General Precautions in the Handling of Microprocessing Unit and Microcontroller Unit Products

The following usage notes are applicable to all Microprocessing unit and Microcontroller unit products from Renesas. For detailed usage notes on the products covered by this document, refer to the relevant sections of the document as well as any technical updates that have been issued for the products.

1. Precaution against Electrostatic Discharge (ESD)
   A strong electrical field, when exposed to a CMOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop the generation of static electricity as much as possible, and quickly dissipate it when it occurs. Environmental control must be adequate. When it is dry, a humidifier should be used. This is recommended to avoid using insulators that can easily build up static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors must be grounded. The operator must also be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions must be taken for printed circuit boards with mounted semiconductor devices.
2. Processing at power-on
   The state of the product is undefined at the time when power is supplied. The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the time when power is supplied. In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the time when power is supplied until the reset process is completed. In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the time when power is supplied until the power reaches the level at which resetting is specified.
3. Input of signal during power-off state
   Do not input signals or an I/O pull-up power supply while the device is powered off. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements. Follow the guideline for input signal during power-off state as described in your product documentation.
4. Handling of unused pins
   Handle unused pins in accordance with the directions given under handling of unused pins in the manual. The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of the LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible.
5. Clock signals
   After applying a reset, only release the reset line after the operating clock signal becomes stable. When switching the clock signal during program execution, wait until the target clock signal is stabilized. When the clock signal is generated with an external resonator or from an external oscillator during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Additionally, when switching to a clock signal produced with an external resonator or by an external oscillator while program execution is in progress, wait until the target clock signal is stable.
6. Voltage application waveform at input pin
   Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between V_{IL} (Max.) and V_{IH} (Min.) due to noise, for example, the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between V_{IL} (Max.) and V_{IH} (Min.).
7. Prohibition of access to reserved addresses
   Access to reserved addresses is prohibited. The reserved addresses are provided for possible future expansion of functions. Do not access these addresses as the correct operation of the LSI is not guaranteed.
8. Differences between products
   Before changing from one product to another, for example to a product with a different part number, confirm that the change will not lead to problems. The characteristics of a microprocessing unit or microcontroller unit products in the same group but having a different part number might differ in terms of internal memory capacity, layout pattern, and other factors, which can affect the ranges of electrical characteristics, such as characteristic values, operating margins, immunity to noise, and amount of radiated noise. When changing to a product with a different part number, implement a system-evaluation test for the given product.

处理微处理单元和微控制器的一般注意事项单位产品

以下使用说明适用于瑞萨的所有微处理单元和微控制器单元产品。有关详细的使用说明本文档所涵盖的产品，请参阅文档的相关部分以及为产品发布的任何技术更新。

1. 防止静电放电(ESD)
   当暴露于CMOS器件时，强电场会导致栅极氧化物的破坏并最终降低器件的运行性能。脚步必须采取措施，尽可能停止静电的产生，并在出现时迅速消散。环境控制必须足够的。干燥时，应使用加湿器。建议避免使用容易产生静电的绝缘体。半导体器件必须在防静电容器、静电屏蔽袋或导电材料中储存和运输。所有测试和包括工作台和地板在内的测量工具必须接地。操作员还必须使用腕带接地。半导体不得赤手触摸设备。对于安装有半导体器件的印刷电路板，必须采取类似的预防措施。
2. 上电处理
   通电时产品的状态是不确定的。LSI内部电路的状态是不确定的，通电时寄存器设置和引脚未定义。在将复位信号施加到外部复位的成品中管脚，从通电到复位过程完成，管脚的状态不能保证。以类似的方式，引脚的状态在通过片内上电复位功能复位的产品中，从供电时间到供电达到指定重置的级别。
3. 断电状态下的信号输入
   请勿在设备断电时输入信号或IO上拉电源。输入此类信号或IO导致的电流注入上拉电源可能会导致故障，此时通过设备的异常电流可能会导致内部退化元素。请按照产品文档中所述的电源关闭状态下的输入信号指南进行操作。
4. 处理未使用的引脚
   按照手册中未使用引脚处理中给出的说明处理未使用的引脚。CMOS产品的输入引脚是一般处于高阻状态。在开路状态下使用未使用的引脚操作时，会在附近感应出额外的电磁噪声LSI，相关的直通电流在内部流动，并且由于将引脚状态错误识别为输入信号而发生故障成为可能。
5. 时钟信号
   应用复位后，只有在工作时钟信号稳定后才释放复位线。在程序中切换时钟信号时执行，等待目标时钟信号稳定。当时钟信号由外部谐振器或外部振荡器产生时在复位期间，确保只有在时钟信号完全稳定后才释放复位线。此外，当切换到时钟信号时在程序执行过程中由外部谐振器或外部振荡器产生，等待目标时钟信号稳定。
6. 输入引脚的电压施加波形
   由于输入噪声或反射波导致的波形失真可能会导致故障。如果CMOS器件的输入保持在VIL之间的区域(Max.)和VIH(Min.)由于噪音，例如，设备可能发生故障。小心，以防止颤动的噪音进入设备时，输入电平是固定的，并且在输入电平通过VIL(Max.)和VIH(Min.)之间的区域时的过渡期间也是如此。
7. 禁止访问保留地址
   禁止访问保留地址。保留地址是为将来可能的功能扩展提供的。不要访问这些不能保证LSI的正确操作。
8. 产品之间的差异
   在从一种产品更改为另一种产品之前，例如更改为具有不同部件号的产品，请确认更改不会导致问题。同一组中的微处理单元或微控制器单元产品的特性，但具有不同的部件号，其特性可能会有所不同内部存储器容量，布局模式和其他因素，这些因素会影响电气特性的范围，例如特性值，工作裕度、抗噪声能力和辐射噪声量。当更改为具有不同部件号的产品时，实施系统-给定产品的评估测试

Table 1.3 System (2 of 2)

Feature	Functional description
Watchdog Timer (WDT)	The Watchdog Timer (WDT) is a 14-bit down-counter that can be used to reset the MCU when the counter underflows because the system has run out of control and is unable to refresh the WDT. In addition, a non-maskable interrupt or interrupt can be generated by an underflow. A refresh-permitted period can be set to refresh the counter and used as the condition for detecting when the system runs out of control. See section 27, Watchdog Timer (WDT).
Independent Watchdog Timer (IWDT)	The Independent Watchdog Timer (IWDT) consists of a 14-bit down-counter that must be serviced periodically to prevent counter underflow. The IWDT provides functionality to reset the MCU or to generate a non-maskable interrupt or interrupt for a timer underflow. Because the timer operates with an independent, dedicated clock source, it is particularly useful in returning the MCU to a known state as a fail-safe mechanism when the system runs out of control. The IWDT can be triggered automatically on a reset, underflow, or refresh error, or by a refresh of the count value in the registers. See section 28, Independent Watchdog Timer (IWDT).

Table 1.4 Event link

Feature	Functional description
Event Link Controller (ELC)	The Event Link Controller (ELC) uses the interrupt requests generated by various peripheral modules as event signals to connect them to different modules, enabling direct interaction between the modules without CPU intervention. See section 19, Event Link Controller (ELC).

Table 1.5 Direct memory access

Feature	Functional description
Data Transfer Controller (DTC)	A Data Transfer Controller (DTC) module is provided for transferring data when activated by an interrupt request. See section 18, Data Transfer Controller (DTC).
DMA Controller (DMAC)	An 8-channel DMA Controller (DMAC) module is provided for transferring data without the CPU. When a DMA transfer request is generated, the DMAC transfers data stored at the transfer source address to the transfer destination address. See section 17, DMA Controller (DMAC).

2.5 Debug Mode

2.5.1 Debug Mode Definition

In single chip mode, the debugger connection state is defined as On-Chip Debugger (OCD) mode, and the non-connected debugger state is defined as User mode. Table 2.4 shows the CPU debug modes and usage conditions.

Table 2.4 CPU debug mode and conditions

Conditions		Mode	
OCD connect	**JTAG/SWD authentication**	**Debug mode**	**Debug authentication**
Not connected	—	User mode	Disabled
Connected	Failed	User mode	Disabled
Connected	Passed	OCD mode	Enabled

Note 1. OCD connect is determined by the CDBGPWRUPREQ bit output in the SWJ-DP register. The bit can only be written by the OCD. However, the level of the bit can be confirmed by reading the DBGSTR.CDBGPWRUPREQ bit.

Note 2. Debug authentication is defined by the Armv7-M architecture. Enabled means that both invasive and non-invasive CPU debugging are permitted. Disabled means that both are not permitted.

2.5.2 Debug Mode Effects

This section describes the effects of debug mode, which occur both internally and externally to the CPU.

2.5.2.1 Low power mode

All CoreSight debug components can store the register settings even when the CPU enters Software Standby, Snooze, or Deep Software Standby mode. However, AHB-AP cannot respond to On-Chip Debug (OCD) access in these low power modes. The OCD must wait for cancellation of the low power mode to access the CoreSight debug components. To request low power mode cancellation, the OCD can set the DBIRQ bit in the MCUCTRL register. For details, see section 2.6.5.3, MCU Control Register (MCUCTRL).

2.5.2.2 Reset

In OCD mode, some resets depend on the CPU status and the DBGSTOPCR setting.

Table 2.5 Reset or interrupt and mode setting (1 of 2)

	Control in On-Chip Debug (OCD) mode	
Reset or interrupt name	**OCD break mode**	**OCD run mode**
RES pin reset	Same as user mode	
Power-on reset	Same as user mode	
Independent watchdog timer reset/interrupt	Does not occur*1	Depends on DBGSTOPCR setting*2
Watchdog timer reset/interrupt	Does not occur*1	Depends on DBGSTOPCR setting*2
Voltage monitor 0 reset	Depends on DBGSTOPCR setting*3	
Voltage monitor 1 reset/interrupt	Depends on DBGSTOPCR setting*3	
Voltage monitor 2 reset/interrupt	Depends on DBGSTOPCR setting*3	

Table 2.3 JTAG/SWD pins

Name	I/O	P/N	Width	Function	不使用时
TCK/SWCLK	Input	Positive	1 bit	JTAG时钟引脚	Pull-up
TMS/SWDIO	I/O	Negative	1 bit	JTAG TMS pin SWD I/O pin	Pull-up
TDI	Input	Positive	1 bit	JTAG TDI pin	Pull-up
TDO/SWO	Output	Negative	1 bit	JTAGTDO引脚与串行线输出复用	Open

2.5 调试模式

2.5.1 调试模式定义

在单芯片模式下，调试器连接状态定义为片上调试器（OCD）模式，未连接调试器状态定义为用户模式。表2.4显示了CPU调试模式和使用条件。

Table 2.4 CPU调试模式和条件

Conditions		Mode	
强迫症连接	**JTAG/SWD authentication**	**调试模式**	**调试认证**
未连接	—	用户模式	Disabled
Connected	Failed	用户模式	Disabled
Connected	Passed	强迫症模式	Enabled

Note 1. OCD连接由SWJ-DP寄存器中的CDBGPWRUPREQ位输出决定。该位只能由强迫症。但是，可以通过读取DBGSTR.CDBGPWUPREQ位来确认该位的电平。

Note 2. 调试身份验证由Armv7-M架构定义。启用意味着允许侵入式和非侵入式CPU调试。禁用意味着两者都不允许。

2.5.2 调试模式效果

本节描述调试模式的影响，它在CPU内部和外部都发生。

2.5.2.1 低功耗模式

即使CPU进入软件待机、贪睡或深度软件待机模式，所有CoreSight调试组件都可以存储寄存器设置。但是，AHB-AP在这些低功耗模式下无法响应片上调试(OCD)访问。OCD必须等待取消低功耗模式才能访问CoreSight调试组件。要请求取消低功耗模式，OCD可以设置MCUCTRL寄存器中的DBIRQ位。有关详细信息，请参见第2.6.5.3节，MCU控制寄存器（MCUCTRL）。

2.5.2.2 Reset

在OCD模式下，一些复位取决于CPU状态和DBGSTOPCR设置。

Table 2.5 复位或中断和模式设置（1of2）

	片上调试(OCD)模式下的控制	
重置或中断名称	**强迫症休息模式**	**强迫症运行模式**

2.6 Programmers Model

2.6.1 Address Spaces

The MCU debug system includes two CoreSight Access Ports (AP):

- AHB-AP, which is connected to the CPU bus matrix and has the same access to the system address space as the CPU
- APB-AP, which has a dedicated address space (OCD address space) and is connected to the OCD register.

Figure 2.2 shows a block diagram of the AP connection and address spaces.

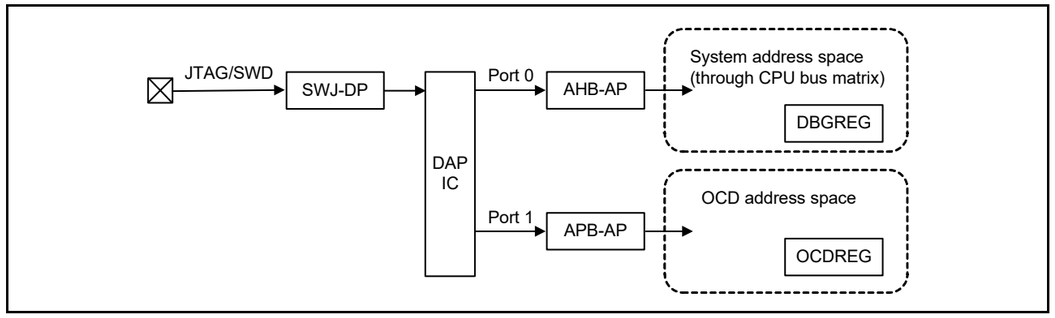

Figure 2.2 JTAG/SWD authentication block diagram

For debugging purposes, there are two register modules, DBGREG and OCDREG. DBGREG is located in the system address space and can be accessed from the OCD emulator, the CPU, and other bus masters in the MCU. OCDREG is located in the OCD address space and can only be accessed from the OCD tool. The CPU and other bus masters cannot access the OCD registers.

2.6.2 Cortex-M4 Peripheral Address Map

In the system address space, the Cortex-M4 core has a Private Peripheral Bus (PPB) that can only be accessed from the CPU and OCD emulator. The PPB is expanded from the Cortex-M4 original implementation for the MCU. Table 2.6 shows the address map of the MCU.

Note 2. IWDT和WDT操作取决于DBGSTOPCR设置。
Note 3. 复位或中断屏蔽取决于DBGSTOPCR设置。

2.6 程序员模型

2.6.1 地址空间

MCU调试系统包括两个CoreSight访问端口(AP)：

- AHB-AP，与CPU总线矩阵相连，与系统地址空间具有相同的访问权限CPU
- APB-AP，它有一个专用的地址空间（OCD地址空间），并与OCD寄存器相连。

图2.2显示了AP连接和地址空间的框图。

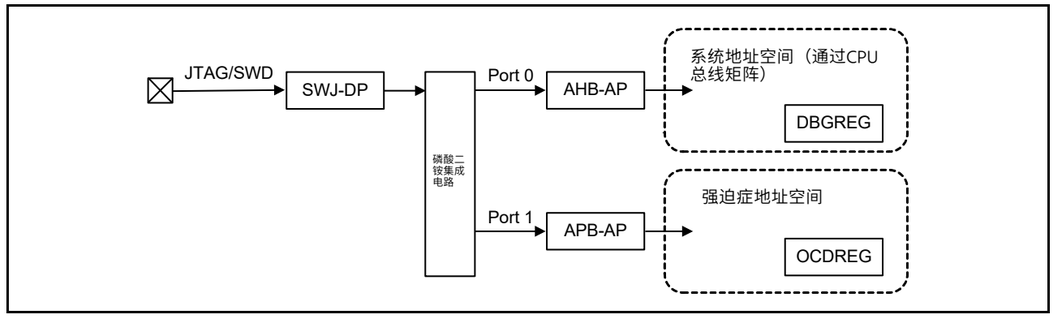

Figure 2.2 JTAGSWD认证框图

出于调试目的，有两个寄存器模块，DBGREG和OCDREG。DBGREG位于系统地址空间中，可以从OCD仿真器、CPU和MCU中的其他总线主控器访问。OCDREG位于OCD地址空间，只能从OCD工具访问。CPU和其他总线主机无法访问OCD寄存器。

2.6.2 Cortex-M4外设地址映射

在系统地址空间中，Cortex-M4内核有一个私有外设总线(PPB)，只能从CPU和强迫症模拟器。PPB从MCU的Cortex-M4原始实现扩展而来。表2.6显示了MCU的地址映射。

Note: OCDREG is located in the dedicated OCD address space. This address map is independent from the system address map. See section 2.6.2, Cortex-M4 Peripheral Address Map.

2.6.5.1 ID Authentication Code Register (IAUTH0 to 3)

Four authentication registers are provided for writing the 128-bit key. These registers must be written in sequential order from IAUTH0 to IAUTH3. If the set of register writes is not compliant with this order, the result is unpredictable.

Only 32-bit writes are permitted. The initial value of the registers is all 1s. This means that JTAG/SWD access is initially permitted when the ID code in the OSIS register has the initial value. See section 2.11.2, Unlock ID Code.

2.6.4.4 DBGREGCoreSight组件寄存器

DBGREG模块提供在ArmCoreSight架构中定义的CoreSight组件寄存器。

2.6.5 OCDREG Module

OCDREG寄存器模块控制片上调试(OCD)仿真器功能，并实现为CoreSight-compliant component.

表2.11显示了除CoreSight组件寄存器之外的OCDREG寄存器。

Note: OCDREG位于专用的OCD地址空间中。该地址映射独立于系统地址映射。
请参阅第2.6.2节，Cortex-M4外设地址映射。

2.6.5.1 ID验证码寄存器（IAUTH0至3）

提供了四个认证寄存器用于写入128位密钥。这些寄存器必须按IAUTH0到IAUTH3的顺序写入。如果寄存器写入的集合不符合此顺序，则结果是不可预测的。

只允许32位写入。寄存器的初始值全为1。这意味着当OSIS寄存器中的ID代码具有初始值时，最初允许JTAGSWD访问。请参阅第2.11.2节，解锁ID代码。

2.7 CoreSight ATB Funnel

MCU中有一个CoreSightATB漏斗。漏斗有两个ATB从站和一个ATB主站，它选择从ETM和ITM到ETB的调试跟踪源。图2.3显示了MCU中的CoreSightATB连接。

Table 2.13 shows the ATB slave connection for the funnel.

Table 2.13 ATB slave connection

ATB slave number	Connected trace source
#0	ITM
#1	ETM

For details of the ATB and funnel, see reference 4.

2.8 Flash Patch and Break Unit

The MCU has a flash patch and break unit. Breakpoint function is available, but flash patch (remap) function is not available. Therefore, do not set the REPLACE bits [31:30] in the FP_COMPn register to 0. Bit [28] of FP_REMAP register is always set to 1. When writing to this register, write 1 to bit [28]. When reading this register, bit [28] is always read as 1. See reference 1.*2.9 for details.

2.9 SysTick System Timer

The SysTick system timer provides a simple 24-bit down counter. The reference clock for the timer can be selected as the CPU clock (ICLK) or SysTick Timer clock (SYSTICCLK). See section 9, Clock Generation Circuit and reference 1.*1 for details.

Note 1. In the reference, the IMPLEMENTATION DEFINED external reference clock is SYSTICCLK (LOCO) and the processor clock is ICLK.

2.10 CoreSight Time Stamp Generator

A CoreSight Time Stamp Generator provides a CPU clock-based timestamp to ITM and ETM. The 48 LSB bits of the 64-bit counter are used for the two components. See reference 4. for details.

2.11 OCD Emulator Connection

A JTAG/SWD authentication mechanism checks access permission for debug and MCU resources. To obtain full debug functionality, a pass result of the authentication mechanism is required.

Figure 2.4 shows a block diagram of the authentication mechanism.

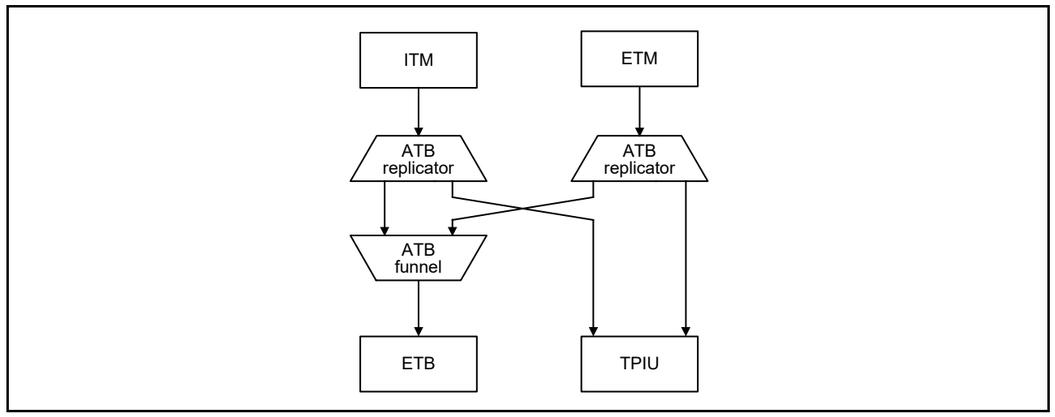

Figure 2.3 CoreSight ATB connection

表2.13显示了漏斗的ATB从属连接。

Table 2.13 ATB从机连接

ATB从机号	连接的跟踪源
#0	ITM
#1	ETM

有关ATB和漏斗的详细信息，请参阅参考4。

2.8 闪存补丁和中断单元

MCU有一个闪存补丁和中断单元。断点功能可用，但闪存补丁（重映射）功能不可用。因此，不要将FP_COMPn寄存器中的REPLACE位[31:30]设置为0。FP_REMAP寄存器的位[28]始终设置为1。写入该寄存器时，将1写入位[28]。读取此寄存器时，位[28]始终读取为1。请参阅参考1。*2.9了解详细信息。

2.9 SysTick系统定时器

SysTick系统定时器提供了一个简单的24位递减计数器。定时器的参考时钟可以选择为CPU时钟(ICLK)或SysTick定时器时钟(SYSTICCLK)。请参阅第9节，时钟生成电路和参考1。*1了解详细信息。

注1.在参考中，实现定义的外部参考时钟是SYSTICCLK(LOCO)，处理器时钟是ICLK。

2.10 CoreSight时间戳生成器

CoreSight时间戳生成器为ITM和ETM提供基于CPU时钟的时间戳。64位计数器的48个LSB位用于这两个组件。详见参考文献4。

2.11 OCD模拟器连接

JTAGSWD验证机制检查调试和MCU资源的访问权限。要获得完整的调试功能，需要验证机制的通过结果。

图2.4显示了认证机制的框图。

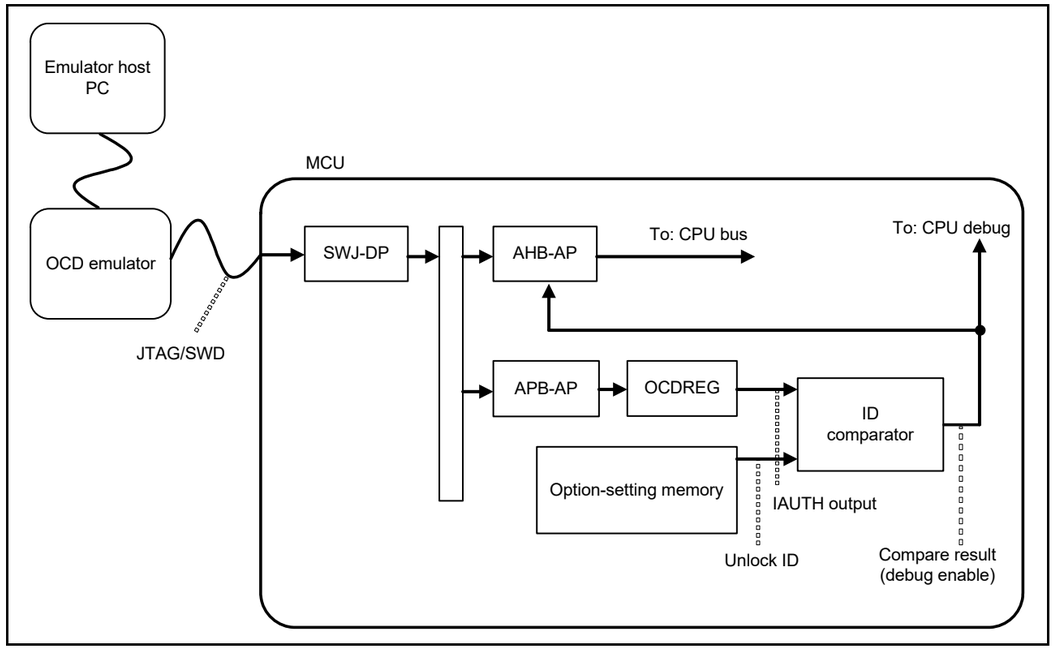

Figure 2.4 Authentication mechanism block diagram

An ID comparator is available in the MCU for authentication. The comparator compares the 128-bit IAUTH output from OCDREG and the 128-bit unlock ID code from the option-setting memory. When the two outputs are identical, the CPU debug functions and system bus access from the OCD emulator are permitted.

2.11.1 DBGEN

After the OCD emulator gets access permission, the OCD emulator must set the DBGEN bit in the System Control OCD Control Register (SYOCDCR). In addition, the OCD emulator must clear the DBGEN bit before disconnecting it. See section 11, Low Power Modes for details.

2.11.2 Unlock ID Code

The unlock ID code is used for checking permissions for debug and access to on-chip resources. If the unlock ID code matches the 128-bit data written in ID Authentication Registers 0 to 3, the JTAG/SWD debugger obtains access permission. Unlock ID code is written in the OCD/Serial Programmer ID Setting Register (OSIS) in the option-setting memory. The initial value of the unlock ID code is all 1s (FFFFFFFF_FFFFFFFF_FFFFFFFFh). See section 7, Option-Setting Memory for details.

2.11.3 Restrictions on Connecting an OCD Emulator

This section describes the restrictions on emulator access.

2.11.3.1 Starting connection while in low power mode

When starting a JTAG/SWD connection from an OCD emulator, the MCU must be in Normal or Sleep mode. If the MCU is in Software Standby, Snooze, or Deep Software Standby mode, the OCD emulator can cause the MCU to hang.

2.11.3.2 Changing low power mode while in OCD mode

When the MCU is in OCD mode, the low power mode can be changed. However, system bus access from AHB-AP is prohibited in Software Standby, Snooze, or Deep Software Standby mode. Only SWJ-DP, APB-AP, and OCDREG can be accessed from the OCD emulator in these modes. Table 2.14 shows the restrictions.

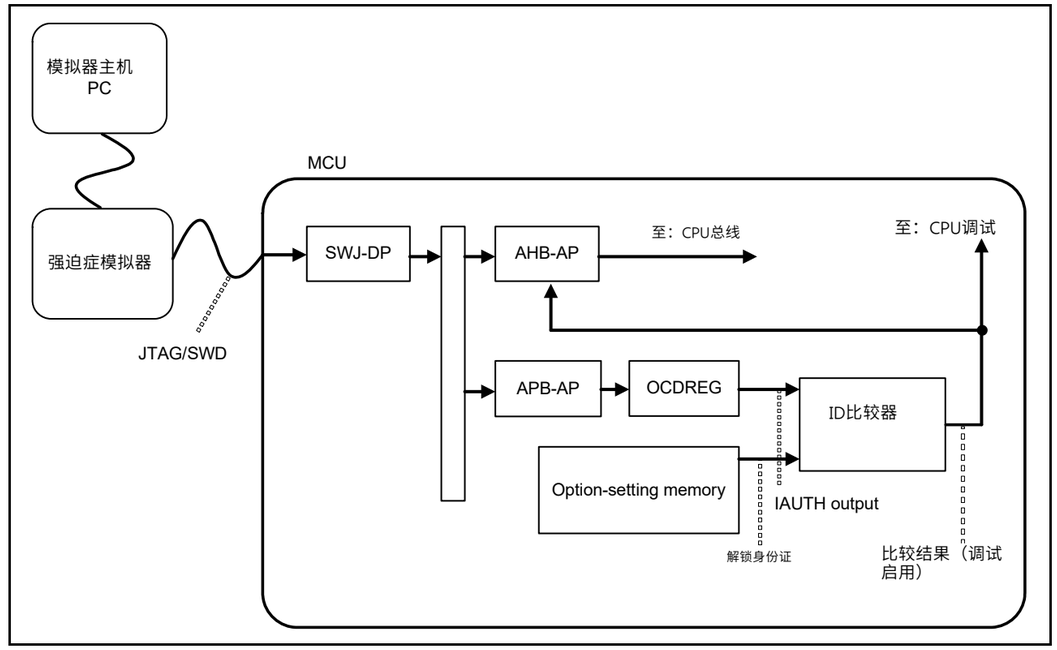

Figure 2.4 认证机制框图

MCU中有一个ID比较器用于身份验证。比较器比较来自OCDREG的128位IAUTH输出和来自选项设置存储器的128位解锁ID代码。当两个输出相同时，允许从OCD仿真器访问CPU调试功能和系统总线。

2.11.1 DBGEN

OCD模拟器获得访问权限后，OCD模拟器必须设置SystemControlOCD中的DBGEN位控制寄存器(SYOCDCR)。此外，OCD仿真器必须在断开连接之前清除DBGEN位。有关详细信息，请参见第11节，低功耗模式。

2.11.2 解锁ID码

解锁ID码用于检查调试权限和对片上资源的访问权限。如果解锁ID代码与ID验证寄存器0到3中写入的128位数据匹配，则JTAGSWD调试器获得访问权限。解锁ID代码写入选项设置存储器中的OCD串行编程器ID设置寄存器(OSIS)。解锁ID码初始值为全1（FFFFFFFF_FFFFFFFF_FFFFFFFFh）。有关详细信息，请参阅第7节，选项设置内存。

2.11.3 连接强迫症模拟器的限制

本节介绍对仿真器访问的限制。

2.11.3.1 在低功耗模式下开始连接

从OCD仿真器启动JTAGSWD连接时，MCU必须处于正常或睡眠模式。如果MCU处于软件待机、贪睡或深度软件待机模式，OCD仿真器会导致MCU挂起。

2.11.3.2 在OCD模式下更改低功耗模式

当MCU处于OCD模式时，可以更改低功耗模式。但是，在软件待机、贪睡或深度软件待机模式下，禁止从AHB-AP访问系统总线。在这些模式下，只能从OCD仿真器访问SWJ-DP、APB-AP和OCDREG。表2.14显示了这些限制。

Table 2.14 Restrictions by mode

Active mode	Start OCD emulator connection	Change low power mode	Access AHB-AP and system bus	Access APB-AP and OCDREG
Normal	Yes	Yes	Yes	Yes
Sleep	Yes	Yes	Yes	Yes
Software Standby	No	Yes	No	Yes
Snooze	No	Yes	No	Yes
Deep Software Standby	No	Yes	No	Yes

If system bus access is required in Software Standby, Snooze, or Deep Software Standby mode, set the OCUCTRL.DBIRG bit in OCDREG to wake up the MCU from the low power modes. Simultaneously, using the OCUCTRL.EDBGRQ bit in OCDREG, the OCD emulator can wake up the MCU without starting CPU execution by using a CPU break.

2.11.3.3 Modifying the unlock ID code in OSIS

After modifying the unlock ID code in the OSIS, the OCD emulator must reset the MCU by asserting the RES pin or setting the SYSRESETREQ bit of the Application Interrupt and Reset Control Register in the system control block to 1. The modified unlock ID code is reflected after reset.

2.11.3.4 Connecting sequence and JTAG/SWD authentication

Because the OCD emulator is protected by the JTAG/SWD authentication mechanism, the OCD might be required to input the ID code to the authentication registers. The OSIS value in the option-setting memory determines whether the code is required.

After the negation of the reset, a 5 µs wait time is required before comparing the OSIS value at cold start.

(1) When MSB of OSIS is 0 (bit [127] = 0)

The ID code is always mismatching and connection to the OCD is prohibited.

(2) When OSIS is all 1s (default)

OCD authentication is not required and the OCD can use the AHB-AP without authentication.

1. Connect the OCD emulator to the MCU through the JTAG or SWD interface.
2. Set up SWJ-DP to access the DAP bus. In the setup, the OCD emulator must assert CDBGPWRUPREQ in the SWJ-DP Control Status Register, then wait until CSDBGPWRUPACK in the same register is asserted.
3. Set up the AHB-AP to access the system address space. The AHB-AP is connected to the DAP bus port 0.
4. Start accessing the CPU debug resources using the AHB-AP.

(3) When OSIS[127:126] = 10b

OCD authentication is required and the OCD must write the unlock ID code to the IAUTH registers 0 to 3 in the OCDREG before using the AHB-AP.

1. Connect the OCD debugger to the MCU through the JTAG or SWD interface.
2. Set up SWJ-DP to access the DAP bus. In the setup, the OCD emulator must assert CDBGPWRUPREQ in the SWJ-DP Control Status Register, and wait until CSDBGPWRUPACK in the same register is asserted.
3. Set up the APB-AP to access OCDREG. The APB-AP is connected to the DAP bus port 1.
4. Write the 128-bit ID code to IAUTH registers 0 to 3 in the OCDREG using the APB-AP.
5. If the 128-bit ID code matches the OSIS value, the AHB-AP is authorized to issue an AHB transaction. The authorization result can be confirmed by the AUTH bit in the MCUSTAT Register or the DbgStatus bit in the AHB-AP Control Status Word Register.
   - When the DbgStatus bit is 1, the 128-bit ID code is a match with the OSIS value. AHB transfers are permitted.

Table 2.14 模式限制

主动模式	启动强迫症模拟器连接	更改低功耗模式	访问AHB-AP和系统总线	访问APB-AP和OCDREG
Normal	Yes	Yes	Yes	Yes
Sleep	Yes	Yes	Yes	Yes
软件待机	No	Yes	No	Yes
Snooze	No	Yes	No	Yes
深度软件待机	No	Yes	No	Yes

如果在软件待机、贪睡或深度软件待机模式下需要系统总线访问，请将OCDREG中的OCUCTRL.DBIRG位将MCU从低功耗模式唤醒。同时，使用OCDREG中的OCUCTRL.EDBGRQ位，OCD仿真器可以通过使用CPU中断来唤醒MCU而无需启动CPU执行。

2.11.3.3 修改OSIS中的解锁ID码

在OSIS中修改解锁ID代码后，OCD仿真器必须通过置位RES引脚或将系统控制块中的应用程序中断和复位控制寄存器的SYSRESETREQ位设置为1来复位MCU。修改后的解锁ID代码被反映复位后。

2.11.3.4 连接顺序和JTAGSWD认证

由于OCD仿真器受JTAGSWD身份验证机制的保护，因此可能需要OCD将ID代码输入到身份验证寄存器中。选项设置内存中的OSIS值决定是否需要该代码。

复位否定后，在冷启动时比较OSIS值之前需要5µs的等待时间。

(1) 当OSIS的MSB为0时（位[127]=0）

ID代码总是不匹配，并且禁止连接到OCD。

(2) 当OSIS全为1时（默认）

不需要OCD身份验证，OCD无需身份验证即可使用AHB-AP。

1. 通过JTAG或SWD接口将OCD仿真器连接到MCU。
2. 设置SWJ-DP以访问DAP总线。在设置中，OCD仿真器必须在SWJ中断言CDBGPWRUPREQ DP控制状态寄存器，然后等到同一寄存器中的CSDBGPWRUPACK置位。
3. 设置AHB-AP以访问系统地址空间。AHB-AP连接到DAP总线端口0。
4. 开始使用AHB-AP访问CPU调试资源。

(3) When OSIS[127:126] = 10b

需要OCD身份验证，并且OCD必须将解锁ID代码写入IAUTH寄存器中的0到3使用AHB-AP之前的OCDREG。

1. 通过JTAG或SWD接口将OCD调试器连接到MCU。
2. 设置SWJ-DP以访问DAP总线。在设置中，OCD仿真器必须在SWJ中断言CDBGPWRUPREQ DP控制状态寄存器，并等待同一寄存器中的CSDBGPWRUPACK置位。
3. 设置APB-AP以访问OCDREG。APB-AP连接到DAP总线端口1。
4. 使用APB-AP将128位ID代码写入OCDREG中的IAUTH寄存器0到3。
5. 如果128位ID代码与OSIS值匹配，则授权AHB-AP发出AHB事务。授权结果可以通过MCUSTAT寄存器中的AUTH位或AHBAP控制状态字寄存器中的DbgStatus位来确认。
   - 当DbgStatus位为1时，128位ID码与OSIS值匹配。允许AHB转移。

- When the DbgStatus bit is 0, the 128-bit ID code is not a match with the OSIS value. AHB transfers are not permitted.

6. Set up the AHB-AP to access the system address space. The AHB-AP is connected to the DAP bus port 0.
7. Start accessing the CPU debug resources using the AHB-AP.

(4) When OSIS[127:126] is 11b

OCD authentication is required and the OCD must write the unlock ID code to IAUTH registers 0 to 3 in the OCDREG. The connection sequence is the same when OSIS[127:126] is 10b except for “ALeRASE” capability.

When IATUH registers 0 to 3 are written with “ALeRASE” in ASCII code (414C_6552_4153_45FF_FFFF_FFFF_FFFF_FFFFh), the contents of the code flash, data flash, and configuration area are erased at once. See section 50, Flash Memory for details.

The ALeRASE sequence is as follows:

1. Connect the OCD debugger to the MCU through the JTAG or SWD interface.
2. Set up SWJ-DP to access DAP bus. In the setup, the OCD emulator must assert CDBGPWRUPREQ in the SWJDP Control Status Register, then wait until CSDBGPWRUPACK in the same register is asserted.
3. Set the APB-AP to access OCDREG. The APB-AP is connected to the DAP bus port 1.
4. Write the 128-bit ID code to IAUTH registers 0 to 3 in the OCDREG using the APB-AP.
5. If the 128-bit ID code is “ALeRASE” in ASCII code, the contents of the code flash, data flash, and configuration area are erased. Thereafter, the MCU transitions to Sleep mode.

- 当DbgStatus位为0时，128位ID代码与OSIS值不匹配。不允许AHB转移。

6. 设置AHB-AP以访问系统地址空间。AHB-AP连接到DAP总线端口0。
7. 开始使用AHB-AP访问CPU调试资源。

(4) 当OSIS[127:126]为11b时

需要OCD身份验证，并且OCD必须将解锁ID代码写入OCDREG中的IAUTH寄存器0到3。
当OSIS[127:126]为10b时，连接顺序相同，但“ALeRASE”功能除外。

当IATUH寄存器0到3用ASCII码(414C_6552_4153_45FF_FFFF_FFFF_FFFF_FFFFh)写入“ALeRASE”时，代码闪存、数据闪存和配置区域的内容会立即被擦除。有关详细信息，请参见第50节，闪存。

ALeRASE序列如下：

1. 通过JTAG或SWD接口将OCD调试器连接到MCU。
2. 设置SWJ-DP以访问DAP总线。在设置中，OCD仿真器必须在SWJDP中断言CDBGPWRUPREQ控制状态寄存器，然后等到同一寄存器中的CSDBGPWRUPACK被断言。
3. 设置APB-AP以访问OCDREG。APB-AP连接到DAP总线端口1。
4. 使用APB-AP将128位ID代码写入OCDREG中的IAUTH寄存器0到3。
5. 如果128位ID代码是ASCII代码中的“ALeRASE”，则代码闪存、数据闪存和配置区域的内容被擦除。此后，MCU转换到休眠模式。

3. Operating Modes

3.1 Overview

Table 3.1 shows the selection of operating modes by the mode-setting pin. For details, see section 3.2, Details of Operating Modes. Operation starts with the on-chip flash memory enabled, regardless of the mode in which operation started.

Table 3.1 Selection of operating modes by the mode-setting pin

Mode-setting pin			
MD	Operating mode	On-chip flash memory	External bus
1	Single-chip mode	Enable	Disable
0	SCI/USB boot mode	Enable	Disable

3.2 Details of Operating Modes

3.2.1 Single-Chip Mode

In single-chip mode, all I/O pins are available for use as input or output port, inputs or outputs for peripheral functions, or as interrupt inputs. When a reset is released while the MD pin is high, the MCU starts in single-chip mode and the on-chip flash is enabled.

3.2.2 SCI Boot Mode

In this mode, the on-chip flash memory programming routine (SCI boot program), stored in a dedicated area within the MCU, is used. The on-chip flash, including the code flash memory and data flash memory, can be modified from outside the MCU by using a universal asynchronous receiver/transmitter (UART) SCI. For details, see section 50, Flash Memory. The MCU starts in SCI boot mode if the MD pin is held low on release from the reset state.

3.2.3 USB Boot Mode

In this mode, the on-chip flash memory programming routine (USB boot program), stored in the boot area within the MCU, is used. The on-chip flash, including the code flash memory and data flash memory, can be modified from outside the MCU by using the USB. For details, see section 50, Flash Memory. The MCU starts in USB boot mode if the MD pin is held low on release from the reset state.

3.3 Operating Mode Transitions

3.2.2 SCI启动模式

在这种模式下，使用存储在MCU内的专用区域中的片上闪存编程例程（SCI引导程序）。片上闪存，包括代码闪存和数据闪存，可以通过使用通用异步接收发送器(UART)SCI从MCU外部进行修改。有关详细信息，请参阅第50节，闪存。如果MD引脚在从复位状态释放时保持低电平，则MCU以SCI启动模式启动。

3.2.3 USB启动模式

5. Memory Mirror Function (MMF)

5.1 Overview

The MCU provides a Memory Mirror Function (MMF). You can configure the MMF to map an application image load address in the code flash memory to the application image link address in the unused 23-bit memory mirror space addresses. Your application code must be developed and linked to run from this MMF destination address. The application code is not required to know the load location where it is stored in the code flash memory.

Table 5.1 lists the MMF specifications.

MEMMIRADDR[15:0] bits (Memory Mirror Address)

The MEMMIRADDR[15:0] bits specify bits [22:7] of the memory mirror address. They define where the start address of the memory mirror space addresses (0200 0000h) is linked to. Writing to these bits is enabled only when this register is accessed in 32-bit words and the value DBh is written to the KEY[7:0] bits.

KEY[7:0] bits (MMSFR Key Code)

The KEY[7:0] bits enable or disable rewriting of the MEMMIRADDR[15:0] bits. Data written to the KEY bits is not saved. These bits are read as 0. The KEY code and MEMMIRADDR[15:0] bits must be written in the same cycle.

5. 内存镜像功能(MMF)

5.1 Overview

MCU提供内存镜像功能(MMF)。您可以配置MMF以将代码闪存中的应用程序映像加载地址映射到未使用的23位内存镜像空间地址中的应用程序映像链接地址。您的应用程序代码必须经过开发和链接才能从此MMF目标地址运行。应用程序代码不需要知道它存储在代码闪存中的加载位置。

表5.1列出了MMF规范。

Writing to the EN bit is enabled only when the MemMirror Enable Register is accessed in 32-bit words and the value DBh is written to the KEY[7:0] bits.

KEY[7:0] bits (MMEN Key Code)

The KEY[7:0] bits enable or disable rewriting of the EN bit. Data written to the KEY[7:0] bits is not saved. These bits are read as 0. The KEY code and the EN bit must be written in the same cycle.

5.3 Operation

5.3.1 MMF Operation

The MMF links the memory mirror space (0200 0000h to 027F FFFFh) to the code flash area. If MMEN.EN = 1, the CPU can access code flash using both normal addresses (starting at 0000 0000h) and memory mirror space addresses (starting at 0200 0000h). Figure 5.1 shows an overview of the MMF. The MMSFR.MEMMIRADDR[15:0] bits specify where the start address of the memory mirror space addresses (0200 0000h) is linked to. Figure 5.2, Figure 5.3, and Figure 5.4 show the MMF operation. Figure 5.5 shows the setting procedure of the MMF.

KEY[7:0]位启用或禁用EN位的重写。写入KEY[7:0]位的数据不保存。这些位读为0。KEY代码和EN位必须在同一个周期内写入。

5.3 Operation

5.3.1 MMF Operation

MMF将内存镜像空间（02000000h到027FFFFFh）链接到代码闪存区域。如果MMEN.EN=1，CPU可以使用普通地址（从00000000h开始）和内存镜像空间地址（从02000000h开始）访问代码闪存。图5.1显示了MMF的概述。MMSFR.MEMMIRADDR[15:0]位指定存储器镜像空间地址(02000000h)的起始地址链接到的位置。图5.2、图5.3和图5.4显示了MMF操作。图5.5显示了MMF的设置过程。

✓: Initialized
×: Not initialized

Note 1. For the initial value of each register, see section 9, Clock Generation Circuit.
Note 2. The RTC has a software reset. RCR1.RTCOS, RCR1.CIE, RCR2.RTCOE, RCR2.ADJ30, and RCR2.RESET are initialized by all types of resets. For details on the target bits, see section 26, Realtime Clock (RTC).
Note 3. Depends on the setting of DPSBYCR.IOKEEP.

The RTC is not initialized by any reset source. SOSC and LOCO can be selected as the clock sources of RTC. Table 6.4 and Table 6.5 show the states of SOSC and LOCO when a reset occurs.

Table 6.4 States of SOSC when a reset occurs

		Reset source	
		POR	**Other**
SOSC	Enable or disable	Initialized to enable	Continue with the state that was selected before the reset occurred
	Drive capability	Continue with the state that was selected before the reset occurred	

Table 6.5 States of LOCO when a reset occurs

		Reset source	
		POR, LVD0, LVD1, LVD2/ Deep Software Standby (DEEPCUT[0] = 1)	**Other**
LOCO	Enable or disable	Initialized to enable	
	Oscillation accuracy*1	Initialized to accuracy before trimming by LOCOUTCR (accuracy: ± 15%)	Continue with the accuracy that was trimmed by LOCOUTCR

Note 1. The LOCO User Trimming Control Register (LOCOUTCR) is reset by POR, LVD0, LVD1, LVD2, and Deep Software Standby (DEEPCUT[0] = 1) resets, returning the LOCO to the default oscillation accuracy. This can affect RTC accuracy if the RTC uses the LOCO (with a user trimming value in LOCOUTCR) as the RTC source clock. To restore the pre-reset LOCO oscillation accuracy, reload the required trimming value into LOCOUTCR after any of these resets.

Table 6.6 lists the pin related to the reset function.

Note 1. 对于每个寄存器的初始值，请参见第9节，时钟生成电路。
Note 2. RTC具有软件复位功能。RCR1.RTCOS、RCR1.CIE、RCR2.RTCOE、RCR2.ADJ30和RCR2.RESET由所有类型的复位初始化。有关目标位的详细信息，请参见第26节，实时时钟(RTC)。
Note 3. 取决于DPSBYCR.IOKEEP的设置。

RTC不会被任何复位源初始化。可选择SOSC和LOCO作为RTC的时钟源。表6.4和表6.5显示了复位发生时SOSC和LOCO的状态。

Table 6.4 发生复位时SOSC的状态

		重置源	
		POR	**Other**
SOSC	启用或禁用	初始化为启用	继续使用重置发生之前选择的状态
	驱动能力	继续使用重置发生之前选择的状态	

Table 6.5 发生复位时的LOCO状态

		重置源	
		POR、LVD0、LVD1、LVD2深度软件待机（DEEPCUT[0]=1）	**Other**
LOCO	启用或禁用	初始化为启用	
	Oscillation accuracy*1	由LOCOUTCR微调前初始化为精度（精度：±15%）	继续使用被修剪的精度LOCOUTCR

Note 1. LOCO用户微调控制寄存器(LOCOUTCR)通过POR、LVD0、LVD1、LVD2和深度软件待机(DEEPCUT[0]=1)复位，将LOCO返回到默认振荡精度。如果RTC使用LOCO（在LOCOUTCR中具有用户修整值）作为RTC源时钟，这可能会影响RTC精度。要恢复预复位的LOCO振荡精度，请在任何这些复位后将所需的微调值重新加载到LOCOUTCR。

表6.6列出了与复位功能相关的引脚。

6.3 Operation

6.3.1 RES Pin Reset

The RES pin generates this reset. When the RES pin is driven low, all the processing in progress is aborted and the MCU enters a reset state. To successfully reset the MCU, the RES pin must be held low for the power supply stabilization time specified at power-on.

When the RES pin is driven high from low, the internal reset is canceled after the post-RES cancellation wait time (t_{RESWT}) elapses. The CPU then starts the reset exception handling.

For details, see section 52, Electrical Characteristics.

6.3.2 Power-On Reset

The power-on reset (POR) is an internal reset generated by the power-on reset circuit. If the RES pin is in a high-level state when power is supplied, a power-on reset is generated. After VCC exceeds V_{POR} and the specified power-on reset time elapses, the internal reset is canceled and the CPU starts the reset exception handling. The power-on reset time is the stabilization period for the external power supply and the MCU circuit. After a power-on reset is generated, the PORF flag in the RSTSR0 is set to 1. The PORF flag is initialized by the RES pin reset.

The voltage monitor 0 reset is an internal reset generated by the voltage monitor circuit. If the Voltage Detection 0 Circuit Start (LVDAS) bit in the Option Function Select Register 1 (OFS1) is 0 (voltage monitor 0 reset is enabled after a reset) and VCC falls below V_{det0}, the RSTSR0.LVD0RF flag is set to 1 and the voltage detection circuit generates voltage monitor 0 reset. Clear the OFS1.LVDAS bit to 0 if the voltage monitor 0 reset is to be used.

After VCC exceeds V_{det0} and the voltage monitor 0 reset time (tLVD0) elapses, the internal reset is canceled and the CPU starts the reset exception handling. The V_{det0} voltage detection level can be changed by the setting in the VDSEL[1:0] bits in Option Function Select Register 1 (OFS1).

Figure 6.1 shows example of operations during a power-on reset and voltage monitor 0 reset.

[Setting condition]

- 当1由软件写入时。将0写入CWSF不会将其设置为0。

[Clearing condition]

6.3 Operation

6.3.1 RES引脚复位

RES引脚产生此复位。当RES引脚被驱动为低电平时，所有正在进行的处理都被中止，MCU进入复位状态。要成功复位MCU，RES引脚必须在上电时指定的电源稳定时间内保持低电平。

当RES引脚从低电平驱动为高电平时，内部复位会在RES取消后等待时间(tRESWT)过去后取消。CPU然后开始复位异常处理。

有关详细信息，请参见第52节，电气特性。

6.3.2 Power-On Reset

上电复位（POR）是由上电复位电路产生的内部复位。如果上电时RES管脚处于高电平状态，则产生上电复位。VCC超过VPOR并经过规定的上电复位时间后，内部复位被取消，CPU开始复位异常处理。上电复位时间是外部电源和MCU电路的稳定期。上电复位产生后，RSTSR0中的PORF标志设置为1。PORF标志由RES引脚复位初始化。

电压监控器0复位是由电压监控器电路产生的内部复位。如果选项功能选择寄存器1(OFS1)中的电压检测0电路启动(LVDAS)位为0（复位后使能电压监视器0复位）并且VCC降至Vdet0以下，则RSTSR0.LVD0RF标志设置为1电压检测电路产生电压监测0复位。如果要使用电压监视器0复位，则将OFS1.LVDAS位清零。

在VCC超过Vdet0并且电压监视器0复位时间(tLVD0)过去后，内部复位被取消，并且CPU启动复位异常处理。Vdet0电压检测电平可以通过在选项功能选择寄存器1(OFS1)中的VDSEL[1:0]位。

图6.1显示了上电复位和电压监视器0复位期间的操作示例。

Note 3. At power-on, VCC should have risen to the minimum guaranteed voltage before the POR reset is released.

Figure 6.1 Example of operations during power-on and voltage monitor 0 resets

6.3.3 Voltage Monitor Reset

The voltage monitor 0 reset is an internal reset generated by the voltage monitor circuit. If the Voltage Detection 0 Circuit Start (LVDAS) bit in the Option Function Select Register 1 (OFS1) is 0 (voltage monitor 0 reset is enabled after a reset) and VCC falls below V_{det0}, the RSTSR0.LVD0RF flag becomes 1 and the voltage detection circuit generates a voltage monitor 0 reset. Clear the OFS1.LVDAS bit to 0 if the voltage monitor 0 reset is to be used. After VCC exceeds V_{det0} and the voltage monitor 0 reset time (tLVD0) elapses, the internal reset is canceled and the CPU starts the reset exception handling.

When the Voltage Monitor 1 Interrupt/Reset Enable bit (RIE) is set to 1 (enabling generation of a reset or interrupt by the voltage detection circuit) and the Voltage Monitor 1 Circuit Mode Select bit (LVD1CR0.RI) is set to 1 (selecting generation of a reset in response to detection of a low voltage) in the Voltage Monitor 1 Circuit Control Register 0 (LVD1CR0), the RSTSR0.LVD1RF flag is set to 1 and the voltage detection circuit generates a voltage monitor 1 reset if VCC falls to or below V_{det1}.

Likewise, when the Voltage Monitor 2 Interrupt/Reset Enable bit (RIE) is set to 1 (enabling generation of a reset or interrupt by the voltage detection circuit) and the Voltage Monitor 2 Circuit Mode Select bit (LVD2CR0.RI) is set to 1 (selecting generation of a reset in response to detection of a low voltage) in Voltage Monitor 2 Circuit Control Register 0 (LVD2CR0), the RSTSR0.LVD2RF flag is set to 1 and the voltage detection circuit generates a voltage monitor 2 reset if VCC falls to or below V_{det2}.

Similarly, timing for release from the voltage monitor 1 reset state is selectable in the Voltage Monitor 1 Reset Negate Select bit (RN) in the LVD1CR0 register. When the LVD1CR0.RN bit is 0 and VCC falls to or below V_{det1}, the CPU is released from the internal reset state and starts reset exception handling when the LVD1 reset time (tLVD1) elapses after VCC rises above V_{det1}. When the LVD1CR0.RN bit is 1 and VCC falls to or below V_{det1}, the CPU is released from the

Figure 6.1 上电和电压监控0复位期间的操作示例

6.3.3 电压监视器复位

电压监控器0复位是由电压监控器电路产生的内部复位。如果电压检测0选项功能选择寄存器1(OFS1)中的电路启动(LVDAS)位为0（复位后使能电压监控器0复位）且VCC低于Vdet0，RSTSR0.LVD0RF标志变为1，电压检测电路产生一个电压监视器0复位。如果要使用电压监视器0复位，则将OFS1.LVDAS位清零。在VCC超过Vdet0并且电压监视器0复位时间(tLVD0)过去后，内部复位被取消，CPU开始复位异常处理。

当电压监视器1中断复位使能位(RIE)设置为1（允许电压检测电路产生复位或中断）并且电压监视器1电路模式选择位(LVD1CR0.RI)设置为1（选择电压监控器1电路控制寄存器0(LVD1CR0)中的低电压检测产生复位），RSTSR0.LVD1RF标志设置为1，如果VCC下降到电压检测电路产生电压监控器1复位或低于Vdet1。

同样，当电压监控器2中断复位允许位(RIE)设置为1（允许电压检测电路产生复位或中断）并且电压监控器2电路模式选择位(LVD2CR0.RI)设置为1时（响应检测到低电压选择产生复位）在电压监控器2电路控制寄存器0(LVD2CR0)中，RSTSR0.LVD2RF标志设置为1，如果VCC下降，电压检测电路产生电压监控器2复位到或低于Vdet2。

类似地，从电压监视器1复位状态释放的时间可在电压监视器1复位否定中选择LVD1CR0寄存器中的选择位(RN)。当LVD1CR0.RN位为0且VCC下降到或低于Vdet1时，CPU会从内部复位状态中释放并在VCC上升到Vdet1以上后经过LVD1复位时间(tLVD1)时开始复位异常处理。当LVD1CR0.RN位为1且VCC下降到或低于Vdet1时，CPU从

Likewise, timing for release from the voltage monitor 2 reset state is selectable in the Voltage Monitor 2 Reset Negate Select bit (RN) in the LDV2CR0 register.

Detection levels V_{det1} and V_{det2} can be changed in the Voltage Detection Level Select Register (LDVLVLR).

6.3.4 Deep Software Standby Reset

The deep software standby reset is an internal reset generated when Deep Software Standby mode is canceled by an associated interrupt. The deep software standby reset is canceled after tDSBY (return time after Deep Software Standby mode cancellation) elapses.

When tDSBYWT (wait time after Deep Software Standby mode cancellation) elapses after Deep Software Standby mode is canceled, the internal reset is canceled and the CPU starts the reset exception handling.

For details on the deep software standby reset, see section 11, Low Power Modes.

6.3.5 Independent Watchdog Timer Reset

The independent watchdog timer reset is an internal reset generated from the Independent Watchdog Timer (IWDT). Output of the reset from the IWDT can be selected in the Option Function Select Register 0 (OFS0).

When output of the independent watchdog timer reset is selected, the reset is generated if the IWDT underflows, or if data is written when refresh operation is disabled. When the internal reset time (tRESW2) elapses after the independent watchdog timer reset is generated, the internal reset is canceled and the CPU starts the reset exception handling.

6.3.4 深度软件待机复位

深度软件待机复位是在深度软件待机模式被相关中断取消时产生的内部复位。深度软件待机复位在tDSBY（深度软件待机模式取消后的返回时间）过去后取消。

当深度软件待机模式取消后经过tDSBYWT（深度软件待机模式取消后的等待时间）时，内部复位被取消并且CPU开始复位异常处理。

有关深度软件待机复位的详细信息，请参见第11节，低功耗模式。

6.3.5 独立看门狗定时器复位

独立看门狗定时器复位是由独立看门狗定时器（IWDT）产生的内部复位。
可以在选项功能选择寄存器0(OFS0)中选择IWDT的复位输出。

For details on the independent watchdog timer reset, see section 28, Independent Watchdog Timer (IWDT).

6.3.6 Watchdog Timer Reset

The watchdog timer reset is an internal reset generated from the Watchdog Timer (WDT). Output of the reset from the WDT can be selected in the WDT Reset Control Register (WDTRCR) or Option Function Select Register 0 (OFS0).

When output of the watchdog timer reset is selected, the reset is generated if the WDT underflows, or if data is written when refresh operation is disabled. When the internal reset time (tRESW2) elapses after the watchdog timer reset is generated, the internal reset is canceled and the CPU starts the reset exception handling.

For details on the watchdog timer reset, see section 27, Watchdog Timer (WDT).

6.3.7 Software Reset

Software reset is an internal reset generated by a software setting of the SYSRESETREQ bit in the AIRCR register in the Arm core. When the SYSRESETREQ bit is set to 1, a software reset is generated. When the internal reset time (tRESW2) elapses after a software reset is generated, the internal reset is canceled and the CPU starts the reset exception handling.

For details on the SYSRESETREQ bit, see the *ARM® Cortex®-M4 Technical Reference Manual*.

6.3.8 Determination of Cold/Warm Start

Read the CWSF flag in RSTSR2 to determine the cause of reset processing. This flag indicates whether a power-on reset caused the reset processing (cold start) or a reset signal input during operation caused the reset processing (warm start).

The CWSF flag is set to 0 when a power-on reset occurs (cold start). Otherwise, the flag is not set to 0. The flag is set to 1 when 1 is written to it through software. It is not set to 0 even on writing 0 to it.

Figure 6.3 shows an example of a cold/warm start determination operation.

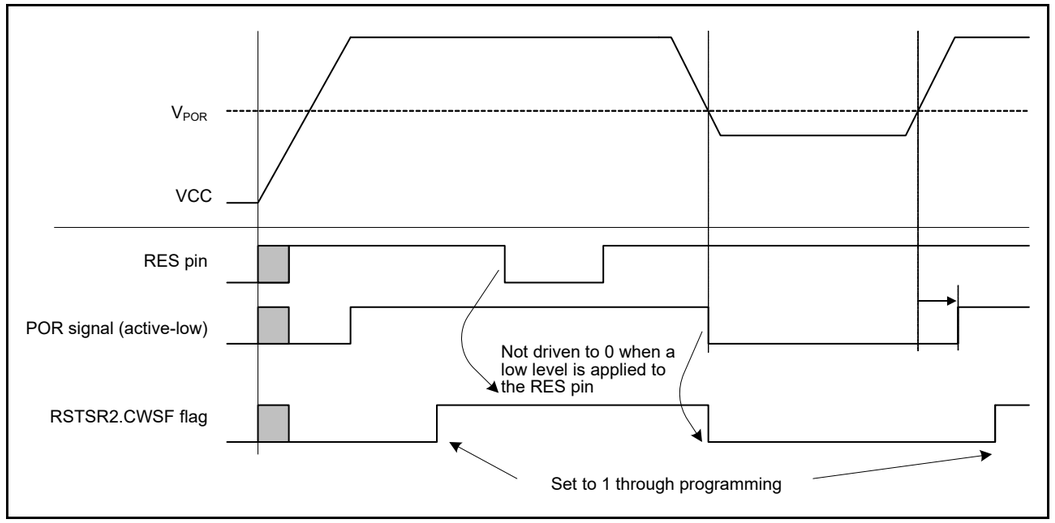

Figure 6.3 Example of a cold/warm start determination operation

6.3.9 Determination of Reset Generation Source

Read RSTSR0 and RSTSR1 to determine which reset executes the reset exception handling. Figure 6.4 shows an example of the flow to identify a reset generation source. The reset flag must be written with 0 after it is read as 1.

有关独立看门狗定时器复位的详细信息，请参见第28节，独立看门狗定时器(IWDT)。

6.3.6 看门狗定时器复位

看门狗定时器复位是由看门狗定时器(WDT)产生的内部复位。从复位输出可以在WDT复位控制寄存器(WDTRCR)或选项功能选择寄存器0(OFS0)中选择WDT。

选择看门狗定时器复位的输出时，如果WDT下溢，或者在禁止刷新操作时写入数据，则产生复位。当看门狗定时器复位产生后经过内部复位时间(tRESW2)时，内部复位被取消，CPU开始复位异常处理。

有关看门狗定时器复位的详细信息，请参见第27节，看门狗定时器(WDT)。

6.3.7 软件复位

软件复位是通过软件设置Arm内核的AIRCR寄存器中的SYSRESETREQ位产生的内部复位。当SYSRESETREQ位设置为1时，会产生软件复位。当软件复位产生后经过内部复位时间(tRESW2)时，内部复位被取消，CPU开始复位异常处理。

有关SYSRESETREQ位的详细信息，请参阅ARM®Cortex®-M4技术参考手册。

6.3.8 冷暖启动的测定

读取RSTSR2中的CWSF标志以确定复位处理的原因。该标志指示是上电复位导致复位处理（冷启动）还是操作期间输入的复位信号导致复位处理（热启动）。

发生上电复位（冷启动）时，CWSF标志设置为0。否则，该标志不设置为0。当通过软件向其写入1时，该标志设置为1。即使向其写入0，它也不会设置为0。

图6.3显示了冷暖启动确定操作的示例。

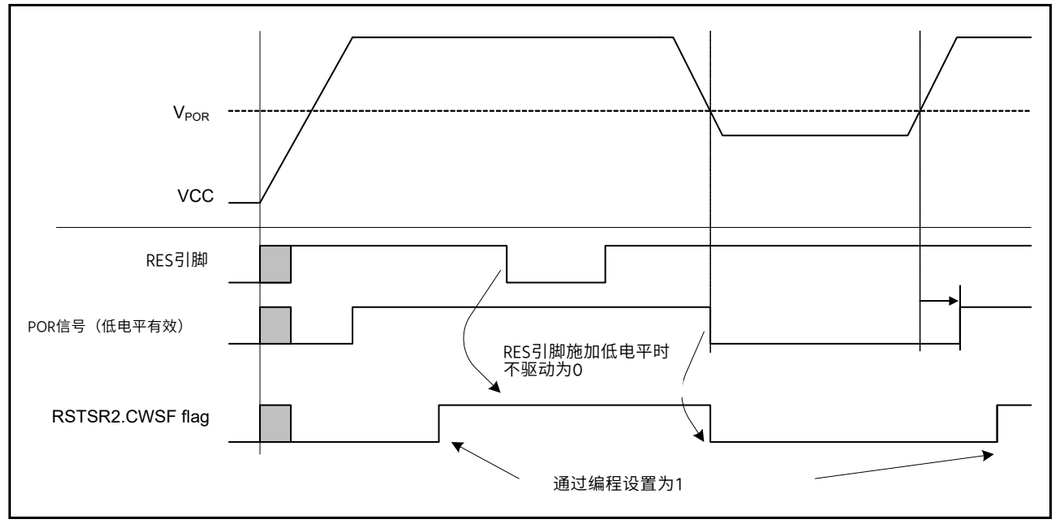

Figure 6.3 冷暖启动判定动作示例

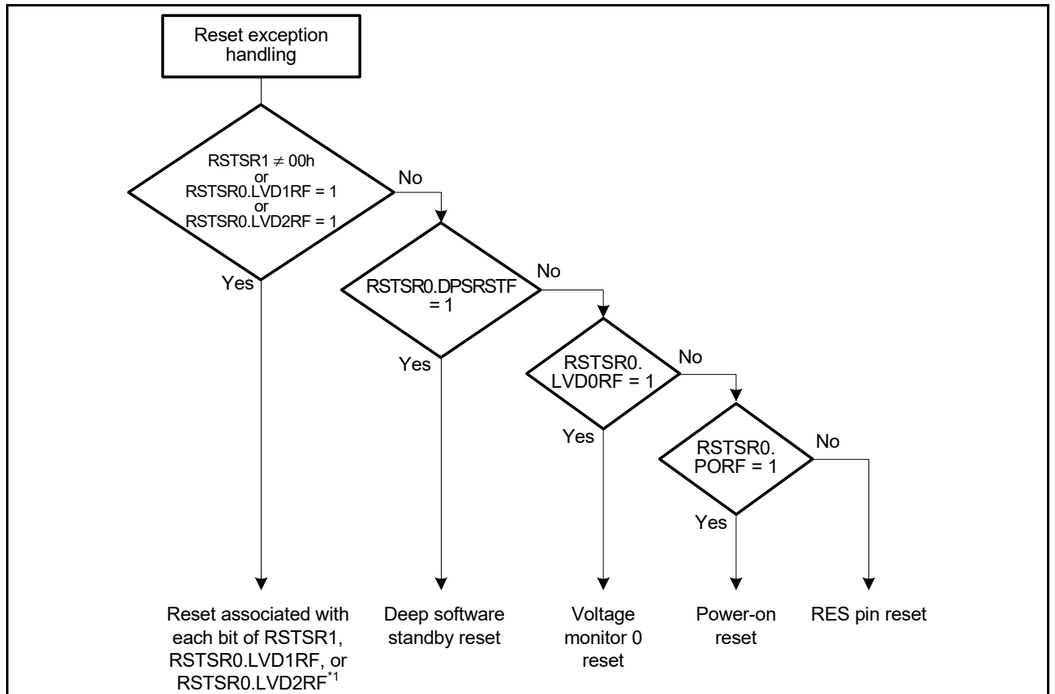
6.3.9 复位产生源的确定

读取RSTSR0和RSTSR1以确定哪个复位执行复位异常处理。图6.4显示了识别复位产生源的流程示例。复位标志读为1后必须写为0。



Note 1. If two or more resets associated with each bit of RSTSR1, RSTSR0.LVD1RF, or RSTSR0.LVD2RF occur at the same time, all reset flags are set to 1.

IWDTSTRT bit (IWDT Start Mode Select)

The IWDTSTRT bit selects the mode in which the IWDT is activated after a reset (stopped state or activated state).

IWDTTOPS[1:0] bits (IWDT Timeout Period Select)

The IWDTTOPS[1:0] bits select the timeout period, that is, the time it takes for the down counter to underflow, as 128, 512, 1024, or 2048 cycles of the frequency-divided clock set in the IWDTCKS[3:0] bits. The number of clock cycles that the counter takes to underflow after a refresh operation is determined by the combination of the IWDTCKS[3:0] and IWDTTOPS[1:0] bits.

For details, see section 28, Independent Watchdog Timer (IWDT).

IWDTCKS[3:0] bits (IWDT-Dedicated Clock Frequency Division Ratio Select)

The IWDTCKS[3:0] bits select the division ratio of the prescaler for dividing the frequency of the clock for the IWDT as 1/1, 1/16, 1/32, 1/64, 1/128, or 1/256. Using this setting combined with the IWDTTOPS[1:0] bit setting, the IWDT counting period can be set from 128 to 524288 IWDT clock cycles.

For details, see section 28, Independent Watchdog Timer (IWDT).

IWDTRPES[1:0] bits (IWDT Window End Position Select)

The IWDTRPES[1:0] bits select the position where the window for the down counter ends as 0%, 25%, 50%, or 75% of the count value. The value of the window end position must be smaller than the value of the window start position. Otherwise, only the value for the window start position is valid.

The counter values associated with the settings for the start and end positions of the window, in the IWDTRPSS[1:0] and IWDTRPES[1:0] bits vary with the setting in the IWDTTOPS[1:0] bits.

For details, see section 28, Independent Watchdog Timer (IWDT).

IWDTRPSS[1:0] bits (IWDT Window Start Position Select)

The IWDTRPSS[1:0] bits select the position where the window for the down counter starts as 25%, 50%, 75%, or 100% of the counted value. The point at which counting starts is 100% and the point at which an underflow occurs is 0%. The interval between the positions where the window starts and ends becomes the period in which a refresh is possible. However, refresh is not possible outside this period.

For details, see section 28, Independent Watchdog Timer (IWDT).

IWDTRSTIRQS bit (IWDT Reset Interrupt Request Select)

The IWDTRSTIRQS bit selects the operation on an underflow of the down counter or generation of a refresh error. The selected operation can be an independent watchdog timer reset, non-maskable interrupt request, or interrupt request.

For details, see section 28, Independent Watchdog Timer (IWDT).

IWDTSTPCTL bit (IWDT Stop Control)

The IWDTSTPCTL bit specifies whether to stop counting when entering Sleep, Snooze, or Software Standby mode.

For details, see section 28, Independent Watchdog Timer (IWDT).

WDTSTRT bit (WDT Start Mode Select)

The WDTSTRT bit selects the mode in which the WDT is activated after a reset (stopped state or activated state). When the WDT is activated in auto start mode, the OFS0 register setting for the WDT is valid.

WDTTOPS[1:0] bits (WDT Timeout Period Select)

The WDTTOPS[1:0] bits select the timeout period, that is, the time it takes for the down counter to underflow, as 1024, 4096, 8192, or 16384 cycles of the frequency-divided clock set in the WDTCKS[3:0] bits. The number of PCLKB cycles that the counter takes to underflow after a refresh operation is determined by the combination of the WDTCKS[3:0] and WDTTOPS[1:0] bits.

For details, see section 27, Watchdog Timer (WDT).

VDSEL0[1:0] bits (Voltage Detection 0 Level Select)

The VDSEL0[1:0] bits select the voltage detection level of the voltage detection 0 circuit.

LVDAS bit (Voltage Detection 0 Circuit Start)

The LVDAS bit selects whether the voltage monitor 0 reset is enabled or disabled after a reset.

HOCOEN bit (HOCO Oscillation Enable)

The HOCOEN bit selects whether the HOCO oscillation is enabled or disabled after a reset. Setting this bit to 0 allows the HOCO oscillation to start before the CPU starts operation, which reduces the wait time for oscillation stabilization.

Note: When the HOCOEN bit is set to 0, the system clock source is not switched to HOCO. The system clock source is only switched to HOCO by setting the Clock Source Select bits (SCKSCR.CKSEL[2:0]). To use the HOCO clock, you must set the OFS1.HOCOFRQ0 bit to an optimum value.

HOCOFRQ0[1:0] bits (HOCO Frequency Setting 0)

The HOCOFRQ0[1:0] bits specify the HOCO frequency after a reset as 16, 18, or 20 MHz.

HOCOEN位（HOCO振荡使能）

HOCOEN位选择在复位后是启用还是禁用HOCO振荡。将此位设置为0允许在CPU开始操作之前启动HOCO振荡，从而减少振荡稳定的等待时间。

Note: 当HOCOEN位设置为0时，系统时钟源不切换到HOCO。系统时钟源只能通过设置时钟源选择位(SCKSCR.CKSEL[2:0])切换到HOCO。要使用HOCO时钟，您必须将OFS1.HOCOFRQ0位设置为最佳值。

HOCOFRQ0[1:0]位（HOCO频率设置0）

HOCOFRQ0[1:0]位指定复位后的HOCO频率为16、18或20MHz。

Issuing the program or erase (P/E) command to an area outside the access window causes a command-locked state. The access window is only valid in the program flash area. The access window provides protection in self-programming mode, serial programming mode, and on-chip debug mode. The access window can be locked by the FSPR bit.

The access window is specified in both the FAWS[10:0] and FAWE[10:0] bits: The settings for the bits are as follows:

- FAWE[10:0] = FAWS[10:0]: The P/E command is allowed to execute in the full program flash area
- FAWE[10:0] > FAWS[10:0]: The P/E command is only allowed to execute in the window from the block pointed to by the FAWS[10:0] bits to the block one lower than the block pointed to by the FAWE[10:0] bits
- FAWE[10:0] < FAWS[10:0]: The P/E command is not allowed to execute in the program flash area.

7.2.4 OCD/Serial Programmer ID Setting Register (OSIS)

The OSIS register stores the ID for ID code protection of the OCD/serial programmer. When connecting the OCD/serial programmer, write values so that the MCU can determine whether to permit the connection. Use this register to check whether a code transmitted from the OCD/serial programmer matches the ID code in the option-setting memory.

When the ID codes match, connection with the OCD/serial programmer is permitted, if not, connection with the OCD/serial programmer is not possible. The OSIS register must be set in 32-bit words.

These fields hold the ID for use in ID authentication for the OCD/serial programmer.

ID code bits [127] and [126] determine whether ID code protection is enabled, and the authentication method to use with the host. Table 7.1 shows how the ID code determines the authentication method.

Setting bit [127] to 0 prevents Renesas from accessing the test mode. Therefore, Renesas cannot perform failure analysis unless provided with bits [126:0]. To process any warranty claim, Renesas must be able to perform failure analysis.

Table 7.1 Specifications for ID code protection

Operating mode on boot up	ID code	State of protection	Operations on connection to programmer or on-chip debugger
Serial programming mode (SCI/USB boot mode) On-chip debug mode (JTAG/SWD boot mode)	FFh, …, FFh (all bytes are FFh)	Protection disabled	The ID code is not checked, the ID code always matches, and the connection to programmer or on-chip debugger is permitted
	Bit [127] = 1, bit [126] = 1, and at least one of the 16 bytes is not FFh.	Protection enabled	Matching ID code indicates that authentication is complete and connection to the programmer or the on-chip debugger is permitted. Mismatching ID code indicates that transition to the ID code protection wait state. When the ID code sent from the programmer or the on-chip debugger is ALeRASE in ASCII code (414C_6552_4153_45FF_FFFF_FFFF_FFFF_FFFFh), the content of the user flash (code and data) area, and configuration area are erased. However, forced erasure is not executed when the FSPR bit is 0.
	Bit [127] = 1 and bit [126] = 0	Protection enabled	Matching ID code indicates that authentication is complete and connection to the programmer or the on-chip debugger is permitted. Mismatching ID code indicates transition to the ID code protection wait state.
	Bit [127] = 0	Protection enabled	The ID code is not checked, the ID code is always mismatching, the connection to the programmer or the on-chip debugger is prohibited, and Renesas cannot access the test mode.

7.2.4 OCD串行编程器ID设置寄存器(OSIS)

OSIS寄存器存储用于保护OCD串行编程器的ID代码的ID。连接OCD串口编程器时，写入数值，让MCU判断是否允许连接。使用该寄存器检查从OCD串行编程器发送的代码是否与选项设置存储器中的ID代码匹配。

当ID码匹配时，允许与OCD串行编程器连接，如果不匹配，则与强迫症串行编程器是不可能的。OSIS寄存器必须设置为32位字。

这些字段保存用于OCD串行编程器身份验证的ID。

ID代码位[127]和[126]确定是否启用ID代码保护，以及与主机一起使用的身份验证方法。表7.1显示了ID代码如何确定身份验证方法。

将位[127]设置为0可防止Renesas进入测试模式。因此，除非提供位[126:0]，否则瑞萨无法执行故障分析。要处理任何保修索赔，瑞萨电子必须能够执行故障分析。

7.3 Setting the Option-Setting Memory

7.3.1 Allocation of Data in the Option-Setting Memory

Programming data is allocated to the addresses in the option-setting memory shown in Figure 7.1. The allocated data is used by tools such as a flash programming software or an on-chip debugger.

Note: Programming formats vary depending on the compiler. See the compiler manual for details.

7.3.2 Setting Data for Programming the Option-Setting Memory

Allocating data according to the procedure described in section 7.3.1, Allocation of Data in the Option-Setting Memory, alone does not actually write the data to the option-setting memory. You must also follow one of the actions described in this section.

(1) Changing the option-setting memory by self-programming

To write data to the program flash area, use the programming command. To write data to the option-setting memory in the configuration setting area, use the configuration setting command. In addition, use the startup area select function to safely update the boot program that includes the option-setting memory.

For details on the programming command, the configuration setting command, and the startup area select function, see section 50, Flash Memory.

Note: While programming the configuration setting area, the following restrictions apply:

- The code must not access addresses that satisfy the ranges described by the expression defined in Expression 1 from all bus masters
- The code must not execute on addresses that satisfy the ranges described by the expression defined in Expression 1.

Expression 1

If (((address & 0x0101F800) = = 0x01010000) || ((address & 0x0101FC00) = = 0x01012000))

For example, the ranges of addresses 0x1FFF0000 to 0x1FFF07FF or 0x1FFF2000 to 0x1FFF23FF are associated with the SRAMHS area that is tagged as restricted. Also, interrupts are allowed, however, the ISR has these specified restrictions. Therefore, it is highly recommended that you disable all interrupts, and bus masters except the CPU while programming the configuration setting area because the interrupts and these modules might access prohibited area in Expression 1.

(2) Debugging through an OCD or programming by a flash writer

This procedure depends on the tool in use, see the tool manual for details.

The MCU provides two setting procedures as follows:

- Read the data allocated as described in section 7.3.1, Allocation of Data in the Option-Setting Memory, from an object file or Motorola S-format file generated by the compiler, and write the data to the MCU
- Use the GUI interface of the tool to program the same data allocated as described in section 7.3.1, Allocation of Data in the Option-Setting Memory.

Note: While programming the OSIS or AWS registers, the following restrictions apply:

- The code must not access addresses that satisfy the ranges described by the expression defined in Expression 1 from all bus masters
- The code must not execute on addresses that satisfy the ranges described by the expression defined in Expression 1.

7.4 Usage Notes

7.4.1 Data for Programming Reserved Areas and Reserved Bits in the Option-Setting Memory

When reserved areas and reserved bits in the option-setting memory are available for programming, write 1 to all bits in reserved areas and all reserved bits. If 0 is written to these bits, normal operation cannot be guaranteed.

7.3 设置选项设置内存

7.3.1 选项设置存储器中的数据分配

编程数据被分配到图7.1所示的选项设置存储器中的地址。分配的数据由闪存编程软件或片上调试器等工具使用。

Note: 编程格式因编译器而异。有关详细信息，请参阅编译器手册。

7.3.2 用于编程选项设置存储器的设置数据

根据第7.3.1节“选项设置内存中的数据分配”中描述的过程分配数据，并不会真正将数据写入选项设置内存。您还必须遵循本节中描述的操作之一。

(1) 通过自编程更改选项设置存储器

要将数据写入程序闪存区域，请使用编程命令。要将数据写入配置设置区域中的选项设置存储器，请使用配置设置命令。此外，使用启动区域选择功能可以安全地更新包含选项设置存储器的引导程序。

有关编程命令、配置设置命令和启动区域选择功能的详细信息，请参见第50节，闪存。

Note: 在对配置设置区域进行编程时，有以下限制：

- 代码不得从所有总线主机访问满足表达式1中定义的表达式所描述范围的地址
- 代码不得在满足表达式1中定义的表达式描述的范围的地址上执行。

Expression 1

If (((address & 0x0101F800) = = 0x01010000) || ((address & 0x0101FC00) = = 0x01012000))

例如，地址范围0x1FFF0000到0x1FFF07FF或0x1FFF2000到0x1FFF23FF与标记为受限的SRAMHS区域相关联。此外，允许中断，但是，ISR有这些指定的限制。因此，强烈建议您在对配置设置区域进行编程时禁用除CPU之外的所有中断和总线主控，因为中断和这些模块可能会访问表达式1中的禁止区域。

(2) 通过OCD进行调试或通过闪存写入器进行编程

此过程取决于所使用的工具，详细信息请参见工具手册。

MCU提供两种设置程序，如下所示：

- 从编译器生成的目标文件或MotorolaS格式文件中读取如第7.3.1节“选项设置内存中的数据分配”中所述分配的数据，并将数据写入MCU
- 使用工具的GUI界面对分配的相同数据进行编程，如第7.3.1节所述，分配选项设置内存中的数据。

Note: 在对OSIS或AWS寄存器进行编程时，适用以下限制：

- 代码不得从所有总线主机访问满足表达式1中定义的表达式所描述范围的地址
- 代码不得在满足表达式1中定义的表达式描述的范围的地址上执行。

7.4 使用说明

7.4.1 用于编程选项设置中的保留区域和保留位的数据 Memory

当保留区域和保留的选项设置内存中可用于编程时，请在保留区域和所有保留位中为所有位写1。如果将0写入这些位，则无法保证正常操作。

8. Low Voltage Detection (LVD)

8.1 Overview

The Low Voltage Detection (LVD) module monitors the voltage level input to the VCC pin, and the detection level can be selected using a software program. The LVD module consists of three separate voltage level detectors, 0, 1, and 2, which measure the voltage level input to the VCC pin. LVD voltage detection registers allow your application to configure detection of VCC changes at various voltage thresholds.

Each voltage level detector has a voltage monitor associated with it, for example voltage monitors 0, 1, and 2. Voltage monitor registers are used to configure the LVD to trigger an interrupt, event link output, or reset when the thresholds are crossed.

Table 8.1 lists the LVD specifications. Figure 8.1 shows a block diagram of voltage detectors 0, 1, and 2, Figure 8.2 shows a block diagram of the voltage monitor 1 interrupt/reset circuit, and Figure 8.3 shows a block diagram of the voltage monitor 2 interrupt/reset circuit.

8. 低电压检测(LVD)

8.1 Overview

低电压检测(LVD)模块监控输入到VCC引脚的电压电平，并且可以使用软件程序选择检测电平。LVD模块由三个独立的电压电平检测器0、1和2组成，它们测量输入到VCC引脚的电压电平。LVD电压检测寄存器允许您的应用程序配置在各种电压阈值下检测VCC变化。

每个电压电平检测器都有一个与之关联的电压监视器，例如电压监视器0、1和2。电压监视器寄存器用于配置LVD，以在超过阈值时触发中断、事件链接输出或复位。

表8.1列出了LVD规格。图8.1显示了电压检测器0、1和2的框图，图8.2显示了电压监视器1中断复位电路的框图，图8.3显示了电压监视器2中断复位电路的框图。

When enabling the event link output function of the LVD, you must enable the LVD before enabling the LVD event link function of the ELC. To stop the event link output function of the LVD, you must stop the LVD before disabling the LVD event link function of the ELC.

8.7.1 Interrupt Handling and Event Linking

The LVD provides bits to individually enable or disable the voltage monitor 1 and 2 interrupts. When an interrupt source is generated and the interrupt is enabled by the interrupt enable bit, the interrupt signal (LVD1CR0.RIE or LVD2CR0.RIE) is output to the CPU.

On the other hand, as soon as an interrupt source is generated, an event link signal is output as the event signal to the other module through the ELC, regardless of the state of the interrupt enable bit.

It is possible to output voltage monitor 1 and 2 interrupts in Software Standby and Deep Software Standby modes. The event signals for the ELC in Software Standby and Deep Software Standby modes are output as follows:

- When a V_{det1} or V_{det2} passage event is detected in Software Standby mode, event signals are not generated for the ELC because the clock is not supplied in Software Standby mode. Because the V_{det1} and V_{det2} passage detection flags are saved, when the clock supply resumes after returning from Software Standby mode, the event signals for the ELC are output based on the state of the V_{det1} and V_{det2} detection flags.
- When a V_{det1} or V_{det2} passage events is detected in Deep Software Standby mode, event signals are not generated for the ELC.

(2) Vdet2交叉检测事件

当电压检测2电路和电压监测器2电路比较结果输出都启用时，LVD检测到电压已超过Vdet2电压时输出事件信号。

使能LVD的事件链接输出功能时，必须先使能LVD，再使能ELC的LVD事件链接功能。要停止LVD的事件链接输出功能，必须先停止LVD，然后再禁用ELC的LVD事件链接功能。

8.7.1 中断处理和事件链接

LVD提供位来单独启用或禁用电压监视器1和2中断。当产生中断源并通过中断使能位使能中断时，向CPU输出中断信号（LVD1CR0.RIE或LVD2CR0.RIE）。

另一方面，一旦产生中断源，无论中断使能位的状态如何，都会通过ELC将事件链接信号作为事件信号输出到其他模块。

在软件待机和深度软件待机模式下，可以输出电压监视器1和2中断。软件待机和深度软件待机模式下ELC的事件信号输出如下：

- 当在软件待机模式下检测到Vdet1或Vdet2通过事件时，不会为ELC生成事件信号，因为在软件待机模式下不提供时钟。因为保存了Vdet1和Vdet2通过检测标志，所以当从软件待机模式恢复后时钟供应恢复时，ELC的事件信号将根据Vdet1和Vdet2检测标志的状态输出。
- 当在深度软件待机模式下检测到Vdet1或Vdet2通过事件时，不会为ELC生成事件信号。

Those clock frequency ranges must be satisfied even when the HOCO has its maximum or minimum frequency. See section 52, Electrical Characteristics.

Note: If the PLL reference clock source is HOCO, the PLL multiplication setting must be set to 120 MHz - 240 MHz in consideration of HOCO frequency (minimum/maximum).

Note 1. The minimum FCLK frequency is 4 MHz in Programming/Erasure (P/E) mode.

和第50节，闪存。即使HOCO具有其最大或最小频率，也必须满足这些时钟频率范围。参见第52节，电气特性。

Note: 如果PLL参考时钟源是HOCO，则PLL倍频设置必须设置为120MHz240MHz考虑到
HOCO frequency (minimum/maximum).

Note 1. 在编程擦除(PE)模式下，最小FCLK频率为4MHz。

Note 1. The association between the frequencies of the system clock (ICLK) and the flash interface clock (FCLK) should be ICLK:FCLK = N:1 (N: integer).
If a setting is made where ICLK < FCLK, then that setting is ignored.
Note 2. The association between the frequencies of the system clock (ICLK) and the external bus clock (BCLK) should be ICLK:BCLK = N:1 (N: integer).
If a setting is made where ICLK < BCLK, then that setting is ignored.
Note 3. The association between the frequencies of the system clock (ICLK) and the peripheral module clocks (PCLKA, PCLKB) should be ICLK:PCLKA = N:1, ICLK:PCLKB = N:1 (N: integer).
If a setting is made where ICLK < PCLKA or ICLK < PCLKB, then that setting is ignored.
Note 4. The association between the frequencies of the system clock (ICLK) and the peripheral module clocks (PCLKC, PCLKD) should be ICLK:PCLKC, PCLKD = N:1 or 1:N (N: integer).
Note 5. The frequency of the system clock (ICLK) is limited to the Flash Wait Cycle register (FLWT). See section 50, Flash Memory.

The SCKDIVCR register selects the frequencies of the system clock (ICLK), the peripheral module clocks (PCLKA, PCLKB, PCLKC, PCLKD), the flash interface clock (FCLK), and the external bus clock (BCLK).

9.2.5 PLL Control Register (PLLCR)

b0	PLLSTP	PLL Stop Control	0: Operate the PLL 1: Stop the PLL.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The PLLCR register controls the operation of the PLL circuit.

PLLSTP bit (PLL Stop Control)

The PLLSTP bit starts or stops the PLL circuit. When selecting the main clock oscillator as the clock source for the PLL in the PLLCCR.PLSRCSEL bit, you must also set the Main Clock Oscillator Wait Control Register (MOSCWTCR).

After setting the PLLSTP bit to 0, confirm that the OSCSF.PLLSF bit is set to 1 before using the PLL clock. A fixed stabilization wait is required after setting the PLL to start operation. A fixed wait time for the oscillation to stop is also required after stopping the PLL operation.

The following restrictions apply when starting and stopping the PLL operation:

- After stopping the PLL, confirm that the OSCSF.PLLSF bit is 0 before restarting the PLL
- Confirm that the PLL operates and that the OSCSF.PLLSF bit is 1 before stopping the PLL
- Regardless of whether the PLL clock is selected as the system clock, after setting the PLL to start operation, confirm that the OSCSF.PLLSF is set to 1 before executing a WFI instruction to place the MCU in Software Standby or Deep Software Standby mode
- When a transition to Software Standby or Deep Software Standby mode is to follow the setting to stop the PLL, confirm that the OSCSF.PLLSF bit is set to 0 before executing the WFI instruction.

Writing 1 to PLLSTP is prohibited under the following condition:

- SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL).

Make sure the following conditions apply before writing 0 to PLLSTP:

- When PLL source clock = MOSC, OSCSF.MOSCSF bit is 1
- When PLL source clock = HOCO, OSCSF.HOCOSF bit is 1.

9.2.5 PLL控制寄存器(PLLCR)

b0	PLLSTP	PLL停止控制	0：运行PLL1：停止PLL。	R/W
b7 to b1	—	Reserved	这些位被读取为0。写入值应为0。	R/W

PLLCR寄存器控制PLL电路的操作。

PLLSTP位（PLL停止控制）

PLLSTP位启动或停止PLL电路。在PLLCCR.PLSRCSEL位中选择主时钟振荡器作为PLL的时钟源时，您还必须设置主时钟振荡器等待控制寄存器(MOSCWTCR)。

将PLLSTP位设置为0后，在使用PLL时钟之前确认OSCSF.PLLSF位设置为1。将PLL设置为开始操作后，需要一个固定的稳定等待。停止PLL操作后，还需要固定的振荡停止等待时间。

启动和停止PLL操作时适用以下限制：

- 停止PLL后，在重启PLL之前确认OSCSF.PLLSF位为0
- 在停止PLL之前确认PLL运行并且OSCSF.PLLSF位为1
- 无论是否选择PLL时钟作为系统时钟，在设置PLL开始运行后，确认OSCSF.PLLSF设置为1，然后再执行WFI指令将MCU置于软件待机或深度软件待机模式
- 当按照设置转换到软件待机或深度软件待机模式以停止PLL时，请在执行WFI指令之前确认OSCSF.PLLSF位设置为0。

在以下情况下禁止向PLLSTP写入1：

- SCKSCR.CKSEL[2:0]=101b（系统时钟源=PLL）。

在将0写入PLLSTP之前，请确保满足以下条件：

- 当PLL源时钟=MOSC时，OSCSF.MOSCSF位为1
- 当PLL源时钟=HOCO时，OSCSF.HOCOSF位为1。

Note 1. The MOMCR register must be set before setting MOSTP to 0.

The MOSCCR register controls the main clock oscillator.

MOSTP bit (Main Clock Oscillator Stop)

The MOSTP bit starts or stops the main clock oscillator. To start the main clock oscillator, set this bit to 0. When changing the value of this bit, only execute subsequent instructions after reading the bit to check that its value is updated.

When using the main clock oscillator, you must set the Main Clock Oscillator Mode Oscillation Control Register (MOMCR) and the Main Clock Oscillator Wait Control Register (MOSCWTCR) before setting MOSTP to 0.

After setting the MOSTP bit to 0, confirm that the OSCSF.MOSCSF bit is set to 1 before using the main clock oscillator. A fixed stabilization wait is required after setting the main clock oscillator to start operation. A fixed wait time for the oscillation to stop is also required after stopping the main clock oscillator.

The following restrictions apply when starting and stopping the main clock oscillator operation:

- After stopping the main clock oscillator, confirm that the OSCSF.MOSCSF bit is 0 before restarting the main clock oscillator
- Confirm that the main clock oscillator operates and that the OSCSF.MOSCSF bit is 1 before stopping the main clock oscillator

将主时钟振荡器设置为开始运行后，需要一个固定的稳定等待时间。停止主时钟振荡器后，还需要一个固定的振荡停止等待时间。

以下限制适用于启动和停止主时钟振荡器操作：

- 停止主时钟振荡器后，在重新启动主时钟振荡器之前确认OSCSF.MOSCSF位为0
- 在停止主时钟振荡器之前，确认主时钟振荡器工作并且OSCSF.MOSCSF位为1
- 无论是否选择主时钟振荡器作为系统时钟，确认OSCSF.MOSCSF

- When a transition to Software Standby or Deep Software Standby mode is to follow the setting to stop the main clock oscillator, confirm that the OSCSF.MOSCSF bit is set to 0 before executing the WFI instruction.

Writing 1 to MOSTP is prohibited under the following conditions:

- SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC)
- PLLCCR.PLSRCSEL = 0 (PLL source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL)

Bit	Symbol	Bit name	Description	R/W

b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. The SOMCR register must be set before setting SOSTP to 0.

The SOSCCR register controls the sub-clock oscillator.

SOSTP bit (Sub-Clock Oscillator Stop)

The SOSTP bit starts or stops the sub-clock oscillator.

When changing the value of the SOSTP bit, only execute subsequent instructions after reading the bit and checking that its value is updated. Use the SOSTP bit when using the sub-clock oscillator as the source for a peripheral module such as the RTC.

When using the sub-clock oscillator, you must set the Sub-Clock Oscillator Mode Control Register (SOMCR) before setting SOSTP to 0.

After setting SOSTP to 0, only use the sub-clock oscillator after the sub-clock oscillation stabilization wait time (tSUBOSCOWT) elapses. A fixed stabilization wait is required after setting the sub-clock oscillator to start operation. A fixed wait time for the oscillation to stop is also required after setting the SOSTP bit.

The following restrictions apply when starting and stopping operation:

- After stopping the sub-clock oscillator, allow a stop interval of at least 5 SOSC clock cycles before restarting it
- Confirm that sub-clock oscillation is stable before stopping the sub-clock oscillator
- Regardless of whether the sub-clock oscillator is selected as the system clock, confirm that the sub-clock oscillation is stable before executing a WFI instruction to place the MCU in Software Standby mode
- When a transition to Software Standby mode is to follow the setting to stop the sub-clock oscillator, wait for at least 3 SOSC clock cycles before executing the WFI instruction.

Writing 1 to SOSTP is prohibited under the following condition:

- SCKSCR.CKSEL[2:0] = 100b (system clock source = SOSC).

在执行WFI指令以将MCU置于软件待机或深度软件待机模式之前，该位设置为1

- 当根据设置转换到软件待机或深度软件待机模式以停止主时钟振荡器时，请在执行WFI指令之前确认OSCSF.MOSCSF位设置为0。

在以下情况下禁止向MOSTP写入1：

- SCKSCR.CKSEL[2:0]=011b（系统时钟源=MOSC）
- PLLCCR.PLSRCSEL=0（PLL源时钟=MOSC）和SCKSCR.CKSEL[2:0]=101b（系统时钟源=PLL）
- PLLCCR.PLSRCSEL=0（PLL源时钟=MOSC）和PLLCR.PLLSTP=0（PLL正在运行）。

SOSCCR寄存器控制副时钟振荡器。

SOSTP位（副时钟振荡器停止）

SONTP位启动或停止副时钟振荡器。

更改SONTP位的值时，仅在读取该位并检查其值是否已更新后执行后续指令。当使用副时钟振荡器作为外围模块（如RTC）的源时，使用SOTP位。

使用副时钟振荡器时，必须先设置副时钟振荡器模式控制寄存器(SOMCR)，然后再将SOSTP设置为0。

将SOSTP设置为0后，仅在副时钟振荡稳定等待时间(tSUBOSCOWT)过后才使用副时钟振荡器。设置副时钟振荡器开始运行后，需要一个固定的稳定等待。设置SOOSTP位后，还需要一个固定的振荡停止等待时间。

启动和停止操作时适用以下限制：

- 停止子时钟振荡器后，在重新启动之前允许至少5个SOSC时钟周期的停止间隔
- 在停止副时钟振荡器之前确认副时钟振荡稳定
- 无论是否选择副时钟振荡器作为系统时钟，在执行WFI指令之前确认副时钟振荡稳定，使MCU进入软件待机模式
- 当根据设置转换到软件待机模式以停止副时钟振荡器时，请等待至少3个SOSC时钟周期，然后再执行WFI指令。

在以下情况下禁止向SOTP写入1：

- SCKSCR.CKSEL[2:0]=100b（系统时钟源=SOSC）。

The LOCOCR register controls the LOCO clock.

LCSTP bit (LOCO Stop)

The LCSTP bit starts or stops the LOCO clock.

After setting the LCSTP bit to 0 to start the LOCO clock, only use the clock after the LOCO clock oscillation stabilization wait time (tLOCOWT) elapses. A fixed stabilization wait is required after setting the LOCO clock to start operation. A fixed wait time for the oscillation to stop is also required.

The following restrictions apply when starting and stopping operation:

- After stopping the LOCO clock, allow a stop interval of at least 5 LOCO clock cycles before restarting it
- Confirm that LOCO oscillation is stable before stopping the LOCO clock
- Regardless of whether the LOCO clock is selected as the system clock, confirm that LOCO oscillation is stable before executing a WFI instruction to place the MCU in Software Standby or Deep Software Standby mode
- When a transition to Software Standby or Deep Software Standby mode is to follow the setting to stop the LOCO clock, wait for at least 3 LOCO clock cycles before executing the WFI instruction.

Writing 1 to LOSTP is prohibited under the following condition:

- SCKSCR.CKSEL[2:0] = 010b (system clock source = LOCO).

Because the LOCO clock measures the wait time for other oscillators, it continues to oscillate while measuring this time, regardless of the setting in LOCOCR.LCSTP. As a result, the LOCO clock might be unintentionally supplied even when the LCSTP is set to stop.

启动和停止操作时适用以下限制：

- 停止LOCO时钟后，在重新启动之前允许至少5个LOCO时钟周期的停止间隔
- 在停止LOCO时钟之前确认LOCO振荡稳定
- 无论是否选择LOCO时钟作为系统时钟，在执行WFI指令将MCU置于软件待机或深度软件待机模式之前，请确认LOCO振荡稳定
- 当按照设置转换到软件待机或深度软件待机模式以停止LOCO时钟时，请等待至少3个LOCO时钟周期，然后再执行WFI指令。

在以下情况下禁止向LOSTP写入1：

- SCKSCR.CKSEL[2:0]=010b（系统时钟源=LOCO）。

因为LOCO时钟测量其他振荡器的等待时间，所以无论LOCOCR.LCSTP中的设置如何，它都会在测量该时间时继续振荡。因此，即使LCSTP设置为停止，也可能会无意中提供LOCO时钟。

Note 1. The value after reset depends on the OFS1.HOCOEN setting.
When OFS1.HOCOEN = 1, the HOCOSF value after reset is 0.
When OFS1.HOCOEN = 0, the HOCOSF value becomes 0 after reset is released, and HOCOSF is set to 1 after the HOCO oscillation stabilization wait time elapses.

Note 2. An appropriate value is set in the Wait Control Register for the given oscillator. If the wait time value is not sufficient, the oscillation stabilization flag is set to 1 and supply of the clock signal to the internal circuits starts before oscillation is stable.

The OSCSF register contains flags to indicate the operating status of the counters in the oscillation stabilization wait circuits for the individual oscillators.

After oscillation starts, these counters measure the wait time until each oscillator output clock is supplied to the internal circuits. An overflow of a counter indicates that the clock supply is stable and available for the associated circuit.

HOCOSF flag (HOCO Clock Oscillation Stabilization Flag)

The HOCOSF flag indicates the operating status of the counter that measures the wait time for the HOCO. When OFS1.HOCOEN is set to 1, confirm that the OSCSF.HOCOSF is also set to 1 before using the HOCO clock.

[Setting condition]

- After the HOCO clock stops and the HOCOCR.HCSTP bit is set to 0, supply of the MCU clock starts after the number of LOCO cycles associated with the HOCOWTCR register setting elapses.

[Clearing condition]

- When the HOCO clock is operating and then is deactivated because the HOCOCR.HCSTP bit is set to 1.

MOSCSF flag (Main Clock Oscillation Stabilization Flag)

The MOSCSF flag indicates the operating status of the counter that measures the wait time for the main clock oscillator.

[Setting condition]

- After the main clock oscillator stops and the MOSCCR.MOSTP bit is set to 0, supply of the MCU clock starts after the number of LOCO cycles associated with the MOSCWTCR register setting elapses.

当OFS1.HOCOEN=0时，复位解除后HOCOSF值变为0，经过HOCO振荡稳定等待时间后HOCOSF设置为1。

Note 2. 给定振荡器的等待控制寄存器中设置了一个适当的值。如果等待时间值不够，则将振荡稳定标志设置为1，并在振荡稳定之前开始向内部电路提供时钟信号。

OSCSF寄存器包含用于指示各个振荡器的振荡稳定等待电路中的计数器的操作状态的标志。

振荡开始后，这些计数器测量等待时间，直到每个振荡器输出时钟被提供给内部电路。计数器溢出表明时钟供应稳定并可用于相关电路。

HOCOSF标志（HOCO时钟振荡稳定标志）

[Clearing condition]

PLLSF flag (PLL Clock Oscillation Stabilization Flag)

The PLLSF flag indicates the operating status of the counter that measures the wait time for the PLL.

[Setting condition]

- After the PLL stops and the PLLCR.PLLSTP bit is set to 0, supply of the MCU clock starts after 31 LOCO cycles. If oscillation by the PLL clock source selected in the PLLCCR.PLSRCSEL bit is not stable when the PLLSTP bit is set to 0, counting of the LOCO cycles continues after the PLL clock source oscillation is stabilized. Wait time is calculated as:

  1 cycle = LOCO (32.768 kHz) x 8 (3.81 µs typical).

[Clearing condition]

- When the PLL is operating and then is deactivated because the PLLCCR.PLLSTP bit is set to 1.

9.2.16 Oscillation Stop Detection Control Register (OSTDCR)

	b7	b6	b5	b4	b3	b2	b1	b0
	OSTDE	—	—	—	—	—	—	OSTDIE
Value after reset:	0	0	0	0	0	0	0	0

b7	OSTDE	Oscillation Stop Detection Function Enable	0: Disable oscillation stop detection function 1: Enable oscillation stop detection function.	R/W

The OSTDCR register controls the oscillation stop detection function.

OSTDIE bit (Oscillation Stop Detection Interrupt Enable)

The OSTDIE bit enables the oscillation stop detection function interrupt. This bit also controls whether oscillation stop detection is reported to the POEG.

If the Oscillation Stop Detection flag in the Oscillation Stop Detection Status Register (OSTDSR.OSTDF) requires clearing, set the OSTDIE bit to 0 before clearing OSTDF. Wait for at least 2 PCLKB cycles before setting the OSTDIE bit to 1. A longer PCLKB wait time might be required, depending on the number of cycles required to read a given I/O register.

OSTDE bit (Oscillation Stop Detection Function Enable)

The OSTDE bit enables the oscillation stop detection function.

When the OSTDE bit is 1 (enabled), the MOCO stop bit (MOCOCR.MCSTP) is set to 0 and MOCO operation starts. The MOCO clock cannot be stopped when the oscillation stop detection function is enabled. Writing 1 to the MOCOCR.MCSTP bit (MOCO stopped) is invalid.

When the Oscillation Stop Detection flag in the Oscillation Stop Detection Status Register (OSTDSR.OSTDF) is 1 (main clock oscillation stop detected), writing 0 to the OSTDE bit is invalid.

The OSTDE bit must be set to 0 before transitioning to Software Standby or Deep Software Standby mode. To transition to either of these modes, first set the OSTDE bit to 0, then execute the WFI instruction.

The following restrictions apply when using the oscillation stop detection function:

- 当主时钟振荡器正在运行，然后因为MOSCCR.MOSTP位设置为1而被停用时。

PLLSF标志（PLL时钟振荡稳定标志）

PLLSF标志指示测量PLL等待时间的计数器的操作状态。

[Setting condition]

1个周期=LOCO(32.768kHz)x8（典型值为3.81µs）
。【结算条件】

OSTDCR寄存器控制振荡停止检测功能。

OSTDIE位（振荡停止检测中断使能）

OSTDIE位使能振荡停止检测功能中断。该位还控制是否将振荡停止检测报告给POEG。

如果振荡停止检测状态寄存器(OSTDSR.OSTDF)中的振荡停止检测标志需要清零，则在清零OSTDF之前将OSTDIE位设置为0。在将OSTDIE位设置为1之前等待至少2个PCLKB周期。可能需要更长的PCLKB等待时间，具体取决于读取给定IO寄存器所需的周期数。

OSTDE位（振荡停止检测功能使能）

OSTDE位使能振荡停止检测功能。

当OSTDE位为1（使能）时，MOCO停止位（MOCOCR.MCSTP）设置为0，MOCO操作开始。
使能振荡停止检测功能时，MOCO时钟不能停止。将1写入
MOCOCR.MCSTP位（MOCO停止）无效。

当振荡停止检测状态寄存器(OSTDSR.OSTDF)中的振荡停止检测标志为1（检测到主时钟振荡停止）时，向OSTDE位写入0无效。

在转换到软件待机或深度软件待机模式之前，必须将OSTDE位设置为0。要转换到这两种模式中的任何一种，首先将OSTDE位设置为0，然后执行WFI指令。

使用振荡停止检测功能时有以下限制：

b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. This bit can only be set to 0.

The OSTDSR register indicates the stop detection status of the main clock oscillator.

OSTDF flag (Oscillation Stop Detection Flag)

The OSTDF flag indicates the main clock oscillator status. When this flag is 1, it indicates that the main clock oscillation stop was detected. After this stop is detected, the OSTDF flag is not set to 0 even when the main clock oscillation is restarted. The OSTDF flag is set to 0 by writing 0 after reading it as 1.

At least 3 ICLK cycles of wait time are required between writing 0 to OSTDF and reading it as 0. If the OSTDF flag is set to 0 when the main clock oscillation is stopped, the OSTDF flag becomes 0 then returns to 1.

The OSTDF flag cannot be set to 0 under the following conditions:

- SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC)
- PLLCCR.PLSRCSEL = 0 (PLL source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL).

The OSTDF flag must be set to 0 after switching the clock source to sources other than the main clock oscillator and PLL.

[Setting condition]

- The main clock oscillator is stopped when OSTDCR.OSTDE = 1 (oscillation stop detection function enabled).

[Clearing condition]

- 1 is read and then 0 is written when the SCKSCR.CKSEL[2:0] bits are neither 011b (system clock = MOSC) nor 101b (system clock = PLL), and the PLLCCR.PLSRCSEL bit is not 0 (PLL source clock = MOSC).

- 在低速模式下，禁止为ICLK、FCLK、BCLK、PCLKA、PCLKB、PCLKC、PCLKD选择1、2、4、8分频。

Note 1. 该位只能设置为0。

OSTDSR寄存器指示主时钟振荡器的停止检测状态。

OSTDF标志（振荡停止检测标志）

OSTDF标志指示主时钟振荡器状态。该标志为1时，表示检测到主时钟振荡停止。检测到此停止后，即使重新启动主时钟振荡，OSTDF标志也不会设置为0。OSTDF标志在读取为1后通过写入0设置为0。

从向OSTDF写入0到将其读取为0之间至少需要3个ICLK周期的等待时间。如果在主时钟振荡停止时将OSTDF标志设置为0，则OSTDF标志变为0然后返回1。

在以下情况下，OSTDF标志不能设置为0：

- SCKSCR.CKSEL[2:0]=011b（系统时钟源=MOSC）
- PLLCCR.PLSRCSEL=0（PLL源时钟=MOSC）和SCKSCR.CKSEL[2:0]=101b（系统时钟源=PLL).

b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

MSTS[3:0] bits (Main Clock Oscillator Wait Time Setting)

The MSTS[3:0] bits specify the oscillation stabilization wait time for the main clock oscillator.

Set the main clock oscillation stabilization time to a period longer than or equal to the stabilization time recommended by the oscillator manufacturer. When the main clock is input externally, set these bits to 0001b, because the oscillation stabilization time is not required.

The wait time set in the MSTS[3:0] bits is counted using:

1 cycle (µs) = 1 / (f_ LOCO [MHz] × 8) = 1 / (0.032768 × 8) = 3.81 (µs).

The LOCO clock automatically oscillates when necessary, regardless of the LOCOCR.LOSTP bit value. After the specified wait time elapses, supply of the main clock oscillator starts internally in the MCU, and the OSCSF.MOSCSF flag is set to 1. If the specified wait time is short, supply of the main clock oscillator starts before oscillation of the clock becomes stable.

Only rewrite the MOSCWTCR register when the MOSCCR.MOSTP bit is 1 and the OSCSF.MOSCSF flag is 0. Do not rewrite this register under any other conditions.

MSTS[3:0]位（主时钟振荡器等待时间设置）

MSTS[3:0]位指定主时钟振荡器的振荡稳定等待时间。

将主时钟振荡稳定时间设置为大于或等于振荡器制造商推荐的稳定时间。当外部输入主时钟时，将这些位设置为0001b，因为不需要振荡稳定时间。

MSTS[3:0]位中设置的等待时间使用以下公式计算：

1个周期(µs)=1(f_LOCO[MHz]×8)=1(0.032768×8)=3.81(µs)。

无论LOCOCR.LOSTP位的值如何，LOCO时钟都会在必要时自动振荡。经过指定的等待时间后，MCU内部开始提供主时钟振荡器，并且OSCSF.MOSCSF标志设置为1。如果指定的等待时间短，则在时钟振荡之前开始提供主时钟振荡器变得稳定。

仅当MOSCCR.MOSTP位为1且OSCSF.MOSCSF标志为0时才重写MOSCWTCR寄存器。在任何其他情况下请勿重写此寄存器。

CKOSEL[2:0] bits (Clock Out Source Select)

The CKOSEL[2:0] bits specify the HOCO, MOCO, LOCO, MOSC, or SOSC clock as the source of the clock to be output from the CLKOUT pin. When changing the CLKOUT source clock, set the CKOEN bit to 0.

CKODIV[2:0] bits (Clock Out Input Frequency Division Select)

The CKODIV[2:0] bits specify the clock division ratio. Set the CKOEN bit to 0 when changing the division ratio. The division ratio of the output clock frequency must be set to a value no higher than the characteristics of the CLKOUT pin output frequency. For details on the characteristics of the CLKOUT pin, see section 52, Electrical Characteristics.

CKOEN bit (Clock Out Enable)

The CKOEN bit enables output from the CLKOUT pin. When CKOEN is set to 1, the selected clock is output. When CKOEN is set to 0, low is output. When changing this bit, confirm that the clock out source clock selected in the CKOSEL[2:0] bits is stable. Otherwise, a glitch might be generated in the output.

The CKOEN bit must be cleared before entering Software Standby or Deep Software Standby mode if the selected clock out source clock is stopped in that mode.

SODRV1位（副时钟振荡器驱动能力切换）

SODRV1位切换副时钟振荡器的驱动能力。该位在第一次上电时未定义，但SOSCCR.SOSTP复位后的值为0（SOSC=运行）。首次上电时按如下方式设置SOSC：

1. 将SOSCCR.SOSTP位设置为1（SOSC=停止）。
2. 将SODRV1位设置为当前电容的正确值。
3. 将SOSCCR.SOSTP位设置为0（SOSC=运行）。

CKOSEL[2:0]位（时钟输出源选择）

CKOSEL[2:0]位指定HOCO、MOCO、LOCO、MOSC或SOSC时钟作为从CLKOUT引脚输出的时钟源。更改CLKOUT源时钟时，将CKOEN位设置为0。

CKODIV[2:0]位（时钟输出输入分频选择）

CKODIV[2:0]位指定时钟分频比。更改分频比时将CKOEN位设置为0。输出时钟频率的分频比必须设置为不高于CLKOUT引脚输出频率特性的值。有关CLKOUT引脚特性的详细信息，请参见第52节，电气特性。

CKOEN位（时钟输出使能）

CKOEN位使能CLKOUT引脚的输出。当CKOEN设置为1时，输出选定的时钟。什么时候CKOEN设置为0，输出低电平。当改变该位时，确认时钟输出源时钟选择在CKOSEL[2:0]位是稳定的。否则，可能会在输出中产生故障。

如果所选时钟输出源时钟在该模式下停止，则必须在进入软件待机或深度软件待机模式之前清零CKOEN位。

The Trace Clock Control Register controls the switching of the trace clock. Before changing the TRCLK frequency, set the TRCKEN bit to 0. The TRCKCR register is initialized by all reset sources.

9.3 Main Clock Oscillator

To supply the clock signal to the main clock oscillator, use one of the following ways:

- Connect an oscillator
- Connect the input of an external clock signal.

9.3.1 Connecting the Crystal Resonator

Figure 9.6 shows an example of connecting a crystal resonator. A damping resistor (R_d) can be added, if required. Because the resistor values vary according to the resonator and the oscillation drive capability, use values recommended by the resonator manufacturer. If the manufacturer recommends using an external feedback resistor (R_f), insert an R_f between EXTAL and XTAL by following the instructions.

When connecting a resonator to supply the clock, the frequency of the resonator must be in the frequency range of the resonator for the main clock oscillator as described in Table 9.1.

9.3 主时钟振荡器

要将时钟信号提供给主时钟振荡器，请使用以下方法之一：

- 连接振荡器
- 连接外部时钟信号的输入。

9.3.1 连接晶体谐振器

图9.6显示了连接晶体谐振器的示例。如果需要，可以添加阻尼电阻器(Rd)。
由于电阻值因谐振器和振荡驱动能力而异，请使用谐振器制造商推荐的值。如果制造商建议使用外部反馈电阻器(Rf)，请按照说明在EXTAL和XTAL之间插入一个Rf。

连接谐振器以提供时钟时，谐振器的频率必须在表9.1中描述的主时钟振荡器的谐振器频率范围内。

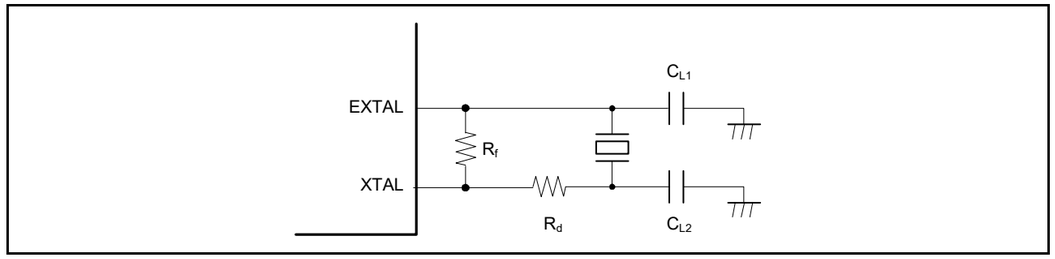

Figure 9.6 晶体谐振器连接示例

图9.7显示了晶体谐振器的等效电路。

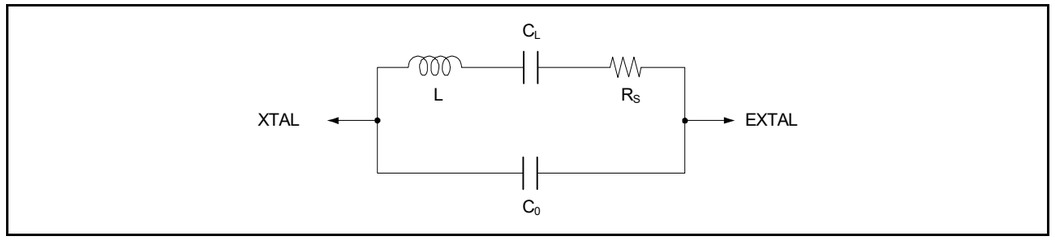

Figure 9.7 Equivalent circuit of the crystal resonator

9.3.2 External Clock Input

Figure 9.8 shows an example for connecting an external clock input. To operate the oscillator with an external clock signal, set the MOMCR.MOSEL bit to 1. The XTAL pin is the function that is set in PFS.P213PFS.

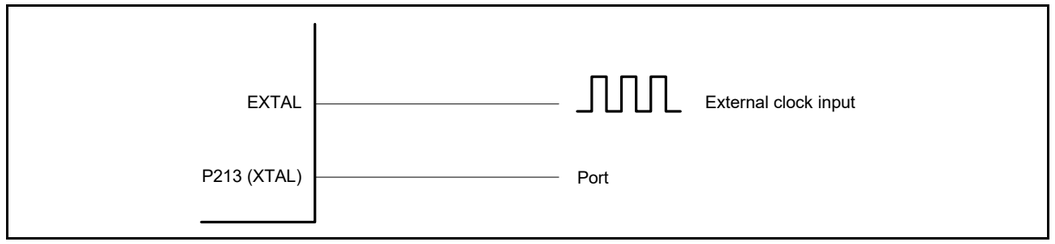

Figure 9.8 Equivalent circuit for external clock

9.3.3 Notes on External Clock Input

The frequency of the external clock input can only be changed when the main clock oscillator is stopped. Do not change the frequency of the external clock input when the Main Clock Oscillator Stop bit (MOSCCR.MOSTP) is 0.

9.4 Sub-Clock Oscillator

The only way of supplying a clock signal to the sub-clock oscillator is by connecting a crystal oscillator.

9.4.1 Connecting a 32.768-kHz Crystal Resonator

To supply a clock to the sub-clock oscillator, connect a 32.768-kHz crystal resonator as shown in Figure 9.9. A damping resistor (R_d) can be added, if required. Because the resistor values vary according to the resonator and the oscillation drive capability, use values recommended by the resonator manufacturer. If the manufacturer recommends using an external feedback resistor (R_f), insert an R_f between XCIN and XCOUT by following the instructions.

When connecting a resonator to supply the clock, the frequency of the resonator must be in the frequency range of the resonator for the sub-clock oscillator as described in Table 9.1.

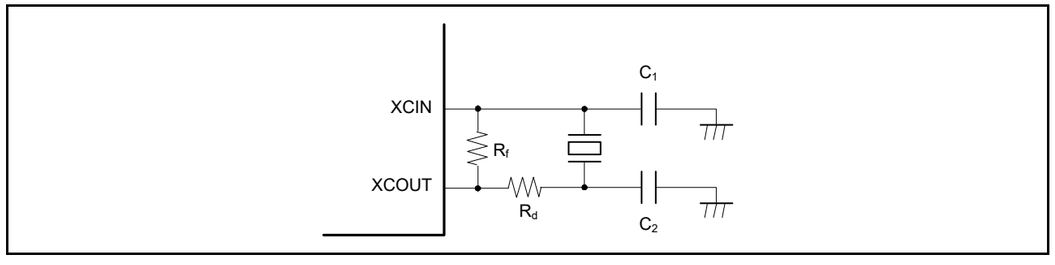

Figure 9.9 Connection example of 32.768-kHz crystal resonator

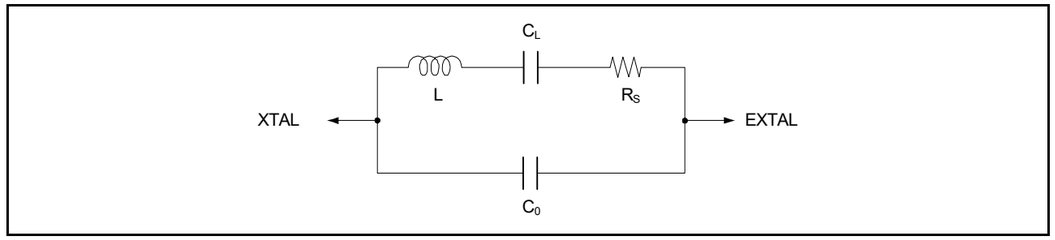

Figure 9.7 晶体谐振器的等效电路

9.3.2 外部时钟输入

图9.8显示了连接外部时钟输入的示例。要使用外部时钟信号操作振荡器，请将MOMCR.MOSEL位设置为1。XTAL引脚是在PFS.P213PFS中设置的功能。

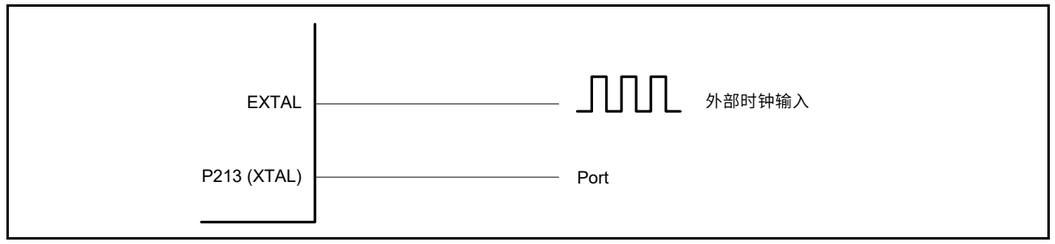

Figure 9.8 外部时钟等效电路

9.3.3 外部时钟输入注意事项

外部时钟输入的频率只有在主时钟振荡器停止时才能改变。当主时钟振荡器停止位(MOSCCR.MOSTP)为0时，请勿更改外部时钟输入的频率。

9.4 Sub-Clock Oscillator

向副时钟振荡器提供时钟信号的唯一方法是连接晶体振荡器。

9.4.1 连接32.768kHz晶体谐振器

要为副时钟振荡器提供时钟，请连接一个32.768-kHz晶体谐振器，如图9.9所示。如果需要，可以添加阻尼电阻器(Rd)。由于电阻值因谐振器和振荡驱动能力而异，请使用谐振器制造商推荐的值。如果制造商建议使用外部反馈电阻(Rf)，请按照说明在XCIN和XCOUT之间插入一个Rf。

连接谐振器以提供时钟时，谐振器的频率必须在表9.1中所述的副时钟振荡器的谐振器频率范围内。

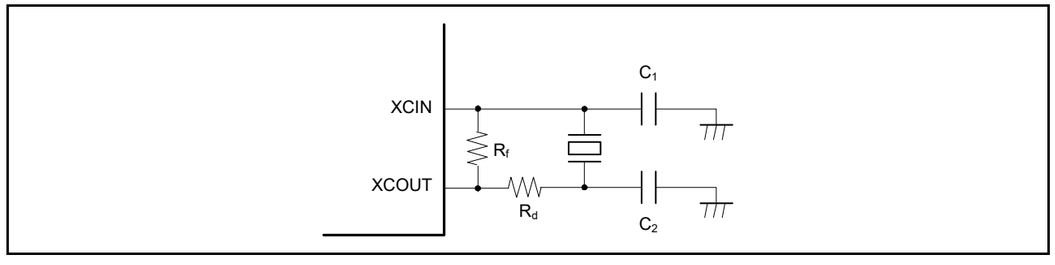

Figure 9.9 32.768-kHz晶体谐振器的连接示例

Figure 9.10 shows an equivalent circuit for the 32.768-kHz crystal resonator.

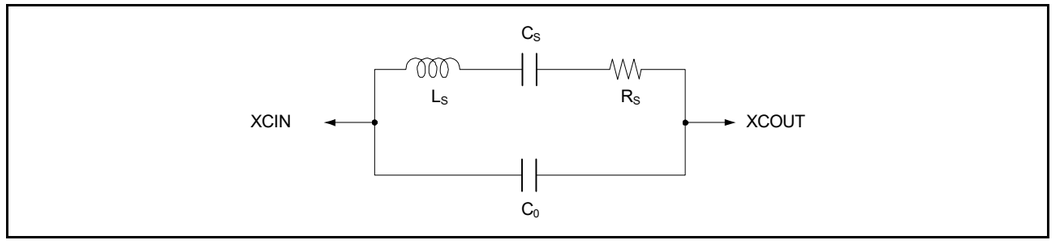

Figure 9.10 Equivalent circuit for the 32.768-kHz crystal resonator

9.4.2 Handling of Pins when the Sub-Clock Oscillator Is Not Used

When the sub-clock oscillator is not in use, connect the XCIN pin to VSS through a resistor (to pull VSS down) and leave the XCOUT pin open as shown in Figure 9.11. In addition, if an oscillator is not connected, set the Sub-clock Oscillator Stop bit (SOSCCR.SOSTP) to 1 to stop the oscillator.

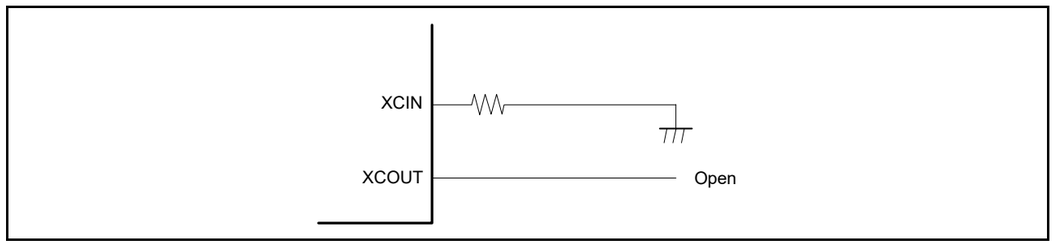

Figure 9.11 Pin handling when the sub-clock oscillator is not used

9.5 Oscillation Stop Detection Function

9.5.1 Oscillation Stop Detection and Operation after Detection

The oscillation stop detection function detects the main clock oscillator stop. When an oscillation stop is detected, the system clock switches as follows:

- If an oscillation stop is detected with SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC), the system clock source switches to the MOCO clock
- If an oscillation stop is detected with PLLCCR.PLSRCSEL = 0 (PLL source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL), the PLL clock remains as the system clock source. The frequency becomes a free-running oscillation frequency, and the setting of SCKSCR.CKSEL[2:0] bits does not change.

An oscillation stop detection interrupt request can be generated when an oscillation stop is detected. In addition, the General PWM Timer (GPT) output can be forced to a high-impedance state on detection.

The main clock oscillation stop is detected when the input clock remains at 0 or 1 for a certain period, for example, when a malfunction occurs in the main clock oscillator. See section 52, Electrical Characteristics.

Switching between the main clock oscillator and the MOCO clock or between the PLL clock and the PLL free-running clock is controlled by the Oscillation Stop Detection flag (OSTDSR.OSTDF).

The OSTDF flag controls the switched clock as follows:

- When SCKSCR.CKSEL[2:0] = 011b (system clock source = MOSC):
  - When OSTDF changes from 0 to 1, the clock source switches to the MOCO clock
  - When OSTDF changes from 1 to 0, the clock source switches to MOSC again.

图9.10显示了32.768-kHz晶体谐振器的等效电路。

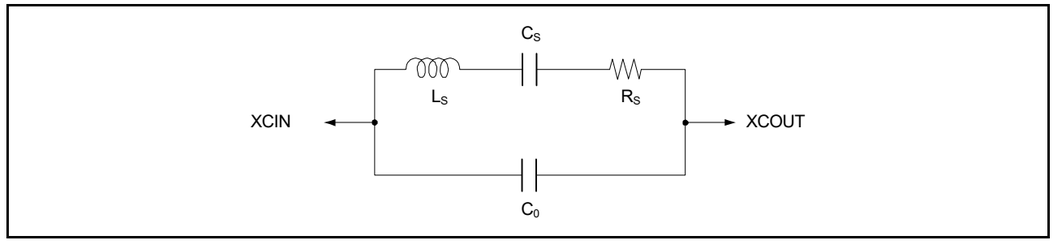

Figure 9.10 32.768kHz晶体谐振器的等效电路

9.4.2 不使用副时钟振荡器时的引脚处理

不使用副时钟振荡器时，通过一个电阻将XCIN引脚连接到VSS（将VSS下拉）并使XCOUT引脚保持开路，如图9.11所示。此外，如果未连接振荡器，请将副时钟振荡器停止位(SOSCCR.SOSTP)设置为1以停止振荡器。

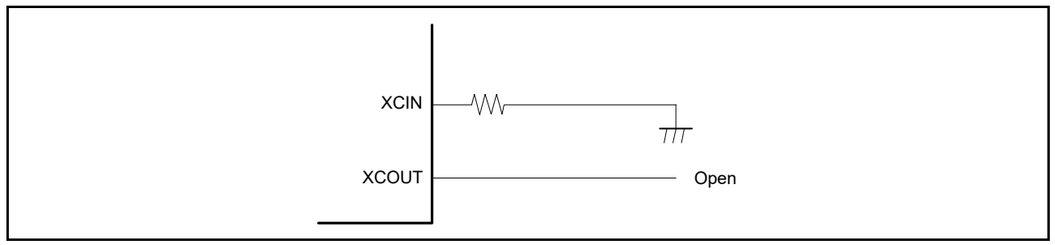

Figure 9.11 不使用副时钟振荡器时的引脚处理

9.5 振荡停止检测功能

9.5.1 振荡停止检测和检测后操作

振荡停止检测功能检测主时钟振荡器停止。当检测到振荡停止时，系统时钟切换如下：

- 如果通过SCKSCR.CKSEL[2:0]=011b（系统时钟源=MOSC）检测到振荡停止，则系统时钟源切换到MOCO时钟
- 如果在PLLCCR.PLSRCSEL=0（PLL源时钟=MOSC）的情况下检测到振荡停止并且SCKSCR.CKSEL[2:0]=101b(系统时钟源=PLL)，PLL时钟保持为系统时钟源。频率变为自由振荡频率，SCKSCR.CKSEL[2:0]位的设置不变。

当检测到振荡停止时，可以产生一个振荡停止检测中断请求。除此之外
通用PWM定时器(GPT)输出可在检测时强制为高阻抗状态。

当输入时钟保持在0或1一段时间，例如，当主时钟振荡器发生故障时，检测到主时钟振荡停止。参见第52节，电气特性。

主时钟振荡器和MOCO时钟之间或PLL时钟和PLL自由运行时钟之间的切换由振荡停止检测标志(OSTDSR.OSTDF)控制。

OSTDF标志控制切换时钟如下：

- 当SCKSCR.CKSEL[2:0]=011b（系统时钟源=MOSC）时：
  - 当OSTDF由0变为1时，时钟源切换为MOCO时钟
  - 当OSTDF从1变为0时，时钟源再次切换到MOSC。

- When PLLCCR.PLSRCSEL = 0 (PLL source clock = MOSC) and SCKSCR.CKSEL[2:0] = 101b (system clock source = PLL):
  - When OSTDF changes from 0 to 1, the clock source switches to the PLL free-running oscillation clock
  - When OSTDF changes from 1 to 0, the clock source switches to PLL again.

To switch the clock source to the main clock oscillator or PLL clock again after oscillation stop detection, set the CKSEL[2:0] bits to a clock source other than the main clock oscillator or PLL clock, and clear the OSTDF flag to 0. Also, check that the OSTDF flag is not 1, and then set the CKSEL[2:0] bits to the main clock oscillator or PLL clock after the specified oscillation stabilization time elapses.

After a reset release, the main clock oscillator is stopped and the oscillation stop detection function is disabled. To enable the oscillation stop detection function, activate the main clock oscillator and write 1 to the Oscillation Stop Detection Function Enable bit (OSTDCR.OSTDE) after the specified oscillation stabilization time elapses.

The oscillation stop detection function detects when the main clock oscillator is stopped by an external cause. This means that the oscillation stop detection function must be disabled before the main clock oscillator is stopped by software or before entering Software Standby or Deep Software Standby mode.

The oscillation stop detection function switches the following clocks to the MOCO clock (when the system clock is MOSC) or to the PLL free-running clock (when the system clock is PLL):

- All clocks that can be selected as the MOSC clock or PLL except CLKOUT
- The system clock (ICLK) frequency during MOCO operation (when the system clock is MOSC) or PLL free-running operation (when the system clock is PLL) is specified in the MOCO oscillation frequency and the division ratio set in the System Clock Select bits (SCKDIVCR.ICK[2:0]).

- 当PLLCCR.PLSRCSEL=0（PLL源时钟=MOSC）且SCKSCR.CKSEL[2:0]=101b（系统时钟源=PLL）时：
  - 当OSTDF由0变为1时，时钟源切换到PLL自由振荡时钟
  - 当OSTDF从1变为0时，时钟源再次切换到PLL。

要在检测到振荡停止后再次将时钟源切换到主时钟振荡器或PLL时钟，请设置CKSEL[2:0]位到主时钟振荡器或PLL时钟以外的时钟源，并将OSTDF标志清除为0。另外，检查OSTDF标志不是1，然后设置CKSEL[2:0]在指定的振荡稳定时间过后，位到主时钟振荡器或PLL时钟。

复位释放后，主时钟振荡器停止，振荡停止检测功能被禁用。要启用振荡停止检测功能，请在指定的振荡稳定时间过后激活主时钟振荡器并将1写入振荡停止检测功能使能位(OSTDCR.OSTDE)。

振荡停止检测功能检测主时钟振荡器何时因外部原因停止。这意味着在软件停止主时钟振荡器之前或进入软件待机或深度软件待机模式之前，必须禁用振荡停止检测功能。

振荡停止检测功能将以下时钟切换到MOCO时钟（当系统时钟为MOSC）或PLL自由运行时钟（当系统时钟为PLL时）：

- 除CLKOUT外，所有可选择作为MOSC时钟或PLL的时钟
- MOCO操作（系统时钟为MOSC时）或PLL自由运行操作（系统时钟为PLL时）期间的系统时钟(ICLK)频率在MOCO振荡频率和系统时钟选择位中设置的分频比中指定(SCKDIVCR.ICK[2:0])。

9.5.2 Oscillation Stop Detection Interrupts

An oscillation stop detection interrupt (MOSC_STOP) is generated when the Oscillation Stop Detection flag (OSTDSR.OSTDF) is 1 and the Oscillation Stop Detection Interrupt Enable bit in the Oscillation Stop Detection Control Register (OSTDCR.OSTDIE) is 1 (enabled). The Port Output Enable for GPT (POEG) is notified of the main clock oscillator stop. On receiving the notification, the POEG sets the Oscillation Stop Detection Flag in the POEG Group n Setting Register (POEGGn.OSTPF) to 1 (n = A, B).

After the oscillation stop is detected, wait at least 10 PCLKB cycles before writing to the POEGGn.OSTPF flag. When the OSTDSR.OSTDF flag requires clearing, do so after clearing the Oscillation Stop Detection Interrupt Enable bit in the Oscillation Stop Detection Control Register (OSTDCR.OSTDIE). Wait for at least 2 PCLKB clock cycles before setting the OSTDCR.OSTDIE bit to 1 again. A longer PCLKB wait time might be required, depending on the number of cycles required to read a given I/O register.

The oscillation stop detection interrupt is a non-maskable interrupt. Because non-maskable interrupts are disabled in the initial state after a reset release, enable non-maskable interrupts through software before using oscillation stop detection interrupts. For details, see section 14, Interrupt Controller Unit (ICU).

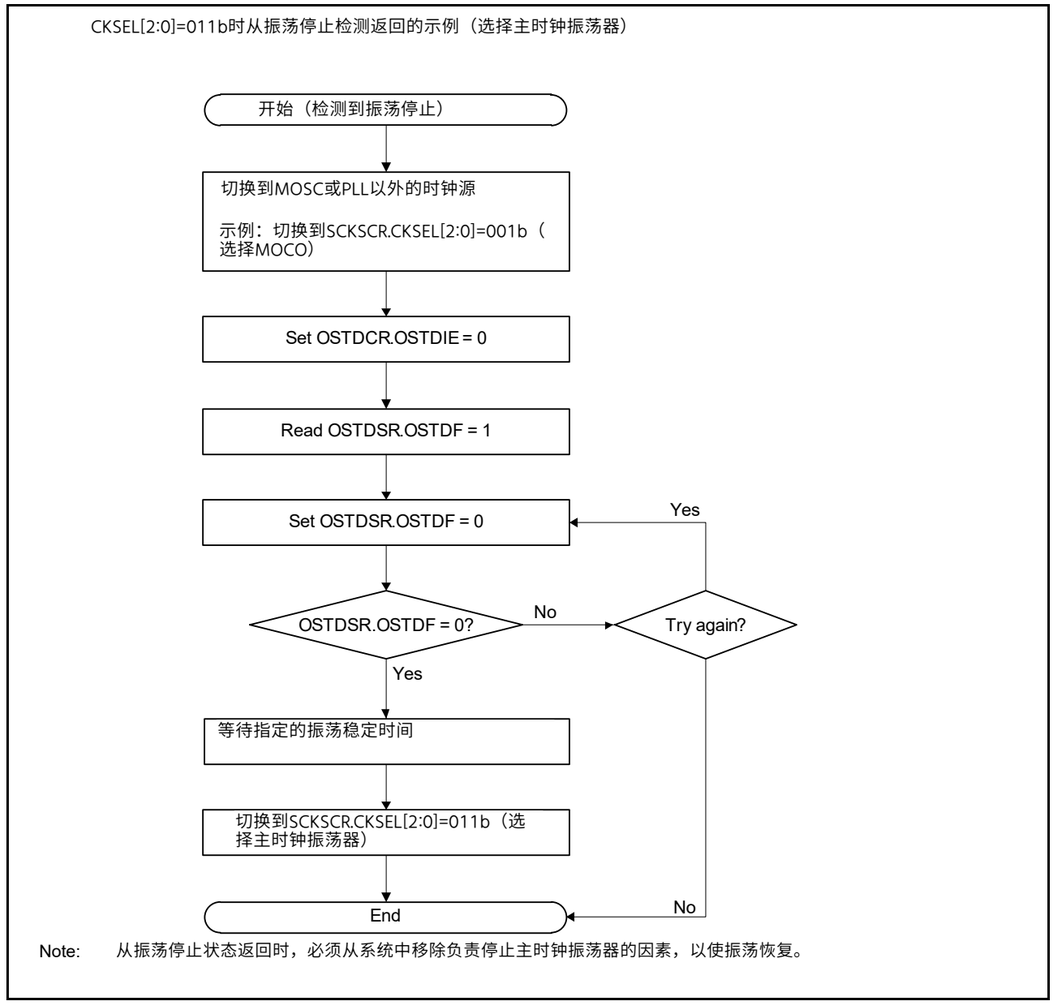

Figure 9.12 检测到振荡器停止时的恢复流程

9.5.2 振荡停止检测中断

当振荡停止检测标志(OSTDSR.OSTDF)为1且振荡停止检测控制寄存器(OSTDCR.OSTDIE)中的振荡停止检测中断使能位为1（使能）时，将产生一个振荡停止检测中断(MOSC_STOP)。GPT端口输出使能(POEG)被通知主时钟振荡器停止。收到通知后，POEG将POEG组n设置寄存器(POEGGn.OSTPF)中的振荡停止检测标志设置为1(n=A B)。

检测到振荡停止后，至少等待10个PCLKB周期，然后再写入POEGGn.OSTPF标志。当需要清除OSTDSR.OSTDF标志时，请在清除振荡停止检测控制寄存器(OSTDCR.OSTDIE)中的振荡停止检测中断使能位后执行此操作。等待至少2个PCLKB时钟周期，然后再将OSTDCR.OSTDIE位设置为1。可能需要更长的PCLKB等待时间，具体取决于读取给定IO寄存器所需的周期数。

振荡停止检测中断是一个不可屏蔽的中断。由于不可屏蔽中断在复位释放后的初始状态下被禁用，因此在使用振荡停止检测中断之前，请通过软件启用不可屏蔽中断。有关详细信息，请参阅第14节，中断控制器单元(ICU)。

9.8 Usage Notes

9.8.1 Notes on Clock Generation Circuit

The frequencies of the system clock (ICLK), peripheral module clock (PCLKA to PCLKD), flash interface clock (FCLK), and external bus clock (BCLK) supplied to each module change according to the settings in SCKDIVCR. Each frequency must meet the following conditions:

- Each frequency must be selected within the operation-guaranteed range of the clock cycle time (t_{cyc}) specified in the AC electrical characteristics, see section 52, Electrical Characteristics
- The frequencies must not exceed the ranges listed in Table 9.2
- The peripheral modules operate on PCLKB and PCLKA. The operating speed of modules such as the timer and SCI varies before and after the frequency is changed.
- The system clock (ICLK), peripheral module clock (PCLKA to PCLKD), flash interface clock (FCLK), and external bus clock (BCLK) must be set according to Table 9.2.

Do not change the clock frequency during external bus access. Additionally, when access by the external bus starts after a change to the clock frequency, confirm that the frequencies changes are complete before accessing the bus. To ensure correct processing after the clock frequency changes, first write to the relevant Clock Control Register to change the frequency, then read the value from the register, and finally perform the subsequent processing.

9.8.2 Notes on Resonator

Because various resonator characteristics relate closely to your board design, adequate evaluation is required before use. See the resonator connection example in Figure 9.9. The circuit constants for the resonator depend on the resonator to be used and the stray capacitance of the mounting circuit. Therefore, consult the resonator manufacturer when determining the circuit constants. The voltage to be applied between the resonator pins must be within the absolute maximum rating.

9.8.3 Notes on Board Design

When using a crystal resonator, place the resonator and its load capacitors as close to the XTAL and EXTAL pins as possible. Route other signal lines away from the oscillation circuit as shown in Figure 9.15, to prevent electromagnetic induction from interfering with correct oscillation.

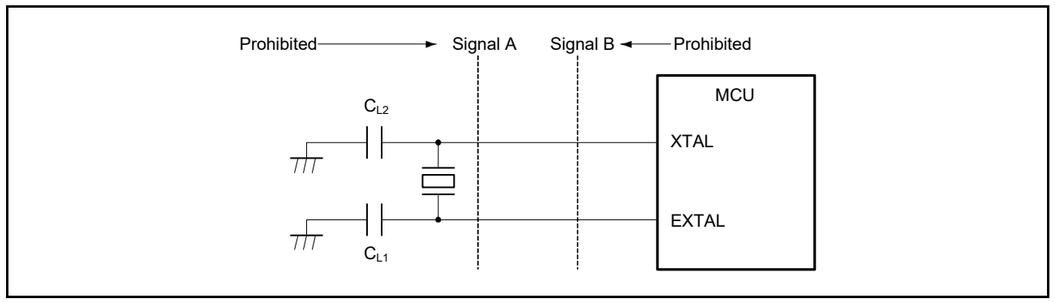

Figure 9.15 Signal routing in board design for oscillation circuit (applies to the sub-clock oscillator for the main clock oscillator)

9.8.4 Notes on the Resonator Connect Pin

When the main clock oscillator is not used, the EXTAL and XTAL pins can be used as general ports P212 and P213. When these pins are used as general ports, the main clock oscillator must be stopped (MOSCCR.MOSTP must be set to 1).

9.8.5 Notes on Using Sub-Clock Oscillator for LGA Packages

The output of P212 (EXTAL), P213 (XTAL), and P708 pins may affect oscillation by the sub-clock oscillator.

If the sub-clock oscillator is used, implement the board design so as not to affect the oscillation. Renesas strongly

9.8 使用说明

9.8.1 时钟产生电路注意事项

提供给每个模块的系统时钟(ICLK)、外围模块时钟(PCLKA至PCLKD)、闪存接口时钟(FCLK)和外部总线时钟(BCLK)的频率根据SCKDIVCR中的设置而变化。每个频率必须满足以下条件：

- 每个频率必须在时钟周期时间(tcyc)中指定的操作保证范围内选择
  交流电气特性，见第52节，电气特性
- 频率不得超过表9.2中列出的范围
- 外围模块在PCLKB和PCLKA上运行。定时器和SCI等模块的运行速度在频率改变前后会发生变化。
- 系统时钟（ICLK）、外设模块时钟（PCLKA到PCLKD）、闪存接口时钟（FCLK）和外部总线时钟（BCLK）必须按照表9.2进行设置。

在外部总线访问期间不要改变时钟频率。此外，在时钟频率更改后开始通过外部总线访问时，请在访问总线之前确认频率更改已完成。为保证时钟频率变化后的正确处理，首先写入相关的时钟控制寄存器改变频率，然后从寄存器中读取值，最后进行后续处理。

9.8.2 谐振器注意事项

由于各种谐振器特性与您的电路板设计密切相关，因此在使用前需要进行充分评估。请参见图9.9中的谐振器连接示例。谐振器的电路常数取决于要使用的谐振器和安装电路的杂散电容。因此，在确定电路常数时，请咨询谐振器制造商。施加在谐振器引脚之间的电压必须在绝对最大额定值范围内。

9.8.3 电路板设计注意事项

使用晶体谐振器时，将谐振器及其负载电容尽可能靠近XTAL和EXTAL引脚。如图9.15所示，将其他信号线远离振荡电路，以防止电磁感应干扰正确的振荡。

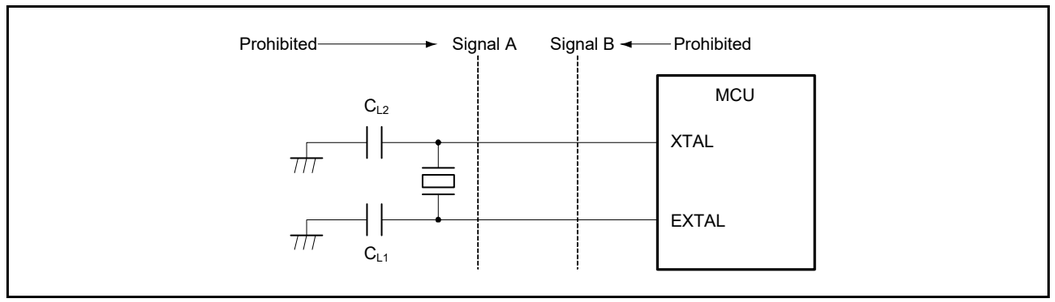

Figure 9.15 振荡电路板设计中的信号走线（适用于主时钟振荡器的副时钟振荡器）

9.8.4 谐振器连接引脚注意事项

当不使用主时钟振荡器时，EXTAL和XTAL引脚可用作通用端口P212和P213。
当这些引脚用作通用端口时，必须停止主时钟振荡器（MOSCCR.MOSTP必须设置为1）。

9.8.5 LGA封装使用副时钟振荡器的注意事项

P212(EXTAL)、P213(XTAL)和P708引脚的输出可能会影响副时钟振荡器的振荡。

如果使用副时钟振荡器，请在不影响振荡的情况下进行板卡设计。瑞萨电子强烈

recommends setting the DSCR[1:0] bits to 00b or 01b when using P212 (EXTAL), P213 (XTAL), and P708 as output pins and using the sub-clock oscillator.

In addition, when using the sub-clock oscillator with middle drive capability (SOMCR.SODRV1 = 1), Renesas recommends not to use two or more ports of P212 (EXTAL), P213 (XTAL), and P708 simultaneously as output pins to avoid affecting the oscillation.

9.8.6 Notes on the Main Clock Oscillator Drive Capability Auto Switching Function

The drive capability of the auto switching function automatically lowers the drive capability of the main clock oscillator, after the main clock oscillator starts and suppresses the associated EMI.

To enable the drive capability of auto switching, set MOMCR.AUTODRVEN to 1 when the main clock oscillator is stopped (MOSCCR.MOSTP = 1). Regardless of the MOMCR.AUTODRVEN setting, the Drive Capability Switching Register (MOMCR.MODRV0[1:0]) must be set properly according to the selected oscillator. Next, enable the main clock oscillator (MOSCCR.MOSTP = 0). After the Oscillation Stabilization flag (OSCSF.MOSCSF) becomes 1, the main clock can be used.

EMI suppression is gained in return for an extension in the oscillation stabilization wait time. For more information, see section 9.2.18, Main Clock Oscillator Wait Control Register (MOSCWTCR).

当使用P212(EXTAL)、P213(XTAL)和P708作为输出引脚并使用副时钟振荡器时，建议将DSCR[1:0]位设置为00b或01b。

此外，在使用具有中间驱动能力的副时钟振荡器（SOMCR.SODRV1=1）时，瑞萨建议不要同时使用P212（EXTAL）、P213（XTAL）和P708的两个或多个端口作为输出引脚，以避免影响振荡。

9.8.6 主时钟振荡器驱动能力自动切换功能注意事项

自动切换功能的驱动能力会在主时钟振荡器启动后自动降低主时钟振荡器的驱动能力并抑制相关的EMI。

要启用自动切换的驱动能力，当主时钟振荡器停止（MOSCCR.MOSTP=1）时，将MOMCR.AUTODRVEN设置为1。无论MOMCR.AUTODRVEN设置如何，驱动能力切换寄存器(MOMCR.MODRV0[1:0])必须根据所选振荡器正确设置。接下来，启用主时钟振荡器(MOSCCR.MOSTP=0)。振荡稳定标志(OSCSF.MOSCSF)变为1后，可以使用主时钟。

获得EMI抑制以换取振荡稳定等待时间的延长。有关详细信息，请参阅第9.2.18节，主时钟振荡器等待控制寄存器(MOSCWTCR)。

10. Clock Frequency Accuracy Measurement Circuit (CAC)

10.1 Overview

The Clock Frequency Accuracy Measurement Circuit (CAC) counts pulses of the clock to be measured (measurement target clock) within the time generated by the clock selected as a measurement reference (measurement reference clock). It determines the accuracy depending on whether the number of pulses is within the allowable range.

The reference clock can be provided externally through an I/O port pin or internally from various on-chip oscillators. When measurement is complete or the number of pulses within the time generated by the measurement reference clock is not within the allowable range, an interrupt request is generated. This feature is useful in implementing a fail-safe mechanism for home and industrial automation applications.

Table 10.1 lists the CAC specifications, Figure 10.1 shows a block diagram, and Table 10.2 shows the I/O pins.

10. 时钟频率精度测量电路(CAC)

10.1 Overview

时钟频率精度测量电路(CAC)在选择作为测量参考的时钟（测量参考时钟）生成的时间内对要测量的时钟（测量目标时钟）的脉冲进行计数。它根据脉冲数是否在允许范围内来确定精度。

参考时钟可以通过IO端口引脚从外部提供，也可以从各种片上振荡器内部提供。
当测量完成或测量参考时钟在时间内产生的脉冲数不在允许范围内时，将产生中断请求。此功能可用于为家庭和工业自动化应用实施故障安全机制。

10.2.6 CAC Upper-Limit Value Setting Register (CAULVR)

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAULVR is a 16-bit read/write register that specifies the upper value of the allowable range. When the counter value exceeds the value specified in this register, a frequency error is detected. Write to this register when the CACR0.CFME bit is 0.

The counter value stored in CACNTBR can vary depending on the difference between the phases of the digital filter and edge-detection circuit, and the signal on the CACREF pin. Ensure that this setting allows an adequate margin.

10.2.7 CAC Lower-Limit Value Setting Register (CALLVR)

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CALLVR is a 16-bit read/write register that specifies the lower value of the allowable range. When the counter value falls below the value specified in this register, a frequency error is detected. Write to this register when the CACR0.CFME bit is 0.

The counter value stored in CACNTBR can vary depending on the difference between the phases of the digital filter and edge-detection circuit, and the signal on the CACREF pin. Ensure that this setting allows an adequate margin.

CACNTBR is a 16-bit read-only register that stores the measurement result.

10.3 Operation

10.3.1 Measuring Clock Frequency

The CAC measures the clock frequency using the CACREF pin input or the internal clock as a reference. Figure 10.2 shows an operating example of the CAC.

重置后的值:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAULVR是一个16位读写寄存器，用于指定允许范围的上限值。当计数器值超过此寄存器中指定的值时，检测到频率错误。当CACR0.CFME位为0时写入该寄存器。

存储在CACNTBR中的计数器值会根据数字滤波器和边沿检测电路的相位差以及CACREF引脚上的信号而变化。确保此设置允许有足够的余量。

CALLVR是一个16位读写寄存器，用于指定允许范围的下限值。当计数器值低于此寄存器中指定的值时，检测到频率错误。当CACR0.CFME位为0时写入该寄存器。

存储在CACNTBR中的计数器值会根据数字滤波器和边沿检测电路的相位差以及CACREF引脚上的信号而变化。确保此设置允许有足够的余量。

CACNTBR是一个16位只读寄存器，用于存储测量结果。

10.3 Operation

10.3.1 测量时钟频率

CAC使用CACREF引脚输入或内部时钟作为参考来测量时钟频率。图10.2显示了CAC的操作示例。

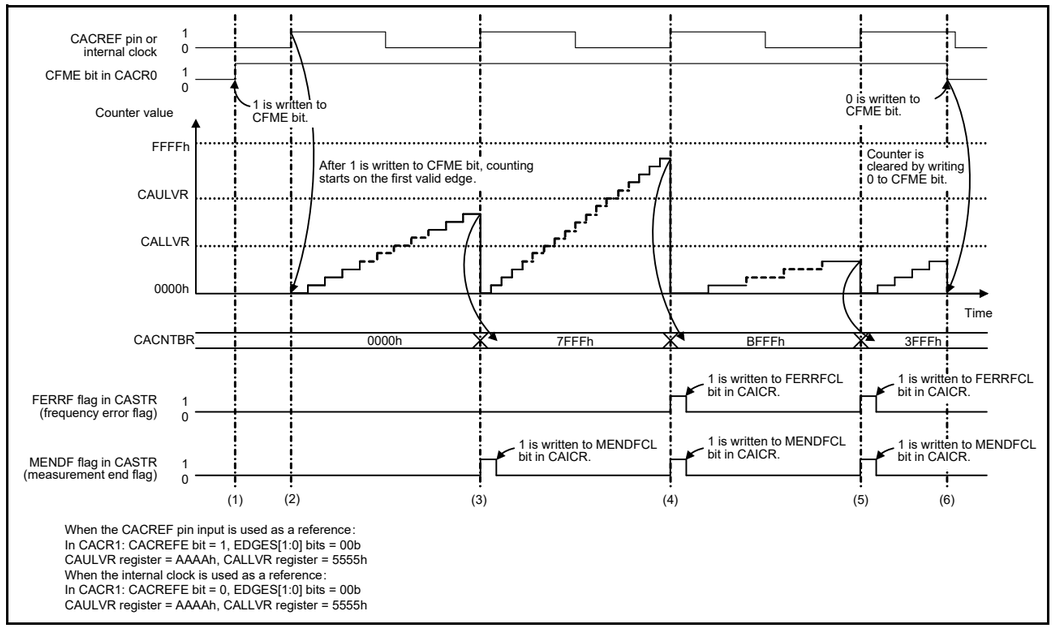

Figure 10.2 CAC operating example

In Figure 10.2:

1. Before writing 1 to CACR0.CFME, set CACR1 and CACR2 to define the measurement target clock and measurement reference clock. Writing 1 to the CACR0.CFME bit enables clock frequency measurement.
2. The timer starts counting up if the valid edge selected in the CACR1.EDGES[1:0] bits is input from the measurement reference clock. In Figure 10.2, the valid edge is a rising edge (CACR1.EDGES[1:0] = 00b).
3. When the next valid edge is input, the counter value is transferred to CACNTBR and compared with the values in CAULVR and CALLVR. If both CACNTBR ≤ CAULVR and CACNTBR ≥ CALLVR are true, only the MENDF flag in CASTR is set to 1, because the clock frequency is correct. If the MENDIE bit in CAICR is 1, a measurement end interrupt is generated.
4. When the next valid edge is input, the counter value is transferred to CACNTBR and compared with the values in CAULVR and CALLVR. If CACNTBR > CAULVR, the FERRF flag in CASTR is set to 1, because the clock frequency is erroneous. If the FERRIE bit in CAICR is 1, a frequency error interrupt is generated. The MENDF flag in CASTR is set to 1 at the end of measurement. If the MENDIE bit in CAICR is 1, a measurement end interrupt is generated.
5. When the next valid edge is input, the counter value is transferred to CACNTBR and compared with the values in CAULVR and CALLVR. If CACNTBR < CALLVR, the FERRF flag in CASTR is set to 1, because the clock frequency is erroneous. If the FERRIE bit in CAICR is 1, a frequency error interrupt is generated. The MENDF flag in CASTR is set to 1 at the end of measurement. If the MENDIE bit in CAICR is 1, a measurement end interrupt is generated.
6. When the CFME bit in CACR0 is 1, the counter value is transferred to CACNTBR and compared with the values in CAULVR and CALLVR every time a valid edge is input. Writing 0 to the CFME bit in CACR0 clears the counter and stops up-counting.

10.3.2 Digital Filtering of Signals on CACREF Pin

The CACREF pin has a digital filter, and levels on the CACREF pin are transmitted to the internal circuitry after three consecutive matches in the selected sampling interval. The same level continues to be transmitted internally until the level on the pin has three consecutive matches again. Enabling or disabling of the digital filter and its sampling clock are selectable.

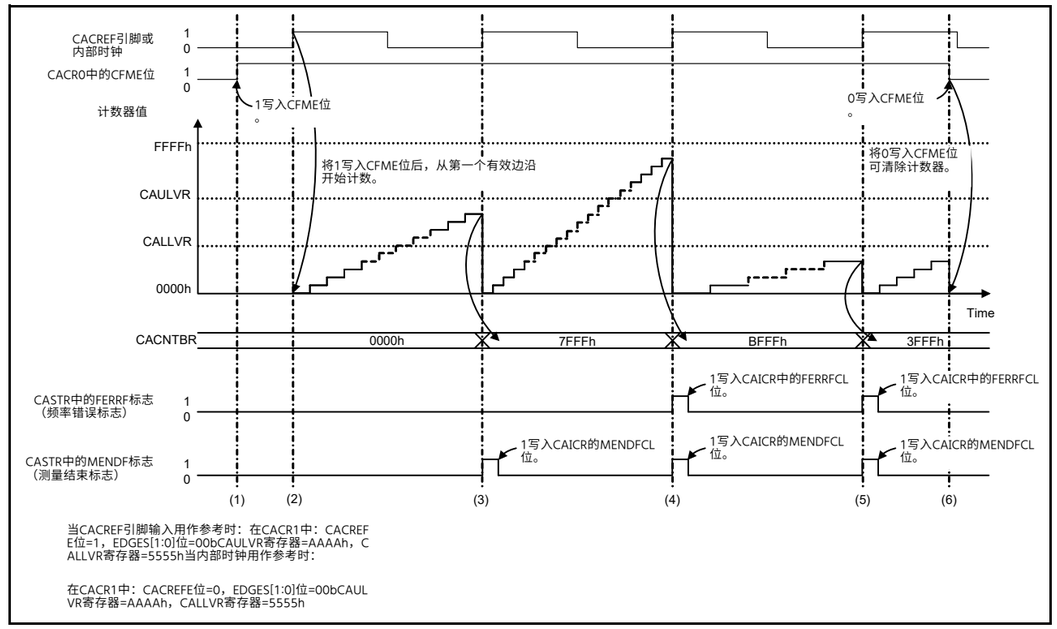

Figure 10.2 CAC操作示例

在图10.2中：

1. 在向CACR0.CFME写入1之前，设置CACR1和CACR2以定义测量目标时钟和测量参考时钟。向CACR0.CFME位写入1可启用时钟频率测量。
2. 如果在CACR1.EDGES[1:0]位中选择的有效边沿从测量参考时钟输入，则定时器开始计数。在图10.2中，有效边沿是上升沿(CACR1.EDGES[1:0]=00b)。
3. 当输入下一个有效边沿时，计数器值被传送到CACNTBR并与CAULVR和CALLVR中的值进行比较。如果CACNTBR≤CAULVR和CACNTBR≥CALLVR都为真，则只有CASTR中的MENDF标志设置为1，因为时钟频率是正确的。如果CAICR中的MENDIE位为1，则产生测量结束中断。
4. 当输入下一个有效边沿时，计数器值被传送到CACNTBR并与CAULVR和CALLVR中的值进行比较。如果CACNTBR>CAULVR，则CASTR中的FERRF标志设置为1，因为时钟频率错误。如果CAICR中的FERRIE位为1，则产生频率错误中断。CASTR中的MENDF标志在测量结束时设置为1。如果CAICR中的MENDIE位为1，则产生测量结束中断。
5. 当输入下一个有效边沿时，计数器值被传送到CACNTBR并与CAULVR和CALLVR中的值进行比较。如果CACNTBR<CALLVR，则CASTR中的FERRF标志设置为1，因为时钟频率错误。如果CAICR中的FERRIE位为1，则产生频率错误中断。CASTR中的MENDF标志在测量结束时设置为1。如果CAICR中的MENDIE位为1，则产生测量结束中断。
6. 当CACR0中的CFME位为1时，每次输入有效边沿时，计数器值被传送到CACNTBR并与CAULVR和CALLVR中的值进行比较。向CACR0中的CFME位写入0将清除计数器并停止向上计数。

10.3.2 CACREF引脚上的信号数字滤波

CACREF引脚有一个数字滤波器，CACREF引脚上的电平在选定的采样间隔内连续三个匹配后传输到内部电路。同一电平继续在内部传输，直到引脚上的电平再次连续匹配三个。可选择启用或禁用数字滤波器及其采样时钟。

The counter value transferred to CACNTBR might be in error by up to 1 cycle of the sampling clock because of the difference between the phases of the digital filter and the signal input to the CACREF pin. When a frequency dividing clock is selected as a count source clock, the counter value error is obtained using the following formula:

Counter value error = (1 cycle of the count source clock) / (1 cycle of the sampling clock)

10.4 Interrupt Requests

The CAC generates three types of interrupt requests:

- Frequency error interrupt
- Measurement end interrupt
- Overflow interrupt.

When an interrupt source is generated, the associated status flag becomes 1. Table 10.3 provides information on the CAC interrupt requests.

Table 10.3 CAC interrupt requests

Interrupt request	Interrupt enable bit	Status flag	Interrupt sources
Frequency error interrupt	CAICR.FERRIE	CASTR.FERRF	The result of comparing CACNTBR with CAULVR and CALLVR is either CACNTBR > CAULVR or CACNTBR < CALLVR
Measurement end interrupt	CAICR.MENDIE	CASTR.MENDF	• Valid edge is input from the CACREF pin or internal clock • Measurement end interrupt does not occur at the first valid edge after writing 1 to the CACR0.CFME bit.
Overflow interrupt	CAICR.OVFIE	CASTR.OVFF	The counter overflows

10.5 Usage Notes

10.5.1 Settings for the Module-Stop Function

The Module Stop Control Register C (MSTPCRC) can enable or disable CAC operation. The CAC module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

由于数字滤波器的相位和输入到CACREF引脚的信号之间的差异，传输到CACNTBR的计数器值可能会出现最多1个采样时钟周期的错误。Whenafrequencydividingclockisselectedasacountsourceclock thecountervaluee rrorisobtainedusingthefollowingformula:

计数器值误差=（计数源时钟的1个周期）（采样时钟的1个周期）

10.4 中断请求

CAC产生三种类型的中断请求：

- 频率错误中断
- 测量结束中断
- 溢出中断。

产生中断源时，相关的状态标志变为1。表10.3提供了有关CAC中断请求的信息。

Table 10.3 CAC中断请求

中断请求	中断使能位	状态标志	中断源
频率错误中断	CAICR.FERRIE	CASTR.FERRF	CACNTBR与CAULVR和CALLVR比较的结果是CACNTBR>CAULVR或CACNTBR<CALLVR
测量结束中断	CAICR.MENDIE	CASTR.MENDF	从CACREF引脚或内部时钟输入有效边沿 将1写入CACR0.CFME位后，在第一个有效边沿不会发生测量结束中断。
溢出中断	CAICR.OVFIE	CASTR.OVFF	计数器溢出

10.5 使用说明

10.5.1 模块停止功能的设置

模块停止控制寄存器C(MSTPCRC)可以启用或禁用CAC操作。CAC模块在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第11节，低功耗模式。

Power-on reset circuit	Operating	Operating	Operating	Operating*16
Other peripheral modules	Selectable	Stop (Retained)	Operation prohibited	Stop (Undefined)
I/O ports	Operating	Retained*17	Operating	Retained*17

Note: Selectable means that operating or not operating can be selected in the control registers.
Stop (Retained) means that the contents of the internal registers are retained but the operations are suspended.
Operation prohibited means that the function must be stopped before entering Software Standby mode.
Stop (Undefined) means that the contents of the internal registers are undefined and power to the internal circuit is cut off.

Note 1. All modules whose module-stop bits are 0 start as soon as PCLKs are supplied after entering Snooze mode. To avoid an increase in power consumption in Snooze mode, set the module-stop bit of modules that are not required in Snooze mode to 1 before entering Software Standby mode.

Note 2. When using SCI0 in Snooze mode, MOSCCR.MOSTP and PLLCR.PLLSTP bits must be 1.

Note 3. If the DPSBYCR.DEEPCUT[1:0] bits are 00b, the oscillator status is the same as before entering Deep Software Standby mode. When the DPSBYCR.DEEPCUT[1:0] bits are not 00b, the oscillator stops when the MCU enters Deep Software Standby mode.

Note 4. Stopped when the Clock Output Source Select bits (CKOCR.CKOSEL[2:0]) are set to a value other than 010b (LOCO) and 100b (SOSC).

Note 5. If the DPSBYCR.DEEPCUT[1:0] bits are 00b, data in the Standby SRAM is retained in Deep Software Standby mode. When the DPSBYCR.DEEPCUT[1:0] bits are not 00b, data in the Standby SRAM is undefined in Deep Software Standby mode.

Note 6. If the DPSBYCR.DEEPCUT[1:0] bits are 00b, the values of the USB Resume Detection Circuit registers are retained and detection of USB resumption is enabled, and the values of other registers are undefined in Deep Software Standby mode. When the DPSBYCR.DEEPCUT[1:0] bits are not 00b, the values of all registers are undefined in Deep Software Standby mode.

Note 7. In IWDT-dedicated on-chip oscillator and IWDT, operating or stopping is selected by setting the IWDT Stop Control bit (IWDTSTPCTL) in Option Function Select register 0 (OFS0) in IWDT auto start mode. In WDT, operating or stopping is selected by setting the WDT Stop Control bit (WDTSTPCTL) in Option Function Select Register 0 (OFS0) in WDT auto start mode.

Note 8. When the RCR4.RCKSEL bit is set to 1 (LOCO), the DPSBYCR.DEEPCUT[1:0] bits must be set to 00b before entering Deep Software Standby mode.

Note 9. AGT0 operation is possible when 100b (AGTLCLK) or 110b (AGTSCLK) is selected in the AGT0.AGTMR1.TCK[2:0] bits.
AGT1 operation is possible when 100b (AGTLCLK), 110b (AGTSCLK), or 101b (underflow event signal from AGT0) is selected in the AGT1.AGTMR1.TCK[2:0] bits.
When 100b (AGTLCLK) is selected in AGTn.AGTMR1.TCK[2:0] bits (n = 0, 1), the DPSBYCR.DEEPCUT[1:0] bits must be set to 00b before entering Deep Software Standby mode.

Note 10. Event lists the restrictions described in section 11.10.13, ELC Events in Snooze Mode.

Note 11. Only VCOUT function is permitted. The VCOUT pin operates when ACMPHS uses no digital filter.
For details on digital filter, see section 45, High-Speed Analog Comparator (ACMPHS).

Note 12. When CMPCTL0.CSTEN bit is 1, canceling Software Standby Mode or entering Snooze mode by the comparator detection is available.

Note 13. IIC0 wakeup interrupt is available.

Note 14. Serial communication mode of SCI0 is asynchronous mode.

Note 15. When using LVD in Deep Software Standby mode, DPSBYCR.DEEPCUT[1:0] bits must be 00b or 01b before entering Deep Software Standby mode.

Note 16. When the MCU enters Deep Software Standby mode with the DPSBYCR.DEEPCUT[1:0] bits set to 11b, the LVD circuit stops and the low power function of the power-on reset circuit is enabled.

Note 17. For the address bus and bus control signals (for SRAM: CS0, CS1, CS4 to CS7, RD, WR0, and ALE), keeping the output state or changing to the high-impedance state can be selected in the SBYCR.OPE bit.

Note 18. When using the 12-bit A/D Converter in Snooze mode, the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits must be 1.

Note 19. When using the Programmable Gain Amplifiers, MSTPDn (n = 15, 16) must be set to 0. For details, see section 42.3.12, Programmable Gain Amplifiers.

Note: 可选意味着可以在控制寄存器中选择操作或不操作。
停止（Retained）表示内部寄存器的内容被保留但操作被暂停。
禁止操作意味着在进入软件待机模式之前必须停止该功能。
停止（未定义）表示内部寄存器的内容未定义，内部电路的电源被切断。

Note 1. 进入贪睡模式后，一旦提供PCLK，所有模块停止位为0的模块都会启动。为避免贪睡模式下的功耗增加，请在进入软件待机模式之前将贪睡模式下不需要的模块的模块停止位设置为1。

Note 2. 在贪睡模式下使用SCI0时，MOSCCR.MOSTP和PLLCR.PLLSTP位必须为1。

Note 3. 如果DPSBYCR.DEEPCUT[1:0]位为00b，则振荡器状态与进入深度软件待机模式之前相同。当DPSBYCR.DEEPCUT[1:0]位不为00b时，当MCU进入深度软件待机模式时振荡器停止。

Note 4. 当时钟输出源选择位(CKOCR.CKOSEL[2:0])设置为010b(LOCO)和100b(SOSC)以外的值时停止。

Note 5. 如果DPSBYCR.DEEPCUT[1:0]位为00b，则待机SRAM中的数据在深度软件待机模式下保留。当DPSBYCR.DEEPCUT[1:0]位不为00b时，在深度软件待机模式下，待机SRAM中的数据未定义。

Note 6. 如果DPSBYCR.DEEPCUT[1:0]位为00b，则USB恢复检测电路寄存器的值被保留并启用USB恢复检测，并且在深度软件待机模式下其他寄存器的值未定义。当DPSBYCR.DEEPCUT[1:0]位不为00b时，深度软件待机模式下所有寄存器的值未定义。

Note 7. 在IWDT专用内部振荡器和IWDT中，在IWDT自动启动模式下，通过设置选项功能选择寄存器0(OFS0)中的IWDT停止控制位(IWDTSTPCL)来选择操作或停止。在WDT中，通过在WDT自动启动模式下设置选项功能选择寄存器0(OFS0)中的WDT停止控制位(WDTSTPCTL)来选择操作或停止。

Note 8. 当RCR4.RCKSEL位设置为1(LOCO)时，DPSBYCR.DEEPCUT[1:0]位必须设置为00b才能进入Deep
软件待机模式。

Note 9. 当在AGT0.AGTMR1.TCK[2:0]位中选择100b(AGTLCLK)或110b(AGTSCLK)时，可以进行AGT0操作。
当在AGT1.AGTMR1.TCK[2:0]位中选择100b(AGTLCLK)、110b(AGTSCLK)或101b（来自AGT0的下溢事件信号）时，可以进行AGT1操作。
当在AGTn.AGTMR1.TCK[2:0]位(n=0 1)中选择100b(AGTLCLK)时，DPSBYCR.DEEPCUT[1:0]位必须在进入深度软件待机模式之前设置为00b。注10.事件列出了第11.10.13节"贪睡模式下的ELC事件"中描述的限制。

注11.仅允许使用VCOUT功能。当ACMPHS不使用数字滤波器时，VCOUT引脚工作。
有关数字滤波器的详细信息，请参见第45节，高速模拟比较器(ACMPHS)。
注12.当CMPCTL0.CSTEN位为1时，可以通过比较器检测取消软件待机模式或进入贪睡模式。注13.IIC0唤醒中断可用。

注16.当MCU进入深度软件待机模式且DPSBYCR.DEEPCUT[1:0]位设置为11b时，LVD电路停止并启用上电复位电路的低功耗功能。注17.对于地址总线和总线控制信号（对于SRAM：CS0、CS1、CS4到CS7、RD、WR0和ALE），可以在SBYCR中选择保持输出状态或变为高阻抗状态。OPE位。注18.在贪睡模式下使用12位AD转换器时，ADCMPCR.CMPAE和ADCMPCR.CMPBE位必须为1。注19.当使用可编程增益放大器时，MSTPDn(n=15 16)必须设置为0.详见42.3.12节，

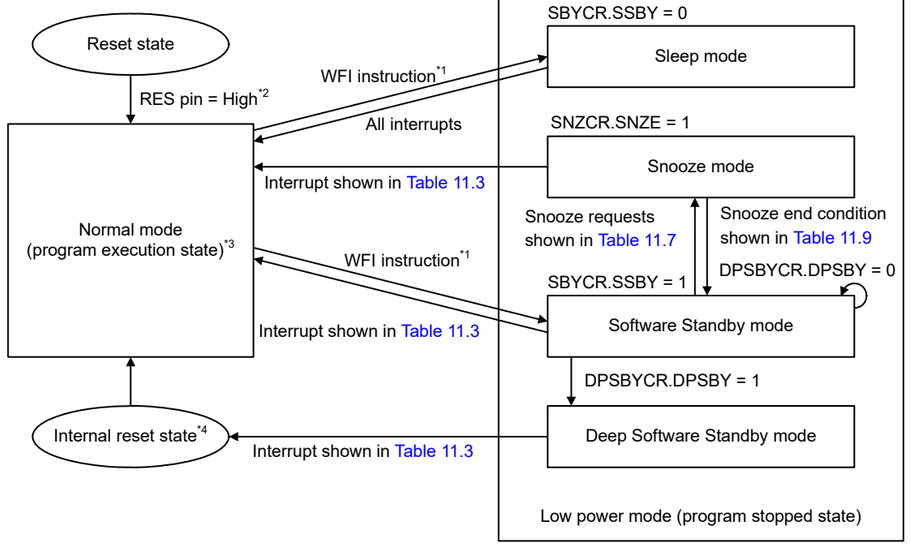
Note 1. 要将中断请求用作退出贪睡模式的触发器，必须在SELSR0中选择该请求。见第14节，中断控制器单元（ICU）。当在SELSR0中选择的触发发生在执行WFI指令之后以及从正常模式到软件待机模式的转换期间，是否可以接受请求取决于发生的时间。

Note 2. 只能选择SCI0_AM或SCI0_RXI_OR_ERI之一。
Note 3. 不得使用由SNZEDCR寄存器启用的事件。



Note 1. When an interrupt that acts as a trigger for cancel is received during a transition to the program-stopped state after the execution of a WFI instruction, the MCU executes interrupt exception handling instead of transitioning to low power mode.
Note 2. The MOCO clock is the source of the operating clock following a transition from the reset state to Normal mode.
Note 3. The transition to Normal mode is made from an interrupt in Sleep mode, Snooze mode, or Software Standby mode. The clock source is the same as before entering the low power mode.
Note 4. When an available interrupt request is generated, an internal reset (Deep Software Standby reset) is generated over a fixed period. Canceling of Deep Software Standby mode accompanies release from the internal reset state, and the MCU transitions to Normal mode and executes a reset exception processing with the MOCO clock as the source of the operating clock.

Note 1. 当在执行WFI指令后转换到程序停止状态期间接收到用作取消触发器的中断时，MCU执行中断异常处理，而不是转换到低功耗模式。
Note 2. MOCO时钟是从复位状态转换到正常模式后的工作时钟源。
Note 3. 通过休眠模式、贪睡模式或软件待机模式下的中断转换到正常模式。时钟源与进入低功耗模式前相同。
Note 4. 当产生可用中断请求时，会在固定周期内产生内部复位（深度软件待机复位）。
深度软件待机模式的取消伴随着内部复位状态的释放，MCU转换到正常模式并以MOCO时钟作为工作时钟源执行复位异常处理。

OPE bit (Output Port Enable)

The OPE bit specifies whether to set to the high-impedance state or to retain the output of the address bus and bus control signals (for SRAM: CS0, CS1, CS4 to CS7, RD, WR0, and ALE) in Software Standby mode or Deep Software Standby mode.

SSBY bit (Software Standby)

The SSBY bit specifies the transition destination after a WFI instruction is executed.

When the SSBY bit is set to 1, the MCU enters Software Standby mode after executing a WFI instruction. When the MCU cancels Software Standby mode by an interrupt, the SSBY bit remains 1. The SSBY bit can be cleared by writing 0 to it.

When the OSTDCR.OSTDE bit is 1, the setting of SSBY bit is ignored. Even if the SSBY bit is 1, the MCU enters Sleep mode on execution of a WFI instruction.

When the FENTRYR.FENTRYi bit (i = 0 to 3) is 1 or the FENTRYR.FENTRYD bit is 1, the setting of SSBY bit is ignored. Even if the SSBY bit is 1, the MCU enters Sleep mode on execution of a WFI instruction. See Table 11.6 for details.

When using the HOCO clock to enter Software Standby mode, STCONR.STCON[1:0] must be set to 00b and HOCOWTCR.HSTS[2:0] must be set to 110b. However, when using SCI0 in Snooze mode, HOCOWTCR.HSTS[2:0] must be set to 010b.

Note 2. When rewriting the MSTPA22 bit from 0 to 1, disable the DMAC and DTC before setting the MSTPA22 bit.

OPE位（输出端口使能）

OPE位指定在软件待机模式下是设置为高阻状态还是保留地址总线和总线控制信号的输出（对于SRAM：CS0、CS1、CS4到CS7、RD、WR0和ALE）或深度软件待机模式。

SSBY位（软件待机）

SSBY位指定执行WFI指令后的转移目标。

当SSBY位设置为1时，MCU在执行WFI指令后进入软件待机模式。当。。。的时候
MCU通过中断取消软件待机模式，SSBY位保持为1。SSBY位可以通过向其写入0来清除。

当OSTDCR.OSTDE位为1时，忽略SSBY位的设置。即使SSBY位为1，MCU也会在执行WFI指令时进入休眠模式。

当FENTRYR.FENTRYi位（i=0到3）为1或FENTRYR.FENTRYD位为1时，忽略SSBY位的设置。即使SSBY位为1，MCU也会在执行WFI指令时进入休眠模式。详见表11.6。

当使用HOCO时钟进入软件待机模式时，STCONR.STCON[1:0]必须设置为00b并且
HOCOWTCR.HSTS[2:0]必须设置为110b。但是，在贪睡模式下使用SCI0时，HOCOWTCR.HSTS[2:0]必须设置为010b。

The OPCCR register is used to reduce power consumption in Normal mode and Sleep mode by specifying a lower operating frequency and operating voltage. For the procedure to change the operating power control modes, see section 11.5, Function for Lower Operating Power Consumption.

When transitioning from Software Standby mode to Normal or Snooze mode, the settings in the OPCCR.OPCM[1:0] and SOPCCR.SOPCM bits are as follows, regardless of their settings before entering Software Standby mode:

- OPCCR.OPCM[1:0] = 00b (High-speed mode)
- SOPCCR.SOPCM = 0b (not Subosc-speed mode).

If Software Standby mode is canceled before the transition to Software Standby completes, the OPCCR.OPCM[1:0] and SOPCCR.SOPCM bits retain their settings from before the WFI instruction is executed. If this causes a problem, set the MCU to High-speed mode during the exception handling procedure when canceling Software Standby mode.

OPCM[1:0] bits (Operating Power Control Mode Select)

The OPCM[1:0] bits select the operating power control mode in Normal mode and Sleep mode. Table 11.4 shows the relationship between the operating power control modes, the OPCM[1:0], and SOPCM bit settings.

OPCMTSF flag (Operating Power Control Mode Transition Status Flag)

The OPCMTSF flag indicates the switching control state when the operating power control mode is switched. This flag becomes 1 when the OPCM[1:0] bits are written, and 0 when the mode transition completes. Read this flag and confirm that it is 0 before proceeding.

11.2.7 Sub Operating Power Control Register (SOPCCR)

Address(es): SYSTEM.SOPCCR 4001 E0AAh

	b7	b6	b5	b4	b3	b2	b1	b0

b4	SOPCMTSF	Sub Operating Power Control Mode Transition Status Flag	0: Transition completed 1: Transition in progress.	R
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SOPCCR register is used to reduce power consumption in Normal and Sleep modes by initiating entry to and exit from Subosc-speed mode. Subosc-speed mode is only available when using the sub-clock oscillator or LOCO without dividing the frequency.

The flash cache function should be set to disabled by setting FCACHEE.FCACHEEN to 0 before switching the operating power control mode. For details, see section 50, Flash Memory.

For the procedure to change operating power control modes, see section 11.5, Function for Lower Operating Power Consumption.

SOPCM bit (Sub Operating Power Control Mode Select)

The SOPCM bit selects the operating power control mode in Normal mode and Sleep mode. Setting this bit to 1 allows transition to Subosc-speed mode. Setting this bit to 0 allows a return to the operating mode (set in OPCCR.OPCM[1:0]) before the transition to Subosc-speed mode.

When transitioning from Software Standby mode to Normal mode or Snooze mode, the OPCCR.OPCM[1:0] and SOPCCR.SOPCM settings are as follows, regardless of their settings before entering Software Standby mode:

- OPCCR.OPCM[1:0] = 00b (High-speed mode)

OPCCR寄存器用于通过指定较低的工作频率和工作电压来降低正常模式和休眠模式下的功耗。有关更改运行功耗控制模式的步骤，请参阅第11.5节“降低运行功耗的功能”。

当从软件待机模式转换到正常或贪睡模式时，OPCCR.OPCM[1:0]中的设置和SOPCCR.SOPCM位如下，无论它们在进入软件待机模式之前的设置如何：

- OPCCR.OPCM[1:0] = 00b (High-speed mode)
- SOPCCR.SOPCM = 0b (not Subosc-speed mode).

如果在转换到软件待机完成之前取消软件待机模式，则OPCCR.OCM[1:0]和SOPCCR.SOPCM位将保留其在执行WFI指令之前的设置。如果这会导致问题，请设置
取消软件待机模式时，MCU在异常处理过程中进入高速模式。

OPCM[1:0]位（工作电源控制模式选择）

OPCM[1:0]位选择正常模式和休眠模式下的工作功率控制模式。表11.4显示了工作功率控制模式、OPCM[1:0]和SOPCM位设置之间的关系。

OPCMTSF标志（工作电源控制模式转换状态标志）

OPCMTSF标志指示切换操作功率控制模式时的切换控制状态。写入OPCM[1:0]位时，该标志变为1，模式转换完成时变为0。阅读此标志并确认其为0，然后再继续。

11.2.7 副操作功率控制寄存器(SOPCCR)

b4	SOPCMTSF	副操作功率控制模式转换状态标志	0：转换完成1：转换进行中。	R
b7 to b5	—	Reserved	这些位被读取为0。写入值应为0。	R/W

SOPCCR寄存器用于通过启动进入和退出Subosc速度模式来降低正常和睡眠模式下的功耗。Subosc速度模式仅在使用副时钟振荡器或LOCO而不分频时可用。

在切换工作电源控制模式之前，应通过将FCACHEE.FCACHEEN设置为0将闪存缓存功能设置为禁用。有关详细信息，请参阅第50节，闪存。

有关更改操作功率控制模式的步骤，请参阅第11.5节，降低操作功率的功能
Consumption.

SOPCM位（副工作功率控制模式选择）

SOPCM位选择正常模式和休眠模式下的工作功率控制模式。将此位设置为1允许转换到Subosc速度模式。将此位设置为0允许在转换到Subosc速度模式之前返回到操作模式（在OPCCR.OPCM[1:0]中设置）。

当从软件待机模式转换到正常模式或贪睡模式时，OPCCR.OCM[1:0]和SOPCCR.SOPCM设置如下，无论其进入软件待机模式前的设置如何：

- OPCCR.OPCM[1:0] = 00b (High-speed mode)

- SOPCCR.SOPCM = 0b (not Subosc-speed mode).

If Software Standby mode is canceled before the transition to Software Standby completes, the OPCCR.OPCM[1:0] and SOPCCR.SOPCM bits retain their settings from before the WFI instruction is executed. If this causes a problem, set the MCU to High-speed mode during the exception handling procedure when canceling Software Standby mode.

Table 11.4 shows the relationship between the operating power control modes, the OPCM[1:0], and SOPCM bit settings.

SOPCMTSF flag (Sub Operating Power Control Mode Transition Status Flag)

The SOPCMTSF flag indicates the switching control state when the operating power control mode is switched from or to Subosc-speed mode. This flag becomes 1 when the SOPCM bit is written, and 0 when mode transition completes. Read this flag and confirm that it is 0 before proceeding.

Table 11.4 shows the operating power control modes.

Table 11.4 Relationship between the operating power control modes, and the OPCM[1:0] and SOPCM bits

Operating power control mode	OPCM[1:0] bits	SOPCM bit	Power consumption
High-speed mode	00b	0	High ↓ Low
Low-speed mode	11b	0	
Subosc-speed mode	00b, 11b	1	

Note: See section 52, Electrical Characteristics for the operating frequency range and voltage range.

High-speed operating mode

After a reset cancellation, the MCU is activated in this mode.

Low-speed mode

The following constraints apply in low-speed mode:

- Programming and erasure operations for the flash memory are prohibited
- Using the PLL is prohibited. See section 11.10.1, Register Access.

In low-speed mode, lower power consumption is possible than in High-speed mode when the same operation is performed under the same conditions, such as operating frequency and operating voltage.

Subosc-speed mode

The following constraints apply in Subosc-speed mode:

- Programming and erasure operations for the flash memory are prohibited
- Reading of the data flash is prohibited
- Using MOSC, PLL, MOCO, or HOCO is prohibited. See section 11.10.1, Register Access.
- Using the divided clock for ICK or FCK is prohibited. See section 11.10.1, Register Access.
- Using the oscillation stop detection function of the main clock oscillator is prohibited.

- SOPCCR.SOPCM = 0b (not Subosc-speed mode).

如果在转换到软件待机完成之前取消软件待机模式，则OPCCR.OCM[1:0]和SOPCCR.SOPCM位将保留其在执行WFI指令之前的设置。如果这会导致问题，请设置
取消软件待机模式时，MCU在异常处理过程中进入高速模式。

表11.4显示了工作功率控制模式、OPCM[1:0]和SOPCM位设置之间的关系。

SOPCMTSF标志（子工作电源控制模式转换状态标志）

SOPCMTSF标志指示当操作功率控制模式从或切换到Subosc速度模式时的切换控制状态。写入SOPCM位时该标志变为1，模式转换完成时变为0。阅读此标志并确认其为0，然后再继续。

表11.4显示了工作功率控制模式。

Table 11.4 工作功率控制模式与OPCM[1:0]和SOPCM位之间的关系

Subosc-speed mode

以下约束适用于Subosc速度模式：

- 禁止对闪存进行编程和擦除操作
- 禁止读取数据闪存
- 禁止使用MOSC、PLL、MOCO或HOCO。请参阅第11.10.1节，注册访问。

b7	SNZE	Snooze Mode Enable	0: Disable Snooze mode 1: Enable Snooze mode.	R/W

RXDREQEN bit (RXD0 Snooze Request Enable)

The RXDREQEN bit specifies whether to detect a falling edge of the RXD0 pin in Software Standby mode. This bit is only available when SCI0 operates in asynchronous mode. To detect a falling edge of the RXD0 pin, set this bit before entering Software Standby mode. When this bit is set to 1, a falling edge of the RXD0 pin in Software Standby mode causes the MCU to enter Snooze mode.

SNZDTCEN bit (DTC Enable in Snooze mode)

The SNZDTCEN bit specifies whether to use the DTC and SRAM in Snooze mode. To use the DTC and SRAM in Snooze mode, set this bit to 1 before entering Software Standby mode. When this bit is set to 1, the DTC can be activated by setting IELSRn (ICU Event Link Setting Register n).

SNZE bit (Snooze Mode Enable)

The SNZE bit enables or disables a transition from Software Standby to Snooze mode. To use Snooze mode, set this bit to 1 before entering Software Standby mode. When this bit is set to 1, a trigger as shown in Table 11.7 in Software Standby mode causes the MCU to enter Snooze mode. After the MCU transitions from Software Standby mode or Snooze mode to Normal mode, clear the SNZE bit once then set it before re-entering Software Standby mode. For details, see section 11.8, Snooze Mode.

SNZDTCEN位（在贪睡模式下启用DTC）

SNZDTCEN位指定是否在贪睡模式下使用DTC和SRAM。使用DTC和SRAM贪睡模式，在进入软件待机模式之前将该位设置为1。当该位设置为1时，可以通过设置IELSRn（ICU事件链接设置寄存器n）来激活DTC。

The SNZREQCR register controls which trigger causes the MCU to switch from Software Standby mode to Snooze mode. If a trigger is selected as a request to cancel Software Standby mode by setting the WUPEN register, see section 14, Interrupt Controller Unit (ICU), the MCU enters Normal mode when the trigger is generated while the associated bit of the SNZREQCR is 1. The setting of the WUPEN register always has a higher priority than the SNZREQCR register settings. For details, see section 11.8, Snooze Mode and section 14, Interrupt Controller Unit (ICU).

SNZREQCR寄存器控制哪个触发器导致MCU从软件待机模式切换到贪睡模式。如果通过设置WUPEN寄存器选择触发作为取消软件待机模式的请求，请参见第14节，中断控制器单元(ICU)，当SNZREQCR的相关位为1时生成触发时，MCU进入正常模式。WUPEN寄存器的设置始终具有比SNZREQCR寄存器设置更高的优先级。有关详细信息，请参阅第11.8节，贪睡模式和第14节，中断控制器单元(ICU)。

The DPSBYCR register is not initialized by the internal reset signal that cancels Deep Software Standby mode. For details, see Table 6.2, Reset detect flags initialized by each reset source.

DEEPCUT[1:0] bits (Power-Supply Control)

The DEEPCUT[1:0] bits control the internal power supply to the Standby SRAM, low-speed on-chip oscillator, AGTn, and USBFS resume detecting unit in Deep Software Standby mode. In addition, these bits control the state of the LVD and power-on reset circuit in Deep Software Standby mode. When a USBFS suspend/resume interrupt is used as a canceling source for Deep Software Standby mode, the DEEPCUT[1:0] bits must be set to 00b. When an LVD interrupt is used in Deep Software Standby mode, the DEEPCUT[1:0] bits must be set to 00b or 01b.

For lower power consumption, set the DEEPCUT[1:0] bits to 11b so that the LVD is stopped and the low power mode function of the power-on reset circuit is enabled. The internal power supply of the SRAM stops in Deep Software Standby mode regardless of the DEEPCUT[1:0] bit settings.

IOKEEP bit (I/O Port Retention)

In Deep Software Standby mode, the I/O ports keep the same states as in Software Standby mode. The IOKEEP bit specifies whether to reset the state of the I/O ports when Deep Software Standby mode is canceled.

DPSBY bit (Deep Software Standby)

The DPSBY bit controls transitions to Deep Software Standby mode. See Table 11.6 for details.

When the WFI instruction is executed while the SBYCR.SSBY and DPSBYCR.DPSBY bits are both 1, the MCU enters Deep Software Standby mode through Software Standby mode.

The DPSBY bit remains 1 when Deep Software Standby mode is canceled by certain pins that are the sources of external pin interrupts (NMI, IRQ0-DS, IRQ1-DS, and IRQ4-DS to IRQ12-DS) or by a peripheral interrupt (RTC alarm, RTC interval, USB suspend/resume, voltage monitor 1, or voltage monitor 2). Write 0 to this bit to clear it.

The DPSBY setting is invalid when the OFS0.IWDTSTPCTL bit is 0 (counting continues), regardless of the setting in the OFS0.IWDTSTRT bit. When the SBYCR.SSBY and DPSBY bits are 1, the MCU transitions to Software Standby mode on execution of a WFI instruction.

The DPSBY setting is invalid when the voltage monitor 1 reset is enabled (LVD1CR0.RI = 1) or when the voltage monitor 2 reset is enabled (LVD2CR0.RI = 1). When the SBYCR.SSBY and the DPSBY bits are 1, the MCU transitions to Software Standby mode on execution of a WFI instruction.

取消深度软件待机模式的内部复位信号不会初始化DPSBYCR寄存器。有关详细信息，请参见表6.2，每个复位源初始化的复位检测标志。

DEEPCUT[1:0]位（电源控制）

DEEPCUT[1:0]位控制深度软件待机模式下待机SRAM、低速片上振荡器、AGTn和USBFS恢复检测单元的内部电源。此外，这些位在深度软件待机模式下控制LVD和上电复位电路的状态。当USBFS挂起恢复中断用作深度软件待机模式的取消源时，DEEPCUT[1:0]位必须设置为00b。在深度软件待机模式下使用LVD中断时，DEEPCUT[1:0]位必须设置为00b或01b。

为降低功耗，将DEEPCUT[1:0]位设置为11b，以使LVD停止并启用上电复位电路的低功耗模式功能。无论DEEPCUT[1:0]位设置如何，SRAM的内部电源都会在深度软件待机模式下停止。

IOKEEP位（IO端口保留）

在深度软件待机模式下，IO端口保持与软件待机模式相同的状态。IOKEEP位指定当深度软件待机模式被取消时是否复位IO端口的状态。

DPSBY位（深度软件待机）

DPSBY位控制向深度软件待机模式的转换。详见表11.6。

当SBYCR.SSBY和DPSBYCR.DPSBY位均为1时执行WFI指令，MCU进入深度软件待机模式到软件待机模式。

当某些作为外部引脚中断源（NMI、IRQ0-DS、IRQ1-DS和IRQ4-DS到IRQ12-DS）或外设中断（RTC）的引脚取消深度软件待机模式时，DPSBY位保持为1报警、RTC间隔、USB暂停恢复、电压监视器1或电压监视器2)。向该位写入0以清除它。

当OFS0.IWDTSTPCTL位为0（计数继续）时，DPSBY设置无效，无论OFS0.IWDTSTRT位中的设置如何。当SBYCR.SSBY和DPSBY位为1时，MCU在执行WFI指令时转换到软件待机模式。

启用电压监视器1复位(LVD1CR0.RI=1)或启用电压监视器2复位(LVD2CR0.RI=1)时，DPSBY设置无效。当SBYCR.SSBY和DPSBY位为1时，MCU在执行WFI指令时转换到软件待机模式。

DOCDF flag (Deep Software Standby OCD Flag)

The DOCDF flag indicates that a Deep Software Standby cancel request is generated by the MCUCTRL.DBIRQ bit. The flag is set to 1 when the cancel request is generated. The flag can be set to 1 when a cancel request is generated in any mode, not only in Deep Software Standby mode. Clear the DOCDF flag to 0 before entering Deep Software Standby mode.

[Setting condition]

- A cancel request generated by the MCUCTRL.DBIRQ bit.

[Clearing condition]

- Writing 0 to the flag after reading it as 1
- When the DBGEN bit is 0.

DBGEN bit (Debugger Enable Bit)

The DBGEN bit enables the OCD mode. This bit must be set to 1 first in OCD mode.

[Setting condition]

- Writing 1 to the bit when the debugger is connected.

[Clearing condition]

- Power-on reset is generated
- Writing 0 to the bit.

11.3 Reducing Power Consumption by Switching Clock Signals

The clock frequency changes when the following bits are set:

- SCKDIVCR.FCK[2:0]
- ICK[2:0]
- BCK[2:0]
- PCKA[2:0]
- PCKB[2:0]

DOCDF标志（深度软件待机OCD标志）

DOCDF标志表示深度软件待机取消请求由MCUCTRL.DBIRQ位生成。生成取消请求时，该标志设置为1。当在任何模式下生成取消请求时，该标志可以设置为1，而不仅仅是在深度软件待机模式下。在进入深度软件待机模式之前将DOCDF标志清零。

[Setting condition]

- 由MCUCTRL.DBIRQ位生成的取消请求。

[Clearing condition]

- 读为1后将0写入标志
- DBGEN位为0时。

DBGEN位（调试器启用位）

DBGEN位使能OCD模式。在OCD模式下，该位必须首先设置为1。

[Setting condition]

- 连接调试器时向该位写入1。

STCON[1:0]位（SSTBY条件位）

当使用HOCO进入软件待机模式时，STCON[1:0]位必须始终设置为00b。

11.3 通过切换时钟信号降低功耗

设置以下位时，时钟频率会发生变化：

- SCKDIVCR.FCK[2:0]
- ICK[2:0]
- BCK[2:0]
- PCKA[2:0]
- PCKB[2:0]

- PCKC[2:0]
- PCKD[2:0].

The module and clock associations are as follows:

- The CPU, DMAC, DTC, flash, and SRAM use the operating clock specified in the ICK[2:0] bits
- Peripheral modules use the operating clocks specified in the PCKA[2:0], PCKB[2:0], PCKC[2:0], and PCKD[2:0] bits
- The flash memory interface uses the operating clock specified in the FCK[2:0] bits
- The external bus uses the operating clock specified in the BCK[2:0] bits.

For details, see section 9, Clock Generation Circuit.

11.4 Module-Stop Function

The module-stop function can be set for each on-chip peripheral module.

When the MSTPmi bit (m = A to D, i = 31 to 0) in MSTPCRA to MSTPCRD is set to 1, the specified module stops operating and enters the module-stop state, but the CPU continues to operate independently. Clearing the MSTPmi bit to 0 cancels the module-stop state, allowing the module to resume operation at the end of the bus cycle. The internal states of the modules are retained in the module-stop state.

After a reset is canceled, all modules other than the DMAC, DTC, and SRAM modules are placed in the module-stop state. Do not access the module while the associated MSTPmi bit is 1, otherwise the read/write data or the operation of the module is not guaranteed. Also, do not set the MSTPmi bit to 1 while the associated module is accessed.

When the PLL is selected as the clock source, MSTPmi bits must only be changed one bit at a time. In this case, wait at least 250 ns after changing each MSTPmi bit before starting subsequent processing if you change any of the following bits:

- MSTPA22 (DMAC, DTC)
- MSTPC31 (SCE7)
- MSTPD5 (GPT32EH, GPT32E).

The recommended method to measure the wait time is through software. Be sure to consider the worst-case conditions to ensure that the required wait time elapses.

11.5 Function for Lower Operating Power Consumption

By selecting an appropriate operating power consumption control mode according to the operating frequency and operating voltage, power consumption can be reduced in Normal mode, Sleep mode, and Snooze mode.

11.5.1 Setting the Operating Power Control Mode

Make sure that the operating conditions such as the voltage and frequency ranges, are always within the specified ranges before and after switching the operating power control modes. This section provides example procedures for switching operating power control modes.

Table 11.5 Available oscillators in each mode

Mode	Oscillator						
	PLL	High-speed on-chip oscillator	Middle-speed on-chip oscillator	Low-speed on-chip oscillator	Main clock oscillator	Sub-clock oscillator	IWDT-dedicated on-chip oscillator

Low-speed	N/A	Available	Available	Available	Available	Available	Available

(1) Switching from a higher to a lower power mode

Example 1: From High-speed mode to Low-speed mode

- PCKC[2:0]
- PCKD[2:0].

模块和时钟关联如下：

- CPU、DMAC、DTC、闪存和SRAM使用ICK[2:0]位指定的工作时钟
- 外设模块使用PCKA[2:0]、PCKB[2:0]、PCKC[2:0]和PCKD[2:0]位中指定的工作时钟
- 闪存接口使用FCK[2:0]位中指定的工作时钟
- 外部总线使用BCK[2:0]位中指定的工作时钟。

有关详细信息，请参见第9节，时钟生成电路。

11.4 Module-Stop Function

可以为每个片上外围模块设置模块停止功能。

当MSTPCRA到MSTPCRD中的MSTPmi位（m=A到D，i=31到0）设置为1时，指定模块停止运行并进入模块停止状态，但CPU继续独立运行。将MSTPmi位清0可取消模块停止状态，允许模块在总线周期结束时恢复运行。模块的内部状态保持在模块停止状态。

取消复位后，除DMAC、DTC和SRAM模块之外的所有模块都置于模块停止状态。相关MSTPmi位为1时请勿访问模块，否则无法保证读写数据或模块的操作。此外，在访问相关模块时不要将MSTPmi位设置为1。

WhenthePLLisselectedastheclocksource MSTPmibitsmustonlybechangedonebitatatime.在这种情况下，如果更改以下任何位，请在更改每个MSTPmi位后至少等待250ns，然后再开始后续处理：

- MSTPA22 (DMAC, DTC)
- MSTPC31 (SCE7)
- MSTPD5 (GPT32EH, GPT32E).

测量等待时间的推荐方法是通过软件。请务必考虑最坏情况，以确保经过所需的等待时间。

11.5 降低运行功耗的功能

通过根据工作频率和工作电压选择合适的工作功耗控制模式，可以在正常模式、睡眠模式和贪睡模式下降低功耗。

11.5.1 设置工作电源控制模式

确保在切换操作功率控制模式之前和之后，电压和频率范围等操作条件始终在指定范围内。本节提供切换操作电源控制模式的示例程序。

11.6 Sleep Mode

When a WFI instruction is executed while the SBYCR.SSBY bit is 0, the MCU enters Sleep mode. In Sleep mode, the CPU stops operating, but the contents of its internal registers are retained. Other peripheral functions do not stop. Available resets or interrupts in Sleep mode cause the MCU to cancel Sleep mode. All interrupt sources are available. If

11.6 睡眠模式

11.6.1 转换到睡眠模式

当SBYCR.SSBY位为0时执行WFI指令时，MCU进入休眠模式。在睡眠模式下，
CPU停止运行，但保留其内部寄存器的内容。其他外围功能不会停止。
休眠模式下可用的复位或中断会导致MCU取消休眠模式。所有中断源均可用。如果

RA生态工作室

using an interrupt to cancel Sleep mode, you must set the associated IELSRn register before executing a WFI instruction. For details, see section 14, Interrupt Controller Unit (ICU).

Counting by the IWDT stops when the MCU enters Sleep mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 1 (IWDT stops in Sleep mode, Software Standby mode, or Snooze mode).

Counting by the IWDT continues when the MCU enters Sleep mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 0 (IWDT does not stop in Sleep mode, Software Standby mode, or Snooze mode).

Counting by the WDT stops when the MCU enters Sleep mode while the WDT is in auto start mode and the OFS0.WDTSTPCTL bit is 1 (WDT stops in Sleep mode). Similarly, counting by the WDT stops when the MCU enters Sleep mode while the WDT is in register start mode and the WDTCSTPR.SLCSTP bit is 1 (WDT stops in Sleep mode).

Counting by the WDT continues when the MCU enters Sleep mode while the WDT is in auto start mode and the OFS0.WDTSTPCTL bit is 0 (WDT does not stop in Sleep mode). Similarly, counting by the WDT continues when the MCU enters Sleep mode while the WDT is in register start mode and the WDTCSTPR.SLCSTP bit is 0 (WDT does not stop in Sleep mode).

11.6.2 Canceling Sleep Mode

Sleep mode is canceled by:

- An interrupt
- A RES pin reset
- A power-on reset
- A voltage monitor reset
- An SRAM parity error reset
- An SRAM ECC error reset
- A bus master MPU error reset
- A bus slave MPU error reset
- A reset caused by an IWDT or WDT underflow.

The operations are as follows:

1. Canceling by an interrupt
   When an available interrupt request (see Table 11.3) is generated, Sleep mode is canceled and the MCU starts the interrupt handling.
2. Canceling by RES pin reset
   When the RES pin is driven low, the MCU enters the reset state. Be sure to keep the RES pin low for the time period specified in section 52, Electrical Characteristics. When the RES pin is driven high after the specified time period, the CPU starts the reset exception handling.
3. Canceling by IWDT reset
   Sleep mode is canceled by an internal reset generated by an IWDT underflow, and the MCU starts the reset exception handling. However, IWDT stops in Sleep mode and an internal reset for canceling Sleep mode is not generated in the following conditions:
   - OFS0.IWDTSTRT = 0 and OFS0.IWDTSTPCTL = 1.
4. Canceling by WDT reset
   Sleep mode is canceled by an internal reset generated by an WDT underflow and the MCU starts the reset exception handling. However, WDT stops in Sleep mode even when counting in Normal mode and an internal reset for canceling Sleep mode is not generated in the following conditions:
   - OFS0.WDTSTRT = 0 (auto start mode) and OFS0.WDTSTPCTL = 1
   - OFS0.WDTSTRT = 1 (register start mode) and WDTCSTPR.SLCSTP = 1.
5. Canceling by other resets available in Sleep mode
   Sleep mode is canceled by other resets and the MCU starts the reset exception handling.

使用中断取消休眠模式，您必须在执行WFI指令之前设置相关的IELSRn寄存器。有关详细信息，请参阅第14节，中断控制器单元(ICU)。

当MCU进入休眠模式且IWDT处于自动启动模式且OFS0.IWDTSTPCTL位为1（IWDT在休眠模式、软件待机模式或贪睡模式下停止）。

当MCU进入休眠模式且IWDT处于自动启动模式且OFS0.IWDTSTPCTL位为0（IWDT在休眠模式、软件待机模式或贪睡模式下不会停止）。

当MCU进入休眠模式且WDT处于自动启动模式且WDT处于自动启动模式时，WDT停止计数OFS0.WDTSTPCTL位为1（WDT在休眠模式下停止）。同样，当MCU进入休眠模式且WDT处于寄存器启动模式且WDTCSTPR.SLCSTP位为1（WDT在休眠模式下停止）时，WDT停止计数。

当MCU进入休眠模式且WDT处于自动启动模式和OFS0时，WDT继续计数。WDTSTPCTL位为0（WDT在休眠模式下不停止）。同样，当MCU进入休眠模式且WDT处于寄存器启动模式且WDTCSTPR.SLCSTP位为0（WDT不会在休眠模式下停止）时，WDT继续计数。

11.6.2 取消睡眠模式

睡眠模式通过以下方式取消：

- 中断
- ARES引脚复位
- A power-on reset
- 电压监视器复位
- SRAM奇偶校验错误复位
- SRAMECC错误复位
- 总线主控MPU错误复位
- 总线从机MPU错误复位
- 由IWDT或WDT下溢引起的复位。

操作如下：

1. 通过中断取消
   当产生可用的中断请求（见表11.3）时，休眠模式被取消，MCU开始中断处理。
2. 通过RES引脚复位取消
   当RES引脚驱动为低电平时，MCU进入复位状态。请务必在第52节“电气特性”中指定的时间段内保持RES引脚为低电平。当RES引脚在指定时间后被驱动为高电平时，CPU开始复位异常处理。
3. 通过IWDT复位取消
   休眠模式由IWDT下溢产生的内部复位取消，MCU开始复位异常处理。但是，IWDT在休眠模式下停止，并且在以下情况下不会产生用于取消休眠模式的内部复位：
   - OFS0.IWDTSTRT = 0 and OFS0.IWDTSTPCTL = 1.
4. 通过WDT复位取消
   睡眠模式由WDT下溢产生的内部复位取消，MCU启动复位异常处理。但是，即使在正常模式下计数，WDT也会在休眠模式下停止，并且在以下情况下不会产生用于取消休眠模式的内部复位：
   - OFS0.WDTSTRT=0（自动启动模式）和OFS0.WDTSTPCTL=1
   - OFS0.WDTSTRT=1（寄存器启动模式）和WDTCSTPR.SLCSTP=1。
5. 通过睡眠模式下可用的其他复位取消
   休眠模式被其他复位取消，MCU开始复位异常处理。

Note: For details on proper setting of the interrupts, see section 14, Interrupt Controller Unit (ICU).

11.7 Software Standby Mode

11.7.1 Transitioning to Software Standby Mode

When a WFI instruction is executed while the SBYCR.SSBY bit is 1 and the DPSBYCR.DPSBY bit is 0, the MCU enters Software Standby mode. In this mode, the CPU, most of the on-chip peripheral functions, and the oscillators stop. However, the contents of the CPU internal registers and SRAM data, the states of the on-chip peripheral functions, and the I/O port states are retained. Software Standby mode allows a significant reduction in power consumption because most of the oscillators stop in this mode. Table 11.2 shows the status of the on-chip peripheral functions and oscillators. Available resets or interrupts in Software Standby mode cause the MCU to cancel Software Standby mode. See Table 11.3 for available interrupt sources and section 14.2.9, Wake Up Interrupt Enable Register (WUPEN) for information on waking up the MCU from Software Standby mode. If using an interrupt to cancel Software Standby mode, you must set the associated IELSRn register before executing a WFI instruction. For details, see section 14, Interrupt Controller Unit (ICU).

The status of the address bus and bus control signals in Software Standby mode can be selected with the SBYCR.OPE bit.

Clear the DMAST.DMST and DTCST.DTCST bits to 0 before executing a WFI instruction, except when using the DTC in Snooze mode. If the DTC is required in Snooze mode, set the DTCST.DTCST bit to 1 before executing a WFI instruction.

Counting by the IWDT stops when the MCU enters Software Standby mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 1 (IWDT stops in Sleep, Software Standby, or Snooze mode).

Counting by the IWDT continues when the MCU enters Software Standby mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 0 (IWDT does not stop in Sleep mode, Software Standby mode, or Snooze mode). The WDT stops counting when the MCU enters Software Standby mode.

Do not enter Software Standby mode while OSTDCR.OSTDE is 1 (oscillation stop detection function enabled). To enter Software Standby mode, execute a WFI instruction after disabling the oscillation stop detection function (OSTDCR.OSTDE is 0). If executing a WFI instruction while OSTDCR.OSTDE is 1, the MCU enters Sleep mode even when SBYCR.SSBY is 1. In addition, do not enter Software Standby mode while the flash memory performs a programming or erasing procedure. To enter Software Standby mode, execute a WFI instruction after the programming or erasing procedure completes.

When the PLL is selected as the clock source, set the following modules to the module-stop state before executing a WFI instruction:

- SCE7
- GPT32EH
- GPT32E.

You must also insert a wait time of at least 750 ns before executing the WFI instruction. The recommended method to measure the wait time is through software. Be sure to consider the worst-case conditions to ensure that the required wait time elapses.

Table 11.6 shows the setting of the related control bits and the modes entered when executing a WFI instruction.

Figure 11.2 shows an example flow for transitioning to Software Standby mode or Deep Software Standby mode.

11.7 软件待机模式

11.7.1 过渡到软件待机模式

当SBYCR.SSBY位为1且DPSBYCR.DPSBY位为0时执行WFI指令，MCU进入软件待机模式。在此模式下，CPU、大部分片上外围功能和振荡器停止。但是，CPU内部寄存器和SRAM数据的内容、片上外围功能的状态以及IO端口的状态都会被保留。软件待机模式可显着降低功耗，因为大多数振荡器在此模式下停止。表11.2显示了片上外围功能和振荡器的状态。软件待机模式下可用的复位或中断会导致MCU取消软件待机模式。有关可用中断源的信息，请参见表11.3，有关将MCU从软件待机模式唤醒的信息，请参见第14.2.9节，唤醒中断使能寄存器(WUPEN)。如果使用中断取消软件待机模式，则必须在执行WFI指令之前设置相关的IELSRn寄存器。有关详细信息，请参阅第14节，中断控制器单元(ICU)。

软件待机模式下的地址总线和总线控制信号的状态可以通过SBYCR.OPE位来选择。

在执行WFI指令之前将DMAST.DMST和DTCST.DTCST位清零，除非在贪睡模式下使用DTC。如果在贪睡模式下需要DTC，请在执行WFI指令之前将DTCST.DTCST位设置为1。

当IWDT处于自动启动模式且OFS0.IWDTSTPCTL位为1（IWDT在休眠、软件待机或贪睡模式下停止）时，当MCU进入软件待机模式时，IWDT停止计数。

当IWDT处于自动启动模式且OFS0.IWDTSTPCTL位为0（IWDT在休眠模式、软件待机模式或贪睡模式下不会停止）时，当MCU进入软件待机模式时，IWDT继续计数。当MCU进入软件待机模式时，WDT停止计数。

OSTDCR.OSTDE为1（振荡停止检测功能启用）时不要进入软件待机模式。要进入软件待机模式，请在禁用振荡停止检测功能（OSTDCR.OSTDE为0）后执行WFI指令。如果在OSTDCR.OSTDE为1时执行WFI指令，即使SBYCR.SSBY为1，MCU也会进入休眠模式。此外，在闪存执行编程或擦除过程时不要进入软件待机模式。要进入软件待机模式，请在编程或擦除过程完成后执行WFI指令。

WhenthePLLisselectedastheclocksource setthefollowingmodulestothemodule-stopstatebeforeexecutingaWFIinstruction:

- SCE7
- GPT32EH
- GPT32E.

您还必须在执行WFI指令之前插入至少750ns的等待时间。测量等待时间的推荐方法是通过软件。请务必考虑最坏情况，以确保经过所需的等待时间。

11.7.2 Canceling Software Standby Mode

Software Standby mode is canceled by:

- An available interrupt shown in Table 11.3
- A RES pin reset
- A power-on reset
- A voltage monitor reset
- A reset caused by an IWDT underflow.

On exiting Software Standby mode, the oscillators that operate before transitioning to the mode restart. After all the oscillators are stabilized, the MCU returns to Normal mode from Software Standby mode. See section 14.2.9, Wake Up Interrupt Enable Register (WUPEN), for information on waking up the MCU from Software Standby mode.

You can cancel Software Standby mode in any of the following ways:

- Canceling by an interrupt
  When an available interrupt request (see Table 11.3) is generated, an oscillator that operates before the transition to Software Standby mode restarts. After all the oscillators are stabilized, the MCU cancels Software Standby mode and starts the interrupt handling. When the PLL is selected as the clock source, you must insert a wait time of at least 250 ns at the beginning of the interrupt handling. The recommended method to measure the wait time is through software. Be sure to consider the worst-case conditions to ensure that the required wait time elapses. Figure 11.3 shows an example flow for canceling Software Standby mode by an interrupt.
- Canceling by a RES pin reset
  When the RES pin is driven low, the MCU enters the reset state, and the oscillators whose default status is operating, start the oscillation. Be sure to keep the RES pin low for the time period specified in section 52, Electrical Characteristics. When the RES pin is driven high after the specified time period, the CPU starts the reset exception handling.
- Canceling by an IWDT reset
  Software Standby mode is canceled by an internal reset generated by an IWDT underflow, and the MCU starts reset exception handling. However, IWDT stops in Software Standby mode and an internal reset for canceling Software Standby mode is not generated in the following conditions:
  - OFS0.IWDTSTRT = 0 and OFS0.IWDTSTPCTL = 1.
- Canceling by other resets available in Software Standby mode
  Software Standby mode is canceled by other resets, and the MCU starts the reset exception handling.

11.7.2 取消软件待机模式

软件待机模式通过以下方式取消：

- 表11.3中显示的可用中断
- ARES引脚复位
- A power-on reset
- 电压监视器复位
- 由IWDT下溢引起的复位。

在退出软件待机模式时，在转换到该模式之前工作的振荡器会重新启动。在所有振荡器稳定后，MCU从软件待机模式返回到正常模式。有关将MCU从软件待机模式唤醒的信息，请参见第14.2.9节，唤醒中断使能寄存器(WUPEN)。

您可以通过以下任一方式取消软件待机模式：

- 通过中断取消
  当一个可用的中断请求（见表11.3）产生时，一个振荡器在转换到
  软件待机模式重新启动。在所有振荡器稳定后，MCU取消软件待机模式并开始中断处理。WhenthePLLisselectedastheclocksource youmustinsertawaittimeofatleast250nsatthebeginningoftheinterrupthandling.
  测量等待时间的推荐方法是通过软件。请务必考虑最坏情况，以确保经过所需的等待时间。图11.3显示了通过中断取消软件待机模式的示例流程。
- 通过RES引脚复位取消
  当RES引脚驱动为低电平时，MCU进入复位状态，默认状态为工作的振荡器开始振荡。请务必在第52节“电气特性”中指定的时间段内保持RES引脚为低电平。当RES引脚在指定时间后被驱动为高电平时，CPU开始复位异常处理。
- 通过IWDT复位取消
  软件待机模式由IWDT下溢产生的内部复位取消，MCU开始复位异常处理。但是，IWDT在软件待机模式下停止，并且在以下情况下不会产生用于取消软件待机模式的内部复位：
  - OFS0.IWDTSTRT = 0 and OFS0.IWDTSTPCTL = 1.
- 通过软件待机模式下可用的其他复位取消
  软件待机模式被其他复位取消，MCU启动复位异常处理。

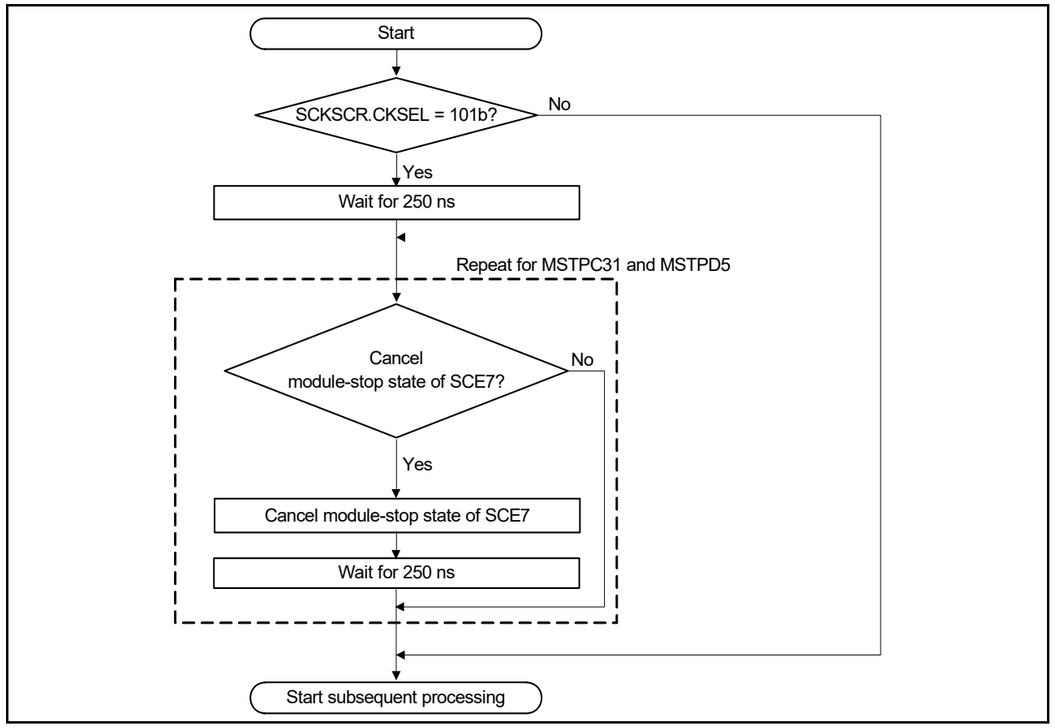

Figure 11.3 Example flow for canceling Software Standby mode

11.7.3 Example of Software Standby Mode Application

Figure 11.4 shows an example of entry to Software Standby mode on detection of a falling edge of the IRQn pin, and exit from Software Standby mode on a rising edge of the IRQn pin.

In this example, an IRQn pin interrupt is accepted when the IRQCRi.IRQMD[1:0] bits of the ICU are set to 01b (falling edge) in Normal mode, and the IRQCRi.IRQMD[1:0] bits set to 10b (rising edge). Next, the SBYCR.SSBY bit is set to 1 and a WFI instruction is executed. As a result, entry to Software Standby mode completes, and exit from Software Standby mode is initiated by a rising edge of the IRQn pin.

Setting the ICU is also required to exit Software Standby mode. For details, see section 14, Interrupt Controller Unit (ICU). The oscillation stabilization time in Figure 11.4 is specified in section 52, Electrical Characteristics.

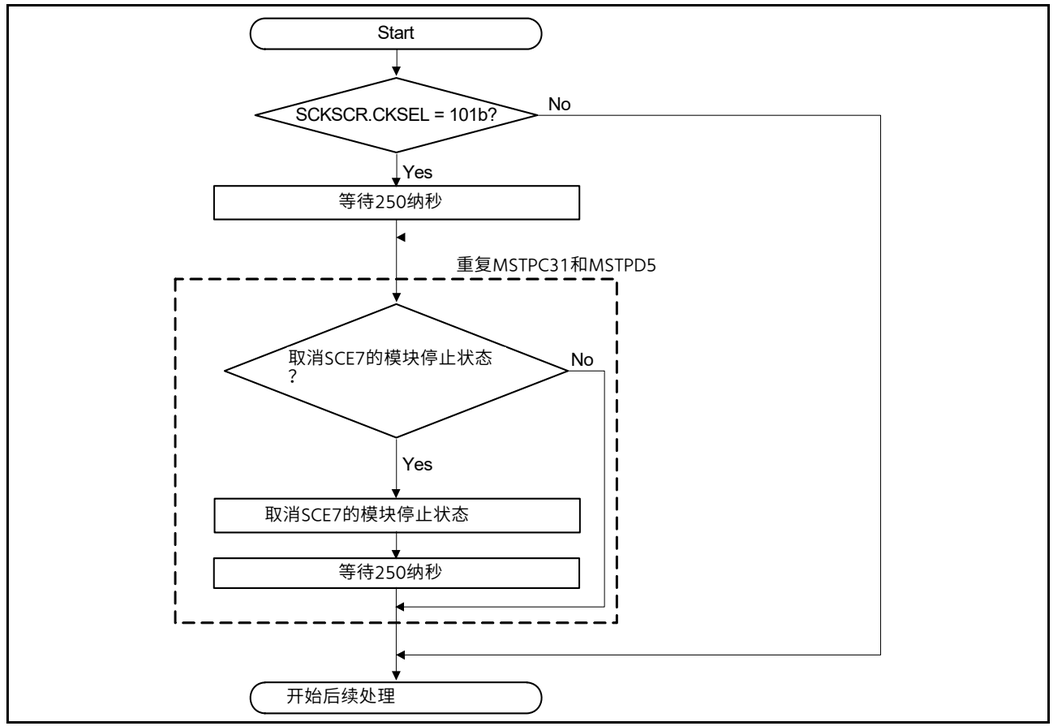

Figure 11.3 取消软件待机模式的示例流程

11.7.3 软件待机模式应用示例

图11.4显示了在检测到IRQn引脚的下降沿进入软件待机模式并在IRQn引脚的上升沿退出软件待机模式的示例。

在此示例中，当ICU的IRQCRi.IRQMD[1:0]位在正常模式下设置为01b（下降沿）并且IRQCRi.IRQMD[1:0]位设置为10b时，将接受IRQn引脚中断（上升沿）。接下来，将SBYCR.SSBY位设置为1，并执行WFI指令。结果，进入软件待机模式完成，并且退出软件待机模式由IRQn引脚的上升沿启动。

退出软件待机模式也需要设置ICU。有关详细信息，请参阅第14节，中断控制器单元(ICU)。图11.4中的振荡稳定时间在第52节“电气特性”中指定。

11.8 Snooze Mode

11.8.1 Transitioning to Snooze Mode

Figure 11.5 shows snooze mode entry configuration. When the snooze control circuit receives a snooze request in Software Standby mode, the MCU transitions to Snooze mode. In this mode, some peripheral modules operate without waking up the CPU. Table 11.2 shows the peripheral modules that can operate in Snooze mode. Also, DTC operation can be selected in Snooze mode by setting the SNZCR.SNZDTCEN bit.

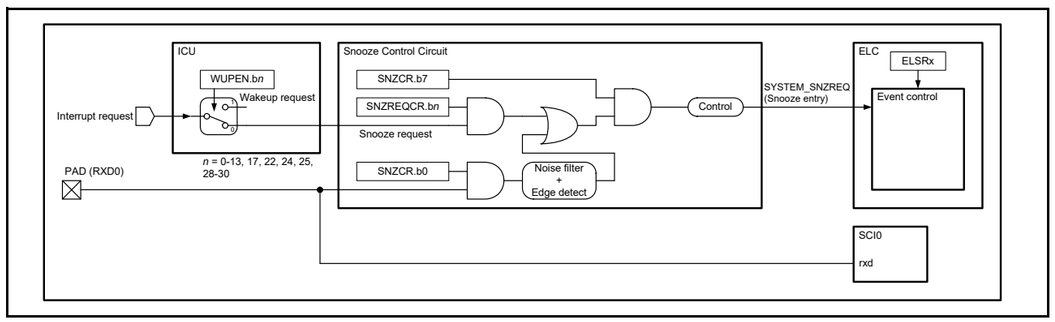

Figure 11.5 Snooze entry configuration

Table 11.7 shows the snooze requests to switch the MCU from Software Standby mode to Snooze mode. To use a listed snooze requests as a trigger to switch to Snooze mode, you must set the associated SNZREQENn bit of the SNZREQCR register or RXDREQEN bit of the SNZCR register before entering Software Standby mode.

软件待机模式，MCU转换到贪睡模式。在这种模式下，一些外围模块在不唤醒CPU的情况下运行。表11.2显示了可以在贪睡模式下运行的外围模块。此外，通过设置SNZCR.SNZDTCEN位，可以在贪睡模式下选择DTC操作。

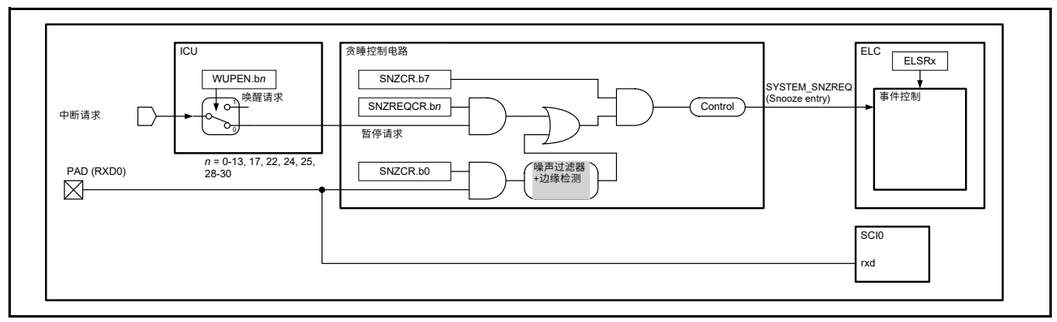

Figure 11.5 贪睡入口配置

表11.7显示了将MCU从软件待机模式切换到贪睡模式的贪睡请求。要将列出的贪睡请求用作切换到贪睡模式的触发器，您必须在进入软件待机模式之前设置SNZREQCR寄存器的相关SNZREQENn位或SNZCR寄存器的RXDREQEN位。

Note 2. Do not set the RXDREQEN bit to 1 except in asynchronous mode.

11.8.2 Canceling Snooze Mode

Snooze mode is canceled by an interrupt request that is available in Software Standby mode or a reset. Table 11.3 shows the requests that can be used to exit each mode. After canceling the Snooze mode, the MCU enters Normal mode and proceeds with exception processing for the given interrupt or reset. The action triggered by the interrupt requests selected in SELSR0, cancels Snooze mode. Interrupt canceling Snooze mode must be selected in IELSRn (n = 0 to 96) to link to the NVIC for the associated interrupt handling. See section 14, Interrupt Controller Unit (ICU), for information on SELSR0 and IELSRn registers.

Note 2. Transition time from Snooze mode to Normal mode.
Note 3. Enable Snooze mode (SNZCR.SNZE = 1) immediately before entering Software Standby mode.
Note 4. Disable Snooze mode (SNZCR.SNZE = 0) immediately after canceling Snooze mode.

11.8.3 Returning to Software Standby Mode

Table 11.8 shows the snooze end requests that can be used as triggers to return to Software Standby mode. The snooze end requests are available only in Snooze mode. If the requests are generated when the MCU is not in Snooze mode, they are ignored. When multiple requests are selected, each one of the requests invokes transition to Software Standby mode from Snooze mode.

Note 2. 除非在异步模式下，否则不要将RXDREQEN位设置为1。

11.8.2 取消贪睡模式

贪睡模式由软件待机模式下可用的中断请求或复位取消。表11.3显示了可用于退出每种模式的请求。取消贪睡模式后，MCU进入正常模式并继续对给定中断或复位进行异常处理。SELSR0中选择的中断请求触发的动作取消贪睡模式。必须在IELSRn（n=0到96）中选择中断取消贪睡模式以链接到NVIC以进行相关的中断处理。有关SELSR0和IELSRn寄存器的信息，请参见第14节，中断控制器单元(ICU)。

11.8.3 返回软件待机模式

Table 11.9 shows the snooze end conditions that consist of the snooze end requests and the conditions of the peripheral modules. The CTSU, SCI0, ADC120, ADC121, and DTC modules can keep the MCU in Snooze mode until they complete their operation. However, an AGT1 underflow as a trigger to return to Software Standby mode cancels Snooze mode without waiting for the completion of the SCI0 operation.

Figure 11.7 shows the timing diagram for the transition from Snooze mode to Software Standby mode. This mode transition occurs according to which snooze end requests are set in the SNZEDCR register. A snooze request is cleared automatically after returning to Software Standby mode.

11.9 Deep Software Standby Mode

11.9.1 Transitioning to Deep Software Standby Mode

The MCU enters Deep Software Standby mode when a WFI instruction is executed with the SBYCR.SSBY bit set to 1 and the DPSBYCR.DPSBY bit set to 1. See Table 11.6 for the settings of the related control bits.

In Deep Software Standby mode, the following modules are stopped:

- The CPU
- The on-chip peripheral functions, except for the RTC alarm, RTC interval, and USB suspend/resume detecting unit
- The SRAM (but not the standby SRAM)
- All oscillators, except for the sub-clock and low-speed on-chip oscillators.

Power consumption is reduced because the internal power supply to these modules is stopped. The contents of all CPU registers and internal peripheral modules, except for the RTC alarm, RTC interval, and USB suspend/resume detecting unit, become undefined.

Data in the standby SRAM is saved if the setting in the DEEPCUT[1:0] bits is 00b. If the setting is 01b, the internal power supply to the standby SRAM and the USB resume detecting unit is cut off, and power consumption is reduced. Data in the standby SRAM becomes undefined at this time.

If the setting in the DEEPCUT[1:0] bits is 11b, the internal power supply to the standby SRAM and the USB resume detecting unit is cut off, the LVD is stopped, and the low power mode function of the power-on reset circuit is enabled. Therefore, power consumption is further reduced. For details, see section 52, Electrical Characteristics.

When the MCU enters Deep Software Standby mode while the IWDT is in auto start mode and the OFS0.IWDTSTPCTL bit is 1, power supply to the IWDT-dedicated clock and the IWDT is cut off. Counting by the IWDT also stops.

When the OFS0.IWDTSTPCTL bit is 0, the MCU enters Software Standby mode instead of Deep Software Standby mode, regardless of the setting in the OFS0.IWDTSTRT or DPSBYCR.DPSBY bit. When the OFS0.IWDTSTPCTL bit is 0 while the OFS0.IWDTSTRT bit is 0 (auto start mode), the IWDT-dedicated clock and IWDT continue operation.

When the LVD1CR0.RI bit is 1 (voltage monitor 1 reset selected) or the LVD2CR0.RI bit is 1 (voltage monitor 2 reset selected), the MCU enters Software Standby mode instead of Deep Software Standby mode. The I/O port states are the same as in Software Standby mode.

When the PLL is selected as the clock source, set the following modules to the module-stop state before executing a WFI instruction:

- SCE7
- GPT32EH
- GPT32E.

In this case, you must also insert a wait time of at least 750 ns before executing the WFI instruction. The recommended method to measure the wait time is through software. Consider the worst-case conditions to ensure that the required wait time elapses.

Figure 11.2 shows an example flow for transitioning to Software Standby mode or Deep Software Standby mode.

Note 1. Conditions on the DTC, DMAC, and IWDT for transitioning to Software Standby mode must be met before the WFI instruction is executed. For details, see section 11.7, Software Standby Mode.

11.9.2 Canceling Deep Software Standby Mode

Deep Software Standby mode is canceled by:

- An interrupt shown in Table 11.3
- A RES pin reset
- A power-on reset
- A voltage monitor 0 reset.

11.9 深度软件待机模式

11.9.1 过渡到深度软件待机模式

当SBYCR.SSBY位设置为1且DPSBYCR.DPSBY位设置为1时执行WFI指令，MCU进入深度软件待机模式。相关控制位设置见表11.6。

在深度软件待机模式下，以下模块将停止：

- 中央处理器
- 片上外围功能，除了RTC警报、RTC间隔和USB挂起恢复检测单元
- SRAM（但不是备用SRAM）
- 所有振荡器，除了子时钟和低速片上振荡器。

由于停止了对这些模块的内部供电，因此降低了功耗。除RTC警报、RTC间隔和USB暂停恢复检测单元外，所有CPU寄存器和内部外围模块的内容都未定义。

如果DEEPCUT[1:0]位的设置为00b，则保存备用SRAM中的数据。如果设置为01b，则对备用SRAM和USB恢复检测单元的内部电源被切断，从而降低功耗。此时备用SRAM中的数据变为未定义。

如果DEEPCUT[1:0]位设置为11b，则内部对待机SRAM和USB恢复检测单元的供电被切断，LVD停止，上电复位的低功耗模式功能电路启用。因此，进一步降低了功耗。有关详细信息，请参见第52节，电气特性。

当MCU在IWDT处于自动启动模式且OFS0.IWDTSTPCTL位为1时进入深度软件待机模式时，IWDT专用时钟和IWDT的电源将被切断。IWDT的计数也停止。

当OFS0.IWDTSTPCTL位为0时，MCU进入软件待机模式而不是深度软件待机模式，无论OFS0.IWDTSTRT或DPSBYCR.DPSBY位的设置如何。当OFS0.IWDTSTPCTL位为0而OFS0.IWDTSTRT位为0（自动启动模式）时，IWDT专用时钟和IWDT继续运行。

当LVD1CR0.RI位为1（选择电压监视器1复位）或LVD2CR0.RI位为1（选择电压监视器2复位）时，MCU进入软件待机模式而不是深度软件待机模式。IO端口状态与软件待机模式相同。

WhenthePLLisselectedastheclocksource setthefollowingmodulestothemodule-stopstatebeforeexecutingaWFIinstruction:

- SCE7
- GPT32EH
- GPT32E.

在这种情况下，您还必须在执行WFI指令之前插入至少750ns的等待时间。测量等待时间的推荐方法是通过软件。考虑最坏的情况，以确保经过所需的等待时间。

图11.2显示了转换到软件待机模式或深度软件待机模式的示例流程。

注1.在DTC、DMAC和IWDT转换到软件待机模式的条件必须在之前满足
执行WFI指令。有关详细信息，请参阅第11.7节，软件待机模式。

11.9.2 取消深度软件待机模式

深度软件待机模式通过以下方式取消：

- 表11.3所示的中断
- ARES引脚复位
- A power-on reset
- 电压监视器0复位。

RA生态工作室

The operations are as follows:

1. Canceling by an interrupt
   Canceling by interrupts is controlled by DPSIERn (n = 0 to 3) and DPSIFRn (n = 0 to 3). When an available interrupt request is generated, the associated flag in DPSIFRn is set to 1. If the interrupt is enabled in DPSIERn, Deep Software Standby mode is canceled. Rising or falling edge detection can be selected in DPSIEGRn (n = 0 to 2). The detection edge can be selected for the NMI, IRQ0-DS, IRQ1-DS, IRQ4-DS to IRQ12-DS, voltage monitor 1, and voltage monitor 2 interrupts. When a Deep Software Standby mode canceling request occurs, internal power is supplied, the MOCO clock starts to oscillate, and an internal reset (deep software standby reset) is generated for the entire MCU. The stable MOCO clock is supplied to the entire MCU and deep software standby reset is canceled. The MCU starts reset exception handling.
   When Deep Software Standby mode is canceled by an external interrupt pin or internal interrupt signal, the RSTSR0.DPSRSTF flag is set to 1.
2. Canceling by a RES pin reset
   When the RES pin is driven low, the MCU cancels Deep Software Standby mode and enters a reset state. Make sure to keep the RES pin low for the time period specified in section 52, Electrical Characteristics. When the RES pin is driven high after the specified time period, the CPU starts reset exception handling.
3. Canceling by a power-on reset
   Deep Software Standby mode is canceled by a power-on reset, and the MCU starts reset exception handling.
4. Canceling by a voltage monitor 0 reset
   Deep Software Standby mode is canceled by a voltage monitor 0 reset from the voltage detection circuit, and the MCU starts reset exception handling.

11.9.3 Pin States when Deep Software Standby Mode is Canceled

In Deep Software Standby mode, the I/O ports retain the same states from Software Standby mode. The MCU is initialized by an internal reset generated when Deep Software Standby mode is canceled, and reset exception handling starts immediately. The DPSBYCR.IOKEEP bit setting determines whether to initialize the I/O ports or to retain the I/O ports states for Software Standby mode. The following is the state of the I/O ports for each bit setting:

- When the DPSBYCR.IOKEEP bit = 0
  The I/O ports are initialized by an internal reset generated when Deep Software Standby mode is canceled.
- When the DPSBYCR.IOKEEP bit = 1
  Although the MCU is initialized by an internal reset generated when Deep Software Standby mode is canceled, the I/O ports retain their states from Software Standby mode regardless of the MCU internal state. The I/O ports states remain unchanged from Software Standby mode even when settings are made to the I/O ports or peripheral modules. The retained I/O ports states are released by clearing the DPSBYCR.IOKEEP bit to 0, and the MCU operates according to the internal state. The DPSBYCR.IOKEEP bit is not initialized by any internal reset generated when Deep Software Standby mode is canceled.

11.9.4 Example of Deep Software Standby Mode Application

(1) Entering and exiting Deep Software Standby mode

Figure 11.10 shows an example transition to Deep Software Standby mode on the falling edge of the IRQn-DS pin, and an exit from Deep Software Standby mode on the rising edge of the IRQn-DS pin. In this example, an IRQn interrupt is accepted with the IRQCRi.IRQMD[1:0] bits of the ICU set to 01b (falling edge). After the DPSIEGRy.DIRQnEG bit (y = 0, 1 and n = 0, 1, 4 to 12) is set to 1 (rising edge) and the SBYCR.SSBY and DPSBYCR.DPSBY bits are both set to 1, the WFI instruction is executed. As a result, the MCU transitions to Deep Software Standby mode. Deep Software Standby mode is then canceled on the rising edge of the IRQn-DS pin.

操作如下：

1. 通过中断取消
   中断取消由DPSIERn(n=0到3)和DPSIFRn(n=0到3)控制。当产生可用中断请求时，DPSIFRn中的相关标志设置为1。如果在DPSIERn中使能中断，则取消深度软件待机模式。上升沿或下降沿检测可以在DPSIEGRn(n=0到2)中选择。可为NMI、IRQ0-DS、IRQ1-DS、IRQ4-DS至IRQ12-DS、电压监视器1和电压监视器2中断选择检测沿。当出现深度软件待机模式取消请求时，内部电源供应，MOCO时钟开始振荡，并为整个MCU产生内部复位（深度软件待机复位）。为整个MCU提供稳定的MOCO时钟，取消深度软件待机复位。MCU开始复位异常处理。

   当深度软件待机模式被外部中断引脚或内部中断信号取消时，
   RSTSR0.DPSRSTF标志设置为1。
2. 通过RES引脚复位取消
   当RES引脚被驱动为低电平时，MCU取消深度软件待机模式并进入复位状态。确保在第52节"电气特性"中指定的时间段内保持RES引脚为低电平。当RES引脚在指定时间后被驱动为高电平时，CPU开始复位异常处理。
3. 通过上电复位取消
   深度软件待机模式通过上电复位取消，MCU开始复位异常处理。
4. 通过电压监视器取消0复位
   深度软件待机模式由电压检测电路复位的电压监视器0取消，并且
   MCU开始复位异常处理。

11.9.3 取消深度软件待机模式时的引脚状态

在深度软件待机模式下，IO端口保持与软件待机模式相同的状态。MCU通过取消深度软件待机模式时产生的内部复位进行初始化，并立即开始复位异常处理。DPSBYCR.IOKEEP位设置确定是初始化IO端口还是保留软件待机模式下的IO端口状态。以下是每个位设置的IO端口状态：

- 当DPSBYCR.IOKEEP位=0
  IO端口由取消深度软件待机模式时产生的内部复位进行初始化。
- 当DPSBYCR.IOKEEP位=1
  虽然MCU由取消深度软件待机模式时产生的内部复位来初始化，但无论MCU内部状态如何，IO端口仍会保持软件待机模式下的状态。即使对IO端口或外围模块进行了设置，IO端口状态在软件待机模式下也保持不变。通过将DPSBYCR.IOKEEP位清0来释放保留的IO端口状态，MCU根据内部状态运行。DPSBYCR.IOKEEP位不会被取消深度软件待机模式时产生的任何内部复位初始化。

11.9.4 深度软件待机模式应用示例

(1) 进入和退出深度软件待机模式

图11.10显示了在IRQn-DS引脚的下降沿转换到深度软件待机模式的示例，以及在IRQn-DS引脚的上升沿退出深度软件待机模式的示例。在此示例中，接受IRQn中断，同时ICU的IRQCRi.IRQMD[1:0]位设置为01b（下降沿）。在DPSIEGRy.DIRQnEG位（y=0、1和n=0、1、4到12）设置为1（上升沿）并且SBYCR.SSBY和DPSBYCR.DPSBY位都设置为1后，WFI指令被执行。结果，MCU转换到深度软件待机模式。然后在IRQn-DS引脚的上升沿取消深度软件待机模式。

11.9.5 Usage Flow for Deep Software Standby Mode

Figure 11.11 shows an example flow for using Deep Software Standby mode. In this example, the RSTSR0.DPSRSTF flag of the reset function is read after reset exception handling to determine whether the reset is generated by the RES pin or by the cancellation of Deep Software Standby mode. For a reset by the RES pin, the MCU transitions to Deep Software Standby mode after the required register settings are made. For a reset by cancellation of Deep Software Standby mode, the DPSBYCR.IOKEEP bit is set to 0 after the I/O port settings are made.

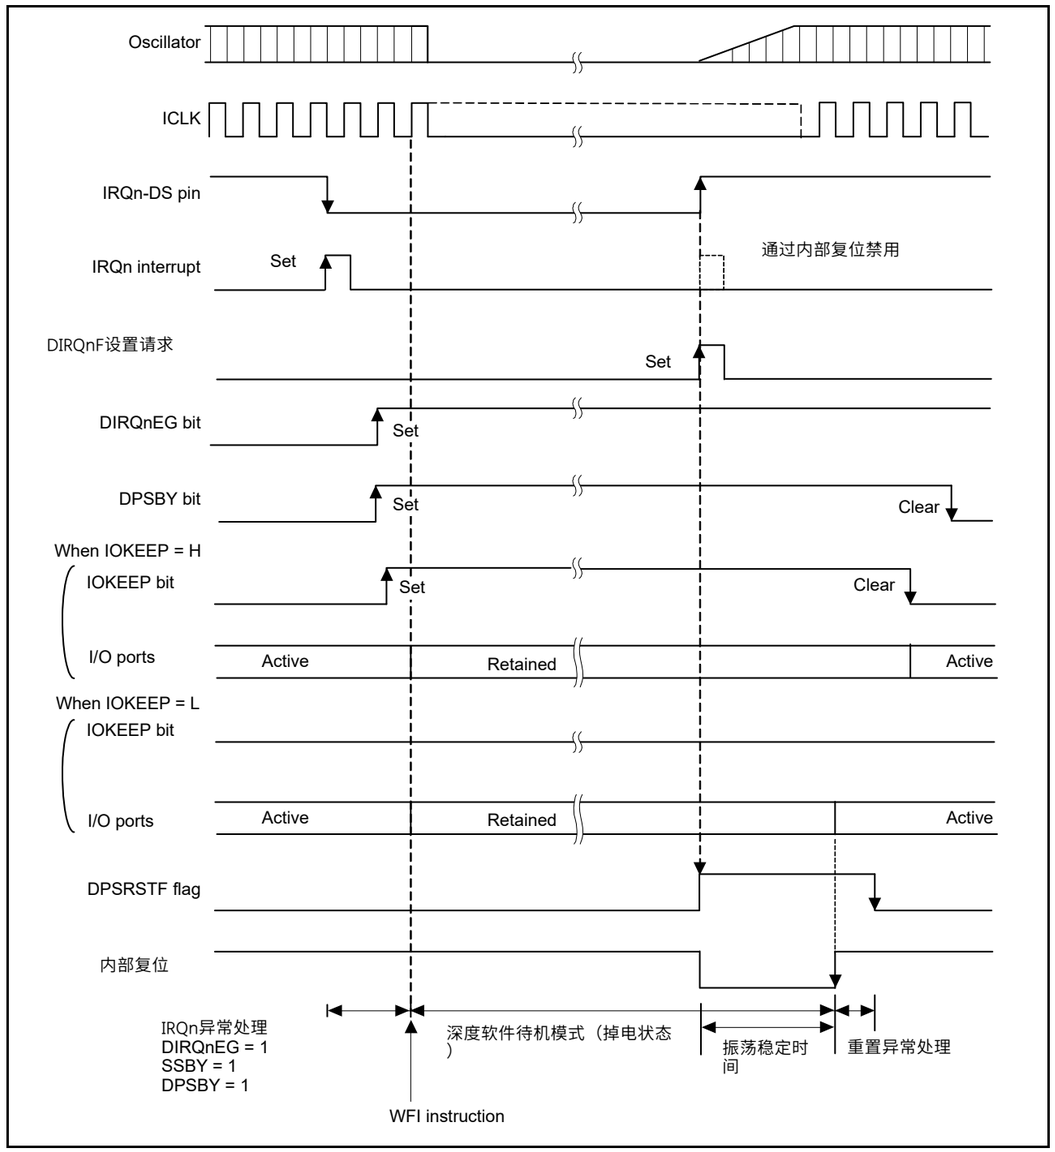

Figure 11.10 深度软件待机模式应用示例

11.9.5 深度软件待机模式的使用流程

图11.11显示了使用深度软件待机模式的示例流程。在本例中，复位异常处理后读取复位功能的RSTSR0.DPRSTF标志，以确定复位是由RES引脚产生还是由深度软件待机模式的取消产生。对于通过RES引脚进行的复位，在进行所需的寄存器设置后，MCU会转换到深度软件待机模式。通过取消DeepSoftware进行重置

待机模式下，在IO端口设置完成后，DPSBYCR.IOKEEP位被设置为0。

(3) subosc-speed模式下的无效寄存器写访问

不要在本节列出的条件下写入寄存器。

[Condition]

- SOPCCR.SOPCM = 1 (Subosc-speed mode).

(4) DTC或DMAC的无效寄存器写访问

不要写入DTC或DMAC在本节中列出的寄存器。

[Registers]

- MSTPCRA, MSTPCRB, MSTPCRC, MSTPCRD.

(5) Invalid register write accesses in Snooze mode

Do not write to registers listed in this section in Snooze mode. They must be set before entering Software Standby mode.

[Registers]

- SNZCR, SNZEDCR, SNZREQCR.

(6) Invalid write access to FLWT.FLWT[2:0]

Do not write any value other than 000b to the FLWT.FLWT[2:0] bits under the listed condition.

[Condition]

- SOPCCR.SOPCM = 1 (Subosc-speed mode)

(7) Invalid write access when PRCR.PRC1 is 0

Do not write to registers listed in this section when the PRCR.PRC1 bit is 0.

[Registers]

- SBYCR, SNZCR, SNZEDCR, SNZREQCR, OPCCR, SOPCCR, DPSBYCR, DPSIERn (n = 0 to 3), DPSIFRn (n = 0 to 3), DPSIEGRn (n = 0 to 2), and SYOCDCR.

11.10.2 I/O Port States

The I/O port states in Software Standby, Deep Software Standby, and Snooze modes (except when modifying in Snooze mode) are the same before entering the modes. Therefore, power consumption is not reduced while the output signals are held high.

11.10.3 Module-Stop State of DMAC and DTC

Before writing 1 to MSTPCRA.MSTPA22, clear the DMAST.DMST bit of the DMAC and the DTCST.DTCST bit of the DTC to 0.

11.10.4 Internal Interrupt Sources

Interrupts do not operate in the module-stop state. If the module-stop bit is set when an interrupt request is generated, a CPU interrupt source or a DMAC or DTC startup source cannot be cleared. Always disable the associated interrupts before setting the module-stop bits.

11.10.5 Input Buffer Control by the DIRQnE Bit (n = 0, 1, 4 to 12)

Setting the DPSIERy.DIRQnE bit (y = 0, 1 and n = 0, 1, 4 to 12) to 1 enables the associated input buffer of the IRQ0-DS, IRQ1-DS, and IRQ4-DS to IRQ12-DS pins. Although inputs to these pins are sent to the DPSIFRy.DIRQnF bits (y = 0, 1 and n = 0, 1, 4 to 12), they are not sent to the ICU, peripheral modules, or I/O ports.

11.10.6 Transitioning to Low Power Modes

Because the MCU does not support wakeup by events, do not enter the low power modes (Sleep, Software Standby, or Deep Software Standby mode) by executing a WFE instruction. Also, do not set the SLEEPDEEP bit of the System Control Register in the Cortex®-M4 core, because the MCU does not support low power modes by SLEEPDEEP.

11.10.7 Timing of WFI Instruction

It is possible for the WFI instruction to be executed before I/O register and CS area writes are complete, in which case operation might not proceed as intended. This can happen if the WFI is placed immediately after a write to an I/O register or CS area. To avoid this problem, read back the register or CS area that was written to confirm that the write completed.

11.10.8 Writing to the WDT and IWDT Registers by the DMAC or DTC in Sleep Mode or Snooze Mode

Do not write to the WDT or IWDT registers by the DMAC or DTC while the WDT or IWDT is stopped after entering Sleep mode or Snooze mode.

(5) 贪睡模式下的无效寄存器写访问

不要在贪睡模式下写入本节中列出的寄存器。必须在进入软件待机模式之前设置它们。

[Registers]

- SNZCR, SNZEDCR, SNZREQCR.

(6) 对FLWT.FLWT[2:0]的写入访问无效

在所列条件下，请勿将000b以外的任何值写入FLWT.FLWT[2:0]位。

[Condition]

- SOPCCR.SOPCM = 1 (Subosc-speed mode)

(7) 当PRCR.PRC1为0时，写入访问无效

当PRCR.PRC1位为0时，不要写入本节中列出的寄存器。

[Registers]

- SBYCR、SNZCR、SNZEDCR、SNZREQCR、OPCCR、SOPCCR、DPSBYCR、DPSIERn（n=0到3）、DPSIFRn（n=0到3）、DPSIEGRN（n=0到2）和SOOCDCR。

11.10.2 IO端口状态

软件待机、深度软件待机和贪睡模式下的IO端口状态（在贪睡模式下修改时除外）在进入这些模式之前是相同的。因此，当输出信号保持为高时，功耗不会降低。

11.10.3 DMAC和DTC的模块停止状态

在将1写入MSTPCRA.MSTPA22之前，清除DMAC的DMAST.DMST位和DTCST.DTCST位
DTC to 0.

11.10.4 内部中断源

中断不会在模块停止状态下运行。如果在产生中断请求时设置模块停止位，则
无法清除CPU中断源或DMAC或DTC启动源。在设置模块停止位之前，始终禁用相关的中断。

11.10.5 DIRQnE位的输入缓冲器控制（n=0、1、4到12）

将DPSIERy.DIRQnE位（y=0 1和n=0 1 4至12）设置为1可启用IRQ0-DS、IRQ1-DS和IRQ4-DS至IRQ12-DS引脚的相关输入缓冲器。尽管这些引脚的输入被发送到DPSIFRy.DIRQnF位（y=0、1和n=0、1、4到12），但它们不会被发送到ICU、外设模块或IO端口。

11.10.6 过渡到低功耗模式

由于MCU不支持事件唤醒，请勿进入低功耗模式（睡眠、软件待机或
深度软件待机模式）通过执行WFE指令。此外，不要设置系统的SLEEPDEEP位
Cortex®-M4内核中的控制寄存器，因为MCU不支持SLEEPDEEP的低功耗模式。

11.10.7 WFI指令的时间安排

WFI指令可能在IO寄存器和CS区域写入完成之前执行，在这种情况下操作可能无法按预期进行。如果在写入IO寄存器或CS区域后立即放置WFI，则会发生这种情况。为避免此问题，请回读已写入的寄存器或CS区域以确认写入已完成。

11.10.8 在休眠模式下由DMAC或DTC写入WDT和IWDT寄存器，或贪睡模式

当WDT或IWDT进入后停止时，请勿通过DMAC或DTC写入WDT或IWDT寄存器
睡眠模式或贪睡模式。

11.10.9 Oscillators in Snooze Mode

Oscillators that stop on entering Software Standby mode automatically restart when a trigger for switching to Snooze mode is generated. The MCU does not enter Snooze mode until all of the oscillators stabilize. In Snooze mode, you must disable oscillators that are not required in Snooze mode before entering Software Standby mode. Otherwise, the transition from Software Standby mode to Snooze mode takes longer.

11.10.10 Snooze Mode Entry by RXD0 Falling Edge

When the SNZCR.RXDREQEN bit is 1, noise on the RXD0 pin might cause the MCU transition from Software Standby mode to Snooze mode. Any subsequent RXD0 data can be received in Snooze mode by noise on the RXD0 pin. If the MCU does not receive any RXD0 data after the noise, interrupts such as SCI0_ERI or SCI0_RXI, and address mismatch events are not generated, and the MCU stays in Snooze mode. To avoid this, an AGT1 underflow interrupt must be used to return to Software Standby mode or Normal mode when using SCI0 in Snooze mode. However, do not use the AGT1 underflow as a source to return to Software Standby mode during an SCI communication. This makes the SCI0 stop the operation in a half-finished state.

11.10.11 Using SCI0 in Snooze Mode

When using SCI0 in Snooze mode, the AGT1 underflow must be used for the interrupt request or snooze end request. Do not use any other trigger.

When using SCI0 in Snooze mode, the following conditions must be satisfied:

- The clock source must be HOCO
- MOCO, the main clock oscillator, and the PLL must be stopped before entering Software Standby mode
- The RXD0 pin must be kept at the high level before entering Software Standby mode
- A transition to Software Standby mode must not occur during an SCI communication
- The MSTPCRC.MSTPC0 bit must be 1 before entering Software Standby mode.

11.10.12 Conditions of A/D Conversion Start in Snooze Mode

The ADC12 can only be triggered by the ELC in Snooze mode. Do not use a software trigger or ADTRGn pin.

11.10.13 ELC Events in Snooze Mode

Only the ELC events listed in this section are available in Snooze mode. Do not use any other events. If starting peripheral modules for the first time after entering Snooze mode, the Event Link Setting Register (ELSRn) must set a Snooze mode entry event (SYSTEM_SNZREQ) as the trigger.

- Snooze mode entry (SYSTEM_SNZREQ)
- DTC transfer end (DTC_DTCEND)
- ADC12n Window A/B compare match (ADC12n_WCMPM) (n = 0, 1)
- ADC12n Window A/B compare mismatch (ADC12n_WCMPUM) (n = 0, 1)
- Data operation circuit interrupt (DOC_DOPCI).

11.10.14 Conditions of CTSU in Snooze Mode

The CTSU can only be started by the ELC in Snooze mode.

11.10.9 贪睡模式下的振荡器

进入软件待机模式时停止的振荡器会在生成切换到贪睡模式的触发器时自动重新启动。在所有振荡器稳定之前，MCU不会进入贪睡模式。在贪睡模式下，您必须先禁用贪睡模式下不需要的振荡器，然后才能进入软件待机模式。否则，从软件待机模式到贪睡模式的转换需要更长的时间。

11.10.10 通过RXD0下降沿进入贪睡模式

当SNZCR.RXDREQEN位为1时，RXD0引脚上的噪声可能会导致MCU从软件待机模式转换到贪睡模式。任何后续的RXD0数据都可以通过RXD0引脚上的噪声在贪睡模式下接收。如果噪声后MCU没有收到任何RXD0数据，则不会产生SCI0_ERI或SCI0_RXI等中断和地址不匹配事件，并且MCU处于贪睡模式。为避免这种情况，在贪睡模式下使用SCI0时，必须使用AGT1下溢中断返回到软件待机模式或正常模式。但是，不要将AGT1下溢用作SCI通信期间返回软件待机模式的源。这使得SCI0在半完成状态下停止操作。

11.10.11 在贪睡模式下使用SCI0

在贪睡模式下使用SCI0时，AGT1下溢必须用于中断请求或贪睡结束请求。不要使用任何其他触发器。

在贪睡模式下使用SCI0时，必须满足以下条件：

- 时钟源必须是HOCO
- MOCO、主时钟振荡器和PLL必须在进入软件待机模式之前停止
- 进入软件待机模式前，RXD0引脚必须保持高电平
- 在SCI通信期间不得转换到软件待机模式
- 在进入软件待机模式之前，MSTPCRC.MSTPC0位必须为1。

11.10.12 贪睡模式下AD转换开始的条件

ADC12只能由ELC在贪睡模式下触发。不要使用软件触发或ADTRGn引脚。

11.10.13 贪睡模式下的ELC事件

只有本节中列出的ELC事件在贪睡模式下可用。不要使用任何其他事件。如果进入贪睡模式后第一次启动外围模块，事件链接设置寄存器（ELSRn）必须设置贪睡模式进入事件（SYSTEM_SNZREQ）作为触发器。

- 贪睡模式进入(SYSTEM_SNZREQ)
- DTC传输结束(DTC_DTCEND)
- ADC12n窗口AB比较匹配(ADC12n_WCMPM)(n=0 1)
- ADC12n窗口AB比较失配(ADC12n_WCMPUM)(n=0 1)
- 数据操作电路中断（DOC_DOPCI）。

11.10.14 CTSU在贪睡模式下的情况

CTSU只能由ELC在贪睡模式下启动。

12. Battery Backup Function

12.1 Overview

The MCU provides a battery backup function that maintains partial battery powering in the event of a power loss. Switching between VCC and VBATT, the battery-powered area includes RTC, SOSC, and backup memory.

During normal operation, the battery-powered area is powered by the main power supply, the VCC pin. When a VCC voltage drop is detected, the power source switches to the dedicated battery backup power pin, the VBATT pin. When the voltage rises again, the power source switches back from VBATT to VCC.

12.1.1 Features of Battery Backup Function

The battery backup features include:

- Battery power supply switch
- Backup registers
- Time capture pin detection.

12.1.2 Battery Power Supply Switch

When the voltage applied to the VCC pin drops, this feature switches the power supply from the VCC pin to the VBATT pin. When the voltage rises, it switches the power supply from the VBATT pin back to the VCC pin.

12.1.3 Backup Registers

The battery-powered area provides 512 one-byte backup registers. These registers retain data only when VBATT is supplied and VCC is powered off.

12.1.4 Time Capture Pin Detection

The RTC detects input level changes on the time capture pin. For more information, see section 26, Realtime Clock (RTC).

Note: When VCC is < VDETBATT and > (VBATT + 0.6 V), the injected current flows from the VCC to the VBATT pin through an internal diode. If the power supply battery connected to the VBATT pin cannot support this current injection, for example if the battery is not rechargeable, Renesas strongly recommends that you connect through a low-voltage threshold diode between the power supply battery and the VBATT pin.

Note: You must enable voltage monitor 0 resets to use the battery backup function. The voltage monitor 0 level must be higher than the VBATT switch level.

Figure 12.1 shows the configuration of the battery backup function.

12. 电池备份功能

12.1 Overview

MCU提供电池备份功能，可在断电时保持部分电池供电。
在VCC和VBATT之间切换，电池供电区域包括RTC、SOSC和备份存储器。

在正常工作期间，电池供电区域由主电源VCC引脚供电。当检测到VCC电压下降时，电源切换到专用电池备用电源引脚VBATT引脚。当电压再次上升时，电源从VBATT切换回VCC。

12.1.1 电池备份功能的特点

电池备份功能包括：

- 电池供电开关
- 备份寄存器
- 时间捕捉引脚检测。

12.1.2 电池电源开关

当施加到VCC引脚的电压下降时，此功能将电源从VCC引脚切换到VBATT引脚。当电压上升时，它将电源从VBATT引脚切换回VCC引脚。

12.1.3 备份寄存器

电池供电区提供512个单字节备份寄存器。这些寄存器仅在提供VBATT且VCC断电时保留数据。

12.1.4 时间捕捉引脚检测

RTC检测时间捕捉引脚上的输入电平变化。有关详细信息，请参阅第26节，实时时钟(RTC)。

Note: 当VCC<VDETBATT且>(VBATT+0.6V)时，注入电流通过内部二极管从VCC流向VBATT引脚。如果连接到VBATT引脚的电源电池不能支持这种电流注入，例如，如果电池不可充电，瑞萨强烈建议您通过电源电池和VBATT引脚之间的低压阈值二极管进行连接。

Note: 您必须启用电压监视器0复位才能使用电池备份功能。电压监视器0电平必须高于VBATT开关电平。

图12.1显示了电池备份功能的配置。

The VCHnINEN bit enables the input direction on the associated VBATT channel. Bits associated with non-existent pins are reserved. The write value should be 0.

For more information on CH0 to CH2 associated function, see section 20.5.5, I/O Buffer Specification.

12.3 Operation

12.3.1 Battery Backup Function

When the voltage on the VCC pin drops, power can be supplied to the RTC and sub-clock oscillator from the VBATT pin. When the power supply drop from the VCC pin is detected, the power connection switches from the power supply to the VBATT pin. The power supply from the VCC pin resumes when the voltage on the VCC pin exceeds $V_{DETBATT}$. This power supply change does not affect the RTC operation.

You must enable voltage monitor 0 resets to use the battery backup function. The RTC supports time capture detection when the time capture pin input level changes.

The VBATT pin supplies power to the following modules:

- RTC
- Sub-clock oscillator (including XCIN and XCOUT pins)
- VBATT Backup Register.

Table 12.1 shows the operating states in VBATT mode.

12.3 Operation

12.3.1 电池备份功能

当VCC引脚上的电压下降时，可以从VBATT引脚为RTC和副时钟振荡器供电。当检测到VCC引脚的电源下降时，电源连接从电源切换到VBATT引脚。当VCC引脚上的电压超过VDETBATT时，来自VCC引脚的电源恢复。此电源更改不会影响RTC操作。

您必须启用电压监视器0复位才能使用电池备份功能。RTC支持时间捕捉引脚输入电平变化时的时间捕捉检测。

VBATT引脚为以下模块供电：

- RTC
- 副时钟振荡器（包括XCIN和XCOUT引脚）
- VBATT备份寄存器。

12.3.2 VBATT Battery Power Supply Switch Usage

The battery power supply switch can switch the power supply from the VCC pin to the VBATT pin when the voltage applied to the VCC pin drops. When the voltage rises, this switch changes the power supply from the VBATT pin to the VCC pin.

Note: You must enable voltage monitor 0 resets to use the battery backup function. Voltage monitor 0 level must be higher than the VBATT switch level.

12.3.3 VBATT Backup Register Usage

Use the VBATT backup registers VBTBKRn, where n = 0 to 511, to store or restore data with an 8-bit read or write operation.

12.4 Usage Notes

1. When the voltage level on VBATT is lower than the guaranteed operation range, operation of the sub-clock oscillator and RTC cannot be guaranteed. The RTC must be initialized to restart the power supply after the VBATT pin falls below the guaranteed operating voltage.
2. If a reset is generated while writing to the registers as described in this section, the register values might be lost.
3. When VCC is higher than $V_{DETBATT}$, the VCC and VBATT pins are separated. When VCC is lower than $V_{DETBATT}$ and the switch is connected to the VBATT pin, and if the voltage on VBATT drops lower than VCC - 0.6 V, the current might flow into the VBATT pin through the parasitic diode between the VCC and VBATT pins.
4. During RTC operation using the voltage from the VBATT pin and the I/O ports (P402, P403 and P404) within the backup, the power supply area can only be used as time capture event input pins for the RTC.

12.3.2 VBATT电池电源开关使用

当施加到VCC引脚的电压下降时，电池电源开关可以将电源从VCC引脚切换到VBATT引脚。当电压上升时，该开关将电源从VBATT引脚切换到VCC引脚。

Note: 您必须启用电压监视器0复位才能使用电池备份功能。电压监视器0电平必须高于VBATT开关电平。

12.3.3 VBATT备份寄存器使用

使用VBATT备份寄存器VBTBKRn，其中n=0到511，通过8位读取或写入操作来存储或恢复数据。

12.4 使用说明

1. 当VBATT上的电压电平低于保证工作范围时，不能保证子时钟振荡器和RTC的工作。在VBATT引脚低于保证工作电压后，必须初始化RTC以重新启动电源。
2. 如果在写入本节所述的寄存器时产生复位，则寄存器值可能会丢失。
3. 当VCC高于VDETBATT时，VCC和VBATT引脚是分开的。当VCC低于VDETBATT并且开关连接到VBATT引脚时，如果VBATT上的电压低于VCC0.6V，电流可能通过VCC和VBATT引脚之间的寄生二极管流入VBATT引脚。
4. 在使用来自VBATT引脚和备用IO端口（P402、P403和P404）的电压进行RTC操作期间，电源区域只能用作RTC的时间捕捉事件输入引脚。

IRQMD[1:0]位设置IRQi外部引脚中断源的检测检测方法。有关设置的更多信息，请参见第14.4.4节，外部引脚中断。

FCLKSEL[1:0]位（IRQi数字滤波器采样时钟选择）

FCLKSEL[1:0]位为外部引脚中断请求IRQi选择数字滤波器采样时钟，可选择：

- PCLKB (every cycle)

- PCLKB/64 (once every 64 cycles).

有关数字滤波器的详细信息，请参阅第14.4.3节，数字滤波器。

FLTEN bit (IRQi Digital Filter Enable)

The FLTEN bit enables the digital filter used for the IRQi external pin interrupt sources. The filter is enabled when FLTEN is 1 and disabled when FLTEN is 0. The IRQi pin level is sampled at the clock cycle specified in the FCLKSEL[1:0] bits. When the sampled level matches three times, the output level from the digital filter changes. For details on the digital filter, see section 14.4.3, Digital Filter.

The NMISR register monitors the status of non-maskable interrupt sources. Writes to the NMISR register are ignored. The setting in the Non-Maskable Interrupt Enable Register (NMIER) does not affect the status flags in this register. Before the end of the non-maskable interrupt handler, check that all of the bits in this register are set to 0 to confirm that no other NMI requests have occurred during handler processing.

Note: This register requires halfword access.

The SELSR0 register selects the events that wake up the CPU from Snooze mode. You can only use the events listed in Table 14.4 checked for Canceling Snooze using SELSR0. Events specified in this register are defined as ICU_SNZCANCEL (02Dh) in Table 14.4. When 02Dh is set in IELSRn.IELS, the SELSR0 event interrupt occurs.

SELS[8:0] bits (SYS Event Link Select)

All SELS[8:0] bits must be written to simultaneously.

14.3.2 Event Numbers

The following table lists heading details for Table 14.4, which describes each event number.

Heading	Description
Interrupt request source	Name of the source generating the interrupt request
Name	Name of the interrupt
Connect to NVIC	"✓" indicates the interrupt can be used as a CPU interrupt (IELSRn setting)
Invoke DTC	"✓" indicates the interrupt can be used to request DTC activation (IELSRn setting)
Invoke DMAC	"✓" indicates the interrupt can be used to request DMAC activation (DELSRn setting)
Canceling Snooze mode	"✓" indicates the interrupt can be used to request a return from Snooze mode using SELSR0. Otherwise, "✓" indicates it can be used directly
Canceling Software Standby mode	"✓" indicates the interrupt can be used to request a return from Software Standby mode
Canceling Deep Software Standby mode	"✓" indicates the interrupt can be used to request a return from Deep Software Standby mode

14.4 中断操作

ICU执行以下功能：

- 检测中断
- 启用和禁用中断
- 选择中断请求目标，例如CPU中断、DTC激活或DMAC激活。

RA生态工作室

14.4.1 Detecting Interrupts

External pin interrupt requests are detected by either:

- Edges (falling edge, rising edge, or rising and falling edges) of the interrupt signal
- Level (low level) of the interrupt signal.

Set the IRQMD[1:0] bits in the IRQCRi register to select the detection mode for the IRQi pins. For interrupt sources associated with peripheral modules, see section 14.3.2, Event Numbers. Events must be accepted by the NVIC before an interrupt occurs and is accepted by the CPU.

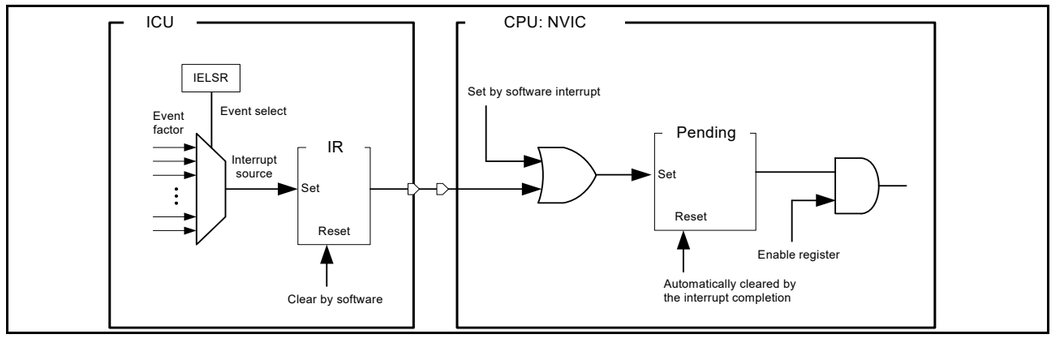

Figure 14.2 Interrupt path of the ICU and CPU: NVIC

Use the following procedures for detecting interrupts.

General operations during an interrupt:

- When a non-software interrupt occurs:
  The IELSRn.IR flag and Interrupt Set/Clear-Pending register (NVIC) are set.
- When a software interrupt occurs:
  Set the Interrupt Set-Pending register.
- When an interrupt is complete:
  Clear the IELSRn.IR flag in the software.
  The Interrupt Set/Clear-Pending register clears automatically.

When interrupts are enabled:

1. Set the Interrupt Set-Enable register (NVIC).
2. Set the IELSRn.IELS bits as the interrupt source.
3. Specify the operation settings for the event source.

When interrupts are disabled:

1. Disable the settings for the event source.
2. Clear the IELSRn.IELS[8:0] bits (IELSRn.IELS[8:0] = 0000h). Clear the IELSRn.IR flag as required.
3. Clear the Interrupt Clear-Enable register. Clear the Interrupt Clear-Pending register as required.

When polling for interrupts:

1. Set the Interrupt Clear-Enable register (disabling interrupts).
2. Set the IELSRn.IELS[8:0] bits (selecting the source).
3. Specify the operation settings for the event source.
4. Poll the Interrupt Set-Pending register.
5. When polling is no longer required, follow the procedure for clearing an interrupt when it is complete. Clear the IELSRn.IR flag through software.

14.4.1 检测中断

外部引脚中断请求通过以下任一方式检测：

- 中断信号的边沿（下降沿、上升沿或上升沿和下降沿）
- 中断信号的电平（低电平）。

设置IRQCRi寄存器中的IRQMD[1:0]位以选择IRQi引脚的检测模式。对于与外围模块相关的中断源，请参见第14.3.2节，事件编号。事件必须在中断发生之前被NVIC接受并被CPU接受。

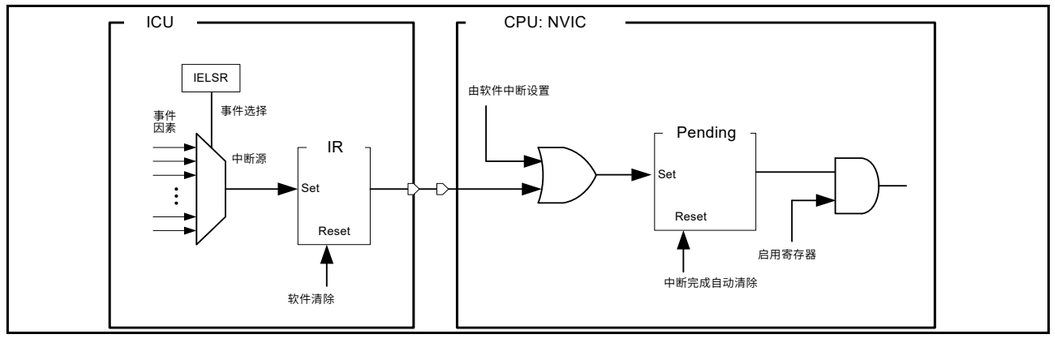

Figure 14.2 ICU和CPU的中断路径：NVIC

使用以下过程检测中断。

中断期间的一般操作：

- 当发生非软件中断时：
  IELSRn.IR标志和中断设置清除挂起寄存器(NVIC)已设置。
- 当发生软件中断时：
  设置中断设置挂起寄存器。
- 当中断完成时：
  清除软件中的IELSRn.IR标志。
  中断设置清除挂起寄存器自动清除。

启用中断时：

1. 设置中断设置启用寄存器(NVIC)。
2. 将IELSRn.IELS位设置为中断源。
3. 指定事件源的操作设置。

当中断被禁用时：

1. 禁用事件源的设置。
2. 清除IELSRn.IELS[8:0]位(IELSRn.IELS[8:0]=0000h)。根据需要清除IELSRn.IR标志。
3. 清除中断清除启用寄存器。根据需要清除中断清除挂起寄存器。

轮询中断时：

1. 设置中断清除启用寄存器（禁用中断）。
2. 设置IELSRn.IELS[8:0]位（选择源）。
3. 指定事件源的操作设置。
4. 轮询中断设置挂起寄存器。
5. 当不再需要轮询时，按照完成后清除中断的过程。清除
   IELSRn.IR标志通过软件。

14.4.2 Selecting Interrupt Request Destinations

The interrupt output destination, CPU, DTC, or DMAC, can be independently selected for each interrupt source. The available destinations are fixed for each interrupt, as described in Table 14.4.

Note: Do not use an interrupt request destination setting that is not indicated by a "✓" in the event list (Table 14.4).

If you select the CPU or DTC in one IELSRn register, setting the same interrupt factor in any other IELSRn register is prohibited. Similarly, if you select the DMAC in one DELSRn register, setting the same interrupt factor in any other DELSRn register is prohibited.

Note: Setting the same interrupt factor for IELSRn and DELSRn is prohibited.

If the DMAC or DTC is selected as the destination for requests from an IRQi pin, you must set the IRQMD[1:0] bits in IRQCRi for that interrupt to select edge detection.

14.4.2.1 CPU interrupt request

When IELSRn.DTCE = 0, the event specified in the IELSRn register is output to the NVIC. Set the IELSRn.IELS bits to the target event and the IELSRn.DTCE bit to 0.

14.4.2.2 DTC activation

When IELSRn.DTCE = 1, the event specified in the IELSRn register is output to the DTC. After DTC transmission completes, the associated interrupt occurs. Use the following procedure:

1. Set the IELSRn.IELS bits to the target event and the IELSRn.DTCE bit to 1.
2. Set the DTC module start bit (DTCST.DTCST) to 1.

Table 14.5 shows operation when the DTC is the request destination.

Table 14.5 Operations when the DTC is activated

Interrupt request destination	DISEL*1	Remaining transfer operations	Operations per request	IR*2	Interrupt request destination after transfer
DTC*3	1	≠ 0	DTC transfer → CPU interrupt	Cleared on interrupt acceptance by the CPU	DTC
		= 0	DTC transfer → CPU interrupt	Cleared on interrupt acceptance by the CPU	The IELSRn.DTCE bit is cleared and the CPU becomes the destination
	0	≠ 0	DTC transfer	Cleared at the start of DTC data transfer after DTC transfer data is read	DTC
		= 0	DTC transfer → CPU interrupt	Cleared on interrupt acceptance by the CPU	The IELSRn.DTCE bit is cleared and the CPU becomes the destination

Note 1. Set the interrupt request mode for the DTC in the DTC.MRB.DISEL bit.
Note 2. When the IELSRn.IR flag is 1, an interrupt request (DTC activation request) that occurs again is ignored.
Note 3. For chain transfers, DTC transfer continues until the last chain transfer ends. At this point, the DISEL bit state and the remaining transfer count determine whether a CPU interrupt occurs, the IELSRn.IR flag clear timing, and the interrupt request destination after transfer. See Table 18.3, Chain transfer conditions, in section 18, Data Transfer Controller (DTC).

14.4.2.3 DMAC activation

Events specified in the DELSRn registers are output to the DMAC. When using interrupts, you must select the DMAC as the interrupt source in the IELSRn.IELS[8:0] bits and enable DMAC output by setting IELSRn.DTCE to 1. When IELSRn.DTCE is 0, the events specified in the IELSRn registers are output to the NVIC. Use the following procedure:

1. Set the DELSRn.DELS[8:0] bits to the target event.

14.4.2 选择中断请求目标

可以为每个中断源独立选择中断输出目标CPU、DTC或DMAC。每个中断的可用目的地都是固定的，如表14.4中所述。

Note: 请勿使用事件列表（表14.4）中未用" "表示的中断请求目标设置。

如果在一个IELSRn寄存器中选择CPU或DTC，则禁止在任何其他IELSRn寄存器中设置相同的中断因子。同样，如果您在一个DELSRn寄存器中选择DMAC，则禁止在任何其他DELSRn寄存器中设置相同的中断因子。

Note: 禁止为IELSRn和DELSRn设置相同的中断因子。

如果选择DMAC或DTC作为来自IRQi引脚的请求的目标，则必须将IRQMD[1:0]位设置为IRQCRi用于选择边缘检测的中断。

14.4.2.1 CPU中断请求

当IELSRn.DTCE=0时，将IELSRn寄存器中指定的事件输出到NVIC。将IELSRn.IELS位设置为目标事件，并将IELSRn.DTCE位设置为0。

14.4.2.2 DTC activation

当IELSRn.DTCE=1时，将IELSRn寄存器中指定的事件输出到DTC。DTC传输完成后，将发生相关中断。使用以下过程：

1. 将IELSRn.IELS位设置为目标事件，并将IELSRn.DTCE位设置为1。
2. 将DTC模块起始位(DTCST.DTCST)设置为1。

表14.5显示了DTC是请求目的地时的操作。

Table 14.5 DTC激活时的操作

中断请求目的地	DISEL*1	剩余的转移操作	每个请求的操作	IR*2	传输后的中断请求目的地
DTC*3	1	≠ 0	DTC传输 CPU中断	CPU接受中断时清零	DTC
		= 0	DTC传输 CPU中断	CPU接受中断时清零	IELSRn.DTCE位清零，CPU成为目标
	0	≠ 0	DTC transfer	读取DTC传输数据后，在DTC数据传输开始时清零	DTC
		= 0	DTC传输 CPU中断	CPU接受中断时清零	IELSRn.DTCE位清零，CPU成为目标

Note 1. 在DTC.MRB.DISEL位中设置DTC的中断请求模式。
Note 2. IELSRn.IR标志为1时，忽略再次发生的中断请求（DTC激活请求）。
Note 3. 对于链式传输，DTC传输将持续到最后一个链式传输结束。此时，DISEL位状态和剩余传输计数决定是否发生CPU中断、IELSRn.IR标志清除时序以及传输后的中断请求目的地。请参阅第18节，数据传输控制器(DTC)中的表18.3，链传输条件。

14.4.2.3 DMAC activation

在DELSRn寄存器中指定的事件被输出到DMAC。使用中断时，必须在IELSRn.IELS[8:0]位中选择DMAC作为中断源，并通过将IELSRn.DTCE设置为1来使能DMAC输出。当IELSRn.DTCE为0时，在IELSRn寄存器中指定的事件输出到NVIC。使用以下过程：

1. 将DELSrn.DELS[8:0]位设置为目标事件。

2. When using interrupts, set the IELSRn.IELS bit to DMAC interrupts as the source, and set the IELSRn.DTCE bit to 1.
3. Set the activation source for the target DMAC channel (DMACm.DMTMD.DCTG[1:0]) to 01b (interrupt module detection).
4. Set the DMAC transfer enable bit for the target DMAC channel (DMACm.DMCNT.DTE) to 1.
5. Set the DMAC operation enable bit (DMACm.DMAST.DMST) to 1.

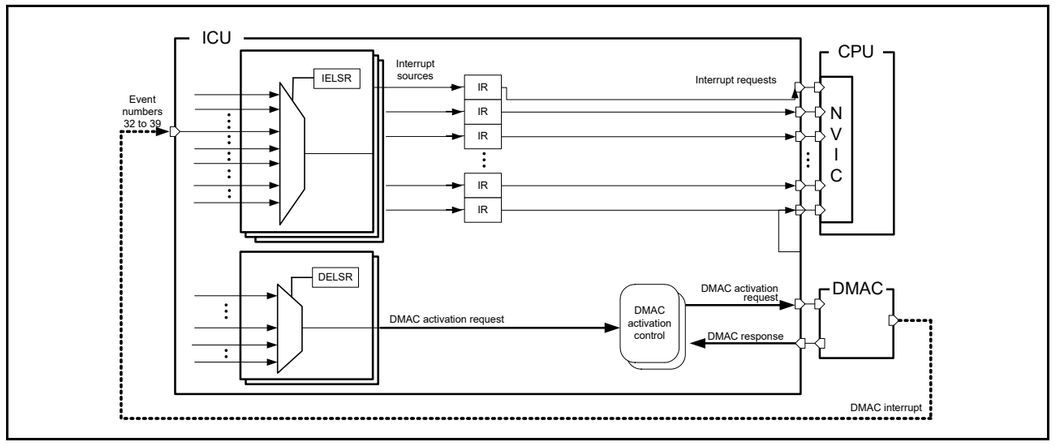

Figure 14.3 DMAC request trigger and interrupt path

14.4.3 Digital Filter

A digital filter function is provided for the external interrupt request pins (IRQi, i = 0 to 13) and NMI pin interrupt. It samples input signals on the filter PCLKB sampling clock, and removes any signal with a pulse width less than 3 sampling cycles.

To use the digital filter for an IRQi pin:

1. Set the sampling clock cycle to PCLKB, PCLKB/8, PCLKB/32, or PCLKB/64 in the IRQCRi.FCLKSEL[1:0] bits.
2. Set the IRQCRi.FLTEN bit to 1 (digital filter enabled).

To use the digital filter for the NMI pin:

1. Set the sampling clock cycle to PCLKB, PCLKB/8, PCLKB/32, or PCLKB/64 in the NMICR.NFCLKSEL[1:0] bits.
2. Set the NMICR.NFLTEN bit to 1 (digital filter enabled).

Figure 14.4 shows an example of digital filter operation.

2. 使用中断时，将IELSRn.IELS位设置为DMAC中断作为源，并将IELSRn.DTCE位设置为1。
3. 将目标DMAC通道(DMACm.DMTMD.DCTG[1:0])的激活源设置为01b（中断模块检测）。
4. 将目标DMAC通道(DMACm.DMCNT.DTE)的DMAC传输使能位设置为1。
5. 将DMAC操作使能位(DMACm.DMAST.DMST)设置为1。

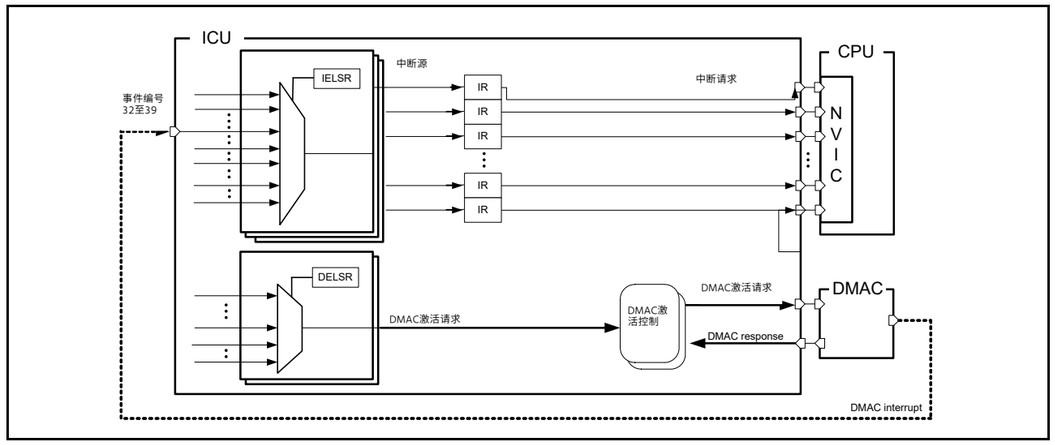

Figure 14.3 DMAC请求触发和中断路径

14.4.3 数字滤波器

为外部中断请求引脚（IRQi，i=0至13）和NMI引脚中断提供了数字过滤功能。它在滤波器PCLKB采样时钟上对输入信号进行采样，并去除脉冲宽度小于3个采样周期的任何信号。

为IRQi引脚使用数字滤波器：

1. 在IRQCRi.FCLKSEL[1:0]位中将采样时钟周期设置为PCLKB、PCLKB8、PCLKB32或PCLKB64。
2. 将IRQCRi.FLTEN位设置为1（启用数字滤波器）。

为NMI引脚使用数字滤波器：

1. 在NMICR.NFCLKSEL[1:0]位中将采样时钟周期设置为PCLKB、PCLKB8、PCLKB32或PCLKB64。
2. 将NMICR.NFLTEN位设置为1（启用数字滤波器）。

图14.4显示了数字滤波器操作的示例。

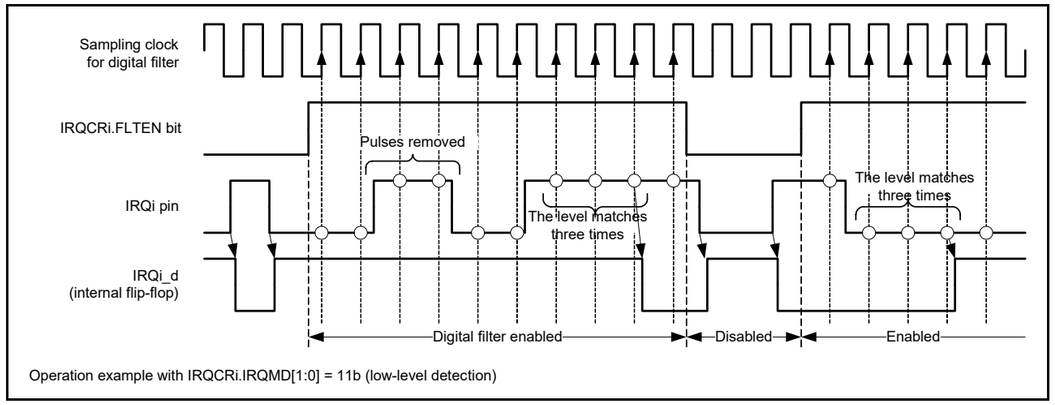

Figure 14.4 Digital filter operation example

Before entering Software Standby mode, disable the digital filters by clearing the IRQCRi.FLTEN and NMICR.NFLTEN bits. The clock for the ICU stops in Software Standby mode. On exiting Software Standby, the circuit detects the edge by comparing the state before standby to the state after standby release. If the input changes during Software Standby, an incorrect edge might be detected. You can enable the digital filters again after exiting Software Standby mode.

14.4.4 External Pin Interrupts

To use external pin interrupts:

1. Clear the IRQCRi.FLTEN bit (i = 0 to 13) to 0 (digital filter disabled).
2. Set or confirm the I/O port settings.
3. Set the IRQMD[1:0] bits, FCLKSEL[1:0] bits, and FLTEN bit of the IRQCRi register.
4. Select the IRQ pin as follows:
   - If the IRQ pin is to be used for CPU interrupt requests, set the IELSRn.IELS bits and set the IELSRn.DTCE bit to 0
   - If the IRQ pin is to be used for DTC activation, set the IELSRn.IELS bits and set the IELSRn.DTCE bit to 1
   - If the IRQ pin is to be used for DMAC activation, set the DELSRn.DELS bits.

14.5 Non-Maskable Interrupt Operation

The following sources can trigger a non-maskable interrupt:

- NMI pin interrupt
- Oscillation stop detection interrupt
- WDT underflow/refresh error interrupt
- IWDT underflow/refresh error interrupt
- Voltage monitor 1 interrupt
- Voltage monitor 2 interrupt
- SRAM parity error interrupt
- SRAM ECC error interrupt
- MPU bus master error interrupt
- MPU bus slave error interrupt
- CPU stack pointer monitor interrupt.

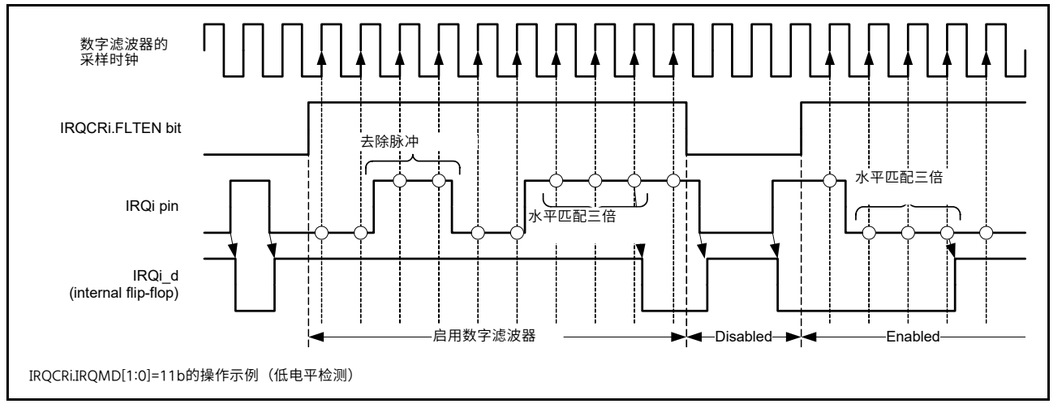

Figure 14.4 数字滤波器操作示例

在进入软件待机模式之前，通过清除IRQCRi.FLTEN和NMICR.NFLTEN位来禁用数字滤波器。ICU的时钟在软件待机模式下停止。在退出软件待机时，电路通过将待机前的状态与待机释放后的状态进行比较来检测边沿。如果在软件待机期间输入发生变化，则可能会检测到不正确的边沿。您可以在退出软件待机模式后再次启用数字滤波器。

14.4.4 外部引脚中断

要使用外部引脚中断：

1. 将IRQCRi.FLTEN位（i=0到13）清零（禁用数字滤波器）。
2. 设置或确认IO端口设置。
3. 设置IRQCRi寄存器的IRQMD[1:0]位、FCLKSEL[1:0]位和FLTEN位。
4. 选择IRQ引脚如下：
   - 如果IRQ引脚用于CPU中断请求，设置IELSRn.IELS位并将IELSRn.DTCE位设置为0
   - 如果IRQ引脚用于DTC激活，设置IELSRn.IELS位并将IELSRn.DTCE位设置为1
   - 如果IRQ引脚用于DMAC激活，则设置DELSRn.DELS位。

14.5 不可屏蔽中断操作

以下源可以触发不可屏蔽中断：

- NMI引脚中断
- 振荡停止检测中断
- WDT下溢刷新错误中断
- IWDT下溢刷新错误中断
- 电压监视器1中断
- 电压监视器2中断
- SRAM奇偶校验错误中断
- SRAMECC错误中断
- MPU总线主机错误中断
- MPU总线从机错误中断
- CPU堆栈指针监视中断。

Non-maskable interrupts can only be used with the CPU, not to activate the DTC or DMAC. Non-maskable interrupts take precedence over all other interrupts. The non-maskable interrupt states can be verified in the Non-Maskable Interrupt Status Register (NMISR). Confirm that all bits in the NMISR are 0 before returning from the NMI handler.

Non-maskable interrupts are disabled by default. To use non-maskable interrupts, you must:

1. Clear the NMICR.NFLTEN bit to 0 (digital filter disabled) to use the NMI pin.
2. Set the NMIMD bit, NFCLKSEL[1:0] bits, and NFLTEN bit of NMICR register to use the NMI pin.
3. Write 1 to the NMICLR.NMICLR bit to clear the NMISR.NMIST flag to 0 to use the NMI pin.
4. Enable the non-maskable interrupt by writing 1 to the associated bit in the Non-Maskable Interrupt Enable Register (NMIER).

After 1 is written to the NMIER register, subsequent write access to the NMIEN bit in NMIER is ignored. An NMI interrupt cannot be disabled when enabled, except by a reset.

14.6 Return from Low Power Modes

Table 14.4 lists the interrupt sources you can use to exit Sleep or Software Standby mode. For more information, see section 11, Low Power Modes. Sections 14.6.1 to 14.6.3 describe how to use interrupts to return from Sleep, Software Standby, and Snooze modes. For Deep Software Standby mode, see section 11.9, Deep Software Standby Mode.

14.6.1 Return from Sleep Mode

To return from Sleep mode in response to an interrupt:

1. Select the CPU as the interrupt request destination.
2. Enable the interrupt in the NVIC.

To return from Sleep mode in response to a non-maskable interrupt, use the NMIER register to enable the target interrupt request.

14.6.2 Return from Software Standby Mode

The ICU can return from Software Standby mode using a non-maskable interrupt or an interrupt selected in the WUPEN register. See section 14.2.9, Wake Up Interrupt Enable Register (WUPEN).

To return from Software Standby mode:

1. Select the interrupt source that enables return from Software Standby:
   - For non-maskable interrupts, use the NMIER register to enable the target interrupt request
   - For maskable interrupts, use the WUPEN register to enable the target interrupt request.
2. Select the CPU as the interrupt request destination.
3. Enable the interrupt in the NVIC.

Interrupt requests through the IRQ pins that do not satisfy these conditions are not detected while the clock is stopped in Software Standby mode.

14.6.3 Return from Snooze Mode

The ICU can return to Normal mode from Snooze mode using the interrupts provided for this mode.

To return to Normal mode from Snooze mode:

1. Use either of the following methods to select the event that you want to trigger a return to Normal mode from Snooze mode:
   - Set the event that you want to trigger a return to Normal mode from Snooze mode in SELSR0.SEL and set the value 02Dh (ICU_SNZCANCEL) in IELSRn.IELS[8:0]
   - Set the event that you want to trigger a return to Normal mode from Snooze mode in IELSRn.IELS[8:0].
2. Select the CPU as the interrupt request destination.

不可屏蔽中断只能用于CPU，不能激活DTC或DMAC。不可屏蔽中断优先于所有其他中断。不可屏蔽中断状态可以在不可屏蔽中断状态寄存器(NMISR)中验证。在从NMI处理程序返回之前，确认NMISR中的所有位都为0。

默认情况下禁用不可屏蔽中断。要使用不可屏蔽中断，您必须：

1. 将NMICR.NFLTEN位清零（禁用数字滤波器）以使用NMI引脚。
2. 设置NMICR寄存器的NMIMD位、NFCLKSEL[1:0]位和NFLTEN位以使用NMI引脚。
3. 将1写入NMICLR.NMICLR位以将NMISR.NMIST标志清零以使用NMI引脚。
4. 通过将1写入不可屏蔽中断启用寄存器(NMIER)中的相关位来启用不可屏蔽中断。

将1写入NMIER寄存器后，随后对NMIER中的NMIEN位的写访问将被忽略。启用时不能禁用NMI中断，除非通过复位。

14.6 从低功耗模式返回

表14.4列出了可用于退出睡眠或软件待机模式的中断源。有关详细信息，请参阅第11节，低功耗模式。14.6.1到14.6.3节描述了如何使用中断从休眠、软件待机和贪睡模式返回。对于深度软件待机模式，请参阅第11.9节，深度软件待机模式。

14.6.1 从睡眠模式返回

从睡眠模式返回以响应中断：

1. 选择CPU作为中断请求目标。
2. 在NVIC中启用中断。

要从休眠模式返回以响应不可屏蔽的中断，请使用NMIER寄存器来启用目标中断请求。

14.6.2 从软件待机模式返回

ICU可以使用不可屏蔽中断或在WUPEN寄存器中选择的中断从软件待机模式返回。请参见第14.2.9节，唤醒中断使能寄存器(WUPEN)。

从软件待机模式返回：

1. 选择允许从软件待机返回的中断源：
   - 对于不可屏蔽中断，使用NMIER寄存器启用目标中断请求
   - 对于可屏蔽中断，使用WUPEN寄存器启用目标中断请求。
2. 选择CPU作为中断请求目标。
3. 在NVIC中启用中断。

不满足这些条件的通过IRQ引脚的中断请求在时钟停止时不会被检测到
软件待机模式。

14.6.3 从贪睡模式返回

ICU可以使用为该模式提供的中断从贪睡模式返回到正常模式。

要从贪睡模式返回正常模式：

1. 使用以下任一方法选择要触发返回正常模式的事件
   Snooze mode:
   - 在SELSR0.SEL中设置要触发从贪睡模式返回正常模式的事件，并在IELSRn.IELS[8:0]中设置值02Dh(ICU_SNZCANCEL)
   - 在IELSRn.IELS[8:0]中设置要触发从贪睡模式返回正常模式的事件。
2. 选择CPU作为中断请求目标。

3. Enable the interrupt in the NVIC.

Note: In Snooze mode, a clock is supplied to the ICU. If an event selected in IELSRn is detected, the CPU can acknowledge the interrupt after returning to Normal mode from Software Standby mode. If an event selected in DELSRn is detected, the DMAC can acknowledge the interrupt after returning to Normal mode from Software Standby mode.

14.7 Using the WFI Instruction with Non-Maskable Interrupts

Whenever a WFI instruction is executed, confirm that all status flags in the NMISR register are 0.

14.8 Reference

ARM® Cortex®-M4 Processor Technical Reference Manual (ARM DDI 0439D).

3. 在NVIC中启用中断。

Note: 在贪睡模式下，向ICU提供时钟。如果检测到在IELSRn中选择的事件，CPU可以在从软件待机模式返回到正常模式后确认中断。如果检测到在DELSRn中选择的事件，则DMAC可以在从软件返回到正常模式后确认中断

待机模式。

14.7 将WFI指令与不可屏蔽中断一起使用

每当执行WFI指令时，请确认NMISR寄存器中的所有状态标志为0。

Arbitration between the DMAC and DTC for the mastership of the DMA bus occurs in the DMAC and DTC. The following fixed-priority order is used:

DMAC0 > DMAC1 > DMAC2 > DMAC3 > DMAC4 > DMAC5 > DMAC6 > DMAC7 > DTC.

Only one DTC channel and DMAC channel that have accepted the activation requests can issue the bus mastership request. In addition, requests for bus access from masters other than the DTC are not accepted during reads of transfer control information for the DTC.

The arbitration protocol is selectable as either fixed-priority or round-robin. For more information, see section 15.3.8, Slave Bus Control Register (BUSSCNT<slave>).

15.2.2 Slave Interface

Products using the Cortex®-M4 core contain ICode and DCode bus areas and a system bus area.

To create the ICode and DCode bus areas, a bus matrix connects the ICode bus, DCode bus, and memory bus 3 from the main bus to the slave interfaces of the code flash memory and SRAMHS. Bus access to the slave interfaces is arbitrated between the three buses. The arbitration protocol is selectable as either fixed-priority or round-robin. For more information, see section 15.3.8, Slave Bus Control Register (BUSSCNT<slave>).

To create the system bus area, a bus matrix connects the system bus, and DMA bus from the main bus to the slave interfaces of the SRAM0, Standby SRAM, data flash memory, internal peripherals, and external bus. Bus access to the slave interfaces is arbitrated between the three buses. The arbitration protocol is selectable as either fixed-priority or round-robin. For more information, see section 15.3.8, Slave Bus Control Register (BUSSCNT<slave>).

For connections from the main bus to the slave interfaces, see the slave interfaces in Table 15.1. For a description of the external bus, see section 15.2.3, External Bus.

Different master and slave transfer combinations can proceed simultaneously.

15.2.3 External Bus

The external bus controller arbitrates requests for bus access on the external address space from the CPU system bus, and DMAC bus. The priority order can be set using the external bus priority control bits (BUSSCNT.ARBMET[1:0]). For more information, see section 15.3.8, Slave Bus Control Register (BUSSCNT<slave>).

The bus system provides an external space for the QSPI. See section 35, Quad Serial Peripheral Interface (QSPI).

Table 15.3 lists the external bus specifications and Table 15.4 lists the I/O pins.

Table 15.3 External bus specifications (1 of 2)

Parameter	Specifications
External address space	• The external address space is divided into 6 CS areas (CS0, CS1, CS4 to CS7) for management • Chip select signals can be output for each area • The bus width can be set for each area: - Separate bus: 8-bit bus space - Address/data multiplexed bus: 8-bit bus space. • Endian mode can be specified for each area.
CS area controller	• Recovery cycles can be inserted: - Read recovery: Up to 15 cycles - Write recovery: Up to 15 cycles. • Cycle wait function: Wait for up to 31 cycles (for page access, up to 7 cycles) • Use wait control to set up: - Assertion and negation timing of chip select signals (CS0, CS1, CS4 to CS7) - Assertion timing of the read signal (RD) and write signals (WR0) - Timing of data output starts and ends. • Write access mode: - Byte strobe mode. • Separate bus or address/data multiplexed bus can be set for each area.
Write buffer function	When write data from the bus master is written to the write buffer, write access by the bus master is complete

DMAC和DTC之间对DMA总线的主控权的仲裁发生在DMAC和DTC中。使用以下固定优先级顺序：

DMAC0 > DMAC1 > DMAC2 > DMAC3 > DMAC4 > DMAC5 > DMAC6 > DMAC7 > DTC.

只有接受了激活请求的DTC通道和DMAC通道可以发出总线主控请求。此外，在读取DTC的传输控制信息期间，不接受来自DTC以外的主机的总线访问请求。

仲裁协议可选择为固定优先级或循环。有关详细信息，请参阅第15.3.8节，从总线控制寄存器（BUSSCNT<slave>）。

15.2.2 从接口

使用Cortex®-M4内核的产品包含ICode和DCode总线区域以及系统总线区域。

为了创建ICode和DCode总线区域，总线矩阵将ICode总线、DCode总线和存储器总线3从主总线连接到代码闪存和SRAMHS的从接口。对从接口的总线访问在三个总线之间进行仲裁。仲裁协议可选择为固定优先级或循环。更多信息，请参见第15.3.8节，从总线控制寄存器(BUSSCNT<slave>)。

为了创建系统总线区域，总线矩阵将系统总线和DMA总线从主总线连接到SRAM0、备用SRAM、数据闪存、内部外围设备和外部总线的从接口。对从接口的总线访问在三个总线之间进行仲裁。仲裁协议可选择为固定优先级或循环。更多信息，请参见第15.3.8节，从总线控制寄存器(BUSSCNT<slave>)。

对于从主总线到从接口的连接，请参见表15.1中的从接口。有关外部总线的描述，请参见第15.2.3节，外部总线。

不同的主从传输组合可以同时进行。

15.2.3 外部总线

外部总线控制器对来自CPU系统总线的外部地址空间的总线访问请求进行仲裁，并且DMAC总线。可以使用外部总线优先级控制位(BUSSCNT.ARBMET[1:0])设置优先级顺序。更多信息，请参见第15.3.8节，从总线控制寄存器(BUSSCNT<slave>)。

总线系统为QSPI提供了一个外部空间。请参见第35节，四通道串行外设接口(QSPI)。

15.2.4 Parallel Operations

Parallel operations are possible when different bus masters request access to different slave modules. For example, if the CPU fetches an instruction from the flash and an operand from the SRAM, the DMAC can handle transfers between a peripheral bus and the external bus at the same time.

An example of parallel operations is shown in Figure 15.2. In this example, the CPU uses the instruction and operand buses for simultaneous access to the flash and SRAM, respectively. Additionally, the DMAC/DTC simultaneously use the DMA bus (DMAC/DTC) for access to a peripheral bus or external bus during access to the flash memory and SRAM by the CPU.

15.2.4 并行操作

当不同的总线主机请求访问不同的从模块时，并行操作是可能的。例如，如果CPU从闪存中获取指令，从SRAM中获取操作数，DMAC可以同时处理外设总线和外部总线之间的传输。

图15.2显示了并行操作的示例。在本例中，CPU使用指令和操作数总线分别同时访问闪存和SRAM。此外，在CPU访问闪存和SRAM期间，DMACDTC同时使用DMA总线(DMACDTC)访问外围总线或外部总线。

b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Do not attempt to write to the CSnCR register while the external bus is being accessed.

EXENB bit (Operation Enable)

The EXENB bit enables operation of the associated CS area. On MCU reset, operation is enabled (EXENB = 1) only for area 0. Operation in other areas is disabled (EXENB = 0). Attempts to access disabled areas have no effect.

BSIZE[1:0] bits (External Bus Width Select)

The BSIZE[1:0] bits specify the data bus width for the associated area. These bits must be set to 10b before writing 1 to the EXENB bit.

EMODE bit (Endian Mode)

The EMODE bit specifies the endianness for the associated area. The Cortex®-M4 core is fixed at little-endian order, so instruction code can only be allocated to external spaces with little-endian specified. If an area is specified as big-endian, no instruction code can be allocated to it.

MPXEN bit (Address/Data Multiplexed I/O Interface Select)

Th MPXEN bit specifies separate bus interface or address/data multiplexed I/O interface of each area.

在访问外部总线时不要尝试写入CSnCR寄存器。

EXENB位（操作使能）

EXENB位使能相关CS区域的操作。在MCU复位时，仅允许区域0的操作（EXENB=1）。禁止其他区域的操作（EXENB=0）。尝试进入残疾人区没有效果。

BSIZE[1:0]位（外部总线宽度选择）

BSIZE[1:0]位指定相关区域的数据总线宽度。在将1写入EXENB位之前，这些位必须设置为10b。

EMODE位（字节序模式）

EMODE位指定相关区域的字节顺序。Cortex®-M4内核固定为little-endian顺序，因此指令代码只能分配到指定little-endian的外部空间。如果一个区域被指定为大端，则不能为其分配指令代码。

MPXEN位（地址数据复用IO接口选择）

MPXEN位指定每个区域的单独总线接口或地址数据复用IO接口。

Do not attempt to write to the CSnREC register while the external bus is being accessed.

When the preceding bus access is from a separate bus, CSnREC is valid when the recovery cycle insertion is enabled in the Separate Bus Recovery Cycle Insertion Enable bit (RCVENi (i = 0 to 7)) in CSRECEN. When the preceding bus access is an address/data multiplexed bus access, CSnREC is valid when the recovery cycle insertion is enabled with the Multiplexed Bus Recovery Cycle Insertion Enable bit (RCVENMj (j = 0 to 7)) in CSRECEN. For more information, see section 15.5.4, Insertion of Recovery Cycles.

RRCV[3:0] bits (Read Recovery)

The RRCV[3:0] bits specify the number of recovery cycles inserted after a read access on the external bus for CSn (n = 0, 1, 4 to 7). When recovery cycle insertion is enabled and a value other than 0000b is set, 1 to 15 recovery cycles are inserted when:

- After a read access to the external bus, a read access is made to the external bus in the same area
- After a read access to the external bus, a read access is made to the external bus in a different area
- After a read access to the external bus, a write access is made to the external bus in the same area
- After a read access to the external bus, a write access is made to the external bus in a different area.

WRCV[3:0] bits (Write Recovery)

The WRCV[3:0] bits specify the number of recovery cycles inserted after a write access on the external bus for CSn (n = 0, 1, 4 to 7). When recovery cycle insertion is enabled and a value other than 0000b is set, 1 to 15 recovery cycles are inserted when:

- After a write access to the external bus, a read access is made to the external bus in the same area
- After a write access to the external bus, a read access is made to the external bus in a different area
- After a write access to the external bus, a write access is made to the external bus in the same area
- After a write access to the external bus, a write access is made to the external bus in a different area.

在访问外部总线时不要尝试写入CSnREC寄存器。

当前面的总线访问来自单独的总线时，CSnREC在CSRECEN的单独总线恢复周期插入使能位(RCVENi(i=0to7))中使能恢复周期插入时有效。当前面的总线访问是地址数据多路复用总线访问时，CSnREC在通过CSRECEN中的多路复用总线恢复周期插入使能位(RCVENMj(j=0至7))使能恢复周期插入时有效。有关详细信息，请参阅第15.5.4节，恢复周期的插入。

RRCV[3:0]位（读取恢复）

RRCV[3:0]位指定在CSn的外部总线上进行读访问后插入的恢复周期数（n=0、1、4到7）。当启用恢复周期插入并设置0000b以外的值时，在以下情况下插入1到15个恢复周期：

- 对外部总线进行读访问后，对同一区域的外部总线进行读访问
- 对外部总线进行读访问后，对不同区域的外部总线进行读访问
- 对外部总线进行读访问后，对同一区域的外部总线进行写访问
- 在对外部总线进行读访问之后，对不同区域中的外部总线进行写访问。

WRCV[3:0]位（写恢复）

WRCV[3:0]位指定在CSn的外部总线上进行写访问后插入的恢复周期数（n=0、1、4到7）。当启用恢复周期插入并设置0000b以外的值时，在以下情况下插入1到15个恢复周期：

- 对外部总线进行写访问后，对同一区域的外部总线进行读访问
- 对外部总线进行写访问后，对不同区域的外部总线进行读访问
- 对外部总线进行写访问后，对同一区域的外部总线进行写访问

RCVENi bit (Separate Bus Recovery Cycle Insertion Enable i) (i = 0 to 7)

The RCVENi bit enables the insertion of read or write recovery cycles when, after a read or write access on the external bus, a read or write access is made on the external bus to the same or different area.

RCVENMj bit (Multiplexed Bus Recovery Cycle Insertion Enable j) (j = 0 to 7)

WRMOD bit (Write Access Mode Select)

The WRMOD bit selects the write access operating mode. Writing 0 selects byte strobe mode. Writing 1 is prohibited.

EWENB bit (External Wait Enable)

The EWENB bit enables external waits. Writing 0 disables the WAIT signal. Writing 1 selects external wait and allows the WAIT signal to control the number of waits per cycle. In this state, wait cycles are inserted when the WAIT signal is low.

PRENB bit (Page Read Access Enable)

The PRENB bit enables page read accesses.

Note: When the address/data multiplexed I/O interface is selected with the CSnCR.MPXEN bit, PRENB should not be set because page read accesses are not supported in the address/data multiplexed I/O interface.

PWENB bit (Page Write Access Enable)

The PWENB bit enables page write accesses.

Note: When the address/data multiplexed I/O interface is selected with the CSnCR.MPXEN bit, PWENB should not be set because page write accesses are not supported in the address/data multiplexed I/O interface.

PRMOD bit (Page Read Access Mode Select)

The PRMOD bit selects the operating mode for page read accesses. Writing 0 selects normal access compatible mode, in which the RD signal is negated and an RD assert wait is inserted each time a unit of data is read. When there is no RD assert wait, the RD signal is negated only in the final transfer of the external bus access.

Writing 1 selects external data read continuous assertion mode, in which an RD assert wait is inserted and the RD signal is continuously asserted during the wait.

WRMOD位（写访问模式选择）

WRMOD位选择写访问操作模式。写0选择字节选通模式。禁止写1。

EWENB位（外部等待使能）

EWENB位使能外部等待。写入0禁用WAIT信号。写1选择外部等待并允许WAIT信号控制每个周期的等待数。在这种状态下，当WAIT信号为低时插入等待周期。

PRENB位（页面读取访问使能）

PRENB位使能页面读取访问。

Note: 当使用CSnCR.MPXEN位选择地址数据复用IO接口时，不应设置PRENB，因为地址数据复用IO接口不支持页面读取访问。

PWENB位（页写访问使能）

PWENB位使能页写访问。

Note: 当使用CSnCR.MPXEN位选择地址数据复用IO接口时，不应设置PWENB，因为地址数据复用IO接口不支持页面写访问。

PRMOD位（页面读取访问模式选择）

PRMOD位选择页面读取访问的操作模式。写入0选择正常访问兼容模式，其中RD信号被否定，并且每次读取一个数据单元时插入一个RD断言等待。当没有RD断言等待时，RD信号仅在外部总线访问的最终传输中被否定。

写1选择外部数据读取连续断言模式，在该模式下插入一个RD断言等待，并且在等待期间RD信号连续断言。

CSROFF[2:0] bits (Read-Access CS Extension Cycle Select)

The CSROFF[2:0] bits specify the number of wait cycles to be inserted during the period from the end of a wait cycle (RD signal negated) until the CSn signal (n = 0, 1, 4 to 7) is negated in read access mode.

Table 15.6 lists the registers associated with each bus type.

ARBMET[1:0] bits (Arbitration Method)

The ARBMET[1:0] bits specify the arbitration protocol, with priority defined for all bus masters. For fixed priority, see Table 15.7. For round-robin, see Table 15.8.

EWRES bit (Early Write Response)

The EWRES bit indicates whether the next write request is accepted before the response for the current write transaction occurs. When the value is 1, the next write request is accepted and high-speed transfer is possible, but AHB-Lite error responses are not detected. Bus errors are returned to the requesting master IP using the error response protocol for AHB-Lite. For details on errors that occur on each bus, see section 15.6, Bus Error Monitoring. Only use the BUSSCNTMBIU, BUSSCNTP0B, and BUSSCNTEXT registers.

BERAD[31:0]位（总线错误地址）

当发生总线错误时，BERAD[31:0]位存储访问地址。有关详细信息，请参阅BUSnERRSTAT.ERRSTAT位描述和第15.6节，总线错误监控。

BUSnERRADD.BERAD[31:0]（n=1到4）的值仅在BUSnERRSTAT.ERRSTAT（n=1到4）设置为1时有效。

Note: This register is cleared only by a reset that is not an MPU-related reset. For more information, see section 6, Resets, and section 16, Memory Protection Unit (MPU).

Table 15.6 lists the registers associated with each bus type.

ACCSTAT bit (Error Access Status)

The ACCSTAT bit indicates the access status, write access or read access, when an error occurs on the associated bus. For more information, see the BUSnERRSTAT.ERRSTAT bit description and section 15.6, Bus Error Monitoring.

The value is only valid when BUSnERRSTAT.ERRSTAT (n = 1 to 4) is set to 1.

ERRSTAT bit (Bus Error Status)

The ERRSTAT bit indicates whether a bus error occurred. When an error occurs on the associated bus, the access address and status of write or read access are stored. BUSnERRSTATn.ERRSTAT (n = 1 to 4) is set to 1.

The following types of errors can occur on each bus:

- Illegal address access
- Bus master MPU error
- Bus slave MPU error
- Time out.

When detecting bus master MPU errors or bus slave MPU errors, and reset is selected in the respective OAD bit, BUSnERRSTAT.ERRSTAT (n = 1 to 4) is not set to 1 if the bus access that caused the MPU error completes later than the internal reset signal being generated, which may occur depending on the wait setting.

When detecting bus master MPU errors or bus slave MPU errors, and NMI is selected in the respective OAD bit, BUSnERRSTAT.ERRSTAT (n = 1 to 4) is set to 1 when the bus access that caused the MPU error completes.

For more information on errors that occur on each bus, see section 15.6, Bus Error Monitoring, and section 16, Memory Protection Unit (MPU).

ACCSTAT位（错误访问状态）

当相关总线上发生错误时，ACCSTAT位指示访问状态、写访问或读访问。
有关详细信息，请参阅BUSnERRSTAT.ERRSTAT位描述和第15.6节，总线错误监控。

该值仅在BUSnERRSTAT.ERRSTAT（n=1到4）设置为1时有效。

ERRSTAT位（总线错误状态）

ERRSTAT位指示是否发生总线错误。当相关总线上发生错误时，将存储访问地址和写入或读取访问的状态。BUSnERRSTATn.ERRSTAT（n=1到4）设置为1。

每条总线上都可能发生以下类型的错误：

- 非法地址访问
- 总线主控MPU错误
- 总线从机MPU错误
- 暂停。

当检测到总线主MPU错误或总线从MPU错误时，在相应的OAD位中选择复位，
如果导致MPU错误的总线访问在内部复位信号生成之后完成，则BUSnERRSTAT.ERRSTAT（n=1到4）不设置为1，这可能取决于等待设置。

当检测到总线主机MPU错误或总线从机MPU错误时，在各自的OAD位中选择NMI，
当导致MPU错误的总线访问完成时，BUSnERRSTAT.ERRSTAT（n=1到4）设置为1。

有关每条总线上发生的错误的更多信息，请参阅第15.6节，总线错误监控和第16节，内存保护单元（MPU）。

15.4 Endianness and Data Alignment

The external bus has a data alignment function. Alignment is based on the data size, and the endian order.

15.4.1 Data Alignment Control for the CS Areas

15.4.1.1 8-bit bus space

When an 8-bit bus space is selected in the BSIZE[1:0] bits in CSnCR, the address buses A12 to A00 are enabled to output address signals in byte units.

In 8-bit bus space, only the WR0 pin is valid, regardless of the write access mode, and it always outputs low during write access.

The valid positions of data external to the chip are D07 to D00, and WR0 is used as the control signal, regardless of the endian mode. See Figure 15.3 and Figure 15.4.

Page access can occur for accesses to data in 16-bit or 32-bit units. Page access can only occur when an access does not extend over a 32-bit boundary. The situations in which page access occurs are indicated by the letter (p) in Figure 15.3 and Figure 15.4.

15.4 字节顺序和数据对齐

外部总线具有数据对齐功能。对齐基于数据大小和字节序。

15.4.1 CS区域的数据对齐控制

15.4.1.1 8位总线空间

当在CSnCR的BSIZE[1:0]位中选择8位总线空间时，地址总线A12到A00被启用，以字节为单位输出地址信号。

在8位总线空间中，只有WR0引脚有效，与写访问模式无关，并且在写访问期间始终输出低电平。

片外数据的有效位置为D07～D00，WR0作为控制信号，与endian模式无关。请参见图15.3和图15.4。

对16位或32位单元中的数据的访问可能会发生页访问。只有当访问不超过32位边界时，才会发生页面访问。页面访问发生的情况由图15.3和图15.4中的字母(p)表示。

15.5 Operation of CS Area Controller

15.5.1 Separate Bus

This section describes the periods shown in the timing diagrams. The CS area controller (CSC) operates in synchronization with the external bus clock, BCLK. Operation cycles, such as wait cycles, specified in the CSC register, are counted on BCLK. In the following description, the frequencies of BCLK and EBCLK pin output are the same, unless otherwise noted. Access through the external bus starts at the same point as the output of a rising edge on the EBCLK pin. However, if the external bus clock, BCLK, and the output on the EBCLK pin are at different frequencies, the wait settings can cause the start of access for the second and subsequent rounds to coincide with the falling edge of the output on the EBCLK pin. See Figure 15.10 to Figure 15.14. If recovery cycles are inserted for bus access, the setting for the number of recovery cycles can also cause the start of access for the second and subsequent rounds to coincide with the falling edge of the output on the EBCLK pin. See Figure 15.32.

15.5.1.1 Tw1 to Twn (clock cycles for waiting for a normal read cycle or normal write cycle)

The period from Tw1 to Twn is the number of clock cycles from the start of access through the external bus clock to 1 cycle before the strobe signal is valid. The number of cycles is selectable from 0 to 31. Within this period, the timing of CSn, RD, and WR0 assertion (driving the signals low) is determined by the respective wait settings. The wait periods are controlled by all of the following:

- CS Assert Wait Select bits (CSON)
- RD Assert Wait Select bits (RDON)
- WR Assert Wait Select bits (WRON)
- Write-Data Output Wait Select bits (WDON) in CSn Wait Control Register 2 (CSnWCR2).

The number of clock cycles for each of these wait periods is selectable as a value from 0 to 7, counted from the start of external bus access. The selectable number of cycles is also within the overall number of clock cycles required for waiting to read or write.

15.5 CS区域控制器的操作

15.5.1 独立巴士

本节介绍时序图中显示的周期。CS区域控制器(CSC)与外部总线时钟BCLK同步运行。在CSC寄存器中指定的操作周期（例如等待周期）在BCLK上计数。在以下描述中，BCLK和EBCLK引脚输出的频率是相同的，除非另有说明。通过外部总线的访问与EBCLK引脚上的上升沿输出在同一点开始。但是，如果外部总线时钟、BCLK和EBCLK引脚上的输出频率不同，则等待设置会导致第二轮和后续轮次的访问开始与EBCLK引脚上输出的下降沿重合. 请参见图15.10至图15.14。如果为总线访问插入恢复周期，则恢复周期数的设置也会导致第二轮和后续轮次的访问开始与EBCLK引脚上输出的下降沿一致。请参见图15.32。

15.5.1.1 Tw1到Twn（等待正常读周期或正常写周期的时钟周期）

从Tw1到Twn的周期是从通过外部总线时钟开始访问到选通信号有效之前的1个周期的时钟周期数。周期数可在0到31之间选择。在此周期内，CSn、RD和WR0置位（驱动信号为低电平）的时序由各自的等待设置决定。等待时间由以下所有控制：

- CS断言等待选择位(CSON)
- RD断言等待选择位(RDON)
- WR断言等待选择位(WRON)
- CSn等待控制寄存器2(CSnWCR2)中的写数据输出等待选择位(WDON)。

每个等待周期的时钟周期数可选择从0到7的值，从外部总线访问开始计算。可选择的周期数也在等待读取或写入所需的时钟周期总数之内。

15.5.1.2 Tend (clock cycle where the strobe signal is valid)

Tend is the next clock cycle after completion of the wait period for a normal cycle of read or write, or for a cycle of page reading or page writing. If the wait select bit for these cycles is 0, bus access starts on the clock cycle where the strobe signal is valid. The RD and WR0 signals are negated in the next clock cycle. For a read access, the clock cycle where the strobe signal is valid is where the data to be read is sampled. If an external wait is enabled, the wait signal is sampled on the cycle where the strobe signal is valid. The bus cycle is extended if the wait signal is low. The bus cycle completes in the next clock cycle if the wait signal is high. Tend indicates the cycle where sampling of the wait signal starts.

After the first cycle where the strobe signal is valid during page access, second and subsequent page access operations (see section 15.5.1.5, Tpw1 to Tpwn (page read cycle wait or page write cycle wait)) start in the next cycle, except during write access with a setting other than 0 for write-data output extension clock cycles (see section 15.5.1.4, Tdw1 to Tdwn (clock cycles for write-data output extension)). If the setting for the RD or WR assertion wait is any value other than 0, the RD and WR0 signals are negated in the next clock cycle. If the setting is 0, assertion continues. Additionally, the CSn signal continues to be asserted rather than negated.

15.5.1.3 Tn1 to Tnm (clock cycles for CS extension)

For normal access, Tn1 to Tnm represent the clock cycles of the period following the cycle where the strobe signal is valid (Tend) up to negation of the CSn signal. For read or write access, the negation timing can be controlled by the read-access CS Extension Cycle Select bits (CSROFF) and the write-access CS Extension Cycle Select bits (CSWOFF) in the CSn Wait Control Register 2 (CSnWCR2). The number of cycles is counted from the cycle following the cycle where the strobe signal is valid.

For page access, Tn1 to Tnm represent the clock cycles of the period following the last cycle where the strobe signal is valid up to negation of the CSn signal.

For write access, setting the Write Data Output Extension Cycle Select bits (WDOFF) controls extension of the period where the address and output data is valid.

15.5.1.4 Tdw1 to Tdwn (clock cycles for write-data output extension)

For write access, if the wait setting for the write-data output extension is any value other than 0, the specified clock cycles are inserted from the cycle following the cycle where the strobe signal is valid (Tend).

For normal access, this period is inserted within the clock cycle period for CS extension (Tn1 to Tnm).

For page access, this period is inserted within the clock cycle period where the strobe signal is valid and subsequent page accesses, or within the clock cycle period for the CS extension (Tn1 to Tnm). Valid address and data output are extended over this period, and the WR0 signal is negated.

15.5.1.5 Tpw1 to Tpwn (page read cycle wait or page write cycle wait)

For the second and subsequent bus cycles during page access, the values for a page read cycle wait or page write cycle wait are used instead of the settings for a normal read or write cycle wait. The settings in the WR Assert Wait Select bits become enabled in the same way as for the first access. The RD assertion control operation depends on the page read access mode setting of the PRMOD bit in CSnMOD, as follows:

- CSnMOD.PRMOD = 0 — A wait for RD assertion is inserted in the same way as for the first access, and the RD signal is negated
- CSnMOD.PRMOD = 1 — Although a wait for RD assertion is inserted in the same way as for normal-access compatibility mode, the RD signal continues to be asserted over this period.

15.5.1.6 Tr1 to Trn (recovery cycles)

Recovery cycles can be inserted from the point where a bus cycle is complete (CSn signal negation). The number of recovery cycles can be controlled by setting the Read Recovery (RRCV) or Write Recovery (WRCV) bits in the CSn Recovery Cycle Register (CSnREC). Both numbers of recovery cycles are counted from the end of a bus cycle (CSn negation) and can be selected from 0 to 15 cycles. For more information, see section 15.5.4, Insertion of Recovery Cycles.

15.5.1.2 Tend（选通信号有效的时钟周期）

Tend是完成正常读取或写入周期或页面读取或页面写入周期的等待周期后的下一个时钟周期。如果这些周期的等待选择位为0，则总线访问在选通信号有效的时钟周期开始。RD和WR0信号在下一个时钟周期被否定。对于读访问，选通信号有效的时钟周期是对要读取的数据进行采样的地方。如果启用了外部等待，则在选通信号有效的周期对等待信号进行采样。如果等待信号为低，则延长总线周期。如果等待信号为高电平，则总线周期在下一个时钟周期完成。Tend表示等待信号采样开始的周期。

在页面访问期间选通信号有效的第一个周期之后，第二个和后续页面访问操作（参见第15.5.1.5节，Tpw1到Tpwn（页面读取周期等待或页面写入周期等待））在下一个周期开始，除了在写入数据输出扩展时钟周期设置为0以外的写入访问（参见第15.5.1.4节，Tdw1到Tdwn（写入数据输出扩展的时钟周期））。如果RD或WR断言等待的设置为0以外的任何值，则RD和WR0信号在下一个时钟周期被否定。如果设置为0，则断言继续。此外，CSn信号继续被断言而不是被否定。

15.5.1.3 Tn1到Tnm（CS扩展的时钟周期）

对于正常访问，Tn1到Tnm表示从选通信号有效(Tend)到CSn信号无效的周期之后的周期的时钟周期。对于读或写访问，取反时序可由CSn等待控制寄存器2(CSnWCR2)中的读访问CS扩展周期选择位(CSROFF)和写访问CS扩展周期选择位(CSWOFF)控制。周期数从选通信号有效的周期之后的周期开始计数。

对于页访问，Tn1到Tnm表示从选通信号有效直到CSn信号取反的最后一个周期之后的周期的时钟周期。

对于写访问，设置写数据输出延长周期选择位(WDOFF)控制地址和输出数据有效期间的延长。

15.5.1.4 Tdw1到Tdwn（写数据输出扩展的时钟周期）

对于写访问，如果写数据输出扩展的等待设置为0以外的任何值，则从选通信号有效(Tend)周期的下一个周期插入指定的时钟周期。

对于正常访问，该周期插入到CS扩展的时钟周期周期内（Tn1到Tnm）。

对于页面访问，该周期插入在选通信号有效的时钟周期周期和后续页面访问中，或者在CS扩展（Tn1到Tnm）的时钟周期周期内。在此期间有效地址和数据输出被延长，WR0信号被取反。

15.5.1.5 Tpw1到Tpwn（页面读取周期等待或页面写入周期等待）

对于页面访问期间的第二个和后续总线周期，使用页面读取周期等待或页面写入周期等待的值，而不是正常读取或写入周期等待的设置。WRAssertWaitSelect位中的设置以与第一次访问相同的方式启用。RD断言控制操作取决于CSnMOD中PRMOD位的页读访问模式设置，如下所示：

- CSnMOD.PRMOD=0—以与第一次访问相同的方式插入等待RD断言，并且RD信号被否定
- CSnMOD.PRMOD=1—尽管以与正常访问兼容模式相同的方式插入等待RD断言，但在此期间继续断言RD信号。

15.5.1.6 Tr1 to Trn (recovery cycles)

恢复周期可以从总线周期完成的点插入（CSn信号否定）。可以通过设置CSn恢复周期寄存器(CSnREC)中的读取恢复(RRCV)或写入恢复(WRCV)位来控制恢复周期的数量。两个恢复周期数都是从总线周期结束（CSn否定）开始计算的，可以从0到15个周期中选择。有关详细信息，请参阅第15.5.4节，恢复周期的插入。

(1) Normal access

When the PRENB and PWENB bits in CSnMOD are set to 0 to disable page read and page write access, all bus accesses take the form of normal read and write operations. Even when these bits are set to 1 to enable page read and page write access, bus access other than page access takes the form of normal read and write operations. Figure 15.5 to Figure 15.7 show the normal access operations.

(2) Page access

When the PRENB and PWENB bits in CSnMOD are set to 1 to enable page read and page write access, the bus access for page access operations becomes page reading and writing. Page access can only occur when two or more rounds of external bus access are required for a single transfer request from the bus master. However, normal access is made when split accesses are not aligned or access extends across the 32-bit boundary. See Figure 15.3 and Figure 15.4 for the conditions under which page access occurs.

Figure 15.15 and Figure 15.16 show examples of page access operations.

(2) 页面访问

当CSnMOD中的PRENB和PWENB位设置为1以启用页面读取和页面写入访问时，页面访问操作的总线访问变为页面读取和写入。只有当来自总线主机的单个传输请求需要两轮或多轮外部总线访问时，才会发生页面访问。但是，当拆分访问未对齐或访问超出32位边界时，将进行正常访问。有关页面访问发生的条件，请参见图15.3和图15.4。

图15.15和图15.16显示了页面访问操作的示例。

15.5.2 Address/Data Multiplexed Bus

When the address/data Multiplexed I/O Interface Select bit (MPXEN) in CSnCR is set to 1, addresses and data can be multiplexing input/output to or from the D07 to D00 pins in the corresponding area. Using this function enables direct connection of the MCU to peripheral LSI requiring address/data multiplexing. When 8-bit width is selected with the BSIZE[1:0] bits in CSnCR, D7 to D00 are multiplexed with A07 to A00. In the address/data multiplexed I/O space, accesses are controlled with the ALE, RD, and WR0 signals.

During the address/data multiplexed I/O space access, after the number of wait cycles specified by the Address Cycle Wait Select bits (AWAIT[1:0]) in CSnWCR2 is inserted in the address output cycle, data access is performed.

15.5.2.1 Ta1 to Tan (Address Cycle Wait)

The period Ta1 to Tan is valid only when the address/data multiplexed I/O space is specified. This period is made up of the number of clock cycles between the start of external bus access and 1 cycle before the address latch (ALE) signal is negated. The number of cycles are selectable within the range from 0 to 3. Addresses are output until the next cycle of ALE signal negation (address cycle). The timing of ALE signal is the same as that of CS assertion. After the address cycle, a data cycle is started. CSnWCR1 and CSnWCR2 should be set so that an address cycle and a data cycle do not overlap.

Page access to the address/data multiplexed I/O space is invalid. When the PRENB or PWENB bit in CSnMOD is set to 1 to enable page-read or page-write access, these settings are ignored and normal read or write operation is performed.

Figure 15.21 to Figure 15.23 show examples of operations with the address/data multiplexed I/O interface.

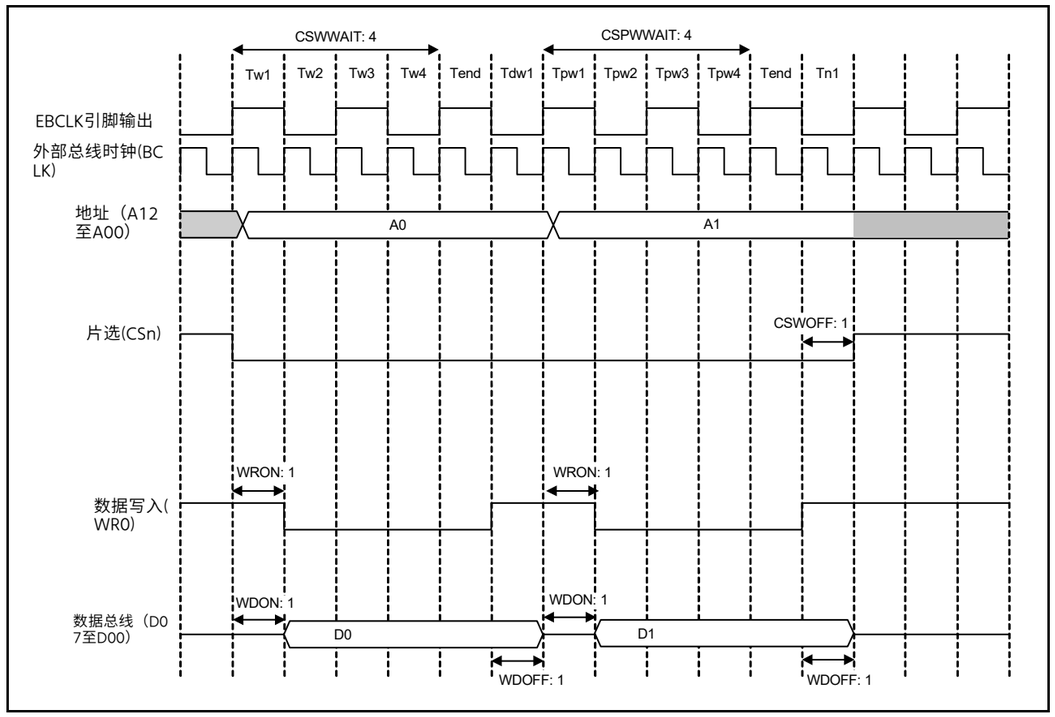

Figure 15.20 当在EBCLK引脚输出选择位中选择BCLK2并且在字节选通模式下（n=0、1、4到7）响应单个传输请求而生成两轮总线访问时的示例页面写访问操作

15.5.2 Address/Data Multiplexed Bus

当CSnCR中的地址数据复用IO接口选择位(MPXEN)设置为1时，地址和数据可以复用到相应区域的D07到D00引脚或从D07到D00引脚输出。使用此功能可以将MCU直接连接到需要地址数据复用的外围LSI。当使用CSnCR中的BSIZE[1:0]位选择8位宽度时，D7至D00与A07至A00复用。在地址数据复用IO空间中，访问由ALE、RD和WR0信号控制。

在地址数据复用IO空间访问期间，经过地址周期指定的等待周期数
在地址输出周期插入CSnWCR2中的等待选择位(AWAIT[1:0])，执行数据访问。

15.5.2.1 Ta1到Tan（地址周期等待）

只有在指定地址数据复用IO空间时，周期Ta1到Tan才有效。该周期由外部总线访问开始到地址锁存(ALE)信号被否定之前的1个周期之间的时钟周期数组成。周期数可在0到3范围内选择。地址输出到ALE信号否定的下一个周期（地址周期）。ALE信号的时序与CS断言的时序相同。在地址周期之后，开始一个数据周期。CSnWCR1和CSnWCR2应设置为地址周期和数据周期不重叠。

页访问地址数据复用的IO空间是无效的。当CSnMOD中的PRENB或PWENB位设置为1以启用页面读取或页面写入访问时，这些设置将被忽略并执行正常的读取或写入操作。

图15.21至图15.23显示了地址数据复用IO接口的操作示例。

15.5.3 External Wait Function

Wait cycles can be extended by the WAIT signal beyond the length of the normal access cycle wait specified in the CSRWAIT[4:0] and CSWWAIT[4:0] bits in CSnWCR1, and the page access cycle wait specified in the CSPRWAIT[2:0] and CSPWWAIT[2:0] bits in CSnWCR1.

When external wait is enabled (EWENB = 1 in CSnMOD), wait cycles are inserted while the WAIT signal is held low. When external wait is disabled (EWENB = 0 in CSnMOD), the WAIT signal has no effect. All wait cycles specified in CSnWCR1 are inserted independently of the WAIT signal.

(1) Normal access

Sampling of the WAIT signal begins on completion of the wait cycle (Tend) specified in CSnWCR1. The bus cycle is extended while the WAIT signal is held low. The wait cycle ends (Tend) at the next cycle after the WAIT signal goes high.

(2) Page access

The first access operation is the same as the normal access operation. Sampling of the WAIT signal begins on completion of the wait cycle (Tend) specified in the CSnWCR1 register. The bus cycle is extended while the WAIT signal is held low. The wait cycle (Tend) ends at the next cycle after the WAIT signal goes high.

For the second and subsequent accesses, sampling of the WAIT signal begins on completion of the page access wait cycle (Tend). The page access wait cycle is extended while the WAIT signal is held low, and ends (Tend) at the next cycle after the WAIT signal goes high.

Figure 15.24 to Figure 15.27 show examples of external wait insertion timing with the separate bus interface.

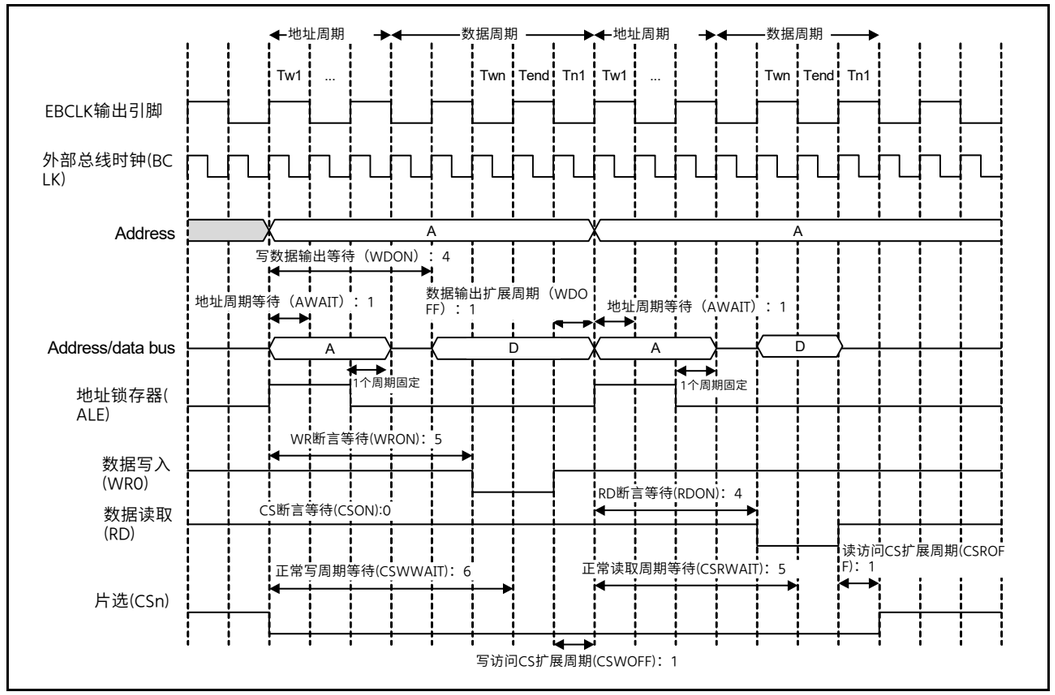

Figure 15.23 地址数据复用IO接口的总线时序示例（n=0、1、4到7）

15.5.3 外部等待功能

等待周期可以通过WAIT信号延长到超出在指定的正常访问周期等待的长度
CSnWCR1中的CSRWAIT[4:0]和CSWWAIT[4:0]位，以及在CSnWCR1中的CSPRWAIT[2:0]和CSWWWAIT[2:0]位中指定的页面访问周期等待。

当启用外部等待时（CSnMOD中的EWENB=1），在WAIT信号保持低电平时插入等待周期。当外部等待被禁用时（CSnMOD中的EWENB=0），WAIT信号无效。中指定的所有等待周期
CSnWCR1独立于WAIT信号插入。

(1) 正常访问

WAIT信号的采样在CSnWCR1中指定的等待周期(Tend)完成时开始。当WAIT信号保持低电平时，总线周期会延长。等待周期在WAIT信号变高后的下一个周期结束(Tend)。

(2) 页面访问

第一次访问操作与正常访问操作相同。WAIT信号的采样在CSnWCR1寄存器中指定的等待周期(Tend)完成时开始。当WAIT信号保持低电平时，总线周期会延长。等待周期(Tend)在WAIT信号变为高电平后的下一个周期结束。

对于第二次和后续访问，WAIT信号的采样在页面访问等待周期(Tend)完成时开始。页面访问等待周期在WAIT信号保持低电平时延长，并在WAIT信号变为高电平后的下一个周期结束(Tend)。

(3) Address/data multiplexed I/O interface

In a data cycle with the address/data multiplexed I/O interface, programmed waits and pin waits using the WAIT pin can be inserted in the same way as that with the separate bus interface.

Address cycles are not affected by the wait control settings. Figure 15.28 shows an example of external wait insertion timing with the address/data multiplexed I/O interface.

在地址数据复用IO接口的数据周期中，编程等待和使用WAIT引脚的引脚等待可以以与单独总线接口相同的方式插入。

地址周期不受等待控制设置的影响。图15.28显示了地址数据复用IO接口的外部等待插入时序示例。

15.5.4 Insertion of Recovery Cycles

Recovery cycles can be inserted between consecutive rounds of external bus access by setting the Recovery Cycle Insertion Enable bit in CSRECEN to 1.

The number of recovery cycles to be inserted after read cycles and write cycles can be independently set for each area using CSnREC. When the preceding bus cycle is a write access, the number of write recovery cycles must be set with the WRCV[3:0] bits for the associated area. When the preceding bus cycle is a read access, the number of read recovery cycles must be set with the RRCV[3:0] bits for the associated area. For example, when a CS1 read access occurs after a CS0 read access, the number of recovery cycles to be inserted is set in the RRCV[3:0] bits in CS0REC.

Recovery cycle insertion can be enabled or disabled with RCVENi (i = 0 to 7) in CSRECEN when the preceding bus access is a separate bus access, and with RCVENMj (j = 0 to 7) when the preceding bus access is an address/data multiplexed bus access.

Recovery cycles can be inserted on any of the following conditions:

- After a read access to the external bus, a read access is made to the external bus in the same area
- After a read access to the external bus, a read access is made to the external bus in a different area
- After a read access to the external bus, a write access is made to the external bus in the same area
- After a read access to the external bus, a write access is made to the external bus in a different area
- After a write access to the external bus, a read access is made to the external bus in the same area
- After a write access to the external bus, a read access is made to the external bus in a different area
- After a write access to the external bus, a write access is made to the external bus in the same area
- After a write access to the external bus, a write access is made to the external bus in a different area.

The recovery cycle starts at the end of the preceding bus cycle, for example when the CSn signal (n = 0, 1, 4 to 7) is negated. A high-level period of the CSn signal is inserted for the specified recovery cycle period starting from this point.

In the fastest case, the CSn signal for the next round of bus access is asserted immediately after the end of the recovery cycles. Even if the next request for access to an external address space is generated during the recovery period, the next access over the external bus starts immediately after the end of the recovery cycles.

15.5.4 恢复周期的插入

通过设置恢复周期，可以在连续几轮外部总线访问之间插入恢复周期
CSRECEN中的插入使能位为1。

可以使用CSnREC为每个区域独立设置读取周期和写入周期后插入的恢复周期数。当前一个总线周期是写访问时，必须使用相关区域的WRCV[3:0]位设置写恢复周期数。当前一个总线周期是读访问时，必须使用相关区域的RRCV[3:0]位设置读恢复周期数。例如，当CS1读访问发生在CS0读访问之后，要插入的恢复周期数在CS0REC的RRCV[3:0]位中设置。

当前面的总线访问是单独的总线访问时，可以使用CSRECEN中的RCVENi(i=0到7)启用或禁用恢复周期插入，
当前面的总线访问是地址数据复用时，可以使用RCVENMj(j=0到7)启用或禁用恢复周期插入总线访问。

可以在以下任何条件下插入恢复周期：

- 对外部总线进行读访问后，对同一区域的外部总线进行读访问
- 对外部总线进行读访问后，对不同区域的外部总线进行读访问
- 对外部总线进行读访问后，对同一区域的外部总线进行写访问
- 对外部总线进行读访问后，对不同区域的外部总线进行写访问
- 对外部总线进行写访问后，对同一区域的外部总线进行读访问
- 对外部总线进行写访问后，对不同区域的外部总线进行读访问
- 对外部总线进行写访问后，对同一区域的外部总线进行写访问
- 在对外部总线进行写访问之后，对不同区域中的外部总线进行写访问。

恢复周期在前一个总线周期结束时开始，例如当CSn信号（n=0、1、4到7）被否定时。从该点开始，在指定的恢复周期周期内插入CSn信号的高电平周期。

在最快的情况下，下一轮总线访问的CSn信号在恢复周期结束后立即生效。即使在恢复期间产生了访问外部地址空间的下一个请求，通过外部总线的下一次访问也会在恢复周期结束后立即开始。

When two or more external bus access cycles are required for a single transfer request from a bus master, and the recovery cycle insertion condition is satisfied, recovery cycles are also inserted between these bus access cycles. However, when page read access is enabled (CSnMOD.PRENB = 1) or page write access is enabled (CSnMOD.PWENB = 1), recovery cycles are not inserted except after the last bus access cycle of the transfer, even if the recovery cycle insertion condition is satisfied. See Figure 15.31.

Similarly, during normal access with page access enabled, recovery cycles are not inserted between bus access cycles but only after the last bus access cycle of the transfer. With the address/data multiplexed I/O interface, when the recovery cycle insertion condition is satisfied, recovery cycles are inserted between bus access cycles regardless of the page access enable setting.

Figure 15.29 to Figure 15.31 show examples of recovery cycle insertion with the separate bus interface.

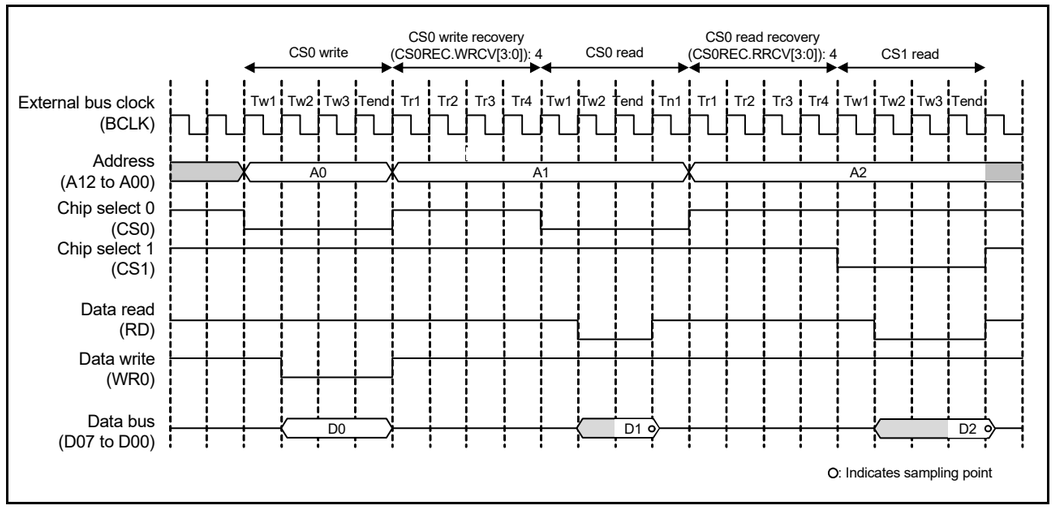

Figure 15.29 Example recovery cycle insertion with separate bus interface

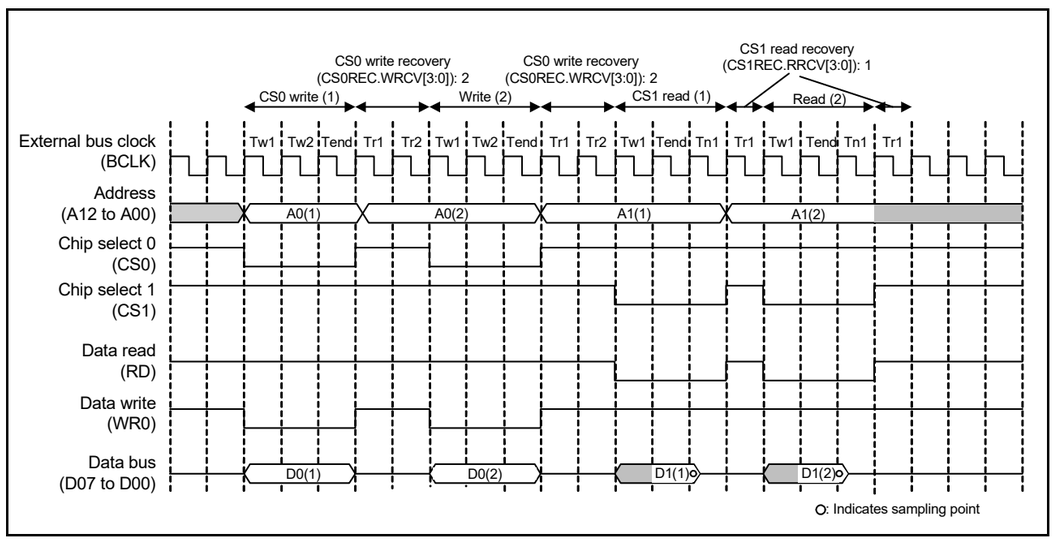

Figure 15.30 Example recovery cycle insertion when bus access is split, with separate bus interface and normal access

当来自总线主机的单个传输请求需要两个或多个外部总线访问周期，并且恢复周期插入条件满足时，恢复周期也在这些总线访问周期之间插入。但是，当启用页面读取访问(CSnMOD.PRENB=1)或启用页面写入访问(CSnMOD.PWENB=1)时，不会插入恢复周期，除非在传输的最后一个总线访问周期之后，即使恢复周期满足插入条件。请参见图15.31。

类似地，在启用页面访问的正常访问期间，恢复周期不会插入总线访问周期之间，而是仅在传输的最后一个总线访问周期之后插入。对于地址数据复用IO接口，当恢复周期插入条件满足时，无论页面访问使能设置如何，都会在总线访问周期之间插入恢复周期。

图15.29至图15.31显示了使用单独的总线接口插入恢复周期的示例。

15.5.5 No Access State

When no external address space is accessed, the CSn, WR0, RD signals are high, ALE signal is low, and D07 to D00 are in the high-impedance state.

15.5.6 Write Buffer Function (External Bus)

In write access, the main bus is released by writing data to the write buffer before the access is complete. This allows the next round of bus access to start. However, if the next access is to an external address space or to a register of the external bus controller, it is suspended until the external bus operations already in progress are complete.

15.5.5 无访问状态

当没有访问外部地址空间时，CSn、WR0、RD信号为高电平，ALE信号为低电平，D07到D00处于高阻状态。

15.5.6 写缓冲功能（外部总线）

在写访问中，通过在访问完成之前将数据写入写缓冲区来释放主总线。这允许下一轮总线访问开始。然而，如果下一次访问是对外部地址空间或外部总线控制器的寄存器，则它会被挂起，直到已经在进行中的外部总线操作完成。

Figure 15.35 shows an example of operation when the write buffer function is in use. When this function is in use, if the next operation after an external write is an internal access, the internal access is executed in parallel with the external write, for example without waiting for completion of the latter operation.

15.5.7 Restrictions

15.5.7.1 Restrictions on using a separate bus interface

Table 15.9 lists the restrictions that apply to bits in the CSn Wait Control Register 1 (CSnWCR1) and CSn Wait Control Register 2 (CSnWCR2) when normal and page accesses occur.

Even if the Page Read Access Enable bit or Page Write Access Enable bit in the CSn Mode Register is set to enable (CSnMOD.PRENB = 1 or CSnMOD.PWENB = 1), the first page access or access that does not fall within the scope of a page access is a normal access operation. Because of this, restrictions on normal access must be satisfied.

Table 15.9 Restrictions on normal access and page access

Note: When two or more external bus access cycles are required for a single transfer request from a bus master, and the recovery cycle insertion condition is satisfied, with page read access enabled (CSnMOD.PRENB = 1) or page write access enabled (CSnMOD.PWENB = 1), recovery cycles are not inserted between bus access cycles but only after the last bus access cycle of the transfer.

15.5.7.2 Restrictions on using address/data multiplexed bus interface

In the address/data multiplexed I/O space, page accesses are invalid. If a page access setting is specified, the setting is ignored and the normal read or write operation is performed.

15.5.7 Restrictions

15.5.7.1 使用单独的总线接口的限制

表15.9列出了适用于CSn等待控制寄存器1(CSnWCR1)和CSn等待控制中的位的限制发生正常和页面访问时的寄存器2(CSnWCR2)。

即使CSn模式寄存器中的页面读访问使能位或页面写访问使能位设置为使能（CSnMOD.PRENB=1或CSnMOD.PWENB=1），第一个页面访问或不在范围内的访问页面访问是正常的访问操作。因此，必须满足对正常访问的限制。

15.5.7.3 Restrictions when BCLK/2 is selected in the EBCLK Pin Output Select bit

When 1/2 BCLK cycle is selected in the EBCLK Pin Output Select bit, the external bus access cycle starts on the rising edge of the EBCLK pin output. However, when 2 or more external bus access cycles are generated for a single transfer request from a bus master, the second or subsequent external bus access cycle can start on the falling edge of the EBCLK pin output, depending on the wait cycle settings. Set the registers appropriately for the specifications of connected devices.

15.5.7.4 Restrictions on instruction code

You must fix the instruction code to little-endian order.

15.6 Bus Error Monitoring

The bus error monitoring system monitors each individual area, and whenever an error is detected, it returns the error to the requesting master IP using the AHB-Lite error response protocol.

15.6.1 Bus Error Types

The following types of errors can occur on each bus:

- Illegal address access
- Bus master MPU error
- Bus slave MPU error
- Timeout.

Table 15.11 lists the address ranges where access leads to illegal address access errors. The reserved area in the slave does not trigger an illegal address access error. For more information on the bus master MPU and bus slave MPU, see section 16, Memory Protection Unit (MPU).

15.6.2 Operation when a Bus Error Occurs

When a bus error occurs, operation is not guaranteed and the error is returned to the requesting master IP. The bus errors that occur for each master are stored in the BUSnERRADD and BUSnERRSTAT registers. These registers must only be cleared by a reset. For more information, see section 15.3.9, Bus Error Address Register (BUSnERRADD) (n = 1 to 4) and section 15.3.10, Bus Error Status Register (BUSnERRSTAT) (n = 1 to 4).

Note: The DMAC and DTC do not receive bus errors. If the DMAC or DTC accesses the bus, the transfer continues.

15.6.3 Conditions Leading to Illegal Address Access Errors

Table 15.11 lists the address spaces for each bus that trigger illegal address access errors.

15.5.7.3 在EBCLK引脚输出选择位中选择BCLK2时的限制

当在EBCLK引脚输出选择位选择12BCLK周期时，外部总线访问周期在EBCLK引脚输出的上升沿开始。然而，当来自总线主机的单个传输请求产生2个或更多外部总线访问周期时，第二个或随后的外部总线访问周期可以在EBCLK引脚输出的下降沿开始，具体取决于等待周期设置。根据连接设备的规格适当设置寄存器。

15.5.7.4 指令代码限制

您必须将指令代码修复为little-endian顺序。

15.6 总线错误监控

总线错误监控系统监控每个单独的区域，每当检测到错误时，它会使用AHB-Lite错误响应协议将错误返回给请求的主IP。

15.6.1 总线错误类型

每条总线上都可能发生以下类型的错误：

- 非法地址访问
- 总线主控MPU错误
- 总线从机MPU错误
- Timeout.

表15.11列出了访问导致非法地址访问错误的地址范围。从机中的保留区域不会触发非法地址访问错误。有关总线主控MPU和总线从属MPU的更多信息，请参阅第16节，内存保护单元(MPU)。

15.6.2 发生总线错误时的操作

当发生总线错误时，无法保证操作，错误会返回到请求的主IP。每个主机发生的总线错误存储在BUSnERRADD和BUSnERRSTAT寄存器中。这些寄存器只能通过复位清除。有关详细信息，请参阅第15.3.9节，总线错误地址寄存器(BUSnERRADD)（n=1到4）和第15.3.10节，总线错误状态寄存器(BUSnERRSTAT)（n=1到4）。

Note: DMAC和DTC不接收总线错误。如果DMAC或DTC访问总线，则传输继续。

15.6.3 导致非法地址访问错误的条件

表15.11列出了触发非法地址访问错误的每条总线的地址空间。

E000 0000h to FFFF FFFFh	System for Cortex®-M4	-	E

E: Path where an illegal address access error occurs.

Note 1. The bus module does not detect whether the Memory Mirror Function (MMF) switched the address. Therefore, if the MMF is enabled and the CPU accesses 0200 0000h, no error occurs. This depends on the switched address. If the MMF is disabled and the CPU accesses 0200 0000h, the bus module can detect the error.

The bus module detects an access error resulting from access to a reserved area, for example if no area is assigned to the slave:

- 0200 0000h to 1FFD FFFFh: access error detection
- 0000 0000h to 01FF FFFFh: memory bus 1 no access error detection.

15.6.4 Timeout

For some peripheral modules, a timeout error occurs with the module-stop function. When there is no response from the slave for a certain period of time, a timeout error is detected and is returned to the requesting master IP using the AHB-Lite error response protocol.

15.7 Notes on using Flash Cache

When using the flash cache through access from the CPU, the Arm MPU should also be set to cacheable. See references 1. and 2. for more information.

E：发生非法地址访问错误的路径。

注1.总线模块不检测内存镜像功能(MMF)是否切换了地址。因此，如果启用MMF并且CPU访问02000000h，则不会发生错误。这取决于交换的地址。如果MMF被禁用并且CPU访问02000000h，则总线模块可以检测到错误。

总线模块检测到因访问保留区域而导致的访问错误，例如，如果没有为从站分配区域：

- 02000000h至1FFDFFFFh：访问错误检测
- 00000000h至01FFFFFFh：内存总线1无访问错误检测。

15.6.4 Timeout

对于某些外围模块，模块停止功能会发生超时错误。当从机在一定时间内没有响应时，检测到超时错误并使用AHBLite错误响应协议返回给请求的主机IP。

15.7 使用FlashCache的注意事项

当通过CPU访问使用闪存缓存时，ArmMPU也应设置为可缓存。有关详细信息，请参阅参考文献1.和2.。

16. Memory Protection Unit (MPU)

16.1 Overview

The MCU has four Memory Protection Units (MPUs) and a CPU stack pointer monitor function. Table 16.1 lists the MPU specifications and Table 16.2 shows the behavior on detection of each MPU error.

Table 16.1 MPU specifications

Classification	Module/Function	Specifications
Illegal memory access	Arm® Cortex®-M4 CPU	• Arm CPU has a default memory map. If the CPU makes an illegal access, an exception interrupt occurs. • The MPU can change a default memory map.
	CPU stack pointer monitor	2 regions: • Main Stack Pointer (MSP) • Process Stack Pointer (PSP).
Memory protection	Arm MPU	Memory protection function for the CPU: • 8 MPU regions with subregions and background region.
	Bus master MPU	Memory protection function for each bus master except for the CPU: • Bus master MPU group A: 32 regions.
	Bus slave MPU	Memory protection function for each bus slave
Security	Security MPU	Protect accesses from non-secure programs to the following secure regions: • 2 regions (PC) • 4 regions (code flash, SRAM, two secure functions).

Table 16.2 Behavior on MPU error detection

MPU type	Notification type	Bus access on error detection	Storing of error access information
CPU stack pointer monitor	Reset or non-maskable interrupt	Don't care	Not stored
Arm MPU	Hard fault	• Does not correctly have write access • Does not correctly have read access.	Stored in the Cortex-M4 processor
Bus master MPU	Reset or non-maskable interrupt	• Write access to the protection region • Read access to the protection region.	Stored
Bus slave MPU	• Reset or non-maskable interrupt • Hard fault.	• Write access ignored • Read access read as 0.	Stored
Security MPU	Not notified	• Does not correctly have write access • Does not correctly have read access.	Not stored

For information on error access for the Arm MPU, see section 16.7. For information on error access for other MPUs, see section 15.3.9, Bus Error Address Register (BUSnERRADD) (n = 1 to 4) and section 15.3.10, Bus Error Status Register (BUSnERRSTAT) (n = 1 to 4) in section 15, Buses.

16.2 CPU Stack Pointer Monitor

The CPU stack pointer monitor detects underflows and overflows of the stack pointer. Because the Arm CPU has two stack pointers, a Main Stack Pointer (MSP) and a Process Stack Pointer (PSP), it supports two CPU stack pointer monitors. If a stack pointer underflow or overflow is detected, the CPU stack pointer monitor generates a reset or a non-maskable interrupt.

The CPU stack pointer monitor is enabled by setting the Stack Pointer Monitor Enable bit in the Stack Pointer Monitor Access Control Register (MSPMPUCTL, PSPMPUCTL) to 1.

16. 内存保护单元(MPU)

16.1 Overview

MCU具有四个内存保护单元(MPU)和一个CPU堆栈指针监控功能。表16.1列出了MPU规格和表16.2显示了检测每个MPU错误时的行为。

Table 16.1 MPU specifications

16.2 CPU堆栈指针监视器

CPU堆栈指针监视器检测堆栈指针的下溢和溢出。由于ArmCPU有两个堆栈指针，一个主堆栈指针(MSP)和一个进程堆栈指针(PSP)，因此它支持两个CPU堆栈指针监视器。如果检测到堆栈指针下溢或溢出，CPU堆栈指针监视器会生成复位或不可屏蔽中断。

通过设置堆栈指针监视器中的堆栈指针监视器启用位来启用CPU堆栈指针监视器访问控制寄存器(MSPMPUCTL PSPMPUCTL)为1。

Table 16.3 lists the specifications of the CPU stack pointer monitor, Figure 16.1 shows a block diagram, and Figure 16.2 shows the register setting flow.

OAD bit (Operation after Detection)

The OAD bit selects either a reset or a non-maskable interrupt when a stack pointer underflow or overflow is detected by the CPU stack pointer monitor.

The main and the process stack pointer monitors each uses an OAD bit to determine which signal is generated when a stack pointer underflow or overflow is detected. When writing to the OAD bit, write A5h simultaneously to the KEY[7:0] bits using halfword access.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writes to the OAD bit. When writing to the OAD bit, write A5h simultaneously to the KEY[7:0] bits. When values other than A5h are written to the KEY[7:0] bits, the OAD bit is not updated. The KEY[7:0] bits are always read as 00h.

注1.写入数据不保存。

OAD位（检测后操作）

当CPU堆栈指针监视器检测到堆栈指针下溢或溢出时，OAD位选择复位或不可屏蔽中断。

主堆栈指针监视器和进程堆栈指针监视器各自使用一个OAD位来确定在检测到堆栈指针下溢或溢出时生成哪个信号。写入OAD位时，使用半字访问同时将A5h写入KEY[7:0]位。

KEY[7:0]位（键码）

KEY[7:0]位启用或禁用对OAD位的写入。写入OAD位时，同时将A5h写入KEY[7:0]位。将A5h以外的值写入KEY[7:0]位时，不会更新OAD位。KEY[7:0]位总是读为00h。

Note 1. The initial value depends on the reset generation source.

ENABLE bit (Stack Pointer Monitor Enable)

The ENABLE bit enables or disables the stack pointer monitor function, independently set for the main stack pointer monitor and the process stack pointer monitor.

When the MSPMPUCTL.ENABLE bit is set to 1, the following registers are available:

- MSPMPUSA
- MSPMPUEA
- MSPMPUOAD.

When the PSPMPUCTL.ENABLE bit is set to 1, the following registers are available:

- PSPMPUSA
- PSPMPUEA
- PSPMPUOAD.

ERROR bit (Stack Pointer Monitor Error Flag)

The ERROR bit indicates the status of the stack pointer monitor. Each stack pointer monitor has an independent ERROR bit.

[Setting condition]

- Overflow or underflow of the stack pointer.

[Clearing condition]

- 0 is written to this bit
- A reset other than the bus master MPU error reset, bus slave MPU error reset, and stack pointer error reset.

Note: Only 0 can be written to the ERROR bit.

注1.初始值取决于复位产生源。

ENABLE位（堆栈指针监视器启用）

ENABLE位启用或禁用堆栈指针监视器功能，分别为主堆栈指针监视器和进程堆栈指针监视器设置。

当MSMPPUCTL.ENABLE位设置为1时，以下寄存器可用：

- MSPMPUSA
- MSPMPUEA
- MSPMPUOAD.

当PSPMPUCTL.ENABLE位设置为1时，以下寄存器可用：

- PSPMPUSA
- PSPMPUEA
- PSPMPUOAD.

ERROR位（堆栈指针监视器错误标志）

ERROR位指示堆栈指针监视器的状态。每个堆栈指针监视器都有一个独立的ERROR位。

[Setting condition]

- 堆栈指针上溢或下溢。

[Clearing condition]

- 0写入该位
- 总线主MPU错误复位、总线从MPU错误复位和堆栈指针错误复位以外的复位。

Note: ERROR位只能写入0。

16.2.1.7 Stack Pointer Monitor Protection Register (MSPMPUPT, PSPMPUPT)

b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	These bits enable or disable writes to the PROTECT bit.	R/(W)*1

Note 1. Write data is not saved.

PROTECT bit (Protection of Register)

The PROTECT bit enables or disables writes to the associated registers to be protected, independently set for the main stack pointer monitor and the process stack pointer monitor.

MSPMPUPT.PROTECT controls the following main stack pointer protection registers:

- MSPMPUCTL
- MSPMPUSA
- MSPMPUEA.

PSPMPUT.PROTECT controls the following process stack pointer protection registers:

- PSPMPUCTL
- PSPMPUSA
- PSPMPUEA.

When writing to the PROTECT bit, simultaneously write A5h to the KEY[7:0] bits, using halfword access.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writes to the PROTECT bit. When writing to the PROTECT bit, simultaneously write A5h to the KEY[7:0] bits. When other values are written, the PROTECT bit is not updated. The KEY[7:0] bits are always read as 00h.

16.2.2 Operation

16.2.2.1 Protecting the registers

To protect registers related to the CPU stack pointer monitor, set the associated PROTECT bit.

16.2.2.2 Overflow and underflow errors

The CPU stack pointer monitor generates an error if an overflow or underflow error is detected. Set the OAD bit to select whether the error is reported as a non-maskable interrupt or reset. The non-maskable interrupt status is indicated in ICU.NMISR.SPEST, see section 14, Interrupt Controller Unit (ICU). Reset status is indicated in SYSTEM.RSTSR1.SPERF, see section 6, Resets.

When ICU.NMISR.SPEST indicates that a CPU stack pointer monitor interrupt occurred, confirm it by checking the ERROR bit in MSPMPUCTL and PSPMPUCTL to determine whether the error is a main stack pointer monitor error or process stack pointer monitor error.

16.2.1.7 堆栈指针监视器保护寄存器(MSPMPUPT PSPMPUPT)

b15 to b8	KEY[7:0]	关键代码	这些位启用或禁用对PROTECT位的写入。	R/(W)*1

注1.写入数据不保存。

PROTECT位（寄存器保护）

PROTECT位启用或禁用对要保护的相关寄存器的写入，为主堆栈指针监视器和进程堆栈指针监视器独立设置。

MSPMPUPT.PROTECT控制以下主堆栈指针保护寄存器：

- MSPMPUCTL
- MSPMPUSA
- MSPMPUEA.

PSPMPUT.PROTECT控制以下进程堆栈指针保护寄存器：

- PSPMPUCTL
- PSPMPUSA
- PSPMPUEA.

写入PROTECT位时，同时使用半字访问将A5h写入KEY[7:0]位。

KEY[7:0]位（键码）

KEY[7:0]位启用或禁用对PROTECT位的写入。写入PROTECT位时，同时将A5h写入KEY[7:0]位。写入其他值时，PROTECT位不会更新。KEY[7:0]位总是读为00h。

16.2.2 Operation

16.2.2.1 保护寄存器

要保护与CPU堆栈指针监视器相关的寄存器，请设置相关的PROTECT位。

16.2.2.2 上溢和下溢错误

如果检测到上溢或下溢错误，CPU堆栈指针监视器会生成错误。设置OAD位以选择将错误报告为不可屏蔽中断还是复位。不可屏蔽中断状态在ICU.NMISR.SPEST中指示，参见第14节，中断控制器单元(ICU)。复位状态显示在

SYSTEM.RSTSR1.SPERF，参见第6节，重置。

当ICU.NMISR.SPEST指示发生CPU堆栈指针监视器中断时，请通过检查
MSPMPUCTL和PSPMPUCTL中的ERROR位来确定该错误是主堆栈指针监视器错误还是进程堆栈指针监视器错误。

A non-maskable interrupt remains set when a stack pointer overflows or underflows. To clear the error, clear the non-maskable interrupt flag by writing 1 to ICU.NMICLR.SPECLR. Write 0 to clear the ERROR bit in MSPMPUCTL or PSPMPUCTL.

16.3 Arm MPU

The Arm MPU provides full support for:

- 8 protected regions
- Overlapping protected regions, with ascending priority:
  7 = highest priority
  0 = lowest priority.
- Access permissions
- Export of memory attributes to the system.

Arm MPU mismatches and permission violations invoke the programmable-priority MemManage fault (HardFault) handler. For details, see section 16.7.

16.4 Bus Master MPU

The bus master MPU monitors the addresses accessed by the bus masters in the entire address space (0000 0000h to FFFF FFFFh). The access control information, consisting of read and write permissions, can be independently set for up to 32 regions. The bus master MPU monitors access to each region based on these settings. If access to a protected region is detected, the bus master MPU generates a reset or a non-maskable interrupt. For details on error access, see section 15.3.9 and section 15.3.10 in section 15, Buses.

Table 16.4 lists the specifications of the bus master MPU and Figure 16.3 shows a block diagram. Figure 16.4 shows bus master MPU group A.

Table 16.4 Bus master MPU specifications

Parameter	Specifications
Protected master groups	Bus master MPU group A: DMA bus.
Protected region	0000 0000h to FFFF FFFFh
Number of regions	Bus master MPU group A: 32 regions.
Address specification for individual regions	Region start and end addresses configurable
Enable/disable setting for memory protection in individual regions	Settings enabled or disabled for the associated region
Access-control settings for individual regions	Permission to read and write
Operation on error detection	Reset or non-maskable interrupt
Register protection	Register can be protected from illegal writes

当堆栈指针上溢或下溢时，不可屏蔽中断保持设置。要清除错误，请通过将1写入ICU.NMICLR.SPECLR来清除不可屏蔽中断标志。写入0以清除MSMPPUCTL或PSPMPUCTL中的ERROR位。

16.3 Arm MPU

ArmMPU全面支持：

- 8个保护区
- 重叠的受保护区域，优先级升序：7=最高优先级0
  =最低优先级。
- 访问权限
- 将内存属性导出到系统。

ArmMPU不匹配和权限违规调用可编程优先级MemManage故障(HardFault)处理程序。有关详细信息，请参阅第16.7节。

16.4 总线主控MPU

总线主控MPU监视总线主控在整个地址空间（00000000h到FFFFFFFFh）。访问控制信息，由读写权限组成，最多可独立设置32个区域。总线主控MPU根据这些设置监控对每个区域的访问。如果检测到对受保护区域的访问，总线主控MPU会产生复位或不可屏蔽中断。有关错误访问的详细信息，请参阅第15节，总线中的第15.3.9节和第15.3.10节。

表16.4列出了总线主控MPU的规格，图16.3显示了框图。图16.4显示了总线主控MPU组A。

ENABLE bit (Master Group Enable)

The ENABLE bit enables or disables the bus master MPU function of master group A. When this bit is set to 1, MMPUACAn is available. When this bit is set to 0, MMPUACAn is unavailable, including permission for all regions. When writing to the ENABLE bit, simultaneously write A5h to the KEY[7:0] bits using halfword access.

OAD bit (Operation After Detection)

The OAD bit generates either a reset or a non-maskable interrupt when access to the protected region is detected by the bus master MPU. When writing to the OAD bit, simultaneously write A5h to the KEY[7:0] bits using halfword access.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writing to the ENABLE and OAD bits. When writing to the ENABLE and OAD bits, simultaneously write A5h to the KEY[7:0] bits. When other values are written, the ENABLE and OAD bits are not updated. The KEY[7:0] bits are always read as 00h.

16.4.2 Operation

16.4.2.1 Memory protection

The bus master MPU monitors memory access using control settings made individually for the access control regions. If access to a protected region is detected, the bus master MPU generates a memory protection error.

The bus master MPU can be configured for up to 32 protected regions. Protected regions include those with overlapping permitted and protected regions, and those with two overlapping permitted regions.

The bus master MPU provides group A. The memory protection function checks the address of the bus for a unified master group, and all master group accesses are protected. The bus master MPU sets the permission for all of the regions after reset. Setting MMPUCTLA.ENABLE to 1 protects all of the regions. A permitted region is set up within the protected region for each region. If access to a protected region is detected, the bus master MPU generates an error.

Figure 16.5 shows the use case of a bus master MPU.

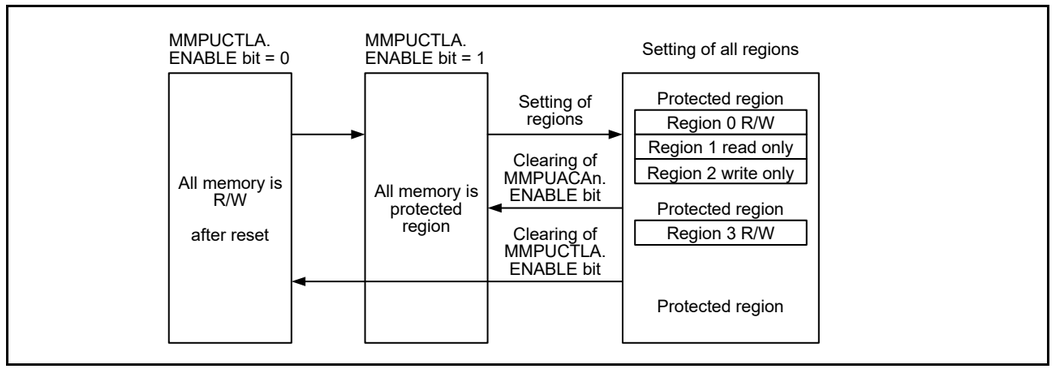

Figure 16.5 Use case of bus master MPU

Figure 16.6 shows the access permission or protection for overlapping bus master MPU regions. Access control for overlapping regions is as follows:

- The region is handled as a protected region when output of one or more region units is a protected region
- The region is handled as a protected region when output of all region units is outside of the regions
- Other cases are handled as permitted regions.

将A5h写入KEY[7:0]位。当A5h以外的值写入KEY[7:0]位时，PROTECT位不会更新。KEY[7:0]位总是读为00h。

16.4.2 Operation

16.4.2.1 内存保护

总线主控MPU使用为访问控制区域单独进行的控制设置来监视内存访问。如果检测到对受保护区域的访问，则总线主控MPU会产生内存保护错误。

总线主控MPU最多可配置为32个受保护区域。保护区包括允许区域和保护区域重叠的区域，以及两个允许区域重叠的区域。

总线主控MPU提供A组。内存保护功能检查总线地址为一个统一的主控组，所有主控组访问都受到保护。总线主控MPU在复位后设置所有区域的权限。将MMPUCTLA.ENABLE设置为1可以保护所有区域。在保护区域内为每个区域设置一个允许区域。如果检测到对受保护区域的访问，则总线主控MPU会产生错误。

图16.5显示了总线主控MPU的用例。

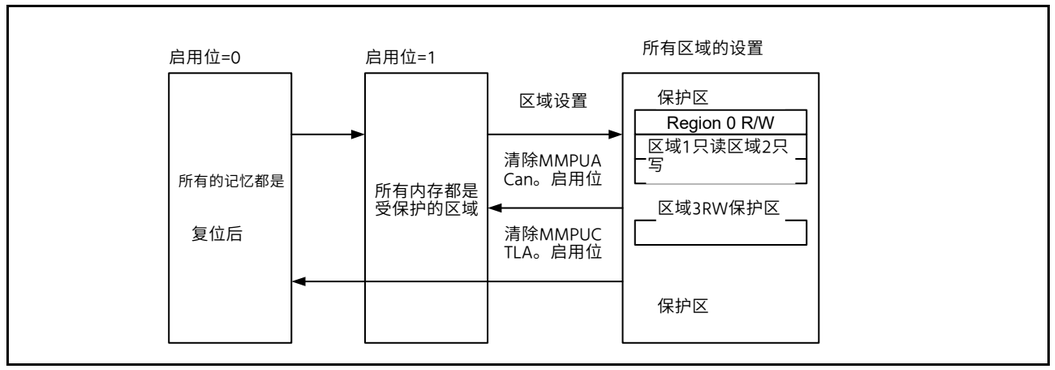

Figure 16.5 总线主控MPU用例

图16.6显示了重叠总线主控MPU区域的访问许可或保护。重叠区域的访问控制如下：

- 当一个或多个区域单元的输出是受保护区域时，该区域被视为受保护区域
- 当所有区域单元的输出都在区域之外时，该区域被视为受保护区域
- 其他情况按许可区域处理。

16.4.2.2 Protecting the registers

To protect the registers related to the bus master MPU, set the PROTECT bit in the associated MMPUPTA register.

16.4.2.3 Memory protection error

If access to a protected region is detected, the bus master MPU generates an error. Set the OAD bit to select whether the error is reported as a non-maskable interrupt or a reset. The non-maskable interrupt status is indicated in ICU.NMISR.BUSMST. For details, see section 14, Interrupt Controller Unit (ICU). The reset status is indicated in SYSTEM.RSTSR1.BUSMRF. For details, see section 6, Resets.

16.5 Bus Slave MPU

The bus slave MPU monitors access to the bus slave functions, such as flash or SRAM. The function can be accessed from two bus masters, the CPU, and the bus master MPU group A. The bus slave MPU has a separate protection register for each of the two bus masters, with individual access protection control, consisting of read and write permissions. If access to a protected region is detected, the bus slave MPU generates a reset or a non-maskable interrupt, and stores the bus error address, bus error status, and error access status. For details, see 15.3.9 and 15.3.10 in section 15, Buses.

Table 16.7 lists the specifications of the bus slave MPU and Figure 16.9 shows a block diagram.

16.4.2.2 保护寄存器

要保护与总线主控MPU相关的寄存器，请设置相关MMPUPTA寄存器中的PROTECT位。

16.4.2.3 内存保护错误

如果检测到对受保护区域的访问，则总线主控MPU会产生错误。设置OAD位以选择将错误报告为不可屏蔽中断还是复位。不可屏蔽中断状态在ICU.NMISR.BUSMST中指示。有关详细信息，请参阅第14节，中断控制器单元(ICU)。复位状态显示在

SYSTEM.RSTSR1.BUSMRF。有关详细信息，请参阅第6节，重置。

16.5 总线从MPU

总线从机MPU监控对总线从机功能的访问，例如闪存或SRAM。该功能可以从两个总线主控CPU和总线主控MPU组A访问。总线从属MPU对两个总线主控中的每一个都有一个单独的保护寄存器，具有单独的访问保护控制，包括读取和写入权限.如果检测到对受保护区域的访问，则总线从MPU产生复位或不可屏蔽中断，并存储总线错误地址、总线错误状态和错误访问状态。有关详细信息，请参阅第15节“公共汽车”中的15.3.9和15.3.10。

b15 to b8	KEY[7:0]	关键代码	这些位启用或禁用对OAD和PROTECT位的写入	R/(W)*1

注1.写入数据不保存。

OAD bit (Operation After Detection)

The OAD bit generates either a reset or non-maskable interrupt when access to the protected region is detected by the bus slave MPU. When writing to the OAD bit, simultaneously write A5h to the KEY[7:0] bits using halfword access.

PROTECT bit (Protection of Register)

The PROTECT bit enables or disables writes to the associated registers to be protected. SMPUCTL.PROTECT controls the following registers:

- SMPUMBIU
- SMPUFBIU
- SMPUSRAM0
- SMPUSRAM1
- SMPUP0BIU
- SMPUP2BIU
- SMPUP6BIU
- SMPUEXBIU
- SMPUEXBIU2.

When writing to the PROTECT bit, simultaneously write A5h to the KEY[7:0] bits using halfword access.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writes to the OAD and PROTECT bits. When writing to the OAD and PROTECT bits, simultaneously write A5h to the KEY[7:0] bits. When other values are written, the OAD and PROTECT bits are not updated. The KEY[7:0] bits are always read as 00h.

16.5.2 Operation

16.5.2.1 Memory protection

The bus slave MPU monitoring uses access control information that is set for the individual access control registers. If access to a protected region is detected, the bus slave MPU generates a memory protection error.

The bus slave MPU is enabled by writing 1 to the Write Protect (WPCPU or WPGRPA) bit or the Read Protect (RPCPU or RPGRPA) bit in the access control registers (SMPUMBIU, SMPUFBIU, SMPUSRAM0, SMPUSRAM1, SMPUP0BIU, SMPUP2BIU, SMPUP6BIU, SMPUEXBIU and SMPUEXBIU2).

16.5.2.2 Protecting the registers

Registers related to the bus slave MPU can be protected with the PROTECT bit in the SMPUCTL register.

16.5.2.3 Memory protection error

If access to a protected region is detected, the bus slave MPU generates a memory protection error. Set the OAD bit to select whether the error is reported as a non-maskable interrupt or a reset.

The non-maskable interrupt status is indicated in ICU.NMISR.BUSSST. For details, see section 14, Interrupt Controller Unit (ICU). The reset status is indicated in SYSTEM.RSTSR1.BUSSRF. For details, see section 6, Resets.

16.6 Security MPU

The MCU incorporates a security MPU with four secure regions that include the code flash, SRAM, and two security functions. The secure regions can be protected from non-secure program accesses. A non-secure program cannot access a protected region.

Table 16.8 lists the specifications of the security MPU and Figure 16.10 shows a block diagram.

OAD位（检测后操作）

当总线从机MPU检测到对受保护区域的访问时，OAD位会产生复位或不可屏蔽中断。写入OAD位时，同时使用半字访问将A5h写入KEY[7:0]位。

PROTECT位（寄存器保护）

PROTECT位启用或禁用对要保护的相关寄存器的写入。SMPUCTL.PROTECT控制以下寄存器：

- SMPUMBIU
- SMPUFBIU
- SMPUSRAM0
- SMPUSRAM1
- SMPUP0BIU
- SMPUP2BIU
- SMPUP6BIU
- SMPUEXBIU
- SMPUEXBIU2.

写入PROTECT位时，同时使用半字访问将A5h写入KEY[7:0]位。

KEY[7:0]位（键码）

KEY[7:0]位启用或禁用对OAD和PROTECT位的写入。写入OAD和PROTECT位时，同时将A5h写入KEY[7:0]位。写入其他值时，不会更新OAD和PROTECT位。KEY[7:0]位总是读为00h。

16.5.2 Operation

16.5.2.1 内存保护

总线从MPU监控使用为各个访问控制寄存器设置的访问控制信息。如果检测到对受保护区域的访问，则总线从MPU会产生内存保护错误。

总线从机MPU通过向访问控制寄存器（SMPUMBIU、SMPUFBIU、SMPUSRAM0、SMPUSRAM1、SMPUP0BIU、SMPUP2BIU、SMPUP6BIU、SMPUEXBIU）中的写保护（WPCPU或WPGRPA）位或读保护（RPCPU或RPGRPA）位写入1来启用和SMPUEXBIU2)。

16.5.2.2 保护寄存器

与总线从MPU相关的寄存器可以通过SMPUCTL寄存器中的PROTECT位进行保护。

16.5.2.3 内存保护错误

如果检测到对受保护区域的访问，则总线从MPU会产生内存保护错误。设置OAD位以选择将错误报告为不可屏蔽中断还是复位。

不可屏蔽中断状态在ICU.NMISR.BUSSST中指示。有关详细信息，请参见第14节，中断控制器单位（ICU）。复位状态在SYSTEM.RSTSR1.BUSSRF中指示。有关详细信息，请参阅第6节，重置。

16.6 Security MPU

MCU包含一个安全MPU，它具有四个安全区域，包括代码闪存、SRAM和两个安全功能。可以保护安全区域免受非安全程序访问。非安全程序无法访问受保护区域。

16.6.2 Memory Protection

The security MPU protects the regions (the code flash, the SRAM, and two security function regions) from being accessed by non-secure programs. If access to a protected region is detected, the access becomes invalid.

When the security MPU is enabled, DISPC0 or DISPC1 in the Security MPU Access Control Register (SECMPUAC), and DIS0, DIS1, DIS2, or DIS3 in the Security MPU Access Control Register (SECMPUAC) must be set to 0.

When the security MPU is disabled, all bits in DISPC0, DISPC1, DIS0, DIS1, DIS2, and DIS3 in the Security MPU Access Control Register (SECMPUAC) must be set to 1. Other settings in the Security MPU Access Control Register (SECMPUAC) are prohibited.

The security MPU provides access protection in the following conditions:

- Secure data is accessed from a non-secure program
- Secure data is accessed from other than the CPU (DMAC, DTC)
- Secure data is accessed from the debugger.

Secure data is accessible only from a secure program.

Note: Secure program: Code flash or SRAM region within the limits set up by SECMPUPCS0 and SECMPUPCE0, code flash or SRAM region within the limits set up by SECMPUPCS1 and SECMPUPCE1.
Non-secure program: All regions outside the secure program.
Secure data: Code flash region within the limits set up by SECMPUS0 and SECMPUE0, SRAM region within the limits set up by SECMPUS1 and SECMPUE1, security function region within the limits set up by SECMPUS2 and SECMPUE2, security Function region within the limits set up by SECMPUS3 and SECMPUE3.

Note: 当闪存被擦除时，安全MPU被禁用。
Note: 要启用或禁用安全MPU，请参阅第16.6.2节，内存保护。

DIS0位（区域0禁用）

DIS0位启用或禁用安全MPU区域0。如果启用安全MPU区域0，则在SECMPUS0和SECMPUE0设置的限制范围内的代码闪存区域是安全数据。

DIS1位（区域1禁用）

DIS1位启用或禁用安全MPU区域1。如果启用安全MPU区域1，则由SECMPUS1和SECMPUE1设置的限制内的SRAM区域是安全数据。

DIS2位（区域2禁用）

DIS2位启用或禁用安全MPU区域2。如果启用安全MPU区域2，则在SECMPUS2和SECMPUE2设置的限制范围内的区域是安全数据。

DIS3位（区域3禁用）

DIS3位启用或禁用安全MPU区域3。如果启用安全MPU区域3，则在SECMPUS3和SECMPUE3设置的限制范围内的区域是安全数据。

DISPC0位（PC区域0禁用）

DISPC0位启用或禁用安全MPUPC区域0。如果启用安全MPUPC区域0，则在SECMPUPCS0和SECMPUPCE0设置的限制范围内的代码闪存或SRAM区域包含安全程序。

DISPC1位（PC区域1禁用）

DISPC1位启用或禁用安全MPUPC区域1。如果启用安全MPUPC区域1，则在SECMPUPCS1和SECMPUPCE1设置的限制范围内的代码闪存或SRAM区域包含安全程序。

16.6.2 内存保护

安全MPU保护区域（代码闪存、SRAM和两个安全功能区域）不被非安全程序访问。如果检测到对受保护区域的访问，则访问变为无效。

启用安全MPU时，必须将安全MPU访问控制寄存器(SECMPUAC)中的DISPC0或DISPC1以及安全MPU访问控制寄存器(SECMPUAC)中的DIS0、DIS1、DIS2或DIS3设置为0。

禁用安全MPU时，安全MPU中DISPC0、DISPC1、DIS0、DIS1、DIS2和DIS3中的所有位访问控制寄存器(SECMPUAC)必须设置为1。禁止安全MPU访问控制寄存器(SECMPUAC)中的其他设置。

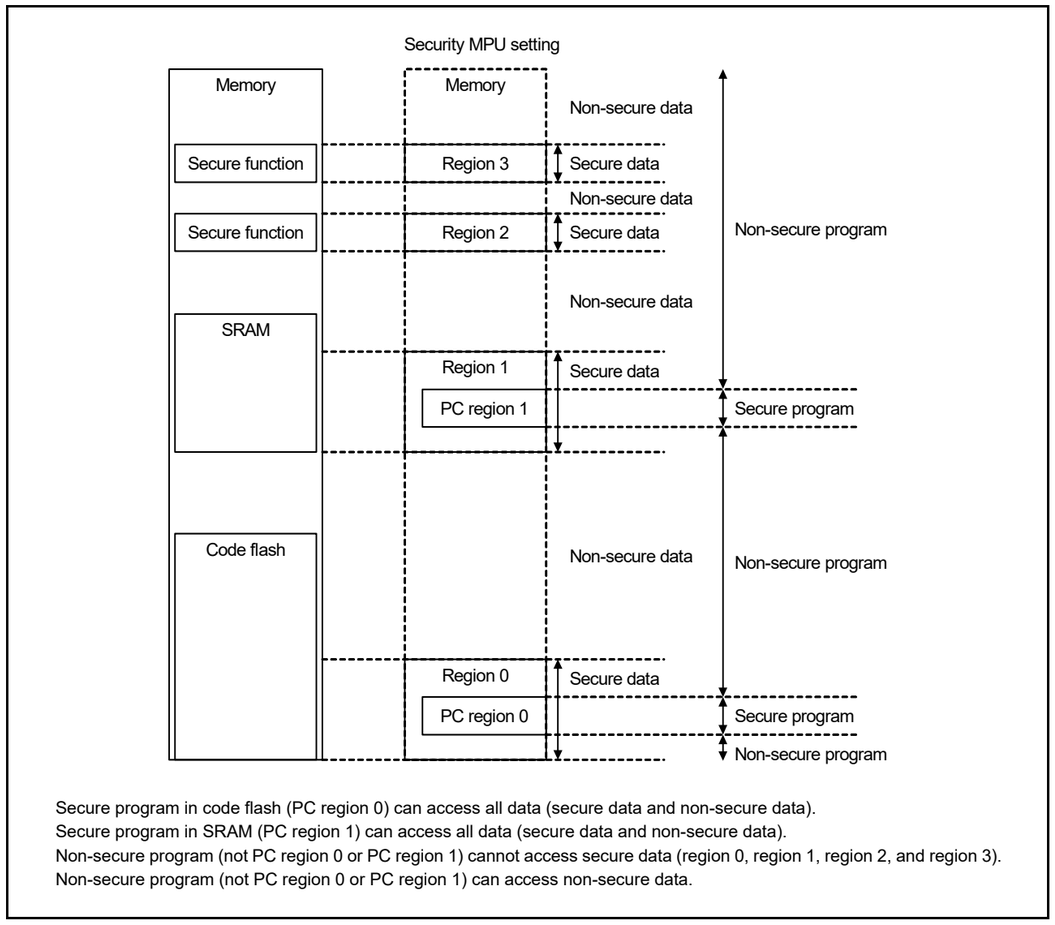
安全MPU在以下情况下提供访问保护：

- 从非安全程序访问安全数据
- 从CPU以外的地方访问安全数据（DMAC、DTC）
- 从调试器访问安全数据。

安全数据只能从安全程序访问。

Note: 安全程序：在SECMPUPCS0和SECMPUPCE0设置的范围内的代码闪存或SRAM区域，在SECMPUPCS1和SECMPUPCE1设置的范围内的代码闪存或SRAM区域。非安全程序：安全程序之外的所有区域。

Secure data: 在SECMPUS0和SECMPUE0设置的限制范围内的代码闪存区域，SRAM区域在SECMPUS1和SECMPUE1设置范围内，安全功能区域在SECMPUS2和SECMPUE2设置范围内，安全功能区域在SECMPUS3和SECMPUE3设置范围内。



Secure program in code flash (PC region 0) can access all data (secure data and non-secure data).
Secure program in SRAM (PC region 1) can access all data (secure data and non-secure data).
Non-secure program (not PC region 0 or PC region 1) cannot access secure data (region 0, region 1, region 2, and region 3).
Non-secure program (not PC region 0 or PC region 1) can access non-secure data.

17. DMA Controller (DMAC)

17.1 Overview

The MCU includes an 8-channel DMA Controller (DMAC) that can transfer data without intervention from the CPU. When a DMA transfer request is generated, the DMAC transfers data stored at the transfer source address to the transfer destination address.

Table 17.1 lists the DMAC specifications and Figure 17.1 shows a block diagram.

Transfer mode	Normal transfer mode	• One data transfer by one DMA transfer request • Selectable free running mode (total number of data transfers is not specified).
	Repeat transfer mode	• One data transfer by one DMA transfer request • Program returns to the transfer start address on completion of the repeat size of data transfer specified for the transfer source or destination • Maximum settable repeat size: 1,024.

Note 1. For details on DMAC activation sources, see Table 14.3, Interrupt vector table in section 14, Interrupt Controller Unit (ICU).

17. DMA Controller (DMAC)

17.1 Overview

MCU包含一个8通道DMA控制器(DMAC)，无需CPU干预即可传输数据。
当产生DMA传输请求时，DMAC将存储在传输源地址的数据传输到传输目标地址。

表17.1列出了DMAC规范，图17.1显示了框图。

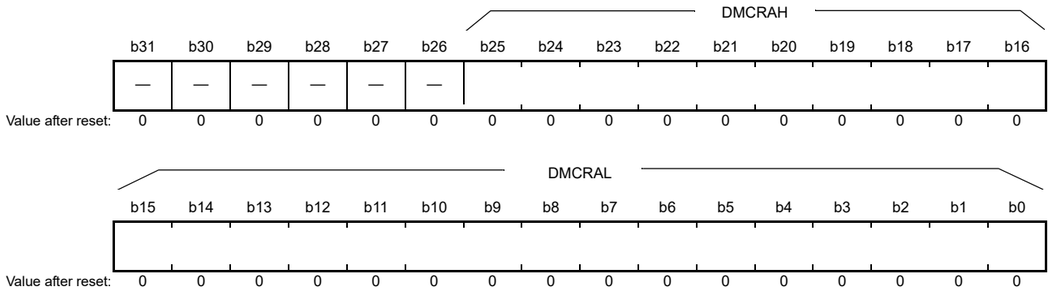
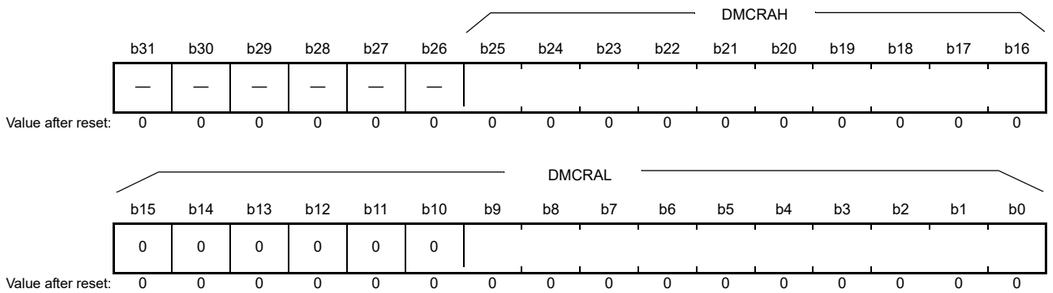
- Normal transfer mode



- Repeat transfer mode, block transfer mode



Symbol	Bit name	Description	R/W
DMCRAL	Lower bits of transfer count	Specifies the number of transfer operations	R/W
DMCRAH	Upper bits of transfer count		R/W

Note: In repeat and block transfer modes, set the same value for DMCRAH and DMCRAL.

(1) Normal transfer mode (MD[1:0] bits in DMACm.DMTMD = 00b)

In normal transfer mode, DMCRAL functions as a 16-bit transfer counter. The number of transfer operations is one when the setting is 0001h, and 65535 when it is FFFFh. The value is decremented by 1 each time data is transferred. A setting of 0000h indicates an unspecified number of transfer operations. Data transfer is performed with the transfer counter stopped, that is, in free running mode.

Do not use DMCRAH in normal transfer mode. Write 0000h to DMCRAH.

(2) Repeat transfer mode (MD[1:0] bits in DMACm.DMTMD = 01b)

In repeat transfer mode, DMCRAH specifies the repeat size and DMCRAL functions as a 10-bit transfer counter. The number of transfer operations is one when the setting is 001h, 1023 when it is 3FFh, and 1024 when it is 000h. In this mode, a value in the range of 000h to 3FFh (1 to 1024) can be set for DMCRAH and DMCRAL.

Setting bits [15:10] in DMCRAL is invalid. Write 0 to these bits. The value in DMCRAL is decremented by 1 each time data is transferred until it reaches 000h, at which time the value in DMCRAH is loaded into DMCRAL.

(3) Block transfer mode (MD[1:0] bits in DMACm.DMTMD = 10b)

In block transfer mode, DMCRAH specifies the block size and DMCRAL functions as a 10-bit block size counter. The block size is one when the setting is 001h, 1023 when it is 3FFh, and 1024 when it is 000h. In this mode, a value in the

DMCRAL	传输计数的低位	指定传输操作的次数	R/W
DMCRAH	传输计数的高位		R/W

Note: 在重复和块传输模式下，为DMCRAH和DMCRAL设置相同的值。

(1) 正常传输模式（DMACm.DMTMD=00b中的MD[1:0]位）

在正常传输模式下，DMCRAL用作16位传输计数器。设置为0001h时传输操作数为1，设置为FFFFh时为65535。每次传输数据时，该值减1。设置为0000h表示未指定数量的传输操作。数据传输是在传输计数器停止的情况下执行的，即在自由运行模式下。

不要在正常传输模式下使用DMCRAH。将0000h写入DMCRAH。

(2) 重复传输模式（DMACm.DMTMD=01b中的MD[1:0]位）

在重复传输模式下，DMCRAH指定重复大小，DMCRAL用作10位传输计数器。设置为001h时传输操作数为1，设置为3FFh时为1023，设置为000h时为1024。在此模式下，可以为DMCRAH和DMCRAL设置000h到3FFh（1到1024）范围内的值。

在DMCRAL中设置位[15:10]无效。将0写入这些位。每次传输数据时，DMCRAL中的值减1，直到到达000h，此时DMCRAH中的值被加载到DMCRAL中。

(3) 块传输模式（DMACm.DMTMD=10b中的MD[1:0]位）

在块传输模式下，DMCRAH指定块大小，DMCRAL用作10位块大小计数器。设置为001h时块大小为1，设置为3FFh时为1023，设置为000h时为1024。在这种模式下，在一个值

Setting bits [15:10] in DMCRAL is invalid. Write 0 to these bits. The value in DMCRAL is decremented by 1 each time data is transferred until it reaches 000h, at which time the value in DMCRAH is loaded into DMCRAL.

b15 to b0	Specifies the number of block or repeat transfer operations	0001h to FFFFh (1 to 65535) 0000h (65536).	R/W

DMCRB specifies the number of operations in block and repeat transfer modes. The number of transfer operations is one when the setting is 0001h, 65535 when it is FFFFh, and 65536 when it is 0000h.

In repeat transfer mode, the value is decremented by 1 when the final data of one repeat size is transferred. In block transfer mode, the value is decremented by 1 when the final data of one block size is transferred. Do not use DMCRB in normal transfer mode as the setting is invalid.

DARIE bit (Destination Address Extended Repeat Area Overflow Interrupt Enable)

When an extended repeat area overflow occurs on the destination address when the DARIE bit is set to 1, the DTE bit in DMCNT is set to 0. At the same time, the ESIF flag in DMSTS is set to 1 to indicate an interrupt request triggered by an extended repeat area overflow on the destination address.

When block transfer mode is used with the extended repeat area function, an interrupt occurs after completion of a 1-block size transfer. When the DTE bit is set to 1 in DMACm.DMCNT of the channel associated with the stopped transfer, the transfer resumes from the state it was in when the transfer stopped. If the extended repeat area is not specified for the destination address, this bit is ignored.

SARIE bit (Source Address Extended Repeat Area Overflow Interrupt Enable)

When an extended repeat area overflow occurs on the source address when the SARIE bit is set to 1, the DTE bit in DMCNT is set to 0. At the same time, the ESIF flag in DMSTS is set to 1 to indicate an interrupt request triggered by an extended repeat area overflow on the source address.

When block transfer mode is used with the extended repeat area function, an interrupt occurs after completion of a 1-block size transfer. When the DTE bit is set to 1 in DMACm.DMCNT of the channel associated with the stopped transfer, the transfer resumes from the state it was in when the transfer stopped. When the extended repeat area is not specified for the source address, this bit is ignored.

RPTIE bit (Repeat Size End Interrupt Enable)

When the RPTIE bit is set to 1 in repeat transfer mode, the DTE bit in DMCNT clears to 0 after completion of a 1-repeat size data transfer. At the same time, the ESIF flag in DMSTS is set to 1 to indicate that the repeat size end interrupt request occurred. The repeat size end interrupt request can be generated even when the DTS[1:0] bits in DMTMD are 10b (repeat area or block area is not specified).

When the RPTIE bit is set to 1 in block transfer mode, the DTE bit in DMCNT sets to 0 after completion of a 1-block

Note 1. 要选择DMAC激活源，请使用ICU的DELSRn寄存器。有关DMAC激活源的详细信息，请参阅表14.4，第14节中的事件表，中断控制器单元(ICU)。

DTS[1:0]位（重复区域选择）

DTS[1:0]位在重复传输模式中选择源或目标作为重复区域，在块传输模式中选择块区域。在正常传输模式下，这些位设置无效。

DARIE位（目标地址扩展重复区域溢出中断使能）

当DARIE位设置为1时，当目标地址发生扩展重复区域溢出时，DMCNT中的DTE位设置为0。同时，DMSTS中的ESIF标志位设置为1，表示触发了中断请求通过目标地址上的扩展重复区域溢出。

当块传输模式与扩展重复区域功能一起使用时，在完成1块大小的传输后会发生中断。当与停止传输关联的通道的DMACm.DMCNT中的DTE位设置为1时，传输将从传输停止时的状态恢复。如果没有为目标地址指定扩展重复区域，则忽略该位。

SARIE位（源地址扩展重复区溢出中断使能）

当SARIE位设置为1时，当源地址发生扩展重复区域溢出时，DTE位DMCNT设置为0。同时，DMSTS中的ESIF标志设置为1，表示源地址上的扩展重复区域溢出触发的中断请求。

当块传输模式与扩展重复区域功能一起使用时，在完成1块大小的传输后会发生中断。当与停止传输关联的通道的DMACm.DMCNT中的DTE位设置为1时，传输将从传输停止时的状态恢复。当源地址没有指定扩展重复区域时，该位被忽略。

RPTIE位（重复大小结束中断使能）

当RPTIE位在重复传输模式下设置为1时，DMCNT中的DTE位在完成1次重复大小的数据传输后清为0。同时，DMSTS中的ESIF标志设置为1，表示发生了重复大小结束中断请求。即使DMTMD中的DTS[1:0]位为10b（未指定重复区域或块区域），也可以产生重复大小结束中断请求。

当RPTIE位在块传输模式下设置为1时，DMCNT中的DTE位在1块完成后设置为0

data transfer in the same way as repeat transfer mode. At the same time, the ESIF flag in DMSTS is set to 1 to indicate that the repeat size end interrupt request occurred. The repeat size end interrupt request can be generated even when the DTS[1:0] bits in DMTMD are 10b (repeat area or block area is not specified).

ESIE bit (Transfer Escape End Interrupt Enable)

The ESIE bit enables the transfer escape end interrupt requests (repeat size end interrupt request and extended repeat area overflow interrupt request) that occur during DMA transfer. The interrupt occurs when this bit is 1 and the ESIF flag in DMSTS is set to 1. To clear the transfer escape end interrupt, clear this bit or the ESIF flag in DMSTS to 0.

DTIE bit (Transfer End Interrupt Enable)

The DTIE bit enables the transfer end interrupt request that occurs on completion of a specified number of data transfers. The interrupt occurs when this bit is 1 and the DTIF flag in DMSTS is set to 1. To clear the transfer end interrupt, clear this bit or the DTIF flag in DMSTS to 0.

DARA[4:0] bits (Destination Address Extended Repeat Area)

The DARA[4:0] bits specify the extended repeat area on the destination address. The extended repeat area function is realized through an update of the specified lower address bits with the remaining upper address bits fixed. The size of the extended repeat area can be any power of 2 between 2 bytes and 128 MB. The start address of the extended repeat area is set when the lower address overflows the extended repeat area on an address increment. Similarly, the end address of the extended repeat area is set when the lower address underflows the extended repeat area on an address decrement.

Do not specify the extended repeat area on the destination address when a repeat or block area is specified as the transfer destination. When repeat or block transfer is selected, and when DMACm.DMTMD.DTS[1:0] = 00b (the transfer destination is specified as the repeat or block area), write 00000b in the DARA[4:0] bits.

To request an interrupt when an overflow or underflow occurs in the extended repeat area, set the DARIE bit in DMINT to 1. Table 17.2 lists the extended repeat areas associated with each setting.

DM[1:0] bits (Destination Address Update Mode)

The DM[1:0] bits select the update mode for the destination address.

数据传输方式与重复传输模式相同。同时，DMSTS中的ESIF标志设置为1，表示发生了重复大小结束中断请求。即使DMTMD中的DTS[1:0]位为10b（未指定重复区域或块区域），也可以产生重复大小结束中断请求。

ESIE位（传输转义结束中断使能）

ESIE位使能在DMA传输期间发生的传输转义结束中断请求（重复大小结束中断请求和扩展重复区域溢出中断请求）。该位为1且DMSTS中的ESIF标志设置为1时发生中断。要清除传输转义结束中断，请将该位或DMSTS中的ESIF标志清除为0。

DTIE位（传输结束中断使能）

DTIE位使能在完成指定数量的数据传输时发生的传输结束中断请求。当该位为1且DMSTS中的DTIF标志设置为1时发生中断。要清除传输结束中断，请将该位或DMSTS中的DTIF标志清除为0。

DARA[4:0]位（目标地址扩展重复区域）

DARA[4:0]位指定目标地址上的扩展重复区域。扩展重复区功能是通过更新指定的低地址位来实现的，而其余的高地址位是固定的。扩展重复区域的大小可以是2字节到128MB之间的任意2次幂。当低地址在地址增量上溢出扩展重复区域时，设置扩展重复区域的起始地址。类似地，在地址减量时，当低位地址下溢扩展重复区域时，设置扩展重复区域的结束地址。

将重复或块区域指定为传输目标时，请勿在目标地址上指定扩展重复区域。选择重复或块传输时，并且当DMACm.DMTMD.DTS[1:0]=00b（传输目标指定为重复或块区域）时，将00000b写入DARA[4:0]位。

要在扩展重复区域发生上溢或下溢时请求中断，请将DMINT中的DARIE位设置为1。表17.2列出了与每个设置相关的扩展重复区域。

DM[1:0]位（目标地址更新模式）

DM[1:0]位选择目标地址的更新模式。

- When increment is selected and the SZ[1:0] bits in DMTMD are set to 00b, 01b, and 10b, the destination address is incremented by 1, 2, and 4, respectively
- When decrement is selected and the SZ[1:0] bits in DMTMD are set to 00b, 01b, and 10b, the destination address is decremented by 1, 2, and 4, respectively
- When offset addition is selected, the offset specified in the DMACm.DMOFR register is added to the address.

SARA[4:0] bits (Source Address Extended Repeat Area)

The SARA[4:0] bits specify the extended repeat area on the source address. The extended repeat area function is realized through an update of the specified lower address bits with the remaining upper address bits fixed. The size of the extended repeat area can be any power of 2 between 2 bytes and 128 MB. The start address of the extended repeat area is set when the lower address overflows the extended repeat area on an address increment. Similarly, the end address of the extended repeat area is set when the lower address underflows the extended repeat area on an address decrement.

Do not specify the extended repeat area on the source address when a repeat or block area is specified as the transfer source. When repeat or block transfer is selected, and when DMACm.DMTMD.DTS[1:0] = 01b (the transfer source is specified as the repeat or block area), write 00000b in the SARA[4:0] bits.

To request an interrupt when an overflow or underflow occurs in the extended repeat area, set the SARIE bit in DMINT to 1. Table 17.2 lists the extended repeat areas associated with each setting.

SM[1:0] bits (Source Address Update Mode)

The SM[1:0] bits select the update mode for the source address:

- When increment is selected and the SZ[1:0] bits in DMTMD are set to 00b, 01b, and 10b, the source address is incremented by 1, 2, and 4, respectively
- When decrement is selected and the SZ[1:0] bits in DMTMD are set to 00b, 01b, and 10b, the source address is decremented by 1, 2, and 4, respectively
- When offset addition is selected, the offset specified in the DMACm.DMOFR register is added to the address.

SARA[4:0]位（源地址扩展重复区）

SARA[4:0]位指定源地址上的扩展重复区域。扩展重复区功能是通过更新指定的低地址位来实现的，而其余的高地址位是固定的。扩展重复区域的大小可以是2字节到128MB之间的任意2次幂。当低地址在地址增量上溢出扩展重复区域时，设置扩展重复区域的起始地址。类似地，在地址减量时，当低位地址下溢扩展重复区域时，设置扩展重复区域的结束地址。

当重复或块区域被指定为传输源时，不要在源地址上指定扩展重复区域。选择重复或块传输时，并且当DMACm.DMTMD.DTS[1:0]=01b（传输源指定为重复或块区域）时，将00000b写入SARA[4:0]位。

要在扩展重复区域发生上溢或下溢时请求中断，请将DMINT中的SARIE位设置为1。表17.2列出了与每个设置相关的扩展重复区域。

b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SWREQ bit (DMA Software Start)

Writing 1 to the SWREQ bit generates a DMA transfer request. After DMA transfer starts, SWREQ sets to 0 if the CLRS bit is 0. SWREQ does not clear if CLRS bit is 1. The DMA transfer request can be issued again after the transfer is complete.

Note: Setting this bit is valid and DMA transfer by software is enabled only when the DCTG[1:0] bits in DMTMD are set to 00b, specifying software as the DMA activation source. Setting this bit is invalid when the DCTG[1:0] bits in DMTMD are set to any value other than 00b.

To start DMA transfer by software with the CLRS bit set to 0, ensure that the SWREQ bit is 0, then write 1 to the SWREQ bit.

[Setting condition]

CLRS bit (DMA Software Start Bit Auto Clear Select)

When an SWREQ setting of 1 triggers a transfer request, the CLRS bit specifies whether to clear the SWREQ bit to 0 after DMA transfer starts. When the CLRS bit is set to 0, SWREQ sets to 0 after DMA transfer starts. When the CLRS bit is set to 1, SWREQ is not set to 0. A DMA transfer request can be issued again after the transfer is complete.

SWREQ位（DMA软件启动）

将1写入SWREQ位会生成DMA传输请求。DMA传输开始后，如果CLRS位为0，则SWREQ设置为0。如果CLRS位为1，则SWREQ不清除。传输完成后可以再次发出DMA传输请求。

Note: 只有当DMTMD中的DCTG[1:0]位设置为00b时，设置该位才有效，并且通过软件启用DMA传输，将软件指定为DMA激活源。当DMTMD中的DCTG[1:0]位设置为00b以外的任何值时，设置该位无效。

要在CLRS位设置为0的情况下通过软件启动DMA传输，请确保SWREQ位为0，然后将1写入SWREQ bit.

[Clearing conditions]

17.3 Operation

17.3.1 Transfer Mode

(1) Normal transfer mode

In normal transfer mode, one data unit is transferred for one transfer request. You can specify the number of transfer operations, up to a maximum of 65535, in DMACm.DMCRAL. When these bits are set to 0000h, no number of operations is specified and data transfer is performed with the transfer counter stopped (free running mode). A transfer end interrupt request can be generated after completion of the specified number of transfer operations, except when in free running mode. Setting DMACm.DMCRB is invalid in normal transfer mode.

17.3.1 传输模式

(1) 正常传输模式

在正常传输模式下，对于一个传输请求传输一个数据单元。您可以在DMACm.DMCRAL中指定传输操作的数量，最多为65535。当这些位设置为0000h时，不指定操作数，并且在传输计数器停止的情况下执行数据传输（自由运行模式）。在完成指定数量的传输操作后，可以生成传输结束中断请求，自由运行模式除外。在正常传输模式下设置DMACm.DMCRB无效。

Figure 17.2 shows the operation in normal transfer mode.

(2) Repeat transfer mode

In repeat transfer mode, one data unit is transferred for one transfer request. The repeat transfer size, up to a maximum of 1K data units, is set in DMACm.DMCRA. The number of repeat transfers, up to a maximum of 64K, is set in DMACm.DMCRB. The total data transfer size can be set to a maximum of 64M data units (1K data units × 64K repeat transfer operations).

You can specify either the transfer source or destination as a repeat area. When transfer of the repeat size data is complete, the address of the specified repeat area (DMSAR or DMDAR in DMACm) returns to the transfer start address. In this mode, when all data of the specified repeat size is transferred, DMA transfer can be stopped and a repeat size end interrupt can be requested. To resume DMA transfer, write 1 to the DTE bit in DMACm.DMCNT during repeat size end interrupt handling.

A transfer end interrupt request can be generated after completion of the specified number of repeat transfers.

Table 17.4 summarizes the register update operation in repeat transfer mode, and Figure 17.3 shows the operation in repeat transfer mode.

(2) 重复传输模式

在重复传输模式中，对于一个传输请求传输一个数据单元。在DMACm.DMCRA中设置了最多1K数据单元的重复传输大小。在DMACm.DMCRB中设置了最多64K的重复传输次数。总数据传输大小最多可设置为64M数据单元（1K数据单元×64K重复传输操作）。

您可以将传输源或目标指定为重复区域。当重复大小数据的传输完成时，指定的重复区域（DMACm中的DMSAR或DMDAR）的地址返回到传输起始地址。在此模式下，当指定重复大小的所有数据都传输完毕后，可以停止DMA传输并请求重复大小结束中断。要恢复DMA传输，请在重复大小结束中断处理期间将1写入DMACm.DMCNT中的DTE位。

完成指定次数的重复传输后，可以产生传输结束中断请求。

(3) Block transfer mode

In block transfer mode, a single data block is transferred for one transfer request. The block size, up to a maximum of 1K data units, is set in DMACm.DMCRA. The number of block transfers, up to a maximum of 64K, is set in DMACm.DMCRB. A total data transfer size up to a maximum of 64M data units (1K data units × 64K block transfer operations) can be set.

You can specify either the transfer source or destination as a block area. When transfer of a single data block is complete, the address of the specified block area (DMSAR or DMDAR in DMACm) returns to the transfer start address. In this mode, when all data in a single block is transferred, DMA transfer can be stopped and a repeat size end interrupt can be requested. To resume DMA transfer, write 1 to the DTE bit in DMACm.DMCNT during repeat size end interrupt handling.

A transfer end interrupt request can be generated after completion of the specified number of block transfers.

在块传输模式下，为一个传输请求传输一个数据块。在DMACm.DMCRA中设置了最多1K个数据单元的块大小。在DMACm.DMCRB中设置了最多64K的块传输次数。总数据传输大小最多可设置为64M数据单元（1K数据单元×64K块传输操作）。

您可以将传输源或目标指定为块区域。当单个数据块的传输完成时，指定块区域的地址（DMACm中的DMSAR或DMDAR）返回到传输起始地址。在这种模式下，当单个块中的所有数据都传输完毕后，可以停止DMA传输并请求重复大小结束中断。要恢复DMA传输，请在重复大小结束中断处理期间将1写入DMACm.DMCNT中的DTE位。

17.3.2 Extended Repeat Area Function

The DMAC supports extended repeat areas on the transfer source and destination addresses, specified separately in the transfer source address register (DMSAR) and transfer destination address register (DMDAR) of DMACm. When this function is set, the address registers repeatedly indicate the addresses of the specified extended repeat areas.

The extended repeat area on the source address is specified in the SARA[4:0] bits in DMACm.DMAMD. The extended repeat area on the destination address is specified in the DARA[4:0] bits in DMACm.DMAMD. You can specify different sizes for the source and destination. However, you must not specify a transfer source or destination that is set as the repeat or block area as the extended repeat area.

When the address register value reaches the end address of the extended repeat area and the extended repeat area overflows, DMA transfer is stopped and an extended repeat area overflow interrupt can be requested. When an overflow occurs in the extended repeat area on the transfer source while the SARIE bit in DMACm.DMINT is set to 1, the ESIF flag in DMACm.DMSTS is set to 1 and the DTE bit in DMACm.DMCNT sets to 0 to stop DMA transfer. At this point, if the ESIE bit in DMACm.DMINT is set to 1, an extended repeat area overflow interrupt is requested. When the DARIE bit in DMACm.DMINT is set to 1, the destination address register becomes a target for the function. To resume DMA transfer, write 1 to the DTE bit in DMACm.DMCNT during interrupt handling.

Figure 17.5 shows an example of the extended repeat area operation.

17.3.2 扩展重复区域功能

DMAC支持在传输源地址和目标地址上扩展重复区域，分别在DMACm的传输源地址寄存器(DMSAR)和传输目标地址寄存器(DMDAR)中指定。设置此功能时，地址寄存器重复指示指定扩展重复区域的地址。

源地址上的扩展重复区域在DMACm.DMAMD中的SARA[4:0]位中指定。目标地址上的扩展重复区域在DMACm.DMAMD中的DARA[4:0]位中指定。您可以为源和目标指定不同的大小。但是，您不能将设置为重复或块区域的传输源或目标指定为扩展重复区域。

当地址寄存器值到达扩展重复区的结束地址并且扩展重复区溢出时，DMA传输停止并且可以请求扩展重复区溢出中断。当DMACm.DMINT中的SARIE位设置为1时，传输源的扩展重复区域发生溢出时，DMACm.DMSTS中的ESIF标志设置为1，DMACm.DMCNT中的DTE位设置为0以停止DMA传输。此时，如果DMACm.DMINT中的ESIE位设置为1，则请求扩展重复区域溢出中断。当DMACm.DMINT中的DARIE位设置为1时，目标地址寄存器成为函数的目标。要恢复DMA传输，请在中断处理期间将1写入DMACm.DMCNT中的DTE位。

图17.5显示了扩展重复区域操作的示例。

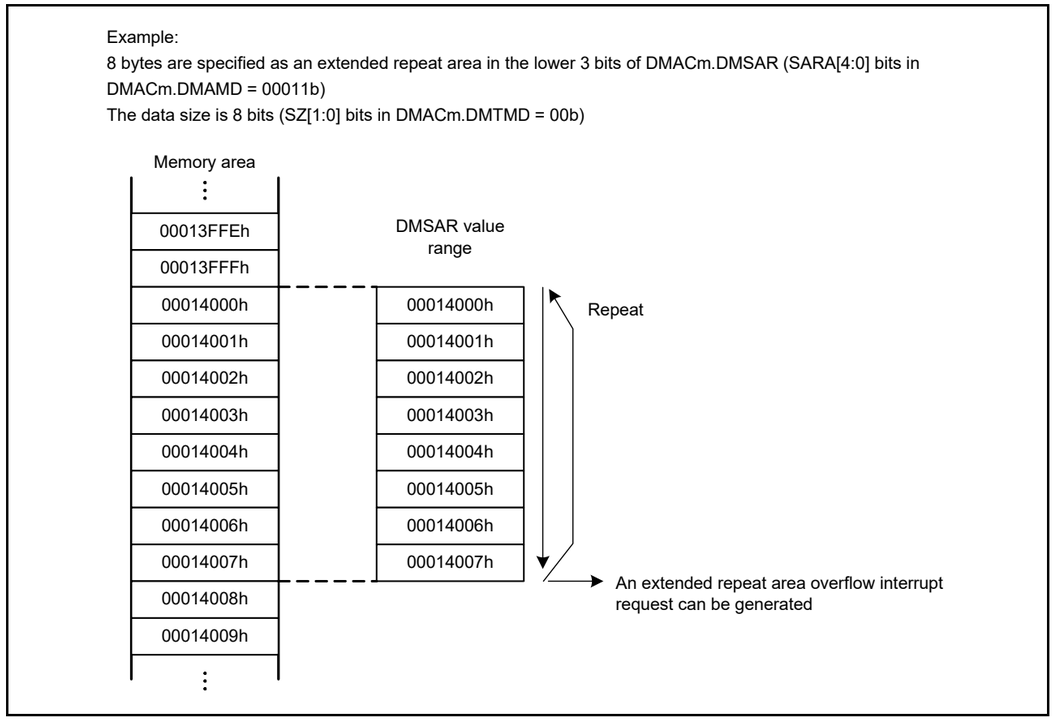

Figure 17.5 Example of extended repeat area operation

When using extended repeat area overflow interrupts in block transfer mode, consider the following points:

- When a transfer is stopped by an extended repeat area overflow interrupt, the address register must be set so that the block size is a power of 2 or the block size boundary is aligned with the extended repeat area boundary. When an overflow on the extended repeat area occurs during a transfer of one block, the overflow interrupt is suspended until transfer of the block is complete, and the transfer overruns.

Figure 17.6 shows an example of using the extended repeat area function in block transfer mode.

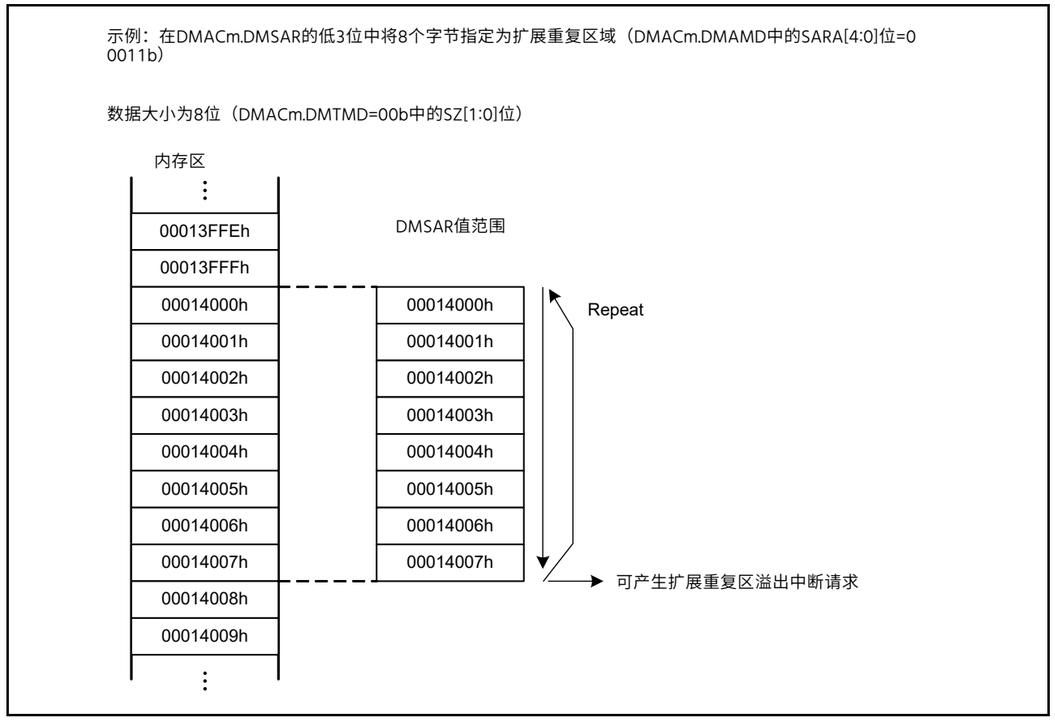

Figure 17.5 扩展重复区域操作示例

在块传输模式下使用扩展重复区域溢出中断时，请考虑以下几点：

- 当传输被扩展重复区域溢出中断停止时，地址寄存器必须设置为块大小为2的幂或块大小边界与扩展重复区域边界对齐。当一个块的传输过程中扩展重复区域发生溢出时，溢出中断被暂停，直到块的传输完成，传输溢出。

图17.6显示了在块传输模式下使用扩展重复区域功能的示例。

17.3.3 Address Update Function Using Offset

The source and destination addresses can be updated by fixing, incrementing, decrementing, or adding an offset. When offset addition is selected, the offset specified in the DMA Offset Register (DMACm.DMOFR) is added to the address every time the DMAC performs one data transfer. You can also subtract an offset by setting a negative value in DMACm.DMOFR. The negative value must be in two's complement.

Table 17.6 shows the address update method in each address update mode.

Table 17.6 Address update method in each address update mode

Address fixed	00b	Fixed		
Offset addition	01b	+DMACm.DMOFR*1		
Increment	10b	+1	+2	+4
Decrement	11b	-1	-2	-4

Note 1. When setting a negative value in the DMA Offset Register, the value must be in two's complement, obtained by the following formula:
Two's complement of a negative offset value = ~ (offset) + 1 (~ = bit inversion)

(1) Basic transfer using offset addition

Figure 17.7 shows an example of address updating using offset addition.

示例：在DMACm.DMSAR的低3位中指定8个字节作为扩展重复区域（DMACm.DMAMD中的SARA[4:0]位=00011b）设置块大小为5的块传输模式（DMACm.DMCRA=00050005h）

传输源地址未指定为块区域
数据大小为8位（DMACm.DMTMD=00b中的SZ[1:0]位）

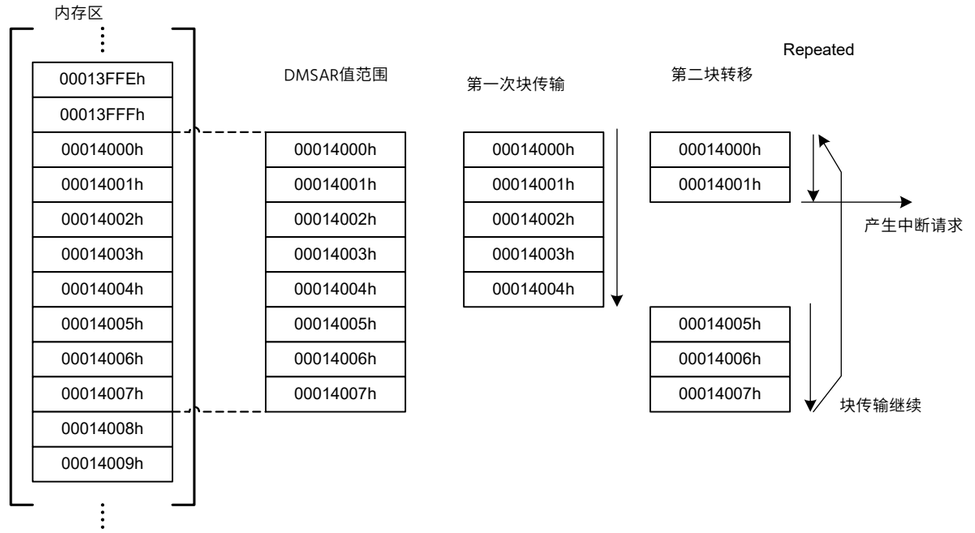

Figure 17.6 块传输模式下的扩展重复区域功能示例

17.3.3 使用偏移的地址更新功能

可以通过固定、递增、递减或添加偏移量来更新源地址和目标地址。选择偏移添加时，DMA偏移寄存器(DMACm.DMOFR)中指定的偏移会在每次DMAC执行一次数据传输时添加到地址。您还可以通过在DMACm.DMOFR中设置负值来减去偏移量。负值必须是二进制补码。

表17.6显示了每种地址更新模式下的地址更新方法。

Table 17.6 各地址更新模式下的地址更新方法

地址更新方式	的设置DMACm.DMAMD.SM[1:0]和DMACm.DMAMD.DM[1:0]用于地址更新模式	不同SZ[1:0]设置的地址更新方法DMACm.DMTMD		
		SZ[1:0] = 00b	SZ[1:0] = 01b	SZ[1:0] = 10b
地址固定	00b	Fixed		
偏移量加法	01b	+DMACm.DMOFR*1		
Increment	10b	+1	+2	+4
Decrement	11b	-1	-2	-4

Note 1. 在DMA偏移寄存器中设置负值时，该值必须是二进制补码，通过以下公式获得：负偏移值的二进制补码=~(offset)+1(~=bitinversion)

(1) 使用偏移加法的基本传输

图17.7显示了使用偏移量加法进行地址更新的示例。

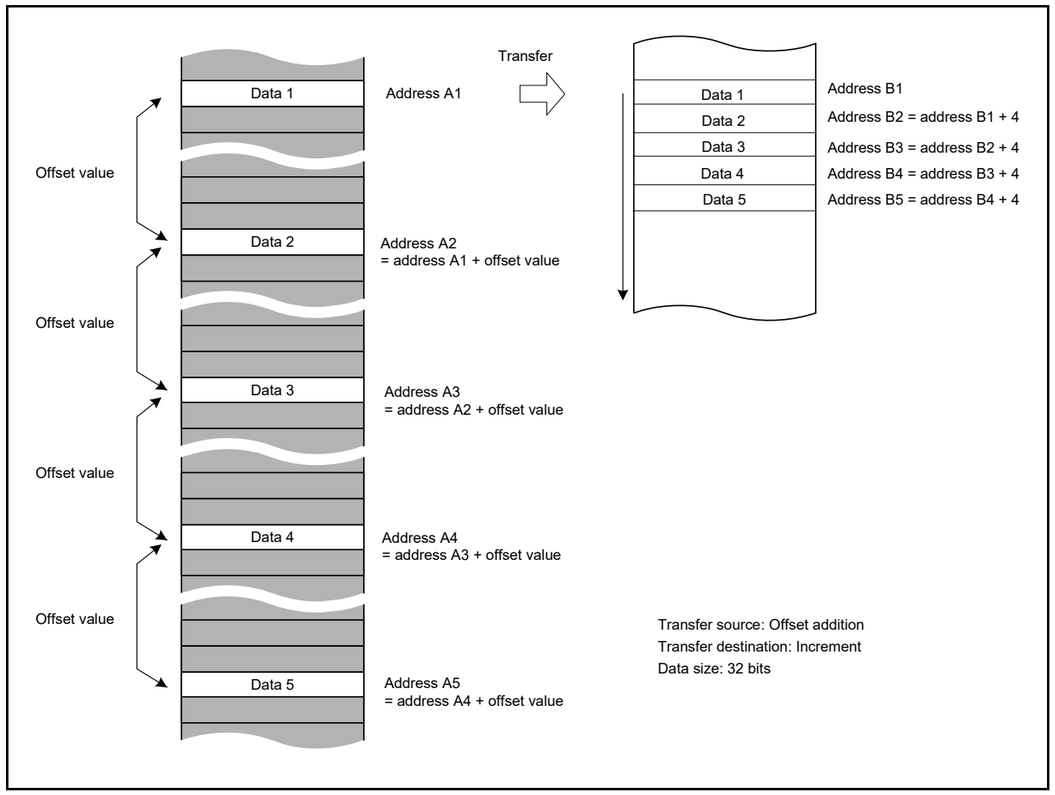

Figure 17.7 Example of address updating through offset addition

In Figure 17.7:

- The transfer data is 32 bits long
- Offset addition is set as the transfer source address update mode
- Increment is set as the transfer destination address update mode.

The second and subsequent data units are each read from the source address obtained by adding the offset value to the previous address. The data read from the addresses at the specified intervals is written to continuous locations on the destination.

(2) Example of XY conversion using offset addition

Figure 17.8 shows XY conversion using offset addition in repeat transfer mode. The settings are as follows:

- DMAC0.DMAMD — Transfer source address update mode: offset addition
- DMAC0.DMAMD — Transfer destination address update mode: destination address is incremented
- DMAC0.DMTMD — Transfer data size select: 32 bits
- DMAC0.DMTMD — Transfer mode select: repeat transfer
- DMAC0.DMTMD — Repeat area select: the source is specified as the repeat area
- DMAC0.DMOFR — Offset address: 10h
- DMAC0.DMCRA — Repeat size: 4h
- DMAC0.DMINT — The repeat size end interrupt is enabled.

- 增量设置为传送目的地地址更新模式。

第二个和随后的数据单元分别从通过将偏移值与前一个地址相加而获得的源地址读取。以指定间隔从地址读取的数据被写入目标上的连续位置。

(2) 使用偏移加法的XY转换示例

- DMAC0.DMCRA — Repeat size: 4h
- DMAC0.DMINT—启用重复大小结束中断。

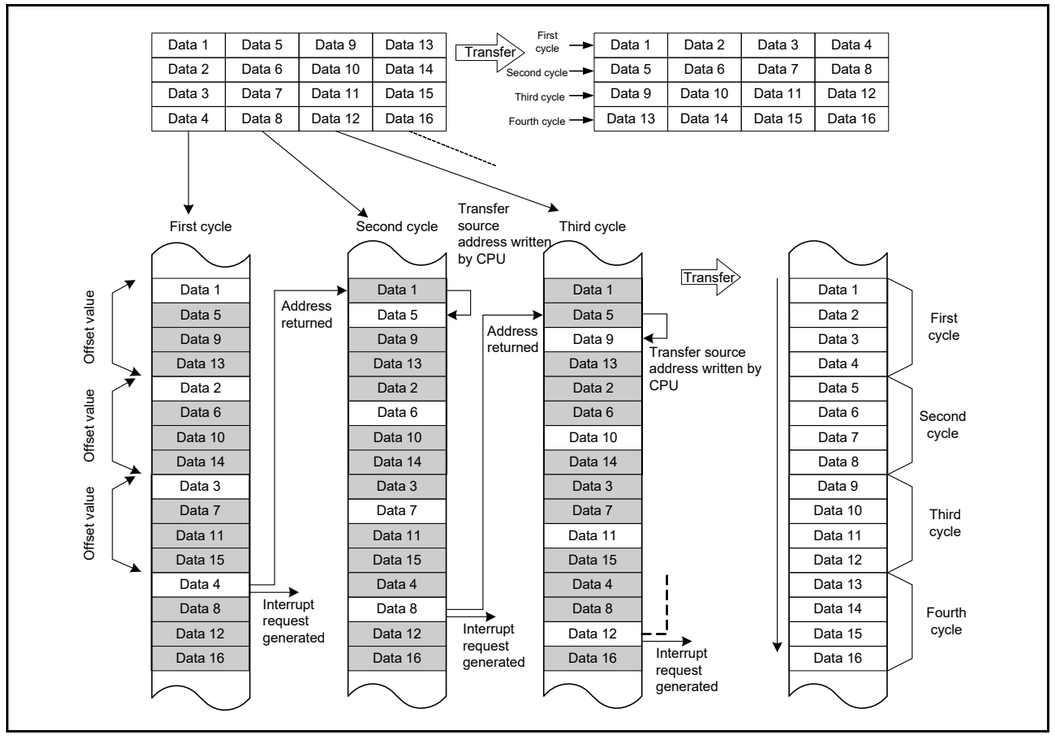

Figure 17.8 XY conversion operation using offset addition in repeat transfer mode

When a transfer starts, the offset value is added to the transfer source address every time data is transferred. The transfer data is written to continuous destination addresses. When data 4 is transferred:

- The repeat size of the transfers is complete
- The transfer source address returns to the transfer start address (the address of data 1 on the transfer source)
- A repeat size end interrupt is requested.

During the time this interrupt pauses the transfer, perform the following:

- DMAC0.DMSAR — Rewrite the DMA transfer source address to the address of data 5 (in this example, the data 1 address + 4)
- DMAC0.DMCNT — Set the DTE bit to 1.

The DMA transfer resumes from the state when the DMA transfer was stopped. The same operations are repeated until the transfer source data is transposed to the destination area (XY conversion).

Figure 17.9 shows a flow of the XY conversion.

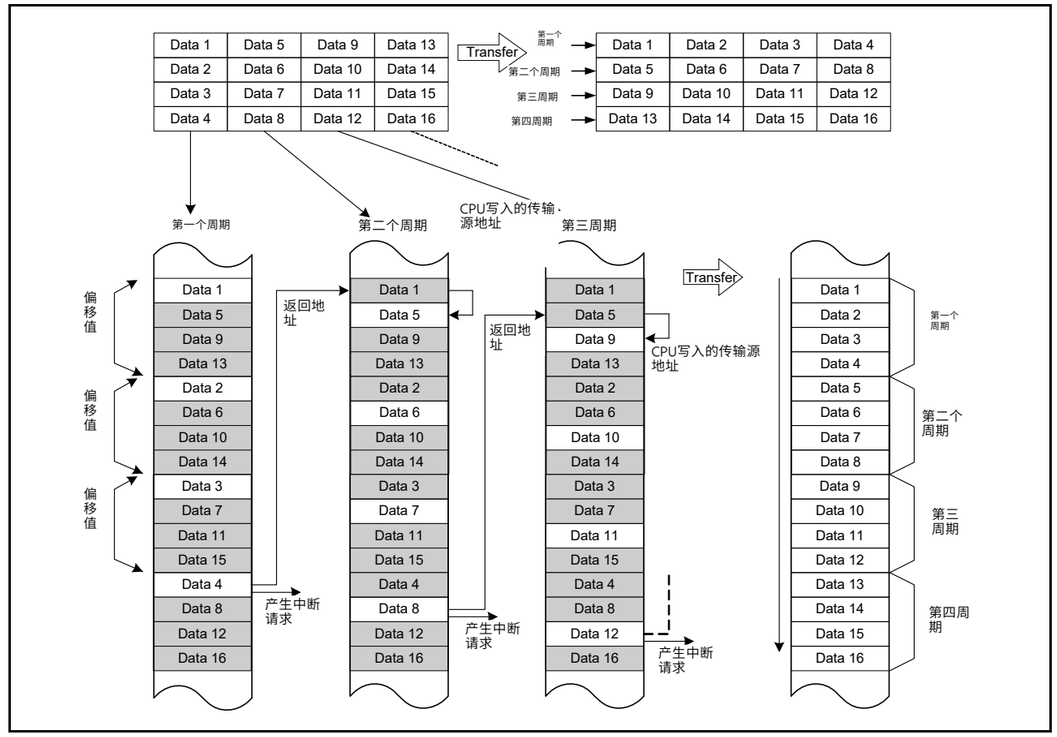

Figure 17.8 重复传输模式下使用偏移加法的XY转换操作

传输开始时，每次传输数据时，都会将偏移值添加到传输源地址。传输数据被写入连续的目标地址。传输数据4时：

- 传输的重复大小已完成
- 传输源地址返回传输起始地址（传输源上数据1的地址）
- 请求重复大小结束中断。

在此中断暂停传输期间，请执行以下操作：

- DMAC0.DMSAR—将DMA传输源地址重写为数据5的地址（在本例中，数据1地址+4）
- DMAC0.DMCNT—将DTE位设置为1。

DMA传输从DMA传输停止时的状态恢复。重复相同的操作，直到将传输源数据转置到目标区域（XY转换）。

17.3.4 Activation Sources

Software, interrupt requests from the peripheral modules, and external interrupt requests can all be specified as DMAC activation sources. Set the DCTG[1:0] bits in DMACm.DMTMD to select the activation source.

(1) DMAC activation through software

To start DMA transfer through software:

1. Set the DCTG[1:0] bits in DMACm.DMTMD to 00b.
2. Set the DTE bit in DMACm.DMCNT to 1 (enable DMA transfer).
3. Set the DMST bit in DMAST to 1 (enable DMAC activation).
4. Set the SWREQ bit in DMACm.DMREQ to 1 (request DMA).

When the DMAC is activated by software while the CLRS bit in DMACm.DMREQ is 0, the SWREQ bit in DMACm.DMREQ sets to 0 after data transfer starts in response to a DMA transfer request.

When the DMAC is activated by software while the CLRS bit is 1, SWREQ does not clear to 0 after data transfer starts. A DMA transfer request is issued again after completion of a transfer.

(2) DMAC activation through interrupt requests from on-chip peripheral modules or external interrupt requests

You can specify interrupt requests from on-chip peripheral modules and external interrupt requests as DMAC activation sources. The activation source can be individually selected for each channel in ICU.DELSRn.DELS[8:0] (n = 0 to 7).

To start DMAC transfer through an interrupt request from an on-chip peripheral module or an external interrupt request:

1. Set the DCTG[1:0] bits in DMACm.DMTMD to 01b (select interrupts from the peripheral modules and the external interrupt pins).
2. Set the DTE bit in DMACm.DMCNT to 1 (enable DMA transfer).
3. Set ICU.DELSRn.DSEL to the event number (select the DMAC event link).
4. Set the DMST bit in DMAST to 1 (enable DMAC activation).

For interrupt requests specified as DMAC activation sources, see Table 14.3, Interrupt vector table in section 14, Interrupt Controller Unit (ICU).

17.3.5 Operation Timing

The following timing diagrams show the minimum number of execution cycles.

17.3.4 激活源

软件、外设模块的中断请求和外部中断请求都可以指定为DMAC激活源。设置DMACm.DMTMD中的DCTG[1:0]位以选择激活源。

(1) 通过软件激活DMAC

通过软件启动DMA传输：

1. 将DMACm.DMTMD中的DCTG[1:0]位设置为00b。
2. 将DMACm.DMCNT中的DTE位设置为1（启用DMA传输）。
3. 将DMAST中的DMST位设置为1（启用DMAC激活）。
4. 将DMACm.DMREQ中的SWREQ位设置为1（请求DMA）。

当DMACm.DMREQ中的CLRS位为0时由软件激活DMAC，则DMACm.DMREQ中的SWREQ位在响应DMA传输请求开始数据传输后，DMACm.DMREQ设置为0。

当CLRS位为1时由软件激活DMAC时，数据传输开始后SWREQ不会清为0。传输完成后再次发出DMA传输请求。

(2) 通过来自片上外围模块的中断请求或外部中断请求激活DMAC

您可以将来自片上外围模块的中断请求和外部中断请求指定为DMAC激活源。可以为ICU.DELSRn.DELS[8:0]（n=0到7）中的每个通道单独选择激活源。

通过来自片上外围模块的中断请求或外部中断请求启动DMAC传输：

1. 将DMACm.DMTMD中的DCTG[1:0]位设置为01b（从外围模块和外部中断引脚选择中断）。
2. 将DMACm.DMCNT中的DTE位设置为1（启用DMA传输）。
3. 将ICU.DELSRn.DSEL设置为事件编号（选择DMAC事件链接）。
4. 将DMAST中的DMST位设置为1（启用DMAC激活）。

对于指定为DMAC激活源的中断请求，请参见表14.3，第14节中的中断向量表，中断控制器单元（ICU）。

Cs = When accessing SRAMHS and peripheral modules related to system control: 2 cycles.
When accessing elsewhere: 0 cycles.
When a slave bus changes by a read/write data transfer, add 1 more cycle.
Note 1. This is the case when the block size is 2 or more. When the block size is 1, normal transfer cycle applies.

Cr and Cw depend on the access destination. For the number of cycles of each access destination, see section 48, SRAM, section 50, Flash Memory, and section 15.2.3, External Bus. The frequency ratio of the system clock and the peripheral clock is also taken into consideration.

The unit for +1 in the data transfer (read) column is 1 system clock cycle, ICLK. For the operation example, see section 17.3.5, Operation Timing.

The DMAC response time is the time from when the DMAC activation source is detected until the DMAC transfer starts. Table 17.7 does not include the time until the DMAC data transfer starts after the DMAC activation source becomes active.

Cr和Cw取决于访问目的地。关于每个访问目标的周期数，请参见第48节，SRAM，第50节，闪存和第15.2.3节，外部总线。系统时钟和外设时钟的频率比也被考虑在内。

Figure 17.12 注册设置步骤

17.3.8 Starting DMA Transfer

To enable a DMA transfer of channel m, set the DTE bit in DMACm.DMCNT to 1 (DMA transfer enabled) and set the DMST bit in DMAST to 1 (DMAC activation enabled). New activation requests are not accepted during the transfer of another DMAC channel or DTC. When the proceeding transfer is complete, channel arbitration selects the DMA transfer request of the highest priority channel, and DMA transfer of that channel starts. When DMA transfer starts, the ACT flag in DMACm.DMSTS is set to 1 (the DMAC is in the active state).

17.3.9 Registers during DMA Transfer

The DMAC registers are updated by a DMA transfer. The value to be updated differs according to the other settings and the transfer state. The registers that are updated are DMSAR, DMDAR, DMCRA, DMCRB, DMCNT, and DMACm.DMSTS, described in the following sections. For details on register update operations in each transfer mode, see Table 17.3 to Table 17.5.

(1) DMA Source Address Register (DMACm.DMSAR)

After the data for one transfer request is transferred, the contents of DMSAR are updated to the address to be accessed by the next transfer request.

(2) DMA Destination Address Register (DMACm.DMDAR)

After the data for one transfer request is transferred, the contents of DMDAR are updated to the address to be accessed by the next transfer request.

(3) DMA Transfer Count Register (DMACm.DMCRA)

After the data for one transfer request is transferred, the count value is updated. The update operation depends on the transfer mode selected.

(4) DMA Block Transfer Count Register (DMACm.DMCRB)

After the data for one transfer request is transferred, the count value is updated. The update operation depends on the transfer mode selected.

(5) DMA Transfer Enable bit (DMACm.DMCNT.DTE)

The DMACm.DMCNT.DTE bit enables or disables data transfer through register write access. It is automatically cleared to 0 by the DMAC based on the DMA transfer state.

The conditions for clearing this bit by the DMAC are as follows:

- When the specified total volume of data transfer is complete
- When DMA transfer is stopped by a repeat size end interrupt
- When DMA transfer is stopped by an extended repeat area overflow interrupt.

Writing to the registers for channels whose associated DMACm.DMCNT.DTE bit is set to 1 is prohibited except for DMACm.DMCNT. Writes are only possible after the bit sets to 0.

(6) DMA Active flag (DMACm.DMSTS.ACT)

The ACT flag in DMSTS of DMACm indicates whether the DMACm is in the idle or active state. This flag is set to 1 when the DMAC starts data transfer, and sets to 0 when data transfer for one transfer request is complete. Even when DMA transfer is stopped by a write of 0 to the DTE bit in DMACm.DMCNT, this flag remains 1 until DMA transfer is complete.

(7) Transfer End Interrupt Flag (DMACm.DMSTS.DTIF)

The DTIF flag in DMACm.DMSTS is set to 1 after DMA transfer of the total transfer size is complete. When both this flag and the DTIE bit in DMACm.DMINT are 1, a transfer end interrupt is requested. This flag is set to 1 when the DMA transfer bus cycle is complete and the ACT flag in DMACm.DMSTS sets to 0, indicating the DMA transfer end. The flag automatically sets to 0 when the DTE bit in DMACm.DMCNT is set to 1 during interrupt handling.

(8) Transfer Escape End Interrupt Flag (DMACm.DMSTS.ESIF)

The ESIF flag in DMACm.DMSTS is set to 1 when a repeat size end interrupt or extended repeat area overflow interrupt

17.3.8 启动DMA传输

要启用通道m的DMA传输，请将DMACm.DMCNT中的DTE位设置为1（启用DMA传输）并将DMAST中的DMST位设置为1（启用DMAC激活）。在传输另一个DMAC通道或DTC期间不接受新的激活请求。当正在进行的传输完成时，通道仲裁选择最高优先级通道的DMA传输请求，并开始该通道的DMA传输。当DMA传输开始时，DMACm.DMSTS中的ACT标志设置为1（DMAC处于活动状态）。

17.3.9 DMA传输期间的寄存器

DMAC寄存器由DMA传输更新。要更新的值根据其他设置和传输状态而有所不同。更新的寄存器是DMSAR、DMDAR、DMCRA、DMRCB、DMCNT和DMACm.DMSTS，如下节所述。每种传输模式下寄存器更新操作的详细信息，请参见表17.3至表17.5。

(1) DMA源地址寄存器(DMACm.DMSAR)

一个传输请求的数据传输完成后，DMSAR的内容被更新为下一个传输请求访问的地址。

(2) DMA目标地址寄存器(DMACm.DMDAR)

一个传输请求的数据被传输后，DMDAR的内容被更新为下一个传输请求要访问的地址。

(3) DMA传输计数寄存器(DMACm.DMCRA)

在传输一个传输请求的数据后，更新计数值。更新操作取决于选择的传输模式。

(4) DMA块传输计数寄存器(DMACm.DMCRB)

在传输一个传输请求的数据后，更新计数值。更新操作取决于选择的传输模式。

(5) DMA传输使能位(DMACm.DMCNT.DTE)

DMACm.DMCNT.DTE位通过寄存器写访问启用或禁用数据传输。它由DMAC根据DMA传输状态自动清零。

DMAC清除该位的条件如下：

- 当指定的总数据传输量完成时
- 当DMA传输因重复大小结束中断而停止时
- 当DMA传输因扩展重复区域溢出中断而停止时。

禁止写入相关DMACm.DMCNT.DTE位设置为1的通道的寄存器，除非DMACm.DMCNT。只有在位设置为0后才能进行写入。

(6) DMA活动标志(DMACm.DMSTS.ACT)

DMACm的DMSTS中的ACT标志指示DMACm是处于空闲状态还是活动状态。该标志在DMAC开始数据传输时设置为1，当一个传输请求的数据传输完成时设置为0。即使通过向DMACm.DMCNT中的DTE位写入0来停止DMA传输，该标志仍 保持为1，直到DMA传输完成。

(7) 传输结束中断标志(DMACm.DMSTS.DTIF)

在完成总传输大小的DMA传输后，DMACm.DMSTS中的DTIF标志设置为1。当该标志和DMACm.DMINT中的DTIE位都为1时，请求传输结束中断。当DMA传输总线周期完成并且DMACm.DMSTS中的ACT标志设置为0时，该标志设置为1，表示DMA传输结束。当DMACm.DMCNT中的DTE位在中断处理期间设置为1时，该标志自动设置为0。

(8) 传输转义结束中断标志(DMACm.DMSTS.ESIF)

当重复大小结束中断或扩展重复区域溢出中断时，DMACm.DMSTS中的ESIF标志设置为1

is requested. When this bit and the ESIE bit in DMACm.DMINT are 1, a transfer escape end interrupt is requested. This flag is set to 1 when the bus cycle of the DMA transfer that caused the interrupt request is complete and the ACT flag in DMACm.DMSTS sets to 0, indicating the DMA transfer end. The flag automatically sets to 0 when the DTE bit in DMACm.DMCNT is set to 1 during interrupt handling.

You must set the interrupt control register before sending an interrupt request from the DMAC to the CPU or the DTC. For more information, see section 14, Interrupt Controller Unit (ICU).

17.3.10 Channel Priority

When multiple DMA transfer requests occur, the DMAC determines the priority of channels that have DMA transfer requests.

The priority is fixed as channel 0 > channel 1 > channel 2 > channel 3 > channel 4 > channel 5 > channel 6 > channel 7. (channel 0 is the highest.)

When a DMA transfer request occurs during data transfer, channel arbitration starts after the final data unit is transferred, and DMA transfer of the highest-priority channel starts.

17.4 Ending DMA Transfer

The operation for ending a DMA transfer depends on the transfer end conditions. When a DMA transfer ends, the DTE bit in DMCNT and the ACT flag in DMACm.DMSTS change from 1 to 0.

17.4.1 Transfer End by Completion of Specified Total Number of Transfer Operations

(1) In normal transfer mode (DMACm.DMTMD.MD[1:0] = 00b)

When the value of DMACm.DMCRAL changes from 1 to 0, DMA transfer ends on the associated channel, the DTE bit in DMACm.DMCNT is set to 0, and the DTIF flag in DMACm.DMSTS is set to 1. If the DTIE bit in DMACm.DMINT is 1 at this time, a transfer end interrupt request is sent to the CPU or the DTC.

(2) In repeat transfer mode (DMACm.DMTMD.MD[1:0] = 01b)

When the value of DMACm.DMCRB changes from 1 to 0, DMA transfer ends on the associated channel, the DTE bit in DMACm.DMCNT is set to 0, and the DTIF flag in DMACm.DMSTS is set to 1. If the DTIE bit in DMACm.DMINT is 1 at this time, an interrupt request is sent to the CPU or the DTC.

(3) In block transfer mode (DMACm.DMTMD.MD[1:0] = 10b)

When the value of DMACm.DMCRB changes from 1 to 0, DMA transfer ends on the associated channel, the DTE bit in DMACm.DMCNT is set to 0, and the DTIF flag in DMACm.DMSTS is set to 1. If the DTIE bit in DMACm.DMINT is 1 at this time, an interrupt request is sent to the CPU or the DTC.

You must set the interrupt control register before sending an interrupt request from the DMAC to the CPU or the DTC. For more information, see section 14, Interrupt Controller Unit (ICU).

17.4.2 Transfer End by Repeat Size End Interrupt

In repeat transfer mode, if the RPTIE bit in DMACm.DMINT is 1, a repeat size end interrupt is requested when transfer of a single repeat size of data is complete. The DTE bit in DMACm.DMCNT is set to 0 and the ESIF flag in DMACm.DMSTS is set to 1. If the ESIE bit in DMACm.DMINT is 1 at this time, an interrupt request is sent to the CPU or the DTC. To resume the transfer, write 1 to the DTE bit in DMACm.DMCNT.

A repeat size end interrupt can also be requested in block transfer mode. When transfer of a single block size of data is complete, the interrupt is requested in the same way as in repeat transfer mode.

You must set the interrupt control register before sending an interrupt request from the DMAC to the CPU or the DTC. For more information, see section 14, Interrupt Controller Unit (ICU).

17.4.3 Transfer End by Interrupt on Extended Repeat Area Overflow

When an overflow on the extended repeat area occurs while the extended repeat area is specified and the SARIE or DARIE bit in DMACm.DMINT is 1, an extended repeat area overflow interrupt is requested. The DMA transfer is terminated, the DTE bit in DMACm.DMCNT is set to 0, and the ESIF flag in DMACm.DMSTS is set to 1. If the ESIE

被要求。当该位和DMACm.DMINT中的ESIE位为1时，请求传输转义结束中断。当导致中断请求的DMA传输的总线周期完成并且DMACm.DMSTS中的ACT标志设置为0时，该标志设置为1，表示DMA传输结束。当DTE位在

DMACm.DMCNT在中断处理期间设置为1。

在从DMAC向CPU或DTC发送中断请求之前，您必须设置中断控制寄存器。
有关详细信息，请参阅第14节，中断控制器单元(ICU)。

17.3.10 频道优先级

当出现多个DMA传输请求时，DMAC确定有DMA传输请求的通道的优先级。

优先级固定为通道0>通道1>通道2>通道3>通道4>通道5>通道6>通道7。（通道0最高。）

当数据传输过程中出现DMA传输请求时，在传输完最后一个数据单元后开始通道仲裁，并开始最高优先级通道的DMA传输。

17.4 结束DMA传输

结束DMA传输的操作取决于传输结束条件。当DMA传输结束时，DMCNT中的DTE位和DMACm.DMSTS中的ACT标志从1变为0。

17.4.1 完成指定的转移操作总数后转移结束

(1) 在正常传输模式下（DMACm.DMTMD.MD[1:0]=00b）

当DMACm.DMCRAL的值从1变为0时，DMA传输在关联通道上结束，DMACm.DMCNT中的DTE位设置为0，并且DMACm.DMSTS中的DTIF标志设置为1。如果DTIE位此时DMACm.DMINT为1，向CPU或DTC发送传输结束中断请求。

(2) 在重复传输模式下（DMACm.DMTMD.MD[1:0]=01b）

当DMACm.DMCRB的值从1变为0时，DMA传输在相关通道上结束，DMACm.DMCNT中的DTE位设置为0，并且DMACm.DMSTS中的DTIF标志设置为1。如果DTIE位此时DMACm.DMINT为1，向CPU或DTC发送中断请求。

(3) 在块传输模式下（DMACm.DMTMD.MD[1:0]=10b）

当DMACm.DMCRB的值从1变为0时，DMA传输在相关通道上结束，DMACm.DMCNT中的DTE位设置为0，并且DMACm.DMSTS中的DTIF标志设置为1。如果DTIE位此时DMACm.DMINT为1，向CPU或DTC发送中断请求。

在从DMAC向CPU或DTC发送中断请求之前，您必须设置中断控制寄存器。
有关详细信息，请参阅第14节，中断控制器单元(ICU)。

17.4.2 按重复大小结束传输结束中断

在重复传输模式下，如果DMACm.DMINT中的RPTIE位为1，则在单个重复大小的数据传输完成时请求重复大小结束中断。DMACm.DMCNT中的DTE位设置为0，DMACm.DMSTS中的ESIF标志位设置为1。如果此时DMACm.DMINT中的ESIE位为1，则向CPU或DTC发送中断请求。要恢复传输，请将1写入DMACm.DMCNT中的DTE位。

在块传输模式下也可以请求重复大小结束中断。当单个块大小的数据传输完成时，以与重复传输模式相同的方式请求中断。

在从DMAC向CPU或DTC发送中断请求之前，您必须设置中断控制寄存器。
有关详细信息，请参阅第14节，中断控制器单元(ICU)。

17.4.3 扩展重复区溢出中断传输结束

如果在指定扩展重复区域且DMACm.DMINT中的SARIE或DARIE位为1时扩展重复区域发生溢出，则请求扩展重复区域溢出中断。DMA传输终止，DMACm.DMCNT中的DTE位设置为0，DMACm.DMSTS中的ESIF标志设置为1。如果ESIE

bit in DMACm.DMINT is 1 at this time, an interrupt request is sent to the CPU or the DTC.

If this interrupt is requested during a read cycle, the subsequent write cycle is performed. In block transfer mode, if the interrupt is requested during a 1-block transfer, the remaining data in the block is transferred before transfer stops.

Before sending an interrupt request from the DMAC to the CPU or the DTC, the interrupt control register must be set. For more information, see section 14, Interrupt Controller Unit (ICU).

17.4.4 Precautions for the End of DMA Transfer

A DMA activation request source might occur in the next request after a DMA transfer completes. If this happens, the DMA transfer starts and the DMA activation request is held in DMAC. To prevent this, stop the DMA activation requests by clearing the DELSRn.DSELS[8:0] bits in the ICU to 0.

When the DMA activation request occurs after the last round of the DMA transfer is generated, clear the DMA activation request by setting ICU.DELSRm.IR bit to 0.

17.5 Interrupts

Each DMAC channel can output an interrupt request (DMACm_INT) to the CPU or DTC after transfer for one request is complete. When the transfer destination is the external bus, an interrupt request is generated after completion of a data write to the write buffer, and not to the actual transfer destination.

Table 17.8 lists the interrupt sources and their associated status flags and enable bits. Figure 17.13 shows the schematic logic diagram of the interrupt outputs (DMAC0 to DMAC7). Figure 17.14 shows the DMAC interrupt handling routine for resuming and terminating DMA transfers.

此时DMACm.DMINT中的位为1，向CPU或DTC发送中断请求。

如果在读周期内请求此中断，则执行后续写周期。在块传输模式下，如果在1块传输期间请求中断，则在传输停止之前传输块中剩余的数据。

在从DMAC向CPU或DTC发送中断请求之前，必须设置中断控制寄存器。
有关详细信息，请参阅第14节，中断控制器单元(ICU)。

17.4.4 DMA传输结束的注意事项

DMA传输完成后的下一个请求中可能会出现DMA激活请求源。如果发生这种情况，
DMA传输开始，DMA激活请求保存在DMAC中。为防止这种情况发生，通过将ICU中的DELSRn.DSELS[8:0]位清除为0来停止DMA激活请求。

当最后一轮DMA传输产生后发生DMA激活请求时，通过将ICU.DELSRm.IR位设置为0来清除DMA激活请求。

17.5 Interrupts

每个DMAC通道可以在一个请求的传输完成后向CPU或DTC输出一个中断请求(DMACm_INT)。当传输目的地是外部总线时，在写入缓冲区的数据写入完成后会产生中断请求，而不是实际传输目的地。

表17.8列出了中断源及其相关的状态标志和使能位。图17.13显示了中断输出（DMAC0到DMAC7）的示意逻辑图。图17.14显示了用于恢复和终止DMA传输的DMAC中断处理程序。

Different procedures are used for canceling an interrupt to restart a DMA transfer as in the following cases:

- When terminating a DMA transfer
- When continuing a DMA transfer.

(1) When terminating a DMA transfer

Write 0 to the DTIF flag in DMACm.DMSTS to clear a transfer end interrupt, and to the ESIF flag in DMACm.DMSTS to clear a repeat size interrupt or an extended repeat area overflow interrupt. DMACm remains in the stopped state. When starting another DMA transfer, set the appropriate registers and set the DTE bit in DMACm.DMCNT to 1 (DMA transfer enabled).

(2) When continuing a DMA transfer

Write 1 to the DTE bit in DMACm.DMCNT. The ESIF flag in DMSTS of DMACm automatically sets to 0 (interrupt source cleared), and the DMA transfer resumes.

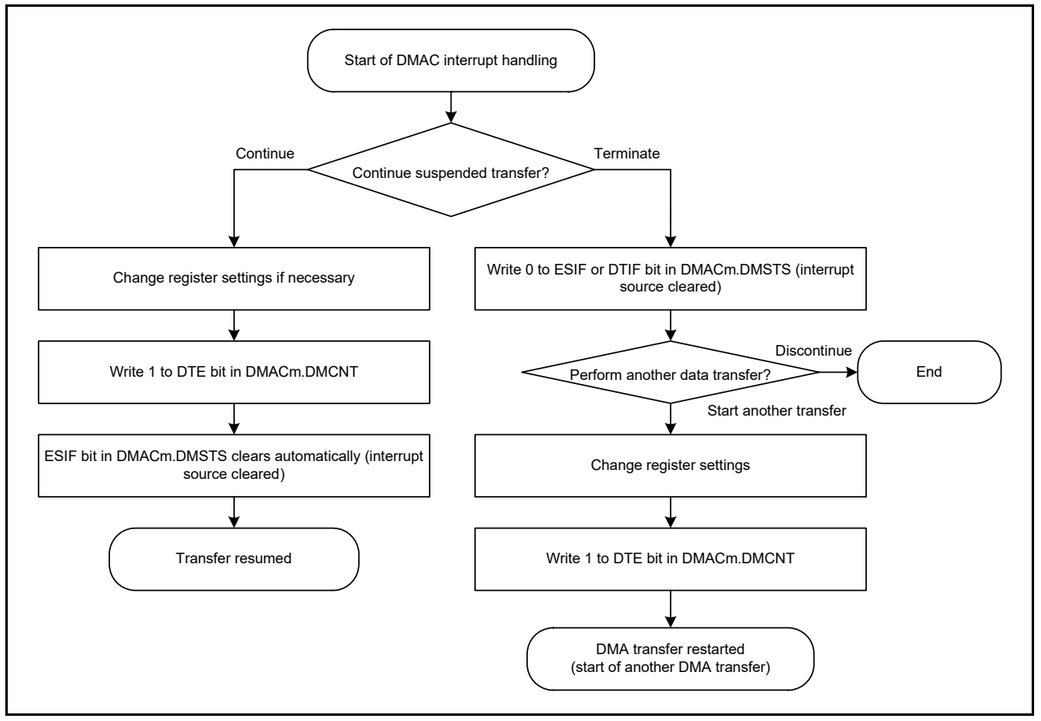

Figure 17.14 DMAC interrupt handling routine to resume or terminate a DMA transfer

17.6 Event Link

Each DMAC channel outputs an event link request signal (DMACm_INT) every time it completes a data transfer, or a block transfer in block transfer mode. When the transfer destination is the external bus, the signal is generated when writing to the write buffer is accepted. For more information, see section 19, Event Link Controller (ELC).

17.7 Low Power Consumption Function

Before entering the module-stop state, Software Standby mode, or Deep Software Standby mode, you must first set the DMST bit in DMAST to 0 (DMAC suspended) and use the settings in the sections that follow.

(1) Module-stop function

Writing 1 to the MSTPA22 bit in MSTPCRA enables the module-stop function of the DMAC. If a DMA transfer is in

不同的程序用于取消中断以重新启动DMA传输，如下所示：

- 终止DMA传输时
- 继续DMA传输时。

(1) 终止DMA传输时

将0写入DMACm.DMSTS中的DTIF标志以清除传输结束中断，并写入DMACm.DMSTS中的ESIF标志以清除重复大小中断或扩展重复区域溢出中断。DMACm保持在停止状态。当开始另一个DMA传输时，设置适当的寄存器并将DMACm.DMCNT中的DTE位设置为1（启用DMA传输）。

(2) 继续DMA传输时

将1写入DMACm.DMCNT中的DTE位。DMACm的DMSTS中的ESIF标志自动设置为0（中断源清除），DMA传输恢复。

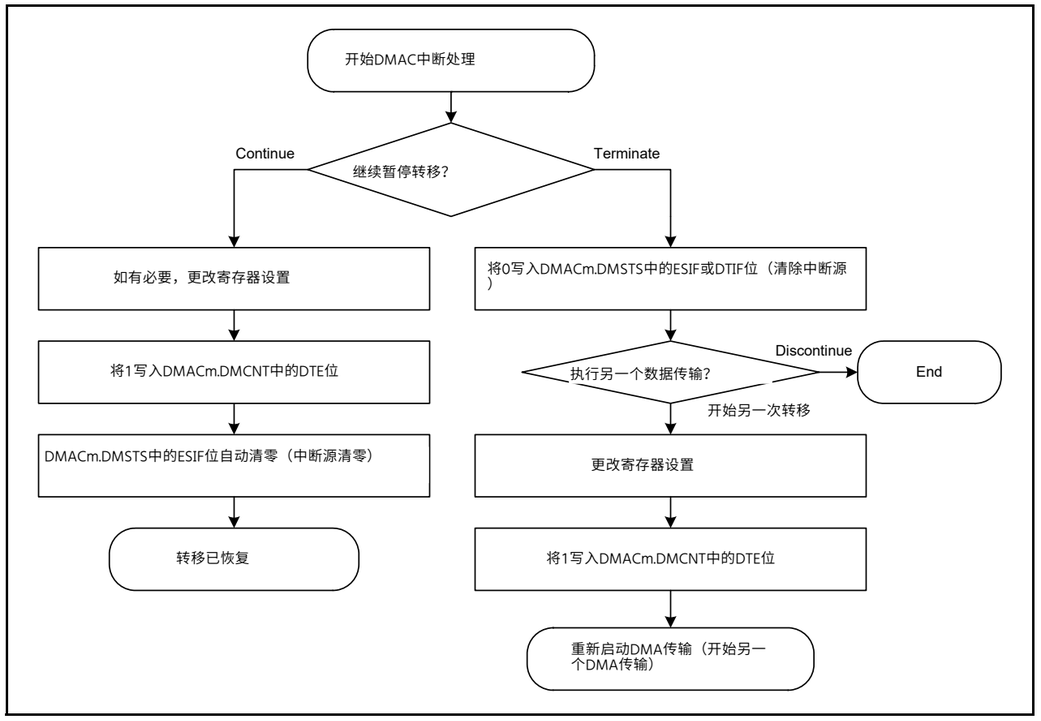

Figure 17.14 用于恢复或终止DMA传输的DMAC中断处理例程

17.6 活动链接

每个DMAC通道在每次完成数据传输或块传输模式下的块传输时都会输出一个事件链接请求信号(DMACm_INT)。当传输目标是外部总线时，当接受写入写缓冲器时产生信号。有关详细信息，请参阅第19节，事件链接控制器(ELC)。

17.7 低功耗功能

在进入模块停止状态、软件待机模式或深度软件待机模式之前，您必须先设置DMAST中的DMST位为0（DMAC暂停）并使用以下部分中的设置。

(1) Module-stop function

向MSTPCRA中的MSTPA22位写入1使能DMAC的模块停止功能。如果DMA传输在

RA生态工作室

progress when 1 is written to MSTPA22, the transition to the module-stop state continues after DMA transfer ends. Access to the DMAC registers is prohibited while MSTPA22 is 1. Writing 0 to the MSTPA22 bit releases the DMAC from the module-stop state.

(2) Software Standby and Deep Software Standby modes

Use the settings described in section 11.7.1, Transitioning to Software Standby Mode and section 11.9.1, Transitioning to Deep Software Standby Mode.

If DMA transfer operations are in progress when the WFI instruction is executed, the DMA transfer completes before the transition to Software Standby mode or Deep Software Standby mode.

(3) Notes on low power consumption function

For information on the WFI instruction and register settings, see section 11.10.7, Timing of WFI Instruction.

To perform a DMA transfer after returning from a low power consumption mode, set the DMST bit in DMAST to 1 again. To use a request that is generated in Software Standby mode as an interrupt request to the CPU but not as a DMAC startup request, specify the CPU as the interrupt request destination, as described in section 14.4.2, Selecting Interrupt Request Destinations, then execute the WFI instruction.

17.8 Usage Notes

17.8.1 DMA Transfer to External Devices

In a DMA transfer to an external device, the ACT flag in DMACm.DMSTS may be set to 0 (DMAC transfer suspended) from the beginning of the final data write to the end of the external bus access.

17.8.2 Access to Registers during DMA Transfer

Do not write to the following registers of DMACm while the ACT flag in DMSTS of the associated channel is set to 1 (DMAC active state) or the DTE bit in DMCNT of the associated channel is set to 1 (DMA transfer enabled):

- DMSAR
- DMDAR
- DMCRA
- DMCRB
- DMTMD
- DMINT
- DMAMD
- DMOFR.

17.8.3 DMA Transfer to Reserved Areas

DMA transfer to reserved areas is prohibited. If such an access is made, transfer results are not guaranteed. For details on reserved areas, see section 4, Address Space.

17.8.4 Setting the DMAC Event Link Setting Register of the Interrupt Controller Unit (ICU.DELSRn)

Before setting the DMAC Event Link Setting Register (ICU.DELSRn), make sure the DMA Transfer Enable bit (DMACm.DMCNT.DTE) is set to 0, to disable DMA transfer. Additionally, ensure that the DTC Activation Enable bit (ICU.IELSRn.DTCE) associated with the event number set in the ICU.DELSRn register is not set to 1. For details on ICU.IELSRn.DTCE and ICU.DELSRn, see section 14, Interrupt Controller Unit (ICU).

17.8.5 Suspending or Restarting DMA Activation

To suspend a DMA activation request, write 0 to the DMAC Event Link Select bits (ICU.DELSRn.DELS[8:0]). To restart the DMA transfer, write the event number to the ICU.DELSRn.DELS[8:0] bits with the settings shown in section 17.3.7, Activating the DMAC.

向MSTPA22写入1时，在DMA传输结束后继续转换到模块停止状态。当MSTPA22为1时，禁止访问DMAC寄存器。将0写入MSTPA22位可将DMAC从模块停止状态释放。

(2) 软件待机和深度软件待机模式

使用第11.7.1节，转换到软件待机模式和第11.9.1节，转换到深度软件待机模式。

如果在执行WFI指令时DMA传输操作正在进行，则DMA传输在转换到软件待机模式或深度软件待机模式之前完成。

(3) 低功耗功能注意事项

有关WFI指令和寄存器设置的信息，请参阅第11.10.7节，WFI指令的时序。

要在从低功耗模式返回后执行DMA传输，请将DMAST中的DMST位再次设置为1。要将在软件待机模式下生成的请求用作对CPU的中断请求但不用作DMAC启动请求，请指定CPU作为中断请求目标，如第14.4.2节，选择中断请求目标中所述，然后执行WFI指令。

17.8 使用说明

17.8.1 DMA传输到外部设备

在到外部设备的DMA传输中，从最终数据写入开始到外部总线访问结束，DMACm.DMSTS中的ACT标志可能设置为0（DMAC传输暂停）。

17.8.2 在DMA传输期间访问寄存器

当相关通道的DMSTS中的ACT标志设置为1（DMAC活动状态）或相关通道的DMCNT中的DTE位设置为1（启用DMA传输）时，请勿写入DMACm的以下寄存器：

- DMSAR
- DMDAR
- DMCRA
- DMCRB
- DMTMD
- DMINT
- DMAMD
- DMOFR.

17.8.3 DMA传输到保留区域

禁止对保留区域进行DMA传输。如果进行此类访问，则无法保证传输结果。有关保留区域的详细信息，请参阅第4节，地址空间。

17.8.4 设置中断控制器单元(ICU.DELSRn)的DMAC事件链接设置寄存器

在设置DMAC事件链接设置寄存器(ICU.DELSRn)之前，确保DMA传输启用位(DMACm.DMCNT.DTE)设置为0，以禁用DMA传输。此外，确保与ICU.DELSRn寄存器中设置的事件编号相关的DTC激活启用位(ICU.IELSRn.DTCE)未设置为1。有关ICU.IELSRn.DTCE和ICU.DELSRn的详细信息，请参阅第14节，中断控制器单元（ICU）。

17.8.5 暂停或重新启动DMA激活

要暂停DMA激活请求，请将0写入DMAC事件链路选择位(ICU.DELSRn.DELS[8:0])。要重新启动DMA传输，请将事件编号写入ICU.DELSRn.DELS[8:0]位，设置见第17.3.7节，激活DMAC。

18.2 Register Descriptions

MRA, MRB, SAR, DAR, CRA, and CRB are all DTC internal registers that cannot be directly accessed from the CPU. Values to be set in these DTC internal registers are placed in the SRAM area as transfer information. When an activation request is generated, the DTC reads the transfer information from the SRAM area and sets it in its internal registers. After the data transfer ends, the internal register contents are written back to the SRAM area as transfer information.

The MRA register cannot be accessed directly from the CPU, however the CPU can access the SRAM area (transfer information (n) start address + 03h) and the DTC automatically transfers the MRA transfer information to and from the MRA register. See section 18.3.1, Allocating Transfer Information and the DTC Vector Table.

18.2 注册说明

MRA、MRB、SAR、DAR、CRA、CRB都是DTC内部寄存器，不能直接从CPU访问。在这些DTC内部寄存器中设置的值作为传输信息放置在SRAM区域中。当产生激活请求时，DTC从SRAM区域读取传输信息并将其设置在其内部寄存器中。数据传输结束后，内部寄存器内容作为传输信息回写到SRAM区域。

The MRB register cannot be accessed directly from the CPU. However, the CPU can access the SRAM area (transfer information (n) start address + 02h) and the DTC automatically transfers the MRB transfer information to and from the MRB register. See section 18.3.1, Allocating Transfer Information and the DTC Vector Table.

DTS bit (DTC Transfer Mode Select)

The DTS bit selects either the transfer source or transfer destination as the repeat area or block area in repeat or block transfer mode.

CHNS bit (DTC Chain Transfer Select)

The CHNS bit selects the chain transfer condition. When CHNE is 0, the CHNS setting is ignored. For details on the conditions for chain transfer, see Table 18.3, Chain transfer conditions.

When the next transfer is a chain transfer, completion of the specified number of transfers is not determined, the activation source flag is not cleared, and an interrupt request to the CPU is not generated.

CHNE bit (DTC Chain Transfer Enable)

The CHNE bit enables chain transfer. The chain transfer condition is selected in the CHNS bit. For details on chain transfer, see section 18.4.6, Chain Transfer.

不能直接从CPU访问MRB寄存器。但是，CPU可以访问SRAM区域（传输信息(n)起始地址+02h），并且DTC会自动将MRB传输信息传输到MRB寄存器或从MRB寄存器传输信息。请参阅第18.3.1节，分配传输信息和DTC向量表。

DTS位（DTC传输模式选择）

在重复或块传输模式下，DTS位选择传输源或传输目标作为重复区域或块区域。

CHNS位（DTC链传输选择）

CHNS位选择链传输条件。当CHNE为0时，忽略CHNS设置。有关链转移条件的详细信息，请参见表18.3，链转移条件。

当下一次传输是链式传输时，指定传输次数的完成未确定，激活源标志未清零，也不向CPU产生中断请求。

CHNE位（DTC链传输使能）

CHNE位启用链式传输。在CHNS位中选择链传输条件。有关链转移的详细信息，请参阅第18.4.6节，链转移。

18.2.3 DTC Transfer Source Register (SAR)

Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

The SAR register sets the transfer source start address and cannot be accessed directly from the CPU. However, the CPU can access the SRAM area (transfer information (n) start address + 04h) and the DTC automatically transfers the SAR transfer information to and from the SAR register. See section 18.3.1, Allocating Transfer Information and the DTC Vector Table.

Note: Misalignment is prohibited for DTC transfers. Bit [0] must be 0 when MRA.SZ[1:0] = 01b. Bits [1] and [0] must be 0 when MRA.SZ[1:0] = 10b.

18.2.4 DTC Transfer Destination Register (DAR)

Address(es): (inaccessible directly from the CPU. See section 18.3.1.)

The DAR register sets the transfer destination start address and cannot be accessed directly from the CPU. However, the CPU can access the SRAM area (transfer information (n) start address + 08h) and the DTC automatically transfers the DAR transfer information to and from the DAR register. See section 18.3.1, Allocating Transfer Information and the DTC Vector Table.

Note: Misalignment is prohibited for DTC transfers. Bit [0] must be 0 when MRA.SZ[1:0] = 01b. Bits [1] and [0] must be 0 when MRA.SZ[1:0] = 10b.

SAR寄存器设置传输源起始地址，不能直接从CPU访问。但是，CPU可以访问SRAM区域（传输信息(n)起始地址+04h），并且DTC会自动将SAR传输信息传入和传出SAR寄存器。请参阅第18.3.1节，分配传输信息和DTC向量表。

Note: DTC传输禁止错位。当MRA.SZ[1:0]=01b时，位[0]必须为0。当MRA.SZ[1:0]=10b时，位[1]和[0]必须为0。

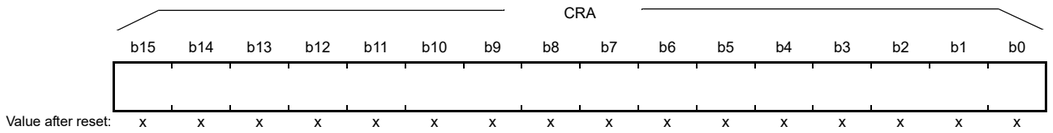
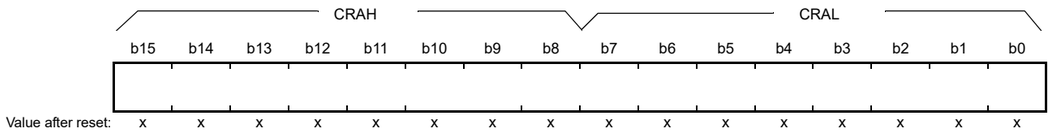
18.2.5 DTC Transfer Count Register A (CRA)

Address(es): (inaccessible directly from the CPU. See section 18.3.1.)

- Normal transfer mode



- Repeat transfer mode/block transfer mode



x: Undefined

Symbol	Register name	Description	R/W
CRAL	Transfer Counter A Lower Register	Specify the transfer count	—
CRAH	Transfer Counter A Upper Register		—

Note: The function depends on the transfer mode.
Note: Set CRAH and CRAL to the same value in repeat transfer mode and block transfer mode.

The CRA register cannot be accessed directly from the CPU. However, the CPU can access the SRAM area (transfer information (n) start address + 0Eh) and the DTC automatically transfers the CRA transfer information to and from the CRA register. See section 18.3.1, Allocating Transfer Information and the DTC Vector Table.

(1) Normal transfer mode (MRA.MD[1:0] = 00b)

In normal transfer mode, CRA functions as a 16-bit transfer counter. The transfer count is 1, 65535, and 65536 when the set value is 0001h, FFFFh, and 0000h, respectively. The CRA value is decremented (-1) on each data transfer.

(2) Repeat transfer mode (MRA.MD[1:0] = 01b)

In repeat transfer mode, the CRAH register holds the transfer count and the CRAL register functions as an 8-bit transfer counter. The transfer count is 1, 255, and 256 when the set value is 01h, FFh, and 00h, respectively. The CRAL value is decremented (-1) on each data transfer. When it reaches 00h, the CRAH value is transferred to CRAL.

(3) Block transfer mode (MRA.MD[1:0] = 10b)

In block transfer mode, the CRAH register holds the transfer count and the CRAL register functions as an 8-bit block size counter. The transfer count is 1, 255, and 256 when the set value is 01h, FFh, and 00h, respectively. The CRAL value is decremented (-1) at each data transfer. When it reaches 00h, the CRAH value is transferred to CRAL.

在正常传输模式下，CRA用作16位传输计数器。当设置值为0001h、FFFFh和0000h时，传输计数分别为1、65535和65536。CRA值在每次数据传输时递减(-1)。

(2) 重复传输模式(MRA.MD[1:0]=01b)

The CRB register sets the block transfer count for block transfer mode. The transfer count is 1, 65535, and 65536 when the set value is 0001h, FFFFh, and 0000h, respectively. The CRB value is decremented (-1) when the final data of a single block size is transferred. When normal transfer mode or repeat transfer mode is selected, this register is not used and the set value is ignored.

CRB cannot be accessed directly from the CPU. However, the CPU can access the SRAM area (transfer information (n) start address + 0Ch) and the DTC automatically transfers the CRB transfer information to and from the CRB register. See section 18.3.1, Allocating Transfer Information and the DTC Vector Table.

RRS bit (DTC Transfer Information Read Skip Enable)

The RRS bit enables skipping of transfer information reads when the vector numbers match. The DTC vector number is compared with the vector number in the previous activation process. When these vector numbers match and the RRS bit is set to 1, DTC data transfer is performed without reading the transfer information. However, when the previous transfer is a chain transfer, the transfer information is read regardless of the value in the RRS bit.

When the transfer counter (CRA register) becomes 0 during the previous normal transfer and when the transfer counter (CRB register) becomes 0 during the previous block transfer, the transfer information is read regardless of the RRS bit value.

VECN[7:0] bits (DTC-Activating Vector Number Monitoring)

While transfer by the DTC is in progress, the VECN[7:0] bits indicate the vector number associated with the activation source for the transfer. The value read from the VECN[7:0] bits is valid if the ACT flag is 1, indicating that a DTC transfer is in progress, and invalid if the ACT flag is 0, indicating that no DTC transfer is in progress.

ACT flag (DTC Active Flag)

The ACT flag indicates the state of the DTC transfer operation.

[Setting condition]

- When the DTC is activated by a transfer request.

[Clearing condition]

- When transfer by the DTC, in response to a transfer request, is complete.

18.3 Activation Sources

The DTC is activated by an interrupt request. Setting the ICU.IELSRn.DTCE bit to 1 enables activation of the DTC by the associated interrupt. The selector output *n* number set in ICU.IELSRn is defined as the interrupt vector number, where n = 0 to 95. For an enabled interrupt, the specific DTC interrupt source associated with each interrupt vector number n is selected in ICU.IELSRn.IELS[8:0] where n = 0 to 95, as listed in Table 14.4, Event table, in section 14, Interrupt Controller Unit (ICU). For activation by software, see section 19.2.2, Event Link Software Event Generation Register n (ELSEGRn) (n = 0, 1).

The interrupt vector number is equivalent to the DTC vector table number. After the DTC accepted an activation request, it does not accept another activation request until transfer for that single request is complete, regardless of the priority of the requests. When multiple activation requests are generated during a DMAC or DTC transfer, a highest priority request is accepted on completion of the transfer. When multiple activation requests are generated while the DTC Module Start bit (DTCST.DTCST) is 0, the DTC accepts the highest-priority request when DTCST.DTCST is subsequently set to 1. The smaller interrupt vector number has higher priority.

The DTC performs the following operations at the start of a single data transfer or for a chain transfer, after the last of the consecutive transfers:

- On completion of a specified round of data transfer, the ICU.IELSRn.DTCE bit is set to 0, and an interrupt request is sent to the CPU
- If the MRB.DISEL bit is 1, an interrupt request is sent to the CPU on completion of a data transfer
- For other transfers, the ICU.IELSRn.IR bit of the activation source is set to 0 at the start of the data transfer.

ACT标志（DTC活动标志）

ACT标志指示DTC传输操作的状态。

[Setting condition]

- 当DTC被传输请求激活时。

[Clearing condition]

- 当DTC响应传输请求传输完成时。

18.3 激活源

DTC由中断请求激活。将ICU.IELSRn.DTCE位设置为1可以通过相关中断激活DTC。ICU.IELSRn中设置的选择器输出n个数被定义为中断向量号，其中n=0到95。对于一个使能的中断，在ICU.IELSRn.IELS中选择与每个中断向量号n相关的特定DTC中断源[8:0]其中n=0到95，如表14.4，事件表，第14节，中断控制器单元(ICU)中所列。对于软件激活，请参见第19.2.2节，事件链接软件事件生成

Register n (ELSEGRn) (n = 0, 1).

中断向量编号相当于DTC向量表编号。在DTC接受激活请求后，它不会接受另一个激活请求，直到该单个请求的传输完成，无论请求的优先级如何。如果在DMAC或DTC传输期间生成多个激活请求，则在传输完成时接受最高优先级的请求。当DTC模块起始位(DTCST.DTCST)为0时产生多个激活请求时，当DTCST.DTCST随后设置为1时，DTC接受最高优先级的请求。较小的中断向量编号具有较高的优先级。

DTC在单次数据传输开始时执行以下操作，或者对于链式传输，在最后一次连续传输之后执行以下操作：

- 完成指定的一轮数据传输后，ICU.IELSRn.DTCE位设置为0，并向CPU发送中断请求
- 如果MRB.DISEL位为1，则在数据传输完成时向CPU发送中断请求
- 对于其他传输，激活源的ICU.IELSRn.IR位在数据传输开始时设置为0。

18.3.1 Allocating Transfer Information and the DTC Vector Table

The DTC reads the start address of the transfer information associated with each activation source from the vector table and reads the transfer information starting at that address.

The vector table must be located so that the lower 10 bits of the base address (start address) are 0. Use the DTC Vector Base Register (DTCVBR) to set the base address of the DTC vector table. Transfer information is allocated in the SRAM area. In the SRAM area, the start address of the transfer information *n* with vector number *n* must be 4n added to the base address in the vector table.

Figure 18.2 shows the relationship between the DTC vector table and transfer information. Figure 18.3 shows the allocation of transfer information in the SRAM area.

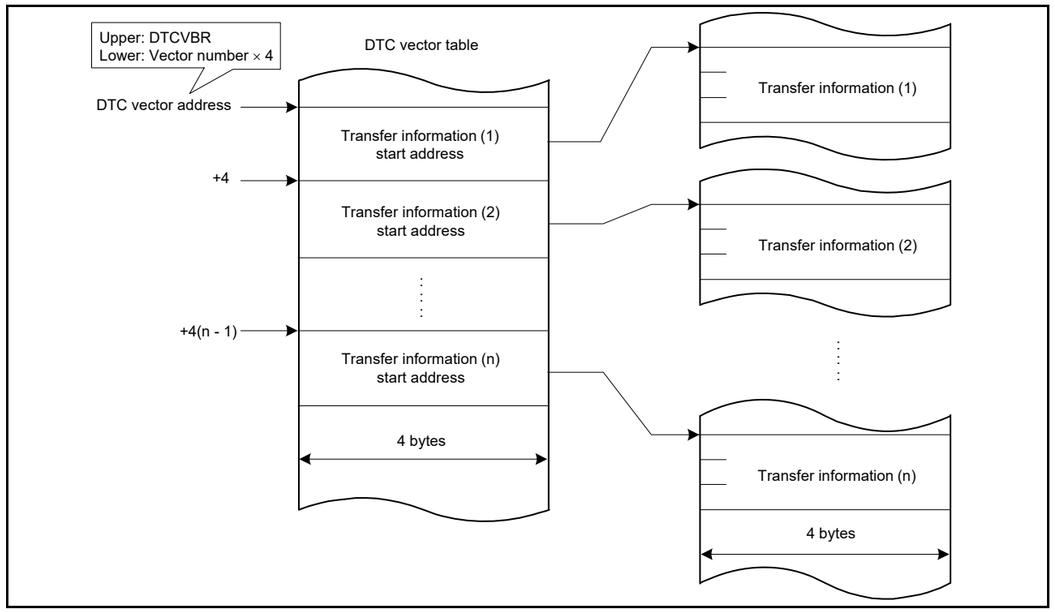

Figure 18.2 DTC vector table and transfer information

18.3.1 分配传输信息和DTC向量表

DTC从向量表中读取与每个激活源相关联的传输信息的起始地址，并读取从该地址开始的传输信息。

向量表的位置必须使基地址（起始地址）的低10位为0。使用DTC向量基址寄存器(DTCVBR)用于设置DTC向量表的基地址。传输信息分配在SRAM区域中。在SRAM区域中，向量编号为n的传输信息n的起始地址必须与向量表中的基地址相加4n。

图18.2显示了DTC向量表和传输信息之间的关系。图18.3显示了SRAM区域中传输信息的分配。

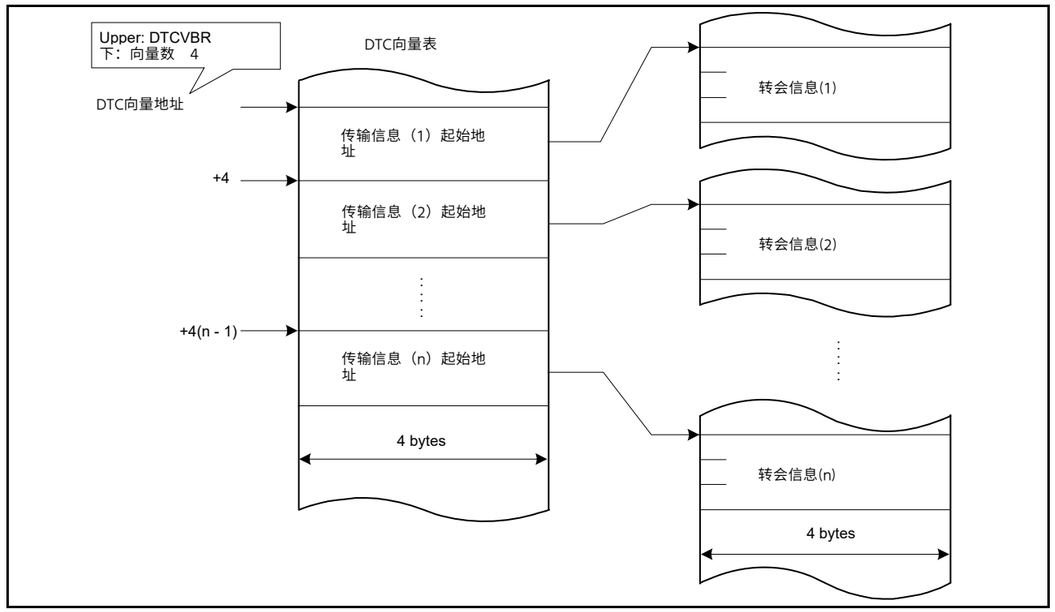

Figure 18.2 DTC向量表和传输信息

RA生态工作室

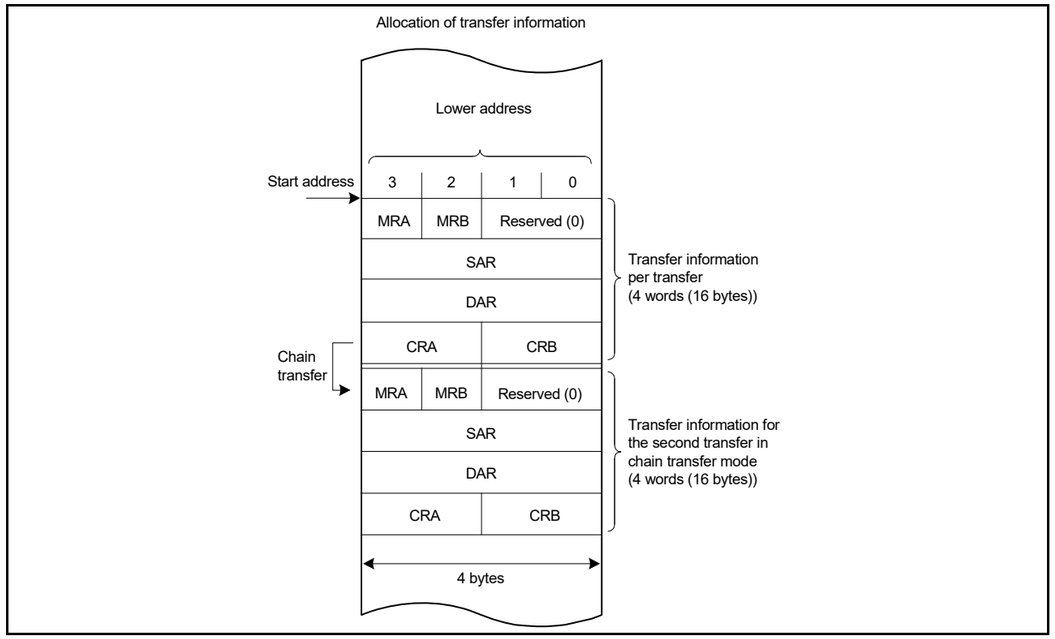

Figure 18.3 Allocation of transfer information in the SRAM area

18.4 Operation

The DTC transfers data according to the transfer information. Storage of the transfer information in the SRAM area is required before a DTC operation. When the DTC is activated, it reads the DTC vector associated with the vector number. The DTC then reads the transfer information from the transfer information store address referenced by the DTC vector and transfers the data. After the data transfer, the DTC writes back the transfer information. Storing the transfer information in the SRAM area allows data transfer of any number of channels.

The transfer modes include:

- Normal transfer mode
- Repeat transfer mode
- Block transfer mode.

The DTC specifies a transfer source address in the SAR register and a transfer destination address in the DAR register. The values in these registers are incremented, decremented, or address-fixed independently after the data transfer.

Table 18.2 describes the DTC transfer modes.

Table 18.2 DTC transfer modes

Transfer mode	Data size transferred on single transfer request	Increment or decrement of memory address	Settable transfer count
Normal transfer mode	1 byte (8 bits), 1 halfword (16 bits), or 1 word (32 bits)	Incremented or decremented by 1, 2, or 4 or address fixed	1 to 65536
Repeat transfer mode*1	1 byte (8 bits), 1 halfword (16 bits), or 1 word (32 bits)	Incremented or decremented by 1, 2, or 4 or address fixed	1 to 256*3
Block transfer mode*2	Block size specified in CRAH (1 to 256 bytes, 1 to 256 halfwords (2 to 512 bytes), or 1 to 256 words (4 to 1024 bytes))	Incremented or decremented by 1, 2, or 4 or address fixed	1 to 65536

Note 1. Set the transfer source or destination as the repeat area.

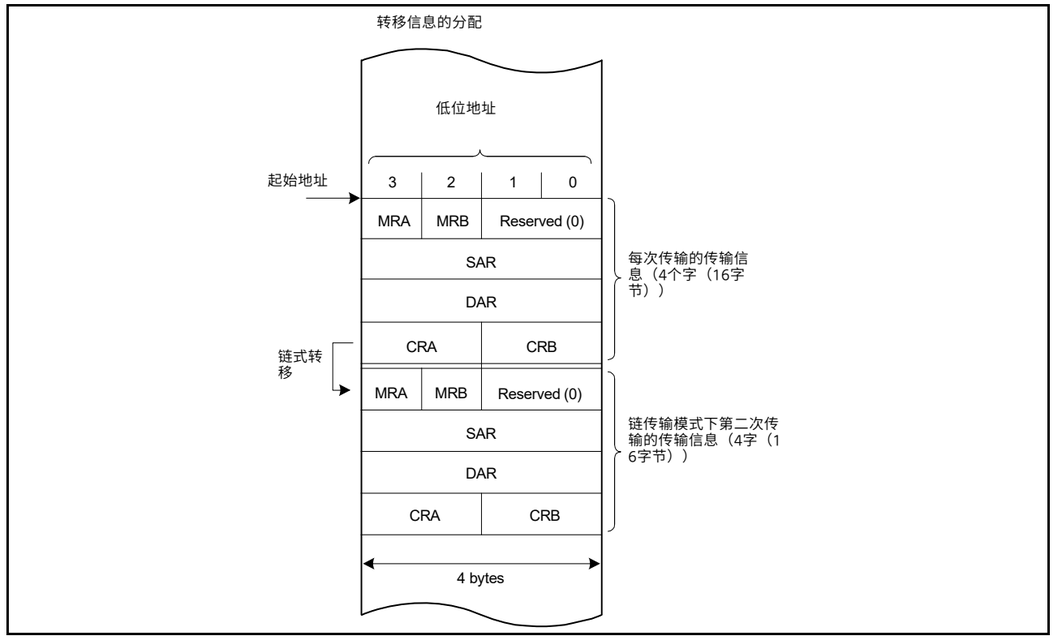

Figure 18.3 SRAM区域中传输信息的分配

18.4 Operation

DTC根据传输信息传输数据。在进行DTC操作之前，需要在SRAM区域中存储传输信息。当DTC被激活时，它会读取与向量编号相关联的DTC向量。然后DTC从DTC向量引用的传输信息存储地址中读取传输信息并传输数据。数据传输后，DTC写回传输信息。将传输信息存储在SRAM区域中可以实现任意数量的通道的数据传输。

传输模式包括：

- 正常传输模式
- 重复传输模式
- 块传输模式。

DTC指定SAR寄存器中的传输源地址和DAR寄存器中的传输目标地址。
这些寄存器中的值在数据传输后独立地递增、递减或固定地址。

表18.2描述了DTC传输模式。

Table 18.2 DTC传输模式

传输模式	在单个传输请求上传输的数据大小	内存地址的递增或递减	可设置的传输次数
正常传输模式	1个字节（8位）、1个半字（16位）或1个字（32位）	递增或递减1、2或4或固定地址	1 to 65536
重复传输模式*1	1个字节（8位）、1个半字（16位）或1个字（32位）	递增或递减1、2或4或固定地址	1 to 256*3
块传输模式*2	CRAH中指定的块大小（1到256字节、1到256个半字（2到512字节）或1到256字（4到1024字节））	递增或递减1、2或4或固定地址	1 to 65536

Note 1. 将传输源或目标设置为重复区域。

Note 2. Set the transfer source or destination as the block area.
Note 3. After a data transfer of the specified count, the initial state is restored and operation restarts.

Setting the MRB.CHNE bit to 1 allows multiple transfers or a chain transfer on a single activation source. It also enables a chain transfer when the specified data transfer is complete.

Figure 18.4 shows the operation flow of the DTC. Table 18.3 lists the chain transfer conditions. The combination of control information for the second and subsequent transfers are omitted in this table.

Note 2. 将传输源或目标设置为块区域。
Note 3. 在指定计数的数据传输后，恢复初始状态并重新开始操作。

将MRB.CHNE位设置为1允许在单个激活源上进行多次传输或链式传输。当指定的数据传输完成时，它还启用链式传输。

图18.4显示了DTC的操作流程。表18.3列出了链转移条件。该表中省略了用于第二次和后续传输的控制信息的组合。

Note 3. Chain transfer can be selected for the second or subsequent transfers. The conditions for the combination of the second transfer and CHNE bit = 1 is omitted.

18.4.1 Transfer Information Read Skip Function

Reading of vector addresses and transfer information can be skipped by setting the DTCCR.RRS bit. When a DTC activation request is generated, the current DTC vector number is compared to the DTC vector number in the previous activation process. When these vector numbers match and the RRS bit is set to 1, the DTC data transfer is performed without reading the vector address and transfer information. However, when the previous transfer is a chain transfer, the vector address and transfer information are read. Additionally, when the transfer counter (CRA register) becomes 0 during the previous normal transfer, or when the transfer counter (CRB register) becomes 0 during the previous block transfer, transfer information is read regardless of the RRS bit. Figure 18.12 shows an example of a transfer information read skip.

To update the vector table and transfer information:

1. Set the RRS bit to 0.
2. Update the vector table and transfer information.
3. Set the RRS bit to 1.

The stored vector number is discarded by setting the RRS bit to 0. The updated DTC vector table and transfer information are read in the next activation process.

18.4.1 传输信息读取跳过功能

通过设置DTCCR.RRS位可以跳过向量地址和传输信息的读取。当产生一个DTC激活请求时，当前的DTC向量编号将与之前激活过程中的DTC向量编号进行比较。当这些向量编号匹配且RRS位设置为1时，执行DTC数据传输而不读取向量地址和传输信息。但是，当上一次传输是链式传输时，会读取向量地址和传输信息。此外，如果在上次正常传输期间传输计数器（CRA寄存器）变为0，或者在前一次块传输期间传输计数器（CRB寄存器）变为0，则无论RRS位如何，都将读取传输信息。图18.12显示了传输信息读取跳过的示例。

更新向量表和传输信息：

1. 将RRS位设置为0。
2. 更新向量表并传递信息。
3. 将RRS位设置为1。

通过将RRS位设置为0来丢弃存储的向量号。在下一个激活过程中读取更新的DTC向量表和传输信息。

18.4.2 Transfer Information Write-Back Skip Function

When the MRA.SM[1:0] bits or the MRB.DM[1:0] bits are set to *address fixed*, a part of the transfer information is not written back. Table 18.4 lists the transfer information write-back skip conditions and the associated registers. The CRA and CRB registers are written back, and the write-back of the MRA and MRB registers is skipped.

18.4.3 Normal Transfer Mode

Normal transfer mode allows a 1-byte (8-bit), 1-halfword (16-bit), or 1-word (32-bit) data transfer on a single activation source. The transfer count can be set from 1 to 65536. Transfer source and destination addresses can be independently set to increment, decrement, or remain fixed. This mode enables an interrupt request to the CPU to be generated at the end of a specified-count transfer.

Table 18.5 lists the register functions in normal transfer mode, and Figure 18.5 shows the memory map of normal transfer mode.

18.4.2 传输信息回写跳过功能

当MRA.SM[1:0]位或MRB.DM[1:0]位设置为addressfixed时，部分传输信息不会写回。表18.4列出了传输信息回写跳过条件和相关寄存器。回写CRA和CRB寄存器，跳过回写MRA和MRB寄存器。

18.4.3 正常传输模式

正常传输模式允许在单个激活源上传输1字节（8位）、1半字（16位）或1字（32位）数据。传输计数可以设置为1到65536。传输源地址和目标地址可以独立设置为递增、递减或保持固定。此模式允许在指定计数传输结束时向CPU生成中断请求。

表18.5列出了正常传输模式下的寄存器功能，图18.5显示了正常传输模式下的内存映射。

18.4.4 Repeat Transfer Mode

Repeat transfer mode allows a 1-byte (8-bit), 1-halfword (16-bit), or 1-word (32-bit) data transfer on a single activation source. Specify either transfer source or transfer destination for the repeat area in the MRB.DTS bit. The transfer count can be set from 1 to 256. When the specified transfer count is complete, the initial value of the address register specified in the repeat area is restored, the initial value of the transfer counter is restored, and transfer is repeated. The other address register is incremented or decremented continuously or remains unchanged.

When the transfer counter CRAL decrements to 00h in repeat transfer mode, the CRAL value is updated to the value set in the CRAH register. As a result, the transfer counter does not clear to 00h, which disables interrupt requests to the CPU when the MRB.DISEL bit is set to 0. An interrupt request to the CPU is generated when the specified data transfer is complete.

Table 18.6 lists the register functions in repeat transfer mode, and Figure 18.6 shows the memory map of repeat transfer mode.

18.4.4 重复传输模式

重复传输模式允许在单个激活源上传输1字节（8位）、1半字（16位）或1字（32位）数据。在MRB.DTS位中指定重复区域的传输源或传输目标。传输计数可设置为1到256。当指定的传输计数完成时，将恢复重复区域中指定的地址寄存器的初始值，恢复传输计数器的初始值，并重复传输。另一个地址寄存器连续递增或递减或保持不变。

当传输计数器CRAL在重复传输模式下递减到00h时，CRAL值将更新为CRAH寄存器中设置的值。因此，传输计数器不会清为00h，这会在MRB.DISEL位设置为0时禁用对CPU的中断请求。当指定的数据传输完成时，会向CPU发出中断请求。

表18.6列出了重复传输模式下的寄存器功能，图18.6显示了重复传输模式的内存映射。

18.4.5 Block Transfer Mode

Block transfer mode allows single-block data transfer on a single activation source. Transfer source or transfer destination for the block area must be specified in the MRB.DTS bit. The block size can be set from 1 to 256 bytes, 1 to 256 halfwords (2 to 512 bytes), or 1 to 256 words (4 to 1024 bytes). When transfer of the specified block completes, the initial values of the block size counter CRAL and the address register (the SAR register when the MRB.DTS bit = 1 or the DAR register when the DTS bit = 0) specified in the block area are restored. The other address register is incremented or decremented continuously or remains unchanged.

The transfer count (block count) can be set from 1 to 65536. This mode enables an interrupt request to the CPU to be generated at the end of the specified-count block transfer.

Table 18.7 lists register functions in block transfer mode, and Figure 18.7 shows the memory map for block transfer mode.

Register	Description	Value written back by writing transfer information
SAR	Transfer source address	• When MRB.DTS bit is 0 Increment, decrement, or fixed*1 • When MRB.DTS bit is 1 SAR register initial value.

18.4.5 块传输模式

块传输模式允许在单个激活源上进行单块数据传输。块区域的传输源或传输目标必须在MRB.DTS位中指定。块大小可以设置为1到256字节、1到256个半字（2到512字节）或1到256字（4到1024字节）。当指定块的传输完成时，块区域中指定的块大小计数器CRAL和地址寄存器（当MRB.DTS位=1时为SAR寄存器或当DTS位=0时为DAR寄存器）的初始值是恢复。另一个地址寄存器连续递增或递减或保持不变。

传输计数（块计数）可设置为1到65536。此模式允许在指定计数块传输结束时向CPU生成中断请求。

表18.7列出了块传输模式下的寄存器功能，图18.7显示了块传输模式下的存储器映射。

18.4.6 Chain Transfer

Setting the MRB.CHNE bit to 1 allows chain transfer to be performed continuously on a single activation source. If MRB.CHNE is set to 1 and CHNS to 0, an interrupt request to the CPU is not generated on completion of the specified number of transfer rounds or by setting the MRB.DISEL bit to 1. An interrupt request is sent to the CPU each time DTC data transfer is performed. Data transfer has no effect on the ICU.IELSRn.IR bit of the activation source.

The SAR, DAR, CRA, CRB, MRA, and MRB registers can be set independently of each other to define the data transfer. Figure 18.8 shows a chain transfer operation.

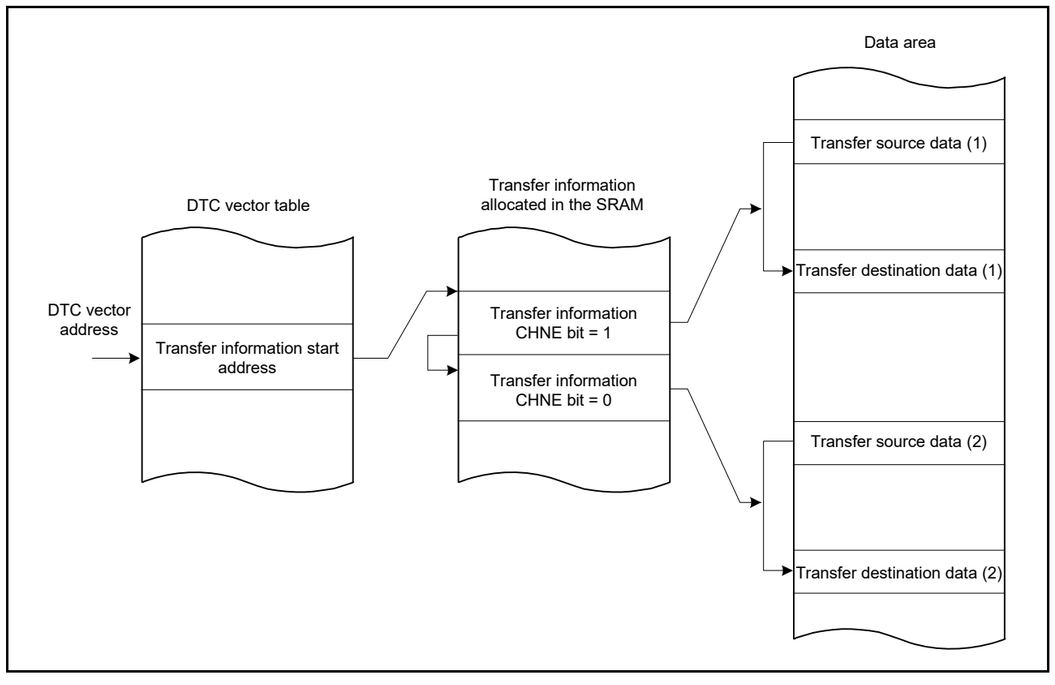

Figure 18.8 Chain transfer operation

18.4.6 链转移

将MRB.CHNE位设置为1允许在单个激活源上连续执行链传输。如果
MRB.CHNE设置为1，CHNS设置为0，在完成指定的传输轮数或将MRB.DISEL位设置为1时，不会向CPU产生中断请求。每次向CPU发送一个中断请求执行DTC数据传输的时间。数据传输对激活源的ICU.IELSRn.IR位没有影响。

SAR、DAR、CRA、CRB、MRA和MRB寄存器可以相互独立设置以定义数据传输。
图18.8显示了一个链式转移操作。

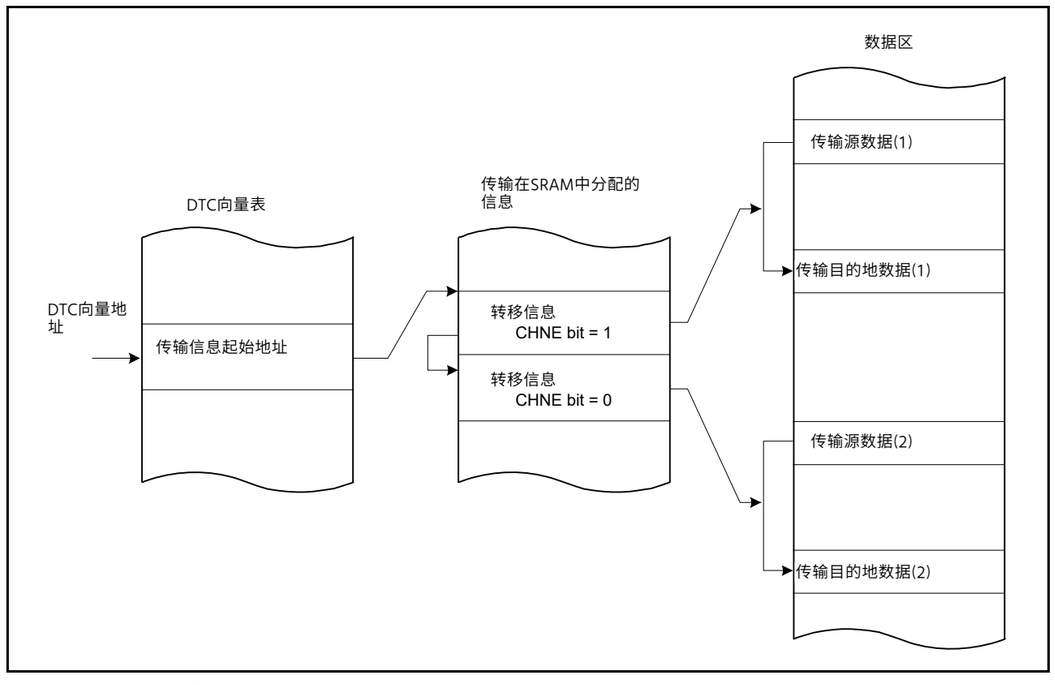

Figure 18.8 链转移操作

Writing 1 to the MRB.CHNE and CHNS bits enables chain transfer to be performed only after completion of the specified data transfer. In repeat transfer mode, chain transfer is performed after completion of the specified data transfer. For details on chain transfer conditions, see Table 18.3, Chain transfer conditions.

18.4.8 Execution Cycles of DTC

Table 18.8 lists the execution cycles of single data transfer of the DTC.

For the order of the execution states, see section 18.4.7, Operation Timing.

The unit is system clock (ICLK) for + 1 in the Vector read, Transfer information read, and Data transfer read columns and 2 in the Internal operation column.
Cv, Ci, Cr, and Cw vary depending on the corresponding access destination. For the number of cycles for respective access destinations, see section 48, SRAM, section 50, Flash Memory, and section 15.2.3, External Bus.
The frequency ratio of the system clock and peripheral clock is also taken into consideration.
The DTC response time is the time from when the DTC activation source is detected until DTC transfer starts.
This table does not include the time until DTC data transfer starts after the DTC activation source becomes active.

18.4.9 DTC Bus Mastership Release Timing

The DTC does not release bus mastership during transfer information reads. Before the transfer information is read or written, the bus is arbitrated according to the priority determined by the bus master arbitrator. For bus arbitration, see section 15, Buses.

18.5 DTC Setting Procedure

Before using the DTC, set the DTC Vector Base Register (DTCVBR). Figure 18.13 shows the procedure for setting the DTC.

18.4.8 DTC的执行周期

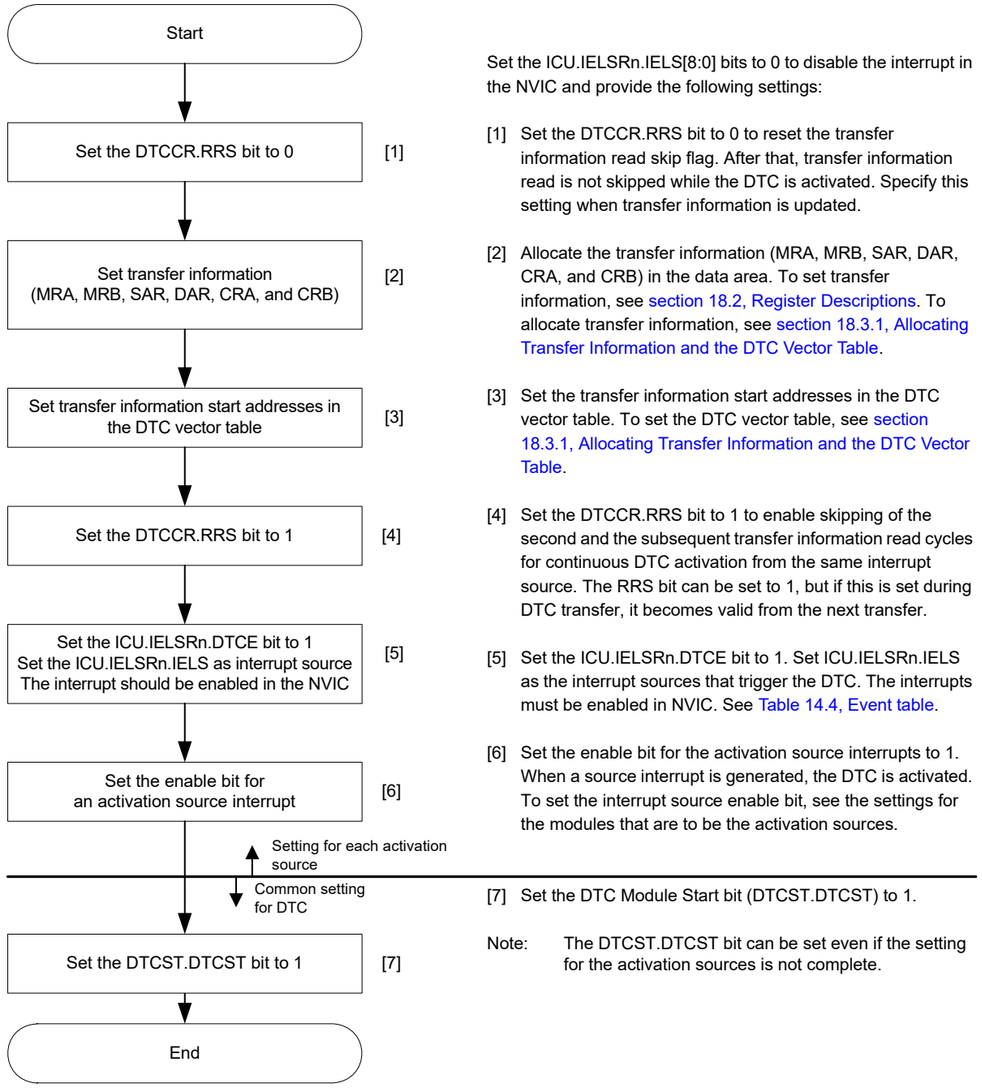
此表不包括从DTC激活源激活到DTC数据传输开始的时间。

18.4.9 DTC总线主控释放时序

在传输信息读取期间，DTC不会释放总线控制权。在读取或写入传输信息之前，根据总线主仲裁器确定的优先级对总线进行仲裁。对于总线仲裁，请参见第15节，总线。

18.5 DTC设置程序

在使用DTC之前，请设置DTC向量基址寄存器(DTCVBR)。图18.13显示了设置DTC.



Set the ICU.IELSRn.IELS[8:0] bits to 0 to disable the interrupt in the NVIC and provide the following settings:

[1] Set the DTCCR.RRS bit to 0 to reset the transfer information read skip flag. After that, transfer information read is not skipped while the DTC is activated. Specify this setting when transfer information is updated.

[2] Allocate the transfer information (MRA, MRB, SAR, DAR, CRA, and CRB) in the data area. To set transfer information, see section 18.2, Register Descriptions. To allocate transfer information, see section 18.3.1, Allocating Transfer Information and the DTC Vector Table.

[3] Set the transfer information start addresses in the DTC vector table. To set the DTC vector table, see section 18.3.1, Allocating Transfer Information and the DTC Vector Table.

[4] Set the DTCCR.RRS bit to 1 to enable skipping of the second and the subsequent transfer information read cycles for continuous DTC activation from the same interrupt source. The RRS bit can be set to 1, but if this is set during DTC transfer, it becomes valid from the next transfer.

[5] Set the ICU.IELSRn.DTCE bit to 1. Set ICU.IELSRn.IELS as the interrupt sources that trigger the DTC. The interrupts must be enabled in NVIC. See Table 14.4, Event table.

[6] Set the enable bit for the activation source interrupts to 1. When a source interrupt is generated, the DTC is activated. To set the interrupt source enable bit, see the settings for the modules that are to be the activation sources.

[7] Set the DTC Module Start bit (DTCST.DTCST) to 1.

Note: The DTCST.DTCST bit can be set even if the setting for the activation sources is not complete.

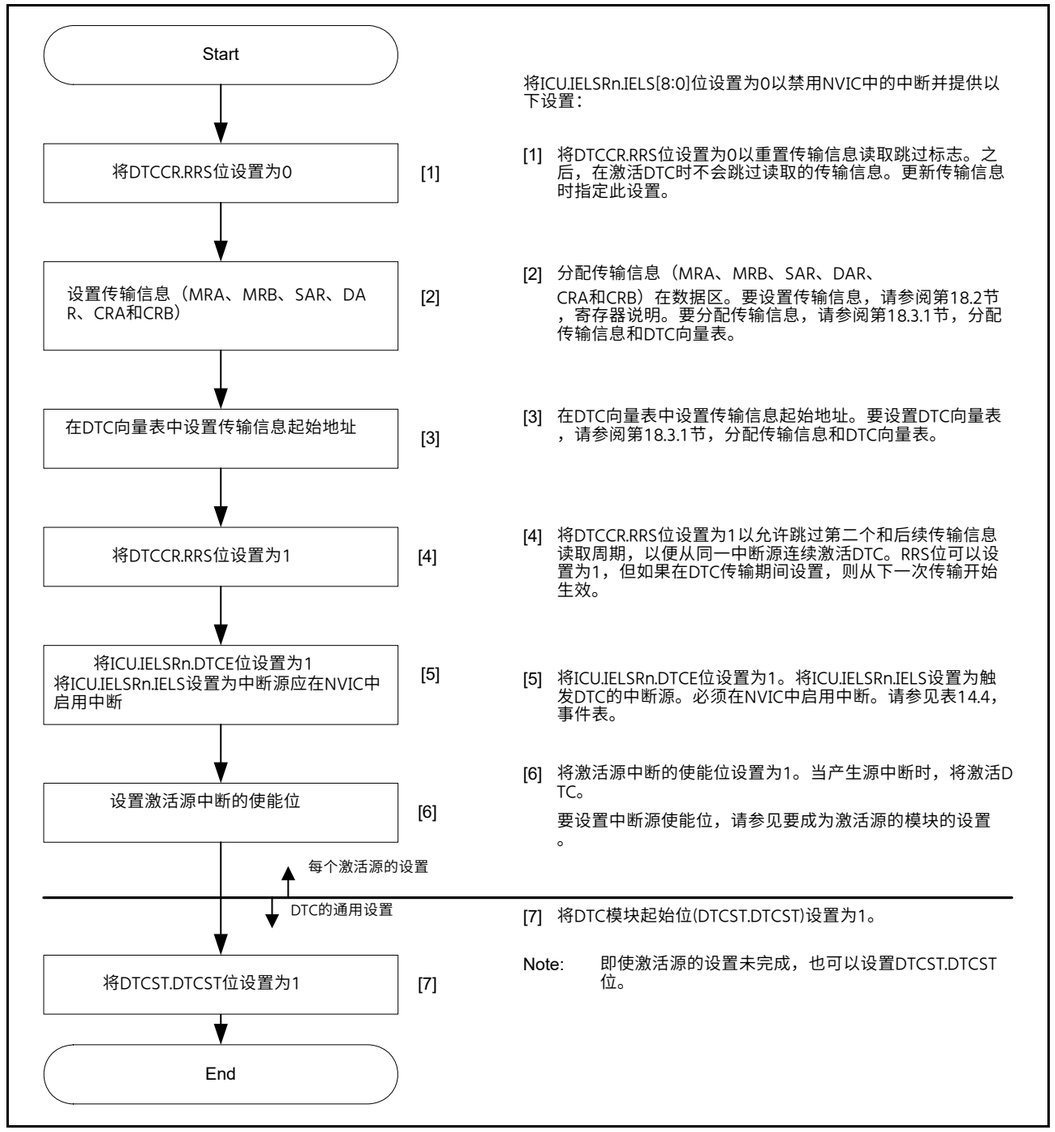
18.6 Examples of DTC Usage



将ICU.IELSRn.IELS[8:0]位设置为0以禁用NVIC中的中断并提供以下设置：

[1] 将DTCCR.RRS位设置为0以重置传输信息读取跳过标志。之后，在激活DTC时不会跳过读取的传输信息。更新传输信息时指定此设置。

[2] 分配传输信息（MRA、MRB、SAR、DAR、CRA和CRB）在数据区。要设置传输信息，请参阅第18.2节，寄存器说明。要分配传输信息，请参阅第18.3.1节，分配传输信息和DTC向量表。

[3] 在DTC向量表中设置传输信息起始地址。要设置DTC向量表，请参阅第18.3.1节，分配传输信息和DTC向量表。

[4] 将DTCCR.RRS位设置为1以允许跳过第二个和后续传输信息读取周期，以便从同一中断源连续激活DTC。RRS位可以设置为1，但如果在DTC传输期间设置，则从下一次传输开始生效。

[5] 将ICU.IELSRn.DTCE位设置为1。将ICU.IELSRn.IELS设置为触发DTC的中断源。必须在NVIC中启用中断。请参见表14.4，事件表。

[6] 将激活源中断的使能位设置为1。当产生源中断时，将激活DTC。
要设置中断源使能位，请参见要成为激活源的模块的设置。

[7] 将DTC模块起始位(DTCST.DTCST)设置为1。

Note: 即使激活源的设置未完成，也可以设置DTCST.DTCST位。

18.6 DTC使用示例

RA生态工作室

18.6.1 Normal Transfer

This section provides an example of DTC usage and its application when receiving 128 bytes of data from an SCI.

(1) Transfer information settings

In the MRA register, select a fixed source address (MRA.SM[1:0] = 00b), normal transfer mode (MRA.MD[1:0] = 00b), and byte-sized transfer (MRA.SZ[1:0] = 00b). In the MRB register, specify incrementation of the destination address (MRB.DM[1:0] = 10b) and single data transfer by a single interrupt (MRB.CHNE = 0 and MRB.DISEL = 0). The MRB.DTS bit can be set to any value. Set the RDR register address of the SCI in the SAR register, the start address of the SRAM area for data storage in the DAR register, and 128 (0080h) in the CRA register. The CRB register can be set to any value.

(2) DTC vector table settings

The start address of the transfer information for the RXI interrupt is set in the vector table for the DTC.

(3) ICU settings and DTC module activation

Set the ICU.IELSRn.DTCE bit to 1 and set ICU.IELSRn.IELS as the SCI interrupt. The interrupt must be enabled in the NVIC. Set the DTCST.DTCST bit to 1.

(4) SCI settings

Enable the RXI interrupt by setting the SCR.RIE bit in the SCI to 1. If a reception error occurs during the SCI receive operation, reception stops. To manage this, use settings that allow the CPU to accept receive error interrupts.

(5) DTC transfer

Each time a reception of 1 byte by the SCI is complete, an RXI interrupt is generated to activate the DTC. The DTC transfers the received byte from the RDR of the SCI to the SRAM, after which the DAR register is incremented and the CRA register is decremented.

(6) Interrupt handling

After 128 rounds of data transfer are complete and the value in the CRA register becomes 0, an RXI interrupt request is generated for the CPU. Complete the process in the handling routine for this interrupt.

18.6.2 Chain Transfer

This section provides an example of chain transfer by the DTC and describes its use in the output of pulses by the General PWM Timer (GPT). You can use chain transfer to transfer PWM timer compare data and change the period of the PWM timer for GPT.

For the first of the chain transfers, normal transfer mode is specified for transfer to the GPT32m.GTCCRC register (m = EH0 to EH3, E4 to E7, 8 to 12). For the second transfer, normal transfer mode is specified for transfer to the GPT32m.GTCCRE register. For the third transfer, normal transfer mode is specified for transfer to the GPT32m.GTPBR register. This is because clearing of the activation source and generation of an interrupt on completion of the specified number of transfers are restricted to the third of the chain transfers, that is, transfer while MRB.CHNE = 0.

The following example shows how to use the counter overflow interrupt with a GPT32EH0.GTPR register as an activating source for the DTC.

(1) First transfer information settings

Set up transfer to the GPT32EH0.GTCCRC register:

1. In the MRA register, select incrementation of the source address (MRA.SM[1:0] = 10b).
2. Set the transfer to normal transfer mode (MRA.MD[1:0] = 00b) and word-sized transfer (MRA.SZ[1:0] = 10b).
3. In the MRB register, select the destination address as fixed (MRB.DM[1:0] = 00b) and set up chain transfer (MRB.CHNE = 1 and MRB.CHNS = 0).
4. Set the SAR register to the first address of the data table.
5. Set the DAR register to the address of the GPT32EH0.GTCCRC register.

18.6.1 正常转移

本节提供从SCI接收128字节数据时的DTC用法及其应用示例。

(1) 传输信息设置

在MRA寄存器中，选择固定源地址（MRA.SM[1:0]=00b）、正常传输模式（MRA.MD[1:0]=00b）和字节大小传输（MRA.SZ[1:0]=00b)。在MRB寄存器中，指定目标地址的递增(MRB.DM[1:0]=10b)和单个中断的单个数据传输(MRB.CHNE=0和MRB.DISEL=0)。MRB.DTS位可以设置为任何值。在SAR寄存器中设置SCI的RDR寄存器地址，在DAR寄存器中设置用于数据存储的SRAM区域的起始地址，在CRA寄存器中设置128（0080h）。CRB寄存器可以设置为任何值。

(2) DTC向量表设置

RXI中断的传输信息的起始地址在DTC的向量表中设置。

(3) ICU设置和DTC模块激活

将ICU.IELSRn.DTCE位设置为1，并将ICU.IELSRn.IELS设置为SCI中断。中断必须在启用
英伟达。将DTCST.DTCST位设置为1。

(4) SCI设置

通过将SCI中的SCR.RIE位设置为1来启用RXI中断。如果在SCI接收操作期间发生接收错误，则接收停止。要管理此问题，请使用允许CPU接受接收错误中断的设置。

(5) DTC transfer

每次SCI完成1个字节的接收，就会产生一个RXI中断来激活DTC。DTC将接收到的字节从SCI的RDR传输到SRAM，之后DAR寄存器递增，CRA寄存器递减。

(6) 中断处理

在128轮数据传输完成后，CRA寄存器中的值变为0，产生一个RXI中断请求给CPU。完成该中断处理程序中的处理。

18.6.2 链转移

本节提供了DTC链传输的示例，并描述了其在DTC输出脉冲中的使用
通用PWM定时器(GPT)。您可以使用链传输来传输PWM定时器比较数据并更改GPT的PWM定时器的周期。

对于第一个链传输，指定正常传输模式以传输到GPT32m.GTCCRC寄存器（m=EH0到EH3，E4到E7，8到12）。对于第二次传输，指定正常传输模式用于传输到
GPT32m.GTCCRE寄存器。对于第三次传输，指定正常传输模式以传输到GPT32m.GTPBR寄存器。这是因为在完成指定数量的传输时清除激活源和产生中断仅限于链传输的第三个，即在MRB.CHNE=0时传输。

以下示例显示如何使用带有GPT32EH0.GTPR寄存器的计数器溢出中断作为DTC的激活源。

(1) 首次转账信息设置

设置传输到GPT32EH0.GTCCRC寄存器：

3. In the MRB register, select the destination address as fixed (MRB.DM[1:0] = 00b) and set up single data transfer per interrupt (MRB.CHNE = 0, MRB.DISEL = 0). The MRB.DTS bit can be set to any value.
4. Set the SAR register to the first address of the data table.
5. Set the DAR register to the address of the GPT32EH0.GTPBR register.

(5) DTC vector table

In the DTC vector table, set the address where the transfer control information for use in transfer to the GPT32EH0.GTCCRC and GPT32EH0.GTCCRE registers starts.

6. 将CRAH和CRAL寄存器设置为数据表的大小。CRB寄存器可以设置为任何值。

(2) 二转信息设置

设置传输到GPT32EH0.GTCCRE寄存器：

1. 在MRA寄存器中，选择源地址的递增(MRA.SM[1:0]=10b)。
2. 将传输设置为正常传输模式(MRA.MD[1:0]=00b)和字大小传输(MRA.SZ[1:0]=10b)。
3. 在MRB寄存器中，选择固定的目标地址（MRB.DM[1:0]=00b）并设置链式传输（MRB.CHNE=1和MRB.CHNS=0）。
4. 将SAR寄存器设置为数据表的首地址。
5. 将DAR寄存器设置为GPT32EH0.GTCCRE寄存器的地址。
6. 将CRAH和CRAL寄存器设置为数据表的大小。CRB寄存器可以设置为任何值。

4. 将SAR寄存器设置为数据表的首地址。
5. 将DAR寄存器设置为GPT32EH0.GTPBR寄存器的地址。
6. 将CRA寄存器设置为数据表的大小。CRB寄存器可以设置为任何值。

(4) 转移信息分配

将用于传输到GPT32EH0.GTPBR的传输信息放置在GPT32EH0.GTCCRC和GPT32EH0.GTCCRE寄存器中使用的传输控制信息之后。

(5) DTC向量表

在DTC向量表中，设置传输控制信息的地址，用于传输到GPT32EH0.GTCCRC和GPT32EH0.GTCCRE寄存器启动。

(6) ICU设置和DTC模块激活

1. 设置与GPT32EH0计数器溢出中断相关的ICU.IELSRn.DTCE位。
2. 将ICU.IELSRn.IELS[8:0]位设置为182(B6h)以用于GPT32EH0计数器溢出。
3. 将DTCST.DTCST位设置为1。

2. 在GPT32EH0.GTCCRA和GPT32EH0.GTCCRB寄存器中设置默认PWM定时器比较值，在GPT32EH0.GTCCRC和GPT32EH0.GTCCRE寄存器中设置下一个PWM定时器比较值。
3. 在GPT32EH0.GTPR寄存器中设置默认PWM定时器周期值，在GPT32EH0.GTPBR寄存器中设置下一个PWM定时器周期值。
4. 将PmnPFS.PDR中的输出位设置为1，并将PmnPFS.PSEL[4:0]中的外设选择位设置为00011b。

(8) GPT activation

将GPT32EH0.GTSTR.CSTRT位设置为1以启动GPT32EH0.GTCNT计数器。

(9) DTC transfer

Each time a GPT32EH0 counter overflow is generated with the GPT32EH0.GTPR register, the next PWM timer compare values are transferred to the GPT32EH0.GTCCRC and GPT32EH0.GTCCRE registers. The setting for the next PWM timer period is transferred to the GPT32EH0.GTPBR register.

(10) Interrupt handling

After the specified rounds of data transfer are complete, for example when the value in the CRA register for GPT transfer becomes 0, a GPT counter overflow interrupt request is issued for the CPU. Complete the process for this interrupt in the handling routine.

18.6.3 Chain Transfer when Counter = 0

The second data transfer is performed only when the transfer counter is set to 0 in the first data transfer, and the first data transfer information is repeatedly changed in the second transfer. Chain transfer enables transfers to be repeated 256 times or more.

The following procedure shows an example of configuring a 128-KB input buffer, where the input buffer is set so that its lower address starts with 0000h. Figure 18.14 shows a chain transfer when the counter = 0.

1. Set the normal transfer mode to input data for the first data transfer. Set the following:
   a. Transfer source address = fixed.
   b. CRA register = 0000h (65536) times.
   c. MRB.CHNE bit = 1 (chain transfer is enabled).
   d. MRB.CHNS bit = 1 (chain transfer is performed only when the transfer counter is 0).
   e. MRB.DISEL bit = 0 (an interrupt request to the CPU is generated when the specified data transfer completes).
2. Prepare the upper 8-bit address of the start address at every 65536 times of the transfer destination address for the first data transfer in different area such as the flash. For example, when setting the input buffer to 20 0000h to 21 FFFFh, prepare 21h and 20h.
3. For the second data transfer:
   a. Set the repeat transfer mode (with the source as the repeat area) to reset the transfer destination address of the first data transfer.
   b. Specify the upper 8 bits of the DAR register in the first transfer information area for the transfer destination.
   c. Set the MRB.CHNE bit = 0 (chain transfer is disabled).
   d. Set the MRB.DISEL bit = 0 (an interrupt request to the CPU is generated when the specified data transfer completes).
   e. When setting the input buffer to 20 0000h to 21 FFFFh, also set the transfer counter to 2.
4. The first data transfer is performed by an interrupt 65536 times. When the transfer counter of the first data transfer becomes 0, the second data transfer starts. Set the upper 8 bits of the transfer destination address of the first data transfer to 21h. The lower 16 bits of the transfer destination address and the transfer counter of the first data transfer becomes 0000h.
5. In succession, the first data transfer is performed by an interrupt 65536 times as specified for the first data transfer. When the transfer counter of the first data transfer becomes 0, the second data transfer starts. Set the upper 8 bits of the transfer destination address of the first data transfer to 20h. The lower 16 bits of the transfer destination address and the transfer counter of the first data transfer becomes 0000h.
6. Steps 4 and 5 are repeated indefinitely. Because the second data transfer is in repeat transfer mode, no interrupt request to the CPU is generated.

(9) DTC transfer

每次使用GPT32EH0.GTPR寄存器产生GPT32EH0计数器溢出时，下一个PWM定时器比较值被传送到GPT32EH0.GTCCRC和GPT32EH0.GTCCRE寄存器。下一个PWM定时器周期的设置被传送到GPT32EH0.GTPBR寄存器。

(10)中断处理

在指定轮次的数据传输完成后，例如当GPT传输的CRA寄存器中的值变为0时，会向CPU发出GPT计数器溢出中断请求。在处理例程中完成该中断的处理。

18.6.3 Counter=0时的链式转移

仅当在第一次数据传输中将传输计数器设置为0时才执行第二次数据传输，并且在第二次传输中重复改变第一数据传输信息。链式转移使转移可以重复256次或更多。

以下过程显示了配置128KB输入缓冲区的示例，其中输入缓冲区设置为使其低地址以0000h开头。图18.14显示了当计数器=0时的链式传输。

1. 将正常传输模式设置为第一次数据传输的输入数据。设置以下内容：
   一个。传输源地址=固定。
   湾。CRA寄存器=0000h(65536)次。
   C。MRB.CHNE位=1（启用链式传输）。
   d。MRB.CHNS位=1（仅当传输计数器为0时才执行链式传输）。
   e.MRB.DISEL位=0（指定数据传输完成时向CPU产生中断请求）。
2. 在flash等不同区域的第一次数据传输中，每65536次传输目标地址准备起始地址的高8位地址。例如，将输入缓冲区设置为200000h到21FFFFh时，准备21h和20h。
3. 对于第二次数据传输：
   一个。设置重复传输模式（以源为重复区域）重置第一次数据传输的传输目标地址。
   湾。在传输目标的第一个传输信息区域中指定DAR寄存器的高8位。
   C。设置MRB.CHNE位=0（禁用链传输）。
   d。设置MRB.DISEL位=0（当指定的数据传输完成时向CPU产生一个中断请求）。
   e.将输入缓冲区设置为200000h至21FFFFh时，还要将传输计数器设置为2。
4. 第一次数据传输由中断执行65536次。当第一次数据传输的传输计数器变为0时，第二次数据传输开始。将第一次数据传输的传输目标地址的高8位设置为21h。第一次数据传输的传输目标地址和传输计数器的低16位变为0000h。
5. 随后，第一次数据传输由中断执行65536次，如为第一次数据传输指定的那样。当第一次数据传输的传输计数器变为0时，第二次数据传输开始。将第一次数据传输的传输目标地址的高8位设置为20h。第一次数据传输的传输目标地址和传输计数器的低16位变为0000h。
6. 步骤4和5无限重复。因为第二次数据传输是重复传输模式，所以不会产生对CPU的中断请求。

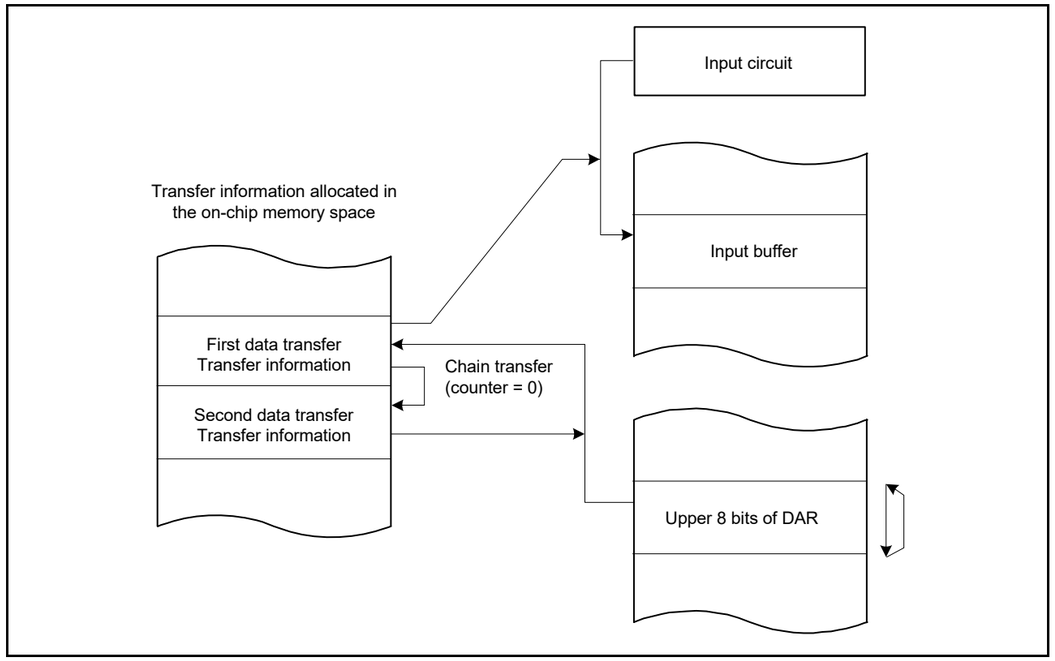

Figure 18.14 Chain transfer when counter = 0

18.7 Interrupt Sources

When the DTC completes data transfer of the specified count or when data transfer with MRB.DISEL set to 1 is complete, a DTC activation source generates an interrupt to the CPU. Interrupts to the CPU are controlled according to the settings in the NVIC and ICU.IELSRn.IELS[8:0] bits. See section 14, Interrupt Controller Unit (ICU).

The DTC prioritizes activation sources by granting the smaller interrupt vector numbers higher priority. The priority of interrupts to the CPU is determined by the NVIC priority.

18.8 Event Link

The DTC can produce an event link request on completion of one transfer request. When the destination for the transfer is an external bus, the event link request is issued after completion of writing to the write buffer rather than after completion of writing to the actual transfer destination.

18.9 Snooze Control Interface

To return to Software Standby mode from Snooze mode through the DTC, set SYSTEM.SNZEDCR.DTCZRED or SYSTEM.SNZEDCR.DTCNZRED to 1. See section 11.8.3, Returning to Software Standby Mode.

SYSTEM.SNZEDCR.DTCZRED enables or disables a snooze end request on completion of the last DTC transmission, detected on DTC transmission completion when CRA and CRB are 0.

SYSTEM.SNZEDCR.DTCNZRED enables or disables a snooze end request on a not last DTC transmission completion (CRA and CRB are not 0), detected on DTC transmission completion when CRA and CRB are not 0.

18.10 Module-Stop Function

Before transitioning to the module-stop function, Software Standby mode without a Snooze mode transition, or Deep Software Standby mode, set the DTCST.DTCST bit to 0, then perform the operations described in the following sections. The DTC is available in Snooze mode by setting LPW.SNZCR.SNZDTCEN to 1. See section 11, Low Power Modes.

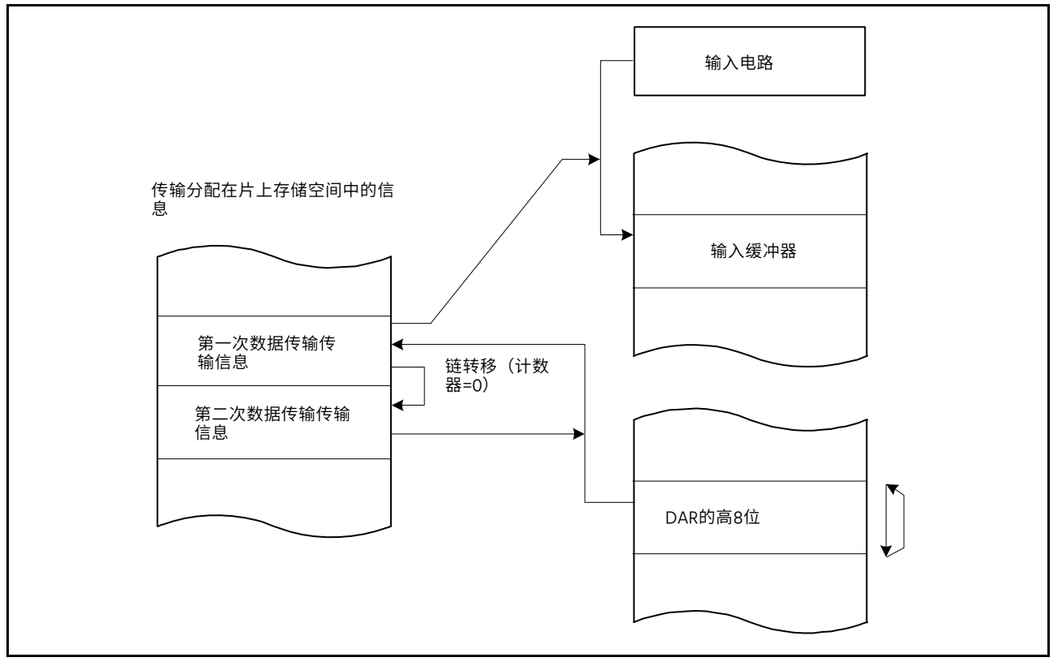

Figure 18.14 counter=0时的链转移

18.7 中断源

当DTC完成指定计数的数据传输或MRB.DISEL设置为1的数据传输完成时，DTC激活源向CPU生成中断。CPU的中断根据NVIC和ICU.IELSRn.IELS[8:0]位中的设置进行控制。参见第14节，中断控制器单元(ICU)。

DTC通过授予较小的中断向量编号较高的优先级来确定激活源的优先级。CPU中断的优先级由NVIC优先级决定。

18.8 活动链接

DTC可以在一个传输请求完成时产生一个事件链接请求。当传输目的地是外部总线时，事件链接请求是在写入缓冲区写入完成后发出，而不是在实际传输目标写入完成后发出。

18.9 贪睡控制界面

要通过DTC从贪睡模式返回到软件待机模式，请设置SYSTEM.SNZEDCR.DTCZRED或SYSTEM.SNZEDCR.DTCNZRED为1。请参阅第11.8.3节，返回到软件待机模式。

SYSTEM.SNZEDCR.DTCZRED在最后一次DTC传输完成时启用或禁用贪睡结束请求，当CRA和CRB为0时在DTC传输完成时检测到。

SYSTEM.SNZEDCR.DTCNZRED在非最后一次DTC传输完成（CRA和CRB不为0）时启用或禁用贪睡结束请求，当CRA和CRB不为0时在DTC传输完成时检测到。

18.10 Module-Stop Function

在转换到模块停止功能、没有贪睡模式转换的软件待机模式或深度软件待机模式之前，将DTCST.DTCST位设置为0，然后执行以下部分中描述的操作。

通过将LPW.SNZCR.SNZDTCEN设置为1，可以在贪睡模式下使用DTC。请参阅第11节，低功耗模式。

(1) Module-stop function

Writing 1 to the MSTPCRA.MSTPA22 bit enables the module-stop function of the DTC. If the DTC transfer is in progress at the time 1 is written to the MSTPCRA.MSTPA22 bit, the transition to the module-stop state proceeds after DTC transfer ends. When the MSTPCRA.MSTPA22 bit is 1, accessing the DTC registers is prohibited. Writing 0 to the MSTPCRA.MSTPA22 bit releases the DTC from the module-stop state.

(2) Software Standby and Deep Software Standby modes

Use the settings described in section 11.7.1, Transitioning to Software Standby Mode, or section 11.9.1, Transitioning to Deep Software Standby Mode.

If DTC transfer operations are in progress when the WFI instruction is executed, the transition to Software Standby mode or Deep Software Standby mode follows the completion of the DTC transfer.

When the snooze control circuit receives a snooze request in Software Standby mode, the MCU transfers to Snooze mode. See section 11.8.1, Transitioning to Snooze Mode. DTC operation in Snooze mode can be selected in the SYSTEM.SNZCR.SNZDTCEN bit. If DTC operation is enabled in Snooze mode, before transitioning to Software Standby mode, set the DTCST.DTCST bit to 1. To return to Software Standby mode through the DTC, set SYSTEM.SNZEDCR.DTCZRED or SYSTEM.SNZEDCR.DTCNZRED to 1. See section 11.8.3, Returning to Software Standby Mode. The DTC activation request from the ICU is stopped during Software Standby mode but not during Snooze mode.

(3) Notes on the module-stop function

For the WFI instruction and the register setting procedure, see section 11, Low Power Modes.

To perform a DTC transfer after returning from a low power mode without a Snooze mode transition, set the DTCST.DTCST bit to 1 again.

To use a request that is generated in Software Standby mode as an interrupt request to the CPU but not as a DTC activation request, specify the CPU as the interrupt request destination as described in section 14.4.2, Selecting Interrupt Request Destinations, then execute a WFI instruction. If DTC operation is enabled in Snooze mode, do not use the module-stop function of the DTC.

18.11 Usage Notes

18.11.1 Transfer Information Start Address

You must set multiples of 4 for the transfer information start addresses in the vector table. Otherwise, such addresses are accessed with their lowest 2 bits regarded as 00b.

(1) Module-stop function

向MSTPCRA.MSTPA22位写入1可启用DTC的模块停止功能。如果在向MSTPCRA.MSTPA22位写入1时DTC传输正在进行，则在DTC传输结束后继续向模块停止状态的转换。当MSTPCRA.MSTPA22位为1时，禁止访问DTC寄存器。将0写入

MSTPCRA.MSTPA22位从模块停止状态释放DTC。

(2) 软件待机和深度软件待机模式

使用第11.7.1节，转换到软件待机模式或第11.9.1节，转换到深度软件待机模式。

如果在执行WFI指令时DTC传输操作正在进行，则在DTC传输完成后转换到软件待机模式或深度软件待机模式。

当贪睡控制电路在软件待机模式下接收到贪睡请求时，MCU转入贪睡模式。请参阅第11.8.1节，转换到贪睡模式。可以在SYSTEM.SNZCR.SNZDTCEN位中选择贪睡模式下的DTC操作。如果在贪睡模式下启用了DTC操作，则在转换到软件之前

待机模式，将DTCST.DTCST位设置为1。要通过DTC返回软件待机模式，请设置SYSTEM.SNZEDCR.DTCZRED或SYSTEM.SNZEDCR.DTCNZRED为1。请参阅第11.8.3节，返回软件待机模式。来自ICU的DTC激活请求在软件待机模式期间停止，但在贪睡模式。

(3) 关于模块停止功能的注意事项

关于WFI指令和寄存器设置过程，请参见第11节，低功耗模式。

要在从低功耗模式返回后执行DTC传输而不进行贪睡模式转换，请将DTCST.DTCST位再次为1。

要将在软件待机模式下生成的请求用作对CPU的中断请求但不用作DTC激活请求，请按照第14.4.2节“选择中断请求目标”中的说明将CPU指定为中断请求目标，然后执行WFI指令。如果在贪睡模式下启用DTC操作，请勿使用DTC的模块停止功能。

18.11 使用说明

18.11.1 传输信息起始地址

您必须为向量表中的传输信息起始地址设置4的倍数。否则，这些地址的最低2位被视为00b。

SEG bit (Software Event Generation)

When 1 is written to the SEG bit while the WE bit is 1, a software event is generated. This bit is read as 0. Even when 1 is written to this bit, data is not stored. The WE bit must be set to 1 before writing to this bit.

A software event can trigger a linked DTC event.

WE bit (SEG Bit Write Enable)

The SEG bit can only be written to when the WE bit is 1. Clear the WI bit to 0 before writing to this bit.

[Setting condition]

- If 1 is written to this bit while the WI bit is 0, this bit becomes 1.

[Clearing condition]

- If 0 is written to this bit while the WI bit is 0, this bit becomes 0.

WI bit (ELSEGR Register Write Disable)

The ELSEGR register can only be written to when the write value to the WI bit is 0. This bit is read as 1. Before setting the WE or SEG bit, the WI bit must be set to 0.

Bit	Symbol	位名称	Description	R/W
b0	SEG	软件事件生成	0：正常操作1：产生软件事件 。	W
b5 to b1	—	Reserved	这些位被读取为0。写入值应为0。	R/W
b6	WE	SEG位写使能	0：禁止写入SEG位1：允许 写入SEG位。	R/W
b7	WI	ELSEGR寄存器写入禁用	0：允许写入ELSEGR寄存器1：禁止写 入ELSEGR寄存器。	W

SEG位（软件事件生成）

当WE位为1时向SEG位写入1时，将产生软件事件。该位被读取为0。即使向该位写入1，也不存储数据。在写入该位之前，WE位必须设置为1。

软件事件可以触发链接的DTC事件。

WE位（SEG位写使能）

SEG位只能在WE位为1时写入。在写入该位之前将WI位清零。

[Setting condition]

- 如果在WI位为0时向该位写入1，则该位变为1。

[Clearing condition]

- 如果在WI位为0时向该位写入0，则该位变为0。

WI位（ELSEGR寄存器写禁止）

只有当WI位的写入值为0时，才能写入ELSEGR寄存器。该位读为1。在设置WE或SEG位之前，必须将WI位设置为0。

19.3 Operation

19.3.1 Relation between Interrupt Handling and Event Linking

Event number for an event link is the same as that for the associated interrupt source. For information on generating event signals, see the explanation in the chapter for each event source module.

19.3.2 Linking Events

When an event occurs and that event is already set as a trigger in the Event Link Setting Register (ELSRn), the associated module is activated. The operation of the module must be set up in advance. Table 19.4 lists the operations of modules when an event occurs.

Table 19.4 Module operations when event occurs (1 of 2)

Module	Operations when event occurs
GPT	• Start counting • Stop counting • Clear counting • Up counting • Down counting • Input capture.

19.3 Operation

19.3.1 中断处理和事件链接的关系

事件链接的事件编号与关联中断源的事件编号相同。有关生成事件信号的信息，请参阅每个事件源模块的章节中的说明。

19.3.2 链接事件

当事件发生并且该事件已在事件链接设置寄存器(ELSRn)中设置为触发器时，将激活相关模块。模块的操作必须提前设置好。表19.4列出了事件发生时模块的操作。

Table 19.4 事件发生时的模块操作(1of2)

Module	事件发生时的操作
GPT	开始计数 停止计数 清除计数 递增计数 递减计数 输入捕获。

CTSU	Start measurement operation
DTC	Start DTC data transfer

19.3.3 Example Procedure for Linking Events

To link events:

1. Set the operation of the module for which an event is to be linked.
2. Set the appropriate ELSRn register for the module to be linked.
3. Set the ELCR.ELCON bit to 1 to enable linkage of all events.
4. Configure the module from which an event is output and activate the module. The link between the two modules is now active.
5. To stop event linkage of modules individually, set 000000000b in the ELSRn.ELS[8:0] bits associated with the modules. To stop linkage of all events, set the ELCR.ELCON bit to 0.

If the event link output from the RTC is to be used, set the ELC after the RTC, for example, initialization and time settings. Unintended events can be generated if the RTC settings are made after the ELC settings.

19.4 Usage Notes

19.4.1 Linking DMAC or DTC Transfer End Signals as Events

When linking the DMAC or DTC transfer end signals as events, do not set the same peripheral module as the DMAC or DTC transfer destination and event link destination. If set, the peripheral module might be started before DMAC or DTC transfer to the peripheral module is complete.

19.4.2 Setting the Clocks

To link events, you must enable the ELC and the related modules. The modules cannot operate if the related modules are in the module-stop state or in the specific low power mode in which the module is stopped (Software Standby mode or Deep Software Standby mode). Some modules can perform in Snooze mode. For more information, see Table 19.3 and section 11, Low Power Modes.

19.4.3 Setting the Module-Stop Function

The Module Stop Control Register C (MSTPCRC) can enable or disable ELC operation. The ELC is initially stopped after reset. Releasing the module-stop state enables access to the registers. The ELCON bit must be set to 0 before disabling ELC operation using the Module Stop Control Register. For more information, see Table 19.3 and section 11, Low Power Modes.

19.4.4 ELC delay time

In Figure 19.2, module A accesses module B through the ELC. There is a delay time in the ELC between module A and module B. The ELC delay time is shown in Table 19.5.

If the clock domains on both modules A and B are the same, the delay time is 0. But, if the clock domains on modules A and B are different, the ELC module has some delay. The time delay is defined by the slower clock frequency between module A and module B.

Table 19.4 事件发生时的模块操作(2of2)

Module	事件发生时的操作
I/O ports	根据EORR（复位）或EOSR（设置）更改引脚输出 将引脚状态锁定为EIDR 以下端口可用于ELC：PORT1PORT2PORT3PORT4。
CTSU	开始测量操作
DTC	开始DTC数据传输

19.3.3 链接事件的示例过程

链接事件：

1. 设置要链接事件的模块的操作。
2. 为要链接的模块设置适当的ELSRn寄存器。
3. 将ELCR.ELCON位设置为1以启用所有事件的链接。
4. 配置输出事件的模块并激活该模块。两个模块之间的链接现在处于活动状态。
5. 要单独停止模块的事件链接，请在与模块关联的ELSRn.ELS[8:0]位中设置000000000b。要停止所有事件的链接，请将ELCR.ELCON位设置为0。

如果要使用RTC的事件链接输出，请在RTC之后设置ELC，例如初始化和时间设置。如果在ELC设置之后进行RTC设置，则可能会生成意外事件。

19.4 使用说明

19.4.1 将DMAC或DTC传输结束信号作为事件链接

将DMAC或DTC传输结束信号作为事件链接时，请勿将外设模块设置为DMAC或DTC传输目标和事件链接目标。如果设置，则外围模块可能会在DMAC或DTC传输到外围模块完成之前启动。

19.4.2 设置时钟

要链接事件，您必须启用ELC和相关模块。如果相关模块处于模块停止状态或模块停止的特定低功耗模式（软件待机模式或深度软件待机模式），则模块无法运行。某些模块可以在贪睡模式下执行。有关详细信息，请参阅表19.3和第11节，低功耗模式。

19.4.3 设置模块停止功能

模块停止控制寄存器C(MSTPCRC)可以启用或禁用ELC操作。ELC在复位后最初停止。释放模块停止状态可以访问寄存器。在使用模块停止控制寄存器禁用ELC操作之前，必须将ELCON位设置为0。有关详细信息，请参阅表19.3和第11节，低功耗模式。

19.4.4 ELC延迟时间

在图19.2中，模块A通过ELC访问模块B。模块A和模块B之间的ELC存在延迟时间。ELC延迟时间如表19.5所示。

如果模块A和B上的时钟域相同，则延迟时间为0。但是，如果模块A和B上的时钟域不同，则ELC模块有一些延迟。时间延迟由模块A和模块B之间较慢的时钟频率定义。

20. I/O Ports

20.1 Overview

The I/O port pins operate as general I/O port pins, I/O pins for peripheral modules, interrupt input pins, analog I/O, port group function for the ELC, or bus control pins. All pins operate as input pins immediately after a reset, and pin functions are switched by register settings. The I/O ports and peripheral modules for each pin are specified in the associated registers.

Figure 20.1 shows a connection diagram for the I/O port registers. The configuration of the I/O ports differs depending on the package. Table 20.1 lists the I/O port specifications by package, and Table 20.2 lists the port functions.

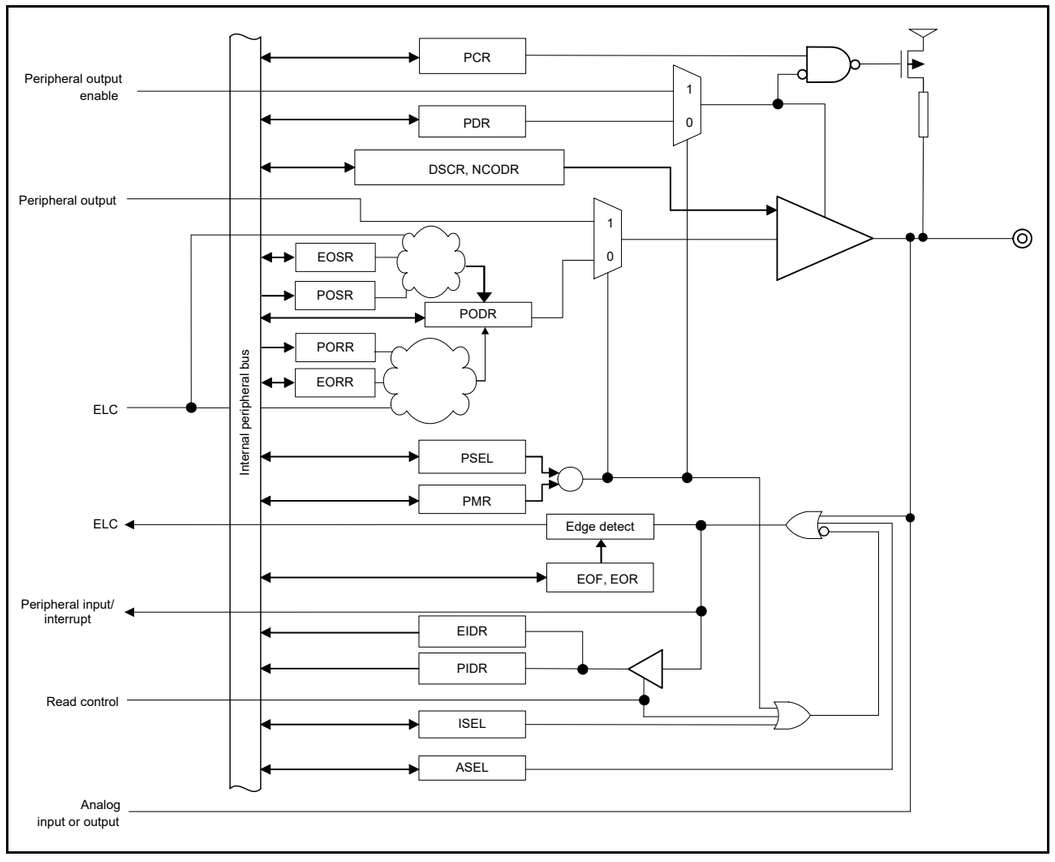

Figure 20.1 Connection diagram for I/O port registers

Note: Figure 20.1 shows a basic port configuration. The configuration differs depending on the ports.

20. I/O Ports

20.1 Overview

IO端口引脚用作通用IO端口引脚、外围模块的IO引脚、中断输入引脚、模拟IO、ELC的端口组功能或总线控制引脚。所有引脚在复位后立即作为输入引脚工作，引脚功能通过寄存器设置进行切换。每个引脚的IO端口和外围模块在相关寄存器中指定。

图20.1显示了IO端口寄存器的连接图。IO端口的配置因封装而异。表20.1按封装列出了IO端口规格，表20.2列出了端口功能。

The Port Control Register 1 (PCNTR1/PODR/PDR) is a 32-bit and 16-bit read/write register that controls the port direction and port output data.

The PCNTR1 specifies the port direction and output data, and is accessed in 32-bit units. The PDRn (bits [15:0] in PCNTR1) and PODRn (bits [31:16] in PCNTR1) respectively, are accessed in 16-bit units.

The PDRn bits select the input or output direction for individual pins on the associated port when the pins are configured as general I/O pins. Each pin on port m is associated with a PORTm.PCNTR1.PDRn bit. The I/O direction can be specified in 1-bit units. Bits associated with non-existent pins are reserved. The write value should always be 0. P000 to P007 and P200 are input only, so PORT0.PCNTR1.PDR00-PDR07 and PORT2.PCNTR1.PDR00 are reserved. The PDRn bit in the PORTm.PCNTR1 register serves the same function as the PDR bit in the PFS.PmnPFS register.

The PODRn bits hold data to be output from the general I/O pins. Bits associated with non-existent pins are reserved. The write value should be 0. P000 to P007 and P200 are input only, so PORT0.PCNTR1.PODR00-PODR07 and PORT2.PCNTR1.PODR00 are reserved. Writes to P000 to P007 and P200 have no effect. The PODRn bit in the PORTm.PCNTR1 register serves the same function as the PODR bit in the PFS.PmnPFS register.

端口控制寄存器1(PCNTR1PODRPDR)是一个32位和16位读写寄存器，用于控制端口方向和端口输出数据。

PCNTR1指定端口方向和输出数据，并以32位为单位进行访问。PDRn（位[15:0]在PCNTR1)和PODRn（PCNTR1中的位[31:16]）分别以16位为单位进行访问。

当引脚配置为通用IO引脚时，PDRn位选择相关端口上各个引脚的输入或输出方向。端口m上的每个引脚都与一个PORTm.PCNTR1.PDRn位相关联。可以以1位为单位指定IO方向。与不存在的引脚相关的位被保留。写入值应始终为0。P000至P007和P200仅为输入，因此保留PORT0.PCNTR1.PDR00-PDR07和PORT2.PCNTR1.PDR00。这

PORTm.PCNTR1寄存器中的PDRn位与PFS.PmnPFS寄存器中的PDR位具有相同的功能。

PODRn位保存要从通用IO引脚输出的数据。与不存在的引脚相关的位被保留。
写入值应为0。P000到P007和P200仅为输入，因此保留PORT0.PCNTR1.PODR00-PODR07和PORT2.PCNTR1.PODR00。写入P000到P007和P200无效。在PODRn位
PORTm.PCNTR1寄存器的功能与PFS.PmnPFS寄存器中的PODR位相同。

m = 0 to 7
n = 00 to 15
x = 1 to 4

Note 1. Supported for PORT1 to PORT4.

The Port Control Register 2 (PCNTR2/EIDR/PIDR) allows read access to the Pmn state and the port event input data using 32-bit or 16-bit access.

The PCNTR2 specifies the Pmn state and port event input data, and is accessed in 32-bit units. The PIDRn (bits [15:0] in PCNTR2) and EIDRn (bits [31:16] in PCNTR2) respectively, are accessed in 16-bit units. Bits associated with non-existent pins are reserved. Reserved bits are read as undefined.

The PIDRn bits reflect the individual pin states of the port, regardless of the values set in PmnPFS.PMR and PORTm.PCNTR1.PDRn. The PIDRn bit in the PORTm.PCNTR2 register serves the same function as the PIDR bit in the PFS.PmnPFS register.

A pin state cannot be reflected in PIDRn when one of the following functions is enabled:

- Main clock oscillator (MOSC)
- CS area controller (CSC)
- Analog function (ASEL = 1)
- Capacitive Touch Sensing Unit (CTSU)
- USB 2.0 Full-Speed Module (USBFS).

The EIDRn bits latch a pin state when an ELC_PORTx signal occurs. Pin states can only be input to EIDRn when PmnPFS.PMR and PORTm.PCNTR1.PDRn are 0. When the PmnPFS.ASEL bit is set to 1, the associated pin state is not reflected in EIDRn.

x = 1 to 4

Note 1. 支持PORT1到PORT4。

端口控制寄存器2(PCNTR2EIDRPIDR)允许使用32位或16位访问对Pmn状态和端口事件输入数据进行读取访问。

PCNTR2指定Pmn状态和端口事件输入数据，并以32位为单位进行访问。PIDRn（位[15:0]在PCNTR2)和EIDRn（PCNTR2中的位[31:16]）分别以16位为单位进行访问。与不存在的引脚相关的位被保留。保留位被读取为未定义。

PIDRn位反映端口的各个引脚状态，与PmnPFS.PMR和PORTm.PCNTR1.PDRn。PORTm.PCNTR2寄存器中的PIDRn位与PFS.PmnPFS register.

当启用以下功能之一时，引脚状态无法反映在PIDRn中：

- 主时钟振荡器(MOSC)
- CS区域控制器(CSC)
- 模拟功能(ASEL=1)
- 电容式触控感应单元(CTSU)
- USB2.0全速模块(USBFS)。

当ELC_PORTx信号出现时，EIDRn位锁存引脚状态。引脚状态只能输入到EIDRn时PmnPFS.PMR和PORTm.PCNTR1.PDRn为0。当PmnPFS.ASEL位设置为1时，相关引脚状态不会反映在EIDRn中。

The Port Control Register 3 (PCNTR3/PORR/POSR) is a 32-bit and 16-bit write register that controls the setting or resetting of the port output data.

The PCNTR3 controls the setting or resetting of the port output data, and is accessed in 32-bit units. The POSRn (bits [15:0] in PCNTR3) and PORRn (bits [31:16] in PCNTR3) respectively, are accessed in 16-bit units.

POSR changes PODR when set by a software write. For example, for P100, when PORT1.PCNTR3.POSR00 is 1, PORT1.PCNTR1.PODR00 outputs 1. Bits associated with non-existent pins are reserved. The write value should always be 0. P000 to P007 and P200 are input only, so PORT0.PCNTR3.POSR00-07 and PORT2.PCNTR3.POSR00 are reserved.

PORR changes PODR when reset by a software write. For example, for P100, when PORT1.PCNTR3.PORR00 is 1, PORT1.PCNTR1.PODR00 outputs 0. Bits associated with non-existent pins are reserved. The write value should always be 0. P000 to P007 and P200 are input only, so PORT0.PCNTR3.PORR00-07 and PORT2.PCNTR3.PORR00 are reserved.

Note: When EORRn or EOSRn is set, writing is prohibited to PODRn, PORRn, and POSRn.
Note: PORRn and POSRn should not be set at the same time.

端口控制寄存器3(PCNTR3PORRPOSR)是一个32位和16位写寄存器，用于控制端口输出数据的设置或复位。

PCNTR3控制端口输出数据的设置或复位，并以32位为单位进行访问。POSRn（PCNTR3中的位[15:0]）和PORRn（PCNTR3中的位[31:16]）分别以16位为单位进行访问。

POSR在通过软件写入设置时改变PODR。例如，对于P100，当PORT1.PCNTR3.POSR00为1时，PORT1.PCNTR1.PODR00输出1。与不存在的引脚相关的位被保留。写入值应始终为0。P000到P007和P200仅为输入，因此保留PORT0.PCNTR3.POSR00-07和PORT2.PCNTR3.POSR00。

PORR在被软件写复位时改变PODR。例如，对于P100，当PORT1.PCNTR3.PORR00为1时，PORT1.PCNTR1.PODR00输出0。与不存在的引脚相关的位被保留。写入值应始终为0。P000至P007和P200仅为输入，因此保留PORT0.PCNTR3.PORR00-07和PORT2.PCNTR3.PORR00。

Note: 当设置EORRn或EOSRn时，禁止写入PODRn、PORRn和POSRn。
Note: PORRn和POSRn不应同时设置。

The Port Control Register 4 (PCNTR4/EORR/EOSR) is a 32-bit and 16-bit read/write register that controls the setting or resetting of the port output data by an event input from the ELC.

The PCNTR4 controls the setting or resetting of the port output data by an event input from the ELC, and is accessed in 32-bit units. The EOSRn (bits [15:0] in PCNTR4) and EORRn (bits [31:16] in PCNTR4) respectively, are accessed in 16-bit units.

EOSR changes PODR when set because an ELC_PORTx signal occurs. For example, for P100, if PORT1.PCNTR4.EOSR00 is set to 1 when the ELC_PORTx occurs, PORT1.PCNTR1.PODR00 outputs 1. Bits associated with non-existent pins are reserved. The write value should always be 0. P200 is input only, so PORT2.PCNTR4.EOSR00 is reserved.

EORR changes PODR when reset because an ELC_PORTx signal occurs. For example, for P100, if PORT1.PCNTR4.EORR00 is set to 1 when the ELC_PORTx occurs, PORT1.PCNTR1.PODR00 outputs 0. Bits associated with non-existent pins are reserved. The write value should always be 0. P200 is input only, so PORT2.PCNTR4.EORR00 is reserved.

Note: When EORRn or EOSRn is set, writing is prohibited to PODRn, PORRn, and POSRn.
Note: EORRn and EOSRn should not be set at the same time.

端口控制寄存器4(PCNTR4EORREOSR)是一个32位和16位读写寄存器，通过来自ELC的事件输入来控制端口输出数据的设置或复位。

PCNTR4通过来自ELC的事件输入来控制端口输出数据的设置或复位，并以32位为单位进行访问。分别以16位为单位访问EOSRn（PCNTR4中的位[15:0]）和EORRn（PCNTR4中的位[31:16]）。

EOSR在设置时会更改PODR，因为发生ELC_PORTx信号。例如，对于P100，如果当ELC_PORTx发生时，PORT1.PCNTR4.EOSR00设置为1，PORT1.PCNTR1.PODR00输出1。与不存在的引脚相关的位被保留。写入值应始终为0。P200仅为输入，因此保留PORT2.PCNTR4.EOSR00。

EORR会在复位时更改PODR，因为发生ELC_PORTx信号。例如，对于P100，如果当ELC_PORTx发生时，PORT1.PCNTR4.EORR00设置为1，PORT1.PCNTR1.PODR00输出0。与不存在的引脚相关的位被保留。写入值应始终为0。P200仅为输入，因此保留PORT2.PCNTR4.EORR00。

Note: 当设置EORRn或EOSRn时，禁止写入PODRn、PORRn和POSRn。
Note: EORRn和EOSRn不应同时设置。

Note 1. Supported for PORT1 to PORT4.
Note 2. The initial value of P000 to P007, P108, P109, P110, P201 and P300 is not 0000_0000h.
P000 to P007 is 0000_8000h, P108 is 0001_0410h, P109 is 0001_0400h, P110 is 0001_0010h, P201 is 0000_0010h, and P300 is 0001_0010h.

The Port mn Pin Function Select register (PmnPFS/PmnPFS_HA/PmnPFS_BY) is a 32-bit, 16-bit, and 8-bit read/write control register that selects the port mn pin function, and is accessed in 32-bit units. PmnPFS_HA (bits [15:0] in PmnPFS) is accessed in 16-bit units. PmnPFS_BY (bits [7:0]) is accessed in 8-bit units.

The PDR/PIDR/PODR bits serve the same function as the PCNTR. When these bits are read, the PCNTR value is read.

The PCR bit enables or disables an input pull-up resistor on the individual port pins. When a pin is in the input state with the associated bit in PmnPFS.PCR set to 1, the pull-up resistor connected to the pin is enabled. When a pin is set as an external bus pin, a general port output pin, or a peripheral function output pin, the pull-up resistor for the pin is disabled regardless of the PCR setting. The pull-up resistor is also disabled in the reset state. Bits associated with non-existent pins are reserved. The write value should be 0.

The NCODR bit specifies the output type for the port pins. Bits associated with non-existent pins are reserved. The write value should be 0.

The DSCR bit switches the drive capacity of the port. If the drive capacity of a pin is fixed, the associated bit is a read/write bit, but the drive capacity cannot be changed. Bits associated with non-existent pins are reserved. The write value should be 0.

The EOR and EOF bits select the edge detection method for the port group input signal. These bits support rising, falling, or both edge detections. When the EOR and EOF bits are set to 01b, 10b, or 11b, the input enable of the I/O cell is asserted. Following that, the event pulse is input from the external pin, and the GPIO outputs the event pulse to the ELC. Bits associated with non-existent pins are reserved. The write value should be 0.

The ISEL bit specifies IRQ input pins. This setting can be used in combination with the peripheral functions, although an IRQn (external pin interrupt) of the same number must only be enabled for one pin.

The ASEL bit specifies analog pins. When a pin is set as an analog pin by this bit:

1. Specify it as a general I/O port with the Port Mode Control bit (PmnPFS.PMR).
2. Disable the Pull-up register with the Pull-up Control bit (PmnPFS.PCR).
3. Specify the input with the Port Direction bit (PmnPFS.PDR). The pin state cannot be read at this point. The PmnPFS register is protected by the Write-Protect Register (PWPR). Release write-protect before modifying the register.

The ISEL bit for an unspecified IRQn is reserved. The ASEL bit for an unspecified analog input/output pin is reserved.

The PMR bit specifies the port pin function. Bits associated with non-existent pins are reserved. The write value should be 0.

The PSEL[4:0] bits assign the peripheral function.

For details on the peripheral settings for each product, see section 20.6, Peripheral Select Settings for each Product.

Note: P009PFS到P013PFS、P202PFS到P204PFS、P505PFS到P507PFS和P603PFS到P607PFS用于32位、16位和8位访问不可用。

Note 1. 支持PORT1到PORT4。
Note 2. P000到P007、P108、P109、P110、P201和P300的初始值不是0000_0000h。
P000至P007为0000_8000h，P108为0001_0410h，P109为0001_0400h，P110为0001_0010h，P201为0000_0010h，以及P300 is 0001_0010h.

端口mn引脚功能选择寄存器（PmnPFSPmnPFS_HAPmnPFS_BY）是选择端口mn引脚功能的32位、16位和8位读写控制寄存器，以32位为单位进行访问。PmnPFS_HA（PmnPFS中的位[15:0]）以16位为单位进行访问。PmnPFS_BY（位[7:0]）以8位为单位进行访问。

PDRPIDRPODR位的功能与PCNTR相同。读取这些位时，将读取PCNTR值。

PCR位启用或禁用各个端口引脚上的输入上拉电阻。当引脚处于输入状态且PmnPFS.PCR中的相关位设置为1时，连接到该引脚的上拉电阻被启用。当引脚设置为外部总线引脚、通用端口输出引脚或外围功能输出引脚时，无论PCR设置如何，该引脚的上拉电阻都被禁用。上拉电阻在复位状态下也被禁用。与不存在的引脚相关的位被保留。写入值应为0。

NCODR位指定端口引脚的输出类型。与不存在的引脚相关的位被保留。写入值应为0。

DSCR位切换端口的驱动能力。如果某个管脚的驱动能力是固定的，那么相关的位就是一个读写位，但是驱动能力是不能改变的。与不存在的引脚相关的位被保留。写入值应为0。

EOR和EOF位选择端口组输入信号的边沿检测方法。这些位支持上升沿、下降沿或两个边沿检测。当EOR和EOF位设置为01b、10b或11b时，IO单元的输入使能有效。随后，事件脉冲从外部引脚输入，GPIO将事件脉冲输出到ELC。与不存在的引脚相关的位被保留。写入值应为0。

ISEL位指定IRQ输入引脚。此设置可以与外围功能结合使用，尽管
相同编号的IRQn（外部引脚中断）只能为一个引脚启用。

ASEL位指定模拟引脚。当一个引脚被该位设置为模拟引脚时：

1. 通过端口模式控制位(PmnPFS.PMR)将其指定为通用IO端口。
2. 使用上拉控制位(PmnPFS.PCR)禁用上拉寄存器。
3. 使用端口方向位(PmnPFS.PDR)指定输入。此时无法读取引脚状态。这
PmnPFS寄存器受写保护寄存器(PWPR)保护。在修改寄存器之前释放写保护。

未指定的IRQn的ISEL位被保留。未指定模拟输入输出引脚的ASEL位被保留。

PMR位指定端口引脚功能。与不存在的引脚相关的位被保留。写入值应为0。

PSEL[4:0]位分配外设功能。

有关每个产品的外设设置的详细信息，请参阅第20.6节，每个产品的外设选择设置。

PFSWE bit (PmnPFS Register Write Enable)

Writing to the PmnPFS register is enabled only when the PFSWE bit is set to 1. You must first write 0 to the B0WI bit before setting PFSWE to 1.

B0WI bit (PFSWE Bit Write Disable)

Writing to the PFSWE bit is enabled only when the B0WI bit is set to 0.

20.3 Operation

20.3.1 General I/O Ports

All pins except P000 to P007, P108 to P110, and P300 operate as general I/O ports after reset. General I/O ports are organized as 16 bits per port and can be accessed by port with the Port Control Registers (PCNTRn, where n = 1 to 4), or by individual pins with the Port mn Pin Function Select register. For details on these registers, see section 20, Register Descriptions.

Each port has the following bits:

- Port Direction bit (PDRn), which selects input or output direction
- Port Output Data bit (PODRn), which holds data for output
- Port Input Data bit (PIDRn), which indicates the pin state
- Event Input Data bit (EIDRn), which indicates the pin state when an ELC_PORT1, 2, 3, or 4 signal occurs
- Port Output Set bit (POSRn), which indicates the output value when a software write occurs
- Port Output Reset bit (PORRn), which indicates the output value when a software write occurs
- Event Output Set bit (EOSRn), which indicates the output value when an ELC_PORT1, 2, 3 or 4 signal occurs
- Event Output Reset bit (EORRn), which indicates the output value when an ELC_PORT1, 2, 3 or 4 signal occurs.

20.3.2 Port Function Select

The following port functions are available for configuring each pin:

- I/O configuration: Complementary or open-drain output, pull-up control, and drive strength
- General I/O port: Port direction, output data setting, and reading input data
- Alternate function: Configured function mapping to the pin.

Each pin is associated with a Port mn Pin Function Select register (PmnPFS), which includes the associated PODR, PIDR, and PDR bits. In addition, the PmnPFS register includes:

20.2.6 Write-Protect Register (PWPR)

PFSWE位（PmnPFS寄存器写使能）

仅当PFSWE位设置为1时才允许写入PmnPFS寄存器。您必须先将0写入B0WI位，然后再将PFSWE设置为1。

B0WI位（PFSWE位写入禁用）

仅当B0WI位设置为0时才允许写入PFSWE位。

20.3 Operation

20.3.1 通用IO端口

除P000到P007、P108到P110和P300之外的所有引脚在复位后都作为通用IO端口工作。通用IO端口组织为每个端口16位，可以通过端口控制寄存器（PCNTRn，其中n=1到4）通过端口访问，或者通过端口mn引脚功能选择寄存器通过单个引脚访问。有关这些寄存器的详细信息，请参见第20节，寄存器说明。

每个端口都有以下位：

- 端口方向位(PDRn)，用于选择输入或输出方向
- 端口输出数据位(PODRn)，用于保存输出数据
- 端口输入数据位(PIDRn)，指示引脚状态
- 事件输入数据位(EIDRn)，指示发生ELC_PORT1、2、3或4信号时的引脚状态
- 端口输出设置位(POSRn)，表示发生软件写入时的输出值
- 端口输出复位位(PORRn)，指示发生软件写入时的输出值
- 事件输出设置位(EOSRn)，指示ELC_PORT1、2、3或4信号发生时的输出值
- 事件输出复位位(EORRn)，指示发生ELC_PORT1、2、3或4信号时的输出值。

20.3.2 端口功能选择

以下端口功能可用于配置每个引脚：

- IO配置：互补或开漏输出、上拉控制和驱动强度
- 通用IO口：端口方向、输出数据设置、读取输入数据
- 备用功能：配置的功能映射到引脚。

每个管脚都与一个端口mn管脚功能选择寄存器(PmnPFS)相关联，其中包括相关的PODR、PIDR和PDR位。此外，PmnPFS寄存器包括：

- PCR: Pull-up resistor control bit that turns the input pull-up MOS on or off
- NCODR: N-channel open-drain control bit that selects the output type for each pin
- DSCR: Drive capacity control bit that selects the drive capacity
- EOR: Event on rising bit used to detect rising edges on the port input
- EOF: Event on falling bit used to detect falling edges on the port input
- ISEL: IRQ input enable bit to specify an IRQ input pin
- ASEL: Analog input enable bit to specify an analog pin
- PMR: Port mode control bit to specify the pin function of each port
- PSEL[4:0]: Port function select bits to select the associated peripheral function.

These configurations can be made by a single-register access to the Port mn Pin Function Select register. For details, see section 20, Port mn Pin Function Select Register (PmnPFS/PmnPFS_HA/PmnPFS_BY) (m = 0 to 7; n = 00 to 15).

20.3.3 Port Group Function for the ELC

In the MCU, PORT1 to PORT4 are assigned for the port group function.

20.3.3.1 Behavior when ELC_PORT1, 2, 3, or 4 is input from the ELC

The MCU supports the two functions described in this section when an ELC_PORT1, 2, 3, or 4 signal comes from the ELC.

(1) Input to EIDR

For the GPI function (PDR = 0 and PMR = 0 in the PmnPFS register), when an ELC_PORT1, 2, 3, or 4 signal comes from the ELC, the input enable of the I/O cell is asserted, and data from the external pins are read into the EIDR bit. See Figure 20.2.

For the GPO function (PDR = 1) or the peripheral mode (PMR = 1), 0 is input into the EIDR bit from the external pins.

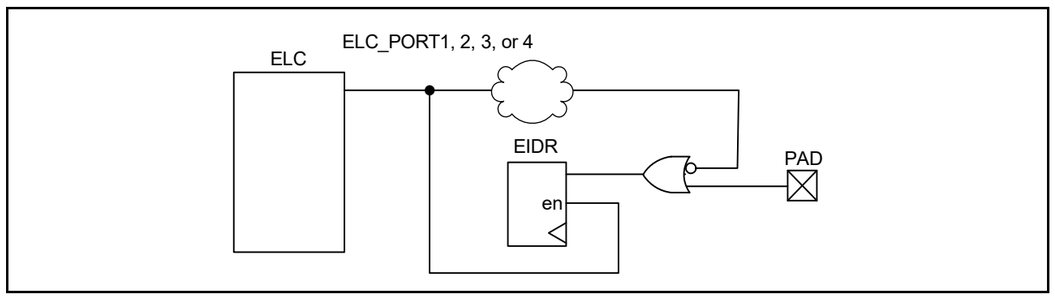

Figure 20.2 Event ports input data

(2) Output from PODR by EOSR/EORR

When an ELC_PORT1, 2, 3, or 4 signal occurs, the data is output from the PODR to the external pin based on the EOSR/EORR bit settings as follows:

- If EOSR is set to 1, when an ELC_PORT1, 2, 3, or 4 signal occurs, the PODR register outputs 1 to the external pin. Otherwise, when EOSR = 0, the PODR value is kept.
- If EORR is set to 1, when an ELC_PORT1, 2, 3, or 4 signal occurs, the PODR register outputs 0 to the external pin. Otherwise, when EORR = 0, the PODR value is kept.

See Figure 20.3.

- PCR：上拉电阻控制位，用于打开或关闭输入上拉MOS
- NCODR：为每个引脚选择输出类型的N通道开漏控制位
- DSCR：选择驱动器容量的驱动器容量控制位
- EOR：上升位事件，用于检测端口输入的上升沿
- EOF：下降位事件，用于检测端口输入的下降沿
- ISEL：IRQ输入使能位，用于指定IRQ输入引脚
- ASEL：模拟输入使能位，用于指定模拟引脚
- PMR：端口模式控制位，指定每个端口的引脚功能
- PSEL[4:0]：端口功能选择位，用于选择相关的外设功能。

这些配置可以通过单个寄存器访问端口mn引脚功能选择寄存器来进行。有关详细信息，请参见第20节，端口mn引脚功能选择寄存器(PmnPFSPmnPFS_HAPmnPFS_BY)(m=0到7；n=00到15)。

20.3.3 ELC的端口组功能

在MCU中，为端口组功能分配了PORT1到PORT4。

20.3.3.1 从ELC输入ELC_PORT1、2、3或4时的行为

当ELC_PORT1、2、3或4信号来自
ELC.

(1) 输入到EIDR

对于GPI功能（PmnPFS寄存器中的PDR=0和PMR=0），当ELC_PORT1、2、3或4信号来自ELC时，IO单元的输入使能有效，并且来自外部引脚的数据被读入EIDR位。请参见图20.2。

对于GPO功能(PDR=1)或外设模式(PMR=1)，0从外部引脚输入到EIDR位。

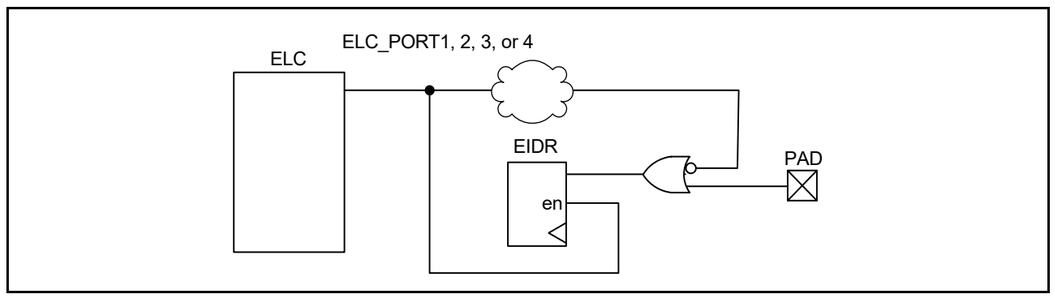

Figure 20.2 事件端口输入数据

(2) EOSREORR从PODR输出

当ELC_PORT1、2、3或4信号发生时，数据从PODR输出到基于外部引脚的
EOSREORR位设置如下：

- 如果EOSR设置为1，当ELC_PORT1、2、3或4信号发生时，PODR寄存器输出1到外部引脚。
  否则，当EOSR=0时，保持PODR值。
- 如果EORR设置为1，则当ELC_PORT1、2、3或4信号发生时，PODR寄存器向外部引脚输出0。
  否则，当EORR=0时，保持PODR值。

请参见图20.3。

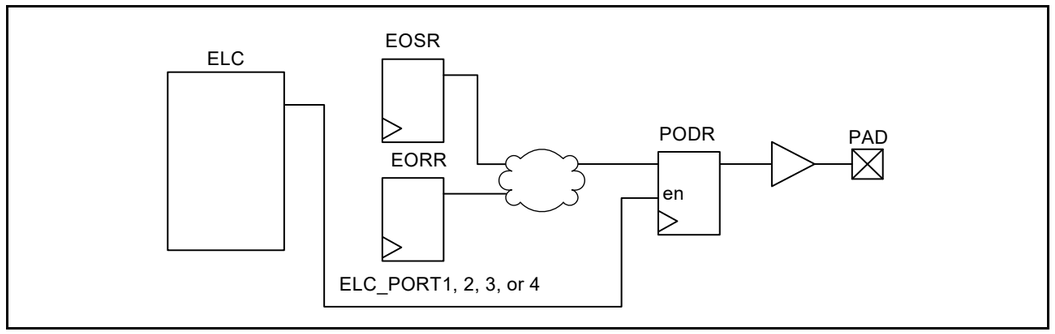

Figure 20.3 Event ports output data

20.3.3.2 Behavior when an event pulse is output to the ELC

To output the event pulse from the external pins to the ELC, set the EOR/EOF bits in the PmnPFS register. For details, see section 20.2.5, Port mn Pin Function Select Register (PmnPFS/PmnPFS_HA/PmnPFS_BY) (m = 0 to 7; n = 00 to 15). When the EOR/EOF bits are set, the input enable of the I/O cell is asserted.

Data from the external pin is the input. For example, for PORT1, when the data is input from P100 to P115, the data of those 16 pins is organized by OR logic. This data is formed into a one-shot pulse that goes to the ELC. The operation of PORT2 to PORT4 is the same. See Figure 20.4.

20.3.3.2 事件脉冲输出到ELC时的行为

要将事件脉冲从外部引脚输出到ELC，请设置PmnPFS寄存器中的EOREOF位。有关详细信息，请参见第20.2.5节，端口mn引脚功能选择寄存器(PmnPFSPmnPFS_HAPmnPFS_BY)(m=0到7；n=00到15)。当EOREOF位被置位时，IO单元的输入使能被断言。

来自外部引脚的数据是输入。例如，对于PORT1，当数据从P100输入到P115时，这16个引脚的数据由OR逻辑组织。该数据形成一个单次脉冲，该脉冲进入ELC。PORT2到PORT4的操作是一样的。请参见图20.4。

Note 1. Clear the PmnPFS.PMR, PmnPFS.ISEL, PmnPFS.PCR, and PmnPFS.ASEL bits to 0.
Note 2. P108, P110, P300 are recommended for pull up VCC (pulled up) through a resistor, because these pins are input pull-up enabled from the initial value (PmnPFS.PCR = 1).
Note 3. P109 is recommended to be set as an output (PCNTR1.PDRn = 1), because this pin is output from the initial value.
Note 4. To reduce input leakage current of P003 and P007, set the P003PFS.ASEL and P007PFS.ASEL bits to 0.
When using 64-pin product, set P007PFS.ASEL bit to 0.

20.5 Usage Notes

20.5.1 Procedure for Specifying the Pin Functions

To specify the I/O pin functions:

1. Clear the B0WI bit in the PWPR register. This enables writing to the PFSWE bit in the PWPR register.
2. Set 1 to the PFSWE bit in the PWPR register. This enables writing to the PmnPFS register.
3. Clear the Port Mode Control bit in the PMR for the target pin to select the general I/O port.
4. Specify the I/O function for the pin through the PSEL[4:0] bit settings in the PmnPFS register.
5. Set the PMR bit to 1 as required to switch to the selected I/O function for the pin.
6. Clear the PFSWE bit in the PWPR register. This disables writing to the PmnPFS register.
7. Set 1 to the B0WI bit in the PWPR register. This disables writing to the PFSWE bit in the PWPR register.

20.5.2 Procedure for Using Port Group Input

To use the port group input (PORT1 to PORT4):

1. Set the ELSRx.ELS[8:0] bits to 0000 0000b to ignore unexpected pulses. For more information, see section 19, Event Link Controller (ELC).
2. Set the EOF/EOR bit of the PmnPFS register to specify the rising, falling, or both edge detections.
3. Execute a dummy read or wait for a short time, for example 100 ns. Ignoring of unexpected pulses depends on the initial value of the external pin.
4. Set the ELSRx.ELS[8:0] bits to enable the event signals.

XTAL	不使用主时钟振荡器时，将MOSCCR.MOSTP位设置为1（通用端口P213）。 当外部时钟输入到EXTAL引脚时，XTAL引脚起到P213的作用。当该管脚不作为端口P213使用时，按照与端口1到7相同的方式进行配置。
XCIN	通过一个电阻连接到VSS（下拉）

P1x to P7x	如果方向设置为输入(PCNTR1.PDRn=0)，则将相关引脚通过电阻连接到VCC（上拉）或通过电阻连接到VSS（下拉）*1、*2 如果设置了方向输出（PCNTR1.PDRn=1），释放引脚*1 *3。
VREFH0, VREFH	连接到AVCC0
VREFL0, VREFL	连接到AVSS0
VBATT	连接到VCC或VSS

Note 1. 将PmnPFS.PMR、PmnPFS.ISEL、PmnPFS.PCR和PmnPFS.ASEL位清除为0。
Note 2. 推荐使用P108、P110、P300通过电阻上拉VCC（上拉），因为这些引脚从初始值（PmnPFS.PCR=1）开始输入上拉使能。
Note 3. 建议将P109设置为输出（PCNTR1.PDRn=1），因为该引脚是从初始值输出的。
Note 4. 要降低P003和P007的输入漏电流，请将P003PFS.ASEL和P007PFS.ASEL位设置为0。
使用64针产品时，将P007PFS.ASEL位设置为0。

20.5 使用说明

20.5.1 指定引脚功能的步骤

要指定IO引脚功能：

1. 将PWPR寄存器中的B0WI位清零。这允许写入PWPR寄存器中的PFSWE位。
2. 将PWPR寄存器中的PFSWE位设置为1。这允许写入PmnPFS寄存器。
3. 清除目标引脚的PMR中的端口模式控制位以选择通用IO端口。
4. 通过PmnPFS寄存器中的PSEL[4:0]位设置指定引脚的IO功能。
5. 根据需要将PMR位设置为1，以切换到为引脚选择的IO功能。
6. 将PWPR寄存器中的PFSWE位清零。这将禁止写入PmnPFS寄存器。
7. 将PWPR寄存器中的B0WI位设置为1。这将禁止写入PWPR寄存器中的PFSWE位。

20.5.2 使用端口组输入的过程

要使用端口组输入（PORT1到PORT4）：

1. 将ELSRx.ELS[8:0]位设置为00000000b以忽略意外脉冲。有关详细信息，请参阅第19节，事件链接控制器（ELC）。
2. 设置PmnPFS寄存器的EOFEOR位以指定上升沿、下降沿或两个边沿检测。
3. 执行虚拟读取或等待一小段时间，例如100ns。忽略意外脉冲取决于外部引脚的初始值。
4. 设置ELSRx.ELS[8:0]位以启用事件信号。

20.5.3 Port Output Data Register (PODR) Summary

This register outputs data as follows:

1. Output 0 if PCNTR4.EORRn is set to 1 when an ELC_PORT1, 2, 3, or 4 signal occurs.
2. Output 1 if PCNTR4.EOSRn is set to 1 when an ELC_PORT1, 2, 3, or 4 signal occurs.
3. Output 0 if PCNTR3.PORRn is set to 1.
4. Output 1 if PCNTR3.POSRn is set to 1.
5. Output 0 or 1 because PCNTR1.PODRn is set.
6. Output 0 or 1 because PmnPFS.PODRn is set.

Numbers in this list correspond to the priority for writing to the PODR. For example, if 1. and 3. from the list occur at the same time, the higher priority event 1. is executed.

20.5.4 Notes on Using Analog Functions

To use an analog function, set the Port Mode Control bit (PMR) and Port Direction bit (PDR) to 0 so that the pin acts as a general input port. Next, set the Analog Input Enable bit (ASEL) in the Port mn Pin Function Select register (PmnPFS.ASEL) to 1.

20.5.5 I/O Buffer Specification

The P402, P403, and P404 can be used as the RTC input, AGT input, and other peripheral functions.

Table 20.4 lists the P402, P403, P404 specifications.

Table 20.4 P402, P403, P404 specifications

Functions					
I/O port	RTC and AGT			Other peripheral	
	RTC and AGT input enable register	RTC	AGT	Other peripheral enable register	CAC, GPT, CAN, SSIE and interrupt
P402	VBTICTLR .VCH0INEN	RTCIC0	AGTIO0 AGTIO1	P402PFS.PSEL and PMR	For details, see Table 20.12 Register settings for I/O pin functions on PORT4
P403	VBTICTLR .VCH1INEN	RTCIC1	AGTIO0 AGTIO1	P403PFS.PSEL and PMR	
P404	VBTICTLR .VCH2INEN	RTCIC2	—	P404PFS.PSEL and PMR	

These RTC and AGT inputs are controlled by the VBTICTLR register, which has the highest priority for selecting the RTC and AGT input functions. See Figure 20.5.

The VBTICTLR register is not initialized on reset. Therefore, when not using the RTC or AGT inputs, the associated bit of the VBTICTLR register must be set to 0 after reset. When using 64-pin product, set VBTICTLR.VCHnINEN (n = 1, 2) bits to 0.

For more information on the VBTICTLR register, see section 12.2.2, VBATT Input Control Register (VBTICTLR).

20.5.3 端口输出数据寄存器(PODR)摘要

该寄存器输出数据如下：

1. 当ELC_PORT1、2、3或4信号出现时，如果PCNTR4.EORRn设置为1，则输出0。
2. 当ELC_PORT1、2、3或4信号出现时，如果PCNTR4.EOSRn设置为1，则输出1。
3. 如果PCNTR3.PORRn设置为1，则输出0。
4. 如果PCNTR3.POSRn设置为1，则输出1。
5. 输出0或1，因为PCNTR1.PODRn已设置。
6. 输出0或1，因为PmnPFS.PODRn已设置。

此列表中的数字对应于写入PODR的优先级。例如，如果列表中的1.和3.同时发生，则执行优先级较高的事件1.。

20.5.4 使用模拟功能的注意事项

要使用模拟功能，请将端口模式控制位(PMR)和端口方向位(PDR)设置为0，以便引脚用作通用输入端口。接下来，将端口mn引脚功能选择寄存器(PmnPFS.ASEL)中的模拟输入使能位(ASEL)设置为1。

20.5.5 IO缓冲器规格

P402、P403和P404可用作RTC输入、AGT输入和其他外围功能。

表20.4列出了P402、P403、P404规格。

Table 20.4 P402, P403, P404 specifications

P402	VBTICTLR .VCH0INEN	RTCIC0	AGTIO0 AGTIO1	P402PFS.PSEL and PMR	详见表20.12 PORT4上IO引脚功能的寄存器设置

P404	VBTICTLR .VCH2INEN	RTCIC2	—	P404PFS.PSEL and PMR	

这些RTC和AGT输入由VBTICTLR寄存器控制，该寄存器具有最高优先级来选择RTC和AGT输入功能。请参见图20.5。

VBTICTLR寄存器在复位时未初始化。因此，当不使用RTC或AGT输入时，VBTICTLR寄存器的相关位必须在复位后设置为0。使用64引脚产品时，将VBTICTLR.VCHnINEN(n=1 2)位设置为0。

有关VBTICTLR寄存器的更多信息，请参见第12.2.2节，VBATT输入控制寄存器(VBTICTLR)。

20.6 Peripheral Select Settings for each Product

This section describes the pin function select configuration by the PmnPFS register. Some pin names have added _A and _B suffixes. When assigning IIC, SPI, SSIE, and SDHI functionality, select the functional pins having the same suffix. The other pins can be selected regardless of the suffix. Assigning the same function to two or more pins simultaneously is prohibited.

20.7 Notes on the PmnPFS Register Setting

(1) In the Port mn Pin Function Select register (PmnPFS), the PSEL bits must be set when the PMR bit of the target pin is 0. If the PSEL bits are set when the PMR bit is 1, unexpected edges might be input for the input function or unexpected pulses might be output to the external pin for the output function.

(2) Only the allowed values (functions) should be specified in the PSEL bits of PmnPFS. If a value that is not allowed for the register is specified, the correct operation is not guaranteed.

(3) A single function should not be assigned to multiple pins by the PmnPFS register.

(4) PORT0 and PORT5 have the analog functions such as A/D converter and D/A converter. When these pins are used as an analog function, to avoid loss of resolution, the PMR and PDR bits should be set to 0. After that, the ASEL bit should be set to 1.

(5) The initial value of the ASEL bit for P003 and P007 is 1. When these pins are not used as an analog function, to reduce the input leakage current, the ASEL bit should be set to 0. When using 64-pin product, clear the P007PFS.ASEL bit to 0.

20.6 每个产品的外设选择设置

本节介绍PmnPFS寄存器的引脚功能选择配置。一些引脚名称添加了_A和_B后缀。分配IIC、SPI、SSIE和SDHI功能时，选择具有相同后缀的功能管脚。无论后缀如何，都可以选择其他引脚。禁止将相同的功能同时分配给两个或多个引脚。

20.7 PmnPFS寄存器设置注意事项

(1)在端口mn引脚功能选择寄存器(PmnPFS)中，当目标引脚的PMR位为0时，必须设置PSEL位。如果在PMR位为1时设置PSEL位，可能会输入意外边沿输入功能或意外脉冲可能会输出到输出功能的外部引脚。

(2)在PmnPFS的PSEL位中只应指定允许的值（功能）。如果指定了寄存器不允许的值，则不能保证正确操作。

(3)PmnPFS寄存器不应将单个功能分配给多个引脚。

(4)PORT0和PORT5具有AD转换器和DA转换器等模拟功能。当这些引脚用作模拟功能时，为避免分辨率损失，应将PMR和PDR位设置为0。之后，应将ASEL位设置为1。

(5)P003和P007的ASEL位初始值为1。当这些引脚不用作模拟功能时，为减少输入漏电流，应将ASEL位设置为0。使用64引脚产品时 将P007PFS.ASEL位清0。

Note 1. Renesas recommends using pins that have a letter appended to their names, for instance “_A” or “_B”, to indicate group membership. For the interface, the AC portion of the electrical characteristics is measured for each group.
Note 2. There are two types of output buffer, middle drive and high drive. Renesas recommends using the same drive buffer for output skew spec (t_{GTISK}).

Note 1. To use this pin function, set the associated pin as a general input (set the PmnPFS.PDR and PmnPFS.PMR bits to 0).
Note 2. Renesas recommends using pins that have a letter appended to their names, for instance "_A" or "_B", to indicate group membership. For the interface, the AC portion of the electrical characteristics is measured for each group.
Note 3. There are two types of output buffer, middle drive and high drive. Renesas recommends using the same drive buffer for output skew spec (t_{GTISK}).

21. Key Interrupt Function (KINT)

21.1 Overview

A key interrupt (KEY_INTKR) can be generated by setting the Key Return Mode Register (KRM) and inputting a rising or falling edge to the key interrupt input pins, KR00 to KR07.

Table 21.1 shows the pin assignment for key interrupt detection, Table 21.2 shows the function configuration, and Figure 21.1 shows a block diagram.

Table 21.1 Assignment of key interrupt detection pins

21.1 Overview

按键中断(KEY_INTKR)可通过设置按键返回模式寄存器(KRM)并向按键中断输入引脚KR00至KR07输入上升沿或下降沿来产生。

表21.1显示按键中断检测的引脚分配，表21.2显示功能配置，图21.1显示框图。

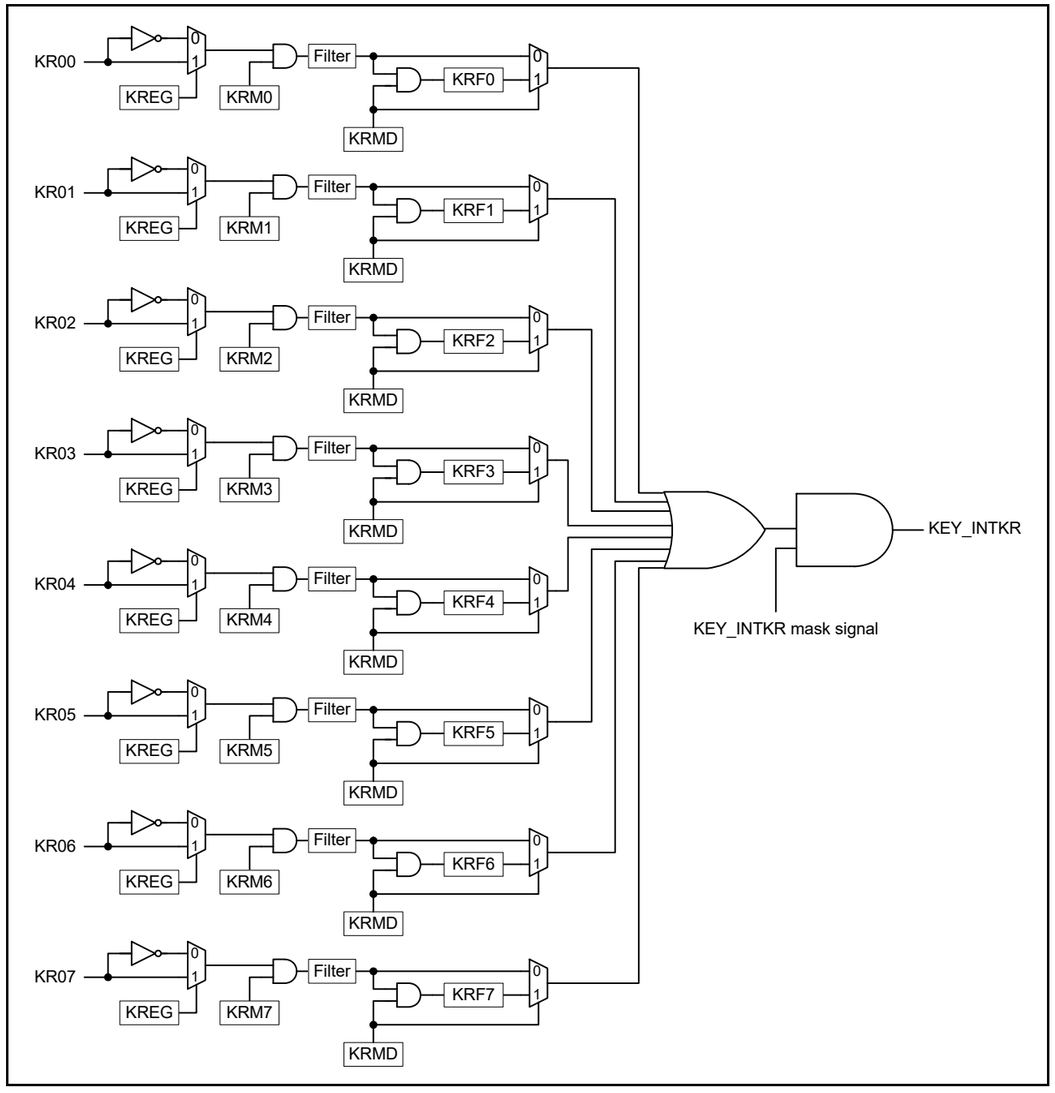

Figure 21.1 Key interrupt function block diagram

Note: In Figure 21.1, all key return factors are merged by an OR gate, and the key interrupt (KEY_INTKR) is the output of the AND gate to mask the merged key return factor by the KEY_INTKR mask signal. When using KRFn (KRMD = 1), the KEY_INTKR mask signal is used as the output mask that is asserted by clearing KRFn.

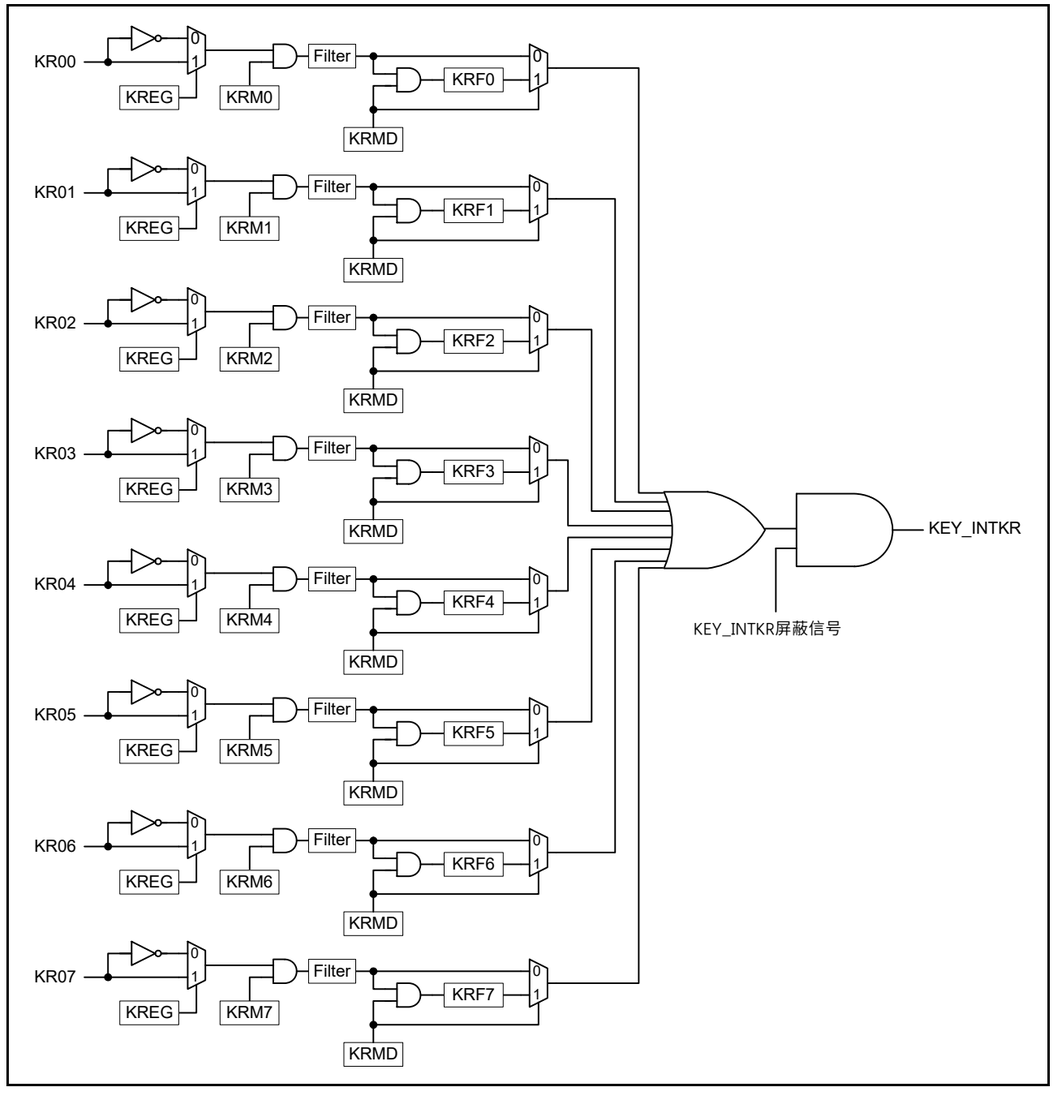

Figure 21.1 按键中断功能框图

Note: 在图21.1中，所有的键返回因子由一个或门合并，键中断（KEY_INTKR）是与门的输出，用于通过KEY_INTKR屏蔽信号屏蔽合并的键返回因子。使用KRFn(KRMD=1)时，KEY_INTKR掩码信号用作通过清除KRFn来断言的输出掩码。

Note: The on-chip pull-up resistors can be applied by setting the associated key interrupt input pin in the pull-up function. For more information, see section 20, I/O Ports.
Key interrupts can be assigned in the PmnPFS.PSEL[4:0] bits. For details, see section 20, I/O Ports.
An interrupt is generated when the target bit in the KRM register is set while a low level (KREG = 0) or a high level (KREG = 1) is being input to the key interrupt input pin. To ignore this interrupt, set the KRM register after disabling the interrupt handling.

The KRM register sets the key interrupt mode.

21.3 Operation

21.3.1 Operation When Not Using Key Interrupt Flag (KRMD = 0)

A key interrupt (KEY_INTKR) is generated when the valid edge specified in the KREG bit is input to a key interrupt pin, KR00 to KR07. To identify the channel to which the valid edge is input, read the port register and check the port level after the key interrupt (KEY_INTKR) is generated.

The KEY_INTKR signal changes based on the input level of the key interrupt input pin, KR00 to KR07.

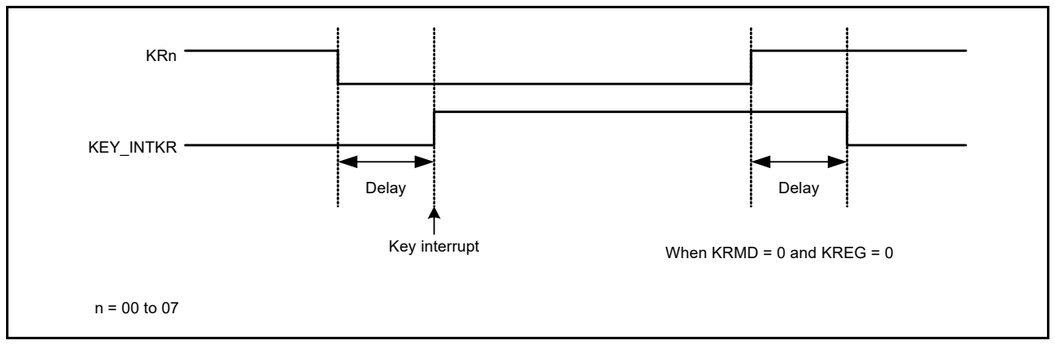

Figure 21.2 Operation of KEY_INTKR signal when a key interrupt is input to a single channel

Figure 21.3 shows the operation when a valid edge is input to multiple key interrupt input pins. The KEY_INTKR signal is set while a low level is being input to one pin (when KREG is 0). Therefore, even if a falling edge is input to another pin in this period, a key interrupt (KEY_INTKR) is not generated again. See [1] in Figure 21.3.

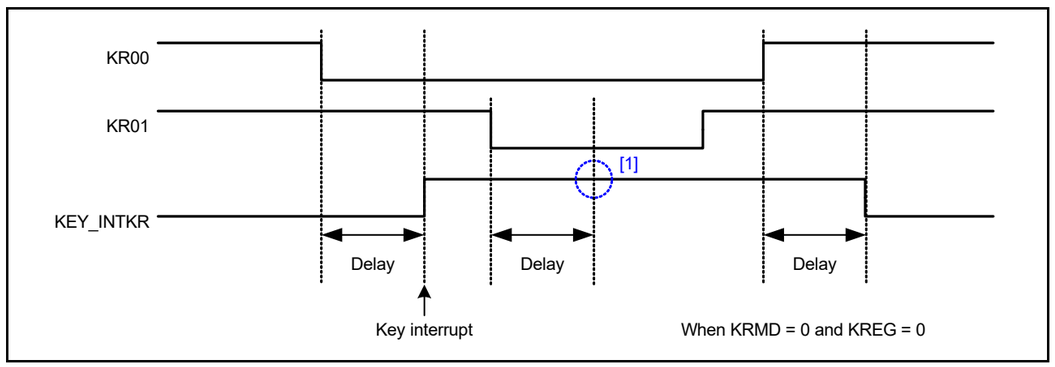

Figure 21.3 Operation of KEY_INTKR signal when key interrupts are input to multiple channels

21.3.2 Operation When Using the Key Interrupt Flags (KRMD = 1)

A key interrupt (KEY_INTKR) is generated when the valid edge specified in the KREG bit is input to a key interrupt pin, KR00 to KR07. To identify the channels to which the valid edge is input, read the Key Return Flag Register (KRF) after the key interrupt (KEY_INTKR) is generated. If the KRMD bit is set to 1, clear the KEY_INTKR signal by clearing the associated bit in the KRF register.

Note: 可以通过在上拉功能中设置相关的按键中断输入引脚来应用片上上拉电阻。有关详细信息，请参阅第20节，IO端口。可以在PmnPFS.PSEL[4:0]位中分配键中断。有关详细信息，请参阅第20节，IO端口。

当低电平(KREG=0)或高电平(KREG=1)被输入到按键中断输入引脚时，如果KRM寄存器中的目标位被置位，就会产生中断。要忽略此中断，请在禁用中断处理后设置KRM寄存器。

KRM寄存器设置按键中断模式。

21.3 Operation

21.3.1 不使用按键中断标志(KRMD=0)时的操作

当KREG位中指定的有效边沿输入到按键中断引脚时，将产生按键中断(KEY_INTKR)，KR00至KR07。要识别输入有效边沿的通道，读取端口寄存器并在按键中断（KEY_INTKR）产生后检查端口电平。

KEY_INTKR信号根据按键中断输入引脚KR00至KR07的输入电平而变化。

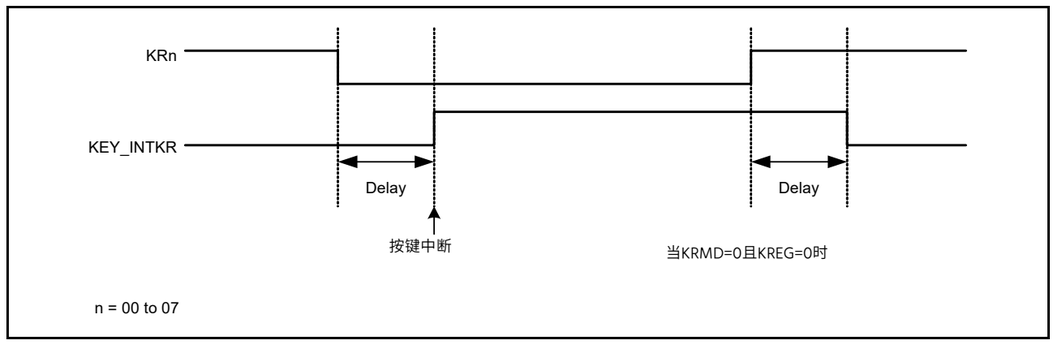

Figure 21.2 按键中断输入到单通道时KEY_INTKR信号的操作

图21.3显示了向多个按键中断输入引脚输入有效边沿时的操作。KEY_INTKR信号在低电平输入到一个引脚时设置（当KREG为0时）。因此，即使在此期间向另一个引脚输入下降沿，也不会再次产生按键中断（KEY_INTKR）。参见图21.3中的[1]。

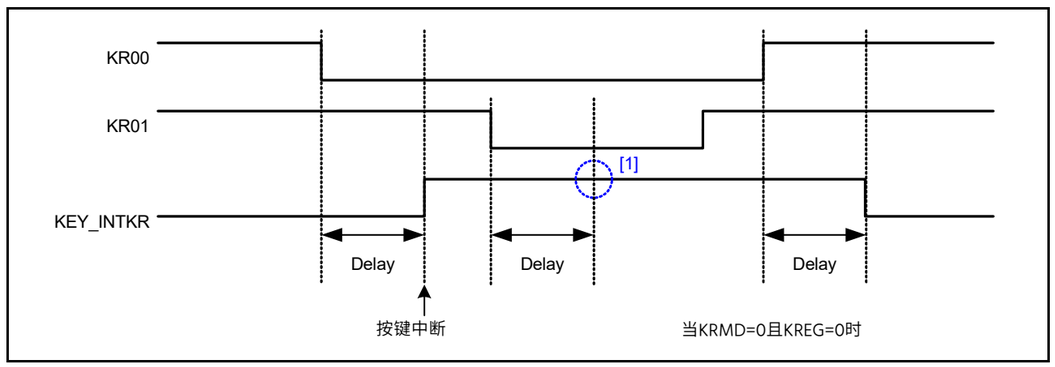

Figure 21.3 按键中断输入到多个通道时KEY_INTKR信号的操作

21.3.2 使用按键中断标志(KRMD=1)时的操作

当KREG位中指定的有效边沿输入到按键中断引脚KR00至KR07时，将产生按键中断(KEY_INTKR)。要识别输入有效边沿的通道，请在生成按键中断(KEY_INTKR)后读取按键返回标志寄存器(KRF)。如果KRMD位设置为1，则通过清除KRF寄存器中的相关位来清除KEY_INTKR信号。

RA生态工作室

As Figure 21.4 shows, only one interrupt is generated each time a falling edge is input to one channel, that is, when KREG = 0, regardless of whether the KRFn bit is cleared before or after a rising edge is input.

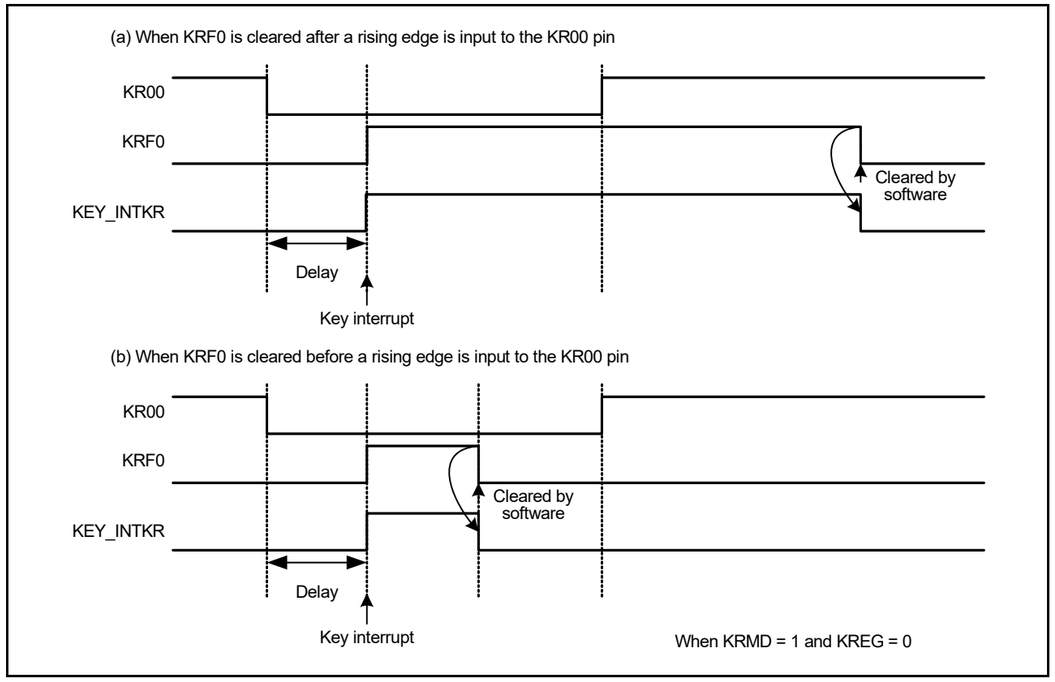

Figure 21.4 Basic operation of KEY_INTKR signal when key interrupt flag is used

Figure 21.5 shows the operation when a valid edge is input to multiple key interrupt input pins. A falling edge is also input to the KR01 and KR05 pins after a falling edge is input to the KR00 pin (when KREG is 0). The KRF1 bit is set when the KRF0 bit is cleared. A key interrupt is generated 1 PCLKB clock cycle, after the KRF0 bit is cleared. See [1] in Figure 21.5. Also, after a falling edge is input to the KR05 pin, the KRF5 bit is set. The KRF1 bit is cleared at time [2] in the figure. A key interrupt is generated 1 PCLKB clock cycle, after the KRF1 bit is cleared. See [3] in the figure. It is therefore possible to generate a key interrupt when a valid edge is input to multiple channels.

如图21.4所示，每次下降沿输入到一个通道时，只产生一个中断，即当KREG=0，无论KRFn位是在输入上升沿之前还是之后清零。

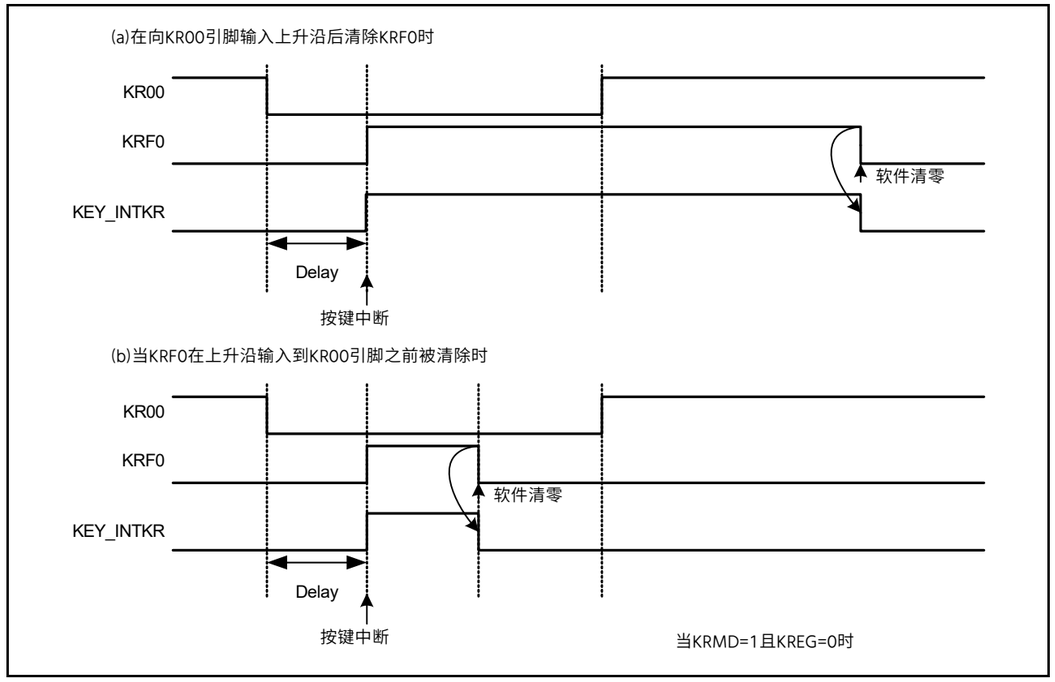

Figure 21.4 使用按键中断标志时KEY_INTKR信号的基本操作

图21.5显示了有效边沿输入到多个按键中断输入引脚时的操作。在向KR00引脚输入下降沿后（当KREG为0时），也会向KR01和KR05引脚输入一个下降沿。当KRF0位被清零时，KRF1位被置位。在KRF0位清零后，1个PCLKB时钟周期产生一个按键中断。请参见图21.5中的[1]。此外，在向KR05引脚输入下降沿后，KRF5位被置位。KRF1位在图中的时间[2]处被清除。在KRF1位清零后，1个PCLKB时钟周期产生一个按键中断。见图[3]。因此，当有效边沿输入到多个通道时，可能会产生按键中断。

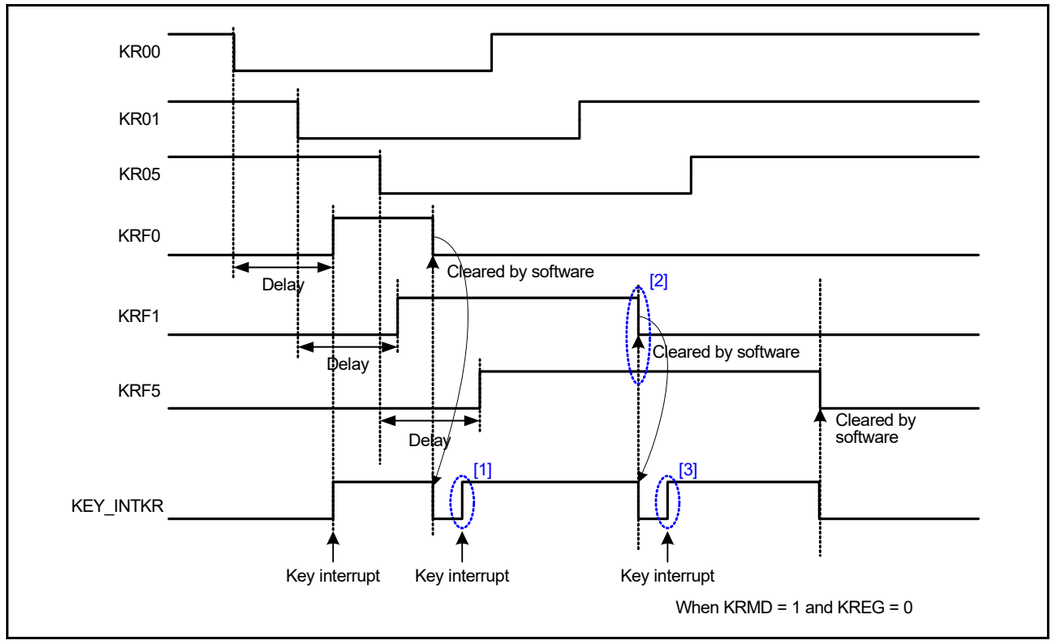

Figure 21.5 Operation of KEY_INTKR signal when key interrupts are input to multiple channels

21.4 Usage Notes

- If KEY_INTKR is used as the snooze request, the KRMD bit must be set to 0.
- If KEY_INTKR is used as the interrupt source for returning to Normal mode from Snooze mode and Software Standby mode, the KRMD bit must be set to 1.
- When the Key Interrupt function (KINT) is assigned to a pin, this pin input is always enabled in Software Standby mode, and if the pin level changes, the associated KRFn flag can be set. Therefore, a key interrupt might occur on canceling Software Standby mode.

To ignore changes to the key interrupt pin during a software standby, clear the associated KRM bit before entering Software Standby mode. After canceling Software Standby mode, you must clear KRFn before the associated KRM bit can be set.

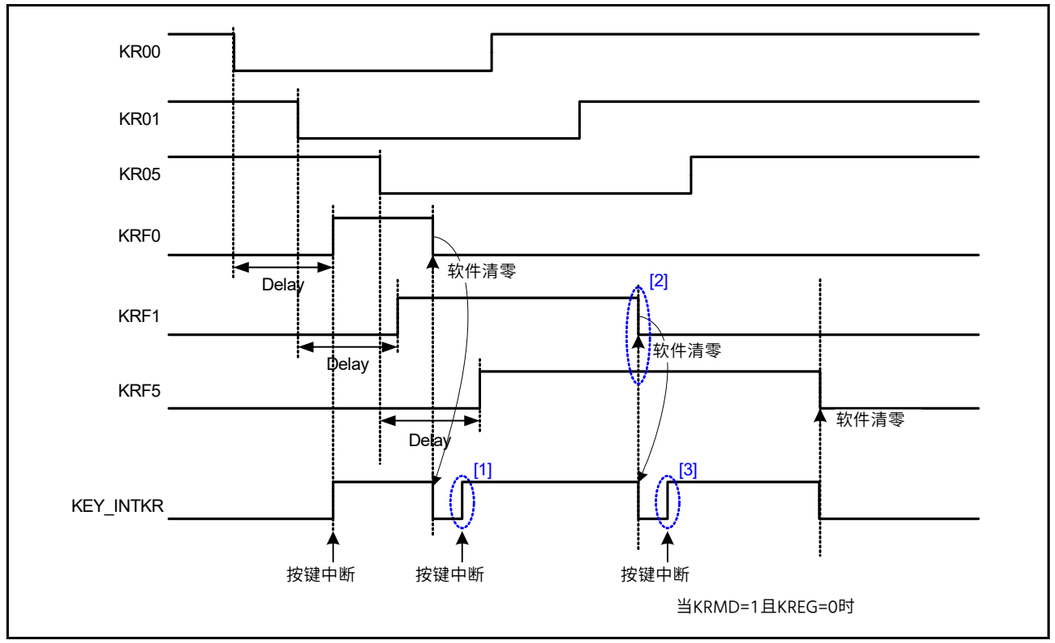

Figure 21.5 按键中断输入到多个通道时KEY_INTKR信号的操作

21.4 使用说明

- 如果KEY_INTKR用作贪睡请求，则KRMD位必须设置为0。
- 如果KEY_INTKR用作从贪睡模式和软件返回正常模式的中断源
  待机模式下，KRMD位必须设置为1。
- 当按键中断功能(KINT)分配给某个引脚时，该引脚输入始终在软件待机模式下启用，如果引脚电平发生变化，则可以设置相关的KRFn标志。因此，取消软件待机模式时可能会发生按键中断。

要在软件待机期间忽略对键中断引脚的更改，请在进入之前清除相关的KRM位
软件待机模式。取消软件待机模式后，必须先清除KRFn，然后才能设置相关的KRM位。

22. Port Output Enable for GPT (POEG)

22.1 Overview

The Port Output Enable for GPT (POEG) function can place the General PWM Timer (GPT) output pins in the output-disable state in one of the following ways:

- Input level detection of the GTETRGn (n = A, B, C, D) pins
- Output-disable request from the GPT
- Comparator interrupt request detection
- Oscillation stop detection of the clock generation circuit
- Register settings.

The GTETRGn (n = A, B, C, D) pins can also be used as GPT external trigger input pins.

Table 22.1 lists the POEG specifications, Figure 22.1 shows a block diagram, and Table 22.2 lists the input pins.

Table 22.1 POEG specifications

Output-disable control through input level detection	The GPT output pins can be disabled when a GTETRGn rising edge or high level is sampled after polarity and filter selection
Output-disable request from the GPT	• When the GTIOCA and the GTIOCB pins are driven to an active level simultaneously, the GPT generates an output-disable request to the POEG.Through reception of these requests, the POEG can control whether the GTIOCA and GTIOCB pins are output-disabled. • GPT output pins can be disabled when the GPT output pins detect a dead time error.
Output-disable control through comparator (ACMPHS) interrupt detection	The GPT output pins can be disabled when an interrupt request is generated by a change in the output results of any of the comparators

The POEGGA to POEGGD registers control the output-disable state of the GPT pins, interrupts, and the external trigger input to the GPT. In the descriptions, POEGGn represents all of the POEGGA to POEGGD registers.

22.3 Output-Disable Control Operation

If any of the following conditions is satisfied, the GTIOCxA, GTIOCxB, and the 3-phase PWM output for BLDC motor control pins can be set to output-disable:

- Input level or edge detection of the GTETRGn pins
  When POEGGn.PIDE is 1, the POEGGn.PIDF flag is set to 1.
- Output-disable request from the GPT
  When POEGGn.IOCE is 1, the POEGGn.IOCF flag is set to 1 if the disable request is enabled in the GTINTAD register. The GTINTAD.GRPDTE, GTINTAD.GRPABH, and GTINTAD.GRPABL settings apply to the group selected in the GPT registers GTINTAD.GRP[1:0] and OPSCR.GRP[1:0].
- Comparator (ACMPHS) interrupt request detection
  Comparator interrupt detection is activated when any of the POEGGn.CDRE[5:0] registers is 1. When the associated comparator interrupt is generated, the GPT output pins are disabled. POEGGn.IOCF indicates the detection status.
- Oscillation stop detection for the clock generation circuit
  When POEGGn.OSTPE is 1, the POEGGn.OSTPF flag is set to 1.
- SSF bit setting
  When POEGGn.SSF is set to 1, the PWM output is disabled.

The output-disable state is controlled in the GPT. The output-disable of the GTIOCxA and GTIOCxB pins is set in the GTINTAD.GRP[1:0], GTIOR.OADF[1:0], and GTIOR.OBDF[1:0] bits in GPTx. The output-disable of the 3-phase PWM output for the BLDC motor control pins is set in the OPSCR.GRP[1:0] bits and OPSCR.GODF bit in GPT_OPS.

22.3.1 Pin Input Level Detection Operation

If the input conditions set in POEGGn.PIDE, POEGGn.NFCS[1:0], POEGGn.NFEN, and POEGGn.INV occur on the GTETRGn pins, the GPT output pins are output-disabled.

22.3.1.1 Digital filter

Figure 22.2 shows high level detection by the digital filter. When a high level associated with the POEGGn.INV polarity setting is detected three times consecutively with the sampling clock selected in POEGGn.NFCS[1:0] and POEGGn.NFEN, the detected level is recognized as high, and the GPT output pins are output-disabled. If even one low level is detected during this interval, the detected level is not recognized as high. In addition, in an interval where the sampling clock is not output, changes of the levels on the GTETRGn pins are ignored.

POEGGA到POEGGD寄存器控制GPT引脚的输出禁用状态、中断和GPT的外部触发输入。在描述中，POEGGn代表所有的POEGGA到POEGGD寄存器。

22.3 输出禁用控制操作

如果满足以下任一条件，则GTIOCxA、GTIOCxB和BLDC电机控制引脚的3相PWM输出可设置为输出禁用：

- GTETRn引脚的输入电平或边沿检测
  当POEGGn.PIDE为1时，POEGGn.PIDF标志设置为1。
- 来自GPT的输出禁用请求
  当POEGGn.IOCE为1时，如果在GTINTAD寄存器中启用了禁用请求，则POEGGn.IOCF标志设置为1。GTINTAD.GRPDTE、GTINTAD.GRPABH和GTINTAD.GRPABL设置适用于在GPT寄存器GTINTAD.GRP[1:0]和OPSCR.GRP[1:0]中选择的组。
- 比较器(ACMPHS)中断请求检测
  当任何POEGGn.CDRE[5:0]寄存器为1时，比较器中断检测被激活。当相关的比较器中断产生时，GPT输出引脚被禁用。POEGGn.IOCF指示检测状态。
- 时钟发生电路的振荡停止检测
  当POEGGn.OSTPE为1时，POEGGn.OSTPF标志设置为1。
- SSF位设置
  当POEGGn.SSF设置为1时，PWM输出被禁用。

输出禁用状态由GPT控制。GTIOCxA和GTIOCxB引脚的输出禁用在GPTx中的GTINTAD.GRP[1:0]、GTIOR.OADF[1:0]和GTIOR.OBDF[1:0]位中设置。三相输出禁用
BLDC电机控制引脚的PWM输出在GPT_OPS中的OPSCR.GRP[1:0]位和OPSCR.GODF位中设置。

22.3.1 引脚输入电平检测操作

如果在POEGGn.PIDE、POEGGn.NFCS[1:0]、POEGGn.NFEN和POEGGn.INV中设置的输入条件发生在GTETRn引脚，GPT输出引脚输出禁用。

22.3.1.1 数字滤波器

图22.2显示了数字滤波器的高电平检测。当在POEGGn.NFCS[1:0]和POEGGn.NFEN中选择的采样时钟连续3次检测到与POEGGn.INV极性设置相关的高电平时，检测到的电平被识别为高电平，并且GPT输出引脚为输出禁用。如果在此间隔期间甚至检测到一个低电平，则检测到的电平不会被识别为高电平。此外，在不输出采样时钟的时间间隔内，GTETRn引脚的电平变化被忽略。

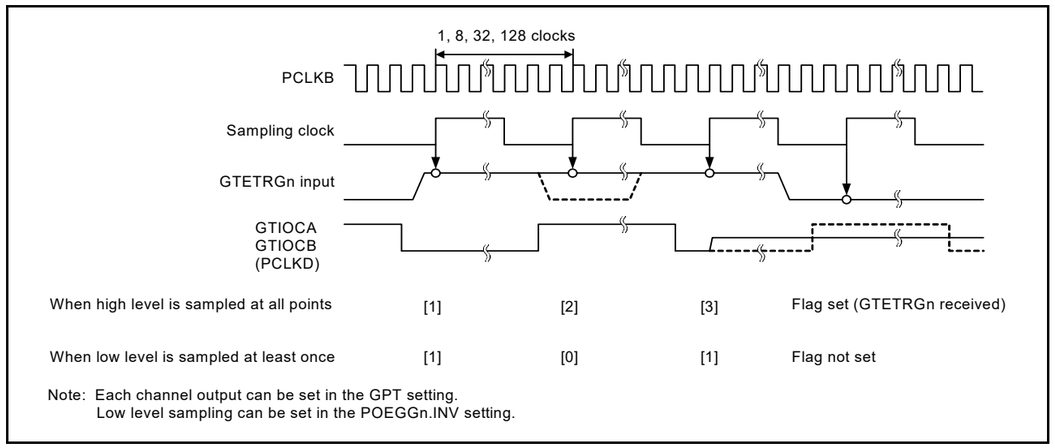

Figure 22.2 Example of digital filter operation

22.3.2 Output-Disable Requests from the GPT

For details on the operation, see the description for GTIOC Pin Output Negate Control in section 23, General PWM Timer (GPT).

22.3.3 Comparator Interrupt Detection

If POEGGn.CDRE[5:0] is 1 when the associated comparator interrupt request is generated, the GPT output pins are output-disabled for each group. The status flag is POEGGn.IOCF, which is shared with GPT output-disable detection.

22.3.4 Output-Disable Control Using Detection of Stopped Oscillation

When the oscillation stop detection function in the clock generation circuit detects stopped oscillation while POEGGn.OSTPE is 1, the GPT output pins are output-disabled for each group.

22.3.5 Output-Disable Control Using Registers

The GPT output pins can be directly controlled by writing to the Software Stop flag, POEGGn.SSF.

22.3.6 Release from Output-Disable

To release the GPT output pins in the output-disabled state, either return them to their initial state with a reset or clear all of the following flags:

- POEGGn.PIDF
- POEGGn.IOCF
- POEGGn.OSTPF
- POEGGn.SSF.

Writing 0 to the POEGGn.PIDF flag is ignored (the flag is not cleared) if the external input pins, GTETRGn, are not disabled and the POEGGn.ST bit is not set to 0.

Writing 0 to the POEGGn.IOCF flag is valid (the flag is cleared) only if all of the GTST.DTEF, GTST.OABHF, and GTST.OABLF flags in the GPT are set to 0.

Writing 0 to the POEGGn.OSTPF flag is ignored (the flag is not cleared) if the OSTDSR.OSTDF flag in the clock generation circuit is not set to 0. In addition, when the flag set and release occur at the same time, the flag set takes precedence.

Figure 22.3 shows the release timing for output-disable. The output-disable is released at the beginning of the next count cycle of the GPT after the flag is cleared.

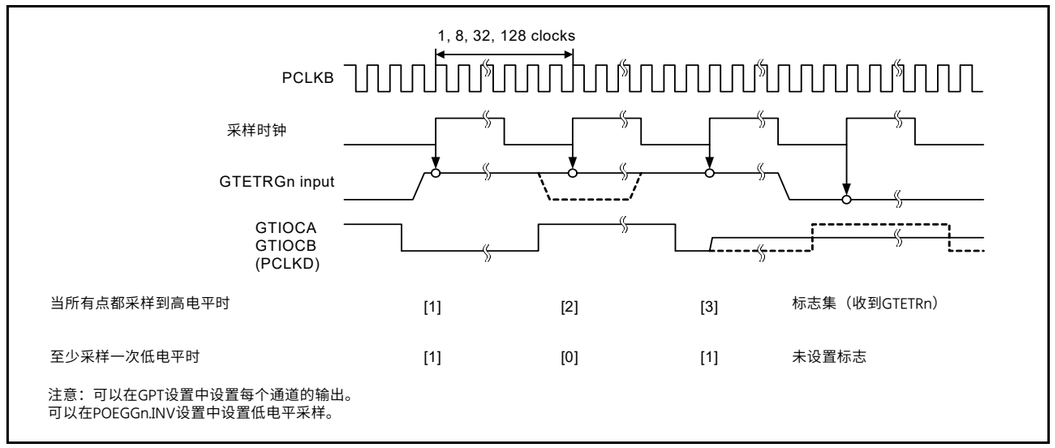

Figure 22.2 数字滤波器操作示例

22.3.2 来自GPT的输出禁用请求

有关操作的详细信息，请参见第23节通用PWM中GTIOC引脚输出否定控制的说明 Timer (GPT).

22.3.3 比较器中断检测

如果在产生相关的比较器中断请求时POEGGn.CDRE[5:0]为1，则每组的GPT输出引脚输出禁用。状态标志是POEGGn.IOCF，它与GPT输出禁用检测共享。

22.3.4 使用停止振荡检测的输出禁用控制

当时钟发生电路中的振荡停止检测功能检测到停止振荡时 POEGGn.OSTPE为1，每组的GPT输出引脚输出禁用。

22.3.5 使用寄存器的输出禁用控制

GPT输出引脚可以通过写入软件停止标志POEGGn.SSF来直接控制。

22.3.6 从输出禁用释放

要释放处于输出禁用状态的GPT输出引脚，可以通过复位将它们返回到初始状态，或者清除以下所有标志：

- POEGGn.PIDF
- POEGGn.IOCF
- POEGGn.OSTPF
- POEGGn.SSF.

如果外部输入引脚GTETRn未禁用且POEGGn.ST位未设置为0，则忽略向POEGGn.PIDF标志写入0（该标志未清除）。

仅当所有GTST.DTEF、GTST.OABHF和 GPT中的GTST.OABLF标志设置为0。

如果时钟生成电路中的OSTDSR.OSTDF标志未设置为0，则忽略向POEGGn.OSTPF标志写入0（该标志不被清除）。此外，当标志设置和释放同时发生时，标志集优先。

图22.3显示了输出禁用的释放时序。标志清零后，在GPT的下一个计数周期开始时，输出禁用被释放。

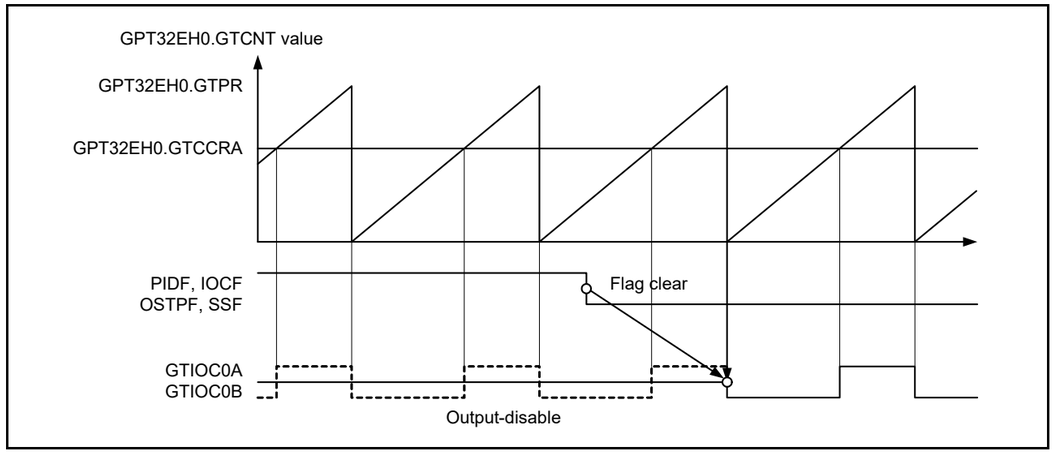

Figure 22.3 Output-disable release timing for the GPT pin outputs

22.4 Interrupt Sources

The POEG generates an interrupt request when triggered by these sources:

- Output-disable control by the input level detection
- Output-disable request from the GPT
- Output-disable request from the comparator interrupt request detection.

Table 22.3 lists the conditions for interrupt requests.

Table 22.3 Interrupt sources and conditions

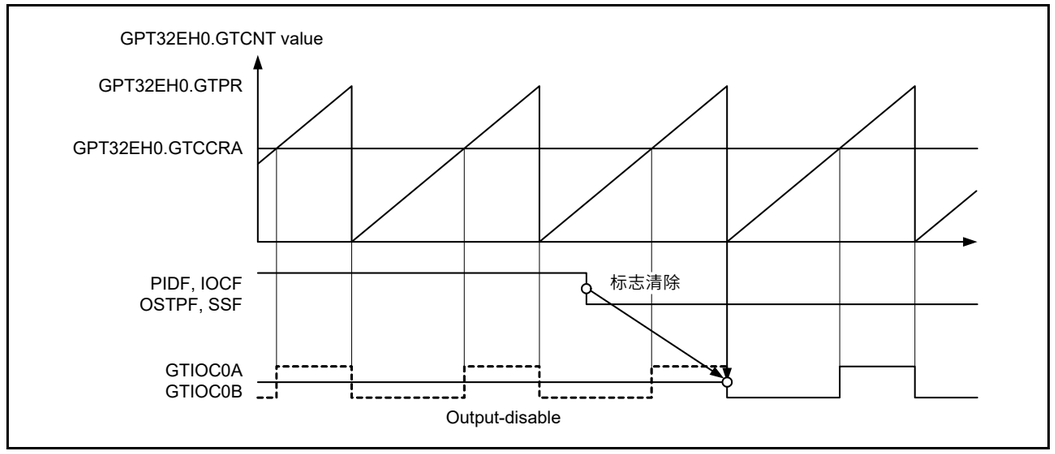

Figure 22.3 GPT引脚输出的输出禁用释放时序

22.4 中断源

当这些源触发时，POEG会产生一个中断请求：

- 通过输入电平检测进行输出禁用控制
- 来自GPT的输出禁用请求
- 来自比较器中断请求检测的输出禁止请求。

表22.3列出了中断请求的条件。

Table 22.3 中断源和条件

中断源	Symbol	相关标志	触发条件
POEGA组中断	POEG_GROUP0	POEGGA.IOCF	发生了来自GPT禁用请求的输出禁用请求

			发生了来自比较器中断请求的输出禁用请求
		POEGGD.PIDF	发生来自GTETRGD引脚的输出禁用请求

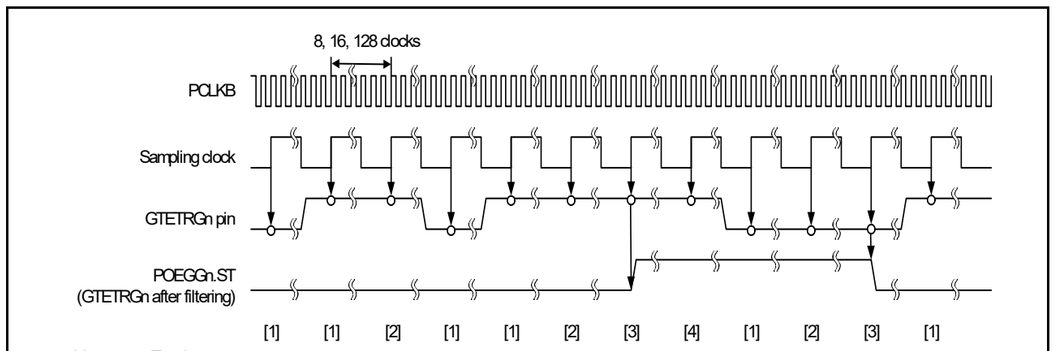
22.5 External Trigger Output to the GPT

The POEG outputs the GTETRGn signals as the GPT operation trigger signal for the following:

- Count start
- Count stop
- Count clear
- Up-count
- Down-count
- Input capture.

For the POEGGn.INV polarity setting signal, when the same level is input three times continuously with the sampling clock selected in POEGGn.NFCS[1:0] and POEGGn.NFEN, that value is output. Set the control registers the same as for the input level detection operation described in section 22.3.1, Pin Input Level Detection Operation. The state after filtering can be monitored in POEGGn.ST.

Figure 22.4 shows the output timing of an external trigger to the GPT.



Note: Each channel output can be set in the GPT settings.

Figure 22.4 Output timing of external trigger to the GPT

22.6 Usage Notes

22.6.1 Transition to Software Standby Mode

When using the POEG, do not invoke Software Standby mode. In this mode, the POEG stops and therefore output-disable of the pins cannot be controlled.

22.6.2 Specifying Pins Associated with the GPT

The POEG controls output-disable only when a pin is associated with the GPT in the PmnPFS.PMR and PmnPFS.PSEL[4:0] settings. When the pin is specified as a general I/O pin, the POEG does not perform output-disable control.

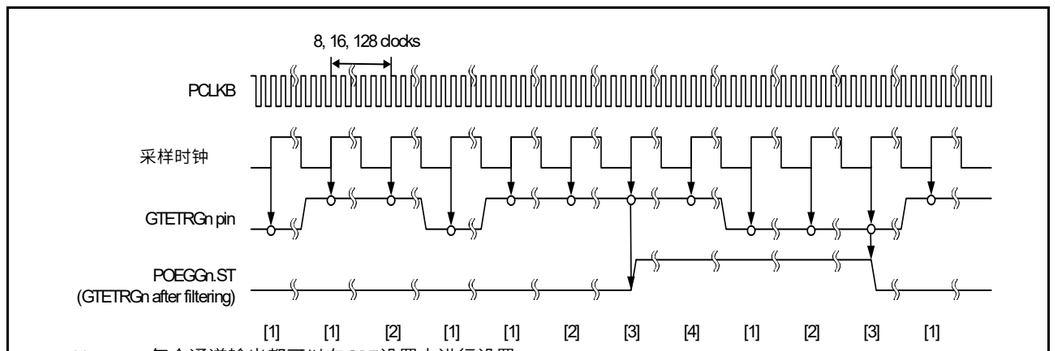
22.5 到GPT的外部触发输出

POEG输出GTETRn信号作为GPT操作触发信号，用于以下用途：

- 计数开始
- 计数停止
- 清点数
- Up-count
- Down-count
- 输入捕获。

对于POEGGn.INV极性设置信号，当在POEGGn.NFCS[1:0]和POEGGn.NFEN中选择的采样时钟连续输入相同电平3次时，输出该值。将控制寄存器设置为与第22.3.1节“引脚输入电平检测操作”中描述的输入电平检测操作相同。过滤后的状态可以在POEGGn.ST中监控。

图22.4显示了外部触发到GPT的输出时序。



Note: 每个通道输出都可以在GPT设置中进行设置。

Figure 22.4 外部触发到GPT的输出时序

22.6 使用说明

22.6.1 过渡到软件待机模式

使用POEG时，请勿调用软件待机模式。在此模式下，POEG停止，因此无法控制引脚的输出禁用。

22.6.2 指定与GPT关联的引脚

仅当引脚与PmnPFS.PMR中的GPT相关联时，POEG才控制输出禁用，并且PmnPFS.PSEL[4:0]设置。当引脚指定为通用IO引脚时，POEG不执行输出禁用控制。

The GTSTR starts the GTCNT counter operation for each channel n, where n = 0 to 12.

The GTSTR bit number represents the channel number. The GTSTR register is shared by all of the channels. The GTCNT counter starts for the channel associated with the GTSTR bit where 1 is written. Writing 0 has no effect on the status of the GTCNT counter and the value of GTSTR register.

For the association between the GTSTR bit number and a channel number, see Figure 23.2.

CSTRT[12:0] bits (Channel n GTCNT Count Start) (n = 0 to 12)

The CSTRT[12:0] bits start channel n of the GTCNT counter operation. Writing to the GTSTR.CSTRTn bit (n = 0 to 12) has no effect unless the GPTm.GTSSR.CSTRT bit is set to 1 (for GPT32EH, m = 0 to 3, for GPT32E, m = 4 to 7, for GPT32, m = 8 to 12). The read data shows the counter status of each channel (GTCR.CST bit). Zero means the counter is stopped and 1 means the counter is running.

GTSTR启动每个通道n的GTCNT计数器操作，其中n=0到12。

GTSTR位号代表通道号。GTSTR寄存器由所有通道共享。这
GTCNT计数器为与写入1的GTSTR位关联的通道启动。写0对GTCNT计数器的状态和GTSTR寄存器的值没有影响
。

关于GTSTR位号和通道号之间的关联，请参见图23.2。

CSTRT[12:0]位（通道nGTCNT计数开始）（n=0到12）

CSTRT[12:0]位启动GTCNT计数器操作的通道n。写入GTSTR.CSTRTn位（n=0到12）无效，除非GPTm.GTSSR.CSTRT位设置为1（对于GPT32EH，m=0到3，对于GPT32E，m=4到7，对于GPT32 m=8到12）。读取的数据显示每个通道的计数器状态（GTCR.CST位）。零表示计数器停止，1表示计数器正在运行。

The GTSTP stops the GTCNT counter operation for each channel n, where n = 0 to 12.

The GTSTP bit number represents the channel number. The GTSTP register is shared by all of the channels. The GTCNT counter stops for the channel associated with the GTSTP bit where 1 is written. Writing 0 has no effect on the status of GTCNT counter and the value of GTSTP register. For the association between the GTSTP bit number and a channel number, see Figure 23.2.

CSTOPn bit (channel n GTCNT Count Stop) (n = 0 to 12)

The CSTOPn bit stops channel n of the GTCNT counter operation. Writing to the GTSTP.CSTOPn bit (n = 0 to 12) has no effect unless the GPTm.GTPSR.CSTOP bit is set to 1 (for GPT32EH, m = 0 to 3, for GPT32E, m = 4 to 7, for GPT32, m = 8 to 12).

Read data shows the counter status of each channel (invert of the GTCR.CST bit). Zero means the counter is running and 1 means the counter stops.

The GTCLR is a write-only register that clears the GTCNT counter operation for each channel n, where n = 0 to 12.

The GTCLR bit number represents the channel number. The GTCLR register is shared by all of the channels. The GTCNT counter is cleared for the channel associated with the GTCLR bit number where 1 is written. Writing 0 has no effect on the status of the GTCNT counter.

For the association between the GTCLR bit number and a channel number, see Figure 23.2.

CCLR[12:0] bits (Channel n GTCNT Count Clear) (n = 0 to 12)

The GTUPSR sets the source to count up the GTCNT counter.

When at least one bit in the GTUPSR register is set to 1, the GTCNT counter is counted up by the source that is set to 1 in this register. In this case, GTCR.TPCS has no effect.

The GTDNSR sets the source to count down the GTCNT counter.

When at least one bit in the GTDNSR register is set to 1, the GTCNT counter is counted up by the source that is set to 1 in this register. In this case, GTCR.TPCS has no effect.

DSGTRGAR bit (GTETRGA Pin Rising Input Source Counter Count Down Enable)

The DSGTRGAR bit enables or disables the GTCNT counter count down on the rising edge of GTETRGA pin input.

The GTUDDTYC sets the direction in which GTCNT counts (up-counting or down-counting) and sets the duty of the GTIOCA/GTIOCB pin output.

Count direction:

- In saw-wave mode.

When the UD value is set to 0 during up-counting, the count direction changes at an overflow (the timing synchronous with count clock after the GTCNT value becomes the GTPR value). When the UD value is set to 1 during down-counting, the count direction changes at an underflow (the timing synchronous with count clock after the GTCNT value becomes 0).

When the UD value changes from 1 to 0 with the UDF bit being 0 and while counting is stopped, the counter starts up-counting and the count direction changes at an overflow (the timing synchronous with count clock after the GTCNT

x: Don’t care

GTUDDTYC设置GTCNT计数的方向（向上计数或向下计数）并设置GTIOCAGTIOCB引脚输出。

Count direction:

- 在锯齿波模式下。

如果在向上计数期间将UD值设置为0，则计数方向会在溢出时发生变化（GTCNT值变为GTPR值后与计数时钟同步的时序）。在递减计数期间将UD值设置为1时，计数方向会在下溢（GTCNT值变为0后与计数时钟同步的时序）下发生变化。

当UD值从1变为0且UDF位为0并且在停止计数时，计数器开始向上计数并且计数方向在溢出时改变（与GTCNT之后的计数时钟同步的时序）

value becomes GTPR value). When the UD value changes from 0 to 1 with the UDF bit being 0 and while counting stops, the counter starts down-counting and the count direction changes at an underflow (the timing synchronous with count clock after the GTCNT value becomes 0).

When the UDF bit is set to 1 while counting stops, the UD bit value is reflected in the count direction when counting starts.

Count direction:

- In triangle-wave mode.

When the UD value changes during counting, the count direction does not change. When the UD value changes while the UDF bit is 0 and counting stops, the change is not reflected in the count direction when counting starts.

When the UDF bit is set to 1 while counting stops, the UD value is reflected in the count direction when counting starts.

UD bit (Count Direction Setting)

The UD bit sets the count direction (up-counting or down-counting) for GTCNT.

UDF bit (Forcible Count Direction Setting)

The UDF bit forcibly sets the count direction when GTCNT starts operation as the UD value. Only write 0 to this bit during counter operation. When 1 is written to the UDF bit while counting stops, return this bit to 0 before counting starts.

Output duty

- In saw-wave mode.

When the OADTY/OBDTY value changes during up-counting, the duty is reflected at an overflow (GTCNT = GTPR). When the OADTY/OBDTY value changes during down-counting, the duty is reflected at an underflow (GTCNT = 0).

When the OADTY/OBDTY value changes to 1 with the OADTYF/OBDTYF bit being 0 and while counting stops, the output duty is not reflected at the starting counter operation. When the count direction is up, the output duty is reflected at an overflow (GTCNT = GTPR). When the count direction is down, the output duty is reflected at an underflow (GTCNT = 0).

When the OADTY/OBDTY value changes to 0 with the OADTYF/OBDTYF bit being 1 and while counting stops, the output duty is reflected at the starting counter operation.

Output duty

- In triangle-wave mode.

When the OADTY/OBDTY value changes during counting, the duty is reflected at an underflow. When the OADTY/OBDTY value changes to 1 with the OADTYF/OBDTYF bit being 0 and while counting stops, the output duty is not reflected at the starting counter operation. The output duty is reflected at an underflow.

When the OADTY/OBDTY value changes to 0 with the OADTYF/OBDTYF bit being 1 and while counting stops, the output duty is reflected at the starting counter operation.

OmDTY[1:0] bits (GTIOCm Output Duty Setting) (m = A, B)

The OmDTY[1:0] bits set the output duty of the GTIOCm pin to either 0%, 100%, or compare match control.

OmDTYF bit (Forcible GTIOCm Output Duty Setting) (m = A, B)

The OmDTYF bit forcibly sets the output duty cycle to the OmDTY setting. Set this bit to 0 during counter operation. When OmDTYF bit is set to 1 while counting stops, return this bit to 0 until the first period ends after the counter starts.

OmDTYR bit (GTIOCm Output Value Selecting after Releasing 0%/100% Duty Setting) (m = A, B)

The OmDTYR bits select the value that is the object of output retained or toggled at cycle end, when the control changes from 0%/100% duty setting to compare match for the GTIOCm pin and GTIOR. The GTIOm[3:2] bits are set to 00b (output retained at cycle end) or the GTIOR.GTIOm[3:2] bits are set to 11b (output toggled at cycle end).

While the duty 0%/100% setting operation is running, the compare match operation continues inside the GPT32. When the OmDTYR bit is set to 1, the GTIOCm pin is in the output state selected by the GTIOR.GTIOm [3:2] bit at the end of

值变为GTPR值）。当UDF位为0且UD值从0变为1且计数停止时，计数器开始递减计数并且计数方向在下溢时改变（GTCNT值变为0后与计数时钟同步的时序）。

当计数停止时UDF位设置为1时，UD位值在计数开始时反映在计数方向上。

Count direction:

- 在三角波模式下。

计数过程中UD值变化时，计数方向不变。当UD值改变而UDF位为0且计数停止，计数开始时变化不反映在计数方向上。

如果在计数停止时UDF位设置为1，则UD值在计数开始时反映在计数方向上。

UD位（计数方向设置）

UD位设置GTCNT的计数方向（向上计数或向下计数）。

UDF位（强制计数方向设置）

当GTCNT开始操作时，UDF位将计数方向强制设置为UD值。仅在计数器操作期间向该位写入0。如果在计数停止时向UDF位写入1，则在计数开始前将该位返回0。

输出占空比

- 在锯齿波模式下。

当OADTYOBDTY值在递增计数期间发生变化时，占空比反映在溢出处(GTCNT=GTPR)。
当向下计数期间OADTYOBDTY值发生变化时，占空比反映为下溢(GTCNT=0)。

当OADTYFOBDTYF位为0且OADTYOBDTY值变为1且计数停止时，输出占空比不会反映在开始计数器操作中。当计数方向向上时，输出占空比反映在溢出处(GTCNT=GTPR)。当计数方向向下时，输出占空比反映为下溢(GTCNT=0)。

当OADTYOBDTY值变为0且OADTYFOBDTYF位为1且计数停止时，输出占空比反映在开始计数器操作中。

输出占空比

- 在三角波模式下。

当计数期间OADTYOBDTY值发生变化时，占空比反映为下溢。当。。。的时候
OADTYOBDTY值在OADTYFOBDTYF位为0时变为1，并且当计数停止时，输出占空比不会反映在开始计数器操作中。输出占空比反映在下溢处。

当OADTYOBDTY值变为0且OADTYFOBDTYF位为1且计数停止时，输出占空比反映在开始计数器操作中。

OmDTY[1:0]位（GTIOCm输出占空比设置）（m=A，B）

OmDTY[1:0]位将GTIOCm引脚的输出占空比设置为0%、100%或比较匹配控制。

OmDTYF位（强制GTIOCm输出占空比设置）（m=A，B）

OmDTYF位强制将输出占空比设置为OmDTY设置。在计数器操作期间将此位设置为0。
如果在计数停止时将OmDTYF位设置为1，则将该位返回0，直到计数器开始后第一个周期结束。

OmDTYR位（释放0%100%占空比设置后选择GTIOCm输出值）（m=A、B）

当控制从0%100%占空比设置更改为GTIOCm引脚和GTIOR比较匹配时，OmDTYR位选择作为输出对象在周期结束时保留或切换的值。GTIOm[3:2]位设置为00b（输出在循环结束时保留）或GTIOR.GTIOm[3:2]位设置为11b（输出在循环结束时切换）。

在运行占空比0%100%设置操作时，比较匹配操作在GPT32内部继续进行。当OmDTYR位设置为1时，GTIOCm引脚处于输出状态，由GTIOR.GTIOm[3:2]位在结束时选择

the cycle in the compare match operation.

The GTIOR sets the functions of the GTIOCA and GTIOCB pins.

GTIOA[4:0] bits (GTIOCA Pin Function Select)

The GTIOA[4:0] bits select the GTIOCA pin function. For details, see Table 23.5.

OADFLT bit (GTIOCA Pin Output Value Setting at the Count Stop)

The OADFLT bit selects whether the GTIOCA pin outputs high or low when counting stops.

OAHLD bit (GTIOCA Pin Output Setting at the Start/Stop Count)

The OAHLD bit specifies whether the GTIOCA pin output level is retained or the level at the start/stop of counting depends on the register setting.

When the OAHLD bit is set to 0:

- The value specified in bit [4] of the GTIOA[4:0] bits is output when counting starts
- The value specified in the OADFLT bit is output when counting stops
- If the OADFLT bit is modified while counting stops, the new value is immediately reflected in the output.

When the OAHLD bit is set to 1:

- The output is retained when counting starts or stops.

OAE bit (GTIOCA Pin Output Enable)

The OAE bit disables or enables the GTIOCA pin output.

When GTCCRA register is used as the input capture register (at least one bit in the GTICASR register is set to 1), the GTIOCA pin does not output regardless of the OAE bit value.

OADF[1:0] bits (GTIOCA Pin Disable Value Setting)

The OADF[1:0] bits select the output value of GTIOCA pin when an output disable request occurs.

NFAEN bit (Noise Filter A Enable)

The NFAEN bit disables or enables the noise filter for input from the GTIOCA pin. Because changing the value of the bit might lead to internal generation of an unexpected edge, select the output compare function for the relevant pin in the GTIOR register before doing so.

NFCSA[1:0] bits (Noise Filter A Sampling Clock Select)

The NFCSA[1:0] bits set the sampling interval for the noise filter of the GTIOCA pin. When setting these bits, wait for 2 cycles of the selected sampling interval before setting the input capture function.

GTIOB[4:0] bits (GTIOCB Pin Function Select)

The GTIOB[4:0] bits select the GTIOCB pin function. For details, see Table 23.5.

OBDFLT bit (GTIOCB Pin Output Value Setting at the Count Stop)

The OBDFLT bit sets whether the GTIOCB pin outputs high or low when counting stops.

OBHLD bit (GTIOCB Pin Output Setting at the Start/Stop Count)

The OBHLD bit specifies whether the GTIOCB pin output level is retained or the level at the start/stop of counting depends on the register setting.

GTIOR设置GTIOCA和GTIOCB引脚的功能。

GTIOA[4:0]位（GTIOCA引脚功能选择）

GTIOA[4:0]位选择GTIOCA引脚功能。详见表23.5。

OADFLT位（计数停止时GTIOCA引脚输出值设置）

OADFLT位选择当计数停止时GTIOCA引脚输出高电平还是低电平。

OAHLD位（开始停止计数时GTIOCA引脚输出设置）

OAHLD位指定是保留GTIOCA引脚输出电平还是计数开始停止时的电平取决于寄存器设置。

当OAHLD位设置为0时：

- 计数开始时输出GTIOA[4:0]位的位[4]中指定的值
- 计数停止时输出OADFLT位中指定的值
- 如果在计数停止时修改OADFLT位，则新值会立即反映在输出中。

当OAHLD位设置为1时：

- 当计数开始或停止时，输出保持不变。

OAE位（GTIOCA引脚输出使能）

OAE位禁用或启用GTIOCA引脚输出。

当GTCCRA寄存器用作输入捕捉寄存器时（GTICASR寄存器中至少有一位设置为1），无论OAE位值如何，GTIOCA引脚都不输出。

OADF[1:0]位（GTIOCA引脚禁用值设置）

当输出禁用请求发生时，OADF[1:0]位选择GTIOCA引脚的输出值。

NFAEN位（噪声滤波器A使能）

NFAEN位禁用或启用来自GTIOCA引脚的输入的噪声滤波器。由于更改该位的值可能会导致内部产生意外边沿，因此在执行此操作之前，请在GTIOR寄存器中为相关引脚选择输出比较功能。

NFCSA[1:0]位（噪声滤波器A采样时钟选择）

NFCSA[1:0]位设置GTIOCA引脚噪声滤波器的采样间隔。设置这些位时，请等待所选采样间隔的2个周期，然后再设置输入捕捉功能。

GTIOB[4:0]位（GTIOCB引脚功能选择）

GTIOB[4:0]位选择GTIOCB引脚功能。详见表23.5。

OBDFLT位（计数停止时GTIOCB引脚输出值设置）

OBDFLT位设置当计数停止时GTIOCB引脚输出高电平还是低电平。

OBHLD位（开始停止计数时GTIOCB引脚输出设置）

OBHLD位指定是保留GTIOCB引脚输出电平还是计数开始停止时的电平取决于寄存器设置。

When the OBHLD bit is set to 0:

- The value specified in bit [4] of the GTIOB[4:0] bits is output when counting starts
- The value specified in the OBDFLT bit is output when counting stops
- If the OBDFLT bit is modified while counting stops, the new value is immediately reflected in the output.

When the OBHLD bit is set to 1:

- The output is retained when counting starts or stops.

OBE bit (GTIOCB Pin Output Enable)

The OBE bit disables or enables the GTIOCB pin output.

When GTCCRB register is used as the input capture register (at least one bit in GTICBSR register is set to 1), the GTIOCB pin does not output regardless of the OBE bit value.

OBDF[1:0] bits (GTIOCB Pin Disable Value Setting)

The OBDF[1:0] bits select the output value of GTIOCB pin when an output disable request occurs.

NFBEN bit (Noise Filter B Enable)

The NFBEN bit disables or enables the noise filter for input from the GTIOCB pin. Because changing the value of the bit might lead to internal generation of an unexpected edge, select the output compare function for the relevant pin in the GTIOR register before doing so.

NFCSB[1:0] bits (Noise Filter B Sampling Clock Select)

The NFCSB[1:0] bits set the sampling interval for the noise filter of the GTIOCB pin. When setting these bits, wait for 2 cycles of the selected sampling interval before setting the input capture function.

OBE位（GTIOCB引脚输出使能）

OBE位禁用或启用GTIOCB引脚输出。

当GTCCRB寄存器用作输入捕捉寄存器时（GTICBSR寄存器中至少有一位设置为1），

1	1	1	1	0			High output at GTCCRA/GTCCRB compare match
1	1	1	1	1			Output toggled at GTCCRA/GTCCRB compare match

Note 1. The cycle end means an overflow (GTCNT changes from GTPR to 0 in up-counting) or underflow (GTCNT changes from 0 to GTPR in down-counting). The GTCNT counter is cleared for saw waves and for the trough (GTCNT changes from 0 to 1) for triangle waves.

Note 2. When the timing of a cycle end and the timing of a GTCCRA/GTCCRB compare match are the same in a compare-match operation, the b3 and b2 settings are given priority in saw-wave PWM mode, and the b1 and b0 settings are given priority in any other mode.

Note 3. In event count operation where at least one bit in GTUPSR or GTDNSR is set to 1, the setting of b3 and b2 is ignored.

1	1	1	1	0			GTCCRAGTCCRB比较匹配时的高输出
1	1	1	1	1			在GTCCRAGTCCRB比较匹配时切换输出

Note 1. 循环结束意味着上溢（向上计数时GTCNT从GTPR变为0）或下溢（向下计数时GTCNT从0变为GTPR）。锯齿波和波谷（GTCNT从0变为1）的三角波清除GTCNT计数器。

Note 2. 在比较匹配操作中，当周期结束的时序和GTCCRAGTCCRB比较匹配的时序相同时，在锯齿波PWM模式下，b3和b2设置优先，b1和b0设置优先在任何其他模式下。

Note 3. 在GTUPSR或GTDNSR中至少一位设置为1的事件计数操作中，忽略b3和b2的设置。

The GTITC register sets the skipping function for the GTCNT counter overflow (GTPR compare match) interrupt (GPTn_OVF) and underflow interrupt (GPTn_UDF). It also specifies whether to link other interrupts and A/D converter start requests with the GPTn_OVF/GPTn_UDF interrupt skipping function. The output disable request to POEG cannot be linked with the GPTn_OVF/GPTn_UDF interrupt skipping function. This register is not available in event count operation. Only GPT32EH and GPT32E have this register. GPT32 does not have this register and it is read as 0.

The GTDTCR enables automatic setting of a compare match value for negative-phase waveform with dead time.

GPT32EH, GPT32E and GPT32 have dead time control function. GPT32 does not have the dead time buffer function and only GTDVU register is used for setting dead time value.

TDE bit (Negative-Phase Waveform Setting)

The TDE bit specifies whether to use GTDVU and GTDVD. When GTDVU and GTDVD are used, the compare match value for a negative-phase waveform with dead time obtained by the compare match value of a positive-phase waveform (GTCCRA) and the dead time value (GTDVU and GTDVD), is automatically set in GTCCRB. The TDE bit setting is ignored in saw-wave PWM mode, and automatic setting does not take place.

The GTCCRB value is automatically set and has the following upper and lower limit values. If the obtained GTCCRB value is not within the upper or lower limit, the following limit value is set in GTCCRB and the GTST.DTEF flag is set to 1. However, in triangle waves, when the obtained GTCCRB value exceeds the upper limit value, the GTST.DTEF flag is set to 0.

- Triangle waves:
  Upper limit value: GTPR - 1
  Lower limit value: 1 in up-counting, 0 in down-counting
- Saw-wave one-shot pulse mode:

  Upper limit value: GTPR
  Lower limit value: 0.

TDBUE bit (GTDVU Buffer Operation Enable)

The TDBUE bit enables buffer operation with GTDVU and GTDBU combined. The buffer transfer timing is the trough for triangle waves, and an overflow or underflow for saw waves.

Only GPT32EH and GPT32E have this bit. GPT32 does not have this bit.

TDBDE bit (GTDVD Buffer Operation Enable)

The TDBDE bit enables buffer operation with GTDVD and GTDBD combined. The buffer transfer timing is the trough for triangle waves, and an overflow or underflow for saw waves. When this bit and the TDFER bit are set to 1 simultaneously, the TDFER bit setting is given priority.

Only GPT32EH and GPT32E have this bit. GPT32 does not have this bit.

TDFER bit (GTDVD Setting)

The TDFER bit selects whether the value written to GTDVU is also set to GTDVD automatically.

Only GPT32EH and GPT32E have this bit. GPT32 does not have this bit.

GTDTCR可以自动设置带死区时间的负相位波形的比较匹配值。

GPT32EH、GPT32E和GPT32具有死区时间控制功能。GPT32没有死区缓冲功能，只有GTDVU寄存器用于设置死区值。

TDE位（负相位波形设置）

TDE位指定是否使用GTDVU和GTDVD。使用GTDVU和GTDVD时，通过正相波形的比较匹配值(GTCCRA)和死区时间值(GTDVU和GTDVD)获得的带死区时间的负相波形的比较匹配值自动设置在GTCCRB。TDE位设置在锯齿波PWM模式下被忽略，并且不会进行自动设置。

GTCCRB值是自动设置的，具有以下上下限值。如果获得的GTCCRB值不在上限或下限内，则在GTCCRB中设置以下限值并将GTST.DTEF标志设置为1。但是，在三角波中，当获得的GTCCRB值超过上限值时，GTST.DTEF标志设置为0。

- Triangle waves:
  上限值：GTPR1
  下限值：加1，减0
- Saw-wave one-shot pulse mode:

  上限值：GTPR
  下限值：0。

TDBUE位（GTDVU缓冲区操作使能）

TDBUE位使　　能结合GTDVU和GTDBU的缓冲器操作。缓冲传输时间是三角波的波谷，锯齿波的上溢或下溢。

只有GPT32EH和GPT32E有这个位。GPT32没有这个位。

TDBDE位（GTDVD缓冲区操作使能）

TDBDE位使能结合GTDVD和GTDBD的缓冲操作。缓冲传输时间是三角波的波谷，锯齿波的上溢或下溢。当该位和TDFER位同时设置为1时，TDFER位设置优先。

只有GPT32EH和GPT32E有这个位。GPT32没有这个位。

TDFER位（GTDVD设置）

TDFER位选择写入GTDVU的值是否也自动设置为GTDVD。

只有GPT32EH和GPT32E有这个位。GPT32没有这个位。

GTDVn is a 32-bit read/write register that sets the dead time for generating PWM waveforms with dead time. GTDVU is used for up-counting and GTDVD is used for down-counting.

Setting a GTDVn value greater than or equal to GTPR is prohibited. Setting a dead time value that exceeds the cycle is prohibited. The compare match value set by the automatic dead time setting function for a negative waveform can be confirmed by reading from GTCCRB.

When GTDVn is used, writing to GTCCRB is not allowed. When this register is set to 0, waveforms without dead time are output. GTDVn must be accessed in 32-bit units. Access in 8-bit/16-bit units is prohibited. The way to rewrite GTDVn differs by GPT channel number.

GPT32EH0 to GPT32EH3 and GPT32E4 to GPT32E7

When GTDVm buffer operation is enabled, GTDBm can be written at anytime. GTDBm is transferred to GTDVm at the cycle end. When GTDVm buffer operation is disabled, stop the GPT using the CST bit in the GTCR register before changing GTDVm to a new value.

GPT328 to GPT3212

While the GPT is running, changing the GTDVU values is prohibited. To change GTDVU to a new value, stop the GPT with the CST bit in the GTCR register.

Only GPT32EH and GPT32E have the GTDVD register. GPT32 does not have the GTDVD register. This register is read with the value after reset.

GTDVn是一个32位读写寄存器，用于设置死区时间，以生成带死区时间的PWM波形。GTDVU用于递增计数，GTDVD用于递减计数。

禁止将GTDVn值设置为大于或等于GTPR。禁止设置超过周期的死区时间值。通过读取GTCCRB可以确认负波形的自动死区时间设置功能设置的比较匹配值。

使用GTDVn时，不允许写入GTCCRB。当该寄存器设置为0时，输出无死区时间的波形。GTDVn必须以32位单元访问。禁止以8位16位为单位进行访问。重写GTDVn的方式因GPT通道号而异。

GPT32EH0到GPT32EH3和GPT32E4到GPT32E7

当启用GTDVm缓冲区操作时，可以随时写入GTDBm。GTDBm在循环结束时转移到GTDVm。当GTDVm缓冲区操作被禁用时，在将GTDVm更改为新值之前，使用GTCR寄存器中的CST位停止GPT。

GPT328 to GPT3212

在GPT运行时，禁止更改GTDVU值。要将GTDVU更改为新值，请使用GTCR寄存器中的CST位停止GPT。

只有GPT32EH和GPT32E有GTDVD寄存器。GPT32没有GTDVD寄存器。用复位后的值读取该寄存器。

Note 1. When OPSCR.GODF = 1 and the signal value selected by the OPSCR.GRP[1:0] bits is high, the OPSCR.EN bit is set to 0.

The OPSCR sets the output of the signal waveform required for brushless DC motor control.

UF, VF, WF bits (Input Phase Soft Setting)

The UF, VF, and WF bits set the input phase from the software settings. When OPSCR.FB bit is 1, these bits are valid. The set value of the UF/VF/WF bits takes the place of the U/V/W external input.

U, V, W bits (Input Phase Monitor)

When the OPSCR.FB bit is 0, external inputs that are synchronized by PCLKD are monitored by these bits. When the OPSCR.FB bit is 1, the OPSCR.U, OPSCR.V, and OPSCR.W bits can read the OPSCR.UF, OPSCR.VF, and OPSCR.WF bits.

EN bit (Enable-Phase Output Control)

The EN bit controls the output enable signal output phase (positive phase/reverse phase).

When the OPSCR.EN bit is 1, the signal waveform is output.

When the OPSCR.EN bit is 0, first set OPSCR.FB, OPSCR.UF/VF/WF (software setting is selected), OPSCR.P/N, OPSCR.INV, OPSCR.RV, OPSCR.ALIGN, OPSCR.GRP, OPSCR.GODF, OPSCR.NFEN, and OPSCR.NFCS. Then, set the EN bit to 1. Also, when OPSCR.GODF is 1 and the signal value selected by the OPSCR.GRP bit is high, the OPSCR.EN bit is set to 0.

FB bit (External Feedback Signal Enable)

The FB bit selects the input phase from the software settings (OPSCR.UF, VF, WF) and external input such as a Hall element.

P bit (Positive-Phase Output (P) Control)

The P bit selects one of the level signal output (PWM of GPT32EH0) or PWM signal output for the positive-phase output (GTOUUP pin, GTOVUP pin, GTOWUP pin).

N bit (Negative-Phase Output (N) Control)

The N bit selects one of the level signal output (PWM of GPT32EH0) or PWM signal output for the negative-phase output (GTOULO pin, GTOVLO pin, GTOWLO pin).

INV bit (Invert-Phase Output Control)

The INV bit selects either positive logic (active-high) output or negative logic (active-low) output for the output phase.

ALIGN bit (Input Phase Alignment)

The ALIGN bit selects the PCLKD or PWM for the sampling of the input phase (input phase is specified in the OPSCR.FB bit). When OPSCR.ALIGN bit is 0, input phase is aligned to PCLKD.

Note: When PWM output is selected (OPSCR.P/N is 1) and the PCLKD input phase is aligned, the PWM pulse might be short-pulsed.

Note: When OPSCR.ALIGN bit is 1, input phase is aligned with PWM output.

Note 1. 当OPSCR.GODF=1且OPSCR.GRP[1:0]位选择的信号值为高时，OPSCR.EN位设置为0。

OPSCR设置无刷直流电机控制所需的信号波形输出。

UF VF WF位（输入相位软设置）

UF、VF和WF位通过软件设置设置输入相位。当OPSCR.FB位为1时，这些位有效。UFVFWF位的设定值代替了UVW外部输入。

U V W位（输入相位监视器）

当OPSCR.FB位为0时，由PCLKD同步的外部输入由这些位监控。当。。。的时候OPSCR.FB位为1，OPSCR.U、OPSCR.V和OPSCR.W位可以读取OPSCR.UF、OPSCR.VF和OPSCR.WF bits.

EN位（使能相位输出控制）

EN位控制输出使能信号的输出相位（正相反相）。

当OPSCR.EN位为1时，输出信号波形。

当OPSCR.EN位为0时，先设置OPSCR.FB、OPSCR.UFVFWF（选择软件设置）、OPSCR.PN、OPSCR.INV、OPSCR.RV、OPSCR.ALIGN、OPSCR.GRP、OPSCR.GODF、OPSCR.NFEN和OPSCR.NFCS。然后，将EN位设置为1。此外，当OPSCR.GODF为1且OPSCR.GRP位选择的信号值为高时，OPSCR.EN位设置为0。

FB位（外部反馈信号使能）

FB位从软件设置（OPSCR.UF、VF、WF）和霍尔元件等外部输入中选择输入相位。

P位（正相输出（P）控制）

P位选择电平信号输出（GPT32EH0的PWM）或正相输出（GTOUUP引脚、GTOVUP引脚、GTOWUP引脚）的PWM信号输出之一。

N位（负相输出（N）控制）

N位选择电平信号输出（GPT32EH0的PWM）或负相输出（GTOULO引脚、GTOVLO引脚、GTOWLO引脚）的PWM信号输出之一。

INV位（反相输出控制）

INV位为输出相位选择正逻辑（高电平有效）输出或负逻辑（低电平有效）输出。

ALIGN位（输入相位对齐）

ALIGN位选择PCLKD或PWM用于输入相位的采样（输入相位在OPSCR.FB位）。当OPSCR.ALIGN位为0时，输入相位与PCLKD对齐。

Note: WhenPWMoutputisselected(OPSCR.PNis1)andthePCLKDinputphaseisaligned thePWMpulsemightbeshort-pulsed.

Note: 当OPSCR.ALIGN位为1时，输入相位与PWM输出对齐。

GRP[1:0] bits (Output Disabled Source Selection)

The GRP[1:0] bits select the output disable source (A to D).

GODF bit (Group Output Disable Function)

When the GODF bit is 1 and the signal value selected by the OPSCR.GRP bit is high, the OPSCR.EN bit is set to 0. When the GODF bit is 0, the bit is ignored.

NFEN bit (External Input Noise Filter Enable)

The NFEN bit selects the noise filter for external input. When OPSCR.NFEN bit is 0, a noise filter is not used for the external input.

Note: When this bit is switched because of an unintentional internal edge, set the OPSCR.EN bit to 0.

NFCS[1:0] bits (External Input Noise Filter Clock Selection)

The NFCS[1:0] bits select the clock for the external input noise filter. When the OPSCR.NFEN bit is 1, noise filter sampling clock setting for external input is enabled.

3. Set the OPSCR.EN bit to 1.

23.3 Operation

23.3.1 Basic Operation

Each channel has a 32-bit timer that performs a periodic count operation using the count clock and hardware sources. The count function provides both up-counting and down-counting. The GTPR controls the count cycle.

When the GTCNT counter value matches the value in GTCCRA or GTCCRB, the output from the associated pin GTIOCA or GTIOCB can be changed. GTCCRA or GTCCRB can be used as an input capture register with hardware resources.

GTCCRC and GTCCRD can function as buffer registers for GTCCRA. GTCCRE and GTCCRF can function as buffer registers for GTCCRB.

23.3.1.1 Counter operation

(1) Counter start and stop

The counter for each channel starts the count operation when GTCR.CST is set to 1. The GTCR.CST bit value is changed by the following sources:

- Writing to GTCR register
- Writing 1 to the bit in GTSTR associated with the GPT channel number when the GTSSR.CSTRT bit is set to 1
- Writing 1 to the bit in GTSTP associated with the GPT channel number when the GTPSR.CSTOP bit is set to 1
- The hardware source selected in the GTSSR register
- The hardware source selected in the GTPSR register.

(2) Periodic count operation in up-counting by count clock

The GTCNT counter in each channel starts up-counting when the associated GTCR.CST bit is set to 1 with the GTUPSR and GTDNSR registers set to 0000 0000h. When the GTCNT value changes from the GTPR value to 0 (overflow), the GTST.TCFPO flag is set to 1. When GTCNT overflows, up-counting resumes from 0000 0000h.

Figure 23.3 shows an example of a periodic count operation in up-counting.

23.3 Operation

23.3.1 基本操作

每个通道都有一个32位定时器，它使用计数时钟和硬件源执行周期性计数操作。
计数功能提供向上计数和向下计数。GTPR控制计数周期。

当GTCNT计数器值与GTCCRA或GTCCRB中的值匹配时，相关引脚的输出
GTIOCA或GTIOCB可以更改。GTCCRA或GTCCRB可用作具有硬件资源的输入捕捉寄存器。

GTCCRC和GTCCRD可以作为GTCCRA的缓冲寄存器。GTCCRE和GTCCRF可以作为GTCCRB的缓冲寄存器。

23.3.1.1 计数器操作

(1) 计数器启动和停止

当GTCR.CST设置为1时，每个通道的计数器开始计数操作。GTCR.CST位值由以下来源更改：

- 写入GTCR寄存器
- 当GTSSR.CSTRT位设置为1时，将1写入GTSTR中与GPT通道号相关的位
- 当GTPSR.CSTOP位设置为1时，将1写入GTSTP中与GPT通道号相关联的位
- GTSSR寄存器中选择的硬件源
- 在GTPSR寄存器中选择的硬件源。

(2) 计数时钟递增计数中的周期计数操作

当相关的GTCR.CST位设置为1且GTUPSR和GTDNSR寄存器设置为00000000h时，每个通道中的GTCNT计数器开始向上计数。当GTCNT值从GTPR值变为0（溢出）时，GTST.TCFPO标志设置为1。当GTCNT溢出时，向上计数从00000000h恢复。

图23.3显示了递增计数中周期性计数操作的示例。

Figure 23.4 shows an example for setting periodic count operation in up-counting.

(3) Periodic count operation in down-counting by count clock

The GTCNT counter in each channel can perform down-counting by setting GTUDDTYC.UD with the GTUPSR and GTDNSR registers set to 0000 0000h. When GTCNT changes from 0 to the GTPR value (underflow), GTST.TCFPU is set to 1. When the GTCNT counter underflows, down-counting resumes from the GTPR value.

(3) 计数时钟递减计数中的周期计数操作

每个通道中的GTCNT计数器可以通过使用GTUPSR设置GTUDDTYC.UD和GTDNSR寄存器设置为00000000h。当GTCNT从0变为GTPR值（下溢）时，GTST.TCFPU设置为1。当GTCNT计数器下溢时，从GTPR值开始向下计数。

Figure 23.6 shows an example setting for periodic count operation in down-counting by the count clock.

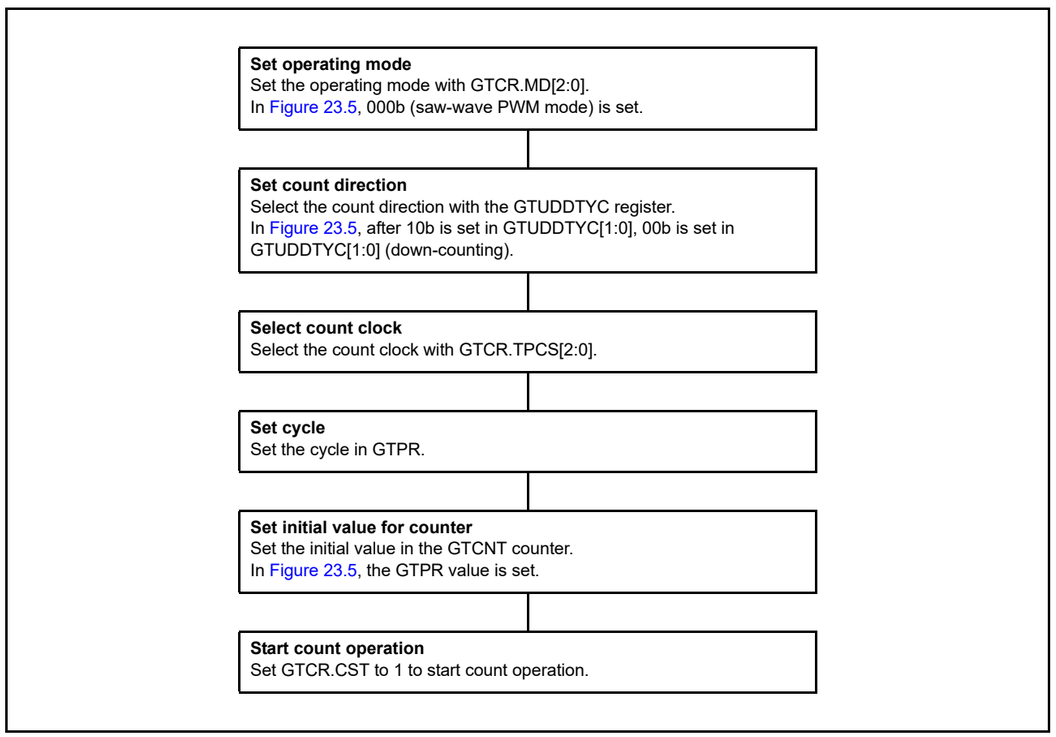

Figure 23.6 Example setting for periodic count operation in down-counting by count clock

(4) Event count operation in up-counting using hardware sources

The GTCNT counter in each channel can perform up-counting using hardware sources as set in GTUPSR.

When GTUPSR is set to enable, the count clock selected in GTCR.TPCS[2:0] and the count direction selected in GTUDDTYC.UD are ignored. If up-counting and down-counting using hardware sources occur at the same time, the GTCNT counter value does not change. The overflow behavior for up-counting using hardware sources is the same as for up-counting by the count clock.

When GTCR.CST bit is set to 1 to count up using hardware sources, the count operation is enabled. When GTCR.CST is set to 1, the counter cannot count up for 1 clock cycle as specified in GTCR.TPCS[2:0] because the count operation is

(4) 使用硬件源的递增计数中的事件计数操作

每个通道中的GTCNT计数器可以使用GTUPSR中设置的硬件源执行递增计数。

当GTUPSR设置为使能时，在GTCR.TPCS[2:0]中选择的计数时钟和在GTUDDTYC.UD被忽略。如果同时使用硬件源进行向上计数和向下计数，则GTCNT计数器值不会改变。使用硬件源进行向上计数的溢出行为与使用计数时钟进行向上计数的溢出行为相同。

当GTCR.CST位设置为1以使用硬件源进行计数时，计数操作被启用。当GTCR.CST设置为1时，计数器不能按GTCR.TPCS[2:0]中的规定向上计数1个时钟周期，因为计数操作是

synchronized by the count clock selected in GTCR.TPCS[2:0]. Set GTCR.TPCS[2:0] to 000b to count up with a 1 PCLKD delay after GTCR.CST is set to 1.

Figure 23.8 shows an example setting for periodic count operation in up-counting by a hardware source.

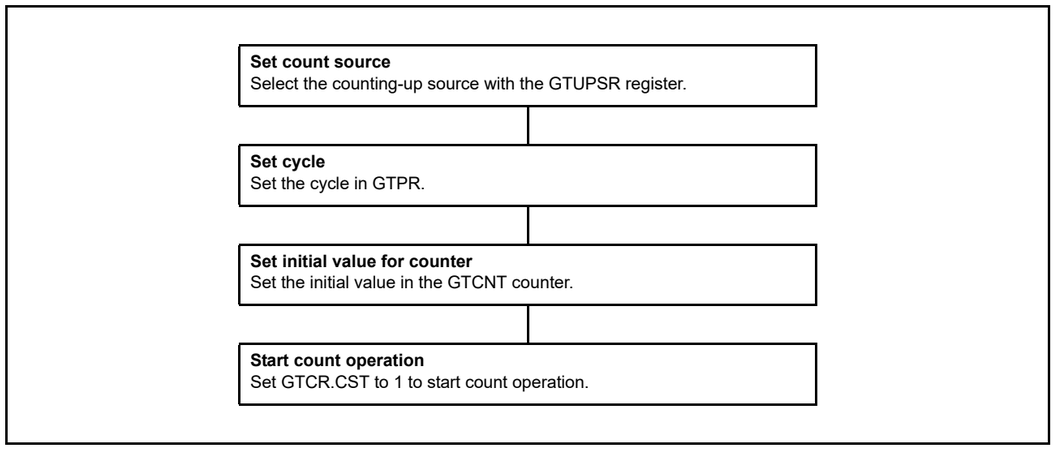

Figure 23.8 Example setting for an event count operation in up-counting using hardware sources

(5) Event count operation in down-counting using hardware sources

The GTCNT counter in each channel can perform down-counting using hardware sources set in the GTDNSR register.

When GTDNSR is set to enable, the count clock selected in GTCR.TPCS[2:0] and the count direction selected in GTUDDTYC.UD are ignored. If up-counting and down-counting using hardware sources occur at the same time, the GTCNT counter value does not change. The underflow behavior for down-counting using hardware sources is the same as for down-counting by the count clock.

When GTCR.CST bit is set to 1 to count down using hardware sources, the count operation is enabled. When GTCR.CST is set to 1, the counter cannot count down for 1 clock cycle as specified in GTCR.TPCS[2:0] because the count operation is synchronized with the count clock selected in GTCR.TPCS[2:0]. Set GTCR.TPCS[2:0] to 000b to count down with a 1 PCLKD delay after GTCR.CST is set to 1.

Figure 23.9 shows an example of a periodic count operation in down-counting by a hardware source (rising edge of the GTETRGA pin).

(5) 使用硬件源的递减计数中的事件计数操作

每个通道中的GTCNT计数器可以使用GTDNSR寄存器中设置的硬件源进行递减计数。

当GTDNSR设置为使能时，在GTCR.TPCS[2:0]中选择的计数时钟和在
GTUDDTYC.UD被忽略。如果同时使用硬件源进行向上计数和向下计数，则
GTCNT计数器值不会改变。使用硬件源向下计数的下溢行为与使用计数时钟向下计数的相同。

当GTCR.CST位设置为1以使用硬件源进行递减计数时，启用计数操作。什么时候
GTCR.CST设置为1，因为计数操作与GTCR.TPCS[2:0]中选择的计数时钟同步，所以计数器不能按GTCR.TPCS[2:0]中的规定递减1个时钟周期。将GTCR.TPCS[2:0]设置为000b以在GTCR.CST设置为1后以1个PCLKD延迟递减计数。

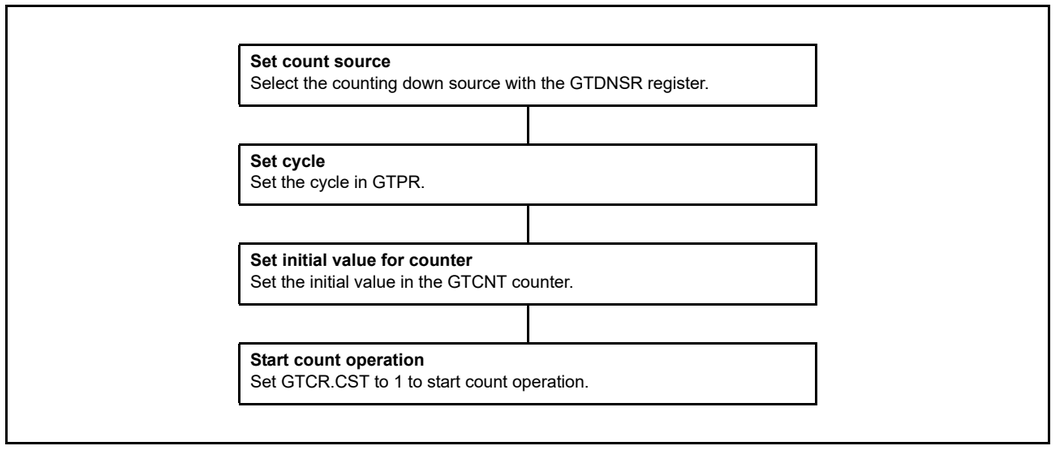

Figure 23.10 Example setting for an event count operation in down-counting using hardware sources

(6) Counter clear operation

The counter of each channel is cleared by the following sources:

- Writing 0 to GTCNT register
- Writing 1 to the bit in GTCLR associated with the GPT channel number when the GTCSR.CCLR bit is set to 1
- The hardware source selected in GTCSR register.

Writing to the GTCNT register is prohibited during count operation. The GTCNT counter can be cleared both by writing 1 to the GTCLR and by the clear request of hardware sources, whether GTCNT is counting (GTCR.CST is 1) or not (GTCR.CST is 0).

For saw waves selected by setting GTCR.MD[2:0] and the count direction flag showing down-counting (GTST.TUCF is 0), the GTCNT register is set to the value of the GTPR register when writing 1 to the GTCLR register or when clearing by hardware sources is performed.

When not in saw wave mode and down-counting, the GTCNT register is set to 0 when writing 1 to the GTCLR register and when clearing by hardware sources is performed.

In event count operation when at least 1 bit in the GTUPSR or GTDNSR is set to 1, after clear sources occur, both writing to the GTCLR register and clearing by hardware sources are performed immediately to synchronize with PCLKD. If other settings are used, clear is synchronized with the counter clock selected in GTCR.TPCS[2:0].

图23.10显示了使用硬件源进行递减计数中的周期性计数操作的示例设置。

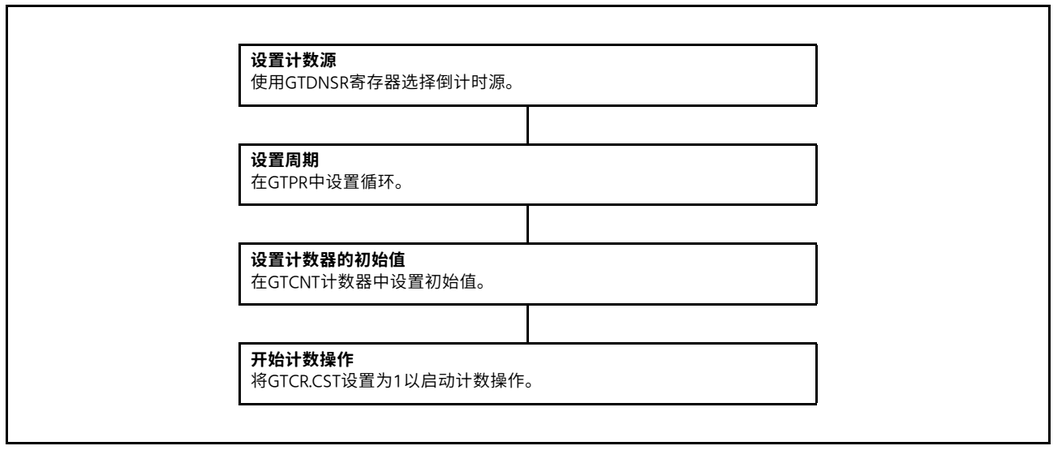

Figure 23.10 使用硬件源的递减计数中的事件计数操作设置示例

(6) 计数器清零操作

每个通道的计数器由以下源清除：

- 将0写入GTCNT寄存器
- 当GTCSR.CCLR位设置为1时，将1写入GTCLR中与GPT通道号相关的位
- 在GTCSR寄存器中选择的硬件源。

计数操作期间禁止写入GTCNT寄存器。GTCNT计数器可以通过向GTCLR写入1和硬件源的清除请求来清除，无论GTCNT正在计数（GTCR.CST为1）还是不计数（GTCR.CST为0）。

对于通过设置GTCR.MD[2:0]和显示递减计数的计数方向标志（GTST.TUCF为0）选择的锯齿波，当向GTCLR寄存器写入1时，GTCNT寄存器设置为GTPR寄存器的值或执行硬件源清除时。

当不处于锯齿波模式和递减计数时，当向GTCLR寄存器写入1并执行硬件源清零时，GTCNT寄存器设置为0。

在GTUPSR或GTDNSR中至少有1位设置为1的事件计数操作中，在清除源发生后，立即执行写入GTCLR寄存器和通过硬件源清除以与PCLKD同步。如果使用其他设置，则清除与GTCR.TPCS[2:0]中选择的计数器时钟同步。

23.3.1.2 Waveform output by compare match

Compare match means that the GTCNT counter value matches the value of GTCCRA or GTCCRB. When a compare match occurs, the compare match flag is generated synchronously with the count clock, including the event count. At the same time the GPT can output low, high, or toggle output from the associated GTIOCA or GTIOCB output pin. In addition, the GTIOCA or GTIOCB pin output can be low, high, or toggled at the cycle end, which is determined by GTPR.

The cycle end is:

- For saw waves in up-counting — when GTCNT changes from the GTPR value to 0 (overflow)
- For saw waves in down-counting — when GTCNT changes from 0 to the GTPR value (underflow)
- For saw waves — when the GTCNT counter is cleared
- For triangle waves — when the GTCNT changes from 0 to 1 (trough).

(1) Low output and high output

Figure 23.11 shows an example of low output and high output operation by a compare match of GTCCRA and GTCCRB.

In this example, the GPT32EH0.GTCNT counter performs up-counting, and settings are made so that high is output from the GTIOC0A pin by a GPT32EH0.GTCCRA compare match, and low is output from the GTOC0B pin by a GPT32EH0.GTCCRB compare match. The pin level does not change when the specified level and pin level match.

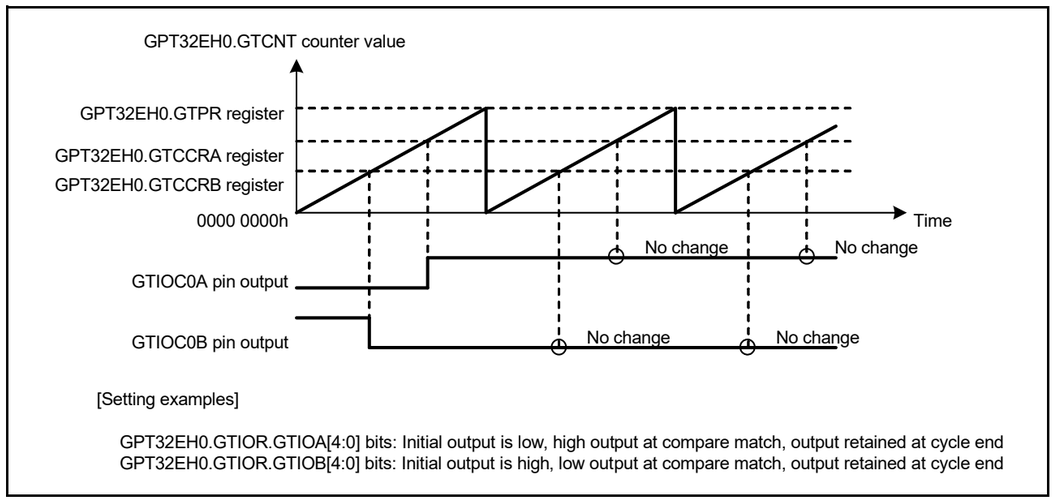

Figure 23.11 Example of low output and high output operation

Figure 23.12 shows an example setting for low output and high output operation.

23.3.1.2 比较匹配的波形输出

比较匹配意味着GTCNT计数器值与GTCCRA或GTCCRB的值匹配。当比较匹配发生时，比较匹配标志与计数时钟同步生成，包括事件计数。同时，GPT可以从相关的GTIOCA或GTIOCB输出引脚输出低、高或切换输出。此外，GTIOCA或GTIOCB引脚输出可以是低电平、高电平或在周期结束时切换，这由GTPR决定。

循环结束为：

- 对于向上计数中的锯齿波——当GTCNT从GTPR值变为0（溢出）时
- 对于向下计数中的锯齿波——当GTCNT从0变为GTPR值时（下溢）
- 对于锯齿波——当GTCNT计数器清零时
- 对于三角波——当GTCNT从0变为1（波谷）时。

In Figure 23.14, the GPT32EH0.GTCNT counter performs up-counting, and settings are made so that the GTIOC0A output is toggled by a compare match of GPT32EH0.GTCCRA and the GTIOC0B output is toggled at the cycle end.

The GTCNT counter value can be transferred to either GTCCRA or GTCCRB on detection of the hardware source that is set in GTICASR and GTICBSR.

Figure 23.16 shows an example of the input capture function.

In this example, the GPT32EH0.GTCNT counter performs up-counting by the count clock, and settings are made so that an input capture is performed to GTICCRA at both edges of the GTIOC0A input pin and to GTICCRB on the rising edge of the GTIOC0B input pin.

23.3.2.1 GTPR register buffer operation

GTPBR can function as a buffer register for GTPR, and GTPDBR can function as a buffer register for GTPBR (double-buffer register for GTPR). The buffer transfer is performed at an overflow (during up-counting) or an underflow (during down-counting) in saw-wave mode or in event count, and at a trough in triangle-wave mode.

In saw-wave mode or in event count, the buffer transfer is performed when the following counter clear operations occur during counting:

- Clear by hardware sources (the clear source is selected in GTCSR[23:0])
- Clear by software (when GTCSR.CCLR bit is 1 and GTCLR[n] bit is set to 1, n = channel number).

To set GTPR to function as double buffer, set GTBER.PR[1:0] to 10b or 11b. To set GTPR to not function as a buffer, set GTBER.PR[1:0] to 00b.

(1) When GTCCRA or GTCCRB functions as an output compare register

Buffer transfer occurs in the following situations:

- Buffer transfer by overflow or underflow
  Buffer transfer is performed at an overflow (during up-counting) or an underflow (during down-counting) in saw-wave mode or in event count operation. In triangle-wave mode, buffer transfer is performed at a trough (triangle-wave PWM mode 1) or a crest and trough (triangle-wave PWM mode 2).
- Buffer transfer by counter clear
  In saw-wave mode or in event count operation, during counting, buffer transfer (which is the same as an overflow during up-counting or an underflow during down-counting) is performed by the counter clear sources similar to the case shown in section 23.3.2.1, GTPR register buffer operation. In triangle-wave mode, buffer transfer is not performed by the counter clear.
- Forcible buffer transfer
  When GTBER.CCRSWT bit is set to 1 while the count operation is stopped, the GTCCRA and the GTCCRB register buffer transfers are performed forcibly in saw-wave mode, in event count operation, and in triangle-wave mode. Additionally, buffer transfer from the GTCCRD register to temporary register A and from the GTCCRF register to temporary register B are performed in saw-wave one-shot pulse mode or triangle-wave PWM mode 3.

Figure 23.22 to Figure 23.24 show examples of GTCCRA and GTCCRB buffer operation and Figure 23.25 shows an example setting for GTCCRA and GTCCRB buffer operation.

(1) 当GTCCRA或GTCCRB用作输出比较寄存器时

缓冲区传输发生在以下情况：

- 通过上溢或下溢进行缓冲区传输
  在锯齿波模式或事件计数操作中，在溢出（向上计数期间）或下溢（向下计数期间）时执行缓冲区传输。在三角波模式中，缓冲区传输在波谷（三角波PWM模式1）或波峰和波谷（三角波PWM模式2）处执行。
- 通过计数器清除缓冲区传输
  在锯齿波模式或事件计数操作中，在计数期间，缓冲区传输（与向上计数期间的溢出或向下计数期间的下溢相同）由计数器清零源执行，类似于章节中所示的情况23.3.2.1、GTPR寄存器缓冲操作。在三角波模式下，计数器清零不执行缓冲区传输。
- 强制缓冲转移
  如果在计数操作停止时将GTBER.CCRSWT位设置为1，则在锯齿波模式、事件计数操作和三角波模式下强制执行GTCCRA和GTCCRB寄存器缓冲传输。此外，从GTCCRD寄存器到临时寄存器A和从GTCCRF寄存器到临时寄存器B的缓冲区传输是在锯齿波一次性脉冲模式或三角波PWM模式3中执行的。

(2) When GTCCRA or GTCCRB functions as an Input Capture Register

When an input capture is generated, the GTCNT counter value is transferred to GTCCRA and GTCCRB and the stored GTCCRA and GTCCRB register values are transferred to the buffer registers. In input capture operation, the buffer transfer is not performed by the counter clear.

23.3.2.3 Buffer operation for GTADTRA and GTADTRB

GTADTBRA can function as the GTADTRA buffer register and GTADTDBRA can function as the GTADTBRA buffer register (double-buffer register for GTADTRA). Similarly, GTADTBRB can function as the GTADTRB buffer register and GTADTDBRB can function as the GTADTBRB buffer register (double-buffer register for GTADTRB).

To set GTADTRA or GTADTRB to function as a double buffer, set GTBER.ADTDA or GTBER.ADTDB to 1. For single-buffer operation, set GTBER.ADTDA or GTBER.ADTDB to 0. To set GTADTRA or GTADTRB to not function as a buffer, set GTBER.ADTTA[1:0] or GTBER.ADTTB[1:0] to 00b.

The buffer transfer timing can be set with the GTBER.ADTTA[1:0] bits. For saw waves, overflows (during up-counting) or underflows (during down-counting) can be selected. For triangle waves, crests are selected when GTBER.ADTTA[1:0] = 01b, troughs are selected when GTBER.ADTTA[1:0] = 10b, and both crests and troughs are selected when GTBER.ADTTA[1:0] = 11b.

Figure 23.29 to Figure 23.31 show examples of GTADTRA and GTADTRB buffer operation and Figure 23.32 shows an example setting for GTDTRA and GTADTRB buffer operation.

23.3.2.3 GTADTRA和GTADTRB的缓冲操作

GTADTBRA可以用作GTADTRA缓冲寄存器，GTADTBRA可以用作GTADTBRA缓冲寄存器（GTADTRA的双缓冲寄存器）。同样，GTADTBRB可以作为GTADTRB缓冲寄存器，GTADTDRBB可以作为GTADTBRB缓冲寄存器（GTADTRB的双缓冲寄存器）。

要将GTADTRA或GTADTRB设置为双缓冲区，请将GTBER.ADTDA或GTBER.ADTDB设置为1。对于单缓冲区操作，将GTBER.ADTDA或GTBER.ADTDB设置为0。要将GTADTRA或GTADTRB设置为不作为缓冲区，将GTBER.ADTTA[1:0]或GTBER.ADTTB[1:0]设置为00b。

可以使用GTBER.ADTTA[1:0]位设置缓冲区传输时序。对于锯齿波，可以选择上溢（向上计数期间）或下溢（向下计数期间）。对于三角波，当GTBER.ADTTA[1:0]=01b时选择波峰，当GTBER.ADTTA[1:0]=10b时选择波谷，当GTBER.ADTTA[1:0]时选择波峰和波谷=11b。

23.3.3 PWM Output Operating Mode

The GPT can output PWM waveforms to the GTIOCA or GTIOCB pin by a compare match between the GTCNT counter and GTCCRA or GTCCRB. By setting GTDTCR, GTDVU, and GTDVD, the compare match value for a negative-phase waveform with dead time can be automatically set to GTCCRB.

23.3.3.1 Saw-wave PWM mode

In saw-wave PWM mode, GTCNT performs saw-wave (half-wave) operation by setting the cycle in GTPR. A PWM waveform is output to the GTIOCA or GTIOCB pin when a GTCCRA or GTCCRB compare match occurs. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the cycle end according to the GTIOR setting.

Figure 23.33 shows an example of saw-wave PWM mode operation, and Figure 23.34 shows an example setting for saw-wave PWM mode.

23.3.3.1 Saw-wave PWM mode

在锯齿波PWM模式下，GTCNT通过在GTPR中设置周期来执行锯齿波（半波）操作。当GTCCRA或GTCCRB比较匹配发生时，PWM波形输出到GTIOCA或GTIOCB引脚。引脚输出值可以根据GTIOR设置分别从低输出、高输出或切换输出中选择，用于比较匹配和循环结束。

23.3.3.2 Saw-wave one-shot pulse mode

The saw-wave one-shot pulse mode is a mode in which the cycle is set in GTPR. The GTCNT counter performs saw-wave (half-wave) operation and a PWM waveform is output to the GTIOCA or GTIOCB pin at a compare match of GTCCRA or GTCCRB with buffer operation fixed.

Buffer operation in saw-wave one-shot pulse mode is different from the usual buffer operation. Buffer transfer is performed from:

- GTCCRC to GTCCRA at the cycle end
- GTCCRE to GTCCRB at the cycle end
- GTCCRD to temporary register A at the cycle end
- GTCCRF to temporary register B at the cycle end
- Temporary register A to GTCCRA at a GTCCRA compare match
- Temporary register B to GTCCRB at a GTCCRB compare match.

The pin output value can be selected from low output, high output, or toggle output separately for a compare match and the cycle end according to the GTIOR setting. When the GTBER.CCRSWT bit is set to 1 while the count operation is stopped, the buffer is transferred forcibly from the GTCCRD register to temporary register A and from the GTCCRF register to temporary register B. By setting GTDTCR, GTDVU, and GTDVD, a compare match value for a negative-phase waveform with dead time can automatically be set to GTCCRB.

Figure 23.35 shows an example of saw-wave one-shot pulse mode operation, and Figure 23.36 shows an example setting for saw-wave one-shot pulse mode.

23.3.3.2 锯波单发脉冲模式

锯齿波单发脉冲模式是在GTPR中设置周期的模式。GTCNT计数器执行锯齿波（半波）操作，并且在GTCCRA或GTCCRB的比较匹配时将PWM波形输出到GTIOCA或GTIOCB引脚，且缓冲器操作固定。

锯波单次脉冲模式中的缓冲操作不同于通常的缓冲操作。缓冲区传输从以下位置执行：

- 循环结束时GTCCRC到GTCCRA
- 循环结束时GTCCRE到GTCCRB
- GTCCRD在循环结束时到临时寄存器A
- GTCCRF在循环结束时到临时寄存器B
- 在GTCCRA比较匹配时将临时寄存器A发送到GTCCRA
- 在GTCCRB比较匹配时，临时寄存器B到GTCCRB。

引脚输出值可以根据GTIOR设置分别从低输出、高输出或切换输出中选择，以进行比较匹配和循环结束。如果在计数操作停止时将GTBER.CCRSWT位设置为1，则缓冲区被强制从GTCCRD寄存器传送到临时寄存器A，并从GTCCRF寄存器强制传送到临时寄存器B。通过设置GTDTCR、GTDVU和GTDVD，a带有死区时间的负相位波形的比较匹配值可以自动设置为GTCCRB。

23.3.3.3 Triangle-wave PWM mode 1 (32-bit transfer at trough)

The triangle-wave PWM mode 1 is a mode in which the cycle is set in GTPR. The GTCNT counter performs triangle-wave (full-wave) operation, and a PWM waveform is output to the GTIOCA or GTIOCB pin when a GTCCRA or GTCCRB compare match occurs. Buffer transfer is performed at the trough. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the cycle end based on the GTIOR setting.

By setting GTDTCR, GTDVU, and GTDVD, a compare match value for a negative-phase waveform with dead time can automatically be set to GTCCRB.

23.3.3.4 Triangle-wave PWM mode 2 (32-bit transfer at crest and trough)

Similarly to triangle-wave PWM mode 1, in triangle-wave PWM mode 2 the cycle is set in GTPR. The GTCNT counter performs triangle-wave (full-wave) operation, and a PWM waveform is output to the GTIOCA or GTIOCB pin when a GTCCRA or GTCCRB compare match occurs. The buffer transfer is performed at both crests and troughs. The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the cycle end according to the GTIOR setting.

By setting GTDTCR, GTDVU, and GTDVD, a compare match value for a negative-phase waveform with dead time can automatically be set to GTCCRB.

23.3.3.4 三角波PWM模式2（波峰和波谷32位传输）

与三角波PWM模式1类似，在三角波PWM模式2中，周期在GTPR中设置。GTCNT计数器执行三角波（全波）操作，当发生GTCCRA或GTCCRB比较匹配时，PWM波形将输出到GTIOCA或GTIOCB引脚。缓冲转移在波峰和波谷进行。引脚输出值可以根据GTIOR设置分别从低输出、高输出或切换输出中选择，用于比较匹配和循环结束。

23.3.3.5 Triangle-wave PWM mode 3 (64-bit transfer at trough)

The triangle-wave PWM mode 3 is a mode in which the cycle is set in GTPR. The GTCNT counter performs triangle-wave (full-wave) operation, and a PWM waveform is output to the GTIOCA or GTIOCB pin at a compare match of GTCCRA or GTCCRB with buffer operation fixed. Buffer operation in triangle-wave PWM mode 3 is different from the usual buffer operation. Buffer transfer is performed from:

- GTCCRC to GTCCRA at the trough
- GTCCRE to GTCCRB at the trough
- GTCCRD to temporary register A at the trough
- GTCCRF to temporary register B at the trough
- Temporary register A to GTCCRA at the crest
- Temporary register B to GTCCRB at the crest.

The pin output value can be selected from low output, high output, or toggle output separately for a compare match and for the cycle end according to the GTIOR setting.

By setting GTDTCR, GTDVU, and GTDVD, a compare match value for a negative-phase waveform with dead time can automatically be set to GTCCRB.

Figure 23.41 shows an example of triangle-wave PWM mode 3 operation, and Figure 23.42 shows an example setting for triangle-wave PWM mode 3.

23.3.3.5 三角波PWM模式3（波谷64位传输）

三角波PWM模式3是在GTPR中设定周期的模式。GTCNT计数器执行三角波（全波）操作，并且在固定缓冲操作的GTCCRA或GTCCRB比较匹配时将PWM波形输出到GTIOCA或GTIOCB引脚。三角波PWM模式3中的缓冲操作与通常的缓冲操作不同。缓冲区传输从以下位置执行：

- GTCCRC到GTCCRA在低谷
- GTCCRE到GTCCRB在低谷
- GTCCRD到谷底临时寄存器A
- GTCCRF到波谷临时寄存器B
- 顶部GTCCRA的临时注册A
- 在顶部的GTCCRB临时寄存器B。

引脚输出值可以根据GTIOR设置分别从低输出、高输出或切换输出中选择，用于比较匹配和循环结束。

通过设置GTDTCR、GTDVU和GTDVD，可以自动将带死区时间的负相位波形的比较匹配值设置为GTCCRB。

23.3.4 Automatic Dead Time Setting Function

By setting GTDTCR, a compare match value for a negative waveform with dead time obtained by a compare match value for a positive waveform (GTCCRA value) and specified dead time values (GTDVU and GTDVD values) can automatically be set to GTCCRB. The automatic dead time setting function can be used in saw-wave one-shot pulse mode and all the triangle PWM modes.

Dead time can be separately set for the first half and second half of a waveform. Dead time for the transition in the first half of a negative waveform is set in GTDVU and that in the second half is set in GTDVD. The same dead time can also be set for the first and second halves by setting the GTDTCR.TDFER bit to 1.

GTDBU can be used as a buffer register of GTDVU, and GTDBD can be used as a buffer register of GTDVD. Buffer transfer is performed at a GTCNT overflow (during up-counting), an underflow (during down-counting), or at a GTCNT counter clear for saw waves and at the trough for triangle waves.

The compare match value set by automatic dead time setting function can be confirmed by reading from GTCCRB. Writing to GTCCRB is prohibited when the automatic dead time setting function is used.

Dead time setting beyond the cycle is prohibited. When a dead time error occurs, the compare match values for positive and negative waveforms are adjusted to generate the waveforms with the dead time as shown in Table 23.6. The adjusted value for the negative waveform is set for GTCCRB automatically. The adjusted value for the positive waveform is used as internal signal and not set for GTCCRA.

In saw-wave one-shot pulse mode, when the adjusted value is beyond the cycle or the adjusted waveform toggle points are in disorder, the complementarity of the waveforms is not guaranteed.

In triangle-wave mode, when the dead time is beyond the cycle by setting the value GTCCR = 0 or GTCCRA ≥ GTPR for GTCCRA, the output protection function keeps the level of output. For details, see section 23.8.4, Output Protection Function for GTIOC Pin Output. When the GTCCRA is GTCCRA ≥ GTPR + GTDVm, GTPR-1 is set for GTCCRB as the upper limit value. The automatic dead time value setting to GTCCRB is performed at the next clock cycle count when registers used for calculating the automatic dead time value are updated.

The way to rewrite GTDVm differs by GPT channel number.

Table 23.6 Compare match value after adjusting for dead time error

PWM output operating mode	Count direction	First half/ Second half	Condition of dead time error	Compare match value after adjusting

GPT32EH0 to GPT32EH3 and GPT32E4 to GPT32E7

When GTDVm buffer operation is enabled, GTDBm can be written at anytime. GTDBm is transferred to GTDVm at the cycle end.

When GTDVm buffer operation is disabled, stop the GPT using the CST bit in the GTCR register before changing GTDVm to a new value.

GPT328 to GPT3212

While GPT is running, changing the GTDVU values is prohibited. To change GTDVU to a new value, first stop the GPT using the CST bit in the GTCR register.

23.3.4 自动死区时间设置功能

通过设置GTDTCR，通过正波形的比较匹配值（GTCCRA值）和指定的死区时间值（GTDVU和GTDVD值）获得的负波形与死区时间的比较匹配值可以自动设置为GTCCRB。自动死区时间设置功能可用于锯齿波一次性脉冲模式和所有三角PWM模式。

可以为波形的前半部分和后半部分分别设置死区时间。在GTDVU中设置负波形前半部分的过渡的死区时间，在GTDVD中设置后半部分的过渡时间。通过将GTDTCR.TDFER位设置为1，也可以为前半部分和后半部分设置相同的死区时间。

GTDBU可以作为GTDVU的缓冲寄存器，GTDBD可以作为GTDVD的缓冲寄存器。在GTCNT上溢（向上计数期间）、下溢（向下计数期间）或GTCNT计数器清除锯齿波和三角波波谷时执行缓冲区传输。

自动死区时间设置功能设置的比较匹配值可以通过读取GTCCRB来确认。
使用自动死区时间设置功能时，禁止写入GTCCRB。

禁止设置超出周期的死区时间。当出现死区时间错误时，调整正负波形的比较匹配值以生成具有死区时间的波形，如表23.6所示。负波形的调整值自动为GTCCRB设置。正波形的调整值用作内部信号，而不是为GTCCRA设置的。

在锯齿波单发脉冲模式下，当调整值超出周期或调整后的波形切换点混乱时，波形的互补性无法保证。

在三角波模式下，当通过设置GTCCRA=0或GTCCRA≥GTCCRA的值使死区时间超出周期时，输出保护功能保持输出电平。有关详细信息，请参见第23.8.4节，GTIOC引脚输出的输出保护功能。当GTCCRA为GTCCRA≥GTPR+GTDVm时，将GTPR−1设置为GTCCRB作为上限值。当用于计算自动死区时间值的寄存器被更新时，在下一个时钟周期计数时执行GTCCRB的自动死区时间值设置。

重写GTDVm的方式因GPT通道号而异。

23.3.5 Count Direction Changing Function

The count direction of the GTCNT counter can be changed by modifying the UD bit in GTUDDTYC.

In saw-wave mode, if the UD bit in GTUDDTYC is modified during count operation, the count direction is changed at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the GTUDDTYC.UD bit is modified while the count operation is stopped and the GTUDDTYC.UDF bit is 0, the GTUDDTYC.UD bit modification is not reflected at the start of counting and the count direction is changed at an overflow or an underflow. If the UDF bit is set to 1 while the count operation is stopped, the GTUDDTYC.UD bit value at that time is reflected at the start of counting.

In triangle-wave mode, the count direction does not change when the UD bit in GTUDDTYC is modified during the count operation. Similarly, when the GTUDDTYC.UD bit is modified while the count operation is stopped and GTUDDTYC.UDF bit is 0, the GTUDDTYC.UD bit value is not reflected in the count operation. If the GTUDDTYC.UDF bit is set to 1 while the count operation is stopped, the GTUDDTYC.UD bit value at that time is reflected at the start of counting.

If the count direction changes during a saw-wave count operation, the GTPR value after the start of up-counting is reflected in the count cycle during up-counting, and the GTPR value before the start of down-counting is reflected during down-counting.

Figure 23.49 shows an example operation of count direction changing function.

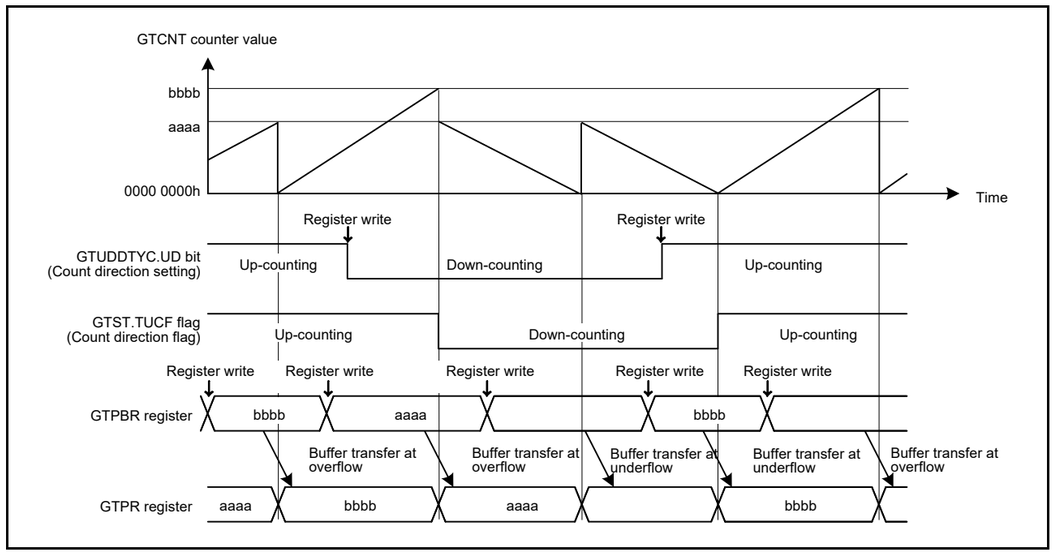

Figure 23.49 Example operation of count direction changing function during buffer operation

23.3.5 计数方向改变功能

GTCNT计数器的计数方向可以通过修改GTUDDTYC中的UD位来改变。

在锯齿波模式下，如果在计数操作期间修改GTUDDTYC中的UD位，则计数方向会在溢出（在向上计数期间修改时）或下溢（在向下计数期间修改时）改变。如果在计数操作停止且GTUDDTYC.UDF位为0时修改GTUDDTYC.UD位，则

GTUDDTYC.UD位修改不会反映在计数开始时，计数方向会在上溢或下溢时改变。如果在计数操作停止时UDF位设置为1，则此时的GTUDDTYC.UD位值将反映在计数开始时。

在三角波模式下，在计数操作期间修改GTUDDTYC中的UD位不会改变计数方向。同样，当计数操作停止且GTUDDTYC.UDF位为0时修改GTUDDTYC.UD位时，GTUDDTYC.UD位值不会反映在计数操作中。如果

计数操作停止时GTUDDTYC.UDF位设置为1，此时的GTUDDTYC.UD位值反映在计数开始时。

如果在锯波计数操作期间计数方向发生变化，则递增计数开始后的GTPR值在递增计数期间反映在计数周期中，递减计数开始之前的GTPR值在递减期间反映数数。

图23.49显示了计数方向改变功能的示例操作。

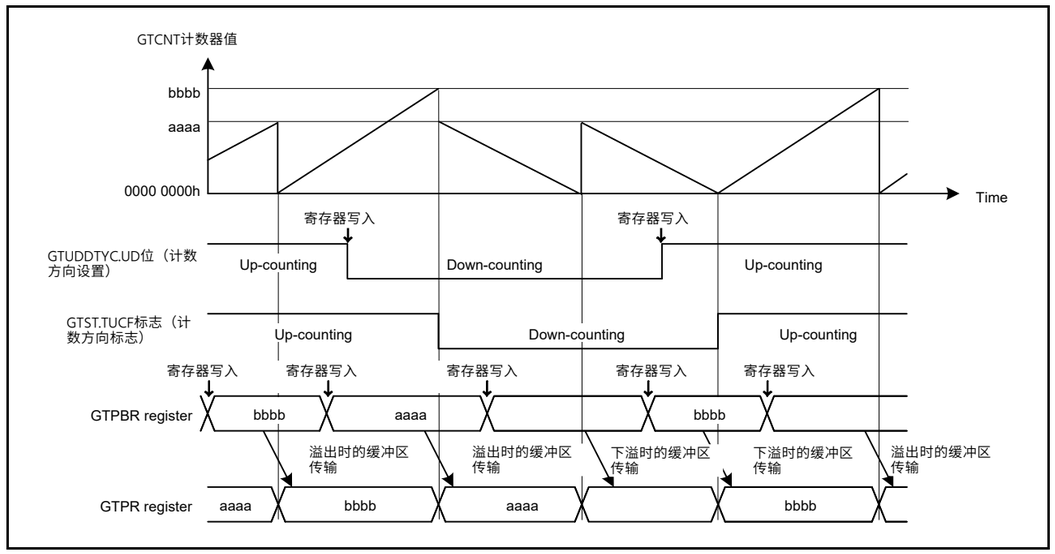

Figure 23.49 缓冲操作期间计数方向改变功能的示例操作

23.3.6 Function of Output Duty 0% and 100%

The output duty of the GTIOCA and GTIOCB pins are set to 0% or 100% by changing the GTUDDTYC.OADTY bit or GTUDDTYC.OBDTY bit.

In saw-wave mode, if the GTUDDTYC.OADTY or GTUDDTYC.OBDTY bit is modified during the count operation, the output duty setting is reflected at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the GTUDDTYC.OADTY or GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF or GTUDDTYC.OBDTYF bit is 0, the output duty modification is not reflected at the start of counting. The output duty changes at an overflow or an underflow. If the GTUDDTYC.OADTYF or GTUDDTYC.OBDTYF bit is set to 1 while the count operation is stopped, the GTUDDTYC.OADTY or GTUDDTYC.OBDTY bit value at that time is reflected at the start of counting.

In triangle-wave mode, if the GTUDDTYC.OADTY or GTUDDTYC.OBDTY bit is modified during the count operation, the output duty setting is reflected at an underflow.

If the GTUDDTYC.OADTY or GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF or GTUDDTYC.OBDTYF bit is 0, the output duty modification is not reflected at the start of counting. The output duty changes at an underflow. If the GTUDDTYC.OADTY or GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF or GTUDDTYC.OBDTYF bit is 1, the output duty modification is reflected at the start of counting.

In performing 0%/100% duty operation, GPT internally continues to:

- Perform compare match operation
- Set compare match flag
- Output interrupt
- Perform buffer operation.

When the control is changed from 0% or 100% duty setting to compare match, the output value of GTIOCA pin at cycle end is determined by GTIOR.GTIOA[3:2] and GTUDDTYC.OADTYR. The output value of GTIOCB pin at cycle end is determined by GTIOR.GTIOB[3:2] and GTUDDTYC.OBDTYR.

When GTIOR.GTIOA[3:2] and GTIOR.GTIOB[3:2] are set to 01b, the output pins output low at cycle end. When GTIOR.GTIOA[3:2] and GTIOR.GTIOB[3:2] are set to 10b, the output pins output high at cycle end.

GTUDDTYC.OADTYR selects the value that is the object of output retained/toggled at cycle end, when GTIOR.GTIOm[3:2] are set to 00b (output retained at cycle end) or when GTIOR.GTIOm[3:2] are set to 11b (output toggled at cycle end). Table 23.7 shows the values of GTIOCA/GTIOCB pin output at cycle end.

Figure 23.50 shows an example of output duty 0% and 100% function.

23.3.6 输出占空比0%和100%的功能

GTIOCA和GTIOCB引脚的输出占空比通过更改GTUDDTYC.OADTY位设置为0%或100%或GTUDDTYC.OBDTY bit.

在锯齿波模式下，如果在计数操作期间修改GTUDDTYC.OADTY或GTUDDTYC.OBDTY位，则输出占空比设置反映在上溢（在向上计数期间修改时）或下溢（在向下计数期间修改时）。如果在计数操作停止且GTUDDTYC.OADTYF或GTUDDTYC.OBDTYF位为0时修改GTUDDTYC.OADTY或GTUDDTYC.OBDTY位，则在计数开始时不反映输出占空比修改。输出占空比在上溢或下溢时发生变化。如果在计数操作停止时将GTUDDTYC.OADTYF或GTUDDTYC.OBDTYF位设置为1，则此时的GTUDDTYC.OADTY或GTUDDTYC.OBDTY位值将反映在计数开始时。

在三角波模式下，如果在计数操作期间修改GTUDDTYC.OADTY或GTUDDTYC.OBDTY位，则输出占空比设置会在下溢时反映。

如果GTUDDTYC.OADTY或GTUDDTYC.OBDTY位在计数操作停止并且GTUDDTYC.OADTYF或GTUDDTYC.OBDTYF位为0，输出占空比修改在计数开始时不反映。输出占空比在下溢时发生变化。如果在计数操作停止且GTUDDTYC.OADTYF或GTUDDTYC.OBDTYF位为1时修改GTUDDTYC.OADTY或GTUDDTYC.OBDTY位，则输出占空比修改反映在计数开始时。

在执行0%100%占空比操作时，GPT在内部继续：

- 执行比较匹配操作
- 设置比较匹配标志
- 输出中断
- 执行缓冲操作。

当控制从0%或100%占空比设置更改为比较匹配时，循环结束时GTIOCA引脚的输出值由GTIOR.GTIOA[3:2]和GTUDDTYC.OADTYR确定。周期结束时GTIOCB引脚的输出值由GTIOR.GTIOB[3:2]和GTUDDTYC.OBDTYR决定。

当GTIOR.GTIOA[3:2]和GTIOR.GTIOB[3:2]设置为01b时，输出引脚在周期结束时输出低电平。什么时候GTIOR.GTIOA[3:2]和GTIOR.GTIOB[3:2]设置为10b，输出引脚在周期结束时输出高电平。

GTUDDTYC.OADTYR选择在循环结束时作为输出保持切换的对象的值，当GTIOR.GTIOm[3:2]设置为00b（输出在循环结束时保留）或GTIOR.GTIOm[3:2]设置为11b（输出在循环结束时切换）。表23.7显示了循环结束时GTIOCAGTIOCB引脚输出的值。

23.3.7.3 Hardware clear operation

The GTCNT counter can be cleared by selecting a hardware source using GTCSR. The GPTn_OVF/GPTn_UDF (n = 0 to 12) interrupt (overflow/underflow interrupt) is not generated when the GTCNT counter is cleared by a hardware source or by software.

Figure 23.57 and Figure 23.58 show examples of the GTCNT counter clearing operation by a hardware source. Figure 23.59 shows the setting example. In this example, the GTCNT counter starts at the edge of the ELC_GPTA event input, and the counter stops and clears at the edge of the ELC_GPTB event input.

23.3.7.3 硬件清除操作

GTCNT计数器可以通过使用GTCSR选择硬件源来清除。当GTCNT计数器被硬件或软件清零时，不会产生GPTn_OVFGPTn_UDF（n=0到12）中断（上溢下溢中断）。

图23.57和图23.58显示了通过硬件源清除GTCNT计数器操作的示例。图23.59显示了设置示例。在本例中，GTCNT计数器在ELC_GPTA事件输入的边沿开始，计数器在ELC_GPTB事件输入的边沿停止并清零。

23.3.8 Synchronized Operation

Synchronized operation on channels such as a synchronized start, stop, and clear operation can be performed.

23.3.8.1 Synchronized operation by software

The GTCNT counters can be started, stopped, and cleared on multiple channels by setting the associated GTSTR, GTSTP, or GTCLR bits simultaneously to 1.

Count start with a phase difference is possible by setting the initial value in the GTCNT counter and setting the associated GTSTR bits simultaneously to 1.

Figure 23.61 shows an example of a simultaneous start, stop, and clear by software. Figure 23.62 shows an example of phase start operation by software.

23.3.8 同步操作

可以对通道进行同步操作，例如同步启动、停止和清除操作。

23.3.8.1 软件同步操作

通过设置相关的GTSTR，可以在多个通道上启动、停止和清除GTCNT计数器，GTSTP或GTCLR位同时为1。

通过在GTCNT计数器中设置初始值并同时将相关的GTSTR位设置为1，可以从相位差开始计数。

图23.61显示了通过软件同时启动、停止和清除的示例。图23.62显示了通过软件进行相位启动操作的示例。

23.3.10 Phase Counting Function

The phase difference between the GTIOCA and GTIOCB pin inputs is detected and the associated GTCNT counts up or counts down. The detectable phase difference is available in any combination with the relationship between the edge and the level of GTIOCA and GTIOCB pin inputs being set in the GTUPSR and GTDNSR registers. For details on count operation, see section 23.3.1.1, Counter operation.

23.3.11 Output Phase Switching (GPT_OPS)

GPT_OPS provides a function for easy control of brushless DC motor operation using the Output Phase Switching Control Register (OPSCR).

GPT_OPS outputs a PWM signal to be used for chopper control or level signal for each phase (U-positive phase/negative phase, V-positive phase/negative phase, W-positive phase/negative phase) of the 6-phase motor control. This function uses a soft setting value (OPSCR.UF, VF, WF) set by software or external signals detected by the Hall element, a PWM waveform of GPT32EH0.GTIOCA.

Figure 23.81 shows the conceptual diagram of GPT_OPS control flow.

23.3.11 输出相位切换(GPT_OPS)

GPT_OPS提供使用输出相位切换轻松控制无刷直流电机运行的功能
控制寄存器(OPSCR)。

GPT_OPS输出用于斩波控制的PWM信号或6相电机控制的每一相（U正相负相、V正相负相、W正相负相）的电平信号。该功能使用软件设置的软设置值（OPSCR.UF、VF、WF）或霍尔元件检测到的外部信号，GPT32EH0.GTIOCA的PWM波形。

23.3.11.1 Input selection and synchronization of external input signal

In the GPT_OPS control flow conceptual diagram shown in Figure 23.81, (1) is a selection of input phase from the software settings and external input by the OPSCR.FB bit.

When OPSCR.FB bit is 0, select the external input. Enable the input signal after synchronization with the GPT core clock (PCLKD). After carrying out noise filtering (optional), set the external input to the input phase of PWM (PWM of GPT32EH0.GTIOCA) using falling edge sampling with OPSCR.ALIGN bit set to 1.

When OPSCR.FB bit is 1, select the software setting (OPSCR.UF, VF, WF) with the value of the input phase of PWM (PWM of GPT32EH0.GTIOCA) using falling edge sampling with OPSCR.ALIGN bit set to 1.

When OPSCR.ALIGN bit is 0, GPT_OPS operates with the input phase of PCLKD synchronization with either OPSCR.FB bit set to 0 or OPSCR.FB bit set to 1. However, in some situations, the PWM pulse width of the output U/V/W phases (PWM output mode) of switch timing (just before or just after) is shortened.

Table 23.18 shows the input selection process and setting of associated OPSCR bits.

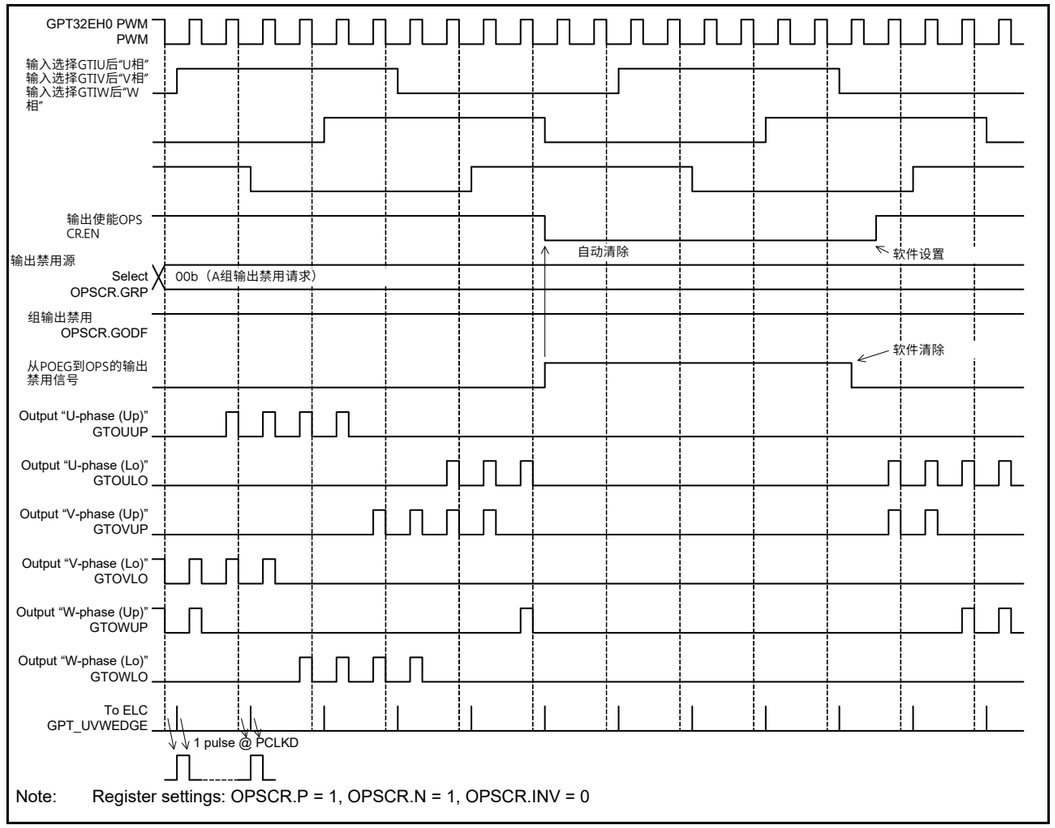

Figure 23.84 组输出禁用控制操作示例

23.3.11.1 外部输入信号的输入选择和同步

在图23.81所示的GPT_OPS控制流程概念图中，(1)是通过OPSCR.FB位从软件设置和外部输入中选择输入相位。

当OPSCR.FB位为0时，选择外部输入。与GPT内核时钟(PCLKD)同步后启用输入信号。执行噪声过滤（可选）后，使用下降沿采样将外部输入设置为PWM的输入相位（GPT32EH0.GTIOCA），并将OPSCR.ALIGN位设置为1。

当OPSCR.FB位为1时，使用OPSCR.ALIGN位设置为1的下降沿采样选择PWM输入相位值（GPT32EH0.GTIOCA的PWM）的软件设置（OPSCR.UF、VF、WF）。

当OPSCR.ALIGN位为0时，GPT_OPS以PCLKD同步的输入相位与任一OPSCR.FB位设置为0或OPSCR.FB位设置为1。但是，在某些情况下，输出的PWM脉冲宽度UVW相位（PWM输出模式）的开关时序（恰好在之前或之后）被缩短。

表23.18显示了输入选择过程和相关OPSCR位的设置。

23.3.11.2 Input sampling

The OPSCR.U, V, W bits indicate the PCLKD sampling results of the input selected by the OPSCR.FB bit.

When OPSCR.FB bit is 0 and after synchronization with the GPT core clock (PCLKD) and noise filtering (optional), OPSCR.U, V, W bits indicate the sampling results of the external input. When OPSCR.FB bit is 1, OPSCR.U, V, W bits have the value (OPSCR.UF, VF, WF) of the software setting.

23.3.11.3 Input phase decode

In the GPT_OPS control flow conceptual diagram shown in Figure 23.81, (2) enables the 6-phase signals by decoding the input phase selected by the OPSCR.FB bit. The 6-phase enable signal is used for internal processing of GPT_OPS.

Table 23.19 shows the decode table of input phase.

23.3.11.3 输入相位解码

在图23.81所示的GPT_OPS控制流程概念图中，(2)通过解码OPSCR.FB位选择的输入相位来启用6相位信号。6相使能信号用于GPT_OPS的内部处理。

23.3.11.4 Output selection control

In the GPT_OPS control flow conceptual diagram in Figure 23.81, (3) represents the selection of the output waveform by setting the OPSCR register bit.

For output selection, the following bits are relevant:

- The OPSCR.EN bit controls whether to output the 6-phase output, or to stop
- The OPSCR.P and OPSCR.N bits can select from the level signal or PWM signal (chopper output) for the output phase
- The polarity of the output phase can be set to positive logic or negative logic by the OPSCR.INV bit.

Table 23.20 and Table 23.21 show the output selection control method using the OPSCR register bit.

23.3.11.4 输出选择控制

在图23.81的GPT_OPS控制流程概念图中，(3)表示通过设置OPSCR寄存器位来选择输出波形。

对于输出选择，以下位是相关的：

- OPSCR.EN位控制是输出6相输出，还是停止
- OPSCR.P和OPSCR.N位可以选择输出相位的电平信号或PWM信号（斩波器输出）
- 输出相位的极性可通过OPSCR.INV位设置为正逻辑或负逻辑。

表23.20和表23.21显示了使用OPSCR寄存器位的输出选择控制方法。

23.3.11.5 Output selection control (group output disable function)

When OPSCR.GODF is 1 and the signal value selected by the OPSCR.GRP bit is high (output disable request), the GPT_OPS output pins change to Hi-Z asynchronously and the OPSCR.EN bit is set to 0 by the output disable request signal synchronized with PCLKD. For the return, set the OPSCR.EN bit to 1 after clearing the output disable request with software.

The timing of OPSCR.EN bit cleared to 0 is 3 PCLKD cycles after generating the output disable request. To perform output disable control reliably, allow at least 4 PCLKD cycles after generating the output disable request (by clearing the output disable request flag in POEG) until the output disable request is terminated. For an example of the operation of group output disable control, see Figure 23.84.

23.3.11.6 Event Link Controller (ELC) output

In the GPT_OPS control flow conceptual diagram shown in Figure 23.81, (5) outputs the Hall sensor input signal edge to the ELC.

The Hall sensor input edge signal is the logical OR of the rising and falling edge signals of each U-phase/V-phase/W-phase input sampled at PCLKD. That is, if the high period of each of the U-phase/V-phase/W-phase input is short in duration, the Hall sensor edge input signal is not output at that time.

When OPSCR.FB bit is 0, the Hall sensor input edge signal is the logical OR of the edge signals of the external input phase sampled at PCLKD.

When OPSCR.FB bit is 1, the Hall sensor input edge signal is the logical OR of the edge of the software setting (OPSCR.UF, VF, WF) sampled at PCLKD.

See Figure 23.82 to Figure 23.84 for examples of the output signal to the ELC.

23.3.11.5 输出选择控制（组输出禁用功能）

当OPSCR.GODF为1且OPSCR.GRP位选择的信号值为高（输出禁用请求）时，GPT_OPS输出引脚异步变为Hi-Z，并且通过与PCLKD同步的输出禁用请求信号将OPSCR.EN位设置为0。对于返回，请在用软件清除输出禁用请求后将OPSCR.EN位设置为1。

OPSCR.EN位清0的时序是在产生输出禁用请求后的3个PCLKD周期。为了可靠地执行输出禁用控制，在生成输出禁用请求后（通过清除POEG中的输出禁用请求标志）至少允许4个PCLKD周期，直到输出禁用请求终止。组输出禁用控制的操作示例见图23.84。

23.3.11.6 事件链接控制器(ELC)输出

在图23.81所示的GPT_OPS控制流程概念图中，(5)将霍尔传感器输入信号沿输出到ELC。

霍尔传感器输入边沿信号是在PCLKD采样的每个U相V相W相输入的上升沿和下降沿信号的逻辑或。即，如果U相V相W相输入中的每一个的高电平时段持续时间短，则此时不输出霍尔传感器边沿输入信号。

当OPSCR.FB位为0时，霍尔传感器输入边沿信号是在PCLKD采样的外部输入相位边沿信号的逻辑或。

当OPSCR.FB位为1时，霍尔传感器输入边沿信号是在PCLKD采样的软件设置（OPSCR.UF、VF、WF）边沿的逻辑或。

有关ELC的输出信号示例，请参见图23.82至图23.84。

23.4 Interrupt Sources

The GPT provides the following interrupt sources:

- GTCCR input capture/compare match
- GTADTR compare match
- GTCNT counter overflow (GTPR compare match)/underflow.

Each interrupt source has its own status flag. When an interrupt source signal is generated, the associated status flag in GTST is set to 1. The associated status flag in GTST can be cleared by writing 0. If flag set and flag clear occur at the same time, flag clear takes priority over flag set. These flags are automatically updated by the internal state.

Table 23.22 lists the GPT interrupt sources.

23.4 中断源

GPT提供以下中断源：

- GTCCR输入捕获比较匹配
- GTADTR比较匹配
- GTCNT计数器上溢（GTPR比较匹配）下溢。

每个中断源都有自己的状态标志。当产生中断源信号时，GTST中的相关状态标志设置为1。GTST中的相关状态标志可以通过写入0来清除。如果标志设置和标志清除同时发生，则标志清除优先于标志放。这些标志由内部状态自动更新。

表23.22列出了GPT中断源。

(1) GPTn_ADTRGA interrupt (n = 0 to 7)

When the GTCNT counter value matches with the GTADTRA register, an interrupt request is generated under the following conditions:

- In up-counting, the interrupt enable bit (ADTRAUEN) in the GTINTAD register is 1
- In down-counting, the interrupt enable bit (ADTRADEN) in the GTINTAD register is 1.

In event count operation, this interrupt request is not generated.

(2) GPTn_ADTRGB interrupt (n = 0 to 7)

When the GTCNT counter value matches with the GTADTRB register, an interrupt request is generated under the following conditions:

- In up-counting, the interrupt enable bit (ADTRBUEN) in the GTINTAD register is 1
- In down-counting, the interrupt enable bit (ADTRBDEN) in the GTINTAD register is 1.

In event count operation, this interrupt request is not generated.

(3) GPTn_CCMPA interrupt (n = 0 to 12)

An interrupt request is generated under the following conditions:

- When the GTCCRA register functions as a compare match register, the GTCNT counter value matches with the GTCCRA register.
- When the GTCCRA register functions as an input capture register, the input-capture signal causes transfer of the GTCNT counter value to the GTCCRA register.

23.4.1 DMAC/DTC Activation

The DMAC and DTC can be activated by the interrupt in each channel. For details, see section 14, Interrupt Controller Unit (ICU), and section 18, Data Transfer Controller (DTC).

23.4.2 Interrupt and A/D Conversion Request Skipping Function

By setting the GTITC register, the GTCNT counter overflow (GTPR compare match) interrupt (GPTn_OVF) and underflow interrupt (GPTn_UDF) can be skipped. Other interrupts and A/D converter start request signals can be skipped in coordination with the GPTn_OVF/GPTn_UDF skipping function.

The interrupt request skipping function only depends on the setting of GTITC register and is independent of the setting of interrupt permission bits in the GTINTAD register.

When both troughs and crests are counted and skipped in triangle-wave mode, if the number of times for skipping is odd, GPTn_OVF/GPTn_UDF interrupt requests cannot be generated at troughs only or at crests only depending on the skipping counter start timing. To count both troughs and crests and generate the GPTn_OVF/GPTn_UDF interrupts at troughs only or crests only in triangle-wave mode, you must set an even number of skips.

Similarly, in saw-wave mode, when both overflows and underflows are counted and skipped with the count direction changed, GPTn_OVF interrupt requests cannot be generated on either overflows or underflows only. To count both overflows and underflows with the count direction changed and generate the GPTn_OVF/GPTn_UDF interrupts on either overflows or underflows only in saw wave mode, you must first check the skipping state.

Before changing the skipping count, you must release the skipping count setting (GTITC.IVTC[1:0] bits = 00b).

Figure 23.86 to Figure 23.91 show examples of skipping function operation.

- 在三角波模式下，在波峰处启用中断请求（GTCNT从GTPR变为GTPR1）
- 在硬件源的计数中，发生了溢出（GTCNT在向上计数中从GTPR变为0）。

(10)GPTn_UDF中断（n=0到12）

在以下情况下会产生中断请求：

- 在锯齿波模式下，中断请求在下溢时启用（当GTCNT计数器值从0变为GTPR during down-counting)
- 在三角波模式下，在波谷处启用中断请求（GTCNT从0变为1）
- 在硬件源的计数中，发生了下溢（向下计数时GTCNT从0变为GTPR）。

23.4.1 DMAC/DTC Activation

DMAC和DTC可以通过每个通道中的中断来激活。有关详细信息，请参见第14节，中断控制器单元(ICU)和第18节，数据传输控制器(DTC)。

23.4.2 中断和AD转换请求跳过功能

通过设置GTITC寄存器，可以跳过GTCNT计数器溢出（GTPR比较匹配）中断（GPTn_OVF）和下溢中断（GPTn_UDF）。其他中断和AD转换器启动请求信号可以与GPTn_OVFGPTn_UDF跳过功能配合跳过。

中断请求跳过功能仅取决于GTITC寄存器的设置，与GTINTAD寄存器中中断允许位的设置无关。

在三角波模式下同时计算波谷和波峰并跳过时，如果跳过的次数是奇数，GPTn_OVFGPTn_UDF中断请求不能仅在波谷或波峰产生，具体取决于跳跃计数器的开始时间。要同时计算波谷和波峰，并在三角波模式下仅在波谷或波峰处生成GPTn_OVFGPTn_UDF中断，您必须设置偶数个跳过。

类似地，在锯齿波模式下，当计数方向改变同时计数和跳过上溢和下溢时，GPTn_OVF中断请求不能仅在上溢或下溢时产生。要在计数方向改变的情况下计算上溢和下溢，并仅在锯齿波模式下在上溢或下溢时生成GPTn_OVFGPTn_UDF中断，您必须首先检查跳过状态。

在更改跳过计数之前，您必须释放跳过计数设置（GTITC.IVTC[1:0]位=00b）。

图23.86至图23.91显示了跳过函数操作的示例。

23.5 A/D Converter Start Request

An A/D converter start request can be issued at a compare match between the GTCNT counter and GTADTRA or GTADTRB, and up-counting only, down-counting only, or both up-counting and down-counting can be specified.

In event count operation performing, A/D converter start requests interrupt cannot be generated. An A/D converter start request does not direct output to the A/D converter module but results in output to ELC as event signals.

GTADTRA and GTADTRB each have two buffer registers. Buffer operation with GTADTRA combined with GTADTBRA and GTADTDBRA, and buffer operation with GTADTRB combined with GTADTBRB and GTADTDBRB can be performed.

Figure 23.92 shows an example of A/D converter start request operation, and Figure 23.93 shows an example setting for A/D converter start request operation.

23.5 AD转换器启动请求

可以在GTCNT计数器和GTADTRA或GTADTRB之间的比较匹配时发出AD转换器启动请求，并且可以指定仅递增计数、仅递减计数或同时递增计数和递减计数。

在执行事件计数操作时，不能产生AD转换器启动请求中断。AD转换器启动请求不会直接输出到AD转换器模块，而是导致作为事件信号输出到ELC。

GTADTRA和GTADTRB各有两个缓冲寄存器。与GTADTRA相结合的缓冲操作GTADTBRA和GTADTBRA，以及将GTADTRB与GTADTBRB和可以执行GTADTDRBB。

23.6 Operations Linked by the ELC

23.6.1 Event Signal Output to the ELC

The GPT can perform operation linked with another module set in advance when its interrupt request signal is used as an event signal by the Event Link Controller (ELC).

A/D converter start requests can be enabled and disabled individually with each up-counting and down-counting for both interrupts and events output to ELC by enable bits of the interrupt request.

The GPT has the following ELC event signals:

- Generation of compare match A interrupt (GPTn_CCMPA (n = 0 to 12))
- Generation of compare match B interrupt (GPTn_CCMPB (n = 0 to 12))
- Generation of compare match C interrupt (GPTn_CMPC (n = 0 to 12))
- Generation of compare match D interrupt (GPTn_CMPD (n = 0 to 12))
- Generation of compare match E interrupt (GPTn_CMPE (n = 0 to 12))
- Generation of compare match F interrupt (GPTn_CMPF (n = 0 to 12))
- Generation of overflow interrupt (GPTn_OVF (n = 0 to 12))
- Generation of underflow interrupt (GPTn_UDF (n = 0 to 12))
- A/D converter start request A interrupt (GPTn_ADTRGA (n = 0 to 7))
- A/D converter start request B interrupt (GPTn_ADTRGB (n = 0 to 7)).

23.6.2 Event Signal Inputs from the ELC

The GPT can perform the following operations in response to a maximum of eight events from the ELC:

- Start counting, stop counting, clear counting
- Up-counting, down counting
- Input capture.

See section 23.3, Operation for detail on hardware resources.

23.7 Noise Filter Function

Each pin for use in input capture and Hall sensor input to the GPT is equipped with a noise filter. The noise filter samples input signals at the sampling clock and removes the pulses whose length is less than 3 sampling cycles.

The noise filter functionality includes enabling and disabling the noise filter for each pin and setting of the sampling clock for each channel.

Figure 23.94 shows the timing of noise filtering.

23.6 由ELC关联的操作

23.6.1 事件信号输出到ELC

当GPT的中断请求信号被事件链接控制器(ELC)用作事件信号时，GPT可以执行与预先设置的另一个模块链接的操作。

D转换器启动请求可以通过中断请求的使能位单独启用和禁用，每次递增和递减中断和事件输出到ELC。

GPT具有以下ELC事件信号：

- 产生比较匹配A中断(GPTn_CCMPA(n=0to12))
- 产生比较匹配B中断(GPTn_CCMPB(n=0to12))
- 产生比较匹配C中断(GPTn_CMPC(n=0to12))
- 产生比较匹配D中断(GPTn_CMPD(n=0to12))
- 产生比较匹配E中断(GPTn_CMPE(n=0to12))
- 产生比较匹配F中断(GPTn_CMPF(n=0to12))
- 产生溢出中断(GPTn_OVF(n=0to12))
- 产生下溢中断(GPTn_UDF(n=0to12))
- AD转换器启动请求A中断(GPTn_ADTRGA(n=0to7))
- AD转换器启动请求B中断(GPTn_ADTRGB(n=0to7))。

23.6.2 来自ELC的事件信号输入

GPT最多可以执行以下操作以响应来自ELC的八个事件：

- 开始计数，停止计数，清除计数
- 递增计数、递减计数
- 输入捕获。

有关硬件资源的详细信息，请参见第23.3节，操作。

23.7 噪音过滤功能

用于GPT的输入捕捉和霍尔传感器输入的每个引脚都配备了噪声滤波器。噪声滤波器以采样时钟对输入信号进行采样，并去除长度小于3个采样周期的脉冲。

噪声过滤器功能包括为每个引脚启用和禁用噪声过滤器以及为每个通道设置采样时钟。

图23.94显示了噪声过滤的时序。

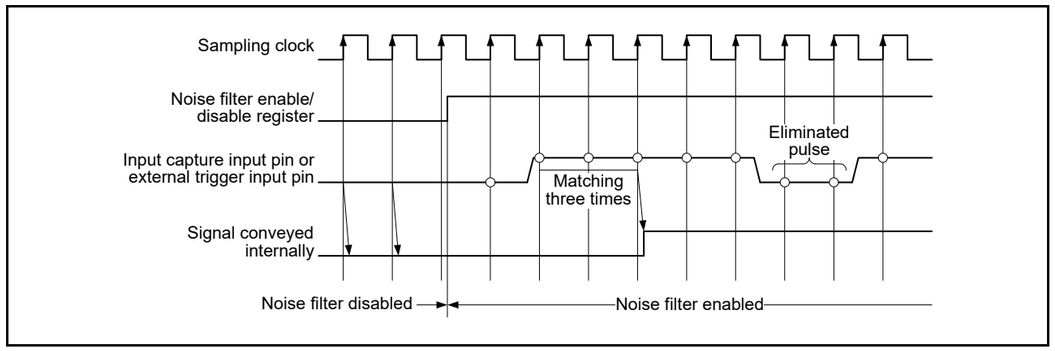

Figure 23.94 Timing of noise filtering

If noise filtering is enabled, the input capture operation or external trigger operation performs on the edges of the noise filtered signal after a delay of a sampling interval × 3 + PCLKD. This is caused by the noise filtering for the input capture input or external trigger operation.

23.8 Protection Function

23.8.1 Write-Protection for Registers

To prevent registers from being accidentally modified, registers can be write-protected in channel units by setting GTWP.WP. Write-protection can be set for the following registers:

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD,GTST, GTBER, GTITC, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTPDBR, GTADTRA, GTADTBRA, GTADTDBRA, GTADTRB, GTADTBRB, GTADTDBRB, GTDTCR, GTDVU, GTDVD, GTDBU, GTDBD, GTSOS, GTSOTR.

23.8.2 Disabling of Buffer Operation

If the timing of buffer register write is delayed relative to the timing for the buffer transfer, buffer operation can be suspended with the GTBER.BD bit setting. Specifically, buffer transfer can be temporarily disabled even when a buffer transfer condition is generated during a buffer register write. This can be done by setting the associated GTBER.BD bit to 1 (buffer operation disabled) before a buffer register write and clearing the bit to 0 (buffer operation enabled) after completion of writing to all the buffer registers.

Figure 23.95 shows an example of operation for disabling buffer operation.

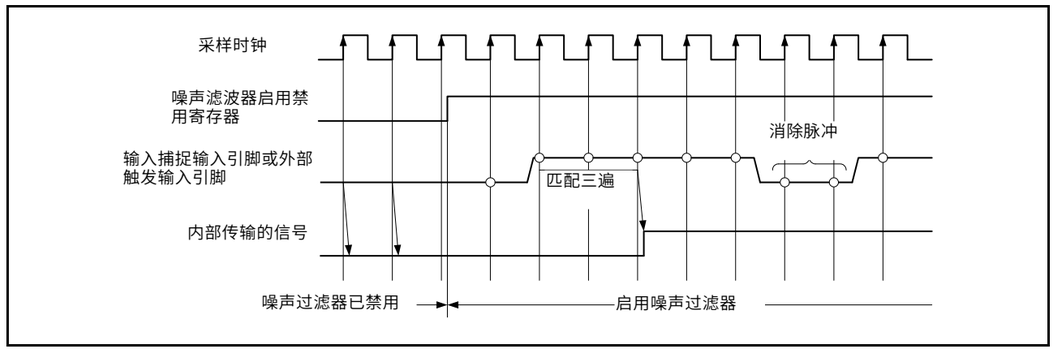

Figure 23.94 噪声过滤的时序

如果噪声过滤使能，输入捕捉操作或外部触发操作在经过一个采样间隔×3+PCLKD的延迟后在噪声过滤信号的边沿上执行。这是由输入捕捉输入或外部触发操作的噪声过滤引起的。

23.8 保护功能

23.8.1 寄存器的写保护

为了防止寄存器被意外修改，可以通过设置以通道为单位对寄存器进行写保护GTWP.WP。可以为以下寄存器设置写保护：

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD,GTST, GTBER, GTITC, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTPDBR, GTADTRA, GTADTBRA, GTADTDBRA, GTADTRB, GTADTBRB, GTADTDBRB, GTDTCR, GTDVU, GTDVD, GTDBU, GTDBD, GTSOS, GTSOTR.

23.8.2 禁用缓冲区操作

如果缓冲寄存器写入的时序相对于缓冲传输的时序延迟，则可以通过GTBER.BD位设置暂停缓冲操作。具体而言，即使在缓冲寄存器写入期间产生了缓冲传送条件，也可以暂时禁用缓冲传送。这可以通过在写入缓冲寄存器之前将相关的GTBER.BD位设置为1（禁用缓冲操作）并在完成对所有缓冲寄存器的写入后将该位清除为0（启用缓冲操作）来完成。

图23.95显示了禁用缓冲区操作的操作示例。

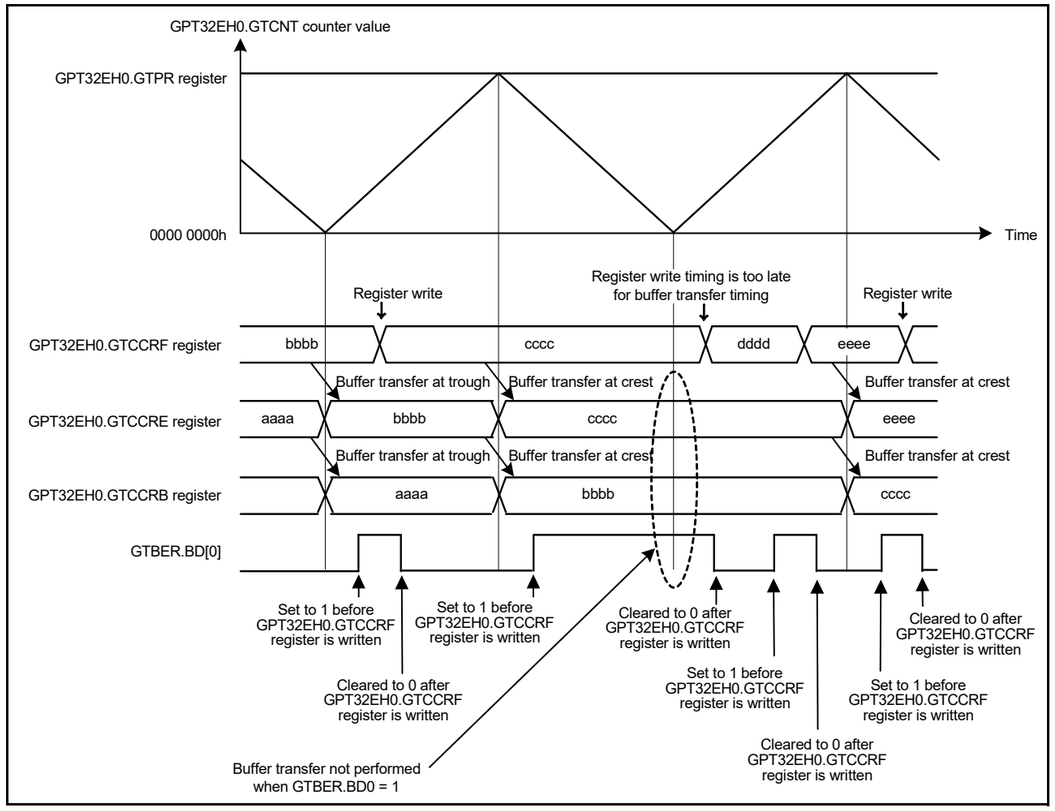

Figure 23.95 Example of operation for disabling buffer operation with triangle waves, double buffer operation, and buffer transfer at both troughs and crests

23.8.3 GTIOC Pin Output Negate Control

For protection from system failure, the output disable control that changes the GTIOC pin output value forcibly is provided for GTIOC pin output by the request of output disable from POEG.

When dead time error occurs or the GTIOCA pin output value is the same as the GTIOCB pin output value, output protection is required. The GPT detects this condition and generates output disable requests to POEG according to the settings in the output disable request permission bits, such as GTINTAD.GRPDTE, GTINTAD.GRPABH, and GTINTAD.GRPABL. After the POEG receives output disable requests from each channel and calculates external input using an OR operation, the POEG generates output disable requests to GPT.

One output disable signal (representing the shared output disable request signal of the GTIOCA pin and the GTIOCB pin) out of four output disable requests generated by the POEG is selected by setting GTINTAD.GRP[1:0]. The status of the selected disable output request is monitored by reading the GTST.ODF bit. The output level during output disable is based on the GTIOR.OADF[1:0] setting for the GTIOCA pin and the GTIOR.OBDF[1:0] setting for the GTIOCB pin.

The change to the output disable state is performed asynchronously by generating the output disable request from the POEG. The release of the output disable state is performed at end of cycle by terminating the output disable request. The timing of release of the output disable state is a minimum of 3 PCLKD cycles after terminating the output disable request. To perform output disable control reliably, allow at least 4 PCLKD cycles after generating the output disable request (by clearing the output disable request flag in POEG) until the output disable request is terminated.

When event count is performed or when the output disable state is to be released immediately without waiting for an end of cycle, GTIOR.OADF[1:0] must be set to 00b (for GTIOCA pin) or GTIOR.OBDF[1:0] must be set to 00b (for GTIOCB pin).

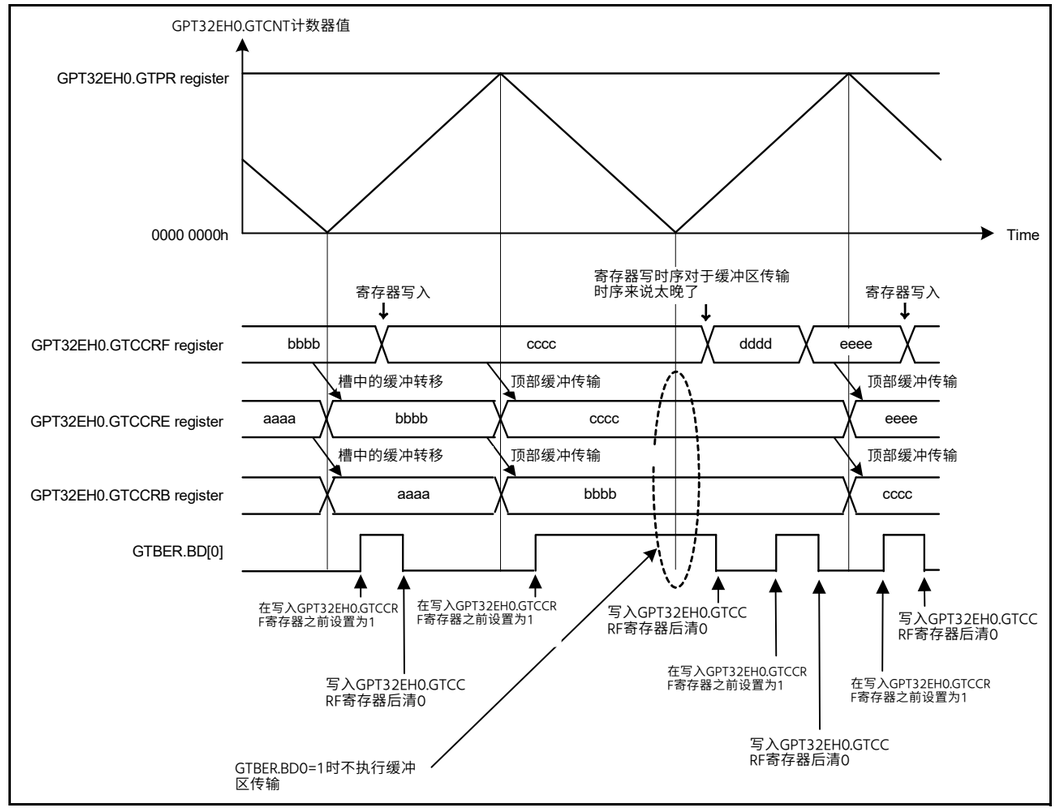

Figure 23.95 三角波缓冲操作、双缓冲操作、波谷和波峰缓冲转移的禁用操作示例

23.8.3 GTIOC引脚输出负控制

为防止系统故障，根据POEG的输出禁用请求，为GTIOC引脚输出提供强制改变GTIOC引脚输出值的输出禁用控制。

当发生死区错误或GTIOCA引脚输出值与GTIOCB引脚输出值相同时，需要输出保护。GPT检测到这种情况并根据输出禁用请求权限位中的设置（例如GTINTAD.GRPDTE、GTINTAD.GRPABH和GTINTAD.GRPABL）向POEG生成输出禁用请求。在POEG接收到来自每个通道的输出禁用请求并使用OR运算计算外部输入后，POEG向GPT生成输出禁用请求。

通过设置GTINTAD.GRP[1:0]，在POEG产生的四个输出禁止请求中选择一个输出禁止信号（代表GTIOCA引脚和GTIOCB引脚的共享输出禁止请求信号）。通过读取GTST.ODF位来监控所选禁用输出请求的状态。输出禁用期间的输出电平基于GTIOCA引脚的GTIOR.OADF[1:0]设置和GTIOCB引脚的GTIOR.OBDF[1:0]设置。

对输出禁用状态的更改是通过从
POEG。通过终止输出禁用请求，在循环结束时执行输出禁用状态的释放。输出禁用状态的释放时间是在终止输出禁用请求后至少3个PCLKD周期。为了可靠地执行输出禁用控制，在生成输出禁用请求后（通过清除POEG中的输出禁用请求标志）至少允许4个PCLKD周期，直到输出禁用请求终止。

当执行事件计数或不等待周期结束而立即释放输出禁用状态时，必须将GTIOR.OADF[1:0]设置为00b（对于GTIOCA引脚）或GTIOR.OBDF[1:0]必须设置为00b（对于GTIOCB引脚）。

Figure 23.96 shows an example of the GTIOC pin output disable control operation.

23.8.4 Output Protection Function for GTIOC Pin Output

In preparation for incorrect settings of the GTCCRA register (settings outside the range of 0 < GTCCRA < GTPR), the output protection function for the GTIOC pin output (disabling function) is activated when the automatic dead time setting (GTDTCR.TDE = 1) is made in triangle-wave mode. The status of the output protection function can be read from GTSOS.SOS[1:0].

Figure 23.97 shows the state transition of the output protection function.

23.8.4 GTIOC引脚输出的输出保护功能

为防止GTCCRA寄存器的错误设置（设置超出0<GTCCRA<GTPR的范围），当自动死区时间设置(GTDTCR.TDE=1)时，将激活GTIOC引脚输出的输出保护功能（禁用功能）是在三角波模式下制作的。输出保护功能的状态可以从GTSOS.SOS[1:0]中读取。

23.8.4.4 Restricted specification of output protection function

The value of the GTCCRA register must be set within the range of (0 < GTCCRA < GTPR) at count start. If an incorrect value is set in the GTCCRA register during counting (a setting outside the range of 0 < GTCCRA < GTPR), the output protection function deactivates the level of one of the positive and negative outputs.

The function does not operate correctly if the following condition is not satisfied:

- 0 < GTCCRA < GTPR when counting starts.

23.8.4.5 Temporary cancellation of output protection function

When the GTSOTR.SOTR bit is set to 1 with GTSOS.SOS[1:0] bits equal to 10b (showing output protection state by GTCCRA ≥ GTPR during buffer transfer at troughs), the output protection function for GTIOCB pin is temporarily canceled. GTSOS.SOS[1:0] bits retain the value of 10b even when the output protection function is canceled. When the SOTR bit is set to 0, the output protection function for GTIOCB pin resumes.

Figure 23.106 shows examples of temporary cancellation of output protection function operation when the GTCCRA ≥ GTPR is set during buffer transfer at troughs.

(4)正常运营期： 比较匹配的切换输出正常执行。

Figure 23.105 峰值缓冲传输期间设置GTCCRA≥GTPR时输出保护功能操作示例，在谷值缓冲传输期间0<GTCCRA <GTPR恢复，低电平有效

23.8.4.4 输出保护功能限制规格

GTCCRA寄存器的值必须在计数开始时设置在(0<GTCCRA<GTPR)的范围内。如果在计数期间在GTCCRA寄存器中设置了不正确的值（设置超出0<GTCCRA<GTPR的范围），则输出保护功能会禁用正输出和负输出之一的电平。

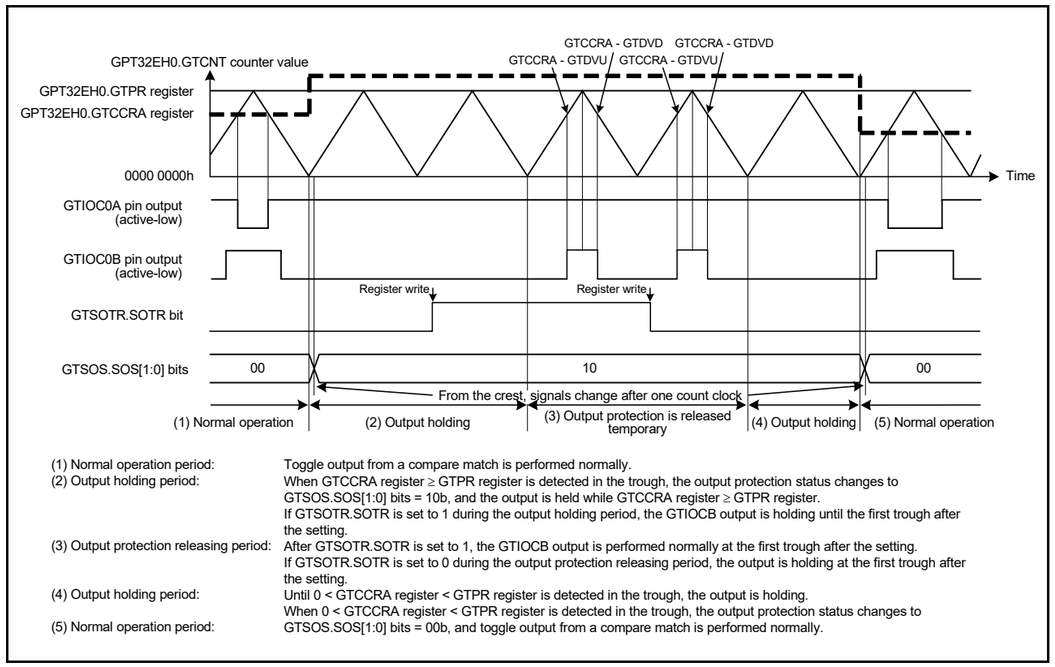
如果不满足以下条件，该功能将无法正常运行：

- 0<GTCCRA<GTPR计数开始时。

23.8.4.5 输出保护功能暂时取消

当GTSOTR.SOTR位设置为1且GTSOS.SOS[1:0]位等于10b时（显示输出保护状态
GTCCRA≥GTPR在低谷缓冲传输期间），GTIOCB引脚的输出保护功能被暂时取消。即使取消了输出保护功能，GTSOS.SOS[1:0]位也保持10b的值。当SOTR位设置为0时，GTIOCB引脚的输出保护功能恢复。

图23.106显示了当GTCCRA≥时输出保护功能操作暂时取消的示例
GTPR在波谷的缓冲区传输期间设置。



(1) Normal operation period:	Toggle output from a compare match is performed normally.
(2) Output holding period:	When GTCCRA register ≥ GTPR register is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 10b, and the output is held while GTCCRA register ≥ GTPR register. (3) Output protection releasing period:	After GTSOTR.SOTR is set to 1, the GTIOCB output is performed normally at the first trough after the setting. If GTSOTR.SOTR is set to 0 during the output protection releasing period, the output is holding at the first trough after the setting.
(4) Output holding period:	Until 0 < GTCCRA register < GTPR register is detected in the trough, the output is holding. When 0 < GTCCRA register < GTPR register is detected in the trough, the output protection status changes to
(5) Normal operation period:	GTSOS.SOS[1:0] bits = 00b, and toggle output from a compare match is performed normally.

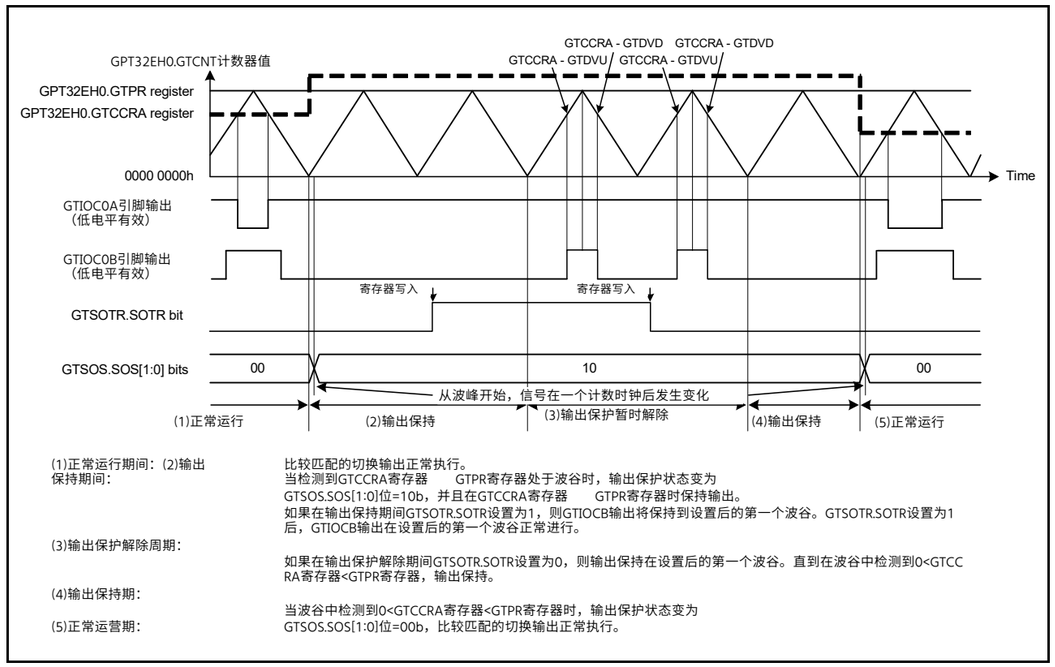
23.9 Initialization Method of Output Pins

23.9.1 Pin Settings after Reset

The GPT registers are initialized at a reset. Start counting after selecting the port pin function with the PmnPFS register, setting GTIOR.OAE and GTIOR.OBE bits, and outputting the GPT function to external pins.



(1)正常运行期间：(2)输出保持期间：	比较匹配的切换输出正常执行。 当检测到GTCCRA寄存器 GTPR寄存器处于波谷时，输出保护状态变为GTSOS.SOS[1:0]位=10b，并且在GTCCRA寄存器 GTPR寄存器时保持输出。 如果在输出保持期间GTSOTR.SOTR设置为1，则GTIOCB输出将保持到设置后的第一个波谷。GTSOTR.SOTR设置为1后，GTIOCB输出在设置后的第一个波谷正常进行。
(3)输出保护解除周期：	如果在输出保护解除期间GTSOTR.SOTR设置为0，则输出保持在设置后的第一个波谷。直到在波谷中检测到0<GTCCRA寄存器<GTPR寄存器，输出保持。
(4)输出保持期：	当波谷中检测到0<GTCCRA寄存器<GTPR寄存器时，输出保护状态变为
(5)正常运营期：	GTSOS.SOS[1:0]位=00b，比较匹配的切换输出正常执行。

23.9 输出管脚的初始化方法

23.9.1 复位后的引脚设置

GPT寄存器在复位时被初始化。通过PmnPFS寄存器选择端口引脚功能，设置GTIOR.OAE和GTIOR.OBE位，并将GPT功能输出到外部引脚后开始计数。

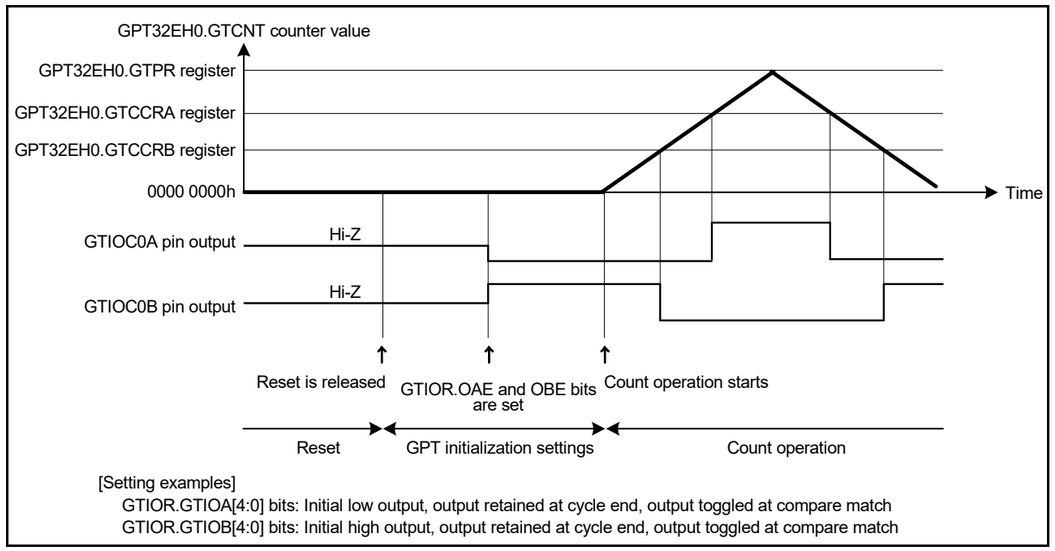

Figure 23.107 Example of pin settings after reset

23.9.2 Pin Initialization Caused by Error during Operation

If an error occurs during GPT operation, the following four types of pin processing can be performed before pin initialization:

- Set the OAHLD and OBHLD bits in GTIOR to 1 and retain the outputs at count stop
- Set the OAHLD and OBHLD bits in GTIOR to 0, specify arbitrary output values of OADFLT and OBDFLT in GTIOR, and output the arbitrary values on count stop
- Set the pin to output an arbitrary value as a general output port by setting the PDR, PODR, and PmnPFS registers of the I/O port in advance. Set the OAE and OBE bits in GTIOR to 0, and the control bit associated with the pin in PmnPFS.PMR to 0 to allow arbitrary values to be output from the pin set as a general output port when an error occurs.
- Drive the output to a high impedance state using the POEG function.

When the automatic dead time setting is made, clear the GTDTCR.TDE bit to 0 after counting stops. When counting stops, only the values of registers that are changed by a GPT external source change. If counting resumes, operation continues from where it stopped. If counting stops, registers must be initialized before counting starts.

23.10 Usage Notes

23.10.1 Module-Stop Function Setting

The Module Stop Control Register can enable or disable GPT operation. The GPT module is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

23.10.2 GTCCRn Settings during Compare Match Operation (n = A to F)

(1) When automatic dead time setting is made in triangle-wave PWM mode

The GTCCRA register must satisfy all of the following conditions:

- GTDVU < GTCCRA
- GTDVD < GTCCRA
- GTCCRA < GTPR.

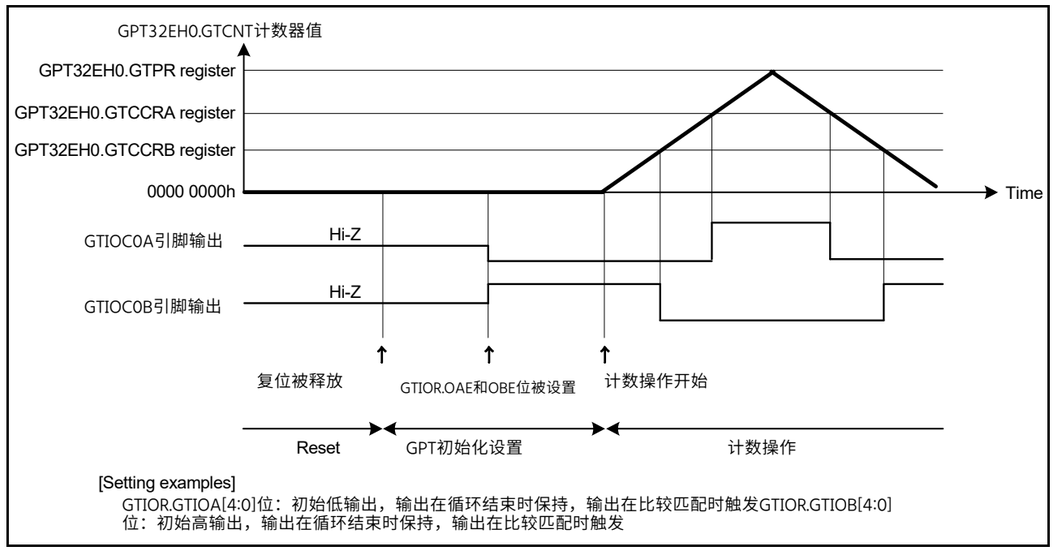

Figure 23.107 复位后的引脚设置示例

23.9.2 操作错误导致的引脚初始化

如果在GPT操作过程中发生错误，可以在引脚初始化之前进行以下四种引脚处理：

- 将GTIOR中的OAHLD和OBHLD位设置为1，并在计数停止时保留输出
- 将GTIOR中的OAHLD和OBHLD位设置为0，指定OADFLT和OBDFLT的任意输出值GTIOR，并在计数停止时输出任意值
- 通过预先设置IO端口的PDR、PODR和PmnPFS寄存器，将引脚设置为输出任意值作为通用输出端口。将GTIOR中的OAE和OBE位设置为0，并将与PmnPFS.PMR中的引脚相关的控制位设置为0，以允许在发生错误时从设置为通用输出端口的引脚输出任意值。
- 使用POEG功能将输出驱动到高阻抗状态。

进行自动死区时间设置时，计数停止后将GTDTCR.TDE位清零。当计数停止时，只有被GPT外部源改变的寄存器的值会改变。如果计数恢复，则操作从停止处继续。如果计数停止，则必须在计数开始前初始化寄存器。

23.10 使用说明

23.10.1 模块停止功能设置

模块停止控制寄存器可以启用或禁用GPT操作。GPT模块在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第11节，低功耗模式。

23.10.2 比较匹配操作期间的GTCCRn设置（n=A到F）

(1) 在三角波PWM模式下进行自动死区时间设置时

GTCCRA寄存器必须满足以下所有条件：

- GTDVU < GTCCRA
- GTDVD < GTCCRA
- GTCCRA < GTPR.

When the setting of GTCCRA = 0 or GTCCRA ≥ GTPR is made during count operation, the output protection function is activated.

However, the function does not operate correctly if the following condition is not satisfied:

- 0 < GTCCRA < GTPR when counting starts.

For details, see section 23.8.4, Output Protection Function for GTIOC Pin Output.

(2) When automatic dead time setting is not made in triangle-wave PWM mode

The GTCCRA register must be set within the range of 0 < GTCCRA < GTPR. If GTCCRA = 0 or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0 or GTCCRA = GTPR is satisfied. When GTCCRA > GTPR, no compare match occurs.

Similarly, GTCCRB must be set within the range of 0 < GTCCRB < GTPR. If GTCCRB = 0 or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB = 0 or GTCCRB = GTPR is satisfied. When GTCCRB > GTPR, no compare match occurs.

(3) When automatic dead time setting is made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, correct output waveforms with secured dead time might not be obtained:

- In up-counting: GTCCRC < GTCCRD, GTCCRC > GTDVU, GTCCRD < GTPR - GTDVD
- In down-counting: GTCCRC > GTCCRD, GTCCRC < GTPR - GTDVU, GTCCRD > GTDVD.

(4) When automatic dead time setting is not made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed:

- In up-counting: 0 < GTCCRC < GTCCRD < GTPR
- In down-counting: GTPR > GTCCRC > GTCCRD > 0.

Similarly, GTCCRE and GTCCRF must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed:

- In up-counting: 0 < GTCCRE < GTCCRF < GTPR
- In down-counting: GTPR > GTCCRE > GTCCRF > 0.

(5) In saw-wave PWM mode

The GTCCRA register must be set with the range of 0 < GTCCRA < GTPR. If GTCCRA = 0 or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0 or GTCCRA = GTPR is satisfied. If GTCCRA > GTPR is set, no compare match occurs.

Similarly, GTCCRB must be set with the range of 0 < GTCCRB < GTPR. If GTCCRB = 0 or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB = 0 or GTCCRB = GTPR is satisfied. If GTCCRB > GTPR is set, no compare match occurs.

23.10.3 Setting Range for the GTCNT Counter

The GTCNT counter register must be set with the range of 0 ≤ GTCNT ≤ GTPR.

23.10.4 Starting and Stopping the GTCNT Counter

The control timing of starting and stopping the GTCNT counter by the GTCR.CST bit synchronizes the count clock that is selected in GTCR.TPCS[2:0]. When GTCR.CST is updated, the GTCNT counter starts/stops after a count clock selected in GTCR.TPCS[2:0]. Therefore, an event generated before the GTCNT counter actually starts is ignored. On the other hand, there might be cases where an event is accepted or an interrupt occurs after GTCR.CST is set to 0.

当在计数操作期间设置GTCCRA=0或GTCCRA≥GTPR时，输出保护功能被激活。

但是，如果不满足以下条件，该功能将无法正常运行：

- 0<GTCCRA<GTPR计数开始时。

有关详细信息，请参见第23.8.4节，GTIOC引脚输出的输出保护功能。

(2) 在三角波PWM模式下未进行自动死区时间设置时

GTCCRA寄存器必须设置在0<GTCCRA<GTPR的范围内。如果设置了GTCCRA=0或GTCCRA=GTPR，则仅当满足GTCCRA=0或GTCCRA=GTPR时，才会在周期内发生比较匹配。当GTCCRA>GTPR时，不发生比较匹配。

同样，GTCCRB必须设置在0<GTCCRB<GTPR的范围内。如果设置了GTCCRB=0或GTCCRB=GTPR，则仅当满足GTCCRB=0或GTCCRB=GTPR时，才会在周期内发生比较匹配。当GTCCRB>GTPR时，不发生比较匹配。

(3) 在锯波单发脉冲模式下进行自动死区时间设置时

GTCCRC和GTCCRD寄存器必须设置为满足以下限制。如果不满足限制条件，则可能无法获得具有安全死区时间的正确输出波形：

- In up-counting: GTCCRC < GTCCRD, GTCCRC > GTDVU, GTCCRD < GTPR - GTDVD
- In down-counting: GTCCRC > GTCCRD, GTCCRC < GTPR - GTDVU, GTCCRD > GTDVD.

(4) 在锯波单发脉冲模式下未进行自动死区时间设置时

GTCCRC和GTCCRD寄存器必须设置为满足以下限制。如果不满足限制，则不会发生两次比较匹配，并且无法执行脉冲输出：

- In up-counting: 0 < GTCCRC < GTCCRD < GTPR
- In down-counting: GTPR > GTCCRC > GTCCRD > 0.

同样，必须设置GTCCRE和GTCCRF以满足以下限制。如果不满足限制，则不会发生两次比较匹配，并且无法执行脉冲输出：

- In up-counting: 0 < GTCCRE < GTCCRF < GTPR
- In down-counting: GTPR > GTCCRE > GTCCRF > 0.

(5) 在锯齿波PWM模式下

GTCCRA寄存器必须设置为0<GTCCRA<GTPR。如果设置了GTCCRA=0或GTCCRA=GTPR，则仅当满足GTCCRA=0或GTCCRA=GTPR时，才会在周期内发生比较匹配。如果设置了GTCCRA>GTPR，则不会发生比较匹配。

类似地，GTCCRB必须设置在0<GTCCRB<GTPR的范围内。如果设置了GTCCRB=0或GTCCRB=GTPR，则仅当满足GTCCRB=0或GTCCRB=GTPR时，才会在周期内发生比较匹配。如果设置了GTCCRB>GTPR，则不会发生比较匹配。

23.10.3 GTCNT计数器的设置范围

GTCNT计数器寄存器的设置范围必须为0≤GTCNT≤GTPR。

23.10.4 启动和停止GTCNT计数器

通过GTCR.CST位启动和停止GTCNT计数器的控制时序与在GTCR.TPCS[2:0]中选择的计数时钟同步。当GTCR.CST更新时，GTCNT计数器在GTCR.TPCS[2:0]中选择的计数时钟后开始停止。因此，在GTCNT计数器实际启动之前生成的事件将被忽略。另一方面，在GTCR.CST设置为0之后，可能会接受事件或发生中断。

23.10.5 Priority Order of Each Event

(1) GTCNT register

Table 23.24 shows a priority order of events updating GTCNT register.

Table 23.24 Priority order of sources updating GTCNT

Source updating GTCNT	Priority order
Writing by CPU (writing to GTCNT/GTCLR)	High ↑
Clear by hardware sources set in GTCSR	
Count up or down by hardware sources set in GTUPSR/GTDNSR	
Count operation	Low ↓

If up-counting and down-counting by hardware sources occur at the same time, the GTCNT counter value does not change. When there is a conflict between updating the GTCNT register and reading by the CPU, pre-update data is read.

(2) GTCR.CST bit

When there is a conflict between starting/stopping by hardware sources set in the GTSSR/GTPSR registers and writing by the CPU (writing to GTCR/GTSTR/GTSTP registers), writing by CPU has priority over starting/stopping by hardware sources.

When there is a conflict between starting by hardware sources set in the GTSSR register and stopping by hardware sources set in GTPSR register, the GTCR.CST bit value does not change. Where there is a conflict between updating the GTCR.CST bit and reading by the CPU, pre-update data is read.

(3) GTCCRm registers (m = A to F)

When there is a conflict between input capture/buffer transfer operation and writing to GTCCRm registers, writing to GTCCRm registers has priority over input capture/buffer transfer operation. When there is a conflict between input capture and writing to the counter register by the CPU or updating the counter register by hardware sources, the pre-update counter value is captured. Where there is a conflict between updating the GTCCRm registers and reading by the CPU, pre-update data is read.

(4) GTPR registers

When there is a conflict between buffer transfer operation and writing to the GTPR register, writing to GTPR register has priority over buffer transfer operation. When there is a conflict between updating GTPR register and reading by the CPU, pre-update data is read.

(5) GTADTRm registers (m = A, B)

When there is a conflict between buffer transfer operation and writing to the GTADTRm registers, writing to the GTADTRm registers has priority over buffer transfer operation. When there is a conflict between updating GTADTRm registers and reading by the CPU, pre-update data is read.

(6) GTDVm registers (m = U, D)

When there is a conflict between buffer transfer operation and writing to GTDVm registers, writing to GTDVm registers has priority over buffer transfer operation. When there is a conflict between updating GTDVm registers and reading by the CPU, pre-update data is read.

23.10.5 每个事件的优先顺序

(1) GTCNT register

表23.24显示了更新GTCNT寄存器的事件的优先级顺序。

Table 23.24 更新GTCNT的源的优先顺序

源更新GTCNT	优先顺序
CPU写入（写入GTCNTGTCLR）	High ↑
由GTCSR中设置的硬件源清除	
通过GTUPSRGTDNSR中设置的硬件源进行向上或向下计数	
计数操作	Low ↓

如果硬件源的递增计数和递减计数同时发生，GTCNT计数器值不会改变。当更新GTCNT寄存器和CPU读取之间存在冲突时，会读取更新前的数据。

(2) GTCR.CST bit

当GTSSRGTPSR寄存器中设置的硬件源启动停止与CPU写入（写入GTCRGTSTRGTSTP寄存器）发生冲突时，CPU写入优先于硬件源启动停止。

当GTSSR寄存器中设置的硬件源启动和GTPSR寄存器中设置的硬件源停止之间存在冲突时，GTCR.CST位的值不会改变。如果更新GTCR.CST位与CPU读取之间存在冲突，则读取更新前的数据。

(3) GTCCRm寄存器（m=A到F）

当输入捕捉缓冲区传输操作和写入GTCCRm寄存器之间存在冲突时，写入GTCCRm寄存器优先于输入捕捉缓冲区传输操作。当输入捕获与CPU写入计数器寄存器或硬件源更新计数器寄存器之间存在冲突时，会捕获更新前的计数器值。如果更新GTCCRm寄存器和CPU读取之间存在冲突，则读取更新前的数据。

(4) GTPR registers

当缓冲区传输操作与写入GTPR寄存器之间存在冲突时，写入GTPR寄存器优先于缓冲区传输操作。当更新GTPR寄存器与CPU读取发生冲突时，读取更新前的数据。

(5) GTADTRm registers (m = A, B)

当缓冲区传输操作和写入GTADTRm寄存器之间存在冲突时，写入GTADTRm寄存器优先于缓冲区传输操作。当更新GTADTRm寄存器与CPU读取之间存在冲突时，会读取更新前的数据。

(6) GTDVm registers (m = U, D)

当缓冲区传输操作和写入GTDVm寄存器之间存在冲突时，写入GTDVm寄存器优先于缓冲区传输操作。当更新GTDVm寄存器和CPU读取之间存在冲突时，会读取更新前的数据。

DLYBSn (n = 0 to 3) bit (PWM Delay Generation Circuit Bypass for channel n)

The DLYBSn bit selects whether delays are applied to PWM output signals from the GTIOCnA and GTIOCnB pins (n = 0 to 3) by the PWM delay generation circuit or whether the circuit is bypassed.

A signal delayed in the PWM delay generation circuit is output 3 PCLKD cycles of GPT operation clock later than if it bypasses the PWM delay generation circuit.

24.3.1 PWM波形上升沿和下降沿时序的调整

从GTIOCnA和GTIOCnB引脚输出的PWM波形的上升沿和下降沿时序（其中n=通道数）可以延迟到GPT工作时钟(PCLKD)周期的1×32的精度。

如果必须调整从GTIOCnA和GTIOCnB引脚输出的PWM波形的上升沿或下降沿时序，请按照图24.2中的步骤初始化PWM生成电路。

In the PWM delay generation circuit, delay can be applied to rising and falling edges of the PWM output to an accuracy of 1/32 of the period of the GPT operation clock (PCLKD). This is described in section 23.3.3, PWM Output Operating Mode. Delays associated with the settings are reflected in the PWM output with the timing described in section 24.3.2, Timing for Transfer of GTDLYRnA, GTLDYRnB, GTDLYFnA, and GTDLYFnB Register Settings.

When the PWM delay generation circuit is in use, the timing with which a PWM output signal rises and falls can be controlled to an accuracy of 1/32 of the period of the GPT operation clock (PCLKD). When this option is not in use, the period of the PWM output waveform is controlled to an accuracy of one period of the input clock for the timer counter, which is PCLKD. With the PWM delay generation circuit, the output can be controlled to an accuracy 32 times better. Additionally, the delay settings also control the periods at high and low level for the PWM waveform to the given accuracy. PWM delay generation circuit channels can be individually enabled or disabled.

当使用PWM延迟产生电路时，PWM输出信号上升和下降的时序可以控制在GPT操作时钟(PCLKD)周期的1×32精度。不使用该选项时，PWM输出波形的周期被控制为定时器计数器输入时钟（即PCLKD）的一个周期的精度。使用PWM延迟产生电路，可以将输出控制精度提高32倍。此外，延迟设置还控制PWM波形的高电平和低电平周期，以达到给定的精度。PWM延迟生成电路通道可以单独启用或禁用。

24.3.2 Timing for Transfer of GTDLYRnA, GTLDYRnB, GTDLYFnA, and GTDLYFnB Register Settings

Settings for the GTDLYRnA, GTLDYRnB, GTDLYFnA, and GTDLYFnB registers are initially transferred to temporary registers, and then reflected in the delay on the GTIOCnA and GTIOCnB (n = 0 to 3) outputs. Transfer of the settings takes place on overflows (in up-counting) or underflows (in down-counting) for saw waves, and in the troughs of triangle waves.

Figure 24.3 and Figure 24.4 show examples of the operation of the GTDLYR0A and GTDLYF0A registers.

24.4 Usage Notes

24.4.1 Module-Stop Function Settings

The Module Stop Control Register D (MSTPCRD) can enable or disable operation of the PWM delay generation circuit. The PWM delay generation circuit is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

24.4.2 Notes on Delay Settings for PWM Delay Generation Circuit

When the PWM delay generation circuit generates delays for a PWM output waveform and the waveform is toggled in response to compare-matches, do not change the settings for delay while the compare-match value is within the ranges listed in Table 24.4. This constraint applies to the GTDLYFnA, GTDLYRnA, GTDLFnB, and GTDLYRnB registers.

Table 24.4 Constraints on delay settings

Mode	Direction of counting	Compare-match value
Saw-wave mode	Up	GTPR - 2 or above
	Down	2 or below
Triangle-wave mode	Down	2 or below

Figure 24.5 shows an example of how the constraints apply to the timing of setting GTDLYFnA in saw-wave waveform one-shot pulse mode (counting up). Do not change the value set in GTDLYFnA while GTCCRD ≥ GTPR - 2.

24.4.2 PWM延迟产生电路的延迟设置注意事项

当PWM延迟生成电路为PWM输出波形产生延迟并且波形响应比较匹配而切换时，当比较匹配值在表24.4中列出的范围内时，请勿更改延迟设置。此约束适用于GTDLYFnA、GTDLYRnA、GTDLFnB和GTDLYRnB寄存器。

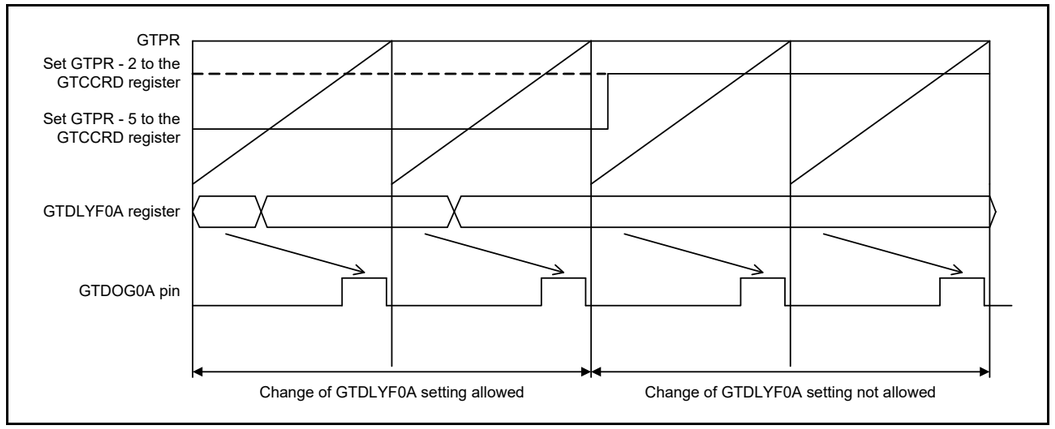

Figure 24.5 Constraints on the timing of GTDLYF0A register settings

Changing the values in the GTDLYFnA, GTDLYRnA, GTDLYFnB, and GTDLYRnB registers during periods where changes to settings are not allowed, might lead to faulty output waveforms such as shifts in the timing of output waveform transitions from the expected values.

25.1 Overview

异步通用定时器(AGT)是一个16位定时器，可用于脉冲输出、外部脉冲宽度或周期测量以及外部事件计数。

这个16位定时器由一个重载寄存器和一个递减计数器组成。重载寄存器和递减计数器分配在同一个地址，可以通过AGT寄存器访问。

表25.1列出了AGT规格，图25.1显示了框图，表25.2列出了IO引脚。

25.2 Register Descriptions

25.2.1 AGT Counter Register (AGT)

Address(es): AGT0.AGT 4008 4000h, AGT1.AGT 4008 4100h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Description	Setting range	R/W
b15 to b0	16-bit counter and reload register *1, *2	0000h to FFFFh	R/W

Note 1. When 1 is written to the TSTOP bit in the AGTCR register, the 16-bit counter is forcibly stopped and set to FFFFh.
Note 2. When the TCK[2:0] bit setting in the AGTMR1 register is a value other than 001b (PCLKB/8) or 011b (PCLKB/2), if the AGT register is set to 0000h, a request signal to the ICU, the DTC, and the ELC is generated once immediately after the count starts. The AGTOn and AGTIOn outputs are toggled.
When the AGT register is set to 0000h in event counter mode, regardless of the value of TCK[2:0] bits, a request signal to the ICU, the DTC, and the ELC is generated once immediately after the count starts.
In addition, the AGTOn output toggles even during a period other than the specified count period. When the AGT register is set to 0001h or more, a request signal is generated each time AGT underflows.

AGT is a 16-bit register. The write value is written to the reload register and the read value is read from the counter.

The states of the reload register and the counter change according to the TSTART bit in the AGTCR register and TCMEA/TCMEB bit in the AGTCMSR register. For details, see section 25.3.1, Reload Register and Counter Rewrite Operation. The AGT register can be set with a 16-bit memory manipulation instruction.

25.2.2 AGT Compare Match A Register (AGTCMA)

Bit	Description	Setting range	R/W
b15 to b0	16-bit compare match A data is stored.*1	0000h to FFFFh	R/W

Note 1. Set the AGTCMA register to FFFFh when the compare match A is not used.

The AGTCMA register is a read/write register to set a value for compare match with the AGT counter. The states of the reload register and compare register A change according to the TSTART bit in the AGTCR register. For details, see section 25.3.2, Reload Register and Compare Register A/B Rewrite Operation. The AGTCMA register can be set by a 16-bit memory manipulation instruction.

25.2 注册说明

25.2.1 AGT计数器寄存器(AGT)

Bit	Description	设定范围	R/W
b15 to b0	16位计数器和重载寄存器*1 *2	0000h to FFFFh	R/W

Note 1. 当AGTCR寄存器的TSTOP位写入1时，16位计数器被强制停止并设置为FFFFh。
Note 2. 当AGTMR1寄存器中的TCK[2:0]位设置为001b(PCLKB8)或011b(PCLKB2)以外的值时，如果AGT寄存器设置为0000h，则向ICU、DTC、并在计数开始后立即生成一次ELC。AGTOn和AGTIOn输出被切换。

当AGT寄存器在事件计数器模式下设置为0000h时，无论TCK[2:0]位的值如何，都会在计数开始后立即生成一次对ICU、DTC和ELC的请求信号。
此外，即使在指定计数周期以外的周期内，AGTOn输出也会切换。当AGT寄存器设置为0001h或更大时，每次AGT下溢时都会产生一个请求信号。

AGT是一个16位的寄存器。写入值写入重载寄存器，读取值从计数器中读取。

重载寄存器和计数器的状态根据AGTCR寄存器中的TSTART位和AGTCMSR寄存器中的TCMEATCMEB位。有关详细信息，请参阅第25.3.1节，重新加载寄存器和计数器重写手术。AGT寄存器可通过16位存储器操作指令进行设置。

Note 2. When count source is AGTSCLK/AGTLCLK, the switch of CKS[2:0] is valid.
Note 3. Do not switch the TCK[2:0] bits in the AGTMR1 register when CKS[2:0] are not 000b. Switch the TCK[2:0] bits in the AGTMR1 register after CKS[2:0] are set to 000b, and wait for 1 cycle of the count source.

LPM bit (Low Power Mode)

The LPM bit sets the low power operation, which impacts access to certain AGT registers. Set this bit to 1 to operate in low power. When this bit is 1, access to the following registers is prohibited:

- AGT/AGTCMA/AGTCMB/AGTCR.

After this bit is switched from 1 to 0, the first access to the register is constrained as follows:

- AGT — Read AGT register twice. Only the second reading of data is valid.
- AGT, AGTCMA, AGTCMB, and AGTCR — Allow at least 2 cycles of the count source clock when writing to the register.

Note 3. 当CKS[2:0]不是000b时，不要切换AGTMR1寄存器中的TCK[2:0]位。在CKS[2:0]设置为000b后，切换AGTMR1寄存器中的TCK[2:0]位，并等待计数源的1个周期。

LPM位（低功耗模式）

LPM位设置低功耗操作，这会影响对某些AGT寄存器的访问。将此位设置为1以在低功耗下工作。该位为1时，禁止访问以下寄存器：

- AGT/AGTCMA/AGTCMB/AGTCR.

该位由1变为0后，对寄存器的第一次访问受到如下约束：

- AGT—读取AGT寄存器两次。只有第二次读取数据是有效的。
- AGT、AGTCMA、AGTCMB和AGTCR—写入寄存器时允许至少2个计数源时钟周期。

25.3 Operation

25.3.1 Reload Register and Counter Rewrite Operation

Regardless of the operating mode, the timing of the rewrite operation to the reload register and the counter differs depending on the value of the TSTART bit in the AGTCR register and of the TCMEA and TCMEB bit in the AGTCMSR register. When the TSTART bit is 0 (count stops), the count value is directly written to the reload register and the counter. When the TSTART bit is 1 (count starts) and the TCMEA and TCMEB bits are 0 (compare match A/B registers are invalid), the value is written to the reload register in synchronization with the count source, and then to the counter in synchronization with the next count source. When the TSTART bit is 1 (count starts) and the TCMEA or TCMEB bit is 1 (compare match A register or compare match B register is valid), the value is written to the reload register in synchronization with the count source, and then to the counter in synchronization with the underflow of the counter.

25.3 Operation

25.3.1 重载寄存器和计数器重写操作

无论工作模式如何，对重载寄存器和计数器的重写操作的时序根据AGTCR寄存器中的TSTART位以及AGTCMSR寄存器中的TCMEA和TCMEB位的值而有所不同。当TSTART位为0（计数停止）时，计数值直接写入重载寄存器和计数器。当TSTART位为1（计数开始）且TCMEA和TCMEB位为0（比较匹配AB寄存器无效）时，将值与计数源同步写入重载寄存器，然后与计数源同步写入计数器下一个计数源。当TSTART位为1（计数开始）且TCMEA或TCMEB位为1（比较匹配A寄存器或比较匹配B寄存器有效）时，该值与计数源同步写入重载寄存器，然后计数器与计数器的下溢同步。

图25.2和图25.3显示了使用TSTART位值和TCMEATCMEB位值进行重写操作的时序。

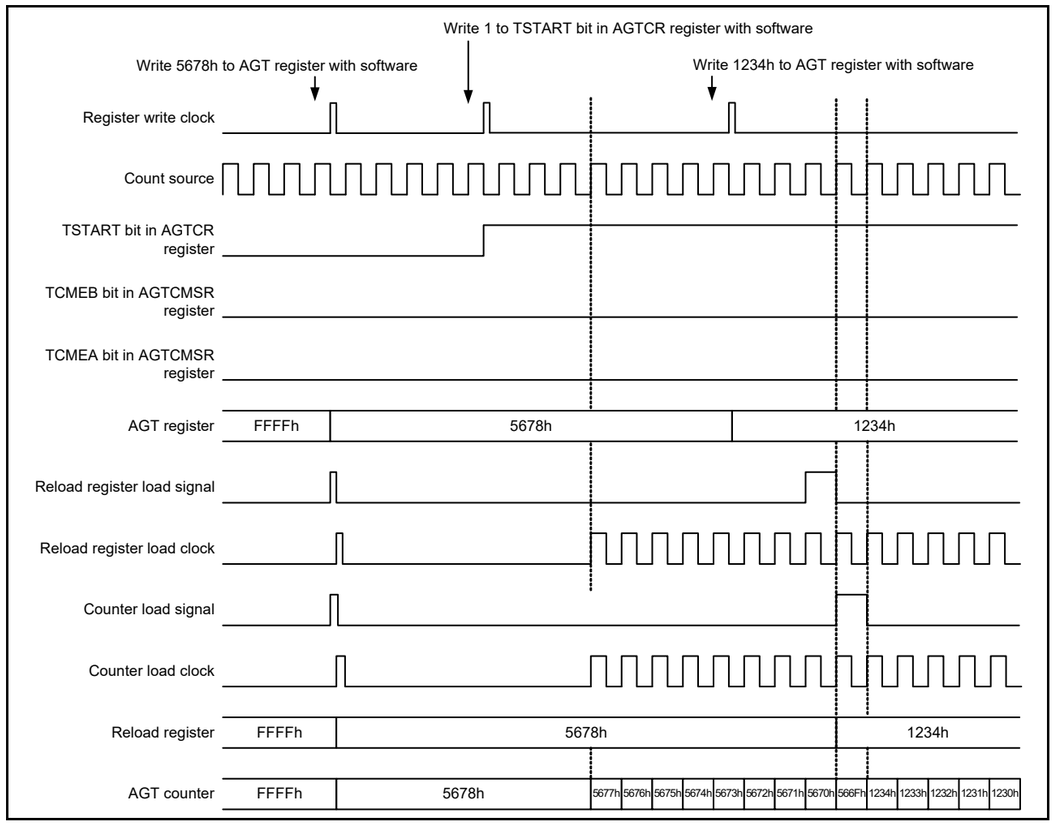

Figure 25.2 Timing of rewrite operation with TSTART bit value and TCMEA or TCMEB bit value when compare match register A or compare match B register is invalid

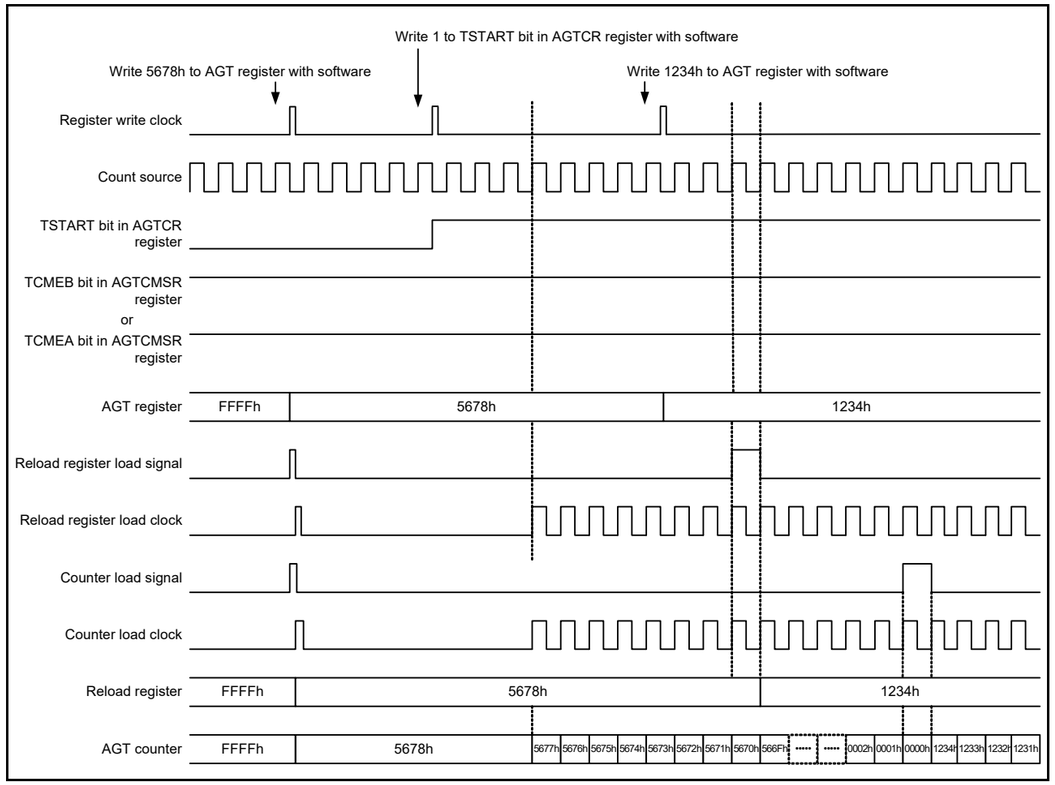

Figure 25.3 Timing of rewrite operation with TSTART bit value and TCMEA or TCMEB bit value when compare match register A or compare match B register is valid

25.3.2 Reload Register and Compare Register A/B Rewrite Operation

Regardless of the operating mode, the timing of the rewrite operation to compare register A/B depends on the value of the TSTART bit in the AGTCR register. When the TSTART bit is 0 (count stops), the count value is directly written to the reload register and compare register A/B. When the TSTART bit is 1 (count starts), the value is written to the reload register in synchronization with the count source, and then to the compare register in synchronization with the underflow of the counter.

Figure 25.4 shows the timing of rewrite operation with TSTART bit value for compare register A. Compare register B has the same timing as compare register A.

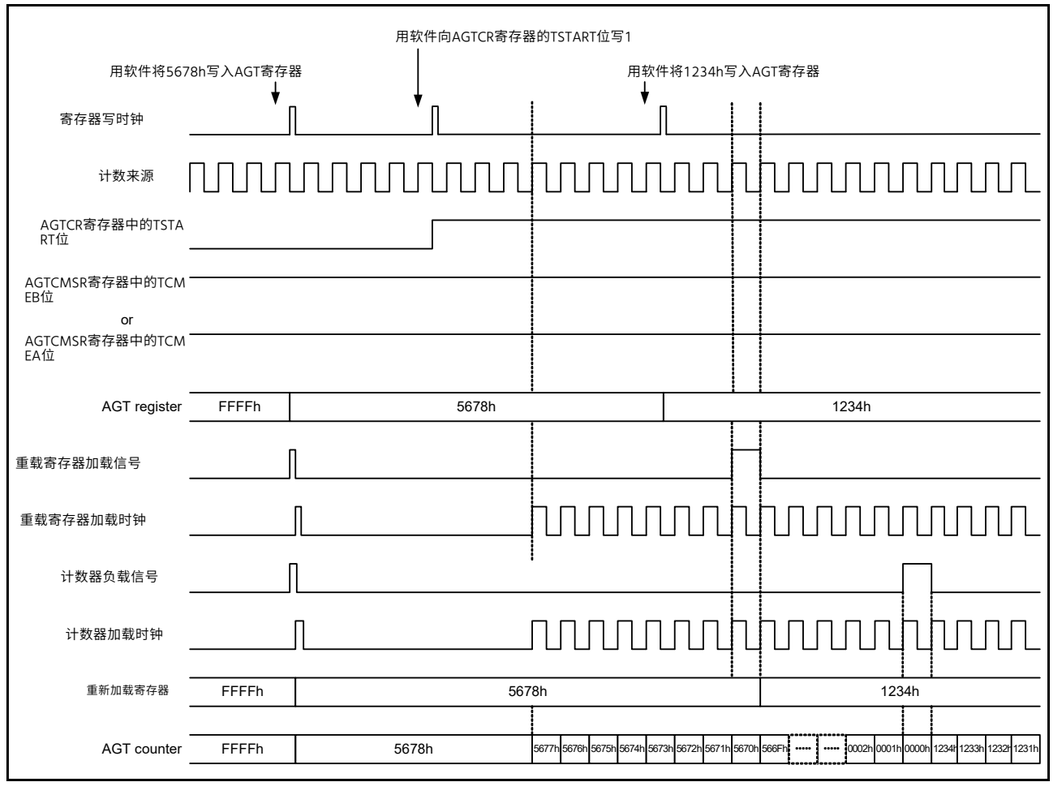

Figure 25.3 当比较匹配寄存器A或比较匹配B寄存器有效时，使用TSTART位值和TCMEA或TCMEB位值进行重写操作的时序

25.3.2 重载寄存器和比较寄存器AB重写操作

不管操作模式如何，对比较寄存器AB的重写操作的时序取决于AGTCR寄存器中TSTART位的值。当TSTART位为0（计数停止）时，将计数值直接写入重载寄存器和比较寄存器AB。当TSTART位为1（开始计数）时，将值同步写入重载寄存器计数源，然后与计数器的下溢同步到比较寄存器。

图25.4显示了比较寄存器A的TSTART位值的重写操作时序。比较寄存器B的时序与比较寄存器A的时序相同。

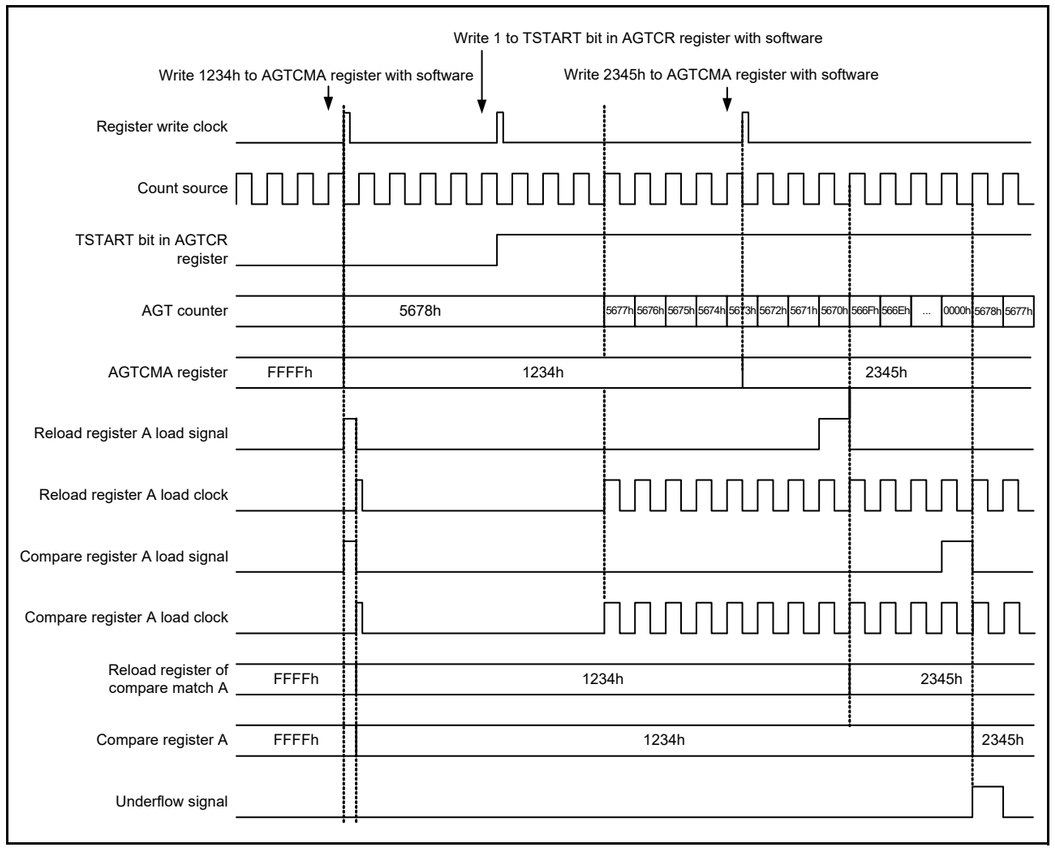

Figure 25.4 Timing of rewrite operation with the TSTART bit value for compare register A

25.3.3 Timer Mode

In timer mode, the AGT counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register. In timer mode, the count value is decremented by 1 on each rising edge of the count source. When the count value reaches 0000h and the next count source is input, an underflow occurs and an interrupt request is generated.

Figure 25.5 shows the operation example in timer mode.

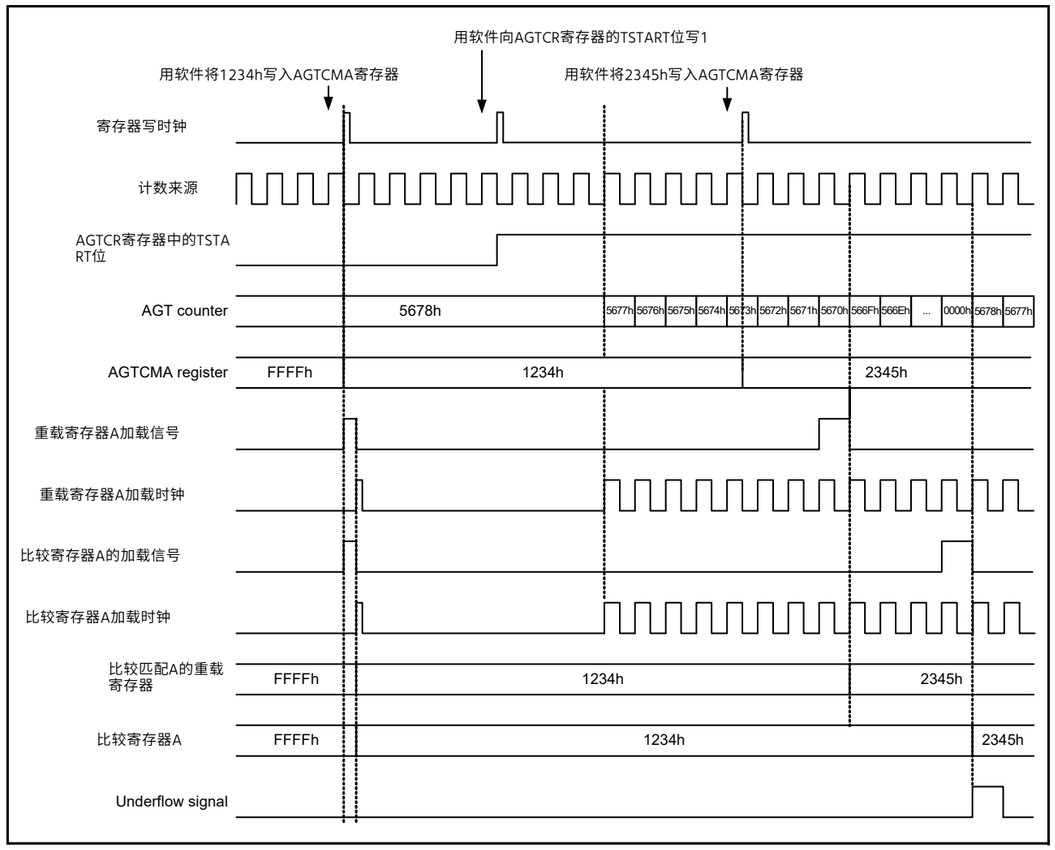

Figure 25.4 比较寄存器A的TSTART位值的重写操作时序

25.3.3 定时器模式

在定时器模式下，AGT计数器由AGTMR1寄存器中的TCK[2:0]位选择的计数源递减。在定时器模式下，计数值在计数源的每个上升沿减1。当计数值达到0000h并输入下一个计数源时，发生下溢并产生中断请求。

图25.5显示了定时器模式下的操作示例。

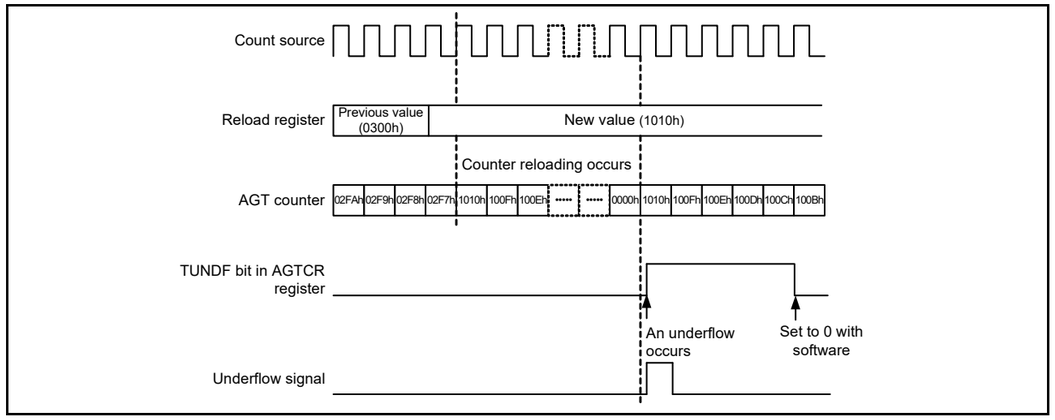

Figure 25.5 Operation example in timer mode

25.3.4 Pulse Output Mode

In pulse output mode, the counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register, and the output level of the AGTIOn and AGTOn pins is inverted each time an underflow occurs.

In pulse output mode, the count value is decremented by 1 on each rising edge of the count source. When the count value reaches 0000h and the next count source is input, an underflow occurs and an interrupt request is generated. In addition, a pulse can be output from the AGTIOn and AGTOn pins. The output level is inverted each time an underflow occurs. The pulse output from the AGTOn pin can be stopped with the TOE bit in the AGTIOC register. The output level can be selected with the TEDGSEL bit in the AGTIOC register.

Figure 25.6 shows the operation example in pulse output mode.

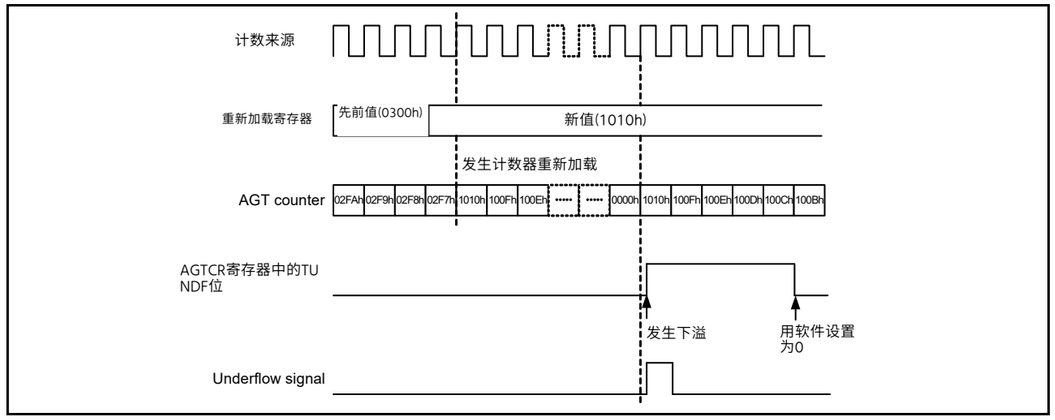

Figure 25.5 定时器模式下的操作示例

25.3.4 脉冲输出方式

在脉冲输出模式下，计数器由AGTMR1寄存器中的TCK[2:0]位选择的计数源递减，每次发生下溢时，AGTIOn和AGTOn引脚的输出电平反转。

在脉冲输出模式下，计数值在计数源的每个上升沿减1。当计数值达到0000h并输入下一个计数源时，发生下溢并产生中断请求。此外，可以从AGTIOn和AGTOn引脚输出脉冲。每次发生下溢时，输出电平都会反转。AGTOn引脚的脉冲输出可通过AGTIOC寄存器中的TOE位停止。可以通过AGTIOC寄存器中的TEDGSEL位选择输出电平。

图25.6显示了脉冲输出模式下的操作示例。

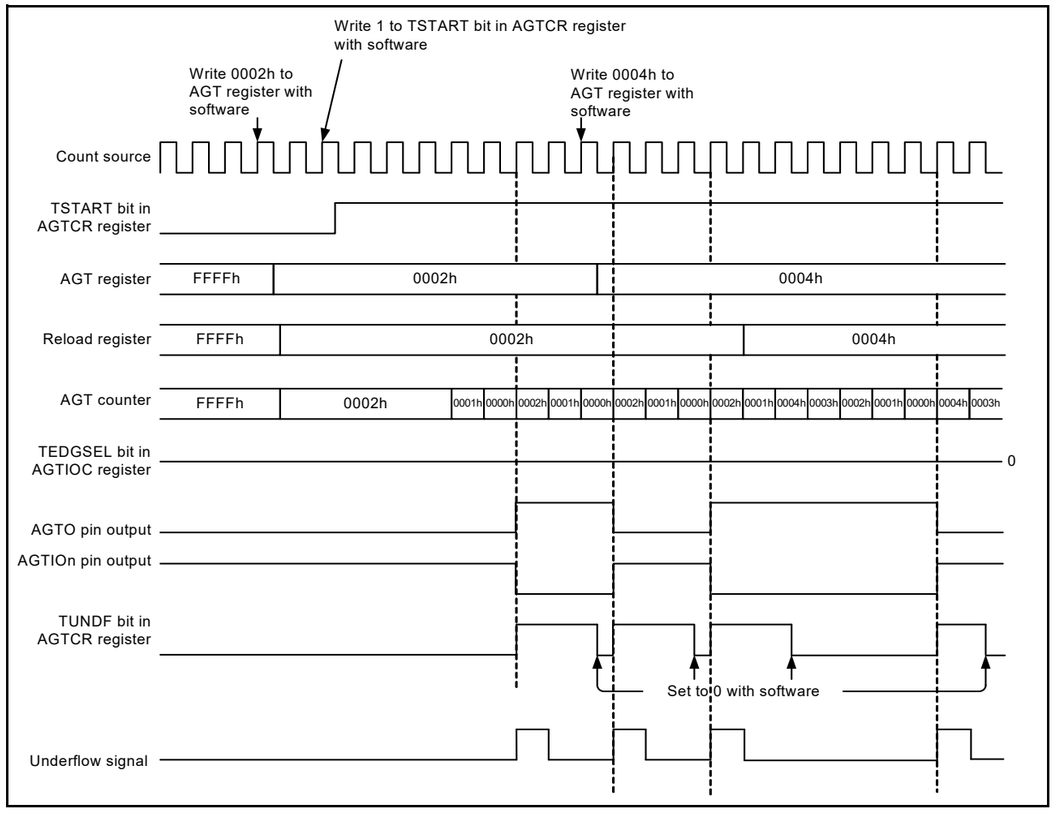

Figure 25.6 Operation example in pulse output mode

25.3.5 Event Counter Mode

In event counter mode, the counter is decremented by an external event signal (count source) input to the AGTIOn pin. Various periods for counting events can be set with the TIOGT[1:0] bits in the AGTIOC and AGTISR registers. In addition, the filter function for the AGTIOn input can be specified with the TIPF[1:0] bits in the AGTIOC register. The output from the AGTOn pin can be toggled even in event counter mode.

Figure 25.7 shows the operation example in event counter mode.

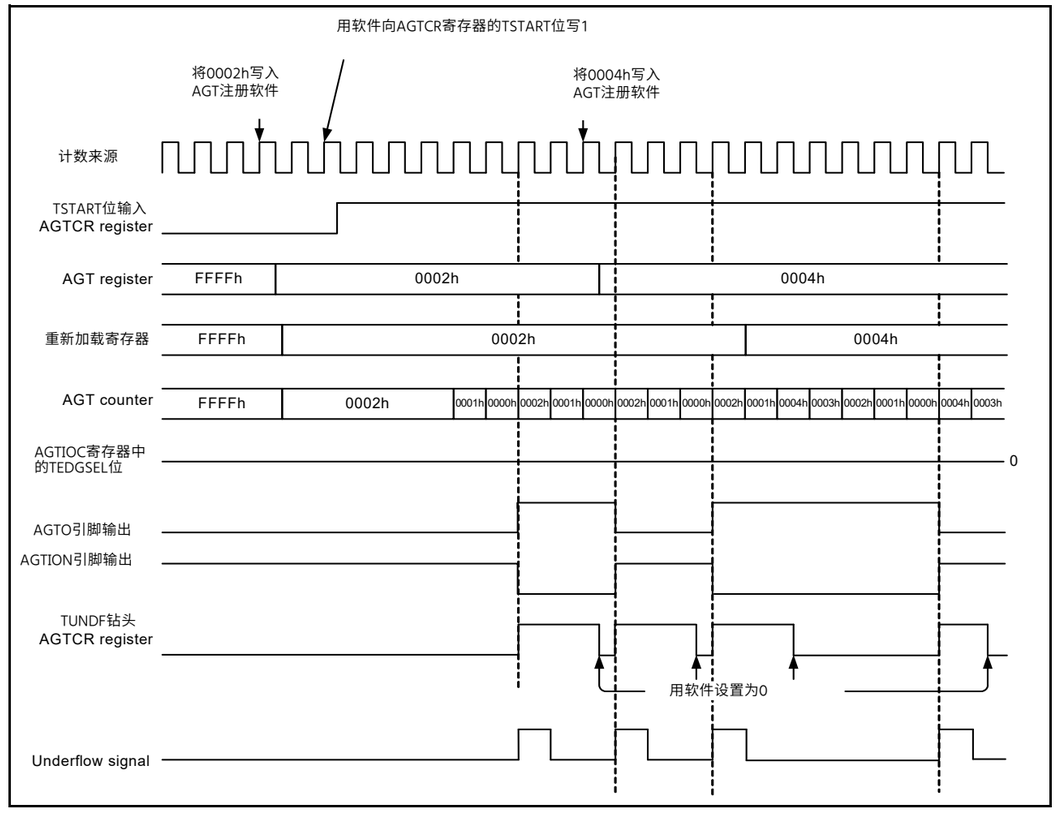

Figure 25.6 脉冲输出模式的动作示例

25.3.5 事件计数器模式

在事件计数器模式下，计数器由输入到AGTIOn引脚的外部事件信号（计数源）递减。可以使用AGTIOC和AGTISR寄存器中的TIOGT[1:0]位设置计数事件的各种周期。此外，可以使用AGTIOC寄存器中的TIPF[1:0]位指定AGTIOn输入的过滤器功能。即使在事件计数器模式下，也可以切换AGTOn引脚的输出。

图25.7显示了事件计数器模式下的操作示例。

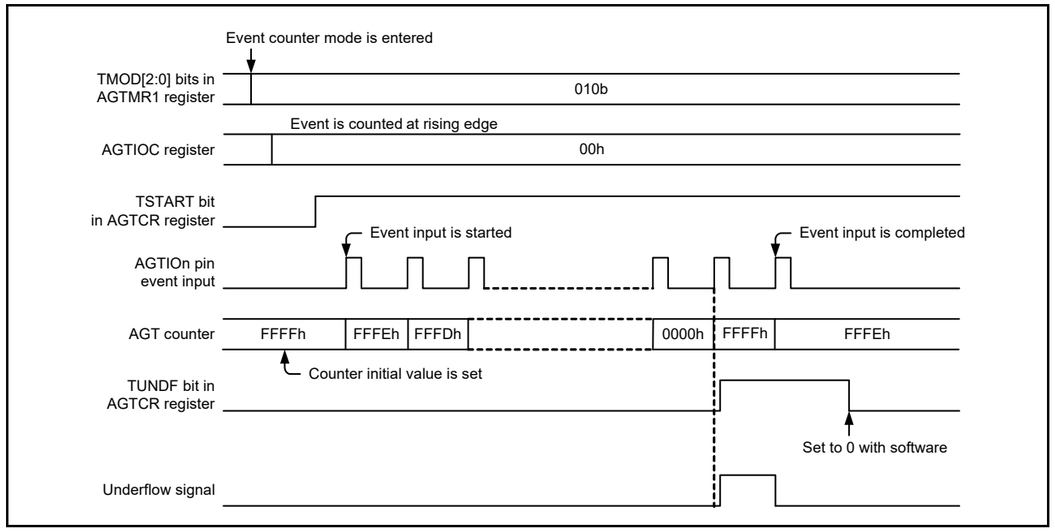

Figure 25.7 Operation example 1 in event counter mode

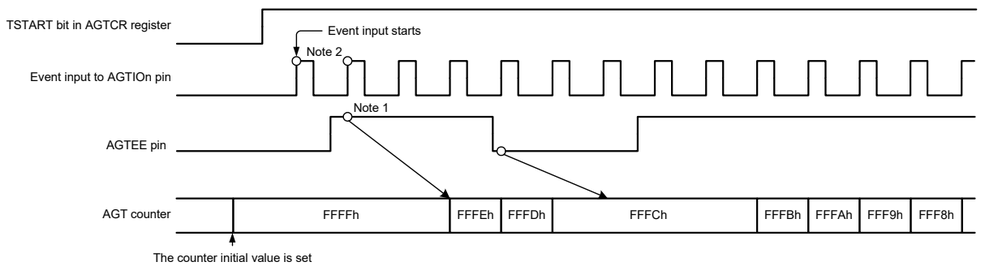
Figure 25.8 shows an operation example for counting during the specified period in event counter mode (TIOGT[1:0] bits in the AGTIOC register are set to 01b).

Timing example when the setting of operating mode is as follows :
AGTMR1 register: TMOD[2:0] = 010b (event counter mode)
AGTIOC register: TIOGT[1:0] = 01b (event is counted during specified period for external interrupt pin)
TIPF[1:0] = 00b (no filter)
TEDGSEL = 1 (count at rising edge)
AGTISR register: EEPS = 1 (high-level period is counted)



Note 1. To control synchronization, there is a delay of 2 cycles of the count source until count operation is affected. It is also possible that the count start timing is shifted by 1 cycle because of the phase difference between the AGTEEn and the sampling clock.

Note 2. Count operation can be performed for 2 cycles of the count source immediately after the count starts, depending on the previous state before the count stops.
To disable the count for 2 cycles immediately after the count starts, write 1 to the TSTOP bit in the AGTCR register to initialize the internal circuit, and then complete the operation settings before starting the count operation.

Figure 25.8 Operation example 2 in event counter mode

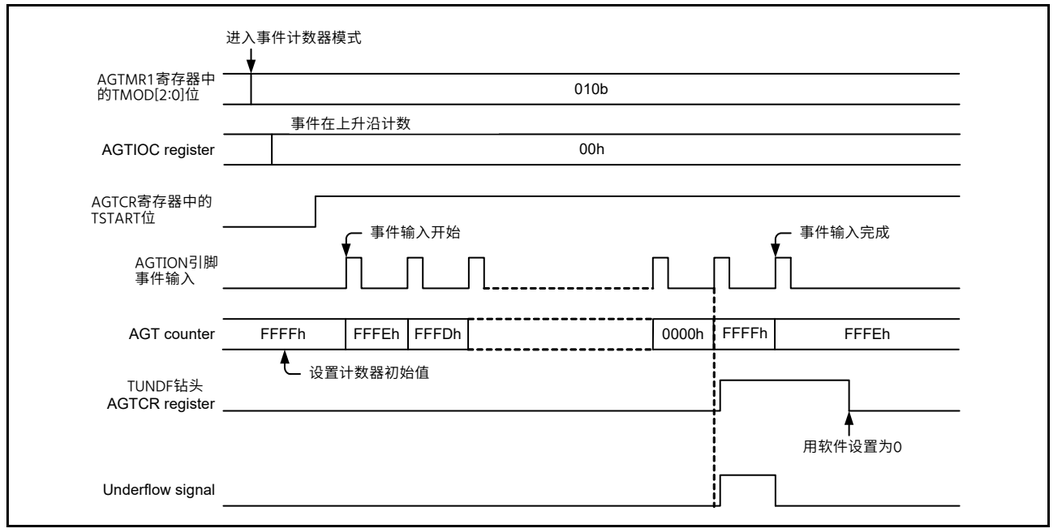


Figure 25.7 事件计数器模式下的操作示例1

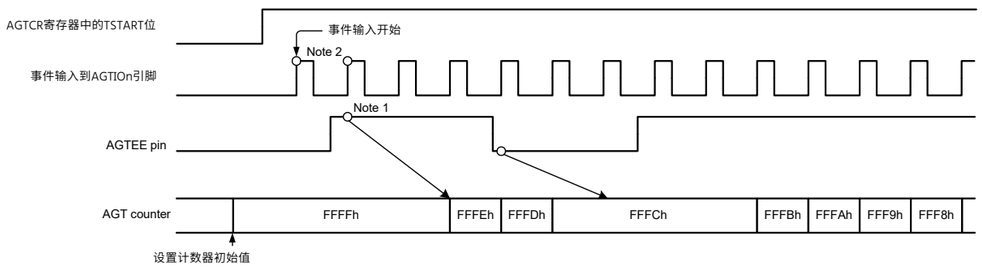
图25.8显示了在事件计数器模式下在指定周期内进行计数的操作示例（AGTIOC寄存器中的TIOGT[1:0]位设置为01b）。

设置工作模式时的时序示例如下：
AGTMR1 register: TMOD[2:0] = 010b (event counter mode)
AGTIOC寄存器：TIOGT[1:0]=01b（事件在外部中断引脚的指定周期内计数）
TIPF[1:0] = 00b (no filter)
TEDGSEL=1（上升沿计数）
AGTISR寄存器：EEPS=1（高电平周期计入）



Note 1. 为了控制同步，计数源有2个周期的延迟，直到计数操作受到影响。由于AGTEEn和采样时钟之间的相位差，计数开始时间也可能偏移1个周期。

Note 2. 计数开始后，计数源的2个周期可以立即执行计数操作，具体取决于计数停止前的先前状态。要在计数开始后立即禁止计数2个周期，将1写入AGTCR寄存器的TSTOP位以初始化内部电路，然后在开始计数操作之前完成操作设置。

25.3.6 Pulse Width Measurement Mode

In pulse width measurement mode, the pulse width of an external signal input to the AGTIOn pin is measured. When the level specified in the TEDGSEL bit in the AGTIOC register is input to the AGTIOn pin, the counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register. When the specified level on the AGTIOn pin ends, the counter is stopped, the TEDGF bit in the AGTCR register is set to 1 (active edge received), and an interrupt request is generated. The measurement of pulse width data is performed by reading the count value while the counter is stopped. Also, when the counter underflows during measurement, the TUNDF bit in the AGTCR register is set to 1 and an interrupt request is generated.

Figure 25.9 shows the operation example in pulse width measurement mode.

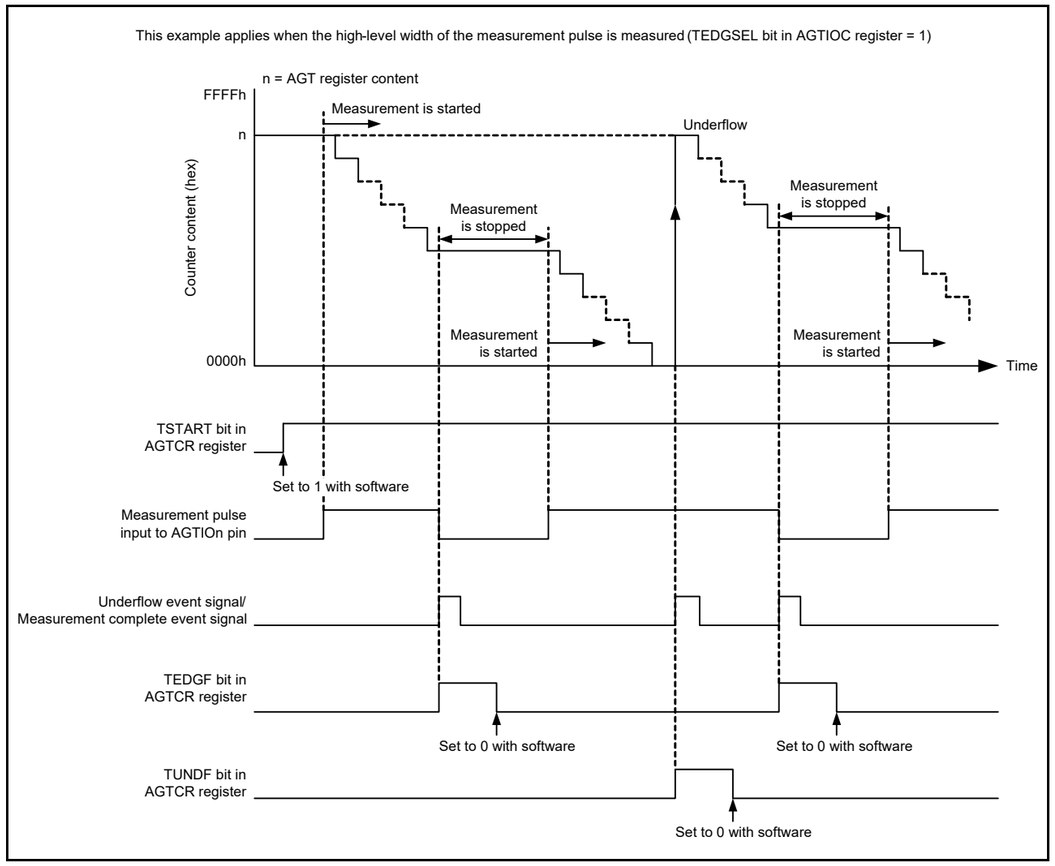

Figure 25.9 Operation example in pulse width measurement mode

25.3.7 Pulse Period Measurement Mode

In pulse period measurement mode, the pulse period of an external signal input to the AGTIOn pin is measured. The counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register. When a pulse with the level specified by the TEDGSEL bit in the AGTIOC register is input to the AGTIOn pin, the count value is transferred to the read-out buffer on the rising edge of the count source. The value in the reload register is loaded to the counter at the next rising edge. Simultaneously, the TEDGF bit in the AGTCR register is set to 1 (active edge received) and an interrupt request is generated. The read-out buffer (AGT register) is read at this time and the difference from the reload value (see section 25.4.5, How to Calculate Event Number, Pulse Width, and Pulse Period) is the period data of the input pulse. The period data is retained until the read-out buffer is read. When the counter underflows, the TUNDF bit in the AGTCR register is set to 1 (underflow) and an interrupt request is generated.

25.3.6 脉冲宽度测量模式

在脉冲宽度测量模式下，测量输入到AGTIOn引脚的外部信号的脉冲宽度。当AGTIOC寄存器的TEDGSEL位指定的电平输入到AGTIOn引脚时，计数器将根据AGTMR1寄存器中的TCK[2:0]位选择的计数源递减。当AGTIOn引脚上的指定电平结束时，计数器停止，AGTCR寄存器中的TEDGF位设置为1（接收到有效沿），并产生中断请求。通过在计数器停止时读取计数值来执行脉冲宽度数据的测量。此外，当测量期间计数器下溢时，AGTCR寄存器中的TUNDF位设置为1，并产生中断请求。

图25.9显示了脉宽测量模式下的操作示例。

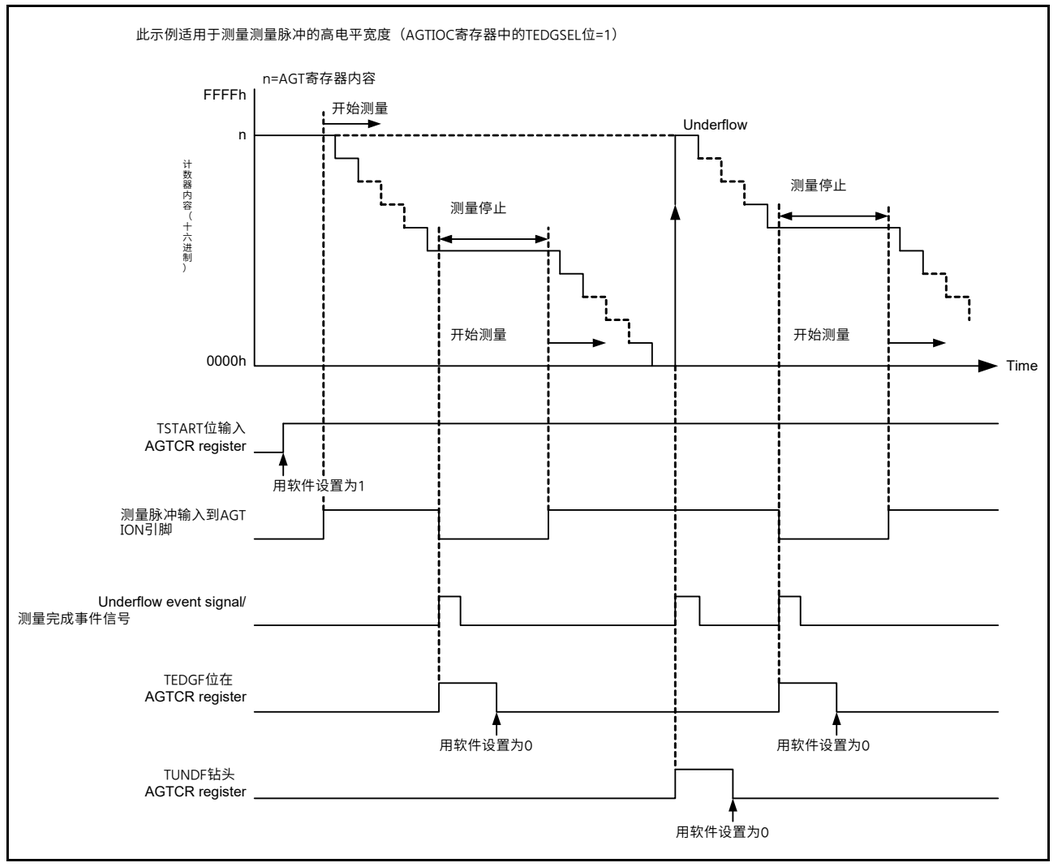

Figure 25.9 脉宽测量模式下的操作示例

25.3.7 脉冲周期测量模式

在脉冲周期测量模式下，测量输入到AGTIOn引脚的外部信号的脉冲周期。计数器按AGTMR1寄存器中的TCK[2:0]位选择的计数源递减。当AGTIOC寄存器中的TEDGSEL位指定电平的脉冲输入到AGTIOn引脚时，计数值在计数源的上升沿传送到读出缓冲器。重载寄存器中的值在下一个上升沿加载到计数器。同时，AGTCR寄存器中的TEDGF位设置为1（接收到有效边沿）并产生中断请求。此时读取读出缓冲区（AGT寄存器），与重载值的差值（参见第25.4.5节，如何计算事件数、脉冲宽度和脉冲周期）是输入脉冲的周期数据。周期数据被保留，直到读出缓冲器被读取。当计数器下溢时，AGTCR寄存器中的TUNDF位设置为1（下溢）并产生中断请求。

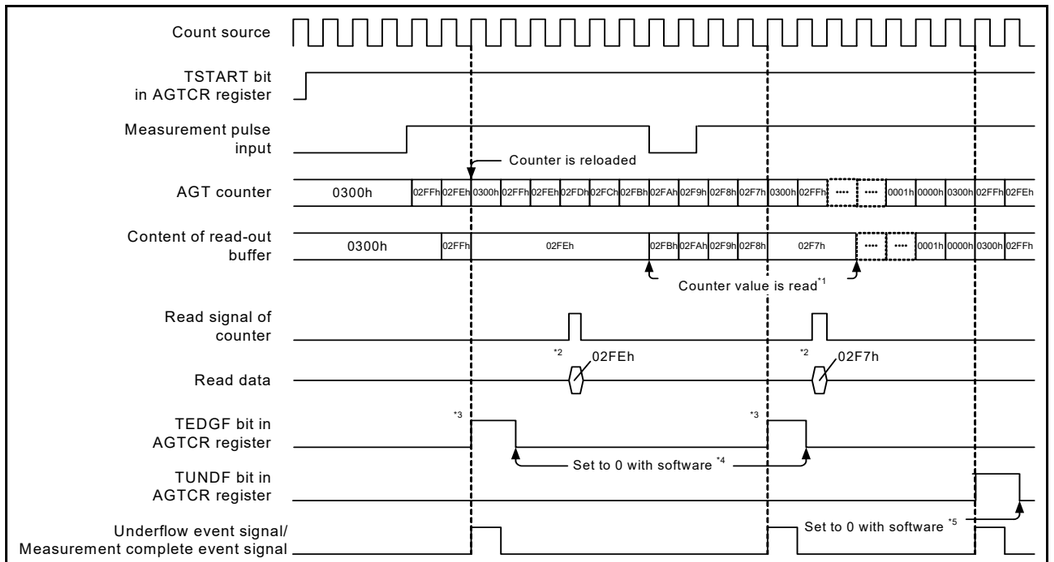
Figure 25.10 shows the operation example in pulse period measurement mode.

Only input pulses with a period longer than twice the period of the count source are measured. Also, the low-level and high-level widths must both be longer than the period of the count source. If a pulse period shorter than these conditions is input, the input might be ignored.



This example applies when the initial value of the AGT register is set to 0300h, the TEDGSEL bit in the AGTIOC register is set to 0, and the period from one rising edge to the next edge of the measurement pulse is measured.

Note 1. Reading from the AGT register must be performed during the period from when the TEDGF bit is set to 1 (active edge received) until the next active edge is input. The content of the read-out buffer is retained until the AGT register is read. If it is not read before the active edge is input, the measurement result of the previous period is retained.
Note 2. When the AGT register is read in pulse period measurement mode, the content of the read-out buffer is read.
Note 3. When the active edge of the measurement pulse is input and then the set edge of an external pulse is input, the TEDGF bit in the AGTCR register is set to 1 (active edge received).
Note 4. To set to 0 with software, write 0 to the TEDGF bit in the AGTCR register using an 8-bit memory manipulation instruction.
Note 5. To set to 0 with software, write 0 to the TUNDF bit in the AGTCR register using an 8-bit memory manipulation instruction.

Figure 25.10 Operation example in pulse period measurement mode

25.3.8 Compare Match Function

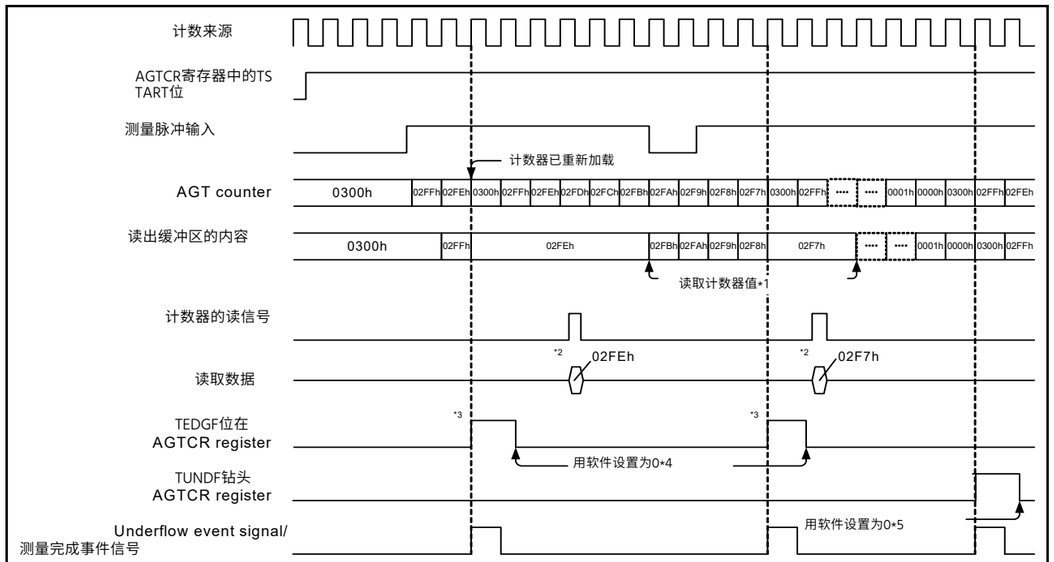
The compare match function detects matches (compare match) between the content of the AGTCMA or AGTCMB register and the content of the AGT register. This function is enabled when the TCMEA or TCMEB bit in the AGTCMSR register is 1 (compare match A register or compare match B register is valid). The counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register, and when the values of AGT and AGTCMA or AGTCMB match, the TCMAF/TCMBF bit in the AGTCR register is set to 1 (match), and an interrupt request is generated.

When compare match function is enabled, the timing of the rewrite operation to the reload register and the counter differs. See section 25.3.1, Reload Register and Counter Rewrite Operation for details. In addition, the output level of the AGTOAn and AGTOBn pins is inverted by the match and by the underflow. The output level can be selected with the TOPOLA or TOPOLB bit in the AGTCMSR register.

Figure 25.11 shows the operation example in compare match mode.

图25.10显示了脉冲周期测量模式下的操作示例。

仅测量周期长于计数源周期两倍的输入脉冲。此外，低电平和高电平宽度都必须长于计数源的周期。如果输入比这些条件短的脉冲周期，输入可能会被忽略。



此示例适用于将AGT寄存器的初始值设置为0300h，将AGTIOC寄存器中的TEDGSEL位设置为0，并测量从一个上升沿到下一个测量脉冲沿的周期的情况。

Note 1. 从TEDGF位设置为1（接收到有效边沿）到输入下一个有效边沿期间，必须从AGT寄存器读取。读出缓冲器的内容一直保留到AGT寄存器被读取。如果在输入有效边沿之前未读取，则保留前一周期的测量结果。
Note 2. 在脉冲周期测量模式下读取AGT寄存器时，会读取读出缓冲区的内容。
Note 3. 当输入测量脉冲的有效边沿，然后输入外部脉冲的设置边沿时，AGTCR寄存器中的TEDGF位设置为1（接收到有效边沿）。
Note 4. 要使用软件设置为0，请使用8位存储器操作指令将0写入AGTCR寄存器中的TEDGF位。
Note 5. 要通过软件设置为0，请使用8位存储器操作指令将0写入AGTCR寄存器中的TUNDF位。

Figure 25.10 脉冲周期测量模式下的操作示例

25.3.8 比较匹配函数

比较匹配功能检测AGTCMA或AGTCMB寄存器的内容与AGT寄存器的内容之间的匹配（比较匹配）。该功能在AGTCMSR寄存器中的TCMEA或TCMEB位为1时使能（比较匹配A寄存器或比较匹配B寄存器有效）。计数器按AGTMR1寄存器中TCK[2:0]位选择的计数源递减，当AGT和AGTCMA或AGTCMB的值匹配时，AGTCR寄存器中的TCMAFTCMBF位设置为1（匹配），并产生中断请求。

当比较匹配功能启用时，对重载寄存器和计数器的重写操作的时序不同。有关详细信息，请参见第25.3.1节，重载寄存器和计数器重写操作。此外，AGTOAn和AGTOBn引脚的输出电平通过匹配和下溢反转。输出电平可以选择与

AGTCMSR寄存器中的TOPOLA或TOPOLB位。

图25.11显示了比较匹配模式下的操作示例。

25.3.11 Interrupt Sources

The AGT has three interrupt sources described in Table 25.11.

Table 25.11 AGT interrupt sources

Name	Interrupt source	DMAC/DTC activation

AGTn_AGTCMBI	When the values of AGT and AGTCMB match	Possible

Note: Channel number (n = 0 or 1).

25.3.12 Event Signal Output to ELC

The AGT uses the Event Link Controller (ELC) to perform a link operation to a specified module using the interrupt request signal as the event signal. The AGT outputs compare match A, compare match B, and underflow/measurement complete signals as event signals. For details, see section 19, Event Link Controller (ELC).

25.4 Usage Notes

25.4.1 Count Operation Start and Stop Control

- When the operating mode (see Table 25.1) is set to other than the event counter mode, or the count source is set to other than AGT0 underflow (TCK[2:0] = 101b):
  - After 1 (count starts) is written to the TSTART bit in the AGTCR register while the count is stopped, the TCSTF bit in the AGTCR register remains 0 (count stops) for 3 cycles of the count source. Do not access the registers associated with AGT*1 other than the TCSTF bit until this bit is set to 1 (count in progress).
  - After 0 (count stops) is written to the TSTART bit during a count operation, the TCSTF bit remains 1 for 3 cycles of the count source. When the TCSTF bit is set to 0, the count stops. Do not access the registers associated with AGT*1 other than the TCSTF bit until this bit is set to 0.
  - Clear the interrupt register before changing the TSTART bit from 0 to 1. See section 14, Interrupt Controller Unit (ICU) for details.

Note 1. Registers associated with AGT: AGT, AGTCMA, AGTCMB, AGTCR, AGTMR1, AGTMR2, AGTIOC, AGTISR, and AGTCMSR.

- When the operating mode (see Table 25.1) is set to event counter mode, or the count source is set to AGT0 underflow (TCK[2:0] = 101b):
  - After 1 (count starts) is written to the TSTART bit in the AGTCR register while the count is stopped, the TCSTF bit in the AGTCR register remains 0 (count stops) for 2 PCLKB cycles. Do not access the registers associated with AGT*1 other than the TCSTF bit until this bit is set to 1 (count in progress).
  - After 0 (count stops) is written to the TSTART bit during a count operation, the TCSTF bit remains 1 for 2 cycles of the PCLKB. When the TCSTF bit is set to 0, the count is stopped. Do not access the registers associated with AGT*1 other than the TCSTF bit until this bit is set to 0.
  - Clear the interrupt register before changing the TSTART bit from 0 to 1. See section 14, Interrupt Controller Unit (ICU) for details.

Note 1. Registers associated with AGT: AGT, AGTCMA, AGTCMB, AGTCR, AGTMR1, AGTMR2, AGTIOC, AGTISR, and AGTCMSR.

25.3.11 中断源

AGT具有表25.11中描述的三个中断源。

Table 25.11 AGT中断源

Name	中断源	DMAC/DTC activation
AGTn_AGTI	当计数器下溢时 当在脉冲宽度测量模式下完成外部输入(AGTIO)的有效宽度测量时 当在脉冲周期测量模式下输入外部输入(AGTIO)的设置边沿时。	Possible
AGTn_AGTCMAI	当AGT和AGTCMA的值匹配时	Possible
AGTn_AGTCMBI	当AGT和AGTCMB的值匹配时	Possible

Note: 通道号（n=0或1）。

25.3.12 事件信号输出到ELC

AGT使用事件链接控制器(ELC)使用中断请求信号作为事件信号执行到指定模块的链接操作。AGT输出比较匹配A、比较匹配B和下溢测量完成信号作为事件信号。有关详细信息，请参阅第19节，事件链接控制器(ELC)。

25.4 使用说明

25.4.1 计数操作启动和停止控制

- 当操作模式（见表25.1）设置为非事件计数器模式，或计数源设置为非AGT0下溢（TCK[2:0]=101b）时：
  - 在计数停止期间将1（计数开始）写入AGTCR寄存器中的TSTART位后，AGTCR寄存器中的TCSTF位在计数源的3个周期内保持为0（计数停止）。不要访问除TCSTF位之外的与AGT*1关联的寄存器，直到该位设置为1（正在进行计数）。
  - 在计数操作期间将0（计数停止）写入TSTART位后，TCSTF位在计数源的3个周期内保持为1。当TCSTF位设置为0时，计数停止。在此位设置为0之前，请勿访问与AGT*1相关的寄存器，而不是TCSTF位。
  - 在将TSTART位从0更改为1之前清除中断寄存器。参见第14节，中断控制器单位(ICU)了解详情。

注1.与AGT相关的寄存器：AGT、AGTCMA、AGTCMB、AGTCR、AGTMR1、AGTMR2、AGTIOC、AGTISR和AGTCMSR。

- 当操作模式（见表25.1）设置为事件计数器模式，或计数源设置为AGT0下溢（TCK[2:0]=101b）时：
  - 在停止计数的同时将1（计数开始）写入AGTCR寄存器中的TSTART位后，AGTCR寄存器中的TCSTF位保持0（计数停止）2个PCLKB周期。不要访问除TCSTF位之外的与AGT*1关联的寄存器，直到该位设置为1（正在进行计数）。
  - 在计数操作期间将0（计数停止）写入TSTART位后，TCSTF位在PCLKB的2个周期内保持为1。当TCSTF位设置为0时，停止计数。在此位设置为0之前，请勿访问与AGT*1相关的寄存器，而不是TCSTF位。
  - 在将TSTART位从0更改为1之前清除中断寄存器。参见第14节，中断控制器单位(ICU)了解详情。

注1.与AGT相关的寄存器：AGT、AGTCMA、AGTCMB、AGTCR、AGTMR1、AGTMR2、AGTIOC、AGTISR和AGTCMSR。

25.4.2 Access to Counter Register

When the TSTART and TCSTF bits in the AGTCR register are both 1 (count starts), allow at least 3 cycles of the count source clock between writes when writing to the AGT register successively.

25.4.3 When Changing Mode

The registers associated with AGT operating mode (AGTMR1, AGTMR2, AGTIOC, AGTISR, AGTCMSR and AGTIOC) can be changed only when the count is stopped with both the TSTART and TCSTF bits set to 0 (count stops). Do not change these registers during count operation.

When the registers associated with AGT operating mode are changed, the values of bits TEDGF, TUNDF, TCMAF and TCMBF are undefined. Before starting the count, write 0 to the following bits:

- TEDGF (no active edge received)
- TUNDF (no underflow)
- TCMAF (no match)
- TCMBF (no match).

25.4.4 Digital Filter

When using the digital filter, do not start the timer operation for 5 cycles of the digital filter clock after setting TIPF[1:0] bits and when the TEDGSEL bit in the AGTIOC register changes.

25.4.5 How to Calculate Event Number, Pulse Width, and Pulse Period

- In event counter mode, event number is expressed mathematically as follows:
  Event number = initial value of counter [AGT register] - counter value of active event end
- In pulse width measurement mode, pulse width is expressed mathematically as follows:
  Pulse width = counter value of stopping measurement - counter value of next stopping measurement
- In pulse period measurement mode, input pulse period is expressed mathematically as follows:
  Period of input pulse = (initial value of counter [AGT register] - reading value of the read-out buffer) + 1

25.4.6 When Count Is Forcibly Stopped by TSTOP Bit

After the counter is forcibly stopped by the TSTOP bit in the AGTCR register, do not access the following I/O registers for 1 cycle of the count source:

- AGT
- AGTCMA
- AGTCMB
- AGTCR
- AGTMR1
- AGTMR2.

25.4.7 When Selecting AGT0 Underflow as the Count Source

Operate the AGT according to the procedures described in this section when selecting the underflow signal of AGT as the count source.

(1) Procedure for starting operation

1. Set AGT0 and AGT1.
2. Start the count operation of AGT1.
3. Start the count operation of AGT0.

25.4.2 访问计数器寄存器

当AGTCR寄存器中的TSTART和TCSTF位都为1（计数开始）时，连续写入AGT寄存器时，在两次写入之间至少允许计数源时钟的3个周期。

25.4.3 更改模式时

与AGT操作模式相关的寄存器（AGTMR1、AGTMR2、AGTIOC、AGTISR、AGTCMSR和
只有在TSTART和TCSTF位都设置为0（计数停止）的情况下停止计数时才能更改AGTIOC）。
在计数操作期间不要更改这些寄存器。

当与AGT工作模式相关的寄存器发生变化时，TEDGF、TUNDF、TCMAF和
TCMBF未定义。在开始计数之前，将0写入以下位：

- TEDGF（未收到有效边沿）
- TUNDF (no underflow)
- TCMAF (no match)
- TCMBF (no match).

25.4.4 数字滤波器

使用数字滤波器时，在设置TIPF[1:0]位后以及AGTIOC寄存器中的TEDGSEL位发生变化时，在数字滤波器时钟的5个周期内不要启动定时器操作。

25.4.5 如何计算事件编号、脉冲宽度和脉冲周期

- 在事件计数器模式下，事件编号以数学方式表示如下：
  事件编号=计数器的初始值[AGT寄存器]活动事件结束的计数器值
- 在脉冲宽度测量模式下，脉冲宽度在数学上表示如下：
  脉冲宽度=停止测量的计数器值下一个停止测量的计数器值
- 在脉冲周期测量模式下，输入脉冲周期在数学上表示如下：
  输入脉冲周期=（计数器初始值[AGT寄存器]读出缓冲器的读取值）+1

25.4.6 当计数被TSTOP位强制停止时

计数器被AGTCR寄存器中的TSTOP位强制停止后，在计数源的1个周期内不要访问以下IO寄存器：

- AGT
- AGTCMA
- AGTCMB
- AGTCR
- AGTMR1
- AGTMR2.

25.4.7 选择AGT0下溢作为计数源时

选择AGT的下溢信号作为计数源时，请按照本节所述的步骤操作AGT。

(1) 开始运行的步骤

1. 设置AGT0和AGT1。
2. 启动AGT1的计数操作。
3. 启动AGT0的计数操作。

(2) Procedure for stopping operation

1. Stop the count operation of AGT0.
2. Stop the count operation of AGT1.
3. Stop the count source clock of AGT1 (write 000b in the AGT1.AGTMR1.TCK[2:0] bits).

25.4.8 Reset of I/O Register

The I/O register of the AGT is not initialized by different types of resets. For details, see section 6, Resets.

25.4.9 When Selecting PCLKB, PCLKB/8, or PCLKB/2 as the Count Source

When a reset is generated, the operation of AGT cannot be guaranteed. Set the registers associated with AGT again.

25.4.10 When Selecting AGTSCLK or AGTLCLK as the Count Source

The MSTPD2 bit in the MSTPCRD register must be set to 1 except when accessing the AGT1 registers. The MSTPD3 bit in the MSTPCRD register must be set to 1 except when accessing the AGT0 registers. When a reset occurs while MSTPD2 or MSTPD3 bit is 0, the operation of AGT1 or AGT0 cannot be guaranteed. Set the registers associated with AGT again.

25.4.11 When Switching Source Clock

When switching a clock source by changing SCKCR.CKSEL[2:0], the clock output from the selector stops for 4 cycles of the switched clock. Therefore, when using the AGTIO, AGTEE, or both input as external event input, the clock source should not be switched. If switching the clock source while using the external event input, extend the input pulse width by 4 clock cycles of the switched source clock cycles.

(2) 停止运行的步骤

1. 停止AGT0的计数操作。
2. 停止AGT1的计数操作。
3. 停止AGT1的计数源时钟（在AGT1.AGTMR1.TCK[2:0]位中写入000b）。

25.4.8 IO寄存器的复位

AGT的IO寄存器不会被不同类型的复位初始化。有关详细信息，请参阅第6节，重置。

25.4.9 选择PCLKB、PCLKB8或PCLKB2作为计数源时

当产生复位时，不能保证AGT的操作。再次设置与AGT关联的寄存器。

25.4.10 选择AGTSCLK或AGTLCLK作为计数源时

除了访问AGT1寄存器时，MSTPCRD寄存器中的MSTPD2位必须设置为1。除了访问AGT0寄存器时，MSTPCRD寄存器中的MSTPD3位必须设置为1。当MSTPD2或MSTPD3位为0时发生复位时，不能保证AGT1或AGT0的操作。设置相关的寄存器

AGT again.

25.4.11 切换源时钟时

当通过改变SCKCR.CKSEL[2:0]来切换时钟源时，选择器的时钟输出在切换时钟的4个周期内停止。因此，当使用AGTIO、AGTEE或两者输入作为外部事件输入时，不应切换时钟源。如果在使用外部事件输入时切换时钟源，请将输入脉冲宽度延长4个切换源时钟周期的时钟周期。

26. Realtime Clock (RTC)

26.1 Overview

The RTC has two counting modes, calendar count mode and binary count mode, that are used by switching register settings. For calendar count mode, the RTC has a 100 year calendar from 2000 to 2099 and automatically adjusts dates for leap years. For binary count mode, the RTC counts seconds and retains the information as a serial value. Binary count mode can be used for calendars other than the Gregorian (Western) calendar.

The sub-clock oscillator or LOCO can be selected as the count source of the time counters. The RTC uses a 128-Hz clock acquired by dividing the count source by a prescaler. Year, month, date, day-of-week, a.m./p.m. (in 12-hour mode), hour, minute, second, or 32-bit binary is counted by 1/128 second.

Table 26.1 lists the RTC specifications, Figure 26.1 shows a block diagram, and Table 26.2 lists the I/O pins.

26. 实时时钟(RTC)

26.1 Overview

RTC有两种计数模式，日历计数模式和二进制计数模式，通过切换寄存器设置使用。对于日历计数模式，RTC有一个从2000年到2099年的100年日历，并自动调整闰年的日期。对于二进制计数模式，RTC会计算秒数并将信息保留为序列值。二进制计数模式可用于公历（西方）以外的日历。

可以选择子时钟振荡器或LOCO作为时间计数器的计数源。RTC使用一个128-Hz时钟，通过预分频器将计数源分频获得。年、月、日、星期、上午、下午（在12小时模式下）时、分、秒或32位二进制按1128秒计数。

表26.1列出了RTC规范，图26.1显示了框图，表26.2列出了IO引脚。

26.2 Register Descriptions

Write or read from the RTC registers as described in section 26.6.5, Notes on Writing to and Reading from Registers.

If the value in an RTC register after a reset is given as x (undefined bits) in the list, it is not initialized by a reset. When RTC enters the reset state or a low power consumption state during counting operations, for example while the RCR2.START bit is 1, the year, month, day of the week, date, hours, minutes, seconds, and 64-Hz counters continue to operate.

Note: A reset generated while writing to a register might destroy the register value. In addition, do not allow the MCU to enter Software Standby mode or Deep Software Standby mode immediately after setting any of these registers. For details, see section 26.6.4, Transitions to Low Power Modes after Setting Registers.

The R64CNT counter is used in both calendar count mode and binary count mode. The 64-Hz counter (R64CNT) generates the period for a second by counting up periods of the 128-Hz clock. The state in the sub-second range can be confirmed by reading this counter.

This counter is set to 00h by an RTC software reset or an execution of a 30-second adjustment. To read this counter, follow the procedure in section 26.3.5, Reading 64-Hz Counter and Time.

26.2 注册说明

写入或读取RTC寄存器，如第26.6.5节"写入和读取寄存器的注意事项"中所述。

如果复位后RTC寄存器中的值在列表中以x（未定义位）的形式给出，则它不会被复位初始化。当RTC在计数操作期间进入复位状态或低功耗状态时，例如当
RCR2.START位为1，年、月、星期、日期、小时、分钟、秒和64-Hz计数器继续工作。

Note: 写入寄存器时产生的复位可能会破坏寄存器值。此外，在设置任何这些寄存器后，不要让MCU立即进入软件待机模式或深度软件待机模式。有关详细信息，请参阅第26.6.4节，设置寄存器后转换到低功耗模式。

b6	PM	PM	Time counter setting for AM/PM: 0: AM 1: PM.	R/W
b7	—	Reserved	Set this bit to 0. It is read as the set value.	R/W

The RHRCNT counter sets and counts the BCD-coded hour value. It counts the carries generated once per hour in the minute counter. The specifiable time differs based on the setting in the hours mode bit (RCR2.HR24):

- When the RCR2.HR24 bit is 0 — from 00 to 11 (in BCD)
- When the RCR2.HR24 bit is 1 — from 00 to 23 (in BCD).

If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation using the START bit in RCR2. The PM bit is only enabled when the RCR2.HR24 bit is 0. Otherwise, the setting in the PM bit has no effect. To read this counter, follow the procedure in section 26.3.5, Reading 64-Hz Counter and Time.

RHRCNT计数器设置并计算BCD编码的小时值。它在分钟计数器中计算每小时生成一次的进位。可指定的时间因小时模式位(RCR2.HR24)中的设置而异：

- 当RCR2.HR24位为0时——从00到11（以BCD表示）
- 当RCR2.HR24位为1时—从00到23（以BCD表示）。

如果指定的值超出此范围，则RTC将无法正确运行。在写入该寄存器之前，请务必使用RCR2中的START位停止计数操作。仅当RCR2.HR24位为0时才启用PM位。否则，PM位中的设置无效。要读取此计数器，请按照第26.3.5节，读取64-Hz计数器和时间中的程序进行操作。

The RDAYCNT counter is used in calendar count mode to set and count the BCD-coded date value. It counts carries generated once per day in the hour counter. The count operation depends on the month and whether the year is a leap year. Leap years are determined according to whether the year counter (RYRCNT) value is divisible by 400, 100, and 4.

A value from 01 through 31 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. RDAYAR is an alarm register associated with the BCD-coded date counter RDAYCNT. When the ENB bit is set to 1, the RDAYAR value is compared with the RDAYCNT value. From the following alarm registers, only those selected with the ENB bits set to 1 are compared with the associated counters:

When all the respective values match, the IR flag associated with the RTC_ALM interrupt is set to 1. The RDAYAR values from 01 through 31 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. This register is set to 00h by an RTC software reset.

Note 1. When LOCO is selected (RCR4.RCKSEL = 1) while PES[3:0] = 0110b, a periodic interrupt is generated every 1/128 second.

The RCR1 register is used in both calendar count mode and in binary count mode. Bits AIE, PIE, and PES[3:0] are updated synchronously with the count source. When the RCR1 register is modified, check that all the bits are updated before proceeding.

AIE bit (Alarm Interrupt Enable)

The AIE bit enables or disables alarm interrupt requests.

If the times indicated in the counters and alarm settings match in Deep Software Standby mode, the MCU returns from the mode regardless of the AIE bit value.

CIE bit (Carry Interrupt Enable)

The CIE bit enables or disables interrupt requests when a carry to the RSECCNT/BCNT0 register occurs, or when a carry to the 64-Hz counter (R64CNT) occurs while reading the 64-Hz counter.

PIE bit (Periodic Interrupt Enable)

The PIE bit enables or disables a periodic interrupt.

If the periods indicated in the counters and PES[3:0] settings match in Deep Software Standby mode, the MCU returns from the mode regardless of the PIE bit value.

RTCOS bit (RTCOUT Output Select)

The RTCOS bit selects the RTCOUT output period. The RTCOS bit must be rewritten while the count operation is stopped (the RCR2.START bit is 0) and the RTCOUT output is disabled (the RCR2.RTCOE bit is 0). When RTCOUT is output to an external pin, the RCR2.RTCOE bit must be enabled. For details on controlling the I/O ports, see section 20.5.1, Procedure for Specifying the Pin Functions.

PES[3:0] bits (Periodic Interrupt Select)

The PES[3:0] bits specify the period for the periodic interrupt. A periodic interrupt is generated with the period specified in these bits.

RCR1寄存器用于日历计数模式和二进制计数模式。AIE、PIE和PES[3:0]位与计数源同步更新。修改RCR1寄存器时，在继续之前检查所有位是否都已更新。

AIE位（报警中断使能）

AIE位启用或禁用警报中断请求。

如果计数器和警报设置中指示的时间在深度软件待机模式下匹配，则无论AIE位值如何，MCU都会从该模式返回。

CIE位（进位中断使能）

当发生对RSECCNTBCNT0寄存器的进位，或在读取64-Hz计数器时发生对64-Hz计数器(R64CNT)的进位时，CIE位启用或禁用中断请求。

PIE位（周期性中断使能）

PIE位启用或禁用周期性中断。

如果计数器中指示的周期和PES[3:0]设置在深度软件待机模式下匹配，则无论PIE位值如何，MCU都会从该模式返回。

RTCOS位（RTCOUT输出选择）

RTCOS位选择RTCOUT输出周期。当计数操作停止（RCR2.START位为0）且RTCOUT输出禁用（RCR2.RTCOE位为0）时，必须重写RTCOS位。当RTCOUT输出到外部引脚时，必须使能RCR2.RTCOE位。有关控制IO端口的详细信息，请参见第20.5.1节，指定引脚功能的过程。

PES[3:0]位（周期性中断选择）

PES[3:0]位指定周期性中断的周期。以这些位中指定的周期生成周期性中断。

START bit (Start)

The START bit stops or restarts the prescaler or time counter operation. This bit is updated in synchronization with the next cycle of the count source. When the START bit is modified, check that the bit is updated before proceeding.

RESET bit (RTC Software Reset)

The RESET bit initializes the prescaler and registers to be reset by RTC software. When 1 is written to the RESET bit, initialization starts in synchronization with the count source. When the initialization is completed, the RESET bit is automatically set to 0. Check that this bit is 0 before proceeding.

RCR2寄存器与小时模式、自动调整功能、启用RTCOUT输出、30秒调整、RTC软件复位和控制计数操作有关。

开始位（开始）

START位停止或重新启动预分频器或时间计数器操作。该位与计数源的下一个周期同步更新。修改START位后，请在继续之前检查该位是否已更新。

RESET位（RTC软件复位）

RESET位初始化预分频器和寄存器以由RTC软件复位。向RESET位写入1时，初始化与计数源同步开始。初始化完成后，RESET位自动设置为0。在继续之前检查该位是否为0。

ADJ30 bit (30-Second Adjustment)

The ADJ30 bit is for 30-second adjustment.

When 1 is written to the ADJ30 bit, the RSECCNT value of 30 seconds or less is rounded down to 00 second and the value of 30 seconds or more is rounded up to 1 minute.

The 30-second adjustment is performed in synchronization with the count source. When 1 is written to this bit, the ADJ30 bit is automatically set to 0 after the 30-second adjustment completes. If 1 is written to the ADJ30 bit, check that the bit is 0 before proceeding. When the 30-second adjustment is performed, the prescaler and R64CNT are also reset. The ADJ30 bit is set to 0 by an RTC software reset.

RTCOE bit (RTCOUT Output Enable)

The RTCOE bit enables output of a 1-Hz/64-Hz clock signal from the RTCOUT pin.

Use the START bit to stop counting before changing the value of the RTCOE bit. Do not stop counting (write 0 to the START bit) and change the value of the RTCOE bit at the same time.

When RTCOUT is to be output from an external pin, enable the RTCOE bit and set up the port control for the pin.

AADJE bit (Automatic Adjustment Enable*2)

The AADJE bit enables or disables automatic adjustment.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJE bit.

The AADJE bit is set to 0 by an RTC software reset.

AADJP bit (Automatic Adjustment Period Select*2)

The AADJP bit selects the automatic-adjustment period.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJP bit.

The AADJP bit is set to 0 by an RTC software reset.

HR24 bit (Hours Mode)

The HR24 bit specifies whether the RTC operates in 12- or 24-hour mode.

Use the START bit to stop counting before changing the value of the HR24 bit. Do not stop counting (write 0 to the START bit) and change the value of the HR24 bit at the same time.

CNTMD bit (Count Mode Select)

The CNTMD bit specifies whether the RTC count mode operates in calendar count mode or in binary count mode.

When setting the count mode, execute an RTC software reset and start again from the initial settings. This bit is updated synchronously with the count source, and its value is fixed before the RTC software reset is complete.

For details on initial settings, see section 26.3.1, Outline of Initial Settings of Registers after Power On.

ADJ30位（30秒调整）

ADJ30位用于30秒调整。

向ADJ30位写入1时，30秒以下的RSECCNT值向下舍入为00秒，30秒以上的值向上舍入为1分钟。

30秒调整与计数源同步进行。当1写入该位时，
30秒调整完成后，ADJ30位自动设置为0。如果将1写入ADJ30位，请在继续之前检查该位是否为0。当执行30秒调整时，预分频器和R64CNT也被复位。RTC软件复位将ADJ30位设置为0。

RTCOE位（RTCOUT输出使能）

RTCOE位使能从RTCOUT引脚输出1-Hz64-Hz时钟信号。

在更改RTCOE位的值之前，使用START位停止计数。不要停止计数（将0写入
START位）并同时更改RTCOE位的值。

当RTCOUT要从外部引脚输出时，使能RTCOE位并设置引脚的端口控制。

在更改HR24位的值之前，使用START位停止计数。不要停止计数（将0写入
START位）并同时更改HR24位的值。

CNTMD位（计数模式选择）

CNTMD位指定RTC计数模式是在日历计数模式还是二进制计数模式下运行。

设置计数模式时，执行RTC软件复位并从初始设置重新开始。该位与计数源同步更新，其值在RTC软件复位完成前固定。

b15 to b0	RFC[15:0]	Frequency Comparison Value	Write 00FFh to this register when using the LOCO	R/W

RFRL is a register for controlling the prescaler when LOCO is selected.

The RTC time counter operates on a 128-Hz clock signal as the base clock. Therefore, when LOCO is selected, LOCO is divided by the prescaler to generate a 128-Hz clock signal. Set the frequency comparison value in the RFC[15:0] bits to generate a 128-Hz clock from the LOCO frequency. Before writing to RFC[15:0] after a cold start, write 0000h to the RFRH register.

A value from 0007h through 01FFh can be specified as the frequency comparison value. If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2. The operating frequency of the peripheral module clock and the LOCO should be such that the peripheral module clock is ≥ to the LOCO.

Calculation method of frequency comparison value:

RFC[15:0] = (LOCO clock frequency) / 128 - 1

When the LOCO frequency is 32.768 kHz, the RFRL register must be set to 00FFh.

RFRL是一个寄存器，用于在选择LOCO时控制预分频器。

RTC时间计数器以128-Hz时钟信号作为基本时钟运行。Therefore whenLOCOisselected LOCOisdividedbytheprescalertogeneratea128-Hzclocksignal设置RFC[15:0]位中的频率比较值以从LOCO频率生成128-Hz时钟。在冷启动后写入RFC[15:0]之前，将0000h写入RFRH寄存器。

可以将0007h到01FFh的值指定为频率比较值。如果指定的值超出此范围，则RTC将无法正确运行。在写入该寄存器之前，请务必通过设置RCR2中的START位来停止计数操作。外围模块时钟和LOCO的工作频率应使外围模块时钟与LOCO相差 。

频率比较值的计算方法：

RFC[15:0] = (LOCO clock frequency) / 128 - 1

当LOCO频率为32.768kHz时，RFRL寄存器必须设置为00FFh。

Adjustment is performed by the addition to or subtraction from the prescaler. If the automatic adjustment enable (RCR2.AADJE) bit is 0, adjustment is performed when writing to the RADJ. If the RCR2.AADJE bit is 1, adjustment is performed in the interval specified in the Automatic Adjustment Period Select bit (RCR2.AADJP).

The current adjustment by software (disabling automatic adjustment) might be invalid if the following adjustment value is specified within 320 cycles of the count source after the register setting. To perform adjustment consecutively, wait for 320 cycles or more of the count source after the register setting, then specify the next adjustment value.

RADJ is updated in synchronization with the count source. When RADJ is modified, check that all the bits are updated before continuing with additional processing. This register is set to 00h by an RTC software reset. The setting of this register is enabled only when the sub-clock oscillator is selected. When LOCO is selected, adjustment is not performed.

ADJ[5:0] bits (Adjustment Value)

The ADJ[5:0] bits specify the adjustment value (number of sub-clock cycles) from the prescaler.

PMADJ[1:0] bits (Plus-Minus)

The PMADJ[1:0] bits select whether the clock is set ahead or back depending on the error-adjustment value set in the ADJ[5:0] bits.

b7	TCEN	Time Capture Event Input Pin Enable	0: The RTCICn pin is disabled as the time capture event input 1: The RTCICn pin is enabled as the time capture event input (n = 0 to 2).	R/W

Note 1. Indicates that an event is detected. Writing 1 to this bit has no effect. Writing 0 sets this bit to 0.

The RTCCRy register is used both in calendar count mode and in binary count mode. RTCCR0, RTCCR1, and RTCCR2 control the RTCIC0, RTCIC1, and RTCIC2 pins, respectively.

RTCCRy is updated in synchronization with the count source. When RTCCRy is modified, check that all the bits except the TCST bit, are updated before continuing with more processing. This register is set to 00h by an RTC software reset. When RTCICn is used as the time capture pin, VBTICTLR.VCHnIEN (n = 0 to 2) must be set to 1. For more information, see section 12, Battery Backup Function.

TCCT[1:0] bits (Time Capture Control)

The TCCT[1:0] bits control the edge detection of the time capture event input pins, RTCIC0, RTCIC1, and RTCIC2. The detection edge is selectable. The TCCT[1:0] bits must be set while the VBTICTLR.VCHnIEN bit is 1.

TCST bit (Time Capture Status)

The TCST bit indicates that an event on the time capture event input pins, RTCIC0, RTCIC1, and RTCIC2, was detected. When the TCST bit is 0, no event is detected. When the TCST bit is 1, this bit indicates that an event was detected on the associated pin and the capture register is valid. When multiple events are detected, the capture time for the first event is retained.

If an event is detected while the count operation is stopped (the RCR2.START bit is 0), the captured value is not guaranteed. In this case, set the TCST bit to 0 to delete the captured value. Writing 0 sets the TCST bit to 0. Writing any value other than 0 has no effect.

Set the TCST bit while the TCCT[1:0] bits are 00b (no event is detected). The TCST bit is set to 0 in synchronization with the count source. When the TCST bit is set to 0, check that the bit is updated before continuing with additional processing.

TCNF[1:0] bits (Time Capture Noise Filter Control)

The TCNF[1:0] bits control the noise filter of the time capture event input pins (RTCIC0, RTCIC1, and RTCIC2).

When the noise filter is on, the count source divided by 1 or divided by 32 is selectable. In this case, when the input level on the time capture event input pin matches three consecutive times at the set sampling period, the input level is determined.

Set the TCNF[1:0] bits while the TCCT[1:0] bits are 00b (no event is detected). When the noise filter is used, set the TCNF[1:0] bits, wait for 3 cycles of the specified sampling period, then set the TCCT[1:0] bits. Set the TCNF[1:0] bits when the VBTICTLR.VCHnIEN bit is 1.

TCEN bit (Time Capture Event Input Pin Enable)

The TCEN bit enables or disables the time capture event input pins (RTCIC0, RTCIC1, and RTCIC2).When the functions of the time capture event input pins are multiplexed, VBTICTLR should be set first. If the TCEN bit is set to 0, also set the TCCT[1:0] bits to 00b.

b7	TCEN	时间捕捉事件输入引脚使能	0：禁止RTCICn引脚作为时间捕捉事件输入1：使能RTCICn引脚作为时间捕捉事件输入（n=0到2）。	R/W

Note 1. 表示检测到事件。向该位写入1无效。写入0将该位设置为0。

RTCCry寄存器用于日历计数模式和二进制计数模式。RTCCR0、RTCCR1和RTCCR2分别控制RTCIC0、RTCIC1和RTCIC2引脚。

RTCCRy与计数源同步更新。修改RTCCRy后，检查除TCST位之外的所有位是否都已更新，然后再继续进行更多处理。该寄存器通过RTC软件复位设置为00h。当RTCICn用作时间捕捉引脚时，VBTICTLR.VCHnIEN(n=0to2)必须设置为1。有关详细信息，请参阅第12节，电池备份功能。

TCCT[1:0]位（时间捕捉控制）

TCCT[1:0]位控制时间捕捉事件输入引脚RTCIC0、RTCIC1和RTCIC2的边沿检测。检测边缘是可选的。当VBTICTLR.VCHnIEN位为1时，必须设置TCCT[1:0]位。

TCST位（时间捕捉状态）

TCST位指示检测到时间捕捉事件输入引脚RTCIC0、RTCIC1和RTCIC2上的事件。当TCST位为0时，未检测到任何事件。当TCST位为1时，该位表示在相关引脚上检测到事件并且捕捉寄存器有效。当检测到多个事件时，将保留第一个事件的捕获时间。

如果在计数操作停止时检测到事件（RCR2.START位为0），则不能保证捕获的值。在这种情况下，将TCST位设置为0以删除捕获的值。写入0会将TCST位设置为0。写入0以外的任何值均无效。

当TCCT[1:0]位为00b（未检测到事件）时，设置TCST位。TCST位与计数源同步设置为0。当TCST位设置为0时，在继续进行其他处理之前检查该位是否已更新。

TCNF[1:0]位（时间捕捉噪声滤波器控制）

TCNF[1:0]位控制时间捕捉事件输入引脚（RTCIC0、RTCIC1和RTCIC2）的噪声滤波器。

当噪声滤波器打开时，计数源除以1或除以32是可选的。在这种情况下，当时间捕捉事件输入引脚上的输入电平在设置的采样周期内连续匹配3次时，确定输入电平。

当TCCT[1:0]位为00b（未检测到事件）时，设置TCNF[1:0]位。使用噪声滤波器时，设置TCNF[1:0]位，等待指定采样周期的3个周期，然后设置TCCT[1:0]位。当VBTICTLR.VCHnIEN位为1时，设置TCNF[1:0]位。

TCEN位（时间捕捉事件输入引脚使能）

TCEN位启用或禁用时间捕捉事件输入引脚（RTCIC0、RTCIC1和RTCIC2）。当时间捕捉事件输入引脚的功能复用时，应首先设置VBTICTLR。如果TCEN位设置为0，也将TCCT[1:0]位设置为00b。

RTCIC0、RTCIC1和RTCIC2引脚检测到的事件检测时间存储在RMONCP0、分别是RMONCP1和RMONCP2寄存器。

该寄存器通过RTC软件复位设置为00h。在读取该寄存器之前，请务必使用RTCCRy.TCCT[1:0]位停止时间捕捉事件检测。

The procedure for reading the time without using interrupts is shown in (a) in Figure 26.6, and the procedure using carry interrupts is shown in (b). To keep the program simple, method (a) should be used in most cases.

26.3.6 Alarm Function

Figure 26.7 shows how to use the alarm function.

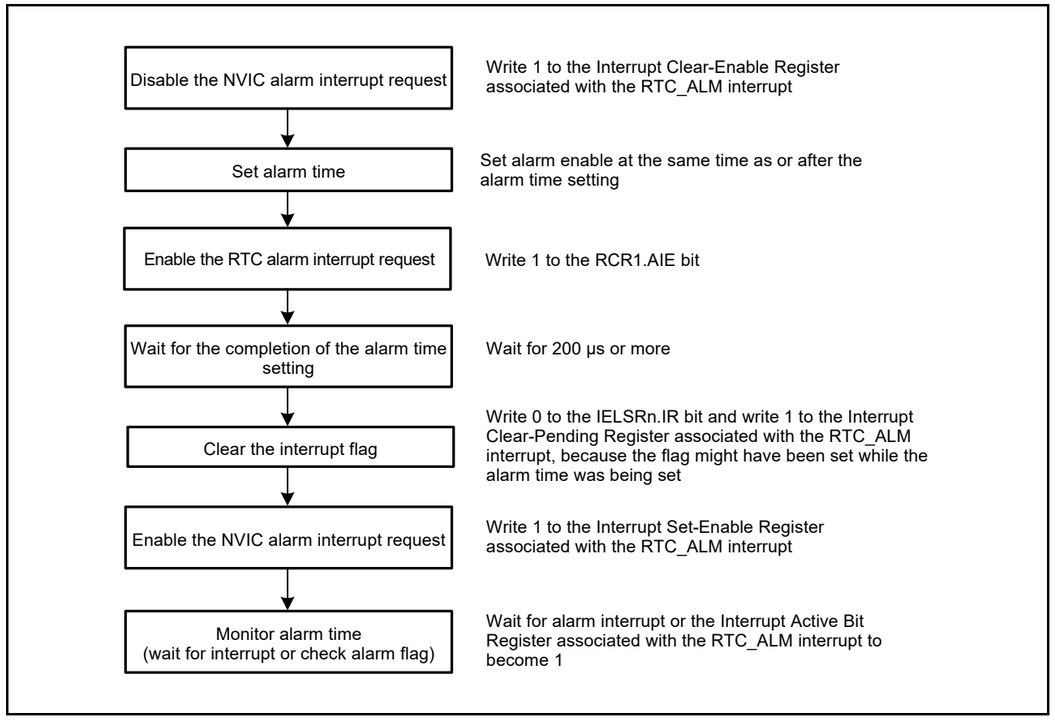

Figure 26.7 Using the alarm function

In calendar count mode, an alarm can be generated by any one of year, month, date, day-of-week, hour, minute or second, or any combination of those. Write 1 to the ENB bit in the alarm registers for alarm setting, and set the alarm time in the lower bits. Write 0 to the ENB bit in registers not involved in the alarm setting.

In binary count mode, an alarm can be generated in any bit combination of 32 bits. Write 1 to the ENB bit of the alarm enable register associated with the target bit of the alarm, and set the alarm time in the alarm register. For bits that are not target of the alarm, write 0 to the ENB bit of the alarm enable register.

When the counter and the alarm time match, the IELSRn.IR bit and Interrupt Set-Pending/Clear-Pending Register associated with the RTC_ALM interrupt are set to 1. Alarm detection can be confirmed by reading the Interrupt Set-Pending Register associated with the RTC_ALM interrupt, but an interrupt should be used in most cases. If 1 is set in the Interrupt Set-Enable Register associated with the RTC_ALM interrupt, an alarm interrupt is generated in the event of the alarm, enabling the alarm to be detected.

Writing 0 sets the IELSRn.IR bit associated with the RTC_ALM interrupt to 0. If interrupt is enabled, the Interrupt Set-Pending/Clear-Pending Register associated with the RTC_ALM interrupt is cleared automatically after exiting the interrupt handler. Otherwise, write 1 to the Interrupt Clear-Pending Register associated with the RTC_ALM interrupt to clear it.

When the counter and the alarm time match in a low power state, the MCU returns from the low power state. In Deep Software Standby mode, the MCU returns from the Deep Software Standby mode even when the alarm interrupt request is disabled.

26.3.7 Procedure for Disabling Alarm Interrupt

Figure 26.8 shows the procedure for disabling the enabled alarm interrupt request.

26.3.6 报警功能

图26.7显示了如何使用报警功能。

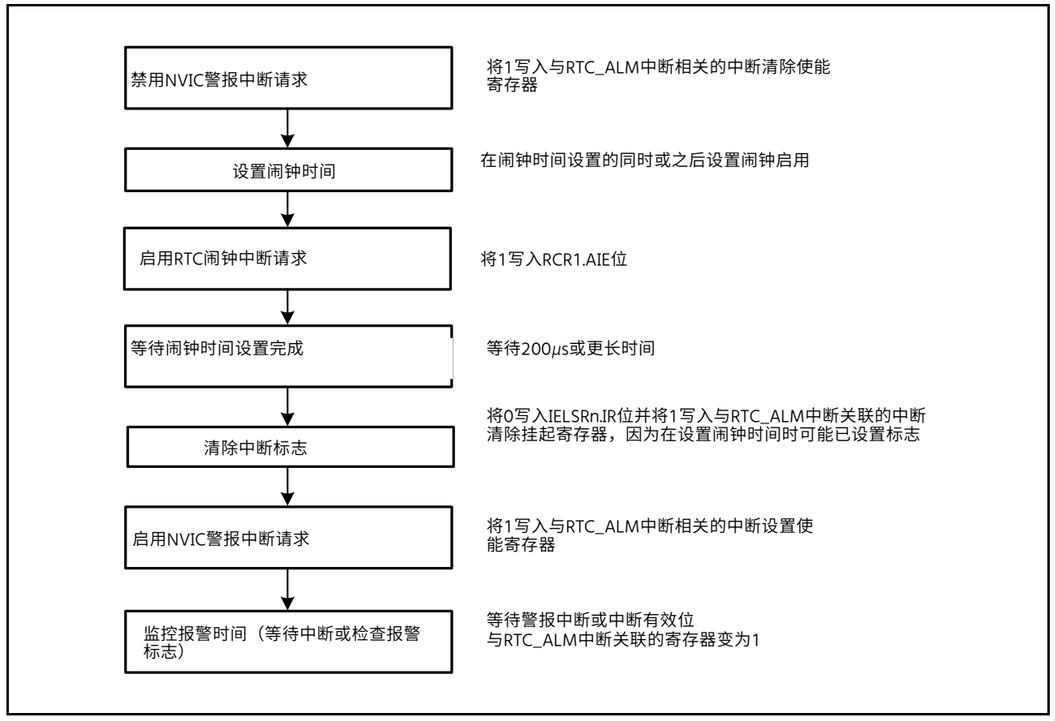

Figure 26.7 使用报警功能

在日历计数模式下，可以通过年、月、日、星期、小时、分钟或秒中的任何一个或它们的任意组合来生成警报。将1写入闹钟寄存器的ENB位进行闹钟设置，并在低位设置闹钟时间。将0写入与报警设置无关的寄存器中的ENB位。

在二进制计数模式下，可以以32位的任意位组合产生报警。将1写入与闹钟目标位相关的闹钟使能寄存器的ENB位，并在闹钟寄存器中设置闹钟时间。对于不是警报目标的位，将0写入警报使能寄存器的ENB位。

当计数器和闹钟时间匹配时，与RTC_ALM中断相关的IELSRn.IR位和中断设置挂起清除挂起寄存器设置为1。可以通过读取与RTC_ALM中断相关的中断设置挂起寄存器来确认警报检测，但在大多数情况下应该使用中断。如果在与RTC_ALM中断相关的中断设置使能寄存器中设置为1，则在发生警报时会产生警报中断，从而能够检测到警报。

写入0会将与RTC_ALM中断关联的IELSRn.IR位设置为0。如果启用中断，则与RTC_ALM中断关联的InterruptSet PendingClear-Pending寄存器会在退出中断处理程序后自动清除。否则，将1写入与RTC_ALM中断相关的中断清除挂起寄存器以将其清除。

当计数器和闹钟时间在低功耗状态下匹配时，MCU从低功耗状态返回。在深软件待机模式，即使警报中断请求被禁用，MCU也会从深度软件待机模式返回。

26.3.7 禁用警报中断的步骤

26.3.8 Time Error Adjustment Function

The time error adjustment function is used to correct errors, running fast or slow, in the time caused by variation in the precision of oscillation by the sub-clock oscillator. Because 32768 cycles of the sub-clock oscillator constitute 1 second of operation when the sub-clock oscillator is selected, the clock runs fast if the sub-clock frequency is high and slow if the sub-clock frequency is low.

The time error adjustment functions include:

- Automatic adjustment
- Adjustment by software.

Use the RCR2.AADJE bit to select automatic adjustment or adjustment by software.

26.3.8.1 Automatic adjustment

Enable automatic adjustment by setting the RCR2.AADJE bit to 1. Automatic adjustment is the addition or subtraction of the value counted by the prescaler to or from the value in the RADJ register every time the adjustment period selected by the RCR2.AADJP bit elapses.

(1) Example 1: Sub-clock oscillator running at 32.769 kHz

(a) Adjustment procedure

When the sub-clock oscillator is running at 32.769 kHz, 1 second elapses every 32769 clock cycles. The RTC is meant to run at 32768 clock cycles, so the clock runs fast by 1 clock cycle every second. The time on the clock is fast by 60 clock cycles per minute, so adjustment can take the form of setting the clock back by 60 cycles every minute.

Register settings when RCR2.CNTMD = 0:

- RCR2.AADJP = 0 (adjustment every minute)
- RADJ.PMADJ[1:0] = 10b (adjustment is performed by the subtraction from the prescaler)
- RADJ.ADJ[5:0] = 60 (3Ch).

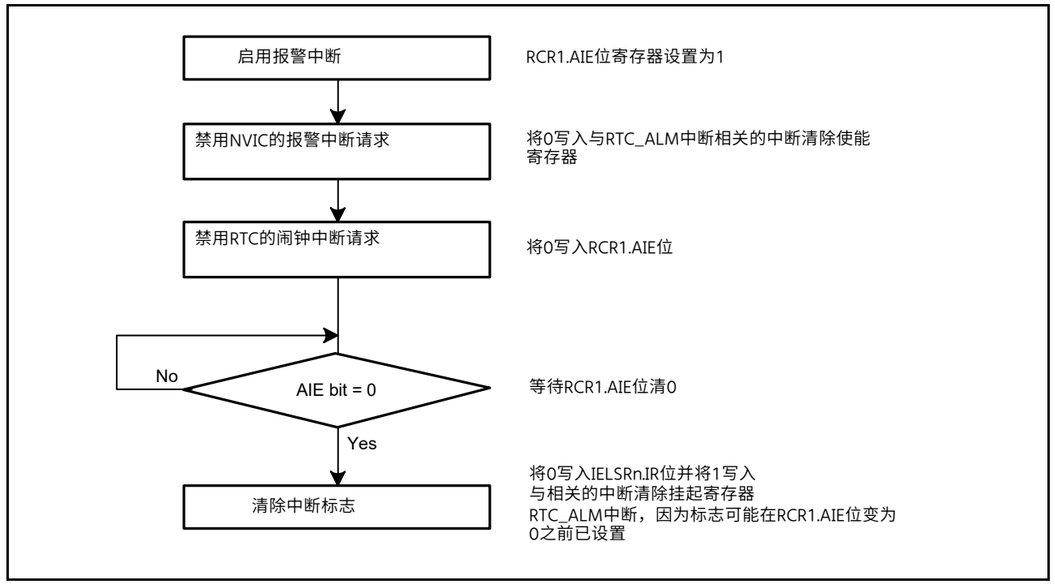

Figure 26.8 禁用报警中断请求的步骤

26.3.8 时间误差调整功能

时间误差调整功能用于校正子时钟振荡器振荡精度变化引起的时间误差，运行速度快或慢。由于在选择子时钟振荡器时，子时钟振荡器的32768个周期构成1秒的运行时间，因此子时钟频率高时时钟运行快，子时钟频率低时时钟运行慢。

时间误差调整功能包括：

- 自动调整
- 通过软件调整。

使用RCR2.AADJE位选择自动调整或软件调整。

26.3.8.1 自动调整

通过将RCR2.AADJE位设置为1来启用自动调整。自动调整是每次经过RCR2.AADJP位选择的调整周期时，将预分频器计数的值与RADJ寄存器中的值相加或相减。

(1) 示例1：运行在32.769kHz的子时钟振荡器

(a) 调整程序

当副时钟振荡器以32.769kHz运行时，每32769个时钟周期经过1秒。RTC旨在以32768个时钟周期运行，因此时钟以每秒1个时钟周期的速度运行。时钟上的时间每分钟快60个时钟周期，因此调整可以采取将时钟每分钟调回60个周期的形式。

RCR2.CNTMD=0时的寄存器设置：

- RCR2.AADJP = 0 (adjustment every minute)
- RADJ.PMADJ[1:0]=10b（通过预分频器的减法进行调整）
- RADJ.ADJ[5:0] = 60 (3Ch).

(2) Example 2: Sub-clock oscillator running at 32.766 kHz

(a) Adjustment procedure

When the sub-clock oscillator is running at 32.766 kHz, 1 second elapses every 32766 clock cycles. The RTC is meant to run at 32768 clock cycles, so the clock runs slow by 2 clock cycles every second. The time on the clock is slow by 20 clock cycles every 10 seconds, so adjustment can take the form of setting the clock forward by 20 cycles every 10 seconds.

Register settings when RCR2.CNTMD = 0:

- RCR2.AADJP = 1 (adjustment every 10 seconds)
- RADJ.PMADJ[1:0] = 01b (adjustment is performed by the addition to the prescaler)
- RADJ.ADJ[5:0] = 20 (14h).

(3) Example 3: Sub-clock oscillator running at 32.764 kHz

(a) Adjustment procedure

When the sub-clock oscillator is running at 32.764 kHz, 1 second elapses on 32764 clock cycles. Because the RTC operates for 32768 clock cycles as 1 second, the clock is delayed for 4 clock cycles per second. In 8 seconds, the delay is 32 clock cycles, therefore correction can be made by advancing the clock 32 clock cycles every 8 seconds.

Register settings when the RCR2.CNTMD bit is 1:

- RCR2.AADJP = 1 (adjustment every 8 seconds)
- RADJ.PMADJ[1:0] = 01b (adjustment is performed by the addition to the prescaler)
- RADJ.ADJ[5:0] = 32 (20h).

26.3.8.2 Adjustment by software

Enable adjustment by software by setting the RCR2.AADJE bit to 0. Adjustment by software is the addition or subtraction of the value counted by the prescaler to or from the value in the RADJ register on execution of a write instruction to the RADJ register.

(1) Example 1: Sub-clock oscillator running at 32.769 kHz

(a) Adjustment procedure

When the sub-clock oscillator is running at 32.769 kHz, 1 second elapses every 32769 clock cycles. The RTC is meant to run at 32768 clock cycles, so the clock runs fast by 1 clock cycle every second. The time on the clock is fast by 1 clock cycle per second, so adjustment can take the form of setting the clock back by 1 cycle every second.

(b) Register settings

- RADJ.PMADJ[1:0] = 10b (adjustment is performed by subtraction from the prescaler)
- RADJ.ADJ[5:0] = 1 (01h)
  This is written to the RADJ register once per 1-second interrupt.

26.3.8.3 Procedure for changing the mode of adjustment

When changing the mode of adjustment, change the value of the AADJE bit in RCR2 after setting the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).

To change adjustment by software to automatic adjustment:

1. Set the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).
2. Set the RCR2.AADJE bit to 1 (automatic adjustment is enabled).
3. Use the RCR2.AADJP bit to select the period of adjustment.
4. In RADJ, set the PMADJ[1:0] bits for addition or subtraction and the ADJ[5:0] bits to the value for use in time error adjustment.

(2) 示例2：以32.766kHz运行的子时钟振荡器

(a) 调整程序

当子时钟振荡器以32.766kHz运行时，每32766个时钟周期经过1秒。RTC旨在以32768个时钟周期运行，因此时钟每秒运行2个时钟周期。时钟上的时间每10秒慢20个时钟周期，因此调整可以采取将时钟每10秒向前20个周期的形式。

RCR2.CNTMD=0时的寄存器设置：

- RCR2.AADJP = 1 (adjustment every 10 seconds)
- RADJ.PMADJ[1:0]=01b（通过加到预分频器进行调整）
- RADJ.ADJ[5:0] = 20 (14h).

(3) 示例3：以32.764kHz运行的子时钟振荡器

(a) 调整程序

当副时钟振荡器以32.764kHz运行时，32764个时钟周期经过1秒。由于RTC以1秒为单位运行32768个时钟周期，因此时钟每秒延迟4个时钟周期。在8秒内，延迟为32个时钟周期，因此可以通过每8秒将时钟提前32个时钟周期来进行校正。

RCR2.CNTMD位为1时的寄存器设置：

- RCR2.AADJP = 1 (adjustment every 8 seconds)
- RADJ.PMADJ[1:0]=01b（通过加到预分频器进行调整）
- RADJ.ADJ[5:0] = 32 (20h).

26.3.8.2 软件调整

通过将RCR2.AADJE位设置为0来启用软件调整。软件调整是在对RADJ寄存器执行写指令时，将预分频器计数的值与RADJ寄存器中的值相加或相减。

(1) 示例1：运行在32.769kHz的子时钟振荡器

(a) 调整程序

当副时钟振荡器以32.769kHz运行时，每32769个时钟周期经过1秒。RTC旨在以32768个时钟周期运行，因此时钟以每秒1个时钟周期的速度运行。时钟上的时间每秒快1个时钟周期，因此调整可以采取将时钟每秒调回1个周期的形式。

(b) 注册设置

- RADJ.PMADJ[1:0]=10b（通过预分频器的减法进行调整）
- RADJ.ADJ[5:0] = 1 (01h)
  每1秒中断一次将其写入RADJ寄存器。

26.3.8.3 更改调整模式的步骤

改变调节方式时，设置好后改变RCR2中ADJE位的值
RADJ.PMADJ[1:0]位到00b（不执行调整）。

将软件调整改为自动调整：

1. 将RADJ.PMADJ[1:0]位设置为00b（不执行调整）。
2. 将RCR2.AADJE位设置为1（启用自动调整）。
3. 使用RCR2.AADJP位选择调整周期。
4. 在RADJ中，将PMADJ[1:0]位设置为加法或减法，并将ADJ[5:0]位设置为用于时间误差调整的值。

To change automatic adjustment to adjustment by software:

1. Set the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).
2. Set the RCR2.AADJE bit to 0 (adjustment by software is enabled).
3. Proceed with the adjustment by setting the RADJ.PMADJ[1:0] bits for addition or subtraction and the RADJ.ADJ[5:0] bits to the value for use in time error adjustment at the target time. After that, the time is adjusted every time a value is written to the RADJ register.

26.3.8.4 Procedure for stopping adjustment

Stop the adjustment by setting the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).

26.3.8.5 Capturing the time

The RTC is capable of storing the month, date, hour, minute and second/binary counters 3 to 0 by detecting an edge of a signal on a time capture event input pin.

A noise filter can also be used on a time capture event input pin. If the noise filter is enabled, the TCST bit is set to 1 when the input level on the pin matches three times.

The noise filter can be switched on or off for each of the time capture event input pins. Set VBTICTLR.VCHnIEN (n = 0 to 2) to 1 to enable the RTCICn input. Operation when the noise filter is off is shown in Figure 26.9 and operation when the noise filter is on is shown in Figure 26.10.

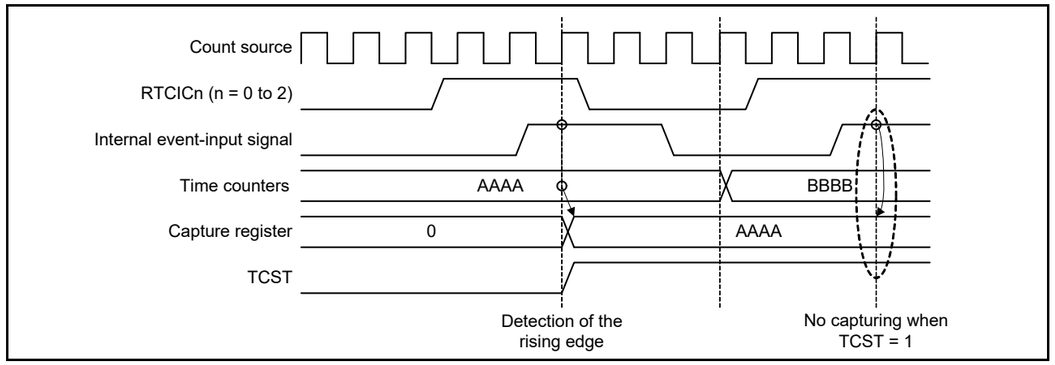

Figure 26.9 Timing of a time capture operation with the filter off

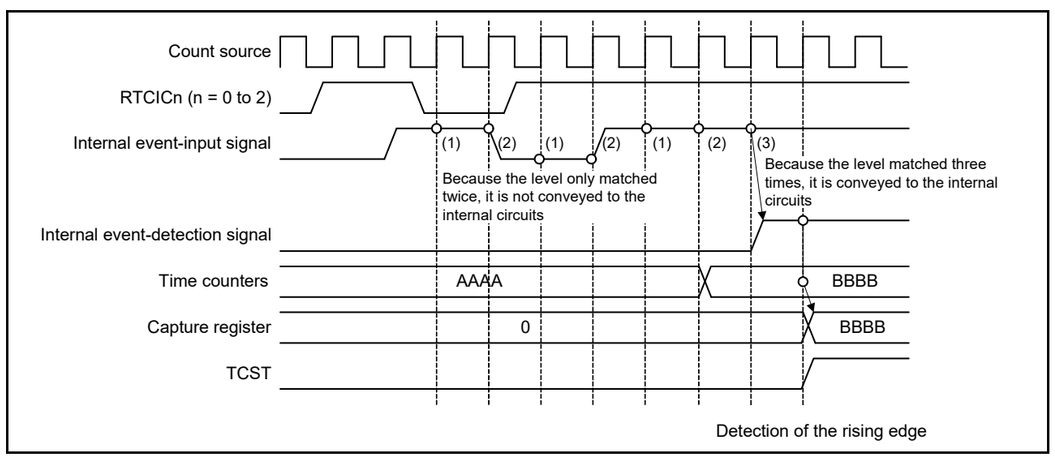

Figure 26.10 Timing of a time capture operation with the filter on

将自动调整更改为软件调整：

1. 将RADJ.PMADJ[1:0]位设置为00b（不执行调整）。
2. 将RCR2.AADJE位设置为0（启用软件调整）。
3. 通过设置RADJ.PMADJ[1:0]位进行加法或减法以及RADJ.ADJ[5:0]位用于在目标时间进行时间误差调整的值。之后，每次将值写入RADJ寄存器时都会调整时间。

26.3.8.4 停止调整的步骤

通过将RADJ.PMADJ[1:0]位设置为00b来停止调整（不执行调整）。

26.3.8.5 捕捉时间

RTC能够通过检测时间捕捉事件输入引脚上的信号沿来存储月、日、小时、分钟和秒二进制计数器3到0。

噪声滤波器也可用于时间捕捉事件输入引脚。如果启用了噪声滤波器，则当引脚上的输入电平匹配3次时，TCST位设置为1。

可以为每个时间捕捉事件输入引脚打开或关闭噪声滤波器。将VBTICTLR.VCHnIEN（n=0到2）设置为1以启用RTCICn输入。噪声滤波器关闭时的操作如图26.9所示，噪声滤波器打开时的操作如图26.10所示。

26.4 Interrupt Sources

The RTC has three interrupt sources and are listed in Table 26.3.

Table 26.3 RTC interrupt sources

Name	Interrupt source
RTC_ALM	Alarm interrupt
RTC_PRD	Periodic interrupt
RTC_CUP	Carry interrupt

(1) Alarm interrupt (RTC_ALM)

This interrupt is generated based on the comparison result between the alarm registers and RTC counters. For details, see section 26.3.6, Alarm Function.
