs, the INST.INEF, NTST.TEF, NTST.TABTF, HTST.TEF and HTST.TABTF flags are set to 1 according to the cause of the error, or the interrupts associated with each flag are asserted (when detection and interrupts are enabled.)

There is a possibility of communication error or internal module error.

Note: If an error occurs, I3C will be suspended (BCTL.RSM becomes 1). After I3C is suspended, the application must write the value 1 to the BCTL.RSM bit to resume I3C operaion and recover from the suspended state.

Figure 25.95 and Figure 25.96 show the error recovery flow.

25.3.2.4.6 错误恢复操作

(1)错误恢复操作

当发生错误时,INST。INEF、NTST。TEF、NTST。TABTF、HTST。TEF 和 HTST。TABTF 标志根据错误原因设置为 1,或者断言与每个标志关联的中断（当启用检测和中断时。）存在通信错误或内部模块错误的可能性。

注意:如果发生错误,I3C 将被暂停（BCTL。RSM 变为 1)。I3C 暂停后,应用程序必须将值 1 写入 BCTL。RSM 位才能恢复 I3C 运算并从暂停状态恢复。

图 25。95 和图 25。96 显示了错误恢复流程。

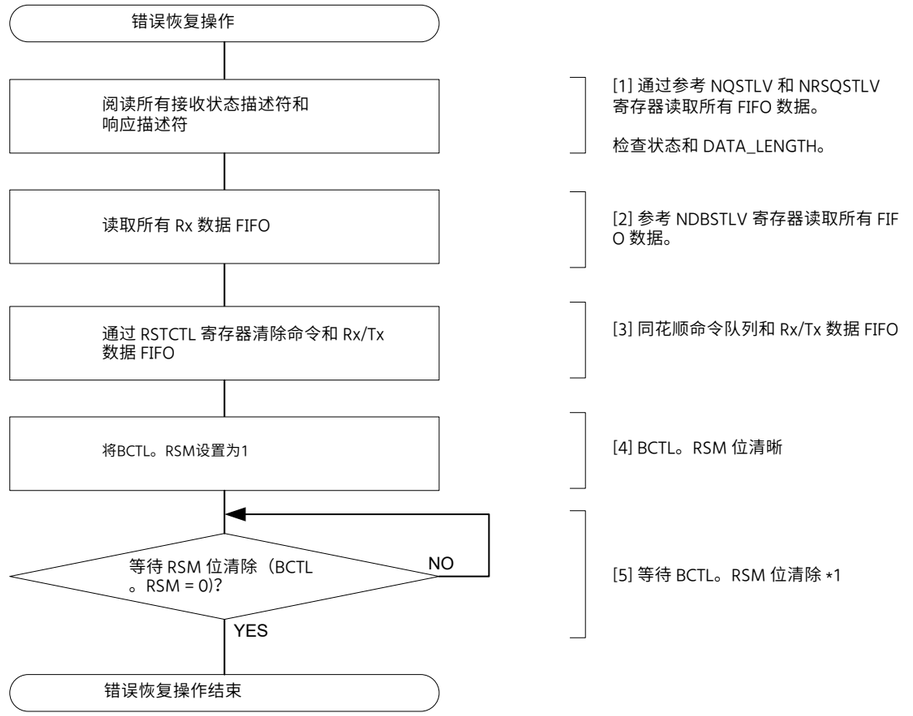
When I3C Slave recovers from an error according to the error recovery flow, after setting BCTL.RSM to 1, BCTL.RSM becomes 0 after detecting a state in which Bus Available period communication is not performed on I3C Bus.

If communication occurs on the I3C bus within the Bus Available period, BCTL.RSM will not be set to 0 and error recovery will not be completed, NACK response will be made to the communication.

(2) Master Error Detection and Escalation Handling

If the Master does not receive an ACK of a transmitted private Message to a Slave and Steps 1 and 2 described in Chapter 5.1.10.2.4 of MIPI I3C Spec v1.0 fail, the processing flow of Step 3 is shown in Figure 25.97 and Figure 25.98.



注1。用于发出 IBI 的命令描述符可以在 RSM 位被清除之前通过写入命令队列端口（NCMDQP）来写入命令队列。

I3C Slave根据错误恢复流从错误中恢复时,在将BCTL。RSM设置为1之后,在检测到在I3C总线上不执行总线可用时段通信的状态后,BCTL。RSM变为0。

Bus 可用期间内在 I3C 总线上发生通信,则 BCTL。RSM 将不会被设置为 0 且错误恢复不会完成,则将对通信进行 NACK 响应。

(2)主控错误检测和升级处理

Master没有接收到发送给从站的私有消息的ACK,MIPI I3C Spec v1。0第5。1。10。2。4章中描述的步骤1和2失败,则步骤3的处理流程如图25。97和图25。98 .所示

25.3.2.5 Low Power Function

25.3.2.5.1 Wake Up function [I2C mode]

I3C is equipped with the Wake-up function that causes the microcomputer to transition from low power consumption mode with system clock is stopped (software standby mode, etc.) to the normal operation. The Wake-up function is used to generate a Wake-up interrupt signal when the received data matches the address set to Wake-up interrupt factor also receives data in a state where the operating clock (PCLK/TCLK) is stopped (PCLK/TCLK asynchronous operation). This wake-up interrupt signal causes the microcomputer to transition to the normal operation. After Wake-up interrupt occurs, switch I3C to PCLK/TCLK synchronous operation, it will be able to continue the communication operation.

The Wake-up function has four wake-up operation modes (normal WU mode 1, normal WU mode 2, command recovery mode, and EEP response mode). The table below describes the behavior in these four wake-up operation modes.

Table 25.15 Wake-up operation mode

	ACK response timing	ACK Type responded before recovery to PCLK/TCLK synchronous operation	SCL state before recovery to PCLK/TCLK synchronous operation
Normal WU mode 1	Before recovery to PCLK/TCLK synchronous operation*1	ACK	Fixed to L
Normal WU mode 2	After recovery to PCLK/TCLK synchronous operation*2	Before recovery: no response (NACK level retained) After recovery: ACK response	Fixed to L
Command recovery mode	Before recovery to PCLK/TCLK synchronous operation*1	ACK	Open
EEP response mode	Before recovery to PCLK/TCLK synchronous operation*1	NACK	Open

Note 1. Switching timing from PCLK/TCLK asynchronous operation to PCLK/TCLK synchronous operation is the fall of the 9th clock of SCL.
Note 2. Switching timing from PCLK/TCLK asynchronous operation to PCLK/TCLK synchronous operation is the fall of the 8th clock of SCL.

The following can be selected as Wake-Up interrupt factor.

- Host address detection (valid when SVCTL.HOAE = 1)
- General call address detection (valid when SVCTL.GCAE = 1)
- Slave address 0*1 detection (valid when SVCTL.SVAF[0] = 1)
- Slave address 1*1 detection (valid when SVCTL.SVAF[1] = 1)

25。3。2。5 低功耗功能

25.3.2.5.1 唤醒功能[I 2 C模式]

I3C 搭载了唤醒功能,使微机从系统时钟停止的低功耗模式（软件待机模式等）过渡到正常运行。当接收到的数据与设置为唤醒中断因子的地址相匹配时,唤醒功能用于生成唤醒中断信号,唤醒中断因子也在停止操作时钟（PCLK/TCLK）的状态下接收数据（PCLK/TCLK）异步操作）。该唤醒中断信号导致微型计算机过渡到正常操作。Wake-up中断发生后,将I3C切换到PCLK/TCLK同步操作,它将能够继续通信操作。

唤醒功能有四种唤醒操作模式（正常WU模式1、正常WU模式2、命令恢复模式、EEP响应模式）。下表描述了这四种唤醒操作模式下的行为。

表 25。15 唤醒操作模式

	ACK 响应时序	ACK Type 在恢复 PCLK/TCLK 同步操作之前做出响应	SCL状态 然后恢复到 PCLK/TCLK 同步操作
正常的WU模式1	恢复PCLK/TCLK同步操作前*1	ACK	固定为 L
正常的WU模式2	恢复PCLK/TCLK同步操作后*2	恢复前:无响应（保留NACK级别）恢复后:ACK响应	固定为 L
命令恢复模式	恢复PCLK/TCLK同步操作前*1	ACK	打开
EEP响应模式	恢复PCLK/TCLK同步操作前*1	NACK	打开

注1。PCLK/TCLK异步操作切换定时到PCLK/TCLK同步操作是SCL第9个时钟的下降。
注2。PCLK/TCLK异步操作切换时序到PCLK/TCLK同步操作是SCL第8个时钟的下降。

以下内容可以选择为唤醒中断因子。

- 主机地址检测（当 SVCTL。HOAE = 1 时有效）
- 一般呼叫地址检测（当 SVCTL。GCAE = 1 时有效）
- 从站地址 0 *1 检测（当 SVCTL。SVAF[0] = 1 时有效）
- 从站地址 1 *1 检测（当 SVCTL。SVAF[1] = 1 时有效）

- Slave address 2*1 detection (valid when SVCTL.SVAF[2] = 1)

Note 1. 7-bit address only can be set. Set SDADLS bit to 0 in SDATBASn .

(1) Normal Wake-Up mode 1

This section describes the behavior, the timing, and a use case of normal WU mode 1.

A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below. Also, the detailed timing is provided in Figure 25.101.

Before wake-up recovery:	ACK is sent in response to the data received with its own slave address.
During wake-up recovery:	ACK response is made at the 9th clock cycle of SCL, and the SCL is held low afterwards.*1
After wake-up recovery:	Normal operation continues.

Note 1. Between ninth clock cycle and first clock cycle during Wake-Up recovery, SCSTRCTL.RWE = 1 does not work.

If the slave address does not match, the SCL line is not held low after the fall of the 9th clock cycle of SCL, and the slave operation continues.

See Figure 25.99 below for a use case.

A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to Figure 25.100.

● 从站地址 2*1 检测（当 SVCTL。SVAF[2] = 1 时有效）注意 1。只能设置 7 位地址。在 SDATBASn 中将 SDADLS 位设置为 0。

（一）普通唤醒模式 1

本节介绍正常 WU 模式 1 的行为、时序和用例。

由从地址匹配触发的唤醒中断以如下所述的方式过渡到正常操作。此外,详细的定时如图 25。101 . 所示

唤醒恢复之前:	ACK是响应于接收到的具有自己的从地址的数据而发送的。
在唤醒恢复期间:	ACK 响应是在 SCL 的第 9 个时钟周期做出的,之后 SCL 保持在较低水平。X数学X_1
唤醒恢复后:	正常运行仍在继续。

注1。在唤醒恢复期间的第九个时钟周期和第一个时钟周期之间,SCSTRCTL。RWE = 1 不起作用。

如果从地址不匹配,则SCL第9个时钟周期下降后SCL线不保持低电平,并且从操作继续。

有关用例,请参阅下面的图 25。99。

如果转换是由从地址匹配生成的唤醒中断信号以外的原因（其他恢复原因（IRQ））触发的,则在转换到正常操作时不会生成唤醒中断。在这种情况下未设置 BST。WUCNDDF。根据图 25。100 . 进行以下处理

(2) Normal Wake Up Mode 2

This section describes the behavior, the timing, and a use case of normal WU mode 2.

A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below.

Also, the detailed timing is provided in Figure 25.103.

Before wake-up recovery:	No response to the data received with its own slave address (until 8th SCL cycle end)
During wake-up recovery:	Holding the SCL line low during the 8th and 9th clock cycles
After wake-up recovery:	Returning ACK at the 9th clock cycle of SCL, and continuing the normal operation

If the slave address does not match, the SCL line is not held low after the fall of the 8th SCL v clock cycle. The slave operation continues.

See Figure 25.102 below for a use case.

A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to Figure 25.100.

(2)正常唤醒模式2

本节介绍正常 WU 模式 2 的行为、时序和用例。

此外,详细的定时如图 25。103 . 所示

唤醒恢复之前:	对使用其自己的从属地址接收的数据没有响应（直到第 8 个 SCL 周期结束）
在唤醒恢复期间:	在第 8 个和第 9 个时钟周期内将 SCL 线保持在较低水平
唤醒恢复后:	SCL第9个时钟周期返回ACK,并继续正常运行

如果从地址不匹配,则在第 8 个 SCL v 时钟周期下降后,SCL 线不会保持在较低位置。奴隶行动仍在继续。

有关用例,请参阅下面的图 25。102。

如果转换是由从地址匹配生成的唤醒中断信号以外的原因（其他恢复原因（IRQ））触发的,则在转换到正常操作时不会生成唤醒中断。在这种情况下未设置 BST。WUCNDDF。根据图 25。100 . 进行以下处理

[6] Interrupt requests are disabled except WUI.

[7] Stop TCLK supply, then stop PCLK supply. (Will continue to receive)

(3) Command recovery mode/ EEP response mode (Special Wake Up mode)

In the command recovery mode and EEP response mode, the SCL line is not held low during the wake-up recovery period (after the rise of the 9th clock cycle of SCL), so other I^2C/I3C devices can use the I^2C bus during this period. This section describes the behavior, the timing, and use cases of the command recovery mode and the EEP response mode.

A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below. Also, the detailed timing is provided in Figure 25.106.

Before wake-up recovery:	In response to the data received with its own slave address, ACK (command recovery mode) or NACK (EEP response mode) is returned.
During wake-up recovery:	The SCL line is not held low.
After wake-up recovery:	Normal operation continues after I3C initial setting.

Note: Because the SCL line is not held low during wake-up recovery, the transmission/reception of the data that follows the slave address is not possible.
Note: The command recovery mode and the EEP response mode are internal reset (RSTCTL.INTLRST = 1) states. Therefore, the match of the slave address does not set the SVST flags (HOAF, GCAF, and SVAF[3:0]).

If the slave address does not match, the slave operation continues.

See Figure 25.105 below for a use case.

A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to Figure 25.105.

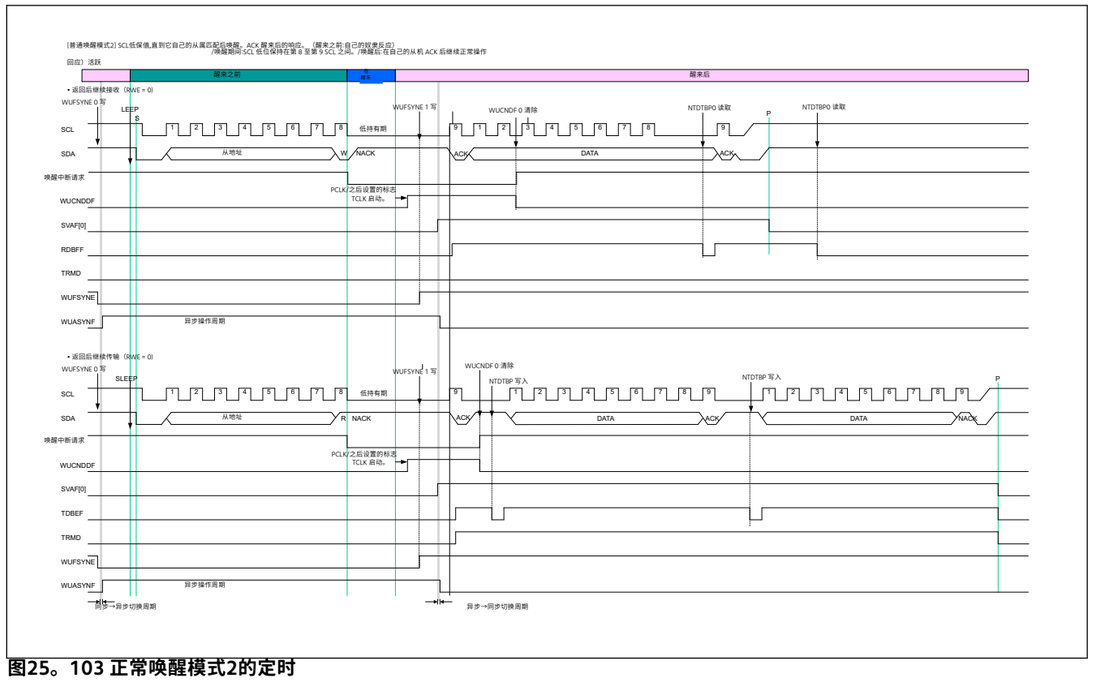

图25。103 正常唤醒模式2的定时

(3) 命令恢复模式/EEP响应模式（特殊唤醒模式）

在命令恢复模式和EEP响应模式下,SCL线在唤醒恢复期间（SCL第9个时钟周期上升之后）不保持低电平,因此其他I 2 C/I3C设备可以在此期间使用I 2 C总线。本节介绍命令恢复模式和 EEP 响应模式的行为、时序和使用情况。

由从地址匹配触发的唤醒中断以如下所述的方式过渡到正常操作。此外,详细的定时如图 25。106 . 所示

唤醒恢复之前:	响应于用其自己的从站地址接收到的数据,返回ACK（命令恢复模式）或NACK（EEP响应模式）。
在唤醒恢复期间:	SCL线保持不低。
唤醒恢复后:	I3C初始设置后继续正常运行。

注意:由于唤醒恢复期间 SCL 线路保持不低,因此无法传输/接收从地址之后的数据。

注意:命令恢复模式和EEP响应模式是内部重置（RSTCTL。INTLRST = 1)状态。因此,从属地址的匹配不会设置 SVST 标志（HOAF、GCAF 和 SVAF[3:0])。

如果从属地址不匹配,则从属操作继续。

有关用例,请参阅下图 25。105。

如果转换是由从地址匹配生成的唤醒中断信号以外的原因（其他恢复原因（IRQ））触发的,则在转换到正常操作时不会生成唤醒中断。在这种情况下未设置 BST。WUCNDDF。根据图 25。105 . 进行以下处理

(4) Precautions on the use of the Wake-Up function

Precautions on the use of the Wake-up function is shown below.

- Do not change the registers in I3C except the WUCTL.WUFSYNE bit while the WUST.WUASYNF flag = 1 (while PCLK/TCLK asynchronous operation).
- Set WUCTL.WUFE = BSTE.WUCNDDE = BIE.WUCNDDIE = 1 and PRSST.CRMS = PRSST.TRMD = 0 (slave reception mode) before switching PCLK/TCLK asynchronous mode.
- Cannot select the device ID and the 10-bit slave address for wake-up interrupt factor. Set the DVIDE bit in SVCTL and SDADLS bit in SDATBASn (n = 0 to 2) to 0.
- Sets all bits in BIE (TENDIE, NACKDIE, SPCNDDIE, STCNDDIE, ALIE, TODIE) and TDBEIE0 and RDBFIE0 bits in NTIE to 0 (Interrupt disabled) before switching the asynchronous operation.
- Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).
- Wake-up interrupt is generated while PCLK/TCLK asynchronous operation (when WUST.WUASYNF = 1). In case of detecting slave address matching, The case of detect slave address match in PCLK/TCLK synchronous mode (WUST.WUASYNF = 0), does not occur Wake-up interrupt, and BST.WUCNDDF flag will be not set also.
- If WUCTL.WUFSYNE bit to 0 write timing and START condition of detecting a conflict, I3C might start the next reception in PCLK/TCLK synchronous operation mode. In this case, WUST.WUASYNF flag becomes 1 (switch to PCLK/TCLK asynchronous mode) when data communication is finished and detected STOP condition and starts the Wake-up event detection.
- If you want to switch from PCLK/TCLK asynchronous operation to PCLK/TCLK synchronous operation without address match detection, it will switch in the STOP condition detection. When the WUCTL.WUFSYNE bit was set to 1 in a bus free state, it is continued PCLK/TCLK asynchronous operation (Reception operation: waiting communication frame). WUST.WUASYNF flag becomes to 0 when I3C detect the STOP condition of the next communication frame, and I3C switches to PCLK/TCLK synchronous operation.
- After writing 0 to WUFSYNE bit in WUCTL, do not change I3C operation mode setting register (BFCTL, SCSTRCTL, ACKCTL, INCTL, SVCTL, SDATBASn (n = 0 to 2)) until switched to the PCLK/TCLK asynchronous operation from

(4) 使用唤醒功能的注意事项

唤醒功能的使用注意事项如下所示。

● 请勿更改 I3C 中的寄存器,但 WUCTL。WUFSYNE 位除外,而 WUST。WUASYNF 标志 = 1（同时 PCLK/TCLK 异步操作）。

● 在切换 PCLK/TCLK 异步模式之前设置 WUCTL。WUFE = BSTE。WUCNDDE = BIE。WUCNDDIE = 1 和 PRSST。CRMS = PRSST。TRMD = 0（从接收模式）。

● 不能选择设备 ID 和唤醒中断因子的 10 位从地址。将 SVCTL 中的 DVIDE 位和 SDATBASn 中的 SDADLS 位（n = 0 到 2)设置为 0。

● 在切换异步操作之前,将 BIE 中的所有位（TENDIE、NACKDIE、SPCNDDIE、STCNDDIE、ALIE、TODIE）以及 NTIE 中的 TDBEIE0 和 RDBFIE0 位设置为 0（中断禁用）。

● 启用唤醒功能时请勿使用超时功能（WUCTL。WUFE = 1)。

● 唤醒中断是在 PCLK/TCLK 异步操作时生成的（当 WUST。WUASYNF = 1 时）。如果检测到从地址匹配,则不会发生PCLK/TCLK同步模式（WUST。WUASYNF = 0)中检测到从地址匹配的情况,并且也不会设置BST。WUCNDDF标志。

● 如果 WUCTL。WUFSYNE 位到 0 写入时序和检测冲突的 START 条件,则 I3C 可能会在 PCLK/TCLK 同步操作模式下启动下一个接收。在这种情况下,当数据通信完成并检测到STOP条件并开始唤醒事件检测时,WUST。WUASYNF标志变为1（切换到PCLK/TCLK异步模式）。

● 若要从PCLK/TCLK异步操作切换到PCLK/TCLK同步操作而没有地址匹配检测,则会在STOP条件检测中切换。当WUCTL。WUFSYNE位在无总线状态下设置为1时,继续PCLK/TCLK异步操作（接收操作:等待通信帧）。WUST。WUASYNF标志变为0当I3C检测到下一个通信帧的STOP条件时,I3C切换到PCLK/TCLK同步操作。

● 在WUCTL中写入0到WUFSYNE位后,在切换到PCLK/TCLK异步操作之前,不要更改I3C操作模式设置寄存器（BFCTL、SCSTRCTL、ACKCTL、INCTL、SVCTL、SDATBASn（n = 0到2))

PCLK/TCLK synchronous operation (while WUST.WUASYNF flag = 1). If register value changes by the interrupt processing etc. in this period, I3C might malfunction without succeeding to the setting to the asynchronous operation.

- During PCLK/TCLK asynchronous operation (WUST.WUASYNF = 1), do not refer to each flag of SVST, BST, NTST, HTST register and BCST.BFREF flag.
- Do not set ACKCTL.ACKT = 1 in order to make an ACK response in the synchronization unit when Wake-up is performed by slave address match in Normal wake-up mode 2.

25.3.2.5.2 Wake Up function

(1) I3C Master Wake-Up

Wake-up interrupt causes of I3C master are shown below.

- SDA low detection (IBI request from I3C slave)

The operation when transitioning to active mode (normal operation) by Wake-Up interrupt of SDA Low detection is shown below.

Before wake-up recovery:	SDA Low Drive is detected and the I3C_WU interrupt is asserted.
During wake-up recovery:	Keep SCL Line High.
After wake-up recovery:	Drive SCL Low and complete START condition. SCL is supplied on the I3C bus and IBI from I3C slave is received.

If transition to active mode (normal operation) due to other factors, disable the Wake-up function as necessary.

After confirming PRSTDBG.SDILV = 1, set WUCTL.WUFE = 0.

Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).

(2) I3C Slave Wake-Up

Wake-up interrupt causes of I3C slave are shown below.

PCLK/TCLK 同步操作（而 WUST。WUASYNF 标志 = 1）。如果在此期间寄存器值因中断处理等而发生变化，则 I3C 可能会在未成功设置为异步操作的情况下发生故障。

- 在 PCLK/TCLK 异步操作期间（WUST。WUASYNF = 1),请勿引用 SVST、BST、NTST、HTST 寄存器和 BCST。BFREF 标志的每个标志。
- 不要设置 ACKCTL。ACKT = 1,以便在正常唤醒模式 2 中通过从地址匹配执行唤醒时在同步单元中做出 ACK 响应。

25。3。2。5。2 唤醒功能

(1)I3C 大师唤醒–向上

I3C master的唤醒中断原因如下所示。

- SDA 低检测（I3C 从站的 IBI 请求）

SDA Low 检测的唤醒中断过渡到活动模式（正常操作）时的操作如下所示。

唤醒恢复之前:	SDA 低驱动器被检测到,并断言 I3C_WU 中断。
在唤醒恢复期间:	保持 SCL 线高位。
唤醒恢复后:	驱动 SCL 低且完整的 START 条件。 SCL在I3C总线上提供,并从I3C从站接收IBI。

如果由于其他因素而过渡到活动模式（正常操作）,请根据需要禁用唤醒功能。

确认 PRSTDBG。SDILV = 1 后,设置 WUCTL。WUFE = 0。

启用唤醒功能时请勿使用超时功能（WUCTL。WUFE = 1)。

(2) I3C 从属唤醒–向上

I3C从机的唤醒中断原因如下所示。

- Broadcast address (0x7E) and detects its own Slave address match

The operation when the Broadcast address (0x7E) and transition to active mode (normal operation) by Wake-up interrupt by detecting its own Slave address match is shown.

Before wake-up recovery:	1. If I3C detects BA (0x7E/W) following a START (or Repeated START) Condition, then I3C shall generates ACK (after 0x7E/W). 2. If I3C detects its own Dynamic address after a Repeated START condition following Step1, then I3C shall generates NACK (after its own Dynamic address) and then issues a I3C_WU interrupt.
During wake-up recovery:	I3C always generates NACK.
After wake-up recovery:	Normal operation continues.

If transition to active mode (normal operation) due to other factors, disable the Wake-up function as necessary. Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).

如果由于其他因素而过渡到活动模式（正常操作）,请根据需要禁用唤醒功能。启用唤醒功能时请勿使用超时功能（WUCTL。WUFE = 1)。

25.3.2.6 Other

25.3.2.6.1 SCL Synchronization Circuit [I^2C mode]

This function is enabled while the PRTS.PRTMD bit is set to 1.

In generation of the SCL clock, I3C starts counting out the value for width at high level specified in STDBR.SBRHO[7:0] when it detects a rising edge on the I3C_SCL line and drives the I3C_SCL line low once counting of the width at high level is complete.

When I3C detects the falling edge of the I3C_SCL line, it starts counting out the width at low level period specified in STDBR.SBRLO[7:0], and then stops driving the I3C_SCL line (releases the line) once counting of the width at low level is complete. The SCL clock is thus generated.

If multiple master devices are connected to the I^2C bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, I3C is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the I3C_SCL line while in master mode.

When I3C has detected a rising edge on the I3C_SCL line and thus started counting out the width at high level specified in STDBR.SBRHO[7:0], and the level on the I3C_SCL line falls because an SCL signal is being generated by another master device, I3C stops counting when it detects the falling edge, drives the level on the I3C_SCL line low, and starts counting out the width at low level specified in STDBR.SBRLO[7:0]. When I3C finishes counting out the width at low level, it stops driving the I3C_SCL line to the low level (releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in this module, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the I3C_SCL line has been released. When I3C finishes outputting the low-level period of the SCL clock, the I3C_SCL line is released and the SCL clock rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the SCSYNE bit in BFCTL is set to 1.

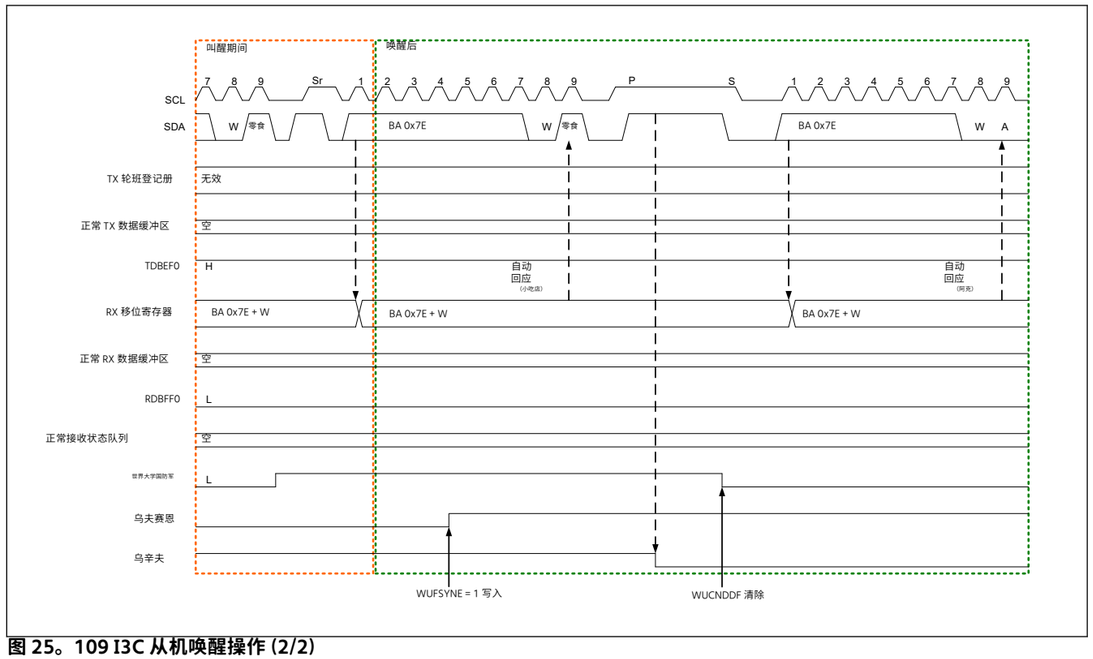

图 25。109 I3C 从机唤醒操作 (2/2)

25。3。2。6 其他

25.3.2.6.1 SCL同步电路[I 2 C模式]

当 PRTS。PRTMD 位设置为 1 时,此功能已启用。

SCL时钟的生成中,当I3C检测到I3C_SCL线上的上升沿并驱动I3C_SCL线一旦高电平宽度计数完成后,I3C开始计算STDBR。SBRHO[7:0]中指定的高电平宽度值。

I3C检测到I3C_SCL线的下降沿时,在STDBR。SBRLO[7:0]中指定的低电平周期开始计数宽度,一旦低电平宽度计数完成,则停止驱动I3C_SCL线（释放线）。SCL时钟由此产生。

I 2 C总线上连接多个主设备,则由于与另一个主设备的争用,可能会出现SCL信号的碰撞。在这种情况下,主设备必须同步其 SCL 信号。SCL信号的这种同步由于必须是逐位的,所以I3C配备了一个设施（SCL同步电路）,在主模式下通过监视I3C_SCL线路来获得SCL时钟信号的逐位同步。

I3C 已检测到 I3C_SCL 线上的一条上升沿并因此开始计算 STDBR。SBRHO[7:0] 中指定的高电平宽度时,I3C_SCL 线上的电平下降是因为另一个主设备正在生成 SCL 信号,I3C 检测到下降沿时停止计数,将 I3C_SCL 线上的电平驱动至低电平, 并开始计算 STDBR。SBRLO [7:0] 中指定的低电平宽度。I3C在低电平完成数出宽度时,它停止将I3C_SCL线驱动到低电平（释放线）。此时,如果来自另一主设备的SCL时钟信号的低电平宽度长于该模块中设置的低电平宽度,则SCL信号的低电平宽度将被扩展。一旦其他主设备的低电平宽度结束,SCL 信号就会上升,因为 I3C_SCL 线路已释放。I3C完成输出SCL时钟的低电平周期时,I3C_SCL线被释放,SCL时钟上升。也就是说,在来自多个主机的SCL信号的争用的情况下,SCL信号的高电平宽度与具有较窄宽度的时钟的宽度同步,并且SCL信号的低电平宽度与具有较宽宽度的时钟的宽度同步。然而,只有当BFCTL中的SCSYNE位设置为1时,才启用SCL信号的这种同步。

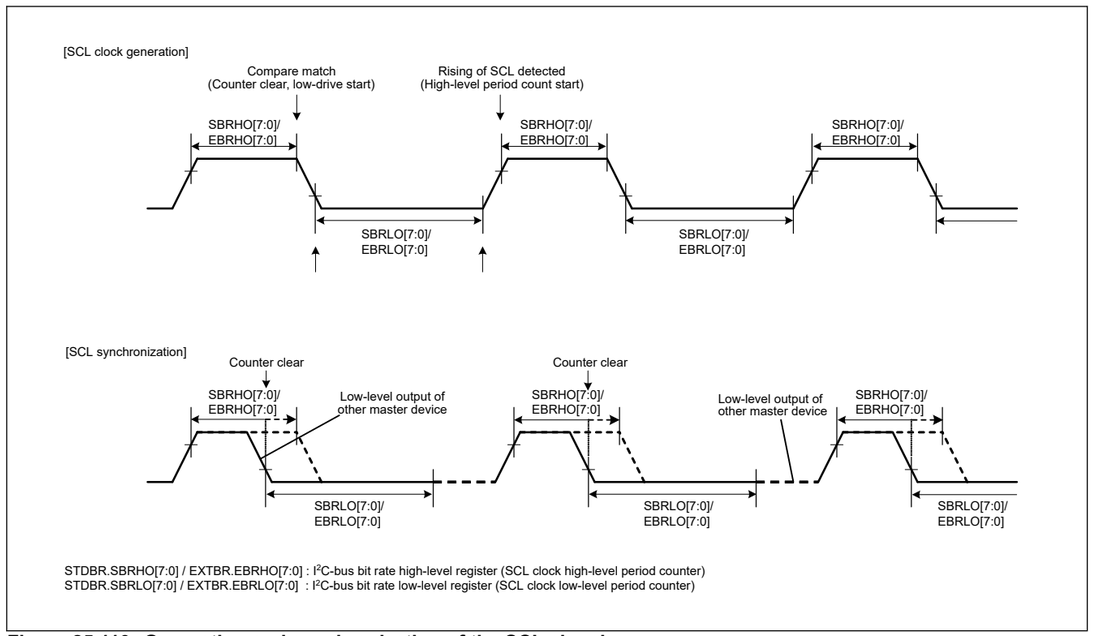

Figure 25.110 Generation and synchronization of the SCL signal

25.3.2.6.2 Facility for Delaying SDA Output [I2C mode]

I3C module incorporates a facility for delaying output on the SDA line. The delay can be applied to all output (issuing of the START, Repeated START, and STOP conditions, data, and the ACK and NACK signals) on the SDA line.

With the SDA output delay facility, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL clock is at the low level. Doing this leads to usage with the aim of preventing erroneous operation of communications devices, with the aim of satisfying the 300 ns (minimum) data-hold time requirement of the SMBus specification.

The output delay facility is enabled by setting the SDOD[2:0] bits in OUTCTL to any value other than 000b, and disabled by setting the same bits to 000b.

While the SDA output delay facility is enabled (while the SDOD[2:0] bits in OUTCTL are set to any value other than 000b), the SDODCS bit in OUTCTL selects the clock source for counting by the SDA output delay counter as the internal base clock (I3Cφ) for I3C module or as a clock signal derived by dividing the frequency of the internal base clock by two (I3Cφ/2). The counter counts the number of cycles set in the SDOD[2:0] bits in OUTCTL. After counting of the set number of cycles of delay is completed, I3C module places the required output (START, Repeated START, or STOP condition, data, or an ACK or NACK signal) on the SDA line.

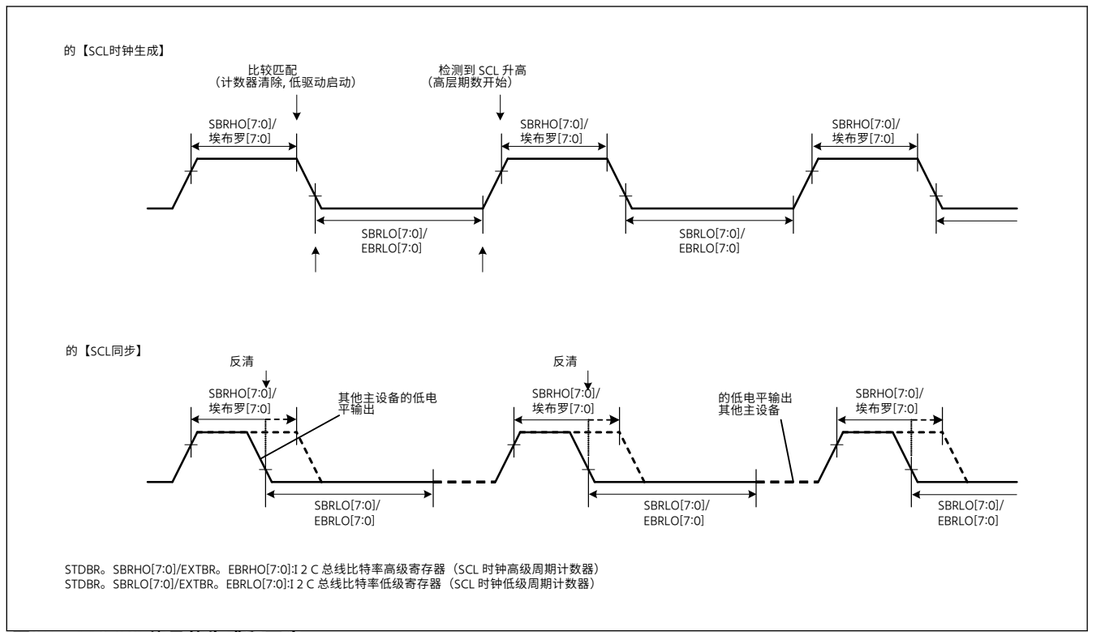

图25。110 SCL信号的生成和同步

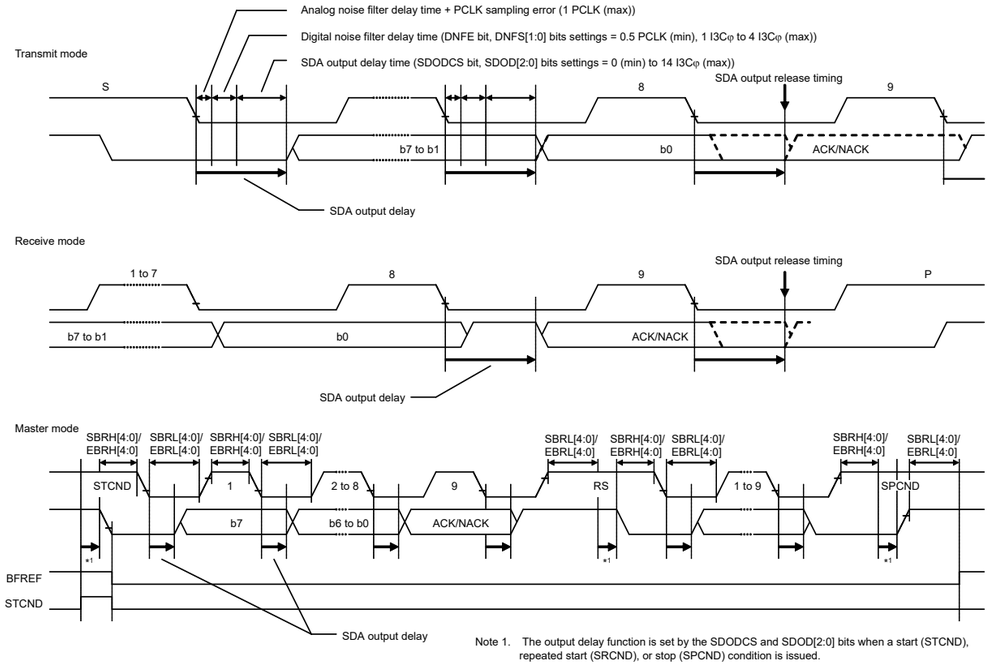
25.3.2.6.2 用于延迟 SDA 输出的设施 [I 2 C 模式]

I3C 模块包含用于延迟 SDA 线路输出的设施。该延迟可以应用于 SDA 线路上的所有输出（发出 START、重复 START 和 STOP 条件、数据以及 ACK 和 NACK 信号）。

利用SDA输出延迟设施,SDA输出从检测到SCL信号的下降沿而被延迟,以确保SDA信号在SCL时钟处于低电平的间隔内输出。这样做会导致使用,以防止通信设备的错误操作,以满足 SMBus 规范的 300 ns（最小）数据保持时间要求。

OUTCTL中的SDOD[2:0]位设置为000b以外的任何值来启用输出延迟设施,并通过将相同的位设置为000b来禁用。

SDA 输出延迟设施启用时（而 OUTCTL 中的 SDOD[2:0] 位设置为 000b 以外的任何值）, OUTCTL中的SDODCS位选择时钟源,用于由SDA输出延迟计数器计数为I3C模块的内部基时钟（I3Cφ）或作为内部基时钟的频率除以二（I3Cφ/2)得出的时钟信号。计数器对 OUTCTL 中 SDOD[2:0] 位中设置的周期数进行计数。I3C 模块在完成对设定的延迟周期数的计数后,将所需的输出（START、重复 START 或 STOP 条件、数据或 ACK 或 NACK 信号）放置在 SDA 线上。



Note 1. The output delay function is set by the SDODCS and SDOD[2:0] bits when a start (STCND), repeated start (SRCND), or stop (SPCND) condition is issued.

25.3.2.6.3 Digital Noise-Filter Circuits [I²C mode]

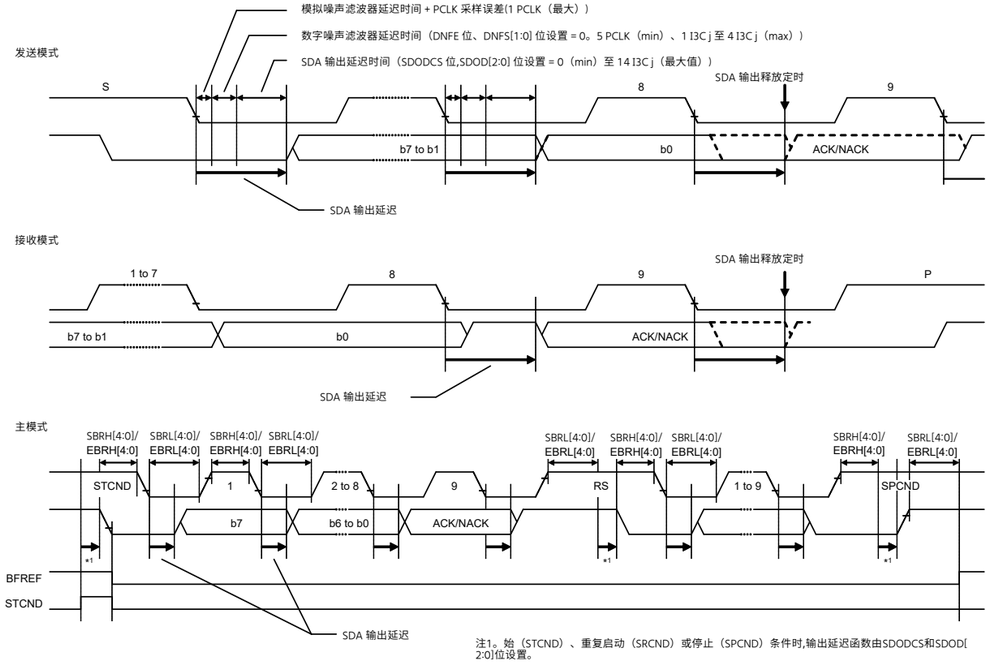
The states of the I3C_SCL and I3C_SDA pins are conveyed to the internal circuitry through digital noise-filter circuits. Figure 25.112 is a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of I3C consists of 16 flip-flop circuit stages connected in series and a match detection circuit. When HS mode is selected, only the first four flip-flop circuits stages are enabled.

The number of effective stages in the digital noise filter is selected by the INCTL.DNFS[3:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to sixteen I3Cφ cycles.

The input signal to the I3C_SCL pin (or I3C_SDA pin) is sampled on rising edges of the I3Cφ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the INCTL.DNFS[3:0] bits, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (TCLK) and the transfer rate is small (For example, data transfer at 400 kbps with TCLK = 4 MHz), the characteristics of the digital noise filter may lead to the elimination of needed signals as noise.



注1。始（STCND）、重复启动（SRCND）或停止（SPCND）条件时,输出延迟函数由SDODCS和SDOD[2:0]位设置。

25.3.2.6.3 数字噪声滤波器电路 [I 2 C 模式]

I3C_SCL和I3C_SDA引脚的状态通过数字噪声滤波电路传送到内部电路。
图25。112是数字噪声滤波器电路的框图。

I3C的片上数字噪声滤波电路由16个串联的触发器电路级和一个匹配检测电路组成。HS 模式时,仅启用前四个触发器电路级。

数字噪声滤波器中的有效级数由INCTL。DNFS[3:0]位选择。所选的有效级数将噪声滤波能力确定为一到十六个 I 3Cφ 周期。

I3C_SCL引脚（或I3C_SDA引脚）的输入信号在I3Cφ信号的上升沿上采样。当输入信号电平与INCTL。DNFS[3:0]位选择的有效触发器电路级数的输出电平匹配时,信号电平被传送到后续级。如果信号电平不匹配,则保留前一个值。

如果内部工作时钟（TCLK）的频率与传输速率之间的比率较小（例如,TCLK = 4 MHz 的 400 kbps 数据传输），则数字噪声滤波器的特性可能会导致消除所需的信号作为噪声。

25.3.3.1 Initial Setting Flow

25.3.3.1.1 I²C Initial Setting Flow (Single Buffer Transfer)

Before starting data transmission and reception, initialize I3C according to the procedure in Figure 25.113.

First, set the BCTL.BUSE bit to 0 (I3C_SCL, I3C_SDA pins not driven).

Next, set the RSTCTL.RI3CRST bit to 1 (I3C reset). This initializes the all registers and internal state. Then, waits for RI3CRST to become 0.

This initializes the various flags and some registers. See section 25.6. Reset Description.

After that, set registers SDATBAS.SDADLS, SDATBAS.SDATAD[9:0], STDBR, INCTL, OUTCTL, TMOCTL, TMOCNT, SCSTRCTL, ACKCTL, and BFCTL, then set the other registers as necessary (for initial settings of I3C, see Figure 25.113).

25。3。3 操作

25。3。3。1 初始设置流程

25.3.3.1.1 I 2 C 初始设置流量（单缓冲区传输）

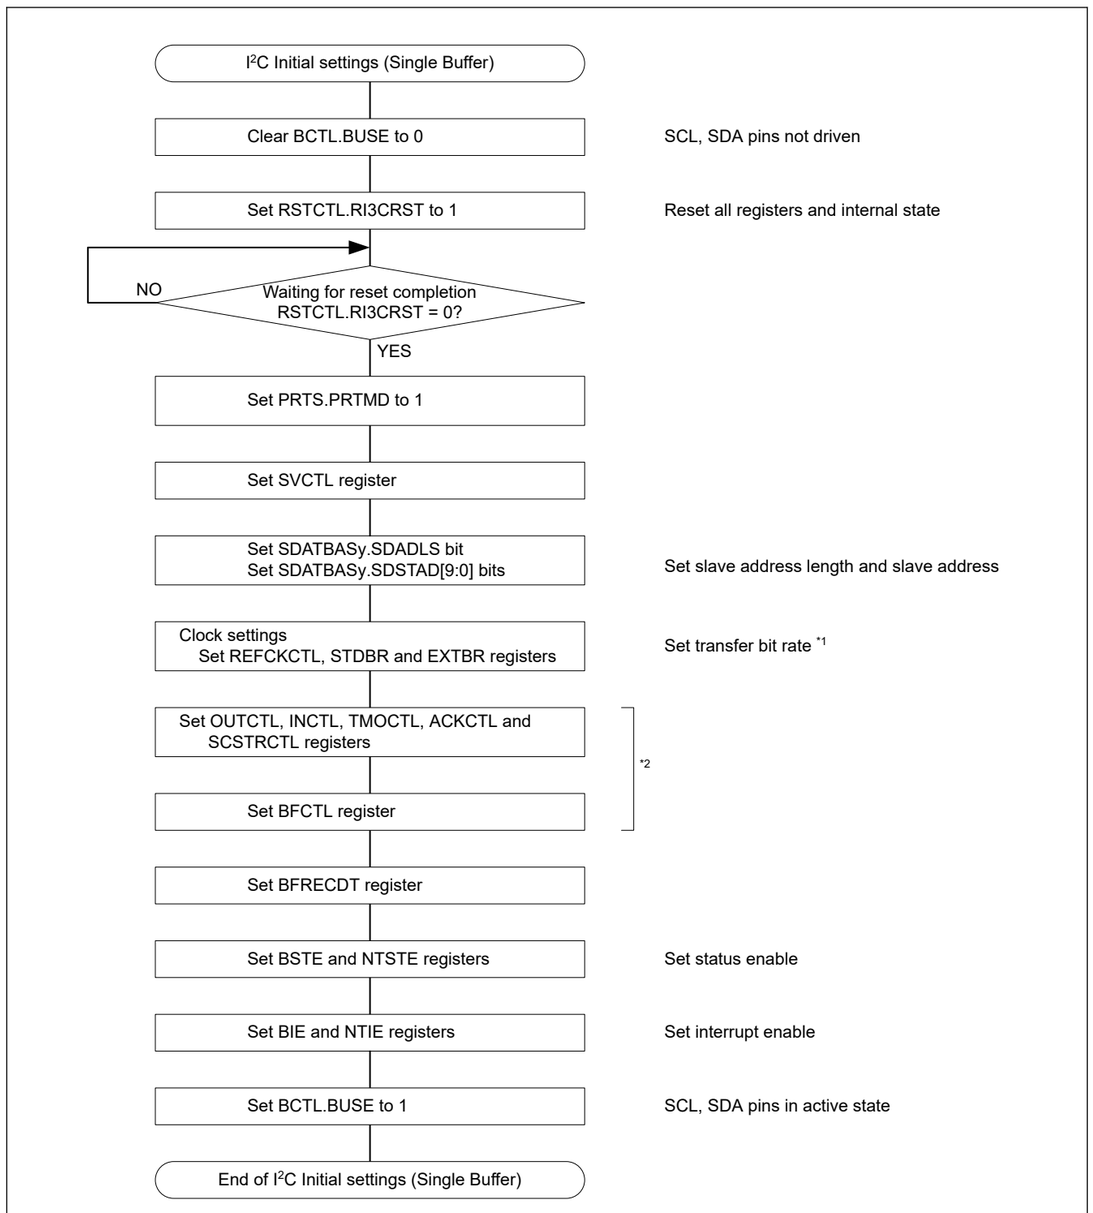
在开始数据传输和接收之前,根据图 25。113 . 中的过程初始化 I3C

首先,将 BCTL。BUSE 位设置为 0（I3C_SCL、I3C_SDA 引脚未驱动）。

接下来,将 RSTCTL。RI3CRST 位设置为 1（I3C 重置）。这初始化了所有寄存器和内部状态。然后,等待RI3CRST变为0。

这初始化了各种标志和一些寄存器。参见第 25。6 节。重置说明 .

之后,设置寄存器SDATBAS。SDADLS、SDATBAS。SDATAD[9:0]、STDBR、INCTL、OUTCTL、TMOCTL、TMOCNT、SCSTRCTL、ACKCTL和BFCTL,然后根据需要设置其他寄存器（对于I3C的初始设置,参见图25。113)。



Note: y = 0 to 2
Note 1. When the I3C is used only in slave mode, set the STDBR register to a value longer than the data setup time.
Note 2. Set these registers as necessary.

注1。I3C 仅在从模式下使用时,将 STDBR 寄存器设置为比数据设置时间更长的值。

25.3.3.2 I3C Communication Flow

Figure 25.115 illustrates how I3C communication is initiated:

- All I3C communication occurs within a frame. The frame begins with a START, followed by one or more transfers, and a STOP.

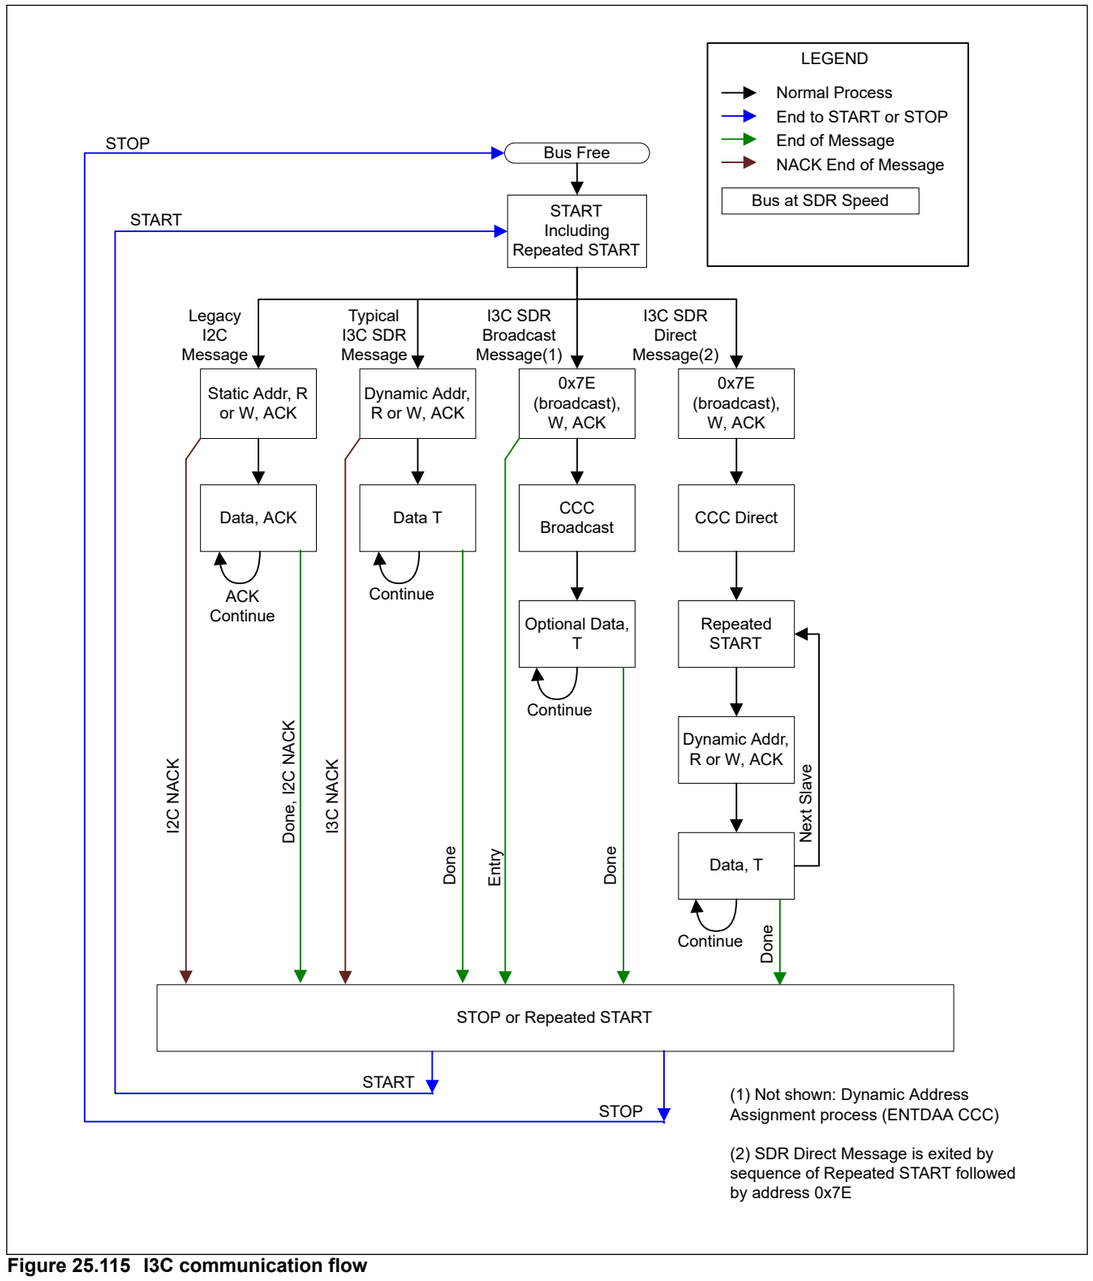

Figure 25.115 I3C communication flow

I3C is based on a frame encapsulation approach. A frame includes a data payload. The transfer protocol for the data payload is either SDR. Frames are bordered by I^2C-like bus management.

25。3。3。2 I3C 通信流程

25。115 说明了 I3C 通信是如何启动的:

● 所有I3C通信都发生在一个帧内。该帧以 START 开始,然后是一次或多次传输和一次 STOP。

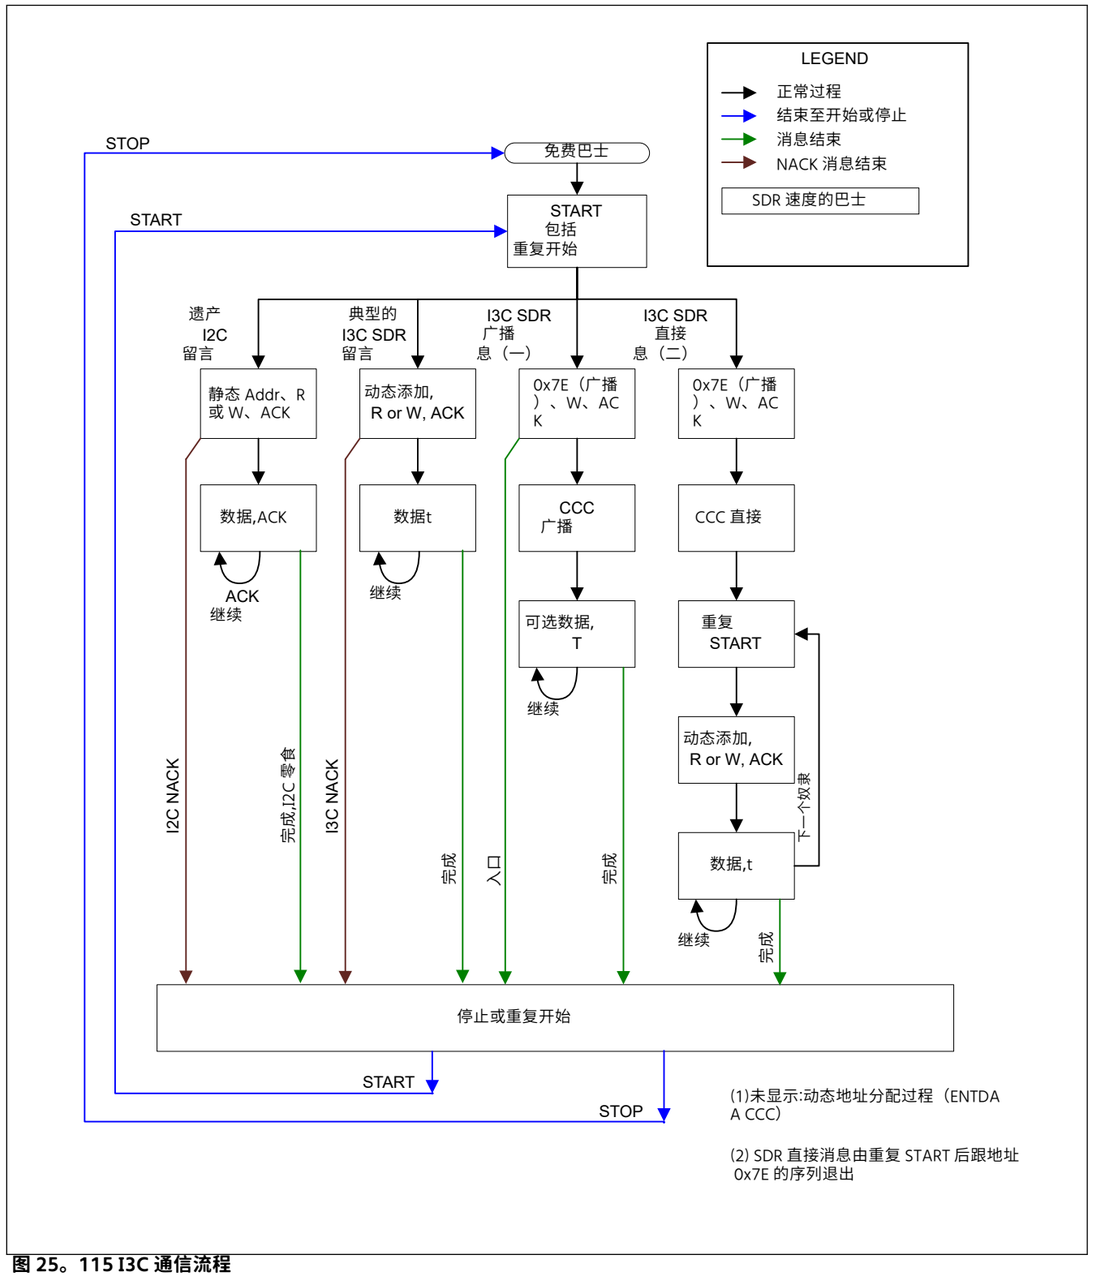

图 25。115 I3C 通信流程

I3C基于帧封装方法。帧包括数据有效负载。数据有效负载的传输协议是 SDR。帧以 I 2 C 样总线管理为边界。

The I3C frame always includes at least the START, the Header, the Data, and the STOP. The Header following a START allows for Bus Arbitration. The Master uses the Header to address Slave device (s). Slave devices (s) may use the Header Arbitration for multiple purposes: for In-Band Interrupt and for Secondary Master functionality.

I3C allows only one Master to have control of the I3C bus at a time. Mechanisms for handoff of the Master role from one device to another device are provided.

I3C 帧总是至少包括 START、标头、数据和 STOP。START 后面的标头允许总线仲裁。Master 使用标头来寻址从属设备。从设备可以将标头仲裁用于多种目的:用于带内中断和辅助主功能。

I3C一次只允许一个Master控制I3C总线。提供了将主角色从一个设备移交给另一设备的机制。

Note: There is a delay time between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared, read the relevant flag again to check whether clearing has been completed, and then return from interrupt handling. Returning from interrupt handling without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.

For I2C Protocol mode:

- Since I3C_TX is an edge-detected interrupted, it does not require clearing. Furthermore, the NTST.TDBEF0 flag (a condition for I3C_TX) is automatically set to 0 when data for transmission are written to NTDTBP0 or a STOP condition is detected (SPCNDDF flag = 1 in BST).

- Since I3C_RX is an edge-detected interrupted, it does not require clearing. Furthermore, the NTST.RDBFF0 flag (a condition for I3C_RX) is automatically set to 0 when data are read from NTDTBP0.

For I3C Protocol mode:

For details, refer to the detailed explanation of each flag bit.

注: CPU执行外设模块的写入指令与实际写入模块之间存在延迟时间。因此,当中断标志被清除时,再次读取相关标志以检查是否已完成清除,然后从中断处理返回。从中断处理返回而不检查对模块的写入是否已完成会产生重复处理同一中断的可能性。

I2C协议模式而言:

I3C_TX由于是边缘检测到的中断,因此不需要清除。此外,当用于传输的数据写入NTDTBP0或检测到STOP条件（SPCNDDF标志=BST中的1)时,NTST。TDBEF0标志（I3C_TX的条件）自动设置为0。

I3C_RX由于是边缘检测到的中断,因此不需要清除。此外,当从NTDTBP0读取数据时,NTST。RDBFF0标志（I3C_RX的条件）自动设置为0。I3C协议模式而言:

详情请参阅各标志位的详细说明。

- The I3C_CMD, I3C_TX, I3C_HCMD, I3C_HTX and I3C_IBI (I3C Slave) interrupts are cleared under the following conditions.
  On completaion of the last write accsess by DMAC/DTC.
  Write 0 to this bit after 1 state is read by CPU.
- The I3C_RESP, I3C_IBI (I3C Master), I3C_RX, I3C_RCV, I3C_HRESP and I3C_HRX interrupts are cleared under the following conditions.
  On completaion of the last read accsess by DMAC/DTC.
  Write 0 to this bit after 1 state is read by CPU.

25.4.2 Buffer Operation for Buffer Full/Empty Interrupts

If the conditions for generating the each buffer full/empty interrupts are satisfied while the corresponding IR flag is 1, the interrupt request is not output for the ICU but retained internally (the capacity for internal retention is one request per source).

An interrupt request that was being retained within the ICU is output when the value of the IELSRn.IR flag becomes 0. Internally retained interrupt requests are automatically cleared under normal conditions of usage. Internally retained interrupt requests can also be cleared by writing 0 to the interrupt enable bit within the given peripheral module.

25.5 Event Link Output

I3C handles event output for the event link controller (ELC) corresponding to the following sources.

(1) Communication event

When a Communication event (arbitration-lost detection, detection of NACK, detection of timeout, detection of a START condition, or detection of a STOP condition) occurs, the corresponding event signal can be output for another module via the ELC.

(2) Receive data full

When a receive data register becomes full, the corresponding event signal can be output for another module via the ELC.

(3) Transmit data empty

When a transmit data register becomes empty, the corresponding event signal can be output for another module via the ELC.

(4) Transmit end

On completion of transfer, the corresponding event signal can be output for another module via the ELC.

25.5.1 Interrupt Handling and Event Linking

I3C module produces four kinds of interrupt: communication event (arbitration-lost detection, detection of NACK, detection of timeout, detection of a START condition, or detection of a STOP condition), receive data full, transmit data empty, and transmit end interrupts. Each of these has an enable bit to control enabling and disabling of the interrupt signal. An interrupt request signal is output for the CPU when an interrupt source condition is satisfied while the setting of the corresponding enable bit is enabled.

The corresponding event link output signals are sent to other modules as event signals via the ELC when the interrupt source conditions are satisfied, regardless of the settings of the interrupt enable bits. For details on interrupt sources, see section 25.4.1. Overview.

- I3C_CMD、I3C_TX、I3C_HCMD、I3C_HTX 和 I3C_IBI（I3C 从机）中断在以下条件下被清除。

  DMAC/DTC 完成最后的写入访问后。
  CPU读取1状态后将0写入此位。

- I3C_RESP、I3C_IBI（I3C Master）、I3C_RX、I3C_RCV、I3C_HRESP 和 I3C_HRX 中断在以下条件下被清除。

  完成 DMAC/DTC 的最后一次阅读访问后。
  CPU读取1状态后将0写入此位。

25.4.2 缓冲区全/空中断的缓冲区操作

如果在相应的IR标志为1时满足生成每个缓冲区满/空中断的条件,则中断请求不是为ICU输出而是保留在内部（内部保留的容量为每个源一个请求）。

当 IELSRn。IR 标志的值变为 0 时,会输出 ICU 内保留的中断请求。
内部保留的中断请求在正常使用条件下会自动清除。内部保留的中断请求也可以通过在给定的外围模块内写入 0 到中断使能位来清除。

25。5 事件链接输出

I3C 为事件链路控制器（ELC）处理与以下源相对应的事件输出。

（一）交流活动

当发生通信事件（仲裁丢失检测、NACK检测、超时检测、START条件检测或STOP条件检测）时,可以通过ELC为另一个模块输出相应的事件信号。

(2)接收数据全

当接收数据寄存器变满时,可以通过ELC为另一个模块输出相应的事件信号。

(3)传送数据为空

当发送数据寄存器变空时,可以通过ELC为另一个模块输出相应的事件信号。

(4)发送端

传输完成后,可以通过ELC为另一个模块输出相应的事件信号。

25.5.1 中断处理和事件链接

I3C模块产生四种中断:通信事件（仲裁丢失检测、检测NACK、检测超时、检测START条件或检测STOP条件）、接收满数据、发送数据空、发送端中断。其中每一个都有一个使能位来控制中断信号的启用和禁用。当满足中断源条件同时启用相应使能位的设置时,为CPU输出中断请求信号。

当满足中断源条件时,无论中断使能位的设置如何,相应的事件链路输出信号都通过ELC作为事件信号发送到其他模块。有关中断源的详细信息,请参阅第 25。4。1 节。概述 .

This RAM is used to store messages after reception or for transmission using a normal message buffer or a FIFO. Each message entry has an individual ID, data length code, data field, message pointer for upper layer application usage and a time stamp.
This RAM is used to store the message acceptance filtering entries. Each acceptance filter entry has an individual ID, data length code, data field, message pointer for upper layer application usage and message direction pointer.

- Acceptance filter:
  Performs filtering of received messages. The entries in the Acceptance filter list RAM are used for the filtering process.
- Two timers:
  - Reception Timestamp function
  - Transmission separation time for FIFO buffers
- Interrupt generator:
  Generates several types of global and channel interrupts
- CAN Special Function Registers (SFRs):
  Registers associated with CAN. See section 26.2. Register Descriptions.

26.1.2 Clock restriction

For the CAN communication the following restriction for the clocks should be satisfied:

- PCLKA / 2 = PCLKB ≥ CANFDCLK
- PCLKA / 2 = PCLKB ≥ CANMCLK

To avoid missing events the CAN engine clock (CANFDCLK or CANMCLK) frequency must be less than the PCLKB clock frequency.

To avoid loss of CAN message, the PCLKB should be set to a clock with a frequacy depend on the CAN communication Baud Rate. The constraint of a baud rate and a PCLKB clock is shown in Table 26.2.

Table 26.2 Clock restriction

	Baud rate	PCLKB
CANFD	1Mbps Nominal 5Mbps Data	PCLKB ≥ 40MHz
	500Kbps Nominall 5Mbps Data	PCLKB ≥ 32MHz
Classical CAN	1Mbps Data	PCLKB ≥ 32MHz

The frequency of CANFD and CANMCLK depend on the required baud rate. For information how to configure the baud rate, refer to section 26.4.1.3. Baud Rate.

26.2 Register Descriptions

26.2.1 Register Table

The reset value shown for the RAM area, consisting of CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r, CFDRMBCPb, CFDRFMBCPb, CFDCFMBCP0, CFDTMBCPb, CFDTHLACC0, CFDTHLACC1 and CFDRPGACCk is valid after initialization of a hardware reset. See section 26.4.2. CAN Module Configuration after Hardware Reset for details of the initialization process.

If a write access with a size of 8 or 16 bits is performed for the RAM area, then the CANFD module does a read-modify write-access to the RAM location, because the RAM requires a 32-bit access through the ECC module.

For single bit error, the correct data is written back. For multiple bit errors, unknown data is written back.

Do not access the space where the register is not assigned.

The read data from the space where the register is not assigned is unknown.

该RAM用于存储接收后的消息或使用普通消息缓冲区或FIFO进行传输。每个消息条目都有一个单独的ID、数据长度代码、数据字段、用于上层应用程序使用的消息指针和一个时间戳。

该RAM用于存储消息接受过滤条目。每个接受过滤器条目都有一个单独的ID、数据长度代码、数据字段、用于上层应用程序使用的消息指针和消息方向指针。

- 验收过滤器:
  对接收到的消息进行过滤。接受过滤器列表 RAM 中的条目用于过滤过程。
- 两个定时器:
  - 接收时间戳功能
  - FIFO 缓冲器的传输分离时间
- 中断生成器:
  生成多种类型的全局中断和信道中断
- CAN 特殊功能寄存器（SFR）：
  CAN 相关的寄存器。参见第 26。2 节。注册说明 .

26.1.2 时钟限制

对于 CAN 通信,应满足以下时钟限制:

- PCLKA / 2 = PCLKB ≥ CANFDCLK
- PCLKA / 2 = PCLKB ≥ CANMCLK

为了避免丢失事件,CAN 引擎时钟（CANFDCLK 或 CANMCLK）频率必须小于 PCLKB 时钟频率。

为了避免丢失 CAN 消息,PCLKB 应设置为频率取决于 CAN 通信波特率的时钟。波特率和PCLKB时钟的约束如表 26。2 .所示

表 26。2 时钟限制

	波特率	PCLKB
CANFD	1Mbps 标称 5Mbps 数据	PCLKB ≥ 40MHz
	500Kbps 名义 5Mbps 数据	PCLKB ≥ 32MHz
古典罐头	1Mbps 数据	PCLKB ≥ 32MHz

CANFD 和 CANMCLK 的频率取决于所需的波特率。有关如何配置波特率的信息,请参阅第 26。4。1。3 节。波特率 .

26。2 寄存器说明

26。2。1 登记表

由CFDGAFLIDr、CFDGAFLMr、CFDGAFLP0r、CFDGAFLP1r、CFDRMBCPb、CFDRFMBCPb、CFDCFMBCP0、CFDTMBCPb、CFDTHLACC0、CFDTHLACC1和CFDRPGACCk组成的RAM区域显示的重置值在硬件重置初始化后有效。参见第 26。4。2 节。硬件重置后的 CAN 模块配置,了解初始化过程的详细信息。

如果对RAM区域执行大小为8或16位的写访问,则CANFD模块对RAM位置进行读修改写访问,因为RAM需要通过ECC模块进行32位访问。

对于单位错误,正确的数据将被写回。对于多个比特错误,将写回未知数据。

请勿访问未分配寄存器的空间。

从未分配寄存器的空间读取的数据未知。

26.2.2 Legend

For all repetitive registers and bits, a lowercase index is used to indicate which slice is being referenced. If an index is being used, it is defined and described in the Register table it is being used in.

There is one global index used across all the registers and bits that need it.

Note: Tq means time quantum.

This register configures the transmission/reception nominal baud rate parameters of the channels.

NBRP[9:0] bits (Channel Nominal Baud Rate Prescaler)

The NBRP[9:0] bits are used to define the peripheral bus clock periods contained in a time quantum.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

NSJW[6:0] bits (Resynchronization Jump Width)

The NSJW[6:0] bits set the synchronization jump width. A value from 1 to 128 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

NTSEG1[7:0] bits (Timing Segment 1)

The NTSEG1[7:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. These bits contain the propagation segment.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

Additionally, configure a Tq value only between 2 and 256, inclusive. See section 26.4.1.2. CAN Bit Timing for more details.

注: Tq表示时间量子。

该寄存器配置信道的传输/接收标称波特率参数。

NBRP[9:0] 位（通道标称波特率预分频器）

NBRP[9:0]位用于定义时间量子中包含的外围总线时钟周期。

CH_OPERATION 或 CH_SLEEP 模式下请勿写入这些位。

CANFD 通道处于 CH_RESET 或 CH_HALT 模式时才写入这些位。

NSJW[6:0] 位（重新同步跳跃宽度）

NSJW[6:0]位设置同步跳跃宽度。1到128个时间量子可以设定一个值。

CH_OPERATION 或 CH_SLEEP 模式下请勿写入这些位。

CANFD 通道处于 CH_RESET 或 CH_HALT 模式时才写入这些位。

NTSEG1[7:0] 位（定时段 1）

NTSEG1[7:0] 位设置段 TSEG1 以补偿 CAN 总线上具有正相位误差的边。这些位包含传播段。

CH_OPERATION 或 CH_SLEEP 模式下请勿写入这些位。

CANFD 通道处于 CH_RESET 或 CH_HALT 模式时才写入这些位。

此外,仅将 Tq 值配置在 2 到 256（含）之间。参见第 26。4。1。2 节。CAN 位定时以获取更多详细信息。

NTSEG2[6:0] bits (Timing Segment 2)

The NTSEG2[6:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

Additionally, configure a Tq value only between 2 and 128, inclusive.

Note 1. These bits are not available in the classical CAN function.

Channel Control register controls the modes of the related channel. It is used to enable generation of interrupts if errors are detected on the CAN bus connected to this channel. It is also used to configure the channel in test mode.

CHMDC[1:0] bits (Channel Mode Control)

The CHMDC[1:0] bits can be used to configure modes of the CAN channel.

CAN mode transitions are described in more details in section 26.3.3. Channel Modes.

Setting CHMDC[1:0] bits to 11b has no effect. When the CANFD module is in GL_HALT mode, these bits can only be set to 10b or 01b. These bits cannot be set in CH_SLEEP mode.

These bits can change automatically when transitioning to Halt mode by the CFDC0CTR.BOM settings.

If CPU write access to CFDC0CTR.CHMDC occurs at the same time when the CAN channel enters Halt mode (at the start of bus-off when CFDC0CTR.BOM = 01b, or at the end of bus-off when CFDC0CTR.BOM = 10b), then the CPU write access has the highest priority.

The CAN channel changes the value of CFDC0CTR.CHMDC within the Channel Control Registers for the specified cases only if the CFDC0CTR.CHMDC value is 00b (Operation mode).

注1。这些位在经典 CAN 函数中不可用。

信道控制寄存器控制相关信道的模式。它用于在连接到该通道的 CAN 总线上检测到错误时启用中断的生成。它还用于在测试模式下配置通道。

CHMDC[1:0] 位（信道模式控制）

CHMDC[1:0] 位可用于配置 CAN 通道的模式。

CAN 模式转换在第 26。3。3 节中有更详细的描述。通道模式 .

CHMDC[1:0]位设置为11b是没有效果的。CANFD模块处于GL_HALT模式时,这些位只能设置为10b或01b。CH_SLEEP模式下无法设置这些位。

当通过 CFDC0CTR。BOM 设置过渡到停止模式时,这些位可以自动更改。

CAN信道进入停止模式时（在总线关闭开始时CFDC0CTR。BOM = 01b,或在总线关闭结束时CFDC0CTR。BOM = 10b）,如果CPU写入访问CFDC0CTR。CHMDC同时发生,则CPU写入访问具有最高优先级。

仅当CFDC0CTR。CHMDC值为00b（操作模式）时,CAN信道才会针对指定情况改变信道控制寄存器内的CFDC0CTR。CHMDC的值。

CSLPR bit (Channel Sleep Request)

When the CSLPR bit is 1, a Sleep mode request is generated for the corresponding CAN channel

When this bit is 0, a request to exit Sleep mode is generated for the related CANFD channel.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

RTBO bit (Return from Bus-Off)

When the protocol controller of the CAN channel enters bus-off state, you can force a recovery from bus-off state by setting the RTBO bit in the Channel Control Register to 1.

The error state changes from bus-off state to integrating with a maximum delay of 1 CAN bit time.

When the RTBO bit is set to 1, the REC and TEC registers are initialized and the Bus-Off Status bit (Channel Bus-off Status, CFDC0STS.BOSTS) is set to 0.

Registers other than the REC and TEC registers are not initialized by this command. Even if CFDC0CTR.BORIE is set, a bus-off recovery interrupt is not generated by this recovery from the bus-off state.

The RTBO bit cannot be set in CH_SLEEP mode. Setting this bit in any state other than bus-off state has no effect and the bit is cleared immediately. The read value is always 0.

Return from the Bus-Off command should be used only when CFDC0CTR.BOM is set to 00b.

Only write to this bit when the related CANFD channel is in CH_OPERATION mode. This bit is automatically cleared when set by software.

BEIE bit (Bus Error Interrupt Enable)

RTBO 位（从总线关闭返回）

CAN信道的协议控制器进入总线关闭状态时,可以通过将信道控制寄存器中的RTBO位设置为1来强制从总线关闭状态恢复。

错误状态从总线关闭状态更改为集成,最大延迟为 1 CAN 位时间。

当RTBO位设置为1时,REC和TEC寄存器被初始化并且总线关闭状态位（信道总线关闭状态,CFDC0STS。BOSTS）被设置为0。

REC和TEC寄存器以外的寄存器不是由该命令初始化的。即使设置了CFDC0CTR。BORIE,从总线关闭状态恢复也不会生成总线关闭恢复中断。

RTBO位不能在CH_SLEEP模式下设置。将此位设置为总线关闭状态以外的任何状态都不会产生任何影响,并且该位会立即清除。读取值始终为 0。

仅当 CFDC0CTR。BOM 设置为 00b 时,才应使用从 Bus-Off 命令返回。

CH_OPERATION 模式时, 相关 CANFD 通道才写入此位。当软件设置时,该位会自动清除。

Do not write to these bits in CH_SLEEP mode. Only write to these bits when the related CANFD channel is in CH_RESET mode.

Only write to these bits when the related CANFD channel is in CH_RESET mode.

ERRD bit (Channel Error Display)

The ERRD bit controls the display mode of the error flag bits [14:8] in the Channel Error Flag Register (CFDC0ERFL).

If the ERRD bit is 0 and more than one error occur at the same time, the error flag bits are set for all the errors that occurred at the same time. No further errors are flagged until CFDC0ERFL[14:8] is cleared.

Do not write to the ERRD bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

CTME bit (Channel Test Mode Enable)

注意:该位在经典 CAN 函数中不可用。

BOM[1:0] 位（信道总线关闭模式）

BOM[1:0]位控制从CANFD信道的Bus-Off模式恢复的时序。

CH_SLEEP 模式下不要写入这些位。仅当相关 CANFD 通道处于 CH_RESET 模式时才写入这些位。

仅当相关 CANFD 通道处于 CH_RESET 模式时才写入这些位。

ERRD 位（信道错误显示）

ERRD位控制信道错误标志寄存器（CFDC0ERFL）中错误标志位[14:8]的显示模式。

ERRD位为0且同时发生多于一个错误,则为同时发生的所有错误设置错误标志位。在 CFDC0ERFL[14:8] 被清除之前,不会标记进一步的错误。

CH_SLEEP 模式下不要写入此位。CANFD 相关通道处于 CH_HALT 模式时才写入此位。

CTMS[1:0] bits (Channel Test Mode Select)

The CTMS[1:0] bits are used to select the required test mode.

Do not write to these bits in CH_SLEEP or CH_RESET mode. Only write to these bits when the related CANFD channel is in CH_HALT mode.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

BFT bit (Bit Flip Test)

The BFT bit checks the internal CRC generator logic of the protocol controller.

It inverts the first bit (ID bit) of the CAN message data stream being received, so that the internal generated CRC result will not match the received CRC value of the frame. Refer to the bit stuffing rule, when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The internal generated CRC value is always observed in the following registers:

- CFDC0ERFL.CRCREG (Classical CAN frames)
- CFDC0FDCRC.CRCREG (CANFD frames).*1

Note 1. This feature is not available in the classical CAN function.

Some restriction exist when using this bit:

Other CAN node will send a reference message and the receiver node(s) can invert one bit of incoming bit stream.

Note: The transmitter and receiver modes share the same CRC generator, therefore it is not necessary to consider the modes separately when testing.

The Bit Flip test mode is enabled if the BFT (new control signal that inverts the first bit of the bit stream) and CTME bits are both 1 and CFDC0CTR.CTMS is 0x00.

If this function is used by a transmitting node, a bit error or an arbitration lost will occur.

Do not write to the BFT bit in CH_SLEEP mode. Users should not use this function when the Self test mode 1 (Internal Loop back mode). Only write to this bit when the related CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

ROM bit (Restricted Operation Mode)

When the ROM and CTME bits are both 1, the restricted operation mode is enabled. This mode should only be used in basic test mode (CFDC0CTR.CTMS[1:0] = 00b).

The ROM bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. Do not set this bit when in Classical CAN mode.

Note: This bit is not available in the classical CAN function.

CTMS[1:0] 位（信道测试模式选择）

CTMS[1:0]位用于选择所需的测试模式。

CH_SLEEP 或 CH_RESET 模式下不要写入这些位。CH_HALT模式时才写入到这些位。

当相关的 CANFD 通道处于 CH_RESET 模式时,这些位会自动清除。

BFT 位（位翻转测试）

BFT 位检查协议控制器的内部 CRC 生成器逻辑。

它反转正在接收的CAN消息数据流的第一位（ID位）,使得内部生成的CRC结果将与接收到的帧的CRC值不匹配。使用此功能时,请参阅位填充规则,因为可能会收到填充错误（由于反转）而不是 CRC 错误。内部生成的 CRC 值始终在以下寄存器中观察到:

● CFDC0ERFL。CRCREG（经典 CAN 帧）

● CFDC0FDCRC。CRCREG（CANFD 帧）。*1 注 1。此功能在经典 CAN 函数中不可用。

使用此位时存在一些限制:

其他 CAN 节点将发送参考消息,并且接收器节点可以反转一位传入比特流。

注:发射机和接收机模式共享相同的CRC发生器,因此测试时无需单独考虑模式。

如果 BFT（反转比特流第一比特的新控制信号）和 CTME 比特均为 1,并且 CFDC0CTR。CTMS 为 0x00,则启用比特翻转测试模式。

如果发送节点使用此函数,则会发生误码或仲裁丢失。

CH_SLEEP 模式下不要写入到 BFT 位。Self 测试模式 1（内部循环返回模式）时,用户不应使用此功能。CANFD 相关通道处于 CH_HALT 模式时才写入此位。

当相关的 CANFD 通道处于 CH_RESET 模式时,该位会自动清除。

ROM位（限制操作模式）

ROM 和 CTME 位均为 1 时, 启用受限操作模式。此模式只能在基本测试模式下使用（CFDC0CTR。CTMS[1:0] = 00b）。

CH_SLEEP 模式下无法设置 ROM 位。CANFD 相关通道处于 CH_HALT 模式时才写入此位。

当相关的 CANFD 通道处于 CH_RESET 模式时,该位会自动清除。在经典 CAN 模式下时请勿设置此位。

注意:该位在经典 CAN 函数中不可用。

Channel Error Flag register shows the status of various error conditions detectable regardless of the setting of the related CAN Channel Error Interrupt Enable Register. It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1) to check when each error condition occurs.

For this register, only a single bit can be cleared by software. Do not use the bit clear instruction to clear the bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Example in assembler language to clear the CFDC0ERFL.BEF bit:

mov.b #0x0FE, CFDC0ERFL ;

BEF bit (Bus Error Flag)

The BEF bit indicates a detection of a CAN channel bus error state, flagged by bits [14:8] in this register.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when a bus error is detected, and is cleared automatically when the related CANFD channel is in CH_RESET mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

EWF bit (Error Warning Flag)

The EWF bit indicates whether an error warning condition has been detected for the CAN channel.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when either TEC or REC exceeds 0x5F.

The setting of this bit only occurs when the TEC or REC initially exceeds 0x5F. Therefore, if the TEC or REC remains > 0x5F and the EWF bit is cleared by software, it is not set again until both the TEC and REC go below 0x60 and either TEC or REC crosses over again from a value 0x5F to a value > 0x5F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

EPF bit (Error Passive Flag)

The EPF bit indicates a detection of a CAN channel error passive state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state becomes error passive state.

通道 0 CANFD 配置寄存器配置计算哪些通信方向（发射机/接收机）错误。

EOCCFG[2:0] bits (Error Occurrence Counter Configuration)

The EOCCFG[2:0] bits select which type of CAN frame configuration and direction, including protocol errors are counted.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

TDCOC bit (Transceiver Delay Compensation Offset Configuration)*1

The TDCOC bit selects which offset is used when defining the position of the secondary sample point (SSP) for the CANFD channel. If the bit is set to 0, the position of the SSP is the measured transceiver delay plus the fixed offset. If the bit is 1, the position of the SSP is defined only by the offset.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

TDCE bit (Transceiver Delay Compensation Enable)*1

The TDCE bit enables the transceiver delay compensation for the CANFD channel.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

ESIC bit (Error State Indication Configuration)*1

The ESIC bit controls the transmission of either the ESI flag information or the message of ESI flag information (CFDCFFDCSTS.CFESI or CFDTMFDCTRb.TMESI).

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

TDCO[7:0] bits (Transceiver Delay Compensation Offset)*1

The TDCO[7:0] bits set the secondary sample point offset. How this value is used, depends on the CFDC0FDCFG.TDCOC setting.

If CFDC0FDCFG.TDCOC = 0, the transceiver delay compensation result is equal to the Trv_Delay (measured delay) + the value in CFDC0FDCFG.TDCO, rounded down to the nearest integer number of time quanta. Otherwise, the result is equal to the value in CFDC0FDCFG.TDCO. See section 26.4.1.5. Transmitter Delay Compensation for details on how CFDC0FDCFG.TDCO is used.

The actual offset value is interpreted as TDCO + 1. For example, if 4 is set in TDCO, the offset is 5 clock cycles. Clock cycle is 1 cycle of CAN channel DLL clock.

Do not write to the TDCO[7:0] bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

FDOE bit (FD-Only Enable)*1

The FDOE bit enables the reception and transmission of CANFD-only frames. If enabled, communication in Classical CAN frame format is disabled. Transmission of Classical CAN frames is not possible because the FDF bit of the message buffer is a don’t care (CFDCFFDCSTS.CFFDF/CFDTMFDCTRb.TMFDF).

If messages with Classical CAN frame format are received, the protocol controller treats them as invalid frames and response with error frames. When a Classical CAN frame is configured for transmitting, the FDF bit is sent as recessive, therefore an FD frame is sent. If the data length code (DLC) is configured of greater than 8 bytes, the remaining data bytes are padded with 0xCC.

The FDOE bit cannot be written in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Do not set CFDC0FDCFG.FDOE and CFDC0FDCFG.CLOE simultaneously.

EOCCFG[2:0] 位（错误发生计数器配置）

EOCCFG[2:0] 位选择计数 CAN 帧配置和方向的类型,包括协议错误。

CH_OPERATION 或 CH_SLEEP 模式下请勿写入这些位。

仅当相关的 CANFD 通道处于 CH_RESET 或 CH_HALT 模式时才写入这些位。

TDCOC 位（收发器延迟补偿偏移配置）*1

TDCOC 位选择在定义 CANFD 通道的辅助采样点（SSP）的位置时使用哪个偏移量。如果位设置为 0,则 SSP 的位置是测量的收发器延迟加上固定偏移量。如果位为 1,则 SSP 的位置仅由偏移量定义。

CH_OPERATION 或 CH_SLEEP 模式下请勿写入此位。

仅当相关 CANFD 通道处于 CH_RESET 或 CH_HALT 模式时才写入此位。在经典 CAN 模式下时请勿设置此位。

TDCE 位（启用收发器延迟补偿）*1

TDCE 位能够对 CANFD 信道进行收发器延迟补偿。

CH_OPERATION 或 CH_SLEEP 模式下请勿写入此位。

仅当相关 CANFD 通道处于 CH_RESET 或 CH_HALT 模式时才写入此位。在经典 CAN 模式下时请勿设置此位。

ESIC 位（错误状态指示配置）*1

ESIC位控制ESI标志信息或ESI标志信息（CFDCFFDCSTS。CFESI或CFDTMFDCTRb。TMESI）的消息的传输。

CH_OPERATION 或 CH_SLEEP 模式下请勿写入此位。

仅当相关 CANFD 通道处于 CH_RESET 或 CH_HALT 模式时才写入此位。在经典 CAN 模式下时请勿设置此位。

TDCO[7:0] 位（收发器延迟补偿偏移）*1

TDCO[7:0] 位设置了次级采样点偏移量。如何使用该值取决于 CFDC0FDCFG。TDCOC 设置。

如果CFDC0FDCFG。TDCOC = 0,则收发器延迟补偿结果等于Trv_Delay（测量的延迟）+CFDC0FDCFG。TDCO中的值,向下舍入到最接近的时间量子整数。否则,结果等于 CFDC0FDCFG。TDCO 中的值。参见第 26。4。1。5 节。发射机延迟补偿有关如何使用 CFDC0FDCFG。TDCO 的详细信息。

实际偏移值解释为 TDCO + 1。例如,如果 TDCO 中设置了 4,则偏移量为 5 个时钟周期。时钟周期是CAN通道DLL时钟的1个周期。

请勿在 CH_OPERATION 或 CH_SLEEP 模式下写入 TDCO[7:0] 位。

仅当相关的 CANFD 通道处于 CH_RESET 或 CH_HALT 模式时才写入这些位。在经典 CAN 模式下时请勿设置此位。

FDOE 位（仅启用 FD）*1

FDOE 位能够接收和传输仅 CANFD 帧。如果启用,则禁用经典 CAN 帧格式的通信。Classical CAN 帧的传输是不可能的,因为消息缓冲区的 FDF 位不在乎（CFDCFFDCSTS。CFFDF/CFDTMFDCTRb。TMFDF）。

Classical CAN 帧格式的消息,则协议控制器将它们视为无效帧,并使用错误帧进行响应。当经典CAN帧被配置为发送时,FDF比特被发送为隐式,因此发送FD帧。如果数据长度代码（DLC）配置为大于 8 字节,则其余数据字节填充为 0xCC。

FDOE 位不能用 CH_OPERATION、CH_HALT 或 CH_SLEEP 模式写入。

请勿同时设置 CFDC0FDCFG。FDOE 和 CFDC0FDCFG。CLOE。

REFE bit (RX Edge Filter Enable)

The REFE bit enables the RX edge filter during the IDLE detection (bus integration). When the bit is enabled, two consecutive dominant time quanta are required to detect a synchronization edge.

The REFE bit cannot be written in CH_OPERATION, CH_HALT and CH_SLEEP mode. Do not set this bit when in Classical CAN mode.

CLOE bit (Classical CAN Enable)*1

The CLOE bit enables the Classical CAN mode. If this bit is 1, the protocol controller can only send classical frames and response with a form or CRC error on FD frames.

Do not set CFDC0FDCFG.CLOE and CFDC0FDCFG.FDOE simultaneously.

CFDC0FDCFG.CLOE	CFDC0FDCFG.FDOE	Channel mode
0	0	CANFD mode
0	1	FD-only mode
1	0	Classical CAN mode
1	1	Reserved

Do not write to this bit in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET mode.

Note 1. These bits are not available in the classical CAN function.

Note 1. These bits are not available in the classical CAN function.

The Channel 0 CANFD Status Register indicates the transceiver compensation delay result and its related FIFO message lost status.

TDCR[7:0] bits (Transceiver Delay Compensation Result)

The TDCR[7:0] bits are set when the transceiver delay has been measured.

The measured delay is a multiple of the CAN channel DLL clock. The result depends on the CFDC0FDCFG.TDCOC configuration and the offset value in CFDC0FDCFG.TDCO. See section 26.4.1.5. Transmitter Delay Compensation for details on how this value is derived.

The TDCR[7:0] bits are updated at the falling edge between FDF and the RES bit when CFDC0FDCFG.TDCOC = 0 and the transceiver delay compensation is enabled (CFDC0FDCFG.TDCE = 1).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

Note: These bits are not available in the classical CAN function.

通道0 CANFD状态寄存器指示收发器补偿延迟结果及其相关的FIFO消息丢失状态。

TDCR[7:0] 位（收发器延迟补偿结果）

TDCR[7:0] 位是在测量收发器延迟时设置的。

测量的延迟是 CAN 通道 DLL 时钟的倍数。结果取决于 CFDC0FDCFG。TDCOC 配置和 CFDC0FDCFG。TDCO 中的偏移值。参见第 26。4。1。5 节。发射机延迟补偿有关如何导出此值的详细信息。

当CFDC0FDCFG。TDCOC = 0并且启用收发器延迟补偿时,TDCR[7:0]位在FDF和RES位之间的下降沿处更新（CFDC0FDCFG。TDCE = 1)。

当相关的 CANFD 通道处于 CH_RESET 模式时,这些位会自动清除。

注: 这些位在经典 CAN 函数中不可用。

EOCO bit (Error Occurrence Counter Overflow)

The EOCO bit indicates whether the related CAN channel error occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDC0FDSTS.EOC is 0xFF and a CAN bus error is detected based on the configuration defined in CFDC0FDCFG.EOCCFG.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

SOCO bit (Successful Occurrence Counter Overflow)

The SOCO bit indicates whether the related CAN channel successful occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDC0FDSTS.SOC is 0xFF and a successful message reception or successful message transmission occurs.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Write to this bit only when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

TDCVF bit (Transceiver Delay Compensation Violation Flag)

The CANFD module captures internally the transmitted data bit-by-bit. This data is then compared against the received CAN bus level which is delayed by the transceiver loop delay.

The transceiver delay has some variations depending on the physical parameters such as temperature. The result bit CFDC0FDSTS.TDCR is updated by each message. However, temporary maximum delay violation could be missed. Therefore, the TDCVF bit captures this violation.

This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when the transceiver delay compensation is greater than the maximum delay compensation (6 data bit times - 2 clk_dlc) and the internal bit is overrun.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Note: This bit is not available in the classical CAN function.

EOC[7:0] bits (Error Occurrence Counter)

The EOC[7:0] bits are used together with the SOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

This higher error rate can be detected depending on the configuration of the CFDC0FDCFG.EOCCFG bits.

The EOC[7:0] bits are set only by CANFD module logic. These bits are cleared by writing 1 to CFDC0FDCTR.EOCCLR. Writing any other value has no effect.

These bits are updated when an error occurs, according to the configuration of the CFDC0FDCFG.EOCCFG bits. When the counter reaches the value of 0xFF, the update stops.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

EOCO 位（错误发生计数器溢出）

EOCO位指示相关CAN信道错误发生计数器是否溢出。该位通过写入 0 来清除。1的书写没有效果。

当CFDC0FDSTS。EOC为0xFF并且基于CFDC0FDCFG。EOCCFG中定义的配置检测到CAN总线错误时,自动设置该位。

如果来自 CAN 通道的集合与写访问的清除同时发生,则该位被设置。

当相关的 CANFD 通道处于 CH_RESET 模式时,该位会自动清除。

仅当相关 CANFD 通道处于 CH_HALT 或 CH_OPERATION 模式时才写入此位。

请勿使用位清除指令来清除此位。MOV指令来确保只清除指定位。
其他位保持 1。

SOCO 位（成功发生计数器溢出）

SOCO位指示相关CAN通道成功发生计数器是否溢出。该位通过写入 0 来清除。1的书写没有效果。

当CFDC0FDSTS。SOC为0xFF并且发生成功的消息接收或成功的消息传输时,该位被自动设置。

如果来自 CAN 通道的集合与写访问的清除同时发生,则该位被设置。

当相关的 CANFD 通道处于 CH_RESET 模式时,该位会自动清除。

仅当相关 CANFD 通道处于 CH_HALT 或 CH_OPERATION 模式时才写入此位。

请勿使用位清除指令来清除此位。MOV指令来确保只清除指定位。
其他位保持 1。

TDCVF 位（收发器延迟补偿违规标志）

CANFD 模块在内部逐位捕获传输的数据。然后将该数据与接收到的由收发器环路延迟延迟的CAN总线电平进行比较。

收发器延迟根据物理参数（例如温度）有一些变化。结果位CFDC0FDSTS。TDCR由每个消息更新。然而,可能会错过临时最大延迟违规。
因此,TDCVF 位捕获了这种违规行为。

该位通过写入 0 来清除。1的书写没有效果。

当收发器延迟补偿大于最大延迟补偿(6个数据位乘以2 clk_dlc）并且内部位超限时,自动设置该位。

如果来自 CAN 通道的集合与写访问的清除同时发生,则该位被设置。

当相关的 CANFD 通道处于 CH_RESET 模式时,该位会自动清除。

仅当相关 CANFD 通道处于 CH_HALT 或 CH_OPERATION 模式时才写入此位。

请勿使用位清除指令来清除此位。MOV指令来确保只清除指定位。
其他位保持 1。

注意:该位在经典 CAN 函数中不可用。

EOC[7:0] 位（错误发生计数器）

EOC[7:0] 位与 SOC[7:0] 位一起使用,以支持主机控制回退到有效负载比特率的选项,当利用减少的有效负载比特长度的消息具有显着更高的错误率时,该选项与仲裁比特率相同与其他消息相比。

根据 CFDC0FDCFG。EOCCFG 位的配置,可以检测到更高的错误率。

EOC[7:0] 位仅由 CANFD 模块逻辑设置。通过将 1 写入 CFDC0FDCTR。EOCCLR 来清除这些位。
写任何其他值都没有任何效果。

当发生错误时,根据 CFDC0FDCFG。EOCCFG 位的配置更新这些位。当计数器达到 0xFF 值时,更新停止。

当相关的 CANFD 通道处于 CH_RESET 模式时,这些位会自动清除。

SOC[7:0] bits (Successful occurrence counter)

The SOC[7:0] bits are used together with the EOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

The SOC[7:0] bits are set only by CANFD module logic. Writing any other value has no effect.

These bits are updated when the occurrence of any error-free messages on the bus is detected through reception or transmission. When the counter reaches the value of 0xFF, the update stops.

Note: In Loopback mode, the counter is incremented twice.

These bits are cleared by writing 1 to CFDC0FDCTR.SOCCLR.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

26.2.11 CFDC0FDCRC : Channel 0 CANFD CRC Register

This register is not available in the classical CAN function.

Base address: CANFD_B = 0x400B_0000

Offset address: 0x0110

Bit position:	31				27			24			20																				0

Bit	Symbol	Function	R/W
20:0	CRCREG[20:0]	CRC Register value These bits show the CRC value calculated for the CANFD frame.	R
23:21	—	These bits are read as 0. The write value should be 0.	R/W
27:24	SCNT[3:0]	Stuff bit count These bits shows the stuff bit count (mod 8) for the CANFD frame.	R
31:28	—	These bits are read as 0. The write value should be 0.	R/W

The Channel 0 CANFD CRC Register holds the CRC value calculated for the CANFD frame.

CRCREG[20:0] bits (CRC Register value)

The CRCREG[20:0] bits contain the CRC value calculated by the CANFD channel logic when the CFDC0CTR.CTME bit is enabled.

The CFDC0FDCRC.CRCREG value is updated in the first bit of the CRC field of the CANFD frame (reception and transmission).

When the CFDC0CTR.CTME bit is 0, the CRCREG[20:0] bits are always read as 0.

When bit 17th of the CRC field is used, CRCREG[20:17] are always read as 0.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

SCNT[3:0] bits (Stuff bit count)

The SCNT[3:0] bits contain the stuff count value of the CANFD frame. These bits indicate the number of inserted stuff bits (modulo 8, Graycoded) for a CANFD frame when the CFDC0CTR.CTME bit is enabled in CFDC0FDCRC.SCNT[3:1]. SCNT[0] is the parity bit.

When the CFDC0CTR.CTME bit is 0, the SCNT[3:0] bits are always read as 0.

The SCNT value is updated in the first bit of CRC field of the CANFD frame (reception and transmission).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

SOC[7:0] 位（成功出现计数器）

SOC[7:0]位与EOC[7:0]位一起使用,以支持主机控制回退到有效负载比特率的选项,当利用减少的有效负载比特长度的消息具有显着更高的错误率时,与仲裁比特率相同与其他消息相比。

SOC[7:0] 位仅由 CANFD 模块逻辑设置。写任何其他值都没有任何效果。

通过将 1 写入 CFDC0FDCTR。SOCCLR 来清除这些位。

当相关的 CANFD 通道处于 CH_RESET 模式时,这些位会自动清除。

全局配置寄存器用于选择用于CAN信道的CAN协议引擎的所有TX消息缓冲区的传输优先级和时钟源。CFDGCFG寄存器还用于选择时间戳时钟的源,并配置时间戳时钟和间隔定时器参考时钟的频率。

TPRI 位（传输优先级）

TPRI位选择CAN信道的传输优先级。

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

Message buffer number priority should not be used together with TX queue transmission.

DCE bit (DLC Check Enable)

The DCE bit enables data length code (DLC) check for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

DRE bit (DLC Replacement Enable)

When the DRE bit is 1 and the DCE is 1, the CANFD stores the configured value (CFDGAFLP0r.GAFLDLC) of the DLC in the destination RX message buffer or FIFO buffer if the DLC check passes. Otherwise, the DLC value in the destination RX message buffer or FIFO buffer is unchanged.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

MME bit (Mirror Mode Enable)

The MME bit enables the Mirror mode for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

DCS bit (Data Link Controller Clock Select)

The DCS bit selects the clock source for CAN communication. Internal clean clock has a smaller clock jitter than the peripheral clock B (PCLKB).

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CANFD module is in GL_RESET mode.

CMPOC bit (CANFD Message Payload Overflow Configuration)

The CMPOC bit controls the message payload acceptance mechanism when the received payload is higher than the message buffer payload size CFDRMNB.RMPLS, CFDRFCCa.RFPLS, and CFDCFCC.CFPLS. The received message payload is always compared with the available message payload size in the message buffer.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CANFD module is in GL_RESET mode.

When this bit is set and payload overflow occurs, the DLC value is stored in the RX message buffer or FIFO buffer unchanged.

Note: This bit is not available in the classical CAN function.

TSP[3:0] bits (Timestamp Prescaler)

The value configured in the TSP[3:0] bits defines the period of the clock source used for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

TSSS bit (Timestamp Source Select)

The TSSS bit allows the selection of the clock source for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode. Additionally, do not set this bit to 1 when CANFD communication is used.*1

Note: The bit time clock varies depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

ITRCP[15:0] bits (Interval Timer Reference Clock Prescaler)

The ITRCP[15:0] bits allow the definition of a reference clock for the FIFO interval timer source clock.

When these bits are 0x0000, the timer is disabled.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

GL_SLEEP 模式下不要写入此位。CANFD 模块处于 GL_RESET 模式时才写入此位。

消息缓冲区号优先级不应与 TX 队列传输一起使用。

DCE 位（启用 DLC 检查）

DCE 位可以对 CAN 通道进行数据长度代码（DLC）检查。

GL_SLEEP 模式下不要写入此位。CANFD 模块处于 GL_RESET 模式时才写入此位。

DRE 位（启用 DLC 替换）

当DRE位为1且DCE为1时,如果DLC检查通过,则CANFD将DLC的配置值（CFDGAFLP0r。GAFLDLC）存储在目的地RX消息缓冲器或FIFO缓冲器中。否则,目标RX消息缓冲区或FIFO缓冲区中的DLC值不变。

GL_SLEEP 模式下不要写入此位。CANFD 模块处于 GL_RESET 模式时才写入此位。

MME 位（镜像模式启用）MME 位启用 CAN 通道的
镜像模式。

GL_SLEEP 模式下不要写入此位。CANFD 模块处于 GL_RESET 模式时才写入此位。

DCS 位（数据链路控制器时钟选择）

DCS位选择时钟源进行CAN通信。内部干净时钟的时钟抖动比外围时钟 B（PCLKB）更小。

GL_SLEEP 或 GL_OPERATION 模式下请勿写入此位。CANFD 模块处于 GL_RESET 模式时才写入此位。

CMPOC 位（CANFD 消息有效负载溢出配置）

当接收到的有效负载高于消息缓冲器有效负载大小CFDRMNB。RMPLS、CFDRFCCa。RFPLS和CFDCFCC。CFPLS时,CMPOC位控制消息有效负载接受机制。接收到的消息有效负载始终与消息缓冲区中的可用消息有效负载大小进行比较。

GL_SLEEP 或 GL_OPERATION 模式下请勿写入此位。CANFD 模块处于 GL_RESET 模式时才写入此位。

当设置该位并发生有效负载溢出时,DLC 值存储在 RX 消息缓冲区或 FIFO 缓冲区中,保持不变。

注意:该位在经典 CAN 函数中不可用。

TSP[3:0] 位（时间戳预分频器）

TSP[3:0]位中配置的值定义了用于时间戳计数器的时钟源的周期。

GL_SLEEP 模式下不要写入此位。CANFD 模块处于 GL_RESET 模式时才写入此位。

TSSS 位（时间戳源选择）

TSSS 位允许为时间戳计数器选择时钟源。

GL_SLEEP 模式下不要写入此位。CANFD 模块处于 GL_RESET 模式时才写入此位。

此外,使用 CANFD 通信时,请勿将此位设置为 1。*1 注意:位时间时钟根据标称和数据速率位配置而变化。

注1。此功能在经典 CAN 函数中不可用。

ITRCP[15:0] 位（区间定时器参考时钟预分频器）

ITRCP[15:0]位允许定义FIFO间隔定时器源时钟的参考时钟。

当这些位为 0x0000 时,定时器将被禁用。

GL_SLEEP 模式下不要写入此位。CANFD 模块处于 GL_RESET 模式时才写入此位。

Note 1. This bit is not available in the classical CAN function.

The Global Control Register controls the global mode of the CANFD module and the timestamp function. The register also enables and disables the global error interrupts.

GMDC bits (Global Mode Control)

The GMDC bits can be used to configure the modes for the CANFD module. Additionally, if CFDGCTR.GSLPR bit is 1 when the CANFD module is in Reset mode, the CANFD module enters Global Sleep mode.

Setting the GMDC bits to 11b has no effect. Mode transition is described in detail in section 26.3.2. Global Modes.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

GSLPR bit (Global Sleep Request)

The GSLPR bit globally selects the sleep request for CANFD module including CAN channels. Channel sleep request is set automatically for channels.

GAFLDLC[3:0] bits (Global Acceptance Filter List DLC Field)

The GAFLDLC[3:0] bits allow the configuration of a minimum data length code (DLC) value for a message to be accepted by the associated entry in the Global Acceptance Filter List (automatic DLC filter function).

The Global Acceptance Filter List Pointer 1 registers are used to configure the FIFO direction pointer fields in each Rule Entry of the Global Acceptance Filter List.

GAFLFDP8, GAFLFDP1, GAFLFDP0 bits (Global Acceptance Filter List FIFO Direction Pointer)

These bits allow the configuration of FIFO Buffers as the target for a received message passing the acceptance check of the related Global Acceptance Filter List entry. Each bit of the GAFLFDP8, GAFLFDP1, GAFLFDP0 is configuring a dedicated FIFO.

Users cannot write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

For storage in Common FIFO, target for reception can only be those Common FIFO Buffers that are configured as RX FIFO.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

Users should only configure up to 2 destination FIFO Buffers or 1 destination FIFO Buffers plus one RX Message Buffer.

The RX Message Buffer Number register is used to configure the total number of RX message buffers allocated to channels.

NRXMB[5:0] bits (Number of RX Message Buffers)

The NRXMB[5:0] bits are used to configure the number of RX message buffers.

Only write to these bits when the CANFD module is in GL_RESET mode.

Enter only values between 0 and 32 inclusive, with 0x00 indicating that no RX message buffer is allocated.

RMPLS[2:0] bits (Reception Message Buffer Payload Data Size)

The RMPLS[2:0] bits are used to configure the message buffer payload data size.

Only write to these bits when the CANFD module is in GL_RESET mode.

全局接受滤波器列表指针1寄存器用于配置全局接受滤波器列表的每个规则条目中的FIFO方向指针字段。

当 CFDGAFLECTR。AFLDAE 位为 0 时,用户无法写入这些位。

对于 Common FIFO 中的存储,接收目标只能是配置为 RX FIFO 的那些 Common FIFO 缓冲区。

仅当相关的 CANFD 通道处于 CH_RESET 或 CH_HALT 模式时才写入这些位。

用户只能配置最多 2 个目标 FIFO 缓冲区或 1 个目标 FIFO 缓冲区加上一个 RX 消息缓冲区。

NRXMB[5:0] 位用于配置 RX 消息缓冲区的数量。

CANFD 模块处于 GL_RESET 模式时才写入这些位。

26.2.25 CFDRMND : RX Message Buffer New Data Register

Base address: CANFD_B = 0x400B_0000
Offset address: 0x0034

Bit position:	31																													0
Bit field:	RMNS[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RMNS[31:0]	RX Message Buffer New Data Status 0: New data not stored in corresponding RX message buffer 1: New data stored in corresponding RX message buffer	R/W

The RX Message Buffer New Data Status Register specifies the new data storage status of the RX message buffers.

RMNS[31:0] bits (RX Message Buffer New Data Status)

The RMNS[31:0] bits indicate the status of new data for the corresponding RX message buffer. RMNS bit [0] corresponds to RX message buffer [0] and so on.

The bit position of CFDRMND corresponds to the buffer number of RXMB.

Do not write to these bits when the CANFD module is in GL_RESET or GL_SLEEP mode. Writing 1 has no effect.

These bits cannot be cleared when message storage in the corresponding RX message buffer is in progress.
Do not use the bit clear instruction to clear these bits. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

These bits are set automatically when storage of new messages are in the corresponding RX message buffer. These bits are cleared by writing 0. These bits are cleared automatically when the CANFD module is in GL_RESET mode.

When CFDRMNB.RMPLS = 000b (maximum 8 bytes payload), the duration of message storage is 6 PCLKB cycles.

When CFDRMNB.RMPLS > 000b, the duration of message storage is 6 PCLKB cycles + 1 for each 4 bytes (maximum of 20 PCLKB cycles for 64 bytes).

Note: This feature is not available in the classical CAN function.

26.2.26 CFDRFCCa : RX FIFO Configuration/Control Registers a (a = 0 to 1)

31:0	RMNS[31:0]	RX 消息缓冲区新数据状态 0:未存储在相应RX消息缓冲器中的新数据 1:存储在相应RX消息缓冲器中的新数据	R/W

RX 消息缓冲区新数据状态寄存器指定 RX 消息缓冲区的新数据存储状态。

RMNS[31:0] 位（RX 消息缓冲区新数据状态）

RMNS[31:0]位指示相应RX消息缓冲器的新数据的状态。RMNS 位 [0] 对应于 RX 消息缓冲区 [0] 等。

CFDRMND 的位位置对应于 RXMB 的缓冲区号。

CANFD 模块处于 GL_RESET 或 GL_SLEEP 模式时,请勿写入这些位。1的书写没有效果。

当相应RX消息缓冲区中的消息存储正在进行时,这些位无法被清除。
请勿使用位清除指令来清除这些位。MOV指令来确保只清除指定位。其他位保持 1。

当新消息的存储在相应的 RX 消息缓冲区中时,这些位会自动设置。这些位通过写入 0 来清除。CANFD 模块处于 GL_RESET 模式时,这些位会自动清除。

CFDRMNB。RMPLS = 000b（最大8字节有效负载）时,消息存储的持续时间为6个PCLKB周期。

CFDRMNB。RMPLS > 000b 时,消息存储的持续时间为 6 个 PCLKB 周期 + 每 4 个字节 1 个(64 个字节最多 20 个 PCLKB 周期）。

注意:此功能在经典 CAN 函数中不可用。

Note 1. These bits are not available in the classical CAN function.

The RX FIFO Configuration/Control Registers are used to configure and control the two RX FIFOs.

RFE bit (RX FIFO Enable)

The RFE bit enables the FIFO. When this bit is set to 0, the RX FIFO is cleared to empty.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

This bit can only be set if the configured FIFO depth is greater than 0x000 (CFDRFCCa.RFDC > 0x000) and less than 0x110.

Set the RFE bit with a separate write access to the CFDRFCCa register, after all the other bits in the CFDRFCCa register are set.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

RFIE bit (RX FIFO Interrupt Enable)

The RFIE bit enables generation of the FIFO interrupt.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

注1。这些位在经典 CAN 函数中不可用。

RX FIFO 配置/控制寄存器用于配置和控制两个 RX FIFO。

RFE 位（RX FIFO 启用）

RFE位启用FIFO,当该位设置为0时,RX FIFO被清除为空。

CANFD 模块处于 GL_HALT 或 GL_OPERATION 模式时才写入此位。

仅当配置的 FIFO 深度大于 0x000（CFDRFCCa。RFDC > 0x000) 且小于 0x000 时才能设置该位 0x110。

在设置 CFDRFCCa 寄存器中的所有其他位之后,使用对 CFDRFCCa 寄存器的单独写入访问来设置 RFE 位。

CANFD 模块处于 GL_RESET 模式时,该位会自动清除。

RFIE 位（启用 RX FIFO 中断）

RFIE 位能够生成 FIFO 中断。

CANFD 模块处于 GL_SLEEP 模式时,请勿写入此位。

RFPLS[2:0] bits (Rx FIFO Payload Data Size Configuration)

The RFPLS[2:0] bits define the message data payload allocation in the RAM.

This is the maximum number of bytes which can be received by this FIFO.

Only write to these bits when the CANFD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

RFDC[2:0] bits (RX FIFO Depth Configuration)

The RFDC[2:0] bits select the depth of the FIFO in terms of the number of messages. If the FIFO depth is configured to 0 messages, the FIFO cannot be used.

Only write to these bits when the CANFD module is in GL_RESET mode.

RFIM bit (RX FIFO Interrupt Mode)

The RFIM bit selects the interrupt generation condition for the FIFO.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

Only write to this bit when the CANFD module is in GL_RESET mode.

RFIGCV[2:0] bits (RX FIFO Interrupt Generation Counter Value)

The RFIGCV[2:0] bits select the counter value of the FIFO for generation of FIFO interrupts. These values represent fractions of the FIFO depth for which an interrupt is generated.

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

The setting of the RFIGCV[2:0] bits should be synchronized with the RFDC[2:0] bits.

Only write to these bits when the CANFD module is in GL_RESET mode.

RFPLS[2:0] 位（Rx FIFO 有效负载数据大小配置）

RFPLS[2:0]位定义RAM中的消息数据有效负载分配。

这是该 FIFO 可以接收的最大字节数。只有当 CANFD 模块处于 GL_R
ESET 模式时才写入这些位。

注意:这些位在经典 CAN 函数中不可用。

RFDC[2:0] 位（RX FIFO 深度配置）

RFDC[2:0]位根据消息的数量来选择FIFO的深度。FIFO 深度配置为 0 条消息,则无法使用 FIFO。

CANFD 模块处于 GL_RESET 模式时才写入这些位。

RFIM 位（RX FIFO 中断模式）

RFIM 位为 FIFO 选择中断生成条件。

CANFD 模块处于 GL_SLEEP 模式时,请勿写入此位。CANFD 模块处
于 GL_RESET 模式时才写入此位。

RFIGCV[2:0] 位（RX FIFO 中断生成计数器值）

RFIGCV[2:0] 位选择 FIFO 的计数器值以生成 FIFO 中断。这些值代表生成中断的 FIFO 深度的分数。

CANFD 模块处于 GL_SLEEP 模式时,请勿写入这些位。

RFIGCV[2:0]位的设置应该与RFDC[2:0]位同步。

CANFD 模块处于 GL_RESET 模式时才写入这些位。

13:8	RFMC[5:0]	RX FIFO Message Count Number of messages stored in FIFO	R
31:14	—	These bits are read as 0. The write value should be 0.	R/W

The RX FIFO Status Registers show the status of messages stored in the corresponding FIFO buffers.

RFEMP bit (RX FIFO Empty)

The RFEMP bit is set automatically when:

- The RFMC bit is 0
- RX FIFO is disabled by setting the CFDRFCCa.RFE bit to 0
- The CANFD module is in GL_RESET mode.

The RFEMP bit is cleared automatically when the first message is stored in the RX FIFO buffer.

RFFLL bit (RX FIFO Full)

The RFFLL bit is set automatically when the number of CAN messages stored in the FIFO buffer matches the configured FIFO depth.

The RFFLL is cleared automatically when:

- The number of CAN messages stored in the FIFO buffer is less than the configured FIFO depth
- RX FIFO is disabled by setting the CFDRFCCa.RFE bit to 0
- The CANFD module is in GL_RESET mode.

RFMLT bit (RX FIFO Message Lost)

Only write to the RFMLT bit when CANFD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically whenever a message is lost due to attempted storage when the FIFO buffer is already full. If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode.

RFIF bit (RX FIFO Interrupt Flag)

The RFIF bit is set automatically when the configured interrupt condition is satisfied. This bit is not automatically cleared when the RX FIFO buffer is disabled.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

The bit is cleared by writing 0 to it. The bit is also cleared when CANFD module is in GL_RESET mode.

RFMC[5:0] bits (RX FIFO Message Count)

The RFMC[5:0] bits indicate the number of CAN messages stored in the RX FIFO buffer that can be read by the CPU.

These bits are cleared automatically when the FIFO is disabled and when the CANFD module is in GL_RESET mode.

位	符号	功能	R/W
13:8	RFMC[5:0]	RX FIFO 消息计数 FIFO 中存储的消息数量	R
31:14	—	这些位读作 0。写入值应为 0。	R/W

RX FIFO 状态寄存器显示存储在相应 FIFO 缓冲区中的消息的状态。

RFEMP 位（RX FIFO 空）

RFEMP位自动设置时:

- RFMC 位为 0
- RX FIFO 通过将 CFDRFCCa。RFE 位设置为 0 来禁用
- CANFD 模块处于 GL_RESET 模式。

当第一条消息存储在 RX FIFO 缓冲区中时,RFEMP 位会自动清除。

RFFLL 位（RX FIFO 全）

FIFO 缓冲区中存储的 CAN 消息数量与配置的匹配时, RFFLL 位自动设置
FIFO 深度。

RFFLL 在以下情况下会自动清除:

- 存储在 FIFO 缓冲区中的 CAN 消息数量小于配置的 FIFO 深度
- RX FIFO 通过将 CFDRFCCa。RFE 位设置为 0 来禁用
- CANFD 模块处于 GL_RESET 模式。

RFMLT 位（RX FIFO 消息丢失）

CANFD 模块处于 GL_HALT 或 GL_OPERATION 模式时才写入 RFMLT 位。1的书写没有效果。请勿使用位清除指令来清除此位。MOV指令来确保只清除指定位。

其他位保持 1。

当 FIFO 缓冲区已满时,每当消息因尝试存储而丢失时,就会自动设置该位。如果来自 CAN 通道的集合与写访问的清除同时发生,则该位被设置。

位清除:

- 通过向其写入 0
- 当CANFD模块处于GL_RESET模式时。

RFIF 位（RX FIFO 中断标志）

RFIF 位在满足配置的中断条件时自动设置。当禁用 RX FIFO 缓冲区时,该位不会自动清除。

CANFD 模块处于 GL_HALT 或 GL_OPERATION 模式时才写入此位。1的书写没有效果。

请勿使用位清除指令来清除此位。MOV指令来确保只清除指定位。
其他位保持 1。

如果来自 CAN 通道的集合与写访问的清除同时发生,则该位被设置。

该位通过写入 0 来清除。CANFD模块处于GL_RESET模式时,该位也被清除。

RFMC[5:0] 位（RX FIFO 消息计数）

RFMC[5:0]位表示存储在RX FIFO缓冲区中可被CPU读取的CAN消息的数量。FIFO被禁用以及当CANFD模块处于GL_RESET模式时,这些位被自动清除。

The RX FIFO Pointer Control Registers can be used to increment the read pointer of the corresponding RX FIFO buffers.

RFPC bits (RX FIFO Pointer Control)

When the value 0xFF is written to the RFPC bits, the pointer of the corresponding RX FIFO buffer is moved to the next FIFO entry. Only write 0xFF to these registers when the corresponding RX FIFO buffer is enabled and not empty.

The read value from these bits is always 0x00.

Only write to these bits when the CANFD module is in GL_HALT or GL_OPERATION mode.

Do not write to the RX FIFO Pointer Control registers when DMA is enabled.

注1。这些位在经典 CAN 函数中不可用。

CFE 位（通用 FIFO 启用）

该位还可以通过清除它来中止在 TX 模式下配置时从 Common FIFO 的传输,或者在 RX 模式下停止接收到 Commo n FIFO。

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFOs configured as TX FIFO.

This bit can only be set if the configured FIFO depth is greater than 0x000 (CFDCFCC.CFDC > 0x000) and less than 0x110 (0x110 > CFDCFCC.CFDC > 0x000).

Set the CFE bit with a separate write access to the CFDCFCC register, after all the other bits in this register are set.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

This bit is also cleared automatically when the related channel is in CH_RESET mode if the FIFO is configured in TX mode.

CFRXIE bit (Common FIFO RX Interrupt Enable)

The CFRXIE bit enables generation of FIFO interrupts when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CFPLS[2:0] bits (Common FIFO Payload Data Size Configuration)

The CFPLS[2:0] bits define the message data payload allocation in the RAM. This is the maximum number of bytes which can be received or transmitted by the FIFO buffer.

Only write to this bit when the CANFD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to these bits when the CANFD module is in GL_RESET mode.

CFITSS bit (Common FIFO Interval Timer Source Select)

The CFITSS bit selects the basic clock source for the Interval Transmission Timer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode. In addition, do not write to this bit when the CFE bit is set to 1.

Do not write 1 to this bit when CANFD communication is used.*1

Note: The bit time clock can vary depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

CFITR bit (Common FIFO Interval Timer Resolution)

The CFITR bit selects the resolution of the reference clock for the Interval Transmission Timer (peripheral clock is the source for the reference clock).

Do not write to this bit when the CANFD module is in GL_SLEEP mode. Also, do not write to this bit when the CFE bit is set to 1.

CFIM bit (Common FIFO Interrupt Mode)

The CFIM bit selects the interrupt generation condition for the FIFO buffer.

Do not write to this bit in GL_SLEEP mode.

仅当 CANFD 模块处于 GL_HALT 或 GL_OPERATION 模式并且相关 CANFD 通道对于配置为 TX FIFO 的 FIFO 不处于 CH_RESET 模式时才写入此位。

在设置该寄存器中的所有其他位之后,使用对 CFDCFCC 寄存器的单独写入访问来设置 CFE 位。

CANFD 模块处于 GL_RESET 模式时,该位会自动清除。

如果 FIFO 配置为 TX 模式,则当相关通道处于 CH_RESET 模式时,该位也会自动清除。

CFRXIE 位（常用 FIFO RX 中断启用）

当在相应的FIFO缓冲区中接收到帧后设置中断标志时,CFRXIE位能够生成FIFO中断。

CANFD 模块处于 GL_SLEEP 模式时,请勿写入此位。

Only write to this bit when the CANFD module is in GL_RESET mode.

CFIGCV[2:0] bits (Common FIFO Interrupt Generation Counter Value)

CFEMP bit (Common FIFO Empty)

The CFEMP bit is set automatically when:

- The CPU has read all messages from the FIFO configured in RX mode
- All messages have been transmitted from the FIFO configured in TX mode
- The FIFO is disabled by setting the CFE bit to 0
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET when FIFO configured in TX mode.

The CFEMP bit is cleared automatically when:

- The first reception message is stored in the FIFO buffer when configured in RX mode
- The first message to be transmitted is stored in the FIFO buffer when configured in TX mode.

CFFLL bit (Common FIFO Full)

The CFFLL bit is set automatically when the number of CAN messages stored in the FIFO matches the configured FIFO depth.

The CFFLL bit is cleared automatically when:

- The number of CAN messages stored in the FIFO is less than the configured FIFO depth
- The FIFO is disabled by setting the CFE bit to 0
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode when FIFO buffer is configured in TX mode.

CFMLT bit (Common FIFO Message Lost)

The CFMLT bit is set automatically whenever a message is lost due to attempted storage of a new message when FIFO is already full in RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The CFMLT bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode
- When the related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

CFRXIF bit (Common RX FIFO Interrupt Flag)

The CFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

CFEMP 位（常用 FIFO 空）

CFEMP 位在以下情况下自动设置:

- CPU 已读取 RX 模式下配置的 FIFO 的所有消息
- 所有消息均已从以 TX 模式配置的 FIFO 传输
- 通过将 CFE 位设置为 0 来禁用 FIFO
- CANFD 模块处于 GL_RESET 模式
- 相关的 CANFD 通道在 TX 模式下配置 FIFO 时处于 CH_RESET。

CFEMP 位在以下情况下自动清除:

- 第一接收消息在RX模式下配置时存储在FIFO缓冲区中
- 在TX模式下配置时,要发送的第一条消息存储在FIFO缓冲区中。

CFFLL 位（通用 FIFO 全）

当 FIFO 中存储的 CAN 消息数量与配置的 FIFO 深度匹配时,会自动设置 CFFLL 位。

CFFLL 位自动清除时:

- 存储在 FIFO 中的 CAN 消息的数量小于配置的 FIFO 深度
- 通过将 CFE 位设置为 0 来禁用 FIFO
- CANFD 模块处于 GL_RESET 模式
- 当 FIFO 缓冲区配置为 TX 模式时,相关的 CANFD 通道处于 CH_RESET 模式。

CFMLT 位（常见 FIFO 消息丢失）

当 FIFO 在 RX 模式下已满时,每当由于尝试存储新消息而导致消息丢失时,CFMLT 位就会自动设置。

如果来自 CAN 通道的集合与写访问的清除同时发生,则该位被设置。

CANFD 模块处于 GL_HALT 或 GL_OPERATION 模式且相关 CANFD 通道未处于 CH_RESET 模式时,才写入此位,对于配置为 TX FIFO 的 FIFO,写入 1 没有效果。

请勿使用位清除指令来清除此位。MOV指令来确保只清除指定位。
其他位保持 1。

CFMLT 位已清除:

- 通过向其写入 0
- 当CANFD模块处于GL_RESET模式时
- 当相关 CANFD 通道处于 CH_RESET 模式时,如果 FIFO 缓冲区配置为 TX 模式。

CFRXIF 位（通用 RX FIFO 中断标志）

如果禁用 Common FIFO 缓冲区,则不会自动清除 CFRXIF 位。

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers when configured in RX mode.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The CFRXIF bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode

CFTXIF bit (Common TX FIFO Interrupt Flag)

The CFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO buffer configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers configured in TX mode.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The CFTXIF bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode
- When the related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

CFMC[5:0] bits (Common FIFO Message Count)

The CFMC[5:0] bits indicate the following:

- Number of CAN messages stored by the CPU in the FIFO buffer configured in TX mode pending for transmission
- Number of CAN messages stored in the FIFO buffer configured in RX mode by CANFD module to be read by the CPU

The CFMC[5:0] bits are cleared automatically when:

- The FIFO is disabled
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

The Common FIFO Pointer Control Registers can be used to increment the read or write pointer of the corresponding Common FIFO buffer.

CFPC[7:0] bits (Common FIFO Pointer Control)

When the value 0xFF is written into the CFPC[7:0] bits, the read pointer of the corresponding Common FIFO buffer (when configured in RX mode), or the write pointer of the corresponding Common FIFO buffer (when configured in TX mode) moves to the next FIFO entry.

The read value from these bits is always 0x00.

Only write to these bits when the CANFD module is in GL_HALT or GL_OPERATION mode.

Only write 0xFF to this register when:

- The Common FIFO buffer is enabled and is not empty if configured in RX mode
- The Common FIFO buffer is enabled and is not full if configured in TX mode

Do not write to the Common FIFO Pointer Control registers when DMA is enabled.

7:3	—	These bits are read as 0. The write value should be 0.	R/W

The TX Message Buffer Control Registers configure the TX message buffer functions.

TMTR bit (TX Message Buffer Transmission Request)

When the TMTR bit is set, the CANFD module logic tries to transmit the message stored in the corresponding message buffer.

Only write to this bit when the related CANFD module is in CH_HALT or CH_OPERATION mode.

Do not set this bit if the corresponding TX message buffer is linked to a COM FIFO in TX mode or is a part of TX Queue.

This bit cannot be directly cleared by a CPU write access.

This bit can only be set when the Transmission Result flag bits (CFDTMSTSj.TMTRF) in the CFDTMSTSj register corresponding to the message buffer are cleared to 00b.

The TMTR bit is automatically cleared by the:

- CANFD module logic at the end of a successful transmission
- CANFD module logic at the end of a transmission abort, requested by the corresponding CFDTMCi.TMTAR bit
- CANFD module logic when there is a detection of a CAN bus error or arbitration loss if CFDTMCi.TMOM bit is set for the message buffer
- CANFD module logic when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

TMTAR bit (TX Message Buffer Transmission Abort Request)

When the TMTAR bit is set, the CANFD module logic tries to abort the transmission of the frame stored in the corresponding message buffer.

In most cases, transmission cannot be aborted if the internal scan for transmission is complete and the message buffer has already been selected for transmission. In this case, frame may be transmitted successfully from the message buffer. The message buffer selection is released by entering CH_HALT mode.

However, message buffer selected for transmission can be aborted by an abort request when the CAN node detects a new message on the bus (RX pin) before it starts transmission from the selected message buffer.

Only write to the TMTAR bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. This bit can only be set when the related transmit request TMTR bit is set.

The TMTAR bit cannot be cleared by a CPU write access. Clearing of this bit by CANFD has priority over setting by a CPU write access.

The TMTAR bit is automatically cleared by:

- The CANFD module logic at the end of a successful transmission
- The CANFD module logic at the end of a transmission abort
- The CANFD module logic when there is detection of a CAN bus error or arbitration loss
- The CANFD module logic when the CANFD module is in GL_RESET mode or the related channel enters CH_RESET mode.

TMOM bit (TX Message Buffer One-shot Mode)

When the TMOM bit is set, the CANFD module logic tries to transmit the message only once.

If the transmission is successful, the CFDTMSTSj.TMTRF bits are set to 10b or 11b. Otherwise, the transmission is automatically aborted and CFDTMSTSj.TMTRF bits are set to 01b due to a bus error or a bus arbitration lost.

The TMOM bit remains set if the transmission has completed successfully or aborted due to an error or a loss of arbitration.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Set this bit at the same time as the TMTR bit. Clear this bit with a write access.

If a message has already been requested for transmission, do not write to this bit until the message has been successfully transmitted or transmission has been aborted.

7:3	—	这些位读作 0。写入值应为 0。	R/W

TX 消息缓冲区控制寄存器配置 TX 消息缓冲区功能。

TMTR 位（TX 消息缓冲区传输请求）

TMTR 位设置时, CANFD 模块逻辑尝试传输存储在相应消息缓冲区中的消息。

仅当相关 CANFD 模块处于 CH_HALT 或 CH_OPERATION 模式时才写入此位。

如果相应的 TX 消息缓冲区在 TX 模式下链接到 COM FIFO 或是 TX 队列的一部分,请勿设置此位。

CPU 写访问无法直接清除该位。

CFDTMSTSj寄存器中与消息缓冲区对应的传输结果标志位（CFDTMSTSj。TMTRF）被清除到00b时,才能设置该位。TMTR 位由以下自动清除:

● CANFD 模块逻辑在成功传输结束时

● CANFD 模块逻辑位于传输中止结束时,由相应的 CFDTMCi。TMTAR 位请求

如果为消息缓冲区设置了 CFDTMCi。TMOM 位,则当检测到 CAN 总线错误或仲裁丢失时,● CANFD 模块逻辑

● CANFD 模块处于 GL_RESET 模式或相关通道处于 CH_RESET 模式时的 CANFD 模块逻辑。

TMTAR 位（TX 消息缓冲区传输中止请求）

TMTAR位设置时,CANFD模块逻辑尝试中止存储在相应消息缓冲区中的帧的传输。

在大多数情况下,如果内部传输扫描完成并且消息缓冲区已被选择用于传输,则传输不能中止。在这种情况下,可以从消息缓冲器成功发送帧。入CH_HALT模式来释放消息缓冲区选择。

然而,当CAN节点在总线（RX引脚）上的新消息从所选消息缓冲区开始传输之前检测到该新消息时,选择用于传输的消息缓冲区可以通过中止请求中止。

仅当相关 CANFD 通道处于 CH_HALT 或 CH_OPERATION 模式时才写入 TMTAR 位。仅当相关发送请求TMTR位被设置时才能设置该位。

CPU 写访问无法清除 TMTAR 位。CANFD 清除此位优先于 CPU 写入访问设置。

TMTAR 位由以下自动清除

● 成功传输结束时的 CANFD 模块逻辑

● 传输中止结束时的 CANFD 模块逻辑

● 当检测到 CAN 总线错误或仲裁丢失时的 CANFD 模块逻辑

● CANFD模块处于GL_RESET模式或相关信道进入CH_RESET模式时的CANFD模块逻辑。

TMOM 位（TX 消息缓冲区一次性模式）

TMOM位被设置时,CANFD模块逻辑尝试仅发送消息一次。

如果传输成功,则CFDTMSTSj。TMTRF位被设置为10b或11b。否则,由于总线错误或总线仲裁丢失,传输自动中止,CFDTMSTSj。TMTRF 位设置为 01b。

如果传输已成功完成或因错误或仲裁失败而中止,则 TMOM 位保持设置。

仅当相关 CANFD 通道处于 CH_HALT 或 CH_OPERATION 模式时才写入此位。

TMTR 位的同时设置该位。通过写访问清除此位。

如果已经请求传输消息,则在消息成功传输或传输中止之前不要写入该位。

The TMOM bit is automatically cleared by the CANFD module logic when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

This bit is cleared automatically when:

- Transmission stops
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

TMTRF[1:0] bits (TX Message Buffer Transmission Result Flag)

The TMTRF[1:0] bits show the result for the corresponding TX message buffer. The status is as follows:

- 11: Transmission was successful from the corresponding TX message buffer, but the CFDTMCi.TMTAR bit was set for this TX message buffer.

Only write to these bits when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

The TMTRF[1:0] bits are cleared automatically when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

CANFD模块处于GL_RESET模式或相关信道处于CH_RESET模式时,TMOM位由CANFD模块逻辑自动清除。

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CANFD channel is in CH_RESET mode.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CANFD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

TXQMC[2:0][13:8] bits (TX Queue Message Count)

The TXQMC[2:0] bits show the number of CAN messages in the TX Queue.

THLEMP bit (TX History List Empty)

The THLEMP bit is set automatically when the CPU has read all the entries from the TX History List buffer.

THLFLL bit (TX History List Full)

The THLFLL bit is set automatically when the number of entries in the TX History List buffer matches the TX History List depth.

Each TX History List can store up to 8 entries.

This bit is cleared automatically when:

- The number of entries in the TX History List buffer is less than the TX History List depth
- The TX History List is disabled
- The related CANFD channel is in CH_RESET mode.

The message buffer configuration consists of four types of Message Buffer components:

- RX Message Buffer Component (CFDRMBCPb[0])
- RX FIFO Access Message Buffer Component (CFDRFMBCPb[0])
- Common FIFO Access Message Buffer Component (CFDCFMBCP0[0])
- TX Message Buffer Component (CFDTMBCPb[0]).

Where b = the Message Buffer component index that has a range that varies based on the type of Message Buffer component.

For a summary of this configuration, see Figure 26.29. For a detailed description of the number of and the different types of message buffers, see section 26.6. FIFO Buffers and Normal Message Buffer Configuration.

As described in section 26.2. Register Descriptions, each Message Buffer component consists of the following registers:

- Identifier (ID)
- Pointer (PTR)
- Data Field (DFp).

Where p = the Data Field register index that has a range that varies based on the type of message buffer component.

Rc is the Message Buffer Component register where c = Message Buffer Component register index that has a range that varies based on the type of Message Buffer component.

A description of the registers, their associated bits and their accessibility are shown below the summary and detailed figures of each component.

In each of the figures, a cell that contains '-' means reserved and has the same behavio as reserved bits for registers in section 26.2.62. Message Buffer Component Structure.

The RX FIFO Access ID Registers b (b = 0 to 1) store the ID field, IDE bit and RTR bit of the message.

RFID[28:0] bits (RX FIFO Buffer ID Field)

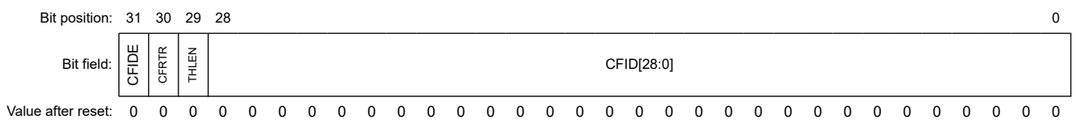
26.2.62.13 CFDCFID : Common FIFO Access ID Register

Base address: CANFD_B = 0x400B_0000

Offset address: 0x05B8



Bit	Symbol	Function	R/W
28:0	CFID[28:0]	Common FIFO Buffer ID Field STD-ID / EXT-ID fields	R/W
29	THLEN	THL Entry enable TX FIFO Mode: 0: Entry will not be stored in THL after successful TX. 1: Entry will be stored in THL after successful TX. RX FIFO Mode: Reserved, this bit is read as 0	R/W

31	CFIDE	Common FIFO Buffer IDE Bit 0: STD-ID will be transmitted or has been received 1: EXT-ID will be transmitted or has been received	R/W

The Common FIFO Access ID registers store the ID field, IDE bit and RTR bit of the message.

In TX mode, users can read data from the FIFO, only for the current entry based on the write pointer value, not for the other entries.

CFID[28:0] bit (Common FIFO Buffer ID Field)

These are the bits of the STD-ID / EXT-ID fields of the message in the FIFO Buffer.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

THLEN bit (THL Entry enable)

This bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

CFRTR bit (Common FIFO Buffer RTR Bit)

This bit selects whether a Data Frame or a Remote Frame will be transmitted from or was received in the FIFO Buffer.

Note: There are no remote frames in CANFD format. In case a CANFD frame was received (RX mode) the register reflects the state of the received value (RRS bit in FD frame format). In case of CANFD transmission (TX mode CFDCFID.CFFDF =1) the bit is always transmitted dominant (Data Frame).

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

CFIDE bit (Common FIFO Buffer IDE Bit)

This bit selects whether a message with EXT-ID or STD-ID will be transmitted from or was received in the FIFO Buffer.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

26.2.62.15 CFDCFFDCSTS:通用 FIFO 访问 CANFD 控制/状态寄存器

基本地址: CANFD_B = 0x400B_0000

偏移地址: 0x05c0

15:10	—	These bits are read as 0. The write value should be 0.	R/W
31:16	CFPTR[15:0]	Common FIFO Buffer Pointer Field	R/W

Note 1. This bit is not available in the classical CAN function.

The Common FIFO Access CANFD Control/Status Registers show the status of the FDF, BRS and ESI bits, including the pointer of the received CANFD frame or the CANFD frame to transmit.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

CFESI bit (Error State Indicator bit)

In TX mode, you can read and write from FIFO buffers. In this mode, when the CANFD module is not in error passive, the CFESI bit equals the write value. Otherwise, it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFESI bit is updated with the ESI bit value of the CANFD frame when it has been received, indicating the error state of the transmitting node. In RX mode, 0 is stored to this bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFBRS bit (Bit Rate Switch bit)

In TX mode, you can read and write from FIFO buffers. In this mode, the CANFD module either transmits a 0 to indicate no bit rate switch in the frame to be transmitted or a 1 to indicate a bit rate switch in the frame to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFBRS bit is updated with the BRS bit value of the CANFD frame when it has been received, indicating whether there is a bit rate switch (1) or (0) on the CANFD frame.

In RX mode, 0 is stored to the CFBRS bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFFDF bit (CAN FD Format bit)

In TX mode, you can read and write from FIFO buffers. In this mode, the CANFD module either transmits a 0 to indicate a CAN 2.0 frame is to be transmitted or a 1 to indicate a CANFD frame is to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFFDF bit is updated with the FDF bit value of the CAN frame when it has been received, indicating whether it is a CAN 2.0 frame (0) or a CANFD frame (1).

Note: This bit is not available in the classical CAN function.

CFIFL[1:0] bits (COMMON FIFO Buffer Information Label Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTS.CFIFL[1:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The information label value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX mode).

位	符号	功能	R/W
1	CFBRS*1	位速率开关位 0:在没有比特率开关的情况下接收或要发送的CANFD帧 1:接收或要在比特率开关的情况下发送的CANFD帧	R/W
2	CFFDF*1	CAN FD 格式位 0:接收或发送的非CANFD帧 1:接收或发送的CANFD帧	R/W
7:3	—	这些位读作 0。写入值应为 0。	R/W
9:8	CFIFL[1:0]	通用 FIFO 缓冲区信息标签字段	R/W
15:10	—	这些位读作 0。写入值应为 0。	R/W
31:16	CFPTR[15:0]	常见 FIFO 缓冲器指针字段	R/W

注1。该位在经典 CAN 函数中不可用。

通用 FIFO 访问 CANFD 控制/状态寄存器显示 FDF、BRS 和 ESI 位的状态,包括接收到的 CANFD 帧或要发送的 CANFD 帧的指针。

在 TX 模式下,您可以从 FIFO 读取数据,仅针对基于写入指针值的当前条目,而不针对其他条目。

CFESI 位（错误状态指示器位）

TX 模式下, 您可以从 FIFO 缓冲区读取和写入。在此模式下,当 CANFD 模块不是无源错误时,CFESI 位等于写入值。否则,它是一个不在乎,并且该位在 CAN 总线上以 1 的形式传输,表明这是一个错误无源节点。

RX 模式下, 您只能从 FIFO 缓冲区读取数据。

RX模式下,CFESI位在接收到CANFD帧的ESI位值时更新,指示发送节点的错误状态。RX模式下,当接收到的FDF位为0时,0被存储到该位,这意味着接收CAN 2。0帧。

注: 该位在经典 CAN 函数中不可用。

CFBRS 位（比特率开关位）

TX 模式下, 您可以从 FIFO 缓冲区读取和写入。在此模式下,CANFD模块发送0以指示要发送的帧中没有比特率开关,或者发送1以指示要发送的帧中的比特率开关。

RX 模式下, 您只能从 FIFO 缓冲区读取数据。

RX模式下,CFBRS位在接收到CANFD帧的BRS位值时更新,指示CANFD帧上是否有比特率开关(1)或(0)。

在RX模式下,当接收到的FDF位为0时,0被存储到CFBRS位,这意味着接收CAN 2。0帧。

注意:该位在经典 CAN 函数中不可用。

CFFDF 位（CAN FD 格式位）

TX 模式下, 您可以从 FIFO 缓冲区读取和写入。在此模式下,CANFD模块要么发送0以指示要发送的CAN 2。0帧,要么发送1以指示要发送的CANFD帧。

RX 模式下, 您只能从 FIFO 缓冲区读取数据。

在RX模式下,CFFDF比特在接收到CAN帧时更新为CAN帧的FDF比特值,指示它是CAN 2。0帧(0)还是CANFD帧(1)。

注意:该位在经典 CAN 函数中不可用。

CFIFL[1:0] 位（通用 FIFO 缓冲区信息标签字段）

如果Common FIFO配置为TX模式,则在成功传输消息后,将CFDCFFDCSTS。CFIFL[1:0]中编程的值与附加消息信息一起存储到TX历史列表中。

来自相关全局接受过滤器列表条目的信息标签值存储在这些位中（如果 FIFO 配置为任一 RX 模式）。

In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

CFPTR[15:0] bits (Common FIFO Buffer Pointer Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTS.CFPTR[15:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The pointer value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX mode).

In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*1

TX 模式下, 您可以从 FIFO 缓冲区读取和写入。RX
模式下, 您只能从 FIFO 缓冲区读取数据。

CFPTR[15:0] 位（常用 FIFO 缓冲器指针字段）

如果Common FIFO配置为TX模式,则在成功传输消息后,将CFDCFFDCSTS。CFPTR[15:0]中编程的值与附加消息信息一起存储到TX历史列表中。

来自相关全局接受过滤器列表条目的指针值存储在这些位中（如果 FIFO 配置为任一 RX 模式）。

TX 模式下, 您可以从 FIFO 缓冲区读取和写入。RX
模式下, 您只能从 FIFO 缓冲区读取数据。

TMID[28:0] bits (TX Message Buffer ID Field)

The TMID[28:0] bits are bits of the STD-ID/EXT-ID fields of the message stored in this TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

THLEN bit (Tx History List Entry)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMRTR bit (TX Message Buffer RTR bit)

The TMRTR bit selects whether a data frame or remote frame is to be transmitted from this TX message buffer.

Note: There are no remote frames in CANFD format. For a CANFD transmission (CFDTMFDCTRb.CFFDF = 1), this bit is always transmitted dominant (data frame).

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMIDE bit (TX Message Buffer IDE bit)

The TMIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from this TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

26.2.62.19 CFDTMPTRb : TX Message Buffer Pointer Register (b = 0 to 3)

31:28	TMDLC[3:0]	TX Message Buffer DLC Field Number of data bytes to be transmitted in a CAN frame.	R/W

Each TX Message Buffer Pointer Register b (b = 0 to 3) is used to store the DLC fields of the message to transmit from the associated buffer.

TMDLC[3:0] bits (TX Message Buffer DLC Field)

The TMDLC[3:0] bits select the number of data bytes to be transmitted from this TX message buffer when the corresponding TMRTR bit is configured as 0.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes to be transmitted.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMID[28:0] 位（TX 消息缓冲区 ID 字段）

TMID[28:0]位是存储在该TX消息缓冲器中的消息的STD-ID/EXT-ID字段的位。

CH_SLEEP 模式时,请勿写入这些位。

TMRTR 位（TX 消息缓冲区 RTR 位）

TMRTR位选择是否要从该TX消息缓冲器发送数据帧或远程帧。

CH_SLEEP 模式时,请勿写入这些位。

TMIDE 位（TX 消息缓冲区 IDE 位）

TMIDE位选择是否要从该TX消息缓冲器发送具有EXT-ID或STD-ID的消息。

CH_SLEEP 模式时,请勿写入这些位。

Do not write to the TMESI bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMBRS bit (Bit Rate Switch bit)

31:24	TMDB_HH[7:0]	TX Message Buffer Data Byte ((p × 4) + 3)	R/W

Each TX Message Buffer Data Field p Register b (p = 0 to 15, b = 0 to 3) is used to store data bytes (p × 4) to data bytes ((p × 4) + 3) of the message to transmit from the associated buffer.

TMDB_LL[7:0] bits (TX Message Buffer Data Byte (p × 4))

TMDB_LL[7:0] bits store data bytes (p × 4) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMDB_LH[7:0] bits (TX Message Buffer Data Byte ((p × 4) + 1))

TMDB_LH[7:0] bits store data bytes ((p × 4) + 1) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMDB_HL[7:0] bits (TX Message Buffer Data Byte ((p × 4) + 2))

TMDB_HL[7:0] bits store data bytes ((p × 4) + 2) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMDB_HH[7:0] bits (TX Message Buffer Data Byte ((p × 4) + 3))

TMDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

26.3 Modes of Operation

26.3.1 Overview

The modes of the CANFD module can be classified into 2 groups:

- Global modes
- Channel modes

26.3.2 Global Modes

These modes are applicable for the complete CANFD module and therefore are called Global modes. The global modes of the CANFD module are:

TMPTR[15:0] 位（TX 消息缓冲器指针字段）

TMPTR[15:0]位存储要复制的指针值,以及TX历史记录中的附加消息信息
成功传输消息后列出。

CH_SLEEP 模式时,请勿写入这些位。

26。3 操作模式

26。3。1 概述

CANFD模块的模式可分为2组:

- 全局模式
- 通道模式

26。3。2 全球模式

这些模式适用于完整的 CANFD 模块,因此称为全局模式。CANFD模块的全局模式是:

- Global Sleep
- Global Reset
- Global Halt
- Global Operation.

Figure 26.2 shows the possible transitions between the Global modes.

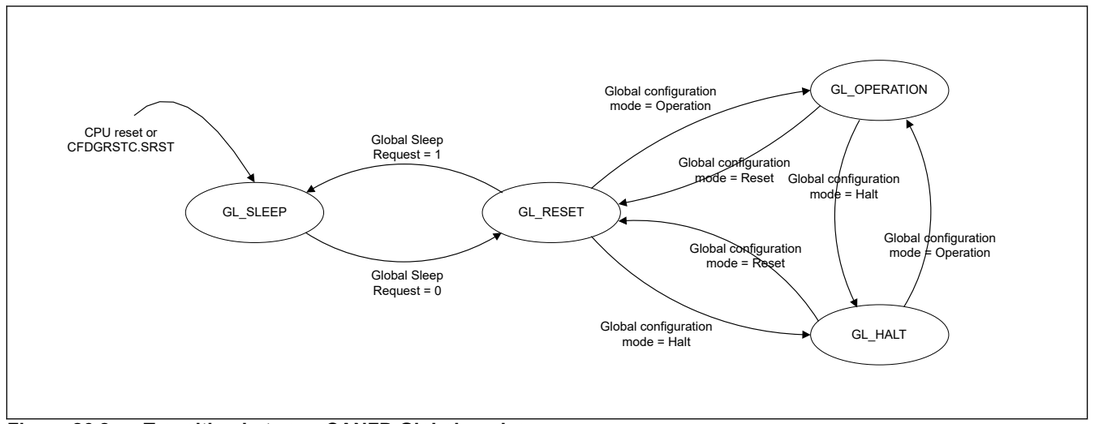

Figure 26.2 Transition between CANFD Global modes

Change in the Global mode can affect the Channel mode. Table 26.14 shows the effect of a Global mode transition on a Channel mode.

Table 26.14 Possible CANFD Channel modes and Global modes

	Sleep	Reset	Halt	Operation
Sleep		Ch-Sleep: Keep Ch-Reset: N/A Ch-Halt: N/A Ch-Oper: N/A		
Reset	Ch-Sleep: Keep Ch-Reset: → Ch-Sleep Ch-Halt: N/A Ch-Oper: N/A		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A
Halt		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: N/A		Ch-Sleep:Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: N/A
Operation		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: → Ch-Reset	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: → Ch-Halt	

26.3.2.1 Global Sleep Mode

After the release of a hardware reset or after setting and clearing a CFDGRSTC.SRST bit, the CANFD module automatically enters Global Sleep mode.

The CANFD module also enters the Global Sleep mode when the Global Sleep Request bit is set while it is in Global Reset mode. This control bit cannot be set in Global Halt mode or Global Operation mode.

Setting the Global Sleep Request bit sets Channel Sleep Request bit and forces the channel into the Channel Sleep mode.

- 全局重置
- 全球停止
- 全球运营。

图 26。2 显示了全局模式之间可能的转换。

全局模式的变化会影响通道模式。表 26。14 显示了全局模式转换对通道模式的影响。

26。3。2。1 全局睡眠模式

硬件重置发布后或设置并清除 CFDGRSTC。SRST 位后,CANFD 模块自动进入全局睡眠模式。

当全局睡眠请求位处于全局重置模式时设置全局睡眠请求位时,CANFD模块也进入全局睡眠模式。该控制位不能设置为全局停止模式或全局操作模式。

设置全局睡眠请求位设置通道睡眠请求位并迫使通道进入通道睡眠模式。

Sleep mode is used for power saving purpose. When CANFD module is in Global Sleep mode, only the clock for CPU write access to the Global Sleep Mode Request bit is active. All other clocks are stopped and all other functions of the CANFD module are suspended.

Read access from all registers is still possible and all register values are preserved.

After setting the Global Sleep Request bit, it is necessary to confirm that the Global Sleep status has been updated, indicating successful transition to Global Sleep mode before the Global Sleep Request bit can be cleared again.

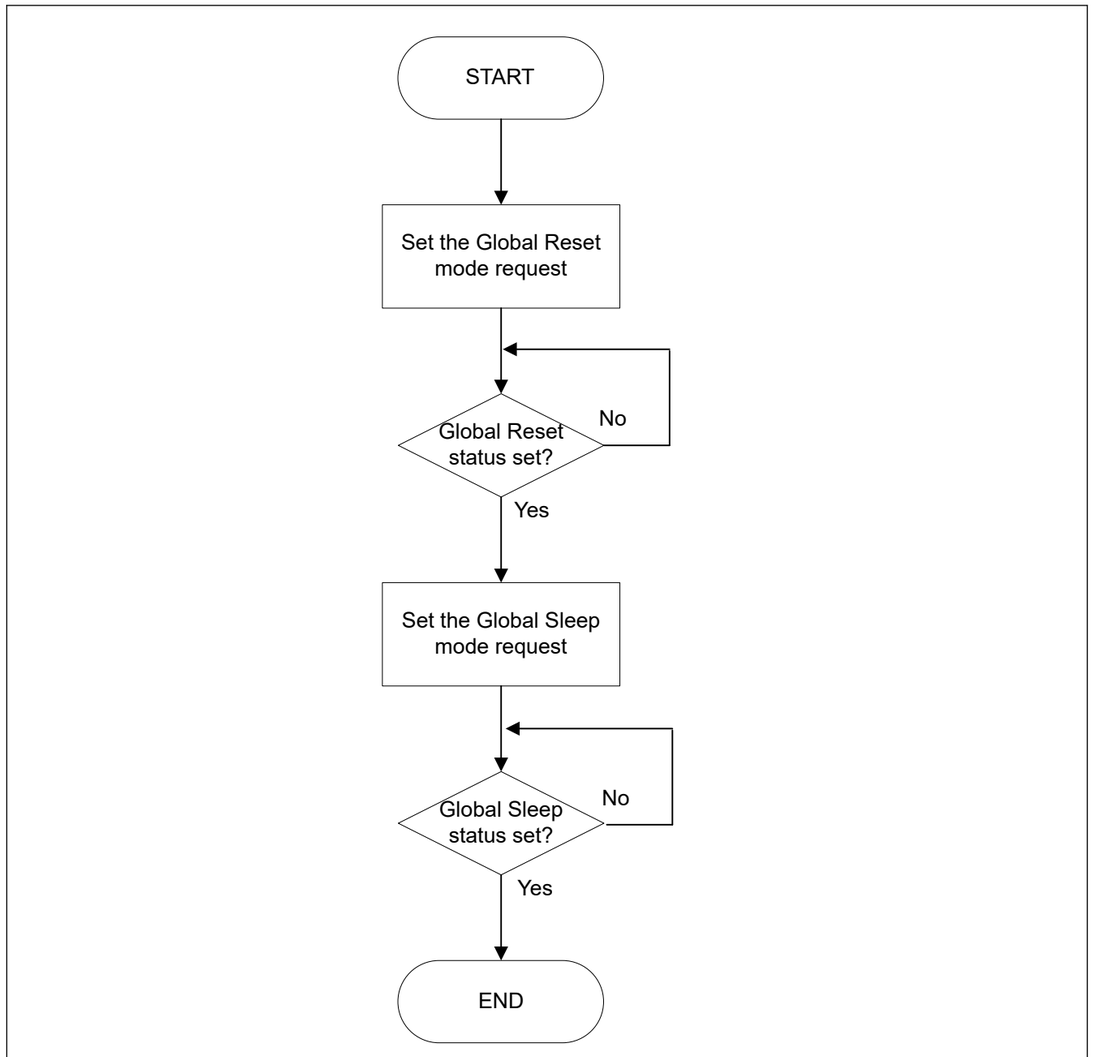

Figure 26.3 Procedure for entering Global Sleep mode

睡眠模式用于省电目的。当CANFD模块处于全局睡眠模式时,只有CPU写入访问全局睡眠模式请求位的时钟处于活动状态。所有其他时钟均停止,CANFD 模块的所有其他功能均暂停。

仍然可以从所有寄存器读取访问权限,并且保留所有寄存器值。

设置全局睡眠请求位后,需要确认全局睡眠状态已更新,表明在再次清除全局睡眠请求位之前成功过渡到全局睡眠模式。

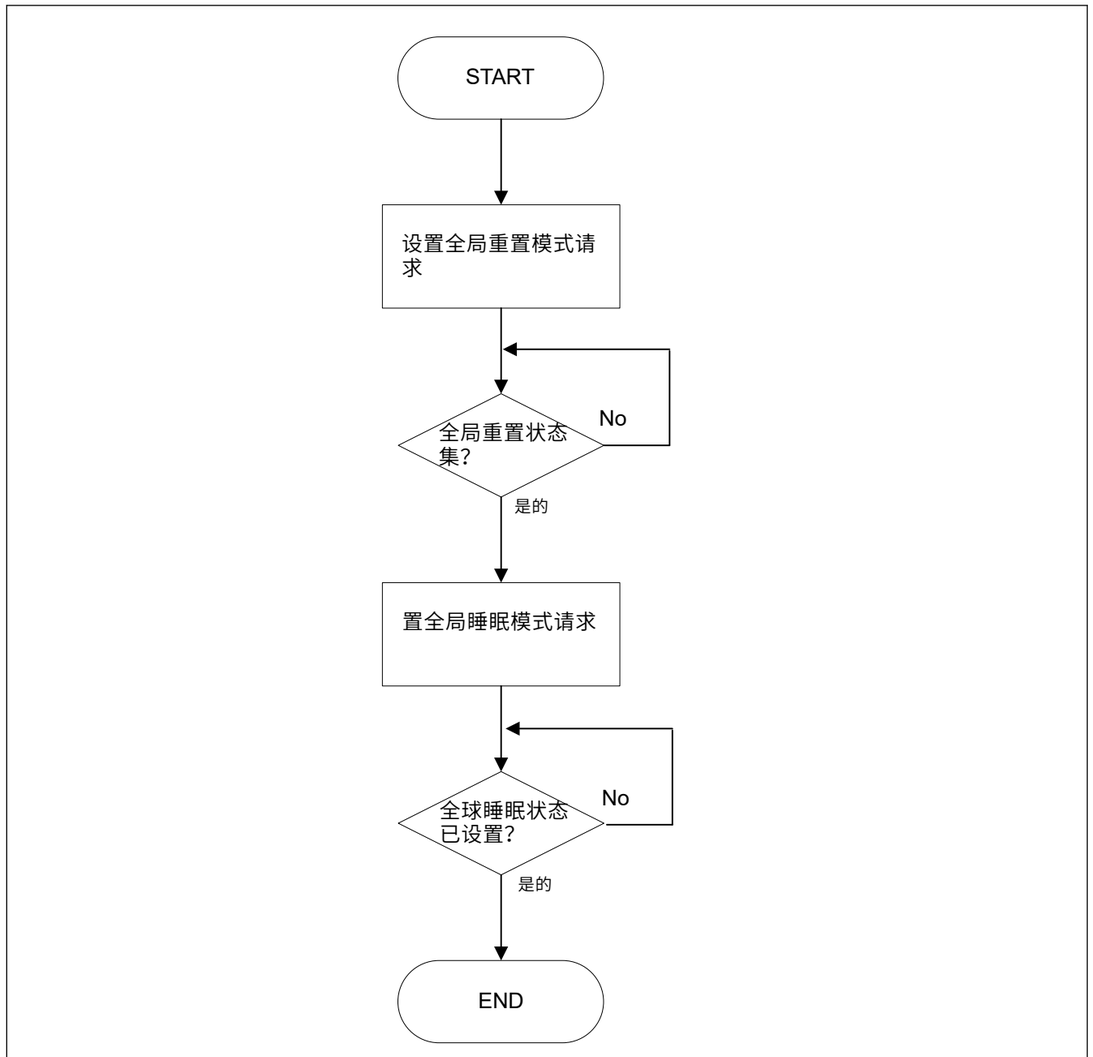

图26。3 进入全局睡眠模式的程序

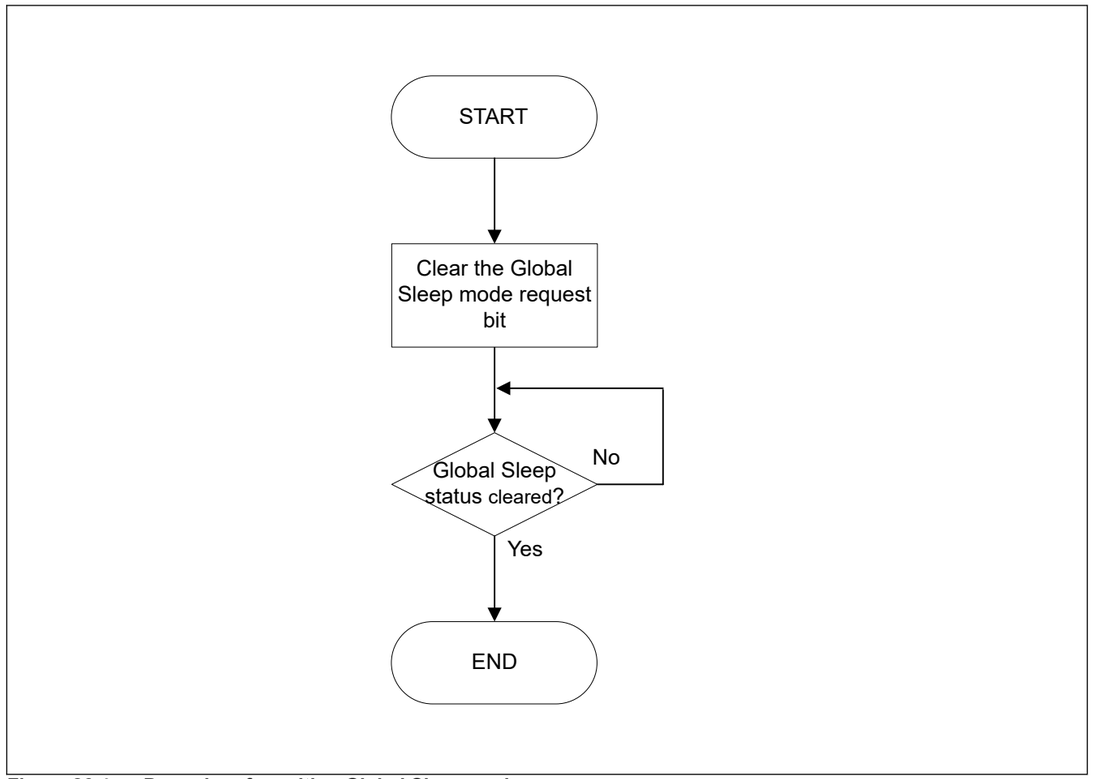

Figure 26.4 Procedure for exiting Global Sleep mode

26.3.2.2 Global Reset Mode

The CANFD module enters this mode in the following ways:

- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Reset mode while the CANFD module is in Global Halt or Global Operation mode
- Global Sleep Mode Request bit is cleared while CANFD module is in Global Sleep mode.

In Global Reset mode, all CANFD module functions are suspended and all status and flag registers are initialized.

Additionally all FIFOs and TX Queues are disabled and transmission control bits are cleared.

Configuration registers (except the test mode registers) are not initialized in this mode to their MCU reset values and the CANFD module can be configured.

See section 26.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Global Reset mode is performed.

Setting the Global mode to Reset by setting the Global Mode Control bits CFDGCTR.GMDC in the Global Control Register to 01b sets Channel Mode Control bits CFDC0CTR.CHMDC in the Channel Control Registers to 01b and forces the channel into the Channel Reset mode.

For channels that are already in Channel Reset mode or Channel Sleep mode, this automatic transition is not performed (CFDC0CTR.CHMDC of related channel already set to 01b).

After setting Global Mode Control bit CFDGCTR.GMDC to Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDGSTS.GRSTSTS in the Global Status Register has been updated, indicating successful transition to Global Reset mode before CFDGCTR.GMDC can be changed again.

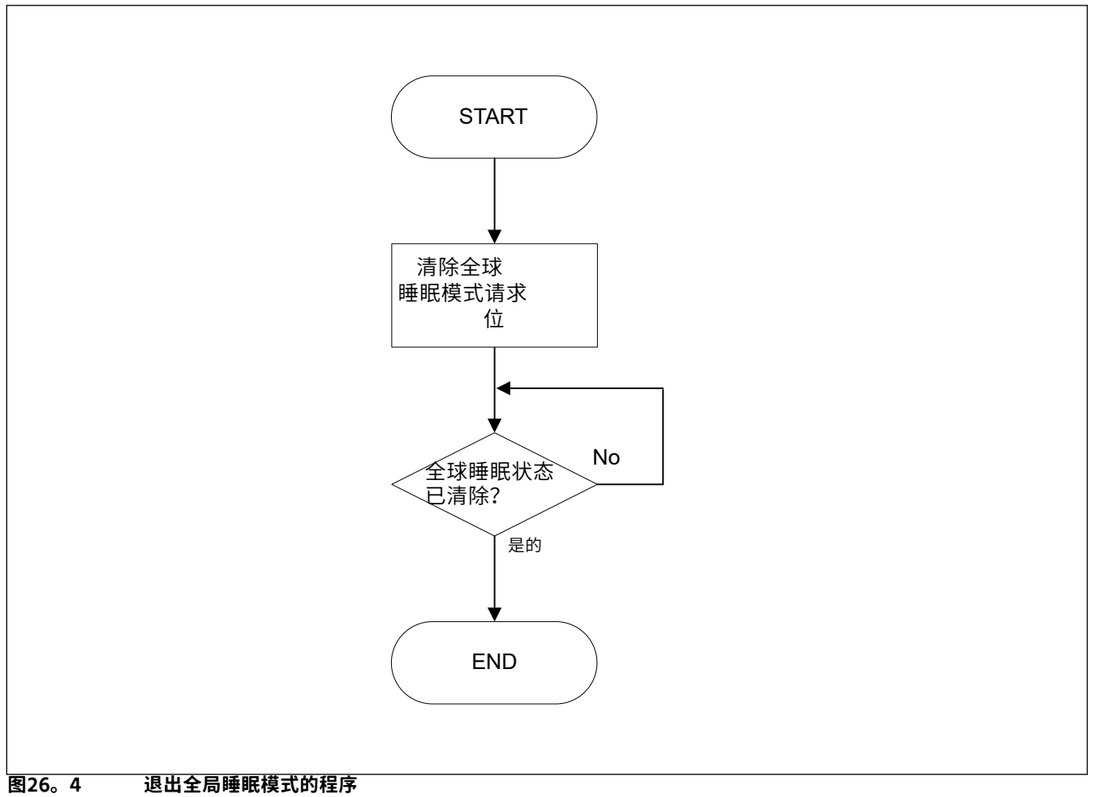

图26。4 退出全局睡眠模式的程序

26。3。2。2 全局重置模式

CANFD模块通过以下方式进入该模式:

- 全局模式控制位 CFDGCTR。GMDC 在全局控制寄存器中配置为全局重置模式,而 CANFD 模块处于全局停止或全局操作模式
- 全局睡眠模式 请求位被清除,而 CANFD 模块处于全局睡眠模式。

在全局重置模式下,所有 CANFD 模块功能均被暂停,所有状态和标志寄存器均被初始化。

此外,所有 FIFO 和 TX 队列都被禁用,传输控制位也被清除。

配置寄存器（测试模式寄存器除外）在此模式下未初始化为其 MCU 重置值,并且可以配置 CANFD 模块。

参见第 26。3。4 节。全局模式和通道模式转换交互,详细描述执行全局重置模式转换时所有寄存器的行为。

通过将全局控制寄存器中的全局模式控制位CFDGCTR。GMDC设置为01b,将全局模式控制位CFDC0CTR。CHMDC设置为01b,并将信道强制进入信道重置模式。

对于已经处于信道重置模式或信道睡眠模式的信道,不执行此自动转换（相关信道的CFDC0CTR。CHMDC已经设置为01b）。

将全局模式控制位CFDGCTR。GMDC设置为重置模式后,需要确认全局状态寄存器中的重置模式状态位CFDGSTS。GRSTSTS已更新,表明在CFDGCTR。GMDC可以再次更改之前成功过渡到全局重置模式。

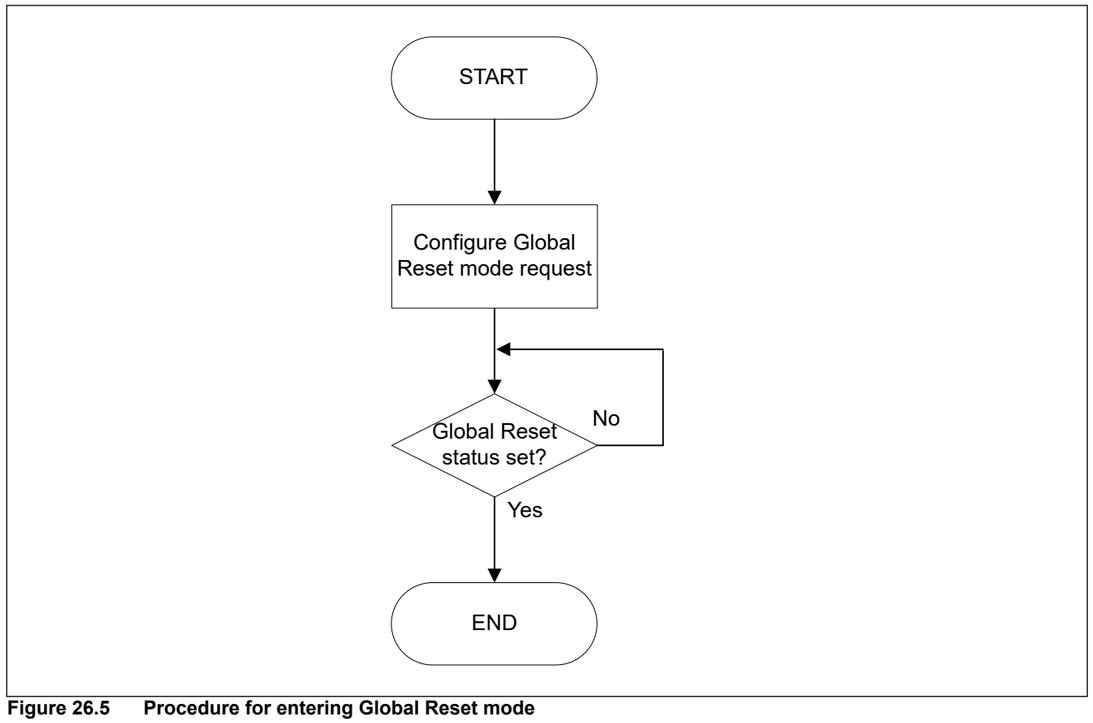

Figure 26.5 Procedure for entering Global Reset mode

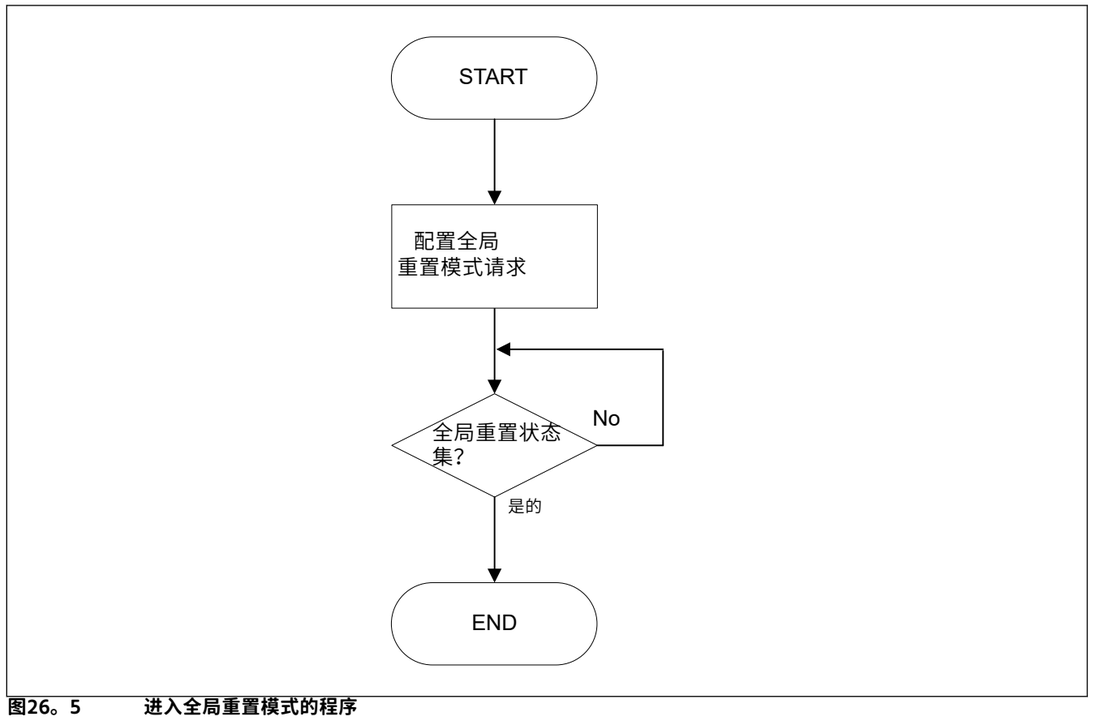

图26。5 进入全局重置模式的程序

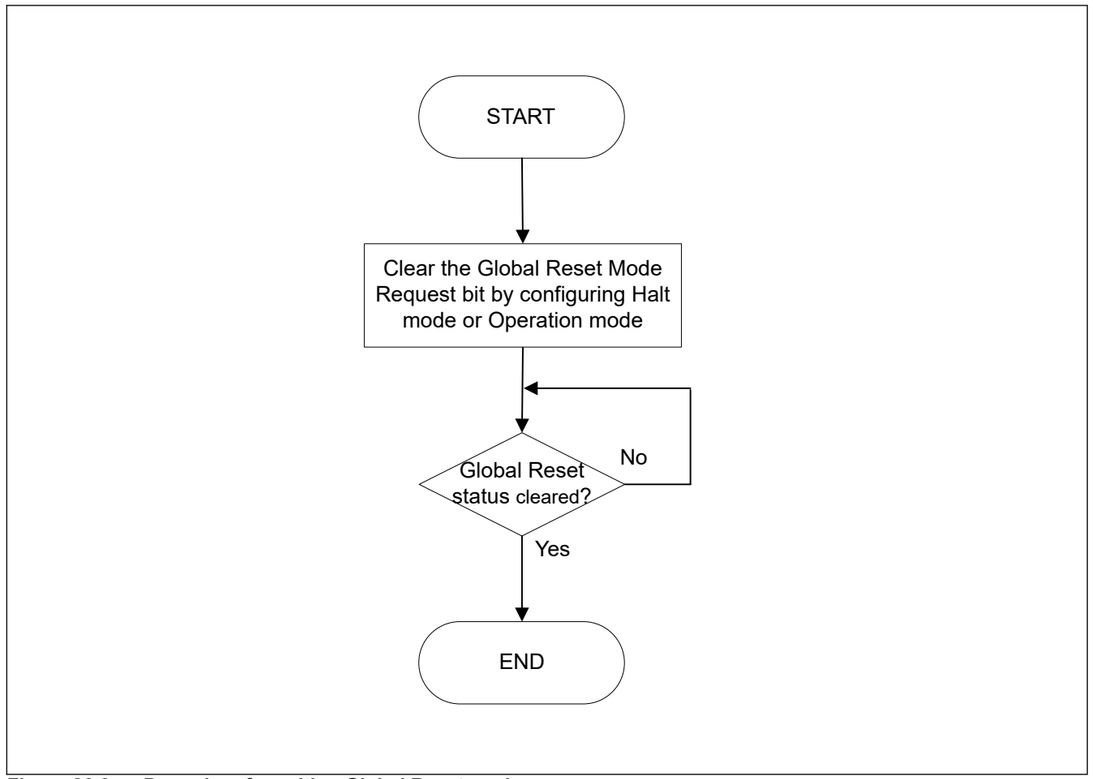

Figure 26.6 Procedure for exiting Global Reset mode

26.3.2.3 Global Halt Mode

The CANFD module enters this mode in the following ways:

- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Halt mode while the CANFD module is in Global Reset mode:
  - the channel in either Channel Reset or Channel Sleep mode remains in this mode
- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Halt mode while the CANFD module is in Global Operation mode:
  - the channel in Channel Reset, Channel Halt, or Channel Sleep mode remains in this mode
  - the channel in Channel Operation mode transitions to Channel Halt mode
  - Global Halt Mode Status bit is set when the channel has left Channel Operation mode.

If a transmission or reception is ongoing for a channel, the transition to Channel Halt mode is delayed until completion of the communication.

Similarly, if a channel is in bus-off, the full bus-off recovery sequence may be delayed depending on the channel configuration.

In Global Halt mode, all communications are suspended and CANFD logic does not cause any change to the Status and Flag registers (only when a channel is in the bus-off that its REC and TEC values are cleared). Additionally, the test mode configuration and control registers are not initialized in this mode.

The Global Halt mode should be used to configure global module test modes.

See section 26.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Global Halt mode is performed.

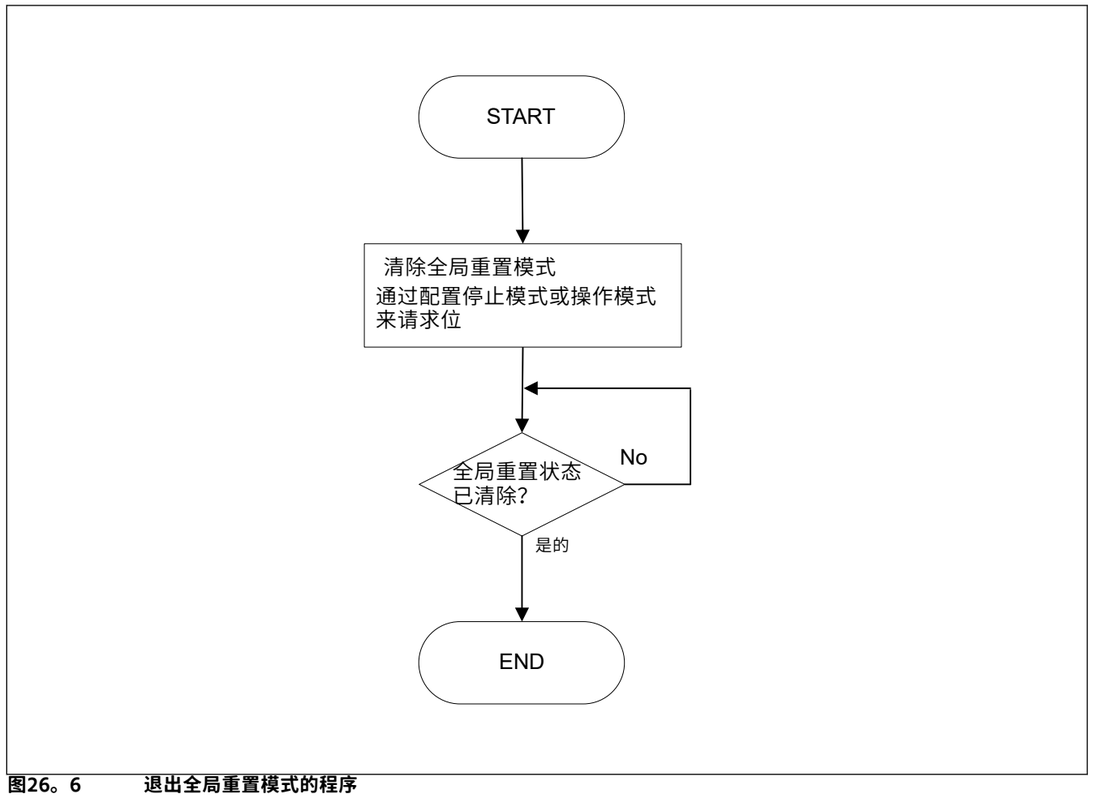

图26。6 退出全局重置模式的程序

26。3。2。3 全局停止模式

CANFD模块通过以下方式进入该模式:

● 全局模式控制位 CFDGCTR。GMDC 在全局控制寄存器中配置为全局停止模式,而 CANFD 模块处于全局重置模式:

– 通道重置或通道睡眠模式下的通道保持在此模式

● 全局模式控制位 CFDGCTR。GMDC 在全局控制寄存器中配置为全局停止模式,而 CANFD 模块处于全局操作模式:

– 通道重置、通道停止或通道睡眠模式中的通道保持在此模式

– 通道操作模式中的通道转换为通道停止模式

–全局停止模式状态位是在通道离开通道操作模式时设置的。

如果信道的发送或接收正在进行中,则向信道停止模式的转换将被延迟到通信完成。

类似地,如果信道处于总线关闭状态,则可以根据信道配置来延迟完整的总线关闭恢复序列。

在全局停止模式下,所有通信都会暂停,并且 CANFD 逻辑不会导致状态和标志寄存器发生任何更改（仅当信道处于总线关闭状态时,其 REC 和 TEC 值才会被清除）。此外,测试模式配置和控制寄存器未在此模式下初始化。

应使用全局停止模式来配置全局模块测试模式。

参见第 26。3。4 节。全局模式和通道模式转换交互,详细描述执行全局停止模式转换时所有寄存器的行为。

Setting the Global mode to Halt by setting the Global Mode Control bit CFDGCTR.GMDC in the Global Control Register to 10b sets Channel Mode Control bits CFDC0CTR.CHMDC in the Channel Control Registers to 10b for the channel that are in Channel Operation mode and forces these channels into the Channel Halt mode.

For the channel that are already in Channel Reset, Channel Halt, or Channel Sleep mode, this automatic transition is not performed.

Therefore, the Global Halt mode request can be used to shut down all CANFD channel communications without loss of messages and disruption on the related CAN bus (no interruption of reception/transmission processes on the channels).

After setting the Global Mode Control bit CFDGCTR.GMDC to Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register has been updated to indicate a successful transition to Global Halt mode. Do not specify any other SFR setting until confirming CFDGSTS.GHLTSTS is set.

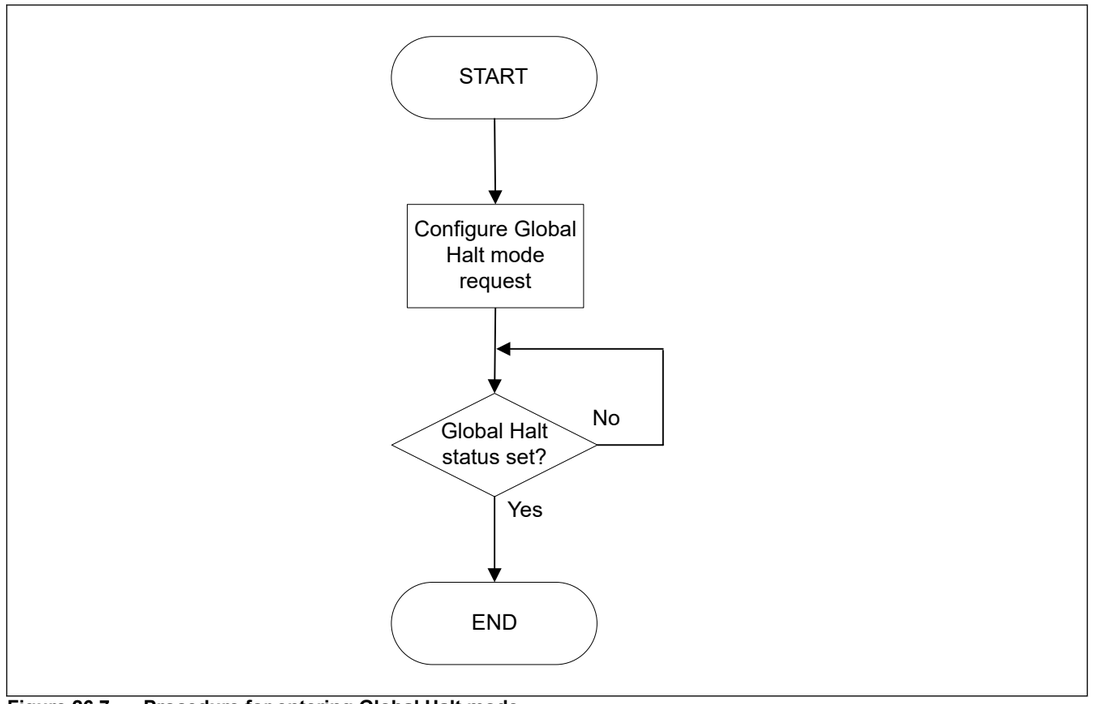

Figure 26.7 Procedure for entering Global Halt mode

通过将全局控制寄存器中的全局模式控制比特CFDGCTR。GMDC设置为10b,将全局模式控制比特CFDC0CTR。CHMDC设置为10b,用于处于信道操作模式的信道并将这些信道强制进入信道停止模式。

对于已经处于通道重置、通道停止或通道睡眠模式的通道,不执行此自动转换。

因此,全局停止模式请求可用于关闭所有CANFD信道通信,而不会丢失消息并中断相关CAN总线（信道上的接收/传输过程不会中断）。

将全局模式控制位CFDGCTR。GMDC设置为停止模式后,需要确认全局状态寄存器中的停止模式状态位CFDGSTS。GHLTSTS已经更新,以指示成功过渡到全局停止模式。在确认 CFDGSTS。GHLTSTS 设置之前,请勿指定任何其他 SFR 设置。

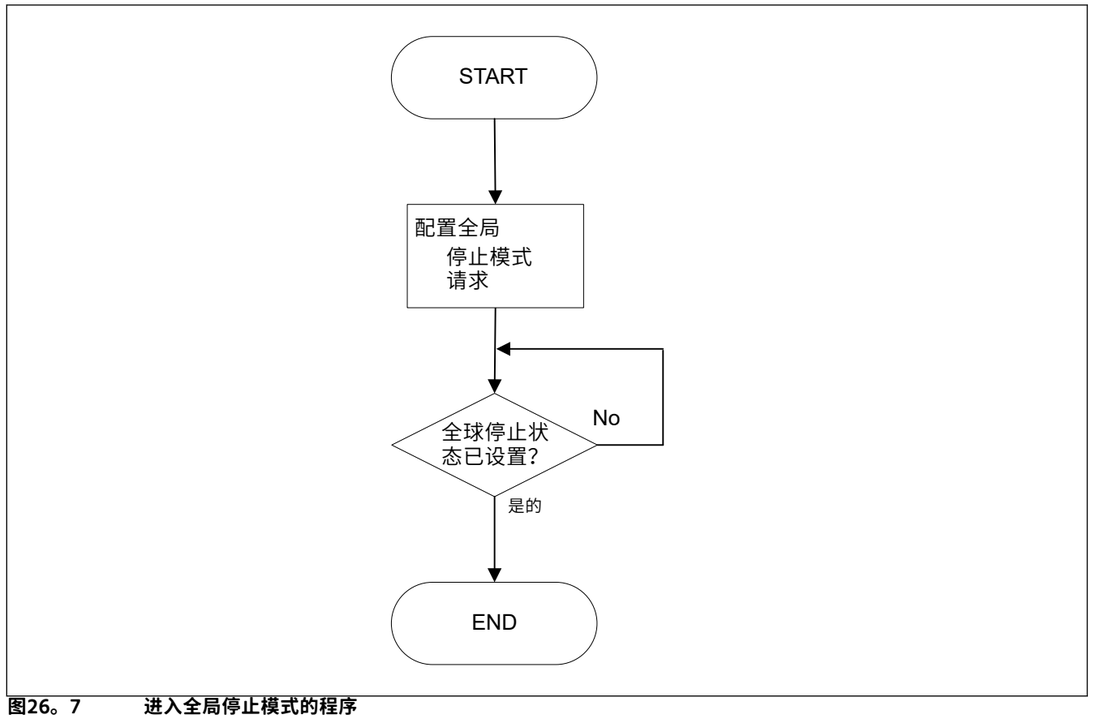

图26。7 进入全局停止模式的程序

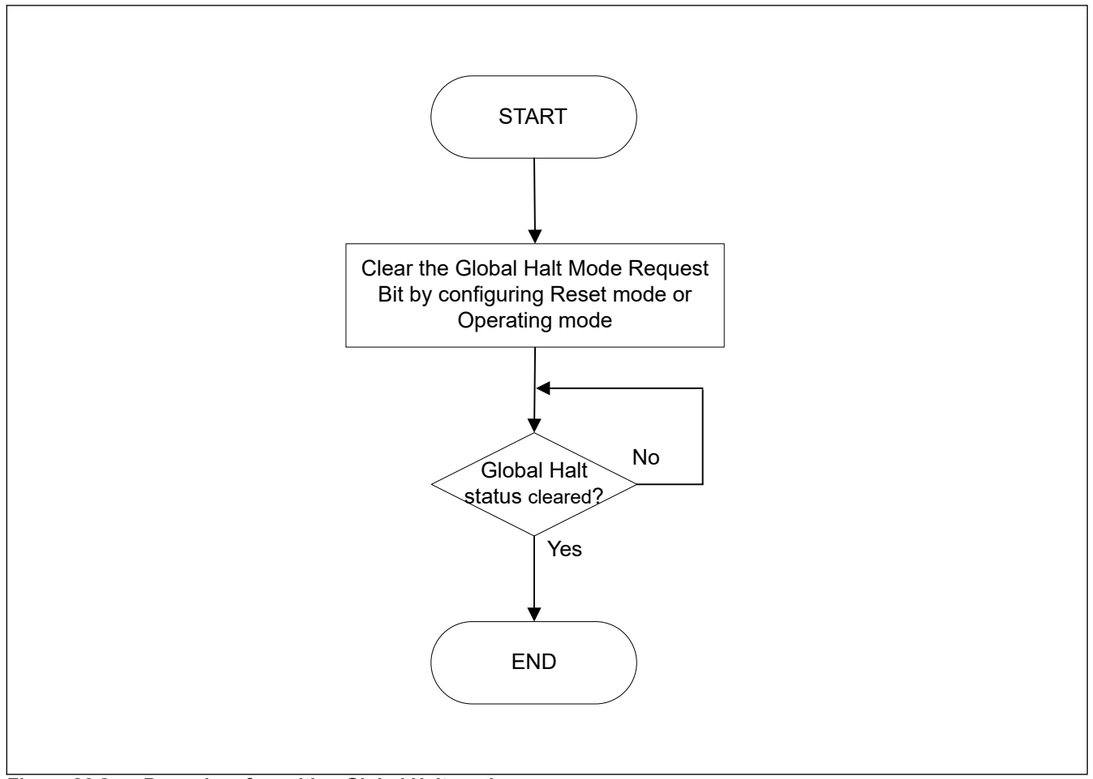

Figure 26.8 Procedure for exiting Global Halt mode

26.3.2.4 Global Operation Mode

The CANFD module enters this mode when the Global Mode Configuration bits are set to Global Operation mode.

The CANFD channel can only be set to Channel Operation mode and start CAN communication when CANFD is in Global Operation mode.

After setting the Global Mode Control bit CFDGCTR.GMDC to Global Operation mode, it is necessary to confirm that the Global Reset Mode Status bit CFDGSTS.GRSTSTS and the Global Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register have been cleared to indicate a successful transition to Global Operation mode before CFDGCTR.GMDC can be modified again.

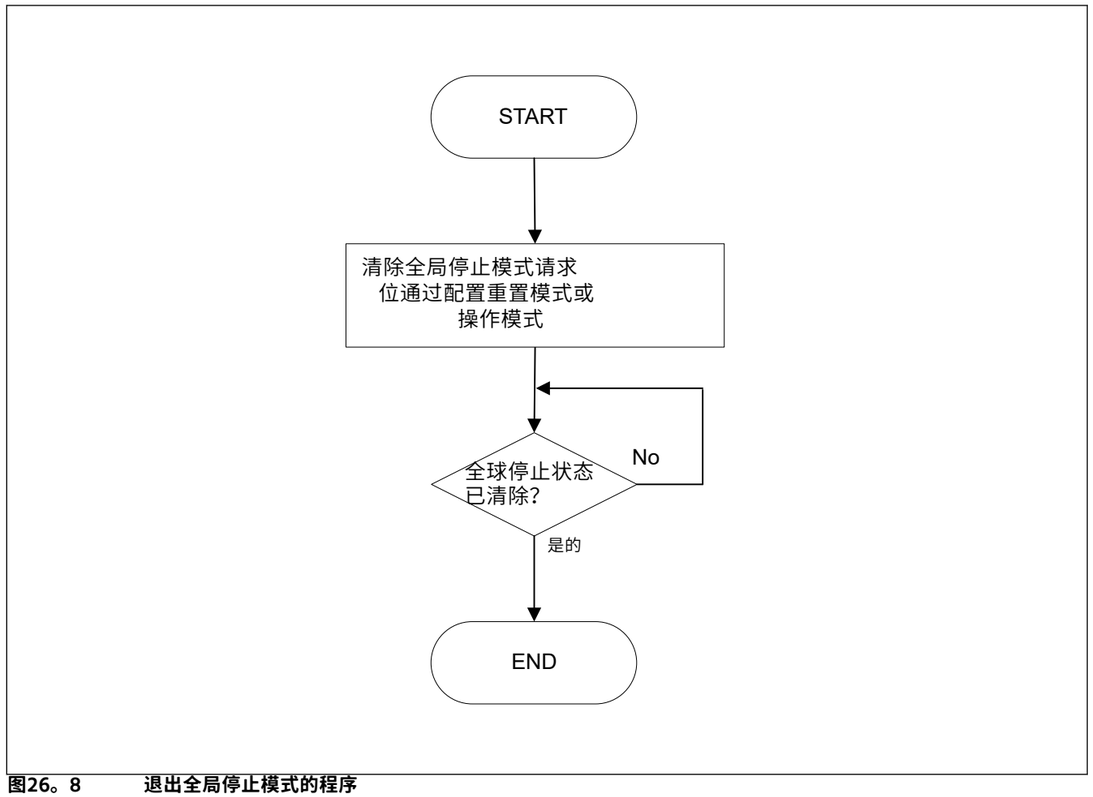

图26。8 退出全局停止模式的程序

26。3。2。4 全球运行模式

当全局模式配置位设置为全局操作模式时,CANFD模块进入该模式。

CANFD信道只能设置为信道操作模式,并在CANFD处于全局操作模式时开始CAN通信。

将全局模式控制位CFDGCTR。GMDC设置为全局操作模式后,需要确认全局重置模式状态位CFDGSTS。GRSTSTS和全局停止模式状态位CFDGSTS。GHLTSTS已清除以指示在 CFDGCTR。GMDC 再次修改之前成功过渡到全局操作模式。

26.3.3 Channel Modes

A CAN channel can be in one of the following four channel modes:

- Reset
- Halt
- Operation
- Sleep.

Figure 26.11 shows the possible transitions between the channel modes.

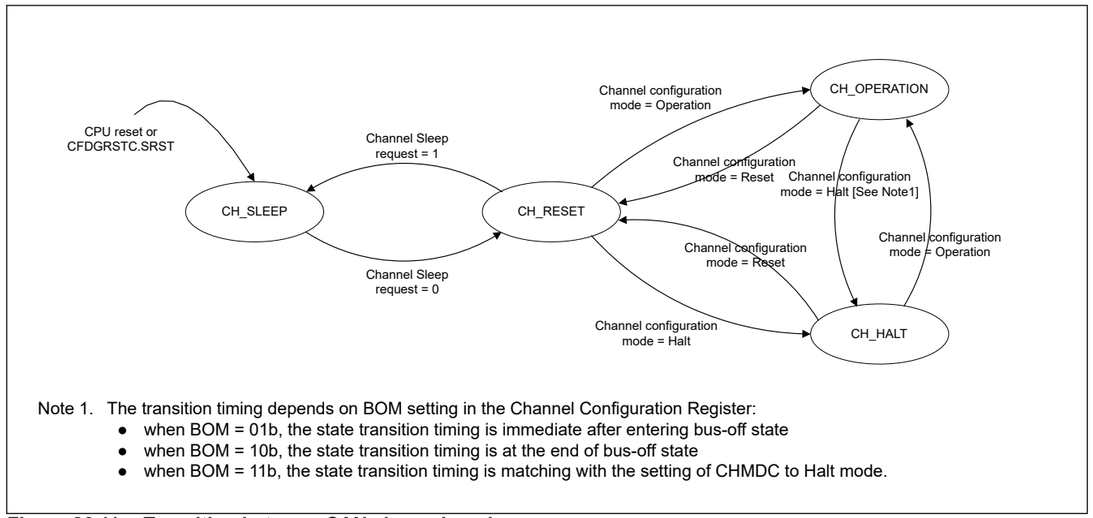
26.3.3 通道模式

CAN 信道可以采用以下四种信道模式之一:

- 重置
- 停止
- 操作
- 睡眠。

图 26。11 显示了信道模式之间可能的转换。



Note 1. The transition timing depends on BOM setting in the Channel Configuration Register:
- when BOM = 01b, the state transition timing is immediate after entering bus-off state
- when BOM = 10b, the state transition timing is at the end of bus-off state
- when BOM = 11b, the state transition timing is matching with the setting of CHMDC to Halt mode.

Figure 26.11 Transition between CAN channel modes

26.3.3.1 CAN Channel Sleep Mode

After the release of a hardware reset or after setting and clearing the CFDGRSTC.SRST bit, a CAN channel of the CANFD module automatically enters Channel Sleep mode.

A CAN channel also enters Channel Sleep mode when the related Channel Sleep Mode Request bit is set while the CAN channel is in Channel Reset mode. Do not set this control bit in Channel Halt mode or Channel Operation mode.

Entering the CAN Channel Sleep mode instantly stops the clock supplied to the CAN channel unit and therefore reduces power consumption.

After setting the Channel Sleep Mode Request bit, it is necessary to confirm that the Channel Sleep mode status has been updated to indicate a successful transition to Channel Sleep mode before the Channel Sleep Mode Request bit can be cleared again.

During Channel Sleep mode, do not write to channel related registers. Read operation is still possible.

26.3.3.2 CAN Channel Reset Mode

A CANFD CAN channel enters this mode in the following ways:

- Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers is configured for Channel Reset mode while the related CAN channel is in Channel Halt mode or Channel Operation mode
- Channel Sleep Mode Request bit is cleared while the related CAN channel is in Channel Sleep mode
- Global Mode Control bit CFDGCTR.GMDC is set to Global Reset mode and CAN channel is not in Channel Sleep mode or Channel Reset mode.

In Channel Reset mode, all CAN channel status and flag registers are initialized.

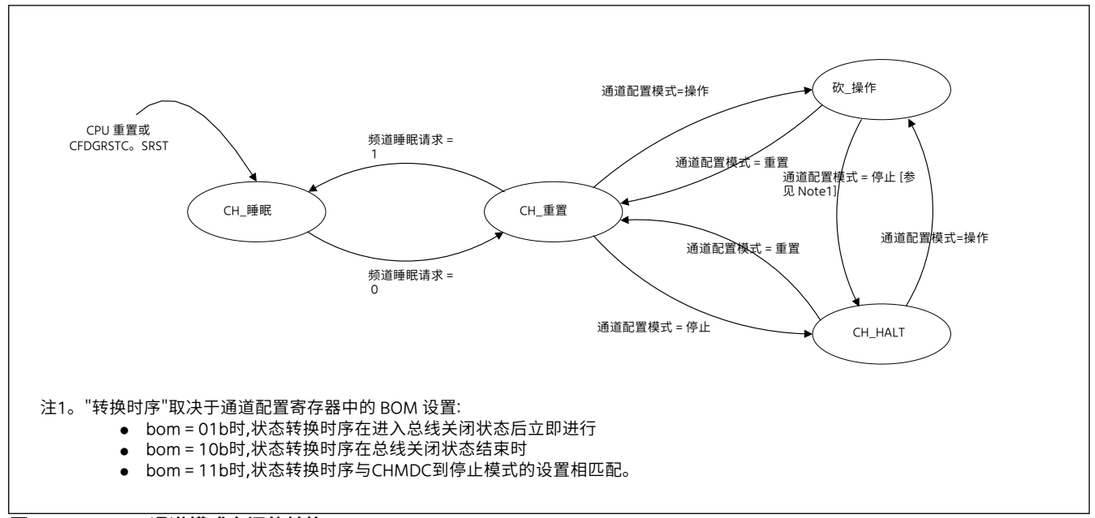
Additionally all channel related transmission control bits are cleared and the channel related TX Queue is disabled.

Configuration registers (except the Channel Test Mode registers) are not initialized in this mode and the CAN channel can be configured for communication.

See section 26.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Channel Reset mode is performed.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDC0STS.CRSTSTS in the related Channel Status Registers has been updated to indicate a successful transition to Channel Reset mode before the related CFDC0CTR.CHMDC bit can be modified again.

See Table 26.15 for the behavior of transitioning to Channel Reset mode while CAN communication is ongoing.



注1。"转换时序"取决于通道配置寄存器中的 BOM 设置:
- bom = 01b时,状态转换时序在进入总线关闭状态后立即进行
- bom = 10b时,状态转换时序在总线关闭状态结束时
- bom = 11b时,状态转换时序与CHMDC到停止模式的设置相匹配。

图 26。11 CAN 通道模式之间的转换

26。3。3。1 CAN 通道睡眠模式

释放硬件重置后或设置并清除CFDGRSTC。SRST位后,CANFD模块的CAN通道自动进入通道睡眠模式。

当CAN信道处于信道重置模式时设置相关信道睡眠模式请求位时,CAN信道也进入信道睡眠模式。请勿在通道停止模式或通道操作模式下设置此控制位。

进入CAN信道睡眠模式会立即停止提供给CAN信道单元的时钟,从而降低功耗。

设置通道睡眠模式请求位后,需要确认通道睡眠模式状态已更新以指示在通道睡眠模式请求位再次清除之前成功过渡到通道睡眠模式。

在频道睡眠模式期间,请勿写入频道相关寄存器。读操作仍然是可能的。

CAN 信道重置模式 CANFD CAN 信道通过以下方式进入此
模式:

● 信道模式控制位 CFDC0CTR。CHMDC 在信道控制寄存器中配置为信道重置模式,而相关的 CAN 信道处于信道停止模式或信道操作模式

●通道睡眠模式请求位被清除,而相关的CAN通道处于通道睡眠模式

● 全局模式控制位 CFDGCTR。GMDC 设置为全局重置模式,CAN 通道不处于通道睡眠模式或通道重置模式。

在信道重置模式下,所有 CAN 信道状态和标志寄存器均已初始化。

此外,所有与信道相关的传输控制位都被清除并且与信道相关的TX队列被禁用。

配置寄存器（信道测试模式寄存器除外）在此模式下未初始化,并且可以配置 CAN 信道用于通信。

参见第 26。3。4 节。全局模式和信道模式转换交互,详细描述执行到信道重置模式转换时所有寄存器的行为。

将信道模式控制位CFDC0CTR。CHMDC设置为信道重置模式后,需要确认相关信道状态寄存器中的重置模式状态位CFDC0STS。CRSTSTS已更新,以指示在相关信道状态寄存器之前成功过渡到信道重置模式。CFDC0CTR。CHMDC位可以再次修改。CAN 通信进行时过渡到信道重置模式的行为见表 26。15。

26.3.3.3 CAN Channel Halt Mode

A CANFD CAN channel enters this mode in the following ways:

- Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers is configured for Channel Halt mode while the related CAN channel is in Channel Reset mode or Channel Operation mode
- Global Mode Control bit CFDGCTR.GMDC is set to Global Halt mode and CAN channel is in Channel Operation mode.

In Channel Halt mode, all channel CAN communication is suspended but all status and flag registers remain unchanged during Channel Halt mode entry (except for the bus-off case where REC and TEC values are cleared for this channel).

In addition, the Channel Test Mode Configuration and Control registers are not initialized in this mode.

The Channel Halt mode should be used to configure channel test modes.

See section 26.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Channel Halt mode is performed.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDC0STS.CHLTSTS in the related Channel Status Register has been updated to indicate a successful transition to Channel Halt mode before the related CFDC0CTR.CHMDC can be modified again.

See Table 26.15 for the transition behavior to Channel Halt mode while CAN communication is ongoing.

Table 26.15 Transition behavior in CAN Reset mode and Halt mode

Mode	State		
	Receiver	Transmitter	Bus-Off
CAN Channel Reset mode (CFDC0CTR.CHMDC = 01b)	The CAN channel enters Channel Reset mode without waiting for the completion of the ongoing reception.*1	The CAN channel enters Channel Reset mode without waiting for the completion of the ongoing transmission.*1	The CAN channel enters Channel Reset mode without waiting for the completion of the bus-off recovery.
CAN Channel Halt mode (CFDC0CTR.CHMDC = 10b)	CAN channel enters Channel Halt mode at the end of the ongoing reception or error.*2	CAN channel enters Channel Halt mode after completion of the ongoing transmission.	When CFDC0CTR.BOM is set to 00b, a Channel Halt mode request is accepted only after the completion of the full bus-off recovery sequence. When CFDC0CTR.BOM is set to 10b, the CAN channel transits automatically to Channel Halt mode after waiting for the completion of the bus-off recovery. When CFDC0CTR.BOM is set to 01b, the CAN channel transits automatically to Channel Halt mode without waiting for the completion of the bus-off recovery. When CFDC0CTR.BOM is set to 11b, the CAN channel enters Channel Halt mode as soon as Channel Halt mode is requested (without waiting for the completion of the bus-off recovery).

Note 1. If the entry to Channel Reset mode is required only at the end of an ongoing communication, then Channel Halt mode can be requested first to prevent interruption of CAN communication by direct transition to Channel Reset mode. After the CAN channel enters Channel Halt mode, the Channel Reset mode can be requested.

Note 2. If CAN communication is locked at dominant level after an error flag, software can detect this situation by monitoring the channel related BusLock flag and resolve lock condition by setting the CAN channel to Channel Reset mode.

26.3.3.4 CAN Channel Operation Mode

The Channel Operation mode is activated by setting the CFDC0CTR.CHMDC bits to 00b. If 11 consecutive recessive bits are detected after entering the CAN Operation mode, the CFDC0STS.COMSTS bit is set and the CAN channel:

26。3。3。3 CAN 通道停止模式

CANFD CAN 通道通过以下方式进入此模式:

- 信道模式控制位 CFDC0CTR。CHMDC 在信道控制寄存器中配置为信道停止模式,而相关 CAN 信道处于信道重置模式或信道操作模式
- 全局模式控制位 CFDGCTR。GMDC 设置为全局停止模式,CAN 通道处于通道操作模式。

在信道停止模式下,所有信道 CAN 通信都会暂停,但在信道停止模式输入期间,所有状态和标志寄存器保持不变（除了为该信道清除 REC 和 TEC 值的总线关闭情况）。

此外,信道测试模式配置和控制寄存器未在此模式下初始化。

应使用通道停止模式来配置通道测试模式。

参见第 26。3。4 节。全局模式和通道模式转换交互,详细描述执行到通道停止模式转换时所有寄存器的行为。

在将信道模式控制位CFDC0CTR。CHMDC设置为信道停止模式之后,需要确认相关信道状态寄存器中的停止模式状态位CFDC0STS。CHLTSTS已经更新以指示在相关信道状态寄存器之前成功过渡到信道停止模式。CFDC0CTR。CHMDC 可以再次修改。

有关 CAN 通信正在进行时向信道停止模式的转换行为,请参阅表 26。15。

表 26。15 CAN 重置模式和停止模式下的转换行为

模式	状态		
	接收器	发射机	公交车关闭
CAN 信道重置模式（CFDC0CTR。CHMDC = 01b）	CAN通道进入 频道重置模式,无需等待正在进行的接收完成。*1	CAN通道进入 信道重置模式,无需等待正在进行的传输完成。*1	CAN通道进入 通道重置模式,无需等待总线关闭恢复完成。
CAN 通道停止模式（CFDC0CTR。CHMDC = 10b）	CAN通道进入通道 在正在进行的接收或错误结束时停止模式。*2	CAN通道进入通道 正在进行的传输完成后停止模式。	CFDC0CTR。BOM设置为00b时,只有在完成完整的总线关闭恢复序列之后才接受信道停止模式请求。 CFDC0CTR。BOM设置为10b时,CAN信道在等待总线关闭恢复完成后自动传输到信道停止模式。 CFDC0CTR。BOM设置为01b时,CAN信道自动传输到信道停止模式,而无需等待总线关闭恢复的完成。 CFDC0CTR。BOM 设置为 11b 时,CAN 通道尽快进入通道停止模式 请求通道停止模式（无需等待总线关闭恢复完成）。

注1。如果仅在正在进行的通信结束时才需要进入信道重置模式,则可以首先请求信道停止模式以防止通过直接过渡到信道重置模式来中断CAN通信。CAN信道进入信道停止模式后,可以请求信道重置模式。

注2。如果在错误标志之后 CAN 通信被锁定在主导级别,软件可以通过监视与通道相关的 BusLock 标志来检测这种情况,并通过将 CAN 通道设置为通道重置模式来解决锁定条件。

26.3.3.4 CAN通道操作模式

通过将CFDC0CTR。CHMDC位设置为00b来激活信道操作模式。CAN 操作模式后检测到连续的 11 个隐性位, 则设置 CFDC0STS。COMSTS 位, CAN 通道:

- Enables the functions of the channel communication by allowing the channel to become an active node on the CAN network
- Releases the internal fault confinement logic including receive and transmit error counters

At this point, the CAN channel can start transmission and reception of CAN messages.

Within the CAN Channel Operation mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (see Figure 26.12):

- Channel idle: The CAN channel is neither receiving nor transmitting
- Channel receives: The channel is receiving a CAN message sent by another CAN node
- Channel transmits: The channel is transmitting a CAN message

  Note: The channel may receive its own message simultaneously when Self-test mode is enabled.
- Channel is in bus-off state: The CAN channel is cut-off from CAN bus communication.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Operation mode, it is necessary to confirm that the Channel Reset Mode Status bit CFDC0STS.CRSTSTS and the Channel Halt Mode Status bit CFDC0STS.CHLTSTS in the Channel Status Register have been updated to indicate a successful transition to Channel Operation mode before the related CFDC0CTR.CHMDC bit can be changed again.

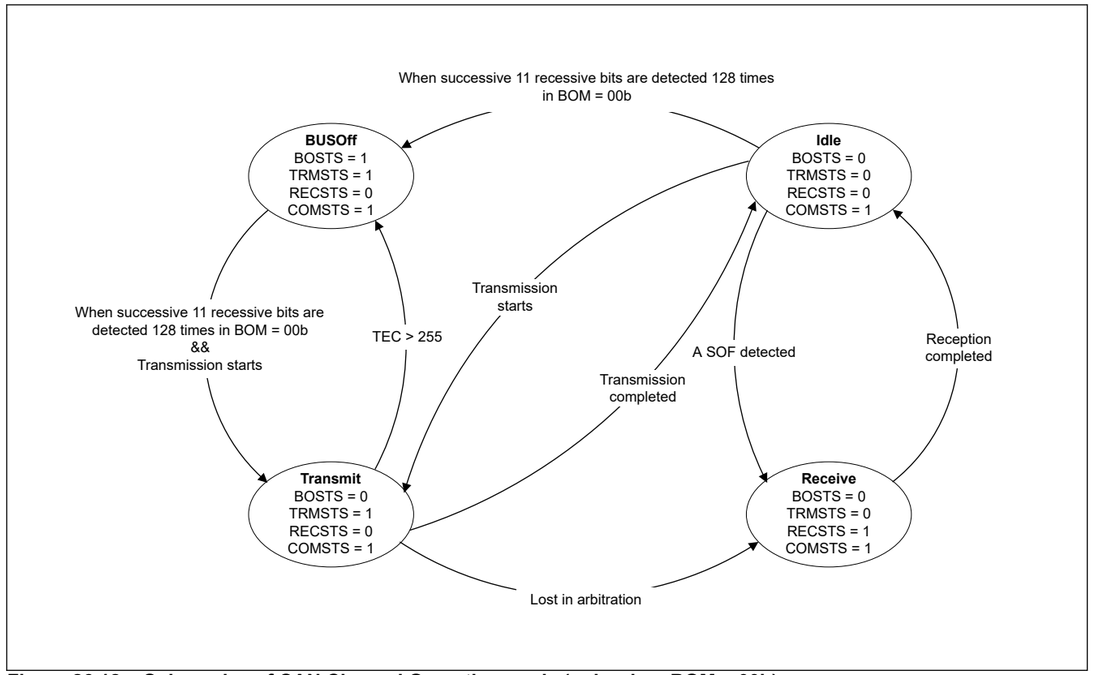


Figure 26.12 Sub-modes of CAN Channel Operation mode (only when BOM = 00b)

26.3.3.5 CAN Channel Bus-Off State

The CAN channel bus-off state is entered according to the fault confinement rules of the CAN specification. The following modes can be configured for returning to the CAN Channel Operation mode from the bus-off state:

- CFDC0CTR.BOM = 00b:
  Bus-Off recovery is compliant to ISO 11898-1, namely the CAN channel re-enters CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. TEC and REC counters are initialized to 0. The Bus-Off Recovery Flag CFDC0ERFL.BORF is set in this case.
- CFDC0CTR.BOM = 01b:

● 通过允许信道成为 CAN 网络上的活动节点来实现信道通信的功能

● 释放包括接收和发送错误计数器的内部故障限制逻辑 此时,CAN 通道可以开始 CAN 消息的发送和接收。

CAN信道操作模式内,信道可能处于四种不同的子模式,具体取决于执行哪种类型的通信功能（参见图 26.12）:)

● 通道空闲:CAN 通道既不接收也不发送
●信道接收:信道正在接收由另一个CAN节点发送的CAN消息
● 通道传输: 通道正在传输 CAN 消息

注意:当启用自检模式时,通道可以同时接收自己的消息。

●信道处于总线关闭状态:CAN信道与CAN总线通信被切断。

将信道模式控制位CFDC0CTR。CHMDC设置为信道操作模式后,需要确认信道状态寄存器中的信道复位模式状态位CFDC0STS。CRSTSTS和信道停止模式状态位CFDC0STS。CHLTSTS已更新以指示在再次更改相关的 CFDC0CTR。CHMDC 位之前成功过渡到信道操作模式。

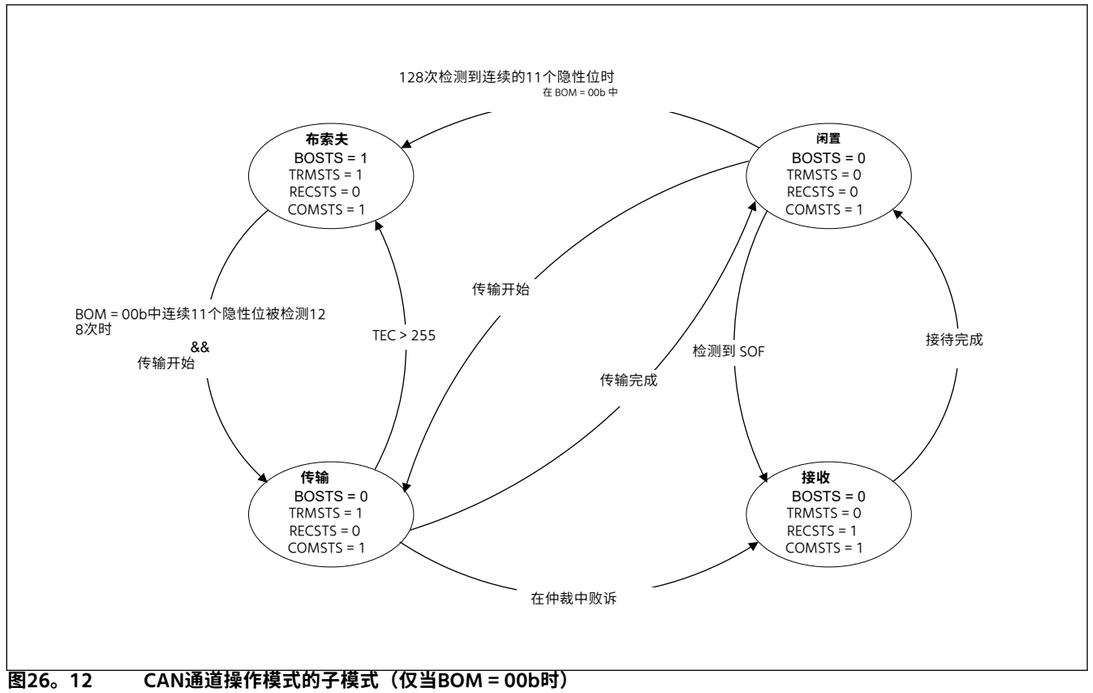

图26。12 CAN通道操作模式的子模式（仅当BOM = 00b时）

26。3。3。5 CAN 通道总线关闭状态

CAN 规范的故障约束规则进入 CAN 信道总线关闭状态。可以配置以下模式用于从总线关闭状态返回到CAN信道操作模式:

● CFDC0CTR。BOM = 00
b: Bus-Off 恢复符合 ISO 11898-1,即在连续检测 11 个隐性位 128 次后,CAN 信道重新进入 CAN 通信（错误活动状态）。TEC 和 REC 计数器初始化为 0。BusOff 恢复标志 CFDC0ERFL。BORF 设置在这种情况下。

● CFDC0CTR。BOM = 01
b:

The CAN channel changes the value of the CFDC0CTR.CHMDC bits within the CAN Channel Control Register to 10b and switches immediately to Channel Halt mode automatically after entering bus-off state. TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is not set in this case.

- CFDC0CTR.BOM = 10b:
  The CAN channel changes the value of the CFDC0CTR.CHMDC bits within the CAN Channel Control Register to 10b as soon as it reaches bus-off state and enters Channel Halt mode automatically after the CAN channel has completed the bus-off recovery sequence (after 11 consecutive recessive bits are detected 128 times). TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is set in this case.
- CFDC0CTR.BOM = 11b:
  Bus-off recovery is initiated but CAN channel can immediately enter Channel Halt mode when still in bus-off state if a request is made to enter Channel Halt mode.
  TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is not set.
  Without setting CFDC0CTR.CHMDC [1:0] = 10b and when 11 recessive bits is detected 128 times continuously, transition conditions become the same as CFDC0CTR.BOM = 00b.

Note: If the recovery from bus-off occurs normally in this mode (after waiting for 128 sequences of 11 consecutive recessive bits), and no halt request has been generated during this period, then the Bus-Off Recovery flag CFDC0ERFL.BORF is set.

When software writes to the CFDC0CTR.CHMDC bit at the same time as the CAN channel enters Halt mode (at the start of bus-off when CFDC0CTR.BOM = 01b, or at the end of bus-off when CFDC0CTR.BOM = 10b), the software request has the highest priority.

Note: In the above case, the automatic setting of the CFDC0CTR.CHMDC bit to Channel Halt mode request is performed when the CFDC0CTR.CHMDC bit value is previously 00b (Channel Operation mode).

Additionally, it is possible to force the CAN channel to recover from the bus-off state by setting CFDC0CTR.RTBO to 1. The error state changes from bus-off state to integrating state with a maximum delay of 1 CAN bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The Bus-Off Recovery Flag is not set in this case, and the TEC and REC counters are initialized to 0.

Before setting CFDC0CTR.RTBO to 1, all pending transmissions from the TX message buffers, TX Queues and/or Common FIFO in TX mode should be disabled.

The disable of the pending transmission message buffer, TX Queue or FIFO must be confirmed by the corresponding acknowledge flags.

For the TX message buffer, the acknowledge flags are the Transmission Result Flags (CFDTMSTSj.TMTRF). For the TX Queue, it is the TX Queue Empty flag (CFDTXQSTS.TXQEMP). For the FIFO, it is the FIFO Empty flag (CFDCFSTS.CFEMP).

The CFDC0CTR.RTBO bit should be used for bus-off recovery only when CFDC0CTR.BOM is set to 00b.

Setting this bit in any state other than bus-off has no effect and the bit is cleared immediately.

Table 26.16 shows the settings for the Bus-Off Entry flag CFDC0ERFL.BOEF and the Bus-Off Recovery flag CFDC0ERFL.BORF for the different configurations of CFDC0CTR.BOM.

Table 26.16 Behavior of Bus-off Entry and Recovery flags

BOM	BOEF bit set	BORF bit set
00b	Always (on entry to bus-off)	Always (on exit from bus-off)
00b CFDC0CTR.RTBO set to 1	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software sets CFDC0CTR.RTBO to 1
01b	Always (on entry to bus-off)	Never
10b	Always (on entry to bus-off)	Always (on exit from bus-off)
11b	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software issues a Halt request

For an efficient software procedure, it is not necessary to wait for the bus-off recovery sequence to end.

CAN信道将CAN信道控制寄存器内的CFDC0CTR。CHMDC比特的值更改为10b,并在进入总线关闭状态后立即自动切换到信道停止模式。TEC 和 REC 计数器初始化为 0,在这种情况下不设置总线关闭恢复标志 CFDC0ERFL。BORF。

- CFDC0CTR。BOM = 10
  b: CAN信道在CAN信道控制寄存器内的CFDC0CTR。CHMDC比特的值一达到总线关闭状态,并在CAN信道完成总线关闭恢复序列后自动进入信道停止模式（连续11个隐性比特被检测128次之后）,就将其值更改为10b。TEC 和 REC 计数器初始化为 0,并且在这种情况下设置总线关闭恢复标志 CFDC0ERFL。BORF。

- **CFDC0CTR。BOM = 11b:**
  总线关闭恢复已启动,但如果请求进入通道停止模式,CAN 通道在仍处于总线关闭状态时可以立即进入通道停止模式。
  TEC 和 REC 计数器初始化为 0,总线关闭恢复标志 CFDC0ERFL。BORF 未设置。
  不设置 CFDC0CTR。CHMDC [1:0] = 10b,并且当连续检测 128 次 11 个隐性位时,转换条件变为与 CFDC0CTR。BOM = 00b 相同。

注意:如果从总线关闭恢复在此模式下正常发生（在等待 11 个连续序列的 128 个序列之后）位（recessive bits）,并且在此期间没有生成停止请求,则设置总线关闭恢复标志CFDC0ERFL。BORF。

CAN信道进入停止模式的同时（在总线关闭开始时,当CFDC0CTR。BOM = 01b,或在总线关闭结束时,当CFDC0CTR。BOM = 10b）,软件请求具有最高优先级。

注意:在上述情况下,当CFDC0CTR。CHMDC比特值先前为00b时,执行CFDC0CTR。CHMDC比特到信道停止模式请求的自动设置（信道操作模式）。

另外,可以通过将CFDC0CTR。RTBO设置为1来强制CAN信道从总线关闭状态恢复。
错误状态从总线关闭状态变为积分状态,最大延迟为1个CAN位时间,检测到连续11个隐性位后,CAN通信再次成为可能。在这种情况下不设置总线关闭恢复标志,并且 TEC 和 REC 计数器初始化为 0。

在将 CFDC0CTR。RTBO 设置为 1 之前,应禁用 TX 模式下来自 TX 消息缓冲区、TX 队列和/或通用 FIFO 的所有待处理传输。

挂起的传输消息缓冲区、TX 队列或 FIFO 的禁用必须由相应的确认标志确认。

对于 TX 消息缓冲区,确认标志是传输结果标志（CFDTMSTSj。TMTRF）。对于 TX 队列,它是 TX 队列空标志（CFDTXQSTS。TXQEMP）。对于 FIFO,它是 FIFO 空标志（CFDCFSTS。CFEMP）。

仅当 CFDC0CTR。BOM 设置为 00b 时,CFDC0CTR。RTBO 位才应用于总线关闭恢复。

将此位设置为总线关闭以外的任何状态都不会产生任何影响,并且该位会立即清除。

表 26。16 显示了 CFDC0CTR。BOM 不同配置的总线关闭入口标志 CFDC0ERFL。BOEF 和总线关闭恢复标志 CFDC0ERFL。BORF 的设置。

表 26。16 总线关闭进入和恢复标志的行为

BOM	BOEF 位集	BORF 位集
00b	始终（进入巴士站时）	始终（在巴士站出口处）
00b CFDC0CTR。RTBO 设置为 1	始终（进入巴士站时）	仅当在软件集之前发生正常的总线关闭恢复时 CFDC0CTR。RTBO 至 1
01b	始终（进入巴士站时）	从来没有
10b	始终（进入巴士站时）	始终（在巴士站出口处）
11b	始终（进入巴士站时）	仅当在软件发出停止请求之前发生正常的总线关闭恢复时

对于高效的软件过程,无需等待总线关闭恢复序列结束。

It is possible to perform a transmission re-initialization during bus-off recovery. To do this, follow the recommended software flow in Figure 26.13.

26。3。4。1 全局模式变化的时间

Global 模式变更的过渡时间如下表所示。表 26。18 全局模式的最大转换时间(2 中的 1)

从	To	最长过渡时间
GL_睡眠	GL_重置	3个外围时钟周期 *2
GL_重置	GL_睡眠	3个外围时钟周期
GL_重置	GL_HALT	10个外围时钟周期
GL_重置	GL_操作	10个外围时钟周期

Table 26.18 Maximum transition time for the global mode (2 of 2)

From	To	Maximum transition time
GL_HALT	GL_RESET	2 CAN bit times
GL_HALT	GL_OPERATION	3 peripheral clock cycles
GL_OPERATION	GL_RESET	2 CAN bit times
GL_OPERATION	GL_HALT	3 CAN frames*1 *3

Note 1. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.
Note 2. Exit GL_SLEEP mode only when CFDGSTS.GRAMINIT is cleared.
Note 3. TQ, CAN frame and CAN bits are related to the individual channels. For the maximum transition time, the channel with the lowest baud rate must be used.

26.3.4.2 Timing of Channel Mode Change

The transition time for the Channel mode changes are shown in the following table.

Table 26.19 Maximum transition time for the channel mode

From	To	max. transition time
CH_SLEEP	CH_RESET	3 peripheral clock cycles
CH_RESET	CH_SLEEP	3 peripheral clock cycles
CH_RESET	CH_HALT	3 CAN bit times
CH_RESET	CH_OPERATION	4 CAN bit times
CH_HALT	CH_RESET	2 CAN bit times
CH_HALT	CH_OPERATION	4 CAN bit times*3
CH_OPERATION	CH_RESET	2 CAN bit times
CH_OPERATION	CH_HALT	2 CAN frames*1 *2

Note 1. The time specified for this transition does not include the case where channel enters bus-off state. For bus-off, the timing depends on the configuration of the CFDC0CTR.BOM[1:0] bits.
Note 2. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.
Note 3. In general, if the baudrate prescaler value CFDC0NCFG.NBRP is changed in CH_HALT mode, the transition time can deviate. The internal prescaler is a free running down counter that creates the TQ clock, and new BRP value is captured when the counter reaches the value 0.

26.4 Initialization

Before joining CAN communications, configure the following settings:

- Clock setting
- Bit timing setting (nominal and data rate)
- Baud Rate setting (nominal and data rate)
- CANFD setting
- Acceptance Filter setting (configuration of Global Acceptance Filter List)
- Reception, Transmission and GW-FIFO setting
- CAN Operation mode setting

The following lines describe the composition of each segment and the restriction that apply to the segment setting.

GL_HALT	GL_操作	3个外围时钟周期
GL_操作	GL_重置	2 CAN 位时间
GL_操作	GL_HALT	3 个 CAN 帧 *1 *3

注1。给定的转换时间是总线上没有任何错误的时间。如果出现错误情况,转换时间可能会延长至未计算的结果。对于锁定 RX 线路或持续错误条件,转换时间也可能进入卡住状态。
注2。仅当 CFDGSTS。GRAMINIT 被清除时才退出 GL_SLEEP 模式。
注3。TQ、CAN 帧和 CAN 位与各个通道相关。对于最大过渡时间,必须使用波特率最低的通道。

26.3.4.2 通道模式更改的时间

通道模式更改的转换时间如下表所示。表 26。19 通道模式的最大转换时间

从	To	最大过渡时间
CH_睡眠	CH_重置	3个外围时钟周期
CH_重置	CH_睡眠	3个外围时钟周期
CH_重置	CH_HALT	3 CAN 位时间
CH_重置	砍_操作	4 CAN 位时间
CH_HALT	CH_重置	2 CAN 位时间
CH_HALT	砍_操作	4 CAN 位倍数 *3
砍_操作	CH_重置	2 CAN 位时间
砍_操作	CH_HALT	2 个 CAN 帧 *1 *2

注1。此转换指定的时间不包括通道进入总线关闭状态的情况。对于总线关闭,定时取决于 CFDC0CTR。BOM[1:0] 位的配置。

注2。给定的转换时间是总线上没有任何错误的时间。如果出现错误情况,转换时间可能会延长至未计算的结果。对于锁定 RX 线路或持续错误条件,转换时间也可能进入卡住状态。
注3。一般来说,如果波特率预分频器值CFDC0NCFG。NBRP在CH_HALT模式下改变,则过渡时间可能会偏差。内部预分频器是一个自由运行的计数器,用于创建 TQ 时钟,当计数器达到值 0 时捕获新的 BRP 值。

26.4.1.2 CAN Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments that can be configured individually for channel using the related CFDC0NCFG and CFDC0DCFG*1 registers.

Note 1. This register is not available in the classical CAN function.

Figure 26.15 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (TQ), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the baud rate prescaler (nominal and data rate).

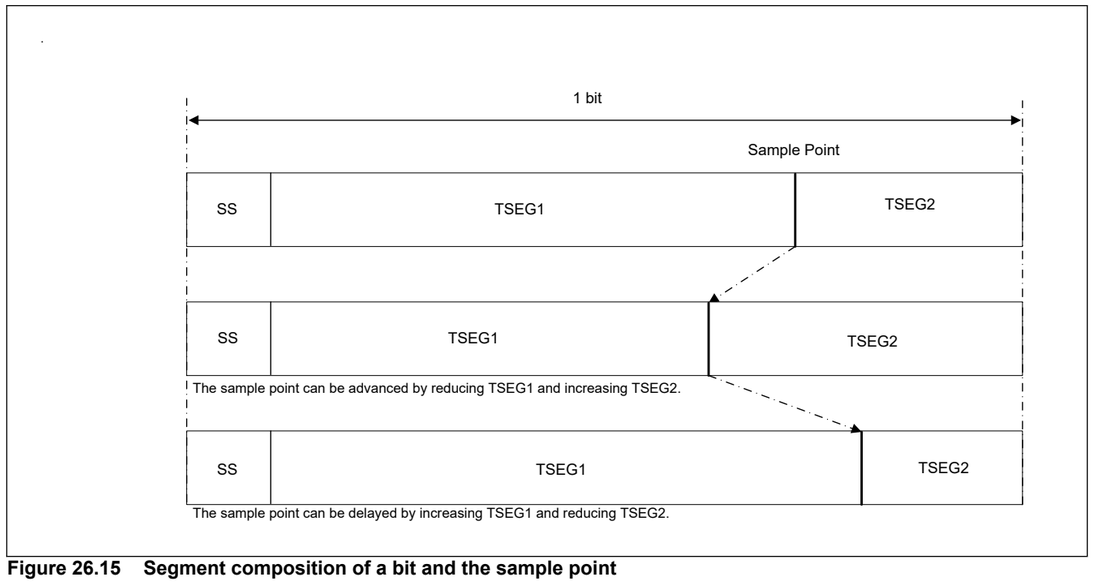

Figure 26.15 Segment composition of a bit and the sample point

1. SS: Synchronization Segment
   This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the interframe space. This comprises of intermission, suspend transmission, bus idle, during bus idle, and all nodes that can start transmission.
2. TSEG1: Time Segment 1
   This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.
3. TSEG2: Time Segment 2
   This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW. While sending or receiving a message, communication frames between some nodes may get out of sync due to a drift in the oscillator frequency or a delay in the transmission path. This is referred to as a phase error.
4. SJW: Resynchronization Jump Width
   This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.

Figure 26.15 shows only one symbolic sample point.

26.4.1.3 Baud Rate

Either the CAN channel system clock (clean clock) or the external oscillator clock can be selected globally as CAN communication clock.

The transfer speed is determined by the DLL clock, the divide-by-N value of the baud rate prescaler, and the number of TQs in one bit.

26。4。1。2 CAN 位定时

CAN协议中,通信帧中的每个位由三个段组成,可以使用相关的CFDC0NCFG和CFDC0DCFG *1寄存器单独配置用于信道。

注1。该寄存器在经典 CAN 函数中不可用。

图 26。15 显示了一位元的段组成及其中的样本点。

在这些段中,时间段 1（TSEG1) 和时间段 2（TSEG2) 用于指定采样点的位置,以便可以通过改变 CAN 总线上的每个位采样的时间来改变这些段的值。

该定时的最小分辨率称为时间量子（TQ）,由提供给 CAN 信道的时钟频率和波特率预分频器的除以 N 值（标称速率和数据速率）决定。

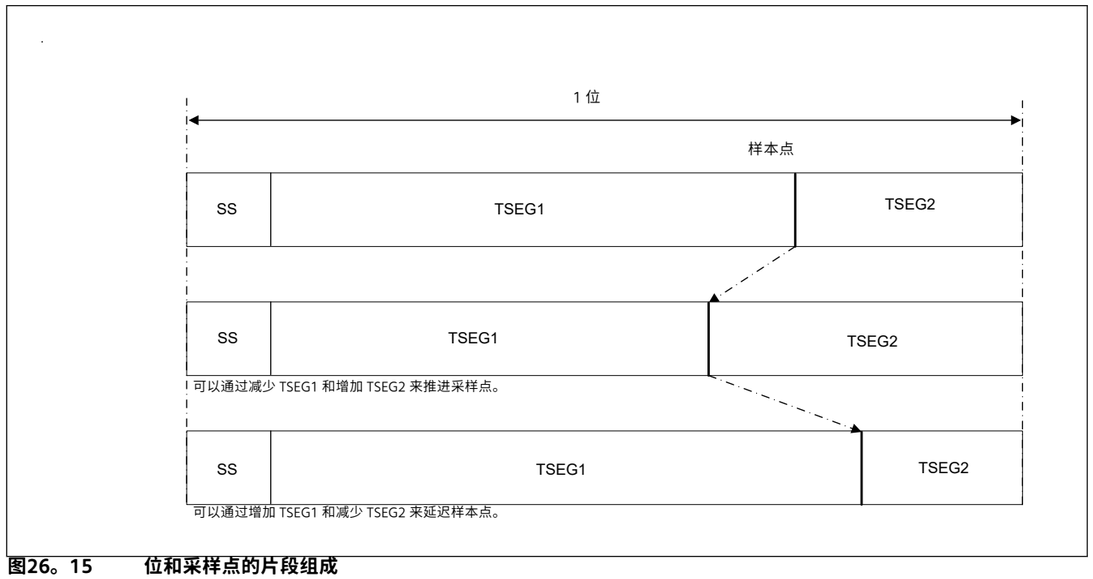

图26。15 位和采样点的片段组成

1。SS:同步段
该段用于通过在帧间空间期间监视隐性到主导边缘来同步位。这包括中场休息、暂停传输、总线空闲、总线空闲期间以及所有可以开始传输的节点。

2锛姣涓涓。TSEG1:时间段 1
该段吸收 CAN 网络上的物理延迟。网络上的物理延迟是总线延迟、输入比较器延迟和输出驱动器延迟总和的两倍。SJW可以加长它。

3锛 娴 。TSEG2:时间段 2
该段用于通过执行重新同步来纠正相位误差。SJW可以缩短它。在发送或接收消息时,一些节点之间的通信帧可能会由于振荡器频率的漂移或传输路径的延迟而不同步。这称为相位误差。

4锛姣涓。SJW:重新同步跳跃宽度
这是校正由于相位误差而不同步的位的最大宽度。

图 26。15 仅显示一个符号样本点。

26.4.1.3 波特率

CAN信道系统时钟（洁净时钟）或外部振荡器时钟都可以全局选择为CAN通信时钟。

传输速度由 DLL 时钟、波特率预分频器的除以 N 值以及一位中的 TQ 数量决定。

$$\text{baudrate} = \frac{\text{DLL\_Clock}}{(\text{number\_of\_time\_quanta\_per\_bit}) \times (\text{BRP} + 1)}$$

Nominal 500 Kbps Data 2 Mbps	80TQ (1)	40TQ (1)

Note: Shown in ( ) are the baud rate prescaler divide-by-N values and this table is not available in the classical CAN function.
Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 - 1023) P: value selected by the BRP bits in the Channel Configuration Registers.

For optimum clock tolerance in networks using the FD frame format, the length of the time quantum should be the same in nominal bit time and in data bit time. This means CFDC0NCFG.NBRP = CFDC0DCFG.DBRP.

Additionally, if transceiver delay compensation is used, do not program the CFDC0DCFG.DBRP bit to be greater than 1, as 1 means divide by 2.

26.4.1.4 Setting of CAN Clock, Bit Timing and Baud Rate

Figure 26.17 shows the procedure for setting the CAN clock and the baud rate for a channel.

These settings should be performed during Channel Reset mode (Configuration mode) for the CAN channels.

Before going to channel communication state, the baud rate must be configured, otherwise the mode does not switch correctly.

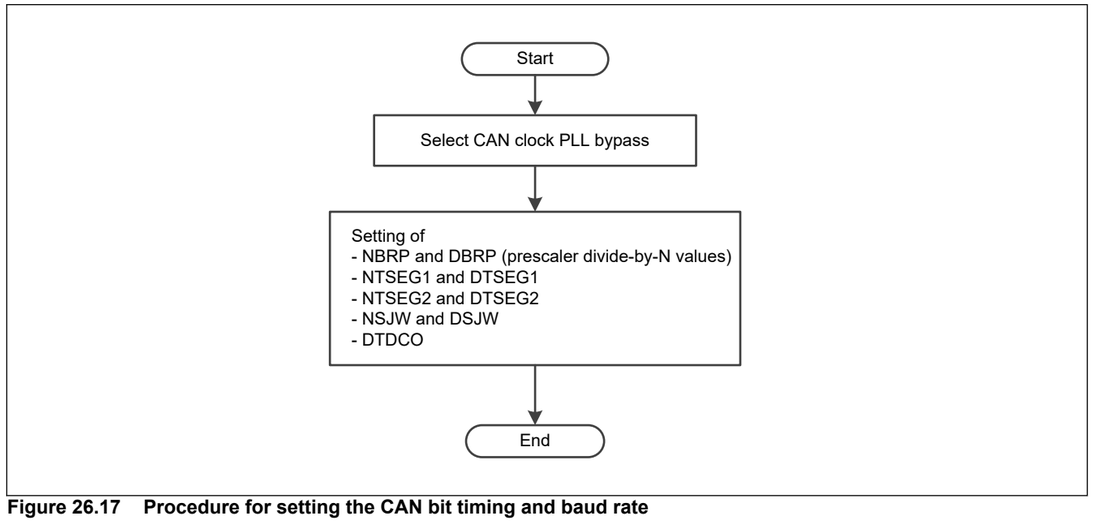

Figure 26.17 Procedure for setting the CAN bit timing and baud rate

26.4.1.5 Transmitter Delay Compensation

This chapter is not valid for classical CAN.

When a high baud rate is used such as 5 Mbps for the data phase, the transmitter delay can become greater than TSEG1. In this case, the transmitter always detects a bit-error in the data phase of the CANFD frame. The TDC compensates for the inability of the transmitter to receive its own transmitted bit at the sample point of that bit.

There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the data phase of CANFD frames. This is derived from the Transceiver Delay Compensation Result bit (CFDC0FDSTS.TDCR) as shown in Figure 26.18.

注1。波特率预分频器除以 N 值 = P + 1（P = 0 1023) P:由通道配置寄存器中的 BRP 位选择的值。

为了使用 FD 帧格式的网络中的最佳时钟容差,标称比特时间和数据比特时间的时间量子长度应该相同。这意味着 CFDC0NCFG。NBRP = CFDC0DCFG。DBRP。

此外,如果使用收发器延迟补偿,请勿将 CFDC0DCFG。DBRP 位编程为大于 1,因为 1 意味着除以 2。

到信道通信状态之前,必须配置波特率,否则模式无法正确切换。

26。4。1。5 发射机延迟补偿

本章对于经典 CAN 不有效。

当数据相位使用5Mbps等高波特率时,发射机延迟可以大于TSEG1。在这种情况下,发射机总是检测到CANFD帧的数据阶段的比特错误。TDC补偿了发射机在该位的采样点处无法接收其自己的发射位。

还有另一个符号采样点,称为辅助采样点（SSP）,仅在 CANFD 帧的数据阶段使用。这源自收发器延迟补偿结果位（CFDC0FDSTS。TDCR）,如图 26。18 . 所示

The resolution of the configuration, measured and offset values is based on the CAN channel DLL clock.

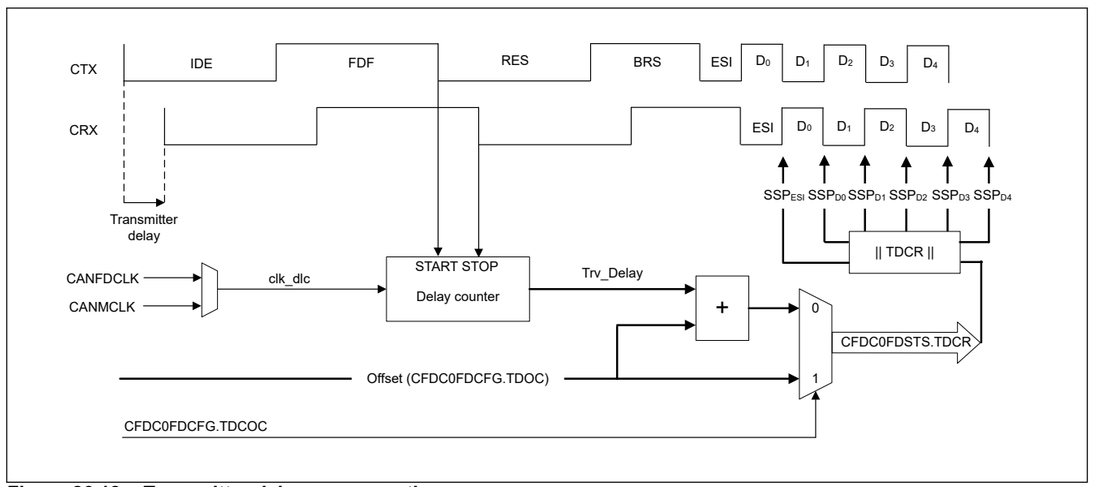

Figure 26.18 Transmitter delay compensation

The measured Trv_Delay is based on the number of clk_dlc clock cycles.The delay is counted up by one for each started clock until the dominant value is seen on CAN_RX. Figure 26.19 shows the measured result. Trv_Delay counted to maximum 127 with a clk_dlc clock.

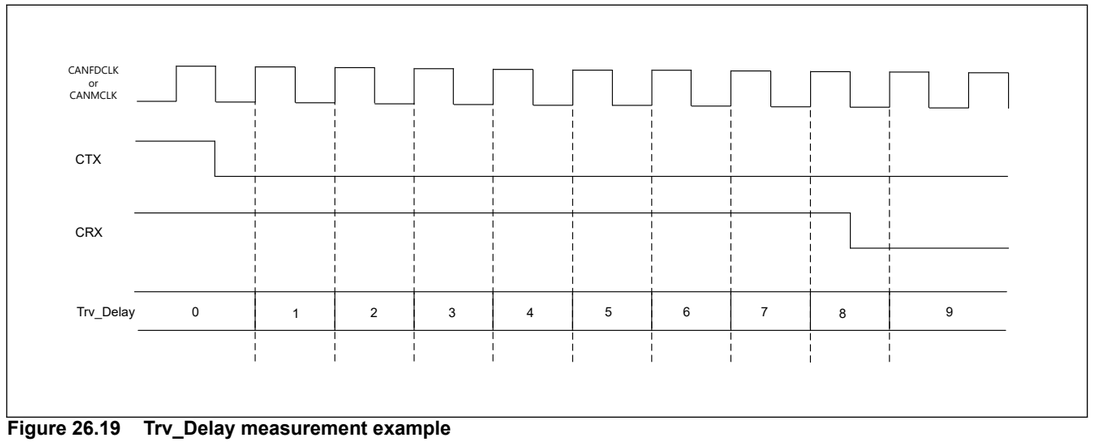

Figure 26.19 Trv_Delay measurement example

The SSP is calculated by taking the result from CFDC0FDSTS.TDCR and rounding the value down to the nearest integer number of data time quanta.

Figure 26.20 shows the positioning of the secondary sample point. When CFDC0FDCFG.TDCOC is equal to 0, the SSP is equal to the Trv_Delay (measured delay) + CFDC0FDCFG.TDCO, rounded down to the nearest integer number of time quanta. Usually, the TDCO value should have the size of (SyncSegmentdata + TSEG1data) to position the SSP to a theoretical location of the sample point.

If the CFDC0FDCFG.TDCOC is equal to 1, the SSP is defined by CFDC0FDCFG.TDCO. If CFDC0DCFG.DBRP is greater than 0, the value is also rounded down to the nearest integer number of time quanta.

图26。18 发射机延迟补偿

Trv_Delay 测得的基于 clk_dlc 时钟周期数,每启动一个时钟延迟都计数一个,直到在 CAN_RX 上看到主导值为止,图 26。19 显示了测得的结果。Trv_Delay 用 clk_dlc 时钟计数到最大 127。

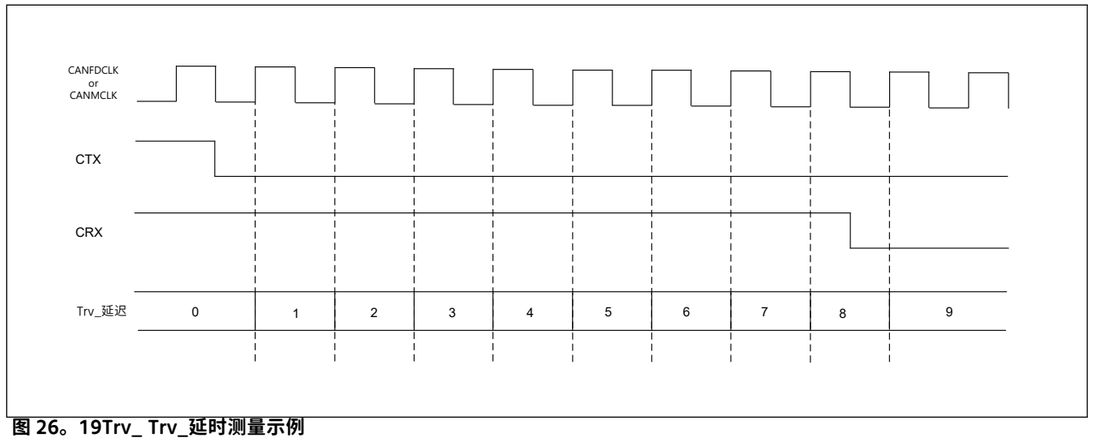

图 26。19Trv_ Trv_延时测量示例

SSP 的计算方法是取 CFDC0FDSTS。TDCR 的结果并将该值四舍五入到最接近的数据时间量子整数。

图26。20显示了次要采样点的定位。CFDC0FDCFG。TDCOC 等于 0 时,SSP 等于 Trv_Delay（测量的延迟）+ CFDC0FDCFG。TDCO,向下舍入到最接近的时间量子整数。通常,TDCO 值应具有（SyncSegmentdata + TSEG1data）的大小,以将 SSP 定位到样本点的理论位置。

如果CFDC0FDCFG。TDCOC等于1,则SSP由CFDC0FDCFG。TDCO定义。如果CFDC0DCFG。DBRP大于0,则该值也向下舍入到最接近的时间量子整数。

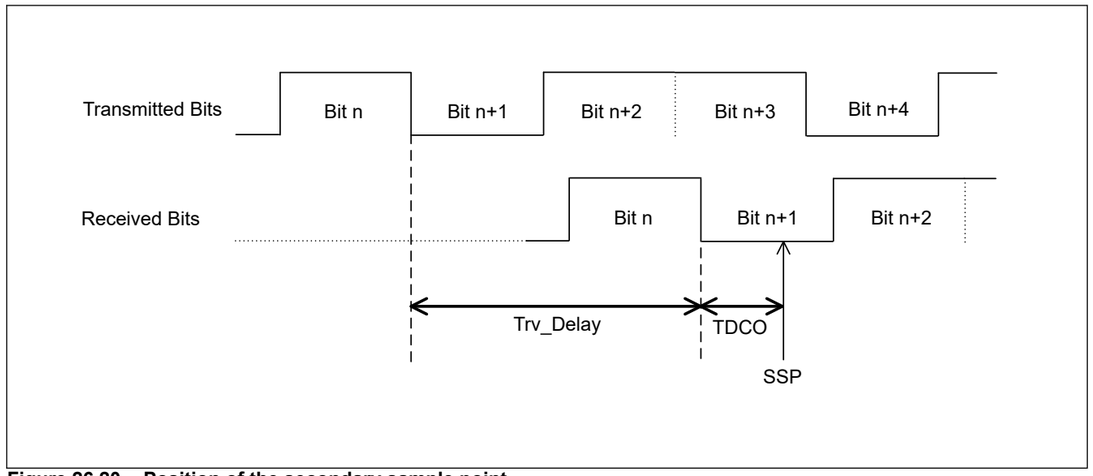

Figure 26.20 Position of the secondary sample point

The maximum delay (Trv_Delay + TDCO) which can be compensated by the CANFD module is (6 data bits - 2clk_dlc).

The ISO 11898-1 allows you to set different values for BRP_data and BRP_nom.

If different values are used for CFDC0NCFG.NBRP and CFDC0DCFG.DBRP, then two CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after sample point of the BRS bit. This condition is shown in Figure 26.21.

The length of the time quantum should be the same in the nominal bit time and in the data bit time. This means CFDC0NCFG.NBRP = CFDC0DCFG.DBRP.

Different bit rates can be achieved by selecting different configuration values for the Time Segments. The nominal bit rate can be configured from 8 to 385 TQs and the data bit rate from 5 to 49 TQs.

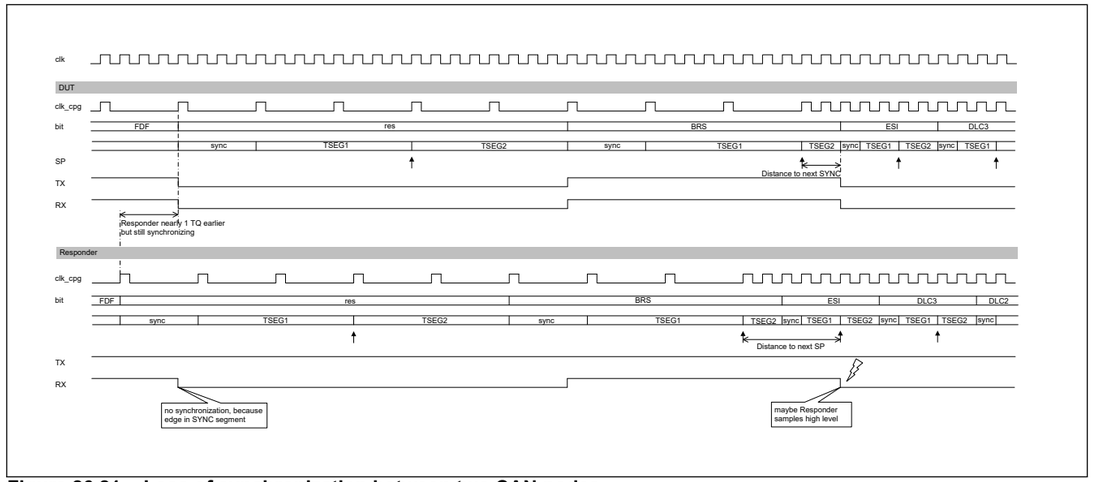

Figure 26.21 Loss of synchronization between two CAN nodes

The transmitter delay compensation measurement result is updated at the falling edge from FDF bit to RES bit when configured accordingly (CFDC0FDCFG.TDCE = 1, CFDC0FDCFG.TDCOC = 0).

Figure 26.22 shows the read flow to get the measured transmitter delay compensation result.

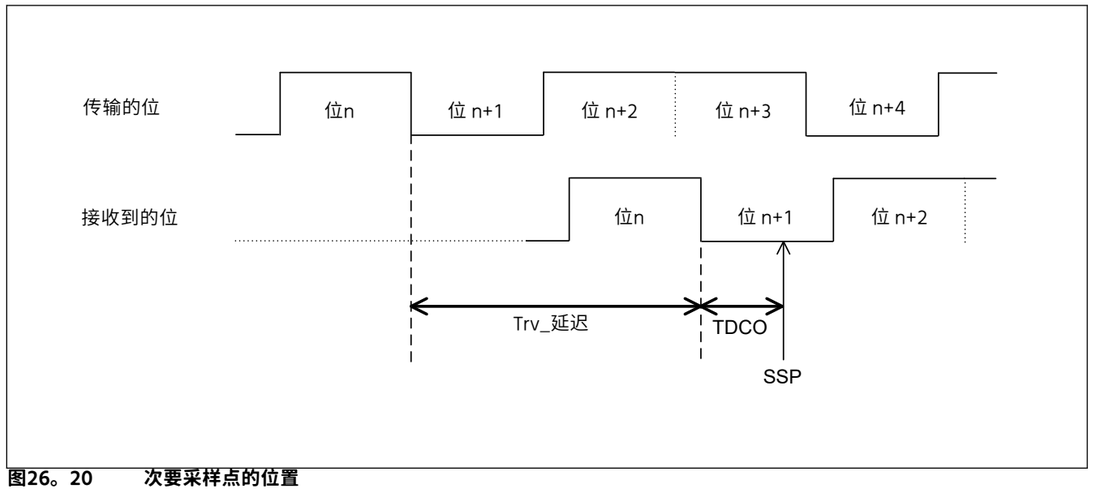

图26。20 次要采样点的位置

CANFD模块可以补偿的最大延迟（Trv_Delay + TDCO）为(6个数据位2clk_dlc）。

ISO 11898-1 允许您为 BRP_data 和 BRP_nom 设置不同的值。

如果CFDC0NCFG。NBRP和CFDC0DCFG。DBRP使用不同的值,则当比特率在BRS比特的采样点之后从标称比特率变为数据比特率时,两个CAN节点可能不同步。此情况如图 26。21 所示。

时间量子在标称比特时间和数据比特时间上的长度应该相同。这意味着
CFDC0NCFG。NBRP = CFDC0DCFG。DBRP。

通过为时间段选择不同的配置值可以实现不同的比特率。标称比特率可配置为8至385TQ,数据比特率可配置为5至49TQ。

当相应地配置时,发射机延迟补偿测量结果在从FDF比特到RES比特的下降沿处更新（CFDC0FDCFG。TDCE= 1,CFDC0FDCFG。TDCOC=0)。

26.4.2 CAN Module Configuration after Hardware Reset

After a hardware reset (power on reset) or after setting and clearing a CFDGRSTC.SRST bit, the CANFD module enters Global Sleep mode automatically.

To enable configuration of the CANFD module, you must exit Sleep mode by clearing the Global Sleep Request bit CFDGCTR.GSLPR to 0.

After a hardware reset, the module starts RAM initialization, the CFDGSTS.GRAMINIT bit in the Global Status Register is set automatically to indicate that the CANFD logic is initializing the RAM.

After RAM initialization is complete, this bit is cleared automatically.

RAM initialization is necessary to avoid setting of false ECC error flag after HW reset the random data presented in the RAM.

Do not access registers of CANFD in either read or write until RAM initialization is complete and the CFDGSTS.GRAMINIT bit is cleared.

Before going to communication mode, the Global Acceptance Filter List and message FIFO buffers must be configured. In addition, CAN channel must be configured such as CAN bit timing. For this configuration, CAN channel must be released from Channel Sleep mode and must be configured for communication in Channel Reset mode (Configuration mode).

Figure 26.23 shows the configuration procedure. For details about each step, seesection 26.5. Acceptance Filtering Function using Global Acceptance Filter List (AFL), section 26.6. FIFO Buffers and Normal Message Buffer Configuration, section 26.7. Interrupts and DMA and section 26.4.1.3. Baud Rate.

The CANFD module does not perform the RAM initialization sequence after executing a software reset by setting CFDGRSTC.SRST.

26.4.2 硬件重置后的 CAN 模块配置

硬件重置（电源重置）后或设置并清除 CFDGRSTC。SRST 位后,CANFD 模块自动进入全局睡眠模式。

要启用 CANFD 模块的配置,您必须通过将全局睡眠请求位 CFDGCTR。GSLPR 清除为 0 来退出睡眠模式。

硬件重置后,模块开始RAM初始化,自动设置全局状态寄存器中的CFDGSTS。GRAMINIT位以指示CANFD逻辑正在初始化RAM。

RAM初始化完成后,该位被自动清除。

RAM初始化是必要的,以避免在HW重置RAM中呈现的随机数据后设置错误的ECC错误标志。

在 RAM 初始化完成并且 CFDGSTS。GRAMINIT 位被清除之前,请勿访问读取或写入中的 CAN FD 寄存器。

在进入通信模式之前,必须配置全局接受过滤器列表和消息 FIFO 缓冲区。此外,CAN信道必须配置为CAN位定时。对于此配置,CAN 通道必须从通道睡眠模式中释放,并且必须配置为在通道重置模式（配置模式）下进行通信。

图26。23显示了配置过程。有关每个步骤的详细信息,请参阅第 26。5 节。使用全局验收滤波器列表（AFL），第 26。6 节的验收滤波功能。FIFO 缓冲区和正常消息缓冲区配置，第 26。7 节。中断和 DMA 以及第 26。4。1。3 节。波特率 .

通过设置CFDGRSTC。SRST执行软件重置后,CANFD模块不执行RAM初始化序列。

26.5 Acceptance Filtering Function using Global Acceptance Filter List (AFL)

26.5.1 Overview

The CANFD module can handle message acceptance filtering with a global Acceptance Filter List (called AFL). Each element of the AFL defines a filter rule for messages received on a specific channel.

The following actions are performed based on the AFL entries:

- Acceptance filtering based on received CAN Identifier and masking

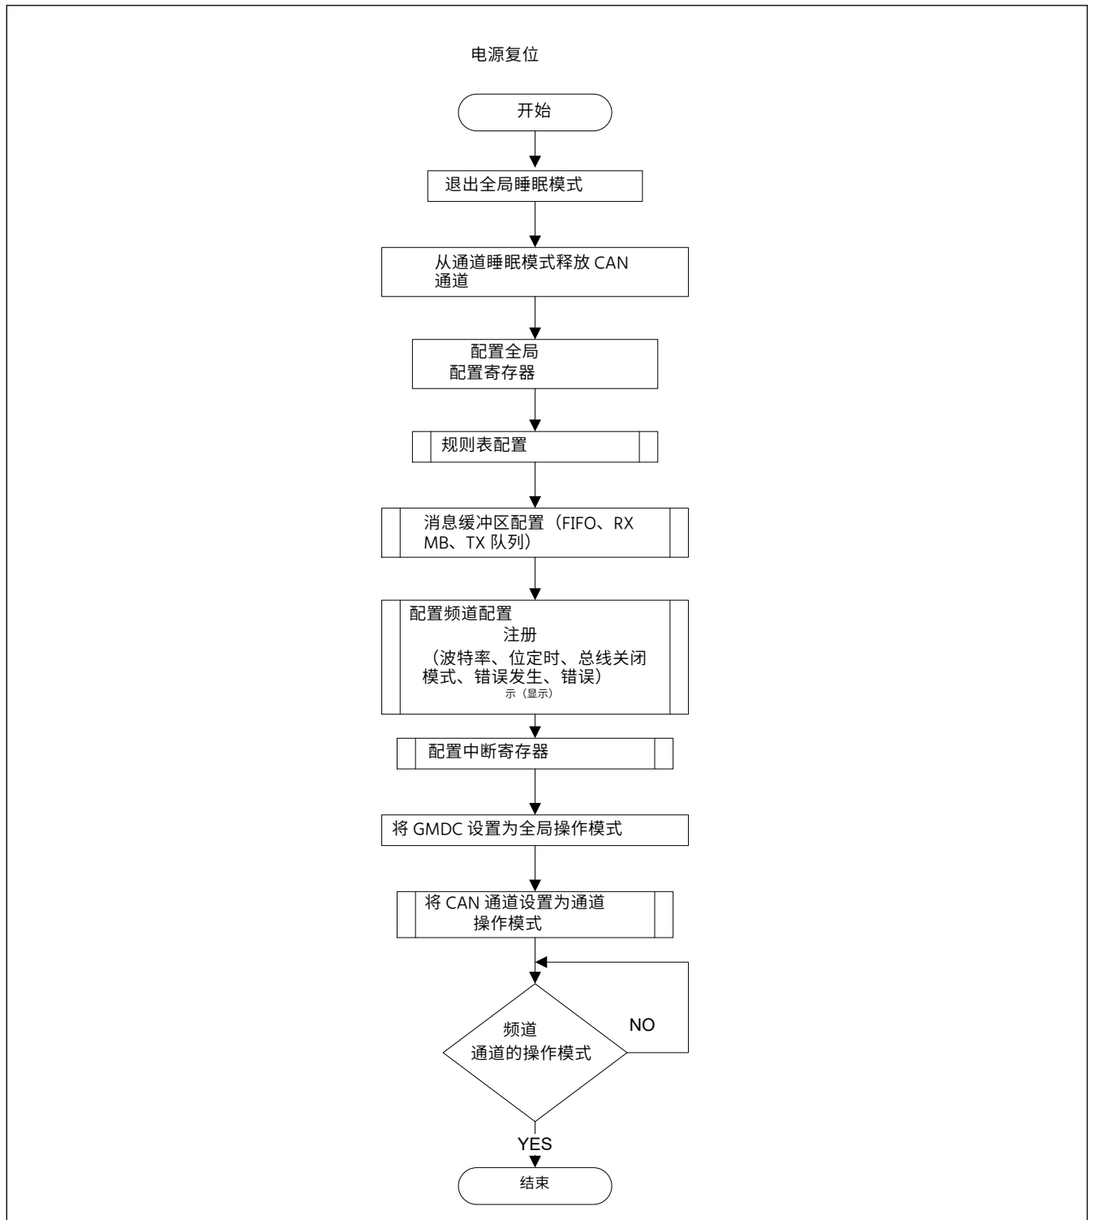

图26。23 硬件重置后的配置过程

26.5 使用全局接受过滤器列表（AFL）的接受过滤功能

26.5.1 概述

CANFD 模块可以处理具有全局接受过滤器列表（称为 AFL）的消息接受过滤。AFL 的每个元素都为在特定信道上接收的消息定义了一个过滤器规则。AFL 条目执行以下操作:

- 基于接收到的 CAN 标识符和屏蔽的接受过滤

- DLC filtering based on received DLC value
- Message data payload according to the CFDGCFG.CMPOC bit*1
- Storage of accepted messages in the message buffer objects defined in the related AFL entry
- Attaching a 16-bit pointer to the stored messages defined in the related AFL entry, for example to support AUTOSAR applications
- Attaching a 2-bit information label to the stored messages defined in the related AFL entry

Note 1. This feature is not available in the classical CAN function.

The CANFD module allows a maximum of 32 AFL entries.

During acceptance filtering process, each AFL entry in a channel is checked against the received message by the acceptance filter unit. The check starts from the lowest AFL entry number for this channel.

AFL search stops when a match of the received identifier with a configured identifier/mask combination occurs or when the received identifier has been compared against all AFL entries defined for the related channel. If no match occurs, then the received message is rejected. No notification is given to the application in this case.

Additionally, an automatic DLC filtering is performed for each accepted message if DLC check is globally enabled. If the DLC value of the received message is equal to or higher than the configured DLC value in the matching AFL entry, the DLC check is passed.

If DLC replacement (CFDGCFG.DRE bit) is enabled, DLC value configured in the matching AFL entry is greater than 0x0 and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination RXMB or FIFO Buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received on the CAN Bus are not stored in the destination RXMB or FIFO Buffer. These additional data bytes are stored as 0x00 in the destination RXMB or FIFO Buffer.

If DLC replacement is enabled and DLC value of matching AFL entry is 0x0, then the received value of DLC is stored in the destination RX MB or FIFO Buffer.

If DLC replacement (the CFDGCFG.DRE bit) is disabled and DLC check passes, then the received value of DLC on the CAN bus is stored in the destination RXMB or FIFO buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received from the CAN bus are also stored in the destination RXMB or FIFO buffer.

If DLC value of the received message is less than the configured DLC value in the matching AFL entry, then DLC check fails. In this case, the received message is rejected and is not stored in any RXMB or FIFO buffer.

Additionally, DLC check failure is flagged by the DLC Error Flag in the Global Error Flag Register. If configured, an error interrupt is also generated. The DLC replacement configuration has no impact if the DLC check fails.

If a message has passed both acceptance filtering and DLC filtering, it is stored in a single reception message buffer and/or in FIFO buffers configured for reception function.

This message storage target information is also defined in the same AFL entry. Do not set a target at the AFL entry which is not configured.

Each accepted received message can be stored into a maximum of 2 different target destinations (single reception message buffer and/or FIFO buffers).

The programming of more than 2 target destinations is not allowed. If more destinations are programmed, then the internal timing might lead to a race condition that prevents the storage of received messages in the message RAM.. Correct configuration of the numbers of target destination is the responsibility of the application.

Additional protection mechanism is made for the case when a received message contains more data payload Bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

If CFDGCFG.CMPOC = 0, the message is completely rejected and is stored in the target destination. When CFDGCFG.CMPOC = 0 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS), the corresponding CFDFMSTS.RFxMLT or CFDFMSTS.CFxMLT bit is not set to 1, respectively.

- DLC 过滤基于接收到的 DLC 值
- 根据 CFDGCFG。CMPOC 位 *1 的消息数据有效负载
- 在相关 AFL 条目中定义的消息缓冲区对象中存储已接受的消息
- 将 16 位指针附加到相关 AFL 条目中定义的存储消息,例如支持 AUTOSAR 应用程序
- 将 2 位信息标签附加到相关 AFL 条目注 1 中定义的存储消息。此功能在经典 CAN 函数中不可用。

CANFD 模块最多允许 32 个 AFL 条目。

在验收过滤过程中,验收过滤单元根据接收到的消息检查信道中的每个AFL条目。支票从该频道的最低 AFL 条目号开始。

当接收到的标识符与配置的标识符/掩码组合的匹配发生时或者当接收到的标识符已经与为相关信道定义的所有AFL条目进行比较时,AFL搜索停止。如果没有发生匹配,则接收到的消息将被拒绝。在这种情况下,不会向申请发出通知。

此外,如果全局启用 DLC 检查,则会对每个接受的消息执行自动 DLC 过滤。如果接收到的消息的DLC值等于或高于匹配AFL条目中配置的DLC值,则通过DLC检查。

如果启用DLC替换（CFDGCFG。DRE位）,则匹配AFL条目中配置的DLC值大于0x0并且DLC检查通过,则匹配AFL条目中配置的DLC值存储在目的地RXMB或FIFO缓冲区中。

如果接收到的DLC值大于匹配AFL条目中配置的DLC值,则在CAN总线上接收到的附加数据字节不存储在目的地RXMB或FIFO缓冲区中。这些附加数据字节以 0x00 的形式存储在目标 RXMB 或 FIFO 缓冲区中。

如果启用 DLC 替换并且匹配 AFL 条目的 DLC 值为 0x0,则接收到的 DLC 值将存储在目标 RX MB 或 FIFO 缓冲区中。

如果禁用 DLC 替换（CFDGCFG。DRE 位）并且 DLC 检查通过,则 CAN 总线上接收到的 DLC 值将存储在目的地 RXMB 或 FIFO 缓冲区中。

DLC的接收值大于匹配AFL条目中配置的DLC值,则从CAN总线接收到的附加数据字节也存储在目的RXMB或FIFO缓冲区中。

如果接收到的消息的DLC值小于匹配AFL条目中配置的DLC值,则DLC检查失败。在这种情况下,接收到的消息被拒绝并且不存储在任何RXMB或FIFO缓冲区中。

此外,DLC 检查失败由全局错误标志寄存器中的 DLC 错误标志标记。如果配置,也会生成错误中断。DLC 检查失败,则 DLC 替换配置不会产生影响。

如果消息已经通过了验收滤波和DLC滤波,则它被存储在单个接收消息缓冲器和/或配置用于接收功能的FIFO缓冲器中。

该消息存储目标信息也在同一AFL条目中定义。请勿在未配置的 AFL 条目处设置目标。

每个接受的接收消息最多可以存储到 2 个不同的目标目的地（单个接收消息缓冲区和/或 FIFO 缓冲区）。

2个以上目标目的地的编程是不允许的。如果对更多目的地进行编程,那么内部定时可能会导致竞争条件,从而阻止将接收到的消息存储在消息 RAM 中。。 正确配置目标目的地数量是应用程序的责任。

当接收到的消息包含比目标目的地可能存储的数据有效负载字节（CFDRMNB。RMPLS、CFDRFCCa。RFPLS 或 CFDCFCC。CFPLS）更多的数据有效负载字节时,会制定额外的保护机制。如果CFDGCFG。CMPOC = 0,则消息被完全拒绝并存储在目标目的地中。当 CFDGCFG。CMPOC = 0 并且包含接收到的消息的 RX 或 Common FIFO full 包含比在目标目的地中存储的数据有效负载字节（CFDRMNB。RMPLS、CFDRFCCa。RFPLS 或 CFDCFCC。CFPLS）更多时,相应的 CFDFMSTS。RFxMLT 或 CFDFMSTS。CFxMLT 位分别不设置为 1。

When CFDGCFG.CMPOC = 1, the received data bytes greater than CFDRMNB.RMPLS is rejected. When CFDGCFG.CMPOC = 1 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS), the corresponding CFDFMSTS.RFxMLT or CFDFMSTS.CFxMLT bit is set to 1, respectively.

Depending on the CFDGCFG.DRE bit, the original received DLC or the DLC value configured at the AFL entry is stored.

Regardless of the CFDGCFG.CMPOC bit setting, CFDGERFL.CMPOF is set to 1 if a payload overflow condition is detected.

The DLC filtering is performed before the payload overflow function. So for one reception frame, only one flag can be set at the same time with CFDGERFL.DEF or CFDGERFL.CMPOF*1.

Note 1. This bit is not available in the classical CAN function.

26.5.2 Allocation of AFL Entries

The number of AFL entries per channel can be configured using the dedicated field in the related Global Acceptance Filter Configuration Registers (see Figure 26.24).

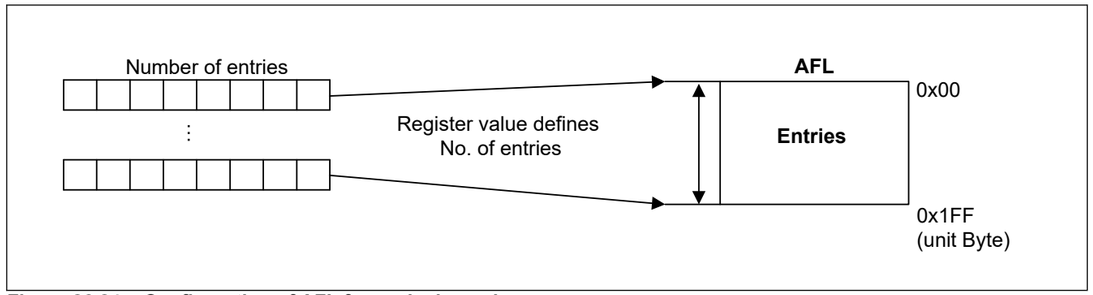

Figure 26.24 Configuration of AFL for each channel

The minimum number of entries for one channel is 0 (no entries defined for the channel) and the maximum number of entries is 32.

All entries are unique for a channel and overlapping or sharing of entries is not supported. Correct configuration of the AFL is the responsibility of the application.

The CANFD module does not flag errors related to the configuration of the AFL.

26.5.3 AFL Entry Description

Each AFL entry consists of 16 bytes. The fields in all entries are identical.

Each entry contains the following information for acceptance filtering and DLC filtering:

- Identifier (11 bits for Standard Frame format, 29 bits for Extended Frame format):
  Acceptance filter unit checks the identifier field of the received message against the identifier field of each AFL entry (full 29 bits masking of identifier bits is possible, see information that follows).
- IDE bit:
  Acceptance filter unit checks the IDE bit of the received message against this bit and selects the relevant part of the identifier field for acceptance filtering (masking of IDE bit is possible, see the information that follows).
- RTR bit:
  Acceptance filter unit only accepts data frames (RTR = 0) or remote frames (RTR = 1) according to the setting of this bit (masking of RTR bit is possible, see the information that follows).
- Loopback Configuration bit:
  This bit can enable or disable the AFL entry depending on the Loopback Configuration or Mirror mode condition.
- Mask for Identifier bits (29 bits):

当CFDGCFG。CMPOC = 1时,接收到的大于CFDRMNB。RMPLS的数据字节被拒绝。当CFDGCFG。CMPOC = 1并且包含接收到的消息的RX或Common FIFO full包含比在目标目的地中存储的数据有效负载字节（CFDRMNB。RMPLS、CFDRFCCa。RFPLS或CFDCFCC。CFPLS）更多时,相应的CFDFMSTS。RFxMLT或CFDFMSTS。CFxMLT位分别设置为1。

根据CFDGCFG。DRE位,存储原始接收到的DLC或在AFL条目处配置的DLC值。

无论 CFDGCFG。CMPOC 位设置如何,如果检测到有效负载溢出情况,CFDGERFL。CMPOF 都会设置为 1。

DLC滤波是在有效负载溢出功能之前执行的。因此,对于一个接收帧,可以使用 CFDGERFL。DEF 或 CFDGERFL。CMPOF *1 . 同时仅设置一个标志

注1。该位在经典 CAN 函数中不可用。

26。5。2 AFL 条目的分配

每个通道的 AFL 条目数量可以使用相关全局接受过滤器配置寄存器中的专用字段进行配置（见图 26。24)。

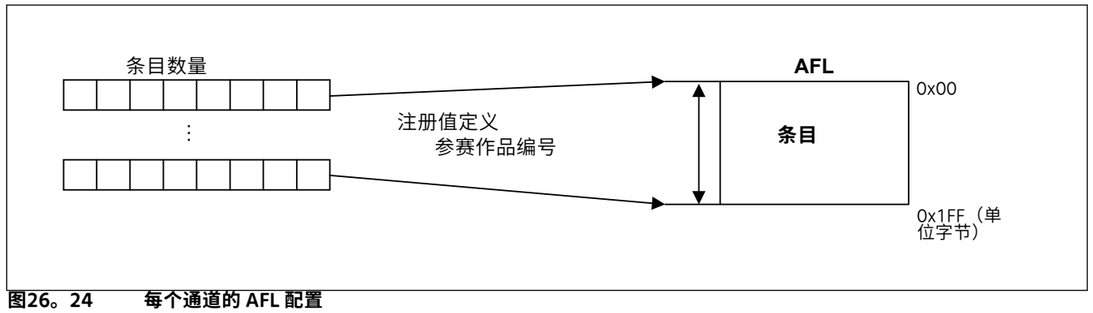

图26。24 每个通道的 AFL 配置

一个通道的最小条目数为 0（没有为通道定义条目）,并且所有条目的最大数量对于通道来说是唯一的,并且不支参赛作品为 32。 叠或共享。AFL的正确配置是应用程序的责任。

CANFD 模块不会标记与 AFL 配置相关的错误。

26。5。3 AFL 条目说明

每个 AFL 条目由 16 个字节组成。所有条目中的字段都是相同的。

每个条目包含以下用于验收过滤和 DLC 过滤的信息:

- 标识符（标准帧格式为 11 位,扩展帧格式为 29 位）:
  接受过滤器单元根据每个AFL条目的标识符字段检查接收到的消息的标识符字段（标识符位的完整29位屏蔽是可能的,请参阅下面的信息）。
- IDE 位:
  接受过滤单元根据该位检查接收到的消息的IDE位,并选择标识符字段的相关部分进行接受过滤（可以屏蔽IDE位,请参阅下面的信息）。
- RTR 位:
  验收滤波器单元仅根据该位的设置接受数据帧（RTR = 0)或远程帧（RTR = 1）（可以屏蔽RTR位,请参阅以下信息）。
- 环回配置位:
  该位可以根据环回配置或镜像模式条件启用或禁用 AFL 条目。
- 标识符位掩码 (29 位）:

Each bit in the identifier mask can mask the corresponding identifier bit in the AFL entry during acceptance filtering, see Figure 26.25.

- Mask for IDE bit:
  If this Mask bit masks the IDE bit of the AFL entry in both Standard Identifier and Extended Identifier format, messages can be accepted by this AFL entry. The identifier of the received message is compared against the Standard Identifier part of the AFL entry for Standard Identifier format messages and against the Extended Identifier part of the AFL entry for Extended Identifier format messages.

- Mask for RTR bit:
  If this Mask bit masks the RTR bit of the AFL entry in both frame formats, data frame and remote frame formats are accepted by this AFL entry.

- Pointer information (16 bits):
  This 16-bit pointer is attached to a received message accepted by the related AFL entry. The pointer is added during message storage in the message buffer area and can be used by application as support function. The pointer information can be used for example to support PDU identifier allocation for the received message in AUTOSAR systems.

- Information label (2 bits):
  This 2-bit label is attached to a received message accepted by the related AFL entry. The label is added during message storage in the message buffer area and can be used by application as support function.

- DLC value for automatic DLC filtering:
  If the DLC value of the received message is equal or higher than the configured DLC value, the DLC check is passed.

If the DLC value in this AFL entry is configured to 0, DLC filtering is effectively disabled for this entry (all accepted messages pass DLC filtering).

Each AFL entry contains the following information for the handling of received messages:

- Message buffer number of one single reception message buffer as target for received message storage
- Single reception message buffer enable bit to configure the single reception message buffer number to be valid or invalid, as target for received message storage
- FIFO direction pointer - each bit of the FIFO direction pointer configures a dedicated FIFO as possible target for a received message

There is no hardware protection against such storage of message. Therefore, the FIFO direction pointer must be configured carefully.

标识符掩码中的每一位都可以在验收滤波期间掩码AFL条目中的相应标识符位,参见图26。25 .

IDE 位的 ● 掩码:
如果该掩码位以标准标识符和扩展标识符格式掩码 AFL 条目的 IDE 位,则该 AFL 条目可以接受消息。将接收到的消息的标识符与标准标识符格式消息的AFL条目的标准标识符部分和扩展标识符格式消息的AFL条目的扩展标识符部分进行比较。

RTR 位的 ● 掩码:
如果该掩码位掩蔽了 AFL 条目中两种帧格式的 RTR 位,则该 AFL 条目接受数据帧和远程帧格式。

● 指针信息(16 位）：
该 16 位指针附加到相关 AFL 条目接受的接收消息。该指针是在消息缓冲区中的消息存储期间添加的,可以由应用程序用作支持功能。例如,指针信息可用于支持AUTOSAR系统中接收到的消息的PDU标识符分配。

● 信息标签(2 位）：
该 2 位标签附加到相关 AFL 条目接受的接收消息上。该标签是在消息缓冲区中的消息存储期间添加的,可以由应用程序用作支持功能。

● DLC 值用于自动 DLC 过滤:
如果接收到的消息的DLC值等于或高于配置的DLC值,则通过DLC检查。

如果此 AFL 条目中的 DLC 值配置为 0,则该条目将有效禁用 DLC 过滤（所有接受的消息都通过 DLC 过滤）。

AFL 的每个条目都包含以下信息, 用于处理接收到的消息:

● 作为接收消息存储目标的一个单个接收消息缓冲区的消息缓冲区编号
● 单接收消息缓冲区使能位将单接收消息缓冲区号配置为有效或无效,作为接收消息存储的目标
● FIFO 方向指针 FIFO 方向指针的每一位都将专用的 FIFO 配置为接收到的消息的可能目标

没有针对此类消息存储的硬件保护。因此,必须仔细配置 FIFO 方向指针。

26.5.4 Entering Entries in the AFL

Application software can enter one full entry into the AFL using the following registers:

- Global AFL ID Entry Register: Part 1 of the AFL entry
- Global AFL Mask Entry Register: Part 2 of the AFL entry
- Global AFL Pointer 0 Entry Register: Part 3 of the AFL entry
- Global AFL Pointer 1 Entry Register: Part 4 of the AFL entry.

16 sets of these registers form a group of AFL entries. Each group can be accessed through a page mechanism. For the CANFD module, 32 of these pages exist to allow access to the whole AFL range. The AFL should only be configured in CH_RESET or CH_HALT mode. Pages are linked to the AFL entries in the following way:

Page 0	Entry 0 — 15
Page 1	Entry 16 — 31

The selection of the AFL access page is done using the Global Acceptance Filter List Entry Control Register (CFDGAFLECTR) (Figure 26.26). This register has the following fields:

- 1 bit to select the AFL page number
- 1 bit to enable or disable the AFL data access to prevent unwanted write access to the AFL.

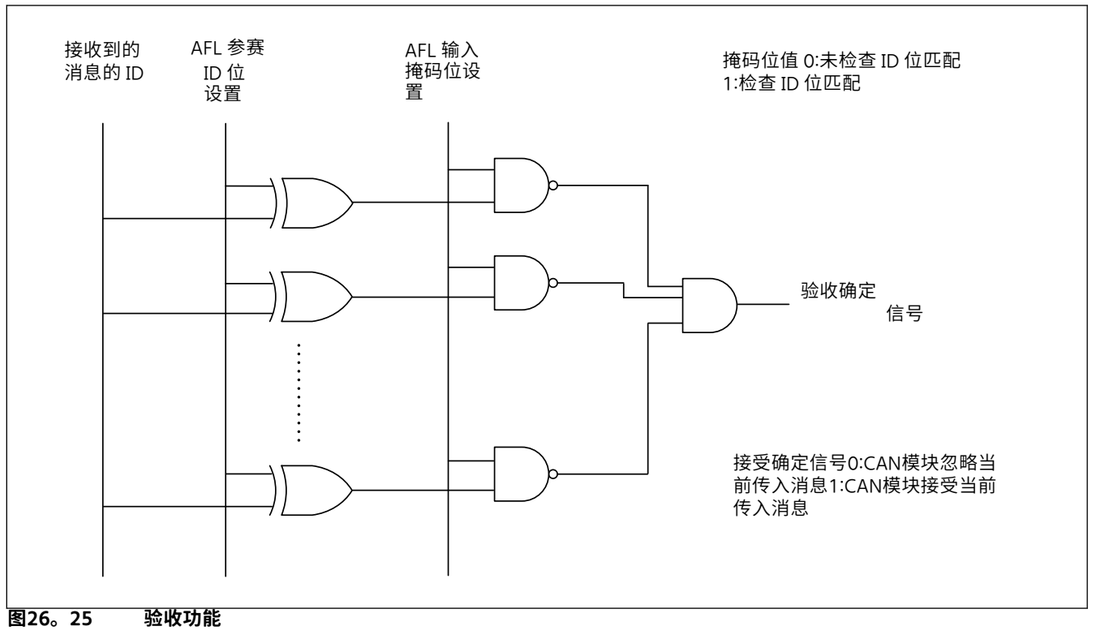

图26。25 验收功能

26。5。4 进入 AFL

应用软件可以使用以下寄存器输入 AFL 的一个完整条目:

- 全球 AFL ID 输入寄存器:AFL 输入的第 1 部分
- 全球 AFL 面罩条目寄存器:AFL 条目第 2 部分
- 全局 AFL 指针 0 输入寄存器:AFL 输入的第 3 部分
- 全局 AFL 指针 1 条目寄存器:AFL 条目的第 4 部分。

16组这些寄存器组成了一组AFL条目。每个组都可以通过页面机制访问。对于 CANFD 模块,存在其中 32 个页面以允许访问整个 AFL 范围。AFL 应仅配置为 CH_RESET 或 CH_HALT 模式。页面通过以下方式链接到 AFL 条目:

0页	条目 0 — 15
第 1 页	条目 16 — 31

AFL 访问页面的选择是使用全局接受过滤器列表进入控制寄存器（CFDGAFLECTR）完成的（图 26。26)。该寄存器具有以下字段:

- 1 位选择 AFL 页码
- 1 位以启用或禁用 AFL 数据访问,以防止对 AFL 进行不需要的写访问。

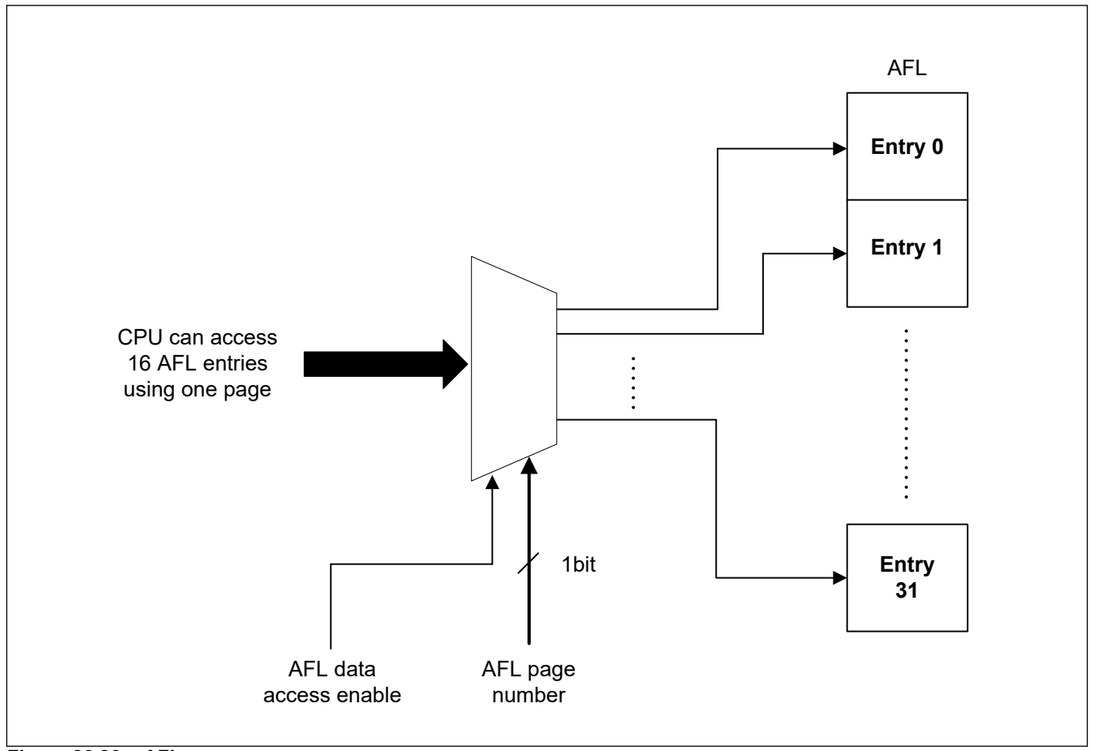

Figure 26.26 AFL page access

Application software should not write numbers higher than 0x1 for the AFL page number.

Follow the configuration shown in Figure 26.27 to program the AFL.

After entering all entries in Configuration mode, locking of the AFL access should be performed to protect unwanted write access to the AFL.

Write protection is active during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION) if the lock bit is set.

Read access to AFL is still possible during all Global modes even when AFL data access is disabled (consistency check of AFL contents is possible during run time).

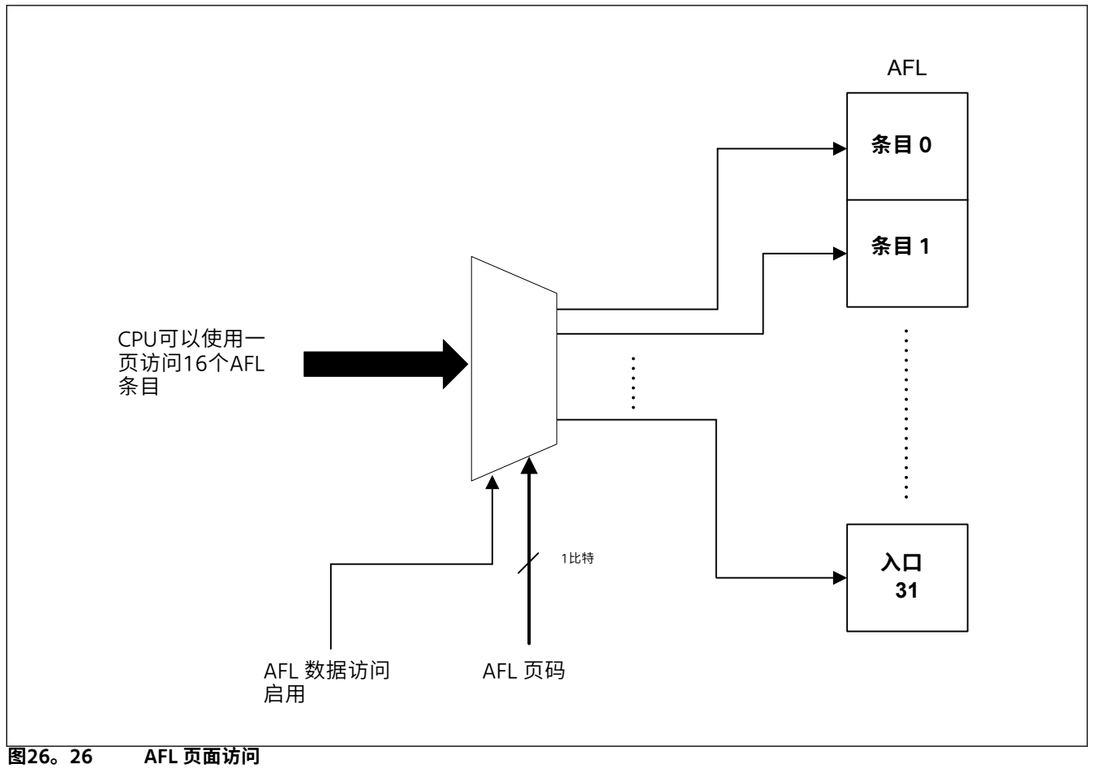

图26。26 AFL 页面访问

应用软件不应为 AFL 页码写入高于 0x1 的数字。

按照图 26。27 所示的配置对 AFL 进行编程。

在配置模式下输入所有条目后,应执行 AFL 访问的锁定,以保护对 AFL 的不需要的写访问。

如果锁位被设置,则在所有全局模式（GL_RESET、GL_HALT 和 GL_OPERATION）期间写保护都是活动的。即使 AFL 数据访问被禁用,在所有全局模式下仍然可以读取 AFL 访问（在运行时间内可以对 AFL 内容进行一致性检查）。

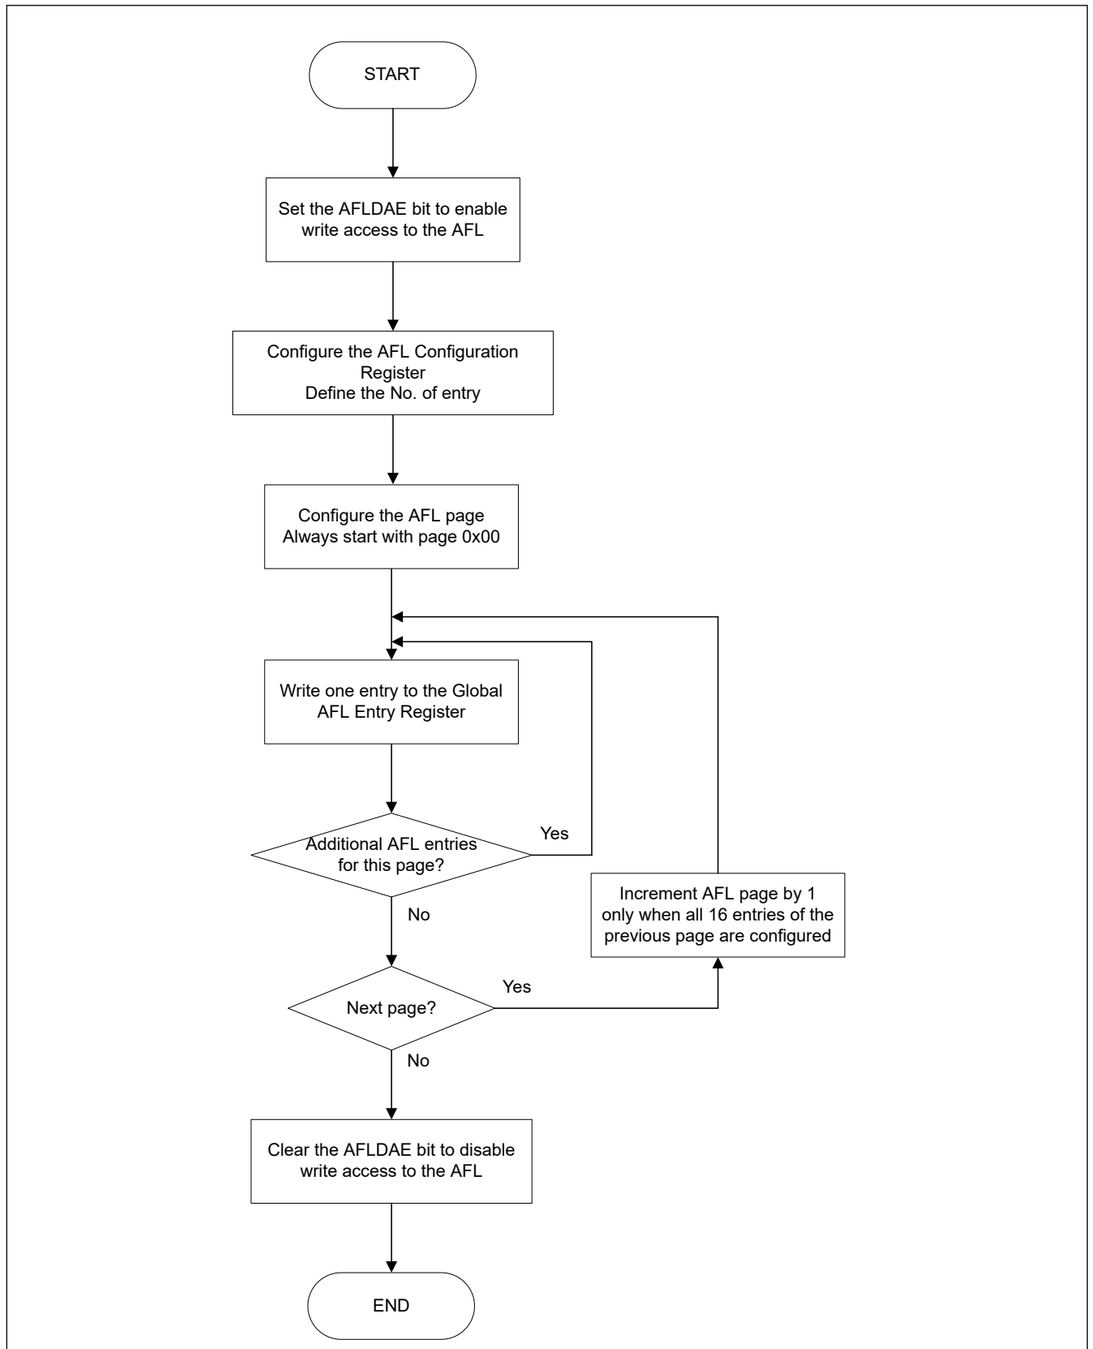

Figure 26.27 AFL configuration flow

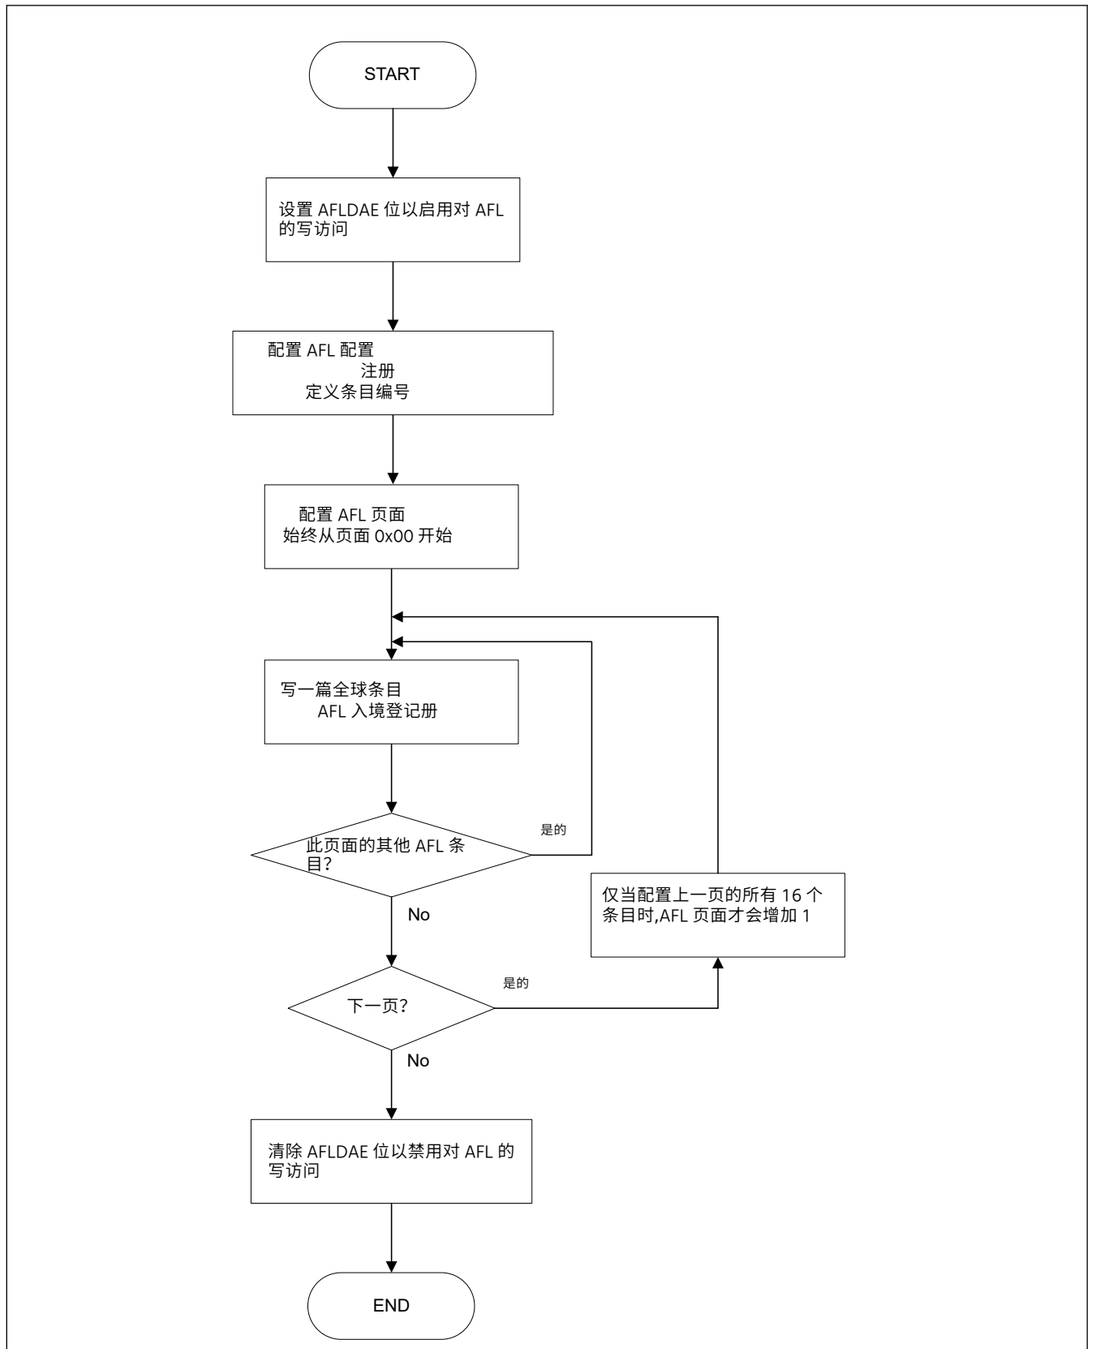

图26。27 AFL 配置流程

26.5.5 Loopback Modes

If the Loopback Configuration bit is set, the AFL entry is only valid in Loopback test mode (Self-test mode 0 or Self-test mode 1) or in mirror mode when receiving messages that were transmitted by the respective CAN channel itself.

The AFL entry is not valid for received messages in loopback mode transmitted by other CAN nodes on the bus. The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID respectively.

If the Loopback Configuration bit is 0, the AFL entry is only valid for:

- Received messages transmitted by other CAN nodes on the bus in normal (non-loopback mode) and mirror modes
- Received messages transmitted by other CAN nodes or the CAN channel itself in Loopback test mode.

The mirror mode can be enabled with the CFDGCFG.MME bit in the Global Configuration Register. If CFDGCFG.MME bit is set, then a successfully transmitted message can be stored back in an RX message buffer or FIFO buffer if a matching entry is configured in the AFL for that channel.

The Loopback Configuration bit in the matching AFL entry must be set to store this frame.

If Mirror mode and Loopback test mode are configured at the same time, the Loopback test mode behavior applies.

Table 26.23 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 26.23 Behavior of acceptance filter based on the loopback configuration setting in AFL entry

Mirror Mode Enable (MME Configuration bit)	Loopback in test mode (Self-test mode 0 or Self-test mode 1)	Channel mode	Loopback Configuration bit in AFL entry	AFL entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

26.5.6 IDE Masking

When the GAFLIDEM bit is 0 in an AFL entry, the IDE bit configured in the AFL entry is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is based on the received IDE bit.

Consider the following example:

- The ID and Mask fields of an AFL entry x is configured as follows:
  - CFDGAFLID [x] = 0xC0553A20 → IDE = 1, RTR = 1, LLB = 0, ID[10:0] = 0x220 / ID[28:0] = 0x00553A20
  - CFDGAFLMr = 0x0000FFFF → IDEM = 0. RTRM = 0, IDM[10:0] = 0x7FF / IDM[28:0] = 0x0000FFFF

26。5。5 环回模式

如果设置了环回配置位,则AFL条目仅在环回测试模式（自检模式0或自检模式1)或接收由相应CAN信道本身发送的消息时在镜像模式下有效。

AFL 条目对于总线上其他 CAN 节点传输的环回模式接收到的消息无效。相关条目的表达式有效或无效意味着该AFL条目分别与接收到的消息ID进行比较或不进行比较。

如果环回配置位为 0,则 AFL 条目仅适用于:

- 收到其他 CAN 节点在普通（非回环模式）和镜像模式下在总线上传输的消息
- 在环回测试模式下接收到的由其他 CAN 节点或 CAN 信道本身传输的消息。

可以通过全局配置寄存器中的 CFDGCFG。MME 位启用镜像模式。如果设置了 CFDGCFG。MME 位,则如果 AFL 中为该信道配置了匹配条目,则可以将成功发送的消息存储回 RX 消息缓冲区或 FIFO 缓冲区中。

必须设置匹配 AFL 条目中的环回配置位来存储该帧。

如果同时配置镜像模式和环回测试模式,则适用环回测试模式行为。

表 26。23 显示了接受滤波器单元根据相关输入信号的设置而采取的行为。

表 26。23 AFL条目中基于环回配置设置的接受滤波器的行为

镜像模式启用（MME 配置位）	测试模式下的环回（自我-测试模式0或自测试模式1)	通道模式	环回配置 AFL 条目中的位	AFL 参赛
0	0	接收器	0	有效
			1	无效
		发射机	0	无效
			1	无效
	1	接收器	0	有效
			1	无效
		发射机	0	有效
			1	有效
1	0	接收器	0	有效
			1	无效
		发射机	0	无效
			1	有效
	1	接收器	0	有效
			1	无效
		发射机	0	有效
			1	有效

注意:相关条目的表达式有效或无效意味着该AFL条目分别与接收到的消息ID进行比较或不进行比较。

26。5。6 IDE 掩蔽

AFL条目中GAFLIDEM位为0时,AFL条目中配置的IDE位不用于ID匹配。在这种情况下,ID[10:0]或ID[28:0]匹配的使用基于接收到的IDE位。

考虑以下示例:

- AFL 条目 x 的 ID 和 Mask 字段配置如下:
  - CFDGAFLID [x] = 0xC0553A20 → IDE = 1,RTR = 1,LLB = 0,ID[10:0] = 0x220/ID[28:0] = 0x00553A20
  - CFDGAFLMr = 0x0000FFFF → IDEM = 0。RTRM = 0,IDM[10:0] = 0x7FF/IDM[28:0] = 0x0000FFFF

- The comparison result for the four different received IDs with AFL entry x is described as follows:
  - If a frame with IDE = 0 and ID = 0x220 is received, this is considered as a match
  - If a frame with IDE = 0 and ID = 0x320 is received, this is not a match
  - If a frame with IDE = 1 and ID = 0x1FFF3A20 is received, this is considered as a match
  - If a frame with IDE = 1 and ID = 0x08803220 is received, this is not a match.

26.5.7 Updating AFL Entry during Communication

You can update the AFL entry without disabling all CAN communications. Choose the entry number to be updated by setting the AFL entry number, and ignore the enable bit.

This entry number is ignored from the AFL matching while the entry is being updated.

Figure 26.28 shows the update flow for an AFL entry.

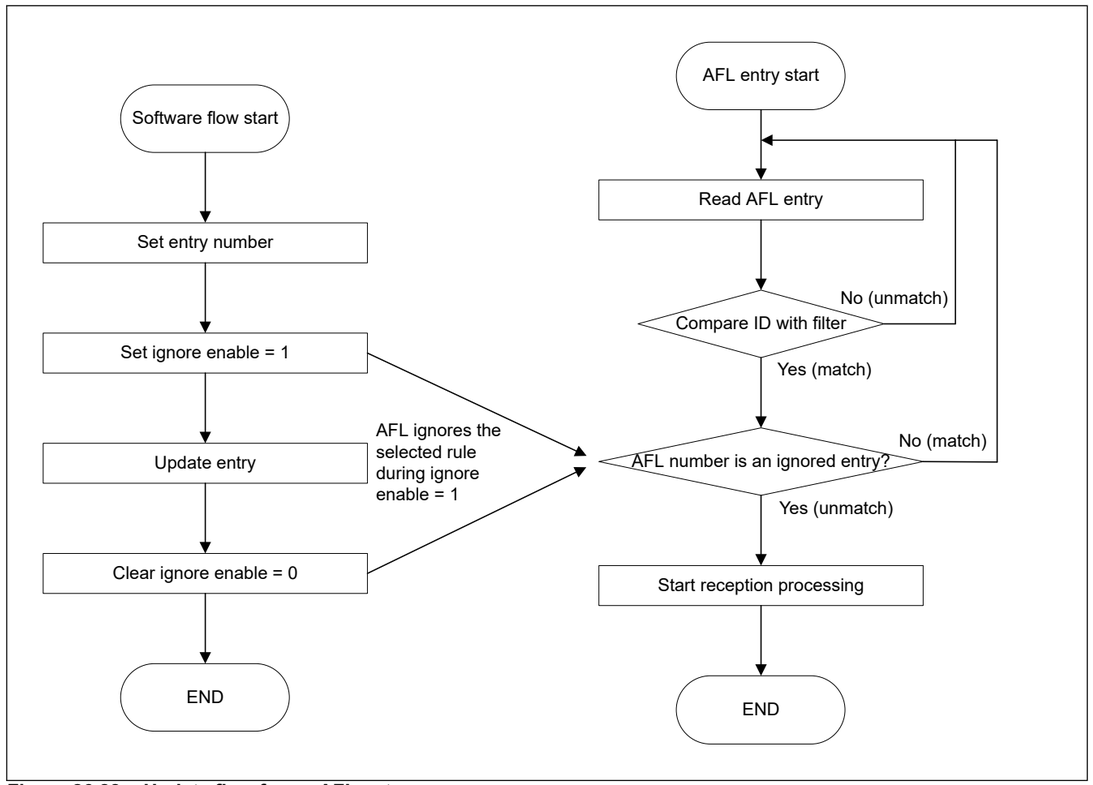

Figure 26.28 Update flow for an AFL entry

The method to update an AFL entry is as follows:

1. Set the entry number to CFDGAFLIGNENT register.
2. Set the value 0xC401 (key code and enable bit) to CFDGAFLIGNCTR register.
3. Set the entry page to CFDGAFLECTR register. This page includes the selected entry. CFDGAFLECTR.AFLDAE is set to 1.
4. Set the new rule to CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r registers.
5. CFDGAFLECTR.AFLDAE is cleared to 0.
6. Set the value 0xC400 (key code and clear enable bit) to CFDGAFLIGNCTR register.

- 四个不同的接收到的带有 AFL 条目 x 的 ID 的比较结果描述如下:
  - 如果收到 IDE = 0 且 ID = 0x220 的帧,则将其视为匹配
  - 如果收到一个 IDE = 0, ID = 0x320 的帧, 这不是匹配
  - 如果收到 IDE = 1 且 ID = 0x1FFF3A20 的帧,则视为匹配
  - 如果收到一个 IDE = 1, ID = 0x08803220 的帧, 这不是匹配。

26。5。7 在通信期间更新 AFL 条目

您可以在不禁用所有 CAN 通信的情况下更新 AFL 条目。通过设置AFL条目号来选择要更新的条目号,并忽略启用位。

在更新条目时,该条目号将从 AFL 匹配中忽略。

图 26。28 显示了 AFL 条目的更新流程。

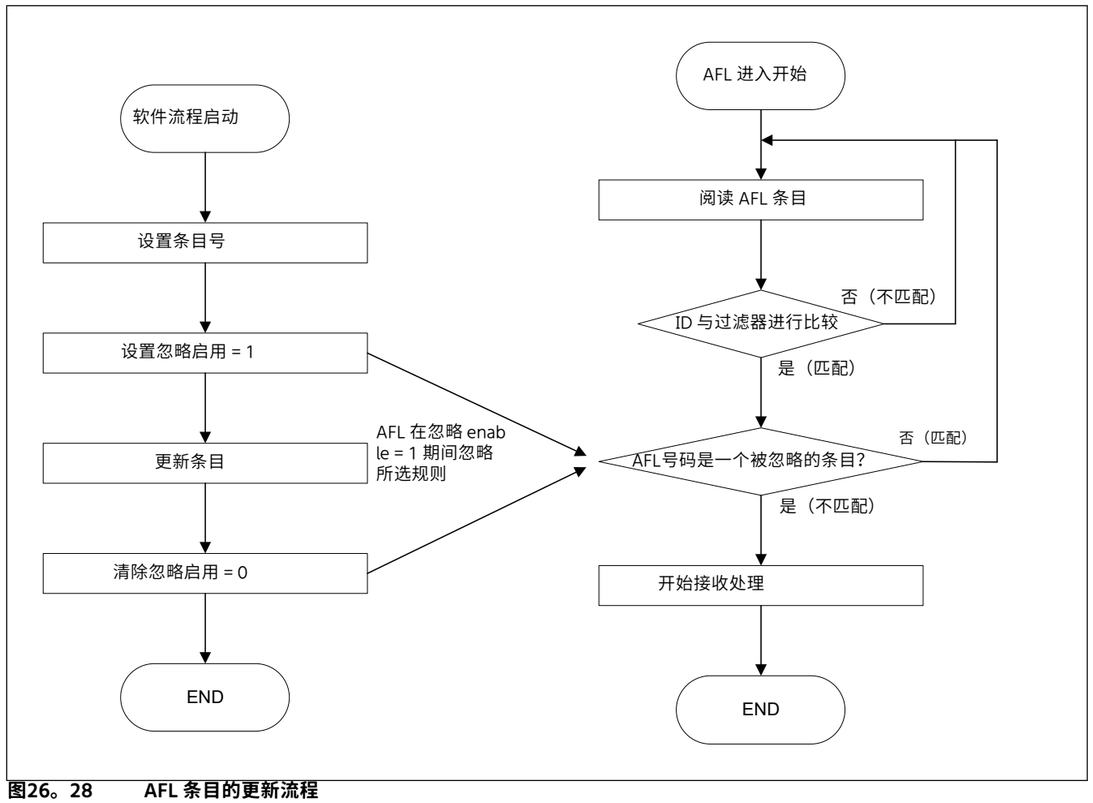

图26。28 AFL 条目的更新流程

AFL 条目更新的方法如下:

1。将条目号设置为 CFDGAFLIGNENT 寄存器。

2锌姣涓涓。将值 0xC401（密钥代码和启用位）设置为 CFDGAFLIGNCTR 寄存器。

3锌 娴 。将条目页设置为 CFDGAFLECTR 注册。此页面包括所选条目。CFDGAFLECTR。AFLDAE 已设置 to 1.

4锌姣涓。将新规则设置为 CFDGAFLIDr、CFDGAFLMr、CFDGAFLP0r、CFDGAFLP1r 寄存器。

5锌姣涓。CFDGAFLECTR。AFLDAE 清除至 0。

6锌 涓€涓。将值 0xC400（密钥代码和清除启用位）设置为 CFDGAFLIGNCTR 寄存器。

5. Set 0x00000000 to CFDGAFLECTR register.
6. Set 0x0000C400 to CFDGAFLIGNCTR register.

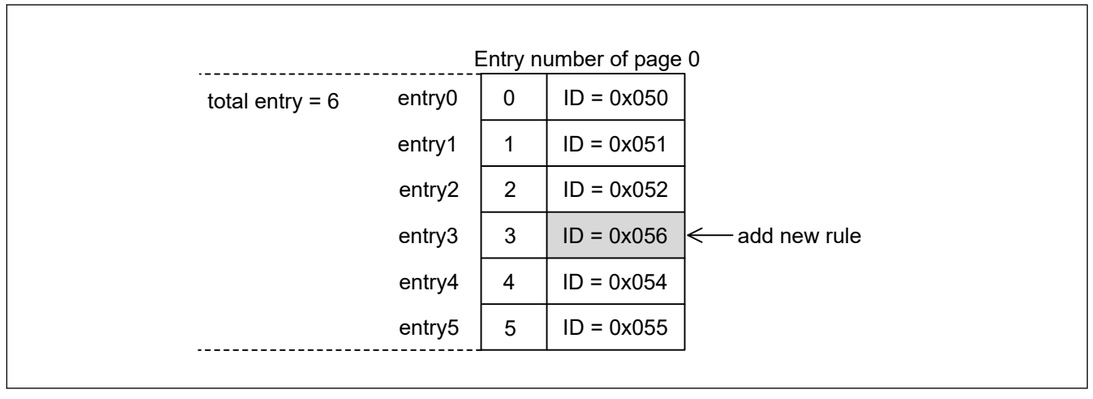
The new entry is now added.



The AFL filter can be used to set CFDGAFLCFG, and addition/deletion of an entry is possible. Therefore, it is necessary to set the maximum number to be used to CFDGAFLCFG.

26.6 FIFO Buffers and Normal Message Buffer Configuration

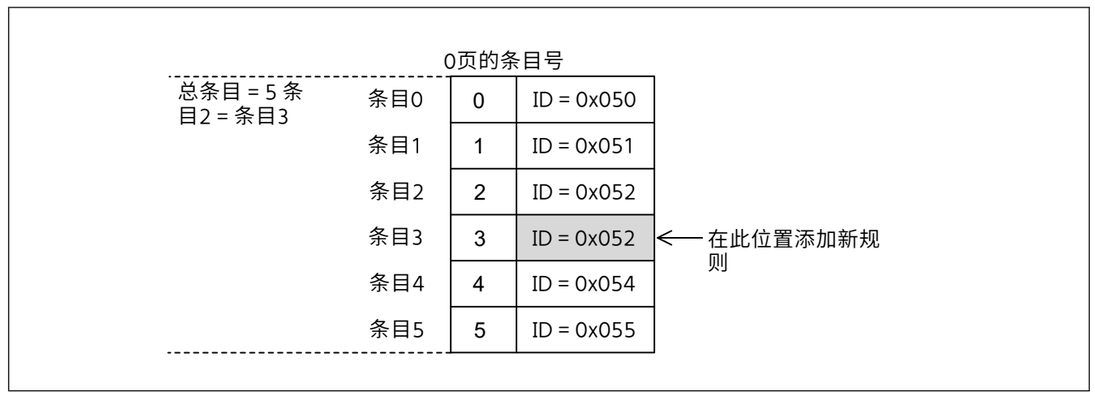
This section describes the process for configuring the number of RX message buffers, the FIFO buffers, and the flat TX message buffers in the CANFD module. The message buffers are mapped as shown in Figure 26.29.

The RX message buffers can be accessed with the RX Message Buffer Registers.

The RX FIFO buffers and the common FIFO buffers configured in RX mode or TX mode can only be accessed with the FIFO Access Registers.

If the common FIFO is configured in TX mode, you can only write data into the FIFO buffer using the FIFO Access registers.

If the common FIFO is configured in RX mode, you can only read data from the FIFO Access Registers.



如何添加条目

1。将 0x00000003 设置为 CFDGAFLIGNENT 寄存器。

2锛姣涓涓。将 0x0000C401 设置为 CFDGAFLIGNCTR 寄存器。

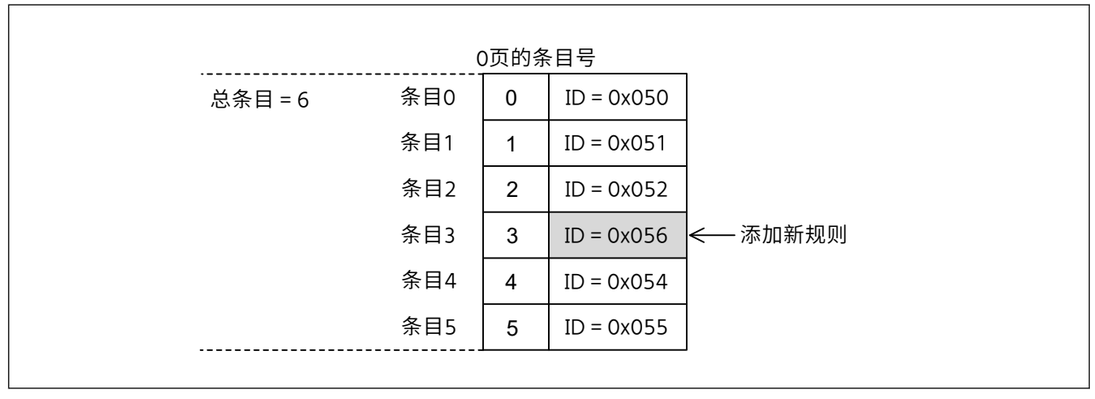
3锛　　娴　　。将 0x00000100 设置为 CFDGAFLECTR 寄存器。

4锛姣涓。通过访问 CFDGAFLIDr、CFDGAFLMr、CFDGAFLP0r、CFDGAFLP1r（r = 3,这是条目 3)来设置新规则。

5锛姣涓。将 0x00000000 设置为 CFDGAFLECTR 寄存器。

6锛　　涓€涓。将 0x0000C400 设置为 CFDGAFLIGNCTR 寄存器。

现在添加新条目。



AFL 滤波器可用于设置 CFDGAFLCFG,并且可以添加/删除条目。因此,有必要设置用于CFDGAFLCFG的最大数量。

26。6 FIFO 缓冲区和正常消息缓冲区配置

本节描述在CANFD模块中配置RX消息缓冲区、FIFO缓冲区和平坦TX消息缓冲区数量的过程。消息缓冲区映射如图 26。29 . 所示

RX 消息缓冲区可以使用 RX 消息缓冲区寄存器访问。

RX FIFO 缓冲区和配置为 RX 模式或 TX 模式的常见 FIFO 缓冲区只能通过 FIFO 访问寄存器访问。

TX 模式配置了通用 FIFO,则只能使用 FIFO 访问寄存器将数据写入 FIFO 缓冲区。

RX 模式下配置了通用 FIFO,则只能从 FIFO 访问寄存器读取数据。

The TX message buffers can be accessed with the TX Message Buffer Registers.

If unused message buffer locations are read, the message buffer locations are read as unknown values.

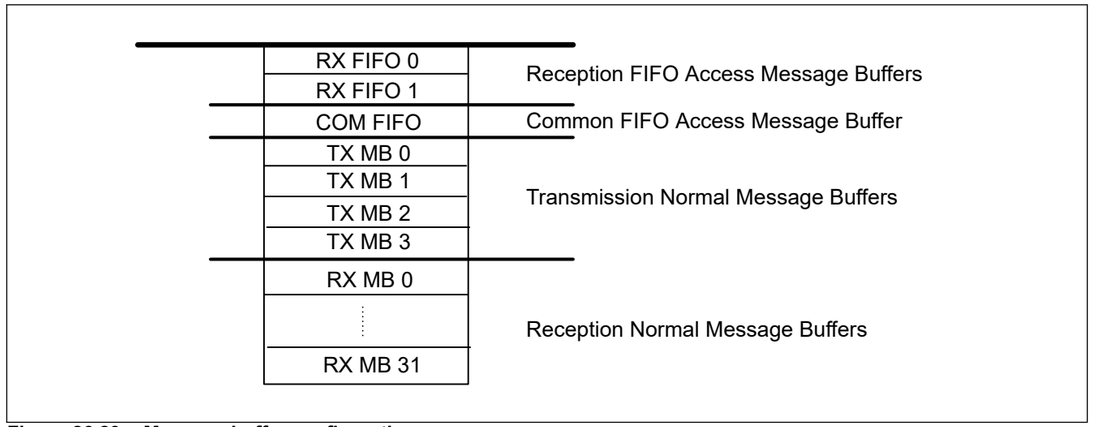


Figure 26.29 Message buffer configuration

26.6.1 Normal RX Message Buffers

In CANFD module, the frames received can be stored in normal RX message buffers based on the configuration of the AFL entries.

Additionally, the number of normal RX message buffers required in the system can be chosen up to a fixed maximum limit.

26.6.1.1 Normal RX Message Buffer Configuration

In CANFD module, the number of normal RX message buffers can be configured by writing to the RX Message Buffer Number Register.

The limiting values for the configuration of number of message buffers are:

- Minimum value = 0x00 (no normal RX MB)
- Maximum value = 0x20

Do not use values outside these limits.

The AFL entries for routing the received messages to normal RX message buffers must be configured to match the requirements of the system.

The AFL entries must also be configured properly, and an AFL entry for normal RX message buffers should not exceed the number of message buffers configured in the RX Message Buffer Number Register.

Note: There is no internal check procedure provided in CANFD module against wrong configuration of the AFL.

The data field size of the RX message buffer can be configured with the CFDRMNB.RMPLS bit. The default size is 8 bytes and the maximum data payload size is 64 bytes.

When the receiving frame exceeds the data field size, then the acceptance depends on the configuration of CFDGCFG.CMPOC (message rejecting or data payload cut).

Note: RMPLS and CMPOC bit is not available in the classical CAN function, so, these feature is not valid for classical CAN.

26.6.2 FIFO Buffers

The CANFD module provides a fixed number of FIFO buffers to support storage of frames for reception and transmission functions .

TX 消息缓冲区可以使用 TX 消息缓冲区寄存器访问。

如果读取未使用的消息缓冲区位置,则消息缓冲区位置被读取为未知值。

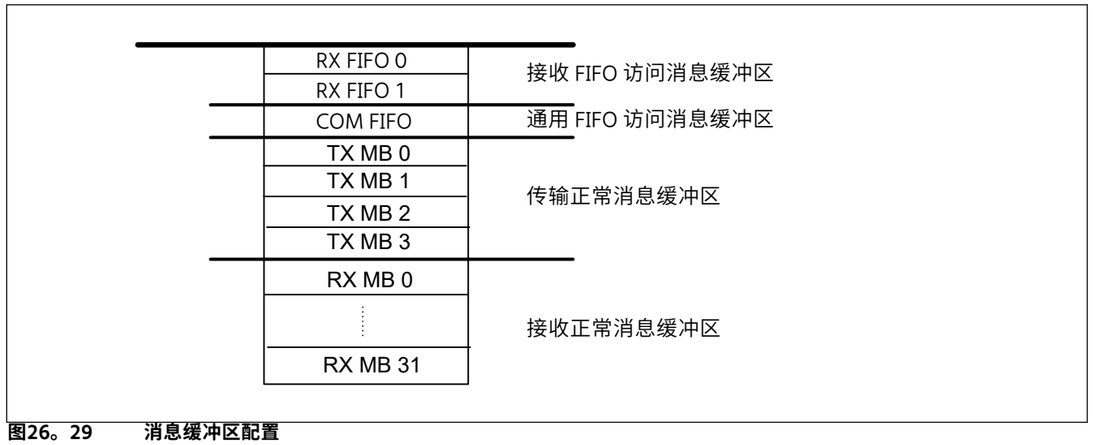

图26。29 消息缓冲区配置

26.6.1 正常 RX 消息缓冲区

在CANFD模块中,接收到的帧可以基于AFL条目的配置存储在普通RX消息缓冲区中。

此外,可以选择系统中所需的正常 RX 消息缓冲区的数量,最多可达固定的最大限制。

26.6.1.1 正常 RX 消息缓冲区配置

在CANFD模块中,可以通过写入RX消息缓冲区号寄存器来配置正常RX消息缓冲区的数量。

消息缓冲区数量的配置的限制值为:

- 最小值 = 0x00（无正常 RX MB）
- 最大值 = 0x20 不要使用这些限制之外的值。

用于将接收到的消息路由到普通 RX 消息缓冲区的 AFL 条目必须配置为匹配系统的要求。

AFL 条目也必须配置正确,普通 RX 消息缓冲区的 AFL 条目不应超过 RX 消息缓冲区号寄存器中配置的消息缓冲区数量。

注意:CANFD 模块中没有针对 AFL 错误配置提供内部检查程序。

RX消息缓冲区的数据字段大小可以用CFDRMNB。RMPLS位来配置。默认大小为 8 字节,最大数据有效负载大小为 64 字节。

当接收帧超过数据字段大小时,接受取决于CFDGCFG。CMPOC的配置（消息拒绝或数据有效负载削减）。

注意:RMPLS 和 CMPOC 位在经典 CAN 函数中不可用,因此,这些功能对于经典 CAN 不有效。

26.6.2 FIFO 缓冲区

CANFD 模块提供固定数量的 FIFO 缓冲器,支持存储用于接收和传输功能的帧。

The number of reception-only FIFO buffers is fixed to 2. However, common FIFO buffer channel can be configured to store messages for transmission or reception function.

These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- Size
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the TX FIFO.

When the receiving frame exceeds the data field size, the acceptance depends on the configuration of the CFDGCFG.CMPOC bit (message rejecting or data payload cut).

26.6.2.1 FIFO Buffers Configuration

In CANFD module, the FIFO buffers can be configured to match the system requirements.

The total number of FIFO buffers = 2 RX FIFO buffers + 1 common FIFO buffer = 3 FIFO buffers.

仅接收 FIFO 缓冲区的数量固定为 2 个。然而,公共FIFO缓冲信道可以被配置为存储用于传输或接收功能的消息。

FIFO 缓冲区可以启用或禁用这些缓冲区, 并且可以配置以下参数以匹配系统要求:

- 大
- 中断结构
- 消息丢失机制
- FIFO 缓冲区的消息覆盖机制
- TX FIFO 的位置。

当接收帧超过数据字段大小时,接受取决于CFDGCFG。CMPOC位的配置（消息拒绝或数据有效负载削减）。

26.6.2.1 FIFO 缓冲区配置

CANFD模块中,FIFO缓冲区可以配置为匹配系统要求。

FIFO 缓冲区总数 = 2 个 RX FIFO 缓冲区 + 1 个常见 FIFO 缓冲区 = 3 个 FIFO 缓冲区。

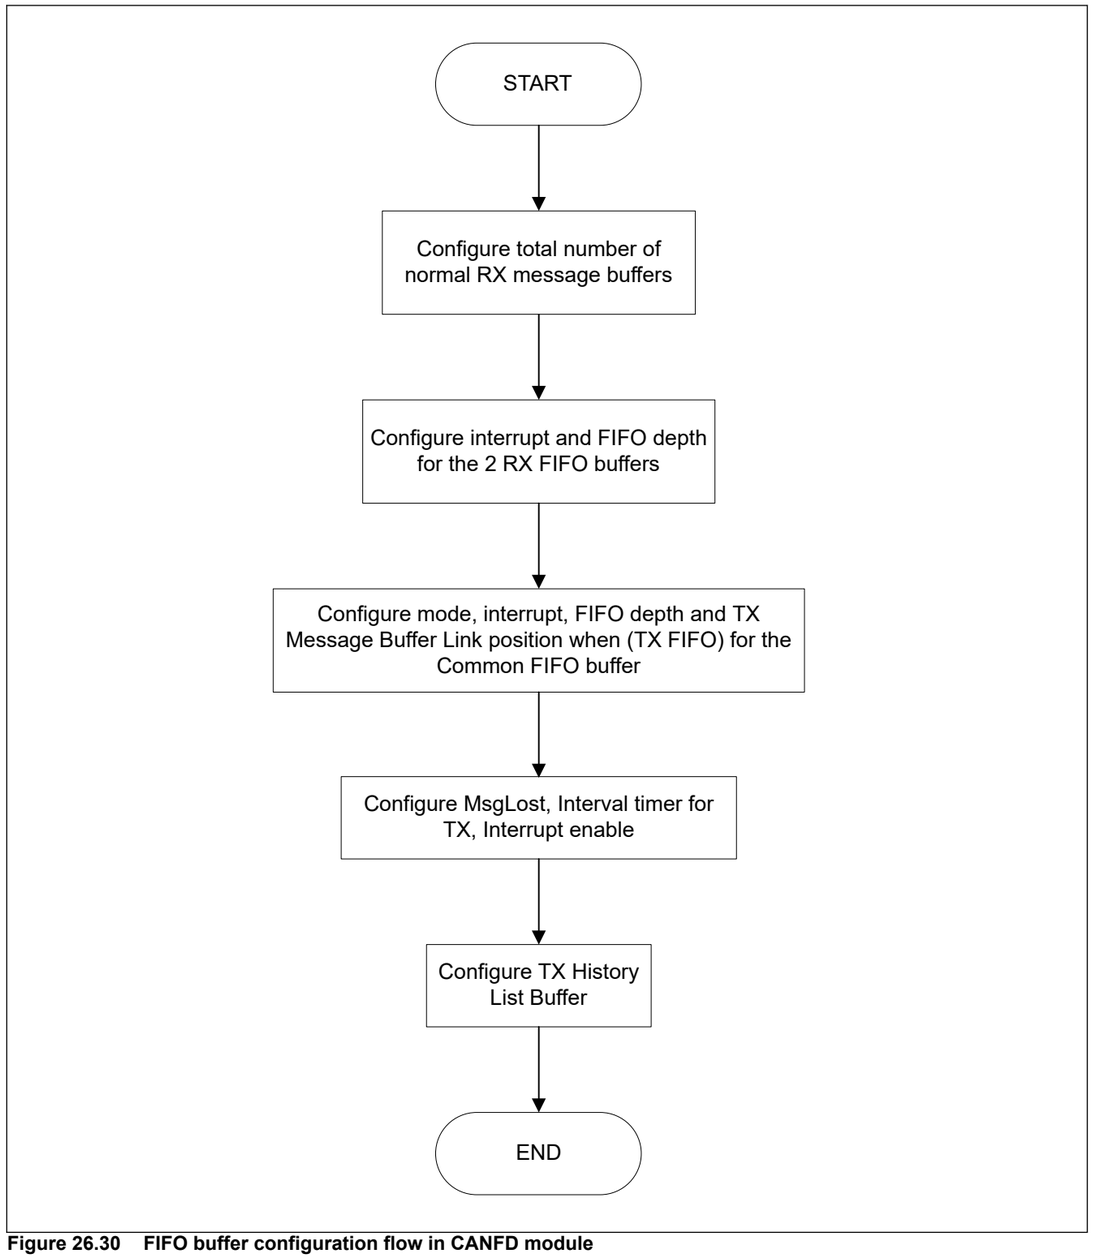

Figure 26.30 FIFO buffer configuration flow in CANFD module

As shown in Figure 26.30, the various FIFO buffers can be configured by writing to the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

For the 2 RX FIFO buffers, the following parameters can be configured:

- Interrupts
- FIFO depth
- FIFO payload data size.

For the common FIFO buffer, the following parameters can be configured:

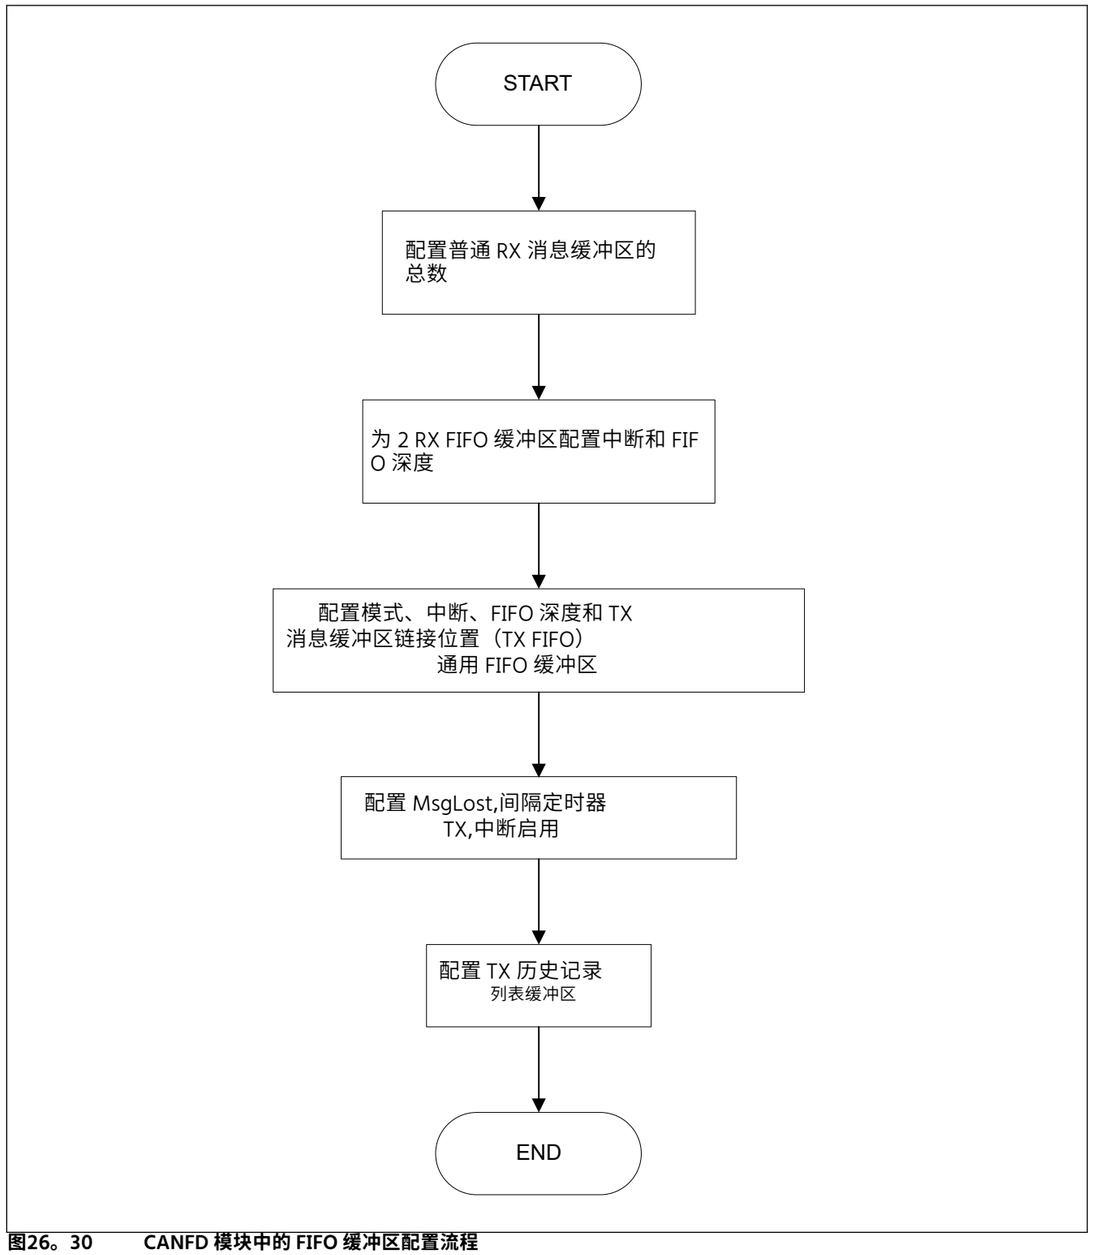

图26。30 CANFD 模块中的 FIFO 缓冲区配置流程

如图26。30所示,可以通过写入RX FIFO配置/控制来配置各种FIFO缓冲区寄存器和通用 FIFO 配置/控制寄存器。

2 个 RX FIFO 缓冲区, 可以配置以下参数:

- 中断
- FIFO 深度
- FIFO 有效负载数据大小。

FIFO 常见缓冲区, 可以配置以下参数:

- Mode
- Interrupts FIFO depth
- FIFO payload data size
- FIFO TX link position.

(1) FIFO mode configuration of Common FIFO buffer

The mode of the common FIFO buffer can be configured by writing to the CFDCFCC.CFM[1:0] bits in the Common FIFO Configuration/Control Register. The possible modes of configuration for Common FIFO buffer are:

- 0b RX mode (default mode after hardware reset)
- 1b TX mode

Messages can only be read from the RX FIFO buffers and the Common FIFO buffer configured in RX mode. Messages are stored by the CAN module in these FIFO buffers based on the AFL entries.

Messages can be read and written into the Common FIFO buffer configured in TX mode. These messages are transmitted on the appropriate CAN channel.

The pointers can only be incremented when a new message is stored in the FIFO buffer and decremented when a message is transmitted on the corresponding CAN channel by the CANFD module.

After a hardware reset, the Common FIFO buffer is configured in RX mode by default. Only enable the FIFO buffers after configuring the Common FIFO buffer in the required modes.

(2) FIFO TX message buffer link configuration

When the common FIFO is configured as TX FIFO, the FIFO buffer must be linked to a normal TX message buffer to participate in the transmission scan.

Do not write data into a TX message buffer that is linked to a Common FIFO buffer. Also, the TX message buffer linked to a Common FIFO buffer should not be a part of the TX Queue.

The TX message buffer link of each Common FIFO buffer can be configured by writing to the CFDCFCC.CFTML[1:0] bits in the Common FIFO Configuration/Control Registers. Available options for TX message buffer link configuration are:

- 0x00: TX Message Buffer 0
- 0x01: TX Message Buffer 1
- 0x10: TX Message Buffer 2
- 0x11: TX Message Buffer 3

(3) FIFO depth configuration

The depth of each FIFO buffer can be configured by writing to the CFDRFCCa.RFDC[2:0] bits and CFDCFCC.CFDC[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The 6 available options for depth configuration are:

- 0x000: 0 Message (FIFO buffer cannot be enabled)
- 0x001: 4 Messages
- 0x010: 8 Messages
- 0x011: 16 Messages
- 0x100: 32 Messages
- 0x101: 48 Messages

The RAM allocation for RX message buffers along with FIFO buffers is limited to 16 messages with 64 data bytes. Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CANFD module logic does not check the validity of the configuration.

Note: If the FIFO depth of a common FIFO is 4 messages or more (CFDCFCC.CFDC[2:0] > 000b), then the Common FIFO TX message buffer link is valid when the FIFO is disabled or enabled.

- 模式
- 中断 FIFO 深度
- FIFO 有效负载数据大
- FIFO TX 链接位置。

(1) 常见 FIFO 缓冲区的 FIFO 模式配置

公共 FIFO 缓冲区的模式可以通过写入公共 FIFO 配置/控制寄存器中的 CFDCFCC。CFM[1:0] 位来配置。Common FIFO 缓冲区的可能配置模式是:

- 0b RX 模式（硬件重置后的默认模式）
- 1b TX 模式

消息只能从 RX FIFO 缓冲区和配置为 RX 模式的通用 FIFO 缓冲区读取。消息由 CAN 模块基于 AFL 条目存储在这些 FIFO 缓冲区中。

消息可以读取并写入以 TX 模式配置的 Common FIFO 缓冲区。这些消息在适当的 CAN 通道上传输。

仅当新消息存储在FIFO缓冲区中时,指针才能递增;当消息由CANFD模块在相应的CAN信道上发送时,指针才能递减。

硬件重置后,默认情况下将 Common FIFO 缓冲区配置为 RX 模式。仅在以所需模式配置 Common FIFO 缓冲区后启用 FIFO 缓冲区。

(2)FIFO TX消息缓冲链接配置

当公共FIFO配置为TX FIFO时,FIFO缓冲区必须链接到普通TX消息缓冲区才能参与传输扫描。

请勿将数据写入链接到 Common FIFO 缓冲区的 TX 消息缓冲区。此外,链接到 Common FIFO 缓冲区的 TX 消息缓冲区不应是 TX 队列的一部分。

每个通用 FIFO 缓冲区的 TX 消息缓冲区链接可以通过写入通用 FIFO 配置/控制寄存器中的 CFDCFCC。CFTML[1:0] 位来配置。TX 消息缓冲区链接配置的可用选项有:

- 0x00:TX 消息缓冲区 0
- 0x01:TX 消息缓冲区 1
- 0x10:TX 消息缓冲区 2
- 0x11:TX 消息缓冲区 3

(3)FIFO深度配置

每个 FIFO 缓冲区的深度可以通过写入 RX FIFO 配置/控制寄存器和通用 FIFO 配置/控制寄存器中的 CFDRFCCa。RFDC[2:0] 位和 CFDCFCC。CFDC[2:0] 位来配置。6 种深度配置可用选项是:

- 0x000: 0 消息（无法启用 FIFO 缓冲区）
- 0x001:4 条消息
- 0x010:8 条消息
- 0x011:16 条消息
- 0x100:32 条消息
- 0x101:48 条消息

RX 消息缓冲区以及 FIFO 缓冲区的 RAM 分配仅限于 16 条消息和 64 个数据字节。
不应配置超过此最大限制的 RX 消息缓冲区以及 FIFO 缓冲区。

CANFD模块逻辑不检查配置的有效性。

注: 如果公共 FIFO 的 FIFO 深度为 4 条或更多消息（CFDCFCC。CFDC[2:0] > 000b）,则当 FIFO 被禁用或启用时,公共 FIFO TX 消息缓冲区链接有效。

If FIFO depth is 0 messages, then the Common FIFO TX message buffer link is not valid when the FIFO is disabled or enabled.

(4) FIFO payload size configuration

The data size of each FIFO buffer can be configured by writing to the CFDRFCCa.RFPLS[2:0] bits and CFDCFCC.CFPLS[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The eight available options for depth configuration are:

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes

The RAM allocation for RX message buffers along with FIFO buffers is limited to 16 messages with 64 data bytes. Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CANFD module logic does not check the validity of the configuration.

Note: This feature is not available in the classical CAN function.

(5) FIFO interrupt configuration

The Interrupt generation conditions for the FIFO buffers can be configured by writing to the CFDRFCCa.RFIM and CFDCFCC.CFIM bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The two available options are:

- 0:
  - RX FIFO mode: Interrupt generated when the Common FIFO counter reaches CFDRFCCa.RFIGCV/ CFDCFCC.CFIGCV value
  - TX FIFO mode: Interrupt generated when the Common FIFO transmits the last message successfully
- 1:
  - RX FIFO mode: Interrupt generated at the end of storage of every received message
  - TX FIFO mode: Interrupt generated for every successfully transmitted message

If the Interrupt Mode bit is 0 for a RX FIFO, then interrupt is generated based on the configuration of the CFDRFCCa.RFIGCV[2:0] bits.

Similarly, if the Interrupt Mode bit is 0 for a Common FIFO configured in RX mode, then interrupt is generated based on the configuration of CFDCFCC.CFIGCV[2:0] bits.

The eight available options for configuring the FIFO counter value for generation of an interrupt are:

- 000b: Interrupt generated when FIFO is 1/8th Full
- 001b: Interrupt generated when FIFO is 1/4th Full
- 010b: Interrupt generated when FIFO is 3/8th Full
- 011b: Interrupt generated when FIFO is 1/2 Full
- 100b: Interrupt generated when FIFO is 5/8th Full
- 101b: Interrupt generated when FIFO is 3/4th Full
- 110b: Interrupt generated when FIFO is 7/8th Full
- 111b: Interrupt generated when FIFO is Full.

如果 FIFO 深度为 0 条消息,则当 FIFO 被禁用或启用时,公共 FIFO TX 消息缓冲区链接无效。

(4) FIFO 有效载荷大小配置

每个 FIFO 缓冲区的数据大小可以通过写入 RX FIFO 配置/控制寄存器和通用 FIFO 配置/控制寄存器中的 CFDRFCCa。RFPLS[2:0] 位和 CFDCFCC。CFPLS[2:0] 位来配置。8个深度配置的可用选项是:

- 000b:8 字节
- 001b:12 字节
- 010b:16 字节
- 011b:20 字
- 100b:24 字节
- 101b:32 字节
- 110b:48 字
- 111b:64 字节

RX 消息缓冲区以及 FIFO 缓冲区的 RAM 分配仅限于 16 条消息和 64 个数据字节。
不应配置超过此最大限制的 RX 消息缓冲区以及 FIFO 缓冲区。

CANFD模块逻辑不检查配置的有效性。

注意:此功能在经典 CAN 函数中不可用。

(5)FIFO中断配置

FIFO缓冲区的中断生成条件可以通过写入RX FIFO配置/控制寄存器和通用FIFO配置/控制寄存器中的CFDRFCCa。RFIM和CFDCFCC。CFIM位来配置。2个可用的选项是:

- 0:
  - RX FIFO 模式:当通用 FIFO 计数器达到 CFDRFCCa。RFIGCV/CFDCFCC。CFIGCV 值时生成中断
  - TX FIFO 模式:当 Common FIFO 成功发送最后一条消息时生成的中断
- 1:
  - RX FIFO 模式:每个接收到的消息存储结束时生成的中断

- TX FIFO 模式:为每条成功传输的消息生成中断 如果 RX FIFO 的中断模式位为 0,则根据 CFDRFCCa。RFIGCV[2:0] 位的配置生成中断。

类似地,如果在RX模式下配置的Common FIFO的中断模式比特为0,则基于CFDCFCC。CFIGCV[2:0]比特的配置生成中断。

用于配置用于生成中断的 FIFO 计数器值的八个可用选项是:

- 000b:FIFO 为 1/8 时生成的中断满
- 001b:FIFO 为 1/4 时生成的中断 Full
- 010b:FIFO 为 3/8 时生成的中断满
- 011b:FIFO 为 1/2 Full 时生成的中断
- 100b:FIFO 为 5/8 时生成的中断满
- 101b:FIFO 为 3/4 时生成的中断 Full
- 110b:当 FIFO 为 7/8 时生成中断 Full
- 111b:FIFO 满时生成的中断。

In this case, an interrupt is generated when the message count matches the configured value.

However, there are some limitations on the configuration of the CFDRFCCa.RFIGCV[2:0] and CFDCFCC.CFIGCV[2:0] bits depending on the FDC[2:0] bits (FIFO Depth Configuration), see Table 26.24.

26.6.2.2 FIFO Buffers Control

The FIFO interrupt must be enabled by setting any one of the following bits in the RX FIFO Configuration/Control Registers:

- CFDRFCCa.RFIE

In addition, the FIFO interrupt must be enabled by setting any one of the following bits in the Common FIFO Configuration/Control Register:

- CFDCFCC.CFRXIE
- CFDCFCC.CFTXIE

After configuration is complete, each FIFO can be enabled by setting the CFDRFCCa.RFE and CFDCFCC.CFE bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Register to allow transmission and reception of messages.

26.7 Interrupts and DMA

26.7.1 Interrupts

The CANFD module generates several interrupts. The interrupt output, which is connected to the Interrupt Controller Unit (ICU), can be controlled by the corresponding interrupt enable bit.

The status flag is set independent from this enable bit.

The channel transmission interrupt has an additional status flag register. The status bits are set when the corresponding interrupt enables are set.

The status flag register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.

The interrupts in the CANFD module can be classified into two groups, global interrupts and channel interrupts:

- Global interrupts:
  The CANFD module can generate 3 global interrupts:
  - Global interrupt for successful reception into the 2 RX FIFO buffers
  - Global error interrupt.
  - Global Interrupt for successful reception into the 32 RX message buffers
- Channel interrupts:
  Channel of the CANFD module can generate 3 channel interrupts:

在这种情况下,当消息计数与配置的值匹配时生成中断。

然而,根据FDC[2:0]位（FIFO深度配置）,CFDRFCCa。RFIGCV[2:0]和CFDCFCC。CFIGCV[2:0]位的配置存在一些限制,参见表26。24 .

26。6。2。2 FIFO 缓冲器控制

RX FIFO 配置/控制寄存器中设置以下任意一位, 必须启用 FIFO 中断:

- CFDRFCCa。RFIE

此外,必须通过在通用 FIFO 配置/控制寄存器中设置以下任意一位来启用 FIFO 中断:

- CFDCFCC。CFRXIE
- CFDCFCC。CFTXIE

配置完成后,可以通过在RX FIFO配置/控制寄存器和通用FIFO配置/控制寄存器中设置CFDRFCCa。RFE和CFDCFCC。CFE位来启用每个FIFO,以允许消息的传输和接收。

26。7 中断和 DMA

26。7。1 中断

CANFD 模块会产生几个中断。连接到中断控制器单元（ICU）的中断输出可以通过相应的中断使能位来控制。状态标志的设置独立于此启用位。

信道传输中断具有附加的状态标志寄存器。当设置相应的中断启用时,设置状态位。

状态标志寄存器支持识别信道传输的中断源,因为该中断由多个触发源驱动。

CANFD模块中的中断可以分为两组, 全局中断和信道中断:

- 全局中断:
  CANFD模块可以生成3个全局中断:
  - 全局中断以成功接收到 2 RX FIFO 缓冲区
  - 全局错误中断。
  - 全局中断以成功接收到 32 RX 消息缓冲区
- 通道中断:
  CANFD模块的通道可以产生3个通道中断:

1. Channel transmission
   - Transmission completion from channel
   - Transmission abort from channel
   - Transmission from TX Queue for a channel
   - Channel THL interrupt
   - Successful transmission from a Common FIFO in TX mode for a channel.
2. Channel error interrupt
3. Successful reception in a Common FIFO in RX mode for a channel.

The interrupts are cleared when the corresponding flag bits are cleared or the Interrupt enable bits are cleared.

Table 26.25 gives an overview of interrupt sources for the different interrupt outputs. The interrupt outputs are active-high.

DMA FIFO pointer decrement is done automatically by reading the last configured data payload byte (CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

Note: The DMA must read the exact length of the configured data payload size (CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

Note: This feature is not available for classical CAN function because CFDRFCCa.RFPLS and CFDCFCC.CFPLS are not in classical CAN.

Do not write to the FIFO control registers when DMA is enabled. The DMA enable of the particular DMA FIFO (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE) can be set at any time. Figure 26.34 shows a configuration flow for an initial setup.

DMA FIFO 指针递减是通过读取最后配置的数据有效负载字节（CFDRFCCa。RFPLS 或 CFDCFCC。CFPLS）自动完成的。

注: DMA 必须读取配置的数据有效负载大小的确切长度（CFDRFCCa。RFPLS 或 CFDCFCC。CFPLS）。

注: 此功能不适用于经典 CAN 函数,因为 CFDRFCCa。RFPLS 和 CFDCFCC。CFPLS 不属于经典 CAN。

启用 DMA 时,请勿写入 FIFO 控制寄存器。可以随时设置特定DMA FIFO（CFDCDTCT。RFDMAE或CFDCDTCT。CF DMAE）的DMA使能。图 26。34 显示了初始设置的配置流程。

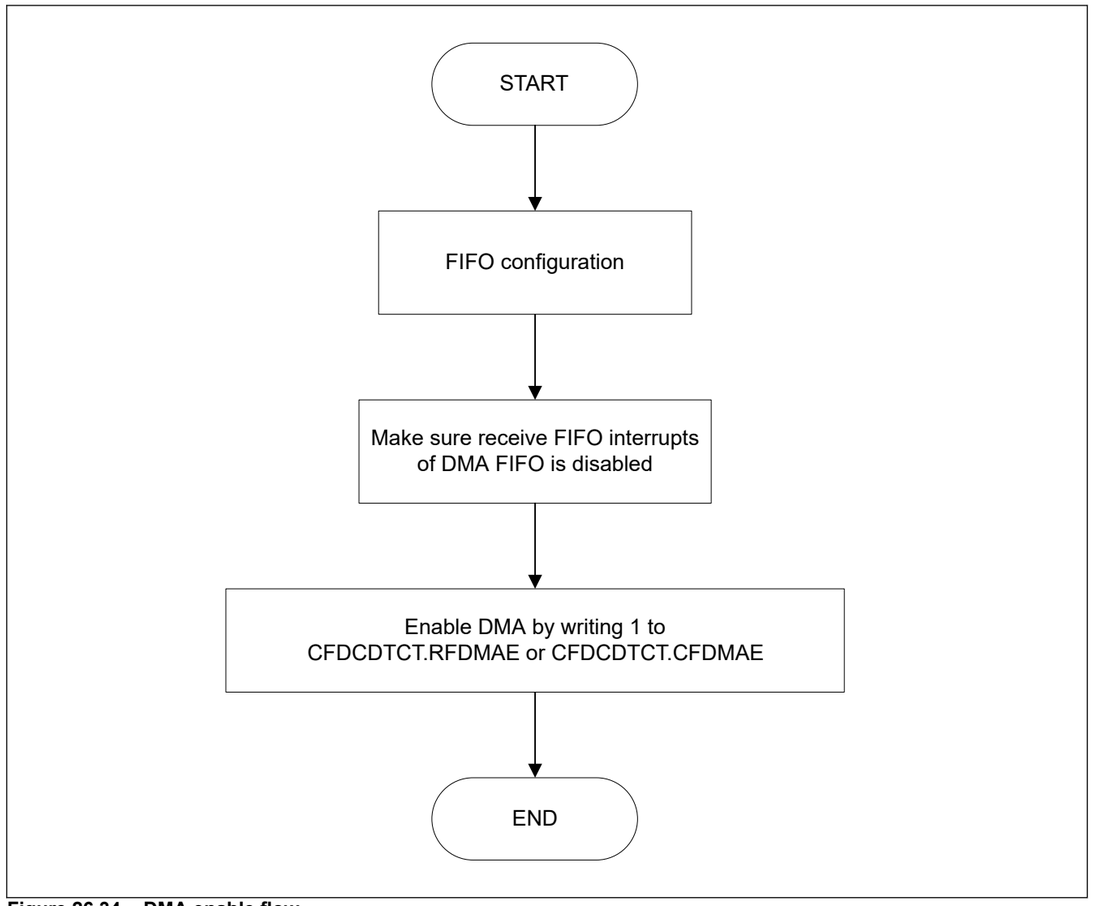

Figure 26.34 DMA enable flow

To disable a DMA transfer request, you must disable the particular DMA enable bit (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE). If the disable is made during an ongoing transfer, then the transfer must be completed first before further action can be taken. The transfer status can be identified by the CFDCDTSTS.RFDMASTS or CFDCDTSTS.CFDMASTS bit. See Figure 26.35 for the DMA disable flow. When the DMA is disabled, consideration should be made for the remaining or new incoming messages to this particular reception FIFO.

When the FIFO is not disabled, reception to the FIFO continues.

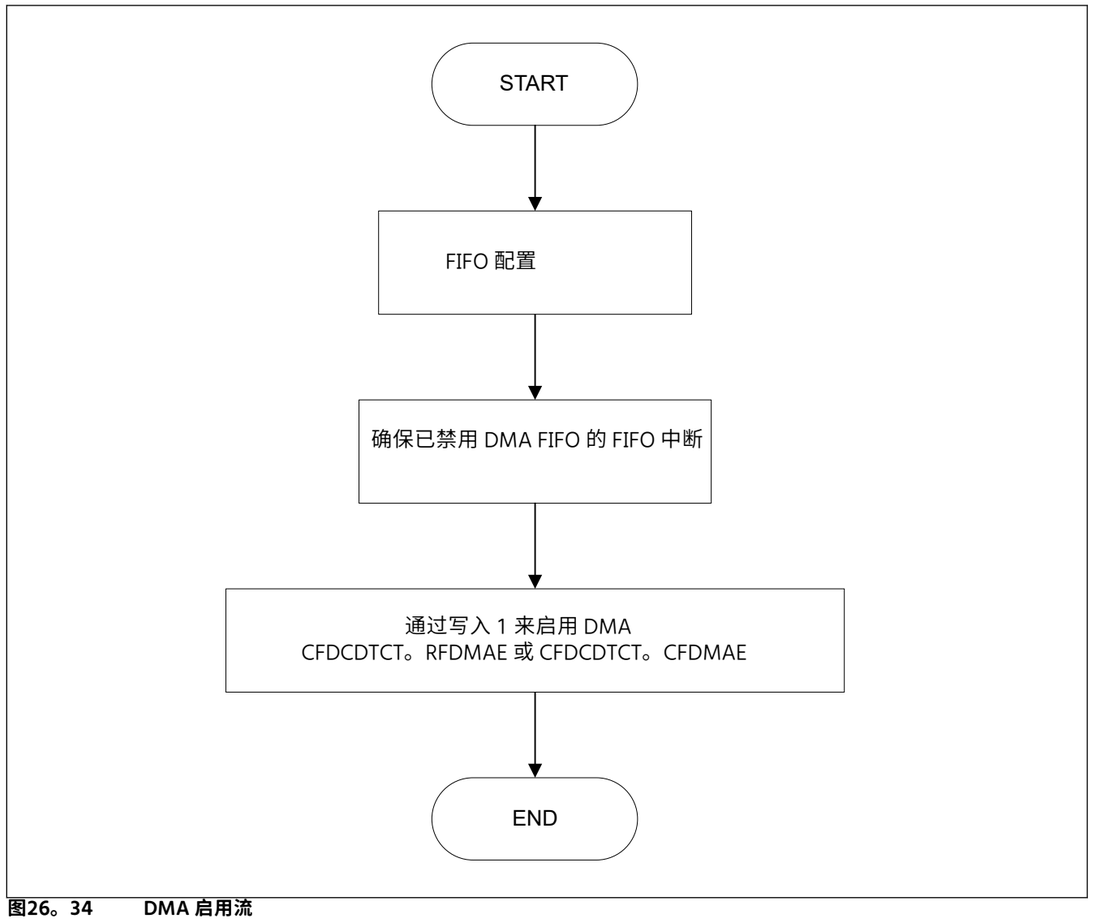

图26。34 DMA 启用流

要禁用 DMA 传输请求,您必须禁用特定的 DMA 启用位（CFDCDTCT。RFDMAE 或 CFDCDTCT。CFDMAE）。如果在正在进行的传输期间禁用,则必须首先完成传输,然后才能采取进一步行动。传输状态可以通过CFDCDTSTS。RFDMASTS或CFDCDTSTS。CFDMASTS位来识别。DMA 禁用流程见图 26。35。当禁用 DMA 时,应考虑发送到此特定接收 FIFO 的剩余或新传入消息。

当 FIFO 未被禁用时,继续接收 FIFO。

26.8 Reception and Transmission

26.8.1 Reception

In the CANFD module, CAN messages received on any of the channels are stored in RX message buffers, RX FIFO buffers, or Common FIFO buffers configured in RX mode depending on the Acceptance Filter List entries.

- Up to 32 RX message buffers can be configured
- 2 RX FIFO buffers available
- 1 Common FIFO Buffer can be configured in RX mode

26。8 接待和传输

26。8。1 接待处

在CANFD模块中,在任何信道上接收的CAN消息存储在RX消息缓冲器、RX FIFO缓冲器或根据接受过滤器列表条目配置在RX模式下的公共FIFO缓冲器中。

- 最多可配置 32 个 RX 消息缓冲区
- 可用 2 RX FIFO 缓冲区
- 1 常见 FIFO 缓冲区可以在 RX 模式下配置

26.8.1.1 Message Storage in RX Message Buffers

When a message is successfully received and stored in a RX message buffer, the corresponding New Data flag is set in the RX Message Buffer New Data Register.

The CAN message can be read from the corresponding RX message buffer.

If a new message is stored into a RX message buffer before the previous message in this message buffer can be read, then the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the RX message buffer. If such a loss of messages is not acceptable, then RX FIFO should be used for storing related messages.

Note: Users should do the same processing as the existing software flow also when using interrupt. (see Figure 26.37)

Note: Unused data bytes are filled with 0x00 depending on the DLC value.

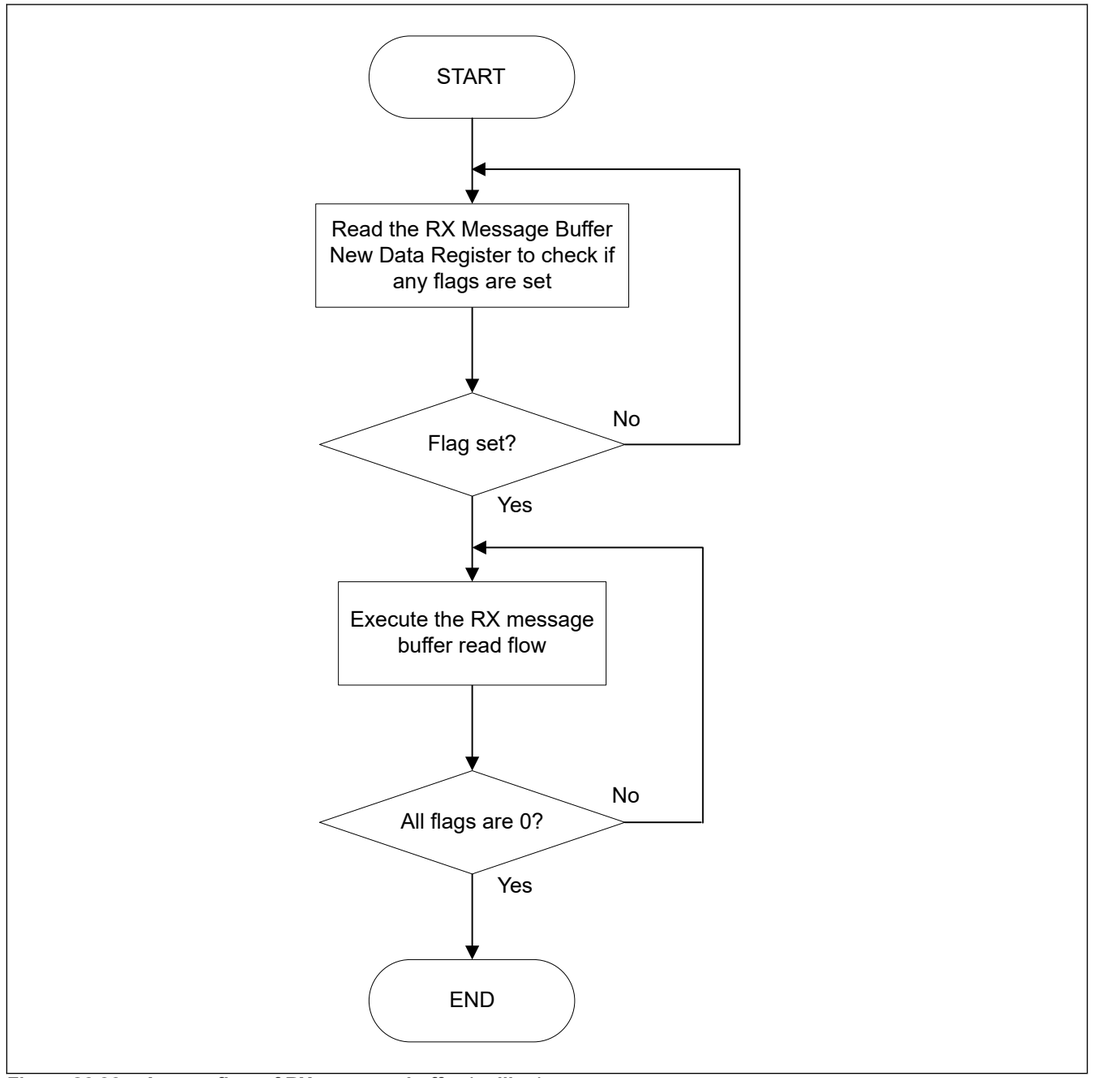

Figure 26.36 Access flow of RX message buffer (polling)

26。8。1。1 RX 消息缓冲区中的消息存储

当消息被成功接收并存储在RX消息缓冲区中时,相应的新数据标志被设置在RX消息缓冲区新数据寄存器中。

CAN消息可以从相应的RX消息缓冲区读取。

如果在该消息缓冲区中的前一条消息被读取之前,新消息被存储到 RX 消息缓冲区中,则原始消息将被覆盖。RX消息缓冲区中没有防止新消息覆盖当前消息的机制。如果这种消息丢失是不可接受的,则应使用 RX FIFO 来存储相关消息。

注意:用户在使用中断时也应进行与现有软件流相同的处理。（见图 26。37) 注意:未使用的数据字节根据 DLC 值填充 0x00。

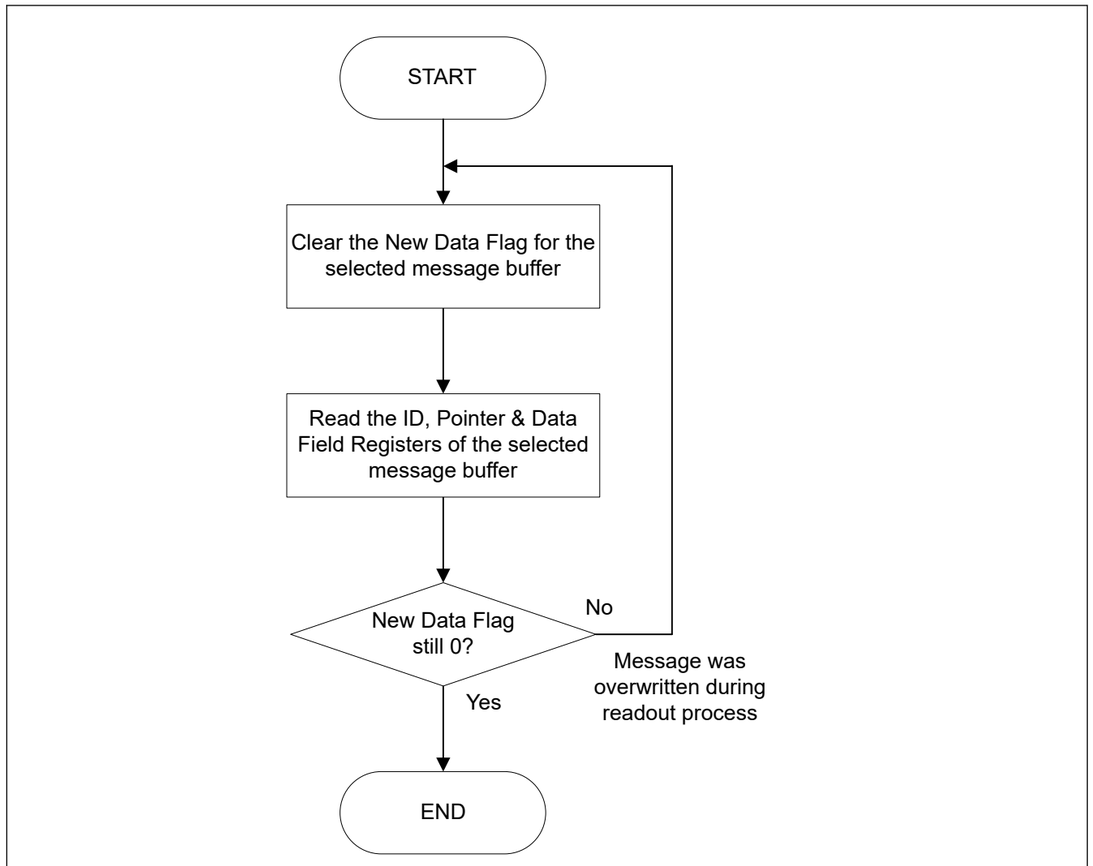

Figure 26.38 Read flow of RX message buffer

26.8.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to RX FIFO buffers or Common FIFO buffer configured in RX mode should be configured based on system requirements.

The CFDGAFLP1r.GAFLFDP[8,1:0] field in the matching AFL entry selects the FIFO buffers to which the related reception message is stored.

When the received message is stored in one or more RX FIFO buffers or Common FIFO buffer configured in RX mode, the message counter value is incremented in the corresponding RX FIFO Status Registers or Common FIFO Status Register.

Depending on the configuration of the FIFO buffers, an interrupt might also be generated.

The message can be read from the corresponding FIFO Access registers.

Note: Because many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, the FIFO Full flag is set.

When the value 0xFF is written to the corresponding FIFO Pointer Control Register, the message count is decremented by 1.

Only write 0xFF to the FIFO Pointer Control register after reading the complete message from the FIFO Access registers of the corresponding FIFO.

When all the messages stored in the FIFO are read, the FIFO Empty flag is set.

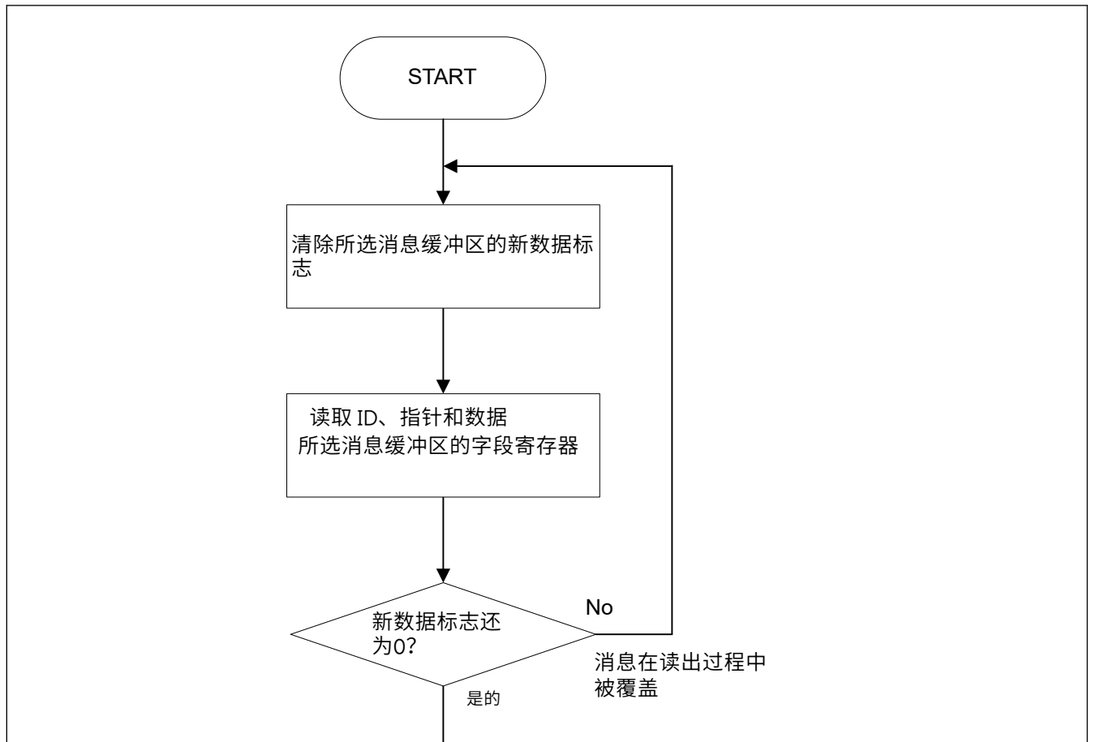

图26。38 RX消息缓冲区的读取流

26.8.1.2 FIFO 缓冲区中的消息存储

用于将接收到的消息路由到以RX模式配置的RX FIFO缓冲区或公共FIFO缓冲区的AFL条目应当根据系统要求进行配置。

匹配的AFL条目中的CFDGAFLP1r。GAFLFDP[8,1:0]字段选择存储相关接收消息的FIFO缓冲区。

当接收到的消息存储在一个或多个以RX模式配置的RX FIFO缓冲器或Common FIFO缓冲器中时,消息计数器值在相应的RX FIFO状态寄存器或Common FIFO状态寄存器中递增。

根据 FIFO 缓冲区的配置,也可能生成中断。

该消息可以从相应的 FIFO Access 寄存器读取。

注意:由于 FIFO 缓冲区中可以存储许多消息,因此读取 FIFO 缓冲区中存储的最新消息可能需要读取多个消息。

如果消息计数值与 FIFO 深度匹配,则设置 FIFO 完整标志。

0xFF的值写入到相应的FIFO指针控制寄存器时,消息计数递减1。只需读取相应 FIFO 的 FIFO Access 寄存器的完整消息后,将 0xFF 写入 FIFO 指针控制寄存器。

当读取 FIFO 中存储的所有消息时,设置 FIFO 空标志。

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

An appropriate value can be configured as warning level to generate an interrupt before the FIFO full condition occurs to avoid loss of a message due to an overrun condition.

Note: The message lost can be set only in RX mode by CAN, and the flag is not set when the CPU is overloading the FIFO buffers.

The RX FIFO buffers and the Common FIFO buffers configured in RX mode can be disabled at any time by clearing the CFDRFCCa.RFE or CFDCFCC.CFE bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

When the CFDRFCCa.RFE or CFDCFCC.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further messages can be stored into the FIFO.

When the RX FIFO buffers or Common FIFO buffer configured in RX mode is assigned as a DMA channel, software should not access the FIFO Access Register of this FIFO buffer or write 0xFF to the FIFO Pointer Control Register (CFDCFPCTR.CFPC or CFDRFPCTRa.RFPC). This can lead to unintended FIFO message decrement. The DMA channel controls the FIFO decrement automatically.

Note: If the interrupt flag is set for a FIFO buffer and then the FIFO is disabled, the interrupt flag is not cleared automatically. The interrupt flag should be cleared before disabling the FIFO.

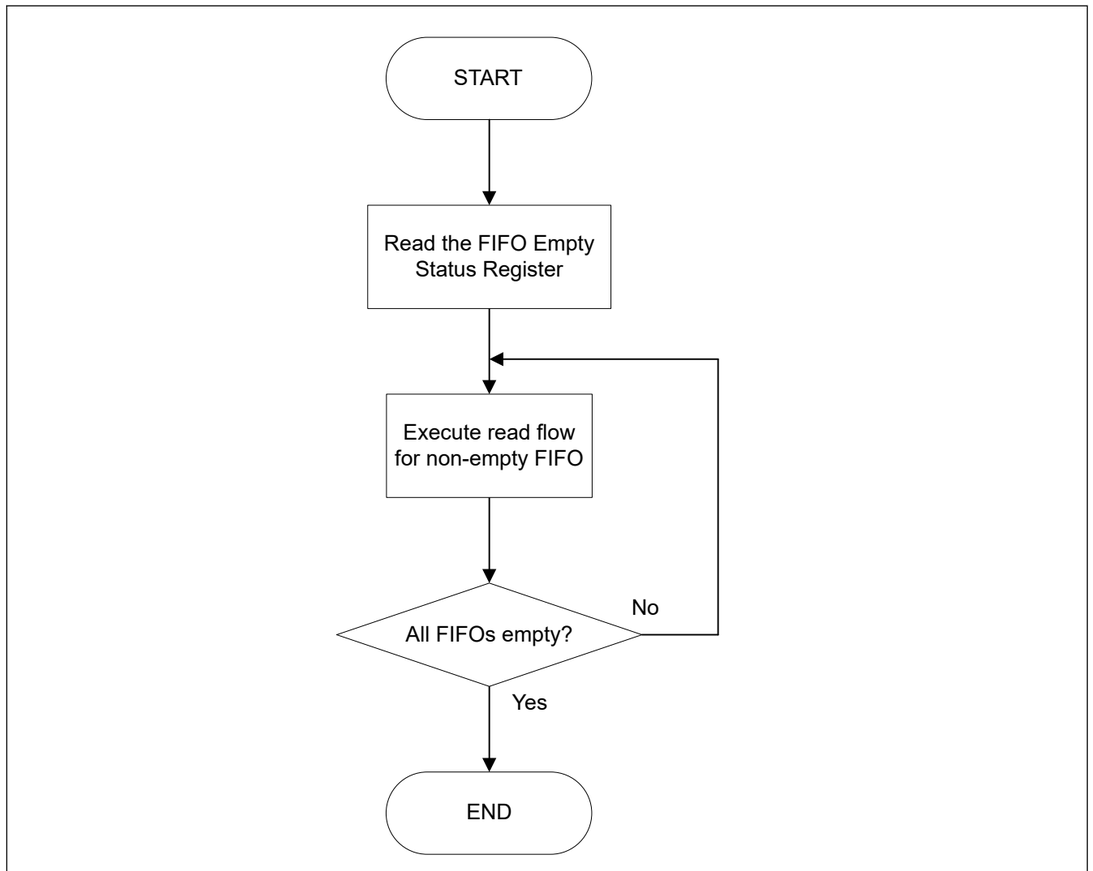

Figure 26.39 Access flow of FIFO buffer message (example for polling case)

如果当 FIFO 消息计数与 FIFO 深度匹配时,新消息被存储到 FIFO 中（FIFO 完整条件）,则设置 FIFO 消息丢失标志并丢失新消息（不会覆盖已存储的消息）。

可以将适当的值配置为警告级别,以在 FIFO 完全条件发生之前生成中断,以避免由于超限条件而丢失消息。

注意:丢失的消息只能由 CAN 在 RX 模式下设置,并且当 CPU 超载 FIFO 缓冲区时不会设置标志。

通过清除RX FIFO配置/控制寄存器和通用FIFO配置/控制寄存器中的CFDRFCCa。RFE或CFDCFCC。CFE位,可以随时禁用以RX模式配置的RX FIFO缓冲器和通用FIFO缓冲器。

当CFDRFCCa。RFE或CFDCFCC。CFE位被清除时,FIFO的消息读写指针被清除并且不再活动。因此,FIFO缓冲区中的所有消息都丢失,并且不能将进一步的消息存储到FIFO中。

当RX模式配置的RX FIFO缓冲区或通用FIFO缓冲区被分配为DMA信道时,软件不应访问该FIFO缓冲区的FIFO访问寄存器或向FIFO指针控制寄存器（CFDCFPCTR。CFPC或CFDRFPCTRa。RFPC）写入0xFF。这可能会导致意外的 FIFO 消息减少。DMA 通道自动控制 FIFO 递减。

注意:如果中断标志设置为 FIFO 缓冲区,然后禁用 FIFO,则中断标志不会自动清除。在禁用 FIFO 之前,应清除中断标志。

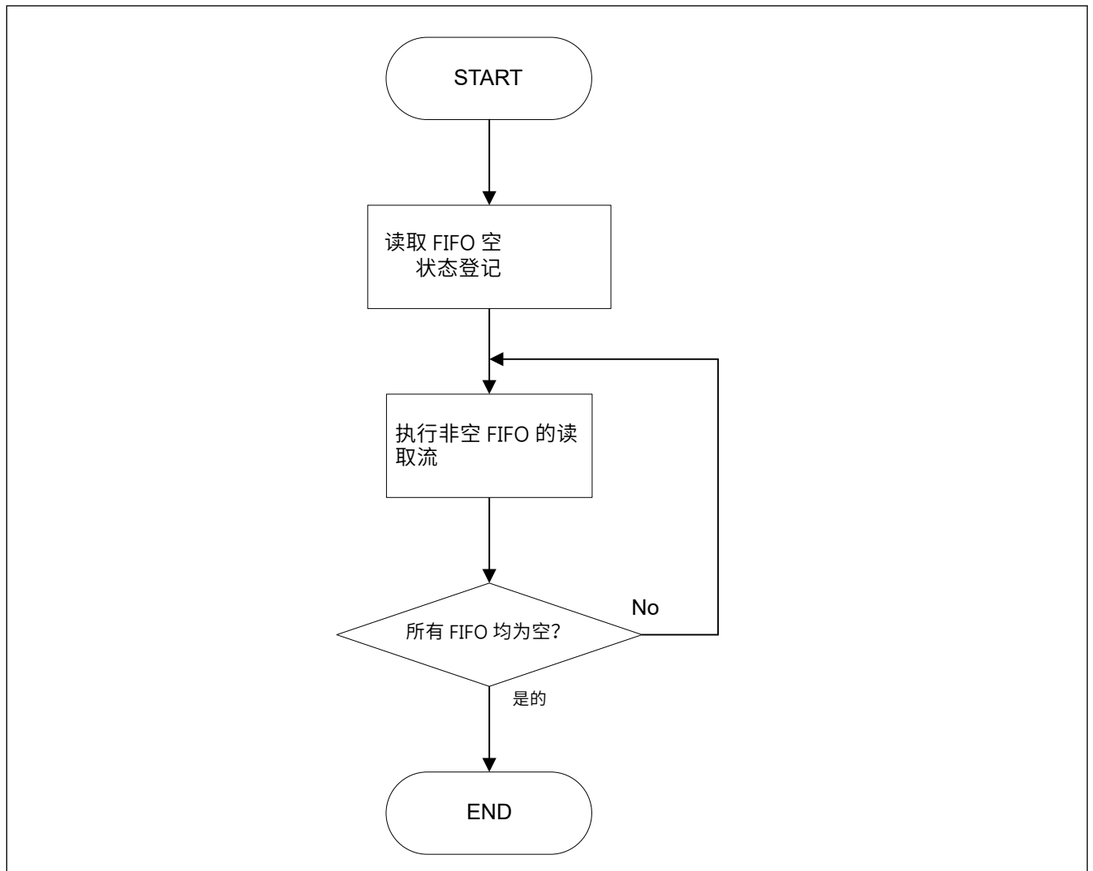

图26。39 FIFO 缓冲区消息的访问流（轮询案例示例）

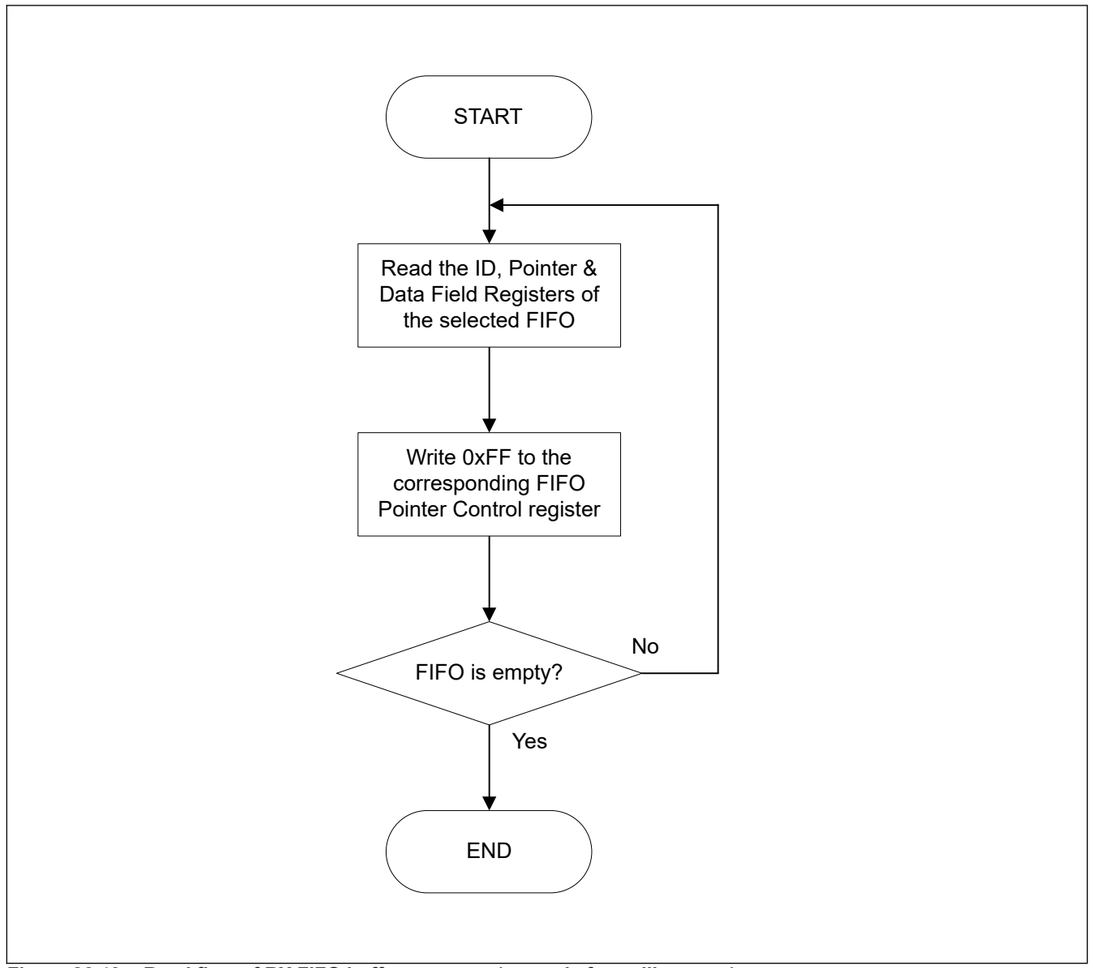

Figure 26.40 Read flow of RX FIFO buffer message (example for polling case)

Note: When the next frame is received before clearing the completion interrupt flag of reception, the completion interrupt of reception is not set again.

Even when an interruption flag is cleared after the completion processing of reception, the already received interrupt flag is not set.

It is necessary to perform the completion processing of reception even before the next completion of frame reception, and to clear an interruption flag.

When processing does not meet the condition, after checking that receiving data is empty, interrupt flag is cleared and it checks that receiving data is empty again.

26.8.1.3 Timestamp

The timestamp counter is a free-running counter that can be used to check reception time of an incoming message or transmission time of successful transmitted messages. The Timestamp counter value is captured based on the CFDGFDCFG.TSCCFG[1:0] configuration (at the sample point of start of frame, point in time when the frame is valid, or for CANFD frames also at the sample point of the RES bit). For reception, it is stored together with the message ID and data into the target RX message buffer or RX FIFO.

For transmit message, the timestamp counter value is stored as part of the TX History List entry.

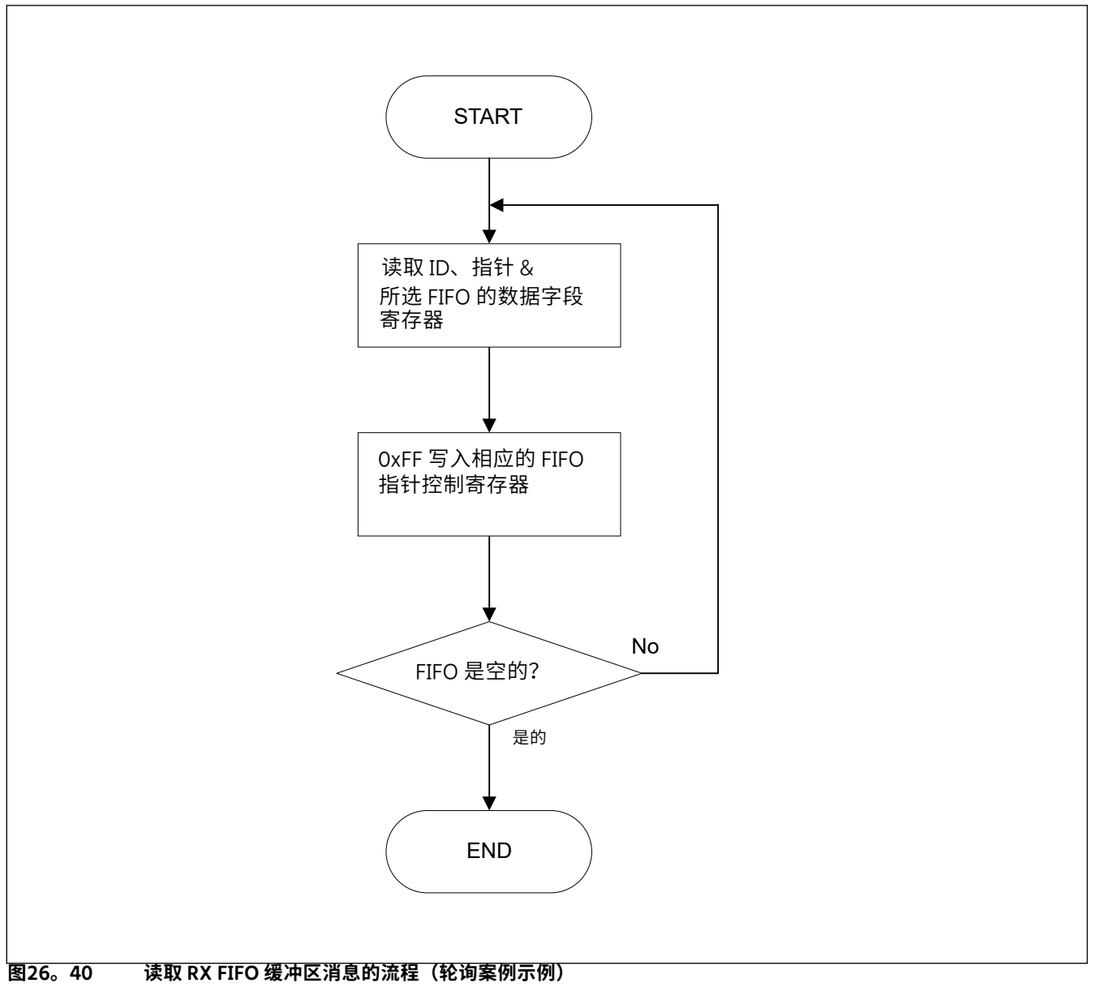

图26。40 读取 RX FIFO 缓冲区消息的流程（轮询案例示例）

注意:当在清除接收的完成中断标志之前接收到下一帧时,不会再次设置接收的完成中断。

即使在接收完成处理之后清除中断标志,也不会设置已经接收到的中断标志。

有必要在下一次帧接收完成之前执行接收的完成处理,并清除中断标志。

当处理不满足条件时,在检查接收数据为空后,清除中断标志并再次检查接收数据为空。

26。8。1。3 时间戳

时间戳计数器是一种自由运行的计数器,可用于检查传入消息的接收时间或成功传送消息的传输时间。Timestamp 计数器值是基于 CFDGFDCFG。TSCCFG[1:0] 配置捕获的（在帧开始的采样点、帧有效的时间点或对于 CANFD 帧也在 RES 位的采样点）。为了接收,它与消息ID和数据一起存储到目标RX消息缓冲器或RX FIFO中。

对于传输消息,时间戳计数器值作为 TX 历史列表条目的一部分存储。

The counter can be clocked with the peripheral clock or with the CAN channel bit timing clock. The counter source clock can be configured with the CFDGCFG.TSSS bit of the Global Configuration Register. If this bit is 0, the peripheral clock is used. If the bit is 1, the selected CAN channel bit time clock is used.

The channel selection is performed with the CFDGCFG.TSBTCS bit of the Global Configuration Register.

Care must be taken when using selected CAN channel bit time clock as the clock source. When entering Channel Halt mode or Channel Reset node, for this channel, the timestamp counter is stopped. For other CAN channels, the timestamp counter value is not updated.

If peripheral clock is selected as the timestamp counter clock source, Channel modes do not affect the timestamp counter function.

The source clock for the timestamp counter can be divided by a factor defined by the CFDGCFG.TSP bits (timestamp prescaler) in the Global Configuration Register.

The timestamp counter can be reset to 0x0000 with the CFDGCTR.TSRST bit (timestamp reset).

26.8.2 Transmission

There are several possible transmission configurations:

- Normal transmission
- FIFO transmission
- TX Queue transmission
  A fixed number of transmission message buffers (4 TX message buffers) are dedicated. These message buffers are only used for transmission and cannot be configured for reception.
  Additionally transmission from TX Queue or Common FIFO in TX mode can be configured in the following way (see Figure 26.41):
  – TX Queue: Up to four transmission message buffers can be grouped to form a TX Queue with a common access window.
    Upper transmission message buffers are used to form the TXQ.
    TXQ has an access window.
    • TXQ is transmission Message Buffer 0.
- Common FIFO (TX mode): Common FIFO in TX mode is linked to a dedicated channel.
  Channel has a fixed number of one Common FIFO assigned to it. Within the channel, a Common FIFO configured in TX mode, can be freely linked (assigned) between 0 and 3 transmission message buffers (only one FIFO to one transmission message buffer).
  The Common FIFO buffer then replaces the transmission message buffer linked to it.
  Transmission Control and Status registers of these transmission message buffers should not be used.

See Figure 26.29 for information about Common FIFO buffer assignment to related channel.

Note: Common FIFO buffer should not be linked to TX message buffers that are already part of a TX Queue.

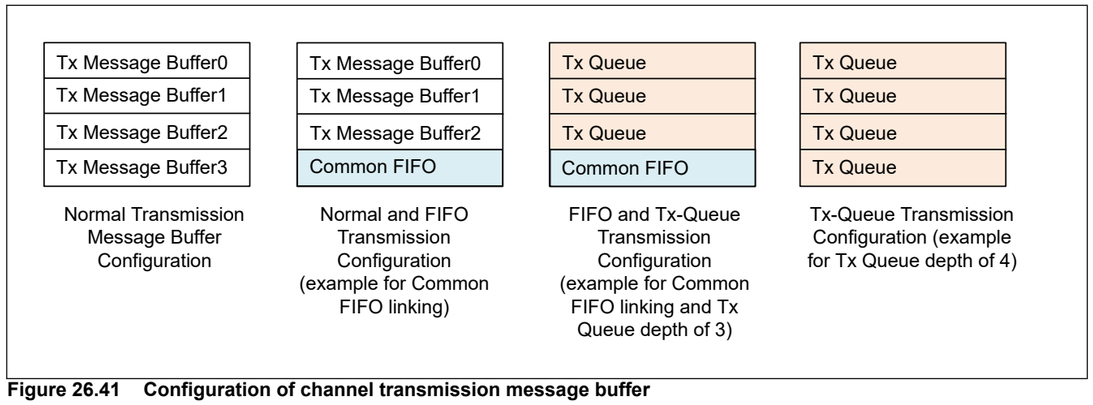

Figure 26.41 Configuration of channel transmission message buffer

计数器可以与外围时钟或 CAN 通道位定时时钟一起计时。计数器源时钟可以用全局配置寄存器的CFDGCFG。TSSS位来配置。如果该位为 0,则使用外围时钟。如果位为1,则使用所选的CAN信道位时钟。

通道选择是使用全局配置寄存器的CFDGCFG。TSBTCS位来执行的。

使用选定的 CAN 通道位时钟作为时钟源时必须小心。进入通道停止模式或通道重置节点时,对于该通道,时间戳计数器停止。对于其他 CAN 通道,时间戳计数器值不会更新。

如果选择外围时钟作为时间戳计数器时钟源,则通道模式不会影响时间戳计数器功能。

时间戳计数器的源时钟可以除以全局配置寄存器中的 CFDGCFG。TSP 位（时间戳预分频器）定义的因子。

使用 CFDGCTR。TSRST 位（时间戳重置）可以将时间戳计数器重置为 0x0000。

26。8。2 传输

有几种可能的传输配置:

- 正常传输
- FIFO 传输
- TX 队列传输
  固定数量的传输消息缓冲区(4 个 TX 消息缓冲区）是专用的。这些消息缓冲区仅用于传输,不能配置为接收。

  此外,可以通过以下方式配置来自 TX 队列或 TX 模式下的通用 FIFO 的传输（参见图 26.41):)

  – TX 队列:最多可以分组四个传输消息缓冲区,以形成具有公共访问窗口的 TX 队列。
    上传输消息缓冲区用于形成 TXQ。
    TXQ 有一个访问窗口。
    • TXQ 是传输消息缓冲区 0。
- 常见 FIFO（TX 模式）:TX 模式下的常见 FIFO 链接到专用通道。
  Channel 有固定编号的一个 Common FIFO 分配给它。在信道内,以TX模式配置的通用FIFO可以在0到3个传输消息缓冲区之间自由链接（分配）（仅一个FIFO到一个传输消息缓冲区）。

  然后,公共 FIFO 缓冲区替换与其链接的传输消息缓冲区。
  不应使用这些传输消息缓冲区的传输控制和状态寄存器。

有关相关信道的通用 FIFO 缓冲区分配的信息,请参阅图 26。29。

注意:通用 FIFO 缓冲区不应链接到已经属于 TX 队列一部分的 TX 消息缓冲区。

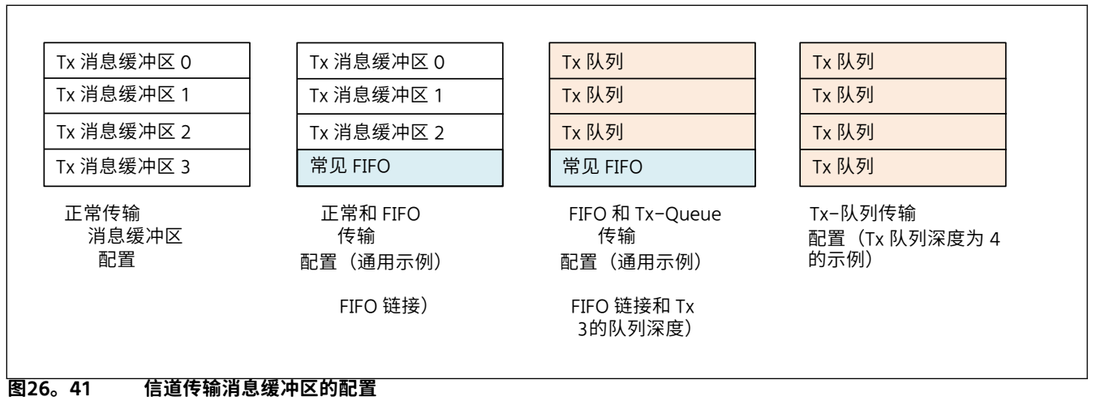

图26。41 信道传输消息缓冲区的配置

26.8.2.1 Transmission Priority

If two or more transmission message buffers of a channel are configured for transmission, then the transmission priority in the CANFD module can be selected from the following two modes:

- CAN ID priority
- Message buffer number priority.

The transmission priority mode is common for all message buffers. It can be configured with the CFDGCFG.TPRI bit in the Global Configuration Register.

For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the TX message buffers linked to the Common FIFO buffer configured in TX mode.

However, message buffer number priority should not be used if TX Queue is enabled.

For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All TX message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the TX message buffers linked to the Common FIFO buffer configured in TX mode and includes the TX Queue message buffers.

If the ID of two or more message buffers is the same, then the smaller message buffer number has higher priority for transmission.

Note: For Common FIFO buffer configured in TX mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.

If the message is being transmitted from the FIFO, then the next pending message within the same FIFO is considered in the transmission arbitration.

In contrast to this, all transmission message buffers of a TX Queue participate in internal transmission arbitration.

Figure 26.42 shows the transmission configuration flow.

26。8。2。1 传输优先级

1 个信道的两个或多个传输消息缓冲区进行传输, 则可以从以下两种模式中选择 CANFD 模块中的传输优先级:

- 可以 ID 优先级
- 消息缓冲区编号优先级。

传输优先模式对于所有消息缓冲区都是通用的。它可以用全局配置寄存器中的 CFDGCFG。TPRI 位进行配置。

对于消息缓冲区号优先级传输,具有传输请求的最小消息缓冲区号具有最高的传输优先级。这还包括链接到以 TX 模式配置的通用 FIFO 缓冲区的 TX 消息缓冲区。

但是,如果启用 TX 队列,则不应使用消息缓冲区号优先级。

CAN ID优先级传输,ID优先级符合CAN总线仲裁规则（如ISO 11898-1规范中规定）。所有TX消息缓冲区都可以输入配置用于传输的消息缓冲区的ID优先级比较。这还包括链接到以TX模式配置的公共FIFO缓冲区的TX消息缓冲区,并且包括TX队列消息缓冲区。

如果两个或多个消息缓冲区的ID相同,则较小的消息缓冲区号的传输优先级较高。

注:对于TX模式配置的通用FIFO缓冲区,传输仲裁中只能包含当前FIFO读指针所指向的消息。

如果消息是从 FIFO 传输的,则在传输仲裁中考虑同一 FIFO 内的下一个待处理消息。

与此相反,TX Queue 的所有传输消息缓冲区都参与内部传输仲裁。

图26。42显示了传输配置流程。

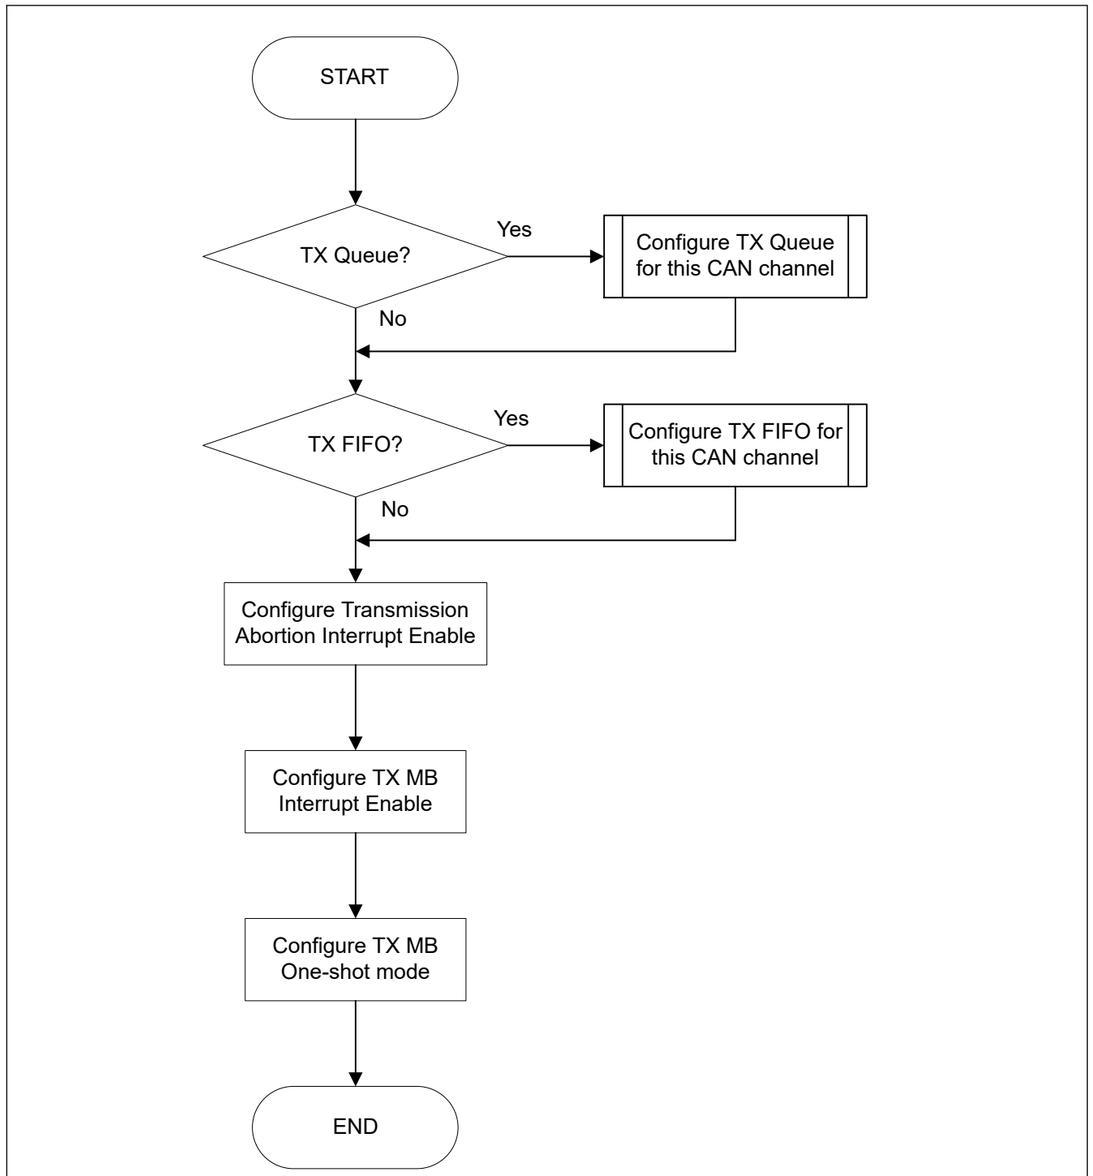

Figure 26.42 Flow for transmission configuration

26.8.2.2 Normal Transmission

Each transmission message buffer has two modes of message transmission:

1. Regular transmission mode
   If the message buffer is placed in regular transmission mode, the data frame or remote frame set in that message buffer can be transmitted.
   Completion of regular transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSj.TMTRF) in the TX Message Buffer Status Registers. These bits are set to 10b or 11b when the regular transmission is successful.

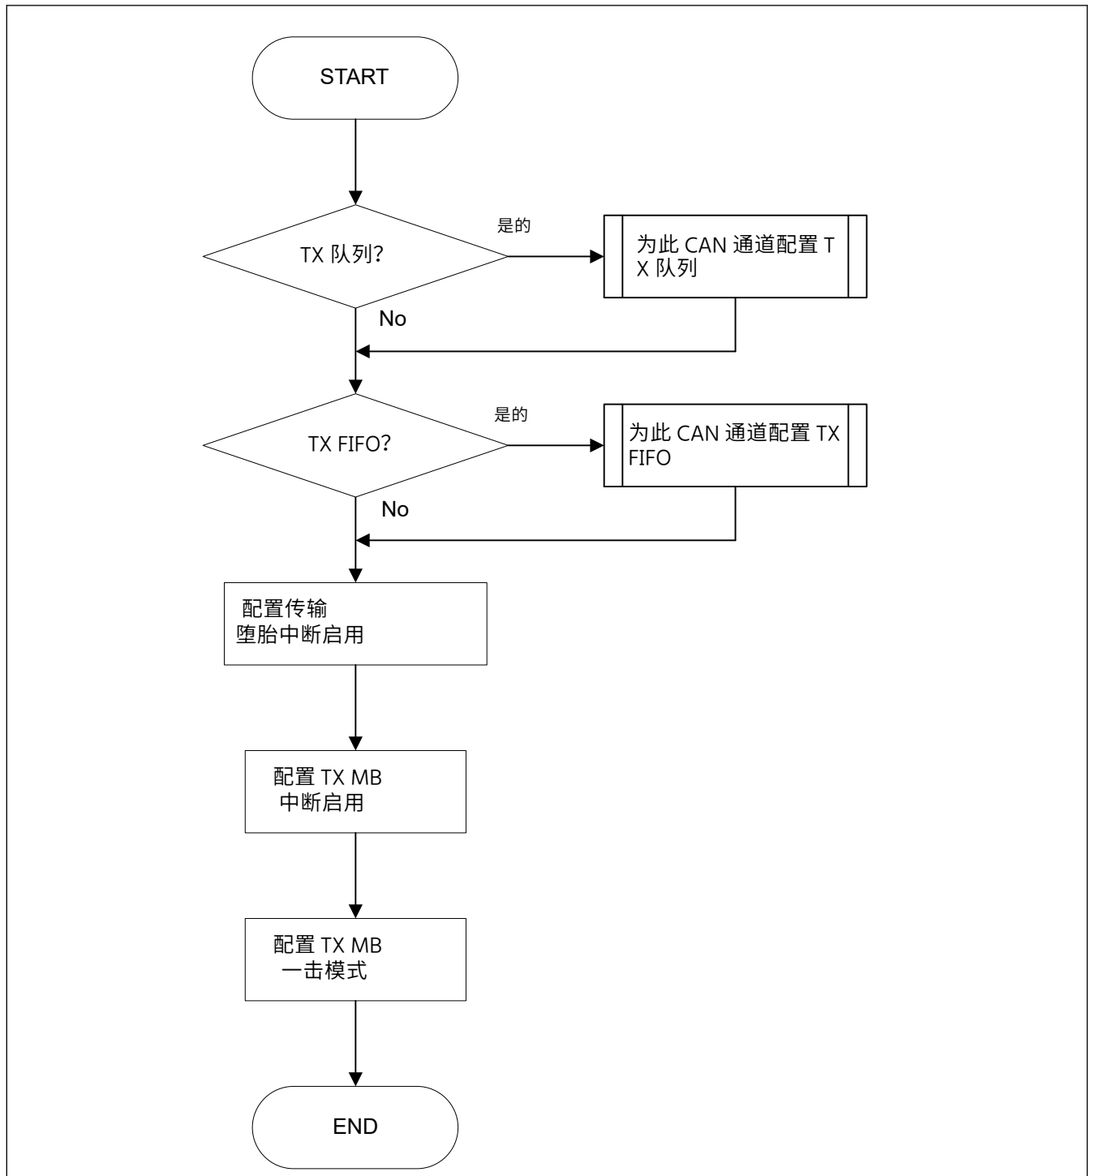

图26。42 用于传输配置的流量

26.8.2.2 正常传输

每个传输消息缓冲区有两种消息传输模式:

1。常规传输模式
如果消息缓冲器处于常规传输模式,则可以传输该消息缓冲器中的数据帧或远程帧集。

常规传输的完成可以通过TX消息缓冲器状态寄存器中的相关TX消息缓冲器传输结果标志位（CFDTMSTSj。TMTRF）来检查。当常规传输成功时,这些位被设置为 10b 或 11b。

When arbitration is lost or an error occurs, message transmission is further attempted if no transmission abort request is set for this transmission message buffer.
New internal transmission arbitration for this channel is performed for all message buffers with transmission request.

2. One-shot transmission mode

When the CFDTMCi.TMOM bit of the TX Message Buffer Control Registers is set for a transmission message buffer, the message buffer is placed in One-shot transmission mode and attempts to transmit a message only once.

Completion of One shot transmission can be checked through the related TX Message Buffer Transmission Result Flag bits (CFDTMSTSj.TMTRF) in the TX Message Buffer Status Registers. The CFDTMSTSj.TMTRF bits are set to 10b or 11b when One-shot transmission is successful.

The CFDTMSTSj.TMTRF bits are set to 01b when arbitration is lost or an error occurs during transmission of the related message buffer.

Additional message transmission is not attempted in this case.

The regular transmission request procedure after a configuration is shown in Figure 26.43.

对具有传输请求的所有消息缓冲区执行该信道的新内部传输仲裁。

2锛姣涓涓。一次性传输模式

当TX消息缓冲器控制寄存器的CFDTMCi。TMOM位被设置为传输消息缓冲器时,消息缓冲器被置于一次性传输模式并尝试仅传输消息一次。

一次拍摄传输的完成可以通过TX消息缓冲器状态寄存器中的相关TX消息缓冲器传输结果标志位（CFDTMSTSj。TMTRF）来检查。CFDTMSTSj。TMTRF 位在一次性传输成功时设置为 10b 或 11b。

CFDTMSTSj。TMTRF 位设置为 01b, 当仲裁丢失或在相关消息缓冲区的传输过程中发生错误时。

在这种情况下,不会尝试额外的消息传输。

1. If the CFDTMCi.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, the message buffer scanning procedure determines the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSj.TMTSTS bit in the related TX Message Buffer Status Registers is set (transmitting/transmitter), and CAN channel starts the transmission *1.
2. At the first bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.
3. If the message has been successfully transmitted, the CFDTMSTSj.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 10b and CFDTMSTSj.TMTSTS and the CFDTMCi.TMTR bits are cleared.
   When the TMIE bit in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSj.TMTRF flag bits.
4. Before starting the next transmission, clear the CFDTMSTSj.TMTRF bits. Load the next message in the transmission message buffer and set the CFDTMCi.TMTR bit again.
   CFDTMCi.TMTR bit cannot be set again before CFDTMSTSj.TMTRF[1:0] bits are cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSj.TMTSTS bit is cleared.

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs either during transmission or following the loss of arbitration, then during the error frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

Note: The setting point of CFDTMSTSj.TMTSTS is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID due to the synchronization logic implemented for the PLL bypass.

Figure 26.45 shows timings for transmission abort for two message buffers.

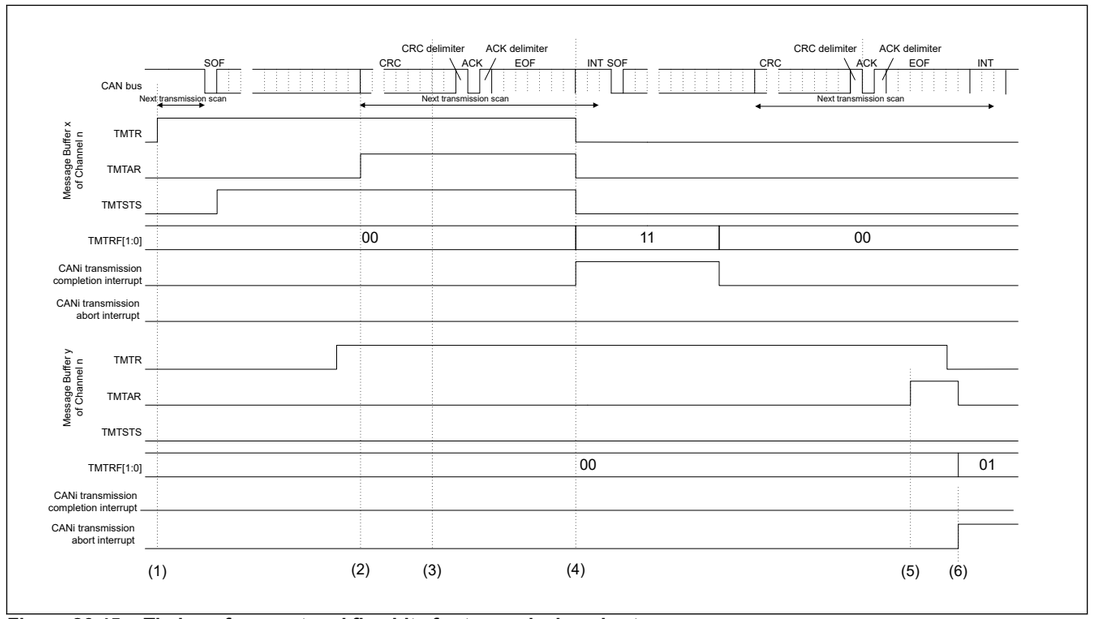

Figure 26.45 Timing of request and flag bits for transmission abort

1. If the CFDTMCi.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, the message buffer scanning procedure determines the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSj.TMTSTS bit in the TX Message Buffer Status Registers is set (transmitting/transmitter), and CAN channel starts the transmission*1.
2. If the CFDTMCi.TMTAR bit is set when the related message buffer is already selected for transmission or currently transmitting, the message is not aborted, if no error occurs or arbitration is lost.
3. At the first CRC bit, the transmission scanning procedure starts for the next transmission. In this example, timing chart message buffer y is not selected as the next transmission message buffer.
4. If the message has been successfully transmitted, the CFDTMSTSj.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 11b and the CFDTMSTSj.TMTSTS and CFDTMCi.TMTR bits are cleared.
   When the TMIE bit in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSj.TMTRF[1:0] bits.
5. Another CAN node is transmitting on the CAN bus (CFDTMSTSj.TMTSTS is not set). If the CFDTMCi.TMTAR bit is set when the related channel is under transmission scan, the transmission request cannot be cleared.
6. After internal processing time, the transmission is aborted and the CFDTMSTSj.TMTRF[1:0] bits are set to 01b.
   If the message buffer is not transmitting or selected as the next transmission message buffer or under transmit scan, then the abort is immediately accepted and the corresponding CFDTMSTSj.TMTRF[1:0] bits in the TX Message Buffer Status Registers are set to 01b.
   In addition, CFDTMCi.TMTR, and CFDTMCi.TMTAR bits are cleared automatically.
   When the transmission abort interrupt enable TAIE bit of the related Channel Control Register is set then an interrupt is generated for successful transmission abort.
   To clear the related interrupt line the CFDTMSTSj.TMTRF[1:0] bits have to be cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSj.TMTSTS bit is cleared.

注意:CFDTMSTSj。TMTSTS 的设置点并不总是在 SOF 开始时固定。由于 PLL 旁路实现的同步逻辑,它可能会延迟到标准 ID 的开始。

此外,CFDTMCi。TMTR 和 CFDTMCi。TMTAR 位会自动清除。

注1。如果在CAN信道开始传输后仲裁失败,则CFDTMSTSj。TMTSTS位被清除。

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs, either during transmission, or following the loss of arbitration, then during the error frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

26.8.2.3 TX FIFO Transmission

One common FIFO buffer is assigned to CANFD module. The FIFO buffer can be linked to any normal TX message buffer position for this channel with the CFDCFCC.CFTML bits in the Common FIFO Configuration/Control Register if configured in TX mode.

When the transmission scan starts and the FIFO buffer corresponding to this TX message buffer is enabled, the relevant message in the FIFO buffer participates in the transmission scan.

Configuration of a TX message buffer linked to a FIFO buffer configured in TX mode should not be done.

(1) TX FIFO Operation

CAN messages can be written into the TX FIFO by writing to the corresponding FIFO Access registers.

When the value 0xFF is written into the corresponding FIFO Pointer Control Register, the message count of the related FIFO is incremented by 1.

Only write to the FIFO Pointer Control register after writing the complete message to the corresponding FIFO Access registers. If the message count matches the FIFO depth, the FIFO Full flag is set.

The oldest message in the TX FIFO is included in the scan for transmission by the corresponding CANFD module channel logic.

When a message is successfully transmitted from the TX FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the FIFO Empty flag is set.

The interrupt generation conditions for the TX FIFO buffer can be configured by configuring the CFDCFCC.CFIM bit in the corresponding Common FIFO Configuration/Control Register.

If CFDCFCC.CFIM bit is 0, then interrupt is generated when the last message is successfully transmitted from the TX FIFO buffer.

If CFDCFCC.CFIM bit is 1, then interrupt is generated for every successfully transmitted message from the TX FIFO buffer.

The Common FIFO can set interrupt when CAN frame transmission is complete.

The Common FIFO buffer configured in TX Mode can be disabled by clearing the CFDCFCC.CFE bit in the Common FIFO Configuration/Control Register. If this bit is cleared to 0, the FIFO Empty flag is set as follows:

- Immediately if the message from the TX FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX FIFO is already scheduled for transmission or already in transmission.

Note: The Common FIFO buffer is considered as disabled after clearing the CFDCFCC.CFE bit only when the Empty flag is set for the corresponding Common FIFO buffer.

Other possible messages pending from the TX FIFO are lost and their transmission must be requested again. Before CFDCFCC.CFE is set again, ensure that CFDCFSTS.CFEMP bit is set and that there are no pending abort from the TX FIFO.

When the CFDCFCC.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after configuration is shown in Figure 26.46.

再次执行传输扫描过程以从第一CRC位开始搜索最高优先级的传输消息缓冲区。

如果在传输期间或在仲裁丢失之后发生错误,则在错误帧期间,再次执行传输扫描过程以搜索最高优先级的传输消息缓冲区。

26。8。2。3 TX FIFO 变速箱

一个常见的 FIFO 缓冲区被分配给 CANFD 模块。如果配置为 TX 模式,则可以使用通用 FIFO 配置/控制寄存器中的 CFDCFCC。CFTML 位将 FIFO 缓冲区链接到该通道的任何正常 TX 消息缓冲区位置。

当传输扫描开始并且启用与该TX消息缓冲器相对应的FIFO缓冲器时,FIFO缓冲器中的相关消息参与传输扫描。

不应完成链接到以 TX 模式配置的 FIFO 缓冲区的 TX 消息缓冲区的配置。

(1)TX FIFO 操作

CAN 消息可以通过写入相应的 FIFO Access 寄存器来写入 TX FIFO。

0xFF 的值写入对应的 FIFO 指针控制寄存器时,相关 FIFO 的报文计数递增 1。

仅在将完整消息写入相应的 FIFO Access 寄存器后才写入 FIFO 指针控制寄存器。如果消息计数与 FIFO 深度匹配,则设置 FIFO 完整标志。

TX FIFO中最古老的消息被包含在扫描中,以便由相应的CANFD模块信道逻辑进行传输。

当消息从TX FIFO成功发送时,消息计数值减小1。当传输来自FIFO的所有消息时,设置FIFO空标志。

TX FIFO缓冲区的中断生成条件可以通过在相应的通用FIFO配置/控制寄存器中配置CFDCFCC。CFIM位来配置。

如果CFDCFCC。CFIM位为0,则当最后一条消息从TX FIFO缓冲区成功发送时生成中断。

如果 CFDCFCC。CFIM 位为 1,则为来自 TX FIFO 缓冲区的每条成功传输的消息生成中断。

当CAN帧传输完成时,Common FIFO可以设置中断。

可以通过清除通用 FIFO 配置/控制寄存器中的 CFDCFCC。CFE 位来禁用以 TX 模式配置的通用 FIFO 缓冲区。如果此位被清除为 0,则 FIFO 空标志设置如下:

- 如果来自 TX FIFO 的消息既没有被安排用于下一次传输,也没有被安排在传输中,则立即
- 传输完成后,如果来自 TX FIFO 的传输已经计划传输或已经在传输中,则检测 CAN 总线上的错误、仲裁丢失或过渡到信道或全局停止模式。

注意:仅当为相应的 Common FIFO 缓冲区设置空标志时,在清除 CFDCFCC。CFE 位后,Common FIFO 缓冲区才被视为禁用。

TX FIFO 悬而未决的其他可能消息丢失,必须再次请求传输。在再次设置 CFDCFCC。CFE 之前,请确保设置 CFD CFSTS。CFEMP 位并且 TX FIFO 中不存在待处理的中止。

当CFDCFCC。CFE位被清除时,FIFO的消息读写指针被清除并且不再活动。因此,FIFO缓冲区中的所有消息都会丢失,并且无法将进一步的消息存储到FIFO中。

配置后的FIFO传输请求过程如图26。46所示。

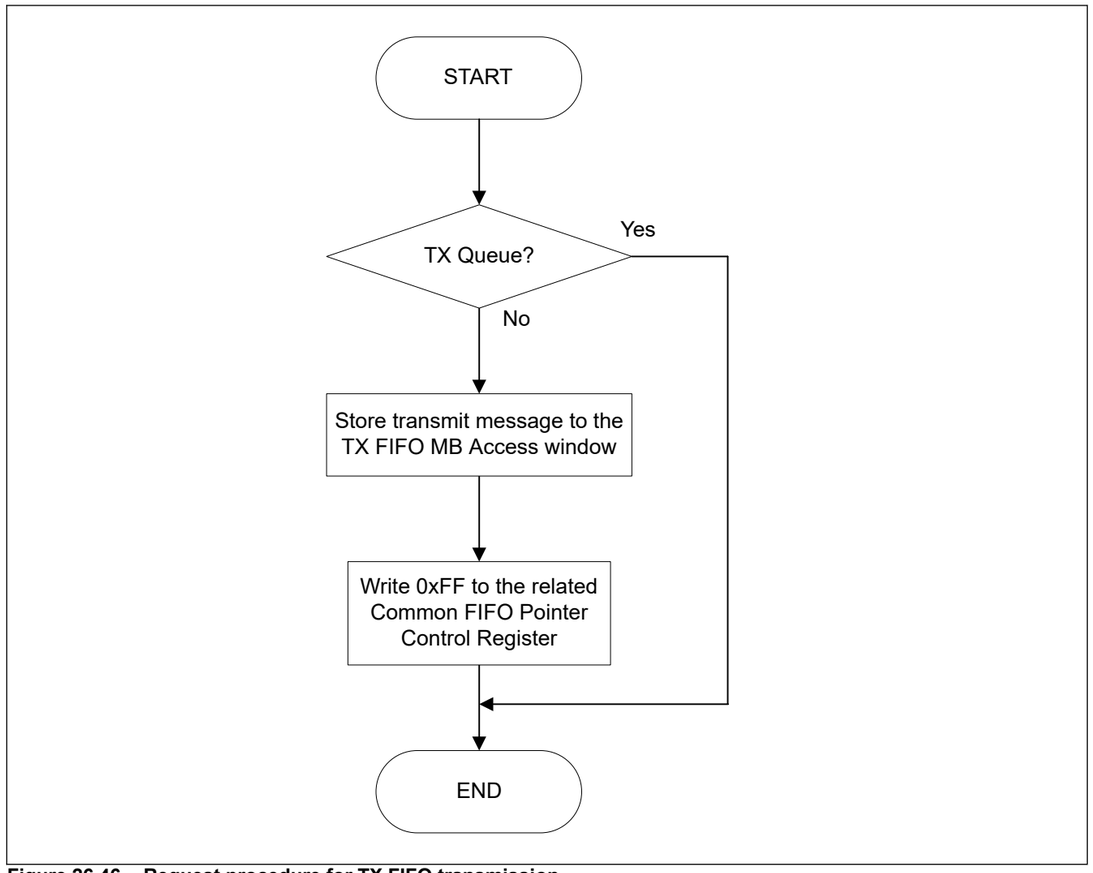

Figure 26.46 Request procedure for TX FIFO transmission

(2) Interval Timer for FIFO Transmission

For each Common FIFO in TX mode, it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFDCFCC.CFE bit is set.

When the Common FIFO in TX mode is enabled, the first message is transmitted without considering this interval time.

The interval timer stops counting when:

- FIFO is disabled by clearing the CFDCFCC.CFE bit.
- CAN channel is in CH_RESET mode.

The interval time is specified by the CFDCFCC.CFITT value from 0 to 255 timer units in the Common FIFO Configuration/Control Register.

The timer unit can be defined based on two different source clocks for the interval timer. To disable the interval timer for FIFO transmission, select a value of 0.

The timer source can be selected with the configuration bit CFITSS in the Common FIFO Configuration/Control Register.

If CAN channel bit time clock is configured as the clock source, and the CAN channel enters CH_HALT, CH_RESET, or CH_SLEEP mode, the interval timer is stopped for that channel.

If peripheral clock is selected as the interval timer clock source, the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.

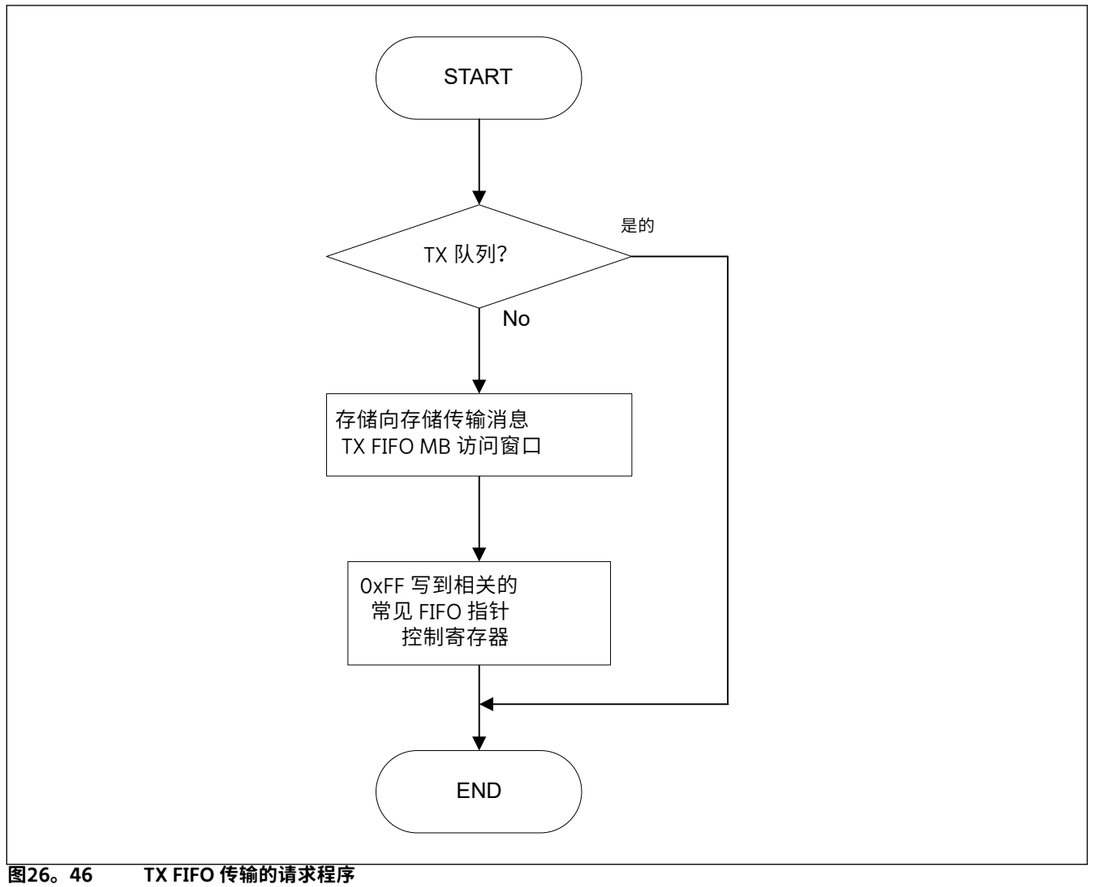

图26。46 TX FIFO 传输的请求程序

(2) FIFO 传输的间隔定时器

对于 TX 模式下的每个通用 FIFO,可以指定配置为从同一 FIFO 缓冲区传输的两个连续消息之间的延迟。这种延迟称为间隔时间。该间隔时间在设置CFDCFCC。CFE位之后从FIFO缓冲器成功发送第一消息之后开始。

TX 模式下的 Common FIFO 启用时,在不考虑该间隔时间的情况下传输第一条消息。

间隔定时器停止计数:

通过清除 CFDCFCC。CFE 位来禁用 ● FIFO。

● CAN 通道处于 CH_RESET 模式。

间隔时间由通用 FIFO 配置/控制寄存器中的 CFDCFCC。CFITT 值从 0 到 255 个定时器单元指定。

定时器单元可以基于间隔定时器的两个不同的源时钟来定义。要禁用 FIFO 传输的间隔定时器,请选择值 0。

可以使用通用 FIFO 配置/控制寄存器中的配置位 CFITSS 选择定时器源。CAN信道位时钟配置为时钟源,并且CAN信道进入CH_HALT、CH_RESET或CH_SLEEP模式,则该信道的间隔定时器停止。

如果选择外围时钟作为间隔定时器时钟源,则仅在CAN信道处于CH_RESET或CH_SLEEP模式时停止间隔定时器。

The reference clock can be used to configure the interval time in fixed time units. It is based on the peripheral clock. The reference clock prescaler value CFDGCFG.ITRCP in the Global Configuration Register defines the relation between the peripheral clock frequency/period and the reference clock period.

See Table 26.28 for CFDGCFG.ITRCP configuration values to achieve different reference clock periods based on the peripheral clock frequency and period.

Table 26.28 Configuration example for the reference clock of the FIFO interval timer

Reference clock/Peripheral clock	1 µs	100 µs	500 µs
16 MHz/62.5 ns	16	1600	8000
20 MHz/50 ns	20	2000	10000
32 MHz/31.25 ns	32	3200	16000
50 MHz/20 ns	50	5000	25000

The reference clock resolution can be specified by the interval timer reference clock resolution value CFDCFCC.CFITR in the Common FIFO Configuration/Control Register.

The interval time is based on the reference clock period multiplied by the configured value (x1 or x10). The reference clock based interval timer can be used to satisfy the requirements of the ISO 15765-2 Separation Time. The whole range for the separation time from 100 µs to 127 ms can be covered.

The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).

When the interval time has elapsed, the next transmission request is raised by the related TX FIFO. Therefore, the interval time defines the minimum time between two messages transmitted from one FIFO.

The next message is sent at earliest after this interval time. Figure 26.47 shows an example timing of the internal processing.

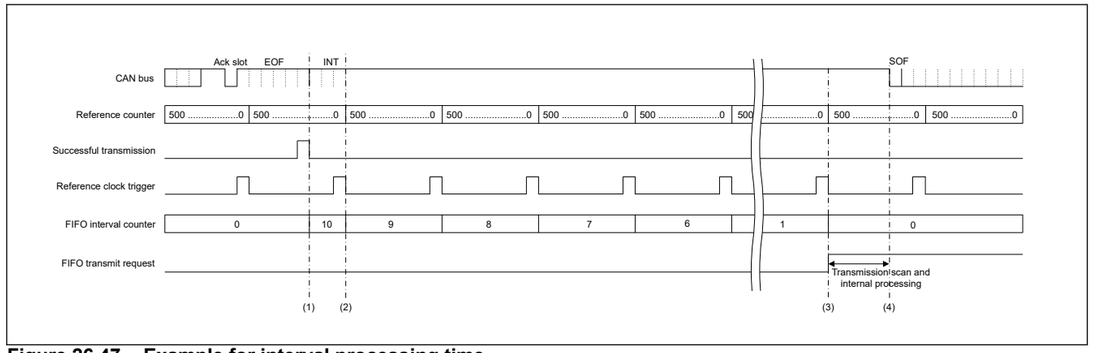

Figure 26.47 Example for interval processing time

The configuration for the timing in Figure 26.47 is as follows:

- Peripheral clock frequency = 50 MHz
- Interval timer reference clock (CFDGCFG.ITRCP) = 500 times
- Reference clock from the settings in Figure 26.47 = 10 µs
- Common FIFO interval timer source selection (CFDCFCC.CFITSS) = 0
- Common FIFO interval timer resolution (CFDCFCC.CFITR) = 0
- Common FIFO interval transmission time (CFDCFCC.CFITT) = 10 times
- Theoretical message separation interval = 100 µs

1. Internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore, the first interval is counting less or equal to 1 reference clock interval.
2. With the next reference clock trigger the FIFO interval timer is decremented.
3. When the FIFO interval timer reached the value 0, the FIFO transmit request is set.

参考时钟可用于以固定时间单位配置间隔时间。它基于外围时钟。全局配置寄存器中的参考时钟预分频器值CFDGCFG。ITRCP定义外围时钟频率/周期与参考时钟周期之间的关系。

CFDGCFG。ITRCP 配置值见表 26。28,以根据外围时钟频率和周期实现不同的参考时钟周期。

表 26。28 FIFO间隔定时器的参考时钟的配置示例

参考时钟/外设时钟	1 µs	100 µs	500 µs
16 MHz/62。5 ns	16	1600	8000
20 MHz/50 ns	20	2000	10000
32 MHz/31。25 ns	32	3200	16000
50 MHz/20 ns	50	5000	25000

参考时钟分辨率可以通过通用FIFO配置/控制寄存器中的间隔定时器参考时钟分辨率值CFDCFCC。CFITR来指定。

间隔时间基于参考时钟周期乘以配置值（x1 或 x10)。基于参考时钟的间隔定时器可用于满足 ISO 15765-2 分离时间的要求。100 µs到127 ms的分离时间的整个范围可以覆盖。

指定的间隔时间在成功传输事件之后（在 CAN 协议的 EOF7 状态之后）开始。

当间隔时间过去时,下一次传输请求由相关的TX FIFO提出。因此,间隔时间定义了从一个FIFO发送的两条消息之间的最小时间。

下一条消息最早在此间隔时间之后发送。图26。47示出了内部处理的示例时序。

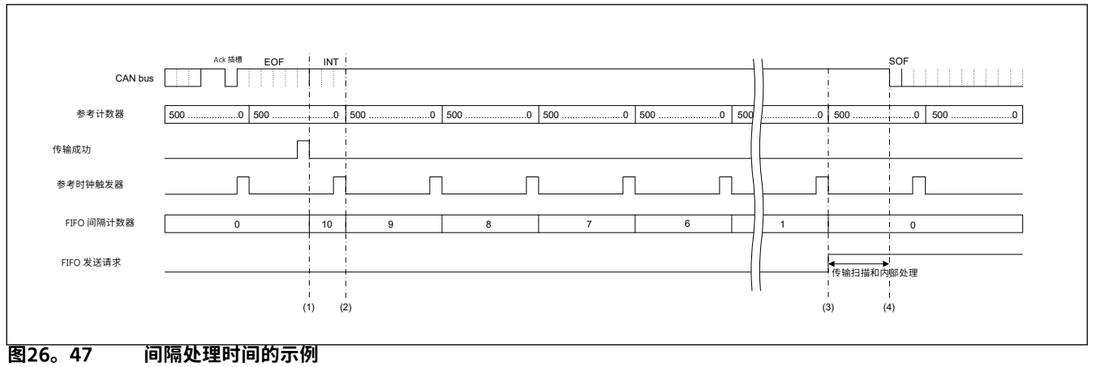

图26。47 间隔处理时间的示例

图 26。47 中的时序配置如下:

- 外设时钟频率 = 50 MHz
- 间隔定时器参考时钟（CFDGCFG。ITRCP）= 500 次
- 参考时钟来自图 26。47 中的设置 = 10 µs
- 常见 FIFO 间隔定时器源选择（CFDCFCC。CFITSS）= 0
- 通用 FIFO 间隔定时器分辨率（CFDCFCC。CFITR）= 0
- 常见 FIFO 间隔传输时间（CFDCFCC。CFITT）= 10 次
- 理论消息分离间隔 = 100 µs

1。随着成功传输结果的发生,内部 FIFO 间隔定时器重新启动。此重启未与参考时钟触发器同步。因此,第一个间隔的计数小于或等于1个参考时钟间隔。

2锛姣涓涓。当下一个参考时钟触发时,FIFO 间隔定时器会减小。

3锛 娴 。FIFO间隔定时器达到值0时,设置FIFO发送请求。

4. When the FIFO is selected for transmission, the transmission starts. Due to internal processing, this usually takes less than 3 CAN bit time, between the internal FIFO transmit request set in step 3. and the actual transmission.

In the worst case when multiple events such as a reception scan, an internal message routing, a transmit scan on all channels occur, it can take up to 126 peripheral clock cycles.

As shown in Figure 26.47, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure CFDCFCC.CFITT to the required minimum value plus 1.

If additional TX message buffers or TX FIFO are configured for transmission of the same channel, the real delay between two messages transmitted from a TX FIFO can be much longer than specified by the interval time. This is due to higher priority message transmission from these TX message buffers or TX FIFO.

Figure 26.48 shows a block diagram of the FIFO interval time generation circuit.

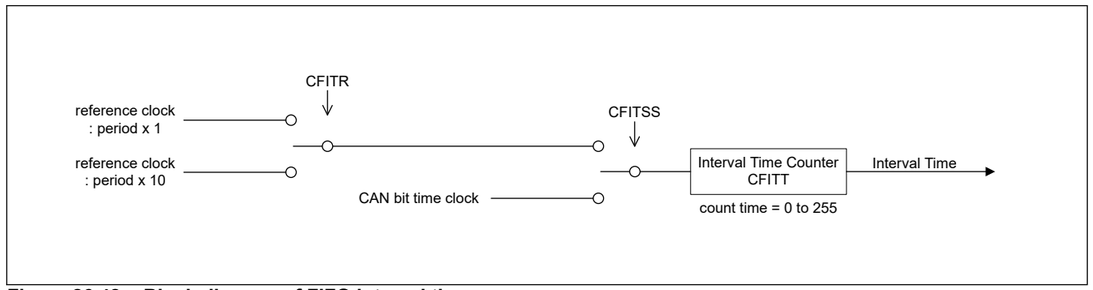

Figure 26.48 Block diagram of FIFO interval timer

26.8.2.4 TX Queue

Each enabled TX Queue for a specific channel consists of 3 to 4 TX message buffers, which are accessed through one access window.

- The first TX Queue can be configured with a depth of three up to four buffers and uses TX Message Buffer No. 0 as access window (referred to as TXQ)

All the TXQ messages enter the priority comparison for the transmission, which should be only ID Priority (CFDGCFG.TPRI = 0).

The registers for TXQ are:

- CFDTXQCC
- CFDTXQSTS
- CFDTXQPCTR

See related access registers TX Message Buffer ID Registers (TMID[m]), TX Message Buffer Pointer Registers (TMPTR[m]), TX Message Buffer Data Field 0 Registers, and TX Message Buffer Data Field 1 Registers (TMDF[0:1][m]) when access window TXQ0 is used.

The depth of each TXQ buffer can be configured by writing to the CFDTXQCC.TXQDC[1:0] bits of the TX Queue Configuration/Control Register. TXQ can be set from TXMB0 to TXMB3 as a queue buffer at the maximum.

The 4 available options for the depth configuration of TXQ buffer are:

- 0x00: TX Queue disabled
- 0x01: reserved
- 0x10: 3 Messages
- 0x11: 4 Messages

Do not access all the TX message buffers forming the TX Queue directly (except TX Message Buffer No. 0, which act as TX Queue access window).

When a system writes in TXQ, it writes in send data, after checking the state of TXQ.

4锛姣涓。当选择FIFO进行传输时,传输开始。由于内部处理,在步骤 3 中设置的内部 FIFO 发送请求和实际传输之间,这通常需要少于 3 个 CAN 位时间。

在最坏的情况下,当发生多个事件（例如接收扫描、内部消息路由、所有信道上的发射扫描）时,最多可能需要 126 个外围时钟周期。

26。47 所示,不保证最小区间始终等于配置值。如果绝不能违反最小时间,请将 CFDCFCC。CFITT 配置为所需的最小值加 1。

如果附加TX消息缓冲器或TX FIFO被配置为传输同一信道,则从TX FIFO发送的两条消息之间的真实延迟可以比间隔时间指定的要长得多。这是由于来自这些 TX 消息缓冲区或 TX FIFO 的更高优先级的消息传输。

图26。48示出了FIFO间隔时间生成电路的框图。

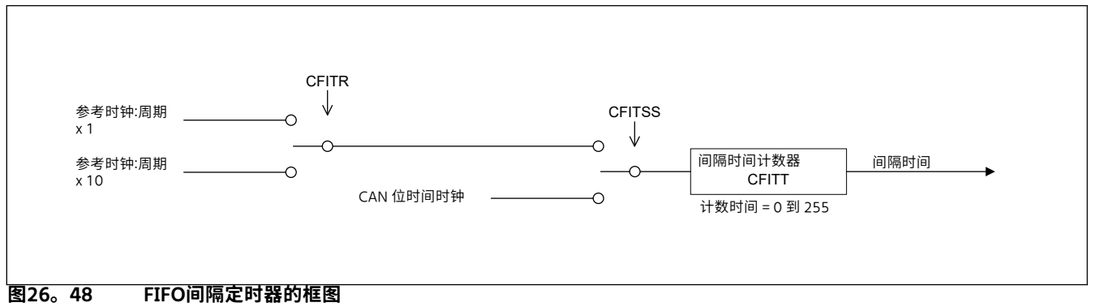

图26。48 FIFO间隔定时器的框图

26。8。2。4 德克萨斯队列

特定通道的每个启用的 TX 队列由 3 到 4 个 TX 消息缓冲区组成,可通过一个访问窗口访问。

- 第一个 TX 队列可以配置三个至多四个缓冲区的深度,并使用 TX 消息缓冲区 0 号作为访问窗口（简称 TXQ）

所有 TXQ 消息都输入传输的优先级比较,该比较应仅为 ID 优先级（CFDGCFG。TPRI = 0)。

TXQ 的寄存器是:

- CFDTXQCC
- CFDTXQSTS
- CFDTXQPCTR

请参阅相关访问寄存器 TX 消息缓冲区 ID 寄存器（TMID[m])、TX 消息缓冲区指针寄存器（TMPTR[m])、TX 消息缓冲区数据字段 0 寄存器和 TX 消息缓冲区数据字段 1 寄存器（TMDF[0:1][m])当使用访问窗口 TXQ0 时。

每个 TXQ 缓冲区的深度可以通过写入 TX 队列的 CFDTXQCC。TXQDC[1:0] 位来配置
配置/控制寄存器。TXQ 可以从 TXMB0 到 TXMB3 设置为最大队列缓冲区。

TXQ 缓冲区深度配置的 4 个可用选项是:

- 0x00:禁用 TX 队列
- 0x01:保留
- 0x10:3 条消息
- 0x11:4 条消息

请勿直接访问形成 TX 队列的所有 TX 消息缓冲区（TX 消息缓冲区 0 除外,该缓冲区充当 TX 队列
TX 队列访问窗口）。

当系统在 TXQ 中写入时,在检查 TXQ 的状态后,它会在发送数据中写入。

Do not access or configure the related TX Message Buffer Control Registers.

The messages stored to the TX Queue access window are internally stored to a free buffer of the TX Queue.

When the buffer is full, no further access should be done to the queue, until it is no longer full. If access is a software write when the buffer of TXQ is full, send data is overwritten.

The TX Queue can be disabled by clearing the TXQE bit in the TX Queue Configuration/Control Register. If this bit is cleared, the TX Queue Empty flag is set as follows:

- Immediately if the message from the TX Queue is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX Queue is already scheduled for transmission or already in transmission.

Note: The TX Queue is disabled only when the Empty flag is set after clearing the TXQE bit for the corresponding TX Queue.

Other possible messages pending from the TX Queue are lost and their transmission must be requested again.

Before TXQE is set again, ensure that the CFDTXQSTS.TXQEMP bit is set and that there is no pending abort from the TX Queue.

When the TXQE bit is cleared, all messages in the TX Queue buffers are lost and no further message should be stored in the TX Queue.

When a message has been stored to the TX Queue, write 0xFF in the TX Queue Pointer Control Register. This sets the transmit request automatically and changes the internal message buffer pointer to the next free message buffer location of the TX Queue.

Note: If two messages with the same ID are stored in the TX Queue, the order of transmission of these messages can be different from the order in which they were stored in the TX Queue.

To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same ID is stored in the TX Queue.

For the TX Queue, a dedicated interrupt can be enabled by setting the TXQIE bit of the TX Queue Configuration/Control Register.

The interrupt mode can be configured with the CFDTXQCC.TXQIM bit of the same register either to generate an interrupt for every transmitted message or for the last transmitted message.

The TX Queue transmission request procedure after configuration is shown in Figure 26.49.

请勿访问或配置相关的 TX 消息缓冲区控制寄存器。

存储到 TX 队列访问窗口的消息在内部存储到 TX 队列的免费缓冲区。

当缓冲区已满时,不应进一步访问队列,直到不再满为止。如果访问是在 TXQ 缓冲区已满时写入的软件,则发送数据将被覆盖。

可以通过清除 TX 队列配置/控制寄存器中的 TXQE 位来禁用 TX 队列。如果此位被清除,则 TX 队列空标志设置如下:

- 如果来自 TX 队列的消息既没有被安排用于下一次传输, 也没有被安排用于传输
- 传输完成后,如果来自 TX 队列的传输已经安排传输或已经在传输中,则检测 CAN 总线上的错误、仲裁丢失或转换到信道或全局停止模式。

注意:仅在清除相应 TX 队列的 TXQE 位后设置空标志时,TX 队列才会被禁用。

TX 队列中待处理的其他可能消息丢失,必须再次请求传输。

在再次设置 TXQE 之前,确保设置 CFDTXQSTS。TXQEMP 位并且不存在从 TX 队列中止的待处理情况。

当 TXQE 位被清除时,TX 队列缓冲区中的所有消息都会丢失,并且不应在 TX 队列中存储进一步的消息。

当消息已存储到 TX 队列时,请在 TX 队列指针控制寄存器中写入 0xFF。这会自动设置传输请求并将内部消息缓冲区指针更改为 TX 队列的下一个免费消息缓冲区位置。

注意:如果两个具有相同 ID 的消息存储在 TX 队列中,则这些消息的传输顺序可能与它们存储在 TX 队列中的顺序不同。

为了避免这种情况,重要的是要确认具有相同 ID 的先前消息在具有相同 ID 的新消息存储在 TX 队列中之前已成功传输。

对于 TX 队列,可以通过设置 TX 队列配置/控制寄存器的 TXQIE 位来启用专用中断。

中断模式可以用同一寄存器的CFDTXQCC。TXQIM比特来配置,以为每个发送的消息或为最后发送的消息生成中断。

配置后的TX队列传输请求过程如图26。49 .所示

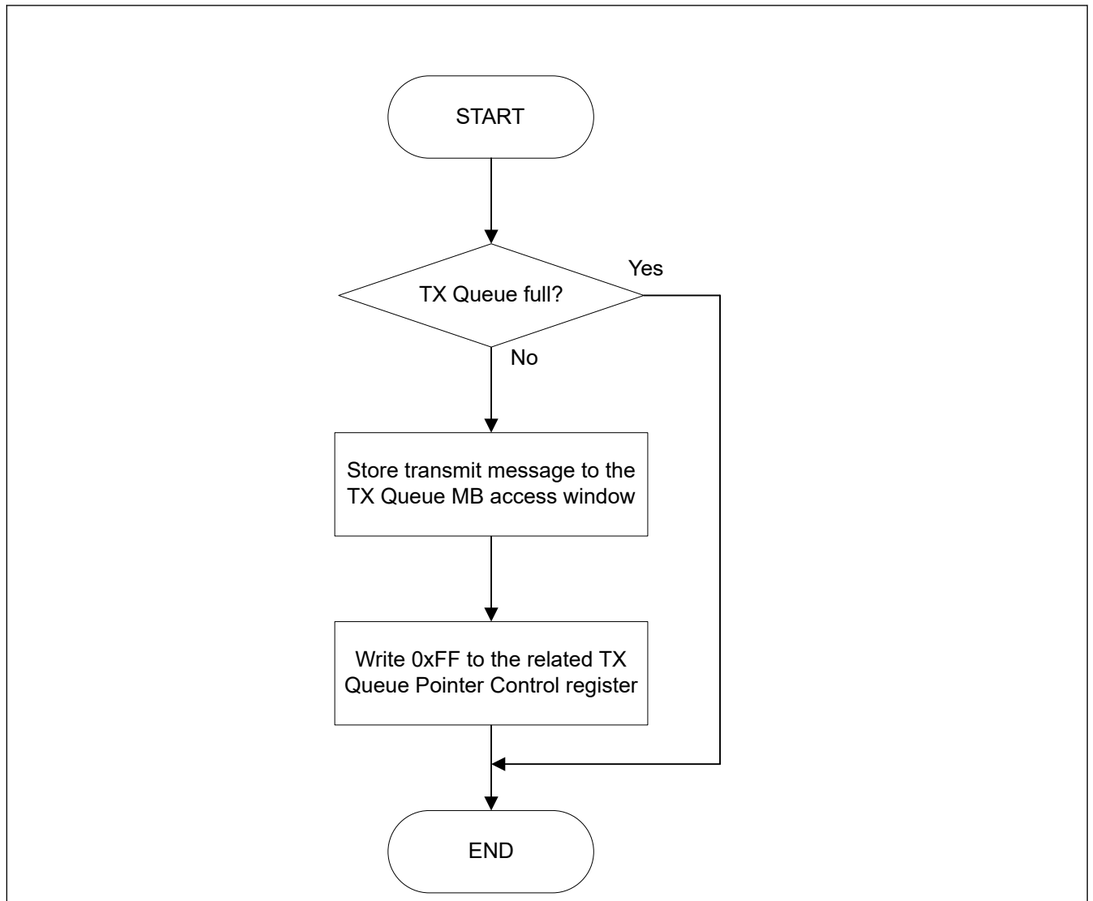

Figure 26.49 TX Queue transmission request

26.8.2.5 TX History List

The TX History List function records the information of the successfully transmitted message in the TX History List Buffers. Two TX History List buffers are provided and THL buffer can store up to 8 TX History List entries.

The CFDTHLCC.THLDTE bit of the TX History List Configuration/Control Register can be used to configure if only message information from TX FIFO or TX Queue is stored, or if all transmit message information from TX Queue, TX FIFO, or normal TX message buffers is stored in the TX History List.

Each transmit message can be individually configured for acceptance to the TX History List with the CFDCFID.THLEN bit in the Message Buffer Pointer Register.

The message information is stored to the TX History List Buffer of a CAN channel after the message is successfully transmitted.

Storing to the list is not synchronized with the status of CFDTMSTSj.TMTRF[1:0] bits in the TX Message Buffer Status Register.

Due to internal processing, the storage to the list can happen with a delay after the successful transmission indication.

Storing the TX History List data can be recognized by the condition that the THLIF is set to 1 when the THLIE bit is configured to 1 or when the TX History List counter CFDTHLSTS.THLMC[5:0] is increased.

In worst case when multi events like reception scan, internal message routing on happen.

26。8。2。5 德克萨斯州历史列表

TX 历史列表功能记录 TX 历史列表中成功传输的消息的信息
缓冲器。提供两个 TX 历史列表缓冲区,THL 缓冲区最多可存储 8 个 TX 历史列表条目。

TX 历史列表配置/控制寄存器的 CFDTHLCC。THLDTE 位可用于配置,前提是仅存储来自 TX FIFO 或 TX 队列的消息信息,或者如果所有传输来自 TX 队列、TX FIFO 或普通 TX 消息缓冲区的消息信息存储在 TX 历史列表中。

每个发送消息都可以单独配置为与消息缓冲器指针寄存器中的 CFDCFID。THLEN 位一起接受 TX 历史列表。

消息成功发送后,消息信息被存储到CAN信道的TX历史列表缓冲区。

存储到列表与 TX 消息缓冲区状态中的 CFDTMSTSj。TMTRF[1:0] 位的状态不同步
注册。

由于内部处理,列表的存储可能会在成功传输指示后延迟进行。

TX历史列表数据的存储可以通过以下条件来识别:当THLIE位配置为1时或者当TX历史列表计数器CFDTHLSTS。THLMC[5:0]增加时THLIF被设置为1。在最坏的情况下,当接收扫描等多事件发生时,就会发生内部消息路由。

- Maximum delay time from setting the CFDTMSTSj.TMTRF to store the TX History List data is 76 peripheral bus clock cycles.

The History list records the following information of a transmitted message:

- Buffer type:
  - 001: TX Message Buffer
  - 010: TX FIFO
  - 100: TX Queue
- Buffer number:
  TX message buffer, TX Queue message buffer or TX message buffer link for the Common FIFO buffer from which transmission occurred. The number depends on the buffer type. See Table 26.29.
- Transmission ID:
  Transmission pointer stored in the transmission message
- Transmit timestamp:
  Message timestamp captured at capture point as configured by CFDGFDCFG.TSCCFG.
- Transmission information label:
  Transmission information label stored in the transmission message.

Table 26.29 TX History List Buffer number entry

Buffer number	BT[2:0] Buffer type		
	001b TX Message Buffer	101b TX FIFO	100b TX Queue
00b	Message Buffer 0	Number shown corresponds to the common FIFO. TX Message Buffer Link CFTML of the related Common FIFO configuration	Number shown corresponds to the Message Buffer belonging to the TX Queue which the frame was transmitted
01b	Message Buffer 1		
10b	Message Buffer 2		
11b	Message Buffer 3		

The Transmission ID entry is used to identify which message of a TX FIFO or TX Queue has been successfully transmitted because the TX FIFO or TX Queue number alone is not sufficient.

Therefore, a unique number can be attached to each transmission message stored in a TX FIFO or TX Queue. This unique identification number should be written to the CFDCFFDCSTS.CFPTR[15:0] part of the Common FIFO Access Pointer Register for a TX FIFO or to the CFDTMFDCTRb.TMPTR[15:0] part of the TX Message Buffer Pointer Register of the TX Queue access window message buffer.

When the message is successfully transmitted, this identification number is stored together with the other message related information to the TX History List and can be read using the Transmission ID (TID) of the TX History List Access Register.

Also, for normal TX message buffers, the CFDTMFDCTRb.TMPTR[15:0] part of the TX Message Buffer Pointer Register is stored in the Transmission History List and the information label is the same.

Figure 26.50 shows a transmission preparation flow when TX History List is used.

Read access to the TX History List Access Register is done for every single entry.

After reading one entry, 0xFF must be written to the corresponding TX History List Pointer Control Register to be able to access the next entry until TX History List is empty.

Figure 26.51 shows an example flow for processing the TX History List information.

The TX History Lists have dedicated interrupts, which can be configured with the CFDTHLCC.THLIM bit of the corresponding TX History List Configuration/Control Register and enabled with the CFDTHLCC.THLIE bit of the same registers, either to generate an interrupt when the History List reached a filling level of 75% or for every new TX History List entry.

An entry lost indication is flagged by the CFDTHLSTS.THLELT bit in the TX History List Status Register. The status of this bit is also shown by the THLES bit in the Global Error Flag Register.

- 从设置 CFDTMSTSj。TMTRF 到存储 TX 历史列表数据的最大延迟时间为 76 个外围总线时钟周期。

- 传输时间戳:
  CFDGFDCFG。TSCCFG 配置的捕获点捕获的消息时间戳。

传输 ID 条目用于识别 TX FIFO 或 TX 队列的哪条消息已成功传输,因为仅 TX FIFO 或 TX 队列号是不够的。

因此,可以将唯一的号码附加到存储在TX FIFO或TX队列中的每个传输消息。该唯一标识号应写入 TX FIFO 通用 FIFO 接入指针寄存器的 CFDCFFDCSTS。CFPTR[15:0] 部分或 TX 的 CFDTMFDCTRb。TMPTR[15:0] 部分

当消息成功传输时,该识别号与其他消息相关信息一起存储到TX历史列表,并且可以使用TX历史列表访问寄存器的传输ID（TID）来读取。此外,对于普通的TX消息缓冲区,TX消息缓冲区指针寄存器的CFDTMFDCTRb。TMPTR[15:0] 部分存储在传输历史列表中并且信息标签是相同的。

图 26。50 显示了使用 TX 历史列表时的传输准备流程。

读取一个条目后,必须将 0xFF 写入相应的 TX 历史列表指针控制寄存器才能访问下一个条目,直到 TX 历史列表为空。

26.8.2.6 TX Data Padding

This chapter is not valid for classical CAN.

If the data length code (DLC) of the transmitting message has a higher number of data bytes than the buffer size, the data bytes beyond the restricted range are replaced by bytes with the value of 0xCC.

This can happen for Common FIFO configured as (TX mode) when the transmit message DLC is higher than the CFDCFCC.CFPLS.

This can also happen in FD only mode, if a Classical frame is configured with a DLC bigger than 8.

26.9 Test Mode

The CANFD module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CANFD module in test modes.

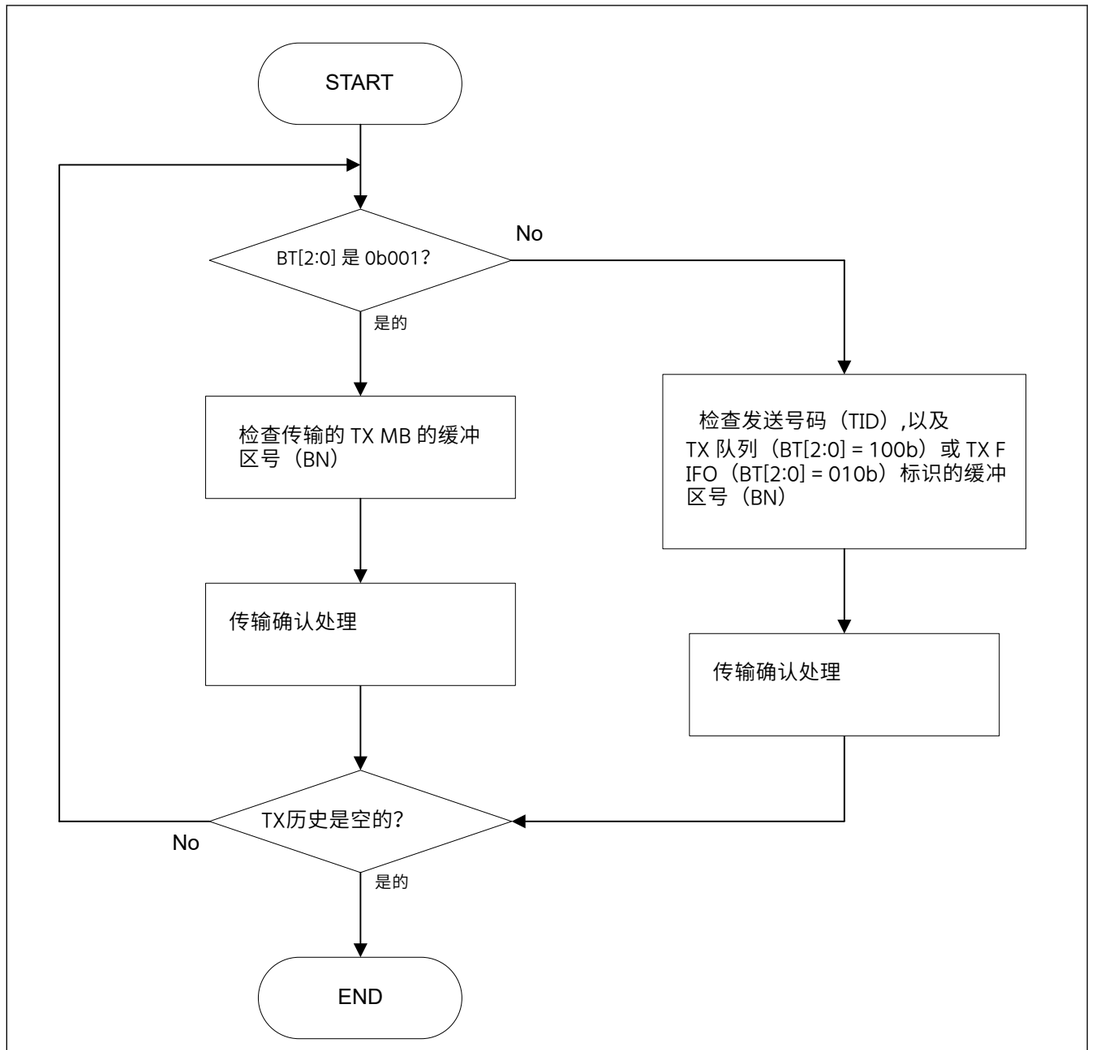

图26。51 TX历史列表处理流程

26.8.2.6 TX 数据填充

本章对于经典 CAN 不有效。

如果发送消息的数据长度码（DLC）的数据字节数高于缓冲区大小,则超出限制范围的数据字节被值为0xCC的字节替换。

当发送消息DLC高于CFDCFCC。CFPLS时,配置为（TX模式）的通用FIFO可能会发生这种情况。

如果经典帧配置的 DLC 大于 8,则这也可能发生在仅 FD 模式下。

26。9 测试模式

CANFD模块可以配置为测试模式,以允许测试某些功能。这些功能仅用于特殊目的,在测试模式下配置 CANFD 模块时必须小心。

Note: All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combination of the various test modes specified in this section.

The test modes can be broadly split into 2 groups:

- Channel specific test modes
- Global test modes.

26.9.1 Channel Specific Test Modes

CAN channel can be configured into the following test modes:

- Basic test mode
- Listen-only mode
- Self-test mode 0 (External loop back mode)
- Self-test mode 1 (Internal loop back mode)
- Restricted operation mode.

26.9.1.1 Basic Test Mode

The basic test mode should be used when there is requirement for a particular test setting to be enabled other than when in Listen-only and Self-test modes.

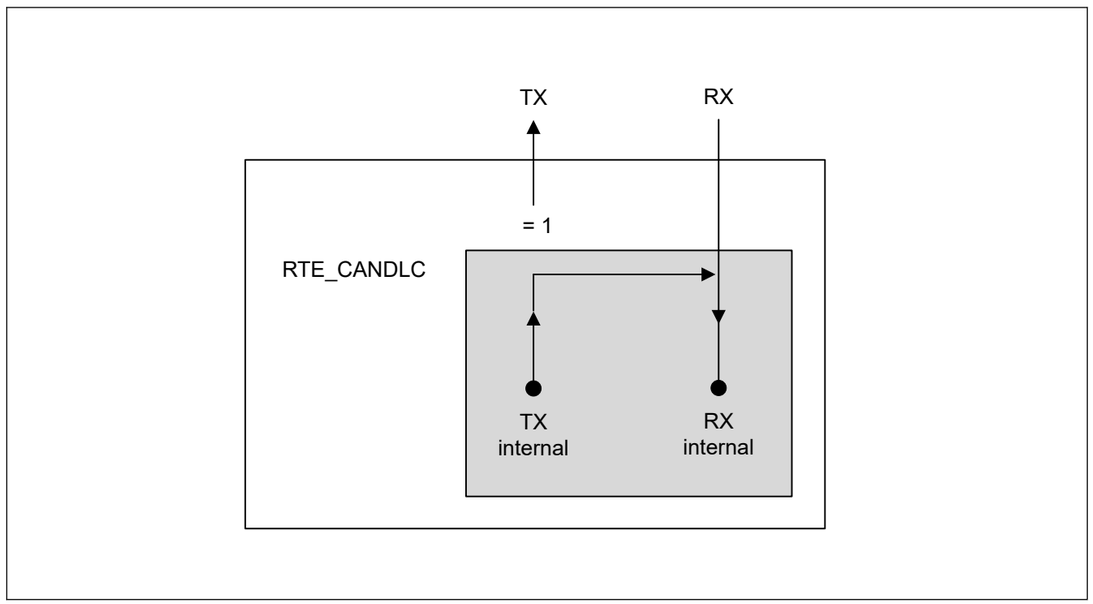
26.9.1.2 Listen-only Mode

The ISO 11898-1 recommends an optional bus-monitoring mode. In this mode, the CAN channel is able to receive valid data frames and valid remote frames. However, it sends only recessive bits on the CAN bus and is not allowed to transmit.

If the CAN engine is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is routed internally so that the CAN engine monitors this as dominant. The external TX pin remains in recessive state.

This mode can be used for baud rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.

In this mode, it is not permitted to request transmission from any normal TX message buffer or TX FIFO.



注意:所有测试模式都是相互排斥的,除非明确说明某些功能可以在其他测试模式上启用。

请勿启用本节中指定的各种测试模式的任何组合。

测试模式可大致分为 2 组:

- 通道特定测试模式
- 全局测试模式。

通道特定测试模式 CAN 通道可配置为以下测试模式:

- 基本测试模式
- 只听模式
- 自检模式 0（外部循环返回模式）
- 自检模式1（内部回环模式）
- 限制操作模式。

26.9.1.1 基本测试模式

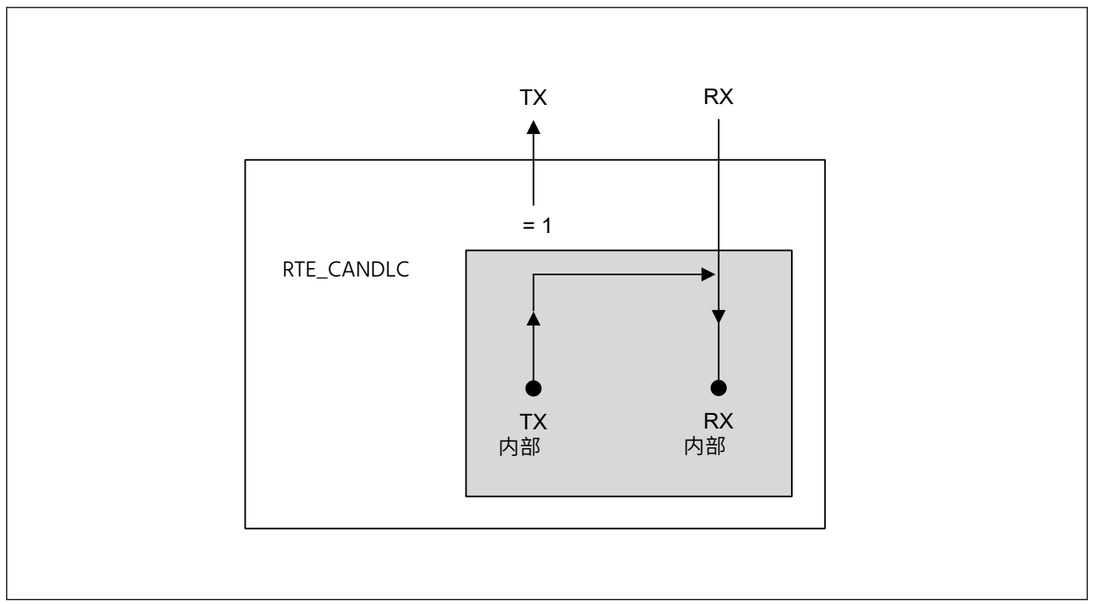
当需要启用特定测试设置时,除非处于只听和自检模式,否则应使用基本测试模式。

26。9。1。2 只听模式

ISO 11898-1 建议采用可选的总线监控模式。在此模式下,CAN通道能够接收有效的数据帧和有效的远程帧。但是,它只在 CAN 总线上发送隐性位,不允许传输。如果需要 CAN 引擎发送主导位（ACK 位、过载标志、主动错误标志）,则该位将在内部路由,以便 CAN 引擎将其监控为主导位。外部 TX 引脚保持隐性状态。

该模式可用于波特率检测。在此模式下,如果发生总线错误并且启用中断,则会生成错误中断。

在此模式下,不允许请求来自任何普通 TX 消息缓冲区或 TX FIFO 的传输。

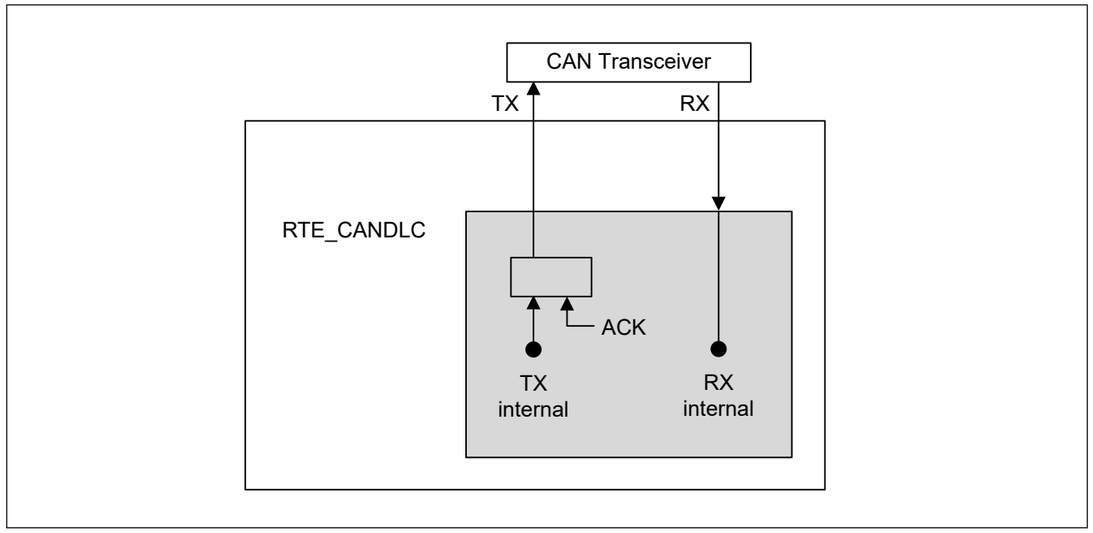


26.9.1.3 Self-test Mode 0 (External loopback mode)

In Self-test mode 0, the CAN engine treats its own transmitted messages as received messages through the CAN transceiver and stores them into its receive message buffers.

To be independent from external stimulation, the engine generates its own Acknowledge bit.

This test can be used for CAN transceiver tests and the RX/TX pins should be connected to the transceiver.



26.9.1.4 Self-test Mode 1 (Internal loopback mode)

In Self-test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent from external stimulation, the CAN engine generates its own Acknowledge bit. In this mode the CAN engine performs an internal feedback from TX internal to RX internal. The actual value of the external RX input is disregarded by the CAN engine.

The external TX pin outputs only recessive bits. The RX/TX pins do not need to be connected to the CAN bus or any external device.

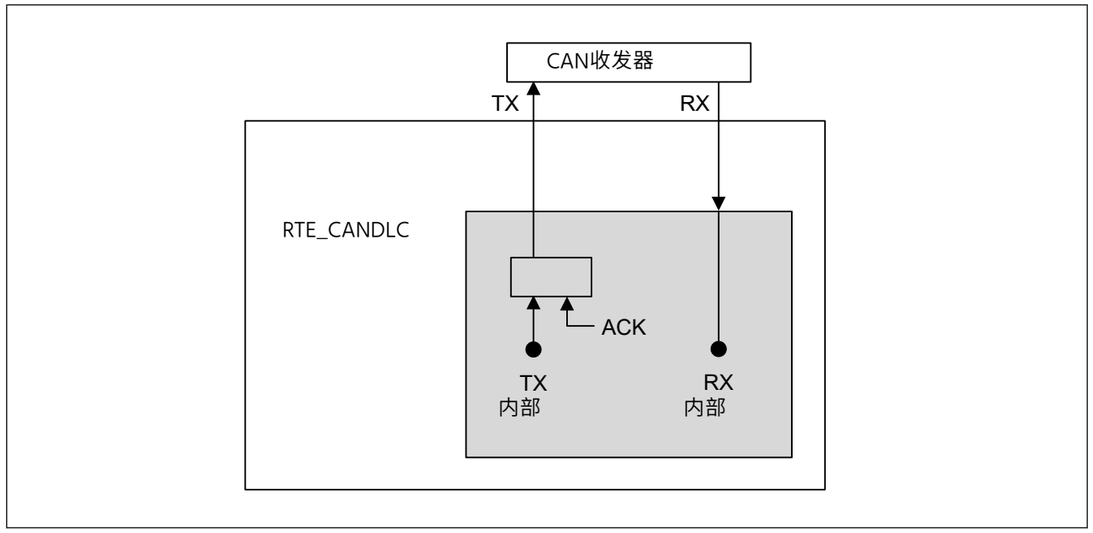
Note: The channel pins are also disconnected from the internal CAN bus communication line.

26。9。1。3 自检模式0（外部回环模式）

Self-test模式0中,CAN引擎将自身传输的消息视为通过CAN收发器接收到的消息,并将它们存储到其接收消息缓冲区中。

为了独立于外部刺激,发动机会生成自己的确认位。

该测试可用于 CAN 收发器测试,并且 RX/TX 引脚应连接到收发器。

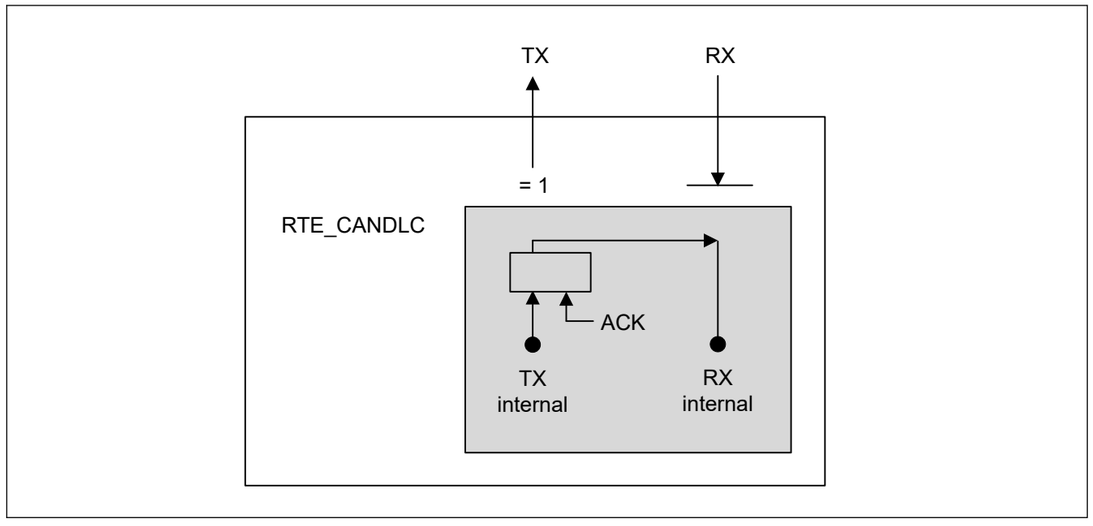


26。9。1。4 自检模式1（内部回环模式）

Self-test模式1中,CAN引擎将自身传输的消息视为接收到的消息,并将它们存储到接收缓冲区中。该模式是为自检功能提供的。为了独立于外部刺激,CAN 引擎会生成自己的确认位。在此模式下,CAN 引擎执行从 TX 内部到 RX 内部的内部反馈。CAN引擎忽略了外部RX输入的实际值。

外部 TX 引脚仅输出隐性位。RX/TX引脚不需要连接到CAN总线或任何外部设备。

注意:通道引脚也与内部 CAN 总线通信线路断开。



26.9.1.5 Restricted Operation Mode

This chapter is not valid for classical CAN.

In Restricted operation mode, the CAN node is able to receive valid data and remote frames generating the Acknowledge bit.

Active error or overload frames cannot be transmitted, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.

Additionally, the Receive and Transmit Error Counter (REC and TEC) are frozen independently from the occurrence of errors. The mode is specified in ISO 11898-1 and the setting of transmit request is permitted.

26.9.2 Global Test Modes

The CANFD module can be configured into the following test modes:

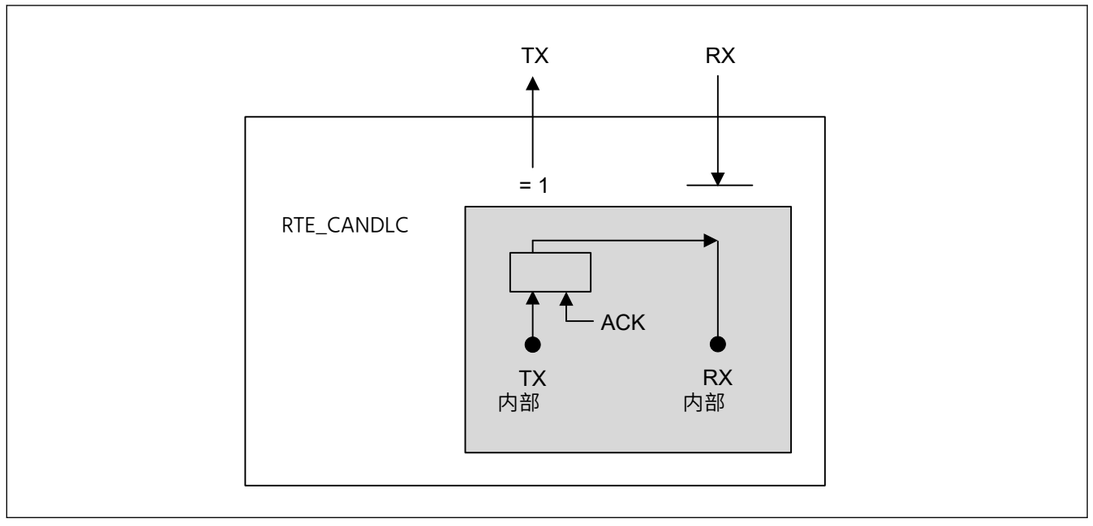
- RAM test mode
- Bit Flip Test

The test modes in the following table are protected by a special software procedure to enable the mode. This software procedure enables write access to the test mode by a specific unlock key as shown in the table.

Test mode	Unlock key 1	Unlock key 2
RAM test mode	0x7575	0x8A8A

If the software sequence of the two consecutive unlock key write accesses (half-word or word access) is interrupted by any other write access to the register or if incorrect data is written to the Global Unlock Key Register, the corresponding test mode cannot be set and the sequence must be restarted.

After the two unlock key write accesses, the next write access should be to set the corresponding test mode enable bit. If this is not followed, the unlock mechanism reset and the test mode enable bit cannot be set and the unlock sequence must be restarted.



26。9。1。5 限制操作模式

本章对于经典 CAN 不有效。

在受限操作模式下,CAN节点能够接收生成确认位的有效数据和远程帧。

主动错误或过载帧无法传输,而是等待总线空闲条件的发生,在发生错误或过载条件后重新同步到CAN通信。

此外,接收和发送错误计数器（REC 和 TEC）独立于错误的发生而被冻结。ISO 11898-1 中指定了模式,并允许设置传输请求。

26。9。2 全局测试模式

CANFD模块可以配置为以下测试模式:

- RAM 测试模式
- 位翻转测试

下表中的测试模式受到特殊软件程序的保护以启用该模式。该软件过程允许通过特定解锁键写入测试模式,如表所示。

测试模式	解锁钥匙 1	解锁钥匙2
RAM 测试模式	0x7575	0x8a8a

如果连续两个解锁密钥写入访问（半字或字访问）的软件序列被寄存器的任何其他写入访问打断,或者如果将不正确的数据写入全局解锁密钥寄存器,则无法设置相应的测试模式并且必须重新启动序列。

2次解锁键写访问后,下一次写访问应该是设置相应的测试模式使能位。如果不遵循此操作,则无法设置解锁机制重置和测试模式启用位,并且必须重新启动解锁序列。

26.9.2.1 RAM Test Mode

The CANFD module can be configured in RAM test mode by setting the CFDGTSTCTR.RTME bit in the Global Test Control Register when the corresponding lock key is previously written. This is a special test mode, in which, the complete RAM area can be accessed.

Note: The actual RAM size is bigger than the RAM area initialized after a hardware reset. Therefore, ECC error flag (of the ECC macro) may be set if CPU reads data from this uninitialized RAM area while CANFD module is in RAM test mode.

In this mode, the RAM area is split into number of pages (pn) of 256 bytes, each which can be accessed with the CFDRPGACCk register.

The page should be selected for read/write access by writing to the CFDGTSTCFG.RTMPS[3:0] bits in the Global Test Control Register. Data can then be read from or written in to the RAM Test Page Access Registers.

Figure 26.53 shows the structure of the pages in the RAM when performing a RAM test mode.

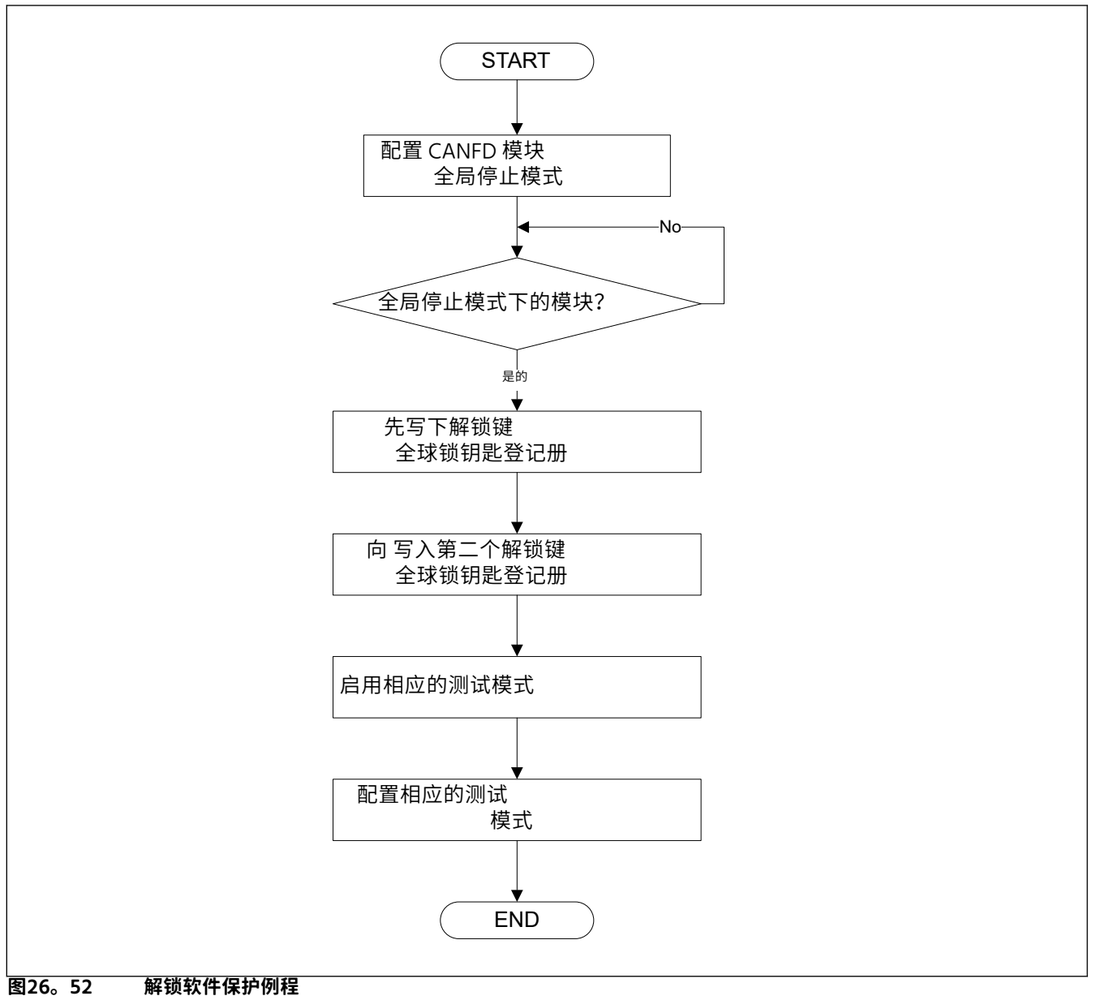

图26。52 解锁软件保护例程

26。9。2。1 RAM 测试模式

当预先写入相应的锁定密钥时,可以通过在全局测试控制寄存器中设置CFDGTSTCTR。RTME位来将CANFD模块配置为RAM测试模式。这是一种特殊的测试模式,可以访问完整的RAM区域。

注意:实际 RAM 大小大于硬件重置后初始化的 RAM 区域。因此,如果CPU从该未初始化的RAM区域读取数据而CANFD模块处于RAM测试模式,则可以设置（ECC宏的）ECC错误标志。

在此模式下,RAM 区域被分成 256 个字节的页数（pn）,每个字节都可以使用 CFDRPGACCk 寄存器访问。

应通过写入全局测试控制寄存器中的 CFDGTSTCFG。RTMPS[3:0] 位来选择该页面进行读/写访问。然后可以将数据从 RAM 测试页面访问寄存器读取或写入。

图26。53示出了执行RAM测试模式时RAM中的页面的结构。

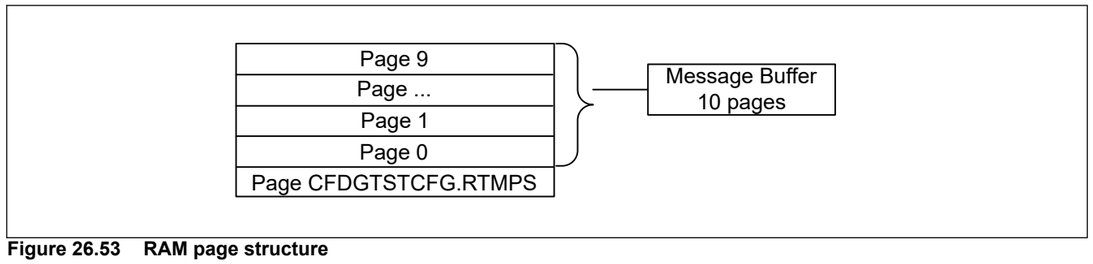

Figure 26.53 RAM page structure

The total available RAM size is 2328 bytes for the Message Buffer RAM.

The pn and CFDGTSTCFG.RTMPS[3:0] values for the MB RAMs are calculated in the following way:

pn = ceil (total RAM size in bytes / number of bytes per page)

- MB RAM:
  pn = ceil (2328 / 256) = 10 pages
  CFDGTSTCFG.RTMPS[3:0] = 0 to 9 inclusive

Figure 26.54 shows the software flow for RAM test mode.

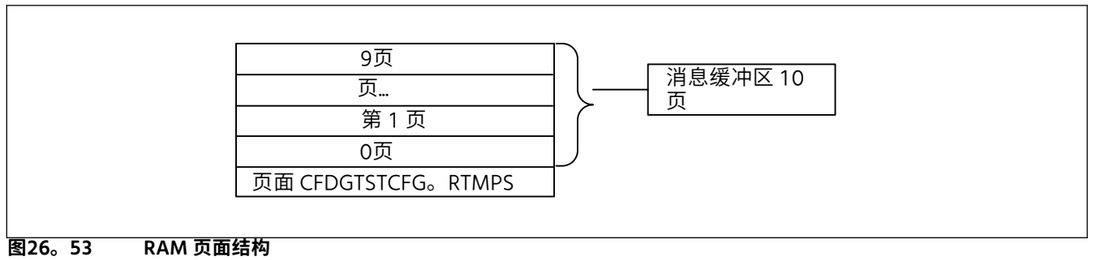

图26。53 RAM 页面结构

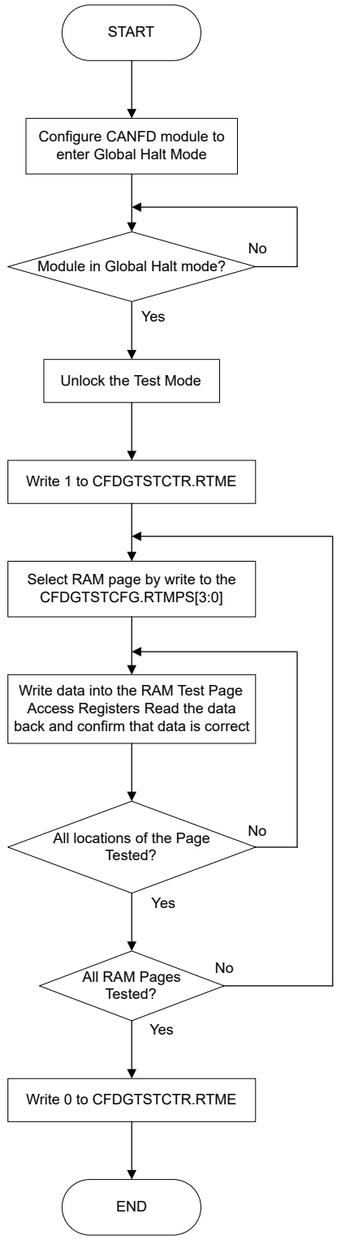
消息缓冲区 RAM 的总可用 RAM 大小为 2328 字节。

MB RAM 的 pn 和 CFDGTSTCFG。RTMPS[3:0] 值按以下方式计算:pn = 上限（总 RAM 大小（以字节为单位）/每页字节数）

- MB RAM:
  pn = 上限 (2328 / 256) = 10 页 CFDGTSTCF
  G。RTMPS[3:0] = 0 至 9（含）

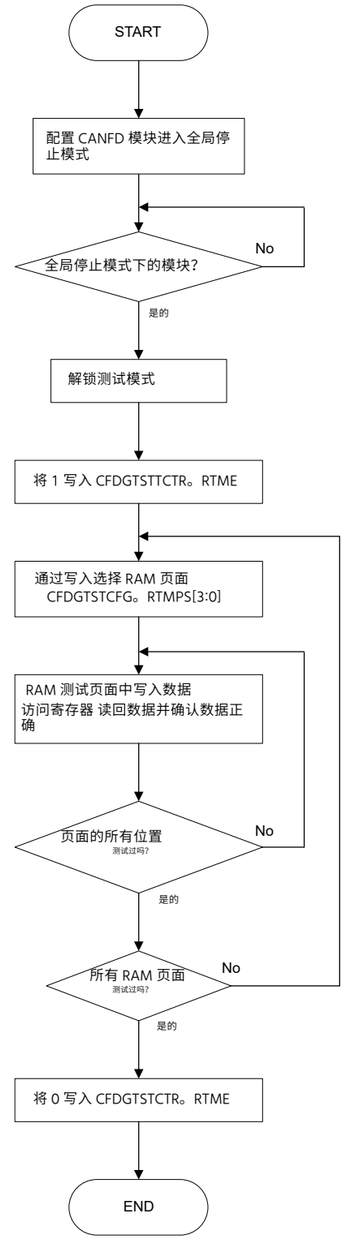
图 26。54 显示了 RAM 测试模式的软件流程。



Note 1. Change into the following status before changing to RAMTEST.
- Cancel of a request for transmission.
- Disable of all the FIFO and TXQ.
- Clear of the receiving flag for a receiving buffer.

Figure 26.54 Software flow for RAM test mode

To exit this test mode, the CFDGTSTCTR.RTME bit must be cleared. The CFDGTSTCTR.RTME bit is cleared by writing 0 to it.



注1。更改为 RAMTEST 之前更改为以下状态。
- 取消传输请求。
- 禁用所有 FIFO 和 TXQ。
- 清除接收缓冲区的接收标志。

图26。54 RAM 测试模式的软件流程

要退出此测试模式,必须清除 CFDGTSTCTR。RTME 位。CFDGTSTCTR。RTME 位通过写入清除0到它。

The CFDGTSTCTR.RTME bit is cleared automatically when the CANFD module enters Global Reset mode from the test mode.

26.9.2.2 Bit Flip Test

Bit Flip Test can invert the bit (the 1st bit of ID) of the beginning of the bit stream to receive.

If this function is used by a transmitting node, a bit error or an arbitration lost will occur.

If this function is used by a receiving node, a CRC error or a stuff error will occur.

Users should refer to the bit stuffing rule when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The following sequence should be used to perform CRC Error testing. In the sequence below CANFD module is the receiver.

1. Set the CFDC0CTR.BFT bit to 1, in order to invert the first bit of the incoming bit stream from sending node.
2. Wait for the can_cherr_int output signal to set to 1.
3. Read either the CFDC0ERFL.CRCREG or the CFDC0FDCRC.CRCREG (depending on the received frame type: Classical or FD). The value should be different from the received CRC value of the reference message from sending node.
4. Check that CFDC0ERFL.CERR is 1.

As the CRC generator logic is shared for RX and TX there is no need to create a separate TX CRC Error test.

当CANFD模块从测试模式进入全局重置模式时,CFDGTSTCR。RTME位被自动清除。

26。9。2。2 位翻转测试

位翻转测试可以反转要接收的位流开头的位（ID 的第 1 位）。

如果发送节点使用此函数,则会发生误码或仲裁丢失。

如果接收节点使用此函数,则会发生 CRC 错误或东西错误。

用户在使用此功能时应参考位填充规则,因为可能会收到填充错误（由于反转）而不是 CRC 错误。

应使用以下序列来执行 CRC 错误测试。CANFD 模块下面的顺序是接收器。

1。将CFDC0CTR。BFT比特设置为1,以便将输入比特流的第一比特从发送节点反转。

2锛姣涓涓。等can_cherr_int输出信号设置为1。

3锛　　娴　　。读取 CFDC0ERFL。CRCREG 或 CFDC0FDCRC。CRCREG（取决于接收到的帧类型:古典或FD）。该值应当与从发送节点接收到的参考消息的CRC值不同。

4锛姣涓。检查 CFDC0ERFL。CERR 是 1。

由于 CRC 生成器逻辑是 RX 和 TX 共享的,因此无需创建单独的 TX CRC 错误测试。

27. CANFD ECC (CNECC)

27.1 Overview

MBRAM have ECC function of 2-bit ECC error detection and 1-bit ECC error detection and correction*1. The ECC module adds 7 bits ECC data to 32 bits RAM data.

Note 1. The ECC module cannot detect 3 or more bits error. In this case, the ECC module detects 1-bit or 2-bit error, does not detect errors, or corrects the erroneous bit to erroneous data by setting. When all RAM data are fixed to 0 or 1, it is detected as 2-bit ECC error.

ECEMF bit (ECC Error Message Flag)

The ECEMF bit shows that there is error in present read data bus. This bit is updated by every RAM output data.

When RAM output data is undefined and the ECERVF bit is set to 1, the value of this bit is undefined.

[Setting condition]

There is bit error in present RAM output data under the condition that error judgement is enabled.

[Clearing condition]

- Under the condition that there is no 1-bit error in input data to decode circuit
- When ECC error judgement is disabled (ECERVF = 0).

ECER1F bit (ECC Error Detection and Correction Flag)

The ECER1F bit shows that the bit errors are detected in the one part of RAM read data [38:0] at RAM read access when the error judgment is enabled.

When the 1-bit error interrupt output is enabled, error interrupt is generated by setting this flag.

This bit is read-only, so writing 1 or 0 has no effect.

At clearing, write 1 to the ECER1C bit.

When 1-bit error is detected again under the condition that this bit is set, the interrupt is not generated.

[Setting condition]

When the error judgment is enabled and there is 1-bit error to RAM output data (when not setting ECER1C = 1).

[Clearing condition]

- Writing ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

ECER2F bit (2-bit ECC Error Detection Flag)

The ECER2F bit shows that the bit errors are detected in the two parts of RAM read data [38:0] at RAM read access when the error judgment is enabled.

When the 2-bit error interrupt output is enabled, error interrupt is generated by setting this flag.

This bit is read-only, so writing 1 or 0 has no effect.

At clearing, write 1 to the ECER2C bit.

When 2-bit error is detected again under the condition that this bit is set, the interrupt is not generated.

[Setting condition]

When the error judgment is enabled and there is 2-bit error to RAM output data (when not setting ECER2C = 1).

[Clearing condition]

ECEMF 位（ECC 错误消息标志）

ECEMF 位显示当前读取数据总线存在错误。该位由每个 RAM 输出数据更新。

RAM 输出数据未定义且 ECERVF 位设置为 1 时,该位的值未定义。

的【设置条件】

在启用错误判断的条件下,当前 RAM 输出数据存在误码。

的【清零条件】

- 在输入数据没有 1 位错误的条件下进行电路解码
- 当 ECC 错误判断被禁用时（ECERVF = 0)。

ECER1F 位（ECC 错误检测和校正标志）

ECER1F位显示,在启用错误判断时,在RAM读取访问的RAM读取数据[38:0]的一部分中检测到位错误。

1 位错误中断输出启用时,通过设置此标志生成错误中断。

该位是只读的,因此写入 1 或 0 没有效果。

清除时,将 1 写入 ECER1C 位。

1位元错误在设定此位元的条件下再次侦测到时,则不会产生中断。

的【设置条件】

当启用错误判断并且 RAM 输出数据存在 1 位错误时（不设置 ECER1C = 1 时）。

的【清零条件】

- 编写 ECER1C = 1
- 当 ECC 错误判断被禁用时（ECERVF = 0)。

ECER2F 位(2 位 ECC 错误检测标志)

ECER2F位显示,在启用错误判断时,在RAM读取访问处RAM读取数据[38:0]的两部分中检测到位错误。

2 位错误中断输出启用时,通过设置此标志生成错误中断。

该位是只读的,因此写入 1 或 0 没有效果。

清除时,将 1 写入 ECER2C 位。

2位元错误在设定此位元的条件下再次侦测时,则不会产生中断。

的【设置条件】

当启用错误判断并且 RAM 输出数据存在 2 位错误时（不设置 ECER2C = 1 时）。

的【清零条件】

- Writing ECER2C = 1
- When ECC error judgement is disabled (ECERVF = 0).

EC1EDIC bit (ECC 1-bit Error Detection Interrupt Control)

The EC1EDIC controls the interrupt output at detecting 1-bit error. By setting 1 to this bit, the 1-bit error interrupt is outputted when 1-bit error detected.

EC2EDIC bit (ECC 2-bit Error Detection Interrupt Control)

The EC2EDIC controls the interrupt output at detecting 2-bit error. By setting 1 to this bit, the 2-bit error interrupt is outputted when 2-bit error detected.

EC1ECP bit (ECC 1-bit Error Correction Permission)

The EC1ECP sets enable or disable to correct the 1-bit error when ECC error detection and correction is valid. By setting 1 to this bit, the non-corrected data is outputted if 1-bit error is detected.

ECERVF bit (ECC Error Judgment Enable Flag)

Setting the ECERVF bit to 1 enables the judgment of error. The correction of output data and the interrupt output depend on setting of the EC1ECP bit, EC2EDIC bit, and EC1EDIC bit.

The write access to this bit is valid when the write value of the EMCA[1:0] is 01b. So only the 16 bits or 32 bits operation command is valid in the case of the write access to this bit.

ECER1C bit (Accumulating ECC Error Detection and Correction Flag Clear)

The ECER1C bit clears the status flag of the ECER1F bit.

The read value is always 0. By writing 0, the internal condition is not changed. When the competition between writing 1 to this bit and setting the ECER1F bit, the former has priority.

The ECER1F bit is cleared by writing 1 to this bit while the ECER1F bit is set. Additionally, the Overflow Detection flag (ECOVFF), ECC Dual Bit Error flag (ECDEDF0) and ECC Single Bit Error flag (ECSEDF0) are also cleared.

ECER2C bit (2-bit ECC Error Detection Flag Clear)

The ECER2C bit clears the status flag of the ECER2F bit.

The read value is always 0. By writing 0, the internal condition is not changed. When the competition between writing 1 to this bit and setting the ECER2F bit, the former has priority.

The ECER2F bit is cleared by writing 1 to this bit while the ECER2F bit is set. Additionally, the Overflow Detection flag (ECOVFF), ECC Dual Bit Error flag (ECDEDF0), and ECC Single Bit Error flag (ECSEDF0) are also cleared.

ECOVFF bit (ECC Overflow Detection Flag)

The ECOVFF bit is set and the overflow interruption is outputted by detecting the new error address under the condition that error address is already captured in the EC710EAD0 register. The overflow interrupt is outputted again when this bit is set and new error is detected.

This bit is read-only, so writing 1 or 0 has no effect.

To clear this bit, write 1 to the ECER2C bit and the ECER1C bit.

[Setting condition]

When new error address is captured under the condition that error address is already captured in the EC710EAD0 register (when not setting ECER2C = 1 or ECER1C = 1).

[Clearing condition]

- Writing ECER2C = 1 or ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

EMCA[1:0] bit (Access Control to ECC Mode Select bit)

The EMCA[1:0] bits are the write trigger reserved bits to the ECERVF bit. The read value is always 0. When the value of these bits is 01b, it is possible to have write access to the ECERVF bit. If these bits are not 01b, write access to the ECERVF bit is ignored and the value is not written.

- 编写 ECER2C = 1
- 当 ECC 错误判断被禁用时（ECERVF = 0)。

EC1EDIC 位（ECC 1 位错误检测中断控制）

EC1EDIC 在检测到 1 位错误时控制中断输出。1 设置为该位,则在检测到 1 位错误时输出 1 位错误中断。

EC2EDIC 位（ECC 2 位错误检测中断控制）

EC2EDIC 在检测到 2 位错误时控制中断输出。通过将 1 设置为该位,当检测到 2 位错误时,会输出 2 位错误中断。

EC1ECP 位（ECC 1 位纠错权限）

EC1ECP 集在 ECC 错误检测和纠正有效时启用或禁用纠正 1 位错误。通过将 1 设置为该位,如果检测到 1 位错误,则输出未校正的数据。

ECERVF 位（ECC 错误判断启用标志）

将 ECERVF 位设置为 1 可以判断错误。输出数据的校正和中断输出取决于EC1ECP位、EC2EDIC位和EC1EDIC位的设置。

EMCA[1:0]的写值为01b时,对该位的写访问是有效的。因此,只有 16 位或 32 位操作命令在该位写访问的情况下有效。

ECER1C 位（累积 ECC 错误检测和校正标志清除）

ECER1C 位清除 ECER1F 位的状态标志。

读取值始终为 0。0写入,内部条件不改变。1写入该位与设置ECER1F位之间的竞争时,前者具有优先权。

ECER1F位在ECER1F位被设置时通过写入1到该位来清除ECER1F位。此外,溢出检测标志（ECOVFF）、ECC双位错误标志（ECDEDF0)和ECC单位错误标志（ECSEDF0)也被清除。

ECER2C 位(2 位 ECC 错误检测标志清除）

ECER2C 位清除 ECER2F 位的状态标志。

读取值始终为 0。0写入,内部条件不改变。1写入该位与设置ECER2F位之间的竞争时,前者具有优先权。

ECER2F位被设置为ECER2F位时,通过写入1到该位来清除ECER2F位。此外,溢出检测标志（ECOVFF）、ECC双位错误标志（ECDEDF0)和ECC单位错误标志（ECSEDF0)也被清除。

ECOVFF 位（ECC 溢出检测标志）

ECOVFF位进行设置,在EC710EAD0寄存器中已经捕获错误地址的情况下,通过检测新的错误地址来输出溢出中断。当设置该位并检测到新错误时,溢出中断将再次输出。

该位是只读的,因此写入 1 或 0 没有效果。

要清除该位,请将 1 写入 ECER2C 位和 ECER1C 位。

的【设置条件】

EC710EAD0寄存器中已经捕获错误地址的条件下捕获新的错误地址时（当未设置ECER2C = 1或ECER1C = 1时）。

的【清零条件】

- 写入 ECER2C = 1 或 ECER1C = 1
- 当 ECC 错误判断被禁用时（ECERVF = 0)。

EMCA[1:0] 位（访问控制到 ECC 模式选择位）

EMCA[1:0] 位是 ECERVF 位的写触发保留位。读取值始终为 0。当这些位的值为01b时,可以对ECERVF位进行写访问。如果这些位不是 01b,则忽略对 ECERVF 位的写访问并且不写入该值。

ECSEDF0 bit (ECC Single bit Error Address Detection Flag)

The ECSEDF0 bit shows that the error is captured in the error address register when error detection is valid. This bit is set by 1-bit error detection.

When 1-bit error is detected after the 2-bit error address is already captured in the EC710EAD0 register, this bit is not updated but the EC710EAD0 register is updated.

This bit is read-only, so writing 1 or 0 has no effect. To clear these bits, write 1 to the ECER1C bit.

[Setting condition]

When there is 1-bit error to RAM output data and error address is captured in EC710EAD0 under the condition that the error judgment is permitted (when not setting ECER1C = 1).

[Clearing condition]

- Writing ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

ECDEDF0 bit (ECC Dual Bit Error Address Detection Flag)

The ECDEDF0 bit shows that the error is captured in the error address register when error detection is valid. This bit is set by 2-bit error detection.

When 2-bit error is detected after the 1-bit error address is already captured in the EC710EAD0 register, this bit is not updated and the EC710EAD0 register is updated.

This bit is read-only, so writing 1 or 0 has no effect. To clear these bits, write 1 to the ECER2C bit.

[Setting condition]

When there is 2-bit error to RAM output data and error address is captured in EC710EAD0 under the condition that the error judgment is permitted (when not setting ECER2C = 1).

[Clearing condition]

- Writing ECER2C = 1
- When ECC error judgement is disabled (ECERVF = 0).

ECSEDF0 位（ECC 单位错误地址检测标志）

ECSEDF0 位显示错误检测有效时,错误地址寄存器中捕获错误。该位由 1 位错误检测设置。

EC710EAD0寄存器中已经捕获2位错误地址后检测到1位错误时,该位不更新但更新EC710EAD0寄存器。

该位是只读的,因此写入 1 或 0 没有效果。要清除这些位,请将 1 写入 ECER1C 位。

的【设置条件】

RAM 输出数据有 1 位错误时,在允许错误判断的条件下（不设置 ECER1C = 1 时）在 EC710EAD0 中捕获错误地址。

的【清零条件】

- 编写 ECER1C = 1
- 当 ECC 错误判断被禁用时（ECERVF = 0)。

ECDEDF0 位（ECC 双位错误地址检测标志）

ECDEDF0位显示错误检测有效时,错误地址寄存器中捕获错误。该位由 2 位错误检测设置。

EC710EAD0 寄存器中已经捕获了 1 位错误地址后检测到 2 位错误时, 该位不会更新, EC710EAD0 寄存器也会更新。

该位是只读的,因此写入 1 或 0 没有效果。要清除这些位,请将 1 写入 ECER2C 位。

的【设置条件】

RAM 输出数据有 2 位错误时,在允许错误判断的条件下（不设置 ECER2C = 1 时）在 EC710EAD0 中捕获错误地址。

的【清零条件】

- 编写 ECER2C = 1
- 当 ECC 错误判断被禁用时（ECERVF = 0)。

ECDCS bit (ECC Decode Input Select)

The ECDCS bit selects either the lower 32 bits data value from RAM or value from the internal test register (EDEDB[31:0] in EC710TED) as input signal to decoder.

The write access to this bit is valid under the condition of ECTMCE = 1 (it is possible to set them at the same time.)

This bit is cleared by setting ECTMCE = 0.

ECTMCE bit (ECC Test Mode Control Enable)

The ECTMCE bit selects the access enable or disable to test register and test control bit.

The write access to this bit is valid under the condition that the value of the ETMA[1:0] bits is 10b.

ETMA[1:0] bits (ECC Test Mode Bit Access Control)

The ETMA[1:0] bits are the write trigger reserved bits to the ECTMCE bit. The read value is always 0. When the value of these bits is 10b, it is possible to have write access to the ECTMCE bit. If these bits are not 10b, the write access to the ECTMCE bit is ignored and the value is not written.

27.2.3 EC710TED : ECC Test Substitute Data Register

When ECDCS in EC710TMC register is 1, the value of this register is bits [31:0] of the input data to the decode circuit.

27.2.4 EC710EAD0 : ECC Error Address Register

Base address: ECCMB = 0x4012_F200

Offset address: 0x10

ECDCS 位（ECC 解码输入选择）

ECDCS 位从 RAM 中选择较低的 32 位数据值或从内部测试寄存器（EC710TED 中的 EDEDB[31:0])中选择值作为解码器的输入信号。

ECTMCE = 1 的条件下对该位的写访问是有效的（可以同时设置它们。）通过设置 ECTMCE = 0 来清除该位
。

ECTMCE 位（启用 ECC 测试模式控制）

ECTMCE 位选择访问启用或禁用以测试寄存器和测试控制位。

ETMA[1:0]位的值为10b的条件下,对该位的写访问是有效的。

ETMA[1:0] 位（ECC 测试模式位访问控制）

ETMA[1:0]位是ECTMCE位的写触发保留位。读取值始终为 0。当这些位的值为10b时,可以对ECTMCE位进行写访问。如果这些位不是 10b,则忽略对 ECTMCE 位的写访问并且不写入该值。

ECEAD[10:0] bits (ECC Error Address)

When ECC error is detected for permitting ECC error judgment, RAM address is captured by the detected signal as a trigger and is hold as the error occurring address. The error address is not captured when the error occurred again to the one held by the same factor.

If 2-bit error occurred under the condition that 1-bit error address is already captured, the 2-bit error address is over-written and the ECDEDF0 bit is set to 1.

If 1-bit error occurred under the condition that 2-bit error address is already captured, the 1-bit error address is not overwritten and the ECSEDF0 bit is not set to 1.

ECEAD[10:0] 位（ECC 错误地址）

Bit	Symbol	Function	R/W

SPMS bit (SPI Mode Select)

The SPMS bit selects SPI operation (4-wire method) or clock synchronous operation (3-wire method).

The SSLn0 to SSLn3 pins are not used in clock synchronous operation. The RSPCKn, MOSIn, and MISOn pins handle communications. For clock synchronous operation in master mode (MSTR = 1), the SPCMDm.CPHA bit can be set to either 0 or 1. For clock synchronous operation in slave mode (MSTR = 0), always set the CPHA bit to 1. Do not perform operations if the CPHA bit is set to 0 for clock synchronous operation in slave mode (MSTR = 0).

TXMD bit (Communications Operating Mode Select)

The TXMD bit selects full-duplex synchronous serial communications or transmit-only operations. When this bit is set to 1, the SPI only performs transmit operations and not receive operations (see section 28.3.6. Data Transfer Modes), and receive buffer full interrupt requests cannot be used.

TXMD setting is invalid in receive only slave mode.

MODFEN bit (Mode Fault Error Detection Enable)

The MODFEN bit enables or disables the detection of mode fault errors (see section 28.3.9. Error Detection). In addition, the SPI determines the I/O direction of the SSLni pins based on combination of the MODFEN and MSTR bits (see section 28.3.2. Controlling the SPI Pins).

MSTR bit (SPI Master/Slave Mode Select)

The MSTR bit selects master or slave mode for the SPI. Based on the MSTR bit settings, the SPI determines the direction of the RSPCKn, MOSIn, MISOn, and SSLni pins.

SPEIE bit (SPI Error Interrupt Enable)

The SPEIE bit enables or disables the generation of SPI error interrupt requests when one of the following occurs:

- The SPI detects a mode fault error or underrun error and sets the SPSR.MODF flag to 1
- The SPI detects an overrun error and sets the SPSR.OVRF flag to 1
- The SPI detects a parity error and sets the SPSR.PERF flag to 1

For details, see section 28.3.9. Error Detection.

SPTIE bit (Transmit Buffer Empty Interrupt Enable)

The SPTIE bit enables or disables the generation of transmit buffer empty interrupt requests when the SPI detects that the transmit buffer is empty. To generate a transmit buffer empty interrupt request when transmission starts, set the SPE and SPTIE bits to 1 at the same time or set the SPE bit to 1 after setting the SPTIE bit to 1.

When the SPTIE bit is 1, transmit buffer interrupts are generated even when the SPI function is disabled (when the SPE bit is changed to 0).

SPE bit (SPI Function Enable)

The SPE bit enables or disables the SPI function. The SPE bit cannot be set to 1 when the SPSR.MODF flag is 1. For details, see section 28.3.9. Error Detection.

Setting the SPE bit to 0 disables the SPI function and initializes a part of the module function. For details, see section 28.3.10. Initializing the SPI. In addition, a transmit buffer empty interrupt request is generated when the SPE bit is changed from 0 to 1 or from 1 to 0.

SPRIE bit (SPI Receive Buffer Full Interrupt Enable)

The SPRIE bit enables or disables the generation of an SPI receive buffer full interrupt request when the SPI detects a receive buffer full write after completion of a serial transfer.

Bit	符号	功能	R/W
7	雪花	SPI 接收缓冲区完全中断启用 0:禁用SPI接收缓冲区全中断请求 1:启用SPI接收缓冲区全中断请求	R/W

SPMS 位（SPI 模式选择）

SPMS位选择SPI操作(4线方式）或时钟同步操作(3线方式）。

SSLn0 到 SSLn3 引脚不用于时钟同步操作。RSPCKn、MOSIn 和 MISOn 引脚处理通信。对于主模式（MSTR = 1)下的时钟同步操作,SPCMDm。CPHA 位可以设置为 0 或 1。对于从模式（MSTR = 0)下的时钟同步操作,始终将 CPHA 位设置为 1。CPHA 位设置为 0, 从模式下时钟同步操作, 请勿执行操作（MSTR = 0)。

TXMD 位（通信操作模式选择）

TXMD位选择全双工同步串行通信或仅发送操作。当该位设置为1时,SPI仅执行发送操作而不执行接收操作（参见第28。3。6节）。式（Data Transfer Modes）,并且接收缓冲区无法使用完全中断请求。

TXMD 设置在仅接收从模式下无效。

MODFEN 位（启用模式故障错误检测）

MODFEN 位启用或禁用模式故障错误的检测（参见第 28。3。9 节）。误（检测）。此外,SPI 基于 MODFEN 和 MSTR 位的组合确定 SSLni 引脚的 I/O 方向（参见第 28。3。2 节）。控制 SPI 引脚).

MSTR 位（SPI 主/从模式选择）

MSTR 位为 SPI 选择主模式或从模式。根据 MSTR 位设置,SPI 确定 RSPCKn、MOSIn、MISOn 和 SSLni 引脚的方向。

SPEIE 位（启用 SPI 错误中断）

SPEIE 位在发生以下情况之一时启用或禁用 SPI 错误中断请求的生成:

- SPI 检测到模式故障错误或欠载错误,并将 SPSR。MODF 标志设置为 1
- SPI 检测到溢出错误并将 SPSR。OVRF 标志设置为 1
- SPI 检测到奇偶校验错误,并将 SPSR。PERF 标志设置为 1 详情请参见第 28。3。9 节。错误检测 .

SPTIE 位（传输缓冲区空中断启用）

当SPI检测到发送缓冲区为空时,SPTIE位启用或禁用发送缓冲区空中断请求的生成。要在传输开始时生成传输缓冲区空中断请求,请同时将 SPE 和 SPTIE 位设置为 1 或在将 SPTIE 位设置为 1 后将 SPE 位设置为 1。

SPTIE 位为 1 时,即使 SPI 函数被禁用（当 SPE 位更改为 0 时）,也会产生传输缓冲区中断。

SPE 位（启用 SPI 功能）

SPE 位启用或禁用 SPI 功能。当SPSR。MODF标志为1时,SPE位不能设置为1。详情请参见第 28。3。9 节。错误检测 .

SPE 位设置为 0 禁用 SPI 函数,初始化模块函数的一部分。详情请参见第 28。3。10 节。初始化 SPI。此外,当SPE位从0更改为1或从1更改为0时,会生成发送缓冲区空中断请求。

SPRIE 位（SPI 接收缓冲区完全中断启用）

当SPI在串行传输完成后检测到接收缓冲区完全写入时,SPRIE位启用或禁用SPI接收缓冲区完全中断请求的生成。

SPLP bit (SPI Loopback)

The SPLP bit selects the mode of the SPI pins. When this bit is set to 1, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0. The SPI then inverts the value of the input path for the shift register and connects it to the output path (loopback mode). For more information, see section 28.3.13. Loopback Mode.

欲了解更多信息,请参阅第 28。3。13 节。环回模式 .

SPLP2 bit (SPI Loopback 2)

The SPLP2 bit selects the mode of the SPI pins. When this bit is set to 1, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0. The SPI then connects the value of the input path for the shift register to the output path (loopback mode) without inverting the value. For more information, see section 28.3.13. Loopback Mode.

MOIFV bit (MOSI Idle Fixed Value)

The MOIFV bit determines the MOSIn pin output value during the SSL negation period (including the SSL retention period during a burst transfer) when the MOIFE bit is 1 in master mode.

MOIFE bit (MOSI Idle Value Fixing Enable)

The MOIFE bit fixes the MOSIn output value when the SPI is in master mode and in an SSL negation period (including the SSL retention period during a burst transfer).When the MOIFE bit is 0, the SPI outputs the last data from the previous serial transfer during the SSL negation period to the MOSIn pin. When the MOIFE bit is 1, the SPI outputs the fixed value set in the MOIFV bit to the MOSIn pin.

MOIFV 位（MOSI 空闲固定值）

MOIFV位在主模式下MOIFE位为1时,确定SSL否定周期（包括突发传输期间的SSL保留周期）期间的MOSIn引脚输出值。

当 SPI 处于主模式且处于 SSL 否定周期（包括突发传输期间的 SSL 保留周期）时,MOIFE 位固定 MOSIn 输出值。MOIFE 位为 0 时,SPI 将 SSL 否定期间前一次串行传输的最后一个数据输出到 MOSIn 引脚。MOIFE 位为 1 时,SPI 将 MOIFV 位中设置的固定值输出到 MOSIn 引脚。

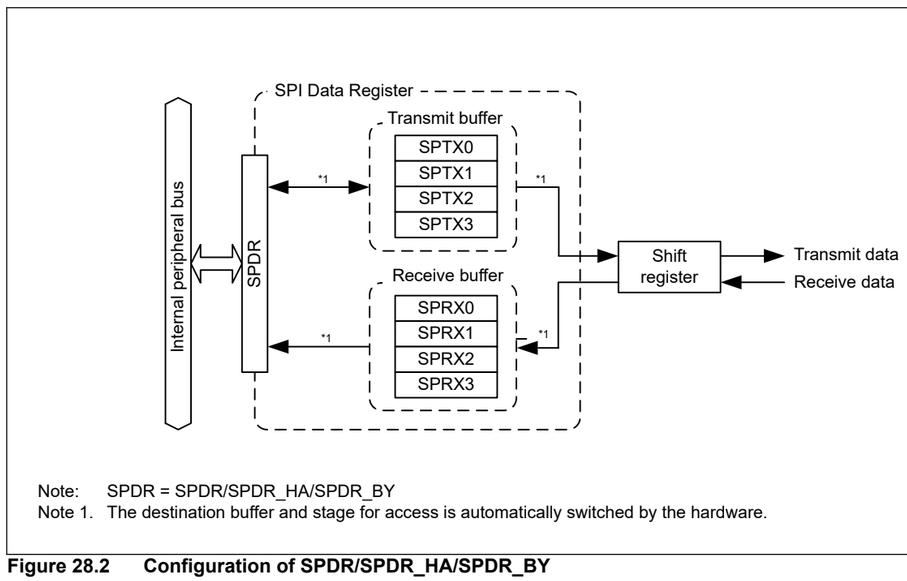
SPDR/SPDR_HA/SPDR_BY is the interface with the buffers that hold data for transmission and reception by the SPI. When accessing this register in words (the SPDCR.SPLW bit is 1), access SPDR. When accessing it in halfwords (the SPLW bit is 0), access SPDR_HA. When accessing it in byte (the SPDCR.SPBYT bit is 1), access SPDR_BY.

The transmit buffer (SPTX) and receive buffer (SPRX) are independent but are both mapped to SPDR/SPDR_HA. Figure 28.2 shows the configuration of the SPDR/SPDR_HA register.



Note: SPDR = SPDR/SPDR_HA/SPDR_BY
Note 1. The destination buffer and stage for access is automatically switched by the hardware.

Figure 28.2 Configuration of SPDR/SPDR_HA/SPDR_BY

The transmit and receive buffers each have one stages. The four stages of the buffer are all mapped to the single address of SPDR/SPDR_HA/SPDR_BY.

Data written to SPDR/SPDR_HA/SPDR_BY is written to a transmit-buffer stage (SPTXn) (n = 0 to 3), and then transmitted from the buffer. The receive buffer holds received data on completion of reception. The receive buffer is not updated if an overrun is generated.

Additionally, if the data length is not 32 bits, bits not referred to in SPTXn (n = 0 to 3) are stored in the associated bits in SPRXn (n = 0 to 3). For example, if the data length is 9 bits, the received data is stored in the SPRXn[8:0] bits, and the SPTXn[31:9] bits are stored in the SPRXn[31:9] bits.

(1) Bus interface

SPDR/SPDR_HA/SPDR_BY is an interface with 32-bit wide transmit and receive buffers, each of which has one stages, for a total of 32 bytes. The 32 bytes are mapped to the 4-byte address space for SPDR/SPDR_HA/SPDR_BY. Additionally, the unit of access for SPDR/SPDR_HA/SPDR_BY is selected by the SPI Word Access/Halfword Access Specification bit in the

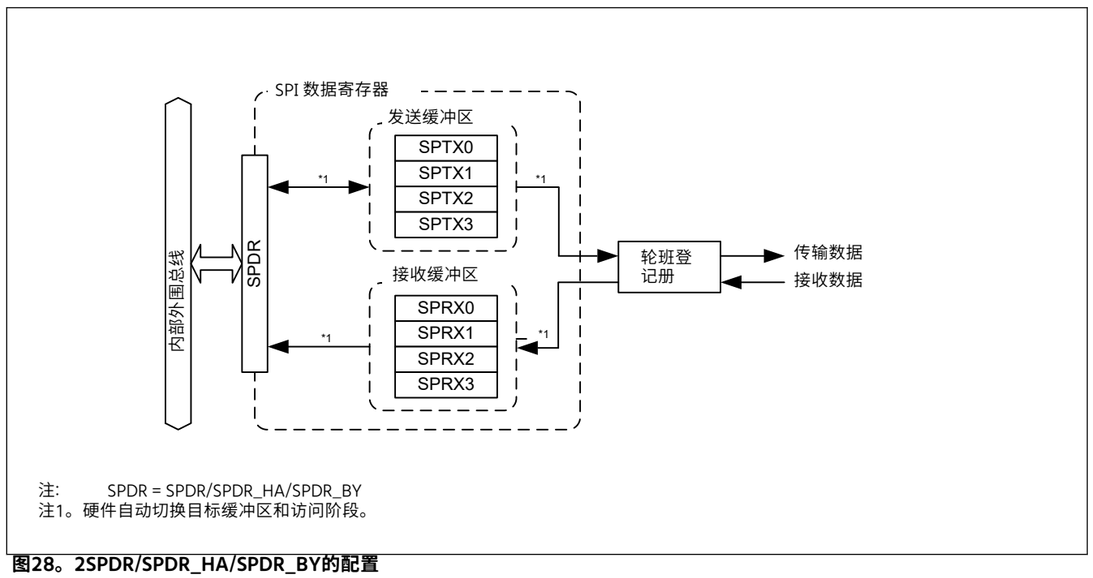
SPDR/SPDR_HA/SPDR_BY 是与缓冲区的接口,缓冲区保存数据以供 SPI 传输和接收。字（SPDCR。SPLW位为1)访问该寄存器时,访问SPDR。当半字访问它时（the SPLW 位为 0),访问 SPDR_HA。字节访问时（SPDCR。SPBYT 位为 1),访问 SPDR_BY。

器（SPTX）和接收缓冲器（SPRX）是独立的,但都映射到SPDR/SPDR_HA。图28。2显示了SPDR/SPDR_HA寄存器的配置。



注: SPDR = SPDR/SPDR_HA/SPDR_BY
注1。硬件自动切换目标缓冲区和访问阶段。

图28。2SPDR/SPDR_HA/SPDR_BY的配置

发射和接收缓冲器各有一个级。缓冲区的四个阶段都映射到SPDR/SPDR_HA/SPDR_BY的单个地址。

写入 SPDR/SPDR_HA/SPDR_BY 的数据被写入发送缓冲区级（SPTXn）（n = 0 至 3),然后从缓冲区传输。接收缓冲器保存接收到的接收完成后的数据。如果生成溢出,则接收缓冲区不会更新。

另外,如果数据长度不是32位,则SPTXn中未提及的位（n=0至3)被存储在SPRXn中的相关位（n=0至3)中。例如,如果数据长度为9位,则接收到的数据存储在SPRXn[8:0]位中,并且SPTXn[31:9]位存储在SPRXn[31:9]位中。

(1)总线接口

SPDR/SPDR_HA/SPDR_BY是一个具有32位宽的发送和接收缓冲区的接口,每个缓冲区都有一个级,总共32个字节。32个字节映射到SPDR/SPDR_HA/SPDR_BY的4字节地址空间。此外,SPDR/SPDR_HA/SPDR_BY 的访问单元由 SPI 字访问/半字访问规范位在 中选择

SPI Data Control Register (SPDCR.SPLW). SPDR can also be accessed with the access size specified by the SPI Byte Access bit in the SPI Data Control Register (SPDCR.SPBYT).

Flush the transmission data at the LSB end of the register, and store the received data at the LSB end.

The following sections describe the operations involved in writing to and reading from SPDR/SPDR_HA/SPDR_BY.

Writing

Data written to SPDR/SPDR_HA/SPDR_BY is written to a transmit buffer (SPTXn). This is not affected by the value of the SPDCR.SPRDTD bit, unlike when reading from SPDR/SPDR_HA/SPDR_BY. The transmit buffer includes a transmit buffer write pointer that is automatically updated to reference the next stage each time data is written to SPDR/SPDR_HA/SPDR_BY.

Figure 28.3 shows the configuration of the bus interface with the transmit buffer when writing to SPDR/SPDR_HA/SPDR_BY.

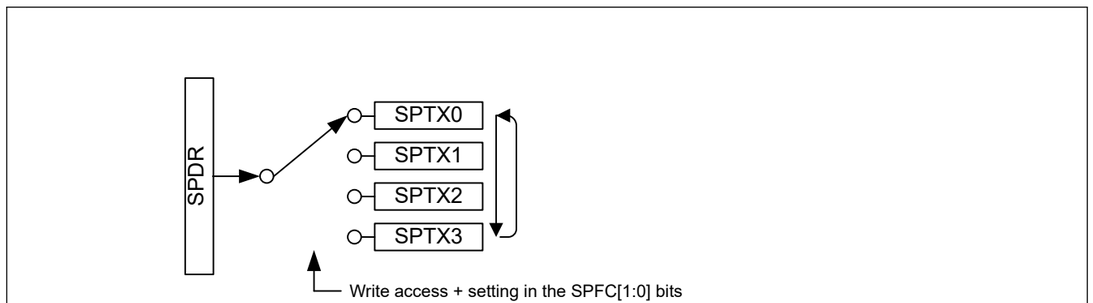


Figure 28.3 Configuration of SPDR/SPDR_HA/SPDR_BY for write access

The sequence for switching the transmit buffer write pointer differs with the setting of the number of frames specification bits in the SPI Data Control Register (SPDCR.SPFC[1:0]). The relationship of the SPFC[1:0] setting and the sequence of pointer switching from SPTX0 to SPTX3 is as follows:

- When SPFC[1:0] = 00b: SPTX0 → SPTX0 → SPTX0 → …
- When SPFC[1:0] = 01b: SPTX0 → SPTX1 → SPTX0 → SPTX1 → …
- When SPFC[1:0] = 10b: SPTX0 → SPTX1 → SPTX2 → SPTX0 → SPTX1 → …
- When SPFC[1:0] = 11b: SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → …

When 1 is written to the SPI Function Enable bit in the SPI Control Register (SPCR.SPE) while the bit is 0, SPTX0 is the destination for the next write.

When writing to the transmit buffer (SPTXn) after generating the transmit buffer empty interrupt (when SPSR.SPTEF is 1), write the number of frames set in SPFC[1:0] in the SPI Data Control Register (SPDCR). Even when the specified number of frames is written to the transmit buffer (SPTXn), the value of the buffer is not updated after completion of the writing and before generation of the next transmit buffer empty interrupt (when SPTEF is 0).

Reading

SPDR/SPDR_HA/SPDR_BY can be accessed to read the value of a receive buffer (SPRXn) or a transmit buffer (SPTXn). The setting in the SPI Receive/Transmit Data Select bit in the SPI Data Control Register (SPDCR.SPRDTD) selects whether reading is of the receive or transmit buffer. The sequence of reading the SPDR/SPDR_HA/SPDR_BY register is controlled by the independent receive buffer and transmit buffer read pointers.

Figure 28.4 shows the configuration of the bus interface with the receive and transmit buffers for reading from SPDR/SPDR_HA/SPDR_BY.

LSB 端刷新寄存器的传输数据,并将接收到的数据存储在 LSB 端。

以下部分描述了写入和读取 SPDR/SPDR_HA/SPDR_BY 所涉及的操作。

写作

写入 SPDR/SPDR_HA/SPDR_BY 的数据被写入传输缓冲区（SPTXn）。与从 SPDR/SPDR_HA/SPDR_BY 读取不同,这不受 SPDCR。SPRDTD 位值的影响。发射缓冲器包括发射缓冲器写入指针,每次数据写入SPDR/SPDR_HA/SPDR_BY时,该发射缓冲器写入指针自动更新以引用下一阶段。

图28。3显示了写入SPDR/SPDR_HA/SPDR_BY时总线接口与发送缓冲区的配置。

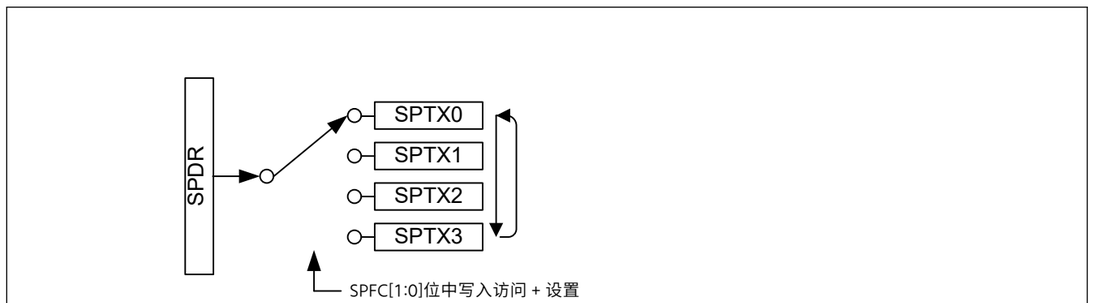

图28。3 SPDR/SPDR_HA/SPDR_BY 的配置用于写入访问

SPI 数据控制寄存器（SPDCR。SPFC[1:0]）中用于切换发送缓冲区写入指针的顺序与帧规范位数的设置不同。SPFC[1:0]设置与从SPTX0到SPTX3的指针切换顺序的关系如下:

- 当 SPFC[1:0] = 00b:SPTX0 → SPTX0 → SPTX0 →…
- 当 SPFC[1:0] = 01b:SPTX0 → SPTX1 → SPTX0 → SPTX1 →…
- 当 SPFC[1:0] = 10b:SPTX0 → SPTX1 → SPTX2 → SPTX0 → SPTX1 →…
- 当 SPFC[1:0] = 11b:SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → … 当 1 写入 SPI 控制寄存器（SPCR。SPE）中的 SPI 函数启用位时,该位为 0,SPTX0 是下一次写入的目的。

（当SPSR。SPTEF为1时）生成发送缓冲区空中断后写入发送缓冲区（SPTXn）时,在SPI数据控制寄存器（SPDCR）中写入SPFC[1:0]中设置的帧数。即使将指定数量的帧写入到发送缓冲区（SPTXn）,在写入完成之后和生成下一个发送缓冲区空中断之前（当SPTEF为0时）,缓冲区的值也不会更新。

Note: SPDR = SPDR/SPDR_HA/SPDR_BY

Figure 28.4 Configuration of SPDR/SPDR_HA/SPDR_BY for read access

Reading the receive buffer switches the receive buffer read pointer to the next buffer automatically. The switching sequence for the receive buffer read pointer is the same as that for the transmit buffer write pointer. However, when 1 is written to the SPI Function Enable bit in the SPI Control Register (SPCR.SPE) while the value of the bit is 1, SPRX0 is referenced by the buffer read pointer for the next read.

The transmit buffer read pointer is updated when writing to SPDR/SPDR_HA/SPDR_BY, but not updated when reading from the transmit buffer. When reading from the transmit buffer, the value most recently written to SPDR/SPDR_HA/SPDR_BY is read.

After a transmit buffer empty interrupt is generated, reading from the transmit buffer returns all 0s after the completion of writing the number of frames of data specified in the SPDCR.SPFC[1:0] bits, until the next buffer empty interrupt is generated (when SPTEF is 0).

读取接收缓冲区会自动将接收缓冲区读取指针切换到下一个缓冲区。接收缓冲区读取指针的切换顺序与发送缓冲区写入指针的切换顺序相同。然而,当将 1 写入 SPI 控制寄存器（SPCR。SPE）中的 SPI 函数启用位时,当该位的值为 1 时,缓冲区读取指针会引用 SPRX0 进行下一次读取。

SPDR/SPDR_HA/SPDR_BY 写入时,发送缓冲区读取指针会更新,但从发送缓冲区读取时不会更新。从发送缓冲区读取时,读取最近写入 SPDR/SPDR_HA/SPDR_BY 的值。

生成发送缓冲区空中断后,从发送缓冲区读取在写入 SPDCR。SPFC[1:0] 位中指定的数据帧数完成后返回所有 0,直到生成下一个缓冲区空中断（当 SPTEF 为 0)。

SPECM[2:0] bits (SPI Error Command)

The SPECM[2:0] bits indicate the SPCMDm register that is specified in the SPCP[2:0] bits when an error is detected during sequence control by the SPI. The SPI updates the SPECM[2:0] bits only when an error is detected. If both the SPSR.OVRF and SPSR.MODF flags are 0 and there is no error, the values of the SPECM[2:0] bits have no meaning.

SPBR sets the bit rate in master mode.

When the SPI is in slave mode, the bit rate depends on the bit rate of the input clock, regardless of the settings in SPBR and the SPCMDm.BRDV[1:0] bits (bit rate division setting). Use bit rates that satisfy the electrical characteristics of the device.

The bit rate is determined by combinations of the SPBR and SPCMDm.BRDV[1:0] settings in the SPI Command Register. The equation for calculating the bit rate is given as follows:

$$\text{Bit rate} = \frac{f(\text{PCLK})}{2 \times (n+1) \times 2^N}$$

(PCLK = PCLKA)

In the equation, n denotes an SPBR setting (0, 1, 2, …, 255), and N denotes a BRDV[1:0] setting (0, 1, 2, 3).

Table 28.3 lists examples of the relationship between the SPBR settings, the BRDV[1:0] settings, and bit rates.

The SPI Data Control Register (SPDCR) is used to read the number of frames that can be stored in the SPDR register,read the SPDR register, and to set the access width for the SPDR register to word access, halfword access, or byte access. Up to four frames can be transmitted or received in one round of transmission or reception. The amount of data in each transfer is controlled by the combination of the SPCMDm.SPB[3:0] bits, the SPSCR.SPSLN[2:0] bits, and the SPFC[1:0] bits.

When changing the SPFC[1:0] bits while the SPCR.SPE bit is 1, check that the SPSR.IDLNF flag is 0.

SPFC[1:0] bits (Number of Frames Specification)

The SPFC[1:0] bits specify the number of frames that can be stored in SPDR/SPDR_HA per transfer activation. Up to four frames can be transmitted or received in one round of transmission or reception.

When the number of transmission data frames specified in the SPFC[1:0] bits is written to the SPDR/SPDR_HA register, SPI clears the SPSR.SPTEF flag to 0 and begins transmitting. After that, when the number of transmission data frames specified in the SPFC[1:0] bits is transmitted to the shift register, the SPI generates the transmit buffer empty interrupt (SPSR.SPTEF sets to 1).

When the number of data frames specified in the SPFC[1:0] bits is received, the SPI generates the receive buffer full interrupt (SPSR.SPRF sets to 1).

SPI 数据控制寄存器（SPDCR）用于读取 SPDR 寄存器中可存储的帧数、读取 SPDR 寄存器,并将 SPDR 寄存器的访问宽度设置为字访问、半字访问或字节访问。在一轮传输或接收中最多可以传输或接收四帧。每次传输中的数据量由SPCMDm。SPB[3:0]位、SPSCR。SPSLN[2:0]位和SPFC[1:0]位的组合控制。

当 SPCR。SPE 位为 1 时更改 SPFC[1:0] 位时,检查 SPSR。IDLNF 标志为 0。

SPFC[1:0] 位（帧数规范）

SPFC[1:0] 位指定每次传输激活可以存储在 SPDR/SPDR_HA 中的帧数。在一轮传输或接收中最多可以传输或接收四帧。

SPFC[1:0]位中指定的传输数据帧数写入SPDR/SPDR_HA寄存器时,SPI将SPSR。SPTEF标志清零并开始传输。此后,当SPFC[1:0]位中指定的传输数据帧的数量被传输到移位寄存器时,SPI生成传输缓冲区空中断（SPSR。SPTEF设置为1)。

SPFC[1:0]位中指定的数据帧数时,SPI生成接收缓冲区全中断（SPSR。SPRF设置为1)。

SPRDTD bit (SPI Receive/Transmit Data Select)

The SPRDTD bit selects whether the SPDR/SPDR_HA reads values from the receive buffer or from the transmit buffer. If reading is from the transmit buffer, the last value written to SPDR/SPDR_HA register is read. Read the transmit buffer after an SPI transmit buffer empty interrupt is generated until data of frames specified by SPFC[1:0] has been written (while the SPSR.SPTEF flag is 1).

For details, see section 28.2.5. SPDR/SPDR_HA/SPDR_BY : SPI Data Register.

SPLW bit (SPI Word Access/Halfword Access Specification)

The SPLW bit specifies the access width for SPDR. Access to SPDR_HA in halfwords is valid when the SPLW bit is 0 and access to SPDR in words is valid when the SPLW bit is 1. Also, when this bit is 0, set the SPI data length setting bits, SPCMDm.SPB[3:0], from 8 to 16 bits. Do not perform any operations when a data length of 20, 24, or 32 bits is specified.

SPBYT bit (SPI Byte Access Specification)

The SPBYT bit is used to set the data width of access to the SPI Data Register (SPDR). When SPBYT = 0, use word or half word access to SPDR/SPDR_HA. When SPBYT = 1 (in that case, SPLW is invalid), use byte access to SPDR_BY.

When SPBYT = 1, set the SPI data length bits (SPB[3:0]) in the SPI Command Register m (SPCMDm) to 8 bits. If SPB[3:0] are set to 9 to 16, 20, 24, or 32 bit, subsequent operation is not guaranteed.

SPRDTD 位（SPI 接收/发送数据选择）

SPRDTD位选择SPDR/SPDR_HA是从接收缓冲器还是从发送缓冲器读取值。如果读取是从发送缓冲区读取的,则读取写入 SPDR/SPDR_HA 寄存器的最后一个值。在生成 SPI 发送缓冲区空中断后读取发送缓冲区,直到写入 SPFC [1:0] 指定的帧数据（而 SPSR。SPTEF 标志为 1)。

详情请参见第 28。2。5 节。SPDR/SPDR_HA/SPDR_BY:SPI 数据寄存器 .

SPLW 位（SPI 字访问/半字访问规范）

SPLW 位指定 SPDR 的访问宽度。SPLW位为0时对半字中的SPDR_HA的访问是有效的,当SPLW位为1时对字中的SPDR的访问是有效的。另外,当该位为0时,将SPI数据长度设置位SPCMDm。SPB[3:0]从8位设置为16位。20、24、32位的数据长度时,不要进行任何操作。

SPBYT 位（SPI 字节访问规范）

SPBYT 位用于设置访问 SPI 数据寄存器（SPDR）的数据宽度。SPBYT = 0时,使用单词或半单词访问SPDR/SPDR_HA。SPBYT = 1时（在这种情况下,SPLW是无效的）,使用字节访问SPDR_BY。SPBYT = 1时,将SPI命令寄存器m（SPCMDm）中的SPI数据长度位（SPB[3:0])设置为8位。SPB[3:0] 设置为 9 到 16、20、24 或 32 位, 则不保证后续操作。

SSLND specifies the SSL negation delay, the period from the transmission of a final RSPCK edge to the negation of the SSLni signal during a serial transfer by the SPI in master mode. If the contents of SSLND are changed while both the SPCR.MSTR and SPCR.SPE bits are 1, do not perform subsequent operations.

SLNDL[2:0] bits (SSL Negation Delay Setting)

The SLNDL[2:0] bits specify an SSL negation delay value when the SLNDEN bit in SPCMDn is 1 and the SPI is in master mode. When using the SPI in slave mode, set the SLNDL[2:0] bits to 000b.

7:5	—	These bits are read as 0. The write value should be 0.	R/W

SPPE bit (Parity Enable)

The SPPE bit enables or disables the parity function.

When the SPCR.TXMD bit is 0 and this bit is 1, the parity bit is added to transmit data and parity checking is performed for receive data.

When the SPCR.TXMD bit is 1 and this bit is 1, the parity bit is added to transmit data but parity checking is not performed for receive data.

SPOE bit (Parity Mode)

The SPOE bit specifies odd or even parity.

When even parity is set, parity bit addition is performed so that the total number of bits whose value is 1 in the transmit or receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit addition is performed so that the total number of bits whose value is 1 in the transmit or receive character plus the parity bit is odd.

The SPOE bit is only valid when the SPPE bit is 1.

SPIIE bit (SPI Idle Interrupt Enable)

The SPIIE bit enables or disables the generation of SPI idle interrupt requests when an idle state is detected in the SPI and the SPSR.IDLNF flag clears is set to 0.

PTE bit (Parity Self-Testing)

The PTE bit enables self-diagnosis of the parity circuit to check whether the parity function is operating correctly.

SPNDL[2:0] 位（SPI 下一个访问延迟设置）

当 SPCMDm。SPNDEN 位为 1 时,SPNDL[2:0] 位指定下一个访问延迟。从模式下使用 SPI 时,将 SPNDL[2:0] 位设置为 000b。

4	SCKASE	RSPCK 自动停止功能启用 0:禁用RSPCK自动停止功能 1:启用RSPCK自动停止功能	R/W
7:5	—	这些位读作 0。写入值应为 0。	R/W

SPPE 位（启用奇偶校验）

SPPE 位启用或禁用奇偶校验函数。

当SPCR。TXMD位为0且该位为1时,添加奇偶校验位以传输数据并对接收数据执行奇偶校验检查。

当SPCR。TXMD位为1并且该位为1时,将奇偶校验位添加到发送数据中,但不对接收数据执行奇偶校验检查。

SPOE 位（奇偶校验模式）

SPOE 位指定奇偶奇偶校验。

当设置偶校验时,执行奇偶校验位相加,使得发送或接收字符中值为1加上奇偶校验位的比特总数为偶数。类似地,当设置奇偶校验时,执行奇偶校验位加法,使得发送或接收字符中值为1加上奇偶校验位的比特总数为奇。

SPOE 位仅在 SPPE 位为 1 时有效。

SPIIE 位（启用 SPI 空闲中断）

当在 SPI 中检测到空闲状态并且 SPSR。IDLNF 标志清除设置为 0 时,SPIIE 位启用或禁用 SPI 空闲中断请求的生成。

PTE 位（奇偶校验自检）

PTE位,可以对奇偶校验电路进行自我诊断,检查奇偶校验功能是否正常运行。

SCKASE bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit enables or disables the RSPCK auto-stop function. When this function is enabled, the RSPCK clock is stopped before an overrun error occurs, when data is received in master mode. For details, see section 28.3.9.1. Overrun errors.

The SPCMDm registers specify the transfer format for the SPI in master mode. Each channel has eight SPCMDm (m = 0 to 7). Some of the bits in the SPCMD0 registers are used to set the transfer mode for the SPI in slave mode. The SPI in master mode sequentially references the SPCMDm registers based on the settings in the SPSCR.SPSLN[2:0] bits and executes the serial transfer that is set in the referenced SPCMDm registers.

Set the SPCMDm registers while the transmit buffer is empty (SPSR.SPTEF is 1 and data for the next transfer is not set) and before the setting of the data to be transmitted when that SPCMDm registers is referenced.

The SPCMDm registers referenced by the SPI in master mode can be checked by means of the SPSSR.SPCP[2:0] bits.

CPHA bit (RSPCK Phase Setting)

The CPHA bit selects the RSPCK phase of the SPI in master or slave mode. Data communications between SPI modules require the same RSPCK phase setting between the modules.

CPOL bit (RSPCK Polarity Setting)

The CPOL bit selects the RSPCK polarity of the SPI in master or slave mode. Data communications between SPI modules require the same RSPCK polarity setting between the modules.

BRDV[1:0] bits (Bit Rate Division Setting)

The BRDV[1:0] bits determine the bit rate in combination with the settings in the SPBR register. (see section 28.2.8. SPBR : SPI Bit Rate Register). The SPBR settings determine the base bit rate. The BRDV[1:0] setting selects the bit rate obtained by dividing the base bit rate by 1, 2, 4, or 8. Different BRDV[1:0] bit settings can be specified in the SPCMD0 register. This enables execution of serial transfers at different bit rates for each command.

SSLA[2:0] bits (SSL Signal Assertion Setting)

The SSLA[2:0] bits control the SSLni signal assertion when the SPI performs serial transfers in master mode. When an SSLni signal is asserted, its polarity is determined by the value set in the associated SSLP. When the SSLA[2:0] bits are set to 000b in multi-master mode, serial transfers are performed with all the SSL signals in the negated state (as the SSLn0 pin acts as input).

When using the SPI in slave mode, set the SSLA[2:0] bits to 000b.

SSLKP bit (SSL Signal Level Keeping)

When the SPI in master mode performs a serial transfer, the SSLKP bit specifies whether the SSLni signal level for the current command is to be kept or negated between the SSL negation associated with the current command and the SSL assertion associated with the next command. Setting the SSLKP bit to 1 enables a burst transfer. For details, see section 28.3.11.1. Master mode operation. When using the SPI in slave mode, set the SSLKP bit to 0.

SPB[3:0] bits (SPI Data Length Setting)

The SPB[3:0] bits specify the transfer data length for the SPI in master or slave mode.

LSBF bit (SPI LSB First)

The LSBF bit specifies the data format of the SPI in master or slave mode to MSB-first or LSB-first.

SPNDEN bit (SPI Next-Access Delay Enable)

The SPNDEN bit specifies the next-access delay, the period from the time the SPI in master mode terminates a serial transfer and sets the SSLni signal inactive until the SPI enables the SSLni signal assertion for the next access. If the SPNDEN bit is 0, the SPI sets the next-access delay to 1 RSPCK + 2 PCLKA. If the SPNDEN bit is 1, the SPI inserts a next-access delay according to the SPND setting.

15	SCKDEN	RSPCK 延迟设置启用 0:选择1个RSPCK的RSPCK延迟 1: 选择 RSPCK 延迟等于 SPI 时钟延迟寄存器中的设置 （最高人民法院）	R/W

SPCMDm 寄存器指定主模式下 SPI 的传输格式。每个通道有八个 SPCMDm（m = 0 to 7）。SPCMD0 寄存器中的一些位用于在从模式下设置 SPI 的传输模式。主模式下的SPI基于SPSCR。SPSLN[2:0]位中的设置顺序引用SPCMDm寄存器并执行在引用的SPCMDm寄存器中设置的串行传输。

在发送缓冲区为空时（SPSR。SPTEF 为 1,并且未设置下一次传输的数据）以及在引用 SPCMDm 寄存器时设置要传输的数据之前设置 SPCMDm 寄存器。

SPI在主模式下引用的SPCMDm寄存器可以通过SPSSR。SPCP[2:0]位来检查。

CPHA 位（RSPCK 相位设置）

CPHA位在主模式或从模式下选择SPI的RSPCK相位。SPI 模块之间的数据通信需要模块之间相同的 RSPCK 相位设置。

CPOL 位（RSPCK 极性设置）

CPOL 位在主模式或从模式下选择 SPI 的 RSPCK 极性。SPI 模块之间的数据通信需要模块之间相同的 RSPCK 极性设置。

BRDV[1:0] 位（比特率划分设置）

BRDV[1:0] 位结合 SPBR 寄存器中的设置确定比特率。（参见第 28。2。8 节。SPBR: SPI 比特率寄存器）。SPBR 设置确定基本比特率。BRDV[1:0] 设置选择将基本比特率除以 1、2、4 或 8 得到的比特率。SPCMD0寄存器中可以指定不同的BRDV[1:0]位设置。这使得能够以每个命令的不同比特率执行串行传输。

SSLA[2:0] 位（SSL 信号断言设置）

SPI 在主模式下执行串行传输时, SSLA[2:0] 位控制 SSLni 信号断言。当断言 SSLni 信号时,其极性由相关 SSLP 中设置的值确定。SSLA[2:0] 位在多主模式下设置为 000b 时,所有 SSL 信号都处于否定状态（因为 SSLn0 引脚充当输入）进行串行传输。

从模式下使用 SPI 时,将 SSLA[2:0] 位设置为 000b。

SSLKP 位（SSL 信号电平保持）

当主模式下的SPI执行串行传输时,SSLKP位指定在与当前命令相关联的SSL否定和与下一个命令相关联的SSL断言之间是否保留或否定当前命令的SSLni信号电平。将 SSLKP 位设置为 1 可以实现突发传输。详情请参见第 28。3。11。1 节。主模式操作。从模式下使用 SPI 时,将 SSLKP 位设置为 0。

SPB[3:0] 位（SPI 数据长度设置）

SPB[3:0] 位指定主模式或从模式下 SPI 的传输数据长度。

LSBF 位（SPI LSB 首先）

LSBF位将主模式或从模式下的SPI的数据格式指定为MSB优先或LSB优先。

SPNDEN 位（SPI 下一个访问延迟启用）

SPNDEN 位指定下一次访问延迟,即从主模式中的 SPI 终止串行传输并将 SSLni 信号设置为非活动到 SPI 为下一次访问启用 SSLni 信号断言的时间段。如果 SPNDEN 位为 0,SPI 将下一次访问延迟设置为 1 RSPCK + 2 PCLKA。如果SPNDEN位为1,则SPI根据SPND设置插入下一个访问延迟。

When using the SPI in slave mode, set the SPNDEN bit to 0.

SLNDEN bit (SSL Negation Delay Setting Enable)

The SLNDEN bit specifies the SSL negation delay, the period from the time the SPI in master mode stops RSPCK oscillation until the SPI sets the SSLni signal to inactive. If the SLNDEN bit is 0, the SPI sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, the SPI negates the SSL signal at the SSL negation delay according to the SSLND setting.

When using the SPI in slave mode, set the SLNDEN bit to 0.

SCKDEN bit (RSPCK Delay Setting Enable)

The SCKDEN bit specifies the SPI clock delay, the period from the point when the SPI in master mode asserts the SSLni signal until the RSPCK starts oscillation. If the SCKDEN bit is 0, the SPI sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, the SPI starts the oscillation of RSPCK at an RSPCK delay according to the SPCKD setting.

When using the SPI in slave mode, set the SCKDEN bit to 0.

28.2.15 SPDCR2 : SPI Data Control Register 2

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x20

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SINV	BYSW
Value after reset:	0	0	0	0	0	0	0	0

1	SINV	Serial Data Invert Bit 0: Not invert serial data 1: Invert serial data	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

SPI Data Control Register 2 (SPDCR2) is the setting register, that is to swap a transmit/receive data in byte units and to invert serial data. If these bits are modified while the SPI in slave mode is enabled (SPCR.SPE = 1), subsequent operation is not guaranteed.

BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. When byte access is valid (SPDCR.SPBYT = 1), byte swap is invalid. When byte swap is valid, parity function must be invalid (SPCR2.SPPE bit = 0). Setting change of BYSW bit must be SPCR.SPE bit = 0.

A data after byte swap is different by a data length (setting of SPCMD.SPB[3:0]).

When byte swap, A data length (setting of SPB[3:0]) must be set to 32 bit or 16bit. Other case of data length (that is 8 to 15, 20, 24 bit length), byte swap is not guaranteed. Before swap and after swap are shown below (length data (32 bit/16 bit)).

- Length data 32 bits (SPB[3:0] = 0010b or 0011b)

  Before swap: [31:24] [23:16] [15:8] [7:0]

  After swap: [7:0] [15:8] [23:16] [31:24]
- Length data 16 bit (SPB[3:0] = 1111b)

  Before swap: [31:24] [23:16]

  After swap: [23:16] [31:24]

When byte access mode (SPDCR.SPBT = 1), byte swap setting is invalid.

从模式下使用 SPI 时,将 SPNDEN 位设置为 0。

SLNDEN 位（启用 SSL 否定延迟设置）

SLNDEN 位指定 SSL 否定延迟,从主模式下的 SPI 停止 RSPCK 振荡到 SPI 将 SSLni 信号设置为非活动期间。如果 SLNDEN 位为 0,SPI 将 SSL 否定延迟设置为 1 RSPCK。如果SLNDEN位为1,则SPI根据SSLND设置在SSL否定延迟处否定SSL信号。

从模式下使用SPI时,将SLNDEN位设置为0。

SCKDEN 位（启用 RSPCK 延迟设置）

SCKDEN 位指定 SPI 时钟延迟,即从主模式中的 SPI 断言 SSLni 信号到 RSPCK 开始振荡的时段。如果 SCKDEN 位为 0,则 SPI 将 RSPCK 延迟设置为 1 RSPCK。如果SCKDEN位为1,则SPI根据SPCKD设置在RSPCK延迟处开始RSPCK的振荡。

从模式下使用 SPI 时,将 SCKDEN 位设置为 0。

28.2.15 SPDCR2:SPI 数据控制寄存器 2

基本地址:SPIn = 0x4011_A000 + 0x0100 × n（n = 0, 1）

偏移地址:0x20

位位置:	7	6	5	4	3	2	1	0
位字段:	—	—	—	—	—	—	SINV	BYSW
重置后的值:	0	0	0	0	0	0	0	0

位	符号	功能	R/W
0	BYSW	字节交换操作模式选择 0:字节交换关闭 1: 字节交换打开	R/W
1	SINV	串行数据反转位 0:不反转串行数据 1:反 转串行数据	R/W
7:2	—	这些位读作 0。写入值应为 0。	R/W

SPI数据控制寄存器2（SPDCR2)是设置寄存器,即以字节为单位交换发送/接收数据并反转串行数据。如果在启用从模式下的 SPI 时修改这些位（SPCR。SPE = 1),则不能保证后续操作。

BYSW 位（字节交换操作模式选择）

它是一个设置位,即交换以字节为单位的发送/接收数据。当字节访问有效时（SPDCR。SPBYT = 1),字节交换无效。当字节交换有效时,奇偶校验函数必须无效（SPCR2)。SPPE 位 = 0)。BYSW 位的设置更改必须为 SPCR。SPE 位 = 0。

字节交换后的数据因数据长度而异（SPCMD。SPB 的设置[3:0])。

Byte 交换时,A 数据长度（设置 SPB[3:0])必须设置为 32 位或 16bit。其他数据长度情况（即 8 至 15、20、24 位长度）,字节交换不保证。交换之前和交换之后如下所示（长度数据(32 位/16 位）)。

● 长度数据 32 位（SPB[3:0] = 0010b 或 0011b）交换前:[31:24] [23:16] [15:8] [7:0]

交换后:[7:0] [15:8] [23:16] [31:24]

● 长度数据 16 位（SPB[3:0] = 1111b）交换前:[31:24] [23:16]

交换后:[23:16] [31:24]

当字节访问模式（SPDCR。SPBT = 1)时,字节交换设置无效。

When byte swap is valid, set parity function to invalid (SPCR2.SPPE = 0). When the parity function set to valid, the behavior is not guaranteed.

SINV bit (Serial Data Invert Bit)

This bit is used to invert transmit data and receive data.

When the SINV bit is set to 1, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/ reception data.

28.2.16 SPCR3 : SPI Control Register 3

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x21

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CENDIE	—	—	BFDS	ETXMD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ETXMD	Extended Communication Mode Select 0: Full-duplex synchronous or transmit-only serial communications. [the SPCR.TXMD bit is enabled] 1: Receive-only serial communications in slave mode (SPCR.MSTR bit = 0). [the SPCR.TXMD bit is disabled] Setting is prohibited in master mode (SPCR.MSTR bit = 1).	R/W
1	BFDS	Between Burst Transfer Frames Delay Select 0: Delay (RSPCK delay, SSL negation delay and next-access delay) between frames is inserted in burst transfer. 1: Delay between frames is not inserted in burst transfer.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	CENDIE	SPI Communication End Interrupt Enable 0: Communication end interrupt request is disabled. 1: Communication end interrupt request is enabled.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

SPI control register 3 (SPCR3) is control register for operation mode. If you change the value of ETXMD and BFDS when the SPCR.SPE bit is 1, the SPI operation does not guarantee.

ETXMD bit (Extended Communication Mode Select)

This bit is valid on slave mode only (the SPCR.MSTR bit is 0). This bit select receive only operation. When the ETXMD bit is 1 on slave mode, the communication is only received not transmit (see section 28.3.6. Data Transfer Modes). When the ETXMD is 1, transmit data empty interrupt can not be used.

The communication state by each mode (master mode, slave mode) is shown as below. It is controlled by the ETXMD bit, the SPCR.MSTR bit and the TXMD bit.

Table 28.5 SPI communication state (master/slave mode)

SPCR.MSTR bit	SPCR3.ETXMD bit	SPCR.TXMD bit	Communication state
1	0	0	Transmit-receive master mode
1	0	1	Transmit master mode
0	0	0	Transmit-receive slave mode (default)
0	0	1	Transmit slave mode
0	1	—	Receive slave mode

当字节交换有效时,将奇偶校验函数设置为无效（SPCR2)。SPPE = 0)。当奇偶校验函数设置为有效时,该行为就无法得到保证。

SINV 位（串行数据反转位）

该位用于反转发送数据和接收数据。

SINV 位设置为 1 时, 将发送缓冲器（SPTX）数据进行反相, 以反相发送数据和接收数据, 然后将反相数据存储在接收缓冲器（SPRX）中。奇偶校验位是与反转的发送/接收数据相对应的值。

SPI控制寄存器3（SPCR3)是用于操作模式的控制寄存器。如果您在 SPCR。SPE 位为 1 时更改 ETXMD 和 BFDS 的值,则 SPI 操作不保证。

ETXMD 位（扩展通信模式选择）

该位仅在从模式下有效（SPCR。MSTR 位为 0)。该位选择仅接收操作。当从模式下的 ETXMD 位为 1 时,仅接收通信而不发送（参见第 28。3。6 节）。的（数据传输模式）。ETXMD为1时,传输数据空中断不能使用。

各模式（主模式、从模式）的通信状态如下所示。它由 ETXMD 位、SPCR。MSTR 位和 TXMD 位控制。

表 28。5 SPI通信状态（主/从模式）

BFDS bit (Between Burst Transfer Frames Delay Select)

This bit controls whether insert the delay time between the burst transfer frames.

This bit is valid when the SPCMD.SSLKP bit is 1 in master mode (the SPCR.MSTR bit is 1).

This bit should be set to 0 in slave mode. The usage of SSL delay control between transfer frames is shown as below. For details, see (4)Burst transfers.

Table 28.6 Usage of SSL delay control between transfer frames (Master mode)

Transmit		SPCMD.SSLKP bit	SPCR3.BFDS bit	SSL delay control register*1 (RSPCK clock delay, SSL negation delay, next access delay)
Non-burst transmit		0	0	Any given value. You can control each delay value according to setting for RSPCK clock delay, SSL negation delay and next access delay.
Burst transmit with delay between frames	From the 1st frame to the last previous frame	1	0	
	The last frame	0	0	
Burst transmit with no delay between frames	From the 1st frame to the last previous frame	1	1	Any given value. But delay is inserted only below. • RSPCK clock delay of the 1st frame • SSL negation delay and next access delay of the last frame
	The last frame	0	1	

Note 1. Whether the setting value of following bits are valid or not depends on the setting value of the SPCMD.SPNDEN bit (see section 28.2.14. SPCMDm : SPI Command Register m (m = 0 to 7)).
The SPCKD.SCKDL[2:0] bits: RSPCK delay
The SSLND.SLNDL[2:0] bits: SSL negate delay
The SPND.SPNDL[2:0] bits: Next access delay

CENDIE bit (SPI Communication End Interrupt Enable)

This bit controls generation of a communication end interrupt request.

28.3 Operation

In this section, the serial transfer period refers to the period from the beginning of driving valid data to the fetching of the final valid data.

28.3.1 Overview of SPI Operation

The SPI is capable of synchronous serial transfers in the following modes:

- Slave mode (SPI operation)
- Single master mode (SPI operation)
- Multi-master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation)

The SPI mode can be selected by using the MSTR, MODFEN, and SPMS bits in SPCR. Table 28.7 lists the relationship between SPI modes and SPCR settings, and a description of each mode.

Table 28.7 Relationship between SPCR settings and SPI modes (1 of 2)

该位控制是否插入突发传输帧之间的延迟时间。

当主模式下的 SPCMD。SSLKP 位为 1（SPCR。MSTR 位为 1)时,该位有效。

从模式下该位应设置为 0。SSL传输帧间延迟控制的使用情况如下所示。详见 (4)Burst 传输 .

Note 4. When the SPCR2.SCKASE bit is 1, overrun error detection does not proceed.
Note 5. When SPI is receive only slave mode, none of transmit buffer empty and underrun error is detected.

28.3.2 Controlling the SPI Pins

Based on the settings of the MSTR, MODFEN, and SPMS bits in SPCR and the PmnPFS.NCODR bit for I/O Ports, the SPI can switch pin states. Table 28.8 lists the relationship between pin states and bit settings. Setting the PmnPFS.NCODR bit for an I/O port to 0 selects the CMOS output. Setting it to 1 selects the open-drain output. The I/O port settings must follow this relationship.

28.3.2 控制 SPI 引脚

基于SPCR中的MSTR、MODFEN和SPMS位以及I/O端口的PmnPFS。NCODR位的设置,SPI可以切换引脚状态。表 28。8 列出了引脚状态和位设置之间的关系。将 I/O 端口的 PmnPFS。NCODR 位设置为 0 选择 CMOS 输出。将其设置为 1 选择开漏输出。I/O 端口设置必须遵循此关系。

Note 1. This function is not supported in this mode.
Note 2. SPI settings are not reflected in multiplexed pins for which the SPI function is not selected.
Note 3. When SSLn0 is at the active level, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SSLP.SSL0P bit.
Note 4. When SSLn0 is at the non-active level or the SPCR.SPE bit is 0, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SSLP.SSL0P bit.
Note 5. These pins are available for use as I/O port pins.

The SPI in single-master mode (SPI operation) or multi-master mode (SPI operation) determines the MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) based on the MOIFE and MOIFV bit settings in SPPCR, as listed in Table 28.9.

28.3.3.1 Single-master/single-slave with the MCU as a master

Figure 28.5 shows a single-master/single-slave SPI system configuration example where the MCU is used as a master. In the single-master/single-slave configuration, the SSLni outputs of the MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in the selected state.*1

Note 1. In the transfer format configured when the SPCMDm.CPHA bit is 0, the SSL signal for some slave devices cannot be fixed to an active level. In this case, always connect the SSLni output of the MCU to the SSL input of the slave device.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

28.3.3.2 Single-master/single-slave with the MCU as a slave

Figure 28.6 shows a single-master/single-slave SPI system configuration example where the MCU is used as a slave. When the MCU operates as a slave, the SSLn0 pin is used as SSL input. The SPI master drives the RSPCK and MOSI signals. The MCU (slave) drives the MISOn signal.*1

Note 1. When SSLn0 is at a non-active level, the pin state is Hi-Z.

In the single-slave configuration when the SPCMDm.CPHA bit is set to 1, the SSLn0 input of the MCU (slave) is fixed to the low level and the MCU (slave) is maintained in the selected state. This enables serial transfer execution (Figure 28.7). However, the communication end interrupt does not output when SSL0 input is fixed as Figure 28.7.

Figure 28.8 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes the MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The MCU (master) drives the RSPCKn, MOSIn, and SSLn0 to SSLn3 signals. Out of the SPI slaves 0 to 3, the slave that receives low-level input into the SSL input drives the MISO signal.

28.3.3.4 Single-master/multi-slave with the MCU as a slave

Figure 28.9 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a slave. In this example, the SPI system includes an SPI master and two MCUs (slaves X and Y).

The SPCK and MOSI outputs of the SPI master are connected to the RSPCKn and MOSIn inputs of the MCUs (slaves X and Y). The MISOn outputs of the MCUs (slaves X and Y) are all connected to the MISO input of the SPI master. The SSLX and SSLY outputs of the SPI master are connected to the SSLn0 inputs of the MCUs (slaves X and Y, respectively).

The SPI master drives the SPCK, MOSI, SSLX, and SSLY signals. Of the MCUs (slaves X and Y), the slave that receives low-level input into the SSLn0 input drives the MISOn signal.

28.3.3.5 Multi-master/multi-slave with the MCU as a master

Figure 28.10 shows a multi-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes two MCUs (masters X and Y) and two SPI slaves (SPI slaves 1 and 2).

The RSPCKn and MOSIn outputs of the MCUs (masters X and Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOn inputs of the MCUs (masters X and Y). Any generic port Y output from the MCU (master X) is connected to the SSLn0 input of the MCU (master Y). Any generic port X output of the MCU (master Y) is connected to the SSLn0 input of the MCU (master X). The SSLn1 and SSLn2 outputs of the MCUs (masters X and Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, because the system can be comprised solely of SSLn0 input, and SSLn1 and SSLn2 outputs for slave connections, the SSLn3 output of the MCU is not required.

The MCU drives the RSPCKn, MOSIn, SSLn1, and SSLn2 signals when the SSLn0 input level is high. When the SSLn0 input level is low, the MCU detects a mode fault error, sets RSPCKn, MOSIn, SSLn1, and SSLn2 to Hi-Z, and releases the SPI bus directly to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives the MISO signal.

图28。10示出了使用MCU作为主的多主/多从SPI系统配置示例。在此示例中,SPI 系统包括两个 MCU（主站 X 和 Y）和两个 SPI 从站（SPI 从站 1 和 2)。

MCU（主X和Y）的RSPCKn和MOSIn输出连接到SPI从1和2的RSPCK和MOSI输入。SPI 从站 1 和 2 的 MISO 输出连接到 MCU（主站 X 和 Y）的 MISOn 输入。MCU（主X）输出的任何通用端口Y连接到MCU（主Y）的SSLn0输入。MCU（主 Y）的任何通用端口 X 输出都连接到 MCU（主 X）的 SSLn0 输入。MCU（主X和Y）的SSLn1和SSLn2输出连接到SPI从1和2的SSL输入。在此配置示例中,由于系统可以仅由SSLn0输入以及用于从属连接的SSLn1和SSLn2输出组成,因此不需要MCU的SSLn3输出。

当SSLn0输入电平较高时,MCU驱动RSPCKn、MOSIn、SSLn1和SSLn2信号。当SSLn0输入电平较低时,MCU检测到模式故障错误,将RSPCKn、MOSIn、SSLn1和SSLn2设置为Hi-Z,并将SPI总线直接释放到另一个主站。在SPI从站1和2中,接收SSL输入中的低电平输入的从站驱动MISO信号。

In addition, SSLn0 to SSLn3 of the MCU (slave) are not used.

The MCU (slave) can only execute serial transfers in the single-slave configuration when the SPCMDm.CPHA bit is set to 1.

28.3.4 Data Formats

The data format of the SPI depends on the settings in SPI Command Register m (SPCMDm) and the parity enable bit in SPI Control Register 2 (SPCR2.SPPE). Regardless of whether the MSB or LSB is first, the SPI treats the range from the LSB bit in the SPI Data Register (SPDR/SPDR_HA) to the bit associated with the selected data length, as transfer data.

This section shows the format of one frame of data before or after transfer.

Data format with parity disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[3:0]).

28。3。4 数据格式

SPI的数据格式取决于SPI命令寄存器m（SPCMDm）中的设置和SPI控制寄存器2（SPCR2)中的奇偶校验使能位。属（属）。MSB还是LSB是第一,SPI都将从SPI数据寄存器中的LSB位（SPDR/SPDR_HA）到与所选数据长度相关联的位的范围视为传输数据。

本节显示传输之前或之后一帧数据的格式。

禁用奇偶校验的数据格式

当禁用奇偶校验时,数据的传输或接收以在SPI命令寄存器m（SPCMDm。SPB[3:0])中的SPI数据长度设置中选择的比特长度进行。

Data format with parity enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[3:0]). In this case, however, the last bit is a parity bit.

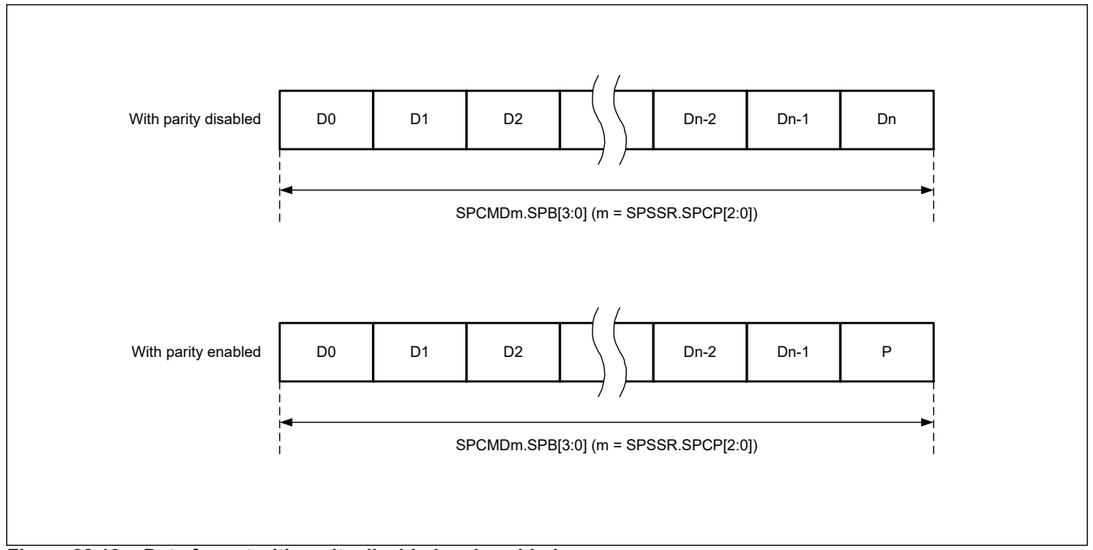

Figure 28.13 Data format with parity disabled and enabled

28.3.4.1 Operation when parity is disabled (SPCR2.SPPE = 0)

When parity is disabled, data for transmission is copied to the shift register with no pre-processing. This section describes the connection between the SPI Data Register (SPDR/SPDR_HA) and the shift register in terms of the combination of MSB- or LSB-first order and data length.

(1) MSB-first transfer with 32-bit data

Figure 28.14 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, a SPI data length of 32 bits, and MSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T31 to T30, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

启用奇偶校验的数据格式

当启用奇偶校验时,数据的传输或接收以在SPI命令寄存器m（SPCMDm。SPB[3:0])中的SPI数据长度设置中选择的比特长度进行。然而,在这种情况下,最后一位是奇偶校验位。

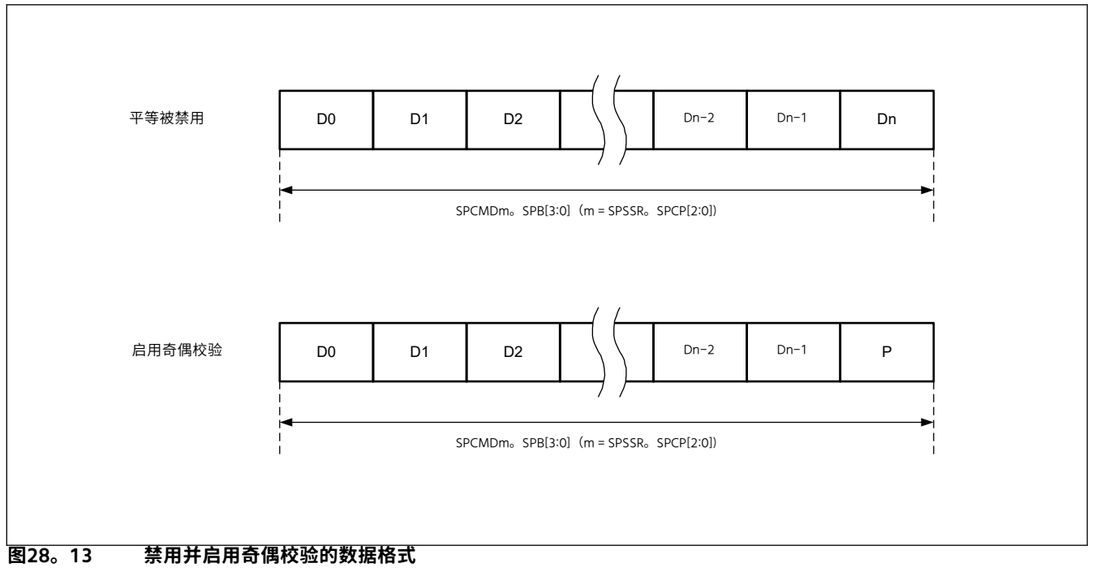

图28。13 禁用并启用奇偶校验的数据格式

28。3。4。1 禁止奇偶校验时的操作（SPCR2。SPPE = 0）

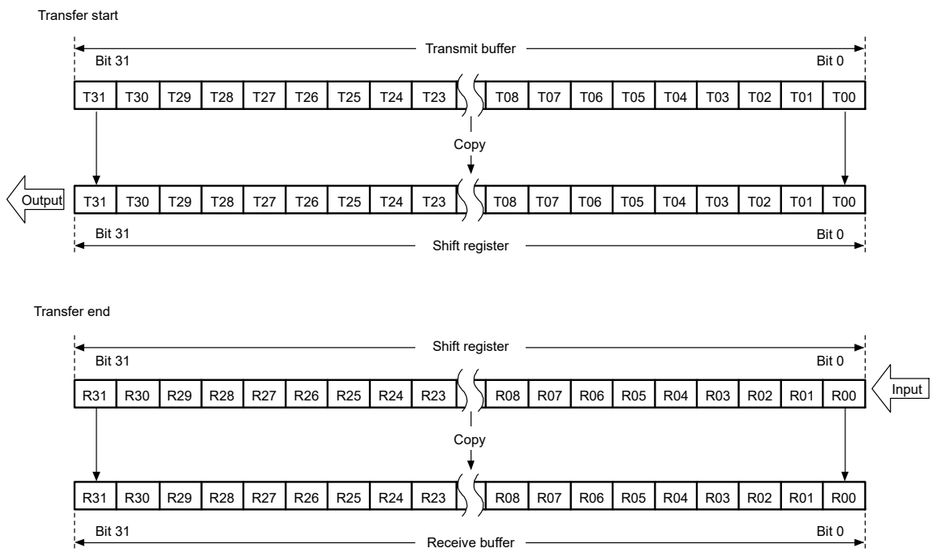
禁用奇偶校验后,用于传输的数据将被复制到移位寄存器,无需预处理。本节根据 MSBor LSB 一阶和数据长度的组合描述 SPI 数据寄存器（SPDR/SPDR_HA）和移位寄存器之间的连接。

(1) 32位数据的MSB优先传输

图 28。14 显示了 SPI 数据寄存器（SPDR）和移位寄存器在禁用奇偶校验、SPI 数据长度为 32 位且首先选择 MSB 的传输中的操作。

在传输中,来自传输缓冲器当前阶段的比特T31至T00被复制到移位寄存器。用于传输的数据从移位寄存器从T31移位到T30,并继续移位到T00。

在接收中,接收到的数据通过移位寄存器的位[0]逐位移位。当输入所需数量的 RSPCK 周期后收集 R31 至 R00 位时,移位寄存器中的值将被复制到接收缓冲区。



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

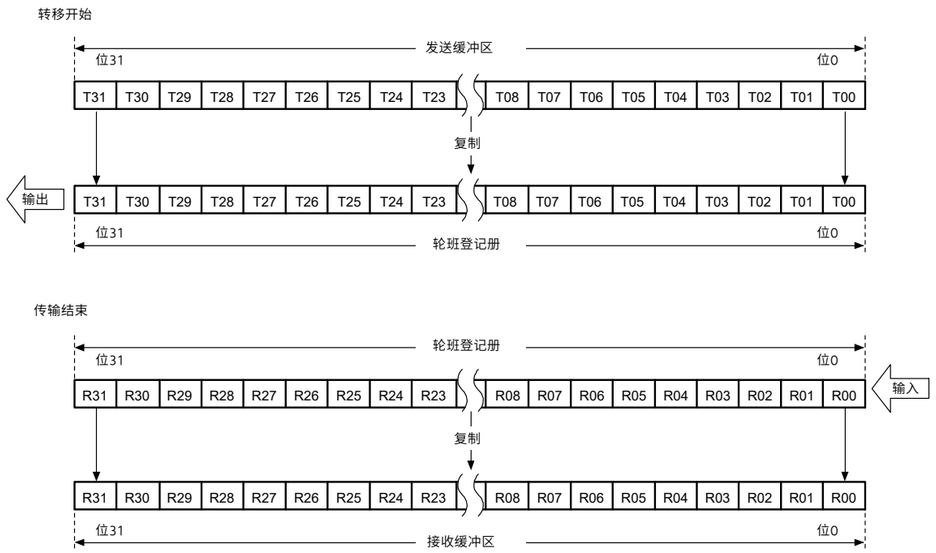
Figure 28.14 MSB-first transfer with 32-bit data and parity disabled

(2) MSB-first transfer with 24-bit data

Figure 28.15 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 24 bits for an example that is not 32 bits, and MSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T23 to T22, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to bits T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.



注: 输出 = MOSI（主）/MISO（从）,输入 = MISO（主）/MOSI（从）

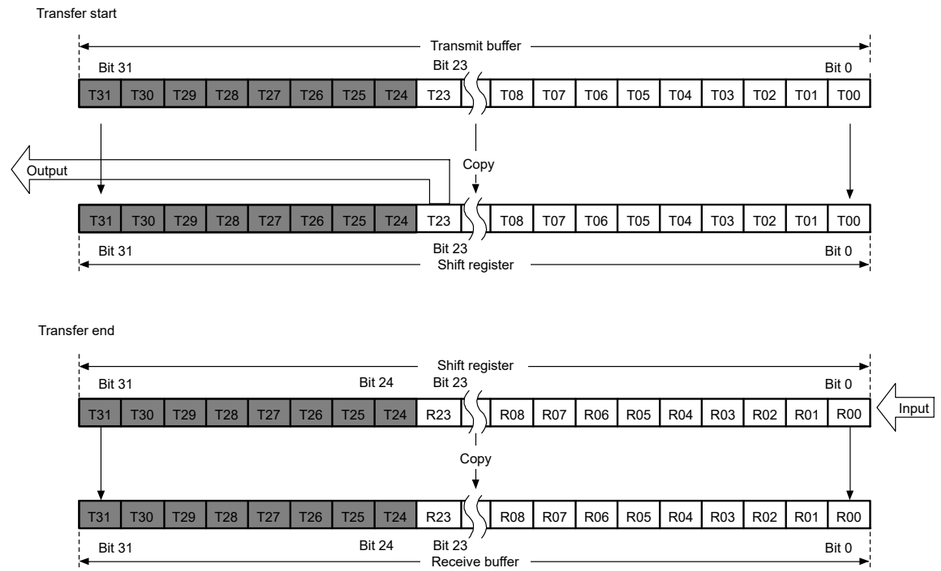
图 28。14 MSB 优先传输 禁用 32 位数据和奇偶校验

(2) 24位数据的MSB优先传输

图28。15显示了SPI数据寄存器（SPDR）和移位寄存器在禁用奇偶校验的传输中的操作,对于不是32位的示例,SPI数据长度为24位,并且首先选择MSB。

在传输中,来自传输缓冲器当前阶段的下24位（T23至T00)被复制到移位寄存器。
用于传输的数据从移位寄存器从T23移位到T22,并继续移位到T00。

在接收中,接收到的数据通过移位寄存器的位[0]逐位移位。当输入所需数量的 RSPCK 周期后收集 R23 至 R00 位时,移位寄存器中的值将被复制到接收缓冲区。在发送-接收操作的情况下,发送缓冲器的上部8位被存储在接收缓冲器的上部8位中。在传输过程中将 0 写入位 T31 至 T24 会导致 0 被插入到接收缓冲区的上部 8 位中。另一方面,在仅接收操作的情况下,接收缓冲区的上部8位被写入0。



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 28.15 MSB-first transfer with 24-bit data and parity disabled

(3) LSB-first transfer with 32-bit data

Figure 28.16 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission is shifted out from the shift register in order from T00 to T01, and continuing to T31.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to R31 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

(3)LSB-与32位数据的首次传输

图 28。16 显示了 SPI 数据寄存器（SPDR）和移位寄存器在禁止奇偶校验、SPI 数据长度为 32 位且首先选择 LSB 的传输中的操作。

在传输中,来自传输缓冲器当前阶段的比特T31至T00被逐位重新排序以获得用于复制到移位寄存器的顺序T00至T31。用于传输的数据从移位寄存器按顺序从T00移位到T01,并继续移位到T31。

在接收中,接收到的数据通过移位寄存器的位[0]逐位移位。当输入所需数量的 RSPCK 周期后收集 R00 至 R31 位时,移位寄存器中的值将被复制到接收缓冲区。

(4) LSB-first transfer with 24-bit data

Figure 28.17 shows the operation of the SPI Data Register (SPDR) and the shift register in transfers with parity disabled, an SPI data length of 24 bits for an example that is not 32, and LSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission is shifted out from the shift register from T00 to T01, and continuing to T23.

In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to R23 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.

(4) 24位数据的LSB优先传输

图28。17显示了SPI数据寄存器（SPDR）和移位寄存器在禁用奇偶校验的传输中的操作,对于不是32的示例,SPI数据长度为24位,并且首先选择LSB。

在传输中,来自传输缓冲器当前阶段的下24位（T23至T00)被逐位重新排序以获得用于复制到移位寄存器的阶数T00至T23。用于传输的数据从移位寄存器从T00移位到T01,并继续移位到T23。

在接收中,接收到的数据通过移位寄存器的位[8]逐位移位。当输入所需数量的 RSPCK 周期后收集 R00 至 R23 位时,移位寄存器中的值将被复制到接收缓冲区。

在发送–接收操作的情况下,发送缓冲器的上部8位被存储在接收缓冲器的上部8位中。在传输过程中写入 0 到 T31 到 T24 会导致 0 被插入到接收缓冲区的上部 8 位中。另一方面,在仅接收操作的情况下,接收缓冲区的上部8位被写入0。

28.3.4.2 Operation when parity is enabled (SPCR2.SPPE = 1)

When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB-first transfer with 32-bit data

Figure 28.18 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T31, T30, …, T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R31 to P is checked for parity.

28.3.4.4 Byte Swap Reception

(1) MSB-first transfer. (When the byte swap is disabled.)

The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31 → R30 → … → R00.

When necessary RSPCK cycles are input and data is stored from Byte0 [R31 to R24] to Byte3 [R07 to R00], the shift register value is copied to the receive buffer.

(2) MSB-first transfer. (When the byte swap is enabled.)

When necessary RSPCK cycles are input and data is stored from Byte3 [R07 to R00] to Byte0 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte0 [R31 to R24] to Byte3 [R07 to R00].

28。3。4。4 字节交换接收

(1)MSB-第一次转移。（当字节交换被禁用时。）

第一接收到的数据（R31)存储在移位寄存器的位0中,并且接收到的数据按照R31 → R30 →的顺序移位 … → R00。

当输入必要的 RSPCK 周期并将数据从 Byte0 [R31 至 R24] 存储到 Byte3 [R07 至 R00] 时,移位寄存器值将被复制到接收缓冲区。

当需要输入 RSPCK 周期并将数据从 Byte3 [R07 至 R00] 存储到 Byte0 [R31 至 R24] 时,移位寄存器中的字节值以字节为单位反转,并按照 Byte0 [R31 的顺序复制到接收缓冲区R24] 到 Byte3 [R07 到 R00]。

(3)LSB-第一次转移。（当字节交换被禁用时。）

28.3.5 Transfer Formats

28.3.5.1 When CPHA = 0

Figure 28.24 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Do not perform clock synchronous operation (SPCR.SPMS = 1) when the SPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 28.24, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0, and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI settings. For details, see section 28.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIn and MISOn signals begins at an SSLni signal assertion. The first RSPCKn signal change that occurs after the SSLni signal assertion becomes the first transfer data fetch. After this, data is sampled every 1 RSPCKn cycle. The change timing for MOSIn and MISOn signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCK signal operation timing as it only affects the signal polarity.

t1 denotes the RSPCK delay, the period from an SSLni signal assertion to RSPCKn oscillation. t2 denotes the SSL negation delay, the period from the termination of RSPCKn oscillation to an SSLni signal negation. t3 denotes the next-access delay,

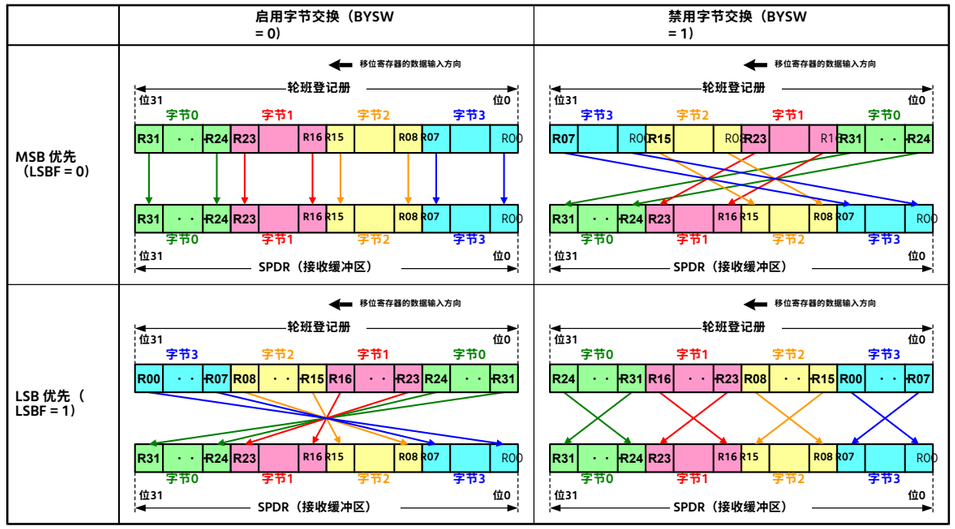
当输入必要的 RSPCK 周期并将数据从字节 0 [R24 至 R31] 存储到字节 3 [R00 至 R07] 时,移位寄存器中每个字节的位值以位单位反转,并按照以下顺序复制到接收缓冲区:字节 0 [R31 至 R24] 至字节 3 [R07 至 R00]。



注: 1。使用字节交换时,将 16 位或 32 位设置为数据长度（SPCMD。SPB[3:0] 设置）。如果设置另一个长度(8 到 15、20、24 位）,则不保证该行为。
2锛姣涓涓。当字节交换有效时,设置奇偶校验函数无效（SPCR2)。SPPE 位 = 0)。如果将奇偶校验函数设置为有效（SPPE 位 = 1),则该行为无法得到保证。
3锛 娴 。设置 SPDCR2。BYSW 位,当 SPCR。SPE 位为 0 时。BYSW位重写的话,当SPE位为1时,其后的行为就不保证了。

图28。24示出了当SPCMDm。CPHA比特为0时8位数据串行传输的示例传输格式。SPI 在从模式下运行时（SPCR。MSTR = 0),CPHA 位为 0 时,请勿执行时钟同步操作（SPCR。SPMS = 1)。在图28。24中,当SPCMDm。CPOL位为0时,RSPCKn（CPOL=0)指示RSPCKn信号波形,当CPOL位为1时,RSPCKn（CPOL=1)指示RSPCKn信号波形。采样时序表示SPI将串行传输数据获取到移位寄存器中的时序。信号的 I/O 方向取决于 SPI 设置。详情请参见第 28。3。2 节。控制 SPI 引脚 .

当SPCMDm。CPHA位为0时,将有效数据驱动到MOSIn和MISOn信号开始于SSLni信号断言。SSLni信号断言后发生的第一个RSPCKn信号变化成为第一个传输数据获取。此后,每 1 个 RSPCKn 周期对数据进行采样。MOSIn 和 MISOn 信号的改变定时为传输数据获取定时后的 1/2 RSPCK 周期。CPOL 位设置不会影响 RSPCK 信号操作时序,因为它仅影响信号极性。

t1 表示 RSPCK 延迟,从 SSLni 信号断言到 RSPCKn 振荡的周期。t2 表示 SSL 否定延迟,从 RSPCKn 振荡终止到 SSLni 信号否定的周期。t3 表示下一次访问延迟,

the period in which SSLni signal assertion is suppressed for the next transfer after the end of serial transfer. t1, t2, and t3 are controlled by a master device running on the SPI system. Figure 28.24 SPI transfer format when CPHA = 0

28.3.5.2 When CPHA = 1

Figure 28.25 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLni signals are not used, and only the three signals RSPCKn, MOSIn, and MISOn handle communications. In Figure 28.25, RSPCK (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0 and RSPCK (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI mode (master or slave mode). For details, see section 28.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOn signal begins at an SSLni signal assertion. The output of valid data to the MOSIn and MISOn signals begins at the first RSPCKn signal change that occurs after the SSLni signal assertion. After this, data is updated every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKn signal operation timing. It only affects the signal polarity.

t1, t2, and t3 are the same as those when CPHA = 0. For a description of t1, t2, and t3 when the SPI of the MCU is in master mode, see section 28.3.11.1. Master mode operation.

28.3.5.2 当CPHA = 1时

图28。25示出了当SPCMDm。CPHA比特为1时用于串行传输8位数据的示例传输格式。

然而,当SPCR。SPMS位为1时,不使用SSLni信号,并且仅使用RSPCKn、MOSIn和MISOn三个信号来处理通信。在图28。25中,当SPCMDm。CPOL比特为0时,RSPCK（CPOL=0)指示RSPCKn信号波形,当CPOL比特为1时,RSPCK（CPOL=1)指示RSPCKn信号波形。采样时序表示SPI将串行传输数据获取到移位寄存器中的时序。信号的 I/O 方向取决于 SPI 模式（主模式或从模式）。详情请参见第 28。3。2 节。控制 SPI 引脚 .

当SPCMDm。CPHA位为1时,将无效数据驱动到MISOn信号开始于SSLni信号断言。向MOSIn和MISOn信号输出有效数据从SSLni信号断言之后发生的第一个RSPCKn信号变化开始。此后,每 1 个 RSPCK 周期更新一次数据。传输数据获取定时是数据更新定时之后的1/2个RSPCK周期。SPCMDm。CPOL 位设置不影响 RSPCKn 信号操作定时。它只影响信号极性。

t1、t2、t3 与 CPHA = 0 时相同。对于当MCU的SPI处于主模式时t1、t2和t3的描述,请参见第28。3。11。1节。主模式操作 .

28.3.6 Data Transfer Modes

Full-duplex synchronous serial communications or transmit operations can only be selected in the Communications Operating Mode Select bit (SPCR.TXMD) when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is 0. The SPI operation is receive only in slave mode (SPCR.MSTR = 0) when the SPCR3.ETXMD bit is 1, because SPCR.TXMD bit does not affect the SPI operation. The register accesses shown in Figure 28.26, Figure 28.27, and Figure 28.28 indicate the condition of access to the SPDR/SPDR_HA register, where W denotes a write cycle.

28.3.6.1 Full-duplex synchronous serial communications (SPCR3.ETXMD = 0, SPCR.TXMD = 0)

Figure 28.26 shows an example of operation when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 0 and the Communications Operating Mode Select bit (SPCR.TXMD) is set to 0. In this example, the SPI performs an 8-bit serial transfer when SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

28。3。6 数据传输模式

当SPI控制寄存器3（SPCR3)中的扩展通信模式选择位（ETXMD）为0时,只能在通信操作模式选择位（SPCR。TXMD）中选择全双工同步串行通信或发送操作。SPI 操作仅在 SPCR3 时以从模式（SPCR。MSTR = 0) 接收。ETXMD 位为 1,因为 SPCR。TXMD 位不影响 SPI 操作。28。26、图28。27、图28。28所示的寄存器访问指示访问SPDR/SPDR_HA寄存器的条件,其中W表示写入周期。

图28。26示出了当SPI控制寄存器3（SPCR3)中的扩展通信模式选择位（ETXMD）被设置为0并且通信操作模式选择位（SPCR。TXMD）被设置为0时的操作示例。在此示例中,当SPDCR。SPFC[1:0]位为00b、SPCMDm。CPHA位为1、SPCMDm。CPOL位为0时,SPI执行8位串行传输。波形中为 RSPCKn 给出的数字表示 RSPCK 周期数,例如传输位数。

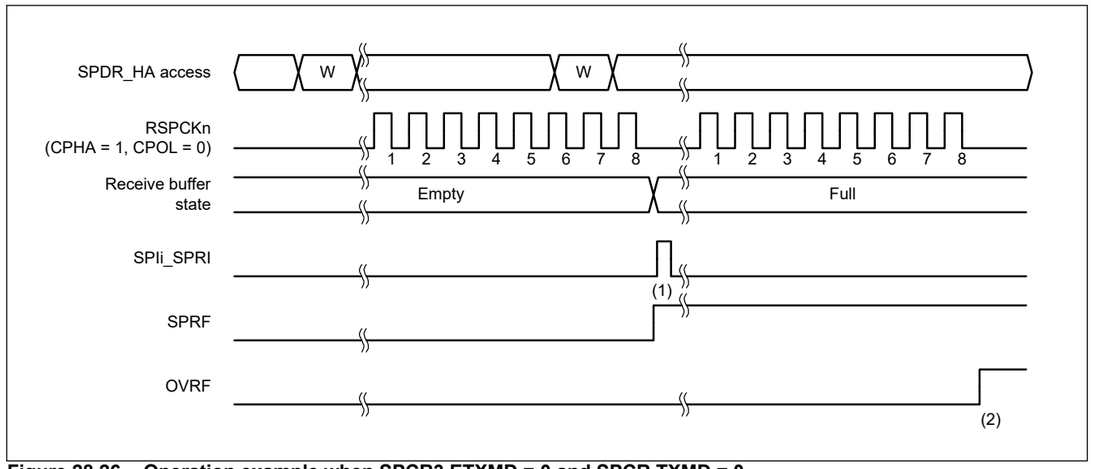

Figure 28.26 Operation example when SPCR3.ETXMD = 0 and SPCR.TXMD = 0

The operation of the flags at timings (1) and (2) in Figure 28.26 is as follows:

1. When a serial transfer ends with the receive buffer of SPDR_HA empty, the SPI generates a receive buffer full interrupt request (SPIi_SPRI), the SPI sets the SPSR.SPRF flag to 1, and copies the received data in the shift register to the receive buffer.
2. When a serial transfer ends with the receive buffer of SPDR_HA holding data that was received in the previous serial transfer, the SPI sets the SPSR.OVRF flag to 1, and discards the received data in the shift register. For details about the operation of the SPSR.OVRF flag, see section 28.3.9.1. Overrun errors.

28.3.6.2 Transmit-Only Serial Communications (SPCR3.ETXMD = 0, SPCR.TXMD = 1)

Figure 28.27 shows an example of operation when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 0 and the Communications Operating Mode Select bit (SPCR.TXMD) is set to 1. In this example, the SPI performs an 8-bit serial transfer when SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

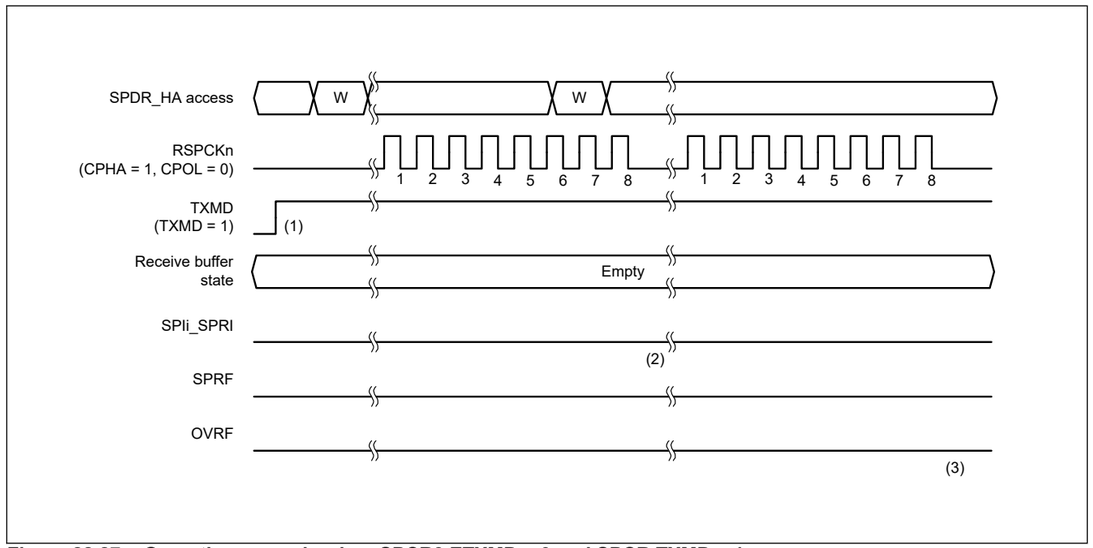

Figure 28.27 Operation example when SPCR3.ETXMD = 0 and SPCR.TXMD = 1

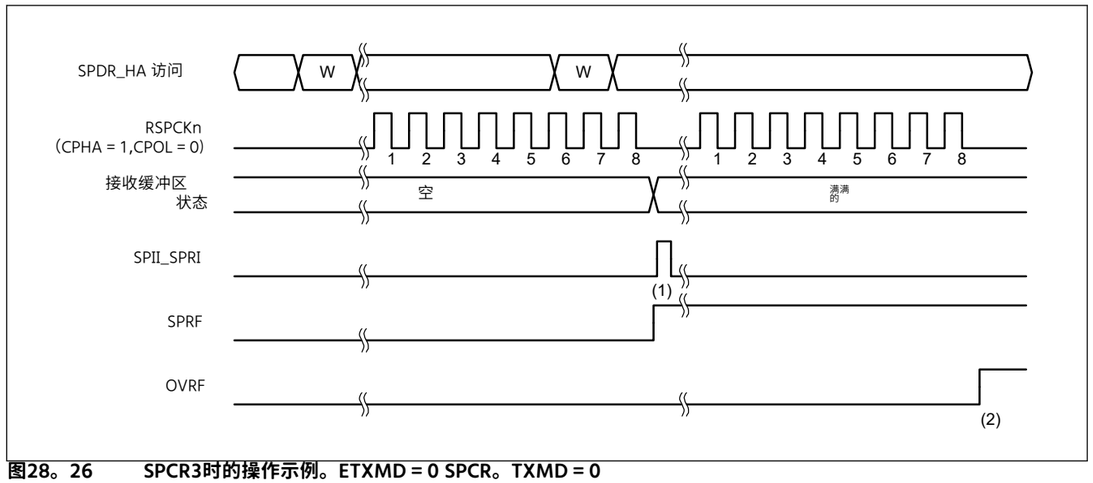

图28。26 SPCR3时的操作示例。ETXMD = 0 SPCR。TXMD = 0

图 28。26 中标志在时间 (1) 和 (2) 处的操作如下:

1。SPDR_HA的接收缓冲区为空的串行传输结束时,SPI生成接收缓冲区全中断请求（SPIi_SPRI）,SPI将SPSR。SPRF标志设置为1,并将移位寄存器中接收到的数据复制到接收缓冲区。

2锛姣涓涓。SPDR_HA 的接收缓冲区保存上一次串行传输中接收到的数据时,串行传输结束,SPI 将 SPSR。OVRF 标志设置为 1,并将接收到的数据丢弃在移位寄存器中。有关 SPSR。OVRF 标志操作的详细信息,请参阅第 28。3。9。1 节。超限错误 .

28。3。6。2 仅传输串行通信（SPCR3。ETXMD = 0 SPCR。TXMD = 1）

图28。27示出了当SPI控制寄存器3（SPCR3)中的扩展通信模式选择位（ETXMD）被设置为0并且通信操作模式选择位（SPCR。TXMD）被设置为1时的操作示例。在此示例中,当SPDCR。SPFC[1:0]位为00b、SPCMDm。CPHA位为1、SPCMDm。CPOL位为0时,SPI执行8位串行传输。波形中为 RSPCKn 给出的数字表示 RSPCK 周期数,例如传输位数。

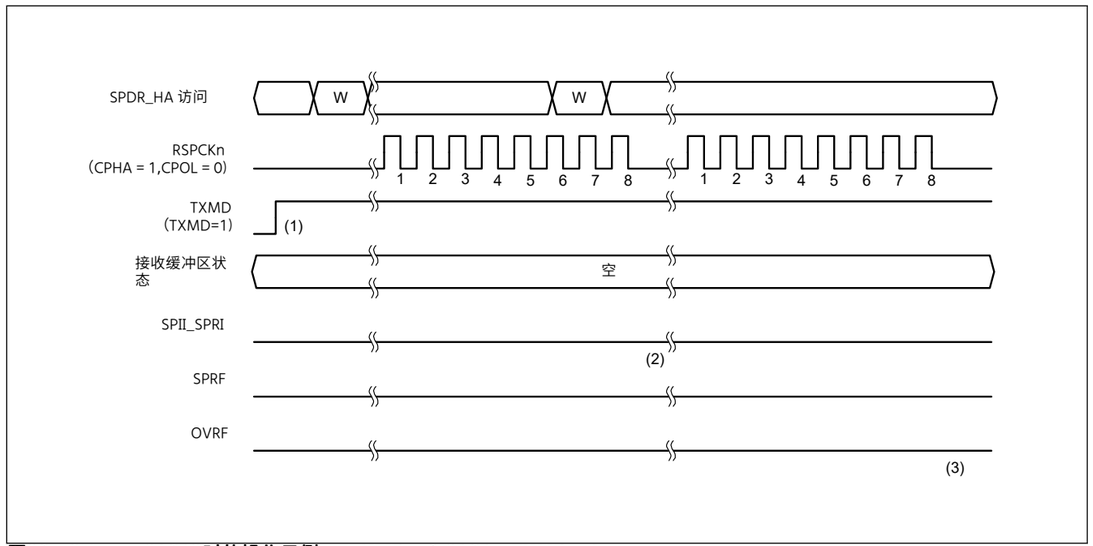

图28。27 SPCR3时的操作示例。ETXMD = 0 SPCR。TXMD = 1

The operation of the flags at timings (1) to (3) in Figure 28.27 is as follows:

1. Make sure there is no data left in the receive buffer (the SPSR.SPRF flag is 0) and the SPSR.OVRF flag is 0 before entering transmit-only mode (SPCR3.ETXMD = 0, SPCR.TXMD = 1).
2. When a serial transfer ends with the receive buffer of SPDR_HA empty, if the transmit-only mode is selected (SPCR3.ETXMD = 0, SPCR.TXMD = 1), the SPSR.SPRF flag retains the value of 0, and the SPI does not copy the data in the shift register to the receive buffer.
3. Because the receive buffer of SPDR_HA does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

In transmit-only mode (SPCR3.ETXMD = 0, SPCR.TXMD = 1), the SPI transmits data but does not receive data. Therefore, the SPSR.SPRF and SPSR.OVRF flags remain 0 at timings (1) to (3).

28.3.6.3 Receive-Only Serial Communication (MSTR = 0, ETXMD = 1)

Figure 28.28 shows an example of operation when the SPI master/slave mode select bit (MSTR) in the SPI control register (SPCR) is set to 0 and the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 1. In the example in Figure 28.28, the SPI performs 8-bit data serial transfer with the settings of SPFC[1:0] in the SPI data control register (SPDCR) = 00b, CPHA in the SPI command register (SPCMD) = 1, and CPOL in SPCMD = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

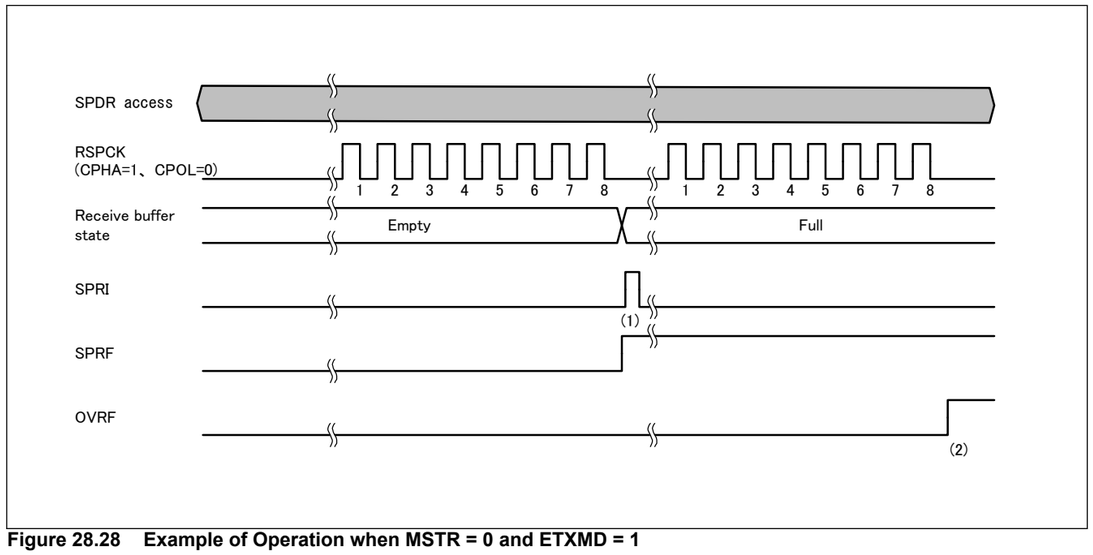

Figure 28.28 Example of Operation when MSTR = 0 and ETXMD = 1

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the SPDR's receive buffer is empty, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer

(2) When serial transfer ends while previously received data is remaining in the SPDR's receive buffer, the SPI sets the OVRF flag in the SPI status register (SPSR) to 1 and discards the received data in the shift register.

28.3.7 Transmit Buffer Empty and Receive Buffer Full Interrupts

Figure 28.29 and Figure 28.30 show examples of operation of the transmit buffer empty interrupt (SPIi_SPTI) and the receive buffer full interrupt (SPIi_SPRI). The SPDR_HA register accesses shown in these figures indicate the conditions of access to the register, where W denotes a write cycle and R a read cycle. In Figure 28.29, the SPI performs an 8-bit serial transfer when SPCR.TXMD bit is 0, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 0, and the SPCMDm.CPOL bit is 0. In Figure 28.30, the SPI performs an 8-bit serial transfer when SPCR.TXMD bit is 0, the

图 28。27 中标志在时间 (1) 至 (3) 处的操作如下:

1。在进入仅发送模式（SPCR3)之前,确保接收缓冲区中没有数据（SPSR。SPRF 标志为 0)并且 SPSR。OVRF 标志为 0。ETXMD = 0,SPCR。TXMD = 1)。

2锛姣涓涓。SPDR_HA 的接收缓冲区为空的串行传输结束时,如果选择仅发送模式（SPCR3)。ETXMD = 0,SPCR。TXMD = 1),SPSR。SPRF标志保留0的值,SPI不将移位寄存器中的数据复制到接收缓冲区。

3锛　　娴　　。SPDR_HA的接收缓冲区因为不保存之前串行传输中接收到的数据,即使串行传输结束时,SPSR。OVRF标志也保留了0的值,移位寄存器中的数据不被复制到接收缓冲区。

因此,SPSR。SPRF 和 SPSR。OVRF 标志在时间 (1) 至 (3) 处保持为 0。

图28。28 MSTR = 0 和 ETXMD = 1 时的操作示例

下面描述标志在上图中的时间(1)和(2)处的操作。

(1) 当串行传输在 SPDR 的接收缓冲区为空时结束, SPI 生成接收缓冲区全中断请求 SPRI（将 SPSR。SPRF 标志设置为 1), 并将移位寄存器中接收到的数据复制到接收缓冲区

(2)当串行传输结束而先前接收的数据保持在SPDR的接收缓冲区中时,SPI将SPI状态寄存器（SPSR）中的OVRF标志设置为1,并将接收到的数据丢弃在移位寄存器中。

SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

Figure 28.30 Operation example of the SPIi_SPTI and SPIi_SPRI interrupts when CPHA = 1 and CPOL = 0 in master mode

The operation of the SPI at timings (1) to (5) in Figure 28.29 and Figure 28.30 is as follows:

1. When transmit data is written to SPDR_HA with the transmit buffer of SPDR_HA is empty and data for the next transfer is not set, the SPI writes data to the transmit buffer and clears the SPSR.SPTEF flag to 0.
2. If the shift register is empty, the SPI copies the data in the transmit buffer to the shift register, generates a transmit buffer empty interrupt request (SPIi_SPTI), and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the SPI mode. For details, see section 28.3. Operation, and section 28.3.12. Clock Synchronous Operation.
3. When transmit data is written to SPDR_HA either by the transmit buffer empty interrupt routine, or by the processing of the transmit buffer empty using the SPTEF flag, the SPI writes data to the transmit buffer and clears the SPTEF flag to 0. Because the data being transferred serially is stored in the shift register, the SPI does not copy the data in the transmit buffer to the shift register.
4. When the serial transfer ends with the receive buffer of SPDR_HA empty, the SPI copies the receive data in the shift register to the receive buffer, generates a receive buffer full interrupt request (SPIi_SPRI), and sets the SPRF flag to 1. Because the shift register becomes empty on completion of the serial transfer, if the transmit buffer is full before the serial transfer ended, the SPI sets the SPTEF flag to 1 and copies data in the transmit buffer to the shift register. Even

图28。30 当 CPHA = 1 且 CPOL = 0 时 SPII_SPTI 和 SPII_SPRI 中断的操作示例 主模式

SPI在图28。29和图28。30中的时间(1)至(5)处的操作如下:

1。SPDR_HA 的发送缓冲区将发送数据写入 SPDR_HA 时为空且未设置下一次传输的数据,SPI 将数据写入发送缓冲区并将 SPSR。SPTEF 标志清除为 0。

2锛姣涓涓。如果移位寄存器为空,则SPI将发送缓冲区中的数据复制到移位寄存器,生成发送缓冲区空中断请求（SPIi_SPTI）,并将SPSR。SPTEF标志设置为1。串行传输如何启动取决于 SPI 模式。详情请参见第 28。3 节。操作和第 28。3。12 节。时钟同步操作 .

3锛　　娴　　。SPDR_HA 写入发送数据时, 要么通过发送缓冲区空中断例程, 要么通过使用 SPTEF 标志处理发送缓冲区空, SPI 将数据写入发送缓冲区并将 SPTEF 标志清除为 0。由于串行传输的数据存储在移位寄存器中,因此 SPI 不会将发送缓冲区中的数据复制到移位寄存器。

4锛姣涓。SPDR_HA 的接收缓冲区为空时串行传输结束,SPI 将移位寄存器中的接收数据复制到接收缓冲区,生成接收缓冲区全中断请求（SPIi_SPRI）,并将 SPRF 标志设置为 1。因为串行传输完成后移位寄存器变为空,所以如果在串行传输结束之前发送缓冲区已满,则SPI将SPTEF标志设置为1并将发送缓冲区中的数据复制到移位寄存器。甚至

when received data is not copied from the shift register to the receive buffer in an overrun error status, on completion of the serial transfer, the SPI determines that the shift register is empty, so data transfer from the transmit buffer to the shift register is enabled.

5. When SPDR_HA is read either by the receive buffer full interrupt routine or processing of the receive buffer full interrupt using the SPRF flag, the receive data can be read.

If SPDR_HA is written to when the transmit buffer holds data that is not yet transmitted (the SPTEF flag is 0), the SPI does not update data in the transmit buffer. When writing to SPDR_HA, always use either a transmit buffer empty interrupt request or processing of the transmit buffer empty interrupt using the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1. If the SPI function is disabled (the SPCR.SPE bit is 0), set the SPTIE bit to 0.

When serial transfer ends and the receive buffer is full (the SPRF flag is 1), the SPI does not copy data from the shift register to the receive buffer, and it detects an overrun error (see section 28.3.9. Error Detection). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an SPI receive buffer full interrupt, set the SPCR.SPRIE bit to 1.

Transmission and reception interrupts or the associated IELSRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers.

Similarly, the SPTEF and SPRF flags can be used to confirm the states of the transmit and receive buffers. See section 12, Interrupt Controller Unit (ICU) for the interrupt vector numbers.

28.3.8 Communication End Interrupt

28.3.8.1 Transmit-Receive/Transmit in Master Mode

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1, when following conditions are satisfied in transmit-receive master mode and transmit master mode. The set timing of the CENDF flag is same as IDLNF flag. The communication end interrupt (SPCI) is one PCLKA width and low active.

- When the value of the SPSSR.SPCP[2:0] bits are same as the SPSCR.SPSLN[2:0] bits.
- When there is no next transmission data.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following tow conditions.

- When the next transmission data is written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 28.31 shows an example of communication end interrupt operation during transmit-receive/transmit master mode.

当接收到的数据没有以超限错误状态从移位寄存器复制到接收缓冲器时,在串行传输完成后,SPI确定移位寄存器为空,因此启用从发送缓冲器到移位寄存器的数据传输。

5锛姣涓。SPDR_HA被接收缓冲区全中断例程或使用SPRF标志处理接收缓冲区全中断读取时,可以读取接收数据。

SPDR_HA写入到发送缓冲区保存尚未发送的数据时（SPTEF标志为0),则SPI不更新发送缓冲区中的数据。SPDR_HA 写入时,始终使用传输缓冲区空中断请求或使用 SPTEF 标志处理传输缓冲区空中断。要使用发送缓冲区空中断,请将 SPCR 中的 SPTIE 位设置为 1。如果 SPI 函数被禁用（SPCR。SPE 位为 0),请将 SPTIE 位设置为 0。

当串行传输结束且接收缓冲区已满（SPRF 标志为 1)时,SPI 不会将数据从移位寄存器复制到接收缓冲区,并且会检测到溢出错误（参见第 28。3。9 节）。误（检测）。为了防止接收数据溢出错误,在下一个串行传输结束之前使用接收缓冲区完全中断请求读取接收到的数据。要使用 SPI 接收缓冲区完全中断,请将 SPCR。SPRIE 位设置为 1。

ICU中的发送和接收中断或相关联的IELSRn。IR标志（其中n是中断向量数）可用于确认发送和接收缓冲区的状态。

类似地,SPTEF和SPRF标志可用于确认发射和接收缓冲器的状态。有关中断向量编号,请参阅第 12 节"中断控制器单元（ICU）"。

28。3。8 通信端中断

28。3。8。1 主模式下的发送–接收/发送

当在发送–接收主模式和发送主模式下满足以下条件时,进行通信端中断（SPCI）并将CENDF标志设置为1。CENDF 标志的设置时序与 IDLNF 标志相同。通信端中断（SPCI）为 1 PCLKA 宽度且低活动。

- 当 SPSSR。SPCP[2:0] 位的值与 SPSCR。SPSLN[2:0] 位相同时。
- 当没有下一个传输数据时。

即使 SPCR。SPE 位在 CENDF = 1 后被清除,CENDF 标志也不会被清除。CENDF 标志将在以下拖曳条件下之一被清除。

- 当下一个传输数据被写入到传输缓冲区（SPTX）时。
- 当 CENDF 标志为 1 时,读取 SPSR 后,将 CENDF 标志写为 0。

图28。31示出了发送–接收/发送主模式期间的通信端中断操作的示例。

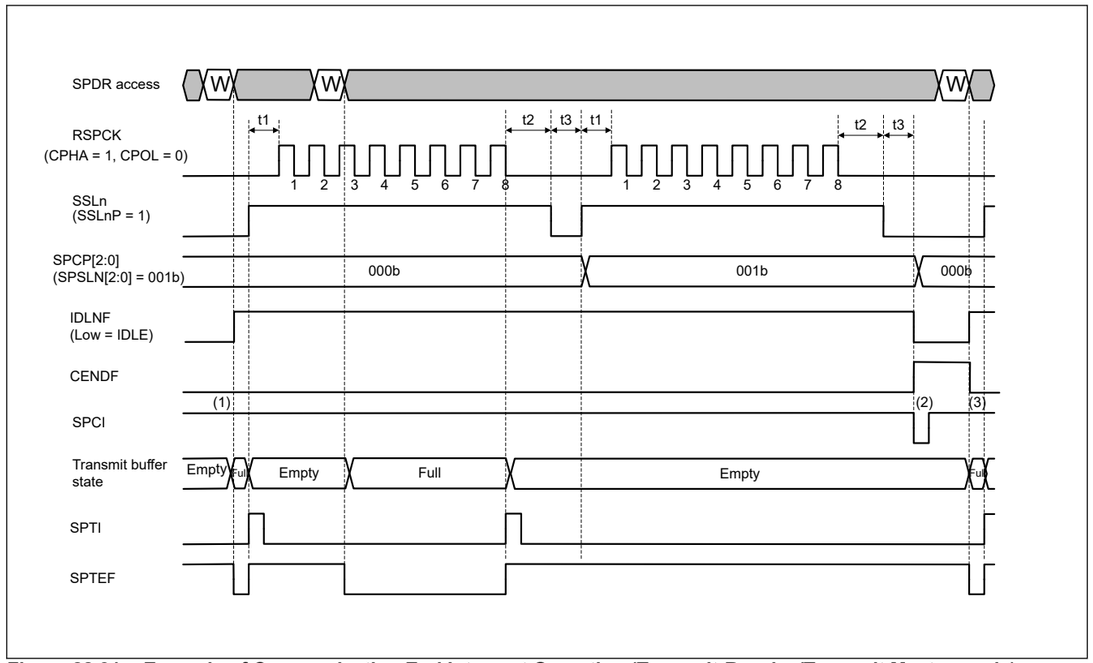

Figure 28.31 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Master mode)

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle, because the next command is 000b and there is no next transmit data, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

In slave mode operation, the output timing of the communication end interrupt is deferent due to the value of the SPCR.SPMS bit (SPI mode select bit), and the clear timing of the communication end interrupt is deferent due to the communication mode (transmit-receive or transmit-only or receive-only).

28.3.8.2 Transmit-Receive/Transmit in Slave Mode on SPI Operation (4-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1, when both SPTX buffer and transmit shift buffer are empty in transmit-receive/transmit slave mode on SPI Operation (4-wire). The set timing of the CENDF flag is same as SSL0 negate timing. The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following tow conditions.

- When the next transmission data is written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 28.32 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on SPI operation.

SPI 操作(4 线）上,当 SPTX 缓冲区和发射移位缓冲区在发射–接收/发射从模式下均为空时,进行通信端中断（SPCI）,并将 CENDF 标志设置为 1。CENDF标志的设定时序与SSL0否定时序相同。通信端中断（SPCI）为 1 PCLKA 宽度且低活动。

即使 SPCR。SPE 位在 CENDF = 1 后被清除,CENDF 标志也不会被清除。CENDF 标志将在以下拖曳条件下之一被清除。

28.3.8.3 Receive Only in Slave Mode on SPI Operation (4-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1 at the SSL0 negate timing in receive only slave mode on SPI operation (4-wire). The number of transmission frame is set by the SPDCR.SPFC[1:0]. Then the SSL0 is negated at the last frame transmission end. The communication end interrupt (SPCI) is one PCLKA width and low active.

- The SSL0 assert timing of next transmission.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

即使 SPCR。SPE 位在 CENDF = 1 后被清除,CENDF 标志也不会被清除。CENDF 标志将在以下拖曳条件下之一被清除。

- SSL0 断言下一次传输的定时。
- 当 CENDF 标志为 1 时,读取 SPSR 后,将 CENDF 标志写为 0。

28.3.8.4 Transmit-Receive/Transmit in Slave Mode on Clock Synchronous Operation (3-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1 when both SPTX buffer and transmit shift register are empty in transmit-receive/transmit slave mode on clock synchronous operation (3-wire). The set timing of CENDF flag is same as the last data sampling of the RSPCK (the last odd edge of RSPCK when the SPCMD0.CPHA bit is 0, the last even edge of RSPCK when the SPCMD0.CPHA bit is 1). The communication end interrupt (SPCI) is one PCLKA width and low active.

28.3.8.6 Common Operation

In this chapter, the operation common to each mode / area option communication in section 28.3.8.1. Transmit-Receive/ Transmit in Master Mode to section 28.3.8.5. Receive Only in Slave Mode on Clock Synchronous Operation (3-wire) is explained. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, a flag of communication end (CENDF) is set and an event of communication end (sp_elccend) is output, but no interrupt is output. However, if the enable of communication end interrupt (CENDIE) is set to 1 before clearing the flag of communication end (CENDF) while the enable of SPI function (SPE) is 1, the communication end interrupt is output.

   - An event of communication end (sp_elccend)
   - The communication end interrupt

28。3。8。6 共同操作

在本章中,第 28。3。8。1 节中每个模式/区域选项通信的通用操作。主模式下的发送-接收/发送至第 28。3。8。5 节。仅在时钟同步操作(3 线）上以从模式接收进行了解释。SPI通信端中断（CENDIE）的使能为0时,在通信完成时,设置通信端标志（CENDF）并输出通信端事件（sp_elccend）,但不输出中断。但是,如果在清除通信端标志（CENDF）之前将通信端中断（CENDIE）的使能设置为1,而SPI功能（SPE）的使能为1,则输出通信端中断。

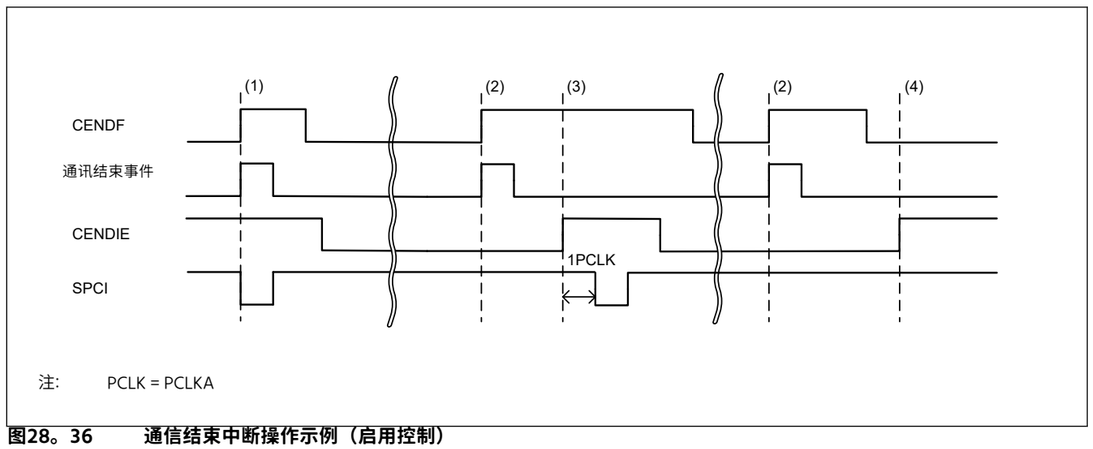

图28。36 通信结束中断操作示例（启用控制）

   - A flag of communication end (CENDF)
   - An event of communication end (sp_elccend)
3. After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt is output after 1 PCLKA.
4. After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt is not output.

28.3.9 Error Detection

In normal SPI serial transfers, data written to the transmit buffer of SPDR/SPDR_HA is transmitted, and received data can be read from the receive buffer of SPDR/SPDR_HA. If access is made to SPDR/SPDR_HA, an abnormal transfer might occur, depending on the status of the transmit or receive buffer or the status of the SPI at the beginning or end of serial transfer.

If an abnormal transfer occurs, the SPI detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 28.10 lists the relationship between non-normal transfer operations and the SPI error detection function.

Table 28.10 Relationship between non-normal transfer operations and SPI error detection

Operation	Occurrence condition	SPI operation	Error detection
1	SPDR/SPDR_HA is written when the transmit buffer is full.	• The contents of the transmit buffer are kept • Write data is missing	None
2	SPDR/SPDR_HA is read when the receive buffer is empty.	The contents of the receive buffer and previously received data are output.	None
3	Serial transfer is started in slave mode when the SPI is not able to transmit data.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Underrun error
4	Serial transfer terminates when the receive buffer is full.	• Keeps the contents of the receive buffer • Missing receive data	Overrun error
5	An incorrect parity bit is received during full-duplex synchronous serial communication with the parity function enabled in following mode: • Transmit-receive master mode • Transmit-receive slave mode • Receive-only slave mode	The parity error flag is asserted	Parity error
6	The SSLn0 input signal is asserted when the serial transfer is idle in multi-master mode.	• Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped • SPI function is disabled	Mode fault error
7	The SSLn0 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped • SPI function is disabled	Mode fault error
8	The SSLn0 input signal is negated during serial transfer in slave mode.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Mode fault error

In operation 1 described in Table 28.10, the SPI does not detect an error. To prevent data omission during writes to SPDR/SPDR_HA, the writes to SPDR/SPDR_HA must be executed using a transmit buffer empty interrupt request (when the SPSR.SPTEF flag is 1).

Similarly, the SPI does not detect an error in operation 2. To prevent extraneous data from being read, SPDR/SPDR_HA read must be executed with an SPI receive buffer full interrupt request (when the SPSR.SPRF flag is 1).

For information on the other errors, see the following sections:

2锛姣涓涓。SPI通信端中断（CENDIE）的使能为0时,在通信完成时,以下两个是相同的时序,但没有中断。

- 通信端标志（CENDF）
- 通信结束的事件（sp_elccend）

3锛　　娴　　。(2)之后,如果当SPI函数（SPE）的使能和通信端的标志（CENDF）为1时设置通信端中断的使能（CENDIE）,则在1 PCLKA之后输出通信端中断。

4锛姣涓。(2)之后,即使在SPI函数（SPE）的使能或通信端（CENDF）的标志为0时设置通信端中断（CENDIE）的使能,也不输出通信端中断。

28。3。9 错误检测

SPI的正常串行传输中,发送写入到SPDR/SPDR_HA的发送缓冲区的数据,并且可以从SPDR/SPDR_HA的接收缓冲区读取接收到的数据。SPDR/SPDR_HA进行访问,则可能会发生异常传输,具体取决于传输或接收缓冲区的状态或串行传输开始或结束时的SPI状态。

如果发生异常传输,SPI 会将该事件检测为欠载错误、溢出错误、奇偶校验错误或模式故障错误。
表28。10列出了非正常传输操作与SPI错误检测功能之间的关系。

表 28。10 非正常传输操作与 SPI 错误检测之间的关系

操作	发生情况	SPI 操作	错误检测
1	SPDR/SPDR_HA 是在发送缓冲区已满时写入的。	• 保留发送缓冲区的内容 • 写入数据缺失	没有
2	SPDR/SPDR_HA 在接收缓冲区为空时读取。	输出接收缓冲区和先前接收的数据的内容。	没有
3	SPI 无法传输数据时以从模式启动串行传输。	• 串行传输暂停 • 传输或接收数据丢失 • MISOn 输出信号的驱动停止 • SPI功能被禁用	欠运行错误
4	当接收缓冲区已满时,串行传输终止。	• 保留接收缓冲区的内容 • 接收数据缺失	超限错误
5	在以下模式下启用奇偶校验函数的全双工同步串行通信期间接收到不正确的奇偶校验位: • 发送-接收主模式 • 发射-接收从模式 • 仅接收从模式	断言奇偶校验错误标志	奇偶校验错误
6	当串行传输在多主模式下空闲时断言SSLn0输入信号。	• 驾驶 RSPCKn、MOSIn、SSLn1 至 SSLn3输出信号停止 • SPI功能被禁用	模式故障错误
7	SSLn0输入信号在多主模式下串行传输时断言。	• 串行传输暂停 • 传输或接收数据丢失 • 驾驶 RSPCKn、MOSIn、SSLn1 至 SSLn3输出信号停止 • SPI功能被禁用	模式故障错误
8	SSLn0输入信号在从模式下串行传输时被否定。	• 串行传输暂停 • 传输或接收数据丢失 • MISOn 输出信号的驱动停止 • SPI功能被禁用	模式故障错误

在表 28。10 中描述的操作 1 中,SPI 不会检测到错误。防止写入 SPDR/期间数据遗漏 SPDR_HA,对 SPDR/SPDR_HA 的写入必须使用发送缓冲区空中断请求执行（当 SPSR。SPTEF 标志是 1)。

类似地,SPI 在操作 2 中不会检测到错误。为了防止读取无关数据,必须使用 SPI 接收缓冲区完全中断请求（当 SPSR。SPRF 标志为 1 时）来执行 SPDR/SPDR_HA 读取。有关其他错误的信息,请参阅以下部分:

28.3.9.1 Overrun errors

If a serial transfer ends when the receive buffer of SPDR/SPDR_HA is full, the SPI detects an overrun error and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the SPI does not copy data from the shift register to the receive buffer, so the data prior to the error occurrence is retained in the receive buffer. To set the OVRF flag to 0, write 0 to the OVRF flag after the CPU reads SPSR with the OVRF flag set to 1.

Figure 28.37 shows an example of operation of the OVRF and SPRF flags. The SPSR and SPDR_HA accesses shown in Figure 28.37 indicate the condition of accesses to the SPSR and SPDR_HA register, where W denotes a write cycle, and R a read cycle. In this example, the SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

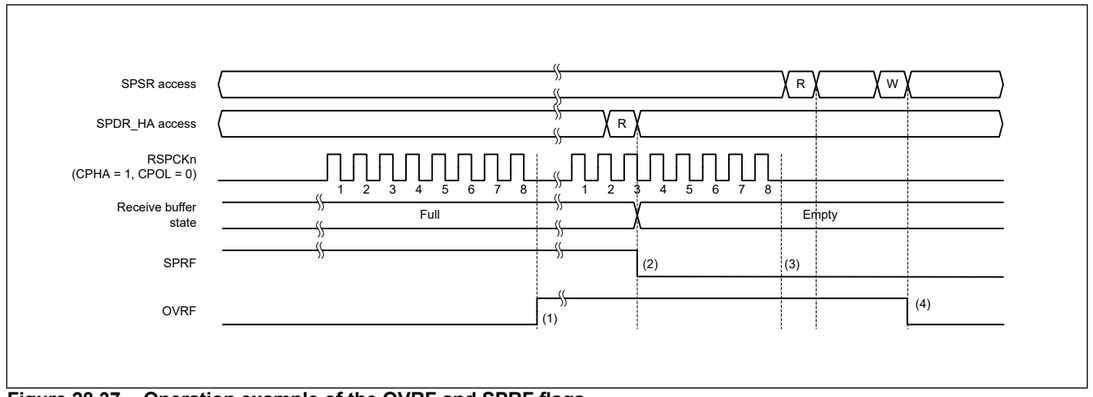

Figure 28.37 Operation example of the OVRF and SPRF flags

The operation of the flags at timings (1) to (4) in Figure 28.37 is as follows:

1. If a serial transfer terminates with the SPRF flag set to 1 (receive buffer full), the SPI detects an overrun error, and sets the OVRF flag to 1. The SPI does not copy the data in the shift register to the receive buffer. Even when the SPPE bit is 1, parity errors are not detected.
2. When SPDR/SPDR_HA is read, the SPI outputs the data in the receive buffer. The SPRF flag is then set to 0. The receive buffer becoming empty does not set the OVRF flag to 0.
3. If the serial transfer ends with the OVRF flag set to 1 (overrun error occurred), the SPI does not copy data in the shift register to the receive buffer (the SPRF flag does not set to 1). A receive buffer full interrupt is not generated. Even when the SPPE bit is 1, parity errors are not detected. In an overrun error state when the SPI does not copy the received data from the shift register to the receive buffer, on termination of the serial transfer, the SPI determines that the shift register is empty. This enables data transfer from the transmit buffer to the shift register.
4. If 0 is written to the OVRF flag after SPSR is read when the OVRF flag is 1, the OVRF flag clears is set to 0.

The occurrence of an overrun can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. When executing a serial transfer, you must ensure that overrun errors are detected early, for example by reading SPSR immediately after SPDR/SPDR_HA/SPDR_BY is read.

If an overrun error occurs and the OVRF flag sets to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

28。3。9。1 超支错误

SPDR/SPDR_HA 的接收缓冲区已满时,串行传输结束,则 SPI 检测到溢出错误,并将 SPSR。OVRF 标志设置为 1。OVRF标志为1时,SPI不会将数据从移位寄存器复制到接收缓冲区,因此错误发生之前的数据被保留在接收缓冲区中。要将 OVRF 标志设置为 0,请在 CPU 读取 SPSR 后将 OVRF 标志写入 0,并将 OVRF 标志设置为 1。

图28。37示出了OVRF和SPRF标志的操作示例。图28。37所示的SPSR和SPDR_HA访问指示对SPSR和SPDR_HA寄存器的访问条件,其中W表示写入周期,R表示读取周期。在此示例中,当 SPCMDm。CPHA 位为 1 且 SPCMDm。CPOL 位为 0 时,SPI 执行 8 位串行传输。波形中为 RSPCKn 给出的数字表示 RSPCK 周期数,例如传输位数。

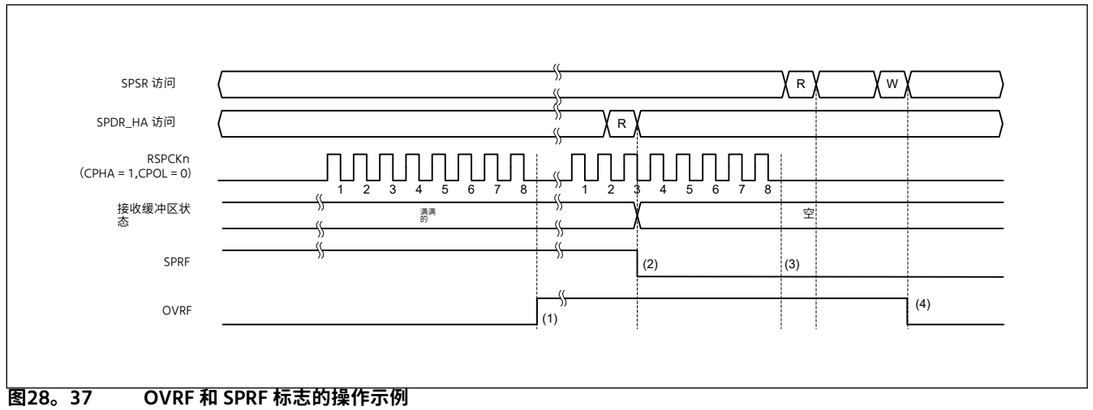

图28。37 OVRF 和 SPRF 标志的操作示例

图 28。37 中标志在时间 (1) 至 (4) 处的操作如下:

1。如果串行传输终止时 SPRF 标志设置为 1（接收缓冲区已满）,SPI 会检测到溢出错误,并将 OVRF 标志设置为 1。SPI 不会将移位寄存器中的数据复制到接收缓冲区。SPPE 位为 1 时, 也未检测到奇偶校验错误。

2锛姣涓涓。SPDR/SPDR_HA被读取时,SPI输出接收缓冲区中的数据。SPRF标志,然后将其设置为0。接收缓冲区变空不会将 OVRF 标志设置为 0。

3锛　　娴　　。如果串行传输以 OVRF 标志设置为 1 结束（发生溢出错误）,SPI 不会将移位寄存器中的数据复制到接收缓冲区（SPRF 标志不设置为 1)。未生成接收缓冲区完全中断。SPPE 位为 1 时, 也未检测到奇偶校验错误。SPI没有将接收到的数据从移位寄存器复制到接收缓冲器时处于超限错误状态,在串行传输终止时,SPI确定移位寄存器为空。这使得数据能够从发送缓冲区传输到移位寄存器。

4锛姣涓。如果当 OVRF 标志为 1 时读取 SPSR 后将 0 写入 OVRF 标志,则 OVRF 标志清除设置为 0。

可以通过读取 SPSR 或使用 SPI 错误中断并读取 SPSR 来检查溢出的发生。
执行串行传输时,必须确保及早检测到溢出错误,例如在读取 SPDR/SPDR_HA/SPDR_BY 后立即读取 SPSR。

OVRF 标志设置为 1 时发生超限错误, 则在 OVRF 标志设置为 0 之前, 无法执行正常的接收操作。

When the RSPCK auto-stop function is enabled (SPCR2.SCKASE = 1) in master mode, an overrun error does not occur. Figure 28.38 and Figure 28.39 show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

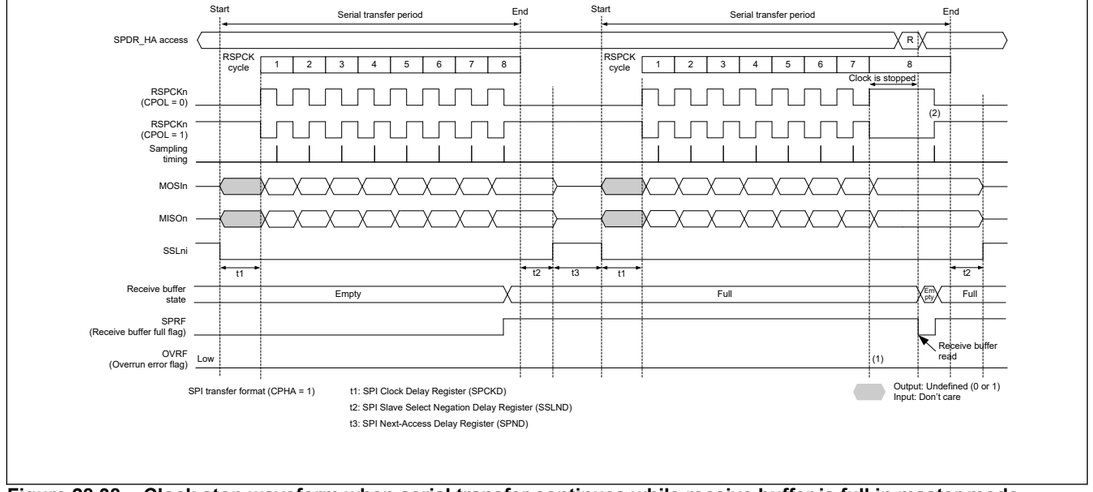

Figure 28.38 Clock stop waveform when serial transfer continues while receive buffer is full in master mode (CPHA = 1)

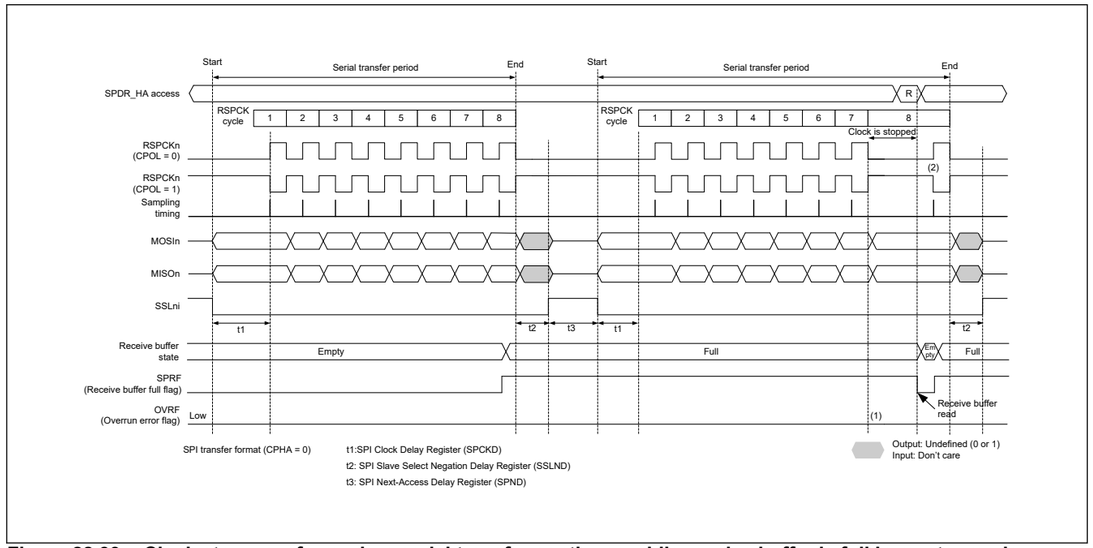

Figure 28.39 Clock stop waveform when serial transfer continues while receive buffer is full in master mode (CPHA = 0)

The operation of the flags at timings (1) and (2) in Figure 28.38 and Figure 28.39 is as follows:

1. When the receive buffer is full, an overrun error does not occur because the RSPCK clock is stopped.
2. If SPDR/SPDR_HA is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts after reading the receive buffer (after the SPSR.SPRF flag is set to 0).

当启用 RSPCK 自动停止功能时（SPCR2)。SCKASE = 1) 在主模式下,不会发生超限错误。

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. 图28。41 主接收缓冲区中连续传输继续时钟停止波形已满式（在突发传输和帧之间没有延迟CPHA = 0）

下面描述标志在上图中的时间(1)和(2)处的操作。

1. While the receive buffer is full, the RSPCK clock is deactivated and no overrun error occurs.
2. Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read (after the SPSR.SPRF flag has been cleared to 0), the RSPCK clock restarts.

28.3.9.2 Parity errors

When full-duplex synchronous serial communications is performed with the SPCR.TXMD bit set to 0 and the SPCR2.SPPE bit set to 1, when serial transfer ends, the SPI checks whether there are parity errors. On detecting a parity error in the received data, the SPI sets the SPSR.PERF flag to 1. Because the SPI does not copy data in the shift register to the receive buffer when the SPSR.OVRF flag is set to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, write 0 to the PERF flag after the SPSR register is read with the PERF flag set to 1.

Figure 28.42 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 28.42 indicates the condition of access to the register, where W denotes a write cycle, and R a read cycle. In this example, full-duplex serial communication is performed while the SPCR2.SPPE bit is 1. The SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

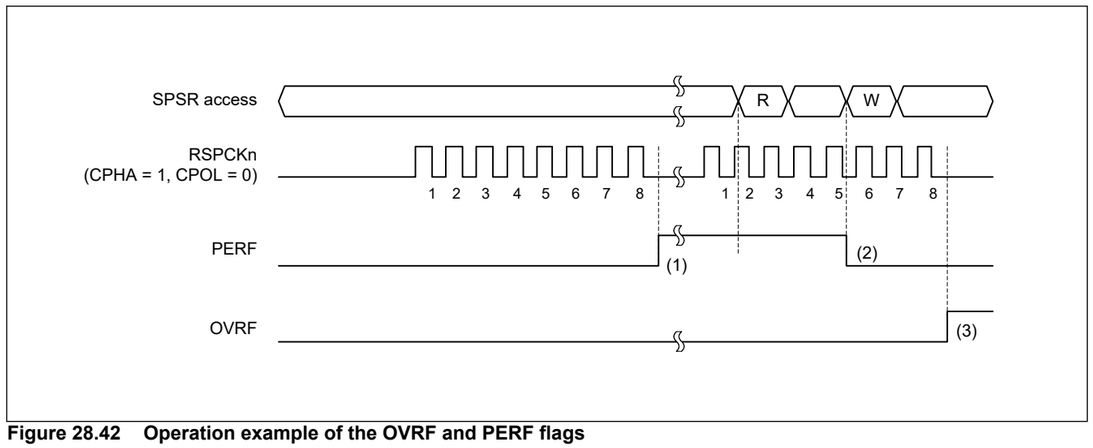

Figure 28.42 Operation example of the OVRF and PERF flags

The operation of the flags at timings (1) to (3) in Figure 28.42 is as follows:

1. If a serial transfer terminates with the SPI not detecting an overrun error, the SPI copies the data in the shift register to the receive buffer. The SPI checks the received data at this time and sets the PERF flag to 1 if a parity error is detected.
2. If 0 is written to the PERF flag after the SPSR register is read when the PERF flag is 1, the PERF flag is set to 0.
3. When the SPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The SPI does not perform parity error detection at this time.

Parity errors can be checked for by either reading the SPSR register or using an SPI error interrupt and reading the SPSR register. When executing a serial transfer, such checks are required to ensure early detection of parity errors. When the SPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits (Only SPI0).

28.3.9.3 Mode fault errors

The SPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input for the SSLn0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of the status of the serial transfer, and sets the SPSR.MODF flag to 1. On detecting the mode fault error, the SPI copies the value of the pointer to SPCMDm to the SPDCR.SPFC[1:0] bits. The active level of the SSLn0 signal is determined by the SSLP.SSL0P bit.

When the MSTR bit is 0, the SPI operates in slave mode. The SPI detects a mode fault error if the MODFEN bit of the SPI in slave mode is 1, and the SPMS bit is 0, and if the SSLn0 input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

1。当接收缓冲区已满时,RSPCK 时钟将被停用,并且不会发生溢出错误。

2锛姣涓涓。可以通过在时钟停止期间读取 SPDR 来读取接收缓冲区数据。读取接收缓冲区数据后（SPSR。SPRF 标志清除至 0 后）,RSPCK 时钟重新启动。

28。3。9。2 奇偶校验误差

当使用设置为0的SPCR。TXMD位和SPCR2执行全双工同步串行通信时。SPPE 位设置为 1,当串行传输结束时,SPI检查是否存在奇偶校验错误。在检测到接收到的数据中的奇偶校验错误时,SPI 将 SPSR。PERF 标志设置为 1。由于当SPSR。OVRF标志设置为1时,SPI不会将移位寄存器中的数据复制到接收缓冲区,因此不会对接收到的数据执行奇偶校验错误检测。要将 PERF 标志设置为 0,请在 SPSR 寄存器读取 PERF 标志设置为 1 后,将 0 写入 PERF 标志。

图 28。42 显示了 OVRF 和 PERF 标志的操作示例。图28。42所示的SPSR访问指示访问寄存器的条件,其中W表示写入周期,R表示读取周期。在此示例中,在 SPCR2 期间执行全双工串行通信。SPPE 位为 1。当SPCMDm。CPHA位为1且SPCMDm。CPOL位为0时,SPI执行8位串行传输。波形中为 RSPCKn 给出的数字表示 RSPCK 周期数,例如传输位数。

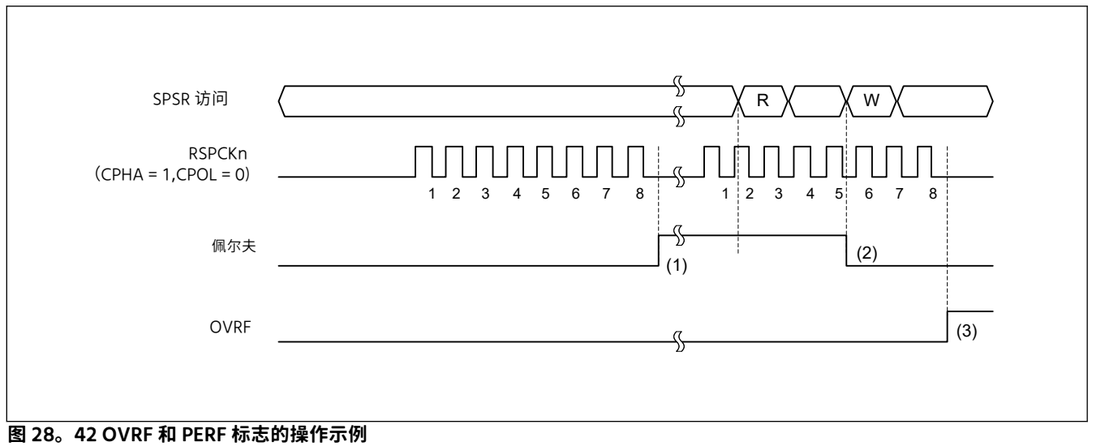

图 28。42 OVRF 和 PERF 标志的操作示例

图 28。42 中标志在时间 (1) 至 (3) 处的操作如下:

1。如果串行传输以 SPI 未检测到溢出错误而终止,则 SPI 将移位寄存器中的数据复制到接收缓冲区。SPI此时检查接收到的数据,如果检测到奇偶校验错误,则将PERF标志设置为1。

2锛姣涓涓。PERF 标志为 1 时读取 SPSR 寄存器后将 0 写入 PERF 标志,则将 PERF 标志设置为 0。

3锛　　娴　　。SPI 检测到超限错误而终止串行传输时,移位寄存器中的数据不会被复制到接收缓冲区。SPI 此时不执行奇偶校验错误检测。

可以通过读取 SPSR 寄存器或使用 SPI 错误中断并读取 SPSR 寄存器来检查奇偶校验错误。执行串行传输时,需要进行此类检查以确保及早检测奇偶校验错误。SPI在主模式下使用时,可以通过读取SPSSR。SPECM[2:0]位（仅SPI 0)来检查错误发生时SPCMDm寄存器的指针值。

28。3。9。3 模式故障错误

当SPCR。MSTR位为1、SPCR。SPMS位为0、SPCR。MODFEN位为1时,SPI以多主模式操作。如果在多主模式下输入SPI的SSLn0输入信号的活动电平,则无论串行传输的状态如何,SPI都会检测到模式故障错误,并将SPSR。MODF标志设置为1。在检测模式故障错误时,SPI 将指向 SPCMDm 的指针值复制到 SPDCR。SPFC[1:0] 位。SSLn0信号的活动电平由SSLP。SSL0P位确定。

MSTR位为0时,SPI以从模式运行。如果从模式下SPI的MODFEN位为1,SPMS位为0,并且如果在串行传输期间（从有效数据的驱动开始到获取最终有效数据的时间）。

On detecting a mode fault error, the SPI stops the driving of the output signals and clears the SPCR.SPE bit to 0 (see section 28.3.10. Initializing the SPI). For multi-master configuration, detection of a mode fault error is used to stop the driving of output signals and the SPI function, which allows the master to be released.

The occurrence of a mode fault error can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting mode-fault errors without using the SPI error interrupt requires polling of SPSR. When using the SPI in master mode, the value of the pointer to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of a mode fault error, the MODF flag must be set to 0.

28.3.9.4 Underrun errors

While the SPI is operating in slave mode (SPCR.MSTR bit = 0) and the Extended Communication Mode Select bit (ETXMD) in the SPI Control Register 3 (SPCR3) is set to 0, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1 (SPI function enabled), the SPI detects an underrun error and sets the SPSR.MODF and SPSR.UDRF flags to 1.

On detecting an underrun error, the SPI stops the driving of output signals and clears the SPCR.SPE bit to 0 (see section 28.3.10. Initializing the SPI).

The occurrence of underrun errors can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting underrun errors without using the SPI error interrupt requires polling of SPSR.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of an underrun error, the MODF flag must be set to 0.

28.3.10 Initializing the SPI

If 0 is written to the SPCR.SPE bit or if the SPI sets the SPE bit to 0 because it detected a mode fault error or an underrun error, the SPI disables the SPI function and initializes some of the module functions. When a system reset is generated, the SPI initializes all of the module functions. This section describes initialization by clearing of the SPCR.SPE bit and by a system reset.

28.3.10.1 Initialization by clearing of the SPCR.SPE bit

When the SPCR.SPE bit is set to 0, the SPI initializes by:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the SPI
- Initializing the transmit buffer of the SPI (the SPSR.SPTEF flag sets to 1)

Initialization by clearing of the SPE bit does not initialize the control bits of the SPI. For this reason, the SPI can be started in the same transfer mode in use prior to initialization when the SPE bit is set to 1 again.

The SPSR.CENDF, SPSR.SPRF, SPSR.OVRF, SPSR.MODF, SPSR.PERF, and SPSR.UDRF flags are not initialized, and the value of the SPI Sequence Status Register (SPSSR) is not initialized. Therefore, even after the SPI is initialized, data from the receive buffer can be read to check the communication completion status and the error status during an SPI transfer.

The transmit buffer is initialized to an empty state (the SPSR.SPTEF flag sets to 1). Therefore, if the SPCR.SPTIE bit is set to 1 after SPI initialization, a transmit buffer empty interrupt is generated. To disable any transmit buffer empty interrupts when the SPI is initialized, write 0 to the SPTIE bit simultaneously while writing 0 to the SPE bit.

28.3.10.2 Initialization by system reset

A system reset completely initializes the SPI by initializing all SPI control bits, status bits, and data registers, in addition to meeting the requirements described in section 28.3.10.1. Initialization by clearing of the SPCR.SPE bit.

在检测到模式故障错误时,SPI 停止输出信号的驱动并将 SPCR。SPE 位清除为 0（参见第 28。3。10 节）。初始化 SPI）。对于多主配置,模式故障误差的检测用于停止输出信号的驱动和SPI功能,从而允许释放主。

模式故障错误的发生可以通过读取 SPSR 或使用 SPI 错误中断并读取 SPSR 来检查。在不使用 SPI 错误中断的情况下检测模式故障错误需要轮询 SPSR。在主模式下使用SPI时,可以通过读取SPSSR。SPECM[2:0]位来检查错误发生时指向SPCMDm寄存器的指针的值。

MODF标志为1时,SPI忽略写入1到SPE位。MODF 标志,要在检测到模式故障错误后启用 SPI 功能,必须设置为 0。

28。3。9。4 欠载错误

当SPI在从模式下操作时（SPCR。MSTR位=0)并且SPI控制寄存器3（SPCR3)中的扩展通信模式选择位（ETXMD）被设置为0,如果在发送数据输出之前开始串行传输准备就绪,SPCR。SPE 位设置为 1（启用 SPI 功能）, SPI 检测到欠载错误并将 SPSR。MODF 和 SPSR。UDRF 标志设置为 1。

在检测到欠载错误时,SPI 停止输出信号的驱动并将 SPCR。SPE 位清除为 0（参见第 28。3。10 节）。初始化 SPI).

可以通过读取 SPSR 或使用 SPI 错误中断并读取 SPSR 来检查欠载错误的发生。在不使用 SPI 错误中断的情况下检测欠载错误需要轮询 SPSR。

MODF标志为1时,SPI忽略写入1到SPE位。要在检测到欠载错误后启用 SPI 功能,必须将 MODF 标志设置为 0。

28。3。10 初始化 SPI

如果将 0 写入 SPCR。SPE 位,或者如果 SPI 由于检测到模式故障错误或欠载错误而将 SPE 位设置为 0,则 SPI 禁用 SPI 函数并初始化一些模块函数。当生成系统重置时,SPI 会初始化所有模块功能。本节描述通过清除 SPCR。SPE 位和系统重置进行初始化。

28。3。10。1 通过清除 SPCR。SPE 位进行初始化

SPCR。SPE 位设置为 0 时, SPI 初始化为:

- 暂停正在执行的任何串行传输
- 停止从模式下输出信号（Hi-Z）的驱动
- 初始化 SPI 的内部状态
- 初始化 SPI 的发射缓冲区（SPSR。SPTEF 标志设置为 1）

通过清除 SPE 位来初始化不会初始化 SPI 的控制位。因此,当 SPE 位再次设置为 1 时,SPI 可以在初始化之前以相同的传输模式启动。

SPSR。CENDF、SPSR。SPRF、SPSR。OVRF、SPSR。MODF、SPSR。PERF 和 SPSR。UDRF 标志未初始化,SPI 序列状态寄存器（SPSSR）的值未初始化。因此,即使在初始化SPI之后,也可以读取来自接收缓冲器的数据以检查SPI传输期间的通信完成状态和错误状态。

发射缓冲区初始化为空状态（SPSR。SPTEF 标志设置为 1)。因此,如果SPI初始化后SPCR。SPTIE位被设置为1,则生成发送缓冲区空中断。为了在 SPI 初始化时禁用任何发送缓冲区空中断,请同时将 0 写入 SPTIE 位,同时将 0 写入 SPE 位。

28.3.10.2 通过系统重置进行初始化

系统重置除了满足第 28。3。10。1 节中描述的要求外,还通过初始化所有 SPI 控制位、状态位和数据寄存器来完全初始化 SPI。通过清除 SPCR。SPE 位 . 进行初始化

28.3.11 SPI Operation

28.3.11.1 Master mode operation

The only difference between single- and multi-master mode operation is the use of mode fault error detection (see section 28.3.9. Error Detection). In single-master mode, the SPI does not detect mode fault errors whereas in multi-master mode, it does. This section explains operations that are common to both modes.

(1) Starting a serial transfer

The SPI updates the data in the transmit buffer (SPTX) when data is written to the SPI Data Register (SPDR/SPDR_HA) with the SPI transmit buffer empty, data for the next transfer is not set, and the SPSR.SPTEF flag is 0. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR/SPDR_HA/SPDR_BY, the SPI copies data from the transmit buffer to the shift register and starts serial transfer. On copying transmit data to the shift register, the SPI changes the status of the shift register to full. On termination of the serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

The polarity of the SSLni output pins depends on the SSLP register settings. For details on the SPI transfer format, see section 28.3.5. Transfer Formats.

(2) Terminating a serial transfer

Regardless of the SPCMDm.CPHA bit setting, the SPI terminates the serial transfer after transmitting an RSPCKn edge associated with the final sampling timing. If free space is available in the receive buffer (SPRX) (the SPSR.SPRF flag is 0), on termination of the serial transfer, the SPI copies data from the shift register to the receive buffer of the SPDR/SPDR_HA register.

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[3:0] bit settings. The polarity of the SSLni output pin depends on the SSLP register settings. For details on the SPI transfer format, see section 28.3.5. Transfer Formats.

(3) Sequence control

The transfer format used in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers.

The SPSCR register determines the sequence configuration for serial transfers that are executed by the SPI in master mode. The following items are set in the SPCMDm register:

- SSLni pin output signal value
- MSB- or LSB-first
- Data length
- Some of the bit rate settings
- RSPCK polarity and phase
- Whether SPCKD is to be referenced
- Whether SSLND is to be referenced
- Whether SPND is to be referenced

SPBR holds some of the bit rate settings, including SPCKD (SPI clock delay), SSLND (SSL negation delay), and SPND (next-access delay).

Based on the sequence length assigned in SPSCR, the SPI makes up a sequence comprised of a part or all of the SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command in the sequence, the SPI sets the pointer to SPCMD0, and in this way the sequence is executed repeatedly.

28。3。11 SPI 操作

28。3。11。1 主模式操作

单主模式和多主模式操作之间的唯一区别是使用模式故障错误检测（参见第 28。3。9 节）。误（检测）。在单主模式下,SPI 不会检测模式故障错误,而在多主模式下,SPI 会检测到模式故障错误。本节解释两种模式共有的操作。

(1)开始串行转移

SPI 将数据写入 SPI 数据寄存器（SPDR/SPDR_HA）时,SPI 会更新发送缓冲区（SPTX）中的数据,其中 SPI 发送缓冲区为空,未设置下一次传输的数据,并且 SPSR。SPTEF 标志为0。SPDCR。SPFC[1:0]位中设置的帧数后移位寄存器为空时写入SPDR/SPDR_HA/SPDR_BY,SPI将数据从发送缓冲区复制到移位寄存器并开始串行传输。将传输数据复制到移位寄存器时,SPI 将移位寄存器的状态更改为完整。串行传输终止后,它会将移位寄存器的状态更改为空。无法引用轮班寄存器的状态。

SSLni 输出引脚的极性取决于 SSLP 寄存器设置。有关 SPI 传输格式的详细信息,请参阅第 28。3。5 节。传输格式 .

（二）终止连续转让

无论 SPCMDm。CPHA 位设置如何,SPI 在发送与最终采样定时相关联的 RSPCKn 边后终止串行传输。如果接收缓冲区（SPRX）中有可用空闲空间（SPSR。SPRF 标志为 0),则在串行传输终止时,SPI 将数据从移位寄存器复制到 SPDR/SPDR_HA 寄存器的接收缓冲区。

最终采样时间根据传输数据的位长度而变化。在主模式下,SPI 数据长度取决于 SPCMDm。SPB[3:0] 位设置。SSLni 输出引脚的极性取决于 SSLP 寄存器设置。有关 SPI 传输格式的详细信息,请参阅第 28。3。5 节。传输格式 .

(3)序列控制

主模式下使用的传输格式由SPSCR、SPCMDm、SPBR、SPCKD、SSLND和SPND寄存器确定。

SPSCR寄存器确定SPI在主模式下执行的串行传输的序列配置。
SPCMDm 寄存器中设置了以下项目:

- SSLni 引脚输出信号值
- MSBor LSB-优先
- 数据长度
- 一些比特率设置
- RSPCK 极性和相位
- 是否要引用 SPCKD
- 是否要引用 SSLND
- 是否要引用 SPND

SPBR 保存一些比特率设置,包括 SPCKD（SPI 时钟延迟）、SSLND（SSL 否定延迟）和 SPND（下一步访问延迟）。

根据 SPSCR 中分配的序列长度,SPI 组成由 SPCMDm 寄存器的一部分或全部组成的序列。SPI 包含一个指向构成序列的 SPCMDm 寄存器的指针。该指针的值可以通过读取SPSSR。SPCP[2:0]位来检查。当SPCR。SPE位设置为1并且启用SPI功能时,SPI将指针加载到SPCMD0中的命令,并在串行传输开始时将SPCMD0设置合并到传输格式中。每次数据传输的下一次访问延迟周期结束时,SPI 都会增加指针。

完成与序列中的最终命令相对应的串行传输后,SPI将指针设置为SPCMD0,这样重复执行序列。

(4) Burst transfers

If the SPCMDm.SSLKP bit that the SPI references during the current serial transfer is 1, the SPI maintains the SSLni signal level during the serial transfer until the beginning of the SSLni signal assertion for the next serial transfer. If the SSLni

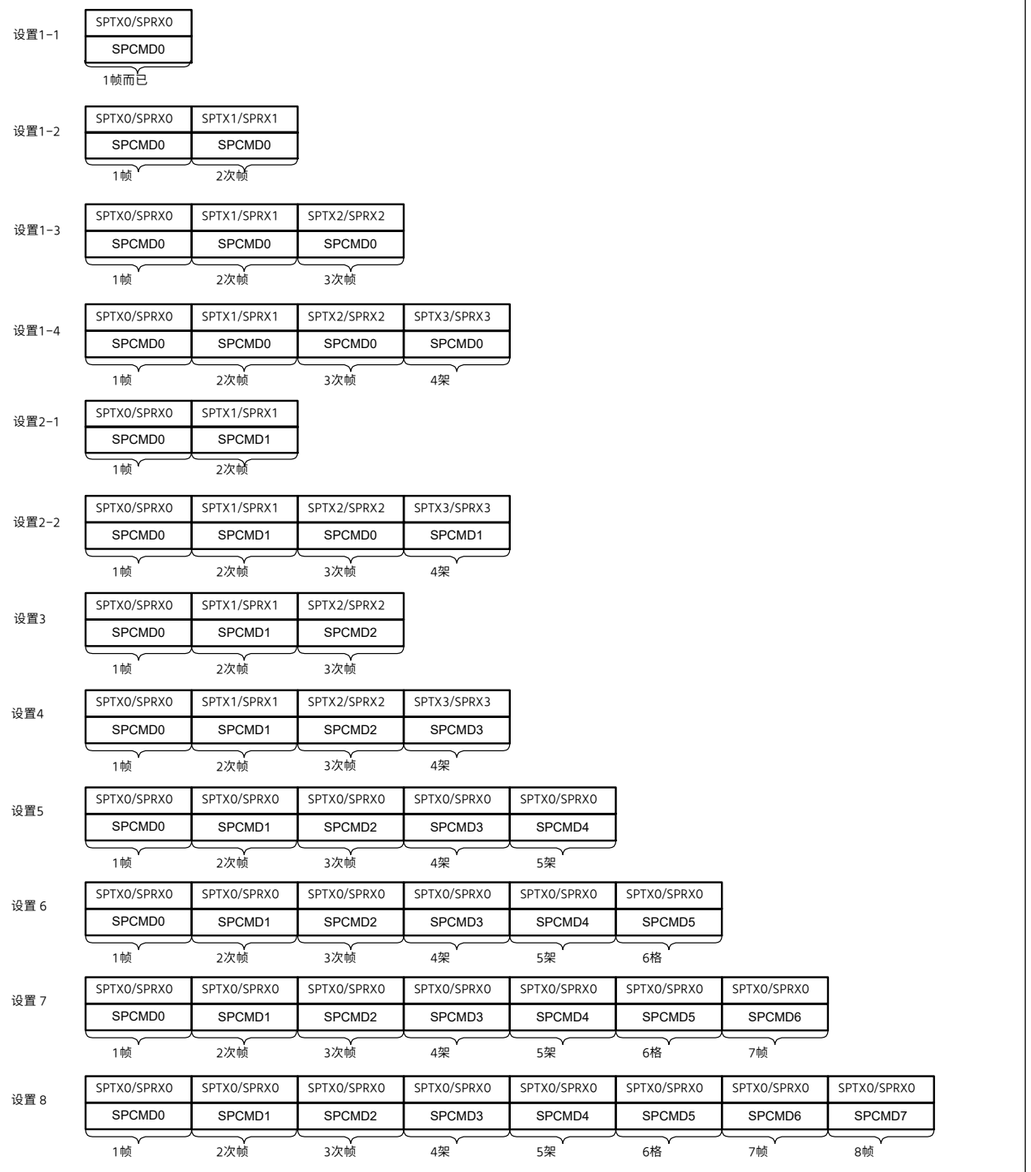

图28。45 SPI 命令寄存器与顺序操作中发送和接收缓冲区之间的对应关系

（四）突发转移

如果当前串行传输期间SPI引用的SPCMDm。SSLKP比特为1,则SPI在串行传输期间维持SSLni信号电平,直到下一个串行传输的SSLni信号断言开始。如果SSLni

signal level for the next serial transfer is the same as the SSLni signal level for the current serial transfer, the SPI can execute continuous serial transfers while keeping the SSLni signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register 3 (SPCR3) is 0.

Figure 28.46 shows an example of an SSLni signal operation for a burst transfer that is implemented using the SPCMD0 and SPCMD1 register settings. This section describes SPI operations (1) to (8) shown in Figure 28.46.

Note: The polarity of the SSLni output signal depends on the SSLP register settings.

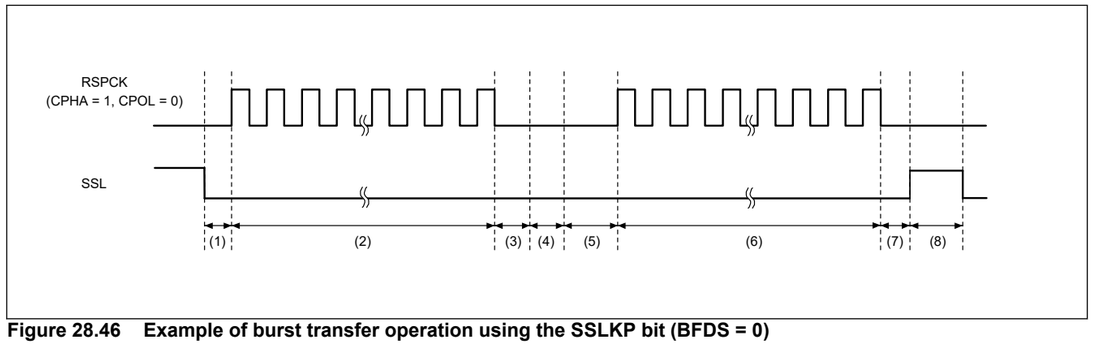

Figure 28.46 Example of burst transfer operation using the SSLKP bit (BFDS = 0)

The SPI operation at times (1) to (8) in the figure is as follows:

1. Based on the SPCMD0 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
2. The SPI executes serial transfers in accordance with the SPCMD0 settings.
3. The SPI inserts an SSL negation delay.
4. Because the SPCMD0.SSLKP bit is 1, the SPI keeps the SSLni signal value specified in SPCMD0. This period is sustained at a minimum for a period equal to the next-access delay in SPCMD0. If the shift register is empty after the passage of the minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
5. Based on the SPCMD1 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
6. The SPI executes serial transfers in accordance with the SPCMD1 settings.
7. Insert SSL negate delay.
8. Because the SPCMD1.SSLKP bit is 0, the SPI negates the SSLni signal. In addition, a next-access delay is inserted in accordance with SPCMD1.

If the SSLni signal output settings in the SPCMDm register where 1 is assigned to the SSLKP bit are different from the SSLni signal output settings in the SPCMDm register to be used in the next transfer, the SPI switches the SSLni signal status to SSLni signal assertion as shown in (5) in Figure 28.46. This corresponds to the command for the next transfer.

Note: If such an SSLni signal switching occurs, the slaves that drive the MISOn signal compete, and collision of signal levels might occur.

The SPI in master mode references the SSLni signal operation within the module when the SSLKP bit is not used. When the SPCMDm.CPHA bit is 0, the SPI can accurately start serial transfers by using the SSLni signal assertion for the next transfer that is detected internally.

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register 3 (SPCR3) is 1.

Figure 28.47 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 28.47. The SSL output signal polarity depends on the set SPI slave select polarity register (SSLP) value.

下一次串行传输的信号电平与当前串行传输的sslni信号电平相同,spi可以执行连续串行传输,同时保持sslni信号断言状态（突发传输）。

- 当突发传输帧之间延迟 SPI 控制寄存器 3（SPCR3）的选择位（BFDS）为 0。

图28。46示出了使用SPCMD0和SPCMD1寄存器设置实现的突发传输的SSLni信号操作的示例。本节描述图 28。46 . 中所示的 SPI 操作 (1) 至 (8)

注意:SSLni 输出信号的极性取决于 SSLP 寄存器设置。

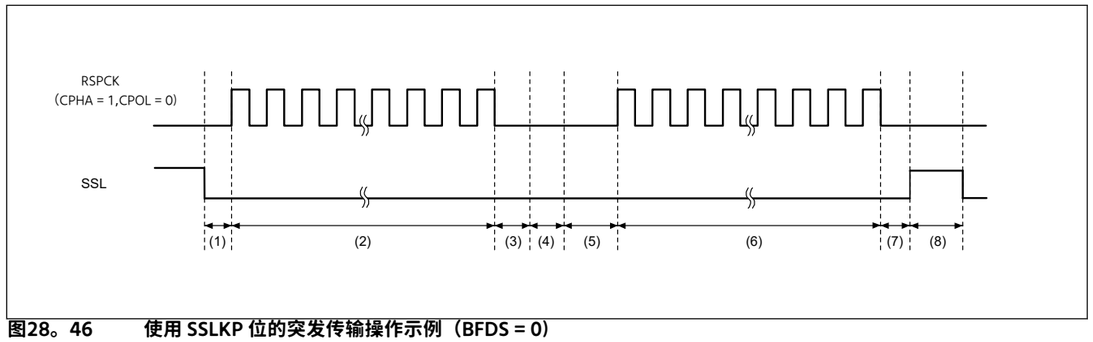

图28。46 使用 SSLKP 位的突发传输操作示例（BFDS = 0）

时(1)～(8)的SPI运算如图所示:

2锛姣涓。SPI 根据 SPCMD0 设置执行串行传输。

3锛 娴 。SPI 插入 SSL 否定延迟。

4锛姣涓。因为SPCMD0。SSLKP 位为 1,SPI 保留 SPCMD0 中指定的 SSLni 信号值。该周期至少持续等于 SPCMD0 中的下一次访问延迟的周期。如果移位寄存器在最小周期通过后为空,则该周期将持续到发送数据存储在移位寄存器中以进行下一次传输。

5锛姣涓。基于 SPCMD1 设置,SPI 断言 SSLni 信号并插入 RSPCK 延迟。

6锛 涓€涓。SPI 根据 SPCMD1 设置执行串行传输。

7锛 娴 。插入 SSL 否定延迟。

8锛 娴 。因为SPCMD1。SSLKP位为0,SPI否定SSLni信号。另外,根据SPCMD1插入下一次访问延迟。

如果分配给SSLKP位的SPCMDm寄存器中的SSLni信号输出设置与下次传输中使用的SPCMDm寄存器中的SSLni信号输出设置不同,则SPI将SSLni信号状态切换为SSLni信号断言如图28。46(5)所示。这对应于下一次传输的命令。

注意:如果发生这样的 SSLni 信号切换,驱动 MISOn 信号的从站会竞争,并且可能会发生信号电平冲突。

当不使用SSLKP位时,主模式下的SPI引用模块内的SSLni信号操作。当SPCMDm。CPHA位为0时,SPI可以通过使用SSLni信号断言来准确地开始串行传输以进行内部检测到的下一次传输。

- 当突发传输帧之间延迟 SPI 控制寄存器 3（SPCR3）的选择位（BFDS）为 1。

图28。47示出了当使用SPCMD0和SPCMD1的设置实现突发传输时SSL信号操作的示例。下面描述图28。47所示的(1)至(6)的SPI操作。SSL 输出信号极性取决于设置的 SPI 从属选择极性寄存器（SSLP）值。

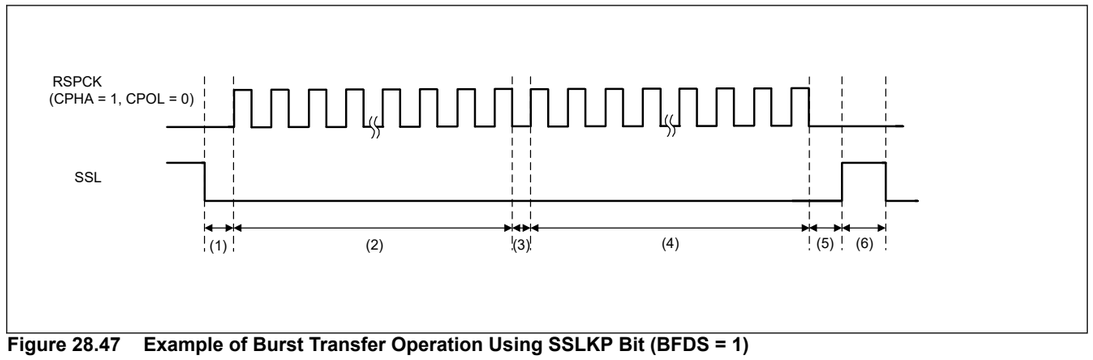

Figure 28.47 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1)

1. Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0. Wait last clock until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
3. The value of SSL signal according to SPCMD0 was hold, because the SPCMD0.SSLKP bit is 1. RSPCK negate period between frames is 0.5RSPCK, if the shift register is not empty.
4. Perform serial transfer according to SPCMD1.
5. Insert SSL negate delay for the last frame.
6. The SSL signal is negated because the SSLKP bit in SPCMD1 is 0. Furthermore, the next-access delay is inserted according to SPCMD1.

(5) RSPCK delay (t1)

The RSPCK delay value of the SPI in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD.SCKDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during a serial transfer by pointer control, and determines an RSPCK delay using the SPCMDm.SCKDEN bit and SPCKD.SCKDL[2:0] bits, as listed in Table 28.11. For a definition of RSPCK delay, see section 28.3.5. Transfer Formats.

RSPCK delay insert to only the first frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay”. (The SPCMD.SSLKP bit is 1 and the SPCR3.BFDS bit is 1.)

SPCMDm.SCKDEN bit	SPCKD.SCKDL[2:0] bits	RSPCK delay
0	000b to 111b	1 RSPCK
1	000b	1 RSPCK

	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(6) SSL negation delay (t2)

The SSL negation delay value of the SPI in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND.SLNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced by pointer control during a serial transfer, and determines an SSL negation delay using the SPCMDm.SLNDEN bit and SSLND.SLNDL[2:0] bits, as listed in Table 28.12. For a definition of SSL negation delay, see section 28.3.5. Transfer Formats.

(5) RSPCK 延迟（t1）

主模式下SPI的RSPCK延迟值取决于SPCMDm。SCKDEN位设置和SPCKD。SCKDL[2:0]位设置。SPI通过指针控制确定串行传输期间要引用的SPCMDm寄存器,并使用SPCMDm。SCKDEN位和SPCKD。SCKDL[2:0]位确定RSPCK延迟,如表28。11中列出的。有关 RSPCK 延迟的定义,请参阅第 28。3。5 节。传输格式 .

RSPCK 延迟仅插入到突发传输的第一帧,当传输时没有 “突发传输帧之间延迟”。（SPCMD。SSLKP 位为 1,SPCR3。BFDS 位是 1。）

(6) SSL 否定延迟（t2）

主模式下SPI的SSL否定延迟值取决于SPCMDm。SLNDEN位设置和SSLND。SLNDL[2:0] 位设置。SPI确定串行传输期间指针控制要引用的SPCMDm寄存器,并使用SPCMDm。SLNDEN位和SSLND。SLNDL[2:0]位确定SSL否定延迟,如表28。12中所列。有关 SSL 否定延迟的定义,请参阅第 28。3。5 节。传输格式。

An SSL negation delay is inserted to only the last frame of the burst transmission, that is, transmit without “between burst transfer frames delay”. (SPCMD.SSLKP bit is 1 and SPCR3.BFDS bit is 1).

	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(7) Next-access delay (t3)

The next-access delay value of the SPI in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND.SPNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and then determines a next-access delay during serial transfer using the SPCMDm.SPNDEN bit and SPND.SPNDL[2:0] bits, as listed in Table 28.13. For a definition of next-access delay, see section 28.3.5. Transfer Formats.

A next-Access delay is inserted to only the last frame of the burst transmission, that is, transmit without “between burst transfer frames delay”. (SPCMD.SSLKP bit is 1 and SPCR3.BFDS bit is 1).

(7) 下一个访问延迟（t3）

主模式下SPI的下一个访问延迟值取决于SPCMDm。SPNDEN位设置和SPND。SPNDL[2:0]位设置。SPI通过指针控制确定串行传输期间要引用的SPCMDm寄存器,然后使用SPCMDm。SPNDEN位和SPND。SPNDL[2:0]位确定串行传输期间的下一次访问延迟,如表28。13中所列。有关下一次访问延迟的定义,请参阅第 28。3。5 节。传输格式 .

下一个访问延迟仅插入到突发传输的最后一个帧,即突发传输帧延迟“之间不带”的传输。（SPCMD。SSLKP 位为 1,SPCR3。BFDS 位为 1)。

(9) Software processing flow

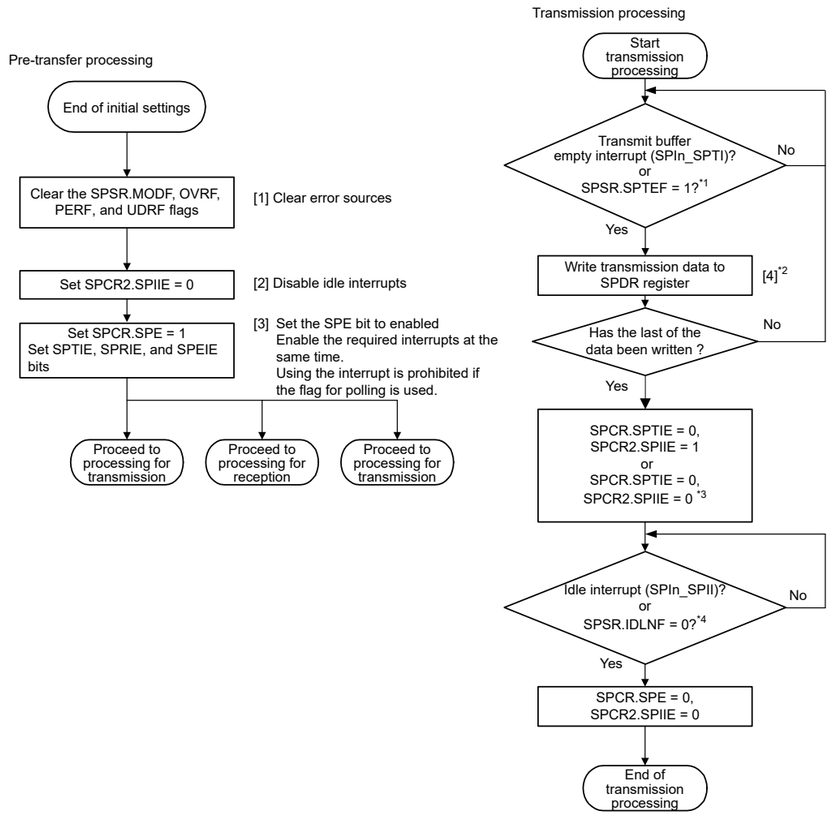
Transmit processing flow

When transmitting data, with the SPIi_SPII interrupt enabled, the CPU is notified of the completion of data transmission after the last data write for transmission.



Note 1. Before writing data for transmission to SPDR/SPDR_HA/SPDR_BY, check that the transmit buffer is empty by reading the SPSR.SPTEF flag, if the flag for polling is used.
Note 2. Setting SPCR2.SPIIE and SPCR3.CENDIE to 0 is prohibited if the flag for polling is used.
Note 3. Wait more than 1 PCLKA, after writing data for transmission to SPDR register, and before starting to poll SPSR.IDLNF flag or SPSR.CENDF, if the flag for polling is used.

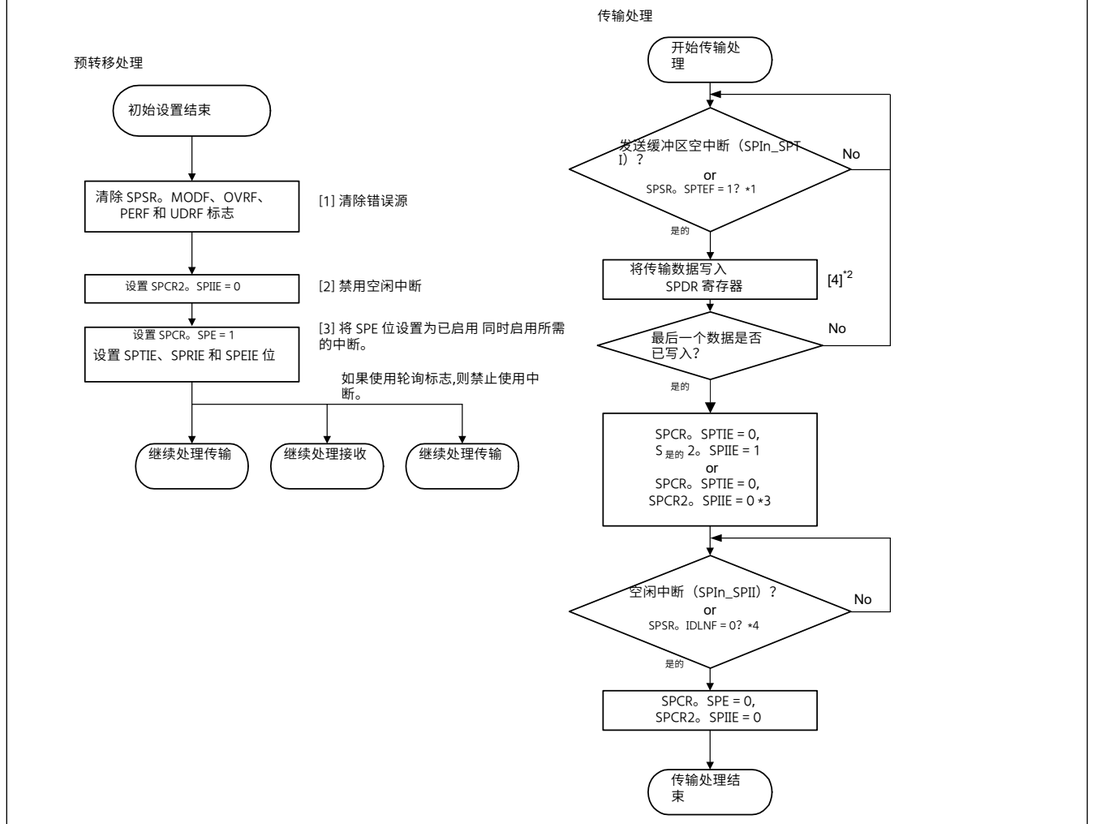
传输处理流程

传输数据时,在启用SPIi_SPII中断的情况下,在上次数据写入传输后,CPU被通知数据传输完成。



注1。在写入数据以传输到 SPDR/SPDR_HA/SPDR_BY 之前,如果使用轮询标志,则通过读取 SPSR。SPTEF 标志来检查传输缓冲区是否为空。
注2。设置SPCR2。SPIIE 和 SPCR3。CENDIE 到 0 是禁止的,如果使用用于轮询的标志。

接收处理流程

Note 1. SPDR = SPDR/SPDR_HA/SPDR_BY

Figure 28.50 Reception flow in master mode

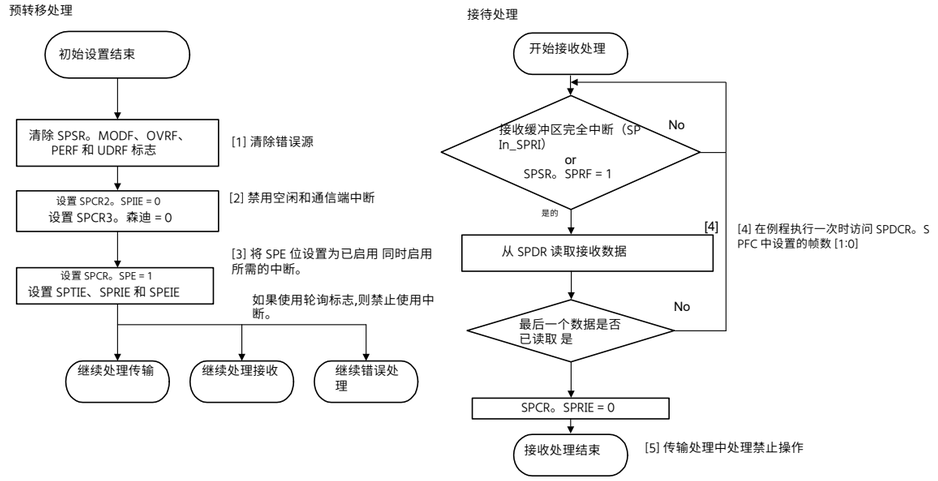
Error processing flow

The SPI detects the following errors:

- Mode fault error
- Underrun error
- Overrun error
- Parity error

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, the SPCR.SPE bit is not cleared and operations for transmission and reception continue. Therefore, Renesas recommends clearing the SPCR.SPE bit to stop operations for errors other than mode fault errors. Not doing so leads to updating of the SPSSR.SPECM[2:0] bits.

When an error is detected using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.



注1。SPDR = SPDR/SPDR_HA/SPDR_BY

图28。50 主模式下的接收流

处理流程出错

SPI 检测以下错误:

- 模式故障错误
- 欠载错误
- 超限错误
- 奇偶校验误差

当产生模式故障错误时,SPCR。SPE 位会自动清除,停止传输和接收操作。对于来自其他来源的错误,SPCR。SPE 位未被清除,并且传输和接收的操作仍在继续。因此,Renesas 建议清除 SPCR。SPE 位以停止操作模式故障错误以外的错误。不这样做会导致 SPSSR。SPECM[2:0] 位的更新。

当使用中断检测到错误时,清除错误处理例程中的 ICU。IELSRn。IR 标志。如果不这样做,ICU。IELSRn。IR 标志可能会继续指示 SPII_SPTI 或 SPII_SPRI 中断请求。SPIi_SPRI 中断请求的指示,则读取接收缓冲区并在 SPI 中初始化测序器。

28.3.11.2 Slave mode operation

(1) Starting a serial transfer

When the SPCMD0.CPHA bit is 0, if the SPI detects an SSLn0 input signal assertion, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLn0 input signal triggers the start of a serial transfer.

When the CPHA bit is 1, if the SPI detects the first RSPCKn edge in an SSLn0 signal asserted condition, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 1, the first RSPCKn edge in an SSLn0 signal asserted condition triggers the start of a serial transfer.

Regardless of the CPHA bit setting, the SPI drives the MISOn output signal on SSLn0 signal assertion. The data that is output by the SPI is either valid or invalid, depending on the CPHA bit setting.

For details on the SPI transfer format, see section 28.3.5. Transfer Formats. The polarity of the SSLn0 input signal depends on the SSLP.SSL0P setting.

(2) Terminating a serial transfer

Regardless of the SPCMD0.CPHA bit setting, the SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR/SPDR_HA register. On termination of a serial transfer, the SPI changes the status of the shift register to empty, regardless of the receive buffer state. A mode fault error occurs if the SPI detects an SSLn0 input signal negation from the beginning of serial transfer to the end of serial transfer (see section 28.3.9. Error Detection).

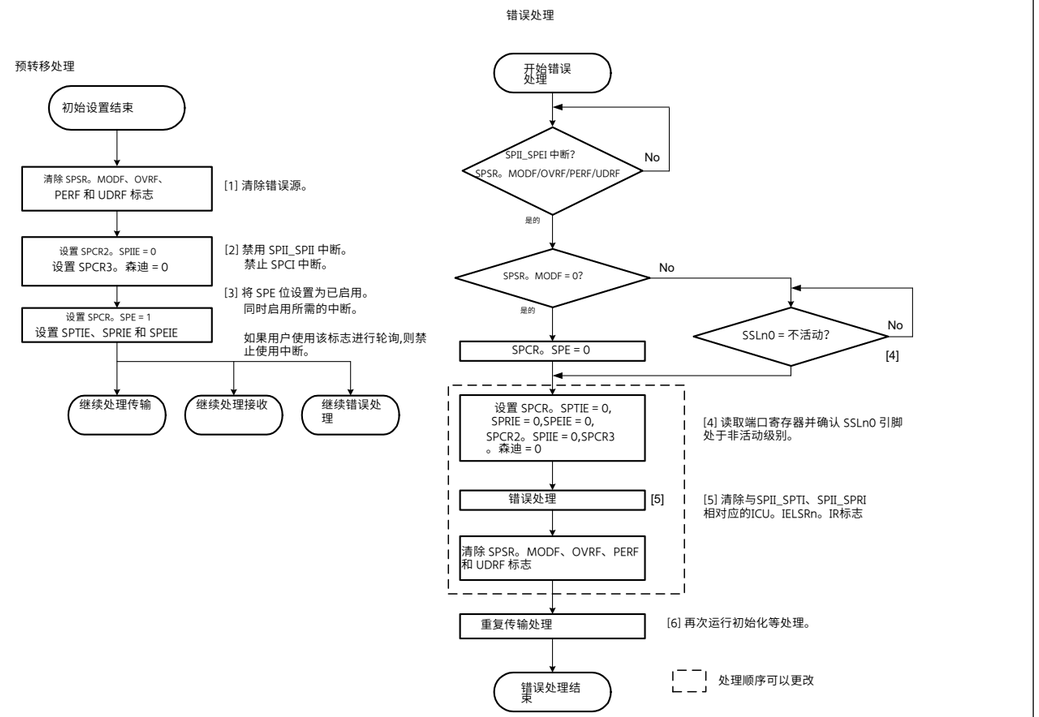

图28。51 主模式下的错误处理流程

28。3。11。2 从模式操作

(1)开始串行转移

当SPCMD0。CPHA位为0,如果SPI检测到一个SSLn0输入信号断言,它必须将有效数据驱动到MISOn输出信号。因此,当CPHA位为0时,SSLn0输入信号的断言触发串行传输的开始。

CPHA位为1时,如果SPI检测到SSLn0信号断言条件下的第一RSPCKn边,则必须将有效数据驱动到MISOn输出信号。因此,当CPHA位为1时,SSLn0信号断言条件中的第一RSPCKn边触发串行传输的开始。

无论 CPHA 位设置如何,SPI 都会在 SSLn0 信号断言上驱动 MISOn 输出信号。SPI 输出的数据要么有效,要么无效,具体取决于 CPHA 位设置。

有关 SPI 传输格式的详细信息,请参阅第 28。3。5 节。传输格式。SSLn0 输入信号的极性取决于 SSLP。SSL0P 设置。

（二）终止连续转让

无论 SPCMD0 是什么。CPHA 位设置, SPI 在检测到与最终采样定时相对应的 RSPCKn 边后终止串行传输。当接收缓冲区中有可用空间时（SPSR。SPRF标志为0),在串行传输终止时,SPI将从移位寄存器接收到的数据复制到SPDR/SPDR_HA寄存器的接收缓冲区。串行传输终止时,SPI 将移位寄存器的状态更改为空,而不管接收缓冲区状态如何。如果 SPI 从串行传输开始到串行传输结束检测到 SSLn0 输入信号否定,则会出现模式故障错误（参见第 28。3。9 节）。错误检测).

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length is determined by the SPCMD0.SPB[3:0] bits setting. The polarity of the SSLn0 input signal is determined by the SSLP.SSL0P bit setting. For details on the SPI transfer format, see section 28.3.5. Transfer Formats.

(3) Notes on single-slave operations

If the SPCMD0.CPHA bit is 0, the SPI starts serial transfers when it detects the assertion edge for an SSLn0 input signal. In the configuration shown in Figure 28.7, if the SPI is used in single-slave mode, the SSLn0 signal is fixed at an active state. Therefore, when the CPHA bit is set to 0, the SPI cannot correctly start a serial transfer. For the SPI to correctly execute transmit and receive operations in slave mode when the SSLn0 input signal is fixed at an active state, the CPHA bit must be set to 1. Do not fix the SSLn0 input signal if there is a requirement for setting the CPHA bit to 0.

(4) Burst transfer

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLn0 input signal. When the CPHA bit is 1, the serial transfer period is the period from the first RSPCKn edge to the sampling timing for the reception of the final bit in an SSLn0 signal active state. Even when the SSLn0 input signal remains at the active level, the SPI can accommodate burst transfers, because it can detect the start of an access.

When the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

(5) Initialization flow

Figure 28.52 shows an example of initialization flow for SPI operation when the SPI is in slave mode. For a description of how to set up the ICU, DTC, and I/O ports, see the descriptions given in the individual blocks.

最终采样时序根据传输数据的位长度而变化。从模式下,SPI数据长度由SPCMD0确定。SPB[3:0] 位设置。SSLn0输入信号的极性由SSLP。SSL0P位设置确定。有关 SPI 传输格式的详细信息,请参阅第 28。3。5 节。传输格式 .

(3)单从操作注意事项

如果SPCMD0。CPHA 位为 0,当 SPI 检测到 SSLn0 输入信号的断言边时,SPI 开始串行传输。28。7所示的配置中,如果SPI在单从模式下使用,则SSLn0信号固定在活动状态。

因此,当CPHA位设置为0时,SPI无法正确启动串行传输。SSLn0输入信号固定在活动状态时,SPI要在从模式下正确执行发送和接收操作,CPHA位必须设置为1。如果需要将 CPHA 位设置为 0,请勿修复 SSLn0 输入信号。

（四）爆仓转让

如果SPCMD0。CPHA位为1,可以执行连续串行传输（突发传输）,同时保留SSLn0输入信号的断言状态。CPHA位为1时,串行传输周期为从第一RSPCKn边到接收处于SSLn0信号活动状态的最终位的采样定时的周期。即使 SSLn0 输入信号保持在活动电平,SPI 也可以适应突发传输,因为它可以检测访问的开始。

CPHA位为0时,突发传输时的第二次及后续串行传输无法正确执行。

Error processing flow

In slave mode operation, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the state of the SSLn0 pin.

If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

28.3.12 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the SPI. In clock synchronous operation, the SSLni pin is not used, and the RSPCKn, MOSIn, and MISOn pins handle communications. All SSLni pins are available as I/O port pins.

Although clock synchronous operation does not require the use of the SSLni pin, operation of the module is the same as in SPI operation. In both master mode and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected, because the SSLni pin is not used.

Additionally, do not perform operation if clock synchronous operation is enabled when the SPCMDm.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).

28.3.12.1 Master mode operation

(1) Starting serial transfer

The SPI updates the data in the transmit buffer (SPTX) of SPDR/SPDR_HA when data is written to the SPDR/SPDR_HA register with the transmit buffer empty, the data for the next transfer not set and the SPSR.SPTEF flag is 1. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR/SPDR_HA, the SPI copies data from the transmit buffer to the shift register and starts serial transmission. On copying transmit data to the shift register, the SPI changes the status of the shift register to full, and on termination of serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 28.3.5. Transfer Formats.

28。3。12 时钟同步操作

将SPCR。SPMS位设置为1选择SPI的时钟同步操作。在时钟同步操作中,不使用 SSLni 引脚,RSPCKn、MOSIn 和 MISOn 引脚处理通信。所有 SSLni 引脚均可作为 I/O 端口引脚使用。

虽然时钟同步操作不需要使用SSLni引脚,但模块的操作与SPI操作相同。在主模式和从模式操作中,通信都可以以与 SPI 操作相同的流程进行。但是,由于未使用 SSLni 引脚,因此未检测到模式故障错误。

另外,当从模式下SPCMDm。CPHA位设置为0时,如果启用时钟同步操作,请勿执行操作（SPCR。MSTR = 0)。

28。3。12。1 主模式操作

(1)开始串行转移

当数据写入 SPDR/SPDR_HA 寄存器时,SPI 更新 SPDR/SPDR_HA 的发送缓冲区（SPTX）中的数据,发送缓冲区为空,未设置下一次传输的数据,并且 SPSR。SPTEF 标志为 1。SPDCR。SPFC[1:0]位中设置的帧数写入SPDR/SPDR_HA后移位寄存器为空时,SPI将数据从发送缓冲区复制到移位寄存器并开始串行传输。在将发送数据复制到移位寄存器时,SPI将移位寄存器的状态更改为满,并且在串行传输终止时,它将移位寄存器的状态更改为空。无法引用轮班寄存器的状态。

时钟同步操作中的传输是在没有 SSLn0 输出信号的情况下进行的。有关 SPI 传输格式的详细信息,请参阅第 28。3。5 节。传输格式 .

(2) Terminating serial transfer

The SPI terminates the serial transfer after transmitting an RSPCKn edge corresponding to the sampling timing. If free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies data from the shift register to the receive buffer of the SPI Data Register (SPDR/SPDR_HA).

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[3:0] bits setting. Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 28.3.5. Transfer Formats.

(3) Sequence control

The transfer format used in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers. Although the SSLni signals are not output in clock synchronous operation, these settings are valid.

The SPSCR register determines the sequence configuration for serial transfers that are executed by the SPI in master mode. The following parameters are specified in the SPCMDm register:

- SSLni output signal value
- MSB or LSB first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPCKD is to be referenced
- Whether SSLND is to be referenced
- Whether SPND is to be referenced

SPBR holds some of the bit rate settings such as SPCKD, an SPI clock delay value, SSLND, an SSL negation delay, and SPND, a next-access delay value.

Based on the sequence length that is assigned to SPSCR, the SPI makes up a sequence comprised of a part or all of SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command comprising the sequence, the SPI sets the pointer to the SPCMD0 register, and in this manner the sequence is executed repeatedly.

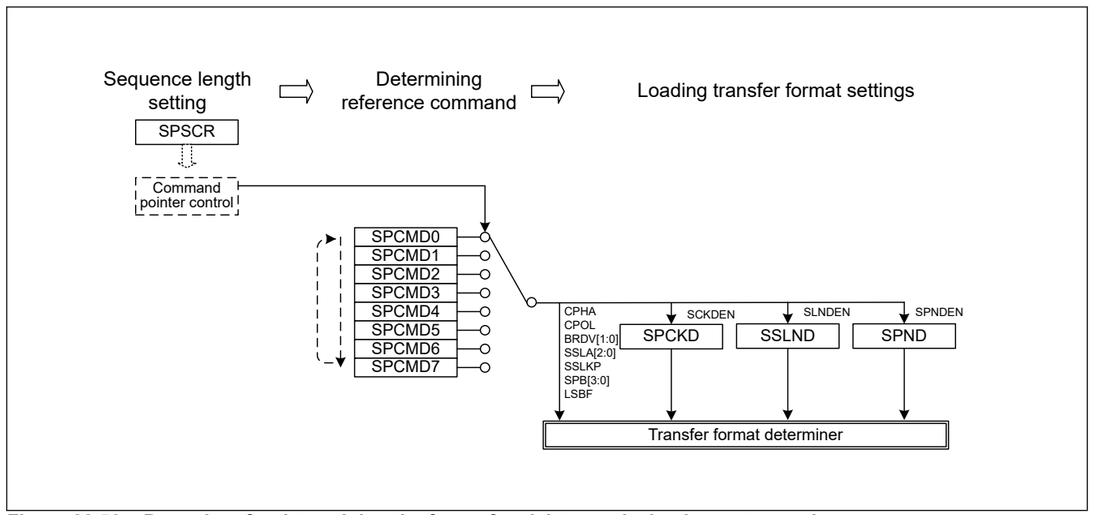

Figure 28.56 Procedure for determining the form of serial transmission in master mode

（二）终止串行转账

SPI在发送与采样定时相对应的RSPCKn边后终止串行传输。如果接收缓冲区中有可用空间（SPSR。SPRF标志为0）,则在串行传输终止时,SPI将数据从移位寄存器复制到SPI数据寄存器的接收缓冲区（SPDR/SPDR_HA）。

最终采样时间根据传输数据的位长度而变化。在主模式下,SPI 数据长度取决于 SPCMDm。SPB[3:0] 位设置。时钟同步操作中的传输是在没有 SSLn0 输出信号的情况下进行的。有关 SPI 传输格式的详细信息,请参阅第 28。3。5 节。传输格式 .

(3)序列控制

主模式下使用的传输格式由SPSCR、SPCMDm、SPBR、SPCKD、SSLND和SPND寄存器确定。SSLni信号虽然在时钟同步操作中没有输出,但这些设置是有效的。

SPSCR寄存器确定SPI在主模式下执行的串行传输的序列配置。
SPCMDm 寄存器中指定了以下参数:

- SSLni 输出信号值
- MSB 或 LSB 首先
- 数据长度
- 一些比特率设置
- RSPCKn 极性和相位
- 是否要引用 SPCKD
- 是否要引用 SSLND
- 是否要引用 SPND

SPBR 保存一些比特率设置,例如 SPCKD（SPI 时钟延迟值）、SSLND（SSL 否定延迟）和 SPND（下一次访问延迟值）。

根据分配给 SPSCR 的序列长度,SPI 组成由 SPCMDm 寄存器的一部分或全部组成的序列。SPI 包含一个指向构成序列的 SPCMDm 寄存器的指针。该指针的值可以通过读取SPSSR。SPCP[2:0]位来检查。当SPCR。SPE位设置为1并且启用SPI功能时,SPI将指针加载到SPCMD0寄存器中的命令,并在串行传输开始时将SPCMD0寄存器设置合并到传输格式中。每次数据传输的下一次访问延迟周期结束时,SPI 都会增加指针。在完成与包括序列的最终命令相对应的串行传输时,SPI将指针设置为SPCMD0寄存器,并且以这种方式重复执行序列。

(5) Software processing flow

Software processing during clock synchronous master operation is the same as that for SPI master operation. For details, see (9) Software processing flow in section 28.3.11.1. Master mode operation. Mode fault errors do not occur in clock synchronous operation.

28.3.12.2 Slave mode operation

(1) Starting serial transfer

When the SPCR.SPMS bit is 1, the first RSPCKn edge triggers the start of a serial transfer in the SPI, and the SPI drives the MISOn output signal. The SSL0 input signal is not used in clock synchronous operation. For details on the SPI transfer format, see section 28.3.5. Transfer Formats.

(2) Terminating serial transfer

The SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR/SPDR_HA register. On termination of a serial transfer, the SPI changes the status of the shift register to empty regardless of the receive buffer.

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length depends on the SPCMD0.SPB[3:0] bits setting. For details on the SPI transfer format, see section 28.3.5. Transfer Formats.

(3) Initialization flow

Figure 28.60 shows an example of initialization flow for clock synchronous operation when the SPI is used in slave mode. For a description of how to set up the ICU, DTC, and I/O ports, see the descriptions given in the individual blocks.

(5)软件处理流程

时钟同步主操作期间的软件处理与 SPI 主操作期间的软件处理相同。详情请参见 (9) 第 28。3。11。1 节中的软件处理流程。主模式操作。时钟同步操作中不会出现模式故障错误。

28。3。12。2 从模式操作

(1)开始串行转移

当SPCR。SPMS位为1时,第一RSPCKn边触发SPI中串行传输的开始,SPI驱动MISOn输出信号。SSL0输入信号不用于时钟同步操作。有关 SPI 传输格式的详细信息,请参阅第 28。3。5 节。传输格式 .

（二）终止串行转账

SPI 在检测到与最终采样定时相对应的 RSPCKn 边后终止串行传输。当接收缓冲区中可用空闲空间时（SPSR。SPRF标志为0),在串行传输终止时,SPI将从移位寄存器接收到的数据复制到SPDR/SPDR_HA寄存器的接收缓冲区。串行传输终止后,无论接收缓冲区如何,SPI 都会将移位寄存器的状态更改为空。

最终采样时序根据传输数据的位长度而变化。从模式下,SPI 数据长度取决于 SPCMD0。SPB[3:0] 位设置。有关 SPI 传输格式的详细信息,请参阅第 28。3。5 节。传输格式 .

(4) Software processing flow

Software processing during clock synchronous slave operation is the same as that for SPI slave operation. For details, see (6)Software processing flow. Mode fault errors do not occur in clock synchronous mode.

28.3.13 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, or between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0, and connects the input and output paths of the shift register, establishing a loopback mode. The SPI does not shut off the path between the MOSIn pin and the shift register if the SPCR.MSTR bit is 1, or between the MISOn pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the SPI or the reversed transmit data becomes the received data for the SPI.

（四）软件处理流程

时钟同步从操作期间的软件处理与 SPI 从操作期间的软件处理相同。详情请参阅(6)软件处理流程。时钟同步模式下不会出现模式故障错误。

28。3。13 环回模式

1写入SPPCR。SPLP2位或SPPCR。SPLP位时,如果SPCR。MSTR位为1,则SPI关闭MISOn引脚和移位寄存器之间的路径;如果SPCR。MSTR位为0,则SPI关闭MOSIn引脚和移位寄存器之间的路径,并连接移位寄存器的输入和输出路径,建立回环模式。如果 SPCR。MSTR 位为 1,则 SPI 不会关闭 MOSIn 引脚和移位寄存器之间的路径;如果 SPCR。MSTR 位为 0,则 SPI 不会关闭 MISOn 引脚和移位寄存器之间的路径。这称为回环模式。当以回环模式执行串行传输时,SPI的发送数据或反向发送数据成为SPI的接收数据。

28.3.14 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. To detect defects in the parity bit adding unit and error detecting unit, the parity circuit performs self-diagnosis as shown in Figure 28.62.

表28。14列出了SPLP2和SPLP比特与接收到的数据之间的关系。图28。61示出了当主模式中的SPI设置为环回模式（SPPCR。SPLP2=0,SPPCR。SPLP=1)时移位寄存器I/O路径的配置。

28.3.14 奇偶校验位函数的自我诊断

奇偶校验电路由用于传输数据的奇偶校验位添加单元和用于接收数据的错误检测单元组成。为检测奇偶校验位添加单元和误差检测单元中的缺陷,奇偶校验电路进行自诊断,如图28。62 .所示

28.3.15 Interrupt Sources

The SPI has the following interrupt sources:

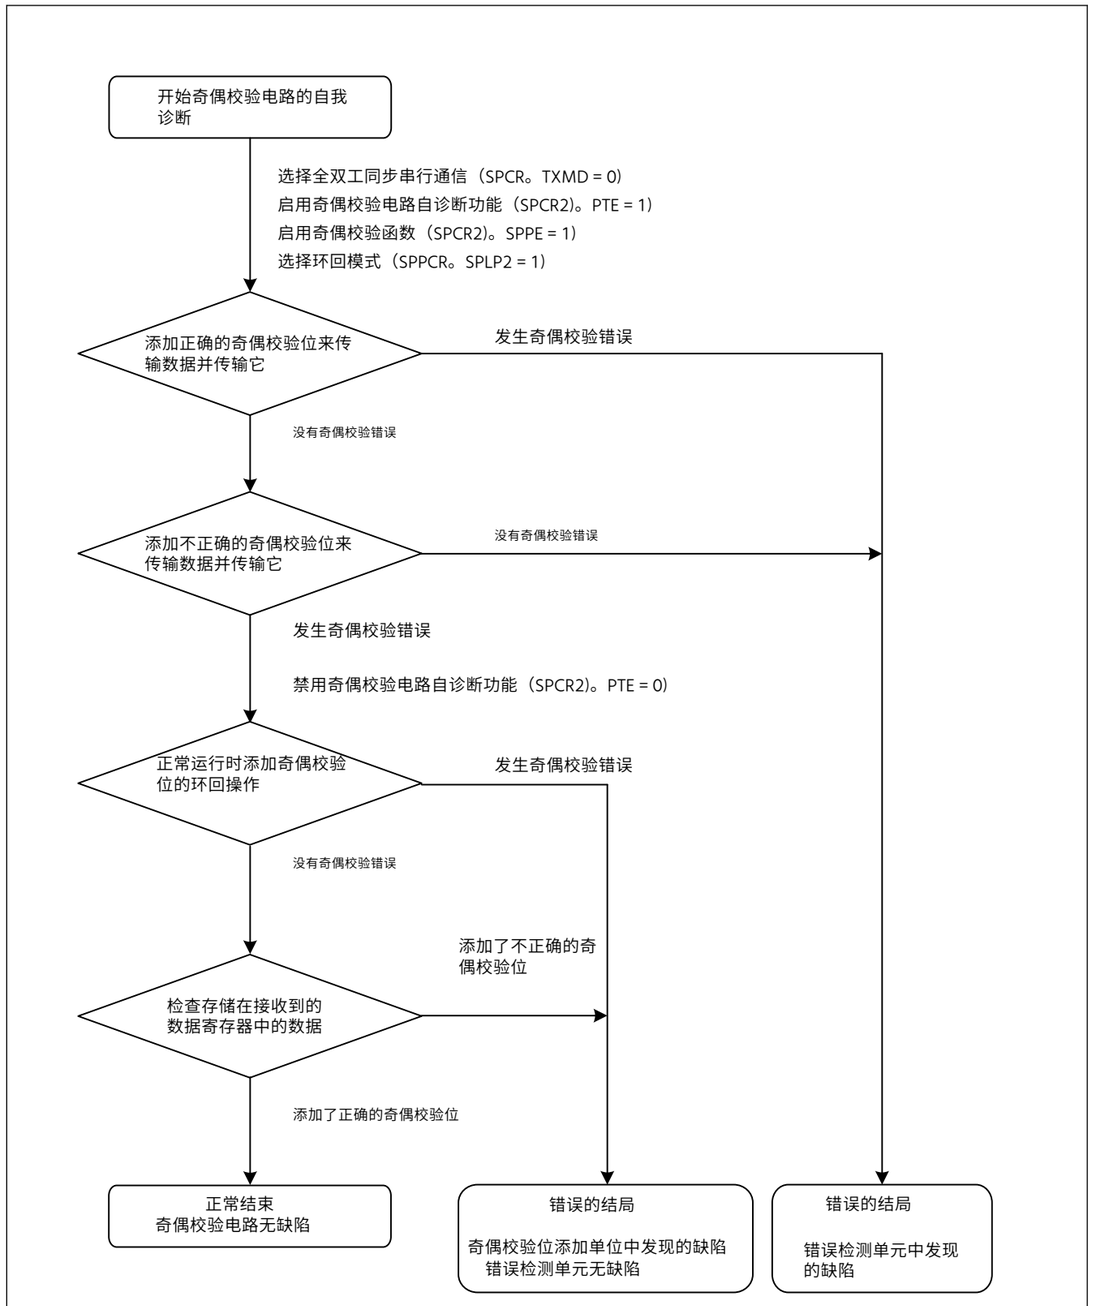

图28。62 奇偶校验电路的自诊断流程

28.3.15 中断源

SPI 有以下中断源:

- Receive buffer full
- Transmit buffer empty
- SPI error (mode-fault, underrun, overrun, or parity error)
- SPI idle
- Communication-end

The DMAC or DTC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Because the vector address for the SPIi_SPEI (SPI error interrupt) is allocated to interrupt requests on mode-fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the SPI are listed in Table 28.15. An interrupt is generated on satisfaction of one of the interrupt conditions in Table 28.15. Clear the receive buffer full and transmit buffer empty sources through a data transfer.

When using the DMAC or DTC to perform data transmission and reception, you must first set up the DMAC or DTC to be in a transfer-enabled status before setting the SPI. For information on setting up the DMAC or DTC, see section 15, DMA Controller (DMAC) and section 16, Data Transfer Controller (DTC).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt occur while the ICU.IELSRn.IR flag is 1, the interrupt is not output as a request for the ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IELSRn.IR flag becomes 0. A retained interrupt request is automatically discarded when it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be set to 0.

Table 28.15 SPI interrupt sources

Interrupt source	Symbol	Interrupt condition	DTC/DMAC activation
Receive buffer full	SPIi_SPRI	The receive buffer becomes full (SPSR.SPRF flag is 1) while the SPCR.SPRIE bit is 1	Possible
Transmit buffer empty	SPIi_SPTI	The transmit buffer becomes empty (SPSR.SPTEF flag is 1) while the SPCR.SPTIE bit is 1	Possible
SPI error (mode-fault, underrun, overrun, or parity error)	SPIi_SPEI	The SPSR.MODF, OVRF, UDRF or PERF flag sets to 1 while the SPCR.SPEIE bit is 1	Impossible
SPI idle	SPIi_SPII	The SPSR.IDLNF flag sets to 0 while the SPCR2.SPIIE bit is 1	Impossible
Communication-end	SPIi_SPCI	CENDIE = 1 and CENDF = 1	Impossible

28.4 Event Link Controller Event Output

The Event Link Controller (ELC) can produce the following event output signals:

- Receive buffer full event output
- Transmit buffer empty event output
- Mode-fault, underrun, overrun, or parity error event output
- SPI idle event output
- Transmission-completed event output

The event link output signal is output regardless of the interrupt enable bit setting.

28.4.1 Receive Buffer Full Event Output

This event signal is output when received data is transferred from the shift register to the SPDR/SPDR_HA on completion of serial transfer.

28.4.2 Transmit Buffer Empty Event Output

This event signal is output when data for transmission is transferred from the transmit buffer to the shift register and when the value of the SPE bit changes from 0 to 1.

● 接收满缓冲区
● 传输缓冲区为空
● SPI 错误（模式故障、欠载、超载或奇偶校验错误）
● SPI 空闲
● 通讯端

DMAC 或 DTC 可由接收缓冲区满或发送缓冲区空中断激活以执行数据传输。

由于 SPIi_SPEI（SPI 错误中断）的向量地址被分配给模式故障、欠载、溢出和奇偶校验错误的中断请求,因此必须从标志确定实际的中断源。SPI 的中断源列于表 28。15 中。满足表 28。15 中的中断条件之一后生成中断。通过数据传输清空接收缓冲区并发送缓冲区空源。

DMAC 或 DTC 进行数据传输和接收时,您必须先将 DMAC 或 DTC 设置为处于支持传输的状态,然后再设置 SPI。DMAC或DTC的设置的信息,请参见第15节,DMA控制器（DMAC）和第16节,数据传输控制器（DTC）.

如果在 ICU。IELSRn。IR 标志为 1 时发生生成发送缓冲区为空或接收缓冲区完全中断的条件,则中断不会作为 ICU 的请求输出,而是保留在内部（保留容量为每个源一个请求）。当 ICU。IELSRn。IR 标志变为 0 时,会输出保留的中断请求。当保留的中断请求作为实际的中断请求输出时,它会自动丢弃。内部保留的中断请求的中断使能位（SPCR。SPTIE 或 SPCR。SPRIE 位）也可以设置为 0。

表 28。15 SPI 中断源

中断源	符号	中断条件	DTC/DMAC 激活
接收完整缓冲区	SPII_SPRI	接收缓冲区变为满（SPSR。SPRF 标志为 1),而 SPCR。SPRIE 位为 1	可能
发送缓冲区为空	SPII_SPTI	发射缓冲区变为空（SPSR。SPTEF 标志为）1) 而 SPCR。SPTIE 位为 1	可能
SPI 错误（模式故障、欠载、超载或奇偶校验错误）	SPII_SPEI	SPSR。MODF、OVRF、UDRF 或 PERF 标志设置为 1,而 SPCR。SPEIE 位为 1	不可能
SPI 空闲	SPII_SPII	SPSR。IDLNF 标志设置为 0,而 SPCR2。SPIIE 位 is 1	不可能
通讯端	SPII_SPCI	CENDIE = 1,CENDF = 1	不可能

28。4 事件链接控制器 事件输出

器（ELC）可以产生如下事件输出信号:

● 接收缓冲区全事件输出
● 传输缓冲区空事件输出
● 模式故障、欠载、超载或奇偶校验错误事件输出
● SPI 空闲事件输出
● 传输完成事件输出

无论中断使能位设置如何,事件链路输出信号都会被输出。

28.4.1 接收缓冲区完整事件输出

当接收到的数据在串行传输完成时从移位寄存器传输到SPDR/SPDR_HA时,该事件信号被输出。

28.4.2 发送缓冲区空事件输出

当用于传输的数据从传输缓冲器传输到移位寄存器并且SPE位的值从0变为1时,输出该事件信号。

28.4.3 Mode-Fault, Underrun, Overrun, or Parity Error Event Output

This event signal is output when mode-fault, underrun, overrun, or parity error is detected. See section 28.5.4. Constraints on Mode-Fault, Underrun, Overrun, or Parity Error Event Output if using this event signal.

(1) Mode-fault

Table 28.16 lists the conditions for occurrence of a mode-fault event.

Table 28.16 Conditions for mode-fault occurrence

SPI mode	SPCR.MODFEN bit	SSLn0 pin	Remarks
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0)	1	Not active	Event is output only when the SSLn0 pin is deactivated during transmission

(2) Underrun

This event signal is output in response to an underrun when a serial transfer starts while the transmission data is not ready, and the value of the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1. Under these conditions, the MODF and UDRF flags are set to 1.

(3) Overrun

This event signal is output in response to an overrun when a serial transfer completes while the receive buffer contains unread data and the value of the SPCR.TXMD bit is 0. Under these conditions, the OVRF flag is set to 1.

(4) Parity error

This event signal is output in response to a parity error detected on completion of a serial transfer while the value of the TXMD bit in SPCR is 0 and the value of the SPPE bit in SPCR2 is 1.

28.4.4 SPI Idle Event Output

(1) In master mode

In master mode, an event is output when the condition for setting the IDLNF flag (SPI idle flag) to 0 is satisfied.

(2) In slave mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (SPI is initialized).

28.4.5 Communication End Event Output

In master mode, an event is output when the IDLNF flag (SPI idle flag) changes from 1 to 0. In slave mode, an event occurs with conditions shown in Table 28.17 and Table 28.18

Table 28.17 Communication End Event Generating Conditions (transmit-receive/transmit slave mode)

	Transmit Buffer Status	Shift Register Status	Others
SPI operation (SPMS = 0)	Empty	Empty	SSL0 input is negated
Clock synchronous operation (SPMS = 1)	Empty	Empty	The last even edge of RSPCK of last data was detected (CPHA = 1)

Table 28.18 Communication End Event Generating Conditions (receive only slave mode)

	Others
SPI operation (SPMS = 0)	SSL0 input is negated
Clock synchronous operation (SPMS = 1)	The last even edge of RSPCK of last data was detected (CPHA = 1)

Regardless of master mode or slave mode, no event is output when 0 is written to the SPCR.SPE bit during transmission or when the SPCR.SPE bit is cleared due to a mode fault error or an underrun error.

A communication end event is output at the following timing. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

28。4。3 模式故障、欠载、超载或奇偶校验错误事件输出

当检测到模式故障、欠载、溢出或奇偶校验错误时,会输出此事件信号。参见第 28。5。4 节。如果使用此事件信号,则对模式故障、欠载、溢出或奇偶校验错误事件输出进行约束。

（一）模式故障

表 28。16 列出了模式故障事件发生的条件。

表 28。16 模式故障发生的条件

SPI 模式	SPCR。MODFEN 位	SSLn0 引脚	备注
SPI 操作（SPMS = 0） 从（SPCR。MSTR = 0）	1	不活跃	仅当 SSLn0 引脚在传输期间停用时才会输出事件

（二）欠款

当串行传输在传输数据未准备就绪时开始时,响应于欠载而输出该事件信号,并且SPCR。MSTR比特的值为0并且SPCR。SPE比特为1。在这些条件下,MODF 和 UDRF 标志设置为 1。

（三）超支

当串行传输完成时,当接收缓冲区包含未读数据并且 SPCR。TXMD 位的值为 0 时,响应于溢出而输出该事件信号。在这些条件下,OVRF标志被设置为1。

(4)奇偶校验误差

该事件信号响应于串行传输完成时检测到的奇偶校验误差而输出,同时SPCR中的TXMD比特的值为0并且SPCR2中的SPPE比特的值为1。

28。4。4 SPI 空闲事件输出

(1)在主模式下

在主模式下,当满足将IDLNF标志（SPI空闲标志）设置为0的条件时,输出事件。

(2)在从模式下

在从模式下,当 SPCR。SPE 位设置为 0（SPI 初始化）时,输出事件。

28。4。5 通信结束事件输出

在主模式下,当 IDLNF 标志（SPI 空闲标志）从 1 更改为 0 时,会输出一个事件。在从模式下,事件发生条件如表28。17和表28。18所示

表 28。17 通信结束事件生成条件（发送-接收/发送从模式）

	发送缓冲区状态	轮班登记状态	其他
SPI 操作（SPMS = 0）	空	空	SSL0输入被否定
时钟同步操作（SPMS = 1）	空	空	RSPCK 的最后一个偶边检测到最后的数据（CPHA = 1）

	其他
SPI 操作（SPMS = 0）	SSL0输入被否定
时钟同步操作（SPMS = 1）	检测到最后数据的 RSPCK 最后偶边（CPHA = 1）

无论主模式或从模式如何,当传输期间将 0 写入 SPCR。SPE 位时,或者当 SPCR。SPE 位由于模式故障错误或欠载错误而被清除时,不会输出任何事件。

在以下时机输出通信结束事件。主操作中的通信结束事件输出定时被省略,因为它与空闲事件在同一定时输出。

28.5 Usage Notes

28.5.1 Settings for the Module-Stop State

The Module Stop Control Register B (MSTPCRB) can enable or disable the SPI operation. The SPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details on the Module Stop Control Register B, see section 10, Low Power Modes.

28.5.2 Constraint on Low-Power Functions

When using the module-stop function and entering a low-power mode other than Sleep mode, set the SPCR.SPE bit to 0 before completing communication.

28.5.3 Constraints on Starting Transfer

If the ICU.IELSRn.IR flag is 1 when transfer starts, the interrupt request is internally retained, which can lead to unanticipated behavior of the ICU.IELSRn.IR flag.

To prevent this, use the following procedure to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1):

1. Confirm that transfer stopped (the SPCR.SPE bit is 0).
2. Set the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.
3. Read the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IELSRn.IR flag to 0.

28.5.4 Constraints on Mode-Fault, Underrun, Overrun, or Parity Error Event Output

Using the mode-fault, underrun, overrun, or parity error event is prohibited if the SPI is in multi-master mode (when the SPCR.SPMS bit is 0, the SPCR.MSTR bit is 1, and the SPCR.MODFEN bit is 1).

28.5.5 Constraints on the SPSR.SPRF and SPSR.SPTEF Flags

If the polling flags, SPRF and SPTEF, are used, using the interrupts is prohibited, and you must set the SPCR.SPRIE and SPCR.SPTIE bits to 0. Either the interrupts or the flags can be used, but not both.

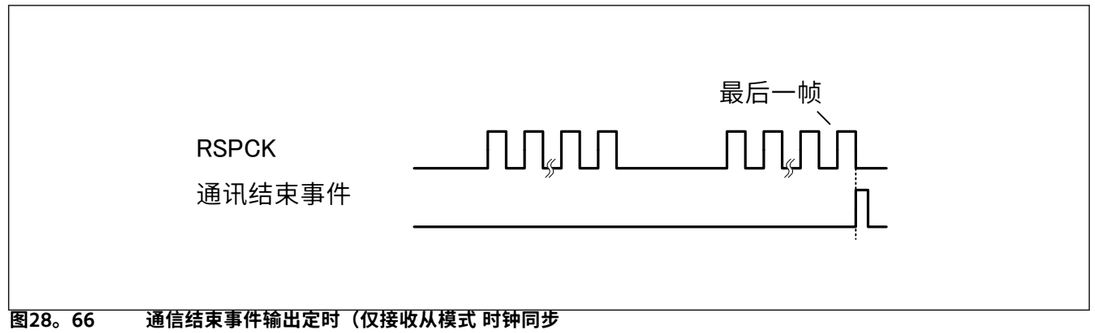

图28。66 通信结束事件输出定时（仅接收从模式 时钟同步动（运作）

28。5 使用说明

28。5。1 模块停止状态的设置

模块停止控制寄存器 B（MSTPCRB）可以启用或禁用 SPI 操作。SPI在重置后最初停止。释放模块停止状态可以访问寄存器。模块停止控制寄存器 B 的详细信息,请参阅第 10 节"低功耗模式 ."

28。5。2 低功耗函数的约束

Sleep模式以外的低功耗模式时 在完成通信前将SPCR。SPE位设置为0。

28。5。3 开始转移的限制

如果传输开始时 ICU。IELSRn。IR 标志为 1,则中断请求会在内部保留,这可能会导致 ICU。IELSRn。IR 标志出现意外行为。

为了防止这种情况发生,请在启用操作之前使用以下过程清除中断请求（通过将 SPCR。SPE 位设置为 1):

1。确认传输停止（SPCR。SPE 位为 0)。

2锛姣涓涓。将关联的中断使能位（SPCR。SPTIE 位或 SPCR。SPRIE 位）设置为 0。

3锛　　娴　　。读取关联的中断使能位（SPCR。SPTIE 位或 SPCR。SPRIE 位）并确认其值为 0。

4锛姣涓。将ICU。IELSRn。IR标志设置为0。

28。5。4 模式故障、欠载、超载或奇偶校验错误事件输出的约束

如果 SPI 处于多主模式（当 SPCR。SPMS 位为 0、SPCR。MSTR 位为 1、SPCR。MODFEN 位为1)。

28。5。5 对 SPSR。SPRF 和 SPSR。SPTEF 标志的限制

如果使用轮询标志 SPRF 和 SPTEF,则禁止使用中断,并且您必须将 SPCR。SPRIE 和 SPCR。SPTIE 位设置为 0。可以使用中断或标志,但不能同时使用。

Bit	Symbol	Function	R/W
31:0	n/a	CRC output data The CRCDOR register is a 32-bit read/write register for CRC-32 or CRC-32C calculation. The CRCDOR_HA (CRCDOR[31:16]) register is a 16-bit read/write register for CRC-16 or CRC-CCITT calculation. The CRCDOR_BY (CRCDOR[31:24]) register is an 8-bit read/write register for CRC-8 calculation. Because its initial value is 0x00000000, rewrite the CRCDOR/CRCDOR_HA/CRCDOR_BY register to perform the calculations using a value other than the initial value. Data written to the CRCDIR/CRCDIR_BY register is CRC calculated and the result is stored in the CRCDOR/CRCDOR_HA/CRCDOR_BY register. If the CRC code is calculated following the transferred data and the result is 0x00000000, there is no CRC error.	R/W

29.3 Operation

29.3.1 Basic Operation

The CRC calculator generates CRC codes for use in LSB-first or MSB-first transfer.

The following examples show CRC code generation for input data (0xF0) using the 16-bit CRC-CCITT generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before CRC calculation.

When an 8-bit CRC (with the polynomial $X^8 + X^2 + X + 1$) is in use, the valid bits of the CRC code are obtained in CRCDOR_BY. When a 32-bit CRC is in use, the valid bits of the CRC code are obtained in CRCDOR.

Figure 29.2 and Figure 29.3 show the LSB-first and MSB-first data transmission examples respectively. Figure 29.4 and Figure 29.5 show the LSB-first and MSB-first data reception examples.

29。3 操作

29。3。1 基本操作

CRC 计算器生成用于 LSB 优先或 MSB 优先传输的 CRC 代码。

以下示例显示了使用 16 位 CRC-CCITT 生成多项式（$X^{16} + X^{12} + X^5 + 1$) 生成输入数据 (0xF0) 的 CRC 代码。在这些示例中,CRC数据输出寄存器（CRCDOR_HA）的值在CRC计算之前被清除。

当使用8位CRC（具有多项式$X^8 + X^2 + X + 1$)时,CRC代码的有效位在CRCDOR_BY中获得。当使用32位CRC时,CRC代码的有效位在CRCDOR中获得。

图29。2和图29。3分别示出了LSB优先和MSB优先数据传输示例。图29。4和图29。5示出了LSB优先和MSB优先数据接收示例。

Operation to find sinθ and cosθ, which are the triangular ratios of the input angle values θ.
atan arithmetic:
Operation to find the angle value between the vector OA (O is the origin and A is the point indicated by the input coordinates x and y) and the positive part of the x-axis.

31. True Random Number Generator (TRNG)

31.1 Overview

Table 31.1 shows specifications of the TRNG (True Random Number Generator).

Table 31.1 TRNG specifications

Parameter	Description
Frequency	100 MHz (max)
SEED generation speed	0.1 to 10 Mbps 32-bit SEED generation
Buffering	None
Interface	8-bit read + 8-bit write/1 clock

Encrypt the SEED generated by the TRNG to use it as a random number (true random number).

The data generated by testing a SEED itself and a random number which is generated from a SEED (using the continuous random number generator test described in NIST FIPS140-2) are the same by a fixed probability according to the bit length of the two generated random numbers.

The probability that a random number of a comparative target is identical in the nth bit (the theoretical value) is $1/2^n$.

31.2 Usage Notes

31.2.1 Module-Stop Function Setting

TRNG operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The TRNG module is initially stopped after reset. Releasing the module-stop state enables access to the registers.

32. 12-Bit A/D Converter (ADC12)

32.1 Overview

The MCU includes 12-bit successive approximation A/D converter (ADC12) unit. Analog input channels are selectable up to 12. The temperature sensor output and an internal reference voltage are selectable for conversion.

The A/D conversion accuracy is selectable from 12-bit, 10-bit, 8-bit conversion, making it possible to optimize the trade-off between speed and resolution in generating a digital value.

The ADC12 supports the following operating modes:

- Single scan mode to convert analog inputs of selected channels in ascending order of channel number
- Continuous scan mode to convert analog inputs of selected channels continuously in ascending order of channel number
- Group scan mode to divide analog inputs of channels into two groups (group A and B) and convert the analog inputs of selected channels for each group in ascending order of channel number.

In group scan mode, select two groups (group A and B). You can individually select the scan start conditions for each group (group A, B) and start scanning of each group at different times. In addition, when group A priority control operation is set, the ADC12 accepts group A scan start during group B A/D conversion, suspending group B conversion. This allows you to assign higher priority to A/D conversion start for group A.

In double trigger mode, the analog input of a selected channel is converted in single scan mode or group scan mode (group A), and data converted by the first and second A/D conversion start triggers are stored in different registers, providing duplexing of A/D converted data.

Self-diagnosis is performed once at the beginning of each scan, and one of the three reference voltage values generated in ADC12 is A/D converted.

The temperature sensor output and the internal reference voltage is selectable at the same time as the analog input of the channel. First A/D conversion is performed for the analog input of the channel, next the temperature sensor output and then for the internal reference voltage.

The ADC12 also provides a compare function (window A and window B). The compare function specifies the upper reference value for window A and lower reference value for window B, and outputs an interrupt when the A/D converted value of the selected channel meets the comparison conditions.

The A/D data storage buffer is a ring buffer consisting of 16 buffers to sequentially store A/D converted data.

Table 32.1lists the ADC12 specifications and Table 32.2 list the functions. Figure 32.1 shows a block diagram of ADC12 and Table 32.3 lists the I/O pins.

32. 12位A/D转换器（ADC12）

32。1 概述

MCU 包括 12 位连续近似 A/D 转换器（ADC12) 单元。模拟输入通道最多可选择 12 个。温度传感器输出和内部参考电压可选择进行转换。

A/D 转换精度可从 12 位、10 位、8 位转换中选择,从而可以优化生成数字值时速度和分辨率之间的权衡。

ADC12 支持以下操作模式:

- 单次扫描模式,将选定通道的模拟输入按照通道数的升序进行转换
- 连续扫描模式,以通道数的升序连续转换所选通道的模拟输入
- 组扫描模式,将通道的模拟输入分为两组（A 组和 B 组）,并按通道号的升序转换每组所选通道的模拟输入。

在组扫描模式下,选择两个组（A 组和 B 组）。组（A、B 组）的扫描开始条件,可以单独选择,在不同时间开始扫描各组。另外,当设置A组优先级控制操作时,ADC12在B组A/D转换期间接受A组扫描开始,暂停B组转换。这允许您为 A 组的 A/D 转换开始分配更高的优先级。

在双触发模式下,所选信道的模拟输入在单扫描模式或组扫描模式（A组）下转换,并且由第一和第二A/D转换启动触发器转换的数据存储在不同的寄存器中,提供双工A/D 转换后的数据。

每次扫描开始时进行一次自我诊断,ADC12 中生成的三个参考电压值之一进行 A/D 转换。

温度传感器输出和内部参考电压可与通道的模拟输入同时选择。首先对通道的模拟输入执行 A/D 转换,然后对温度传感器输出执行 A/D 转换,然后对内部参考电压执行 A/D 转换。

ADC12还提供了一个比较功能（窗口A和窗口B）。比较函数指定窗口A的上参考值和窗口B的下参考值,并在所选信道的A/D转换值满足比较条件时输出中断。

A/D数据存储缓冲器是由16个缓冲器组成的环形缓冲器,用于顺序存储A/D转换的数据。

ADDRn registers are 16-bit read-only registers to store A/D conversion results.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 32.4 shows the example of bit assignment for 12-bit accuracy.

Table 32.4 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 32.5 shows example of the bit assignment for 12-bit accuracy.

ADTSDR register is a 16-bit read-only register to store A/D conversion result of the temperature sensor output.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 32.10 shows the example of bit assignment for 12-bit accuracy.

Table 32.10 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Note 1. To start A/D conversion using an external pin (asynchronous trigger):
After a high-level signal is input to the external pin (ADTRG0), write 1 to both the TRGE and EXTRG bits in the ADCSR register and drive the ADTRG0 pin low. With these settings, the scan conversion process starts on detection of the falling edge of ADTRG0. The pulse width of the low-level input must be at least PCLKA 1.5 clock cycles.

注1。使用外部引脚（异步触发器）启动 A/D 转换:
高电平信号输入到外部引脚（ADTRG0) 后,将 1 写入 ADCSR 寄存器中的 TRGE 和 EXTRG 位,并将 ADTRG0 引脚驱动至低电平。通过这些设置,扫描转换过程从检测到 ADTRG0 的落边开始。低电平输入的脉冲宽度必须至少为 PCLKA 1。5 个时钟周期。

The ADCSR register sets double-trigger mode and A/D conversion start trigger, enables or disables scan end interrupt, selects the scan mode, and starts or stops A/D conversion.

DBLANS[4:0] bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one channel for A/D conversion data duplication in double-trigger mode. This can be selected by setting the binary value of the channel number to be duplicated. The A/D conversion results of the analog input of the channel selected in the DBLANS[4:0] bits are stored in A/D Data Register y when conversion is started by the first trigger, and in the A/D Data Duplexing Register when conversion is started by the second trigger.

In double-trigger mode, the channels selected in the ADANSA0 and ADANSA1 registers, are invalid, and the channel selected in the DBLANS[4:0] bits is A/D converted instead.

When double-trigger mode is used in group scan mode, double-trigger control is only applied to group A and not to group B. Therefore, multiple channel analog input can be selected for group B even in double-trigger mode.

Only set the DBLANS[4:0] bits when the ADST bit is 0. Do not set the DBLANS[4:0] bits at the same time that you write 1 to the ADST bit.

To enter A/D-converted value addition/average mode when in double-trigger mode, select the channel using the DBLANS[4:0] bits in the ADANSA0 and ADANSA1 registers.

A/D-converted data from the self-diagnosis function temperature sensor output and internal reference voltage cannot be used in double-trigger mode.

GBADIE bit (Group B Scan End Interrupt and ELC Event Enable)

The GBADIE bit enables or disables group B scan end interrupt (ADC120_GBADI) in group scan mode.

DBLE bit (Double Trigger Mode Select)

The DBLE bit selects or deselects double-trigger mode. Double-trigger mode can only be operated by the synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits.

Double-trigger operation is as follows:

1. The ADC120_ADI interrupt is not output on completion of the first conversion but on completion of the second conversion.
2. The A/D conversion results from the duplication channel (selected in DBLANS[4:0]) started by the first trigger are stored in A/D Data Register y and those started by the second trigger are stored in the A/D Data Duplexing Register.

When the DBLE bit is set (double-trigger mode is selected), the channels specified in the ADANSA0 and ADANSA1 registers are invalid. Double-trigger mode is deselected by setting DBLE to 0. Setting DBLE to 1 again enables the same double-trigger operation described in 1. and 2. for first time scanning with the first trigger.

Do not select double-trigger mode in continuous scan mode. Software triggering cannot be used in double-trigger mode. Always set the ADST bit to 0 before setting the DBLE bit. Do not set the DBLE bit at that same time as writing 1 to the ADST bit.

EXTRG bit (Trigger Select)

The EXTRG bit selects the synchronous or asynchronous trigger as the trigger for starting A/D conversion.

In group scan mode, the setting of this bit takes effect on the trigger selected for group A. For group B, A/D conversion is started by the selected synchronous trigger regardless of this bit setting.

TRGE bit (Trigger Start Enable)

The TRGE bit enables or disables A/D conversion by the synchronous and asynchronous triggers. In group scan mode, set this bit to 1.

ADCS[1:0] bits (Scan Mode Select)

The ADCS[1:0] bits select the scan mode.

In single scan mode, A/D conversion is performed for the analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, the scan conversion stops.

ADCSR寄存器设置双触发模式和A/D转换启动触发,启用或禁用扫描端中断,选择扫描模式,启动或停止A/D转换。

DBLANS[4:0] 位（双触发通道选择）

DBLANS[4:0] 位选择一个通道用于双触发模式下的 A/D 转换数据复制。这可以通过设置要重复的信道号的二进制值来选择。DBLANS[4:0]位中选择的通道的模拟输入的A/D转换结果,在第一触发器启动转换时存储在A/D数据寄存器y中,在第二触发器启动转换时存储在A/D数据双工寄存器中。

在双触发模式下,ADANSA0和ADANSA1寄存器中选择的信道无效,并且DBLANS[4:0]位中选择的信道被A/D转换。

当在组扫描模式下使用双触发模式时,双触发控制仅应用于A组而不是B组,因此即使在双触发模式下也可以为B组选择多通道模拟输入。

ADST 位为 0 时才设置 DBLANS[4:0] 位。请勿在将 1 写入 ADST 位的同时设置 DBLANS[4:0] 位。

要在双触发模式下输入 A/D 转换的加值/平均模式,请使用 ADANSA0 和 ADANSA1 寄存器中的 DBLANS[4:0] 位选择通道。

A/D 转换的数据来自自诊断功能温度传感器输出和内部参考电压不能在双触发模式下使用。

GBADIE 位（B 组扫描结束中断和启用 ELC 事件）

GBADIE 位在组扫描模式下启用或禁用 B 组扫描端中断（ADC120_GBADI）。

DBLE 位（双触发模式选择）

DBLE 位选择或取消选择双触发模式。双触发模式只能由 ADSTRGR。TRSA[5:0] 位中选择的同步触发器（ELC）操作。

双触发操作如下:

1。ADC120_ADI中断不是在第一次转换完成时输出,而是在第二次转换完成时输出。

2锛姣涓涓。A/D 转换结果来自由第一触发器启动的复制通道（在 DBLANS[4:0] 中选择）存储在 A/D 数据寄存器 y 中,由第二触发器启动的 A/D 转换结果存储在 A/D 数据双工寄存器中。

DBLE 位设置时（选择双触发模式）,ADANSA0 和 ADANSA1 寄存器中指定的通道无效。通过将 DBLE 设置为 0 来取消选择双触发模式。将 DBLE 设置为 1 再次启用 1。和 2。中描述的相同双触发操作,首次使用第一个触发器进行扫描。

请勿在连续扫描模式下选择双触发模式。软件触发不能在双触发模式下使用。在设置 DBLE 位之前,始终将 ADST 位设置为 0。请勿在将 1 写入 ADST 位的同时设置 DBLE 位。

EXTRG 位（触发器选择）

EXTRG位选择同步或异步触发器作为启动A/D转换的触发器。

在组扫描模式下,该位的设置对为A组选择的触发器生效。对于B组,无论该位设置如何,由所选择的同步触发器启动A/D转换。

TRGE 位（启用触发器启动）

TRGE 位通过同步和异步触发器启用或禁用 A/D 转换。在组扫描模式下,将此位设置为 1。

ADCS[1:0] 位（扫描模式选择）

ADCS[1:0] 位选择扫描模式。

在单扫描模式下,按照通道号的升序对 ADANSA0 和 ADANSA1 寄存器中选择的通道的模拟输入执行 A/D 转换。当所有选定通道的 1 个 A/D 转换周期完成时,扫描转换停止。

In continuous scan mode, when the ADCSR.ADST bit is 1, A/D conversion is performed for the analog inputs of the channels selected with the ADANSA0 and ADANSA1 registers , in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion repeats from the first channel. If the ADCSR.ADST bit is set to 0 during continuous scan, A/D conversion stops even if scanning is in progress.

In group scan mode:

- Group A scanning is started by the synchronous trigger (ELC) selected in the TRSA[5:0] bits in the ADSTRGR register. A/D conversion is performed on group A analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.
- Group B scanning is started by the synchronous trigger (ELC) selected in the ADSTRGR.TRSB[5:0] bits. A/D conversion is performed on group B analog inputs of the channels selected in the ADANSB0 and ADANSB1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.

If the conversion processes in group A and group B occur at the same time, those conversions cannot be controlled separately. In this case, set group A Priority Control Setting bit (ADGSPCR.PGS) in the A/D Group Scan Priority Control Register (ADGSPCR) to 1 to assign a priority to group A conversion.

In group scan mode, select different channels and triggers for group A and group B.

Only set the ADCS[1:0] bits when the ADST bit is 0. Do not set the ADCS[1:0] bits at the same time that you write 1 to the ADST bit.

ADST bit (A/D Conversion Start)

The ADST bit starts or stops the A/D conversion process. Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and the conversion target analog input.

[Setting conditions]

- 1 is written.
- The synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits is detected when ADCSR.EXTRG is 0 and ADCSR.TRGE is 1.
- The synchronous trigger (ELC) selected in the ADSTRGR.TRSB[5:0] bits is detected when ADCSR.TRGE is set to 1 in group scan mode.
- The asynchronous trigger is detected when the ADCSR.TRGE and ADCSR.EXTRG bits are set to 1 and the ADSTRGR.TRSA[5:0] bits are set to 0x00.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRP bit is set to 1, and each time A/D conversion on the group with the lowest priority is started.

[Clearing conditions]

- 0 is written.

在连续扫描模式下,当ADCSR。ADST比特为1时,按照信道号的升序对使用ADANSA0和ADANSA1寄存器选择的信道的模拟输入执行A/D转换。当所有选定的通道完成 1 个 A/D 转换周期时,A/D 转换从第一个通道重复。ADCSR。ADST 位在连续扫描期间设置为 0,则即使扫描正在进行,A/D 转换也会停止。

在分组扫描模式下:

- 组 A 扫描由 ADSTRGR 寄存器中 TRSA[5:0] 位中选择的同步触发器（ELC）启动。A/D 转换按照通道号的升序对 ADANSA0 和 ADANSA1 寄存器中选择的通道的 A 组模拟输入执行。当所有选定通道的 1 个 A/D 转换周期完成时,A/D 转换停止。

- B 组扫描由 ADSTRGR。TRSB[5:0] 位中选择的同步触发器（ELC）启动。A/D 转换按照通道号的升序对 ADANSB0 和 ADANSB1 寄存器中选择的通道的 B 组模拟输入执行。当所有选定通道的 1 个 A/D 转换周期完成时,A/D 转换停止。

A组和B组的转换过程同时发生,则不能分别控制这些转换。在这种情况下,将A/D组扫描优先级控制寄存器（ADGSPCR）中的A组优先级控制设置位（ADGSPCR。PGS）设置为1以将A组转换的优先级分配。

在组扫描模式下,为 A 组和 B 组选择不同的通道和触发器。

ADST位为0时才设置ADCS[1:0]位。不要在将 1 写入 ADST 位的同时设置 ADCS[1:0] 位。

Only set the ADANSB1 register when the ADCSR.ADST bit is 0.

The ADANSB1 register selects any combination of analog input channels in group B for A/D conversion when group scan mode is selected. The ADANSB1 register is used for group scan mode only and not for any other modes.

Do not select channels specified in group A as selected in the ADANSA0 and ADANSA1 registers or the ADCSR.DBLANS[4:0] bits in double-trigger mode.

ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA0 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB0 register

ADSn 位（A/D 转换的增值/平均通道选择）

ADSn 位确定哪些 A/D 转换的信道受到 A/D 转换的加值/平均的影响。当一个ADSn位与选择用于A/D转换的信道相关联设置为1,相应信道的模拟输入的A/D转换依次执行1、2、3、4或16次,如ADADC寄存器中的ADC[2:0]位中指定。

当ADADC。AVEE位为0时,通过相加获得的值存储在A/D数据寄存器中。当ADADC。AVEE 位为 1,加法得到的结果的平均值存储在 A/D 数据寄存器中。

ADSn 位仅适用于以下选项中选择用于 A/D 转换的信道:

- ADANSA0 寄存器中的 ANSAn 位或 ADCSR 寄存器中的 DBLANS[4:0] 位
- ADANSB0 寄存器中的 ANSBn 位

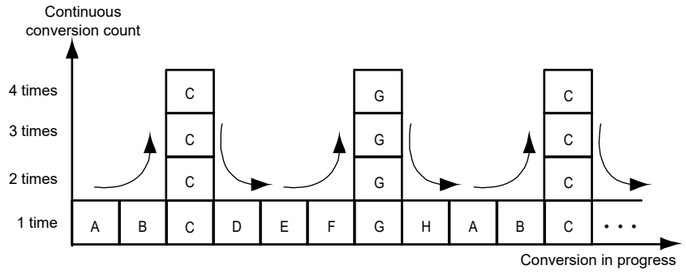
For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS0 register bits when the ADCSR.ADST bit is 0.

Figure 32.2 shows a scanning operation sequence in which the ADADS0 register bits (channel c and g) are set to 1. In this figure:

- Addition mode is selected (ADADC.AVEE = 0)
- The number of conversions is set to 4 (ADADC.ADC[1:0] = 11b)
- The analog input channels (a to h) are selected by ADANSA0 register in continuous scan mode (ADCSR.ADCS[1:0] = 10b).

The conversion process begins with analog input A (channel a). The analog input C (channel c) conversion is performed successively 4 times and the added value is returned to A/D Data Register c (ADDRc). Next, the analog input D (channel d) conversion process is started. The analog input G (channel g) is performed successively 4 times and the added value is returned to A/D Data Register g (ADDRg). After conversion of analog input H (channel h), the conversion operation repeats in the same sequence starting with analog input A (channel a).



Note: A to H are analog inputs (channel a to h)

ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA1 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB1 register.

For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

For details, see section 32.3.6. Analog Input Sampling and Scan Conversion Timesection 45.3.6, Analog Input Sampling and Scan Conversion Time. ACE bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0) of the ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, or ADOCDR register after any of these registers is read by the CPU or DTC. Automatic clearing of the A/D data registers enables detection of failures that are not updated in the A/D data registers. For details, see section 32.3.7. Usage Example of A/D Data Register Automatic Clearing Function.

DIAGVAL[1:0] bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis fixed voltage mode. For details, see the DIAGLD bit description.

Do not execute self-diagnosis by setting the DIAGLD bit to 1 when the DIAGVAL[1:0] bits are set to 00b.

DIAGLD bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated, or the fixed voltage is used in self-diagnosis.

Setting the DIAGLD bit to 0 selects conversion of the voltages in rotation mode, where 0 V, the reference voltage × 1/2, and the reference voltage are converted, in that order. After reset and when self-diagnosis voltage rotation mode is selected, self-diagnosis is executed from 0 V. The self-diagnosis voltage value does not return to 0 V when scan conversion completes. When scan conversion is restarted, rotation starts at the voltage value following the previous value.

Setting the DIAGLD bit to 1 selects fixed voltage, in which the fixed voltage specified in the ADCER.DIAGVAL[1:0] bits is converted. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

Only set the DIAGLD bit when the ADCSR.ADST bit is 0.

DIAGM bit (Self-Diagnosis Enable)

The DIAGM bit enables or disables self-diagnosis.

Self-diagnosis is used to detect a failure of the ADC12. In self-diagnosis mode, one of the three voltage values (0 V, the reference voltage × 1/2, or the reference voltage) is converted. When conversion completes, information on the converted voltage and the conversion result is stored into the A/D Self-Diagnosis Data Register (ADRD). The ADRD register can be read to determine whether the conversion result falls within the normal or abnormal range.

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. In double trigger mode (ADCSR.DBLE = 1), self-diagnosis (DIAGM = 0) is deselected. When self-diagnosis is selected in group scan mode, self-diagnosis is executed separately for group A and group B.

Only set the DIAGM bit when the ADCSR.ADST bit is 0.

ADRFMT bit (A/D Data Register Format Select)

The ADRFMT bit specifies flush-right or flush-left for data to be stored in the ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADCMPDR0/1, ADWINLLB, ADWINULB, or ADRD register.

Only set the ADRFMT bit when the ADCSR.ADST bit is 0.

ACE 位（A/D 数据寄存器自动清除启用）

在 CPU 或 DTC 读取任何这些寄存器后,ACE 位启用或禁用 ADRy、ADRD、ADDBLDR、ADDBLDRA、ADDBLDRB、ADTSDR 或 ADOCDR 寄存器的自动清除（所有 0)。A/D 数据寄存器的自动清除可以检测 A/D 数据寄存器中未更新的故障。详情请参见第 32。3。7 节。A/D数据寄存器自动清除功能的使用示例 .

DIAGVAL[1:0] 位（自诊断转换电压选择）

DIAGVAL[1:0] 位选择自诊断固定电压模式下使用的电压值。有关详细信息,请参阅 DIAGLD 位描述。

DIAGVAL[1:0] 位设置为 00b 时,请勿通过将 DIAGLD 位设置为 1 来执行自诊断。

DIAGLD 位（自诊断模式选择）

DIAGLD位选择三个电压值是否旋转,或者固定电压用于自我诊断。

将 DIAGLD 位设置为 0 选择旋转模式下电压的转换,其中 0 V、参考电压 × 1/2 和参考电压按该顺序转换。复位后,选择自诊断电压旋转模式时,从0V执行自诊断。扫描转换完成时,自诊断电压值不会恢复到0V。

当扫描转换重新启动时,旋转从上一个值之后的电压值开始。

DIAGLD 位设置为 1 选择固定电压, 其中转换 ADCER。DIAGVAL[1:0] 位中指定的固定电压。如果固定模式切换到旋转模式,则以固定电压值开始旋转。

仅当 ADCSR。ADST 位为 0 时设置 DIAGLD 位。

DIAGM 位（启用自我诊断）

DIAGM 位启用或禁用自我诊断。

自诊断用于检测 ADC12 的故障。在自诊断模式下,转换三个电压值之一(0 V、参考电压× 1/2或参考电压）。转换完成后,有关转换电压和转换结果的信息将存储到 A/D 自诊断数据寄存器（ADRD）中。ADRD寄存器可以被读取,以确定转换结果是否落在正常或异常范围内。

每次扫描开始时执行一次自我诊断,并转换三个电压之一。在双触发模式（ADCSR。DBLE = 1)下,取消选择自我诊断（DIAGM = 0)。当在组扫描模式下选择自我诊断时,A组和B组分别执行自我诊断。

仅当 ADCSR。ADST 位为 0 时设置 DIAGM 位。

ADRFMT 位（A/D 数据寄存器格式选择）

ADRFMT 位指定将数据存储在 ADRy、ADDBLDR、ADDBLDRA、ADDBLDRB、ADTSDR、ADOCDR、ADCMPDR0/1、ADWINLLB、ADWINULB 或 ADRD 寄存器中的向右齐平或向左齐平。

仅当 ADCSR。ADST 位为 0 时设置 ADRFMT 位。

15:14	—	These bits are read as 0. The write value should be 0.	R/W

TRSB[5:0] bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits must only be set in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. In group scan mode, set the TRSB[5:0] bits to a value other than 0x00 and set the ADCSR.TRGE bit to 1.

When group A is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 0x3F. The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than t_{SCAN}, A/D conversion by the trigger might have no effect.

Table 32.18 lists the A/D conversion startup sources selected in the TRSB[5:0] bits.

TRSA[5:0] bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode, or the trigger to start scanning of group A analog inputs in group scan mode. When scanning is executed in group scan mode or double trigger mode, software trigger or asynchronous trigger is prohibited.

- When using a synchronous trigger (ELC), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 0.
- When using the asynchronous trigger (ADTRG0), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, or the TRSA[5:0] bits.

The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by a trigger might have no effect.

TRSB[5:0] 位（B 组的 A/D 转换开始触发器选择）

TRSB[5:0]位选择触发器开始扫描在B组中选择的模拟输入,TRSB[5:0]位必须仅在组扫描模式下设置,并且在任何其他扫描模式下都不使用。B组的扫描转换启动触发,禁止设置软件触发或异步触发。在组扫描模式下,将TRSB[5:0]位设置为0x00以外的值,并将ADCSR。TRGE位设置为1。

A组在组扫描模式下被优先考虑时,将ADGSPCR。GBRP位设置为1允许B组在单次扫描模式下连续运行。ADGSPCR。GBRP 位设置为 1 时,将 TRSB[5:0] 位设置为 0x3F,转换触发器的发出周期必须大于或等于实际扫描转换时间（t SCAN）。如果发行期限小于t SCAN,则触发器的A/D转换可能没有效果。

● 使用同步触发器（ELC）时,将ADCSR寄存器中的TRGE位设置为1,将ADCSR寄存器中的EXTRG位设置为0。

Bit	Symbol	Function	R/W
7:0	SST[7:0]	Sampling Time Setting These bits set the sampling time in the range from 5 to 255 states.	R/W

The ADSSTRn register sets the sampling time for analog input.

The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow. The set value indicates the time for one ADCLK cycle, and the required sampling time is specified by the voltage conditions. For details, see section 41.4. ADC12 Characteristics.

The lower limit of the sampling time setting depends on the frequency ratio:

- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:1, 2:1, 4:1, or 8:1 the sampling time must be set to a value of more than 5 states
- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:2 or 1:4, the sampling time must be set to a value of more than 6 states.

Table 32.20 shows the relationship between the A/D Sampling State Register and the associated channels. For details, see section 32.3.6. Analog Input Sampling and Scan Conversion Time.

Only set the SST[7:0] bits when the ADCSR.ADST bit is 0.

- 如果 PCLKA 与 PCLKC（ADCLK）的频率比 = 1:1、2:1、4:1 或 8:1,则采样时间必须设置为超过 5 个状态的值
- 如果 PCLKA 与 PCLKC（ADCLK）的频率比 = 1:2 或 1:4,则采样时间必须设置为超过 6 个状态的值。

SSTSH[7:0] bits (Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting)

The SSTSH[7:0] bits set the sampling time for the channel-dedicated sample-and-hold circuits. If one state is 1 ADCLK (A/D conversion clock) cycle and the ADCLK clock is 50 MHz, one state is 20.0 ns. The initial value is 24 states. The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow.

Only set the SSTSH[7:0] bits while the ADCSR.ADST bit is 0. The sampling time must be set to a value that is 4 states or more and 255 or less.

SSTSH[7:0]位（信道专用采样–保持电路采样时间设置）

SSTSH[7:0]位设置通道专用采样保持电路的采样时间。如果一种状态是 1 ADCLK（A/D 转换时钟）周期并且 ADCLK 时钟是 50 MHz,则一种状态是 20。0 ns。初始值为 24 个状态。如果模拟输入信号源的阻抗太高而无法确保足够的采样时间,或者 ADCLK 时钟很慢,则可以调整采样时间。

仅设置 SSTSH[7:0] 位,而 ADCSR。ADST 位为 0。采样时间必须设置为 4 种状态或更多且 255 种或更少的值。

SHANS[2:0] 位（通道专用采样和保持电路旁路选择）

SHANS[0]位与AN000相关联,SHANS[1]位与AN001相关联,SHANS[2]位与AN002相关联。

A组优先级控制下操作处于组扫描模式时,如果为B组选择AN000至AN002的任何信道,则使用此设置绕过该信道的专用采样保持电路。

0	SHMD	Sampling Operation Selection 0: Disable continuous sampling function 1: Enable continuous sampling function	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: The ADCSR.ADST bit must become 1 after a time of 400 ns or more elapses after the SHMD bit is set to 1 (when the permissible signal source impedance is 1 kΩ). The sampling period of the sample-and-hold circuit must be 400 ns or more (when the permissible signal source impedance is 1 kΩ). If only the channel with sample-and-hold circuit is selected and continuous scan is performed, the period of the second and subsequent constant-sampling of the continuous scan will be insufficient. When performing continuous scan with constant-sampling enabled using the sample-and-hold circuit, select another channel that does not implement the sample-and-hold circuit to ensure the period of constant-sampling.

SHMD bit (Sampling Operation Selection)

Setting SHMD to 1 enables the constant sampling function of the channel-dedicated sample-and-hold selected in the ADSHCR.SHANS[2:0] bits. Only set the SHMD bit while the ADCSR.ADST bit is 0.

When the sampling function is enabled, the sample-and-hold circuit operates sampling while the ADC12 is not operating, and operates holding while the ADC12 is operating.

32.2.21 ADDISCR : A/D Disconnection Detection Control Register

Base address: ADC120 = 0x4017_0000

Offset address: 0x07A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PCHG	ADNDIS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

4	PCHG	Precharge/discharge select 0: Discharge 1: Precharge	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

The ADDISCR register selects either precharge or discharge, and the period of precharge or discharge for the A/D disconnection detection assist function. Only set the ADDISCR register when the ADCSR.ADST bit is 0. When thetemperature sensor output or internal reference voltage is converted, the A/D converter executes discharge automatically.

Disable the disconnection detection assist function if any of the following functions are used:

- The temperature sensor
- The internal reference voltage
- A/D self-diagnosis
- Programmable gain amplifier without bypass enabled

ADNDIS[3:0] bits (Disconnection Detection Assist Setting)

The ADNDIS[3:0] bits specify the period of precharge or discharge. When ADNDIS[3:0] = 0000b, the disconnection detection assist function is disabled. Setting the ADNDIS[3:0] bits to 0001b is prohibited. Except when ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge or discharge. When the ADNDIS[3:0] bits are set to any values other than 0000b or 0001b, the disconnection detection assistance function is enabled.

0	SHMD	采样操作选择 0:禁用连续采样功能 1:启用连续采样功能	R/W
7:1	—	这些位读作 0。写入值应为 0。	R/W

注意:在 SHMD 位设置为 1（当允许信号源阻抗为 1 kΩ 时）后,经过 400 ns 或更长时间后,ADCSR。ADST 位必须变为 1。400 ns或更多（当允许信号源阻抗为1 kΩ时）采样保持电路的采样周期。如果仅选择具有采样保持电路的信道并执行连续扫描,则连续扫描的第二次及后续恒定采样的周期将不够。当使用采样保持电路执行启用恒定采样的连续扫描时,选择另一个不实现采样保持电路的通道以确保恒定采样的周期。

SHMD 位（采样操作选择）

SHMD 设置为 1 能够实现 ADSHCR。SHANS[2:0] 位中选择的通道专用采样和保持的恒定采样功能。仅设置 SHMD 位,而 ADCSR。ADST 位为 0。

启用采样功能后,采样保持电路在ADC12不工作时进行采样,在ADC12工作时进行保持。

如果使用以下任何功能,请禁用断开检测辅助功能:

- 温度传感器
- 内部参考电压
- A/D 自我诊断
- 可编程增益放大器,无需启用旁路

ADNDIS[3:0] 位（断开连接检测辅助设置）

ADNDIS[3:0] 位指定预充电或放电的周期。ADNDIS[3:0] = 0000b时,断开检测辅助功能被禁用。禁止将 ADNDIS[3:0] 位设置为 0001b。ADNDIS[3:0] = 0000b或0001b时除外,规定值表示预充或放电期间的状态数。ADNDIS[3:0]位设置为0000b或0001b以外的任何值时,断开检测辅助功能被启用。

PCHG bit (Precharge/discharge select)

The PCHG bit selects either precharge or discharge.

1	GBRSCN	Lower-Priority Group Restart Setting (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Disable rescanning of the group that was stopped in group priority operation 1: Enable rescanning of the group that was stopped in group priority operation.	R/W

15	GBRP	Single Scan Continuous Start*2 (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Single scan is not continuously activated. 1: Single scan for the group with the lower-priority is continuously activated.	R/W

Note 1. The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting PGS to 1. Operation is not guaranteed if these bits are set to any other value.

Note 2. When the GBRP bit is set to 1, single scan is performed continuously for the group with the lower-priority regardless of the setting in the GBRSCN bit.

PGS bit (Group Priority Operation Setting)

The PGS bit controls group priority operation in group scan mode. Set the PGS bit to 1 to enable group priority operation.

The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting the PGS bit to 1. Operation is not guaranteed if the bits are set to any other value.

When the PGS bit is set to 0, a clear operation must be performed by software as described in section 32.6.3. Constraints on Stopping A/D Conversion. When the PGS bit is set to 1, use the settings described in section 32.3.4.3. Group Priority Operation.

GBRSCN bit (Lower-Priority Group Restart Setting)

The GBRSCN bit controls the restarting of scan operation in group priority operation.

When the GBRSCN bit is set to 1, if the scan operation of a lower-priority group is stopped by a trigger input of a priority group, the lower-priority group scanning is restarted on completion of the priority group scanning. If a trigger of a lower-priority group is input during scanning of the priority group, the lower-priority group scanning is started on completion of the priority group scanning.

When the GBRSCN bit is set to 0, triggers input during scanning are ignored. Set the GBRSCN bit while the ADCSR.ADST bit is 0.

LGRRS bit (Restart Channel Select)

This bit sets the channel from which rescanning is to be started in group priority operation. The setting of the LGRRS bit is valid when the PGS and GBRSCN bits are 1.

PCHG 位（预充电/放电选择）

PCHG 位选择预充电或放电。

32.2.22 ADGSPCR:A/D 组扫描优先级控制寄存器

基本地址: ADC120 = 0x4017_0000

位	符号	功能	R/W
0	PGS	组优先级操作设置 *1 0:无需组优先级控制即可操作。1:以组优先控制进行操作。	R/W
1	GBRSCN	低优先级组重新启动设置（仅在 PGS = 1 时启用,在 PGS = 0 时保留。） 0: 禁用在组优先级操作中停止的组的重新扫描 1: 启用在组优先级操作中停止的组的重新扫描。	R/W
13:2	—	这些位读作 0。写入值应为 0。	R/W
14	LGRRS	重新启动频道选择 仅当 PGS = 1 和 GBRSCN = 1 时启用。 0:从第一通道开始重新扫描进行扫描 1:从未完成A/D转换的通道开始重新扫描。	R/W
15	GBRP	单次扫描连续开始 *2（仅在 PGS = 1 时启用,在 PGS = 0 时保留。） 0:单次扫描不连续激活。 1:连续激活优先级较低组的单次扫描。	R/W

注1。ADCSR。ADCS[1:0]位必须设置为01b（组扫描模式）,然后才能将PGS设置为1。如果将这些位设置为任何其他值,则无法保证操作。

注2。GBRP 位设置为 1 时,无论 GBRSCN 位中的设置如何,都对优先级较低的组连续执行单次扫描。

PGS 位（组优先级操作设置）

PGS 位控制组扫描模式下的组优先级操作。PGS 位设置为 1 以启用组优先级操作。

ADCSR。ADCS[1:0] 位必须设置为 01b（组扫描模式）,然后才能将 PGS 位设置为 1。如果位设置为任何其他值,则无法保证操作。

当 PGS 位设置为 0 时,必须按照第 32。6。3 节中的描述通过软件执行清晰的操作。停止 A/D 转换的限制。PGS 位设置为 1 时,请使用第 32。3。4。3 节中描述的设置。组优先操作 .

GBRSCN 位（低优先级组重启设置）

GBRSCN 位在组优先级操作中控制扫描操作的重启。

GBRSCN位设置为1时,如果优先级组的触发输入停止低优先级组的扫描操作,则在优先级组扫描完成后重启低优先级组扫描。如果在优先级组扫描期间输入低优先级组的触发器,则在优先级组扫描完成时开始低优先级组扫描。

GBRSCN 位设置为 0 时, 忽略扫描期间的触发输入。设置 GBRSCN 位,而 ADCSR。ADST 位为 0。

LGRRS 位（重新启动通道选择）

该位设置在组优先级操作中要开始重新扫描的通道。当PGS和GBRSCN比特为1时,LGRRS比特的设置是有效的。

If the LGRRS bit is 0, scanning of a lower-priority group that was stopped in group priority operation is restarted from the first channel after scanning of the priority group completes.

If the LGRRS bit is 1, scanning of a lower-priority group that was stopped in group priority operation is restarted (upon completion of scanning of the priority group) from the channel for which A/D conversion is not complete. If A/D conversion of the addition setting channel was not completed the specified number of times when scanning stopped, A/D conversion of the addition setting channel is performed again the specified number of times when scanning restarts.

Set the LGRRS bit while the ADCSR.ADST bit is 0.

GBRP bit (Single Scan Continuous Start)

The GBRP bit is set when a single scan operation is to be performed continuously on the group with the lower-priority.

Setting the GBRP bit to 1 starts a single scan of the group with the lower-priority. On completion of the scan, another single scan of the group with the lower-priority is started automatically. If scanning has been stopped during group priority operation, single scan of the group with the lower-priority is automatically restarted on completion of the A/D conversion of the priority group.

Before setting the GBRP bit to 1, disable input of a trigger for the lower-priority group. If the GBRP bit is set to 1, rescanning is performed only on the group with the lower-priority even if the GBRSCN bit is set to 0.

13	CMPBIE	Compare B Interrupt Enable 0: Disable ADC120_CMPBI interrupt when comparison conditions (window B) are met. 1: Enable ADC120_CMPBI interrupt when comparison conditions (window B) are met.	R/W

如果LGRRS位为0,则在优先级组的扫描完成后,从第一通道重新开始对在组优先级操作中停止的较低优先级组的扫描。

如果LGRRS位为1,则从A/D转换未完成的信道重新开始对在组优先级操作中停止的较低优先级组的扫描（在完成优先级组的扫描后）。如果添加设置信道的A/D转换未完成扫描停止时的指定次数,则在扫描重新启动时再次执行添加设置信道的A/D转换的指定次数。

设置 LGRRS 位,而 ADCSR。ADST 位为 0。

GBRP 位（单次扫描连续启动）

当要以较低优先级对组连续执行单个扫描操作时,设置 GBRP 位。

将 GBRP 位设置为 1 会以较低优先级开始对组进行单次扫描。扫描完成后,将自动开始对优先级较低的组进行另一次扫描。如果在组优先级操作期间已停止扫描,则在完成优先级组的A/D转换后自动重新启动优先级较低的组的单次扫描。

GBRP 位设置为 1 之前,请禁用较低优先级组的触发器的输入。GBRP 位设置为 1,则即使 GBRSCN 位设置为 0,也仅对优先级较低的组执行重新扫描。

CMPLTSA bit (Compare Window A Temperature Sensor Output Comparison Condition Select)

The CMPLTSA bit specifies comparison conditions when the temperature sensor output is the target for the Window A comparison condition. When the temperature sensor output comparison result meets the set condition, the ADCMPSER.CMPSTTSA flag sets to 1 and a compare interrupt (ADC120_CMPAI) is generated.

CMPLOCA bit (Compare Window A Internal Reference Voltage Comparison Condition Select)

The CMPLOCA bit specifies comparison conditions when the internal reference voltage is the target for the Window A comparison condition. When the internal reference voltage comparison result meets the set condition, the ADCMPSER.CMPSTOCA flag sets to 1 and a compare interrupt (ADC120_CMPAI) is generated.

Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ADCMPDRy (y = 0, 1) register specifies the reference data when the compare window A function is used. ADCMPDR0 sets the lower reference for window A, and ADCMPDR1 sets the upper reference for window A.

ADCMPDRy are read/write registers.

ADCMPDRy are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

Set these registers so that the upper reference is not less than the lower reference (ADCMPDR1 ≥ ADCMPDR0). ADCMPDR1 are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See Figure 32.4. If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

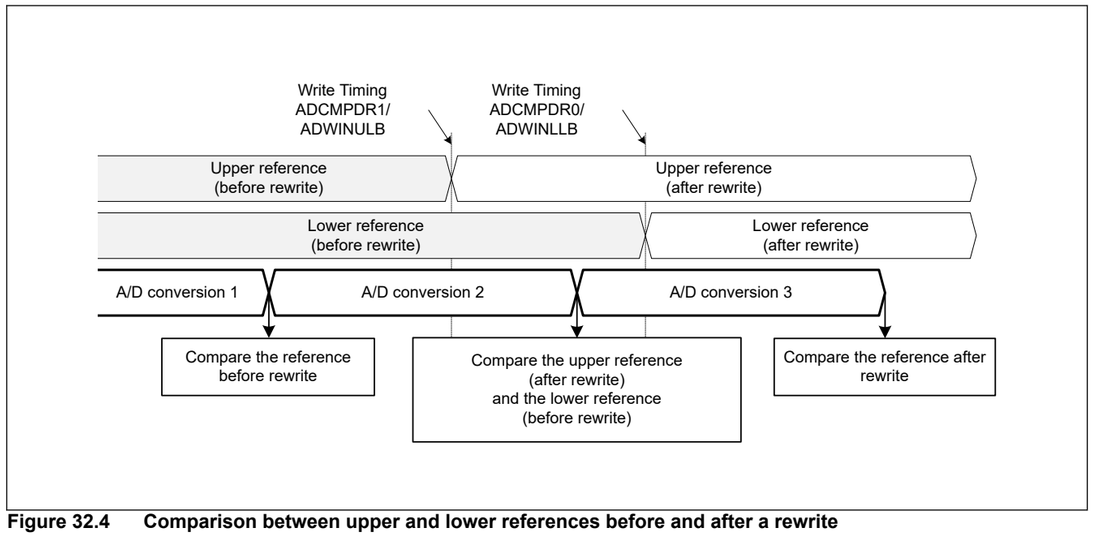

Figure 32.4 Comparison between upper and lower references before and after a rewrite

CMPLTSA 位（比较窗口 A 温度传感器输出比较条件选择）

CMPLTSA 位指定当温度传感器输出是 Window A 比较条件的目标时的比较条件。当温度传感器输出比较结果满足设定条件时,ADCMPSER。CMPSTTSA标志设置为1并生成比较中断（ADC120_CMPAI）。

CMPLOCA 位（比较窗口 A 内部参考电压比较条件选择）

当内部参考电压是 Window A 比较条件的目标时,CMPLOCA 位指定比较条件。当内部参考电压比较结果满足设定条件时,ADCMPSER。CMPSTOCA标志设置为1并生成比较中断（ADC120_CMPAI）。

ADCMPDRy（y = 0, 1）寄存器指定使用比较窗口 A 函数时的参考数据。
ADCMPDR0 设置窗口 A 的下部参考,ADCMPDR1 设置窗口 A 的上部参考。

ADCMPDRy 是读/写寄存器。

ADCMPDRy 即使在 A/D 转换期间也是可写的。A/D 转换期间重写寄存器值可以动态地改变参考数据 *1 *。

设置这些寄存器,使上参考不小于下参考（ADCMPDR1 ≥ ADCMPDR0)。
禁用窗口功能时不使用 ADCMPDR1。

注1。当每个寄存器被写入时,下部和上部的引用都会发生变化。例如,当改变上参考值并且改变下参考值时,MCU将上参考值（重写之后）和下参考值（重写之前）与A/D转换结果进行比较。参见图 32。4。如果这两个引用重写过程中的比较是错误的,则当 ADCSR。ADST 和目标比较窗口操作启用位（ADCMPCR。CMPAE 或 ADCMPCR。CMPBE）均为 0 时,重写这些参考值。

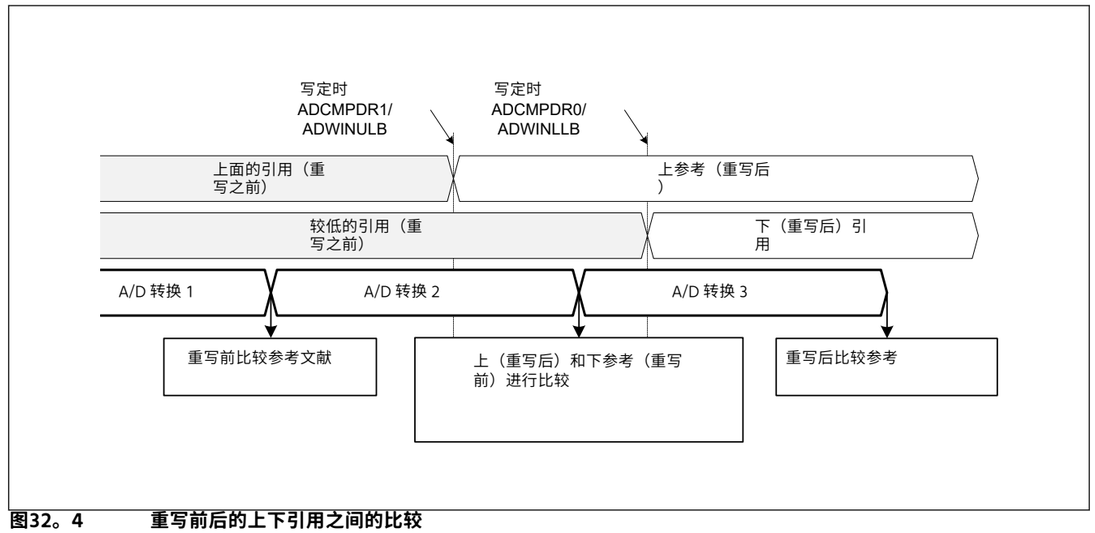

图32。4 重写前后的上下引用之间的比较

The ADCMPDRy registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
   - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
   - Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
   - Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
   - Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid
2. When A/D-converted value addition mode is selected

32.2.31 ADWINnLB : A/D Compare Function Window B Lower-Side/Upper-Side Level Setting Register (n = L, U)

Base address: ADC120 = 0x4017_0000

Offset address: 0x0A8 (n = L)
0x0AA (n = U)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ADWINULB and ADWINLLB registers specify the reference data when the compare window B function is used. ADWINLLB sets the lower reference for window B, and ADWINULB sets the upper reference for window B.

ADWINnLB are read/write registers.

ADWINnLB are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

Set these registers so that the upper reference is not less than the lower reference (ADWINULB ≥ ADWINLLB). ADWINULB are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See Figure 32.5. If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

ADCMPDRy 寄存器根据以下条件使用不同的格式:

- A/D 转换准确度的值 选择位(12 位、10 位、8 位）
- A/D转换后的加值/平均通道的值 选择位（选择或不选择A/D转换后的加值模式）。

ADWINULB 和 ADWINLLB 寄存器指定使用比较窗口 B 函数时的参考数据。
ADWINLLB 为窗口 B 设置下部参考,ADWINULB 为窗口 B 设置上部参考。

ADWINnLB 是读/写寄存器。

ADWINnLB 即使在 A/D 转换期间也是可写的。A/D转换*1 .期间可以通过重写寄存器值来动态地改变参考数据

设置这些寄存器,使上参考不小于下参考（ADWINULB ≥ ADWINLLB）。
禁用窗口功能时不使用 ADWINULB。

注1。当每个寄存器被写入时,下部和上部的引用都会发生变化。例如,当改变上参考值并且改变下参考值时,MCU将上参考值（重写之后）和下参考值（重写之前）与A/D转换结果进行比较。参见图 32。5。如果这两个引用重写过程中的比较是错误的,则当 ADCSR。ADST 和目标比较窗口操作启用位（ADCMPCR。CMPAE 或 ADCMPCR。CMPBE）均为 0 时,重写这些参考值。

- The condition set in ADCMPBNSR.CMPLB is met when ADCMPCR.CMPBE = 1.

[Clearing condition]

- Writing 0 after reading 1.

7:5	—	These bits are read as 0. The write value should be 0.	R/W

ADBUFPTR is a register that indicates the data buffer pointer and overflow status.

BUFPTR[3:0] bit (Data Buffer Pointer)

These bits indicate the number of data buffer to which the next A/D converted data is transferred.

When data has been transferred to data buffer 15, the pointer value becomes 0000b and the PTROVF bit is set to 1.

When the next data has been transferred, the data in data buffer 0 is overwritten.

Writing 0x00 to this register clears the value of these bits. Writing a value other than 0x00 is disabled.

PTROVF bit (Pointer Overflow Flag)

This bit indicates whether the data buffer pointer has overflowed. This bit is set to 1 when the pointer value becomes 0000b (overflow).

Writing 0x00 to this register clears this bit value. Writing a value other than 0x00 is disabled.

32.2.40 ADBUFn : A/D Data Buffer Registers n (n = 0 to 15)

ADBUFn registers are 16-bit read-only registers that sequentially store all A/D conversion results. The automatic clear function is not applied to these registers.

ADBUFn settings are the same as the A/D data register format settings.

The following conditions determine the formats for data in the ADBUFn registers:

- Setting of the Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)

当下一个数据已经被传输时,数据缓冲器0中的数据被覆盖。

0x00 写入此寄存器可以清除这些位的值。0x00 以外的值编写被禁用。

PTROVF 位（指针溢出标志）

该位指示数据缓冲器指针是否溢出。0000b（溢出）的指针值时,该位被设置为 1。

0x00 写入此寄存器可以清除此位值。0x00 以外的值编写被禁用。

15:0	阿德布夫[15:0]	转换值 15 到 0 功能根据所选模式和准确性而有所不同。参见表32。21和表32。22。	R

ADBUFn 寄存器是 16 位只读寄存器,依次存储所有 A/D 转换结果。自动清除功能不适用于这些寄存器。

ADBUFn 设置与 A/D 数据寄存器格式设置相同。

以下条件决定了 ADBUFn 寄存器中数据的格式:

- 寄存器格式的设置 选择位（ADCER。ADRFMT）（向左齐平或向右齐平）
- 加法/平均计数的设置 选择位（ADADC。ADC[2:0])(1、2、3、4 或 16 次）

- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 32.21 shows the bit assignment for each accuracy.

Table 32.21 Bit assignment for each accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value															These bits are read as 0.

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, This register indicatesThese registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicatesthese registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 32.22 shows the bit assignment for each accuracy.

Table 32.22 Bit assignment for each accuracy when A/D-converted value addition mode is selected

For example, to set the gain to × 1.5 using P000 for pseudo-differential input, set:

ADPGAGS0.P000GAIN[3:0] = 0001b

ADPGADCR0.P000DG[1:0] = 00b.

PnDG[1:0]位指定使用伪差分输入时每个PGA放大器Pn的增益。这些位仅在 PnDEN 位为 1、PnGEN 位为 1 时才有效。

要使用 PGA 进行伪差分输入,请设置 ADPGADCR0。PnDG[1:0] 位与 ADPGAGS0。PnGAIN[3:0] 位。

例如,要使用 P000 进行伪差分输入将增益设置为 × 1。5,请设置:

ADPGAGS0。P000GAIN[3:0] = 0001b

ADPGADCR0。P000DG[1:0] = 00b。

PnDEN bit (Pn Differential Input Enable) (n = 000 to 002)

The PnDEN bit enables or disables pseudo-differential inputs for each PGA amplifier Pn.

32.3 Operation

32.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

Scan conversion is performed in any of the three operating modes:

- Single scan mode
- Continuous scan mode
- Group scan mode

In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until software sets the ADCSR.ADST bit to 0. In group scan mode, the selected channels in group A, B are scanned once after scan starts in response to the respective synchronous trigger.

In single scan mode and continuous scan mode, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n. In group scan mode, A/D conversion is performed for the ANn channels in group A selected in the ADANSA0 and ADANSA1 registers, and for the ANn channels in group B selected in the ADANSB0 and ADANSB1 registers, starting from the channel with the smallest number n.

When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three reference voltages is converted.

The temperature sensor output and internal reference voltage can be selected at the same time as the analog input of the channels, and A/D conversion is performed on the analog input of channels, temperature sensor output, and internal reference voltage, in that order.

Double trigger mode can be used with single scan mode or group scan mode. With double trigger mode enabled (ADCSR.DBLE = 1), A/D conversion data of a channel selected in the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits. In group scan mode, only group A can use double trigger mode.

In the extended operation of double trigger mode, the A/D conversion operation is generated from the synchronous trigger combination selected in the ADSTRGR.TRSA[5:0] bits. In addition to normal double trigger mode operation, A/ D conversion data with odd number trigger (ELC_AD00) is stored in A/D Data Duplexing Register A (ADDBLDRA), and A/D conversion data with even number trigger (ELC_AD01) is stored in A/D Data Duplexing Register B (ADDBLDRB). In the extended operation of double trigger mode, when one of the trigger combinations occurs at the same time, the data duplexing register settings for the specified triggers do not work, and A/D conversion data is stored in A/D Data Duplexing Register B (ADDBLDRB).

The ADC12 ignores a synchronous trigger that occurs during the A/D conversion started by another synchronous trigger.

When any of the AN000 to AN002 channels are set as a channel-dedicated sample-and-hold circuit in the SHANS[2:0] bits in ADSHCR, the target analog input specified is sampled and held before the first A/D conversion of each scan.

32.3.2 Single Scan Mode

32.3.2.1 Basic Operation without Channel-Dedicated Sample-and-Hold Circuits

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (ELC), or an asynchronous trigger input, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC120_ADI interrupt request is generated .

PnDEN 位（Pn 差分输入启用）（n = 000 至 002）

PnDEN 位为每个 PGA 放大器 Pn 启用或禁用伪差分输入。

32。3 操作

32。3。1 扫描操作

在扫描中,对指定通道的模拟输入依次执行A/D转换。

扫描转换以三种操作模式中的任何一种进行:

- 单次扫描模式
- 连续扫描模式
- 组扫描模式

在单次扫描模式下,扫描一次一个或多个指定通道。在连续扫描模式下,重复扫描一个或多个指定通道,直到软件将ADCSR。ADST位设置为0。在组扫描模式下,响应于相应的同步触发,扫描开始后对A、B组中选定的通道进行扫描一次。

ADANSA0 和 ADANSA1 寄存器中选择的 ANn 通道, 在单扫描模式和连续扫描模式下, 从编号最小的通道 n 开始, 对 ADANSA0 和 ADANSA1 寄存器中选择的 ANn 通道进行 A/D 转换。ADANSA0和ADANSA1寄存器中选择的A组中的ANn信道,以及ADANSB0和ADANSB1寄存器中选择的B组中的ANn信道,在组扫描模式下,从编号最小的信道开始进行A/D转换n。

选择自我诊断时,每次扫描开始时执行一次,并转换三个参考电压之一。

温度传感器输出和内参考电压可以与通道的模拟输入同时选择,并且依次对通道的模拟输入、温度传感器输出和内参考电压进行A/D转换。

双触发模式可与单扫描模式或群扫描模式一起使用。在启用双触发模式的情况下（ADCSR。DBLE = 1),只有当转换由 ADCSR。DBLANS[4:0] 位中选择的同步触发器（ELC）启动时,才会复制 ADCSR。DBLANS[4:0] 位中选择的信道的 A/D 转换数据。ADSTRGR。TRSA[5:0] 位。在组扫描模式下,只有A组可以使用双触发模式。

在双触发模式的扩展操作中,A/D转换操作是从ADSTRGR。TRSA[5:0]位中选择的同步触发组合生成的。除了正常的双触发模式操作之外,奇数触发的A/D转换数据（ELC_AD00)存储在A/D数据双工寄存器A（ADDBLDRA）中,偶数触发的A/D转换数据（ELC_AD01)存储在A/D数据双工寄存器B（ADDBLDRB）中。在双触发模式的扩展操作中,当其中一个触发组合同时发生时,指定触发器的数据双工寄存器设置不起作用,A/D转换数据存储在A/D数据双工寄存器B中（ADDBLDRB）。

ADC12忽略了由另一个同步触发器启动的A/D转换期间发生的同步触发。

AN000至AN002信道中的任何一个被设置为ADSHCR中的SHANS[2:0]位中的信道专用采样保持电路时,在每次扫描的第一次A/D转换之前对指定的目标模拟输入进行采样并保持。

32。3。2 单次扫描模式

32。3。2。1 无通道专用采样和保持电路的基本操作

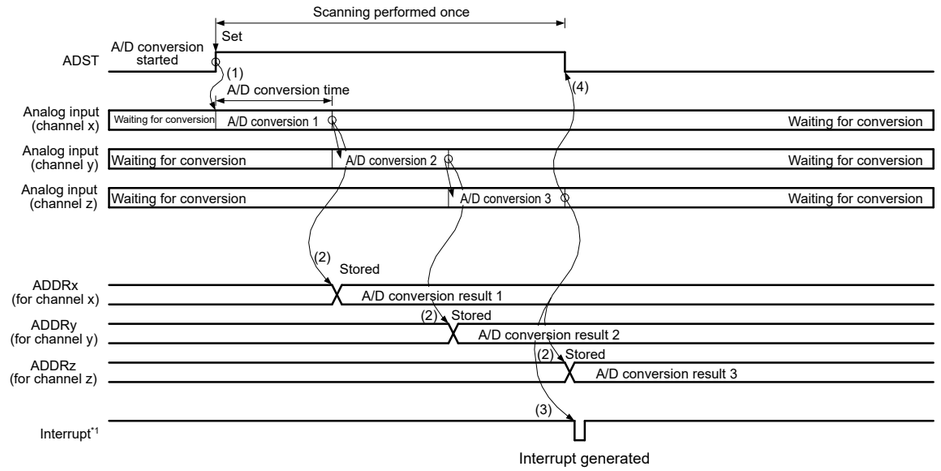
在单扫描模式的基本操作中,对指定通道的模拟输入执行一次A/D转换如下:

1。ADCSR。ADST位通过软件触发器、同步触发输入（ELC）或异步触发输入设置为1（A/D转换开始）时,对ADANSA0和ADANSA1寄存器中选择的ANn信道执行A/D转换,从最小数n的信道开始。

2锛姣涓涓。每次完成单个通道的A/D转换时,A/D转换结果都存储在相关联的A/D数据寄存器（ADDRy）中。

3锛　　娴　　。A/D 转换完成所有选定通道时,会生成 ADC120_ADI 中断请求。

4. The ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.



Note: x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. ADC120_ADI

Figure 32.7 Example basic operation in single scan mode when the analog inputs (channel x to z) are selected

32.3.2.2 Basic Operation with Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled

When the channel-dedicated sample-and-hold circuit is used, sample-and-hold operation is first performed, and then A/D conversion is performed once on the analog input of all the specified channels. The channels whose dedicated sampleand-hold circuit is to be used can be selected in the SHANS[2:0] bits in ADSHCR.

The operation is as follows:

1. Analog input sampling of all channels whose dedicated sample-and-hold circuit is to be used starts when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (ELC), or asynchronous trigger input.
2. After sample-and-hold operation, A/D conversion is performed on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC120_ADI interrupt request is generated (no register setting).
5. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state.

32.3.2.3 Basic Operation with Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operation is performed first, followed by A/D conversion once on the analog inputs of all selected channels. The ADSHCR.SHANS[2:0] bits specify the channels for which the channel-dedicated sample-and-hold circuits are to be used.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (ELC), or input of an asynchronous trigger.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
5. When A/D conversion of all the selected channels completes, an ADC120_ADI interrupt request is generated (without register setting).
6. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).
7. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.

2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.

32.3.2.7 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is performed first on the analog input of the selected channels, and once on the temperature sensor output or internal reference voltage. When both temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order. With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of the temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC120_ADI interrupt request is generated (no register setting).
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 on completion of A/D conversion. Then, the ADC12 enters a wait state.

操作如下:

1。当软件触发器、同步触发器（ELC）或异步触发器将ADCSR。ADST位设置为1（A/D转换开始）时,对ADANSA0和ADANSA1寄存器中选择的ANn信道执行A/D转换,从具有最小数字n的信道。

32.3.2.8 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in single scan mode, two rounds of single scan operation started by a synchronous trigger (ELC) are performed in sequence.

Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA and ADEXICR.TSSB) and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In double trigger mode, select a synchronous trigger (ELC) with the ADSTRGR.TRSA[5:0] bits. Additionally, set the ADCSR.EXTRG bit to 0 and the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (ELC), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC120_ADI interrupt request is not generated .
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion is completed, the result is stored in the A/D Data Duplexing Register (ADDBLDR), which is exclusively used in double-trigger mode.
6. An ADC120_ADI interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion is completed. Then the ADC12 enters a wait state.

32。3。2。8 双触发模式下的 A/D 转换

当在单扫描模式下选择双触发模式时,依次执行由同步触发器（ELC）启动的两轮单扫描操作。

取消选择自诊断,并将温度传感器输出A/D转换选择位（ADEXICR。TSSA和ADEXICR。TSSB）和内部参考电压A/D转换选择位（ADEXICR。OCSA和ADEXICR。OCSB）设置为0。

A/D 转换数据的复制是通过设置要在 ADCSR。DBLANS[4:0] 位中复制的信道号并将 ADCSR。DBLE 位设置为 1 来实现的。当ADCSR。DBLE位设置为1时,使用ADANSA0和ADANSA1寄存器的信道选择无效。

在双触发模式下,选择具有 ADSTRGR。TRSA[5:0] 位的同步触发器（ELC）。另外,将ADCSR。EXTRG位设置为0,将ADCSR。TRGE位设置为1。请勿使用软件触发器。

操作如下:

1。当ADCSR。ADST位被同步触发输入（ELC）设置为1（A/D转换开始）时,A/D转换在ADCSR。DBLANS[4:0]位中选择的单个通道上开始。

2锛姣涓涓。每次完成单个通道的A/D转换时,A/D转换结果被存储在相关联的A/D数据寄存器y（ADDRy）中。

32.3.2.9 Extended Operations When Double-Trigger Mode Is Selected

When double trigger mode is selected in single scan mode, and a synchronous trigger (ELC_AD00/ELC_AD01) is selected as the trigger for the start of A/D conversion, two rounds of single scan operation are performed.

Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA and ADEXICR.TSSB), and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In extended double trigger mode, select a synchronous trigger combination ELC_AD00/ELC_AD01 by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, set the ADCSR.EXTRG bit to 0, and set the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (ELC_AD00/ ELC_AD01), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. When A/D conversion completes, the A/D conversion result is stored in the associated A/D Data Register (ADDRy) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 0).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC120_ADI interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger (ELC_AD00/ELC_AD01), A/ D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion completes, the A/D conversion result is stored in the A/D Data Duplexing Register (ADDBLDR) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 0).
6. An ADC120_ADI interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion completes. The ADC12 then enters a wait state.

32。3。2。9 选择双触发模式时的扩展操作

A/D 转换开始时,在单扫描模式下选择双触发模式,并选择同步触发（ELC_AD00/ELC_AD01）作为触发时,进行两轮单扫描操作。

取消选择自诊断,并将温度传感器输出A/D转换选择位（ADEXICR。TSSA和ADEXICR。TSSB）和内部参考电压A/D转换选择位（ADEXICR。OCSA和ADEXICR。OCSB）设置为0。

通过将要复制的信道号设置为 ADCSR。DBLANS[4:0] 位并将 ADCSR。DBLE 位设置为 1,可以实现 A/D 转换数据的复制。当ADCSR。DBLE位设置为1时,使用ADANSA0和ADANSA1寄存器的信道选择无效。

在扩展双触发模式下,通过将ADSTRGR。TRSA[5:0]位设置为0x0B来选择同步触发组合ELC_AD00/ELC_AD01,将ADCSR。EXTRG位设置为0,并将ADCSR。TRGE位设置为1。请勿使用软件触发器。

操作如下:

1。ADCSR。ADST位被同步触发输入（ELC_AD00/ELC_AD01)设置为1（A/D转换开始）时,A/D转换在ADCSR。DBLANS[4:0]位中选择的单通道上开始。

32.3.3 Continuous Scan Mode

32.3.3.1 Basic Operation without channel-dedicated sample-and-hold circuits

In continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (ELC), or an asynchronous trigger input, A/D conversion is performed for ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC120_ADI interrupt request is generated. The ADC12 sequentially starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. The ADCSR.ADST bit is not automatically cleared, and steps 2. and 3. are repeated as long as ADCSR.ADST remains 1 (A/ D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
5. When the ADCSR.ADST bit is later set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.

操作如下:

1。ADCSR。ADST位通过软件触发器、同步触发输入（ELC）或异步触发输入设置为1（A/D转换开始）时,对AD ANSA0和ADANSA1寄存器中选择的ANn信道执行A/D转换,从最小数n的信道开始。

32.3.3.2 Basic Operation with Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled

When the channel-dedicated sample-and-hold circuit is used with the continuous sampling disabled, sample-and-hold operation is performed first, and then A/D conversion is repeated on the analog input of all the specified channels. The channels whose dedicated sample-and-hold circuit is to be used can be selected in the SHANS[2:0] bits in ADSHCR.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC120_ADI interrupt request is generated (no register setting). At the same time, analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used.
5. The ADST bit is not automatically cleared, and steps 2 to 4 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is then set to 1 (A/D conversion start), analog input sampling starts again for all the channels whose dedicated sample-and-hold circuit is to be used.

32.3.3.3 Basic Operation with Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled

When a channel-dedicated sample-and-hold circuit is used with continuous sampling enabled, sample-and-hold operations are performed first, after which the analog inputs on all selected channels are A/D-converted as described in this section. The channels for which the channel-dedicated sample-and-hold circuits are to be used can be selected in the ADSHCR.SHANS[2:0] bits.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) elapse after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
5. When A/D conversion of all the selected channels completes, an ADC120_ADI interrupt request is generated (without register setting). Also, analog input holding starts for all channels for which the channel dedicated sample-and-hold circuits are to be used.
6. The ADCSR.ADST bit is not automatically cleared, and steps 3. to 5. are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
7. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.
8. When the ADSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
9. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.

Note: If continuous scanning is performed when only the channels with the sample-and-hold circuits are selected, time for continuous sampling cannot be secured in the second and subsequent continuous scans. When continuous sampling by the channel-dedicated sample-and-hold circuits is enabled for continuous scanning, select one or more channels from AN004 to AN008, AN011 to AN013, AN016, temperature sensor output, and internal reference voltage, and set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).

32。3。3。3 使用通道专用采样和保持电路并启用连续采样的基本操作

当使用通道专用采样保持电路并启用连续采样时,首先执行采样保持操作,之后所有选定通道上的模拟输入都按照本节中的描述进行 A/D 转换。
可以在ADSHCR。SHANS[2:0]位中选择要使用通道专用采样和保持电路的通道。

操作如下:

1。ADSHMSR。SHMD 位设置为 1 时,ADSHCR。SHANS[2:0] 位中选择的采样保持电路开始连续采样。

2锛姣涓涓。当 ADCSR。ADST 位通过软件触发器、同步触发器输入设置为 1（A/D 转换开始）时,将使用通道专用采样和保持电路的所有通道的模拟输入保持开始信号（ELC）或异步触发器的输入。ADSHMSR。SHMD 位设置为 1 后至少经过 400 ns（当允许信号源阻抗为 1 kΩ 时）将 ADCSR。ADST 位设置为 1。

3锛　　娴　　。ADANSA0 和 ADANSA1 寄存器中选择的 ANn 通道,在采样保持电路的稳定时间过后,从数量最小的 n 的通道开始,对 ADANSA0 和 ADANSA1 寄存器中选择的 ANn 通道进行 A/D 转换。

4锛姣涓。A/D 转换的单通道每次完成时, A/D 转换结果存储在关联的 A/D 数据寄存器 y（ADDRy）中, 采样保持电路重新启动连续采样。

5锛姣涓。A/D 转换完成所有选定通道时,会生成 ADC120_ADI 中断请求（不设置寄存器）。此外,对于要使用通道专用采样保持电路的所有通道,模拟输入保持开始。

6锛　　涓€涓。ADCSR。ADST 位不会自动清除,只要该位保持 1,就会重复步骤 3。至 5。当ADCSR。ADST位设置为0（A/D转换停止）时,A/D转换停止并且ADC12进入等待状态。

7锛　　娴　　。当 ADSHMSR。SHMD 位设置为 0 时,采样保持电路停止。

8锛　　娴　　。当ADSHMSR。SHMD位然后设置为1时,ADSHCR。SHANS[2:0]位中选择的采样保持电路开始连续采样。

9锛　　涓€涓。当 ADCSR。ADST 位随后设置为 1（A/D 转换开始）时,将使用通道专用采样和保持电路的所有通道开始模拟输入保持。

注意:如果仅选择具有采样保持电路的通道时执行连续扫描,则在第二次及后续连续扫描中无法确保连续采样的时间。AN004至AN008、AN011至AN013、AN016、温度传感器输出、内部参考电压中选择一个或多个通道,并设定采样保持电路的连续采样时间至少为400 ns（当允许信号源阻抗为1 kΩ时）。

32.3.3.4 Channel Selection and Self-Diagnosis without channel-dedicated sample-and-hold circuits

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage (×0, ×1/2, or ×1) supplied to the ADC12, and A/D conversion is performed on the analog input of the selected channels. This sequence is repeated as described in the section that follows.

The operation is as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the corresponding A/D Data Register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC120_ADI interrupt request is generated. At the same time, the ADC12 starts A/D conversion for self-diagnosis and then on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. The ADCSR.ADST bit is not automatically cleared, and steps 2. to 4. are repeated as long as the ADCSR.ADST bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is later set to 1 (A/D conversion start), the A/D conversion for self-diagnosis is started again.

32.3.3.7 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then the A/D conversion of the temperature sensor output or internal reference voltage is repeated. When both the temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order.

With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC120_ADI interrupt request is generated. In addition, the ADC12 continuously starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.
5. The ADCSR.ADST bit is not cleared automatically, and steps 2 to 4 are repeated as long as this bit remains set to 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.

当同时选择通道和温度传感器输出或内部参考电压时,首先对所选通道的模拟输入进行A/D转换,然后重复温度传感器输出或内部参考电压的A/D转换。当选择温度传感器输出和内部参考电压时,按照该顺序执行温度传感器输出和内部参考电压的A/D转换。

通过取消选择通道,也可以仅选择温度传感器输出或内部参考电压。

操作如下:

1。当软件触发器、同步触发器（ELC）或异步触发器将ADCSR。ADST位设置为1（A/D转换开始）时,对ADANSA0和ADANSA1寄存器中选择的ANn信道执行A/D转换,从具有最小数字n的信道。

32.3.4 Group Scan Mode

32.3.4.1 Basic Operation

In group scan mode, A/D conversion is performed once on the analog input of all the specified channels in group A and B after scanning is started by a synchronous trigger (ELC). The scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A and B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger.

The group A channels to be A/D-converted are selected using the ADANSA0 and ADANSA1 registers and the ADEXICR.TSSA and OCSA bits. The group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers and the ADEXICR.TSSB and OCSB bits. Group A and B cannot use the same channels.

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for Group A and B.

The following sequence describes operation in group scan mode using a synchronous trigger from the ELC. In this example, the ELC_AD00 trigger from the ELC is used to start conversion of group A and the ELC_AD01 trigger from the ELC is used to start conversion of group B. In addition, ELC_AD00 and ELC_AD01 are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group A is started by ELC_AD00.
2. When group A scanning completes, an ADC120_ADI interrupt is generated (no register setting).
3. Scanning of group B is started by ELC_AD01.
4. When group B scanning completes, an ADC120_GBADI interrupt is generated if the ADCSR.GBADIE bit is 1 (ADC120_GBADI interrupt when scanning completion is enabled).

32。3。4 组扫描模式

32。3。4。1 基本操作

在组扫描模式下,在同步触发器（ELC）启动扫描后,对A组和B组中所有指定通道的模拟输入执行一次A/D转换。各组的扫描操作与单次扫描模式下的扫描操作类似。

同步触发器可以在 A 组的 ADSTRGR。TRSA[5:0] 位和 B 组的 ADSTRGR。TRSB[5:0] 位中选择。对 A 组和 B 组使用不同的触发器以防止同时 A/D两组的转换。请勿使用软件触发器。

使用 ADANSA0 和 ADANSA1 寄存器以及 ADEXICR。TSSA 和 OCSA 位选择要 A/D 转换的 A 组通道。使用 ADANSB0 和 ADANSB1 寄存器以及 ADEXICR。TSSB 和 OCSB 位选择要 A/D 转换的 B 组通道。A组和B组不能使用相同的通道。当在分组扫描模式下选择自我诊断时,A组和B组分别执行自我诊断。

以下序列描述了使用来自 ELC 的同步触发器在组扫描模式下的操作。在此示例中,来自 ELC 的 ELC_AD00 触发器用于开始 A 组的转换,来自 ELC 的 ELC_AD01 触发器用于开始 B 组的转换。此外,选择 ELC_AD00 和 ELC_AD01 用于GPT 事件在关联的 ELC。ELSRn 寄存器中。

操作如下:

1。A组的扫描由ELC_AD00启动。

2锛姣涓涓。A 组扫描完成时,会生成 ADC120_ADI 中断（无寄存器设置）。

3锛　　娴　　。B组的扫描由ELC_AD01启动。

4锛姣涓。B 组扫描完成时,如果 ADCSR。GBADIE 位为 1,则生成 ADC120_GBADI 中断（启用扫描完成时 ADC120_GBADI 中断）。

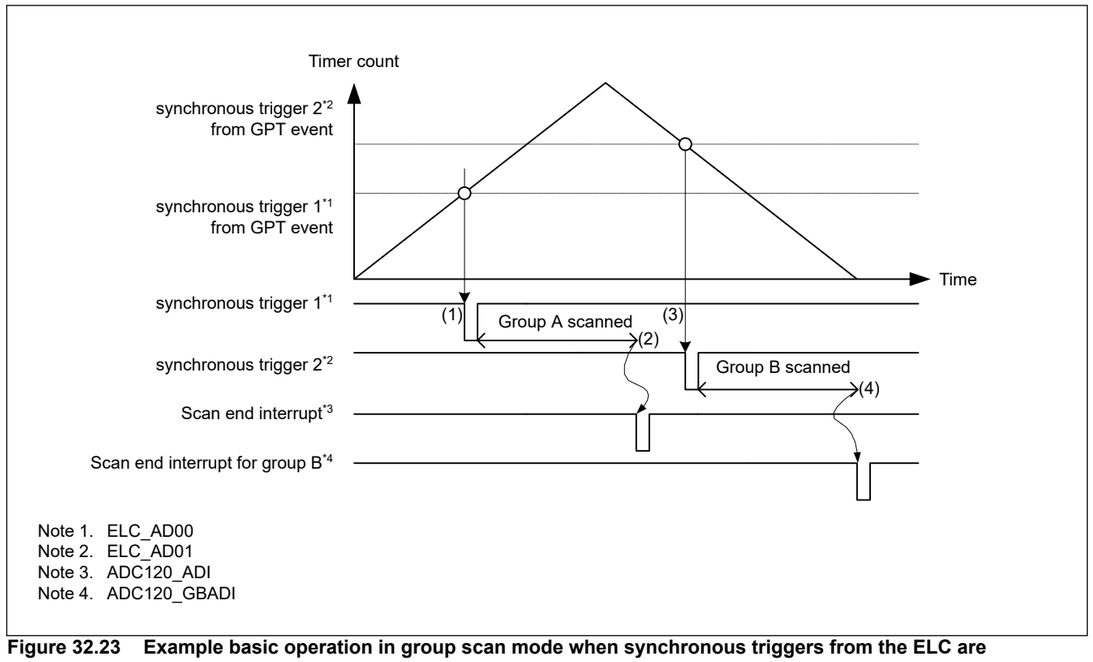

Figure 32.23 Example basic operation in group scan mode when synchronous triggers from the ELC are used

32.3.4.2 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger (ELC) are performed as a sequence for group A. For group B, single scan operation started by a synchronous trigger (ELC) is performed once.

In group scan mode, the synchronous trigger can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for groupA, B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger or an asynchronous trigger.

When an ELC_AD00/ELC_AD01 is selected as group A synchronous triggers by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, operation proceeds in extended double trigger mode.

The group A channel to be A/D-converted is selected using the DBLANS[4:0] bits in the ADCSR register, while the group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers. Group A, B cannot use the same channels.

When double-trigger mode is selected in group scan mode, set the A/D conversion select bits for both the temperature sensor output (ADEXICR.TSSA) and the internal reference voltage (ADEXICR.OCSA) to 0 (deselected).

Self-diagnosis cannot be selected when double trigger mode is selected in group scan mode.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following sequence describes operation in group scan mode with double trigger mode selected and using a synchronous trigger from the ELC. In this example, the ELC_AD00 trigger is used to start conversion of group A and the ELC_AD01 trigger is used to start conversion of group B. In addition, ELC_AD00 and ELC_AD01 are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group B is started by the ELC_AD00 trigger from the ELC.
2. When group B scanning completes, an ADC120_GBADI interrupt is generated if the GBADIE bit in ADCSR is 1 (ADC120_GBADI interrupt when scanning completion is enabled).
3. The first scan of group A is started by the first ELC_AD01 trigger.

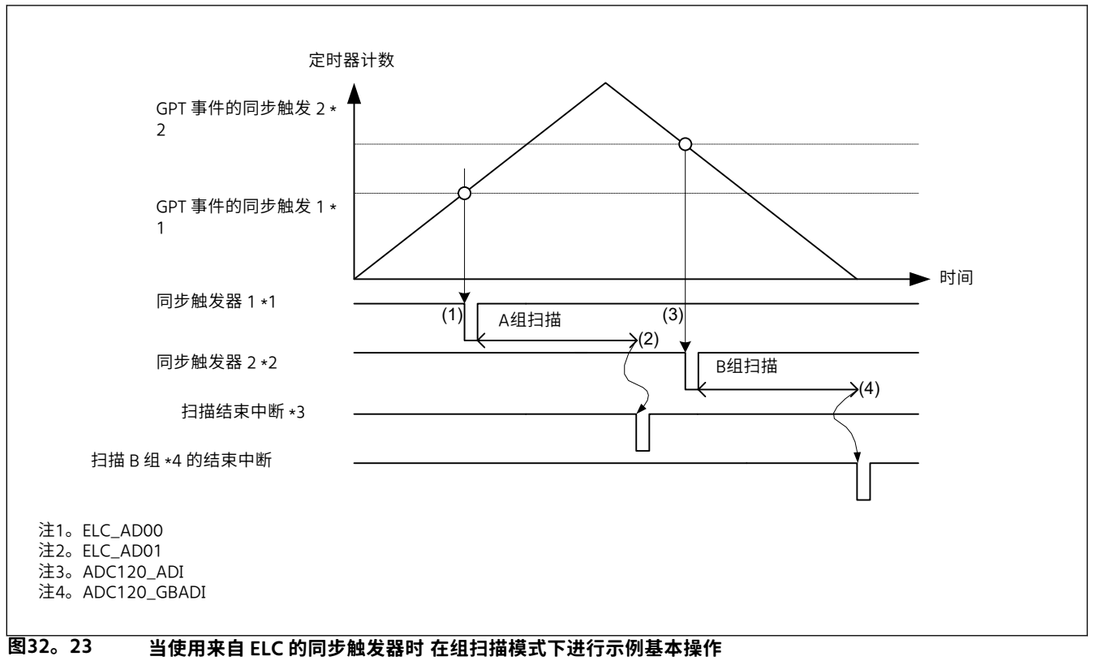

图32。23 当使用来自 ELC 的同步触发器时 在组扫描模式下进行示例基本操作

32.3.4.2 双触发模式下的 A/D 转换

当在组扫描模式中选择双触发模式时,对A组执行由同步触发器（ELC）启动的两轮单扫描操作。对于B组,由同步触发器（ELC）启动的单扫描操作一次。

在组扫描模式下,可以在A组的ADSTRGR。TRSA[5:0]位和B组的ADSTRGR。TRSB[5:0]位中选择同步触发器。对A组、B组使用不同的触发器以防止同时两组的 A/D 转换。请勿使用软件触发或异步触发。

ELC_AD00/ELC_AD01通过设置ADSTRGR。TRSA[5:0]位被选择为A组同步触发器时0x0B,操作在扩展双触发模式下进行。

使用ADCSR寄存器中的DBLANS[4:0]位选择要A/D转换的A组信道,而使用ADANSB0和ADANSB1寄存器选择要A/D转换的B组信道。A组,B不能使用相同的通道。

当在组扫描模式下选择双触发模式时,将温度传感器输出（ADEXICR。TSSA）和内部参考电压（ADEXICR。OCSA）的A/D转换选择位设置为0（取消选择）。

当在组扫描模式下选择双触发模式时,无法选择自我诊断。

A/D 转换数据的复制是通过设置要在 ADCSR。DBLANS[4:0] 位中复制的信道号并将 ADCSR。DBLE 位设置为 1 来实现的。

以下序列描述了在组扫描模式下操作,其中选择双触发模式并使用来自ELC的同步触发。在此示例中,ELC_AD00触发器用于启动A组的转换,ELC_AD01触发器用于启动B组的转换。此外,ELC_AD00和ELC_AD01被选择用于相关联的ELC中的GPT事件。ELSRn 寄存器。

操作如下:

1。B组的扫描由来自ELC的ELC_AD00触发器启动。

2锛姣涓涓。B 组扫描完成时,如果 ADCSR 中的 GBADIE 位为 1,则生成 ADC120_GBADI 中断（启用扫描完成时 ADC120_GBADI 中断）。

3锛　　娴　　。A组的第一次扫描由第一个ELC_AD01触发器启动。

4. When the first scan of group A completes, the conversion result is stored in the associated A/D Data Register y (ADDRy); an ADC120_ADI interrupt request is not generated.
5. The second scan of group A is started by the second ELC_AD01 trigger.
6. When the second scan of group A completes, the conversion result is stored in ADDBLDR. An ADC120_ADI interrupt is generated.

32.3.4.3 Group Priority Operation

Group priority operation is performed by setting the ADGSPCR.PGS bit to 1 in group-scan mode. The priority of groups is group A > group B.

When setting the PGS bit in the ADGSPCR register to 1, follow the procedure described in Figure 32.25. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

As the basic operation in group-scan mode, a trigger input generated during A/D conversion of group A, B is ignored, and the A/D conversion operation of each group is similar to the operation in single-scan mode.

In group priority operation, if a trigger for a priority group is input during scanning of a lower-priority group, A/D conversion for the lower-priority group is stopped and A/D conversion for the priority group is performed.

If the setting of the ADGSPCR.GBRSCN bit is 0, the lower-priority group enters a wait state when A/D conversion for the priority group completes. A trigger input of the lower-priority group generated during A/D conversion is ignored.

If the setting of the ADGSPCR.GBRSCN bit is 1, A/D conversion for the lower-priority group automatically restarts upon completion of A/D conversion for the priority group. A trigger input of the lower-priority group generated during A/D conversion on the priority group takes effect, and A/D conversion for the lower-priority group is automatically performed upon completion of A/D conversion on the priority group.

If the ADGSPCR.GBRSCN bit is 1 and the ADGSPCR.LGRRS bit is 0, A/D conversion for the lower-priority group is restarted from the first channel. If the setting of the ADGSPCR.LGRRS bit is 1, A/D conversion for the lower-priority group is restarted from the channel for which the conversion stopped. However, if the self-diagnosis function is used, the A/D conversion is restarted from the channel for which the conversion stopped after self-diagnosis completed.

Table 32.23 summarizes operations in response to the input of a trigger during A/D conversion with the settings of the ADGSPCR.GBRSCN bit.

32。3。4。3 集团优先运营

组优先级操作是通过在组扫描模式下将ADGSPCR。PGS位设置为1来执行的。组的优先级是A组>B组。

当将 ADGSPCR 寄存器中的 PGS 位设置为 1 时,请按照图 32。25 中描述的程序进行操作。如果不遵循该过程,则无法保证A/D转换操作和存储的数据。

作为群扫描模式下的基本操作,忽略A、B群的A/D转换期间生成的触发输入,并且每个群的A/D转换操作与单扫描模式下的操作类似。

在组优先级操作中,如果在扫描低优先级组期间输入优先级组的触发器,则停止低优先级组的A/D转换并执行优先级组的A/D转换。

如果ADGSPCR。GBRSCN位的设置为0,则当优先级组的A/D转换完成时,较低优先级组进入等待状态。A/D转换时产生的低优先级组的触发输入被忽略。

如果ADGSPCR。GBRSCN位的设置为1,则优先级较低组的A/D转换在优先级组的A/D转换完成后自动重新启动。A/D转换时产生的优先级较低组的触发输入在优先级组上生效,在优先级组上完成A/D转换后自动执行优先级较低组的A/D转换。

如果ADGSPCR。GBRSCN比特为1并且ADGSPCR。LGRRS比特为0,则从第一通道重新启动低优先级组的A/D转换。如果ADGSPCR。LGRRS位的设置为1,则从转换停止的信道重新启动低优先级组的A/D转换。然而,如果使用自诊断功能,则A/D转换从自诊断完成后转换停止的通道重新启动。

表 32。23 总结了 A/D 转换期间响应触发器输入的操作以及 ADGSPCR。GBRSCN 位的设置。

If the setting of the ADGSPCR.GBRP bit is 1, A/D conversion operation for the lowest-priority group is to continuously perform single scans.

For the trigger settings in group-scan mode, select a synchronous trigger for group A by using the ADSTRGR.TRSA[5:0] bits, a synchronous trigger for group B by using the ADSTRGR.TRSB[5:0] bits. Each trigger must be different from each other. Set the ADSTRGR.TRSB[5:0] bits to 0x3F when setting the ADGSPCR.GBRP bit to 1.

The channels to be scanned must be selected in the registers shown in section 32.3.4. Group Scan Mode.

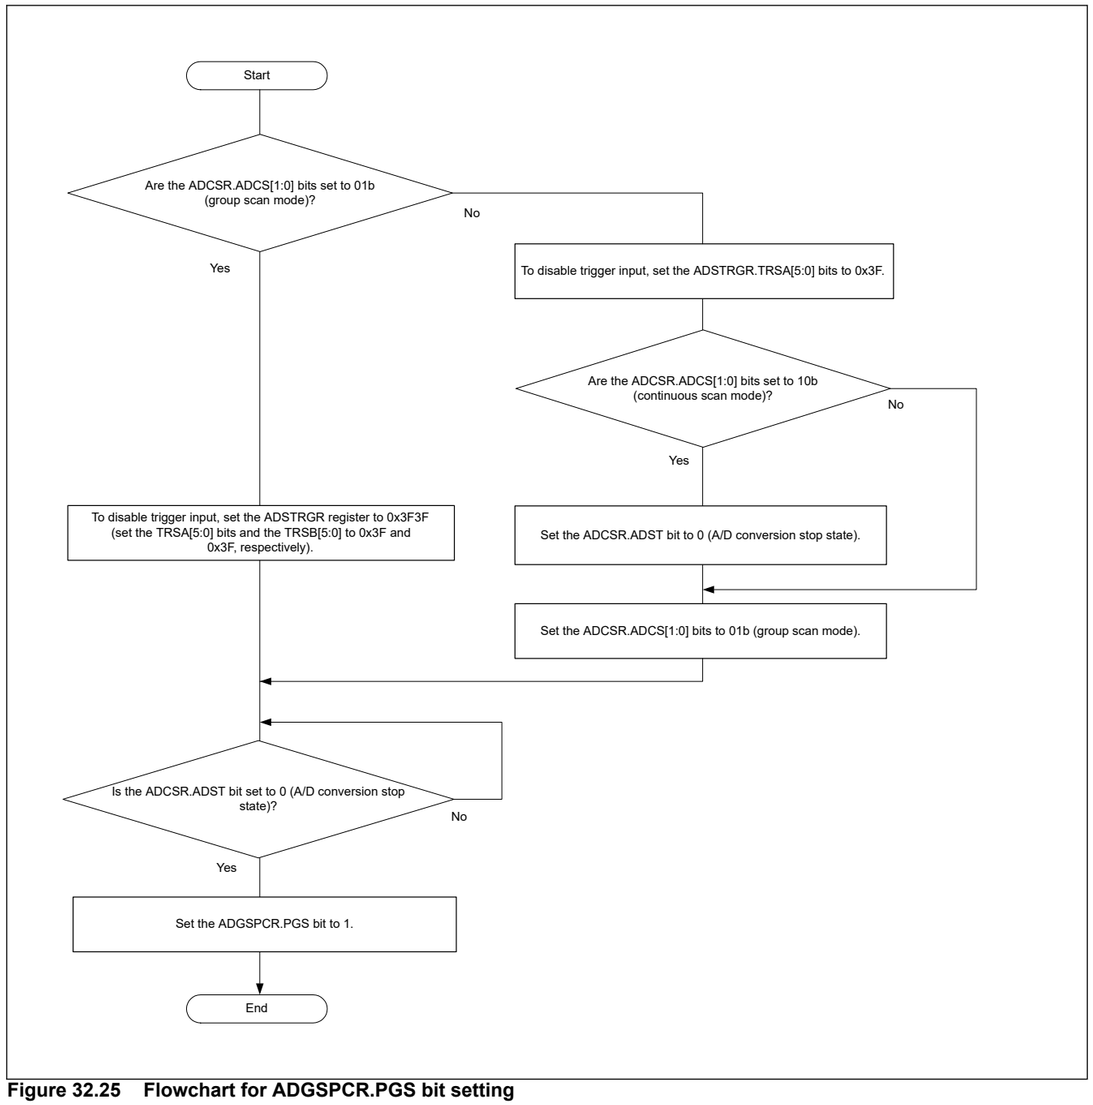

Figure 32.25 Flowchart for ADGSPCR.PGS bit setting

如果ADGSPCR。GBRP位的设置为1,则最低优先级组的A/D转换操作是连续执行单次扫描。

对于组扫描模式下的触发器设置,使用ADSTRGR。TRSA[5:0]位选择A组的同步触发器,使用ADSTRGR。TRSB[5:0]位选择B组的同步触发器。每个触发器必须彼此不同。ADGSPCR。GBRP 位设置为 1 时,将 ADSTRGR。TRSB[5:0]位设置为 0x3F。

必须在第 32。3。4 节所示的寄存器中选择要扫描的通道。组扫描模式 .

Figure 32.27 Example of group priority operation 1-2: Group A trigger input during rescanning of group B when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-3: “Group B trigger input during group A scan” when rescanning is enabled

The following describes the operation when the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation) and a trigger for group B is input during scanning operation for group A.

If the setting of the ADGSPCR.GBRSCN bit is 0, any trigger for group B that is input during scanning operation for group A is invalid.

1. When input of a trigger for group A sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n.
2. When a trigger for group B is input during A/D conversion for group A, group B is ready for A/D conversion.
3. On completion of A/D conversion for each channel in group A, the result is stored in the corresponding A/D Data Register y (ADDRy).
4. An ADC120_ADI interrupt request is generated.
5. When A/D conversion for group A completes, while the ADCSR.ADST bit remains 1, A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
   (As with the case of operation example 1-1, if a trigger for group A is input during A/D conversion for group B, A/D conversion for group A starts. Then A/D conversion for group B starts upon completion of A/D conversion for group A.)
6. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
7. Upon completion of A/D conversion for group B, a group B scan end interrupt request is generated if the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan).
8. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.

Operation example 1-4: “Group A trigger input during group B scan” when rescanning is disabled

1. When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.

32.3.5 Compare Function for Windows A and B

32.3.5.1 Compare Function Windows A and B

The compare function compares a reference value with the A/D conversion result. The reference value can be set for Window A and Window B independently. When the compare function is in use, the self-diagnosis function and double trigger mode cannot be used. The main differences between Window A and Window B are their different interrupt output signals and the constraint on Window B of only one selectable channel.

This section provides an example operation that combines continuous scan mode and the compare function.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, a synchronous trigger (ELC) or an asynchronous trigger, A/D conversion starts in the order of the selected channels , temperature sensor, and internal reference voltage.
2. On completion of A/D conversion, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy, ADTSDR, or ADOCDR). When ADCMPCR.CMPAE = 1, if bits in the ADCMPANSRy register or the ADCMPANSER register are set for Window A, the A/D conversion result is compared with the set ADCMPDR0/1 register value. When ADCMPCR.CMPBE = 1, if bits in the ADCMPBNSR register are set for Window B, the A/D conversion result is compared with the ADWINULB/ADWINLLB register setting.

8锛 娴 。如果ADCSR。GBADIE位的设置为1（在B组扫描完成时启用中断生成）,则生成B组扫描结束中断请求。

9锛 涓€涓。如果设置ADGSPCR。GBRP = 1（连续执行单次扫描）,则ADANSB0和ADANSB1寄存器中选择的B组模拟输入通道的A/D转换根据最小数字n的通道的转换顺序重新启动,而ADCSR。ADST 保持 1（开始 A/D 转换）。

只要 ADGSPCR。GBRP 位保持 1,就重复步骤 6 至 9。只要 ADGSPCR。GBRP 位为 1,请勿清除 ADCSR。ADST 位。ADGSPCR。GBRP = 1 时强制停止 A/D 转换,请按照图 32。41 . 所示的程序进行操作

32.3.5 比较 Windows A 和 B 的功能

32。3。5。1 比较功能 Windows A 和 B

比较函数将参考值与A/D转换结果进行比较。可以独立设置窗口A和窗口B的参考值。比较功能在使用时,不能使用自诊断功能和双触发模式。窗口A和窗口B之间的主要区别在于它们不同的中断输出信号以及对窗口B仅一个可选择通道的约束。

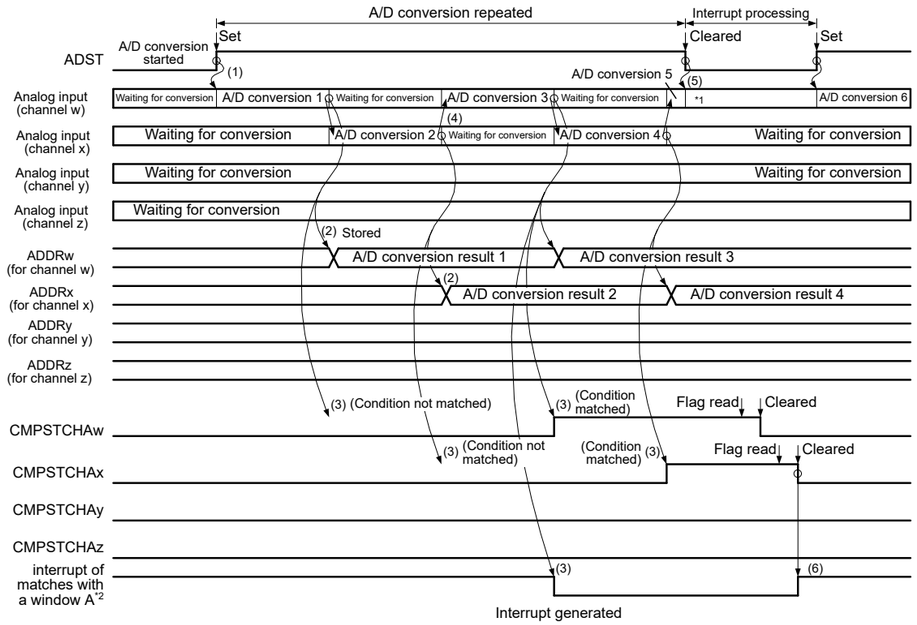
本节提供了结合连续扫描模式和比较功能的示例操作。

操作如下:

1。当 ADCSR。ADST 位通过软件、同步触发器（ELC）或异步触发器设置为 1（A/D 转换开始）时,A/D 转换按照所选通道、温度传感器和内部参考的顺序开始电压。

2锛姣涓涓。A/D转换完成后,A/D转换结果被存储在相关联的A/D数据寄存器y（ADDRy、ADTSDR或ADOCDR）中。当ADCMPCR。CMPAE = 1时,如果为窗口A设置ADCMPANSRy寄存器或ADCMPANSER寄存器中的位,则将A/D转换结果与设置的ADCMPDR0/1寄存器值进行比较。当ADCMPCR。CMPBE = 1时,如果为窗口B设置ADCMPBNSR寄存器中的位,则将A/D转换结果与ADWINULB/ADWINLLB寄存器设置进行比较。

3. As a result of the comparison, when Window A meets the condition set in ADCMPLR0/1 or ADCMPLER, the Compare Function Window A Flag (ADCMPSR0.CMPSTCHAn, ADCMPSR1.CMPSTCHAn, ADCMPSER.CMPSTTSA or ADCMPSER.CMPSTOCA) sets 1. At this time, if the ADCMPCR.CMPAIE bit is 1, an ADC120_CMPAI interrupt request is generated. In the same way, when Window B meets the condition set in ADCMPBNSR.CMPLB, the Compare Function Window B Flag (ADCMPBSR.CMPSTB) sets to 1. At this time, if the ADCMPCR.CMPBIE bit is 1, an ADC120_CMPBI interrupt request is generated.
4. On completion of all selected A/D conversions and comparisons, scan restarts.
5. After the ADC120_CMPAI and ADC120_CMPBI interrupts are accepted, the ADCSR.ADST bit is set to 0 (A/D conversion stop) and processing is performed for channels for which the compare flag is set to 1.
6. When all compare flags of Window A are cleared, the ADC120_CMPAI interrupt request is canceled. In the same way, when all compare flags of Window B are cleared, the ADC120_CMPBI interrupt request is reset. To perform comparison again, restart the A/D conversion.



Note: w, x, y, and z (w < x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. Data on conversion is ignored.
Note 2. ADC120_CMPAI

Figure 32.31 Example of compare function operation, when the analog inputs (channel w to z) are compared

32.3.5.2 Event Output of Compare Function

The event output of the compare function specifies the upper-side reference voltage value and the lower-side reference voltage value for window A and window B, respectively. The output compares the A/D converted value of the selected channel with the upper and lower side reference voltage value and outputs events (ADC120_WCMPM/ ADC120_WCMPUM) based on event conditions (A or B, A and B, A xor B) and comparison result of window A and window B.

If more than one channel is selected for window A, and even when one channel in window A meets the comparison condition, the comparison result of window A is met. When using this function, perform A/D conversion in single scan mode.

3锛 娴 。比较的结果是,当窗口 A 满足 ADCMPLR0/1 或 ADCMPLER 中设置的条件时,比较功能窗口 A 标志（ADCMPSR0)。CMPSTCHAn、ADCMPSR1。CMPSTCHAn、ADCMPSER。CMPSTTSA 或
ADCMPSER。CMPSTOCA）第 1 组。此时,如果ADCMPCR。CMPAIE位为1,则生成ADC120_CMPAI中断请求。同样,当窗口 B 满足 ADCMPBNSR。CMPLB 中设置的条件时,比较函数窗口 B 标志（ADCMPBSR。CMPSTB）设置为 1。此时,如果 ADCMPCR。CMPBIE 位为 1,则
ADC120_CMPBI 中断请求生成。

4锛姣涓。完成所有选定的 A/D 转换和比较后,扫描重新启动。

5锛姣涓。ADC120_CMPAI 和 ADC120_CMPBI 中断被接受后,ADCSR。ADST 位被设置为 0（A/D 转换停止）,并对比较标志被设置为 1 的通道进行处理。

6锛 涓€涓。Window A 的所有比较标志被清除时,ADC120_CMPAI 中断请求将被取消。同样,当清除窗口 B 的所有比较标志时,ADC120_CMPBI 中断请求将被重置。要再次执行比较,请重新启动 A/D 转换。

注1。有关转换的数据将被忽略。

32。3。5。2 比较函数的事件输出

比较函数的事件输出分别指定窗口A和窗口B的上侧参考电压值和下侧参考电压值。输出将所选通道的A/D转换值与上侧和下侧参考电压值进行比较,并根据事件条件（A或B、A和B、A异或B）输出事件（ADC120_WCMPM/ADC120_WCMPUM）以及窗口 A 和窗口 B 的比较结果。

A窗口选择多于一个通道,即使A窗口中一个通道满足比较条件,也满足A窗口的比较结果。使用此功能时,在单扫描模式下进行A/D转换。

Any channels from analog input, internal reference voltage, and temperature sensor output are selectable for window A.

One channel from analog input, internal reference voltage, and temperature sensor output is selectable for window B.

The following sequence is an example of how to set up and use the event output of the compare function:

1. Confirm that the value in the ADCSR.ADCS bits is 00b (single scan mode).
2. Select the channel for window A in the ADCMPANSR0/1 and ADCMPANSER registers. Set the compare function window conditions in the ADCMPLR0/1 and ADCMPLER registers. Set the upper-side and lower-side reference values in the ADCMPDR0/1 registers.
3. Select the channel and comparison conditions for Window B in the ADCMPBNSR register, and set the upper and lower reference values in the ADWINULB and ADWINLLB registers.
4. Set the composite conditions for window A/B, window A/B operation enable, and interrupt output enable in the ADCMPCR register.

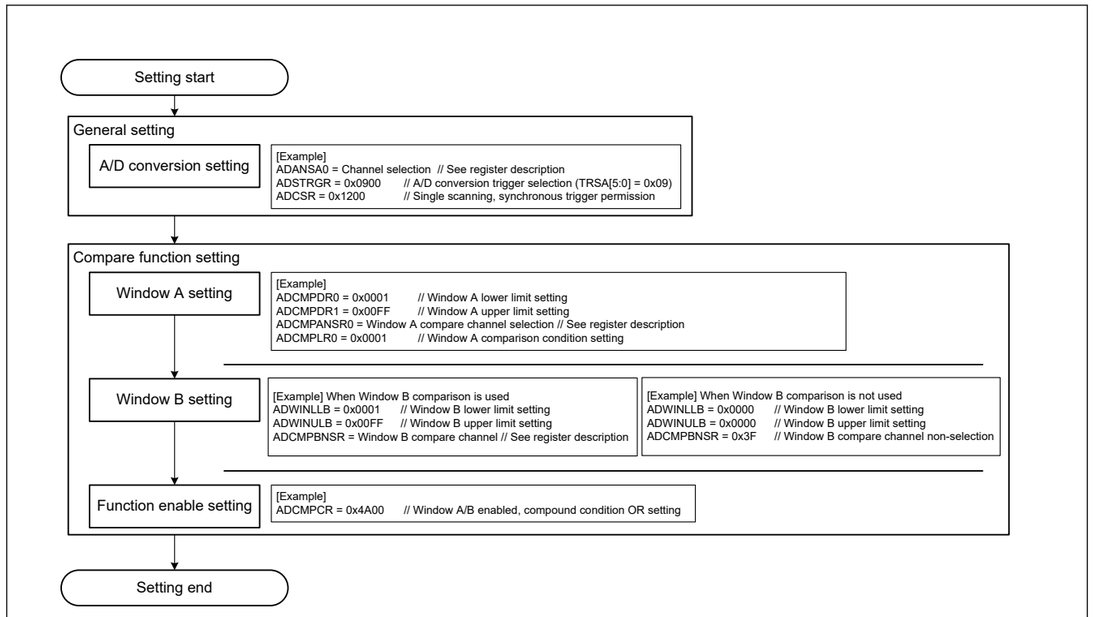

Figure 32.32 Setting example when using the event output of the compare function

For event output usage when using only window A for the compare function, note the following:

- Enable both Window A and Window B (ADCMPCR.CMPAE = 1, ADCMPCR.CMPBE = 1)
- Set the compound condition of Window A and Window B to “OR condition” (ADCMPCR.CMPAB[1:0] = 00b)
- Set the compared channel of Window B to “No selection” (ADCMPBNSR.CMPCHB[5:0] = 0x3F)
- Set the compare condition of Window B to “0 < results < 0 always means mismatch”. (ADCMPCR.WCMPE = 1, ADWINLLB[15:0] = ADWINULB[15:0] = 0x0000, and ADCMPBNSR.CMPLB = 1)

Figure 32.33 shows the event output operation example of compare function.

A scan end event (ADC120_ADI) is output with the same timing as single scan completion. A match or mismatch event (ADC120_WCMPM/ADC120_WCMPUM) is output with 1 PCLKA cycle delay depending on the ADCMPCR.CMPAB[1:0] settings.

Note: The match and mismatch events are exclusive, so both events are never output simultaneously.

来自模拟输入、内部参考电压和温度传感器输出的任何通道都可以选择用于窗口 A。

窗口 B 可选择来自模拟输入、内部参考电压和温度传感器输出的一个通道。

图32。32 使用比较函数的事件输出时设置示例

对于仅使用比较函数的窗口 A 时的事件输出使用情况,请注意以下事项:

● 启用窗口 A 和窗口 B（ADCMPCR。CMPAE = 1,ADCMPCR。CMPBE = 1）

● 将窗口 A 和窗口 B 的复合条件设置为 “OR 条件”（ADCMPCR。CMPAB[1:0] = 00b）

● 将窗口 B 的比较通道设置为 “No selection”（ADCMPBNSR。CMPCHB[5:0] = 0x3F）

● 将窗口 B 的比较条件设置为 “0 < 结果 < 0 总是意味着不匹配”。（ADCMPCR。WCMPE = 1,ADWINLLB[15:0] = ADWINULB[15:0] = 0x0000,以及 ADCMPBNSR。CMPLB = 1）

图32。33示出了比较函数的事件输出操作示例。

A扫描结束事件（ADC120_ADI）以与单次扫描完成相同的时序输出。根据 ADCMPCR。CMPAB[1:0] 设置,以 1 PCLKA 周期延迟输出匹配或不匹配事件（ADC120_WCMPM/ADC120_WCMPUM）。

注: 匹配和不匹配事件是独占的,因此这两个事件永远不会同时输出。

Note: Event output of compare function outputs match/mismatch from the comparison results of Window A and Window B, based on the ADCMPCR.CMPAB[1:0] settings.
Note: The comparison result of Window A is the logical addition of the comparison results of the comparison target channels of Window A. The comparison results of Window A and Window B are updated by each A/D conversion, and are kept even when single scan ends. Set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0 to clear the comparison results to 0.

32.3.5.3 Restrictions on Compare Function

The following constraints apply for the compare function:

- The compare function cannot be used together with the self-diagnosis function or double-trigger mode. (The compare function is not available for ADRD, ADDBLDR, ADDBLDRA, and ADDBLDRB.)
- Specify single scan mode when using match/mismatch event outputs.
- When the temperature sensor output, internal reference voltage is selected for Window A, Window B operations are prohibited.
- When the temperature sensor output, internal reference voltage is selected for Window B, Window A operations are prohibited.
- Setting the same channel for Window A and Window B is prohibited.
- Set the reference voltage values so that the high-potential reference voltage value is equal to or larger than the low potential reference voltage value.

图32。33 比较函数事件输出的示例操作 当比较模拟输入（通道 x 和 y）时

注意:基于 ADCMPCR。CMPAB[1:0] 设置,比较函数输出的事件输出与窗口 A 和窗口 B 的比较结果匹配/不匹配。

注意:窗口A的比较结果是窗口A的比较目标通道的比较结果的逻辑相加。窗口A和窗口B的比较结果通过每个A/D转换进行更新,并且即使在单次扫描结束时也保持不变。将 ADCMPCR。CMPAE 和 ADCMPCR。CMPBE 设置为 0,将比较结果清除为 0。

32。3。5。3 对比较功能的限制

比较函数适用以下约束:

- 比较功能不能与自诊断功能或双触发模式一起使用。（比较功能不适用于 ADRD、ADDBLDR、ADDBLDRA 和 ADDBLDRB。）
- 使用匹配/不匹配事件输出时指定单次扫描模式。
- 当温度传感器输出时, 窗A选择内部参考电压, 禁止窗B操作。
- 当温度传感器输出时, 窗户B选择内部参考电压, 禁止窗户A操作。
- 禁止为窗口 A 和窗口 B 设置相同的通道。
- 设置参考电压值,使高电位参考电压值等于或大于低电位参考电压值。

32.3.6 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated either by a software trigger, a synchronous trigger (ELC), or an asynchronous trigger (ADTRG0). After the start-of-scanning-delay time (t_D) has elapsed, processing by the channel-dedicated sample-and-hold circuits, processing for disconnection detection assistance, and processing of conversion for self-diagnosis all proceed, followed by processing for A/D conversion.

Figure 32.34 shows the scan conversion timing, in which scan conversion is activated by a software trigger or a synchronous trigger (ELC). Figure 32.35 shows the scan conversion timing, in which scan conversion is activated by an asynchronous trigger (ADTRG0). The scan conversion time (t_{SCAN}) includes the start-of-scanning-delay time (t_D), channel dedicated sample-and-hold circuit processing time (t_{SPLSH})*1, disconnection detection assistance processing time (t_{DIS})*2, self-diagnosis A/D conversion processing time (t_{DIAG} and t_{DSD})*3, A/D conversion processing time (t_{CONV}), channel-dedicated sample-and-hold circuit end time (t_{SHED})*4, and end-of-scanning-delay time (t_{ED}).

The A/D conversion processing time (t_{CONV}) consists of input sampling time (t_{SPL}) and time for conversion by successive approximation (t_{SAM}). The sampling time (t_{SPL}) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/ D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTRn register.

The time for conversion by successive approximation (t_{SAM}) is the following

- 13 ADCLK states with 12-bit accuracy selected.
- 11 ADCLK states with 10-bit accuracy selected.
- 9 ADCLK states with 8-bit accuracy selected.

Table 32.25 shows the time for conversion by successive approximation (t_{SAM}).

The scan conversion time (t_{SCAN}) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = t_D + t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{ED} + (t_{CONV} \times n)\ ^{*5}$$

The scan conversion time for the first cycle in continuous scan mode is t_{SCAN} for single scan minus t_{ED} . The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed in the following:

$$t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{DSD} + t_{SHED} + (t_{CONV} \times n)\ ^{*5}$$

Note 1. When no channel-dedicated sample-and-hold circuits are used, t_{SPLSH} = 0.
Note 2. When disconnection detection assistance is not selected, t_{DIS} = 0.

Only when the temperature sensor or internal reference voltage is A/D-converted, the auto-discharge period of 15 ADCLK states is inserted.

Note 3. When the self-diagnosis function is not used, t_{DIAG} = 0, t_{DSD} = 0.
Note 4. When no channel-dedicated sample-and-hold circuits are used, t_{SHED} = 0, assuming continuous scan mode is active. In single scan mode and group scan mode, t_{SHED} is included in the end-of-scanning-delay (t_{ED}).
Note 5. When input sampling times (t_{SPL}) of all selected channels are the same, this element equals t_{CONV} × n. If each channel has a different sampling time, this element equals that of t_{SPL} and t_{SAM} set to each selected channel.

Table 32.25 shows the times for conversion during scanning.

32。3。6 模拟输入采样和扫描转换时间

扫描转换可以通过软件触发器、同步触发器（ELC）或异步触发器（ADTRG0）激活。开始扫描延迟时间（t D）已经过去）后,通道专用采样保持电路的处理、断开检测辅助的处理以及自诊断转换的处理都继续进行,然后进行处理用于 A/D 转换。

图32。34示出了扫描转换定时,其中扫描转换由软件触发器或同步触发器（ELC）激活。图32。35示出了扫描转换定时,其中扫描转换由异步触发器（ADTRG0）激活。扫描转换时间（tSCAN）包括开始扫描延迟时间（t D）、信道专用采样保持电路处理时间（tSPLSH）*1)、断开检测辅助处理时间（tDIS）*2,)自诊断A/D 转换处理时间（tDIAG 和 tDSD）*3、A/D 转换处理时间（tCONV）、 通道专用采样保持电路结束时间（tshed）*4 和扫描结束延迟时间（t ED）.)

A/D 转换处理时间（tCONV）由输入采样时间（tSPL）和逐次近似转换时间（tSAM）组成。采样时间（tSPL）用于对 A/D 转换器中的采样保持电路进行充电。如果由于模拟输入信号源的高阻抗而没有足够的采样时间,或者A/D转换时钟（ADCLK）较慢,则可以使用ADSSTRn寄存器调整采样时间。通过连续近似（tSAM）进行转换的时间如下

- 13 ADCLK 状态,并选择了 12 位精度。
- 11 ADCLK 状态,选择 10 位精度。
- 9 ADCLK 状态,并选择 8 位精度。

表 32。25 显示了通过连续近似（t SAM）进行转换的时间。

单次扫描模式下选择通道数为n的扫描转换时间（t SCAN）可以如下确定:

X数学X_0 ( ) ( )

连续扫描模式下第一个周期的扫描转换时间为单次扫描的 tSCAN 减去 t ED。连续扫描模式下第二个及后续周期的扫描转换时间固定如下:

$t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{DSD} + t_{SHED} + (t_{CONV} \times n)\ ^{*5}$ 注 1。当不使用通道专用采样保持电路时,tSPLSH = 0。

注2。当未选择断开检测辅助时,tDIS = 0。

仅当温度传感器或内部参考电压为A/D转换时,才插入15个ADCLK状态的自动放电周期。

注3。当不使用自我诊断功能时,tDIAG = 0,tDSD = 0。

注4。当不使用通道专用采样和保持电路时,假设连续扫描模式处于活动状态,tSHED = 0。在单扫描模式和组扫描模式下,tSHED 包含在扫描结束延迟（t ED）.) 中

注5。当所有选定通道的输入采样时间（tSPL）相同时,该元素等于 tCONV × n。如果每个通道具有不同的采样时间,则该元素等于设置为每个选定通道的 tSPL 和 tSAM 的元素。

表 32。25 显示了扫描过程中的转换时间。

32.3.7 Usage Example of A/D Data Register Automatic Clearing Function

Setting the ADCER.ACE bit to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR) to 0x0000 when the A/D data registers are read by the CPU or DTC or DMAC.

图32。35 异步触发输入（ADTRG0）激活时扫描转换时序

32.3.7 A/D数据寄存器自动清除功能的使用示例

当 CPU 或 DTC 或 DMAC 读取 A/D 数据寄存器时,将 ADCER。ACE 位设置为 1 会自动清除 A/D 数据寄存器（ADDRy、ADRD、ADDBLDR、ADDBLDRA、ADDBLDRB、ADTSDR、ADOCDR）至 0x0000。

This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR). This section describes examples in which the function to automatically clear the ADDRy register is enabled and disabled.

- If the ADCER.ACE bit is 0 (automatic clearing is disabled) and for some reason, if the A/D conversion result (0x0222) is not written to the ADDRy register, the ADDRy value retains the old data (0x0111). In addition, if this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, the old data (0x0111) can be saved in the general-purpose register. When checking whether there is an update failure, it is necessary to frequently save the old data in SRAM or in a general-purpose register.
- If the ADCER.ACE bit is 1 (automatic clearing is enabled), when ADDRy = 0x0111 is read by the CPU or DTC or DMAC, ADDRy is automatically set to 0x0000. Next, if the A/D conversion result of 0x0222 cannot be transferred to ADDRy for some reason, the cleared data (0x0000) remains as the ADDRy value. If this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, 0x0000 is saved in the general-purpose register. Occurrence of an ADDRy update failure can be determined by checking that the read data value is 0x0000.

32.3.8 A/D-Converted Value Addition/Average Mode

A/D-converted value addition/average mode can be used when A/D conversion of the analog input of the selected channels, the temperature sensor output, the internal reference voltage is selected.

In A/D-converted value addition mode, the same channel is A/D-converted 1, 2, 3, 4, or 16 consecutive times, and the sum of the converted values is stored in the data register. The conversion count of the addition function can be set to 16 only when 12-bit accuracy is selected. In A/D-converted value average mode, the same channel is A/D-converted 2 or 4 consecutive times, and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition/average function can be used when A/D conversion of the analog inputs of the selected channels or A/D conversion of the temperature sensor output or A/D conversion of the internal reference voltage is selected. The A/D-converted value addition/average function can also be used for channels for which the double-trigger function is selected.

The addition function for self-diagnosis is not provided.

32.3.9 Disconnection Detection Assist Function

The ADC12 incorporates a function to fix the charge for sampling capacitance to the specified state VREFH0 or VREFL0 before the start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

When using the disconnection detection assist function for the channel-dedicated sample-and-hold circuit, set ADSHMSR.SHMD bit to 0 (select disable continuous sampling function).

Figure 32.36 shows the A/D conversion operation when the disconnection detection assist function is used. Figure 32.37 shows an example of disconnection detection when precharge is selected. Figure 32.38 shows an example of disconnection detection when discharge is selected.

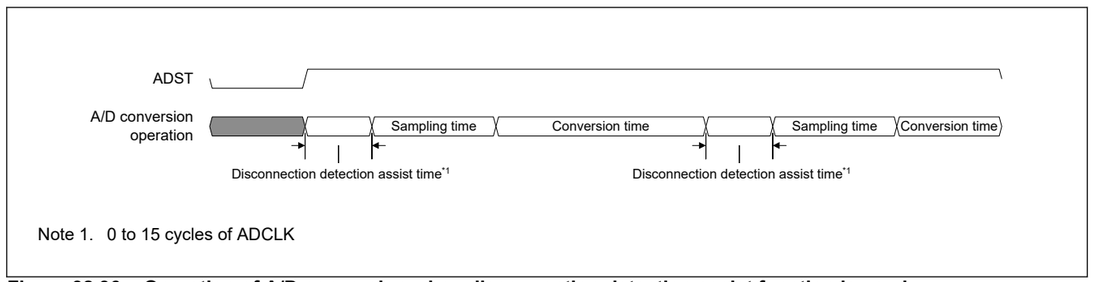

Figure 32.36 Operation of A/D conversion when disconnection detection assist function is used

该功能能够检测 A/D 数据寄存器（ADDRy、ADRD、ADDBLDR、ADDBLDRA、ADDBLDRB、ADTSDR、ADOCDR）的更新故障。本节描述了启用和禁用自动清除 ADDRy 寄存器的功能的示例。

- 如果 ADCER。ACE 位为 0（禁用自动清除），并且由于某种原因,如果 A/D 转换结果 (0x0222) 未写入 ADDRy 寄存器,则 ADDRy 值保留旧数据 (0x0111)。另外,如果使用A/D扫描端中断将该ADDRy值读入通用寄存器,则可以将旧数据(0x0111)保存在通用寄存器中。检查是否存在更新失败时,需要经常将旧数据保存在SRAM或通用寄存器中。
- 如果 ADCER。ACE 位为 1（启用自动清除），当 CPU 或 DTC 或 DMAC 读取 ADDRy = 0x0111 时,ADDRy 自动设置为 0x0000。接下来,如果0x0222的A/D转换结果由于某种原因不能传输到ADDRy,则清除的数据(0x0000)保留为ADDRy值。A/D扫描端中断将该ADDRy值读入通用寄存器,则0x0000保存在通用寄存器中。ADDRy更新失败的发生可以通过检查读取的数据值为0x0000来确定。

32。3。8 A/D 转换后的增值/平均模式

当选择所选通道的模拟输入、温度传感器输出、内部参考电压的A/D转换时,可以使用A/D转换的加值/平均模式。

A/D 转换的加值模式下,同一通道是连续 A/D 转换的 1、2、3、4 或 16 次,转换后的值之和存储在数据寄存器中。12位精度时,才能将加法函数的转换计数设置为16。A/D 转换值平均模式下,同一通道连续 A/D 转换 2 次或 4 次,转换值的均值存储在数据寄存器中。使用这些结果的平均值可以提高 A/D 转换的准确性,具体取决于存在的噪声分量的类型。然而,该功能并不总是能保证 A/D 转换精度的提高。

当选择所选通道的模拟输入的A/D转换或温度传感器输出的A/D转换或内部参考电压的A/D转换时,可以使用A/D转换的加值/平均函数。
A/D转换后的加值/平均值函数也可用于选择双触发函数的通道。

不提供自我诊断的附加功能。

32.3.9 断开检测辅助功能

ADC12 包含一个功能,可在 A/D 转换开始之前将采样电容的电荷固定为指定状态 VREFH0 或 VREFL0。该功能可以在模拟输入接线时进行断开检测。当使用通道专用采样保持电路的断开检测辅助功能时,将ADSHMSR。SHMD位设置为0（选择禁用连续采样功能）。

图32。36示出了当使用断开检测辅助功能时的A/D转换操作。图 32。37 显示了选择预充电时断开检测的示例。图32。38示出了选择放电时的断开检测的示例。

32.3.10 Starting A/D Conversion with an Asynchronous Trigger

A/D conversion can be started by the input of an asynchronous trigger. To start A/D conversion by an asynchronous trigger, set the pin function in the PmnPFS register, set the A/D Conversion Start Trigger Select bits (ADSTRGR.TRSA[5:0]) to 0x00, then input a high-level signal to the asynchronous trigger (ADTRG0 pin). Finally, set both the ADCSR.TRGE and ADCSR.EXTRG bits to 1. Figure 32.39 shows timing of the asynchronous trigger input.

An asynchronous trigger cannot be selected in the A/D conversion start trigger for group B used in group scan mode. For details on setting the pin function, see section 18, I/O Ports.

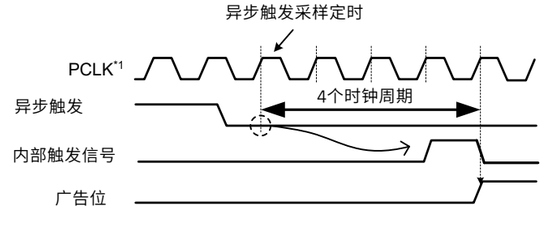
32.3.10 使用异步触发器启动 A/D 转换

A/D转换可以通过输入异步触发器来启动。要通过异步触发器启动 A/D 转换,请在 PmnPFS 寄存器中设置引脚函数,将 A/D 转换启动触发器选择位（ADSTRGR。TRSA[5:0]）设置为0x00,然后输入高电平信号给异步触发器（ADTRG0引脚）。最后,将ADCSR。TRGE和ADCSR。EXTRG位设置为1。图 32。39 显示了异步触发输入的定时。

在群扫描模式下使用的B组的A/D转换开始触发器中不能选择异步触发器。有关设置引脚功能的详细信息,请参阅第 18 节"I/O 端口 ."



注1。PCLKA

图32。39 异步触发输入定时

32.3.11 Starting A/D Conversion with a Synchronous Trigger from a Peripheral Module

A/D conversion can be started by a synchronous trigger (ELC). To do this, set the ADCSR.TRGE bit to 1 and the ADCSR.EXTRG bit to 0, and select the relevant sources in the ADSTRGR.TRSA[5:0] bits and ADSTRGR.TRSB[5:0] bits.

32.3.12 Using Data Buffers

This IP is provided with a ring buffer function consisting of 16 A/D data buffers. This function sequentially stores A/D conversion results other than self-diagnosis result (including addition/average results) in data buffers (ADBUFn, n = 0 to 15).

Each conversion result is stored at the timing when the A/D conversion result is stored in the data register, and most recent 16 conversion result data are retained.

The figure-below shows the schematic of data buffers, pointer, and overflow flag operations. When the BUFEN bit is set to 1, the A/D conversion result is transferred at each end of A/D conversion. The pointer indicates the number of data buffer to which the next transferred data is to be written. When data is written to up to buffer 15, the pointer is reset to 0000b and the overflow flag is set to 1. Subsequently transferred data overwrites the previously written data.

The overflow flag is reset to the initial value by writing 0x00 to the ADBUFPTR register.

32。3。11 使用外围模块的同步触发器启动 A/D 转换

A/D 转换可以通过同步触发器（ELC）启动。为此,将ADCSR。TRGE位设置为1,将ADCSR。EXTRG位设置为0,并在ADSTRGR。TRSA[5:0]位和ADSTRGR。TRSB[5:0]位中选择相关源。

32。3。12 使用数据缓冲区

该IP具有由16个A/D数据缓冲器组成的环形缓冲器功能。该函数将自我诊断结果（包括加法/平均结果）以外的A/D 转换结果顺序存储在数据缓冲区（ADBUFn,n = 0 至 15)中。

A/D转换结果存储在数据寄存器中的时序存储每个转换结果,并保留最近的16个转换结果数据。

下图显示了数据缓冲区、指针和溢出标志操作的示意图。BUFEN位设置为1时,A/D转换结果在A/D转换的每一端被传送。该指针指示下一个传输数据要写入的数据缓冲区的数量。Data写入到缓冲区15时,指针被重置为0000b,溢出标志被设置为1。随后传输的数据覆盖了先前写入的数据。

通过向 ADBUFPTR 寄存器写入 0x00,溢出标志被重置为初始值。

32.3.13 Programmable Gain Amplifiers

Up to three programmable gain amplifiers (PGAs) can be used in each unit. Select a gain in the ADPGAGS0.PnGAIN[3:0] bits (n = 000 to 002) and select an operational amplifier to be used in the ADPGACR.PnSEL bits.

These PGAs accept pseudo-differential inputs. Pins that accept pseudo-differential inputs are PGAVSS000 for AN000 to AN002. To use pseudo-differential inputs, set the pseudo-differential input gain in the ADPGADCR0.PnDG[2:0] bits, enable the pseudo-differential input gain setting in the ADPGADCR0.PnGEN bits, and then select the pseudo-differential input amplifier in the ADPGADCR0.PnDEN bits. The PGA register is selectable as shown in Table 32.26.

这些 PGA 接受伪微分输入。接受伪差分输入的引脚是 AN000 至 AN002 的 PGAVSS000。要使用伪差分输入,请在 ADPGADCR0 中设置伪差分输入增益。PnDG[2:0]位,启用ADPGADCR0中的伪差分输入增益设置。PnGEN 位,然后在 ADPGADCR0 中选择伪差分输入放大器。PnDEN 位。PGA寄存器是可选择的,如表32。26 .所示

32.4 Interrupt Sources and DTC, DMAC Transfer Requests

32.4.1 Interrupt Requests

The ADC12 can send scan end interrupt requests ADC120_ADI and ADC120_GBADI to the CPU. The ADC12 also generates the ADC120_CMPAI/ADC120_CMPBI interrupt for the CPU in response to matches with a condition for comparison.

An ADC120_ADI interrupt is always generated. An ADC120_GBADI interrupt can be generated by setting the ADCSR.GBADIE bit to 1. Similarly, ADC120_CMPAI and ADC120_CMPBI interrupts can be generated by setting the ADCMPCR.CMPAIE and ADCMPCR.CMPBIE bit to 1.

In addition, the DTC or DMAC can be started when an ADC120_ADI or an ADC120_GBADI interrupt is generated. Using an ADC120_ADI or ADC120_GBADI interrupt to activate the DTC or DMAC to read the converted data enables continuous conversion without a burden on software.

Table 32.28 describes the interrupt sources and ELC events available for the ADC12.

32。4 中断源和 DTC、DMAC 传输请求

32。4。1 中断请求

ADC12可以向CPU发送扫描端中断请求ADC120_ADI和ADC120_GBADI。ADC12还响应于具有比较条件的匹配,为CPU生成ADC120_CMPAI/ADC120_CMPBI中断。

ADC120_ADI 中断总是会生成。ADCSR。GBADIE 位设置为 1 可以生成 ADC120_GBADI 中断。类似地,ADC120_CMPAI和ADC120_CMPBI中断可以通过将ADCMPCR。CMPAIE和ADCMPCR。CMPBIE位设置为1来生成。

此外,当生成ADC120_ADI或ADC120_GBADI中断时,可以启动DTC或DMAC。使用 ADC120_ADI 或 ADC120_GBADI 中断来激活 DTC 或 DMAC 来读取转换后的数据可以实现连续转换,而不会给软件带来负担。

表 32。28 描述了 ADC12 可用的中断源和 ELC 事件。

32.5 Event Link Function

32.5.1 Event Output to the ELC

The ELC uses the ADC120_ADI interrupt request signal as an event signal ADC120_ADI, enabling link operation for the preset module. The ADC120_GBADI interrupt and ADC120_CMPAI/ADC120_CMPBI interrupts cannot be used as an event signal. For details, see Table 32.28.

An event signal can be output regardless of the settings of the corresponding interrupt request enable bits. For the scan end event(ADC120_ADI), a high-level pulse for one PCLKA cycle is output at the same output timing as the interrupt output (ADC120_ADI) shown in Table 32.28. For a compare function match (ADC120_WCMPM) and mismatch event (ADC120_WCMPUM) to the ELC, a high-level pulse for one PCLKA cycle is output at the timing delayed by one cycle (PCLKA) from the interrupt output (ADC120_ADI) shown in Table 32.28.

To use compare function match (ADC120_WCMPM) or mismatch event (ADC120_WCMPUM) to the ELC, specify single-scan mode.

32.5.2 ADC12 Operation through an Event from the ELC

The ADC12 can start A/D conversion by the preset event specified in the ELSRn settings for the ELC as follows:

- Select the ELC_AD00 signal in the ELC.ELSR8 register
- Select the ELC_AD01 signal in the ELC.ELSR9 register

32。5 事件链接功能

32。5。1 ELC 的事件输出

ELC使用ADC120_ADI中断请求信号作为事件信号ADC120_ADI,实现对预设模块的链路操作。ADC120_GBADI中断和ADC120_CMPAI/ADC120_CMPBI中断不能用作事件信号。有关详细信息,请参阅表 32。28 .

无论相应的中断请求使能位的设置如何,都可以输出事件信号。对于扫描结束事件（ADC120_ADI）,在与表32。28所示的中断输出（ADC120_ADI）相同的输出定时下输出一个PCLKA周期的高电平脉冲。对于与 ELC 的比较函数匹配（ADC120_WCMPM）和不匹配事件（ADC120_WCMPUM）,从中断输出（ADC120_ADI）延迟一个周期（PCLKA）的定时输出一个 PCLKA 周期的高级脉冲表 32。28 . 中所示

要使用与 ELC 的比较功能匹配（ADC120_WCMPM）或不匹配事件（ADC120_WCMPUM）,请指定单扫描模式。

32。5。2 ADC12 通过 ELC 的事件进行操作

ADC12 可以通过 ELC 的 ELSRn 设置中指定的预设事件开始 A/D 转换, 如下所示:

- 在 ELC。ELSR8 寄存器中选择 ELC_AD00 信号
- 在 ELC。ELSR9 寄存器中选择 ELC_AD01 信号

If an ELC event occurs during A/D conversion, the event is disabled.

32.6 Usage Notes

32.6.1 Constraints on Setting the Registers

Set each register while the ADCSR.ADST bit is 0.

32.6.2 Constraints on Reading the Data Registers

The following registers must be read in halfword units:

- A/D Data Registers
- A/D Data Duplexing Register
- A/D Data Duplexing Register A
- A/D Data Duplexing Register B
- A/D Temperature Sensor Data Register
- A/D Internal Reference Voltage Register
- A/D Self-Diagnosis Data Register
- A/D Data Buffer Registers n (N = 0 to 15)

If a register is read twice in byte units, that is, the upper byte and lower byte are read separately, the A/D-converted value read initially might disagree with the A/D-converted value read subsequently. To prevent this, never read the data registers in byte units.

32.6.3 Constraints on Stopping A/D Conversion

(1) A/D Conversion Stop Procedure

To stop A/D conversion when an asynchronous trigger or a synchronous trigger is selected as the condition for starting A/D conversion, follow the procedure shown in Figure 32.41.

A/D转换时发生ELC事件,则该事件被禁用。

32.6 使用说明

设置寄存器的约束 设置每个寄存器,而 ADCSR。ADST 位为 0。

读取数据寄存器的限制 以下寄存器必须以半字为单位读取:

- A/D 数据寄存器
- A/D 数据复式寄存器
- A/D 数据双工寄存器 A
- A/D 数据复式寄存器 B
- A/D 温度传感器数据寄存器
- A/D 内部参考电压寄存器
- A/D 自诊断数据寄存器
- A/D 数据缓冲区寄存器 n（N = 0 到 15）

如果以字节为单位读取寄存器两次,即分别读取上字节和下字节,则最初读取的 A/D 转换值可能与随后读取的 A/D 转换值不一致。为了防止这种情况发生,切勿读取字节单元中的数据寄存器。

32。6。3 停止 A/D 转换的限制

(1)A/D转换停止程序

A/D转换时,选择异步触发器或同步触发器作为开始A/D转换的条件时,请按照图32。41 .所示的程序进行

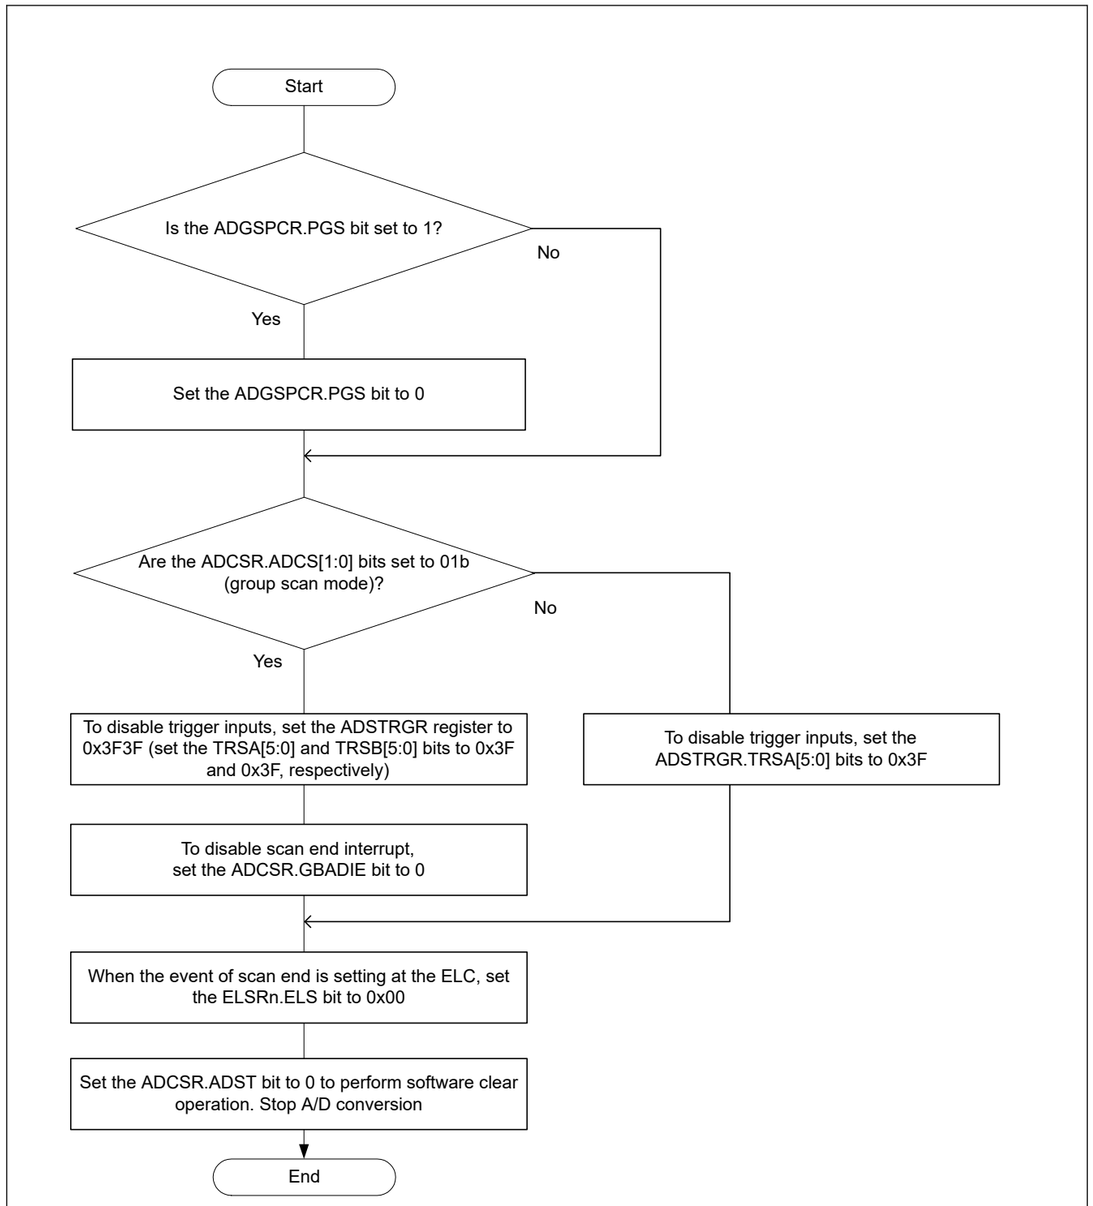

Figure 32.41 Procedures for clearing the ADCSR.ADST bit by software

To specify the following settings after performing the clear operation by software, provide a wait period for at least two ADCLK cycles.

- Enabling scan end interrupts
- Enabling scan end events for the event link controller
- Starting A/D conversion by software
- Enabling trigger input

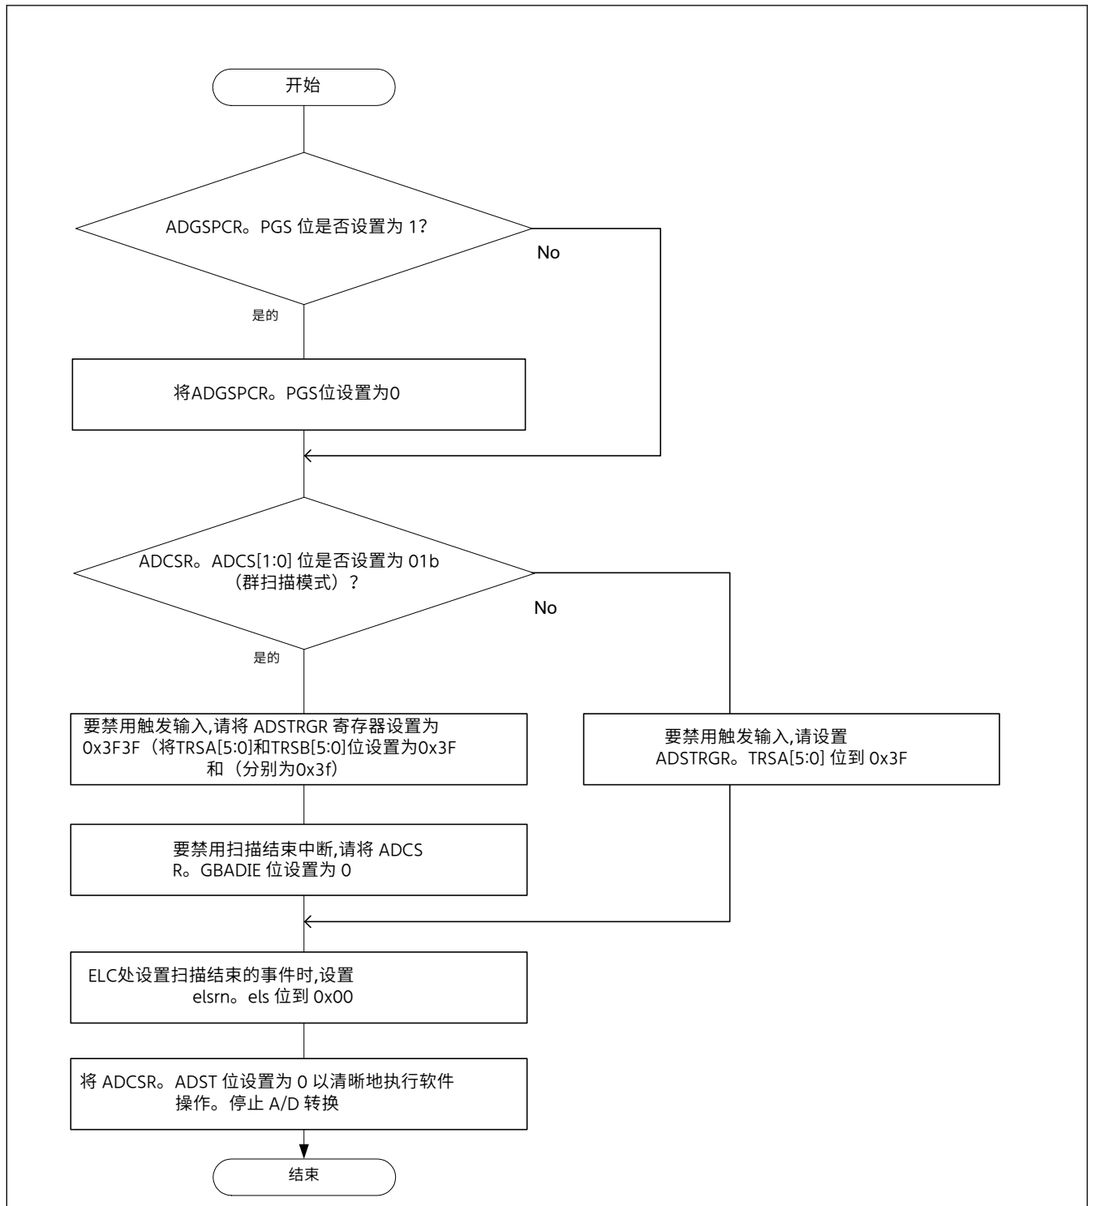

图32。41 通过软件清除 ADCSR。ADST 位的程序

要在通过软件执行清晰操作后指定以下设置,请提供至少两个 ADCLK 周期的等待期。

- 启用扫描端中断
- 为事件链路控制器启用扫描结束事件
- 通过软件启动 A/D 转换
- 启用触发输入

(2) Notes on Modes and Status Bits

If necessary, individually initialize or set again the voltage status for self-diagnosis, the judgment of the even number or odd number specified for double-trigger mode, and the monitor flags of the compare function.

- To set again the voltage status for self-diagnosis, set the ADCER.DIAGLD bit to 1 and then set a desired value in the ADCER.DIAGVAL[1:0] bits.
- If the setting of the ADCSR.DBLE bit is changed from 0 to 1, the double-trigger mode operation starts from the first scanning.
- To initialize the monitor flags of the compare function (MONCMPA, MONCMPB, and MONCOMB), set the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits to 0.

32.6.4 A/D Conversion Restart and Termination Timing

A maximum of 6 ADCLK cycles is required for the idle analog unit of the ADC12 to restart on setting the ADCSR.ADST bit to 1. A maximum of 2 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0.

32.6.5 Constraints on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data. This occurs when the CPU does not complete the reading of the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

32.6.6 Settings for the Module-Stop Function

The Module Stop Control Register can enable or disable ADC12 operation. The ADC12 is initially stopped after a reset. The registers become accessible on release from the module-stop state. After release from the module-stop state, wait for at least 1 µs before starting A/D conversion. For details, see section 10, Low Power Modes.

32.6.7 Notes on Entering the Low-Power States

Before entering the module-stop state or Software Standby mode, be sure to stop A/D conversion. Set the ADCSR.ADST bit in ADCSR to 0 and secure certain period until the analog unit of the ADC12 stops. Follow the procedure shown in Figure 32.41 to clear the ADCSR.ADST bit with software. Then, wait for 2 clock cycles of ADCLK before entering the module-stop state or Software Standby mode.

32.6.8 Error in Absolute Accuracy When Disconnection Detection Assistance Is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the ADC12. This error arises because an erroneous voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull- down resistor (Rp) and the resistance of the signal source (Rs). This error in absolute accuracy is calculated from the following formula:

$$\text{Maximum error in absolute accuracy (LSB)} = \left(2^{\text{Resolution}} - 1\right) \times \text{Rs} / \left(\text{Rs} + \text{Rp}\right)$$

Only use disconnection detection assistance after thorough evaluation.

32.6.9 Available Functions and Register Settings of AN000 to AN002, AN007

Table 32.29 shows the available functions and register settings of AN000 to AN002, AN007, and Figure 32.42 shows the setting procedure of registers. To use each function, set the register value shown in Table 32.29.

When the PGA is used with pseudo-differential input enabled, a negative voltage can be input for AN000 to AN002 and PGAVSS000 after setting the registers.

When the PGA is used with pseudo-differential input enabled, all PGA amplifiers in each unit must be set to pseudo-differential input in the ADPGADCR0 register.

When the PGA is used with pseudo-differential input disabled, the associated PGAVSS pin must be connected to AVSS0. When the PGA is not used, the associated PGAVSS can be used as an input port or analog input.

(2)模式与状态位注意事项

如有必要,单独初始化或再次设置用于自我诊断的电压状态、双触发模式指定的偶数或奇数的判断以及比较功能的监视器标志。

- 要再次设置用于自我诊断的电压状态,请将 ADCER。DIAGLD 位设置为 1,然后在 ADCER。DIAGVAL[1:0] 位中设置所需值。
- 如果 ADCSR。DBLE 位的设置从 0 更改为 1,则从第一次扫描开始双触发模式操作。
- 要初始化比较函数（MONCMPA、MONCMPB 和 MONCOMB）的监视器标志,请将 ADCMPCR。CMPAE 和 ADCMPCR。CMPBE 位设置为 0。

32。6。4 A/D 转换重启和终止时序

ADC12 的空闲模拟单元在将 ADCSR。ADST 位设置为 1 时重新启动最多需要 6 个 ADCLK 周期。ADC12 的操作模拟单元在将 ADCSR。ADST 位设置为 0 时终止,最多需要 2 个 ADCLK 周期。

32。6。5 扫描端中断处理的约束

当使用任何触发器扫描同一模拟输入两次时,第一个 A/D 转换的数据会被第二个 A/D 转换的数据覆盖。当在生成第一扫描端中断之后第二扫描的第一模拟输入的A/D转换结束时CPU尚未完成对A/D转换数据的读取时,就会发生这种情况。

32。6。6 模块停止功能的设置

模块停止控制寄存器可以启用或禁用 ADC12 操作。ADC12 在重置后最初停止。

寄存器在从模块停止状态释放时变得可访问。从模块停止状态释放后,至少等待 1 µs 才能开始 A/D 转换。有关详细信息,请参阅第 10 节"低功耗模式 ."

32。6。7 关于进入低权力国家的说明

在进入模块停止状态或软件待机模式之前,请务必停止 A/D 转换。将 ADCSR 中的 ADCSR。ADST 位设置为 0 并确保一定周期,直到 ADC12 的模拟单元停止。按照图 32。41 所示的程序使用软件清除 ADCSR。ADST 位。然后,等待 2 个 ADCLK 时钟周期,然后进入模块停止状态或软件待机模式。

32。6。8 断开检测辅助使用时绝对精度错误

使用断开检测辅助会导致 ADC12 的绝对精度错误。出现此错误是因为由于上拉或下拉电阻器（Rp）与信号源电阻（Rs）之间的电阻电压划分,模拟输入引脚输入了错误的电压。该绝对精度误差由以下公式计算:

X数学X_0 ( ) ( )

仅在彻底评估后使用断开检测辅助。

32。6。9 AN000 至 AN002、AN007 的可用功能和寄存器设置

表32。29显示了AN000至AN002、AN007的可用功能和寄存器设置,图32。42显示了寄存器的设置过程。要使用每个函数,请设置表 32。29 . 中所示的寄存器值

当PGA在启用伪差分输入的情况下使用时,设置寄存器后可以输入AN000至AN002和PGAVSS000的负电压。

PGA与启用伪差分输入一起使用时,必须将每个单元中的所有PGA放大器设置为ADPGADCR0寄存器中的伪差分输入。

PGA与伪差分输入禁用一起使用时,关联的PGAVSS引脚必须连接到AVSS0。
PGA时,关联的PGAVSS可以作为输入端口或模拟输入。

When transitioning to the ADC module-stop state or Software Standby mode from the state of using PGA or sample-and-hold circuit, if the corresponding bit in ADPGACR or ADSHCR register of each ADC12 is set to 0 before transitioning, power consumption can be reduced.

The initial value of the ASEL bit of P003 is 1. When these pins are not used as an analog function, the ASEL bit should be set to 0 to reduce the input leakage current.

32.6.10 Constraints on Operating Modes and Status Bits

Initialize or set again individually, if necessary, the voltage values in self-diagnosis, the value of the first scan or second scan in double trigger mode, the data buffer pointer, and status monitor in the compare function.

- Select the voltage values in self-diagnosis (ADCER.DIAGVAL[1:0]) after setting ADCER.DIAGLD to 1.
- Double-trigger mode operates as the first scan after setting ADCSR.DBLE from 0 to 1.
- The status monitor bits (MONCMPA, MONCMPB, MONCOMB) in the compare function are initialized after setting ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

32.6.11 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible. In addition, digital circuit signal lines and analog circuit signal lines should not intersect or be placed near each other. If these rules are not followed, noise can occur on analog signals and A/D conversion accuracy is affected. The analog input pins, reference power supply pin (VREFH0), reference ground pin (VREFL0), and analog power supply (AVCC0) should be separated from digital circuits using the analog ground (AVSS0). The analog ground (AVSS0) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

32.6.12 Constraints on Noise Prevention

To prevent the analog input pins from being destroyed by abnormal voltage such as excessive surge, insert a capacitor between AVCC0 and AVSS0 and between VREFH0 and VREFL0. Additionally, connect a protection circuit to protect the analog input pins as shown in Figure 32.43.

如有必要,在比较功能中单独初始化或再次设置自我诊断中的电压值、双触发模式下的第一扫描或第二扫描的值、数据缓冲指针和状态监视器。

- 将 ADCER。DIAGLD 设置为 1 后, 选择自我诊断（ADCER。DIAGVAL[1:0]) 中的电压值。
- 双触发模式作为将 ADCSR。DBLE 从 0 设置为 1 后的第一次扫描进行操作。
- 将 ADCMPCR。CMPAE 和 ADCMPCR。CMPBE 设置为 0 后,对比较函数中的状态监视器位（MONCMPA、MONCMPB、MONCOMB）进行初始化。

32。6。11 板设计注释

电路板的设计应使数字电路和模拟电路尽可能彼此分离。此外,数字电路信号线和模拟电路信号线不应相交或彼此靠近放置。如果不遵守这些规则,模拟信号上可能会出现噪声,并且 A/D 转换精度会受到影响。模拟输入引脚、参考电源引脚（VREFH0)、参考接地引脚（VREFL0) 和模拟电源（AVCC0) 应使用模拟接地（AVSS0) 与数字电路分离。板（单点接地平面连接）上模拟接地（AVSS0)应连接到稳定的数字接地（VSS）。

32。6。12 噪音预防限制

为了防止模拟输入引脚被异常电压（例如过度浪涌）破坏,请在 AVCC0 和 AVSS0 之间以及 VREFH0 和 VREFL0 之间插入电容器。另外,连接保护电路以保护模拟输入引脚,如图 32。43 . 所示

32.6.13 Port Settings When Using the ADC12 Input

When using the high-precision channels, do not use PORT0 as general I/O. Renesas recommends that you do not use the digital output that is also used as the AD analog input if normal-precision channel is used. If the digital output that is also used as the AD analog input is used for output signals, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

32.6.14 Relationship Between ADC12 and ACMPHS

The A/D conversion targets in Table 32.30 should not be selected as ACMPHS input during A/D conversion, because these pins are multiplexed with the ADC12 and ACMPHS.

32.6.13 使用 ADC12 输入时的端口设置

使用高精度通道时,请勿使用 PORT0 作为一般 I/O。如果使用普通精度通道,瑞萨建议您不要使用也用作 AD 模拟输入的数字输出。AD模拟输入同样使用的数字输出,如果用于输出信号,则进行几次A/D转换,消除最大值和最小值,得到其他结果的平均值。

32.6.14 ADC12 和 ACMPHS 之间的关系

表 32。30 中的 A/D 转换目标不应在 A/D 转换期间选择为 ACMPHS 输入,因为这些引脚与 ADC12 和 ACMPHS 复用。

32.6.15 Notes on Canceling Software Standby Mode

After software standby mode is canceled, wait at least 1 µs after the stabilization time for the oscillator elapses and before starting A/D conversion. For details, see section 10, Low Power Modes

32.6.16 Calculation for Sampling Time

The sampling time can be easily estimated by the following figure and formula. This is the time to reach the voltage within 1/4 LSB.

$$t_{SPL} = (R_{EXT} + R_{AD}) \times (C_{EXT} + C_{AD}) \times \ln (C_{AD} / (C_{EXT} + C_{AD}) \times 2^{N+2})$$

R_{EXT} shows external signal source impedance
C_{EXT} shows external capacitance (pin capacitance*1 + PCB parasitic capacitance)
N = 12, 10 or 8 (conversion resolution)
C_{AD} = 5 pF (internal capacitance)
R_{AD} = 1.0 kΩ (internal resistance, case of high-speed channels)
R_{AD} = 2.5 kΩ (internal resistance, case of normal-speed channels)

Note 1. Typical value of analog input pin is 5 pF

For example, if R_{EXT} is 1 kΩ, C_{EXT} is 10 pF and N is 12 bits, t_{SPL} of high-speed channel is 258 ns.

This formula simplifies the general use case. This formula is not guaranteed and should be used only for estimation.

32。6。15 关于取消软件待机模式的说明

取消软件待机模式后,振荡器的稳定时间过后至少等待 1 µs,然后再开始 A/D 转换。有关详细信息,请参阅第 10 节 "低功耗模式"

32.6.16 采样时间的计算

采样时间可以通过下图和公式轻松估计。这是达到 1/4 LSB 以内的电压的时间。

$$t_{SPL} = (R_{EXT} + R_{AD}) \times (C_{EXT} + C_{AD}) \times \ln (C_{AD} / (C_{EXT} + C_{AD}) \times 2^{N+2})$$

R EXT 显示外部信号源阻抗
C EXT 显示外部电容（引脚电容 *1 + PCB 寄生电容）
N = 12、10 或 8（转换分辨率）
C AD = 5 pF（内部电容）
R AD = 1。0 kΩ（内阻,高速通道的情况）
R AD = 2。5 kΩ（内阻,常速通道的情况）

注1。模拟输入引脚的典型值为 5 pF

例如,如果 R EXT 为 1 kΩ,C EXT 为 10 pF,N 为 12 位,则高速通道的 t SPL 为 258 ns。

该公式简化了一般用例。该公式没有保证,只能用于估计。

	1	0	• Disable D/A conversion of channel 0 and enable D/A conversion of channel 1 • Disable analog output of channel 0 (DA0)*1 and enable analog output of channel 1 (DA1)

1	x	x	• Enable D/A conversion of channels 0 and 1 • Collective enable analog output of channels 0 and 1 (DA0, DA1)

Note: x: Don't care
Note 1. When analog output is disabled, the analog output signal is placed in the Hi-Z state.

Only set this register while the ADC12 is halted when the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled). Only set DACR while the ADCSR.ADST bit is 0 and after selecting the software trigger, for the ADC12 trigger to securely stop the ADC12.

DAE bit (D/A Enable)

The DAE bit controls D/A conversion, amplifier operation, and analog output in combination with the DAOEi bit (i = 0, 1) and the DAAMPCR.DAAMPi bit (i = 0, 1). See Table 33.4.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the ADCSR.ADST bit of the ADC12 to 0. Then, select the software trigger for the ADC12 trigger to securely stop the ADC12.

DAOEi bit (D/A Output Enable i)

The DAOEi bit (i = 0, 1) controls D/A conversion, amplifier operation, and analog output in combination with the DAE bit and DAAMPCR.DAAMPi bit (i = 0, 1). See Table 33.4.

When both the DAOEi bit (i = 0, 1) and DAE bit are 0, D/A conversion of channel i (i = 0, 1) is not processed, and no conversion result is output.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAOEi bit while the ADCSR.ADST bit of the ADC12 is set to 0. Then, select the software trigger for the ADC12 trigger to securely stop the ADC12.

The event link function can be used to set the DAOEi bit to 1. The DAOE0 bit is set to 1 when the event specified in the ELSR12 register of the ELC (ELC_DA0 event) occurs, and output of the D/A conversion results starts. The DAOE1 bit is set to 1 when the event specified in the ELSR13 register of the ELC (ELC_DA1 event) occurs, and output of the D/A conversion results starts.

注1。当模拟输出被禁用时,模拟输出信号被置于Hi-Z状态。

仅在 DAADSCR。DAADST 位为 1 时停止 ADC12 时设置此寄存器（启用 D/A 和 A/D 转换之间的干扰减少）。仅在 ADCSR。ADST 位为 0 时设置 DACR,并在选择软件触发器后,ADC12 触发器才能安全地停止 ADC12。

DAE 位（D/A 启用）

DAE 位与 DAOEi 位（i = 0, 1) 和 DAAMPCR。DAAMPi 位（i = 0, 1) 结合控制 D/A 转换、放大器操作和模拟输出。参见表 33。4 .

当启用 D/A 和 A/D 转换之间的干扰减少时（DAADSCR。DAADST = 1),将 ADC12 的 ADCSR。ADST 位设置为 0。然后,选择ADC12触发器的软件触发器,安全停止ADC12。

DAOEi 位（D/A 输出启用 i）

DAOEi 位（i = 0, 1) 与 DAE 位和 DAAMPCR。DAAMPi 位（i = 0, 1) 结合控制 D/A 转换、放大器操作和模拟输出。参见表 33。4 .

DAOEi位（i = 0,1)和DAE位均为0时,不处理通道i（i = 0,1)的D/A转换,不输出转换结果。

当启用 D/A 和 A/D 转换之间的干扰减少时（DAADSCR。DAADST = 1),设置 DAOEi 位,而 ADC12 的 ADCSR。ADST 位设置为 0。然后,选择ADC12触发器的软件触发器,安全停止ADC12。

事件链接功能可用于将DAOEi位设置为1。ELC的ELSR12寄存器中指定的事件（ELC_DA0事件）发生时将DAOE0位设置为1,开始输出D/A转换结果。ELC的ELSR13寄存器中指定的事件（ELC_DA1事件）发生时将DAOE1位设置为1,开始输出D/A转换结果。

To minimize interference between D/A and A/D conversion, the DAADSCR register enables synchronization of the start timing of D/A conversion with the ADC12 synchronous D/A conversion enable input signal.

Only set this register while the ADC12 is halted, that is, while the ADCSR.ADST bit is 0 after selecting the software trigger as the ADC12 trigger.

Select the target ADC12 unit before setting the DAADST bit to 1. Set DAADUSR[0] bit to 1 to select unit 0.

DAADST bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the DADRn register value to be converted into analog data at any time. Setting the DAADST bit to 1 allows synchronization of D/A conversion with the synchronous D/A conversion enable input signal from the ADC12. With this bit set, D/A conversion does not start until the ADC12 completes A/D conversion, even when the DADRn register is changed.

为了最小化D/A和A/D转换之间的干扰,DAADSCR寄存器使得D/A转换的开始定时能够与ADC12同步D/A转换使能输入信号同步。

仅在 ADC12 停止时设置此寄存器,即在选择软件触发器作为 ADC12 触发器后 ADCSR。ADST 位为 0 时。

DAADST 位设置为 1 之前选择目标 ADC12 单元。DAADUSR[0] 位设置为 1 以选择单元 0。

DAADST 位（D/A A/D 同步转换）

DAADST 位设置为 0 允许 DADRn 寄存器值随时转换为模拟数据。设置
DAADST 位到 1 允许 D/A 转换与来自 ADC12 的同步 D/A 转换使能输入信号同步。使用此位集,即使 DADRn 寄存器发生更改,直到 ADC12 完成 A/D 转换时,D/A 转换才会开始。

Set this bit while the ADCSR.ADST bit is set to 0. Then, select the software trigger for the ADC12 trigger to securely stop the ADC12. Set the DAADUSR.AMADSEL0 bit to 1 before setting the DAADST bit to 1.

The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR12 and ELSR13 registers of the ELC. The setting of the DAADST bit is shared by channels 0 and 1 of the DAC12.

33.2.5 DAAMPCR : D/A Output Amplifier Control Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAAMP1	DAAMP0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

7	DAAMP1	Amplifier Control 1 0: Do not use channel 1 output amplifier 1: Use channel 1 output amplifier	R/W

The DAAMPCR register selects D/A output with or without using the amplifier.

DAAMP0 bit (Amplifier Control 0)

When the DAAMP0 bit is 0, analog values are output for D/A output of channel 0 without using the amplifier. When the DAAMP0 bit is 1, analog values are output for D/A output of channel 0 through the amplifier.

When both the DACR.DAE and DACR.DAOE0 bits are 0, the amplifier is not used regardless of the setting of the DAAMP0 bit. See Table 33.4 for details.

DAAMP1 bit (Amplifier Control 1)

When the DAAMP1 bit is 0, analog values are output for D/A output of channel 1 without using the amplifier. When the DAAMP1 bit is 1, analog values are output for D/A output of channel 1 through the amplifier.

When both the DACR.DAE and DACR.DAOE1 bits are 0, the amplifier is not used regardless of the setting of the DAAMP1 bit. See Table 33.4 for details.

33.2.6 DAASWCR : D/A Amplifier Stabilization Wait Control Register

设置此位,而 ADCSR。ADST 位设置为 0。然后,选择ADC12触发器的软件触发器,安全停止ADC12。将 DAADUSR。AMADSEL0 位设置为 1,然后将 DAADST 位设置为 1。

DAADST 位设置为 1 时无法使用事件链接函数。ELC的ELSR12和ELSR13寄存器来停止事件链接功能。DAADST 位的设置由 DAC12 的通道 0 和 1 共享。

The DAASWCR register controls D/A output with the output amplifier or D/A output for internal modules. This register is used in the initialization procedure to wait for stabilization of the D/A output amplifier. Each bit in DAASWCR should be set to 1 when both the DACR.DAE bit and the DACR.DAOEi (i = 0, 1) bit are 0 . See section 33.6.5. Initialization Procedure with the Output Amplifier.

DAASW0 bit (D/A Amplifier Stabilization Wait 0)

Set the DAASW0 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 0 output amplifier. When DAASW0 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 0. When the DAASW0 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 0 is the output amplifier to the DA0 pin. When the amplifier is not used (DAAMPCR.DAAMP0 bit is 0) and DAASW0 is set to 1, D/A conversion result of channel 0 is output to the internal modules.

DAASW1 bit (D/A Amplifier Stabilization Wait 1)

Set the DAASW1 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 1 output amplifier. When DAASW1 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 1. When the DAASW1 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 1 is the output amplifier to the DA1 pin. When the amplifier is not used (DAAMPCR.DAAMP1 bit is 0) and DAASW1 is set to 1, D/A conversion result of channel 1 is output to the internal modules.

1	—	This bit is read as 0. The write value should be 0.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

The DAADUSR register selects the target ADC12 unit for D/A and A/D synchronous conversions. Set the AMADSEL0 bit to 1 to select unit 0 as the target synchronous unit for the MCU. When setting the DAADSCR.DAADST bit to 1 for synchronous conversions, select the target unit in this register in advance.

DAASWCR 寄存器通过输出放大器控制 D/A 输出或内部模块的 D/A 输出。该寄存器在初始化过程中用于等待 D/A 输出放大器的稳定。当 DACR。DAE 位和 DACR。DAOEi（i = 0, 1）位均为 0 时,DAASWCR 中的每个位应设置为 1。参见第 33。6。5 节。使用输出放大器 . 进行初始化过程

DAASW0 位（D/A 放大器稳定等待 0）

DAASW0 位在初始化过程中设置为 1,以等待 D/A 通道 0 输出放大器的稳定。DAASW0设置为1时,D/A转换工作,但D/A的转换结果不是从通道0输出。DAASW0位为0时,稳定等待时间停止,通道0的D/A转换结果为输出放大器到DA0引脚。当不使用放大器（DAAMPCR。DAAMP0位为0)并且DAASW0设置为1时,通道0的D/A转换结果被输出到内部模块。

DAASW1 位（D/A 放大器稳定等待 1）

DAASW1 位在初始化过程中设置为 1,以等待 D/A 通道 1 输出放大器的稳定。DAASW1设置为1时,D/A转换工作,但D/A的转换结果不是从通道1输出。DAASW1位为0时,稳定等待时间停止,通道1的D/A转换结果为输出放大器到DA1引脚。当不使用放大器（DAAMPCR。DAAMP1位为0)并且DAASW1设置为1时,通道1的D/A转换结果被输出到内部模块。

DAADUSR 寄存器选择目标 ADC12 单元进行 D/A 和 A/D 同步转换。AMADSEL0位设置为1,以选择单元0作为MCU的目标同步单元。DAADSCR。DAADST 位设置为 1 进行同步转换时,请提前选择此寄存器中的目标单元。

Only set the DAADUSR register while the ADCSR.ADST bit of the ADC12 is set to 0 and the DAADSCR.DAADST bit is set to 0.

33.3 Operation

The DAC12 includes D/A conversion circuits for two channles, each of which can operate independently. When the DAOEn bit (n = 0, 1) in DACR is set to 1, DAC12 is enabled and the conversion result is output.

This following example shows D/A conversion on channel 0. Figure 33.2 shows the timing of this operation.

To process D/A conversion on channel 0:

1. Set the data for D/A conversion in the DADR0 register and the data format in the DADPR.DPSEL bit.
2. Set the DACR.DAOE0 bit to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time t_{DCONV} elapses. The conversion result continues to be output until DADR0 is written to again or the DAOE0 bit is set to 0. The output value (reference) is expressed by the following formula:

$$\frac{\text{Setting in DADR0}}{4096} \times \text{VREFH}$$

3. To start conversion again, write another value to DADR0. The conversion result is output after the conversion time t_{DCONV} elapses.
   When the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled), a maximum of one A/D conversion time is required for D/A conversion to start. When ADCLK is faster than the peripheral clock, a longer time might be required.
4. To disable analog output, set the DAOE0 bit to 0.

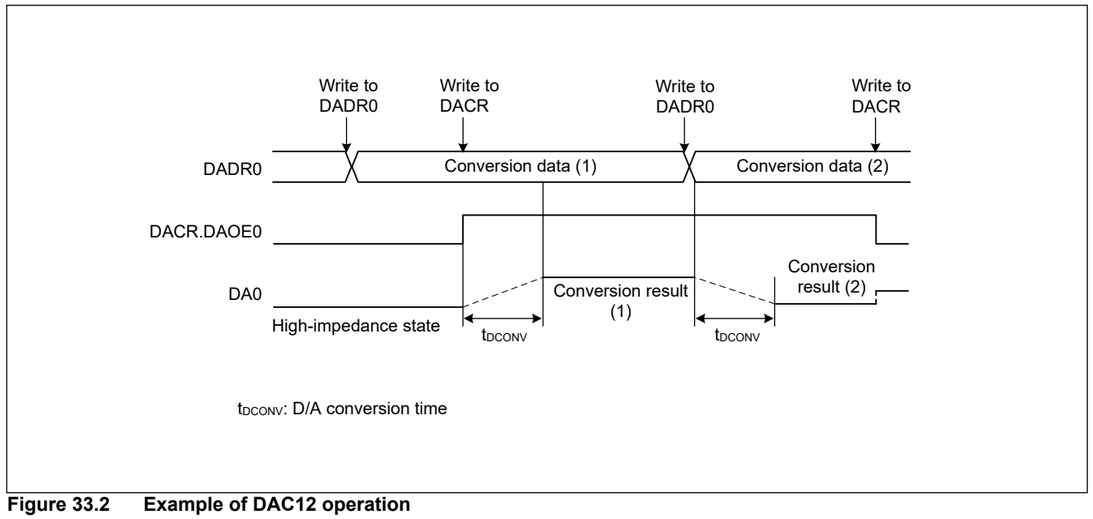

Figure 33.2 Example of DAC12 operation

33.3.1 Reducing Interference between D/A and A/D Conversion

When D/A conversion starts, the DAC12 generates inrush current. Because the DAC12 and ADC12 share the same analog power supply, the generated inrush current can interfere with ADC12 operation.

While the DAADSCR.DAADST bit is 1, D/A conversion does not start immediately on updating the DADRm register. Instead:

- If the DADRm register data is modified while the ADC12 is halted, D/A conversion starts in 1 PCLKA cycle.
- If the DADRm register data is modified while the ADC12 is performing a 12-bit A/D conversion, D/A conversion starts on A/D conversion completion. Therefore, it takes up to one A/D conversion time period for the DADRm register data update to be reflected as the D/A conversion circuit output. Until the D/A conversion completes, the DADRm register value does not correspond to the analog output value.

仅设置 DAADUSR 寄存器,而 ADC12 的 ADCSR。ADST 位设置为 0,DAADSCR。DAADST 位设置为 0。

33。3 操作

DAC12包括用于两个通道的D/A转换电路,每个通道可以独立操作。DACR中的DAOEn位（n = 0,1)设置为1时,启用DAC12,输出转换结果。

以下示例显示了通道 0 上的 D/A 转换。图 33。2 显示了此操作的时机。

要处理通道 0 上的 D/A 转换:

1。在 DADR0 寄存器中设置 D/A 转换数据,在 DADPR。DPSEL 位中设置数据格式。

2锛姣涓涓。将 DACR。DAOE0 位设置为 1 以开始 D/A 转换。转换结果在转换时间tDCONV过后从模拟输出引脚 DA0输出。转换结果继续输出,直到再次写入 DADR0 或将 DAOE0 位设置为 0。值（参考）由下式表示:

$$\frac{\text{Setting in DADR0}}{4096} \times \text{VREFH}$$

3锛　　娴　　。要再次开始转换,请将另一个值写入 DADR0。转换结果在转换时间t DCONV过去后输出。

DAADSCR。DAADST 位为 1 时（启用 D/A 和 A/D 转换之间的干扰减少）,D/A 转换启动最多需要一个 A/D 转换时间。ADCLK比外设时钟更快时,可能需要更长的时间。

4锛姣涓。要禁用模拟输出,请将 DAOE0 位设置为 0。

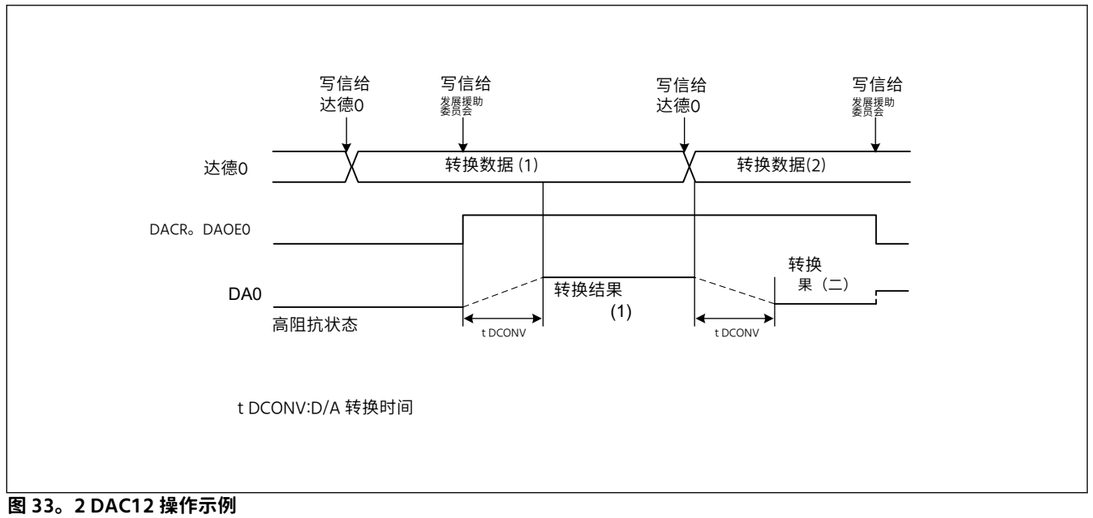

图 33。2 DAC12 操作示例

33。3。1 减少 D/A 和 A/D 转换之间的干扰

D/A转换开始时,DAC12会产生浪涌电流。由于 DAC12 和 ADC12 共享相同的模拟电源,因此产生的浪涌电流会干扰 ADC12 的运行。

虽然 DAADSCR。DAADST 位是 1,但 D/A 转换不会在更新 DADRm 寄存器时立即开始。
相反:

- 如果在 ADC12 停止的同时修改 DADRm 寄存器数据,则 D/A 转换在 1 PCLKA 循环中开始。
- 如果在 ADC12 执行 12 位 A/D 转换时修改 DADRm 寄存器数据,则 D/A 转换在 A/D 转换完成时开始。因此,DADRm寄存器数据更新需要多达一个A/D转换时间段才能反映为D/A转换电路输出。D/A转换完成之前,DADRm寄存器值与模拟输出值不对应。

When the DAADSCR.DAADST bit is 1, it is not possible to check through software whether the DADRm register value was D/A-converted.

The following sequence provides an example of channel 0 D/A conversion, in which the DAC12 is synchronized with the ADC12. Figure 33.3 shows the timing of this operation.

To perform D/A conversion on channel 0 in synchronization with the ADC12:

1. Confirm that the ADC12 is halted and set the DAADUSR.AMADSEL0 bit to 1.
2. Confirm that the ADC12 is halted and set the DAADSCR.DAADST bit to 1.
3. Confirm that the ADC12 is halted and set the DACR.DAOE0 bit to 1.
4. Set the DADR0 register. If ADCLK is faster than the peripheral clock, D/A conversion might be delayed for longer than one A/D conversion time.
   - If the ADC12 is halted (ADCSR.ADST = 0) when the DADR0 register is modified, D/A conversion starts in 1 PCLKA cycle.
   - If the 12-bit A/D conversion is in progress (ADCSR.ADST = 1) when the DADR0 register is modified, D/A conversion starts on A/D conversion completion. If the DADR0 register is modified twice during A/D conversion, the first update might not be converted.

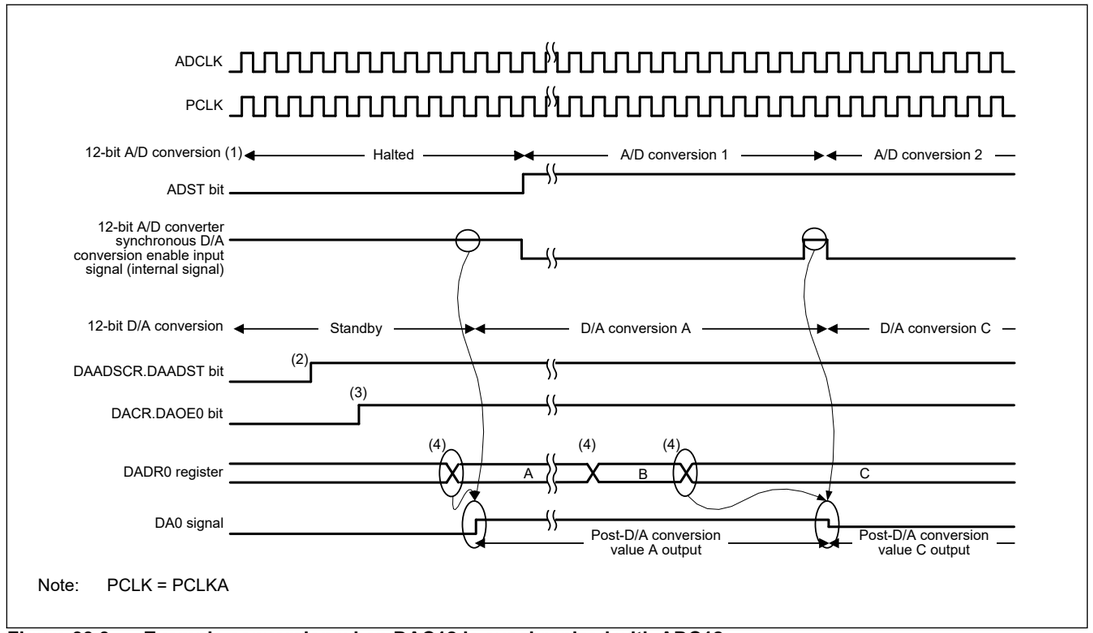

Figure 33.3 Example conversion when DAC12 is synchronized with ADC12

When ADCLK is faster than PCLKA, the DAC12 might not be able to capture the synchronous D/A conversion enable input signal from the ADC12 during the 1 ADCLK cycle that is output between A/D conversion 1 and A/D conversion 2, as shown in Figure 33.4. In this case, post-D/A conversion value A is continuously output as the DA0 signal.

DAADSCR。DAADST位为1时,无法通过软件检查DADRm寄存器值是否被D/A转换。

以下序列提供了通道 0 D/A 转换的示例,其中 DAC12 与通道 0 D/A 同步
ADC12。图 33。3 显示了此操作的时机。

ADC12 同步在通道 0 上执行 D/A 转换:

1。确认 ADC12 已停止并将 DAADUSR。AMADSEL0 位设置为 1。

2锛姣涓涓。确认 ADC12 已停止并将 DAADSCR。DAADST 位设置为 1。

3锛　　娴　　。确认 ADC12 停止并将 DACR。DAOE0 位设置为 1。

4锛姣涓。设置 DADR0 寄存器。如果 ADCLK 比外围时钟快,则 D/A 转换可能会延迟超过一个 A/D 转换时间。

- 如果 DADR0 寄存器修改时 ADC12 停止（ADCSR。ADST = 0),则 D/A 转换在 1 PCLKA 循环中开始。
- 如果修改 DADR0 寄存器时 12 位 A/D 转换正在进行中（ADCSR。ADST = 1),则 D/A 转换从 A/D 转换完成时开始。A/D 转换期间对 DADR0 寄存器进行两次修改,则可能无法转换第一次更新。

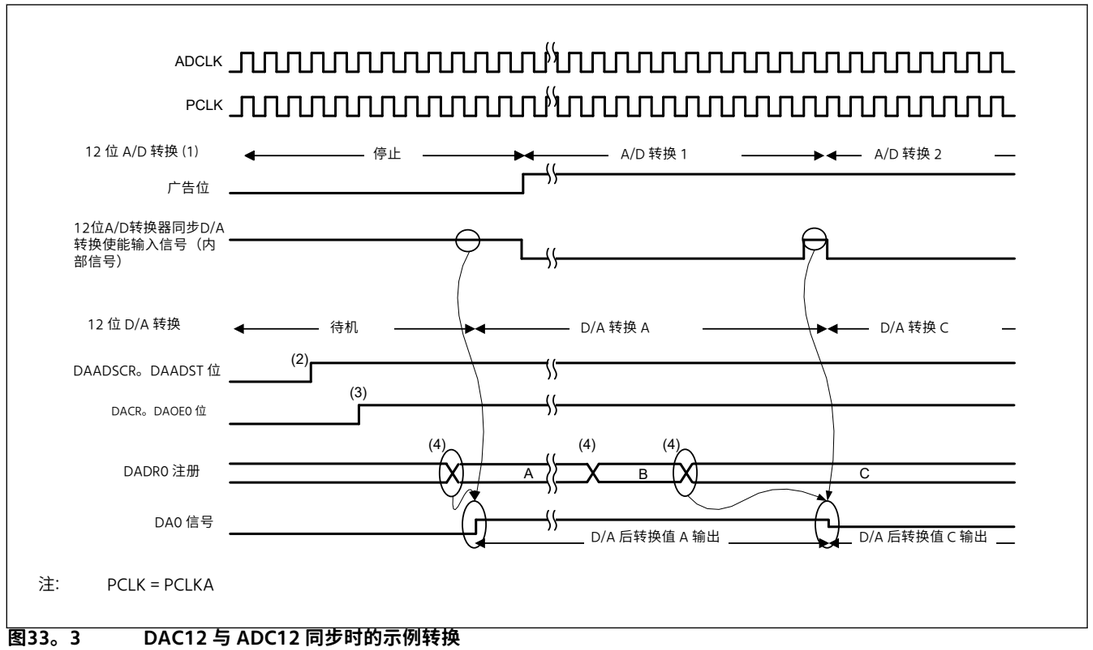

图33。3 DAC12 与 ADC12 同步时的示例转换

当ADCLK比PCLKA更快时,DAC12可能无法在A/D转换1和A/D转换2之间输出的1个ADCLK周期期间捕获来自ADC12的同步D/A转换使能输入信号,如图所示33。4。在这种情况下,D/A后转换值A作为DA0信号连续输出。

33.4 Event Link Operation Setting Procedure

This section describes the procedures used in event link operation.

33.4.1 DA0 Event Link Operation Setting Procedure

To set up DA0 event link operation:

1. Set the DADPR.DPSEL bit and the data for D/A conversion in the DADR0 register.
2. Set the ELC_DA0 event signal to be linked to each peripheral module in the ELSR12 register.
3. Set the ELCR.ELCON bit to 1. This enables event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit becomes 1, and D/A conversion starts on channel 0.
5. Set the ELSR12 register to 0x0000 to stop event link operation of DAC12 channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

33.4.2 DA1 Event Link Operation Setting Procedure

To set up DA1 event link operation:

1. Set the DADPR.DPSEL bit and set the data for D/A conversion in the DADR1 register.
2. Set the ELC_DA1 event signal to be linked to each peripheral module in the ELSR13 register.
3. Set the ELCR.ELCON bit to 1. This enables the event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE1 bit is becomes 1, and D/A conversion starts on channel 1.
5. Set the ELSR13 register to 0x0000 to stop event link operation on DAC12 channel 1. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

33。4 事件链路操作设置过程 本节描述事件链路操作中使用的过程。

33.4.1 DA0 事件链接操作设置程序

DA0 事件链接操作的设置:

1。在 DADR0 寄存器中设置 DADPR。DPSEL 位和 D/A 转换数据。

2锛姣涓涓。ELC_DA0 事件信号设置为链接到 ELSR12 寄存器中的每个外围模块。

3锛　　娴　　。将 ELCR。ELCON 位设置为 1。这使得能够对所有模块进行事件链接操作,并选择事件链接功能。

4锛姣涓。设置事件输出源模块以激活事件链接。事件从模块输出后,DACR。DAOE0 位变为 1,D/A 转换从通道 0 开始。

5锛姣涓。ELSR12寄存器设置为0x0000,停止DAC12信道0的事件链路操作。当 ELCR。ELCON 位设置为 0 时,所有事件链路操作都会停止。

33。4。2 DA1 事件链路操作设置程序

DA1 事件链接操作的设置:

1。设置 DADPR。DPSEL 位并设置 DADR1 寄存器中 D/A 转换的数据。

2锛姣涓涓。ELC_DA1 事件信号设置为链接到 ELSR13 寄存器中的每个外围模块。

3锛　　娴　　。将 ELCR。ELCON 位设置为 1。这使得能够对所有模块进行事件链接操作,并选择事件链接功能。

4锛姣涓。设置事件输出源模块以激活事件链接。从模块输出事件后,DACR。DAOE1 位变为 1,D/A 转换从通道 1 开始。

5锛姣涓。将 ELSR13 寄存器设置为 0x0000 以停止 DAC12 通道 1 上的事件链路操作。当 ELCR。ELCON 位设置为 0 时,所有事件链路操作都会停止。

33.5 Usage Notes on Event Link Operation

- When the event link function is used, do not use the amplifier output function.
- When the event link function is used, set the DACR.DAE bit to 0.
- When the event specified for the ELC_DA0 event signal is generated while a write to the DACR.DAOE0 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- When the event specified for the ELC_DA1 event signal is generated while a write to the DACR.DAOE1 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 to reduce interference between D/A and A/D conversions.

33.6 Usage Notes

33.6.1 Settings for the Module-Stop Function

DAC12 operation can be disabled or enabled using the Module Stop Control Register. The DAC12 is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

33.6.2 DAC12 Operation in the Module-Stop State

When the MCU enters the module-stop state with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in the module-stop state, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

33.6.3 DAC12 Operation in Software Standby Mode

When the MCU enters Software Standby mode with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in Software Standby mode, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

33.6.4 Constraint on Entering Deep Software Standby Mode

When the MCU enters Deep Software Standby mode with D/A conversion enabled, the outputs of the DAC12 are placed in a high impedance state.

33.6.5 Initialization Procedure with the Output Amplifier

Use the following initialization procedures with the output amplifier. The example shows the case for channel 0.

To initialize the DAC12 with the output amplifier:

1. Write 0x0000 to the DADR0 register.
2. Set the DAASWCR.DAASW0 bit to 1.
3. Set the DAAMPCR.DAAMP0 bit to 1.
4. Set the DACR.DAE bit or the DACR.DAOE0 bit to 1 to start operation of the amplifier.
5. Clear the DAASWCR.DAASW0 bit to 0 after waiting for the duration of D/A conversion time t_{DCONV}.
6. Write the value to be converted in the DADR0 register.

33。5 事件链接操作使用说明

● 事件链路函数时,不要使用放大器输出函数。

● 事件链接函数时,将 DACR。DAE 位设置为 0。

● 当在对DACR。DAOE0位进行写入的同时生成为ELC_DA0事件信号指定的事件时,停止写入周期,并且生成的事件在将该位设置为1时优先。

● 当在对DACR。DAOE1位进行写入的同时生成为ELC_DA1事件信号指定的事件时,停止写入周期,并且生成的事件在将该位设置为1时优先。

● 当 DAADSCR。DAADST 位设置为 1 以减少 D/A 和 A/D 转换之间的干扰时, 禁止使用事件链接函数。

33。6 使用说明

33。6。1 模块停止功能的设置

DAC12 操作可以使用模块停止控制寄存器禁用或启用。DAC12在重置后最初停止。释放模块停止状态可以访问寄存器。有关详细信息,请参阅第 10 节"低功耗模式 ."

33。6。2 DAC12 在模块停止状态下的操作

MCU在启用D/A转换的情况下进入模块停止状态时,保留D/A输出,模拟电源电流与D/A转换时相同。如果模拟电源电流必须在模块停止状态下减少,则通过将 DACR。DAOE1、DAOE0 和 DAE 位设置为 0 来禁用 D/A 转换。

33。6。3 软件待机模式下的DAC12操作

MCU 进入软件待机模式时启用 D/A 转换,则保留 D/A 输出,模拟电源电流与 D/A 转换时相同。如果在软件待机模式下必须减少模拟电源电流,则通过将 DACR。DAOE1、DAOE0 和 DAE 位设置为 0 来禁用 D/A 转换。

33。6。4 进入深度软件待机模式的约束

MCU 进入深度软件待机模式并启用 D/A 转换时,DAC12 的输出被放置在a 高阻抗状态。

33。6。5 使用输出放大器的初始化过程

使用输出放大器进行以下初始化过程。该示例显示了通道 0 的情况。

要使用输出放大器初始化 DAC12:

1。将 0x0000 写入 DADR0 寄存器。

2锛姣涓涓。将 DAASWCR。DAASW0 位设置为 1。

3锛　　娴　　。将 DAAMPCR。DAAMP0 位设置为 1。

4锛姣涓。将DACR。DAE位或DACR。DAOE0位设置为1以开始放大器的操作。

5锛姣涓。DAASWCR。DAASW0 位在等待 D/A 转换时间的持续时间 tDCONV . 后清除为 0

While the amplifier is running, clearing the DACR.DAE and DACR.DAOE0 bits to 0 allows the amplifier to stop operation. To use the amplifier again, repeat steps 1 to 6.

33.6.6 Initialization Procedure of the Output to internal modules

Use the following initialization procedures for the output to internal modules.

The example shows the case for channel 0.

1. Set the DAASWCR.DAASW0 bit to 1.
2. Set the DACR.DAE bit or the DACR.DAOE0 bit to 1.
3. Write the value to be converted in the DADR0 register.

33.6.7 Constraint on Usage When Interference Reduction between D/A and A/D Conversion Is Enabled

When the DAADSCR.DAADST bit is 1, enabling interference reduction between D/A and A/D conversion, do not place the ADC12 in the module-stop state. Doing so can halt D/A conversion in addition to A/D conversion.

33。6。7 启用 D/A 和 A/D 转换之间的干扰减少时对使用的限制

当 DAADSCR。DAADST 位为 1 时,能够减少 D/A 和 A/D 转换之间的干扰,请勿将 ADC12 置于模块停止状态。除了 A/D 转换之外,这样做还可以停止 D/A 转换。

34. Temperature Sensor (TSN)

34.1 Overview

The on-chip Temperature Sensor (TSN) determines and monitors the die temperature for reliable operation of the device. The sensor outputs a voltage directly proportional to the die temperature, and the relationship between the die temperature and the output voltage is fairly linear. The output voltage is provided to the ADC12 for conversion and can be further used by the end application.

Table 34.1 lists the TSN specifications, and Figure 34.1 shows a block diagram.

34.3 Using the Temperature Sensor

The temperature sensor outputs a voltage that varies with the temperature. This voltage is converted to a digital value by the 12-bit A/D converter. To obtain the die temperature, convert this value into the temperature.

34.3.1 Preparation for Using the Temperature Sensor

The ambient temperature (T) is proportional to the temperature sensor voltage output (Vs), so ambient temperature is calculated with the following formula:

T = (Vs - V1) / slope + T1

- T: Ambient temperature of MCU as calculation result (°C)
- Vs: Voltage output by the temperature sensor on temperature measurement (V)
- T1: Temperature experimentally measured at one point (°C)
- V1: Voltage output by the temperature sensor on measurement of T1 (V)
- T2: Temperature experimentally measured at a second point (°C)
- V2: Voltage output by the temperature sensor on measurement of T2 (V)
- Slope: Temperature gradient of the temperature sensor (V / °C), slope = (V2 - V1) / (T2 -T1)

Characteristics vary between sensors, so Renesas recommends measuring two different sample temperatures as follows:

1. Use the 12-bit A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1.
2. Again use the 12-bit A/D converter to measure the voltage V2 output by the temperature sensor at a different temperature T2.
3. Obtain the temperature gradient (slope = (V2 - V1) / (T2 - T1)) from these results.
4. Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic (T = (Vs - V1) / slope + T1).

If you are using the temperature gradient given in section 41, Electrical Characteristics, use the A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1, then calculate the temperature characteristic using the following formula:

T = (Vs - V1) / slope + T1

Note: This method produces less accurate temperatures than measurement at two points.

In this MCU, the TSCDR register stores the temperature value (CAL127) of the temperature sensor measured under the condition Ta = Tj = 127°C and AVCC0 = VREFH0 = 3.3 V. If you use this value as the sample measurement result at the first point, you can omit the preparation before using the temperature sensor.

V1 is calculated from CAL127:

V1 = 3.3 × CAL127 / 4096 [V] (In case of 12 bit accuracy)

Using this value, the measured temperature can be calculated according to the following formula:

T = (Vs - V1) / slope + 127 [°C]

- T: Ambient temperature of MCU as calculation result (°C)
- Vs: Voltage output by the temperature sensor when the temperature is measured (V)
- V1: Voltage output by the temperature sensor when Ta = Tj = 127°C and AVCC0 = VREFH0 = 3.3 V (V)
- Slope: Temperature gradient of the temperature sensor*1 / 1000 (V/°C)

Note 1. See section 41, Electrical Characteristics

34.3.2 Procedures for Using the Temperature Sensor

Figure 34.2 shows the procedure for using the TSN.

温度传感器校准数据存储在 TSCDR 寄存器的较低 12 位中。

34。3 使用温度传感器

温度传感器输出随温度变化的电压。该电压由 12 位 A/D 转换器转换为数字值。要获得模具温度,请将该值转换为温度。

34。3。1 温度传感器的使用准备

度（T）与温度传感器电压输出（Vs）成正比,因此用以下公式计算环境温度:

T =（Vs V1)/斜率 + T1

- T:作为计算结果的 MCU 环境温度 (°C)
- Vs:温度传感器对温度测量输出的电压（V）
- T1:在一点(°C）处通过实验测量的温度
- V1: 温度传感器在测量 T1（V）时输出的电压
- T2:在第二点 (°C）处通过实验测量的温度
- V2: 温度传感器在测量 T2（V）时输出的电压
- 斜率:温度传感器的温度梯度（V / °C）,斜率 =（V2 V1) /（T2 −T1）

传感器之间的特性各不相同,因此瑞萨建议测量两种不同的样品温度如下:

1。12 位 A/D 转换器来测量温度传感器在温度 T1 时输出的电压 V1。

2锛姣涓涓。再次使用12位A/D转换器测量温度传感器在不同温度T2下输出的电压V2。

3锛　　娴　　。从这些结果中获得温度梯度（斜率=（V2 V1)/（T2 T1))。

4锛姣涓。随后,通过将斜率代入温度特性公式（T =（Vs V1)/斜率 + T1)来获得温度。

41 节"电气特性"中给出的温度梯度, 则使用 A/D 转换器测量温度传感器在温度 T1 时输出的电压 V1, 则使用以下公式计算温度特性:

T =（Vs V1)/斜率 + T1

注意:该方法产生的温度不如两点测量准确。

在此 MCU 中,TSCDR 寄存器存储在 Ta = Tj = 127°C 和 AVCC0 = VREFH0 = 3。3 V 条件下测量的温度传感器的温度值（CAL127)。如果在第一点使用该值作为样品测量结果,可以使用温度传感器之前可以省略准备工作。

V1 由 CAL127 计算得出:

V1 = 3。3 × CAL127 / 4096 [V]（在精度为 12 位的情况下）

使用该值,可以根据以下公式计算测量的温度:

T =（Vs V1)/斜率 + 127 [°C]

- T:作为计算结果的 MCU 环境温度 (°C)
- Vs:温度传感器测量温度时输出的电压（V）
- V1: 当 Ta = Tj = 127°C 和 AVCC0 = VREFH0 = 3。3 V（V）时温度传感器输出的电压
- 斜率:温度传感器的温度梯度*1 / 1000（V/°C）注 1。参见第 41 节"电气特性"

35. High-Speed Analog Comparator (ACMPHS)

35.1 Overview

The High-Speed Analog Comparator (ACMPHS) can be used to compare a test voltage with a reference voltage and to provide a digital output based on the result of conversion. Both the test voltage and the reference voltage can be provided to the ACMPHS from internal sources (D/A converter output, Programable Gain Amplifire (PGA) output) and an external source. Such flexibility is useful in applications that require go/no-go comparisons to be performed between analog signals without necessarily requiring A/D conversion.

Table 35.1 lists the ACMPHS specifications, Figure 35.1 shows a block diagram, and Table 35.2 shows the input source configurations.

Note 1. Disable the ACMPHS output (COE= 0) before changing the CDFS[1:0] and CINV bits.
Note 2. If the CDFS[1:0] and CINV bits are changed, an ACMPHS interrupt request and an ELC event might be generated. Before changing these bits, set the ELSRn register to 0 (the ACMPHS output is not linked). After changing these bits, clear the IR flag in the IELSRn register to 0 to clear the interrupt status.
Note 3. If the CDFS[1:0] bits are changed from 00b (noise filter not used) to a value other than 00b (noise filter used), perform sampling four times and update the filter output, and then use the ACMPHS interrupt request or the ELC event.
Note 4. A stabilization wait time is required to permit ACMPHS operation after enabling it (HCMPON = 1). The operation stabilization wait time for ACMPHS is 300 ns.
Note 5. Set the CSTEN bit to 1 and the CDFS[1:0] bits to 00b if the ACMPHS interrupt causes the release of Software Standby or Snooze modes. CSTEN is supported only by the ACMPHS0. ACMPHSn.CMPCTL.CTESN (n = 1 to 5) must be set to 0.

Note: Set this register before setting registers in the POEG when using comparator output as a POEG source.

The CMPCTL register controls the ACMPHS operation, enables or disables the ACMPHS output, selects the noise filter, selects the valid edge of the interrupt signal, and selects the interrupt.

注1。更改 CDFS[1:0] 和 CINV 位之前禁用 ACMPHS 输出（COE= 0)。
注2。如果更改 CDFS[1:0] 和 CINV 位,则可能会生成 ACMPHS 中断请求和 ELC 事件。在更改这些位之前,将 ELSRn 寄存器设置为 0（ACMPHS 输出未链接）。更改这些位后,将 IELSRn 寄存器中的 IR 标志清除为 0 以清除中断状态。

注3。CDFS[1:0]位从00b（未使用噪声滤波器）更改为00b以外的值（使用噪声滤波器）,则进行四次采样并更新滤波器输出,然后使用ACMPHS中断请求或ELC事件。
注4。启用后需要稳定等待时间才能允许 ACMPHS 运行（HCMPON = 1)。ACMPHS 的运行稳定等待时间为 300 ns。

注5。如果 ACMPHS 中断导致软件待机或打瞌睡的发布,则将 CSTEN 位设置为 1,将 CDFS[1:0] 位设置为 00b
模式。CSTEN 仅由 ACMPHS0 支持。ACMPHSn。CMPCTL。CTESN（n = 1 至 5)必须设置为 0。

注意:使用比较器输出作为 POEG 源时,在 POEG 中设置寄存器之前设置此寄存器。

CMPCTL寄存器控制ACMPHS操作,启用或禁用ACMPHS输出,选择噪声滤波器,选择中断信号的有效边缘,选择中断。

Note 1. When ACMPHS operation is enabled (HCMPON = COE = 1) but the noise filter is not in use (CDFS[1:0] = 00b), design the software so that the CMPMON bit is read twice and the values are only used after the two consecutive values match.

35.3 Operation

The ACMPHS compares a reference voltage to an analog input voltage. Operation is not guaranteed when the values of registers are changed during ACMPHS operation. Table 35.3 shows the procedures for setting the registers associated with ACMPHS.

注2。ACMPHSn 设置后,可能会发生不必要的中断,直到操作变得稳定,因此初始化事件链路 select。图 35。2 显示了 ACMPHS 操作的示例。VCOUT输出在模拟输入电压高于ACMPHS参考输入电压时变为1,在模拟输入电压低于参考电压时变为0。当ACMPHS输出改变时,输出中断请求和ELC事件。

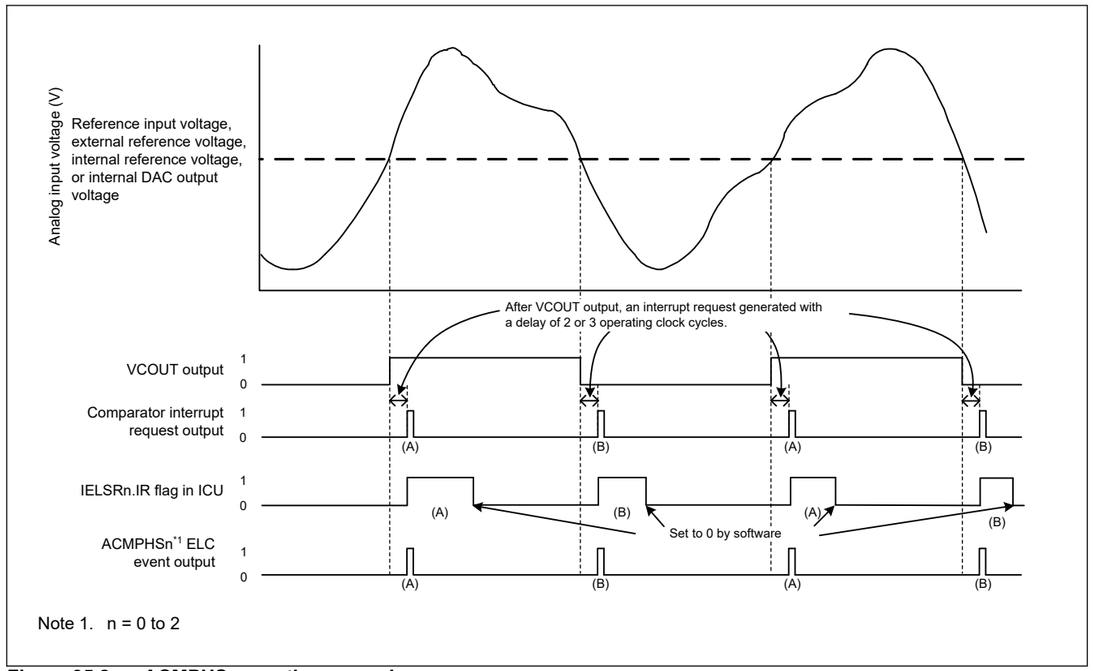

Figure 35.2 ACMPHS operation example

Figure 35.2 applies when CPOE = 1 (pin output enabled), CDFS[1:0] = 00b (filter not used), and CEG1 = CEG0 = 1 (both-edge detection selected). When CINV = 0, CEG0 = 1, and CEG1 = 0 (rising-edge detection selected for non-inversion output signal from the ACMPHS), the IELSR.IR flag changes as shown by (A) only. When CINV = 0, CEG0 = 0, and CEG1 = 1 (falling-edge detection selected for non-inversion output signal from the ACMPHS), the IR flag changes as shown by (B) only.

35.4 Noise Filter

The ACMPHS contains a noise filter. The sampling clock can be selected in the CMPCTL.CDFS[1:0] bits. The comparator output signal is sampled every sampling clock, and if the same value is sampled three times, the noise filter output at the next sampling clock cycle is used as the ACMPHS output.

Figure 35.3 shows the configuration of the noise filter and edge detector, and Figure 35.4 shows an example of noise filter and interrupt operation.

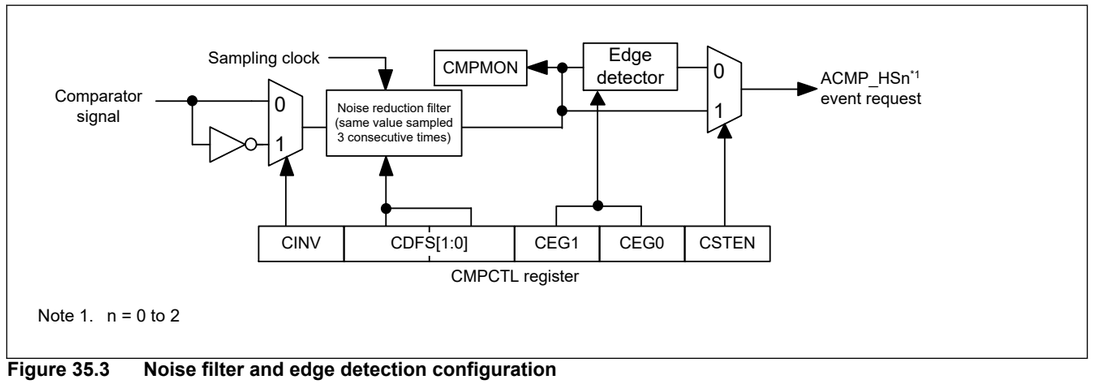

Figure 35.3 Noise filter and edge detection configuration

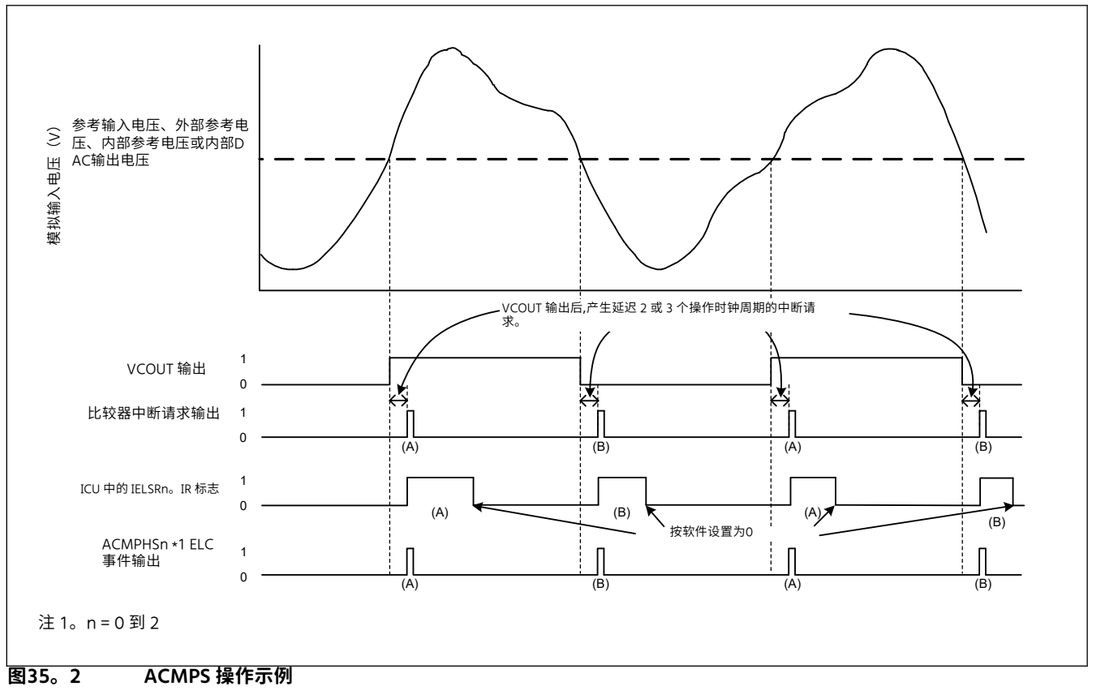

图35。2 ACMPS 操作示例

CPOE = 1（启用引脚输出）、CDFS[1:0] = 00b（未使用滤波器）和 CEG1 = CEG0 = 1（选择套管检测）时,图 35。2 适用。当 CINV = 0、CEG0 = 1 和 CEG1 = 0（为来自 ACMPHS 的非反转输出信号选择的上升沿检测）时,IELSR。IR 标志仅如（A）所示发生变化。当 CINV = 0、CEG0 = 0 和 CEG1 = 1（为来自 ACMPHS 的非反转输出信号选择的落边检测）时,IR 标志仅如（B）所示发生变化。

35。4 噪声滤波器

ACMPHS 包含一个噪声滤波器。采样时钟可以在CMPCTL。CDFS[1:0]位中选择。每个采样时钟对比较器输出信号进行采样,如果对相同值进行三次采样,则使用下一个采样时钟周期的噪声滤波器输出作为ACMPHS输出。

图35。3示出了噪声滤波器和边缘检测器的配置,图35。4示出了噪声滤波器和中断操作的示例。

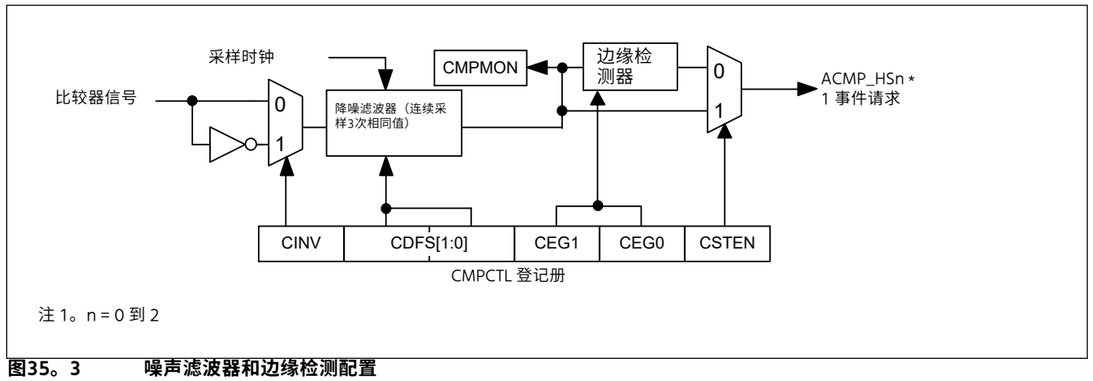

图35。3 噪声滤波器和边缘检测配置

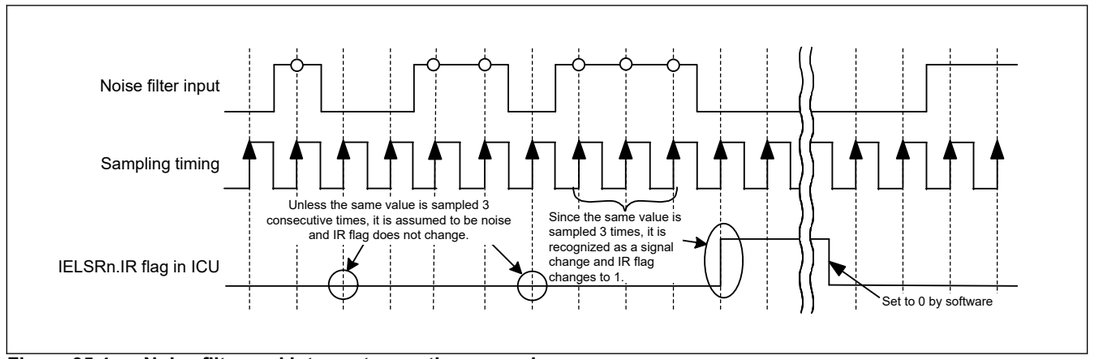

Figure 35.4 Noise filter and interrupt operation example

The operation example in Figure 35.4 applies when the CMPCTL.CDFS[1:0] bits are 01b, 10b, or 11b (noise filter used).

35.5 ACMPHS Interrupts

The ACMPHS generates four interrupt requests from sources ACMPHSn (n = 0 to 2). To use an ACMPHS interrupt, select it in the IELSR register in the Interrupt Controller Unit (ICU). Select the interrupt request in the CMPCTL.CSTEN bit, either through the edge selector, or not.

When using the ACMPHS interrupt through the edge selector, set at least one of the CMPCTL.CEG0 and CMPCTL.CEG1 bits to 1 (to a value other than 00b for no edge selection). In most cases, set the CMPCTL.CSTEN bit to 0 (output through the edge selector). Set this bit to 1 only to release Software Standby mode or Snooze mode.

To use the ACMPHS interrupt in Software Standby mode or Snooze mode, set the CMPCTL.CSTEN bit to 1 (direct output), set the CMPCTL.CDFS[1:0] bits to 00b (digital noise filter not used), and set CMPCTL.CINV as follows:

- When detecting compare result 1 to 0, set CMPCTL.CINV to 0 (comparator output not inverted).
- When detecting compare result 0 to 1, set CMPCTL.CINV to 1 (comparator output inverted).

An ACMPHS0 interrupt request can be used to release Software Standby mode or Snooze mode. ACMPHS1 and ACMPHS2 cannot be used.

For details on the register settings related to ACMPHS interrupt requests, see section 35.2.1. CMPCTL : Comparator Control Register.

35.6 ACMPHS Output to the Event Link Controller (ELC)

The ELC uses the ACMPHS interrupt request signal as an ELC event signal, enabling link operation for the preset module. To use the ACMPHS ELC event, select them in the ELSR register in the ELC. When using the ELC event request, set the CMPCTL.CSTEN bit to 0 (output through the edge selector). Also, set at least one of the CMPCTL.CEG0 and CMPCTL.CEG1 bits to 1 (to a value other than 00b for no edge selection).

35.7 ACMPHS Pin Output

The comparison result from the ACMPHS can be output to external pins. Use the CMPCTL.CINV and CPIOC.CPOE bits to set the output polarity (non-inverted or inverted output) and enable or disable output. To output the ACMPHS comparison result to the VCOUT pin, set the associated port mn pin function control register (PmnPFS) in the I/O register.

35.8 Usage Notes

35.8.1 Settings for the Module-Stop Function

ACMPHS operation can be disabled or enabled using the Module Stop Control Register. The ACMPHS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

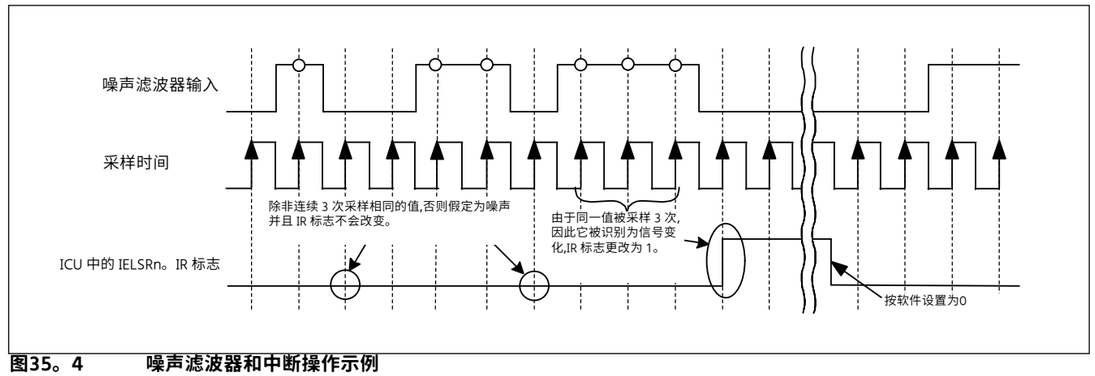

图35。4 噪声滤波器和中断操作示例

CMPCTL。CDFS[1:0] 位为 01b、10b 或 11b（使用噪声滤波器）时,适用图 35。4 中的操作示例。

35。5 ACMPHS 中断

ACMPHS 从源 ACMPHSn 生成四个中断请求（n = 0 到 2)。要使用 ACMPHS 中断,请在中断控制器单元（ICU）的 IELSR 寄存器中选择它。通过边缘选择器或不通过边缘选择器在 CMPCTL。CSTEN 位中选择中断请求。

ACMPHS 通过边缘选择器中断时, 将 CMPCTL。CEG0 和 CMPCTL。CEG1 位中的至少一个设置为 1（对于无边缘选择, 设置为 00b 以外的值）。在大多数情况下,将 CMPCTL。CSTEN 位设置为 0（通过边缘选择器输出）。将此位设置为 1 仅用于释放软件待机模式或贪睡模式。

在软件待机模式或Snooze模式下使用ACMPHS中断,将CMPCTL。CSTEN位设置为1（直接输出）,将CMPCTL。CDFS[1:0]位设置为00b（未使用数字噪声滤波器）,并将CMPCTL。CINV设置如下:

- 检测比较结果 1 到 0 时,将 CMPCTL。CINV 设置为 0（比较器输出未反转）。
- 检测比较结果 0 到 1 时,将 CMPCTL。CINV 设置为 1（比较器输出反转）。

ACMPHS0 中断请求可用于释放软件待机模式或贪睡模式。ACMPHS1 和 ACMPHS2 不能使用。

有关 ACMPHS 中断请求相关的寄存器设置的详细信息,请参阅第 35。2。1 节。CMPCTL:比较器控制寄存器。

35。6 ACMPHS 输出到事件链路控制器（ELC）

ELC 使用 ACMPHS 中断请求信号作为 ELC 事件信号,从而实现预设模块的链路操作。要使用 ACMPHS ELC 事件,请在 ELC 中的 ELSR 寄存器中选择它们。ELC 事件请求时,将 CMPCTL。CSTEN 位设置为 0（通过边缘选择器输出）。此外,将 CMPCTL。CEG0 和 CMPCTL。CEG1 位中的至少一位设置为 1（对于无边缘选择,设置为 00b 以外的值）。

35。7 ACMPHS 引脚输出

ACMPHS 的比较结果可以输出到外部引脚。使用 CMPCTL。CINV 和 CPIOC。CPOE 位设置输出极性（非反相或反相输出）并启用或禁用输出。要将 ACMPHS 比较结果输出到 VCOUT 引脚,请在 I/O 寄存器中设置关联的端口 mn 引脚函数控制寄存器（PmnPFS）。

35。8 使用说明

35。8。1 模块停止功能的设置

ACMPHS 操作可以使用模块停止控制寄存器禁用或启用。ACMPHS 最初在重置后停止。释放模块停止状态可以访问寄存器。有关详细信息,请参阅第 10 节"低功耗模式."

35.8.2 Relationship with the ADC12

Restrictions apply on the simultaneous use of the ACMPHS analog input and ADC12 analog input. For details, see section 32.6.14. Relationship Between ADC12 and ACMPHS.

35。8。2 与 ADC 的关系 12

同时使用 ACMPHS 模拟输入和 ADC12 模拟输入受到限制。详情请参见第 32。6。14 节。ADC12 和 ACMPHS 之间的关系

The DOC outputs an event signal for the ELC under the following conditions:

- The compared values either match or mismatch
- The data addition result is greater than 0xFFFF
- The data subtraction result is less than 0x0000

This signal can be used to initiate operations by other modules selected in advance and can also be used as an interrupt request. When an event signal is generated, the DOC Flag (DOCR.DOPCF) is set to 1.

36.6 Usage Notes

36.6.1 Settings for the Module-Stop State

The module Stop Control Register C (MSTPCRC) can enable or disable DOC operation. The DOC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

表 36。2 DOC 的中断请求

中断请求	状态标志	中断源
DOC 中断	DOPCF	• 数据比较的结果与 DOCR。DCSEL 位中选择的条件匹配。 • 数据相加的结果大于0xFFFF。 • 数据减法的结果小于0x0000。

36。5 向事件链路控制器（ELC）输出事件信号

DOC 在以下条件下为 ELC 输出一个事件信号:

- 比较的值要么匹配,要么不匹配
- 数据相加结果大于 0xFFFF
- 数据减法结果小于 0x0000

该信号可用于启动预先选择的其他模块的操作,也可用作中断请求。当生成事件信号时,DOC标志（DOCR。DOPCF）被设置为1。

37.2.2 PARIOAD : SRAM Parity Error Operation After Detection Register

Base address: SRAM = 0x4000_2000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation After Detection 0: Non-maskable interrupt 1: Reset	R/W

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The PARIOAD register controls the operation on detection of a parity error. The SRAM Protection Register (SRAMPRCR) protects this register against writes. Always set the SRAMPRCR bit in SRAMPRCR to 1 before writing to this bit. Do not write to the PARIOAD register while accessing the SRAM.

OAD bit (Operation After Detection)

The OAD bit specifies the generation of either a reset or non-maskable interrupt when a parity error is detected. The OAD bit is commonly used for SRAM0 (without ECC).

37.2.2 PARIOAD:检测寄存器后 SRAM 奇偶校验错误操作

基本地址: SRAM = 0x4000_2000

偏移地址: 0x00

位位置:	7	6	5	4	3	2	1	0
位字段:	—	—	—	—	—	—	—	OAD
重置后的值:	0	0	0	0	0	0	0	0

位	符号	功能	R/W
0	OAD	检测后操作 0:不可屏蔽中断 1:重置	R/W

注: 如果安全属性配置为安全:
- 允许安全访问和非安全读取访问
- 非安全写访问被忽略,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全访问。

PARIOAD 寄存器控制检测奇偶校验错误的操作。SRAM 保护寄存器（SRAMPRCR）保护此寄存器免遭写入。在写入此位之前,请务必将 SRAMPRCR 中的 SRAMPRCR 位设置为 1。访问 SRAM 时请勿写入 PARIOAD 寄存器。

OAD 位（检测后操作）

OAD 位指定检测到奇偶校验错误时重置或不可屏蔽中断的生成。OAD 位通常用于 SRAM0（不带 ECC）。

37.2.3 SRAMPRCR : SRAM Protection Register

Base address: SRAM = 0x4000_2000

Offset address: 0x04

Bit position:	7						1	0
Bit field:	KW[6:0]							SRAMPRCR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRAMPRCR	Register Write Control 0: Disable writes to protected registers 1: Enable writes to protected registers	R/W
7:1	KW[6:0]	Write Key Code These bits enable or disable writes to the SRAMPRCR bit	W

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

SRAMPRCR bit (Register Write Control)

The SRAMPRCR bit controls the write mode of the PARIOAD register. Setting the bit to 1 enables writes to the PARIOAD register. When you write to this bit, always write 0x78 to KW[6:0] bits simultaneously.

KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the SRAMPRCR bit. When you write to the SRAMPRCR bit, always write 0x78 to these bits simultaneously. When a value other than 0x78 is written to KW[6:0], the SRAMPRCR bit is not updated. The KW[6:0] bits are always read as 0x00.

37.2.4 SRAMWTSC : SRAM Wait State Control Register

Base address: SRAM = 0x4000_2000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SRAM0WTEN
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	SRAM0WTEN	SRAM0 wait enable 0: No wait 1: Add wait state in read access cycle to SRAM0	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

This register can be rewritten only when the SRAMPRCR2 bit in the SRAMPRCR2 register is 1.

The protection register (SRAMPRCR2) protects this register against writing. Change the effective bit in the protection register (SRAMPRCR2) to write in this register.

Do not write to SRAMWTSC while access to SRAM is in progress.

37。2。3 SRAMPRCR:SRAM 保护寄存器

基本地址: SRAM = 0x4000_2000

偏移地址: 0x04

位位置:	7						1	0
位字段:	KW[6:0]							SRAMPRCR
重置后的值:	0	0	0	0	0	0	0	0

位	符号	功能	R/W
0	SRAMPRCR	注册写入控制 0:禁用写入受保护寄存器 1:启用写入受保护寄存器	R/W
7:1	KW[6:0]	编写密钥代码 这些位启用或禁用对 SRAMPRCR 位的写入	W

注: 如果安全属性配置为安全:
- 允许安全访问和非安全读取访问
- 非安全写访问被忽略,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全访问。

SRAMPRCR 位（注册写入控制）

SRAMPRCR 位控制 PARIOAD 寄存器的写入模式。将位设置为 1 可以写入 PARIOAD 寄存器。当您写入此位时,始终同时写入 0x78 至 KW[6:0] 位。

KW[6:0] 位（编写密钥代码）

KW[6:0] 位启用或禁用对 SRAMPRCR 位的写入。当您写入 SRAMPRCR 位时,始终写入 0x78 同时到这些位。0x78 以外的值写入 KW[6:0] 时,SRAMPRCR 位不会更新。KW[6:0] 位始终读作 0x00。

37。2。4 SRAMWTSC:SRAM 等待状态控制寄存器

基本地址: SRAM = 0x4000_2000

偏移地址: 0x08

位位置:	7	6	5	4	3	2	1	0
位字段:	—	—	—	—	—	—	—	SRAM0WTEN
重置后的值:	0	0	0	0	0	0	0	1

位	符号	功能	R/W
0	SRAM0WTEN	SRAM0 等待启用 0:不等了 1:将读取访问周期中的等待状态添加到SRAM0	R/W
7:1	—	这些位读作 0。写入值应为 0。	R/W

注: 如果安全属性配置为安全:
- 允许安全访问和非安全读取访问
- 非安全写访问被忽略,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全访问。

仅当 SRAMPRCR2 寄存器中的 SRAMPRCR2 位为 1 时,才能重写该寄存器。

保护寄存器（SRAMPRCR2）保护该寄存器免于写入。将保护寄存器（SRAMPRCR2）中的有效位更改为在此寄存器中写入。

在访问 SRAM 期间,请勿写信给 SRAMWTSC。

SRAM0WTEN bit (SRAM0 wait enable)

This bit sets the wait cycle to the operation region in SRAM0 (Both parity and ECC areas). When it is set 1 in the SRAM0WTEN bit, 1 wait cycle is inserted into the read cycle of operation region in SRAM0. And 1 wait cycle is also inserted between the “write to read/write” sequential cycle in the same region of SRAM0. When read access frequency is more than 100 MHz, it is necessary to set 1 wait cycle in SRAM0WTEN bit.

37.2.5 SRAMPRCR2 : SRAM Protection Register 2

Base address: SRAM = 0x4000_2000

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	KW[6:0]							SRAMPRCR2
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRAMPRCR2	Register Write Control 0: Disable writes to the protectedregisters 1: Enable writes to the protected registers	R/W
7:1	KW[6:0]	Write Key Code These bits enable or disable writes to the SRAMPRCR2 bit	W

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

SRAMPRCR2 bit (Register Write Control)

The SRAMPRCR2 bit controls the write mode of the SRAMWTSC register. Setting the bit to 1 enables writes to the SRAMWTSC register. When you write to this bit, always write 0x78 to KW[6:0] at the same time.

KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the SRAMPRCR2 bit. When you write to SRAMPRCR2 bit, always write 0x78 to these bits at the same time. When a value other than 0x78 is written to KW[6:0], the SRAMPRCR2 bit is not updated. The KW[6:0] bits are always read as 0x00.

SRAM0WTEN 位（SRAM0 等待启用）

该位将等待周期设置为 SRAM0 中的操作区域（奇偶校验和 ECC 区域）。SRAM0WTEN 位中设置为 1 时,在 SRAM0 中将 1 个等待周期插入到操作区域的读取周期中。并且在 SRAM0 同一区域中的 “写入到读/写” 顺序周期之间也插入了 1 个等待周期。当读取访问频率超过100MHz时,需要在SRAM0WTEN位中设置1个等待周期。

If the security attribution is configured as Non-secure:

The ECC Protection Register 2 (ECCPRCR2) protects this register against writes. Before writing to this bit, set the ECCPRCR2 bit in the ECCPRCR2 register to 1 (write protection disabled). Do not write to the ECCETST register while accessing the SRAM.

TSTBYP bit (ECC Bypass Select)

The TSTBYP bit enables direct access to the ECC code by bypassing the ECC function. When the ECC bypass function is used, the ECCMOD[1:0] bits in the ECCMODE register are set to 00b. The ECC must be accessed in 32 bits using the same address for 32-bit data. The ECC code is assigned to the lower 7 bits of the 32-bit data. When writing the ECC code, the upper 25 bits are ignored. When reading the ECC code, the upper 25 bits are undefined.

Note: For details of ECC test, see section 37.3.4. ECC Decoder Testing.

The ECC Protection Register (ECCPRCR) protects this register against writes. Before writing to this bit, set the ECCPRCR bit in the ECCPRCR register to 1 (write protection disabled). Do not write to the ECCOAD register while accessing the SRAM.

OAD bit (Operation After Detection)

The OAD bit selects whether to generate a reset or a non-maskable interrupt when an ECC error is detected. The OAD bit in the ECCOAD register is used for SRAM0 (ECC area).

37.3 Operation

37.3.1 Module Stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

SRAM0 is controlled by SRAM0 bit in MSTPCRA register and, in the case of 1, SRAM0 becomes the clock stop state.

注: 如果安全属性配置为安全:

- 非安全写访问被忽略,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全访问。

ECC 保护寄存器 2（ECCPRCR2）保护该寄存器免遭写入。在写入此位之前,将 ECCPRCR2 寄存器中的 ECCPRCR2 位设置为 1（禁用写保护）。访问 SRAM 时请勿写入 ECCETST 寄存器。

TSTBYP 位（ECC 旁路选择）

TSTBYP 位能够绕过 ECC 函数直接访问 ECC 代码。ECC旁路函数时,将ECCMODE寄存器中的ECCMOD[1:0]位设置为00b。32 位数据必须使用相同的地址以 32 位访问 ECC。ECC代码分配给32位数据的较低7位。ECC代码时,忽略了上面的25位。ECC代码时,上面的25位是未定义的。

注: ECC 测试的详细信息,请参见第 37。3。4 节。ECC 解码器测试。

注: 如果安全属性配置为安全:

ECC 保护寄存器（ECCPRCR）保护该寄存器免遭写入。在写入此位之前,将 ECCPRCR 寄存器中的 ECCPRCR 位设置为 1（禁用写保护）。访问 SRAM 时请勿写入 ECCOAD 寄存器。

OAD 位（检测后操作）

OAD 位在检测到 ECC 错误时选择是否生成重置或不可屏蔽中断。ECCOAD寄存器中的OAD位用于SRAM0（ECC区域）。

37。3 操作

37。3。1 模块停止功能

通过设置模块停止控制寄存器 A（MSTPCRA）以停止向 SRAM 提供时钟信号,可以降低功耗。

SRAM0 由 MSTPCRA 寄存器中的 SRAM0 位控制,在 1 的情况下,SRAM0 成为时钟停止状态。

The SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The SRAM operates after a reset.

SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to SRAM is in progress.

Access to the SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see section 10, Low Power Modes.

37.3.2 Correction of ECC errors

Enabling and disabling of ECC error correction can be selected through ECCMODE register setting. In the initial state, ECC error correction is disabled. The ECC check type is SEC-DED (Single-Error Correction and Double-Error Detection Code).

When ECC function is enabled, 7-bit check bits are appended to 32-bit data for writing. For reading, 39-bit (data: 32 bits, check bits: 7 bits) data is read out from the SRAM (ECC area).

When ECC function is enabled and error checking is selected by setting ECCMOD[1:0] in the ECCMODE register to 00b, error correction is done if a 1-bit error occurs and the ECC1ERR bit in the ECC1STS register is set to 1 if the E1STSEN bit in the ECC1STSEN register is 1. If a 2-bit error occurs, error detection is done and the ECC2ERR bit in the ECC2STS register is set to 1, though error correction is not performed.

When ECC function is enabled and the error checking is disable, error correction is done if a 1-bit error occurs but ECC1ERR bit in the ECC1STS register is not updated although E1STSEN bit in the ECC1STSEN register is 1. If a 2-bit error occurs, this error is detected but the ECC2ERR bit in the ECC2STS register is not updated, and error correction is not performed.

When ECC function is disable, neither error correction nor error detection is done although 1-bit or 2-bit error occur.

So ECC1ERR bit and ECC2ERR bit are not updated.

There is no way to confirm the location where the error was found. Therefore, when after the occurrence of an error, update all the data.

When updating all the data after the occurrence of an error, the 32-bit data writing is only supported.

Since the SRAM data is undefined after power on and release from Deep Software Standby mode, accessing the SRAM when ECC function is enabled and error checking is selected causes an ECC error to occur. Therefore, before using ECC function, initial writing with 32-bit data size to the area to be used in the SRAM should be done.

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.

37.3.3 ECC Error Interrupt Function

When ECC function is enabled and error checking is applied to the SRAM (ECC area), an ECC error occurs when either the ECC2ERR bit in the ECC2STS register or the ECC1ERR bit in the ECC1STS register becomes 1 to indicate that ECC checking revealed a 2-bit error or a 1-bit error, respectively.

An ECC erroris output with a pulse width of ICLK.When the ECC 1-bit error is to be masked, set the ECC1STSEN.E1STSEN bit to 0 to disable updating of the ECC1ERR bit. An ECC error will not be generated while ECC function is disabled or when ECC function is enabled but error checking is not selected.

ECC error can choose non maskable interrupt or reset by ECCOAD register. When set 1 in the OAD bit of the ECCOAD register, ECC error is output to the Reset function. When set 0 in the OAD bit of the ECCOAD register, ECC Error interrupt is output to the ICU as non-maskable interrupt.

37.3.4 ECC Decoder Testing

Figure 37.1 shows the ECC decoder testing.

因此,通过停止时钟信号的供应,SRAM 被置于模块停止状态。SRAM 在重置后运行。

如果 SRAM 处于模块停止状态,则无法访问。在访问 SRAM 时不应过渡到模块停止状态。

禁止在模块停止状态下访问 SRAM。如果尝试访问,则不能保证正确操作。

MSTPCRA寄存器的详细信息,请参见第10节低功耗模式.

37。3。2 ECC 错误的更正

ECC纠错的启用和禁用可以通过ECCMODE寄存器设置来选择。在初始状态下,ECC纠错被禁用。ECC检查类型为SEC-DED（单误差校正和双误差检测代码）。ECC 函数启用时,7 位校验位附加到 32 位数据中进行写入。为了读取,从 SRAM（ECC 区域）读出 39 位（数据:32 位,校验位:7 位）数据。

ECC 函数被启用,并且通过将 ECCMODE 寄存器中的 ECCMOD[1:0] 设置为 00b 来选择错误检查时,如果发生 1 位错误,并且如果 ECC1STSEN 寄存器中的 ECC1STSEN 位为 1,则进行纠错。如果发生 2 位错误,则完成错误检测并将 ECC2STS 寄存器中的 ECC2ERR 位设置为 1,但不会执行纠错。

当启用ECC功能并且禁用错误检查时,如果发生1位错误但ECC1STS寄存器中的ECC1ERR位未更新,尽管ECC1STSEN寄存器中的E1STSEN位为1,则进行纠错。如果发生2位错误,则检测到该错误,但不会更新ECC2STS寄存器中的ECC2ERR位,也不会执行纠错。

ECC 功能被禁用时,尽管会出现 1 位或 2 位错误,但不会进行纠错或错误检测。

所以ECC1ERR位和ECC2ERR位没有更新。

没有办法确认发现错误的位置。因此,当发生错误后,更新所有数据。

发生错误后更新所有数据时,仅支持32位数据写入。

由于SRAM数据在Deep Software Standby模式上电和释放后未定义,因此在启用ECC功能并选择错误检查时访问SRAM会导致ECC错误发生。因此,在使用ECC函数之前,应先对SRAM中使用的区域进行32位数据大小的初始写入。

当在写访问之后连续执行读访问时,优先执行读访问。因此,在初始化期间,不要在写访问之后连续执行读访问。

37。3。3 ECC 错误中断功能

当启用 ECC 函数并将错误检查应用于 SRAM（ECC 区域）时,当 ECC2STS 寄存器中的 ECC2ERR 位或 ECC1STS 寄存器中的 ECC1ERR 位变为 1 以指示 ECC 检查显示 2 位时,就会发生 ECC 错误分别是错误或 1 位错误。

脉冲宽度为 ICLK 的 ECC 错误输出。当要屏蔽 ECC 1 位错误时,将 ECC1STSEN。E1STSEN 位设置为 0 以禁用 ECC 1ERR 位的更新。ECC 函数被禁用时或当启用 ECC 函数但没有选择错误检查时,不会生成 ECC 错误。

ECC 错误可以选择不可屏蔽的中断或由 ECCOAD 寄存器重置。ECCOAD寄存器的OAD位中设置1时,ECC错误被输出到复位函数。ECCOAD 寄存器的 OAD 位中设置为 0 时,ECC 错误中断作为不可屏蔽中断输出到 ICU。

37.3.5 Parity Calculation Function

The IEC60730 standard requires the checking of SRAM data. When data is written, a parity bit is added to every 8-bit data in the SRAM which has 32-bit data width, and when data is read, the parity is checked. When a parity error occurs, a parity-error notification is generated. This function can also be used to trigger a reset.

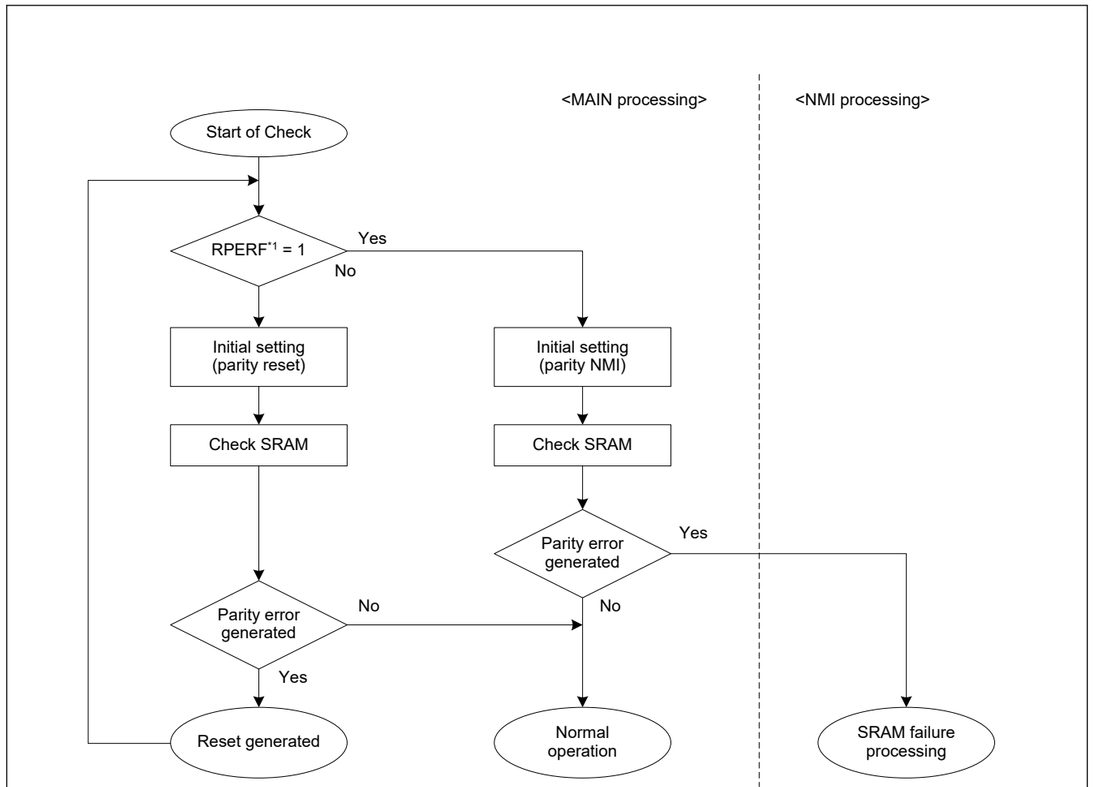
37。3。5 奇偶校验计算函数

IEC60730标准要求对SRAM数据进行检查。写入数据时,SRAM中每8位数据添加一个奇偶校验位,数据宽度为32位,读取数据时检查奇偶校验位。当发生奇偶校验错误时,会生成奇偶校验错误通知。该函数还可用于触发重置。

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the PARIOAD register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

Parity errors can be occasionally caused by noise. To confirm whether the cause of the parity error is noise or corruption, follow the parity check flows shown in Figure 37.2 and Figure 37.3.

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.



Note 1. RPERF: SRAM Parity Error Reset Detect Flag (RSTSR1.RPERF bit)

Figure 37.2 Flow of SRAM parity check when SRAM parity reset is enabled

奇偶校验错误通知可以指定为不可屏蔽中断或 PARIOAD 寄存器的 OAD 位中的重置。OAD位设置为1时,奇偶校验误差输出到复位函数。OAD位设置为0时,奇偶校验误差作为不可屏蔽中断输出到ICU。

奇偶校验误差有时可能是由噪声引起的。要确认奇偶校验错误的原因是噪声还是损坏,请按照图 37。2 和图 37。3 . 所示的奇偶校验流程进行操作

当在写访问之后连续执行读访问时,优先执行读访问。因此,在初始化期间,不要在写访问之后连续执行读访问。

37.3.6 TrustZone Filter function

There are two types of TrustZone Filter function for SRAM.

- TrustZone Filter for SRAM register protection
- TrustZone Filter for SRAM memory protection

37.3.6.1 TrustZone Filter for SRAM register protection

SRAM registers can be protected with a Security Attribution (SA) from Non-secure access. When SA indicates that SRAM registers are secure status, non-secure access cannot overwrite them because TrustZone Filter detects finds an error and protects the write access. SA for SRAM registers is just one to be used commonly among SRAM registers.

Table 37.2 Register protection (1 of 2)

SA	Access status	Write access	Read access
Secure	Secure	Permit	Permit
	Non-secure	TrustZone Filter error Protected	Permit

37。3。6 TrustZone 过滤器功能

SRAM 有两种类型的 TrustZone Filter 函数。

用于 SRAM 寄存器保护的 ● TrustZone 过滤

用于 SRAM 内存保护的 ● TrustZone 过滤器

37。3。6。1 用于 SRAM 寄存器保护的 TrustZone 过滤器

SRAM 寄存器可以通过安全属性（SA）受到非安全访问的保护。SA 指示 SRAM 寄存器是安全状态时,非安全访问无法覆盖它们,因为 TrustZone Filter 检测到发现错误并保护写访问。SRAM 寄存器的 SA 只是 SRAM 寄存器中常用的一种。

表 37。2 注册保护(2 中的 1)

SA	访问状态	写访问	读访问
安全	安全	许可	许可
	非安全	TrustZone 过滤器错误受保护	许可

Table 37.2 Register protection (2 of 2)

SA	Access status	Write access	Read access
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

When TrustZone Filter error for SRAM register access occurs, no error notification and no error response occurs.

37.3.6.2 TrustZone Filter for SRAM memory protection

SRAM memory, for example, SRAM0 include ECC region and Parity can be divided into Secure/Non secure callable/Non secure status with Memory Security Attribution (MSA) and can be protected from Non-secure access. When MSA indicates that SRAM memory region are Secure or Non secure callable status, Non-secure access cannot overwrite them.

Table 37.3 Memory protection

SA	Access status	Write access	Read access
Secure / Non secure callable	Secure	Permit	Permit
	Non-secure	TrustZone Filter error • Protected • Error response occurs	TrustZone Filter error • Read data is 0 • Error response occurs
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

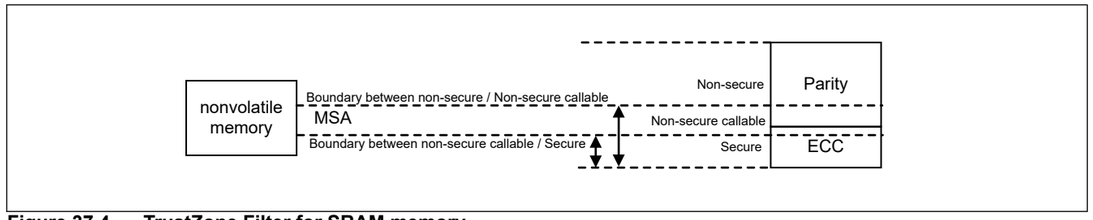

Figure 37.4 TrustZone Filter for SRAM memory

When TrustZone Filter error for SRAM memory access occurs, an error notification which become Reset request or NMI request occurs. See section 40.2. Arm TrustZone Security .

37.3.7 Interrupt Source

The SRAM interrupt source includes an ECC error, Parity error and TrustZone filter error. ECC error and Parity error can choose non-maskable interrupt or reset by OAD bit. When the debugger is connected, reset and non-maskable interrupt are maskable. Also, if these masks are set by the debugger, each status register is not set even if an ECC error occurs. For details on the debug mode, see section 2, CPU.

Name	Interrupt source	DTC activation	DMAC activation
ECCERR	ECC error (ECC operation region in SRAM0)	Not possible	Not possible
PARITYERR	Parity error	Not possible	Not possible

37.3.8 Wait state

Depending on the operating frequency of ICLK, the WAIT setting for SRAM access has the following conditions:

[ICLK frequency] (SRAM0):

- 100 MHz ≥ ICLK = No wait

37。3。6。2 用于 SRAM 内存保护的 TrustZone 过滤器

SRAM 内存,例如,SRAM0 包括 ECC 区域,Parity 可以分为具有内存安全归属（MSA）的安全/非安全可调用/非安全状态,并且可以免受非安全访问。MSA 指示 SRAM 内存区域为安全或非安全可调用状态时,非安全访问无法覆盖它们。

当 SRAM 内存访问的 TrustZone Filter 错误发生时,会发生成为重置请求或 NMI 请求的错误通知。参见第 40。2 节。Arm TrustZone 安全 .

37。3。7 中断源

SRAM 中断源包括 ECC 错误、Parity 错误和 TrustZone 过滤器错误。ECC 错误和奇偶校验错误可以选择不可屏蔽的中断或通过 OAD 位重置。当调试器连接时,重置和不可屏蔽中断是可屏蔽的。另外,如果调试器设置了这些掩码,则即使发生ECC错误,也不会设置每个状态寄存器。有关调试模式的详细信息,请参阅第 2 节 CPU .

37.3.10 ECC encode specification

The following table shows ECC encoding specifications. Add the ECC cord (eout [6:0]) formed by the following calculating formula to higher 7 bits (din [38:32]) of write data and write in it at SRAM.

3	DFAE	Data Flash Memory Access Violation Flag 0: No data flash memory access violation has occurred 1: A data flash memory access violation has occurred.	R/W*1
4	CMDLK	Command Lock Flag 0: The flash sequencer is not in the command-locked state 1: The flash sequencer is in the command-locked state.	R
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	CFAE	Code Flash Memory Access Violation Flag 0: No code flash memory access violation has occurred 1: A code flash memory access violation has occurred.	R/W*1

Note 1. Only 0 can be written to clear the flag after 1 is read.

The FASTAT register indicates whether a code flash or data flash memory access violation has occurred. If any of the CFAE, CMDLK, and DFAE bits is set to 1, the flash sequencer enters the command-locked state (see section 38.11.2. Error Protection). To release it from the command-locked state, issue a status clear command or Forced Stop command to the flash sequencer.

DFAE bit (Data Flash Memory Access Violation Flag)

The DFAE bit indicates whether a data flash memory access violation occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the data flash P/E mode are as follows:

- The setting of the FSADDR or FEADDR register is the reserved portion of the data area
- FACI commands of non-secure access are issued while the setting of the FSADDR or FEADDR register is the secure region address.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1
- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CMDLK bit (Command Lock Flag)

The CMDLK bit indicates that the flash sequencer is in the command-locked state.

[Setting conditions]

- The flash sequencer detects an error and enters the command-locked state.

[Clearing conditions]

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CFAE bit (Code Flash Memory Access Violation Flag)

The CFAE bit indicates whether a code flash memory access violation has occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

命令	地址边界
序（代码闪存）	128字节的
序（数据闪存）	4、8、16 字节

FSADDR[31:0] bits (Start Address for FACI Command Processing)

The FSADDR[31:0] bits specify the start address for FACI command processing. Bits [31:24] are ignored in FACI command processing for the code flash memory. Bits [31:17] are ignored in FACI command processing for the data flash memory. Bits associated with the address bits of lower order than the address boundary listed in Table 38.4 are also ignored.

For information on the addresses of the code flash memory and the data flash memory, see section 38.2. Structure of Memory.

For information on the addresses of the configuration setting, see section 38.9.3.15. Configuration Set Command.

38.4.13 FEADDR : FACI Command End Address Register

Bit field:	FEADDR[31:0]
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	FEADDR[31:0]	End Address for FACI Command Processing	R/W*1

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that bit [0] and bit [1] are read-only.

The FEADDR register specifies the end address of the target area for Multi Block Erase and Blank Check command processing. When incremental mode is selected as the addressing mode for Blank Checking (when FBCCNT.BCDIR = 0), the address specified in the FSADDR register should be equal to or smaller than the address in the FEADDR register. Conversely, the address in the FSADDR register should be equal to or larger than the address in the FEADDR register when decremental mode is selected as the addressing mode for Blank Check (i.e. when FBCCNT.BCDIR = 1). If the BCDIR, FSADDR, and FEADDR bit settings are inconsistent with the specified rules, the flash sequencer enters the command-locked state (see section 38.11.2. Error Protection).

The FEADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

FEADDR[31:0] bits (End Address for FACI Command Processing)

The FEADDR[31:0] bits specify the end address for Multi Block Erase and Blank Check command processing. In command processing, bits 31 to 17 and any bits that do not reach the address boundaries listed in the section 38.4.12. FSADDR : FACI Command Start Address Register are ignored.

重置后值:00
0

	符号	功能	R/W
31:0	FEADDR[31:0]	FACI 命令处理的结束地址	R/W *1

注1。FSTATR 寄存器中的 FRDY 位为 1 时,可以写入这些位。FRDY位为0时忽略对这些位的写入。

FEADDR 寄存器指定用于多块擦除和空白检查命令处理的目标区域的结束地址。当选择增量模式作为空白校验的寻址模式时（当FBCCNT。BCDIR = 0时）,FSADDR寄存器中指定的地址应等于或小于FEADDR寄存器中的地址。

相反,当选择递减模式作为空白校验的寻址模式时（即当FBCCNT。BCDIR = 1时）,FSADDR寄存器中的地址应当等于或大于FEADDR寄存器中的地址。如果 BCDIR、FSADDR 和 FEADDR 位设置与指定规则不一致,则闪存排序器进入命令锁定状态（参见第 38。11。2 节）。错误保护).

当 FSUINITR 寄存器中的 SUINIT 位设置为 1 时,FEADDR 值被初始化。它也通过重置来初始化。

FEADDR[31:0] 位（FACI 命令处理的结束地址）

7:1	—	这些位读作 0。写入值应为 0。	R/W
15:8	KEY[7:0]	密钥代码	W*3

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while the FRDY bit = 0 is ignored.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY bits is 0xD9.

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BPCN1	Block Protection for Secure Cancel 0: Block protection is enabled 1: Block protection is disabled.	R/W*1 *2
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*3

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while FRDY bit = 0 is ignored.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xB1.
Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT1 register is used to disable the block protect function for secure developer. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT1 value is initialized when the SUINIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

- The FENTRYR register value is 0x0000.

注1。FSTATR 寄存器中的 FRDY 位为 1 时,才可能写入该位。FRDY 位 = 0 时写入该位被忽略。

注2。16位写入并且写入KEY位的值为0xD9时,才可能写入该位。
注3。这些位不会保留写入的值（始终读作 0x00)。
注4。只有安全访问才能写入此寄存器。允许安全访问和非安全读取访问。非安全写访问被拒绝,但不会生成 TrustZone 访问错误。

CEPROT 位（代码闪存 P/E 模式输入保护）

CEPROT 位指定 FENTRYR 寄存器中 FRNTRYC 位的保护设置。

的【设置条件】

启用写入 FMEPROT 时将 ● 1 写入 CEPROT 位。

的【清零条件】

启用写入 FMEPROT 时将 ● 0 写入 CEPROT 位。

0	BPCN1	安全取消的阻止保护 0: 启用块保护 1: 禁用块保护。	R/W *1 *2
7:1	—	这些位读作 0。写入值应为 0。	R/W
15:8	KEY[7:0]	密钥代码	W*3

注1。FSTATR 寄存器中的 FRDY 位为 1 时,才可能写入该位。FRDY 位 = 0 时写入该位被忽略。
注2。16位写入并且写入KEY[7:0]位的值为0xB1时,才可能写入该位。
注3。这些位不会保留写入的值（始终读作 0x00)。

FBPROT1 寄存器用于禁用安全开发人员的块保护功能。当块保护设置被永久块设置锁定时,该寄存器不能禁用它。

当 FSUINITR 中的 SUINIT 位设置为 1 时,FBPROT1 值被初始化,因为 FENTRYR 值被初始化为 0x0000。它也通过重置来初始化。

BPCN1 位（用于安全取消的块保护）

BPCN1 位禁用块保护设置以获得安全功能。

的【设置条件】

- 当满足写入使能条件且 FENTRYR 不为 0x0000 时,将 1 写入 BPCN1。

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x1E.

基本地址: FACI = 0x407F_E000

偏移地址: 0xE4

位位置:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
位字段:	KEY[7:0]								PCKA[7:0]

7:0	PCKA[7:0]	闪光测序仪操作时钟通知 这些比特用于在处理时设置闪存音序器的工作频率 FACI 命令。	R/W*1*2
15:8	KEY[7:0]	密钥代码	W*3

注1。FSTATR 寄存器中的 FRDY 位为 1 时,可以写入该位。FRDY位为0时忽略写入该位。
注2。16位写入并且写入KEY[7:0]位的值为0x1E时,才可能写入这些位。
注3。这些位不会保留写入的值（始终读取 0x00)。

FPCKAR 在处理 FACI 命令时指定闪存音序器的工作频率。给定产品的最高工作频率设置为初始值。

PCKA[7:0] 位（闪存定序器操作时钟通知）

PCKA[7:0]位指定在处理FACI命令时闪存定序器的工作频率。FACI 命令之前为这些位设置所需的频率。具体来说,将频率（以 MHz 为单位）转换为二进制数并将其设置为这些位。

示例:

频率为 35。9 MHz（PCKA = 0x24）

Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics cannot be guaranteed. If the value set in these bits is greater than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics can be guaranteed but the FACI command processing time such as the time programming/erasure takes will increase. The minimum FACI command processing time is obtained when the operating frequency of the flash sequencer is the same as the PCKA value.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the PCKA bit.

Bit	Symbol	Function	R/W
7:0	FCKMHZ[7:0]	Data Flash Access Frequency Register These bits optimize the speed of reading the data flash memory.	R/W

35。9 MHz 的小数点后第一位四舍五入为整数 (= 36),并将其转换为二进制数。

如果这些位中设置的值小于闪存测序器的实际工作频率,则无法保证闪存编程/擦除特性。如果这些比特中设置的值大于闪存测序器的实际工作频率,则可以保证闪存编程/擦除特性,但是诸如编程/擦除所花费的时间之类的FACI命令处理时间将会增加。当闪光测序仪的工作频率与PCKA值相同时,获得最短FACI命令处理时间。

Note: If the security attribution is configured as Secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

This register optimizes the speed of reading the data flash memory.

Set the frequency of the peripheral module clock (FCLK) of internal peripheral bus which is the clock for access to the data flash memory, in MHz units. For example, 35.9 MHz should be rounded up and set the frequency to 36. Number of cycles required for access to the data flash memory are inserted according to the frequency. When changing the frequency of the FCLK, follow the procedure below to modify the value of the data flash access frequency register (FCKMHZ) in either of the following ways according to whether operation is at a lower frequency before or after the change.

- When changing the speed from low to high: Modify FCKMHZ. After confirming the change by reading FCKMHZ, change the frequency.
- When changing the speed from high to low: Change the frequency. After the frequency is changed, modify FCKMHZ.

38.5 Flash Cache

38.5.1 Feature of flash cache

The FCACHE (Flash Cache) speeds up read access from bus master to the flash memory. The FCACHE includes:

注意:如果安全属性配置为 Secure:
- 允许安全访问和非安全读取访问
- 忽略了非安全的写访问,并且不会生成 TrustZone 访问错误。

如果安全属性配置为非安全:
- 允许安全和非安全访问。

该寄存器优化了读取数据闪存的速度。

设置内部外围总线的外围模块时钟（FCLK）的频率,该时钟是用于访问数据闪存的时钟,以MHz为单位。例如,35。9 MHz 应四舍五入并将频率设置为 36。根据频率插入访问数据闪存所需的周期数。当改变FCLK的频率时,按照以下过程根据改变之前或之后的操作是否处于较低频率,以以下任一方式修改数据闪存访问频率寄存器（FCKMHZ）的值。

- 速度由低变高时: 修改 FCKMHZ 读取 FCKMHZ 确认改变后, 改变频率。
- 将速度由高变低时: 改变频率。更改频率后,修改FCKMHZ。

38.6.1 ID Code Protection

This function prohibits programming and on-chip debugging. The device validates or invalidates the ID code and determines the ID code based on an ID code stored in the flash memory. When ID code protection is enabled, the ID code sent from the host is compared with the ID code in the flash memory to determine whether they match. Programming and on-chip debugging are enabled only when the two match. The ID code in flash memory consists of four 32-bit words.

ID code bits [127] and [126] determine whether ID code protection is enabled and the method of authentication to use with the host. Table 38.10 shows how the ID code determines the method of authentication.

Setting bit [127]=0 or bit [126]=0 prevents Renesas from accessing the test mode. Therefore, Renesas cannot perform failure analysis unless bit [127] = 1 and bit [126] = 1 are set. To process any warranty claim, Renesas must be able to perform failure analysis.

Table 38.10 Specifications for ID code protection

Operating mode on boot up	ID code	State of protection	Operations on connection with the programmer or on-chip debugger
Serial programming mode (SCI/SWD boot mode) On-chip debug mode (SWD boot mode)	0xFF, …, 0xFF (All bytes = 0xFF)	Protection disabled	Connection to programmer or on-chip debugger is permitted. The connection to the programmer does not check the ID code, the ID code always matches, and the connection to the programmer is permitted. The on-chip debugger needs to send 0xFF, …, 0xFF (All bytes = 0xFF) on connection.
	Bit [127] = 1, Bit [126] = 1, and at least one of the 16 bytes are not 0xFF	Protection enabled	Matching ID code: Authentication ends and connection to the programmer or on-chip debugger is permitted. Mismatching ID code: Additional transition to the ID code protection waiting state. When the ID code sent from the programmer or the on-chip debugger is “ALeRASE” in ASCII code (0x414C_6552_4153_45FF_FFFF_FFFF_FFFF_FFFF), the content of the user flash area is erased. However, forced erasure is not executed when the SAS.FSPR*1 bit is 0 or there is a block with permanent block protection.
	Bit [127] = 1 and bit [126] = 0	Protection enabled	Matching ID code: Authentication ends and connection to the programmer or the on-chip debugger is permitted. Mismatching ID code: Additional transition to the ID code protection waiting state. Renesas cannot access the test mode.
	Bit [127] = 0	Protection enabled	ID code validation is not performed, the ID code is always mismatching, and connection to the programmer or the on-chip debugger is prohibited and Renesas cannot access the test mode.

Note 1. For details on the SAS.FSPR bit, see section 38.4.23. FSUASMON : Flash Startup Area Select Monitor Register.

38。6。1 ID 代码保护

此功能禁止编程和片上调试。设备验证或使ID码无效,并根据存储在闪存中的ID码确定ID码。ID码保护时,将从主机发送的ID码与闪存中的ID码进行比较,以确定它们是否匹配。仅当两者匹配时才启用编程和片上调试。闪存中的 ID 代码由四个 32 位字组成。

ID码位[127]和[126]确定是否启用ID码保护以及认证方法与主机一起使用。表 38。10 显示了 ID 代码如何确定身份验证方法。

位[127]=0或位[126]=0的设置阻止瑞萨访问测试模式。因此,除非设置位 [127] = 1 和位 [126] = 1,否则瑞萨无法执行故障分析。要处理任何保修索赔,瑞萨必须能够执行故障分析。

表 38。10 ID码保护的规范

串行编程模式（SCI/SWD启动模式）片上调试模式（SWD启动模式）	0xFF, ..., 0xFF（所有字节 = 0xFF）	保护已禁用	允许连接到程序员或片上调试器。与程序员的连接不检查ID代码,ID代码始终匹配,并且允许与程序员的连接。片上调试器需要在连接时发送 0xFF, ..., 0xFF（所有字节 = 0xFF）。
	位[127] = 1,位[126] = 1,并且16个字节中的至少一个不是0xFF	保护已启用	匹配 ID 代码:允许身份验证结束并连接到程序员或片上调试器。 ID码不匹配:额外过渡到ID码保护等待状态。 当从程序员或片上调试器发送的ID码为ASCII码(0x414C_6552_4153_45FF_FFFF_FFFF_FFFF）中的“ALeRASE”时,用户闪存区域的内容被擦除。 然而,强制擦除不会在执行时执行 SAS。FSPR *1 位为 0 或有一个具有永久块保护的块。
	位 [127] = 1 和位 [126] = 0	保护已启用	匹配 ID 代码:允许身份验证结束并连接到程序员或片上调试器。 ID码不匹配:额外过渡到ID码保护等待状态。瑞萨无法访问测试模式。
	位[127]=0	保护已启用	ID码验证不执行,ID码总是不匹配,禁止与程序员或片上调试器连接,瑞萨无法访问测试模式。

38.7 Overview of Functions

By using a dedicated flash-memory programmer to program the flash memory through a serial interface (serial programming) or SWD interface (on-chip debug mode), the device can be rewritten regardless of whether this is before or after it is mounted on the target system.

Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties.

Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations. Table 38.11 lists the overview of the methods of programming and the corresponding operating modes.

Table 38.11 Programming methods

Programming method	Functional overview	Operating mode
Serial programming	A dedicated flash-memory programmer through the SCI or SWD interface enables on-board programming of the flash memory after the device is mounted on the target system.	Serial programming mode
	A dedicated flash-memory programmer through the SCI or SWD interface and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	
Self-programming	A user program written to memory in advance of serial programming execution can also program the flash memory. The background operation capability makes it possible to fetch instructions or otherwise read data from the code flash memory while the data flash memory is programmed. As a result, a program resident in the code flash memory is able to program the data flash memory. For background operations that are not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while the code flash memory is being programmed by self-programming. In such cases, a program for programming from the internal SRAM must be transferred in advance and executed.	Normal operating mode
SWD programming	A dedicated flash-memory programmer or an on-chip debugger through SWD enables on-board programming of the flash memory after the device is mounted on the target system. A dedicated flash-memory programmer or an on-chip debugger through SWD and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system. Table 38.12 lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FACI command or the user program realizes each function of self-programming.

38。7 功能概述

通过使用专用闪存程序员通过串行接口（串行编程）或SWD接口（片上调试模式）对闪存进行编程,无论设备安装在目标系统之前还是之后,都可以重写设备。

此外,还纳入了禁止重写或读取写入闪存的用户程序的安全功能,这可以防止第三方伪造和非法读取程序。

用户程序编程（自编程）可用于适合目标系统上的应用程序在制造或发货后可能需要更新的应用程序。还结合了用于安全重写闪存的保护功能。此外,支持自编程过程中的中断处理,因此编程可以与外部通信等的处理同时进行,并且在各种情况下都是这种情况。表 38。11 列出了编程方法和相应操作模式的概述。

表 38。11 编程方法

编程方法	功能概述	操作模式
串行编程	通过 SCI 或 SWD 接口的专用闪存编程器可以在设备安装在目标系统上后对闪存进行板载编程。	串行编程模式
	通过 SCI 或 SWD 接口的专用闪存编程器和专用编程适配器板允许对闪存进行板外编程,例如在设备安装在目标系统上之前对其进行编程。	
自编程	在串行编程执行之前写入存储器的用户程序也可以对闪存进行编程。后台操作能力使得在对数据闪存进行编程时可以从代码闪存中获取指令或以其他方式读取数据。因此,驻留在代码闪存中的程序能够对数据闪存进行编程。 对于不可能的后台操作,当通过自编程对代码闪存进行编程时,无法获取代码闪存中的指令并且无法访问数据。在这种情况下,必须提前传输并执行来自内部SRAM的编程程序。	正常工作模式
SWD 编程	专用闪存程序员或片上调试器通过 SWD 在设备安装在目标系统上后, 能够对闪存进行板载编程。 专用闪存程序员或片上调试器通过 SWD和专用编程适配器板允许对闪存进行板外编程,例如,在设备安装在目标系统上之前对其进行编程。	片上调试模式

38.8 Operating Modes of the Flash Sequencer

The flash sequencer has three operating modes as shown in Figure 38.6. Transitions between modes are initiated by changing the value of the FENTRYR register.

When the value of the FENTRYR register is 0x0000, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. The code flash memory and data flash memory are both readable.

When the value of the FENTRYR register is 0x0001, the flash sequencer is in code flash P/E mode where the code flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is readable.

When the value of the FENTRYR register is 0x0080, the flash sequencer is in data flash P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

38。8 闪光测序仪的操作模式

闪光测序仪具有三种操作模式,如图 38。6 所示。模式之间的转换是通过更改 FENTRYR 寄存器的值来启动的。

FENTRYR 寄存器的值为 0x0000 时, 闪光测序器处于读取模式。在此模式下,它不会接收 FACI 命令。代码闪存和数据闪存都是可读的。

当FENTRYR寄存器的值为0x0001时,闪存测序器处于代码闪存P/E模式,其中代码闪存可以通过FACI命令进行编程或擦除。在此模式下,数据闪存是可读的。

当FENTRYR寄存器的值为0x0080时,闪存测序器处于数据闪存P/E模式,其中数据闪存可以通过FACI命令进行编程或擦除。在此模式下,数据闪存不可读。但是,代码闪存是可读的。

The FACI commands are issued by writing to the FACI command-issuing area (see Table 38.3). When write access as shown in Table 38.15 proceeds in the specified state, the flash sequencer executes the processing associated with the given command (see section 38.9.2. Relationship between the Flash Sequencer State and FACI Commands).

Note: WDN (N = 1, 2, …): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY bit to 0 at the start of a command processing other than the Status Clear command, and sets this bit to 1 on completion.

If the FRDYIE.FRDYIE bit setting is 1, a flash ready (FRDY) interrupt is generated when the FSTATR.FRDY bit is set to 1.

38.9.2 Relationship between the Flash Sequencer State and FACI Commands

The FACI commands are accepted according to the mode/state of the flash sequencer. FACI commands should be issued after transitioning of the flash sequencer to the code flash P/E mode or data flash P/E mode and after checking the state of the flash sequencer.

Use the FSTATR and FASTAT registers to check the state of the flash sequencer. In addition, the occurrence of errors in general can be checked by reading the CMDLK bit in the FASTAT register. The value of the CMDLK bit is the logical OR of the following bits in the FSTATR register:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR
- FLWEERR.

Table 38.16 lists the available FACI commands in each operating mode.

FACI 命令是通过写入 FACI 命令发布区域来发布的（见表 38。3)。当表 38。15 所示的写访问在指定状态下进行时,闪存排序器执行与给定命令关联的处理（参见第 38。9。2 节）。Flash 测序器状态和 FACI 命令). 之间的关系

块擦除（数据区域 6 4 字节）	2	0x20	0xD0	—	—

空白检查	2	0x71	0xD0	—	—
配置集 N = 8	11	0x40	0x08 (=N)	WD1 至 WD8	0xD0

注:WDN（N = 1, 2,…):第 N 个要编程的 16 位数据。

闪存排序器在状态清除命令以外的命令处理开始时将 FSTATR。FRDY 位清除为 0,并在完成后将该位设置为 1。

如果 FRDYIE。FRDYIE 位设置为 1,则当 FSTATR。FRDY 位设置为 1 时,会生成闪存就绪（FRDY）中断。

38。9。2 闪存测序器状态与 FACI 命令之间的关系

FACI 命令根据闪存音序器的模式/状态被接受。FACI 命令应在闪光测序器转换为代码闪光 P/E 模式或数据闪光 P/E 模式后以及检查闪光测序器的状态后发出。

使用 FSTATR 和 FASTAT 寄存器检查闪光测序器的状态。此外,一般可以通过读取FASTAT寄存器中的CMDLK位来检查错误的发生。CMDLK 位的值是 FSTATR 寄存器中以下位的逻辑 OR:

- 伊格勒
- ILGCOMERR
- FESETERR
- SECERR
- 奥特
- 错误
- PRGERR
- 弗维尔。

To issue FACI commands for the data flash memory, a transition to data flash P/E mode is required by setting the FENTRYD bit in the FENTRYR register to 1.

Figure 38.10 shows the procedure to transition to data flash P/E mode.

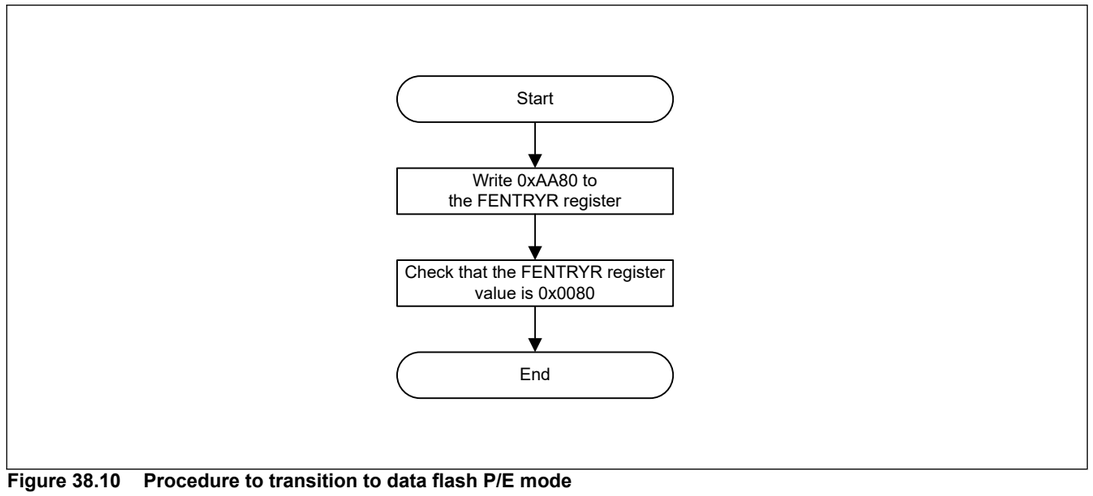

Figure 38.10 Procedure to transition to data flash P/E mode

38.9.3.5 Transition to Read Mode

To read the flash memory, a transition to read mode is required by setting the FENTRYR register to 0x0000. The transition to read mode should be made after the flash sequencer completes the processing and while operation is not in the command-locked state.

Figure 38.11 shows the procedure to transition to read mode.

38.9.3.4 过渡到数据闪存 P/E 模式

为了向数据闪存发出 FACI 命令,需要通过设置来过渡到数据闪存 P/E 模式 FENTRYR 寄存器中的 FENTRYD 位为 1。

图 38。10 显示了转换为数据闪存 P/E 模式的过程。

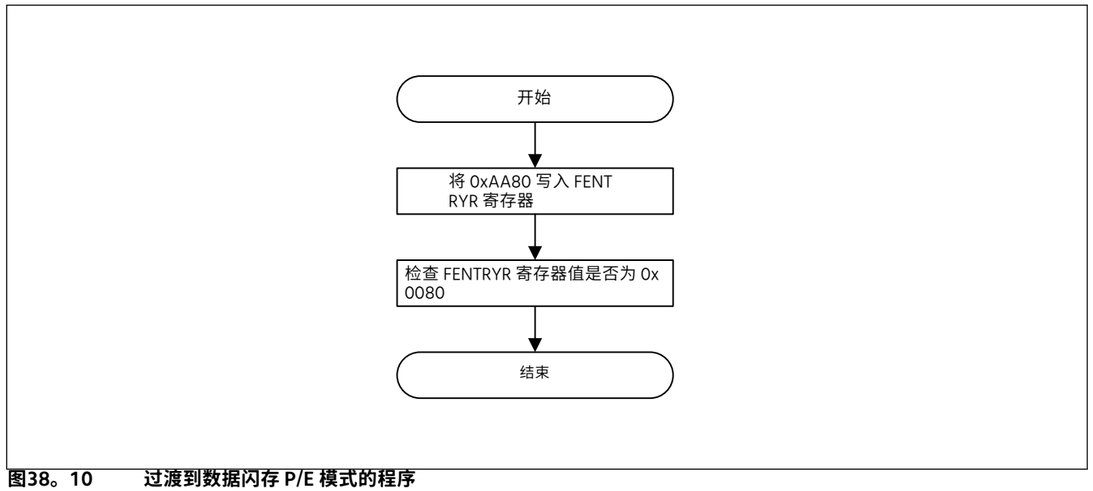

图38。10 过渡到数据闪存 P/E 模式的程序

38.9.3.5 过渡到读取模式

要读取闪存,需要通过将 FENTRYR 寄存器设置为 0x0000 来转换为读取模式。应在闪存定序器完成处理后且操作未处于命令锁定状态时过渡到读取模式。

图 38。11 显示了转换为读取模式的过程。

38.9.3.6 Recovery from the Command-Locked State

When the flash sequencer enters the command-locked state, FACI commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, forced stop command, or FASTAT register.

When the command-locked state is detected by checking for an error before issuing the P/E suspend command, the FRDY bit in the FSTATR register might be 0 even though command processing has not completed. If processing is not complete by the maximum programming/erasure time specified in the electrical characteristics, this is a timeout and the flash sequencer must be stopped with the forced stop command.

The FLWEERR bit in the FSTATR register does not change from 1 to 0 with the status clear command. When these bits are set to 1, use the forced stop command to release from the command-locked state. Bits other than FRDY and FLWEERR in FSTATR register that indicate the command-locked state can be changed from 1 to 0 with the status clear or forced stop command.

Figure 38.12 shows the recovery flow from the command-locked state.

38。9。3。6 从命令锁定状态恢复

Flash 音序器进入命令锁定状态时,FACI 命令不能被接受。要从命令锁定状态释放定序器,请使用状态清除命令、强制停止命令或 FASTAT 寄存器。

当在发出P/E挂起命令之前通过检查错误来检测到命令锁定状态时,即使命令处理尚未完成,FSTATR寄存器中的FRDY位也可能为0。如果处理未在电气特性中指定的最大编程/擦除时间内完成,则这是超时,并且必须使用强制停止命令停止闪光测序器。

FSTATR 寄存器中的 FLWEERR 位在状态清除命令下不会从 1 更改为 0。当这些位设置为 1 时,使用强制停止命令从命令锁定状态释放。FSTATR 寄存器中除 FRDY 和 FLWEERR 之外的指示命令锁定状态的位可以在状态清除或强制停止命令的情况下从 1 更改为 0。

38.9.3.7 Program Command

The program command is used for writing to the user area and data area. Before issuing the FACI program command, set the first address of the target block in the FSADDR register. Writing 0xD0 at the final access of the FACI command-issuing area starts the program command processing. If the target area of program command processing contains area that are not for writing, write 0xFFFF to the corresponding area.

Issuing the program command while the FACI internal data buffer is full leads to a wait on the peripheral bus that might affect communications performance of other peripheral modules. To avoid a wait, set the DBFULL bit in the FSTATR register to 0 when issuing the FACI command. Writing to the data area does not lead to the data buffer becoming full.

Figure 38.13 shows the usage of the program command.

38。9。3。7 程序命令

程序命令用于写入用户区域和数据区域。FACI程序命令之前,在FSADDR寄存器中设置目标块的第一个地址。FACI命令发出区域的最终访问处写入 0xD0 开始程序命令处理。如果程序命令处理的目标区域包含不用于写入的区域,则将 0xFFFF 写入相应的区域。

FACI 内部数据缓冲区已满时发出程序命令会导致在外围总线上等待,这可能会影响其他外围模块的通信性能。为了避免等待,在发出 FACI 命令时,将 FSTATR 寄存器中的 DBFULL 位设置为 0。写入数据区域不会导致数据缓冲区变满。

38.9.3.8 Block Erase Command

The block erase command is used for erasing user area or data area. The erase unit is one block. Before issuing a block erase command, set the first address of the target block to FSADDR register. Writing 0xD0 at the second write access of the FACI command triggers the FACI to start the block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

38.9.3.9 Multi Block Erase Command

The multi block erase command is used for erasing data area. The erase unit is 64, 128, or 256 bytes. Before issuing the multi block erase command, set the start address to FSADDR register and the end address to FEADDR register. Writing 0xD0 at the second write access of the FACI command triggers FACI to start the multi block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the multi block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

块擦除命令用于擦除用户区域或数据区域。擦除单元是一个块。在发出块擦除命令之前,将目标块的第一个地址设置为 FSADDR 寄存器。FACI 命令的第二个写入访问写入 0xD0 会触发 FACI 启动块擦除命令处理。可以用FSTATR寄存器的FRDY位来确认命令处理的完成。

在发出块擦除命令之前设置 FCPSR 寄存器。此外,当要切换擦除暂停模式时,必须设置 FCPSR。

38.9.3.10 P/E Suspend Command

The P/E suspend command is used to suspend programming/erasure. Before issuing a P/E suspend command, check that the CMDLK bit in the FASTAT register is 0, and that the execution of programming/erasure is performed normally. To confirm that the P/E suspend command can be received, check that the SUSRDY bit in the FSTATR register is 1. After issuing a P/E suspend command, read the CMDLK bit to confirm that no error occurs.

If an error occurs during programming/erasure, the CMDLK bit is set to 1. When programming/erasure processing has finished from the time when the SUSRDY bit is 1 to when the P/E suspend command is received, no error occurs and the

38。9。3。10 P/E 暂停命令

P/E 暂停命令用于暂停编程/擦除。P/E 挂起命令之前,检查 FASTAT 寄存器中的 CMDLK 位为 0,并且编程/擦除的执行是否正常。要确认可以接收到 P/E 暂停命令,请检查 FSTATR 寄存器中的 SUSRDY 位是否为 1。发出 P/E 暂停命令后,读取 CMDLK 位以确认没有发生错误。

如果在编程/擦除期间发生错误,则 CMDLK 位设置为 1。当从SUSRDY位为1到接收到P/E挂起命令时编程/擦除处理完成时,没有发生错误

suspended state is not entered (the FRDY bit in the FSTATR register is 1 and the ERSSPD and PRGSPD bits in FSTATR are 0).

When a P/E suspend command is received and the programming/erasure suspend processing finishes normally, the flash sequencer enters the suspended state, the FRDY bit is set to 1, and the ERSSPD or PRGSPD bit is 1. After issuing a P/E suspend command, check that the ERSSPD or PRGSPD bit is 1 and the suspended state is entered, then proceed with the subsequent flow. If a P/E resume command is issued in the subsequent flow even when the suspended state is not entered, an illegal command error occurs and the flash sequencer shifts to the command-locked state (see section 38.11.2. Error Protection).

If the erasure suspended state is entered, programming to blocks other than an erasure target block can be performed. Additionally, the programming and erasure suspended states can shift to read mode by clearing the FENTRYR register.

Figure 38.16 shows the usage of the P/E suspend command.

如果进入擦除暂停状态,则可以对除擦除目标块之外的块进行编程。

当在闪存编程期间发出 P/E suspend 命令时,闪存定序器会暂停编程处理。图 38。17 显示了暂停编程操作。当接收到编程相关命令时,闪存测序器将 FSTATR 寄存器中的 FRDY 位清除为 0 以开始编程。如果闪光测序器进入状态

in which the P/E suspend command can be received after programming starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0. If the flash sequencer receives a P/E suspend command while a programming pulse is applied, the flash sequencer continues with the pulse. After the specified pulse application time, the flash sequencer finishes pulse application, starts the programming suspend processing, and sets the PRGSPD bit in the FSTATR register to 1.

When a suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the programming suspended state. When receiving a P/E resume command in the programming suspended state, the flash sequencer clears the FRDY and PRGSPD bits to 0 and resumes programming.

Figure 38.17 shows the timing for suspension during programming.

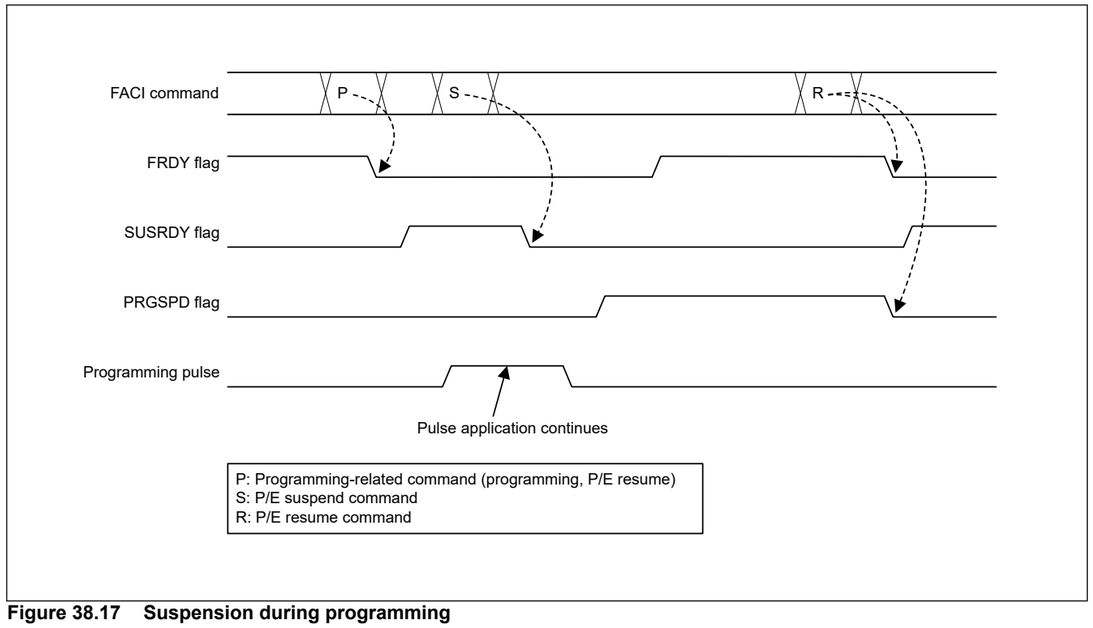

Figure 38.17 Suspension during programming

(2) Suspension during Erasure (Suspension Priority Mode)

The flash sequencer has a suspension priority mode for the suspension of erasure. Figure 38.18 shows the suspend operation of erasure when the erasure suspend mode is set to the suspension priority mode (the ESUSPMD bit in the FCPSR register is 0).

When receiving an erasure-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start erasure. If the flash sequencer enters the state in which the P/E suspend command can be received after erasure starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0.

When receiving a suspend command during erasure, the flash sequencer starts the suspend processing and sets the ERSSPD bit in the FSTATR register to 1 even when it is applying an erasure pulse. When the suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the erasure suspended state. When receiving a P/E resume command in the erasure suspended state, the flash sequencer clears the FRDY and ERSSPD bits to 0 and resumes erasure. Operations of the FRDY, SUSRDY, and ERSSPD bits at the suspension and resumption of erasure are the same, regardless of the erasure suspend mode.

The setting of the erasure suspend mode affects the control method of erasure pulses. In suspension priority mode, when receiving a P/E suspend command while erasure pulse A that has not been previously suspended is being applied, the flash sequencer suspends the application of erasure pulse A and enters the erasure suspended state. When receiving a P/E suspend command while reapplying erasure pulse A after erasure is resumed with a P/E resume command, the flash sequencer

其中编程开始后可以接收到P/E suspend命令,它将FSTATR寄存器中的SUSRDY位设置为1。

当发出 P/E 暂停命令时,闪存排序器接收该命令并将 SUSRDY 位清除为 0。如果在应用编程脉冲时闪光测序器接收到 P/E 暂停命令,则闪光测序器继续使用脉冲。指定脉冲应用时间后,闪光测序仪完成脉冲应用,开始编程暂停处理,并将FSTATR寄存器中的PRGSPD位设置为1。

当悬浮处理完成时,闪存测序器将FRDY位设置为1以进入编程悬浮状态。当接收到处于编程暂停状态的P/E恢复命令时,闪存音序器将FRDY和PRGSPD位清除为0并恢复编程。

图 38。17 显示了编程期间暂停的时间。

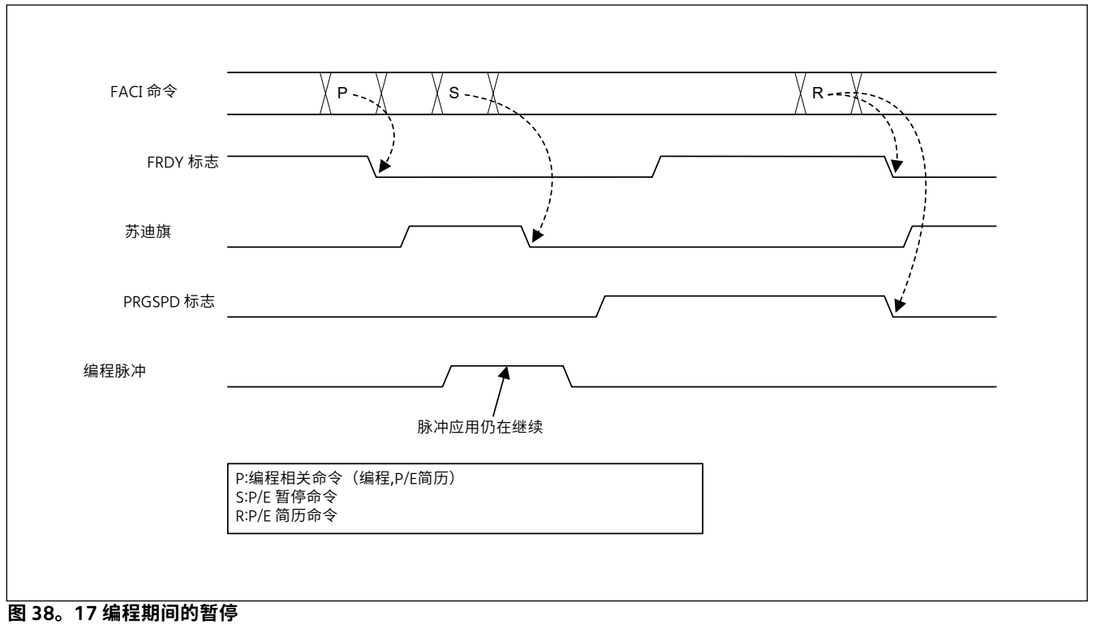

图 38。17 编程期间的暂停

(2)擦除时的悬挂（悬挂优先模式）

闪光测序仪具有用于暂停擦除的暂停优先模式。图38。18示出了当擦除暂停模式设置为暂停优先模式（FCPSR寄存器中的ESUSPMD位为0)时擦除的暂停操作。

当接收到与擦除相关的命令时,闪存测序器将 FSTATR 寄存器中的 FRDY 位清除为 0 以开始擦除。如果闪存排序器进入擦除开始后可以接收到P/E挂起命令的状态,则将FSTATR寄存器中的SUSRDY位设置为1。

当发出 P/E 暂停命令时,闪存排序器接收该命令并将 SUSRDY 位清除为 0。

当在擦除期间接收到暂停命令时,闪存测序器启动暂停处理并将FSTATR寄存器中的ERSSPD位设置为1,即使它正在应用擦除脉冲。当悬浮处理完成时,闪光测序仪将FRDY位设置为1以进入擦除悬浮状态。当接收到处于擦除暂停状态的 P/E 恢复命令时,闪存音序器将 FRDY 和 ERSSPD 位清除为 0 并恢复擦除。无论擦除暂停模式如何,FRDY、SUSRDY 和 ERSSPD 位在暂停和恢复擦除时的操作都是相同的。

擦除暂停模式的设置影响擦除脉冲的控制方法。在暂停优先模式下,当在施加先前未暂停的擦除脉冲A时接收到P/E暂停命令时,闪光测序器暂停擦除脉冲A的施加并进入擦除暂停状态。当在用P/E恢复命令恢复擦除之后在重新应用擦除脉冲A时接收到P/E暂停命令时,闪光测序器

continues to apply erasure pulse A. After the specified pulse application time, the flash sequencer finishes erasure pulse application and enters the erasure suspended state.

When the flash sequencer receives a P/E resume command next and erasure pulse B is being applied, the flash sequencer receives a P/E suspend command again, and the application of erasure pulse B is then suspended. In suspension priority mode, delays due to suspension can be minimized because the application of an erasure pulse is suspended once per pulse, and priority is given to the suspend processing.

If the interval of suspension after resume is longer than t_{REST1} (Resume time: priority on suspension, resume after the 1st suspend for the same pulse), suspend delay will be always t_{SESD1} (Suspend delay: priority on suspension, the 1st suspend for the same pulse).

If the interval of suspension after resume is shorter than t_{REST1}, suspend delay becomes either t_{SESD1} or t_{SESD2} (Suspend delay: priority on suspension, the 2nd suspend for the same pulse).

(The value of t_{REST1} / t_{SESD1} / t_{SESD2}, see section 41, Electrical Characteristics.)

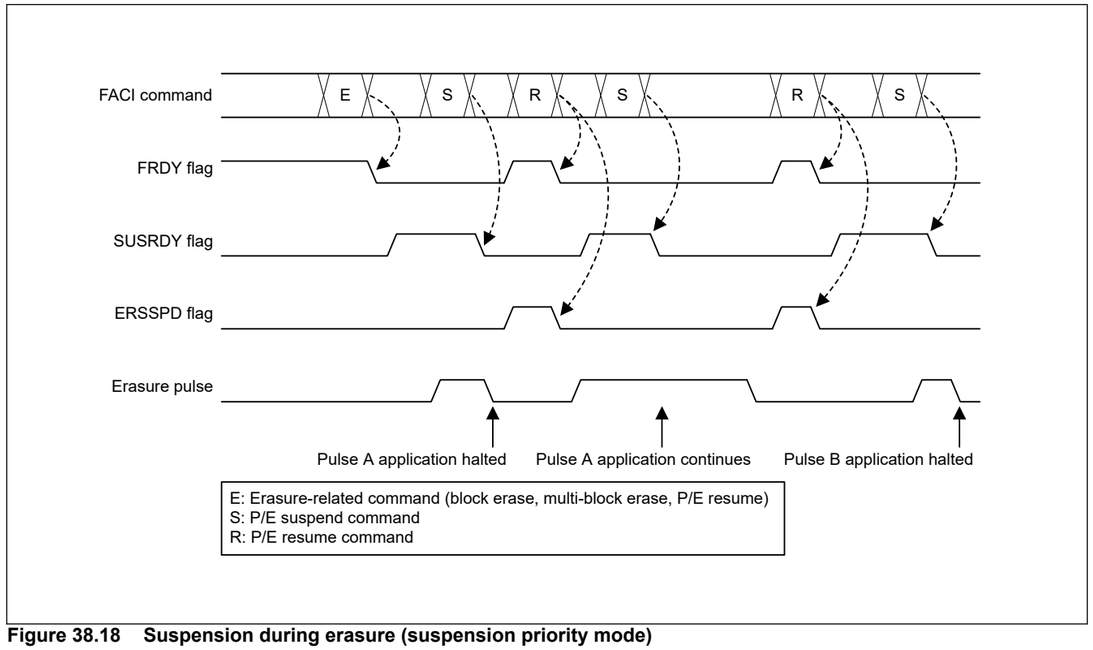

Figure 38.18 Suspension during erasure (suspension priority mode)

(3) Suspension during Erasure (Erasure Priority Mode)

The flash sequencer has an erasure priority mode for the suspension of erasure. Figure 38.19 shows the suspend operation of erasure when the erasure suspend mode is set to the erasure priority mode (the ESUSPMD bit in the FCPSR register is 1). The control method of erasure pulses in erasure priority mode is the same as that of programming pulses for the programming suspend processing.

If the flash sequencer receives a P/E suspend command while an erasure pulse is applied, the flash sequencer continues to apply the pulse. In this mode, the required time for the erasure processing can be reduced compared to the suspension priority mode because the re-application of erasure pulses does not occur when a P/E resume command is issued.

A 继续施加擦除脉冲,在规定的脉冲施加时间后,闪光测序仪完成擦除脉冲施加,进入擦除暂停状态。

当闪光测序器接下来接收到P/E恢复命令并且正在施加擦除脉冲B时,闪光测序器再次接收到P/E暂停命令,然后暂停施加擦除脉冲B。在暂停优先模式下,由于每个脉冲暂停一次擦除脉冲的应用,并且优先考虑暂停处理,因此可以最小化由于暂停造成的延迟。

如果恢复后暂停的间隔长于 tREST1（恢复时间:暂停优先,同一脉冲暂停 1 次后恢复）,则暂停延迟将始终为 tSESD1（暂停延迟:暂停优先,同一脉冲暂停 1 次）。

如果恢复后的暂停间隔短于 tREST1,则暂停延迟变为 tSESD1 或 tSESD2（暂停延迟:优先暂停,同一脉冲的第二个暂停）。

（tREST1/tSESD1/tSESD2 的值,请参见第 41 节,电气特性 .）

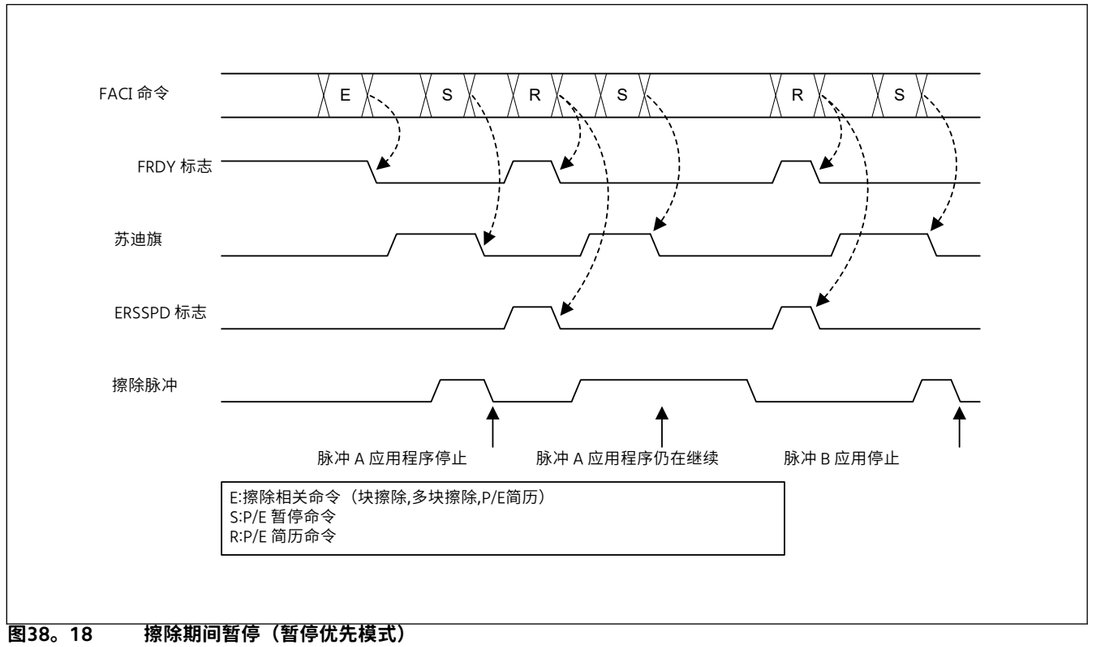

图38。18 擦除期间暂停（暂停优先模式）

(3)擦除时的悬挂（擦除优先模式）

闪光测序仪具有用于暂停擦除的擦除优先模式。图38。19示出了当擦除暂停模式设置为擦除优先模式（FCPSR寄存器中的ESUSPMD位为1)时擦除的暂停操作。
擦除优先模式下的擦除脉冲的控制方法与编程暂停处理的编程脉冲的控制方法相同。

如果闪光测序仪在施加擦除脉冲时接收到 P/E 暂停命令,则闪光测序仪继续施加脉冲。在此模式下,与暂停优先模式相比,可以减少擦除处理所需的时间,因为当发出P/E恢复命令时不会发生擦除脉冲的重新应用。

38.9.3.11 P/E Resume Command

The P/E resume command is used to resume suspended programming or erasure. 38.9.3.12 Status Clear Command

The status clear command is used to clear the command-locked state (see section 38.9.3.6. Recovery from the Command-Locked State).

You can use the status clear command to clear the following bits in the FSTATR register in the command-locked state:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR

Figure 38.21 shows usage of the status clear command.

38.9.3.13 Forced Stop Command

The forced stop command is used to forcibly end command processing by the flash sequencer. Although this command halts command processing more quickly than the P/E suspension command, values from the programming or erasure that are in progress are not guaranteed. Additionally, resumption of processing is not possible. Processing of programming or erasure that is halted by the forced stop command is also defined as one programming round.

Executing the forced stop command also initializes part of the FACI, the whole FCU, the FSTATR and FASTAT registers. This command can be used in the procedure for recovery from the command-locked state and for processing in response to a timeout of the flash sequencer (see section 38.9.3.6. Recovery from the Command-Locked State).

38.9.3.13 强制停止命令

强制停止命令用于强制结束闪存定序器的命令处理。尽管该命令比 P/E 暂停命令更快地停止命令处理,但无法保证正在进行的编程或擦除的值。此外,不可能恢复处理。被强制停止命令停止的编程或擦除的处理也被定义为一轮编程。

执行强制停止命令还初始化部分 FACI、整个 FCU、FSTATR 和 FASTAT 寄存器。

该命令可用于从命令锁定状态恢复以及响应闪存定序器的超时进行处理的过程（参见第 38。9。3。6 节）。从命令锁定状态). 恢复

Note 1. Judgment of the timeout is based on 1.1 times the maximum time of the Forced Stop command latency.
See section 41, Electrical Characteristics.

Figure 38.22 Usage flow of the forced stop command

(1) Notes on Using the Forced Stop Command during Command Issue

When using the forced stop command at the timeout occurrence by DBFULL bit of the program command, writing in the FACI command-issuing area is sometimes processed as writing in data of the program command. See Table 38.3 in section 38.3. Address Space for information on the FACI command-issuing area to force a command lock. Then issue a forced stop command with return method from the command lock status (see Figure 38.13). Locking commands is possible in any case where the unit for reading the FACI command issuing area is 8, 16, or 32 bits.

38.9.3.14 Blank Check Command

The blank check command is used to confirm that an area is in the non-programmed state. Values read from the data flash memory that have been erased but not yet programmed again that is in the non-programmed state, are undefined.

Before issuing the Blank Check command, set addressing mode, start address, and end address of the target area for Blank Check to the FBCCNT, FSADDR, and FEADDR registers. When Blank Check addressing mode is set to decremental mode (i.e. FBCCNT.BCDIR = 1), address specified in FSADDR should be equal to or larger than address in FEADDR.

On the other hand, the address in FSADDR should be equal to or smaller than address in FEADDR when Blank Check addressing mode is set to incremental mode (i.e. FBCCNT.BCDIR = 0).

If the settings of the BCDIR bit, FSADDR, and FEADDR are inconsistent, the flash sequencer enters the command-locked state. The size of the target area for Blank Check is in the range from 4 bytes to the data flash memory capacity and is set in units of 4 bytes.

Write 0x71 and 0xD0 to the FACI command-issuing area to start Blank Check. Completion of processing can be confirmed by the FRDY bit of the FSTATR register. At the end of processing, the result of Blank Check is stored in the BCST bit in the FBCSTAT register. If non-programmed data exists within the target area for Blank Check, flash sequencer stops Blank Check command operation. In this case, address of non-programmed data is indicated to FPSADDR register.

Figure 38.23 shows usage of the blank check command.

参见第 41 节,电气特性 .

图 38。22 强制停止命令的使用流程

(1) 指令发出时使用强制停止指令的注意事项

当程序命令的DBFULL位在超时发生时使用强制停止命令时,FACI命令发出区域中的写入有时被处理为程序命令的数据中的写入。参见第 38。3 节中的表 38。3。FACI命令发布区域的信息的地址空间,以强制命令锁定。然后从命令锁定状态发出带有返回方法的强制停止命令（见图 38。13)。在读取 FACI 命令发布区域的单元为 8、16 或 32 位的任何情况下,锁定命令都是可能的。

38。9。3。14 空白检查命令

空白检查命令用于确认某个区域处于非编程状态。从数据闪存读取的已擦除但尚未再次编程且处于非编程状态的值未定义。

发出空白校验命令之前,将空白校验目标区域的寻址模式、起始地址和结束地址设置为 FBCCNT、FSADDR 和 FEADDR 寄存器。Blank Check寻址模式设置为递减模式时（即。FBCCNT。BCDIR = 1),FSADDR 中指定的地址应等于或大于 FEADDR 中的地址。

FSADDR中的地址,另一方面,当空白校验寻址模式设置为增量模式时,FSADDR中的地址应等于或小于FEADDR中的地址（即。FBCCNT。BCDIR = 0)。

BCDIR位、FSADDR、FEADDR的设置不一致,则闪存定序器进入命令锁定状态。Blank Check 的目标区域的大小在从 4 字节到数据闪存容量的范围内,并以 4 字节为单位设置。

将 0x71 和 0xD0 写入 FACI 命令发布区域以开始空白检查。处理的完成可以通过 FSTATR 寄存器的 FRDY 位来确认。处理结束时,空白校验的结果存储在 FBCSTAT 寄存器中的 BCST 位中。如果空白检查的目标区域内存在非编程数据,则闪存排序器停止空白检查命令操作。在这种情况下,非编程数据的地址被指示到 FPSADDR 寄存器。

图 38。23 显示了空白检查命令的使用情况。

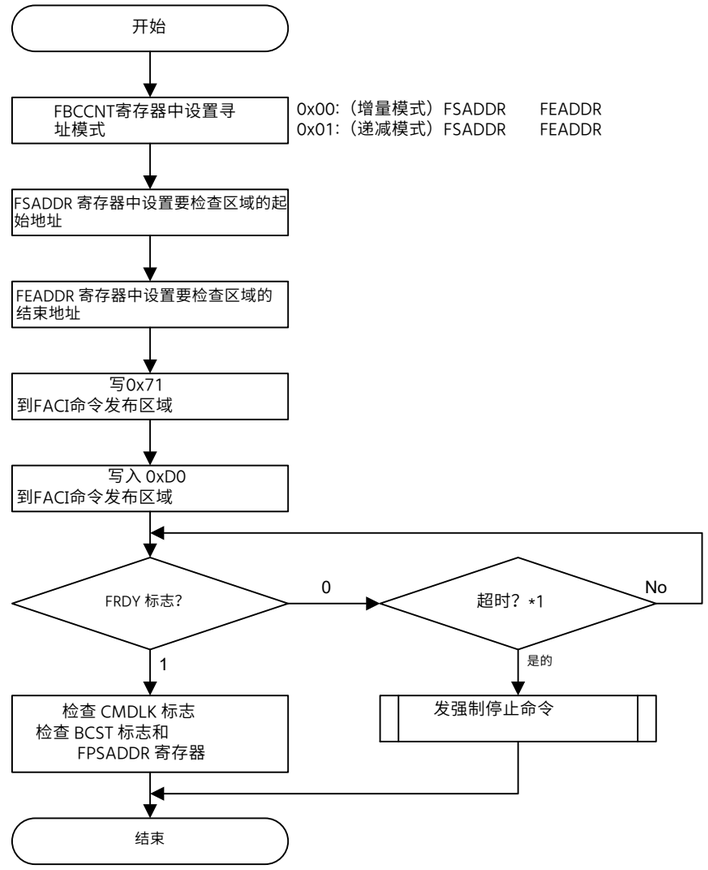
38.9.3.15 Configuration Set Command

The Configuration set command is used to set option-setting memory. Before issuing the Configuration set command, set the specified address (shown in Table 38.19) in the FSADDR register. Writing 0xD0 to the FACI command-issuing area in the final access for issuing the FACI command starts FACI processing of the Configuration set command.

Figure 38.24 shows usage of the configuration set command.



注1。超时的判断基于整个目标范围空白检查最大时间的 1。1 倍。请参阅第 41 节"电气特性"。

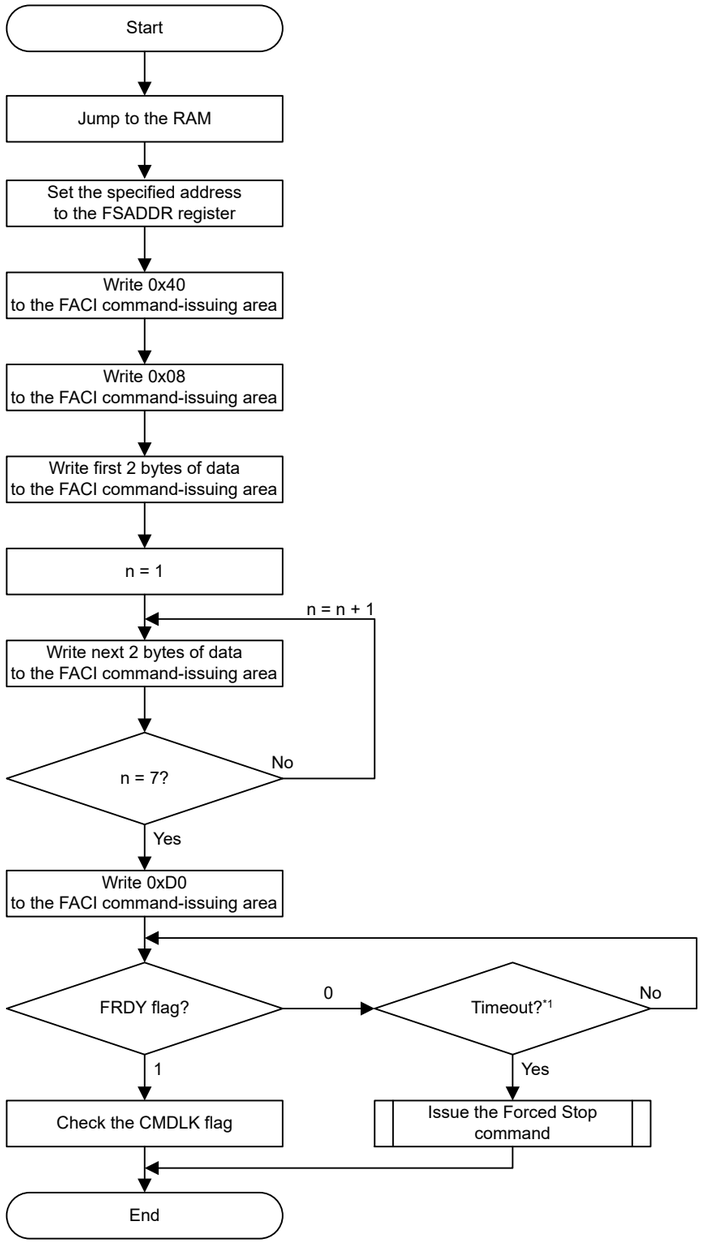
38。9。3。15 配置集命令

配置设置命令用于设置选项设置内存。发配置集命令之前,在 FSADDR 寄存器中设置指定的地址（如表 38。19 所示）。在发出 FACI 命令的最终访问中将 0xD0 写入 FACI 命令发出区域,开始对配置集命令进行 FACI 处理。

图 38。24 显示了配置集命令的使用情况。



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of programing in option-setting memory. See section 41, Electrical Characteristics.

图38。24 配置集命令的使用流程

The correspondence between the possible target data for configuration setting and the address value set in the FSADDR register is shown in Table 38.19. For details, see section 38.4.12. FSADDR : FACI Command Start Address Register.

Table 38.19 Address used by configuration set command

Address	FSADDR register value	Setting data	Operation of additional writing		Timing when the setting is enabled
			SAS.FSPR bit is 1	SAS.FSPR bit is 0	
0x0100_A100	0x0100_A100	Option Function Select Register 0 (OFS0)	Writable	Writable	At a reset
0x0100_A120 to 0x0100_A12C	0x0100_A120	OCD/Serial Programmer ID Setting Register (OSIS)	Writable	Writable	At a reset
0x0100_A134	0x0100_A130	Start-up Area Setting Register (SAS)	Writable	Not writable*1	When a reset or command is executed
0x0100_A200	0x0100_A200	Option Function Select Register 1 Secure (OFS1)	Writable	Writable	At a reset
0x0100_A240	0x0100_A240	Block Protect Setting Register Secure (BPS)	Writable*2	Writable*2	When a reset or command is executed
0x0100_A260	0x0100_A260	Permanent Block Protect Setting Register Secure (PBPS)	Writable*3 (from 1 to 0 only)	Writable*3 (from 1 to 0 only)	When a reset or command is executed

Note 1. The SAS.FSPR bit cannot be restored to 1 by using the Configuration set command once it is set to 0. Therefore, setting the start-up area select flags again becomes impossible. (when the Configuration set command is issued to the address of 0x0100A134, the command is locked.) Exercise extra caution when handling the SAS.FSPRbit.
Note 2. Once PBPS[n] bit is set to 0, the BPS[n] bit cannot be restored to 1 by using the Configuration set command.
Note 3. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS[n] bit cannot be set to 0 by using the Configuration set command when the BPS[n] bit is 1.

38.10 Suspend Operation

Reading from the flash memory is not possible during programming or erasure if the conditions for background operation given in Table 38.29 are not satisfied. When a P/E suspend command is issued to suspend the programming or erasure of the flash memory, reading from the flash memory is enabled. Regarding P/E suspend commands, there are one suspend command mode for programming and two suspend command modes for erasure (suspension priority mode and erasure priority mode). To resume suspended programming or erasure, the P/E resume command is available. For details on the suspend operation, see Figure 38.16.

38.11 Protection Function

38.11.1 Software Protection

Software protection disables programming and erasure of the code flash memory through the settings of control registers and block protect setting in the user area. If an attempt is made to issue an FACI command against software protection, the flash sequencer enters the command-locked state.

38.11.1.1 Protection through FWEPROR

Unless the FWEPROR.FLWE[1:0] bits are set to 01b, programming cannot proceed in any mode.

38.11.1.2 Protection by FENTRYR

When the FENTRYR register is set to 0x0000, the flash sequencer enters read mode. In read mode, FACI commands cannot be accepted. If an attempt is made to issue an FACI command in read mode, the flash sequencer enters the command-locked state.

38.11.1.3 Protection by Block Protect Setting

Each block in user area has the block protect setting (BPS). When the FBPROT1 register is 0x0000 and the block protect bit is 0, issuing the Program or Block Erase command to user area of the code flash causes the command-locked state. To program or erase the block whose block protect bit is 0, set the FBPROT1 register to 0x0001.

用于配置设置的可能目标数据与FSADDR寄存器中设置的地址值之间的对应关系如表38。19所示。详情请参见第 38。4。12 节。FSADDR:FACI 命令启动地址寄存器 .

表 38。19 配置集命令使用的地址

地址	FSADDR 寄存器值设置	数据	额外写作的操作		启用设置时的定时
			SAS。FSPR 位为 1	SAS。FSPR 位为 0	
0x0100_a100	0x0100_a100	选项功能选择 注册 0（OFS0）	可写	可写	在重置
0x0100_A120 至 0x0100_a12c	0x0100_a120	OCD/串行程序员 ID 设置寄存器（OSIS）	可写	可写	在重置
0x0100_a134	0x0100_a130	启动区域设置 册（非甾体抗炎药）	可写	不可写 *1	当执行重置或命令时
0x0100_a200	0x0100_a200	选项功能选择 注册 1 Secure（OFS1）	可写	可写	在重置
0x0100_a240	0x0100_a240	阻止保护设置寄存器 安全（bps）	可写 *2	可写 *2	当执行重置或命令时
0x0100_a260	0x0100_a260	永久块保护 设置寄存器安全（PBPS ）	可写 *3（仅从 1 到 0）	可写 *3（仅从 1 到 0）	当执行重置或命令时

注1。SAS。FSPR 位一旦设置为 0,就无法通过使用配置设置命令将其恢复为 1。因此,设置启动区域选择标志再次变得不可能。（当配置集命令发出到 0x0100A134 的地址时,该命令将被锁定。）处理 SAS。FSPRbit 时要格外小心。

注2。PBPS[n]位设置为0后,BPS[n]位就不能通过使用配置集命令恢复为1。
注3。一旦这些位设置为 0,就无法使用配置设置命令将这些位恢复为 1。PBPS[n]位在BPS[n]位为1时,不能通过使用配置集命令将PBPS[n]位设置为0。

38.10 暂停操作

如果不满足表 38。29 中给出的后台操作条件,则在编程或擦除期间不可能从闪存读取。当发出 P/E suspend 命令来暂停闪存的编程或擦除时,将启用从闪存读取。P/E 挂起命令,有一种挂起命令模式用于编程,两种挂起命令模式用于擦除（挂起优先模式和擦除优先模式）。要恢复暂停的编程或擦除,可以使用 P/E 恢复命令。有关暂停操作的详细信息,请参见图 38。16 .

38。11 保护功能

38。11。1 软件保护

软件保护通过用户区域中的控制寄存器设置和块保护设置来禁用代码闪存的编程和擦除。如果尝试针对软件保护发出 FACI 命令,则闪存排序器将进入命令锁定状态。

38。11。1。1 通过 FWEPROR 进行保护

FWEPROR。FLWE[1:0] 位设置为 01b 否则编程不能以任何模式进行。

38。11。1。2 FENTRYR 的保护

FENTRYR 寄存器设置为 0x0000 时, 闪光测序器进入读取模式。在读取模式下,FACI 命令不能被接受。如果尝试在读取模式下发出 FACI 命令,则闪存排序器进入命令锁定状态。

38。11。1。3 通过块保护设置进行保护

用户区域中的每个块都有块保护设置（BPS）。FBPROT1 寄存器为 0x0000 且块保护位为 0 时,向代码闪存的用户区域发出程序或块擦除命令会导致命令锁定状态。要对块保护位为 0 的块进行编程或擦除,请将 FBPROT1 寄存器设置为 0x0001。

The block protect setting can be locked by the permanent block protect setting (PBPS). When the permanent block protect setting and the block protect setting are 0, issuing a Program or Block erase command to user area of the code flash causes the flash sequencer to enter the command-locked state regardless of the FBPROT1 register settings.

See section 38.12.4. Permanent Block Protect Setting for details of the block protect setting and permanent block protect setting. See section 38.4.15. FBPROT1 : Flash Block Protection for Secure Register for more information.

For details of block protect setting (BPS), see section 6, Option-Setting Memory.

The protected area by the block protect setting is always determined by the address of the FSADDR register setting regardless of the address swapping function setting (the startup area select). Table 38.20 to Table 38.21 show the relation of user area and the block protect setting in each function setting.

- BPS[0] to BPS[n] are assigned to the block of user area (for example, address is 0x00_0000 to the last block address).
- BPS[0] and BPS[1] are assigned to the block of user area depending on the startup area select setting (SAS.BTFLG bit). (See section 38.11.3. Start-Up Program Protection.)

Table 38.20 shows the block protect setting when the startup area select is disabled (not swapping).

Table 38.21 shows example of the block protect setting when the address conversion function is used.

块保护设置可以通过永久块保护设置（PBPS）锁定。当永久块保护设置和块保护设置为0时,向代码flash的用户区域发出程序或块擦除命令导致flash排序器进入命令锁定状态,而不管FBPROT1寄存器设置如何。

参见第 38。12。4 节。永久块保护设置 有关块保护设置和永久块保护设置的详细信息。参见第 38。4。15 节。FBPROT1:用于安全注册的闪存块保护以获取更多信息。

块保护设置（BPS）的详细信息,请参见第6节,选项设置内存.

无论地址交换功能设置如何（启动区域选择）,块保护设置的保护区域始终由 FSADDR 寄存器设置的地址确定。表38。20至表38。21显示了每个功能设置中用户区域和块保护设置的关系。

- BPS[0] 到 BPS[n] 分配给用户区域的块（例如,地址为 0x00_0000 到最后一个块地址）。
- BPS[0] 和 BPS[1] 根据启动区域选择设置（SAS。BTFLG 位）分配给用户区域的块。（见第38。11。3节。启动程序保护 .）

表 38。20 显示了禁用启动区域选择（不交换）时的块保护设置。

表38。21示出了使用地址转换函数时的块保护设置的示例。

38.11.2 Error Protection

Error protection detects the issuing of illegal FACI commands, illegal access, and flash sequencer malfunction. FACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue the Status Clear or Forced Stop command. The Status Clear command can only be used while the FRDY bit in the FSTATR register is 1. The Forced Stop command can be used regardless of the value of the FRDY bit. While the CMDLKIE bit in the FAEINT register is 1, a flash access error (FIFERR) interrupt is generated if the flash sequencer enters the command-locked state (the CMDLK bit in the FASTAT register is set to 1).

If the flash sequencer enters the command-locked state in response to a command other than the P/E suspend command during programming or erasure processing, the flash sequencer continues the processing for programming or erasure. In this state, the P/E suspend command cannot be used to suspend the processing for programming or erasure. If a command is issued in the command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set from previous error detection.

Table 38.22 shows the error protection types and status bit values after error detections.

Error type	Description	ILGCOMERR	FESETERR	SECERR	OTERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE

38。11。2 错误保护

错误保护可检测非法 FACI 命令的发出、非法访问和闪存定序器故障。FACI命令接受被禁用（命令锁定状态）,以响应这些错误的检测。当闪存定序器处于命令锁定状态时,闪存无法被编程或擦除。要从命令锁定状态释放,请发出状态清除或强制停止命令。状态清除命令只能在 FSTATR 寄存器中的 FRDY 位为 1 时使用。无论 FRDY 位的值如何,都可以使用强制停止命令。虽然 FAEINT 寄存器中的 CMDLKIE 位为 1,但如果闪存定序器进入命令锁定状态（FASTAT 寄存器中的 CMDLK 位设置为 1),则会生成闪存访问错误（FIFERR）中断。

如果闪光测序器在编程或擦除处理期间响应于P/E挂起命令以外的命令进入命令锁定状态,则闪光测序器继续进行编程或擦除的处理。在此状态下,P/E suspend 命令不能用于暂停编程或擦除的处理。如果在命令锁定状态下发出命令,则 ILGLERR 位变为 1,其他位保留先前错误检测中设置的值。

表38。22显示了错误检测后的错误保护类型和状态位值。

38.11.3 Start-Up Program Protection

Protection of the startup program is for protection of the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.

The startup area is 8 Kbytes in size and is assigned to the user area in the code flash memory. This function uses the values of the SAS.BTFLG bit and the FSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see Figure 38.25 to Figure 38.28).

In protection of the startup program, the state of the selection of the startup area can be fixed by the FSPR bit. However, the SAS.FSPR bit never be restored to 1 once the flag is set to 0. Exercise extra caution when handling the SAS.FSPR bit.

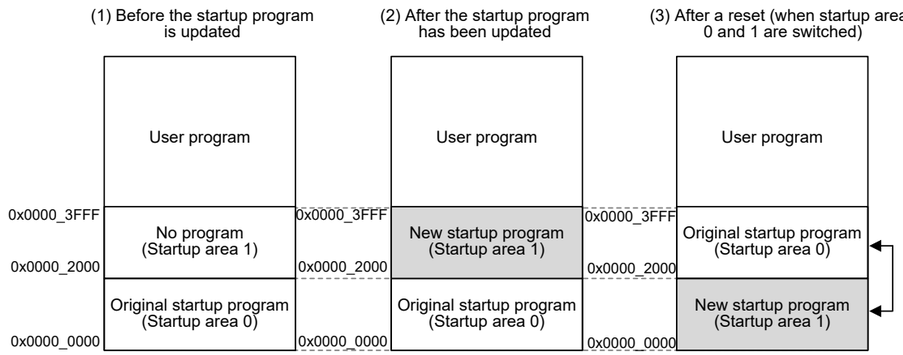
38.11.3 启动程序保护

启动程序的保护是为了保护重置后要启动的程序（启动程序）。此功能提供了一种在重置期间暂停重写时安全更新启动程序的方法。

启动区域大小为 8 KB,分配给代码闪存中的用户区域。该函数使用 SAS。BTFLG 位和 FSUACR。SAS[1:0] 位的值来更改以块为单位存储启动程序的区域（参见图 38。25 至图 38。28)。

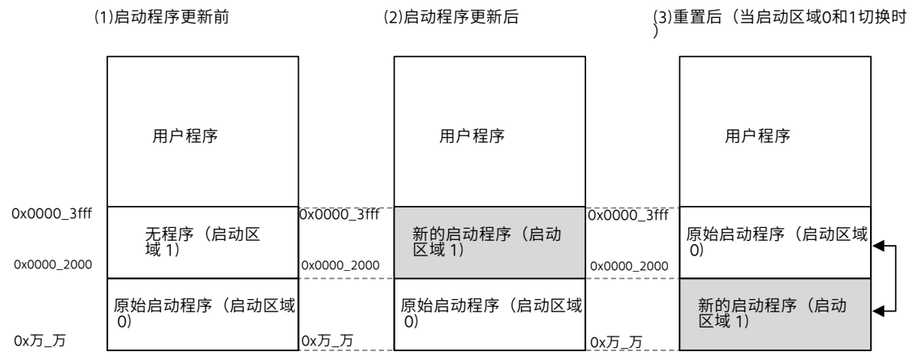
为了保护启动程序,可以通过FSPR位来修复启动区域的选择状态。然而,一旦标志设置为 0,SAS。FSPR 位就永远不会恢复到 1。处理 SAS。FSPR 位时要格外小心。



Note: The addresses are used for reading, programming, and erasure. Startup area 0 is erased when Block Erase command is issued for the address 0x00000000 with allocation shown under 3.

1. Before the startup program is updated
   When the SAS.BTFLG bit is 1 and the FSUACR.SAS[1:0] bits are 0xb, the address range from 0x00002000 to 0x00003FFF is selected as startup area 1 and the address range from 0x00000000 to 0x00001FFF is selected as startup area 0.
2. After the startup program has been updated
   A new startup program can be written to startup area 1. At this time, startup area 0 will still contain the previous startup program, so rewriting by starting up from startup area 0 remains possible if rewriting to the startup area 1 fails.
3. After a reset (when startup areas 0 and 1 are switched)
   When rewriting startup area 1 is successfully completed, switch the assignment of startup areas 0 and 1 by rewriting the startup area selection bit (the SAS.BTFLG bit) with Configuration set command. Afterwards, the program is started up from startup area 1 after a reset.

Figure 38.25 Concept of protection of the startup program



注: 这些地址用于读取、编程和擦除。当为地址 0x000000000 发出块擦除命令时,启动区域 0 被擦除,分配显示在 3 下。

1。在更新启动程序之前
SAS。BTFLG 位为 1 且 FSUACR。SAS[1:0] 位为 0xb 时,地址范围为 0x00002000 至 0x00003FFF被选择为启动区域1并且地址范围从0x00000000到0x00001FFF被选择为启动区域0。

2锛姣涓涓。启动程序更新后
新的启动程序可以写入启动区域 1。此时,启动区域0仍将包含先前的启动程序,因此如果重写到启动区域1失败,则从启动区域0启动重写仍然是可能的。

3锛　　娴　　。重置后（当启动区域 0 和 1 切换时）
成功完成重写启动区域1时,通过使用配置集命令重写启动区域选择位（SAS。BTFLG位）来切换启动区域0和1的分配。之后,程序在重置后从启动区域1启动。

38.12 Security Function

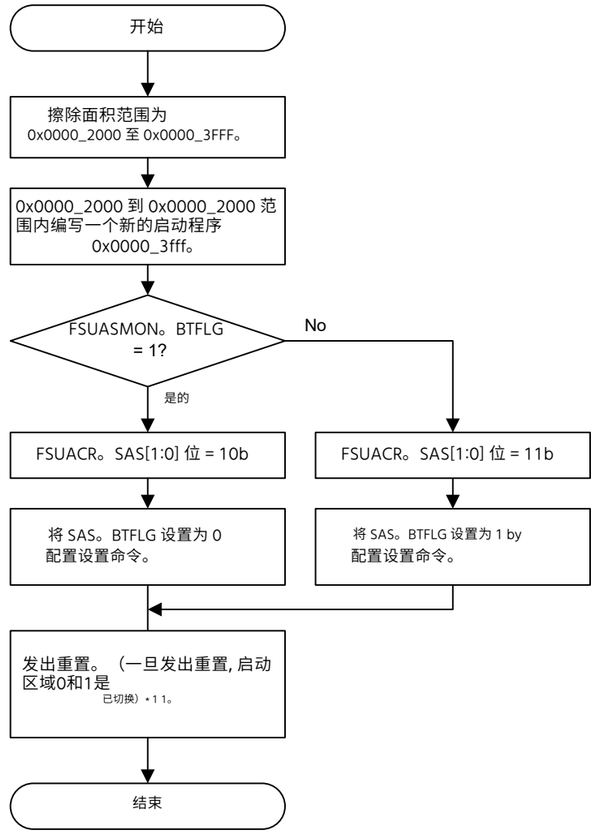
The flash sequencer supports the following security functions:

- Serial Programming Mode Protection
- OCD Mode Protection
- Security flag for startup area
- Permanent block protect setting
- Flash memory protection for TrustZone

38.12.1 Serial Programming Mode Protection

The serial programming mode features the ID authentication.

FACI protects the reception of all FACI commands according to the ID authentication result. When the ID authentication is enabled and passed, FACI validates FACI commands.



注1。详情见图38。26和图38。27。

图38。28 保护启动计划的概念

38。12 安全功能

Flash 音序器支持以下安全功能:

- 串行编程模式保护
- 强迫症模式保护
- 启动区域的安全标志
- 永久块保护设置
- TrustZone 的闪存保护

38.12.1 串行编程模式保护

串行编程模式具有 ID 身份验证功能。

FACI根据ID认证结果保护所有FACI命令的接收。ID 身份验证启用并通过后,FACI 会验证 FACI 命令。

38.12.2 OCD Mode Protection

The entry system of the on-chip debugger controls the protection by ID authentication.

38.12.3 Security Flag for Startup Area Select

The security flag (SAS.FSPR) for the startup area is located in the option-setting memory.

When the SAS.FSPR bit is 0, issuing the configuration set command to change the SAS.BTFLG bit causes the flash sequencer to be in the command-locked state. Also, when the SAS.FSPR bit is 0, it is invalid to write to the Startup Area Select bits SAS[1:0] in the FSUACR register. The SAS.FSPR bit enables protection.

38.12.4 Permanent Block Protect Setting

The permanent block protect setting is the clear protection for the block protection setting. User area cannot be permanently updated by the FACI command when the permanent block protect setting is enabled. See section 38.11.1.3. Protection by Block Protect Setting for more details.

The block protect setting and the permanent block protect setting have the write/clear protection against the configuration set command. The flash sequencer does not detect an error when the configuration set command is issued to the write/clear protected settings.

Figure 38.29 and Table 38.23 show the write/clear protection against the block protect setting (BPS[n]) and the permanent protect setting (PBPS[n]).

For details of permanent block protect setting (PBPS), see section 6, Option-Setting Memory.

38.12.5 Flash Memory Protection for TrustZone

Information in this section focuses on the flash sequencer operation.

38。12。2 强迫症模式保护

片上调试器的输入系统通过ID认证控制保护。

38。12。3 启动区域的安全标志 选择

启动区域的安全标志（SAS。FSPR）位于选项设置内存中。

当SAS。FSPR位为0时,发出配置集命令来改变SAS。BTFLG位导致闪存定序器处于命令锁定状态。另外,当SAS。FSPR位为0时,写入FSUACR寄存器中的启动区域选择位SAS[1:0]无效。SAS。FSPR 位可实现保护。

38。12。4 永久块保护设置

永久块保护设置是对块保护设置的明确保护。当启用永久块保护设置时,FACI 命令无法永久更新用户区域。参见第 38。11。1。3 节。通过块保护设置进行保护了解更多详细信息。

块保护设置和永久块保护设置具有针对配置设置命令的写/清除保护。当向写入/清除受保护设置发出配置设置命令时,闪存排序器不会检测到错误。

图 38。29 和表 38。23 显示了针对块保护设置（BPS[n]) 和永久保护设置（PBPS[n]) 的写/清除保护。

置（PBPS）的永久块保护的详细信息,请参见第6节,选项设置内存.

38。12。5 本节中的 TrustZone 信息的闪存保护重点关注闪存音序器操作。

The flash memory provides the following types of protect function against non-secure access:

- Protection for flash memory area (P/E)
- Protection for flash memory area (read)
- Protection for registers
- Protection during FACI command operation
- Code flash P/E mode entry protection

38.12.5.1 Protection for Flash Memory Area (P/E)

This function protects the secure region of the code flash and data flash from FACI commands of non-secure access. The condition of protection depends on the FACI command, the access attribution, and the memory boundary setting.

For details of secure region, see section 40, Security Features .

See Table 38.24 for information on protection of the flash memory area (P/E).

Table 38.24 Protection for the flash memory area (P/E)

FACI command	Target area		Issuing of FACI command by non-secure access	Issuing of FACI command by secure access
Program Block erase	Code flash memory	User area (non-secure area)	✓	✓
		User area (secure area)	X	✓
	Data flash memory	Data area (non-secure area)	✓	✓
		Data area (secure area)	X	✓
Multi block erase Blank check	Data flash memory	Data area (non-secure area)	✓	✓
		Data area (secure area)	X	✓
Configuration set	Code flash memory	option-setting memory (secure area)	X	✓

Note:
- ✓ indicates FACI command operation is not prohibited.
- X indicates FACI command operation is prohibited. Error occurs when the area is selected, and the FACI command is executed.

When the target area of FACI command is the user area of code flash, the flash sequencer compares the FSADDR register setting with the memory boundary setting of the code flash and determines whether the target area is in the secure region.

The memory boundary can be set to 0x0000_0000 to 0x00FF_8000 in 32 KB unit.

Figure 38.30 shows details of the non-secure/secure attribute of user area in the code flash.

闪存提供以下类型的非安全访问保护功能:

- 闪存区域保护（P/E）
- 保护闪存区域（已读）
- 对寄存器的保护
- FACI 命令操作期间的保护
- 代码闪存 P/E 模式进入保护

38。12。5。1 闪存区域保护（P/E）

该功能保护代码闪存和数据闪存的安全区域免受非安全访问的 FACI 命令的影响。保护条件取决于 FACI 命令、访问归因和内存边界设置。

有关安全区域的详细信息,请参阅第 40 节"安全功能 ."
有关闪存区域保护的信息（P/E）,请参阅表 38。24。

表 38。24 闪存区域保护（P/E）

FACI 命令	目标区域		通过非安全访问发布 FACI 命令	通过安全访问发布 FACI 命令
程序 块擦除	代码闪存	用户区域（非安全区域）	✓	✓
		用户区域（安全区域）	X	✓
	数据闪存	数据区域（非安全区域）	✓	✓
		数据区域（安全区域）	X	✓
多块擦除 空白检查	数据闪存	数据区域（非安全区域）	✓	✓

- ✓ 表示不禁止 FACI 命令操作。
- X 表示禁止 FACI 命令操作。选择该区域并执行 FACI 命令时会出现错误。

FACI命令的目标区域为代码闪存的用户区域时,闪存定序器将FSADDR寄存器设置与代码闪存的内存边界设置进行比较,判断目标区域是否在安全区域。

32 KB 单位内可将内存边界设置为 0x0000_0000 到 0x00FF_8000。

Note 1. Comparing FSADDR with memory boundary setting of user area and judges whether the target area is in secure area.

Figure 38.30 Secure/non-secure region in user area

When the target area of the issuing FACI command is the data area of data flash, the flash sequencer compares the FSADDR/FEADDR register setting with the memory boundary setting of the data flash and determines whether the target area is in secure region. The memory boundary can be set to 0x0800_0000 to 0x0800_FC00 in 1 KB unit. Figure 38.31 shows details of the non-secure/secure attribute of data area in the data flash.

- NS indicates the FACI command by the non-secure access.
- ✓ indicates read/write access is possible by the non-secure access.
- X indicates read/write access is not possible by the non-secure access. Write data is ignored and read data is always 0.

Note 1. The FACI command issued by the non-secure access is not allowed.

Code flash programming/erasure can be protected by the FMEPROT register of secure function. Therefore, it does not assume that secure function issues P/E suspend command during code flash programming/erasure of non-secure function.

Data flash programming/erasure of non-secure can be suspended by secure function. If secure function issues P/E suspend command during data flash programming/erasure of non-secure function, secure function should issue P/E resume command. When secure function issues P/E resume command, secure function should notify non-secure function that data flash programming/erasure is complete and return to non-secure function. See Figure 38.34 and Figure 38.35 in example of issuing P/E suspend of secure function during programming/erasure of non-secure function.

注意:
- S 表示安全访问的 FACI 命令。
- NS 通过非安全访问指示 FACI 命令。
- ✓ 表示非安全访问可以进行读/写访问。
- X 表示非安全访问无法进行读/写访问。写入数据被忽略,读取数据始终为 0。

注1。不允许非安全访问下发的 FACI 命令。

代码闪存编程/擦除可以由安全函数的 FMEPROT 寄存器保护。因此,它不假设安全函数在代码闪存编程/擦除非安全函数期间发出 P/E 暂停命令。数据闪存编程/非安全擦除可以通过安全功能暂停。如果安全功能在数据闪存编程/擦除非安全功能期间发出 P/E 暂停命令,则安全功能应发出 P/E 恢复命令。Secure 函数发出 P/E 简历命令时, secure 函数应通知非安全函数数据闪存编程/擦除完成, 并返回到非安全函数。请参阅图 38。34 和图 38。35,了解在非安全函数的编程/擦除期间发出安全函数的 P/E 挂起的示例。

38.12.5.5 Code Flash P/E Mode Entry Protection

The flash sequencer has protection function of code flash P/E by the FMEPROT register for the secure developer. Secure function can prevent disturbance of reading code flash memory by this protection function. See section 38.4.14. FMEPROT : Flash P/E Mode Entry Protection Register.

For applications that do not require non-secure region programming/erasure other than from secure function, it is recommended to always disable non-secure function of code flash programming/erasure by enabling the protection function of FMEPROT register.

For details, see Figure 38.36 of the code flash P/E sequence example by non-secure function.

38。12。5。5 代码闪存 P/E 模式输入保护

闪存定序器具有安全开发人员的FMEPROT寄存器代码闪存P/E的保护功能。安全功能可以通过此保护功能防止读取代码闪存的干扰。参见第 38。4。14 节。

FMEPROT:闪存 P/E 模式输入保护寄存器 .

对于除安全功能之外不需要非安全区域编程/擦除的应用程序,建议始终通过启用 FMEPROT 寄存器的保护功能来禁用代码闪存编程/擦除的非安全功能。

有关详细信息,请参阅代码闪存 P/E 序列示例（按非安全函数）的图 38。36。

38.13 Boot Mode

There are two serial programming modes; the boot mode (for the SCI interface) with SCI9 and the boot mode (for the SWD interface) with SWD. The available interfaces and connection times to the tool vary depending on the clock source connected to the MCU. Table 38.27 lists the I/O pins used in boot mode. Table 38.28 lists the available communication interface and the connection time depending on the clock sources in the boot mode.

38。13 启动模式

有两种串行编程模式; SCI9 的启动模式（用于 SCI 接口）和 SWD 的启动模式（用于 SWD 接口）。工具的可用接口和连接时间根据连接到 MCU 的时钟源而变化。表 38。27 列出了启动模式下使用的 I/O 引脚。表 38。28 列出了可用的通信接口和连接时间,具体取决于启动模式下的时钟源。

MD	Input	Boot mode (for the SCI interface) Boot mode (for the SWD interface)	Selection of operating mode
P110/RXD9	Input	Boot mode (for the SCI interface)	For host communication (to receive data through SCI)
P109/TXD9	Output		For host communication (to transmit data through SCI)
SWCLK	Input	Boot mode (for the SWD interface)	Serial wire clock pin

Main clock oscillator	Sub-clock oscillator	Available interface	Tool connection time*2
Connected	Don't care	SCI	Up to 1 second
Unconnected	Connected*1	SCI	Up to 2 seconds
Unconnected	Unconnected	SCI	Up to 3 seconds

Note 1. The drive capability of the sub-clock oscillator is set to standard by SOMCR.SODRV bit. Note that if you use the crystal resonator corresponding to the low drive capability on your board, the crystal resonator may not oscillate in the boot mode.
Note 2. Tool connection time means that it takes for communication to be established between MCU and the host. For details, see the boot firmware application note.

38.13.1 Boot Mode (for the SCI Interface)

In boot mode (for the SCI interface), the host sends control commands and data for programming, and the flash memory is programmed or erased accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When this MCU is activated in boot mode (for the SCI interface), the program on the dedicated area the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.

Figure 38.37 shows the system configuration for operations in boot mode (for the SCI interface).

注2。工具连接时间是指MCU与主机之间建立通信所需的时间。有关详细信息,请参阅启动固件应用程序说明。

38。13。1 启动模式（用于 SCI 接口）

在启动模式下（对于SCI接口）,主机发送控制命令和数据进行编程,并且闪存被相应地编程或擦除。片上 SCI 以异步模式处理主机和该 MCU 之间的传输。
用于传输控制命令的工具和用于编程的数据必须在主机中准备。

当该 MCU 在启动模式下激活（对于 SCI 接口）时,执行 MCU 专用区域上的程序。
Boot程序自动调整SCI的比特率,通过接收来自主机的控制命令来控制编程/擦除。

图 38。37 显示了启动模式下操作的系统配置（对于 SCI 接口）。

38.13.2 Boot Mode (for the SWD Interface)

In boot mode (with the SWD interface), the flash memory can be programmed or erased by sending control commands and program data from the host. An on-chip SWD is used for communications between the host and this MCU. The host requires tools for sending control commands and data for programming. Figure 38.38 shows the configuration of a system for use in boot mode (for the SWD interface). The SWD interface must be connected on reset release.

38.14 Using the Serial Programmer for Rewriting

A serial programmer can be used to rewrite flash memory in boot mode.

(1) Serial Programming

This MCU is mounted on the system board at the time of serial programming. Providing a connector to the board enables rewriting of this MCU by the serial programmer to proceed.

38.14.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU with data are described below.

38。13。2 启动模式（适用于 SWD 接口）

在启动模式下（具有SWD接口）,可以通过从主机发送控制命令和程序数据来对闪存进行编程或擦除。片上 SWD 用于主机和该 MCU 之间的通信。主机需要发送控制命令的工具和编程数据。图 38。38 显示了在启动模式下使用的系统配置（用于 SWD 接口）。SWD 接口必须在重置释放时连接。

38.14 使用串行程序员进行重写

串行程序员可用于在启动模式下重写闪存。

(1) 串行编程

该 MCU 在串行编程时安装在系统板上。向板提供连接器使得串行程序员能够继续重写该 MCU。

38.15 Programming through Self-Programming

38.15.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACI commands can be used with user programs for writing to the flash memory. This allows upgrading of user programs and rewriting of constant data fields.

The program for rewriting must be transferred to the internal RAM in advance when the BGO is not available or when rewriting the option-setting memory.

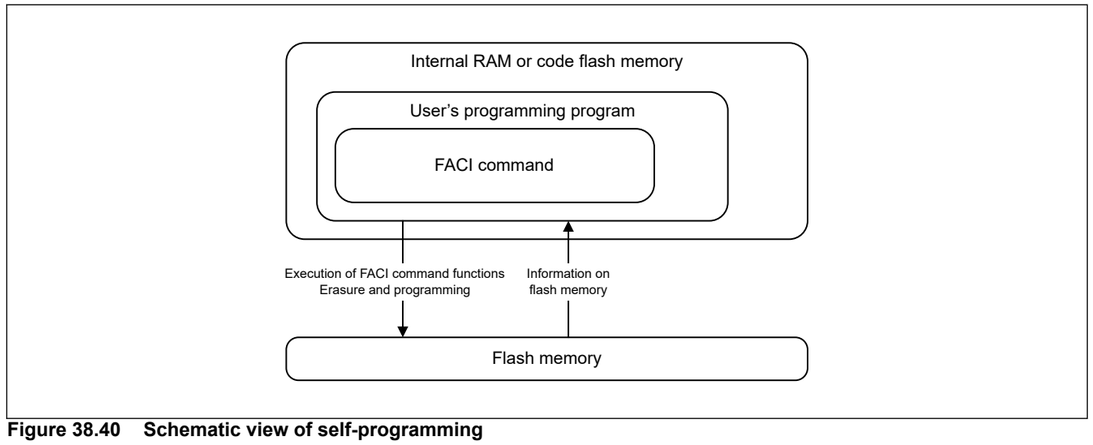

Figure 38.40 Schematic view of self-programming

For comprehensive information on the self-programming, see section 38.9. FACI Commands.

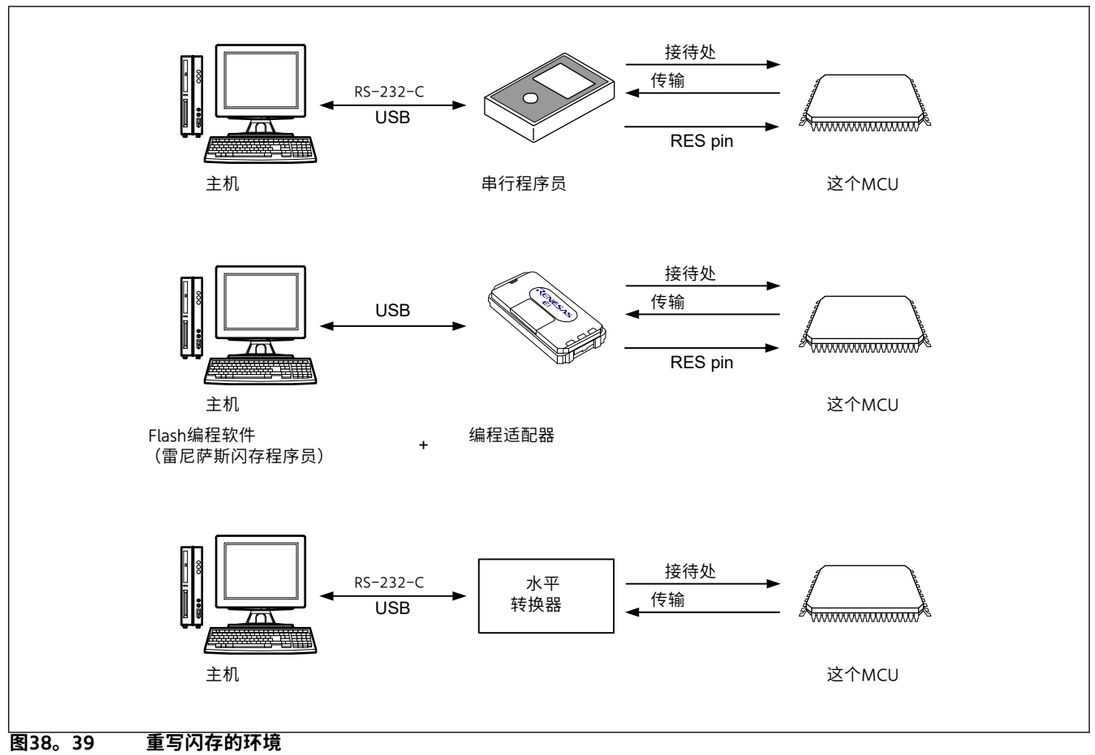

图38。39 重写闪存的环境

38.15 通过自我编程进行编程

38。15。1 概述

该MCU支持用户程序本身对闪存进行编程。FACI 命令可以与用户程序一起使用,用于写入闪存。这允许升级用户程序和重写恒定数据字段。

BGO不可用或重写选项设置内存时,必须提前将重写的程序传输到内部RAM。

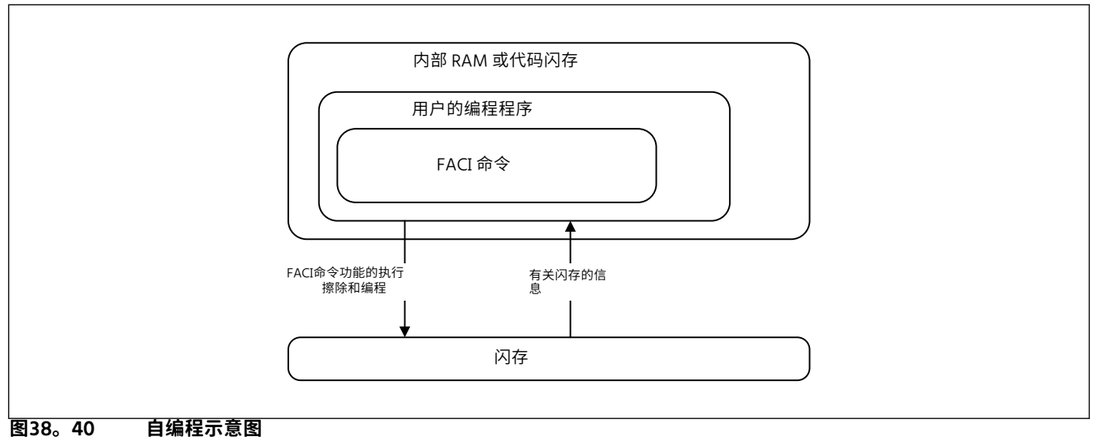

图38。40 自编程示意图

有关自编程的全面信息,请参阅第 38。9 节。FACI 命令。

38.15.2 Background Operation

The background operation (BGO) can be used to execute the flash rewrite routine on the code flash memory when the data flash memory is rewritten.

Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed below.

Table 38.29 Conditions under which background operation is usable

	Range for rewriting	Range for reading
Common	Code flash memory	Data flash memory
	Data flash memory	Code flash memory

38.16 Reading Flash Memory

38.16.1 Reading Code Flash Memory

Special settings are not required to read code flash memory after release from the reset state. Data can simply be read out through access to addresses in the code flash memory.

When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

38.16.2 Reading Data Flash Memory

Special settings are not required to read data flash memory after release from the reset state. Data can simply be read out through access to addresses in the data flash memory.

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

38.16.3 Access Cycle

When the CPU cache is hit, access is one cycle.

For the CPU cache is missed while CPU cache operation is enabled, or CPU cache is disabled. (This operation only guarantees the first read access of a wrapping burst in AHB protocol. Otherwise, access wait occurs until the CPU cache is filled.)

Table 38.30 Code flash memory

Flash cache operation	FLWT register setting	Read cycle (ICLK)
enable and hit	—	3
disable or miss	0x00	3
	0x01	4

Table 38.31 Data flash memory (1 of 2)

FCKMHZ register setting	Read (cycle)
0x00 to 0x09	Min: 2 ICLK + 3 FCLK Max: (n + 1) ICLK + 3 FCLK
0x0A to 0x13	Min: 2 ICLK + 4 FCLK Max: (n + 1) ICLK + 4 FCLK

38。15。2 背景操作

后台操作（BGO）可用于在重写数据闪存时在代码闪存上执行闪存重写例程。

当用于重写的闪存和用于读取的闪存的组合是下面列出的任何一个时,可以使用背景操作。

表 38。29 后台操作可用的条件

	重写范围	阅读范围
共同的	代码闪存	数据闪存
	数据闪存	代码闪存

38。16 读取闪存

38.16.1 读取代码闪存

从重置状态释放后,不需要特殊设置来读取代码闪存。通过访问代码闪存中的地址可以简单地读出数据。

（即处于非编程状态）读取已擦除但尚未再次编程的代码闪存时, 所有位都读为 1。

38。16。2 读取数据闪存

从复位状态释放后,不需要特殊设置来读取数据闪存。通过访问数据闪存中的地址可以简单地读出数据。

（即处于非编程状态）已擦除但尚未再次编程的数据闪存读取的值未定义。当您需要确认某个区域处于非编程状态时,请使用空白检查。

38。16。3 访问周期

CPU缓存被击中时,访问是一个周期。

因为在启用CPU缓存操作或禁用CPU缓存时错过了CPU缓存。（此操作仅保证 AHB 协议中包裹突发的第一次读取访问。否则,将进行访问等待,直到 CPU 缓存被填充。）

38.17 Usage Notes

(1) Reading Area Where Programming/Erasure was Interrupted and Area Targeted for Suspension

The data stored in the area where programming or erasure has been suspended or the area where programming or erasure has been suspended by using the suspend command are undefined. To avoid faulty operation caused by reading undefined data, take care not to fetch instructions or read data from areas where programming or erasure was suspended and where programming or erasure was suspended by using the suspend command.

(2) Suspension During Programming/Erasure

When processing of programming/erasure is stopped by issuing the P/E suspend command, the programming/erasure processing can be resumed by issuing the P/E resume command. If the flash sequencer enters the command-locked state for any reason and issues the forced stop command after the suspended processing is normally completed and the ERSSPD flag or PRGSPD flag is set to 1, the suspended processing cannot be resumed. In addition, the values in the area where the processing was suspended are not guaranteed. Erase that area

(3) Prohibition of Additional Programming

Programming a given area of the code flash memory or data flash memory twice is not possible. To program the code flash memory or data flash memory where has been programed, erase the target area. Programming can be added to the option-setting memory.

(4) Resets During Programming/Erasure, or Blank Checking

In the case of a reset due to the signal on the RES pin during programming/erasure, or blank checking of the flash memory, wait for at least t_{RESW} (see section 41, Electrical Characteristics) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics, then release the device from the reset state.

(5) Allocation of Vectors for Interrupts and Other Exceptions During Programming/Erasure

Generation of an interrupt or other exception during programming/erasure may lead to fetching of the vector from the code flash memory. Under conditions where BGO cannot be used, set the address of the vector to an address that is not in the code flash memory. Alternatively, make sure that no handling of interrupts or exceptions proceeds during programming/erasure.

(6) Items Prohibited During Programming/Erasure, or Blank Checking

High voltage is applied to the flash memory during programming/erasure, or blank checking. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0]bits.
- Change the OPCCR.OPCM[2:0] and SOPCCR.SOPCM bits.
- Change the SCKDIVCR.FCK[2:0]bits.
- Change the SCKSCR.CKSEL[2:0]bits.
- Transition to the software standby mode, or deep software standby mode.

(7) Programming/Erasure in Low-Speed Modes and Subosc-Speed Mode

Do not programming/erasure the flash memory when low-speed mode or subosc-speed mode is selected with the operating power control register (OPCCR or SOPCCR).

表 38。31 数据闪存(2 个中的 2 个)

FCKMHZ 寄存器设置	读（周期）
0x32	最少:2 ICLK + 8 FCLK 最大：(n + 1) ICLK + 8 FCLK

注: ICLK:FCLK的频率比为n:1时

38。17 使用说明

（一）程序设计/擦除被中断的阅读区域和被针对暂停的区域

使用挂起命令存储在已暂停编程或擦除的区域或已暂停编程或擦除的区域中的数据未定义。为避免因读取未定义数据而导致操作错误,请注意不要使用挂起命令从暂停编程或擦除以及暂停编程或擦除的区域获取指令或读取数据。

(2)编程/擦除时的暂停

当通过发出P/E暂停命令来停止编程/擦除处理时,可以通过发出P/E恢复命令来恢复编程/擦除处理。Flash 测序器因任何原因进入命令锁定状态,在暂停处理正常完成且 ERSSPD 标志或 PRGSPD 标志设置为 1 后发出强制停止命令,则无法恢复暂停处理。此外,暂停处理区域的值也无法得到保证。擦除该区域

（三）禁止附加编程

无法对代码闪存或数据闪存的给定区域进行两次编程。要对已编程的代码闪存或数据闪存进行编程,请删除目标区域。可以将编程添加到选项设置内存中。

(4)在编程/擦除期间重置 或空白检查

如果在编程/擦除期间由于 RES 引脚上的信号而复位,或者对闪存进行空白检查,则一旦工作电压处于工作电压状态,就等待复位输入周期的至少 tRESW（参见第 41 节"电气特性")。在电气特性规定的范围内,然后将设备从复位状态中释放。

(5) 编程/擦除期间中断和其他异常的向量分配

在编程/擦除期间生成中断或其他异常可能会导致从代码闪存中获取向量。BGO不能使用的条件下,将向量的地址设置为代码闪存中没有的地址。或者,确保在编程/擦除期间不会继续处理中断或异常。

(6)编程/擦除期间禁止的项目,或空白检查

在编程/擦除或空白检查期间向闪存施加高压。为了防止闪存损坏,请勿执行以下操作。

- 使电源的工作电压超出允许的范围。
- 更改 FWEPROR。FLWE[1:0] 位。
- 更改 OPCCR。OPCM[2:0] 和 SOPCCR。SOPCM 位。
- 更改 SCKDIFCR。FCK[2:0] 位。
- 更改 SCKSCR。CKSEL[2:0] 位。
- 过渡到软件待机模式,或深度软件待机模式。

(7)在低速模式和子sc-速度模式下的编程/擦除

当使用工作功率控制寄存器（OPCCR 或 SOPCCR）选择低速模式或子扫描速度模式时,请勿对闪存进行编程/擦除。

40.2.6 TrustZone Access Error

Table 40.7 shows the behavior when TrustZone access error. The behavior varies depending on the master or slave area to be accessed.

Table 40.7 The Behavior When TrustZone Access Error

Area	CPU	DMAC/DTC
Code flash, Data flash, SRAM	Detect SecureFault exception*2	• Transfer does not start • Occur NMI or reset*1 • Occur interrupt (DMA_TRANSERR)
Other area	• Detect BusFault exception*2 *3 • Occur NMI or reset*1*2 *3	• Stop transfer*4 • Occur NMI or reset *1 *4 • Occur interrupt (DMA_TRANSERR)*4

Note 1. NMI or reset is selected with TZFOAD.OAD bit.
Note 2. When TrustZone access error occurs by the debugger access, exception, NMI, or reset does not occurs.Only the error response is returned.
Note 3. These error behaviors does not occur for write access to the PHBIU or PLBIU address space which memory attribute is set to "Early Write Acknowledgment" by the ARM MPU.
Note 4. These error behaviors does not occer for write access from DMAC to the PHBIU or PLBIU address space when the bufferable write is enabled by DMBWR.BWE.

40.3 ID authentication

This function prohibits programming and on-chip debugging. The device validates or invalidates the ID code and determines the ID code based on an ID code stored in the flash memory. When ID code protection is enabled, the ID code sent from the host is compared with the ID code in the flash memory to determine whether they match. Programming and on-chip debugging are enabled only when the two match. The ID code in flash memory consists of four 32-bit words.

ID code bits [127] and [126] determine whether ID code protection is enabled and the method of authentication to use with the host. Table 40.8 shows how the ID code determines the method of authentication.

For details on how to set the ID code, see section 6.2.2. OSIS : OCD/Serial Programmer ID Setting Register.

40。2。6 TrustZone 访问错误

表 40。7 显示了 TrustZone 访问错误时的行为。行为因主人或从属区域而异被访问。

表 40。7 TrustZone 访问错误时的行为

区域	CPU	DMAC/DTC
代码闪存、数据闪存、SRAM	检测 SecureFault 异常 *2	• 转移不会开始 • 发生 NMI 或重置 *1 • 发生中断（DMA_TRANSERR）
其他地区	• 检测总线故障异常 *2 *3 • 发生 NMI 或重置 *1*2 *3	• 停止传输*4 • 发生 NMI 或重置 *1 *4 • 发生中断（DMA_TRANSERR）*4

注1。使用 TZFOAD。OAD 位选择 NMI 或重置。
注2。当调试器访问出现 TrustZone 访问错误时,不会发生异常、NMI 或重置。仅返回错误响应。

注3。对于对 PHBIU 或 PLBIU 地址空间的写访问,ARM MPU 将内存属性设置为"早期写入确认",不会发生这些错误行为。

注4。当 DMBWR。BWE 启用可缓冲写入时,从 DMAC 到 PHBIU 或 PLBIU 地址空间的写入访问不会发生这些错误行为。

40。3 ID 身份验证

此功能禁止编程和片上调试。设备验证或使ID码无效,并根据存储在闪存中的ID码确定ID码。ID码保护时,将从主机发送的ID码与闪存中的ID码进行比较,以确定它们是否匹配。仅当两者匹配时才启用编程和片上调试。闪存中的 ID 代码由四个 32 位字组成。

ID码位[127]和[126]确定是否启用ID码保护以及认证方法与主机一起使用。表 40。8 显示了 ID 代码如何确定身份验证方法。

有关如何设置 ID 代码的详细信息,请参阅第 6。2。2 节。OSIS:OCD/串行程序员 ID 设置寄存器 .

Table 40.8 Specifications for ID code protection

Operating mode on boot up	ID code	State of protection	Operations on connection with the programmer or on-chip debugger
Serial programming mode (SCI/SWD boot mode) On-chip debug mode (SWD boot mode)	0xFF, …, 0xFF (All bytes = 0xFF)	Protection disabled	Connection to programmer or on-chip debugger is permitted. The connection to the programmer does not check the ID code, the ID code always matches, and the connection to the programmer is permitted. The on-chip debugger needs to send 0xFF, …, 0xFF (All bytes = 0xFF) or needs to send nothing on connection.
	Bit [127] = 1, Bit [126] = 1, and at least one of the 16 bytes are not 0xFF	Protection enabled	Matching ID code: Authentication ends and connection to the programmer or on-chip debugger is permitted. Mismatching ID code: Additional transition to the ID code protection waiting state. When the ID code sent from the programmer or the on-chip debugger is “ALeRASE” in ASCII code (0x414C_6552_4153_45FF_FFFF_FFFF_FFFF_FFFF), the content of the user flash area is erased. However, forced erasure is not executed when the SAS.FSPR*1 bit is 0 or there is a block with permanent block protection.
	Bit [127] = 1 and bit [126] = 0	Protection enabled	Matching ID code: Authentication ends and connection to the programmer or the on-chip debugger is permitted. Mismatching ID code: Additional transition to the ID code protection waiting state. Renesas cannot access the test mode.
	Bit [127] = 0	Protection enabled	ID code validation is not performed, the ID code is always mismatching, and connection to the programmer or the on-chip debugger is prohibited, and Renesas cannot access the test mode.

Note 1. For details on the SAS.FSPR bit, see section 6.2.3. SAS : Startup Area Setting Register.

40.3.1 Failure analysis

If the customer requests the failure analysis to Renesas, it is necessary to send the device after changing the bits[127:126] of OSIS register to 11b. If bits[127:126] of the OSIS register are not 11b, this prevents Renesas from accessing the test mode. Therefore, Renesas cannot perform failure analysis unless bits[127:126] of OSIS register are set to 11b.

Devices sent to Renesas will not be returned to customers. The device will be discarded.

	位 [127] = 1 和位 [126] = 0	保护已启用	匹配 ID 代码:允许身份验证结束并连接到程序员或片上调试器。 ID码不匹配:额外过渡到ID码保护等待状态。瑞萨无法访问测试模式。
	位[127]=0	保护已启用	ID码验证不进行,ID码总是不匹配,禁止连接程序员或片上调试器,瑞萨无法访问测试模式。

注1。有关 SAS。FSPR 位的详细信息,请参阅第 6。2。3 节。SAS:启动区域设置寄存器。

40。3。1 故障分析

OSIS寄存器的位[127:126]更改为11b后,如果客户向瑞萨请求故障分析,就需要发送设备。OSIS 寄存器的位 [127:126] 不是 11b, 这会阻止瑞萨访问测试模式。
因此,除非 OSIS 寄存器的位 [127:126] 设置为 11b,否则 Renesas 无法执行故障分析。

发送到瑞萨的设备不会退还给客户。该设备将被丢弃。

OAD bit (Operation after detection)

The OAD bit is specified to generate either reset or non-maskable interrupt when the access to the protect region is detected by the TrustZone Filter.

When the OAD bit is set, write 0xA5 in the KEY[7:0] bits at the same time.

KEY[7:0] bits (KeyCode)

The KEY[7:0] bits are used to enable or disable writing of the OAD bit. When writing the OAD bit, write 0xA5 in the KEY[7:0] bits at the same time.

When the KEY[7:0] bits value except 0xA5 is written in, the OAD bit is not updated.

The KEY[7:0] bits are read always as 0x00.

PROTECT bit (Protection of register)

The PROTECT bit controls enable or disable writing to the corresponding registers to be protected. TZFOAD register is protected by PROTECT.

When the PROTECT bit is set, write 0xA5 in the KEY[7:0] bits at the same time.

KEY[7:0] bits (KeyCode)

The KEY[7:0] bits are used to enable or disable writing of the PROTECT bit. When writing the PROTECT bit, write 0xA5 in the KEY[7:0] bits at the same time.

When the KEY[7:0] bits value except 0xA5 is written in, the PROTECT bit is not updated.

The KEY[7:0] bits are read always as 0x00.

40.5 Usage Notes

40.5.1 SAU setting

After reset, all of address space is marked as Secure by SAU default setting. SAU_CTRL register should be set to 0x2 to enable the IDAU security attribution. That is, after setting SAU_CTRL register to 0x2, the address space security attribution becomes as shown in Table 40.6.

40.5.2 Non-secure exception during the setting of FACI registers

As shown in Table 40.5, the registers related to FACI are protected from non-secure access only during programming/erasure or during suspend programming/erasure. Outside of this state, the access from non-secure region is not protected. For example, when programming by the secure user, the non-secure user can rewrite the FSADDR if a non-secure exception occurs immediately after “Set the start address of the target block to the FSADDR register” flow in Figure 38.13. If the FACI command is issued after the non-secure exception processing is completed and the CPU state returns to the secure state, data will be programmed to an address not intended by the secure user.

To prevent such a things, secure user needs to set not to accept the non-secure exception during the following period.

- Set not to accept the non-secure exeption before setting FWEPROR to 0x01 or setting FENTRYR to other than 0x0000, that is before lereasing the protection of FWEPROR or FENTRYR.
- Set to accept the non-secure exception after all write access to the FACI command-issuing area is completed.

40.5.3 FCU interrupt usage

It is recommended that secure users do not use the FCU interrupts, but rather use the register polling. Because non-secure users can program/erase the data flash without calling the secure gateway, if secure user uses FCU interrupts, the unintentional exception handliing may be exeuted when data flash is programmed/erased by a non-secure user.

PROTECT 位（寄存器的保护）

PROTECT 位控件启用或禁用写入到要保护的相应寄存器。TZFOAD 寄存器受 PROTECT 保护。

PROTECT 位设置时,同时在 KEY[7:0] 位中写入 0xA5。

键[7:0] 位（KeyCode）

KEY[7:0] 位用于启用或禁用 PROTECT 位的写入。PROTECT 位时,同时在 KEY[7:0] 位中写入 0xA5。

KEY[7:0]位值除0xA5写入时,保护位不更新。

KEY[7:0] 位始终读取为 0x00。

40。5 使用说明

40。5。1 SAU 设置

重置后,所有地址空间均通过 SAU 默认设置标记为 Secure。SAU_CTRL 寄存器应设置为 0x2 以启用 IDAU 安全属性。即,将SAU_CTRL寄存器设置为0x2后,地址空间安全属性变为如表40。6 .所示

40.5.2 FACI 寄存器设置过程中的非安全异常

如表 40。5 所示,与 FACI 相关的寄存器仅在编程/擦除期间或暂停编程/擦除期间受到保护,免受非安全访问。在该状态之外,来自非安全区域的访问不受保护。

例如,当安全用户编程时,如果在 “将目标块的起始地址设置为图 38。13 中的 FSADDR 寄存器” 流之后立即出现非安全异常,则非安全用户可以重写 FSADDR。如果在非安全异常处理完成并且CPU状态返回到安全状态之后发出FACI命令,则数据将被编程到安全用户不打算使用的地址。

为了防止这种情况发生,安全用户需要设置在接下来的一段时间内不接受非安全异常。

- 在将 FWEPROR 设置为 0x01 或将 FENTRYR 设置为 0x0000 之外之前,即在放松对 FWEPROR 或 FENTRYR 的保护之前,设置为不接受非安全例外。
- 设置为在完成对 FACI 命令发布区域的所有写访问后接受非安全异常。

40。5。3 FCU 中断使用

建议安全用户不要使用 FCU 中断,而是使用寄存器轮询。由于非安全用户可以在不调用安全网关的情况下对数据闪存进行编程/擦除,因此如果安全用户使用FCU中断,则当非安全用户对数据闪存进行编程/擦除时,可能会执行无意的异常操作。

41.2.7 Thermal Characteristics

Maximum value of junction temperature (Tj) must not exceed the value of "section 41.2.1. Tj/Ta Definition".

Tj is calculated by either of the following equations.

- Tj = Ta + θja × Total power consumption
- Tj = Tt + Ψjt × Total power consumption
  - Tj : Junction Temperature (°C)
  - Ta : Ambient Temperature (°C)
  - Tt : Top Center Case Temperature (°C)
  - θja : Thermal Resistance of "Junction"-to-"Ambient" (°C/W)
  - Ψjt : Thermal Resistance of "Junction"-to-"Top Center Case" (°C/W)
- Total power consumption = Voltage × (Leakage current + Dynamic current)
- Leakage current of IO = Σ (I_{OL} × V_{OL}) /Voltage + Σ (|I_{OH}| × |VCC – V_{OH}|) /Voltage
- Dynamic current of IO = Σ IO (C_{in} + C_{load}) × IO switching frequency × Voltage
  - C_{in}: Input capacitance

假设:

- 封装 64 引脚 LQFP:θja = 41。3 °C/W
- Ta = 100 °C
- I_{CC}max = 40 mA
- VCC = 3。5 V（VCC = AVCC0）

- I OL = 1 mA,V OL = 0。5 V,8 个输出
- C in = 8 pF,8 个引脚,输入频率 = 10 MHz
- C 负载 = 30 pF,8 个引脚,输出频率 = 10 MHz

IO = Σ（V OL × I OL）/电压 + Σ（（VCC V OH）× I OH）/电压的泄漏电流

= (20 mA × 1 V）× 6 / 3。5 V + (1 mA × 0。5 V）× 8 / 3。5 V + (（VCC（VCC 0。5 V））× 1 mA）× 8 / 3。5 V

= 34.29 mA + 1.14 mA + 1.14 mA
= 36.6 mA

Dynamic current of IO = Σ IO (C_{in} + C_{load}) × IO switching frequency × Voltage
= ((8 pF × 8) × 10 MHz + (30 pF × 8) × 10 MHz) × 3.5 V

Total power consumption = Voltage × (Leakage current + Dynamic current)
= (40 mA × 3.5 V) + (36.6 mA + 10.6 mA) × 3.5 V

Tj = Ta + θja × Total power consumption
= 100 °C + 41.3 °C/W × 0.305 W
= 112.6 °C

Note 1. When setting up the main clock oscillator, ask the oscillator manufacturer for an oscillation evaluation, and use the results as the recommended oscillation stabilization time. Set the MOSCWTCR register to a value equal to or greater than the recommended value.
After changing the setting in the MOSCCR.MOSTP bit to start main clock operation, read the OSCSF.MOSCSF flag to confirm that it is 1, and then start using the main clock oscillator.
Note 2. This is the time from release from reset state until the HOCO oscillation frequency (f_{HOCO}) reaches the range for guaranteed operation.

Note 1. When setting up the sub-clock oscillator, ask the oscillator manufacturer for an oscillation evaluation and use the results as the recommended oscillation stabilization time.
After changing the setting in the SOSCCR.SOSTP bit to start sub-clock operation, only start using the sub-clock oscillator after the sub-clock oscillation stabilization time elapses with an adequate margin. A value that is two times the value shown is recommended.

Note 1. The recovery time is determined by the system clock source. When multiple oscillators are active, the recovery time can be determined with the following equation:
Total recovery time = recovery time for an oscillator as the system clock source + the longest tSBYOSCWT in the active oscillators - tSBYOSCWT for the system clock + 2 LOCO cycles (when LOCO is operating) + Subosc is oscillating and MSTPC0 = 0 (CAC module stop))
Note 2. When the frequency of the crystal is 24 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 1.
Note 3. When the frequency of PLL is 200 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 4.
Note 4. When the frequency of the external clock is 24 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 1.
Note 5. When the frequency of PLL is 200 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 4.
Note 6. The Sub-clock oscillator frequency is 32.768 KHz and the greatest value of the internal clock division setting is 1.
Note 7. The LOCO frequency is 32.768 kHz and the greatest value of the internal clock division setting is 1.
Note 8. The HOCO frequency is 20 MHz and the greatest value of the internal clock division setting is 1.
Note 9. The PLL frequency is 200 MHz and the greatest value of the internal clock division setting is 4.
Note 10. The MOCO frequency is 8 MHz and the greatest value of the internal clock division setting is 1.
Note 11. In Subosc-speed mode, the sub-clock oscillator or LOCO continues oscillating in Software Standby mode.
Note 12. When the SNZCR.RXDREQEN bit is set to 0, the following time is added as the power supply recovery time: 16 µs (typical), 48 µs (maximum).
Note 13. The recovery time can be calculated with the equation of tSBYOSCWT + tSBYSEQ. And they can be determined with the following value and equation. For n, the greatest value is selected from among the internal clock division settings.

2. The following pins do not require setting: SDA0_D, SCL0_D.
3. Use pins that have a letter appended to their names, for instance "_A" or "_B", to indicate group membership. For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Note 2. The Master may use a shorter Low period if it knows that this is safe, i.e., that SDA is already above VIH
Note 3. Based on t_{SPIKE}, rise and fall times, and interconnect
Note 4. This maximum High period may be exceeded when the signals can be safely seen by Legacy I^2C Devices, and/or in consideration of the interconnect (e.g., a short Bus).
As a product specification, if this Max value cannot be guaranteed, change this Max value and specify that it cannot be used in the Mixed Bus.
Note 5. On a legacy bus where I^2C devices need to see Start
Note 6. Slaves that do not support the optional ENTASx CCCs shall use the t_{CAS} Max value shown for ENTAS3
Note 7. On a mixed bus with Fm Legacy I^2C Devices, t_{AVAL} is 300 ns shorter than the Fm Bus Free Condition time (t_{BUF})

注2。Master如果知道这是安全的,即SDA已经高于VIH注释3,则可以使用更短的低周期。基于tSPIKE、涨跌时间、互连
注4。Legacy I 2 C设备可以安全地看到信号时,和/或考虑到互连（例如,短总线）,可能会超过该最大高周期。

Note 3. When communicating with an I3C Device on a mixed Bus, the $t_{DIG\_H\_MIXED}$ period must be constrained in order to make sure that I^2C Devices do not interpret I3C signaling as valid I^2C signaling.
Note 4. As both edges are used, the hold time needs to be satisfied for the respective edges; i.e., t_{CF} + 3 for falling edge clocks, and t_{CR} + 3 for rising edge clocks.

Note: These specification values apply when there is no access to the external bus during A/D conversion. If access occurs during A/D conversion, values might not fall within the indicated ranges.
The use of PORT0 as digital outputs is not allowed when the 12-Bit A/D converter is used.
The characteristics apply when AVCC0, AVSS0, VREFH0, VREFL0, and 12-bit A/D converter input voltage are stable.

Note 1. The conversion time includes the sampling and comparison times. The number of sampling states is indicated for the test conditions.

Note 2. Values in parentheses indicate the sampling time.

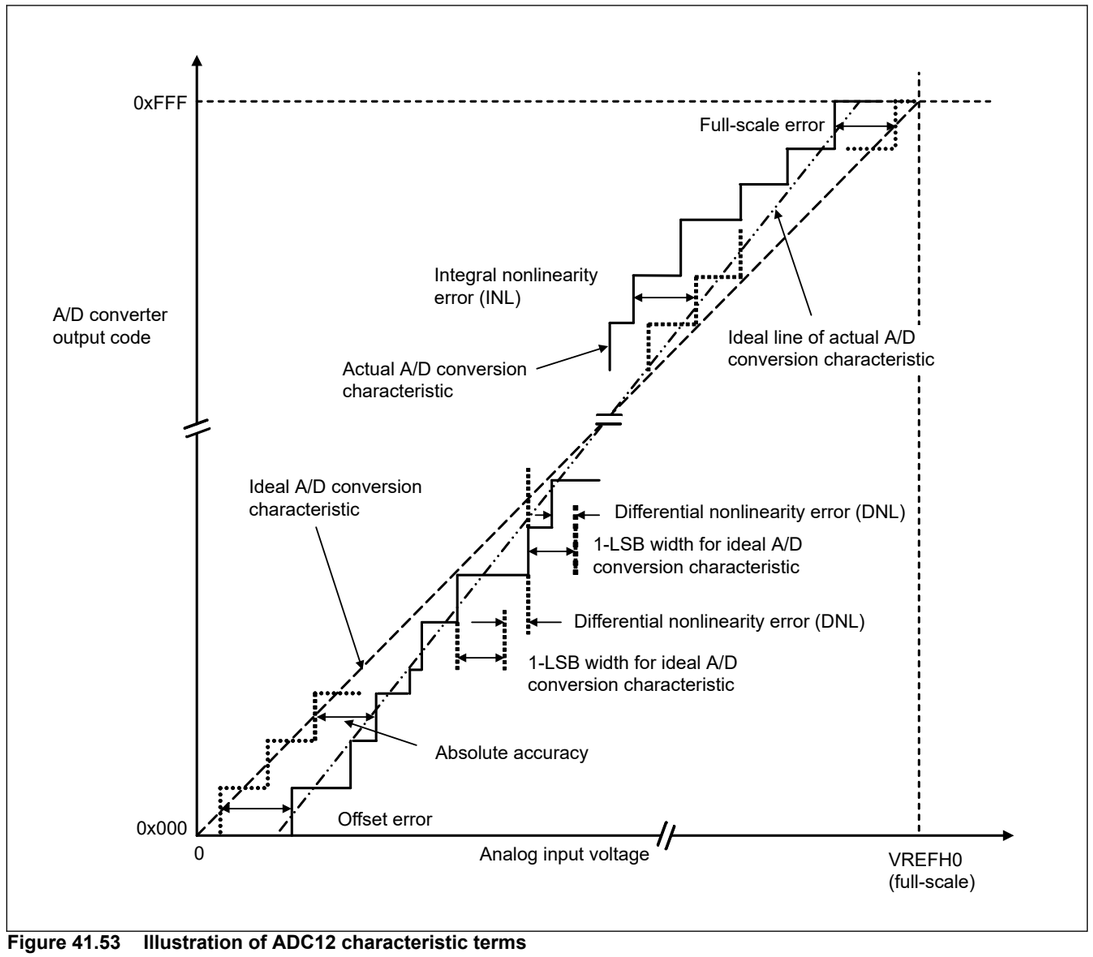

Figure 41.53 Illustration of ADC12 characteristic terms

Absolute accuracy

Absolute accuracy is the difference between output code based on the theoretical A/D conversion characteristics, and the actual A/D conversion result. When measuring absolute accuracy, the voltage at the midpoint of the width of the analog input voltage (1-LSB width), which can meet the expectation of outputting an equal code based on the theoretical A/D conversion characteristics, is used as an analog input voltage. For example, if 12-bit resolution is used and the reference voltage VREFH0 = 3.072 V, then the 1-LSB width becomes 0.75 mV, and 0 mV, 0.75 mV, and 1.5 mV are used as the analog input voltages. If the analog input voltage is 6 mV, an absolute accuracy of ±5 LSB means that the actual A/D conversion result is in the range of 0x003 to 0x00D, though an output code of 0x008 can be expected from the theoretical A/D conversion characteristics.

Integral nonlinearity error (INL)

Integral nonlinearity error is the maximum deviation between the ideal line when the measured offset and full-scale errors are zeroed, and the actual output code.

Differential nonlinearity error (DNL)

Differential nonlinearity error is the difference between the 1-LSB width based on the ideal A/D conversion characteristics and the width of the actual output code.

Offset error

Offset error is the difference between the transition point of the ideal first output code and the actual first output code.

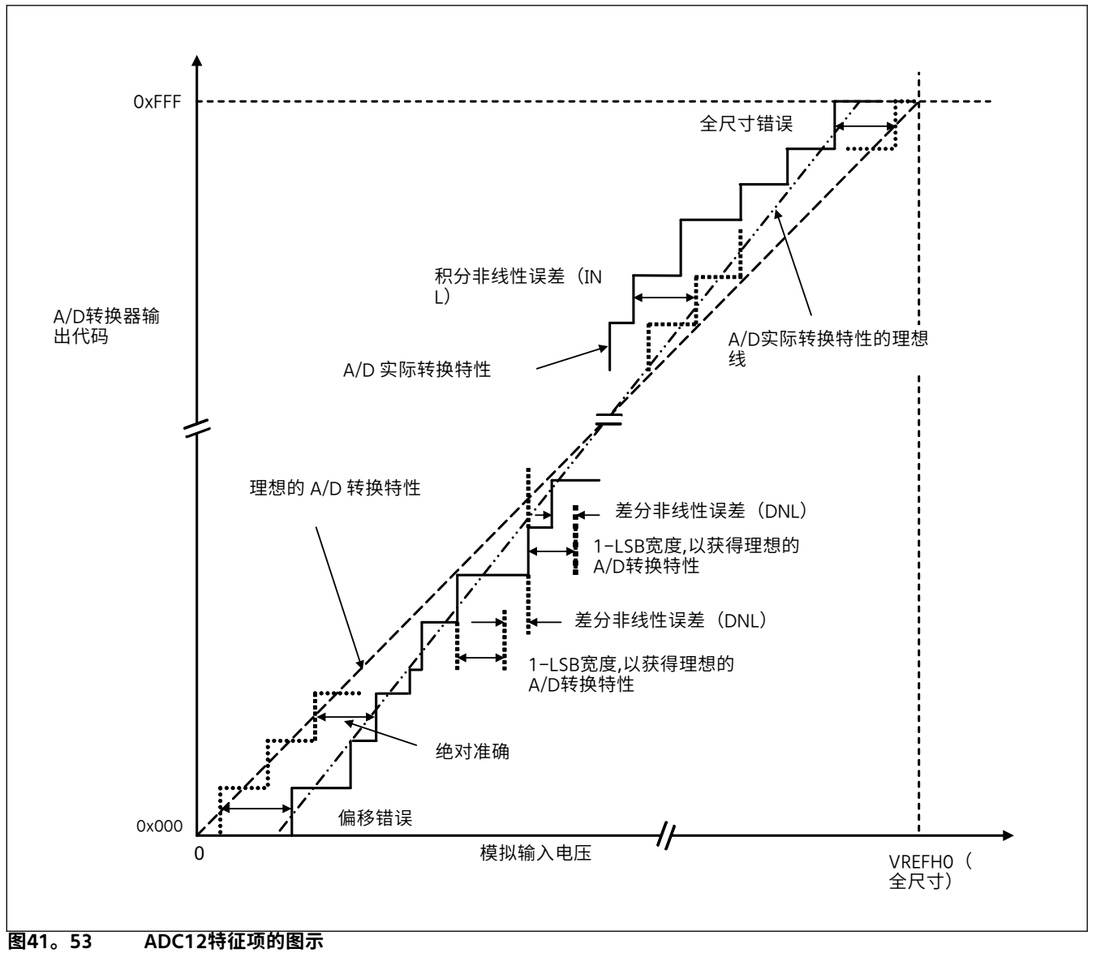

图41。53 ADC12特征项的图示

绝对准确

绝对精度是基于理论A/D转换特性的输出代码与实际A/D转换结果之间的差异。测绝对精度时,以模拟输入电压宽度(1-LSB宽度）中点电压为模拟输入电压,可满足基于理论A/D转换特性输出等码的期望。电压。例如,如果使用12位分辨率并且参考电压VREFH0=3。072V,则1-LSB宽度变为0。75mV,并且使用0mV、0。75mV和1。5mV作为模拟输入电压。如果模拟输入电压为 6 mV,则绝对精度为 ±5 LSB 意味着实际 A/D 转换结果在 0x003 至 0x00D 范围内,尽管从理论 A/D 可以预期输出代码为 0x008转换特性。

积分非线性误差（INL）

积分非线性误差是测量偏移量和满量程误差归零时理想线与实际输出代码之间的最大偏差。

差分非线性误差（DNL）

差分非线性误差是基于理想的 A/D 转换特性的 1-LSB 宽度与实际输出代码宽度之间的差值。

偏移错误

偏移误差是理想第一输出码和实际第一输出码的过渡点之间的差值。

Full-scale error

Full-scale error is the difference between the transition point of the ideal last output code and the actual last output code.

Note 4. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 10,000), erasing can be performed n times for each block. For example, when 128-byte programming is performed 64 times for different addresses in 8-KB blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. Overwriting is prohibited.
Note 5. Time for resumption includes time for reapplying the erasing pulse (up to one full pulse) that was cut off at the time of suspension.
Note 6. The reference value at VCC = 3.3V and room temperature.

3.2 Access Cycles

This section provides access cycle information for the I/O registers described in this manual.

- Registers are grouped by associated module.
- The number of access cycles indicates the number of cycles based on the specified reference clock.
- In the internal I/O area, reserved addresses that are not allocated to registers must not be accessed, otherwise operations cannot be guaranteed.
- The number of I/O access cycles depends on bus cycles of the internal peripheral bus, divided clock synchronization cycles, and wait cycles of each module. Divided clock synchronization cycles differ depending on the frequency ratio between ICLK and PCLK.
- When the frequency of ICLK is equal to that of PCLK, the number of divided clock synchronization cycles is always constant.
- When the frequency of ICLK is greater than that of PCLK, at least 1 PCLK cycle is added to the number of divided clock synchronization cycles.

3。2 访问周期

本节提供本手册中描述的 I/O 寄存器的访问周期信息。

- 寄存器按关联模块分组。
- 访问周期数表示基于指定参考时钟的周期数。
- 在内部I/O区域,不得访问未分配给寄存器的保留地址,否则无法保证操作。
- I/O 访问周期数取决于内部外围总线的总线周期、划分的时钟同步周期以及每个模块的等待周期。分频时钟同步周期根据 ICLK 和 PCLK 之间的频率比而有所不同。
- 当 ICLK 的频率等于 PCLK 的频率时,划分的时钟同步周期数始终恒定。
- 当ICLK的频率大于PCLK时,在划分的时钟同步周期数中至少增加1个PCLK周期。

- The number of write access cycles indicates the number of cycles obtained by non-bufferable write access.

Note: This applies to the number of cycles when access from the CPU does not conflict with the instruction fetching to the external memory or bus access from other bus masters such as DTC or DMAC.

Peripherals	Address		Number of access cycles				Cycle Unit	Related function
			ICLK = FCLK		ICLK > FCLK*1

FLAD, FACI	0x407F_C000	0x407F_EFFF	5	4	2 to 5	2 to 4	FCLK	Data Flash, Flash Application Command Interface

Note 1. If the number of PCLK or FCLK cycles is non-integer (for example 1.5), the minimum value is without the decimal point, and the maximum value is rounded up to the decimal point. For example, 1.5 to 2. 5 is 1 to 3.

Note 2. When accessing a 16-bit register (FTDRHL, FRDRHL, FCR, FDR, LSR, and CDR), access is 2 cycles more than the value shown in Table 3.2. When accessing an 8-bit register (including FTDRH, FTDRL, FRDRH, and FRDRL), the access cycles are as shown in Table 3.2.

Note 3. When accessing the 32-bit register (SPDR), access is 2 cycles more than the value in Table 3.2. When accessing an 8-bit or 16-bit register (SPDR_HA), the access cycles are as shown in Table 3.2.

注1。PCLK或FCLK循环次数为非整数（例如1。5),则最小值为无小数点,最大值四舍五入至小数点。例如,1。5到2。5是1到3。

注2。访问 16 位寄存器（FTDRHL、FRDRHL、FCR、FDR、LSR 和 CDR）时,访问比表 3。2 中所示的值多 2 个周期。8位寄存器（包括FTDRH、FTDRL、FRDRH和FRDRL）时,访问周期如表3。2 .所示

注3。32位寄存器（SPDR）时,访问比表3。2中的值多2个周期。8位或16位寄存器（SPDR_HA）时,访问周期如表3。2 .所示
