26.2 Register Descriptions

Write or read from the RTC registers as described in section 26.6.5, Notes on Writing to and Reading from Registers.

If the value in an RTC register after a reset is given as x (undefined bits) in the list, it is not initialized by a reset. When RTC enters the reset state or a low power consumption state during counting operations, for example while the RCR2.START bit is 1, the year, month, day of the week, date, hours, minutes, seconds, and 64-Hz counters continue to operate.

Note: A reset generated while writing to a register might destroy the register value. In addition, do not allow the chip to enter Software Standby mode or Deep Software Standby mode immediately after setting any of these registers. For details, see section 26.6.4, Transitions to Low Power Modes after Setting Registers.

26.2.1 64-Hz Counter (R64CNT)

b4	F4HZ	4 Hz		R
b5	F2HZ	2 Hz		R
b6	F1HZ	1 Hz		R
b7	—	Reserved	This bit is read as 0.	R

The R64CNT counter is used in both calendar count mode and in binary count mode. The 64-Hz counter (R64CNT) generates the period for a second by counting up periods of the 128-Hz clock. The state in the sub-second range can be confirmed by reading this counter.

This counter is cleared to 00h by an RTC software reset or an execution of a 30-second adjustment. To read this counter, follow the procedure in section 26.3.5, Reading 64-Hz Counter and Time.

26.2 注册说明

写入或读取RTC寄存器，如第26.6.5节“写入和读取寄存器的注意事项”中所述。

如果复位后RTC寄存器中的值在列表中以x（未定义位）的形式给出，则它不会被复位初始化。当RTC在计数操作期间进入复位状态或低功耗状态时，例如当
RCR2.START位为1，年、月、星期、日期、小时、分钟、秒和64-Hz计数器继续工作。

Note: 写入寄存器时产生的复位可能会破坏寄存器值。此外，不要让芯片在设置这些寄存器后立即进入软件待机模式或深度软件待机模式。有关详细信息，请参阅第26.6.4节，设置寄存器后转换到低功耗模式。

R64CNT计数器用于日历计数模式和二进制计数模式。64-Hz计数器(R64CNT)通过向上计数128-Hz时钟的周期来生成一秒的周期。亚秒范围内的状态可以通过读取该计数器来确认。

通过RTC软件复位或执行30秒调整，该计数器清零。要读取此计数器，请按照第26.3.5节，读取64-Hz计数器和时间中的程序进行操作。

b7	—	Reserved	Set this bit to 0. It is read as the set value.	R/W

The RSECCNT counter sets and counts the BCD-coded second value. It counts the carries generated once per second in the 64-Hz counter.

The setting range is decimal 00 to 59. The RTC does not operate normally if any other value is set. Before writing to this register, be sure to stop the count operation using the START bit in RCR2.

To read this counter, follow the procedure in section 26.3.5, Reading 64-Hz Counter and Time.

b7	—	Reserved	Set this bit to 0. It is read as the set value.	R/W

The RMINCNT counter sets and counts the BCD-coded minute value. It counts the carries generated once every minute in the second counter.

A value from 00 through 59 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation using the START bit in RCR2. To read this counter, follow the procedure in section 26.3.5, Reading 64-Hz Counter and Time.

RSECCNT计数器设置并计算BCD编码的第二个值。它对64-Hz计数器中每秒生成一次的进位进行计数。

设置范围为十进制00到59。如果设置任何其他值，RTC将无法正常工作。在写入该寄存器之前，请务必使用RCR2中的START位停止计数操作。

要读取此计数器，请按照第26.3.5节，读取64-Hz计数器和时间中的程序进行操作。

b6	PM	PM	AM/PM select for time counter setting. 0: AM 1: PM.	R/W
b7	—	Reserved	Set this bit to 0. It is read as the set value.	R/W

The RHRCNT counter sets and counts the BCD-coded hour value. It counts the carries generated once per hour in the minute counter. The specifiable time differs based on the setting in the hours mode bit (RCR2.HR24):

- When the RCR2.HR24 bit is 0 — from 00 to 11 (in BCD)
- When the RCR2.HR24 bit is 1 — from 00 to 23 (in BCD).

If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation using the START bit in RCR2. The PM bit is only enabled when the RCR2.HR24 bit is 0. Otherwise, the setting in the PM bit has no effect. To read this counter, follow the procedure in section 26.3.5, Reading 64-Hz Counter and Time.

b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The RDAYCNT counter is used in calendar count mode to set and count the BCD-coded date value. It counts the carries generated once per day in the hour counter. The count operation depends on the month and whether the year is a leap year. Leap years are determined according to whether the year counter (RYRCNT) value is divisible by 400, 100, and 4.

A value from 01 through 31 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. When specifying a value, the range of specifiable days depends on the month and whether the year is a leap year. Before writing to this register, be sure to stop the count operation using the START bit in RCR2. To read this counter, follow the procedure in section 26.3.5, Reading 64-Hz Counter and Time.

b7, b6	—	Reserved	这些位被读取为0。写入值应为0。	R/W

RDAYCNT计数器用于日历计数模式以设置和计数BCD编码的日期值。它计算小时计数器中每天生成一次的进位。计数操作取决于月份以及年份是否为闰年。闰年根据年份计数器(RYRCNT)值是否可被400、100和4整除来确定。

可以指定从01到31的值（以BCD表示）。如果指定的值超出此范围，则RTC将无法正确运行。指定值时，可指定天数的范围取决于月份以及年份是否为闰年。在写入该寄存器之前，请务必使用RCR2中的START位停止计数操作。要读取此计数器，请按照第26.3.5节，读取64-Hz计数器和时间中的程序进行操作。

b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The RYRCNT counter is used in calendar count mode to set and count the BCD-coded year value. It counts the carries generated once per year in the month counter.

A value from 00 through 99 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation using the START bit in RCR2. To read this counter, follow the procedure in section 26.3.5, Reading 64-Hz Counter and Time.

RHRAR is an alarm register associated with the BCD-coded hour counter RHRCNT. When the ENB bit is set to 1, the RHRAR value is compared with the RHRCNT value. From the following alarm registers, only those selected with the ENB bits set to 1 are compared with the associated counters:

- RSECAR
- RMINAR
- RHRAR
- RWKAR
- RDAYAR
- RMONAR
- RYRAREN.

When all the respective values match, the IR flag associated with the RTC_ALM interrupt is set to 1. The specifiable time differs according to the setting in the hours mode bit (RCR2.HR24):

- When the RCR2.HR24 bit is 0 — From 00 to 11 (in BCD)
- When the RCR2.HR24 bit is 1 — From 00 to 23 (in BCD).

If a value outside of this range is specified, the RTC does not operate correctly. When the RCR2.HR24 bit is 0, be sure to set the PM bit. When the RCR2.HR24 bit is 1, the setting in the PM bit has no effect. This register is cleared to 00h by an RTC software reset.

RMONAR is an alarm register associated with the BCD-coded month counter RMONCNT. When the ENB bit is set to 1, the RMONAR value is compared with the RMONCNT value. From the following alarm registers, only those selected with the ENB bits set to 1 are compared with the associated counters:

- RSECAR
- RMINAR
- RHRAR
- RWKAR
- RDAYAR
- RMONAR
- RYRAREN.

When all the respective values match, the IR flag associated with the RTC_ALM interrupt is set to 1. RMONAR values from 01 through 12 (in BCD) can be specified. If a value outside of this range is specified, the RTC does not operate correctly. This register is cleared to 00h by an RTC software reset.

Note 1. When LOCO is selected (RCR4.RCKSEL = 1) while PES[3:0] = 0110b, a periodic interrupt is generated every 1/128 second.

The RCR1 register is used in both calendar count mode and in binary count mode. Bits AIE, PIE, and PES[3:0] are updated synchronously with the count source. When the RCR1 register is modified, check that all the bits are updated before proceeding.

AIE bit (Alarm Interrupt Enable)

The AIE bit enables or disables alarm interrupt requests.

If the times indicated in the counters and alarm settings match in Deep Software Standby mode, the MCU returns from the mode regardless of the AIE bit value.

CIE bit (Carry Interrupt Enable)

The CIE bit enables or disables interrupt requests when a carry to the RSECCNT/BCNT0 register occurs, or when a carry to the 64-Hz counter (R64CNT) occurs while reading the 64-Hz counter.

PIE bit (Periodic Interrupt Enable)

The PIE bit enables or disabled a periodic interrupt.

If the periods indicated in the counters and PES[3:0] settings match in Deep Software Standby mode, the MCU returns from the mode regardless of the PIE bit value.

RTCOS bit (RTCOUT Output Select)

The RTCOS bit selects the RTCOUT output period. The RTCOS bit must be rewritten while the count operation is stopped (the RCR2.START bit is 0) and the RTCOUT output is disabled (the RCR2.RTCOE bit is 0). When RTCOUT is output to an external pin, the RCR2.RTCOE bit must be enabled. For details on controlling the I/O ports, see section 20.5.1, Procedure for Specifying the Pin Functions.

RCR1寄存器用于日历计数模式和二进制计数模式。AIE、PIE和PES[3:0]位与计数源同步更新。修改RCR1寄存器时，在继续之前检查所有位是否都已更新。

AIE位（报警中断使能）

AIE位启用或禁用警报中断请求。

如果计数器和警报设置中指示的时间在深度软件待机模式下匹配，则无论AIE位值如何，MCU都会从该模式返回。

CIE位（进位中断使能）

当发生对RSECCNTBCNT0寄存器的进位，或在读取64-Hz计数器时发生对64-Hz计数器(R64CNT)的进位时，CIE位启用或禁用中断请求。

PIE位（周期性中断使能）

PIE位启用或禁用周期性中断。

如果计数器中指示的周期和PES[3:0]设置在深度软件待机模式下匹配，则无论PIE位值如何，MCU都会从该模式返回。

RTCOS位（RTCOUT输出选择）

RTCOS位选择RTCOUT输出周期。当计数操作停止（RCR2.START位为0）且RTCOUT输出禁用（RCR2.RTCOE位为0）时，必须重写RTCOS位。当RTCOUT输出到外部引脚时，必须使能RCR2.RTCOE位。有关控制IO端口的详细信息，请参见第20.5.1节，指定引脚功能的过程。

PES[3:0] bits (Periodic Interrupt Select)

RCR2寄存器与小时模式、自动调整功能、启用RTCOUT输出、30秒调整、RTC软件复位和控制计数操作有关。

开始位（开始）

START位停止或重新启动预分频器或时间计数器操作。该位与计数源的下一个周期同步更新。修改START位后，请在继续之前检查该位是否已更新。

RESET bit (RTC Software Reset)

The RESET bit initializes the prescaler and registers to be reset by RTC software.

When 1 is written to the RESET bit, initialization starts in synchronization with the count source. When the initialization is complete, the RESET bit is automatically set to 0. Check that this bit is 0 before proceeding.

ADJ30 bit (30-Second Adjustment)

The ADJ30 bit is for 30-second adjustment.

When 1 is written to the ADJ30 bit, the RSECCNT value of 30 seconds or less is rounded down to 00 second and the value of 30 seconds or more is rounded up to 1 minute.

The 30-second adjustment is performed in synchronization with the count source. When 1 is written to this bit, the ADJ30 bit is automatically set to 0 after the 30-second adjustment is complete. If 1 is written to the ADJ30 bit, check that the bit is 0 before proceeding. When the 30-second adjustment is performed, the prescaler and R64CNT are also reset. The ADJ30 bit is cleared to 0 by an RTC software reset.

RTCOE bit (RTCOUT Output Enable)

The RTCOE bit enables output of a 1-Hz/64-Hz clock signal from the RTCOUT pin.

Use the START bit to stop counting before changing the value of the RTCOE bit. Do not stop counting (write 0 to the START bit) and change the value of the RTCOE bit at the same time.

When RTCOUT is to be output from an external pin, enable the RTCOE bit and set up the port control for the pin.

AADJE bit (Automatic Adjustment Enable*2)

The AADJE bit controls (enables or disables) automatic adjustment.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJE bit.

The AADJE bit is cleared to 0 by an RTC software reset.

AADJP bit (Automatic Adjustment Period Select*2)

The AADJP bit selects the automatic-adjustment period.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJP bit.

The AADJP bit is cleared to 0 by an RTC software reset.

HR24 bit (Hours Mode)

The HR24 bit specifies whether the RTC operates in 12- or 24-hour mode.

Use the START bit to stop counting before changing the value of the HR24 bit. Do not stop counting (write 0 to the START bit) and change the value of the HR24 bit at the same time.

CNTMD bit (Count Mode Select)

The CNTMD bit specifies whether the RTC count mode operates in calendar count mode or in binary count mode.

When setting the count mode, execute an RTC software reset and start again from the initial settings. This bit is updated synchronously with the count source, and its value is fixed before the RTC software reset is complete.

For details on initial settings, see section 26.3.1, Outline of Initial Settings of Registers after Power On.

RESET位（RTC软件复位）

RESET位初始化预分频器和寄存器以由RTC软件复位。

向RESET位写入1时，初始化与计数源同步开始。初始化完成后，RESET位自动设置为0。在继续之前检查该位是否为0。

ADJ30位（30秒调整）

ADJ30位用于30秒调整。

向ADJ30位写入1时，30秒以下的RSECCNT值向下舍入为00秒，30秒以上的值向上舍入为1分钟。

30秒调整与计数源同步进行。当1写入该位时，
30秒调整完成后，ADJ30位自动设置为0。如果将1写入ADJ30位，请在继续之前检查该位是否为0。当执行30秒调整时，预分频器和R64CNT也被复位。RTC软件复位将ADJ30位清零。

RTCOE位（RTCOUT输出使能）

RTCOE位使能从RTCOUT引脚输出1-Hz64-Hz时钟信号。

在更改RTCOE位的值之前，使用START位停止计数。不要停止计数（将0写入START位）并同时更改RTCOE位的值。

当RTCOUT要从外部引脚输出时，使能RTCOE位并设置引脚的端口控制。

ADJE位（自动调整使能*2）

AADJE位控制（启用或禁用）自动调整。

通过RTC软件复位将ADJE位清零。

AADJP位（自动调整周期选择*2）

AADJP位选择自动调整周期。

在更改

AADJP位通过RTC软件复位清零。

HR24位（小时模式）

HR24位指定RTC是在12小时还是24小时模式下运行。

在更改HR24位的值之前，使用START位停止计数。不要停止计数（将0写入START位）并同时更改HR24位的值。

CNTMD位（计数模式选择）

CNTMD位指定RTC计数模式是在日历计数模式还是二进制计数模式下运行。

设置计数模式时，执行RTC软件复位并从初始设置重新开始。该位与计数源同步更新，其值在RTC软件复位完成前固定。

有关初始设置的详细信息，请参阅第26.3.1节“通电后寄存器初始设置概述”。

START bit (Start)

The START bit stops or restarts the prescaler or counter (clock) operation. The bit is updated in synchronization with the count source. When the START bit is modified, check that the bit is updated before proceeding.

RESET bit (RTC Software Reset)

The RESET bit initializes the prescaler and registers to be reset by RTC software.

When 1 is written to this bit, initialization starts in synchronization with the count source. When the initialization is complete, the RESET bit is automatically set to 0. When 1 is written to the RESET bit, check that the bit is 0 before proceeding.

RTCOE bit (RTCOUT Output Enable)

The RTCOE bit enables output of a 1-Hz/64-Hz clock signal from the RTCOUT pin.

Use the START bit to stop counting before changing the value of the RTCOE bit. Do not stop counting (write 0 to the START bit) and change the value of the RTCOE bit at the same time. When an RTCOUT signal is to be output from an external pin, enable the port control in addition to setting this bit.

开始位（开始）

START位停止或重新启动预分频器或计数器（时钟）操作。该位与计数源同步更新。修改START位后，请在继续之前检查该位是否已更新。

RESET位（RTC软件复位）

RESET位初始化预分频器和寄存器以由RTC软件复位。

当向该位写入1时，初始化与计数源同步开始。初始化完成后，RESET位自动设置为0。当向RESET位写入1时，在继续之前检查该位是否为0。

RTCOE位（RTCOUT输出使能）

RTCOE位使能从RTCOUT引脚输出1-Hz64-Hz时钟信号。

在更改RTCOE位的值之前，使用START位停止计数。不要停止计数（将0写入START位）并同时更改RTCOE位的值。当要从外部引脚输出RTCOUT信号时，除了设置该位外，还启用端口控制。

AADJE bit (Automatic Adjustment Enable)

The AADJE bit controls (enables or disables) automatic adjustment.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJE bit. The AADJE bit is cleared to 0 by an RTC software reset.

AADJP bit (Automatic Adjustment Period Select)

The AADJP bit selects the automatic-adjustment period.

Correction period can be selected from 32 second units or 8 second units in binary count mode.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJP bit. The AADJP bit is cleared to 0 by an RTC software reset.

CNTMD bit (Count Mode Select)

The CNTMD bit specifies whether the RTC count mode operates in calendar count mode or in binary count mode.

When setting the count mode, execute an RTC software reset and start again from the initial settings. This bit is updated synchronously with the count source, and its value is fixed before the RTC software reset is complete.

For details on initial settings, see section 26.3.1, Outline of Initial Settings of Registers after Power On.

The RCR4 register selects the count source and is used in both calendar count mode and binary count mode.

When the RCKSEL bit is set to 0, the time is counted with the sub-clock oscillator. When the bit is set to 1, the time is counted with LOCO.

RCKSEL bit (Count Source Select)

The RCKSEL bit selects the count source from the sub-clock oscillator and LOCO.

The count source must be selected only once before specifying the initial settings of the RTC registers at power on.

Bit	Symbol	Bit name	Description	R/W
b15 to b0	RFC[15:0]	Frequency Comparison Value	Write 00FFh to this register when using the LOCO	R/W

RFRL is a register for controlling the prescaler when LOCO is selected.

The RTC time counter operates on a 128-Hz clock signal as the base clock. Therefore, when LOCO is selected, LOCO is divided by the prescaler to generate a 128-Hz clock signal. Set the frequency comparison value in the RFC[15:0] bits to generate a 128-Hz clock from the LOCO frequency. Before writing to RFC[15:0] after a cold start, write 0000h to the RFRH register.

A value from 0007h through 01FFh can be specified as the frequency comparison value. If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2. The operating frequency of the peripheral module clock and the LOCO should be such that the peripheral module clock is ≥ to the LOCO.

Calculation method of frequency comparison value:

RFC[15:0] = (LOCO clock frequency) / 128 - 1

When the LOCO frequency is 32.768 kHz, the RFRL register should be set to 00FFh.

RFRL是一个寄存器，用于在选择LOCO时控制预分频器。

RTC时间计数器以128-Hz时钟信号作为基本时钟运行。Therefore whenLOCOisselected LOCOisdividedbytheprescalertogeneratea128-Hzclocksignal设置RFC[15:0]位中的频率比较值以从LOCO频率生成128-Hz时钟。在冷启动后写入RFC[15:0]之前，将0000h写入RFRH寄存器。

可以将0007h到01FFh的值指定为频率比较值。如果指定的值超出此范围，则RTC将无法正确运行。在写入该寄存器之前，请务必通过设置RCR2中的START位来停止计数操作。外围模块时钟和LOCO的工作频率应使外围模块时钟与LOCO相差 。

频率比较值的计算方法：

RFC[15:0] = (LOCO clock frequency) / 128 - 1

当LOCO频率为32.768kHz时，RFRL寄存器应设置为00FFh。

Adjustment is performed by the addition to or subtraction from the prescaler. If the automatic adjustment enable (RCR2.AADJE) bit is 0, adjustment is performed when writing to the RADJ. If the RCR2.AADJE bit is 1, adjustment is performed in the interval specified in the automatic adjustment period select (RCR2.AADJP) bit.

The current adjustment by software (disabling automatic adjustment) might be invalid if the following adjustment value is specified within 320 cycles of the count source after the register setting. To perform adjustment consecutively, wait for 320 cycles or more of the count source after the register setting, then specify the next adjustment value.

RADJ is updated in synchronization with the count source. When RADJ is modified, check that all the bits are updated before continuing with more processing. This register is cleared to 00h by an RTC software reset. The setting of this register is enabled only when the sub-clock oscillator is selected. When LOCO is selected, adjustment is not performed.

ADJ[5:0] bits (Adjustment Value)

The ADJ[5:0] bits specify the adjustment value (number of sub-clock cycles) from the prescaler.

PMADJ[1:0] bits (Plus-Minus)

The PMADJ[1:0] bits select whether the clock is set ahead or back depending on the error-adjustment value set in the ADJ[5:0] bits.

Note 1. Indicates that an event is detected. Writing 1 to this bit has no effect. Writing 0 sets this bit to 0.

The RTCCRy register is used both in calendar count mode and in binary count mode. RTCCR0, RTCCR1, and RTCCR2 control the RTCIC0, RTCIC1, and RTCIC2 pins, respectively.

RTCCRy is updated in synchronization with the count source. When RTCCRy is modified, check that all the bits except the TCST bit are updated before continuing with more processing. This register is cleared to 00h by an RTC software reset. When RTCICn is used as the time capture pin, VBTICTLR.VCHnIEN (n = 0 to 2) must be set to 1. For more information, see section 12, Battery Backup Function.

TCCT[1:0] bits (Time Capture Control)

The TCCT[1:0] bits control the edge detection of the time capture event input pins, RTCIC0, RTCIC1, and RTCIC2. The detection edge is selectable. The TCCT[1:0] bits must be set while the VBTICTLR.VCHnIEN bit is 1.

TCST bit (Time Capture Status)

The TCST bit indicates that an event on the time capture event input pins, RTCIC0, RTCIC1, and RTCIC2, was detected. When the TCST bit is 0, no event is detected. When the TCST bit is 1, this bit indicates that an event was detected on the associated pin and the capture register is valid. When multiple events are detected, the capture time for the first event is retained.

If an event is detected while the count operation is stopped (the RCR2.START bit is 0), the captured value is not guaranteed. In this case, set the TCST bit to 0 to delete the captured value. Writing 0 sets the TCST bit to 0. Writing any value other than 0 has no effect.

Set the TCST bit while the TCCT[1:0] bits are 00b (no event is detected). The TCST bit is set to 0 in synchronization with the count source. When the TCST bit is set to 0, check that the bit is updated before continuing with additional processing.

TCNF[1:0] bits (Time Capture Noise Filter Control)

The TCNF[1:0] bits control the noise filter of the time capture event input pins (RTCIC0, RTCIC1, and RTCIC2).

When the noise filter is on, the count source divided by 1 or divided by 32 is selectable. In this case, when the input level on the time capture event input pin matches three consecutive times at the set sampling period, the input level is determined.

Set the TCNF[1:0] bits while the TCCT[1:0] bits are 00b (no event is detected). When the noise filter is used, set the TCNF[1:0] bits, wait for 3 cycles of the specified sampling period, and then set the TCCT[1:0] bits. Set the TCNF[1:0] bits when the VBTICTLR.VCHnIEN bit is 1.

TCEN bit (Time Capture Event Input Pin Enable)

The TCEN bit enables or disables the time capture event input pins RTCIC0, RTCIC1, and RTCIC2. When the functions of the time capture event input pins are multiplexed, set VBTICTLR first. If the TCEN bit is set to 0, also set the TCCT[1:0] bits to 00b.

RTCCRy与计数源同步更新。修改RTCCRy后，请检查除TCST位之外的所有位是否都已更新，然后再继续进行更多处理。该寄存器通过RTC软件复位清零。当RTCICn用作时间捕捉引脚时，VBTICTLR.VCHnIEN(n=0to2)必须设置为1。有关详细信息，请参阅第12节，电池备份功能。

TCCT[1:0]位（时间捕捉控制）

TCCT[1:0]位控制时间捕捉事件输入引脚RTCIC0、RTCIC1和RTCIC2的边沿检测。检测边缘是可选的。当VBTICTLR.VCHnIEN位为1时，必须设置TCCT[1:0]位。

TCST位（时间捕捉状态）

TCST位指示检测到时间捕捉事件输入引脚RTCIC0、RTCIC1和RTCIC2上的事件。当TCST位为0时，未检测到任何事件。当TCST位为1时，该位表示在相关引脚上检测到事件并且捕捉寄存器有效。当检测到多个事件时，将保留第一个事件的捕获时间。

如果在计数操作停止时检测到事件（RCR2.START位为0），则不能保证捕获的值。在这种情况下，将TCST位设置为0以删除捕获的值。写入0会将TCST位设置为0。写入0以外的任何值均无效。

当TCCT[1:0]位为00b（未检测到事件）时，设置TCST位。TCST位与计数源同步设置为0。当TCST位设置为0时，在继续进行其他处理之前检查该位是否已更新。

TCNF[1:0]位（时间捕捉噪声滤波器控制）

TCNF[1:0]位控制时间捕捉事件输入引脚（RTCIC0、RTCIC1和RTCIC2）的噪声滤波器。

当噪声滤波器打开时，计数源除以1或除以32是可选的。在这种情况下，当时间捕捉事件输入引脚上的输入电平在设置的采样周期内连续匹配3次时，确定输入电平。

当TCCT[1:0]位为00b（未检测到事件）时，设置TCNF[1:0]位。使用噪声滤波器时，设置TCNF[1:0]位，等待指定采样周期的3个周期，然后设置TCCT[1:0]位。当VBTICTLR.VCHnIEN位为1时，设置TCNF[1:0]位。

TCEN位（时间捕捉事件输入引脚使能）

TCEN位启用或禁用时间捕捉事件输入引脚RTCIC0、RTCIC1和RTCIC2。当时间捕捉事件输入引脚的功能复用时，首先设置VBTICTLR。如果TCEN位设置为0，也将TCCT[1:0]位设置为00b。

26.3.6 Alarm Function

Figure 26.7 shows how to use the alarm function.

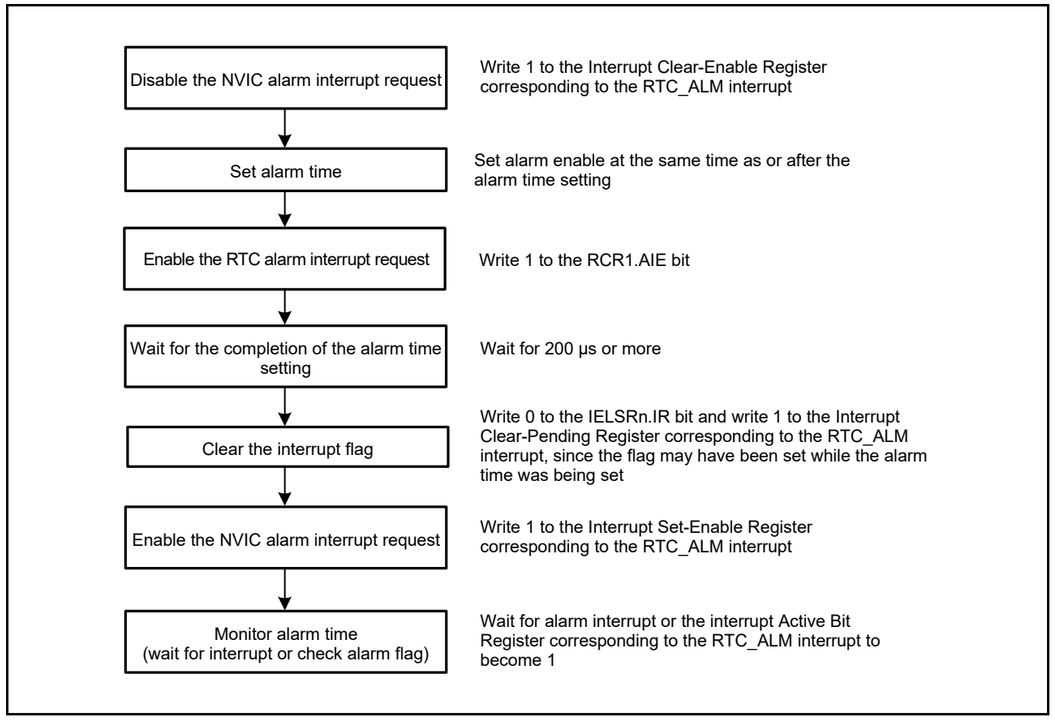

Figure 26.7 Using the alarm function

In calendar count mode, an alarm can be generated by any one of year, month, date, day-of-week, hour, minute or second, or any combination of those. Write 1 to the ENB bit in the alarm registers involved in the alarm setting, and set the alarm time in the lower bits. Write 0 to the ENB bit in registers not involved in the alarm setting.

In binary count mode, an alarm can be generated in any bit combination of 32 bits. Write 1 to the ENB bit of the alarm enable register associated with the target bit of the alarm, and set the alarm time in the alarm register. For bits that are not the target of the alarm, write 0 to the ENB bit of the alarm enable register.

When the counter and the alarm time match, the IELSRn.IR bit and Interrupt Set-Pending/Clear-Pending Register associated with the RTC_ALM interrupt are set to 1. Alarm detection can be confirmed by reading the interrupt Set-Pending Register associated with the RTC_ALM interrupt, but an interrupt should be used in most cases. If 1 is set in the Interrupt Set-Enable Register associated with the RTC_ALM interrupt, an alarm interrupt is generated in the event of the alarm, enabling the alarm to be detected.

Writing 0 sets the IELSRn.IR bit associated with the RTC_ALM interrupt to 0. If interrupt is enabled, the Interrupt Set-Pending/Clear-Pending Register associated with the RTC_ALM interrupt is cleared automatically after exiting the interrupt handler. Otherwise, write 1 to the Interrupt Clear-Pending Register associated with the RTC_ALM interrupt to clear it.

When the counter and the alarm time match in a low power state, the MCU returns from the low power state. In Deep Software Standby mode, the MCU returns from the Deep Software Standby mode even when the alarm interrupt request is disabled.

图26.7显示了如何使用报警功能。

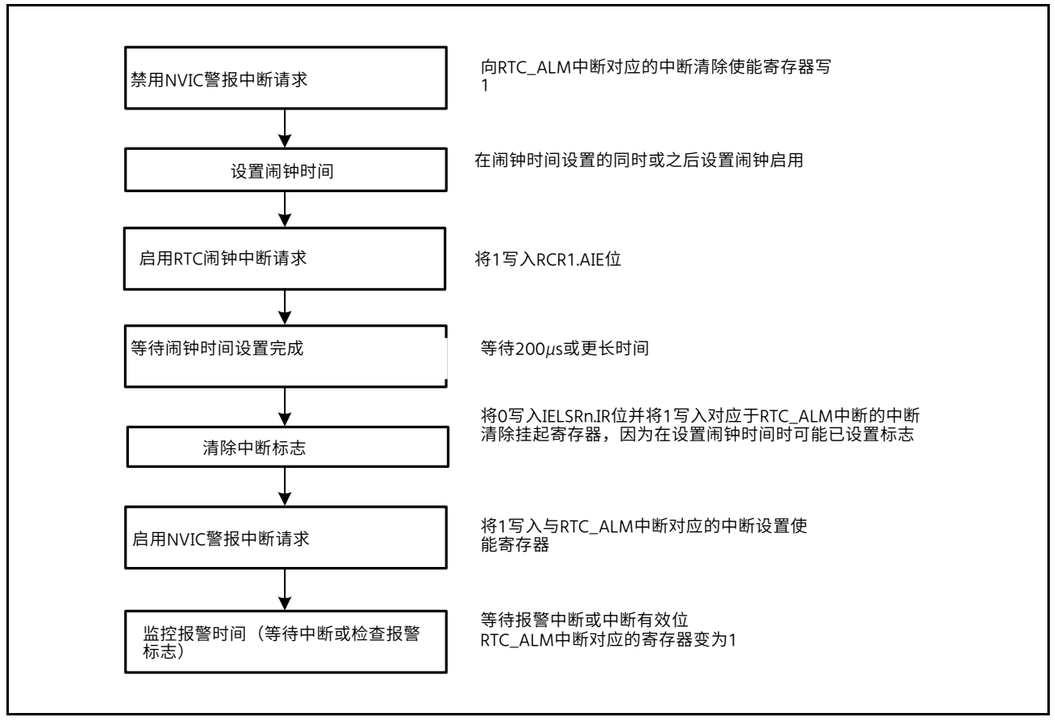

Figure 26.7 使用报警功能

在日历计数模式下，可以通过年、月、日、星期、小时、分钟或秒中的任何一个或它们的任意组合来生成警报。将1写入涉及闹钟设置的闹钟寄存器的ENB位，并在低位设置闹钟时间。将0写入与报警设置无关的寄存器中的ENB位。

在二进制计数模式下，可以以32位的任意位组合产生报警。将1写入与闹钟目标位相关的闹钟使能寄存器的ENB位，并在闹钟寄存器中设置闹钟时间。对于不是警报目标的位，将0写入警报使能寄存器的ENB位。

当计数器和闹钟时间匹配时，与RTC_ALM中断相关的IELSRn.IR位和中断设置挂起清除挂起寄存器设置为1。可以通过读取与RTC_ALM中断相关的中断设置挂起寄存器来确认报警检测，但在大多数情况下应该使用中断。如果在与RTC_ALM中断相关的中断设置使能寄存器中设置为1，则在发生警报时会产生警报中断，从而能够检测到警报。

写入0会将与RTC_ALM中断关联的IELSRn.IR位设置为0。如果启用中断，则与RTC_ALM中断关联的InterruptSetPendingClear-Pending寄存器会在退出中断处理程序后自动清除。否则，将1写入与RTC_ALM中断相关的中断清除挂起寄存器以将其清除。

当计数器和闹钟时间在低功耗状态下匹配时，MCU从低功耗状态返回。在深软件待机模式，即使警报中断请求被禁用，MCU也会从深度软件待机模式返回。

26.3.7 禁用警报中断的步骤

图26.8显示了禁用启用的警报中断请求的过程。

26.3.8 Time Error Adjustment Function

The time error adjustment function is used to correct errors, running fast or slow, in the time caused by variation in the precision of oscillation by the sub-clock oscillator. Because 32,768 cycles of the sub-clock oscillator constitute 1 second of operation when the sub-clock oscillator is selected, the clock runs fast if the sub-clock frequency is high and slow if the sub-clock frequency is low.

The time error adjustment functions include:

- Automatic adjustment
- Adjustment by software.

Use the RCR2.AADJE bit to select automatic adjustment or adjustment by software.

26.3.8.1 Automatic adjustment

Enable automatic adjustment by setting the RCR2.AADJE bit to 1. Automatic adjustment is the addition or subtraction of the value counted by the prescaler to or from the value in the RADJ register every time the adjustment period selected by the RCR2.AADJP bit elapses.

(1) Example 1: Sub-clock oscillator running at 32.769 kHz

(a) Adjustment procedure

When the sub-clock oscillator is running at 32.769 kHz, 1 second elapses every 32,769 clock cycles. The RTC is meant to run at 32,768 clock cycles, so the clock runs fast by 1 clock cycle every second. The time on the clock is fast by 60 clock cycles per minute, so adjustment can take the form of setting the clock back by 60 cycles every minute.

Register settings: (when RCR2.CNTMD = 0)

- RCR2.AADJP = 0 (adjustment every minute)
- RADJ.PMADJ[1:0] = 10b (adjustment is performed by the subtraction from the prescaler)
- RADJ.ADJ[5:0] = 60 (3Ch).

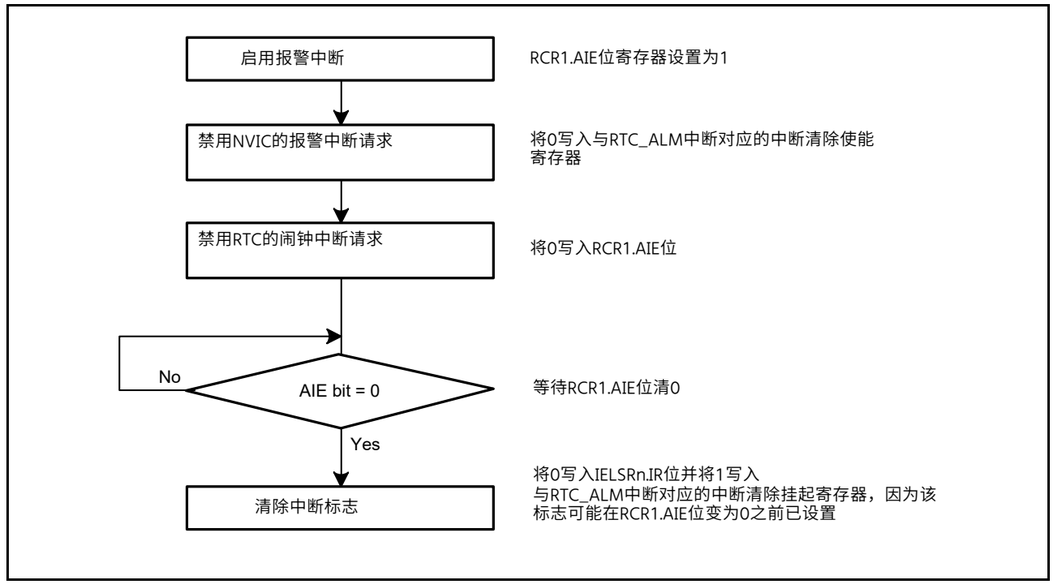

Figure 26.8 禁用报警中断请求的步骤

26.3.8 时间误差调整功能

时间误差调整功能用于校正子时钟振荡器振荡精度变化引起的时间误差，运行速度快或慢。由于在选择子时钟振荡器时，子时钟振荡器的32 768个周期构成1秒的运行时间，因此如果子时钟频率高，则时钟运行快，如果子时钟频率低，则时钟运行慢。

时间误差调整功能包括：

- 自动调整
- 通过软件调整。

使用RCR2.AADJE位选择自动调整或软件调整。

26.3.8.1 自动调整

通过将RCR2.AADJE位设置为1来启用自动调整。自动调整是每次经过RCR2.AADJP位选择的调整周期时，将预分频器计数的值与RADJ寄存器中的值相加或相减。

(1) 示例1：运行在32.769kHz的子时钟振荡器

(a) 调整程序

当副时钟振荡器以32.769kHz运行时，每32 769个时钟周期经过1秒。RTC旨在以32 768个时钟周期运行，因此时钟以每秒1个时钟周期的速度运行。时钟上的时间每分钟快60个时钟周期，因此调整可以采取将时钟每分钟调回60个周期的形式。

Register settings: (when RCR2.CNTMD = 0)

- RCR2.AADJP = 0 (adjustment every minute)
- RADJ.PMADJ[1:0]=10b（通过预分频器的减法进行调整）
- RADJ.ADJ[5:0] = 60 (3Ch).

(2) Example 2: Sub-clock oscillator running at 32.766 kHz

(a) Adjustment procedure

When the sub-clock oscillator is running at 32.766 kHz, 1 second elapses every 32,766 clock cycles. The RTC is meant to run at 32,768 clock cycles, so the clock runs slow by 2 clock cycles every second. The time on the clock is slow by 20 clock cycles every 10 seconds, so adjustment can take the form of setting the clock forward by 20 cycles every 10 seconds.

Register settings: (when RCR2.CNTMD = 0)

- RCR2.AADJP = 1 (adjustment every 10 seconds)
- RADJ.PMADJ[1:0] = 01b (adjustment is performed by the addition to the prescaler)
- RADJ.ADJ[5:0] = 20 (14h).

(3) Example 3: Sub-clock oscillator running at 32.764 kHz

(a) Adjustment procedure

At 32.764 kHz, 1 second elapses on 32,764 clock cycles. Because the RTC operates for 32,768 clock cycles as 1 second, the clock is delayed for 4 clock cycles per second. In 8 seconds, the delay is 32 clock cycles, therefore correction can be made by advancing the clock 32 clock cycles every 8 seconds.

Register settings when the RCR2.CNTMD bit is 1

- RCR2.AADJP = 1 (adjustment every 8 seconds)
- RADJ.PMADJ[1:0] = 01b (adjustment is performed by the addition to the prescaler)
- RADJ.ADJ[5:0] = 32 (20h).

26.3.8.2 Adjustment by software

Enable adjustment by software by setting the RCR2.AADJE bit to 0. Adjustment by software is the addition or subtraction of the value counted by the prescaler to or from the value in the RADJ register on execution of a write instruction to the RADJ register.

(1) Example 1: Sub-clock oscillator running at 32.769 kHz

(a) Adjustment procedure

When the sub-clock oscillator is running at 32.769 kHz, 1 second elapses every 32,769 clock cycles. The RTC is meant to run at 32,768 clock cycles, so the clock runs fast by one clock cycle every second. The time on the clock is fast by one clock cycle per second, so adjustment can take the form of setting the clock back by 1 cycle every second.

(b) Register settings

- RADJ.PMADJ[1:0] = 10b (adjustment is performed by the subtraction from the prescaler)
- RADJ.ADJ[5:0] = 1 (01h).
  This is written to the RADJ register once per 1-second interrupt.

26.3.8.3 Procedure for changing the mode of adjustment

When changing the mode of adjustment, change the value of the AADJE bit in RCR2 after setting the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).

To change adjustment by software to automatic adjustment:

1. Set the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).
2. Set the RCR2.AADJE bit to 1 (automatic adjustment is enabled).
3. Use the RCR2.AADJP bit to select the period of adjustment.
4. In RADJ, set the PMADJ[1:0] bits for addition or subtraction and the ADJ[5:0] bits to the value for use in time error adjustment.

(2) 示例2：以32.766kHz运行的子时钟振荡器

(a) 调整程序

当副时钟振荡器以32.766kHz运行时，每32 766个时钟周期经过1秒。RTC旨在以32 768个时钟周期运行，因此时钟每秒运行2个时钟周期。时钟上的时间每10秒慢20个时钟周期，因此调整可以采取将时钟每10秒向前20个周期的形式。

Register settings: (when RCR2.CNTMD = 0)

- RCR2.AADJP = 1 (adjustment every 10 seconds)
- RADJ.PMADJ[1:0]=01b（通过加到预分频器进行调整）
- RADJ.ADJ[5:0] = 20 (14h).

(3) 示例3：以32.764kHz运行的子时钟振荡器

(a) 调整程序

在32.764kHz时，32 764个时钟周期经过1秒。由于RTC以1秒为单位运行32 768个时钟周期，因此时钟每秒延迟4个时钟周期。在8秒内，延迟为32个时钟周期，因此可以通过每8秒将时钟提前32个时钟周期来进行校正。

RCR2.CNTMD位为1时的寄存器设置

- RCR2.AADJP = 1 (adjustment every 8 seconds)
- RADJ.PMADJ[1:0]=01b（通过加到预分频器进行调整）
- RADJ.ADJ[5:0] = 20 (14h).

26.3.8.2 软件调整

通过将RCR2.AADJE位设置为0来启用软件调整。软件调整是在对RADJ寄存器执行写指令时，将预分频器计数的值与RADJ寄存器中的值相加或相减。

(1) 示例1：运行在32.769kHz的子时钟振荡器

(a) 调整程序

当副时钟振荡器以32.769kHz运行时，每32 769个时钟周期经过1秒。RTC旨在以32 768个时钟周期运行，因此时钟以每秒一个时钟周期的速度运行。时钟上的时间每秒快一个时钟周期，因此调整可以采取将时钟每秒调回一个周期的形式。

(b) 注册设置

- RADJ.PMADJ[1:0]=10b（通过预分频器的减法进行调整）
- RADJ.ADJ[5:0] = 1 (01h).
  每1秒中断一次将其写入RADJ寄存器。

26.3.8.3 更改调整模式的步骤

改变调节方式时，设置好后改变RCR2中ADJE位的值
RADJ.PMADJ[1:0]位到00b（不执行调整）。

将软件调整改为自动调整：

1. 将RADJ.PMADJ[1:0]位设置为00b（不执行调整）。
2. 将RCR2.AADJE位设置为1（启用自动调整）。
3. 使用RCR2.AADJP位选择调整周期。
4. 在RADJ中，将PMADJ[1:0]位设置为加法或减法，并将ADJ[5:0]位设置为用于时间误差调整的值。

To change automatic adjustment to adjustment by software:

1. Set the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).
2. Set the RCR2.AADJE bit to 0 (adjustment by software is enabled).
3. Proceed with the adjustment by setting the RADJ.PMADJ[1:0] bits for addition or subtraction and the RADJ.ADJ[5:0] bits to the value for use in time error adjustment at the wanted time. After that, the time is adjusted every time a value is written to the RADJ register.

26.3.8.4 Procedure for stopping adjustment

Stop the adjustment by setting the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).

26.3.8.5 Capturing the time

The RTC is capable of storing the month, date, hour, minute and second/binary counters 3 to 0 by detecting an edge of a signal on a time capture event input pin.

A noise filter can also be used on a time capture event input pin. If the noise filter is enabled, the TCST bit is set to 1 when the input level on the pin matches three times.

The noise filter can be switched on or off for each of the time capture event input pins. Set VBTICTLR.VCHnIEN (n = 0 to 2) to 1 to enable the RTCICn input. Operation when the noise filter is off is shown in Figure 26.9 and operation when the noise filter is on is shown in Figure 26.10.

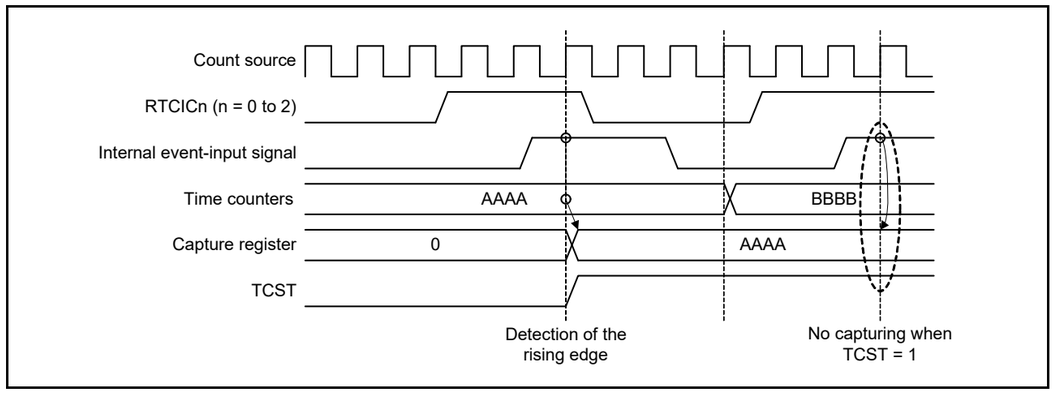

Figure 26.9 Timing of a time capture operation with the filter off

将自动调整更改为软件调整：

1. 将RADJ.PMADJ[1:0]位设置为00b（不执行调整）。
2. 将RCR2.AADJE位设置为0（启用软件调整）。
3. 通过设置RADJ.PMADJ[1:0]位进行加法或减法以及RADJ.ADJ[5:0]位用于在所需时间进行时间误差调整的值。之后，每次将值写入RADJ寄存器时都会调整时间。

26.3.8.4 停止调整的步骤

通过将RADJ.PMADJ[1:0]位设置为00b来停止调整（不执行调整）。

26.3.8.5 捕捉时间

RTC能够通过检测时间捕捉事件输入引脚上的信号沿来存储月、日、小时、分钟和秒二进制计数器3到0。

噪声滤波器也可用于时间捕捉事件输入引脚。如果启用了噪声滤波器，则当引脚上的输入电平匹配3次时，TCST位设置为1。

可以为每个时间捕捉事件输入引脚打开或关闭噪声滤波器。将VBTICTLR.VCHnIEN（n=0到2）设置为1以启用RTCICn输入。噪声滤波器关闭时的操作如图26.9所示，噪声滤波器打开时的操作如图26.10所示。

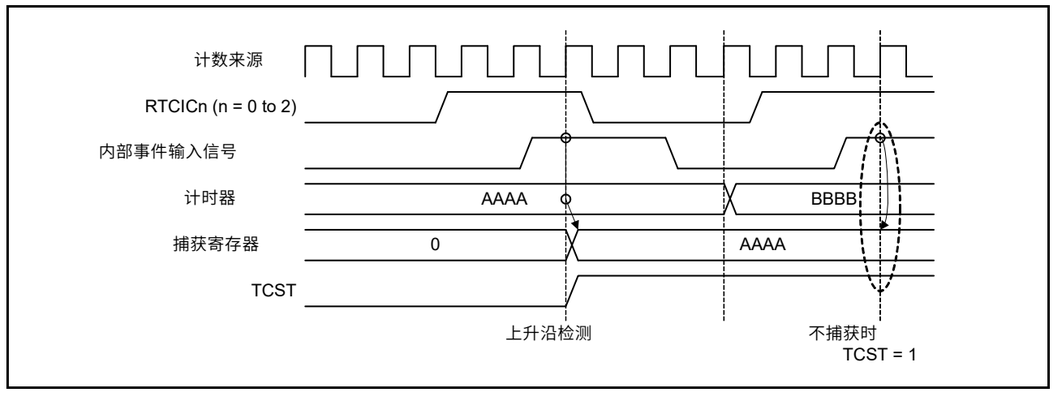

Figure 26.9 过滤器关闭的时间捕获操作的时序

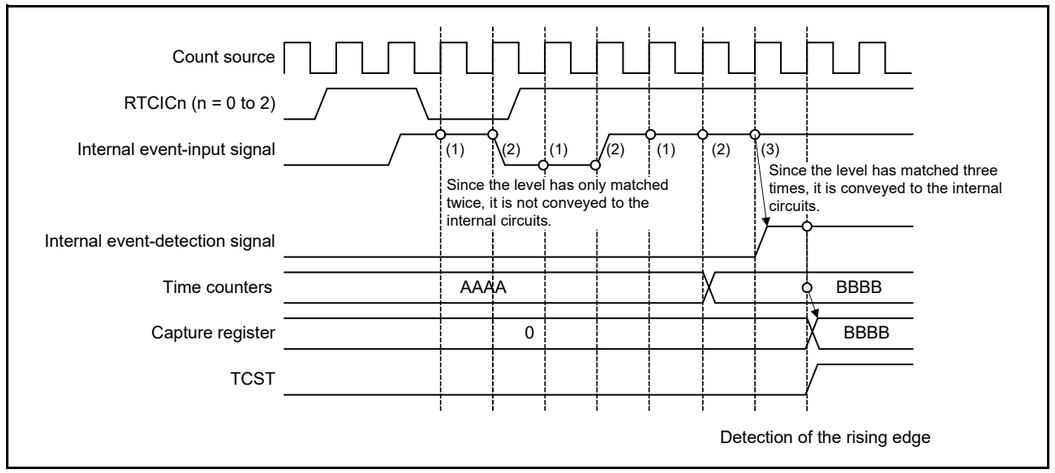

Figure 26.10 Timing of a time capture operation with the filter on

26.4 Interrupt Sources

The RTC has three interrupt sources and are listed in Table 26.3.

Table 26.3 RTC interrupt sources

Name	Interrupt source
RTC_ALM	Alarm interrupt
RTC_PRD	Periodic interrupt
RTC_CUP	Carry interrupt

(1) Alarm interrupt (RTC_ALM)

This interrupt is generated based on the result of comparison between the alarm registers and RTC counters. For details, see section 26.3.6, Alarm Function.

Because there is a possibility that the interrupt flag might be set to 1 when the settings of the alarm registers match the clock counters, wait for the alarm time settings to be confirmed and clear the IELSRn.IR bit and the interrupt Set-Pending Register associated with the RTC_ALM interrupt to 0 again after modifying values of the alarm registers. After the interrupt flag for the alarm interrupt is set to 1 and the state is returned to non-matching of the alarm registers and clock counters, the flag is not set again until there is another match or the values of the alarm registers are modified again.

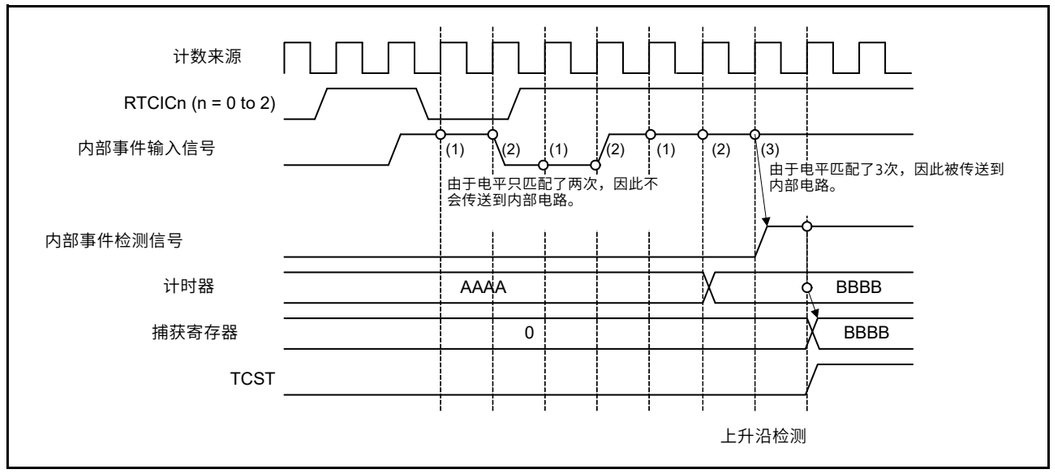

Figure 26.10 开启滤波器的时间捕获操作的时序

26.4 中断源

RTC具有三个中断源，列于表26.3中。

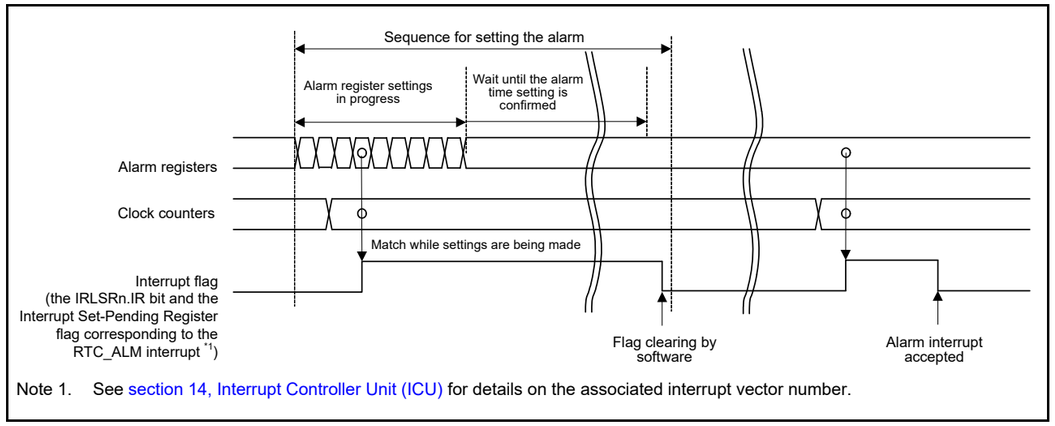
Table 26.3 RTC中断源

Name	中断源
RTC_ALM	报警中断
RTC_PRD	周期性中断
RTC_CUP	进位中断

(1) 闹钟中断(RTC_ALM)

该中断是根据闹钟寄存器和RTC计数器的比较结果产生的。有关详细信息，请参见第26.3.6节，报警功能。

因为当闹钟寄存器的设置与时钟计数器匹配时中断标志可能被设置为1，请等待闹钟时间设置被确认并清除IELSRn.IR位和与修改闹钟寄存器的值后，RTC_ALM中断再次为0。报警中断的中断标志置1后，状态返回到报警寄存器和时钟计数器不匹配，直到再次匹配或再次修改报警寄存器的值时才重新设置该标志.



Note 1. See section 14, Interrupt Controller Unit (ICU) for details on the associated interrupt vector number.

Figure 26.11 Timing diagram for the alarm interrupt (RTC_ALM)

(2) Periodic interrupt (RTC_PRD)

This interrupt is generated at intervals of 2 seconds, 1 second, 1/2 second, 1/4 second, 1/8 second, 1/16 second, 1/32 second, 1/64 second, 1/128 second, or 1/256 second. The interrupt interval can be selected through the RCR1.PES[3:0] bits.

(3) Carry interrupt (RTC_CUP)

This interrupt is generated when a carry to the second counter/binary counter 0 occurred or a carry to the R64CNT counter occurred during read access to the 64-Hz counter.

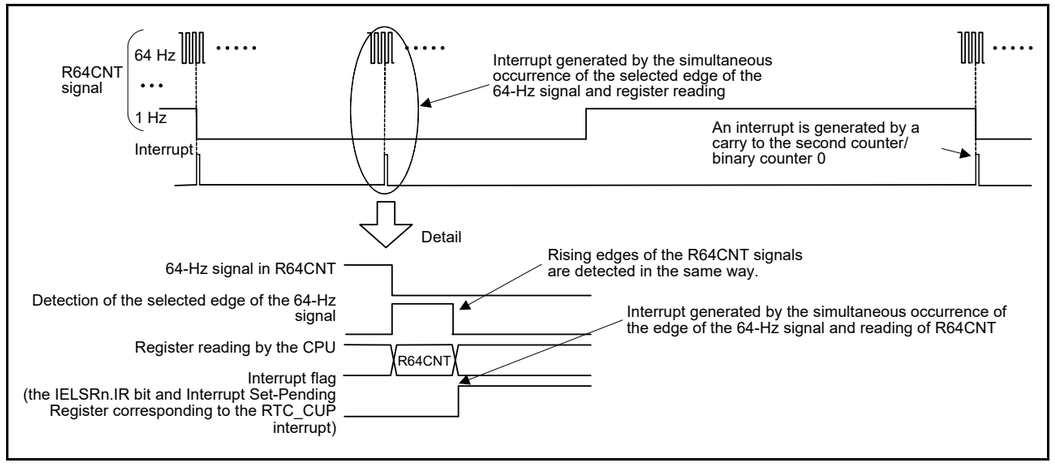


Figure 26.12 Timing diagram for the carry interrupt (RTC_CUP)

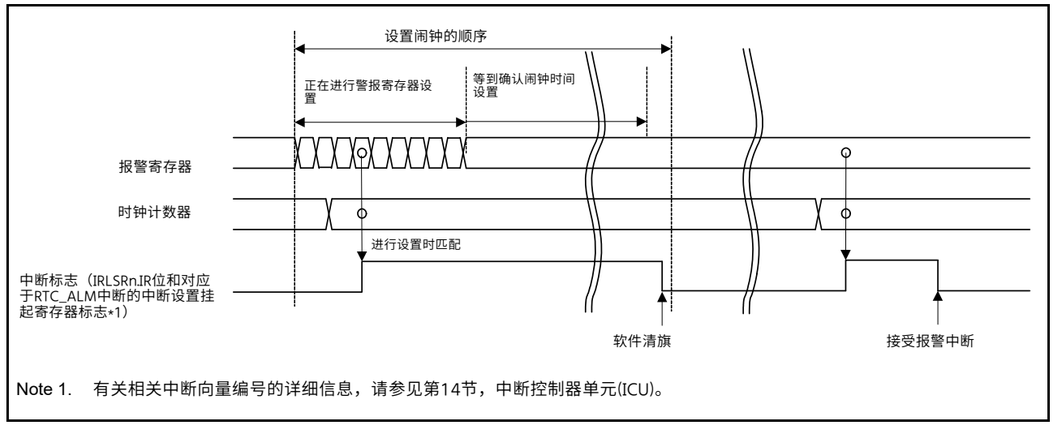
26.5 Event Link Output

The RTC generates periodic event output (RTC_PRD) event signal for the Event Link Controller (ELC) that can be used to initiate operations by other modules selected in advance.

The periodic event signal is output at the interval selected from 1/256, 1/128, 1/64, 1/32, 1/16, 1/8, 1/4, 1/2, 1, and 2 seconds by setting the RCR1.PES[3:0] bits.

The event generation period immediately after the event generation is selected is not guaranteed.



Note 1. 有关相关中断向量编号的详细信息，请参见第14节，中断控制器单元(ICU)。

Figure 26.11 闹钟中断(RTC_ALM)的时序图

(2) 周期性中断(RTC_PRD)

此中断以2秒、1秒、12秒、14秒、18秒、116秒、132秒、164秒、1128秒或1256秒的间隔生成。可以通过RCR1.PES[3:0]位选择中断间隔。

(3) 进位中断(RTC_CUP)

当第二个计数器二进制计数器0的进位发生或在对64-Hz计数器的读访问期间发生对R64CNT计数器的进位时，将产生此中断。

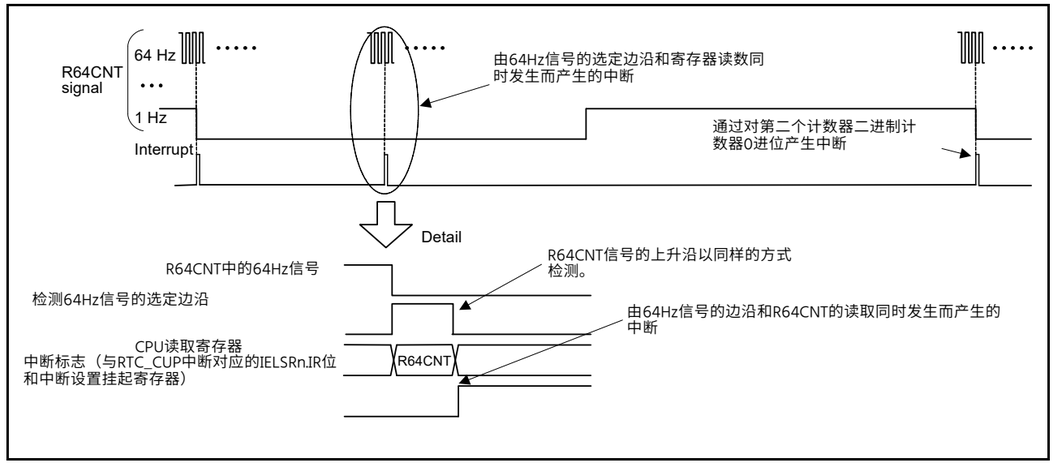


Figure 26.12 进位中断(RTC_CUP)的时序图

26.5 事件链接输出

RTC为事件链接控制器(ELC)生成周期性事件输出(RTC_PRD)事件信号，该信号可用于启动预先选择的其他模块的操作。

通过设置RCR1.PES[3:0，以从1256、1128、164、132、116、18、14、12、1和2秒中选择的间隔输出周期性事件信号]位。

不保证选择事件生成后的事件生成周期。

Note: If event linking from the RTC is used, only set the ELC after setting the RTC, for example initialization and time settings. Setting the RTC after the ELC can lead to output of unexpected event signals.

26.5.1 Interrupt Handling and Event Linking

The RTC has a bit to enable or disable periodic interrupts. An interrupt request signal is output for the CPU when an interrupt source is generated while the associated enable bit is enabled.

In contrast, an event link output signal is sent to other modules as an event signal through the ELC when an interrupt source is generated, regardless of the setting of the associated interrupt enable bit.

Note: Although alarm and periodic interrupts can still be output during Software Standby mode or Deep Software Standby mode, the periodic event signals for the ELC are not output.

26.6 Usage Notes

26.6.1 Register Writing during Counting

The following registers must not be written to during counting, that is, while the RCR2.START bit is 1:

- RSECCNT/BCNT0
- RMINCNT/BCNT1
- RHRCNT/BCNT2
- RDAYCNT
- RWKCNT/BCNT3
- RMONCNT
- RYRCNT
- RCR1.RTCOS
- RCR2.RTCOE
- RCR2.HR24
- RFRL.

The counter must be stopped before writing to any of these registers.

26.6.2 Use of Periodic Interrupts

The procedure for using periodic interrupts is shown in Figure 26.13.

The generation and period of the periodic interrupt can be changed by setting the RCR1.PES[3:0] bits. However, because the prescaler R64CNT and RSECCNT/BCNT0 are used to generate interrupts, the interrupt period is not guaranteed immediately after setting the RCR1.PES[3:0] bits. In addition, any of the following operation can affect the interrupt period:

- Stopping/restarting or resetting counter operation
- Reset by RTC software
- 30-second adjustment by changing the RCR2 value.

When the time error adjustment function is used, the interrupt generation period after adjustment is added or subtracted based on the adjustment value.

Note: 如果使用来自RTC的事件链接，请仅在设置RTC后设置ELC，例如初始化和时间设置。在ELC之后设置RTC会导致意外事件信号的输出。

26.5.1 中断处理和事件链接

RTC有一个位来启用或禁用周期性中断。当相应的使能位使能时产生中断源时，将向CPU输出中断请求信号。

相反，当产生中断源时，事件链接输出信号作为事件信号通过ELC发送到其他模块，而不管相关中断使能位的设置如何。

Note: 虽然在软件待机模式或深度软件期间仍然可以输出警报和周期性中断
待机模式下，不输出ELC的周期性事件信号。

26.6 使用说明

26.6.1 计数期间的寄存器写入

计数期间不得写入以下寄存器，即RCR2.START位为1时：

- RSECCNT/BCNT0
- RMINCNT/BCNT1
- RHRCNT/BCNT2
- RDAYCNT
- RWKCNT/BCNT3
- RMONCNT
- RYRCNT
- RCR1.RTCOS
- RCR2.RTCOE
- RCR2.HR24
- RFRL.

在写入任何这些寄存器之前，必须停止计数器。

26.6.2 使用周期性中断

使用周期性中断的过程如图26.13所示。

可以通过设置RCR1.PES[3:0]位来更改周期性中断的产生和周期。但是，因为预分频器R64CNT和RSECCNTBCNT0用于产生中断，所以在设置RCR1.PES[3:0]位后不能立即保证中断周期。此外，以下任何操作都会影响中断周期：

- 停止重新启动或重置计数器操作
- 通过RTC软件复位
- 通过更改RCR2值进行30秒调整。

使用时间误差调整功能时，根据调整值加减调整后的中断产生周期。

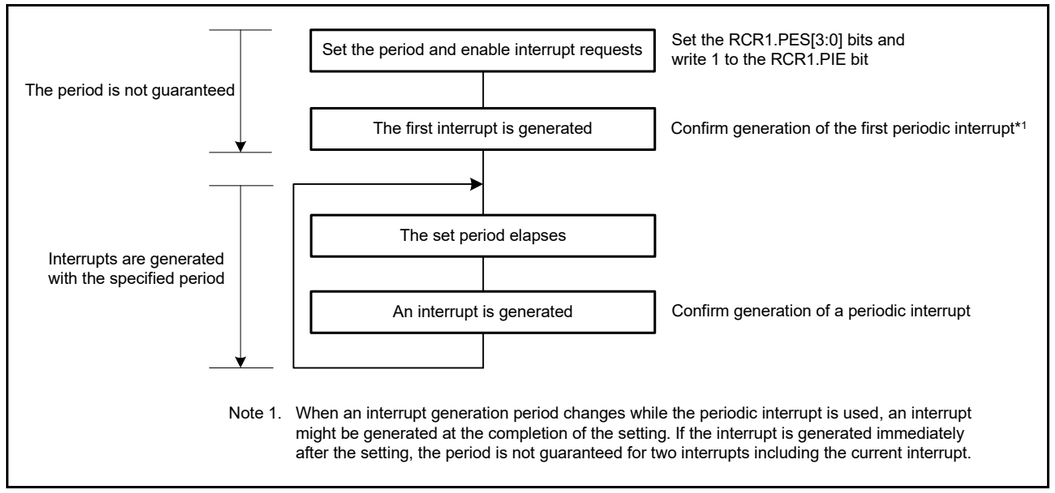

Figure 26.13 Using the periodic interrupt function

26.6.3 RTCOUT (1-Hz/64-Hz) Clock Output

Stopping/restarting or resetting counter operation, reset by RTC software, and the 30-second adjustment by changing the RCR2 value affects the period of RTCOUT (1-Hz/64-Hz) output. When the time error adjustment function is used, the period of RTCOUT (1-Hz/64-Hz) output after adjustment is added or subtracted based on the adjustment value.

26.6.4 Transitions to Low Power Modes after Setting Registers

A transition to a low power state (Software Standby mode, Deep Software Standby mode, or battery backup) during a write to an RTC register might corrupt the value in the register. After setting the register, confirm that the setting is in place before initiating a transition to a low power state.

26.6.5 Notes on Writing to and Reading from Registers

- When reading a counter register such as the second counter after writing to the counter register, follow the procedure in section 26.3.5, Reading 64-Hz Counter and Time
- The value written to the count registers, alarm registers, year alarm enable register, bits RCR2.AADJE, AADJP, and HR24, RCR4 register, or frequency register is reflected when four read operations are performed after writing
- The values written to the RCR1.CIE, RCR1.RTCOS, and RCR2.RTCOE bits can be read immediately after writing
- To read the value from the timer counter after return from a reset, Software Standby mode, Deep Software Standby mode, or the battery backup state, wait for 1/128 second while the clock is operating (RCR2.START bit is 1)
- After a reset is generated, write to the RTC register after 6 cycles of the count source clock elapse.

26.6.6 Changing the Count Mode

When changing the count mode (calendar/binary), set the RCR2.START bit to 0, stop the counting operation, then restart it from the initial setting. For details on the initial setting, see section 26.3.1, Outline of Initial Settings of Registers after Power On.

26.6.7 Initialization Procedure when the RTC Is Not To Be Used

Registers in the RTC are not initialized by a reset. Depending on the initial state, the generation of an unintentional interrupt request or operation of the counter might lead to increased power consumption.

For applications that do not require a realtime clock, initialize the registers by following the initialization procedure shown in Figure 26.14.

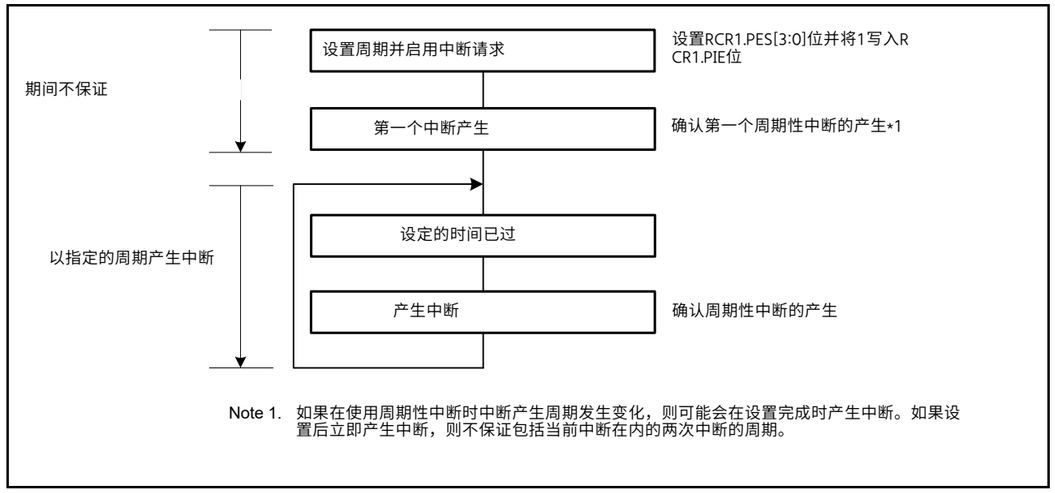

Figure 26.13 使用周期性中断功能

26.6.3 RTCOUT(1-Hz64-Hz)时钟输出

停止重新启动或重置计数器操作，通过RTC软件重置，并通过更改30秒调整RCR2值影响RTCOUT(1-Hz64-Hz)输出的周期。使用时间误差调整功能时，调整后的RTCOUT（1-Hz64-Hz）输出的周期根据调整值加减。

26.6.4 设置寄存器后转换到低功耗模式

在写入RTC寄存器期间转换到低功耗状态（软件待机模式、深度软件待机模式或电池备份）可能会损坏寄存器中的值。设置寄存器后，在开始转换到低功耗状态之前确认设置到位。

26.6.5 关于写入和读取寄存器的注意事项

- 在写入计数器寄存器后读取计数器寄存器（例如第二个计数器）时，请按照第26.3.5节中的步骤，读取64-Hz计数器和时间
- 写入计数寄存器、闹钟寄存器、年份闹钟启用寄存器、位RCR2.AADJE、AADJP和HR24、RCR4寄存器或频率寄存器在写后进行四次读操作时反映
- 写入RCR1.CIE、RCR1.RTCOS和RCR2.RTCOE位的值可在写入后立即读取
- 要在从复位、软件待机模式、深度软件待机模式或电池备份状态返回后从定时器计数器读取值，请在时钟运行时等待1128秒（RCR2.START位为1）
- 产生复位后，在经过6个计数源时钟周期后写入RTC寄存器。

26.6.6 更改计数模式

更改计数模式（日历二进制）时，将RCR2.START位设置为0，停止计数操作，然后从初始设置重新启动。有关初始设置的详细信息，请参阅第26.3.1节“通电后寄存器初始设置概述”。

26.6.7 不使用RTC时的初始化程序

RTC中的寄存器不会因复位而初始化。根据初始状态，意外中断请求的生成或计数器的操作可能会导致功耗增加。

对于不需要实时时钟的应用程序，按照图26.14所示的初始化过程初始化寄存器。

Alternatively, when the sub-clock oscillator is not used as the system clock or realtime clock, the counter can be stopped by writing 0 (subclock oscillator is selected) to the RCR4.RCKSEL bit and stopping the sub-clock oscillator. To stop the sub-clock oscillator, write 1 to the SOSCCR.SOSTP bit.

For details on the setting of the SOSCCR.SOSTP bit, see section 9, Clock Generation Circuit.

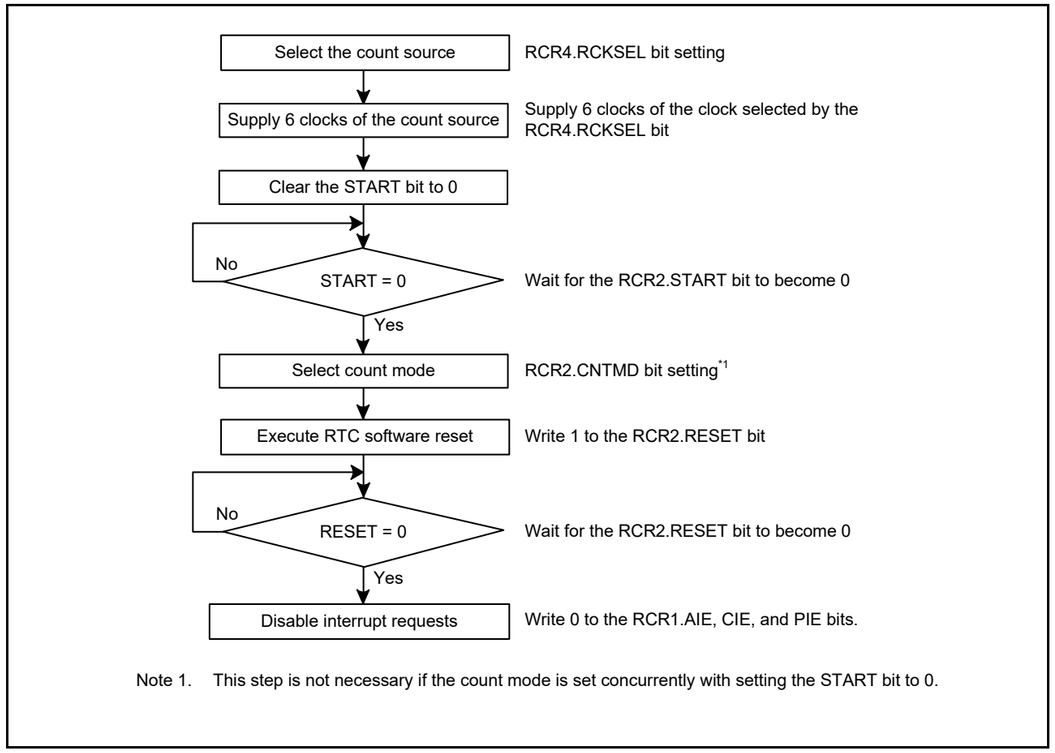

Figure 26.14 Initialization procedure

26.6.8 When Switching Source Clock

When switching a clock source by changing SCKSCR.CKSEL[2:0], the clock output from the selector stops for 4 cycles of the switched clock. If the RTC periodical interrupt or RTC periodical event output was generated at this time, the interrupt or event is invalid.

或者，当副时钟振荡器不用作系统时钟或实时时钟时，可以通过向RCR4.RCKSEL位写入0（选择副时钟振荡器）并停止副时钟振荡器来停止计数器。要停止副时钟振荡器，将1写入SOSCCR.SOSTP位。

有关SOSCCR.SOSTP位设置的详细信息，请参见第9节，时钟生成电路。

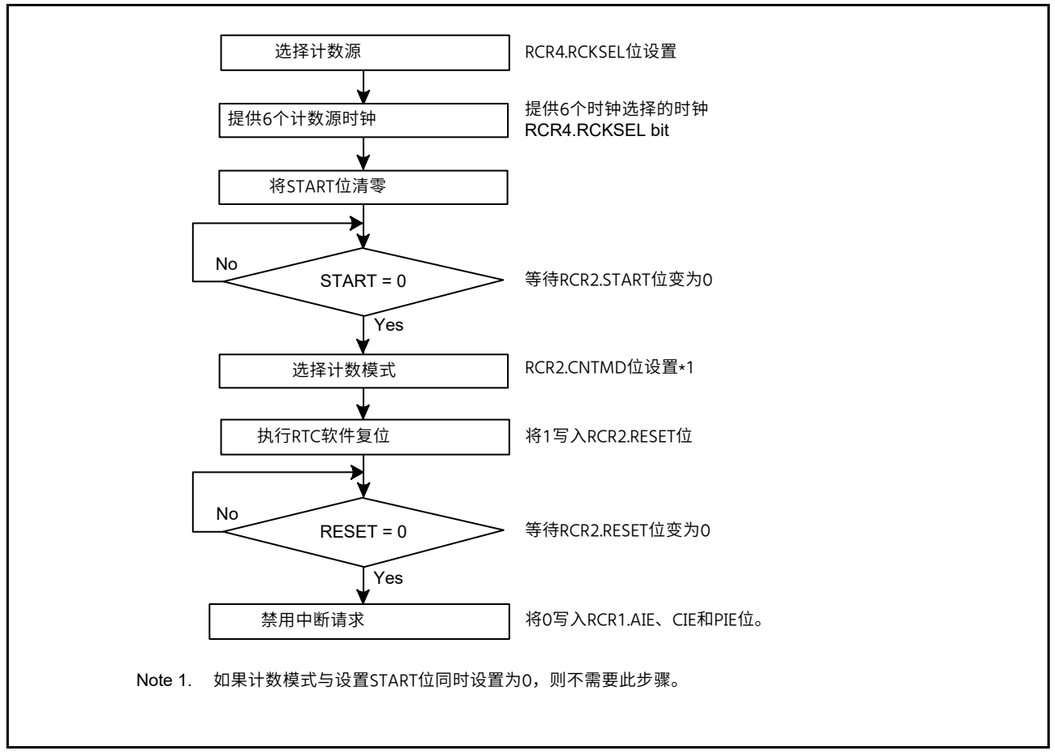

Figure 26.14 初始化程序

26.6.8 切换源时钟时

当通过改变SCKSCR.CKSEL[2:0]来切换时钟源时，选择器的时钟输出在切换时钟的4个周期内停止。如果此时产生了RTC周期性中断或RTC周期性事件输出，则该中断或事件无效。

27. Watchdog Timer (WDT)

27.1 Overview

The Watchdog Timer (WDT) is a 14-bit down-counter and can be used to reset the MCU when the counter underflows because the system has run out of control and become unable to refresh the WDT. In addition, the WDT can be used to generate a non-maskable interrupt or an underflow interrupt. The refresh-permitted period can be set to refresh the counter and to detect when the system runs out of control.

Table 27.1 lists the WDT specifications and Figure 27.1 shows a block diagram.

Table 27.1 WDT specifications

Parameter	Specifications
Count source	Peripheral clock (PCLKB)
Clock division ratio	Division by 4, 64, 128, 512, 2,048, or 8,192
Counter operation	Counting down using a 14-bit down-counter
Conditions for starting the counter	• Auto start mode: Counting automatically starts after a reset, or after an underflow or refresh error occurs • Register start mode: Counting is started with a refresh by writing to the WDTRR register.
Conditions for stopping the counter	• Reset (the down-counter and other registers return to their initial values) • A counter underflows or a refresh error is generated.
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods)
WDT reset sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error).
Non-maskable interrupt/interrupt sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error).
Reading of the counter value	The down-counter value can be read by the WDTSR register
Event link function (output)	• Down-counter underflow event output • Refresh error event output.
Output signal (internal signal)	• Reset output • Interrupt request output • Sleep-mode count stop control output.

27. 看门狗定时器(WDT)

27.1 Overview

看门狗定时器(WDT)是一个14位递减计数器，可用于在计数器下溢时复位MCU，因为系统已经失控并且无法刷新WDT。此外，WDT可用于产生不可屏蔽中断或下溢中断。可以设置刷新允许周期来刷新计数器并检测系统何时失控。

表27.1列出了WDT规范，图27.1显示了框图。

Value after reset:	1	1	1	1	1	1	1	1

Bit	Description	R/W
b7 to b0	The down-counter is refreshed by writing 00h and then writing FFh to this register	R/W

The WDTRR register refreshes the down-counter of the WDT.

The down-counter of the WDT is refreshed by writing 00h and then writing FFh to WDTRR (refresh operation) within the refresh-permitted period.

After the down-counter is refreshed, it starts counting down from the value selected in the WDT Timeout Period Select bits (OFS0.WDTTOPS[1:0]) in Option Function Select Register 0 in auto start mode. In register start mode, counting down starts from the value selected in the Timeout Period Select bits (WDTCR.TOPS[1:0]) in the WDT Control Register.

When 00h is written, the read value is 00h. When a value other than 00h is written, the read value is FFh. For details on the refresh operation, see section 27.3.3, Refresh Operation.

Bit	Description	R/W
b7 to b0	通过写入00h然后将FFh写入该寄存器来刷新递减计数器	R/W

WDTRR寄存器刷新WDT的递减计数器。

WDT的递减计数器通过写入00h进行刷新，然后在允许刷新期间将FFh写入WDTRR（刷新操作）。

递减计数器刷新后，在自动启动模式下，它从选项功能选择寄存器0中的WDT超时周期选择位(OFS0.WDTTOPS[1:0])中选择的值开始递减计数。在寄存器启动模式下，倒计时从WDT控制寄存器的超时周期选择位(WDTCR.TOPS[1:0])中选择的值开始。

写入00h时，读取值为00h。写入00h以外的值时，读取值为FFh。有关刷新操作的详细信息，请参阅第27.3.3节，刷新操作。

Some constraints apply to writes to the WDTCR register. For details, see section 27.3.2, Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the settings in the WDTCR register are disabled, and the settings in Option Function Select Register 0 (OFS0) are enabled. The settings for the WDTCR register can also be made for the OFS0 register. For details, see section 27.3.7, Associations between Option Function Select Register 0 (OFS0) and WDT Registers.

TOPS[1:0] bits (Timeout Period Select)

The TOPS[1:0] bits select the timeout period, the period until the down-counter underflows, from 1,024, 4,096, 8,192, and 16,384 cycles, taking the divided clock specified in the CKS[3:0] bits as 1 cycle. After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the number of PCLKB cycles until the counter underflows.

Table 27.2 lists the relationship between the CKS[3:0] and TOPS[1:0] bit settings, the timeout period, and the number of PCLKB cycles.

一些限制适用于写入WDTCR寄存器。有关详细信息，请参阅第27.3.2节，控制对WDTCR、WDTRCR和WDTCSTPR寄存器。

在自动启动模式下，WDTCR寄存器中的设置被禁用，而选项功能选择寄存器0(OFS0)中的设置被启用。WDTCR寄存器的设置也可以对OFS0寄存器进行。有关详细信息，请参阅第27.3.7节，选项功能选择寄存器0(OFS0)和WDT寄存器之间的关联。

TOPS[1:0]位（超时周期选择）

TOPS[1:0]位从1 024、4 096、8 192和16 384个周期中选择超时周期，即递减计数器下溢之前的周期，将CKS[3:0]位中指定的分频时钟作为1个周期.向下计数器刷新后，CKS[3:0]和TOPS[1:0]位的组合决定了PCLKB周期数，直到计数器下溢。

表27.2列出了CKS[3:0]和TOPS[1:0]位设置、超时时间和
PCLKB cycles.

				1	0		8,192	67,108,864
				1	1		16,384	134,217,728

CKS[3:0] bits (Clock Division Ratio Select)

The CKS[3:0] bits specify the division ratio of the clock used for the down-counter. The division ratio can be selected from the peripheral clock (PCLKB) divided by 4, 64, 128, 512, 2048, and 8192. Combined with the TOPS[1:0] bit setting, this allows the WDT to be configured to a count period between 4,096 and 134,217,728 cycles of the PCLKB clock.

RPES[1:0] bits (Window End Position Select)

The RPES[1:0] bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. Set the window end position to a value less than the value for the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.

RPSS[1:0] bits (Window Start Position Select)

The RPSS[1:0] bits specify the window start position that indicates the refresh-permitted period. 100%, 75%, 50%, or 25% of the timeout period can be selected for the window start position. Set the window start position to a value greater than the value for the window end position. If the window start position is set to a value less than or equal to the window end position, the window end position is set to 0%.

Table 27.3 lists the counter values for the window start and end positions, and Figure 27.2 shows the refresh-permitted period set in the RPSS[1:0], RPES[1:0], and TOPS[1:0] bits.

				1	1		16,384	134,217,728

CKS[3:0]位（时钟分频比选择）

CKS[3:0]位指定用于递减计数器的时钟的分频比。分频比可以从外设时钟(PCLKB)除以4、64、128、512、2048和8192中选择。结合TOPS[1:0]位设置，这允许将WDT配置为计数PCLKB时钟周期在4 096到134 217 728个周期之间。

RPES[1:0]位（窗口结束位置选择）

RPES[1:0]位指定指示刷新允许周期的窗口结束位置。可以为窗口结束位置选择75%、50%、25%或0%的超时时间。将窗口结束位置设置为小于窗口起始位置的值（窗口起始位置>窗口结束位置）。如果窗口结束位置大于窗口起始位置，则仅启用窗口起始位置设置。

RPSS[1:0]位（窗口起始位置选择）

RPSS[1:0]位指定指示允许刷新周期的窗口起始位置。窗口起始位置可选择100%、75%、50%或25%的超时时间。将窗口开始位置设置为大于窗口结束位置的值。如果窗口开始位置设置为小于或等于窗口结束位置的值，则窗口结束位置设置为0%。

表27.3列出了窗口开始和结束位置的计数器值，图27.2显示了在RPSS[1:0]、RPES[1:0]和TOPS[1:0]位中设置的允许刷新周期。

Address(es): WDT.WDTSR 4004 4204h

Bit	Symbol	位名称	Description	R/W
b13 to b0	CNTVAL[13:0]	Down-Counter Value	递减计数器计数的值	R
b14	UNDFF	Underflow Flag	0：未发生下溢1：发生下溢。	R(/W) *1
b15	REFEF	刷新错误标志	0：未发生刷新错误1：发生刷新错误。	R(/W) *1

Note 1. 只能写入0来清除标志。

CNTVAL[13:0] bits (Down-Counter Value)

Read the CNTVAL[13:0] bits to confirm the value of the down-counter. The read value might differ from the actual count by 1.

UNDFF flag (Underflow Flag)

Read the UNDFF flag to confirm whether an underflow occurred in the down-counter. A value of 1 indicates that the down-counter underflowed. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N+1) PCLKB cycles. In addition, clearing of the flag is ignored for (N+1) PCLKB cycles after an underflow. N is specified in the WDTCR.CKS[3:0] bits as follows:

- When WDTCR.CKS[3:0] = 0001b, N = 4
- When WDTCR.CKS[3:0] = 0100b, N = 64
- When WDTCR.CKS[3:0] = 1111b, N = 128
- When WDTCR.CKS[3:0] = 0110b, N = 512
- When WDTCR.CKS[3:0] = 0111b, N = 2048
- When WDTCR.CKS[3:0] = 1000b, N = 8192.

REFEF flag (Refresh Error Flag)

Read the REFEF flag to confirm whether a refresh error occurred, indicating that a refresh operation was performed during a prohibited period. A value of 1 indicates that a refresh error occurred. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the REFEF flag takes (N+1) PCLKB cycles. In addition, clearing of the flag is ignored for (N+1) PCLKB cycles after a refresh error. N is specified in the WDTCR.CKS[3:0] bits as follows:

- When WDTCR.CKS[3:0] = 0001b, N = 4
- When WDTCR.CKS[3:0] = 0100b, N = 64
- When WDTCR.CKS[3:0] = 1111b, N = 128
- When WDTCR.CKS[3:0] = 0110b, N = 512
- When WDTCR.CKS[3:0] = 0111b, N = 2048
- When WDTCR.CKS[3:0] = 1000b, N = 8192

Some constraints apply to writes to the WDTRCR register. For details, see section 27.3.2, Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the WDTRCR register settings are disabled, and the settings in Option Function Select Register 0 (OFS0) are enabled. The settings for the WDTCR register can also be made for the OFS0 register. For details, see section

CNTVAL[13:0]位（递减计数器值）

读取CNTVAL[13:0]位以确认递减计数器的值。读取的值可能与实际计数相差1。

UNDFF flag (Underflow Flag)

读取UNDFF标志以确认递减计数器中是否发生下溢。值1表示递减计数器下溢。将0写入标志以将值设置为0。写入1无效。

清除UNDFF标志需要(N+1)个PCLKB周期。此外，在下溢后的(N+1)个PCLKB周期内忽略标志的清除。N在WDTCR.CKS[3:0]位中指定如下：

- When WDTCR.CKS[3:0] = 0001b, N = 4
- When WDTCR.CKS[3:0] = 0100b, N = 64
- When WDTCR.CKS[3:0] = 1111b, N = 128
- When WDTCR.CKS[3:0] = 0110b, N = 512
- When WDTCR.CKS[3:0] = 0111b, N = 2048
- When WDTCR.CKS[3:0] = 1000b, N = 8192.

REFEF标志（刷新错误标志）

读取REFEF标志，确认是否发生刷新错误，表示在禁止期间进行了刷新操作。值1表示发生了刷新错误。将0写入标志以将值设置为0。写入1无效。

清除REFEF标志需要(N+1)个PCLKB周期。此外，在刷新错误后的(N+1)个PCLKB周期内，标志的清除将被忽略。N在WDTCR.CKS[3:0]位中指定如下：

- When WDTCR.CKS[3:0] = 0001b, N = 4
- When WDTCR.CKS[3:0] = 0100b, N = 64
- When WDTCR.CKS[3:0] = 1111b, N = 128
- When WDTCR.CKS[3:0] = 0110b, N = 512
- When WDTCR.CKS[3:0] = 0111b, N = 2048

The WDTCSTPR register controls whether to stop the WDT counter in a low power mode. Some constraints apply to writes to the WDTCSTPR register. For details, see section 27.3.2, Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the WDTCSTPR register settings are disabled, and the settings in Option Function Select register 0 (OFS0) are enabled. The settings for the WDTCSTPR register can also be made for the OFS0 register. For details, see section 27.3.7, Associations between Option Function Select Register 0 (OFS0) and WDT Registers.

SLCSTP bit (Sleep-Mode Count Stop Control)

The SLCSTP bit selects whether to stop counting when transition to Sleep mode.

27.2.6 Option Function Select Register 0 (OFS0)

For information on the OFS0 register, see section 27.3.7, Associations between Option Function Select Register 0 (OFS0) and WDT Registers.

27.3 Operation

27.3.1 Count Operation in Each Start Mode

The WDT has two start modes:

- Auto start mode, in which counting automatically starts after a release from the reset state
- Register start mode, in which counting is started with a refresh by writing to the register.

In auto start mode, counting automatically starts after release from the reset state in accordance with the settings in Option Function Select Register 0 (OFS0) in the flash.

In register start mode, counting starts with a refresh by writing to the register after the respective registers are set after a release from the reset state.

Select auto start mode or register start mode by setting the WDT Start Mode Select bit (OFS0.WDTSTRT) in the OFS0 register. When the auto start mode is selected, the settings in the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are disabled, and the settings in the OFS0 register are enabled. When the register start mode is selected, the OFS0 register settings are disabled, and the settings in the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are enabled.

27.3.1.1 Register start mode

When the WDT Start Mode Select bit (OFS0.WDTSTRT) is 1, register start mode is selected and the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are enabled.

27.3 Operation

27.3.1 每种启动模式下的计数操作

WDT有两种启动模式：

- 自动启动模式，从复位状态释放后自动开始计数
- 寄存器启动模式，在这种模式下，通过写入寄存器来启动计数。

在自动启动模式下，从复位状态释放后，按照
选项功能选择闪存中的寄存器0(OFS0)。

在寄存器启动模式中，在从复位状态释放后，在设置各个寄存器后，通过写入寄存器来开始计数。

通过设置OFS0寄存器中的WDT启动模式选择位(OFS0.WDTSTRT)来选择自动启动模式或寄存器启动模式。选择自动启动模式后，WDT控制寄存器（WDTCR）中的设置，WDTRESET控制寄存器（WDTRCR）和WDT计数停止控制寄存器（WDTCSTPR）被禁用，并启用OFS0寄存器中的设置。选择寄存器启动模式后，禁用了OFS0寄存器设置，并在WDT控制寄存器（WDTCR）中的设置，WDTRESETCONTROL寄存器（WDTRCR）和WDTCountCountStopControl寄存器（WDTCSTPR）启用。

27.3.1.1 注册启动模式

当WDT启动模式选择位(OFS0.WDTSTRT)为1时，选择寄存器启动模式并且WDT控制
使能寄存器(WDTCR)、WDT复位控制寄存器(WDTRCR)和WDT计数停止控制寄存器(WDTCSTPR)。

After the reset state is released, set the following to Sleep mode in the WDTCSTPR register:

- Clock division ratio
- Window start and end positions
- Timeout period in the WDTCR register
- Reset output or interrupt request output in the WDTRCR register
- Counter stop control during transitions to Sleep mode in the WDTCSTPR register.

Refresh the down-counter to start counting down from the value set in the Timeout Period Select bits (WDTCR.TOPS[1:0]).

Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and down-counting continues. The WDT does not output the reset signal as long as counting continues. However, if the down-counter underflows because the down-counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the WDT outputs a reset signal or a non-maskable interrupt request/interrupt request (WDT_NMIUNDF). Reset output or interrupt request output can be selected in the WDT Reset Interrupt Request Select bit (WDTRCR.RSTIRQS). Non-maskable interrupt request or interrupt request can be selected in the WDT Underflow/Refresh Error Interrupt Enable bit (NMIER.WDTEN).

Figure 27.3 shows an example of operation under the following conditions:

- Register start mode (OFS0.WDTSTRT = 1)
- Reset output is enabled (WDTRCR.RSTIRQS = 1)
- The window start position is 75% (WDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (WDTCR.RPES[1:0] = 10b).

释放复位状态后，在WDTCSTPR寄存器中将以下内容设置为休眠模式：

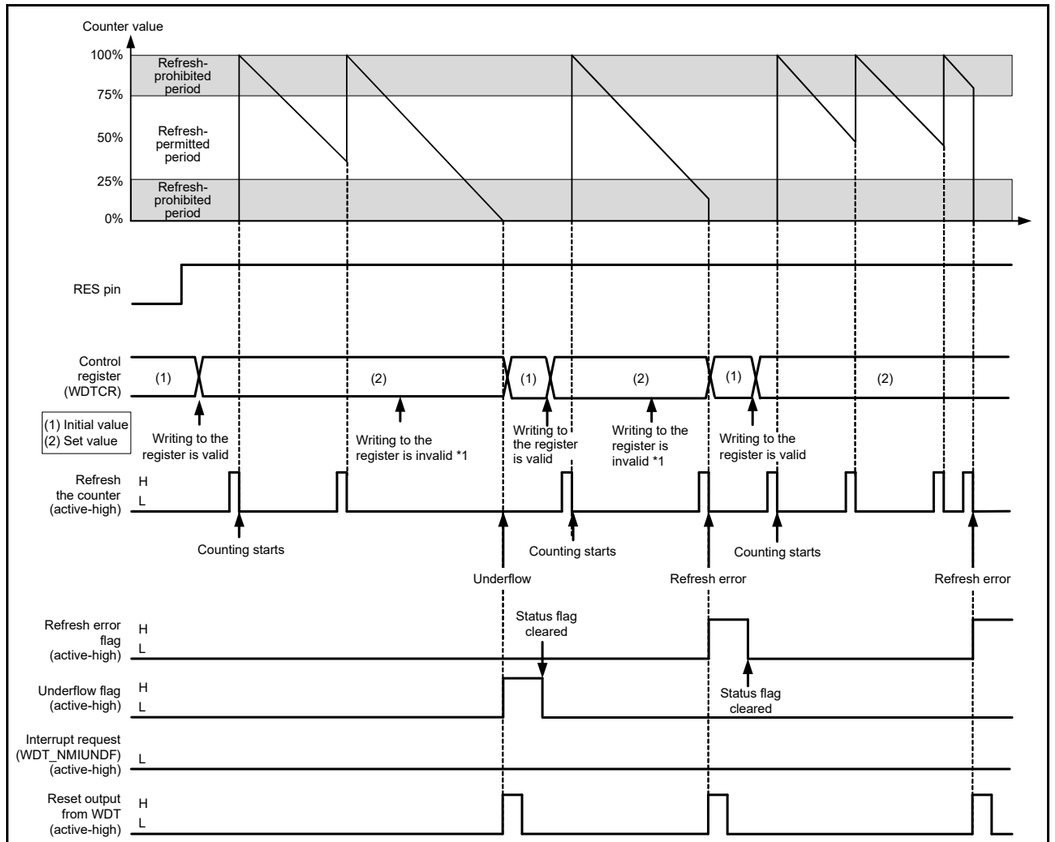
- 时钟分频比
- 窗口开始和结束位置
- WDTCR寄存器中的超时时间
- WDTRCR寄存器中的复位输出或中断请求输出
- 在WDTCSTPR寄存器中转换到休眠模式期间的计数器停止控制。

刷新递减计数器以从超时周期选择位(WDTCR.TOPS[1:0])中设置的值开始递减计数。

此后，只要在可刷新期间刷新计数器，每次刷新计数器时计数器中的值都会被重置，并继续递减计数。只要继续计数，WDT就不会输出复位信号。但是，如果由于程序失控导致递减计数器无法刷新而导致递减计数器下溢，或者由于计数器在刷新允许时间之外刷新而发生刷新错误，则WDT输出复位信号或非可屏蔽中断请求中断请求(WDT_NMIUNDF)。可以在WDT复位中断请求选择位(WDTRCR.RSTIRQS)中选择复位输出或中断请求输出。可以在WDT下溢刷新错误中断　　允许位(NMIER.WDTEN)中选择不可屏蔽的中断请求或中断请求。

图27.3显示了以下条件下的操作示例：

- 寄存器启动模式（OFS0.WDTSTRT=1）
- 使能复位输出(WDTRCR.RSTIRQS=1)
- 窗口起始位置为75%(WDTCR.RPSS[1:0]=10b)
- 窗口结束位置为25%(WDTCR.RPES[1:0]=10b)。



Note 1. See section 27.3.2, Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

Figure 27.3 Operation example in register start mode

27.3.1.2 Auto start mode

When the WDT Start Mode Select bit (OFS0.WDTSTRT) in the Option Function Select Register 0 (OFS0) is 0, auto start mode is selected. The WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are disabled while the settings in the OFS0 register are enabled.

Within the reset state, the following values in Option Function Select register 0 (OFS0) are set in the WDT registers:

- Clock division ratio
- Window start and end positions
- Timeout period
- Reset output or interrupt request
- Counter stop control on transition to Sleep mode.

When the reset state is released, the down-counter automatically starts counting down from the value set in the WDT Timeout Period Select bits (OFS0.WDTTOPS[1:0]).

Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and down-counting continues. The WDT does not output the reset signal as long as the counting continues. However, if the down-counter underflows because refreshing of the down-counter is not possible due to a runaway program or if a refresh error occurs due to refreshing outside the refresh-permitted period, the WDT asserts the

27.3.1.2 自动启动模式

当WDT启动模式选择位置（OFS0.WDTSTRT）中的选项功能选择寄存器0（OFS0）为0时，选择了自动启动模式。WDT控制寄存器(WDTCR)、WDT复位控制寄存器(WDTRCR)和WDT计数停止控制寄存器(WDTCSTPR)被禁用，而OFS0寄存器中的设置被启用。

在复位状态下，选项功能选择寄存器0(OFS0)中的以下值在WDT寄存器中设置：

- 时钟分频比
- 窗口开始和结束位置
- 超时时间
- 复位输出或中断请求
- 转换到睡眠模式时的计数器停止控制。

当复位状态解除时，递减计数器自动从WDT中设置的值开始递减计数
超时周期选择位(OFS0.WDTTOPS[1:0])。

此后，只要在可刷新期间刷新计数器，每次刷新计数器时计数器中的值都会被重置，并继续递减计数。只要继续计数，WDT就不会输出复位信号。但是，如果由于程序失控而无法刷新递减计数器导致递减计数器下溢，或者由于刷新允许刷新时间之外的刷新而发生刷新错误，则WDT断言

reset signal or non-maskable interrupt request/interrupt request (WDT_NMIUNDF).

After the reset signal or non-maskable interrupt request/interrupt request is generated, the counter reloads the timeout period after counting for 1 cycle. The value of the timeout period is set in the down-counter and counting restarts.

Reset output or interrupt request output can be selected in the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS). Non-maskable interrupt request or interrupt request can be selected in the WDT Underflow/Refresh Error Interrupt Enable bit (NMIER.WDTEN).

Figure 27.4 shows an example of operation (non-maskable interrupt) under the following conditions:

- Auto start mode (OFS0.WDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.WDTRSTIRQS = 0)
- The window start position is 75% (WDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (WDTCR.RPES[1:0] = 10b).

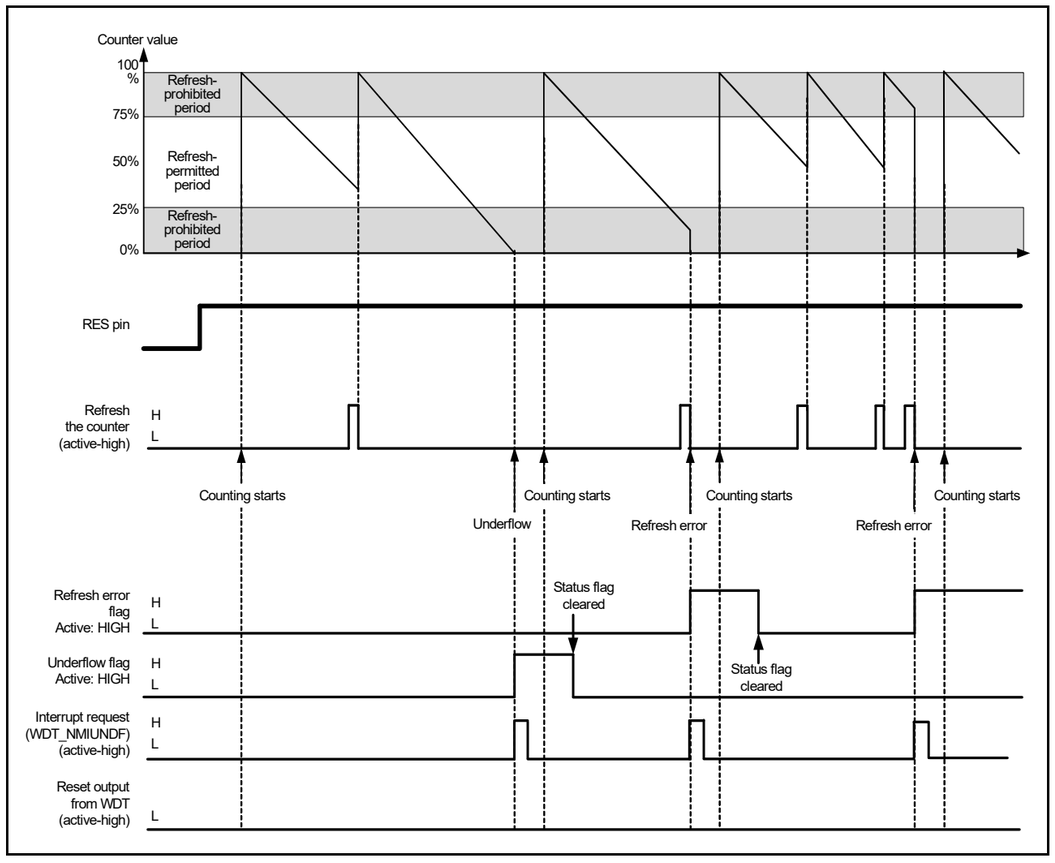

Figure 27.4 Operation example in auto start mode

27.3.2 Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers

Writing to the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), or WDT Count Stop Control Register (WDTCSTPR) is possible once between the release from the reset state and the first refresh operation.

After a refresh (counting starts) or a write to WDTCR, WDTRCR or WDTCSTPR, the protection signal in the WDT becomes 1 to protect WDTCR, WDTRCR and WDTCSTPR against subsequent write attempts. This protection is released by the reset source of the WDT. With other reset sources, the protection is not released.

复位信号或不可屏蔽中断请求中断请求(WDT_NMIUNDF)。

复位信号或不可屏蔽中断请求中断请求产生后，计数器在计数1个周期后重新加载超时周期。超时时间的值在递减计数器中设置并重新开始计数。

可以在WDT复位中断请求选择位(OFS0.WDTRSTIRQS)中选择复位输出或中断请求输出。可以在WDT下溢刷新错误中断　　允许位(NMIER.WDTEN)中选择不可屏蔽的中断请求或中断请求。

图27.4显示了以下条件下的操作示例（不可屏蔽中断）：

- 自动启动模式（OFS0.WDTSTRT=0）
- 使能不可屏蔽中断请求输出(OFS0.WDTRSTIRQS=0)
- 窗口起始位置为75%(WDTCR.RPSS[1:0]=10b)
- 窗口结束位置为25%(WDTCR.RPES[1:0]=10b)。

27.3.2 控制对WDTCR、WDTRCR和WDTCSTPR寄存器的写入

写入WDT控制寄存器(WDTCR)、WDT复位控制寄存器(WDTRCR)或WDT计数停止控制寄存器(WDTCSTPR)在从复位状态释放到第一次刷新操作之间是可能的。

在刷新（计数开始）或写入WDTCR、WDTRCR或WDTCSTPR后，WDT中的保护信号变为1，以保护WDTCR、WDTRCR和WDTCSTPR免受后续写入尝试。该保护由WDT的复位源解除。使用其他复位源时，不会解除保护。

Figure 27.5 shows control waveforms produced in response to writing to the WDTCR.

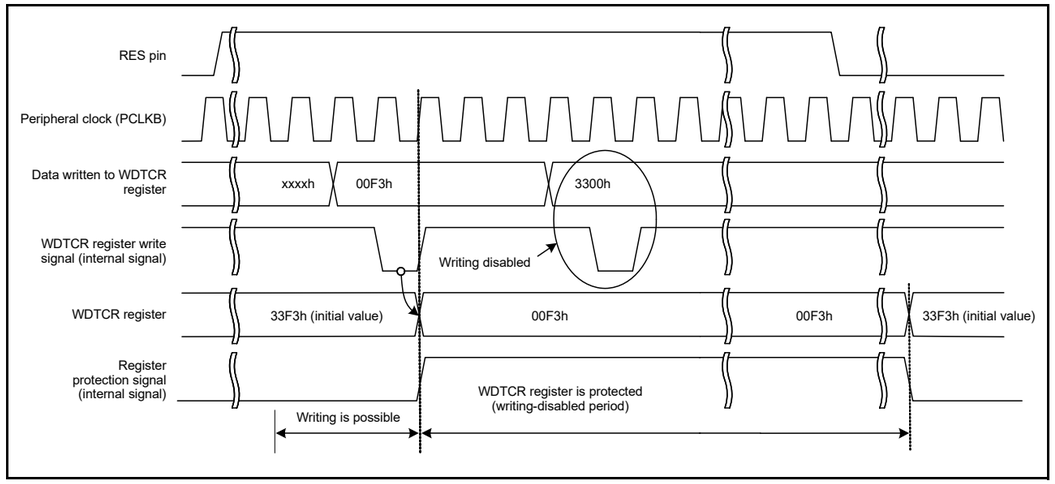

Figure 27.5 Control waveforms produced in response to writes to the WDTCR register

27.3.3 Refresh Operation

The down-counter is refreshed by writing the values 00h and FFh to the WDT Refresh Register (WDTRR). If a value other than FFh is written after 00h, the down-counter is not refreshed. After an invalid value is written, correct refreshing resumes by writing 00h and FFh to the WDTRR register.

When a register other than WDTRR is accessed or WDTRR is read between writing 00h and writing FFh to WDTRR, correct refreshing is performed.

Writing to refresh the counter must be performed within the refresh-permitted period and whether this is done is determined by writing FFh. For this reason, correct refreshing is performed even when 00h is written outside the refresh-permitted period.

[Example write sequences that are valid for refreshing the counter]

- 00h → FFh
- 00h (n-1th time) → 00h (nth time) → FFh
- 00h → access to another register or read from WDTRR → FFh.

[Example write sequences that are invalid for refreshing the counter]

- 23h (a value other than 00h) → FFh
- 00h → 54h (a value other than FFh)
- 00h→ AAh (00h and a value other than FFh) → FFh.

After FFh is written to the WDT Refresh Register (WDTRR), refreshing the down-counter requires up to 4 cycles of the signal for counting. To meet this requirement, complete writing FFh to WDTRR 4 count cycles before the down-counter underflows.

Figure 27.6 shows the WDT refresh-operation waveforms when the clock division ratio = PCLKB/64.

图27.5显示了响应写入WDTCR产生的控制波形。

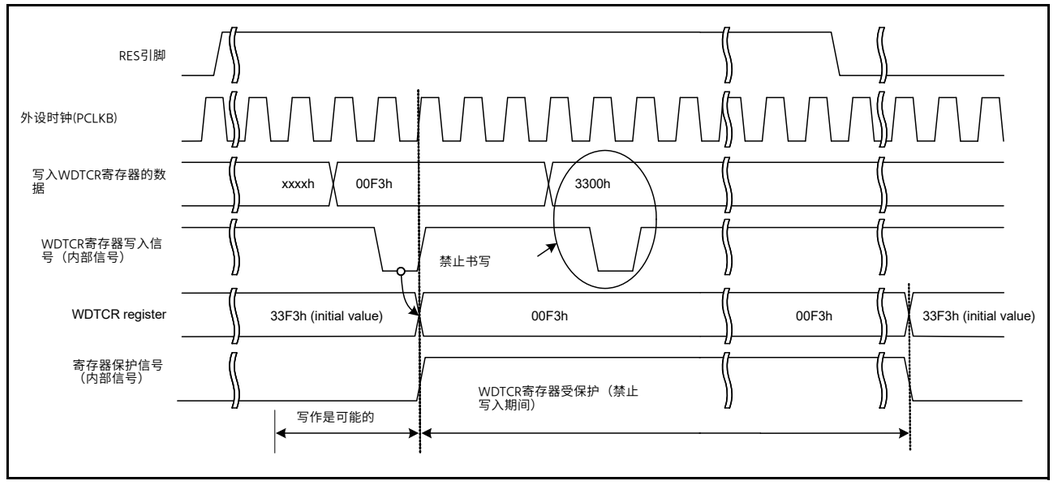

Figure 27.5 响应写入WDTCR寄存器而产生的控制波形

27.3.3 刷新操作

通过将值00h和FFh写入WDT刷新寄存器(WDTRR)来刷新递减计数器。如果在00h之后写入FFh以外的值，则不刷新递减计数器。写入无效值后，通过将00h和FFh写入WDTRR寄存器来恢复正确刷新。

在写入00h到写入FFh到WDTRR之间访问WDTRR以外的寄存器或读取WDTRR时，执行正确的刷新。

刷新计数器的写入必须在允许刷新的周期内执行，是否执行由写入FFh确定。因此，即使在允许刷新期间之外写入00h，也会执行正确的刷新。

[对刷新计数器有效的示例写入序列]

- 00h → FFh
- 00h (n-1th time) → 00h (nth time) → FFh
- 00h→访问另一个寄存器或从WDTRR→FFh读取。

[对刷新计数器无效的示例写入序列]

- 23h（00h以外的值）→FFh
- 00h→54h（FFh以外的值）
- 00h→AAh（00h和FFh以外的值）→FFh。

将FFh写入WDT刷新寄存器(WDTRR)后，刷新递减计数器最多需要4个信号周期进行计数。为满足此要求，请在递减计数器下溢之前的4个计数周期内将FFh写入WDTRR。

图27.6显示了时钟分频比=PCLKB64时的WDT刷新操作波形。

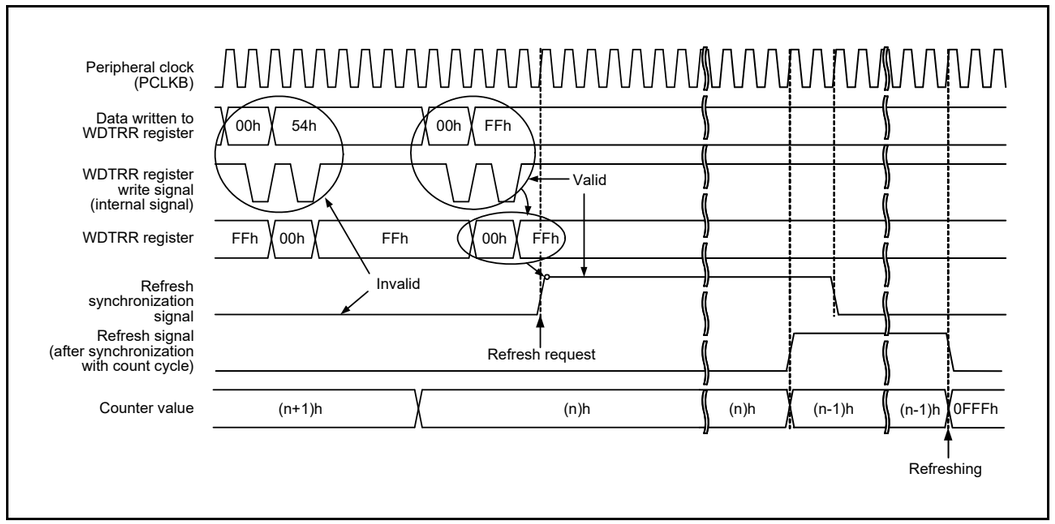

Figure 27.6 WDT refresh operation waveforms when WDTCR.CKS[3:0] = 0100b and WDTCR.TOPS[1:0] = 01b

27.3.4 Reset Output

When the Reset Interrupt Request Select bit (WDTRCR.RSTIRQS) is set to 1 in register start mode, or when the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 1 in auto start mode, a reset signal is output for 1 cycle count when an underflow in the down-counter or a refresh error occurs.

In register start mode, the down-counter is initialized (all bits set to 0) and stopped in that state after output of a reset signal. After the reset state is released and the program is restarted, the counter is set up and counting down starts again with a refresh. In auto start mode, counting down starts automatically after the reset state is released.

27.3.5 Interrupt Sources

When the Reset Interrupt Request Select bit (WDTRCR.RSTIRQS) is set to 0 in register start mode or when the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS) in Option Function Select Register 0 (OFS0) is set to 0 in auto start mode, an interrupt signal (WDT_NMIUNDF) is generated when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or an interrupt. For details, see section 14, Interrupt Controller Unit (ICU).

27.3.6 Reading the Down-Counter Value

The WDT stores the counter value in the down-counter value bits (WDTSR.CNTVAL[13:0]) of the WDT Status Register. Check these bits to obtain the counter value.

Figure 27.7 shows the processing for reading the WDT down-counter value when the clock division ratio = PCLKB/64.

27.3.4 复位输出

当重置中断请求选择位（wdtrcr.rstirqs）在寄存器开始模式下设置为1，或者在wdtrepreptinterrupt请求中选择位（ofs0.wdtrstirqs）在选项函数函数选择寄存器0（OFS0）中设置为1in在自动启动模式下，当递减计数器下溢或发生刷新错误时，会在1个周期计数内输出复位信号。

在寄存器启动模式下，递减计数器被初始化（所有位设置为0）并在输出复位信号后停止在该状态。复位状态解除并重新启动程序后，计数器设置并通过刷新重新开始倒计时。在自动启动模式下，复位状态解除后自动开始倒计时。

27.3.5 中断源

当在寄存器启动模式下复位中断请求选择位(WDTRCR.RSTIRQS)设置为0或WDT
选项功能选择寄存器0(OFS0)中的复位中断请求选择位(OFS0.WDTRSTIRQS)在自动启动模式下设置为0，当计数器下溢或发生刷新错误时会产生中断信号(WDT_NMIUNDF)。此中断可用作不可屏蔽中断或中断。有关详细信息，请参阅第14节，中断控制器单元(ICU)。

登记。检查这些位以获得计数器值。

27.3.7 Associations between Option Function Select Register 0 (OFS0) and WDT Registers

Table 27.5 lists the associations between Option Function Select register 0 (OFS0), used in auto start mode, and the registers used in register start mode. Do not change the OFS0 register settings during WDT operation. For details on Option Function Select register 0 (OFS0), see section 7, Option Function Select Register 0 (OFS0).

27.4 Link Operation by ELC

The WDT is capable of a link operation for the previously specified module when interrupt request signal is used as an event signal by the ELC. The event signal is output by the counter underflow or refresh error.

An event signal is output regardless of the setting in the WDTRCR.RSTIRQS bit in register start mode or the OFS0.WDTRSTIRQS bit in auto start mode. An event signal can also be output when the next interrupt source is generated while the Refresh Error Flag (WDTSR.REFEF) or Underflow Flag (WDTSR.UNDFF) is 1. For details, see section 19, Event Link Controller (ELC).

27.5 Usage Notes

27.5.1 Restrictions on the ICU Event Link Setting Register n (IELSRn) Setting

Setting 47h to the ICU Event Link Setting Register n (IELSRn.IELS[8:0] bits) is prohibited when enabling the WDT reset assertion (OFS0.WDTRSTIRQS = 1 or WDTRCR.RSTIRQS = 1) or when enabling the event link operation (47h is set to ELSRm.ELS[8:0]).

27.4 ELC的链接操作

当ELC将中断请求信号用作事件信号时，WDT能够对先前指定的模块进行链接操作。事件信号由计数器下溢或刷新错误输出。

无论寄存器启动模式下的WDTRCR.RSTIRQS位的设置如何，都会输出事件信号。
自动启动模式下的OFS0.WDTRSTIRQS位。当刷新错误标志(WDTSR.REFEF)或下溢标志(WDTSR.UNDFF)为1时，也可以在产生下一个中断源时输出事件信号。有关详细信息，请参阅第19节，事件链接控制器(ELC)。

28. Independent Watchdog Timer (IWDT)

28.1 Overview

The Independent Watchdog Timer (IWDT) is a 14-bit down counter that must be serviced periodically to prevent counter underflow. The IWDT can be used to reset the MCU or to generate a non-maskable interrupt or an underflow interrupt. Because the timer operates using an independent, dedicated clock source, it is particularly useful in returning the MCU to a known state as a failsafe mechanism when the system runs out of control. The IWDT can be triggered automatically by a reset, underflow, refresh error, or a refresh of the count value in the registers.

The IWDT functions differ from those of the WDT as follows:

- The divided IWDT-dedicated clock (IWDTCLK) is used as the count source (not affected by PCLKB)
- IWDT does not support the register start mode
- When transitioning to a low power mode (excluding Deep Software Standby mode), the OFS0.IWDTSTPCTL bit can be used to select whether to stop the counter or not.

Table 28.1 lists the IWDT specifications and Figure 28.1 shows a block diagram.

Table 28.1 IWDT specifications

Parameter	Specifications
Count source*1	IWDT-dedicated clock (IWDTCLK)
Clock division ratio	Division by 1, 16, 32, 64, 128, or 256
Counter operation	Counting down using a 14-bit down-counter
Condition for starting the counter	• Counting automatically starts after a reset
Conditions for stopping the counter	• Reset (the down-counter and other registers return to their initial values) • A counter underflows or a refresh error is generated (and counting restarts automatically)
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods)
IWDT reset sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error)
Non-maskable interrupt/interrupt sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error)
Reading of the counter value	The down-counter value can be read by the IWDTSR register
Event link function (output)	• Down-counter underflow event output • Refresh error event output
Output signal (internal signal)	• Reset output • Interrupt request output • Sleep-mode count stop control output
Auto start mode	Configurable to the following triggers: • Clock frequency division ratio after a reset (OFS0.IWDTCKS[3:0] bits) • Timeout period of the IWDT (OFS0.IWDTTOPS[1:0] bits) • Window start position in the IWDT (OFS0.IWDTRPSS[1:0] bits) • Window end position in the IWDT (OFS0.IWDTRPES[1:0] bits) • Reset output or interrupt request output (OFS0.IWDTRSTIRQS bit) • Down-count stop function on transition to Sleep mode, Software Standby mode, or Snooze mode (OFS0.IWDTSTPCTL bit)

Note 1. This must satisfy the frequency of the peripheral module clock (PCLKB) ≥ 4 × (the frequency of the count clock source after division).

To use the IWDT, you must supply the IWDT-dedicated clock (IWDTCLK). The bus interface and registers operate with PCLKB, and the 14-bit counter and control circuits operate with IWDTCLK.

28. 独立看门狗定时器(IWDT)

28.1 Overview

独立看门狗定时器(IWDT)是一个14位递减计数器，必须定期对其进行服务以防止计数器下溢。IWDT可用于复位MCU或产生不可屏蔽中断或下溢中断。由于定时器使用独立的专用时钟源运行，因此当系统失控时，它在将MCU作为故障保护机制返回到已知状态时特别有用。IWDT可以通过复位、下溢、刷新错误或寄存器中的计数值的刷新来自动触发。

IWDT的功能与WDT的不同之处如下：

- 分频的IWDT专用时钟（IWDTCLK）用作计数源（不受PCLKB影响）
- IWDT不支持寄存器启动模式
- 当转换到低功耗模式（不包括深度软件待机模式）时，OFS0.IWDTSTPCL位可用于选择是否停止计数器。

表28.1列出了IWDT规范，图28.1显示了框图。

Table 28.1 IWDT specifications

Parameter	Specifications
Count source*1	IWDT-dedicated clock (IWDTCLK)
时钟分频比	除以1、16、32、64、128或256
计数器操作	使用14位递减计数器进行递减计数
启动计数器的条件	复位后自动开始计数
停止计数器的条件	复位（递减计数器和其他寄存器恢复到初始值） 计数器下溢或产生刷新错误（计数自动重新开始）
窗口功能	可以指定窗口开始和结束位置（允许刷新和禁止刷新期间）
IWDT复位源	递减计数器下溢 在允许刷新的时间之外刷新（刷新错误）
Non-maskable interrupt/interrupt sources	递减计数器下溢 在允许刷新的时间之外刷新（刷新错误）
读取计数器值	递减计数器的值可以通过IWDTSR寄存器读取
事件链接功能（输出）	递减计数器下溢事件输出 刷新错误事件输出
输出信号（内部信号）	复位输出 中断请求输出 睡眠模式计数停止控制输出
自动启动模式	可配置为以下触发器： 复位后的时钟分频比（OFS0.IWDTCKS[3:0]位） IWDT的超时周期（OFS0.IWDTTOPS[1:0]位） IWDT中的窗口开始位置（OFS0.IWDTRPSS[1:0]位） IWDT中的窗口结束位置（OFS0.IWDTRPES[1:0]位） 复位输出或中断请求输出（OFS0.IWDTRSTIRQS位） 向下计数停止功能在转换到睡眠模式、软件待机模式或贪睡模式（OFS0.IWDTSTPCL位）

Note 1. 这必须满足外围模块时钟(PCLKB)的频率 4×(分频后的计数时钟源的频率)。

要使用IWDT，您必须提供IWDT专用时钟(IWDTCLK)。总线接口和寄存器操作PCLKB、14位计数器和控制电路使用IWDTCLK工作。

28.2.1 IWDT Refresh Register (IWDTRR)

Address(es): IWDT.IWDTRR 4004 4400h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

Bit	Description	R/W
b7 to b0	The down-counter is refreshed by writing 00h and then writing FFh to this register.	R/W

The IWDTRR register refreshes the down-counter of the IWDT. The down-counter of the IWDT is refreshed by writing 00h and then writing FFh to IWDTRR (refresh operation) within the refresh-permitted period. After the counter is refreshed, it starts counting down from the value selected in the IWDT Timeout Period Select bits (OFS0.IWDTTOPS[1:0]) in Option Function Select Register 0 (OFS0).

When 00h is written, the read value is 00h. When a value other than 00h is written, the read value is FFh. For details on the refresh operation, see section 28.3.2, Refresh Operation.

Bit	Description	R/W
b7 to b0	通过写入00h然后将FFh写入该寄存器来刷新递减计数器。	R/W

IWDTRR寄存器刷新IWDT的递减计数器。IWDT的递减计数器通过写入00h进行刷新，然后在允许刷新期间将FFh写入IWDTRR（刷新操作）。计数器刷新后，它从选项功能选择寄存器0(OFS0)的IWDT超时周期选择位(OFS0.IWDTTOPS[1:0])中选择的值开始递减计数。

写入00h时，读取值为00h。写入00h以外的值时，读取值为FFh。有关刷新操作的详细信息，请参阅第28.3.2节，刷新操作。

	REFEF	UNDFF	CNTVAL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b13 to b0	CNTVAL[13:0]	Counter Value	Value counted by the down-counter	R
b14	UNDFF	Underflow Flag	0: No underflow occurred 1: Underflow occurred.	R/(W)*1
b15	REFEF	Refresh Error Flag	0: No refresh error occurred 1: Refresh error occurred.	R/(W)*1

Note 1. Only 0 can be written to clear the flag.

CNTVAL[13:0] bits (Counter Value)

Read the CNTVAL[13:0] bits to confirm the value of the down-counter. The read value might differ from the actual count by 1.

UNDFF flag (Underflow Flag)

Read the UNDFF flag to confirm whether an underflow occurred in the counter. A value of 1 indicates that the down-counter underflowed. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N+2) IWDTCLK cycles and 2 PCLKB cycles. In addition, clearing of the flag is ignored for (N+2) IWDTCLK cycles after an underflow. N is specified in the IWDTCKS[3:0] bits as follows:

- When IWDTCKS[3:0] = 0000b, N = 1
- When IWDTCKS[3:0] = 0010b, N = 16
- When IWDTCKS[3:0] = 0011b, N = 32
- When IWDTCKS[3:0] = 0100b, N = 64
- When IWDTCKS[3:0] = 1111b, N = 128
- When IWDTCKS[3:0] = 0101b, N = 256

REFEF flag (Refresh Error Flag)

Read the REFEF flag to confirm whether a refresh error occurred, indicating that a refresh operation was performed during a prohibited period. A value of 1 indicates that a refresh error occurred. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the REFEF flag takes (N+2) IWDTCLK cycles and 2 PCLKB cycles. In addition, clearing of the flag is ignored for (N+2) IWDTCLK cycles after a refresh error. N is specified in the IWDTCKS[3:0] bits as follows:

- When IWDTCKS[3:0] = 0000b, N = 1
- When IWDTCKS[3:0] = 0010b, N = 16
- When IWDTCKS[3:0] = 0011b, N = 32
- When IWDTCKS[3:0] = 0100b, N = 64
- When IWDTCKS[3:0] = 1111b, N = 128
- When IWDTCKS[3:0] = 0101b, N = 256.

重置后的值：	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	位名称	Description	R/W
b13 to b0	CNTVAL[13:0]	计数器值	递减计数器计数的值	R
b14	UNDFF	Underflow Flag	0：未发生下溢1：发生下溢。	R/(W)*1
b15	REFEF	刷新错误标志	0：未发生刷新错误1：发生刷新错误。	R/(W)*1

Note 1. 只能写入0来清除标志。

CNTVAL[13:0]位（计数器值）

读取CNTVAL[13:0]位以确认递减计数器的值。读取的值可能与实际计数相差1。

UNDFF flag (Underflow Flag)

读取UNDFF标志以确认计数器是否发生下溢。值1表示递减计数器下溢。将0写入标志以将值设置为0。写入1无效。

清除UNDFF标志需要(N+2)个IWDTCLK周期和2个PCLKB周期。此外，在下溢后的(N+2)个IWDTCLK周期内忽略标志的清除。N在IWDTCKS[3:0]位中指定如下：

- When IWDTCKS[3:0] = 0000b, N = 1
- When IWDTCKS[3:0] = 0010b, N = 16
- When IWDTCKS[3:0] = 0011b, N = 32
- When IWDTCKS[3:0] = 0100b, N = 64
- When IWDTCKS[3:0] = 1111b, N = 128
- When IWDTCKS[3:0] = 0101b, N = 256

REFEF标志（刷新错误标志）

读取REFEF标志，确认是否发生刷新错误，表示在禁止期间进行了刷新操作。值1表示发生了刷新错误。将0写入标志以将值设置为0。写入1无效。

清除REFEF标志需要(N+2)个IWDTCLK周期和2个PCLKB周期。此外，在刷新错误后的(N+2)个IWDTCLK周期内，标志的清除将被忽略。N在IWDTCKS[3:0]位中指定如下：

- When IWDTCKS[3:0] = 0000b, N = 1
- When IWDTCKS[3:0] = 0010b, N = 16
- When IWDTCKS[3:0] = 0011b, N = 32
- When IWDTCKS[3:0] = 0100b, N = 64
- When IWDTCKS[3:0] = 1111b, N = 128
- When IWDTCKS[3:0] = 0101b, N = 256.

28.2.3 Option Function Select Register 0 (OFS0)

For information on Option Function Select Register 0 (OFS0), see section 7.2.1, Option Function Select Register 0 (OFS0).

IWDTTOPS[1:0] bits (IWDT Timeout Period Select)

The IWDTTOPS[1:0] bits select the timeout period, the period until the down-counter underflows, from 128, 512, 1024, or 2048 cycles, taking the divided clock specified in the IWDTCKS[3:0] bits as 1 cycle. After the down-counter is refreshed, the combination of the IWDTCKS[3:0] and IWDTTOPS[1:0] bits determines the number of IWDTCLK cycles until the counter underflows.

Table 28.2 lists the relationship between the IWDTCKS[3:0] and IWDTTOPS[1:0] bit settings, the timeout period, and the number of IWDTCLK cycles.

Table 28.2 Timeout period settings

IWDTCKS[3:0] bits (IWDT-Dedicated Clock Frequency Division Ratio Select)

The IWDTCKS[3:0] bits specify the division ratio of the clock used for the down-counter. The division ratio can be selected from the IWDT-dedicated clock (IWDTCLK) divided by 1, 16, 32, 64, 128, and 256. Combined with the IWDTTOPS[1:0] bit setting, this allows the IWDT to be configured to a count period between 128 and 524288 IWDTCLK cycles.

IWDTRPES[1:0] bits (IWDT Window End Position Select)

The IWDTRPES[1:0] bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. Set the window end position to a value less than

28.2.3 选项功能选择寄存器0(OFS0)

有关选项功能选择寄存器0(OFS0)的信息，请参阅第7.2.1节，选项功能选择寄存器0(OFS0)。

IWDTTOPS[1:0]位（IWDT超时周期选择）

IWDTTOPS[1:0]位从128、512、1024或2048个周期中选择超时周期，直到递减计数器下溢的周期，将IWDTCKS[3:0]位中指定的分频时钟作为1个周期.向下计数器刷新后，IWDTCKS[3:0]和IWDTTOPS[1:0]位的组合决定了在计数器下溢之前的IWDTCLK周期数。

表28.2列出了IWDTCKS[3:0]和IWDTTOPS[1:0]位设置、超时周期和IWDTCLK周期数之间的关系。

Table 28.2 超时时间设置

IWDTCKS[3:0]位（IWDT专用时钟分频比选择）

IWDTCKS[3:0]位指定用于递减计数器的时钟分频比。分频比可以从IWDT专用时钟(IWDTCLK)除以1、16、32、64、128和256中选择。结合IWDTTOPS[1:0]位设置，这允许将IWDT配置为128到524288之间的计数周期

IWDTCLK cycles.

IWDTRPES[1:0]位（IWDT窗口结束位置选择）

IWDTRPES[1:0]位指定指示刷新允许周期的窗口结束位置。可以为窗口结束位置选择75%、50%、25%或0%的超时时间。将窗口结束位置设置为小于

the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.

IWDTRPSS[1:0] bits (IWDT Window Start Position Select)

The IWDTRPSS[1:0] bits specify the window start position that indicates the refresh-permitted period. 100%, 75%, 50%, or 25% of the timeout period can be selected for the window start position. Set the window start position to a value greater than the window end position. If the window start position is less than or equal to the window end position, the window end position is set to 0%.

Table 28.3 lists the counter values for the window start and end positions, and Figure 28.2 shows the refresh-permitted period set in the IWDTRPSS[1:0], IWDTRPES[1:0], and IWDTTOPS[1:0] bits.

IWDTRSTIRQS bit (IWDT Reset Interrupt Request Select)

The IWDTRSTIRQS bit specifies the behavior when an underflow or a refresh error occurs. Setting 1 selects reset output. Setting 0 selects non-maskable interrupt or interrupt.

IWDTSTPCTL bit (IWDT Stop Control)

The IWDTSTPCTL bit controls whether to stop counting on transition to Sleep, Snooze, or Software Standby mode.

IWDTRSTIRQS位（IWDT复位中断请求选择）

IWDTRSTIRQS位指定发生下溢或刷新错误时的行为。设置1选择复位输出。设置0选择不可屏蔽中断或中断。

IWDTSTPCTL位（IWDT停止控制）

IWDTSTPCTL位控制在转换到休眠、贪睡或软件待机模式时是否停止计数。

28.3 Operation

28.3.1 Auto Start Mode

When the IWDT Start Mode Select bit (OFS0.IWDTSTRT) is 0, auto start mode is selected. Otherwise, the IWDT is disabled.

Within the reset state, the following values in Option Function Select Register 0 (OFS0) are set in the IWDT registers:

- Clock division ratio
- Window start and end positions
- Timeout period
- Reset output or interrupt request
- Counter stop control on transition to the low power modes.

When the reset state is released, the down-counter automatically starts counting down from the value set in the IWDT Timeout Period Select bits (OFS0.IWDTTOPS[1:0]).

After that, as long as the program continues normal operation and the counter is refreshed within the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and down-counting continues. The IWDT does not output the reset signal as long as this procedure continues. However, if the counter underflows because the program crashes, or because a refresh error occurs when an attempt is made to refresh outside the refresh-permitted period, the IWDT asserts the reset signal or non-maskable interrupt request/interrupt request (IWDT_NMIUNDF).

After the reset signal or non-maskable interrupt request/interrupt request is generated, the counter reloads the timeout period after counting for 1 cycle, and restarts the count. Reset output or interrupt request output can be selected in the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS). Non-maskable interrupt request or interrupt request can be selected in the IWDT Underflow/Refresh Error Interrupt Enable bit (NMIER.IWDTEN).

Figure 28.3 shows an example of operation under the following conditions:

- Auto start mode (OFS0.IWDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.IWDTRSTIRQS = 0)
- The window start position is 75% (OFS0.IWDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.IWDTRPES[1:0] = 10b).

28.3 Operation

28.3.1 自动启动模式

当IWDT启动模式选择位(OFS0.IWDTSTRT)为0时，选择自动启动模式。否则，禁用IWDT。

在复位状态下，选项功能选择寄存器0(OFS0)中的以下值在IWDT寄存器中设置：

- 时钟分频比
- 窗口开始和结束位置
- 超时时间
- 复位输出或中断请求
- 转换到低功耗模式时的计数器停止控制。

复位状态解除后，递减计数器自动从IWDT中设置的值开始递减计数
超时周期选择位(OFS0.IWDTOPS[1:0])。

之后，只要程序继续正常运行，并且在允许刷新的时间内刷新计数器，每次刷新计数器并继续递减计数时，计数器中的值都会被复位。只要此过程继续，IWDT就不会输出复位信号。但是，如果由于程序崩溃或由于在刷新允许周期之外尝试刷新时发生刷新错误而导致计数器下溢，则IWDT将置位复位信号或不可屏蔽中断请求中断请求(IWDT_NMIUNDF)。

复位信号或不可屏蔽中断请求中断请求产生后，计数器在计数1个周期后重新加载超时周期，重新开始计数。可以在IWDT复位中断请求选择位(OFS0.IWDTRSTIRQS)中选择复位输出或中断请求输出。可以在IWDT下溢刷新错误中断　　允许位(NMIER.IWDTEN)中选择不可屏蔽的中断请求或中断请求。

图28.3显示了以下条件下的操作示例：

- 自动启动模式（OFS0.IWDTSTRT=0）
- 使能不可屏蔽中断请求输出(OFS0.IWDTRSTIRQS=0)
- 窗口起始位置为75%(OFS0.IWDTRPSS[1:0]=10b)
- 窗口结束位置为25%(OFS0.IWDTRPES[1:0]=10b)。

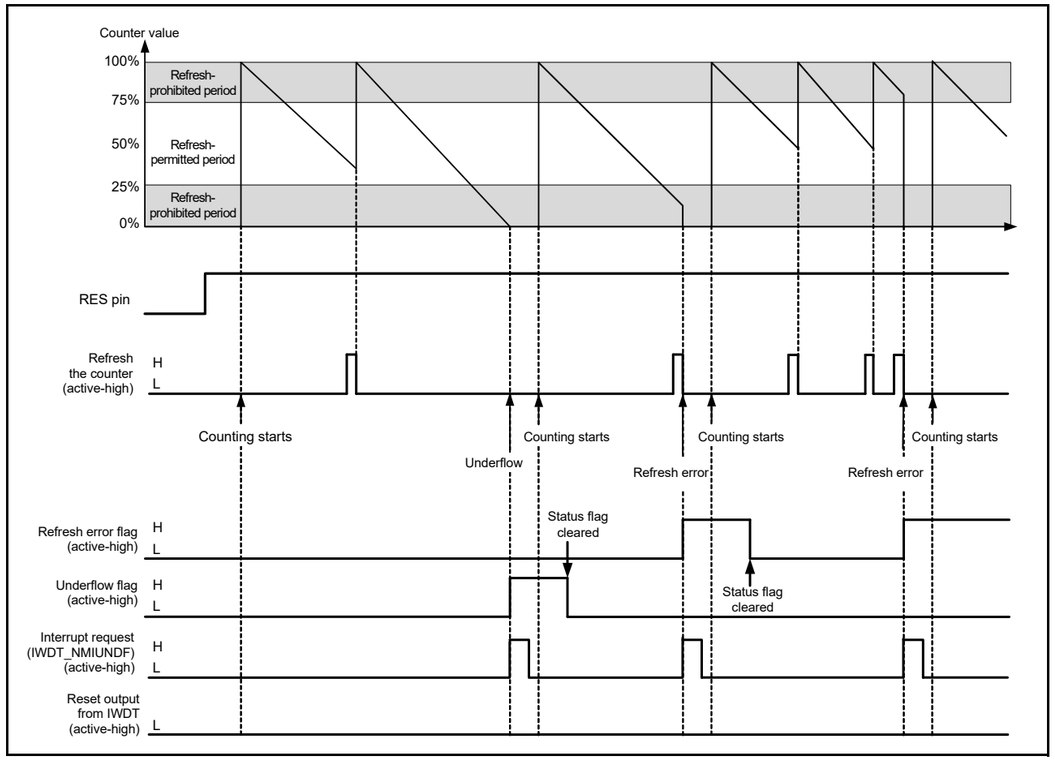

Figure 28.3 Operation example in auto start mode

28.3.2 Refresh Operation

The down-counter is refreshed by writing the values 00h and FFh to the IWDT Refresh Register (IWDTRR). If a value other than FFh is written after 00h, the down-counter is not refreshed. If an invalid value is written, correct refreshing resumes on a write of 00h and FFh to the IWDTRR register.

When writes are made in the order of 00h (first time) → 00h (second time), and if FFh is written after that, the writing order 00h → FFh is satisfied. Writes of 00h (n-1th time) → 00h (nth time) → FFh are valid, and the refresh is performed correctly. Even when the first value written before 00h is not 00h, correct refreshing is performed as long as the operation contains the write sequence of 00h → FFh.

Correct refreshing is also performed when a register other than IWDTRR is accessed or IWDTRR is read between writing 00h and writing FFh to IWDTRR. Writes to refresh the counter must be made within the refresh-permitted period, and this is determined by the FFh write. For this reason, correct refreshing is performed even when 00h is written outside the refresh-permitted period.

[Example write sequences that are valid for refreshing the counter]

- 00h → FFh
- 00h (n-1th time) → 00h (nth time) → FFh
- 00h → access to another register or read from IWDTRR → FFh.

[Example write sequences that are invalid for refreshing the counter]

- 23h (a value other than 00h) → FFh
- 00h → 54h (a value other than FFh)
- 00h → AAh (00h and a value other than FFh) → FFh.

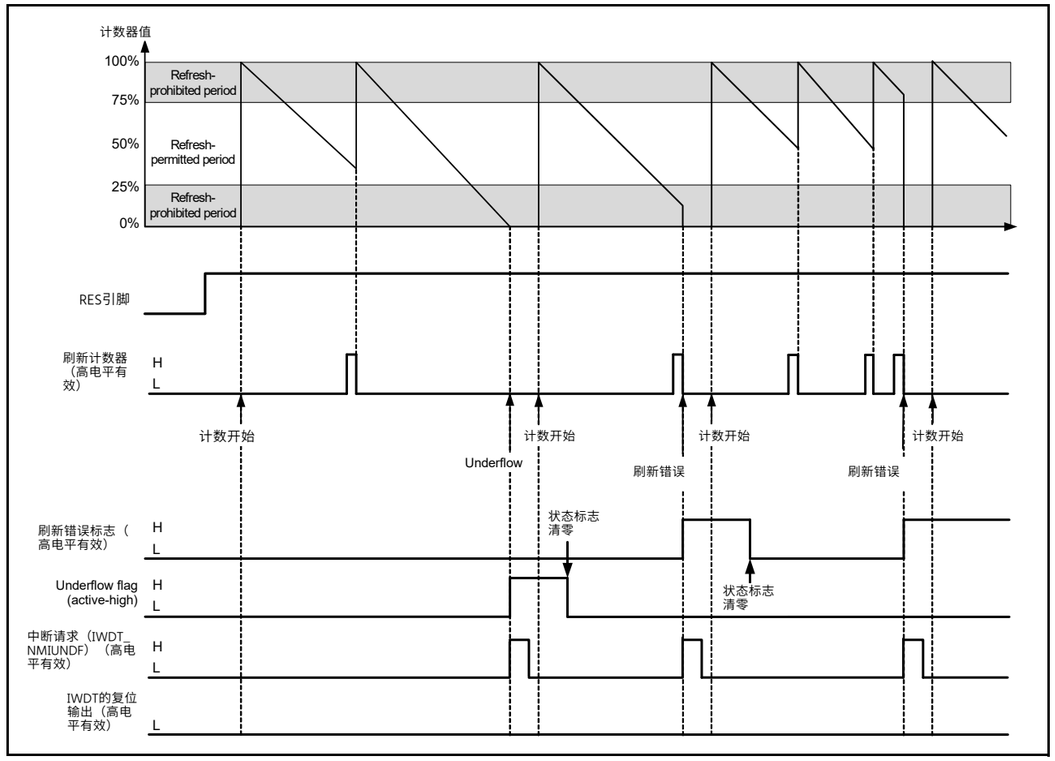

Figure 28.3 自动启动模式下的操作示例

28.3.2 刷新操作

通过将值00h和FFh写入IWDT刷新寄存器(IWDTRR)来刷新递减计数器。如果在00h之后写入FFh以外的值，则不刷新递减计数器。如果写入无效值，则在将00h和FFh写入IWDTRR寄存器时会恢复正确刷新。

当以00h（第一次）→00h（第二次）的顺序进行写入时，如果在此之后写入FFh，则满足写入顺序00h→FFh。00h（第n-1次）→00h（第n次）→FFh的写入有效，刷新正确。即使在00h之前写入的第一个值不是00h，只要操作包含00h→FFh的写入序列，就会执行正确的刷新。

当访问IWDTRR以外的寄存器或在写入00h和将FFh写入IWDTRR之间读取IWDTRR时，也会执行正确刷新。刷新计数器的写操作必须在允许刷新的时间内进行，这由FFh写操作决定。因此，即使在刷新允许期间之外写入00h，也会执行正确的刷新。

[对刷新计数器有效的示例写入序列]

- 00h → FFh
- 00h (n-1th time) → 00h (nth time) → FFh
- 00h→访问另一个寄存器或从IWDTRR→FFh读取。

[对刷新计数器无效的示例写入序列]

- 23h（00h以外的值）→FFh
- 00h→54h（FFh以外的值）
- 00h→AAh(00h和FFh以外的值)→FFh。

After FFh is written to the IWDT Refresh Register (IWDTRR), refreshing the down-counter requires up to 4 cycles of the signal for counting (the IWDT-dedicated clock frequency division ratio select bits (OFS0.IWDTCKS[3:0]) determine how many cycles of the IWDT-dedicated clock (IWDTCLK) make up 1 counting cycle). To meet this requirement, complete writing FFh to IWDTRR 4 count cycles before the end of the refresh-permitted period or a counter underflow. The value of the counter can be checked in the counter bits (IWDTSR.CNTVAL[13:0]).

[Example refreshing timings]

- When the window start position is set to 1FFFh, even if 00h is written to IWDTRR before 1FFFh is reached (at 2002h, for example), refreshing occurs if FFh is written to IWDTRR after the value of the IWDTSR.CNTVAL[13:0] bits reaches 1FFFh.
- When the window end position is set to 1FFFh, refreshing occurs if 2003h (four count cycles before 1FFFh) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after a write of 00h → FFh to IWDTRR.
- When the refresh-permitted period continues until count 0000h, refreshing can be performed immediately before an underflow. In this case, if 0003h (four count cycles before an underflow) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after a write of 00h → FFh to IWDTRR, no underflow occurs and refreshing is performed.

Figure 28.4 shows the IWDT refresh-operation waveforms when PCLKB > IWDTCLK and the clock division ratio is IWDTCLK.

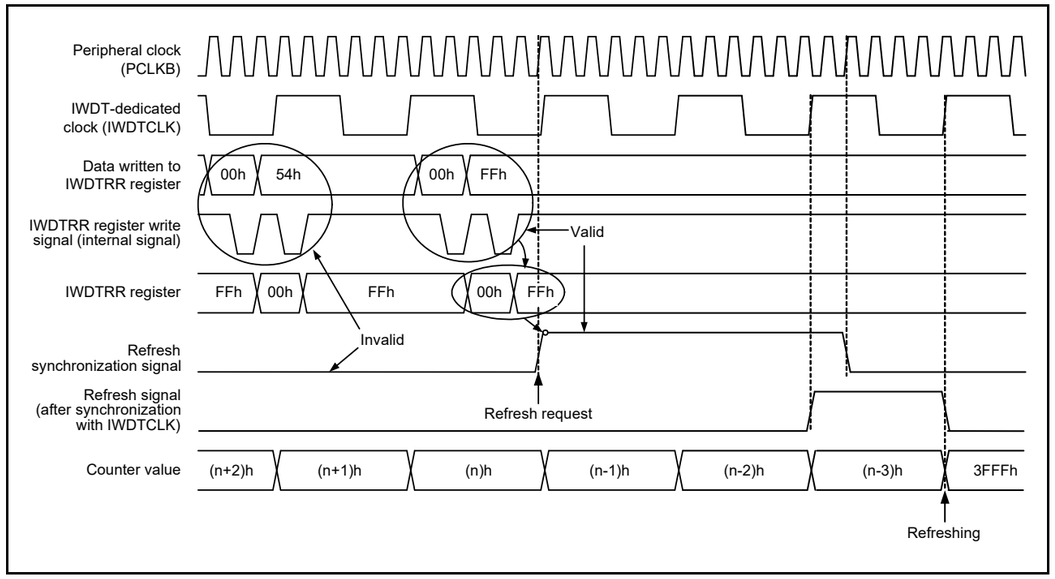

Figure 28.4 IWDT refresh operation waveforms when OFS0.IWDTCKS[3:0] = 0000b and OFS0.IWDTTOPS[1:0] = 11b

28.3.3 Status Flags

The refresh error (IWDTSR.REFEF) and underflow (IWDTSR.UNDFF) flags retain the source of the reset signal output from the IWDT or the source of the interrupt request from the IWDT. After a release from the reset state or interrupt request generation, read the IWDTSR.REFEF and UNDFF flags to check for the reset or interrupt source. For each flag, writing 0 clears the bit and writing 1 has no effect.

Leaving the status flags unchanged does not affect operation. If the flags are not cleared on the next reset or interrupt request from the IWDT, the earlier reset or interrupt source is cleared and the new reset or interrupt source is written. After 0 is written to each flag, up to 3 IWDTCLK cycles and 2 PCLKB cycles are required before the value is reflected.

将FFh写入IWDT刷新寄存器(IWDTRR)后，刷新递减计数器需要最多4个周期的计数信号（IWDT专用时钟分频比选择位(OFS0.IWDTCKS[3:0])确定IWDT专用时钟(IWDTCLK)的多少个周期构成1个计数周期）。为满足此要求，请在刷新允许周期结束或计数器下溢之前4个计数周期将FFh写入IWDTRR。可以在计数器位(IWDTSR.CNTVAL[13:0])中检查计数器的值。

[Example refreshing timings]

- 当窗口起始位置设置为1FFFh时，即使在到达1FFFh之前（例如在2002h）将00h写入IWDTRR，如果在IWDTSR.CNTVAL[13:0]的值之后将FFh写入IWDTRR，也会发生刷新位达到1FFFh。
- 当窗口结束位置设置为1FFFh时，如果在将00h→FFh写入IWDTRR后立即从IWDTSR.CNTVAL[13:0]位读取2003h（1FFFh之前的四个计数周期）或更大的值，则会发生刷新。
- 当刷新允许周期持续到计数0000h时，可以在下溢之前立即执行刷新。在这种情况下，如果在将00h→FFh写入IWDTRR后立即从IWDTSR.CNTVAL[13:0]位读取0003h（下溢之前的四个计数周期）或更大的值，则不会发生下溢并执行刷新。

图28.4显示了当PCLKB>IWDTCLK并且时钟分频比为时的IWDT刷新操作波形
IWDTCLK.

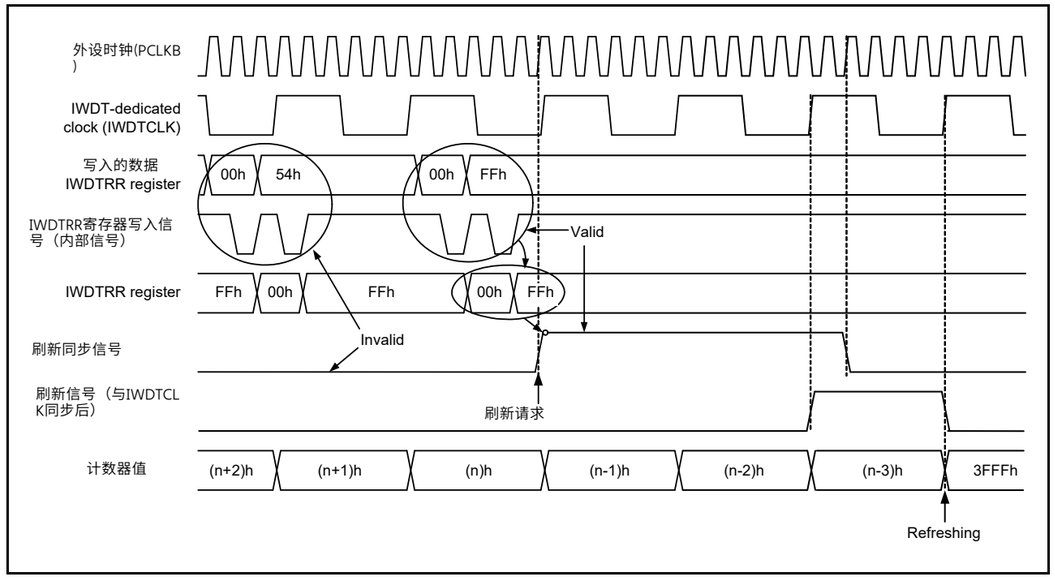

Figure 28.4 当OFS0.IWDTCKS[3:0]=0000b且OFS0.IWDTCKS[1:0]=11b时的IWDT刷新操作波形

28.3.3 状态标志

刷新错误(IWDTSR.REFEF)和下溢(IWDTSR.UNDFF)标志保留IWDT的复位信号输出源或IWDT的中断请求源。从复位状态释放或产生中断请求后，读取IWDTSR.REFEF和UNDFF标志以检查复位或中断源。对于每个标志，写入0清除该位，写入1无效。

保持状态标志不变不会影响操作。如果在IWDT发出的下一次复位或中断请求时未清除标志，则清除较早的复位或中断源并写入新的复位或中断源。将0写入每个标志后，最多需要3个IWDTCLK周期和2个PCLKB周期才能反映该值。

28.3.4 Reset Output

When the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS) in Option Function Select Register 0 (OFS0) is set to 1, a reset signal is output when an underflow in the down-counter or a refresh error occurs. Counting down starts automatically after the reset output.

28.3.5 Interrupt Sources

When the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS) in Option Function Select Register 0 (OFS0) is set to 0, an interrupt signal (IWDT_NMIUNDF) is generated when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or an interrupt. For details, see section 14, Interrupt Controller Unit (ICU).

Table 28.4 IWDT interrupt source

Name	Interrupt source	DTC activation	DMAC activation
IWDT_NMIUNDF	• Down-counter underflow • Refresh error	Not possible	Not possible

28.3.6 Reading the Down-Counter Value

Because the counter is the IWDT-dedicated clock (IWDTCLK), the counter value cannot be read directly. The IWDT synchronizes the counter value with the peripheral clock (PCLKB) and stores it in the down-counter value bits (IWDTSR.CNTVAL[13:0]) of the IWDT Status register. Check these bits to obtain the counter value indirectly. Reading the counter value requires multiple PCLKB clock cycles (up to four clock cycles), and the read counter value might differ from the actual counter value by a value of one count.

Figure 28.5 shows the processing for reading the IWDT counter value when PCLKB > IWDTCLK and the clock division ratio is IWDTCLK.

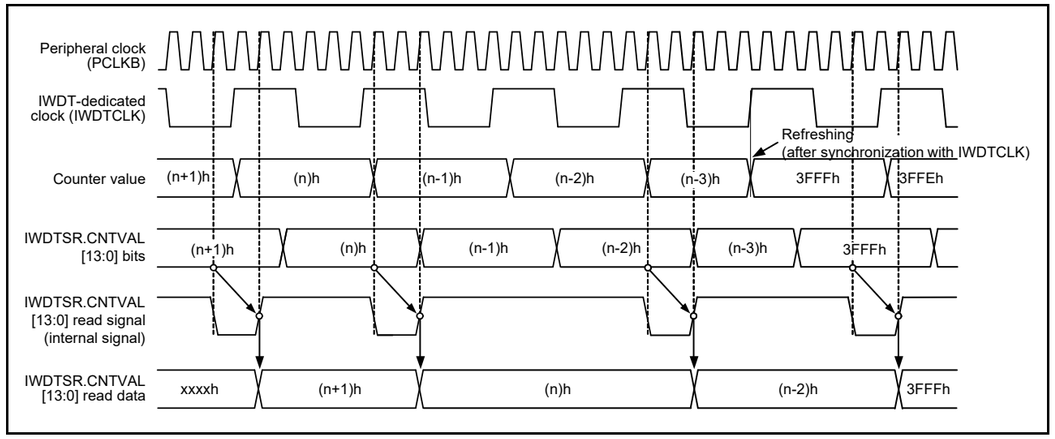

Figure 28.5 Processing for reading IWDT counter value when OFS0.IWDTCKS[3:0] = 0000b and OFS0.IWDTTOPS[1:0] = 11b

28.4 Output to the Event Link Controller (ELC)

The IWDT is capable of link operation for a specified module when the interrupt request signal is used as an event signal by the ELC. The event signal is output by the counter underflow or refresh error.

An event signal is output regardless of the setting in the OFS0.WDTRSTIRQS bit. An event signal can also be output when the next interrupt source is generated while the Refresh Error Flag (IWDTSR.REFEF) or Underflow Flag (IWDTSR.UNDFF) is 1. For details, see section 19, Event Link Controller (ELC).

28.3.4 复位输出

当IWDT重置中断请求选择位置（OFS0.IWDTRSTIRQS）在选项函数选择寄存器0（OFS0）中的BIT（OFS0）设置为1时，当下部访问中的下流或刷新错误发生时，将输出重置信号。复位输出后自动开始倒计时。

28.3.5 中断源

当IWDT重置中断请求选择位置（OFS0.IWDTRSTIRQS）中的选项功能选择寄存器0（OFS0）设置为0时，当计数器中的下流或刷新错误时，会生成中断信号（IWDT_NMIUNDF）。此中断可用作不可屏蔽中断或中断。有关详细信息，请参阅第14节，中断控制器单元(ICU)。

Table 28.4 IWDT中断源

Name	中断源	DTC activation	DMAC activation
IWDT_NMIUNDF	递减计数器下溢 刷新错误	不可能	不可能

28.3.6 读取递减计数器值

因为计数器是IWDT专用时钟（IWDTCLK），所以无法直接读取计数器值。IWDT将计数器值与外设时钟(PCLKB)同步，并将其存储在IWDT状态寄存器的递减计数器值位(IWDTSR.CNTVAL[13:0])中。检查这些位以间接获得计数器值。读取计数器值需要多个PCLKB时钟周期（最多四个时钟周期），并且读取的计数器值可能与实际计数器值相差一个计数值。

图28.5显示了当PCLKB>IWDTCLK并且时钟分频比为IWDTCLK时读取IWDT计数器值的处理。

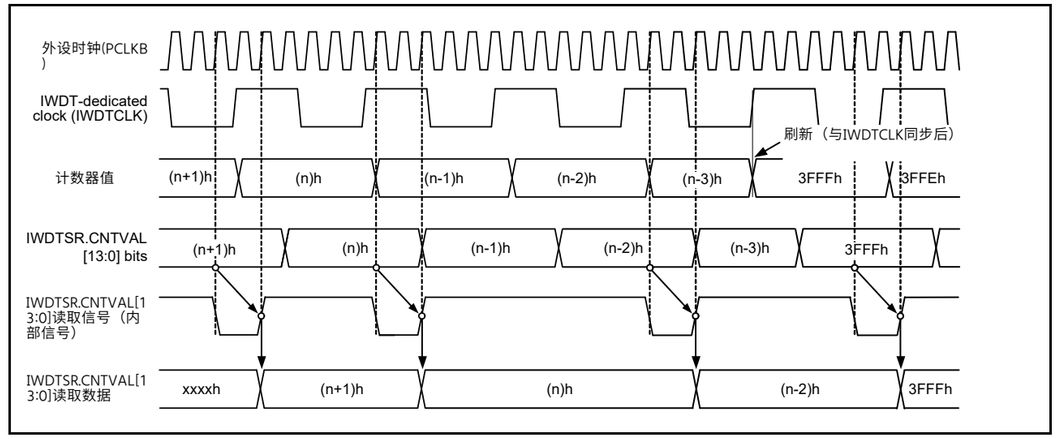

Figure 28.5 当OFS0.IWDTCKS[3:0]=0000b和时读取IWDT计数器值的处理 OFS0.IWDTTOPS[1:0] = 11b

28.4 输出到事件链接控制器(ELC)

当中断请求信号被ELC用作事件信号时，IWDT能够对指定模块进行链接操作。事件信号由计数器下溢或刷新错误输出。

无论OFS0.WDTRSTIRQS位的设置如何，都会输出事件信号。当刷新错误标志(IWDTSR.REFEF)或下溢标志(IWDTSR.UNDFF)为1时，也可以在产生下一个中断源时输出事件信号。有关详细信息，请参阅第19节，事件链接控制器(ELC)。

28.5 Usage Notes

28.5.1 Refresh Operations

While configuring the refresh time, consider variations in the range of errors given the accuracy of PCLKB and IWDTCLK. Set values that ensure refreshing is possible.

28.5.2 Constraints on the Clock Division Ratio Setting

Satisfy the following required frequency of the peripheral module clock (PCLKB):

PCLKB ≥ 4 × (the frequency of the count clock source after division).

28.5.1 刷新操作

在配置刷新时间时，考虑到给定PCLKB精度和误差范围的变化IWDTCLK。设置确保可以刷新的值。

28.5.2 时钟分频比设置的约束

满足以下所需的外围模块时钟（PCLKB）频率：

PCLKB 4 （分频后计数时钟源的频率）。

29. Ethernet MAC Controller (ETHERC)

29.1 Overview

The MCU provides a one-channel Ethernet Controller (ETHERC) compliant with the Ethernet or IEEE802.3 Media Access Control (MAC) layer protocol. ETHERC channel has one channel of the MAC layer interface. Connecting the MCU to the physical layer LSI (PHY-LSI) allows transmission and reception of frames compliant with the Ethernet/IEEE802.3 standard. The ETHERC is connected through the Ethernet PTP Controller (EPTPC) to the Ethernet DMA Controller (EDMAC), so data can be transferred without using the CPU. When the EPTPC is not used, bypass the EPTPC by setting the bypass registers in the EPTPC. See section 30.2.79, Bypass 1588 Module Register (BYPASS).

Table 29.1 lists the ETHERC specifications, Figure 29.1 shows the configuration, and Table 29.2 lists the I/O pins. Figure 29.2 and Figure 29.3 show examples connections of the MCU to an external PHY-LSI.

29. 以太网MAC控制器(ETHERC)

29.1 Overview

MCU提供符合以太网或IEEE802.3媒体访问控制(MAC)层协议的单通道以太网控制器(ETHERC)。ETHERC通道有一个MAC层接口通道。将MCU连接到物理层LSI(PHY-LSI)允许发送和接收符合以太网的帧

IEEE802.3标准。ETHERC通过以太网PTP控制器(EPTPC)连接到以太网DMA控制器(EDMAC)，因此可以在不使用CPU的情况下传输数据。不使用EPTPC时，绕过
EPTPC通过设置EPTPC中的旁路寄存器。请参阅第30.2.79节，绕过1588模块寄存器(BYPASS)。

表29.1列出了ETHERC规范，图29.1显示了配置，表29.2列出了IO引脚。

ECMR寄存器控制ETHERC操作。除TE和RE位外，在复位后初始化期间设置此寄存器中的位。在初始化过程之外重写该寄存器时，将EDMAC0.EDMR.SWR位设置为1以复位EDMAC和ETHERC，然后再次设置该寄存器。

PRM bit (Promiscuous Mode)

When the PRM bit is set to 1, the ETHERC operates in promiscuous mode, where all Ethernet frames are received. In promiscuous mode, the ETHERC receives all valid frames regardless of whether the address matches the destination or broadcast address and regardless of the multicast bit setting.

RTM bit (Bit Rate)

The RTM bit sets the bit rate when the RMII is selected.

ILB bit (Internal Loopback Mode)

When the ILB bit is set to 1, transmit frames can be looped back in the MCU. Set the DM bit to 1 (full-duplex mode) to perform a loopback test.

TE bit (Transmission Enable)

When the TE bit is set to 1, the ETHERC transmit function is enabled. When the TE bit is set to 0, the transmit function is disabled after the frame being processed is completely transmitted.

RE bit (Reception Enable)

When the RE bit is set to 1, the ETHERC receive function is enabled. When the RE bit is set to 0, the receive function is disabled after the frame being processed is completely received.

PRCEF bit (CRC Error Frame Receive Mode)

When the PRCEF bit is set to 1, the EDMAC is not notified that a CRC error has occurred even when the error is detected in a receive frame. Accordingly, the EDMAC0.EESR.CERF flag and RFS0 bit in receive descriptor 0 (RD0) do not become 1.

ZPF bit (0 Time PAUSE Frame Enable)

When the ZPF bit is 1, a PAUSE frame with a pause_time parameter of 0 is transmitted when a PAUSE frame transmit request is canceled before the PAUSE time of the previously transmitted PAUSE frame has elapsed. After the PAUSE frame containing the pause_time parameter of 0 is received, the ETHERC is ready for transmission.

When the ZPF bit is 0, even if the PAUSE frame transmit request from the receive FIFO is canceled, the next PAUSE frame is not transmitted until the PAUSE time of the previously transmitted PAUSE frame has elapsed. When a PAUSE frame containing a pause_time parameter of 0 is received, it is discarded.

PRM位（混杂模式）

当PRM位设置为1时，ETHERC以混杂模式运行，其中接收所有以太网帧。在混杂模式下，ETHERC接收所有有效帧，无论地址是否匹配目标地址或广播地址，也无论多播位设置如何。

RTM位（比特率）

选择RMII时，RTM位设置了比特率。

ILB位（内部环回模式）

当ILB位设置为1时，发送帧可以在MCU中环回。将DM位设置为1（全双工模式）以执行环回测试。

TE位（传输使能）

当TE位设置为1时，使能ETHERC发送功能。当TE位设置为0时，正在处理的帧发送完毕后，发送功能被禁用。

RE位（接收使能）

当RE位设置为1时，使能ETHERC接收功能。当RE位设置为0时，接收功能在正在处理的帧被完全接收后被禁用。

PRCEF位（CRC错误帧接收模式）

当PRCEF位设置为1时，即使在接收帧中检测到错误，也不通知EDMAC发生CRC错误。因此，接收描述符0(RD0)中的EDMAC0.EESR.CERF标志和RFS0位不会变为1。

ZPF位（0时间暂停帧使能）

当ZPF位为1时，如果在先前发送的PAUSE帧的PAUSE时间过去之前取消PAUSE帧发送请求，则发送一个pause_time参数为0的PAUSE帧。在接收到包含pause_time参数为0的PAUSE帧后，ETHERC准备好传输。

当ZPF位为0时，即使来自接收FIFO的PAUSE帧发送请求被取消，直到前一个发送的PAUSE帧的PAUSE时间过去后，下一个PAUSE帧才会发送。当接收到包含pause_time参数为0的PAUSE帧时，将其丢弃。

Bit	Symbol	Bit name	Description	R/W
b11 to b0	RFL[11:0]	Receive Frame Maximum Length	The set value becomes the maximum frame length. The minimum value that can be set is 1,518 bytes, and the maximum value that can be set is 2,048 bytes. Values less than 1,518 bytes are regarded as 1,518 bytes, and values larger than 2,048 bytes are regarded as 2,048 bytes.	R/W
b31 to b12	—	Reserved	The read value is 0. The write value should be 0.	R/W

The RFLR register specifies the maximum frame length that can be received by the MCU. Set the length in bytes. Do not rewrite this register while the ECMR.RE bit is 1 (receive function enabled).

RFL[11:0] bits (Receive Frame Maximum Length)

The RFL[11:0] bits set the frame length to be checked. The frame length is the number of bytes in a field, extending from the destination address to the frame check sequence [FCS] of the received frame. When this length exceeds the RFL[11:0] bit value, the EDMAC is notified of a frame-too-long error, and the excess data is discarded.

b31 to b12	—	Reserved	读取值为0。写入值应为0。	R/W

RFLR寄存器指定MCU可以接收的最大帧长度。以字节为单位设置长度。当ECMR.RE位为1（启用接收功能）时不要重写该寄存器。

RFL[11:0]位（接收帧最大长度）

RFL[11:0]位设置要检查的帧长度。帧长度是一个字段中的字节数，从目标地址延伸到接收帧的帧校验序列[FCS]。当此长度超过RFL[11:0]位值时，EDMAC会收到帧太长错误的通知，并丢弃多余的数据。

b31 to b6	—	Reserved	The read value is 0. The write value should be 0.	R/W

Note 1. Write 1 to clear the flag.

The ECSR register indicates the status of the ETHERC. When any flag in the ECSR register is set to 1 while the associated bit in the ECSIPR register is 1 (interrupt enabled), the EDMAC0.EESR.ECI flag is set to 1.

ICD flag (False Carrier Detect Flag)

The ICD flag indicates that the PHY-LSI has detected a false carrier on the line. The flag is set to 1 when a receive error signal shown in Figure 29.11 is received from the PHY-LSI. The information might not be correct when signals input from the PHY-LSI change faster than software recognizes the change. Check the timing of the PHY-LSI.

LCHNG flag (Link Signal Change Flag)

The LCHNG flag indicates that the ET0_LINKSTA signal input from the PHY-LSI has changed from high to low, or from low to high. Check the PSR.LMON flag for the current link status. See section 29.5.1, Preventing the LCHNG Flag from Erroneously Setting to 1 for more information.

PSRTO flag (PAUSE Frame Retransmit Over Flag)

The PSRTO flag indicates that the number of retransmissions reached the value set in the TPAUSER register when retransmitting a PAUSE frame while automatic PAUSE frame transmission is enabled.

Note 1. 写1清除标志。

ECSR寄存器指示ETHERC的状态。当ECSR寄存器中的任何标志设置为1且ECSIPR寄存器中的相关位为1（允许中断）时，EDMAC0.EESR.ECI标志设置为1。

ICD标志（假载波检测标志）

ICD标志表示PHY-LSI检测到线路上的错误载波。当从PHY-LSI接收到图29.11所示的接收错误信号时，该标志设置为1。当来自PHY-LSI的信号输入变化快于软件识别变化的速度时，该信息可能不正确。检查PHY-LSI的时序。

LCHNG标志（链路信号变化标志）

LCHNG标志表示从PHY-LSI输入的ET0_LINKSTA信号已由高变为低，或由低变为高。检查当前链接状态的PSR.LMON标志。有关详细信息，请参阅第29.5.1节，防止LCHNG标志错误地设置为1。

PSRTO标志（暂停帧重传标志）

PSRTO标志表示在启用自动PAUSE帧传输时重传PAUSE帧时重传次数达到TPAUSER寄存器中设置的值。

b31 to b5	—	Reserved	The read value is 0. The write value should be 0.	R/W

The IPGR register specifies the interpacket gap (IPG) value. Do not rewrite this register while the ECMR.TE bit is 1 (transmit function enabled) or while the ECMR.RE bit is 1 (receive function enabled). See section 29.3.6, Adjusting Transmission Efficiency by Changing the IPG for details on the IPG.

b31 to b16	—	Reserved	The read value is 0. The write value should be 0.	R/W

The APR register specifies the PAUSE time for PAUSE frames that are automatically transmitted. The value set in the APR register is used for the pause_time parameter of the PAUSE frame. Do not rewrite this register while the ECMR.TE bit is 1 (transmit function enabled) or while the ECMR.RE bit is 1 (receive function enabled).

b31 to b16	—	Reserved	The read value is 0. The write value should be 0.	W

The MPR register specifies the PAUSE time for PAUSE frames that are manually transmitted. The value set in the MPR register is used for the pause_time parameter of the PAUSE frame. When a value is set to this register, a PAUSE frame is transmitted. Rewrite this register while the ECMR.TE bit is 1 (transmit function enabled).

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	MAHR[31:0]	MAC Address Upper Bit	See the description following this table	R/W

The MAHR register specifies the upper 32 bits ([47:16]) of the 48-bit MAC address. For example, if the MAC address is 01-23-45-67-89-AB, set the register to 0123 4567h.

Set the MAHR register during initialization after a reset. Do not rewrite this register while the ECMR.TE bit is 1 (transmit function enabled) or while the ECMR.RE bit is 1 (receive function enabled). When rewriting this register, set the EDMAC0.EDMR.SWR bit to 1 to reset the EDMAC and ETHERC, then set this register again.

29.2.16 MAC Address Lower Bit Register (MALR)

b31 to b16	—	Reserved	The read value is 0. The write value should be 0.	R/W

The MALR register specifies the lower 16 bits of the 48-bit MAC address. For example, if the MAC address is 01-23-45-67-89-AB, set the register to 0000 89ABh.

Set the MALR register during initialization after a reset. Do not rewrite this register while the ECMR.TE bit is 1 (transmit function enabled) or while the ECMR.RE bit is 1 (receive function enabled). When rewriting this register, set the EDMAC0.EDMR.SWR bit to 1 to reset the EDMAC and ETHERC, then set this register again.

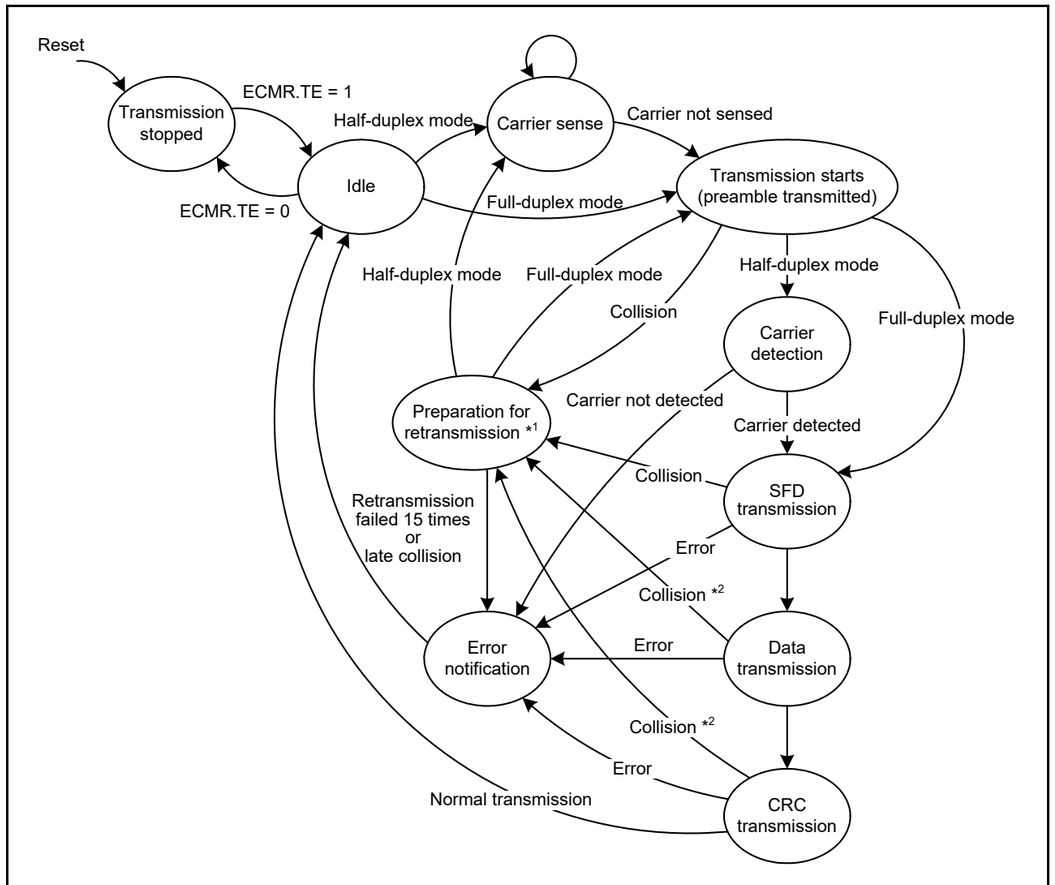
MAFCR寄存器是一个计数器，用于指示接收到设置了多播地址的帧的次数。
当寄存器值变为FFFFFFFFh时，计数器停止。向MAFCR寄存器写入任何值都会将计数器值清除为0。

29.3 Operation

This section provides an overview of the ETHERC operations. The ETHERC supports flow control compliant with IEEE802.3x, and can transmit and receive PAUSE frames. When using the ETHERC, set the clock to ICLK = PCLKA beforehand.

29.3.1 Transmission

The ETHERC transmitter assembles transmit data into a frame and outputs it to the MII or RMII when a transmit request is received from the EDMAC. The frame transmitted through the MII or RMII is transmitted on the line by the PHY-LSI. Figure 29.4 shows the state transitions of the ETHERC transmitter.



Note 1. Preparation for retransmission after a collision is detected includes transmitting a jam signal and adjusting transmission time intervals using the backoff algorithm.

Note 2. Preparation for retransmission is performed only when a collision is detected within 512 bit times after preamble transmission starts. When a collision is detected after 512 bit times, only a jam signal is transmitted and processing using the backoff algorithm is not performed.

Figure 29.4 ETHERC transmitter state transitions

The ETHERC transmitter state transitions are as follows:

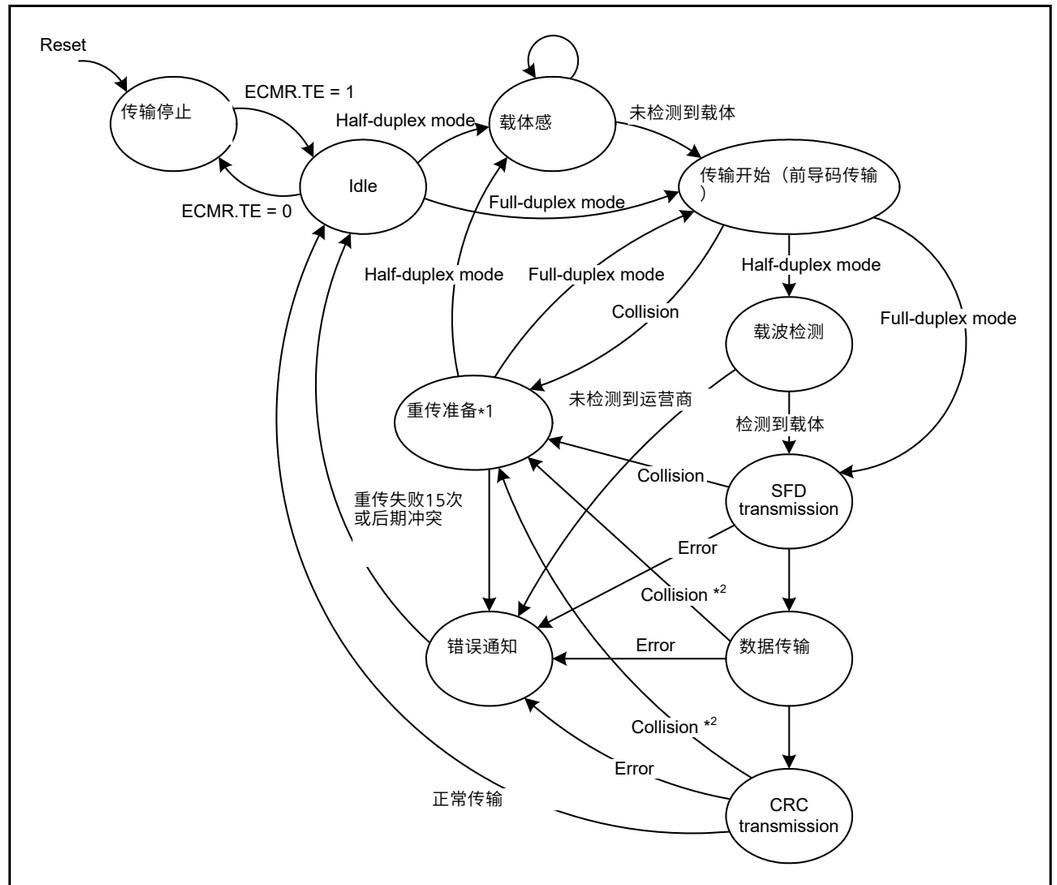
1. When the ECMR.TE bit is set to 1, the ETHERC enters the transmit idle state.
2. When a transmit request is received from the EDMAC, the ETHERC enters the carrier sense state. The ETHERC waits for the interpacket gap and then transmits a preamble to the MII or RMII. When full-duplex mode is selected,

29.3 Operation

本节概述了ETHERC操作。ETHERC支持符合以下标准的流量控制
IEEE802.3x，可收发PAUSE帧。使用ETHERC时，请预先将时钟设置为ICLK=PCLKA。

29.3.1 Transmission

当收到来自EDMAC的发送请求时，ETHERC发送器将发送数据组合成一个帧并将其输出到MII或RMII。通过MII或RMII传输的帧由PHY-LSI在线路上传输。图29.4显示了ETHERC发送器的状态转换。



Note 1. 检测到冲突后的重传准备包括传输阻塞信号和使用退避算法调整传输时间间隔。

Note 2. 只有在前导码传输开始后的512比特时间内检测到冲突时，才执行重传准备。当在512位时间后检测到冲突时，仅传输阻塞信号，并且不执行使用退避算法的处理。

Figure 29.4 ETHERC发送器状态转换

ETHERC发送器状态转换如下：

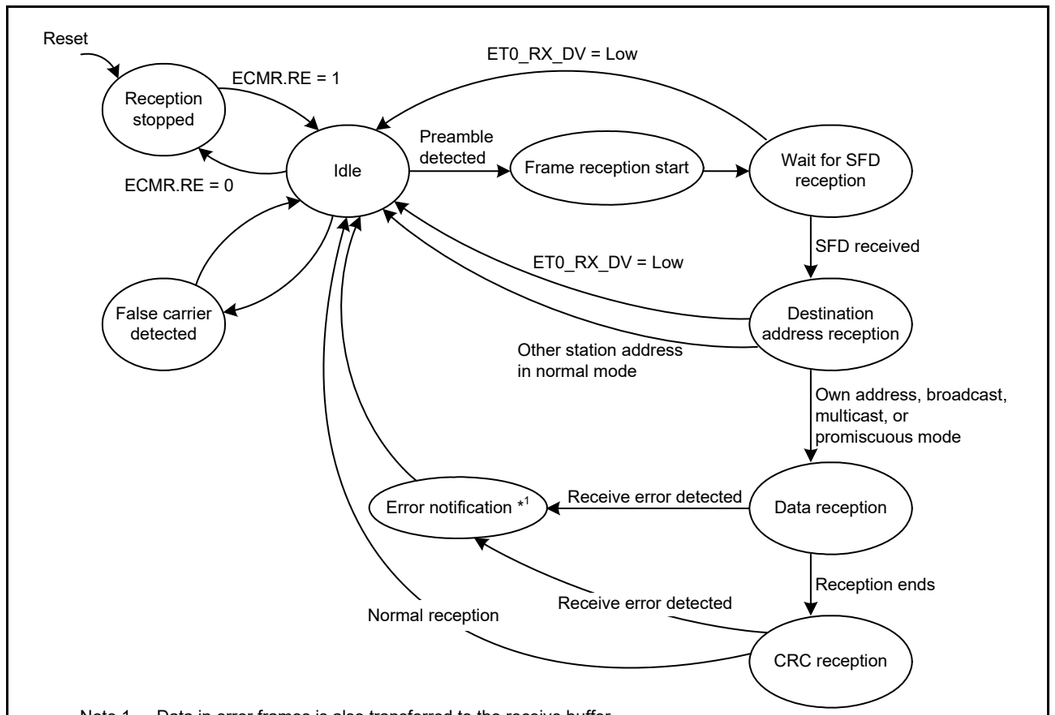
1. 当ECMR.TE位设置为1时，ETHERC进入发送空闲状态。
2. 当收到来自EDMAC的发送请求时，ETHERC进入载波侦听状态。ETHERC等待包间间隙，然后将前同步码发送到MII或RMII。Whenfull-duplexmodeisselected

carrier sensing is not required, so the ETHERC transmits a preamble immediately after receiving a transmit request from the EDMAC.

3. The ETHERC transmits the Start Frame Delimiter (SFD), transmit data, and CRC sequentially. When the transmission completes successfully, the ETHERC notifies the EDMAC of successful completion, and the EDMAC sets the EDMAC0.EESR.TC flag to 1. When a late collision or loss of carrier is detected during data transmission, the ETHERC stops the transmission and notifies the EDMAC of the error.
4. After the time specified as the interpacket gap has elapsed, the ETHERC enters the idle state and continues transmission when transmit data remains.

29.3.2 Reception

The ETHERC receiver separates the frame input from the MII or RMII into the preamble, SFD, receive data, and CRC, and transmits only the receive data (destination address, source address, type/length, data/LLC). Figure 29.5 shows the state transitions of the ETHERC receiver.



Note 1. Data in error frames is also transferred to the receive buffer.

Figure 29.5 ETHERC receiver state transitions

The ETHERC receiver state transitions are as follows:

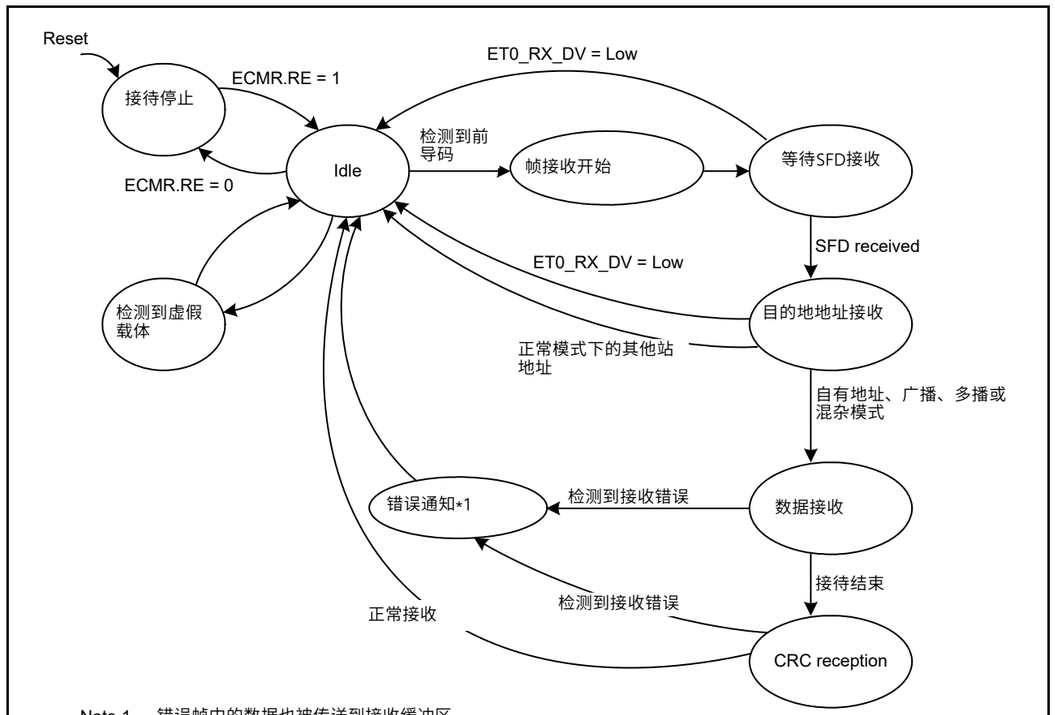
1. When the ECMR.RE bit is set to 1, the ETHERC enters the receive idle state.
2. When the SFD following the preamble of the receive packet is detected, the ETHERC starts reception. If the received SFD is invalid, the ETHERC discards the frame.
3. In normal mode, the ETHERC starts data reception when the destination address of the receive frame is the address of the MCU or the receive frame is a broadcast or multicast frame. In promiscuous mode, the ETHERC starts data reception regardless of the receive frame type.
4. After receiving data from the MII or RMII, the ETHERC performs a CRC check. The ETHERC notifies the EDMAC of the CRC check result. After the received data is transferred to the receive buffer, the CRC check result

不需要载波侦听，因此ETHERC在收到来自EDMAC的发送请求后立即发送前导码。

3. ETHERC依次传输起始帧定界符(SFD)、传输数据和CRC。当传输成功完成时，ETHERC通知EDMAC成功完成，EDMAC将EDMAC0.EESR.TC标志设置为1。当在数据传输过程中检测到延迟冲突或载波丢失时，ETHERC停止传输并通知错误的EDMAC。
4. 在指定为包间间隙的时间过去后，ETHERC进入空闲状态并在传输数据剩余时继续传输。

29.3.2 Reception

ETHERC接收器将从MII或RMII输入的帧分离为前导码、SFD、接收数据和CRC，并仅发送接收数据（目标地址、源地址、类型长度、数据LLC）。图29.5显示了ETHERC接收器的状态转换。



Note 1. 错误帧中的数据也被传送到接收缓冲区。

Figure 29.5 ETHERC接收器状态转换

ETHERC接收器状态转换如下：

1. 当ECMR.RE位设置为1时，ETHERC进入接收空闲状态。
2. 当检测到接收数据包前导码之后的SFD时，ETHERC开始接收。如果接收到的SFD无效，则ETHERC丢弃该帧。
3. 在正常模式下，当接收帧的目的地址是MCU的地址或接收帧是广播或组播帧时，ETHERC开始数据接收。在混杂模式下，无论接收帧类型如何，ETHERC都会开始数据接收。
4. 从MII或RMII接收数据后，ETHERC执行CRC校验。ETHERC通知CRC校验结果的EDMAC。接收到的数据传送到接收缓冲区后，CRC校验结果

is written back to the receive descriptor as status. The result is also reflected in the EDMAC0.EESR.CERF flag.

5. When the ECMR.RE bit is 1 after one frame is received, the ETHERC prepares to receive the next frame.

29.3.4 Accessing the MII and RMII Registers

Use the PIR register to access the MII and RMII registers in the PHY-LSI. Serial data in the MII and RMII management frame format is transmitted and received through the ET0_MDC and ET0_MDIO pins controlled by software.

29.3.4.1 MII and RMII management frame format

Table 29.3 lists the MII and RMII management frame formats.

Table 29.3 MII and RMII management frame formats

Access type		MII and RMII management frame							
	Parameter	PRE	ST	OP	PHYAD	REGAD	TA	DATA	IDLE
	Number of bits	32	2	2	5	5	2	16	1
Read		1...1	01	10	00001	RRRRR	Z0	DDDDDDDDDDDDDDDD	Z
Write		1...1	01	01	00001	RRRRR	10	DDDDDDDDDDDDDDDD	Z

Note: PRE (preamble): Send 32 consecutive 1s.
ST (start of frame): Send 01b.
OP (operation code): Send 10b for read or 01b for write.
PHYAD (PHY address): Up to 32 PHY-LSIs can be connected to one MAC. PHY-LSIs are selected with these 5 bits. When the PHY-LSI address is 1, send 00001b.
REGAD (register address): One register is selected from up to 32 registers in the PHY-LSI. When the register address is 1, send 00001b.
TA (turnaround): Use 2-bit turnaround time to avoid contention between the register address and data during a read operation. Send 10b during a write operation. Release the bus for 1 bit during a read operation (Z is output).
(This is indicated as Z0 because 0 is output from the PHY-LSI on the next clock cycle.)
DATA (data): 16-bit data. Sequentially send or receive starting from the MSB.
IDLE (IDLE condition): Wait time before inputting the next MII or RMII management format. Release the bus during a write operation (Z is output). No control is required, because a bus was already released during a read operation.

29.3.4.2 MII and RMII register access procedure

Access to the MII and RMII registers includes writing data in 1-bit units, reading data in 1-bit units, and releasing the bus. Figure 29.15 to Figure 29.18 show examples of the MII and RMII register access timing. The access timing differs with the PHY-LSI type.

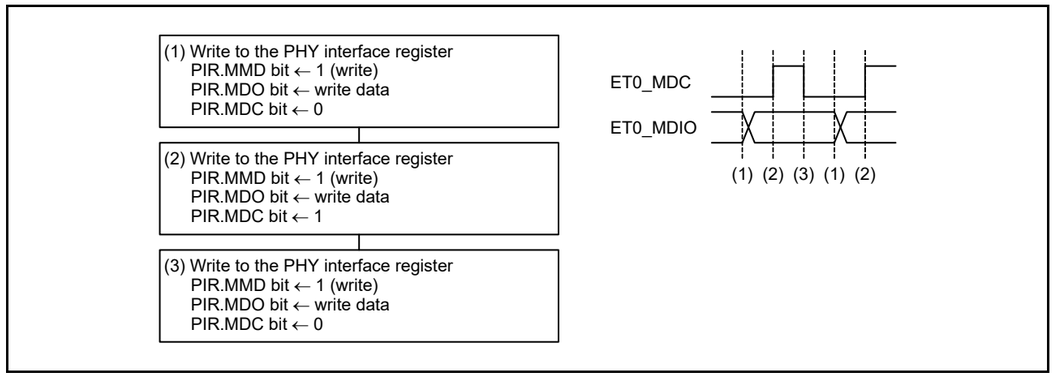

Figure 29.15 1-bit data write flow

29.3.4 访问MII和RMII寄存器

使用PIR寄存器访问PHY-LSI中的MII和RMII寄存器。MII和RMII管理帧格式的串行数据通过软件控制的ET0_MDC和ET0_MDIO引脚发送和接收。

29.3.4.1 MII和RMII管理帧格式

表29.3列出了MII和RMII管理帧格式。

Table 29.3 MII和RMII管理帧格式

访问类型		MII和RMII管理框架							
	Parameter	PRE	ST	OP	PHYAD	REGAD	TA	DATA	IDLE
	位数	32	2	2	5	5	2	16	1
Read		1...1	01	10	00001	RRRRR	Z0	DDDDDDDDDDDDDDDD	Z
Write		1...1	01	01	00001	RRRRR	10	DDDDDDDDDDDDDDDD	Z

Note: PRE（前导码）：发送32个连续的1。
ST（帧开始）：发送01b。
OP（操作码）：发送10b读或01b写。
PHYAD（PHY地址）：一个MAC最多可以连接32个PHY-LSI。使用这5位选择PHY-LSI。当。。。的时候
PHY-LSI地址为1，发送00001b。
REGAD（寄存器地址）：从PHY-LSI的最多32个寄存器中选择一个寄存器。当寄存器地址为1时，发送00001b。TA（周转）：使用2位周转时间来避免读取操作期间寄存器地址和数据之间的争用。

在写操作期间发送10b。在读操作期间释放总线1位（Z为输出）。（这表示为Z0，因为在下一个时钟周期从PHY-LSI输出0。）DATA（数据）：16位数据。从MSB开始顺序发送或接收。

IDLE（IDLE条件）：输入下一个MII或RMII管理格式前的等待时间。在写操作期间释放总线（Z为输出）。不需要控制，因为在读取操作期间总线已被释放。

29.3.4.2 MII和RMII寄存器访问过程

对MII和RMII寄存器的访问包括以1位为单位写入数据、以1位为单位读取数据以及释放总线。图29.15至图29.18显示了MII和RMII寄存器访问时序的示例。访问时序因PHY-LSI类型而异。

29.3.5 Magic Packet Detection

The ETHERC supports Wake-on-LAN (WOL). WOL is a function to detect a Magic Packet transmitted from a host device or other device and wake the MCU from a low power mode such as Sleep. When the ETHERC detects a Magic Packet, it outputs high on the ET0_WOL pin. Write 1 to the EDMAC0.EDMR.SWR bit to drive the ET0_WOL pin low.

Because a Magic Packet is transmitted in broadcast mode, it is received regardless of the destination MAC address selected in the format. The ETHERC outputs high on the ET0_WOL pin only when the destination MAC address matches its own MAC address. See the technical documentation provided by Advanced Micro Devices, Inc., for details on the Magic Packet.

To use WOL in the MCU, use the procedure in the following example:

1. Configure the ICU to disable ETHER_EINT0 interrupt requests.
2. Set the ECMR.MPDE bit to 1 to enable Magic Packet detection, and set the ECMR.RE bit to 1 to enable reception.
3. Set the ECSIPR.MPDIP bit to 1 to enable notification of Magic Packet detection interrupts.
4. Set the EDMAC0.EESIPR.ECIIP bit to 1 to enable ETHERC status register source interrupts.
5. Configure the ICU to enable ETHER_EINT0 interrupt requests.
6. Change the CPU operating mode to Sleep mode or place unused peripherals in the module-stop state, as required.
7. When a Magic Packet is detected, an interrupt request is sent to the CPU. High is output on the ET0_WOL pin to notify peripheral devices that the Magic Packet was detected.

29.3.5.1 Constraints on Magic Packet detection

The ETHERC receives packets, including broadcast packets, even when waiting to receive a Magic Packet. This means that receive data might already be stored in the receive FIFO of the EDMAC when a Magic Packet is detected. Also, flags in the ECSR and EDMAC0.EESR registers might have changed. When returning to normal operation after detecting a Magic Packet, set the EDMAC0.EDMR.SWR bit to 1 to reset the ETHERC and EDMAC.

29.3.6 Adjusting Transmission Efficiency by Changing the IPG

The IPG is a non-transmit period between transmit frames. The ETHERC can change the value of the IPG to increase or decrease transmission efficiency based on the value set in the IPGR register. Typical values are specified in the IEEE802.3 standard. When changing the setting, confirm that all devices in the same network operate normally.

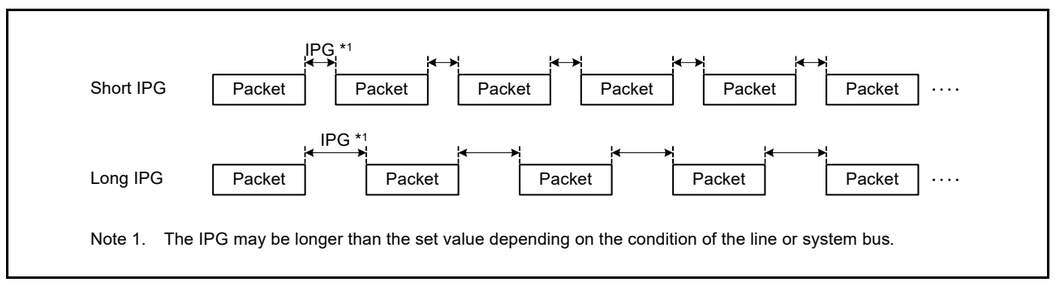

Figure 29.19 Differences in transmission efficiency based on changes in the IPG

29.3.5 魔术包检测

ETHERC支持网络唤醒(WOL)。WOL是一种检测从主机设备或其他设备发送的魔术包并将MCU从低功耗模式（例如睡眠）唤醒的功能。当ETHERC检测到一个魔术包时，它在ET0_WOL引脚上输出高电平。将1写入EDMAC0.EDMR.SWR位以将ET0_WOL引脚驱动为低电平。

因为MagicPacket以广播模式传输，所以无论格式中选择的目标MAC地址如何，都会接收到它。仅当目标MAC地址与其自己的MAC地址匹配时，ETHERC才会在ET0_WOL引脚上输出高电平。有关MagicPacket的详细信息，请参阅AdvancedMicroDevices Inc.提供的技术文档。

要在MCU中使用WOL，请使用以下示例中的过程：

1. 将ICU配置为禁用ETHER_EINT0中断请求。
2. 将ECMR.MPDE位设置为1以启用魔术包检测，并将ECMR.RE位设置为1以启用接收。
3. 将ECSIPR.MPDIP位设置为1以启用魔术包检测中断通知。
4. 将EDMAC0.EESIPR.ECIIP位设置为1以启用ETHERC状态寄存器源中断。
5. 配置ICU以启用ETHER_EINT0中断请求。
6. 根据需要，将CPU操作模式更改为睡眠模式或将未使用的外设置于模块停止状态。
7. 当检测到MagicPacket时，会向CPU发送中断请求。ET0_WOL引脚上输出高电平以通知外围设备检测到魔术包。

29.3.5.1 魔术包检测的约束

ETHERC接收数据包，包括广播数据包，即使在等待接收魔术数据包时也是如此。这意味着当检测到魔术包时，接收数据可能已经存储在EDMAC的接收FIFO中。此外，ECSR和EDMAC0.EESR寄存器中的标志可能已更改。检测到魔术包后返回正常操作时，将EDMAC0.EDMR.SWR位设置为1以复位ETHERC和EDMAC。

29.3.6 改变IPG调整传输效率

IPG是传输帧之间的非传输周期。ETHERC可以根据IPGR寄存器中设置的值改变IPG的值来提高或降低传输效率。典型值在IEEE802.3标准中指定。更改设置时，请确认同一网络中的所有设备都正常运行。

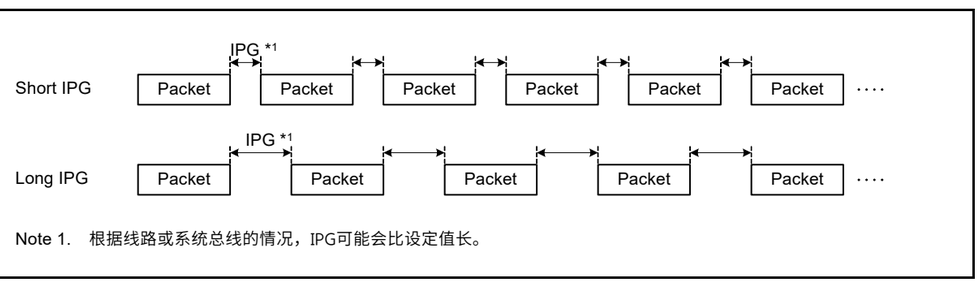

Figure 29.19 基于IPG变化的传输效率差异

29.3.7 Flow Control

The ETHERC can perform flow control compliant with IEEE802.3x in full-duplex mode, and the receiver and transmitter can be set independently. PAUSE frames can be transmitted automatically or manually.

29.3.7.1 Automatic PAUSE frame transmission

When the ECMR.TXF bit is set to 1, automatic PAUSE frame transmission is enabled. A PAUSE frame is automatically transmitted by a PAUSE frame transmit request from the EDMAC. The APR.AP[15:0] bit value is used for the pause_time parameter of the PAUSE frame.

When a PAUSE frame is transmitted, if the EDMAC is still requesting PAUSE frame transmission after the PAUSE time elapses, a PAUSE frame is transmitted again. The maximum number of PAUSE frame retransmissions can be set in the TPAUSER.TPAUSE[15:0] bits. If the maximum number of retransmissions is reached, subsequent PAUSE frames are not transmitted.

Figure 29.20 shows the procedure for setting up automatic PAUSE frame transmission.

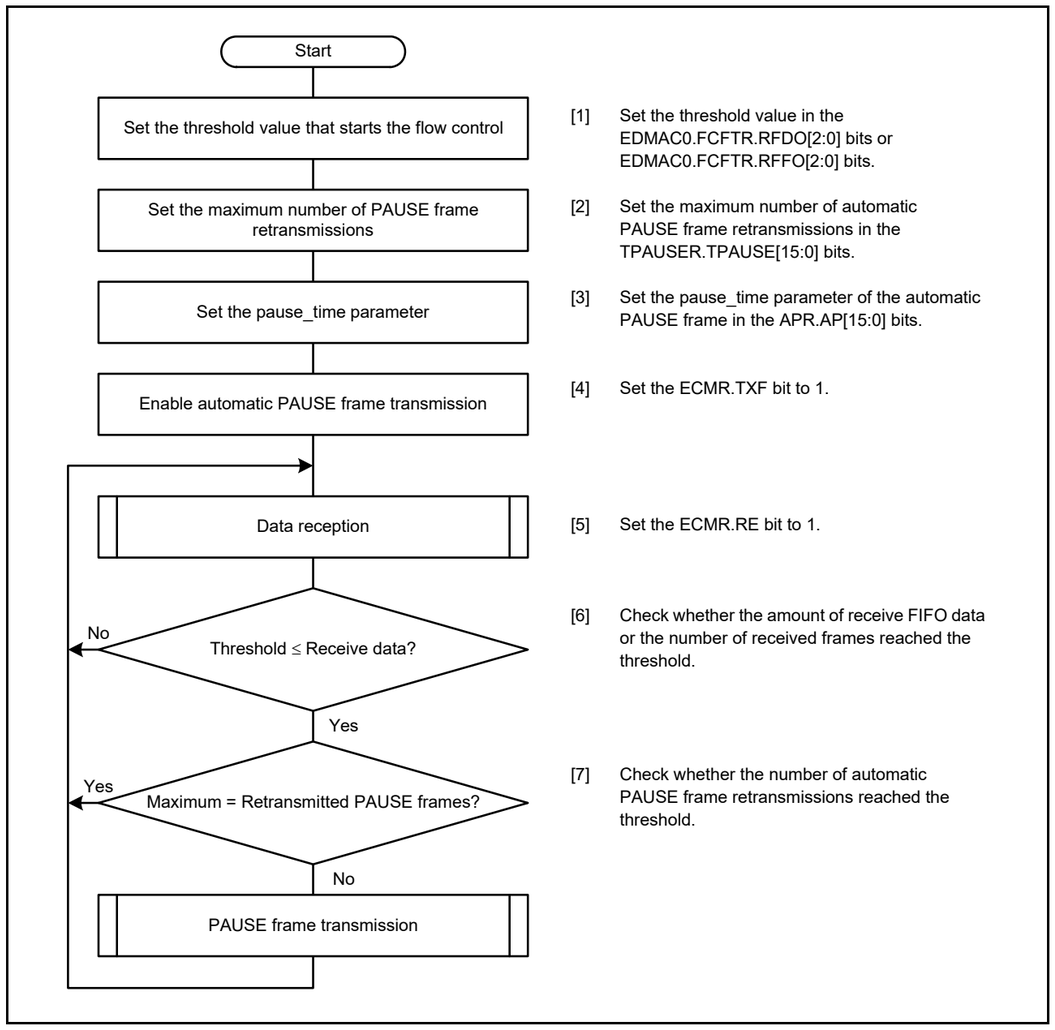

Figure 29.20 Example procedure for setting up automatic PAUSE frame transmission

29.3.7 流量控制

ETHERC可以在全双工模式下进行符合IEEE802.3x的流量控制，接收端和发送端可以独立设置。PAUSE帧可以自动或手动传输。

29.3.7.1 自动暂停帧传输

当ECMR.TXF位设置为1时，启用自动暂停帧传输。PAUSE帧由来自EDMAC的PAUSE帧发送请求自动发送。APR.AP[15:0]位值用于PAUSE帧的pause_time参数。

当发送暂停帧时，如果在暂停时间过去后EDMAC仍在请求暂停帧发送，则再次发送暂停帧。PAUSE帧重传的最大次数可以在TPAUSER.TPAUSE[15:0]位中设置。如果达到最大重传次数，则不传输后续PAUSE帧。

图29.20显示了设置自动暂停帧传输的过程。

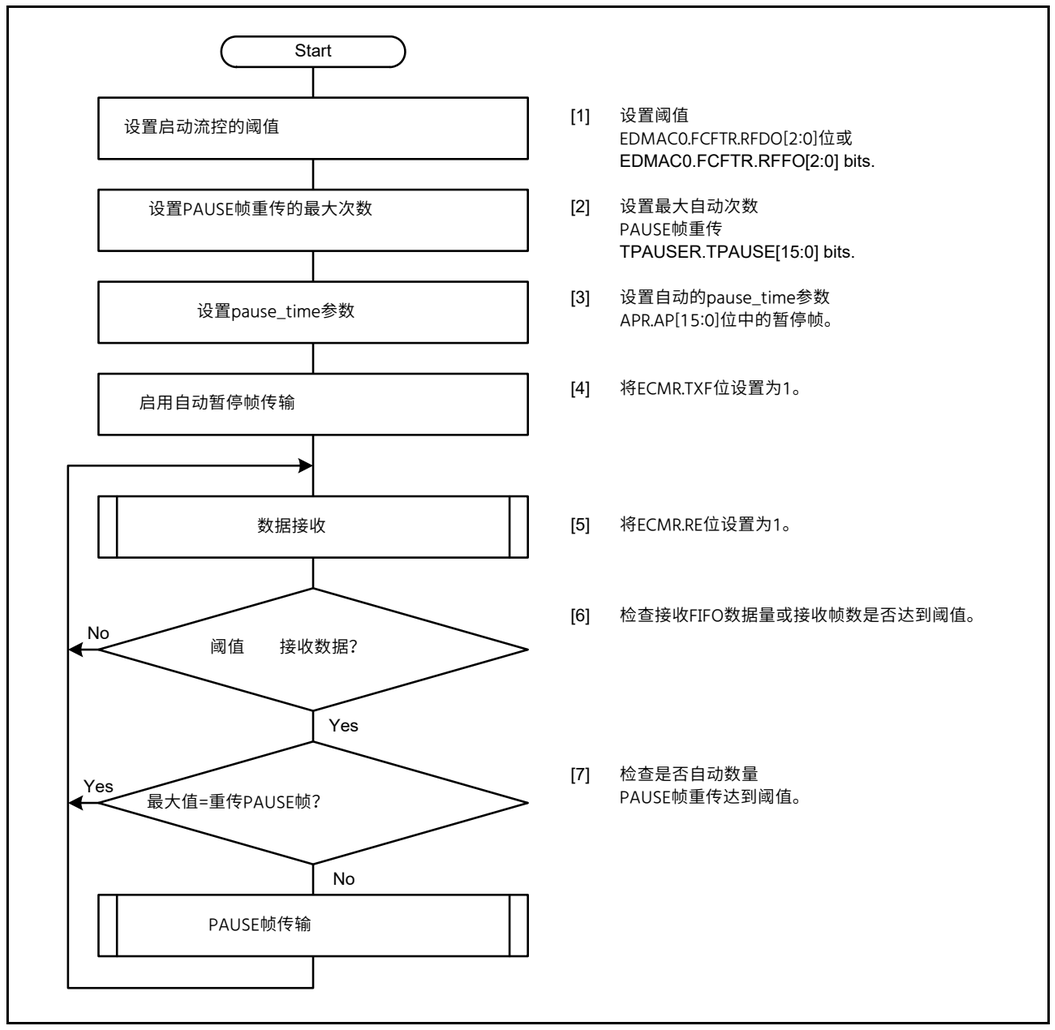

Figure 29.20 设置自动暂停帧传输的示例过程

29.3.7.2 Manual PAUSE frame transmission

A PAUSE frame can be manually transmitted at any time. When the software writes the pause_time parameter of the PAUSE frame to the MPR.MP[15:0] bits, the ETHERC transmits a PAUSE frame once. To transmit a PAUSE frame more than once, write to the MPR.MP[15:0] bits for each transmission.

29.3.7.3 PAUSE frame reception

When the ECMR.RXF bit is set to 1, PAUSE frame detection is enabled. After a PAUSE frame is received, the ETHERC completes transmission of the current frame and waits for the PAUSE time of the received PAUSE frame to elapse before it can transmit the next frame. The ETHERC also increments the RFCF.RPAUSE[7:0] bit value.

However, while waiting for the PAUSE time to elapse, if a PAUSE frame that contains a pause_time parameter of 0 is received and the ECMR.ZPF bit is 1, the ETHERC becomes ready to transmit immediately.

29.4 Interrupts

When a flag in the ECSR register sets to 1 and the associated bit in the ECSIPR register is 1, the ETHERC notifies the EDMAC of the interrupt source status. After receiving the notification, the EDMAC sets the EDMAC0.EESR.ECI flag to 1. When the EDMAC0.EESIPR.ECIIP bit is 1, the EDMAC sends an ETHER_EINT0 interrupt request to the CPU. For details, see section 31, Ethernet DMA Controller (EDMAC).

29.5 Usage Notes

29.5.1 Preventing the LCHNG Flag from Erroneously Setting to 1

The ECSR.LCHNG flag might set to 1 even when the input level of the ET0_LINKSTA pin remains the same. In this case, high is input to the ET0_LINKSTA pin when setting the PFS.PmnPFS register to assign the ET0_LINKSTA signal to a port or when releasing the ETHERC and EDMAC software reset using the EDMAC0.EDMR.SWR bit. The ECSR.LCHNG flag sets to 1 because the ET0_LINKSTA signal in the ETHERC is fixed low regardless of the input level to the external pin if the MPC does not assign the ET0_LINKSTA signal or during an ETHERC and EDMAC software reset.

To avoid erroneously generating a link signal change interrupt, clear the ECSR.LCHNG flag, and then set the ECSIPR.LCHNGIP bit to 1.

29.5.2 Input to RMII0_RX_ER Pin while RMII Is Selected

When the width of a reception error signal received from the PHY-LSI is only 1 cycle of the REF50CK0 clock (50 MHz) while the RMII is selected, the signal is not recognized as an error signal.

29.5.3 Processing when Erroneous Frame Is Detected

If an erroneous frame is detected due to a corrupted frame or noise in the external circuit when the ETHERC and EPTPC are receiving data, subsequent normal frames might not be received properly.

Reset the EDMAC, ETHERC, and EPTPC after an erroneous frame is detected. Then, wait for the required number of cycles before setting communications again.

When set to bypass EPTPC, you do not need to reset the processing. See section 30.2.79, Bypass 1588 Module Register (BYPASS).

(1) Detecting an erroneous frame

An erroneous frame can be detected by reading the INFABT flag in the SYNFP Status Register (SYSR) of EPTPCn. Even when the EPTPCn is not used but only the EDMACn and ETHERCn are used to receive and transmit standard Ethernet frames, read the INFABT flag to detect an erroneous frame (n = 0).

(2) Resetting after detection of an erroneous frame

When the EPTPCn.SYSR.INFABT flag becomes 1, reset EPTPCn, EDMACn, and ETHERCn according to the channel. Then wait for the required number of cycles before setting the registers. Even when the EPTPCn is not used but only the EDMACn and ETHERCn are used to receive and transmit standard Ethernet frames, reset the EPTPCn and the registers. In this case, you do not need to reset PTPEDMAC. The following steps show the resetting procedure where n = 0:

29.3.7.2 手动暂停帧传输

PAUSE帧可以随时手动发送。当软件将PAUSE帧的pause_time参数写入MPR.MP[15:0]位时，ETHERC发送一次PAUSE帧。要多次传输PAUSE帧，请在每次传输时写入MPR.MP[15:0]位。

29.3.7.3 暂停帧接收

当ECMR.RXF位设置为1时，启用PAUSE帧检测。接收到PAUSE帧后，ETHERC完成当前帧的传输，并等待接收到的PAUSE帧的PAUSE时间过去，然后才能传输下一帧。ETHERC还会增加RFCF.RPAUSE[7:0]位的值。

然而，在等待PAUSE时间过去时，如果接收到包含pause_time参数为0的PAUSE帧并且ECMR.ZPF位为1，则ETHERC立即准备好发送。

29.4 Interrupts

当ECSR寄存器中的标志设置为1并且ECSIPR寄存器中的相关位为1时，ETHERC通知EDMAC中断源状态。EDMAC收到通知后，将EDMAC0.EESR.ECI标志设置为1。当EDMAC0.EESIPR.ECIIP位为1时，EDMAC向CPU发送ETHER_EINT0中断请求。有关详细信息，请参阅第31节，以太网DMA控制器(EDMAC)。

29.5 使用说明

29.5.1 防止LCHNG标志错误设置为1

即使ET0_LINKSTA引脚的输入电平保持不变，ECSR.LCHNG标志也可能设置为1。在这种情况下，当设置PFS.PmnPFS寄存器以将ET0_LINKSTA信号分配给端口或使用EDMAC0.EDMR.SWR位释放ETHERC和EDMAC软件复位时，ET0_LINKSTA引脚输入高电平。ECSR.LCHNG标志设置为1，因为如果MPC未分配ET0_LINKSTA信号或在ETHERC和EDMAC软件复位期间，无论外部引脚的输入电平如何，ETHERC中的ET0_LINKSTA信号都固定为低。

为避免错误地生成链接信号更改中断，请清除ECSR.LCHNG标志，然后设置ECSIPR.LCHNGIP位为1。

29.5.2 选择RMII时输入到RMII0_RX_ER引脚

选择RMII时，如果从PHY-LSI接收到的接收错误信号的宽度仅为REF50CK0时钟(50MHz)的1个周期，则该信号不会被识别为错误信号。

29.5.3 检测到错误帧时的处理

如果在ETHERC和EPTPC接收数据时，由于帧损坏或外部电路中的噪声而检测到错误帧，则可能无法正确接收后续正常帧。

在检测到错误帧后重置EDMAC、ETHERC和EPTPC。然后，在再次设置通信之前等待所需的周期数。

当设置为绕过EPTPC时，您不需要重置处理。请参阅第30.2.79节，绕过1588模块寄存器(BYPASS)。

(1) 检测错误帧

可以通过读取EPTPCn的SYNFP状态寄存器(SYSR)中的INFABT标志来检测错误帧。即使不使用EPTPCn而仅使用EDMACn和ETHERCn来接收和发送标准
以太网帧，读取INFABT标志以检测错误帧(n=0)。

(2) 检测到错误帧后重置

当EPTPCn.SYSR.INFABT标志变为1时，根据通道复位EPTPCn、EDMACn和ETHERCn。然后在设置寄存器之前等待所需的周期数。即使不使用EPTPCn，而仅使用EDMACn和ETHERCn来接收和发送标准以太网帧，也要复位EPTPCn和寄存器。

在这种情况下，您不需要重置PTPEDMAC。以下步骤显示了n=0时的重置过程：

1. Set the EPTPC_CFG.PTRSTR.RESET bit to 1 (reset the EPTPCn through software).
2. Set the EDMACn.EDMR.SWR bit to 1 (reset the EDMACn and ETHERCn through software).
3. Wait for at least 64 cycles of the peripheral module clock (PCLKA). This step is necessary to initialize EDMACn and ETHERCn. Use a software loop or timer to wait for at least 64 PCLKA cycles.
4. Set the EPTPC_CFG.PTRSTR.RESET bit to 0 (release the EPTPCn reset).
5. Reset communications.
6. Set the EDMACn, ETHERCn, PTPEDMAC, and EPTPCn registers to enable communications.

29.5.4 Collision Occurrence in Half-Duplex Mode

Transmission might start and communication might collide within 21 clock cycles (50 MHz) from reception in half-duplex mode.

1. 将EPTPC_CFG.PTRSTR.RESET位设置为1（通过软件复位EPTPCn）。
2. 将EDMACn.EDMR.SWR位设置为1（通过软件复位EDMACn和ETHERCn）。
3. 等待至少64个外围模块时钟(PCLKA)周期。这一步是初始化EDMACn和ETHERCn所必需的。使用软件循环或定时器等待至少64个PCLKA周期。
4. 将EPTPC_CFG.PTRSTR.RESET位设置为0（释放EPTPCn复位）。
5. 重置通讯。
6. 设置EDMACn、ETHERCn、PTPEDMAC和EPTPCn寄存器以启用通信。

29.5.4 半双工模式下的冲突发生

在半双工模式下，从接收开始的21个时钟周期(50MHz)内，传输可能会开始并且通信可能会发生冲突。

30. Ethernet PTP Controller (EPTPC)

30.1 Overview

The MCU provides an on-chip Precision Time Protocol (PTP) module for the Ethernet Controller (EPTPC). The module applies the PTP as defined in version 2 of the IEEE 1588-2008 standard to handle timing and synchronization between devices. The EPTPC is composed of a Synchronization Frame Processing unit (SYNFP0) and a Statistical Time Correction Algorithm unit (STCA).

The EPTPC is used in combination with the on-chip Ethernet Controller (ETHERC) and the DMA Controller for the PTP Ethernet Controller (PTPEDMAC). When the EPTPC is not used, you can bypass it by setting the bypass registers in the EPTPC. See section 30.2.79, Bypass 1588 Module Register (BYPASS).

Table 30.1 lists the EPTPC specifications, and Figure 30.1 shows the configuration.

Table 30.1 EPTPC specifications

Parameter	Specifications
Protocol	Compliant with the Precision Time Protocol (PTP) defined in IEEE 1588.
Synchronization Frame Processing unit (SYNFP0)	• Transmission and reception of PTP messages as a master or slave • Support for clock device: - Ordinary clock (OC) • Calculation of meanPathDelay and offsetFromMaster as defined in IEEE 1588 • Capable of generating a master clock • Hardware filtering of received multicast packets with a MAC address • Capable of hardware filtering with the type of PTP message • Support for PTP message frames in layer 4 (IPv4 and UDP) and layer 2 (Ethernet frames) • Can be used as a normal Ethernet port when time synchronization is not in use
Statistical Time Correction Algorithm unit (STCA)	• Frequency of the clock supplied to the Statistical Time Correction Algorithm unit is selectable as 20, 25, 50, or 100 MHz • In slave operation, the synchronized state can be indicated by the offsetFromMaster value staying below a threshold specified in advance or calculated statistically from collected positive and negative gradient values (worst-10 acquisition) • Local clock counter holds corrected time information obtained from a master clock • STCA clock can be used as the clock source for generating pulse signals from pulse output timer m (m = 0 to 5) • Peripheral modules such as GPT can be started or stopped on the edge of pulses synchronized with the master clock in response to interrupt requests by the pulse output timer or the output of event signals to the ELC
Interrupt sources	ETHER_MINT interrupt: • Requested when the state of the individual modules is changed • Requested on rising edges of the pulse signal generated by the pulse output timer. ETHER_IPLS interrupt: • Requested on rising or falling edges of the pulse signal generated by the previously selected pulse output timer group • Can be requested on every edge or only once
Event linking	• Event signal is output to the ELC on a rising or falling edge of the pulse signal generated by the pulse output timer • Event signal can be output on every edge or only once

30. 以太网PTP控制器(EPTPC)

30.1 Overview

MCU为以太网控制器(EPTPC)提供片上精确时间协议(PTP)模块。该模块应用IEEE1588-2008标准第2版中定义的PTP来处理设备之间的定时和同步。EPTPC由同步帧处理单元（SYNFP0）和统计时间校正算法单元（STCA）组成。

EPTPC与片上以太网控制器(ETHERC)和用于PTP以太网控制器(PTPEDMAC)的DMA控制器结合使用。不使用EPTPC时，可以通过在
EPTPC。请参阅第30.2.79节，绕过1588模块寄存器(BYPASS)。

表30.1列出了EPTPC规格，图30.1显示了配置。

同步帧 处理单元(SYNFP0)	作为主机或从机发送和接收PTP消息 支持时钟设备：普通时钟(OC) 计算IEEE1588中定义的meanPathDelay和offsetFromMaster 能够生成主时钟 使用MAC地址 能够对PTP消息类型进行硬件过滤 支持第4层（IPv4和UDP）和第2层（以太网帧）中的PTP消息帧 在不使用时间同步时可用作普通以太网端口
统计时间 校正算法单元(STCA)	提供给StatisticalTimeCorrectionAlgorithm单元的时钟频率可选择为20、25、50或100MHz 在从属操作中，可以通过offsetFromMaster值保持在预先指定的阈值以下或统计计算来指示同步状态从收集的正负梯度值（最差10采集）本地时钟计数器保存从主时钟获得的校正时间信息STCA时钟可用作时钟源，用于从脉冲输出定时器m（m=0到5） GPT等外围模块可以在与主时钟同步的脉冲沿启动或停止，以响应脉冲输出定时器的中断请求或向ELC输出事件信号
中断源	ETHER_MINT中断： 当各个模块的状态改变时请求 在脉冲输出定时器产生的脉冲信号的上升沿请求。ETHER_IPLS中断： 在先前选择的脉冲输出定时器组生成的脉冲信号的上升沿或下降沿请求 可以在每个沿或仅一次请求
事件链接	事件信号在脉冲输出定时器产生的脉冲信号的上升沿或下降沿输出到ELC 事件信号可以在每个沿输出或仅输出一次

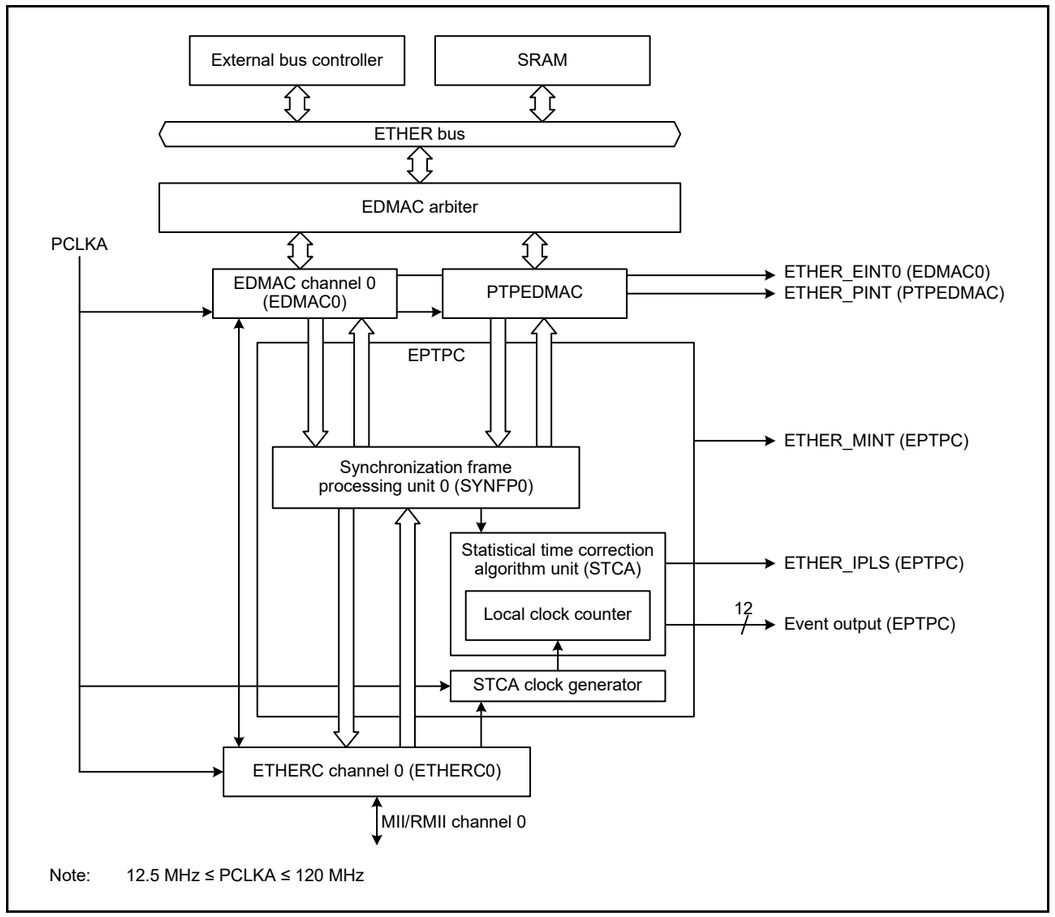

Figure 30.1 EPTPC configuration

In this section, individual channels might not be mentioned in the overall descriptions of modules that have multiple channels. Table 30.2 lists examples of the notation.

Table 30.2 Notation examples

30.1.1 Combination of Clock Device and Ethernet Port

The EPTPC supports operation as one type of clock device:

- Ordinary clock (OC)

In addition, it supports both end-to-end (E2E) and peer-to-peer (P2P) operation. Table 30.3 lists the available combinations for usage of Ethernet ports 0.

Table 30.3 Combination of clock devices and Ethernet ports

Clock device	Ethernet port 0	
No control by EPTPC	PTP packets are not handled	
Ordinary clock (OC) Only Ethernet port 0 is used for handling PTP packets	Master	End-to-end (E2E)
		Peer-to-peer (P2P)
	Slave	E2E
		P2P

30.1.2 Frame Format of PTP Messages

The frame format of PTP messages can be selected from the four types by setting the FORM0 and FORM1 bits in the SYNFP Frame Format Setting Register (SYFORMR). Figure 30.2 shows the PTP message formats for transmission and reception by the EPTPC.

Ethernet header			Ethernet data

Figure 30.2 Frame format of PTP messages

The EPTPC module is capable of transmitting PTP messages. When it sends a PTP message, multicast addresses as defined in IEEE 1588 are normally specified as the destination MAC address and IP address, depending on the type of PTP message to be sent. In addition, when a PTP message is encapsulated for use with UDP, the port number must also be specified in accordance with the message type, as stipulated in IEEE 1588.

Table 30.4 provides a summary of the information required to specify the Ethernet frame format for PTP messages.

30.1.1 时钟设备和以太网端口的组合

EPTPC支持作为一种时钟设备运行：

- 普通时钟(OC)

此外，它支持端到端(E2E)和点对点(P2P)操作。表30.3列出了以太网端口0的可用组合。

Table 30.3 时钟设备和以太网端口的组合

时钟装置	以太网端口0	
不受EPTPC控制	不处理PTP数据包	
普通时钟(OC) 仅以太网端口0用于处理PTP数据包	Master	End-to-end (E2E)
		Peer-to-peer (P2P)
	Slave	E2E
		P2P

30.1.2 PTP消息的帧格式

PTP消息的帧格式可以通过设置FORM0和FORM1位从四种类型中选择SYNFP帧格式设置寄存器(SYFORMR)。图30.2显示了EPTPC发送和接收的PTP消息格式。

Figure 30.2 PTP消息的帧格式

EPTPC模块能够传输PTP消息。当它发送PTP消息时，IEEE1588中定义的多播地址通常指定为目标MAC地址和IP地址，具体取决于要发送的PTP消息的类型。此外，当PTP消息被封装用于UDP时，还必须按照IEEE1588的规定，根据消息类型指定端口号。

表30.4提供了为PTP消息指定以太网帧格式所需的信息摘要。

Bit	Symbol	Bit name	Description	R/W
b31 to b22	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 clears the flag. Writing 0 does not affect the flag value.

The MIESR register indicates changes in the states of the STCA and SYNFP0 units, which act as ETHER_MINT interrupt sources, and enables the detection of rising edges on pulse output timers m (m = 0 to 5). For more the ETHER_MINT interrupt, see section 30.4, Interrupts.

ST flag (STCA Status Flag)

The ST flag indicates changes in the state of the STCA unit.

[Setting condition]

- A change in the state of a flag in the STSR register for which notification is enabled in the STIPR register.

[Clearing conditions]

When any of the following conditions is met:

- The flags in the STSR register are all 0
- The bits in the STIPR register are all 0
- A bit is set to 1 in the STIPR register, but the associated flag in the STSR register is 0.

SY0 flag (SYNFP0 Status Flag)

The SY0 flag indicates changes in the state of the SYNFP0 unit.

[Setting condition]

- A change in the state of a flag in the SYSR register for which notification is enabled in the SYIPR register.

[Clearing conditions]

When any of the following conditions is met:

- The flags in the SYSR register are all 0
- The bits in the SYIPR register are all 0
- A bit is set to 1 in the SYIPR register, but the associated flag in the SYSR register is 0.

CYCm flag (Pulse Output Timer m Rising Edge Detection Flag)

The CYCm flag indicates detection of a rising edge on the periodic pulse signal produced by the associated pulse output timer m (m = 0 to 5).

[Setting condition]

- Detection of a rising edge on the periodic pulse signal produced by a pulse output timer for which notification is enabled in the MITSELR register.

[Clearing condition]

- 1 is written to this flag.
  After the flag is cleared to 0, it is set to 1 again on detection of a rising edge on the periodic pulse signal from the associated pulse output timer.

Bit	Symbol	位名称	Description	R/W
b31 to b22	—	Reserved	这些位被读取为0。写入值应为0。	R/W

Note 1. 写1清除标志。写入0不影响标志值。

MIESR寄存器指示STCA和SYNFP0单元的状态变化，它们充当ETHER_MINT中断源，并启用脉冲输出定时器m（m=0到5）上的上升沿检测。有关ETHER_MINT中断的更多信息，请参阅第30.4节，中断。

ST标志（STCA状态标志）

ST标志指示STCA单元状态的变化。

[Setting condition]

- STSR寄存器中标志状态的变化，在STIPR寄存器中启用通知。

[Clearing conditions]

当满足以下任一条件时：

- STSR寄存器中的标志全为0
- STIPR寄存器中的位全为0
- STIPR寄存器中的某个位设置为1，但STSR寄存器中的相关标志为0。

SY0标志（SYNFP0状态标志）

SY0标志指示SYNFP0单元状态的变化。

[Setting condition]

- SYSR寄存器中标志状态的变化，在SIIPR寄存器中启用通知。

[Clearing conditions]

当满足以下任一条件时：

- SYSR寄存器中的标志位全为0
- SYIPR寄存器中的位全为0
- SYIPR寄存器中的某个位设置为1，但SYSR寄存器中的相关标志为0。

CYCm标志（脉冲输出定时器m上升沿检测标志）

CYCm标志表示检测到由相关脉冲输出定时器m（m=0到5）产生的周期性脉冲信号的上升沿。

[Setting condition]

- 检测脉冲输出定时器产生的周期性脉冲信号的上升沿，在MITSELR寄存器中启用通知。

[Clearing condition]

- 1写入该标志。标志清除为0后，在检测到来自相关脉冲输出定时器的周期脉冲信号的上升沿时再次设置为1。

The ELIPPR register determines whether rising and falling edges of the periodic pulse signals produced by pulse output timers m are output as event signals to the ELC. The register also enables or disables ETHER_IPLS interrupts triggered by rising or falling edges of signals from the pulse output timer selected in the IPTSELR register.

Peripheral modules such as the GPT can be controlled with the clock synchronized by the PTP by using the ELC linking function to set a periodic pulse generated by pulse output timer m as a trigger for operations of the peripheral module.

The ELIPACR register can be used to set up the one-time-only output of event signals to the ELC or of ETHER_IPLS interrupt requests. For more on the ETHER_IPLS interrupt, see section 30.4, Interrupts.

ELIPPR寄存器决定脉冲输出定时器m产生的周期脉冲信号的上升沿和下降沿是否作为事件信号输出到ELC。该寄存器还启用或禁用由来自IPTSELR寄存器中选择的脉冲输出定时器的信号的上升沿或下降沿触发的ETHER_IPLS中断。

GPT等外围模块可以通过PTP同步的时钟进行控制，方法是使用ELC链接功能将脉冲输出定时器m产生的周期脉冲设置为外围模块操作的触发器。

ELIPACR寄存器可用于设置事件信号到ELC或ETHER_IPLS中断请求的一次性输出。有关ETHER_IPLS中断的更多信息，请参阅第30.4节，中断。

The ELIPACR register enables one-time output of each event to the ELC or each ETHER_IPLS interrupt request triggered by detecting edges of the periodic pulses of pulse output timer m. Normally, an event is output to the ELC or an ETHER_IPLS interrupt request is generated on each edge of the periodic pulses of pulse output timer m while the associated bit in the ELIPPR register is 1 (enabled). When a bit in the ELIPPR register is 1 while the associated bit in the ELIPACR register is also 1, the bit in the ELIPPR register automatically clears to 0 when the event signal for the ELC or ETHER_IPLS interrupt request is generated. For more on the ETHER_IPLS interrupt, see section 30.4, Interrupts.

ELIPACR寄存器允许将每个事件一次性输出到ELC或通过检测脉冲输出定时器m的周期性脉冲的边沿触发的每个ETHER_IPLS中断请求。通常，当ELIPPR寄存器中的相关位为1（启用）时，在脉冲输出定时器m的周期脉冲的每个边沿上都会向ELC输出一个事件或一个ETHER_IPLS中断请求。当ELIPPR寄存器中的某个位为1且ELIPACR寄存器中的相关位也为1时，ELIPPR寄存器中的位会在ELC或

ETHER_IPLS中断请求产生。有关ETHER_IPLS中断的更多信息，请参阅第30.4节，中断。

b31 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When the SYNSTARTR.STR bit is 0, the value of the associated flag stays the same.
Note 1. Writing 1 clears the flag. Writing 0 does not affect the flag value.

The STSR register indicates the state of the STCA module.

SYNC flag (Synchronized State Detection Flag)

The SYNC flag indicates that synchronization has occurred more than the number of times specified in the STMR.SYTH[3:0] bits in succession when the STMR.ALEN0 bit is 1. When the STMR.ALEN0 bit is 0, the SYNC flag is not set to 1 even if synchronization has occurred more than the specified number of times in succession.

SYNCOUT flag (Synchronization Loss Detection Flag)

The SYNCOUT flag indicates that loss of synchronization has occurred more than the number of times specified in the STMR.DVTH[3:0] bits in succession when the STMR.ALEN0 bit is 1. Because the time is not synchronized immediately after time synchronization is started (when the SYNSTARTR.STR bit is set to 1), SYNCOUT is set to 1 regardless of the STMR.ALEN0 bit setting. When using the SYNTOUT flag, set the SYNTOUT flag to 0 immediately after starting time synchronization.

When the STMR.ALEN0 bit is 0, the SYNCOUT flag is not set to 1 even if loss of synchronization occurs more than the specified number of times in succession after time synchronization starts and the SYNTOUT flag is immediately set to 0.

SYNTOUT flag (Sync Message Reception Timeout Detection Flag)

The SYNTOUT flag indicates that a Sync message was not received during the period specified in the SYNTOR register when the STMR.ALEN1 bit is 1. The SYNTOUT flag is set to 1 immediately after time synchronization is started (when the SYNSTARTR.STR bit is set to 1) when no Sync message is received after the EPTPC starts. When using the SYNTOUT flag, set the SYNTOUT flag to 0 immediately after starting time synchronization.

W10D flag (Worst 10 Acquisition Completion Flag)

The W10D flag indicates that acquisition of the worst 10 values is complete.

STSR寄存器指示STCA模块的状态。

SYNC标志（同步状态检测标志）

SYNC标志表示当STMR.ALEN0位为1时，同步发生的次数连续超过STMR.SYTH[3:0]位中指定的次数。当STMR.ALEN0位为0时，SYNC标志为即使同步已连续发生超过指定次数，也不会设置为1。

SYNCOUT标志（同步丢失检测标志）

SYNCOUT标志表示同步丢失发生的次数超过了在
当STMR.ALEN0位为1时，STMR.DVTH[3:0]位连续。因为在时间同步开始后（当SYNSTARTR.STR位设置为1时）时间不会立即同步，所以SYNCOUT设置为1无论STMR.ALEN0位设置如何。使用SYNTOUT标志时，在开始时间同步后立即将SYNTOUT标志设置为0。

当STMR.ALEN0位为0时，即使在时间同步开始后连续发生超过指定次数的同步丢失，SYNCOUT标志也不设置为1，并且SYNTOUT标志立即设置为0。

SYNTOUT标志（同步消息接收超时检测标志）

SYNTOUT标志表示当STMR.ALEN1位为1时，在SYNTOR寄存器中指定的时间段内没有接收到同步消息。在时间同步开始后（当设置SYNSTARTR.STR位时，SYNTOUT标志立即设置为1到1)当EPTPC启动后没有收到Sync消息时。使用SYNTOUT标志时，在开始时间同步后立即将SYNTOUT标志设置为0。

W10D标志（最差10次采集完成标志）

W10D标志表示已完成最差10个值的采集。

STCF[1:0] bits (STCA Clock Frequency)

The STCF[1:0] bits select the frequency of the STCA clock. To enable synchronous control in compliance with IEEE 1588, the STCA clock frequency must be specified as 20, 25, 50, or 100 MHz. Operation is not guaranteed if the frequency selected in these bits differs from the clock frequency actually input to the STCA module.

STCF[1:0]位（STCA时钟频率）

STCF[1:0]位选择STCA时钟的频率。要启用符合IEEE1588的同步控制，STCA时钟频率必须指定为20、25、50或100MHz。如果在这些位中选择的频率与实际输入到STCA模块的时钟频率不同，则无法保证操作。

WINT[7:0] bits (Worst 10 Acquisition Time)

The WINT[7:0] bits set the time for acquiring the worst 10 gradients (the number of times Sync messages are received). Renesas recommends setting the number of Sync message receptions to 32 or more in most cases.

CMOD bit (Time Synchronization Correction Mode)

Mode 1 or mode 2 can be selected in the CMOD bit to correct the local time information when the EPTPC operates as a slave clock. Select the appropriate mode for your system configuration. Table 30.7 provides a summary of the two correction modes.

Table 30.7 Correction mode features

Correction mode	Function	Features	Notes
Mode 1	Mode for correcting the counter every Sync message reception by using the current offsetFromMaster. Operation is in mode 1 after the start of correction, then shifts to the specified mode.	The time information of the master clock is set as the local time information at a specific time.	Synchronization is not guaranteed if calculating offsetFromMaster is not possible, for example if packets are temporarily being discarded because of a failure of communications.
Mode 2	In mode 2, the gradient value calculated from offsetFromMaster (worst-10 control) is retained and used in correcting the local time information so that it approximates the time information of the master clock.	Even when calculating offsetFromMaster is not possible, a certain level of synchronization can be guaranteed in this mode, because the counter is still corrected from the gradient information.	Establishing synchronization takes longer.

W10S bit (Worst 10 Acquisition Control Select)

The W10S bit selects the value used for measuring and filtering the worst 10 gradients. When this bit is set to 0, the values acquired in the PW10VRU, PW10VRM, and PW10VRL registers and the MW10RU, MW10RM, and MW10RL registers are used as the limit for the filter. When the bit is set to 1, the values set in the PLIMITRU, PLIMITRM, and PLIMITRL registers and the MLIMITRU, MLIMITRM, and MLIMITRL registers are used as the limit for the filter.

SYTH[3:0] bits (Synchronized State Detection Threshold Setting)

The SYTH[3:0] bits specify the number of consecutive times that a value should fall within the thresholds set in registers SYNTDBRU and SYNTDBRL, to be considered as a synchronized state. When the ALEN0 bit is 1, the STSR.SYNCOUT flag becomes 1.

DVTH[3:0] bits (Synchronization Loss Detection Threshold Setting)

The DVTH[3:0] bits specify a value for the number of consecutive times the offsetFromMaster value must exceed the specified thresholds for the STCA module to detect loss of synchronization. The thresholds are specified in the SYNTDARU and SYNTDARL registers. When the ALEN0 bit is 1, the STSR.SYNCOUT flag is set to 1 on loss of synchronization detection.

ALEN0 bit (Alarm Detection Enable 0)

When the ALEN0 bit is 1, the STSR.SYNC or SYNCOUT flag is set to 1 on detection of synchronization or loss of synchronization. When this bit is 0, the SYNC or SYNCOUT flag is not set to 1 even if synchronization or loss of synchronization is detected.

ALEN1 bit (Alarm Detection Enable 1)

When the ALEN1 bit is 1, the STSR.SYNTOUT flag is set to 1 if a Sync message is not received within the time specified in the SYNTOR register. When this bit is 0, the SYNTOUT flag is not set to 1 even if a reception timeout occurs.

WINT[7:0]位（最差10次采集时间）

WINT[7:0]位设置获取最差10个梯度的时间（接收同步消息的次数）。
Renesas建议在大多数情况下将同步消息接收数设置为32或更多。

CMOD位（时间同步校正模式）

当EPTPC作为从时钟运行时，可以在CMOD位中选择模式1或模式2来校正本地时间信息。为您的系统配置选择适当的模式。表30.7总结了两种校正模式。

Table 30.7 校正模式功能

校正模式	Function	Features	Notes
Mode 1	通过使用当前的offsetFromMaster来纠正每次接收Sync消息的计数器的模式。校正开始后运行在模式1，然后切换到指定模式。	主时钟的时间信息被设置为特定时间的本地时间信息。	如果无法计算offsetFromMaster，则无法保证同步，例如，如果由于通信失败而暂时丢弃数据包。
Mode 2	在模式2中，从offsetFromMaster（worst-10控制）计算的梯度值被保留并用于校正本地时间信息，使其接近主时钟的时间信息。	即使在无法计算offsetFromMaster的情况下，在这种模式下也可以保证一定程度的同步，因为计数器仍然根据梯度信息进行校正。	建立同步需要更长的时间。

W10S位（最差10采集控制选择）

W10S位选择用于测量和过滤最差10个梯度的值。当该位设置为0时，在PW10VRU、PW10VRM和PW10VRL寄存器以及MW10RU、MW10RM和MW10RL寄存器中获取的值用作滤波器的限值。当该位设置为1时，在PLIMITRU、PLIMITRM和PLIMITRL寄存器以及MLIMITRU、MLIMITRM和MLIMITRL寄存器中设置的值用作过滤器的限制。

SYTH[3:0]位（同步状态检测阈值设置）

SYTH[3:0]位指定值应落在寄存器中设置的阈值内的连续次数
SYNTDBRU和SYNTDBRL，被视为同步状态。当ALEN0位为1时，
STSR.SYNCOUT标志变为1。

DVTH[3:0]位（同步丢失检测阈值设置）

DVTH[3:0]位指定offsetFromMaster值必须超过STCA模块检测同步丢失的指定阈值的连续次数的值。阈值在SYNTDARU和SYNTDARL寄存器中指定。当ALEN0位为1时，STSR.SYNCOUT标志在同步丢失检测时设置为1。

ALEN0位（报警检测使能0）

当ALEN0位为1时，STSR.SYNC或SYNCOUT标志在检测到同步或同步丢失时设置为1。当该位为0时，即使检测到同步或同步丢失，SYNC或SYNCOUT标志也不会设置为1。

ALEN1位（报警检测使能1）

当ALEN1位为1时，如果在SYNTOR寄存器中指定的时间内未接收到同步消息，则STSR.SYNTOUT标志设置为1。当该位为0时，即使发生接收超时，SYNTOUT标志也不会设置为1。

The IPTSELR register selects the pulse output timers that generate ETHER_IPLS interrupt requests. Each pulse output timer m (m = 0 to 5) takes the clock signal from the STCA as its clock source and produces pulses with a specified period and duty cycle. An ETHER_IPLS interrupt is requested on rising edges if the ELIPPR.PLSP bit is set to 1 and on falling edges if the PLSN bit in the same register is set to 1. When multiple channels are selected in this register, the interrupt request signal becomes the logical OR of the interrupt requests from the selected channels. For more on the ETHER_IPLS interrupt, see section 30.4, Interrupts.

b31 to b0	—	—	These bits specify the lower-order 32 bits of the threshold for detection of loss of synchronization.	R/W

The SYNTDARU and SYNTDARL registers specify the threshold value for offsetFromMaster to be used in determining loss of synchronization. When setting a threshold value, write the upper-order 32 bits to SYNTDARU and the lower-order 32 bits to SYNTDARL, in that order and in consecutive operations. If the offsetFromMaster value exceeds the value specified in SYNTDARU and SYNTDARL, a loss of synchronization is detected. Set the value in SYNTDARU and SYNTDARL in nanoseconds. SYNTDARU and SYNTDARL are not used when the device is operating as a master clock.

The LCIVRU, LCIVRM, and LCIVRL registers specify the initial value in seconds of the clock counter. When setting an initial value, write the upper-order 16 bits of the integer portion to LCIVRU, the lower-order 32 bits of the integer portion to LCIVRM, and the fractional portion in nanoseconds to LCIVRL, in that order and in consecutive operations.

The value in these registers can be used as the initial value of the local clock counter. When setting these register values in the local clock counter, set the LCIVLDR.LOAD bit to 1.

(1) Example

When 2.000000025 (s) is set as the initial value, write the following values to the registers:

- LCIVRU: 0000_0000h
- LCIVRM: 0000_0002h
- LCIVRL: 0000_0019h.

b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not set this bit to 1 while the STMR.W10S bit is 0.

Software uses the GETW10R register to start calculation of gradient values for use in selecting the worst 10 values. A gradient value is the amount by which the timer counter of a slave is incremented when a given interval elapses. Setting the GW10 bit to 1 while the value of the STMR.W10S bit is 1 selects calculation of a gradient value by the EPTPC each time it receives a Sync message. Gradient values are calculated the number of times specified in the STMR.WINT[7:0] bits. The GW10 bit clears to 0 on completion of this number of calculations. The GETW10R register is not used when the device is operating as a master clock.

LCIVRU、LCIVRM和LCIVRL寄存器指定时钟计数器的初始值（以秒为单位）。设置初始值时，将整数部分的高16位写入LCIVRU，将整数部分的低32位写入LCIVRM，将小数部分（以纳秒为单位）写入LCIVRL，按此顺序和连续操作。

这些寄存器中的值可以作为本地时钟计数器的初始值。在本地时钟计数器中设置这些寄存器值时，将LCIVLDR.LOAD位设置为1。

(1) Example

当2.000000025(s)设置为初始值时，将以下值写入寄存器：

- LCIVRU: 0000_0000h
- LCIVRM: 0000_0002h
- LCIVRL: 0000_0019h.

The PLIMITRU, PLIMITRM, and PLIMITRL registers specify an upper limit on the gradient (= positive gradient) used in time synchronization. When setting the upper limit, write to the registers consecutively in the order of PLIMITRU, PLIMITRM, PLIMITRL. Gradients that exceed the value specified in these registers are not used in time synchronization. These registers are not used when the device is operating as a master clock. The registers are valid while the STMR.CMOD and W10S bits are 1.

Use the following expression to calculate the gradient value to be set in the registers:

PLIMITRU, PLIMITRM, and PLIMITRL register values = A (s)/T (s) × 2^{32}

A: Time (s) by which the slave local clock counter advances during the interval between received Sync messages

T: Actual time (s) between received Sync messages

For example, if the interval between Sync messages is 0.5 seconds and the local clock counter advances by 0.7 seconds during that time, and this is to be set as the limit, then the setting for PLIMITR = 0.7/0.5 × 2^{32} = 6 012 954 214 = 1 6666 6666h, and the settings for the individual registers are as follows:

- PLIMITRU = 0000_0000h
- PLIMITRM = 0000_0001h
- PLIMITRL = 6666_6666h.

The minimum setting depends on the STCA clock frequency as the clock source for counting by the local clock counter. For example, if the STCA clock frequency is 50 MHz, then the minimum allowable setting for PLIMITRU, PLIMITRM, and PLIMITRL = (1/50 (MHz)) (s)/0.5 (s) × 2^{32} = 172 = ACh, and the settings for the individual registers are as follows:

- PLIMITRU = 0000_0000h
- PLIMITRM = 0000_0000h
- PLIMITRL = 0000_00ACh.

The gradient limit values to be set are valid when time synchronization correction mode is mode 2 (STMR.CMOD is 1) and the gradient is controlled by software (STMR.W10S is 1).

PLIMITRU、PLIMITRM和PLIMITRL寄存器指定时间同步中使用的梯度（=正梯度）的上限。设置上限时，按PLIMITRU、PLIMITRM、PLIMITRL的顺序连续写入寄存器。超过这些寄存器中指定值的梯度不用于时间同步。当器件作为主时钟运行时，不使用这些寄存器。当STMR.CMOD和W10S位为1时，寄存器有效。

使用以下表达式计算要在寄存器中设置的梯度值：

PLIMITRU、PLIMITRM和PLIMITRL寄存器值=A(s)T(s)×232

A：从本地时钟计数器在接收到的同步消息之间的间隔内前进的时间（秒）

T：接收到的同步消息之间的实际时间（秒）

例如，如果Sync消息之间的间隔为0.5秒，并且在此期间本地时钟计数器提前0.7秒，并且将其设置为限制，则设置PLIMITR=0.70.5×232=6012954214=166666666h，各个寄存器的设置如下：

- PLIMITRU = 0000_0000h
- PLIMITRM = 0000_0001h
- PLIMITRL = 6666_6666h.

最小设置取决于作为本地时钟计数器计数的时钟源的STCA时钟频率。例如，如果STCA时钟频率为50MHz，则PLIMITRU、PLIMITRM和PLIMITRL的最小允许设置=(150(MHz))(s)0.5(s)×232=172=ACh，并且设置个人登记册如下：

- PLIMITRU = 0000_0000h
- PLIMITRM = 0000_0000h
- PLIMITRL = 0000_00ACh.

当时间同步校正模式为模式2（STMR.CMOD为1）且梯度由软件控制（STMR.W10S为1）时，要设置的梯度限制值有效。

The MLIMITRU, MLIMITRM, and MLIMITRL registers specify a lower limit on the gradient (= negative gradient) used in time synchronization. Use a two's complement value to set the lower limit. When setting the lower limit, write to the registers consecutively in the order of MLIMITRU, MLIMITRM, MLIMITRL. Gradients that are less than the value specified in these registers are not used in time synchronization. These registers are not used when the device is operating as a master clock. The registers are valid while the STMR.CMOD and W10S bits are 1.

The procedure for setting the value, and the minimum value that can be set, are the same as for the PLIMITRU, PLIMITRM, and PLIMITRL registers.

b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The GETINFOR register controls retention of the following statistical information:

- LCCVRU, LCCVRM, and LCCVRL registers
- PW10VRU, PW10VRM, and PW10VRL registers
- MW10RU, MW10RM, and MW10RL registers.

The only value that is writable to the INFO bit is 1. When setting a value in the PW10VRU, PW10VRM, and PW10VRL registers, or the MW10RU, MW10RM, and MW10RL registers, only set the INFO bit to 1 while the STMR.W10S bit is 1. If the INFO bit is set to 1 before acquisition of the worst 10 values is complete, the information retained in the PW10VRU, PW10VRM, and PW10VRL registers and MW10RU, MW10RM, and MW10RL registers is not guaranteed to be correct. Use the GETW10R.GW10 bit to confirm that acquisition is completed before setting the INFO bit to 1. The INFO bit automatically returns to 0 on completion of information fetching.

- MW10RU、MW10RM和MW10RL寄存器。

可写入INFO位的唯一值是1。在PW10VRU、PW10VRM和PW10VRL寄存器或MW10RU、MW10RM和MW10RL寄存器中设置值时，仅将INFO位设置为1，而STMR.W10S位为1。如果在获取最差10个值之前将INFO位设置为1，则不能保证PW10VRU、PW10VRM和PW10VRL寄存器以及MW10RU、MW10RM和MW10RL寄存器中保留的信息是正确的。在将INFO位设置为1之前，使用GETW10R.GW10位确认采集已完成。信息获取完成后，INFO位自动返回0。

b31 to b0	—	—	These bits indicate the fractional portion of the value in the local clock counter (in nanoseconds).	R

The LCCVRU, LCCVRM, and LCCVRL registers indicate the value of the local clock counter. When the GETINFOR.INFO bit is set to 1, the value of the local clock counter at that time is stored in these registers as follows:

- LCCVRU: Upper-order 16 bits of the integer portion in seconds
- LCCVRM: Lower-order 32 bits of the integer portion in seconds
- LCCVRL: Fractional portion in nanoseconds.

For example, if the local time information is 14:25, 44 seconds, 10 milliseconds, 23 microseconds, and 39 nanoseconds, the registers have 14 × 3600 + 25 × 60 + 44 = 51944 (s) = 0000_0000_CAE8h as the setting of the upper-order 48 bits and $10 \times 10^6 + 23 \times 10^3 + 39 = 10023039$ (ns) = 0098_F07Fh as the setting of the lower-order 32 bits.

b31 to b0	—	—	These bits specify the lower-order 32 bits of the start time of the pulse output timer in nanoseconds.	R/W

The TMSTTRUm and TMSTTRLm register specify the start time of pulse output timer m. Set the start time of pulse output timer m (64 bits) in nanoseconds. Although the setting is in nanoseconds, the start time of pulse output timer m depends on the resolution of the STCA clock. For example, if the STCA clock is running at 50 MHz, 1 cycle takes 20 ns, so the time at which the timer starts might differ from the time set in these registers by up to 20 ns. When writing to the registers, write values consecutively in the order of TMSTTRUm, TMSTTRLm, while the TMSTARTR.ENm bit is 0. The format for setting times in these registers differs from that described in section 30.2.23, Local Clock Counter (LCCVRU, LCCVRM, LCCVRL).

b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The TMCYCRm registers specify the period of the output signal generated by the associated pulse output timer m. Set a value in nanoseconds that is equivalent to at least 4 cycles of the STCA clock while the value of the TMSTARTR.ENm bit is 0. Although the setting is in nanoseconds, the period of the output signal generated by pulse output timer m and the time at which the timer starts depend on the period of the STCA clock. For example, if the STCA clock is running at 50 MHz, 1 cycle takes 20 ns, so the clock source for counting by pulse output timer m might differ from the period set in these registers by up to 19 ns. The SYNFP module handles calculations to correct this difference.

For example, if the setting for the timer period is 81 ns and the STCA clock is running at 50 MHz, the only available settings close to the actual timer period are for 80 or 100 ns. By setting the timer period in the SYNFP module to 80 ns for 19 and to 100 ns for 1 of every 20 cycles, the average period can be adjusted to 81 ns.

$$(80\ (\text{ns}) \times 19 + 100\ (\text{ns}) \times 1)/20 = 81\ (\text{ns})$$

The minimum value that can be set in a TMCYCRm register is 4 cycles of the STCA clock. For example, if the STCA clock is running at 50 MHz, the minimum setting corresponds to 80 ns. Timer operation is not guaranteed if a value set in one of these registers is less than this value.

TMCYCRm寄存器指定由相关脉冲输出定时器m生成的输出信号的周期。当TMSTARTR.ENm位的值为0时，设置一个以纳秒为单位的值，该值相当于STCA时钟的至少4个周期。虽然设置以纳秒为单位，但脉冲输出定时器m产生的输出信号的周期和定时器启动的时间取决于STCA时钟的周期。例如，如果STCA时钟以50MHz运行，则1个周期需要20ns，因此脉冲输出定时器m计数的时钟源可能与这些寄存器中设置的周期相差最多19ns。SYNFP模块处理计算以纠正这种差异。

例如，如果定时器周期设置为81ns，并且STCA时钟运行在50MHz，则接近实际定时器周期的唯一可用设置是80或100ns。通过将SYNFP模块中的定时器周期设置为19个80ns和每20个周期中的1个100ns，可以将平均周期调整为81ns。

$$(80\ (\text{ns}) \times 19 + 100\ (\text{ns}) \times 1)/20 = 81\ (\text{ns})$$

可以在TMCYCRm寄存器中设置的最小值是STCA时钟的4个周期。例如，如果STCA时钟以50MHz运行，则最小设置对应于80ns。如果这些寄存器之一中设置的值小于该值，则不能保证定时器操作。

The TMPLSRm registers specify the high-level width of the output signal generated by the associated pulse output timer m. When the TMSTARTR.ENm bit is 0, set a value corresponding to a time no shorter than 2 cycles of the STCA clock in nanoseconds. Although the setting is in nanoseconds, the high-level width of the signal from the timer depends on the period of the STCA clock. The method for correcting the high-level width of the signal from the timer is the same as that for correcting the timer periods set in the TMCYCRm register.

The upper-order 3 bits of the TMPLSRm register are reserved. These bits are read as 000b. When writing, write 000b to these bits.

Note 1. Writing 1 clears the flag. Writing 0 does not affect the flag value.

The SYSR register indicates the state of the SYNFP module.

OFMUD flag (offsetFromMaster Value Update Flag)

The OFMUD flag indicates that the value of offsetFromMaster was updated.

INTCHG flag (Receive logMessageInterval Value Change Detection Flag)

The INTCHG flag indicates that the logMessageInterval value of the Delay_Resp, Sync or Announce message differs from the previously received value.

Note 1. 写1清除标志。写入0不影响标志值。

SYSR寄存器指示SYNFP模块的状态。

OFMUD标志（offsetFromMaster值更新标志）

OFMUD标志表示offsetFromMaster的值已更新。

INTCHG标志（接收logMessageInterval值变化检测标志）

INTCHG标志指示Delay_Resp、Sync或Announce消息的logMessageInterval值与先前接收的值不同。

MPDUD flag (meanPathDelay Value Update Flag)

The MPDUD flag indicates that the value of meanPathDelay was updated.

DRPTO flag (Delay_Resp/Pdelay_Resp Reception Timeout Detection Flag)

The DRPTO flag indicates that a Delay_Resp or Pdelay_Resp message was not received within the period set in the RSTOUTR register.

INTDEV flag (Receive logMessageInterval Value Out-of-Range Flag)

The INTDEV flag indicates that a Delay_Resp message was received with a logMessageInterval value outside the range, -7 to +6.

DRQOVR flag (Delay_Req Reception FIFO Overflow Detection Flag)

The DRQOVR flag indicates that the FIFO buffer for storing information from received Delay_Req messages holds 32 or more entries.

RECLP flag (Loop Reception Detection Flag)

The RECLP flag indicates that the value of the sourcePortIdentity field in a received PTP message matches the local PortIdentity as set in the SYCIDRU, SYCIDRL, and SYPNUMR registers.

INFABT flag (Control Information Abnormality Detection Flag)

The INFABT flag indicates that the control information includes a mismatch. If an erroneous frame is detected because of a corrupted frame or noise in the external circuit when the ETHERC and EPTPC are receiving data, subsequent normal frames might not be received properly.

Reset the EDMAC, ETHERC, and EPTPC after an erroneous frame is detected. Then, wait for the required number of cycles before setting communications again.

- Detecting an erroneous frame

  To detect an erroneous frame, read the INFABT flag in the SYNFP Status Register (SYSR) of EPTPC0. An INFABT flag is provided for EPTPC0.
  When the EPTPC0 is not used and only the EDMAC0 and ETHERC0 are used to receive and transmit standard Ethernet frames, read the INFABT flag to detect an erroneous frame.

- Resetting after detection of an erroneous flag

  When the EPTPC0.SYSR.INFABT flag is set to 1, reset the EPTPC0 and ETHERC0, and then wait for the required number of cycles before setting the registers.
  When the EPTPC0 is not used and only the EDMAC0 and ETHERC0 are used to receive and transmit standard Ethernet frames, reset the EPTPC0 and the registers. In this case, resetting PTPEDMAC is not required.
  To reset the EPTPC0 and the registers:

  a. Set the EPTPC_CFG.PTRSTR.RESET bit to 1 (reset the EPTPC0 by software).
  b. Set the EDMAC0.EDMR.SWR bit to 1 (reset the EDMAC0 and ETHERC0 by software).
  c. Use a software loop or timer to wait for at least 64 cycles of the peripheral module clock, PCLKA. This step is necessary to initialize EDMAC0 and ETHERC0.
  d. Set the EPTPC_CFG.PTRSTR.RESET bit to 0 (release the EPTPC0 reset).
  e. Reset communications by setting the EDMAC0, ETHERC0, PTPEDMAC, and EPTPC0 registers to enable communications.

RESDN flag (Response Stop Completion Detection Flag)

The RESDN flag indicates the end of processing for transmission of a Delay_Resp or Pdelay_Resp as response messages when the handling of a received Delay_Req or Pdelay_Req by the SYNFP module is disabled in the SYRFL1R or SYRVLDR register.

MPDUD标志（meanPathDelay值更新标志）

MPDUD标志表明meanPathDelay的值已更新。

DRPTO标志（Delay_RespPdelay_Resp接收超时检测标志）

DRPTO标志表明延迟_Resp或Pdelay_Resp消息在设置的周期内没有收到。
RSTOUTR register.

INTDEV标志（接收logMessageInterval值超出范围标志）

INTDEV标志指示接收到的Delay_Resp消息的logMessageInterval值超出了-7到+6的范围。

DRQOVR标志（Delay_Req接收FIFO溢出检测标志）

DRQOVR标志指示用于存储来自接收到的Delay_Req消息的信息的FIFO缓冲区包含32个或更多条目。

RECLP标志（循环接收检测标志）

RECLP标志表示接收到的PTP消息中的sourcePortIdentity字段的值与本地
在SYCIDRU、SYCIDRL和SYPNUMR寄存器中设置的PortIdentity。

INFABT标志（控制信息异常检测标志）

INFABT标志指示控制信息包括不匹配。如果在ETHERC和EPTPC接收数据时，由于帧损坏或外部电路中的噪声而检测到错误帧，则可能无法正确接收后续正常帧。

在检测到错误帧后重置EDMAC、ETHERC和EPTPC。然后，在再次设置通信之前等待所需的周期数。

- 检测错误帧

  要检测错误帧，请读取EPTPC0的SYNFP状态寄存器(SYSR)中的INFABT标志。一个
  为EPTPC0提供了INFABT标志。
  不使用EPTPC0仅使用EDMAC0和ETHERC0接收和发送标准时
  以太网帧，读取INFABT标志以检测错误帧。

- 检测到错误标志后重置

  当EPTPC0.SYSR.INFABT标志设置为1时，复位EPTPC0和ETHERC0，然后在设置寄存器之前等待所需的周期数。不使用EPTPC0仅使用EDMAC0和ETHERC0接收和发送标准时

  以太网帧，复位EPTPC0和寄存器。在这种情况下，不需要重置PTPEDMAC。
  复位EPTPC0和寄存器：a．将EPTPC_CFG.PTRSTR.RESET位设置为1（通过软件复位EPTPC0）。

  湾。将EDMAC0.EDMR.SWR位设置为1（通过软件复位EDMAC0和ETHERC0）。

  C。使用软件循环或定时器等待外设模块时钟PCLKA的至少64个周期。这一步是初始化EDMAC0和ETHERC0所必需的。

  d。将EPTPC_CFG.PTRSTR.RESET位设置为0（释放EPTPC0复位）。

  e.通过设置EDMAC0、ETHERC0、PTPEDMAC和EPTPC0寄存器来复位通信以启用通信。

RESDN标志（响应停止完成检测标志）

当在SYRFL1R或SYRVLDR寄存器中禁用SYNFP模块对接收到的Delay_Req或Pdelay_Req的处理时，RESDN标志指示作为响应消息发送Delay_Resp或Pdelay_Resp的处理结束。

GENDN flag (Generation Stop Completion Detection Flag)

The GENDN flag indicates the end of processing for transmission of messages of a type disabled in the SYTRENR or SYRVLDR register.

Bit	Symbol	Bit name	Description	R/W
b3 to b0	VER[3:0]	versionPTP Field Value	These bits specify the versionPTP field value of the PTP v2 header. When a message is received, this value is compared with the versionPTP field of the received frame. In generating messages, the value is used for the versionPTP field of the frame to be transmitted. Set these bits to 0010b (PTP v2).	R/W
b7 to b4	TRSP[3:0]	transportSpecific Field Value	These bits specify the transportSpecific field value of the PTP v2 header. When a message is received, this value is compared with the transportSpecific field of the received frame. In generating messages, the value is used for the transportSpecific field of the frame to be transmitted. Set these bits to 0000b (IEEE 1588).	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SYSPVRR register specifies the transportSpecific and versionPTP field values of the PTP v2 message header. Do not change the settings while reception or transmission of PTP messages is enabled.

Note 1. This bit is reserved for Pdelay_Resp messages. Set the bit to 0.
Note 2. This bit is reserved for Delay_Resp messages.

The DYRPFR register specifies the flagField section of the header when the SYNFP module is to generate a Delay_Resp or Pdelay_Resp message. The values specified in this register are only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1. Do not change the settings in this register while transmission of Delay_Resp or Pdelay_Resp messages is enabled. After disabling this transmission processing, do not change the settings in this register until the SYSR.RESDN flag sets to 1.

b31 to b0	—	—	These bits specify the lower-order 32 bits of the clock-ID of the local port.	R/W

The SYCIDR register specifies the clock-ID of the local port. The clock-ID is used for the clockIdentity section in the sourcePortIdentity field of the header when the SYNFP module is to generate a PTP message. When a PTP message is received, the value in these registers is compared with the clockIdentity section in the sourcePortIdentity field of the PTP message to determine whether the message is one that was transmitted by your application. Renesas recommends making this setting the same as the value of portDS.portIdentity.clockIdentity in most cases.

Do not change the settings in these registers while reception or transmission of PTP messages is enabled.

The SYPNUMR register specifies the port number of the local port. This register is used for the portNumber section in the sourcePortIdentity field of the header when the SYNFP module is to generate a PTP message. When a PTP message is received, the value in this register is compared with the portNumber section in the sourcePortIdentity field of the PTP message to determine whether the message is one that was transmitted by the local device. Renesas recommends making this setting the same as the value of portDS.portIdentity.portNumber in most cases.

The SYRFL1R register specifies filtering for the reception of PTP messages. Multiple bits corresponding to different types of messages can be set to 1. Setting all bits for a type of message to 0 leads to all messages of the given type being discarded. The values specified in this register are only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

Note 1. PTP messages other than PTP v2 messages and messages of undefined type are handled as illegal messages.

The SYRFL2R register specifies filtering for the reception of PTP messages. Multiple bits corresponding to different types of messages can be set to 1. Setting all bits for a type of message to 0 leads to all messages of the given type being discarded. The values specified in this register are only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SYTLIR register specifies the interval for the transmission of messages generated by the SYNFP module. The setting is an integer logarithm in base 2 (log2(x)) and determines a value x in seconds. In other words, the interval for transmission is 2^n (s), where n is the setting. The available settings are from -7 (F9h) to +6 (06h).

Examples:

- If the setting is 06h, then the interval for transmission is $2^6 = 64$ (s)
- If the setting is 00h, then the interval for transmission is $2^0 = 1$ (s)

b31 to b24	—	Reserved	这些位被读取为0。写入值应为0。	R/W

SYTLIR寄存器指定传输由SYNFP模块生成的消息的时间间隔。该设置是一个以2为底的整数对数(log2(x))，并以秒为单位确定值x。换言之，传输的间隔是2n(s)，其中n是设置。可用设置从-7(F9h)到+6(06h)。

Examples:

- 如果设置为06h，则传输间隔为26=64(s)
- 如果设置为00h，则传输间隔为20=1(s)

- If the setting is FFh, then the interval for transmission is 2^{-1} = 0.5 (s) = 500 (ms)
- If the setting is F9h, then the interval for transmission is 2^{-7} = 0.0078125 (s) = 7.8125 (ms).

The value specified in the ANCE[7:0] bits is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1. The values specified in the DREQ[7:0] and SYNC[7:0] bits are only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

The OFMRU and OFMRL registers indicate the calculated offsetFromMaster value. The value is expressed as a two's complement in nanoseconds. The numeric representation differs from that of the offsetFromMaster member of the current data set (currentDS), as shown in the following note. For reads, access the registers in the order of OFMRU, OFMRL.

Note 1. The value of currentDS.offsetFromMaster is multiplied by 2^{16}. Example: 2.5 (ns) = 0000_0000_0002_8000h

Bit	Symbol	Bit name	Description	R/W
b31 to b0	—	—	These bits indicate the lower-order 32 bits of the calculated meanPathDelay value.	R

The MPDRU and MPDRL registers indicate the calculated meanPathDelay value. The value is expressed as a two's complement in nanoseconds. The numeric representation differs from that of the meanPathDelay member of the current data set (currentDS), as shown in the following note. For reads, access the registers in the order of MPDRU, MPDRL.

Note 1. The value of currentDS.meanPathDelay is multiplied by 2^{16}. Example: 2.5 (ns) = 0000_0000_0002_8000h

Bit	Symbol	Bit name	Description	R/W
b7 to b0	GMPR2[7:0]	grandmasterPriority2 Field Value Setting	These bits specify the value of the grandmasterPriority2 fields of Announce messages.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	GMPR1[7:0]	grandmasterPriority1 Field Value Setting	These bits specify the value of the grandmasterPriority1 fields of Announce messages.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The GMPR register specifies the grandmasterPriority1 and grandmasterPriority2 field values of Announce messages generated by the SYNFP module. The values specified in this register are only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

Bit	Symbol	位名称	Description	R/W

The PPMACRU and PPMACRL registers specify the destination MAC address for PTP-primary messages. In normal usage, set 01:1B:19:00:00:00 in these registers. The value is used in the destination MAC address field when generating an Ethernet frame for a PTP-primary message. It is also used as a determining condition for received frames carrying PTP messages. Set these registers before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

The PDMACRU and PDMACRL registers specify the destination MAC address for PTP-pdelay messages. In normal usage, set 01:80:C2:00:00:0E in these registers. This value is used in the destination MAC address field when generating frames carrying PTP-pdelay messages in the Ethernet format. It is also used as a determining condition for received frames carrying PTP messages. Set these registers before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

Note 1. The setting in these bits is only valid when the EXTPRM bit is 0.

The FFLTR register switches extended promiscuous mode on or off and selects how filtering is handled when multicast frames other than PTP messages are received. To enable the filter for the reception of multicast frames other than PTP messages, set the ENB, PRT, and SEL bits to 110b or 111b. Frames passed by the filter are then transferred by EDMAC0.

Set this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

b15 to b0	EGP[15:0]	Output Port Timestamp Latency Setting	These bits specify the timestamp latency (ns) for the output ports.	R/W
b31 to b16	INGP[15:0]	Input Port Timestamp Latency Setting	These bits specify the timestamp latency (ns) for the input ports.	R/W

The TSLATR register specifies the amount of latency in timestamp acquisition in nanoseconds. Do not change the settings while reception or transmission of PTP messages is enabled.

EGP[15:0] bits (Output Port Timestamp Latency Setting)

Set the EGP[15:0] bits to the fixed values listed in Table 30.8 for the target system. The timestamp latency differs with the link transfer rate (100 or 10 Mbps) and the frequency of the STCA clock (20, 25, 50, or 100 MHz).

Table 30.8 EGP[15:0] bit settings (ns)

Link transfer rate		STCA clock frequency 20 MHz	25 MHz	50 MHz	100 MHz
MII	100 Mbps	590	625	695	730
	10 Mbps	7430	7465	7535	7570
RMII	100 Mbps	770	805	875	910
	10 Mbps	9230	9265	9335	9370

INGP[15:0] bits (Input Port Timestamp Latency Setting)

Set the INGP[15:0] bits to the fixed values listed in Table 30.9 for the target system. The timestamp latency differs with the link transfer rate (100 or 10 Mbps) and the frequency of the STCA clock (20, 25, 50, or 100 MHz).

Table 30.9 INGP[15:0] bit settings (ns)

TSLATR寄存器指定时间戳采集的延迟量（以纳秒为单位）。在启用PTP消息的接收或传输时不要更改设置。

EGP[15:0]位（输出端口时间戳延迟设置）

将目标系统的EGP[15:0]位设置为表30.8中列出的固定值。时间戳延迟因链路传输速率（100或10Mbps）和STCA时钟频率（20、25、50或100MHz）而异。

b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SYCONFR register controls operation of the SYNFP module. Set this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

TCYC[7:0] bits (PTP Message Transmission Interval Setting)

The TCYC[7:0] bits specify a wait time between packets to secure a fixed transmission delay. The setting defines the interval from input of the transmission completed signal from the ETHERC to output of the next transmission request as a number of cycles of the transmission clock, which runs at 2.5 MHz if the link transfer rate is 10 Mbps and 25 MHz if the rate is 100 Mbps.

SBDIS bit (Sync Message Transmission Bandwidth Securing Disable)

The SBDIS bit disables securing of bandwidth to increase accuracy of the interval for the transmission of SYNC messages.

FILDIS bit (Receive Message domainNumber Filter Disable)

The FLDIS bit selects whether or not to include comparison with the domainNumber field in the filtering conditions for the reception of PTP messages.

SYCONFR寄存器控制SYNFP模块的操作。在启动EDMAC之前设置该寄存器，ETHERC或PTPEDMAC。请勿在EPTPC运行时更改设置。

TCYC[7:0]位（PTP消息传输间隔设置）

TCYC[7:0]位指定数据包之间的等待时间，以确保固定的传输延迟。该设置定义了从ETHERC输入传输完成信号到输出下一个传输请求的间隔，作为传输时钟的周期数，如果链路传输速率为10Mbps，则以2.5MHz运行，如果链路传输速率为25MHz，则以25MHz运行。速率为100Mbps。

SBDIS位（同步消息传输带宽保护禁用）

SBDIS位禁用带宽保护以提高SYNC消息传输间隔的准确性。

FILDIS位（接收消息域编号过滤器禁用）

FLDIS位选择是否在接收PTP消息的过滤条件中包括与domainNumber字段的比较。

b31 to b0	—	Response Message Reception Timeout Time Setting	If no response message is received within n × 1024 (ns), where n is the setting in these bits, a timeout is detected.	R/W

The RSTOUTR register specifies the time for detection of a timeout during the reception of PTP response messages (Delay_Resp and Pdelay_Resp). If no Delay_Resp or Pdelay_Resp message is received within the time specified in this register after transmission of a Delay_Req or Pdelay_Req message, the SYSR.DRPTO flag is set to 1. The value specified in this register is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

Note: Do not access the BYPASS register while the Ether module is in operation. When the EPTPC is not used, bypass it by setting the BYPASS register.

30.3 Operation

After release from the reset state, the EPTPC is set to not receive (analyze) or transmit (generate) PTP messages, so it has no effect on the transmission or reception of frames by the ETHERC and EDMAC at that time. The EPTPC registers must be configured to transmit and receive PTP messages for the ETHERC and EDMAC to be able to use packet filtering by MAC address in the SYNFP module.

Figure 30.3 shows a block diagram of the modules involved in frame transfer.

SCLKDIV[2:0]位（PCLKA时钟分频）

SCLKDIV[2:0]位选择PCLKA的分频比。当SCLKSEL[2:0]位设置为000b时，分频PCLKA用作STCA时钟信号。

SCLKSEL[2:0]位（STCA时钟选择）

SCLKSEL[2:0]位选择用于EPTPC的STCA时钟信号。

Note: 在以太模块运行时不要访问BYPASS寄存器。当不使用EPTPC时，通过设置BYPASS寄存器绕过它。

30.3 Operation

从复位状态释放后，EPTPC被设置为不接收（分析）或发送（生成）PTP消息，因此对当时的ETHERC和EDMAC发送或接收帧没有影响。必须将EPTPC寄存器配置为发送和接收PTP消息，以便ETHERC和EDMAC能够使用SYNFP模块中的MAC地址进行数据包过滤。

图30.3显示了帧传输中涉及的模块的框图。

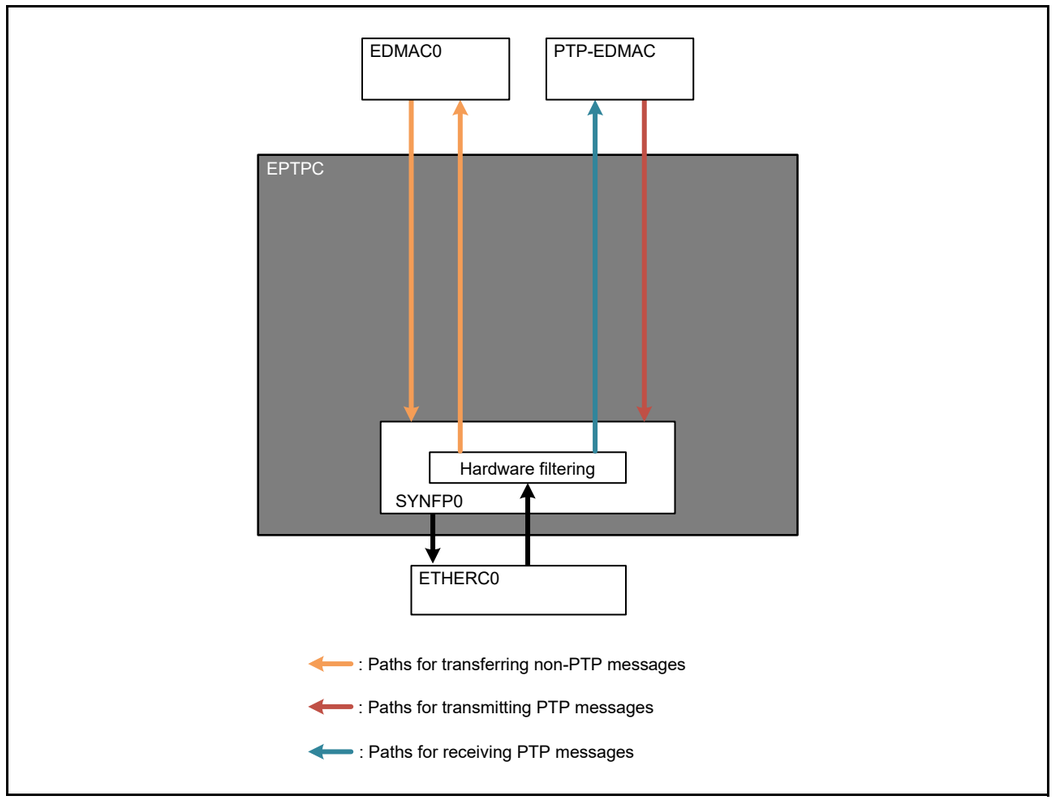

Figure 30.3 Block diagram of the modules involved in frame transfers

30.3.1 Transmission and Reception of Non-PTP Messages

The EPTPC operates in extended promiscuous mode when the FFLTR.EXTPRM bit setting is 1. In this mode, all frames received by the Ethernet ports are transferred to the EDMAC without filtering. The EPTPC operates in normal mode when the FFLTR.EXTPRM bit setting is 0. In this mode, the SYNFP module applies its hardware filtering function to filter frames received by the Ethernet ports.

The EPTPC and EDMAC transfer received unicast frames if they are for the given node.

Operation when multicast frames are received can be selected from the following: frames are transferred to the EDMAC, frames are not transferred to the EDMAC, or frames are transferred to the EDMAC only when the address matches the specified MAC address.

The EPTPC transfers received broadcast frames to the EDMAC for the receiving Ethernet port.

30.3.2 Paths for the Transfer of Non-PTP Messages

Messages received through the Ethernet port are transferred to the EDMAC. Figure 30.4 is a diagram of paths for the transmission and reception of non-PTP messages.

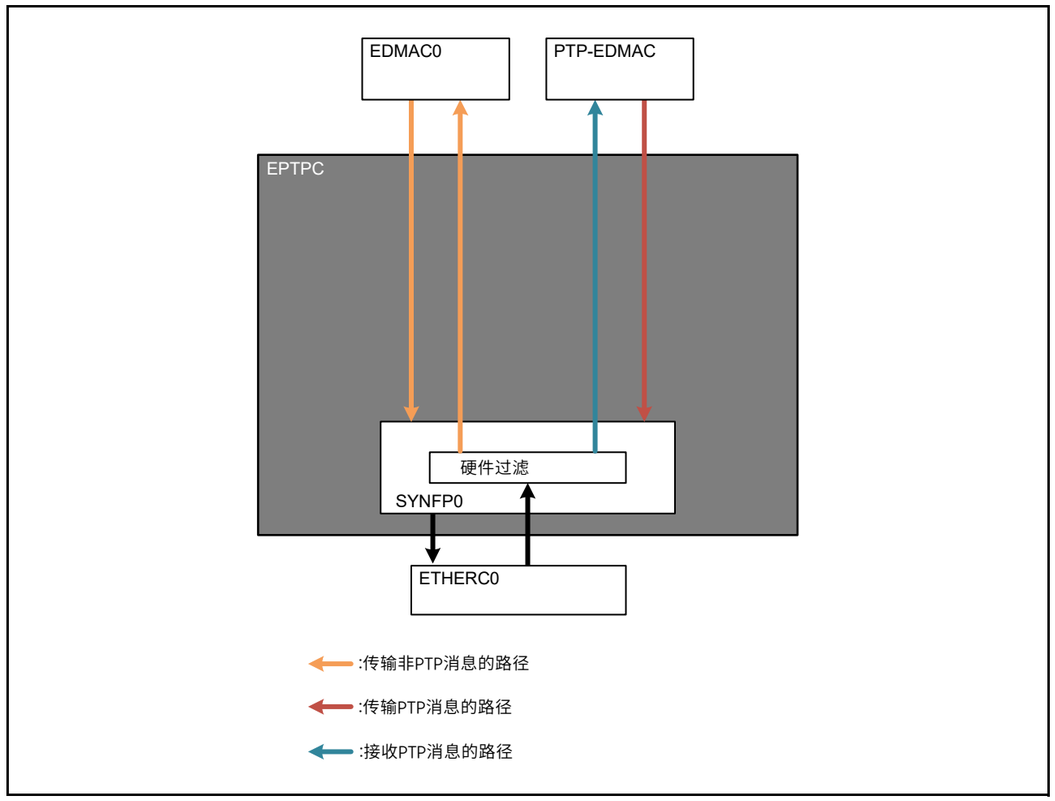

Figure 30.3 涉及帧传输的模块框图

30.3.1 非PTP消息的传输和接收

当FFLTR.EXTPRM位设置为1时，EPTPC在扩展混杂模式下运行。在这种模式下，以太网端口接收到的所有帧都被传输到EDMAC而不进行过滤。当FFLTR.EXTPRM位设置为0时，EPTPC在正常模式下运行。在这种模式下，SYNFP模块应用其硬件过滤功能来过滤以太网端口接收到的帧。

EPTPC和EDMAC传输接收到的单播帧，如果它们是给定节点的。

接收到多播帧时的操作可以从以下选择：将帧传输到EDMAC，不将帧传输到EDMAC，或仅当地址与指定的MAC地址匹配时才将帧传输到EDMAC。

EPTPC将接收到的广播帧传输到接收以太网端口的EDMAC。

30.3.2 非PTP消息的传输路径

通过以太网端口接收的消息被传输到EDMAC。图30.4是发送和接收非PTP消息的路径图。

30.3.3 Transmission and Reception of PTP Messages

The EPTPC hardware automatically handles analysis and extraction of fields from received PTP messages, and generation and transmission of PTP messages. However, the software must still handle the transmission of certain PTP messages. Table 30.10 shows the specifications for control over the transmission and reception of the different PTP message types.

Table 30.10 Control over the transmission and reception of PTP messages

30.3.4 Paths for the Transfer of PTP Messages

Transfer paths for the PTP messages differ based on whether transfer requires processing by software or is automatically processed by hardware.

30.3.4.1 Paths for the transfer of PTP messages requiring processing by software

Figure 30.5 shows the paths for the transfer of PTP messages where transfer requires software processing. The figure shows paths for all message, clock-type, and process combinations for which “(software)” is indicated in Table 30.10.

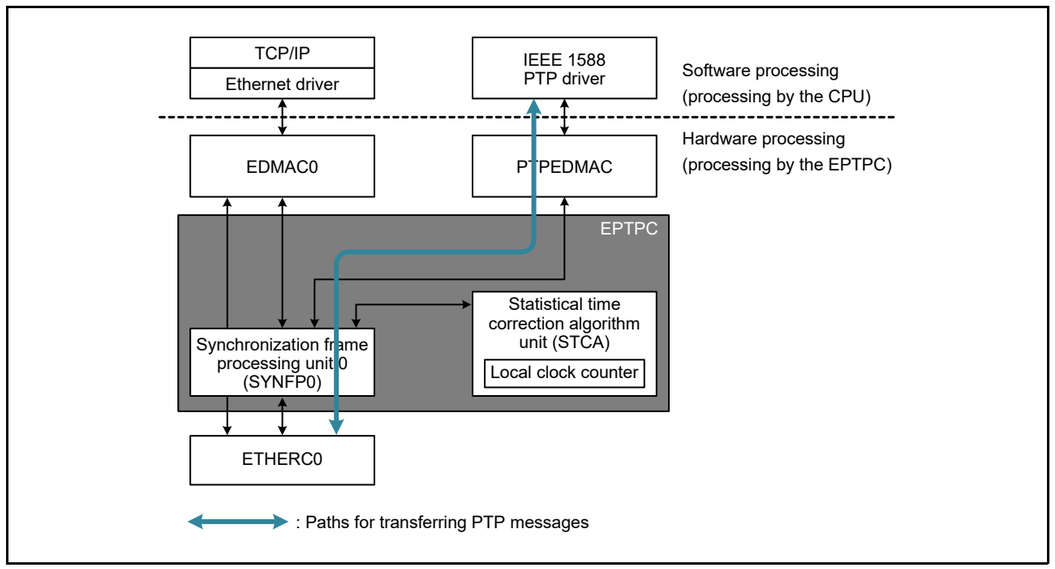

Figure 30.5 Paths for the transfer of PTP messages requiring software processing

30.3.4.2 Paths for the transfer of PTP messages handled automatically by hardware

For PTP messages for which the hardware automatically handles the processing, the SYNFP modules handle transmission and reception.

(1) Generation of and response to PTP messages by hardware

Figure 30.6 shows the transfer paths in the automatic generation of and response to PTP messages by the SYNFP module. The paths in the figure are used for the “Generation (automatic)”, “Reception (automatic)”, and “Generation and reception (automatic)” operations indicated in Table 30.10.

30.3.4 PTP消息的传输路径

PTP消息的传输路径根据传输是需要软件处理还是由硬件自动处理而有所不同。

30.3.4.1 需要软件处理的PTP消息的传输路径

图30.5显示了PTP消息的传输路径，其中传输需要软件处理。该图显示了表30.10中指示“（软件）”的所有消息、时钟类型和进程组合的路径。

30.3.5 Clock Devices

The EPTPC can operate as the clock devices defined in IEEE 1588.

30.3.5.1 End-to-End (E2E)

(1) Master

PTP messages are transmitted and received as described in Table 30.11 in operation as an end-to-end (E2E) master.

Table 30.11 Processing of PTP messages by an E2E master

Message type	Message	The EPTPC...
Event	Sync	Transmits Sync messages at the fixed interval specified in the SYTLIR.SYNC[7:0] bits.
	Delay_Req	When this message is received, transmits a Delay_Resp message in response.
	Pdelay_Req	—
	Pdelay_Resp	—
General	Announce	Transmits Announce messages at the fixed interval specified in the SYTLIR.ANCE[7:0] bits.
	Follow_Up	—
	Delay_Resp	Transmits this as the response to a received Delay_Req messages.
	Pdelay_Resp_Follow_Up	—
	Management	Transmits and receives Management messages by software through the PTPEDMAC.
	Signaling	Transmits and receives Signaling messages by software through the PTPEDMAC.

(2) Slave

PTP messages are transmitted and received as described in Table 30.12 in operation as an E2E slave, and the calculated offsetFromMaster is used to correct the local time information.

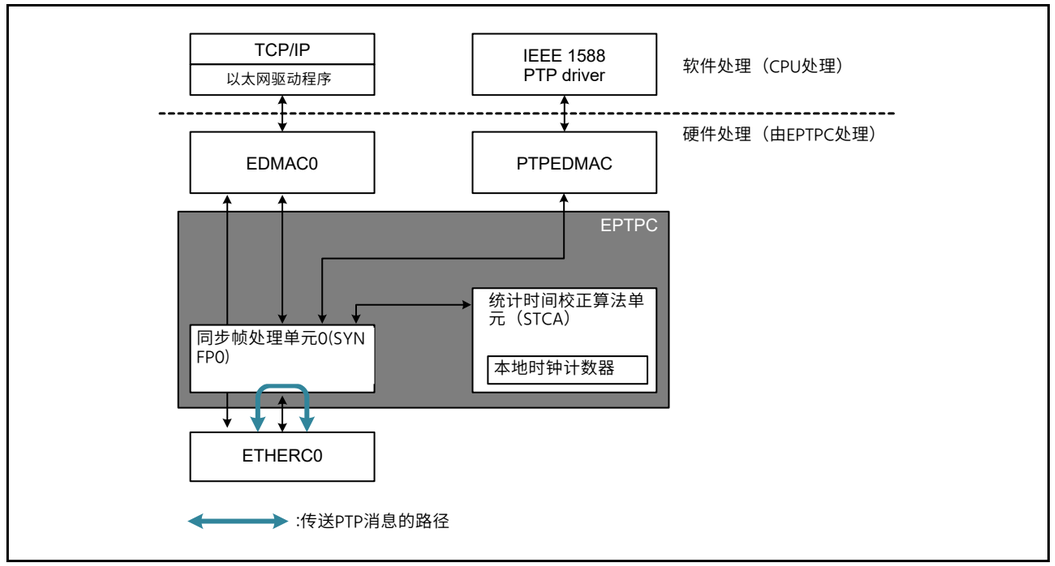

Figure 30.6 硬件生成和响应PTP消息的路径

30.3.5 时钟设备

EPTPC可以作为IEEE1588中定义的时钟设备运行。

30.3.5.1 End-to-End (E2E)

(1) Master

PTP消息的发送和接收如表30.11中所述，作为端到端(E2E)主机运行。

Table 30.11 E2E主站对PTP消息的处理

消息类型	Message	The EPTPC...
Event	Sync	以SYTLIR.SYNC[7:0]位中指定的固定间隔发送同步消息。

	Pdelay_Req	—
	Pdelay_Resp	—
General	Announce	Transmits Announce messages by software through the PTPEDMAC.
	Follow_Up	Calculates the offsetFromMaster value when this message is received if twoStepFlag in flagField of the most recently received Sync message was TRUE (two-step clock).
	Delay_Resp	Calculates the meanPathDelay value when this message is received.
	Pdelay_Resp_Follow_Up	—
	Management	Transmits and receives Management messages by software through the PTPEDMAC.
	Signaling	Transmits and receives Signaling messages by software through the PTPEDMAC.

30.3.5.2 Peer-to-Peer (P2P)

(1) Master

PTP messages are transmitted and received as described in Table 30.13 in operation as a Peer-to-Peer (P2P) master.

Table 30.13 Processing of PTP messages by a P2P master

	Signaling	Transmits and receives Signaling messages by software through the PTPEDMAC.

30.3.5.3 Ordinary Clock (OC)

PTP messages are transmitted and received through one Ethernet port in operation as an ordinary clock. An ordinary clock operates as the grand master clock or as a slave clock in the master-slave hierarchy. For operation as an E2E master, E2E slave, P2P master, or P2P slave, see the following sections:

- section 30.3.7, Operation as an E2E Master
- section 30.3.8, Operation as an E2E Slave
- section 30.3.10, Operation as a P2P Master
- section 30.3.11, Operation as a P2P Slave.

30.3.6 EPTPC Initialization

Transmitting and receiving PTP messages requires the settings in the EPTPC registers listed in Table 30.15. Set the registers associated with the Ethernet port used. Also set the registers listed in Table 30.16 if UDP and IPv4 are used for the frame format of the PTP messages.

Table 30.15 Registers requiring settings for EPTPC initialization (1 of 2)

Register name	Settings	Description
STCFR	Example: 0000_0002h	The value of 50 MHz is given as an example. Three other settings are also available.
SYCONFR	Example: 0000_0028h	The setting differs with the type of PTP clock operation.

SYSPVRR	0000_0002h	transportSpecific and version fields
SYDOMR	As wanted	—
SYCIDRU, SYCIDRL	As wanted	—
SYPNUMR	0000_0001h	If the PTP clock operates as an OC, the setting is 0000_0001h.
PPMACRU, PPMACRL	01:1B:19:00:00:00	MAC address for PTP-primary messages
PDMACRU, PDMACRL	01:80:C2:00:00:0E	MAC address for PTP-pdelay messages
DASYMRU, DASYMRL	0000_0000h	—
TSLATR	As wanted	Depends on the link transfer rate and STCA clock frequency

	Management	软件通过PTPEDMAC发送和接收管理消息。
	Signaling	软件通过PTPEDMAC发送和接收信令消息。

30.3.5.3 普通时钟(OC)

PTP消息通过一个以太网端口作为普通时钟进行传输和接收。普通时钟作为主时钟或主从层次结构中的从时钟运行。对于作为E2E主站、E2E从站、P2P主站或P2P从站的操作，请参阅以下部分：

- 第30.3.7节，作为E2E主站操作
- 第30.3.8节，作为E2E从站操作
- 第30.3.10节，作为P2P主机操作
- 第30.3.11节，作为P2P从站操作。

30.3.6 EPTPC Initialization

发送和接收PTP消息需要在表30.15中列出的EPTPC寄存器中进行设置。设置与使用的以太网端口相关的寄存器。如果UDP和IPv4用于PTP消息的帧格式，还要设置表30.16中列出的寄存器。

Figure 30.8 shows the procedure for settings to start operation as an E2E master.

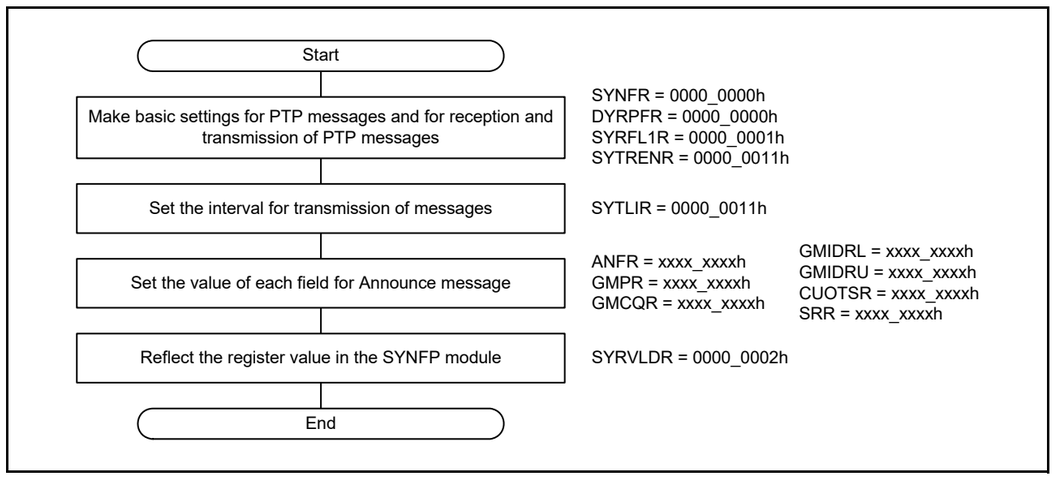

Figure 30.8 Procedure for starting operation as an E2E master

30.3.7.3 Procedure for changing the settings

Increases in the frequency of receiving Delay_Req messages caused by network conditions might lead to an overflow of the FIFO buffer that receives the Delay_Req messages. In such cases, change the value of the logMessageInterval field of Delay_Resp messages so that the slave sending the Delay_Req messages lengthens the interval between the messages. Figure 30.9 shows the procedure for changing the value of the logMessageInterval field.

30.3.8 Operation as an E2E Slave

30.3.8.1 Preparatory settings

Table 30.18 lists the registers for use in operation as an E2E slave. To reflect the value set in the register in SYNFP operations, you must set the SYRVLDR.STUP, ANUP, or BMUP bit to 1.

Note 1. During the reception of Delay_Resp messages by an E2E slave, the SYTLIR.DREQ[7:0] bits must be adjusted if the value of the SYRLIR.DRESP[7:0] flags is to be altered. The SYTLIR.DREQ[7:0] bits specify a value in the range from -7 to +6. Set the SYTLIR.DREQ[7:0] bits to -7 if the value indicated in the SYRLIR.DRESP[7:0] flags is less than or equal to -8 and to 6 if the value indicated in the SYRLIR.DRESP[7:0] flags is greater than or equal to 7.

30.3.8.3 Procedure for changing the settings

IEEE 1588 stipulates that the average interval for the transmission of Delay_Req messages must be adjusted in response to changes in the value of the logMessageInterval field of received Delay_Resp messages. The EPTPC sets the SYSR.INTCHG flag to 1 if the logMessageInterval value of a received message differs from that of the previous message. When this happens, the application must set the SYTLIR.DREQ[7:0] bits to the value in the SYRLIR.DRESP[7:0] bits. The SYTLIR.DREQ[7:0] bits specify a value in the range from -7 to +6. Set the SYTLIR.DREQ[7:0] bits to -7 if the value indicated in the SYRLIR.DRESP[7:0] flags is less than or equal to -8 and to 6 if the value indicated in the SYRLIR.DRESP[7:0] bits is greater than or equal to 7.

30.3.8.4 Procedure for stopping operations

Figure 30.13 shows the procedure for stopping operation as an E2E slave. To confirm that operation as an E2E slave is completely stopped, read the SYSR.GENDN flag to check that generation is completely stopped.

30.3.8.3 更改设置的步骤

IEEE1588规定，必须根据接收到的Delay_Resp消息的logMessageInterval字段值的变化来调整传输Delay_Req消息的平均间隔。如果接收到的消息的logMessageInterval值与前一个消息的值不同，则EPTPC将SYSR.INTCHG标志设置为1。发生这种情况时，应用程序必须将SYTLIR.DREQ[7:0]位设置为SYRLIR.DRESP[7:0]位中的值。SYTLIR.DREQ[7:0]位指定范围从-7到+6的值。设置

如果SYRLIR.DRESP[7:0]标志中指示的值小于或等于-8，则SYTLIR.DREQ[7:0]位为-7；如果SYRLIR.DRESP[7]中指示的值，则为6：0]位大于等于7。

30.3.9 P2P Operation (Shared by Master and Slave)

Table 30.19 lists the registers for use in P2P operation. When the EPTPC is to be operated with P2P protocol, the SYNFP module handles the processing of PTP-pdelay messages regardless of whether operation is as a master or slave. The interval for Pdelay_Req transmission and the parameters for monitoring of Pdelay_Resp messages must be set at the same time.

30.3.12 Monitoring of Received Messages

30.3.12.1 Reception of announce messages

The EPTPC does not detect timeouts during the reception of Announce messages. To detect timeouts, monitor the reception of Announce messages by software.

30.3.12.2 Reception of sync messages

The STSR.SYNTOUT flag is set to 1 when a timeout occurs during the reception of a Sync message while correcting time synchronization.

The SYSR.OFMUD flag is set to 1 when a Sync message is received, regardless of whether time synchronization is being corrected. Accordingly, the reception of Sync messages is detectable by referencing this flag even when the correction of time synchronization stops because a timeout occurs during the reception of a Sync message.

30.3.12.3 Reception of Delay_Resp and Pdelay_Resp messages

The SYSR.DRPTO flag is set to 1 when a timeout occurs during the reception of a Delay_Resp message after the transmission of a Delay_Req message while operating as an E2E slave, or when a timeout occurs during the reception of a Pdelay_Resp message after the transmission of a Pdelay_Req message while operating as a P2P.

The SYSR.MPDUD flag is set to 1 when a Delay_Resp or Pdelay_Resp message is received, so the reception of these messages is still detectable when a timeout occurs during reception.

30.3.13 Correcting Time Synchronization

A slave detects differences in the clock gradient relative to the master clock. The offsetFromMaster values calculated using the standard IEEE 1588 algorithm are used to calculate the clock gradient, so the result includes elements of network fluctuation that are not frequency differences. The EPTPC has a worst-10 function to eliminate fluctuations caused by network load and other dynamic conditions. With these functions, the time is corrected from the calculated gradient difference values and results of correction are obtained as shown in Figure 30.21.

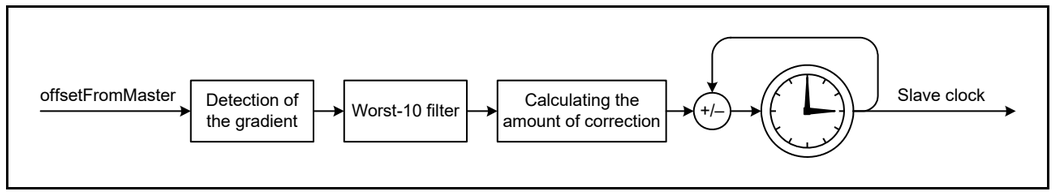

Figure 30.20 Configuration of the time correction circuit

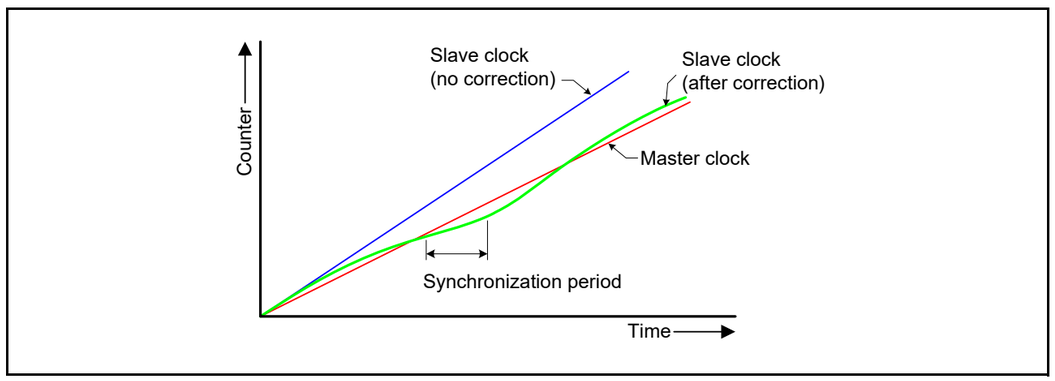

Figure 30.21 Overview of time correction

30.3.12 监控收到的消息

30.3.12.1 接收公告信息

EPTPC在接收Announce消息期间不检测超时。要检测超时，请监控软件对Announce消息的接收。

30.3.12.2 接收同步消息

当在纠正时间同步时接收同步消息期间发生超时时，STSR.SYNTOUT标志设置为1。

当接收到同步消息时，SYSR.OFMUD标志设置为1，无论时间同步是否正在被纠正。因此，即使在时间同步的校正由于在接收同步消息期间发生超时而停止时，也可以通过参考该标志来检测同步消息的接收。

30.3.12.3 接收Delay_Resp和Pdelay_Resp消息

SYSR.DRPTO标志设置为1，当在作为E2E从机运行时发送Delay_Req消息后接收Delay_Resp消息期间发生超时时，或者当在传输后接收Pdelay_Resp消息期间发生超时时作为P2P操作时的Pdelay_Req消息。

当接收到Delay_Resp或Pdelay_Resp消息时，SYSR.MPDUD标志设置为1，因此当接收期间发生超时时，仍可检测到这些消息的接收。

30.3.13 校正时间同步

从设备检测时钟梯度相对于主时钟的差异。使用标准IEEE1588算法计算的offsetFromMaster值用于计算时钟梯度，因此结果包括不是频率差异的网络波动元素。EPTPC具有最差10功能，可消除由网络负载和其他动态条件引起的波动。使用这些函数，根据计算出的梯度差值校正时间，并获得校正结果，如图30.21所示。

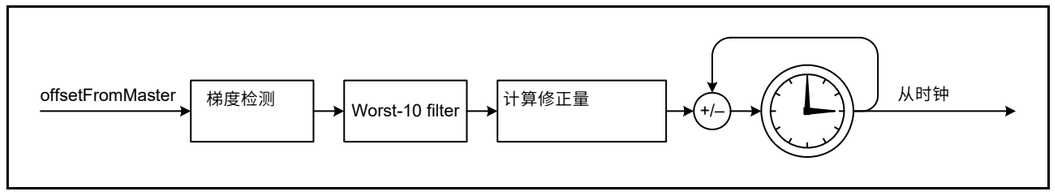

Figure 30.20 时间校正电路的构成

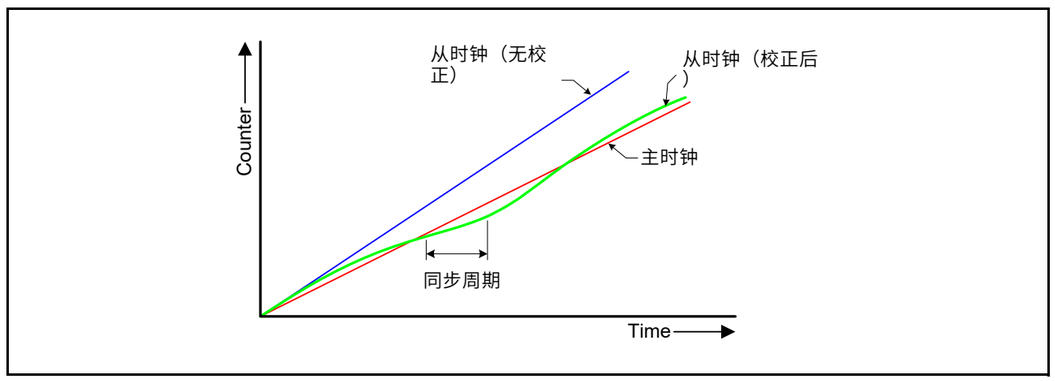

Figure 30.21 时间校正概述

30.3.13.1 Determining synchronization and loss of synchronization

Loss of synchronization is detected if the absolute value of offsetFromMaster reaches or exceeds the value specified in the SYNTDARU or SYNTDARL register. Synchronization is considered maintained if the absolute value of offsetFromMaster is less than the absolute values of the synchronization detection threshold registers, SYNTDBRU and SYNTDBRL.

The STSR.SYNCOUT flag is set to 1 when synchronization is lost, and the SYNC flags is set to 1 when synchronization is obtained. Hysteresis can be obtained by setting the threshold registers to appropriate different values. In addition, the STMR.DVTH[3:0] and SYTH[3:0] bits can be used to set the consecutive number of times detection must occur for the determination of synchronization and loss of synchronization.

For systems in which control must be aborted if synchronization is lost because of fluctuations in network conditions, set the SYNTDARU and SYNTDARL registers to low values and set the number of times detection is required to trigger a loss of synchronization to one. In systems where these conditions do not apply, set the SYNTDARU and SYNTDARL registers and the number of times detection is required to large values.

Figure 30.22 shows an example of a situation where synchronization is lost and regained. In this example, the number of consecutive times detection is required is three for both synchronization and loss of synchronization.

Note: The setting of the STSR.SYNCOUT flag is 1 when time synchronization starts, even if the condition for determining loss of synchronization is not satisfied at this stage. For this reason, detection of loss of synchronization must be ignored immediately after time synchronization starts.

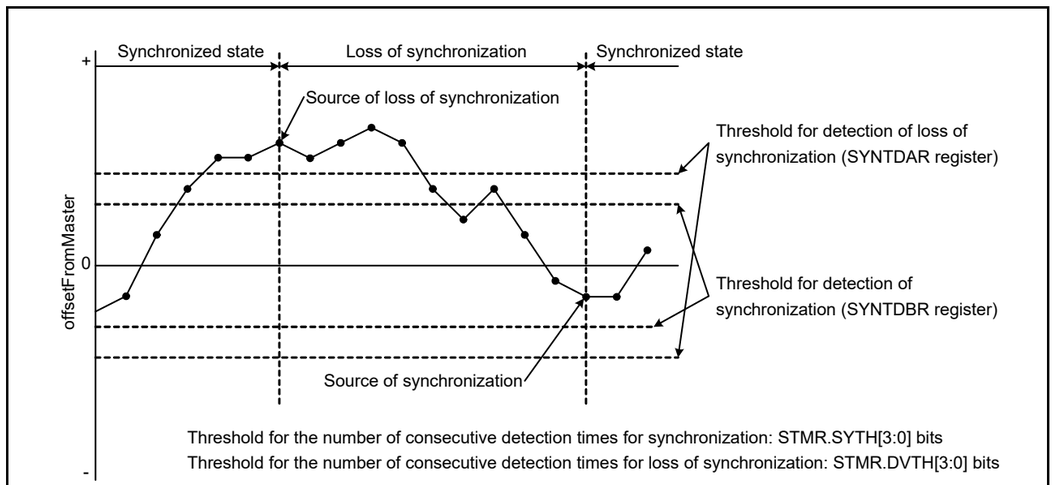

Figure 30.22 Example of a situation where synchronization is lost and regained, when the number of consecutive detections is set to three in the STMR.DVTH[3:0] and SYTH[3:0] bits

30.3.13.2 Worst-10 function

The worst-10 function is used to impose limits on exceedingly large and small values among the calculated values for clock gradient differences. These values are collected by observing the transfer over a specified interval, and threshold values to impose limits are extracted from the observed values. Fluctuations in network conditions must be considered in addition to clock errors, and differences in both the positive and negative directions are collected, as shown in Figure 30.23.

The function selects the largest gradient values from the collected values for positive and negative gradient differences, orders them from first to tenth (worst to tenth worst), and uses the tenth worst as a threshold value. Fluctuations in the time kept by a slave clock can be suppressed by continually overwriting the tenth worst value with new values large enough to exceed the threshold. Periodic collections of gradient values can also be made for updating the threshold values during operations or for using the method of setting threshold values from previously measured results.

30.3.13.1 确定同步和同步丢失

如果offsetFromMaster的绝对值达到或超过SYNTDARU或SYNTDARL寄存器中指定的值，则检测到同步丢失。如果offsetFromMaster的绝对值小于同步检测阈值寄存器SYNTDBRU和SYNTDBRL的绝对值，则认为保持同步。

STSR.SYNCOUT标志在同步丢失时设置为1，而SYNC标志在获得同步时设置为1。可以通过将阈值寄存器设置为适当的不同值来获得滞后。此外，STMR.DVTH[3:0]和SYTH[3:0]位可用于设置必须发生的连续检测次数，以确定同步和同步丢失。

对于如果由于网络条件波动而失去同步而必须中止控制的系统，请将SYNTDARU和SYNTDARL寄存器设置为低值，并将触发同步丢失所需的检测次数设置为1。在不适用这些条件的系统中，将SYNTDARU和SYNTDARL寄存器以及需要检测的次数设置为较大的值。

图30.22显示了同步丢失和重新获得的情况的示例。在本例中，同步和失步都需要连续检测3次。

Note: 当时间同步开始时，STSR.SYNCOUT标志的设置为1，即使在此阶段不满足确定同步丢失的条件。因此，必须在时间同步开始后立即忽略同步丢失的检测。

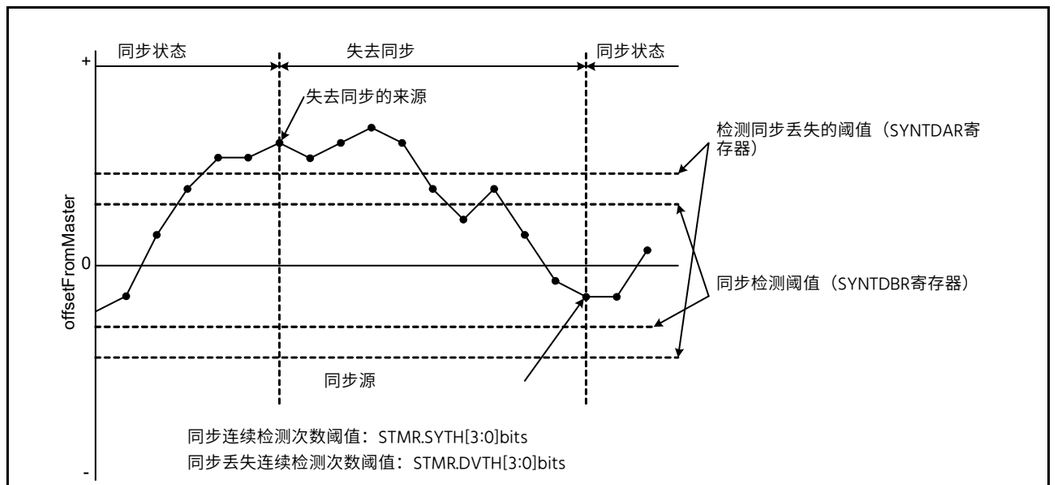

Figure 30.22 当STMR.DVTH[3:0]和SYTH[3:0]位中的连续检测数设置为3时，同步丢失和重新获得的情况示例

30.3.13.2 Worst-10 function

最差10函数用于对时钟梯度差的计算值中的极大值和极小值施加限制。这些值是通过在指定的时间间隔内观察传输来收集的，并且从观察值中提取施加限制的阈值。除了时钟误差外，还必须考虑网络条件的波动，收集正负两个方向的差异，如图30.23所示。

该函数从收集的正负梯度差值中选择最大的梯度值，将它们从第一个到第十个（最差到第十个最差）排序，并使用第十个最差作为阈值。从时钟保持的时间波动可以通过用大到足以超过阈值的新值连续覆盖第十个最差值来抑制。梯度值的定期收集也可以用于在操作期间更新阈值或使用根据先前测量结果设置阈值的方法。

However, while fluctuations in the time kept by a slave clock can be suppressed by the valid filtering of values for gradient difference (collecting the worst 10 values and using the tenth worst), this slows down the following of time kept by a master clock.

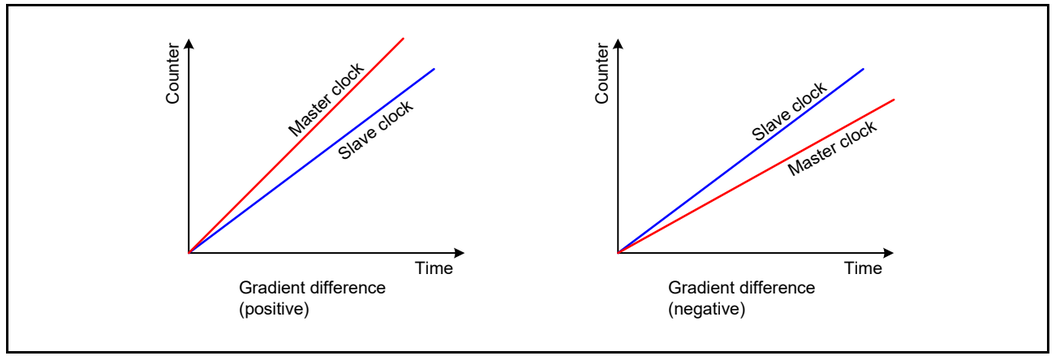

Figure 30.23 Overview of gradient differences

30.3.13.3 Collecting differences in clock gradient and extracting the worst ten values

During slave operation, the EPTPC can calculate the offsetFromMaster values from received messages and calculate gradient differences between the local clock (acting as a slave clock) and master clock from those values. Specifically, the worst ten values are extracted from the sets of collected values for gradient difference. Either automatic filtering by the hardware or software-triggered filtering can be designated for acquisition of the sets of the worst 10 values. Figure 30.24 gives an overview of the collection of gradient difference values.

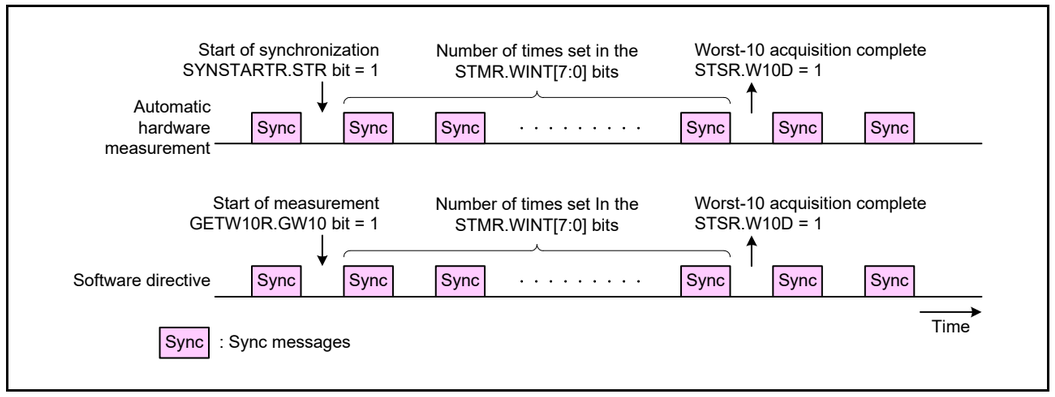

Figure 30.24 Overview of the collection of gradient difference values

(1) Collecting gradient differences and extracting the worst ten values by hardware

The EPTPC automatically collects the gradient difference values by hardware if the STMR.W10S bit is 0.

When the SYNSTARTR.STR bit is set to 1 (starting slave time synchronization), the EPTPC collects gradient difference values for the number of times set in the STMR.WINT[7:0] bits. When the collection of gradient difference values is finished, the tenth largest values on the positive and negative sides are stored as the tenth worst values in the PW10VRU, PW10VRM, and PW10VRL registers and the MW10RU, MW10RM, and MW10RL registers. When acquisition of the worst 10 values completes, the STSR.W10D flag sets to 1. Filtering of gradient difference values by using the stored tenth worst values then proceeds automatically.

If the number of times set in the STMR.WINT[7:0] bits is less than ten, the double of the best of the collected values on the positive side is stored in the PW10VRU, PW10VRM, and PW10VRL registers. The half of the best of the collected values on the negative side is stored in the MW10RU, MW10RM, and MW10RL registers.

然而，虽然从时钟保持的时间波动可以通过梯度差值的有效过滤（收集最差的10个值并使用第十个最差的值）来抑制，但这会减慢主时钟保持的时间跟踪。

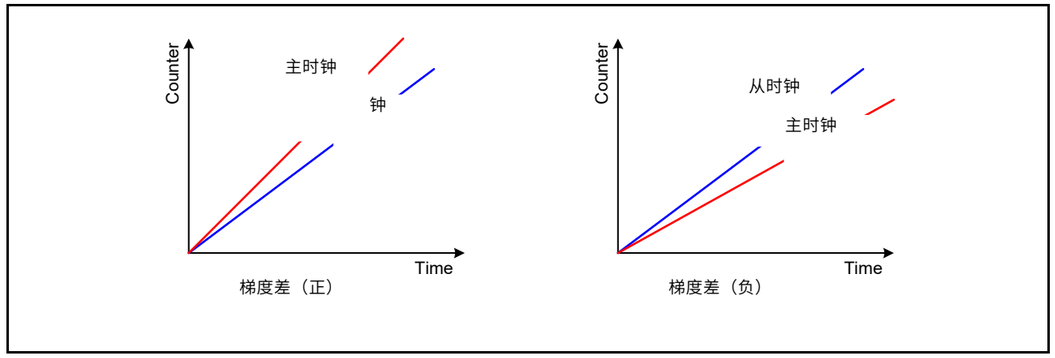

Figure 30.23 梯度差异概述

30.3.13.3 收集时钟梯度的差异并提取最差的十个值

在从属操作期间，EPTPC可以根据接收到的消息计算offsetFromMaster值，并根据这些值计算本地时钟（充当从属时钟）和主时钟之间的梯度差。具体而言，从梯度差的收集值集中提取最差的十个值。可以指定硬件自动过滤或软件触发过滤来获取最差的10个值的集合。图30.24给出了梯度差值集合的概览。

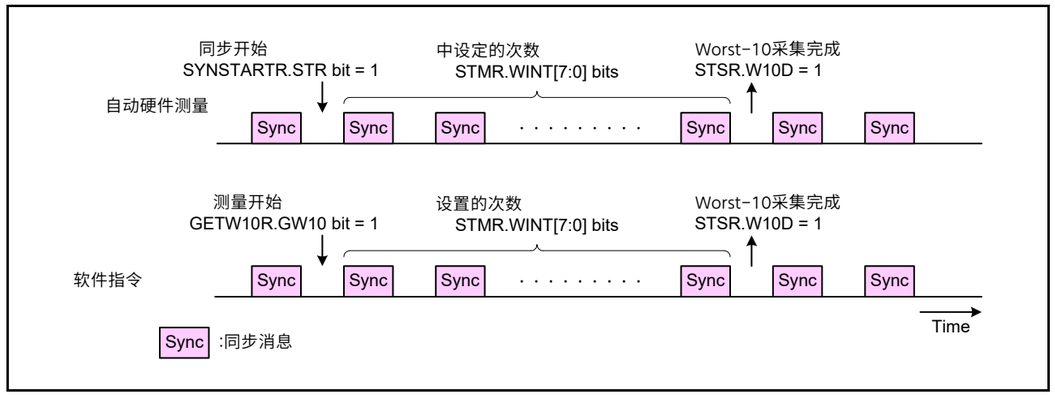

Figure 30.24 梯度差值收集概述

(1) 收集梯度差异并通过硬件提取最差的十个值

如果STMR.W10S位为0，EPTPC会通过硬件自动收集梯度差值。

当SYNSTARTR.STR位设置为1（启动从属时间同步）时，EPTPC收集在STMR.WINT[7:0]位中设置的次数的梯度差值。梯度差值采集完成后，正负侧第10个最大值作为第10个最差值存储在PW10VRU、PW10VRM和PW10VRL寄存器和MW10RU、MW10RM和MW10RL寄存器中。当最差10个值的采集完成时，STSR.W10D标志设置为1。然后使用存储的第10个最差值过滤梯度差值，然后自动进行。

如果在STMR.WINT[7:0]位中设置的次数小于10，则正侧收集的最佳值的两倍存储在PW10VRU、PW10VRM和PW10VRL寄存器中。负侧收集的最佳值的一半存储在MW10RU、MW10RM和MW10RL寄存器中。

(2) Collecting gradient differences and extracting the worst ten values by software

The EPTPC collects gradient difference values by software if the STMR.W10S bit is 1.

When the GETW10R.GW10 bit is set to 1 after time synchronization starts, the EPTPC collects gradient difference values for the number of times set in the STMR.WINT[7:0] bits. When the collection of gradient difference values is finished, the tenth largest values on the positive and negative sides are stored as the tenth worst values in the PW10VRU, PW10VRM, and PW10VRL registers and the MW10RU, MW10RM, and MW10RL registers. When acquisition of the worst 10 values completes, the STSR.W10D flag is set to 1.

Because filtering of gradient difference values proceeds with the values set in the PLIMITRU, PLIMITRM, and PLIMITRL registers as the upper filtering limits and the MLIMITRU, MLIMITRM, and MLIMITRL registers as the lower filtering limit, you must write the values stored in the PW10VRU, PW10VRM, and PW10VRL registers to PLIMITRU, PLIMITRM, and PLIMITRL, and write the values stored in the MW10RU, MW10RM, and MW10RL registers to MLIMITRU, MLIMITRM, and MLIMITRL.

If the number of times set in the STMR.WINT[7:0] bits is less than ten, the double of the best of the collected values on the positive is stored in the PW10VRU, PW10VRM, and PW10VRL registers. The half of the best of the collected values on the negative side is stored in the MW10RU, MW10RM, and MW10RL registers.

(2) 通过软件收集梯度差异并提取最差的十个值

如果STMR.W10S位为1，EPTPC通过软件收集梯度差值。

当GETW10R.GW10位在时间同步开始后设置为1时，EPTPC将收集STMR.WINT[7:0]位中设置的次数的梯度差值。梯度差值采集完成后，正负侧第10个最大值作为第10个最差值存储在PW10VRU、PW10VRM和PW10VRL寄存器和MW10RU、MW10RM和MW10RL寄存器中。当最差10个值的采集完成时，STSR.W10D标志设置为1。

因为梯度差值的过滤使用PLIMITRU、PLIMITRM和PLIMITRL寄存器作为滤波上限，MLIMITRU、MLIMITRM和MLIMITRL寄存器作为滤波下限，必须将PW10VRU、PW10VRM和PW10VRL寄存器中存储的值写入PLIMITRU、PLIMITRM和PLIMITRL，并将存储的值写入MW10RU、MW10RM和MW10RL寄存器中的MLIMITRU、MLIMITRM和MLIMITRL。

如果在STMR.WINT[7:0]位中设置的次数小于10，则正极上收集到的最佳值的两倍存储在PW10VRU、PW10VRM和PW10VRL寄存器中。负侧收集的最佳值的一半存储在MW10RU、MW10RM和MW10RL寄存器中。

The flow in Figure 30.25 shows an example of the procedure for software-triggered acquisition of the worst 10 values.

30.3.14 Local Clock Counter

The local clock counter retains the synchronized time information. The counter starts counting from 0 after the ETHERC is released from the module-stop state or the EPTPC is released from the software reset state. The local clock counter can then be set to any value. Figure 30.26 shows the procedure for setting the initial value in the local clock counter.

The time information kept by the local clock counter is also readable. Figure 30.27 shows the procedure for reading the time information kept by the local clock counter.

30.3.14 本地时钟计数器

本地时钟计数器保留同步的时间信息。ETHERC从模块停止状态释放或EPTPC从软件复位状态释放后，计数器从0开始计数。然后可以将本地时钟计数器设置为任何值。图30.26显示了在本地时钟计数器中设置初始值的过程。

本地时钟计数器保存的时间信息也是可读的。图30.27显示了读取本地时钟计数器保存的时间信息的过程。

30.3.15 Pulse Output Timer

The STCA module of the EPTPC incorporates six timers (pulse output timers 0 to 5) that operate independently of each other. The pulse output timers produce periodic pulses, and the rising or falling edges of these pulses can be used as interrupt requests or output to the ELC as event signals. The time at which a pulse output timer starts operating (t_{start}), and the period (t_c) and pulse width (t_w) of the output pulses, can be specified.

Figure 30.28 shows the timing of pulse output timer operation, and Table 30.22 lists the constraints on the settings.

30.3.15 脉冲输出定时器

EPTPC的STCA模块包含六个相互独立运行的定时器（脉冲输出定时器0到5）。脉冲输出定时器产生周期性脉冲，这些脉冲的上升沿或下降沿可用作中断请求或作为事件信号输出到ELC。可以指定脉冲输出定时器开始工作的时间(tstart)，以及输出脉冲的周期(tc)和脉冲宽度(tw)。

图30.28显示了脉冲输出定时器操作的时序，表30.22列出了设置的限制条件。

30.3.15.1 Procedure for setting a pulse output timer

Figure 30.29 shows the procedure for setting a pulse output timer.

Note: A timer does not produce periodic pulses if the time set in the TMSTTRUm and TMSTTRLm registers (m = 0 to 5) has elapsed. Set the time for a pulse output timer to start at a later time than that when the timer is set.

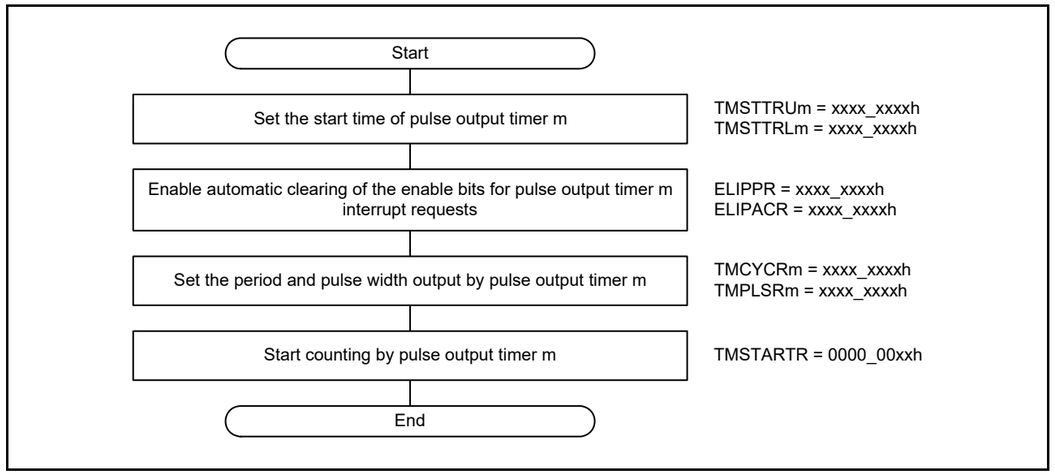

Figure 30.29 Procedure for setting a pulse output timer

30.3.15.2 Output of periodic pulses as interrupt requests or event signals

ETHER_MINT interrupt requests, ETHER_IPLS interrupt requests, or event output signals for the ELC can be generated on detection of rising or falling edges of the periodic pulses from the pulse output timer. The detection edge and the pulse output timer used are configurable, and automatic clearing of enable bits for the ETHER_IPLS interrupt or event output can be set. Make the required settings before setting the TMSTARTR.ENm bit to 1 (starting pulse output timer m).

(1) ETHER_MINT interrupt request

ETHER_MINT interrupt requests can be generated on rising edges of the periodic pulses from the pulse output timers. They cannot be generated on falling edges. Select the pulse output timers for generating these requests in the MITSELR.MINTENm bits. Automatic clearing of the enable bits for ETHER_MINT interrupt requests is not available.

(2) ETHER_IPLS interrupt request

ETHER_IPLS interrupt requests can be generated on either rising or falling edges of the periodic pulses from the pulse output timers. Select the pulse output timers for generating these requests in the IPTSELR.IPTSELm bits. Setting the ELIPACR.PLSP or PLSN bit enables automatic clearing of the enable bits for ETHER_IPLS interrupt requests.

(3) Output of event signals to the ELC

Event signals can be output to the ELC on either rising or falling edges of the periodic pulses from the pulse output timers. Select the pulse output timers for event signal output and the valid edge in the ELIPPR.CYCPm or CYCNm bits. Setting the ELIPACR.CYCPm or CYCNm bits enables automatic clearing of the event output enable bits.

图30.29显示了设置脉冲输出定时器的过程。

Note: 如果TMSTTRUm和TMSTTRLm寄存器（m=0到5）中设置的时间已过，则定时器不会产生周期性脉冲。将脉冲输出定时器的启动时间设置为比定时器设置的时间晚。

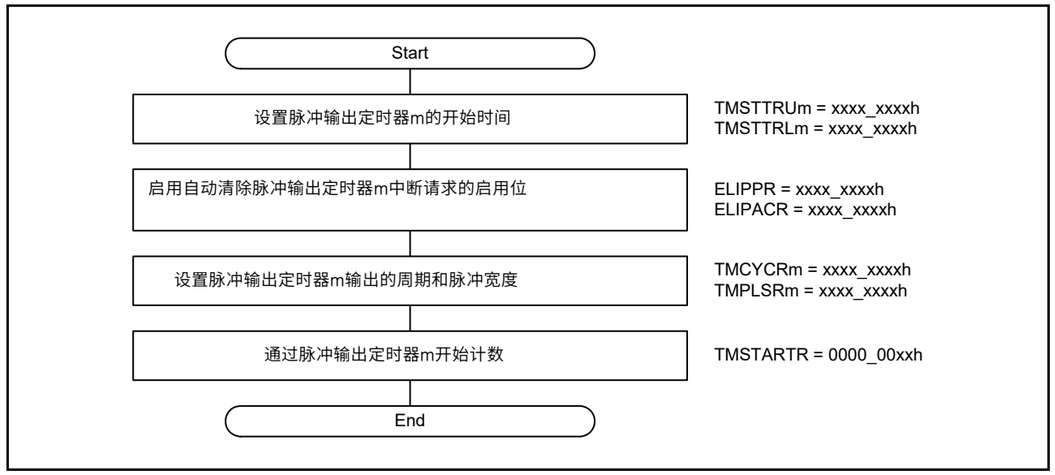

Figure 30.29 设置脉冲输出定时器的步骤

30.3.15.2 输出周期性脉冲作为中断请求或事件信号

ETHER_MINT中断请求、ETHER_IPLS中断请求或ELC的事件输出信号可以在检测到来自脉冲输出定时器的周期性脉冲的上升沿或下降沿时生成。使用的检测边沿和脉冲输出定时器是可配置的，并且可以设置ETHER_IPLS中断或事件输出的使能位的自动清除。在将TMSTARTR.ENm位设置为1（启动脉冲输出定时器m）之前进行所需的设置。

(1) ETHER_MINT中断请求

ETHER_MINT中断请求可以在来自脉冲输出定时器的周期性脉冲的上升沿产生。它们不能在下降沿生成。选择脉冲输出定时器以在

MITSELR.MINTENm位。无法自动清除ETHER_MINT中断请求的启用位。

(2) ETHER_IPLS中断请求

ETHER_IPLS中断请求可以在来自脉冲输出定时器的周期性脉冲的上升沿或下降沿产生。在IPTSELR.IPTSELm位中选择用于生成这些请求的脉冲输出定时器。设置ELIPACR.PLSP或PLSN位可以自动清除ETHER_IPLS中断请求的启用位。

(3) 向ELC输出事件信号

事件信号可以在脉冲输出定时器的周期脉冲的上升沿或下降沿输出到ELC。在ELIPPR.CYCPm或CYCNm位中选择事件信号输出的脉冲输出定时器和有效边沿。设置ELIPACR.CYCPm或CYCNm位可以自动清除事件输出使能位。

30.3.16.2 确保传输同步消息的带宽

EPTPC为同步消息的传输确保带宽，并且能够以非常精确的间隔处理传输。

如果Sync消息以固定间隔的传输与PTPEDMAC的传输同时进行，

because transmission of the Sync message proceeds when the other processing is complete, the interval for transmission is no longer fixed. Securing bandwidth for the transmission of Sync messages limits the transmission of messages from EDMAC0 and the PTPEDMAC, allowing Sync message transmission to be handled without fluctuations. To disable securing of bandwidth for Sync message transmission, set the SYCONFR.SBDIS bit to 1.

Figure 30.31 gives a schematic view of securing bandwidth for the transmission of Sync messages.

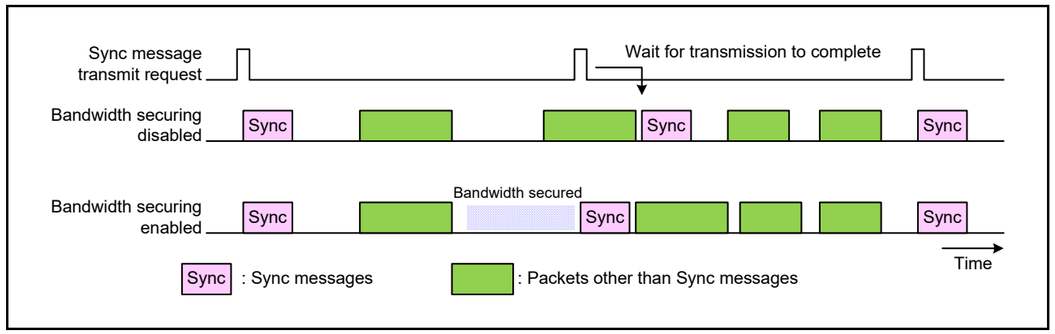

Figure 30.31 Securing of bandwidth for Sync message transmission

30.3.16.3 Securing of transmission interval

In the transmission of messages by the ETHERC, if there is a fixed delay from the time of a request for transmission to the time of transmission on the MII of Ethernet port 0, PTP message timestamps can be used for accurately obtaining the size of the delay during slave operation. However, for continuous transfer where processing of messages to wait for inter-packet gap times is required, delay times might fluctuate.

To enable the ETHERC to secure the reliability of timestamp values, specify an interval for frame transmission in the SYCONFR.TCYC[7:0] bits to control the interval between the completion of transmission and the next request for transmission. This avoids the effects of inter-packet gap times and a fixed delay for transmission.

30.4 Interrupts

The EPTPC provides the ETHER_MINT and ETHER_IPLS interrupt requests. Figure 30.32 shows the relationship between the two interrupt requests. Figure 30.33 shows the details on interrupt requests of the pulse output timer.

因为当其他处理完成时同步消息的传输继续，传输间隔不再是固定的。确保同步消息传输的带宽限制了来自EDMAC0和PTPEDMAC的消息传输，从而允许处理同步消息传输而不会出现波动。要禁用同步消息传输的带宽保护，请将SYCONFR.SBDIS位设置为1。

图30.31给出了为Sync消息的传输确保带宽的示意图。

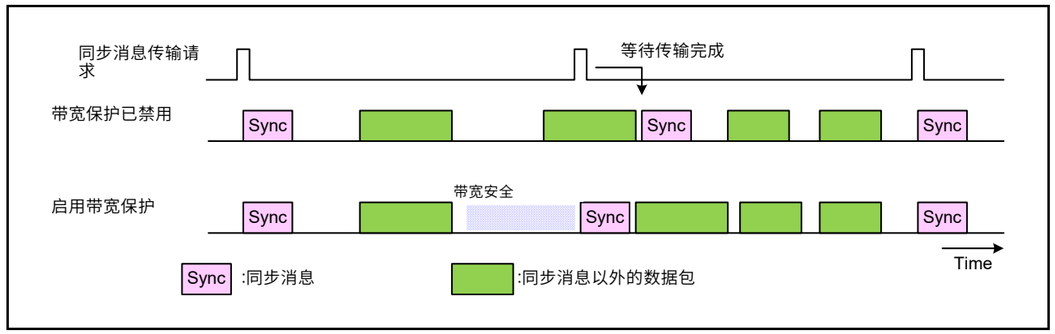

Figure 30.31 确保同步消息传输的带宽

30.3.16.3 确保传输间隔

在ETHERC传输消息时，如果从请求传输的时间到以太网端口0的MII上传输的时间之间存在固定的延迟，则可以使用PTP消息时间戳来准确获取延迟的大小在从属操作期间。但是，对于需要处理消息以等待包间间隙时间的连续传输，延迟时间可能会波动。

为了使ETHERC能够确保时间戳值的可靠性，请在SYCONFR.TCYC[7:0]位控制传输完成和下一次传输请求之间的间隔。这避免了包间间隙时间和传输的固定延迟的影响。

30.6 Usage Notes

30.6.1 Constraints on Register Access

When the EPTPC and PTPEDMAC operations are enabled (MSTPCRB.MSTPB13 = 0), some registers in the EPTPC become inaccessible depending on the setting combination of the MSTPCRB.MSTPB15 bit and EPTPC bypass bit (BYPASS.BYPASS0 bit). Table 30.24 to Table 30.25 summarize the constraints on access to the registers.

Table 30.24 Constraints on register access when no channels are bypassed (BYPASS.BYPASS0 = 0)

0	Accessible	Access prohibited	Access prohibited	Access prohibited
1	Accessible	Access prohibited	Access prohibited	Access prohibited

Note: Access to an access-prohibited register can lead to a bus timeout error. If a bus timeout error occurs, set the PTRSTR.RESET bit to 1 to reset the EPTPC by software.

30.6.2 Wait Cycles for Register Access

Access to registers in the EPTPC involves the arbitration of different clock signals, specifically the peripheral module clock signal (PCLKA), the STCA clock signal, and the MII clock signals such as TX_CLK. Accordingly, the number of wait cycles for register access differs depending on the combination of the frequency settings for these clock signals.

Table 30.26 gives examples of numbers of wait cycles for different combinations. Add 1 to 2 cycles to these values to obtain the number of access cycles.

Table 30.26 Wait cycles for register access when the STCA clock is 20 MHz

	STCA clock = 20 MHz							
	Peripheral module clock PCLKA = 120 MHz				Peripheral module clock PCLKA = 20 MHz

Note 1. The number of wait cycles in access to the STCA-related registers (W_{STCA}) can be calculated to the following range from the periods of the peripheral module clock ($t_{c(PCLKA)}$) and STCA clock ($t_{c(STCA)}$).
Minimum value of W_{STCA} = Int ($t_{c(STCA)}/t_{c(PCLKA)}$) × 2 + 15 ($t_{c(PCLKA)} \leq t_{c(STCA)}$)

30.6 使用说明

30.6.1 注册访问的限制

当EPTPC和PTPEDMAC操作被启用(MSTPCRB.MSTPB13=0)时，根据MSTPCRB.MSTPB15位和EPTPC旁路位(BYPASS.BYPASS0位)的设置组合，EPTPC中的一些寄存器变得不可访问。表30.24至表30.25总结了对寄存器访问的限制。

1	Accessible	禁止访问	禁止访问	禁止访问

Note: 访问禁止访问的寄存器会导致总线超时错误。如果发生总线超时错误，将PTRSTR.RESET位设置为1以通过软件复位EPTPC。

30.6.2 寄存器访问的等待周期

EPTPC中寄存器的访问涉及到不同时钟信号的仲裁，具体是外设模块时钟信号（PCLKA）、STCA时钟信号和TX_CLK等MII时钟信号。因此，寄存器访问的等待周期数取决于这些时钟信号的频率设置的组合。

表30.26给出了不同组合的等待周期数示例。将这些值加上1到2个周期以获得访问周期数。

Table 30.26 STCA时钟为20MHz时寄存器访问的等待周期

	STCA clock = 20 MHz							
	外设模块时钟PCLKA=120MHz				外设模块时钟PCLKA=20MHz			
	MII clock 25 MHz (100 Mbps)		MII clock 2.5 MHz (10 Mbps)		MII clock 25 MHz (100 Mbps)		MII clock 2.5 MHz (10 Mbps)

Note 1. 访问STCA相关寄存器的等待周期数(WSTCA)可以从外围模块时钟(tc(PCLKA))和STCA时钟(tc(STCA))的周期计算到以下范围。WSTCA的最小值

= 15 ($t_{c(PCLKA)} > t_{c(STCA)}$)

Maximum value of W_{STCA} = Int ($t_{c(STCA)}/t_{c(PCLKA)}$) × 4 + 17 ($t_{c(PCLKA)} \leq t_{c(STCA)}$)

= 17 ($t_{c(PCLKA)} > t_{c(STCA)}$)

- Int(A) is the calculation of the largest integer not greater than A.
- This calculation assumes that the CPU clock and peripheral module clock have the same periods.

For example, if the frequency of the peripheral module clock is 120 MHz and that of the STCA clock is 1/6 that of the peripheral module clock (= 20 MHz),

Minimum value of W_{STCA} = Int (50 [ns]/8.3 [ns]) × 2 + 15 = 27, and

Maximum value of W_{STCA} = Int (50 [ns]/8.3 [ns]) × 4 + 17 = 41.

If REF50CK0 is used as the STCA clock, the frequency of the STCA clock is 25 MHz.

Note 2. The number of wait cycles in access to the SYNFP-related registers (W_{SYNF}) can be calculated to the following range from the periods of the peripheral module clock ($t_{c(PCLKA)}$) and MII clock ($t_{c(MII)}$).

Minimum value of W_{SYNF} = Int ($t_{c(MII)}/t_{c(PCLKA)}$) × 2 + 15 ($t_{c(PCLKA)} \leq t_{c(MII)}$)

= 15 ($t_{c(PCLKA)} > t_{c(MII)}$)

Maximum value of W_{SYNF} = Int ($t_{c(MII)}/t_{c(PCLKA)}$) × 4 + 17 ($t_{c(PCLKA)} \leq t_{c(MII)}$)

= 17 ($t_{c(PCLKA)} > t_{c(MII)}$)

- Int(A) is the calculation of the largest integer not greater than A.
- This calculation assumes that the CPU clock and peripheral module clock have the same periods.

For example, if the frequency of the peripheral module clock is 120 MHz and the transmission rate is 10 Mbps (so the MII clock is running at 2.5 MHz),

Minimum value of W_{SYNF} = Int (400 [ns]/8.3 [ns]) × 2 + 15 = 111, and

Maximum value of W_{SYNF} = Int (400 [ns]/8.3 [ns]) × 4 + 17 = 209.

= 15 (t > t)

WSTCA的最大值=Int(tc(STCA)tc(PCLKA))×4+17(tc(PCLKA) tc(STCA))=17(tc(PCLKA)>tc(STCA))•Int(A)是不大于A的最大整数的计算。•该计算假设CPU时钟和外围模块时钟具有相同的周期。

例如，如果外围模块时钟频率为120MHz，STCA时钟频率为外围模块时钟频率的16(=20MHz)，则WSTCA的最小值

=整数(50[ns]8.3[ns])×2+15=27，并且

WSTCA的最大值=Int(50[ns]8.3[ns])×4+17=41。如果使用REF50CK0作为STCA时钟，则STCA时钟的频率为25MHz。

Note 2. 访问SYNFP相关寄存器的等待周期数(WSYNF)可以从外围模块时钟(tc(PCLKA))和MII时钟(tc(MII))的周期计算到以下范围。WSYNF的最小值

= 15 (t > t)

WSYNF的最大值=Int(tc(MII)tc(PCLKA))×4+17(tc(PCLKA) tc(MII))=17(tc(PCLKA)>tc(MII))•Int(A)是不大于A的最大整数的计算。•该计算假设CPU时钟和外围模块时钟具有相同的周期。

例如，如果外围模块时钟的频率为120MHz，传输速率为10Mbps（因此MII时钟运行在2.5MHz），

WSYNF的最小值 =整数(400[ns]8.3[ns])×2+15=111，并且

WSYNF的最大值 = Int (400 [ns]/8.3 [ns]) × 4 + 17 = 209.

31. Ethernet DMA Controller (EDMAC)

31.1 Overview

The MCU provides two channels for the Ethernet DMA Controller (EDMAC), one channel for the Ethernet Controller (ETHERC) and one channel for the Ethernet PTP Controller (EPTPC). EDMAC0 controls data transmission and reception for ETHERC0. The PTPEDMAC controls data transmission and reception for ETHERC0 based on the EPTPC settings.

The EDMAC controls most of the transmit and receive buffer management for communications. This reduces the load on the CPU and allows efficient data transmission and reception. The data transfers are controlled according to the information referred to as descriptors, in memory.

Table 31.1 lists the EDMAC specifications and Figure 31.1 shows the configuration. Figure 31.2 shows the configuration of descriptors and transmit and receive buffers in memory.

Table 31.1 EDMAC specifications

Parameter	Specifications
Data transmission and reception	• Controls data transmission and reception according to descriptors • Supports single buffer frame transmission and reception (1 buffer per frame) and multi-buffer frame transmission and reception (multiple buffers per frame)
Functions	• Minimizes system bus occupancy time using block transfer (32-byte units) • Writes back the transmit or receive frame state to descriptors • Inserts padding in receive data
Module-stop function	Module-stop state can be set to reduce power consumption

31. 以太网DMA控制器(EDMAC)

31.1 Overview

MCU为以太网DMA控制器(EDMAC)提供两个通道，一个为以太网控制器(ETHERC)提供一个通道，一个为以太网PTP控制器(EPTPC)提供一个通道。EDMAC0控制ETHERC0的数据传输和接收。PTPEDMAC根据EPTPC设置控制ETHERC0的数据传输和接收。

EDMAC控制大部分用于通信的发送和接收缓冲区管理。这减少了CPU的负载并允许高效的数据传输和接收。数据传输是根据内存中称为描述符的信息进行控制的。

表31.1列出了EDMAC规范，图31.1显示了配置。图31.2显示了内存中描述符以及发送和接收缓冲区的配置。

Table 31.1 EDMAC specifications

Parameter	Specifications
数据传输和接收	根据描述符控制数据发送和接收 支持单缓冲区帧发送和接收（每帧1个缓冲区）和多缓冲区帧发送和接收（每帧多个缓冲区）
Functions	使用块传输（32字节单位）最小化系统总线占用时间 将发送或接收帧状态写回描述符 在接收数据中插入填充
Module-stop function	可设置模块停止状态以降低功耗

b6	DE	Big Endian Mode/Little Endian Mode*1	0: Big endian mode 1: Little endian mode.	R/W
b31 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. This setting applies to data for the transmit and receive buffers. It does not apply to transmit and receive descriptors and registers.

The EDMR register controls EDMAC operation. Set the EDMR register during initialization process after a reset. When rewriting this register outside of the initialization process, set the SWR bit to 1 to reset the EDMAC and ETHERC, and then set this register again. If the ETHERC and EDMAC are reset during data transmission or reception, abnormal data might be sent on the line. Do not rewrite this register while the ETHERC transmit or receive function is enabled. It takes 64 cycles of the peripheral module clock (PCLKA) to initialize the ETHERC and EDMAC. Complete the initialization before accessing registers in the ETHERC and EDMAC.

Note 1. 此设置适用于发送和接收缓冲区的数据。它不适用于发送和接收描述符和寄存器。

EDMR寄存器控制EDMAC操作。在复位后的初始化过程中设置EDMR寄存器。在初始化过程之外重写该寄存器时，将SWR位设置为1以复位EDMAC和ETHERC，然后再次设置该寄存器。如果ETHERC和EDMAC在数据传输或接收过程中被复位，可能会在线路上发送异常数据。在启用ETHERC发送或接收功能时不要重写该寄存器。初始化ETHERC和EDMAC需要64个外围模块时钟(PCLKA)周期。在访问ETHERC和EDMAC中的寄存器之前完成初始化。

31.2.2 EDMAC Transmit Request Register (EDTRR)

Address(es): EDMAC0.EDTRR 4006 4008h, PTPEDMAC.EDTRR 4006 4408h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	TR	Transmit Request	When 1 is written, the EDMAC reads the associated descriptor and transmits frames where the TD0.TACT bit is 1. The TR bit clears to 0 after all the valid frames are transmitted. Writing 0 to this bit has no effect.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The EDTRR register controls EDMAC transmission. After the EDMAC transmits one frame, it reads the next descriptor. When the TD0.TACT bit in the descriptor is 1, the EDMAC continues transmission. When the TD0.TACT bit is 0, the EDMAC sets the TR bit to 0 and stops transmission.

31.2.3 EDMAC Receive Request Register (EDRRR)

Address(es): EDMAC0.EDRRR 4006 4010h, PTPEDMAC.EDRRR 4006 4410h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	RR	Receive Request	0: Disable the receive function*1 1: Read receive descriptor and enable the receive function.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. If the receive function is disabled during frame reception, write-back to the receive descriptor is not performed successfully. Subsequent pointers for reading a receive descriptor become abnormal and the EDMAC cannot operate normally. In this case, to enable the EDMAC receive function again, execute a software reset by setting the EDMR.SWR bit to 1.
To disable the EDMAC receive function without resetting the EDMAC, set the ETHERC0.ECMR.RE bit to 0. After the EDMAC completes reception and write-back to the receive descriptor is confirmed, set the RR bit to 0.

The EDRRR register controls EDMAC reception. When the RR bit sets to 1, the EDMAC reads the receive descriptor. When the RD0.RACT bit is 1, the EDMAC waits for a receive request from the ETHERC. When the EDMAC has received data for the receive buffer size, it reads the next descriptor and waits to receive a frame. If the RD0.RACT bit is 0, the EDMAC sets the RR bit to 0 and stops reception.

31.2.2 EDMAC发送请求寄存器(EDTRR)

b31 to b1	—	Reserved	这些位被读取为0。写入值应为0。	R/W

EDTRR寄存器控制EDMAC传输。EDMAC传输一帧后，读取下一个描述符。
当描述符中的TD0.TACT位为1时，EDMAC继续传输。当TD0.TACT位为0时，EDMAC将TR位设置为0并停止传输。

b0	RR	接收请求	0：关闭接收功能*11：读取接收描述符，开启接收功能。	R/W
b31 to b1	—	Reserved	这些位被读取为0。写入值应为0。	R/W

Note 1. 如果在帧接收期间禁用接收功能，则无法成功执行对接收描述符的回写。
后续读取接收描述符的指针异常，EDMAC不能正常工作。在这种情况下，要再次启用EDMAC接收功能，通过将EDMR.SWR位设置为1来执行软件复位。要禁用EDMAC接收功能而不重置EDMAC，请将ETHERC0.ECMR.RE位设置为0。EDMAC完成接收并确认回写到接收描述符，将RR位设置为0。

EDRRR寄存器控制EDMAC接收。当RR位设置为1时，EDMAC读取接收描述符。
当RD0.RACT位为1时，EDMAC等待来自ETHERC的接收请求。当EDMAC接收到接收缓冲区大小的数据时，它会读取下一个描述符并等待接收帧。如果RD0.RACT位为0，则EDMAC将RR位设置为0并停止接收。

b24	RFCOF	Receive Frame Counter Overflow Flag	0: Receive frame counter did not overflow 1: Receive frame counter overflowed.	R/W
b25	RABT	Receive Abort Detect Flag	0: Frame reception not aborted or no reception requested 1: Frame reception aborted.	R/W
b26	TABT	Transmit Abort Detect Flag	0: Frame transmission not aborted or no transmission requested. 1: Frame transmission aborted.	R/W
b29 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b30	TWB	Write-Back Complete Flag	0: Write-back not complete or no transmission requested 1: Write-back to the transmit descriptor completed.	R/W
b31	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. The ECI flag is read-only. When the source in the ETHERC0.ECSR register is cleared, the ECI flag is also cleared.
Note 2. When an address error is detected, the EDMAC halts the process. To resume operation, set the EDMR.SWR bit to 1 (resetting the EDMAC and ETHERC), and then reconfigure the EDMAC and ETHERC.

The EDMAC0.EESR register indicates the ETHERC and EDMAC communication status. Each flag in the EESR register can be output as an interrupt request signal (ETHER_EINT0) from the EDMAC. Writing 1 clears all of the flags except ECI to 0. Writing 0 does not affect any of the flag values. The interrupt sources are enabled by setting the associated bits in the EDMAC0.EESIPR register.

CERF flag (CRC Error Flag)

The CERF flag sets to 1 when an error is detected while checking the frame check sequence (FCS) field of the receive frame.

PRE flag (PHY-LSI Receive Error Flag)

The PRE flag indicates that the RX_ER signal output from the PHY-LSI is high.

RTSF flag (Frame-Too-Short Error Flag)

The RTSF flag indicates that a received frame is less than 64 bytes.

RTLF flag (Frame-Too-Long Error Flag)

The RTLF flag indicates that a received frame is greater than the upper limit of the receive frame length set in the ETHERC0.RFLR register. The excess data is discarded.

RRF flag (Alignment Error Flag)

The RRF flag indicates that a frame is not an integral number of octets. The last word that is not an integral number of octets is not transferred.

RMAF flag (Multicast Address Frame Receive Flag)

The RMAF flag indicates that a multicast frame was received.

TRO flag (Transmit Retry Over Flag)

The TRO flag indicates that a collision occurred again during the 15th retry of frame transmission.

CD flag (Late Collision Detect Flag)

The CD flag indicates that a late collision was detected during frame transmission.

DLC flag (Loss of Carrier Detect Flag)

The DLC flag indicates that a loss of carrier was detected during frame transmission.

Bit	Symbol	位名称	Description	R/W
b22	ECI	ETHERC状态寄存器源 Flag	0：未检测到ETHERC状态中断源1：检测到ETHERC状态中断源。	R*1
b23	ADE	地址错误标志	0：未检测到无效内存地址（正常操作）1：检测到无效内存地址。*2	R/W
b24	RFCOF	接收帧计数器溢出 Flag	0：接收帧计数器未溢出1：接收帧计数器溢出。	R/W
b25	RABT	接收中止检测标志	0：未中止帧接收或未请求接收1：中止帧接收。	R/W
b26	TABT	发送中止检测标志	0：帧传输未中止或未请求传输。1：帧传输中止。	R/W
b29 to b27	—	Reserved	这些位被读取为0。写入值应为0。	R/W
b30	TWB	回写完成标志	0：回写未完成或未请求传输1：对传输描述符的回写完成。	R/W
b31	—	Reserved	该位读取为0。写入值应为0。	R/W

Note 1. ECI标志是只读的。当ETHERC0.ECSR寄存器中的源被清除时，ECI标志也被清除。
Note 2. 当检测到地址错误时，EDMAC会停止该过程。要恢复操作，请将EDMR.SWR位设置为1（重置EDMAC和ETHERC），然后重新配置EDMAC和ETHERC。

EDMAC0.EESR寄存器指示ETHERC和EDMAC通信状态。EESR寄存器中的每个标志都可以作为中断请求信号（ETHER_EINT0）从EDMAC输出。写入1会将除ECI之外的所有标志清除为0。写入0不会影响任何标志值。通过设置EDMAC0.EESIPR寄存器中的相关位来启用中断源。

CERF标志（CRC错误标志）

当在检查接收帧的帧校验序列(FCS)字段时检测到错误时，CERF标志设置为1。

PRE标志（PHY-LSI接收错误标志）

PRE标志表示从PHY-LSI输出的RX_ER信号为高电平。

RTSF标志（Frame-Too-ShortErrorFlag）

RTSF标志表示接收到的帧小于64字节。

RTLF标志（帧过长错误标志）

RTLF标志表示接收到的帧大于设置的接收帧长度的上限ETHERC0.RFLR寄存器。多余的数据被丢弃。

RRF标志（对齐错误标志）

RRF标志表明一个帧不是整数个八位字节。不是整数八位字节的最后一个字不被传送。

RMAF标志（组播地址帧接收标志）

RMAF标志指示接收到多播帧。

TRO标志（传输重试结束标志）

TRO标志表示在第15次帧传输重试期间再次发生冲突。

CD标志（后期碰撞检测标志）

CD标志表示在帧传输期间检测到后期冲突。

DLC标志（丢失载波检测标志）

DLC标志表示在帧传输期间检测到载波丢失。

CND flag (Carrier Not Detect Flag)

The CND flag sets to 1 when a carrier is not detected during preamble transmission.

RFOF flag (Receive FIFO Overflow Flag)

The RFOF flag indicates that the receive FIFO overflowed during frame reception.

RDE flag (Receive Descriptor Empty Flag)

The RDE flag indicates that the read receive descriptor is invalid. When this flag sets to 1, set the RD0.RACT bit in the receive descriptor to 1 and set the EDRRR.RR bit to 1 to resume reception.

FR flag (Frame Receive Flag)

The FR flag indicates that a frame was received and the receive descriptor was updated. The FR flag sets to 1 every time a frame is received.

TFUF flag (Transmit FIFO Underflow Flag)

The TFUF flag indicates that no data remains in the transmit FIFO during frame transmission. Incomplete data is sent to the line.

TDE flag (Transmit Descriptor Empty Flag)

The TDE flag indicates that the TD0.TACT bit of the transmit descriptor is 0 while the previous transmit descriptor indicates that the frame is not complete (TD0.TFP[1:0] bits are 10b or 00b) in multi-buffer frame transmission. As a result, an incomplete frame might be sent.

When this flag sets to 1, perform a software reset and then set the EDTRR.TR bit to 1 to resume transmission. Transmission starts from the address stored in the TDLAR register.

TC flag (Frame Transfer Complete Flag)

The TC flag indicates that all the data specified in the transmit descriptor was transmitted from the ETHERC. This flag sets to 1 when one frame was transmitted in single-buffer frame transmission or when the last data of a frame is transmitted in multi-buffer frame transmission and the TD0.TACT bit in the next transmit descriptor is 0. After frame transmission is complete, the EDMAC writes the transfer status back to the descriptor.

ECI flag (ETHERC Status Register Source Flag)

The ECI flag sets to 1 when an interrupt request is generated by the ETHERC.ECSR register.

ADE flag (Address Error Flag)

The ADE flag indicates that the memory address that the EDMAC tried to use for transfer is invalid.

RFCOF flag (Receive Frame Counter Overflow Flag)

The RFCOF flag indicates that the next frame reception started while the number of frames stored in the receive FIFO reached the maximum number of frames (16 frames). The received frame is discarded while the RFCOF flag is 1.

RABT flag (Receive Abort Detect Flag)

The RABT flag indicates that the ETHERC aborted frame reception because of a CRC error, PHY-LSI receive error, frame-too-short error, frame-too-long error, or other error.

TABT flag (Transmit Abort Detect Flag)

The TABT flag indicates that the ETHERC aborted frame transmission because of transmit retry over, loss of carrier, no carrier detection, or other error.

TWB flag (Write-Back Complete Flag)

The TWB flag indicates the EDMAC completed writing back to the descriptor after frame transmission. This flag sets to 1 after each frame transmission when the TRIMD.TIM bit is 0. It only sets to 1 when the TRIMD.TIS bit is 1.

CND标志（载波未检测标志）

当在前导码传输期间未检测到载波时，CND标志设置为1。

RFOF标志（接收FIFO溢出标志）

RFOF标志表示接收FIFO在帧接收期间溢出。

RDE标志（接收描述符空标志）

RDE标志指示读取的接收描述符无效。当该标志设置为1时，将接收描述符中的RD0.RACT位设置为1，并将EDRRR.RR位设置为1以恢复接收。

FR标志（帧接收标志）

FR标志表示接收到一个帧并且接收描述符已更新。每次接收到一帧时，FR标志设置为1。

TFUF标志（发送FIFO下溢标志）

TFUF标志表示在帧传输期间没有数据保留在传输FIFO中。不完整的数据被发送到线路。

TDE标志（传输描述符空标志）

TDE标志表示发送描述符的TD0.TACT位为0，而前一个发送描述符表示在多缓冲区帧传输中该帧未完成（TD0.TFP[1:0]位为10b或00b）。因此，可能会发送不完整的帧。

当该标志设置为1时，执行软件复位，然后将EDTRR.TR位设置为1以恢复传输。
传输从存储在TDLAR寄存器中的地址开始。

TC标志（帧传输完成标志）

TC标志表示发送描述符中指定的所有数据都是从ETHERC发送的。当在单缓冲帧传输中传输一帧或在多缓冲帧传输中传输一帧的最后一个数据并且下一个传输描述符中的TD0.TACT位为0时，此标志设置为1。完成后，EDMAC将传输状态写回描述符。

ECI标志（ETHERC状态寄存器源标志）

当ETHERC.ECSR寄存器产生中断请求时，ECI标志设置为1。

ADE标志（地址错误标志）

ADE标志表示EDMAC尝试用于传输的内存地址无效。

RFCOF标志（接收帧计数器溢出标志）

RFCOF标志表示在接收FIFO中存储的帧数达到最大帧数（16帧）时开始下一帧接收。当RFCOF标志为1时，接收到的帧被丢弃。

RABT标志（接收中止检测标志）

RABT标志指示ETHERC由于CRC错误、PHY-LSI接收错误、帧太短错误、帧太长错误或其他错误而中止帧接收。

TABT标志（发送中止检测标志）

TABT标志指示ETHERC由于传输重试、载波丢失、未检测到载波或其他错误而中止帧传输。

TWB标志（回写完成标志）

TWB标志表示EDMAC在帧传输后完成写回描述符。当TRIMD.TIM位为0时，此标志在每帧传输后设置为1。仅当TRIMD.TIS位为1时设置为1。

Note 1. When an address error is detected, the EDMAC halts the process. To resume operation, set the EDMR.SWR bit to 1 (resetting the EDMAC and ETHERC), and then reconfigure the EDMAC and ETHERC.

The PTPEDMAC.EESR register indicates the PTPEDMAC communication status. Each flag in the EESR register can be output as an interrupt request signal (ETHER_PINT) from the PTPEDMAC. Writing 1 clears the flags to 0. Writing 0 does not affect the flag values. All of the interrupt sources, except for the TYPE[3:0] flag, are enabled by setting the associated bits in the PTPEDMAC.EESIPR register.

TYPE[3:0] flags (PTP v2 Message Type Flag)

The TYPE[3:0] flags indicate the type of received PTP message.

PVER flag (PTP v2 Packet Flag)

The PVER flag indicates whether the received packet is a PTP v2 packet.

MACE flag (MAC Address Mismatch Flag)

The MACE flag indicates that the source MAC address is different from the set value.

RFOF flag (Receive FIFO Overflow Flag)

The RFOF flag indicates that the receive FIFO overflowed during frame reception.

RDE flag (Receive Descriptor Empty Flag)

The RDE flag indicates that the read receive descriptor is invalid. When this flag sets to 1, set the RD0.RACT bit in the receive descriptor to 1 and set the EDRRR.RR bit to 1 to resume reception.

FR flag (Frame Receive Flag)

The FR flag indicates that a frame was received and the receive descriptor was updated. The FR flag sets to 1 every time a frame is received.

TFUF flag (Transmit FIFO Underflow Flag)

The TFUF flag indicates that no data remains in the transmit FIFO during frame transmission. Incomplete data is sent to the line.

TDE flag (Transmit Descriptor Empty Flag)

The TDE flag indicates that the TD0.TACT bit of the transmit descriptor is 0 while the previous transmit descriptor indicates that the frame is not complete (TD0.TFP[1:0] bits are 10b or 00b) in multi-buffer frame transmission. As a result, an incomplete frame might be sent.

When this flag sets to 1, perform a software reset and then set the EDTRR.TR bit to 1 to resume transmission. Transmission starts from the address stored in the TDLAR register.

TC flag (Frame Transfer Complete Flag)

The TC flag indicates that all the data specified in the transmit descriptor was transmitted from the ETHERC. This flag sets to 1 when one frame is transmitted in single-buffer frame transmission or when the last data of a frame is transmitted in multi-buffer frame transmission and the TD0.TACT bit in the next transmit descriptor is 0. After frame transmission is complete, the PTPEDMAC writes the transfer status back to the descriptor.

ADE flag (Address Error Flag)

The ADE flag indicates that the memory address that the PTPEDMAC tried to use for transfer is invalid.

Bit	Symbol	位名称	Description	R/W
b26	TABT	发送中止检测标志	0：未中止帧传输或未请求传输1：中止帧传输。	R/W

b31	—	Reserved	该位读取为0。写入值应为0。	R/W

Note 1. 当检测到地址错误时，EDMAC会停止该过程。要恢复操作，请将EDMR.SWR位设置为1（重置EDMAC和ETHERC），然后重新配置EDMAC和ETHERC。

PTPEDMAC.EESR寄存器指示PTPEDMAC通信状态。EESR寄存器中的每个标志都可以作为来自PTPEDMAC的中断请求信号(ETHER_PINT)输出。写入1会将标志清除为0。写入0不会影响标志值。除TYPE[3:0]标志外，所有中断源都通过设置PTPEDMAC.EESIPR寄存器中的相关位来启用。

TYPE[3:0]标志（PTPv2消息类型标志）

TYPE[3:0]标志指示接收到的PTP消息的类型。

PVER标志（PTPv2数据包标志）

PVER标志指示接收到的数据包是否是PTPv2数据包。

MACE标志（MAC地址不匹配标志）

MACE标志表示源MAC地址与设置值不同。

RFOF标志（接收FIFO溢出标志）

RFOF标志表示接收FIFO在帧接收期间溢出。

RDE标志（接收描述符空标志）

RDE标志指示读取的接收描述符无效。当该标志设置为1时，将接收描述符中的RD0.RACT位设置为1，并将EDRRR.RR位设置为1以恢复接收。

FR标志（帧接收标志）

FR标志表示接收到一个帧并且接收描述符已更新。每次接收到一帧时，FR标志设置为1。

TFUF标志（发送FIFO下溢标志）

TFUF标志表示在帧传输期间没有数据保留在传输FIFO中。不完整的数据被发送到线路。

TDE标志（传输描述符空标志）

TDE标志表示发送描述符的TD0.TACT位为0，而前一个发送描述符表示在多缓冲区帧传输中该帧未完成（TD0.TFP[1:0]位为10b或00b）。因此，可能会发送不完整的帧。

当该标志设置为1时，执行软件复位，然后将EDTRR.TR位设置为1以恢复传输。
传输从存储在TDLAR寄存器中的地址开始。

TC标志（帧传输完成标志）

TC标志表示发送描述符中指定的所有数据都是从ETHERC发送的。当在单缓冲帧传输中传输一帧或在多缓冲帧传输中传输一帧的最后一个数据并且下一个传输描述符中的TD0.TACT位为0时，此标志设置为1。完成后，PTPEDMAC将传输状态写回描述符。

ADE标志（地址错误标志）

ADE标志指示PTPEDMAC尝试用于传输的内存地址无效。

RFCOF flag (Receive Frame Counter Overflow Flag)

The RFCOF flag indicates that the next frame reception started while the number of frames stored in the receive FIFO reached the maximum number of frames (16 frames). Received frames are discarded while the RFCOF flag is 1.

TABT flag (Transmit Abort Detect Flag)

The TABT flag indicates that the ETHERC aborted frame transmission because of transmit retry over, loss of carrier, no carrier detection, or other error.

TWB flag (Write-Back Complete Flag)

The TWB flag indicates that the PTPEDMAC completed writing back to the descriptor after frame transmission. This flag sets to 1 after each frame transmission when the TRIMD.TIM bit is 0. It only sets to 1 when the TRIMD.TIS bit is 1.

RFCOF标志（接收帧计数器溢出标志）

RFCOF标志表示在接收FIFO中存储的帧数达到最大帧数（16帧）时开始下一帧接收。RFCOF标志为1时丢弃接收的帧。

TABT标志（发送中止检测标志）

TABT标志指示ETHERC由于传输重试、载波丢失、未检测到载波或其他错误而中止帧传输。

TWB标志（回写完成标志）

TWB标志表明PTPEDMAC在帧传输后完成了对描述符的写回。当TRIMD.TIM位为0时，此标志在每帧传输后设置为1。仅当TRIMD.TIS位为1时设置为1。

The EDMAC0.TRSCER register selects whether the receive status indicated in the EDMAC0.EESR.RMAF and RRF flags is reflected in the RFE bit of the receive descriptor as a summary. The bits in this register are associated with bits in the EESR register that have the same number. When the RMAFCE or RRFCE bit is set to 0, the associated receive status is reflected in the RFE bit. When the RMAFCE or RRFCE bit is set to 1, the associated receive status is not reflected.

Bit	Symbol	Bit name	Description	R/W
b15 to b0	MFC[15:0]	Missed-Frame Counter	These bits indicate the number of frames that are discarded and not transferred to the receive buffer during reception.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The RMFCR register indicates that the number of frames that could not be stored in the receive FIFO and so were discarded during reception. When the receive FIFO overflows, it stops receiving data, and the rest of frames are discarded. At the same time, the RMFCR register value is incremented. When the RMFCR register value reaches FFFFh, count-up is halted. Writing any value to the RMFCR register clears the counter value to 0.

For frames that are not completely received, after data in the receive FIFO is transferred to the receive buffer, the RACT bit in the receive descriptor 0 (RD0) clears to 0 (descriptor disabled), the RFS9 bit sets to 1 (receive FIFO overflowed), and the EDMAC0.EESR.RFOF or PTPEDMAC.EESR.RFOF flag sets to 1 (overflow detected).

b31 to b16	—	Reserved	这些位被读取为0。写入值应为0。	R/W

RMFCR寄存器指示无法存储在接收FIFO中并因此在接收期间被丢弃的帧数。当接收FIFO溢出时，它停止接收数据，其余帧被丢弃。同时，RMFCR寄存器值递增。当RMFCR寄存器值达到FFFFh时，停止向上计数。向RMFCR寄存器写入任何值都会将计数器值清零。

对于未完全接收的帧，接收FIFO中的数据传输到接收缓冲区后，接收描述符0（RD0）中的RACT位清为0（描述符禁用），RFS9位设置为1（接收FIFO溢出），并且EDMAC0.EESR.RFOF或PTPEDMAC.EESR.RFOF标志设置为1（检测到溢出）。

b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When starting transmission before one frame data is completely written, take care to prevent an underflow. To prevent a transmit underflow, Renesas recommends using the initial value (store-and-forward mode).

The TFTR register specifies the transmit FIFO threshold at which the first transmission starts. The actual threshold is the set value multiplied by 4.

The ETHERC starts transmission when the amount of data in the transmit FIFO exceeds the number of bytes set in this register, when the transmit FIFO is full, or when one frame of data is completely written. Set the TFTR register while the EDTRR.TR bit is 0.

b31 to b11	—	Reserved	这些位被读取为0。写入值应为0。	R/W

Note: 在完全写入一帧数据之前开始传输时，请注意防止下溢。为防止发送下溢，瑞萨推荐使用初始值（存储转发模式）。

TFTR寄存器指定第一次发送开始时的发送FIFO阈值。实际阈值是设定值乘以4。

当发送FIFO中的数据量超过此寄存器中设置的字节数、发送FIFO已满或一帧数据被完全写入时，ETHERC开始发送。当EDTRR.TR位为0时设置TFTR寄存器。

b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The FDR register specifies the transmit and receive FIFO depths. Set this register to 0000_070Fh before starting transmission and reception.

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	RNR	Receive Request Reset	0: EDRRR.RR bit (receive request bit) is cleared to 0 when one frame is received 1: EDRRR.RR bit (receive request bit) is not cleared to 0 when one frame is received.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The RMCR register specifies how to control the EDRRR.RR bit when receiving a frame. When the RNR bit is 0, the EDRRR.RR bit clears to 0 when one frame is received, so it must be set to 1 by software to receive the subsequent frame. When the RNR bit is 1, the EDRRR.RR bit does not clear to 0 when one frame is received, and the EDMAC reads the next receive descriptor and continues frame reception. Renesas recommends setting the RNR bit to 1 when receiving data continuously. Set the RMCR register while the EDRRR.RR bit is 0.

b31 to b1	—	Reserved	这些位被读取为0。写入值应为0。	R/W

RMCR寄存器指定接收帧时如何控制EDRRR.RR位。当RNR位为0时，
EDRRR.RR位在接收到一帧后清为0，因此必须通过软件设置为1才能接收后续帧。
当RNR位为1时，接收到一帧时EDRRR.RR位不清为0，EDMAC读取下一个接收描述符并继续帧接收。Renesas建议在连续接收数据时将RNR位设置为1。当EDRRR.RR位为0时设置RMCR寄存器。

b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The IOSR register selects the output level of the ETHERC external output pin (ET0_EXOUT) in external loopback mode. The ELB bit value is output on the ET0_EXOUT pin, which can be used to set loopback mode for the PHY-LSI. To use the loopback function of the PHY-LSI through this register, you must connect the PHY-LSI to the ET0_EXOUT pin.

R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The FCFTR register specifies the ETHERC flow control. Set the threshold to automatically transmit a PAUSE frame. The threshold can be set using the data size (RFDO[2:0] bits) and the number of frames (RFFO[2:0] bits) stored in the receive FIFO. Flow control starts when the stored data size or the number of stored frames reaches its threshold.

The RBWAR register indicates the last address that the EDMAC wrote data to when writing to the receive buffer. Check the contents of this register to identify which address in the receive buffer the EDMAC is writing data to. The address that the EDMAC is outputting to the receive buffer might not match the read value of the RBWAR register during data reception. The RBWAR register is read-only. Do not write to this register.

31.3 Operation

The EDMAC transfers data according to the information written in the descriptor. Two descriptors are provided: transmit and receive. A descriptor includes the buffer size, address, and transmit or receive status. The EDMAC transmits or receives data continuously by using sequentially arranged descriptors.

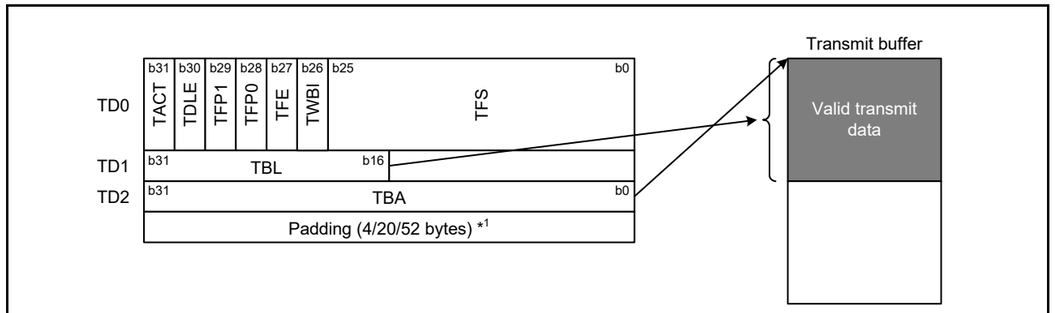
31.3.1 Descriptor Lists and Data Buffers

To transfer data using the EDMAC, create the transmit and receive descriptor lists in memory, set the start address of the transmit descriptor list in the TDLAR register, and set the start address of the receive descriptor list in the RDLAR register. Also, transmit and receive buffers associated with each descriptor are required.

Align the descriptor list on the appropriate address boundary according to the descriptor length set in the EDMR.DL[1:0] bits. The transmit buffer can be aligned on a word boundary, halfword boundary, or byte boundary. When the valid transmit buffer size is 16 bytes or less, align it on a 32-byte boundary. Align the receive buffer on a 32-byte boundary. Set different addresses for the transmit and receive descriptors and buffers for EDMAC0 and the PTPEDMAC.

31.3.1.1 Transmit descriptor

Figure 31.3 shows the relationship between a transmit descriptor and transmit buffer. A transmit descriptor consists of TD0 to TD2. The transmit frame and transmit buffer configuration can be specified as one buffer per frame (single-buffer frame transmission) or multiple buffers per frame (multi-buffer frame transmission) by setting the transmit descriptor.



Note 1. The padding size is determined by the descriptor length (16/32/64 bytes).

Figure 31.3 Relationship between transmit descriptor and transmit buffer

31.3 Operation

EDMAC根据描述符中写入的信息传输数据。提供了两个描述符：发送和接收。描述符包括缓冲区大小、地址和发送或接收状态。EDMAC通过使用顺序排列的描述符连续发送或接收数据。

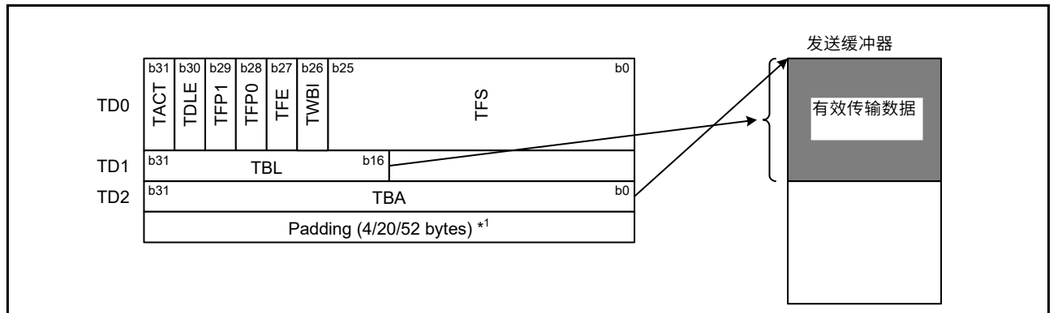
31.3.1 描述符列表和数据缓冲区

要使用EDMAC传输数据，在内存中创建发送和接收描述符列表，在TDLAR寄存器中设置发送描述符列表的起始地址，在RDLAR寄存器中设置接收描述符列表的起始地址。此外，还需要与每个描述符关联的发送和接收缓冲区。

根据在EDMR.DL[1:0]位中设置的描述符长度将描述符列表对齐在适当的地址边界上。发送缓冲区可以在字边界、半字边界或字节边界上对齐。当有效发送缓冲区大小为16字节或更少时，将其对齐在32字节边界上。在32字节边界上对齐接收缓冲区。为EDMAC0和PTPEDMAC的发送和接收描述符和缓冲区设置不同的地址。

31.3.1.1 传输描述符

图31.3显示了发送描述符和发送缓冲区之间的关系。发送描述符由TD0到TD2组成。通过设置传输描述符，可以将传输帧和传输缓冲区配置指定为每帧一个缓冲区（单缓冲区帧传输）或每帧多个缓冲区（多缓冲区帧传输）。



Note 1. 填充大小由描述符长度（163264字节）确定。

(1) Transmit descriptor 0 (TD0)

Bit	Symbol	Bit name	Description	R/W
b25 to b0	TFS	Transmit Frame Status	Set all bits to 0 when creating a descriptor. After write-back, the bits indicate the following: • For EDMAC0: TFS25 to TFS9: Reserved TFS8: Transmit abort was detected (value is equivalent to the EESR.TABT flag) TFS7 to TFS4: Reserved TFS3: No carrier was detected (value is equivalent to the EESR.CND flag) TFS2: Loss of carrier was detected (value is equivalent to the EESR.DLC flag) TFS1: Late collision during transmission was detected (value is equivalent to the EESR.CD flag) TFS0: Transmit retry over (value is equivalent to the EESR.TRO flag). When a bit sets to 1, it indicates that the associated error occurred during frame transmission. When any of the TFS bits sets to 1, the TFE bit also sets to 1. When any of bits TFS3 to TFS0 sets to 1, TFS8 also sets to 1. • For the PTPEDMAC: TFS25 to TFS9: Reserved TFS8: Transmit abort was detected (value is equivalent to the EESR.TABT flag) TFS7 to TFS1: Reserved TFS0: The transmission source MAC address of the transmit frame data did not match the set value (value is equivalent to the EESR.MACE flag). When a bit sets to 1, it indicates that the associated error occurred during frame transmission. When any of the TFS bits sets to 1, the TFE bit also sets to 1. When TFS0 sets to 1, TFS8 also sets to 1.	R/W
b26	TWBI	Write-Back Complete Interrupt Enable	0: Do not generate interrupt when write-back to this descriptor is complete 1: Generate interrupt when write-back to this descriptor is complete.	R/W
b27	TFE	Transmit Frame Error	0: Frame transmission is successfully complete 1: Error occurred during frame transmission (transmission aborted).	R/W
b29, b28	TFP[1:0]	Transmit Frame Position	b29 b28 0 0: Transmit buffer indicated in this descriptor is the middle of a transmit frame (frame information is incomplete) 0 1: Transmit buffer indicated in this descriptor is the end of a transmit frame (frame information is complete) 1 0: Transmit buffer indicated in this descriptor is the head of a transmit frame (frame information is incomplete) 1 1: Transmit buffer indicated in this descriptor is all of a transmit frame (one buffer per frame).	R/W
b30	TDLE	Transmit Descriptor List End	When this bit is 1, it indicates that this descriptor is the last in the descriptor list.	R/W
b31	TACT	Transmit Descriptor Valid	This bit indicates that this descriptor is valid.	R/W

Note: Bits for write-back are underlined.

TD0 specifies the transmit frame settings and indicates the status after transmission.

TFE bit (Transmit Frame Error)

When the TFE bit is 1, it indicates that any of the TFS bits is 1.

TFP[1:0] bits (Transmit Frame Position)

The TFP[1:0] bits indicate which part of a transmit frame corresponds to the transmit buffer indicated in this descriptor. The TFP[1:0] and TD1.TBL bit settings must be logically consistent in the previous and next descriptors.

(1) 发送描述符0(TD0)

Bit	Symbol	位名称	Description	R/W
b25 to b0	TFS	发送帧状态	创建描述符时将所有位设置为0。回写后，这些位指示以下内容： 对于EDMAC0：TFS25到TFS9：保留 TFS8：检测到发送中止（值相当于EESR.TABT flag) TFS7到TFS4：保留 TFS3：未检测到载波（值相当于EESR.CND标志）TFS2：检测到载波丢失（值相当于EESR.DLC flag) TFS1：在传输过程中检测到后期冲突（值相当于EESR.CD标志）TFS0：传输重试结束（值相当于EESR.TRO标志）。当某个位设置为1时，表示在帧传输期间发生了相关错误。当任何TFS位设置为1时，TFE位也设置为1。当任何位TFS3到TFS0设置为1时，TFS8也设置为1。 对于PTPEDMAC：TFS25到TFS9：保留 TFS8：检测到发送中止（值相当于EESR.TABT flag) TFS7到TFS1：保留 TFS0：发送帧数据的发送源MAC地址与设定值不匹配（值相当于EESR.MACE标志）。 当某个位设置为1时，表示在帧传输期间发生了相关错误。当任何TFS位设置为1时，TFE位也设置为1。当TFS0设置为1时，TFS8也设置为1。	R/W
b26	TWBI	Write-Back Complete 中断使能	0：回写该描述符完成时不产生中断1：回写该描述符完成时产生中断。	R/W
b27	TFE	传输帧错误	0：帧传输成功完成1：帧传输过程中发生错误（传输中止）。	R/W
b29, b28	TFP[1:0]	发送帧位置	b29b2800：此描述符中指示的传输缓冲区是传输帧的中间（帧信息不完整）01：此描述符中指示的传输缓冲区是传输帧的结尾（帧信息完整）10：传输此描述符中指示的缓冲区是传输帧的头部（帧信息不完整）11：此描述符中指示的传输缓冲区是一个传输帧的全部（每帧一个缓冲区）。	R/W
b30	TDLE	传输描述符列表结束	当该位为1时，表示该描述符是描述符列表中的最后一个。	R/W
b31	TACT	传输描述符有效	该位指示该描述符有效。	R/W

Note: 用于回写的位带有下划线。

TD0指定传输帧设置并指示传输后的状态。

TFE位（发送帧错误）

当TFE位为1时，表示任何TFS位为1。

TFP[1:0]位（发送帧位置）

TFP[1:0]位指示发送帧的哪一部分对应于该描述符中指示的发送缓冲区。
TFP[1:0]和TD1.TBL位设置在前一个和下一个描述符中必须在逻辑上一致。

TACT bit (Transmit Descriptor Valid)

The TACT bit indicates that this descriptor is valid. The TACT bit is set to 1 by software. This bit clears to 0 when the transmit frame is transferred or when the transmission is aborted.

(2) Transmit descriptor 1 (TD1)

Bit	Symbol	Bit name	Description	R/W
b15 to b0	—	Reserved	The read value is 0. The write value should be 0.	R/W
b31 to b16	TBL	Transmit Buffer Length	Specifies the valid byte length of the associated transmit buffer. Set a value equal to or greater than 1.	R/W

TD1 specifies the valid byte length of the transmit buffer.

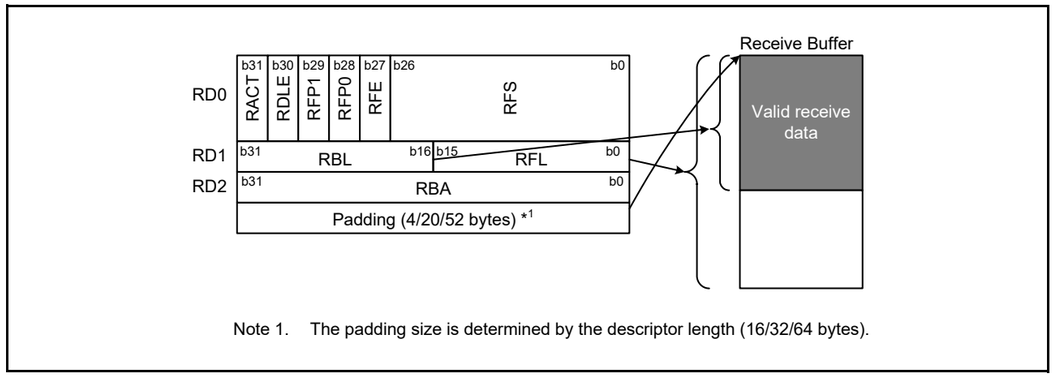
(3) Transmit descriptor 2 (TD2)

Bit	Symbol	Bit name	Description	R/W
b31 to b0	TBA	Transmit Buffer Address	Specifies the start address of the transmit buffer. When the TD1.TBL bit value is 1 to 16 bytes, align it on a 32-byte boundary.	R/W

TD2 specifies the start address of the transmit buffer.

31.3.1.2 Receive descriptor

Figure 31.4 shows the relationship between a receive descriptor and receive buffer. The receive frame and receive buffer configuration can be specified as one buffer per frame (single-buffer frame transmission) or multiple buffers per frame (multi-buffer frame transmission) by setting the receive descriptor. If the receive buffer length (RBL) is set to 0, operation indicated in the descriptor is not guaranteed.



Note 1. The padding size is determined by the descriptor length (16/32/64 bytes).

Figure 31.4 Relationship between receive descriptor and receive buffer

TACT位（发送描述符有效）

TACT位指示该描述符是有效的。TACT位由软件设置为1。当传输帧被传输或传输被中止时，该位清零。

(2) 传输描述符1(TD1)

Bit	Symbol	位名称	Description	R/W
b15 to b0	—	Reserved	读取值为0。写入值应为0。	R/W
b31 to b16	TBL	发送缓冲区长度	指定相关传输缓冲区的有效字节长度。设置一个等于或大于1的值。	R/W

TD1指定发送缓冲区的有效字节长度。

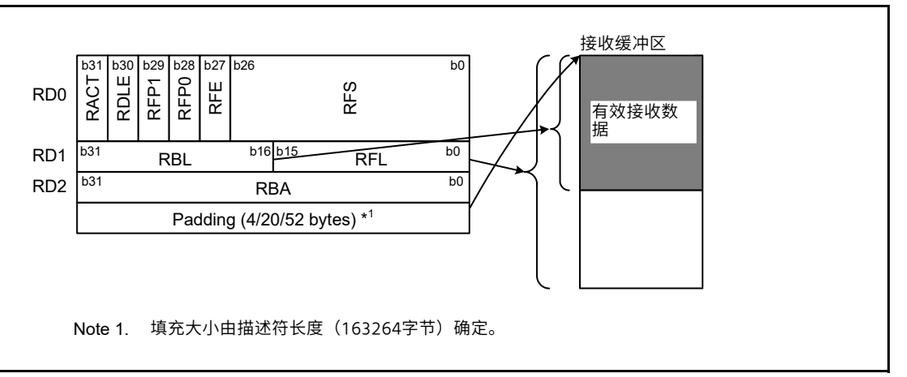
(3) 传输描述符2(TD2)

Bit	Symbol	位名称	Description	R/W
b31 to b0	TBA	发送缓冲区地址	指定发送缓冲区的起始地址。当TD1.TBL位值为1到16字节时，将其对齐在32字节边界上。	R/W

TD2指定发送缓冲区的起始地址。

31.3.1.2 接收描述符

图31.4显示了接收描述符和接收缓冲区之间的关系。通过设置接收描述符，可以将接收帧和接收缓冲区配置指定为每帧一个缓冲区（单缓冲区帧传输）或每帧多个缓冲区（多缓冲区帧传输）。如果接收缓冲区长度(RBL)设置为0，则无法保证描述符中指示的操作。



Note 1. 填充大小由描述符长度（163264字节）确定。

(1) Receive descriptor 0 (RD0)

Bit	Symbol	Bit name	Description	R/W
b26 to b0	RFS	Receive Frame Status	Set all bits to 0 when creating a descriptor. After write-back, the bits indicate the following: • For EDMAC0: RFS26 to RFS10: Reserved RFS9: Receive FIFO overflow (value is equivalent to the EESR.RFOF flag) RFS8: Receive abort was detected (value is equivalent to the EESR.RABT flag) RFS7: Multicast address frame was received (value is equivalent to the EESR.RMAF flag) RFS6 and RFS5: Reserved RFS4: Alignment error was detected (value is equivalent to the EESR.RRF flag) RFS3: Frame-too-long error (value is equivalent to the EESR.RTLF flag) RFS2: Frame-too-short error (value is equivalent to the EESR.RTSF flag) RFS1: PHY-LSI receive error (value is equivalent to the EESR.PRE flag) RFS0: CRC error (value is equivalent to the EESR.CERF flag). When a bit sets to 1, it indicates that the associated error occurred during frame reception. When any of the RFS bits sets to 1, the RFE bit also sets to 1. (Set the TRSCER register to select whether bits RFS7 and RFS4 are reflected in the RFE bit.) When any of bits RFS3 to RFS0 sets to 1, RFS8 also sets to 1. • For the PTPEDMAC: RFS26 to RFS10: Reserved RFS9: Receive FIFO overflow (value is equivalent to the EESR.RFOF flag) RFS8: Reserved RFS4: PTPV2 packet was received (value is equivalent to the EESR.PVER flag) (The PTPEDMAC can only receive PTP packets. If a non-PTP packet is received, the packet is not transferred to the PTPEDAC, and it is discarded.) RFS3 to RFS0: Type of the received PTP message (value is equivalent to the EESR.TYPE[3:0] flags). Each bit indicates the status of the received frame.	R/W
b27	RFE	Receive Frame Error	• For EDMAC0: 0: No error occurred in the received frame 1: Error occurred in the received frame. • For the PTPEDMAC: Reserved.	R/W
b29, b28	RFP[1:0]	Receive Frame Position	b29 b28 0 0: Receive buffer indicated in this descriptor is the middle of a receive frame (frame information is incomplete) 0 1: Receive buffer indicated in this descriptor is the end of a receive frame (frame information is complete) 1 0: Receive buffer indicated in this descriptor is the head of a receive frame (frame information is incomplete) 1 1: Receive buffer indicated in this descriptor is all of a receive frame (one buffer per frame).	R/W
b30	RDLE	Receive Descriptor List End	When this bit is 1, it indicates that this descriptor is the last in the descriptor list.	R/W
b31	RACT	Receive Descriptor Valid	Indicates that this descriptor is valid.	R/W

Note: Bits for write-back are underlined.

RD0 indicates the receive frame status.

RFE bit (Receive Frame Error)

When the RFE bit is 1, it indicates that any of the RFS bits is 1. Set the TRSCER register to select whether the RFS7 and RFS4 bits of EDMAC0 are reflected in the RFE bit.

RFP[1:0] bits (Receive Frame Position)

The RFP[1:0] bits indicate which part of a receive frame corresponds to the receive buffer indicated in this descriptor.

(1) 接收描述符0(RD0)

Bit	Symbol	位名称	Description	R/W
b26 to b0	RFS	接收帧 Status	创建描述符时将所有位设置为0。回写后，这些位指示以下内容： 对于EDMAC0：RFS26到RFS 10：保留 RFS9：接收FIFO溢出（值相当于EESR.RFOF标志） RFS8：检测到接收中止（值等同于EESR.RABT标志） RFS7：收到多播地址帧（值相当于 EESR.RMAF flag) RFS6和RFS5：保留 RFS4：检测到对齐错误（值等同于EESR.RRF标志） RFS3：帧过长错误（值相当于EESR.RTLF标志）RFS2：帧过短错误（值相当于EESR.RTSF标志）RFS1：PHY-LSI接收错误（值相当于EESR.PRE标志） RFS0：CRC错误（值相当于EESR.CERF标志）。 当某个位设置为1时，表示在帧接收期间发生了相关错误。当任何RFS位设置为1时，RFE位也设置为1。（设置TRSCER寄存器以选择位RFS7和RFS4是否反映在RFE位中。）当任何位RFS3至RFS0设置为1时，RFS8也设置为1。 对于PTPEDMAC：RFS26到R FS10：保留 RFS9：接收FIFO溢出（值相当于EESR.RFOF标志） RFS8: Reserved RFS4:PTPV2packetwasreceived（值相当于EESR.PVER标志）（PTPEDMAC只能接收PTP数据包，如果接收到非PTP数据包，则该数据包不会传输到PTPEDAC，会被丢弃。）RFS3到RFS0：接收到的PTP消息的类型（值相当于 EESR.TYPE[3:0] flags). 每个位表示接收帧的状态。	R/W
b27	RFE	接收帧错误	对于EDMAC0：0：接收帧中没有发生错误1：接收帧中发生错误。 对于PTPEDMAC：保留 。	R/W
b29, b28	RFP[1:0]	接收帧 Position	b29b2800：此描述符中指示的接收缓冲区是接收帧的中间（帧信息不完整）01：此描述符中指示的接收缓冲区是接收帧的结尾（帧信息完整）10：接收此描述符中指示的缓冲区是接收帧的头部（帧信息不完整）11：此描述符中指示的接收缓冲区是一个接收帧的全部（每帧一个缓冲区）。	R/W
b30	RDLE	接收描述符列表结束	当该位为1时，表示该描述符是描述符列表中的最后一个。	R/W
b31	RACT	接收描述符 Valid	表示此描述符有效。	R/W

Note: 用于回写的位带有下划线。

RD0指示接收帧状态。

RFE位（接收帧错误）

当RFE位为1时，表示任何一个RFS位为1。设置TRSCER寄存器以选择是否RFS7和EDMAC0的RFS4位反映在RFE位中。

RFP[1:0]位（接收帧位置）

RFP[1:0]位指示接收帧的哪一部分对应于该描述符中指示的接收缓冲区。

RACT bit (Receive Descriptor Valid)

The RACT bit indicates that this descriptor is valid. The RACT bit is set to 1 by software. This bit clears to 0 when all data is transferred to the receive buffer indicated in RD2 or when the receive buffer becomes full.

(2) Receive descriptor 1 (RD1)

Bit	Symbol	Bit name	Description	R/W
b15 to b0	RFL	Receive Frame Length	Specifies the length (number of bytes) of the receive frame stored in the buffer. This does not include the number of bytes for padding set in the RPADIR register. These bits are written back to the descriptor associated with the end of a frame.	R/W
b31 to b16	RBL	Receive Buffer Length	Specifies the byte length of the associated receive buffer. Set an integral multiple of 32 as the buffer length.	R/W

Note: Bits for write-back are underlined.

RD1 specifies the receive buffer length. When reception is complete, the receive frame length is written back.

(3) Receive descriptor 2 (RD2)

Bit	Symbol	Bit name	Description	R/W
b31 to b0	RBA	Receive Buffer Address	Specifies the start address of the receive buffer. Align the buffer address on a 32-byte boundary.	R/W

RD2 specifies the start address of the receive buffer.

RACT位（接收描述符有效）

RACT位指示该描述符是有效的。RACT位由软件设置为1。当所有数据传输到RD2中指示的接收缓冲区或接收缓冲区已满时，该位清0。

(2) 接收描述符1(RD1)

Bit	Symbol	位名称	Description	R/W
b15 to b0	RFL	接收帧 Length	指定存储在缓冲区中的接收帧的长度（字节数）。这不包括RPADIR寄存器中设置的填充字节数。这些位被写回与帧结束相关的描述符。	R/W
b31 to b16	RBL	接收缓冲区长度	指定相关接收缓冲区的字节长度。设置32的整数倍作为缓冲区长度。	R/W

Note: 用于回写的位带有下划线。

RD1指定接收缓冲区长度。当接收完成时，接收帧长度被写回。

(3) 接收描述符2(RD2)

Bit	Symbol	位名称	Description	R/W
b31 to b0	RBA	接收缓冲区 Address	指定接收缓冲区的起始地址。在32字节边界上对齐缓冲区地址。	R/W

RD2指定接收缓冲区的起始地址。

31.3.2 Transmission

When the EDTRR.TR bit is set to 1 while the ETHERC0.ECMR.TE bit is 1, the EDMAC reads the descriptor following the previously used descriptor in the transmit descriptor list (or the descriptor indicated in the TDLAR register after a reset). When the TACT bit is 1 in the transmit descriptor (TD0), the EDMAC sequentially reads transmit data from the start address of the transmit buffer indicated in transmit descriptor 2 (TD2) and transfers it to the ETHERC through the transmit FIFO. The ETHERC creates a transmit frame and starts transmission to the MII or RMII. When all data indicated in the TD1.TBL bit is transferred, write-back is performed based on the TD0.TFP[1:0] bit setting as follows:

- When the TD0.TFP[1:0] bits are 00b or 10b (frame is incomplete), the TD0.TACT bit is written back
- When the TD0.TFP[1:0] bits are 01b or 11b (frame is complete), the TD0.TACT, TD0.TFS, and TD0.TFE bits are written back.

When the TD0.TACT bit in the read descriptor is 1, the EDMAC continues reading descriptors and transmit frames. When the TD0.TACT bit in the read descriptor is 0, the EDMAC sets the EDTRR.TR bit to 0 and stops transmission.

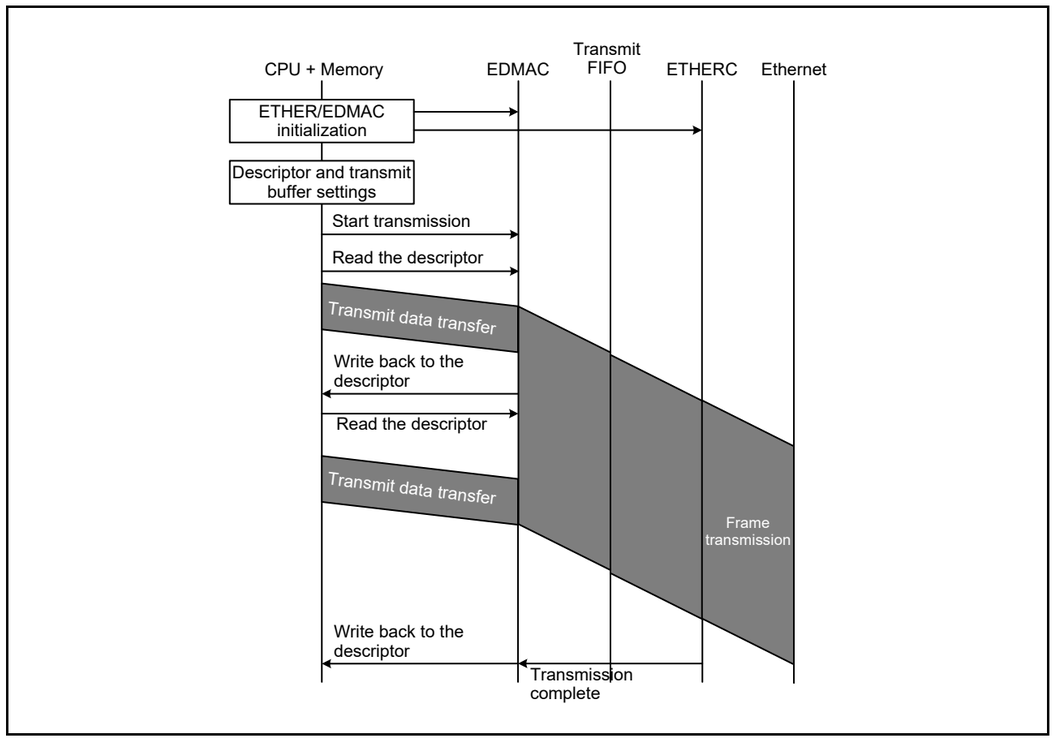

Figure 31.5 Example of transmission flow

31.3.2 Transmission

当EDTRR.TR位设置为1而ETHERC0.ECMR.TE位为1时，EDMAC读取发送描述符列表中先前使用的描述符之后的描述符（或复位后TDLAR寄存器中指示的描述符）。当发送描述符(TD0)中的TACT位为1时，EDMAC从发送描述符2(TD2)中指示的发送缓冲区的起始地址顺序读取发送数据，并通过发送FIFO将其传输到ETHERC。ETHERC创建一个传输帧并开始传输到MII或RMII。当传输TD1.TBL位中指示的所有数据时，将根据TD0.TFP[1:0]位设置执行回写，如下所示：

- 当TD0.TFP[1:0]位为00b或10b（帧不完整）时，回写TD0.TACT位
- 当TD0.TFP[1:0]位为01b或11b（帧完成）时，TD0.TACT、TD0.TFS和TD0.TFE位被写回。

当读取描述符中的TD0.TACT位为1时，EDMAC继续读取描述符并发送帧。当读描述符中的TD0.TACT位为0时，EDMAC将EDTRR.TR位设置为0并停止传输。

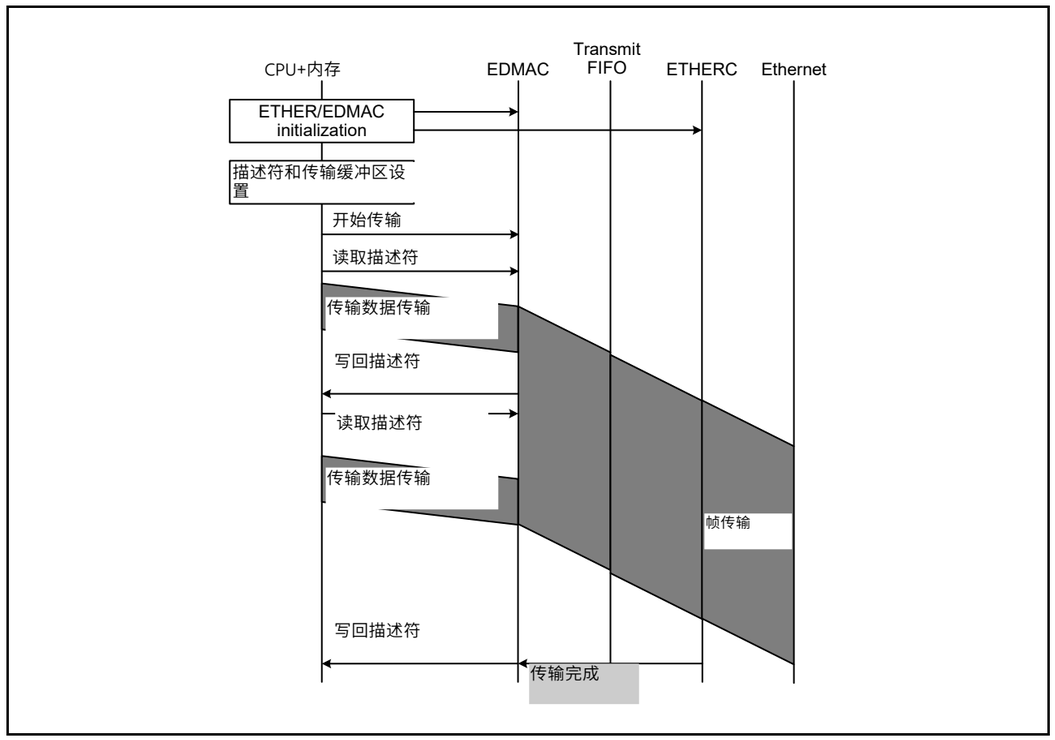

Figure 31.5 传输流程示例

31.3.3 Reception

When the EDRRR.RR bit is set to 1 while the ETHERC0.ECMR.RE bit is 1, the EDMAC reads the receive descriptor following the previously used descriptor (or the descriptor indicated in the RDLAR register after a reset) and then waits for reception. When the RD0.RACT bit is 1, if the data stored in the receive FIFO is 32 bytes or more, or if the end byte of the frame is stored in the receive buffer, the EDMAC transfers data from the receive FIFO to the receive buffer indicated in receive descriptor 2 (RD2).

If the data length of the received frame is longer than the buffer length set in the RBL bit in receive descriptor 1 (RD1), the EDMAC writes back 10b or 00b to the RD0.RFP[1:0] bits and 0 to the RD0.RACT bit when the receive buffer becomes full, and then the EDMAC reads the next data. After that, the EDMAC transfers data to another receive buffer.

When the frame reception is complete or when the frame reception is aborted by an error, the EDMAC writes back 11b or 01b to the RD0.RFP[1:0] bits, 0 to the RD0.RACT bit, and the receive frame length to the RD1.RFL bit. When the RMCR.RNR bit is 1, the EDMAC reads the next descriptor and waits for reception. When the RNR bit is 0, the EDMAC sets the EDRRR.RR bit to 0 and stops reception.

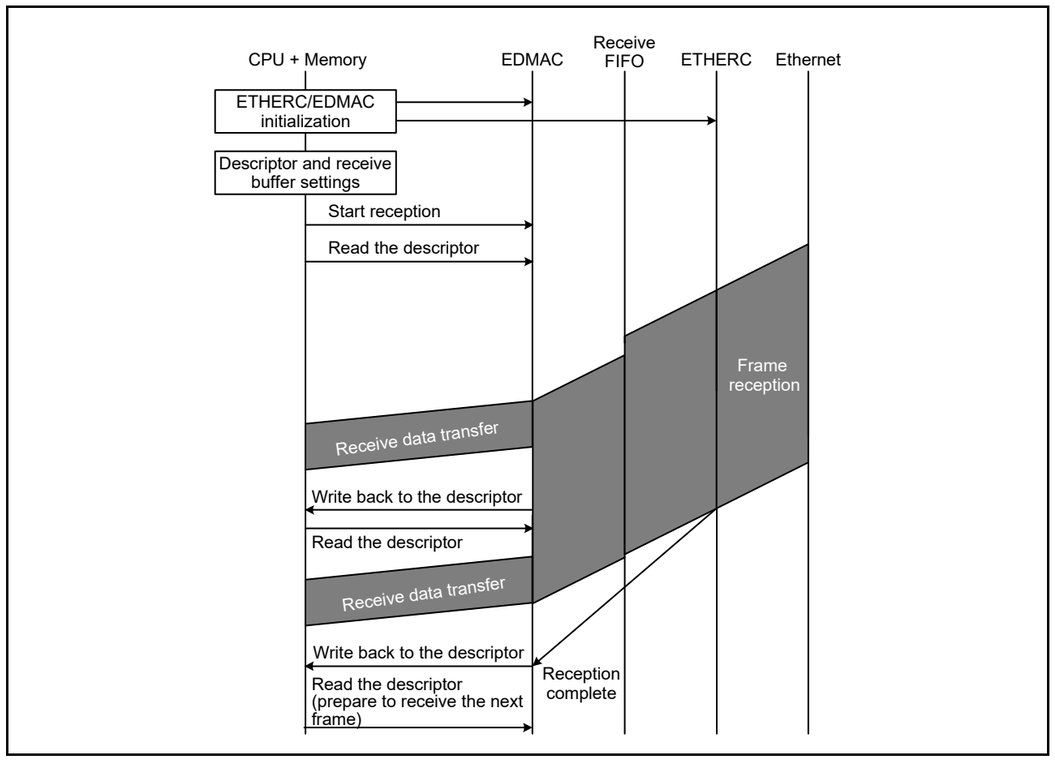

Figure 31.6 Example of reception flow

31.3.3 Reception

当EDRRR.RR位设置为1而ETHERC0.ECMR.RE位为1时，EDMAC读取先前使用的描述符（或复位后RDLAR寄存器中指示的描述符）之后的接收描述符，然后等待接收.当RD0.RACT位为1时，如果存储在接收FIFO中的数据为32字节或更多，或者如果帧的结束字节存储在接收缓冲区中，则EDMAC将数据从接收FIFO传输到接收缓冲区在接收描述符2(RD2)中指示。

如果接收帧的数据长度大于接收描述符1(RD1)中RBL位中设置的缓冲区长度，则EDMAC将10b或00b写回RD0.RFP[1:0]位，并将0写回RD0.RACT位当接收缓冲器变满时，EDMAC读取下一个数据。之后，EDMAC将数据传输到另一个接收缓冲区。

当帧接收完成或帧接收因错误而中止时，EDMAC将11b或01b写回RD0.RFP[1:0]位，将0写回RD0.RACT位，并将接收帧长度写入RD1.RFL位。当RMCR.RNR位为1时，EDMAC读取下一个描述符并等待接收。当RNR位为0时，EDMAC将EDRRR.RR位设置为0并停止接收。

31.3.4 Multi-Buffer Frame Transmission

31.3.4.1 Error processing while transmitting multi-buffer frame

If an error occurs during multi-buffer frame transmission, the EDMAC performs the processing shown in Figure 31.7. In the figure, when the TACT bit of transmit descriptor 0 (TD0) is 0, the descriptor indicates that all data in the buffer is successfully transmitted. When the TACT bit is 1, the descriptor indicates that data in the buffer is not yet transmitted. If a frame transmit error*1 occurs in the head or middle of the frame while the TD0.TACT bit is 1, the EDMAC stops data transmission from the transmit FIFO and EDMAC data transfer, and sets the TD0.TACT bit to 0.

After that, the EDMAC reads the next descriptor to see if the descriptor indicates the middle of the frame (TD0.TFP[1:0] bits are 00b) or the end of the frame (TD0.TFP[1:0] bits are 01b). When the descriptor indicates the middle of the frame, the EDMAC sets the TD0.TACT bit to 0 and reads the next descriptor. When the descriptor indicates the end of the frame, in addition to setting the TD0.TACT bit to 0, the EDMAC also writes back to the TD0.TFE and TD0.TFS bits.

After an error occurs, data in the buffer is not transmitted until write-back to the descriptor for the end of the frame. When the associated transmit error interrupt is enabled in the EESIPR register, an interrupt request is generated immediately after write-back to the descriptor for the end of the frame.

Note 1. For EDMAC0, a transmit retry-over condition, late collision, or loss of carrier is detected, or a carrier is not detected. For the PTPEDMAC, the MAC address does not match the set value.

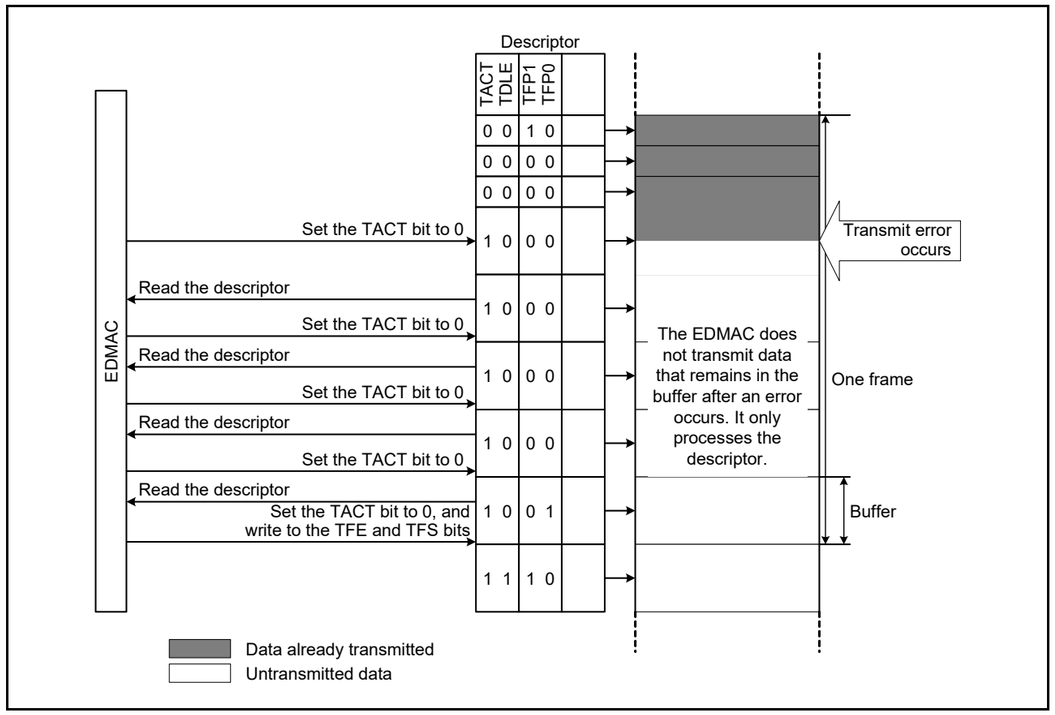

Figure 31.7 EDMAC operation after transmit error occurs

31.3.4 多缓冲区帧传输

31.3.4.1 传输多缓冲帧时的错误处理

如果在多缓冲帧传输过程中发生错误，EDMAC将执行图31.7所示的处理。图中，当发送描述符0（TD0）的TACT位为0时，描述符表示缓冲区中的所有数据都发送成功。当TACT位为1时，描述符指示缓冲区中的数据尚未传输。如果在TD0.TACT位为1时在帧的头部或中间发生帧发送错误*1，则EDMAC停止来自发送FIFO的数据传输和EDMAC数据传输，并将TD0.TACT位设置为0。

之后，EDMAC读取下一个描述符，看描述符是表示帧中间（TD0.TFP[1:0]位为00b）还是帧结束（TD0.TFP[1:0]位为01b)。当描述符指示帧的中间时，EDMAC将TD0.TACT位设置为0并读取下一个描述符。当描述符指示帧结束时，除了将TD0.TACT位设置为0外，EDMAC还写回TD0.TFE和TD0.TFS位。

发生错误后，缓冲区中的数据不会传输，直到写回帧结束的描述符。
当在ESIPR寄存器中使能相关的发送错误中断时，在帧结束写回描述符后立即生成中断请求。

注1.对于EDMAC0，检测到传输重试条件、延迟冲突或载波丢失，或未检测到载波。对于PTPEDMAC，MAC地址与设定值不匹配。

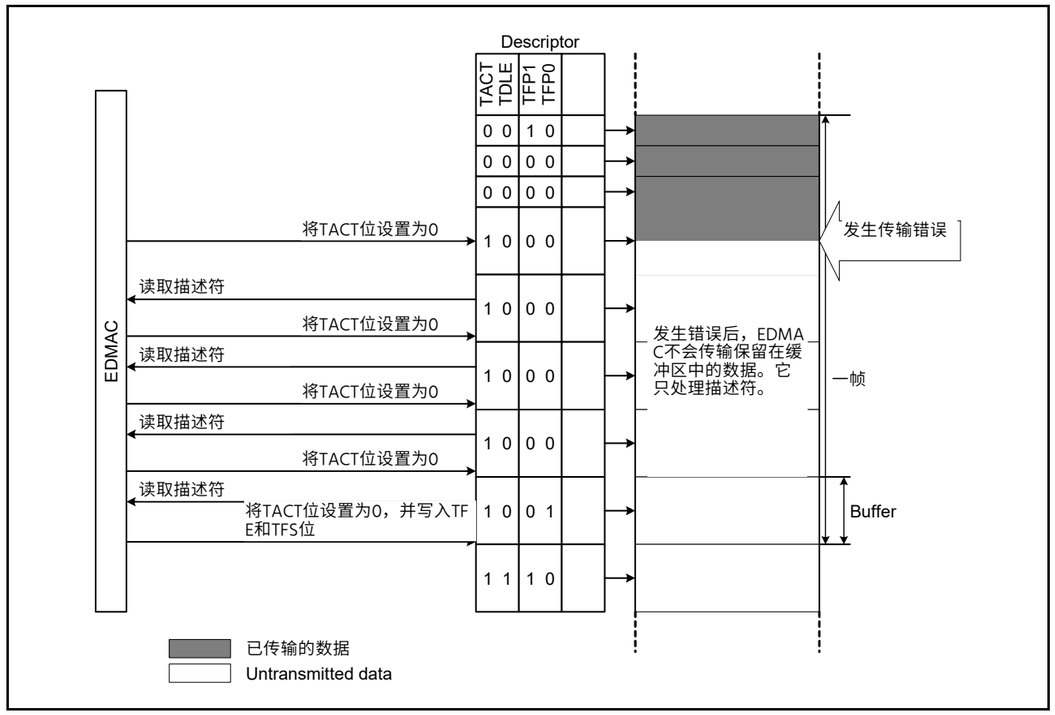

Figure 31.7 发生传输错误后的EDMAC操作

31.3.4.2 Error processing while receiving multi-buffer frame

If an error occurs during multi-buffer frame reception, the EDMAC performs the processing shown in Figure 31.8. In the figure, when the RACT bit of receive descriptor 0 (RD0) is 0, the descriptor indicates that data was successfully received in the buffer. When the RACT bit is 1, the descriptor indicates that data is not yet received in the buffer. If a frame receive error*1 occurs, the EDMAC stops receiving new data, but it transfers data that is already stored in the receive FIFO to the receive buffer.

When the receive buffer becomes full during transfer, the EDMAC sets the RACT bit to 0 and the RFP[1:0] bits to 10b or 00b and reads the next descriptor. After all data in the receive FIFO is transferred, the EDMAC writes back the status to the descriptor.

When the associated receive error interrupt is enabled in the EESIPR register, an interrupt request is generated immediately after write-back to the descriptor. When there is a request to receive a new frame, the EDMAC continues reception using the descriptor following the descriptor where the error occurred.

Note 1. For EDMAC0, a CRC error, PHY-LSI receive error, frame-too-short error, frame-too-long error, or alignment error is detected. For the PTPEDMAC, a parity error is detected.

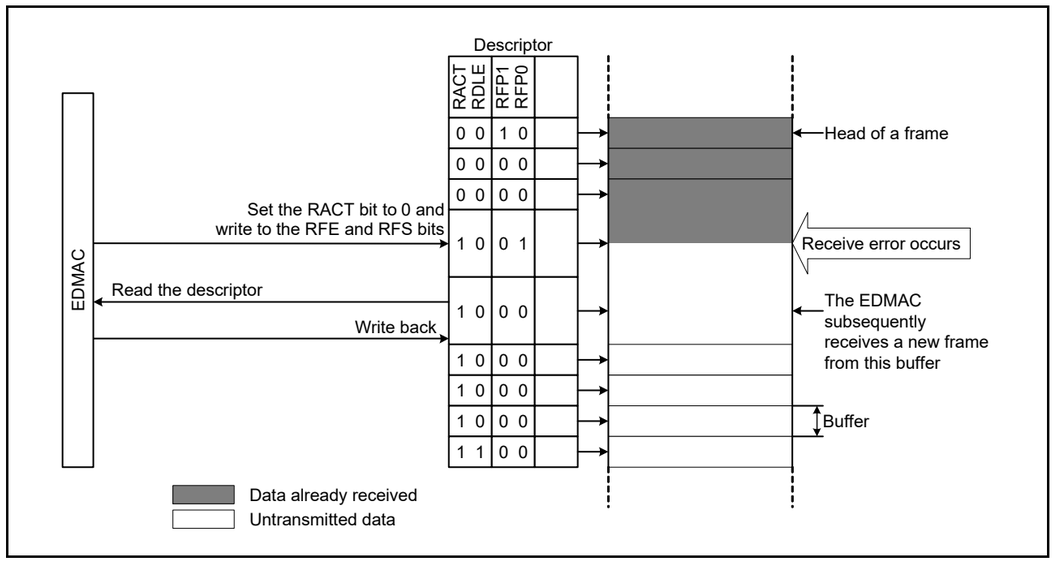

Figure 31.8 EDMAC operation after receive error occurs

31.3.4.2 接收多缓冲帧时的错误处理

如果在多缓冲区帧接收过程中发生错误，EDMAC将执行图31.8所示的处理。图中，当接收描述符0（RD0）的RACT位为0时，描述符表示缓冲区成功接收到数据。当RACT位为1时，描述符指示缓冲区中尚未接收到数据。如果发生帧接收错误*1，EDMAC将停止接收新数据，但会将已存储在接收FIFO中的数据传输到接收缓冲区。

当接收缓冲区在传输过程中变满时，EDMAC将RACT位设置为0，并将RFP[1:0]位设置为10b或00b并读取下一个描述符。接收FIFO中的所有数据传输完毕后，EDMAC将状态写回描述符。

当在ESIPR寄存器中启用相关的接收错误中断时，在写回描述符后立即生成中断请求。当有接收新帧的请求时，EDMAC使用发生错误的描述符之后的描述符继续接收。

注1.对于EDMAC0，检测到CRC错误、PHY-LSI接收错误、帧太短错误、帧太长错误或对齐错误。对于PTPEDMAC，检测到奇偶校验错误。

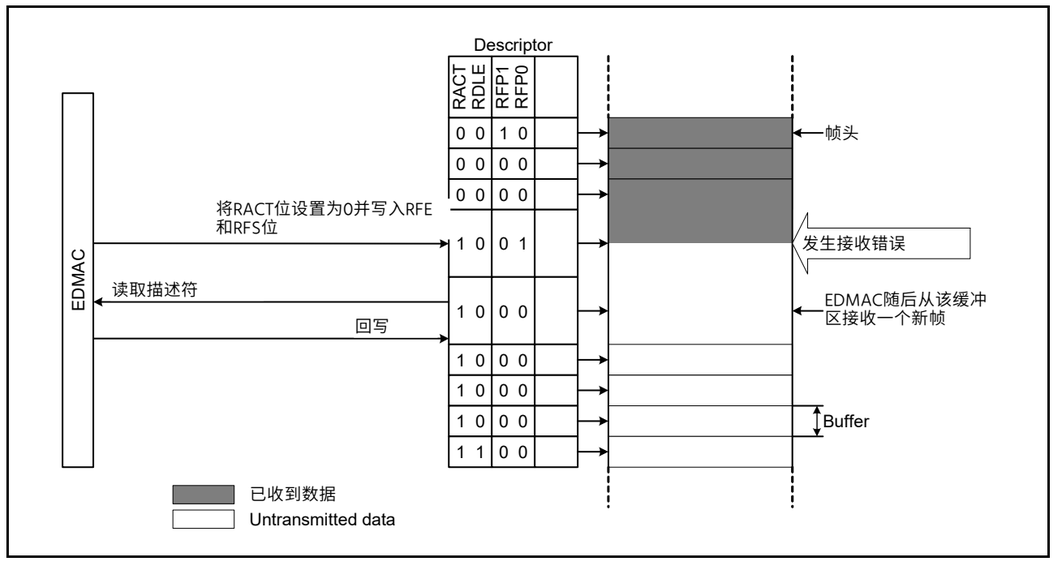

Figure 31.8 发生接收错误后的EDMAC操作

31.3.5 EDMAC Channel Priority

This section describes the priority of the two EDMAC channels (EDMAC0, PTPEDMAC). Each time transfer of one channel is complete, that channel takes the lowest priority. This operation is shown in Figure 31.9. After a reset, the priority is EDMAC0 > PTPEDMAC.

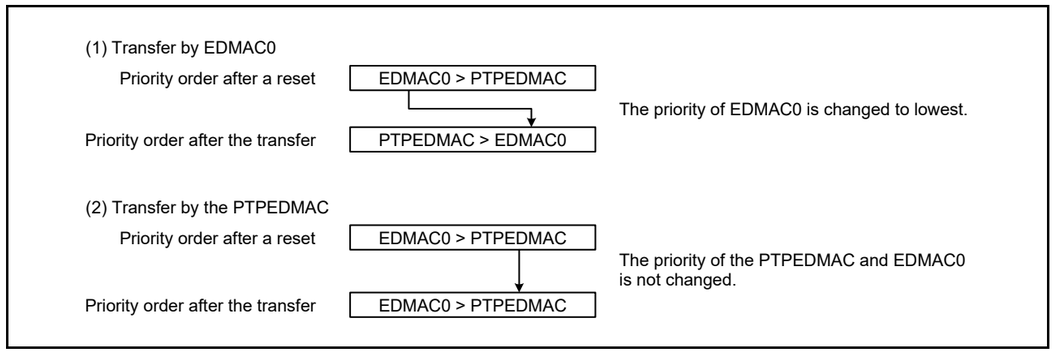

Figure 31.9 Channel priority order

Figure 31.10 shows the change in the channel priority order when transfer requests are concurrently generated to EDMAC0 and the PTPEDMAC.

The operations in the figure are as follows:

1. Transfer requests are concurrently sent to EDMAC0.
2. The EDMAC0 starts a transfer.
3. After EDMAC0 ends the transfer, the priority of EDMAC0 is changed to the lowest.
4. Transfer requests are concurrently sent to EDMAC0 and the PTPEDMAC.
5. Because PTPEDMAC has higher priority than the EDMAC0 at this time, PTPEDMAC starts a transfer and the EDMAC0 waits.
6. After PTPEDMAC ends the transfer, the priority of PTPEDMAC is changed to the lowest.
7. EDMAC0 starts a transfer.
8. After the EDMAC0 ends the transfer, the priority of EDMAC0 is changed to the lowest.

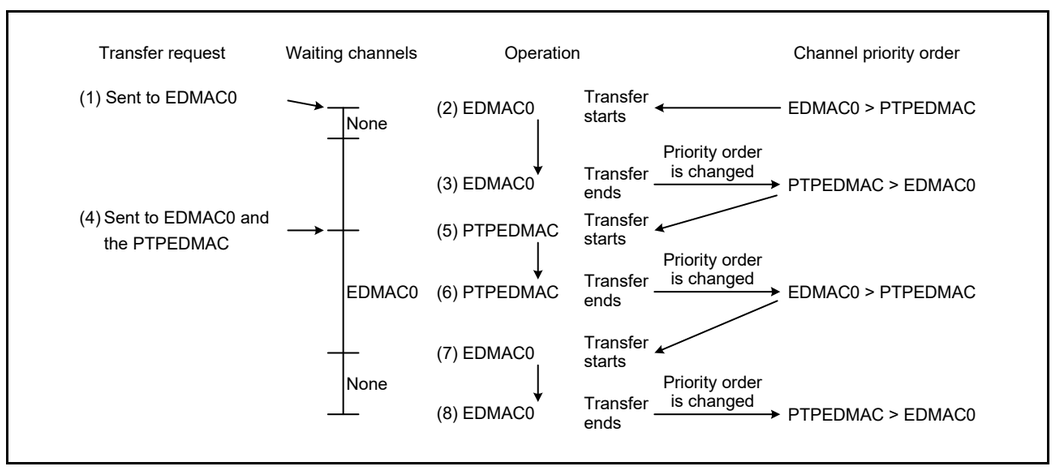

Figure 31.10 Example of channel priority order change

31.3.5 EDMAC通道优先级

本节介绍两个EDMAC通道（EDMAC0、PTPEDMAC）的优先级。每次完成一个通道的传输时，该通道的优先级最低。该操作如图31.9所示。复位后，优先级为EDMAC0>PTPEDMAC。

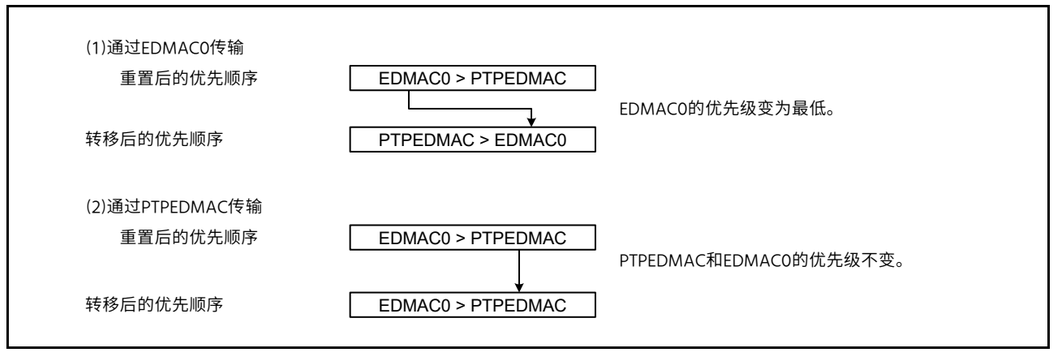

Figure 31.9 频道优先顺序

图31.10显示了同时生成传输请求时通道优先级顺序的变化EDMAC0和PTPEDMAC。

图中的操作如下：

1. 传输请求同时发送到EDMAC0。
2. EDMAC0开始传输。
3. EDMAC0结束传输后，EDMAC0的优先级变为最低。
4. 传输请求同时发送到EDMAC0和PTPEDMAC。
5. 由于此时PTPEDMAC的优先级高于EDMAC0，因此PTPEDMAC开始传输，并且EDMAC0 waits.
6. PTPEDMAC结束传输后，PTPEDMAC的优先级变为最低。
7. EDMAC0开始传输。
8. EDMAC0结束传输后，EDMAC0的优先级变为最低。

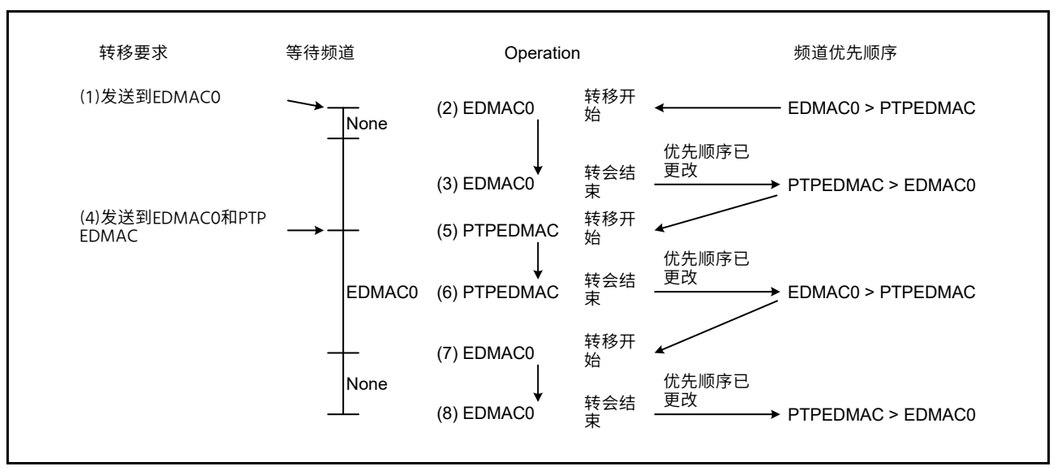

Figure 31.10 频道优先顺序更改示例

31.4 Interrupts

When any of the status flags in the EESR register sets to 1 while the associated interrupt request enable bit in the EESIPR register is 1, EDMAC0 issues an ETHER_EINT0 interrupt request or the PTPEDMAC issues an ETHER_PINT interrupt request to the CPU.

31.5 Usage Notes

31.5.1 Settings for the Module-Stop Function

The following bits in Module Stop Control Register B (MSTPCRB) enable or disable EDMAC module operation:

- The MSTPB15 bit in enables or disables ETHERC0 and EDMAC0 operation
- The MSTPCRB.MSTPB13 bit enables or disables EPTPC and PTPEDMAC operation.

The modules are initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

Note: When EPTPC and PTPEDMAC operation is enabled (MSTPB13 = 0), some registers in the EPTPC module become inaccessible depending on the combination of the MSTPB15 bit and EPTPC bypass bit (BYPASS.BYPASS0) settings. See section 30.6.1, Constraints on Register Access.

31.5.2 Stopping the EDMAC during Operation

When stopping EDMAC operation by using a Sleep instruction or the module-stop function while the EDMAC is running, confirm that the EDTRR.TR and EDRRR.RR bits are 0. If the EDMAC is stopped while the EDTRR.TR or EDRRR.RR bit is 1, the data for the frame that is being transmitted or received might not be complete, and EDMAC operation after exiting Sleep mode or the module-stop state is not guaranteed.

31.4 Interrupts

当EESR寄存器中的任何状态标志设置为1而ESIPR寄存器中的相关中断请求使能位为1时，EDMAC0向CPU发出ETHER_EINT0中断请求或PTPEDMAC向CPU发出ETHER_PINT中断请求。

31.5 使用说明

31.5.1 模块停止功能的设置

模块停止控制寄存器B(MSTPCRB)中的以下位启用或禁用EDMAC模块操作：

- MSTPB15位启用或禁用ETHERC0和EDMAC0操作
- MSTPCRB.MSTPB13位启用或禁用EPTPC和PTPEDMAC操作。

模块在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第11节，低功耗模式。

Note: 当EPTPC和PTPEDMAC操作使能(MSTPB13=0)时，EPTPC模块中的某些寄存器变得不可访问，具体取决于MSTPB15位和EPTPC旁路位(BYPASS.BYPASS0)设置的组合。请参阅第30.6.1节，寄存器访问限制。

31.5.2 在运行期间停止EDMAC

在EDMAC运行时使用休眠指令或模块停止功能停止EDMAC操作时，请确认EDTRR.TR和EDRRR.RR位为0。如果在EDTRR.TR或EDRRR.RR位时停止EDMAC为1，正在发送或接收的帧的数据可能不完整，并且无法保证退出休眠模式或模块停止状态后的EDMAC操作。

32. USB 2.0 Full-Speed Module (USBFS)

32.1 Overview

The MCU provides a USB 2.0 Full-Speed module (USBFS) that operates as a host or device controller compliant with the Universal Serial Bus (USB) specification revision 2.0. The host controller supports USB 2.0 full-speed and low-speed transfers, and the device controller supports USB 2.0 full-speed transfers. The USBFS has an internal USB transceiver and supports all of the transfer types defined in the USB 2.0 specification.

The USBFS has FIFO buffer for data transfers, providing a maximum of 10 pipes. Any endpoint number can be assigned to pipes 1 to 9, based on the peripheral devices or the communication requirements for your system.

Table 32.1 lists the USBFS specifications, Figure 32.1 shows a block diagram, and Table 32.2 lists the I/O pins.

Table 32.1 USBFS specifications

Parameter	Specifications
Features	• USB Device Controller (UDC) and USB 2.0 transceiver supporting host controller, device controller, and On-The-Go (OTG) functions (one channel) • Host and device controller can be switched by software • Self-power or bus power mode selectable.
	Host controller features: • Full-speed transfer (12 Mbps) and low-speed transfer (1.5 Mbps) • Automatic scheduling for SOF and packet transmissions • Programmable intervals for isochronous and interrupt transfers • Communications with multiple peripheral devices connected through a single hub.
	Device controller features: • Full-speed transfer (12 Mbps)*1 • Control transfer stage control function • Auto response function for SET_ADDRESS request • SOF interpolation.
Supported transfer types	• Control transfer • Bulk transfer • Interrupt transfer • Isochronous transfer.
Pipe configuration	• FIFO buffer for USB communication • Up to 10 pipes selectable, including the Default Control Pipe (DCP) • Pipes 1 to 9 assignable to any endpoint number.
	Transfer conditions specifiable for each pipe: • Pipe 0: Control transfer with 64-byte single buffer • Pipes 1 and 2: Selectable to bulk transfer with 64-byte double buffer or isochronous transfer with 256-byte double buffer • Pipes 3 to 5: Bulk transfer with 64-byte double buffer • Pipes 6 to 9: Interrupt transfer with 64-byte single buffer.
Other features	• Reception end function using transaction count • Function that changes the BRDY interrupt event notification timing (BFRE) • Automatic clearing of the FIFO buffer after the data for the pipe specified in the DnFIFO port (n = 0, 1) is read (DCLRM) • NAK setting function for response PID generated on transfer end (SHTNAK) • On-chip pull-up and pull-down resistors for D+ and D-.
Module-stop function	Module-stop state can be set to reduce power consumption

Note 1. Low-speed transfer (1.5 Mbps) is not supported.

32. USB2.0全速模块(USBFS)

32.1 Overview

MCU提供USB2.0全速模块(USBFS)，可作为主机或设备控制器运行，符合通用串行总线(USB)规范修订版2.0。主机控制器支持USB2.0全速和低速传输，设备控制器支持USB2.0全速传输。USBFS有一个内部USB收发器，支持USB2.0规范中定义的所有传输类型。

USBFS具有用于数据传输的FIFO缓冲区，最多提供10个管道。根据外围设备或系统的通信要求，可以将任何端点编号分配给管道1到9。

表32.1列出了USBFS规范，图32.1显示了框图，表32.2列出了IO引脚。

USBE bit (USBFS Operation Enable)

The USBE bit enables or disables operation of the USBFS.

Changing the USBE bit from 1 to 0 initializes the bits listed in Table 32.3. Only change this bit while the SCKE bit is 1. In host controller mode, this bit must be set to 1 after setting the DRPD bit to 1, eliminating SYSSTS0.LNST[1:0] flag chattering, and confirming that the USB bus state is stable.

USBE位（USBFS操作使能）

USBE位启用或禁用USBFS的操作。

将USBE位从1更改为0会初始化表32.3中列出的位。仅在SCKE位为1时更改该位。在主机控制器模式下，必须在将DRPD位设置为1后将该位设置为1，消除SYSSTS0.LNST[1:0]标志抖动，并确认USB总线状态是稳定的。

DPRPU位（D+线路电阻控制）

DPRPU位启用或禁用在设备控制器模式下上拉D+线。

当DPRPU位在设备控制器模式下设置为1时，USBFS将D+线上拉以通知USB主机它

attached. Changing the DPRPU bit from 1 to 0 releases the pull-up, thereby notifying the USB host that it detached.

Set this bit to 1 in device controller mode and to 0 in host controller mode.

DRPD bit (D+/D- Line Resistor Control)

The DRPD bit enables or disables pulling down D+ and D- lines in host controller mode.

Set this bit to 1 in host controller mode and to 0 in device controller mode.

DCFM bit (Controller Function Select)

The DCFM bit selects the host or device function of the USBFS.

Only change this bit when the DPRPU and DRPD bits are both 0.

SCKE bit (USB Clock Enable)

The SCKE bit stops or enables the 48-MHz clock supply to the USBFS.

When this bit is 0, only SYSCFG is permitted to be read from and written to; the other registers related to the USB should not be read from or written to.

LNST[1:0] bits (USB Data Line Status Monitor)

The LNST[1:0] bits indicate the state of the USB data lines, D+ and D-. For details, see Table 32.4.

In device controller mode, read the LNST[1:0] bits after connection processing (SYSCFG.DPRPU bit = 1). In host controller mode, read them after enabling pull-down of the lines (SYSCFG.DRPD bit = 1).

随附的。将DPRPU位从1更改为0会释放上拉电阻，从而通知USB主机它已分离。

在设备控制器模式下将此位设置为1，在主机控制器模式下设置为0。

DRPD位（D+DLine电阻控制）

DRPD位在主机控制器模式下启用或禁用下拉D+和Dlines。

在主机控制器模式下将此位设置为1，在设备控制器模式下设置为0。

DCFM位（控制器功能选择）

DCFM位选择USBFS的主机或设备功能。

仅当DPRPU和DRPD位都为0时更改该位。

SCKE位（USB时钟使能）

SCKE位停止或启用向USBFS提供48MHz时钟。

该位为0时，只允许读写SYSCFG；不应读取或写入与USB相关的其他寄存器。

SOFEA bit (Active Monitor When the Host Controller Is Selected)

The SOFEA bit is used in host controller mode to check whether the output of the last SOF is complete when the USBFS is suspended because of a 0 setting to the DVSTCTR0.UACT bit.

In host controller mode, check that both the HTACT and SOFEA bits are 0 before setting the SYSCFG.USBE bit to 0 to stop the USBFS or setting the SYSCFG.SCKE bit to 0 to stop the clock signal supply during communication.

HTACT bit (USB Host Sequencer Status Monitor)

The HTACT bit is set to 0 when the host sequencer of the USBFS is completely stopped.

In host controller mode, check that the HTACT bit is 0 before setting the DVSTCTR0.UACT bit to 0 to place the USBFS in the suspended state or setting the SCKE bit to 0 to stop the clock signal supply during communication.

OVCMON[1:0] bits (External USB_OVRCURA/ USB_OVRCURB Input Pin Monitor)

The OVCMON[1:0] bits indicate the status of the overcurrent signals from an external power supply IC.

SOFEA位（选择主机控制器时的主动监视器）

SOFEA位在主机控制器模式下用于检查当USBFS因为DVSTCTR0.UACT位设置为0而暂停时最后一个SOF的输出是否完成。

在主机控制器模式下，在将SYSCFG.USBE位设置为0以停止USBFS或将SYSCFG.SCKE位设置为0以在通信期间停止时钟信号供应之前，请检查HTACT和SOFEA位是否都为0。

HTACT位（USB主机定序器状态监视器）

当USBFS的主机定序器完全停止时，HTACT位设置为0。

在主机控制器模式下，在将DVSTCTR0.UACT位设置为0以将USBFS置于挂起状态或将SCKE位设置为0以在通信期间停止时钟信号供应之前，请检查HTACT位是否为0。

OVCMON[1:0]位（外部USB_OVRCURAUSB_OVRCURB输入引脚监视器）

OVCMON[1:0]位指示来自外部电源IC的过流信号的状态。

x: Don't care

The USBFS controller does not support low-speed connections in device controller mode. When this value is read, abnormal connection processing must be executed in higher level application software.

RHST[2:0] bits (USB Bus Reset Status)

The RHST[2:0] bits indicate the status of the USB bus reset.

In host controller mode, writing 1 to the USBRST bit causes the RHST[2:0] bits to set to 100b. When 0 is written to the USBRST bit and the USBFS ends the SE0 state, the RHST[2:0] bits update to a new value.

In device controller mode, if the USBFS detects a USB bus reset, the RHST[2:0] bits indicate 010b if the DPRPU bit is 1, and a DVST interrupt is generated.

UACT bit (USB Bus Enable)

When set to 1 in host controller mode, the UACT bit enables USB bus operation by controlling SOF packet transmission to the USB bus in addition to data and reception. The USBFS starts SOF packet output within one frame period after the UACT bit is set to 1. When UACT is set to 0, the USBFS enters the idle state after the SOF packet output.

The USBFS sets the UACT bit to 0 on any of the following conditions:

- A DTCH interrupt is detected during communication (when UACT = 1)
- An EOFERR interrupt is detected during communication (when UACT = 1).

Always write 1 to the UACT bit at the end of the USB bus reset processing (writing 0 to the USBRST bit) or at the end of resume processing from the suspended state (writing 0 to the RESUME bit).

In device controller mode, always set this bit to 0.

RESUME bit (Resume Output)

The RESUME bit controls the resume signal output in host controller mode.

When this bit is set to 1, the USBFS drives the USB port to the K-state and outputs the resume signal. The USBFS sets the bit to 1 on detection of a remote wakeup signal while the RWUPE bit is 1 and in the USB Suspend state.

The USBFS continues outputting the K-state while the RESUME bit is 1, until the bit is cleared to 0 by software. The RESUME bit must be 1 (resume period) for the time defined in the USB 2.0 specification. Only set this bit to 1 while the interface is in the Suspend state. Write 1 to the UACT bit simultaneously with the end of the resume processing (writing 0 to the RESUME bit).

Always set this bit to 0 in device controller mode.

USBRST bit (USB Bus Reset Output)

The USBRST bit controls the output of the USB bus signal in host controller mode. When this bit set to 1, the USBFS drives the USB port to the SE0 state to reset the USB bus. The USBFS continues outputting SE0 while the USBRST bit is 1, until the bit is cleared to 0 by software. The USBRST bit must be 1 (USB bus reset period) for the time defined in the USB 2.0 specification. Writing 1 to the USBRST bit during communication (UACT bit = 1) or during resume processing (RESUME bit = 1) prevents the USBFS from starting USB bus reset processing until both the UACT and RESUME bits become 0. Write 1 to the UACT bit simultaneously with the end of the USB bus reset processing (writing 0 to the USBRST bit).

Always set this bit to 0 in device controller mode.

b15 to b12	—	Reserved	这些位被读取为0。写入值应为0。	R/W

x: Don't care

USBFS控制器不支持设备控制器模式下的低速连接。当读取此值时，必须在更高级别的应用软件中执行异常连接处理。

RHST[2:0]位（USB总线复位状态）

RHST[2:0]位指示USB总线复位的状态。

在主机控制器模式下，将1写入USBRST位会导致RHST[2:0]位设置为100b。当0被写入USBRST位和USBFS结束SE0状态，RHST[2:0]位更新为新值。

在设备控制器模式下，如果USBFS检测到USB总线复位，如果DPRPU位为1，则RHST[2:0]位指示010b，并产生DVST中断。

UACT位（USB总线使能）

在主机控制器模式下设置为1时，UACT位通过控制向USB总线发送SOF数据包以及数据和接收来启用USB总线操作。USBFS在UACT位设置为1后的一帧周期内开始SOF数据包输出。当UACT设置为0时，USBFS在SOF数据包输出后进入空闲状态。

USBFS在以下任何条件下将UACT位设置为0：

- 在通信期间检测到DTCH中断（当UACT=1时）
- 通信期间检测到EOFERR中断（当UACT=1时）。

在USB总线复位处理结束（将0写入USBRST位）或从挂起状态恢复处理结束（将0写入RESUME位）时，始终向UACT位写入1。

在设备控制器模式下，始终将此位设置为0。

RESUME位（恢复输出）

RESUME位控制主机控制器模式下的恢复信号输出。

当该位设置为1时，USBFS将USB端口驱动到K状态并输出恢复信号。当RWUPE位为1且处于USB挂起状态时，USBFS在检测到远程唤醒信号时将该位设置为1。

当RESUME位为1时，USBFS继续输出K状态，直到该位被软件清除为0。这在USB2.0规范中定义的时间内，RESUME位必须为1（恢复周期）。仅当接口处于挂起状态时将此位设置为1。在恢复处理结束的同时向UACT位写入1（向RESUME位写入0）。

在设备控制器模式下始终将此位设置为0。

USBRST位（USB总线复位输出）

USBRST位控制主机控制器模式下USB总线信号的输出。当该位设置为1时，USBFS将USB端口驱动到SE0状态以复位USB总线。当USBRST位为1时，USBFS继续输出SE0，直到该位被软件清零。在USB2.0规范中定义的时间内，USBRST位必须为1（USB总线复位周期）。在通信期间（UACT位=1）或恢复处理期间（RESUME位=1）向USBRST位写入1可防止USBFS开始USB总线复位处理，直到UACT和RESUME位都变为0。同时向UACT位写入1随着USB总线复位处理的结束（向USBRST位写入0）。

在设备控制器模式下始终将此位设置为0。

RWUPE bit (Wakeup Detection Enable)

The RWUPE bit enables or disables remote wakeup signals (resume signals) from downstream peripheral devices in host controller mode. When this bit is set to 1, the USBFS detects a remote wakeup signal (K-state for 2.5 µs) from a downstream peripheral device, and performs resume processing, driving the K-state. When the RWUPE bit is set to 0, the USBFS ignores remote wakeup signals (K-states) from peripheral devices connected to the USB port.

Do not stop the internal clock when the RWUPE bit is 1, even in the Suspend state (SYSCFG.SCKE bit must be set to 1).

Always set this bit to 0 in device controller mode.

WKUP bit (Wakeup Output)

The WKUP bit enables or disables remote wakeup signals (resume signals) to the USB bus in device controller mode.

The USBFS controls the output timing of the remote wakeup signals. When this bit is set to 1, the USBFS clears it to 0 after outputting the K-state for 10 ms. The USB 2.0 specification specifies that the USB bus idle state must be kept for 5 ms or longer before a remote wakeup signal is sent. If the USBFS writes 1 to the WKUP bit immediately after detecting the Suspend state, the K-state is output after 2 ms.

Only write 1 to the WKUP bit when the device is in the Suspend state (INTSTS0.DVSQ[2:0] bits = 1xxb) and the USB host enables the remote wakeup signal (RWUPE = 1). Do not stop the internal clock while this bit is 1, even in the Suspend state (SYSCFG.SCKE bit must be set to 1).

Always set this bit to 0 in host controller mode.

HNPBTOA bit (Host Negotiation Protocol (HNP) Control)

The HNPBTOA bit is used when switching from device B to device A while in OTG mode.

If the HNPBTOA bit is 1, the internal function control maintains the Suspend state until HNP processing ends, even if the SYSCFG.DPRPU bit is set to 0 or the SYSCFG.DCFM bit is set to 1. Resume interrupts (RESM) are not generated even if a falling edge of D+ is detected.

The HNP processing ends when a host attach event is detected, because of a pull-up by the initiating party, or the HNPBTOA bit is cleared to 0 by software because the HNP processing times out.

RUPE位（唤醒检测使能）

在主机控制器模式下，RWUPE位启用或禁用来自下游外围设备的远程唤醒信号（恢复信号）。当该位设置为1时，USBFS检测到来自下游外围设备的远程唤醒信号（K状态持续2.5µs），并执行恢复处理，驱动K状态。当RHUPE位设置为0时，USBFS忽略来自连接到USB端口的外围设备的远程唤醒信号（K状态）。

当RHUPE位为1时不要停止内部时钟，即使处于挂起状态（SYSCFG.SCKE位必须设置为1）。

在设备控制器模式下始终将此位设置为0。

WKUP位（唤醒输出）

WKUP位在设备控制器模式下启用或禁用到USB总线的远程唤醒信号（恢复信号）。

USBFS控制远程唤醒信号的输出时序。当该位设置为1时，USBFS在输出K状态10ms后将其清除为0。USB2.0规范规定，在发送远程唤醒信号之前，USB总线空闲状态必须保持5ms或更长时间。如果USBFS在检测到Suspend状态后立即向WKUP位写入1，则在2ms后输出K-state。

仅当设备处于挂起状态（INTSTS0.DVSQ[2:0]位=1xxb）且USB主机使能远程唤醒信号（RWUPE=1）时，向WKUP位写入1。当该位为1时不要停止内部时钟，即使处于挂起状态（SYSCFG.SCKE位必须设置为1）。

在主机控制器模式下始终将此位设置为0。

HNPBTOA位（主机协商协议(HNP)控制）

在OTG模式下从设备B切换到设备A时使用HNPBTOA位。

如果HNPBTOA位为1，内部功能控制保持暂停状态直到HNP处理结束，即使SYSCFG.DPRPU位设置为0或SYSCFG.DCFM位设置为1。不产生恢复中断(RESM)即使检测到D+的下降沿。

当检测到主机连接事件时，HNP处理结束，因为发起方的上拉，或者由于HNP处理超时，HNPBTOA位由软件清零。

Note 1. The valid bits depend on the MBW settings (CFIFOSEL.MBW, D0FIFOSEL.MBW, and D1FIFOSEL.MBW) and BIGEND settings (CFIFOSEL.BIGEND, D0FIFOSEL.BIGEND, and D1FIFOSEL.BIGEND) in the associated port select register. See Table 32.5 and Table 32.6.

Three FIFO ports are available:

- CFIFO
- D0FIFO
- D1FIFO.

Each FIFO port is configured with:

- A port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer and writing of data to the FIFO buffer
- A port select register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that selects the pipe assigned to the FIFO port
- A port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR).

Each FIFO port has the following constraints:

- Access to the FIFO buffer for DCP control transfers is through the CFIFO port
- Access to the FIFO buffer for DMA or DTC transfers is through the D0FIO or D1FIFO port
- The D0FIFO and D1FIFO ports can also be accessed by the CPU
- When using functions specific to the FIFO port, such as the DMA or DTC transfer function, you cannot change the pipe number selected in the CURPIPE[3:0] bits of the port select register
- Registers configuring a FIFO port do not affect other FIFO ports
- The same pipe must not be assigned to two or more FIFO ports
- There are two FIFO buffer states, one giving access rights to the CPU and the other to the serial interface engine (SIE). When the SIE has access rights, the FIFO buffer cannot be accessed by the CPU.

FIFOPORT[15:0] bits (FIFO Port)

When the FIFOPORT bit is accessed, the USBFS reads the received data from the FIFO buffer or writes the transmit data to the FIFO buffer. The FIFO port register can be accessed only when the FRDY bit in the associated port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is 1.

The valid bits in the FIFO port register depend on the MBW and BIGEND settings in the port select register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL). See Table 32.5 and Table 32.6.

Note 1. Writing to or reading from these areas is not allowed.

Note 1. 有效位取决于相关端口选择寄存器中的MBW设置（CFIFOSEL.MBW、D0FIFOSEL.MBW和D1FIFOSEL.MBW）和BIGEND设置（CFIFOSEL.BIGEND、D0FIFOSEL.BIGEND和D1FIFOSEL.BIGEND）。请参见表32.5和表32.6。

三个FIFO端口可用：

- CFIFO
- D0FIFO
- D1FIFO.

每个FIFO端口配置有：

- 处理从FIFO缓冲区读取数据和将数据写入FIFO缓冲区的端口寄存器（CFIFO、D0FIFO或D1FIFO）
- 选择分配给FIFO端口的管道的端口选择寄存器（CFIFOSEL、D0FIFOSEL或D1FIFOSEL）
- 端口控制寄存器（CFIFOCTR、D0FIFOCTR或D1FIFOCTR）。

每个FIFO端口具有以下约束：

- 通过CFIFO端口访问DCP控制传输的FIFO缓冲区
- 通过D0FIO或D1FIFO端口访问DMA或DTC传输的FIFO缓冲区
- CPU也可以访问D0FIFO和D1FIFO端口
- 当使用特定于FIFO端口的功能时，例如DMA或DTC传输功能，您无法更改在端口选择寄存器的CURPIPE[3:0]位中选择的管道编号
- 配置FIFO端口的寄存器不会影响其他FIFO端口
- 不得将同一管道分配给两个或多个FIFO端口
- 有两种FIFO缓冲区状态，一种授予CPU访问权限，另一种授予串行接口引擎(SIE)。当SIE有访问权限时，CPU不能访问FIFO缓冲区。

FIFOPORT[15:0]位（FIFO端口）

当访问FIFOPORT位时，USBFS从FIFO缓冲区读取接收数据或将发送数据写入FIFO缓冲区。只有当相关端口控制寄存器（CFIFOCTR、D0FIFOCTR或D1FIFOCTR）中的FRDY位为1时，才能访问FIFO端口寄存器。

FIFO端口寄存器中的有效位取决于端口选择寄存器（CFIFOSEL、D0FIFOSEL或D1FIFOSEL）中的MBW和BIGEND设置。请参见表32.5和表32.6。

Note 1. Only 0 can be read.

Do not specify the same pipe number in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

Do not change the pipe number while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (CFIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number to use for reading or writing data through the CFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Note 1. 只能读取0。

不要在CFIFOSEL、D0FIFOSEL和D1FIFOSEL寄存器的CURPIPE[3:0]位中指定相同的管道编号。当D0FIFOSEL和D1FIFOSEL寄存器中的CURPIPE[3:0]位设置为0000b时，不选择管道。

启用DMA或DTC传输时不要更改管道编号。

CURPIPE[3:0]位（CFIFO端口访问管道规范）

CURPIPE[3:0]位指定用于通过CFIFO端口读取或写入数据的管道编号。写入这些位后，读取它们以检查写入的值是否与读取的值一致，然后再进行下一个过程。不要为CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位设置相同的管道编号。

During FIFO buffer access, even when an attempt is made to change the CURPIPE[3:0] setting, the current access setting is retained until access is complete.

ISEL bit (CFIFO Port Access Direction When DCP Is Selected)

After writing a new value to the ISEL bit with the DCP as the selected pipe, read the ISEL bit to check that the written value agrees with the read value before proceeding to the next process. Set the ISEL and CURPIPE[3:0] bits simultaneously.

MBW bit (CFIFO Port Access Bit Width)

The MBW bit specifies the bit width for accessing the CFIFO port.

When the selected pipe is receiving, set the CURPIPE[3:0] and MBW bits simultaneously. After a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read. When reading the FIFO buffer, read with the access size set in MBW.

When the selected pipe is transmitting, the bit width cannot be changed from 8-bit to 16-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double buffering, this setting enables re-reading of the currently-read FIFO buffer plane from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the REW bit to 1, be sure to check that the FRDY bit is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

在FIFO缓冲区访问期间，即使尝试更改CURPIPE[3:0]设置，当前访问设置也会保留，直到访问完成。

ISEL位（选择DCP时的CFIFO端口访问方向）

在以DCP作为选定管道的情况下将新值写入ISEL位后，读取ISEL位以检查写入的值是否与读取的值一致，然后再进行下一个过程。同时设置ISEL和CURPIPE[3:0]位。

MBW位（CFIFO端口访问位宽度）

MBW位指定访问CFIFO端口的位宽。

当所选管道正在接收时，同时设置CURPIPE[3:0]和MBW位。在写入这些位开始从FIFO缓冲区读取数据后，在读取所有数据之前不要更改这些位。读取FIFO缓冲区时，读取以MBW为单位设置的访问大小。

当所选管道正在传输时，位宽不能从8位更改为16位，同时数据正在写入FIFO缓冲区。

即使选择了16位宽度，也可以通过字节访问控制写入奇数个字节。

REW位（缓冲区指针倒带）

REW位指定是否倒回缓冲区指针。

当所选管道正在接收时，在读取FIFO缓冲区时将此位设置为1允许从第一个数据重新读取FIFO缓冲区。在双缓冲中，此设置允许从第一个条目重新读取当前读取的FIFO缓冲区平面。

请勿在同时更改CURPIPE[3:0]位时将此位设置为1。在将REW位设置为1之前，请务必检查FRDY位是否为1。

要从传输管道的第一个数据重写FIFO缓冲区，请使用BCLR位。

Note 1. Only 0 can be read.

The same pipe must not be specified in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected. The pipe number must not be changed while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number to use for reading or writing data through the DnFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, even when an attempt is made to change the CURPIPE[3:0] setting, the current access setting is retained until access is complete.

MBW bit (FIFO Port Access Bit Width)

The MBW bit specifies the bit width for accessing the DnFIFO port.

When the selected pipe is receiving, after a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read. Set the CURPIPE[3:0] and MBW bits simultaneously. When reading the FIFO buffer, read with the access size set in MBW.

When the selected pipe is transmitting, the bit width cannot be changed from 8-bit to 16-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

DREQE bit (DMA/DTC Transfer Request Enable)

The DREQE bit enables or disables issuing of DMA or DTC transfer requests. To enable DMA or DTC transfer requests, set this bit to 1 after setting the CURPIPE[3:0] bits. To change the CURPIPE[3:0] setting, first set this bit to 0.

DCLRM bit (Auto Buffer Memory Clear Mode Accessed after Specified Pipe Data is Read)

The DCLRM bit enables or disables automatic FIFO buffer clearing after data in the selected pipe is read.

When this bit is set to 1, on receiving a zero-length packet while the FIFO buffer assigned to the selected pipe is empty, or when reading of a received short packet is complete while the PIPECFG.BFRE bit is 1, the USBFS sets the BCLR bit in the FIFO port control register to 1.

When using the USBFS with the SOFCFG.BRDYM bit set to 1, set this bit to 0.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double buffering, this setting enables re-reading of the currently-read FIFO buffer plane

Note 1. 只能读取0。

不能在CFIFOSEL、D0FIFOSEL和D1FIFOSEL寄存器的CURPIPE[3:0]位中指定相同的管道。当D0FIFOSEL和D1FIFOSEL寄存器中的CURPIPE[3:0]位设置为0000b时，不选择管道。启用DMA或DTC传输时，不得更改管道编号。

CURPIPE[3:0]位（FIFO端口访问管道规范）

CURPIPE[3:0]位指定用于通过DnFIFO端口读取或写入数据的管道编号。写入这些位后，读取它们以检查写入的值是否与读取的值一致，然后再进行下一个过程。不要为CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位设置相同的管道编号。

在FIFO缓冲区访问期间，即使尝试更改CURPIPE[3:0]设置，当前访问设置也会保留，直到访问完成。

MBW位（FIFO端口访问位宽）

MBW位指定访问DnFIFO端口的位宽。

当所选管道正在接收时，在写入这些位后开始从FIFO缓冲区读取数据，在读取所有数据之前不要更改这些位。同时设置CURPIPE[3:0]和MBW位。读取FIFO缓冲区时，读取以MBW为单位设置的访问大小。

当所选管道正在传输时，位宽不能从8位更改为16位，同时数据正在写入FIFO缓冲区。

即使选择了16位宽度，也可以通过字节访问控制写入奇数个字节。

DREQE位（DMADTC传输请求使能）

DREQE位启用或禁用DMA或DTC传输请求的发出。要启用DMA或DTC传输请求，请在设置CURPIPE[3:0]位后将此位设置为1。要更改CURPIPE[3:0]设置，首先将该位设置为0。

DCLRM位（读取指定管道数据后访问的自动缓冲存储器清除模式）

在读取所选管道中的数据后，DCLRM位启用或禁用自动FIFO缓冲区清除。

当该位设置为1时，在分配给所选管道的FIFO缓冲区为空时接收到零长度数据包，或者当PIPECFG.BFRE位为1时完成读取接收到的短数据包时，USBFS设置FIFO端口控制寄存器中的BCLR位为1。

当使用SOFCFG.BRDYM位设置为1的USBFS时，将此位设置为0。

REW位（缓冲区指针倒带）

REW位指定是否倒回缓冲区指针。

当所选管道正在接收时，在读取FIFO缓冲区时将此位设置为1允许从第一个数据重新读取FIFO缓冲区。在双缓冲中，此设置允许重新读取当前读取的FIFO缓冲平面

from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the bit to 1, be sure to check that the FRDY bit is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

RCNT bit (Read Count Mode)

The RCNT bit specifies the read mode for the value in the CFIFOCTR.DTLN bit. When accessing DnFIFO with the PIPECFG.BFRE bit set to 1, set the RCNT bit to 0.

Note 1. Only 0 can be read.

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[8:0] bits (Receive Data Length)

The DTLN[8:0] bits indicate the length of the receive data.

While the FIFO buffer is being read, the DTLN[8:0] bits indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1), as follows:

- RCNT = 0
  The USBFS sets the DTLN[8:0] bits to indicate the length of the receive data until the CPU or DMA/DTC has read all of the received data from a single FIFO buffer plane.
  While the PIPECFG.BFRE bit = 1, the USBFS retains the length of the receive data until the BCLR bit is set to 1, even after all the data is read.
- RCNT = 1
  The USBFS decrements the value indicated in the DTLN[8:0] bits each time data is read from the FIFO buffer. The value is decremented by 1 when MBW = 0, and by 2 when MBW = 1.
  The USBFS sets these bits to 0 when all the data is read from one FIFO buffer plane. In double buffer mode, if data is received in one FIFO buffer plane before all of the data is read from the other plane, the USBFS sets these bits to indicate the length of the receive data in the former plane when all of the data is read from the latter plane.

要从传输管道的第一个数据重写FIFO缓冲区，请使用BCLR位。

RCNT位（读取计数模式）

RCNT位指定CFIFOCTR.DTLN位中值的读取模式。当使用DnFIFO访问PIPECFG.BFRE位设置为1，将RCNT位设置为0。

Note 1. 只能读取0。

CFIFOCTR、D0FIFOCTR和D1FIFOCTR寄存器对应于CFIFO、D0FIFO和D1FIFO缓冲区。

DTLN[8:0]位（接收数据长度）

DTLN[8:0]位指示接收数据的长度。

在读取FIFO缓冲区时，DTLN[8:0]位指示不同的值，具体取决于DnFIFOSEL.RCNT位(n=0 1)，如下所示：

- RCNT = 0
  USBFS设置DTLN[8:0]位以指示接收数据的长度，直到CPU或DMADTC从单个FIFO缓冲区平面读取所有接收数据。当PIPECFG.BFRE位=1时，USBFS将保留接收数据的长度，直到BCLR位设置为1，即使在读取所有数据之后也是如此。
- RCNT = 1
  每次从FIFO缓冲区读取数据时，USBFS都会递减DTLN[8:0]位中指示的值。当MBW=0时该值减1，当MBW=1时减2。当从一个FIFO缓冲区平面读取所有数据时，USBFS将这些位设置为0。在双缓冲区模式下，如果在一个FIFO缓冲区平面中的所有数据从另一个平面读取之前接收到数据，USBFS设置这些位以指示在读取所有数据时前一个平面中接收数据的长度从后一个平面。

FRDY bit (FIFO Port Ready)

The FRDY bit indicates whether the FIFO port can be accessed by the CPU or DMA/DTC.

In the following cases, the USBFS sets the FRDY bit to 1 but data cannot be read through the FIFO port because there is no data to be read:

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit = 1.

In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

BCLR bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU side for the selected pipe.

When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USBFS clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the DCP is the selected pipe, setting the BCLR bit to 1 allows the USBFS to clear the FIFO buffer regardless of whether the CPU or SIE has access rights. To clear the buffer when the SIE has access rights, set the DCPCTR.PID[1:0] bits to 00b (NAK response) before setting the BCLR bit to 1.

When the selected pipe is transmitting, if 1 is written to the BVAL flag and the BCLR bit simultaneously, the USBFS clears the data that is already written, enabling transmission of a zero-length packet.

When the selected pipe is not the DCP, only write 1 to the BCLR bit while the FRDY bit in the FIFO port control register is 1 (set by the USBFS).

BVAL flag (Buffer Memory Valid Flag)

Set the BVAL flag to 1 when data is completely written to the FIFO buffer on the CPU side for the pipe selected in CURPIPE[3:0].

When the selected pipe is transmitting, set this flag to 1 in the following cases:

- To transmit a short packet, set this flag to 1 after data is written
- To transmit a zero-length packet, set this flag to 1 before data is written to the FIFO buffer.

The USBFS then switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When data of the maximum packet size is written for the pipe in continuous transfer mode, the USBFS sets the BVAL flag to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

Only write 1 to the BVAL flag while the FRDY bit is 1 (set by the USBFS). When the selected pipe is receiving, do not set the BVAL flag to 1.

FRDY位（FIFO端口就绪）

FRDY位指示FIFO端口是否可以被CPU或DMADTC访问。

在以下情况下，USBFS将FRDY位设置为1，但由于没有数据可读取，因此无法通过FIFO端口读取数据：

- 当分配给所选管道的FIFO缓冲区为空时，接收到零长度数据包
- 当PIPECFG.BFRE位=1时，接收到一个短数据包并完全读取数据。

在这些情况下，将BCLR位设置为1以清除FIFO缓冲区，并启用下一个数据的发送和接收。

BCLR位（CPU缓冲区清除）

将BCLR位设置为1以清除所选管道的CPU端的FIFO缓冲区。

当分配给所选管道的FIFO缓冲区设置为双缓冲区模式时，USBFS仅清除
即使两个平面都已启用读取，也有FIFO缓冲区。

当DCP为选定管道时，将BCLR位设置为1允许USBFS清除FIFO缓冲区，而不管CPU或SIE是否具有访问权限。要在SIE具有访问权限时清除缓冲区，请将DCPCTR.PID[1:0]位设置为00b（NAK响应），然后再将BCLR位设置为1。

当所选管道正在传输时，如果同时向BVAL标志和BCLR位写入1，则USBFS会清除已写入的数据，从而可以传输零长度数据包。

当所选管道不是DCP时，仅在FIFO端口控制寄存器中的frdy位为1（由USBF设置）时，仅将1个写入BCLR位。

BVAL标志（缓冲存储器有效标志）

当数据完全写入CPU端的FIFO缓冲区时，将BVAL标志设置为1，用于在CURPIPE[3:0]。

当所选管道正在传输时，在以下情况下将此标志设置为1：

- 要发送短数据包，请在写入数据后将此标志设置为1
- 要发送长度为零的数据包，请在将数据写入FIFO缓冲区之前将此标志设置为1。

然后USBFS将FIFO缓冲区从CPU端切换到SIE端，从而启用传输。

当在连续传输模式下为管道写入最大数据包大小的数据时，USBFS将BVAL标志设置为1，并将FIFO缓冲区从CPU侧切换到SIE侧，从而启用传输。

仅在FRDY位为1（由USBFS设置）时将1写入BVAL标志。当所选管道正在接收时，不要将BVAL标志设置为1。

The BEMPENB register enables or disables the INTSTS0.BEMP bit to be set to 1 when a BEMP interrupt is detected for each pipe.

When a status flag in the BEMPSTS register sets to 1 and the associated PIPEnBEMPE (n = 0 to 9) bit setting in the BEMPENB register is 1, the INTSTS0.BEMP flag sets to 1. In this case, if the BEMPE bit in INTENB0 is 1, the USBFS generates a BEMP interrupt request. While at least one PIPEnBEMP bit indicates 1, the USBFS generates the BEMP interrupt request when the associated interrupt request enable bit in the BEMPENB register is changed from 0 to 1 by software.

当检测到每个管道的BEMP中断时，BEMPENB寄存器启用或禁用INTSTS0.BEMP位设置为1。

当BEMPSTS寄存器中的状态标志设置为1并且BEMPENB寄存器中相关的PIPEnBEMPE（n=0到9）位设置为1时，INTSTS0.BEMP标志设置为1。在这种情况下，如果INTENB0中的BEMPE位为1，USBFS产生一个BEMP中断请求。当至少一个PIPEnBEMP位指示1时，当BEMPENB寄存器中相关的中断请求使能位由软件从0变为1时，USBFS产生BEMP中断请求。

BRDYM bit (BRDY Interrupt Status Clear Timing)

The BRDYM bit specifies how the BRDY interrupt status flags for the pipes are cleared.

TRNENSEL bit (Transaction-Enabled Time Select)

When the USB port is in use for full- or low-speed communications, the TRNENSEL bit specifies the timing with which the USBFS issues tokens in a frame (transaction-enabled time).

Set this bit to 1 when a low-speed device is connected directly or through a hub. The bit is only valid in host controller mode. Set this bit to 0 in device controller mode.

BRDYM位（BRDY中断状态清除时序）

BRDYM位指定如何清除管道的BRDY中断状态标志。

TRNENSEL位（事务使能时间选择）

当USB端口用于全速或低速通信时，TRNENSEL位指定USBFS在帧中发出令牌的时间（事务启用时间）。

当低速设备直接或通过集线器连接时，将此位设置为1。该位仅在主机控制器模式下有效。在设备控制器模式下将此位设置为0。

Note 1. The value is 0 when the MCU is reset and 1 after a USB bus reset.
Note 2. The value is 1 when the USB_VBUS pin is high and 0 when the USB_VBUS pin is low.
Note 3. The value is 000b when the MCU is reset and 001b after a USB bus reset.
Note 4. To clear the VBINT, RESM, SOFR, DVST, CTRT, or VALID bits, write 0 only to the bits to be cleared. Write 1 to the other bits. Do not write 0 to the status bits indicating 0.
Note 5. The status of the RESM, DVST, and CTRT bits are changed only in device controller mode. Set the associated interrupt enable bits to 0 (disabled) in host controller mode.
Note 6. The USBFS detects a change in the status indicated in the VBINT and RESM bits even while the clock supply is stopped (SCKE bit = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply before clearing the status by software.

CTSQ[2:0] bits (Control Transfer Stage)

In host controller mode, the read value of the CTSQ[2:0] bits is invalid.

VALID bit (USB Request Reception)

In host controller mode, the read value of the VALID bit is invalid.

DVSQ[2:0] bits (Device State)

The DVSQ[2:0] bits are initialized by a USB bus reset. In host controller mode, the read value is invalid.

BRDY flag (Buffer Ready Interrupt Status)

The BRDY flag indicates the BRDY interrupt status.

The USBFS sets the BRDY bit to 1 when it detects a BRDY interrupt status (PIPEnBRDY = 1, n = 0 to 9) on at least one pipe for which BRDY interrupts are enabled (BRDYENB.PIPEnBRDYE = 1).

For the conditions that cause the PIPEnBRDY status to be asserted, see section 32.3.3.1, BRDY interrupt.

The USBFS sets the BRDY bit to 0 when the software writes 0 to all of the PIPEnBRDY bits associated with the PIPEnBRDYE bits that are set to 1. Writing 0 to the BRDY flag in the software does not clear the flag.

NRDY flag (Buffer Not Ready Interrupt Status)

The NRDY flag indicates the NRDY interrupt status.

The USBFS sets the NRDY bit to 1 when it detects a NRDY interrupt status (PIPEnNRDY = 1, n = 0 to 9) on at least one pipe for which NRDY interrupts are enabled (NRDYENB.PIPEnNRDYE = 1).

For the conditions that cause the PIPEnNRDY status to be asserted, see section 32.3.3.2, NRDY interrupt.

The USBFS sets the NRDY bit to 0 when the software writes 0 to all of the PIPEnNRDY bits associated with the PIPEnNRDYE bits that are set to 1. Writing 0 to the NRDY flag in the software does not clear the flag.

BEMP flag (Buffer Empty Interrupt Status)

The BEMP flag indicates the BEMP interrupt status.

The USBFS sets the BEMP bit to 1 when it detects a BEMP interrupt status (PIPEnBEMP = 1, n = 0 to 9) on at least one pipe for which BEMP interrupts are enabled (BEMPENB.PIPEnBEMPE = 1).

For the conditions that cause the PIPEnBEMP status to be asserted, see section 32.3.3.3, BEMP interrupt.

The USBFS sets the BEMP bit to 0 when the software writes 0 to all of the PIPEnBEMP bits associated with the PIPEnBEMPE bits that are set to 1. Writing 0 to the BEMP flag in the software does not clear the flag.

CTRT flag (Control Transfer Stage Transition Interrupt Status)

In device controller mode, the USBFS updates the value of the CTSQ[2:0] bits and sets the CTRT flag to 1 on detecting a transition in the control transfer stage. When a control transfer stage transition interrupt occurs, clear the CTRT flag before the USBFS detects the next control transfer stage transition.

Values read from the CTRT flag in host controller mode are invalid.

DVST flag (Device State Transition Interrupt Status)

In device controller mode, the USBFS updates the value of the DVSQ[2:0] bits and sets the DVST flag to 1 on detecting a change in the device state. When a device state transition interrupt occurs, clear the DVST flag before the USBFS

Note 1. MCU复位时为0，USB总线复位后为1。
Note 2. 当USB_VBUS引脚为高电平时值为1，当USB_VBUS引脚为低电平时值为0。
Note 3. MCU复位时值为000b，USB总线复位后值为001b。
Note 4. 要清除VBINT、RESM、SOFR、DVST、CTRT或VALID位，只需将0写入要清除的位。将1写入其他位。不要将0写入指示0的状态位。
Note 5. RESM、DVST和CTRT位的状态仅在设备控制器模式下更改。在主机控制器模式下，将相关的中断使能位设置为0（禁用）。
Note 6. USBFS检测到VBINT和RESM位指示的状态变化，即使在时钟供应停止（SCKE位=0）时，它也会在相关的中断请求位为1时请求中断。在清除时钟之前启用时钟供应软件状态。

CTSQ[2:0]位（控制传输阶段）

在主机控制器模式下，CTSQ[2:0]位的读取值无效。

有效位（USB请求接收）

在主机控制器模式下，VALID位的读取值无效。

DVSQ[2:0]位（设备状态）

DVSQ[2:0]位由USB总线复位初始化。在主机控制器模式下，读取的值无效。

BRDY标志（缓冲区就绪中断状态）

BRDY标志指示BRDY中断状态。

当USBFS在至少一个启用了BRDY中断(BRDYENB.PIPEnBRDYE=1)的管道上检测到BRDY中断状态(PIPEnBRDY=1 n=0到9)时，将BRDY位设置为1。

有关导致PIPEnBRDY状态被断言的条件，请参见第32.3.3.1节，BRDY中断。

当软件将0写入与
设置为1的PIPEnBRDYE位。在软件中将0写入BRDY标志不会清除该标志。

NRDY标志（缓冲区未就绪中断状态）

NRDY标志指示NRDY中断状态。

当USBFS在至少一个启用了NRDY中断(NRDYENB.PIPEnNRDYE=1)的管道上检测到NRDY中断状态(PIPEnNRDY=1 n=0到9)时，将NRDY位设置为1。

有关导致PIPEnNRDY状态被断言的条件，请参见第32.3.3.2节，NRDY中断。

USBFS将NRDY位设置为0，当软件将0写入与
设置为1的PIPEnNRDYE位。在软件中将0写入NRDY标志不会清除该标志。

BEMP标志（缓冲区空中断状态）

BEMP标志指示BEMP中断状态。

当USBFS在至少一个启用了BEMP中断(BEMPENB.PIPEnBEMPE=1)的管道上检测到BEMP中断状态(PIPEnBEMP=1 n=0到9)时，将BEMP位设置为1。

有关导致PIPEnBEMP状态被断言的条件，请参阅第32.3.3.3节，BEMP中断。

当软件将0写入与
PIPEnBEMPE位设置为1。在软件中将0写入BEMP标志不会清除该标志。

CTRT标志（控制传输阶段转换中断状态）

在设备控制器模式下，USBFS更新CTSQ[2:0]位的值，并在检测到控制传输阶段的转换时将CTRT标志设置为1。
当控制传输阶段转换中断发生时，在USBFS检测到下一个控制传输阶段转换之前清除CTRT标志。

在主机控制器模式下从CTRT标志读取的值无效。

DVST标志（设备状态转换中断状态）

在设备控制器模式下，USBFS更新DVSQ[2:0]位的值，并在检测到设备状态发生变化时将DVST标志设置为1。
当发生设备状态转换中断时，在USBFS之前清除DVST标志

detects the next device state transition.

Values read from the DVST flag in host controller mode are invalid.

SOFR flag (Frame Number Refresh Interrupt Status)

In host controller mode, the USBFS sets the SOFR flag to 1 on updating the frame number when the DVSTCTR0.UACT bit is set to 1 by software. A SOFR interrupt is detected every 1 ms.

In device controller mode, the USBFS sets the SOFR flag to 1 on updating the frame number. A frame number refresh interrupt is detected every 1 ms.

The USBFS can detect an SOFR interrupt through the internal interpolation function even when a corrupted SOF packet is received from the USB host.

RESM flag (Resume Interrupt Status)

In device controller mode, the USBFS sets the RESM flag to 1 on detecting the falling edge of the signal on the USB_DP pin in the Suspend state (DVSQ[2:0] = 1xxb). Values read from the RESM flag in host controller mode are invalid.

VBINT flag (VBUS Interrupt Status)

The USBFS sets the VBINT flag to 1 on detecting a level change (high to low or low to high) in the USB_VBUS pin input value. The USBFS sets the VBSTS flag to indicate the USB_VBUS pin input value. When a VBUS interrupt occurs, eliminate transient elements by reading the VBSTS flag at least three times through software processing and check that the values read are the same.

检测下一个设备状态转换。

在主机控制器模式下从DVST标志读取的值无效。

SOFR标志（帧号刷新中断状态）

在主机控制器模式下，当软件将DVSTCTR0.UACT位设置为1时，USBFS在更新帧号时将SOFR标志设置为1。每1 ms检测一次SOFR中断。

在设备控制器模式下，USBFS在更新帧号时将SOFR标志设置为1。每1ms检测一次帧号刷新中断。

即使从USB主机接收到损坏的SOF数据包，USBFS也可以通过内部插值功能检测SOFR中断。

RESM标志（恢复中断状态）

在设备控制器模式下，USBFS在检测到处于挂起状态(DVSQ[2:0]=1xxb)的USB_DP引脚上的信号下降沿时将RESM标志设置为1。在主机控制器模式下从RESM标志读取的值无效。

VBINT标志（VBUS中断状态）

USBFS在检测到USB_VBUS引脚输入值的电平变化（从高到低或从低到高）时将VBINT标志设置为1。USBFS设置VBSTS标志以指示USB_VBUS引脚输入值。当发生VBUS中断时，通过软件处理至少3次读取VBSTS标志来消除瞬态元素，并检查读取的值是否相同。

Note 1. 要清除INTSTS1中的位，只需将0写入要清除的位。将1写入其他位。
Note 2. 即使在停止提供时钟（SYSCFG.SCKE=0）时，USBFS也会检测到OVRCR或BCHG位的状态变化，并在相关的中断请求位为1时请求中断。启用时钟提供（SYSCFG.SCKE=1）

before clearing the status through the software. No other interrupts can be detected while the clock supply is stopped (SYSCFG.SCKE bit = 0).

INTSTS1 is used to confirm the status of each interrupt in host controller mode. Only enable the status change interrupts indicated in the bits in INTSTS1 in host controller mode.

SACK flag (Setup Transaction Normal Response Interrupt Status)

The SACK flag indicates the status of the setup transaction normal response interrupt in host controller mode.

The USBFS detects the SACK interrupt and sets this flag to 1 when an ACK response is returned from a peripheral device during the setup transactions issued by the USBFS. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

Values read from the SACK flag in device controller mode are invalid.

SIGN flag (Setup Transaction Error Interrupt Status)

The SIGN flag indicates the status of setup transaction error interrupts in host controller mode.

The USBFS detects the SIGN interrupt and sets this flag to 1 when an ACK response is not returned from a peripheral device three consecutive times during the setup transactions issued by the USBFS. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS detects the SIGN interrupt when any of the following response conditions occur for three consecutive setup transactions:

- Timeout is detected by the USBFS when the peripheral device has returned no response
- A corrupted ACK packet is received
- A handshake other than ACK (NAK, NYET, or STALL) is received.

Values read from the SIGN flag in device controller mode are invalid.

EOFERR flag (EOF Error Detection Interrupt Status)

The EOFERR flag indicates the status of EOF error detection interrupts in host controller mode.

The USBFS detects the EOFERR interrupt and sets this flag to 1 on detecting that communication did not complete at the EOF2 timing defined in the USB 2.0 specification. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

After detecting the EOFERR interrupt, the USBFS controls the hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt was detected to 0
- Puts the port in which the EOFERR interrupt occurred into the idle state.

The software must terminate all pipes in which communications are being carried out and re-enumerate the USB port.

Values read from the EOFERR flag in device controller mode are invalid.

ATTCH flag (ATTCH Interrupt Status)

The ATTCH flag indicates the status of USB attach detection interrupts in host controller mode.

The USBFS detects the ATTCH interrupt and sets this flag to 1 on detecting a J- or K-state on the full- or low-speed signal level for 2.5 µs. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS detects the ATTCH interrupt on any of the following conditions.

- K-state, SE0, or SE1 changes to J-state, and J-state continues for 2.5 µs
- J-state, SE0, or SE1 changes to K-state, and K-state continues for 2.5 µs.

Values read from the ATTCH flag in device controller mode are invalid.

DTCH flag (USB Disconnection Detection Interrupt Status)

The DTCH flag indicates the status of USB disconnection detection interrupts in host controller mode.

在通过软件清除状态之前。停止提供时钟（SYSCFG.SCKE位=0）时，不会检测到其他中断。

INTSTS1用于确认主机控制器模式下每个中断的状态。仅在主机控制器模式下启用INTSTS1位中指示的状态更改中断。

SACK标志（设置事务正常响应中断状态）

SACK标志指示主机控制器模式下设置事务正常响应中断的状态。

在USBFS发出的设置事务期间，当外围设备返回ACK响应时，USBFS检测到SACK中断并将该标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

在设备控制器模式下从SACK标志读取的值无效。

SIGN标志（设置事务错误中断状态）

SIGN标志指示主机控制器模式下设置事务错误中断的状态。

在USBFS发出的设置事务期间，如果外围设备连续3次没有返回ACK响应，则USBFS检测到SIGN中断并将该标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

当三个连续的设置事务发生以下任何响应条件时，USBFS检测到SIGN中断：

- 当外围设备没有返回响应时，USBFS检测到超时
- 收到损坏的ACK数据包
- 收到除ACK（NAK、NYET或STALL）以外的握手。

在设备控制器模式下从SIGN标志读取的值无效。

EOFERR标志（EOF错误检测中断状态）

EOFERR标志指示主机控制器模式下EOF错误检测中断的状态。

USBFS检测到EOFERR中断，并在检测到通信未完成时将此标志设置为1
USB2.0规范中定义的EOF2时序。如果相关的中断使能位由软件设置为1，则
USBFS产生中断。

检测到EOFERR中断后，USBFS对硬件进行如下控制，而不考虑相关的中断使能位设置：

- 将检测到EOFERR中断的端口的DVSTCTR0.UACT位设置为0
- 将发生EOFERR中断的端口置于空闲状态。

软件必须终止正在执行通信的所有管道并重新枚举USB端口。

在设备控制器模式下从EOFERR标志读取的值无效。

ATTCH标志（ATTCH中断状态）

ATTCH标志指示主机控制器模式下USB连接检测中断的状态。

USBFS检测到ATTCH中断，并在检测到全速或低速信号电平上的JorK状态持续2.5µs时将此标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

USBFS在以下任何条件下检测ATTCH中断。

- K-state、SE0或SE1变为J-state，J-state持续2.5µs
- J-state、SE0或SE1变为K-state，K-state持续2.5µs。

在设备控制器模式下从ATTCH标志读取的值无效。

DTCH标志（USB断线检测中断状态）

DTCH标志指示主机控制器模式下USB断开检测中断的状态。

The USBFS detects the DTCH interrupt and sets this flag to 1 on detecting a USB bus detach event. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS detects bus detach events based on the USB 2.0 specification.

After detecting the DTCH interrupt, the USBFS controls hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt was detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state.

The software must terminate all pipes in which communications are being carried out and invoke the wait state for attaching to the USB port (waiting for ATTCH interrupt generation).

Values read from the DTCH flag in device controller mode are invalid.

BCHG flag (USB Bus Change Interrupt Status)

The BCHG flag indicates the status of USB bus change interrupts in host controller mode.

The USBFS detects the BCHG interrupt and sets this flag to 1 when a change in the full- or low-speed signal level occurs on the USB port. This includes any change from J-state, K-state, or SE0 to J-state, K-state, or SE0. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS sets the LNST[1:0] flags to indicate the input state of the USB port. When a BCHG interrupt occurs, eliminate transient elements by repeat reading the LNST[1:0] flags by software until the same value is read at least three times.

Change in the USB bus state can be detected while the internal clock is stopped.

Values read from the BCHG flag in device controller mode are invalid.

OVRCR flag (Overcurrent Input Change Interrupt Status)

The OVRCR flag indicates the status of USB_OVRCURA and USB_OVRCURB input pin change interrupts.

The USBFS detects the OVRCR interrupt and sets this flag to 1 when a change (high to low or low to high) occurs in at least one of the input values to the USB_OVRCURA and USB_OVRCURB pins. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

USBFS检测到DTCH中断并在检测到USB总线分离事件时将此标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

USBFS根据USB2.0规范检测总线分离事件。

检测到DTCH中断后，USBFS对硬件进行如下控制，而不管相关的中断使能位设置如何：

- 将检测到DTCH中断的端口的DVSTCTR0.UACT位设置为0
- 将发生DTCH中断的端口置于空闲状态。

软件必须终止正在执行通信的所有管道并调用等待状态以连接到USB端口（等待ATTCH中断生成）。

在设备控制器模式下从DTCH标志读取的值无效。

BCHG标志（USB总线更改中断状态）

BCHG标志指示主机控制器模式下USB总线更改中断的状态。

当USB端口上发生全速或低速信号电平变化时，USBFS检测到BCHG中断并将该标志设置为1。这包括从J-state、K-state或SE0到J-state、K-state或SE0的任何更改。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

USBFS设置LNST[1:0]标志以指示USB端口的输入状态。当发生BCHG中断时，通过软件重复读取LNST[1:0]标志来消除瞬态元素，直到至少读取相同的值3次。

当内部时钟停止时，可以检测到USB总线状态的变化。

在设备控制器模式下从BCHG标志读取的值无效。

OVRCR标志（过流输入变化中断状态）

OVRCR标志指示USB_OVRCURA和USB_OVRCURB输入引脚变化中断的状态。

当USB_OVRCURA和USB_OVRCURB引脚的至少一个输入值发生变化（从高到低或从低到高）时，USBFS检测到OVRCR中断并将该标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

FRNM[10:0] flags (Frame Number)

The USBFS sets the FRNM[10:0] flags to indicate the latest frame number, which is updated every 1 ms, when an SOF packet is issued or received.

CRCE flag (Receive Data Error)

The CRCE flag sets to 1 when a CRC error or bit stuffing error occurs during isochronous transfer. On detecting a CRC error in host controller mode, the USBFS generates an internal NRDY interrupt.

To clear the CRCE flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

OVRN flag (Overrun/Underrun Detection Status)

The OVRN flag sets to 1 when an overrun or underrun error occurs during isochronous transfer. To clear the flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

In host controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the time to issue an OUT token comes before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the time to issue an IN token comes when no FIFO buffer planes are empty.

In device controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the IN token is received before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the OUT token is received when no FIFO buffer planes are empty.

FRNM[10:0]标志（帧号）

USBFS设置FRNM[10:0]标志以指示最新的帧号，该帧号每1ms更新一次，当发出或接收SOF数据包时。

CRCE标志（接收数据错误）

当同步传输期间发生CRC错误或位填充错误时，CRCE标志设置为1。在主机控制器模式下检测到CRC错误时，USBFS会生成内部NRDY中断。

要清除CRCE标志，向其写入0，同时向FRMNUM寄存器中的其他位写入1。

OVRN标志（溢出欠载检测状态）

当同步传输期间发生溢出或欠载错误时，OVRN标志设置为1。要清除该标志，请向其写入0，同时向FRMNUM寄存器中的其他位写入1。

在主机控制器模式下，OVRN标志在以下任何条件下设置为1：

- 对于传输同步管道，发出OUT令牌的时间出现在所有传输数据写入FIFO缓冲区之前
- 对于接收同步管道，在没有FIFO缓冲区平面为空时发出IN令牌。

在设备控制器模式下，OVRN标志在以下任何条件下设置为1：

- 对于传输同步管道，在所有传输数据写入FIFO缓冲区之前接收到IN令牌
- 对于接收同步管道，当没有FIFO缓冲区平面为空时接收OUT令牌。

b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

USBADDR[6:0] bits (USB Address)

In device controller mode, the USBADDR[6:0] flags indicate the USB address received when the USBFS processed a SetAddress request successfully. The USBFS sets the USBADDR[6:0] bits to 00h on detecting a USB bus reset.

Writing to these bits is enabled while the DVCHGR.DVCHG bit is set to 1. On recovering from a USB power shut-off, the operation can resume from the USB address set before the software shut-off.

In host controller mode, the USBADDR[6:0] bits are invalid.

STSRECOV[3:0] bits (Status Recovery)

Use the STSRECOV[3:0] bits to resume the state of the internal sequencer on recovering from USB power shut-off. For details, see section 32.3.1.5, Release from deep software standby mode because of USB suspend/resume interrupts.

Writing to these bits is enabled while the DVCHGR.DVCHG bit is set to 1.

USBADDR[6:0]位（USB地址）

在设备控制器模式下，USBADDR[6:0]标志指示当USBFS处理一个SetAddress请求成功。USBFS在检测到USB总线复位时将USBADDR[6:0]位设置为00h。

当DVCHGR.DVCHG位设置为1时，允许写入这些位。从USB电源关闭恢复后，操作可以从软件关闭前设置的USB地址恢复。

在主机控制器模式下，USBADDR[6:0]位无效。

STSRECOV[3:0]位（状态恢复）

使用STSRECOV[3:0]位在从USB电源关闭恢复时恢复内部定序器的状态。有关详细信息，请参阅第32.3.1.5节，由于USB挂起恢复中断而从深度软件待机模式中释放。

当DVCHGR.DVCHG位设置为1时，可以写入这些位。

32.2.21 USB Request Type Register (USBREQ)

b15 to b8	BREQUEST[7:0]	Request	USB request bRequest value	R/W *1

Note 1. In device controller mode, these bits can be read, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

USBREQ stores setup requests for control transfers.

In device controller mode, the USBREQ stores the received bRequest and bmRequestType values. In host controller mode, it sets to the bRequest and bmRequestType values to be transmitted.

USBREQ is initialized by a USB bus reset.

BMREQUESTTYPE[7:0] bits (Request Type)

The BMREQUESTTYPE[7:0] bits hold the bmRequestType value of USB requests.

- In host controller mode:
  Set these bits to the value of the USB request data in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:
  These bits indicate the value of the USB request data in reception setup transactions. Writing to the bits has no effect.

BREQUEST[7:0] bits (Request)

The BREQUEST[7:0] bits store bRequest value of the USB request.

- In host controller mode:
  Set these bits to the value of the USB request data in setup transmission transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:
  These bits indicate the value of the USB request data in reception setup transactions. Writing to the bits has no effect.

32.2.21 USB请求类型寄存器(USBREQ)

Note 1. 在设备控制器模式下，可以读取这些位，但写入它们无效。在主机控制器模式下，这些位都是读写位。

USBREQ存储控制传输的设置请求。

在设备控制器模式下，USBREQ存储接收到的bRequest和bmRequestType值。在主机控制器模式下，它设置为要传输的bRequest和bmRequestType值。

USBREQ由USB总线复位初始化。

BMREQUESTTYPE[7:0]位（请求类型）

BMREQUESTTYPE[7:0]位保存USB请求的bmRequestType值。

- 在主机控制器模式下：
  在传输设置事务中将这些位设置为USB请求数据的值。当DCPCTR.SUREQ位为1时，不要更改位的值。
- 在设备控制器模式下：
  这些位指示接收设置事务中USB请求数据的值。写入位无效。

BREQUEST[7:0]位（请求）

BREQUEST[7:0]位存储USB请求的bRequest值。

- 在主机控制器模式下：
  在设置传输事务中将这些位设置为USB请求数据的值。当DCPCTR.SUREQ位为1时，不要更改位的值。
- 在设备控制器模式下：
  这些位指示接收设置事务中USB请求数据的值。写入位无效。

In device controller mode, USBVAL stores the received wValue value. In host controller mode, it sets to the wValue value to be transmitted is set.

USBVAL is initialized by a USB bus reset.

WVALUE[15:0] bits (Value)

The WVALUE[15:0] bits store wValue value of the USB request.

- In host controller mode:
  Set these bits to the value of the wValue field in USB requests of transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:
  These bits indicate the wValue value of USB requests in reception setup transactions. Writing to the bits has no effect.

在设备控制器模式下，USBVAL存储接收到的wValue值。在主机控制器模式下，它设置为要传输的wValue值。

USBVAL由USB总线复位初始化。

WVALUE[15:0]位（值）

WVALUE[15:0]位存储USB请求的wValue值。

- 在主机控制器模式下：
  将这些位设置为USB传输设置事务请求中wValue字段的值。当DCPCTR.SUREQ位为1时，不要更改位的值。
- 在设备控制器模式下：
  这些位指示接收设置事务中USB请求的wValue值。写入位无效。

USBLENG stores setup requests for control transfers.

In device controller mode, the value of wLength that is received is stored. In host controller mode, the value of wLength to be transmitted is set.

USBLENG is initialized by a USB bus reset.

WLENTUH[15:0] bits (Length)

The WLENTUH[15:0] bits hold the wLength value of a USB request.

- In host controller mode:
  Set these bits to the wLength value in USB requests in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:

Bit	Symbol	Bit name	Description	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only set this bit while the PID is NAK. Before setting this bit, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

DIR bit (Transfer Direction)

In host controller mode, the DIR bit sets the transfer direction of the data stage and status stage for control transfers. In device controller mode, set the DIR bit to 0.

SHTNAK bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to change PID to NAK on transfer end when the selected pipe is receiving. It is only valid when the selected pipe is receiving.

When the SHTNAK bit is 1, the USBFS changes the DCPCTR.PID[1:0] bits for the DCP to NAK on determining that a transfer has ended. The USBFS determines transfer end on the following condition:

- A short packet, including a zero-length packet, is successfully received.

32.2.26 DCP Maximum Packet Size Register (DCPMAXP)

Note 1. Only set the MXPS[6:0] bits while PID is NAK. Before setting these bits, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary. After the MXPS[6:0] bits are set and the DCP is set to the CURPIPE[3:0] bits in a port select register, clear the buffer by setting the BCLR bit in the port control register to 1.

Note 2. Only set the DEVSEL[3:0] bits while PID is NAK and the DCPCTR.SUREQ bit is 0. Before setting these bits, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

MXPS[6:0] bits (Maximum Packet Size)

The MXPS[6:0] bits specify the maximum data payload (maximum packet size) for the DCP. The initial value is 40h (64 bytes). Set the bits to a USB 2.0-compliant value. Do not write to the FIFO buffer or set PID = BUF while MXPS[6:0] is set to 0.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target peripheral device for a control transfer. Set up the device address in the associated DEVADDn (n = 0 to 5) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0010b, for example, first set the address in the DEVADD2 register.

Bit	Symbol	位名称	Description	R/W
b15 to b8	—	Reserved	这些位被读取为0。写入值应为0。	R/W

Note 1. 仅在PID为NAK时设置该位。在设置该位之前，请检查DCPCTR.PBUSY位是否为0，然后将DCP的DCPCTR.PID[1:0]位从BUF更改为NAK。如果PID[1:0]位被USBFS更改为NAK，则检查
PBUSY位不需要通过软件。

DIR位（传输方向）

在主机控制器模式下，DIR位设置控制传输的数据阶段和状态阶段的传输方向。在设备控制器模式下，将DIR位设置为0。

SHTNAK位（传输结束时管道禁用）

SHTNAK位指定当所选管道正在接收时，是否在传输结束时将PID更改为NAK。仅在所选管道正在接收时有效。

当SHTNAK位为1时，USBFS在确定传输已结束时将DCPCR.PID[1:0]位更改为DCP为NAK。USBFS在以下条件下确定传输结束：

- 成功接收到一个短数据包，包括一个长度为零的数据包。

Note 1. 仅在PID为NAK时设置MXPS[6:0]位。在设置这些位之前，请检查DCPCTR.PBUSY位是否为0，然后将DCP的DCPCTR.PID[1:0]位从BUF更改为NAK。如果PID[1:0]位被USBFS更改为NAK，则无需通过软件检查PBUSY位。在设置MXPS[6:0]位并将DCP设置为端口选择寄存器中的CURPIPE[3:0]位后，通过将端口控制寄存器中的BCLR位设置为1来清除缓冲区。

Note 2. 仅在PID为NAK且DCPCTR.SUREQ位为0时设置DEVSEL[3:0]位。在设置这些位之前，请检查DCPCTR.PBUSY位是否为0，然后更改DCPCTR.PID[1:0]从BUF到NAK的DCP位。如果PID[1:0]位被USBFS更改为NAK，则无需通过软件检查PBUSY位。

MXPS[6:0]位（最大数据包大小）

MXPS[6:0]位指定DCP的最大数据有效载荷（最大数据包大小）。初始值为40h（64字节）。将这些位设置为符合USB2.0的值。当MXPS[6:0]设置为0时，不要写入FIFO缓冲区或设置PID=BUF。

DEVSEL[3:0]位（设备选择）

在主机控制器模式下，DEVSEL[3:0]位指定目标外围设备的地址以进行控制传输。首先在相关的DEVADDn（n=0到5）寄存器中设置设备地址，然后将这些位设置为相应的值。例如，要将DEVSEL[3:0]位设置为0010b，首先要设置DEVADD2寄存器中的地址。

In device controller mode, set these bits to 0000b.

PID[1:0] bits (Response PID)

The PID[1:0] bits control the USB response type during control transfers.

In host controller mode, to change the PID[1:0] setting from NAK to BUF:

- When the transmitting direction is set:

Note 1. 该位读为0。
Note 2. 仅在PID为NAK时设置SQSET和SQCLR位。在设置这些位之前，请检查PBUSY位是否为0，然后将DCP的PID[1:0]位从BUF更改为NAK。如果PID[1:0]位被USBFS更改为NAK，则无需通过软件检查PBUSY位。

PID[1:0]位（响应PID）

PID[1:0]位在控制传输期间控制USB响应类型。

在主机控制器模式下，要将PID[1:0]设置从NAK更改为BUF：

- 设置传输方向时：

a. Write all of the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and PID is NAK.

b. Set PID[1:0] bits to 01b (BUF).
The USBFS then executes the OUT transaction.

- When the receiving direction is set:

a. Check that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and PID is NAK.

b. Set PID[1:0] bits to 01b (BUF).
The USBFS then executes the IN transaction.

The USBFS changes the PID[1:0] setting as follows:

- When the PID[1:0] bits are set to BUF (01b) by software and the USBFS has received data exceeding MaxPacketSize, the USBFS sets the PID[1:0] to STALL (11b)
- When a reception error, such as a CRC error, is detected three times consecutively, the USBFS sets the PID[1:0] bits to NAK (00b)
- On receiving the STALL handshake, the USBFS sets PID[1:0] to STALL (11b).

In device controller mode, the USBFS changes the PID[1:0] setting as follows:

- On receiving a setup packet, the USBFS sets PID[1:0] to NAK (00b). The USBFS then sets the INTSTS0.VALID flag to 1, and the PID[1:0] setting cannot be changed until the software clears the VALID flag to 0.
- When the PID[1:0] bits are set to BUF (01b) by software and the USBFS has received data exceeding MaxPacketSize, the USBFS sets PID[1:0] to STALL (11b)
- On detecting a control transfer sequence error, the USBFS sets PID[1:0] to STALL (1xb)
- On detecting a USB bus reset, the USBFS sets PID[1:0] to NAK.

The USBFS does not check the PID[1:0] setting while processing a SET_ADDRESS request.

The PID[1:0] bits are initialized by a USB bus reset.

CCPL bit (Control Transfer End Enable)

In device controller mode, setting the CCPL bit to 1 enables the status stage of the control transfer to be completed. When the bit is set to 1 by software while the associated PID[1:0] bits are set to BUF, the USBFS completes the control transfer status stage.

During control read transfers, the USBFS transmits the ACK handshake in response to the OUT transaction from the USB host. During control write or no-data control transfers, it transmits the zero-length packet in response to the IN transaction from the USB host. On detecting a SET_ADDRESS request, the USBFS operates in auto response mode from the setup stage up to status stage completion regardless of the CCPL bit setting.

The USBFS changes the CCPL bit from 1 to 0 on receiving a new setup packet. The software cannot write 1 to the bit while the INTSTS0.VALID bit is 1. The bit is initialized by a USB bus reset.

In host controller mode, always write 0 to the CCPL bit.

PBUSY bit (Pipe Busy)

The PBUSY bit indicates whether DCP is used for the transaction when USBFS changes the PID[1:0] bits from BUF to NAK. The USBFS changes the PBUSY bit from 0 to 1 on start of a USB transaction for the selected pipe. It changes the PBUSY bit from 1 to 0 on completion of one transaction.

After PID is set to NAK by software, the value in the PBUSY bit indicates whether changes to pipe settings can proceed.

For details, see section 32.3.4.1, Pipe control register switching procedures.

SQMON bit (Sequence Toggle Bit Monitor)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

The USBFS toggles the bit on normal completion of the transaction. It does not toggle the bit, however, when a DATA-PID mismatch occurs during a transfer in the receiving direction.

一个。当DVSTCTR0.UACT位为1且PID为NAK时，将所有发送数据写入FIFO缓冲区。

湾。将PID[1:0]位设置为01b(BUF)。
然后USBFS执行OUT事务。

- 设置接收方向时：

一个。在DVSTCTR0.UACT位为1且PID为NAK时检查FIFO缓冲区是否为空（或清空缓冲区）。

湾。将PID[1:0]位设置为01b(BUF)。
然后USBFS执行IN事务。

USBFS更改PID[1:0]设置如下：

- 当PID[1:0]位被软件设置为BUF(01b)并且USBFS接收到的数据超过MaxPacketSize，USBFS将PID[1:0]设置为STALL(11b)
- 当连续3次检测到接收错误（例如CRC错误）时，USBFS将PID[1:0]位设置为NAK(00b)
- 在接收到STALL握手时，USBFS将PID[1:0]设置为STALL(11b)。

在设备控制器模式下，USBFS将PID[1:0]设置更改如下：

- 接收到设置数据包后，USBFS将PID[1:0]设置为NAK(00b)。然后USBFS将INTSTS0.VALID标志设置为1，并且在软件将VALID标志清除为0之前无法更改PID[1:0]设置。
- 当PID[1:0]位被软件设置为BUF(01b)并且USBFS接收到的数据超过MaxPacketSize，USBFS将PID[1:0]设置为STALL(11b)
- 在检测到控制传输序列错误时，USBFS将PID[1:0]设置为STALL(1xb)
- 在检测到USB总线复位时，USBFS将PID[1:0]设置为NAK。

USBFS在处理SET_ADDRESS请求时不检查PID[1:0]设置。

PID[1:0]位由USB总线复位初始化。

CCPL位（控制传输结束使能）

在设备控制器模式下，将CCPL位设置为1可以完成控制传输的状态阶段。
当该位由软件设置为1且相关的PID[1:0]位设置为BUF时，USBFS完成控制传输状态阶段。

在控制读取传输期间，USBFS发送ACK握手以响应来自USB主机的OUT事务。在控制写入或无数据控制传输期间，它传输零长度数据包以响应来自USB主机的IN事务。在检测到SET_ADDRESS请求时，USBFS从设置阶段到状态阶段完成以自动响应模式运行，无论CCPL位设置如何。

USBFS在接收到新的设置数据包时将CCPL位从1更改为0。当INTSTS0.VALID位为1时，软件无法向该位写入1。该位由USB总线复位初始化。

在主机控制器模式下，始终将0写入CCPL位。

PBUSY位（管道忙）

PBUSY位指示当USBFS将PID[1:0]位从BUF更改为NAK时是否使用DCP进行事务处理。USBFS在所选管道的USB事务开始时将PBUSY位从0更改为1。它改变了
PBUSY位在一个事务完成时从1变为0。

在软件将PID设置为NAK后，PBUSY位中的值指示是否可以继续对管道设置进行更改。

详见32.3.4.1管道控制寄存器切换流程。

SQMON位（序列切换位监视器）

SQMON位指示DCP传输期间下一个事务的序列切换位的预期值。

USBFS在事务正常完成时切换该位。然而，它不会切换该位，当一个DATA
PID不匹配发生在接收方向的传输过程中。

In device controller mode, the USBFS sets the SQMON bit to 1 (specifies DATA1 as the expected value) on successful reception of the setup packet.

In device controller mode, the USBFS does not reference this bit during IN or OUT transactions at the status stage, and it does not toggle the bit on normal completion.

SQSET bit (Sequence Toggle Bit Set)

The SQSET bit specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SQCLR bit (Sequence Toggle Bit Clear)

The SQCLR bit specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer. It is read as 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SUREQCLR bit (SUREQ Bit Clear)

In host controller mode, setting the SUREQCLR bit to 1 clears the SUREQ bit to 0. The bit is read as 0.

If transfer stops while the SUREQ bit is set to 1 in a setup transaction, set the SUREQCLR bit to 1 by software. This is not necessary at the end of a normal setup transaction, because the USBFS automatically clears the SUREQ bit to 0.

Only control the SUREQ bit through the SUREQCLR bit while the DVSTCTR0.UACT bit is 0. When UACT is 0, communication is halted or no transfer is occurring because a bus disconnection was detected.

In device controller mode, always write 0 to this bit.

SUREQ bit (Setup Token Transmission)

In host controller mode, setting the SUREQ bit to 1 triggers the USBFS to transmit the setup packet. After completing the setup transaction process, the USBFS generates either the SACK or SIGN interrupt and clears the SUREQ bit to 0. The USBFS also clears the SUREQ bit to 0 when the software sets the SUREQCLR bit to 1.

Before setting the SUREQ bit to 1, set the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, and USBLENG appropriately to transmit the target USB request in the setup transaction. Also check that the PID[1:0] bits for the DCP are set to NAK. After setting the SUREQ bit to 1, do not change the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, or USBLENG until the setup transaction is complete (SUREQ bit = 1). Write 1 to the SUREQ bit only when transmitting the setup token. Otherwise, write 0.

In device controller mode, always write 0 to this bit.

BSTS flag (Buffer Status)

The BSTS flag indicates the status of access to the DCP FIFO buffer. The meaning of this flag varies as follows depending on the CFIFOSEL.ISEL setting:

- When ISEL = 0, the bit indicates whether receive data can be read from the buffer
- When ISEL = 1, the bit indicates whether transmit data can be written to the buffer.

在设备控制器模式下，USBFS在成功接收到设置数据包时将SQMON位设置为1（指定DATA1作为预期值）。

在设备控制器模式下，USBFS在状态阶段的IN或OUT事务期间不引用该位，并且它不会在正常完成时切换该位。

SQSET位（序列切换位设置）

SQSET位将DATA1指定为DCP传输期间下一个事务的序列切换位的预期值。

不要同时将SQCLR和SQSET位设置为1。

SQCLR位（序列切换位清除）

SQCLR位将DATA0指定为DCP传输期间下一个事务的序列切换位的预期值。读为0。

不要同时将SQCLR和SQSET位设置为1。

SUREQCLR位（SUREQ位清零）

在主机控制器模式下，将SUREQCLR位设置为1会将SUREQ位清除为0。该位被读取为0。

如果在设置事务中将SUREQ位设置为1时传输停止，则通过软件将SUREQCLR位设置为1。这在正常设置事务结束时不是必需的，因为USBFS会自动将SUREQ位清除为0。

当DVSTCTR0.UACT位为0时，仅通过SUREQCLR位控制SUREQ位。当UACT为0时，由于检测到总线断开，通信停止或没有传输发生。

在设备控制器模式下，始终向该位写入0。

SUREQ位（设置令牌传输）

在主机控制器模式下，将SUREQ位设置为1会触发USBFS发送设置数据包。完成设置事务处理后，USBFS产生SACK或SIGN中断并将SUREQ位清零。当软件将SUREQCLR位设置为1时，USBFS也将SUREQ位清零。

在将SUREQ位设置为1之前，适当地设置DCPMAXP.DEVSEL[3:0]位、USBREQ、USBVAL、USBINDX和USBLENG以在设置事务中传输目标USB请求。还要检查DCP的PID[1:0]位是否设置为NAK。将SUREQ位设置为1后，在设置事务完成（SUREQ位=1）之前，不要更改DCPMAXP.DEVSEL[3:0]位、USBREQ、USBVAL、USBINDX或USBLENG。将1写入

仅在发送设置令牌时才使用SUEQ位。否则，写0。

在设备控制器模式下，始终向该位写入0。

BSTS标志（缓冲区状态）

BSTS标志指示访问DCPFIFO缓冲区的状态。根据CFIFOSEL.ISEL设置，该标志的含义如下：

- 当ISEL=0时，该位指示是否可以从缓冲区中读取接收数据
- 当ISEL=1时，该位指示是否可以将发送数据写入缓冲区。

Set pipes 1 to 9 using the PIPESEL, PIPECFG, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN registers (n = 0 to 9).

After selecting the pipe in the PIPESEL register, pipe functions must be set in the associated PIPECFG, PIPEMAXP, and PIPEPERI registers. PIPEnCTR, PIPEnTRE, and PIPEnTRN can be set independently of the pipe selection in this register.

PIPESEL[3:0] bits (Pipe Window Select)

The PIPESEL[3:0] bits select the pipe number associated with the PIPECFG, PIPEMAXP, and PIPEPERI registers used for data writing and reading. Selecting a pipe number in the PIPESEL[3:0] bits allows writing to and reading from PIPECFG, PIPEMAXP, and PIPEPERI associated with the selected pipe number.

When PIPESEL[3:0] = 0000b, 0 is read from all of the bits in PIPECFG, PIPEMAXP, and PIPEPERI. Writing to these bits has no effect.

Note 1. Only set the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 2. Only set the BFRE, DBLB, and DIR bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 3. To change the BFRE, DBLB, or DIR bits after completing USB communication on the selected pipe, in addition to the constraints described in Note 2, write 1 and 0 to the PIPEnCTR.ACLRM bit continuously through the software and clear the FIFO buffer assigned to the pipe.

PIPECFG specifies the transfer type, FIFO buffer access direction, and endpoint numbers for pipes 1 to 9. It also selects single or double buffer mode, and whether to continue or disable pipe operation at the end of transfer.

EPNUM[3:0] bits (Endpoint Number)

The EPNUM[3:0] bits specify the endpoint number for the selected pipe. Setting 0000b indicates the pipe not used.

Set these bits so that the combination of the DIR and EPNUM[3:0] settings is different from those for other pipes. The EPNUM[3:0] bits can be set to 0000b for all pipes.

DIR bit (Transfer Direction)

The DIR bit specifies the transfer direction for the selected pipe.

When the software sets this bit to 0, the USBFS uses the selected pipe for receiving. When the software sets this bit to 1, the USBFS uses the selected pipe for transmitting.

SHTNAK bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to change the PIPEnCTR.PID[1:0] bits to 00b (NAK) at the end of transfer when the selected pipe is set in the receiving direction. The bit is valid for pipes 1 to 5 in the receiving direction.

When the software sets this bit to 1 for a receiving pipe, the USBFS changes the associated PIPEnCTR.PID[1:0] bits to 00b (NAK) on determining the transfer end. The USBFS determines that the transfer has ended on the following conditions:

- A short packet data (including a zero-length packet) was successfully received

Note 1. 仅在PID为NAK时设置TYPE[1:0]、SHTNAK和EPNUM[3:0]位。在设置这些位之前，请检查PIPEnCTR.PBUSY位为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

Note 2. 仅在PID为NAK且在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置BFRE、DBLB和DIR位。在设置这些位之前，请检查PIPEnCTR.PBUSY位是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

Note 3. 要在选定管道上完成USB通信后更改BFRE、DBLB或DIR位，除了注释2中描述的约束外，还可以通过软件连续向PIPEnCTR.ACLRM位写入1和0，并清除分配给管道。

PIPECFG指定管道1到9的传输类型、FIFO缓冲区访问方向和端点编号。它还选择单缓冲区或双缓冲区模式，以及在传输结束时是继续还是禁用管道操作。

EPNUM[3:0]位（端点编号）

EPNUM[3:0]位指定所选管道的端点号。设置0000b表示管道未使用。

设置这些位，以便DIR和EPNUM[3:0]设置的组合不同于其他管道的设置。这
对于所有管道，EPNUM[3:0]位可以设置为0000b。

DIR位（传输方向）

DIR位指定所选管道的传输方向。

当软件将此位设置为0时，USBFS使用所选管道进行接收。当软件将此位设置为1时，USBFS使用所选管道进行传输。

SHTNAK位（传输结束时管道禁用）

SHTNAK位指定当所选管道设置为接收方向时，是否在传输结束时将PIPEnCTR.PID[1:0]位更改为00b(NAK)。该位对接收方向的管道1到5有效。

当软件将该位设置为1用于接收管道时，USBFS在确定传输结束时将相关的PIPEnCTR.PID[1:0]位更改为00b(NAK)。USBFS在以下条件下确定传输已结束：

- 成功接收到一个短包数据（包括一个零长度包）

- The transaction counter is used and the number of packets specified for the transaction counter are successfully received.

DBLB bit (Double Buffer Mode)

The DBLB bit selects either single or double buffer mode for the FIFO buffer used by the selected pipe. The bit is valid for pipes 1 to 5.

BFRE bit (BRDY Interrupt Operation Specification)

The BFRE bit specifies the BRDY interrupt generation timing from the USBFS to the CPU for the selected pipe.

When the software sets the BFRE bit to 1 and the selected pipe is in the receiving direction, the USBFS detects the transfer completion and generates the BRDY interrupt on reading the packet.

When a BRDY interrupt is generated with this setting, the software must write 1 to the BCLR bit in the port control register. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to the BCLR bit.

When the BFRE bit is set to 1 by software and the selected pipe is in the transmitting direction, the USBFS does not generate the BRDY interrupt. For details, see section 32.3.3.1, BRDY interrupt.

TYPE[1:0] bits (Transfer Type)

The TYPE[1:0] bits specify the transfer type for the pipe selected in the PIPESEL.PIPESEL[3:0] bits. Before setting PID to BUF and starting USB communication on the selected pipe, set the TYPE[1:0] bits to a value other than 00b.

Note 1. The value of the MXPS[8:0] bits is 000h when no pipe is selected in the PIPESEL.PIPESEL[3:0] bits and 040h when a pipe is selected.

Note 2. Only set the MXPS[8:0] bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 3. Only set the DEVSEL[3:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS,

- 使用事务计数器并成功接收为事务计数器指定的数据包数量。

DBLB位（双缓冲模式）

DBLB位为所选管道使用的FIFO缓冲区选择单缓冲区模式或双缓冲区模式。该位对管道1到5有效。

BFRE位（BRDY中断操作规范）

BFRE位为所选管道指定从USBFS到CPU的BRDY中断生成时序。

当软件将BFRE位设置为1且所选管道处于接收方向时，USBFS检测到传输完成并在读取数据包时产生BRDY中断。

当使用该设置产生BRDY中断时，软件必须将1写入端口控制寄存器中的BCLR位。在将1写入BCLR位之前，分配给所选管道的FIFO缓冲区不会用于接收。

当BFRE位由软件设置为1且所选管道处于发送方向时，USBFS不会产生BRDY中断。有关详细信息，请参阅第32.3.3.1节，BRDY中断。

TYPE[1:0]位（传输类型）

TYPE[1:0]位指定在PIPESEL.PIPESEL[3:0]位中选择的管道的传输类型。在将PID设置为BUF并在所选管道上启动USB通信之前，请将TYPE[1:0]位设置为00b以外的值。

Note 3. 仅在PID为NAK时设置DEVSEL[3:0]位。在设置这些位之前，请检查PIPEnCTR.PBUSY位是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，

checking the PBUSY bit through the software is not necessary.

PIPEMAXP specifies the maximum packet size for pipes 1 to 9.

MXPS[8:0] bits (Maximum Packet Size)

The MXPS[8:0] bits specify the maximum data payload (maximum packet size) for the selected pipe.

Set these bits to the appropriate value for each transfer type based on the USB 2.0 specification. When MXPS[8:0] = 0, do not write to the FIFO buffer or set PID to BUF. These writes have no effect.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target device for USB communication. Set up the device address in the associated DEVADDn (n = 0 to 5) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0010b, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0000b.

b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only set the IITV[2:0] bits while PID is NAK. Before setting these bits, check that the PBUSY bit is 0, and then change the PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

PIPEPERI selects whether the buffer is flushed or not when an interval error occurred during isochronous IN transfers, and sets the interval error detection interval for pipes 1 to 9.

IITV[2:0] bits (Interval Error Detection Interval)

To change the IITV[2:0] bits to another value after they are set and USB communication is performed, set the PIPEnCTR.PID[1:0] bits to 00b (NAK) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer.

The IITV[2:0] bits are not provided for pipes 3 to 5. Write 000b to bit positions of the IITV[2:0] bits associated with pipes 3 to 5.

IFIS bit (Isochronous IN Buffer Flush)

The IFIS bit specifies whether to flush the buffer when the pipe selected in the PIPESEL.PIPESEL[3:0] bits is used for isochronous IN transfers.

In device controller mode when the selected pipe is for isochronous IN transfers, the USBFS automatically clears the FIFO buffer if the USBFS fails to receive the IN token from the USB host within the interval set in the IITV[2:0] bits in terms of frames.

When double buffering is specified (PIPECFG.DBLB = 1), the USBFS only clears the data in the previously used plane.

The USBFS clears the FIFO buffer on receiving the SOF packet immediately after the frame in which the USBFS

无需通过软件检查PBUSY位。

PIPEMAXP指定管道1到9的最大数据包大小。

MXPS[8:0]位（最大数据包大小）

MXPS[8:0]位指定所选管道的最大数据有效负载（最大数据包大小）。

根据USB2.0规范将这些位设置为每种传输类型的适当值。当MXPS[8:0]=0时，不要写入FIFO缓冲区或将PID设置为BUF。这些写入没有效果。

DEVSEL[3:0]位（设备选择）

在主机控制器模式下，DEVSEL[3:0]位指定USB通信的目标设备的地址。首先在相关的DEVADDn（n=0到5）寄存器中设置设备地址，然后将这些位设置为相应的值。例如，要将DEVSEL[3:0]位设置为0010b，首先要设置DEVADD2寄存器中的地址。

在设备控制器模式下，将这些位设置为0000b。

PIPEPERI选择在同步IN传输期间发生间隔错误时是否刷新缓冲区，并设置管道1到9的间隔错误检测间隔。

IITV[2:0]位（间隔错误检测间隔）

要在设置IITV[2:0]位并在执行USB通信后将其更改为另一个值，请设置PIPEnCTR.PID[1:0]位为00b(NAK)，然后将PIPEnCTR.ACLRM位设置为1以初始化间隔定时器。

不为管道3到5提供IITV[2:0]位。将000b写入与管道3到5相关联的IITV[2:0]位的位位置。

IFIS位（同步IN缓冲区刷新）

IFIS位指定当在PIPESEL.PIPESEL[3:0]位中选择的管道用于同步IN传输时是否刷新缓冲区。

在设备控制器模式下，当所选管道用于同步IN传输时，USBFS会自动清除
如果USBFS未能在IITV[2:0]位（以帧为单位）设置的间隔内接收来自USB主机的IN令牌，则FIFO缓冲区。

当指定双缓冲时（PIPECFG.DBLB=1），USBFS只清除先前使用的平面中的数据。

USBFS在接收到SOF数据包的帧之后立即清除FIFO缓冲区

Note 3. 仅在PID为NAK时以及在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置ACLRM位。在设置该位之前，请检查PBUSY位是否为0，然后将PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位由USBFS更改为00(NAK)，无需通过软件检查PBUSY位。

PIPEnCTR可以为PIPESEL寄存器中的任何管道选择设置。

PID[1:0]位（响应PID）

PID[1:0]位指定所选管道上下一个事务的响应类型。

The default PID[1:0] setting is NAK. Change the PID[1:0] setting to BUF to use the associated pipe for USB transfer. Table 32.7 and Table 32.8 show the basic operations of the USBFS (when there are no errors in the communication packets) based on the PID[1:0] bit setting.

After changing the PID[1:0] setting from BUF to NAK through the software during USB communication on the selected pipe, check that the PBUSY bit is 1 to see if USB transfer on the pipe has actually entered the NAK state. If the USBFS changes the PID[1:0] bits to NAK, checking the PBUSY bit through the software is not necessary.

The USBFS changes the PIPEnCTR.PID[1:0] setting in the following cases:

- The USBFS sets PID to NAK on recognizing completion of the transfer when the selected pipe is in the receiving direction and the PIPECFG.SHTNAK bit for the selected pipe is set to 1 by software
- The USBFS sets PID to STALL (11b) on receiving a data packet with a payload exceeding the maximum packet size of the selected pipe
- The USBFS sets PID to NAK on detecting a USB bus reset in device controller mode
- The USBFS sets PID to NAK on detecting a reception error, such as a CRC error, three consecutive times in host controller mode
- The USBFS sets PID to STALL (11b) on receiving the STALL handshake in host controller mode.

To specify the response type, set the PID[1:0] bits as follows:

- To transition from NAK (00b) to STALL, set 10b
- To transition from BUF (01b) to STALL, set 11b
- To transition from STALL (11b) to NAK, set 10b and then 00b
- To transition from STALL to BUF, transition to NAK and then BUF.

Table 32.7 Operation of the USBFS based on the PID[1:0] setting in host controller mode

PID[1:0] value	Transfer type	Transfer direction (DIR bit)	USBFS operation
00b (NAK)	Does not depend on the setting	Does not depend on the setting	Does not issue tokens

10b (STALL) or 11b (STALL)	Does not depend on the setting	Does not depend on the setting	Does not issue tokens.

Table 32.8 Operation of the USBFS based on the PID[1:0] setting in device controller mode (1 of 2)

PID[1:0] value	Transfer type	Transfer direction (DIR bit)	USBFS operation
00b (NAK)	Bulk or interrupt	Does not depend on the setting	Returns NAK in response to the token from the USB host
	Isochronous	Does not depend on the setting	Returns nothing in response to the token from the USB host

默认PID[1:0]设置为NAK。将PID[1:0]设置更改为BUF以使用关联的管道进行USB传输。
表32.7和表32.8显示了基于PID[1:0]位设置的USBFS的基本操作（当通信数据包中没有错误时）。

在选定管道上进行USB通信期间，通过软件将PID[1:0]设置从BUF更改为NAK后，检查PBUSY位是否为1，以查看管道上的USB传输是否真正进入了NAK状态。如果USBFS将PID[1:0]位更改为NAK，则无需通过软件检查PBUSY位。

USBFS在以下情况下更改PIPEnCTR.PID[1:0]设置：

- 当所选管道处于接收方向并且所选管道的PIPECFG.SHTNAK位由软件设置为1时，USBFS在识别到传输完成时将PID设置为NAK
- USBFS在接收到有效载荷超过所选管道的最大数据包大小的数据包时将PID设置为STALL(11b)
- USBFS在设备控制器模式下检测到USB总线复位时将PID设置为NAK
- USBFS在主机控制器模式下连续3次检测到接收错误（例如CRC错误）时将PID设置为NAK
- USBFS在主机控制器模式下接收到STALL握手时将PID设置为STALL(11b)。

要指定响应类型，请按如下方式设置PID[1:0]位：

- 要从NAK(00b)转换到STALL，请设置10b
- 要从BUF(01b)转换到STALL，请设置11b
- 要从STALL(11b)转换到NAK，请设置10b，然后设置00b
- 要从STALL过渡到BUF，先过渡到NAK，然后再过渡到BUF。

Table 32.7 USBFS在主机控制器模式下基于PID[1:0]设置的操作

PID[1:0] value	传输类型	传输方向（DIR位）	USBFS operation
00b (NAK)	不依赖于设置	不依赖于设置	不发行代币
01b (BUF)	批量或中断	不依赖于设置	当DVSTCTR0.UACT位为1并且与所选管道关联的FIFO缓冲区已准备好进行发送和接收时，发出令牌。当DVSTCTR0.UACT位为0或 与所选管道关联的FIFO缓冲区尚未准备好进行发送或接收。
	Isochronous	不依赖于设置	无论与所选管道关联的FIFO缓冲区的状态如何，都会发出令牌。
10b (STALL) or 11b (STALL)	不依赖于设置	不依赖于设置	不发行代币。

Table 32.8 基于设备控制器模式下的PID[1:0]设置的USBFS操作（1of2）

PID[1:0] value	传输类型	传输方向（DIR位）	USBFS operation
00b (NAK)	批量或中断	不依赖于设置	返回NAK以响应来自USB主机的令牌
	Isochronous	不依赖于设置	响应来自USB主机的令牌，不返回任何内容

Table 32.8 Operation of the USBFS based on the PID[1:0] setting in device controller mode (2 of 2)

PID[1:0] value	Transfer type	Transfer direction (DIR bit)	USBFS operation
01b (BUF)	Bulk	Receiving direction (DIR = 0)	Receives data and returns ACK in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception
	Interrupt	Receiving direction (DIR = 0)	Receives data and returns ACK in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception
	Bulk or interrupt	Transmitting direction (DIR = 1)	Transmits data in response to the token from the USB host if the FIFO buffer associated with the selected pipe is ready for transmission. Otherwise, returns NAK.
	Isochronous	Receiving direction (DIR = 0)	Receives data in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, discards the data.
	Isochronous	Transmitting direction (DIR = 1)	Transmits data in response to the token from the USB host if the associated FIFO buffer is ready for transmission. Otherwise, transmits a zero-length packet.
10b (STALL) or 11b (STALL)	Bulk or interrupt	Does not depend on the setting	Returns STALL in response to the token from the USB host
	Isochronous	Does not depend on the setting	Returns nothing in response to the token from the USB host

PBUSY bit (Pipe Busy)

The PBUSY bit indicates whether the selected pipe is being used for the current transaction.

The USBFS changes the PBUSY bit from 0 to 1 on start of the USB transaction for the selected pipe, and changes the PBUSY bit from 1 to 0 on completion of one transaction.

Reading the PBUSY bit by software after PID is set to NAK allows you to check whether changing the pipe setting is possible. For details, see section 32.3.4.1, Pipe control register switching procedures.

SQMON bit (Sequence Toggle Bit Confirmation)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.

When the selected pipe is not the isochronous transfer type, the USBFS toggles the SQMON flag on successful completion of the transaction. However, the USBFS does not toggle the SQMON flag when a DATA-PID mismatch occurs during transfer in the receiving direction.

SQSET bit (Sequence Toggle Bit Set)

Setting the SQSET bit to 1 through the software causes the USBFS to set DATA1 as the expected value of the sequence toggle bit for the next transaction on the selected pipe. The USBFS clears the SQSET bit to 0.

SQCLR bit (Sequence Toggle Bit Clear)

Setting the SQCLR bit to 1 through the software causes the USBFS to clear the expected value of the sequence toggle bit for the next transaction on the selected pipe to DATA0. The USBFS clears the SQCLR bit to 0.

ACLRM bit (Auto Buffer Clear Mode)

The ACLRM bit enables or disables auto buffer clear mode for the selected pipe. To completely clear the data in the FIFO buffer allocated to the selected pipe, write 1 and then 0 to the ACLRM bit continuously.

Table 32.9 shows the data cleared by writing 1 and 0 to the ACLRM bit continuously and the cases in which this processing is required.

Table 32.9 Data cleared by the USBFS when ACLRM = 1 (1 of 2)

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear
1	All data in the FIFO buffer allocated to the selected pipe (two FIFO buffers in double buffer mode)	When initializing the selected pipe

Table 32.8 基于设备控制器模式下的PID[1:0]设置的USBFS操作（2之2）

PID[1:0] value	传输类型	传输方向（DIR位）	USBFS operation
01b (BUF)	Bulk	接收方向(DIR=0)	如果与所选管道关联的FIFO缓冲区已准备好接收，则接收数据并返回ACK以响应来自USB主机的OUT令牌
	Interrupt	接收方向(DIR=0)	如果与所选管道关联的FIFO缓冲区已准备好接收，则接收数据并返回ACK以响应来自USB主机的OUT令牌
	批量或中断	发射方向(DIR=1)	传输数据以响应来自USB主机的令牌，如果与所选管道关联的FIFO缓冲区已准备好进行传输。否则，返回NAK。
	Isochronous	接收方向(DIR=0)	如果与所选管道关联的FIFO缓冲区已准备好接收，则接收数据以响应来自USB主机的OUT令牌。否则，丢弃数据。
	Isochronous	发射方向(DIR=1)	如果关联的FIFO缓冲区已准备好传输，则传输数据以响应来自USB主机的令牌。否则，发送零长度数据包。
10b (STALL) or 11b (STALL)	批量或中断	不依赖于设置	返回STALL以响应来自USB主机的令牌
	Isochronous	不依赖于设置	响应来自USB主机的令牌，不返回任何内容

PBUSY位（管道忙）

PBUSY位指示所选管道是否正在用于当前事务。

USBFS在所选管道的USB事务开始时将PBUSY位从0更改为1，并更改PBUSY位在一个事务完成时从1变为0。

在PID设置为NAK后，通过软件读取PBUSY位可以检查是否可以更改管道设置。详见32.3.4.1管道控制寄存器切换流程。

SQMON位（序列切换位确认）

SQMON位指示所选管道的下一个事务的序列切换位的预期值。

当所选管道不是同步传输类型时，USBFS在事务成功完成时切换SQMON标志。但是，当在接收方向的传输过程中发生DATA-PID不匹配时，USBFS不会切换SQMON标志。

SQSET位（序列切换位设置）

通过软件将SQSET位设置为1会导致USBFS将DATA1设置为所选管道上下一个事务的序列切换位的预期值。USBFS将SQSET位清0。

SQCLR位（序列切换位清除）

通过软件将SQCLR位设置为1会导致USBFS将所选管道上下一个事务的序列切换位的预期值清除为DATA0。USBFS将SQCLR位清0。

ACLRM位（自动缓冲区清除模式）

ACLRM位启用或禁用所选管道的自动缓冲区清除模式。彻底清除数据库中的数据FIFO缓冲区分配给所选管道，向ACLRM位连续写入1和0。

表32.9显示了通过向ACLRM位连续写入1和0来清除的数据以及需要进行此处理的情况。

Table 32.9 当ACLRM=1(1of2)时USBFS清除的数据

Number	通过设置ACLRM位清除数据	需要数据清楚的情况

4	FIFO buffer toggle control	When changing the PIPECFG.DBLB setting
5	Internal flags related to the transaction count	When forcing the transaction count function to terminate

ATREPM bit (Auto Response Mode)

The ATREPM bit enables or disables auto response mode for the selected pipe.

This bit can be set to 1 in device controller mode when the selected pipe is the bulk transfer type. When the bit is set to 1, the USBFS responds to the token from the USB host as follows:

- When the selected pipe is set for bulk IN transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 1):
  a. When the ATREPM bit = 1 and PID = BUF, the USBFS transmits a zero-length packet in response to the IN token.
  b. The USBFS updates (allows toggling of) the sequence toggle bit (DATA-PID) each time the USBFS receives ACK from the USB host. In a single transaction, the IN token is received, a zero-length packet is transmitted, and then ACK is received. The USBFS does not generate the BRDY or BEMP interrupt.
- When the selected pipe is set for bulk OUT transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 0):

  When the ATREPM bit = 1 and PID = BUF, the USBFS returns NAK in response to the OUT token and generates an NRDY interrupt.

For USB communication in auto response mode, set the ATREPM bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode. When the selected pipe uses isochronous transfer, always set this bit to 0.

In host controller mode, always set the ATREPM bit to 0.

INBUFM bit (Transmit Buffer Monitor)

The INBUMFM bit indicates the FIFO buffer status for the selected pipe in the transmitting direction.

When the selected pipe is set in the transmitting direction (PIPECFG.DIR = 1), the USBFS sets this bit to 1 when the CPU or DMA/DTC completes writing data to at least one FIFO buffer plane.

The USBFS sets this bit to 0 when the USBFS completes transmission of the data from the FIFO buffer plane to which all the data is written. In double buffer mode (PIPECFG.DBLB = 1), the USBFS sets the INBUFM bit to 0 when the USBFS completes transmission of the data from the two FIFO buffer planes before the CPU or DMA/DTC completes writing data to one FIFO buffer plane.

The INBUFM bit indicates the same value as the BSTS bit when the selected pipe is in the receiving direction (PIPECFG.DIR = 0).

BSTS bit (Buffer Status)

The BSTS bit indicates the FIFO buffer status for the selected pipe.

The meaning of the BSTS bit depends on the PIPECFG.DIR, PIPECFG.BFRE, and DnFIFOSEL.DCLRM settings, as shown in Table 32.10.

5	与事务计数相关的内部标志	强制事务计数函数终止时

ATREPM位（自动响应模式）

ATREPM位启用或禁用所选管道的自动响应模式。

当所选管道为批量传输类型时，该位可以在设备控制器模式下设置为1。当该位设置为1时，USBFS响应来自USB主机的令牌，如下所示：

- 当所选管道设置为批量IN传输时（PIPECFG.TYPE[1:0]=01b和PIPECFG.DIR=1）：

  一个。当ATREPM位=1且PID=BUF时，USBFS发送一个长度为零的数据包以响应IN令牌。

  湾。每次USBFS从USB主机接收到ACK时，USBFS都会更新（允许切换）序列切换位(DATA-PID)。在单个事务中，收到IN令牌，发送零长度数据包，然后收到ACK。USBFS不会产生BRDY或BEMP中断。

- 当所选管道设置为批量OUT传输时（PIPECFG.TYPE[1:0]=01b和PIPECFG.DIR=0）：

当ATREPM位=1且PID=BUF时，USBFS返回NAK以响应OUT令牌并产生NRDY中断。对于自动响应模式下的USB通信，当FIFO缓冲区为空时，将ATREPM位设置为1。在自动响应模式下的USB通信期间不要写入FIFO缓冲区。当所选管道使用同步传输时，始终将此位设置为0。

在主机控制器模式下，始终将ATREPM位设置为0。

INBUFM位（发送缓冲区监视器）

INBUMFM位指示发送方向上所选管道的FIFO缓冲区状态。

当所选管道设置为发送方向（PIPECFG.DIR=1）时，USBFS将该位设置为1，当CPU或DMADTC完成将数据写入至少一个FIFO缓冲平面。

当USBFS完成从写入所有数据的FIFO缓冲区平面传输数据时，USBFS将该位设置为0。在双缓冲模式(PIPECFG.DBLB=1)下，当USBFS在CPU或DMADTC完成将数据写入一个FIFO缓冲层之前完成从两个FIFO缓冲层的数据传输时，USBFS将INBUFM位设置为0。

当所选管道处于接收方向时（PIPECFG.DIR=0），INBUFM位指示与BSTS位相同的值。

BSTS位（缓冲区状态）

BSTS位指示所选管道的FIFO缓冲区状态。

BSTS位的含义取决于PIPECFG.DIR、PIPECFG.BFRE和DnFIFOSEL.DCLRM设置，如表32.10所示。

Table 32.10 BSTS bit operation

DIR value	BFRE value	DCLRM value	BSTS bit function
0	0	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read

Note 1. Only 0 can be read. Only 1 can be written.
Note 2. Only write 1 to the SQCLR or SQSET bit while PID is NAK. Before setting these bits, check that the PBUSY bit is 0, and then change the PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.
Note 3. Only set the ACLRM bit while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting this bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF)

Note 1. 只能读取0。只能写1个。
Note 2. PID为NAK时，仅向SQCLR或SQSET位写入1。在设置这些位之前，请检查PBUSY位是否为0，然后将PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

Note 3. 仅在PID为NAK时以及在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置ACLRM位。
在设置此位之前，请检查PIPEnCTR.PBUSY位是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改

to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

PID[1:0] bits (Response PID)

The PID[1:0] bits specify the response type for the next transaction of the selected pipe.

The default PID[1:0] setting is NAK. Change the PID[1:0] setting to BUF to use the associated pipe for USB transfer. Table 32.7 and Table 32.8 show the basic operation (when there are no errors in the transmitted and received packets) of the USBFS depending on the PID[1:0] setting.

After changing the PID[1:0] setting from BUF to NAK through the software during USB communication on the selected pipe, check that the PBUSY bit is 1 to see if USB transfer on the selected pipe has actually entered the NAK state. If the USBFS changes the PID[1:0] bits to NAK, checking the PBUSY bit through the software is not necessary.

The USBFS changes the PIPEnCTR.PID[1:0] setting in the following cases:

- The USBFS sets PID to STALL (11b) on receiving a data packet with a payload exceeding the maximum packet size of the selected pipe
- The USBFS sets PID to NAK on detecting a USB bus reset in device controller mode
- The USBFS sets PID to NAK on detecting a reception error, such as a CRC error, three consecutive times in host controller mode
- The USBFS sets PID to STALL (11b) on receiving the STALL handshake in host controller mode.

To specify each response type, set the PID[1:0] bits as follows:

- To transition from NAK (00b) to STALL, set 10b
- To transition from BUF (01b) to STALL, set 11b
- To transition from STALL (11b) to NAK, set 10b and then 00b
- To transition from STALL to BUF, transition to NAK and then BUF.

PBUSY bit (Pipe Busy)

The PBUSY bit indicates whether the selected pipe is being used for the current transaction.

The USBFS changes the PBUSY bit from 0 to 1 on start of the USB transaction for the selected pipe, and changes the PBUSY bit from 1 to 0 on completion of one transaction.

Reading the PBUSY bit by software after PID is set to NAK allows you to check whether changing the pipe setting is possible.

SQMON bit (Sequence Toggle Bit Confirmation)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.

The USBFS toggles the SQMON bit on successful completion of the transaction. However, the USBFS does not toggle the SQMON bit when a DATA-PID mismatch occurs during transfer in the receiving direction.

SQSET bit (Sequence Toggle Bit Set)

Setting the SQSET bit to 1 through the software causes the USBFS to set DATA1 as the expected value of the sequence toggle bit for the next transaction on the selected pipe. The USBFS sets the SQSET bit to 0.

SQCLR bit (Sequence Toggle Bit Clear)

Setting the SQCLR bit to 1 through the software causes the USBFS to clear the expected value of the sequence toggle bit for the next transaction on the selected pipe to DATA0. The USBFS sets the SQCLR bit to 0.

ACLRM bit (Auto Buffer Clear Mode)

The ACLRM bit enables or disables auto buffer clear mode for the selected pipe. To completely clear the data in the FIFO buffer allocated to the selected pipe, write 1 and then 0 to the ACLRM bit continuously.

Table 32.11 shows the data cleared by writing 1 and 0 continuously to the ACLRM bit and the cases in which this processing is required.

到00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

PID[1:0]位（响应PID）

PID[1:0]位指定所选管道的下一个事务的响应类型。

默认PID[1:0]设置为NAK。将PID[1:0]设置更改为BUF以使用关联的管道进行USB传输。
表32.7和表32.8显示了取决于PID[1:0]设置的USBFS的基本操作（在发送和接收的数据包中没有错误时）。

在选定管道上进行USB通信期间，通过软件将PID[1:0]设置从BUF更改为NAK后，检查PBUSY位是否为1，以查看选定管道上的USB传输是否真正进入了NAK状态。如果USBFS将PID[1:0]位更改为NAK，则无需通过软件检查PBUSY位。

USBFS在以下情况下更改PIPEnCTR.PID[1:0]设置：

- USBFS在接收到有效载荷超过所选管道的最大数据包大小的数据包时将PID设置为STALL(11b)
- USBFS在设备控制器模式下检测到USB总线复位时将PID设置为NAK
- USBFS在主机控制器模式下连续3次检测到接收错误（例如CRC错误）时将PID设置为NAK
- USBFS在主机控制器模式下接收到STALL握手时将PID设置为STALL(11b)。

要指定每种响应类型，请按如下方式设置PID[1:0]位：

- 要从NAK(00b)转换到STALL，请设置10b
- 要从BUF(01b)转换到STALL，请设置11b
- 要从STALL(11b)转换到NAK，请设置10b，然后设置00b
- 要从STALL过渡到BUF，先过渡到NAK，然后再过渡到BUF。

PBUSY位（管道忙）

PBUSY位指示所选管道是否正在用于当前事务。

USBFS在所选管道的USB事务开始时将PBUSY位从0更改为1，并更改
PBUSY位在一个事务完成时从1变为0。

在PID设置为NAK后，通过软件读取PBUSY位可以检查是否可以更改管道设置。

SQMON位（序列切换位确认）

SQMON位指示所选管道的下一个事务的序列切换位的预期值。

USBFS在事务成功完成时切换SQMON位。但是，当在接收方向的传输过程中发生DATA-PID不匹配时，USBFS不会触发SQMON位。

SQSET位（序列切换位设置）

通过软件将SQSET位设置为1会导致USBFS将DATA1设置为所选管道上下一个事务的序列切换位的预期值。USBFS将SQSET位设置为0。

SQCLR位（序列切换位清除）

通过软件将SQCLR位设置为1会导致USBFS将所选管道上下一个事务的序列切换位的预期值清除为DATA0。USBFS将SQCLR位设置为0。

ACLRM位（自动缓冲区清除模式）

ACLRM位启用或禁用所选管道的自动缓冲区清除模式。彻底清除数据库中的数据
FIFO缓冲区分配给所选管道，向ACLRM位连续写入1和0。

表32.11显示了通过向ACLRM位连续写入1和0来清除的数据以及需要进行此处理的情况。

Table 32.11 Data cleared by the USBFS when ACLRM = 1

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear
1	All data in the FIFO buffer allocated to the selected pipe	When initializing the selected pipe
2	Interval count value when the selected pipe is the isochronous transfer type	When resetting the interval count value
3	Internal flags related to the PIPECFG.BFRE bit	When changing the PIPECFG.BFRE setting
4	Internal flags related to the transaction count	When forcing the transaction count function to terminate

BSTS bit (Buffer Status)

The BSTS bit indicates the FIFO buffer status for the selected pipe.

The meaning of the BSTS bit depends on the PIPECFG.DIR, PIPECFG.BFRE, and DnFIFOSEL.DCLRM settings, as shown in Table 32.10.

b9	TRENB	Transaction Counter Enable	0: Disable transaction counter 1: Enable transaction counter.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Set each bit in PIPEnTRE while PID is NAK. Before setting these bits after changing the PIPEnCTR.PID[1:0] bits for the selected pipe from BUF to NAK, check that the PIPEnCTR.PBUSY bit is 0. However, if the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

TRCLR bit (Transaction Counter Clear)

When the TRCLR bit sets to 1, the USBFS clears the value of the transaction counter associated with the selected pipe and then sets the TRCLR bit to 0.

TRENB bit (Transaction Counter Enable)

The TRENB bit enables or disables the transaction counter.

For receiving pipes, setting the TRENB bit to 1 after setting the total number of the packets to be received in the PIPEnTRN.TRNCNT[15:0] bits through the software allows the USBFS to control hardware on having received the number of packets equal to the TRNCNT[15:0] setting, as follows:

- When the PIPECFG.SHTNAK bit is 1, the USBFS changes the PID bits to NAK for the associated pipe on having received the number of packets equal to the TRNCNT[15:0] setting
- When the PIPECFG.BFRE bit is 1, the USBFS asserts the BRDY interrupt on having received the number of packets equal to the TRNCNT[15:0] setting and then reading the last received data.

For transmitting pipes, set the TRENB bit to 0.

When the transaction counter is not used, set this bit to 0. When the transaction counter is used, set the TRNCNT[15:0] bits before setting this bit to 1. Set this bit to 1 before receiving the first packet to be counted by the transaction counter.

TRCLR位（事务计数器清零）

当TRCLR位设置为1时，USBFS清除与所选管道关联的事务计数器的值，然后将TRCLR位设置为0。

TRENB位（事务计数器使能）

TRENB位启用或禁用事务计数器。

对于接收管道，在设置接收管道的总包数后，将TRENB位设置为1
PIPEnTRN.TRNCNT[15:0]位通过软件允许USBFS在接收到等于TRNCNT[15:0]设置的数据包数量时控制硬件，如下所示：

- 当PIPECFG.SHTNAK位为1时，USBFS在接收到等于TRNCNT[15:0]设置的数据包数量时将关联管道的PID位更改为NAK
- 当PIPECFG.BFRE位为1时，USBFS在接收到等于TRNCNT[15:0]设置的数据包数量并读取最后接收到的数据时断言BRDY中断。

对于传输管道，将TRENB位设置为0。

当不使用事务计数器时，将该位设置为0。当使用事务计数器时，将该位设置为1之前设置TRNCNT[15:0]位。在接收第一个要计数的数据包之前将该位设置为1由交易柜台。

The PIPEnTRN registers retain their settings during a USB bus reset.

TRNCNT[15:0] bits (Transaction Counter)

The USBFS increments the value of the TRNCNT[15:0] bits by 1 when all of the following conditions are satisfied on receiving the packet:

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value ≠ current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[8:0] setting.

The USBFS clears the value of the TRNCNT[15:0] bits to 0 when any of the following conditions are satisfied:

All of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value = current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[8:0] setting.

Both of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The USBFS received a short packet.

Both of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The PIPEnTRE.TRCLR bit was set to 1 by software.

For transmitting pipes, set the TRNCNT[15:0] bits to 0. When the transaction counter is not used, set the TRNCNT[15:0] bits to 0.

Setting the number of transactions to be transferred to the TRNCNT[15:0] bits is only enabled when the PIPEnTRE.TRENB bit is 0. To set the number of transactions to be transferred, set the TRCLR bit to 1 to clear the current counter value before setting the PIPEnTRE.TRENB bit to 1.

PIPEnTRN寄存器在USB总线复位期间保留其设置。

TRNCNT[15:0]位（事务计数器）

当接收到数据包时满足以下所有条件时，USBFS将TRNCNT[15:0]位的值加1：

- PIPEnTRE.TRENB位=1
- (TRNCNT[15:0]设定值≠当前计数器值+1)收到数据包
- 接收到的数据包的有效负载与PIPEMAXP.MXPS[8:0]设置一致。

当满足以下任一条件时，USBFS将TRNCNT[15:0]位的值清零：

满足以下所有条件：

- PIPEnTRE.TRENB位=1
- (TRNCNT[15:0]设置值=当前计数器值+1)接收数据包时
- 接收到的数据包的有效负载与PIPEMAXP.MXPS[8:0]设置一致。

满足以下两个条件：

- PIPEnTRE.TRENB位=1
- USBFS收到一个短数据包。

满足以下两个条件：

- PIPEnTRE.TRENB位=1
- PIPEnTRE.TRCLR位由软件设置为1。

对于传输管道，将TRNCNT[15:0]位设置为0。当不使用事务计数器时，将TRNCNT[15:0]位设置为0。

设置要传输到TRNCNT[15:0]位的事务数仅在PIPEnTRE.TRENB位为0。要设置要传输的事务数，请将TRCLR位设置为1以清除当前计数器值，然后再将PIPEnTRE.TRENB位设置为1。

The DEVADDn register specifies the transfer speed of the peripheral device that is the communication target for pipes 0 to 9.

In host controller mode, set all DEVADDn bits before starting communication to any pipes. Only change the bits in DEVADDn when no valid pipes are using the bit settings. A valid pipe is defined as one that satisfies both of the following conditions:

- DEVADDn is selected in the DEVSEL[3:0] bits
- The PID[1:0] bits are set to BUF for the selected pipe, or the selected pipe is the DCP with the DCPCTR.SUREQ bit set to 1.

In device controller mode, set all bits in this register to 0.

USBSPD[1:0] bits (Transfer Speed of Communication Target Device)

The USBSPD[1:0] bits specify the USB transfer speed of the target peripheral device. Set these bits to 10b when a full-speed device is connected through the hub. In host controller mode, the USBFS generates packets based on the USBSPD[1:0] setting. In device controller mode, set these bits to 00b.

DEVADDn寄存器指定作为管道0到9的通信目标的外围设备的传输速度。

在主机控制器模式下，在开始与任何管道通信之前设置所有DEVADDn位。仅更改中的位DEVADDn当没有有效管道使用位设置时。有效管道被定义为同时满足以下两个条件的管道：

- DEVADDn在DEVSEL[3:0]位中选择
- 所选管道的PID[1:0]位设置为BUF，或者所选管道是DCPCTR.SUREQ位设置为1的DCP。

在设备控制器模式下，将此寄存器中的所有位设置为0。

USBSPD[1:0]位（通信目标设备的传输速度）

USBSPD[1:0]位指定目标外围设备的USB传输速度。当通过集线器连接全速设备时，将这些位设置为10b。在主机控制器模式下，USBFS根据USBSPD[1:0]设置生成数据包。在设备控制器模式下，将这些位设置为00b。

DPINTE0 bit (USB DP Interrupt Enable/Clear)

The DPINET0 bit enables or disables triggering of recovery from Deep Software Standby mode by the DP input of the USBFS. Writing 0 to this bit while the DPINT0 bit is 1 sets the DPINT0 bit to 0.

DMINTE0 bit (USB DM Interrupt Enable/Clear)

The DMINTE0 bit enables or disables triggering of recovery from Deep Software Standby mode by the DM input of the USBFS. Writing 0 to this bit while the DMINT0 bit is 1 clears the DMINTE0 bit to 0.

DOVRCRAE0 bit (USB OVRCURA Interrupt Enable/Clear)

The DOVRCRAE0 bit enables or disables triggering of recovery from Deep Software Standby mode by the OVRCURA input of the USBFS. Writing 0 to this bit while the DOVRCRA0 bit is 1 clears the DOVRCRAE0 bit to 0.

DOVRCRBE0 bit (USB OVRCURB Interrupt Enable/Clear)

The DOVRCRBE0 bit enables or disables triggering of recovery from Deep Software Standby mode by the OVRCURB input of the USBFS. Writing 0 to this bit while the DOVRCRB0 bit is 1 clears the DOVRCRB0 bit to 0.

DVBSE0 bit (USB VBUS Interrupt Enable/Clear)

The DVBSE0 bit enables or disables triggering of recovery from Deep Software Standby mode by the VBUS input of the USBFS. Writing 0 to this bit while the DVBINT0 bit is 1 clears the DVBINT0 bit to 0.

DPINT0 bit (USB DP Interrupt Source Recovery)

The DPINT0 bit indicates that the system has returned from Deep Software Standby mode because of the DP input of the USBFS. This recovery is only enabled when the DPINTE0 bit is 1. Writing 0 to the DPINTE0 bit while this bit is 1 clears this bit to 0.

DMINT0 bit (USB DM Interrupt Source Recovery)

The DMINT0 bit indicates that the system has returned from Deep Software Standby mode because of the DM input of the USBFS. This recovery is only enabled when the DMINTE0 bit is 1. Writing 0 to the DPINTE0 bit while this bit is 1 clears this bit to 0.

DOVRCRA0 bit (USB OVRCURA Interrupt Source Recovery)

The DOVRCRA0 bit indicates that the system has returned from Deep Software Standby mode because of the OVRCURA input of the USBFS. This recovery is only enabled when the DOVRCRAE0 bit is 1. Writing 0 to the DOVRCRAE0 bit while this bit is 1 clears this bit to 0.

DOVRCRB0 bit (USB OVRCURB Interrupt Source Recovery)

The DOVRCRB0 bit indicates that the system has returned from Deep Software Standby mode because of the OVRCURB input of the USBFS. This recovery is only enabled when the DOVRCRBE0 bit is 1. Writing 0 to the DOVRCRBE0 bit while this bit is 1 clears this bit to 0.

DVBINT0 bit (USB VBUS Interrupt Source Recovery)

The DVBINT0 bit indicates that the system has returned from Deep Software Standby mode because of the VBUS input of the USBFS. This recovery is only enabled when the DVBSE0 bit is 1. Writing 0 to the DVBSE0 bit while this bit is 1 clears this bit to 0.

DPINTE0位（USBDP中断使能清除）

DPINET0位启用或禁用触发从深度软件待机模式恢复由DP输入USBFS。当DPINT0位为1时向该位写入0会将DPINT0位设置为0。

DMINTE0位（USBDM中断使能清除）

DMINTE0位启用或禁用触发从深度软件待机模式恢复由DM输入USBFS。当DMINT0位为1时向该位写入0会将DMINTE0位清除为0。

DOVRCRAE0位（USBOVRCURA中断使能清除）

DOVRCRAE0位通过USBFS的OVRCURA输入启用或禁用从深度软件待机模式恢复的触发。当DOVRCRA0位为1时向该位写入0会将DOVRCRAE0位清除为0。

DOVRCRBE0位（USBOVRCURB中断使能清除）

DOVRCRBE0位通过USBFS的OVRCURB输入启用或禁用从深度软件待机模式恢复的触发。当DOVRCRB0位为1时向该位写入0会将DOVRCRB0位清除为0。

DVBSE0位（USBVBUS中断使能清除）

DVBSE0位通过VBUS输入启用或禁用从深度软件待机模式恢复的触发USBFS。当DVBINT0位为1时向该位写入0会将DVBINT0位清除为0。

DPINT0位（USBDP中断源恢复）

由于USBFS的DP输入，DPINT0位指示系统已从深度软件待机模式返回。此恢复仅在DPINTE0位为1时启用。当该位为1时向DPINTE0位写入0将该位清除为0。

DMINT0位（USBDM中断源恢复）

由于USBFS的DM输入，DMINT0位指示系统已从深度软件待机模式返回。此恢复仅在DMINTE0位为1时启用。当该位为1时将0写入DPINTE0位可将该位清除为0。

DOVRCRA0位（USBOVRCURA中断源恢复）

DOVRCRA0位指示系统已从深度软件待机模式返回，因为USBFS的OVRCURA输入。此恢复仅在DOVRCRAE0位为1时启用。将0写入DOVRCRAE0位当该位为1时将该位清除为0。

DOVRCRB0位（USBOVRCURB中断源恢复）

DOVRCRB0位指示系统已从深度软件待机模式返回，因为USBFS的OVRCURB输入。此恢复仅在DOVRCRBE0位为1时启用。将0写入DOVRCRBE0位当该位为1时将该位清除为0。

DVBINT0位（USBVBUS中断源恢复）

由于USBFS的VBUS输入，DVBINT0位指示系统已从深度软件待机模式返回。此恢复仅在DVBSE0位为1时启用。当该位为1时将0写入DVBSE0位可将该位清除为0。

32.3 Operation

32.3.1 System Control

This section describes register settings required for initializing the USBFS and controlling power consumption.

32.3.1.1 Setting data to the USBFS registers

Setting the SYSCFG.USBE bit to 1 after starting the clock supply (SYSCFG.SCKE bit = 1) enables and starts USBFS operation.

32.3.1.2 Selecting the controller function

The USBFS can operate as either a host or device controller.

Use the SYSCFG.DCFM bit to select one of these USBFS functions. The DCFM bit must be changed in the initial settings immediately after a reset or in the D+ pull-up-disabled state (SYSCFG.DPRPU bit = 0) and D+ and D- pull-down-disabled state (SYSCFG.DRPD bit = 0).

32.3.1.3 Controlling the USB data bus using resistors

The USBFS provides pull-up and pull-down resistors for the D+ and D- lines. Pull these lines up or down by setting the SYSCFG.DPRPU and DRPD bits.

In device controller mode, confirm that connection to the USB host is made, and then set the SYSCFG.DPRPU bit to 1 and pull up the D+ line (in full-speed communication).

When the SYSCFG.DPRPU bit is set to 0 during communication with a PC, the USBFS disables the pull-up resistor of the USB data line, thereby notifying the USB host of disconnection.

In host controller mode, set the SYSCFG.DRPD bit to 1 to pull down the D+ and D- lines.

Table 32.12 USB data bus resistor control

SYSCFG register settings		USB data bus control		
DRPD bit	DPRPU bit	D-	D+	Function
0	0	Open	Open	When resistors not used
0	1	Open	Pull-up	When operating as a device controller at full-speed
1	0	Pull-down	Pull-down	When operating as a host controller
1	1	—	—	Setting prohibited

32.3.1.4 Example external connection circuits

Figure 32.2 shows an example OTG connection in the self-powered system. The USBFS controls the pull-up resistor of the D+ line and the pull-down resistor of D+ and D- lines. Select pull-up and pull-down for the lines in the SYSCFG.DPRPU and SYSCFG.DRPD bits. In device controller mode, the pull-up resistor of USB data line is disabled if SYSCFG.DPRPU bit is set to 0 while communicating with the USB host. The USBFS can use this to notify the USB host of a device disconnect.

32.3 Operation

32.3.1 系统控制

本节介绍初始化USBFS和控制功耗所需的寄存器设置。

32.3.1.1 将数据设置到USBFS寄存器

启动时钟供应（SYSCFG.SCKE位=1）后将SYSCFG.USBE位设置为1启用并启动USBFS操作。

32.3.1.2 选择控制器功能

USBFS可以作为主机或设备控制器运行。

使用SYSCFG.DCFM位选择这些USBFS功能之一。DCFM位必须在复位后立即更改为初始设置或在D+上拉禁用状态（SYSCFG.DPRPU位=0）和D+和Dpulldown禁用状态（SYSCFG.DRPD位=0）。

32.3.1.3 使用电阻控制USB数据总线

USBFS为D+和Dlines提供上拉和下拉电阻。通过设置SYSCFG.DPRPU和DRPD位。

在设备控制器模式下，确认与USB主机的连接已建立，然后将SYSCFG.DPRPU位设置为1并拉高D+线（全速通信）。

当SYSCFG.DPRPU位在与PC通信期间设置为0时，USBFS禁用USB数据线的上拉电阻，从而通知USB主机断开连接。

在主机控制器模式下，将SYSCFG.DRPD位设置为1以拉低D+和Dlines。

Table 32.12 USB数据总线电阻控制

SYSCFG寄存器设置		USB数据总线控制		
DRPD bit	DPRPU bit	D-	D+	Function
0	0	Open	Open	不使用电阻时
0	1	Open	Pull-up	作为设备控制器全速运行时
1	0	Pull-down	Pull-down	作为主机控制器运行时
1	1	—	—	禁止设定

32.3.1.4 外部连接电路示例

图32.2显示了自供电系统中的示例OTG连接。USBFS控制D+线的上拉电阻和D+和Dlines的下拉电阻。为SYSCFG.DPRPU和SYSCFG.DRPD位中的线路选择上拉和下拉。在设备控制器模式下，如果在与USB主机通信时将SYSCFG.DPRPU位设置为0，则禁用USB数据线的上拉电阻。USBFS可以使用它来通知USB主机设备断开连接。

32.3.1.5 Release from deep software standby mode because of USB suspend/resume interrupts

Deep Software Standby mode can be canceled by a USB suspend/resume interrupt. USB suspend/resume interrupts are detected by the USB resume detecting unit, which controls and monitors the USB I/O pins to detect the interrupts.

Figure 32.6 shows a schematic diagram of the connection between the USB resume detecting unit and the USB I/O pins.

32.3.1.5 由于USB挂起恢复中断而从深度软件待机模式中释放

深度软件待机模式可以通过USB挂起恢复中断来取消。USB暂停恢复中断由USB恢复检测单元检测，该单元控制和监视USBIO引脚以检测中断。

32.3.2 Interrupts

Table 32.14 lists the interrupt sources in the USBFS. When an interrupt generation condition is satisfied and the interrupt output is enabled using the associated interrupt enable register, a USBFS interrupt request is issued to the Interrupt Controller Unit (ICU) and an USBFS interrupt is generated.

32.3.3 Interrupt Descriptions

32.3.3.1 BRDY interrupt

The BRDY interrupt is generated in both host and device controller modes. This section describes the conditions in which the USBFS sets the associated bit in BRDYSTS to 1. Under these conditions, the USBFS generates a BRDY interrupt if the software has set the bit in BRDYENB associated with the given pipe to 1 and the INTENB0.BRDYE bit to 1.

The conditions for generating and clearing the BRDY interrupt depend on the SOFCFG.BRDYM and PIPECFG.BFRE settings for each pipe as follows:

(1) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.

On any of the following conditions, the USBFS generates an internal BRDY interrupt request trigger and sets the BRDYSTS.PIPEnBRDY bit associated with the selected pipe to 1.

(a) For transmitting pipes

- When the DIR bit is changed from 0 to 1 by software
- When packet transmission is complete for a pipe while write-access from the CPU to the FIFO buffer for the pipe is disabled (when the BSTS bit is read as 0)
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is complete
- When the hardware flushes the buffer of the pipe for isochronous transfers
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to transition from the write-disabled to write-enabled state.

No request trigger is generated for the DCP, that is, during data transmission for control transfers.

(b) For receiving pipes

- When packet reception is successfully complete, enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the given pipe is disabled (when the BSTS bit is read as 0). No request trigger is generated for transactions in which a DATA-PID mismatch has occurred.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode. No request trigger is generated until completion of reading data from the currently-read FIFO buffer, even if reception by the other FIFO buffer is complete.

In device controller mode, the BRDY interrupt is not generated in the status stage of control transfers. The PIPEnBRDY

32.3.3 中断说明

32.3.3.1 BRDY interrupt

在主机和设备控制器模式下都会产生BRDY中断。本节介绍USBFS将BRDYSTS中的相关位设置为1的条件。在这些条件下，如果软件将BRDYENB中与给定管道相关的位设置为1并且INTENB0.BRDYE位，USBFS将生成BRDY中断为1。

产生和清除BRDY中断的条件取决于每个管道的SOFCFG.BRDYM和PIPECFG.BFRE设置，如下所示：

(1) 当SOFCFG.BRDYM=0且PIPECFG.BFRE=0时

通过这些设置，BRDY中断指示FIFO端口可访问。

在以下任何一种情况下，USBFS都会产生一个内部BRDY中断请求触发器并设置BRDYSTS.PIPEnBRDY位与所选管道相关联为1。

(a) 用于传输管道

- 当DIR位由软件从0变为1时
- 当管道的数据包传输完成而从CPU到管道的FIFO缓冲区的写访问被禁用时（当BSTS位被读取为0时）
- 双缓冲模式下，当一个FIFO缓冲区在完成向另一个FIFO缓冲区写入数据时为空时
- 直到完成向当前写入的FIFO缓冲区写入数据之前，不会生成请求触发，即使传输到另一个FIFO缓冲区已完成
- 当硬件刷新管道缓冲区以进行同步传输时
- 当1写入PIPEnCTR.ACLRM位时，这会导致FIFO缓冲区从写禁止状态转换为写使能状态。

没有为DCP生成请求触发，即在控制传输的数据传输期间。

(b) 用于接收管道

- 当数据包接收成功完成后，在从CPU到给定管道的FIFO缓冲区被禁用（当BSTS位被读取为0时）。对于发生DATA-PID不匹配的事务，不会生成请求触发器。
- 当一个FIFO缓冲区在双缓冲区模式下完成从另一个FIFO缓冲区读取数据后启用读取。在从当前读取的FIFO缓冲区读取数据完成之前，不会生成请求触发，即使其他FIFO缓冲区的接收已完成。

在设备控制器模式下，在控制传输的状态阶段不会产生BRDY中断。PIPEnBRDY

interrupt status of the selected pipe can be set to 0 by writing 0 to the associated PIPEnBRDY bit through software. In this case, the other PIPEnBRDY bit should be set to 1.

Clear the BRDY status before accessing the FIFO buffer.

(2) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 1

With these settings, the USBFS generates a BRDY interrupt on completion of reading all data for a single transfer using the receiving pipe, and sets the bit in BRDYSTS associated with the pipe to 1.

On any of the following conditions, the USBFS determines that the last data for a single transfer was received.

- When a short packet including a zero-length packet is received
- When the PIPEn transaction counter register (PIPEnTRN) is used and the number of packets specified in the PIPEnTRN.TRNCNT[15:0] bits are completely received.

When the data is completely read after any of these conditions is satisfied, the USBFS determines that all data for a single transfer is completely read.

When a zero-length packet is received while the FIFO buffer is empty, the USBFS determines that all data for a single transfer is completely read when the FRDY bit in the FIFO port control register is 1 and the DTLN[8:0] bits are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the associated port control register through the software. With these settings, the USBFS does not detect a BRDY interrupt for the transmitting pipe.

The PIPEnBRDY interrupt status of a pipe can be set to 0 by writing 0 to the associated BRDYSTS.PIPEnBRDY bit through the software. In this case, 1s must be written to the PIPEnBRDY bits for the other pipes.

In this mode, do not change the PIPECFG.BFRE bit setting until all data for a single transfer is processed. When it is necessary to change the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pipe must be cleared using the PIPEnCTR.ACLRM bit.

(3) When SOFCFG.BRDYM = 1 and PIPECFG.BFRE = 0

With these settings, the BRDYSTS.PIPEnBRDY values are linked to the BSTS bit setting for each pipe. In other words, the BRDY interrupt status bits (PIPEnBRDY) are set to 1 or 0 by the USB depending on the FIFO buffer status.

(a) For transmitting pipes

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for write access, and are set to 0 when it is not ready. The BRDY interrupt is not generated for the DCP in the transmitting direction even when it is ready for write access.

(b) For receiving pipes

The BRDY interrupt status bits set to 1 when the FIFO buffer is ready for read access, and set to 0 when all data is read (not ready for read access).

When a zero-length packet is received while the FIFO buffer is empty, the associated bit is set to 1 and the BRDY interrupt is continuously generated until the software writes 1 to BCLR. With this setting, the PIPEnBRDY bit cannot be set to 0 by software.

When the SOFCFG.BRDYM bit is set to 1, set the PIPECFG.BFRE bit for all pipes to 0.

Figure 32.11 shows the timing of BRDY interrupt generation.

通过软件将0写入相关的PIPEnBRDY位，可以将所选管道的中断状态设置为0。在这种情况下，其他PIPEnBRDY位应设置为1。

在访问FIFO缓冲区之前清除BRDY状态。

(2) 当SOFCFG.BRDYM=0且PIPECFG.BFRE=1时

使用这些设置，USBFS在完成使用接收管道读取单次传输的所有数据时生成BRDY中断，并将BRDYSTS中与管道关联的位设置为1。

在以下任何一种情况下，USBFS都会确定已接收到单次传输的最后一个数据。

- 当接收到包含零长度数据包的短数据包时
- 当使用PIPEn事务计数器寄存器(PIPEnTRN)并且在PIPEnTRN.TRNCNT[15:0]位被完全接收。

当满足其中任何一个条件后数据被完全读取时，USBFS确定单次传输的所有数据都被完全读取。

当FIFO缓冲区为空时接收到零长度数据包时，当FIFO端口控制寄存器中的FRDY位为1且DTLN[8:0]位为0.在这种情况下，要开始下一次传输，通过软件向相关端口控制寄存器中的BCLR位写入1。使用这些设置，USBFS不会检测到传输管道的BRDY中断。

通过软件将0写入相关的BRDYSTS.PIPEnBRDY位，可以将管道的PIPEnBRDY中断状态设置为0。在这种情况下，必须将1写入其他管道的PIPEnBRDY位。

在此模式下，在处理完单次传输的所有数据之前，不要更改PIPECFG.BFRE位设置。当需要在处理完成之前更改PIPECFG.BFRE位时，必须使用PIPEnCTR.ACLRM位清除管道的所有FIFO缓冲区。

(3) 当SOFCFG.BRDYM=1且PIPECFG.BFRE=0时

通过这些设置，BRDYSTS.PIPEnBRDY值链接到每个管道的BSTS位设置。换言之，BRDY中断状态位(PIPEnBRDY)由USB设置为1或0，具体取决于FIFO缓冲区状态。

(a) 用于传输管道

当FIFO缓冲区准备好进行写访问时，BRDY中断状态位设置为1，当它未准备好时设置为0。发送方向上的DCP不会产生BRDY中断，即使它已准备好进行写访问。

(b) 用于接收管道

当FIFO缓冲区准备好进行读取访问时，BRDY中断状态位设置为1，并在读取所有数据（未准备好进行读取访问）时设置为0。

当FIFO缓冲区为空时接收到零长度数据包时，相关位设置为1，并且持续产生BRDY中断，直到软件将1写入BCLR。使用此设置，PIPEnBRDY位不能通过软件设置为0。

当SOFCFG.BRDYM位设置为1时，将所有管道的PIPECFG.BFRE位设置为0。

图32.11显示了BRDY中断产生的时序。

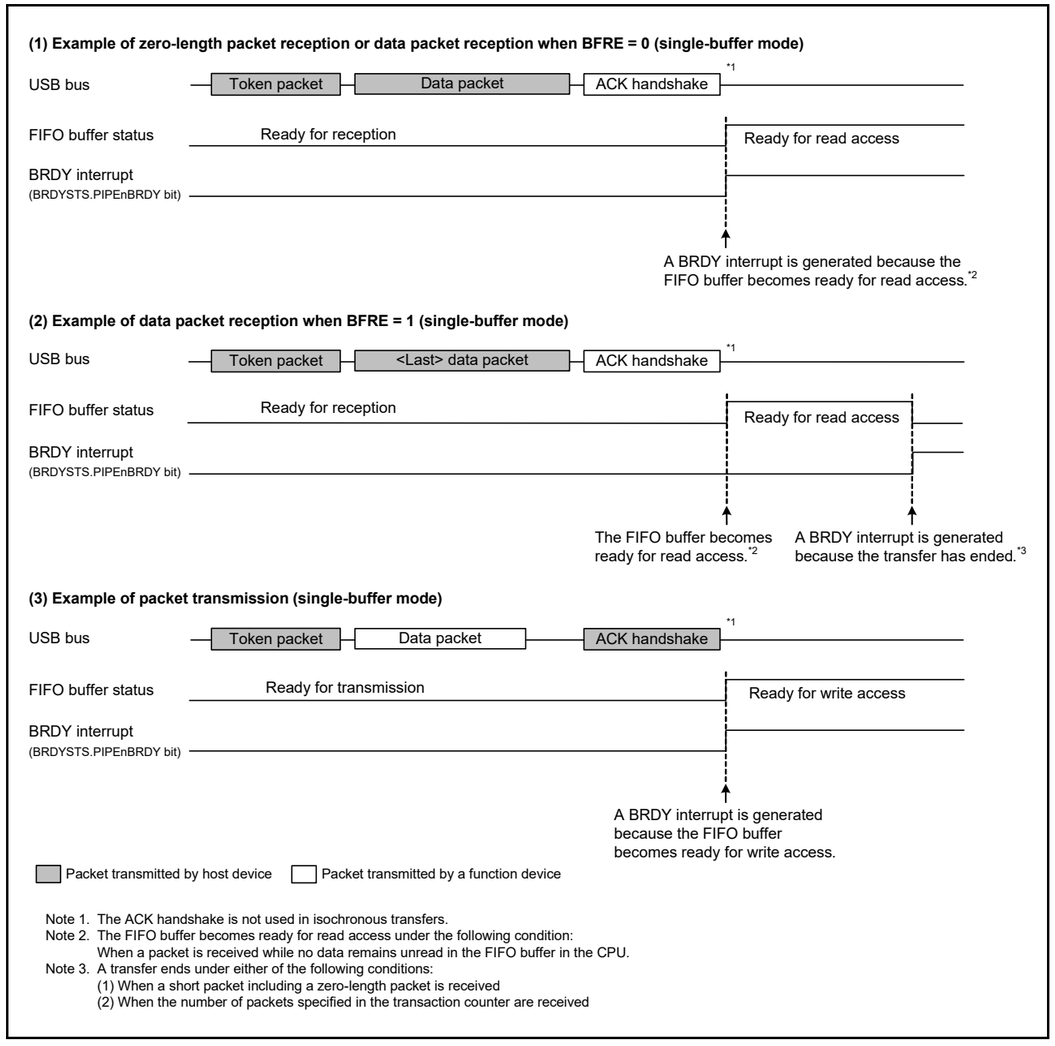

Figure 32.11 Timing of BRDY interrupt generation

The condition for clearing the INTSTS0.BRDY bit depends on the SOFCFG.BRDYM bit setting, as shown in Table 32.16.

32.3.3.2 NRDY interrupt

On generating an internal NRDY interrupt request for the pipe whose PID bits are set to BUF by software, the USBFS sets the associated PIPEnNRDY bit in NRDYSTS to 1. If the associated bit in NRDYENB is set to 1 by software, the USBFS sets the INTSTS0.NRDY bit to 1 and generates a USBFS interrupt.

32.3.3.2 NRDY interrupt

在为PID位由软件设置为BUF的管道生成内部NRDY中断请求时，USBFS将NRDYSTS中的相关PIPEnNRDY位设置为1。如果NRDYENB中的相关位由软件设置为1，则USBFS设置INTSTS0.NRDY位为1并产生USBFS中断。

This section describes the conditions in which the USBFS generates the internal NRDY interrupt request for a given pipe.

The internal NRDY interrupt request is not generated during setup transaction execution in host controller mode. During setup transactions in host controller mode, the SACK or SIGN interrupt is detected.

The internal NRDY interrupt request is not generated during status stage execution of the control transfer in device controller mode.

(1) In host controller mode

(a) For transmitting pipes

On any of the following conditions, the USBFS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBFS transmits a zero-length packet following the OUT token and sets the associated NRDYSTS.PIPEnNRDY bit and the FRMNUM.OVRN bit to 1.
- During communications other than setup transactions on pipes not used for isochronous transfers, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device
  - An error is detected in the packet from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the associated PID[1:0] setting for the pipe to NAK.
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the PID[1:0] setting for the associated pipe to STALL (11b).

(b) For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBFS discards the received data for the IN token and sets the PIPEnNRDY bit associated with the pipe and the OVRN bit to 1. When a packet error is detected in the received data for the IN token, the USBFS also sets the FRMNUM.CRCE bit to 1.
- For non-isochronous transfer pipes, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device for the IN token issued by the USBFS (when timeout is detected before detection of the DATA packet from the peripheral device)
  - An error is detected in the packet from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the associated PID[1:0] setting for the pipe to NAK.
- For isochronous transfer pipes, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe to 1. The PID[1:0] setting for the pipe is not changed.
- For isochronous transfer pipes, when a CRC error or a bit stuffing error is detected in the received data packet. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe and the CRCE bit to 1.
- When the STALL handshake is received. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe to 1 and changes the PID[1:0] setting for the associated pipe to STALL.

(2) In device controller mode

(a) For transmitting pipes

- When an IN token is received while there is no data to be transmitted in the FIFO buffer. In this case, the USBFS generates a NRDY interrupt request on reception of the IN token and sets the NRDYSTS.PIPEnNRDY bit to 1. For an isochronous transfer pipe in which an interrupt is generated, the USBFS transmits a zero-length packet and sets the FRMNUM.OVRN bit to 1.

本节描述USBFS为给定管道生成内部NRDY中断请求的条件。

内部NRDY中断请求在主控制器模式下的设置事务执行期间不会产生。在主机控制器模式下的设置事务期间，检测到SACK或SIGN中断。

在设备控制器模式下控制传输的状态阶段执行期间，不会产生内部NRDY中断请求。

(1) 在主机控制器模式下

(a) 用于传输管道

在以下任何一种情况下，USBFS都会检测到NRDY中断：

- 对于同步传输管道，当发出OUT令牌的时间到来时，FIFO缓冲区中没有要传输的数据。在这种情况下，USBFS在OUT令牌之后发送一个长度为零的数据包，并将相关的NRDYSTS.PIPEnNRDY位和FRMNUM.OVRN位设置为1。
- 在不用于同步传输的管道上的设置事务以外的通信期间，当以下两种情况的任意组合连续发生3次时：
  - 外围设备没有返回响应（当在检测到来自外围设备的握手包之前检测到超时时
  - 在来自外围设备的数据包中检测到错误。在这种情况下，USBFS设置关联的PIPEnNRDY位为1并将管道的相关PID[1:0]设置更改为NAK。
- 在设置事务以外的通信期间，当从外围设备接收到STALL握手时。在这种情况下，USBFS将相关的PIPEnNRDY位设置为1，并将相关管道的PID[1:0]设置更改为STALL(11b)。

(b) 用于接收管道

- 对于同步传输管道，当发出IN令牌的时间到来但FIFO缓冲区中没有可用空间时。在这种情况下，USBFS丢弃接收到的IN令牌数据，并将与管道关联的PIPEnNRDY位和OVRN位设置为1。当在接收到的IN令牌数据中检测到数据包错误时，USBFS也会设置FRMNUM.CRCE位为1。
- 对于非等时传输管道，当下列两种情况的任意组合连续出现3次时：
  - USBFS发出的IN令牌没有从外围设备返回响应（当在检测到来自外围设备的DATA包之前检测到超时时）
  - 在来自外围设备的数据包中检测到错误。在这种情况下，USBFS设置关联的PIPEnNRDY位为1并将管道的相关PID[1:0]设置更改为NAK。
- 对于同步传输管道，当外围设备没有返回对IN令牌的响应时（在检测到来自外围设备的DATA数据包之前检测到超时）或在来自外围设备的数据包中检测到错误。在这种情况下，USBFS将与管道关联的PIPEnNRDY位设置为1。管道的PID[1:0]设置不会更改。
- 对于同步传输管道，当在接收到的数据包中检测到CRC错误或位填充错误时。在这种情况下，USBFS将与管道关联的PIPEnNRDY位和CRCE位设置为1。
- 当收到STALL握手时。在这种情况下，USBFS将与管道关联的PIPEnNRDY位设置为1，并将关联管道的PID[1:0]设置更改为STALL。

(2) 在设备控制器模式下

(a) 用于传输管道

- 当FIFO缓冲区中没有要传输的数据时接收到IN令牌。在这种情况下，USBFS在接收到IN令牌时产生一个NRDY中断请求，并将NRDYSTS.PIPEnNRDY位设置为1。对于产生中断的同步传输管道，USBFS发送一个长度为零的数据包并将FRMNUM.OVRN位为1。

(b) For receiving pipes

- When an OUT token is received but there is no space available in the FIFO buffer. For an isochronous transfer pipe in which an interrupt is generated, the USBFS generates a NRDY interrupt request on reception of the OUT token and sets the PIPEnNRDY bit to 1 and OVRN bit to 1. For a non-isochronous transfer pipe in which an interrupt is generated, the USBFS generates a NRDY interrupt request when a NAK handshake is transferred after the data following the OUT token is received, and sets the PIPEnNRDY bit to 1. The NRDY interrupt request is not generated during retransmission because of a DATA-PID mismatch. In addition, the NRDY interrupt request is not generated if an error occurs in the DATA packet.
- For isochronous transfer pipes, when a token is not received successfully within an interval frame. In this case, the USBFS generates an NRDY interrupt request when the SOF is received, and sets the PIPEnNRDY bit to 1.

Figure 32.12 shows the timing of NRDY interrupt generation in device controller mode.

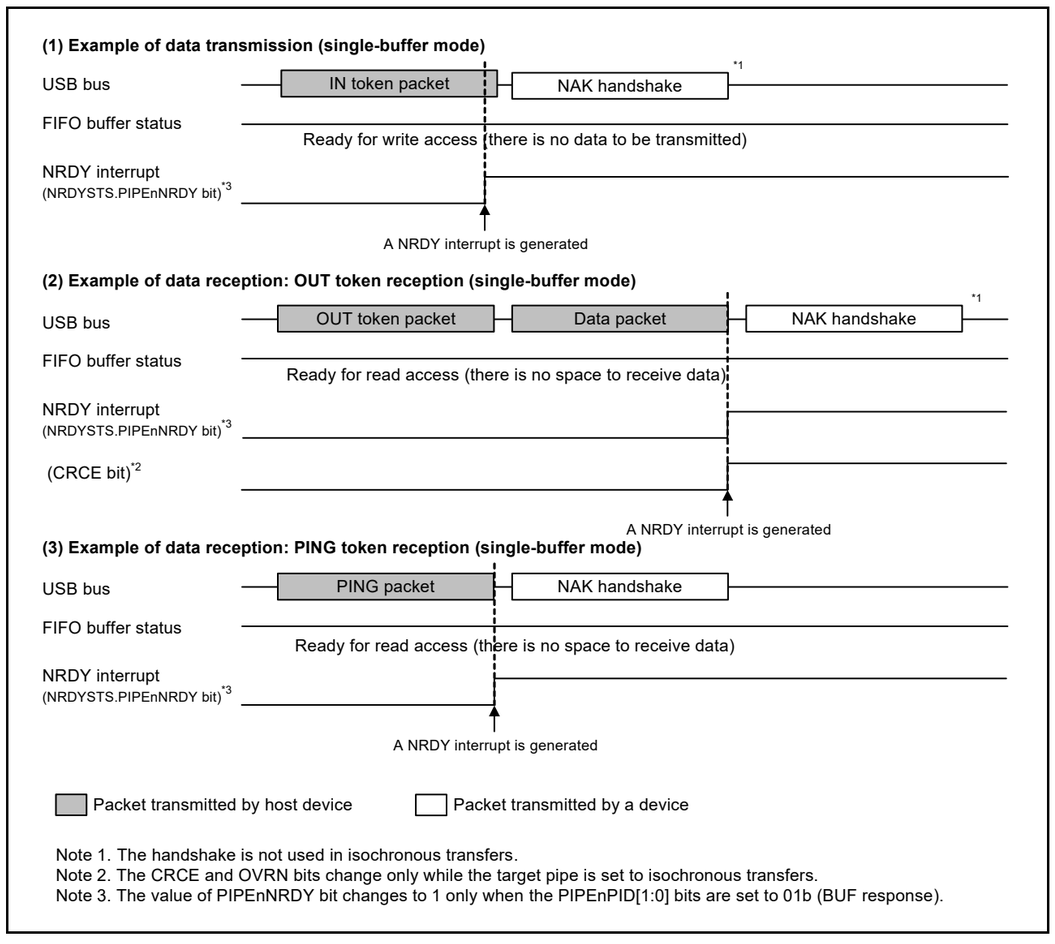

Figure 32.12 Timing of NRDY interrupt generation in device controller mode

32.3.3.3 BEMP interrupt

On detecting a BEMP interrupt for the pipe whose PID bits are set to BUF by software, the USBFS sets the associated BEMPSTS.PIPEnBEMP bit to 1. If the associated bit in BEMPENB is set to 1 by software, the USBFS sets the INTSTS0.BEMP bit to 1 and generates a USBFS interrupt. This section describes the conditions in which the USBFS generates an internal BEMP interrupt request.

(b) 用于接收管道

- 当接收到OUT令牌但FIFO缓冲区中没有可用空间时。对于产生中断的同步传输管道，USBFS在接收到OUT令牌时产生一个NRDY中断请求，并将PIPEnNRDY位设置为1，并将OVRN位设置为1。USBFS在接收到OUT令牌之后的数据后，在传输NAK握手时产生NRDY中断请求，并将PIPEnNRDY位设置为1。由于DATA-PID不匹配，重传期间不会产生NRDY中断请求。此外，如果DATA包发生错误，则不会产生NRDY中断请求。
- 对于同步传输管道，当在间隔帧内未成功接收到令牌时。在这种情况下，USBFS在接收到SOF时产生一个NRDY中断请求，并将PIPEnNRDY位设置为1。

图32.12显示了设备控制器模式下NRDY中断产生的时序。

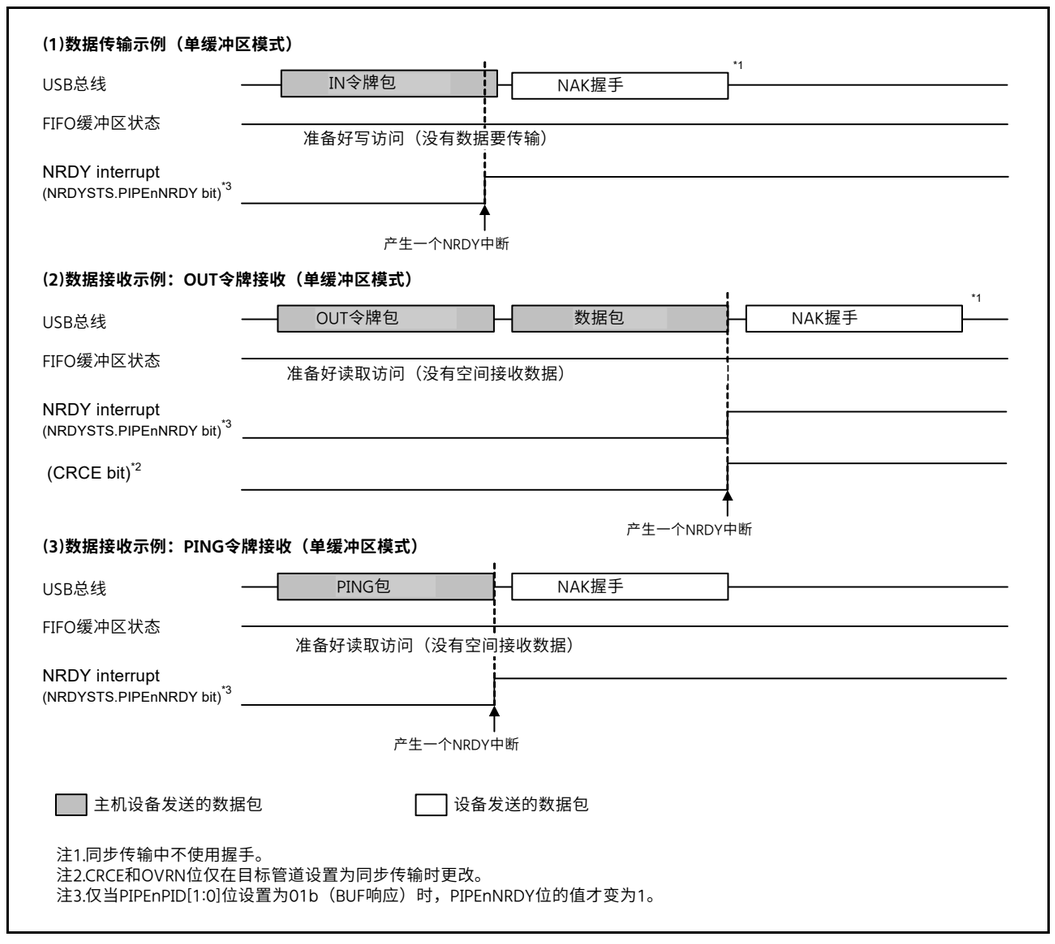

Figure 32.12 设备控制器模式下NRDY中断产生的时序

32.3.3.3 BEMP interrupt

在检测到PID位被软件设置为BUF的管道的BEMP中断时，USBFS将相关的BEMPSTS.PIPEnBEMP位设置为1。如果BEMPENB中的相关位被软件设置为1，USBFS将设置
INTSTS0.BEMP位为1并产生USBFS中断。本节介绍USBFS产生内部BEMP中断请求的条件。

(1) For transmitting pipes

When the FIFO buffer of the associated pipe is empty on completion of transmission, including zero-length packet transmission, and in single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for a non-DCP pipe. The internal BEMP interrupt request is not generated in any of the following conditions:

- When the CPU or DMA/DTC has already started writing data to the FIFO buffer of the CPU on completion of transmitting data from one FIFO buffer in double buffer mode
- When the buffer is cleared (emptied) by setting the PIPEnCTR.ACLRM or the BCLR bit to 1 in the port control register
- When an IN transfer (zero-length packet transmission) is performed during the control transfer status stage in device controller mode.

(2) For receiving pipes

When a successfully-received data packet size exceeds the specified maximum packet size. In this case, the USBFS generates a BEMP interrupt request, sets the associated BEMPSTS.PIPEnBEMP bit to 1, discards the received data, and changes the associated PID[1:0] setting for the pipe to STALL (11b). The USBFS returns no response in host controller mode, and returns STALL response in device controller mode.

The internal BEMP interrupt request is not generated in any of the following conditions:

- When a CRC error or a bit stuffing error is detected in the received data
- When a setup transaction is being performed:
  - Writing 0 to the BEMPSTS.PIPEnBEMP bit clears the status
  - Writing 1 to the BEMPSTS.PIPEnBEMP bit has no effect.

Figure 32.13 shows the timing of BEMP interrupt generation in device controller mode.

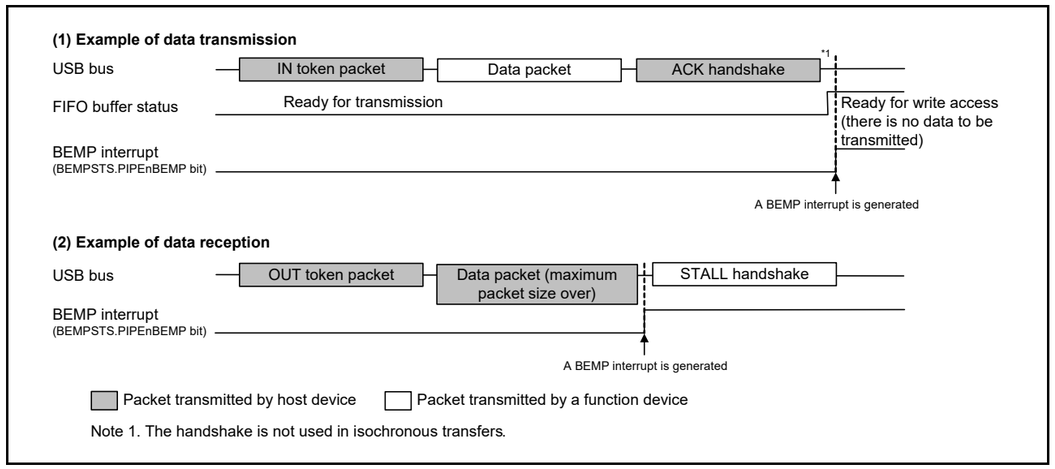

Figure 32.13 Timing of BEMP interrupt generation in device controller mode

32.3.3.4 Device state transition interrupt (device controller mode)

Figure 32.14 shows a diagram of the USBFS device state transitions. The USBFS controls device states and generates device state transition interrupts. However, recovery from the Suspend state (resume signal detection) is detected by means of the resume interrupt. Device state transition interrupts can be enabled or disabled independently in INTENB0. Devices whose states have changed can be checked in the INTSTS0.DVSQ[2:0] bits.

When a transition is made to the default state, a device state transition interrupt is generated after a USB bus reset is detected.

The USBFS controls device states, and device state transition interrupts can be generated, only in device controller

(1) 用于传输管道

当相关管道的FIFO缓冲区在传输完成时为空时，包括零长度数据包传输，并且在单缓冲区模式下，内部BEMP中断请求与非DCP管道的BRDY中断同时生成。在以下任何一种情况下都不会产生内部BEMP中断请求：

- 当CPU或DMADTC在双缓冲模式下从一个FIFO缓冲区完成数据传输后已经开始向CPU的FIFO缓冲区写入数据时
- 当通过将端口控制寄存器中的PIPEnCTR.ACLRM或BCLR位设置为1来清除（清空）缓冲区时
- 在设备控制器模式下的控制传输状态阶段执行IN传输（零长度数据包传输）时。

(2) 用于接收管道

当成功接收的数据包大小超过指定的最大包大小时。在这种情况下，USBFS生成一个BEMP中断请求，将相关的BEMPSTS.PIPEnBEMP位设置为1，丢弃接收到的数据，并将管道的相关PID[1:0]设置更改为STALL(11b)。USBFS在主机控制器模式下不返回响应，在设备控制器模式下返回STALL响应。

在以下任何一种情况下都不会产生内部BEMP中断请求：

- 在接收到的数据中检测到CRC错误或位填充错误时
- 执行设置事务时：
  - 将0写入BEMPSTS.PIPEnBEMP位可清除状态
  - 向BEMPSTS.PIPEnBEMP位写入1无效。

图32.14显示了USBFS设备状态转换的示意图。USBFS控制设备状态并产生设备状态转换中断。但是，从挂起状态的恢复（恢复信号检测）是通过恢复中断来检测的。可以在INTENB0中独立启用或禁用设备状态转换中断。可以在INTSTS0.DVSQ[2:0]位中检查状态已更改的设备。

当转换到默认状态时，检测到USB总线复位后会产生设备状态转换中断。

32.3.3.5 Control transfer stage transition interrupt (device controller mode)

Figure 32.15 shows a diagram of the control transfer stage transitions of the USBFS. The USBFS controls the control transfer sequence and generates control transfer stage transition interrupts. Control transfer stage transition interrupts can be enabled or disabled independently in INTENB0. Transfer stages that have transitioned can be checked in the INTSTS0.CTSQ[2:0] bits.

Control transfer stage transition interrupts are generated only in device controller mode. This section describes control transfer sequence errors. If an error occurs, the DCPCTR.PID[1:0] bits are set to 1xb (STALL response).

(1) Control read transfer errors

- An OUT token is received but no data is transferred in response to the IN token at the data stage
- An IN token is received at the status stage
- A data packet with DATAPID = DATA0 is received at the status stage.

(2) Control write transfer errors

- An IN token is received but no ACK is returned in response to the OUT token at the data stage
- A data packet with DATAPID = DATA0 is received as the first data packet at the data stage
- An OUT token is received at the status stage.

(3) Control write no data transfer errors

- An OUT token is received at the status stage.

At the control write transfer data stage, if the receive data length exceeds the wLength value of the USB request, it is not recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (INTSTS0.CTRT = 1), the CTSQ[2:0] = 110b value is saved until the CTRT bit is set to 0, clearing the interrupt status. While CTSQ[2:0] = 110b is being saved, no CTRT interrupt for ending the setup stage is generated, even if a new USB request is received. The USBFS saves the setup stage completion status, and it generates a CTRT interrupt after the interrupt status is cleared by software.

32.3.3.6 Frame update interrupt

In host controller mode, an interrupt is generated when the frame number is updated.

In device controller mode, an SOFR interrupt is generated when the frame number is updated. The USBFS updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation.

32.3.3.7 VBUS interrupt

When the USB_VBUS pin level changes, a VBUS interrupt is generated. The level of the USB_VBUS pin can be

(1) 控制读取传输错误

- 接收到OUT令牌，但在数据阶段没有响应IN令牌传输数据
- 在状态阶段收到一个IN令牌
- 在状态阶段接收到一个DATAPID=DATA0的数据包。

(2) 控制写入传输错误

- 在数据阶段接收到IN令牌但没有返回ACK以响应OUT令牌
- DATAPID=DATA0的数据包作为数据阶段的第一个数据包被接收
- 在状态阶段收到一个OUT令牌。

(3) 控制写入无数据传输错误

- 在状态阶段收到一个OUT令牌。

在控制写入传输数据阶段，如果接收数据长度超过USB请求的wLength值，则不被识别为控制传输序列错误。在控制读取传输状态阶段，除了零长度数据包之外的数据包被一个ACK响应接收并且传输正常结束。

当CTRT中断响应序列错误(INTSTS0.CTRT=1)时，将保存CTSQ[2:0]=110b值，直到CTRT位设置为0，清除中断状态。在保存CTSQ[2:0]=110b时，不会产生用于结束设置阶段的CTRT中断，即使收到新的USB请求也是如此。USBFS保存设置阶段完成状态，软件清除中断状态后产生CTRT中断。

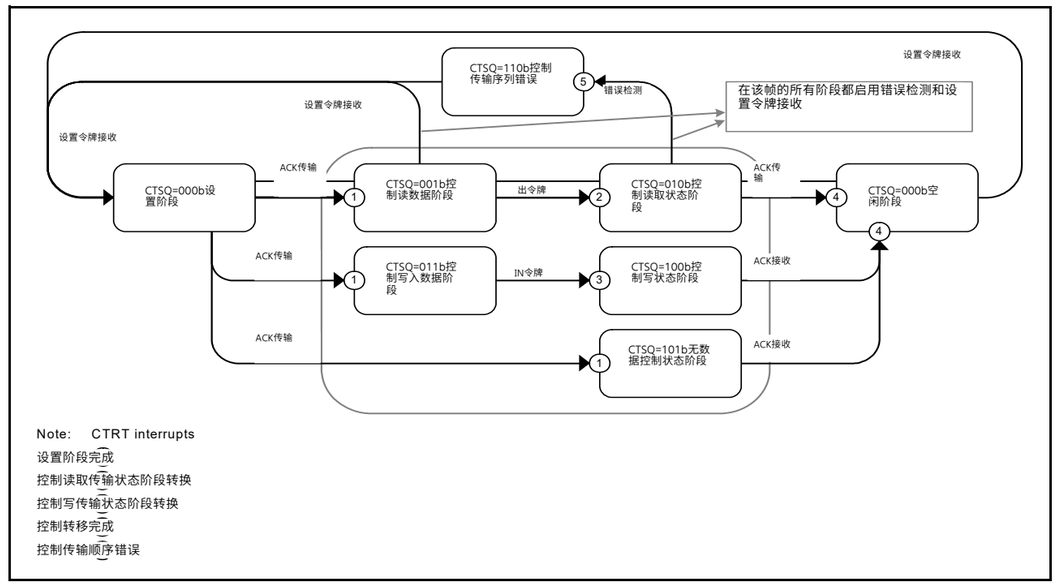

Figure 32.15 控制转移阶段转换

32.3.3.6 帧更新中断

在主机控制器模式下，更新帧号时会产生中断。

在设备控制器模式下，更新帧号时会产生SOFR中断。如果USBFS在全速运行期间检测到新的SOF数据包，则USBFS会更新帧号并生成SOFR中断。

32.3.3.7 VBUS interrupt

当USB_VBUS引脚电平改变时，会产生VBUS中断。USB_VBUS引脚的电平可以是

checked with the INTSTS0.VBSTS bit. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. If the system is activated with the host controller connected, the first VBUS interrupt is not generated, because there is no change in the USB_VBUS pin level.

32.3.3.8 Resume interrupt

In device controller mode, a resume interrupt is generated when the device state is the Suspend state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the Suspend state is detected by means of the resume interrupt.

In host controller mode, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

32.3.3.9 OVRCR interrupt

An OVRCR interrupt is generated when the USB_OVRCURA or USB_OVRCURB pin level has changed. The levels of the USB_OVRCURA and USB_OVRCURB pins can be checked in the SYSSTS0.OVCMON[1:0] flags. The external power supply IC can check whether overcurrent is detected using the OVRCR interrupt.

For OTG connections, the OVRCR interrupt allows you to check whether a change is detected in the VBUS comparator.

32.3.3.10 BCHG interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether a peripheral device is connected and can also be used to detect a remote wakeup in host controller mode. The BCHG interrupt is generated in both host and device controller modes.

32.3.3.11 DTCH interrupt

A DTCH interrupt occurs when a USB bus disconnect is detected in host controller mode. The USBFS detects bus disconnects in compliance with the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software. The pipes enter the wait state for a bus connection to the port, waiting for an ATTCH interrupt to occur. Regardless of the value set in the associated interrupt enable bit, the USBFS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt is detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state.

32.3.3.12 SACK interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet is received from the peripheral device in host controller mode. The SACK interrupt can be used to confirm that the setup transaction is successfully complete.

32.3.3.13 SIGN interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet is not correctly received from the peripheral device three consecutive times in host controller mode. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

32.3.3.14 ATTCH interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5 µs in host controller mode. To be more specific, an ATTCH interrupt is detected on any of the following conditions:

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5 µs
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5 µs.

32.3.3.15 EOFERR interrupt

An EOFERR interrupt occurs when the USBFS detects that communication is not complete at the EOF2 timing defined in the USB 2.0 specification.

用INTSTS0.VBSTS位检查。主控制器是连接还是断开可以使用VBUS中断来确认。如果系统在连接主机控制器的情况下激活，则不会产生第一个VBUS中断，因为USB_VBUS引脚电平没有变化。

32.3.3.8 恢复中断

在设备控制器模式下，当设备状态为Suspend状态且USB总线状态发生变化（从J-state到K-state，或从J-state到SE0）时，会产生恢复中断。通过恢复中断检测从挂起状态的恢复。

在主机控制器模式下，不会产生恢复中断。使用BCHG中断来检测USB总线状态的变化。

32.3.3.9 OVRCR interrupt

当USB_OVRCURA或USB_OVRCURB引脚电平发生变化时，会产生OVRCR中断。USB_OVRCURA和USB_OVRCURB引脚的电平可以在SYSSTS0.OVCMON[1:0]标志中检查。外部电源IC可以使用OVRCR中断检查是否检测到过电流。

对于OTG连接，OVRCR中断允许您检查是否在VBUS比较器中检测到变化。

32.3.3.10 BCHG interrupt

当USB总线状态改变时会产生BCHG中断。BCHG中断可用于检测是否连接了外围设备，也可用于检测主机控制器模式下的远程唤醒。BCHG中断在主机和设备控制器模式下产生。

32.3.3.11 DTCH interrupt

当在主机控制器模式下检测到USB总线断开连接时，会发生DTCH中断。USBFS检测符合USB2.0规范的总线断开连接。

在检测到中断时，为相关端口执行通信的所有管道必须由软件终止。管道进入等待状态，等待总线连接到端口，等待ATTCH中断发生。无论相关中断使能位中设置的值如何，USBFS硬件：

- 将检测到DTCH中断的端口的DVSTCTR0.UACT位设置为0
- 将发生DTCH中断的端口置于空闲状态。

32.3.3.12 SACK中断

当在主机控制器模式下从外围设备接收到对发送的设置数据包的ACK响应时，将产生SACK中断。SACK中断可用于确认设置事务成功完成。

32.3.3.13 标志中断

在主机控制器模式下，如果连续三次未从外围设备正确接收到已发送的设置数据包的ACK响应，则会产生SIGN中断。SIGN中断可用于检测没有从外围设备发送的ACK响应或ACK数据包的损坏。

32.3.3.14 ATTCH interrupt

在主机控制器模式下，当在USB端口上检测到全速信号电平的J状态或K状态持续2.5µs时，将产生ATTCH中断。更具体地说，在以下任何条件下都会检测到ATTCH中断：

- 当K-state、SE0或SE1变为J-state时，J-state持续2.5μs
- 当J-state、SE0或SE1变为K-state时，K-state持续2.5μs。

32.3.3.15 EOFERR interrupt

当USBFS检测到在USB2.0规范中定义的EOF2时序未完成通信时，将发生EOFERR中断。

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software, and the port must be re-enumerated. Regardless of the value set in the associated interrupt enable bit, the USBFS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt is detected to 0
- Puts the port in which the EOFERR interrupt is generated into the idle state.

32.3.4 Pipe Control

Table 32.17 lists the pipe settings for the USBFS. USB data transfer is performed through logical pipes that the software associates with endpoints. The USBFS provides 10 pipes that are used for data transfer. Set up the pipes based on your system specifications.

Table 32.17 Pipe settings

Register name	Bit name	Setting	Notes
DCPCFG PIPECFG	TYPE	Transfer type	Pipes 1 to 9: Settable
	BFRE	BRDY interrupt mode	Pipes 1 to 5: Settable
	DBLB	Double buffer select	Pipes 1 to 5: Settable
	DIR	Transfer direction select	IN or OUT settable
	EPNUM	Endpoint number	Pipes 1 to 9: Settable A value other than 0000b must be set when the pipe is used.
	SHTNAK	Selects disabled state for pipe when transfer ends	Pipes 1 and 2: Settable only for bulk transfers Pipes 3 to 5: Settable
DCPMAXP PIPEMAXP	DEVSEL	Device select	Referenced only in host controller mode.
	MXPS	Maximum packet size	Compliant with the USB 2.0 specification.
PIPEPERI	IFIS	Buffer flush	Pipes 1 and 2: Settable only for isochronous transfers Pipes 3 to 9: Setting disabled
	IITV	Interval counter	Pipes 1 and 2: Settable only for isochronous transfers Pipes 3 to 5: Setting disabled Pipes 6 to 9: Settable only in host controller mode
DCPCTR PIPEnCTR	BSTS	Buffer status	For the DCP, receive buffer status and transmit buffer status are switched with the ISEL bit.
	INBUFM	IN buffer monitor	Available only for pipes 1 to 5.
	SUREQ	Setup request	Settable only for the DCP and controlled in host controller mode
	SUREQCLR	SUREQ clear	Settable only for the DCP and controlled in host controller mode
	ATREPM	Auto response mode	Pipes 1 to 5: Settable only in device controller mode
	ACLRM	Auto buffer clear	Pipes 1 to 9: Settable
	SQCLR	Sequence clear	Clears the data toggle bit
	SQSET	Sequence set	Sets the data toggle bit
	SQMON	Sequence monitor	Monitors the data toggle bit
	PBUSY	Pipe busy status	-
	PID	Response PID	See section 32.3.4.6, Response PID.
PIPEnTRE	TRENB	Transaction counter enable	Pipes 1 to 5: Settable
	TRCLR	Current transaction counter clear	Pipes 1 to 5: Settable
PIPEnTRN	TRNCNT	Transaction counter	Pipes 1 to 5: Settable

32.3.4.1 Pipe control register switching procedures

The following bits in the pipe control registers can be changed only when USB communication is prohibited (PID = NAK).

Do not change the following registers and bits when USB communication is enabled (PID = BUF):

在检测到中断时，所有为相关端口执行通信的管道必须由软件终止，并且必须重新枚举该端口。无论相关中断使能位中设置的值如何，USBFS硬件：

- 将检测到EOFERR中断的端口的DVSTCTR0.UACT位设置为0
- 将产生EOFERR中断的端口置于空闲状态。

32.3.4 管道控制

表32.17列出了USBFS的管道设置。USB数据传输是通过软件与端点关联的逻辑管道执行的。USBFS提供了10个用于数据传输的管道。根据您的系统规格设置管道。

Table 32.17 管道设置

注册名称	位名称	Setting	Notes
DCPCFG PIPECFG	TYPE	传输类型	管道1至9：可设置
	BFRE	BRDY中断模式	管道1至5：可设置
	DBLB	双缓冲选择	管道1至5：可设置
	DIR	传输方向选择	输入或输出可设置
	EPNUM	端点编号	管道1至9：可设置 使用管道时，必须设置0000b以外的值。
	SHTNAK	传输结束时为管道选择禁用状态	管道1和2：仅可设置用于批量传输 管道3至5：可设置
DCPMAXP PIPEMAXP	DEVSEL	设备选择	仅在主机控制器模式下引用。
	MXPS	最大数据包大小	符合USB2.0规范。
PIPEPERI	IFIS	缓冲区刷新	管道1和2：仅可设置用于同步传输 管道3到9：设置禁用
	IITV	间隔计数器	管道1和2：仅可设置用于同步传输 管道3到5：禁用设置 管道6到9：仅在主机控制器模式下可设置
DCPCTR PIPEnCTR	BSTS	缓冲状态	对于DCP，接收缓冲器状态和发送缓冲器状态通过ISEL位切换。
	INBUFM	IN缓冲监视器	仅适用于管道1到5。
	SUREQ	设置请求	只能为DCP设置并在主机控制器模式下控制
	SUREQCLR	SUREQ clear	只能为DCP设置并在主机控制器模式下控制
	ATREPM	自动响应模式	管道1到5：仅在设备控制器模式下可设置
	ACLRM	自动缓冲区清除	管道1至9：可设置
	SQCLR	序列清晰	清除数据切换位
	SQSET	序列集	设置数据切换位
	SQMON	序列监视器	监控数据切换位
	PBUSY	管道繁忙状态	-
	PID	响应PID	请参阅第32.3.4.6节，响应PID。
PIPEnTRE	TRENB	事务计数器启用	管道1至5：可设置

PIPEnTRN	TRNCNT	交易柜台	管道1至5：可设置

32.3.4.1 管道控制寄存器切换程序

只有当USB通信被禁止（PID=
NAK).

当启用USB通信(PID=BUF)时，请勿更改以下寄存器和位：

- Bits in DCPCFG and DCPMAXP
- SQCLR and SQSET bits in DCPCTR
- Bits in PIPECFG, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPEnCTR
- Bits in PIPEnTRE and PIPEnTRN.

To set these bits when USB communication is enabled (PID = BUF):

1. A request to change the bits in the pipe control register occurs.
2. Set the PID[1:0] bits associated with the pipe to NAK.
3. Wait until the associated PBUSY bit clears to 0.
4. Set the bits in the pipe control register.

The following bits in the pipe control registers can be changed only when the selected pipe information is not set in the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Do not set the following registers when the CURPIPE[3:0] bits are set:

- Bits in DCPCFG and DCPMAXP
- Bits in PIPECFG, PIPEMAXP and PIPEPERI.

To change pipe information, you must set the CURPIPE[3:0] bits in the port select registers to a pipe other than the one to be changed. For the DCP, the buffer must be cleared using the BCLR bit in the Port Control Register after the pipe information is changed.

32.3.4.2 Transfer types

The PIPECFG.TYPE[1:0] bits specify the following transfer types for each pipe:

- DCP: No setting is necessary (fixed at control transfer)
- Pipes 1 and 2: Set to bulk or isochronous transfer
- Pipes 3 to 5: Set to bulk transfer
- Pipes 6 to 9: Set to interrupt transfer.

32.3.4.3 Endpoint number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to 15.

- DCP: No setting is necessary (fixed at endpoint 0)
- Pipes 1 to 9: Select and set the endpoint numbers from 1 to 15 so that the combination of the PIPECFG.DIR and EPNUM[3:0] bits is unique.

32.3.4.4 Maximum packet size setting

Specify the maximum packet size for each pipe in the DCPMAXP.MXPS[6:0] and PIPEMAXP.MXPS[8:0] bits. The DCP and pipes 1 to 5 can be set to any of the maximum pipe sizes defined in the USB 2.0 specification. For pipes 6 to 9, the maximum packet size is 64 bytes. Set the maximum packet size as follows before starting a transfer (PID = BUF):

- DCP: Set to 8, 16, 32, or 64
- Pipes 1 to 5: Set to 8, 16, 32, or 64 for bulk transfers
- Pipes 1 and 2: Set between 1 and 256 for isochronous transfers
- Pipes 6 to 9: Set between 1 and 64.

32.3.4.5 Transaction counter for pipes 1 to 5 in the receiving direction

When the specified number of transactions is complete in the data packet receiving direction, the USBFS recognizes that

- DCPCFG和DCPMAXP中的位
- DCPCTR中的SQCLR和SQSET位
- PIPECFG、PIPEMAXP和PIPEPERI中的位
- PIPEnCTR中的ATREPM、ACLRM、SQCLR和SQSET位
- PIPEnTRE和PIPEnTRN中的位。

要在启用USB通信(PID=BUF)时设置这些位：

1. 发生更改管道控制寄存器中的位的请求。
2. 将与管道关联的PID[1:0]位设置为NAK。
3. 等到相关的PBUSY位清除为0。
4. 设置管道控制寄存器中的位。

管道控制寄存器中的以下位只有在所选管道信息未设置时才能更改CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位。

设置CURPIPE[3:0]位时不要设置以下寄存器：

- DCPCFG和DCPMAXP中的位
- PIPECFG、PIPEMAXP和PIPEPERI中的位。

要更改管道信息，您必须将端口选择寄存器中的CURPIPE[3:0]位设置为要更改的管道以外的管道。对于DCP，必须在管道信息更改后使用端口控制寄存器中的BCLR位清除缓冲区。

32.3.4.2 传输类型

PIPECFG.TYPE[1:0]位为每个管道指定以下传输类型：

- DCP：无需设置（控制转移时固定）
- 管道1和2：设置为批量传输或同步传输
- 管道3到5：设置为批量传输
- 管道6到9：设置为中断传输。

32.3.4.3 端点编号

PIPECFG.EPNUM[3:0]位用于设置每个管道的端点编号。DCP固定在端点0。其他管道可以设置从端点1到15。

- DCP：无需设置（固定在端点0）
- 管道1到9：选择并设置从1到15的端点编号，以便PIPECFG.DIR和EPNUM[3:0]位是唯一的。

32.3.4.4 最大数据包大小设置

在DCPMAXP.MXPS[6:0]和PIPEMAXP.MXPS[8:0]位中指定每个管道的最大数据包大小。DCP和管道1到5可以设置为USB2.0规范中定义的任何最大管道尺寸。对于管道6到9，最大数据包大小为64字节。在开始传输之前设置最大数据包大小如下（PID=BUF）：

- DCP：设置为8、16、32或64
- 管道1到5：设置为8、16、32或64以进行批量传输
- 管道1和2：设置在1和256之间，用于同步传输
- 管道6到9：设置在1到64之间。

32.3.4.5 接收方向上管道1到5的事务计数器

当在数据包接收方向完成指定数量的事务时，USBFS识别

the transfer ended. Two transaction counters are provided: one is the PIPEnTRN register, which specifies the number of transactions to be executed, and the other is the current counter, which internally counts the number of executed transactions. If the PIPECFG.SHTNAK bit is set to 1, when the current counter value matches the specified number of transactions, the associated PIPEnCTR.PID[1:0] bits are set to NAK and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The data read from PIPEnTRN differs depending on the PIPEnTRE.TRENB setting as follows:

- The TRENB bit = 0: Specified transaction counter value can be read
- The TRENB bit = 1: Current counter value indicating the internally counted number of executed transactions can be read.

The following constraints apply when working with the TRCLR bit:

- If the transactions are being counted and PID = BUF, the current counter cannot be cleared
- If there is any data left in the buffer, the current counter cannot be cleared.

32.3.4.6 Response PID

Specify the response PID for each pipe in the PID[1:0] bits in DCPCTR and PIPEnCTR. This section describes the USBFS operation with different response PID settings.

(1) Software response PID settings in host controller mode

Select the response PID to specify the execution of transactions as follows:

- NAK setting: Using pipes is disabled and no transactions are executed
- BUF setting: Transactions are executed based on the FIFO buffer state:
  - OUT direction: An OUT token is issued if the FIFO buffer contains transmit data.
  - IN direction: An IN token is issued if the FIFO buffer is not full and can receive data.
- STALL setting: Using pipes is disabled and no transactions are executed.

Note: Use the DCPCTR.SUREQ bit to execute setup transactions for the DCP.

(2) Software response PID settings in device controller mode

Select the response PID to respond as follows to transactions from the host:

- NAK setting: A NAK response is returned to all generated transactions
- BUF setting: A response is returned to transactions based on the FIFO buffer
- STALL setting: A STALL response is returned to all generated transactions.

Note: For setup transactions, an ACK response is always returned, regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

Sections (3) and (4) describe situations in which the USBFS writes to the PID[1:0] bits because of specific transaction results.

(3) Hardware response PID settings in host controller mode

- NAK setting: PID = NAK is set in the following cases, and issuing of tokens is automatically stopped:
  - When a non-isochronous transfer is performed and an NRDY interrupt is generated (For details, see section 32.3.3.2, NRDY interrupt.)
  - If a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
  - If transaction counting ends when the SHTNAK bit is set to 1 for bulk transfers.
- BUF setting: The USBFS does not write this setting.

转移结束。提供了两个事务计数器：一个是PIPEnTRN寄存器，指定要执行的事务数，另一个是当前计数器，内部统计执行的事务数。如果PIPECFG.SHTNAK位设置为1，则当当前计数器值与指定的事务数匹配时，相关的PIPEnCTR.PID[1:0]位将设置为NAK，并禁用后续传输。通过PIPEnTRE.TRCLR位初始化事务计数器功能的当前计数器，事务可以从头开始重新计数。从PIPEnTRN读取的数据因PIPEnTRE.TRENB设置而异，如下所示：

- TRENB位=0：可以读取指定的事务计数器值
- TRENB位=1：可以读取表示内部计数的已执行事务数的当前计数器值。

使用TRCLR位时适用以下约束：

- 如果正在对事务进行计数且PID=BUF，则无法清除当前计数器
- 如果缓冲区中还有任何数据，则无法清除当前计数器。

32.3.4.6 响应PID

在DCPCTR和PIPEnCTR的PID[1:0]位中指定每个管道的响应PID。本节介绍具有不同响应PID设置的USBFS操作。

(1) 主机控制器模式下的软件响应PID设置

选择响应PID来指定事务的执行，如下所示：

- NAK设置：禁用使用管道并且不执行任何事务
- BUF设置：根据FIFO缓冲区状态执行事务：
  - OUT方向：如果FIFO缓冲区包含发送数据，则发出OUT令牌。
  - IN方向：如果FIFO缓冲区未满并且可以接收数据，则发出IN令牌。
- STALL设置：禁用使用管道并且不执行任何事务。

Note: 使用DCPCTR.SUREQ位执行DCP的设置事务。

(2) 设备控制器模式下的软件响应PID设置

选择响应PID以对来自主机的事务进行如下响应：

- NAK设置：向所有生成的事务返回NAK响应
- BUF设置：根据FIFO缓冲区向事务返回响应
- STALL设置：向所有生成的事务返回一个STALL响应。

Note: 对于设置事务，无论PID[1:0]位设置如何，始终返回ACK响应，并且USB请求存储在寄存器中。

第(3)和(4)节描述了USBFS由于特定事务结果而写入PID[1:0]位的情况。

(3) 主机控制器模式下的硬件响应PID设置

- NAK设置：PID=NAK在以下情况下设置，并且自动停止发行令牌：
  - 当执行非同步传输并产生NRDY中断时（详情请参阅第32.3.3.2节，NRDY中断。）
  - 如果在PIPECFG.SHTNAK位设置为1以进行批量传输时接收到短数据包
  - 如果在SHTNAK位设置为1以进行批量传输时事务计数结束。
- BUF设置：USBFS不写入此设置。

- STALL setting: PID = STALL is set in the following cases, and issuing of tokens is automatically stopped:
  - When STALL is received in response to a transmitted token
  - When a received data packet exceeds the maximum packet size.

(4) Hardware response PID settings in device controller mode

- NAK setting: PID = NAK is set in the following cases, and a NAK response is returned to transactions:
  - When the setup token is received normally (DCP only)
  - If transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers.
- BUF setting: There is no BUF writing by the USBFS.
- STALL setting: PID = STALL is set in the following cases, and a STALL response is returned to transactions:
  - When a received data packet exceeds the maximum packet size
  - When a control transfer sequence error is detected (DCP only).

32.3.4.7 Data PID sequence bit

The USBFS automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON bit in DCPCTR and PIPEnCTR. When data is transmitted, the sequence bit toggles on ACK handshake reception. When data is received, the sequence bit toggles on ACK handshake transmission. The SQCLR and SQSET bits in DCPCTR and PIPEnCTR registers can be used to change the data PID sequence bit.

In device controller mode when control transfers are used, the USBFS automatically sets the sequence bit for stage transitions. DATA1 is returned when the setup stage ends. The sequence bit is not referenced and PID = DATA1 is returned in the status stage. Therefore, no software settings are required. However, in host controller mode when control transfers are used, the sequence bit must be set by software for the stage transitions.

For ClearFeature requests for transmission or reception, the data PID sequence bit must be set by software in both host and device controller modes.

32.3.4.8 Response PID = NAK function

The USBFS provides a function for disabling pipe operation (PID response = NAK) when the final data packet of a transaction is received. The USBFS automatically distinguishes this based on reception of a short packet or the transaction counter. Enable this function by setting the PIPECFG.SHTNAK bit to 1.

When the double buffer mode is being used for the FIFO buffer, using this function enables reception of data packets in transfer units. If pipe operation is disabled, the software must enable the pipe again (PID response = BUF).

The response PID = NAK function can be used only for bulk transfers.

32.3.4.9 Auto response mode

For bulk transfer pipes (1 to 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (PIPECFG.DIR = 0), OUT-NAK mode is invoked, and during an IN transfer (DIR = 1), null auto response mode is invoked.

32.3.4.10 OUT-NAK mode

For bulk OUT transfer pipes, NAK is returned in response to an OUT token, and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To transition from normal mode to OUT-NAK mode, specify OUT-NAK mode while pipe operation is disabled (PID[1:0] = 00b for NAK response). Next enable pipe operation (PID[1:0] = 01b for BUF response), on which OUT-NAK mode becomes valid. If an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To transition from OUT-NAK mode to normal mode, cancel OUT-NAK mode while pipe operation is disabled (NAK). Next enable pipe operation (BUF). In normal mode, reception of OUT data is enabled.

- STALL设置：PID=STALL在以下情况下设置，并且自动停止发行令牌：
  - 当接收到STALL以响应传输的令牌时
  - 当接收到的数据包超过最大包大小时。

(4) 设备控制器模式下的硬件响应PID设置

- NAK设置：PID=NAK在以下情况下设置，并向事务返回NAK响应：
  - 正常接收设置令牌时（仅DCP）
  - 如果在PIPECFG.SHTNAK位设置为1以进行批量传输时，事务计数结束或收到短数据包。
- BUF设置：USBFS没有写入BUF。
- STALL设置：PID=STALL在以下情况下设置，并向事务返回STALL响应：
  - 当接收到的数据包超过最大包大小时
  - 当检测到控制传输序列错误时（仅限DCP）。

32.3.4.7 数据PID序列位

当数据在控制传输数据阶段、批量传输和中断传输成功传输时，USBFS会自动切换数据PID中的序列位。下一个要发送的数据PID的序列位可以通过DCPCTR和PIPEnCTR中的SQMON位来确认。发送数据时，序列位在ACK握手接收时切换。当接收到数据时，序列位在ACK握手传输上切换。DCPCTR和PIPEnCTR寄存器中的SQCLR和SQSET位可用于更改数据PID序列位。

在使用控制传输的设备控制器模式下，USBFS自动设置阶段转换的序列位。DATA1在设置阶段结束时返回。不引用序列位，在状态阶段返回PID=DATA1。因此，不需要任何软件设置。但是，在使用控制传输的主机控制器模式下，必须由软件设置序列位以进行阶段转换。

对于发送或接收的ClearFeature请求，数据PID序列位必须由软件在主机和设备控制器模式下设置。

32.3.4.8 响应PID=NAK功能

USBFS提供了在接收到事务的最终数据包时禁用管道操作（PID响应=NAK）的功能。USBFS根据收到的短数据包或事务计数器自动区分这一点。通过将PIPECFG.SHTNAK位设置为1来启用此功能。

当FIFO缓冲区使用双缓冲区模式时，使用此功能可以接收以传输为单位的数据包。如果管道操作被禁用，软件必须再次启用管道（PID响应=BUF）。

响应PID=NAK函数只能用于批量传输。

32.3.4.9 自动响应模式

对于批量传输管道（1到5），当PIPEnCTR.ATREPM位设置为1时，将转换到自动响应模式。在OUT传输期间(PIPECFG.DIR=0)，将调用OUT-NAK模式，在IN传输期间(DIR=1)，将调用空自动响应模式。

32.3.4.10 OUT-NAK mode

对于批量OUT传输管道，NAK响应OUT令牌返回，并且当PIPEnCTR.ATREPM位设置为1时输出NRDY中断。要从正常模式转换到OUT-NAK模式，请指定OUT-NAK模式，同时管道操作被禁用（PID[1:0]=00b用于NAK响应）。接下来启用管道操作（PID[1:0]=01b用于BUF响应），此时OUT-NAK模式变为有效。如果在禁用管道操作之前立即收到OUT令牌，则正常接收令牌数据，并向主机返回ACK。

要从OUT-NAK模式转换到正常模式，请在禁用管道操作(NAK)时取消OUT-NAK模式。
接下来启用管道操作(BUF)。在正常模式下，可以接收OUT数据。

32.3.4.11 Null auto response mode

For bulk IN transfer pipes, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To transition from normal mode to null auto response mode, specify null auto response mode while pipe operation is disabled (response PID = NAK). Next enable pipe operation (response PID = BUF) on which null auto response mode becomes valid. Before setting null auto response mode, check that PIPEnCTR.INBUFM = 0, because the mode can be set only when the buffer is empty. If the INBUFM bit is 1, empty the buffer using the PIPEnCTR.ACLRM bit. Do not write data from the FIFO port while a transition to null auto response mode is being made.

To transition from null auto response mode to normal mode, keep pipe operation disabled (response PID = NAK) for the period of the zero-length packet transmission (about 10 µs) before canceling the null auto response mode. In normal mode, data can be written from the FIFO port, so packet transmission to the host is enabled by enabling pipe operation (response PID = BUF).

32.3.5 FIFO Buffer

The USBFS provides a FIFO buffer for data transfers, and it manages the memory area used for each pipe. The FIFO buffer has two states depending on whether the access right is assigned to the system (CPU side) or the USBFS (SIE side).

(1) Buffer status

Table 32.18 and Table 32.19 show the buffer status in the USBFS. The FIFO buffer status can be confirmed using the DCPCTR.BSTS and PIPEnCTR.INBUFM bits. The transfer direction for the FIFO buffer can be specified in either the PIPECFG.DIR or CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM bit is valid for pipes 0 to 5 in the transmitting direction.

When a transmitting pipe uses double buffering, the software can read the BSTS bit to monitor the FIFO buffer status on the CPU side and the INBUFM bit to monitor the FIFO buffer status on the SIE side. When write access to the FIFO port by the CPU or DMA/DTC is slow and the buffer empty status cannot be determined using the BEMP interrupt, the software can use the INBUFM bit to confirm the end of transmission.

Table 32.18 Buffer status indicated in the BSTS bit

ISEL or DIR	BSTS	FIFO buffer status
0 (receiving direction)	0	There is no received data, or data is being received. Reading from the FIFO port is disabled.
0 (receiving direction)	1	There is received data, or a zero-length packet is received. Reading from the FIFO port is allowed. When a zero-length packet is received, reading is not possible and the buffer must be cleared.
1 (transmitting direction)	0	Transmission has not completed. Writing to the FIFO port is disabled.
1 (transmitting direction)	1	Transmission is complete. CPU write is allowed.

Table 32.19 Buffer status indicated in the INBUFM bit

DIR	INBUFM	FIFO buffer status
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	Transmission is complete. There is no data waiting to be transmitted.
1 (transmitting direction)	1	The FIFO port has written data to the buffer. There is data to be transmitted.

32.3.6 FIFO Buffer Clearing

Table 32.20 shows the methods for clearing the FIFO buffer. The FIFO buffer can be cleared using BCLR bit in the port control register, DnFIFOSEL.DCLRM, or the PIPEnCTR.ACLRM bit.

32.3.4.11 空自动响应模式

对于批量IN传输管道，当PIPEnCTR.ATREPM位设置为1时，将连续传输零长度数据包。

要从正常模式转换为空自动响应模式，请在禁用管道操作时指定空自动响应模式（响应PID=NAK）。接下来启用空自动响应模式有效的管道操作（响应PID=BUF）。在设置空自动响应模式之前，请检查PIPEnCTR.INBUFM=0，因为只有在缓冲区为空时才能设置模式。如果INBUFM位为1，则使用PIPEnCTR.ACLRM位清空缓冲区。在转换到空自动响应模式时，不要从FIFO端口写入数据。

要从空值自动响应模式转换到正常模式，在取消空值自动响应模式之前，在零长度数据包传输期间（约10µs）保持管道操作禁用（响应PID=NAK）。在正常模式下，可以从FIFO端口写入数据，因此通过启用管道操作（响应PID=BUF）来启用到主机的数据包传输。

32.3.5 FIFO Buffer

USBFS为数据传输提供FIFO缓冲区，并管理用于每个管道的内存区域。根据访问权限是分配给系统（CPU端）还是USBFS（SIE端），FIFO缓冲区有两种状态。

(1) 缓冲状态

表32.18和表32.19显示了USBFS中的缓冲区状态。FIFO缓冲区状态可以使用确认DCPCTR.BSTS和PIPEnCTR.INBUFM位。FIFO缓冲区的传输方向可以在任一pipecfg.dir或cfifosel.isel位（选择DCP时）。

INBUFM位对传输方向的管道0到5有效。

当传输管道使用双缓冲时，软件可以读取BSTS位来监控CPU侧的FIFO缓冲区状态，以及读取INBUFM位来监控SIE侧的FIFO缓冲区状态。当CPU或DMADTC对FIFO端口的写访问速度较慢且无法使用BEMP中断确定缓冲区空状态时，软件可以使用INBUFM位来确认传输结束。

Table 32.18 BSTS位中指示的缓冲区状态

ISEL或DIR	BSTS	FIFO缓冲区状态
0 (receiving direction)	0	没有接收到数据，或正在接收数据。 禁止从FIFO端口读取。
0 (receiving direction)	1	有接收数据，或接收到零长度数据包。 允许从FIFO端口读取。 当接收到零长度数据包时，无法读取，必须清除缓冲区。
1 (transmitting direction)	0	传输尚未完成。 禁止写入FIFO端口。
1 (transmitting direction)	1	传输完成。 允许CPU写入。

Table 32.19 INBUFM位中指示的缓冲区状态

DIR	INBUFM	FIFO缓冲区状态
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	传输完成。 没有等待传输的数据。
1 (transmitting direction)	1	FIFO端口已将数据写入缓冲区。 有数据要传输。

32.3.6 FIFO缓冲区清除

表32.20显示了清除FIFO缓冲区的方法。可以使用端口控制寄存器中的BCLR位、DnFIFOSEL.DCLRM或PIPEnCTR.ACLRM位清除FIFO缓冲区。

Single or double buffering can be selected for pipes 1 to 5 in the PIPECFG.DBLB bit.

Table 32.20 Buffer clearing methods

FIFO buffer clearing mode	Clearing FIFO buffer on the CPU side	Mode for automatically clearing the FIFO buffer after reading the specified pipe data	Auto buffer clear mode for discarding all received packets
Register used	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Bit used	BCLR	DCLRM	ACLRM
Clearing condition	Cleared by writing 1	1: Mode valid 0: Mode invalid	1: Mode valid 0: Mode invalid

(1) Auto buffer clear mode function

The USBFS discards all received data packets if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet is received, the ACK response is returned to the host controller. The auto buffer clear mode function can only be set in the FIFO buffer reading direction.

Setting the ACLRM bit to 1 and then to 0 clears the FIFO buffer of the selected pipe regardless of the access direction. An access cycle of at least 100 ns is required for the internal hardware sequence processing between ACLRM = 1 and ACLRM = 0.

32.3.7 FIFO Port Functions

Table 32.21 shows the settings for the FIFO port functions. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, set the BVAL flag in the port control register to end writing. To send a zero-length packet, use the BCLR bit to clear the buffer, and then set the BVAL flag to end writing.

In reading, reception of new packets is automatically enabled when all data is read. Data cannot be read when a zero-length packet is received (DTLN[8:0] = 0), so the buffer must be cleared with the BCLR bit. The length of the receive data can be confirmed in the DTLN[8:0] bits in the port control register.

Table 32.21 FIFO port function settings

Register name	Bit name	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	Selects DTLN[8:0] read mode
	REW	FIFO buffer rewind (re-read, rewrite)
	DCLRM	Automatically clears receive data for a specified pipe after the data is read (only for DnFIFO)
	DREQE	Enables DMA/DTC transfers (only for DnFIFO)
	MBW	FIFO port access bit width
	BIGEND	Selects FIFO port endian
	ISEL	FIFO port access direction (only for DCP)
	CURPIPE	Selects the current pipe
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	Ends writing to the FIFO buffer
	BCLR	Clears the FIFO buffer on the CPU side
	DTLN	Checks the length of receive data

(1) FIFO port selection

Table 32.22 shows the pipes that can be selected with the different FIFO ports. The pipe to be accessed must be selected in the CURPIPE[3:0] bits in the port select register. After the pipe is selected, the software must check whether the written value can be read correctly from the CURPIPE[3:0] bits. (If the previous pipe number is read, it indicates that the USBFS is modifying the pipe.) Next, the software checks that the FRDY bit in the port control register is 1.

In addition, the software must specify the bus width to be accessed in the MBW bit in the port select register. The FIFO buffer access direction conforms to the PIPECFG.DIR setting. For the DCP only, the ISEL bit in the port select register

可以在PIPECFG.DBLB位中为管道1到5选择单缓冲或双缓冲。

Table 32.20 缓冲区清除方法

FIFO缓冲区清除模式	清除FIFO缓冲区CPU端	读取指定管道数据后自动清除FIFO缓冲区的模式	自动缓冲区清除模式，用于丢弃所有接收到的数据包
注册使用	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
使用的位	BCLR	DCLRM	ACLRM
清算条件	通过写1清除	1：模式有效0 ：模式无效	1：模式有效0 ：模式无效

(1) 自动缓冲清除模式功能

如果PIPEnCTR.ACLRM位设置为1，USBFS将丢弃所有接收到的数据包。如果接收到正确的数据包，则向主机控制器返回ACK响应。自动缓冲区清除模式功能只能在FIFO缓冲区读取方向设置。

无论访问方向如何，将ACLRM位设置为1，然后设置为0都会清除所选管道的FIFO缓冲区。ACLRM=1和之间的内部硬件序列处理需要至少100ns的访问周期
ACLRM = 0.

32.3.7 FIFO端口功能

表32.21显示了FIFO端口功能的设置。在写访问中，在达到最大数据包大小之前写入数据会自动启用数据传输。要在达到最大数据包大小之前启用传输，请设置端口控制寄存器中的BVAL标志以结束写入。要发送零长度数据包，请使用BCLR位清除缓冲区，然后设置BVAL标志以结束写入。

在读取中，当所有数据被读取时，自动启用新数据包的接收。接收到零长度数据包时（DTLN[8:0]=0）无法读取数据，因此必须使用BCLR位清除缓冲区。接收数据的长度可以在端口控制寄存器的DTLN[8:0]位中确认。

Table 32.21 FIFO端口功能设置

注册名称	位名称	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	选择DTLN[8:0]读取模式
	REW	FIFO缓冲区倒带（重新读取、重写）
	DCLRM	读取数据后自动清除指定管道的接收数据（仅适用于DnFIFO）
	DREQE	启用DMADTC传输（仅适用于DnFIFO）
	MBW	FIFO端口访问位宽
	BIGEND	选择FIFO端口字节序
	ISEL	FIFO端口访问方向（仅适用于DCP）
	CURPIPE	选择当前管道
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	结束写入FIFO缓冲区
	BCLR	清除CPU端的FIFO缓冲区
	DTLN	检查接收数据的长度

(1) 先进先出端口选择

表32.22显示了可以使用不同FIFO端口选择的管道。必须在端口选择寄存器的CURPIPE[3:0]位中选择要访问的管道。选择管道后，软件必须检查是否可以从CURPIPE[3:0]位正确读取写入的值。（如果读取了之前的管道号，则表明USBFS正在修改管道。）接下来，软件检查端口控制寄存器中的FRDY位是否为1。

此外，软件必须在端口选择寄存器的MBW位中指定要访问的总线宽度。FIFO缓冲区访问方向符合PIPECFG.DIR设置。仅对于DCP，端口选择寄存器中的ISEL位

determines the direction.

Table 32.22 FIFO port access by pipe

Pipe	Access method	Ports that can be used
DCP	CPU access	CFIFO port register
Pipes 1 to 9	CPU access	• CFIFO port register • D0FIFO/D1FIFO port register
	DMA/DTC access	D0FIFO/D1FIFO port register

(2) REW bit

It is possible to temporarily stop access to a pipe currently being accessed, access a different pipe, and then continue processing for the first pipe again. The REW bit in the port select register is used for this processing.

If a pipe is selected in the CURPIPE[3:0] bits in the port select register with the REW bit set to 1, the pointer used for reading from and writing to the FIFO buffer is reset, and reading or writing can be carried out from the first byte. If a pipe is selected with 0 set for the REW bit, data can be read and written in continuation from the previous selection, without the pointer being reset.

To access the FIFO port, the software must check that the FRDY bit in the port control register is 1 after selecting a pipe.

32.3.8 DMA Transfers (D0FIFO and D1FIFO Ports)

(1) Overview of DMA transfers

For pipes 1 to 9, the FIFO port can be accessed using the DMAC. When buffer access for a pipe targeted for DMA transfer is enabled, a DMA transfer request is issued.

Select the unit of transfer to the FIFO port in the DnFIFOSEL.MBW bit, and select the pipe targeted for the DMA transfer in the DnFIFOSEL.CURPIPE[3:0] bits. Do not change the selected pipe during the DMA transfer.

(2) DnFIFO auto clear mode (D0FIFO and D1FIFO port reading direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USBFS automatically clears the FIFO buffer of the selected pipe when reading of data from the FIFO buffer is complete.

Table 32.23 shows the packet reception and FIFO buffer clearing processing by software for each of the settings. As shown in the table, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA transfers without involving software.

The DnFIFO auto clear mode can only be set in the FIFO buffer reading direction.

Table 32.23 Packet reception and FIFO buffer clearing processing by software

Buffer status when packet is received	Register setting			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	No clearing required	No clearing required	No clearing required	No clearing required
Zero-length packet reception	Clearing required	Clearing required	No clearing required	No clearing required
Normal short packet reception	No clearing required	Clearing required	No clearing required	No clearing required
Transaction count end	No clearing required	Clearing required	No clearing required	No clearing required

32.3.9 Control Transfers Using the DCP

The DCP is used for data transfers in the control transfer data stage. The FIFO buffer of the DCP is a 64-byte single buffer with a fixed area for both control reads and control writes. The FIFO buffer can be accessed only through the CFIFO port.

决定方向。

Table 32.22 通过管道访问FIFO端口

Pipe	访问方法	可以使用的端口
DCP	CPU访问	CFIFO端口寄存器
管道1至9	CPU访问	CFIFO端口寄存器 D0FIFOD1FIFO端口寄存器
	DMA/DTC access	D0FIFOD1FIFO端口寄存器

(2) REW位

可以暂时停止对当前正在访问的管道的访问，访问不同的管道，然后再次继续处理第一个管道。端口选择寄存器中的REW位用于此处理。

如果在端口选择寄存器的CURPIPE[3:0]位中选择了一个管道，并且REW位设置为1，则用于读取和写入FIFO缓冲区的指针复位，可以进行读取或写入从第一个字节开始。如果在REW位设置为0的情况下选择管道，则可以从先前的选择继续读取和写入数据，而无需重置指针。

要访问FIFO端口，软件必须在选择管道后检查端口控制寄存器中的FRDY位是否为1。

32.3.8 DMA传输（D0FIFO和D1FIFO端口）

(1) DMA传输概述

对于管道1到9，可以使用DMAC访问FIFO端口。当启用以DMA传输为目标的管道的缓冲区访问时，将发出DMA传输请求。

在DnFIFOSEL.MBW位中选择传输到FIFO端口的单位，并在DnFIFOSEL.CURPIPE[3:0]位中选择DMA传输的目标管道。在DMA传输期间不要更改选定的管道。

(2) DnFIFO自动清除模式（D0FIFO和D1FIFO端口读取方向）

如果DnFIFOSEL.DCLRM位设置为1，USBFS会在从FIFO缓冲区读取数据完成时自动清除所选管道的FIFO缓冲区。

表32.23显示了针对每个设置通过软件进行的数据包接收和FIFO缓冲区清除处理。如表所示，缓冲区清除条件取决于PIPECFG.BFRE位中设置的值。使用DnFIFOSEL.DCLRM位无需在任何需要清除缓冲区的情况下通过软件清除缓冲区。这可以在不涉及软件的情况下实现DMA传输。

DnFIFO自动清除模式只能设置在FIFO缓冲区读取方向。

Table 32.23 通过软件进行数据包接收和FIFO缓冲区清除处理

收到数据包时的缓冲区状态	注册设置			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
缓冲区已满	无需清算	无需清算	无需清算	无需清算
零长度数据包接收	需要清算	需要清算	无需清算	无需清算
正常短包接收	无需清算	需要清算	无需清算	无需清算
交易计数结束	无需清算	需要清算	无需清算	无需清算

32.3.9 使用DCP进行控制传输

DCP用于控制传输数据阶段的数据传输。DCP的FIFO缓冲区是一个64字节的单缓冲区，具有用于控制读取和控制写入的固定区域。FIFO缓冲区只能通过CFIFO端口访问。

32.3.9.1 Control transfers in host controller mode

(1) Setup stage

The USQREQ, USBVAL, USBINDX, and USBLENG registers are used to transmit USB requests for setup transactions. Writing the setup packet data to the registers and then writing 1 to the DCPCTR.SUREQ bit transmits the specified data for the setup transaction. On completion of the transaction, the SUREQ bit clears to 0. Do not change these USB request registers while SUREQ = 1.

When an attached function device is detected, the software must issue the first setup transaction for the device using this sequence with the DCPMAXP.DEVSEL[3:0] bits cleared to 0 and the DEVADD0.USBSPD[1:0] bits set appropriately.

When an attached function device is shifted to the Address state, the software must issue setup transactions using this sequence with the assigned USB address set in the DEVSEL[3:0] bits and the bits in DEVADDn corresponding to the specified USB address set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in DEVADD2. When PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in DEVADD5.

When the setup transaction data is sent, an interrupt request is generated based on the response from the peripheral device (SIGN or SACK bit in INTSTS1). This interrupt request allows the software to check the setup transaction result.

A DATA0 data packet (USB request) for the setup transaction is always transmitted regardless of the status of the DCPCTR.SQMON bit.

(2) Data stage

The data stage is used to transfer data using the DCP FIFO buffer.

Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit. Specify the transfer direction in the DCPCFG.DIR bit.

For the first data packet of the data stage, the data PID must be transferred as DATA1. Set data PID = DATA1 in the DCPCTR.SQSET bit and set the PID bits = BUF. Completion of data transfer is detected using the BRDY or BEMP interrupt.

For control write transfers, when the number of data bytes to be sent is an integer multiple of the maximum packet size, the software must send a zero-length packet at the end.

(3) Status stage

The status stage is used for zero-length packet data transfers in the reverse direction of the data stage. As in the data stage, data is transfered using the DCP FIFO buffer. Transactions are executed using the same procedure as the data stage.

Data packets in the status stage must be transmitted and received with the data PID set to DATA1 using the DCPCTR.SQSET bit.

When a zero-length packet is received, check the receive-data length in the CFIFOCTR.DTLN[8:0] bits after a BRDY interrupt is generated, and then clear the FIFO buffer using the BCLR bit.

32.3.9.2 Control transfers in device controller mode

(1) Setup stage

The USBFS sends an ACK response to a normal setup packet for the USBFS. The USBFS operates in the setup stage as follows:

On receiving a new setup packet, the USBFS sets the following bits:

- Sets the INTSTS0.VALID bit to 1
- Sets the DCPCTR.PID[1:0] bits to NAK
- Sets the DCPCTR.CCPL bit to 0.

When the USBFS receives a data packet following a setup packet, it stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Before performing the response processing for a control transfer, set the VALID flag to 0. When the VALID bit = 1, PID

32.3.9.1 主机控制器模式下的控制传输

(1) 设置阶段

USQREQ、USBVAL、USBINDX和USBLENG寄存器用于传输设置事务的USB请求。将设置数据包数据写入寄存器，然后向DCPCTR.SUREQ位写入1，以传输设置事务的指定数据。事务完成后，SUREQ位清除为0。在SUREQ=1时不要更改这些USB请求寄存器。

当检测到连接的功能器件时，软件必须使用此序列为器件发出第一个设置事务，其中DCPMAXP.DEVSEL[3:0]位清零，DEVADD0.USBSPD[1:0]位适当设置。

当连接的功能器件转移到地址状态时，软件必须使用此序列发出设置事务，其中指定的USB地址设置在DEVSEL[3:0]位中，并且DEVADDn中的位对应于指定的USB地址设置适当。例如，当PIPEMAXP.DEVSEL[3:0]=0010b时，在DEVADD2中进行适当的设置。当PIPEMAXP.DEVSEL[3:0]=0101b时，在DEVADD5中进行适当的设置。

发送设置事务数据时，根据外围设备的响应（INTSTS1中的SIGN或SACK位）生成中断请求。该中断请求允许软件检查设置事务结果。

一个DATA0数据包（USB请求）用于设置事务总是被传输，无论状态如何
DCPCTR.SQMON bit.

(2) 数据阶段

数据级用于使用DCPFIFO缓冲区传输数据。

在访问DCPFIFO缓冲区之前，请在CFIFOSEL.ISEL位中指定访问方向。在DCPCFG.DIR位中指定传输方向。

对于数据阶段的第一个数据包，数据PID必须作为DATA1传输。在DCPCTR.SQSET位中设置数据PID=DATA1，并设置PID位=BUF。使用BRDY或BEMP中断检测数据传输的完成。

对于控制写传输，当要发送的数据字节数是最大数据包大小的整数倍时，软件必须在最后发送一个长度为零的数据包。

(3) 状态阶段

状态阶段用于在数据阶段的相反方向上进行零长度分组数据传输。与数据阶段一样，使用DCPFIFO缓冲区传输数据。事务使用与数据阶段相同的过程执行。

状态阶段的数据包必须在数据PID设置为DATA1的情况下使用
DCPCTR.SQSET bit.

当接收到零长度数据包时，在产生BRDY中断后检查CFIFOCTR.DTLN[8:0]位中的接收数据长度，然后使用BCLR位清除FIFO缓冲区。

32.3.9.2 设备控制器模式下的控制传输

(1) 设置阶段

USBFS向USBFS的正常设置数据包发送ACK响应。USBFS在设置阶段运行如下：

在接收到新的设置数据包时，USBFS设置以下位：

- 将INTSTS0.VALID位设置为1
- 将DCPCTR.PID[1:0]位设置为NAK
- 将DCPCTR.CCPL位设置为0。

当USBFS在setup数据包之后接收到数据包时，它会将USB请求参数存储在USBREQ中，
USBVAL, USBINDX, and USBLENG.

在执行控制传输的响应处理之前，将VALID标志设置为0。当VALID位=1时，PID

= BUF cannot be set, and the data stage cannot be terminated.

Using the VALID bit function, the USBFS can suspend a request being processed when it receives a new USB request during a control transfer and return a response to the latest request.

In addition, the USBFS automatically detects the direction bit (bmRequestType bit [8]) and the request data length (wLength) in the received USB request. It distinguishes between control read transfers, control write transfers, and no-data control transfers, and it controls stage transitions. For an incorrect sequence, a sequence error occurs in the control transfer stage transition interrupt, and the interrupt is reported to the software. For a diagram of the stage control by the USBFS, see Figure 32.15.

(2) Data stage

The DCP must be used to execute data transfers for received USB requests. Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit.

If the transfer data is larger than the size of the DCP FIFO buffer, execute the data transfer using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

(3) Status stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to BUF.

After this setting is made, the USBFS automatically executes the status stage based on the data transfer direction determined at the setup stage. The procedure is as follows:

- For control read transfers
  The USBFS receives a zero-length packet from the USB host and transmits an ACK response.
- For control write transfers and no-data control transfers
  The USBFS transmits a zero-length packet and receives an ACK response from the USB host.

(4) Control transfer auto response function

The USBFS automatically responds to a correct SET_ADDRESS request. If any of the following errors occurs in the SET_ADDRESS request, a response from the software is necessary.

- bmRequestType is not 00h: Any transfer other than a control write transfer
- wIndex is not 00h: Request error
- wLength is not 00h: Any transfer other than a no-data control transfer
- wValue is larger than 7Fh: Request error
- INTSTS0.DVSQ[2:0] are 011b (Configured state): Control transfer of a device state error.

For all requests other than the SET_ADDRESS request, a response is required from the corresponding software.

32.3.10 Bulk Transfers (Pipes 1 to 5)

The FIFO buffer usage (single/double buffer setting) is configurable for bulk transfers. The USBFS provides the following functions for bulk transfers:

- BRDY interrupt function (PIPECFG.BFRE bit), see section 32.3.3.1, (2) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 1
- Transaction count function (PIPEnTRE.TRENB, TRCLR, and PIPEnTRN.TRNCNT[15:0] bits), see section 32.3.4.5, Transaction counter for pipes 1 to 5 in the receiving direction
- Response PID = NAK function (PIPECFG.SHTNAK bit), see section 32.3.4.8, Response PID = NAK function
- Auto response mode (PIPEnCTR.ATREPM bit), see section 32.3.4.9, Auto response mode.

32.3.11 Interrupt Transfers (Pipes 6 to 9)

In device controller mode, the USBFS performs interrupt transfers based on the timing dictated by the host controller.

In host controller mode, the software can set the timing for issuing tokens using the interval counter.

=BUF不能设置，数据阶段不能终止。

使用VALID位功能，USBFS可以在控制传输期间接收到新的USB请求时暂停正在处理的请求，并返回对最新请求的响应。

此外，USBFS会自动检测接收到的USB请求中的方向位（bmRequestTypebit[8]）和请求数据长度（wLength）。它区分控制读取传输、控制写入传输和无数据控制传输，并控制阶段转换。对于不正确的序列，在控制转移阶段转换中断中发生序列错误，并将中断报告给软件。有关USBFS的阶段控制图，请参见图32.15。

(2) 数据阶段

DCP必须用于执行接收到的USB请求的数据传输。在访问DCPFIFO缓冲区之前，请在CFIFOSEL.ISEL位中指定访问方向。

如果传输数据大于DCPFIFO缓冲区的大小，则使用控制写传输的BRDY中断和控制读传输的BEMP中断执行数据传输。

(3) 状态阶段

通过将DCPCTR.CCPL位设置为1而将DCPCTR.PID[1:0]位设置为BUF来终止控制传输。

完成此设置后，USBFS根据设置阶段确定的数据传输方向自动执行状态阶段。程序如下：

- 对于控制读取传输
  USBFS从USB主机接收零长度数据包并发送ACK响应。
- 用于控制写传输和无数据控制传输
  USBFS发送一个长度为零的数据包并接收来自USB主机的ACK响应。

(4) 控制转移自动响应功能

USBFS自动响应正确的SET_ADDRESS请求。如果出现以下任何错误
SET_ADDRESS请求，需要软件的响应。

- bmRequestType不是00h：控制写入传输以外的任何传输
- wIndex不是00h：请求错误
- wLength不是00h：除无数据控制传输之外的任何传输
- wValue大于7Fh：请求错误
- INTSTS0.DVSQ[2:0]为011b（已配置状态）：设备状态错误的控制传输。

对于除SET_ADDRESS请求之外的所有请求，都需要相应软件的响应。

32.3.10 批量传输（管道1到5）

FIFO缓冲区使用（单双缓冲区设置）可配置为批量传输。USBFS为批量传输提供以下功能：

- BRDY中断功能（PIPECFG.BFRE位），见第32.3.3.1节，(2)当SOFCFG.BRDYM=0且PIPECFG.BFRE = 1
- 事务计数函数（PIPEnTRE.TRENB、TRCLR和PIPEnTRN.TRNCNT[15:0]位），参见第32.3.4.5节，接收方向管道1到5的事务计数器
- 响应PID=NAK功能（PIPECFG.SHTNAK位），请参见第32.3.4.8节，响应PID=NAK功能
- 自动响应模式（PIPEnCTR.ATREPM位），请参见第32.3.4.9节，自动响应模式。

32.3.11 中断传输（管道6到9）

在设备控制器模式下，USBFS根据主机控制器规定的时序执行中断传输。

在主机控制器模式下，软件可以使用间隔计数器设置发布令牌的时间。

32.3.11.1 Interval counter for interrupt transfers in host controller mode

Specify the transaction interval for interrupt transfers in the PIPEPERI.IITV[2:0] bits. The USBFS issues interrupt transfer tokens based on this interval.

(1) Counter initialization

The USBFS initializes the interval counter under the following conditions:

- Power-on reset
  This initializes the IITV[2:0] bits.
- FIFO buffer initialization using the PIPEnCTR.ACLRM bit:
  This does not initialize the IITV[2:0] bits, but does initialize the count value. Setting the PIPEnCTR.ACLRM bit to 0 starts counting from the value set in IITV[2:0].

The interval counter is not initialized in the following case:

- USB bus reset or USB suspended
  The IITV[2:0] bits are not initialized. Setting 1 to the DVSTCTR0.UACT bit starts counting from the value saved before entering the USB bus reset state or USB suspend state.

(2) Operation when tokens cannot be transmitted or received even on token generation

No token is generated in the following cases even at token generation time. In these cases, the USBFS tries to execute the transaction in the next interval.

- When the PID is set to NAK or STALL
- When the FIFO buffer is full at token transmit time in the receiving (IN) direction
- When there is no data to be transmitted in the FIFO buffer at token transmit time in the transmitting (OUT) direction.

32.3.12 Isochronous Transfers (Pipes 1 and 2)

The USBFS provides the following functions for isochronous transfers:

- Notification of isochronous transfer error
- Interval counter specified in the PIPEPERI.IITV[2:0] bits
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function specified in the PIPEPERI.IFIS bit.

32.3.12.1 Error detection in isochronous transfers

The USBFS provides a function for detecting the errors described in this section, so that when errors occur in isochronous transfers, they can be controlled by software. Table 32.24 and Table 32.25 show the priority order for errors detected by the USBFS and the associated interrupts.

(a) PID errors

- The PID value of the received packet is invalid.

(b) CRC errors and bit stuffing errors

- A CRC error is found in a received packet or the bit stuffing is illegal.

(c) Maximum packet size exceeded

- The data size of the received packet exceeds the specified maximum packet size.

(d) Overrun and underrun errors

In host controller mode:

- The FIFO buffer is full at token transmit time in the IN (receiving) direction
- There is no data to be sent in the FIFO buffer at token transmit time in the OUT (transmitting) direction.

32.3.11.1 主机控制器模式下中断传输的间隔计数器

在PIPEPERI.IITV[2:0]位中指定中断传输的事务间隔。USBFS基于此间隔发出中断传输令牌。

(1) 计数器初始化

USBFS在以下条件下初始化间隔计数器：

- Power-on reset
  这将初始化IITV[2:0]位。
- 使用PIPEnCTR.ACLRM位初始化FIFO缓冲区：
  这不会初始化IITV[2:0]位，但会初始化计数值。将PIPEnCTR.ACLRM位设置为0从IITV[2:0]中设置的值开始计数。

在以下情况下不初始化间隔计数器：

- USB总线复位或USB挂起
  IITV[2:0]位未初始化。将DVSTCTR0.UACT位置1从进入USB总线复位状态或USB挂起状态之前保存的值开始计数。

(2) 即使在生成令牌时也无法发送或接收令牌时的操作

在以下情况下，即使在生成令牌时也不会生成令牌。在这些情况下，USBFS会尝试在下一个时间间隔执行事务。

- 当PID设置为NAK或STALL时
- 当FIFO缓冲区在接收(IN)方向的令牌传输时间已满时
- 在发送(OUT)方向的令牌发送时间，当FIFO缓冲区中没有要发送的数据时。

32.3.12 同步传输（管道1和2）

USBFS为同步传输提供以下功能：

- 同步传输错误通知
- 在PIPEPERI.IITV[2:0]位中指定的间隔计数器
- 同步IN传输数据设置控制（IDLY功能）
- 在PIPEPERI.IFIS位中指定的同步IN传输缓冲区刷新功能。

32.3.12.1 同步传输中的错误检测

USBFS提供了检测本节所述的错误的功能，以便在同步传输中发生错误时，可以通过软件进行控制。表32.24和表32.25显示了USBFS检测到的错误和相关中断的优先级顺序。

(a) PID错误

- 接收到的数据包的PID值无效。

(b) CRC错误和位填充错误

- 在收到的数据包中发现CRC错误或比特填充是非法的。

(c) 超出最大数据包大小

- 接收到的数据包的数据大小超过了指定的最大数据包大小。

(d) 溢出和欠载错误

在主机控制器模式下：

- FIFO缓冲区在IN（接收）方向的令牌发送时间已满
- 在OUT（发送）方向的令牌发送时，FIFO缓冲区中没有要发送的数据。

In device controller mode:

- There is no data to be sent in the FIFO buffer at token receive time in the IN (transmitting) direction
- The FIFO buffer is full at token receive time in the OUT (receiving) direction.

(e) Interval errors

In device controller mode, the following cases are treated as an interval error:

- Failure to receive an IN token in the interval frame during an isochronous IN transfer
- Failure to receive an OUT token in the interval frame during an isochronous OUT transfer.

Table 32.24 Error detection for token transmission and reception

Detection priority	Error	Generated interrupt and status
1	PID error	No interrupts are generated in either host or device controller mode (ignored as a corrupted packet)
2	CRC or bit stuffing error	No interrupts are generated in either host or device controller mode (ignored as a corrupted packet)
3	Overrun or underrun error	An NRDY interrupt is generated to set the FRMNUM.OVRN bit to 1 in both host and device controller modes. In device controller mode, a zero-length packet is transmitted in response to an IN token. No data packets are received in response to OUT token.
4	Interval error	An NRDY interrupt is generated in device controller mode. No interrupt is generated in host controller mode.

Table 32.25 Error detection for data packet reception

Detection priority	Error	Generated interrupt and status
1	PID error	No interrupts are generated (ignored as a corrupted packet)
2	CRC or bit stuffing error	An NRDY interrupt is generated and the FRMNUM.CRCE bit sets to 1 in both host and device controller modes
3	Maximum packet size exceeded error	A BEMP interrupt is generated and the PID[1:0] bits set to STALL in both host and device controller modes

32.3.12.2 DATA-PID

In device controller mode, the USBFS responds to a received PID as follows:

(1) IN direction

- DATA0: Transmitted as data packet PID
- DATA1: Not transmitted
- DATA2: Not transmitted
- mDATA: Not transmitted.

(2) OUT direction

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets ignored
- mDATA: Packets ignored.

32.3.12.3 Interval counter

The isochronous transfer interval can be set in the PIPEPERI.IITV[2:0] bits. In device controller mode, the interval

在设备控制器模式下：

- 在IN（发送）方向的令牌接收时间，FIFO缓冲区中没有要发送的数据
- FIFO缓冲区在OUT（接收）方向上的令牌接收时间已满。

(e) 间隔错误

在设备控制器模式下，以下情况被视为间隔错误：

- 在同步IN传输期间未能在间隔帧中接收IN令牌
- 在同步OUT传输期间未能在间隔帧中接收OUT令牌。

Table 32.24 令牌发送和接收的错误检测

检测优先级	Error	产生的中断和状态
1	PID错误	在主机或设备控制器模式下都不会产生中断（被忽略为损坏的数据包）
2	CRC或位填充错误	在主机或设备控制器模式下都不会产生中断（被忽略为损坏的数据包）
3	溢出或欠载错误	在主机和设备控制器模式下，都会产生一个NRDY中断来将FRMNUM.OVRN位设置为1。在设备控制器模式下，发送一个零长度数据包以响应IN令牌。 没有接收到响应OUT令牌的数据包。
4	间隔误差	在设备控制器模式下会产生一个NRDY中断。在主机控制器模式下不产生中断。

Table 32.25 数据包接收错误检测

检测优先级	Error	产生的中断和状态
1	PID错误	不产生中断（作为损坏的数据包被忽略）
2	CRC或位填充错误	在主机和设备控制器模式下都会产生一个NRDY中断并且FRMNUM.CRCE位设置为1
3	超出最大数据包大小错误	在主机和设备控制器模式下都会产生BEMP中断并且PID[1:0]位设置为STALL

32.3.12.2 DATA-PID

在设备控制器模式下，USBFS响应接收到的PID如下：

(1) 在方向

- DATA0：作为数据包PID发送
- DATA1：未发送
- DATA2：未传输
- mDATA：未传输。

(2) 出方向

- DATA0：作为数据包PID正常接收
- DATA1：作为数据包PID正常接收
- DATA2：数据包被忽略
- mDATA：数据包被忽略。

32.3.12.3 间隔计数器

同步传输间隔可以在PIPEPERI.IITV[2:0]位中设置。在设备控制器模式下，间隔

counter enables the functions as shown in Table 32.26. In host controller mode, the USBFS generates the token issuance timing, and the interval counter operation is the same as that for interrupt transfers.

Table 32.26 Interval counter functions in device controller mode

Transfer direction	Function	Conditions for detection
IN	Transmit buffer flush	Failure to receive an IN token successfully in the interval frame during an isochronous IN transfer.
OUT	Notification of no reception of token	Failure to receive an OUT token successfully in the interval frame during an isochronous OUT transfer.

The interval count is performed when an SOF is received or for interpolated SOFs, so the isochronism can be maintained even if an SOF is corrupt. The frame interval can be set to 2^{IITV} frames.

(1) Counter initialization in device controller mode

The USBFS initializes the interval counter under the following conditions:

- Power-on reset
  This initializes the PIPEPERI.IITV[2:0] bits.
- FIFO buffer initialization using the ACLRM bit
  This does not initialize the IITV[2:0] bits, but does initialize the count value.

After the interval counter is initialized, the interval count starts under one of the following conditions when a packet is transferred successfully:

- An SOF is received after data is transmitted in response to an IN token when PID = BUF
- An SOF is received after data is received in response to an OUT token when PID = BUF.

The interval counter is not initialized in the following conditions:

- When the PID[1:0] bits are set to NAK or STALL
  This does not stop the interval timer. The USBFS attempts the transaction in the next interval.
- When the USB bus is reset or USBFS is suspended
  This does not initialize the IITV[2:0] bits. When an SOF is received, the interval counter starts counting from the value set before SOF was received.

(2) Interval counting and transfer control in host controller mode

The USBFS controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bit settings. Specifically, the USBFS issues a token for a selected pipe once every 2^{IITV} frames.

The USBFS starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits are set to BUF by software.

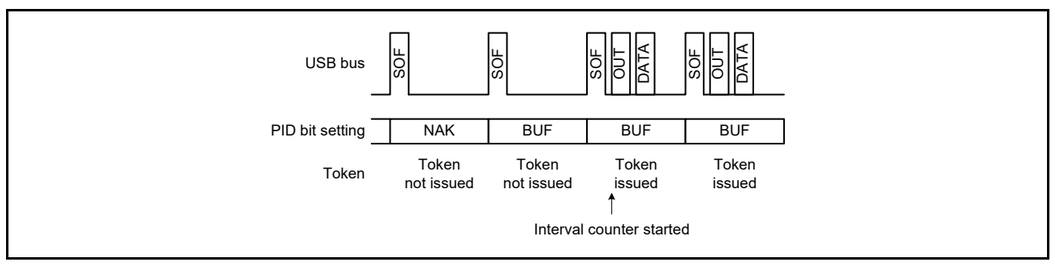

Figure 32.16 Token issuance when IITV = 0

计数器启用表32.26中所示的功能。在主机控制器模式下，USBFS产生令牌发布时序，间隔计数器操作与中断传输相同。

Table 32.26 设备控制器模式下的间隔计数器功能

转移方向	Function	检测条件
IN	发送缓冲区刷新	在同步IN传输期间未能在间隔帧中成功接收IN令牌。
OUT	未收到令牌的通知	在等时期间未能在间隔帧中成功接收OUT令牌 输出传输。

间隔计数在接收到SOF时执行或对插值SOF执行，因此即使SOF损坏也可以保持等时性。帧间隔可以设置为2个IITV帧。

(1) 设备控制器模式下的计数器初始化

USBFS在以下条件下初始化间隔计数器：

- Power-on reset
  这将初始化PIPEPERI.IITV[2:0]位。
- 使用ACLRM位初始化FIFO缓冲区
  这不会初始化IITV[2:0]位，但会初始化计数值。

间隔计数器初始化后，当数据包传输成功时，间隔计数在以下条件之一开始：

- 当PID=BUF时，响应IN令牌传输数据后收到SOF
- 当PID=BUF时，接收到响应于OUT令牌的数据后接收到SOF。

间隔计数器在以下情况下不会初始化：

- 当PID[1:0]位设置为NAK或STALL
  这不会停止间隔计时器。USBFS在下一个间隔尝试事务。
- 当USB总线复位或USBFS暂停时
  这不会初始化IITV[2:0]位。当接收到SOF时，间隔计数器从接收到SOF之前设置的值开始计数。

(2) 主机控制器模式下的间隔计数和传输控制

USBFS根据PIPEPERI.IITV[2:0]位设置控制令牌发布操作之间的间隔。
具体来说，USBFS每2个IITV帧为所选管道发布一次令牌。

USBFS在PID[1:0]位被软件设置为BUF的帧之后的帧开始计算令牌发布间隔。

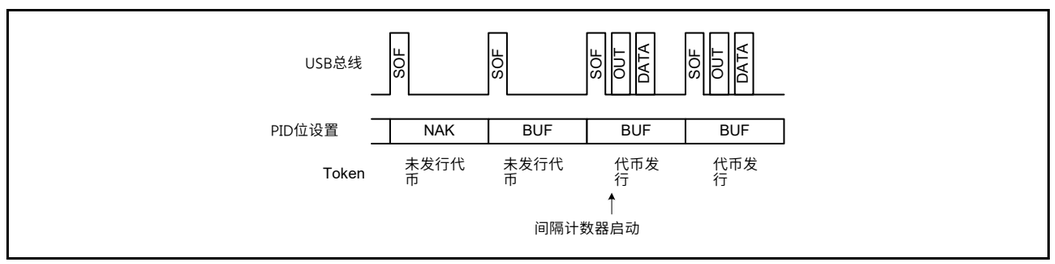

Figure 32.16 IITV=0时的代币发行

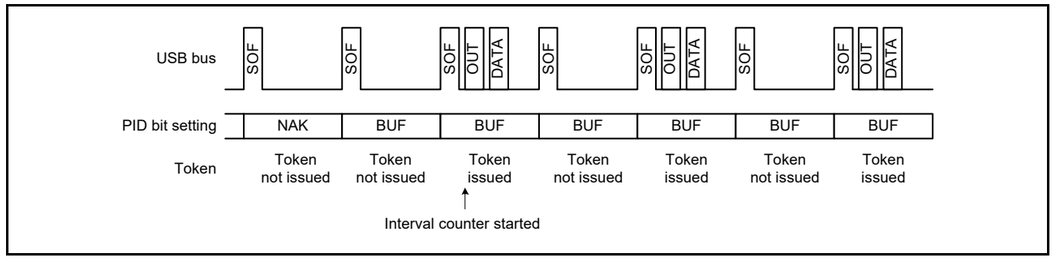

Figure 32.17 Token issuance when IITV = 1

When the selected pipe is set for isochronous transfers, the USBFS performs the following operation in addition to controlling the token issuance interval. The USBFS issues a token even when the NRDY interrupt generation condition is satisfied.

(a) When the selected pipe is for isochronous IN transfers

The USBFS generates an NRDY interrupt when the USBFS issues an IN token but does not successfully receive a packet from a peripheral device (no response or packet error).

The USBFS sets the FRMNUM.OVRN bit to 1, generating an NRDY interrupt, when the time to issue an IN token occurs while the USBFS cannot receive data because the FIFO buffer is full, because the CPU or DMAC/DTC is too slow in reading data from the FIFO buffer.

(b) When the selected pipe is for isochronous OUT transfers

The USBFS sets the OVRN bit to 1, generating an NRDY interrupt and transmitting a zero-length packet, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer, or because the CPU or DMAC/DTC is too slow in writing data to the FIFO buffer.

The token issuance interval is reset on any of the following conditions:

- When the USBFS is reset through a reset pin
  This initializes the IITV[2:0] bits.
- When the PIPEnCTR.ACLRM bit is set to 1 by software.

(3) Interval counting and transfer control in device controller mode

(a) When the selected pipe is for isochronous OUT transfers

The USBFS generates an NRDY interrupt when it fails to receive a data packet within the interval set in the PIPEPERI.IITV[2:0] bits.

The USBFS also generates an NRDY interrupt when it fails to receive data because of a CRC error or other errors contained in the data packet or because the FIFO buffer is full.

The NRDY interrupt is generated on SOF packet reception. Even if the SOF packet is corrupted, internal interpolation allows the interrupt to be generated when the SOF packet is received. However, when the IITV bits are set to a value other than 0, the USBFS generates an NRDY interrupt on receiving an SOF packet for every interval after interval counting starts.

When the PID[1:0] bits are set to NAK by software after starting the interval timer, the USBFS does not generate an NRDY interrupt on receiving an SOF packet.

The timing for starting interval counting depend on the IITV[2:0] setting as follows:

- When the IITV[2:0] bits = 0:
  Interval counting starts at the next frame after the software changes the PID[1:0] bits of the selected pipe to BUF.
- When the IITV[2:0] bits ≠ 0:
  Interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe are changed to BUF.

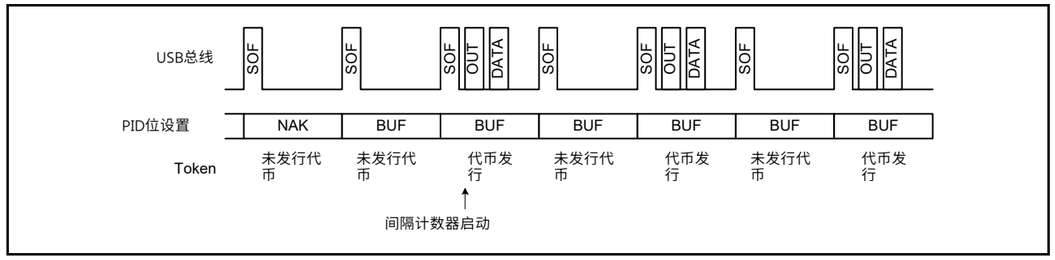

Figure 32.17 IITV=1时的代币发行

当所选管道设置为同步传输时，USBFS除了控制令牌发布间隔外，还执行以下操作。即使满足NRDY中断生成条件，USBFS也会发出令牌。

(a) 当所选管道用于同步IN传输时

当USBFS发出IN令牌但未成功接收到来自外围设备的数据包（无响应或数据包错误）时，USBFS会生成NRDY中断。

USBFS将FRMNUM.OVRN位设置为1，产生一个NRDY中断，此时发生发出IN令牌的时间，而USBFS无法接收数据，因为FIFO缓冲区已满，因为CPU或DMACDTC读取数据太慢从FIFO缓冲区。

(b) 当所选管道用于同步OUT传输时

USBFS将OVRN位设置为1，产生一个NRDY中断并发送一个长度为零的数据包，当发出OUT令牌的时间到来而FIFO缓冲区中没有要发送的数据时，或者因为CPU或DMACDTC将数据写入FIFO缓冲区太慢。

令牌发行间隔在以下任何条件下重置：

- 当USBFS通过复位引脚复位时
  这将初始化IITV[2:0]位。
- 当PIPEnCTR.ACLRM位由软件设置为1时。

(3) 设备控制器模式下的间隔计数和传输控制

(a) 当所选管道用于同步OUT传输时

当USBFS在设置的时间间隔内没有接收到数据包时，会产生一个NRDY中断。
PIPEPERI.IITV[2:0] bits.

当由于数据包中包含的CRC错误或其他错误或FIFO缓冲区已满而无法接收数据时，USBFS也会产生NRDY中断。

NRDY中断在SOF数据包接收时产生。即使SOF数据包损坏，内部插值也允许在接收到SOF数据包时产生中断。但是，当IITV位设置为0以外的值时，USBFS会在间隔计数开始后的每个间隔接收到SOF数据包时产生NRDY中断。

当PID[1:0]位在启动间隔定时器后由软件设置为NAK时，USBFS不会产生
接收到SOF数据包时的NRDY中断。

开始间隔计数的时间取决于IITV[2:0]设置，如下所示：

- 当IITV[2:0]位=0时：
  软件将所选管道的PID[1:0]位更改为BUF后，间隔计数从下一帧开始。
- 当IITV[2:0]位≠0时：
  在所选管道的PID[1:0]位更改为BUF后，成功接收第一个数据包后，间隔计数开始。

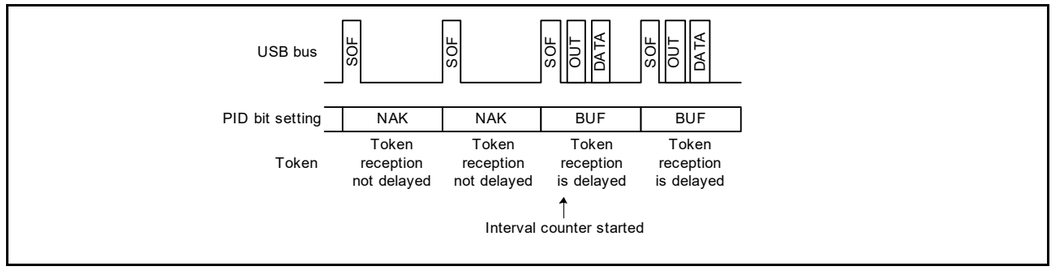

Figure 32.18 Relationship between frames and expected token reception when IITV[2:0] = 0

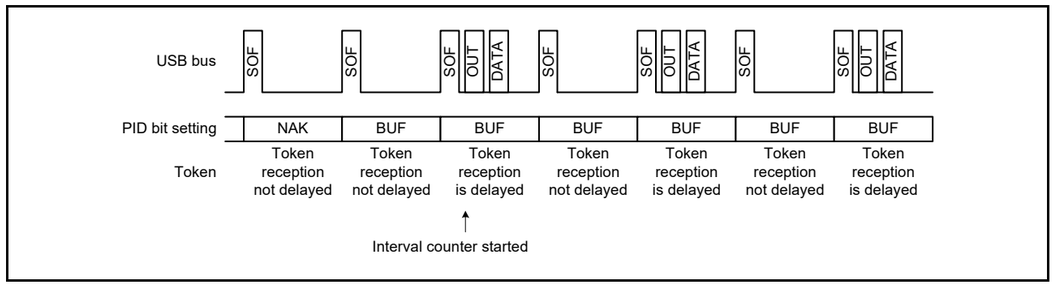

Figure 32.19 Relationship between frames and expected token reception when IITV[2:0] ≠ 0

(b) When the selected pipe is for isochronous IN transfers

The PIPEPERI.IFIS bit must be 1 for this use case. When IFIS = 0, the USBFS transmits a data packet in response to a received IN token regardless of the PIPEPERI.IITV[2:0] setting.

When IFIS is 1 and there is data to be transmitted in the FIFO buffer, the USBFS clears the FIFO buffer when it fails to receive an IN token in the frame at the interval set in the IITV[2:0] bits.

The USBFS also clears the FIFO buffer when it fails to receive an IN token successfully because of a bus error, such as a CRC error, contained in the IN token.

The FIFO buffer is cleared on SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the FIFO buffer to be cleared when the SOF packet is received.

The timing to start interval counting depends on the IITV[2:0] setting, as with OUT transfers.

The interval is counted on any of the following conditions in device controller mode:

- When a hardware reset is applied to the USBFS (which also sets the IITV[2:0] bits to 000b)
- When the PIPEnCTR.ACLRM bit is set to 1 by software
- When the USBFS detects a USB bus reset.

(4) Transmit data setup for isochronous transfers in device controller mode

With isochronous data transmission using the USBFS in device controller mode, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the SOF packet is detected. This isochronous transfer transmit data setup function can identify the frame that started transmission.

When the double buffering is used, transmission is only enabled for the buffer where data writing was completed first, even after the data write to both buffers is complete. Accordingly, even if multiple IN tokens are received, only the one packet of FIFO buffer data is transmitted.

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transferred and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

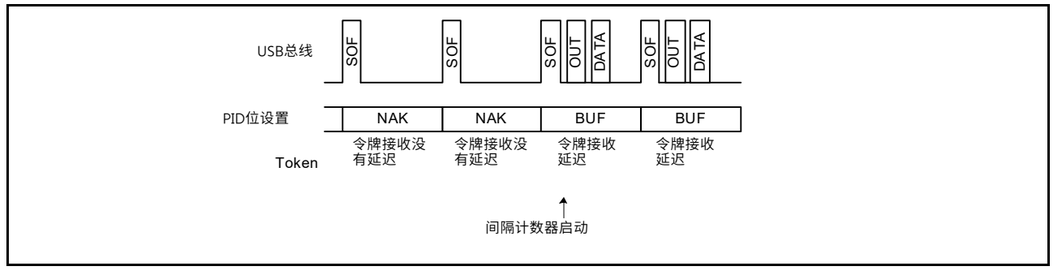

Figure 32.18 IITV[2:0]=0时帧与预期令牌接收之间的关系

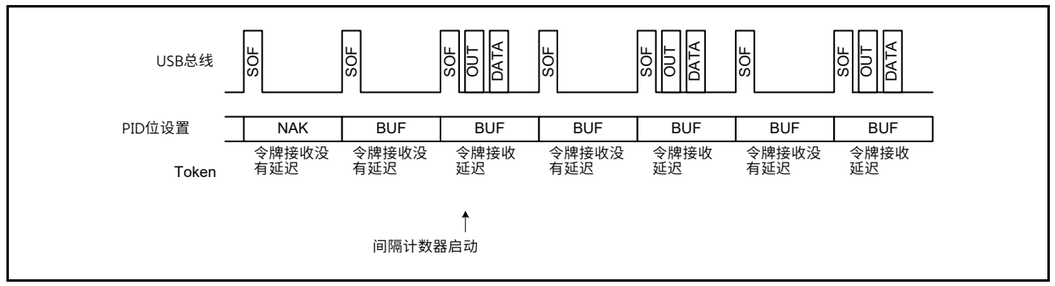

Figure 32.19 IITV[2:0]≠0时帧与预期令牌接收的关系

(b) 当所选管道用于同步IN传输时

对于此用例，PIPEPERI.IFIS位必须为1。当IFIS=0时，无论PIPEPERI.IITV[2:0]设置如何，USBFS都会发送一个数据包以响应接收到的IN令牌。

当IFIS为1且FIFO缓冲区中有数据要发送时，如果USBFS在IITV[2:0]位设置的时间间隔内未能接收到帧中的IN令牌，则清除FIFO缓冲区。

当USBFS由于总线错误（例如
CRC错误，包含在IN令牌中。

FIFO缓冲区在SOF数据包接收时被清除。即使SOF数据包损坏，内部插值也允许在接收到SOF数据包时清除FIFO缓冲区。

开始间隔计数的时间取决于IITV[2:0]设置，与OUT传输一样。

在设备控制器模式下，根据以下任何条件计算间隔：

- 当对USBFS应用硬件复位时（也将IITV[2:0]位设置为000b）
- 当PIPEnCTR.ACLRM位由软件设置为1时
- 当USBFS检测到USB总线复位时。

(4) 设备控制器模式下同步传输的传输数据设置

在设备控制器模式下使用USBFS进行同步数据传输，数据写入FIFO缓冲区后，可在检测到SOF包后的第一帧发送数据包。此同步传输传输数据设置功能可以识别开始传输的帧。

使用双缓冲时，仅对先完成数据写入的缓冲区启用传输，即使在两个缓冲区的数据写入完成后也是如此。因此，即使接收到多个IN令牌，也仅发送一包FIFO缓冲器数据。

当接收到IN令牌时，当FIFO缓冲区准备好传输数据时，将传输数据并返回正常响应。但是，如果FIFO缓冲区无法传输数据，则会传输零长度数据包并发生欠载错误。

Figure 32.20 shows an example transmission using the isochronous transfer transmission data setup function when IITV = 0 (every frame) is set.

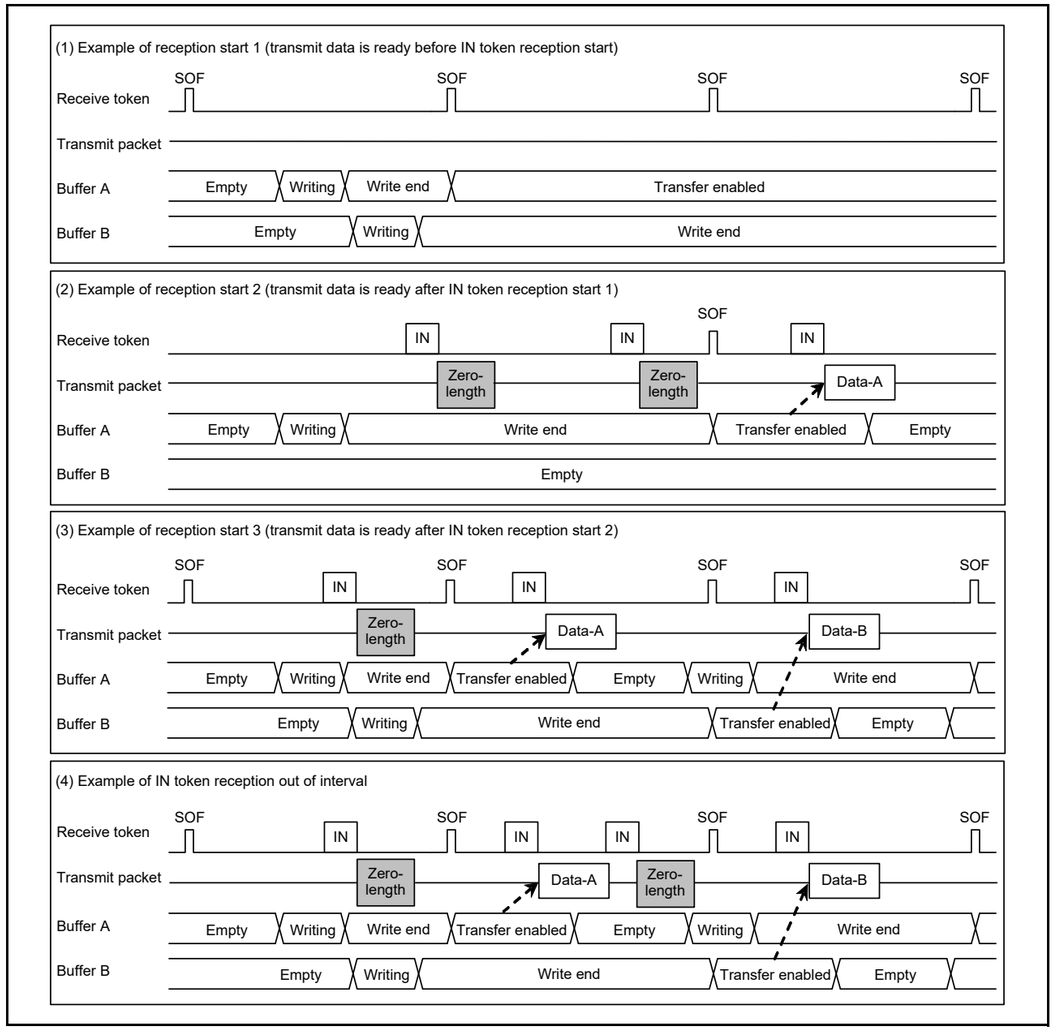

Figure 32.20 Example data setup operation

(5) Transmit buffer flush for isochronous transfers in device controller mode

In device controller mode during isochronous data transmission, if the USBFS receives an SOF packet for the next frame without receiving an IN token in the interval frame, it operates as if the IN token is corrupt and clears the buffer that is enabled for transmission, putting that buffer in the writing enabled state.

When double buffering is used and writing to both buffers is complete, the cleared FIFO buffer is assumed to be the one where the data was transmitted in the interval frame, and transmission is enabled for the FIFO buffer that was not cleared on SOF packet reception.

The timing of the buffer flush function depends on the PIPEPERI.IITV[2:0] setting as follows:

- When IITV = 0:
  The buffer flush operation starts from the first frame after the pipe is enabled.

图32.20显示了在设置IITV=0（每帧）时使用同步传输传输数据设置功能的示例传输。

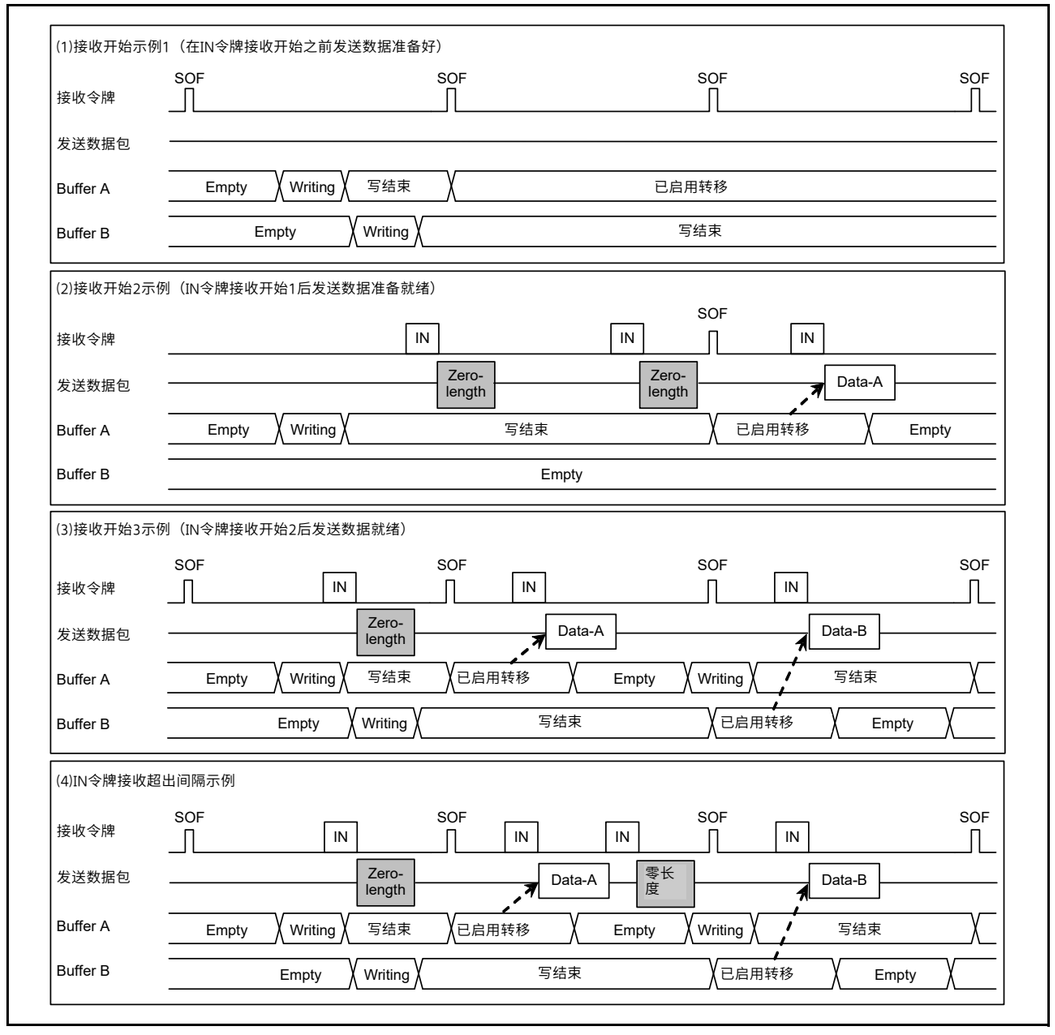

Figure 32.20 示例数据设置操作

(5) 设备控制器模式下同步传输的传输缓冲区刷新

在同步数据传输期间的设备控制器模式下，如果USBFS接收到下一帧的SOF数据包，而在间隔帧中没有接收到IN令牌，则它会像IN令牌损坏一样操作并清除启用传输的缓冲区，将该缓冲区处于写入启用状态。

当使用双缓冲并完成对两个缓冲区的写入时，已清除的FIFO缓冲区被假定为在间隔帧中传输数据的缓冲区，并为接收SOF数据包时未清除的FIFO缓冲区启用传输。

缓冲区刷新功能的时间取决于PIPEPERI.IITV[2:0]设置，如下所示：

- When IITV = 0:
  缓冲区刷新操作从启用管道后的第一帧开始。

- When IITV ≠ 0:
  The buffer flush operation starts after the first normal transaction.

Figure 32.21 shows an example buffer flush. When an unanticipated token is received before the interval frame, the USBFS sends the write data or a zero-length packet as an underrun error, depending on the data setup status.

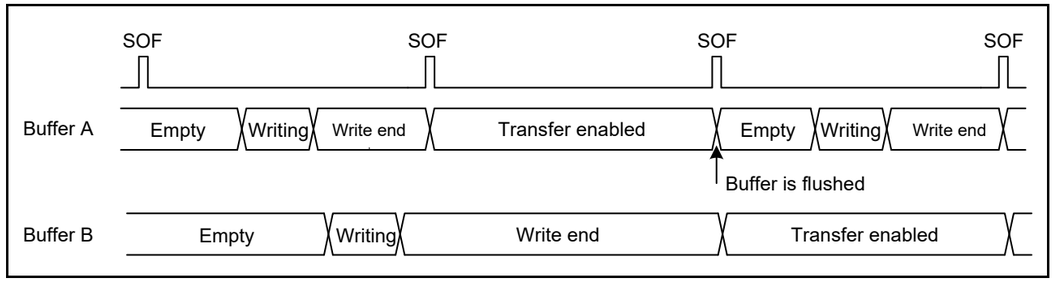

Figure 32.21 Example buffer flush operation

Figure 32.22 shows an example interval error occurrence. There are five types of interval errors, as shown in the figure. An interval error occurs at timing ①, and the buffer flush function is activated.

If an interval error occurs during an IN transfer, the buffer flush function is activated. If it occurs during an OUT transfer, an NRDY interrupt is generated. Use the FRMNUM.OVRN bit to distinguish between this and NRDY interrupts triggered by received packet errors and overrun errors.

For tokens that are shaded in the figure, responses are returned based on the FIFO buffer status.

- IN direction:
  - If the buffer is ready to transfer data, the data is transferred and a normal response is returned
  - If the buffer is not ready to transfer data, a zero-length packet is transmitted and an underrun error occurs.
- OUT direction:
  - If the buffer is ready to receive data, the data is received and a normal response is returned
  - If the buffer is not ready to receive data, the received data is discarded and an overrun error occurs.

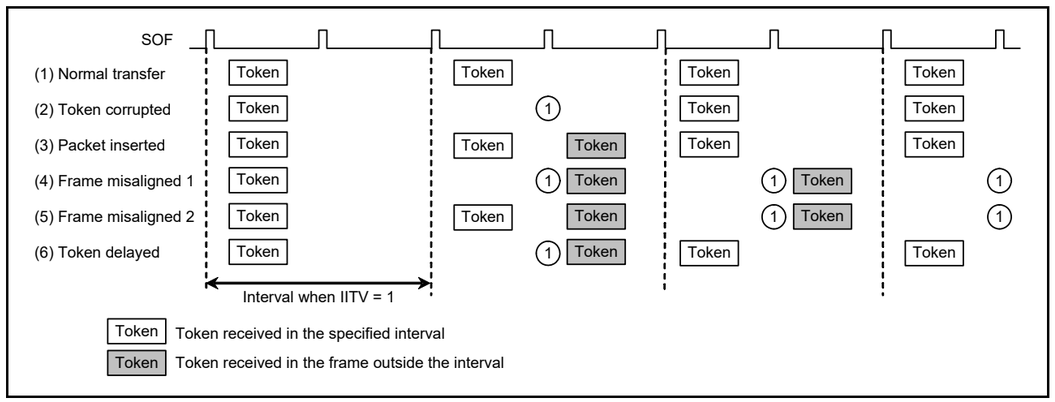

Figure 32.22 Example interval error occurrence when IITV = 1

32.3.13 SOF Interpolation Function

In device controller mode, if packet reception is disabled at intervals of 1 ms because the SOF packet is corrupted or missing, the USBFS interpolates the SOF. SOF interpolation begins when the USBE and SCKE bits in SYSCFG are set to 1 and an SOF packet is received.

- When IITV ≠ 0:
  缓冲区刷新操作在第一个正常事务之后开始。

图32.21显示了一个示例缓冲区刷新。当在间隔帧之前收到未预料到的令牌时，USBFS根据数据设置状态将写入数据或零长度数据包作为欠载错误发送。

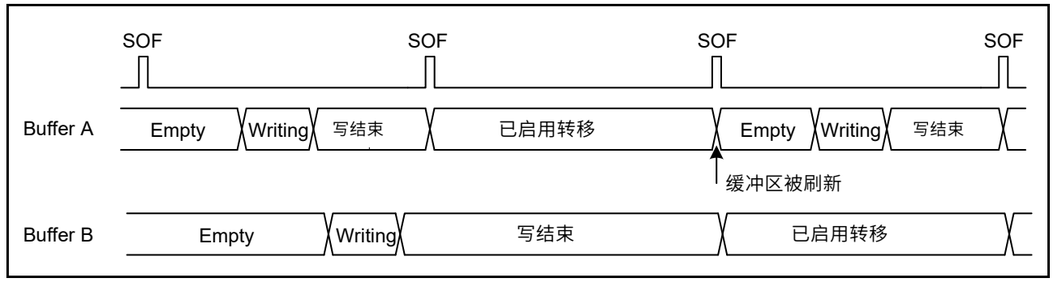

Figure 32.21 缓冲区刷新操作示例

图32.22显示了一个发生间隔错误的示例。如图所示，有五种区间误差。
定时出现间隔错误 ① 并且缓冲区刷新功能被激活。

如果在IN传输期间发生间隔错误，则会激活缓冲区刷新功能。如果它发生在OUT传输期间，则会产生NRDY中断。使用FRMNUM.OVRN位来区分此中断和由接收数据包错误和溢出错误触发的NRDY中断。

对于图中带阴影的令牌，根据FIFO缓冲区状态返回响应。

- IN direction:
  - 如果缓冲区准备好传输数据，则传输数据并返回正常响应
  - 如果缓冲区尚未准备好传输数据，则会传输零长度数据包并发生欠载错误。
- OUT direction:
  - 如果缓冲区准备好接收数据，则接收数据并返回正常响应
  - 如果缓冲区没有准备好接收数据，则丢弃接收到的数据并发生溢出错误。

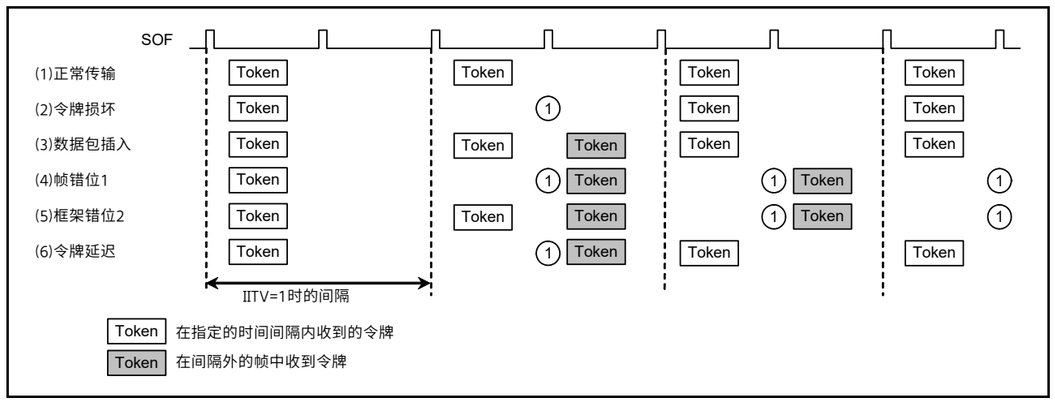

Figure 32.22 IITV=1时发生的示例间隔错误

32.3.13 SOF插值函数

在设备控制器模式下，如果由于SOF数据包损坏或丢失而每隔1ms禁用数据包接收，则USBFS会内插SOF。当SYSCFG中的USBE和SCKE位设置为1并且接收到SOF数据包时，SOF内插开始。

The interpolation function is initialized under the following conditions:

- MCU reset
- USB bus reset
- Suspend state detection.

The SOF interpolation operates as follows:

- The interpolation function is not activated until an SOF packet is received.
- When the first SOF packet is received, interpolation is performed by counting 1 ms on the 48-MHz internal clock
- When the second and subsequent SOF packets are received, interpolation is performed at the previous reception interval
- Interpolation is not performed in the Suspend state or on reception of a USB bus reset.

The USBFS supports the following functions controlled by SOF packet reception. These functions operate normally with SOF interpolation if the SOF packet is missing:

- Updating of the frame number
- SOFR interrupt timing
- Isochronous transfer interval count.

If an SOF packet is missing during full-speed operation, the FRMNUM.FRNM[10:0] bits are not updated.

32.3.14 Pipe Schedule

32.3.14.1 Conditions for generating transactions

In host controller mode and when the DVSTCTR0.UACT bit is set to 1, the USBFS generates transactions under the conditions shown in Table 32.27.

Table 32.27 Conditions for generating transactions

	Conditions for generation				
Transaction	**DIR**	**PID**	**IITV0**	**Buffer state**	**SUREQ**
Setup	—*1	—*1	—*1	—*1	1 setting
Control transfer data stage, status stage, bulk transfer	IN	BUF	Invalid	Receive area exists	—*1
	OUT	BUF	Invalid	Transmit data exists	—*1
Interrupt transfer	IN	BUF	Valid	Receive area exists	—*1
	OUT	BUF	Valid	Transmit data exists	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

Note 1. An em dash (—) in the table indicates that the condition is unrelated to the generating of tokens. “Valid” indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter. “Invalid” indicates that a transaction is generated regardless of the interval counter.

Note 2. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.

Note 3. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

插值函数在以下条件下初始化：

- MCU reset
- USB总线复位
- 暂停状态检测。

SOF插值操作如下：

- 在接收到SOF数据包之前，不会激活插值功能。
- 当接收到第一个SOF数据包时，通过在48-MHz内部时钟上计数1ms来执行插值
- 当接收到第二个和随后的SOF数据包时，以先前的接收间隔执行插值
- 在挂起状态或接收到USB总线复位时不执行插值。

USBFS支持以下由SOF数据包接收控制的功能。这些功能正常运行
如果SOF数据包丢失，则SOF插值：

- 更新帧号
- SOFR中断时序
- 同步传输间隔计数。

如果在全速运行期间丢失SOF数据包，则不会更新FRMNUM.FRNM[10:0]位。

32.3.14 管道计划

32.3.14.1 产生交易的条件

在主机控制器模式下，当DVSTCTR0.UACT位设置为1时，USBFS在表32.27所示的条件下生成事务。

Table 32.27 产生交易的条件

	生成条件				
Transaction	**DIR**	**PID**	**IITV0**	**缓冲状态**	**SUREQ**
Setup	—*1	—*1	—*1	—*1	1 setting
控制传输数据阶段、状态阶段、批量传输	IN	BUF	Invalid	接收区存在	—*1
	OUT	BUF	Invalid	传输数据存在	—*1
中断传输	IN	BUF	Valid	接收区存在	—*1
	OUT	BUF	Valid	传输数据存在	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

Note 1. 表中的破折号(—)表示该条件与令牌的生成无关。“有效”表示，对于中断传输和同步传输，事务仅在基于间隔计数器的传输帧中生成。“无效”表示无论间隔计数器如何都生成事务。

Note 2. 这表示不管是否有接收区域，都会产生一个事务。但是，如果没有接收区域，则丢弃接收到的数据。

Note 3. 这表明无论是否有任何数据要传输，都会生成一个事务。然而，如果没有要传输的数据，则传输零长度数据包。

32.3.14.2 Transfer schedule

This section describes the transfer scheduling within a frame of the USBFS. After the USBFS sends an SOF, the transfer is carried out in the following sequence:

1. Execution of periodic transfers:
   A pipe is searched for in the order of pipe 1 → pipe 2 → pipe 6 → pipe 7 → pipe 8 → pipe 9, and then if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.
2. Setup transactions for control transfers:
   The DCP is checked, and if a setup transaction is possible, it is sent.
3. Execution of bulk transfers, control transfer data stages, and control transfer status stages:
   A pipe is searched for in the order of DCP → pipe 1 → pipe 2 → pipe 3 → pipe 4 → pipe 5, and then if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.
   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

32.3.14.3 Enabling USB communication

Setting the DVSTCTR0.UACT bit to 1 initiates an SOF transmission, and transaction generation is enabled. Setting the UACT bit to 0 stops SOF transmission and the Suspend state is invoked. If the UACT setting is changed from 1 to 0, processing stops after the next SOF is sent.

32.4 Usage Notes

32.4.1 Settings for the Module-Stop State

USBFS operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The USBFS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

32.4.2 Clearing the Interrupt Status Register on Exiting Software Standby Mode

Because the input buffer is always enabled in Software Standby mode, an unexpected interrupt might occur under the following conditions:

- When the interrupt is enabled in Normal mode
- When the interrupt is disabled in Software Standby mode
- When the input level of the pin that cancels software standby is changed in Software Standby mode.

These conditions might cause the associated interrupt flag in the Interrupt Status Register to set unexpectedly. After the MCU exits the Software Standby mode, the unexpected interrupt might be sent to the interrupt controller. To avoid this, always clear the INTSTS0 and INTSTS1 registers in the canceling sequence.

32.4.3 Clearing the Interrupt Status Register after Setting Up the Port Function

The input buffer is disabled before the PmnPFS.PSEL and PmnPFS.PMR port is set up, so the internal signal is fixed high or low. The input buffer is enabled after the port is set so that the external pin state is propagated to the MCU. An unexpected interrupt might occur at this time, causing the VBINT and OVRCR bits in INTSTS0 and INTSTS1, or other interrupt status flags to set to 1. To avoid a malfunction, always clear the INTSTS0 and INTSTS1 registers after setting up the port.

32.3.14.2 转移时间表

本节介绍USBFS帧内的传输调度。USBFS发送SOF后，按以下顺序进行传输：

1. 执行定期转账：
   按照管道1 管道2 管道6 管道7 管道8 管道9的顺序搜索管道，然后如果存在可以生成等时或中断传输事务的管道，则生成事务.
2. 为控制转移设置交易：
   DCP被检查，如果设置事务是可能的，它被发送。
3. 批量传输、控制传输数据阶段和控制传输状态阶段的执行：
   管道按DCP 管道1 管道2 管道3 管道4 管道5的顺序搜索，然后如果存在要进行批量传输的事务、控制传输数据阶段或可以生成控制转移状态阶段，生成事务。生成事务时，无论来自外围设备的响应是ACK还是NAK，处理都会转移到下一个管道事务。如果帧内有时间进行传输，则重复步骤3。

32.3.14.3 启用USB通信

将DVSTCR0.UACT位设置为1启动SOF传输，并启用事务生成。设置UACT位为0停止SOF传输并调用暂停状态。如果UACT设置从1更改为0，则在发送下一个SOF后处理停止。

32.4 使用说明

32.4.1 模块停止状态的设置

可以使用模块停止控制寄存器B(MSTPCRB)禁用或启用USBFS操作。USBFS在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第11节，低功耗模式。

32.4.2 退出软件待机模式时清除中断状态寄存器

由于在软件待机模式下始终启用输入缓冲区，因此在以下情况下可能会发生意外中断：

- 在正常模式下启用中断时
- 在软件待机模式下禁用中断时
- 当取消软件待机的引脚的输入电平在软件待机模式下发生变化时。

这些情况可能会导致中断状态寄存器中的相关中断标志意外设置。MCU退出软件待机模式后，可能会向中断控制器发送意外中断。为避免这种情况，请始终在取消序列中清除INTSTS0和INTSTS1寄存器。

32.4.3 设置端口功能后清除中断状态寄存器

在设置PmnPFS.PSEL和PmnPFS.PMR端口之前，输入缓冲器被禁用，因此内部信号固定为高电平或低电平。设置端口后启用输入缓冲器，以便将外部引脚状态传播到MCU。此时可能会发生意外中断，导致INTSTS0和INTSTS1中的VBINT和OVRCR位或其他中断状态标志设置为1。为避免故障，请在设置端口后始终清除INTSTS0和INTSTS1寄存器。

33. USB 2.0 High-Speed Module (USBHS)

33.1 Overview

The MCU provides a USB 2.0 High-Speed Module (USBHS) that operates as a host or a device controller compliant with the Universal Serial Bus (USB) Specification revision 2.0. The host controller supports USB 2.0 high-speed, full-speed, and low-speed transfers, and the device controller supports USB 2.0 high-speed and full-speed transfers. The USBHS has an internal USB transceiver and supports all of the transfer types defined in the USB 2.0 specification.

The USBHS has FIFO buffer for data transfers, providing a maximum of 10 pipes. Any endpoint number can be assigned to pipes 1 to 9, based on the peripheral devices or the communication requirements for your system.

Table 33.1 lists the USBHS specifications, Figure 33.1 shows a block diagram, and Table 33.2 lists the I/O pins.

Table 33.1 USBHS specifications

Parameter	Specifications
Features	• USB Device Controller (UDC) and USB 2.0 transceiver supporting host controller, device controller, and On-The-Go (OTG) functions • Software can switch between host and device controller modes.
	Host controller features: • High-speed transfer (480 Mbps), full-speed transfer (12 Mbps), and low-speed transfer (1.5 Mbps) • Automatic scheduling for SOF and packet transmissions • Programmable intervals for isochronous and interrupt transfers • Communications with multiple peripheral devices connected through a single hub.
	Device controller features: • High-speed transfer (480 Mbps) and full-speed transfer (12 Mbps) • Control transfer stage control function • Device state control function • Auto response function for SET_ADDRESS request • SOF complementation.
Supported transfer types	• Control transfer • Bulk transfer • Interrupt transfer • Isochronous transfer.
Pipe configuration	• FIFO buffer of up to 8.5 KB for USB communications • Up to 10 pipes selectable, including the default control pipe • Programmable pipe configurations • Pipes 1 to 9 assignable to any endpoint number.
	Transfer conditions specifiable for each pipe: • Pipe 0: Control transfer with 64-byte single buffer • Pipes 1 and 2: Bulk isochronous transfer continuous transfer mode with programmable buffer size up to 2 KB and optional double buffer • Pipes 3 to 5: Bulk transfer continuous transfer mode with programmable buffer size up to 2 KB and optional double buffer • Pipes 6 to 9: Interrupt transfer with 64-byte single buffer.
Other features	• Force-end transfer function using transaction count • Function that changes the BRDY interrupt event notification timing • Automatic clearing of the FIFO buffer after data for the pipe specified in the DnFIFO port (n = 0, 1) is read • NAK setting function for response PID generated on transfer end • On-chip pull-up and pull-down resistors for D+ and D- • Support for Link Power Management (LPM) ECN, including a new Sleep state (the L1 state) • Compliance with Battery Charging Class Specification Revision 1.2 • For power reduction, selectable classic-only mode (CL-only mode) in which operation is only USB 1.1-compliant

33. USB2.0高速模块(USBHS)

33.1 Overview

MCU提供USB2.0高速模块(USBHS)，可作为主机或设备控制器运行，符合通用串行总线(USB)规范2.0版。主机控制器支持USB2.0高速、全速和低速传输，设备控制器支持USB2.0高速和全速传输。USBHS具有内部USB收发器，并支持USB2.0规范中定义的所有传输类型。

USBHS具有用于数据传输的FIFO缓冲区，最多提供10个管道。根据外围设备或系统的通信要求，可以将任何端点编号分配给管道1到9。

表33.1列出了USBHS规范，图33.1显示了框图，表33.2列出了IO引脚。

Writing to the SYSCFG register can proceed while the PHY clock is stopped. However, written values are only reflected in the SYSCFG register after the PHY clock is oscillating again.

USBE bit (USBHS Operation Enable)

The USBE bit enables or disables operation of USBHS.

Changing the USBE bit from 1 to 0 initializes the bits listed in Table 33.3. Only change this bit after specifying the input clock in the PHYSET.CLKSEL[1:0] bits and confirming that the PLLSTA.PLLLOCK flag is 1. In CL-only mode, change the USBE bit after setting the PHYSET.HSEB bit to 1. At that time, the UCLK must be set to 48 MHz and PCLKB must be set to 60 MHz. For the clock settings, see section 33.3.3, Supplying the Clock.

In host controller mode, always set this bit to 1 after setting the DRPD bit to 1, eliminating SYSSTS0.LNST[1:0] bit chattering, and confirming that the USB bus state is stable.

USBE位（USBHS操作使能）

USBE位启用或禁用USBHS的操作。

将USBE位从1更改为0会初始化表33.3中列出的位。仅在PHYSET.CLKSEL[1:0]位中指定输入时钟并确认PLLSTA.PLLLOCK标志为1后更改该位。在CL-only模式下，将PHYSET.HSEB位设置为1后更改USBE位.那时，UCLK必须设置为48MHz，PCLKB必须设置为60MHz。有关时钟设置，请参阅第33.3.3节，提供时钟。

在主机控制器模式下，在将DRPD位设置为1后始终将此位设置为1，消除SYSSTS0.LNST[1:0]位抖动，并确认USB总线状态稳定。

DPRPU bit (D+ Line Resistor Control)

The DPRPU bit enables or disables pulling up the D+ line in device controller mode.

When the DPRPU bit is set to 1 in device controller mode, the USBHS pulls up the D+ line to notify the USB host that it attached. Changing the DPRPU bit from 1 to 0 releases the pull-up, thereby notifying the USB host that it detached.

Set this bit to 1 in device controller mode and to 0 in host controller mode.

DRPD bit (D+/D- Line Resistor Control)

The DRPD bit enables or disables pulling down D+ and D- lines in host controller mode.

Set this bit to 1 in host controller mode. Set it to 0 when OTG is not used in device controller mode.

DCFM bit (Controller Operation Select)

The DCFM bit selects the host or device function of the USBHS.

Only change this bit when the DPRPU and DRPD bits are both 0.

HSE bit (High-Speed Operation Enable)

The HSE bit enables or disables high-speed operation.

When this bit is 1, the USBHS operates in high- or full-speed based on the results of the reset handshake.

In host controller mode, setting this bit to 0 allows the USBHS to operate in low- or full-speed. If the DVSTCTR0.RHST[2:0] flags indicate that a low-speed device has attached, set the HSE bit to 0.

In host controller mode, setting this bit to 1 allows the USBHS to operate in high- or full-speed based on the results of the reset handshake. Change the HSE bit after detection of an attach event (ATTCH interrupt) and before the USB bus reset (when DVSTCTR0.USBRST = 1), or after detection of a detach event.

In device controller mode, setting this bit to 0 allows the USBHS to operate in full-speed. Setting the bit to 1 allows the USBHS to perform the reset handshake and then operate in high-speed or full-speed, based on the results.

In device controller mode, only change this bit when the DPRPU bit is 0.

CNEN bit (Single-ended Receiver Enable)

Setting the CNEN bit to 1 enables single-ended receiver operation and selects monitoring of the D+ and D- line states in the SYSSTS0.LNST[1:0] flags. Use this bit to prevent through-current damage that might otherwise be caused during single-ended receiver operation, where the terminals are floating while the USBHS is detached.

In host controller mode, set this bit to 1 after confirming that the PHY clock is being supplied. In device controller mode, set this bit to 1 when the VBUS is detected because of a VBUS interrupt, and set it to 0 when the VBUS line is removed.

DPRPU位（D+线路电阻控制）

DPRPU位启用或禁用在设备控制器模式下上拉D+线。

当DPRPU位在设备控制器模式下设置为1时，USBHS拉高D+线以通知USB主机它已连接。将DPRPU位从1更改为0会释放上拉电阻，从而通知USB主机它已分离。

在设备控制器模式下将此位设置为1，在主机控制器模式下设置为0。

DRPD位（D+DLine电阻控制）

DRPD位在主机控制器模式下启用或禁用下拉D+和Dlines。

在主机控制器模式下将此位设置为1。在设备控制器模式下不使用OTG时将其设置为0。

DCFM位（控制器操作选择）

DCFM位选择USBHS的主机或设备功能。

仅当DPRPU和DRPD位都为0时更改该位。

HSE位（高速操作使能）

HSE位启用或禁用高速操作。

当该位为1时，USBHS根据复位握手的结果以高速或全速运行。

在主机控制器模式下，将该位设置为0允许USBHS以低速或全速运行。如果DVSTCTR0.RHST[2:0]标志表示已连接低速设备，将HSE位设置为0。

在主机控制器模式下，将此位设置为1允许USBHS根据复位握手的结果以高速或全速运行。在检测到附加事件（ATTCH中断）和USB总线复位之前（当DVSTCTR0.USBRST=1时）或检测到分离事件之后，更改HSE位。

在设备控制器模式下，将该位设置为0允许USBHS全速运行。将该位设置为1允许USBHS根据结果执行复位握手，然后以高速或全速运行。

在设备控制器模式下，仅当DPRPU位为0时更改该位。

CNEN位（单端接收器使能）

将CNEN位设置为1可启用单端接收器操作，并在SYSSTS0.LNST[1:0]标志中选择监视D+和Dline状态。使用该位可防止在单端接收器操作期间可能造成的直通电流损坏，其中在USBHS分离时端子处于浮动状态。

在主机控制器模式下，在确认提供PHY时钟后将该位设置为1。在设备控制器模式下，当由于VBUS中断而检测到VBUS时将该位设置为1，并在移除VBUS线时将其设置为0。

BWAIT[3:0] bits (CPU Bus Access Wait Specification)

The BWAIT[3:0] bits specify the wait time for access to the USBHS registers.

When accessing the registers at addresses in the range beginning at 4006 0004h, set the cycle time for consecutive access to at least 40.8 ns. The initial value is 1111b (17 cycles), but Renesas recommends that you satisfy this condition by setting the best wait time for the frequency of the CPU clock in your application.

This setting is the same as the wait time for accesses to the FIFO port register. The maximum speed of access to the FIFO port is as follows:

- MBW[1:0] = 10b (32-bit width): Maximum 60 MB/s
- MBW[1:0] = 01b (16-bit width): Maximum 30 MB/s
- MBW[1:0] = 00b (8-bit width): Maximum 15 MB/s

BWAIT[3:0]位（CPU总线访问等待规范）

BWAIT[3:0]位指定访问USBHS寄存器的等待时间。

当访问地址范围从40060004h开始的寄存器时，将连续访问的周期时间设置为至少40.8ns。初始值为1111b（17个周期），但瑞萨建议您通过在应用程序中为CPU时钟频率设置最佳等待时间来满足此条件。

该设置与访问FIFO端口寄存器的等待时间相同。访问FIFO端口的最大速度如下：

- MBW[1:0] = 10b (32-bit width): Maximum 60 MB/s
- MBW[1:0] = 01b (16-bit width): Maximum 30 MB/s
- MBW[1:0] = 00b (8-bit width): Maximum 15 MB/s

LNST[1:0] flags (USB Data Line Status Monitor Flag)

The LNST[1:0] flags indicate the state of the USB data lines, D+ and D-. For details, see Table 33.4.

In device controller mode, read the LNST[1:0] flags after setting the SYSCFG.CNEN and SYSCFG.USBE bits to 1. In host controller mode, read them after setting the SYSCFG.DRPD bit to 1.

When you are checking hardware contacts for the battery charging function in device controller mode, read the LNST[1:0] flags after setting the SYSCFG.DRPD, SYSCFG.CNEN, and BCCTRL.IDPSRCE bits to 1. For details, see section 33.3.15, Battery charging detection processing.

Chirp K: Chirp K-State

SOFEA flag (SOF Active Monitor Flag While Host Controller Operation Is Selected)

The SOFEA flag is used in host controller mode to check whether the output of the last SOF is complete when the USBHS is suspended because of a 0 setting to the DVSTCTR0.UACT bit.

In host controller mode, check that both the HTACT and SOFEA flags are 0 before setting the SYSCFG.USBE bit to 0 to stop the USBHS or setting the LPSTS.SUSPENDM bit to 0 to stop the clock signal supply during communication.

HTACT flag (Host Sequencer Status Monitor Flag)

The HTACT flag clears to 0 when the host sequencer of the USBHS is completely stopped.

In host controller mode, check that the HTACT flag is 0 before setting the DVSTCTR0.UACT bit to 0 to place the USBHS in the Suspend state or setting the LPSTS.SUSPENDM bit to 0 to stop the clock signal supply during communication.

OVCMON[1:0] flags (External USBHS_OVRCURA/USBHS_OVRCURB Input Pin Monitor Flag)

The OVCMON[1:0] flags indicate the status of the overcurrent signals from an external power supply IC.

LNST[1:0]标志（USB数据线状态监控标志）

LNST[1:0]标志指示USB数据线D+和D−的状态。详见表33.4。

在设备控制器模式下，将SYSCFG.CNEN和SYSCFG.USBE位设置为1后读取LNST[1:0]标志。在主机控制器模式下，将SYSCFG.DRPD位设置为1后读取它们。

在设备控制器模式下检查电池充电功能的硬件触点时，请阅读将SYSCFG.DRPD、SYSCFG.CNEN和BCCTRL.IDPSRCE位设置为1后的LNST[1:0]标志。有关详细信息，请参见第33.3.15节，电池充电检测处理。

SOFEA标志（选择主机控制器操作时的SOF活动监视器标志）

SOFEA标志用于主机控制器模式，用于检查最后一个SOF的输出是否完成。
由于DVSTCTR0.UACT位设置为0，USBHS被挂起。

在主机控制器模式下，在将SYSCFG.USBE位设置为0以停止USBHS或将LPSTS.SUSPENDM位设置为0以在通信期间停止时钟信号供应之前，请检查HTACT和SOFEA标志是否为0。

HTACT标志（主机定序器状态监视器标志）

当USBHS的主机定序器完全停止时，HTACT标志清零。

在主机控制器模式下，在将DVSTCTR0.UACT位设置为0之前检查HTACT标志是否为0以放置USBHS处于Suspend状态或将LPSTS.SUSPENDM位设置为0以在通信期间停止时钟信号供应。

OVCMON[1:0]标志（外部USBHS_OVRCURAUSBHS_OVRCURB输入引脚监控标志）

OVCMON[1:0]标志指示来自外部电源IC的过流信号的状态。

RHST[2:0] flags (USB Bus Reset Status Flag)

The RHST[2:0] flags indicate the USB bus reset status.

In host controller mode, writing 1 to the USBRST bit causes the RHST[2:0] flags to set to 100b. When 0 is written to the USBRST bit and the USBHS ends the SE0 state, the RHST[2:0] flags update to a new value.

In device controller mode, if the USBHS detects a USB bus reset, the RHST[2:0] flags set to 010b if an attach event occurs while the DPRPU bit is 1, and a DVST interrupt is generated.

UACT bit (USB Bus Operation Enable for the Host Controller Operation)

When set to 1 in host controller mode, the UACT bit enables USB bus operation by controlling SOF packet transmission to the USB bus in addition to data and reception. The USBHS starts SOF packet output within one frame period after the this bit is set to 1. If UACT is set to 0, the USBHS enters the idle state after the SOF packet output.

The USBHS sets the bit to 0 on any of the following conditions:

- A DTCH interrupt is detected during communication (while UACT = 1)
- An EOFERR interrupt is detected during communication (while UACT = 1).

Always write 1 to the UACT bit at the end of the USB bus reset processing (on a 0 write to the USBRST bit) or at the end of resume processing from the Suspend state (on a 0 write to the RESUME bit).

The USBHS clears the UACT bit to 0 if it receives an ACK response to an LPM token while the HL1CTRL1.L1REQ bit is set to 1. The USBHS sets the UACT bit to 1 when it finishes resume processing from the L1 state.

In device controller mode, always set this bit to 0.

RESUME bit (Resume Signal Output for the Host Controller Operation)

The RESUME bit controls the resume signal output in host controller mode.When this bit is set to 1, the USBHS drives the USB port to the K-state and outputs the resume signal. The USBHS sets the bit to 1 on detection of a remote wakeup signal while the RWUPE bit is 1 and in the USB suspend state. The USBHS continues outputting the K-state while the RESUME bit is 1, until the bit is cleared to 0 by software. The RESUME bit must be 1 (= resume period) for the time defined in the USB 2.0 specification. Only set this bit to 1 while the interface is in the Suspend state. Write 1 to the UACT bit simultaneously with the end of the resume processing (0 write to the RESUME bit).

Setting the RESUME bit to 1 during transition to the L1 state allows the USBHS to drive the USB port to the K-state and output the resume signal. The USBHS clears the RESUME bit to 0 at the end of the resume period, the value set in the HL1CTRL2.HIRD[3:0] bits.

Always set this bit to 0 in device controller mode.

USBRST bit (USB Bus Reset Output for the Host Controller Operation)

The USBRST bit controls the output of the USB bus signal in host controller mode. When this bit set to 1, the USBHS drives the USB port to the SE0 state to reset the USB bus. The USBHS continues outputting SE0 while the USBRST bit is 1, until the bit is cleared to 0 by software. The USBRST bit must be 1 (= USB bus reset period) for the time defined in

b15 to b12	—	Reserved	读取值未定义。写入值应为0。	R/W

RHST[2:0]标志（USB总线复位状态标志）

RHST[2:0]标志指示USB总线复位状态。

在主机控制器模式下，将1写入USBRST位会导致RHST[2:0]标志设置为100b。当0被写入USBRST位和USBHS结束SE0状态，RHST[2:0]标志更新为新值。

在设备控制器模式下，如果USBHS检测到USB总线复位，如果在DPRPU位为1时发生连接事件并产生DVST中断，则RHST[2:0]标志设置为010b。

UACT位（主机控制器操作的USB总线操作使能）

在主机控制器模式下设置为1时，UACT位通过控制向USB总线发送SOF数据包以及数据和接收来启用USB总线操作。USBHS在该位设置为1后的一帧周期内开始SOF数据包输出。如果UACT设置为0，则USBHS在SOF数据包输出后进入空闲状态。

USBHS在以下任何条件下将该位设置为0：

- 在通信期间检测到DTCH中断（当UACT=1时）
- 通信期间检测到EOFERR中断（当UACT=1时）。

在USB总线复位处理结束时（向USBRST位写入0）或从挂起状态恢复处理结束时（向RESUME位写入0），始终向UACT位写入1。

如果USBHS在HL1CTRL1.L1REQ位设置为1时接收到对LPM令牌的ACK响应，则将UACT位清除为0。USBHS在完成从L1状态恢复处理时将 UACT位设置为1。

在设备控制器模式下，始终将此位设置为0。

RESUME位（主机控制器操作的恢复信号输出）

RESUME位控制主机控制器模式下的恢复信号输出。当该位设置为1时，USBHS将USB端口驱动到K状态并输出恢复信号。当RUPE位为1且处于USB挂起状态时，USBHS在检测到远程唤醒信号时将该位设置为1。当RESUME位为1时，USBHS继续输出K状态，直到该位被软件清零。在USB2.0规范中定义的时间内，RESUME位必须为1（=恢复周期）。仅当接口处于挂起状态时将此位设置为1。在恢复处理结束的同时向UACT位写入1（向RESUME位写入0）。

在转换到L1状态期间将RESUME位设置为1允许USBHS将USB端口驱动到K状态并输出恢复信号。USBHS在恢复周期结束时将RE SUME位清除为0，该值在HL1CTRL2.HIRD[3:0]位中设置。

在设备控制器模式下始终将此位设置为0。

USBRST位（用于主机控制器操作的USB总线复位输出）

USBRST位控制主机控制器模式下USB总线信号的输出。当该位设置为1时，USBHS将USB端口驱动到SE0状态以复位USB总线。当USBRST位为1时，USBHS继续输出SE0，直到该位被软件清零。USBRST位在定义的时间内必须为1（=USB总线复位周期）

the USB 2.0 specification. Writing 1 to the USBRST bit during communication (UACT bit = 1) or during resume processing (RESUME bit = 1) prevents the USBHS from starting USB bus reset processing until both the UACT and RESUME bits clear to 0. Write 1 to the UACT bit simultaneously with the end of the USB bus reset processing (0 write to the USBRST bit).

Always set this bit to 0 in device controller mode.

RWUPE bit (Remote Wakeup Detection Enable for the Host Controller Operation)

The RWUPE bit enables or disables remote wakeup signals (resume signals) from downstream peripheral devices in host controller mode. When this bit is set to 1, the USBHS detects a remote wakeup signal (K-state for 2.5 µs) from a downstream peripheral device, and it performs resume processing, driving the K-state. When the RWUPE bit is set to 0, the USBHS ignores remote wakeup signals (K-states) from peripheral devices connected to the USB port.

Do not stop the PHY clock while the RWUPE bit is 1, even in the Suspend state (the LPSTS.SUSPENDM bit must be set to 1). Also, do not reset the USB bus (setting USBRST to 1) from the Suspend state. This is prohibited in the USB 2.0 specification.

The RWUPE bit is also used to enable or disable detection of a remote wakeup signal during transition to the L1 state.

Always set this bit to 0 in device controller mode.

WKUP bit (Remote Wakeup Output for the Device Controller Operation)

The WKUP bit enables or disables remote wakeup signals (resume signals) to the USB bus in device controller mode.

The USBHS controls the output timing of the remote wakeup signals. When this bit is set to 1, the USBHS clears it to 0 after outputting the K-state for 10 ms. The USB 2.0 specification dictates that the USB bus idle state must be maintained for 5 ms or longer before a remote wakeup signal is sent. If the USBHS writes 1 to the WKUP bit immediately after detecting the Suspend state, the K-state is output after 2 ms.

Only write 1 to the WKUP bit when the device is in the Suspend state (the PL1CTRL1.DVSQ[3:0] flags are 01xxb) and the USB host enables the remote wakeup signal (RWUPE = 1). Do not stop the PHY clock while this bit is 1, even in the Suspend state (the LPSTS.SUSPENDM bit must be set to 1).

If the WKUP bit is set to 1 during transition to the L1 state, the USBHS outputs the K-state for 50 µs and then clears the bit to 0. Before writing 1 to the bit during the L1 state, check that the PL1CTRL1.DVSQ[3:0] flags are 10xxb.

Always set this bit to 0 in host controller mode.

HNPBTOA bit (Host Negotiation Protocol (HNP) Control)

The HNPBTOA bit is used when switching from device B to device A while in OTG mode.

If the HNPBTOA bit is 1, the internal function control maintains the Suspend state until HNP processing ends, even if the SYSCFG.DPRPU bit is set to 0 or the SYSCFG.DCFM bit is set to 1. Resume interrupts (RESM) are not generated even if a falling edge of D+ is detected.

The HNP processing ends when a host attach event is detected, because of a pull-up by the initiating party, or the HNPBTOA bit is cleared to 0 by software because the HNP processing times out.

USB2.0规范。在通信期间（UACT位=1）或恢复处理期间（RESUME位=1）向USBRST位写入1可防止USBHS启动USB总线复位处理，直到UACT和RESUME位都清零。向UACT位写入1同时结束USB总线复位处理（0写入USB RST位）。

在设备控制器模式下始终将此位设置为0。

RHUPE位（主机控制器操作的远程唤醒检测使能）

在主机控制器模式下，RWUPE位启用或禁用来自下游外围设备的远程唤醒信号（恢复信号）。当该位设置为1时，USBHS检测到来自下游外围设备的远程唤醒信号（K状态持续2.5µs），并执行恢复处理，驱动K状态。当RWUPE位设置为0时，USBHS忽略来自连接到USB端口的外围设备的远程唤醒信号（K状态）。

当RHUPE位为1时不要停止PHY时钟，即使处于挂起状态（LPSTS.SUSPENDM位必须设置为1）。此外，不要将USB总线（将USBRST设置为1）从挂起状态复位。这在USB2.0规范中是禁止的。

RWUPE位还用于在转换到L1状态期间启用或禁用远程唤醒信号的检测。

在设备控制器模式下始终将此位设置为0。

WKUP位（设备控制器操作的远程唤醒输出）

WKUP位在设备控制器模式下启用或禁用到USB总线的远程唤醒信号（恢复信号）。

USBHS控制远程唤醒信号的输出时序。当该位设置为1时，USBHS在输出K状态10ms后将其清除为0。USB2.0规范规定，在发送远程唤醒信号之前，USB总线空闲状态必须保持5ms或更长时间。如果USBHS在检测到Suspend状态后立即向WKUP位写入1，则在2ms后输出K状态。

仅当器件处于挂起状态（PL1CTRL1.DVSQ[3:0]标志为01xxb）且USB主机使能远程唤醒信号（RWUPE=1）时向WKUP位写入1。当该位为1时不要停止PHY时钟，即使处于挂起状态（LPSTS.SUSPENDM位必须设置为1）。

如果在转换到L1状态期间WKUP位设置为1，则USBHS输出K状态50µs，然后将该位清除为0。在L1状态期间向该位写入1之前，请检查PL1CTRL1.DVSQ[3:0]标志为10xxb。

在主机控制器模式下始终将此位设置为0。

HNPBTOA位（主机协商协议(HNP)控制）

在OTG模式下从设备B切换到设备A时使用HNPBTOA位。

如果HNPBTOA位为1，内部功能控制保持暂停状态直到HNP处理结束，即使SYSCFG.DPRPU位设置为0或SYSCFG.DCFM位设置为1。不产生恢复中断(RESM)即使检测到D+的下降沿。

当检测到主机连接事件时，HNP处理结束，因为发起方的上拉，或者
由于HNP处理超时，HNPBTOA位由软件清零。

Host controller mode

In host controller mode, these bits can be set after setting the SYSCFG.DRPD bit to 1. After the UTST[3:0] bits are set, the USBHS outputs waveforms to the USB port by setting the DVSTCTR0.UACT bit to 1. The USBHS also performs high-speed termination for the USB port by setting these bits in host controller mode.

To set the UTST[3:0] bits in host controller mode:

1. Reset the hardware.
2. Start supplying the PHY clock, and then set the LPSTS.SUSPENDM bit to 1.
3. Set the SYSCFG.DCFM and SYSCFG.DRPD bits to 1. (Setting the SYSCFG.HSE bit to 1 is not required.)
4. Set the SYSCFG.USBE bit to 1.
5. Set the UTST[3:0] bits based on the test requirements.
6. Set the DVSTCTR0.UACT bit to 1.

Assuming the initial steps (1) to (6) are already complete, to change the UTST[3:0] bits in host controller mode:

1. Set the DVSTCTR0.UACT and SYSCFG.USBE bits to 0.
2. Set the SYSCFG.USBE bit to 1.
3. Set the UTST[3:0] bits based on the test requirements.
4. Set the DVSTCTR0.UACT bit to 1.

When the UTST[3:0] bits are set to 1011b (Test_SE0_NAK), the USBHS does not output SOF packets to ports for which the DVSTCTR0.UACT bit is set to 1.

When the UTST[3:0] bits are set to 1101b (Test_Force_Enable), the USBHS outputs SOF packets to ports for which the DVSTCTR0.UACT bit is set to 1. In this test mode, the USBHS does not control the hardware related to attach detection, even if it detects a high-speed detach event (DTCH interrupt).

Before setting the UTST[3:0] bits, set the PID[1:0] bits of all pipe control registers to 00b (NAK response). To return to normal USB communication after setting a test mode, issue a hardware reset.

Device controller mode

In device controller mode, set these bits using a SetFeature request from the USB host during high-speed communication. The USBHS does not enter the Suspend state while these bits are 0001b to 0100b. To return to normal USB communication after setting a test mode, issue a hardware reset.

Bit	Symbol	位名称	Description	R/W
b15 to b4	—	Reserved	读取值未定义。写入值应为0。	R/W

UTST[3:0]位（测试模式）

将值写入UTST[3:0]位允许USBHS在高速操作模式下输出USB测试信号。表33.5显示了测试模式操作设置。

Table 33.5 测试模式操作设置

测试模式	UTST[3:0]位设置	
	在设备控制器模式下	在主机控制器模式下
普通手术	0000b	0000b
Test_J	0001b	1001b
Test_K	0010b	1010b
Test_SE0_NAK	0011b	1011b
Test_Packet	0100b	1100b
Test_Force_Enable	—	1101b
Reserved	0101b to 0111b	1110b to 1111b

主机控制器模式

在主机控制器模式下，可在将SYSCFG.DRPD位设置为1后设置这些位。设置UTST[3:0]位后，通过将DVSTCTR0.UACT位设置为1，USBHS将波形输出到USB端口。USBHS还通过在主机控制器模式下设置这些位来为USB端口执行高速端接。

在主机控制器模式下设置UTST[3:0]位：

1. 重置硬件。
2. 开始提供PHY时钟，然后将LPSTS.SUSPENDM位设置为1。
3. 将SYSCFG.DCFM和SYSCFG.DRPD位设置为1。（不需要将SYSCFG.HSE位设置为1。）
4. 将SYSCFG.USBE位设置为1。
5. 根据测试要求设置UTST[3:0]位。
6. 将DVSTCTR0.UACT位设置为1。

假设初始步骤(1)到(6)已经完成，在主机控制器模式下更改UTST[3:0]位：

1. 将DVSTCTR0.UACT和SYSCFG.USBE位设置为0。
2. 将SYSCFG.USBE位设置为1。
3. 根据测试要求设置UTST[3:0]位。
4. 将DVSTCTR0.UACT位设置为1。

当UTST[3:0]位设置为1011b(Test_SE0_NAK)时，USBHS不会将SOF数据包输出到DVSTCTR0.UACT位设置为1的端口。

当UTST[3:0]位设置为1101b(Test_Force_Enable)时，USBHS将SOF数据包输出到DVSTCTR0.UACT位设置为1的端口。在此测试模式下，USBHS不控制与连接检测，即使它检测到高速分离事件（DTCH中断）。

在设置UTST[3:0]位之前，将所有管道控制寄存器的PID[1:0]位设置为00b（NAK响应）。要在设置测试模式后返回正常USB通信，请发出硬件复位。

设备控制器模式

在设备控制器模式下，在高速通信期间使用来自USB主机的SetFeature请求设置这些位。当这些位为0001b至0100b时，USBHS不会进入暂停状态。要在设置测试模式后返回正常USB通信，请发出硬件复位。

Note 1. The valid bits depend on the MBW[1:0] and BIGEND settings in the associated port selection register.

Three FIFO ports are provided:

- CFIFO
- D0FIFO
- D1FIFO.

Each FIFO port is configured with:

- A port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer and writing of data to the FIFO buffer
- A port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that selects the pipe assigned to the FIFO port
- A port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR).

Each FIFO port has the following constraints:

- Access to the FIFO buffer for DCP control transfers is through the CFIFO port
- Access to the FIFO buffer for DMA or DTC transfers is through the D0FIFO or D1FIFO port
- The D0FIFO and D1FIFO ports can also be accessed by the CPU
- When using functions specific to the FIFO port, such as the DMA or DTC transfer function, you cannot change the pipe number selected in the CURPIPE[3:0] bits of the Port Selection Register
- Registers configuring one FIFO port do not affect other FIFO ports
- The same pipe must not be assigned to two or more FIFO ports

Note 1. 有效位取决于相关端口选择寄存器中的MBW[1:0]和BIGEND设置。

提供了三个FIFO端口：

- CFIFO
- D0FIFO
- D1FIFO.

每个FIFO端口配置有：

- 处理从FIFO缓冲区读取数据和将数据写入FIFO缓冲区的端口寄存器（CFIFO、D0FIFO或D1FIFO）
- 端口选择寄存器（CFIFOSEL、D0FIFOSEL或D1FIFOSEL），用于选择分配给FIFO端口的管道
- 端口控制寄存器（CFIFOCTR、D0FIFOCTR或D1FIFOCTR）。

每个FIFO端口具有以下约束：

- 通过CFIFO端口访问DCP控制传输的FIFO缓冲区
- 通过D0FIFO或D1FIFO端口访问DMA或DTC传输的FIFO缓冲区
- CPU也可以访问D0FIFO和D1FIFO端口
- 当使用特定于FIFO端口的功能时，例如DMA或DTC传输功能，您无法更改在端口选择寄存器的CURPIPE[3:0]位中选择的管道编号
- 配置一个FIFO端口的寄存器不会影响其他FIFO端口
- 不得将同一管道分配给两个或多个FIFO端口

- There are two FIFO buffer states, one giving access rights to the CPU and the other to the serial interface engine (SIE). When the SIE has access rights, the FIFO buffer cannot be accessed by the CPU.

FIFOPORT bit (FIFO Port)

When the FIFOPORT bit is accessed, the USBHS reads the received data from the FIFO buffer or writes the transmission data to the FIFO buffer. The FIFO port register can be accessed only when the FRDY flag in the associated port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is 1.

The valid bits in the FIFO port register depend on the MBW[1:0] and BIGEND settings in the port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL). See Table 33.6 to Table 33.8.

- 有两种FIFO缓冲区状态，一种授予CPU访问权限，另一种授予串行接口引擎(SIE)。当SIE有访问权限时，CPU不能访问FIFO缓冲区。

FIFOPORT位（FIFO端口）

当访问FIFOPORT位时，USBHS从FIFO缓冲区读取接收数据或将发送数据写入FIFO缓冲区。只有当相关端口控制寄存器（CFIFOCTR、D0FIFOCTR或D1FIFOCTR）中的FRDY标志为1时，才能访问FIFO端口寄存器。

FIFO端口寄存器中的有效位取决于端口选择寄存器（CFIFOSEL、D0FIFOSEL或D1FIFOSEL）中的MBW[1:0]和BIGEND设置。见表33.6至表33.8。

Do not specify the same pipe number in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.

Do not change the pipe number while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number used to read or write data through the CFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, the pipe specification is maintained until the access is complete, even if the software attempts to change the CURPIPE[3:0] setting. Access continues after the current value is written back to the CURPIPE[3:0] bits.

ISEL bit (FIFO Port Access Direction when DCP Is Selected)

After writing a new value to the ISEL bit while the DCP is the selected pipe, read this bit to check that the written value agrees with the read value before proceeding to the next process. Set the ISEL and CURPIPE[3:0] bits simultaneously.

不要在CFIFOSEL、D0FIFOSEL和D1FIFOSEL寄存器的CURPIPE[3:0]位中指定相同的管道编号。

启用DMA或DTC传输时不要更改管道编号。

CURPIPE[3:0]位（FIFO端口访问管道规范）

CURPIPE[3:0]位指定用于通过CFIFO端口读取或写入数据的管道号。写入这些位后，读取它们以检查写入的值是否与读取的值一致，然后再进行下一个过程。不要为CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位设置相同的管道编号。

在FIFO缓冲区访问期间，管道规范一直保持到访问完成，即使软件尝试更改CURPIPE[3:0]设置。将当前值写回CURPIPE[3:0]位后继续访问。

ISEL位（选择DCP时的FIFO端口访问方向）

在DCP为选定管道时向ISEL位写入新值后，读取该位以检查写入的值是否与读取的值一致，然后再进行下一个过程。同时设置ISEL和CURPIPE[3:0]位。

BIGEND bit (FIFO Port Endian Control)

Use the BIGEND bit to set the byte endian order of the CFIFO port to be the same as that selected in the endian selection register (MDE).

MBW[1:0] bits (CFIFO Port Access Bit Width)

The MBW[1:0] bits specify the bit width for accessing the CFIFO port.

When the selected pipe is receiving, after a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read. When reading the FIFO buffer, read with the access size set in MBW.

When the selected pipe is transmitting, set the CURPIPE[3:0] and MBW[1:0] bits simultaneously. The bit width cannot be changed from 8-bit to 16- or 32-bit, or from 16-bit to 32-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16- or 32-bit width is selected.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether or not to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double-buffering when reading is already in progress, this setting enables reading either FIFO buffer from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the bit to 1, always check that the FRDY flag is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

RCNT bit (Read Count Mode)

When the RCNT bit set to 0, the USBHS clears the CFIFOCTR.DTLN[11:0] flags to 0 on finishing reading all of the received data in the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits, or after reading a single plane in double buffer mode.

With this bit set to 1, the USBHS decrements the value in the CFIFOCTR.DTLN[11:0] flags each time it reads data received from the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits.

BIGEND位（FIFO端口字节序控制）

使用BIGEND位将CFIFO端口的字节字节序设置为与在字节序选择寄存器(MDE)中选择的相同。

MBW[1:0]位（CFIFO端口访问位宽）

MBW[1:0]位指定访问CFIFO端口的位宽。

当所选管道正在接收时，在写入这些位后开始从FIFO缓冲区读取数据，在读取所有数据之前不要更改这些位。读取FIFO缓冲区时，读取以MBW为单位设置的访问大小。

当所选管道正在传输时，同时设置CURPIPE[3:0]和MBW[1:0]位。当数据写入FIFO缓冲区时，位宽不能从8位更改为16位或32位，或从16位更改为32位。

即使选择了16位或32位宽度，也可以通过字节访问控制写入奇数个字节。

REW位（缓冲区指针倒带）

REW位指定是否回绕缓冲区指针。

当所选管道正在接收时，在读取FIFO缓冲区时将此位设置为1允许从第一个数据重新读取FIFO缓冲区。在读取已经在进行时的双缓冲中，此设置允许从第一个条目读取任一FIFO缓冲区。

请勿在同时更改CURPIPE[3:0]位时将此位设置为1。在将该位设置为1之前，请始终检查FRDY标志是否为1。

要从传输管道的第一个数据重写FIFO缓冲区，请使用BCLR位。

RCNT位（读取计数模式）

当RCNT位设置为0时，USBHS在完成读取分配给CURPIPE[3:0]位指定的管道的FIFO缓冲区中的所有接收数据后，将CFIFOCTR.DTLN[11:0]标志清除为0，或在双缓冲模式下读取单个平面后。

该位设置为1时，USBHS每次读取从分配给CURPIPE[3:0]位指定的管道的FIFO缓冲区接收到的数据时都会递减CFIFOCTR.DTLN[11:0]标志中的值。

Do not specify the same pipe number in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

Do not change the pipe number while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number used to read or write data through the DnFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, the pipe specification is maintained until the access is complete, even if the software attempts to change the CURPIPE[3:0] setting. Access continues after the current value is written back to the CURPIPE[3:0] bits.

BIGEND bit (FIFO Port Endian Control)

Use the BIGEND bit to set the byte endian order of the D0FIFO or D1FIFO port to be the same as that selected in the endian selection register (MDE).

MBW[1:0] bits (FIFO Port Access Bit Width)

The MBW[1:0] bits specify the bit width for accessing the DnFIFO port.

When the selected pipe is receiving, after a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read. When reading the FIFO buffer, read with the access size set in MBW.

When the selected pipe is transmitting, set the CURPIPE[3:0] and MBW[1:0] bits simultaneously. The bit width cannot be changed from 8-bit to 16- or 32-bit, or from 16-bit to 32-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16- or 32-bit width is selected.

DREQE bit (DMA/DTC Transfer Request Enable)

The DREQE bit enables or disables issuing of DMA or DTC transfer requests. Only change the settings of DREQE bit when the CURPIPE[3:0] bits are 0000b.

To enable DMA or DTC transfer requests, set this bit to 1 after setting the CURPIPE[3:0] bits to 0000b, and then set the CURPIPE[3:0] bits to the PIPE number for the transfer.

DCLRM bit (Auto FIFO Buffer Clear Mode after Specified Pipe is Read)

The DCLRM bit enables or disables automatic FIFO buffer clearing after data in the selected pipe is read.

When this bit is set to 1, on receiving a zero-length packet while the FIFO buffer assigned to the selected pipe is empty,

不要在CFIFOSEL、D0FIFOSEL和D1FIFOSEL寄存器的CURPIPE[3:0]位中指定相同的管道编号。当D0FIFOSEL和D1FIFOSEL寄存器中的CURPIPE[3:0]位设置为0000b时，不选择管道。

启用DMA或DTC传输时不要更改管道编号。

CURPIPE[3:0]位（FIFO端口访问管道规范）

CURPIPE[3:0]位指定用于通过DnFIFO端口读取或写入数据的管道编号。写入这些位后，读取它们以检查写入的值是否与读取的值一致，然后再进行下一个过程。不要为CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位设置相同的管道编号。

在FIFO缓冲区访问期间，管道规范一直保持到访问完成，即使软件尝试更改CURPIPE[3:0]设置。将当前值写回CURPIPE[3:0]位后继续访问。

BIGEND位（FIFO端口字节序控制）

使用BIGEND位将D0FIFO或D1FIFO端口的字节字节序设置为与在字节序选择寄存器(MDE)中选择的相同。

MBW[1:0]位（FIFO端口访问位宽）

MBW[1:0]位指定访问DnFIFO端口的位宽。

当所选管道正在接收时，在写入这些位后开始从FIFO缓冲区读取数据，在读取所有数据之前不要更改这些位。读取FIFO缓冲区时，读取以MBW为单位设置的访问大小。

当所选管道正在传输时，同时设置CURPIPE[3:0]和MBW[1:0]位。当数据写入FIFO缓冲区时，位宽不能从8位更改为16位或32位，或从16位更改为32位。

即使选择了16位或32位宽度，也可以通过字节访问控制写入奇数个字节。

DREQE位（DMADTC传输请求使能）

DREQE位启用或禁用DMA或DTC传输请求的发出。仅当CURPIPE[3:0]位为0000b时更改DREQE位的设置。

要启用DMA或DTC传输请求，请在将CURPIPE[3:0]位设置为0000b后将此位设置为1，然后将CURPIPE[3:0]位到用于传输的PIPE编号。

DCLRM位（读取指定管道后自动FIFO缓冲区清除模式）

在读取所选管道中的数据后，DCLRM位启用或禁用自动FIFO缓冲区清除。

当该位设置为1时，在分配给所选管道的FIFO缓冲区为空时接收到长度为零的数据包时，

or when reading of a received short packet is complete while the PIPECFG.BFRE bit is 1, the USBHS sets the BCLR bit in the FIFO port control register to 1.

When using the USBHS with the SOFCFG.BRDYM bit set to 1, set this bit to 0.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether or not to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double-buffering when reading is already in progress, this setting enables reading either FIFO buffer from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the bit to 1, always check that the FRDY flag is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

RCNT bit (Read Count Mode)

When the RCNT bit set to 0, the USBHS clears the DnFIFOCTR.DTLN[11:0] flags (n = 0, 1) to 0 on finishing reading all of the received data in the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits, or after reading a single plane in double buffer mode.

With this bit set to 1, the USBHS decrements the value in the CFIFOCTR.DTLN[11:0] flags each time it reads data received from the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits. When accessing DnFIFO with the PIPECFG.BFRE bit set to 1, set the RCNT bit to 0.

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[11:0] flags (Receive Data Length Flag)

The DTLN[11:0] flags indicate the length of the receive data.

或者当PIPECFG.BFRE位为1时完成读取接收到的短数据包时，USBHS将FIFO端口控制寄存器中的BCLR位设置为1。

当使用SOFCFG.BRDYM位设置为1的USBHS时，将此位设置为0。

REW位（缓冲区指针倒带）

REW位指定是否回绕缓冲区指针。

当所选管道正在接收时，在读取FIFO缓冲区时将此位设置为1允许从第一个数据重新读取FIFO缓冲区。在读取已经在进行时的双缓冲中，此设置允许从第一个条目读取任一FIFO缓冲区。

请勿在同时更改CURPIPE[3:0]位时将此位设置为1。在将该位设置为1之前，请始终检查FRDY标志是否为1。

要从传输管道的第一个数据重写FIFO缓冲区，请使用BCLR位。

RCNT位（读取计数模式）

当RCNT位设置为0时，USBHS清除DnFIFOCTR.DTLN[11:0]标志(n=0 1)为0完成读取分配给CURPIPE中指定管道的FIFO缓冲区中的所有接收数据[3:0]位，或在双缓冲模式下读取单个平面后。

该位设置为1时，USBHS每次读取从分配给CURPIPE[3:0]位指定的管道的FIFO缓冲区接收到的数据时都会递减CFIFOCTR.DTLN[11:0]标志中的值。当PIPECFG.BFRE位设置为1访问DnFIFO时，将RCNT位设置为0。

DTLN[11:0]标志（接收数据长度标志）

DTLN[11:0]标志指示接收数据的长度。

While the FIFO buffer is being read, the DTLN[11:0] bits indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1), as follows:

- RCNT = 0:
  The USBHS sets the DTLN[11:0] flags to indicate the length of the receive data until the CPU or DMA/DTC has read all of the received data in the FIFO buffer (or until it has read a single plane in double buffer mode).
  While the PIPECFG.BFRE bit is 1, the USBHS retains the length of the receive data until the BCLR bit is set to 1, even after all the data is read.
- RCNT = 1:
  The USBHS decrements the value indicated in the DTLN[11:0] flags each time the CPU or DMA/DTC reads the receive data from the FIFO buffer. (The value is decremented by 1 when MBW[1:0] = 00b, by 2 when MBW[1:0] = 01b, and by 4 when MBW[1:0] = 10b.)
  The USBHS sets these flags to 0 when all the data is read from the FIFO buffer. In double buffer mode, if data is received in one FIFO buffer plane before all of the data is read from the other plane, the USBHS sets these bits to indicate the length of the receive data in the latter plane when all of the data is read from the former plane.
  When the RCNT bit is 1, reading the DTLN[11:0] flags while the FIFO buffer is being read returns the latest value within 150 ns after the FIFO port read cycle.

FRDY flag (FIFO Port Ready Flag)

The FRDY flag indicates whether the FIFO port can be accessed by the CPU or DMA/DTC.

In the following cases, the USBHS sets the FRDY flag to 1 but data cannot be read through the FIFO port because there is no data to be read:

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit is 1.

In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

BCLR bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU for the selected pipe.

When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USBHS clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the DCP is the selected pipe, setting the BCLR bit to 1 allows the USBHS to clear both sets of FIFO buffers regardless of whether the CPU or SIE has access rights. To clear the buffer when the SIE has access rights, set the DCPCTR.PID[1:0] bits to 00b (NAK response) before setting the BCLR bit to 1.

When the selected pipe is not the DCP, only write 1 to the BCLR bit while the FRDY flag in the FIFO port control register is 1 (set by the USBHS).

BVAL bit (FIFO Buffer Valid Flag)

Set the BVAL bit to 1 when data is completely written to the FIFO buffer on the CPU for the pipe selected in CURPIPE[3:0].

When the selected pipe is transmitting, set this bit to 1 in the following cases:

- To transmit a short packet, set this bit to 1 after data is written
- To transmit a zero-length packet, set this bit to 1 before data is written to the FIFO buffer
- Set this bit to 1 after the specified number of data bytes is written for the pipe in continuous transfer mode, where the number is a natural integer multiple of the maximum packet size and less than the buffer size.

The USBHS then switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When the selected pipe is in use for transmission, simultaneously setting the BVAL flag and the BCLR bit to 1 causes the USBHS to clear the data that is already written and enables transmission of a zero-length packet. When data of the maximum packet size is written for the pipe in non-continuous transfer mode, the USBHS sets this bit to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

Only write 1 to the BVAL flag while the FRDY bit is 1 (set by the USBHS). When the selected pipe is receiving, do not

在读取FIFO缓冲区时，DTLN[11:0]位指示不同的值，具体取决于DnFIFOSEL.RCNT位(n=0 1)，如下所示：

- RCNT = 0:
  USBHS设置DTLN[11:0]标志以指示接收数据的长度，直到CPU或DMADTC已读取FIFO缓冲区中的所有接收数据（或直到它在双缓冲区模式下读取单个平面）.当PIPECFG.BFRE位为1时，USBHS将保留接收数据的长度，直到BCLR位设置为1，即使在读取所有数据之后也是如此。
- RCNT = 1:
  每次CPU或DMADTC从FIFO缓冲区读取接收数据时，USBHS都会递减DTLN[11:0]标志中指示的值。（当MBW[1:0]=00b时该值减1，当MBW[1:0]=01b时减2，当MBW[1:0]=10b时减4。）USBHS将这些标志设置为0当从FIFO缓冲区中读取所有数据时。在双缓冲模式下，如果在一个FIFO缓冲平面中的所有数据从另一个平面读取之前接收到数据，则USBHS设置这些位以指示在读取所有数据时后一个平面中接收数据的长度从前飞机。当RCNT位为1时，在读取FIFO缓冲区时读取DTLN[11:0]标志会在FIFO端口读取周期后150ns内返回最新值。

FRDY标志（FIFO端口就绪标志）

FRDY标志指示CPU或DMADTC是否可以访问FIFO端口。

在以下情况下，USBHS将FRDY标志设置为1，但由于没有数据可读取，因此无法通过FIFO端口读取数据：

- 当分配给所选管道的FIFO缓冲区为空时，接收到零长度数据包
- 当PIPECFG.BFRE位为1时，接收到一个短数据包并完全读取数据。

在这些情况下，将BCLR位设置为1以清除FIFO缓冲区，并启用下一个数据的发送和接收。

BCLR位（CPU缓冲区清除）

将BCLR位设置为1以清除CPU上所选管道的FIFO缓冲区。

当为分配给所选管道的FIFO缓冲区设置双缓冲区模式时，USBHS仅清除FIFO缓冲区的一个平面，即使两个平面都已启用读取。

当DCP为选定管道时，将BCLR位设置为1允许USBHS清除两组FIFO缓冲区，而不管CPU或SIE是否具有访问权限。要在SIE具有访问权限时清除缓冲区，请将DCPCTR.PID[1:0]位设置为00b（NAK响应），然后再将BCLR位设置为1。

当所选管道不是DCP时，仅在FIFO端口控制寄存器中的Frdy标志为1（由USBH设置）时，仅将1个写入BCLR位。

BVAL位（FIFO缓冲区有效标志）

当数据完全写入CPU上的FIFO缓冲区时，将BVAL位设置为1，用于
CURPIPE[3:0].

当所选管道正在传输时，在以下情况下将此位设置为1：

- 要发送短数据包，请在写入数据后将此位设置为1
- 要发送长度为零的数据包，请在将数据写入FIFO缓冲区之前将此位设置为1
- 在连续传输模式下为管道写入指定数量的数据字节后，将此位设置为1，其中该数字是最大数据包大小的自然整数倍，并且小于缓冲区大小。

然后USBHS将FIFO缓冲区从CPU侧切换到SIE侧，从而启用传输。

当所选管道用于传输时，同时将BVAL标志和BCLR位设置为1会导致USBHS清除已写入的数据并启用零长度数据包的传输。当在非连续传输模式下为管道写入最大数据包大小的数据时，USBHS将该位设置为1，并将FIFO缓冲区从CPU侧切换到SIE侧，从而启用传输。

仅在FRDY位为1（由USBHS设置）时将1写入BVAL标志。Whentheselectedpipeisreceiving donot

set the BVAL flag to 1.

当INTSTS1寄存器中的状态标志设置为1并且相关的中断请求使能位设置在INTENB1寄存器为1，USBHS发出USBHS中断请求。

无论INTENB1寄存器设置如何，INTSTS1寄存器中的状态标志都会设置为1，以响应满足相关条件的状态更改。

当INTENB1寄存器中的中断请求使能位从0切换到1且INTSTS1寄存器中的相关状态标志设置为1时，请求USBHS中断。

Note 1. Each bit number corresponds to the same pipe number.

The BRDYENB register enables or disables the INTSTS0.BRDY bit to be set to 1 when a BRDY interrupt is detected for each pipe.

When a status flag in the BRDYSTS register sets to 1 and the associated PIPEBRDYEn (n = 9 to 0) bit setting in the BRDYENB register is 1, the INTSTS0.BRDY flag sets to 1. In this case, if the BRDYE bit in INTENB0 is 1, the USBHS generates a BRDY interrupt request. While at least one PIPEBRDYEn flag indicates 1, the INTSTS0.BRDY flag sets to 1 when the associated interrupt request enable bit in the BRDYENB register is changed from 0 to 1 by software.

EDGESTS flag (Interrupt Edge Processing Status Flag)

The EDGESTS flag indicates 1 during the edge processing of an edge interrupt output signal. Confirm that this flag is 0 before stopping the PHY clock.

BRDYM bit (PIPEBRDY Interrupt Status Clear Timing)

The BRDYM bit specifies how the BRDY interrupt status flags for the pipes are cleared.

TRNENSEL bit (Transaction-Enabled Time Select)

When the USB port is in use for full- or low-speed communications, the TRNENSEL bit specifies the timing with which the USBHS issues tokens in a frame (transaction-enabled time).

Set this bit to 1 when a low-speed device is connected directly or through a full-speed hub. The bit is only valid in host controller mode. Set this bit to 0 when the interface is in use as a device controller.

CLKSEL[1:0] bits (Input System Clock Frequency)

The CLKSEL[1:0] bits select the transfer clock source for the USBHS.

For the transfer clock generated in the USB-PHY internal PLL, these bits set the input clock frequency. To input the

EDGESTS标志（中断边缘处理状态标志）

EDGESTS标志在边沿中断输出信号的边沿处理期间指示为1。在停止PHY时钟之前确认该标志为0。

BRDYM位（PIPEBRDY中断状态清除时序）

BRDYM位指定如何清除管道的BRDY中断状态标志。

TRNENSEL位（事务使能时间选择）

当USB端口用于全速或低速通信时，TRNENSEL位指定USBHS在帧中发出令牌的时间（事务启用时间）。

当低速设备直接连接或通过全速集线器连接时，将此位设置为1。该位仅在主机控制器模式下有效。当接口用作设备控制器时，将此位设置为0。

CLKSEL[1:0]位（输入系统时钟频率）

CLKSEL[1:0]位选择USBHS的传输时钟源。

对于USB-PHY内部PLL中生成的传输时钟，这些位设置输入时钟频率。要输入

clock source from the EXTAL pin, the USB 2.0 clock specification must be strictly followed.

Writing to the CKSEL[1:0] bits is invalid in CL-only mode because the internal PLL is stopped (see the description for HSEB bit (CL-only mode)). For the clock settings, see section 33.3.3, Supplying the Clock.

HSEB bit (CL-only mode)

The HSEB bit selects whether the USBHS operates in CL-only mode. High-speed transfer by the USBHS requires the use of internal high-speed analog circuits including the PLL, clock, and data recovery (CDR) circuit in the USB-PHY block.

CL-only mode limits the transfer to the USB 1.1 specification (full- and low-speed transfer only). Power consumption can be reduced by stopping the internal PLL of the PHY module and other high-speed analog circuits.

In CL-only mode, the USBHS requires supply clocks of 48 MHz and 60 MHz, generated in the Clock Generation Circuit. For the clock supply method, see section 9, Clock Generation Circuit.

来自EXTAL引脚的时钟源，必须严格遵循USB2.0时钟规范。

在CL-only模式下写入CKSEL[1:0]位无效，因为内部PLL已停止（请参见HSEB位（仅限CL模式））。有关时钟设置，请参阅第33.3.3节，提供时钟。

HSEB位（仅CL模式）

HSEB位选择USBHS是否工作在CL-only模式。USBHS的高速传输需要使用内部高速模拟电路，包括USB-PHY模块中的PLL、时钟和数据恢复(CDR)电路。

仅CL模式将传输限制为USB1.1规范（仅限全低速传输）。通过停止PHY模块的内部PLL和其他高速模拟电路可以降低功耗。

在CL-only模式下，USBHS需要48MHz和60MHz的电源时钟，在时钟生成中生成电路。关于时钟提供方法，请参见第9节"时钟生成电路"。

x: Don't care

Note 1. The CTSQ[2:0], VALID, and DVSQ[2:0] flags are only valid in device controller mode.
Note 2. The status of the CTRT, DVST, and RESM flags are changed only in device controller mode. Set the associated interrupt enable bits to 0 (disabled) in host controller mode.
Note 3. To clear the CTRT, DVST, SOFR, RESM, or VBINT flags, write 0 only to the flags to be cleared. Write 1 to the other flags. Do not write 0 to the status flags indicating 0.
Note 4. The USBHS detects a change in the status in the RESM or VBINT flag even while the clock supply is stopped (LPSTS.SUSPENDM = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply before clearing the status by software.

BRDY flag (BRDY Interrupt Status Flag)

The BRDY flag indicates the BRDY interrupt state. For the conditions that cause the flag to be set, see section 33.2.13, BRDY Interrupt Enable Register (BRDYENB).

The USBHS clears the BRDY flag to 0 when 0 is written to the BRDYSTS.PIPEBRDYn (n = 0 to 9) flags for all pipes for which the BRDY interrupt is enabled (BRDYENB.PIPEBRDYEn bits). Writing 0 to the BRDY flag in the software does not clear the flag.

NRDY flag (NRDY Interrupt Status Flag)

The NRDY flag indicates the NRDY interrupt state. For the conditions that cause the flag to be set, see section 33.2.14, NRDY Interrupt Enable Register (NRDYENB).

The USBHS clears the NRDY flag to 0 when 0 is written to the NRDYSTS.PIPENRDYn (n = 0 to 9) flags for all pipes for which the NRDY interrupt is enabled (NRDYENB.PIPENRDYEn bits). Writing 0 to the NRDY flag in the software does not clear the flag.

BEMP flag (BEMP Interrupt Status Flag)

The BEMP indicates the BEMP interrupt state. For the conditions that cause the flag to be set, see section 33.2.15, BEMP Interrupt Enable Register (BEMPENB).

The USBHS clears the BEMP flag to 0 when 0 is written to the BEMPSTS.PIPEBEMPn (n = 0 to 9) flags for all pipes for which the BEMP interrupt is enabled (BEMPENB.PIPEBEMPEn bits). Writing 0 to the BEMP flag in the software does not clear the flag.

CTRT flag (Control Transfer Stage Transition Interrupt Status Flag)

In device controller mode, the USBHS updates the value of the CTSQ[2:0] bits and sets the CTRT flag to 1 on detecting a transition in the control transfer stage. When a control transfer stage transition interrupt occurs, clear the CTRT flag before the USBHS detects the next control transfer stage transition.

Values read from the CTRT flag in host controller mode are invalid.

DVST flag (Device State Transition Interrupt Status Flag)

In device controller mode, the USBHS updates the value of the PL1CTRL1.DVSQ[3:0] bits and sets the DVST flag to 1 on detecting a change in the device state. When a device state transition interrupt occurs, clear the DVST flag before the USBHS detects the next device state transition.

Values read from the DVST flag in host controller mode are invalid.

SOFR flag (Frame Number Refresh Interrupt Status Flag)

In host controller mode, the USBHS sets the SOFR flag to 1 on updating the frame number when the DVSTCTR0.UACT bit is set to 1 by software. An SOFR interrupt is detected every 1 ms.

In device controller mode, the USBHS sets the SOFR flag to 1 on updating the frame number. An SOFR interrupt is

x: Don't care

Note 1. CTSQ[2:0]、VALID和DVSQ[2:0]标志仅在设备控制器模式下有效。
Note 2. CTRT、DVST和RESM标志的状态仅在设备控制器模式下更改。在主机控制器模式下，将相关的中断使能位设置为0（禁用）。
Note 3. 要清除CTRT、DVST、SOFR、RESM或VBINT标志，只需将0写入要清除的标志。将1写入其他标志。不要将0写入指示0的状态标志。
Note 4. 即使在时钟供应停止时（LPSTS.SUSPENDM=0），USBHS也会检测到RESM或VBINT标志的状态变化，并在相关的中断请求位为1时请求中断。在清除软件状态。

BRDY标志（BRDY中断状态标志）

BRDY标志指示BRDY中断状态。有关导致设置标志的条件，请参阅第33.2.13节，BRDY中断使能寄存器(BRDYENB)。

当0写入BRDYSTS.PIPEBRDYn（n=0到9）标志时，USBHS将BRDY标志清除为0，用于所有启用了BRDY中断的管道（BRDYENB.PIPEBRDYEn位）。在软件中将0写入BRDY标志不会清除该标志。

NRDY标志（NRDY中断状态标志）

NRDY标志指示NRDY中断状态。有关导致设置标志的条件，请参阅第33.2.14节，NRDY中断使能寄存器(NRDYENB)。

当0写入所有启用了NRDY中断的管道（NRDYENB.PIPENRDYEn位）的NRDYSTS.PIPENRDYn（n=0到9）标志时，USBHS将NRDY标志清除为0。在软件中将0写入NRDY标志不会清除该标志。

BEMP标志（BEMP中断状态标志）

BEMP指示BEMP中断状态。有关导致设置标志的条件，请参阅第33.2.15节，BEMP中断使能寄存器(BEMPENB)。

当0写入所有启用了BEMP中断的管道（BEMPENB.PIPEBEMPEn位）的BEMPSTS.PIPEBEMPn（n=0到9）标志时，USBHS将BEMP标志清除为0。在软件中将0写入BEMP标志不会清除该标志。

CTRT标志（控制传输阶段转换中断状态标志）

在设备控制器模式下，USBHS更新CTSQ[2:0]位的值并将CTRT标志设置为1检测到控制传输阶段的转换。当控制传输阶段转换中断发生时，在USBHS检测到下一个控制传输阶段转换之前清除CTRT标志。

在主机控制器模式下从CTRT标志读取的值无效。

DVST标志（设备状态转换中断状态标志）

在设备控制器模式下，USBHS更新PL1CTRL1.DVSQ[3:0]位的值并将DVST标志设置为1，以检测设备状态的变化。当设备状态转换中断发生时，在USBHS检测到下一个设备状态转换之前清除DVST标志。

在主机控制器模式下从DVST标志读取的值无效。

SOFR标志（帧号刷新中断状态标志）

在主机控制器模式下，当DVSTCTR0.UACT位被软件设置为1时，USBHS在更新帧号时将SOFR标志设置为1。每1 ms检测一次SOFR中断。

在设备控制器模式下，USBHS在更新帧号时将SOFR标志设置为1。SOFR中断是

detected every 1 ms. The USBHS can detect an SOFR interrupt through the SOF complementation function even when a corrupted SOF packet is received from the USB host. See section 33.3.13, SOF Complementation Function.

RESM flag (Resume Interrupt Status Flag)

In device controller mode, the USBHS sets the RESM flag to 1 on detecting the falling edge of the signal on the USBHS_DP pin in the Suspend state (PL1CTRL1.DVSQ[3:0] = 01xxb).

Values read from the RESM flag in host controller mode are invalid.

VBINT flag (VBUS Interrupt Status Flag)

The USBHS sets the VBINT flag to 1 on detecting a level change (high to low or low to high) in the USBHS_VBUS pin input value. The USBHS sets the VBSTS flag to indicate the USBHS_VBUS pin input value. When a VBINT interrupt occurs, eliminate transient elements by reading the VBSTS flag at least three times through software processing and check that the values read are the same.

Note: Only enable the status change interrupts indicated in the flags in INTSTS1 in host controller mode, except for the PDDET detection interrupt.

Note 1. The USBHS detects a change in the status in the PDDETINT, BCHG, or OVRCR flag even while the clock supply is stopped (LPSTS.SUSPENDM = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply before clearing the status by software. No other interrupts can be detected while the clock supply is stopped (LPSTS.SUSPENDM = 0).

每1ms检测一次。即使从USB主机接收到损坏的SOF数据包，USBHS也可以通过SOF补充功能检测SOFR中断。请参阅第33.3.13节，SOF互补功能。

RESM标志（恢复中断状态标志）

在设备控制器模式下，USBHS在检测到信号的下降沿时将RE SM标志设置为1
USBHS_DP引脚处于挂起状态(PL1CTRL1.DVSQ[3:0]=01xxb)。

在主机控制器模式下从RESM标志读取的值无效。

VBINT标志（VBUS中断状态标志）

USBHS在检测到USBHS_VBUS引脚输入值的电平变化（从高到低或从低到高）时将VBINT标志设置为1。USBHS设置VBSTS标志以指示USBHS_VBUS引脚输入值。当发生VBINT中断时，通过软件处理至少3次读取VBSTS标志来消除瞬态元素，并检查读取的值是否相同。

Note: 仅在主机控制器模式下启用INTSTS1中标志指示的状态更改中断，PDDET检测中断除外。

Note 1. USBHS检测到PDDETINT、BCHG或OVRCR标志中的状态变化，即使在时钟供应停止(LPSTS.SUSPENDM=0)时，它也会在相关的中断请求位为1时请求中断。启用时钟供应在通过软件清除状态之前。停止提供时钟(LPSTS.SUSPENDM=0)时无法检测到其他中断。

Note 2. To clear the flags in INTSTS1, write 0 only to the flags to be cleared. Write 1 to the other bits.

PDDETINT flag (PDDET Detection Interrupt Status Flag*1)

The USBHS sets the PDDETINT flag to 1 on detecting a level change (high to low or low to high) in the PDDET pin input value. When the PDDETINT interrupt is generated, perform debouncing by reading the PDDETSTS flag at least three times through software processing and checking that the values read are the same.

SACK flag (Setup Transaction Normal Response Interrupt Status Flag)

The SACK flag indicates the status of the setup transaction normal response interrupt in host controller mode.

The USBHS detects the SACK interrupt and sets this bit to 1 when an ACK response is returned from a peripheral device during the setup transactions issued by the USBHS. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

Values read from the SACK flag in device controller mode are invalid.

SIGN flag (Setup Transaction Error Interrupt Status Flag)

The SIGN flag indicates the status of setup transaction error interrupts in host controller mode.

The USBHS detects the SIGN interrupt and sets this bit to 1 when an ACK response is not returned from a peripheral device three consecutive times during the setup transactions issued by the USBHS. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS detects the SIGN interrupt when any of the following response conditions occur for three consecutive setup transactions:

- Timeout is detected by the USBHS when the peripheral device has returned no response
- A corrupted ACK packet is received
- A handshake other than ACK (NAK, NYET, or STALL) is received.

Values read from the SIGN flag in device controller mode are invalid.

EOFERR flag (EOF Error Detection Interrupt Status Flag)

The EOFERR flag indicates the status of EOF error detection interrupts in host controller mode.

The USBHS detects the EOFERR interrupt and sets this bit to 1 on detecting that communication did not complete at the EOF2 timing defined in the USB 2.0 specification. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

After detecting the EOFERR interrupt, the USBHS controls the hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt was detected to 0
- Puts the port in which the EOFERR interrupt occurred into the idle state.

The software must terminate all pipes in which communications are being carried out and re-enumerate the USB port.

Values read from the EOFERR flag in device controller mode are invalid.

LPMEND flag (LPM Transaction End Interrupt Status Flag)

The PLPMEND flag indicates the status of LPM transaction end interrupts in host controller mode.

When the HL1CTRL1.L1REQ bit sets to 1, the USBHS sends an LPM token. When the LPM transaction is ended because a response from the function device or a timeout is detected, the USBHS sets this flag to 1.

Values read from the LPMEND flag in device controller mode are invalid.

L1RSMEND flag (L1 Resume End Interrupt Status Flag)

The L1RSMEND flag indicates the status of L1 resume end interrupts in host controller mode.

When performing resume processing after transitioning to the L1 state because an ACK was received in response to an LPM token, the USBHS sets this flag to 1.

Note 2. 要清除INTSTS1中的标志，只需将0写入要清除的标志。将1写入其他位。

PDDETINT标志（PDDET检测中断状态标志*1）

USBHS在检测到PDDET引脚输入值的电平变化（从高到低或从低到高）时将PDDETINT标志设置为1。当产生PDDETINT中断时，通过软件处理至少3次读取PDDETSTS标志并检查读取的值是否相同来执行去抖动。

SACK标志（设置事务正常响应中断状态标志）

SACK标志指示主机控制器模式下设置事务正常响应中断的状态。

在USBHS发出的设置事务期间，当外围设备返回ACK响应时，USBHS检测到SACK中断并将该位设置为1。如果相关的中断使能位由软件设置为1，则USBHS产生中断。

在设备控制器模式下从SACK标志读取的值无效。

SIGN标志（设置事务错误中断状态标志）

SIGN标志指示主机控制器模式下设置事务错误中断的状态。

在USBHS发出的设置事务期间，如果外围设备连续3次没有返回ACK响应，则USBHS检测到SIGN中断并将该位设置为1。如果相关的中断使能位由软件设置为1，则USBHS产生中断。

当三个连续的设置事务发生以下任何响应条件时，USBHS检测到SIGN中断：

- 当外围设备没有返回响应时，USBHS检测到超时
- 收到损坏的ACK数据包
- 收到除ACK（NAK、NYET或STALL）以外的握手。

在设备控制器模式下从SIGN标志读取的值无效。

EOFERR标志（EOF错误检测中断状态标志）

EOFERR标志指示主机控制器模式下EOF错误检测中断的状态。

USBHS检测到EOFERR中断并在检测到通信未完成时将该位设置为1
USB2.0规范中定义的EOF2时序。如果相关的中断使能位由软件设置为1，则
USBHS产生中断。

检测到EOFERR中断后，USBHS对硬件进行如下控制，而不考虑相关的中断使能位设置：

- 将检测到EOFERR中断的端口的DVSTCTR0.UACT位设置为0
- 将发生EOFERR中断的端口置于空闲状态。

软件必须终止正在执行通信的所有管道并重新枚举USB端口。

在设备控制器模式下从EOFERR标志读取的值无效。

LPMEND标志（LPM事务结束中断状态标志）

PLPMEND标志指示主机控制器模式下LPM事务结束中断的状态。

当HL1CTRL1.L1REQ位设置为1时，USBHS发送一个LPM令牌。当LPM事务因检测到来自功能设备的响应或超时而结束时，USBHS将此标志设置为1。

在设备控制器模式下从LPMEND标志读取的值无效。

L1RSMEND标志（L1恢复结束中断状态标志）

L1RSMEND标志指示主机控制器模式下L1恢复结束中断的状态。

在转换到L1状态后执行恢复处理时，因为接收到ACK以响应
LPM令牌，USBHS将此标志设置为1。

Values read from the L1RSMEND flag in device controller mode are invalid.

ATTCH flag (USB Connection Detection Interrupt Status Flag)

The ATTCH flag indicates the status of USB attach detection interrupts in host controller mode.

The USBHS detects the ATTCH interrupt and sets this bit to 1 on detecting a J- or K-state on the full- or low-speed signal level for 2.5 µs. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS detects the ATTCH interrupt on any of the following conditions:

- K-state, SE0, or SE1 changes to J-state, and J-state continues for 2.5 µs
- J-state, SE0, or SE1 changes to K-state, and K-state continues for 2.5 µs.

Values read from the ATTCH flag in device controller mode are invalid.

DTCH flag (USB Disconnection Detection Interrupt Status Flag)

The DTCH flag indicates the status of USB detach detection interrupts in host controller mode.

The USBHS detects the DTCH interrupt and sets this bit to 1 on detecting a USB bus detach event. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS detects bus detach events based on the USB 2.0 specification.

After detecting the DTCH interrupt, the USBHS controls hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt was detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state.

The software must terminate all pipes in which communications are being carried out and invoke the wait state for attaching to the USB port (waiting for ATTCH interrupt generation).

Values read from the DTCH flag in device controller mode are invalid.

BCHG flag (USB Bus Change Interrupt Status Flag*1)

The BCHG flag indicates the status of USB bus change interrupts in host controller mode.

The USBHS detects the BCHG interrupt and sets this bit to 1 when a change in the full-speed signal level occurs on the USB port. This includes any change from J-state, K-state, or SE0 to J-state, K-state, or SE0. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS sets the SYSSTS0.LNST[1:0] flags to indicate the input state of the USB port. When a BCHG interrupt occurs, eliminate transient elements by repeat reading the LNST[1:0] bits by software until the same value is read at least three times.

Changes in the USB bus state can be detected while the PHY clock is stopped.

Values read from the BCHG flag in device controller mode are invalid.

OVRCR flag (OVRCR Interrupt Status Flag*1)

The OVRCR flag indicates the input status on the USBHS_OVCUR0A pin or changes on the USBHS_OVCUR0B pin. If the INTENB1.OVRCRE bit sets to 1, the USBHS requests the interrupt.

The USBHS sets the SYSSTS0.OVCMON[1:0] flags to indicate the input state of the USBHS_OVCUR0A and USBHS_OVCUR0B pins.

These pins allow overcurrent detection by software in host controller mode. To implement this function, connect the overcurrent signal from the external power supply IC that supplies VBUS to connected USB devices to the OVCUR0A or OVCUR0B pin. On detection of an OVRCR interrupt, eliminate transients by repeatedly reading the OVCMON[1:0] flags through the software until the same value is read at least three times.

在设备控制器模式下从L1RSMEND标志读取的值无效。

ATTCH标志（USB连接检测中断状态标志）

ATTCH标志指示主机控制器模式下USB连接检测中断的状态。

USBHS检测到ATTCH中断并在检测到全速或低速信号电平上的JorK状态持续2.5µs时将该位设置为1。如果相关的中断使能位由软件设置为1，则USBHS产生中断。

USBHS在以下任何条件下检测ATTCH中断：

- K-state、SE0或SE1变为J-state，J-state持续2.5µs
- J-state、SE0或SE1变为K-state，K-state持续2.5µs。

在设备控制器模式下从ATTCH标志读取的值无效。

DTCH标志（USB断线检测中断状态标志）

DTCH标志指示主机控制器模式下USB分离检测中断的状态。

USBHS检测到DTCH中断并在检测到USB总线分离事件时将该位设置为1。如果相关的中断使能位由软件设置为1，则USBHS产生中断。

USBHS根据USB2.0规范检测总线分离事件。

检测到DTCH中断后，USBHS对硬件进行如下控制，而不管相关的中断使能位设置如何：

- 将检测到DTCH中断的端口的DVSTCTR0.UACT位设置为0
- 将发生DTCH中断的端口置于空闲状态。

软件必须终止正在执行通信的所有管道并调用等待状态以连接到USB端口（等待ATTCH中断生成）。

在设备控制器模式下从DTCH标志读取的值无效。

BCHG标志（USB总线变化中断状态标志*1）

BCHG标志指示主机控制器模式下USB总线更改中断的状态。

当全速信号电平发生变化时，USBHS检测到BCHG中断并将该位设置为1。
USB端口。这包括从J-state、K-state或SE0到J-state、K-state或SE0的任何更改。如果相关的中断使能位由软件设置为1，则USBHS产生中断。

USBHS设置SYSSTS0.LNST[1:0]标志以指示USB端口的输入状态。当发生BCHG中断时，通过软件重复读取LNST[1:0]位来消除瞬态元素，直到至少读取3次相同的值。

当PHY时钟停止时，可以检测到USB总线状态的变化。

在设备控制器模式下从BCHG标志读取的值无效。

OVRCR标志（OVRCR中断状态标志*1）

OVRCR标志指示USBHS_OVCUR0A引脚上的输入状态或USBHS_OVCUR0B引脚上的变化。
如果INTENB1.OVRCRE位设置为1，则USBHS请求中断。

USBHS设置SYSSTS0.OVCMON[1:0]标志以指示USBHS_OVCUR0A的输入状态和
USBHS_OVCUR0B pins.

这些引脚允许在主机控制器模式下通过软件进行过流检测。要实现此功能，请将来自为所连接的USB设备提供VBUS的外部电源IC的过流信号连接到OVCUR0A或OVCUR0B引脚。在检测到OVRCR中断时，通过软件重复读取OVCMON[1:0]标志来消除瞬变，直到至少读取相同的值3次。

PIPEBRDY[9:0] flags (BRDY Interrupt Status Flag for Pipe[9:0])

When the BRDY interrupt is detected, the USBHS sets the associated bit in the PIPEBRDY[9:0] flags to 1. For details on BRDY interrupts, see section 33.3.6.1, BRDY interrupt.

Note 2. To clear the status indicated in the PIPENRDY[9:0] flags, write 0 only to the bits to be cleared. Write 1 to the other bits.

PIPENRDY[9:0] flags (NRDY Interrupt Status Flag for Pipe[9:0])

If an internal NRDY interrupt is detected while the PID[1:0] bits in a pipe control register are 01b (BUF response), the USBHS sets the associated bit in the PIPENRDY[9:0] flags to 1. For details on NRDY interrupts, see section 33.3.6.2, NRDY interrupt.

Note 1. 每个位号对应相同的管道号。
Note 2. 当SOFCFG.BRDYM位设置为0时，要清除PIPEBRDY[9: 0]标志中指示的状态，只需将0写入要清除的位。将1写入其他位。当SOFCFG.BRDYM位设置为0时，在访问FIFO之前清除BRDY中断。

PIPEBRDY[9: 0]标志（管道[9:0]的BRDY中断状态标志）

当检测到BRDY中断时，USBHS将PIPEBRDY[9: 0]标志中的相关位设置为1。有关详细信息BRDY中断，请参阅第33.3.6.1节，BRDY中断。

Note 1. Each bit number corresponds to the same pipe number.
Note 2. To clear the status indicated in the PIPEBEMP[9:0] flags, write 0 only to the bits to be cleared. Write 1 to the other bits.

PIPEBEMP[9:0] flags (BEMP Interrupt Status Flag for Pipe[9:0])

If an BEMP interrupt is detected while the PID[1:0] bits in a pipe control register are 01b (BUF response), the USBHS sets the associated bit in the PIPEBEMP[9:0] flags to 1. For details on BEMP interrupts, see section 33.3.6.3, BEMP interrupt.

b13 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	CRCE	CRC Error Detection Status Flag	0: No error occurred 1: Error occurred.	R/(W)
b15	OVRN	Overrun/Underrun Detection Status Flag	0: No error occurred 1: Error occurred.	R/(W)

Note: The OVRN flag is for debugging. Design the timing so that no overrun or underrun occurs in the system.

FRNM[10:0] flags (Frame Number Flag)

The USBHS sets the FRNM[10:0] flags to indicate the latest frame number, which is updated every 1 ms, when an SOF packet is issued or received.

CRCE flag (CRC Error Detection Status Flag)

The CRCE flag sets to 1 when a CRC error or bit stuffing error occurs during isochronous transfer. On detecting a CRC error, the USBHS generates an internal NRDY interrupt.

To clear the CRCE flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

OVRN flag (Overrun/Underrun Detection Status Flag)

The OVRN flag sets to 1 when an overrun or underrun error occurs during isochronous transfer. To clear the flag, write 0

b15	OVRN	Overrun/Underrun Detection 状态标志	0：未发生错误1：发生错误。	R/(W)

Note: OVRN标志用于调试。设计时序，使系统不会发生溢出或欠载。

FRNM[10:0]标志（帧号标志）

USBHS设置FRNM[10:0]标志以指示最新的帧号，该帧号每1ms更新一次，当发出或接收SOF数据包时。

CRCE标志（CRC错误检测状态标志）

当同步传输期间发生CRC错误或位填充错误时，CRCE标志设置为1。在检测到CRC错误时，USBHS产生一个内部NRDY中断。

要清除CRCE标志，向其写入0，同时向FRMNUM寄存器中的其他位写入1。

OVRN标志（溢出欠载检测状态标志）

当同步传输期间发生溢出或欠载错误时，OVRN标志设置为1。要清除标志，请写入0

to it while writing 1 to the other bits in the FRMNUM register.

In host controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the time to issue an OUT token comes before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the time to issue an IN token comes when no FIFO buffer planes are empty.

In device controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the IN token is received before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the OUT token is received when no FIFO buffer planes are empty.

UFRNM[2:0] flags (Microframe Number)

The USBHS sets the UFRNM[2:0] flags to indicate the microframe number during high-speed operation. When not in high-speed operation, the USBHS sets these bits to 00h.

Read these bits repeatedly until the same value is read twice.

33.2.25 USB Address Register (USBADDR)

将1写入FRMNUM寄存器中的其他位。

在主机控制器模式下，OVRN标志在以下任何条件下设置为1：

- 对于传输同步管道，发出OUT令牌的时间出现在所有传输数据写入FIFO缓冲区之前
- 对于接收同步管道，在没有FIFO缓冲区平面为空时发出IN令牌。

在设备控制器模式下，OVRN标志在以下任何条件下设置为1：

- 对于传输同步管道，在所有传输数据写入FIFO缓冲区之前接收到IN令牌
- 对于接收同步管道，当没有FIFO缓冲区平面为空时接收OUT令牌。

UFRNM[2:0]标志（微帧号）

USBHS设置UFRNM[2:0]标志以指示高速操作期间的微帧数。当不处于高速操作时，USBHS将这些位设置为00h。

重复读取这些位，直到读取两次相同的值。

33.2.25 USB地址寄存器(USBADDR)

Other settings are prohibited.	R/W
b15 to b11	—	Reserved	The read value is undefined. The write value should be 0.	R/W

USBADDR[6:0] flags (USB Address Flag)

In device controller mode, the USBADDR[6:0] flags indicate the USB address received when the USBHS processed a SetAddress request successfully. The USBHS sets the USBADDR[6:0] bits to 00h on detecting a USB bus reset.

In host controller mode, the USBADDR[6:0] bits are invalid.

STSRECOV0[2:0] bits (Status Recovery)

Use the STSRECOV[3:0] bits to resume the state of the internal sequencer on recovering from USB power shut-off. For details, see section 33.3.17, Release from Deep Software Standby Mode Because of USB Suspend/Resume Interrupts.

Writing to these bits is enabled while the DVCHGR.DVCHG bit is set to 1.

33.2.26 USB Request Type Register (USBREQ)

b15 to b8	BREQUEST[7:0]	Request	USB request bRequest value	R/W*1

Note 1. In device controller mode, these bits can be read, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

BMREQUESTTYPE[7:0] bits (Request Type)

The BMREQUESTTYPE[7:0] bits hold the bmRequestType value of USB requests.

- In host controller mode:
  Set these bits to the value of the USB request data in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:
  These bits indicate the value of the USB request data in reception setup transactions. Writing to the bits has no effect.

b15 to b11	—	Reserved	读取值未定义。写入值应为0。	R/W

USBADDR[6:0]标志（USB地址标志）

在设备控制器模式下，USBADDR[6:0]标志指示当USBHS处理一个SetAddress请求成功。USBHS在检测到USB总线复位时将USBADDR[6:0]位设置为00h。

在主机控制器模式下，USBADDR[6:0]位无效。

STSRECOV0[2:0]位（状态恢复）

使用STSRECOV[3:0]位在从USB电源关闭恢复时恢复内部定序器的状态。有关详细信息，请参阅第33.3.17节，由于USB挂起恢复中断而从深度软件待机模式中释放。

当DVCHGR.DVCHG位设置为1时，可以写入这些位。

WINDEX[15:0] bits (Index)

The WINDEX[15:0] bits hold the wIndex value of USB requests.

- In host controller mode:
  Set these bits to the wIndex value of USB requests in transmission setup transactions. Do not change the value of

BREQUEST[7:0]位（请求）

BREQUEST[7:0]位保存USB请求的bRequest值。

- 在主机控制器模式下：
  在传输设置事务中将这些位设置为USB请求数据的值。当DCPCTR.SUREQ位为1时，不要更改位的值。
- 在设备控制器模式下：

DIR bit (Transfer Direction)

In host controller mode, the DIR bit sets the transfer direction of the data stage and status stage for control transfers. In device controller mode, set the DIR bit to 0.

SHTNAK bit (Pipe Blocking on End of Transfer)

The SHTNAK bit specifies whether to change PID to NAK on transfer end when the selected pipe is receiving. It is only valid when the selected pipe is receiving.

When the SHTNAK bit is 1, the USBHS changes the DCPCTR.PID[1:0] bits for the DCP to NAK on determining that a transfer has ended. The USBHS determines transfer end on the following condition:

- A short packet, including a zero-length packet, is successfully received.

CNTMD bit (Continuous Transfer Mode)

The CNTMD bit indicates whether transfer through the default control pipe is in continuous transfer mode.

Note 1. Only set the MXPS[6:0] bits while PID is NAK. Before setting this bit, check that the CSSTS and PBUSY bits are 0, and then change the DCPCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK), and the CFIFOSEL.CURPIPE[3:0] bits to 0000b. If the DCPCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY bits through software is not necessary. After the MXPS[6:0] bits are set and the DCP is set to the CURPIPE[3:0] bits in a port select register, clear the buffer by setting the BCLR bit the port control register to 1.

Note 2. Only set the DEVSEL[3:0] bits while PID is NAK and the DCPCTR.SUREQ bits are 0. Before setting these bits, check that the CSSTS and PBUSY flags are 0, and then change the DCPCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK), and the DCPCTR.SUREQ[3:0] bits to 0. If the DCPCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY bits through software is not necessary.

MXPS[6:0] bits (Maximum Packet Size)

The MXPS[6:0] bits specify the maximum data payload (maximum packet size) for the DCP. The initial value is 40h (64 bytes). Set the bits to a USB 2.0-compliant value. Do not write to the FIFO buffer or set PID = BUF while MXPS[6:0] is set to 0.

DIR位（传输方向）

在主机控制器模式下，DIR位设置控制传输的数据阶段和状态阶段的传输方向。在设备控制器模式下，将DIR位设置为0。

SHTNAK位（传输结束时管道阻塞）

SHTNAK位指定当所选管道正在接收时，是否在传输结束时将PID更改为NAK。仅在所选管道正在接收时有效。

当SHTNAK位为1时，USBHS在确定传输已经结束时将DCPCR.PID[1:0]位更改为NAK。USBHS在以下条件下确定传输结束：

- 成功接收到一个短数据包，包括一个长度为零的数据包。

CNTMD位（连续传输模式）

CNTMD位指示通过默认控制管道的传输是否处于连续传输模式。

Note 1. 仅在PID为NAK时设置MXPS[6:0]位。在设置该位之前，检查CSSTS和PBUSY位是否为0，然后将DCPCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)，以及CFIFOSEL.CURPIPE[3:0]位到0000b。如果DCPCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查CSSTS和PBUSY位。在设置MXPS[6:0]位并将DCP设置为端口选择寄存器中的CURPIPE[3:0]位后，通过将端口控制寄存器的BCLR位设置为1来清除缓冲区。

Note 2. 仅在PID为NAK且DCPCTR.SUREQ位为0时设置DEVSEL[3:0]位。在设置这些位之前，请检查CSSTS和PBUSY标志是否为0，然后更改DCPCTR.PID[1:0]从01b(BUF)到00b(NAK)的位，以及
DCPCTR.SUREQ[3:0]位为0。如果DCPCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查CSSTS和PBUSY位。

MXPS[6:0]位（最大数据包大小）

MXPS[6:0]位指定DCP的最大数据有效载荷（最大数据包大小）。初始值为40h（64字节）。将这些位设置为符合USB2.0的值。当MXPS[6:0]设置为0时，不要写入FIFO缓冲区或设置PID=BUF。

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target peripheral device for a control transfer. Set up the device address in the associated DEVADDm (m = 0 to A) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0010b, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0000b.

DEVSEL[3:0]位（设备选择）

在主机控制器模式下，DEVSEL[3:0]位指定目标外围设备的地址以进行控制传输。首先在相关的DEVADDm（m=0到A）寄存器中设置设备地址，然后将这些位设置为相应的值。例如，要将DEVSEL[3:0]位设置为0010b，首先要设置DEVADD2寄存器中的地址。

在设备控制器模式下，将这些位设置为0000b。

Note 1. Only set the SQSET, SQCLR, and PINGE bits while PID is NAK. Before setting these bits, check that the CSSTS and PBUSY bits are 0, and then change the DCPCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the DCPCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY bits through the software is not necessary.

PID[1:0] bits (Response PID)

The PID[1:0] bits control the USB response type during control transfers.

In host controller mode, to change the PID[1:0] setting from NAK to BUF:

- When the transmitting direction is set:
  a. Write all of the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  b. Set PID[1:0] bits to 01b (BUF).
  The USBHS then executes the OUT transaction (or PING transaction).
- When the receiving direction is set:
  c. Check that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  d. Set PID[1:0] bits to 01b (BUF).
  The USBHS then executes the IN transaction.

The USBHS changes the PID[1:0] setting as follows:

- When the PID[1:0] bits are set to BUF (01b) by software and the USBHS has received data exceeding MaxPacketSize, the USBHS sets PID[1:0] to STALL (11b)
- When a reception error, such as a CRC error, is detected three times consecutively, the USBHS sets PID[1:0] to NAK (00b)
- On receiving the STALL handshake, the USBHS sets PID[1:0] to STALL (11b).

In device controller mode, the USBHS changes the PID[1:0] setting as follows:

- On receiving a setup packet, the USBHS sets PID[1:0] to NAK (00b). The USBHS then sets the INTSTS0.VALID flag to 1, and the PID[1:0] setting cannot be changed until the software clears the VALID flag to 0.
- When the PID[1:0] bits are set to BUF (01b) by software and the USBHS has received data exceeding MaxPacketSize, the USBHS sets PID[1:0] to STALL (11b)
- On detecting a control transfer sequence error, the USBHS sets PID[1:0] to STALL (1xb)
- On detecting a USB bus reset, the USBHS sets PID[1:0] to NAK.

The USBHS does not check the PID[1:0] setting while processing a SET_ADDRESS request.

CCPL bit (Control Transfer End Enable)

In device controller mode, setting the CCPL bit to 1 enables the status stage of the control transfer to be completed. When the bit is set to 1 by software while the associated PID[1:0] bits are set to BUF, the USBHS completes the control transfer status stage.

During control read transfers, the USBHS transmits the ACK handshake in response to the OUT transaction from the USB host. During control write or no-data control transfers, it transmits the zero-length packet in response to the IN transaction from the USB host. On detecting a SET_ADDRESS request, the USBHS operates in auto response mode from the setup stage up to status stage completion regardless of the CCPL bit setting.

The USBHS changes the CCPL bit from 1 to 0 on receiving a new setup packet. The software cannot write 1 to the bit while the INTSTS0.VALID bit is 1. The bit is initialized by a USB bus reset.

In host controller mode, always write 0 to the CCPL bit.

PINGE bit (PING Token Issue Enable)

In host controller mode, when the software sets the PINGE bit to 1, the USBHS issues a PING token for transfer in the transmitting direction, which triggers the transfer to start. If an ACK handshake is detected in the PING transaction, the OUT transaction is executed in the next transaction. If a NAK or NYET handshake is detected in the OUT transaction, the PING transaction is executed in the next transaction.

Note 1. 仅在PID为NAK时设置SQSET、SQCLR和PINGE位。在设置这些位之前，请检查CSSTS和PBUSY位是否为0，然后将DCPCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果DCPCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查CSSTS和PBUSY位。

PID[1:0]位（响应PID）

PID[1:0]位在控制传输期间控制USB响应类型。

在主机控制器模式下，要将PID[1:0]设置从NAK更改为BUF：

- 设置传输方向时：
  一个。当DVSTCTR0.UACT位为1且PID为NAK时，将所有发送数据写入FIFO缓冲区。
  湾。将PID[1:0]位设置为01b(BUF)。
  然后USBHS执行OUT事务（或PING事务）。
- 设置接收方向时：
  C。在DVSTCTR0.UACT位为1且PID为NAK时检查FIFO缓冲区是否为空（或清空缓冲区）。
  d。将PID[1:0]位设置为01b(BUF)。
  然后USBHS执行IN事务。

USBHS将PID[1:0]设置更改如下：

- 当PID[1:0]位被软件设置为BUF(01b)并且USBHS接收到的数据超过MaxPacketSize，USBHS将PID[1:0]设置为STALL(11b)
- 当连续3次检测到接收错误（例如CRC错误）时，USBHS将PID[1:0]设置为NAK (00b)
- 在接收到STALL握手时，USBHS将PID[1:0]设置为STALL(11b)。

在设备控制器模式下，USBHS将PID[1:0]设置更改如下：

- 接收到设置数据包后，USBHS将PID[1:0]设置为NAK(00b)。然后USBHS将INTSTS0.VALID标志设置为1，并且在软件将VALID标志清除为0之前无法更改PID[1:0]设置。
- 当PID[1:0]位被软件设置为BUF(01b)并且USBHS接收到的数据超过MaxPacketSize，USBHS将PID[1:0]设置为STALL(11b)
- 在检测到控制传输序列错误时，USBHS将PID[1:0]设置为STALL(1xb)
- 在检测到USB总线复位时，USBHS将PID[1:0]设置为NAK。

USBHS在处理SET_ADDRESS请求时不检查PID[1:0]设置。

CCPL位（控制传输结束使能）

在设备控制器模式下，将CCPL位设置为1可以完成控制传输的状态阶段。
当该位由软件设置为1且相关的PID[1:0]位设置为BUF时，USBHS完成控制传输状态阶段。

在控制读取传输期间，USBHS发送ACK握手以响应来自USB主机的OUT事务。在控制写入或无数据控制传输期间，它传输零长度数据包以响应来自USB主机的IN事务。在检测到SET_ADDRESS请求时，USBHS从设置阶段到状态阶段完成以自动响应模式运行，无论CCPL位设置如何。

USBHS在接收到新的设置数据包时将CCPL位从1更改为0。当INTSTS0.VALID位为1时，软件无法向该位写入1。该位由USB总线复位初始化。

在主机控制器模式下，始终将0写入CCPL位。

PINGE位（PING令牌发布启用）

在主机控制器模式下，当软件将PINGE位设置为1时，USBHS会发出一个PING令牌以进行传输方向的传输，从而触发传输开始。如果在PING事务中检测到ACK握手，则在 下一个事务中执行OUT事务。如果在OUT事务中检测到NAK或NYET握手，则在 下一个事务中执行PING事务。

If the software sets this bit to 0, the USBHS issues no PING token for transfer in the transmitting direction. All transfers in the transmitting direction are executed in the OUT transaction.

PBUSY flag (Pipe Busy Flag)

The PBUSY bit indicates whether DCP is used for the transaction when USBHS changes the PID[1:0] bits from BUF to NAK. The USBHS changes the PBUSY flag from 0 to 1 on start of a USB transaction for the selected pipe. It changes the PBUSY flag from 1 to 0 on completion of one transaction.

After PID is set to NAK by software, the value in the PBUSY flag indicates whether changes to pipe settings can proceed.

For details, see section 33.3.7.1, Pipe control register switching procedures.

SQMON flag (Sequence Toggle Bit Monitor Flag)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

The USBHS toggles the bit on normal completion of the transaction. It does not toggle the bit, however, when a DATA-PID mismatch occurs during a transfer in the receiving direction.

In device controller mode, the USBHS sets the SQMON bit to 1 (specifies DATA1 as the expected value) on successful reception of the setup packet.

In device controller mode, the USBHS does not reference this bit during IN or OUT transactions at the status stage, and it does not toggle the bit on normal completion.

SQSET bit (Sequence Toggle Bit Set)

The SQSET bit specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SQCLR bit (Sequence Toggle Bit Clear)

The SQCLR bit specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer. It is read as 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SUREQCLR bit (SUREQ Bit Clear)

In host controller mode, setting the SUREQCLR bit to 1 clears the SUREQ bit to 0. The bit is read as 0.

If transfer stops while the SUREQ bit is set to 1 in a setup transaction, set the SUREQCLR bit to 1 through software. This is not necessary at the end of a normal setup transaction, because the USBHS automatically clears the SUREQ bit to 0.

Only control the SUREQ bit through the SUREQCLR bit while the DVSTCTR0.UACT bit is 0. When UACT is 0, communication is halted or no transfer is occurring because a bus disconnection was detected.

In device controller mode, always write 0 to the SUREQCLR bit.

CSSTS flag (CSSTS Status Flag)

In host controller mode, the CSSTS flag indicates the complete-split state in split transactions for pipes that are not isochronous. The USBHS sets the CSSTS flag to 1 at the beginning of a complete-split transaction and sets the flag back to 0 when it detects transaction completion.

Values read from the CSSTS flag in device controller mode are invalid.

CSCLR bit (CSSTS Status Flag Clear)

In host controller mode, setting the CSCLR bit to 1 clears the CSSTS bit to 0.

Set this bit to 1 through software when forcing the next transfer to restart from start-split in transfers using split transactions. This is not necessary at the end of a successful complete-split transaction in a normal split transaction, because the USBHS automatically clears the CSSTS flag to 0.

如果软件将此位设置为0，则USBHS不会发出PING令牌以进行传输方向的传输。发送方向的所有传输都在OUT事务中执行。

PBUSY标志（管道忙标志）

当USBHS将PID[1:0]位从BUF更改为
纳克。USBHS在所选管道的USB事务开始时将PBUSY标志从0更改为1。它在一个事务完成时将PBUSY标志从1更改为0。

软件将PID设置为NAK后，PBUSY标志中的值指示是否可以继续对管道设置进行更改。

详见33.3.7.1管道控制寄存器切换流程。

SQMON标志（序列切换位监视器标志）

SQMON位指示DCP传输期间下一个事务的序列切换位的预期值。

USBHS在事务正常完成时切换该位。然而，它不会切换该位，当一个DATA
PID不匹配发生在接收方向的传输过程中。

在设备控制器模式下，USBHS在成功接收到设置数据包时将SQMON位设置为1（指定DATA1作为预期值）。

在设备控制器模式下，USBHS在状态阶段的IN或OUT事务期间不参考该位，并且在正常完成时不切换该位。

SQSET位（序列切换位设置）

SQSET位将DATA1指定为DCP传输期间下一个事务的序列切换位的预期值。

不要同时将SQCLR和SQSET位设置为1。

SQCLR位（序列切换位清除）

SQCLR位将DATA0指定为DCP传输期间下一个事务的序列切换位的预期值。读为0。

不要同时将SQCLR和SQSET位设置为1。

SUREQCLR位（SUREQ位清零）

在主机控制器模式下，将SUREQCLR位设置为1会将SUREQ位清除为0。该位被读取为0。

如果在设置事务中将SUREQ位设置为1时传输停止，则通过软件将SUREQCLR位设置为1。
这在正常设置事务结束时不是必需的，因为USBHS会自动将SUREQ位清除为0。

当DVSTCTR0.UACT位为0时，仅通过SUREQCLR位控制SUREQ位。当UACT为0时，由于检测到总线断开，通信停止或没有传输发生。

在设备控制器模式下，始终将0写入SUREQCLR位。

CSSTS标志（CSSTS状态标志）

在主机控制器模式下，CSSTS标志指示非同步管道的拆分事务中的完全拆分状态。USBHS在完全拆分事务开始时将CSSTS标志设置为1，并在检测到事务完成时将该标志设置回0。

在设备控制器模式下从CSSTS标志读取的值无效。

CSCLR位（CSSTS状态标志清除）

在主机控制器模式下，将CSCLR位设置为1会将CSSTS位清零。

在使用拆分事务的传输中强制下一次传输从start-split重新启动时，通过软件将此位设置为1。在正常拆分事务中成功完成拆分事务结束时，这不是必需的，因为USBHS会自动将CSSTS标志清除为0。

Only control the CSSTS flag through the CSCLR bit while the DVSTCTR0.UACT bit is 0. When UACT is 0, communication is halted or no transfer is occurring because a port disconnection was detected. Writing 1 to this bit while the CSSTS flag is 0 has no effect; the flag remains 0.

In device controller mode, always write 0 to this bit.

SUREQ bit (SETUP Token Transmission)

In host controller mode, setting the SUREQ bit to 1 triggers the USBHS to transmit the setup packet. After completing the setup transaction process, the USBHS generates either the SACK or SIGN interrupt and clears the SUREQ bit to 0. The USBHS also clears the SUREQ bit to 0 when the software sets the SUREQCLR bit to 1.

Before setting the SUREQ bit to 1, set the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, and USBLENG appropriately to transmit the wanted USB request in the setup transaction. Also check that the PID[1:0] bits for the DCP are set to NAK. After setting the SUREQ bit to 1, do not change the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, or USBLENG until the setup transaction is complete (SUREQ bit = 1). Write 1 to the SUREQ bit only when transmitting the setup token. Otherwise, write 0.

In device controller mode, always write 0 to this bit.

BSTS flag (Buffer Status Flag)

The BSTS flag indicates the status of access to the DCP FIFO buffer. The meaning of this flag varies as follows depending on the CFIFOSEL.ISEL setting:

- When ISEL = 0, the bit indicates whether receive data can be read from the buffer
- When ISEL = 1, the bit indicates whether transmit data can be written to the buffer.

Set pipes 1 to 9 using the PIPESEL, PIPECFG, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN registers (n = 0 to 9).

After selecting the pipe in the PIPESEL register, pipe functions must be set in the associated PIPECFG, PIPEMAXP, and PIPEPERI registers. PIPEnCTR, PIPEnTRE, and PIPEnTRN can be set independently of the pipe selection in this register.

PIPESEL[3:0] bits (Pipe Window Select)

The PIPESEL[3:0] bits select the pipe number associated with the PIPECFG, PIPEMAXP, and PIPEPERI registers used

仅当DVSTCTR0.UACT位为0时，通过CSCLR位控制CSSTS标志。当UACT为0时，由于检测到端口断开，通信停止或不发生传输。CSSTS标志为0时向该位写入1无效；标志保持为0。

在设备控制器模式下，始终向该位写入0。

SUREQ位（SETUP令牌传输）

在主机控制器模式下，将SUREQ位设置为1会触发USBHS发送设置数据包。完成设置事务处理后，USBHS产生SACK或SIGN中断并将SUREQ位清零。当软件将SUREQCLR位设置为1时，USBHS也将SUREQ位清零。

在将SUREQ位设置为1之前，适当地设置DCPMAXP.DEVSEL[3:0]位、USBREQ、USBVAL、USBINDX和USBLENG以在设置事务中传输所需的USB请求。还要检查DCP的PID[1:0]位是否设置为NAK。将SUREQ位设置为1后，在设置事务完成（SUREQ位=1）之前，不要更改DCPMAXP.DEVSEL[3:0]位、USBREQ、USBVAL、USBINDX或USBLENG。将1写入

仅在发送设置令牌时才使用SUEQ位。否则，写0。

在设备控制器模式下，始终向该位写入0。

BSTS标志（缓冲区状态标志）

BSTS标志指示访问DCPFIFO缓冲区的状态。根据CFIFOSEL.ISEL设置，该标志的含义如下：

- 当ISEL=0时，该位指示是否可以从缓冲区中读取接收数据
- 当ISEL=1时，该位指示是否可以将发送数据写入缓冲区。

Note 1. Only set the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY flags through the software is not necessary.

Note 2. Only set the BFRE, DBLB, and DIR bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Note 3. 要在选定管道上完成USB通信后更改BFRE、DBLB或DIR位，除了注释2中描述的约束外，通过软件连续向PIPEnCTR.ACLRM位写入1和0，并清除FIFO缓冲区

assigned to the pipe.

EPNUM[3:0] bit (Endpoint Number)

The EPNUM[3:0] bits specify the endpoint number for the selected pipe. Setting 0000b indicates the pipe not used.

Set these bits so that the combination of the DIR and EPNUM[3:0] settings is different from those for other pipes. (The EPNUM[3:0] bits can be set to 0000b for all pipes.)

DIR bit (Transfer Direction)

The DIR bit specifies the transfer direction for the selected pipe.

When the software sets this bit to 0, the USBHS uses the selected pipe for receiving. When the software sets this bit to 1, the USBHS uses the selected pipe for transmitting.

SHTNAK bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to change the PIPEnCTR.PID[1:0] bits to 00b (NAK) at the end of transfer when the selected pipe is set in the receiving direction. The bit is valid for pipes 1 to 5 in the receiving direction.

When the software sets this bit to 1 for a receiving pipe, the USBHS changes the associated PIPEnCTR.PID[1:0] bits to 00b (NAK) on determining the transfer end. The USBHS determines that the transfer has ended on the following conditions:

- Short packet data (including a zero-length packet) was successfully received
- The transaction counter is used and the number of packets specified for the transaction counter were successfully received.

CNTMD bit (Continuous Transfer Mode)

The CNTMD bit specifies whether to operate the selected pipe in continuous transfer mode. The bit is valid for pipes 1 to 5 of the bulk transfer type.

Based on this bit setting, the USBHS determines the completion of transmission or reception for the FIFO buffer allocated to the selected pipe as shown in Table 33.9.

Table 33.9 Relationship between the CNTMD setting and methods for determining completion of FIFO buffer transmission or reception

CNTMD bit setting	Methods for determining readable state and transmittable state
0	Condition for FIFO buffer readable state in receiving direction (DIR = 0): • The USBHS received one packet.
	Conditions for FIFO buffer transmittable state in transmitting direction (DIR = 1): When one of (1) or (2) of the following is satisfied: (1) Software (or DMAC/DTC) wrote data of the maximum packet size to the FIFO buffer. (2) Software (or DMAC/DTC) wrote data of the short packet size (including 0 bytes) to the FIFO buffer and set the BVAL flag in the port control register to 1.
1	Condition for FIFO buffer readable state in receiving direction (DIR = 0): (1) The byte count of data received in the FIFO buffer allocated to the selected pipe is equal to the allocated byte count ((BUFSIZE + 1) × 64). (2) The USBHS received a short packet, other than a zero-length packet. (3) The USBHS received a zero-length packet when data was already contained in the FIFO buffer allocated to the selected pipe. (4) Software received the number of packets specified for the transaction counter set for the selected pipe.
	Conditions for FIFO buffer transmittable state in transmitting direction (DIR = 1): When one of (1) to (3) of the following is satisfied. (1) The amount of data written by software (or DMAC/DTC) is equal to the size of the FIFO buffer allocated to the selected pipe. (2) The software (or DMAC/DTC) wrote data of smaller size than that of the FIFO buffer allocated to the selected pipe (including 0 bytes) and set the BVAL flag in the port control register to 1. (3) The software (or DMAC/DTC) wrote data of smaller size than that of one FIFO buffer allocated to the selected pipe (including 0 bytes) and asserted the DENDx_N signal on the last write.

分配给管道。

EPNUM[3:0]位（端点编号）

EPNUM[3:0]位指定所选管道的端点号。设置0000b表示管道未使用。

设置这些位，以便DIR和EPNUM[3:0]设置的组合不同于其他管道的设置。（这所有管道的EPNUM[3:0]位都可以设置为0000b。）

DIR位（传输方向）

DIR位指定所选管道的传输方向。

当软件将此位设置为0时，USBHS使用所选管道进行接收。当软件将该位设置为1时，USBHS使用选定的管道进行传输。

SHTNAK位（传输结束时管道禁用）

SHTNAK位指定当所选管道设置为接收方向时，是否在传输结束时将PIPEnCTR.PID[1:0]位更改为00b(NAK)。该位对接收方向的管道1到5有效。

当软件将该位设置为1用于接收管道时，USBHS在确定传输结束时将相关的PIPEnCTR.PID[1:0]位更改为00b(NAK)。USBHS在以下条件下确定传输已结束：

- 成功接收短包数据（包括零长度包）
- 使用事务计数器，并且成功接收到为事务计数器指定的数据包数。

CNTMD位（连续传输模式）

CNTMD位指定是否在连续传输模式下操作选定的管道。该位对批量传输类型的管道1到5有效。

根据该位设置，USBHS确定分配给所选管道的FIFO缓冲区的发送或接收是否完成，如表33.9所示。

Table 33.9 CNTMD设置与确定FIFO缓冲区发送或接收完成的方法之间的关系

CNTMD位设置	确定可读状态和可传输状态的方法
0	接收方向上FIFO缓冲区可读状态的条件（DIR=0）： USBHS接收到一个数据包。
	发送方向(DIR=1)的FIFO缓冲区可发送状态的条件： 当满足以下(1)或(2)之一时：(1)软件（或DMACDTC）将最大数据包大小的数据写入FIFO缓冲区。(2)软件（或DMACDTC）将短包大小（包括0字节）的数据写入FIFO缓冲区，并将端口控制寄存器中的BVAL标志设置为1。
1	接收方向（DIR=0）FIFO缓冲区可读状态的条件：（1）分配给所选管道的FIFO缓冲区中接收到的数据的字节数等于分配的字节数（（BUFSIZE+1）×64）。(2)USBHS接收到一个短数据包，而不是一个零长度数据包。(3)当数据已包含在分配给所选管道的FIFO缓冲区中时，USBHS接收到一个零长度数据包。(4)软件接收到为所选管道设置的事务计数器指定的数据包数量。
	发送方向(DIR=1)的FIFO缓冲区可发送状态的条件： 当满足以下（1）至（3）之一时。(1)软件（或DMACDTC）写入的数据量等于分配给所选管道的FIFO缓冲区的大小。(2)软件（或DMACDTC）写入比分配给所选管道的FIFO缓冲区更小的数据（包括0字节），并将端口控制寄存器中的BVAL标志设置为1。(3)软件（或DMACDTC）写入的数据小于分配给所选管道的一个FIFO缓冲区（包括0字节），并在最后一次写入时置位DENDx_N信号。

DBLB bit (Double Buffer Mode)

The DBLB bit selects either single or double buffer mode for the FIFO buffer used by the selected pipe. The bit is valid for pipes 1 to 5.

When the software sets this bit to 1, the USBHS allocates twice the FIFO buffer size specified in the PIPEBUF.BUFSIZE[5:0] bits for the selected pipe. The FIFO buffer size that the USBHS allocates to the selected pipe is as follows:

(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

BFRE bit (BRDY Interrupt Operation Specification)

The BFRE bit specifies the BRDY interrupt generation timing from the USBHS to the CPU for the selected pipe.

When the software sets the BFRE bit to 1 and the selected pipe is in the receiving direction, the USBHS detects the transfer completion and generates the BRDY interrupt on reading the packet.

When a BRDY interrupt is generated with this setting, the software must write 1 to the BCLR bit in the port control register. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to the BCLR bit.

When the BFRE bit is set to 1 by software and the selected pipe is in the transmitting direction, the USBHS does not generate the BRDY interrupt. For details, see section 33.3.6.1, BRDY interrupt.

TYPE[1:0] bits (Transfer Type)

The TYPE[1:0] bits specify the transfer type for the pipe selected in the PIPESEL.PIPESEL[3:0] bits. Before setting PID to BUF and starting USB communication on the selected pipe, set the TYPE[1:0] bits to a value other than 00b.

Note 1. Only set the bits in the PIPEBUF register while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY flags through the software is not necessary.

BUFNMB[7:0] bits (Buffer Number)

The BUFNMB[7:0] bits specify the first block number of the FIFO buffer to be allocated to the selected pipe.

The USBHS allocates the FIFO buffer blocks to the selected pipe as follows:

Block number: BUFNMB to block number: BUFNMB + (BUFSIZE + 1) × (DBLB + 1) - 1

Set a value within the memory size range for these bits (0 [00h] to 8640 [87h] for 8.5 KB), while observing the following conditions:

DBLB位（双缓冲模式）

DBLB位为所选管道使用的FIFO缓冲区选择单缓冲区模式或双缓冲区模式。该位对管道1到5有效。

当软件将该位设置为1时，USBHS分配两倍于
所选管道的PIPEBUF.BUFSIZE[5:0]位。USBHS分配给所选管道的FIFO缓冲区大小如下：

(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

BFRE位（BRDY中断操作规范）

BFRE位为所选管道指定从USBHS到CPU的BRDY中断生成时序。

当软件将BFRE位设置为1且所选管道处于接收方向时，USBHS检测到传输完成并在读取数据包时产生BRDY中断。

当使用该设置产生BRDY中断时，软件必须将1写入端口控制寄存器中的BCLR位。在将1写入BCLR位之前，分配给所选管道的FIFO缓冲区不会用于接收。

当BFRE位由软件设置为1且所选管道处于发送方向时，USBHS不会产生BRDY中断。有关详细信息，请参阅第33.3.6.1节，BRDY中断。

TYPE[1:0]位（传输类型）

TYPE[1:0]位指定在PIPESEL.PIPESEL[3:0]位中选择的管道的传输类型。在将PID设置为BUF并在所选管道上启动USB通信之前，请将TYPE[1:0]位设置为00b以外的值。

Note 1. 仅在PID为NAK时以及在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置PIPEBUF寄存器中的位。在设置这些位之前，请检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PIPEnCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查CSSTS和PBUSY标志。

BUFNMB[7:0]位（缓冲区编号）

BUFNMB[7:0]位指定要分配给所选管道的FIFO缓冲区的第一个块号。

USBHS将FIFO缓冲区块分配给所选管道，如下所示：

块号：BUFNMB到块号：BUFNMB+(BUFSIZE+1)×(DBLB+1)1

为这些位设置一个内存大小范围内的值（0[00h]到8640[87h]，对于8.5KB），同时遵守以下条件：

- 00h is for DCP only
- 04h is for pipe 6 only, but is available for other pipes when pipe 6 is not used. When pipe 6 is selected, writes to these bits are disabled. The USBHS automatically allocates 04h to the BUFNMB bits for pipe 6.
- 05h is for pipe 7 only, but is available for other pipes when pipe 7 is not used. When pipe 7 is selected, writes to these bits are disabled. The USBHS automatically allocates 05h to the BUFNMB bits for pipe 7.
- 06h is for pipe 8 only, but is available for other pipes when pipe 8 is not used. When pipe 8 is selected, writes to these bits are disabled. The USBHS automatically allocates 06h to the BUFNMB bits for pipe 8.
- 07h is for pipe 9 only, but is available for other pipes when pipe 9 is not used. When pipe 9 is selected, writes to these bits are disabled. The USBHS automatically allocates 07h to the BUFNMB bits for pipe 9.

BUFSIZE[4:0] bits (Buffer Size)

The BUFSIZE[4:0] bits specify the FIFO buffer size (number of blocks) to be allocated to the selected pipe. One block is 64 bytes.

When the software sets the DBLB bit to 1, the USBHS allocates twice the FIFO buffer size specified in these bits to the selected pipe. The DBLB = 1 setting is valid for pipes 1 to 5.

The USBHS allocates the FIFO buffer blocks to the selected pipe as follows:

(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

Set the value within the following range:

- For pipes 1 to 5, set a value from 00h to 1Fh (up to 2 KB)
- For pipes 6 to 9, only set a value of 00h (64 bytes).

BUFSIZE[4:0]位（缓冲区大小）

BUFSIZE[4:0]位指定要分配给所选管道的FIFO缓冲区大小（块数）。一个块是64字节。

当软件将DBLB位设置为1时，USBHS将这些位中指定的两倍FIFO缓冲区大小分配给所选管道。DBLB=1设置对管道1到5有效。

USBHS将FIFO缓冲区块分配给所选管道，如下所示：

(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

将值设置在以下范围内：

- 对于管道1到5，设置一个从00h到1Fh的值（最大2KB）
- 对于管道6到9，仅设置值00h（64字节）。

PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY flags through the software is not necessary.

Note 3. Only set the DEVSEL[3:0] bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

MXPS[10:0] bits (Maximum Packet Size)

The MXPS[10:0] bits specify the maximum data payload (maximum packet size) for the selected pipe.

Set these bits to the appropriate value for each transfer type based on the USB 2.0 specification. When MXPS[10:0] = 0, do not write to the FIFO buffer or set PID to BUF. These writes have no effect.

To communicate on an isochronous pipe using a split transaction, set the value in the MXPS[10:0] bits to 188 bytes or less.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target device for USB communication. Set up the device address in the associated DEVADDm (m = 0 to A) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0010b, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0000b.

Note 1. Only set the IITV[2:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

PIPEPERI selects whether the buffer is flushed or not when an interval error occurred during isochronous IN transfers, and sets the interval error detection interval for pipes 1 to 9.

IITV[2:0] bits (Interval Error Detection Interval)

To change the IITV[2:0] bits to another value after they are set and USB communication is performed, set the PIPEnCTR.PID[1:0] bits to 00b (NAK) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer.

The IITV[2:0] bits are not provided for pipes 3 to 5. Write 000b to bit positions of the IITV[2:0] bits associated with pipes 3 to 5.

IFIS bit (Isochronous IN Buffer Flush)

The IFIS bit specifies whether to flush the buffer when the pipe specified in the PIPESEL.PIPESEL[3:0] bits is used for isochronous IN transfers.

PIPEnCTR.PID[1:0]位从01b(BUF)到00b(NAK)。如果PIPEnCTR.PID[1:0]位被更改为00b(NAK)
USBHS，不需要通过软件检查CSSTS和PBUSY标志。

Note 3. 仅在PID为NAK且在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置DEVSEL[3:0]位。在设置这些位之前，请检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PIPEnCTR.PID[1:0]位被更改为00b(NAK)
USBHS，不需要通过软件检查PBUSY标志。

MXPS[10:0]位（最大数据包大小）

MXPS[10:0]位指定所选管道的最大数据有效负载（最大数据包大小）。

根据USB2.0规范将这些位设置为每种传输类型的适当值。当MXPS[10:0]=0时，不要写入FIFO缓冲区或将PID设置为BUF。这些写入没有效果。

要使用拆分事务在同步管道上进行通信，请将MXPS[10:0]位中的值设置为188字节或更少。

DEVSEL[3:0]位（设备选择）

在主机控制器模式下，DEVSEL[3:0]位指定USB通信的目标设备的地址。首先在相关的DEVADDm（m=0到A）寄存器中设置设备地址，然后将这些位设置为相应的值。例如，要将DEVSEL[3:0]位设置为0010b，首先要设置DEVADD2寄存器中的地址。

在设备控制器模式下，将这些位设置为0000b。

PIPEPERI选择在同步IN传输期间发生间隔错误时是否刷新缓冲区，并设置管道1到9的间隔错误检测间隔。

IITV[2:0]位（间隔错误检测间隔）

要在设置IITV[2:0]位并在执行USB通信后将其更改为另一个值，请设置PIPEnCTR.PID[1:0]位为00b(NAK)，然后将PIPEnCTR.ACLRM位设置为1以初始化间隔定时器。

不为管道3到5提供IITV[2:0]位。将000b写入与管道3到5相关联的IITV[2:0]位的位位置。

IFIS位（同步IN缓冲区刷新）

IFIS位指定当PIPESEL.PIPESEL[3:0]位中指定的管道用于同步IN传输时是否刷新缓冲区。

In device controller mode when the selected pipe is for isochronous IN transfers, the USBHS automatically clears the FIFO buffer if the USBHS fails to receive the IN token from the USB host within the interval set in the IITV[2:0] bits in terms of frames.

When double buffering is specified (PIPECFG.DBLB = 1), the USBHS only clears the data in the previously used plane.

The USBHS clears the FIFO buffer on receiving the SOF packet immediately after the frame in which the USBHS expected to receive the IN token. Even if the SOF packet is corrupted, the FIFO buffer is cleared at the time the SOF packet is expected to be received by using the internal complementation function.

In host controller mode, set the IITV[2:0] bits to 000b.

Set the IITV[2:0] bits to 000b when the selected pipe is not used for isochronous transfers.

在设备控制器模式下，当所选管道用于同步IN传输时，USBHS会自动清除
如果USBHS未能在IITV[2:0]位（以帧为单位）设置的间隔内接收来自USB主机的IN令牌，则FIFO缓冲区。

当指定双缓冲时（PIPECFG.DBLB=1），USBHS仅清除先前使用的平面中的数据。

在USBHS预期接收IN令牌的帧之后，USBHS在接收到SOF数据包后立即清除FIFO缓冲区。即使SOF数据包已损坏，FIFO缓冲区也会在预期接收SOF数据包时使用内部补充功能清除。

在主机控制器模式下，将IITV[2:0]位设置为000b。

当所选管道不用于同步传输时，将IITV[2:0]位设置为000b。

Note 1. Only set the ATREPM bit while PID is NAK. Before setting this bit, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.
Note 2. Only set the ACLRM bit while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting this bit, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.
Note 3. The ATREPM bit and the INBUFM flag in the PIPE6CTR to PIPE9CTR registers are reserved. The read value is undefined. The write value must be 0.

PID[1:0] bits (Response PID)

The PID[1:0] bits specify the response type for the next transaction on the selected pipe.

The default PID[1:0] setting is NAK. Change the PID[1:0] setting to BUF to use the associated pipe for USB transfer. Table 33.10 and Table 33.11 show the basic operations of the USBHS (when there are no errors in the communication packets) based on the PID[1:0] bit setting.

After changing the PID[1:0] setting from BUF to NAK through the software during USB communication on the selected pipe, check that the PBUSY bit is 1 to see if USB transfer on the selected pipe has actually entered the NAK state. If the USBHS changes the PID[1:0] bits to NAK, checking the PBUSY bit through the software is not necessary.

The USBHS changes the PIPEnCTR.PID[1:0] setting in the following cases:

- The USBHS sets PID to NAK on recognizing completion of the transfer when the selected pipe is in the receiving direction and the PIPECFG.SHTNAK bit for the selected pipe is set to 1 by software
- The USBHS sets PID to STALL (11b) on receiving a data packet with a payload exceeding the maximum packet size of the selected pipe
- The USBHS sets PID to NAK on detecting a USB bus reset in device controller mode
- The USBHS sets PID to NAK on detecting a reception error, such as a CRC error, three consecutive times in host controller mode
- The USBHS sets PID to STALL (11b) on receiving the STALL handshake in host controller mode.

To specify the response type, set the PID[1:0] bits as follows:

- To transition from NAK (00b) to STALL, set 10b
- To transition from BUF (01b) to STALL, set 11b
- To transition from STALL (11b) to NAK, set 10b and then 00b
- To transition from STALL to BUF, set 00b (NAK) and then 01b (BUF).

Table 33.10 Operation of the USBHS based on the PIPEnCTR.PID[1:0] setting in host controller mode

PID[1:0] value	Transfer type (TYPE[1:0] value)	Transfer direction (DIR value)	USBHS operation
00b (NAK)	Does not depend on the setting	Does not depend on the setting	Does not issue tokens
01b (BUF)	Bulk or Interrupt	Does not depend on the setting	Issues tokens when the DVSTCTR0.UACT bit is 1 and the FIFO buffer associated with the selected pipe is ready for transmission and reception. Does not issue tokens when the DVSTCTR0.UACT bit is 0 or the FIFO buffer associated with the selected pipe is not ready for transmission or reception.
	Isochronous	Does not depend on the setting.	Issues tokens when the DVSTCTR0.UACT bit is 1, regardless of the state of the FIFO buffer associated with the selected pipe. Does not issue tokens when UACT = 0.
10b (STALL) or 11b (STALL)	Does not depend on the setting.	Does not depend on the setting.	Does not issue tokens.

Note 1. 仅在PID为NAK时设置ATREPM位。在设置该位之前，检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PIPEnCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查PBUSY标志。

Note 2. 仅在PID为NAK时以及在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置ACLRM位。
在设置该位之前，检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志是否为0，然后更改PIPEnCTR.PID[1:0]位从01b(BUF)到00b(NAK)。如果PIPEnCTR.PID[1:0]位被更改为00b(NAK)USBHS，不需要通过软件检查PBUSY标志。
Note 3. PIPE6CTR到PIPE9CTR寄存器中的ATREPM位和INBUFM标志被保留。读取值未定义。
写入值必须为0。

PID[1:0]位（响应PID）

PID[1:0]位指定所选管道上下一个事务的响应类型。

默认PID[1:0]设置为NAK。将PID[1:0]设置更改为BUF以使用关联的管道进行USB传输。表33.10和表33.11显示了基于PID[1:0]位设置的USBHS的基本操作（通信数据包中没有错误时）。

在选定管道上进行USB通信期间，通过软件将PID[1:0]设置从BUF更改为NAK后，检查PBUSY位是否为1，以查看选定管道上的USB传输是否真正进入了NAK状态。如果USBHS将PID[1:0]位更改为NAK，则无需通过软件检查PBUSY位。

USBHS在以下情况下更改PIPEnCTR.PID[1:0]设置：

- 当所选管道处于接收方向并且所选管道的PIPECFG.SHTNAK位由软件设置为1时，USBHS在识别到传输完成时将PID设置为NAK
- USBHS将PID设置为STALL(11b)在接收到有效载荷超过所选管道的最大数据包大小的数据包时
- USBHS在设备控制器模式下检测到USB总线复位时将PID设置为NAK
- USBHS在主机控制器模式下连续3次检测到接收错误（例如CRC错误）时将PID设置为NAK
- USBHS在主机控制器模式下接收到STALL握手时将PID设置为STALL(11b)。

要指定响应类型，请按如下方式设置PID[1:0]位：

- 要从NAK(00b)转换到STALL，请设置10b
- 要从BUF(01b)转换到STALL，请设置11b
- 要从STALL(11b)转换到NAK，请设置10b，然后设置00b
- 要从STALL转换到BUF，请设置00b(NAK)，然后设置01b(BUF)。

Table 33.10 USBHS在主机控制器模式下基于PIPEnCTR.PID[1:0]设置的操作

PID[1:0] value	传输类型（TYPE[1:0]值）	传输方向（DIR值）	USBHS operation
00b (NAK)	不依赖于设置	不依赖于设置	不发行代币
01b (BUF)	批量或中断	不依赖于设置	当DVSTCTR0.UACT位为1并且与所选管道关联的FIFO缓冲区已准备好进行发送和接收时，发出令牌。当DVSTCTR0.UACT位为0或与所选管道关联的FIFO缓冲区未准备好进行发送或接收时，不发出令牌。
	Isochronous	不依赖于设置。	当DVSTCTR0.UACT位为1时发出令牌，无论与所选管道关联的FIFO缓冲区的状态如何。当UACT=0时不发行令牌。
10b (STALL) or 11b (STALL)	不依赖于设置。	不依赖于设置。	不发行代币。

Table 33.11 Operation of the USBHS based on the PIPEnCTR.PID[1:0] setting in device controller mode

PID[1:0] value	Transfer type (TYPE[1:0] value)	Transfer direction (DIR value)	USBHS operation
00b (NAK)	Bulk or Interrupt	Does not depend on the setting	Returns NAK in response to the token from the USB host
	Isochronous	Receiving direction (DIR = 0)	Returns nothing in response to the token from the USB host
		Transmitting direction (DIR = 1)	Transmits a zero-length packet in response to the token from the USB host
01b (BUF)	Bulk	Receiving direction (DIR = 0)	Receives data and returns ACK or NYET in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, returns NAK. Returns ACK in response to the PING token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, returns NAK.
	Interrupt	Receiving direction (DIR = 0)	Receives data and returns ACK response in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, returns NAK.
	Bulk or Interrupt	Transmitting direction (DIR = 1)	Transmits data in response to the token from the USB host if the FIFO buffer associated with the selected pipe is ready for transmission. Otherwise, returns NAK.
	Isochronous	Receiving direction (DIR = 0)	Receives data in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, discards the data.
		Transmitting direction (DIR = 1)	Transmits data in response to the token from the USB host if the associated FIFO buffer is ready for transmission. Otherwise, transmits a zero-length packet.
10b (STALL) or 11b (STALL)	Bulk or Interrupt	Does not depend on the setting.	Returns STALL in response to the token from the USB host
	Isochronous	Does not depend on the setting.	Returns nothing in response to the token from the USB host

PBUSY flag (Pipe Busy Flag)

The PBUSY flag indicates whether the selected pipe is being used for the current transaction.

The USBHS changes the PBUSY bit from 0 to 1 on start of the USB transaction for the selected pipe, and changes the PBUSY bit from 1 to 0 on completion of one transaction.

Reading the PBUSY bit by software after PID is set to NAK allows you to check whether changing the pipe setting is possible. For details, see section 33.3.7.1, Pipe control register switching procedures.

SQMON flag (Sequence Toggle Bit Monitor Flag)

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.

When the selected pipe is not the isochronous transfer type, the USBHS toggles the SQMON flag on successful completion of the transaction. However, the USBHS does not toggle the SQMON flag when a DATA-PID mismatch occurs during transfer in the receiving direction.

SQSET bit (Sequence Toggle Bit Set)

Setting the SQSET bit to 1 through the software causes the USBHS to set DATA1 as the expected value of the sequence toggle bit for the next transaction on the selected pipe.

SQCLR bit (Sequence Toggle Bit Clear)

Setting the SQCLR bit to 1 through the software causes the USBHS to clear the expected value of the sequence toggle bit for the next transaction on the selected pipe to DATA0.

Table 33.11 USBHS在设备控制器模式下基于PIPEnCTR.PID[1:0]设置的操作

PID[1:0] value	传输类型（TYPE[1:0]值）	传输方向（DIR值）	USBHS operation
00b (NAK)	批量或中断	不依赖于设置	返回NAK以响应来自USB主机的令牌
	Isochronous	接收方向(DIR=0)	响应来自USB主机的令牌，不返回任何内容
		发射方向(DIR=1)	传输一个长度为零的数据包以响应来自USB主机的令牌
01b (BUF)	Bulk	接收方向(DIR=0)	如果与所选管道关联的FIFO缓冲区已准备好接收，则接收数据并返回ACK或NYET以响应来自USB主机的OUT令牌。否则，返回NAK。如果与所选管道关联的FIFO缓冲区已准备好接收，则返回ACK以响应来自USB主机的PING令牌。否则，返回NAK。
	Interrupt	接收方向(DIR=0)	如果与所选管道关联的FIFO缓冲区已准备好接收，则接收数据并返回ACK响应以响应来自USB主机的OUT令牌。否则，返回NAK。
	批量或中断	发射方向(DIR=1)	如果与所选管道关联的FIFO缓冲区已准备好传输，则传输数据以响应来自USB主机的令牌。否则，返回NAK。
	Isochronous	接收方向(DIR=0)	如果与所选管道关联的FIFO缓冲区已准备好接收，则接收数据以响应来自USB主机的OUT令牌。否则，丢弃数据。
		发射方向(DIR=1)	如果关联的FIFO缓冲区已准备好传输，则传输数据以响应来自USB主机的令牌。否则，发送零长度数据包。
10b (STALL) or 11b (STALL)	批量或中断	不依赖于设置。	返回STALL以响应来自USB主机的令牌
	Isochronous	不依赖于设置。	响应来自USB主机的令牌，不返回任何内容

PBUSY标志（管道忙标志）

PBUSY标志指示所选管道是否正在用于当前事务。

USBHS在所选管道的USB事务开始时将PBUSY位从0更改为1，并更改PBUSY位在一个事务完成时从1变为0。

在PID设置为NAK后，通过软件读取PBUSY位可以检查是否可以更改管道设置。详见33.3.7.1管道控制寄存器切换流程。

SQMON标志（序列切换位监视器标志）

SQMON标志指示所选管道的下一个事务的序列切换位的预期值。

当所选管道不是同步传输类型时，USBHS在事务成功完成时切换SQMON标志。但是，当在接收方向的传输过程中发生DATA-PID不匹配时，USBHS不会触发SQMON标志。

SQSET位（序列切换位设置）

通过软件将SQSET位设置为1会导致USBHS将DATA1设置为所选管道上下一个事务的序列切换位的预期值。

SQCLR位（序列切换位清除）

通过软件将SQCLR位设置为1会导致USBHS将所选管道上下一个事务的序列切换位的预期值清除为DATA0。

In host controller mode, when this bit is set to 1 for a bulk OUT transfer pipe, the USBHS starts the next transfer for the selected pipe from a PING token.

ACLRM bit (Auto Buffer Clear Mode)

The ACLRM bit enables or disables auto buffer clear mode for the selected pipe. To completely clear the data in the FIFO buffer allocated to the selected pipe, write 1 and then 0 to the ACLRM bit continuously.

Table 33.12 shows the data cleared by writing 1 and 0 continuously to the ACLRM bit and the cases in which this processing is required.

Table 33.12 Data cleared by the USBHS when ACLRM = 1

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear
1	All data in the FIFO buffer allocated to the selected pipe (two FIFO buffers in double buffer mode)	When clearing all data in the FIFO buffer allocated to the selected pipe
2	Interval count value when the selected pipe is the isochronous transfer type	When resetting the interval count value

ATREPM bit (Auto Response Mode)

The ATREPM bit enables or disables auto response mode for the selected pipe.

This bit can be set to 1 in device controller mode when the selected pipe is the bulk transfer type. When the bit is set to 1, the USBHS responds to the token from the USB host as follows:

- When the selected pipe is set for bulk IN transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 1):
  a. When the ATREPM bit = 1 and PID = BUF, the USBHS transmits a zero-length packet in response to the IN token.
  b. The USBHS updates (allows toggling of) the sequence toggle bit (DATA-PID) each time the USBHS receives ACK from the USB host. In a single transaction, the IN token is received, a zero-length packet is transmitted, and then ACK is received. The USBHS does not generate the BRDY or BEMP interrupt.
- When the selected pipe is set for bulk OUT transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 0):

  When the ATREPM bit = 1 and PID = BUF, the USBHS returns NAK in response to the OUT token or PING token and generates an NRDY interrupt.

For USB communication in auto response mode, set the ATREPM bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode. When the selected pipe uses isochronous transfer, always set this bit to 0.

In host controller mode, always set the ATREPM bit to 0.

CSSTS flag (CSSTS Status Flag)

In host controller mode, the CSSTS flag indicates the complete-split status of a split transaction. It is valid for pipes that are not the isochronous transfer type.

The USBHS sets the CSSTS flag to 1 at the beginning of the complete-split transaction, and sets the CSSTS flag to 0 on detecting completion of the complete-split transaction. If a detach event is detected during the transaction, the CSSTS flag might stay set to 1. In this case, clear the CSSTS flag by setting the CSCLR bit to 1.

Values read from the CSSTS flag in device controller mode are invalid.

CSCLR bit (CSPLIT Status Clear)

In host controller mode, if the software sets the CSCLR bit to 1, the USBHS clears the CSSTS flag to 0. In split transactions, set the CSCLR bit to 1 by software to force the next transfer to restart from start-split. Because the USBHS automatically clears the CSSTS flag to 0 at the end of a successful complete-split transaction in a normal split transaction, clearing the flag through software is not required. Only clear the CSSTS flag using the CSCLR bit when the DVSTCTR0.UACT bit is set to 0 or when no transfer was made after a detach detect. If the CSCLR bit is set to 1 while the CSSTS flag is 0, the CSSTS flag remains 0.

In device controller mode, always write 0 to the CSCLR bit.

在主机控制器模式下，当该位为批量OUT传输管道设置为1时，USBHS从PING令牌开始选定管道的下一次传输。

ACLRM位（自动缓冲区清除模式）

ACLRM位启用或禁用所选管道的自动缓冲区清除模式。彻底清除数据库中的数据FIFO缓冲区分配给所选管道，向ACLRM位连续写入1和0。

表33.12显示了通过向ACLRM位连续写入1和0来清除的数据以及需要进行此处理的情况。

Table 33.12 当ACLRM=1时USBHS清除的数据

Number	通过设置ACLRM位清除数据	需要数据清楚的情况
1	FIFO缓冲区中的所有数据分配给所选管道（双缓冲区模式下的两个FIFO缓冲区）	清除分配给所选管道的FIFO缓冲区中的所有数据时
2	选择管道为等时传输类型时的间隔计数值	重置间隔计数值时

ATREPM位（自动响应模式）

ATREPM位启用或禁用所选管道的自动响应模式。

当所选管道为批量传输类型时，该位可以在设备控制器模式下设置为1。当该位设置为1时，USBHS响应来自USB主机的令牌，如下所示：

- 当所选管道设置为批量IN传输时（PIPECFG.TYPE[1:0]=01b和PIPECFG.DIR=1）：

  一个。当ATREPM位=1且PID=BUF时，USBHS发送一个长度为零的数据包以响应IN令牌。

  湾。每次USBHS从USB主机接收到ACK时，USBHS都会更新（允许切换）序列切换位(DATA-PID)。在单个事务中，收到IN令牌，发送零长度数据包，然后收到ACK。USBHS不会产生BRDY或BEMP中断。

- 当所选管道设置为批量OUT传输时（PIPECFG.TYPE[1:0]=01b和PIPECFG.DIR=0）：

当ATREPM位=1且PID=BUF时，USBHS返回NAK以响应OUT令牌或PING令牌并产生NRDY中断。对于自动响应模式下的USB通信，当FIFO缓冲区为空时，将ATREPM位设置为1。在自动响应模式下的USB通信期间不要写入FIFO缓冲区。当所选管道使用同步传输时，始终将此位设置为0。

在主机控制器模式下，始终将ATREPM位设置为0。

CSSTS标志（CSSTS状态标志）

在主机控制器模式下，CSSTS标志指示拆分事务的完全拆分状态。它对非同步传输类型的管道有效。

USBHS在完成拆分事务开始时将CSSTS标志设置为1，并在检测到完成拆分事务完成时将CSSTS标志设置为0。如果在事务期间检测到分离事件，CSSTS标志可能保持设置为1。在这种情况下，通过将CSCLR位设置为1来清除CSSTS标志。

在设备控制器模式下从CSSTS标志读取的值无效。

CSCLR位（CSPLIT状态清除）

在主机控制器模式下，如果软件将CSCLR位设置为1，则USBHS将CSSTS标志清除为0。在拆分事务中，通过软件将CSCLR位设置为1，以强制下一次传输从start-split重新开始。由于USBHS在正常拆分事务中成功完成拆分事务结束时会自动将CSSTS标志清零，因此不需要通过软件清除该标志。仅当DVSTCTR0.UACT位设置为0或在分离检测后未进行传输时，才使用CSCLR位清除CSSTS标志。如果CSCLR位在CSSTS标志为0时设置为1，则CSSTS标志保持为0。

在设备控制器模式下，始终将0写入CSCLR位。

INBUFM flag (Transmit Buffer Monitor Flag)

The INBUMFM flag indicates the FIFO buffer status for the selected pipe in the transmitting direction.

When the selected pipe is set in the transmitting direction (PIPECFG.DIR = 1), the USBHS sets this bit to 1 when the CPU or DMA/DTC completes writing data to at least one FIFO buffer plane.

The USBHS sets this bit to 0 when the USBHS completes transmission of data from the FIFO buffer plane to which all the data is written. In double buffer mode (PIPECFG.DBLB = 1), the USBHS sets the INBUFM flag to 0 when the USBHS completes transmission of data from the two FIFO buffer planes before the CPU or DMA/DTC completes writing data to one FIFO buffer plane.

The INBUFM flag indicates the same value as the BSTS flag when the selected pipe is in the receiving direction (PIPECFG.DIR = 0).

BSTS flag (Buffer Status Flag)

The BSTS flag indicates the FIFO buffer status for the selected pipe. The meaning of the BSTS flag depends on the PIPECFG.DIR, PIPECFG.BFRE, and DnFIFOSEL.DCLRM settings, as shown in Table 33.13.

Table 33.13 BSTS flag operation

DIR value	BFRE value	DCLRM value	Meaning of BSTS flag
0	0	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read
		1	Setting prohibited
	1	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 when the software sets the BCLR bit in the port control register to 1 after the data read is complete
		1	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read
1	0	0	Sets to 1 when transmit data can be written to the FIFO buffer, and clears to 0 on completion of data write

INBUFM标志（发送缓冲区监控标志）

INBUMFM标志指示发送方向上所选管道的FIFO缓冲区状态。

当所选管道设置为发送方向（PIPECFG.DIR=1）时，USBHS将此位设置为1，此时CPU或DMADTC完成将数据写入至少一个FIFO缓冲平面。

当USBHS完成从写入所有数据的FIFO缓冲区平面的数据传输时，USBHS将该位设置为0。在双缓冲模式(PIPECFG.DBLB=1)中，当USBHS在CPU或DMADTC完成将数据写入一个FIFO缓冲平面之前完成从两个FIFO缓冲平面的数据传输时，USBHS将INBUFM标志设置为0。

当所选管道处于接收方向时（PIPECFG.DIR=0），INBUFM标志表示与BSTS标志相同的值。

BSTS标志（缓冲区状态标志）

BSTS标志指示所选管道的FIFO缓冲区状态。BSTS标志的含义取决于PIPECFG.DIR、PIPECFG.BFRE和DnFIFOSEL.DCLRM设置，如表33.13所示。

Table 33.13 BSTS标志操作

方向值	BFRE value	DCLRM value	BSTS标志的含义
0	0	0	当接收数据可以从FIFO缓冲区读取时设置为1，并在数据读取完成时清除为0

Note: 仅在PIPEnCTR.CSSTS标志为0且PIPEnCTR.PID[1:0]位为00b（NAK响应）时更改PIPEnTRE设置。仅将所选管道的PIPEnCTR.PID[1:0]位从01b（BUF响应）更改为00b（NAK响应）

after confirming that the value of the PIPEnCTR.PBUSY and PIPEnCTR.CSSTS flags is 0. However, software processing to check the PIPEnCTR.PBUSY flag is not required if the USBHS has changed the PID[1:0] bits to 00b (NAK response).

TRCLR bit (Transaction Counter Clear)

When the TRCLR bit sets to 1, the USBHS clears the count value of the transaction counter associated with the selected pipe and then clears the TRCLR bit to 0.

TRENB bit (Transaction Counter Enable)

The TRENB bit enables or disables the transaction counter.

For receiving pipes, setting the TRENB bit to 1 after setting the total number of the packets to be received in the PIPEnTRN.TRNCNT[15:0] bits through the software allows the USBHS to control hardware on having received the number of packets equal to the TRNCNT[15:0] setting as follows:

- When the PIPECFG.SHTNAK bit is 1, the USBHS changes the PID bits to NAK for the associated pipe on having received the number of packets equal to the TRNCNT[15:0] setting
- When the PIPECFG.BFRE bit is 1, the USBHS asserts the BRDY interrupt on having received the number of packets equal to the TRNCNT[15:0] setting and then reading the last received data.

For transmitting pipes, set the TRENB bit to 0.

When the transaction counter is not used, set this bit to 0. When the transaction counter is used, set the TRNCNT[15:0] bits before setting this bit to 1. Set this bit to 1 before receiving the first packet to be counted by the transaction counter.

33.2.40 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5)

Address(es): USBHS.PIPE1TRN 4006 0092h, USBHS.PIPE2TRN 4006 0096h, USBHS.PIPE3TRN 4006 009Ah, USBHS.PIPE4TRN 4006 009Eh, USBHS.PIPE5TRN 4006 00A2h

Bit	Symbol	Bit name	Description	R/W
b15 to b0	TRNCNT[15:0]	Transaction Counter*1	• When written to: Specifies the total packets (number of transactions) to be received by pipe n. • When read from: When PIPEnTRE.TRENB is 0, indicates the specified number of transactions. When PIPEnTRE.TRENB is 1, indicates the current transaction count.	R/W

Note 1. Only set the TRNCNT[15:0] bits while PID is NAK and PIPEnTRE.TRENB is 0. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

The PIPEnTRN registers retain their settings during a USB bus reset.

TRNCNT[15:0] bits (Transaction Counter)

The USBHS increments the value of the TRNCNT[15:0] bits by one when all of the following conditions are satisfied on receiving the packet:

- The PIPEnTRE.TRENB bit is 1
- (TRNCNT[15:0] set value ≠ current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[8:0] setting.

The USBHS clears the value of the TRNCNT[15:0] bits to 0 when any of the following conditions is satisfied.

在确认PIPEnCTR.PBUSY和PIPEnCTR.CSSTS标志的值为0之后。但是，如果USBHS已将PID[1:0]位更改为00b（NAK响应），则不需要检查PIPEnCTR.PBUSY标志的软件处理）。

TRCLR位（事务计数器清零）

当TRCLR位设置为1时，USBHS清除与所选管道关联的事务计数器的计数值，然后将TRCLR位清除为0。

TRENB位（事务计数器使能）

TRENB位启用或禁用事务计数器。

对于接收管道，在设置接收管道的总包数后，将TRENB位设置为1
PIPEnTRN.TRNCNT[15:0]位通过软件允许USBHS在接收到等于TRNCNT[15:0]设置的数据包数量时控制硬件，如下所示：

- 当PIPECFG.SHTNAK位为1时，USBHS在接收到等于TRNCNT[15:0]设置的数据包数量时将关联管道的PID位更改为NAK
- 当PIPECFG.BFRE位为1时，USBHS在接收到等于TRNCNT[15:0]设置的数据包数量时断言BRDY中断，然后读取最后接收到的数据。

对于传输管道，将TRENB位设置为0。

当不使用事务计数器时，将该位设置为0。当使用事务计数器时，将该位设置为1之前设置TRNCNT[15:0]位。在接收第一个要计数的数据包之前将该位设置为1由交易柜台。

Note 1. 仅在PID为NAK且PIPEnTRE.TRENB为0时设置TRNCNT[15:0]位。在设置这些位之前，请检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PIPEnCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查PBUSY标志。

PIPEnTRN寄存器在USB总线复位期间保留其设置。

TRNCNT[15:0]位（事务计数器）

当接收到数据包时满足以下所有条件时，USBHS将TRNCNT[15:0]位的值加一：

- PIPEnTRE.TRENB位为1
- (TRNCNT[15:0]设定值≠当前计数器值+1)收到数据包
- 接收到的数据包的有效负载与PIPEMAXP.MXPS[8:0]设置一致。

当满足以下任一条件时，USBHS将TRNCNT[15:0]位的值清零。

All of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value = current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[8:0] setting.

Both the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The USBHS received a short packet.

Both the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The PIPEnTRE.TRCLR bit was set to 1 by software.

For transmitting pipes, set the TRNCNT[15:0] bits to 0. When the transaction counter is not used, set the TRNCNT[15:0] bits to 0.

Setting the number of transactions to be transferred to the TRNCNT[15:0] bits is enabled only when the PIPEnTRE.TRENB bit is 0. To set the number of transactions to be transferred, set the TRCLR bit to 1 to clear the current counter value before setting the PIPEnTRE.TRENB bit to 1.

The DEVADDm register specifies the transfer speed of the peripheral device that is the communication target for pipes 0 to 9.

In host controller mode, set all DEVADDm bits before starting communication to any pipes. Only change the bits in DEVADDm when no valid pipes are using the bit settings. A valid pipe is defined as one that satisfies both of the following conditions:

- DEVADDm is selected in the DEVSEL[3:0] bits
- The PID[1:0] bits are set to BUF for the selected pipe, or the selected pipe is the DCP with the DCPCTR.SUREQ bit set to 1.

满足以下所有条件：

- PIPEnTRE.TRENB位=1
- (TRNCNT[15:0]设置值=当前计数器值+1)接收数据包时
- 接收到的数据包的有效负载与PIPEMAXP.MXPS[8:0]设置一致。

满足以下两个条件：

- PIPEnTRE.TRENB位=1
- USBHS收到一个短数据包。

满足以下两个条件：

- PIPEnTRE.TRENB位=1
- PIPEnTRE.TRCLR位由软件设置为1。

对于传输管道，将TRNCNT[15:0]位设置为0。当不使用事务计数器时，将TRNCNT[15:0]位设置为0。

设置要传输到TRNCNT[15:0]位的事务数仅在PIPEnTRE.TRENB位为0。要设置要传输的事务数，请将TRCLR位设置为1以清除当前计数器值，然后再将PIPEnTRE.TRENB位设置为1。

HWUPM bit (Resume Return Mode Setting)

The HWUPM bit specifies whether to enable hardware processing for return from low power mode even while the CPU clock is inactive.

In device controller mode, processing for return from low power mode on detecting Resume is enabled even while the CPU clock is inactive.

This bit specifies whether to detect Resume while the CPU clock is inactive. The PL1CTRL1.L1EXTMD bit controls whether to make a hardware return. To make a hardware return from the LPM L1 low power state while the CPU clock is inactive, set this bit and the PL1CTRL1.L1EXTMD bit to 1.

SUSPENDM bit (UTMI SuspendM Control)

The SUSPENDM bit controls the SuspendM signal to be sent to the PHY designed under the UTMI specification. The initial value is 0 with the UTMI is in suspension mode.

Set this bit to 1 to supply the PHY clock to operate the USB2.0 host or device controller.

In compliance with the UTMI specification, clock output is normally controlled by the SuspendM signal. When the SUSPENDM bit is 0, the clock to LINK is stopped. Because the PHY in this MCU follows the UTMI specification, setting the SUSPENDM bit to 1 is required to supply the PHY clock. For the clock settings, see section 33.3.3, Supplying the Clock.

When the SUSPENDM bit is 0, the USBHS cannot be written to but can be read from. The registers listed in Table 33.14 are writable even when the SUSPENDM bit is 0.

Table 33.14 Registers that can be written to by software when SUSPENDM = 0

Address	Register or bit name
4006 0000h	SYSCFG register

4006 0100h	LPCTRL register
4006 0102h	LPSTS register
4006 0140h	BCCTRL register

The value written to the SYSCFG register while the PHY clock is inactive is updated only after the PHY clock begins oscillating. The PHY clock oscillates in the following cases described in this section.

When SUSPENDM bit is set to 1, the PLLSTA.PLLLOCK flag is set to 1 after the predetermined time has passed. The USB-PHY internal PLL is stopped when the SUSPENDM bit is set to 0.

For details on CL-only mode, see section 33.2.17, PHY Setting Register (PHYSET).

If the PL1CTRL1.L1EXTMD bit is 0, setting or clearing of this bit is controlled by software. If the PL1CTRL1.L1EXTMD bit is 1, transitions to the L1 or L2 state of this bit are controlled by software and recovery from the L1 or L2 state is controlled by hardware.

SUSPENDM位（UTMISuspendM控制）

SUSPENDM位控制要发送到根据UTMI规范设计的PHY的SuspendM信号。初始值为0，UTMI处于暂停模式。

将此位设置为1以提供PHY时钟以操作USB2.0主机或设备控制器。

根据UTMI规范，时钟输出通常由SuspendM信号控制。当SUSPENDM位为0时，LINK的时钟停止。由于该MCU中的PHY遵循UTMI规范，因此需要将SUSPENDM位设置为1以提供PHY时钟。有关时钟设置，请参阅第33.3.3节，提供时钟。

当SUSPENDM位为0时，USBHS不能被写入但可以被读取。即使SUSPENDM位为0，表33.14中列出的寄存器也是可写的。

Table 33.14 SUSPENDM=0时软件可写入的寄存器

PHY时钟不活动时写入SYSCFG寄存器的值仅在PHY时钟开始振荡后更新。PHY时钟在本节所述的以下情况下振荡。

当SUSPENDM位设置为1时，PLLSTA.PLLLOCK标志在经过预定时间后设置为1。这
当SUSPENDM位设置为0时，USB-PHY内部PLL停止。

有关CL-only模式的详细信息，请参见第33.2.17节，PHY设置寄存器(PHYSET)。

如果PL1CTRL1.L1EXTMD位为0，则该位的设置或清除由软件控制。如果
PL1CTRL1.L1EXTMD位为1，转换到该位的L1或L2状态由软件控制，从L1或L2状态恢复由硬件控制。

IDPSRCE bit (IDPSRC Control)

In device controller mode, set the IDPSRCE bit to 1 to perform data contact detection.

The Battery Charging Standard provides two ways to handle data contact detection, one through the software and one using hardware to contact the data line. The IDPSRE bit uses the hardware method.

When the IDPSRE bit is set to 1, the USBHS enables the IDP_SRC circuit and, at the same time, controls D- pull-down. (D- pull-down is controlled with the VUH_DMPULLDOWN signal.)

IDMSINKE bit (IDMSINK Control)

In device controller mode, set the IDMSINKE bit to 1 to perform primary detection.

允许执行主要检测的设备确定充电器检测方法。

DCPMODE位（DCP模式控制）

将DCPMODE位设置为1可用作专用充电端口(DCP)。将此位设置为1将禁用USB通信。

CHGDETSTS标志（CHGDET状态标志）

CHGDETSTS标志指示充电器端口检测状态。

PDDETSTS标志（PDDET状态标志）

PDDETSTS标志根据控制器模式指示以下状态：

- 主控制器模式下：PD检测状态
- 在设备控制器模式下：DCP检测状态。

L1RESPEN位（L1响应使能）

如果USBHS在L1RESPEN位为0时接收到LPM令牌，则它不返回任何响应。如果USBHS收到一个

LPM token while this bit is 1, it returns a response based on the L1RESPMD[1:0] setting.

L1RESPMD[1:0] bits (L1 Response Mode)

When the L1RESPEN bit is set to 1, the USBHS returns a response to the LPM token based on the setting in the L1RESPMD[1:0] bits.

L1NEGOMD bit (L1 Response Negotiation Control)

The L1NEGOMD bit specifies the negotiation function for the HIRD value.

HIRDTHR[3:0] bits (L1 Response Negotiation Threshold Value)

The HIRDTHR[3:0] bits specify the HIRD threshold value used for L1NEGOMD. The format of the set value is the same as the HIRD field in HL1CTRL.

L1EXTMD bit (PHY Control Mode at L1 Return)

The L1EXTMD bit specifies the LPSTS.SUSPENDM bit control method when a host K signal is received in the L1 state while the LPSTS.SUSPENDM bit is 0 and the PHY is inactive.

Similar to the Suspend constraints, because the minimum host K period is 50 µs, the PHY might not recover within the host K period specified for software settings on return. The initial value is within software control, so set this bit to 1 during the initialization process when the L1 state is supported.

The LPSTS.SUSPENDM bit is controlled by software on transition to the L1 state regardless of the setting in this bit. It is not cleared by hardware.

When this bit is set to 1, the LPSTS.SUSPENDM bit is also set to 1 on return from L2.

HIRDMON[3:0] bits (HIRD Value Monitor)

Access the HIRDMON[3:0] bits when monitoring the HIRD field value of the received LPM token. The bits reflect the HIRD field value of the last received LPM token.

RWEMON bit (RWE Value Monitor)

Access the RWEMON bit when monitoring the RWE field value of the received LPM token. The bits reflect the RWE field value of the last received LPM token.

当该位为1时，LPM令牌会根据L1RESPMD[1:0]设置返回响应。

L1RESPMD[1:0]位（L1响应模式）

当L1RESPEN位设置为1时，USBHS根据
L1RESPMD[1:0] bits.

L1NEGOMD位（L1响应协商控制）

L1NEGOMD位指定HIRD值的协商功能。

HIRDTHR[3:0]位（L1响应协商阈值）

HIRDTHR[3:0]位指定用于L1NEGOMD的HIRD阈值。设置值的格式与HL1CTRL中的HIRD字段相同。

L1EXTMD位（L1返回时的PHY控制模式）

L1EXTMD位指定LPSTS.SUSPENDM位在L1状态下接收到主机K信号而LPSTS.SUSPENDM位为0且PHY处于非活动状态时的LPSTS.SUSPENDM位控制方法。

与挂起约束类似，由于最小主机K周期为50μs，因此PHY可能无法在返回时为软件设置指定的主机K周期内恢复。初始值在软件控制范围内，因此在支持L1状态的初始化过程中将此位设置为1。

LPSTS.SUSPENDM位在转换到L1状态时由软件控制，无论该位的设置如何。它不会被硬件清除。

当该位设置为1时，LPSTS.SUSPENDM位在从L2返回时也设置为1。

L1REQ bit (L1 Transition Request)

Set the L1REQ bit to 1 to transition to the L1 state. When the USBHS detects that this bit is 1, it starts the LPM transaction. The USBHS clears this bit to 0 through hardware on completion of the transaction.

L1STATUS[1:0] bits (L1 Request Completion Status)

The L1STATUS[1:0] bits indicate the result of the LPM transaction initiated by the L1REQ bit.

HIRD[3:0] bits (LPM Token HIRD)

The HIRD[3:0] bits specify the value to be set in the HIRD field of the LPM token that the USBHS transmits when the HL1CTRL1.L1REQ bit is set to 1. Table 33.15 shows the relationship between the HIRD settings and the HIRD field values.

Note: The set value of the HIRD bit is used for the host K drive period on host resume and for the host K period on remote wakeup.

L1RWE bit (LPM Token L1 RemoteWake Enable)

The L1RWE bit specifies the value to be set in the RWE field of the LPM token that the USBHS transmits when the HL1CTRL1.L1REQ bit is set to 1.

The USBHS does not control detection of the remote wakeup signal in the L1 state with this bit. The remote wakeup signal is controlled by the DVSTCTR0.RWUPE bit, as with Suspend.

BESL bit (BESL & Alternate HIRD)

The BESL bit selects the K-state drive period on L1 Resume. For details, see the description of the HIRD bits.

HIRD[3:0]位（LPM令牌HIRD）

HIRD[3:0]位指定要在USBHS发送的LPM令牌的HIRD字段中设置的值。
HL1CTRL1.L1REQ位设置为1。表33.15显示了HIRD设置和HIRD字段值之间的关系。

Table 33.15 HIRD位设置和HIRD字段值之间的关系

Note: HIRD位的设置值用于主机恢复时的主机K驱动周期和远程唤醒时的主机K周期。

L1RWE位（LPM令牌L1远程唤醒启用）

L1RWE位指定在USBHS发送的LPM令牌的RWE字段中设置的值。
HL1CTRL1.L1REQ位设置为1。

USBHS不通过该位控制L1状态下远程唤醒信号的检测。远程唤醒信号由DVSTCTR0.RWUPE位控制，与挂起一样。

BESL位（BESL和备用HIRD）

BESL位选择L1Resume上的K状态驱动周期。有关详细信息，请参见HIRD位的说明。

33.3 Operation

33.3.1 System Control

This section describes register settings required for initializing the USBHS and controlling power consumption.

33.3.1.1 Setting data to the USBHS registers

Setting the SYSCFG.USBE bit to 1 after starting the PHY clock supply enables and starts USBHS operation. For information on how to supply the PHY clock, see section 33.3.3, Supplying the Clock.

33.3.1.2 Selecting the controller function

The USBHS can operate as a host or device controller.

Use the SYSCFG.DCFM bit to select one of these USBHS functions. The DCFM bit must be changed in the initial settings immediately after a reset or in the D+ pull-up-disabled state (SYSCFG.DPRPU bit = 0) and D+ and D- pull-down-disabled state (SYSCFG.DRPD bit = 0).

33.3.2 Controlling the USB data bus using resistors

The USBHS provides pull-up and pull-down resistors for the D+ and D- lines. Pull these lines up or down by setting the SYSCFG.DPRPU and DRPD bits.

In device controller mode, confirm that connection to the USB host is made, and then set the SYSCFG.DPRPU bit to 1 and pull up the D+ line (in full-speed communication).

When the SYSCFG.DPRPU bit is set to 0 during communication with a PC, the USBHS disables the pull-up resistor for the USB data line, thereby notifying the USB host of disconnection.

In host controller mode, set the SYSCFG.DRPD bit to 1 to pull down the D+ and D- lines.

Table 33.16 shows the settings for controlling the resistors for the USB data bus. Control the USB data bus appropriately for your system using the DRPD and DPRPU bit settings.

Table 33.16 Control settings for the USB data bus resistors (excluding OTG operation)

DRPD bit	**DPRPU bit**	**D-Line**	**D+Line**	**Function**
0	0	Open	Open	When resistors not used
0	1	Open	Pull-Up	When operating as a device controller at full-speed
1	0	Pull-Down	Pull-Down	When operating as a host controller
1	1	—	—	Setting prohibited except during OTG operation

33.3.3 Supplying the Clock

Table 33.17 shows the two input clocks required for the USBHS.

Table 33.17 Input clocks

Input clock name	Description
PCLKA	Peripheral module clock A input. There is no constraint on the frequency of the PCLKA input.
PHY clock	PHY clock generated from external input or internal supply • External input: The clock is generated by the USB-PHY internal PLL based on a 12-MHz, 20-MHz, or 24-MHz clock supplied to the EXTAL pin from outside the MCU. For the external clock specifications, especially the jitter characteristics, strictly follow the specifications of ±50 ppm. • Internal supply: The clock is generated by supplying 48 MHz and 60 MHz to the USB-PHY module and selecting CL-only mode (PHYSET.HSEB). High-speed operation is not supported with this mode.

33.3 Operation

33.3.1 系统控制

本节介绍初始化USBHS和控制功耗所需的寄存器设置。

33.3.1.1 将数据设置到USBHS寄存器

启动PHY时钟电源后将SYSCFG.USBE位设置为1使能并启动USBHS操作。有关如何提供PHY时钟的信息，请参阅第33.3.3节，提供时钟。

33.3.1.2 选择控制器功能

USBHS可以作为主机或设备控制器运行。

使用SYSCFG.DCFM位选择这些USBHS功能之一。DCFM位必须在复位后立即更改为初始设置或在D+上拉禁用状态（SYSCFG.DPRPU位=0）和D+和Dpulldown禁用状态（SYSCFG.DRPD位=0）。

33.3.2 使用电阻控制USB数据总线

USBHS为D+和Dlines提供上拉和下拉电阻。通过设置SYSCFG.DPRPU和DRPD位。

在设备控制器模式下，确认与USB主机的连接已建立，然后将SYSCFG.DPRPU位设置为1并拉高D+线（全速通信）。

当SYSCFG.DPRPU位在与PC通信期间设置为0时，USBHS禁用USB数据线的上拉电阻，从而通知USB主机断开连接。

在主机控制器模式下，将SYSCFG.DRPD位设置为1以拉低D+和Dlines。

表33.16显示了用于控制USB数据总线电阻器的设置。使用DRPD和DPRPU位设置为您的系统适当控制USB数据总线。

Table 33.16 USB数据总线电阻的控制设置（不包括OTG操作）

DRPD bit	**DPRPU bit**	**D-Line**	**D+Line**	**Function**
0	0	Open	Open	不使用电阻时
0	1	Open	Pull-Up	作为设备控制器全速运行时
1	0	Pull-Down	Pull-Down	作为主机控制器运行时

33.3.3 提供时钟

表33.17显示了USBHS所需的两个输入时钟。

Table 33.17 输入时钟

输入时钟名称	Description
PCLKA	外设模块时钟A输入。 PCLKA输入的频率没有限制。
PHY clock	从外部输入或内部电源生成的PHY时钟外部输入： 时钟由USB-PHY内部PLL基于从MCU外部提供给EXTAL引脚的12-MHz、20-MHz或24-MHz时钟生成。对于外部时钟规范，尤其是抖动特性，严格遵循±50ppm的规范。 内部供应： 通过向USB-PHY模块提供48MHz和60MHz并选择仅CL模式(PHYSET.HSEB)。此模式不支持高速操作。

Figure 33.2 illustrates the PHY clock settings.

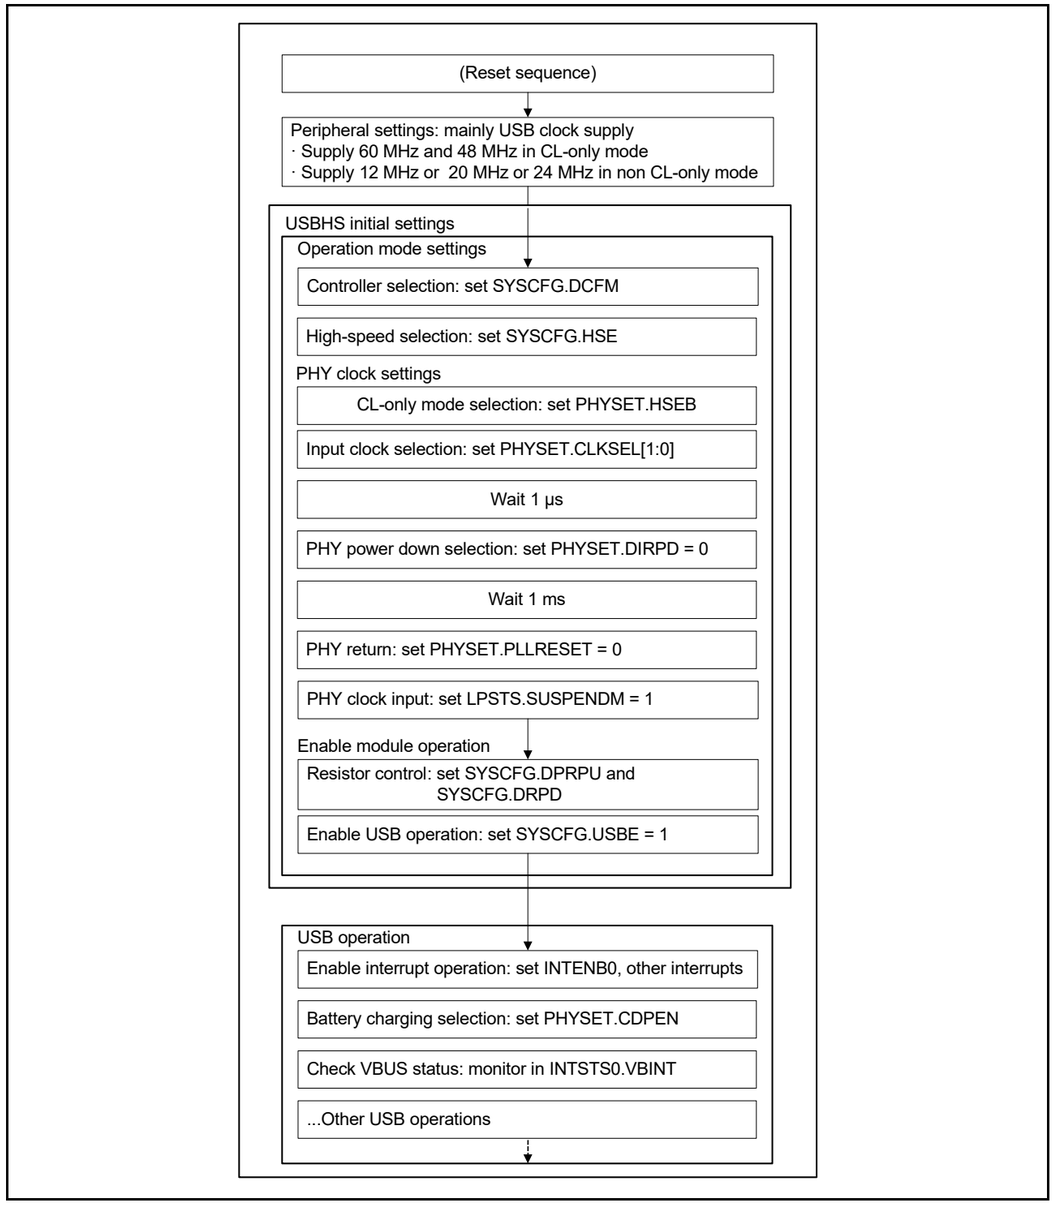

Figure 33.2 PHY clock settings

33.3.4 Constraints on Stopping the Clock

PCLKA and PHY clock can be stopped during disconnection or suspension. However, to stop any of these clocks while the USB is suspended in device controller mode, the stopped clock must be resupplied using the resume interrupt. The PHY clock must be resupplied within 5.5 ms after the resume interrupt is generated.

图33.2说明了PHY时钟设置。

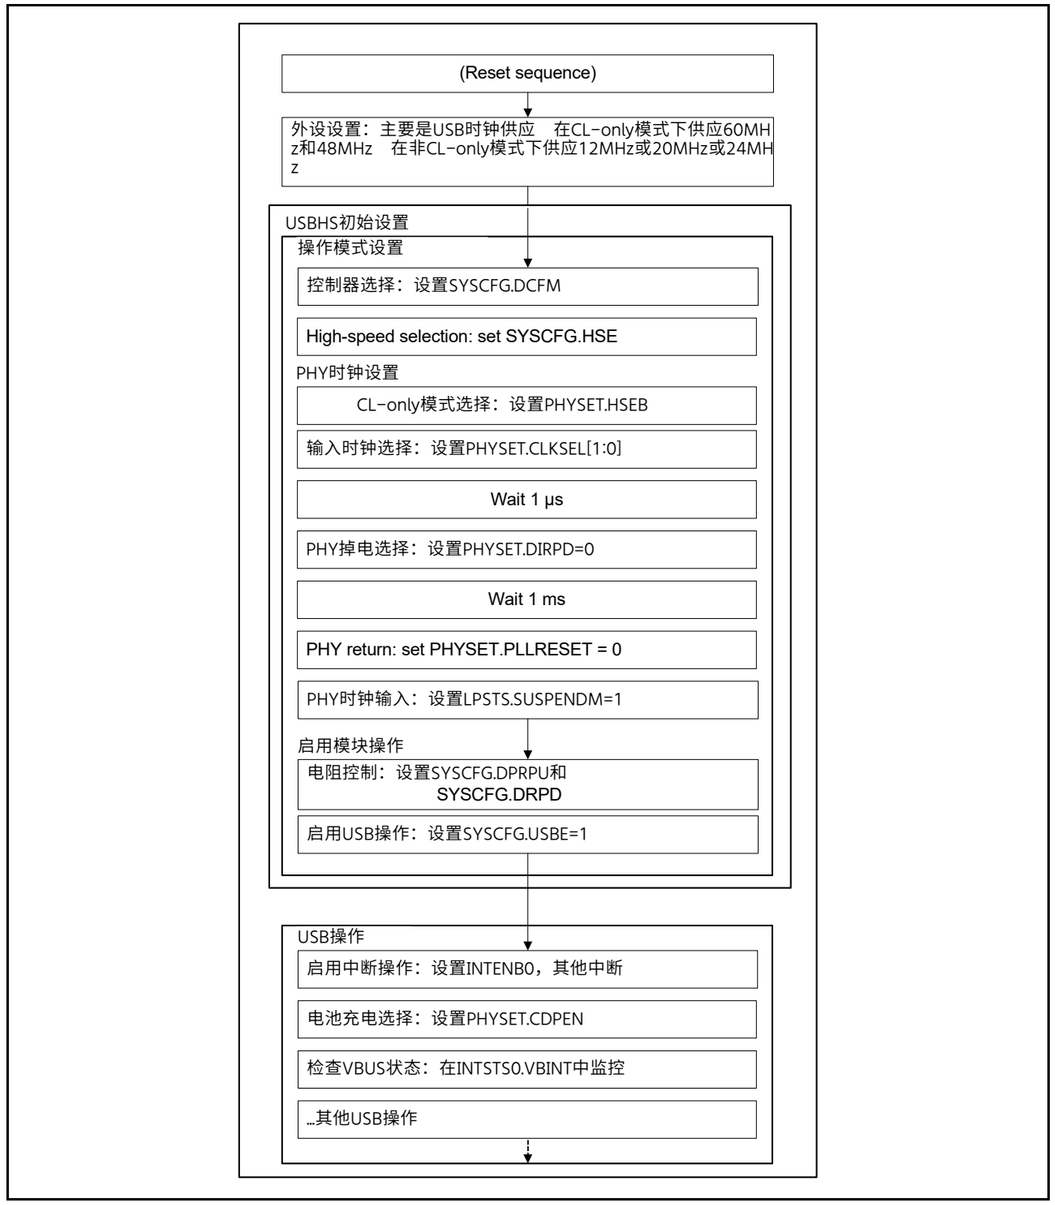

Figure 33.2 PHY时钟设置

33.3.4 停止时钟的限制

PCLKA和PHY时钟可以在断开或挂起期间停止。但是，要在USB在设备控制器模式下暂停时停止任何这些时钟，必须使用恢复中断重新提供停止的时钟。PHY时钟必须在产生恢复中断后的5.5ms内重新提供。

33.3.5 Interrupts

Table 33.18 lists the interrupt sources in the USBHS. When an interrupt generation condition is satisfied and the interrupt output is enabled using the associated interrupt enable register, the USBHS issues a USBHS interrupt request to the Interrupt Controller Unit (ICU) and a USBHS interrupt is generated.

Note 1. Although this interrupt can be generated in host controller mode, it is not usually used in this mode.

33.3.5.1 Selecting the USBHS interrupt detection method

Table 33.19 shows operations for an USBHS interrupt output from the USBHS. In case two or more interrupt sources are generated, the USBHS interrupt output method can be set in the SOFCFG.INTL bit. Set the USBHS interrupt output operation based on your system.

Table 33.19 USBHS interrupt operation

33.3.6 Interrupt Descriptions

33.3.6.1 BRDY interrupt

The BRDY interrupt is generated in both host and device controller modes. This section describes the conditions in which the USBHS sets the associated bit in BRDYSTS to 1. Under these conditions, the USBHS generates a BRDY interrupt if the software sets the bit in BRDYENB associated with the given pipe to 1 and INTENB0.BRDYE bit to 1.

The conditions for generating and clearing the BRDY interrupt depend on the SOFCFG.BRDYM and PIPECFG.BFRE settings for each pipe as follows:

(1) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.

On any of the following conditions, the USBHS generates an internal BRDY interrupt request trigger and sets the BRDYSTS.PIPEBRDY flag associated with the pipe to 1.

(a) For transmitting pipes

- When the DIR bit is changed from 0 to 1 by software
- When writing by the CPU to the FIFO buffer is disabled for a pipe (when the BSTS flag is read as 0) and the USBHS has completed packet transmission. In continuous transfer, a BRDY interrupt is generated on completion of the transmission of data from one FIFO buffer.
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is complete
- When the hardware flushes the buffer of the pipe for isochronous transfers
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to transition from the write-disabled to write-enabled state.

No request trigger is generated for the DCP, that is, during data transmission for control transfers.

(b) For receiving pipes

- When packet reception is successfully complete, enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the given pipe is disabled (when the BSTS flag is read as 0). No request trigger is generated for transactions in which DATA-PID mismatch has occurred. In continuous transmission or reception mode, the request trigger is not generated when the data is of the specified maximum packet size and the buffer has available space. When a short packet is received, the request trigger is generated even if the FIFO buffer has available space. When the transaction counter is used, the request trigger is generated on receiving the specified number of packets. In this case, the request trigger is generated even if the FIFO buffer has available space.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode. No request trigger is generated until completion of reading data from the currently-read FIFO buffer, even if reception by the other FIFO buffer is complete.

33.3.6 中断说明

33.3.6.1 BRDY interrupt

在主机和设备控制器模式下都会产生BRDY中断。本节介绍USBHS将BRDYSTS中的相关位设置为1的条件。在这些条件下，如果软件将与给定管道相关的BRDYENB中的位设置为1，并且将INTENB0.BRDYE位设置为1，USBHS将生成BRDY中断.

产生和清除BRDY中断的条件取决于每个管道的SOFCFG.BRDYM和PIPECFG.BFRE设置，如下所示：

(1) 当SOFCFG.BRDYM=0且PIPECFG.BFRE=0时

通过这些设置，BRDY中断指示FIFO端口可访问。

在以下任何一种情况下，USBHS产生一个内部BRDY中断请求触发并设置与管道关联的BRDYSTS.PIPEBRDY标志为1。

(a) 用于传输管道

- 当DIR位由软件从0变为1时
- 当CPU对FIFO缓冲区的写入被禁用时（当BSTS标志被读取为0时）并且USBHS已完成数据包传输。在连续传输中，一个FIFO缓冲区的数据传输完成时会产生一个BRDY中断。
- 双缓冲模式下，当一个FIFO缓冲区在完成向另一个FIFO缓冲区写入数据时为空时
- 直到完成向当前写入的FIFO缓冲区写入数据之前，不会生成请求触发，即使传输到另一个FIFO缓冲区已完成
- 当硬件刷新管道缓冲区以进行同步传输时
- 当1写入PIPEnCTR.ACLRM位时，这会导致FIFO缓冲区从写禁止状态转换为写使能状态。

没有为DCP生成请求触发，即在控制传输的数据传输期间。

(b) 用于接收管道

- 当数据包接收成功完成时，允许读取FIFO缓冲区，同时禁用从CPU对给定管道的FIFO缓冲区的读取访问（当BSTS标志被读取为0时）。对于发生DATA-PID不匹配的事务，不会生成请求触发器。在连续发送或接收模式下，当数据达到指定的最大数据包大小且缓冲区有可用空间时，不会生成请求触发。当接收到一个短数据包时，即使FIFO缓冲区有可用空间，也会生成请求触发。当使用事务计数器时，在接收到指定数量的数据包时生成请求触发器。在这种情况下，即使FIFO缓冲区有可用空间，也会生成请求触发。
- 当一个FIFO缓冲区在双缓冲区模式下完成从另一个FIFO缓冲区读取数据后启用读取。在从当前读取的FIFO缓冲区读取数据完成之前，不会生成请求触发，即使其他FIFO缓冲区的接收已完成。

In device controller mode, the BRDY interrupt is not generated in the status stage of control transfers. The PIPEBRDY interrupt status of the selected pipe can be set to 0 by writing 0 to the associated PIPEBRDY flag through the software. In this case, 1s must be written to the associated bits for the other pipes. Clear the BRDY status before accessing the FIFO buffer.

(2) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 1

With these settings, the USBHS generates a BRDY interrupt on completion of reading all data for a single transfer using the receiving pipe, and sets the bit in BRDYSTS associated with the pipe to 1.

On any of the following conditions, the USBHS determines that the last data for a single transfer was received:

- When a short packet including a zero-length packet is received
- When the PIPEnTRN register is used and the number of packets specified in the PIPEnTRN.TRNCNT[15:0] bits are completely received.

When the data is completely read after any of these conditions is satisfied, the USBHS determines that all data for a single transfer is completely read.

When a zero-length packet is received while the FIFO buffer is empty, the USBHS determines that all data for a single transfer is completely read when the FRDY flag in the FIFO port control register is 1 and the DTLN[11:0] flags are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the associated port control register through software. With these settings, the USBHS does not detect a BRDY interrupt for the transmitting pipe.

The PIPEBRDY interrupt status of a pipe can be set to 0 by writing 0 to the associated BRDYSTS.PIPEBRDY flag through the software. In this case, 1s must be written to the PIPEBRDY bits for the other pipes.

In this mode, do not change the PIPECFG.BFRE bit setting until all data for a single transfer is processed. When it is necessary to change the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pipe must be cleared using the PIPEnCTR.ACLRM bit.

(3) When SOFCFG.BRDYM = 1 and PIPECFG.BFRE = 0

With these settings, the BRDYSTS.PIPEBRDY flag values are linked to the BSTS flag setting for each pipe. In other words, the BRDY interrupt status bits are set to 1 or 0 by the USBHS depending on the FIFO buffer status.

(a) For transmitting pipes

The BRDY interrupt status bits are set to 1 when the FIFO port is ready for write access, and are set to 0 when it is not ready. The BRDY interrupt is not generated for the DCP in the transmitting direction even when it is ready for write access.

(b) For receiving pipes

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for read access, and are set to 0 when all data is read (not ready for read access).

When a zero-length packet is received while the FIFO buffer is empty, the associated bit is set to 1 and the BRDY interrupt is continuously generated until the software writes 1 to BCLR. With this setting, the PIPEBRDY flag cannot be set to 0 by software.

When the SOFCFG.BRDYM bit is set to 1, set the PIPECFG.BFRE bit for all pipes to 0, and the SOFCFG.INTL bit to 1 for level detection.

Figure 33.5 shows the timing of BRDY interrupt generation.

在设备控制器模式下，在控制传输的状态阶段不会产生BRDY中断。通过软件将0写入相关的PIPEBRDY标志，可以将所选管道的PIPEBRDY中断状态设置为0。在这种情况下，必须将1写入其他管道的相关位。在访问FIFO缓冲区之前清除BRDY状态。

(2) 当SOFCFG.BRDYM=0且PIPECFG.BFRE=1时

使用这些设置，USBHS在完成使用接收管道读取一次传输的所有数据时生成BRDY中断，并将BRDYSTS中与管道相关的位设置为1。

在以下任何一种情况下，USBHS都会确定接收到单次传输的最后一个数据：

- 当接收到包含零长度数据包的短数据包时
- 当使用PIPEnTRN寄存器并且完全接收到PIPEnTRN.TRNCNT[15:0]位中指定的数据包数量时。

当满足这些条件中的任何一个后数据被完全读取时，USBHS确定单次传输的所有数据都被完全读取。

当FIFO缓冲区为空时接收到零长度数据包时，当FIFO端口控制寄存器中的FRDY标志为1且DTLN[11:0]标志为0.在这种情况下，要开始下一次传输，通过软件向相关端口控制寄存器中的BCLR位写入1。使用这些设置，USBHS不会检测到传输管道的BRDY中断。

通过软件将0写入相关的BRDYSTS.PIPEBRDY标志可以将管道的PIPEBRDY中断状态设置为0。在这种情况下，必须将1写入其他管道的PIPEBRDY位。

在此模式下，在处理完单次传输的所有数据之前，不要更改PIPECFG.BFRE位设置。当需要在处理完成之前更改PIPECFG.BFRE位时，必须使用PIPEnCTR.ACLRM位清除管道的所有FIFO缓冲区。

(3) 当SOFCFG.BRDYM=1且PIPECFG.BFRE=0时

通过这些设置，BRDYSTS.PIPEBRDY标志值链接到每个管道的BSTS标志设置。换言之，BRDY中断状态位由USBHS设置为1或0，具体取决于FIFO缓冲区状态。

(a) 用于传输管道

当FIFO端口准备好进行写访问时，BRDY中断状态位设置为1，当它未准备好时设置为0。发送方向上的DCP不会产生BRDY中断，即使它已准备好进行写访问。

(b) 用于接收管道

当FIFO缓冲区准备好进行读取访问时，BRDY中断状态位设置为1，当读取所有数据（未准备好进行读取访问）时设置为0。

当FIFO缓冲区为空时接收到零长度数据包时，相关位设置为1，并且持续产生BRDY中断，直到软件将1写入BCLR。使用此设置，PIPEBRDY标志不能由软件设置为0。

当SOFCFG.BRDYM位设置为1时，将所有管道的PIPECFG.BFRE位设置为0，并将SOFCFG.INTL位设置为1以进行电平检测。

图33.5显示了BRDY中断产生的时序。

The condition for clearing the INTSTS0.BRDY flag depends on the SOFCFG.BRDYM bit setting value, as shown in Table 33.21.

33.3.6.2 NRDY interrupt

On generating an internal NRDY interrupt request for the pipe whose PID[1:0] bits are set to 01b (BUF response) by software, the USBHS sets the associated NRDYSTS.PIPENRDY flag to 1. If the associated bit in NRDYENB is set to 1 by software, the USBHS sets the INTSTS0.NRDY flag to 1 and generates a USBHS interrupt.

This section describes the conditions in which the USBHS generates the internal NRDY interrupt request for a given

33.3.6.2 NRDY interrupt

在为PID[1:0]位被软件设置为01b（BUF响应）的管道生成内部NRDY中断请求时，USBHS将相关的NRDYSTS.PIPENRDY标志设置为1。如果NRDYENB中的相关位设置为通过软件置1，USBHS将INTSTS0.NRDY标志设置为1并产生USBHS中断。

The internal NRDY interrupt request is not generated during setup transaction execution in host controller mode. During setup transactions in host controller mode, the SACK or SIGN interrupt is detected.

The internal NRDY interrupt request is not generated during status stage execution of the control transfer in device controller mode.

(1) In host controller mode when no split transactions occur in the connection

(a) For transmitting pipes

On any of the following conditions, the USBHS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS transmits a zero-length packet following the OUT token and sets the associated NRDYSTS.PIPENRDY flag and the FRMNUM.OVRN flag to 1.
- During communications other than setup transactions on pipes not used for isochronous transfers, when any combination of the following two conditions occurs three consecutive times:
  - No response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device
  - An error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the PID[1:0] setting for the associated pipe to 00b (NAK response)
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device (includes STALL for both OUT and PING). In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the PID[1:0] setting for the associated pipe to 11b (STALL response).

(b) For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBHS discards the received data for the IN token and sets the associated PIPENRDY flag and the OVRN flag to 1. When a packet error is detected in the received data for the IN token, the USBHS also sets the FRMNUM.CRCE flag to 1.
- For non-isochronous transfer pipes, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device for the IN token issued by the USBHS (when timeout is detected before detection of the DATA packet from the peripheral device)
  - An error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response).
- For isochronous transfer pipes, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1. The PID[1:0] setting for the pipe is not changed.
- For isochronous transfer pipes, when a CRC error or a bit stuffing error is detected in the received data packet. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe and the CRCE flag to 1.
- When the STALL handshake is received. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1 and changes the PID[1:0] setting for the associated pipe to STALL.

(2) In host controller mode when split transactions occur in the connection

(a) For transmitting pipes

On any of the following conditions, the USBHS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS sets the associated RDYSTS.PIPENRDY flag for the given pipes to 1 on issuing a start-split transaction and sets the FRMNUM.OVRN flag to 1. The USBHS also transmits a zero-length

内部NRDY中断请求在主控制器模式下的设置事务执行期间不会产生。在主机控制器模式下的设置事务期间，检测到SACK或SIGN中断。

在设备控制器模式下控制传输的状态阶段执行期间，不会产生内部NRDY中断请求。

(1) 在主机控制器模式下，连接中没有发生拆分事务

(a) 用于传输管道

在以下任何一种情况下，USBHS都会检测到NRDY中断：

- 对于同步传输管道，当发出OUT令牌的时间到来时，FIFO缓冲区中没有要传输的数据。在这种情况下，USBHS在OUT令牌之后发送一个长度为零的数据包，并将相关的NRDYSTS.PIPENRDY标志和FRMNUM.OVRN标志设置为1。
- 在不用于同步传输的管道上的设置事务以外的通信期间，当以下两种情况的任意组合连续发生3次时：
  - 外围设备没有返回响应（当在检测到来自外围设备的握手包之前检测到超时时
  - 在来自外围设备的数据包中检测到错误。在这种情况下，USBHS设置相关的PIPENRDY标志为1并将关联管道的PID[1:0]设置更改为00b（NAK响应）
- 在设置事务以外的通信期间，当从外围设备接收到STALL握手时（包括OUT和PING的STALL）。在这种情况下，USBHS将关联的PIPENRDY标志设置为1，并将关联管道的PID[1:0]设置更改为11b（STALL响应）。

(b) 用于接收管道

- 对于同步传输管道，当发出IN令牌的时间到来但FIFO缓冲区中没有可用空间时。在这种情况下，USBHS丢弃IN令牌的接收数据并将相关的PIPENRDY标志和OVRN标志设置为1。当在IN令牌的接收数据中检测到数据包错误时，USBHS也会设置FRMNUM.CRCE标志为1。
- 对于非等时传输管道，当下列两种情况的任意组合连续出现3次时：
  - USBHS发出的IN令牌没有从外围设备返回响应（当在检测到来自外围设备的DATA数据包之前检测到超时时）
  - 在来自外围设备的数据包中检测到错误。在这种情况下，USBHS设置相关的PIPENRDY标志为1并将管道的相关PID[1:0]设置更改为00b（NAK响应）。
- 对于同步传输管道，当外围设备没有返回对IN令牌的响应时（在检测到来自外围设备的DATA数据包之前检测到超时）或在来自外围设备的数据包中检测到错误。在这种情况下，USBHS将每个管道的相关NRDYSTS.PIPENRDY标志设置为1。管道的PID[1:0]设置不会更改。
- 对于同步传输管道，当在接收到的数据包中检测到CRC错误或位填充错误时。在这种情况下，USBHS为每个管道设置相关的NRDYSTS.PIPENRDY标志，并将CRCE标志设置为1。
- 当收到STALL握手时。在这种情况下，USBHS将每个管道的相关NRDYSTS.PIPENRDY标志设置为1，并将相关管道的PID[1:0]设置更改为STALL。

(a) 用于传输管道

在以下任何一种情况下，USBHS都会检测到NRDY中断：

- 对于同步传输管道，当发出OUT令牌的时间到来时，FIFO缓冲区中没有要传输的数据。在这种情况下，USBHS将给定管道的相关RDYSTS.PIPENRDY标志设置为1，然后将FRMNUM.OVRN标志设置为1。USBHS还传输零长度

- For non-isochronous transfer pipes, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for start-split and complete-split transactions (when timeout is detected before detection of the handshake packet from the hub)
  - An error is detected in the packet from the hub. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response).When an NRDY interrupt is detected on complete-split issuance, the USBHS clears the CSSTS flag to 0.
- When a STALL handshake is received for the complete-split transaction. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, changes the associated PID[1:0] setting for the pipe to 11b (STALL response), and clears the CSSTS flag to 0. An interrupt is not detected during setup transaction.

(b) For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the given pipe and the FRMNUM.OVRN flag to 1 on start-split issuance. The USBHS discards the received data for the IN token.
- During bulk-pipe transfers or transfers other than setup transactions with the DCP, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for the IN token the USBHS issued on issuance of the start-split or complete-split transactions (when timeout is detected before detection of the data packet from the hub)
  - An error is detected in the packet from the hub. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response). When this condition occurs during complete-split, the USBHS clears the CSSTS flag to 0.
- During a complete-split transaction for isochronous transfer or interrupt transfer pipes, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for the IN token issued by the USBHS (when a timeout is detected before detection of the DATA packet from the hub)
  - An error is detected in the packet from the hub. On generating this condition for an interrupt transfer pipe, the USBHS sets the associated NRDYSTS.PIPENRDY flag to 1, changes the associated PID[1:0] setting for the pipe to 00b (NAK response), and clears the CSSTS flag to 0. On generating this condition for the pipe for isochronous transfers, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, CRCE flag to 1, and clears the CSSTS bit to 0. It does not change the PID[1:0] setting.
- During a complete-split transaction, when the STALL handshake is received for a non-isochronous transfer pipe. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, changes the associated PID[1:0] setting for the pipe to 11b (STALL response), and clears the CSSTS flag to 0.
- During a complete-split transaction, when the NYET handshake is received for an isochronous transfer or interrupt transfer pipe for the microframe number = 4. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1 and the CRCE flag to 1, and clears the CSSTS flag to 0. It does not change the PID[1:0] setting.

  - 集线器没有响应开始拆分和完成拆分事务（在检测到来自集线器的握手数据包之前检测到超时）
  - 在来自集线器的数据包中检测到错误。在这种情况下，USBHS设置相关的管道的NRDYSTS.PIPENRDY标志为1，并将管道的相关PID[1:0]设置更改为00b（NAK响应）。当在发出完全拆分时检测到NRDY中断时，USBHS将CSSTS标志清除为0.
- 当收到完整拆分事务的STALL握手时。在这种情况下，USBHS将管道的相关NRDYSTS.PIPENRDY标志设置为1，将管道的相关PID[1:0]设置更改为11b（STALL响应），并将CSSTS标志清除为0。中断是在设置事务期间未检测到。

(b) 用于接收管道

- 对于同步传输管道，当发出IN令牌的时间到来但FIFO缓冲区中没有可用空间时。在这种情况下，USBHS将给定管道的相关NRDYSTS.PIPENRDY标志和FRMNUM.OVRN标志设置为1在开始拆分发布时。USBHS丢弃接收到的IN令牌数据。
- 在与DCP进行批量管道传输或设置交易以外的传输期间，当以下两种情况的任意组合连续发生3次时：
  - 没有从集线器返回对USBHS在发布开始拆分或完成拆分事务时发出的IN令牌的响应（当在检测到来自集线器的数据包之前检测到超时时）
  - 在来自集线器的数据包中检测到错误。在这种情况下，USBHS设置相关的管道的NRDYSTS.PIPENRDY标志为1，并将管道的相关PID[1:0]设置更改为00b（NAK响应）。如果在完全拆分期间发生这种情况，USBHS会将CSSTS标志清除为0。
- 在同步传输或中断传输管道的完全拆分事务期间，当以下两种情况的任意组合连续发生3次时：
  - 对于USBHS发出的IN令牌，集线器没有返回响应（在检测到来自集线器的DATA数据包之前检测到超时）
  - 在来自集线器的数据包中检测到错误。在为中断传输管道生成此条件时，USBHS将相关的NRDYSTS.PIPENRDY标志设置为1，将管道的相关PID[1:0]设置更改为00b（NAK响应），并将CSSTS标志清除为0。在为同步传输的管道生成此条件时，USBHS将管道的相关NRDYSTS.PIPENRDY标志设置为1，CRCE标志设置为1，并将CSSTS位清除为0。它不会更改PID[1:0]环境。
- 在完全拆分事务期间，当接收到非同步传输管道的STALL握手时。在这种情况下，USBHS将管道的相关NRDYSTS.PIPENRDY标志设置为1，将管道的相关PID[1:0]设置更改为11b（STALL响应），并将CSSTS标志清除为0。
- 在完全拆分事务期间，当微帧编号=4的同步传输或中断传输管道接收到NYET握手时。在这种情况下，USBHS将每个管道的相关NRDYSTS.PIPENRDY标志设置为1，并将CRCE标志设置为为1，并将CSSTS标志清除为0。它不会更改PID[1:0]设置。

(3) 在设备控制器模式下

(a) 用于传输管道

- 当FIFO缓冲区中没有要传输的数据时接收到IN令牌。在这种情况下，USBHS在接收到IN令牌时产生一个NRDY中断请求，并将NRDYSTS.PIPENRDY标志设置为1。对于产生中断的同步传输管道，USBHS发送一个长度为零的数据包并将FRMNUM.OVRN标志为1。

For a non-isochronous transfer pipe in which an interrupt is generated, the USBHS generates an NRDY interrupt request when an NAK handshake is transferred after the data following the OUT token is received, and sets the NRDYSTS.PIPENRDY flag to 1. The NRDY interrupt request is not generated during retransmission because of a DATA-PID mismatch. In addition, the NRDY interrupt request is not generated if an error occurs in the DATA packet.

- On receiving a PING token when there is no space available in the FIFO buffer. The USBHS generates an NRDY interrupt request on reception of the PING token, setting the NRDYSTS.PIPENRDY flag to 1.
- For isochronous transfer pipes, when a token is not received successfully within an interval frame. In this case, the USBHS generates an NRDY interrupt request when the SOF is received, and sets the NRDYSTS.PIPENRDY flag to 1.

conditions in which the USBHS generates an internal BEMP interrupt request.

(1) For transmitting pipes

When the FIFO buffer of the associated pipe is empty on completion of transmission, including zero-length packet transmission, and in single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for a non-DCP pipe. The internal BEMP interrupt request is not generated in any of the following conditions:

- When the CPU or DMA/DTC has already started writing data to the FIFO buffer of the CPU on completion of transmitting data from one FIFO buffer in double buffer mode
- When the buffer is cleared (emptied) by setting 1 to the PIPEnCTR.ACLRM or the BCLR bit in the port control register
- When an IN transfer (zero-length packet transmission) is performed during the control transfer status stage in device controller mode.

(2) For receiving pipes

When a successfully-received data packet size exceeds the specified maximum packet size. In this case, the USBHS generates a BEMP interrupt request, sets the associated BEMPSTS.PIPEBEMP flag to 1, discards the received data, and changes the associated PID[1:0] setting for the pipe to STALL (11b). The USBHS returns no response in host controller mode, and returns STALL response in device controller mode.

The internal BEMP interrupt request is not generated in any of the following conditions:

- When a CRC error or a bit stuffing error is detected in the received data
- When a setup transaction is being performed:
  - Writing 0 to the BEMPSTS.PIPEBEMP flag clears the status
  - Writing 1 to the BEMPSTS.PIPEBEMP flag has no effect.

33.3.6.4 Device state transition interrupt (device controller mode)

Figure 33.8 shows a diagram of the USBHS device state transitions. The USBHS controls device states and generates device state transition interrupts. However, recovery from the Suspend state (resume signal detection) is detected by means of the resume interrupt. Device state transition interrupts can be enabled or disabled independently in INTENB0. Devices whose states have changed can be checked in the PL1CTRL.DVSQ[3:0] flags.

When a transition is made to the default state, a device state transition interrupt is generated after a USB bus reset is

(1) 用于传输管道

当相关管道的FIFO缓冲区在传输完成时为空时，包括零长度数据包传输，并且在单缓冲区模式下，内部BEMP中断请求与非DCP管道的BRDY中断同时生成。在以下任何一种情况下都不会产生内部BEMP中断请求：

- 当CPU或DMADTC在双缓冲模式下从一个FIFO缓冲区完成数据传输后已经开始向CPU的FIFO缓冲区写入数据时
- 当通过将PIPEnCTR.ACLRM或端口控制寄存器中的BCLR位设置为1来清除（清空）缓冲区时
- 在设备控制器模式下的控制传输状态阶段执行IN传输（零长度数据包传输）时。

(2) 用于接收管道

当成功接收的数据包大小超过指定的最大包大小时。在这种情况下，USBHS生成一个BEMP中断请求，将相关的BEMPSTS.PIPEBEMP标志设置为1，丢弃接收到的数据，并将管道的相关PID[1:0]设置更改为STALL(11b)。USBHS在主机控制器模式下不返回响应，在设备控制器模式下返回STALL响应。

在以下任何一种情况下都不会产生内部BEMP中断请求：

- 在接收到的数据中检测到CRC错误或位填充错误时
- 执行设置事务时：
  - 将0写入BEMPSTS.PIPEBEMP标志会清除状态
  - 向BEMPSTS.PIPEBEMP标志写入1无效。

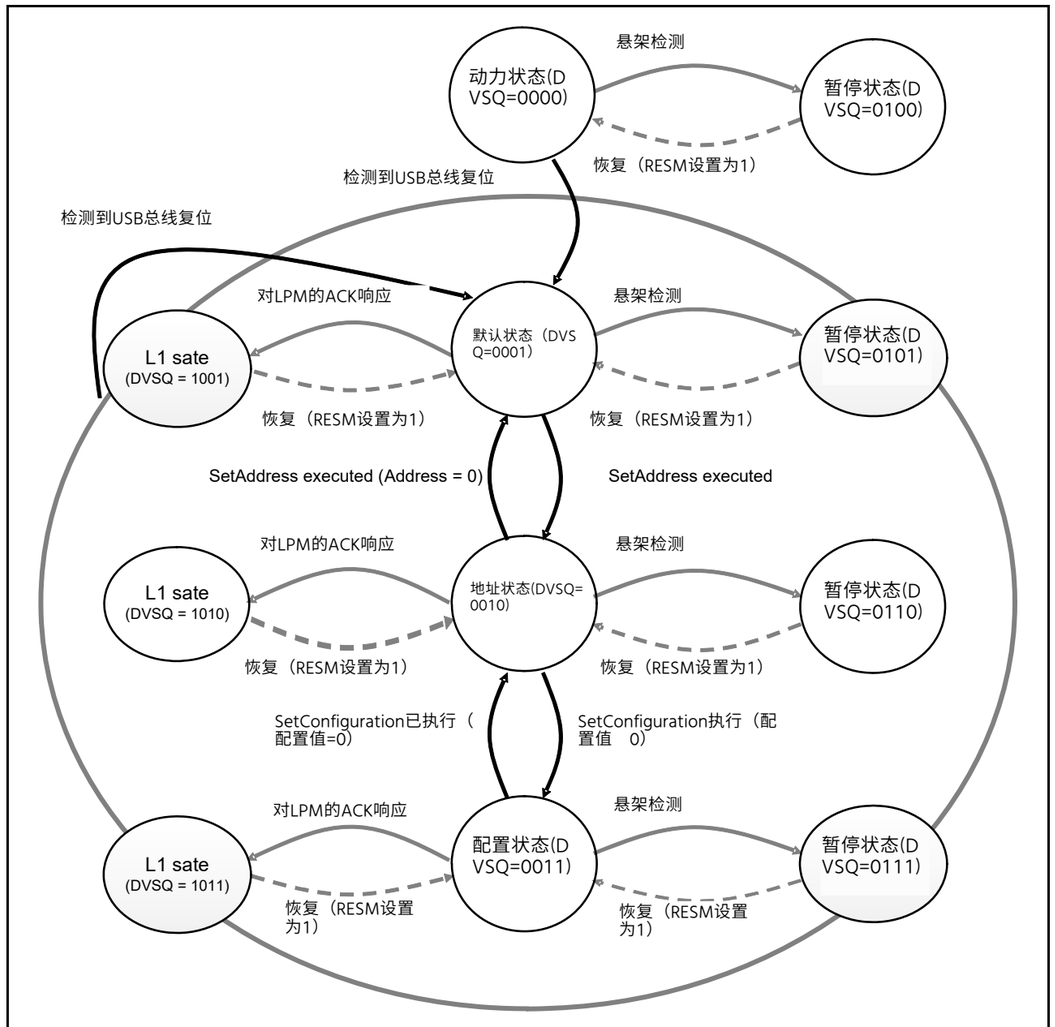
USBHS控制设备状态，并且只能在设备控制器模式下产生设备状态转换中断。



Note: 对于由实线指示的转换，DVST位设置为1。对于由虚线指示的恢复，RESM位设置为1。

Figure 33.8 设备状态转换

33.3.6.5 控制转移阶段转换中断（设备控制器模式）

图33.9显示了USBHS的控制传输阶段转换图。USBHS控制控制传输序列并产生控制传输阶段转换中断。控制转移阶段转换中断可以在INTENB0中独立启用或禁用。可以在INTSTS0.CTSQ[2:0]位中检查已转换的传输阶段。

控制转移阶段转换中断仅在设备控制器模式下产生。本节描述控制传输序列错误。发生错误时，DCPCTR.PID[1:0]位设置为1xb（STALL响应）。

(1) Control read transfer errors

- An OUT token or PING token is received but no data is transferred in response to the IN token at the data stage
- An IN token is received at the status stage
- A data packet with DATAPID = DATA0 is received at the status stage.

(2) Control write transfer errors

- An IN token is received but no ACK returned in response to the OUT token in the data stage
- A data packet with DATAPID = DATA0 is received as the first data packet at the data stage
- An OUT token or PING token is received in the status stage.

(3) Control write no data transfer errors

- An OUT token or PING token is received at the status stage.

At the control write transfer data stage, if the receive data length exceeds the wLength value of the USB request, it is not recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (INTSTS0.CTRT flag = 1), the CTSQ[2:0] = 110b value is saved until CTRT flag clears to 0, clearing the interrupt status. While CTSQ[2:0] bits = 110b is being saved, no CTRT interrupt for ending the setup stage is generated, even if a new USB request is received. The USBHS saves the setup stage completion status, and it generates a CTRT interrupt after the interrupt status is cleared by software.

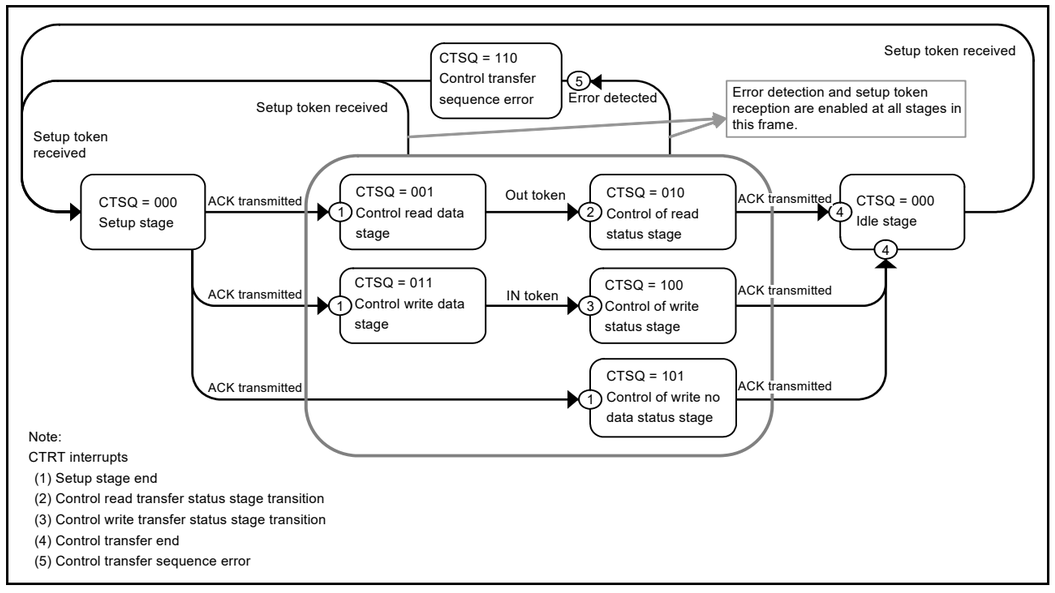


Figure 33.9 Control transfer stage transitions

33.3.6.6 Frame update interrupt

In host controller mode, an interrupt is generated when the frame number is updated.

In device controller mode, an SOFR interrupt is generated when the frame number is updated. The USBHS updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation.

33.3.6.7 VBUS interrupt

When the USBHS_VBUS pin level changes, a VBUS interrupt is generated. The level of the USBHS_VBUS pin can be

(1) 控制读取传输错误

- 接收到OUT令牌或PING令牌，但在数据阶段没有响应IN令牌传输数据
- 在状态阶段收到一个IN令牌
- 在状态阶段接收到一个DATAPID=DATA0的数据包。

(2) 控制写入传输错误

- 接收到IN令牌，但在数据阶段没有响应OUT令牌返回ACK
- DATAPID=DATA0的数据包作为数据阶段的第一个数据包被接收
- 在状态阶段收到一个OUT令牌或PING令牌。

(3) 控制写入无数据传输错误

- 在状态阶段收到OUT令牌或PING令牌。

在控制写入传输数据阶段，如果接收数据长度超过USB请求的wLength值，则不被识别为控制传输序列错误。在控制读取传输状态阶段，除了零长度数据包之外的数据包被一个ACK响应接收并且传输正常结束。

当CTRT中断响应序列错误（INTSTS0.CTRT标志=1）时，CTSQ[2:0]=110b值被保存，直到CTRT标志清除为0，清除中断状态。在保存CTSQ[2:0]位=110b时，不会产生用于结束设置阶段的CTRT中断，即使收到新的USB请求也是如此。USBHS保存建立阶段完成状态，软件清除中断状态后产生CTRT中断。

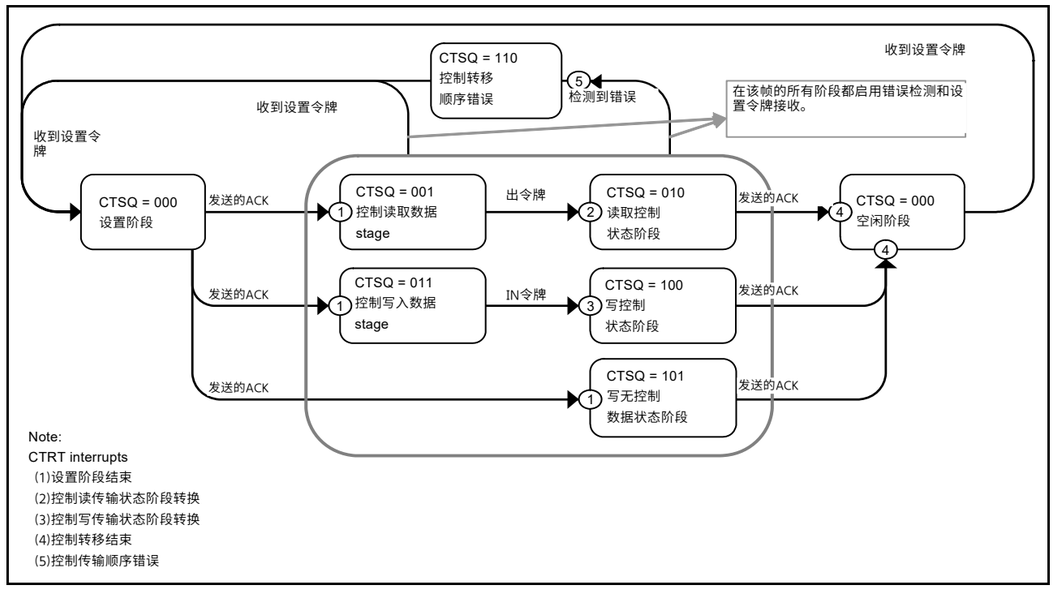

Figure 33.9 控制转移阶段转换

33.3.6.6 帧更新中断

在主机控制器模式下，更新帧号时会产生中断。

在设备控制器模式下，更新帧号时会产生SOFR中断。如果在全速运行期间检测到新的SOF数据包，USBHS会更新帧号并生成SOFR中断。

33.3.6.7 VBUS interrupt

当USBHS_VBUS引脚电平改变时，会产生VBUS中断。USBHS_VBUS引脚的电平可以是

checked in the INTSTS0.VBSTS flag. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. If the system is activated with the host controller connected, the first VBUS interrupt is not generated, because there is no change in the USBHS_VBUS pin level.

33.3.6.8 Resume interrupt

In device controller mode, a resume interrupt is generated when the device is in the Suspend state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the Suspend state is detected by means of the resume interrupt.

In host controller mode, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

33.3.6.9 OVRCR interrupt

An OVRCR interrupt is generated when the USBHS_OVRCURA or USBHS_OVRCURB pin level has changed. The levels of the USBHS_OVRCURA and USBHS_OVRCURB pins can be checked in the SYSSTS0.OVCMON[1:0] flags. The external power supply IC can check whether overcurrent is detected using the OVRCR interrupt.

For OTG connections, the OVRCR interrupt allows you to check whether a change is detected in the VBUS comparator.

33.3.6.10 BCHG interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether a peripheral device is connected. It can also be used to detect a remote wakeup in host controller mode. The BCHG interrupt is generated in both host and device controller modes.

33.3.6.11 DTCH interrupt

A DTCH interrupt occurs when a USB bus disconnect is detected in host controller mode. The USBHS detects bus disconnects in compliance with the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software. The pipes enter the wait state for a bus connection to the port, waiting for an ATTCH interrupt to occur. Regardless of the value set in the associated interrupt enable bit, the USBHS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt is detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state.

33.3.6.12 SACK interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet is received from the peripheral device in host controller mode. The SACK interrupt can be used to confirm that the setup transaction is successfully complete.

33.3.6.13 SIGN interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet is not correctly received from the peripheral device three consecutive times in host controller mode. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

33.3.6.14 ATTCH interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5 µs in host controller mode. To be more specific, an ATTCH interrupt is detected in any of the following conditions:

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5 µs
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5 µs.

33.3.6.15 EOFERR interrupt

An EOFERR interrupt occurs when the USBHS detects that communication is not complete at the EOF2 timing defined in the USB 2.0 specification.

检查INTSTS0.VBSTS标志。主控制器是连接还是断开可以使用VBUS中断来确认。如果系统在连接主机控制器的情况下激活，则不会产生第一个VBUS中断，因为USBHS_VBUS引脚电平没有变化。

33.3.6.8 恢复中断

在设备控制器模式下，当设备处于Suspend状态并且USB总线状态发生变化（从J-state到K-state，或从J-state到SE0）时，会产生一个恢复中断。通过恢复中断检测从挂起状态的恢复。

在主机控制器模式下，不会产生恢复中断。使用BCHG中断来检测USB总线状态的变化。

33.3.6.9 OVRCR interrupt

当USBHS_OVRCURA或USBHS_OVRCURB引脚电平发生变化时，会产生OVRCR中断。USBHS_OVRCURA和USBHS_OVRCURB引脚的电平可以在SYSSTS0.OVCMON[1:0]标志中检查。外部电源IC可以使用OVRCR中断检查是否检测到过电流。

对于OTG连接，OVRCR中断允许您检查是否在VBUS比较器中检测到变化。

33.3.6.10 BCHG interrupt

当USB总线状态改变时会产生BCHG中断。BCHG中断可用于检测是否连接了外围设备。它还可用于检测主机控制器模式下的远程唤醒。BCHG中断在主机和设备控制器模式下产生。

33.3.6.11 DTCH interrupt

当在主机控制器模式下检测到USB总线断开连接时，会发生DTCH中断。USBHS检测符合USB2.0规范的总线断开连接。

在检测到中断时，为相关端口执行通信的所有管道必须由软件终止。管道进入等待状态，等待总线连接到端口，等待ATTCH中断发生。无论相关中断使能位中设置的值如何，USBHS硬件：

- 将检测到DTCH中断的端口的DVSTCTR0.UACT位设置为0
- 将发生DTCH中断的端口置于空闲状态。

33.3.6.12 SACK中断

当在主机控制器模式下从外围设备接收到对发送的设置数据包的ACK响应时，将产生SACK中断。SACK中断可用于确认设置事务成功完成。

33.3.6.13 标志中断

在主机控制器模式下，如果连续三次未从外围设备正确接收到已发送的设置数据包的ACK响应，则会产生SIGN中断。SIGN中断可用于检测没有从外围设备发送的ACK响应或ACK数据包的损坏。

33.3.6.14 ATTCH interrupt

在主机控制器模式下，当在USB端口上检测到全速信号电平的J状态或K状态持续2.5µs时，将产生ATTCH中断。更具体地说，在以下任何一种情况下都会检测到ATTCH中断：

- 当K-state、SE0或SE1变为J-state时，J-state持续2.5μs
- 当J-state、SE0或SE1变为K-state时，K-state持续2.5μs。

33.3.6.15 EOFERR interrupt

当USBHS检测到在USB2.0规范中定义的EOF2时序未完成通信时，将发生EOFERR中断。

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software, and the port must be re-enumerated. Regardless of the value set in the associated interrupt enable bit, the USBHS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt is detected to 0
- Puts the port in which the EOFERR interrupt is generated into the idle state.

33.3.6.16 PDDETINT interrupt

The USBHS sets the INTSTS1.PDDETINT flag to 1 on detecting a level change (high to low or low to high) in the PDDET pin input value and generates the PDDETINT interrupt. When the PDDETINT interrupt is generated, use software to repeatedly read the BCCTRL.PDDETSTS flag until the same value is read three or more times, and perform debounce processing.

33.3.6.17 LPMEND interrupt

When the LPM transaction ends because a response from the peripheral device or a timeout is detected, the INTSTS1.LPMEND flag sets to 1 and the LPMEND interrupt is generated.

33.3.6.18 L1RSMEND interrupt

When performing resume processing when the USBHS has transitioned to the L1 state because an ACK is received in response to an LPM token, the USBHS sets the INTSTS1.L1RSMEND flag to 1 on completion of the resume processing.

33.3.7 Pipe Control

Table 33.22 lists the pipe settings for the USBHS. USB data transfer is performed through logical pipes that the software associates with endpoints. The USBHS provides 10 pipes for data transfer. Set up the pipes based on your system specifications.

Table 33.22 Pipe settings (1 of 2)

Register name	Bit name	Setting	Notes
DCPCFG PIPECFG	TYPE[1:0]	Transfer type	Pipes 1 to 9: Settable
	BFRE	BRDY interrupt mode	Pipes 1 to 5: Settable
	DBLB	Double buffer select	Pipes 1 to 5: Settable
	CNTMD	Selection of continuous transfer or discontinuous transfer	Pipes 1, 2: Settable only for bulk transfers Pipes 3 to 5: Settable
	DIR	Transfer direction select	IN or OUT settable
	EPNUM[3:0]	Endpoint number	Pipes 1 to 9: Settable Set this number to a value other than 0000 when one or more pipes are used.
	SHTNAK	Selects disabled state for pipe when transfer ends	Pipes 1, 2: Settable only for bulk transfers Pipes 3 to 5: Settable
PIPEBUF	BUFSIZE	FIFO buffer size	DCP: Setting disabled (fixed to 256 bytes) Pipes 1 to 5: Settable up to 2 KB Pipes 6 to 9: Setting disabled (fixed to 64 bytes)
	BUFNMB	FIFO buffer number	DCP: Setting disabled (fixed to 0h-3h area) Pipes 1 to 5: Setting disabled (8h-87h area specifiable) Pipes 6 to 9: Setting disabled (fixed to 4h-7h area)
DCPMAXP PIPEMAXP	DEVSEL[3:0]	Device select	Viewable only in host controller mode
	MXPS	Maximum packet size	Setting compliant with USB specification
PIPEPERI	IFIS	Buffer flush	Pipes 1, 2: Settable only for isochronous transfers Pipes 3 to 5: Setting disabled Pipes 6 to 9: Setting disabled
	IITV[2:0]	Interval counter	Pipes 1, 2: Settable only for isochronous transfers Pipes 3 to 5: Setting disabled Pipes 6 to 9: Settable only in host controller mode

在检测到中断时，所有为相关端口执行通信的管道必须由软件终止，并且必须重新枚举该端口。无论相关中断使能位中设置的值如何，USBHS硬件：

- 将检测到EOFERR中断的端口的DVSTCTR0.UACT位设置为0
- 将产生EOFERR中断的端口置于空闲状态。

33.3.6.16 PDDETINT interrupt

USBHS将INTSTS1.PDDETINT标志设置为1在检测到电平变化（高到低或低到高）在PDDET引脚输入值并产生PDDETINT中断。当PDDETINT中断产生时，用软件反复读取BCCTRL.PDDETSTS标志，直到读取3次以上相同的值，并进行去抖动处理。

33.3.6.17 LPMEND interrupt

当LPM事务由于检测到来自外围设备的响应或超时而结束时，INTSTS1.LPMEND标志设置为1并产生LPMEND中断。

33.3.6.18 L1RSMEND interrupt

当USBHS由于接收到响应LPM令牌的ACK而转换到L1状态时执行恢复处理时，USBHS在恢复处理完成时将INTSTS1.L1RSMEND标志设置为1。

33.3.7 管道控制

表33.22列出了USBHS的管道设置。USB数据传输是通过软件与端点关联的逻辑管道执行的。USBHS提供了10个用于数据传输的管道。根据您的系统规格设置管道。

33.3.7.1 Pipe control register switching procedures

The following bits in the pipe control registers can be changed only when USB communication is prohibited (PID[1:0] bits are 00b (NAK response)). Figure 33.10 shows pipe control register switching procedures when USB communication is enabled (PID[1:0] bits are 00b (BUF response)).

Do not change the following registers and bits when USB communication is enabled (PID[1:0] bits are 01b (BUF response)):

- Bits in DCPCFG and DCPMAXP
- SQCLR and SQSET bits in DCPCTR
- Bits in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPEnCTR
- Bits in PIPEnTRE and PIPEnTRN
- Bits in DEVADDm (m = 0 to A).

To set the CSCLR bits and bits in DEVADDm (m = 0 to A), follow the procedures described in section 33.2, Register Descriptions.

33.3.7.1 管道控制寄存器切换程序

只有当USB通信被禁止时（PID[1:0]位为00b（NAK响应））才能更改管道控制寄存器中的以下位。图33.10显示了启用USB通信时的管道控制寄存器切换过程（PID[1:0]位为00b（BUF响应））。

启用USB通信时，请勿更改以下寄存器和位（PID[1:0]位为01b（BUF响应））：

- DCPCFG和DCPMAXP中的位
- DCPCTR中的SQCLR和SQSET位
- PIPECFG、PIPEBUF、PIPEMAXP和PIPEPERI中的位
- PIPEnCTR中的ATREPM、ACLRM、SQCLR和SQSET位
- PIPEnTRE和PIPEnTRN中的位
- DEVADDm中的位（m=0到A）。

要设置DEVADDm中的CSCLR位和位（m=0到A），请按照第33.2节“寄存器”中描述的程序进行操作Descriptions.

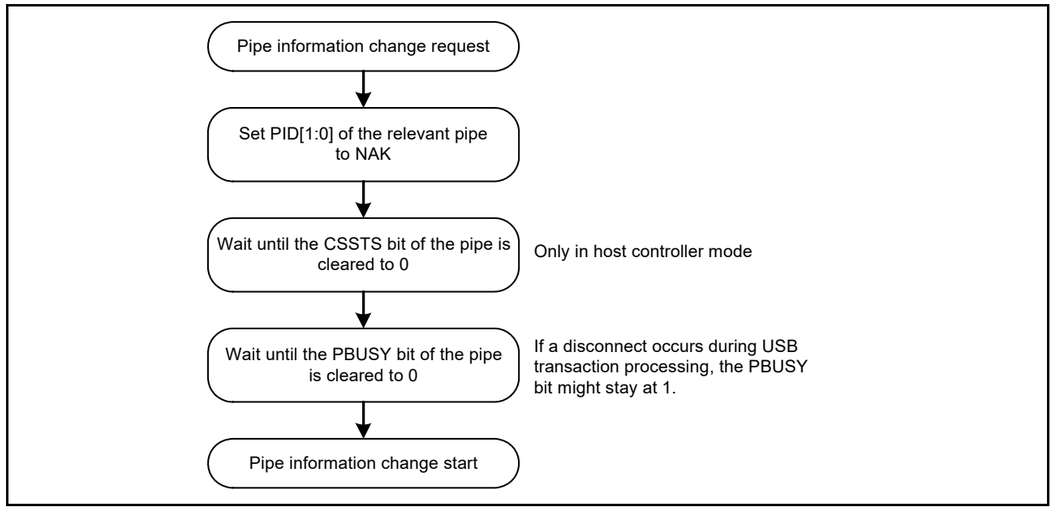

Figure 33.10 Procedure for changing pipe information when USB communication is enabled and PID[1:0] bits are 01b (BUF response)

The following bits in the pipe control registers can be changed only when the selected pipe information is not set in the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Do not set the following registers while the CURPIPE[3:0] bits are set:

- Bits in DCPCFG and DCPMAXP
- Bits in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- PIPEnCTR and ACLRM bits.

To change pipe information, you must set the CURPIPE[3:0] bits to a pipe other than the one to be changed. For the DCP, the buffer must be cleared using the BCLR bit after the pipe information is changed.

33.3.7.2 Transfer types

The PIPECFG.TYPE[1:0] bits specify the following transfer types for each pipe:

- DCP: No setting necessary (fixed at control transfer)
- Pipes 1 and 2: Set to bulk transfer or isochronous transfer
- Pipes 3 to 5: Set to bulk transfer
- Pipes 6 to 9: Set to interrupt transfer.

33.3.7.3 Endpoint number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to 15.

- DCP: No setting is necessary (fixed at endpoint 0)
- Pipes 1 to 9: Select and set the endpoint numbers from 1 to 15 so that the combination of the PIPECFG.DIR and EPNUM[3:0] bits is unique.

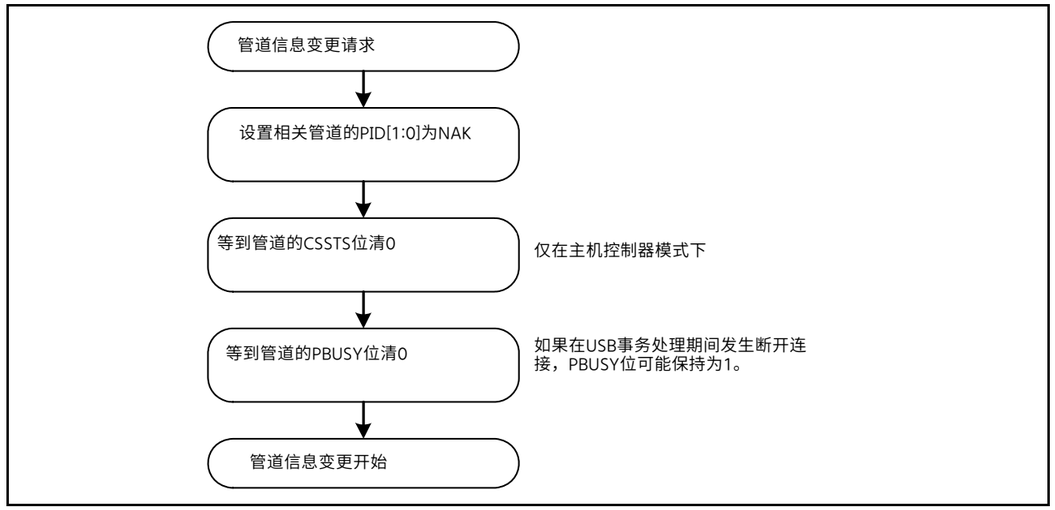

Figure 33.10 USB通信启用且PID[1:0]位为01b（BUF响应）时更改管道信息的过程

管道控制寄存器中的以下位只有在所选管道信息未设置时才能更改CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位。

设置CURPIPE[3:0]位时不要设置以下寄存器：

- DCPCFG和DCPMAXP中的位
- PIPECFG、PIPEBUF、PIPEMAXP和PIPEPERI中的位
- PIPEnCTR和ACLRM位。

要更改管道信息，您必须将CURPIPE[3:0]位设置为要更改的管道以外的管道。对于DCP，必须在管道信息更改后使用BCLR位清除缓冲区。

33.3.7.2 传输类型

PIPECFG.TYPE[1:0]位为每个管道指定以下传输类型：

- DCP：无需设置（控制转移时固定）
- 管道1和2：设置为批量传输或同步传输
- 管道3到5：设置为批量传输
- 管道6到9：设置为中断传输。

33.3.7.3 端点编号

PIPECFG.EPNUM[3:0]位用于设置每个管道的端点编号。DCP固定在端点0。其他管道可以设置从端点1到15。

- DCP：无需设置（固定在端点0）
- 管道1到9：选择并设置从1到15的端点编号，以便PIPECFG.DIR和EPNUM[3:0]位是唯一的。

33.3.7.4 Maximum packet size setting

Specify the maximum packet size for each pipe in the MXPS bits in DCPMAXP and PIPEMAXP. The DCP and pipes 1 to 5 can be set to any of the maximum pipe sizes defined in the USB 2.0 specification. For pipes 6 to 9, the maximum packet size is 64 bytes. Set the maximum packet size as follows before starting a transfer (PID[1:0] bits are set to 01b (BUF response)):

- DCP: Set to 64 for high-speed operation
- DCP: Set to 8, 16, 32, or 64 for full-speed operation
- Pipes 1 to 5: Set to 512 for high-speed bulk transfers
- Pipes 1 to 5: Set to 8, 16, 32, or 64 for full-speed bulk transfers
- Pipes 1, 2: Set between 1 and 1024 for high-speed isochronous transfers
- Pipes 1, 2: Set between 1 and 1023 for full-speed isochronous transfers
- Pipes 6 to 9: Set between 1 and 64.

High-bandwidth interrupt transfers and isochronous transfers are not supported.

33.3.7.5 Transaction counter for pipes 1 to 5 in the receiving direction

When the specified number of transactions is complete in the data packet receiving direction, the USBHS recognizes that the transfer has ended. Two transaction counters are provided. One is the PIPEnTRN register, which specifies the number of transactions to be executed, and the other is the current counter, which internally counts the number of executed transactions. If the PIPECFG.SHTNAK bit is set to 1, when the current counter value matches the specified number of transactions, the associated PIPEnCTR.PID[1:0] bits are set to 00b (NAK response) and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The data read from PIPEnTRN differs depending on the PIPEnTRE.TRENB setting as follows:

- The TRENB bit = 0: Specified transaction counter value can be read
- The TRENB bit = 1: Current counter value indicating the internally counted number of executed transactions can be read.

The following constraints apply when working with the TRCLR bit:

- If the transactions are being counted and the PIPEnCTR.PID[1:0] bits are set to 01b (BUF response), the current counter cannot be cleared
- If there is any data left in the buffer, the current counter cannot be cleared.

33.3.7.6 Response PID

Specify the response PID for each pipe in the PID[1:0] bits in DCPCTR and PIPEnCTR. This section describes the USBHS operation with different response PID settings.

(1) Software response PID settings in host controller mode

Select the response PID to specify the execution of transactions as follows:

- NAK setting: Using pipes is disabled and no transactions are executed
- BUF setting: Transactions are executed based on the FIFO buffer state:
  OUT direction: An OUT token is issued if the FIFO buffer contains transmit data.
  IN direction: An IN token is issued if the FIFO buffer is not full and can receive data.
- STALL setting: Using pipes is disabled and no transactions are executed.

Note: Use the SUREQ bit to execute setup transactions for the DCP.

33.3.7.4 最大数据包大小设置

在DCPMAXP和PIPEMAXP的MXPS位中指定每个管道的最大数据包大小。DCP和管道1到5可以设置为USB2.0规范中定义的任何最大管道尺寸。对于管道6到9，最大数据包大小为64字节。在开始传输之前设置最大数据包大小如下（PID[1:0]位设置为01b（BUF响应））：

- DCP：设置为64用于高速运行
- DCP：设置为8、16、32或64以实现全速运行
- 管道1到5：设置为512用于高速批量传输
- 管道1到5：设置为8、16、32或64以实现全速批量传输
- 管道1、2：设置在1到1024之间，用于高速同步传输
- 管道1、2：设置在1和1023之间，用于全速同步传输
- 管道6到9：设置在1到64之间。

不支持高带宽中断传输和同步传输。

33.3.7.5 接收方向上管道1到5的事务计数器

当在数据包接收方向完成指定数量的事务时，USBHS识别传输已结束。提供了两个交易柜台。一个是PIPEnTRN寄存器，它指定要执行的事务数，另一个是当前计数器，它在内部对执行的事务数进行计数。如果PIPECFG.SHTNAK位设置为1，则当当前计数器值与指定的事务数匹配时，相关的PIPEnCTR.PID[1:0]位设置为00b（NAK响应）并禁用后续传输。通过PIPEnTRE.TRCLR位初始化事务计数器功能的当前计数器，事务可以从头开始重新计数。从PIPEnTRN读取的数据因PIPEnTRE.TRENB设置而异，如下所示：

- TRENB位=0：可以读取指定的事务计数器值
- TRENB位=1：可以读取表示内部计数的已执行事务数的当前计数器值。

使用TRCLR位时适用以下约束：

- 如果正在对事务进行计数并且PIPEnCTR.PID[1:0]位设置为01b（BUF响应），则无法清除当前计数器
- 如果缓冲区中还有任何数据，则无法清除当前计数器。

33.3.7.6 响应PID

在DCPCTR和PIPEnCTR的PID[1:0]位中指定每个管道的响应PID。本节介绍具有不同响应PID设置的USBHS操作。

(1) 主机控制器模式下的软件响应PID设置

选择响应PID来指定事务的执行，如下所示：

- NAK设置：禁用使用管道并且不执行任何事务
- BUF设置：根据FIFO缓冲区状态执行事务：
  OUT方向：如果FIFO缓冲区包含发送数据，则发出OUT令牌。
  IN方向：如果FIFO缓冲区未满并且可以接收数据，则发出IN令牌。
- STALL设置：禁用使用管道并且不执行任何事务。

Note: 使用SUREQ位执行DCP的设置事务。

(2) Software response PID settings in device controller mode

Select the response PID to respond as follows to transactions from the host:

- NAK setting: A NAK response is returned to all generated transactions
- BUF setting: A response is returned to transactions based on the FIFO buffer
- STALL setting: A STALL response is returned to all generated transactions.

Note: For setup transactions, an ACK response is always returned, regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

(3) and (4) describe situations in which the USBHS writes to the PID[1:0] bits because of specific transaction results.

(3) Hardware response PID settings in host controller mode

- NAK setting: The PID[1:0] bits are set to 00b (NAK response) in the following cases, and issuing of tokens is automatically stopped:
  - When a non-isochronous transfer is performed and an NRDY interrupt is generated. For details, see section 33.3.6.2, NRDY interrupt.
  - If a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
  - If transaction counting ends when the SHTNAK bit is set to 1 for bulk transfers.
- BUF setting: The USBHS does not write this setting
- STALL setting: The PID[1:0] bits are set to STALL in the following cases, and issuing of tokens is automatically stopped:
  - When STALL is received in response to a transmitted token
  - When a received data packet exceeds the maximum packet size.

(4) Hardware response PID settings in device controller mode

- NAK setting: The PID[1:0] bits are set to 00b (NAK response) in the following cases, and a NAK response is returned to transactions:
  - When the setup token is received normally (DCP only)
  - If transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers.
- BUF setting: The USBHS does not write this setting
- STALL setting: The PID[1:0] bits are set to STALL in the following cases, and a STALL response is returned to transactions:
  - When a received data packet exceeds the maximum packet size
  - When a control transfer sequence error is detected.

33.3.7.7 Data PID sequence bit

The USBHS automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON bit in DCPCTR and PIPEnCTR. When data is transmitted, the sequence bit toggles on ACK handshake reception. When data is received, the sequence bit toggles on ACK handshake transmission. The SQCLR bit in DCPCTR and the SQSET bit in PIPEnCTR can be used to change the data PID sequence bit.

In device controller mode when control transfers are used, the USBHS automatically sets the sequence bit for stage transitions. DATA1 is returned when the setup stage ends. The sequence bit is not referenced and PID = DATA1 is returned in the status stage. Therefore, no software settings are required. However, in host controller mode when control transfers are used, the sequence bit must be set by software for the stage transitions.

For ClearFeature requests for transmission or reception, the data PID sequence bit must be set by software in both host

(2) 设备控制器模式下的软件响应PID设置

选择响应PID以对来自主机的事务进行如下响应：

- NAK设置：向所有生成的事务返回NAK响应
- BUF设置：根据FIFO缓冲区向事务返回响应
- STALL设置：向所有生成的事务返回一个STALL响应。

Note: 对于设置事务，无论PID[1:0]位设置如何，始终返回ACK响应，并且USB请求存储在寄存器中。

(3)和(4)描述了USBHS由于特定事务结果而写入PID[1:0]位的情况。

(3) 主机控制器模式下的硬件响应PID设置

- NAK设置：在以下情况下，PID[1:0]位设置为00b（NAK响应），并自动停止发出令牌：
  - 当执行非同步传输并产生NRDY中断时。有关详细信息，请参阅第33.3.6.2节，NRDY中断。
  - 如果在PIPECFG.SHTNAK位设置为1以进行批量传输时接收到短数据包
  - 如果在SHTNAK位设置为1以进行批量传输时事务计数结束。
- BUF设置：USBHS不写入此设置
- STALL设置：PID[1:0]位在以下情况下设置为STALL，并且令牌的发行自动停止：
  - 当接收到STALL以响应传输的令牌时
  - 当接收到的数据包超过最大包大小时。

(4) 设备控制器模式下的硬件响应PID设置

- NAK设置：在以下情况下，PID[1:0]位设置为00b（NAK响应），并向事务返回NAK响应：
  - 正常接收设置令牌时（仅DCP）
  - 如果在PIPECFG.SHTNAK位设置为1以进行批量传输时，事务计数结束或收到短数据包。
- BUF设置：USBHS不写入此设置
- STALL设置：PID[1:0]位在以下情况下设置为STALL，并向事务返回STALL响应：
  - 当接收到的数据包超过最大包大小时
  - 当检测到控制传输序列错误时。

33.3.7.7 数据PID序列位

当数据在控制传输数据阶段、批量传输和中断传输中成功传输时，USBHS会自动切换数据PID中的序列位。下一个要发送的数据PID的序列位可以通过DCPCTR和PIPEnCTR中的SQMON位来确认。发送数据时，序列位在ACK握手接收时切换。当接收到数据时，序列位在ACK握手传输上切换。DCPCTR中的SQCLR位和PIPEnCTR中的SQSET位可用于更改数据PID序列位。

在使用控制传输的设备控制器模式下，USBHS自动设置阶段转换的序列位。DATA1在设置阶段结束时返回。不引用序列位，在状态阶段返回PID=DATA1。因此，不需要任何软件设置。但是，在使用控制传输的主机控制器模式下，必须由软件设置序列位以进行阶段转换。

对于发送或接收的ClearFeature请求，数据PID序列位必须由两个主机中的软件设置

and device controller modes.

33.3.7.8 Response PID = NAK function

The USBHS provides a function for disabling pipe operation (PID[1:0] bits are set to 00b (NAK response)) when the final data packet of a transaction is received. The USBHS automatically distinguishes this based on reception of a short packet or the transaction counter. Enable this function by setting the PIPECFG.SHTNAK bit to 1.

When the double buffer mode is being used for the FIFO buffer, using this function enables reception of data packets in transfer units. If pipe operation is disabled, software must enable the pipe again (PID[1:0] bits are set to 01b (BUF response)).

The response PID = NAK function can be used only for bulk transfers.

33.3.7.9 Auto response mode

For bulk transfer pipes (1 to 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (PIPECFG.DIR = 0), OUT-NAK mode is invoked, and during an IN transfer (DIR = 1), null auto response mode is invoked.

33.3.7.10 OUT-NAK mode

For bulk OUT transfer pipes, NAK is returned in response to an OUT token, and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To transition from normal mode to OUT-NAK mode, specify OUT-NAK mode while pipe operation is disabled (PID[1:0] = 00b for NAK response). Next, enable pipe operation (PID[1:0] = 01b for BUF response), on which OUT-NAK mode becomes valid. If an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To transition from OUT-NAK mode to normal mode, cancel OUT-NAK mode while pipe operation is disabled (NAK). Next enable pipe operation (BUF). In normal mode, reception of OUT data is enabled.

33.3.7.11 Null auto response mode

For bulk IN transfer pipes, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To transition from normal mode to null auto response mode, specify null auto response mode while pipe operation is disabled (PID[1:0] bits are set to 00b (NAK response)). Next, enable pipe operation (PID[1:0] bits are set to 01b (BUF response)), on which null auto response mode becomes valid. Before setting null auto response mode, check that PIPEnCTR.INBUFM = 0, because the mode can be set only when the buffer is empty. If the INBUFM bit is 1, empty the buffer using the PIPEnCTR.ACLRM bit. Do not write data from the FIFO port while a transition to null auto response mode is being made.

To transition from null auto response mode to normal mode, keep pipe operation disabled (PID[1:0] bits are set to 00b (NAK response)) for the period of the zero-length packet transmission (about 10 µs) before canceling the null auto response mode. In normal mode, data can be written from the FIFO port, so packet transmission to the host is enabled by enabling pipe operation (PID[1:0] bits are set to 01b (BUF response)).

33.3.8 FIFO Buffer

The USBHS provides a FIFO buffer for data transfers, and it manages the memory area used for each pipe. The FIFO buffer has two states depending on whether the access right is assigned to the system (CPU side) or the USBHS (SIE side).

33.3.8.1 Buffer status

Table 33.23 and Table 33.24 show the buffer status in the USBHS. The FIFO buffer status can be confirmed using the DCPCTR.BSTS and PIPEnCTR.INBUFM bits. The transfer direction for the FIFO buffer can be specified in the PIPECFG.DIR or CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM bit is valid for pipes 1 to 5 in the transmitting direction.

When a transmitting pipe uses double buffering, the software can read the BSTS bit to monitor the FIFO buffer status on the CPU side and the INBUFM bit to monitor the FIFO buffer status on the SIE side. When write access to the FIFO port

和设备控制器模式。

33.3.7.8 响应PID=NAK功能

USBHS提供了在接收到事务的最终数据包时禁用管道操作（PID[1:0]位设置为00b（NAK响应））的功能。USBHS根据收到的短数据包或事务计数器自动区分这一点。通过将PIPECFG.SHTNAK位设置为1来启用此功能。

当FIFO缓冲区使用双缓冲区模式时，使用此功能可以接收以传输为单位的数据包。如果禁用管道操作，软件必须再次启用管道（PID[1:0]位设置为01b（BUF响应））。

响应PID=NAK函数只能用于批量传输。

33.3.7.9 自动响应模式

对于批量传输管道（1到5），当PIPEnCTR.ATREPM位设置为1时，将转换到自动响应模式。在OUT传输期间(PIPECFG.DIR=0)，将调用OUT-NAK模式，在IN传输期间(DIR=1)，将调用空自动响应模式。

33.3.7.10 OUT-NAK mode

对于批量OUT传输管道，NAK响应OUT令牌返回，并且当PIPEnCTR.ATREPM位设置为1时输出NRDY中断。要从正常模式转换到OUT-NAK模式，请指定OUT-NAK模式，同时管道操作被禁用（PID[1:0]=00b用于NAK响应）。接下来，启用管道操作（PID[1:0]=01b用于BUF响应），此时OUT-NAK模式变为有效。如果在禁用管道操作之前立即收到OUT令牌，则正常接收令牌数据，并向主机返回ACK。

要从OUT-NAK模式转换到正常模式，请在禁用管道操作(NAK)时取消OUT-NAK模式。
接下来启用管道操作(BUF)。在正常模式下，可以接收OUT数据。

33.3.7.11 空自动响应模式

对于批量IN传输管道，当PIPEnCTR.ATREPM位设置为1时，将连续传输零长度数据包。

要从正常模式转换为空自动响应模式，请在禁用管道操作时指定空自动响应模式（PID[1:0]位设置为00b（NAK响应））。接下来，启用管道操作（PID[1:0]位设置为01b（BUF响应）），此时空自动响应模式变为有效。在设置空自动响应模式之前，请检查PIPEnCTR.INBUFM=0，因为只有在缓冲区为空时才能设置模式。如果INBUFM位为1，则使用PIPEnCTR.ACLRM位清空缓冲区。在转换到空自动响应模式时，不要从FIFO端口写入数据。

要从空自动响应模式转换到正常模式，请在零长度数据包传输期间（约10μs）保持管道操作禁用（PID[1:0]位设置为00b（NAK响应）），然后再取消空自动响应模式。在正常模式下，数据可以从FIFO端口写入，因此通过启用管道操作（PID[1:0]位设置为01b（BUF响应））来启用到主机的数据包传输。

33.3.8 FIFO Buffer

USBHS为数据传输提供FIFO缓冲区，并管理用于每个管道的内存区域。FIFO缓冲区有两种状态，具体取决于访问权限是分配给系统（CPU端）还是USBHS（SIE端）。

33.3.8.1 缓冲状态

表33.23和表33.24显示了USBHS中的缓冲区状态。FIFO缓冲区状态可以使用确认DCPCTR.BSTS和PIPEnCTR.INBUFM位。FIFO缓冲区的传输方向可以在pipecfg.dir或cfifosel.isel位（选择DCP时）。

INBUFM位对传输方向的管道1到5有效。

当传输管道使用双缓冲时，软件可以读取BSTS位来监控CPU侧的FIFO缓冲区状态，以及读取INBUFM位来监控SIE侧的FIFO缓冲区状态。当对FIFO端口进行写访问时

by the CPU or DMA/DTC is slow and the buffer empty status cannot be determined using the BEMP interrupt, the software can use the INBUFM bit to confirm the end of transmission.

Table 33.23 Buffer status indicated in the BSTS flag

ISEL or DIR	BSTS	FIFO buffer status
0 (receiving direction)	0	There is no received data, or data is being received. Reading from the FIFO port is disabled.
0 (receiving direction)	1	There is received data, or a zero-length packet is received. Reading from the FIFO port is allowed. When a zero-length packet is received, reading is not possible and the buffer must be cleared.
1 (transmitting direction)	0	Transmission is not complete. Writing to the FIFO port is disabled.
1 (transmitting direction)	1	Transmission is complete. CPU write is allowed.

Table 33.24 Buffer status indicated in the INBUFM bit

DIR	INBUFM	FIFO buffer status
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	Transmission is complete. There is no data waiting to be transmitted.
1 (transmitting direction)	1	The FIFO port has written data to the buffer. There is data to be transmitted.

33.3.8.2 FIFO buffer clearing

Table 33.25 shows the methods for clearing the FIFO buffer. The FIFO buffer can be cleared using the BCLR bit in the port control register, DnFIFOSEL.DCLRM, or the PIPEnCTR.ACLRM bit.

Single or double buffering can be selected for pipes 1 to 5 in the PIPECFG.DBLB bit.

Table 33.25 Buffer clearing methods

FIFO buffer clearing mode	Clearing the FIFO buffer on the CPU side	Mode for automatically clearing the FIFO buffer after reading the specified pipe data	Auto buffer clear mode for discarding all received packets
Register used	• CFIFOCTR • DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Bit used	BCLR	DCLRM	ACLRM
Clearing condition	Cleared by writing 1	1: Mode valid 0: Mode invalid.	1: Mode valid 0: Mode invalid.

(1) Auto buffer clear mode function

The USBHS discards all received data packets if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet is received, the ACK response is returned to the host controller. The auto buffer clear mode function can only be set in the FIFO buffer reading direction.

Setting the ACLRM bit to 1 and then to 0 clears the FIFO buffer of the selected pipe regardless of the access direction. An access cycle of at least 100 ns is required for the internal hardware sequence processing between ACLRM = 1 and ACLRM = 0.

33.3.8.3 FIFO port functions

Table 33.26 shows the settings for the FIFO port functions. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, set the BVAL flag in the port control register to end writing. To send a zero-length packet, use the BCLR bit to clear the buffer, and then set the BVAL flag to end writing.

由于CPU或DMADTC速度慢且无法使用BEMP中断确定缓冲区空状态，软件可以使用INBUFM位来确认传输结束。

Table 33.23 BSTS标志中指示的缓冲区状态

ISEL或DIR	BSTS	FIFO缓冲区状态
0 (receiving direction)	0	没有接收到数据，或正在接收数据。 禁止从FIFO端口读取。
0 (receiving direction)	1	有接收数据，或接收到零长度数据包。 允许从FIFO端口读取。 当接收到零长度数据包时，无法读取，必须清除缓冲区。
1 (transmitting direction)	0	传输未完成。 禁止写入FIFO端口。
1 (transmitting direction)	1	传输完成。 允许CPU写入。

Table 33.24 INBUFM位中指示的缓冲区状态

DIR	INBUFM	FIFO缓冲区状态
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	传输完成。 没有等待传输的数据。
1 (transmitting direction)	1	FIFO端口已将数据写入缓冲区。 有数据要传输。

33.3.8.2 FIFO缓冲区清除

表33.25显示了清除FIFO缓冲区的方法。可以使用端口控制寄存器中的BCLR位、DnFIFOSEL.DCLRM或PIPEnCTR.ACLRM位清除FIFO缓冲区。

可以在PIPECFG.DBLB位中为管道1到5选择单缓冲或双缓冲。

Table 33.25 缓冲区清除方法

FIFO缓冲区清除模式	清除CPU端的FIFO缓冲区	读取指定管道数据后自动清除FIFO缓冲区的模式	自动缓冲区清除模式，用于丢弃所有接收到的数据包
注册使用	• CFIFOCTR • DnFIFOCTR	DnFIFOSEL	PIPEnCTR
使用的位	BCLR	DCLRM	ACLRM
清算条件	通过写1清除	1：模式有效0 ：模式无效。	1：模式有效0 ：模式无效。

(1) 自动缓冲清除模式功能

如果PIPEnCTR.ACLRM位设置为1，USBHS将丢弃所有接收到的数据包。如果接收到正确的数据包，则向主机控制器返回ACK响应。自动缓冲区清除模式功能只能在FIFO缓冲区读取方向设置。

无论访问方向如何，将ACLRM位设置为1，然后设置为0都会清除所选管道的FIFO缓冲区。ACLRM=1和之间的内部硬件序列处理需要至少100ns的访问周期
ACLRM = 0.

33.3.8.3 先进先出端口功能

表33.26显示了FIFO端口功能的设置。在写访问中，在达到最大数据包大小之前写入数据会自动启用数据传输。要在达到最大数据包大小之前启用传输，请设置端口控制寄存器中的BVAL标志以结束写入。要发送零长度数据包，请使用BCLR位清除缓冲区，然后设置BVAL标志以结束写入。

In reading, reception of new packets is automatically enabled when all data is read. Data cannot be read when a zero-length packet is received (DTLN[11:0] = 0), so the buffer must be cleared with the BCLR bit. The length of the receive data can be confirmed in the DTLN[11:0] flags in the port control register.

Table 33.26 FIFO port function settings

Register name	Bit name	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	Selects DTLN[11:0] read mode
	REW	FIFO buffer rewind (re-read, rewrite)
	DCLRM	Automatically clears receive data for a specified pipe after the data is read (only for DnFIFO)
	DREQE	Enables DMA/DTC transfers (only for DnFIFO)
	MBW[1:0]	FIFO port access bit width
	BIGEND	Selects FIFO port endian
	ISEL	FIFO port access direction (only for DCP)
	CURPIPE[3:0]	Selects the current pipe
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	Ends writing to the FIFO buffer
	BCLR	Clears the FIFO buffer on the CPU side
	DTLN[11:0]	Checks the length of receive data

33.3.8.4 FIFO port selection

Table 33.27 shows the pipes that can be selected with the different FIFO ports. The pipe to be accessed must be selected in the CURPIPE[3:0] bits in the port selection register. After a pipe is selected, the software must check whether the written value can be correctly read from the CURPIPE[3:0] bits. (If the previous pipe number is read, it indicates that the USBHS is modifying the pipe.) Next, the software checks that the FRDY flag in the port control register is 1.

In addition, the software must specify the bus width to be accessed in the MBW[1:0] bits in the port selection register. The FIFO buffer access direction conforms to the PIPECFG.DIR setting. For the DCP only, the ISEL bit in the port selection register determines the direction.

Table 33.27 FIFO port access by pipe

Pipe	Access Method	Port that can be used
DCP	CPU access	CFIFO port register
Pipes 1 to 9	CPU access	CFIFO port register D0FIFO/D1FIFO port register
	DMA/DTC access	D0FIFO/D1FIFO port register

(1) REW bit

It is possible to temporarily stop access to a pipe being accessed, access a different pipe, and then continue processing for the first pipe again. The REW bit in the port selection register is used for this processing.

If a pipe is selected in the CURPIPE[3:0] bits in the port selection register with the REW bit set to 1, the pointer used for reading from and writing to the FIFO buffer is reset, and reading or writing can be carried out from the first byte. If a pipe is selected with the REW bit set to 0, data can be read and written in continuation from the previous selection, without the pointer being reset.

To access the FIFO port, the software must check that the FRDY bit in the port control register is 1 after selecting a pipe.

33.3.8.5 DMA/DTC transfers (D0FIFO and D1FIFO ports)

For pipes 1 to 9, the FIFO port can be accessed using the DMAC/DTC. When buffer access for the pipe targeted for DMA/DTC transfer is enabled, a DMA/DTC transfer request is issued.

Select the unit of transfer to the FIFO port in the DnFIFOSEL.MBW[1:0] bits, and select the pipe targeted for the DMA/DTC transfer in the DnFIFOSEL.CURPIPE[3:0] bits. Do not change the selected pipe during the DMA transfer.

在读取中，当所有数据被读取时，自动启用新数据包的接收。接收到零长度数据包时（DTLN[11:0]=0）无法读取数据，因此必须使用BCLR位清除缓冲区。接收数据的长度可以在端口控制寄存器中的DTLN[11:0]标志中确认。

Table 33.26 FIFO端口功能设置

注册名称	位名称	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	选择DTLN[11:0]读取模式
	REW	FIFO缓冲区倒带（重新读取、重写）
	DCLRM	读取数据后自动清除指定管道的接收数据（仅适用于DnFIFO）
	DREQE	启用DMADTC传输（仅适用于DnFIFO）
	MBW[1:0]	FIFO端口访问位宽
	BIGEND	选择FIFO端口字节序
	ISEL	FIFO端口访问方向（仅适用于DCP）
	CURPIPE[3:0]	选择当前管道
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	结束写入FIFO缓冲区
	BCLR	清除CPU端的FIFO缓冲区
	DTLN[11:0]	检查接收数据的长度

33.3.8.4 先进先出端口选择

表33.27显示了可以使用不同FIFO端口选择的管道。必须在端口选择寄存器的CURPIPE[3:0]位中选择要访问的管道。选择管道后，软件必须检查是否可以从CURPIPE[3:0]位正确读取写入的值。（如果读取到之前的管道号，则表明USBHS正在修改管道。）接下来，软件检查端口控制寄存器中的FRDY标志为1。

此外，软件必须在端口选择寄存器的MBW[1:0]位中指定要访问的总线宽度。
FIFO缓冲区访问方向符合PIPECFG.DIR设置。仅对于DCP，端口选择寄存器中的ISEL位决定方向。

Table 33.27 通过管道访问FIFO端口

Pipe	访问方法	可以使用的端口
DCP	CPU访问	CFIFO端口寄存器
管道1至9	CPU访问	CFIFO端口寄存器 D0FIFOD1FIFO端口寄存器
	DMA/DTC access	D0FIFOD1FIFO端口寄存器

(1) REW位

可以暂时停止对正在访问的管道的访问，访问不同的管道，然后再次继续处理第一个管道。端口选择寄存器中的REW位用于此处理。

如果在端口选择寄存器的CURPIPE[3:0]位中选择了一个管道，并且REW位设置为1，则用于读取和写入FIFO缓冲区的指针复位，可以进行读取或写入从第一个字节开始。如果在REW位设置为0的情况下选择了管道，则可以从先前的选择继续读取和写入数据，而无需重置指针。

要访问FIFO端口，软件必须在选择管道后检查端口控制寄存器中的FRDY位是否为1。

33.3.8.5 DMADTC传输（D0FIFO和D1FIFO端口）

对于管道1到9，可以使用DMACDTC访问FIFO端口。当对目标管道进行缓冲区访问时启用DMADTC传输，发出DMADTC传输请求。

在DnFIFOSEL.MBW[1:0]位中选择传输到FIFO端口的单位，并选择目标管道DnFIFOSEL.CURPIPE[3:0]位中的DMADTC传输。在DMA传输期间不要更改选定的管道。

(1) DnFIFO auto clear mode (D0FIFO and D1FIFO port reading direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USBHS automatically clears the FIFO buffer of the selected pipe when reading of data from the FIFO buffer is complete.

Table 33.28 shows the packet reception and FIFO buffer clearing processing by software for each of the different settings. As shown in the table, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA/DTC transfers without involving software.

The DnFIFO auto clear mode can only be set in the FIFO buffer reading direction.

Table 33.28 Packet reception and FIFO buffer clearing processing by software

Buffer status when packet is received	Register setting			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1

33.3.8.6 Allocating the FIFO buffer

Figure 33.11 shows an example of a memory map of the FIFO buffer. The FIFO buffer is an area shared by the USBHS and the control CPU of the application. There are two situations for the FIFO buffer: (1) access rights are given to the application (CPU side), and (2) access rights are given to the USBHS (SIE side).

An independent area is set for the FIFO buffer for each pipe. A memory area is determined by the first block number and the number of blocks (specified in the BUFNMB[7:0] and BUFSIZE[4:0] bits in PIPEBUF), where 64 bytes is regarded as one block. When the continuous transfer mode is selected in the CNTMD bit in PIPECFG, set the BUFSIZE[4:0] bits to an integral multiple of the maximum packet size. When double buffering is selected in the DBLB bit in PIPECFG, twice the memory area specified in the BUFSIZE[4:0] bits in PIPEBUF is allocated to the same pipe.

Three FIFO ports are used to access (read data from and write data to) the FIFO buffer. Specify the number of the pipe to be allocated to the FIFO port in the CURPIPE[3:0] bits in C/DnFIFOSEL.

The FIFO buffer status of each pipe can be checked in the DCPCTR.BSTS, PIPEnCTR, and INBUFM bits. The FIFO port access rights can be checked in the FRDY flag in C/DnFIFOCTR.

(1) DnFIFO自动清除模式（D0FIFO和D1FIFO端口读取方向）

如果DnFIFOSEL.DCLRM位设置为1，USBHS会在从FIFO缓冲区读取数据完成时自动清除所选管道的FIFO缓冲区。

表33.28显示了软件对每个不同设置的数据包接收和FIFO缓冲区清除处理。如表所示，缓冲区清除条件取决于PIPECFG.BFRE位中设置的值。使用DnFIFOSEL.DCLRM位无需在任何需要清除缓冲区的情况下通过软件清除缓冲区。这可以在不涉及软件的情况下实现DMADTC传输。

DnFIFO自动清除模式只能设置在FIFO缓冲区读取方向。

Table 33.28 通过软件进行数据包接收和FIFO缓冲区清除处理

收到数据包时的缓冲区状态	注册设置			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1

33.3.8.6 分配FIFO缓冲区

图33.11显示了FIFO缓冲区的内存映射示例。FIFO缓冲区是由USBHS和应用程序的控制CPU共享的区域。FIFO缓冲区有两种情况：（1）访问权限给应用程序（CPU端），（2）访问权限给USBHS（SIE端）。

为每个管道的FIFO缓冲区设置一个独立的区域。内存区域由第一个块号和块数（在PIPEBUF中的BUFNMB[7:0]和BUFSIZE[4:0]位指定）确定，其中64个字节被视为一个块。在PIPECFG的CNTMD位中选择连续传输模式时，将BUFSIZE[4:0]位设置为最大数据包大小的整数倍。当在PIPECFG的DBLB位中选择双缓冲时，PIPEBUF中的BUFSIZE[4:0]位指定的内存区域的两倍将分配给同一管道。

三个FIFO端口用于访问（读取数据和写入数据）FIFO缓冲区。在CDnFIFOSEL的CURPIPE[3:0]位中指定要分配给FIFO端口的管道编号。

可以在DCPCTR.BSTS、PIPEnCTR和INBUFM位中检查每个管道的FIFO缓冲区状态。可以在CDnFIFOCTR中的FRDY标志中检查FIFO端口访问权限。

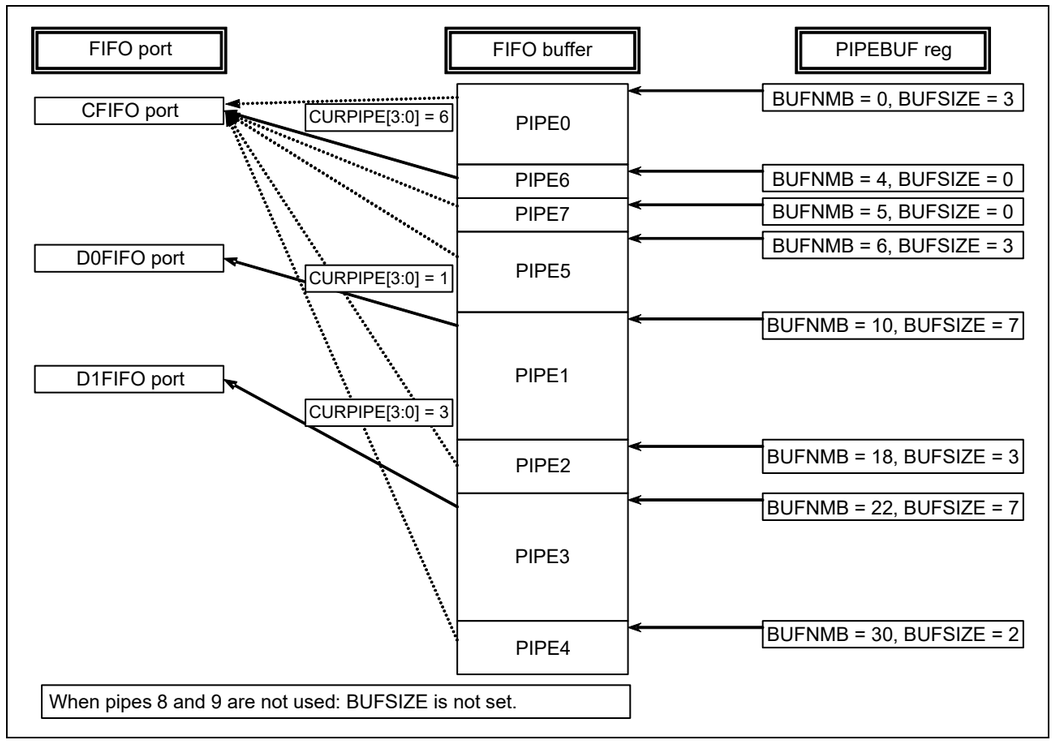

Figure 33.11 Example memory map of the FIFO buffer

33.3.9 Control Transfers Using the DCP

The Default Control Pipe (DCP) is used for data transfers in the control transfer data stage. The FIFO buffer of the DCP is a 64-byte single buffer with a fixed area for both control reads and control writes. The FIFO buffer can be accessed only through the CFIFO port.

33.3.9.1 Control transfers in host controller mode

(1) Setup stage

The USBREQ, USBVAL, USBINDX, and USBLENG registers are used to transmit USB requests for setup transactions. Writing the setup packet data to the register and then writing 1 to the DCPCTR.SUREQ bit transmits the specified data for the setup transaction. On completion of the transaction, the SUREQ bit clears to 0. Do not change these USB request registers while SUREQ = 1.

When an attached function device is detected, the software must issue the first setup transaction for the device using this sequence with the DCPMAXP.DEVSEL[3:0] bits cleared to 0 and the DEVADD0.USBSPD[1:0] bits set appropriately.

When an attached function device is shifted to the Address state, the software must issue setup transactions using this sequence with the assigned USBAddress set in the DEVSEL[3:0] bits and the bits in DEVADDm (m = 0 to A) corresponding to the specified USBAddress set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in DEVADD2. When PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in DEVADD5.

When the setup transaction data is sent, an interrupt request is generated based on the response from the peripheral device (SIGN or SACK bit in INTSTS1). This interrupt request allows the software to check the setup transaction result.

The DATA0 data packet (USB request) for the setup transaction is always transmitted regardless of the status of the DCPCTR.SQMON flag.

33.3.9 使用DCP进行控制传输

默认控制管道(DCP)用于控制传输数据阶段的数据传输。DCP的FIFO缓冲区是一个64字节的单缓冲区，具有用于控制读取和控制写入的固定区域。FIFO缓冲区只能通过CFIFO端口访问。

33.3.9.1 主机控制器模式下的控制传输

(1) 设置阶段

USBREQ、USBVAL、USBINDX和USBLENG寄存器用于传输设置事务的USB请求。将设置数据包数据写入寄存器，然后向DCPCTR.SUREQ位写入1，以传输设置事务的指定数据。事务完成后，SUREQ位清除为0。在SUREQ=1时不要更改这些USB请求寄存器。

当检测到连接的功能器件时，软件必须使用此序列为器件发出第一个设置事务，其中DCPMAXP.DEVSEL[3:0]位清零，DEVADD0.USBSPD[1:0]位适当设置。

当连接的功能器件转移到地址状态时，软件必须使用此序列发出设置事务，其中指定的USBAddress设置在DEVSEL[3:0]位和DEVADDm中的位（m=0到A）对应于指定的USBAddress设置得当。例如，当PIPEMAXP.DEVSEL[3:0]=0010b时，在DEVADD2中进行适当的设置。当PIPEMAXP.DEVSEL[3:0]=0101b时，在DEVADD5中进行适当的设置。

发送设置事务数据时，根据外围设备的响应（INTSTS1中的SIGN或SACK位）生成中断请求。该中断请求允许软件检查设置事务结果。

用于设置事务的DATA0数据包（USB请求）始终被传输，无论
DCPCTR.SQMON flag.

(2) Data stage

The data stage is used to transfer data using the DCP FIFO buffer.

Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit. Specify the transfer direction in the DCPCFG.DIR bit.

For the first data packet of the data stage, the data PID must be transferred as DATA1. Set data PID to DATA1 in the DCPCTR.SQSET bit and set the PID[1:0] bits to 01b (BUF response). Completion of data transfer is detected using the BRDY or BEMP interrupt.

Data transfer of multiple packets is enabled in continuous transfer mode. However, when continuous transfer is specified in the receiving direction, the BRDY interrupt is not generated unless the buffer becomes full or a short packet is received (for 256 bytes or less, which is an integral multiple of the maximum packet size). If the transmit data size is an integral multiple of the maximum packet size, control the control write transfer through the software to transmit a zero-length packet last.

(3) Status stage

The status stage is used for zero-length packet data transfers in the reverse direction of the data stage. As in the data stage, data is transfered using the DCP FIFO buffer. Transactions are executed using the same procedure as the data stage.

Data packets in the status stage must be transmitted and received with the data PID set to DATA1 using the DCPCTR.SQSET bit.

When a zero-length packet is received, check the receive-data length in the CFIFOCTR.DTLN[11:0] flags after a BRDY interrupt is generated, and then clear the FIFO buffer using the BCLR bit.

33.3.9.2 Control transfers in device controller mode

(1) Setup stage

The USBHS returns an ACK response to a normal setup packet for the USBHS. The USBHS operates in the setup stage as follows:

On receiving a new setup packet, the USBHS sets the following bits:

- Sets the INTSTS0.VALID flag to 1
- Sets the DCPCTR.PID[1:0] bits to 00b (NAK response)
- Sets the DCPCTR.CCPL bit to 0.

When the USBHS receives a data packet following a setup packet, it stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Before performing the response processing for a control transfer, set the VALID flag to 0. When the VALID flag = 1, the PID[1:0] bits cannot be set to 01b (BUF response), and the data stage cannot be terminated.

Using the VALID flag function, the USBHS can suspend a request being processed when it receives a new USB request during a control transfer and return a response to the latest request.

In addition, the USBHS automatically detects the direction bit (bmRequestType bit 8) and the request data length (wLength) in the received USB request. It distinguishes between control read transfers, control write transfers, and no-data control transfers, and it controls stage transitions. For an incorrect sequence, a sequence error occurs in the control transfer stage transition interrupt, and the interrupt is reported to the software. For a diagram of the stage control by the USBHS, see Figure 33.9.

(2) Data stage

The DCP must be used to execute data transfers for received USB requests. Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit.

If the transfer data is larger than the size of the DCP FIFO buffer, execute the data transfer using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

In high-speed control write transfers, a NYET handshake response is returned based on the FIFO buffer status.

(2) 数据阶段

数据级用于使用DCPFIFO缓冲区传输数据。

在访问DCPFIFO缓冲区之前，请在CFIFOSEL.ISEL位中指定访问方向。在DCPCFG.DIR位中指定传输方向。

对于数据阶段的第一个数据包，数据PID必须作为DATA1传输。将数据PID设置为DATA1 DCPCTR.SQSET位并将PID[1:0]位设置为01b（BUF响应）。使用检测到数据传输的完成 BRDY或BEMP中断。

在连续传输模式下启用多个数据包的数据传输。但是，当在接收方向指定连续传输时，除非缓冲区变满或接收到短数据包（256字节或更少，这是最大数据包大小的整数倍），否则不会产生BRDY中断。如果传输数据大小是最大数据包大小的整数倍，则通过软件控制控制写入传输，最后传输一个零长度数据包。

(3) 状态阶段

状态阶段用于在数据阶段的相反方向上进行零长度分组数据传输。与数据阶段一样，使用DCPFIFO缓冲区传输数据。事务使用与数据阶段相同的过程执行。

状态阶段的数据包必须在数据PID设置为DATA1的情况下使用 DCPCTR.SQSET bit.

当接收到零长度数据包时，在产生BRDY中断后检查CFIFOCTR.DTLN[11:0]标志中的接收数据长度，然后使用BCLR位清除FIFO缓冲区。

33.3.9.2 设备控制器模式下的控制传输

(1) 设置阶段

USBHS向USBHS的正常设置数据包返回ACK响应。USBHS在设置阶段运行如下：

在接收到新的设置数据包时，USBHS设置以下位：

- 将INTSTS0.VALID标志设置为1
- 将DCPCTR.PID[1:0]位设置为00b（NAK响应）
- 将DCPCTR.CCPL位设置为0。

当USBHS在设置包之后接收到数据包时，它会将USB请求参数存储在USBREQ中， USBVAL, USBINDX, and USBLENG.

在执行控制传输的响应处理之前，将VALID标志设置为0。当VALID标志=1时， PID[1:0]位不能设置为01b（BUF响应），并且不能终止数据阶段。

使用VALID标志功能，USBHS可以在控制传输期间接收到新的USB请求时暂停正在处理的请求，并返回对最新请求的响应。

此外，USBHS会自动检测接收到的USB请求中的方向位（bmRequestTypebit8）和请求数据长度（wLength）。它区分控制读取传输、控制写入传输和无数据控制传输，并控制阶段转换。对于不正确的序列，在控制转移阶段转换中断中发生序列错误，并将中断报告给软件。有关USBHS的舞台控制图，请参见图33.9。

(2) 数据阶段

DCP必须用于执行接收到的USB请求的数据传输。在访问DCPFIFO缓冲区之前，请在CFIFOSEL.ISEL位中指定访问方向。

如果传输数据大于DCPFIFO缓冲区的大小，则使用控制写传输的BRDY中断和控制读传输的BEMP中断执行数据传输。

在高速控制写入传输中，根据FIFO缓冲区状态返回NYET握手响应。

(3) Status stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to 01b (BUF response).

After this setting is made, the USBHS automatically executes the status stage based on the data transfer direction determined at the setup stage. The status stage is executed as follows:

- For control read transfers:
  The USBHS receives a zero-length packet from the USB host and transmits an ACK response
- For control write transfer and no data control transfer:
  The USBHS transmits a zero-length packet and receives an ACK response from the USB host.

(4) Control transfer auto response function

The USBHS automatically responds to a normal SET_ADDRESS request. If the SET_ADDRESS request contains any of the following errors, a response must be returned by software.

- When bmRequestType is not 00h: except control write transfer
- When wIndex is not 00h: request error
- When wLength is not 00h: except no data control transfer
- When wValue is larger than 7Fh: request error
- When PL1CTRL.DVSQ[3:0] flags are 0011b (Configured): control transfer of device state error

A response by the corresponding software is required to all requests other than SET_ADDRESS.

33.3.10 Bulk Transfers (Pipes 1 to 5)

The FIFO buffer usage (setting of single buffer/double buffer or continuous/discontinuous transfer mode) is configurable for bulk transfers. The FIFO buffer size can be set up to 2 KB. The USBHS manages the FIFO buffer state and automatically responds to the PING packet and the NYET handshake.

33.3.10.1 PING packet control in host controller mode

In the OUT direction, a PING packet is automatically transmitted by the USBHS. The USBHS starts communication in the transmitting direction beginning with the PING packet. When it receives an ACK handshake in response to the PING packet, the USBHS transmits an OUT packet. The USBHS returns to the PING transmission state on receiving a NAK or NYET response during an OUT transaction. The procedure is as follows:

Starting OUT data transmission
(1) Transmit PING packet
(2) Receive NAK handshake
(3) Transmit PING packet
(4) Receive ACK handshake
(5) Transmit OUT data packet
(6) Receive ACK handshake
(7) Transmit OUT data packet
:
(8) Receive NAK/NYET handshake

The USBHS returns to the PING packet transmission state when a hardware reset is issued, the NYET or NAK handshake is received, the sequence toggle bit is cleared (SQCLR), or the buffer clear bit (ACLRM) is set.

33.3.10.2 NYET handshake control in device controller mode

Table 33.29 lists responses to received tokens during bulk and control transfers. The USBHS returns a NYET response

(3) 状态阶段

通过将DCPCTR.CCPL位设置为1而将DCPCTR.PID[1:0]位设置为01b（BUF响应）来终止控制传输。

完成此设置后，USBHS根据设置阶段确定的数据传输方向自动执行状态阶段。状态阶段执行如下：

- 对于控制读取传输：
  USBHS接收来自USB主机的零长度数据包并发送ACK响应
- 对于控制写传输和无数据控制传输：
  USBHS发送一个长度为零的数据包并接收来自USB主机的ACK响应。

(4) 控制转移自动响应功能

USBHS自动响应正常的SET_ADDRESS请求。如果SET_ADDRESS请求包含以下任何错误，则必须由软件返回响应。

- bmRequestType不为00h时：控制写入传输除外
- wIndex不为00h时：请求错误
- wLength不为00h时：除非没有数据控制传输
- wValue大于7Fh时：请求错误
- 当PL1CTRL.DVSQ[3:0]标志为0011b（已配置）时：设备状态错误的控制传输

除SET_ADDRESS之外的所有请求都需要相应软件的响应。

33.3.10 批量传输（管道1到5）

FIFO缓冲区使用（设置单缓冲区双缓冲区或连续不连续传输模式）可配置为批量传输。FIFO缓冲区大小可设置为2KB。USBHS管理FIFO缓冲区状态并自动响应PING数据包和NYET握手。

33.3.10.1 主机控制器模式下的PING包控制

在OUT方向，USBHS自动发送一个PING数据包。USBHS从PING数据包开始在传输方向上开始通信。当它接收到响应PING数据包的ACK握手时，USBHS发送一个OUT数据包。USBHS在OUT事务期间收到NAK或NYET响应后返回PING传输状态。程序如下：

开始OUT数据传输
(1)发送PING包
(2)接收NAK握手
(3)发送PING包
(4)接收ACK握手
(5)发送OUT数据包
(6)接收ACK握手
(7)发送OUT数据包
:
(8)接收NAKNYET握手

当发出硬件复位、接收到NYET或NAK握手、清除序列切换位(SQCLR)或设置缓冲区清除位(ACLRM)时，USBHS将返回PING数据包传输状态。

33.3.10.2 设备控制器模式下的NYET握手控制

表33.29列出了在批量和控制传输期间对接收到的令牌的响应。USBHS返回NYET响应

when an available area for only one packet is left in the FIFO buffer when the USBHS has received an OUT token during a bulk or control transfer. When the USBHS receives a short packet, however, it returns an ACK response instead of NYET even when this condition occurs.

Table 33.29 Responses to received tokens

PID[1:0] bit setting	FIFO buffer state	Received token	Response	Note
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY	OUT/PING	ACK	When OUT token is received, data packet is received.*1
	RCV-BRDY	OUT	NYET	Data packet is received*2
	RCV-BRDY	OUT (Short)	ACK	Data packet is received*2
	RCV-BRDY	PING	ACK	*2
	RCV-NRDY	OUT/PING	NAK	—
	TRN-BRDY	IN	DATA0/1	Data packet is transmitted
	TRN-NRDY	IN	NAK	—

Note 1. RCV-BRDY: An available area for two packets is left in the FIFO buffer when an OUT token or a PING token is received.
Note 2. RCV-BRDY: An available area for only one packet is left in the FIFO buffer when an OUT token is received.
RCV-NRDY: No available area is left in the FIFO buffer when a PING token is received.
TRN-BRDY: The FIFO buffer contains transmit data when an IN token is received.
TRN-NRDY: The FIFO buffer contains no transmit data when an IN token is received.

33.3.11 Interrupt Transfers (Pipes 6 to 9)

In device controller mode, the USBHS performs interrupt transfers based on the timing dictated by the host controller. In the interrupt transfer, the USBHS ignores PING packets (no response) and does not transmit the NYET handshake, but returns an ACK, NAK, or STALL response.

In host controller mode, the software can set the timing for issuing tokens using the interval counter. The USBHS does not issue a PING token but issues an OUT token, including for transfers in the OUT direction.

The USBHS does not support high-bandwidth interrupt transfers.

33.3.11.1 Interval counter for interrupt transfers in host controller mode

Specify the transaction interval for interrupt transfers in the PIPEPERI.IITV[2:0] bits. The USBHS issues interrupt transfer tokens based on this interval.

(1) Initializing the counter

The USBHS initializes the interval counter under the following conditions:

- Power-on reset:
  This initializes the IITV[2:0] bits
- FIFO buffer initialization using the PIPEnCTR.ACLRM bit:
  This does not initialize the IITV[2:0] bits, but does initialize the count value. Setting the PIPEnCTR.ACLRM bit to 0 starts counting from the value set in IITV[2:0].

(2) Operation when tokens cannot be transmitted or received even on token generation

No token is generated in the following cases even at token generation time. In these cases, the USBHS tries to execute the transaction in the next interval.

- When the PID[1:0] bits are set to NAK or STALL
- When the FIFO buffer is full at token transmit time in the receiving (IN) direction
- When there is no data to be transmitted in the FIFO buffer at token transmit time in the transmitting (OUT)

当USBHS在批量传输或控制传输期间接收到OUT令牌时，FIFO缓冲区中只剩下一个数据包的可用区域。但是，当USBHS接收到一个短数据包时，即使发生这种情况，它也会返回ACK响应而不是NYET。

Table 33.29 对收到的令牌的响应

PID[1:0]位设置	先进先出缓冲器状态	收到令牌	Response	Note
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY	OUT/PING	ACK	接收到OUT令牌时，接收数据包。*1
	RCV-BRDY	OUT	NYET	收到数据包*2
	RCV-BRDY	OUT (Short)	ACK	收到数据包*2
	RCV-BRDY	PING	ACK	*2
	RCV-NRDY	OUT/PING	NAK	—
	TRN-BRDY	IN	DATA0/1	传输数据包
	TRN-NRDY	IN	NAK	—

Note 1. RCV-BRDY：当接收到OUT令牌或PING令牌时，FIFO缓冲区中留有两个数据包的可用区域。
Note 2. RCV-BRDY：当接收到OUT令牌时，FIFO缓冲区中只剩下一个数据包的可用区域。
RCV-NRDY：接收到PING令牌时，FIFO缓冲区中没有可用区域。
TRN-BRDY：接收到IN令牌时，FIFO缓冲区包含发送数据。
TRN-NRDY：接收到IN令牌时，FIFO缓冲区不包含发送数据。

33.3.11 中断传输（管道6到9）

在设备控制器模式下，USBHS根据主机控制器规定的时序执行中断传输。在中断传输中，USBHS忽略PING数据包（无响应）并且不发送NYET握手，而是返回ACK、NAK或STALL响应。

在主机控制器模式下，软件可以使用间隔计数器设置发布令牌的时间。USBHS不会发出PING令牌，但会发出OUT令牌，包括用于OUT方向的传输。

USBHS不支持高带宽中断传输。

33.3.11.1 主机控制器模式下中断传输的间隔计数器

在PIPEPERI.IITV[2:0]位中指定中断传输的事务间隔。USBHS基于此间隔发出中断传输令牌。

(1) 初始化计数器

USBHS在以下条件下初始化间隔计数器：

- Power-on reset:
  这将初始化IITV[2:0]位
- 使用PIPEnCTR.ACLRM位初始化FIFO缓冲区：
  这不会初始化IITV[2:0]位，但会初始化计数值。将PIPEnCTR.ACLRM位设置为0从IITV[2:0]中设置的值开始计数。

(2) 即使在生成令牌时也无法发送或接收令牌时的操作

在以下情况下，即使在生成令牌时也不会生成令牌。在这些情况下，USBHS尝试在下一个时间间隔执行事务。

- 当PID[1:0]位设置为NAK或STALL
- 当FIFO缓冲区在接收(IN)方向的令牌传输时间已满时
- 当在发送(OUT)中的令牌发送时间FIFO缓冲区中没有要发送的数据时

direction.

33.3.12 Isochronous Transfers (Pipes 1 and 2)

The USBHS does not support high-bandwidth isochronous transfers but provides the following functions for isochronous transfers:

- Notification of isochronous transfer error
- Interval counter (specified in the PIPEPERI.IITV[2:0] bits)
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function (specified in the PIPEPERI.IFIS bit)
- SOF pulse output function.

33.3.12.1 Error detection in isochronous transfers

The USBHS provides a function for detecting the errors described in this section, so that when errors occur in isochronous transfers, they can be controlled by software. Table 33.30 and Table 33.31 show the priority order for errors detected by the USBHS and the associated interrupts.

(1) PID errors

- The PID value of the received packet is invalid.

(2) CRC errors and bit stuffing errors

- A CRC error is found in a received packet or the bit stuffing is illegal.

(3) Maximum packet size exceeded

- The data size of the received packet exceeds the specified maximum packet size.

(4) Overrun and underrun errors

In host controller mode:

- The FIFO buffer is full at token transmit time in the IN (receiving) direction
- There is no data to be sent in the FIFO buffer at token transmit time in the OUT (transmitting) direction.

In device controller mode:

- There is no data to be sent in the FIFO buffer at token receive time in the IN (transmitting) direction
- The FIFO buffer is full at token receive time in the OUT (receiving) direction.

(5) Interval error

In device controller mode, the following cases are treated as an interval error:

- Failure to receive an IN token in the interval frame during an isochronous IN transfer
- Failure to receive an OUT token in the interval frame during an isochronous OUT transfer.

Table 33.30 Error detection for token transmission and reception (1 of 2)

Detection priority	Error type	Interrupt generated at error detection and status
1	PID error	No interrupts are generated in either host or device controller mode. (Ignored as a corrupted packet.)
2	CRC or bit stuffing error	No interrupts are generated in either host or device controller mode. (Ignored as a corrupted packet.)
3	Overrun or underrun error	An NRDY interrupt is generated to set the OVRN flag to 1 in both host and device controller modes. In device controller mode, a zero-length packet is transmitted in response to an IN token. No data packets are received in response to the OUT token.

33.3.12 同步传输（管道1和2）

USBHS不支持高带宽同步传输，但为同步传输提供以下功能：

- 同步传输错误通知
- 间隔计数器（在PIPEPERI.IITV[2:0]位中指定）
- 同步IN传输数据设置控制（IDLY功能）
- 同步IN传输缓冲区刷新功能（在PIPEPERI.IFIS位中指定）
- SOF脉冲输出功能。

33.3.12.1 同步传输中的错误检测

USBHS提供了检测本节描述的错误的功能，因此当同步传输中出现错误时，可以通过软件进行控制。表33.30和表33.31显示了USBHS检测到的错误和相关中断的优先级顺序。

(1) PID错误

- 接收到的数据包的PID值无效。

(2) CRC错误和位填充错误

- 在收到的数据包中发现CRC错误或比特填充是非法的。

(3) 超出最大数据包大小

- 接收到的数据包的数据大小超过了指定的最大数据包大小。

(4) 溢出和欠载错误

在主机控制器模式下：

- FIFO缓冲区在IN（接收）方向的令牌发送时间已满
- 在OUT（发送）方向的令牌发送时，FIFO缓冲区中没有要发送的数据。

在设备控制器模式下：

- 在IN（发送）方向的令牌接收时间，FIFO缓冲区中没有要发送的数据
- FIFO缓冲区在OUT（接收）方向上的令牌接收时间已满。

(5) 间隔误差

在设备控制器模式下，以下情况被视为间隔错误：

- 在同步IN传输期间未能在间隔帧中接收IN令牌
- 在同步OUT传输期间未能在间隔帧中接收OUT令牌。

Table 33.30 令牌发送和接收的错误检测（1of2）

检测优先级	错误类型	错误检测和状态产生的中断
1	PID错误	在主机或设备控制器模式下都不会产生中断。（作为损坏的数据包被忽略。）
2	CRC或位填充错误	在主机或设备控制器模式下都不会产生中断。（作为损坏的数据包被忽略。）
3	溢出或欠载错误	在主机和设备控制器模式下，都会产生一个NRDY中断来将OVRN标志设置为1。在设备控制器模式下，发送一个零长度数据包以响应IN令牌。 没有接收到响应OUT令牌的数据包。

4	Interval error	An NRDY interrupt is generated in device controller mode. No interrupt is generated in host controller mode.

Table 33.31 Error detection for data packet reception

Detection priority	Error type	Interrupt generated at error detection and status
1	PID error	No interrupt is generated. (Ignored as a corrupted packet.)
2	CRC or bit stuffing error	An NRDY interrupt is generated and the FRMNUM.CRCE bit sets to 1 in both host and device controller modes.
3	Maximum packet size exceeded error	A BEMP interrupt is generated and the PID[1:0] bits set to STALL in both host and device controller modes.

33.3.12.2 DATA PID

The USBHS does not support high-bandwidth transfers. In device controller mode, the USBHS responds as follows to a received PID:

(1) IN direction

- DATA0: Transmitted as data packet PID
- DATA1: Not transmitted
- DATA2: Not transmitted
- mDATA: Not transmitted.

(2) OUT direction (full-speed operation)

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets ignored
- mDATA: Packets ignored.

(3) OUT direction (high-speed operation)

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Received normally as data packet PID
- mDATA: Received normally as data packet PID.

33.3.12.3 Interval counter

The isochronous transfer interval can be set in the PIPEPERI.IITV[2:0] bits. In device controller mode, the interval counter enables functions as shown in Table 33.32. In host controller mode, the USBHS generates the token issuance timing, and the interval counter operation is the same as that for interrupt transfers.

Table 33.32 Interval counter functions in device controller mode

Transfer direction	Function	Conditions for detection
IN	Transmit buffer flush	Failure to receive an IN token successfully in the interval frame during an isochronous IN transfer
OUT	Notification of no reception of token	Failure to receive an OUT token successfully in the interval frame during an isochronous OUT transfer

The interval count is performed when an SOF is received or for complemented SOFs, so the isochronism can be maintained even if an SOF is corrupt. The frame interval can be set to 2IITV (μ) frames.

Table 33.30 令牌发送和接收的错误检测(2of2)

4	间隔误差	在设备控制器模式下会产生一个NRDY中断。在主机控制器模式下不产生中断。

Table 33.31 数据包接收错误检测

检测优先级	错误类型	错误检测和状态产生的中断
1	PID错误	不产生中断。（作为损坏的数据包被忽略。）
2	CRC或位填充错误	在主机和设备控制器模式下，都会产生一个NRDY中断并且FRMNUM.CRCE位设置为1。
3	超出最大数据包大小错误	在主机和设备控制器模式下，都会产生BEMP中断并且PID[1:0]位设置为STALL。

33.3.12.2 数据PID

USBHS不支持高带宽传输。在设备控制器模式下，USBHS对接收到的PID做出如下响应：

(1) 在方向

- DATA0：作为数据包PID发送
- DATA1：未发送
- DATA2：未传输
- mDATA：未传输。

(2) OUT方向（全速运行）

- DATA0：作为数据包PID正常接收
- DATA1：作为数据包PID正常接收
- DATA2：数据包被忽略
- mDATA：数据包被忽略。

(3) OUT方向（高速运转）

- DATA0：作为数据包PID正常接收
- DATA1：作为数据包PID正常接收
- DATA2：作为数据包PID正常接收
- mDATA：作为数据包PID正常接收。

33.3.12.3 间隔计数器

同步传输间隔可以在PIPEPERI.IITV[2:0]位中设置。在设备控制器模式下，间隔计数器启用表33.32中所示的功能。在主机控制器模式下，USBHS产生令牌发布时序，间隔计数器操作与中断传输相同。

Table 33.32 设备控制器模式下的间隔计数器功能

转移方向	Function	检测条件
IN	发送缓冲区刷新	在等时期间未能在间隔帧中成功接收IN令牌转入
OUT	未收到令牌的通知	在等时期间未能在间隔帧中成功接收OUT令牌转出

间隔计数是在接收到SOF时执行的，或者是针对补充的SOF执行的，因此即使SOF损坏也可以保持等时性。帧间隔可以设置为2IITV(μ)帧。

(1) Counter initialization in device controller mode

The USBHS initializes the interval counter under the following conditions:

- Power-on reset:
  This initializes the PIPEPERI.IITV[2:0] bits
- FIFO buffer initialization using the ACLRM bit:
  This does not initialize the IITV[2:0] bits, but does initialize the count value.

After the interval counter is initialized, the interval count starts under either of the following conditions when a packet is transferred successfully:

- An SOF is received after data is transmitted in response to an IN token, with the PID[1:0] bits set to 01b (BUF response)
- An SOF is received after data is received in response to an OUT token, with PID[1:0] bits set to 01b (BUF response).

The interval counter is not initialized under the following conditions:

- When the PID[1:0] bits are set to NAK or STALL
  This does not stop the interval timer. The USBHS attempts the transaction in the next interval.
- USB bus reset and USB suspension
  This does not initialize the IITV[2:0] bits. When an SOF is received, the interval counter starts counting from the value set before SOF was received.

(2) Interval counting and transfer control in host controller mode

The USBHS controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bit settings. Specifically, the USBHS issues a token for a selected pipe once every 2^{IITV} frames.

The USBHS starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits are set to 01b (BUF response) by software.

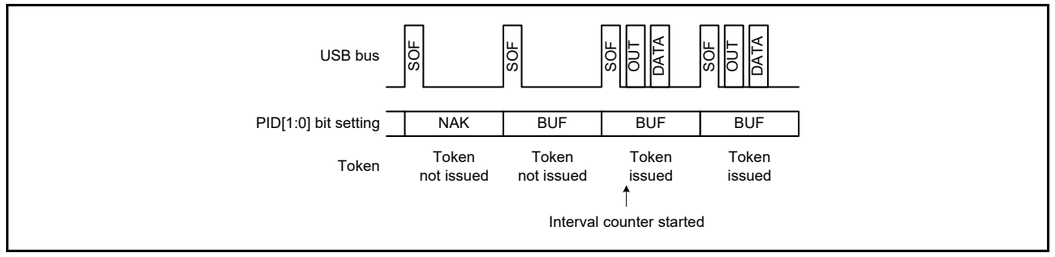

Figure 33.12 Token issuance when IITV[2:0] = 0

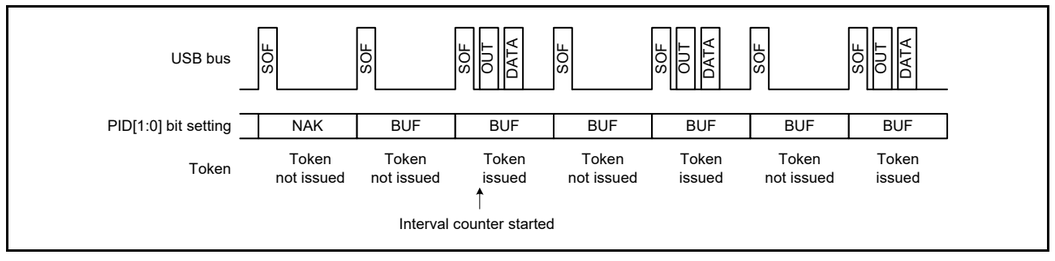

Figure 33.13 Token issuance when IITV[2:0] = 1

When the selected pipe is set for isochronous transfers, the USBHS carries out the following operation in addition to controlling the token issuance interval. The USBHS issues a token even when the NRDY interrupt generation condition is satisfied.

(1) 设备控制器模式下的计数器初始化

USBHS在以下条件下初始化间隔计数器：

- Power-on reset:
  这将初始化PIPEPERI.IITV[2:0]位
- 使用ACLRM位初始化FIFO缓冲区：
  这不会初始化IITV[2:0]位，但会初始化计数值。

间隔计数器初始化后，当数据包传输成功时，间隔计数在以下任一条件下开始：

- 在响应IN令牌传输数据后接收SOF，PID[1:0]位设置为01b（BUF响应）
- 在接收到响应OUT令牌的数据后接收SOF，PID[1:0]位设置为01b（BUF响应）。

间隔计数器在以下情况下不会初始化：

- 当PID[1:0]位设置为NAK或STALL
  这不会停止间隔计时器。USBHS在下一个时间间隔尝试事务。
- USB总线复位和USB暂停这不会初始化IITV[2:0]位。当接收到SOF时，间隔计数器从接收到SOF之前设置的值开始计数。

(2) 主机控制器模式下的间隔计数和传输控制

USBHS根据PIPEPERI.IITV[2:0]位设置控制令牌发布操作之间的间隔。
具体来说，USBHS每2个IITV帧为选定管道发布一次令牌。

USBHS在软件将PID[1:0]位设置为01b（BUF响应）的帧之后的帧开始计算令牌发布间隔。

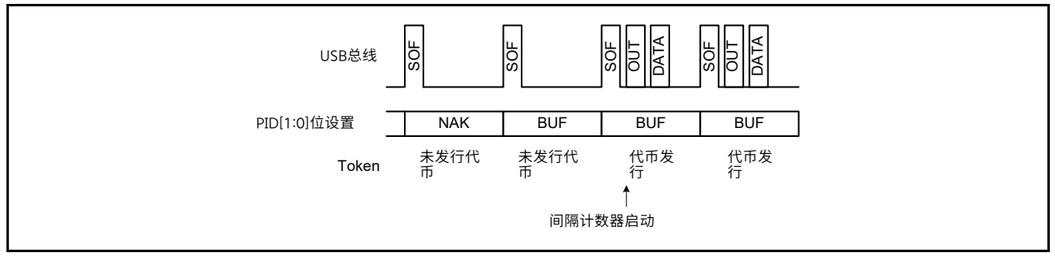

Figure 33.12 IITV[2:0]=0时的代币发行

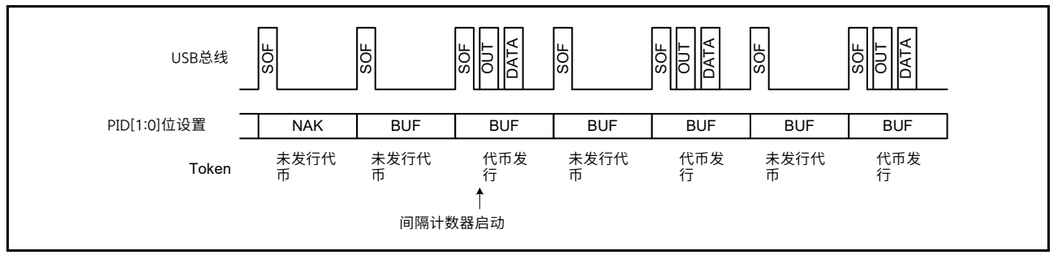

Figure 33.13 IITV[2:0]=1时的代币发行

当所选管道设置为同步传输时，USBHS除了控制令牌发布间隔外，还会执行以下操作。即使满足NRDY中断产生条件，USBHS也会发出一个令牌。

(a) When the selected pipe is for isochronous IN transfers

The USBHS generates an NRDY interrupt when the USBHS issues an IN token but does not receive a packet successfully from a peripheral device (no response or packet error).

(b) When the selected pipe is for isochronous OUT transfers

The USBHS sets the OVRN flag to 1, generating an NRDY interrupt and transmitting a zero-length packet, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer, because the CPU or DMA/DTC is too slow in writing data to the FIFO buffer.

The token issuance interval is reset on any of the following conditions:

- When the MCU is reset
  This initializes the IITV[2:0] bits
- When the PIPEnCTR.ACLRM bit is set to 1 by software.

(3) Interval counting and transfer control in device controller mode

(a) When the selected pipe is for isochronous OUT transfers

The USBHS generates an NRDY interrupt when it fails to receive a data packet within the interval set in the PIPEPERI.IITV[2:0] bits.

The USBHS also generates an NRDY interrupt when it fails to receive data because of a CRC error or other errors contained in the data packet or because of the FIFO buffer is full.

The NRDY interrupt is generated on SOF packet reception. Even if the SOF packet is corrupted, internal complementation allows the interrupt to be generated when the SOF packet is received. However, when the IITV[2:0] bits are set to a value other than 0, the USBHS generates an NRDY interrupt on receiving an SOF packet for every interval after interval counting starts.

When the PID[1:0] bits are set to 00b (NAK response) by software after starting the interval timer, the USBHS does not generate an NRDY interrupt on receiving an SOF packet.

The timing for starting interval counting depend on the IITV[2:0] setting as follows:

- When the IITV[2:0] bits = 0:
  The interval counting starts when the PID[1:0] bits of the selected pipe are changed to BUF
- When the IITV[2:0] bits ≠ 0:
  The interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe are changed to 01b (BUF response).

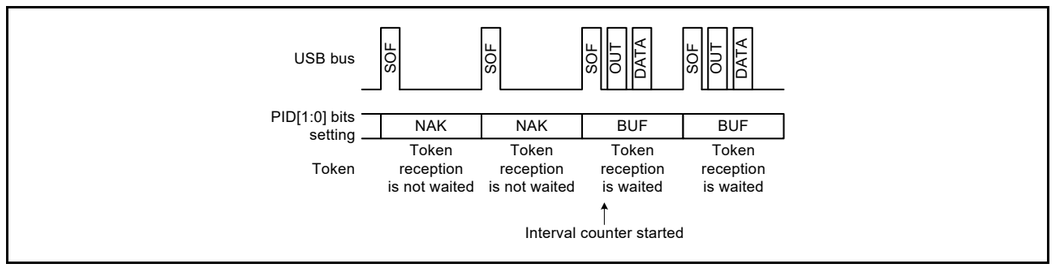

Figure 33.14 Relationship between frames and expected token reception when IITV[2:0] = 0

(a) 当所选管道用于同步IN传输时

当USBHS发出IN令牌但未成功接收到来自外围设备的数据包（无响应或数据包错误）时，USBHS生成NRDY中断。

(b) 当所选管道用于同步OUT传输时

USBHS将OVRN标志设置为1，产生一个NRDY中断并发送一个长度为零的数据包，当发出OUT令牌的时间到来而FIFO缓冲区中没有要发送的数据时，因为CPU或DMADTC是将数据写入FIFO缓冲区太慢。

令牌发行间隔在以下任何条件下重置：

- MCU复位时
  这将初始化IITV[2:0]位
- 当PIPEnCTR.ACLRM位由软件设置为1时。

(3) 设备控制器模式下的间隔计数和传输控制

(a) 当所选管道用于同步OUT传输时

当USBHS在设置的时间间隔内未能接收到数据包时，会产生一个NRDY中断。
PIPEPERI.IITV[2:0] bits.

当由于数据包中包含的CRC错误或其他错误或由于FIFO缓冲区已满而无法接收数据时，USBHS也会产生NRDY中断。

NRDY中断在SOF数据包接收时产生。即使SOF数据包损坏，内部补码也允许在接收到SOF数据包时产生中断。但是，当IITV[2:0]位设置为0以外的值时，USBHS会在间隔计数开始后的每个间隔接收到SOF数据包时产生NRDY中断。

当PID[1:0]位在启动间隔定时器后由软件设置为00b（NAK响应）时，USBHS在接收到SOF数据包时不会产生NRDY中断。

开始间隔计数的时间取决于IITV[2:0]设置，如下所示：

- 当IITV[2:0]位=0时：
  当所选管道的PID[1:0]位更改为BUF时，间隔计数开始
- 当IITV[2:0]位≠0时：
  在所选管道的PID[1:0]位更改为01b（BUF响应）后，第一个数据包的成功接收完成后，间隔计数开始。

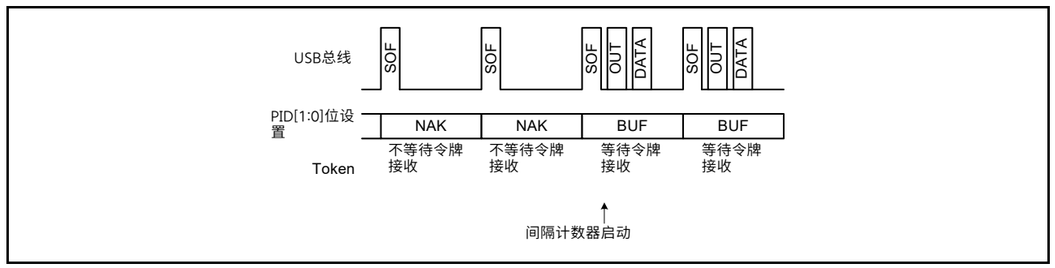

Figure 33.14 IITV[2:0]=0时帧与预期令牌接收之间的关系

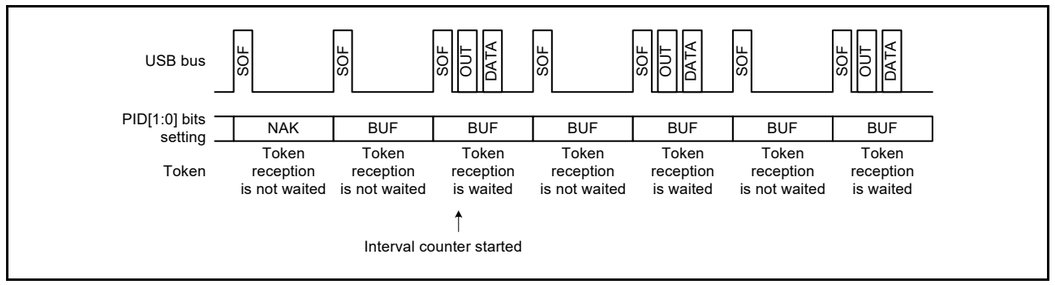

Figure 33.15 Relationship between frames and expected token reception when IITV[2:0] ≠ 0

(b) When the selected pipe is for isochronous IN transfers

The PIPEPERI.IFIS bit must be 1 for this use case. When the IFIS bit is cleared to 0, the USBHS transmits a data packet in response to a received IN token, regardless of the PIPEPERI.IITV[2:0] setting.

When IFIS is 1 and there is data to be transmitted in the FIFO buffer, the USBHS clears the FIFO buffer when it fails to receive an IN token in the frame at the interval set in the IITV[2:0] bits.

The USBHS also clears the FIFO buffer when it fails to receive an IN token successfully because of a bus error, such as a CRC error, contained in the IN token.

The FIFO buffer is cleared on SOF packet reception. Even if the SOF packet is corrupted, the internal complementation allows the FIFO buffer to be cleared when the SOF packet is received.

The timing to start interval counting depends on the IITV[2:0] setting, as with OUT transfers.

The interval is counted on any of the following conditions in device controller mode:

- When a hardware reset is applied to the USBHS (which also sets the IITV[2:0] bits to 000b)
- When the PIPEnCTR.ACLRM bit is set to 1 by software
- When the USBHS detects a USB bus reset.

(4) Transmit data setup for isochronous transfers in device controller mode

With isochronous data transmission using the USBHS in device controller mode, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the SOF packet is detected. This isochronous transfer transmit data setup function can identify the frame that started transmission.

When the double buffering is used, transmission is only enabled for the buffer in which data writing was completed first, even after the data write to both buffers is complete. Accordingly, even if multiple IN tokens are received, only the one packet of FIFO buffer data is transmitted.

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transferred and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

Figure 33.16 shows an example of transmission using the isochronous transfer transmit data setup function when the IITV[2:0] bits are set to 0 (every frame).

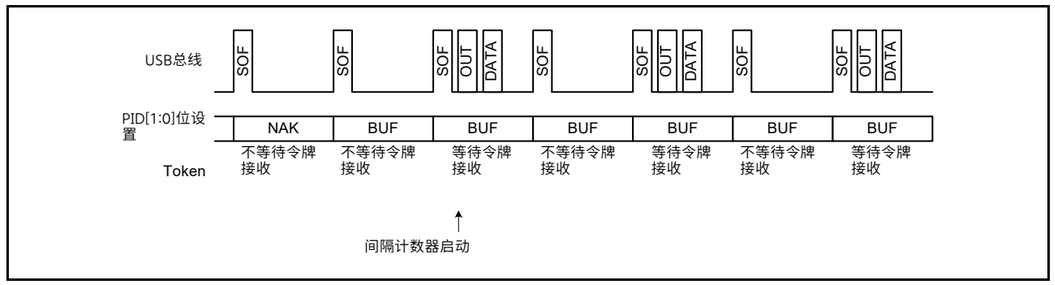

Figure 33.15 IITV[2:0]≠0时帧与预期令牌接收的关系

(b) 当所选管道用于同步IN传输时

对于此用例，PIPEPERI.IFIS位必须为1。当IFIS位清0时，USBHS发送数据包以响应接收到的IN令牌，无论PIPEPERI.IITV[2:0]设置如何。

当IFIS为1且FIFO缓冲区中有数据要发送时，USBHS会在其未能按照IITV[2:0]位设置的时间间隔接收帧中的IN令牌时清除FIFO缓冲区。

当由于IN令牌中包含的总线错误（例如CRC错误）而未能成功接收IN令牌时，USBHS也会清除FIFO缓冲区。

FIFO缓冲区在SOF数据包接收时被清除。即使SOF数据包损坏，内部补码也允许在接收到SOF数据包时清除FIFO缓冲区。

开始间隔计数的时间取决于IITV[2:0]设置，与OUT传输一样。

在设备控制器模式下，根据以下任何条件计算间隔：

- 当对USBHS应用硬件复位时（也将IITV[2:0]位设置为000b）
- 当PIPEnCTR.ACLRM位由软件设置为1时
- 当USBHS检测到USB总线复位时。

(4) 设备控制器模式下同步传输的传输数据设置

在设备控制器模式下使用USBHS进行等时数据传输，数据写入FIFO缓冲区后，可在检测到SOF包后的第一帧发送数据包。此同步传输传输数据设置功能可以识别开始传输的帧。

当使用双缓冲时，即使在两个缓冲区的数据写入都完成之后，也只对首先完成数据写入的缓冲区启用传输。因此，即使接收到多个IN令牌，也仅发送一包FIFO缓冲器数据。

当接收到IN令牌时，当FIFO缓冲区准备好传输数据时，将传输数据并返回正常响应。但是，如果FIFO缓冲区无法传输数据，则会传输零长度数据包并发生欠载错误。

图33.16显示了使用同步传输传输数据设置功能的传输示例，当IITV[2:0]位设置为0（每帧）。

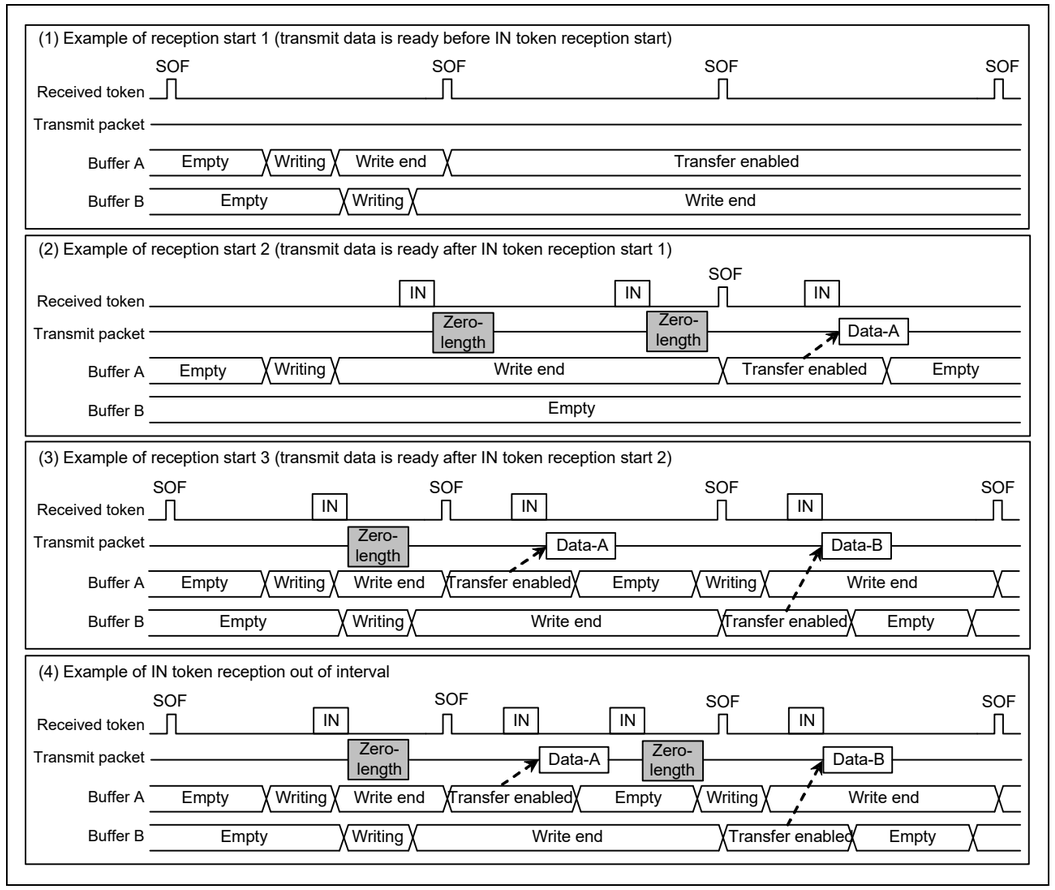

Figure 33.16 Example data setup operation

(5) Isochronous transfer transmit buffer flush in device controller mode

In device controller mode during isochronous data transmission, if the USBHS receives an SOF packet for the next frame without receiving an IN token in the interval frame, it operates as if the IN token is corrupt and clears the buffer that is enabled for transmission, putting that buffer in the writing enabled state.

When double buffering is used and writing to both buffers is complete, the cleared FIFO buffer is assumed to be the one where the data was transmitted in the interval frame, and transmission is enabled for the FIFO buffer that was not cleared on SOF packet reception.

The timing of the buffer flush function depends on the PIPEPERI.IITV[2:0] setting as follows:

- When IITV[2:0] = 0:
  The buffer flush operation starts from the first frame after the pipe is enabled
- When IITV[2:0] ≠ 0:
  The buffer flush operation starts after the first normal transaction.

Figure 33.17 shows an example buffer flush. When an unanticipated token is received before the interval frame, the USBHS sends the write data or a zero-length packet as an underrun error, depending on the data setup status.

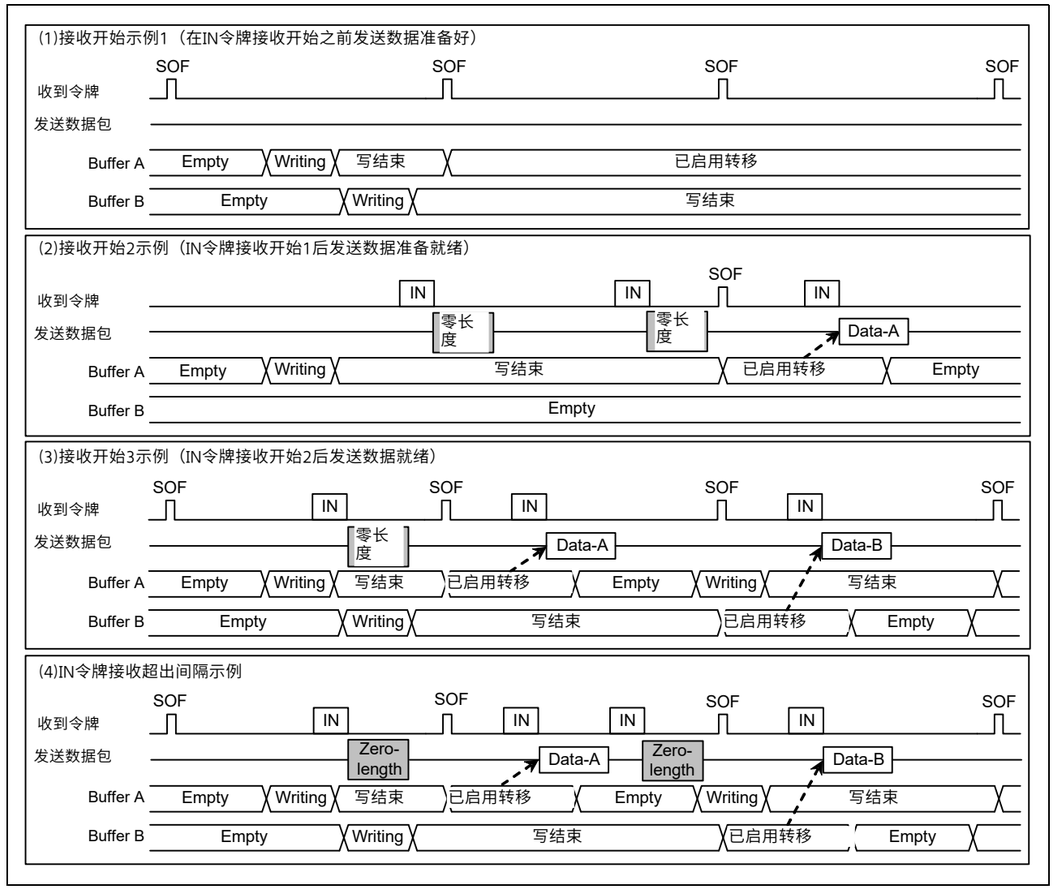

Figure 33.16 示例数据设置操作

(5) 设备控制器模式下的同步传输发送缓冲区刷新

在同步数据传输期间的设备控制器模式下，如果USBHS接收到下一帧的SOF数据包而没有在间隔帧中接收到IN令牌，则它会像IN令牌损坏一样操作并清除启用传输的缓冲区，将该缓冲区处于写入启用状态。

当使用双缓冲并完成对两个缓冲区的写入时，已清除的FIFO缓冲区被假定为在间隔帧中传输数据的缓冲区，并为接收SOF数据包时未清除的FIFO缓冲区启用传输。

缓冲区刷新功能的时间取决于PIPEPERI.IITV[2:0]设置，如下所示：

- When IITV[2:0] = 0:
  缓冲区刷新操作从启用管道后的第一帧开始
- When IITV[2:0] ≠ 0:
  缓冲区刷新操作在第一个正常事务之后开始。

图33.17显示了一个示例缓冲区刷新。当在间隔帧之前收到未预料到的令牌时，USBHS根据数据设置状态将写入数据或零长度数据包作为欠载错误发送。

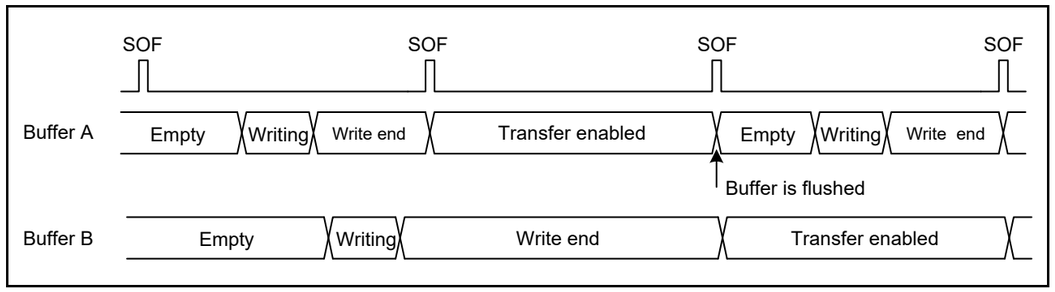

Figure 33.17 Example buffer flush operation

Figure 33.18 shows an example interval error occurrence. There are five types of interval errors, as shown in the figure. An interval error occurs at timing ①, and the buffer flush function is activated.

If an interval error occurs during an IN transfer, the buffer flush function is activated. If it occurs during an OUT transfer, an NRDY interrupt is generated. Use the FRMNUM.OVRN bit to distinguish between this and NRDY interrupts triggered by received packet errors and overrun errors.

For tokens that are shaded in the figure, responses are returned based on the FIFO buffer status.

- IN direction:
  - If the buffer is ready to transfer data, the data is transferred and a normal response is returned
  - If the buffer is not ready to transfer data, a zero-length packet is transmitted and an underrun error occurs.
- OUT direction:
  - If the buffer is ready to receive data, the data is received and a normal response is returned
  - If the buffer is not ready to receive data, the received data is discarded and an overrun error occurs.

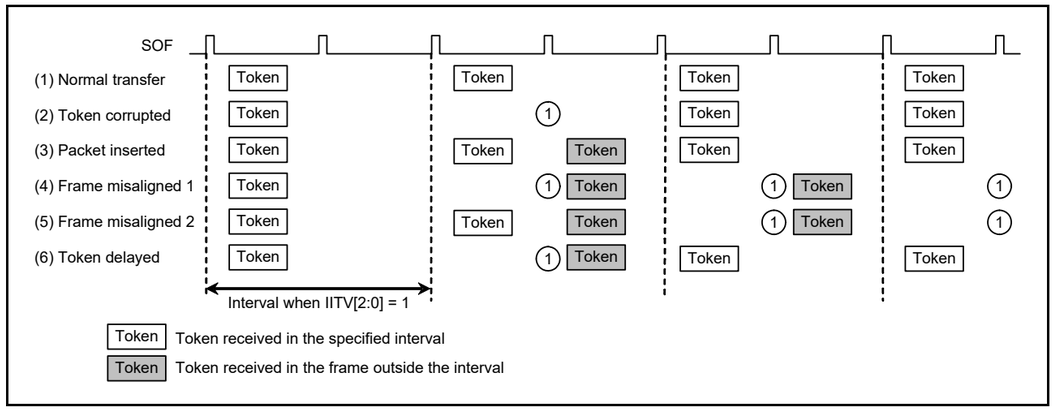

Figure 33.18 Example interval error occurrence when PIPEPERI.IITV[2:0] = 1

33.3.13 SOF Complementation Function

In device controller mode, if packet reception is disabled at intervals of 1 ms in full-speed mode or 125 µs in high-speed mode because the SOF packet is missing or corrupted, the USBHS complements the SOF. SOF complementation begins when the SYSCFG.USBE and LPSTS.SUSPENDM bits are set to 1 and an SOF packet is received. The complementation function is initialized under the following conditions:

- Power-on reset
- USB bus reset

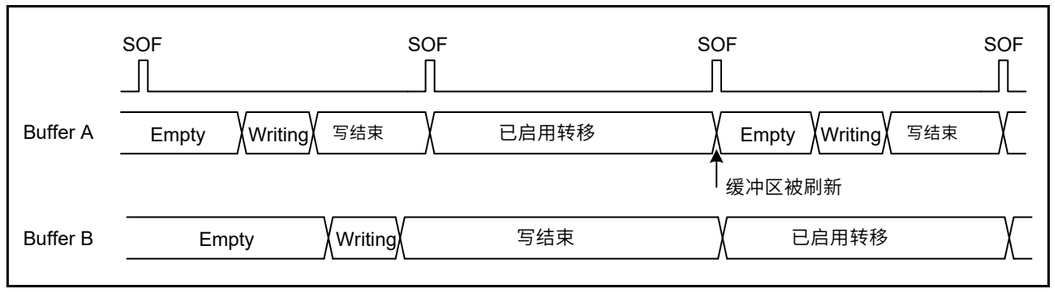

Figure 33.17 缓冲区刷新操作示例

图33.18显示了一个发生间隔错误的示例。如图所示，有五种区间误差。
定时出现间隔错误 ① 并且缓冲区刷新功能被激活。

如果在IN传输期间发生间隔错误，则会激活缓冲区刷新功能。如果它发生在OUT传输期间，则会产生NRDY中断。使用FRMNUM.OVRN位来区分此中断和由接收数据包错误和溢出错误触发的NRDY中断。

对于图中带阴影的令牌，根据FIFO缓冲区状态返回响应。

- IN direction:
  - 如果缓冲区准备好传输数据，则传输数据并返回正常响应
  - 如果缓冲区尚未准备好传输数据，则会传输零长度数据包并发生欠载错误。
- OUT direction:
  - 如果缓冲区准备好接收数据，则接收数据并返回正常响应
  - 如果缓冲区没有准备好接收数据，则丢弃接收到的数据并发生溢出错误。

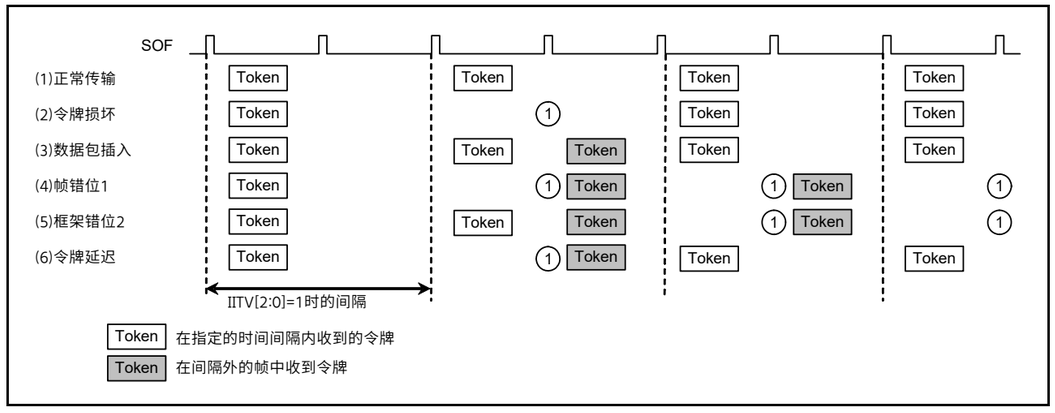

Figure 33.18 PIPEPERI.IITV[2:0]=1时发生的示例间隔错误

33.3.13 SOF互补函数

在设备控制器模式下，如果在全速模式下每隔1ms或在高速模式下每隔125µs禁用数据包接收，因为SOF数据包丢失或损坏，USBHS会补充SOF。当SYSCFG.USBE和LPSTS.SUSPENDM位设置为1并且接收到SOF数据包时，SOF补码开始。补码函数在以下条件下初始化：

- Power-on reset
- USB总线复位

- Suspend state detection.

The SOF complementation function operates as follows:

- The frame interval (125 µs or 1 ms) is determined by the reset handshake protocol result
- The complementation function is not activated until an SOF packet is received
- When the first SOF packet is received, complementation is performed by counting 125 µs or 1 ms on the 48-MHz internal clock
- When the second or subsequent SOF packets are received, complementation is performed at the previous reception interval
- Complementation is not performed in the Suspend state or on reception of a USB bus reset. During high-speed operation, complementation continues for 3 ms from the last packet on transition to the Suspend state.

The USBHS supports the following functions controlled by SOF packet reception. These functions operate normally with SOF complementation if the SOF packet is missing:

- Updating of the frame number and micro frame number
- SOFR interrupt and micro-SOF lock
- SOF pulse output
- Isochronous transfer interval count.

If an SOF packet is missing during full-speed operation, the FFRMNUM.FRNM[10:0] flags are not updated. If a micro-SOF packet is missing during high-speed operation, the URMNUM.UFRNM[2:0] bits are updated.

However, if a micro-SOF packet is missing while the UFRNM[2:0] bits are set to 000b, the FRNM bits are not updated. In this case, even if a subsequent micro-SOF packet with a value other than UFRNM[2:0] bits = 000b is received successfully while UFRNM[2:0] bits are set to the value other than 000b, the FRNM bits are not updated.

33.3.14 Pipe Schedule

33.3.14.1 Conditions for generating transactions

In host controller mode and when the DVSTCTR0.UACT bit is set to 1, the USBHS generates transactions under the conditions as shown in Table 33.33.

Table 33.33 Conditions for generating transactions

	Conditions for generation				
Transaction	**DIR**	**PID[1:0]**	**IITV0**	**Buffer state**	**SUREQ**
Setup	—*1	—*1	—*1	—*1	1 setting
Control transfer data stage, status stage, bulk transfer	IN	BUF	—*1	Receive area exists	—*1
	OUT	BUF	—*1	Transmit data exists	—*1
Interrupt transfer	IN	BUF	Valid	Receive area exists	—*1
	OUT	BUF	Valid	Transmit data exists	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

Note 1. An em dash (—) in the table indicates that the condition is unrelated to the generating of tokens. “Valid” indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter. “Invalid” indicates that a transaction is generated regardless of the interval counter.
Note 2. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.
Note 3. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

- 暂停状态检测。

SOF互补函数的操作如下：

- 帧间隔（125µs或1ms）由复位握手协议结果决定
- 直到收到SOF数据包才激活补充功能
- 当接收到第一个SOF数据包时，通过在48-MHz内部时钟上计数125µs或1ms来执行补码
- 当接收到第二个或随后的SOF数据包时，在前一个接收间隔执行补充
- 在挂起状态或接收到USB总线复位时不执行补码。在高速操作期间，从最后一个数据包转换到暂停状态的时间为3ms。

USBHS支持以下由SOF数据包接收控制的功能。如果SOF数据包丢失，这些功能在SOF补充的情况下正常运行：

- 更新帧号和微帧号
- SOFR中断和micro-SOF锁定
- SOF脉冲输出
- 同步传输间隔计数。

如果在全速操作期间丢失SOF数据包，则FFRMNUM.FRNM[10:0]标志不会更新。如果一个微SOF数据包在高速运行期间丢失，URMNUM.UFRNM[2:0]位被更新。

但是，如果在UFRNM[2:0]位设置为000b时缺少micro-SOF数据包，则不会更新FRNM位。
在这种情况下，即使在将UFRNM[2:0]位设置为000b以外的值时成功接收到具有非UFRNM[2:0]位=000b的值的后续micro-SOF数据包，FRNM位仍为未更新。

33.3.14 管道计划

33.3.14.1 产生交易的条件

在主机控制器模式下，当DVSTCTR0.UACT位设置为1时，USBHS在表33.33所示的条件下生成事务。

Table 33.33 产生交易的条件

	生成条件				
Transaction	**DIR**	**PID[1:0]**	**IITV0**	**缓冲状态**	**SUREQ**
Setup	—*1	—*1	—*1	—*1	1 setting
控制传输数据阶段、状态阶段、批量传输	IN	BUF	—*1	接收区存在	—*1
	OUT	BUF	—*1	传输数据存在	—*1
中断传输	IN	BUF	Valid	接收区存在	—*1
	OUT	BUF	Valid	传输数据存在	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

Note 1. 表中的破折号(—)表示该条件与令牌的生成无关。“有效”表示，对于中断传输和同步传输，事务仅在基于间隔计数器的传输帧中生成。“无效”表示无论间隔计数器如何都生成事务。

Note 2. 这表示不管是否有接收区域，都会产生一个事务。但是，如果没有接收区域，则丢弃接收到的数据。

Note 3. 这表明无论是否有任何数据要传输，都会生成一个事务。然而，如果没有要传输的数据，则传输零长度数据包。

33.3.14.2 Transfer schedule

This section describes the transfer scheduling within a frame of the USBHS. After the USBHS sends an SOF, the transfer is carried out in the following sequence:

1. Execution of periodic transfers:
   A pipe is searched for in the order of pipe 1 → pipe 2 → pipe 6 → pipe 7 → pipe 8 → pipe 9, and then if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.
2. Setup transactions for control transfers:
   The DCP is checked, and if a setup transaction is possible, it is sent.
3. Execution of bulk transfers, control transfer data stages, and control transfer status stages:
   A pipe is searched for in the order of DCP → pipe 1 → pipe 2 → pipe 3 → pipe 4 → pipe 5, and then if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.
   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

33.3.14.3 Enabling USB communication

Setting the DVSTCTR0.UACT bit to 1 initiates an SOF transmission, and transaction generation is enabled. Setting the UACT bit to 0 stops SOF transmission, and the Suspend state is invoked. If the UACT setting is changed from 1 to 0, processing stops after the next SOF is sent.

33.3.15 Battery charging detection processing

The USBHS provides control over the data contact detection processing (D+ line contact checking), primary detection processing (charger detection processing), and secondary detection processing (charger determination processing) as defined in the Battery Charging Specification.

This section describes operations required in device and host controller modes.

33.3.15.1 Processing in device controller mode

To operate a function device as a battery charging portable device:

1. Start primary detection processing after detecting contact with the D+ and D- lines. The Battery Charging Specification describes two processing methods for Data Contact Detection. The USBHS supports both methods as follows:
   - Software processing
     After a VBINT interrupt or polling of the VBSTS flag indicates a change in the state of the USBHS_VBUS input pin, software controls a wait from 300 to 900 ms. The BCCTRL.VDPSRCE and IDMSINKE bits are then both set to 1, enabling the VDP_SRC and IMP_SINK circuits, respectively, to start primary detection processing.
   - Hardware processing
     Apply 7 to 13 µA of current to the D+ line to hold the D+ line at the logical high level. This is done to detect the D+ and D- lines going to the logical low level because of pull-down resistors on the host device side when the D+ and D- lines come in contact with those of the host. Monitor the SYSSTS0.LNST[1:0] flags while the BCCTRL.IDPSRCE bit is set to 1, enabling the IDP_SRC circuit, to see when the level on the D+ line changes from high to low. After detecting a low level on the D+ line, clear the BCCTRL.IDPSRCE bit to 0, disabling the IDP_SRC circuit, and set both the BCCTRL.VDPSRCE and IDMSINKE bits to 1, enabling the VDP_SRC and IDM_SINK circuits, respectively, to start primary detection processing. The VDPSRCE and IDMSINKE bits must be set to 1 simultaneously.
2. After the start of primary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL.CHGDETSTS flag. A value of 1 indicates detection of a charger, and secondary detection processing starts.*1
3. To start secondary detection processing, clear both the BCCTRL.VDPSRCE and IDMSINKE bits to 0, disabling the VDP_SRC and IDM_SINK circuits, respectively. Next, set both the BCCTRL.VDMSRCE and IDPSINKE bits to 1, enabling the VDM_SRC and IDP_SINK circuits, respectively.

33.3.14.2 转移时间表

本节介绍USBHS帧内的传输调度。USBHS发送SOF后，按以下顺序进行传输：

1. 执行定期转账：
   按照管道1 管道2 管道6 管道7 管道8 管道9的顺序搜索管道，然后如果存在可以生成等时或中断传输事务的管道，则生成事务.
2. 为控制转移设置交易：
   DCP被检查，如果设置事务是可能的，它被发送。
3. 批量传输、控制传输数据阶段和控制传输状态阶段的执行：
   管道按DCP 管道1 管道2 管道3 管道4 管道5的顺序搜索，然后如果存在要进行批量传输的事务、控制传输数据阶段或可以生成控制转移状态阶段，生成事务。生成事务时，无论来自外围设备的响应是ACK还是NAK
   ，处理都会转移到下一个管道事务。如果帧内有时间进行传输，则重复步骤3。

33.3.14.3 启用USB通信

将DVSTCR0.UACT位设置为1启动SOF传输，并启用事务生成。设置
UACT位为0停止SOF传输，并调用暂停状态。如果UACT设置从1更改为0，则在发送下一个SOF后处理停止。

33.3.15 电池充电检测处理

USBHS提供对电池充电规范中定义的数据接触检测处理（D+线路接触检查）、一次检测处理（充电器检测处理）和二次检测处理（充电器确定处理）的控制。

本节介绍设备和主机控制器模式所需的操作。

33.3.15.1 设备控制器模式下的处理

将功能设备作为电池充电便携式设备操作：

1. 在检测到与D+和Dlines的接触后开始初级检测处理。电池充电
   规范描述了数据接触检测的两种处理方法。USBHS支持以下两种方法：
   - 软件处理
     在VBINT中断或轮询VBSTS标志指示USBHS_VBUS输入引脚的状态发生变化后，软件控制从300到900ms的等待。然后BCCTRL.VDPSRCE和IDMSINKE位都设置为1，分别使VDP_SRC和IMP_SINK电路开始主要检测处理。
   - 硬件加工
     向D+线施加7到13µA的电流，以将D+线保持在逻辑高电平。这样做是为了检测
     当D+和Dlines与主机的电阻接触时，由于主机设备侧的下拉电阻，D+和Dlines变为逻辑低电平。监控SYSSTS0.LNST[1:0]标志，而
     BCCTRL.IDPSRCE位设置为1，启用IDP_SRC电路，以查看D+线上的电平何时从高变为低。检测到D+线上的低电平后，将BCCTRL.IDPSRCE位清除为0，禁用IDP_SRC电路，并将BCCTRL.VDPSRCE和IDMSINKE位都设置为1，启用VDP_SRC和
     IDM_SINK电路分别启动初级检测处理。VDPSRCE和IDMSINKE位必须同时设置为1。
2. 在主要检测处理开始后，软件控制等待40毫秒后，检查
   BCCTRL.CHGDETSTS标志。值为1表示检测到充电器，并开始二次检测处理。*1
3. 要启动二次检测处理，请将BCCTRL.VDPSRCE和IDMSINKE位都清除为0，分别禁用VDP_SRC和IDM_SINK电路。接下来，将BCCTRL.VDMSRCE和IDPSINKE位都设置为1，分别启用VDM_SRC和IDP_SINK电路。

4. After the start of secondary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL.PDDETSTS flag. A value of 1 indicates that secondary detection processing is complete.

Note 1. In primary detection processing, detection of a voltage above the range from 0.25 to 0.4 V and below the range from 0.8 to 2.0 V on the D-Line indicates that the other device is a host device that supports battery charging (charging downstream port). The BCCTRL.CHGDETSTS flag in the PHY block only indicates whether the voltage on the D- line is higher than the range from 0.25 to 0.4 V, so add processing as required to read the SYSSTS0.LNST[1:0] flags and confirm that the voltage on the D- line is also below the range from 0.8 to 2.0 V.

Figure 33.19 illustrates this processing flow.

4. 在二次检测处理开始后，软件控制等待40毫秒，检查BCCTRL.PDDETSTS标志。值为1表示二次检测处理完成。

注1.在初级检测处理中，在D-Line上检测到高于0.25至0.4V范围且低于0.8至2.0V范围的电压表示其他设备是支持电池充电的主机设备（充电下游港口）。PHY块中的BCCTRL.CHGDETSTS标志位仅指示Dline上的电压是否高于0.25至0.4V的范围，因此根据需要添加处理以读取SYSSTS0.LNST[1:0]标志并确认电压Dline上的电压也低于0.8至2.0V的范围。

图33.19说明了这个处理流程。

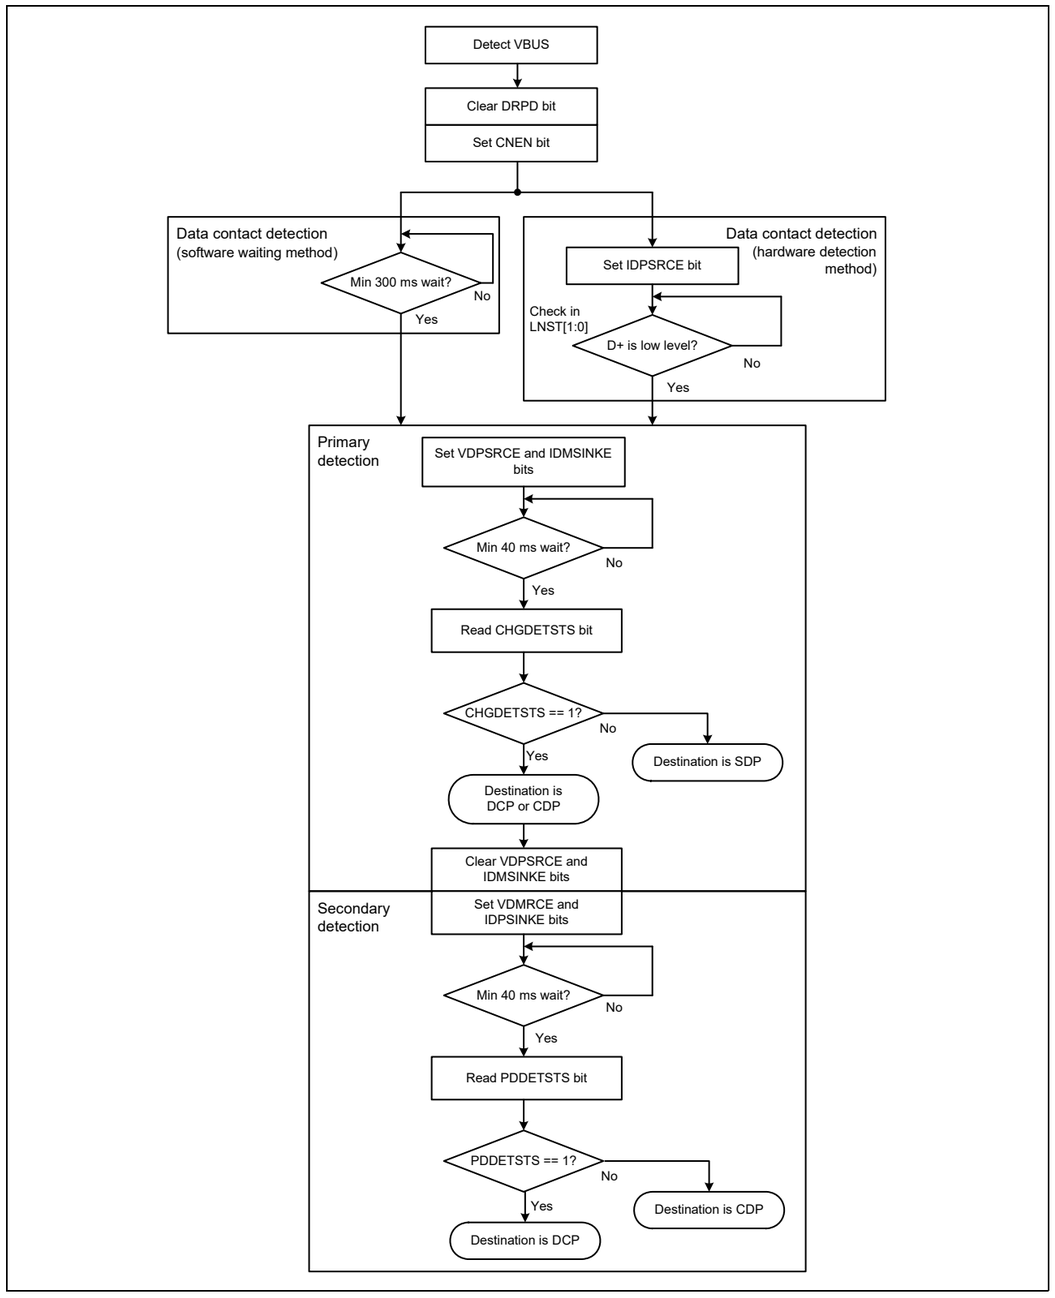

Figure 33.19 Processing flow as portable device

33.3.15.2 Processing in host controller mode

In host controller mode, driving the D- line is required for a portable device to perform primary detection. The USBHS supports the following two primary detection methods:

- When the hardware has a portable device detection function

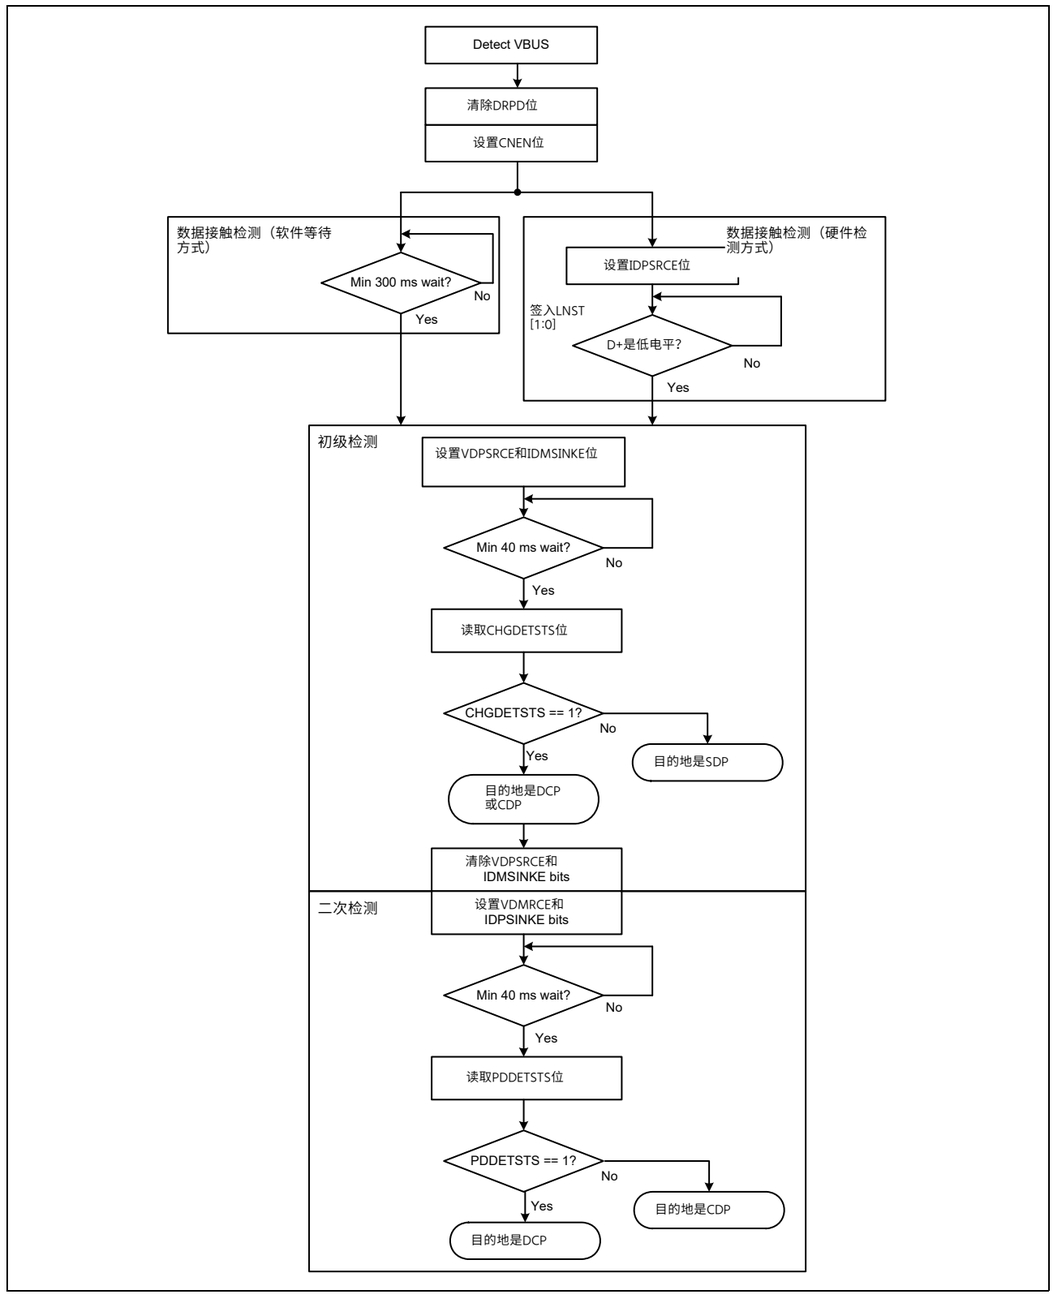

Figure 33.19 作为便携式设备的处理流程

33.3.15.2 主机控制器模式下的处理

在主机控制器模式下，便携式设备需要驱动Dline才能执行初级检测。USBHS支持以下两种主要检测方法：

- 当硬件具有便携设备检测功能时

- When the hardware does not have the function or the function is present but not used.

Figure 33.20 and Figure 33.21 show the processing flows for these methods.

(1) When the hardware has a portable device detection function

a. Start driving the USBHS_VBUS input pin.

b. Set the BCCTRL.IDMSINKE bit to 1 to enable the portable device detection circuit.

c. Monitor the portable device detection signal and start driving the D-line when the level of the portable device detection signal is high*1.

d. Stop driving the D-line when the portable device detection signal is at the low level*1.

Note 1. The PDDETINT interrupt indicates a change in the level of the portable device detection signal (EUH_CPDDET), and the current level can be obtained by reading the PDDETSTS flag.

(2) When the hardware does not have a portable device detection function or the function is not used

Software handles the timing of steps a. and b.

a. After a disconnect is detected, start driving the D-line within 200 ms.

b. After a connect is detected, stop driving the D-line within 10 ms.

33.3.16 Link Power Management Processing

The Link Power Management standard defines the existing Suspend state as the L2 state and also defines the L1 state as a state that allows transition and return with lower latency than the L2 state (Suspend). Table 33.34 provides a comparison between the L2 (Suspend) and L1 states.

Table 33.34 Comparison between L2 (Suspend) state and L1 state (1 of 2)

Parameter	L1 state	L2 (Suspend) state
Transition	LPM transaction	Idle for 3 ms
Return caused by host	Host: Minimum drive period (75 µs to 1.175 ms) can be specified by the host. Function: 10-µs K drive	Host: Minimum 20-ms K drive Function: 10-ms K drive

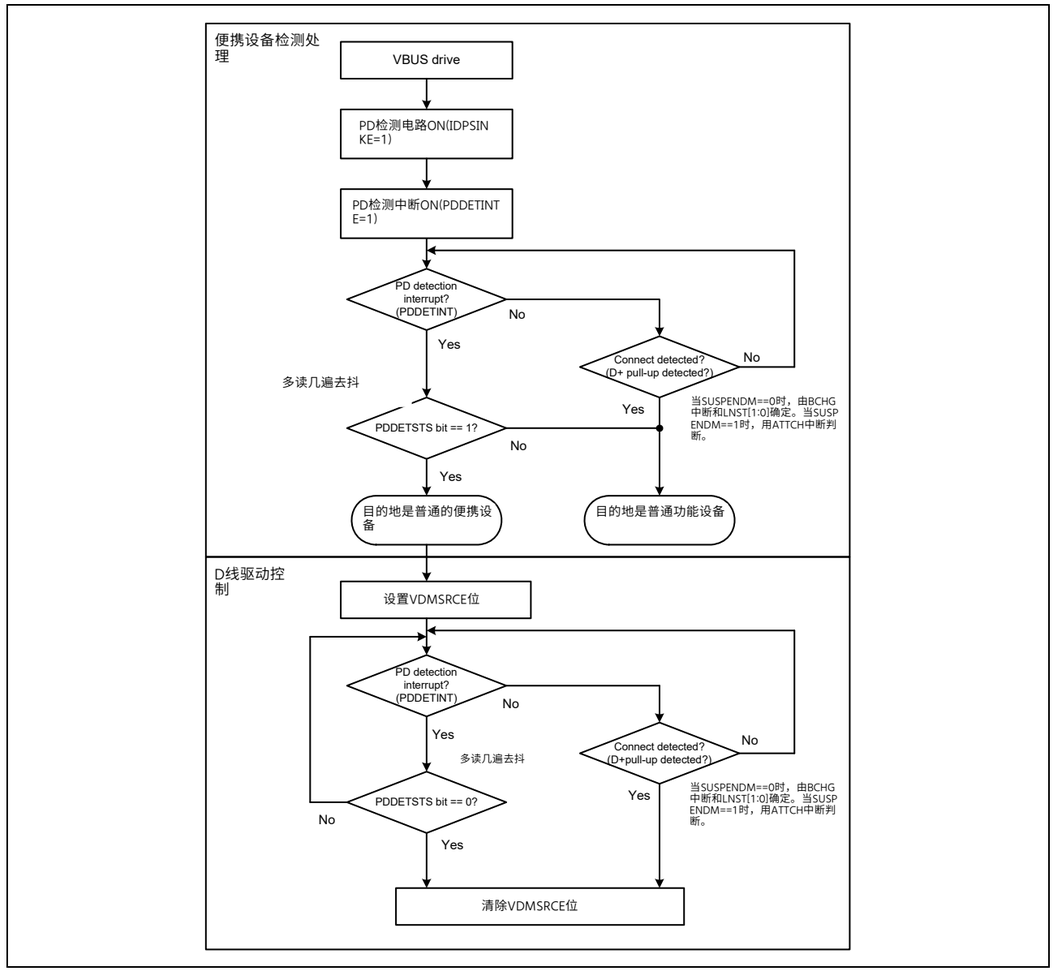

Figure 33.21 具有硬件便携设备检测功能的充电下行端口的处理流程

33.3.16 链路电源管理处理

LinkPowerManagement标准将现有的Suspend状态定义为L2状态，并将L1状态定义为允许转换和返回时延迟低于L2状态(Suspend)的状态。表33.34提供了L2（挂起）和L1状态之间的比较。

Table 33.34 L2（挂起）状态和L1状态之间的比较（1of2）

33.3.16.1 Processing in device controller mode

(1) Descriptor contents

In device controller mode, the USBHS must return its descriptor on receiving the GetDescriptor command.

Change the content of the descriptor to be returned depending on whether the transition to and return from the L1 state corresponds to the processing for the LPM transaction. The following table shows the relationship between LPM correspondence and the descriptor.

Table 33.35 Relationship between LPM correspondence and descriptor

Correspondence with LPM	bcdUSB field	USB2.0 extension descriptor		Response to received LPM request	Notes
		Provided/ not provided	Value of LPM bit		
Does not correspond	0200h	Not provided	—	No response	Normal operation when the LPM is not supported
	0201h	Provided	0	STALL	Setting for clear non-correspondence to LPM. In this case, a STALL response must be returned.
Corresponds	0201h	Provided	1	ACK or NYET	Normal operation when the LPM is supported

Declare whether to correspond to the transition to and return from L1 in the LPM bit in the USB 2.0 extension descriptor. To provide the USB2.0 extension descriptor, the bcdUSB field of the device descriptor must be set to a value of 0201h or larger.

When the LPM is not supported, the USB2.0 extension descriptor is not provided and the bcdUSB field value must be 0200h. If an LPM token is received in this case, it must be ignored. It is also possible to set the bcdUSB field value to 0201h and the LPM bit in the USB2.0 extension descriptor to 0 (LPM tokens not supported). In this case, the LPM token cannot be ignored and a STALL response must be returned.

When the LPM token is supported, set the bcdUSB field value to 0201h and set the LPM bit in the USB 2.0 extension descriptor to 1 (LPM tokens supported). This allows acknowledgment when returning a NYET or ACK response to the LPM token.

(2) Processing during LPM token reception

Transition to and return from the L1 state in device controller mode is as follows:

a. When the USBHS receives an LPM token from the host, the L1RESPEN, L1RESPMD[1:0], and L1NEGOMD settings in PL1CTRL1 determine whether a response packet is sent or the token is ignored and, if a response is to be sent, whether it is an ACK, NYET, or STALL packet.

b. If an ACK response to the LPM token is sent and the host does not transmit another LPM token in 8 µs, the USBHS enters the L1 state. The USBHS handles detection of the newly transmitted packet and the transition to the L1 state. The DVST interrupt can be used to detect the transition.

c. Two types of processing can return the USBHS from the L1 state:

- When the host drives the D-line in the K-state:
  The function device detects the K-state and starts processing the return from the L1 state in response to an

Table 33.34 L2（挂起）状态和L1状态之间的比较（2个中的2个）

Parameter	L1 state	L2 (Suspend) state
函数导致的返回	Device: 50-µs K drive Function: 60- to 990-µs K drive Device: 10-µs K drive	Function: 1- to 15-ms K drive Host: 最小20毫秒K驱动器 Function: 10-ms K drive
Signaling	Low- and full-speed idle	Low- and full-speed idle

33.3.16.1 设备控制器模式下的处理

(1) 描述符内容

在设备控制器模式下，USBHS必须在接收到GetDescriptor命令时返回其描述符。

根据L1状态的转换和返回是否对应于LPM事务的处理，更改要返回的描述符的内容。下表显示了LPM对应关系和描述符之间的关系。

Table 33.35 LPM对应与描述符的关系

与LPM的通信	bcdUSB field	USB2.0扩展描述符		收到的回复 LPM request	Notes
		提供未提供	LPM位的值		
不对应	0200h	不提供	—	没有反应	不支持LPM时的正常操作
	0201h	Provided	0	STALL	设置明确不对应 LPM。在这种情况下，必须返回一个STALL响应。
Corresponds	0201h	Provided	1	ACK或NYET	支持LPM时的正常操作

在USB2.0扩展描述符中的LPM位中声明是否对应于L1的转换和返回。要提供USB2.0扩展描述符，设备描述符的bcdUSB字段必须设置为0201h或更大的值。

不支持LPM时，不提供USB2.0扩展描述符，bcdUSB字段值必须为0200h。如果在这种情况下接收到LPM令牌，则必须将其忽略。也可以将bcdUSB字段值设置为0201h，并将USB2.0扩展描述符中的LPM位设置为0（不支持LPM令牌）。在这种情况下，不能忽略LPM令牌并且必须返回STALL响应。

当支持LPM令牌时，将bcdUSB字段值设置为0201h，并将USB2.0扩展描述符中的LPM位设置为1（支持LPM令牌）。这允许在向LPM令牌返回NYET或ACK响应时进行确认。

(2) LPM令牌接收期间的处理

设备控制器模式下L1状态的转换和返回如下：

一个。当USBHS接收到来自主机的LPM令牌时，PL1CTRL1中的L1RESPEN、L1RESPMD[1:0]和L1NEGOMD设置确定是发送响应包还是忽略令牌，如果要发送响应，是否是ACK、NYET或STALL数据包。

湾。如果发送了对LPM令牌的ACK响应并且主机在8µs内没有发送另一个LPM令牌，则
USBHS进入L1状态。USBHS处理新传输数据包的检测和向L1状态的转换。DVST中断可用于检测转换。

C。两种类型的处理可以使USBHS从L1状态返回：

- 当主机在K态驱动D线时：
  功能设备检测到K状态并开始处理从L1状态返回以响应

RESM interrupt request

- When the function device outputs a remote wakeup signal:
  If the software on the function device sets the DVSTCTR0.WKUP bit to 1, it sends a remote wakeup signal to the host.

The software clears the DVSTCTR0.WKUP bit to 0 on returning from the L2 (Suspend) state, and the USBHS clears the DVSTCTR0.WKUP bit to 0 for return from the L1 state.

(3) HIRD field value negotiation function

The HIRD field value included in the LPM token indicates the host K-drive period on return from the L1 state. The HIRD field value can be adjusted according to the requirements of the target system. For example, a small HIRD field value is better for systems focusing on higher transfer efficiency, while a large HIRD field value is better for systems focusing on low power consumption.

Based on the L1NEGOMD and HIRDTHR[3:0] settings in PL1CTRL1, an ACK response is returned when the received HIRD field value is in the expected range, and otherwise a NYET response is returned, requesting the host to change the HIRD field value.

Note: This HIRD field value negotiation function at the host must also support negotiation processing.

33.3.16.2 Processing in host controller mode

(1) Processing during LPM token transmission

Transition to and return from the L1 state in host controller mode is as follows:

a. When the HL1CTRL.L1REQ bit is set to 1, an LPM token is sent to the function device from the host device.

b. If an ACK response is received from the function device, a transition to the L1 state starts within 10 µs and is complete within 50 µs. If a transaction error is detected, another LPM token is transmitted within 8 µs. Retransmission can proceed up to two times. The USBHS handles all of this processing.

c. Two types of processing can return the USBHS from the L1 state:

- When the host drives the D-line for the K state:
  When the DVSTCTR0.RESUME bit is set to 1, the host device starts driving the D-line for the K-state and starts processing the return
- When the function device generates a remote wakeup signal:
  When the host device detects a remote wakeup signal from the function device, it sets the DVSTCTR0.RESUME bit to 1 and starts driving the D-line for the K-state.

Unlike when returning from the Suspend (L2) state, the USBHS clears the DVSTCTR0.RESUME bit to 0. After clearing the RESUME bit, it sets the DVSTCTR0.UACT bit to 1 and issues an L1RSMEND interrupt request.

33.3.17 Release from Deep Software Standby Mode Because of USB Suspend/Resume Interrupts

Deep Software Standby mode can be canceled by a USB suspend/resume interrupt. USB suspend/resume interrupts are detected by the USB resume detecting unit, which controls and monitors the USB I/O pins to detect the interrupts.

Figure 33.22 shows the flow for setting the USBHS when entering Deep Software Standby mode from either host or device controller mode. Figure 33.23 and Figure 33.24 show the flows for setting the USBHS when canceling Deep Software Standby mode from host controller mode. Figure 33.25 shows the flow for setting the USBHS when canceling Deep Software Standby mode from device controller mode.

RESM中断请求

- 当功能设备输出远程唤醒信号时：
  如果功能器件上的软件将DVSTCTR0.WKUP位设置为1，它会向主机发送远程唤醒信号。

软件在从L2（挂起）状态返回时将DVSTCTR0.WKUP位清除为0，并且USBHS清除
DVSTCTR0.WKUP位为0表示从L1状态返回。

(3) HIRD字段值协商功能

LPM令牌中包含的HIRD字段值指示从L1状态返回的主机K-drive周期。这
HIRD字段值可以根据目标系统的要求进行调整。例如，较小的HIRD字段值更适合专注于更高传输效率的系统，而较大的HIRD字段值更适合专注于低功耗的系统。

根据PL1CTRL1中的L1NEGOMD和HIRDTHR[3:0]设置，当接收到的HIRD字段值在预期范围内时返回ACK响应，否则返回NYET响应，请求主机更改
HIRD字段值。

Note: 主机上的这个HIRD字段值协商功能也必须支持协商处理。

33.3.16.2 主机控制器模式下的处理

(1) LPM令牌传输期间的处理

主机控制器模式下L1状态的转换和返回如下：

一个。当HL1CTRL.L1REQ位设置为1时，LPM令牌从主机设备发送到功能设备。

湾。如果从功能设备接收到ACK响应，则在10µs内开始转换到L1状态，并在50µs内完成。如果检测到事务错误，则会在8µs内发送另一个LPM令牌。重传最多可以进行两次。USBHS处理所有这些处理。

C。两种类型的处理可以使USBHS从L1状态返回：

- 当主机驱动D线为K状态时：
  当DVSTCTR0.RESUME位设置为1时，主机设备开始驱动D线为K状态并开始处理返回
- 当功能设备产生远程唤醒信号时：
  当主机设备检测到来自功能设备的远程唤醒信号时，它设置
  DVSTCTR0.RESUME位为1并开始驱动D线为K状态。

与从挂起(L2)状态返回时不同，USBHS将DVSTCTR0.RESUME位清除为0。清除RESUME位后，将DVSTCTR0.UACT位设置为1并发出L1RSMEND中断请求。

33.3.17 由于USB挂起恢复而从深度软件待机模式中释放 Interrupts

深度软件待机模式可以通过USB挂起恢复中断来取消。USB暂停恢复中断由USB恢复检测单元检测，该单元控制和监视USBIO引脚以检测中断。

图33.22显示了从主机或设备控制器模式进入深度软件待机模式时设置USBHS的流程。图33.23和图33.24显示了从主机控制器模式取消深度软件待机模式时设置USBHS的流程。图33.25显示取消时设置USBHS的流程

33.4 Usage Notes

33.4.1 Settings for the Module-Stop Function

USBHS operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The USBHS is initially stopped after reset. Releasing the module-stop state enables access to the registers. After releasing module stop, make settings required to activate the PHY circuit, including the input system clock frequency setting, and then clear the PHYSET.DIRPD bit to 0. For details, see section 11, Low Power Modes.

33.4.2 Setup for Transitioning to Deep Software Standby Mode

Before transitioning to Deep Software Standby mode, clear the DVSTCTR0.VBUSEN bit to 0.

33.4.3 Clearing the Interrupt Status Register on Exiting Software Standby Mode

Because the input buffer is always enabled in Software Standby mode, an unexpected interrupt might occur under the following conditions:

- When the interrupt is enabled in Normal mode
- When the interrupt is disabled in Software Standby mode
- When the input level of the pin that cancels Software Standby is changed in Software Standby mode.

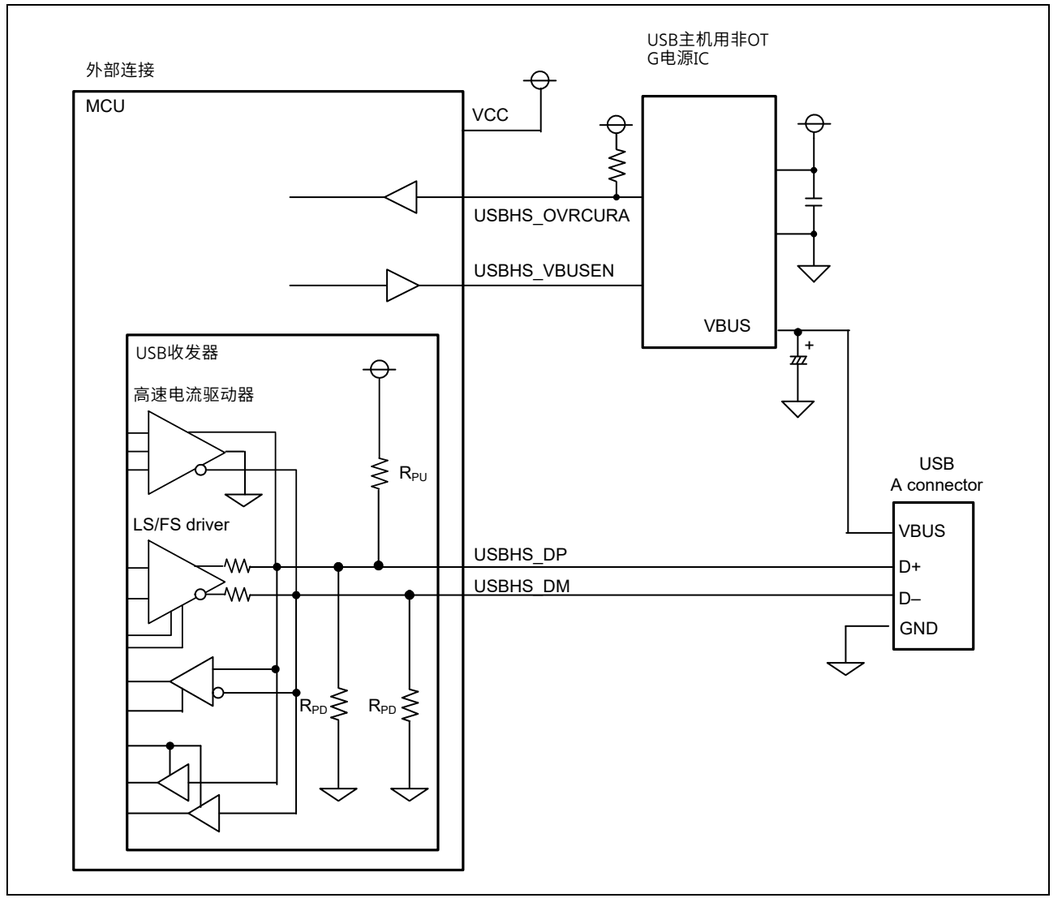

Figure 33.30 示例USB主机连接

33.4 使用说明

33.4.1 模块停止功能的设置

可以使用模块停止控制寄存器B(MSTPCRB)禁用或启用USBHS操作。USBHS在复位后最初停止。释放模块停止状态可以访问寄存器。释放模块停止后，进行激活PHY电路所需的设置，包括输入系统时钟频率设置，然后将PHYSET.DIRPD位清为0。详细信息请参见第11节，低功耗模式。

33.4.2 转换到深度软件待机模式的设置

在转换到深度软件待机模式之前，将DVSTCTR0.VBUSEN位清零。

33.4.3 退出软件待机模式时清除中断状态寄存器

由于在软件待机模式下始终启用输入缓冲区，因此在以下情况下可能会发生意外中断：

- 在正常模式下启用中断时
- 在软件待机模式下禁用中断时
- 在软件待机模式下，当取消软件待机的引脚的输入电平发生变化时。

These conditions might cause the associated interrupt flag in the Interrupt Status Register to set unexpectedly. After the MCU exits the Software Standby mode, the unexpected interrupt might be sent to the interrupt controller. To avoid this, always clear the INTSTS0 and INTSTS1 registers in the canceling sequence.

33.4.4 Clearing the Interrupt Status Register after Setting Up the Port Function

The input buffer is disabled before the PmnPFS.PSEL and PmnPFS.PMR ports are set up, so the internal signal is fixed high or low. The input buffer is enabled after the port is set so that the external pin state is propagated to the MCU. An unexpected interrupt might occur at this time, causing the VBINT and OVRCR bits in INTSTS0 and INTSTS1, or other interrupt status flags to set to 1. To avoid a malfunction, always clear the INTSTS0 and INTSTS1 registers after setting up the port.

这些情况可能会导致中断状态寄存器中的相关中断标志意外设置。MCU退出软件待机模式后，可能会向中断控制器发送意外中断。为避免这种情况，请始终在取消序列中清除INTSTS0和INTSTS1寄存器。

33.4.4 设置端口功能后清除中断状态寄存器

在设置PmnPFS.PSEL和PmnPFS.PMR端口之前，输入缓冲器被禁用，因此内部信号固定为高或低。设置端口后启用输入缓冲器，以便将外部引脚状态传播到MCU。此时可能会发生意外中断，导致INTSTS0和INTSTS1中的VBINT和OVRCR位或其他中断状态标志设置为1。为避免故障，请在设置端口后始终清除INTSTS0和INTSTS1寄存器。

34. Serial Communications Interface (SCI)

34.1 Overview

The Serial Communications Interface (SCI) is configurable to five asynchronous and synchronous serial interfaces:

- Asynchronous interfaces (UART and Asynchronous Communications Interface Adapter (ACIA))
- 8-bit clock synchronous interface
- Simple IIC (master-only)
- Simple SPI
- Smart card interface.

The smart card interface complies with the ISO/IEC 7816-3 standard for electronic signals and transmission protocol. Each SCI has FIFO buffers to enable continuous and full-duplex communication, and the data transfer speed can be configured independently using an on-chip baud rate generator.

Table 34.1 lists the SCI specifications, Figure 34.1 shows a block diagram of SCI channel n, and Table 34.2 lists the I/O pins by mode.

Table 34.1 SCI specifications (1 of 2)

Parameter	Specifications
Serial communication modes	• Asynchronous • Clock synchronous • Smart card interface • Simple IIC • Simple SPI.
Transfer speed	Bit rate specifiable with the on-chip baud rate generator
Full-duplex communications	• Transmitter: Continuous transmission possible using double-buffering • Receiver: Continuous reception possible using double-buffering
I/O pins	See Table 34.2
Data transfer	Selectable as LSB-first or MSB-first transfer
Interrupt sources	Transmit end, transmit data empty, receive data full, receive error, receive data ready, and address match Completion of generation of a start condition, restart condition, or stop condition (for simple IIC mode)
Module-stop function	Module-stop state can be set for each channel
Snooze end request	SCI0 address mismatch (SCI0_DCUF)

34. 串行通信接口(SCI)

34.1 Overview

串行通信接口(SCI)可配置为五个异步和同步串行接口：

- 异步接口（UART和异步通信接口适配器(ACIA)）
- 8位时钟同步接口
- Simple IIC (master-only)
- 简单的SPI
- 智能卡接口。

智能卡接口符合ISOIEC7816-3电子信号和传输协议标准。
每个SCI都有FIFO缓冲区以实现连续和全双工通信，并且可以使用片上波特率发生器独立配置数据传输速度。

表34.1列出了SCI规格，图34.1显示了SCI通道n的框图，表34.2列出了按模式划分的IO引脚。

34.2 Register Descriptions

34.2.1 Receive Shift Register (RSR)

RSR is a shift register that receives serial data input from the RXDn pin and converts it into parallel data. When one frame of data is received, it is automatically transferred to the RDR register, RDRHL register, or receive FIFO. The RSR register cannot be directly accessed by the CPU.

34.2.2 Receive Data Register (RDR)

Address(es): SCI0.RDR 4007 0005h, SCI1.RDR 4007 0025h, SCI2.RDR 4007 0045h, SCI3.RDR 4007 0065h, SCI4.RDR 4007 0085h, SCI5.RDR 4007 00A5h, SCI6.RDR 4007 00C5h, SCI7.RDR 4007 00E5h, SCI8.RDR 4007 0105h, SCI9.RDR 4007 0125h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

RDR is an 8-bit register that stores receive data. When one frame of serial data is received, it is transferred from the RSR register to the RDR register, and the RSR register can receive more data. Because RSR and RDR function as a double buffer in this way, continuous receive operations can be performed.

Read the RDR register only once after a receive data full interrupt (SCIn_RXI) occurs.

Note: If the next frame of data is received before the receive data is read from the RDR register, an overrun error occurs. The RDR register cannot be written to by the CPU.

34.2 注册说明

34.2.1 接收移位寄存器(RSR)

RSR是一个移位寄存器，它接收从RXDn引脚输入的串行数据并将其转换为并行数据。当接收到一帧数据时，它会自动传输到RDR寄存器、RDRHL寄存器或接收FIFO。CPU不能直接访问RSR寄存器。

34.2.2 接收数据寄存器(RDR)

Address(es): SCI0.RDR 4007 0005h, SCI1.RDR 4007 0025h, SCI2.RDR 4007 0045h, SCI3.RDR 4007 0065h, SCI4.RDR 4007 0085h, SCI5.RDR 4007 00A5h, SCI6.RDR 4007 00C5h, SCI7.RDR 4007 00E5h, SCI8.RDR 4007 0105h, SCI9.RDR 4007 0125h

	b7	b6	b5	b4	b3	b2	b1	b0
重置后的值:	0	0	0	0	0	0	0	0

RDR是一个8位寄存器，用于存储接收数据。当接收到一帧串行数据时，从RSR寄存器传送到RDR寄存器，RSR寄存器可以接收更多的数据。由于RSR和RDR以这种方式充当双缓冲器，因此可以执行连续接收操作。

在接收数据完全中断(SCIn_RXI)发生后，仅读取一次RDR寄存器。

Note: 如果在从RDR寄存器读取接收数据之前接收到下一帧数据，则会发生溢出错误。RDR寄存器不能被CPU写入。

34.2.3 Receive 9-Bit Data Register (RDRHL)

Address(es): SCI0.RDRHL 4007 0010h, SCI1.RDRHL 4007 0030h, SCI2.RDRHL 4007 0050h, SCI3.RDRHL 4007 0070h, SCI4.RDRHL 4007 0090h, SCI5.RDRHL 4007 00B0h, SCI6.RDRHL 4007 00D0h, SCI7.RDRHL 4007 00F0h, SCI8.RDRHL 4007 0110h, SCI9.RDRHL 4007 0130h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RDRHL is a 16-bit register that stores receive data. Use the RDRHL register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of RDRHL are a shadow register of RDR, so access to the RDRHL register affects the RDR register. Access to the RDRHL register is prohibited if 7-bit or 8-bit data length is selected.

After one frame of data is received, the received data is transferred from the RSR register to the RDRHL register, allowing the RSR register to receive more data.

The RSR and RDRHL registers have a double-buffered construction to enable continuous reception. The RDRHL register must be read only when a receive data full interrupt (SCIn_RXI) request is issued. An overrun error occurs when the next frame of data is received before the received data is read from the RDRHL register.

The CPU cannot write to the RDRHL register. Bits [15:9] are fixed to 0. These bits are read as 0. The write value should be 0.

34.2.4 Receive FIFO Data Register H, L, HL (FRDRH, FRDRL, FRDRHL)

Receive FIFO Data Register H (FRDRH)

34.2.3 接收9位数据寄存器(RDRHL)

Address(es): SCI0.RDRHL 4007 0010h, SCI1.RDRHL 4007 0030h, SCI2.RDRHL 4007 0050h, SCI3.RDRHL 4007 0070h, SCI4.RDRHL 4007 0090h, SCI5.RDRHL 4007 00B0h, SCI6.RDRHL 4007 00D0h, SCI7.RDRHL 4007 00F0h, SCI8.RDRHL 4007 0110h, SCI9.RDRHL 4007 0130h

重置后的值:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RDRHL是一个16位寄存器，用于存储接收数据。选择异步模式和9位数据长度时，请使用RDRHL寄存器。

RDRHL的低8位是RDR的影子寄存器，因此对RDRHL寄存器的访问会影响RDR寄存器。
如果选择7位或8位数据长度，则禁止访问RDRHL寄存器。

接收到一帧数据后，将接收到的数据从RSR寄存器传送到RDRHL寄存器，让RSR寄存器接收更多数据。

RSR和RDRHL寄存器具有双缓冲结构以实现连续接收。仅当发出接收数据完整中断(SCIn_RXI)请求时，必须读取RDRHL寄存器。在从RDRHL寄存器读取接收到的数据之前接收到下一帧数据时，会发生溢出错误。

CPU无法写入RDRHL寄存器。位[15:9]固定为0。这些位被读取为0。写入值应为0。

R*1
b15	—	Reserved	This bit is read as 0.	R

Note 1. If this flag is read, it indicates the same value as that read from the SSR_FIFO register. Write 0 to the SSR_FIFO register to clear the flag.

FRDRHL is a 16-bit register that consists of the 8-bit FRDRH and FRDRL registers.

FRDRH and FRDRL constitute a 16-stage FIFO register that stores serial receive data and related status information readable by software. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

The SCI completes reception of one frame of serial data by transferring the received data from the Receive Shift Register (RSR) into FRDRH and FRDRL for storage. Continuous reception is executed until 16 stages are stored. If data is read when there is no received data in FRDRH and FRDRL, the value is undefined. When FRDRH and FRDRL are full, subsequent serial receive data is lost. The CPU can read from the FRDRH and FRDRL registers but cannot write to them.

Reading 1 from the RDF, ORER, or DR flags of the FRDRH register is the same as reading from those bits in the SSR_FIFO register. When writing 0 to clear a flag in the SSR_FIFO register after reading the FRDRH register, write 0 only to the flag that is to be cleared and write 1 to the other flags.

When reading both the FRDRH and FRDRL registers, read in order from FRDRH to FRDRL. The FRDRHL register can be accessed in 16-bit units.

TDR is an 8-bit register that stores transmit data.

When the SCI detects that the TSR register is empty, it transfers the transmit data written in the TDR register to the TSR register and starts transmission.

The double-buffered structure of the TDR and TSR registers enables continuous serial transmission. If the next transmit data is already written to TDR when one frame of data is transmitted, the SCI transfers the written data to the TSR

Note 1. 如果读取该标志，则表示与从SSR_FIFO寄存器读取的值相同。将0写入SSR_FIFO寄存器以清除标志。

FRDRHL是一个16位寄存器，由8位FRDRH和FRDRL寄存器组成。

FRDRH和FRDRL构成一个16级FIFO寄存器，用于存储串行接收数据和软件可读的相关状态信息。该寄存器仅在异步模式下有效，包括多处理器模式或时钟同步模式。

SCI通过将接收到的数据从接收移位寄存器（RSR）传送到FRDRH和FRDRL中进行存储，从而完成一帧串行数据的接收。执行连续接收，直到存储16个阶段。如果在FRDRH和FRDRL中没有接收到数据时读取数据，则该值未定义。当FRDRH和FRDRL已满时，后续的串行接收数据会丢失。CPU可以读取FRDRH和FRDRL寄存器，但不能写入它们。

从FRDRH寄存器的RDF、ORER或DR标志读取1与从SSR_FIFO寄存器。在读取FRDRH寄存器后写入0以清除SSR_FIFO寄存器中的标志时，仅将0写入要清除的标志，将1写入其他标志。

读取FRDRH和FRDRL寄存器时，按从FRDRH到FRDRL的顺序读取。FRDRHL寄存器可以以16位为单位进行访问。

TDR是一个8位寄存器，用于存储发送数据。

当SCI检测到TSR寄存器为空时，将写入TDR寄存器的发送数据传送到TSR寄存器并开始发送。

TDR和TSR寄存器的双缓冲结构可实现连续串行传输。如果在发送一帧数据时，下一个发送数据已经写入TDR，则SCI将写入的数据传输到TSR

TDRHL is a 16-bit register that stores transmit data. Use the TDRHL register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of TDRHL are a shadow register of TDR, so access to TDRHL affects the TDR register. Access to the TDRHL register is prohibited if 7-bit or 8-bit data length is selected.

When empty space is detected in the TSR register, the transmit data stored in the TDRHL register is transferred to the TSR register and transmission is started.

The TSR and TDRHL registers have a double-buffered structure to support continuous transmission. When the next data to be transmitted is stored in TDRHL after one frame of data is transmitted, the transmitting operation is continued by transferring the data from the TDRHL register to the TSR register.

The CPU can read from and write to the TDRHL register. Bits [15:9] in the TDRHL register are fixed to 1. These bits are read as 1. The write value should be 1.

Write transmit data to the TDRHL register only once when a transmit data empty interrupt (SCIn_TXI) request is issued.

注册以继续传输。

CPU可以随时读取或写入TDR。每次发送数据空中断(SCIn_TXI)后，仅将发送数据写入TDR一次。

TDRHL是一个16位寄存器，用于存储发送数据。选择异步模式和9位数据长度时，请使用TDRHL寄存器。

TDRHL的低8位是TDR的影子寄存器，因此访问TDRHL会影响TDR寄存器。访问
如果选择7位或8位数据长度，则禁止TDRHL寄存器。

当在TSR寄存器中检测到空空间时，存储在TDRHL寄存器中的发送数据被传送到
TSR寄存器和传输开始。

TSR和TDRHL寄存器具有双缓冲结构以支持连续传输。当下一个要发送的数据在发送一帧数据后存储在TDRHL中时，通过将数据从TDRHL寄存器传送到TSR寄存器来继续发送操作。

CPU可以读取和写入TDRHL寄存器。TDRHL寄存器中的位[15:9]固定为1。这些位被读取为1。写入值应为1。

当发出发送数据空中断(SCIn_TXI)请求时，仅将发送数据写入TDRHL寄存器一次。

FTDRHL is a 16-bit register that consists of the 8-bit FTDRH and FTDRL registers.

FTDRH and FTDRL constitute a 16-stage FIFO register that stores data for serial transmission and a multi-processor transfer bit. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

When the SCI detects that the Transmit Shift Register (TSR) is empty, it transfers data written in the FTDRH and FTDRL registers to the TSR register and starts serial transmission. Continuous serial transmission is executed until no transmit data is left in FTDRH and FTDRL. When FTDRHL is full of transmit data, no more data can be written. If writing new data is attempted, the data is ignored. The CPU can write to the FTDRH and FTDRL registers but cannot read them.

When writing to both the FTDRH and FTDRL registers, write in order from FTDRH to FTDRL.

MPBT flag (Multi-Processor Transfer Bit Flag)

The MPBT flag specifies the value of the multi-processor bit of the transmit frame. When FCR.FM = 1, SSR.MPBT is invalid.

34.2.8 Transmit Shift Register (TSR)

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first automatically transfers transmit data from TDR, TDRHL, or transmit FIFO to the TSR register, and then sends the data to the TXDn pin. The CPU cannot directly access the TSR register.

FTDRHL是一个16位寄存器，由8位FTDRH和FTDRL寄存器组成。

FTDRH和FTDRL构成一个16级FIFO寄存器，用于存储串行传输的数据和一个多处理器传输位。该寄存器仅在异步模式下有效，包括多处理器模式或时钟同步模式。

当SCI检测到发送移位寄存器(TSR)为空时，它会传输写入FTDRH中的数据并FTDRL注册到TSR寄存器并开始串行传输。执行连续串行传输，直到在FTDRH和FTDRL中没有剩余传输数据。当FTDRHL充满传输数据时，不能再写入数据。如果尝试写入新数据，则忽略该数据。CPU可以写入FTDRH和FTDRL寄存器，但不能读取它们。

当同时写入FTDRH和FTDRL寄存器时，按照从FTDRH到FTDRL的顺序写入。

MPBT标志（多处理器传输位标志）

MPBT标志指定发送帧的多处理器位的值。FCR.FM=1时，SSR.MPBT无效。

34.2.8 发送移位寄存器(TSR)

TSR是传送串行数据的移位寄存器。进行串行数据传输时，SCI首先自动将发送数据从TDR、TDRHL或发送FIFO传输到TSR寄存器，然后将数据发送到TXDn引脚。CPU不能直接访问TSR寄存器。

b7	CM	Communication Mode	0: Asynchronous mode or simple IIC mode 1: Clock synchronous mode or simple SPI mode.	R/W*4

Note 1. n is the decimal notation of the value of n in the BRR register. See section 34.2.17, Bit Rate Register (BRR).
Note 2. In any mode other than asynchronous mode, this bit setting is invalid and a fixed data length of 8 bits is used.
Note 3. LSB-first is fixed and the MSB (bit [7]) in the TDR register is not transmitted in transmit mode.
Note 4. Writable only when SCR.TE = 0 and SCR.RE = 0 (both serial transmission and reception are disabled).

The SMR register sets the communication format and clock source for the on-chip baud rate generator.

CKS[1:0] bits (Clock Select)

The CKS[1:0] bits select the clock source for the on-chip baud rate generator. For the relationship between the settings of these bits and the baud rate, see section 34.2.17, Bit Rate Register (BRR).

MP bit (Multi-Processor Mode)

The MP bit disables or enables the multi-processor communications function. The PE and PM bit settings are invalid in multi-processor mode.

Note 1. n是BRR寄存器中n值的十进制表示法。请参阅第34.2.17节，比特率寄存器(BRR)。
Note 2. 在异步模式以外的任何模式下，该位设置无效，使用固定的8位数据长度。
Note 3. LSB-first是固定的，并且TDR寄存器中的MSB（位[7]）在发送模式下不发送。
Note 4. 仅当SCR.TE=0和SCR.RE=0时可写（串行发送和接收均禁用）。

SMR寄存器设置片内波特率发生器的通信格式和时钟源。

CKS[1:0]位（时钟选择）

CKS[1:0]位选择片内波特率发生器的时钟源。有关这些位的设置与波特率之间的关系，请参见第34.2.17节，比特率寄存器(BRR)。

MP位（多处理器模式）

MP位禁用或启用多处理器通信功能。PE和PM位设置在多处理器模式下无效。

STOP bit (Stop Bit Length)

The STOP bit selects the stop bit length in transmission.

In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

PM bit (Parity Mode)

The PM bit selects the parity mode (even or odd) for transmission and reception. The PM bit setting is invalid in multi-processor mode.

PE bit (Parity Enable)

When the PE bit is set to 1, the parity bit is added to transmit data, and the parity bit is checked in reception. Regardless of the PE bit setting, the parity bit is not added or checked in multi-processor format.

CHR bit (Character Length)

The CHR bit selects the data length for transmission and reception in combination with the SCMR.CHR1 bit. In modes other than asynchronous, a fixed data length of 8 bits is used.

CM bit (Communication Mode)

The CM bit selects the communication mode:

- Asynchronous mode or simple IIC mode
- Clock synchronous mode or simple SPI mode.

Note 2. Writable only when SCR_SMCI.TE = 0 and SCR_SMCI.RE = 0 (both serial transmission and reception are disabled).

停止位（停止位长度）

STOP位选择传输中的停止位长度。

在接收中，无论该位设置如何，都只检查第一个停止位。如果第二个停止位为0，则将其视为下一个发送帧的起始位。

PM位（奇偶校验模式）

PM位选择发送和接收的奇偶校验模式（偶数或奇数）。PM位设置在多处理器模式下无效。

PE位（奇偶校验使能）

当PE位设置为1时，发送数据时添加奇偶校验位，接收时检查奇偶校验位。无论PE位设置如何，在多处理器格式中都不会添加或检查奇偶校验位。

CHR位（字符长度）

CHR位与SCMR.CHR1位一起选择发送和接收的数据长度。在非异步模式下，使用8位的固定数据长度。

CM位（通信模式）

CM位选择通信模式：

Note 1. n是BRR寄存器中n值的十进制表示法。请参阅第34.2.17节，比特率寄存器(BRR)。
Note 2. 仅当SCR_SMCI.TE=0且SCR_SMCI.RE=0时可写（串行传输和接收均禁用）。

The SMR_SMCI register sets the communication format and clock source for the on-chip baud rate generator.

CKS[1:0] bit (Clock Select)

The CKS[1:0] bits select the clock source for the on-chip baud rate generator. For the relationship between the settings of these bits and the baud rate, see section 34.2.17, Bit Rate Register (BRR).

BCP[1:0] bits (Base Clock Pulse)

The BCP[1:0] bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set these bits in combination with the SCMR.BCP2 bit.

For details, see section 34.6.4, Receive Data Sampling Timing and Reception Margin.

Table 34.3 Combinations of SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits

SCMR.BCP2 bit	SMR_SMCI.BCP[1:0] bits	Number of base clock cycles for 1-bit transfer period
0	00	93 clock cycles (S = 93)*1
0	01	128 clock cycles (S = 128)*1
0	10	186 clock cycles (S = 186)*1
0	11	512 clock cycles (S = 512)*1
1	00	32 clock cycles (S = 32)*1 (initial value)
1	01	64 clock cycles (S = 64)*1
1	10	372 clock cycles (S = 372)*1
1	11	256 clock cycles (S = 256)*1

Note 1. See section 34.2.17, Bit Rate Register (BRR).

PM bit (Parity Mode)

The PM bit selects the parity mode for transmission and reception (even or odd). For details on the usage of this bit in smart card interface mode, see section 34.6.2, Data Format (Except in Block Transfer Mode).

PE bit (Parity Enable)

Set the PE bit to 1. The parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

BLK bit (Block Transfer Mode)

Setting the BLK bit to 1 enables block transfer mode operation. For details, see section 34.6.3, Block Transfer Mode.

GM bit (GSM Mode)

Setting the GM bit to 1 enables GSM mode operation. In GSM mode, the SSR_SMCI.TEND flag set timing is moved forward to 11.0 ETUs (elementary time unit = 1-bit transfer time) from the start bit, and clock output control is added. For details, see section 34.6.6, Serial Data Transmission (Except in Block Transfer Mode) and section 34.6.8, Clock Output Control.

SMR_SMCI寄存器设置片内波特率发生器的通信格式和时钟源。

CKS[1:0]位（时钟选择）

CKS[1:0]位选择片内波特率发生器的时钟源。有关这些位的设置与波特率之间的关系，请参见第34.2.17节，比特率寄存器(BRR)。

BCP[1:0]位（基本时钟脉冲）

BCP[1:0]位选择智能卡接口模式下1位数据传输时间内的基本时钟周期数。将这些位与SCMR.BCP2位一起设置。

有关详细信息，请参阅第34.6.4节，接收数据采样时序和接收余量。

1	11	256个时钟周期(S=256)*1

Note 1. 请参阅第34.2.17节，比特率寄存器(BRR)。

PM位（奇偶校验模式）

PM位选择发送和接收的奇偶校验模式（偶数或奇数）。有关该位在智能卡接口模式下的使用详情，请参见第34.6.2节，数据格式（块传输模式除外）。

PE位（奇偶校验使能）

将PE位设置为1。发送数据前添加奇偶校验位，接收时校验奇偶校验位。

BLK位（块传输模式）

将BLK位设置为1可启用块传输模式操作。有关详细信息，请参阅第34.6.3节，块传输模式。

GM位（GSM模式）

将GM位设置为1启用GSM模式操作。在GSM模式下，SSR_SMCI.TEND标志设置时序从起始位前移到11.0ETU（基本时间单位=1位传输时间），并添加了时钟输出控制。有关详细信息，请参见第34.6.6节，串行数据传输（块传输模式除外）和第34.6.8节，时钟
输出控制。

Note 1. Writable only when TE = 0 and RE = 0.
Note 2. 1 can be written only when TE = 0 and RE = 0, when the SMR.CM bit is 1. After setting TE or RE to 1, only 0 can be written to TE and RE. When the SMR.CM bit is 0 and the SIMR1.IICM bit is 0, writing is enabled under any condition.
Note 3. When writing a new value to a bit other than the MPIE bit of this register in multi-processor mode (SMR.MP bit = 1), write 0 to the MPIE bit using the store instruction to avoid accidentally setting the MPIE bit to 1 by a read-modify-write operation when using a bit manipulation instruction.

The SCR register controls operation and clock source selection for transmission and reception.

Note 1. 仅当TE=0且RE=0时可写。
Note 2. 只有当TE=0且RE=0时，SMR.CM位为1时才能写入1。将TE或RE设置为1后，TE和RE只能写入0。当SMR.CM位为0且SIMR1.IICM位为0时，在任何情况下都可以写入。
Note 3. 在多处理器模式下（SMR.MP位=1）向该寄存器的MPIE位以外的位写入新值时，使用存储指令将0写入MPIE位，以避免意外将MPIE位设置为1使用位操作指令时的读-修改-写操作。

SCR寄存器控制发送和接收的操作和时钟源选择。

CKE[1:0] bits (Clock Enable)

The CKE[1:0] bits select the clock source and the SCKn pin function.

TEIE bit (Transmit End Interrupt Enable)

The TEIE bit enables or disables SCIn_TEI interrupt requests. Set TEIE to 0 to disable an SCIn_TEI interrupt request.

In simple IIC mode, SCIn_TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STIn). In this case, the TEIE bit can be used to enable or disable the STI.

MPIE bit (Multi-Processor Interrupt Enable)

When the MPIE bit is set to 1 and data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags RDRF, ORER, and FER in SSR/SSR_FIFO to 1 is disabled. When data with the multi-processor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and non-multi processor reception resumes. For details, see section 34.4, Multi-Processor Communication Function.

When the MPB bit in the SSR register is 0, the receive data is not transferred from the RSR register to the RDR register, a receive error is not detected, and setting the flags ORER and FER to 1 is disabled.

When the MPB bit is set to 1, the MPIE bit is automatically cleared to 0, SCIn_RXI and SCIn_ERI interrupt requests are enabled (if the RIE bit in SCR is set to 1), and setting of the ORER and FER flags to 1 is enabled.

Set MPIE to 0 if the multi-processor communications function is not used.

RE bit (Receive Enable)

The RE bit enables or disables serial reception. When the RE bit is set to 1, serial reception starts by detecting the start bit in asynchronous mode or the synchronous clock input in clock synchronous mode. Set the reception format in the SMR register before setting the RE bit to 1.

In non-FIFO operation, when reception is halted by setting the RE bit to 0, the RDRF, ORER, FER, and PER flags in the SSR register are not affected, and the previous values are retained.

When FIFO operation is selected and reception is halted by setting the RE bit to 0, the RDF, ORER, FER, PER, and DR flags in SSR_FIFO are not affected and the previous values are retained.

TE bit (Transmit Enable)

The TE bit enables or disables serial transmission.

When the TE bit is set to 1, serial transmission is started by writing transmit data to the TDR register. Set the transmission format in the SMR register before setting the TE bit to 1.

RIE bit (Receive Interrupt Enable)

The RIE bit enables or disables SCIn_RXI and SCIn_ERI interrupt requests.

SCIn_RXI and SCIn_ERI interrupt requests are disabled by setting the RIE bit to 0.

An SCIn_ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in SSR/SSR_FIFO then setting the flag to 0, or by setting the RIE bit to 0.

TIE bit (Transmit Interrupt Enable)

The TIE bit enables or disables SCIn_TXI interrupt requests. SCIn_TXI interrupt requests are disabled by setting the TIE bit to 0. Set the TIE bit to 1 while the TE bit is 1. The SCIn_TXI interrupt occurs after TE and TIE bits are set to 1 simultaneously, before transfer starts.

CKE[1:0]位（时钟使能）

CKE[1:0]位选择时钟源和SCKn引脚功能。

TEIE位（发送结束中断使能）

TEIE位启用或禁用SCIn_TEI中断请求。将TEIE设置为0以禁用SCIn_TEI中断请求。

在简单IIC模式下，SCIn_TEI在完成发出启动、重新启动或停止条件(STIn)时分配给中断。在这种情况下，TEIE位可用于启用或禁用STI。

MPIE位（多处理器中断使能）

当MPIE位设置为1并且接收到多处理器位设置为0的数据时，不读取数据并且将SSRSSR_FIFO中的状态标志RDRF、ORER和FER设置为1被禁用。当接收到多处理器位设置为1的数据时，MPIE位自动清除为0，并恢复非多处理器接收。有关详细信息，请参阅第34.4节，多处理器通信功能。

当SSR寄存器的MPB位为0时，接收数据不会从RSR寄存器传送到RDR寄存器，不会检测到接收错误，并且将标志ORER和FER设置为1被禁止。

当MPB位设置为1时，MPIE位自动清零，启用SCIn_RXI和SCIn_ERI中断请求（如果SCR中的RIE位设置为1），并且启用ORER和FER标志设置为1.

如果不使用多处理器通信功能，则将MPIE设置为0。

RE位（接收使能）

RE位启用或禁用串行接收。当RE位设置为1时，串行接收通过检测异步模式下的起始位或时钟同步模式下的同步时钟输入来启动。在将RE位设置为1之前，在SMR寄存器中设置接收格式。

在非FIFO操作中，当通过将RE位设置为0来停止接收时，RDRF、ORER、FER和PER标志SSR寄存器不受影响，保留之前的值。

WhenFIFOoperationisselectedandreceptionishaltedbysettingtheREbitto0 theRDF ORER FER PER andDRflagsinSSR_FIFOarenotaffectedandthepreviousvaluesareretained.

TE位（发送使能）

TE位启用或禁用串行传输。

当TE位设置为1时，通过将发送数据写入TDR寄存器开始串行发送。在将TE位设置为1之前，在SMR寄存器中设置传输格式。

RIE位（接收中断使能）

RIE位启用或禁用SCIn_RXI和SCIn_ERI中断请求。

通过将RIE位设置为0来禁用SCIn_RXI和SCIn_ERI中断请求。

SCIn_ERI中断请求可以通过从SSRSSR_FIFO中的ORER、FER或PER标志读取1然后将该标志设置为0或通过将RIE位设置为0来取消。

TIE位（发送中断使能）

TIE位启用或禁用SCIn_TXI中断请求。通过将TIE位设置为0来禁用SCIn_TXI中断请求。在TE位为1时将TIE位设置为1。在TE和TIE位同时设置为1之后，在传输开始之前发生SCIn_TXI中断。

The SCR_SMCI register sets transmission and reception control, interrupt control, and clock source selection for transmission and reception.

For details on interrupt requests, see section 34.10, Interrupt Sources.

CKE[1:0] bits (Clock Enable)

The CKE[1:0] bits control the clock output from the SCKn pin. In GSM mode, clock output can be dynamically switched. For details, see section 34.6.8, Clock Output Control.

TEIE bit (Transmit End Interrupt Enable)

Set the TEIE bit to 0 in smart card interface mode.

MPIE bit (Multi-Processor Interrupt Enable)

Set the MPIE bit to 0 in smart card interface mode.

RE bit (Receive Enable)

The RE bit enables or disables serial reception. When the RE bit is set to 1, serial reception starts by detecting the start bit. Set the reception format in the SMR_SMCI register before setting the RE bit to 1.

CKE[1:0]位控制SCKn引脚的时钟输出。在GSM模式下，时钟输出可以动态切换。有关详细信息，请参见第34.6.8节，时钟输出控制。

TEIE位（发送结束中断使能）

在智能卡接口模式下将TEIE位设置为0。

MPIE位（多处理器中断使能）

在智能卡接口模式下将MPIE位设置为0。

RE位（接收使能）

RE位启用或禁用串行接收。当RE位设置为1时，串行接收通过检测起始位开始。在将RE位设置为1之前，在SMR_SMCI寄存器中设置接收格式。

If reception is halted by setting the RE bit to 0, the ORER, FER, and PER flags in SSR_SMCI are not affected and the previous values are retained.

TE bit (Transmit Enable)

The TE bit enables or disables serial transmission. When the TE bit is set to 1, serial transmission is started by writing transmit data to TDR. Set the transmission format in the SMR_SMCI register before setting the TE bit to 1.

RIE bit (Receive Interrupt Enable)

The RIE bit enables or disables SCIn_RXI and SCIn_ERI interrupt requests.

SCIn_RXI and SCIn_ERI interrupt requests are disabled by setting the RIE bit to 0.

An SCIn_ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in the SSR_SMCI register, and then setting the flag to 0, or by setting the RIE bit to 0.

TIE bit (Transmit Interrupt Enable)

The TIE bit enables or disables SCIn_TXI interrupt requests. SCIn_TXI interrupt requests are disabled by setting the TIE bit to 0. Set the TIE bit to 1 while the TE bit is 1. The SCIn_TXI interrupt occurs after TE and TIE bits are set to 1 simultaneously, before transfer starts.

The SSR register provides SCI status flags and transmission and reception multi-processor bits.

如果通过将RE位设置为0来停止接收，则SSR_SMCI中的ORER、FER和PER标志不受影响，并且保留以前的值。

TE位（发送使能）

TE位启用或禁用串行传输。当TE位设置为1时，通过将发送数据写入TDR开始串行发送。在将TE位设置为1之前，在SMR_SMCI寄存器中设置传输格式。

RIE位（接收中断使能）

RIE位启用或禁用SCIn_RXI和SCIn_ERI中断请求。

通过将RIE位设置为0来禁用SCIn_RXI和SCIn_ERI中断请求。

通过从SSR_SMCI寄存器中的ORER、FER或PER标志读取1，然后将该标志设置为0，或将RIE位设置为0，可以取消SCIn_ERI中断请求。

TIE位（发送中断使能）

TIE位启用或禁用SCIn_TXI中断请求。通过将TIE位设置为0来禁用SCIn_TXI中断请求。在TE位为1时将TIE位设置为1。在TE和TIE位同时设置为1之后，在传输开始之前发生SCIn_TXI中断。

SSR寄存器提供SCI状态标志和发送和接收多处理器位。

MPBT bit (Multi-Processor Bit Transfer)

The MPBT bit sets the value of the multi-processor bit in the transmit frame.

MPB bit (Multi-Processor)

The MPB bit holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

TEND flag (Transmit End Flag)

The TEND flag indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled) and the FCR.FM bit is set to 0 (non-FIFO selected). When the SCR.TE bit is set to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated on transmission of the tail-end bit of a character being transmitted.

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR.TE bit is 1
- When 0 is written to TDRE after 1 is read while the SCR.TE bit is 1.

PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

  Although receive data is transferred to the RDR register when the parity error occurs, no SCIn_RXI interrupt request occurs. When the PER flag is set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to the PER flag after 1 is read. After writing 0 to this flag, read it to verify that its value is 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

The FER flag indicates that a framing error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When 0 is sampled as the stop bit during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

  In 2-stop-bit mode, only the first stop bit is checked. The second stop bit is not checked. Although receive data is transferred to the RDR register when the framing error occurs, no SCIn_RXI interrupt request occurs. When the FER flag is to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to FER after 1 is read. After writing 0 to this flag, read it to verify that its value is 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error and a framing error is read from the RDR register.

MPBT位（多处理器位传输）

MPBT位设置发送帧中多处理器位的值。

MPB bit (Multi-Processor)

MPB位保存接收帧中多处理器位的值。该位不改变时
SCR.RE位为0。

TEND标志（发送结束标志）

TEND标志表示传输完成。

[Setting conditions]

- 当SCR.TE位设置为0（禁用串行传输）且FCR.FM位设置为0（选择非FIFO）时。
  当SCR.TE位设置为1时，TEND标志不受影响并保持值1。
- 当TDR寄存器未在传输字符的尾端位时更新时。

[Clearing conditions]

- 当SCR.TE位为1时将发送数据写入TDR寄存器
- 当SCR.TE位为1时读取1后将0写入TDRE。

PER标志（奇偶校验错误标志）

PER标志表示在异步模式接收过程中发生奇偶校验错误，接收异常结束。

[Setting condition]

- 当地址匹配功能被禁用(DCCR.DCME=0)时，在异步模式接收期间检测到奇偶校验错误。

尽管发生奇偶校验错误时接收数据被传送到RDR寄存器，但不会发生SCIn_RXI中断请求。当PER标志设置为1时，后续接收数据不会传送到RDR寄存器。【结算条件】

- 读取1后将0写入PER标志时。将0写入此标志后，读取它以验证其值为0。

当SCR.RE位设置为0（禁用串行接收）时，PER标志不受影响并保留其先前的值。

FER标志（帧错误标志）

FER标志表示在异步模式下接收过程中发生了帧错误，并且接收异常结束。

[Setting condition]

- 当地址匹配功能被禁用(DCCR.DCME=0)时，在异步模式接收期间采样0作为停止位。

在2停止位模式下，仅检查第一个停止位。不检查第二个停止位。虽然发生帧错误时接收数据被传输到RDR寄存器，但不会发生SCIn_RXI中断请求。当FER标志为1时，后续接收数据不传送到RDR寄存器。【结算条件】

- 在读取1后将0写入FER时。将0写入此标志后，读取它以验证其值为0。

当SCR.RE位设置为0（禁用串行接收）时，FER标志不受影响并保留其先前的值。

ORER标志（溢出错误标志）

ORER标志表示接收期间发生溢出错误，接收异常结束。

[Setting condition]

- 在接收没有奇偶校验错误和帧错误的数据之前接收下一个数据时，从RDR寄存器中读取。

The data received before an overrun error occurred is saved in the RDR register, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register. In clock synchronous mode, serial transmission and reception are stopped.

[Clearing condition]

- When 0 is written to the ORER flag after 1 is read. After writing 0 to this flag, read it to verify that its value is 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing conditions]

- When 0 is written to the RDRF flag after 1 is read
- When data is read from the RDR register.

Note: Do not clear RDRF flag by accessing RDRF bit in the SSR register unless communication is aborted.

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates the presence of transmit data in the TDR register.

[Setting conditions]

- When the SCR.TE bit is 0
- When data is transmitted from the TDR register to the TSR register.

[Clearing conditions]

- When 0 is written to the TDRE flag after 1 is read
- When the SCR.TE bit is 1 and data is written to the TDR register.

Note: Do not clear TDRE flag by accessing TDRE bit in the SSR register unless communication is aborted.

溢出错误发生前接收到的数据保存在RDR寄存器中，但错误发生后接收到的数据丢失。当ORER标志设置为1时，接收数据不转发到RDR寄存器。在时钟同步模式下，串行发送和接收停止。【结算条件】

- 在读取1后将0写入ORER标志时。将0写入此标志后，读取它以验证其值为0。

当SCR.RE位设置为0（禁用串行接收）时，ORER标志不受影响并保留其先前的值。

RDRF标志（接收数据满标志）

RDRF标志指示RDR寄存器中存在接收数据。

[Setting condition]

- 当接收正常结束时，接收数据从RSR寄存器转发到RDR寄存器。

[Clearing conditions]

- 读取1后向RDRF标志写入0时
- 从RDR寄存器读取数据时。

Note: 除非通信中止，否则不要通过访问SSR寄存器中的RDRF位来清除RDRF标志。

TDRE标志（传输数据空标志）

TDRE标志表示TDR寄存器中存在发送数据。

[Setting conditions]

- 当SCR.TE位为0时
- 当数据从TDR寄存器传输到TSR寄存器时。

[Clearing conditions]

- 读取1后向TDRE标志写入0时
- 当SCR.TE位为1且数据写入TDR寄存器时。

Note: 除非通信被中止，否则不要通过访问SSR寄存器中的TDRE位来清除TDRE标志。

b7	TDFE	Transmit FIFO Data Empty Flag	0: The amount of transmit data written in FTDRHL exceeds the specified transmit triggering number 1: The amount of transmit data written in FTDRHL is equal to or less than the specified transmit triggering number.	R/(W)*1

Note 1. Only 0 can be written, to clear the flag after reading 1.

The SSR_FIFO register provides the SCI with FIFO mode status flags.

DR flag (Receive Data Ready Flag)

The DR flag indicates that the amount of data stored in the Receive FIFO Data Register (FRDRHL) falls below the specified receive triggering number, and that no next data is received after 15 ETUs (elementary time units) from the last stop bit in asynchronous mode. This flag is valid only in asynchronous mode, including multi-processor mode, when FIFO operation is selected.

In clock synchronous mode, the DR flag is not set to 1.

[Setting condition]

- When FRDRHL contains less data than the specified receive triggering number, and no next data is received after 15 ETUs*1 from the last stop bit, and the SSR_FIFO.FER and SSR_FIFO.PER flags are 0.

[Clearing conditions]

- When 1 is read from DR, after all received data is read
- When the FCR.FM bit is changed from 0 to 1.

Note 1. This is equivalent to 1.5 frames in the 8-bit format with one stop bit.
The DR flag is only set to 1 when FIFO is selected in asynchronous mode, including multi-processor mode. It is not set to 1 in other operation modes.

TEND flag (Transmit End Flag)

The TEND flag indicates that FTDRHL does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

- When FTDRHL does not contain transmit data when the last bit of a 1-byte serial character is transmitted.

[Clearing conditions]

- When transmit data is written to FTDRHL while the SCR.TE bit is 1
- When 0 is written to the TEND flag after 1 is read while the SCR.TE bit is 1
- When the FCR.FM bit is changed from 0 to 1.

Bit	Symbol	位名称	Description	R/W
b2	TEND	发送结束标志	0：正在传输字符1：字符传输完成。	R/(W)*1

b5	ORER	溢出错误标志	0：未发生溢出错误1：发生溢出错误。	R/(W)*1
b6	RDF	接收FIFO数据满标志	0：写入FRDRHL的接收数据量小于指定的接收触发数1：写入FRDRHL的接收数据量为 等于或大于指定的接收触发数。	R/(W)*1
b7	TDFE	发送FIFO数据空标志	0：写入FTDRHL的发送数据量超过指定的发送触发数1：写入FTDRHL的发送数据量等于或小于指定的发送触发数。	R/(W)*1

Note 1. 只能写入0，读取1后清除标志。

SSR_FIFO寄存器为SCI提供FIFO模式状态标志。

DR标志（接收数据就绪标志）

DR标志表示存储在接收FIFO数据寄存器(FRDRHL)中的数据量低于指定的接收触发数，并且在异步模式下从最后一个停止位开始15个ETU（基本时间单位）后没有接收到下一个数据.此标志仅在选择FIFO操作时在异步模式下有效，包括多处理器模式。

在时钟同步模式下，DR标志不设置为1。

[Setting condition]

- 当FRDRHL包含的数据少于指定的接收触发数，并且从最后一个停止位开始15个ETU*1后没有接收到下一个数据，并且SSR_FIFO.FER和SSR_FIFO.PER标志为0。

[Clearing conditions]

- 从DR读取1时，在读取所有接收到的数据之后
- 当FCR.FM位从0变为1时。

注1.这相当于8位格式的1.5帧，带有一位停止位。
只有在异步模式（包括多处理器模式）下选择FIFO时，DR标志才设置为1。在其他操作模式下不设置为1。

TEND标志（发送结束标志）

TEND标志表明FTDRHL在发送串行字符的最后一位时不包含有效数据，因此暂停发送。

[Setting condition]

- 当传输1字节串行字符的最后一位时FTDRHL不包含传输数据。

[Clearing conditions]

- 当SCR.TE位为1时将发送数据写入FTDRHL
- 当SCR.TE位为1时读取1后将0写入TEND标志
- 当FCR.FM位从0变为1时。

PER flag (Parity Error Flag)

The PER flag indicates whether there is a parity error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When data is received and a parity error is detected, when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to the PER flag after 1 is read.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a parity error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

The FER flag indicates whether there is a framing error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When 0 is sampled as the stop bit during reception when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to the FER flag after 1 is read.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a framing error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

The ORER flag indicates that the receive operation stopped abnormally because an overrun error occurred.

[Setting condition]

- When the next serial reception completes while the receive FIFO is full with 16-byte receive data.

[Clearing condition]

- When 0 is written to the ORER flag after 1 is read.

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.

RDF flag (Receive FIFO Data Full Flag)

The RDF flag indicates that receive data was transferred to the FRDRHL register, and the amount of data in FRDRHL is equal to or exceeds the specified receive triggering number. When RTRG is set to 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0.

[Setting condition]

- When the amount of receive data equal to or greater than the specified receive triggering number is stored in FRDRHL,*1 and the FIFO is not empty.

[Clearing conditions]

- When 0 is written to the RDF flag after 1 is read
- When FRDRHL is read by the DMAC or DTC, but only when the block transfer is the last transmission
- When the setting and clearing conditions occur at the same time, the RDF flag is set to 0. After that, when the amount of data stored in the FRDRHL register is equal to or greater than the RTRG value, RDF is set to 1 after 1

PER标志（奇偶校验错误标志）

PER标志指示在禁用地址匹配功能（DCCR.DCME=0）时，异步模式下从FRDRHL寄存器读取的数据是否存在奇偶校验错误。

[Setting condition]

- 当接收到数据并检测到奇偶校验错误时，当地址匹配功能被禁用时(DCCR.DCME=0)。

[Clearing condition]

- 读取1后将0写入PER标志时。

接收操作是连续的，接收数据存储在FRDRHL寄存器中，即使在接收过程中发生奇偶校验错误。

当SCR.RE位设置为0（禁用串行接收）时，PER标志不受影响并保留其先前的值。

FER标志（帧错误标志）

FER标志指示在禁用地址匹配功能（DCCR.DCME=0）时，异步模式下从FRDRHL寄存器读取的数据是否存在帧错误。

[Setting condition]

- 当地址匹配功能被禁用(DCCR.DCME=0)时，在接收期间采样0作为停止位。

[Clearing condition]

- 读取1后将0写入FER标志时。

接收操作是连续的，接收数据存储在FRDRHL寄存器中，即使在接收过程中发生帧错误。

当SCR.RE位设置为0（禁用串行接收）时，FER标志不受影响并保留其先前的值。

ORER标志（溢出错误标志）

ORER标志指示接收操作由于发生溢出错误而异常停止。

[Setting condition]

- 当接收FIFO充满16字节接收数据时，下一次串行接收完成。

[Clearing condition]

- 在读取1后将0写入ORER标志时。

当SCR.RE位设置为0（禁用串行接收）时，ORER标志不受影响并保留其先前的值。

RDF标志（接收FIFO数据满标志）

RDF标志表示接收数据已传送到FRDRHL寄存器，并且FRDRHL中的数据量等于或超过指定的接收触发数。当RTRG设置为0时，即使接收FIFO中的数据量等于0，RDF标志也不会设置。

[Setting condition]

- 当接收数据量等于或大于指定的接收触发数时存储在FRDRHL *1且FIFO不为空。

[Clearing conditions]

- 读取1后向RDF标志写入0时
- 当DMAC或DTC读取FRDRHL时，但仅当块传输是最后一次传输时
- 当置位和清零条件同时发生时，RDF标志置0。之后，当FRDRHL寄存器中存储的数据量等于或大于RTRG值时，RDF在1后置1

PCLKA.

Note: Do not clear RDF flags by accessing RDF bit in the SSR register before reading receive data unless communication is aborted.

Note 1. Because FRDRHL is a 16-stage FIFO register, the maximum amount of data that can be read when RDF is 1 is equivalent to the specified receive triggering number. If an attempt is made to read after all the data in FRDRHL is read, the data is undefined.

TDFE flag (Transmit FIFO Data Empty Flag)

The TDFE flag indicates that data is transferred from the FTDRHL register into the TSR register, the amount of data in FTDRHL is below the specified transmit triggering number, and writing of transmit data to FTDRHL is enabled.

[Setting conditions]

- When the TE bit in SCR is 0
- When the amount of transmit data written in FTDRHL is equal to or less than the specified transmit triggering number.*1

[Clearing conditions]

- When writing to FTDRHL is executed on the last transmission while the DTC or DMAC is activated
- When 0 is written to the TDFE flag after reading 1 is read.
  The setting conditions are given priority when TE = 0. When the setting condition and clearing condition occur at the same time, the TDFE flag is set to 0. After that, when the amount of data stored in the FTDRHL register is equal to or less than the TTRG value, TDFE is set to 1 after 1 PCLKA.

Note: Do not clear TDFE flags by accessing TDFE bit in the SSR register before writing transmit data unless communication is aborted.

Note 1. Because the FTDRHL register is a 16-stage FIFO register, when the TDFE flag is 1, the maximum amount of data that can be written to the FTDRHL register is 16 minus FDR.T[4:0] bytes. If more data is written, data is discarded.

注意：除非通信中止，否则在读取接收数据之前不要通过访问SSR寄存器中的RDF位来清除RDF标志。注1.因为FRDRHL是16级FIFO寄存器，所以当RDF为1时可以读取的最大数据量等于指定的接收触发数。如果在读取FRDRHL中的所有数据后尝试读取，则数据未定义。

TDFE标志（发送FIFO数据空标志）

TDFE标志表示数据从FTDRHL寄存器传送到TSR寄存器，在
FTDRHL低于指定的发送触发数，并且允许将发送数据写入FTDRHL。

[Setting conditions]

- 当SCR的TE位为0时
- 当写入FTDRHL的传输数据量等于或小于指定的传输触发数时。*1

[Clearing conditions]

- 当DTC或DMAC被激活时，在最后一次传输上执行写入FTDRHL
- 当读取1后将0写入TDFE标志。
  当TE=0时，设置条件优先。当设置条件和清除条件同时发生时，TDFE标志设置为0。之后，当FTDRHL寄存器中存储的数据量等于或小于比TTRG值，TDFE在1个PCLKA之后设置为1。

注意：除非通信被中止，否则在写入发送数据之前不要通过访问SSR寄存器中的TDFE位来清除TDFE标志。注1.由于FTDRHL寄存器为16级FIFO寄存器，因此当TDFE标志为1时，可写入FTDRHL寄存器的最大数据量为16减去FDR.T[4:0]字节。如果写入更多数据，则丢弃数据。

Bit	Symbol	Bit name	Description	R/W
b7	TDRE	Transmit Data Empty Flag	0: Transmit data in TDR register 1: No transmit data in TDR register.	R/(W)*1

Note 1. Only 0 can be written, to clear the flag after 1 is read.

The SSR_SMCI register provides the SCI with smart card interface mode status flags.

TEND flag (Transmit End Flag)

When there is no error signal from the receiving side, the TEND flag is set to 1 when more data for transfer is ready to be transferred to the TDR register.

[Setting conditions]

- When the SCR_SMCI.TE bit = 0 (serial transmission is disabled).
  When the SCR_SMCI.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period elapses after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated.

  The set timing is determined by the following register settings:
  - When SMR_SMCI.GM = 0 and SMR_SMCI.BLK = 0, 12.5 ETUs after the start of transmission
  - When SMR_SMCI.GM = 0 and SMR_SMCI.BLK = 1, 11.5 ETUs after the start of transmission
  - When SMR_SMCI.GM = 1 and SMR_SMCI.BLK = 0, 11.0 ETUs after the start of transmission
  - When SMR_SMCI.GM = 1 and SMR_SMCI.BLK = 1, 11.0 ETUs after the start of transmission.

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR_SMCI.TE bit is 1
- When 0 is written to the TDRE flag after 1 is read while the SCR_SMCI.TE bit is 1.

PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception. Although receive data is transferred to RDR when a parity error occurs, no SCIn_RXI interrupt request occurs. After the PER flag is set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to the PER flag after 1 is read. After writing 0 to this flag, read it to verify that its value is 0.

When the RE bit in SCR_SMCI is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

ERS flag (Error Signal Status Flag)

[Setting condition]

- When a low error signal is sampled.

[Clearing condition]

- When 0 is written to the ERS flag after 1 is read.

ORER flag (Overrun Error Flag)

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error is read from the RDR register.

Bit	Symbol	位名称	Description	R/W
b7	TDRE	传输数据空标志	0：在TDR寄存器中发送数据1：在TDR寄存器中不发送数据。	R/(W)*1

Note 1. 只能写入0，读取1后清除标志。

SSR_SMCI寄存器为SCI提供智能卡接口模式状态标志。

TEND标志（发送结束标志）

当接收端没有错误信号时，当更多数据准备好传输到TDR寄存器时，TEND标志设置为1。

[Setting conditions]

- 当SCR_SMCI.TE位=0时（禁用串行传输）。
  当SCR_SMCI.TE位从0变为1时，TEND标志不受影响并保持值1。
- 在最后一次发送1个字节后经过指定时间后，ERS标志为0，并且不更新TDR寄存器。

  设置时序由以下寄存器设置确定：
  - 当SMR_SMCI.GM=0且SMR_SMCI.BLK=0时，传输开始后12.5ETU
  - 当SMR_SMCI.GM=0且SMR_SMCI.BLK=1时，传输开始后11.5ETU
  - 当SMR_SMCI.GM=1且SMR_SMCI.BLK=0时，传输开始后11.0ETU
  - 当SMR_SMCI.GM=1和SMR_SMCI.BLK=1时，传输开始后11.0ETU。

[Clearing conditions]

- 当SCR_SMCI.TE位为1时将发送数据写入TDR寄存器
- 当SCR_SMCI.TE位为1时读取1后将0写入TDRE标志。

PER标志（奇偶校验错误标志）

PER标志表示在异步模式接收过程中发生奇偶校验错误，接收异常结束。

[Setting condition]

- 在接收过程中检测到奇偶校验错误时。尽管发生奇偶校验错误时将接收数据传输到RDR，但不会发生SCIn_RXI中断请求。PER标志设置为1后，后续接收数据不会传输到RDR。

[Clearing condition]

- 读取1后将0写入PER标志时。将0写入此标志后，读取它以验证其值为0。

当SCR_SMCI中的RE位设置为0（禁用串行接收）时，PER标志不受影响并保留其先前的值。

ERS标志（错误信号状态标志）

[Setting condition]

- 当对低误差信号进行采样时。

[Clearing condition]

- 读取1后将0写入ERS 标志时。

ORER标志（溢出错误标志）

ORER标志表示接收期间发生溢出错误，接收异常结束。

[Setting condition]

- 在从RDR寄存器读取没有奇偶校验错误的接收数据之前接收到下一个数据时。

The data received before an overrun error occurred is saved in the RDR, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register.

[Clearing condition]

- When 0 is written to the ORER flag after 1 is read. After writing 0 to this flag, read it to verify that its value is 0.

When the RE bit in SCR_SMCI is set to 0, the ORER flag is not affected and retains its previous value.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing conditions]

- When 0 is written to the RDRF flag after 1 is read
- When data is read from the RDR register.

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates the presence of transmit data in the TDR register.

[Setting conditions]

- When the SCR_SMCI.TE bit is 0
- When data is transmitted from the TDR register to the TSR register.

[Clearing conditions]

- When 0 is written to the TDRE flag after 1 is read
- When the SCR_SMCI.TE bit is 1 and data is written to the TDR register.

Note: Do not clear TDRE flags by accessing TDRE bit in the SSR register unless communication is aborted.

b2	SINV	Transmitted/Received Data Invert	0: TDR register contents are transmitted as they are. Receive data is stored as received in the RDR register. 1: TDR register contents are inverted before transmission. Receive data is stored in inverted form in the RDR register. The SINV bit can be used in the following modes: • Smart card interface mode • Asynchronous mode (including multi-processor mode) • Clock synchronous mode • Simple SPI mode. Set the SINV bit to 0 for operation in simple IIC mode.	R/W*1

发生溢出错误前接收的数据保存在RDR中，但错误发生后接收的数据会丢失。
当ORER标志设置为1时，接收数据不转发到RDR寄存器。

[Clearing condition]

- 在读取1后将0写入ORER标志时。将0写入此标志后，读取它以验证其值为0。

当SCR_SMCI中的RE位设置为0时，ORER标志不受影响并保留其先前的值。

RDRF标志（接收数据满标志）

RDRF标志指示RDR寄存器中存在接收数据。

[Setting condition]

- 当接收正常结束时，接收数据从RSR寄存器转发到RDR寄存器。

[Clearing conditions]

- 读取1后向RDRF标志写入0时
- 从RDR寄存器读取数据时。

TDRE标志（传输数据空标志）

TDRE标志表示TDR寄存器中存在发送数据。

[Setting conditions]

- 当SCR_SMCI.TE位为0时
- 当数据从TDR寄存器传输到TSR寄存器时。

[Clearing conditions]

- 读取1后向TDRE标志写入0时
- 当SCR_SMCI.TE位为1且数据写入TDR寄存器时。

Note: 除非通信被中止，否则不要通过访问SSR寄存器中的TDRE位来清除TDRE标志。

b7	BCP2	Base Clock Pulse 2	Selects the number of base clock cycles in combination with the SMR_SMCI.BCP[1:0] bits. Table 34.4 lists the combinations of the SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits.	R/W*1

Note 1. Writable only when the TE and RE bits in SCR/SCR_SMCI are 0 (both serial transmission and reception are disabled).
Note 2. The setting is invalid and a fixed data length of 8 bits is used in modes other than asynchronous mode.
Note 3. LSB-first must be selected and the value of the MSB (bit [7]) in TDR cannot be transmitted.

The SCMR register selects the smart card interface and communication format.

SMIF bit (Smart Card Interface Mode Select)

Setting the SMIF bit to 1 selects smart card interface mode. Setting it to 0 selects all other modes:

- Asynchronous mode, including multi-processor mode
- Clock synchronous mode
- Simple SPI mode
- Simple IIC mode.

SINV bit (Transmitted/Received Data Invert)

The SINV bit inverts the transmit and receive data logic level. It does not affect the logic level of the parity bit. To invert the parity bit, invert the PM bit in SMR or SMR_SMCI.

CHR1 bit (Character Length 1)

The CHR1 bit selects the data length of transmit and receive data in combination with the CHR bit in the SMR register. A fixed data length of 8 bits is used in modes other than asynchronous mode.

BCP2 bit (Base Clock Pulse 2)

The BCP2 bit selects the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set this bit in combination with the SMR_SMCI.BCP[1:0] bits.

Table 34.4 Combinations of the SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits (1 of 2)

Note 1. 仅当SCRSCR_SMCI中的TE和RE位为0时可写（串行发送和接收都被禁用）。
Note 2. 该设置无效，并且在非异步模式下使用了固定的8位数据长度。
Note 3. 必须选择LSB优先，并且不能传输TDR中的MSB（位[7]）的值。

SCMR寄存器选择智能卡接口和通信格式。

SMIF位（智能卡接口模式选择）

将SMIF位设置为1选择智能卡接口模式。将其设置为0会选择所有其他模式：

- 异步模式，包括多处理器模式
- 时钟同步模式
- 简单SPI模式
- 简单的IIC模式。

SINV位（发送接收数据反转）

SINV位反转发送和接收数据逻辑电平。它不影响奇偶校验位的逻辑电平。要反转奇偶校验位，请反转SMR或SMR_SMCI中的PM位。

CHR1位（字符长度1）

CHR1位结合SMR寄存器中的CHR位选择发送和接收数据的数据长度。
在异步模式以外的模式中使用8位的固定数据长度。

BCP2位（基本时钟脉冲2）

BCP2位选择智能卡接口模式下1位数据传输时间内的基本时钟周期数。将该位与SMR_SMCI.BCP[1:0]位一起设置。

BRR is an 8-bit register that adjusts the bit rate.

As each SCI channel has independent baud rate generator control, different bit rates can be set for each channel. Table 34.5 shows the relationship between the setting (N) in the BRR and the bit rate (B) for asynchronous mode, multi-processor transfer, clock synchronous mode, smart card interface mode, simple SPI mode, and simple IIC mode.

The initial value of the BRR register is FFh. The BRR register can be read by the CPU, but it can be written to only when the TE and RE bits in SCR/SCR_SMCI are 0.

BRR是一个8位寄存器，用于调整比特率。

由于每个SCI通道都有独立的波特率发生器控制，因此可以为每个通道设置不同的比特率。表34.5显示了BRR中的设置(N)与异步模式、多处理器传输、时钟同步模式、智能卡接口模式、简单SPI模式和简单IIC模式的比特率(B)之间的关系。

BRR寄存器的初始值为FFh。BRR寄存器可以被CPU读取，但只有当SCRSCR_SMCI中的TE和RE位为0时才能写入。

1	0 1	64 clock cycles	64
1	1 0	372 clock cycles	372
1	1 1	256 clock cycles	256

Table 34.9 and Table 34.10 list examples of BRR (N) settings in asynchronous mode. Table 34.11 lists the maximum bit rate settable for each operating frequency. Table 34.15 lists examples of BRR (N) settings in smart card interface mode.

In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, see section 34.6.4, Receive Data Sampling Timing and Reception Margin. Table 34.12 and Table 34.14 list the maximum bit rates with external clock input.

When either the Asynchronous Mode Base Clock Select bit (ABCS) or the Baud Rate Generator Double-speed Mode Select bit (BGDM) in the Serial Extended Mode Register (SEMR) is set to 1 in asynchronous mode, the bit rate becomes twice the value listed in Table 34.16. When both of those registers are set to 1, the bit rate becomes four times the listed value.

表34.9和表34.10列出了异步模式下的BRR(N)设置示例。表34.11列出了每个工作频率可设置的最大比特率。表34.15列出了智能卡接口模式下的BRR(N)设置示例。

在智能卡接口模式下，可以选择1位数据传输时间内的基本时钟周期数S。有关详细信息，请参阅第34.6.4节，接收数据采样时序和接收余量。表34.12和表34.14列出了外部时钟输入的最大比特率。

当异步模式基本时钟选择位(ABCS)或波特率发生器双速模式
串行扩展模式寄存器(SEMR)中的选择位(BGDM)在异步模式下设置为1，比特率变为表34.16中列出的值的两倍。当这两个寄存器都设置为1时，比特率变为所列值的四倍。

Space: Setting prohibited.
—: Can be set, but an error occurs.

Note 1. Continuous transmission or reception is not possible. After transmitting or receiving one frame of data, a 1-bit period elapses before starting to transmit or receive the next frame of data. The output of the synchronization clock is stopped for a 1-bit period. Therefore, it takes 9 bits worth of time to transfer one frame (8 bits) of data, and the average transfer rate is 8/9 times the bit rate. When the FIFO is selected, this setting (BRR = 00h and SMR.CKS[1:0] = 00b) is not available.

空格：禁止设置。—：可以设置，
但发生错误。

Note 1. 无法连续发送或接收。在发送或接收一帧数据后，在开始发送或接收下一帧数据之前会经过1位周期。同步时钟的输出停止1位周期。因此，传输一帧（8位）数据需要9位的时间，平均传输速率为89倍的位速率。选择FIFO时，此设置（BRR=00h且SMR.CKS[1:0]=00b）不可用。

The MDDR register corrects the bit rate adjusted by the BRR register.

When the SEMR.BRME bit is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected using the settings in the MDDR register (M/256). Table 34.19 shows the relationship between the MDDR setting (M) and the

MDDR寄存器校正由BRR寄存器调整的比特率。

当SEMR.BRME位设置为1时，片上波特率发生器生成的比特率使用MDDR寄存器(M256)中的设置进行均匀校正。表34.19显示了MDDR设置(M)和

bit rate (B).

The initial value of the MDDR register is FFh. Bit [7] in this register is fixed to 1. The CPU can read the MDDR register, but the MDDR register is only writable when the TE and RE bits in SCR/SCR_SMCI are 0.

比特率(B)。

MDDR寄存器的初始值为FFh。该寄存器中的Bit[7]固定为1。CPU可以读取MDDR寄存器，但MDDR寄存器只有在SCRSCR_SMCI中的TE和RE位为0时才可写。

B：比特率（bps）
M: MDDR setting (128 ≤ MDDR ≤ 255)
N：波特率发生器的BRR设置（0≤N≤255）
PCLKA：工作频率(MHz)n和S：由SMRSMR_SMCI和SCMR寄存器设置决定，如第34节，比特率寄存器(BRR)中的表34.7和表34.8中所列。

Note 1. 请勿在时钟同步模式或简单SPI模式的最高速度设置中使用此功能（SMR.CKS[1:0]=00b，SCR.CKE[1] = 0, and BRR = 0).
Note 2. 调整码率，使简单IIC模式下SCL输出的高低电平宽度满足I2C总线标准。

表34.20和表34.21列出了异步模式下BRR中的N设置和MDDR中的M设置的示例。

Note 1. Writable only when the TE and RE bits in SCR/SCR_SMCI are 0 (both serial transmission and reception are disabled).

The SEMR register selects the clock source for the 1-bit period in asynchronous mode.

BRME bit (Bit Rate Modulation Enable)

The BRME bit enables or disables the bit rate modulation function. The bit rate generated by the on-chip baud rate generator is evenly corrected when this function is enabled.

ABCSE bit (Asynchronous Mode Extended Base Clock Select 1)

The ABCSE bit sets the pulse number for the base clock in a 1-bit period to 6, and the double-frequency clock is output from the baud rate generator. When the bit rate is set to 6 while dividing the bus clock frequency, use this bit and set SMR.CKS[1:0] = 00b and BRR = 0. Set this bit to 0 except in asynchronous mode.

Note 1. 仅当SCRSCR_SMCI中的TE和RE位为0时可写（串行发送和接收都被禁用）。

SEMR寄存器选择异步模式下1位周期的时钟源。

BRME位（比特率调制使能）

BRME位启用或禁用比特率调制功能。该功能使能时，片内波特率发生器产生的比特率得到均匀校正。

ABCSE位（异步模式扩展基本时钟选择1）

ABCSE位将基本时钟在1位周期内的脉冲数设置为6，并从波特率发生器输出双频时钟。当比特率设置为6并同时分频总线时钟频率时，使用该位并设置SMR.CKS[1:0]=00b和BRR=0。除异步模式外，将此位设置为0。

ABCS bit (Asynchronous Mode Base Clock Select)

The ABCS bit selects the number of clock cycles for a 1-bit period. Set this bit to 0 except in asynchronous mode.

NFEN bit (Digital Noise Filter Function Enable)

The NFEN bit enables or disables the digital noise filter function.

When the digital noise filter function is enabled:

- Noise cancellation is applied to the RXDn input signal in asynchronous mode
- Noise cancellation is applied to the SDAn and SCLn input signals in simple IIC mode.

In all other modes, set the NFEN bit to 0 to disable the digital noise filter function. When the function is disabled, input signals are transferred as received.

BGDM bit (Baud Rate Generator Double-Speed Mode Select)

The BGDM bit selects whether or not to double the base clock frequency output from the baud rate generator.

The BGDM bit is valid when the on-chip baud rate generator is selected as the clock source (SCR.CKE[1] = 0) in asynchronous mode (SMR.CM = 0). The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.

Set this bit to 0 in modes other than asynchronous mode.

RXDESEL bit (Asynchronous Start Bit Edge Detection Select)

The RXDSEL bit selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data reception operation depends on the setting of this bit. Set this bit to 1 when reception must be stopped while a break occurs or when reception must be started without keeping the RXDn pin input at the high level for the period of one data frame or longer after completion of the break.

Set this bit to 0 in modes other than asynchronous mode.

Note 1. Writing to these bits is only possible when the RE and TE bits in SCR/SCR_SMCI are 0 (serial reception and transmission disabled).

ABCS位（异步模式基本时钟选择）

ABCS位选择1位周期的时钟周期数。除异步模式外，将此位设置为0。

NFEN位（数字噪声滤波器功能使能）

NFEN位启用或禁用数字噪声滤波器功能。

启用数字噪声滤波器功能时：

- 噪声消除应用于异步模式下的RXDn输入信号
- 噪声消除应用于简单IIC模式下的SDAn和SCLn输入信号。

在所有其他模式下，将NFEN位设置为0以禁用数字噪声滤波器功能。禁用该功能时，输入信号按接收到的方式传输。

BGDM位（波特率发生器双速模式选择）

BGDM位选择是否将波特率发生器输出的基本时钟频率加倍。

当在异步模式（SMR.CM=0）下选择片内波特率发生器作为时钟源（SCR.CKE[1]=0）时，BGDM位有效。基本时钟由波特率发生器的时钟输出生成。当BGDM位设置为1时，基本时钟周期减半，比特率加倍。

在异步模式以外的模式下将此位设置为0。

RXDESEL位（异步起始位边沿检测选择）

RXDSEL位选择异步模式下接收起始位的检测方法。发生中断时，数据接收操作取决于该位的设置。如果在发生中断时必须停止接收，或者在中断完成后RXDn引脚输入在一个数据帧或更长时间内不保持高电平而必须开始接收时，将该位设置为1。

The SNFR register sets the digital noise filter clock.

NFCS[2:0] bits (Noise Filter Clock Select)

The NFCS[2:0] bits select the sampling clock for the digital noise filter. To use the noise filter in asynchronous mode, set these bits to 000b. In simple IIC mode, set the bits to a value in the range from 001b to 100b.

SIMR1 selects simple IIC mode and the number of delay stages for the SDAn output.

IICM bit (Simple IIC Mode Select)

In combination with the SCMR.SMIF bit, the IICM bit selects the operating mode.

IICDL[4:0] bits (SDA Delay Output Select)

The IICDL[4:0] bits specify an output delay on the SDAn pin relative to the falling edge of the output on the SCLn pin.

The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generator as the base. The signal obtained by frequency-dividing PCLKA by the divisor set in SMR.CKS[1:0] is supplied as the clock signal from the on-chip baud rate generator. Set these bits to 00000b unless operation is in simple IIC mode. In simple IIC mode, set the bits to a value in the range from 00001b to 11111b.

SIMR2 selects how reception and transmission are controlled in simple IIC mode.

IICINTM bit (IIC Interrupt Mode Select)

The IICINTM bit selects the sources of interrupt requests in simple IIC mode.

IICCSC bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SCL clock signal is to be synchronized when the SCLn pin is driven low because a wait was inserted by another other device.

The SCL clock signal is not synchronized if the IICCSC bit is 0. The SCL clock signal is generated according to the rate selected in the BRR register regardless of the level being input on the SCLn pin.

Set the IICCSC bit to 1 except during debugging.

IICACKT bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set the IICACKT bit to 1 when ACK and NACK bits are received.

Note 1. Only generate a start condition after checking the bus state and confirming that the bus is free.
Note 2. Generate a restart or stop condition after checking the bus state and confirming that the bus is busy.
Note 3. Do not set more than one of the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.
Note 4. Write only 0. When 1 is written, the value is ignored.
Note 5. Execute the generation of a condition after the value of the IICSTIF flag is 0.
Note 6. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

IICSTAREQ bit (Start Condition Generation)

When a start condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICSTAREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of start condition generation.

IICRSTAREQ bit (Restart Condition Generation)

When a restart condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICRSTAREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of restart condition generation.

IICSTPREQ bit (Stop Condition Generation)

When a stop condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICSTPREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of stop condition generation.

IICSTIF flag (Issuing of Start, Restart, or Stop Condition Completed Flag)

After generating a condition, the IICSTIF flag indicates that the condition generation is complete. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.

Note 1. 只有在检查总线状态并确认总线空闲后才产生启动条件。
Note 2. 在检查总线状态并确认总线繁忙后生成重新启动或停止条件。
Note 3. 在给定时间，不要将IICSTAREQ、IICRSTAREQ和IICSTPREQ位中的一个以上设置为1。
Note 4. 仅写入0。写入1时，忽略该值。
Note 5. 在IICSTIF标志的值为0后执行条件的生成。
Note 6. 请勿在该位为1时向其写入0。当该位为1时，向该位写入0可暂停条件的生成。

IICSTAREQ位（开始条件生成）

当要产生一个开始条件时，除了设置IICSDAS[1:0]和IICSCLS[1:0]为01b IICSTAREQ位为1。

[Setting condition]

- 在向该位写入1时。

[Clearing condition]

- 完成启动条件生成。

IICRSTAREQ位（重启条件生成）

当要产生重启条件时，除了设置IICSDAS[1:0]和IICSCLS[1:0]为01b IICRSTAREQ位为1。

[Setting condition]

- 在向该位写入1时。

[Clearing condition]

- 完成重启条件生成。

IICSTPREQ位（停止条件生成）

当要产生停止条件时，除了设置IICSDAS[1:0]和IICSCLS[1:0]为01b IICSTPREQ位为1。

[Setting condition]

- 在向该位写入1时。

[Clearing condition]

- 停止条件生成完成后。

IICSTIF标志（发出启动、重启或停止条件完成标志）

生成条件后，IICSTIF标志指示条件生成完成。使用时 IICSTAREQ、IICRSTAREQ或IICSTPREQ位会导致条件生成，请在将IICSTIF标志设置为0后执行此操作。

When the IICSTIF flag is 1 while an interrupt request is enabled by setting the SCR.TEIE bit, an STI request is output.

[Setting condition]

- On completion of a start, restart, or stop condition generation.

  If the setting condition conflicts with any of the clearing conditions for the flag, the clearing condition takes precedence.

[Clearing conditions]

- On writing 0 to the bit. After writing 0 to the IICSTIF bit, read the bit to check that it is actually set to 0.
- On writing 0 to the SIMR1.IICM bit when operation is not in simple IIC mode
- On writing 0 to the SCR.TE bit.

IICSDAS[1:0] bits (SDA Output Select)

The IICSDAS[1:0] bits control output from the SDAn pin. Set IICSDAS[1:0] and IICSCLS[1:0] to the same value.

IICSCLS[1:0] bits (SCL Output Select)

The IICSCLS[1:0] bits control output from the SCLn pin. Set IICSCLS[1:0] and IICSDAS[1:0] to the same value.

IICACKR flag (ACK Reception Data Flag)

Received ACK and NACK bits can be read from the IICACKR flag. The IICACKR flag is updated on the rising edge of the SCLn clock for the received ACK/NACK bit.

当IICSTIF标志为1且通过设置SCR.TEIE位使能中断请求时，输出STI请求。

[Setting condition]

- 在完成启动、重新启动或停止条件生成时。

如果设置条件与标志的任何清除条件冲突，则清除条件优先。【清算条件】

- 将0写入该位。将0写入IICSTIF位后，读取该位以检查它是否实际设置为0。
- 在非简单IIC模式下向SIMR1.IICM位写入0
- 向SCR.TE位写入0。

IICSDAS[1:0]位（SDA输出选择）

IICSDAS[1:0]位控制SDAn引脚的输出。将IICSDAS[1:0]和IICSCLS[1:0]设置为相同的值。

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).
Note 2. Only 0 can be written to this bit, to clear the flag.

The SPMR register selects settings for simple SPI mode.

SSE bit (SSn Pin Function Enable)

Set the SSE bit to 1 to use the SSn pin to control transmission and reception in simple SPI mode. Set this bit to 0 in all other modes. In simple SPI mode, when master mode is selected (SCR.CKE[1:0] = 00b and SPMR.MSS = 0) and there is a single master, the SSn pin on the master side is not required to control reception and transmission. In such a case, set the SSE bit to 0. Do not set both the SSE and CTSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

CTSE bit (CTS Enable)

Set the CTSE bit to 1 if the SSn pin is to be used for inputting the CTS control signal to control transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, and simple IIC mode. Do not set both the CTSE and SSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

MSS bit (Master Slave Select)

The MSS bit selects master or slave operation in simple SPI mode. The functions of the TXDn and RXDn pins are reversed when this bit is set to 1, so that data is received through the TXDn pin and transmitted through the RXDn pin. Set this bit to 0 in modes other than simple SPI mode.

MFF flag (Mode Fault Flag)

The MFF flag indicates mode fault errors. In a multi-master configuration, determine the mode fault error occurrence by reading this flag.

Note 1. 只有当SCR寄存器中的RE和TE位为0（串行发送和接收都被禁用）时，才能写入这些位。

Note 2. 只能向该位写入0，以清除标志。

SPMR寄存器选择简单SPI模式的设置。

SSE位（SSn引脚功能使能）

将SSE位设置为1以使用SSn引脚控制简单SPI模式下的发送和接收。在所有其他模式下将此位设置为0。在简单的SPI模式下，选择主模式（SCR.CKE[1：0]=00B和SPMR.MSS=0），并且有一个主人，主侧不需要SSNPIN来控制接收和传输.在这种情况下，请将SSE位设置为0。不要将SSE和CTSE位都设置为1。如果进行此设置，则操作与将这些位设置为0时的操作相同。

CTSE位（CTS使能）

如果SSn引脚用于输入CTS控制信号以控制发送和接收，请将CTSE位设置为1。当该位设置为0时输出RTS信号。在智能卡接口模式、简单SPI模式和简单IIC模式下将该位设置为0。不要将CTSE和SSE位都设置为1。如果进行此设置，则操作与将这些位设置为0时的操作相同。

MSS位（主从选择）

MSS位选择简单SPI模式下的主机或从机操作。当该位设置为1时，TXDn和RXDn引脚的功能相反，因此数据通过TXDn引脚接收并通过RXDn引脚发送。在简单SPI模式以外的模式下将此位设置为0。

MFF标志（模式故障标志）

MFF标志指示模式故障错误。在多主机配置中，通过读取该标志确定模式故障错误发生。

[Setting condition]

- When input on the SSn pin is low during master operation in simple SPI mode (SSE bit = 1 and MSS bit = 0).

[Clearing condition]

- On writing 0 to the bit after it is read as 1.

CKPOL bit (Clock Polarity Select)

The CKPOL bit selects the polarity of the clock signal output through the SCKn pin. See Figure 34.70 for details. Set the CKPOL bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

CKPH bit (Clock Phase Select)

The CKPH bit selects the phase of the clock signal output through the SCKn pin. See Figure 34.70 for details. Set the CKPH bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

[Setting condition]

- 在简单SPI模式（SSE位=1和MSS位=0）下主机操作期间SSn引脚上的输入为低电平时。

[Clearing condition]

- 在读取为1后向该位写入0。

CKPOL位（时钟极性选择）

CKPOL位选择通过SCKn引脚输出的时钟信号的极性。有关详细信息，请参见图34.70。设置在除简单SPI模式和时钟同步模式之外的所有模式中，CKPOL位为0。

CKPH位（时钟相位选择）

CKPH位选择通过SCKn引脚输出的时钟信号的相位。有关详细信息，请参见图34.70。设置CKPH位在除简单SPI模式和时钟同步模式之外的所有模式下为0。

Note 1. 仅当TE=0且RE=0时可写。

FCR selects FIFO mode, resets FTDRHL and FRDRHL, selects the FIFO data trigger number for transmission or reception, and selects the RTS output active trigger number.

FM bit (FIFO Mode Select)

When the FM bit is set to 1, FTDRHL and FRDRHL are selected for communication. When the FM bit is set to 0, TDR and RDR, or TDRHL and RDRHL are selected for communication.

RFRST bit (Receive FIFO Data Register Reset)

When the RFRST bit is set to 1, the FRDRHL register is reset and the received data count resets to 0. When 1 is written to the RFRST bit, it clears to 0 after 1 PCLKA.

TFRST bit (Transmit FIFO Data Register Reset)

When the TFRST bit is set to 1, the FTDRHL register is reset and the transmit data count resets to 0. When 1 is written to the TFRST bit, it clears to 0 after 1 PCLKA.

DRES bit (Receive Data Ready Error Select Bit)

When detecting a receive data ready error, the selection can be made from an SCIn_RXI interrupt request or an SCIn_ERI interrupt request. When starting DMAC or DTC and reading from the FRDRH and FRDRL registers, set the DRES bit to 1.

TTRG[3:0] bits (Transmit FIFO Data Trigger Number)

The TDFE flag is set to 1 when the amount of transmit data in FTDRHL is equal to or less than the transmit triggering number specified in the TTRG[3:0] bits, and software can write data to FTDRHL. If SCR.TIE = 1, an SCIn_TXI interrupt request occurs.

RTRG[3:0] bits (Receive FIFO Data Trigger Number)

The RDF flag is set to 1 when the amount of receive data in FRDRHL is equal to or greater than the receive triggering number specified in the RTRG[3:0] bits, and software can read data from FRDRHL. If SCR.RIE = 1, an SCIn_RXI interrupt request occurs.

When RTRG[3:0] is 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0, and an SCIn_RXI interrupt does not occur.

RSTRG[3:0] bits (RTS Output Active Trigger Number Select)

When the amount of receive data stored in FRDRHL is equal to or greater than the receive triggering number specified in the RSTRG[3:0] bits, the RTS signal goes high.

When RSTRG[3:0] is 0, the RTS signal does not go high even when the amount of data in FRDRHL is equal to 0.

34.2.27 FIFO Data Count Register (FDR)

Bit	Symbol	Bit name	Description	R/W
b4 to b0	R[4:0]	Receive FIFO Data Count	Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode, when FCR.FM = 1. Indicates the amount of receive data stored in FRDRHL.	R
b7 to b5	—	Reserved	These bits are read as 0.	R

FCR选择FIFO模式，复位FTDRHL和FRDRHL，选择发送或接收的FIFO数据触发数，选择RTS输出激活触发数。

FM位（FIFO模式选择）

当FM位设置为1时，选择FTDRHL和FRDRHL进行通信。当FM位设置为0时，选择TDR和RDR，或TDRHL和RDRHL进行通信。

RFRST位（接收FIFO数据寄存器复位）

当RFRST位设置为1时，FRDRHL寄存器复位，接收数据计数复位为0。当RFRST位写入1时，在1个PCLKA后清为0。

TFRST位（发送FIFO数据寄存器复位）

当TFRST位设置为1时，FTDRHL寄存器复位，发送数据计数复位为0。当TFRST位写入1时，在1个PCLKA后清为0。

DRES位（接收数据就绪错误选择位）

当检测到接收数据就绪错误时，可以从SCIn_RXI中断请求或SCIn_ERI中断请求。当启动DMAC或DTC并读取FRDRH和FRDRL寄存器时，设置DRES位为1。

TTRG[3:0]位（发送FIFO数据触发数）

当FTDRHL中的发送数据量等于或小于TTRG[3:0]位中指定的发送触发数时，TDFE标志设置为1，并且软件可以将数据写入FTDRHL。如果SCR.TIE=1，则发生SCIn_TXI中断请求。

RTRG[3:0]位（接收FIFO数据触发数）

当FRDRHL中的接收数据量等于或大于RTRG[3:0]位中指定的接收触发数时，RDF标志设置为1，并且软件可以从FRDRHL中读取数据。如果SCR.RIE=1，则发生SCIn_RXI中断请求。

当RTRG[3:0]为0时，即使接收FIFO中的数据量等于0，RDF标志也不置位，并且SCIn_RXI中断不发生。

RSTRG[3:0]位（RTS输出有效触发数选择）

当FRDRHL中存储的接收数据量等于或大于RSTRG[3:0]位中指定的接收触发数时，RTS信号变为高电平。

当RSTRG[3:0]为0时，即使FRDRHL中的数据量等于0，RTS信号也不会变高。

b15 to b13	—	Reserved	These bits are read as 0.	R

The FDR register indicates the amount of data stored in FRDRHL and FTDRHL.

R[4:0] bits (Receive FIFO Data Count)

The R[4:0] bits indicate the amount of receive data stored in FRDRHL. 00h means no receive data, and 10h means that the maximum received data is stored in FRDRHL.

T[4:0] bits (Transmit FIFO Data Count)

The T[4:0] bits indicate the amount of non-transmitted data stored in FTDRHL. 00h means no transmit data, and 10h means that all (maximum amount) of the data to be transmitted is stored in FTDRHL.

Note 1. Write 0 to SSR_FIFO.ORER to clear the flag.

The LSR register indicates the receive error status.

ORER bit (Overrun Error Flag)

The ORER bit reflects the value in SSR_FIFO.ORER.

FNUM[4:0] bits (Framing Error Count)

The FNUM[4:0] value indicates the amount of data with a framing error stored in the FRDRHL register.

PNUM[4:0] bits (Parity Error Count)

The PNUM[4:0] value indicates the amount of data with a parity error stored in the FRDRHL register.

Bit	Symbol	位名称	Description	R/W

FDR寄存器指示存储在FRDRHL和FTDRHL中的数据量。

R[4:0]位（接收FIFO数据计数）

R[4:0]位指示存储在FRDRHL中的接收数据量。00h表示没有接收数据，10h表示最大接收数据存储在FRDRHL中。

T[4:0]位（发送FIFO数据计数）

T[4:0]位指示存储在FTDRHL中的未传输数据量。00h表示不发送数据，10h表示所有（最大量）要发送的数据都存储在FTDRHL中。

The CDR register sets the compare data for the address match function.

CMPD[8:0] bits (Compare Match Data)

The CMPD[8:0] bits set the data to be compared to receive data for the address match function, when the address match function is enabled (DCCR.DCME = 1).

Three bit lengths are available:

- CMPD[6:0] with 7-bit length
- CMPD[7:0] with 8-bit length
- CMPD[8:0] with 9-bit length.

CMPD[8:0]位（比较匹配数据）

当地址匹配功能启用时（DCCR.DCME=1），CMPD[8:0]位设置要比较的数据以接收地址匹配功能的数据。

提供三种位长：

- 7位长度的CMPD[6:0]
- CMPD[7:0]8位长度
- CMPD[8:0]，长度为9位。

Note 1. 只能写入0，读取1后清除标志。

The DCCR register controls the address match function.

DCMF flag (Data Compare Match Flag)

The DCMF flag indicates that the SCI detected a receive data match with the comparison data (CDR.CMPD).

[Setting condition]

- On match of the comparison data (CDR.CMPD) with the receive data when DCCR.DCME = 1.

[Clearing condition]

- When 0 is written after 1 is read from DCMF.

Clearing the SCR.RE bit to 0 does not affect the DCMF flag, which retains its previous value.

DPER flag (Data Compare Match Parity Error Flag)

The DPER flag indicates that a parity error occurred on address match detection (receive data match detection).

[Setting condition]

- When a parity error is detected in a frame in which an address match is detected.

[Clearing conditions]

- When 0 is written after 1 is read from DPER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DPER flag is not affected and retains its previous value.

DFER flag (Data Compare Match Framing Error Flag)

The DFER flag indicates that a framing error occurred on address match detection (receive data match detection).

[Setting conditions]

- When a stop bit of a frame in which an address match is detected is 0.

  When in 2-stop-bit mode, only the first bit of the stop bits is checked for a value of 1 (the second stop bit is not checked).

[Clearing conditions]

- When 0 is written after 1 is read from DFER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DFER flag is not affected and retains its previous value.

IDSEL bit (ID Frame Select)

The IDSEL bit selects whether to compare data regardless of the MPB bit value or to compare data only when MPB = 1 (ID frame), when the address match function is enabled.

DCME bit (Data Compare Match Enable)

The DCME bit enables or disables the address match function (data compare match function).

If the SCI detects a match to the comparison data (CDR.CMPD) with the receive data, the DCME bit clears automatically, after which SCI operation mode is in receive mode without data compare match function. See section 34.3.6, Address Match (Receive Data Match Detection) Function.

The write value must be 0 for all modes other than asynchronous mode.

DCCR寄存器控制地址匹配功能。

DCMF标志（数据比较匹配标志）

DCMF标志表示SCI检测到接收数据与比较数据(CDR.CMPD)匹配。

[Setting condition]

- 当DCCR.DCME=1时，比较数据(CDR.CMPD)与接收数据匹配。

[Clearing condition]

- 从DCMF读取1后写入0时。

将SCR.RE位清除为0不会影响DCMF标志，它保留其先前的值。

DPER标志（数据比较匹配奇偶校验错误标志）

DPER标志表示在地址匹配检测（接收数据匹配检测）时发生奇偶校验错误。

[Setting condition]

- 在检测到地址匹配的帧中检测到奇偶校验错误时。

[Clearing conditions]

- 当从DPER读取1后写入0。

当SCR.RE位设置为0（禁用串行接收）时，DPER标志不受影响并保留其先前的值。

DFER标志（数据比较匹配成帧错误标志）

DFER标志表示在地址匹配检测（接收数据匹配检测）时发生了帧错误。

[Setting conditions]

- 当检测到地址匹配的帧的停止位为0时。

在2停止位模式下，仅检查停止位的第一位是否为1（不检查第二个停止位）。【清算条件】

- 从DFER读取1后写入0。

当SCR.RE位设置为0（禁用串行接收）时，DFER标志不受影响并保留其先前的值。

IDSEL位（ID帧选择）

IDSEL位选择无论MPB位值如何比较数据，还是仅在MPB=1（ID帧）时比较数据，当地址匹配功能启用时。

DCME位（数据比较匹配使能）

DCME位启用或禁用地址匹配功能（数据比较匹配功能）。

如果SCI检测到比较数据（CDR.CMPD）与接收数据匹配，则DCME位自动清零，此后SCI操作模式为接收模式，没有数据比较匹配功能。请参见第34.3.6节，地址匹配（接收数据匹配检测）功能。

对于异步模式以外的所有模式，写入值必须为0。

The SPTR register provides confirmation of the serial reception pin (RXDn pin) status and sets the transmission pin (TXDn pin) status.

This register can only be used in asynchronous mode.

The TXDn pin status is determined by the combination of SCR.TE, SPTR.SPB2IO, and SPTR.SPB2DT settings, as shown in Table 34.22.

Table 34.22 TXDn pin status

Value of SCR.TE	Value of SPTR.SPB2IO	Value of SPTR.SPB2DT	TXDn pin status

0	1	0	Low level output
0	1	1	High level output
1	x	x	Serial transmit data is output

x: Don’t care.

Note: Use the SPTR register in asynchronous mode only. Using this register in any other mode is not guaranteed.

34.3 Operation in Asynchronous Mode

Figure 34.2 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit or receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communications line is held in the mark state (high level) when not communicating.

The SCI monitors the communications line. When the SCI detects a low, it regards that as a start bit and starts serial communication.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and receiver have a double-buffered structure in addition to FIFO mode, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

SPTR寄存器提供串行接收引脚（RXDn引脚）状态的确认并设置发送引脚（TXDn引脚）状态。

该寄存器只能在异步模式下使用。

TXDn引脚状态由SCR.TE、SPTR.SPB2IO和SPTR.SPB2DT设置的组合决定，如表34.22所示。

Table 34.22 TXDn引脚状态

Note: 仅在异步模式下使用SPTR寄存器。不保证在任何其他模式下使用该寄存器。

34.3 异步模式下的操作

图34.2显示了异步串行通信的一般格式。一帧由起始位（低电平）、发送或接收数据、奇偶校验位和停止位（高电平）组成。在异步串行通信中，通信线在不通信时保持在标记状态（高电平）。

SCI监控通信线路。当SCI检测到低电平时，将其视为起始位并开始串行通信。

在SCI内部，发射器和接收器是独立的单元，可实现全双工通信。发送器和接收器除了FIFO模式外，都具有双缓冲结构，从而可以在发送或接收过程中读取或写入数据，从而实现数据的连续发送和接收。

34.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate.

In reception, the SCI samples the falling edge of the start bit using the base clock, and performs synchronization.

Because receive data is sampled on the rising edge of the 8th pulse*1 of the base clock, data is latched at the middle of each bit, as shown in Figure 34.3. The reception margin in asynchronous mode is determined by the following formula (1):

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)\ F - \frac{\lfloor D - 0.5 \rfloor}{N}\ (1 + F) \right| \times 100\ [\%] \cdots \text{Formula (1)}$$

M: Reception margin
N: Ratio of bit rate to clock
(N = 16 when SEMR.ABCSE = 0 and SEMR.ABCS = 0. N = 8 when SEMR.ABCS = 1. N = 6 when SEMR.ABCSE = 1.)
D: Duty cycle of clock (D = 0.5 to 1.0)
L: Frame length (L = 9 to 13)
F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined using the following formula:

$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\%$

This represents the computed value. Renesas recommends a margin of 20% to 30% in system design.

Note 1. In this example, the SEMR.ABCS bit is 0 and the SEMR.ABCSE is 0. When the ABCS bit is 1 and the ABCSE bit is 0, a frequency of 8 times the bit rate is used as a base clock, and receive data is sampled on the rising edge of the 4th pulse of the base clock.
When the ABCSE bit is 1, a sextuple frequency of a bit rate is used as a base clock, and receive data is sampled on the rising edge of the 3rd pulse of the base clock.

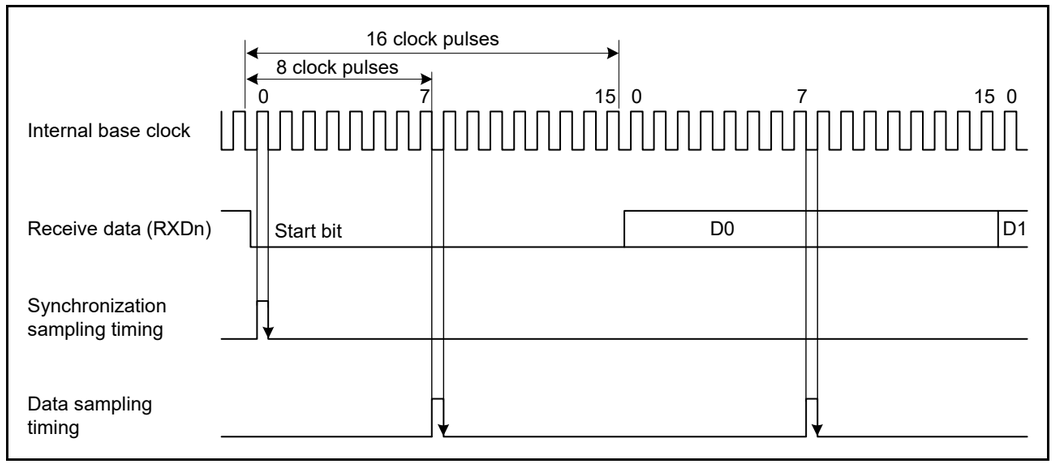

Figure 34.3 Receive data sampling timing in asynchronous mode

34.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the transfer clock of the SCI, based on the SMR.CM and SCR.CKE[1:0] settings.

When an external clock is input to the SCKn pin, the clock frequency must be 16 times the bit rate (when SEMR.ABCS = 0) or 8 times the bit rate (when SEMR.ABCS = 1).

MPB: Multi-processor bit

34.3.2 异步模式下接收数据采样时序和接收余量

在异步模式下，SCI在频率为16倍*1比特率的基本时钟上运行。

在接收时，SCI使用基本时钟对起始位的下降沿进行采样，并执行同步。

因为接收数据是在基本时钟的第8个脉冲*1的上升沿采样的，所以数据在每个位的中间锁存，如图34.3所示。异步模式下的接收余量由以下公式（1）确定：

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)\ F - \frac{\lfloor D - 0.5 \rfloor}{N}\ (1 + F) \right| \times 100\ [\%] \cdots \text{Formula (1)}$$

M：接收余量
N：比特率与时钟的比率（当SEMR.ABCSE=0和SEMR.ABCS=0时，N=16。当SEMR.ABCS=1时，N=8。当SEMR.ABCSE=1时，N=6。）D：占空比时钟（D=0.5到1.0）

L：帧长（L=9到13）
F：时钟频率偏差的绝对值

假设公式（1）中的F=0和D=0.5的值，接收裕量使用以下公式确定：

$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\%$

这表示计算值。瑞萨建议在系统设计中留出20%到30%的余量。

注1.本例中，SEMR.ABCS位为0，SEMR.ABCSE位为0。当ABCS位为1，ABCSE位为0时，使用8倍比特率的频率作为基准时钟，并在基本时钟的第4个脉冲的上升沿对接收数据进行采样。当ABCSE位为1时，以比特率的六倍频为基准时钟，在基准时钟的第3个脉冲的上升沿对接收数据进行采样。

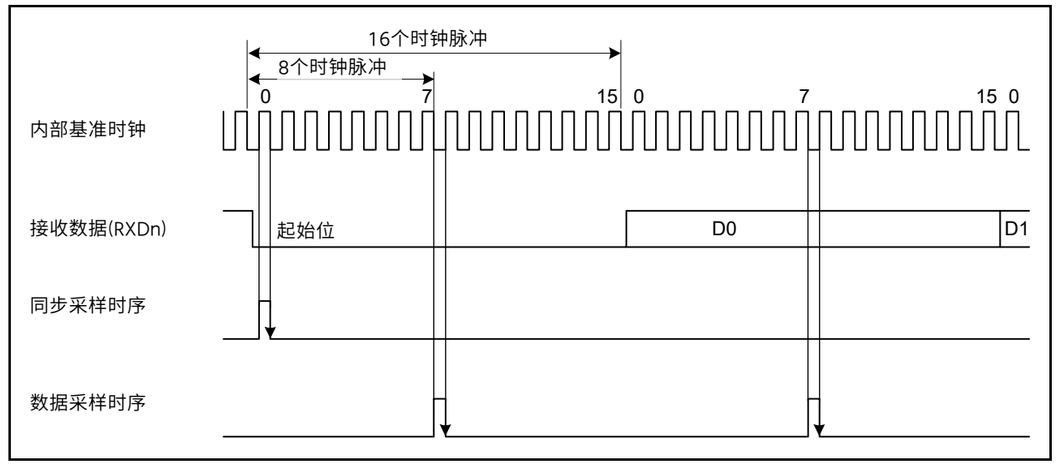

Figure 34.3 异步模式下接收数据采样时序

34.3.3 Clock

根据SMR.CM和SCR.CKE[1:0]设置，可以选择片内波特率发生器产生的内部时钟或输入到SCKn引脚的外部时钟作为SCI的传输时钟。

当外部时钟输入到SCKn引脚时，时钟频率必须为比特率的16倍（SEMR.ABCS=0时）或比特率的8倍（SEMR.ABCS=1时）。

When the SCI uses its internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is configured so that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 34.4.

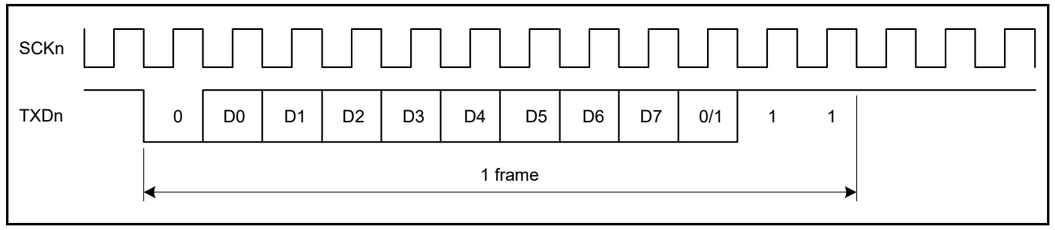

Figure 34.4 Phase relationship between output clock and transmit data in asynchronous mode when SMR.CHR = 0, PE = 1, MP = 0, and STOP = 1

34.3.4 Double-Speed Operation and Frequency of 6 Times the Bit Rate

When the SEMR.ABCS bit is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0. When the SEMR.BGDM bit is set to 1, the cycle of the base clock is half and the bit rate is double that of when BGDM is set to 0. When the SCR.CKE[1] bit is set to 0 and the on-chip baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the SCI to operate at a bit rate four times that when the ABCS and BGDM bits are set to 0. When the SEMR.ABCSE bit is set to 1, the number of basic clock pulses is 6 during a period of 1 bit, and the SCI operates at a bit rate 16/3 times that when SEMR.ABCS = 0, SEMR.BGDM = 0, and SMER.ABCSE = 0.

As shown by Formula (1) in section 34.3.2, Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, the reception margin decreases when the SEMR.ABCS or SEMR.ABCSE bit in SEMR is set to 1. Therefore, if the target bit rate can be obtained with ABCS or ABCSE set to 0, it is recommended that you use the SCI with ABCS and ABCSE set to 0.

34.3.5 CTS and RTS Functions

The CTS function uses input on the CTSn_RTSn pin in transmission control. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, placing a low level on the CTSn_RTSn pin causes transmission to start.

Driving the CTSn_RTSn pin high while transmission is in progress does not affect transmission of the current frame.

In the RTS function, which uses output on the CTSn_RTSn pin, a low level is output when reception becomes possible. Conditions for output of the low and high levels are shown in this section.

[Conditions for low-level output]

(a) Non-FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit is 1
- Reception is not in progress
- There is no received data yet to be read
- The ORER, FER, and PER flags in the SSR register are all 0.

(b) FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit is 1
- The amount of receive data written in FRDRHL is equal to or less than the specified receive triggering number
- The ORER bit in the SSR_FIFO register (ORER in FRDRH) is 0.

当SCI使用其内部时钟时，时钟可以从SCKn引脚输出。在这种情况下，时钟输出的频率等于比特率，并配置相位，使时钟的上升沿位于发送数据的中间，如图34.4所示。

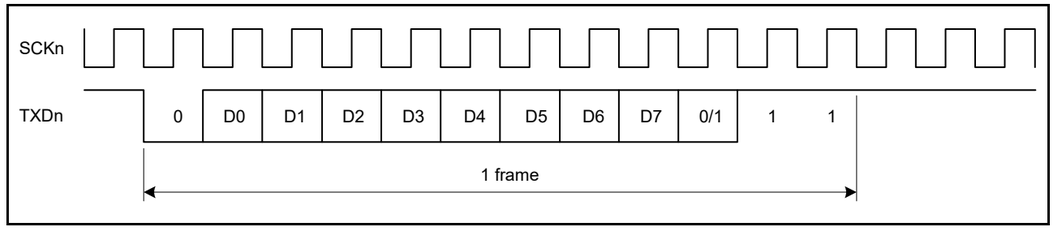

Figure 34.4 异步模式下输出时钟与传输数据的相位关系 SMR.CHR=0，PE=1，MP=0，STOP=1

34.3.4 双倍速操作和6倍比特率的频率

当SEMR.ABCS位设置为1并选择1位周期的8个基本时钟脉冲时，SCI以ABCS设置为0时的两倍比特率运行。当SEMR.BGDM位为设置为1，基本时钟的周期是BGDM设置为0时的一半，比特率是两倍。当SCR.CKE[1]位设置为0并且选择片内波特率发生器时，将ABCS和BGDM位设置为1允许SCI以ABCS和BGDM位设置为0时的四倍的比特率运行。当SEMR.ABCSE位设置为1时，基本时钟脉冲数为6在1位周期内，SCI以16的比特率运行，是SEMR.ABCS=0、SEMR.BGDM=0和SMER.ABCSE=0时的3倍。

如34.3.2节，异步接收数据采样时序和接收裕度中的公式（1）所示模式下，SEMR中的SEMR.ABCS或SEMR.ABCSE位设置为1时，接收余量减小。因此，如果将ABCS或ABCSE设置为0即可获得目标码率，建议您使用SCI与ABCS和ABCSE设置为0。

34.3.5 CTS和RTS函数

CTS功能在传输控制中使用CTSn_RTSn引脚上的输入。将SPMR.CTSE位设置为1可启用CTS功能。当CTS功能使能时，将CTSn_RTSn引脚置于低电平会导致传输开始。

在传输过程中将CTSn_RTSn引脚驱动为高电平不会影响当前帧的传输。

在使用CTSn_RTSn引脚输出的RTS功能中，当可以接收时输出低电平。
本节显示了低电平和高电平的输出条件。

[Conditions for low-level output]

(a) 满足以下所有条件时选择非FIFO

- SCR.RE位的值为1
- 接收未进行
- 没有接收到的数据尚未读取
- SSR寄存器中的ORER、FER和PER标志位均为0。

(b) 满足以下所有条件时选择FIFO

- SCR.RE位的值为1
- FRDRHL中写入的接收数据量等于或小于指定的接收触发数
- SSR_FIFO寄存器中的ORER位（FRRDH中的ORER）为0。

[Condition for high-level output]

(a Non-FIFO selected

- The conditions for low-level output are not satisfied
- When reception is terminated with SCR.RE = 0 without reading the RDR register after reception is complete, RTS remains high. At this time, read the SCR register for dummy values after writing 0 to SCR.RE.

(b) FIFO selected

- The conditions for low-level output are not satisfied.

34.3.6 Address Match (Receive Data Match Detection) Function

The address match function can be used only in asynchronous mode.

If the DCCR.DCME bit is set to 1*4, when one frame of data is received, the SCI compares that received data with the data set in CDR.CMPD. If the SCI detects a match to the comparison data (CDR.CMPD*3) with the received data, the SCI can issue the SCIn_RXI interrupt request.

If the SMR.MP bit is set to 0, comparison occurs only for valid data in receive format. In multi-processor mode (SMR.MP bit = 1), if the DCCR.IDSEL bit is set to 1, receive data where the MPB bit is 1 is subject to comparison for address match and receive data where the MPB bit is 0 is always treated as a mismatch.

If the DCCR.IDSEL bit is set to 0, SCI performs address match detection regardless of the MPB bit value of the received data. Until SCI detects a match between the comparison data (CDR.CMPD*3) and the receive data, the received data is skipped (discarded), and the SCI cannot detect a parity error or framing error.

When SCI detects a match, the DCCR.DCME bit is automatically cleared, and the DCCR.DCMF flag is set to 1. If the DCCR.IDSEL bit is set to 1, the SCR.MPIE bit is automatically cleared. If DCCR.IDSEL is set to 0, the value of the SCR.MPIE bit is retained. If the SCR.RIE bit is set to 1, the SCI issues an SCIn_RXI interrupt request.

If the SCI detects a framing error in the receive data for which a match is detected, the DCCR.DFER bit is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER bit is set to 1. The compared receive data is not stored in the RDR register*1, and SSR.RDRF remains 0.*2

After the SCI detects a match, and DCCR.DCME is automatically cleared, the SCI receives the next data continuously based on the current register setting.

When the DCCR.DFER or DCCR.DPER flag is set, the address match is not performed. Before enabling the address match function, set the DCCR.DFER and DCCR.DPER flags to 0.

Examples of the address match function are shown in Figure 34.5 and Figure 34.6.

Note 1. When FCR.FM = 1, this refers to the FRDRHL register.
Note 2. When FCR.FM = 1, this refers to the SSR_FIFO.RDF flag.
Note 3. This comparative target can select one length of 3 types: CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.
Note 4. Set the DCCR.DCME bit to 1 before receiving the start bit of the received frame that performs address matching.

[Condition for high-level output]

(a Non-FIFO selected

- 不满足低电平输出的条件
- 当接收结束后接收结束且SCR.RE=0且未读取RDR寄存器时，RTS保持高电平。此时，将0写入SCR.RE后，读取SCR寄存器的虚拟值。

(b) FIFO selected

- 不满足低电平输出的条件。

34.3.6 地址匹配（接收数据匹配检测）功能

地址匹配功能只能在异步模式下使用。

如果DCCR.DCME位设置为1*4，当接收到一帧数据时，SCI会将接收到的数据与CDR.CMPD中设置的数据进行比较。如果SCI检测到比较数据(CDR.CMPD*3)与接收到的数据匹配，则SCI可以发出SCIn_RXI中断请求。

如果SMR.MP位设置为0，则仅对接收格式的有效数据进行比较。在多处理器模式下（SMR.MP位=1），如果DCCR.IDSEL位设置为1，则接收MPB位为1的数据进行地址匹配比较，接收MPB位为0的数据总是被视为不匹配。

如果DCCR.IDSEL位设置为0，SCI执行地址匹配检测，而不管接收数据的MPB位值如何。直到SCI检测到比较数据（CDR.CMPD*3）与接收数据匹配，接收数据被跳过（丢弃），SCI无法检测奇偶校验错误或成帧错误。

当SCI检测到匹配时，自动清除DCCR.DCME位，并将DCCR.DCMF标志设置为1。如果DCCR.IDSEL位设置为1，SCR.MPIE位自动清零。如果DCCR.IDSEL设置为0，则SCR.MPIE位被保留。如果SCR.RIE位设置为1，则SCI发出SCIn_RXI中断请求。

如果SCI在检测到匹配的接收数据中检测到帧错误，则DCCR.DFER位设置为1，如果SCI在该帧中检测到奇偶校验错误，则DCCR.DPER位设置为1。比较后的接收数据不存入RDR寄存器*1，SSR.RDRF保持为0。*2

SCI检测到匹配后，DCCR.DCME自动清零，SCI根据当前寄存器设置连续接收下一个数据。

当设置DCCR.DFER或DCCR.DPER标志时，不执行地址匹配。在启用地址匹配功能之前，将DCCR.DFER和DCCR.DPER标志设置为0。

地址匹配函数的例子如图34.5和图34.6所示。

34.3.7 异步模式下的SCI初始化

在发送和接收数据之前，首先将初始值00h写入SCR寄存器，然后继续执行图34.7和图34.8所示的SCI初始化过程（选择非FIFO或FIFO）。每当

operating mode or transfer format is to be changed, the SCR register must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied during initialization.

Note: When the SCR.RE bit is set to 0, the ORER, FER, RDRF, RDF, PER, and DR flags in SSR/SSR_FIFO, and the RDR and RDRHL registers are not initialized. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: Switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of an SCIn_TXI interrupt request.

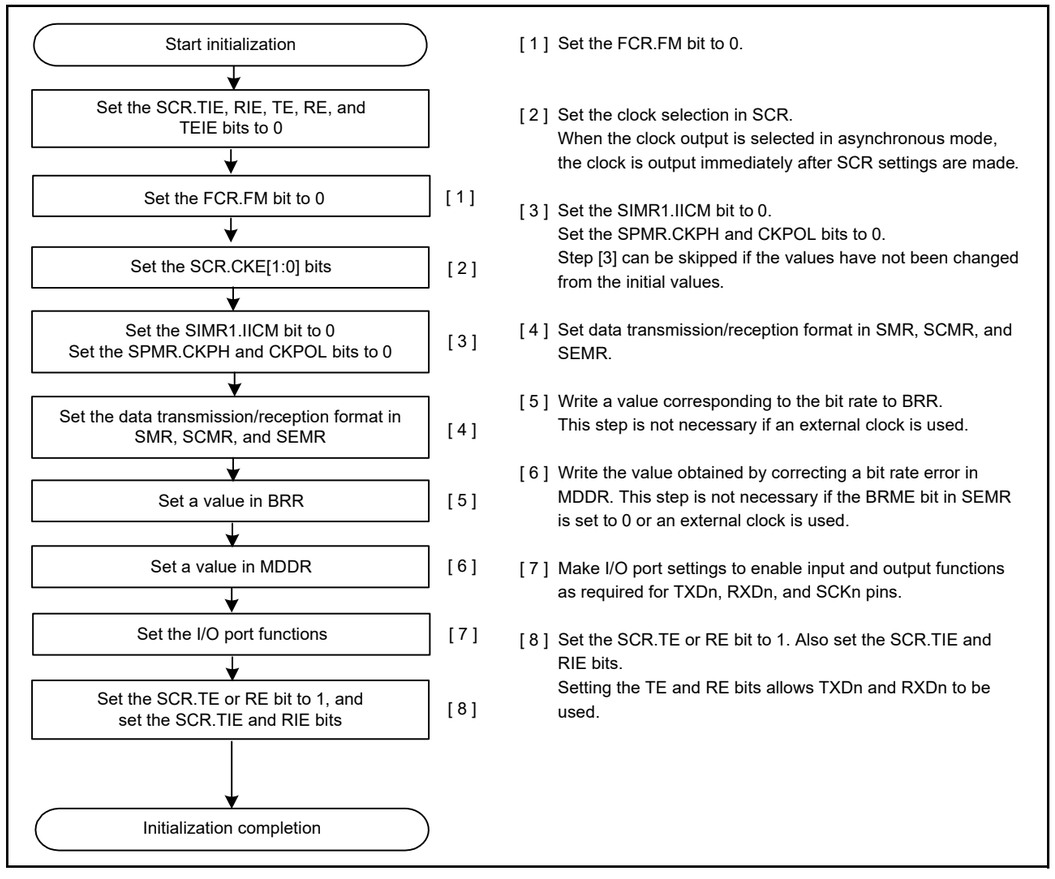

Figure 34.7 Example flow of SCI initialization in asynchronous mode with non-FIFO selected

要更改操作模式或传输格式，必须在更改之前初始化SCR寄存器。

在异步模式下使用外部时钟时，请确保在初始化期间提供时钟信号。

Note: 当SCR.RE位设置为0时，SSRSSR_FIFO中的ORER、FER、RDRF、RDF、PER和DR标志，以及RDR和RDRHL寄存器未初始化。当TE位设置为0时，所选FIFO缓冲区的TEND标志未初始化。

Note: 当SCR.TIE位为1时，将SCR.TE位的值从1切换到0或0到1会导致生成SCIn_TXI中断请求。

34.3.8 Serial Data Transmission in Asynchronous Mode

(1) Non-FIFO selected

Figure 34.9, Figure 34.10, and Figure 34.11 show examples of serial transmission in asynchronous mode.

In serial transmission, the SCI operates as described in this section. When the SCR.TE bit is set to 1, the high level for one frame (preamble) is output to TXD.

1. The SCI transfers data from the TDR*1 register to the TSR register when data is written to TDR*1 in the SCIn_TXI interrupt handling routine.
   The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the TDR*1 register to the TSR register. If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to the TDR*1 register in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is

34.3.8 异步模式下的串行数据传输

(1) Non-FIFO selected

图34.9、图34.10和图34.11显示了异步模式下的串行传输示例。

在串行传输中，SCI的操作如本节所述。当SCR.TE位设置为1时，一帧（前导码）的高电平输出到TXD。

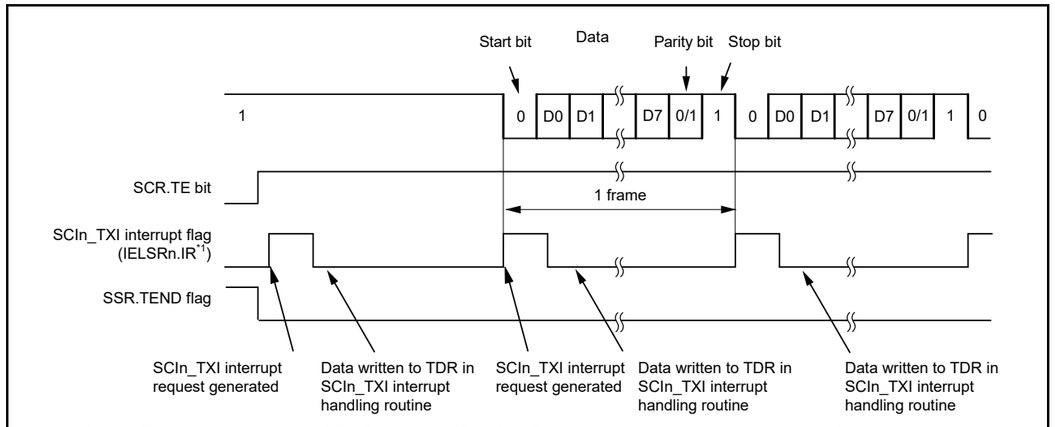
1. 当数据在SCIn_TXI中断处理程序中写入TDR*1时，SCI将数据从TDR*1寄存器传输到TSR寄存器。当一条指令同时将SCR.TE和SCR.TIE位设置为1时，会在传输开始时产生SCIn_TXI中断请求。
2. 在SPMR.CTSE位设置为0（禁用CTS功能）或低电平后开始发送
   CTSn_RTSn引脚导致数据从TDR*1寄存器传输到TSR寄存器。如果SCR.TIE位为1，则
   SCIn_TXI中断请求产生。在发送当前发送数据之前，通过将下一个发送数据写入SCIn_TXI中断处理程序中的TDR*1寄存器，可以实现连续发送

complete. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR*1 register from the handling routine for SCIn_TXI requests.

3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data
   - Parity bit or multi-processor bit (can be omitted depending on the format)
   - Stop bit.
4. The SCI checks for update of the TDR register on output of the stop bit.
5. When the TDR register is updated, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from the TDR*1 register to the TSR register and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register is not updated, the SSR.TEND flag is set to 1, the stop bit is sent, and the mark state is entered, in which 1 is output. If the SCR.TEIE bit is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Note 1. Only write data to the TDRHL register when 9-bit data length is selected.

Figure 34.9, Figure 34.10, and Figure 34.11 show examples of serial transmission in asynchronous mode.



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

完全的。使用SCIn_TEI中断请求时，在写入要发送的最后一个数据后，将SCR.TIE位设置为0（禁止SCIn_TXI中断请求）并将SCR.TEIE位设置为1（启用SCIn_TEI中断请求）从SCIn_TXI请求的处理例程到TDR*1寄存器。

3. 数据按以下顺序从TXDn引脚发送：
   - 起始位
   - 传输数据
   - 奇偶校验位或多处理器位（可根据格式省略）
   - 停止位。
4. SCI在停止位输出时检查TDR寄存器的更新。
5. 更新TDR寄存器时，将SPMR.CTSE位设置为0（禁用CTS功能）或CTSn_RTSn引脚上的低电平输入会导致下一个发送数据从TDR*1寄存器传输到TSR寄存器并发送停止位，之后开始下一帧的串行传输。
6. 如果TDR寄存器没有更新，则SSR.TEND标志置1，发送停止位，进入标记状态，其中输出1。如果SCR.TEIE位为1，则SSR.TEND标志设置为1，并产生SCIn_TEI中断请求。

注意1.选择9位数据长度时，仅将数据写入TDRHL寄存器。

Figure 34.13 Data format written to FTDRH and FTDRL with FIFO selected

In serial transmission, the SCI operates as described in this section. When the TE bit is set to 1, the high level is output to TXD for one frame (preamble).

1. The SCI transfers data from the FTDRL*1 register to the TSR register when data is written to FTDRL*1 in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the FTDRL*1 register to the TSR register. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, SSR_FIFO.TDFE is set to 1. If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to FTDRL*1 in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the FTDRL*1 *2 register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data
   - Parity bit or multi-processor bit (can be omitted depending on the format)
   - Stop bit.
4. On output of the stop bit, the SCI checks whether non-transmitted data remains in the FTDRL*3 register.
5. When data is set to FTDRL*3, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from FTDRL*1 to TSR and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set in FTDRL*3, the TEND flag in SSR_FIFO is set to 1, the stop bit is sent, and the mark state is entered in which 1 is output. If the SCR.TEIE bit is 1, the SSR_FIFO.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Note 1. Write data not to FTDRL but to the FTDRH and FTDRL registers.
Note 2. Write data in order from FTDRH to FTDRL when 9-bit data length is selected.
Note 3. The SCI only checks for update to the FTDRL register and not the FTDRH register when 9-bit data length is selected.

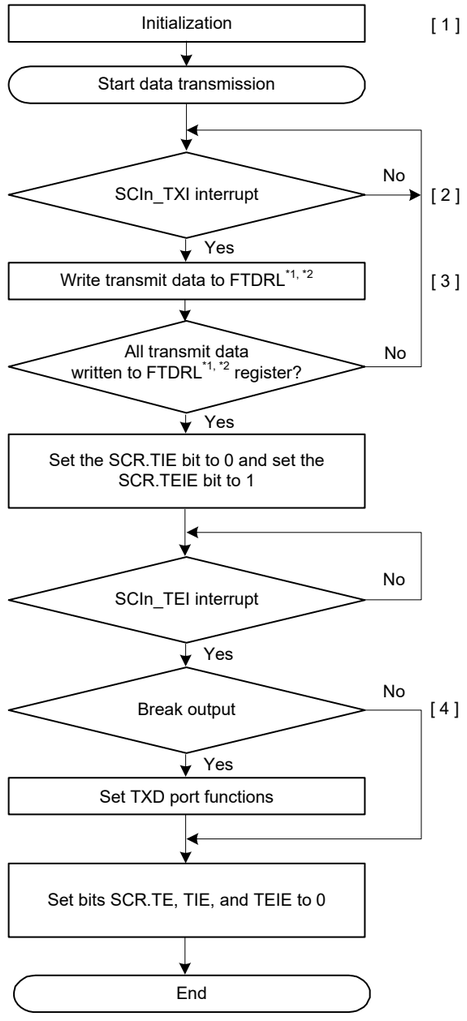
Figure 34.13 选择FIFO写入FTDRH和FTDRL的数据格式

在串行传输中，SCI的操作如本节所述。当TE位设置为1时，高电平输出到一帧的TXD（前导码）。

1. 当数据写入FTDRL*1时，SCI将数据从FTDRL*1寄存器传输到TSR寄存器SCIn_TXI中断处理程序。可写入FTDRL的数据量为16减去FDR.T[4:0]字节。当一条指令同时将SCR.TE和SCR.TIE位设置为1时，会在传输开始时产生SCIn_TXI中断请求。
2. 在SPMR.CTSE位设置为0（禁用CTS功能）或低电平后开始发送CTSn_RTSn引脚导致数据从FTDRL*1寄存器传输到TSR寄存器。当写入FTDRL的发送数据量等于或小于指定的发送触发数时，SSR_FIFO.TDFE设置为1。如果SCR.TIE位为1，则产生SCIn_TXI中断请求。在当前传输数据传输完成之前，通过在SCIn_TXI中断处理例程中将下一个传输数据写入FTDRL*1可以实现连续传输。使用SCIn_TEI中断请求时，在写入最后一个要发送的数据后，将SCR.TIE位设置为0（禁止SCIn_TXI中断请求）并将SCR.TEIE位设置为1（启用SCIn_TEI中断请求）从SCIn_TXI请求的处理例程到FTDRL*1*2寄存器。
3. 数据按以下顺序从TXDn引脚发送：
   - 起始位
   - 传输数据
   - 奇偶校验位或多处理器位（可根据格式省略）
   - 停止位。
4. 在停止位输出时，SCI检查未发送的数据是否保留在FTDRL*3寄存器中。
5. 当数据设置为FTDRL*3时，将SPMR.CTSE位设置为0（禁用CTS功能）或低电平输入CTSn_RTSn管脚使下一个传输数据从FTDRL*1传输到TSR并传输停止位，然后开始下一帧的串行传输。
6. 如果FTDRL*3中未设置数据，则将SSR_FIFO中的TEND标志设置为1，发送停止位，并进入输出1的标记状态。如果SCR.TEIE位为1，则SSR_FIFO.TEND标志设置为1，并产生SCIn_TEI中断请求。

注1.不要将数据写入FTDRL，而是写入FTDRH和FTDRL寄存器。
注2.选择9位数据长度时，按从FTDRH到FTDRL的顺序写入数据。
注意3.SCI仅检查对FTDRL寄存器的更新，而不是选择9位数据长度时的FTDRH寄存器。

图34.14显示了选择FIFO的异步模式下串行传输的示例流程。



[1] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame (preamble), and transmission is enabled.

[2] Transmit data write to FTDRL*1 by an SCIn_TXI interrupt request:
When transmit data is transferred from FTDRL to TSR, when the quantity of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL*1, *2 once in the SCIn_TXI interrupt handling routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data to FTDRL using an SCIn_TXI interrupt request and clear the SSR_FIFO.TDFE flag to 0. The number of transmission data it is possible to write in is 16 - (the number of stored transmit FIFO data).
Transmit data can also be written to FTDRL by activating the DMAC or DTC. When writing the data to FTDRL by DMAC or DTC, the TDFE flag is cleared automatically, so do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to FTDRL.

To output a break in serial transmission, after setting the output state (LOW level output) of TXDn pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

Note 1. When data length is 9 bits, this refers to FTDRH and FTDRL registers.
Note 2. When data length is 9 bits, write in order from FTDRH to FTDRL.

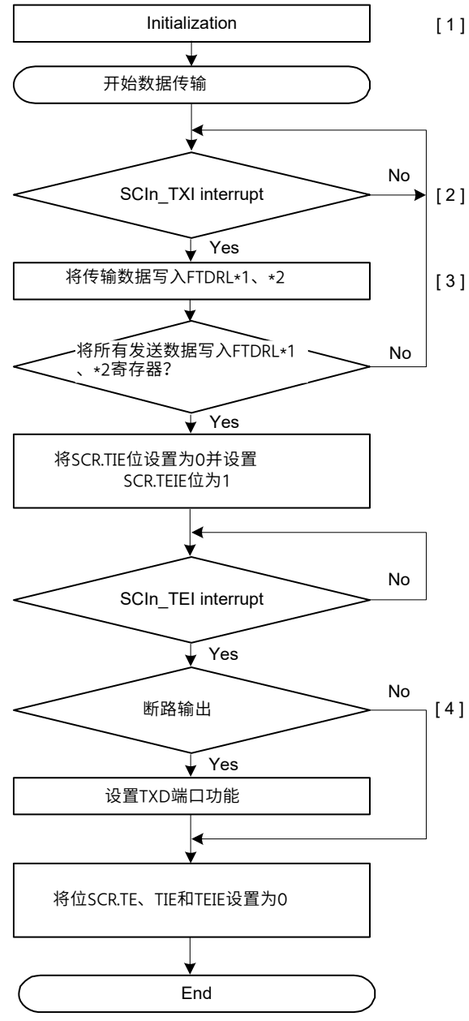
34.3.9 Serial Data Reception in Asynchronous Mode

(1) Non-FIFO selected

Figure 34.15 and Figure 34.16 show an example of the operation for serial data reception in asynchronous mode.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and when it detects a start bit, the SCI performs internal synchronization, stores receive data in RSR, and checks the parity bit and stop bit.
3. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR*1 register.



[1] SCI initialization:
设置数据传输。
SCR.TE位设置为1后，为一个帧（前导码）输出1，并启用传输。

[2] 通过SCIn_TXI中断请求将发送数据写入FTDRL*1：当发送数据从FTDRL传输到TSR时，当写入FTDRL的发送数据量等于或小于指定的发送触发数时，发送数据FIFO空中断(SCIn_TXI)请求产生。在SCIn_TXI中断处理例程中将发送数据写入FTDRL*1、*2一次。

[3] 串行传输继续程序：
要继续串行传输，请将所有传输数据写入FTDRL使用SCIn_TXI中断请求并将SSR_FIFO.TDFE标志清除为0。可以写入的传输数据数为16（存储的传输FIFO数据数）。也可以通过激活DMAC或DTC将传输数据写入FTDRL。通过DMAC或DTC将数据写入FTDRL时，TDFE标志会自动清除，因此不要写入TDFE标志。当SCIn_TEI中断请求正在使用时，设置

在将要传输的最后一个数据写入FTDRL后，SCR.TIE位为0，SCR.TEIE位为1。

[4] 串行传输结束时中断输出：
要在串行传输中输出中断，在通过SPTR.SPB2IO和SPTR.SPB2DT位设置TXDn引脚的输出状态（低电平输出）后，将SCR.TE位设置为0。

Note 1. 当数据长度为9位时，这是指FTDRH和FTDRL registers.
Note 2. 当数据长度为9位时，按照FTDRH到FTDRL的顺序写入。

34.3.9 异步模式下的串行数据接收

(1) Non-FIFO selected

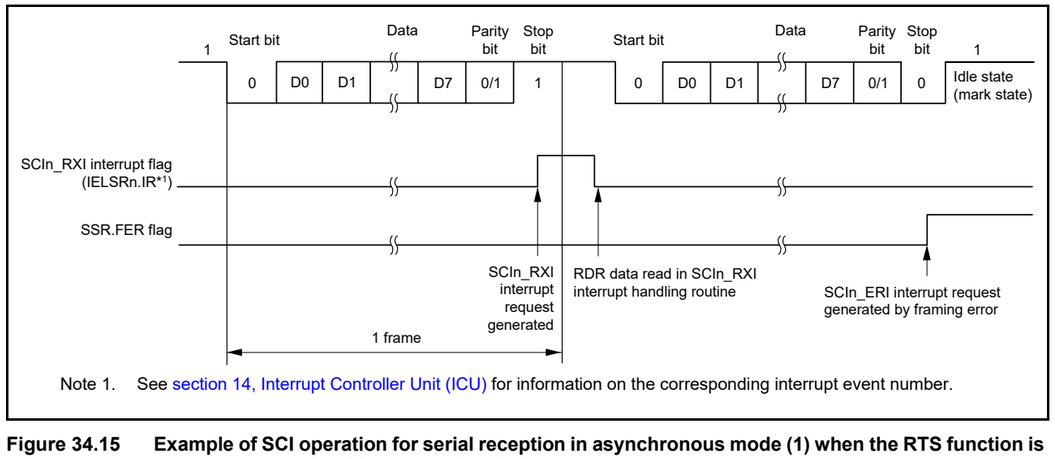
图34.15和图34.16显示了异步模式下串行数据接收操作的示例。

在串行数据接收中，SCI操作如下：

1. 当SCR.RE位的值变为1时，CTSn_RTSn引脚上的输出信号变为低电平。
2. SCI监视通信线路，当它检测到起始位时，SCI执行内部同步，将接收数据存储在RSR中，并检查奇偶校验位和停止位。
3. 如果发生溢出错误，则SSR.ORER标志设置为1。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。接收数据不传送到RDR*1寄存器。

4. If a parity error is detected, the SSR.PER flag is set to 1 and receive data is transferred to the RDR*1 register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
5. If a framing error is detected, the SSR.FER flag is set to 1 and receive data is transferred to the RDR*1 register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
6. When reception finishes successfully, receive data is transferred to the RDR*1 register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that was transferred to the RDR register causes the CTSn_RTSn pin to output low.

Note 1. Only read data in the RDRHL register when 9-bit data length is selected.



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Table 34.24 lists the states of the flags in the SSR register and receive data handling when a receive error is detected.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER bits to 0 before resuming reception. In addition, be sure to read the RDR or RDRHL register during overrun error

4. 如果检测到奇偶校验错误，则将SSR.PER标志设置为1，并将接收数据传输到RDR*1寄存器。如果SCR.RIE位为1，产生SCIn_ERI中断请求。
5. 如果检测到帧错误，则将SSR.FER标志设置为1，并将接收数据传输到RDR*1寄存器。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。
6. 当接收成功完成时，接收数据被传送到RDR*1寄存器。如果SCR.RIE位为1，则产生SCIn_RXI中断请求。在接收下一个接收数据完成之前，通过在SCIn_RXI中断处理例程中读取传输到RDR寄存器的接收数据来启用连续接收。读取传输到RDR寄存器的接收数据会导致CTSn_RTSn引脚输出低电平。

注1.选择9位数据长度时，仅读取RDRHL寄存器中的数据。

如果检测到接收错误，则会产生SCIn_ERI中断请求，但不会产生SCIn_RXI中断请求。当接收错误标志为1时，无法恢复数据接收。因此，在恢复接收之前，请将ORER、FER和PER位设置为0。另外，请务必在溢出错误期间读取RDR或RDRHL寄存器

[1] SCI initialization:
Set data reception.

[2] [3] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. An error is identified by reading the ORER, PER, and FER flags in SSR. After performing the appropriate error processing, always set the ORER, PER, and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. For a framing error, a break can be detected by reading the value of the input port associated with the RXDn pin.

[4] Read the receive data in RDR once in the SCIn_RXI interrupt handling routine.

[5] Serial reception continuation procedure:
To continue serial reception, before the stop bit of a frame is received, read data from RDR in the SCIn_RXI interrupt processing routine. The RDR data can also be read by activating the DMAC or DTC.

Note 1. Do not set RE to 0 before reading RDR.
Note 2. The RDR register becomes the RDRHL register when 9-bit data length is selected.

When data length is 7 bits, 0 is always read for FRDRH[0] and FRDRL[7].
When data length is 8 bits, 0 is always read for FRDRH[0].
FRDRH[7] bit is read as an indefinite value.

Figure 34.19 Data format stored in FRDRH and FRDRL with FIFO selected

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and, when it detects a start bit, the SCI performs internal synchronization, stores receive data in the RSR register, and checks the parity bit and stop bit.
3. If an overrun error occurs, the SSR_FIFO.ORER flag is set to 1. If the SCR.RIE bit in SCR is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the FRDRL*1 register.
4. If a parity error is detected, the PER flag and receive data are transferred to the FRDRL*1 register. If the RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
5. If a framing error is detected, the FER flag and receive data are transferred to the FRDRL*1 register. If the RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
6. After a framing error is detected and when SCI detects that the continuous receive data is for one frame, reception stops.
7. When the amount of data stored in the FRDRL register falls below the specified receive triggering number, and the next data is not received after 15 ETUs from the last stop bit in asynchronous mode, the SSR_FIFO.DR bit is set to 1. When the RIE bit is 1 and the FCR.DRES bit is 0, the SCI generates an SCIn_RXI interrupt request. When the FCR.DRES bit is 1, SCI generates an SCIn_ERI interrupt request.
8. When reception finishes successfully, receive data is transferred to the FRDRL*1 register. The RDF bit is set to 1 when the amount of receive data written to FRDRHL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit in SCR is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the FRDRL*2 register in the SCIn_RXI interrupt handling routine, before an overrun error occurs. If the received data that is transferred to FRDRL*3 is less than the RTS trigger number, the CTSn_RTSn pin outputs low.

Note 1. Only read data in the FRDRH and FRDRL registers when 9-bit data length is selected.
Note 2. Read data in order from FRDRH to FRDRL when 9-bit data length is selected.
Note 3. The SCI only checks for update to the FRDRL register and not to the FRDRH register when 9-bit data length is selected.

在串行数据接收中，SCI操作如下：

1. 当SCR.RE位的值变为1时，CTSn_RTSn引脚上的输出信号变为低电平。
2. SCI监视通信线路，当它检测到起始位时，SCI执行内部同步，将接收数据存储在RSR寄存器中，并检查奇偶校验位和停止位。

4. 如果检测到奇偶校验错误，则将PER标志和接收数据传送到FRDRL*1寄存器。如果RIE位设置为1，则产生SCIn_ERI中断请求。
5. 如果检测到帧错误，则将FER标志和接收数据传送到FRDRL*1寄存器。如果RIE位设置为1，则产生SCIn_ERI中断请求。
6. 检测到帧错误后，当SCI检测到连续接收数据为一帧时，接收停止。
7. 当存储在FRDRL寄存器中的数据量低于指定的接收触发数，并且在异步模式下从最后一个停止位开始15个ETU后没有接收到下一个数据时，SSR_FIFO.DR位设置为1。当RIE位为1且FCR.DRES位为0，SCI产生一个SCIn_RXI中断请求。当FCR.DRES位为1时，SCI产生一个SCIn_ERI中断请求。
8. 当接收成功完成时，接收数据被传送到FRDRL*1寄存器。当写入FRDRHL的接收数据量等于或大于指定的接收触发数时，RDF位设置为1。如果SCR中的SCR.RIE位为1，则产生SCIn_RXI中断请求。在发生溢出错误之前，通过在SCIn_RXI中断处理例程中读取传输到FRDRL*2寄存器的接收数据来启用连续接收。如果传送到FRDRL*3的接收数据小于RTS触发数，CTSn_RTSn引脚输出低电平。

[1] SCI initialization:
Set data reception.

[2] [3] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. A break can be detected by reading the SPTR.RXDMON bit. An error is identified by reading the ORER*1, PER, DR*1, and FER flags in SSR_FIFO. After performing the appropriate error processing, be sure to set the ORER*1 flag to 0. Reception cannot be resumed if ORER*1 flag is set to 1. The reception operation is continuous, even if the FER = 1 or PER = 1 or DR*1 = 1.

[4] Read the receive data in FRDRHL in the SCIn_RXI interrupt handling routine. The receive data stored in the FRDRHL register is read until the number of stored data is below the FCR.RTRG value. Confirm the number of the reception data in the FIFO by reading FDR.R.

[5] Serial reception continuation procedure:
To continue serial reception, before an overrun error occurs, read data from FRDRHL in the SCIn_RXI interrupt handling routine and clear RDF and DR flags to 0.
The FRDRHL data can also be read by activating the DMA or DTC. The RDF flag is cleared automatically in this case, so do not write to the RDF flag.

Note 1. Can be read in the FRDRHL.ORER and DR flags.

34.4 多处理器通信功能

多处理器通信功能使SCI能够在多个处理器之间发送和接收数据

by sharing an asynchronous serial communication line that has an added multi-processor bit. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station.

The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle:

- When the multi-processor bit is set to 1, the transmission cycle is the ID transmission cycle
- When the multi-processor bit is set to 0, the transmission cycle is the data transmission cycle.

Figure 34.22 shows an example of communication between processors using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits communication data in which the multi-processor bit set to 0 is added to the transmit data. After receiving communication data with the multi-processor bit set to 1, the receiving station compares the received ID with the ID of the receiving station itself. If the two match, the receiving station receives communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until it receives data in which the multi-processor bit is set to 1.

(1) Non-FIFO selected

To support this function, the SCI provides the SCR.MPIE bit. When the MPIE bit is set to 1, the following operations are disabled until the reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR register (the RDRHL register when 9-bit data length is selected)
- Detection of a receive error
- Setting of the respective RDRF, ORER, and FER status flags in the SSR register.

When the SCI receives a character in which the multi-processor bit is set to 1, the SSR.MPBT bit is set to 1 and the SCR.MPIE bit is automatically cleared, returning the SCI to non-multi processor reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in non-multi processor asynchronous mode. The clock used for the multi-processor communication is the same as the clock used in non-multi processor asynchronous mode.

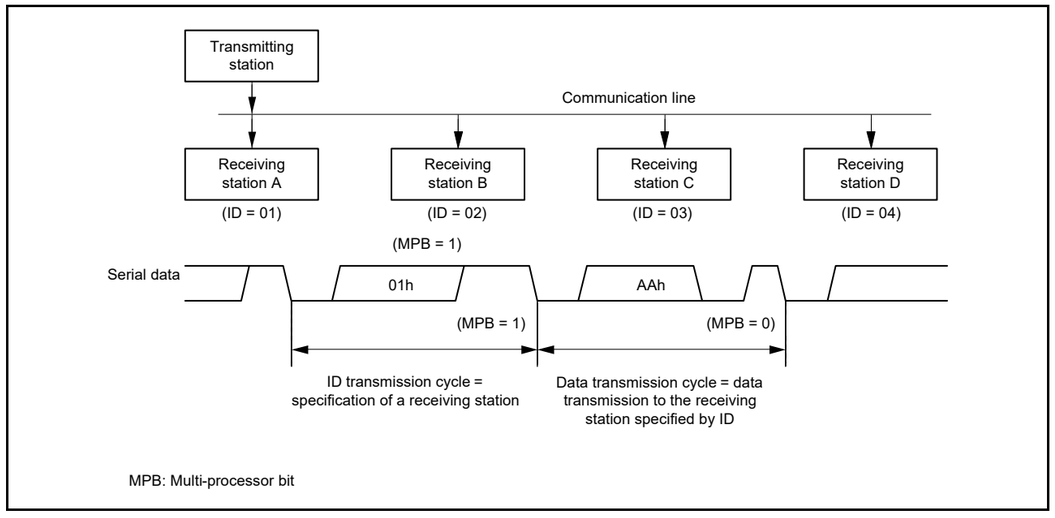

Figure 34.22 Example of communication using multi-processor format with transmission of data AAh to receiving station A

通过共享具有附加多处理器位的异步串行通信线。在多处理器通信中，为每个接收站分配一个唯一的ID代码。串行通信周期由指定接收站的ID传输周期和向指定接收站传输数据的数据传输周期组成。

多处理器位用于区分ID传输周期和数据传输周期：

- 当多处理器位设置为1时，发送周期为ID发送周期
- 当多处理器位设置为0时，传输周期为数据传输周期。

图34.22显示了使用多处理器格式的处理器之间的通信示例。首先，发送站发送将设置为1的多处理器位添加到接收站的ID码的通信数据。接着，发送站发送在发送数据中附加了多处理器比特为0的通信数据。接收站接收到多处理器位设置为1的通信数据后，将接收到的ID与接收站自身的ID进行比较。如果两者匹配，则接收站接收随后发送的通信数据。如果接收到的ID与接收站的ID不匹配，则接收站跳过通信数据，直到接收到多处理器位设置为1的数据。

(1) Non-FIFO selected

为了支持这个功能，SCI提供了SCR.MPIE位。当MPIE位设置为1时，以下操作被禁止，直到接收到多处理器位设置为1的数据：

- 将接收数据从RSR寄存器传送到RDR寄存器（选择9位数据长度时的RDRHL寄存器）
- 检测接收错误
- 在SSR寄存器中设置相应的RDRF、ORER和FER状态标志。

当SCI接收到多处理器位设置为1的字符时，SSR.MPBT位设置为1，并且SCR.MPIE位自动清零，将SCI返回到非多处理器接收操作。如果SCR.RIE位设置为1，则会产生SCIn_RXI中断。

当指定多处理器格式时，奇偶校验位功能被禁用。除此之外，与非多处理器异步模式下的操作没有区别。多处理器通信使用的时钟与非多处理器异步模式使用的时钟相同。

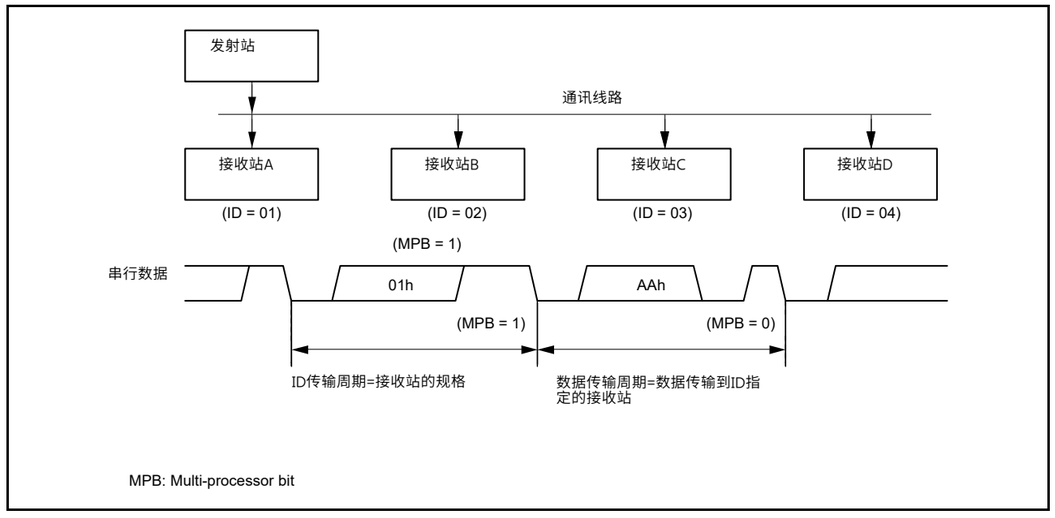

Figure 34.22 使用多处理器格式的通信示例，将数据AAh传输到接收站A

(2) FIFO selected

For data transmission, software must write data to FTDRHL.MPBT that corresponds to transmit data in FTDRHL.TDAT. For data reception, the multi-processor bit that is part of the receive data is written to FRDRHL.MPB and receive data is written to FRDRL.

When the MPIE bit is set to 1, the following operations are disabled until reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the FRDRHL register
- Detection of a receive error
- Break
- Setting of the respective RDF, ORER, and FER status flags in the SSR_FIFO register.

When the SCI receives an 8-bit character in which the multi-processor bit is set to 1, the FRDRHL.MPB bit is set to 1 and receive data is written to FRDRHL.RDAT. The SCR.MPIE bit is automatically cleared, returning the SCI to non-multi processor reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in non-multi processor asynchronous mode with non-FIFO selected.

34.4.1 Multi-Processor Serial Data Transmission

(1) Non-FIFO selected

Figure 34.23 shows an example flow of multi-processor data transmission. In the ID transmission cycle, the ID must be transmitted with the SSR.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in asynchronous mode.

(2) FIFO selected

对于数据传输，软件必须将数据写入与FTDRHL.TDAT中的传输数据相对应的FTDRHL.MPBT。对于数据接收，作为接收数据一部分的多处理器位被写入FRDRHL.MPB，接收数据被写入FRDRL。

当MPIE位设置为1时，以下操作被禁止，直到接收到多处理器位设置为1的数据：

- 将接收数据从RSR寄存器传送到FRDRHL寄存器
- 检测接收错误
- Break
- 在SSR_FIFO寄存器中设置相应的RDF、ORER和FER状态标志。

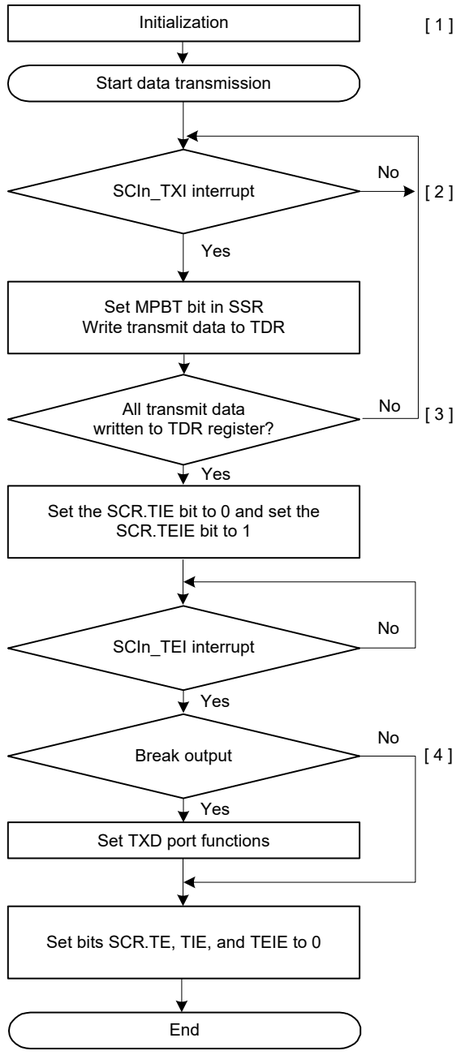
当SCI接收到多处理器位设置为1的8位字符时，FRDRHL.MPB位设置为1，接收数据写入FRDRHL.RDAT。SCR.MPIE位自动清零，将SCI返回到非多处理器接收操作。如果SCR.RIE位设置为1，则会产生SCIn_RXI中断。

当指定多处理器格式时，奇偶校验位功能被禁用。除此之外，与选择非FIFO的非多处理器异步模式下的操作没有区别。

34.4.1 多处理器串行数据传输

(1) Non-FIFO selected

图34.23显示了多处理器数据传输的示例流程。在ID传输周期，ID必须在SSR.MPBT位设置为1的情况下传输。在数据传输周期，数据必须在MPBT位设置为0的情况下传输。其余操作与操作相同在异步模式下。



[1] SCI initialization:

After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[2] SCIn_TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated.
Set the MPBT bit in SSR to 0 or 1, and write transmit data to TDR once in the SCIn_TXI interrupt processing routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR once using an SCIn_TXI interrupt request.
Transmit data can also be written to TDR by activating the DMAC or DTC.

34.4.2 Multi-Processor Serial Data Reception

(1) Non-FIFO selected

Figure 34.27 and Figure 34.28 are example flows of multi-processor data reception. When the SCR.MPIE bit is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to the RDR register (the RDRHL register when 9-bit data length is selected), and the SCIn_RXI interrupt request is generated. The rest of the operations are the same as operations in asynchronous mode.

(2) FIFO selected

Figure 34.29 shows an example of a data format that is written to FRDRH and FRDRL in multi-processor mode.

In multi-processor mode, the MPB value that is a part of the receive data is written to the FRDRH.MPB flag. A value of 0 is written to the FRDRH.PER flag. Data is written to FRDRH and FRDRL with the correct data length. Unused bits are written with 0. Read in order from FRDRH to FRDRL. When software reads the FRDRL register, the SCI updates FER, MPB, and receive data (RDAT[8:0]) in FRDRL with the next data. The RDF, ORER and DR flags in the FRDRH register always reflect the associated flags in the SSR_FIFO register.

34.5 Operation in Clock Synchronous Mode

Figure 34.31 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8-bit data. In clock synchronous mode, no parity bit can be added.

In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the last bit as output state. When the SPMR.CKPH bit is 1 in slave mode, the

34.5 时钟同步模式下的操作

图34.31显示了时钟同步串行数据通信的数据格式。

在时钟同步模式下，数据的发送或接收与时钟脉冲同步。传输数据中的一个字符由8位数据组成。在时钟同步模式下，不能添加奇偶校验位。

在数据传输中，SCI从同步时钟的一个下降沿输出数据到下一个下降沿。在数据接收中，SCI与同步时钟的上升沿同步接收数据。8位数据输出后，传输线保持最后一位作为输出状态。当SPMR.CKPH位在从模式下为1时，

transmission line holds the first bit output state.

Within the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by using a shared clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

However, it is not possible to perform continuous transfer in the fastest bit rate setting (BRR[7:0] = 00h and SMR.CKS[1:0] = 00b). Therefore, when the FIFO is selected, this setting (BRR[7:0] = 00h and SMR.CKS[1:0] = 00b) is not available.

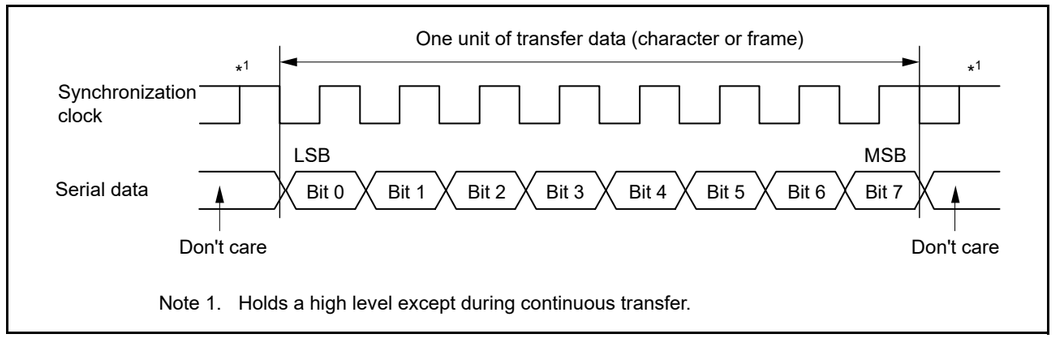

Figure 34.31 Data format in clock synchronous serial communications with LSB-first order

34.5.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected based on the SCR.CKE[1:0] setting.

When the SCI operates on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character. When no transfer is performed, the clock is held high. However, when only data reception is performed while the CTS function is disabled, the synchronization clock output starts when the SCR.RE bit set to 1. The synchronization clock stops when it goes high*1 and an overrun error occurs or the SCR.RE bit is set to 0.

When only data reception is performed and the CTS function is enabled, the clock output does not start when the SCR.RE bit set to 1 and the CTSn_RTSn pin input is high. The synchronization clock output starts when the SCR.RE bit is set to 1 and the CTSn_RTSn pin input is low. Following that, when the CTSn_RTSn pin input is high on completion of the frame reception, the synchronization clock output stops when it goes high. If the CTSn_RTSn pin input continues to be low, the synchronization clock stops when it goes high*1 and an overrun error occurs or the SCR.RE bit is set to 0.

Note 1. The signal is held high while (SPMR.CKPH = 0 && SPMR.CKPOL = 0) or (SPMR.CKPH = 1 && SPMR.CKPOL = 1). It is held low while (SPMR.CKPH = 0 && SPMR.CKPOL = 1) or (SPMR.CKPH = 1 && SPMR.CKPOL = 0).

34.5.2 CTS and RTS Functions

In the CTS function, the CTSn_RTSn pin input controls the start of data reception or transmission when the clock source is the internal clock. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, setting the CTSn_RTSn pin low causes data reception or transmission to start.

Setting the CTSn_RTSn pin high while the data transmission or reception is in progress does not affect transmission or reception of the current frame.

In the RTS function, the CTSn_RTSn pin output is used to request the start of data reception or transmission when the clock source is an external synchronizing clock. The CTSn_RTSn output goes low when serial communication becomes possible. Conditions for output of the CTSn_RTSn low and high are shown as follows:

传输线保持第一位输出状态。

在SCI中，发送器和接收器是独立的单元，通过使用共享时钟实现全双工通信。发送端和接收端都具有双缓冲结构，可以在发送时写入下一个发送数据，或者在接收时读取前一个接收数据，实现数据的连续传输。

但是，在最快的比特率设置（BRR[7:0]=00h和SMR.CKS[1:0]=00b)。Therefore whentheFIFOisselected thissetting(BRR[7:0]=00handSMR.CKS[1:0]=00b)isnot available.

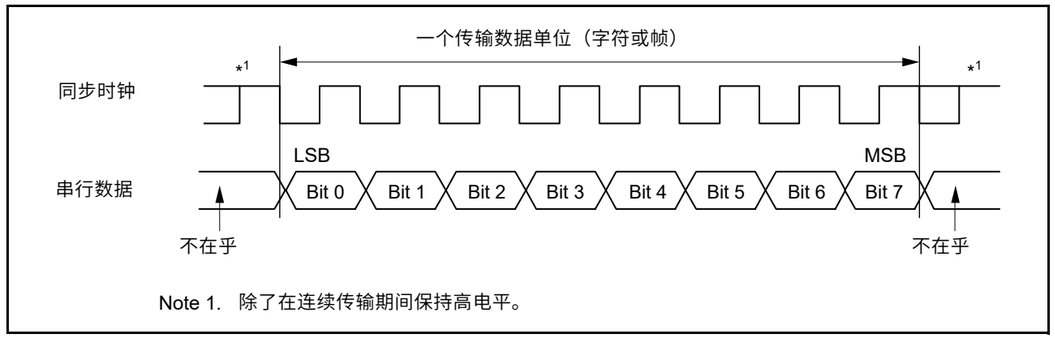

Figure 34.31 具有LSB优先顺序的时钟同步串行通信中的数据格式

34.5.1 Clock

由片内波特率发生器产生的内部时钟或外部同步时钟输入SCKn引脚可根据SCR.CKE[1:0]设置进行选择。

当SCI在内部时钟上运行时，同步时钟从SCKn引脚输出。在一个字符的传输中输出八个同步时钟脉冲。当不执行传输时，时钟保持高电平。但是，当CTS功能禁用时仅执行数据接收时，同步时钟输出在SCR.RE位设置为1时开始。同步时钟在变为高电平时停止*1并且发生溢出错误或SCR.RE位设置为0。

仅进行数据接收且使能CTS功能时，时钟输出不会在SCR.RE位设置为1，CTSn_RTSn引脚输入为高电平。当SCR.RE位设置为1且CTSn_RTSn引脚输入为低电平时，同步时钟输出开始。之后，当CTSn_RTSn引脚输入在帧接收完成时为高电平时，同步时钟输出在其变为高电平时停止。如果CTSn_RTSn引脚输入持续为低电平，则同步时钟在变为高电平时停止*1并发生溢出错误或SCR.RE位设置为0。

注1.当(SPMR.CKPH=0&&SPMR.CKPOL=0)或(SPMR.CKPH=1&&SPMR.CKPOL=1)时，信号保持高电平。它在(SPMR.CKPH=0&&SPMR.CKPOL=1)或(SPMR.CKPH=1&&SPMR.CKPOL=0)时保持低电平。

34.5.2 CTS和RTS函数

在CTS功能中，当时钟源为内部时钟时，CTSn_RTSn引脚输入控制数据接收或发送的开始。将SPMR.CTSE位设置为1可启用CTS功能。当CTS功能使能时，将CTSn_RTSn引脚设置为低电平会导致数据接收或发送开始。

在数据发送或接收过程中将CTSn_RTSn引脚设置为高电平不会影响当前帧的发送或接收。

在RTS功能中，当时钟源为外部同步时钟时，CTSn_RTSn引脚输出用于请求开始数据接收或发送。当串行通信成为可能时，CTSn_RTSn输出变为低电平。CTSn_RTSn低电平和高电平的输出条件如下所示：

[Conditions for low output]

Satisfaction of all the following conditions:

(a) Non-FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- When serial communication is enabled
- There is no received data available to be read when the SCR.RE bit is 1
- Data is available for transmission in the TSR register when SCR.TE bit is 1
- The SSR.ORER flag is 0.

(b) FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- When serial communication is enabled
- The amount of receive data written in FRDRHL is less than the specified CTSn_RTSn output triggering number when SCR.RE = 1
- Data that has not been transmitted is available in FTDRHL when SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR_FIFO.ORER flag is 0.

[Condition for high output]

(a) Non-FIFO selected

- The conditions for low output are not satisfied
- When reception is terminated with SCR.RE = 0 without reading the RDR register after reception is complete, RTS remains high. At this time, read the SCR register for dummy values after writing 0 to SCR.RE.

(b) FIFO selected

- The conditions for low output are not satisfied.

34.5.3 SCI Initialization in Clock Synchronous Mode

Before transmitting and receiving data, start by writing the initial value 00h to the SCR register, then continue through the SCI initialization procedure given in the sections describing non-FIFO and FIFO selection in 34.5.2 CTS and RTS Functions. Anytime the operating mode or transfer format is to be changed, the SCR register must be initialized before the change can be made.

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, RDRF, RDF, PER, and DR flags in SSR/SSR_FIFO nor the RDR and RDRHL register. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: Switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 when the SCR.TIE bit is 1 generates an SCIn_TXI interrupt request.

[低输出的条件]

满足以下所有条件：

(a) 满足以下所有条件时选择非FIFO

- SCR.RE位或SCR.TE位的值为1
- 启用串行通信时
- 当SCR.RE位为1时，没有可读取的接收数据
- 当SCR.TE位为1时，TSR寄存器中的数据可用于传输
- SSR.ORER标志为0。

(b) 满足以下所有条件时选择FIFO

- SCR.RE位或SCR.TE位的值为1
- 启用串行通信时
- 当SCR.RE=1时，FRDRHL中写入的接收数据量小于指定的CTSn_RTSn输出触发数
- 当SCR.TE位为1且SCR.CKE[1]位为0时，FTDRHL中的数据可用
- 当SCR.TE位为1且SCR.CKE[1]位为1时，TSR寄存器中的数据可用于传输
- SSR_FIFO.ORER标志为0。

【高输出条件】

(a) Non-FIFO selected

- 不满足低输出条件
- 当接收结束后接收结束且SCR.RE=0且未读取RDR寄存器时，RTS保持高电平。此时，将0写入SCR.RE后，读取SCR寄存器的虚拟值。

(b) FIFO selected

- 不满足低输出的条件。

34.5.3 时钟同步模式下的SCI初始化

在发送和接收数据之前，首先将初始值00h写入SCR寄存器，然后继续执行34.5.2CTS和RTS功能中描述非FIFO和FIFO选择部分中给出的SCI初始化过程。任何时候要更改操作模式或传输格式，必须先初始化SCR寄存器，然后才能进行更改。

Note: 将SCR.RE位设置为0不会初始化ORER、FER、RDRF、RDF、PER和DR标志SSRSSR_FIFO也不是RDR和RDRHL寄存器。当TE位设置为0时，选择的TEND标志FIFO缓冲区未初始化。

Note: 当SCR.TIE位为1时，将SCR.TE位的值从1切换到0或0到1会产生SCIn_TXI中断请求。

(1) Non-FIFO selected

Figure 34.34, Figure 34.35, and Figure 34.36 show examples of serial transmission in clock synchronous mode.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. The SCIn_TXI interrupt request at the beginning of transmission is generated when the TE bit is set to 1 but only after the TIE bit in the SCR is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data finishes. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.

34.5.4 时钟同步模式下的串行数据传输

(1) Non-FIFO selected

图34.34、图34.35和图34.36显示了时钟同步模式下的串行传输示例。

在串行数据传输中，SCI操作如下：

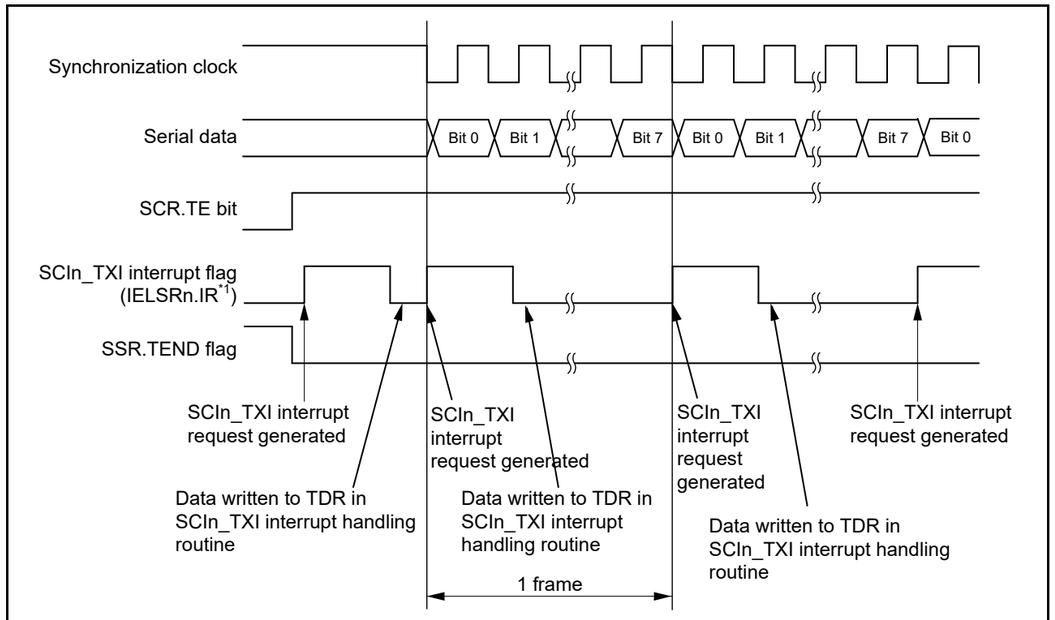
1. 当数据在SCIn_TXI中断处理程序中写入TDR时，SCI将数据从TDR寄存器传输到TSR寄存器。发送开始时的SCIn_TXI中断请求在TE位设置为1时产生，但仅在SCR中的TIE位也设置为1或当这两个位通过一条指令同时设置为1时产生。
2. 将数据从TDR传输到TSR后，SCI开始传输。当SCR.TIE位设置为1时，一个SCIn_TXI中断请求产生。在当前发送数据发送完成之前，通过在SCIn_TXI中断处理例程中将下一个发送数据写入TDR来启用连续发送。什么时候
SCIn_TEI中断请求正在使用中，在SCIn_TXI请求的处理程序将要发送的最后一个数据写入TDR寄存器后，将SCR.TIE位设置为0并将SCR.TEIE位设置为1。

3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks for update to the TDR register on output of the last bit.
5. When the TDR register is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame starts.
6. If TDR is not updated, the SSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Figure 34.34, Figure 34.35, and Figure 34.36 show examples of serial data transmission.

Transmission does not start while a receive error flag (ORER, FER, or PER in SSR) is set to 1. Always set the receive error flags to 0 before starting transmission.

Note: Setting the SCR.RE bit to 0 does not clear the receive error flags.



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.34 Example of serial data transmission in clock synchronous mode when the CTS function is not used at the beginning of transmission

3. 指定时钟输出模式时，与输出时钟同步，指定使用外部时钟时，与输入时钟同步，从TXDn引脚发送8位数据。当SPMR.CTSE位为1时，时钟信号的输出被暂停，直到输入CTS信号为低电平。
4. SCI在最后一位输出时检查对TDR寄存器的更新。
5. 当更新TDR寄存器时，下一个发送数据从TDR传输到TSR，并开始下一帧的串行传输。
6. 如果TDR未更新，则SSR.TEND标志设置为1。TXDn引脚保持最后一位的输出状态。如果SCR.TEIE位为1，产生SCIn_TEI中断请求且SCKn引脚保持高电平。

图34.34、图34.35和图34.36显示了串行数据传输的示例。

当接收错误标志（SSR中的ORER、FER或PER）设置为1时，发送不会开始。在开始发送之前，请务必将接收错误标志设置为0。

Note: 将SCR.RE位设置为0不会清除接收错误标志。

[1] SCI initialization:
Set data transmission.

[2] Write transmit data to TDR by an SCIn_TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated.
Transmit data is written to TDR once from the handling routine for SCIn_TXI requests.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR on accepting a transmit data empty interrupt (SCIn_TXI) request.
Transmit data can also be written to TDR by activating the DMAC or DTC by the SCIn_TXI interrupt request.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to TDR.

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCK pin for the last bit sets the SSR.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

Figure 34.37 Example flow of serial transmission in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 34.38 shows an example of serial transmission in clock synchronous mode with FIFO selected.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the FTDRL*1 register to the TSR register when data is written to FTDRL*1 in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 but only after the SCR.TIE bit is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from FTDRL to TSR, the SCI starts transmission. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, the SSR_FIFO.TDFE is set to 1. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to FTDRL in the SCIn_TXI interrupt handling routine before transmission of the current transmit data has finished. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL from the handling routine for SCIn_TXI requests.

(2) FIFO selected

图34.38显示了在时钟同步模式下选择FIFO的串行传输示例。

在串行数据传输中，SCI操作如下：

1. 当数据写入FTDRL*1时，SCI将数据从FTDRL*1寄存器传输到TSR寄存器
   SCIn_TXI中断处理程序。可写入FTDRL的数据量为16减去FDR.T[4:0]字节。发送开始时的SCIn_TXI中断请求在SCR.TE位被设置为1时产生，但仅在SCR.TIE位也被设置为1或当这两个位被一条指令同时设置为1时产生。
2. 将数据从FTDRL传输到TSR后，SCI开始传输。当写入FTDRL的发送数据量等于或小于指定的发送触发数时，SSR_FIFO.TDFE设置为1。当SCR.TIE位设置为1时，产生SCIn_TXI中断请求。在当前发送数据的发送完成之前，通过在SCIn_TXI中断处理例程中将下一个发送数据写入FTDRL来启用连续发送。当使用SCIn_TEI中断请求时，在将要传输的最后一个数据从处理例程写入FTDRL后，将SCR.TIE位设置为0，并将SCR.TEIE位设置为1。

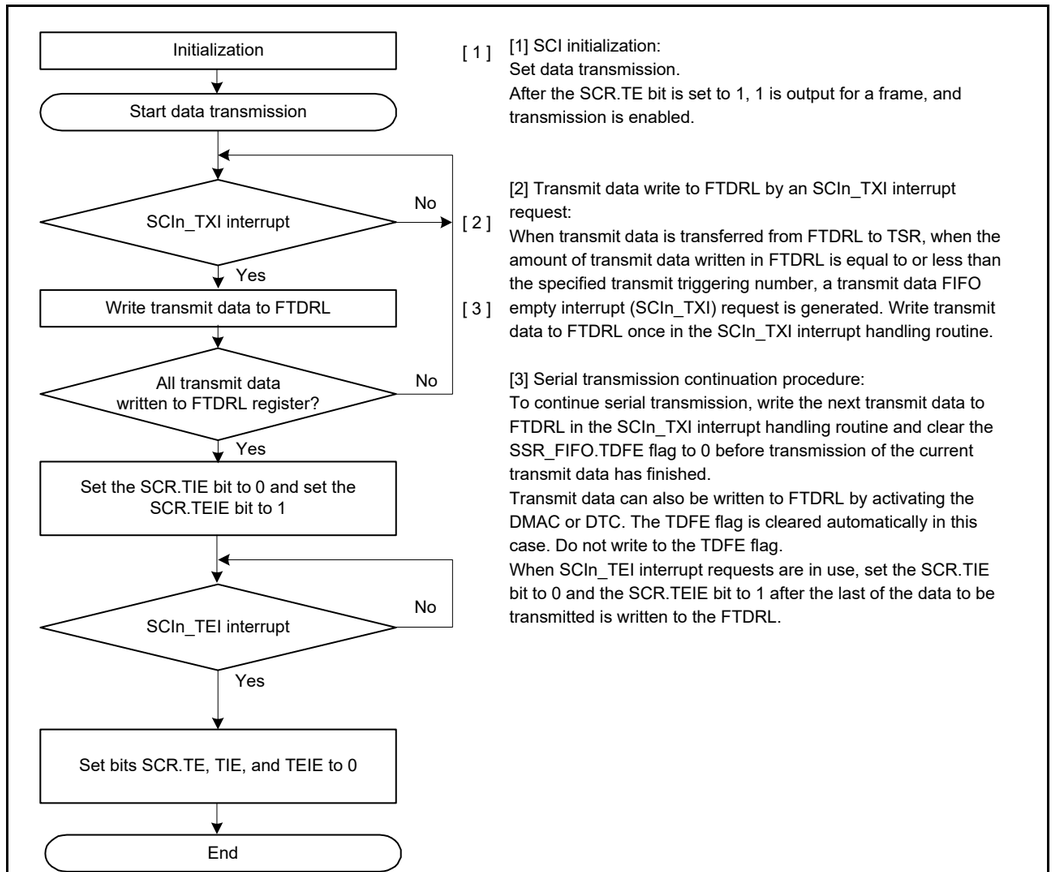
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks whether non-transmitted data remains in FTDRL on output of the stop bit.
5. When FTDRL is updated, the next transmit data is transferred from FTDRL to TSR and serial transmission of the next frame starts.
6. If FTDRL is not updated, the SSR_FIFO.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Note 1. In clock synchronous mode, FTDRH is not used.



Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCK pin for the last bit sets the SSR_FIFO.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

(1) Non-FIFO selected

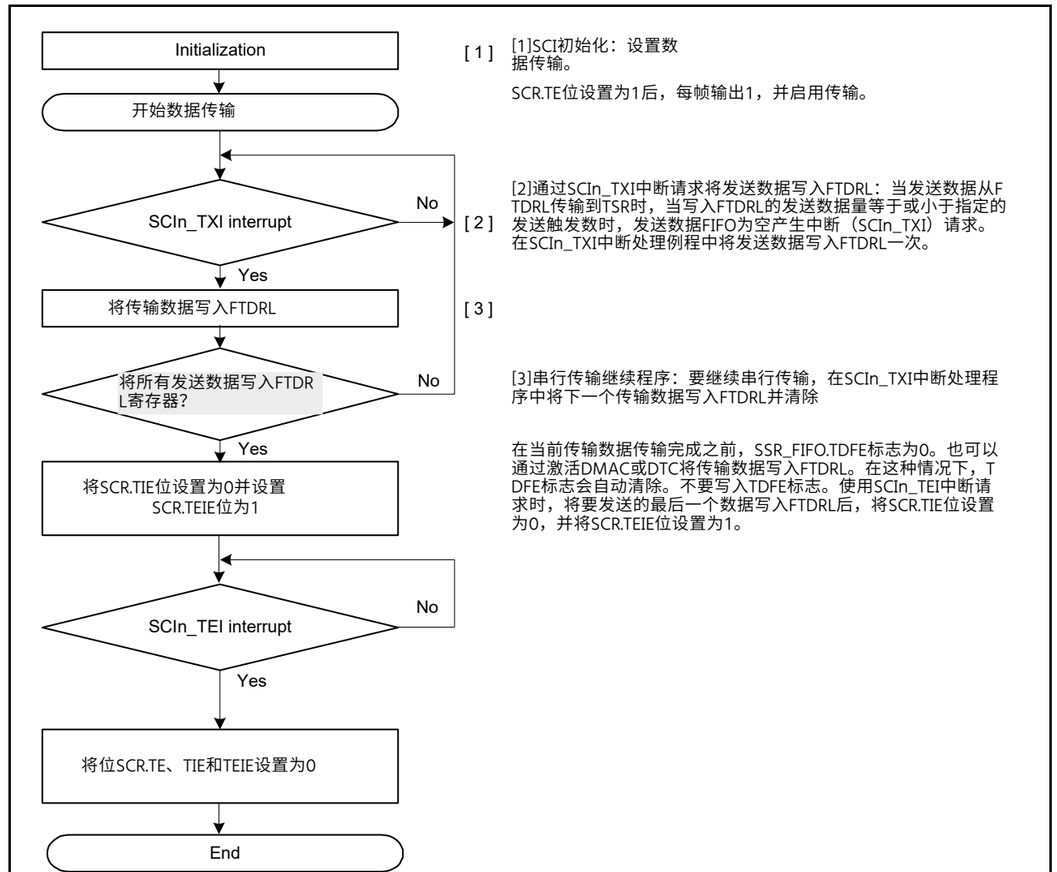
3. 指定时钟输出模式时，与输出时钟同步，指定使用外部时钟时，与输入时钟同步，从TXDn引脚发送8位数据。当SPMR.CTSE位为1时，时钟信号的输出被暂停，直到输入CTS信号为低电平。
4. SCI在停止位输出时检查未传输的数据是否保留在FTDRL中。
5. 当FTDRL被更新时，下一个传输数据从FTDRL传输到TSR并开始下一帧的串行传输。
6. 如果FTDRL未更新，则SSR_FIFO.TEND标志设置为1。TXDn引脚保持最后一位的输出状态。如果SCR.TEIE位为1，则产生SCIn_TEI中断请求并且SCKn引脚保持高电平。

注1.在时钟同步模式下，不使用FTDRH。



Note: 当使用外部时钟时（SCR.CKE[1:0]位的值为10b或11b），SCK引脚上最后一位的上升沿将SSR_FIFO.TEND标志设置为1。设置SCR.TE位在这之后立即变为0可能会导致接收端接收数据保持时间不足。

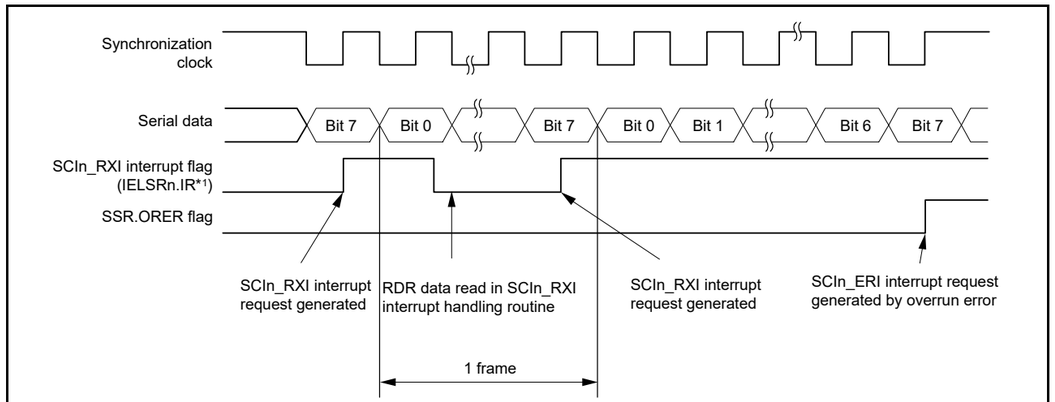
34.5.5 时钟同步模式下的串行数据接收

(1) Non-FIFO selected

图34.39和图34.40显示了时钟同步模式下串行接收的SCI操作示例。

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the SSR.ORER bit is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.
4. When reception completes successfully, receive data is transferred to the RDR register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the received data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that is transferred to RDR causes the CTSn_RTSn pin to output low.



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Data transfer cannot resume while the receive error flag is 1. Therefore, clear the ORER, FER, and PER bits in the SSR

在串行数据接收中，SCI操作如下：

1. 当SCR.RE位的值变为1时，CTSn_RTSn引脚变为低电平。
2. SCI执行内部初始化并与同步时钟输入或输出同步开始接收数据，并将接收数据存储在RSR寄存器中。
3. 如果发生溢出错误，则SSR.ORER位设置为1。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。接收数据不传送到RDR寄存器。
4. 当接收成功完成时，接收数据被传送到RDR寄存器。如果SCR.RIE位为1，则产生SCIn_RXI中断请求。在接收下一个接收数据完成之前，通过在SCIn_RXI中断处理例程中读取传输到RDR寄存器的接收数据来启用连续接收。读取传输到RDR的接收数据会导致CTSn_RTSn引脚输出低电平。

当接收错误标志为1时，数据传输无法恢复。因此，清除SSR中的ORER、FER和PER位

register to 0 before resuming data reception. Additionally, always read the RDR register during overrun error processing. When a data reception is forced to terminate by a 0 write to the SCR.RE bit during operation, read the RDR register because received data that is not yet read might be left in the RDR register.

在恢复数据接收之前注册为0。此外，在溢出错误处理期间始终读取RDR寄存器。如果在操作期间通过向SCR.RE位写入0来强制终止数据接收，请读取RDR寄存器，因为尚未读取的已接收数据可能留在RDR寄存器中。

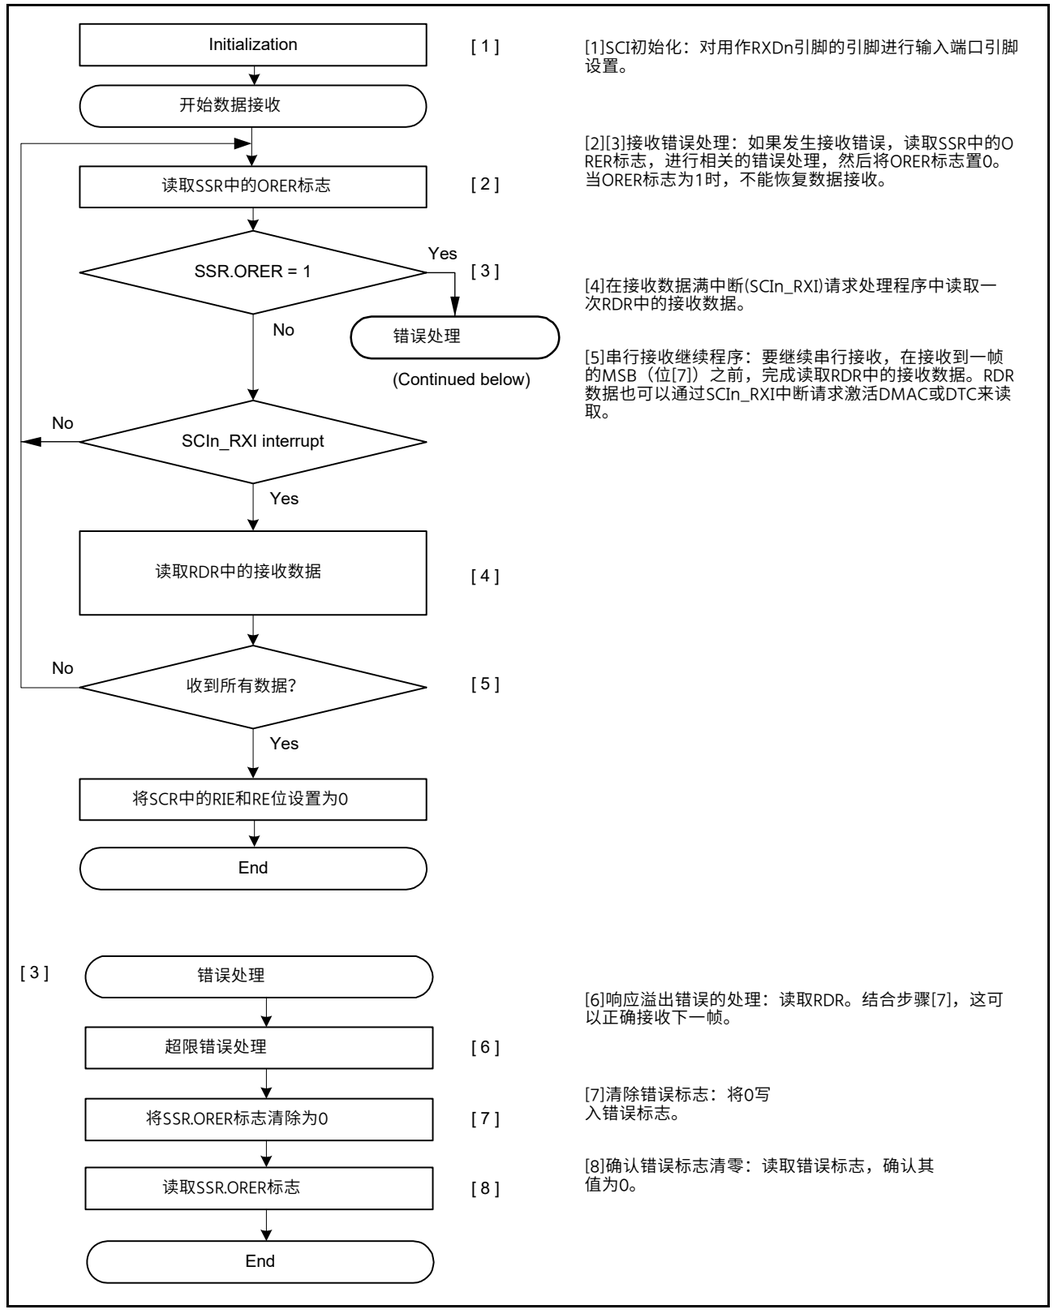

Figure 34.41 选择非FIFO的时钟同步模式下的串行接收示例流程

(2) FIFO selected

Figure 34.42 shows an example of serial reception in clock synchronous mode with FIFO selected.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the SSR_FIFO.ORER bit is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Received data is not transferred to the FRDRL*1 register.
4. When data reception completes successfully, the receive data is transferred to the FRDRL*1 register. The RDF bit is set to 1 when the amount of the receive data stored in FRDRL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous data reception is enabled by reading the receive data transferred to FRDRL*2 in the SCIn_RXI interrupt handling routine before an overrun error occurs. If the amount of received data that is transferred to FRDRL is less than the RTS trigger number, the CTSn_RTSn pin goes low.

Note 1. In clock synchronous mode, FRDRH is not used.
Note 2. Read data in order from FRDRH to FRDRL when RDF and ORER are read with receive data.

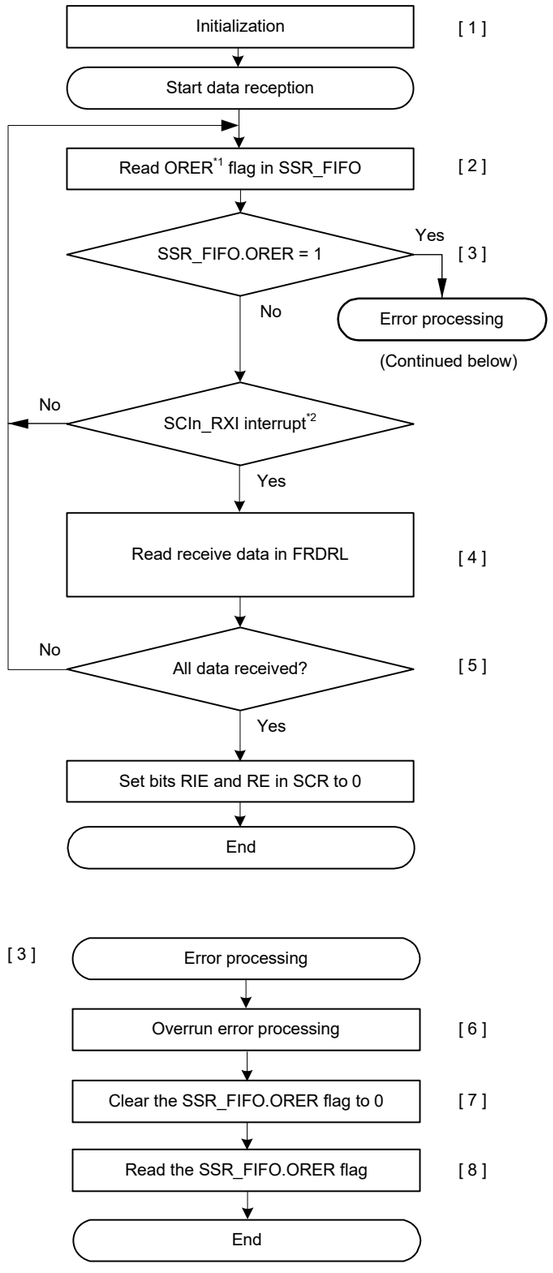
(2) FIFO selected

图34.42显示了选择FIFO的时钟同步模式下的串行接收示例。

在串行数据接收中，SCI操作如下：

1. 当SCR.RE位的值变为1时，CTSn_RTSn引脚变为低电平。
2. SCI执行内部初始化并与同步时钟输入或输出同步开始接收数据，并将接收数据存储在RSR寄存器中。
3. 如果发生溢出错误，则SSR_FIFO.ORER位设置为1。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。接收到的数据不传送到FRDRL*1寄存器。
4. 当数据接收成功完成时，接收数据被传送到FRDRL*1寄存器。当存储在FRDRL中的接收数据量等于或大于指定的接收触发数时，RDF位设置为1。如果SCR.RIE位为1，则产生SCIn_RXI中断请求。在发生溢出错误之前，通过在SCIn_RXI中断处理例程中读取传输到FRDRL*2的接收数据来启用连续数据接收。如果传输到FRDRL的接收数据量小于RTS触发数，则CTSn_RTSn引脚变为低电平。

注1.在时钟同步模式下，不使用FRDRH。
注2.RDF和ORER与接收数据一起读取时，按FRDRH到FRDRL的顺序读取数据。



[1] SCI initialization:
Make input port-pin settings for pins to be used as RXDn pins.

[2] [3] Receive error processing:
If a receive error occurs, read the ORER flag in SSR_FIFO, perform the relevant error processing, then set the SSR_FIFO.ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] The receive data stored in FRDRL register is read until the number of stored data is less than the FCR.RTRG value. Software can check readable data in FDR.R[4:0].

[5] Serial reception continuation procedure:
To continue serial reception, before overrun error occurs, finish reading the receive data in FRDRL and clear the SSR_FIFO.RDF flag to 0. The FRDRL data can also be read by activating the DMAC or DTC by an SCIn_RXI interrupt request. The RDF flag is cleared automatically in this case. Do not write to the RDF flag.

[6] Processing in response to an overrun error:
Read the FRDRL. In combination with step [7], this enables correct reception of the next frame.

[7] Clearing the error flag:
Write 0 to the error flag.

[8] Confirming that the error flag is cleared:
Read the error flag to confirm that its value is 0.

Note 1. It can also be read from FRDRH.ORER. However, to clear the ORER flag, write 0 to the associated bit in the SSR_FIFO register.
Note 2. It should be all receive data and is an integer times the FIFO triggering number.

[6]响应溢出错误的处理：读取FRDRL。结合步骤[7]，这可以正确接收下一帧。

[7]清除错误标志：将0写入错误标志。

[8]确认错误标志清零：读取错误标志，确认其值为0。

34.5.6 Simultaneous Serial Data Transmission and Reception in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 34.43 shows an example flow of simultaneous serial transmission and reception operations in clock synchronous mode. After initializing the SCI, use the following procedure for simultaneous serial data transmission and reception operations.

To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data transmission by verifying that the SSR.TEND flag is set to 1.
2. Initialize the SCR register, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data reception.
2. Set the RIE and RE bits to 0, and then check that the receive error flag ORER in the SSR register is 0.
3. Set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

(1) Non-FIFO selected

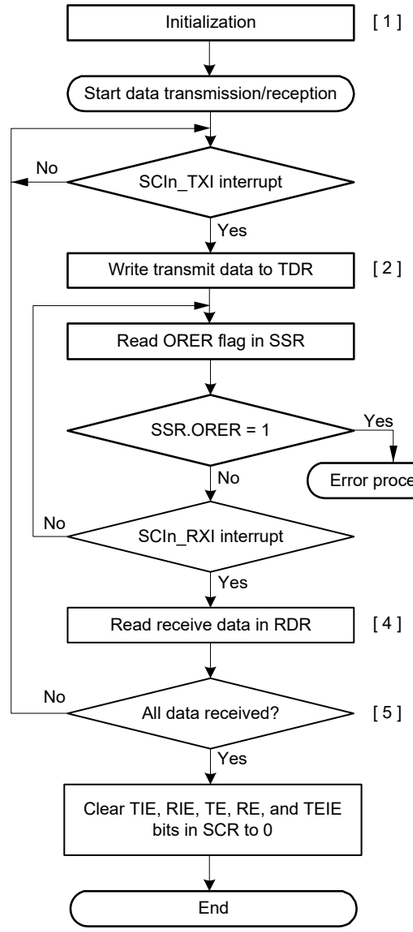
图34.43显示了时钟同步模式下同时串行发送和接收操作的示例流程。初始化SCI后，使用以下程序同时进行串行数据发送和接收操作。

从发送模式切换到同时发送和接收模式：

1. 通过验证SSR.TEND标志是否设置为1来检查SCI是否完成了数据传输。
2. 初始化SCR寄存器，然后通过一条指令同时将SCR寄存器中的TIE、RIE、TE和RE位设置为1。

从接收模式切换到同时发送和接收模式：

1. 检查SCI是否完成数据接收。
2. 将RIE和RE位设置为0，然后检查SSR寄存器中的接收错误标志ORER是否为0。
3. 通过一条指令同时将SCR寄存器中的TIE、RIE、TE和RE位设置为1。



[1] SCI initialization:
The TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[2] Transmit data write:
Write transmit data to TDR once in the SCIn_TXI interrupt request handling routine.

[3] Receive error processing:
If a receive error occurs, read the ORER flag in SSR, perform the relevant error processing, then set the ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] Reading receive data:
Read the receive data in RDR once in the SCIn_RXI interrupt request handling routine.

[5] Serial transmission or reception continuation procedure:
To continue serial transmission and reception, before the MSB (bit [7]) of the current frame is received, finish reading the receive data in RDR by the SCIn_RXI interrupt. Also, before the MSB (bit [7]) of the current frame is transmitted, write data to TDR by the SCIn_TXI interrupt.
Transmit data can also be written to TDR by activating the DMAC or DTC by a transmit data empty interrupt (SCIn_TXI) request. Similarly, the RDR data can also be read by activating the DMAC or DTC by a receive data full interrupt (SCIn_RXI) request.

Note: When switching from transmit or receive operation to simultaneous transmit and receive operations, first set the TIE, RIE, TE, RE, and TEIE bits in SCR to 0, then set TIE, RIE, TE, and RE bits to 1 simultaneously.

(2) FIFO selected

Figure 34.44 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode with FIFO selected.

After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.

To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the transmission by verifying that the SSR_FIFO.TEND flag is set to 1.
2. Initialize the SCR register, then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the reception.

[2]发送数据写入：在SCIn_TXI中断请求处理程序中将发送数据写入TDR一次。

[3]接收错误处理：如果发生接收错误，读取SSR中的ORER标志，进行相关的错误处理，然后将ORER标志设置为0。当ORER标志为1时，不能恢复数据接收。

[4]读取接收数据：在SCIn_RXI中断请求处理程序中读取一次RDR中的接收数据。

[5]串行发送或接收继续程序：要继续串行发送和接收，在

接收到当前帧的MSB（bit[7]），通过SCIn_RXI中断完成读取RDR中的接收数据。此外，在发送当前帧的MSB（位[7]）之前，通过SCIn_TXI中断将数据写入TDR。发送数据也可以通过发送数据空中断(SCIn_TXI)请求激活DMAC或DTC写入TDR。同样，也可以通过接收数据完全中断(SCIn_RXI)请求激活DMAC或DTC来读取RDR数据。

Note: 从发送或接收操作切换到同时发送和接收操作时，首先设置TIE，SCR中的RIE、TE、RE和TEIE位为0，然后将TIE、RIE、TE和RE位同时设置为1。

Figure 34.43 选择非FIFO的时钟同步模式下同时串行发送和接收的示例流程

(2) FIFO selected

图34.44显示了在时钟同步模式下同时串行发送和接收操作的示例流程，并选择了FIFO。

初始化SCI后，使用以下程序同时进行串行数据发送和接收操作。

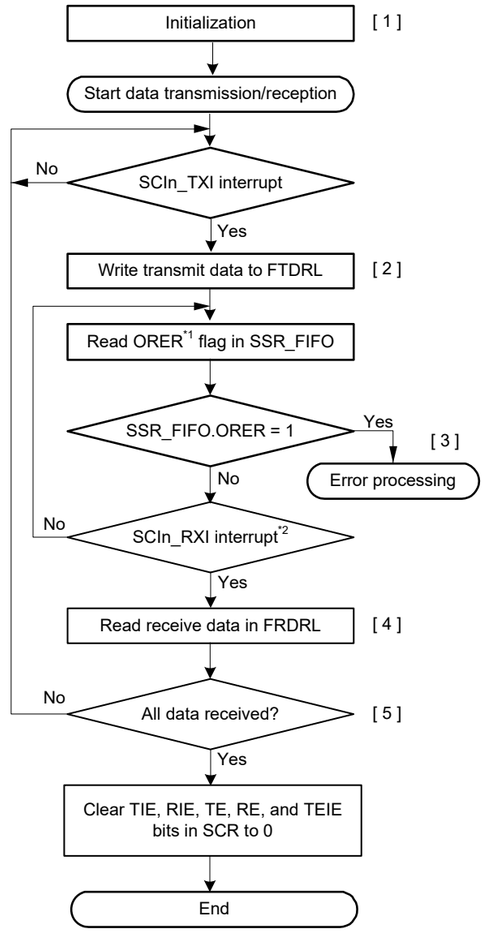
从发送模式切换到同时发送和接收模式：

1. 通过验证SSR_FIFO.TEND标志是否设置为1来检查SCI是否完成了传输。
2. 初始化SCR寄存器，然后通过一条指令同时将SCR寄存器中的TIE、RIE、TE和RE位设置为1。

从接收模式切换到同时发送和接收模式：

1. 检查SCI是否完成接收。

2. Set the RIE and RE bits to 0, then check that the receive error flag ORER in SSR_FIFO is 0.
3. Set the TIE, RIE, TE, and RE bits in SCR to 1 simultaneously by a single instruction.



[1] SCI initialization:
The TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[2] Transmit data write:
Write transmit data to FTDRL in the SCIn_TXI Interrupt request handling routine. The amount of transmit data it is possible to write in is 16 minus the amount of stored transmit FIFO data.

[3] Receive error processing:
If a receive error occurs, read the ORER flag in SSR_FIFO, perform the relevant error processing, then set the ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] Reading receive data:
The receive data stored in FRDRL register is read until the number of stored data is less than the FCR.RTRG value. Software can check readable data in FDR.R[4:0].

[5] Serial transmission or reception continuation procedure:
To continue serial reception, before overrun error occurs, finish reading the receive data in FRDRL and clear the SSR_FIFO.RDF flag to 0. To continue serial transmission, before transmission of the current transmit data has finished, write the next transmit data to FTDRL in the SCIn_TXI interrupt handling routine and clear the SSR_FIFO.TDFE flag to 0.
Transmit data can also be written to FTDRL by activating the DMAC or DTC by a transmit FIFO data empty interrupt (SCIn_TXI) request. Similarly, the FRDRL data can also be read by activating the DMAC or DTC by a receive FIFO data full interrupt (SCIn_RXI) request. The RDF and TDFE flags are cleared automatically in this case. Do not write to the RDF and TDFE flags.

Note 1. ORER can also read from FRDRH.ORER. To clear the ORER flag, write 0 to SSR_FIFO.ORER.
Note 2. The total receive data amount must be an integral multiple of the FIFO triggering number.

34.6 Operation in Smart Card Interface Mode

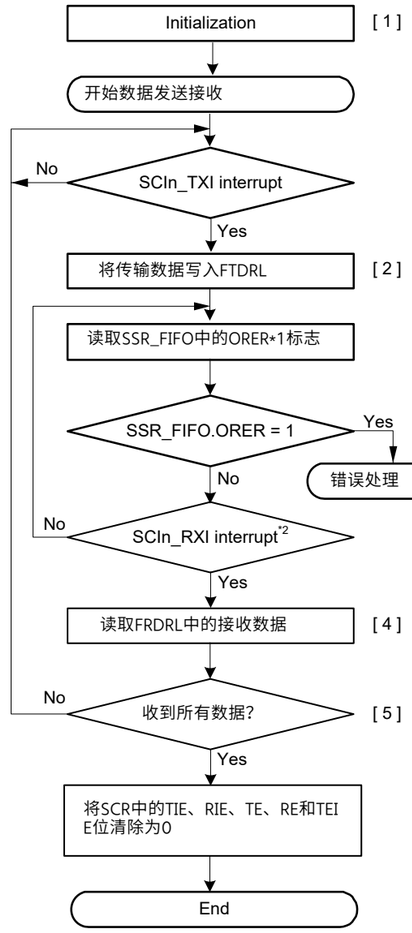
The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

34.6.1 Example Connection

Figure 34.45 shows an example connection between a smart card (IC card) and the MCU. As shown in Figure 34.45, because the MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

2. 将RIE和RE位设置为0，然后检查SSR_FIFO中的接收错误标志ORER是否为0。
3. 通过一条指令同时将SCR中的TIE、RIE、TE和RE位设置为1。



[1]SCI初始化：TXDn管脚可以作为发送数据的输出管脚，RXDn管脚同时可以作为接收数据的输入管脚。

[2]发送数据写入：在SCIn_TXI中断请求处理程序中将发送数据写入FTDRL。可以写入的发送数据量是16减去存储的发送FIFO数据量。

[3]接收错误处理：如果发生接收错误，读取ORER标志

SSR_FIFO，进行相应的错误处理，然后将ORER标志置0。当ORER标志为1时，不能恢复数据接收。

[4]读取接收数据：读取存储在FRRDL寄存器中的接收数据，直到存储的数据个数小于FCR.RTRG值。软件可以检查FDR.R[4:0]中的可读数据。

[5]串行发送或接收继续程序：继续串行接收，在溢出错误发生之前，完成FRRDL中的接收数据读取并将SSR_FIFO.RDF标志清0。继续串行发送，在当前发送数据发送之前完成后，在SCIn_TXI中断处理程序中将下一个发送数据写入FTDRL并清除

SSR_FIFO.TDFE标志为0。
发送数据也可以通过发送FIFO数据空中断(SCIn_TXI)请求激活DMAC或DTC写入FTDRL。同样，也可以通过接收FIFO数据满中断(SCIn_RXI)请求激活DMAC或DTC来读取FRDRL数据。在这种情况下，RDF和TDFE标志会自动清除。不要写入RDF和TDFE标志。

Note 1. ORER也可以从FRDRH.ORER中读取。要清除ORER标志，请将0写入SSR_FIFO.ORER。
Note 2. 总接收数据量必须是FIFO触发数的整数倍。

34.6 智能卡接口模式下的操作

SCI支持符合ISOIEC7816-3（识别卡标准）的智能卡（IC卡）接口，作为SCI的扩展功能。

可以使用适当的寄存器选择智能卡接口模式。

34.6.1 示例连接

图34.45显示了智能卡（IC卡）和MCU之间的示例连接。如图34.45所示，由于MCU使用单条传输线与IC卡通信，因此将TXDn和RXDn引脚互连，并使用电阻将数据传输线上拉到VCC。

Setting the SCR_SMCI.TE and SCR_SMCI.RE bits to 1 with an IC card disconnected enables closed-loop transmission or reception, allowing self-diagnosis. To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.

An output port of the MCU can be used to output a reset signal.

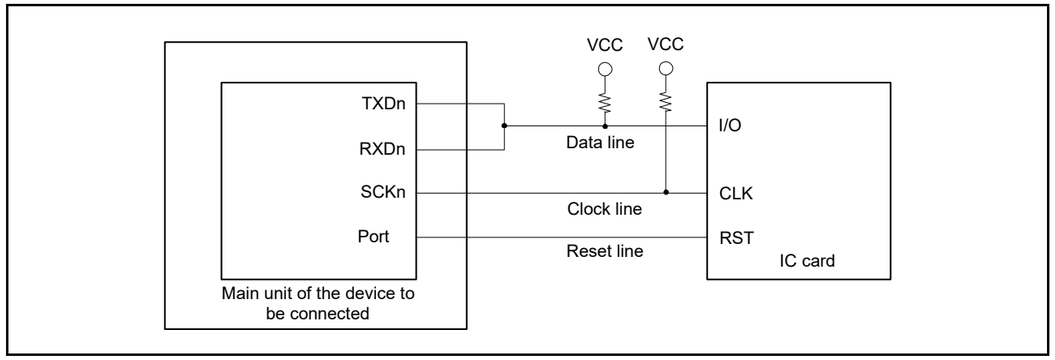

Figure 34.45 Example connection with a smart card (IC card)

34.6.2 Data Format (Except in Block Transfer Mode)

Figure 34.46 shows the data transfer formats in smart card interface mode:

- One frame consists of 8-bit data and a parity bit in asynchronous mode
- During transmission, at least 2 ETUs (elementary time unit — the time required for transferring 1 bit) is set as a guard time from the end of the parity bit until the start of the next frame
- If a parity error is detected during reception, a low error signal is output for 1 ETU after 10.5 ETUs elapse from the start bit
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 ETUs.

在断开IC卡的情况下将SCR_SMCI.TE和SCR_SMCI.RE位设置为1可启用闭环发送或接收，从而实现自诊断。要将SCI产生的时钟脉冲提供给IC卡，请将SCKn引脚输出输入到IC卡的CLK引脚。

MCU的输出端口可用于输出复位信号。

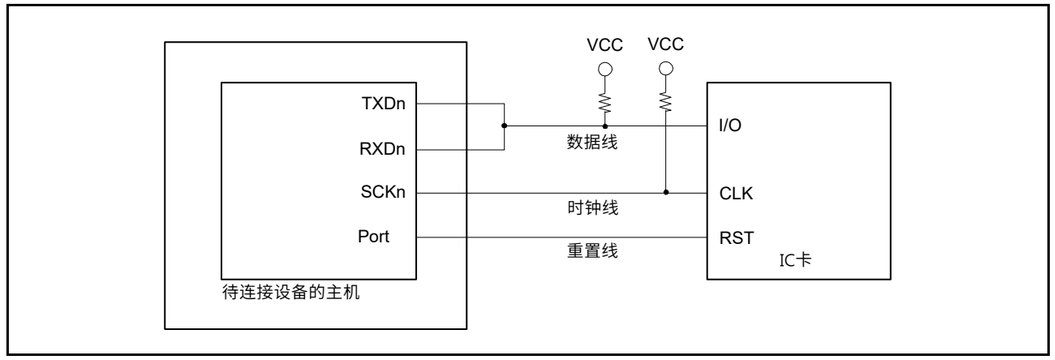

Figure 34.45 与智能卡（IC卡）的连接示例

34.6.2 数据格式（块传输模式除外）

图34.46显示了智能卡接口模式下的数据传输格式：

- 一帧由异步模式下的8位数据和一个奇偶校验位组成
- 在传输过程中，至少有2个ETU（基本时间单位——传输1位所需的时间）设置为从奇偶校验位结束到下一帧开始的保护时间
- 如果在接收期间检测到奇偶校验错误，则在从起始位经过10.5ETU后输出1ETU的低错误信号
- 如果在传输过程中对错误信号进行采样，则在至少2个ETU后会自动重新传输相同的数据。

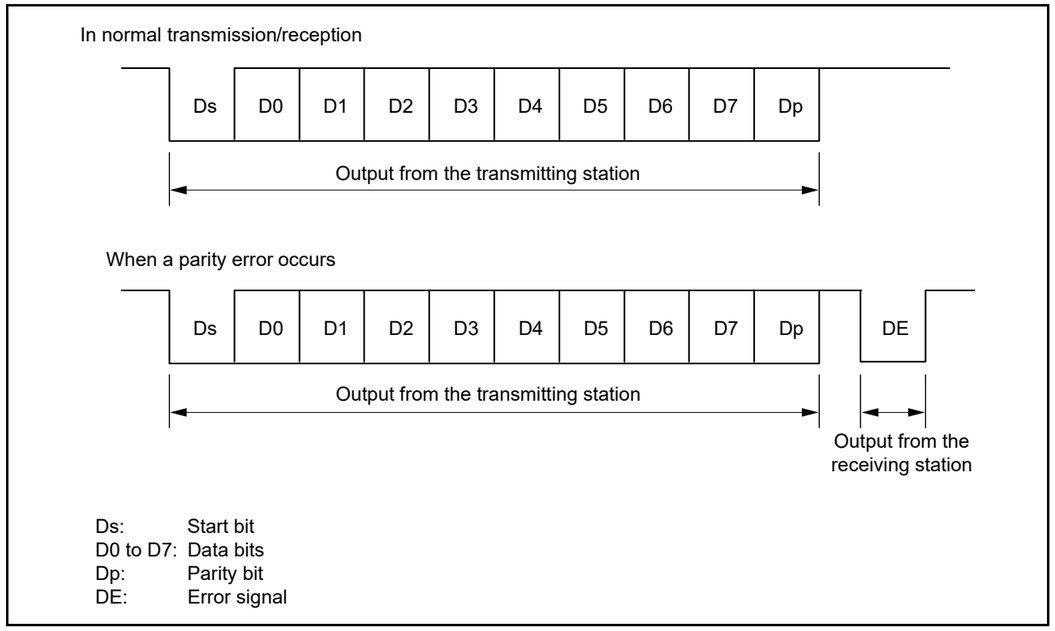

Figure 34.46 Data formats in smart card interface mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedures in this section.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 indicate the Z and A states, respectively, and data is transferred with LSB-first for the start character, as shown in Figure 34.47. Therefore, data in the start character in the figure is 3Bh.

When using the direct convention type, write 0 to both the SCMR.SDIR and SCMR.SINV bits. Write 0 to the SMR_SMCI.PM bit to use even parity, which is required by the smart card standard.

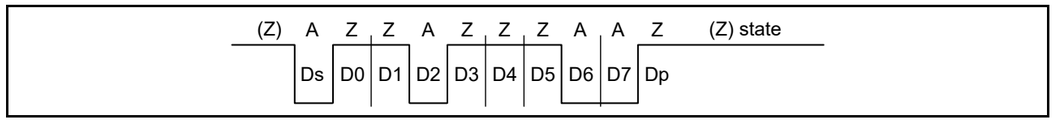

Figure 34.47 Direct convention with SDIR in SCMR = 0, SINV in SCMR = 0, and PM in SMR_SMCI = 0

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 indicate the A and Z states, respectively, and data is transferred with MSB-first for the start character, as shown in Figure 34.48. Therefore, data in the start character in the figure is 3Fh.

When using the inverse convention type, write 1 to both the SCMR.SDIR and SCMR.SINV bits. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to the Z state. Because the SINV bit of the MCU only inverts data bits D7 to D0, write 1 to the PM bit in SMR_SMCI to invert the parity bit for both transmission and reception.

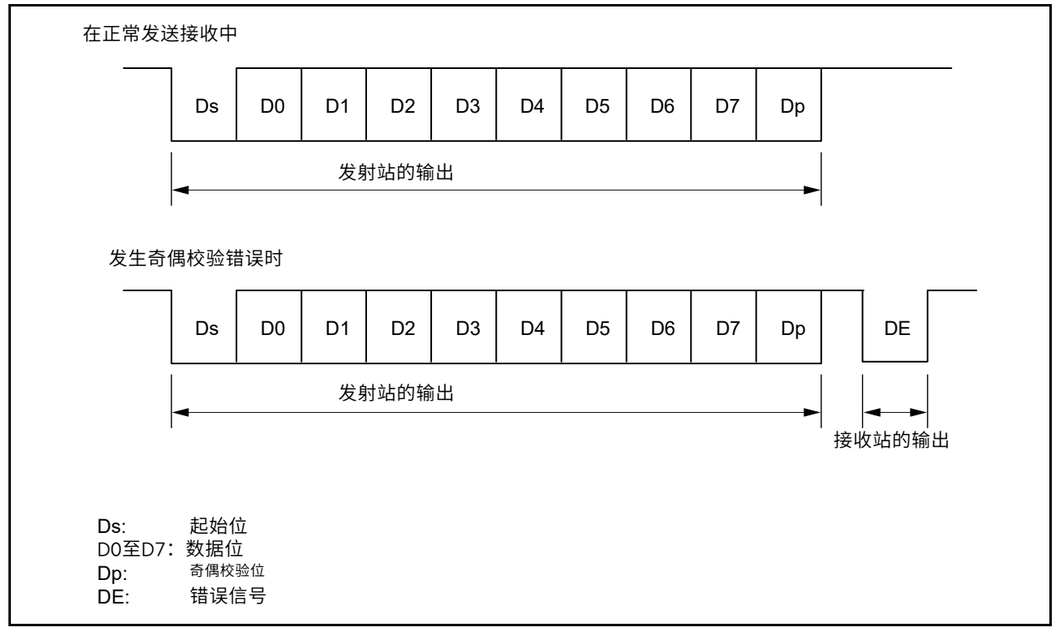

Figure 34.46 智能卡接口模式下的数据格式

与直接约定型和逆约定型IC卡进行通信时，请按照本节的步骤进行。

(1) 直接约定型

对于直接约定类型，逻辑电平1和0分别表示Z和A状态，数据通过LSB-first为起始字符，如图34.47所示。因此，图中起始字符中的数据为3Bh。

使用直接约定类型时，将0写入SCMR.SDIR和SCMR.SINV位。将0写入SMR_SMCI.PM位使用智能卡标准所要求的偶校验。

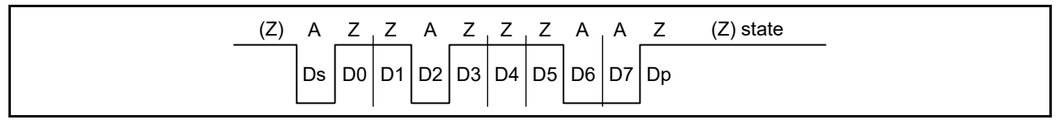

Figure 34.47 与SCMR=0中的SDIR、SCMR=0中的SINV和SMR_SMCI=0中的PM的直接约定

(2) 逆约定型

对于逆约定类型，逻辑电平1和0分别表示A和Z状态，数据通过MSB-first为起始字符，如图34.48所示。因此，图中起始字符中的数据为3Fh。

使用逆约定类型时，将1写入SCMR.SDIR和SCMR.SINV位。奇偶校验位为逻辑电平0，产生偶校验，这是智能卡标准规定的，对应于Z状态。由于MCU的SINV位仅将数据位D7反转为D0，因此向SMR_SMCI中的PM位写入1以反转发送和接收的奇偶校验位。

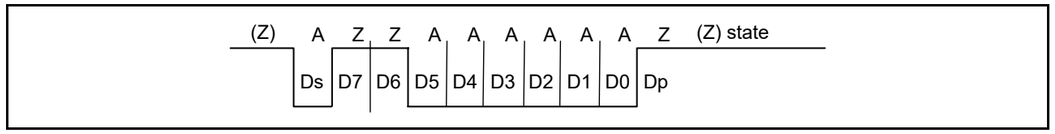

Figure 34.48 Inverse convention with SDIR in SCMR = 1, SINV in SCMR = 1, and PM in SMR_SMCI = 1

34.6.3 Block Transfer Mode

Block transfer mode differs from non-block transfer mode of smart card interface mode as follows:

- Even if a parity error is detected during reception, no error signal is output. Because the PER bit in SSR_SMCI is set by error detection, clear the PER bit before receiving the parity bit of the next frame.
- During transmission, at least 1 ETU is set as a guard time from the end of the parity bit until the start of the next frame
- Because the same data is not retransmitted, the TEND flag in SSR_SMCI is set to 11.5 ETUs after transmission starts
- In block transfer mode, the ERS flag in SSR_SMCI indicates the error signal status as in non-block transfer mode of smart card interface mode, but the flag is read as 0 because no error signal is transferred.

34.6.4 Receive Data Sampling Timing and Reception Margin

Only the clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate set up in the SCMR.BCP2 and the SMR_SMCI.BCP[1:0] bits.

For data reception, the falling edge of the start bit is sampled with the base clock to perform synchronization.

Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 34.49. The reception margin is determined by the following formula:

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)\,F - \frac{\left| D - 0.5 \right|}{N}(1 + F) \right| \times 100\ [\%]$$

M: Reception margin (%)

N: Ratio of bit rate to clock (N = 32, 64, 372, 256)

D: Duty cycle of clock (D = 0 to 1.0)

L: Frame length (L = 10)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the specified formula, the reception margin is determined using the following formula:

$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\%$

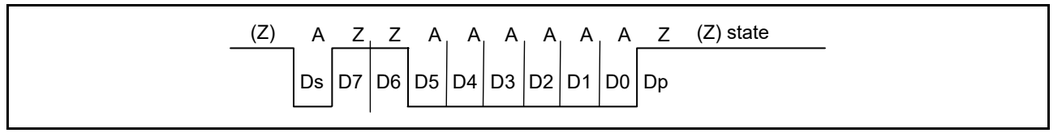

Figure 34.48 SCMR=1中的SDIR、SCMR=1中的SINV和SMR_SMCI=1中的PM的逆约定

34.6.3 块传输模式

块传输模式与智能卡接口模式的非块传输模式的区别如下：

- 即使在接收过程中检测到奇偶校验错误，也不会输出错误信号。因为SSR_SMCI中的PER位是通过错误检测设置的，所以在接收下一帧的奇偶校验位之前清除PER位。
- 在传输过程中，从奇偶校验位结束到下一帧开始至少设置1个ETU作为保护时间
- 因为没有重传相同的数据，所以在传输开始后SSR_SMCI中的TEND标志设置为11.5ETU
- 在块传输模式下，SSR_SMCI中的ERS 标志指示错误信号状态，与智能卡接口模式的非块传输模式一样，但该标志被读取为0，因为没有传输错误信号。

34.6.4 接收数据采样时序和接收裕量

只有片内波特率发生器产生的时钟可以用作智能卡接口模式下的传输时钟。

在这种模式下，SCI可以在频率为SCMR.BCP2和SMR_SMCI.BCP[1:0]位。

对于数据接收，起始位的下降沿与基本时钟一起采样以执行同步。

接收数据在基本时钟的第16、32、186、128、46、64、93和256个上升沿进行采样，以便在每个位的中间锁存，如图34.49所示。接收余量由以下公式确定：

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)\,F - \frac{\left| D - 0.5 \right|}{N}(1 + F) \right| \times 100\ [\%]$$

M：接收余量（%）

N：比特率与时钟的比率（N=32、64、372、256）

D：时钟的占空比（D=0到1.0）

L：帧长（L=10）

F：时钟频率偏差的绝对值

假设指定公式中的F=0、D=0.5和N=372的值，则使用以下公式确定接收余量：

$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\%$

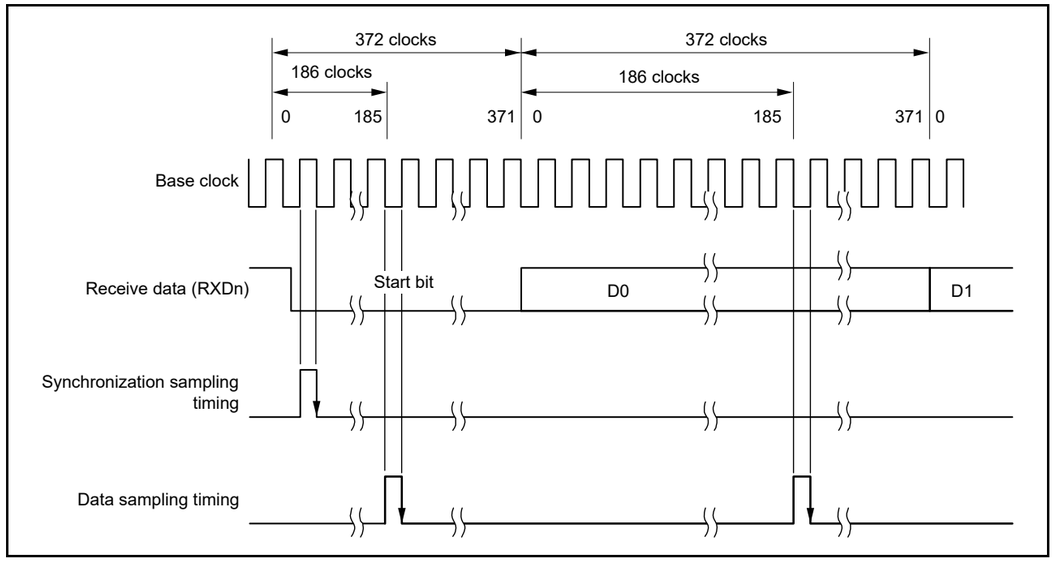

Figure 34.49 Receive data sampling timing in smart card interface mode when clock frequency is 372 times the bit rate

34.6.5 Initialization of the SCI

Before transmitting and receiving data, write the initial value 00h in the SCR_SMCI register and initialize the SCI following the example flow shown in Figure 34.50.

Always set the initial value in the TIE, RIE, TE, RE, TEIE bits in the SCR_SMCI register before switching from transmission to reception mode or from reception to transmission mode. When SCR_SMCI.RE is set to 0, the RDR register is not initialized.

To change from reception mode to transmission mode, first check that reception has completed, then initialize the SCI. At the end of initialization, set SSR_SMCI.TE = 1 and SSR_SMCI.RE = 0. Reception completion can be verified by reading the SCIn_RXI request, ORER, or PER flag in SSR_SMCI.

To change transmission mode to reception mode, first check that transmission has completed, then initialize the SCI. At the end of initialization, set SSR_SMCI.TE = 0 and SSR_SMCI.RE = 1. Transmission completion can be verified by reading the TEND flag in SSR_SMCI.

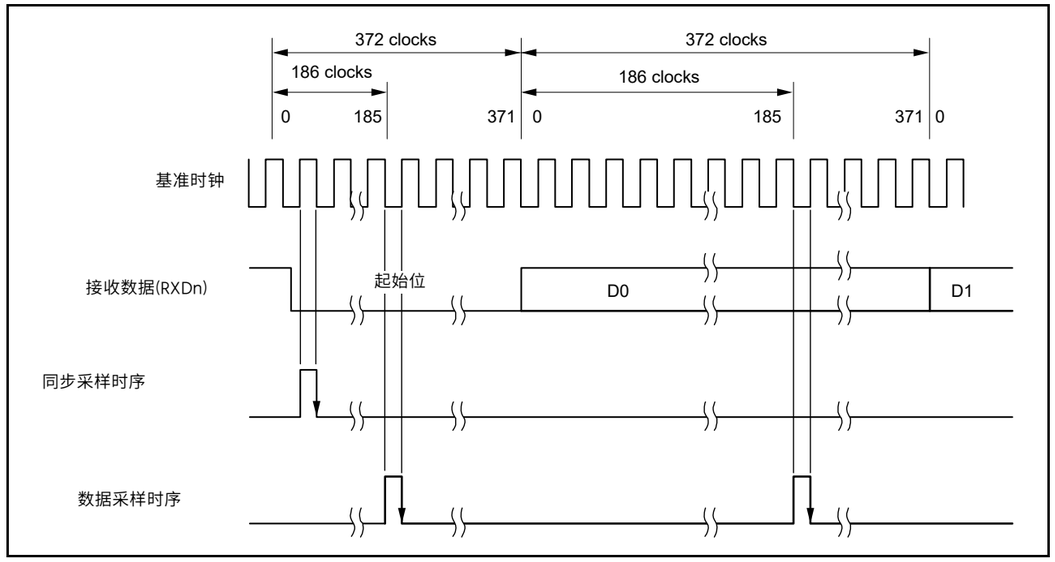

Figure 34.49 时钟频率为372倍比特率时智能卡接口模式下的接收数据采样时序

34.6.5 SCI的初始化

在发送和接收数据之前，将初始值00h写入SCR_SMCI寄存器并按照图34.50所示的示例流程初始化SCI。

在从发送模式切换到接收模式或从接收模式切换到发送模式之前，请务必在SCR_SMCI寄存器中的TIE、RIE、TE、RE、TEIE位中设置初始值。当SCR_SMCI.RE设置为0时，RDR寄存器未初始化。

要从接收模式更改为发送模式，首先检查接收是否完成，然后初始化SCI。
在初始化结束时，设置SSR_SMCI.TE=1和SSR_SMCI.RE=0。可以通过读取SSR_SMCI中的SCIn_RXI请求、ORER或PER标志来验证接收完成。

要将传输模式更改为接收模式，首先检查传输是否完成，然后初始化SCI。在初始化结束时，设置SSR_SMCI.TE=0和SSR_SMCI.RE=1。可以通过读取SSR_SMCI中的TEND标志来验证传输完成。

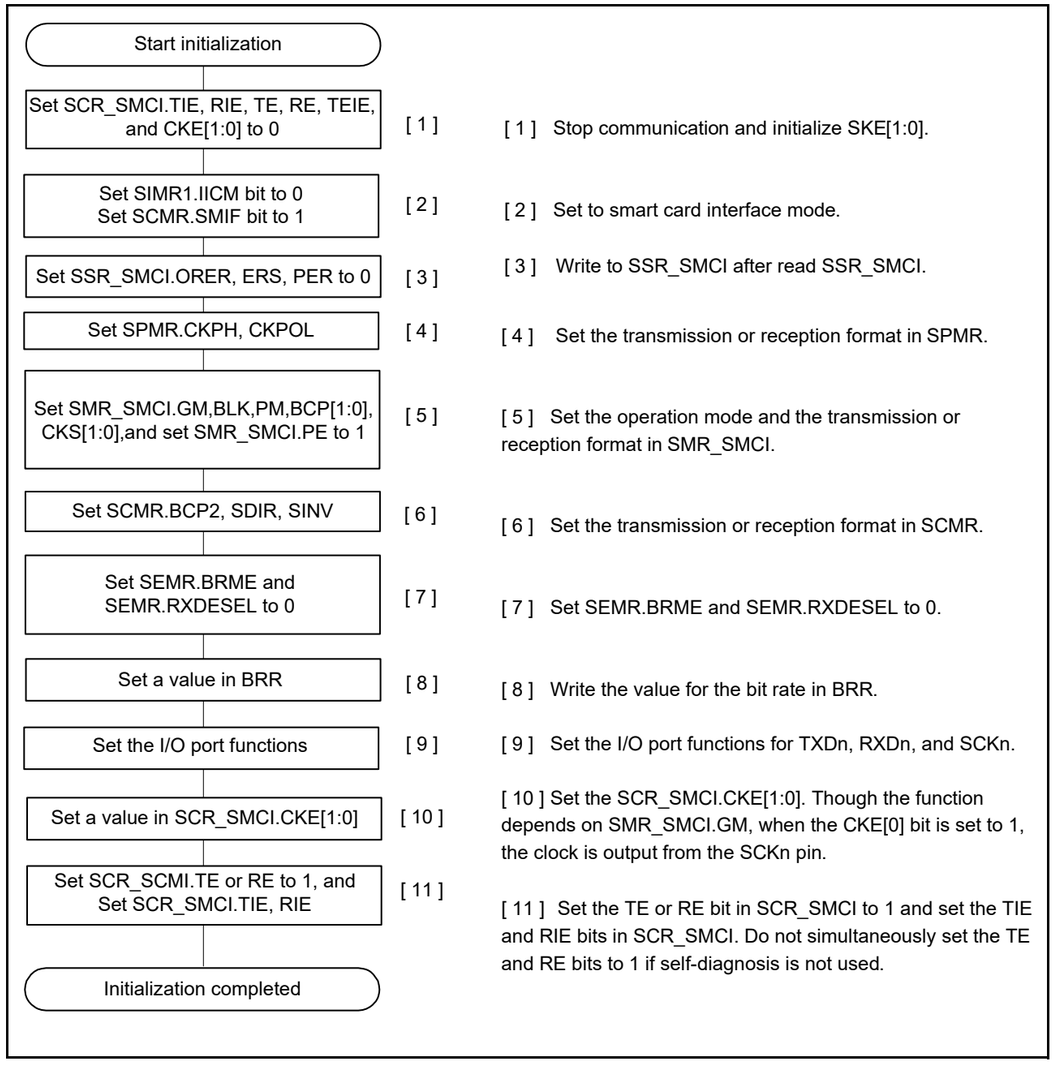

Figure 34.50 Example flow of SCI initialization in smart card interface mode

Figure 34.51 shows a timing diagram when data transmission is performed by transitioning to smart card interface mode according to the flow in Figure 34.50. Figure 34.51 shows when the GM bit in SMR_SMCI is set to 0. The timing in Figure 34.51 shows when the port is connected as SCKn pin and TXDn pin, the pins are Hi-Z because CKE[0] bit in SCR_SMCI is 0.

Start the clock output to the SCK pin by setting CKE[0] bit in SCR_SMCI to 1, then start data transmission by writing transmit data after setting TE bit in SCR_SMCI to 1. When the TE bit in SCR_SMCI changes from 0 to 1, there is a preamble period for one frame before data transmission starts. In smart card interface mode, the TXDn pin is Hi-Z during the preamble period. Pull-up or pull-down for the SCKn and TXDn pins is required outside the MCU.

In the smart card interface mode, even when the TE and RE bits in SCR_SMCI are 0, the clock is continuously output if the clock output setting is used.

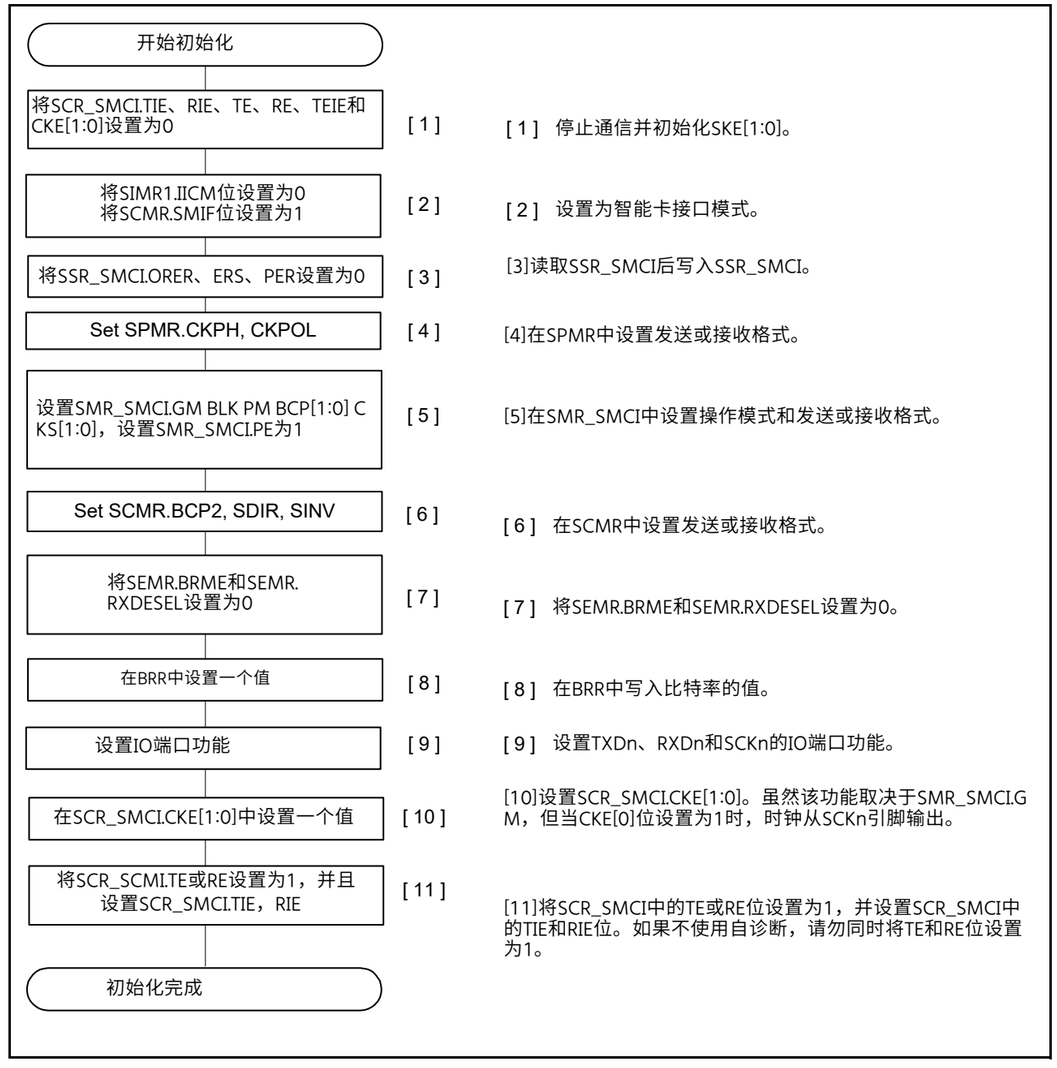

Figure 34.50 智能卡接口模式下SCI初始化流程示例

图34.51显示了根据图34.50中的流程通过转换到智能卡接口模式执行数据传输时的时序图。图34.51显示了SMR_SMCI中的GM位设置为0时。图34.51中的时序显示了当端口连接为SCKn引脚和TXDn引脚时，引脚为Hi-Z，因为CKE[0]位在

SCR_SMCI is 0.

通过将SCR_SMCI中的CKE[0]位设置为1，开始向SCK引脚输出时钟，然后在将SCR_SMCI中的TE位设置为1后，通过写入发送数据开始数据传输。当SCR_SMCI中的TE位从0变为1时，有是数据传输开始前一帧的前导周期。在智能卡接口模式下，TXDn引脚在前导期间为Hi-Z。SCKn和TXDn引脚的上拉或下拉需要在MCU外部进行。

在智能卡接口模式下，即使SCR_SMCI中的TE和RE位为0，如果使用时钟输出设置，时钟也会持续输出。

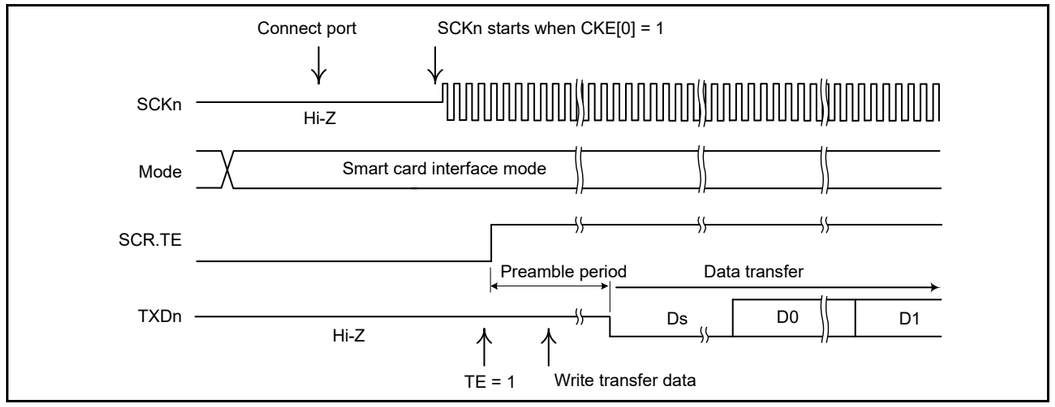

Figure 34.51 Example timing of data transmission in smart card interface mode

34.6.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode) is different from that in non-smart card interface mode, in that an error signal is sampled and data can be re-transmitted in smart card mode. Figure 34.52 shows the data re-transfer operation during transmission.

- [1] indicates when an error signal from the receiver end is sampled after 1-frame data is transmitted, the SSR_SMCI.ERS flag is set to 1. If the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
- [2] indicates for a frame in which an error signal is received, the SSR_SMCI.TEND flag is not set. Data is re-transferred from TDR to TSR, allowing automatic data retransmission.
- [3] indicates if no error signal is returned from the receiver, the ERS flag is not set to 1.
- [4] indicates the SCI determines that transmission of 1-frame data, including the re-transfer, is complete, and the TEND flag is set. If the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated. Write transmit data to the TDR to start transmission of the next data.

Figure 34.54 shows an example flow of serial transmission. All the processing steps are automatically performed using an SCIn_TXI interrupt request to activate the DTC or DMAC.

When the SSR_SMCI.TEND flag is set to 1 in transmission and when the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated.

The DTC or DMAC is activated by an SCIn_TXI interrupt request if the SCIn_TXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission when an error occurs. Because the ERS flag is not automatically cleared, set the RIE bit to 1 before enabling an SCIn_ERI interrupt request to be generated if an error occurs, and clear the ERS flag to 0.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings.

For DTC or DMAC settings, see section 17, DMA Controller (DMAC) and section 18, Data Transfer Controller (DTC).

34.6.6 串行数据传输（块传输模式除外）

智能卡接口模式下的串行数据传输（块传输模式除外）与非智能卡接口模式下的串行数据传输不同之处在于，在智能卡模式下对错误信号进行采样，数据可以重新传输。图34.52显示了传输过程中的数据重传操作。

- [1]表示在发送1帧数据后采样到来自接收端的错误信号时，SSR_SMCI.ERS标志置1。如果SCR_SMCI.RIE位为1，则产生SCIn_ERI中断请求。在采样下一个奇偶校验位之前将ERS 标志清零。
- [2]表示对于接收到错误信号的帧，未设置SSR_SMCI.TEND标志。数据从TDR重新传输到TSR，允许自动数据重新传输。
- [3]表示如果接收器没有返回错误信号，则ERS 标志不设置为1。
- [4]表示SCI确定1帧数据的传输（包括重新传输）已完成，并且设置了TEND标志。如果SCR_SMCI.TIE位为1，则产生SCIn_TXI中断请求。将传输数据写入TDR以开始传输下一个数据。

图34.54显示了串行传输的示例流程。所有处理步骤都使用SCIn_TXI中断请求自动执行以激活DTC或DMAC。

当发送中SSR_SMCI.TEND标志设置为1且SCR_SMCI.TIE位为1时，将产生SCIn_TXI中断请求。

如果先前将SCIn_TXI中断请求指定为DTC或DMAC激活源，则DTC或DMAC由SCIn_TXI中断请求激活，从而允许传输发送数据。当DTC或DMAC传输数据时，TEND标志自动设置为0。

如果发生错误，SCI会自动重新传输相同的数据。在此重传期间，TEND标志保持为0，并且DTC或DMAC未激活。因此，SCI和DTC或DMAC会自动传输指定的字节数，包括发生错误时的重传。因为ERS 标志不会自动清零，所以如果发生错误，在使能SCIn_ERI中断请求之前将RIE位设置为1，并将ERS 标志清零。

使用DTC或DMAC发送或接收数据时，请务必在进行SCI设置之前启用DTC或DMAC。

有关DTC或DMAC设置，请参阅第17节，DMA控制器(DMAC)和第18节，数据传输控制器(DTC)。

34.6.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 34.55 shows the data re-transfer operation in reception mode.

- [1] indicates if a parity error is detected in the receive data, the SSR_SMCI.PER flag is set to 1. When the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
- [2] indicates for a frame in which a parity error is detected, no SCIn_RXI interrupt is generated.
- [3] indicates when no parity error is detected, the SCR_SMCI.PER flag is not set to 1.
- [4] indicates the data is determined to be received successfully. When the SCR_SMCI.RIE bit is 1, an SCIn_RXI interrupt request is generated.

Figure 34.56 shows an example flow of serial data reception. All the processing steps are automatically performed using

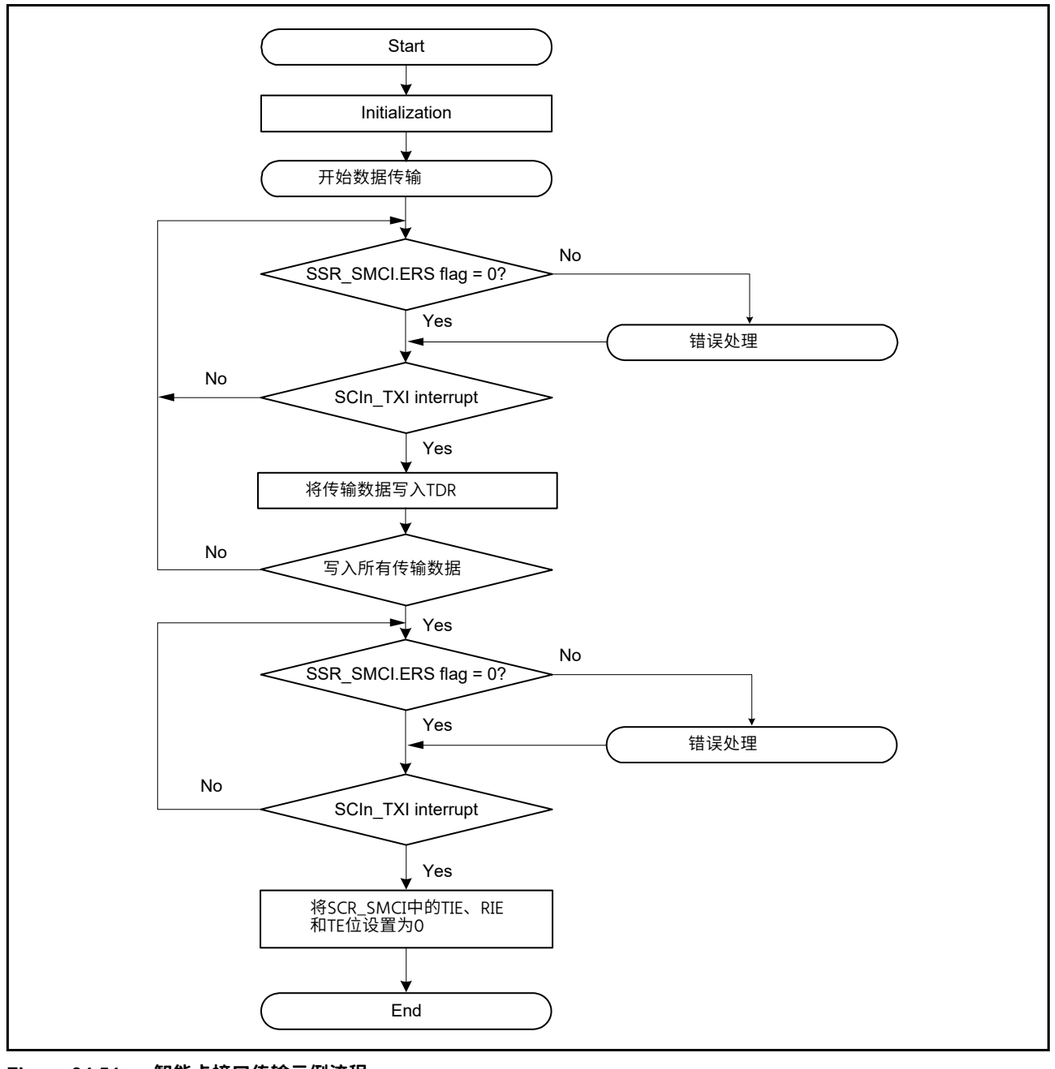

Figure 34.54 智能卡接口传输示例流程

34.6.7 串行数据接收（块传输模式除外）

智能卡接口模式下的串行数据接收与非智能卡接口模式下的串行数据接收类似。图34.55显示了接收模式下的数据重传操作。

- [1]表示如果在接收数据中检测到奇偶校验错误，则SSR_SMCI.PER标志设置为1。当SCR_SMCI.RIE位为1时，产生SCIn_ERI中断请求。在采样下一个奇偶校验位之前将PER标志清零。
- [2]表示对于检测到奇偶校验错误的帧，不产生SCIn_RXI中断。
- [3]表示当没有检测到奇偶校验错误时，SCR_SMCI.PER标志不设置为1。
- [4]表示确定数据接收成功。当SCR_SMCI.RIE位为1时，产生SCIn_RXI中断请求。

图34.56显示了串行数据接收的示例流程。所有处理步骤都使用自动执行

an SCIn_RXI interrupt request to activate the DTC or DMAC.

In reception, setting the RIE bit to 1 allows an SCIn_RXI interrupt request to be generated. The DTC or DMAC is activated by an SCIn_RXI interrupt request if the SCIn_RXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in SSR_SMCI is set to 1, a receive error interrupt (SCIn_ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.

If a parity error occurs and the PER flag is set to 1 during reception, the receive data is transferred to RDR, allowing the data to be read.

When a reception is forced to terminate by setting SCR_SMCI.RE to 0 during operation, read the RDR register because the received data that is not yet read might be left in the RDR.

Note: For operations in block transfer mode, see section 34.3.9, Serial Data Reception in Asynchronous Mode.

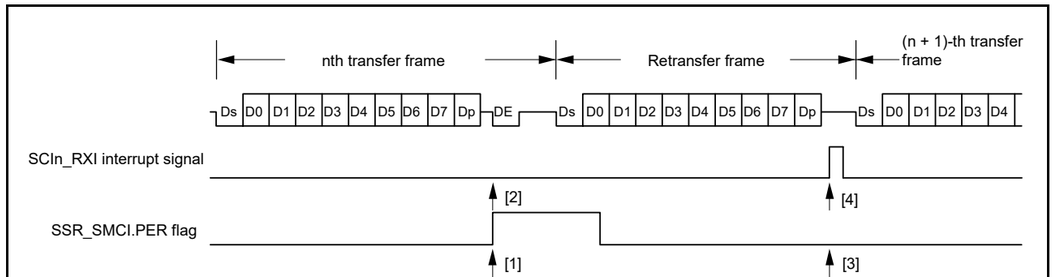

Figure 34.55 Data retransfer operation in SCI reception mode

SCIn_RXI中断请求以激活DTC或DMAC。

在接收时，将RIE位设置为1允许产生SCIn_RXI中断请求。如果先前将SCIn_RXI中断请求指定为DTC或DMAC激活源，则DTC或DMAC由SCIn_RXI中断请求激活，从而允许传输接收数据。

如果接收期间发生错误并且SSR_SMCI中的ORER或PER标志设置为1，则会生成接收错误中断(SCIn_ERI)请求。错误发生后清除错误标志。如果发生错误，则不会激活DTC或DMAC并跳过接收数据。因此，将传输DTC或DMAC中指定的接收数据字节数。

如果在接收过程中发生奇偶校验错误并且PER标志设置为1，则接收数据将传输到RDR，从而可以读取数据。

如果在操作期间通过将SCR_SMCI.RE设置为0来强制终止接收，请读取RDR寄存器，因为尚未读取的已接收数据可能留在RDR中。

Note: 有关块传输模式下的操作，请参见第34.3.9节，异步模式下的串行数据接收。

34.6.8 Clock Output Control

When the GM bit in SMR_SMCI is set to 1, the clock output can be controlled by the CKE[1: 0] bits in SCR_SMCI. For details on the CKE[1:0] bits, see section 34.2.12, Serial Control Register for Smart Card Interface Mode (SCR_SMCI) (SCMR.SMIF = 1). When setting the clock output, the base clock described in section 34.6.4, Receive Data Sampling Timing and Reception Margin is output.

Figure 34.57 shows an example timing for the clock output control when the CKE[1] bit in SCR_SMCI is set to 0 and the CKE[0] bit in SCR_SMCI is controlled.

When the GM bit in SMR_SMCI is 0, output control by the CKE[0] bit in SCR_SMCI is immediately reflected on the SCK pin, so there is a possibility that pulses with an unintended width might be output from the SCK pin.

When the GM bit in SMR_SMCI is 1, the clock with the same pulse width as the base clock is output even if the CKE[0] bit in SCR_SMCI is changed.

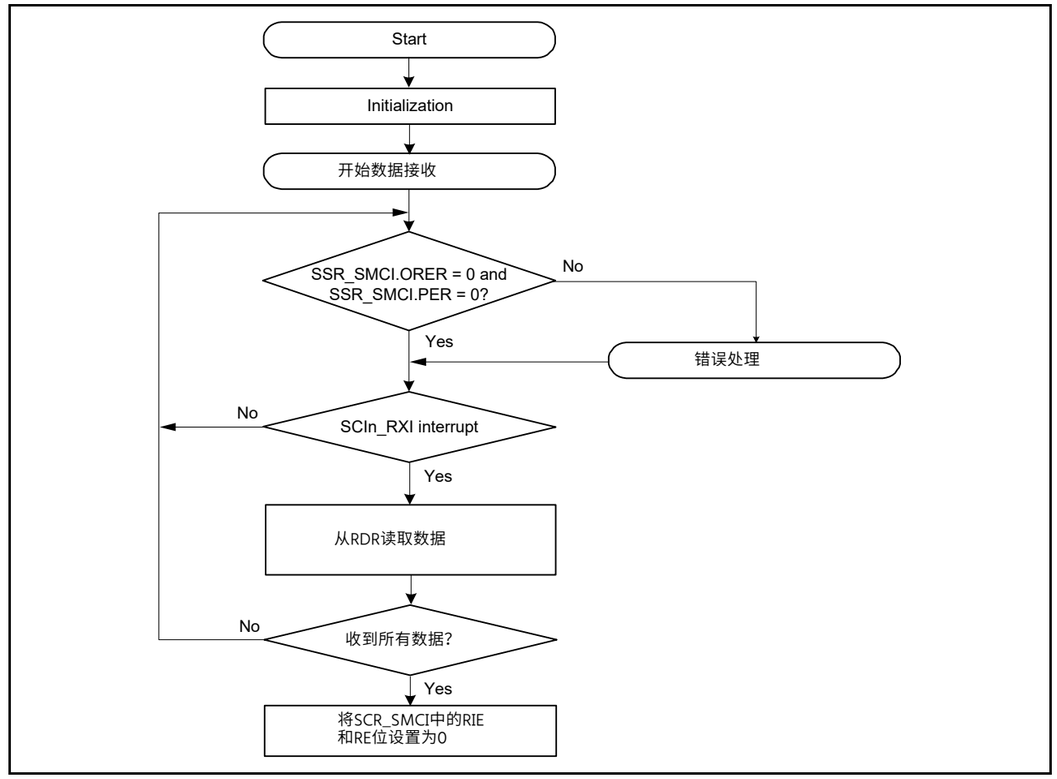

Figure 34.56 智能卡接口接收示例流程

34.6.8 时钟输出控制

当SMR_SMCI中的GM位设置为1时，时钟输出可由SCR_SMCI中的CKE[1:0]位控制。有关CKE[1:0]位的详细信息，请参见第34.2.12节，智能卡接口模式的串行控制寄存器(SCR_SMCI)(SCMR.SMIF=1)。设置时钟输出时，输出第34.6.4节"接收数据采样时序和接收裕度"中描述的基本时钟。

图34.57显示了当SCR_SMCI中的CKE[1]位设置为0且
控制SCR_SMCI中的CKE[0]位。

当SMR_SMCI中的GM位为0时，SCR_SMCI中CKE[0]位的输出控制立即反映在
SCK引脚，因此有可能会从SCK引脚输出具有意外宽度的脉冲。

当SMR_SMCI中的GM位为1时，即使SCR_SMCI中的CKE[0]位发生变化，也会输出与基本时钟脉冲宽度相同的时钟。

34.7 Operation in Simple IIC Mode

Simple IIC mode format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device can specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8 data bits in all frames are transmitted in order from the MSB.

The I²C bus format and timing of the I²C bus are shown in Figure 34.58 and Figure 34.59.

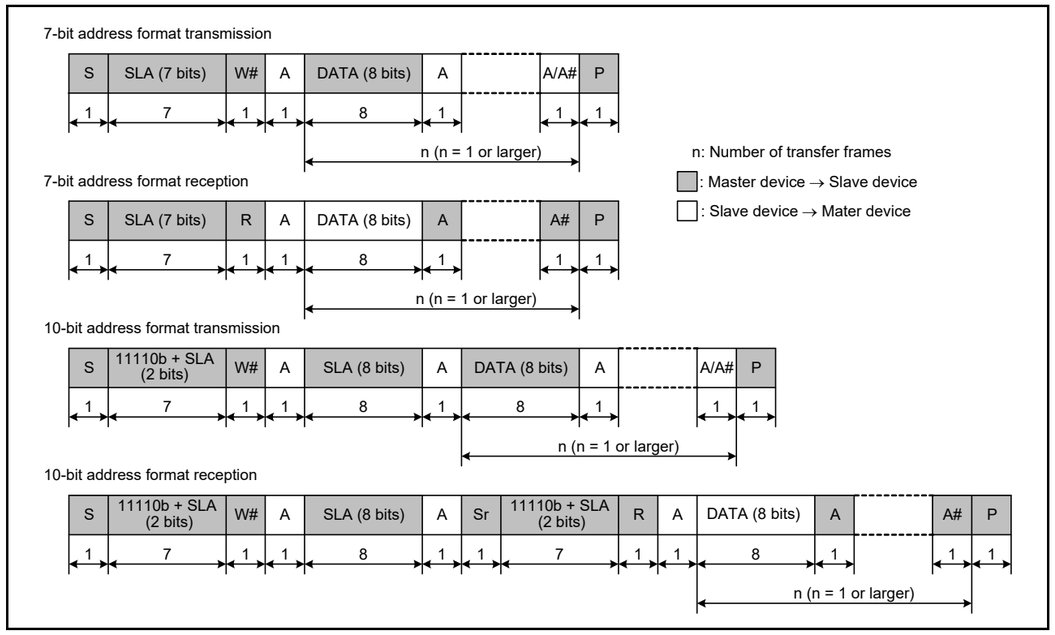

Figure 34.58 I²C bus format

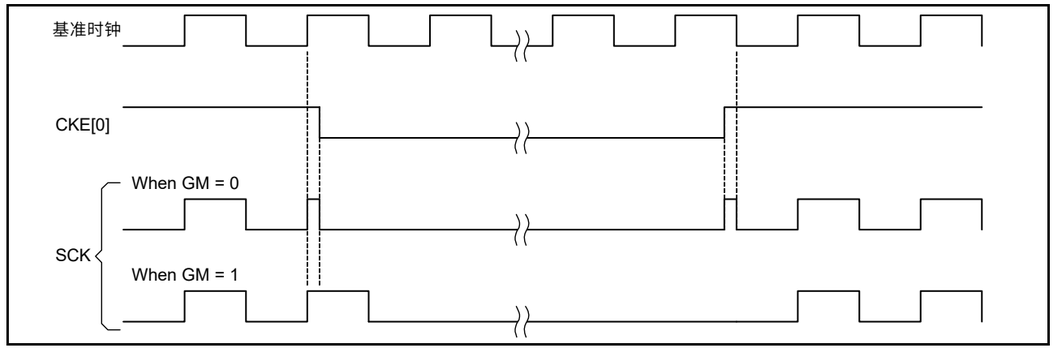

Figure 34.57 时钟输出控制

34.7 简单IIC模式下的操作

简单IIC模式格式由8个数据位和一个确认位组成。通过在启动条件或重新启动条件之后继续进入从地址帧，主设备可以指定从设备作为通信伙伴。当前指定的从设备保持有效，直到指定新的从设备或满足停止条件。

所有帧中的8个数据位从MSB开始按顺序传输。

I2C总线格式和I2C总线时序如图34.58和图34.59所示。

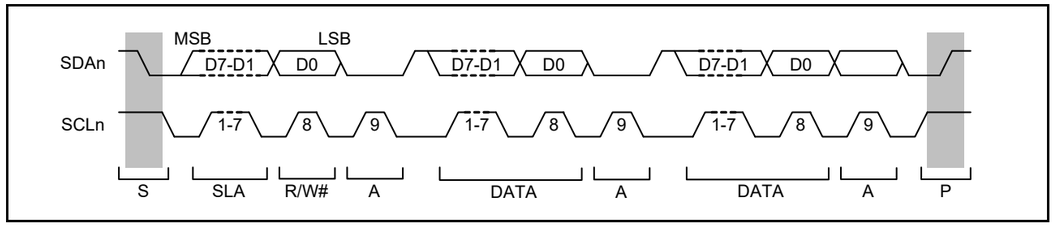

Figure 34.59 I²C bus timing when SLA is 7 bits

- S: Indicates a start condition, when the master device changes the level on the SDAn line from high to low while the SCLn line is high
- SLA: Indicates a slave address, by which the master device selects a slave device
- R/W#: Indicates the direction of transfer (reception or transmission). The value 1 indicates transfer from the slave device to the master device and 0 indicates transfer from the master device to the slave device.
- A/A#: Indicates an acknowledge bit. This is returned by the slave device for master transmission and by the master device for master reception. Return low indicates ACK and return high indicates NACK.
- Sr: Indicates a restart condition, when the master device changes the level on the SDAn line from high to low while the SCLn line is high and after the setup time elapses
- DATA: Indicates the data being received or transmitted
- P: Indicates a stop condition, when the master device changes the level on the SDAn line from low to high while the SCLn line is high.

34.7.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the SIMR3.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept in the released state
- The hold time for the start condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the IICSTAREQ bit in SIMR3 is set to 0, and a start-condition generated interrupt is output.

Writing 1 to the IICRSTAREQ bit in SIMR3 causes the generation of a restart condition. The generation of a restart condition proceeds through the following operations:

- The SDAn line is released and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SDAn line falls (from the high level to the low level)
- The hold time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the SIMR3.IICRSTAREQ bit is set to 0, and a restart-condition generated interrupt is output.

Writing 1 to the SIMR3.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting

34.7.1 启动、重启和停止条件的生成

将1写入SIMR3.IICSTAREQ位会导致产生启动条件。开始条件的生成通过以下操作进行：

- SDAn线上的电平下降（从高电平到低电平），SCLn线保持在释放状态
- 开始条件的保持时间设置为比特周期的一半，比特率由BRR设置确定
- SCLn线上的电平下降（从高电平变为低电平），SIMR3中的IICSTAREQ位设置为0，并输出一个起始条件产生的中断。

将1写入SIMR3中的IICRSTAREQ位会导致产生重启条件。重新启动条件的生成通过以下操作进行：

- SDAn线被释放，SCLn线保持在低电平
- SCLn线的低电平周期设置为比特周期的一半，比特率由BRR设置确定
- SCLn线被释放（从低电平过渡到高电平）
- 当在SCLn线上检测到高电平时，重新启动条件的建立时间设置为比特周期的一半，比特率由BRR设置确定

- SDAn线上的电平下降（从高电平到低电平）
- 重启条件的保持时间设置为比特周期的一半，比特率由BRR设置确定
- SCLn线上的电平下降（从高电平变为低电平），SIMR3.IICRSTAREQ位设置为0，并输出重启条件产生的中断。

将1写入SIMR3.IICSTPREQ位会导致产生停止条件。停止条件的生成通过以下操作进行：

- SDAn线上的电平下降（从高电平到低电平），SCLn线上保持低电平
- SCLn线的低电平周期设置为比特周期的一半，比特率由BRR设置确定

- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the stop condition is set as half of a bit period at the bit rate determined by the BRR setting
- The SDAn line is released (transition from the low to the high level), the SIMR3.IICSTPREQ bit is set to 0, and a stop-condition generated interrupt is output.

Figure 34.60 shows the timing of operations in the generation of start, restart, and stop conditions.

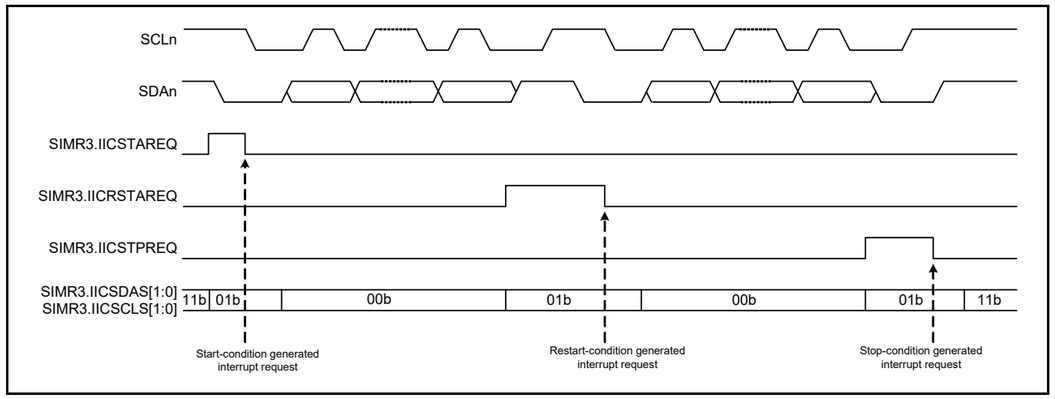

Figure 34.60 Timing of operations in generation of start, restart, and stop conditions

34.7.2 Clock Synchronization

The SCLn line can be driven low if a wait is inserted by a slave device at the other side of the transfer. Setting the SIMR2.IICCSC bit to 1 applies control to obtain synchronization when a difference arises between the levels of the internal SCLn clock signal and the level being input on the SCLn pin.

When the SIMR2.IICCSC bit is set to 1, the level of the internal SCLn clock signal changes from low to high. Counting to determine the period at a high level stops while the low level is being input on the SCLn pin. Counting to determine the period at a high level starts after the transition of the input on the SCLn pin to the high level.

The interval from this time until counting to determine the period at high level starts on the transition of the SCLn pin to the high level, is the total of the delay of SCLn output, delay for noise filtering of the input on the SCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLKA). The period at high level of the internal SCLn clock is extended even when other devices do not place the low level on the SCLn line.

If the SIMR2.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SCLn pin and the internal SCLn clock. If the SIMR2.IICCSC bit is 0, synchronization with the internal SCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a wait period into the interval until the transition of the internal SCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a wait period after the transition of the internal SCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the waiting period, generation of the condition itself is not guaranteed. Figure 34.61 shows an example operation for synchronizing the clocks.

- SCLn线被释放（从低电平过渡到高电平）
- 当在SCLn线上检测到高电平时，停止条件的建立时间设置为由BRR设置确定的比特率的半个比特周期
- SDAn线被释放（从低电平转换为高电平），SIMR3.IICSTPREQ位设置为0，并输出停止条件产生的中断。

图34.60显示了生成启动、重启和停止条件的操作时序。

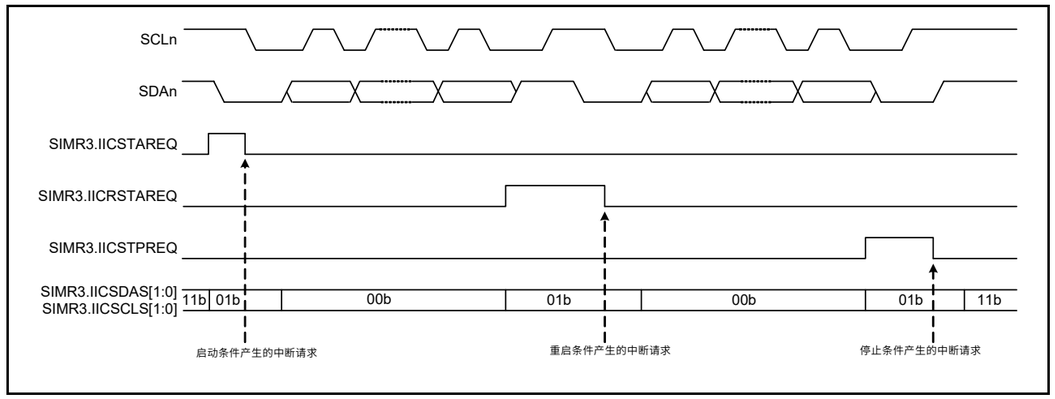

Figure 34.60 生成启动、重启和停止条件时的操作时序

34.7.2 时钟同步

如果从设备在传输的另一侧插入等待，则可以将SCLn线驱动为低电平。设置SIMR2.IICCSC位为1时，当内部SCLn时钟信号的电平与输入到SCLn引脚的电平之间出现差异时，应用控制以获得同步。

当SIMR2.IICCSC位设置为1时，内部SCLn时钟信号的电平由低变为高。当SCLn引脚输入低电平时，停止计数以确定高电平周期。在SCLn引脚上的输入转换为高电平后，开始计数以确定高电平的周期。

从这个时间到从SCLn引脚转换为高电平开始计数确定高电平周期的时间间隔是SCLn输出延迟的总和，SCLn引脚上输入的噪声过滤延迟（2或3个周期的采样时钟用于噪声滤波器），以及延迟用于内部处理（1或2个PCLKA周期）。即使其他设备没有将低电平置于SCLn线上，内部SCLn时钟的高电平周期也会延长。

如果SIMR2.IICCSC位为1，则通过对SCLn引脚上的输入和内部SCLn时钟进行逻辑与来获得数据发送和接收的同步。如果SIMR2.IICCSC位为0，则与内部SCLn时钟同步以进行数据的发送和接收。

如果从设备在发出启动、重新启动或停止条件的生成请求后，在内部SCLn时钟信号从低电平转变为高电平之前的间隔中插入一个等待周期，则直到生成的时间为延长了那个时期。

如果从设备在内部SCLn时钟信号从低电平转变为高电平之后插入等待周期，尽管在不停止等待周期的情况下发出生成完成中断，但不能保证条件本身的生成。图34.61显示了同步时钟的示例操作。

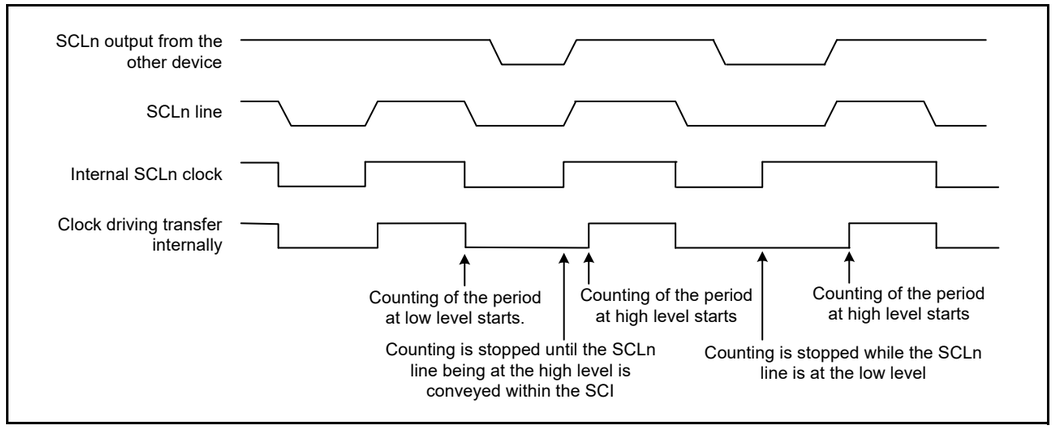

Figure 34.61 Example operations for clock synchronization

34.7.3 SDA Output Delay

The SIMR1.IICDL[4:0] bits can be used to set a delay for output on the SDAn pin relative to falling edges of output on the SCLn pin. Delay settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, PCLKA, by the divisor selected in the SMR.CKS[1:0] bits). A delay for output on the SDAn pin applies to the start condition/restart condition/stop condition signal, 8-bit transmit data, and acknowledge bit.

If the SDA output delay is shorter than the time for the level on the SCLn pin to fall, the change of the output on the SDAn pin starts while the output level on the SCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SDAn pin specify times greater than the time output on the SCLn pin takes to fall (300 ns for IIC in standard mode and fast mode).

Before transferring data, write the initial value 00h to SCR and initialize the interface following the example shown in Figure 34.63.

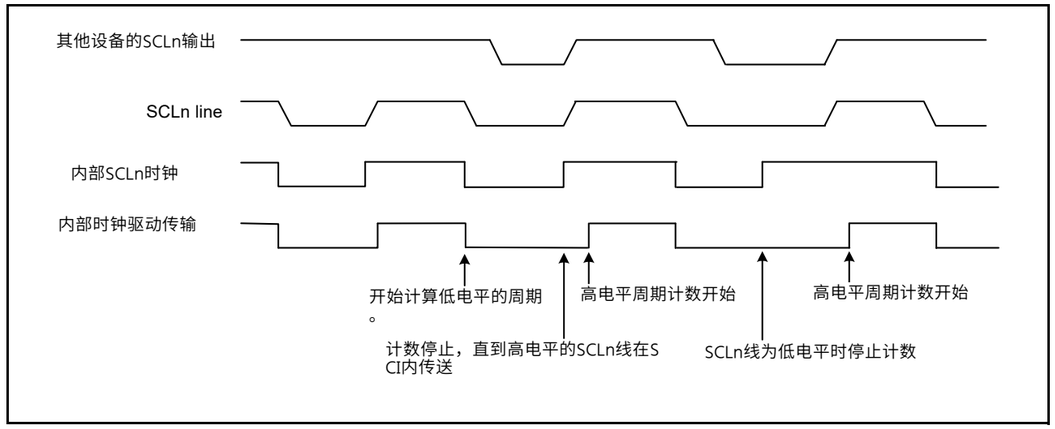

Figure 34.61 时钟同步的示例操作

34.7.3 SDA输出延迟

SIMR1.IICDL[4:0]位可用于设置SDAn引脚输出相对于SCLn引脚输出下降沿的延迟。可选择从0到31的延迟设置，表示来自片上波特率发生器的时钟信号的相应周期数的周期（通过将基本时钟PCLKA分频得到SMR.CKS中选择的除数）[1:0]位）。SDAn引脚上的输出延迟适用于启动条件重启条件停止条件信号、8位发送数据和确认位。

如果SDA输出延迟小于SCLn引脚电平下降的时间，则SDAn引脚在SCLn引脚上的输出电平下降时启动，从而为从设备产生错误操作的可能性。确保SDAn引脚上的输出延迟设置指定的时间大于SCLn引脚上输出的下降时间（标准模式和快速模式下的IIC为300ns）。

34.8 Operation in Simple SPI Mode

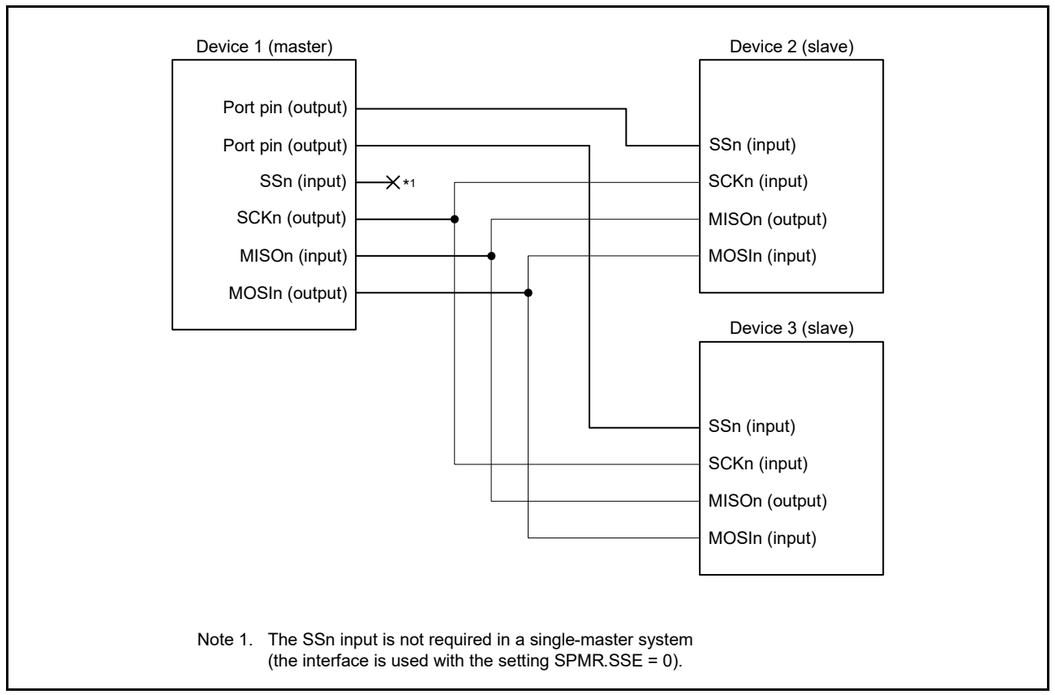
As an extended function, the SCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Using the settings for clock synchronous mode (SCMR.SMIF = 0, SIMR1.IICM = 0, SMR.CM = 1) and setting the SPMR.SSE bit to 1 places the SCI in simple SPI mode. However, the SSn pin function on the master side is not required for connection of the device used as the master in simple SPI mode when the configuration only has a single master. Therefore, set the SPMR.SSE bit to 0 in such cases.

Figure 34.69 shows an example of connections for simple SPI mode. Control a general port pin to produce the SSn output signal from the master.

In simple SPI mode, data is transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended. The data can be inverted by setting the SCMR.SINV bit to 1.

Because the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a shared clock signal. Additionally, because both the transmitter and receiver have a buffered structure, writing the next transmit data while transmission is in progress and reading previously received data while reception is in progress are both possible. This enables continuous transfer.



Note 1. The SSn input is not required in a single-master system (the interface is used with the setting SPMR.SSE = 0).

Figure 34.69 Example connections using simple SPI mode in single master mode with SPMR.SSE bit = 0

34.8.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (SCR.CKE[1:0] = 00b or 01b and SPMR.MSS = 0) or slave (SCR.CKE[1:0] = 10b or 11b and SPMR.MSS = 1).

Table 34.25 lists the relationship between the pin states, mode, and level on the SSn pin.

34.8 简单SPI模式下的操作

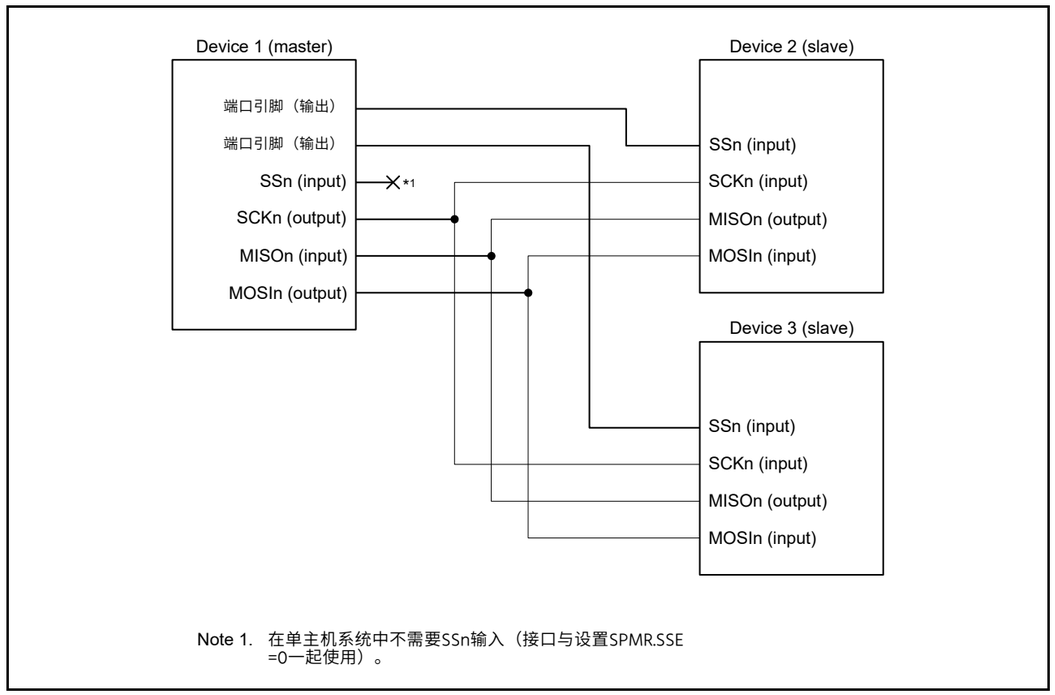
作为一项扩展功能，SCI支持简单的SPI模式，可处理一个或多个主设备与多个从设备之间的传输。

使用时钟同步模式的设置（SCMR.SMIF=0，SIMR1.IICM=0，SMR.CM=1）并将SPMR.SSE位设置为1将SCI置于简单SPI模式。但是，当配置只有一个主控时，在简单SPI模式下连接用作主控的设备不需要主控侧的SSn引脚功能。因此，在这种情况下，将SPMR.SSE位设置为0。

图34.69显示了简单SPI模式的连接示例。控制一个通用端口引脚以产生来自主机的SSn输出信号。

在简单SPI模式下，数据与时钟脉冲同步传输，方式与时钟同步模式相同。1个字符的传输数据由8位数据组成，不能附加奇偶校验位。可以通过将SCMR.SINV位设置为1来反转数据。

由于接收器和发送器在SCI模块中彼此独立，因此可以使用共享时钟信号进行全双工通信。此外，由于发送器和接收器都具有缓冲结构，因此在发送过程中写入下一个发送数据和在接收过程中读取先前接收到的数据都是可能的。这使得连续传输成为可能。



Note 1. 在单主机系统中不需要SSn输入（接口与设置SPMR.SSE=0一起使用）。

Figure 34.69 在SPMR.SSE位=0的单主模式下使用简单SPI模式的示例连接

34.8.1 主从模式下的引脚状态

简单SPI模式接口的引脚方向（输入或输出）根据设备是主设备（SCR.CKE[1:0]=00b或01b且SPMR.MSS=0）还是从设备（SCR.CKE）而不同[1:0]=10b或11b且SPMR.MSS=1)。

表34.25列出了SSn引脚上的引脚状态、模式和电平之间的关系。

Table 34.25 States of pins by mode and input level on SSn pin

Mode	Input on SSn pin	State of TXDn pin	State of RXDn pin	State of SCKn pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance
Slave mode	High level (transfer cannot proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer can proceed)	Input for received data	Output for data transmission	Clock input

Note 1. When there is only a single master (SPMR.SSE = 0), transfer is possible regardless of the input level on the SSn pin. This is equivalent to input of a high level on the SSn pin. Because the SSn pin function is not required, the pin is available for other purposes.
Note 2. The MOSIn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE bit = 0).
Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE and RE bits = 00b) in a multi-master configuration (SPMR.SSE = 1).

34.8.2 SS Function in Master Mode

Setting the SCR.CKE[1:0] bits to 00b and the SPMR.MSS bit to 0 selects master operation.

In single-master configurations (SPMR.SSE = 0), the SSn pin is not used, and so transmission or reception can proceed regardless of the value of the SSn pin.

When the level on the SSn pin is high in a multi-master configuration (SPMR.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission.

When the level on the SSn pin is low in a multi-master configuration (SPMR.SSE = 1), there are other masters, and this indicates that transmission or reception is in progress. The MOSIn output and SCKn pins are placed in the high-impedance state and starting transmission or reception is not possible. Additionally, the value of the SPMR.MFF bit is 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading SPMR.MFF flag. Even if a mode fault error occurs while transmission or reception is in progress, transmission or reception does not stop, but the MOSIn and SCKn pin outputs are placed in the high-impedance state after completion of the transfer. Use a general port pin to produce the SS output signal from the master.

34.8.3 SS Function in Slave Mode

Setting the SCR.CKE[1:0] bits to 10b and the SPMR.MSS bit to 1 selects slave operation. When the SSn pin is high, the MISOn output pin is in the high-impedance state and clock input through the SCKn pin is ignored. When the SSn pin is low, clock input through the SCKn pin is valid and transmission or reception can proceed.

If the input on the SSn pin changes from low to high during transmission or reception, the MISOn output pin is placed in the high-impedance state. Meanwhile, the internal processing for transmission or reception continues at the rate of the clock input through the SCKn pin until processing for the character being transmitted or received is complete, after which it stops, and the appropriate interrupt (SCIn_TXI, SCIn_RXI, or SCIn_TEI) is generated.

34.8.4 Relationship between Clock and Transmit/Receive Data

The CKPOL and CKPH bits in the SPMR register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in Figure 34.70. The relation is the same for both master and slave operation. This is the same as when the level on the SSn pin is high.

Table 34.25 SSn引脚上的模式和输入电平的引脚状态

Mode	SSn引脚上的输入	TXDn引脚状态	RXDn引脚状态	SCKn引脚状态
Master mode*1	高电平（可以进行转移）	数据传输输出*2	接收数据的输入	Clock output*3
	低电平（传输无法进行）	High-impedance	接收数据的输入（但禁用）	High-impedance
从机模式	高电平（传输无法进行）	接收数据的输入（但禁用）	High-impedance	时钟输入（但禁用）
	低电平（可以继续传输）	接收数据的输入	数据传输输出	时钟输入

注1.当只有一个主机(SPMR.SSE=0)时，无论SSn引脚上的输入电平如何，都可以进行传输。这相当于在SSn引脚上输入高电平。由于不需要SSn引脚功能，因此该引脚可用于其他用途。注2.当串行传输被禁用（SCR.TE位=0）时，MOSIn引脚输出处于高阻抗状态。

注3.在多主机配置(SPMR.SSE=1)中禁用串行传输(SCR.TE和RE位=00b)时，SCKn引脚输出处于高阻抗状态。

34.8.2 主控模式下的SS功能

将SCR.CKE[1:0]位设置为00b并将SPMR.MSS位设置为0选择主机操作。

在单主机配置(SPMR.SSE=0)中，不使用SSn引脚，因此无论SSn引脚的值如何，都可以进行发送或接收。

在多主机配置（SPMR.SSE=1）中，当SSn引脚上的电平为高电平时，主机设备在开始发送或接收之前从SCKn引脚输出时钟信号，以指示没有其他主机或另一个主机在进行接收或发送。

在多主机配置中（SPMR.SSE=1），当SSn引脚上的电平为低电平时，还有其他主机，这表明正在发送或接收。MOSIn输出和SCKn引脚处于高阻抗状态，无法开始发送或接收。此外，SPMR.MFF位的值为1，表示模式故障错误。在多主机配置中，通过读取SPMR.MFF标志开始错误处理。即使在发送或接收过程中发生模式故障错误，发送或接收也不会停止，而是在传输完成后将MOSIn和SCKn引脚输出置于高阻抗状态。使用通用端口引脚从主机产生SS输出信号。

34.8.3 从模式下的SS功能

将SCR.CKE[1:0]位设置为10b并将SPMR.MSS位设置为1选择从机操作。当SSn引脚为高电平时，MIOn输出引脚处于高阻状态，通过SCKn引脚输入的时钟被忽略。当SSn引脚为低电平时，通过SCKn引脚输入的时钟有效，可以进行发送或接收。

如果SSn引脚上的输入在发送或接收期间从低电平变为高电平，则MISOn输出引脚处于高阻抗状态。同时，发送或接收的内部处理以通过SCKn引脚输入的时钟速率继续进行，直到对正在发送或接收的字符的处理完成，之后它停止，并出现适当的中断（SCIn_TXI、SCIn_RXI或SCIn_TEI）生成。

34.8.4 时钟与发送接收数据的关系

SPMR寄存器中的CKPOL和CKPH位可用于以四种不同的方式设置用于发送和接收的时钟。时钟信号与数据收发的关系如图34.70所示。主从操作的关系是相同的。这与SSn引脚上的电平为高电平时相同。

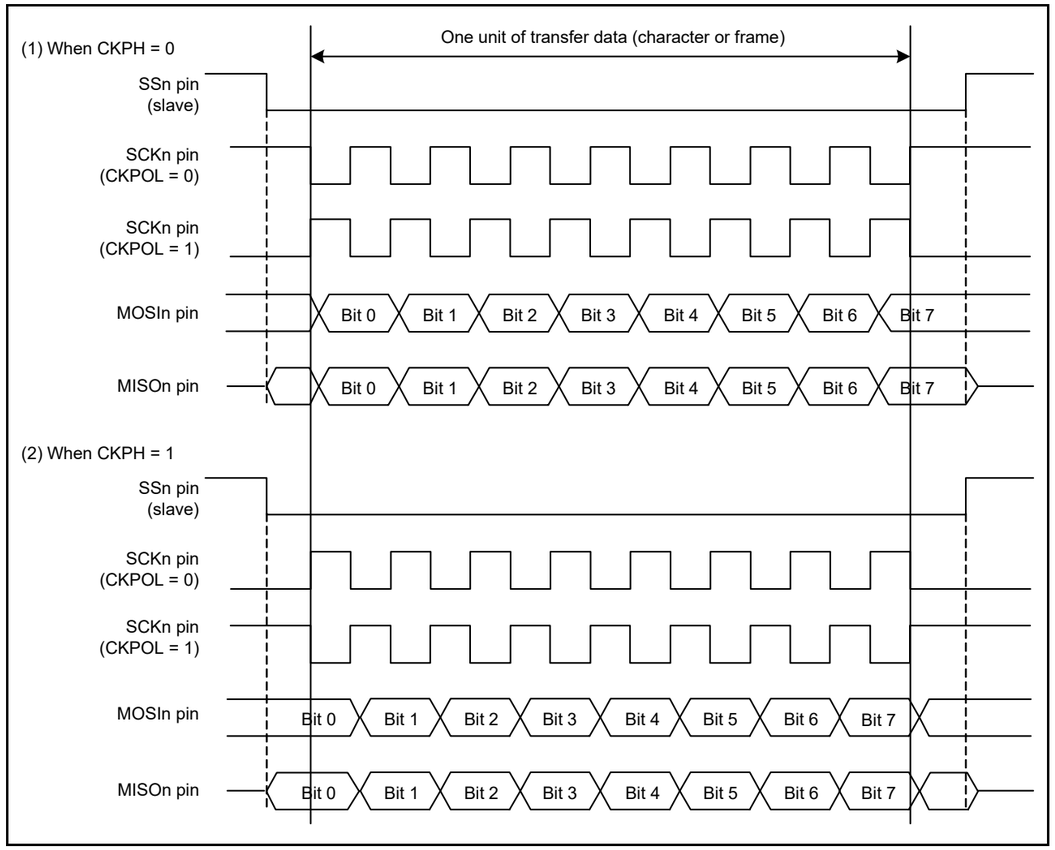


Figure 34.70 Relation between clock signal and transmit or receive data in simple SPI mode

34.8.5 SCI Initialization in Simple SPI Mode

Initialization in simple SPI mode is the same as in clock synchronous mode. See Figure 34.32 for an example initialization flow. The CKPOL and CKPH bits in the SPMR register must be set to ensure that the clock signal is suitable for both master and slave devices.

Always initialize the SCR register before making any changes to the operating mode or transfer format.

Note 1. Only the RE bit is set to 0. The SSR.ORER, FER, PER, and RDR flags are not initialized.
Note 2. Changing the value of the TE bit from 1 to 0 or from 0 to 1 leads to the generation of a transmit data empty interrupt (SCIn_TXI) if the value of the SCR.TIE bit is 1.

34.8.6 Transmission and Reception of Serial Data in Simple SPI Mode

In master operation, ensure that the SSn pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. Otherwise, the procedures are the same as in clock synchronous mode.

34.9 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be evenly corrected using the number specified in the MDDR register when the PCLKA is selected in the CKS[1:0] bits in SMR/SMR_SMCI.

Figure 34.71 shows an example where the PCLKA is selected in the CKS[1:0] bits in SMR/SMR_SMCI, the BRR bit is set to 0, and the MDDR is set to 160 in asynchronous mode. In this example, the cycle of the base clock is evenly

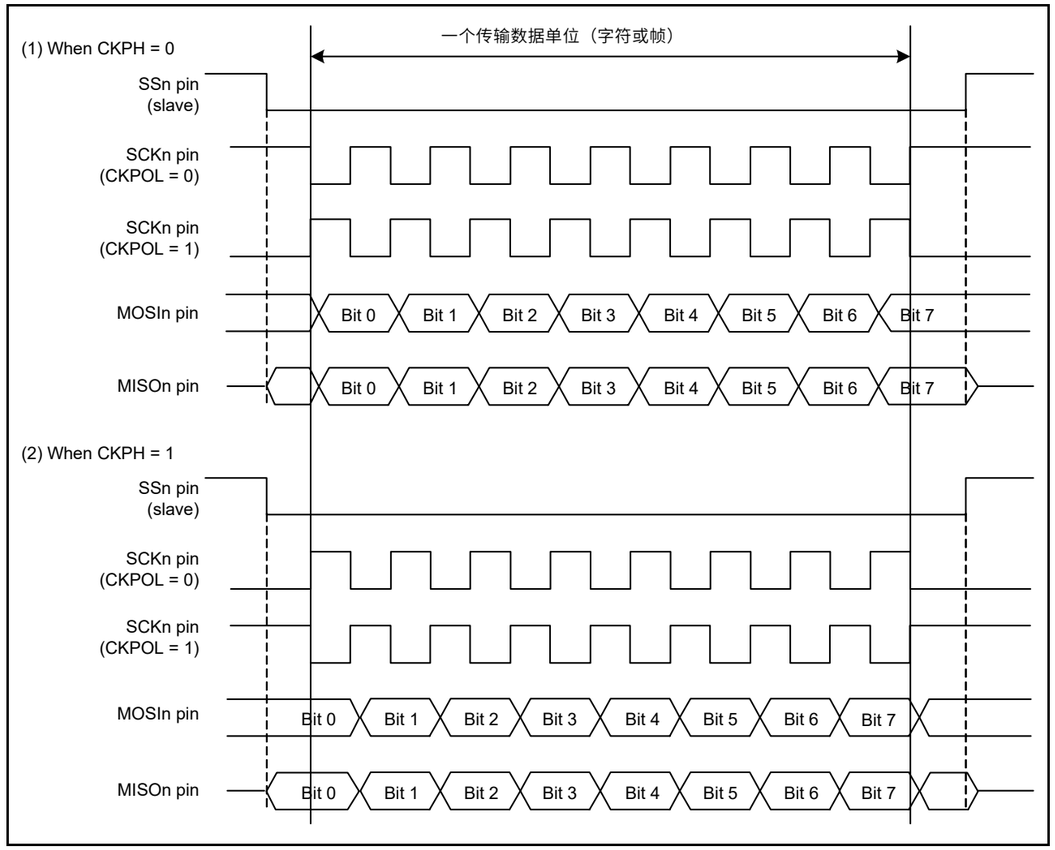

Figure 34.70 简单SPI模式下时钟信号与发送或接收数据的关系

34.8.5 简单SPI模式下的SCI初始化

简单SPI模式的初始化与时钟同步模式相同。有关示例初始化流程，请参见图34.32。必须设置SPMR寄存器中的CKPOL和CKPH位，以确保时钟信号适用于主设备和从设备。

在对操作模式或传输格式进行任何更改之前，始终初始化SCR寄存器。

注1.只有RE位设置为0。SSR.ORER、FER、PER和RDR标志未初始化。
注2.如果SCR.TIE位的值为1，则将TE位的值从1更改为0或从0更改为1会导致产生发送数据空中断(SCIn_TXI)。

34.8.6 简单SPI模式下串行数据的发送和接收

在主机操作中，确保传输另一侧的从设备的SSn管脚在开始传输前为低电平，在传输完成时为高电平。否则，过程与时钟同步模式相同。

34.9 比特率调制功能

使用比特率调制功能，当在SMRSMR_SMCI的CKS[1:0]位中选择PCLKA时，可以使用MDDR寄存器中指定的数字均匀地校正比特率。

图34.71显示了一个示例，其中在SMRSMR_SMCI的CKS[1:0]位中选择PCLKA，BRR位设置为0，异步模式下MDDR设置为160。在这个例子中，基本时钟的周期是均匀的

corrected (256/160) and the bit rate is also corrected (160/256).

Note: Enabling an internal clock causes bias, and expansion and contraction are generated in the pulse width of the internal base clock.

Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

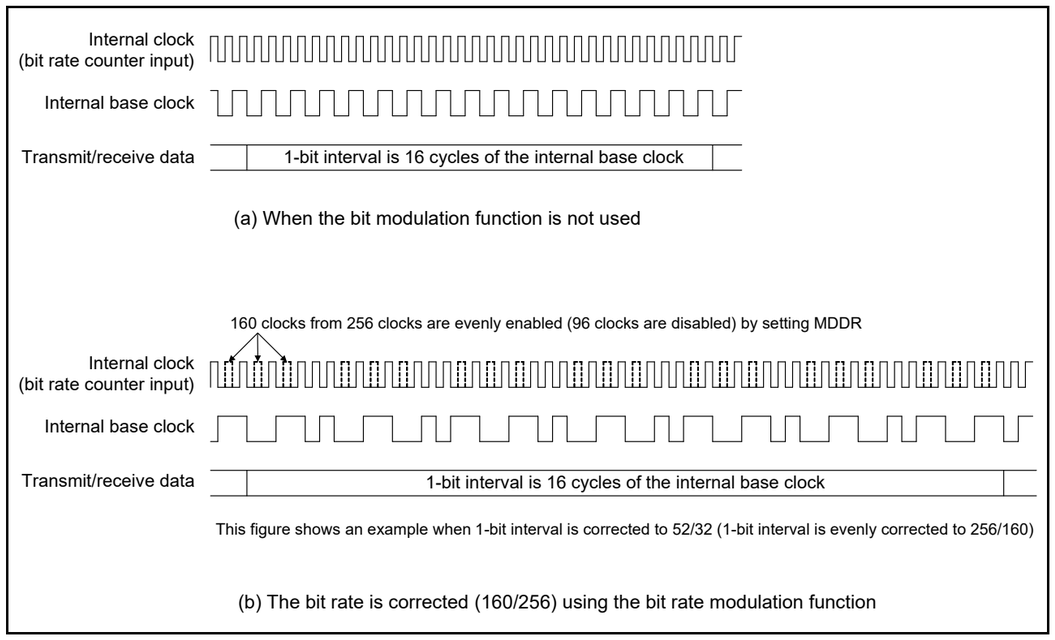

Figure 34.71 Example internal base clock when bit rate modulation function is used

34.10 Interrupt Sources

34.10.1 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (non-FIFO selected)

If the conditions for an SCIn_TXI and SCIn_RXI interrupt are satisfied while the interrupt status flag in the Interrupt Controller Unit (ICU) is 1, the ICU does not output the interrupt request but retains it internally (with a capacity for retention of one request per source).

When the interrupt status flag in the ICU is set to 0, the interrupt request retained within the ICU is output. The internally retained interrupt request is automatically discarded when the actual interrupt is output. Clearing of the associated interrupt enable bit (the TIE or RIE bit in the SCR/SCR_SMCI) can also be used to discard an internally retained interrupt request.

34.10.2 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (FIFO selected)

Even when an interrupt status flag in the ICU is set to 1, the SCIn_TXI and SCIn_RXI interrupts do not output interrupt requests to the ICU. When an interrupt status flag of the ICU is cleared to 0, and if the conditions for an SCIn_TXI and SCIn_RXI interrupts are satisfied, an interrupt request is generated.

34.10.3 Interrupts in Asynchronous, Clock Synchronous, and Simple SPI Modes

(1) Non-FIFO selected

Table 34.26 lists interrupt sources in asynchronous mode, clock synchronous mode, and simple SPI mode. A different interrupt vector can be assigned to each interrupt source. Individual interrupt sources can be enabled or disabled with the

Note: 启用内部时钟会导致偏差，并且会在内部基本时钟的脉冲宽度中产生扩展和收缩。

不要在时钟同步模式和简单SPI模式的最高速度设置（SMR.CKS[1:0]=00b，SCR.CKE[1]=0和BRR=0）中使用此功能。

34.10 中断源

34.10.1 SCIn_TXI和SCIn_RXI中断的缓冲区操作（选择非FIFO）

如果满足SCIn_TXI和SCIn_RXI中断的条件，同时中断中的中断状态标志控制器单元(ICU)为1，ICU不输出中断请求，而是在内部保留它（每个源可以保留一个请求）。

当ICU中的中断状态标志设置为0时，输出ICU中保留的中断请求。当实际中断输出时，内部保留的中断请求会被自动丢弃。清除相关中断使能位（SCRSCR_SMCI中的TIE或RIE位）也可用于丢弃内部保留的中断请求。

34.10.2 SCIn_TXI和SCIn_RXI中断的缓冲区操作（选择FIFO）

即使ICU中的中断状态标志设置为1，SCIn_TXI和SCIn_RXI中断也不会向ICU输出中断请求。当ICU的中断状态标志清为0时，如果满足SCIn_TXI和SCIn_RXI中断的条件，则产生中断请求。

34.10.3 异步、时钟同步和简单SPI模式下的中断

(1) Non-FIFO selected

表34.26列出了异步模式、时钟同步模式和简单SPI模式下的中断源。可以为每个中断源分配不同的中断向量。个别中断源可以启用或禁用与

enable bits in the SCR register.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when transmit data is transferred from the TDR or TDRHL register*1 to the TSR register. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TE and SCR.TIE bits to 1 at the same time. An SCIn_TXI interrupt request can activate the DTC or DMAC to handle data transfer.

An SCIn_TXI interrupt request is not generated by setting the SCR.TE bit to 1 when SCR.TIE is 0 or by setting the SCR.TIE bit to 1 when the SCR.TE is 1.*2

When new data is not written by the time of transmission of the last bit of the current transmit data and SCR.TEIE is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated. Additionally, when SCR.TE is 1, the SSR.TEND flag retains the value 1 until more transmit data is written to the TDR or TDRHL register*1, and setting SCR.TEIE to 1 leads to the generation of an SCIn_TEI interrupt request.

Writing data to the TDR or TDRHL register*1 leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the SCIn_TEI interrupt request.

If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated when received data is stored in the RDR register. An SCIn_RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting any of the ORER, FER, and PER flags in the SSR register to 1 while the SCR.RIE bit is 1 leads to the generation of an SCIn_ERI interrupt request. An SCIn_RXI interrupt request is not generated at this time. Clearing all three flags (ORER, FER, and PER) leads to discarding of the SCIn_ERI interrupt request.

(2) FIFO selected

Table 34.27 lists interrupt sources in FIFO selected mode.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when the stored amount of data in the FTDRL register becomes the threshold value indicated in FCR.TTRG or below. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TE and SCR.TIE bits to 1 at the same time.

An SCIn_TXI interrupt request is not generated by setting SCR.TE to 1 when SCR.TIE is 0 or by setting SCR.TIE to 1 when SCR.TE is 1.

If SCR.TEIE is 1 and if the next data is not written to the FTDRL register by the time the last bit of the transmit data is sent, the SSR_FIFO.TEND flag is set to 1 and the SCIn_TEI interrupt request is generated.

If SCR.RIE is 1, the SCIn_RXI interrupt request is generated when the stored amount of data in the FRDRL register is equal to or greater than the threshold value indicated in FCR.RTRG. When RTRG is 0, an SCIn_RXI interrupt does not occur even when the amount of data in the receive FIFO is equal to 0.

If the SCR.RIE bit is 1, when the SSR_FIFO.ORER flag is set to 1 or data with a framing error or a parity error is stored in the FRDRL register, the SCIn_ERI interrupt request is generated. When the amount of data stored in the FRDRL register is at the threshold value or above, the SCIn_RXI interrupt request is also generated. The SCIn_ERI interrupt request can be canceled, in which case SSR_FIFO.ORER, FER, and PER flags are all cleared.

Note 1. When asynchronous mode and 9-bit data length are selected.
Note 2. To temporarily prohibit SCIn_TXI interrupts on transmission of the last of the data when a new round of transmission is to be started, after handling the transmission-completed interrupt, control activation of the interrupt by using the interrupt request enable bit in the ICU rather than using the SCR.TIE bit. This approach can prevent the suppression of SCIn_TXI interrupt requests in the transfer of new data.

SCR寄存器中的使能位。

如果SCR.TIE位为1，则当发送数据从TDR传输或
TDRHL寄存器*1到TSR寄存器。也可以使用一条指令同时将SCR.TE和SCR.TIE位设置为1，从而产生SCIn_TXI中断请求。SCIn_TXI中断请求可以激活DTC或DMAC来处理数据传输。

当SCR.TIE为0时将SCR.TE位设置为1或通过设置
当SCR.TE为1时，SCR.TIE位为1。*2

当当前发送数据的最后一位发送时没有写入新数据且SCR.TEIE为1，则SSR.TEND标志设置为1，并产生SCIn_TEI中断请求。此外，当SCR.TE为1时，SSR.TEND标志保持值1，直到更多发送数据写入TDR或TDRHL寄存器*1，并设置

SCR.TEIE为1导致产生SCIn_TEI中断请求。

将数据写入TDR或TDRHL寄存器*1会导致SSR.TEND标志清零，并在一定时间后丢弃SCIn_TEI中断请求。

如果SCR.RIE位为1，则当接收到的数据存储在RDR寄存器中时会产生SCIn_RXI中断请求。一个SCIn_RXI中断请求可以激活DTC或DMAC来处理数据传输。

当SCR.RIE位为1时，将SSR寄存器中的任何ORER、FER和PER标志设置为1会导致产生SCIn_ERI中断请求。此时不产生SCIn_RXI中断请求。清除所有三个标志（ORER、FER和PER）会导致丢弃SCIn_ERI中断请求。

(2) FIFO selected

表34.27列出了FIFO选择模式下的中断源。

如果SCR.TIE位为1，当FTDRL寄存器中存储的数据量变为FCR.TTRG中指示的阈值或更低时，将产生SCIn_TXI中断请求。也可以使用一条指令同时将SCR.TE和SCR.TIE位设置为1，从而产生SCIn_TXI中断请求。

当SCR.TIE为0时将SCR.TE设置为1，或者当SCR.TE为1时将SCR.TIE设置为1，不会产生SCIn_TXI中断请求。

如果SCR.TEIE为1，并且在发送数据的最后一位时下一个数据未写入FTDRL寄存器，则SSR_FIFO.TEND标志设置为1，并产生SCIn_TEI中断请求。

如果SCR.RIE为1，则当FRDRL寄存器中存储的数据量等于或大于FCR.RTRG中指示的阈值时，将产生SCIn_RXI中断请求。当RTRG为0时，即使接收FIFO中的数据量等于0，也不会发生SCIn_RXI中断。

如果SCR.RIE位为1，当SSR_FIFO.ORER标志设置为1或帧错误或奇偶校验错误的数据存储在FRDRL寄存器中时，将产生SCIn_ERI中断请求。当FRDRL寄存器中存储的数据量在阈值或以上时，也会产生SCIn_RXI中断请求。SCIn_ERI中断请求可以被取消，在这种情况下SSR_FIFO.ORER、FER和PER标志都被清除。

注意1.选择异步模式和9位数据长度时。
注2.为了在新一轮传输开始时，在传输最后一个数据时暂时禁止SCIn_TXI中断，在处理完传输完成中断后，使用ICU中的中断请求使能位控制中断的激活而不是使用SCR.TIE位。这种方法可以防止在传输新数据时抑制SCIn_TXI中断请求。

34.10.4 Interrupts in Smart Card Interface Mode

Table 34.28 lists interrupt sources in smart card interface mode. A transmit end interrupt (SCIn_TEI) request and an address match (SCIn_AM) request cannot be used in this mode.

Table 34.28 SCI Interrupt sources

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC activation	DMAC activation
SCIn_ERI	Receive error or error signal detection	ORER, FER, ERS	RIE	Not possible	Not possible
SCIn_RXI	Receive data full	RDRF	RIE	Possible	Possible
SCIn_TXI	Transmit end	TEND	TIE	Possible	Possible

Data transmission or reception using the DTC or DMAC is also possible in smart card interface mode. In transmission, when the SSR_SMCI.TEND flag is set to 1, an SCIn_TXI interrupt request is generated. This SCIn_TXI interrupt request activates the DTC or DMAC, allowing transfer of transmit data if the SCIn_TXI request is previously specified as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission after an error occurrence. However, the SSR_SMCI.ERS flag is not automatically cleared to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the SCR_SMCI.RIE bit to 1 to enable an SCIn_ERI interrupt request to be generated at error occurrence.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings. For DTC or DMAC settings, see section 17, DMA Controller (DMAC) and section 18, Data Transfer Controller (DTC).

In reception, an SCIn_RXI interrupt request is generated when receive data is set to the RDR register. This SCIn_RXI interrupt request activates the DTC or DMAC, allowing transfer of the receive data if the SCIn_RXI request is previously specified as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an SCIn_ERI interrupt request is issued to the CPU instead. The error flag must be cleared.

34.10.4 智能卡接口模式中的中断

表34.28列出了智能卡接口模式下的中断源。在此模式下不能使用发送结束中断(SCIn_TEI)请求和地址匹配(SCIn_AM)请求。

Table 34.28 SCI中断源

Name	中断源	中断标志	中断使能	DTC activation	DMAC activation

SCIn_RXI	接收数据已满	RDRF	RIE	Possible	Possible
SCIn_TXI	发射端	TEND	TIE	Possible	Possible

在智能卡接口模式下也可以使用DTC或DMAC进行数据传输或接收。在发送过程中，当SSR_SMCI.TEND标志设置为1时，会产生一个SCIn_TXI中断请求。该SCIn_TXI中断请求激活DTC或DMAC，如果之前将SCIn_TXI请求指定为DTC或DMAC激活源，则允许传输数据。当DTC或DMAC传输数据时，TEND标志自动设置为0。

如果发生错误，SCI会自动重新传输相同的数据。在重传期间，TEND标志保持为0，并且DTC或DMAC不被激活。因此，SCI和DTC或DMAC会自动传输指定的字节数，包括发生错误后的重传。但是，发生错误时，SSR_SMCI.ERS标志不会自动清除为0。因此，必须通过预先将SCR_SMCI.RIE位设置为1来清除ERS 标志，以在发生错误时启用SCIn_ERI中断请求。

使用DTC或DMAC发送或接收数据时，请务必在进行SCI设置之前启用DTC或DMAC。有关DTC或DMAC设置，请参阅第17节，DMA控制器(DMAC)和第18节，数据传输控制器(DTC)。

在接收中，当接收数据设置到RDR寄存器时，会产生SCIn_RXI中断请求。该SCIn_RXI中断请求激活DTC或DMAC，如果先前将SCIn_RXI请求指定为DTC或DMAC激活源，则允许传输接收数据。如果发生错误，则设置错误标志。因此，不会激活DTC或DMAC，而是向CPU发出SCIn_ERI中断请求。必须清除错误标志。

34.10.5 Interrupts in Simple IIC Mode

Table 34.29 lists the interrupt sources in simple IIC mode. The STI interrupt is allocated to the transmit end interrupt (SCIn_TEI) request. The receive error interrupt (SCIn_ERI) and the address match (SCIn_AM) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple IIC mode.

When the SIMR2.IICINTM bit is 1:

- An SCIn_RXI request is generated on the falling edge of the SCLn signal for the 8th bit. If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.
- An SCIn_TXI request is generated on the falling edge of the SCLn signal for the 9th bit (acknowledge bit). If SCIn_TXI is previously set up as an activation source for the DTC or DMAC, the SCIn_TXI request activates the DTC or DMAC to handle transfer of the transmit data.

When the SIMR2.IICINTM bit is 0:

- An SCIn_RXI request (ACK detection) is generated if the input on the SDAn pin is low on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- An SCIn_TXI request (NACK detection) is generated if the input on the SDAn pin is high on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.

If the DTC or DMAC is used for data transfer in reception or transmission, always set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in SIMR3 are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

SCIn_TXI	Transmission, NACK detection	—	TIE	Possible	Possible
STIn	Completion of generation of a start, restart, or stop condition	IICSTIF	TEIE	Not possible	Not possible

Note 1. Activation of the DTC is only possible when the SIMR2.IICINTM bit is 1 (use reception and transmission interrupts).

34.11 Event Linking

By using interrupt request signals as event signals, the SCI can provide linked operation through the ELC for modules selected in advance.

Event signals can be output regardless of the values of the associated interrupt request enable bits.

(1) Error event output (receive error or error signal detected)

- Indicates abnormal termination because of a parity error during reception in asynchronous mode
- Indicates abnormal termination because of a framing error during reception in asynchronous mode
- Indicates abnormal termination because of an overrun error during reception
- Indicates detection of the error signal during transmission in smart card interface mode
- The SSR_FIFO.FER and PER flags are 0, and receive data less than the receive FIFO data trigger number is set in a reception FIFO buffer, and it indicates that 15 ETUs elapse when FIFO is selected and the FCR.DRES bit is 1.

34.10.5 简单IIC模式下的中断

表34.29列出了简单IIC模式下的中断源。STI中断分配给发送结束中断(SCIn_TEI)请求。不能使用接收错误中断(SCIn_ERI)和地址匹配(SCIn_AM)请求。

DTC或DMAC也可用于处理简单IIC模式下的传输。

当SIMR2.IICINTM位为1时：

- SCIn_RXI请求在第8位的SCLn信号的下降沿产生。如果SCIn_RXI先前设置为DTC或DMAC的激活源，则SCIn_RXI请求将激活DTC或DMAC以处理接收数据的传输。
- SCIn_TXI请求在第9位（确认位）的SCLn信号的下降沿生成。如果SCIn_TXI先前设置为DTC或DMAC的激活源，SCIn_TXI请求激活DTC或DMAC来处理传输数据的传输。

当SIMR2.IICINTM位为0时：

- 如果SDAn引脚上的输入在第9位的SCLn信号（确认位）
- 如果SDAn引脚上的输入在第9位的SCLn信号（确认位）
- 如果SCIn_RXI先前设置为DTC或DMAC的激活源，则SCIn_RXI请求会激活DTC或DMAC处理接收数据的传输。

如果DTC或DMAC用于接收或传输中的数据传输，请务必在设置SCI之前设置并启用DTC或DMAC。

当SIMR3中的IICSTAREQ、IICRSTAREQ和IICSTPREQ位用于生成开始条件、重新启动条件或停止条件时，生成完成时会发出STI请求。

34.11 事件链接

通过使用中断请求信号作为事件信号，SCI可以通过ELC为预先选择的模块提供联动操作。

无论相关中断请求使能位的值如何，都可以输出事件信号。

(1) 错误事件输出（接收错误或检测到错误信号）

- 表示在异步模式下接收期间由于奇偶校验错误而异常终止
- 指示在异步模式下接收期间由于帧错误而异常终止
- 表示接收期间由于溢出错误而异常终止
- 指示在智能卡接口模式下传输期间检测到错误信号
- ssr_fifo.fer和每个标志为0，并且接收数据小于接收FIFO数据触发器编号在接收FIFO缓冲区中设置，这表明选择FIFO时15ETUSETALESE，而FCR.DRES位为1。

(2) Receive data full event output

- Indicates that ACK is detected if the SIMR2.IICINTM bit is 0 in simple IIC mode
- Indicates that the 8th-bit SCLn falling edge is detected if the SIMR2.IICINTM bit is 1 in simple IIC mode
- When the SIMR2.IICINTM bit is 1 during master transmission in simple IIC mode, set the ELC so that receive data full events are not used.

(a) Non-FIFO selected

- Indicates that received data is set in the Receive Data Register (RDR or RDRHL).

(b) FIFO selected

- Using this event output is prohibited.

(3) Transmit data empty event output

- Indicates that the SCR/SCR_SMCI.TE bit is changed from 0 to 1
- Indicates that transmission is complete in smart card interface mode
- Indicates that NACK is detected if the SIMR2.IICINTM bit is 0 in simple IIC mode
- Indicates that the 9th-bit SCLn falling edge is detected if the SIMR2.IICINTM bit is 1 in simple IIC mode.

(a) Non-FIFO selected

- Indicates that transmit data is transferred from the Transmit Data Register (TDR or TDRHL) to the Transmit Shift Register (TSR).

(b) FIFO selected

- Using this event output is prohibited.

(4) Transmit end event output

- Indicates the completion of transmission
- Indicates that the starting condition, resumption condition, or termination condition is generated in simple IIC mode
- When FIFO is selected, using this event output is prohibited.

(5) Address match event output

- Indicates a match of the comparison data (CDR.CMPD) with one frame of receive data when DCCR.DCME is set to 1 in asynchronous mode, including multi-processor mode.

34.12 Address Mismatch Event Output (SCI0_DCUF)

SCI0_DCUF indicates the mismatch of comparison data (CDR.CMPD) with one frame of receive data when DCCR.DCME is set to 1 in asynchronous mode, including multi-processor mode. This event can be used for Snooze end request only.

34.13 Noise Cancellation Function

Figure 34.72 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a 2-stage flip-flop circuit and a match detection circuit. When the input signals of the noise filter and the output signals of the 2-stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. When the same level is retained for 3 cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for 3 cycles or shorter is considered as noise, not as a receive signal.

When SEMR.ABCS = 0 and SEMR.ABCSE = 0, the cycle is 1/16 the period of 1 transfer bit.

When SEMR.ABCS = 1 and SEMR.ABCSE = 0, the cycle is 1/8 the period of 1 transfer bit.

When SEMR.ABCSE = 1, the cycle is 1/6 the period of 1 transfer bit.

(2) 接收数据满事件输出

- 如果SIMR2.IICINTM位在简单IIC模式下为0，则表示检测到ACK
- 表示如果SIMR2.IICINTM位在简单IIC模式下为1，则检测到第8位SCLn下降沿
- 当SIMR2.IICINTM位在简单IIC模式下主机发送期间为1时，设置ELC以便不使用接收数据满事件。

(a) Non-FIFO selected

- 表示接收数据设置在接收数据寄存器（RDR或RDRHL）中。

(b) FIFO selected

- 禁止使用此事件输出。

(3) 传输数据空事件输出

- 表示SCRSCR_SMCI.TE位由0变为1
- 表示在智能卡接口模式下传输完成
- 如果SIMR2.IICINTM位在简单IIC模式下为0，则表示检测到NACK
- 表示如果SIMR2.IICINTM位在简单IIC模式下为1，则检测到第9位SCLn下降沿。

(a) Non-FIFO selected

- 表示发送数据从发送数据寄存器（TDR或TDRHL）传输到发送移位 Register (TSR).

(b) FIFO selected

- 禁止使用此事件输出。

(4) 发送结束事件输出

- 表示传输完成
- 指示在简单IIC模式下生成启动条件、恢复条件或终止条件
- 选择FIFO时，禁止使用该事件输出。

(5) 地址匹配事件输出

- 当DCCR.DCME在异步模式（包括多处理器模式）下设置为1时，表示比较数据(CDR.CMPD)与一帧接收数据的匹配。

34.12 地址不匹配事件输出(SCI0_DCUF)

SCI0_DCUF表示比较数据（CDR.CMPD）与一帧接收数据不匹配时
DCCR.DCME在异步模式下设置为1，包括多处理器模式。此事件仅可用于贪睡结束请求。

34.13 降噪功能

图34.72显示了用于噪声消除的噪声滤波器的配置。噪声滤波器由一个2级触发器电路和一个匹配检测电路组成。当噪声滤波器的输入信号和2级触发器电路的输出信号完全匹配时，匹配的电平作为内部信号传送。除非另有匹配，否则将保留先前的值。当相同电平在噪声滤波器的采样时钟上保持3个周期或更长时间时，它被认为是有效的接收信号。3个周期或更短的脉冲变化被认为是噪声，而不是接收信号。

当SEMR.ABCS=0且SEMR.ABCSE=0时，周期为1161个传输位的周期。

当SEMR.ABCS=1和SEMR.ABCSE=0时，周期为181个传输位的周期。

当SEMR.ABCSE=1时，周期为161个传输位的周期。

In asynchronous mode, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The receive level of the RXDn is taken in the flip-flop circuit of the noise filter on the base clock of asynchronous mode.

In simple IIC mode, this function can be used for each input on SDAn and SCLn. The sampling clock for the noise cancellation function is selected in the SNFR.NFCS bit by dividing the baud rate generator source clock by 1, 2, 4, or 8.

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR.TE and SCR.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, the function determines that a level match is detected and the result is conveyed as an internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles.

34.14 Usage Notes

34.14.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable SCI operation. The SCI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

34.14.2 SCI Operation during Low Power State

(1) Transmission

When setting the module to the stopped state or in transitions to Software Standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR/SCR_SMCI to 0) after switching the TXDn pin to the general I/O port pin function. When setting I/O port as an SCI connection, the SPTR register can control the state of the TXDn pin. Setting the TE bit to 0 initializes the TSR register and the TEND bit in the SSR/SSR_SMCI is initialized to 1 with non-FIFO selected. The value is saved with FIFO selected. Depending on the port settings and SPTR register settings, output pins might output the level before a transition to the low power state is made after release from the module-stop state or Software Standby mode. When transitions to these states are made during transmission, the transmitted data becomes indeterminate.

To transmit data in the same transmission mode after cancellation of the low power state:

1. Set the TE bit to 1.
2. Read SSR/SSR_FIFO/SSR_SMCI.
3. Write data to TDR sequentially to start data transmission.

在异步模式下，可以对输入到RXDn引脚的接收信号应用噪声消除功能。RXDn的接收电平是在异步模式的基本时钟上的噪声滤波器的触发器电路中获取的。

在简单IIC模式下，该功能可用于SDAn和SCLn上的每个输入。通过将波特率发生器源时钟除以1、2、4或8，在SNFR.NFCS位中选择噪声消除功能的采样时钟。

如果在启用噪声滤波器的情况下基准时钟停止一次，然后再次重新启动基准时钟输入，则噪声滤波器操作将从时钟停止的状态恢复。当SCR.TE和SCR.RE在基本时钟输入期间设置为0时，所有噪声滤波器触发器值都被初始化为1。因此，如果在接收操作恢复时输入数据为1，则该函数确定一个电平检测到匹配并将结果作为内部信号传送。当输入的电平对应于0时，保留噪声滤波器的初始输出，直到电平在三个连续的采样周期中匹配。

34.14 使用说明

34.14.1 模块停止功能的设置

模块停止控制寄存器B(MSTPCRB)可以启用或禁用SCI操作。SCI在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第11节，低功耗模式。

34.14.2 低功耗状态下的SCI操作

(1) Transmission

将模块设置为停止状态或转换到软件待机时，在将TXDn引脚切换到通用IO端口引脚功能后停止操作（通过将SCRSCR_SMCI中的TIE、TE和TEIE位设置为0）。当设置IO端口为SCI连接时，SPTR寄存器可以控制TXDn引脚的状态。将TE位设置为0会初始化TSR寄存器，并且SSRSSR_SMCI中的TEND位会在选择非FIFO时初始化为1。该值在选择FIFO的情况下保存。根据端口设置和SPTR寄存器设置，输出引脚可能会在从模块停止状态或软件待机模式释放后转换到低功耗状态之前输出电平。在传输过程中转换到这些状态时，传输的数据变得不确定。

在取消低功耗状态后以相同的传输模式传输数据：

1. 将TE位设置为1。
2. Read SSR/SSR_FIFO/SSR_SMCI.
3. 将数据顺序写入TDR以开始数据传输。

To transmit data with a different transmission mode, initialize the SCI first.

Figure 34.73 shows an example flow of transition to Software Standby mode during transmission. Figure 34.74 and Figure 34.75 show the port pin states during transition to Software Standby mode.

Before specifying the module-stop state or making a transition to Software Standby mode from the transmission mode using DTC transfer, stop the transmit operations (TE = 0). To start transmission after cancellation using the DTC, set the TE bit to 1. The SCIn_TXI interrupt flag is set to 1 and transmission starts using the DTC.

(2) Reception

(a) When address match function is not used as wakeup condition

Before specifying the module-stop state or making a transition to Software Standby mode, stop the receive operations (RE = 0 in SCR/SCR_SMCI). If transition is made during data reception, the received data is invalid.

Figure 34.76 shows an example flow of transition to Software Standby mode during reception.

(b) When address match function is used as wakeup condition

Before specifying the module-stop state or making a transition to Software Standby mode:

1. Set the operations after cancellation of the low power state.
2. Set CDR.CMPD and DCCR.DCME to 1.
3. Set the receive operations (RE = 1 in SCR/SCR_SMCI).
4. Set the module-stop state or Software Standby mode.

When SCI transfers to low power mode, if the receive data pin (RXD) is at the low level, set SEMR.RXDESEL = 0. When setting SEMR.RXDESEL = 1, there is a possibility that a start bit (falling edge of RXDn pin) cannot be detected on release of the low power mode.

Figure 34.77 shows an example flow of transition to Software Standby mode during reception with address match.

(c) When using SCI0 in Snooze mode

When using SCI0 in Snooze mode, some restrictions apply, including maximum bit rates. For details, see section 11, Low Power Modes.

要以不同的传输模式传输数据，请先初始化SCI。

图34.73显示了传输期间转换到软件待机模式的示例流程。图34.74和
图34.75显示了转换到软件待机模式期间的端口引脚状态。

在使用DTC传输指定模块停止状态或从传输模式转换到软件待机模式之前，请停止传输操作(TE=0)。要在使用DTC取消后开始发送，请将TE位设置为1。SCIn_TXI中断标志 设置为1并使用DTC开始发送。

(2) Reception

(a) 当地址匹配功能不用作唤醒条件时

在指定模块停止状态或转换到软件待机模式之前，停止接收操作（SCRSCR_SMCI中的RE=0）。如果在数据接收期间进行转换，则接收到的数据无效。

图34.76显示了接收期间转换到软件待机模式的示例流程。

(b) 当地址匹配功能用作唤醒条件时

在指定模块停止状态或转换到软件待机模式之前：

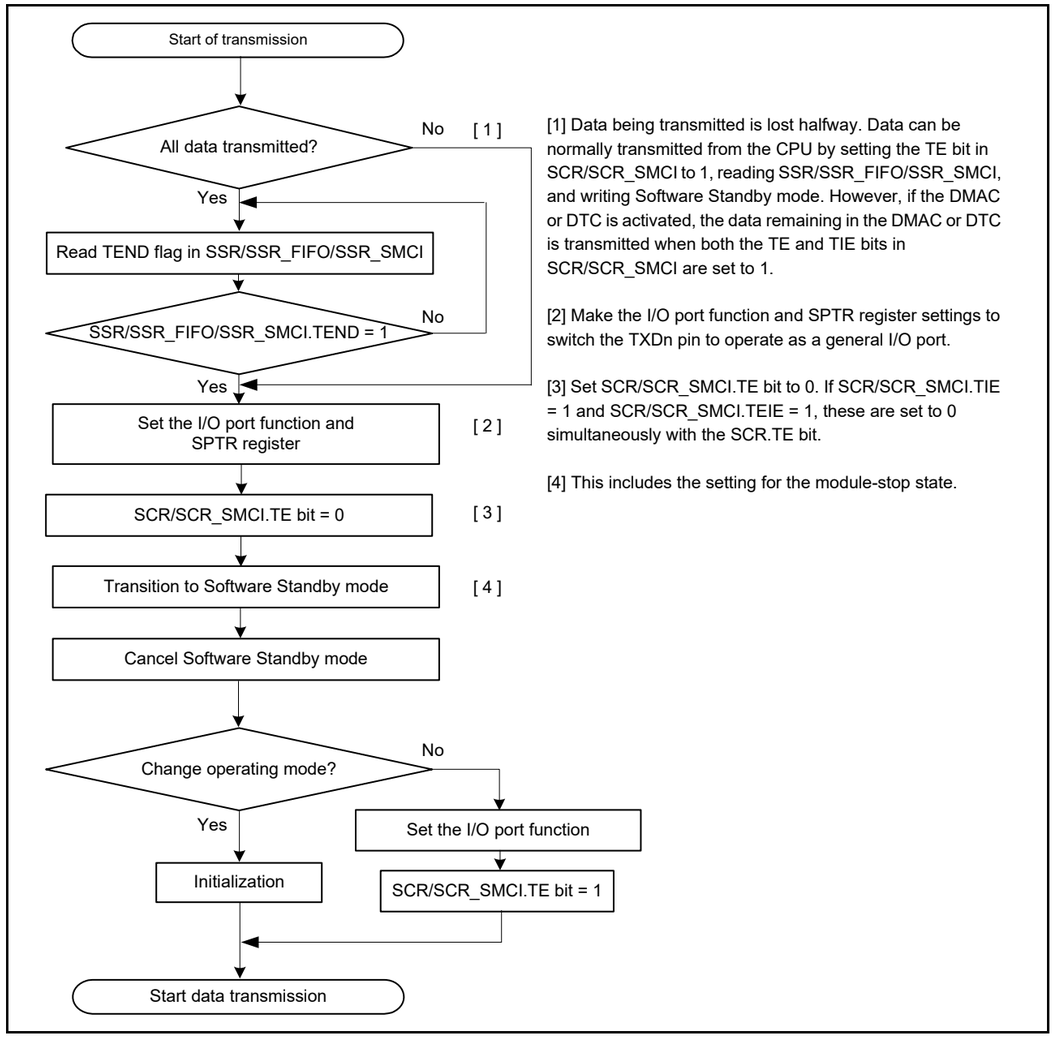
1. 设置取消低功耗状态后的操作。
2. 将CDR.CMPD和DCCR.DCME设置为1。
3. 设置接收操作（在SCRSCR_SMCI中RE=1）。
4. 设置模块停止状态或软件待机模式。

当SCI转移到低功耗模式时，如果接收数据引脚(RXD)为低电平，则设置SEMR.RXDESEL=0。
当设置SEMR.RXDESEL=1时，在解除低功耗模式时可能无法检测到起始位（RXDn引脚的下降沿）。

图34.77显示了在地址匹配的接收期间转换到软件待机模式的示例流程。

(c) 在贪睡模式下使用SCI0时

在贪睡模式下使用SCI0时，有一些限制，包括最大比特率。有关详细信息，请参阅第11节，低功耗模式。



[1] Data being transmitted is lost halfway. Data can be normally transmitted from the CPU by setting the TE bit in SCR/SCR_SMCI to 1, reading SSR/SSR_FIFO/SSR_SMCI, and writing Software Standby mode. However, if the DMAC or DTC is activated, the data remaining in the DMAC or DTC is transmitted when both the TE and TIE bits in SCR/SCR_SMCI are set to 1.

[2] Make the I/O port function and SPTR register settings to switch the TXDn pin to operate as a general I/O port.

[3] Set SCR/SCR_SMCI.TE bit to 0. If SCR/SCR_SMCI.TIE = 1 and SCR/SCR_SMCI.TEIE = 1, these are set to 0 simultaneously with the SCR.TE bit.

[4] This includes the setting for the module-stop state.

[2]进行IO端口功能和SPTR寄存器设置以切换TXDn引脚作为通用IO端口操作。

34.14.3 Break Detection and Processing

(1) Non-FIFO selected

When a framing error is detected, a break can be detected by reading the RXDn pin value directly. In a break, the input from the RXDn pin becomes all 0s, and the SSR.FER flag is set to 1 to indicate a framing error, and the SSR.PER flag might also be set to 1 to indicate a parity error. The SCI continues the receive operation even after a break is received. Therefore, even if the FER flag is 0, indicating that no framing error occurred, it is set to 1 again. When the SEMR.RXDESEL bit is 1, the SCI sets the SSR.FER flag to 1 and stops receiving operations until a start bit of the next data frame is detected. If the SSR.FER flag is set to 0, the SSR.FER flag retains 0 during the break.

When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit on the first falling edge of the

[2]包括模块停止状态的设置。

Figure 34.77 在地址匹配的接收期间转换到软件待机模式的示例流程

34.14.3 断裂检测和处理

(1) Non-FIFO selected

当检测到帧错误时，可以通过直接读取RXDn引脚值来检测中断。在中断时，来自RXDn引脚的输入变为全0，并且SSR.FER标志设置为1表示帧错误，SSR.PER标志也可能设置为1表示奇偶校验错误。即使在收到中断后，SCI仍继续接收操作。因此，即使FER标志为0，表示没有发生帧错误，它也会再次设置为1。当。。。的时候

SEMR.RXDESEL位为1，SCI将SSR.FER标志设置为1，并停止接收操作，直到检测到下一个数据帧的起始位。如果SSR.FER标志设置为0，则SSR.FER标志在中断期间保持0。

当RXDn引脚设置为1且中断结束时，在第一个下降沿检测起始位的开始

RXDn pin allows the SCI to start the receiving operation.

(2) FIFO selected

After a framing error is detected and when the SCI detects that continuous receive data is 0 for 1 frame, reception stops. When a framing error is detected, a break can be detected by reading the SPTR.RXDMON bit value. After the RXD signal is in the mark state and the break is finished, data reception to the FRDRHL register resumes.

34.14.4 Mark State and Production of Breaks

When the SCR/SCR_SMCI.TE bit is 0, disabling serial transmission, the state of the TXDn pin can be set using the SPTR.SPB2IO and SPTR.SPB2DT bits. With this approach, a TXDn pin can be placed in the mark state to transmit a break.

Before setting the SCR/SCR_SMCI.TE bit to 1, enabling serial transmission, set the SPB2IO and SPB2DT bits to put the communication line in the mark state (the state of 1), and change the TxDn pin using I/O port function. To output a break on data transmission, after setting the TXDn pin to output 0 by setting the SPB2IO and SPB2DT bits, change the TXDn pin using the I/O port function and set the SCR/SCR_SMCI.TE bit to 0. When the SCR/SCR_SMCI.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

34.14.5 Receive Error Flags and Transmit Operation in Clock Synchronous and Simple SPI Modes

Transmission cannot start when a receive error flag (ORER) in SSR/SSR_FIFO is set to 1, even when data is written to TDR or FTDRL*2. Always set the receive error flags to 0 before starting transmission.

Note 1. The receive error flags cannot be set to 0 when serial reception is disabled by setting the RE bit in SCR/SCR_SMCI to 0.
Note 2. Do not use the FTDRH register in simple SPI mode.

34.14.6 Restrictions on Clock Synchronous Transmission in Clock Synchronous and Simple SPI Modes

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

Wait at least the following time from writing transmit data to TDR to the start of the external clock input:
1 PCLKA cycle + data output delay time for the slave (t_{DO}) + setup time for the master (t_{SU}). See Figure 34.78.

(2) Continuous transmission

Write the next transmit data to TDR or TDRHL before the falling edge of the transmit clock for bit [7] (see Figure 34.78).

When updating TDR after bit [7] has started to transmit, update TDR while the synchronization clock is in the low-level period, and set the high-level width of the transmit clock (bit [7]) to 4 PCLKA cycles or longer (see Figure 34.78).

RXDn引脚允许SCI开始接收操作。

(2) FIFO selected

检测到帧错误后，当SCI检测到1帧连续接收数据为0时，接收停止。
当检测到帧错误时，可以通过读取SPTR.RXDMON位的值来检测中断。在RXD信号处于标记状态且中断完成后，FRDRHL寄存器的数据接收恢复。

34.14.4 标记状态和产生的中断

当SCRSCR_SMCI.TE位为0时，禁用串行传输，TXDn引脚的状态可以使用SPTR.SPB2IO和SPTR.SPB2DT位。使用这种方法，可以将TXDn引脚置于标记状态以发送中断。

在设置SCRSCR_SMCI.TE位为1，使能串行传输之前，设置SPB2IO和SPB2DT位使通信线处于标记状态（状态为1），并使用IO端口功能更改TxDn引脚。要输出数据传输中断，通过设置SPB2IO和SPB2DT位将TXDn引脚设置为输出0后，使用IO端口功能更改TXDn引脚并将SCRSCR_SMCI.TE位设置为0。当SCRSCR_SMCI.TE位设置为0，无论当前的传输状态如何，都初始化发送器。

34.14.5 在时钟同步和简单的接收错误标志和发送操作 SPI模式

当SSRSSR_FIFO中的接收错误标志(ORER)设置为1时，传输无法开始，即使数据已写入TDR或FTDRL*2。在开始传输之前，始终将接收错误标志设置为0。

注1.当通过设置RE位禁用串行接收时，接收错误标志不能设置为0 SCR/SCR_SMCI to 0.
注2.不要在简单SPI模式下使用FTDRH寄存器。

34.14.6 时钟同步和时钟同步传输的限制 简单的SPI模式

当外部时钟源用作同步时钟时，有以下限制。

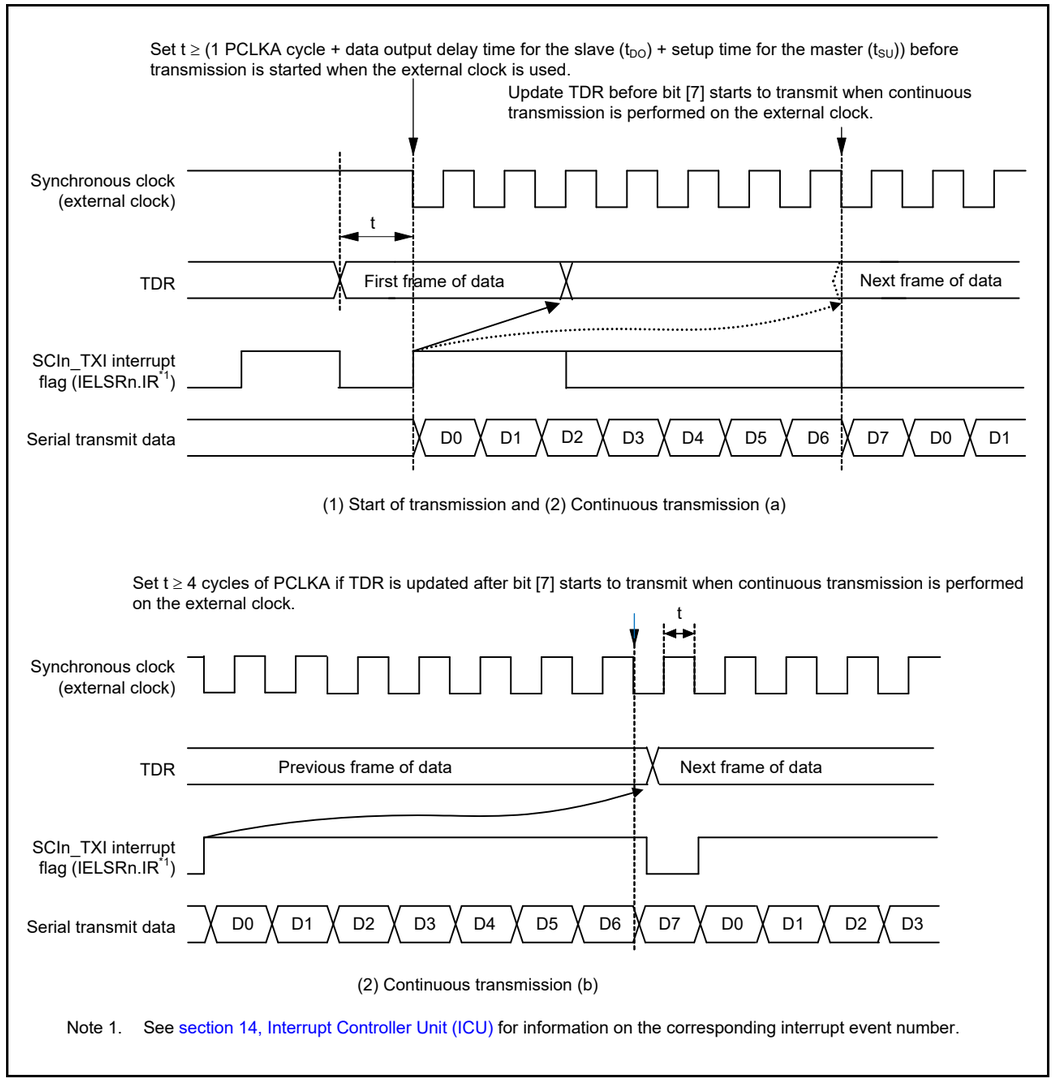
(1) 传输开始

从将发送数据写入TDR到开始外部时钟输入，至少等待以下时间：1个PCLKA周期+从设备的数据输出延迟时间(tDO)+主设备的建立时间(tSU)。请参见图34.78。

(2) 连续传输

在位[7]的发送时钟下降沿之前将下一个发送数据写入TDR或TDRHL（参见图34.78）。

在bit[7]开始发送后更新TDR时，在同步时钟处于低电平期间更新TDR，并将发送时钟（bit[7]）的高电平宽度设置为4个PCLKA周期或更长（见图34.78）。



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.78 Restrictions on use of external clock in clock synchronous transmission

34.14.7 Restrictions on Using DMAC or DTC

During transmission or reception operations using the DMAC or DTC, do not set transfer data for the DMAC/DTC.

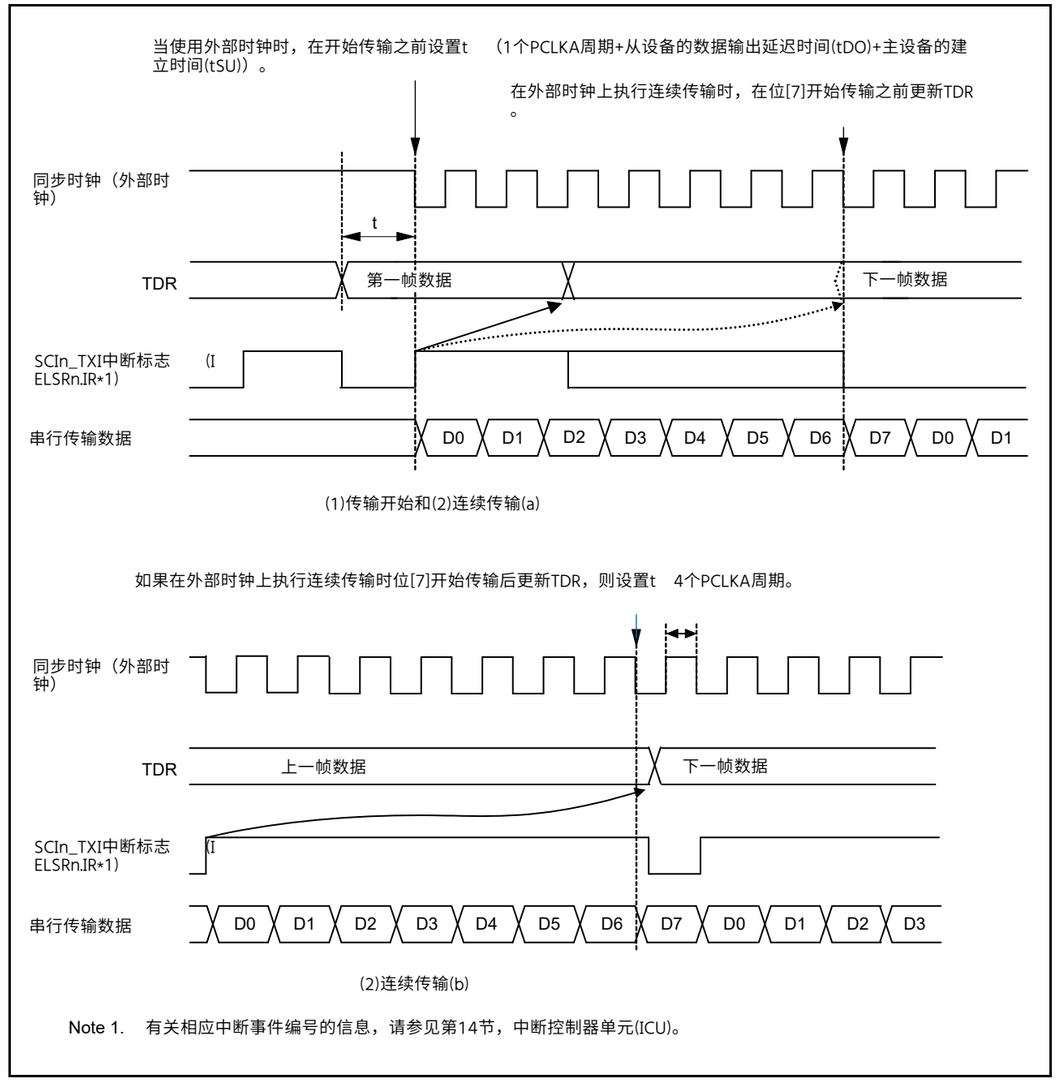
(1) Writing data to TDR (FTDRHL)

(a) Non-FIFO selected

Data can be written to TDR and TDRHL. However, if new data is written to TDR or TDRHL when transmit data remains in TDR or TDRHL, the previous data in TDR and TDRHL is lost because it was not transferred to TSR yet. When using DTC or DMAC, always write transmit data to TDR or TDRHL in the SCIn_TXI interrupt request handling routine.

(b) FIFO selected

It is possible to write data to the FTDRH and FTDRL registers when SCR.TE is 1. Confirm the amount of writable data



Note 1. 有关相应中断事件编号的信息，请参见第14节，中断控制器单元(ICU)。

Figure 34.78 时钟同步传输中使用外部时钟的限制

34.14.7 使用DMAC或DTC的限制

在使用DMAC或DTC进行发送或接收操作期间，请勿为DMACDTC设置传输数据。

(1) 将数据写入TDR(FTDRHL)

(a) Non-FIFO selected

数据可以写入TDR和TDRHL。但是，如果在发送数据保留在TDR或TDRHL中时将新数据写入TDR或TDRHL，则TDR和TDRHL中的先前数据将丢失，因为它尚未传输到TSR。使用DTC或DMAC时，始终在SCIn_TXI中断请求处理程序中将发送数据写入TDR或TDRHL。

(b) FIFO selected

当SCR.TE为1时，可以将数据写入FTDRH和FTDRL寄存器。确认可写入数据量

using the FDR.T[4:0] bits.

(2) Reading data from RDR (FRDRHL)

When using the DMAC or DTC to read RDR and RDRHL, always set the receive data full interrupt (SCIn_RXI) as the activation source of the relevant SCI.

34.14.8 Notes on Starting Transfer

When transfer starts while the Interrupt Status flag (IELSRn.IR) in the ICU is 1, follow the procedure in this section to clear interrupt requests before permitting operations (by setting the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit to 1). For details on the Interrupt Status flag, see section 14, Interrupt Controller Unit (ICU).

- Confirm that transfer has stopped (the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit is 0)
- Set the associated interrupt enable bit (SCR/SCR_SMCI.TIE or SCR/SCR_SMCI.RIE) to 0
- Read the associated interrupt enable bit (SCR/SCR_SMCI.TIE or SCR/SCR_SMCI.RIE bit) to check that it actually becomes 0
- Set the Interrupt Status flag, IELSRn.IR, in the ICU to 0.

34.14.9 External Clock Input in Clock Synchronous and Simple SPI Modes

In clock synchronous mode and simple SPI mode, the external clock (SCKn) must be input as follows:

High-pulse period, low-pulse period = 2 PCLKA cycles or more, period = 6 PCLKA cycles or more.

34.14.10 Limitations on Simple SPI Mode

(1) Master mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set in the SPMR.CKPH and CKPOL bits when the SPMR.SSE bit is 1.

  This prevents the clock line from being placed in the high-impedance state when the SCR.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR.TE bit changes from 0 to 1. When the SPMR.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not required because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.
- For the clock delay setting (SPMR.CKPH bit is 1), the receive data full interrupt (SCIn_RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 34.79. If the TE and RE bits in the SCR register become 0 before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Additionally, an SCIn_RXI interrupt might lead to the input signal on the SSn pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, the SCKn pin output goes to high-impedance while the input on the SSn pin is at the low level if a mode fault error occurs while a character is being transferred, stopping supply of the clock signal to the connected slave. Reset the connected slave to avoid misaligned bits when transfer is restarted.

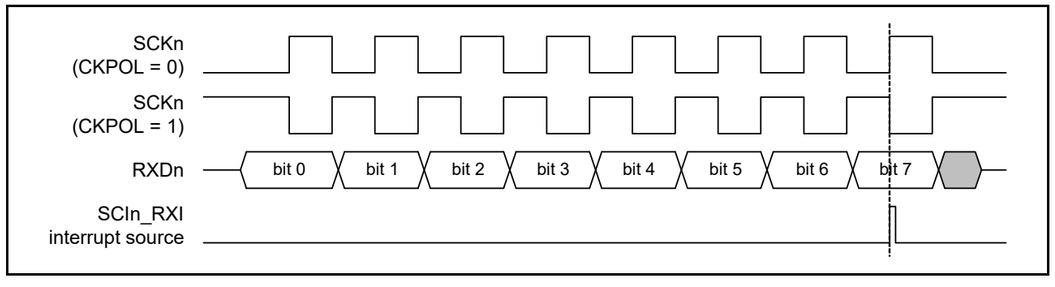


Figure 34.79 Timing of SCIn_RXI interrupt in simple SPI mode with clock delay

使用FDR.T[4:0]位。

(2) 从RDR(FRDRHL)读取数据

使用DMAC或DTC读取RDR和RDRHL时，始终将接收数据满中断（SCIn_RXI）设置为相关SCI的激活源。

34.14.8 开始转移注意事项

当ICU中的中断状态标志(IELSRn.IR)为1时开始传输时，请按照本节中的程序在允许操作之前清除中断请求（通过将SCRSCR_SMCI.TE或SCRSCR_SMCI.RE位设置为1）。有关中断状态标志的详细信息，请参见第14节，中断控制器单元(ICU)。

- 确认传输已停止（SCRSCR_SMCI.TE或SCRSCR_SMCI.RE位为0）
- 将相关的中断使能位（SCRSCR_SMCI.TIE或SCRSCR_SMCI.RIE）设置为0
- 读取相关的中断使能位（SCRSCR_SMCI.TIE或SCRSCR_SMCI.RIE位）以检查它是否实际变为0
- 将ICU中的中断状态标志IELSRn.IR设置为0。

34.14.9 时钟同步和简单SPI模式下的外部时钟输入

在时钟同步模式和简单SPI模式下，外部时钟（SCKn）必须输入如下：

高脉冲周期，低脉冲周期=2个PCLKA周期或更多，周期=6个PCLKA周期或更多。

34.14.10 简单SPI模式的限制

(1) 主模式

- 使用电阻上拉或下拉与传输时钟设置的初始设置相匹配的时钟线SPMR.SSE位为1时的SPMR.CKPH和CKPOL位。

  这可以防止当SCR.TE位设置为0时时钟线处于高阻抗状态，或者当SCR.TE位从0变为1时在时钟线上产生意外边沿。SSE位在单主机模式下为0，不需要上拉或下拉时钟线，因为即使SCR.TE位设置为0，时钟线也不会处于高阻状态。
- 对于时钟延迟设置（SPMR.CKPH位为1），接收数据完全中断（SCIn_RXI）在SCKn引脚上的最终时钟沿之前产生，如图34.79所示。如果SCR寄存器中的TE和RE位在SCKn引脚上的时钟信号的最后一个边沿之前变为0，则SCKn引脚处于高阻状态，因此传输时钟的最后一个时钟脉冲的宽度为缩短。此外，SCIn_RXI中断可能会导致所连接从机的SSn引脚上的输入信号在SCKn引脚上的时钟信号的最后一个边沿之前变为高电平，从而导致从机的错误操作。
- 在多主机配置中，如果在传输字符时发生模式故障错误，则SCKn引脚输出变为高阻态，而SSn引脚上的输入处于低电平，从而停止向连接的时钟信号提供奴隶。重新启动传输时，重置连接的从机以避免未对齐的位。

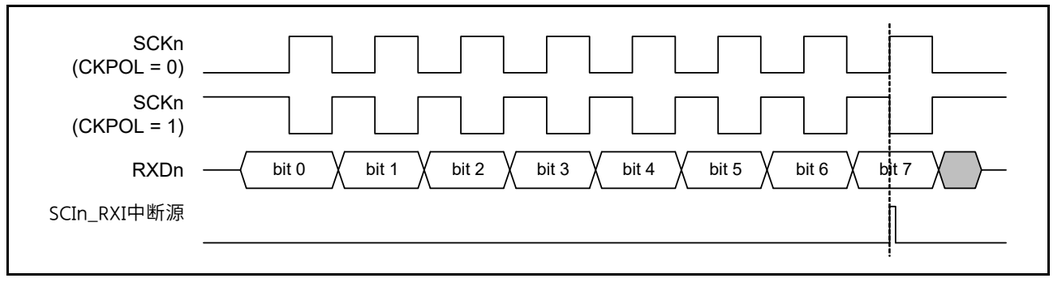

Figure 34.79 带时钟延迟的简单SPI模式下SCIn_RXI中断的时序

(2) Slave mode

- Wait at least the following time from writing transmit data in the TDR register to the start of the external clock input.
  1 PCLKA cycle + data output delay for the slave (tDO) + setup time for the master (tSU)

  Also wait at least 5 PCLKA cycles from the input of the low level on the SSn pin to the start of the external clock input.
- Provide an external clock signal to the master the same as the data length for transfer
- Control the input on the SSn pin before the start and after the end of data transfer
- When the input level on the SSn pin is to be changed from low to high while a character is being transferred, set the TE and RE bits in the SCR register to 0 and, after restoring the settings, restart transfer of the first byte.

(2) 从机模式

- 从将发送数据写入TDR寄存器到开始外部时钟输入，至少等待以下时间。1个PCLKA周期+从机的数据输出延迟(tDO)+主机的建立时间(tSU)

  还要等待至少5个PCLKA周期，从SSn引脚上的低电平输入到外部时钟输入开始。
- 向主机提供与传输数据长度相同的外部时钟信号
- 在数据传输开始之前和结束之后控制SSn引脚上的输入
- 当SSn引脚上的输入电平要在传输字符时从低电平变为高电平时，设置SCR寄存器中的TE和RE位为0，并在恢复设置后重新开始传输第一个字节。

35. IrDA Interface

35.1 Overview

The IrDA interface sends and receives IrDA data communication waveforms in cooperation with the SCI1 based on the IrDA (Infrared Data Association) standard 1.0.

Enabling the IrDA function in the IRE bit in the IRCR register allows encoding and decoding of the TXD1 and RXD1 signals of the SCI1 to the waveforms conforming to the IrDA standard 1.0 (IRTXD1 and IRRXD1 pins). Connecting the waveforms to an infrared transmitter/receiver implements infrared data communication conforming to the IrDA standard 1.0 system.

With the IrDA standard 1.0 system, data transfer can be started at 9,600 bps and the transfer rate can be changed whenever necessary. Because the IrDA interface cannot change the transfer rate automatically, the transfer rate must be changed through the software.

Figure 35.1 shows the cooperation between the IrDA interface and SCI1.

35. IrDA Interface

35.1 Overview

IrDA接口与SCI1配合发送和接收IrDA数据通信波形，基于
IrDA（红外数据协会）标准1.0。

在IRCR寄存器的IRE位中使能IrDA功能，可以将SCI1的TXD1和RXD1信号编码和解码为符合IrDA标准1.0（IRTXD1和IRRXD1引脚）的波形。将波形连接到红外发射器接收器可实现符合IrDA标准1.0系统的红外数据通信。

使用IrDA标准1.0系统，可以以9 600bps开始数据传输，并且可以随时更改传输速率。因为IrDA接口不能自动改变传输速率，所以必须通过软件来改变传输速率。

IRRXINV bit (IRRXD Polarity Switching)

The IRRXINV bit inverts the logic level of the IRRXD input. When inverted, the high-level pulse width is applied to the low-level pulse width.

IRTXINV bit (IRTXD Polarity Switching)

The IRTXINV bit inverts the logic level of the IRTXD output. When inverted, the high-level pulse width is applied to the low-level pulse width.

IRE bit (IrDA Enable)

The IRE bit configures the I/O pins for normal communication mode or IrDA data communication mode.

35.3 Operation

35.3.1 IrDA Interface Setup Procedure

To set up IrDA interface operation:

1. Set the associated pins to IRTXD1 and IRRXD1 in the Pin Function Control Register (PmnPFS.PSEL = 00101b) of the I/O ports function.
2. Specify the peripheral function in the Pin Function Control Register (PmnPFS.PMR = 1) of the I/O ports function.
3. Specify the IrDA function in the IRCR register.
4. Set the SCI1-related registers of the Serial Communications Interface (SCI).

35.3.2 Transmission

During transmission, the signals output from the SCI1 (UART frames) are converted to the IR frame data through the IrDA interface (see Figure 35.2). When the IRCR.IRTXINV bit is 0 and serial data is 0, high-level pulses with 3/16 the width of the bit rate (1-bit width period) are output (initial setting). The standard prescribes that the minimum high-level pulse width must be 1.41 µs and the maximum high-level pulse width must be (3/16 + 2.5%) × bit rate or (3/16 × bit rate) + 1.08 µs. When the serial data is 1, no pulses are output.

Note: IRCR寄存器值在休眠、软件待机和深度软件待机模式下保持不变。

IRRXINV位（IRRXD极性切换）

IRRXINV位反转IRRXD输入的逻辑电平。反转时，高电平脉冲宽度应用于低电平脉冲宽度。

IRTXINV位（IRTXD极性切换）

IRTXINV位反转IRTXD输出的逻辑电平。反转时，高电平脉冲宽度应用于低电平脉冲宽度。

IRE位（IrDA使能）

IRE位将IO引脚配置为正常通信模式或IrDA数据通信模式。

35.3 Operation

35.3.1 IrDA接口设置程序

设置IrDA接口操作：

1. 在IO端口功能的引脚功能控制寄存器(PmnPFS.PSEL=00101b)中将相关引脚设置为IRTXD1和IRRXD1。
2. 在IO端口功能的引脚功能控制寄存器(PmnPFS.PMR=1)中指定外设功能。
3. 在IRCR寄存器中指定IrDA功能。
4. 设置串行通信接口(SCI)的SCI1相关寄存器。

35.3.2 Transmission

在传输过程中，从SCI1输出的信号（UART帧）通过IrDA接口（见图35.2）。当IRCR.IRTXINV位为0且串行数据为0时，输出具有316位速率宽度（1位宽度周期）的高电平脉冲（初始设置）。标准规定最小高电平脉冲宽度必须为1.41µs，最大高电平脉冲宽度必须为（316+2.5%）×比特率或（316×比特率）+1.08µs。当串行数据为1时，不输出脉冲。

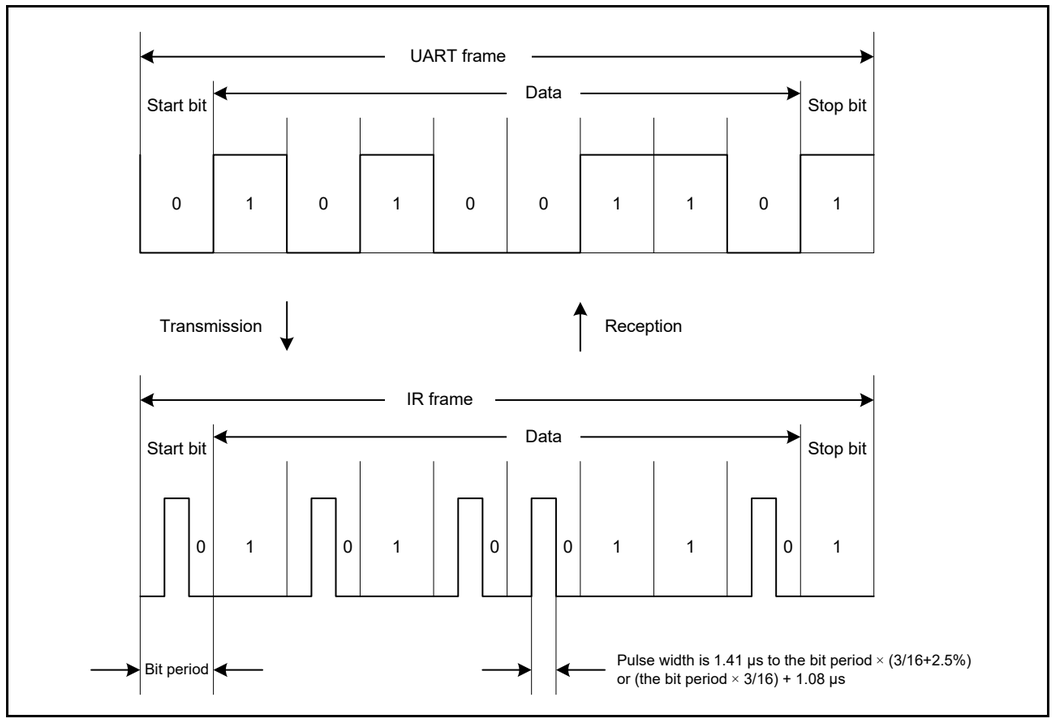

Figure 35.2 IrDA transmission and reception

35.3.3 Reception

During reception, the IR frame data is converted to the UART frame data through the IrDA interface and is input to the SCI1. Low-level data is input to SCI1 when the IRCR.IRRXINV bit is 0 and a high-level pulse is detected. High-level data is input to SCI1 when no pulse is detected for a 1-bit period.

35.4 Usage Notes

35.4.1 Settings for the Module-Stop Function

IrDA operation can be disabled or enabled using the Module Stop Control Register. The IrDA is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

35.4.2 Asynchronous Reference Clock for SCI1

The IrDA receives a clock with a frequency 16 times the bit rate from SCI1 and operates in conjunction with SCI1. When using the IrDA, set the SCI1.SEMR.ABCS bit to 0.

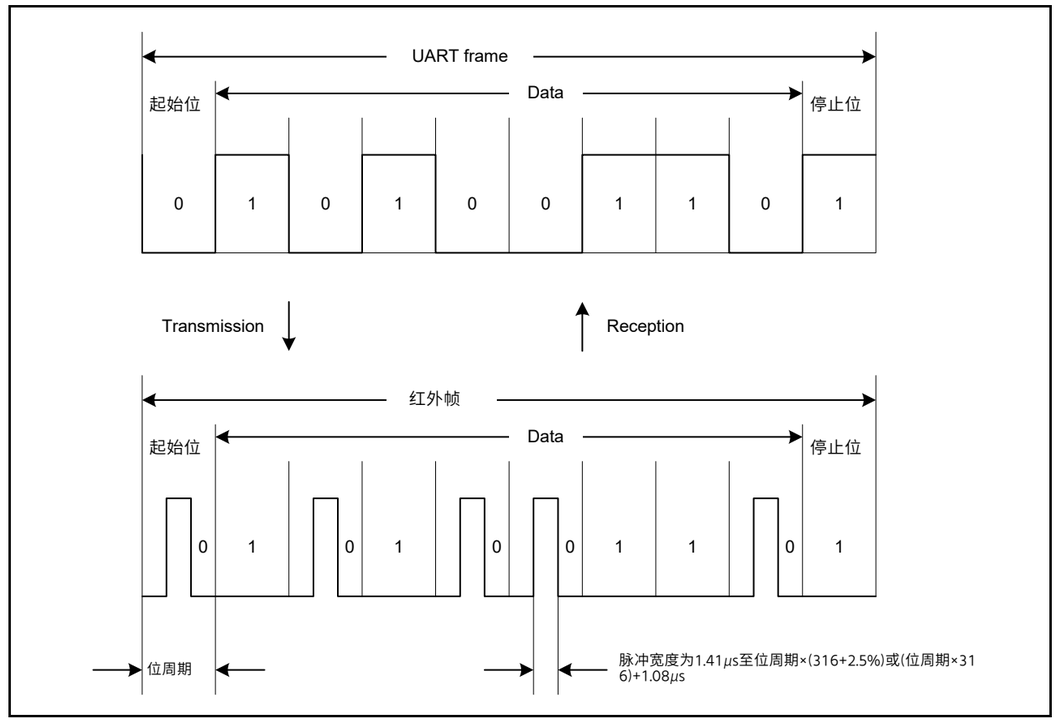

Figure 35.2 IrDA发射和接收

35.3.3 Reception

接收时，IR帧数据通过IrDA接口转换为UART帧数据，输入到SCI1。当IRCR.IRRXINV位为0且检测到高电平脉冲时，低电平数据输入到SCI1。当1位周期内没有检测到脉冲时，高电平数据输入到SCI1。

35.4 使用说明

35.4.1 模块停止功能的设置

可以使用模块停止控制寄存器禁用或启用IrDA操作。IrDA在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第11节，低功耗模式。

35.4.2 SCI1的异步参考时钟

IrDA从SCI1接收频率为比特率16倍的时钟，并与SCI1一起工作。使用IrDA时，将SCI1.SEMR.ABCS位设置为0。

36. I2C Bus Interface (IIC)

36.1 Overview

The 3-channel I2C Bus Interface (IIC) module conforms with and provides a subset of the NXP I2C bus (inter-integrated circuit bus) interface functions. Table 36.1 lists the IIC specifications, Figure 36.1 shows a block diagram, and Figure 36.2 shows an example of I/O pin connections to external circuits, with an I2C bus configuration. Table 36.2 lists the I/O pins.

Table 36.1 IIC specifications (1 of 2)

Parameter	Specifications
Communications format	• I2C-bus format or SMBus format • Master or slave mode selectable • Automatic securing of the setup times, hold times, and bus-free times for the transfer rate
Transfer rate	Fast-mode Plus supported, up to 1 Mbps
SCL clock	For master operation, the duty cycle of the SCL clock is selectable in the range from 4% to 96%
Issuing and detecting conditions	• Start, restart, and stop conditions are automatically generated • Start conditions (including restart conditions) and stop conditions are detectable
Slave address	• Configurable for up to three different slave addresses • 7- and 10-bit address formats supported, including simultaneous use • General call addresses, device ID addresses, and SMBus host addresses detectable
Acknowledgment	• For transmission, automatic loading of the acknowledge bit Transfer of the next transmit data can be automatically suspended on detection of a not-acknowledge bit. • For reception, automatical transmission of the acknowledge bit If a wait between the eighth and ninth clock cycles is selected, the software can control the value in the acknowledge field in response to the received value.
Wait function	During reception, the following wait periods are available by holding the SCL clock low: • Waiting between the eighth and ninth clock cycles • Waiting between the ninth clock cycle and the first clock cycle of the next transfer
SDA output delay function	Output timing of transmitted data, including the acknowledge bit, can be delayed
Arbitration	• For multi-master operation: - SCL clock synchronization is possible when conflict occurs with the SCL signal from another master - When issuing the start condition would create conflict on the bus, loss of arbitration is detected by testing for non-matching between the internal signal for the SDA line and the level on the SDA line - In master operation, loss of arbitration is detected by testing for non-matching between the signal on the SDA line and the internal signal for the SDA line • Loss of arbitration because the start condition occurs while the bus is busy is detectable, to prevent the issuing of double start conditions • Loss of arbitration is detectable on transfer of a not-acknowledge bit because the internal signal for the SDA line and the level on the SDA line do not match • Loss of arbitration because non-matching of internal and line levels for data is detectable in slave transmission
Timeout function	Internal detection of long-interval stops of the SCL clock
Noise cancellation	• Digital noise filters for both the SCL and SDA signals • Programmable window for noise cancellation by the filters
Interrupt sources	• Transfer error or event occurrence (arbitration-lost, NACK, timeout, start or restart condition, or stop condition) • Receive data full, including matching with a slave address • Transmit data empty, including matching with a slave address • Transmit end
Module-stop function	Module-stop state can be set to reduce power consumption
IIC operating modes	• Master transmit • Master receive • Slave transmit • Slave receive

36. I2C总线接口(IIC)

36.1 Overview

3通道I2C总线接口(IIC)模块符合并提供NXPI2C总线（集成电路间总线）接口功能的子集。表36.1列出了IIC规范，图36.1显示了框图，图36.2显示了IO引脚连接到外部电路的示例，具有I2C总线配置。表36.2列出了IO引脚。

SDAO bit (SDA Output Control/Monitor) and SCLO bit (SCL Output Control/Monitor)

The SDAO bit directly controls the SDAn and SCLn signals output from the IIC. When writing to these bits, also write 0 to the SOWP bit. Setting these bits results in input to the IIC by the input buffer. When slave mode is selected, a start condition might be detected and the bus might be released, depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, transmission, or reception. Operation after rewriting under these conditions is not guaranteed. When reading these bits, the state of signals output from the IIC can be read.

CLO bit (Extra SCL Clock Cycle Output)

The CLO bit allows output of an extra SCL clock cycle for debugging or error processing. Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error. For details on this function, see section 36.12.2, Extra SCL Clock Cycle Output Function.

IICRST bit (IIC-Bus Interface Internal Reset)

The IICRST bit initiates an internal state reset of the IIC. Setting this bit to 1 initiates an IIC reset or internal reset.

SDAO位（SDA输出控制监视器）和SCLO位（SCL输出控制监视器）

SDAO位直接控制IIC输出的SDAn和SCLn信号。写入这些位时，还要向SOWP位写入0。设置这些位会导致输入缓冲器向IIC输入。选择从模式时，可能会检测到启动条件并释放总线，具体取决于位设置。

不要在开始条件、停止条件、重启条件、发送或接收期间重写这些位。不保证在这些条件下重写后的操作。读取这些位时，可以读取IIC输出的信号状态。

CLO位（额外SCL时钟周期输出）

CLO位允许输出额外的SCL时钟周期用于调试或错误处理。通常，将该位设置为0。
在正常通信状态下将该位设置为1会导致通信错误。有关此功能的详细信息，请参见第36.12.2节，额外SCL时钟周期输出功能。

IICRST位（IIC总线接口内部复位）

IICRST位启动IIC的内部状态复位。将此位设置为1会启动IIC复位或内部复位。

Whether an IIC reset or internal reset is initiated is determined by the settings of this bit in combination with the ICE bit. Table 36.3 lists the IIC resets.

The IIC reset initializes all registers except ICCR1.ICE and ICCR1.IICRST bits, and internal states of the IIC.

The internal reset initializes the following in addition to the internal states of the IIC:

- Bit counter (ICMR1.BC[2:0] bits)
- I2C Bus Shift Register (ICDRS)
- I2C Bus Status Registers (ICSR1 and ICSR2)
- SDAO and SCLO Output Control/Monitor (ICCR1.SCLO and ICCR1.SDAO bits)
- I2C Bus Control Register 2 (except ICCR2.BBSY bit).

For the reset conditions for each register, see section 36.15, State of Registers when Issuing each Condition.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the IIC without initializing the port settings and the control and setting registers of the IIC when the bus or IIC hangs up because of a communication error. If the IIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the SCLn pin and SDAn pin at high impedance.

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up that occurs during communication with the master device in slave mode, the slave and master devices might enter different states, because the bit counter information differs. For this reason, do not initiate an internal reset in slave mode. Initiate recovery processing from the master device. If an internal reset is necessary because the IIC hangs up with the SCLn line in a low level output state in slave mode, initiate an internal reset, and then issue a restart condition from the master device, or issue a stop condition and resume communication from the start condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start or restart condition from the master device, synchronization is lost because the master and slave devices operate asynchronously.

Table 36.3 IIC resets

IICRST	ICE	State	Specifications
1	0	IIC reset	Resets all registers except ICCR1.ICE and ICCR1.IICRST bits, and internal states of the IIC
	1	Internal reset	Resets the ICMR1.BC[2:0] bits, the ICSR1, ICSR2, ICDRS registers, and SDAO and SCLO Output Control/Monitor (ICCR1.SCLO and ICCR1.SDAO bits), I2C Bus Control Register 2 (except ICCR2.BBSY bit) and the internal states of the IIC

ICE bit (IIC-Bus Interface Enable)

The ICE bit selects the active or inactive state of the SCLn and SDAn pins. It can also be combined with the IICRST bit to initiate two types of resets. See Table 36.3 for the reset descriptions.

Set the ICE bit to 1 when using the IIC. The SCLn and SDAn pins are placed in the active state when the ICE bit is set to 1. Set the ICE bit to 0 when the IIC is not used. The SCLn and SDAn pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCLn or SDAn pin to the IIC when setting up the pin function control. Slave address comparison is performed if the pins are assigned to the IIC.

是IIC复位还是内部复位由该位的设置和ICE位共同决定。
表36.3列出了IIC复位。

IIC复位初始化除ICCR1.ICE和ICCR1.IICRST位之外的所有寄存器，以及IIC的内部状态。

除了IIC的内部状态之外，内部复位还会初始化以下内容：

- 位计数器（ICMR1.BC[2:0]位）
- I2C总线移位寄存器(ICDRS)
- I2C总线状态寄存器（ICSR1和ICSR2）
- SDAO和SCLO输出控制监视器（ICCR1.SCLO和ICCR1.SDAO位）
- I2C总线控制寄存器2（ICCR2.BBSY位除外）。

有关每个寄存器的复位条件，请参阅第36.15节，发出每个条件时的寄存器状态。

在操作期间将IICRST位设置为1（ICE位设置为1）启动的内部复位会在总线或IIC挂起时复位IIC的内部状态，而无需初始化IIC的端口设置以及控制和设置寄存器因为通讯错误。如果IIC在低电平输出状态下挂起，复位内部状态会取消低电平输出状态并释放总线，同时SCLn引脚和SDAn引脚处于高阻态。

Note: 如果在从模式下与主设备通信期间发生的总线挂断使用IICRST位启动内部复位，则从设备和主设备可能会进入不同的状态，因为位计数器信息不同。因此，不要在从模式下启动内部复位。从主设备启动恢复处理。如果由于IIC在从模式下SCLn线处于低电平输出状态而挂起而需要内部复位，则启动内部复位，然后从主设备发出重新启动条件，或者发出停止条件并从主设备恢复通信开始条件。如果通过仅在从设备中启动复位来重新启动通信，而没有从主设备发出启动或重新启动条件，则由于主设备和从设备异步操作而失去同步。

Table 36.3 IIC resets

IICRST	ICE	State	Specifications
1	0	IIC reset	复位除ICCR1.ICE和ICCR1.IICRST位之外的所有寄存器，以及内部状态 IIC
	1	内部复位	复位ICMR1.BC[2:0]位、ICSR1、ICSR2、ICDRS寄存器以及SDAO和SCLO输出控制监视器（ICCR1.SCLO和ICCR1.SDAO位），I2C总线控制 寄存器2（ICCR2.BBSY位除外）和IIC的内部状态

ICE位（IIC总线接口使能）

ICE位选择SCLn和SDAn引脚的有效或无效状态。它也可以与IICRST位组合来启动两种类型的复位。复位说明见表36.3。

使用IIC时将ICE位设置为1。当ICE位设置为1时，SCLn和SDAn引脚处于活动状态。不使用IIC时，将ICE位设置为0。当ICE位设置为0时，SCLn和SDAn引脚处于无效状态。在设置引脚功能控制时，不要将SCLn或SDAn引脚分配给IIC。如果引脚分配给IIC，则执行从地址比较。

Note 1. The MST and TRS bits can be written to when the ICMR1.MTWP bit is set to 1.

ST bit (Start Condition Issuance Request)

The ST bit requests transition to master mode and triggers a start condition. When this bit is set to 1, a start condition is issued when the BBSY flag is set to 0 (bus free state). For details on this function, see section 36.11, Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the ST bit.

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Only set the ST bit to 1 (start condition issuance request) when the BBSY flag is set to 0 (bus free state). Arbitration might be lost if the ST bit is set to 1 (start condition request) when the BBSY flag is 1 (bus busy state).

RS bit (Restart Condition Issuance Request)

The RS bit requests that a restart condition be issued in master mode. When this bit is set to 1 to request a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 36.11, Start, Restart, and Stop Condition Issuing Function.

- 发出启动条件时（检测到启动条件）
- ICSR2中的AL（仲裁失败）标志设置为1时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

Note: 仅当BBSY标志设置为0（总线空闲状态）时，才将ST位设置为1（开始条件发出请求）。
如果在BBSY标志为1（总线繁忙状态）时将ST位设置为1（开始条件请求），则仲裁可能会丢失。

RS位（重启条件发布请求）

RS位请求在主机模式下发出重启条件。当该位设置为1以请求重新启动条件时，当BBSY标志设置为1（总线繁忙状态）且MST位设置为1（主模式）时，发出重新启动条件。有关此功能的详细信息，请参阅第36.11节“启动、重启和停止条件发出功能”。

[Setting condition]

- 当ICCR2中的BBSY标志设置为1时，将1写入RS位。

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Do not set the RS bit to 1 while issuing a stop condition.
Note: If 1 (restart condition request) is written to the RS bit in slave mode, the restart condition is not issued, but the RS bit remains set to 1. If the operating mode changes to master mode without the bit being cleared, a restart condition might be issued.

SP bit (Stop Condition Issuance Request)

The SP bit requests that a stop condition be issued in master mode. When this bit is set to 1, a stop condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 36.11, Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the MST bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition is issued (a stop condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Writing to the SP bit is not possible while the BBSY flag is 0 (bus free state).
Note: Do not set the SP bit to 1 while a restart condition is being issued.

TRS bit (Transmit/Receive Mode)

The TRS bit indicates transmit or receive mode. The IIC is in receive mode when the TRS bit is 0 and in transmit mode when the bit is 1. The combination of this bit and the MST bit indicates the operating mode of the IIC.

The value of the TRS bit automatically changes to 1 for transmit mode or 0 for receive mode when a start condition is issued or detected and the R/W# bit is set. Although writing to the TRS bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not necessary during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When a restart condition is issued normally because of a restart condition request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit appended to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in ICSER, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When the R/W# bit appended to the slave address is set to 1 in master mode
- In slave mode, on a match between the received address and the address enabled in ICSER when the value of the

- 当0写入RS位时
- 发出重新启动条件时（检测到启动条件）
- ICSR2中的AL（仲裁失败）标志设置为1时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

Note: 发出停止条件时不要将RS位设置为1。
Note: 如果在从模式下将1（重新启动条件请求）写入RS位，则不会发出重新启动条件，但RS位保持设置为1。如果操作模式更改为主模式而未清除该位，则重新启动条件可能会发出。

SP位（停止条件发出请求）

SP位请求在主机模式下发出停止条件。当该位设置为1时，当BBSY标志设置为1（总线繁忙状态）且MST位设置为1（主模式）时，发出停止条件。有关此功能的详细信息，请参阅第36.11节“启动、重启和停止条件发出功能”。

[Setting condition]

- 当1写入SP位时，且ICCR2中的BBSY标志和MST位都设置为1。

[Clearing conditions]

- 当0写入SP位时
- 发出停止条件时（检测到停止条件）
- ICSR2中的AL（仲裁失败）标志设置为1时
- 当检测到启动条件和重新启动条件时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

Note: 当BBSY标志为0（总线空闲状态）时，不能写入SP位。
Note: 发出重启条件时不要将SP位设置为1。

TRS位（发送接收模式）

TRS位指示发送或接收模式。当TRS位为0时IIC处于接收模式，当该位为1时IIC处于发送模式。该位和MST位的组合指示IIC的工作模式。

当发出或检测到启动条件并且设置RW#位时，TRS位的值自动更改为1（发送模式）或0（接收模式）。虽然当ICMR1的MTWP位设置为1时可以写入TRS位，但在正常使用期间不需要写入该位。

[Setting conditions]

- 由于启动条件请求而正常发出启动条件时（在ST位设置为1的情况下检测到启动条件时）
- 由于重新启动条件请求而正常发出重新启动条件时（在RS位设置为1的情况下检测到重新启动条件时）
- 当附加到从地址的RW#位在主模式下设置为0时
- 当从机模式接收到的地址与ICSER中使能的地址匹配时，RW#位设置为1
- 当将1写入TRS位且ICMR1中的MTWP位设置为1时。

[Clearing conditions]

- 检测到停止条件时
- ICSR2中的AL（仲裁失败）标志设置为1时
- 当附加到从地址的RW#位在主模式下设置为1时
- 在从模式下，当接收到的地址与ICSER中启用的地址匹配时，

received R/W# bit is 0, including when the received address is the general call address

- In slave mode, when a restart condition is detected (a restart condition is detected with ICCR2.BBSY = 1 and ICCR2.MST = 0)
- When 0 is written to the TRS bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

MST bit (Master/Slave Mode)

The MST bit indicates master or slave mode. The IIC is in slave mode when the MST bit is 0 and is in master mode when the bit is 1. The combination of this bit and the TRS bit indicates the operating mode of the IIC.

The value of the MST bit automatically changes to 1 for master mode or 0 for slave mode when a start condition is issued or a stop condition is issued or detected. Although writing to the MST bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not necessary during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 0 is written to the MST bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

BBSY flag (Bus Busy Detection Flag)

The BBSY flag indicates whether the I2C bus is occupied (bus busy state) or released (bus free state). The flag is set to 1 when the SDAn line changes from high to low when the SCLn line is high, assuming that a start condition was issued. The flag then is set to 0 if a start condition is not detected for the bus free time (ICBRL setting), assuming that a stop condition was issued.

[Setting condition]

- When a start condition is detected.

[Clearing conditions]

- When a start condition is not detected for the bus free time (ICBRL setting) after detecting a stop condition
- When 1 is written to the IICRST bit in ICCR1 with the ICE bit in ICCR1 set to 0 (IIC reset).

接收到的RW#位为0，包括接收到的地址是广播地址时

- 在从模式下，当检测到重启条件时（检测到重启条件时ICCR2.BBSY=1并且ICCR2.MST = 0)
- 当将0写入TRS位且ICMR1中的MTWP位设置为1时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

MST位（主从模式）

MST位指示主机或从机模式。当MST位为0时IIC处于从机模式，当该位为1时IIC处于主机模式。该位和TRS位的组合表示IIC的工作模式。

当发出启动条件或发出或检测到停止条件时，MST位的值自动变为1（主机模式）或0（从机模式）。虽然当ICMR1的MTWP位设置为1时可以写入MST位，但在正常使用期间不需要写入该位。

[Setting conditions]

- 由于启动条件请求而正常发出启动条件时（在ST位设置为1的情况下检测到启动条件时）
- 当ICMR1中的MTWP位设置为1时，将1写入MST位。

[Clearing conditions]

- 检测到停止条件时
- ICSR2中的AL（仲裁失败）标志设置为1时
- 将0写入MST位且ICMR1中的MTWP位设置为1时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

BBSY标志（总线忙检测标志）

BBSY标志指示I2C总线是被占用（总线繁忙状态）还是被释放（总线空闲状态）。当SCLn线为高时SDAn线从高变为低时，该标志设置为1，假设发出了启动条件。如果在总线空闲时间（ICBRL设置）没有检测到启动条件，则该标志设置为0，假设发出了停止条件。

[Setting condition]

- 当检测到启动条件时。

[Clearing conditions]

- 检测到停止条件后，在总线空闲时间（ICBRL设置）未检测到启动条件时
- 当ICCR1中的IICRST位写入1且ICCR1中的ICE位设置为0时（IIC复位）。

Note 1. Rewrite the BC[2:0] bits and set the BCWP bit to 0 at the same time.

BC[2:0] bits (Bit Counter)

The BC[2:0] bits function as a counter indicating the number of bits remaining to be transferred on detection of a rising edge on the SCLn line. Although BC[2:0] are read/write bits, it is not normally necessary to access these bits.

To write to these bits, specify the number of bits to be transferred plus one, for an additional acknowledge bit, between transferred frames when the SCLn line is at a low level. The value in the BC[2:0] bits returns to 000b at the end of a data transfer, including the acknowledge bit, or when a start or restart condition is detected.

BC[2:0]位（位计数器）

BC[2:0]位用作计数器，指示在检测到SCLn线上的上升沿时要传输的剩余位数。虽然BC[2:0]是读写位，但通常不需要访问这些位。

要写入这些位，在SCLn线处于低电平时，指定要传输的位数加1，作为附加确认位，在传输的帧之间。BC[2:0]位中的值在数据传输结束时返回到000b，包括确认位，或者当检测到启动或重启条件时。

Note 1. The setting DLCS = 1 (IICϕ/2) is only valid when SCL is low. When SCL is high, the DLCS = 1 setting becomes invalid and the clock source becomes the internal reference clock (IICϕ).

TMOS bit (Timeout Detection Time Select)

The TMOS bit selects long or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE = 1). When this bit is set to 0, long mode is selected. When it is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14-bit counter. While the SCLn line is in the state that enables this counter as specified in the TMOH and TMOL bits, the counter counts up in synchronization with the internal reference clock (IICϕ) as a count source. For details on this function, see section 36.12.1, Timeout Function.

TMOL bit (Timeout L Count Control)

The TMOL bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held low and the timeout function is enabled (ICFER.TMOE = 1).

TMOH bit (Timeout H Count Control)

The TMOH bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held high and the timeout function is enabled (ICFER.TMOE = 1).

SDDL[2:0] bits (SDA Output Delay Counter)

The SDDL[2:0] bits can be used to delay the SDA output. This counter works with the clock source selected in the DLCS bit. This setting can be used for all types of SDA output, including transmission of the acknowledge bit.

Set the SDA output delay to meet the I2C bus standard for the data enable time/acknowledge enable time,*1 or the SMBus standard, within [data hold time (300 ns or more + the SCL-clock low-level period) - the data setup time (250 ns)]. If a value outside the standard is set, communication between devices might malfunction or falsely indicate a start or stop condition, depending on the bus state.

For details on this function, see section 36.5, SDA Output Delay Function.

Note 1. 设置DLCS=1(IIC 2)仅在SCL为低电平时有效。当SCL为高电平时，DLCS=1设置无效，时钟源变为内部参考时钟(IIC)。

TMOS位（超时检测时间选择）

当使能超时功能（ICFER.TMOE=1）时，TMOS位为超时检测时间选择长模式或短模式。当该位设置为0时，选择长模式。当设置为1时，选择短模式。在长模式下，超时检测内部计数器用作16位计数器。在短模式下，计数器用作14位计数器。当SCLn线处于启用TMOH和TMOL位中指定的计数器的状态时，计数器与作为计数源的内部参考时钟(IIC)同步递增计数。有关此功能的详细信息，请参阅第36.12.1节，超时功能。

TMOL位（超时L计数控制）

TMOL位启用或禁用超时功能内部计数器的递增计数，同时SCLn线保持低电平且启用超时功能(ICFER.TMOE=1)。

TMOH位（超时H计数控制）

TMOH位启用或禁用超时功能内部计数器的递增计数，同时SCLn线保持高电平且启用超时功能(ICFER.TMOE=1)。

SDDL[2:0]位（SDA输出延迟计数器）

SDDL[2:0]位可用于延迟SDA输出。该计数器与在DLCS位中选择的时钟源一起工作。该设置可用于所有类型的SDA输出，包括确认位的传输。

设置SDA输出延迟以满足I2C总线标准的数据启用时间确认启用时间，*1或SMBus标准，在[数据保持时间（300ns或更长+SCL时钟低电平周期）数据建立时间（250ns）内]。如果设置了超出标准的值，则设备之间的通信可能会发生故障或错误地指示开始或停止条件，具体取决于总线状态。

有关此功能的详细信息，请参阅第36.5节，SDA输出延迟功能。

Note 2. The WAIT and RDRFS bits are only valid in receive mode (invalid in transmit mode).

NF[1:0] bits (Noise Filter Stage Select)

The NF[1:0] bits select the number of stages in the digital noise filter. For details on this function, see section 36.6, Digital Noise Filter Circuits.

Note: Set the noise range to be filtered within a range less than the SCLn line high- or low-level period. If the noise range is set to a value of [SCL clock width: high- or low-level period, whichever is shorter] - [1.5 internal reference clock (IICϕ) cycles + analog noise filter: 120 ns (reference values)] or more, the SCL clock is regarded as noise, which might prevent the IIC from operating normally.

ACKBR bit (Receive Acknowledge)

The ACKBR bit stores the acknowledge bit information received from the receive device in transmit mode.

Note 1. 仅当ACKWP位已经为1时才写入ACKBT位。如果应用程序同时向ACKWP和ACKBT位写入1，则ACKBT位不会设置为1。

Note 2. WAIT和RDRFS位仅在接收模式下有效（在发送模式下无效）。

NF[1:0]位（噪声滤波器级选择）

NF[1:0]位选择数字噪声滤波器的级数。有关此功能的详细信息，请参阅第36.6节，数字噪声滤波电路。

Note: 将要过滤的噪声范围设置在小于SCLn线高电平或低电平周期的范围内。如果噪声范围设置为[SCL时钟宽度：高电平或低电平周期，以较短者为准][1.5内部参考时钟(IIC)周期+模拟噪声滤波器：120ns（参考值）]或更大的值，SCL时钟被视为噪声，可能会导致IIC无法正常工作。

ACKBR位（接收确认）

ACKBR位存储在发送模式下从接收设备接收到的确认位信息。

[Setting condition]

- 当ICCR2中的TRS位设置为1接收到1作为确认位时。

[Clearing conditions]

- 当ICCR2中的TRS位设置为1接收到0作为确认位时

- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKBT bit (Transmit Acknowledge)

The ACKBT bit sets the acknowledge bit to be sent in receive mode.

[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1.

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition issuance is detected (when a stop condition is detected with the SP bit in ICCR2 set to 1)
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKWP bit (ACKBT Write Protect)

The ACKWP bit controls write enabling of the ACKBT bit.

RDRFS bit (RDRF Flag Set Timing Select)

The RDRFS bit selects the RDRF flag set timing in receive mode and also selects whether to hold the SCLn line low on the falling edge of the eighth SCL clock cycle.

When the RDRFS bit is 0, the SCLn line is not held low on the falling edge of the eighth SCL clock cycle, and the RDRF flag is set to 1 on the rising edge of the ninth SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 on the rising edge of the eighth SCL clock cycle, and the SCLn line is held low on the falling edge of the eighth SCL clock cycle. The low-hold of the SCLn line is released by a write to the ACKBT bit.

After data is received with this setting, the SCLn line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1), based on the receive data.

WAIT bit (WAIT)

The WAIT bit controls whether to force a low-hold between the ninth SCL clock cycle and the first SCL clock cycle, until the receive data buffer (ICDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation is continued without a low-hold between the ninth and the first SCL clock cycle. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCLn line is held low from the falling edge of the ninth clock cycle until the ICDRR value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When the value of the WAIT bit is to be read, always read ICDRR first.

SMBS bit (SMBus/IIC-Bus Select)

Setting the SMBS bit to 1 selects the SMBus and enables the HOAE bit in ICSER.

- 当ICCR1中的IICRST位写入1而ICCR1中的ICE位为0时（IIC复位）。

ACKBT位（发送确认）

ACKBT位设置要在接收模式下发送的确认位。

[Setting condition]

- 当1写入该位且ACKWP位设置为1时。

[Clearing conditions]

- 当0写入该位且ACKWP位设置为1时
- 当检测到停止条件发出时（当ICCR2的SP位设置为1时检测到停止条件时）
- 当ICCR1中的IICRST位写入1而ICCR1中的ICE位为0时（IIC复位）。

ACKWP位（ACKBT写保护）

ACKWP位控制ACKBT位的写使能。

RDRFS位（RDRF标志设置时序选择）

RDRFS位选择接收模式下的RDRF标志设置时序，还选择是否在第8个SCL时钟周期的下降沿保持SCLn线为低电平。

当RDRFS位为0时，SCLn线在第8个SCL时钟周期的下降沿不保持低电平，在第9个SCL时钟周期的上升沿将RDRF标志设置为1。

当RDRFS位为1时，RDRF标志在第8个SCL时钟周期的上升沿设置为1，并且SCLn线在第8个SCL时钟周期的下降沿保持低电平。SCLn线的低保持通过写ACKBT位来释放。

使用此设置接收数据后，SCLn线在发送确认位之前自动保持低电平。这使处理能够根据接收数据发送ACK(ACKBT=0)或NACK(ACKBT=1)。

等待位（等待）

WAIT位控制是否在第9个SCL时钟周期和第一个SCL时钟周期之间强制保持低电平，直到每次在接收模式下接收到单字节数据时完全读取接收数据缓冲区(ICDRR)。

当WAIT位为0时，接收操作继续，在第9个和第一个SCL时钟周期之间没有低电平保持。当RDRFS和WAIT位都为0时，双缓冲器使能连续接收操作。

当WAIT位为1时，SCLn线从第9个时钟周期的下降沿保持低电平，直到每次接收到单字节数据时读取ICDRR值。这启用了以字节为单位的接收操作。

Note: 当要读取WAIT位的值时，总是先读取ICDRR。

SMBS位（SMBusIIC−Bus选择）

将SMBS位设置为1可选择SMBus并启用ICSER中的HOAE位。

Note 1. The Fast-mode Plus enable bit (FMPE) is supported only by IIC0 (SCL0-A, SDA0-A). Bit [7] is reserved in IIC1 and IIC2.

TMOE bit (Timeout Function Enable)

The TMOE bit enables or disables the timeout function. For details on this function, see section 36.12.1, Timeout Function.

MALE bit (Master Arbitration-Lost Detection Enable)

The MALE bit specifies whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

The NALE bit specifies whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode, for example when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with a different number of receive bytes.

SALE bit (Slave Arbitration-Lost Detection Enable)

The SALE bit specifies whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode, for example when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs because of noise.

NACKE bit (NACK Reception Transfer Suspension Enable)

The NACKE bit specifies whether to continue or discontinue the transfer operation when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended. When the NACKE bit is

TMOE位（超时功能使能）

TMOE位启用或禁用超时功能。有关此功能的详细信息，请参阅第36.12.1节，超时 Function.

MALE位（主仲裁丢失检测使能）

MALE位指定是否在主机模式下使用仲裁丢失检测功能。通常，将此位设置为1。

NALE位（NACK传输仲裁丢失检测使能）

NALE位指定在接收模式下发送NACK期间检测到ACK时是否导致仲裁丢失，例如，当总线上存在具有相同地址的从设备时，或者当两个或多个主设备同时选择相同的从设备时接收字节数。

SALE位（从设备仲裁丢失检测使能）

SALE位指定当在从发送模式下在总线上检测到与正在发送的值不同的值时，是否导致仲裁丢失，例如，当总线上存在具有相同地址的从机或与发送数据不匹配时由于噪音而发生。

NACKE位（NACK接收传输暂停使能）

NACKE位指定在发送模式下接收到NACK时是继续还是停止传输操作。通常，将此位设置为1。

当在NACKE位设置为1的情况下接收到NACK时，暂停下一个传输操作。当NACKE位是

0, the next transfer operation is continued regardless of the received acknowledge content.

For details, see section 36.9.2, NACK Reception Transfer Suspension Function.

SCLE bit (SCL Synchronous Circuit Enable)

The SCLE bit specifies whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCLE bit is set to 0 (no SCL synchronous circuit used), the IIC does not synchronize the SCL clock with the SCL input clock. With this setting, the IIC outputs the SCL clock at the transfer rate set in ICBRH and ICBRL, regardless of the SCLn line state. For this reason, if the bus load of the I2C bus line is much larger than the specification value, or if the SCL clock output overlaps in multiple masters, a short-cycle SCL clock that does not meet the specification might be output. When no SCL synchronous circuit is used, it also affects the issuance of the start, restart, and stop conditions, and the continuous output of extra SCL clock cycles.

Do not set this bit to 0 except when checking the output of the set transfer rate.

FMPE bit (Fast-Mode Plus Enable)

The FMPE bit specifies whether to use a slope control circuit for Fast-mode Plus (Fm+).

When this bit is set to 1, a slope control circuit conforming to the I2C bus Fast-mode Plus (Fm+) standard (tof) is selected. When this bit is set to 0, a slope control circuit conforming to the I2C bus Standard-mode (Sm) and Fast-mode (Fm) standards (tof) is selected.

Set this bit to 1 when using transmission rates up to 1 Mbps (Fast-mode Plus (Fm+) standard). Set it to 0 when using other transmission rates (up to 100 kbps (Sm) or up to 400 kbps (Fm)) or for SMBus (10 to 100 kbps).

b7	HOAE	Host Address Enable	0: Disable host address detection 1: Enable host address detection.	R/W

SARyE bit (Slave Address Register y Enable) (y = 0 to 2)

The SARyE bit enables or disables the received slave address and the slave address set in SARLy and SARUy.

When this bit is set to 1, the slave address set in SARLy and SARUy is enabled and is compared with the received slave address. When this bit is set to 0, the slave address set in SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

0，无论接收到的确认内容如何， 都继续下一个传输操作。

有关详细信息，请参阅第36.9.2节，NACK接收传输暂停功能。

SCLE位（SCL同步电路使能）

SCLE位指定是否将SCL时钟与SCL输入时钟同步。通常，将此位设置为1。

当SCLE位设置为0（不使用SCL同步电路）时，IIC不会将SCL时钟与SCL输入时钟同步。使用此设置，无论SCLn线路状态如何，IIC都以ICBRH和ICBRL中设置的传输速率输出SCL时钟。因此，如果I2C总线的总线负载远大于规格值，或者多个主机的SCL时钟输出重叠，则可能会输出不符合规格的短周期SCL时钟。当不使用SCL同步电路时，也会影响启动、重启和停止条件的发出，以及额外SCL时钟周期的连续输出。

除非检查设置传输速率的输出，否则不要将此位设置为0。

FMPE位（快速模式加启用）

FMPE位指定是否对Fast-modePlus(Fm+)使用斜率控制电路。

当该位设置为1时，选择符合I2C总线快速模式加(Fm+)标准(tof)的斜率控制电路。当该位设置为0时，选择符合I2C总线标准模式(Sm)和快速模式(Fm)标准(tof)的斜率控制电路。

当使用高达1Mbps的传输速率（Fast-modePlus(Fm+)标准）时，将此位设置为1。当使用其他传输速率（最高100kbps(Sm)或最高400kbps(Fm)）或SMBus（10至100kbps）时，将其设置为0。

SARyE位（从地址寄存器y使能）（y=0到2）

SARyE位启用或禁用接收到的从机地址和设置在SARLy和SARUy中的从机地址。

当该位设置为1时，设置在SARLy和SARUy中的从机地址被启用，并与接收到的从机地址进行比较。当该位设置为0时，设置在SARLy和SARUy中的从机地址被禁用并被忽略，即使它与接收到的从机地址匹配。

GCAE bit (General Call Address Enable)

The GCAE bit specifies whether to ignore the general call address (0000 000b + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the IIC recognizes the received slave address as the general call address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the data receive operation. When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

DIDE bit (Device-ID Address Detection Enable)

The DIDE bit specifies whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first frame after a start or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the IIC recognizes that the device-ID address was received. When the next R/W# bit is 0 (W), the IIC recognizes the second and the subsequent frames as slave addresses and continues the receive operation. When this bit is set to 0, the IIC ignores the received first frame even if it matches the device-ID address, and it recognizes the first frame as a normal slave address.

For details on this function, see section 36.7.3, Device-ID Address Detection.

HOAE bit (Host Address Enable)

The HOAE bit specifies whether to ignore the received host address (0001 000b) when the SMBS bit in ICMR3 is 1.

When this bit is set to 1 while the SMBS bit in ICMR3 is 1, if the received slave address matches the host address, the IIC recognizes the received slave address as the host address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the receive operation.

When the SMBS bit in ICMR3 or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

GCAE位（广播呼叫地址使能）

GCAE位指定接收到的广播调用地址（0000000b+0[W]：全0）是否忽略。

当该位设置为1时，如果接收到的从机地址与广播呼叫地址匹配，则IIC将接收到的从机地址识别为广播呼叫地址，而与在SARLy和SARUy中设置的从机地址（y=0到2）无关，并执行数据接收操作。当该位设置为0时，即使接收到的从机地址与广播呼叫地址匹配，也会忽略它。

DIDE位（设备ID地址检测使能）

DIDE位指定在检测到启动或重新启动条件后的第一帧中接收到设备ID(1111100b)时是否识别和执行设备ID地址。

当该位设置为1时，如果接收到的第一个帧与设备ID匹配，则IIC识别出设备ID地址已被接收。当下一个RW#位为0(W)时，IIC将第二个和后续帧识别为从地址并继续接收操作。当该位设置为0时，IIC忽略接收到的第一帧，即使它与设备ID地址匹配，并将第一帧识别为正常的从地址。

有关此功能的详细信息，请参阅第36.7.3节，设备ID地址检测。

HOAE位（主机地址使能）

HOAE位指定当ICMR3中的SMBS位为1时是否忽略接收到的主机地址（0001000b）。

当该位设置为1且ICMR3中的SMBS位为1时，如果接收到的从机地址与主机地址匹配，则IIC将接收到的从地址识别为主机地址，与SARLy中设置的从地址无关，并且SARUy（y=0到2）并执行接收操作。

当ICMR3中的SMBS位或HOAE位设置为0时，即使接收到的从机地址与主机地址匹配，也会忽略它。

TMOIE bit (Timeout Interrupt Request Enable)

The TMOIE bit enables or disables timeout interrupt (TMOI) requests when the TMOF flag in ICSR2 is 1. To cancel a TMOI interrupt request, set the TMOF flag or the TMOIE bit to 0.

ALIE bit (Arbitration-Lost Interrupt Request Enable)

The ALIE bit enables or disables arbitration-lost interrupt (ALI) requests when the AL flag in ICSR2 is 1. To cancel an ALI interrupt request, set the AL flag or the ALIE bit to 0.

STIE bit (Start Condition Detection Interrupt Request Enable)

The STIE bit enables or disables start condition detection interrupt (STI) requests when the START flag in ICSR2 is 1. To cancel an STI interrupt request, set the START flag or the STIE bit to 0.

SPIE bit (Stop Condition Detection Interrupt Request Enable)

The SPIE bit enables or disables stop condition detection interrupt (SPI) requests when the STOP flag in ICSR2 is 1. To cancel an SPI interrupt request, set the STOP flag or the SPIE bit to 0.

NAKIE bit (NACK Reception Interrupt Request Enable)

The NAKIE bit enables or disables NACK reception interrupt (NAKI) requests when the NACKF flag in ICSR2 is 1. To cancel an NAKI interrupt request, set the NACKF flag or the NAKIE bit to 0.

RIE bit (Receive Data Full Interrupt Request Enable)

The RIE bit enables or disables receive data full interrupt (IICn_RXI) requests when the RDRF flag in ICSR2 is 1.

TEIE bit (Transmit End Interrupt Request Enable)

The TEIE bit enables or disables transmit end interrupt (IICn_TEI) requests when the TEND flag in ICSR2 is 1. To cancel an IICn_TEI interrupt request, set the TEND flag or the TEIE bit to 0.

TIE bit (Transmit Data Empty Interrupt Request Enable)

The TIE bit enables or disables transmit data empty interrupt (IICn_TXI) requests when the TDRE flag in ICSR2 is 1.

TMOIE位（超时中断请求使能）

当ICSR2中的TMOF标志为1时，TMOIE位启用或禁用超时中断(TMOI)请求。取消一个TMOI中断请求，设置TMOF标志或TMOIE位为0。

ALIE位（仲裁丢失中断请求使能）

当ICSR2中的AL标志为1时，ALIE位启用或禁用仲裁丢失中断(ALI)请求。取消ALI中断请求，设置AL标志或ALIE位为0。

STIE位（启动条件检测中断请求使能）

当ICSR2中的START标志为1时，STIE位启用或禁用启动条件检测中断(STI)请求。要取消STI中断请求，请将START标志或STIE位设置为0。

SPIE位（停止条件检测中断请求使能）

当ICSR2中的STOP标志为1时，SPIE位启用或禁用停止条件检测中断(SPI)请求。要取消SPI中断请求，请将STOP标志或SPIE位设置为0。

NAKIE位（NACK接收中断请求使能）

当ICSR2中的NACKF标志为1时，NAKIE位启用或禁用NACK接收中断(NAKI)请求。要取消NAKI中断请求，请将NACKF标志或NAKIE位设置为0。

RIE位（接收数据满中断请求使能）

当ICSR2中的RDRF标志为1时，RIE位启用或禁用接收数据完整中断(IICn_RXI)请求。

TEIE位（发送结束中断请求使能）

当ICSR2中的TEND标志为1时，TEIE位启用或禁用发送结束中断(IICn_TEI)请求。要取消IICn_TEI中断请求，请将TEND标志或TEIE位设置为0。

TIE位（发送数据空中断请求使能）

当ICSR2中的TDRE标志为1时，TIE位启用或禁用发送数据空中断（IICn_TXI）请求。

AASy flag (Slave Address y Detection Flag) (y = 0 to 2)

The AASy flag indicates whether slave address y was detected.

[Setting conditions]

For 7-bit address format (SARUy.FS = 0):

- When the received slave address matches the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format: (SARUy.FS = 1):

- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address matches the SARLy value, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the AASy flag after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

For 7-bit address format (SARUy.FS = 0):

- When the received slave address does not match the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format (SARUy.FS = 1):

- When the received slave address does not match a value of (11110b + SVA[1:0] in SARUy), with the SARyE bit in ICSER set to 1 (slave address y detection enabled)
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address does not match the SARLy value, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

GCA flag (General Call Address Detection Flag)

The GCA flag indicates whether the general call address was detected.

[Setting condition]

- When the received slave address matches the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSER set to 1 (general call address detection enabled).
  The GCA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the GCA flag after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSER set to 1 (general call address detection enabled)

Note 1. 只能写入0，以清除标志。

AASy标志（从机地址y检测标志）（y=0到2）

AASy标志指示是否检测到从地址y。

[Setting conditions]

对于7位地址格式(SARUy.FS=0)：

- 当接收到的从机地址与SARLy中的SVA[6:0]值匹配时，ICSER中的SARyE位设置为1（启用从机地址y检测）。AASy标志在帧中第9个SCL时钟周期的上升沿设置为1。

对于10位地址格式：(SARUy.FS=1)：

- 当接收到的从地址与(SARUy中的11110b+SVA[1:0])值匹配，并且后续地址与SARLy值匹配时，ICSER中的SARyE位设置为1（启用从地址y检测）。AASy标志在帧中第9个SCL时钟周期的上升沿设置为1。

[Clearing conditions]

- 读取AASy=1后将0写入AASy标志时
- 检测到停止条件时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

对于7位地址格式(SARUy.FS=0)：

- 当接收到的从地址与SARLy中的SVA[6:0]值不匹配时，ICSER中的SARyE位设置为1（从地址y检测使能）。AASy标志在帧中第9个SCL时钟周期的上升沿设置为0。

对于10位地址格式(SARUy.FS=1)：

- 当接收到的从机地址与（SARUy中的11110b+SVA[1:0]）的值不匹配时，使用SARyE位
  ICSER设置为1（启用从地址y检测）
  AASy标志在帧中第9个SCL时钟周期的上升沿设置为0。
- 当接收到的从地址与(SARUy中的11110b+SVA[1:0])的值匹配，并且后续地址与SARLy值不匹配时，ICSER中的SARyE位设置为1（启用从地址y检测）。AASy标志在帧中第9个SCL时钟周期的上升沿设置为0。

GCA标志（广播呼叫地址检测标志）

GCA标志指示是否检测到广播呼叫地址。

[Setting condition]

- 当接收到的从机地址与广播地址（0000000b+0[W]）匹配时，GCAE位在
  ICSER设置为1（启用广播呼叫地址检测）。
  GCA标志在帧中第9个SCL时钟周期的上升沿设置为1。

[Clearing conditions]

- 读取GCA=1后将0写入GCA标志时
- 检测到停止条件时
- 当接收到的从机地址与广播地址（0000000b+0[W]）不匹配时，GCAE位在
  ICSER设置为1（启用广播地址检测）

The GCA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

DID flag (Device-ID Address Detection Flag)

The DID flag indicates whether the device-ID address was detected.

[Setting condition]

- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), with the DIDE bit in ICSER set to 1 (device-ID address detection enabled).
  The DID flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the DID flag after reading DID = 1
- When a stop condition is detected
- When the first frame received immediately after a start or restart condition is detected does not match a value of (device ID (1111 100b)), with the DIDE bit in ICSER set to 1 (device-ID address detection enabled)
  The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), and the second frame does not match any slave address from 0 to 2, with the DIDE bit in ICSER set to 1 (device-ID address detection enabled)
  The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

HOA flag (Host Address Detection Flag)

The HOA flag indicates whether the host address was detected.

[Setting condition]

- When the received slave address matches the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled).
  The HOA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the HOA flag after reading HOA = 1
- When a stop condition is detected
- When the received slave address does not match the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled)
  The HOA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

DID标志（Device-ID地址检测标志）

DID标志指示是否检测到设备ID地址。

[Setting condition]

- 当检测到启动或重新启动条件后立即接收到的第一帧与(设备ID(1111100b)+0[W])的值匹配，且ICSER中的DIDE位设置为1（启用设备ID地址检测）。DID标志在帧中第9个SCL时钟周期的上升沿设置为1。

[Clearing conditions]

- 当读取DID=1后将0写入DID标志
- 检测到停止条件时
- 当检测到启动或重新启动条件后立即接收的第一帧与（设备ID（1111100b））的值不匹配时，ICSER中的DIDE位设置为1（启用设备ID地址检测）DID标志为在帧的第9个SCL时钟周期的上升沿设置为0。
- 当检测到启动或重新启动条件后立即接收到的第一帧与(设备ID(1111100b)+0[W])的值匹配，并且第二帧不匹配从0到2的任何从地址时，使用DIDEICSER中的位设置为1（启用设备ID地址检测）

  DID标志在帧中第9个SCL时钟周期的上升沿设置为0。
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

HOA标志（主机地址检测标志）

HOA标志指示是否检测到主机地址。

[Setting condition]

- 当接收到的从机地址与主机地址（0001000b）匹配时，ICSER中的HOAE位设置为1（主机地址检测使能）。HOA标志在帧中第9个SCL时钟周期的上升沿设置为1。

Note 1. Only 0 can be written, to clear the flag.

TMOF flag (Timeout Detection Flag)

The TMOF flag is set to 1 when the IIC detects a timeout because the SCLn line state remains unchanged for the set period.

[Setting condition]

- When the SCLn line state remains unchanged for the period specified in the ICMR2.TMOH, TMOL, and TMOS bits while the ICFER.TMOE bit is 1 (timeout function enabled) in master or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF flag after reading TMOF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

AL flag (Arbitration-Lost Flag)

The AL flag indicates that bus mastership was lost in arbitration because of a bus conflict or some other reason when a start condition was issued or an address and data was transmitted. The IIC monitors the level on the SDAn line during transmission and, if the level on the line does not match the value of the bit being output, is set the value of the AL flag to 1 to indicate that the bus is occupied by another device.

The IIC can also set the flag to indicate the detection of arbitration loss during NACK transmission or during data transmission.

[Setting conditions]

When master arbitration-lost detection is enabled (ICFER.MALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock except for the ACK period during data transmission in master transmit mode
- When a start condition is detected while the ST bit in ICCR2 is 1 (start condition requested) or the internal SDA output state does not match the SDAn line level
- When the ST bit in ICCR2 is 1 (start condition requested), with the BBSY flag in ICCR2 set to 1.

When NACK arbitration-lost detection is enabled (ICFER.NALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICFER.SALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock, except for the ACK period during data transmission in slave transmit mode.

b7	TDRE	传输数据空标志	0：ICDRT包含发送数据1：ICDRT不 包含发送数据。	R

Note 1. 只能写入0，以清除标志。

TMOF标志（超时检测标志）

当IIC检测到超时时，TMOF标志设置为1，因为SCLn线路状态在设置的周期内保持不变。

[Setting condition]

- 当SCLn线状态在ICMR2.TMOH、TMOL和TMOS位指定的时间段内保持不变，而ICFER.TMOE位在主机或从机模式下为1（启用超时功能）并且接收到的从机地址匹配。

[Clearing conditions]

- 读取TMOF=1后向TMOF标志写入0时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

AL标志（仲裁失败标志）

AL标志表明在发出启动条件或传输地址和数据时，由于总线冲突或其他原因，总线控制权在仲裁中丢失。IIC在传输过程中监视SDAn线上的电平，如果线上的电平与正在输出的位的值不匹配，则将AL标志的值设置为1，以指示总线被另一个设备占用.

IIC还可以设置该标志以指示在NACK传输期间或数据传输期间检测到仲裁丢失。

[Setting conditions]

当启用主机仲裁丢失检测时(ICFER.MALE=1)：

- 当内部SDA输出状态与SCL时钟上升沿上的SDAn线电平不匹配时，除了在主传输模式下的数据传输期间的ACK周期
- 当ICCR2中的ST位为1（请求启动条件）或内部SDA输出状态与SDAn线电平不匹配时检测到启动条件
- ICCR2中的ST位为1（请求启动条件）时，ICCR2中的BBSY标志设置为1。

当启用NACK仲裁丢失检测时(ICFER.NALE=1)：

- 当内部SDA输出状态与SCL时钟上升沿上的SDAn线电平不匹配时
接收模式下NACK传输期间的ACK周期。

当启用从设备仲裁丢失检测时(ICFER.SALE=1)：

- 当内部SDA输出状态与SCL时钟上升沿上的SDAn线电平不匹配时，除了从机发送模式下数据传输期间的ACK周期。

[Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

START flag (Start Condition Detection Flag)

The START flag indicates whether a start condition was detected.

[Setting condition]

- When a start (or restart) condition is detected.

[Clearing conditions]

- When 0 is written to the START flag after reading START = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

STOP flag (Stop Condition Detection Flag)

The STOP flag indicates whether a stop condition was detected.

[Setting condition]

- When a stop condition is detected.

[Clearing conditions]

- When 0 is written to the STOP flag after reading STOP = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

NACKF flag (NACK Detection Flag)

The NACKF flag indicates whether a NACK was detected.

[Setting condition]

- When acknowledge is not received (NACK received) from the receive device in transmit mode, with the NACKE bit in ICFER set to 1 (transfer suspension enabled).

[Clearing conditions]

- When 0 is written to the NACKF flag after reading NACKF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1, the IIC suspends data transmission and reception. Writing to ICDRT in transmit

[Clearing conditions]

- 读取AL=1后向AL标志写入0时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

START标志（开始条件检测标志）

START标志指示是否检测到启动条件。

[Setting condition]

- 当检测到启动（或重新启动）条件时。

[Clearing conditions]

- 读取START=1后将0写入START标志时
- 检测到停止条件时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

停止标志（停止条件检测标志）

STOP标志指示是否检测到停止条件。

[Setting condition]

- 当检测到停止条件时。

[Clearing conditions]

- 在读取STOP=1后将0写入STOP标志时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

NACKF标志（NACK检测标志）

NACKF标志指示是否检测到NACK。

[Setting condition]

- 当在发送模式下没有从接收设备接收到确认（NACK接收）时，ICFER中的NACKE位设置为1（使能传输暂停）。

[Clearing conditions]

- 读取NACKF=1后将0写入NACKF标志时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

Note: 当NACKF标志设置为1时，IIC暂停数据发送和接收。在传输中写入ICDRT

mode or reading from ICDRR in receive mode with the NACKF flag set to 1 does not enable data transmit or receive operation. To restart data transmission or reception, set the NACKF flag to 0.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates whether the IDCRR contains receive data.

[Setting conditions]

- When receive data is transferred from ICDRS to ICDRR
  The RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL clock cycle (selected in the RDRFS bit in ICMR3).
- When the received slave address matches after a start (or restart) condition is detected with the TRS bit in ICCR2 set to 0.

[Clearing conditions]

- When 0 is written to the RDRF flag after reading RDRF = 1
- When data is read from ICDRR
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

TEND flag (Transmit End Flag)

The TEND flag indicates whether data transmission is still being transmitted or is complete.

[Setting condition]

- On the rising edge of the ninth SCL clock cycle while the TDRE flag is 1.

[Clearing conditions]

- When 0 is written to the TEND flag after reading TEND = 1
- When data is written to ICDRT
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates whether the ICDRT contains transmit data.

[Setting conditions]

- When data is transferred from ICDRT to ICDRS and ICDRT becomes empty
- When the TRS bit in ICCR2 is set to 1
- When the received slave address matches while the TRS bit is 1.

[Clearing conditions]

- When data is written to ICDRT
- When the TRS bit in ICCR2 is set to 0
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1 while the NACKE bit in ICFER is 1, the IIC suspends data transmission and reception. Here, if the TDRE flag is 0 (next transmit data written), data is transferred to the ICDRS register and the ICDRT register becomes empty on the rising edge of the ninth clock cycle, but the TDRE flag does not set to 1.

模式或在NACKF标志设置为1的接收模式下从ICDRR读取不会启用数据发送或接收操作。要重新开始数据发送或接收，请将NACKF标志设置为0。

RDRF标志（接收数据满标志）

RDRF标志指示IDCRR是否包含接收数据。

[Setting conditions]

- 当接收数据从ICDRS传输到ICDRR
  RDRF标志在第8个或第9个SCL时钟周期的上升沿设置为1（在RDRFS位中选择ICMR3).
- 当ICCR2中的TRS位设置为0检测到启动（或重新启动）条件后接收到的从机地址匹配时。

[Clearing conditions]

- 读取RDRF=1后向RDRF标志写入0时
- 从ICDRR读取数据时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

TEND标志（发送结束标志）

TEND标志指示数据传输是否仍在传输中或已完成。

[Setting condition]

- 在第9个SCL时钟周期的上升沿，同时TDRE标志为1。

[Clearing conditions]

- 读取TEND=1后将0写入TEND标志时
- 数据写入ICDRT时
- 检测到停止条件时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

TDRE标志（传输数据空标志）

TDRE标志指示ICDRT是否包含发送数据。

[Setting conditions]

- 当数据从ICDRT传输到ICDRS并且ICDRT变为空时
- ICCR2中的TRS位设置为1时
- 当TRS位为1时接收到的从机地址匹配。

[Clearing conditions]

- 数据写入ICDRT时
- ICCR2中的TRS位设置为0时
- 当向ICCR1中的IICRST位写入1时，应用IIC复位或内部复位。

Note: 当ICFER的NACKE位为1时NACKF标志设置为1，IIC暂停数据发送和接收。此处，如果TDRE标志为0（写入下一个发送数据），则数据被传送到ICDRS寄存器，并且ICDRT寄存器在第9个时钟周期的上升沿变为空，但TDRE标志不设置为1。

WUSEN bit (Wakeup Function Synchronous Enable)

It combines with the WUASYF flag (or WUSYF flag) at wakeup effective function (ICWUR.WUE = 1), and the PCLKB synchronous operation and the PCLKB asynchronous operation are switched.

[When switching from the PCLKB synchronous operation to the PCLKB asynchronous operation]

It changes into the PCLKB asynchronous operation when the ICCR2.BBSY flag is 0 if the WUASYF flag writes 0 in the WUSEN bit in the state of 0. The reception can operate without depending on the state of operation of PCLKB (with PCLKB stopped) after it switches to the PCLKB asynchronous operation (wakeup event detection operation).

[When switching from the PCLKB asynchronous operation to the PCLKB synchronous operation]

It changes into the PCLKB synchronization and the WUASYF flag becomes 0 at once after writing of 1 when the wakeup event is detected if 1 is written in the WUSEN bit when the WUASYF flag is 1. At the same time, WUASYF flag becomes 0. In other case, it changes into the PCLKB synchronous operation when the stop condition is detected at the wakeup event undetected.

WUASYF flag (Wakeup Function Asynchronous Operation Status Flag)

It is shown that IIC is in the PCLKB asynchronous operation at wakeup effective function (ICWUR.WUE = 1).

[Setting condition]

- When the ICCR2.BBSY flag is 0 with the ICWUR.WUE bit set to 1 after writing 0 to the WUSEN bit.

[Clearing conditions]

- When 1 is written to the WUSEN bit after detecting the wakeup event with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wakeup event with WUASY flag set to 1 with ICWUR.WUE bit set to 1.
- When you write 1 in the WUSEN bit with the WUASYF flag detected 1 and the wakeup event in the state of ICWUR.WUE = 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

WUSYF flag (Wakeup Function Synchronous Operation Status Flag)

It is shown that IIC is in the PCLKB synchronous operation at wakeup effective function (ICWUR.WUE = 1). This flag is a value in which the WUASYF flag is always reserved.

WUSEN位（唤醒功能同步使能）

它在唤醒有效功能（ICWUR.WUE=1）时与WUASYF标志（或WUSYF标志）结合，切换PCLKB同步操作和PCLKB异步操作。

[从PCLKB同步操作切换到PCLKB异步操作时]

如果WUASYF标志在
WUSEN位处于0状态。接收可以在不依赖于PCLKB的操作状态的情况下进行操作（与PCLKB停止）后切换到PCLKB异步操作（唤醒事件检测操作）。

[从PCLKB异步操作切换到PCLKB同步操作时]

当WUASYF标志为1时，如果向WUSEN位写入1，则当WUASYF标志为1时，写入1后，WUASYF标志立即变为0。同时，WUASYF标志变为0。其他情况下，当在未检测到唤醒事件时检测到停止条件时，它变为PCLKB同步操作。

WUASYF标志（唤醒功能异步操作状态标志）

SVA0 bit (10-Bit Address LSB)

When the 10-bit address format is selected (SARUy.FS = 1), the SVA0 bit functions as the LSB of a 10-bit address and is combined with the SVA[6:0] bits to form the lower 8 bits of a 10-bit address.

This bit is valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in this bit is ignored.

SVA[6:0] bits (7-Bit Address/10-Bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS = 0), the SVA[6:0] bits function as a 7-bit address. When the 10-bit address format is selected (SARUy.FS = 1), these bits combine with the SVA0 bit to form the lower 8 bits of a 10-bit address.

ICBRL is a 5-bit register that sets the low-level period of the SCL clock. ICBRL also works to generate the data setup time for the automatic SCL low-hold operation (see section 36.9, Automatic Low-Hold Function for SCL). When the IIC is used only in slave mode, this register must be set to a value longer than the data setup time.*1 ICBRL counts the low-level period with the internal reference clock source (IICϕ) specified in the CKS[2:0] bits in ICMR1. If the digital noise filter is enabled (the NFE bit in ICFER is 1), set the ICBRL register to a value at least one greater than the number of stages in the noise filter. For this number, see the description of the ICMR3.NF[1:0] bits.

ICBRL是一个5位寄存器，用于设置SCL时钟的低电平周期。ICBRL还用于为自动SCL低保持操作生成数据建立时间（参见第36.9节，SCL的自动低保持功能）。当IIC仅用于从机模式时，该寄存器必须设置为比数据建立时间更长的值。*1ICBRL使用ICMR1的CKS[2:0]位中指定的内部参考时钟源(IIC)对低电平周期进行计数。如果启用了数字噪声滤波器（ICFER中的NFE位为1），请将ICBRL寄存器设置为至少比噪声滤波器中的级数大1的值。对于这个数字，请参见ICMR3.NF[1:0]位的描述。

ICBRH is a 5-bit register that sets the high-level period of the SCL clock. ICBRH is valid in master mode. If the IIC is used only in slave mode, no setting is required in this register. ICBRH counts the high-level period with the internal reference clock source (IICϕ) specified in the CKS[2:0] bits in ICMR1. If the digital noise filter is enabled (the NFE bit in ICFER is 1), set the ICBRH register to a value at least one greater than the number of stages in the noise filter. For this number, see the description of the ICMR3.NF[1:0] bits.

The IIC transfer rate and the SCL clock duty are calculated using the following expressions (1) to (5):

1. ICFER.SCLE = 0
   Transfer rate = $1/\{[(BRH + 1) + (BRL + 1)]/IIC\varphi^{*1} + tr^{*2} + tf^{*2}\}$
   Duty cycle = $\{tr + [(BRH + 1)/IIC\varphi]\}/\{tr + tf + [(BRH + 1) + (BRL + 1)]/IIC\varphi\}$

   Transfer rate = $1/\{[(BRH + 3) + (BRL+ 3)]/IIC\varphi + tr + tf\}$
   Duty cycle = $\{tr + [(BRH + 3)/IIC\varphi]\}/\{tr + tf + [(BRH + 3) + (BRL + 3)]/IIC\varphi\}$
3. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = $1/\{[(BRH + 3 + nf^{*3}) + (BRL + 3 + nf)]/IIC\varphi + tr + tf\}$
   Duty cycle = $\{tr + [(BRH + 3 + nf)/IIC\varphi]\}/\{tr + tf + [(BRH + 3 + nf) + (BRL + 3 + nf)]/IIC\varphi\}$
4. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] ≠ 000b
   Transfer rate = $1/\{[(BRH + 2) + (BRL + 2)]/IIC\varphi + tr + tf\}$
   Duty cycle = $\{tr + [(BRH + 2)/IIC\varphi]\}/\{tr + tf + [(BRH + 2) + (BRL + 2)]/IIC\varphi\}$
5. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] ≠ 000b
   Transfer rate = $1/\{[(BRH + 2 + nf) + (BRL + 2 + nf)]/IIC\varphi + tr + tf\}$
   Duty cycle = $\{tr + [(BRH + 2 + nf)/IIC\varphi]\}/\{tr + tf + [(BRH + 2 + nf) + (BRL + 2 + nf)]/IIC\varphi\}$

Note 1. IICφ = PCLKB × division ratio
Note 2. The SCLn line rise time (tr) and SCLn line fall time (tf) depend on the total bus line capacitance (Cb) and the pull-up resistor (Rp). For details, see the I2C bus standard from NXP Semiconductors.
Note 3. nf = Number of digital noise filters selected in the ICMR3.NF bit.

ICBRH是一个5位寄存器，用于设置SCL时钟的高电平周期。ICBRH在主模式下有效。如果IIC仅用于从机模式，则无需对该寄存器进行设置。ICBRH使用ICMR1的CKS[2:0]位中指定的内部参考时钟源(IIC　)计算高电平周期。如果启用了数字噪声滤波器（ICFER中的NFE位为1），请将ICBRH寄存器设置为至少比噪声滤波器中的级数大1的值。对于这个数字，请参见ICMR3.NF[1:0]位的描述。

IIC传输速率和SCL时钟占空比使用以下表达式(1)到(5)计算：

1. ICFER.SCLE = 0
   传输率=$1\{[(BRH+1)+(BRL+1)]IIC\phi*1+tr*2+tf*2$

Value after reset:	1	1	1	1	1	1	1	1

When ICDRT detects a space in the IIC-Bus Shift Register (ICDRS), it transfers the transmit data that was written to ICDRT to ICDRS and starts transmitting data in transmit mode. The double-buffer structure of ICDRT and ICDRS allows continuous transmit operation if the next transmit data is written to ICDRT while the ICDRS data is being transmitted.

ICDRT can always be read and written to. Write transmit data to ICDRT once when a transmit data empty interrupt (IICn_TXI) request is generated.

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

When 1 byte of data is received, the received data is transferred from the IIC-Bus Shift Register (ICDRS) to ICDRR to enable the next data to be received. The double-buffer structure of ICDRS and ICDRR allows continuous receive operation if the received data is read from ICDRR while ICDRS is receiving data. ICDRR cannot be written to. Read data from ICDRR once when a receive data full interrupt (IICn_RXI) request is generated.

If ICDRR receives the next receive data before the current data is read from ICDRR (while the RDRF flag in ICSR2 is 1), the IIC automatically holds the SCL clock low 1 cycle before the RDRF flag is set to 1 next.

重置后的值：	1	1	1	1	1	1	1	1

当ICDRT检测到IIC总线移位寄存器(ICDRS)中有空间时，它会将写入的发送数据传输到ICDRT到ICDRS并开始在传输模式下传输数据。ICDRT和ICDRS的双缓冲结构允许在传输ICDRS数据的同时将下一个传输数据写入ICDRT的连续传输操作。

ICDRT始终可以被读取和写入。当产生发送数据空中断（IICn_TXI）请求时，将发送数据写入ICDRT。

36.2.18 I2C总线接收数据寄存器(ICDRR)

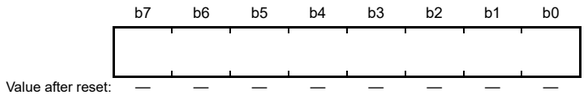
Address(es): IIC0.ICDRR 4005 3013h, IIC1.ICDRR 4005 3113h, IIC2.ICDRR 4005 3213h

	b7	b6	b5	b4	b3	b2	b1	b0
重置后的值：	0	0	0	0	0	0	0	0

当接收到1个字节的数据时，接收到的数据会从IIC总线移位寄存器(ICDRS)传输到ICDRR，以便接收下一个数据。如果在ICDRS正在接收数据时从ICDRR读取接收到的数据，ICDRS和ICDRR的双缓冲结构允许连续接收操作。无法写入ICDRR。当产生接收数据完全中断(IICn_RXI)请求时，从ICDRR读取数据一次。

如果ICDRR在从ICDRR读取当前数据之前接收到下一个接收数据（此时ICSR2中的RDRF标志为1），则IIC在下一个RDRF标志设置为1之前自动将SCL时钟保持低1个周期。

36.2.19 I2C Bus Shift Register (ICDRS)



ICDRS is an 8-bit shift register for data transmit and receive. During transmission, transmit data is transferred from ICDRT to ICDRS and is transmitted from the SDAn pin. During reception, data is transferred from ICDRS to ICDRR after 1 byte of data is received. ICDRS cannot be accessed directly.

36.3 Operation

36.3.1 Communication Data Format

The I2C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start or restart condition is an address frame that specifies a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 36.3 shows the I2C bus format, and Figure 36.4 shows the I2C bus timing.

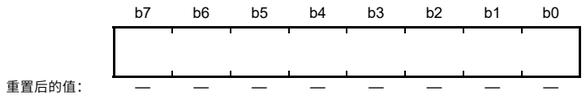
SLA: Slave address, by which the master device selects a slave device.

36.2.19 I2C总线移位寄存器(ICDRS)



ICDRS是一个用于数据发送和接收的8位移位寄存器。在传输过程中，传输数据从ICDRT到ICDRS并从SDAn引脚传输。在接收过程中，接收到1个字节的数据后，数据从ICDRS传输到ICDRR。ICDRS不能直接访问。

36.3 Operation

36.3.1 通讯数据格式

I2C总线格式由8位数据和1位确认组成。开始或重启条件之后的帧是地址帧，它指定与主设备通信的从设备。指定的从站有效，直到指定新的从站或发出停止条件。

图36.3显示了I2C总线格式，图36.4显示了I2C总线时序。

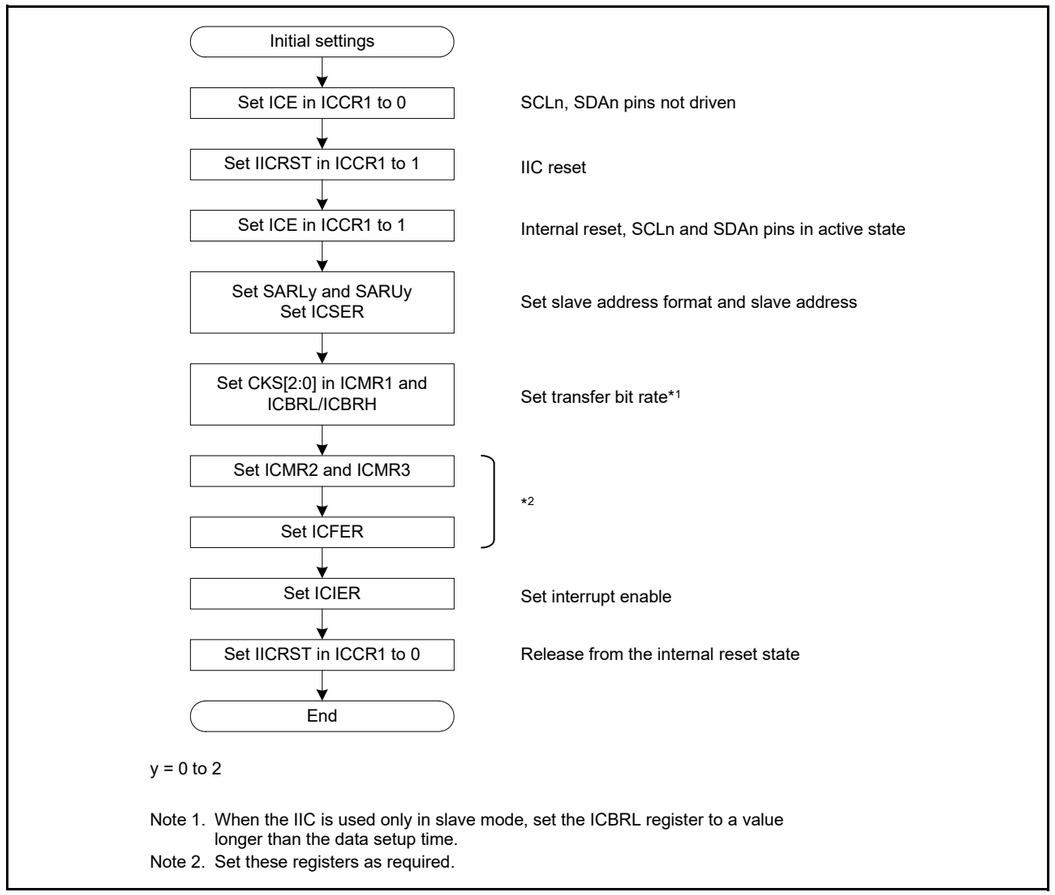
DATA: Transmitted or received data.

P: Stop condition. The master device drives the SDAn line high from low while the SCLn line is high.

36.3.2 Initial Settings

Before starting data transmission and reception, initialize the IIC using the procedure shown in Figure 36.5. Set the ICCR1.ICE bit to 1 (internal reset) after setting the ICCR1.IICRST bit to 1 (IIC reset) with the ICCR1.ICE bit set to 0 (SCLn and SDAn pins in inactive state). This internal reset procedure initializes the flags and the internal state of the ICSR1 register. Next, set the SARLy, SARUy, ICSER, ICMR1, ICBRH, and ICBRL registers (y = 0 to 2), and set the other registers as required (for the initial IIC settings, see Figure 36.5). When the required register settings are complete, set the ICCR1.IICRST bit to 0, releasing the IIC reset. This step is not necessary if initialization of the IIC is already complete.



Note 1. When the IIC is used only in slave mode, set the ICBRL register to a value longer than the data setup time.
Note 2. Set these registers as required.

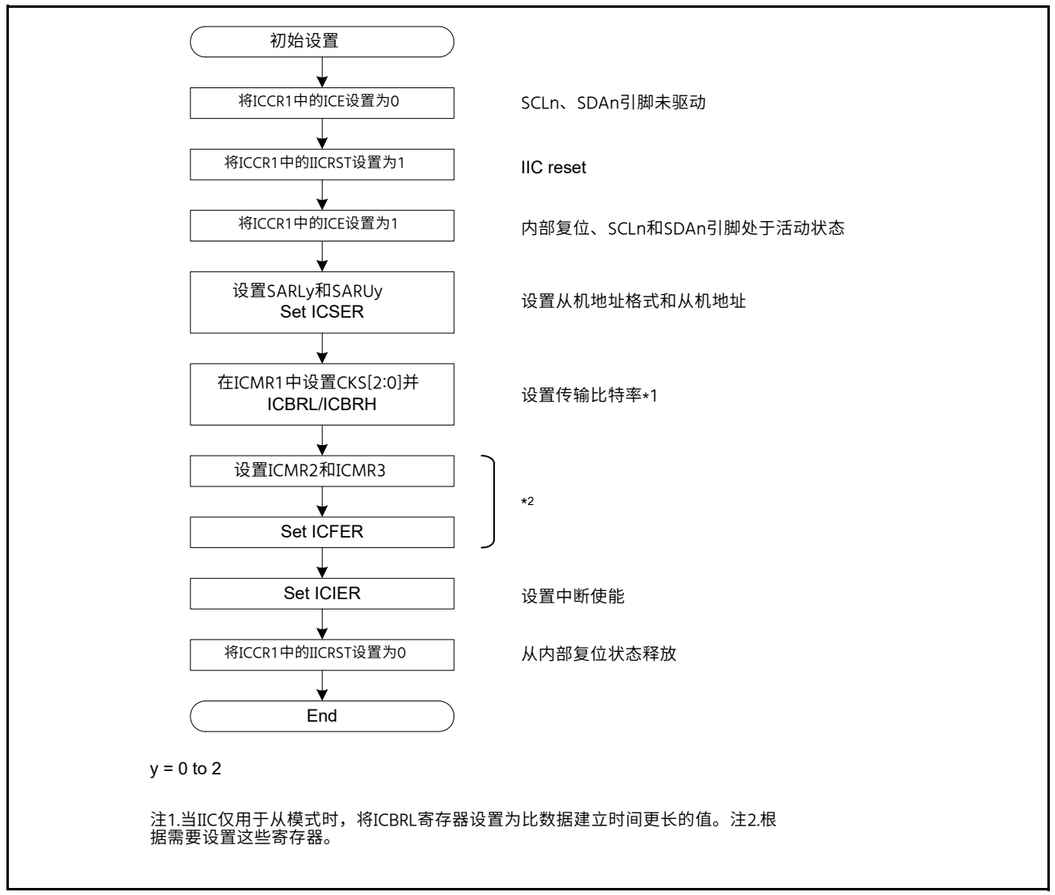
36.3.2 初始设置

在开始数据发送和接收之前，使用图36.5所示的过程初始化IIC。设置
将ICCR1.IICRST位设置为1（IIC复位）且ICCR1.ICE位设置为0（SCLn和SDAn引脚处于非活动状态）后，ICCR1.ICE位为1（内部复位）。此内部复位程序初始化ICSR1寄存器的标志和内部状态。接下来，设置SARLy、SARUy、ICSER、ICMR1、ICBRH和ICBRL寄存器（y=0到2），并根据需要设置其他寄存器（有关初始IIC设置，请参见图36.5）。当所需的寄存器设置完成后，将ICCR1.IICRST位设置为0，释放IIC复位。如果IIC的初始化已经完成，则不需要此步骤。



注1.当IIC仅用于从模式时，将ICBRL寄存器设置为比数据建立时间更长的值。注2.根据需要设置这些寄存器。

Figure 36.5 示例IIC初始化流程

36.3.3 Master Transmit Operation

In master transmit operation, the IIC outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 36.6 shows an example of master transmission, and Figure 36.7 to Figure 36.9 show the operation timing in master transmission.

To set up and perform master transmission:

1. Process initial settings. For details, see section 36.3.2, Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and START flags in ICSR2 automatically set to 1 and the ST bit automatically is set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. After the byte containing the slave address and R/W# bit is transmitted, the value of the TRS bit automatically updates to select master transmit or master receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the IIC continues in master transmit mode.
   Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For data transmission with an address in the 10-bit format, start by writing 1111 0b, the 2 higher-order bits of the slave address, and W to ICDRT as the first address transmission. For the second address transmission, write the 8 lower-order bits of the slave address to ICDRT.
4. Check that the TDRE flag in ICSR2 is 1, and then write the transmit data to the ICDRT register. The IIC automatically holds the SCLn line low until the transmit data is ready or a stop condition is issued.
5. After all bytes of transmit data are written to the ICDRT register, wait until the value in the TEND flag in ICSR2 returns to 1, and then set the SP bit in ICCR2 to 1 (stop condition requested). On receiving a stop condition request, the IIC issues the stop condition. For details on issuing a stop condition, see section 36.11.3, Issuing a Stop Condition.
6. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, it automatically sets the TDRE and TEND flags to 0, and sets the STOP flag in ICSR2 to 1.
7. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

36.3.3 主发送操作

在主设备发送操作中，IIC作为主设备输出SCL时钟和发送的数据信号，从设备返回确认。图36.6显示了主传输的示例，图36.7至图36.9显示了主传输中的操作时序。

设置和执行主传输：

1. 处理初始设置。有关详细信息，请参阅第36.3.2节，初始设置。
2. 读取ICCR2中的BBSY标志以检查总线是否空闲，然后将ICCR2中的ST位设置为1（启动条件请求）。收到请求后，IIC发出一个开始条件。同时，ICSR2中的BBSY和START标志位自动置1，ST位自动置0。此时，如果检测到启动条件，内部电平为SDA输出状态和当ST位为1时SDAn线匹配，IIC识别出ST位请求的启动条件的发布已成功完成，并且ICCR2中的MST和TRS位自动设置为1，将IIC置于主机发送模式。ICSR2中的TDRE标志也自动设置为1，以响应TRS位设置为1。
3. 检查ICSR2中的TDRE标志是否为1，然后将要发送的值（从机地址和RW#位）写入ICDRT。当发送数据写入ICDRT时，TDRE标志自动设置为0，数据从ICDRT传输到ICDRS，TDRE标志再次设置为1。在发送包含从机地址和RW#位的字节后，TRS位的值会自动更新，以根据发送的RW#位的值选择主机发送或主机接收模式。如果RW#位的值为0，则IIC继续处于主机发送模式。因为此时ICSR2.NACKF标志为1表示没有从设备识别该地址或通信中有错误，所以向ICCR2.SP位写入1以发出停止条件。对于地址为10位格式的数据传输，首先将11110b、从机地址的高2位和W写入ICDRT作为第一个地址传输。对于第二次地址传输，将从地址的低8位写入ICDRT。
4. 检查ICSR2中的TDRE标志是否为1，然后将发送数据写入ICDRT寄存器。IIC自动将SCLn线保持为低电平，直到发送数据准备好或发出停止条件。
5. 将发送数据的所有字节写入ICDRT寄存器后，等待ICSR2中的TEND标志中的值返回1，然后将ICCR2中的SP位设置为1（请求停止条件）。在收到停止条件请求时，IIC发出停止条件。有关发出停止条件的详细信息，请参阅第36.11.3节，发出停止条件。
6. 在检测到停止条件时，IIC自动将ICCR2中的MST和TRS位设置为00b并进入从机接收模式。此外，它自动将TDRE和TEND标志设置为0，并将ICSR2中的STOP标志设置为1。
7. 检查ICSR2.STOP标志是否为1，然后将ICSR2.NACKF和STOP标志设置为0以进行下一次传输操作。

36.3.4 Master Receive Operation

In master receive operation, the IIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because the IIC must start by sending a slave address to the associated slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 36.10 and Figure 36.11 show examples of master reception (7-bit address format), and Figure 36.12 to Figure 36.14 show the operation timing in master reception.

To set up and perform master reception:

1. Process initial settings. For details, see section 36.3.2, Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. When the IIC detects the start condition, the BBSY and START flags in ICSR2 automatically set to 1, and the ST bit automatically is set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. When the byte containing the slave address and R/W# bit is transmitted, the value of the ICCR2.TRS bit automatically updates to select transmit or receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit is 1, the TRS bit is set to 0 on the rising edge of the ninth cycle of the SCL clock, placing the IIC in master receive mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag automatically is set to 1.
   Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 1111 0b, the two higher-order bits of the slave address, and the R bit places the IIC in master receive mode.
4. Dummy read ICDRR after confirming that the RDRF flag in ICSR2 is 1. This makes the IIC start output of the SCL

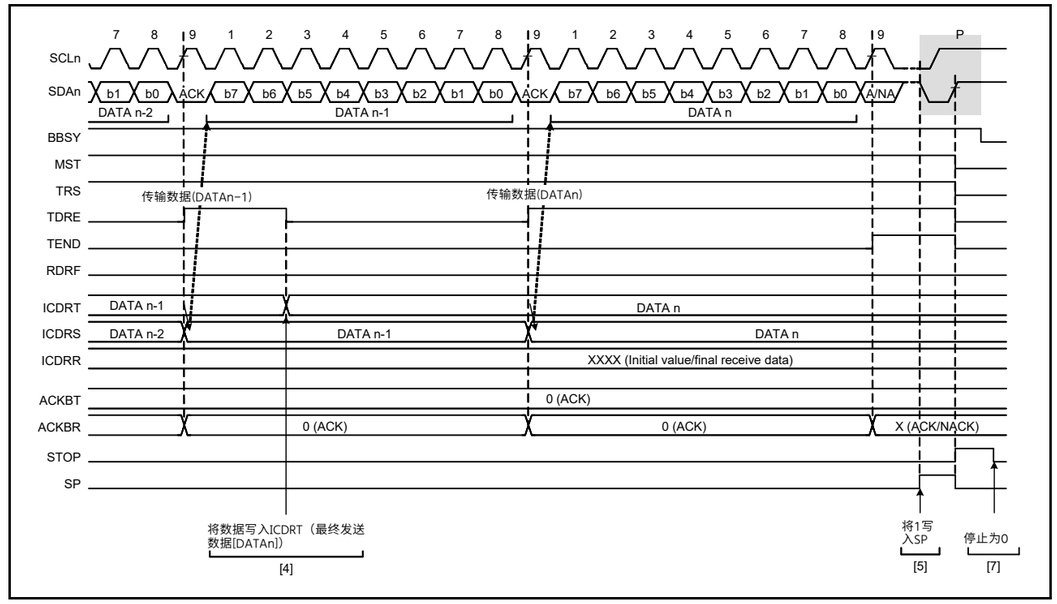

Figure 36.9 主机发送操作时序（3）

36.3.4 主接收操作

在主设备接收操作中，作为主设备的IIC输出SCL时钟，从从设备接收数据，并返回确认。因为IIC必须首先向相关的从设备发送一个从地址，所以这部分程序在主发送模式下执行，但后续步骤在主接收模式下执行。

图36.10和图36.11显示了主机接收示例（7位地址格式），图36.12至图36.14显示了主机接收的操作时序。

设置和执行主接收：

1. 处理初始设置。有关详细信息，请参阅第36.3.2节，初始设置。
2. 读取ICCR2中的BBSY标志以检查总线是否空闲，然后将ICCR2中的ST位设置为1（启动条件请求）。收到请求后，IIC发出一个开始条件。当IIC检测到启动条件时，ICSR2中的BBSY和START标志位自动置1，ST位自动置0。此时，如果检测到启动条件，则SDA输出的电平和电平当ST位为1时SDAn线匹配时，IIC识别出由ST位请求的启动条件的发布已成功完成，并且ICCR2中的MST和TRS位自动设置为1，将IIC置于主机发送模式。ICSR2中的TDRE标志也自动设置为1，以响应TRS位设置为1。
3. 检查ICSR2中的TDRE标志是否为1，然后将要发送的值（第一个字节表示从机地址和RW#位的值）写入ICDRT。当发送数据写入ICDRT时，TDRE标志自动设置为0，数据从ICDRT传输到ICDRS，TDRE标志再次设置为1。当发送包含从机地址和RW#位的字节时，ICCR2.TRS位的值自动更新以根据发送的RW#位的值选择发送或接收模式。如果RW#位的值为1，则在SCL时钟的第9个周期的上升沿将TRS位设置为0，将IIC置于主机接收模式。此时TDRE标志置0，ICSR2.RDRF标志自动置1。因为此时ICSR2.NACKF标志为1表示没有从设备识别该地址或通信出现错误，向ICCR2.SP位写入1以发出停止条件。对于来自具有10位地址的设备的主机接收，首先使用主机发送来发出10位地址，然后发出重启条件。之后，发送11110b、从机地址的两个高位和R位将IIC置于主机接收模式。
4. 确认ICSR2中的RDRF标志为1后虚拟读取ICDRR。这使得SCL的IIC开始输出

clock and start data reception.

5. After 1 byte of data is received, the RDRF flag in ICSR2 is set to 1 on the rising edge of the eighth or ninth cycle of the SCL clock, as selected in the RDRFS bit in ICMR3. Reading ICDRR at this time produces the received data, and the RDRF flag automatically is set to 0 at the same time. Additionally, the value of the acknowledgment field received during the ninth cycle of the SCL clock is returned as the value set in the ICMR3.ACKBT bit. If the next byte to be received is the second-to-last byte, set the ICMR3.WAIT bit to 1, for wait insertion, before reading ICDRR, containing the second-to-last byte. In addition to enabling NACK output, even when interrupts or other operations result in delays in setting the ICMR3.ACKBT bit to 1 (NACK) in step (6), this fixes the SCLn line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, which enables the issuing of a stop condition.
6. When the ICMR3.RDRFS bit is 0, and the slave device must be notified that it is to end transfer for data reception after transfer of the next and final byte, set the ICMR3.ACKBT bit to 1 (NACK).
7. After reading the second-to-last byte from the ICDRR register, if the value of the ICSR2.RDRF flag is 1, write 1 to the SP bit in ICCR2 (stop condition requested), and then read the last byte from ICDRR. When ICDRR is read, the IIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is complete or the SCLn line is released from the low-hold state.
8. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, detection of the stop condition sets the ICSR2.STOP flag to 1.
9. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

时钟并开始数据接收。

5. 在接收到1个字节的数据后，ICSR2中的RDRF标志在SCL时钟的第8个或第9个周期的上升沿被设置为1，这在ICMR3中的RDRFS位中选择。此时读取ICDRR产生接收数据，同时RDRF标志位自动置0。此外，在SCL时钟的第9个周期内接收到的确认字段的值作为ICMR3.ACKBT位中设置的值返回。如果要接收的下一个字节是倒数第二个字节，则将ICMR3.WAIT位设置为1，等待插入，然后再读取包含倒数第二个字节的ICDRR。除了使能NACK输出外，即使在中断或其他操作导致在步骤(6)中将ICMR3.ACKBT位设置为1(NACK)时出现延迟，这也会在第9次的上升沿将SCLn线固定为低电平接收最后一个字节的时钟周期，它可以发出停止条件。
6. 当ICMR3.RDRFS位为0，并且必须通知从设备在传输下一个和最后一个字节后结束传输以进行数据接收时，将ICMR3.ACKBT位设置为1(NACK)。
7. 从ICDRR寄存器中读取倒数第二个字节后，如果ICSR2.RDRF标志的值为1，则将1写入ICCR2中的SP位（请求停止条件），然后从ICDRR中读取最后一个字节。当读取ICDRR时，IIC从等待状态中释放，并在第9个时钟周期的低电平输出完成或SCLn线从低保持状态释放后发出停止条件。
8. 在检测到停止条件时，IIC自动将ICCR2中的MST和TRS位设置为00b并进入从机接收模式。此外，检测到停止条件会将ICSR2.STOP标志设置为1。
9. 检查ICSR2.STOP标志是否为1，然后将ICSR2.NACKF和STOP标志设置为0以进行下一次传输操作。

36.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL clock, the IIC transmits data as a slave device, and the master device returns acknowledgments.

Figure 36.15 shows an example of slave transmission, and Figure 36.16 and Figure 36.17 show the operation timing in slave transmission.

To set up and perform slave transmission:

1. Process initial settings. For details, see section 36.3.2, Initial Settings.
   After the initial settings, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit that was also received at this time is 1, the IIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.
3. Check that the ICSR2.TEND flag is 1, and then write the transmit data to the ICDRT register. At this time, if the IIC receives no acknowledge from the master device (receives an NACK signal) while the ICFER.NACKE bit is 1, the IIC suspends transfer of the next data.
4. Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the IIC drives the SCLn line low on the ninth falling edge of the SCL clock.
5. When the ICSR2.NACKF flag or the ICSR2.TEND flag is 1, dummy read ICDRR to complete the processing. This releases the SCLn line.
6. On detecting the stop condition, the IIC automatically sets the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2), the ICSR2.TDRE and TEND flags, and the ICCR2.TRS bit to 0, and enters slave receive mode.
7. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

36.3.5 从机发送操作

在从发送操作中，主设备输出SCL时钟，IIC作为从设备发送数据，主设备返回确认。

图36.15显示了从机传输的示例，图36.16和图36.17显示了从机传输的操作时序。

设置和执行从属传输：

1. 处理初始设置。有关详细信息，请参阅第36.3.2节，初始设置。
   初始设置后，IIC一直处于待机状态，直到收到匹配的从机地址。
2. 接收到匹配的从地址后，IIC在SCL时钟的第九个周期的上升沿将相关的ICSR1.HOA、GCA和AASy标志之一（y=0到2）设置为1，并输出设置的值在SCL时钟的第9个周期将ICMR3.ACKBT位转换为确认位。如果此时也接收到的RW#位的值为1，则IIC通过将ICCR2.TRS位和ICSR2.TDRE标志都设置为1自动将自身置于从发送模式。
3. 检查ICSR2.TEND标志是否为1，然后将发送数据写入ICDRT寄存器。此时，如果IIC在ICFER.NACKE位为1时没有收到来自主设备的确认（接收到NACK信号），则IIC暂停下一个数据的传输。
4. 等到ICSR2.TEND标志设置为1，而ICSR2.TDRE标志为1，在ICSR2.NACKF标志设置为1或将要发送的最后一个字节写入ICDRT寄存器之后。当ICSR2.NACKF标志或TEND标志为1时，IIC在SCL时钟的第九个下降沿将SCLn线驱动为低电平。
5. 当ICSR2.NACKF标志或ICSR2.TEND标志为1时，假读ICDRR以完成处理。这将释放SCLn线。
6. 在检测到停止条件时，IIC自动设置ICSR1.HOA、GCA和AASy标志（y=0到2），ICSR2.TDRE和TEND标志位，且ICCR2.TRS位为0，进入从机接收模式。
7. 检查ICSR2.STOP标志是否为1，然后将ICSR2.NACKF和STOP标志设置为0以进行下一次传输操作。

36.3.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the IIC returns acknowledgments as a slave device.

Figure 36.18 shows an example of slave reception, and Figure 36.19 and Figure 36.20 show the operation timing in slave reception.

To set up and perform slave reception:

1. Process initial settings. For details, see section 36.3.2, Initial Settings.
   After the initial settings, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit that was also received at this time is 0, the IIC continues to place itself in slave receive mode and sets the RDRF flag in ICSR2 to 1.
3. Check that the ICSR2.STOP flag is 0 and the ICSR2.RDRF flag is 1, and then dummy read ICDRR. The dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected.
4. When ICDRR is read, the IIC automatically sets the ICSR2.RDRF flag to 0. If reading of ICDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the IIC holds the SCLn line low until one SCL cycle before the point where RDRF must be set. In this case, reading ICDRR releases the SCLn line from being held at the low level.
   When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1, read ICDRR until all the data is completely received.
5. On detecting the stop condition, the IIC automatically clears the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 0.
6. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.STOP flag to 0 for the next transfer operation.

36.3.6 从机接收操作

在从机接收操作中，主设备输出SCL时钟并发送数据，IIC作为从设备返回确认。

图36.18显示了从机接收的示例，图36.19和图36.20显示了从机接收的操作时序。

设置和执行从属接收：

1. 处理初始设置。有关详细信息，请参阅第36.3.2节，初始设置。
   初始设置后，IIC一直处于待机状态，直到收到匹配的从机地址。
2. 接收到匹配的从地址后，IIC在SCL时钟的第九个周期的上升沿将相关的ICSR1.HOA、GCA和AASy标志之一（y=0到2）设置为1，并输出设置的值在SCL时钟的第9个周期将ICMR3.ACKBT位转换为确认位。如果此时也接收到的RW#位的值为0，则IIC继续将自身置于从接收模式并将ICSR2中的RDRF标志设置为1。
3. 检查ICSR2.STOP标志是否为0，ICSR2.RDRF标志是否为1，然后虚拟读取ICDRR。Thedummyvalueconsistsoftheslaveaddressand RW#bitwhenthe7-bitaddressformatisselected orthelower8bitswhenthe10-bitaddressformatisselected.
4. 当读取ICDRR时，IIC自动将ICSR2.RDRF标志设置为0。如果ICDRR的读取延迟并且在RDRF标志仍设置为1时接收到下一个字节，则IIC将SCLn线保持为低电平，直到一个SCL周期在必须设置RDRF之前。在这种情况下，读取ICDRR会解除SCLn线保持在低电平的状态。当ICSR2.STOP标志为1且ICSR2.RDRF标志也为1时，读取ICDRR直到完全接收到所有数据。
5. 在检测到停止条件时，IIC自动将ICSR1.HOA、GCA和AASy标志（y=0到2）清除为0。
6. 检查ICSR2.STOP标志是否为1，然后将ICSR2.STOP标志设置为0以进行下一次传输操作。

36.4 SCL Synchronization Circuit

For generation of the SCL clock, the IIC starts counting the value for the high-level period specified in ICBRH when it detects a rising edge on the SCLn line, and it drives the SCLn line low when it completes counting. When the IIC detects the falling edge of the SCLn line, it starts counting the value for the low-level period specified in ICBRL, and then it stops driving the SCLn line, releasing the line, when it completes counting. The IIC repeats this process to generate the SCL clock.

If multiple master devices are connected to the I2C bus, a collision of SCL signals might arise because of contention with another master device. In such cases, the master devices must synchronize their SCL signals. Because this synchronization of SCL signals must be bit by bit, the IIC is equipped with an SCL synchronization circuit to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When the IIC detects a rising edge on the SCLn line and so starts counting out the high-level period specified in ICBRH, and the level on the SCLn line falls because an SCL signal is being generated by another master device, the IIC stops counting when it detects the falling edge, drives the level on the SCLn line low, and starts counting the low-level period specified in ICBRL. When the IIC finishes counting the low-level period, it stops driving the SCLn line low to release the line. At this time, if the low-level period of the SCL clock signal from the other master device is longer than the low-level period set in the IIC, the low-level period of the SCL signal is extended. When the low-level period for the other master device has ended, the SCL signal rises because the SCLn line was released. When the IIC finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, when SCL signals from more than one master are contending, the high-level period of the SCL signal is synchronized with that of the clock with the narrower period, and the low-level period of the SCL signal is synchronized with that of the clock with the broader period. This synchronization of the SCL signal is only enabled when the SCLE bit in ICFER is set to 1.

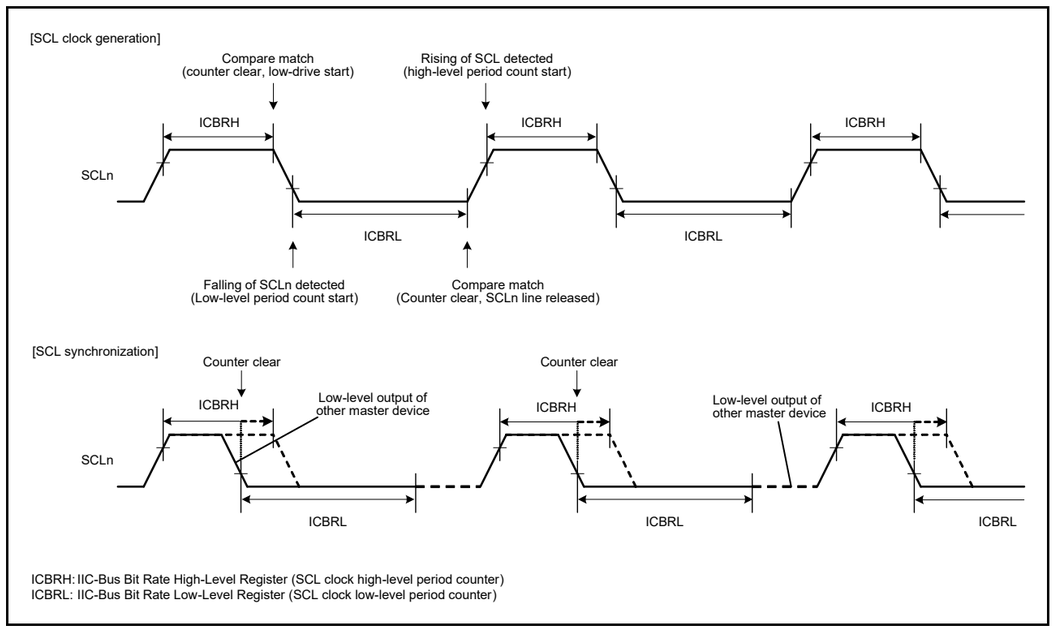

Figure 36.21 Generation and synchronization of SCL signal from IIC

36.4 SCL同步电路

为了生成SCL时钟，IIC在检测到SCLn线上的上升沿时开始对ICBRH中指定的高电平周期的值进行计数，并在完成计数时将SCLn线驱动为低电平。当IIC检测到SCLn线的下降沿时，它开始计数ICBRL中指定的低电平周期的值，然后停止驱动SCLn线，当它完成计数时释放线。IIC重复此过程以生成SCL时钟。

如果多个主设备连接到I2C总线，由于与另一个主设备争用，可能会出现SCL信号冲突。在这种情况下，主设备必须同步它们的SCL信号。由于SCL信号的这种同步必须逐位进行，因此IIC配备了SCL同步电路，通过在主机模式下监视SCLn线来获得SCL时钟信号的逐位同步。

当IIC检测到SCLn线上的上升沿并开始计数ICBRH中指定的高电平周期，并且SCLn线上的电平由于另一个主设备正在生成SCL信号而下降，IIC停止计数它检测下降沿，将SCLn线上的电平驱动为低电平，并开始计算ICBRL中指定的低电平周期。当IIC完成对低电平周期的计数时，它停止将SCLn线驱动为低电平以释放该线。此时，如果来自其他主设备的SCL时钟信号的低电平周期长于IIC中设置的低电平周期，则延长SCL信号的低电平周期。当另一个主设备的低电平周期结束时，SCL信号上升，因为SCLn线被释放。当IIC输出完SCL时钟的低电平周期后，SCLn线被释放，SCL时钟上升。即当来自多个主控的SCL信号竞争时，SCL信号的高电平周期与周期较窄的时钟同步，SCL信号的低电平周期与主控的低电平周期同步。具有更广泛周期的时钟。仅当ICFER中的SCLE位设置为1时，才启用SCL信号的这种同步。

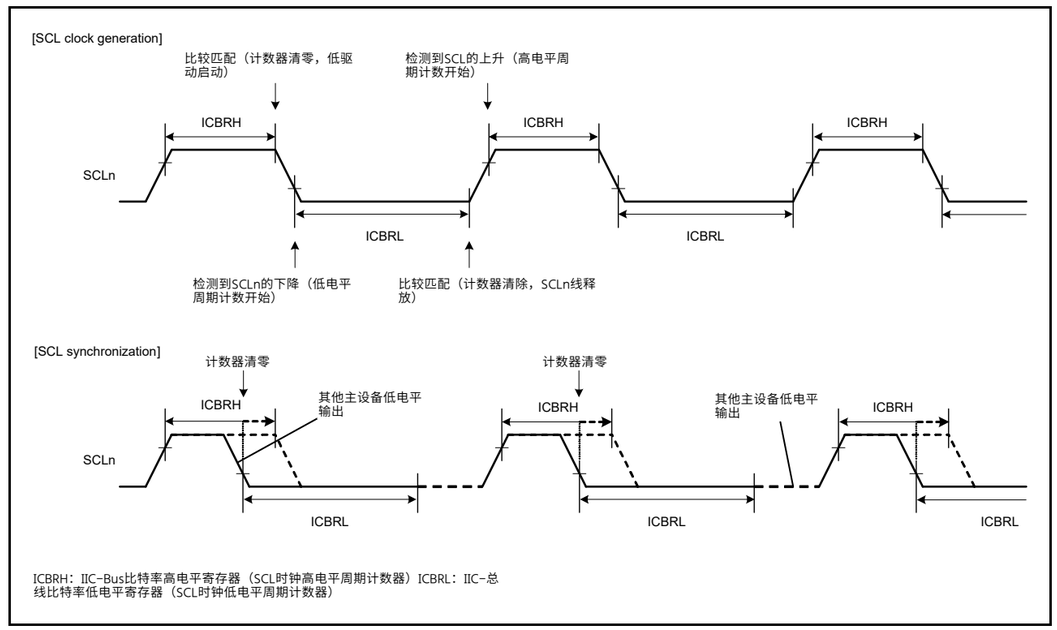

Figure 36.21 从IIC生成和同步SCL信号

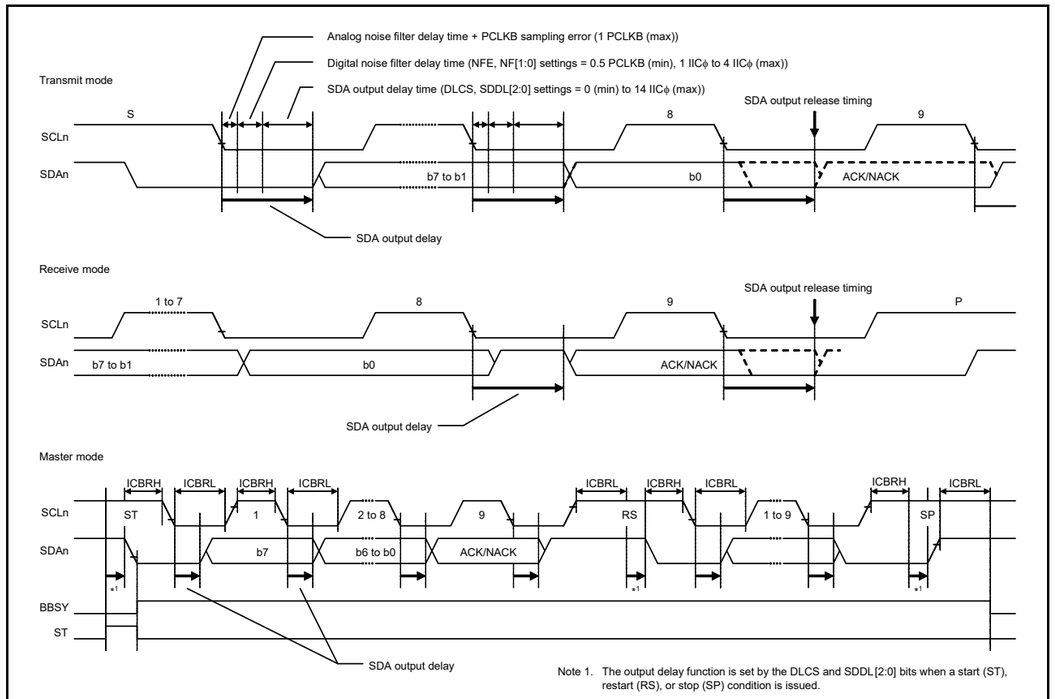
36.5 SDA Output Delay Function

The IIC module incorporates a function for delaying output on the SDA line. The delay can be applied to all output on the SDA line, including issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals.

With this function, SDA output is delayed from the detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval during which the SCL clock is low. This approach helps prevent erroneous operation of communications devices, with the aim of satisfying the 300-ns minimum data-hold time requirement of the SMBus specification. The output delay function is enabled by setting the SDDL[2:0] bits in ICMR2 to any value other than 000b, and disabled by setting the same bits to 000b.

While the SDA output delay function is enabled, for example, while the SDDL[2:0] bits in ICMR2 are set to any value other than 000b, the DLCS bit in ICMR2 selects the clock source for counting by the SDA output delay counter either as the internal base clock (IICϕ) for the IIC module or as the internal base clock divided by 2 (IICϕ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in ICMR2. After the delay cycles count is complete, the IIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.



Note 1. The output delay function is set by the DLCS and SDDL[2:0] bits when a start (ST), restart (RS), or stop (SP) condition is issued.

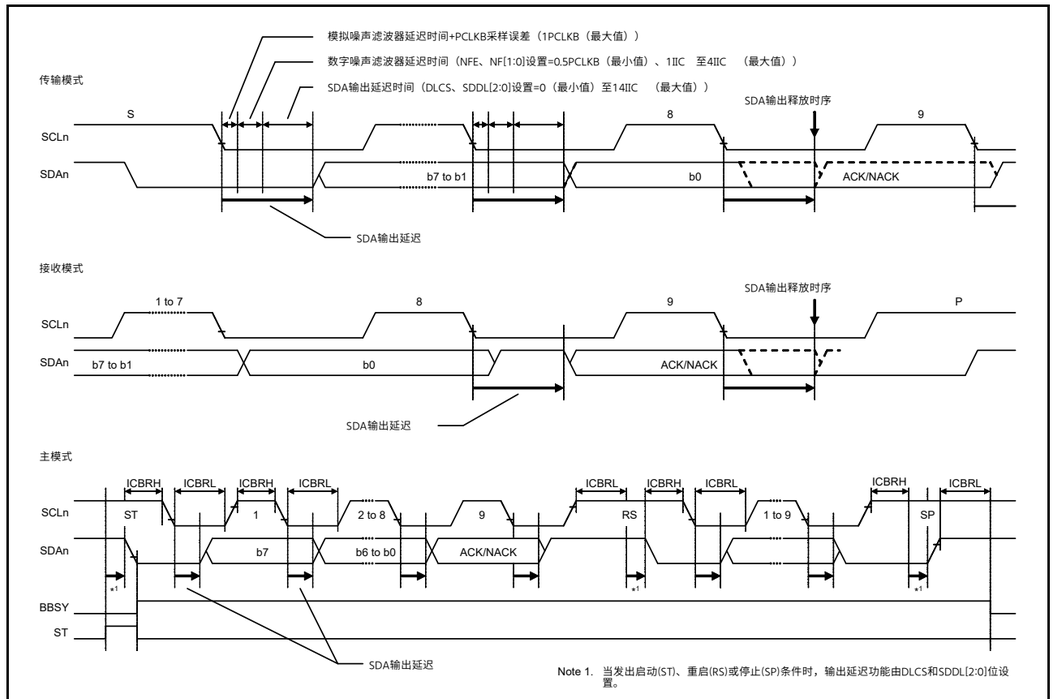
Figure 36.22 SDA output delay function

36.5 SDA输出延迟功能

IIC模块包含延迟SDA线上输出的功能。延迟可应用于SDA线上的所有输出，包括发出启动、重启和停止条件、数据以及ACK和NACK信号。

使用此功能，SDA输出从检测到SCL信号的下降沿开始延迟，以确保在SCL时钟为低电平的时间间隔内输出SDA信号。这种方法有助于防止通信设备的错误操作，旨在满足SMBus规范的300ns最小数据保持时间要求。通过将ICMR2中的SDDL[2:0]位设置为000b以外的任何值来启用输出延迟功能，并通过将相同位设置为000b来禁用输出延迟功能。

当SDA输出延迟功能使能时，例如，当ICMR2中的SDDL[2:0]位设置为000b以外的任何值时，ICMR2中的DLCS位选择时钟源以供SDA输出延迟计数器计数作为IIC模块的内部基本时钟(IIC)或除以2的内部基本时钟(IIC 2)。计数器计算ICMR2中SDDL[2:0]位中设置的周期数。延迟周期计数完成后，IIC模块将所需的输出（启动、重启或停止条件、数据或ACK或NACK信号）放在SDA线上。



Note 1. 当发出启动(ST)、重启(RS)或停止(SP)条件时，输出延迟功能由DLCS和SDDL[2:0]位设置。

Figure 36.22 SDA输出延迟功能

36.6 Digital Noise Filter Circuits

The states of the SCLn and SDAn pins are conveyed to the internal circuitry through analog and digital noise-filter circuits. Figure 36.23 shows a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the IIC consists of four flip-flop circuit stages connected in series and a match-detection circuit. The number of valid stages in the digital noise filter is selected in the NF[1:0] bits in ICMR3. The selected number of valid stages determines the noise-filtering capability as a period from one to four IICϕ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on falling edges of the IICϕ signal. When the input signal level matches the output level of the number of valid flip-flop circuit stages as selected in the NF[1:0] bits in ICMR3, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is saved.

If the ratio between the frequency of the internal operating clock (PCLKB) and the transfer rate is small, for example, if data transfer is 400 kbps with PCLKB = 4 MHz, the characteristics of the digital noise filter might lead to the elimination of required signals as noise. In such cases, it is possible to disable the digital noise-filter circuit, by setting the ICFER.NFE bit to 0, and use only the analog noise filter circuit.

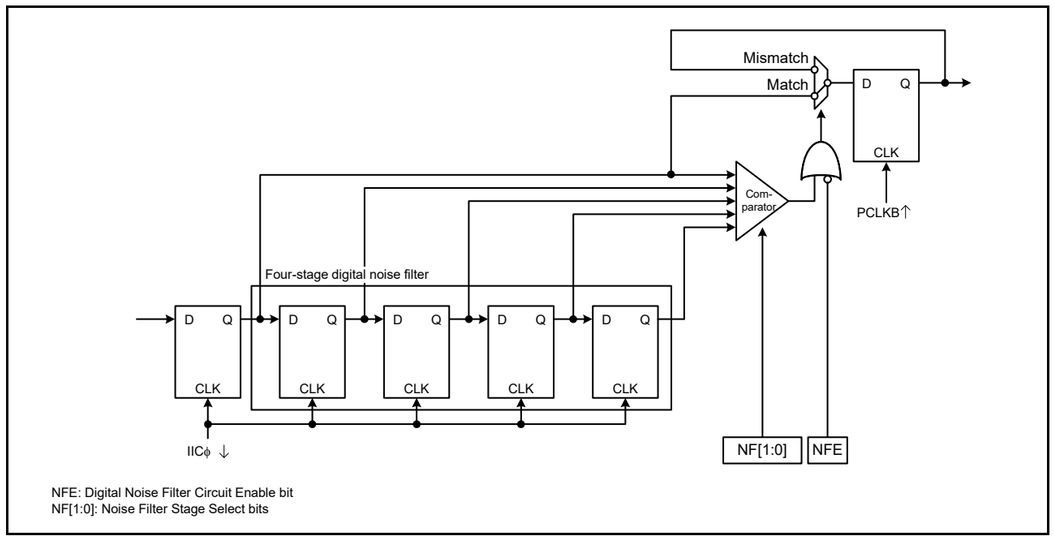


Figure 36.23 Digital noise filter circuit block diagram

36.7 Address Match Detection

The IIC can set three unique slave addresses in addition to the general call address and host address, and also can set 7- or 10-bit slave addresses.

36.7.1 Slave-Address Match Detection

The IIC can set three unique slave addresses and has a slave address detection function for each unique slave address. When the SARyE bit (y = 0 to 2) in ICSER is set to 1, the slave addresses set in SARUy and SARLy (y = 0 to 2) can be detected.

When the IIC detects a match of the set slave address, the associated AASy flag (y = 0 to 2) in ICSR1 is set to 1 on the rising edge of the ninth SCL clock cycle, and the RDRF flag in ICSR2 or the TDRE flag in ICSR2 is set to 1 by the subsequent R/W# bit. This causes a receive data full interrupt (IICn_RXI) or transmit data empty interrupt (IICn_TXI) to be generated. The AASy flag identifies which slave address is specified.

Figure 36.24 to Figure 36.26 show the AASy flag set timing in three cases.

36.6 数字噪声滤波器电路

SCLn和SDAn引脚的状态通过模拟和数字噪声滤波器电路传送到内部电路。图36.23显示了数字噪声滤波器电路的框图。

IIC的片上数字噪声滤波器电路由四个串联的触发器电路级和一个匹配检测电路组成。数字噪声滤波器的有效级数在ICMR3的NF[1:0]位中选择。选定的有效级数决定了噪声过滤能力，周期为1到4个IIC 周期。

SCLn引脚（或SDAn引脚）的输入信号在IIC 信号的下降沿采样。当输入信号电平与在ICMR3的NF[1:0]位中选择的有效触发器电路级数的输出电平匹配时，信号电平被传送到下一级。如果信号电平不匹配，则保存先前的值。

如果内部工作时钟(PCLKB)的频率与传输速率之间的比率很小，例如，如果数据传输为400kbps，PCLKB=4MHz，则数字噪声滤波器的特性可能会导致消除所需的信号作为噪声。在这种情况下，可以通过将ICFER.NFE位设置为0来禁用数字噪声滤波器电路，并仅使用模拟噪声滤波器电路。

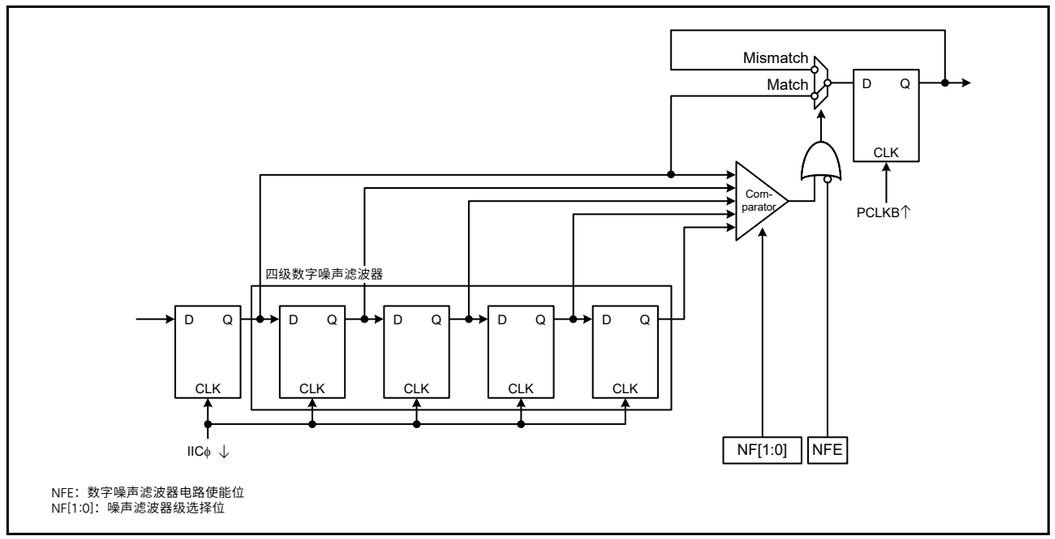

Figure 36.23 数字噪声滤波器电路框图

36.7 地址匹配检测

IIC除了可以设置广播地址和主机地址外，还可以设置三个唯一的从机地址，也可以设置7位或10位的从机地址。

36.7.1 从地址匹配检测

IIC可以设置三个唯一的从机地址，并对每个唯一的从机地址具有从机地址检测功能。
当ICSER中的SARyE位（y=0到2）设置为1时，可以检测到设置在SARUy和SARLy（y=0到2）中的从机地址。

当IIC检测到与设置的从地址匹配时，ICSR1中相关的AASy标志（y=0到2）在第9个SCL时钟周期的上升沿设置为1，并且ICSR2中的RDRF标志或TDRE标志ICSR2中的1由随后的RW#位设置为1。这会导致产生接收数据满中断（IICn_RXI）或发送数据空中断（IICn_TXI）。AASy标志标识指定了哪个从地址。

36.7.2 Detection of General Call Address

The IIC provides detection of the general call address (0000 000b + 0 [W]). This is enabled by setting the GCAE bit in ICSER to 1.

If the address received after a start or restart condition is issued is 0000 000b + 1[R] (start byte), the IIC recognizes this as the address of a slave device with an all-zero address, but not as the general call address.

When the IIC detects the general call address, both the GCA flag in ICSR1 and the RDRF flag in ICSR2 set to 1 on the rising edge of the ninth cycle of the SCL clock. This leads to the generation of a receive data full interrupt (IICn_RXI). The value of the GCA flag can be checked to confirm that the general call address was transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

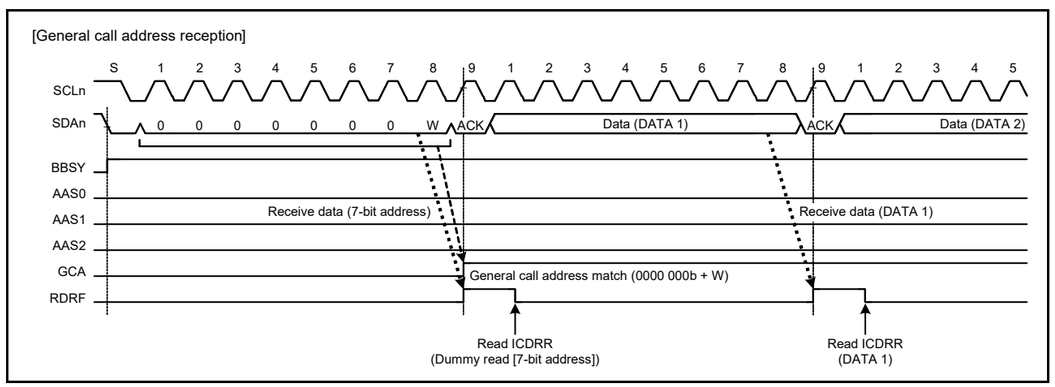

Figure 36.27 Timing of GCA flag setting during reception of general call address

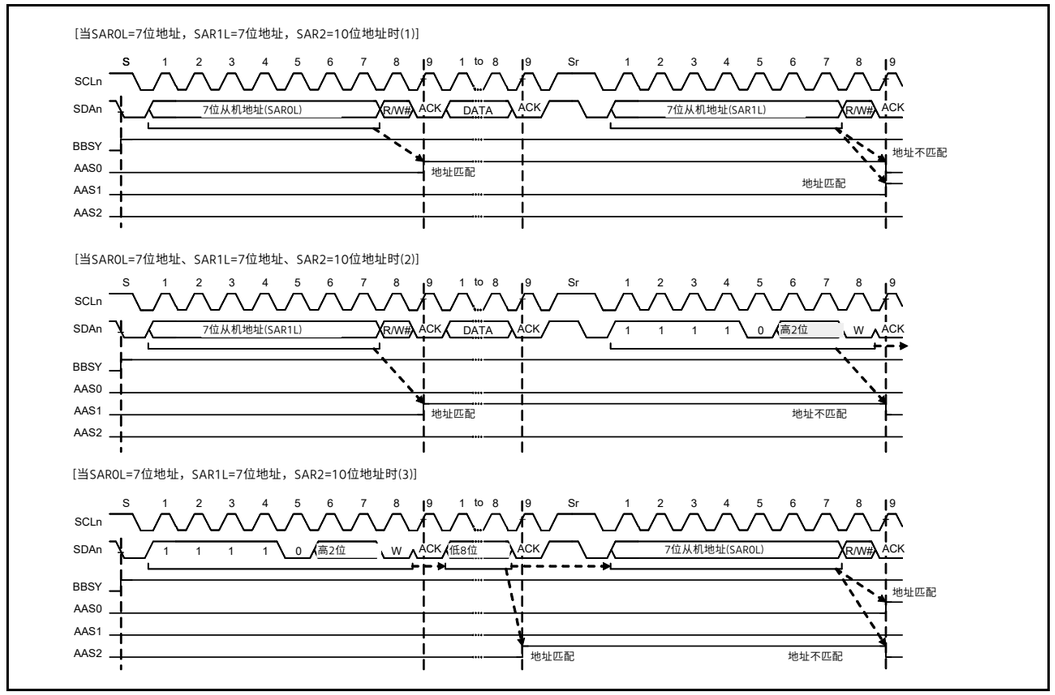

Figure 36.26 混合7位和10位地址格式的AASy标志设置和清除时序

36.7.2 广播呼叫地址检测

IIC提供对广播呼叫地址(0000000b+0[W])的检测。这是通过设置GCAE位启用
ICSER to 1.

如果在发出启动或重新启动条件后接收到的地址是0000000b+1[R]（起始字节），则IIC将其识别为具有全零地址的从设备的地址，但不是广播地址.

当IIC检测到广播呼叫地址时，ICSR1中的GCA标志和ICSR2中的RDRF标志都在SCL时钟的第9个周期的上升沿设置为1。这会导致接收数据完全中断(IICn_RXI)的产生。可以检查GCA标志的值以确认广播呼叫地址已被传输。

检测到广播呼叫地址后的操作与正常的从机接收操作相同。

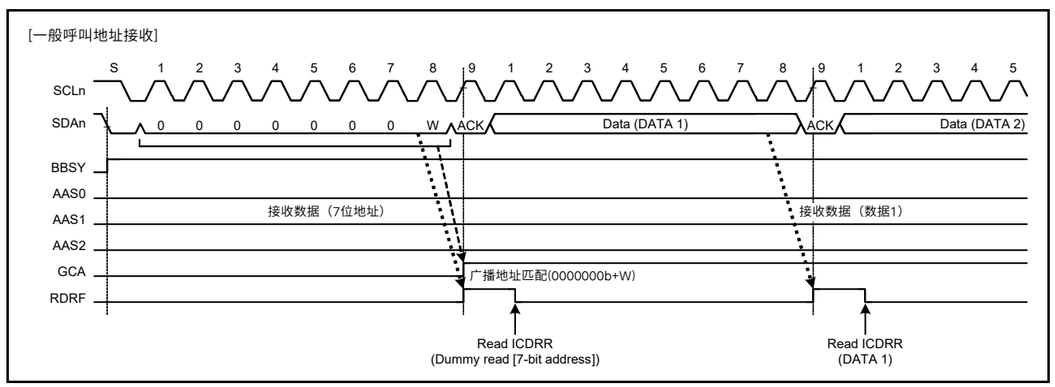

Figure 36.27 在接收广播呼叫地址期间设置GCA标志的时机

36.7.3 Device-ID Address Detection

The IIC module provides detection of device-ID address compliant with the I2C bus specification (revision 03). When the IIC receives 1111 100b as the first byte after a start or restart condition was issued with the DIDE bit in ICSER set to 1, it recognizes the address as a device ID, sets the DID flag in ICSR1 to 1 on the rising edge of the 9th SCL clock cycle when the subsequent R/W# bit is 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the IIC sets the associated AASy flag (y = 0 to 2) in ICSR1 to 1.

After that, when the first byte received after issuance of a start or restart condition matches the device ID address (1111 100b) again and the subsequent R/W# bit is 1, the IIC does not compare the second and subsequent bytes and sets the ICSR2.TDRE flag to 1.

In the device-ID address detection function, the IIC sets the DID flag to 0 if a match with the IIC slave address is not obtained or a match with the device ID address is not obtained after a match with the IIC slave address and the detection of a restart condition. If the first byte after detection of a start or restart condition matches the device-ID address (1111 100b), and the R/W# bit is 0, the IIC sets the DID flag to 1 and compares the second and subsequent bytes with the slave address of the IIC. If the R/W# bit is 1, the DID flag holds the previous value and the IIC does not compare the second and subsequent bytes. In this way, the reception of a device-ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Additionally, prepare the device-ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal transmit data. For details on the information that must be included in device-ID fields, contact NXP Semiconductors.

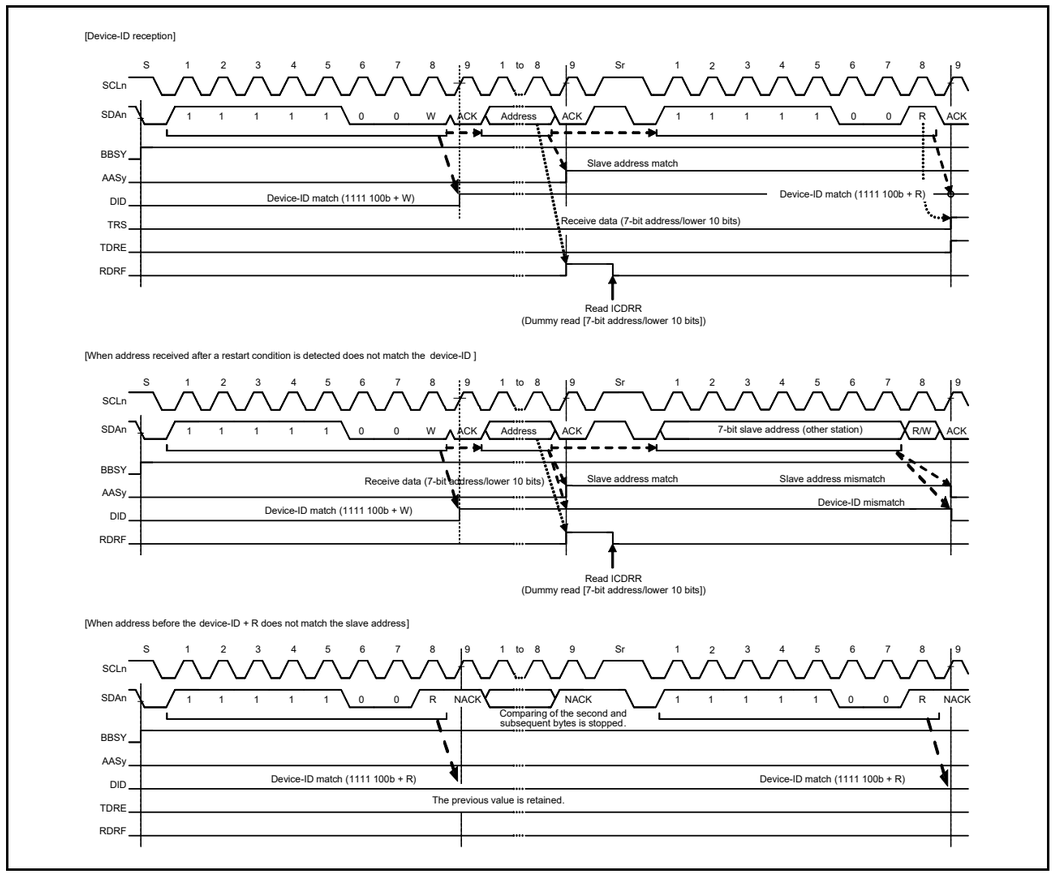

Figure 36.28 AASy and DID flag set and clear timing during reception of device-ID

36.7.3 设备ID地址检测

IIC模块提供符合I2C总线规范（修订版03）的设备ID地址检测。当IIC在ICSER中的DIDE位设置为1的情况下发出启动或重启条件后接收到1111100b作为第一个字节时，它将地址识别为设备ID，在ICSR1的上升沿将DID标志设置为1当后续的RW#位为0时，第9个SCL时钟周期，然后将第二个和后续字节与自己的从地址进行比较。如果地址与从地址寄存器中的值匹配，则IIC将ICSR1中相关的AASy标志（y=0到2）设置为1。

之后，当发出启动或重启条件后接收到的第一个字节再次与设备ID地址(1111100b)匹配且后续RW#位为1时，IIC不比较第二个和后续字节并设置ICSR2。TDRE标志为1。

在device-ID地址检测功能中，如果与IIC从机地址匹配未得到匹配或与IIC从机地址匹配后未得到与设备ID地址匹配，则IIC将DID标志设置为0。的重新启动条件。如果检测到启动或重启条件后的第一个字节与设备ID地址(1111100b)匹配，并且RW#位为0，则IIC将DID标志设置为1，并将第二个和后续字节与从机地址进行比较IIC的。如果RW#位为1，则DID标志保持前一个值，并且IIC不比较第二个和后续字节。这样，在确认TDRE=1后，可以通过读取DID标志来检查设备ID地址的接收。

此外，准备设备ID字段（3个字节：12位表示制造商+9位表示部件+3位表示修订）在接收到连续的设备ID字段作为正常发送数据后必须发送到主机.有关必须包含在设备ID字段中的信息的详细信息，请联系NXPSemiconductors。

36.7.4 Host Address Detection

The IIC provides host address detection while the SMBus is operating. When the HOAE bit in ICSER is set to 1 while the SMBS bit in ICMR3 is 1, the IIC can detect the host address (0001 000b) in slave receive mode (MST and TRS bits = 00b in ICCR2).

When the IIC detects the host address, the HOA flag in ICSR1 is set to 1 on the rising edge of the ninth SCL clock cycle, and at the same time, the RDRF flag in ICSR2 is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (IICn_RXI) to be generated. The HOA flag indicates that the host address was sent from another device.

If the bit following the host address (0001 000b) is an Rd bit (R/W# bit = 1), the IIC can also detect the host address. After the host address is detected, the IIC operates in the same manner as in normal slave operation.

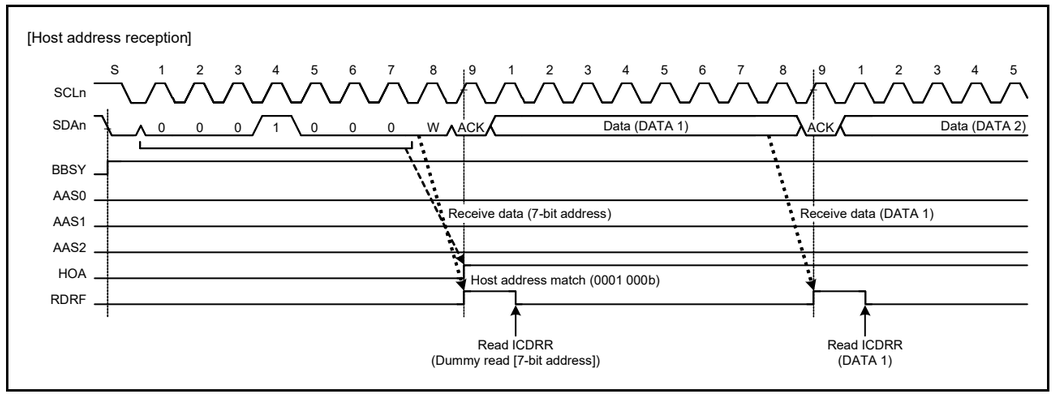

Figure 36.29 HOA flag set timing during reception of host address

36.8 Wakeup Function

The IIC provides a wakeup function that causes the MCU to transition from Software Standby mode to normal operation. The wakeup function enables the reception of data when the system clock is stopped, and it generates a wakeup interrupt signal on the match of the slave address of the received data. This interrupt signal triggers the return to normal operation.

The wakeup function has four operation modes: normal wakeup mode 1, normal wakeup mode 2, command recovery mode, and EEP response mode. Table 36.9 describes the behavior in these modes.

Table 36.9 Wakeup operation modes

Operation mode	ACK response timing	ACK response before wakeup	SCL state during wakeup
Normal wakeup mode 1	Before wakeup	ACK	Fixed low
Normal wakeup mode 2	After wakeup	Before wakeup: no response After wakeup: ACK response	Fixed low
Command recovery mode	Before wakeup	ACK	Open
EEP response mode	Before wakeup	NACK	Open

Precautions on the use of the wakeup function

1. Disable the wakeup function (WUE = 0) after a wakeup interrupt triggers the transition from Software Standby mode to normal operation.
2. Do not change the content of the IIC registers while WUF = 0, even if the wakeup interrupt recovers the system clock. Make register settings after confirming that WUF = 1.
3. Set WUE = WUIE = 1 and MST = TRS = 0 (slave reception mode) before entering Software Standby mode.
4. Do not invoke Software Standby mode while BBSY = 1.
5. The wakeup function supports the 7-bit slave address of slave address register SARL0, the general call address, and

36.7.4 主机地址检测

IIC在SMBus运行时提供主机地址检测。当ICSER中的HOAE位设置为1而ICMR3中的SMBS位为1时，IIC可以在从机接收模式下检测主机地址（0001000b）（ICCR2中的MST和TRS位=00b）。

当IIC检测到主机地址时，ICSR1中的HOA标志在第9个SCL时钟周期的上升沿置1，同时在RW#位为0时ICSR2中的RDRF标志置1（写位）。这会导致产生接收数据完全中断（IICn_RXI）。HOA标志表明主机地址是从另一个设备发送的。

如果主机地址（0001000b）后面的位是Rd位（RW#位=1），则IIC也可以检测主机地址。
检测到主机地址后，IIC以与正常从机操作相同的方式运行。

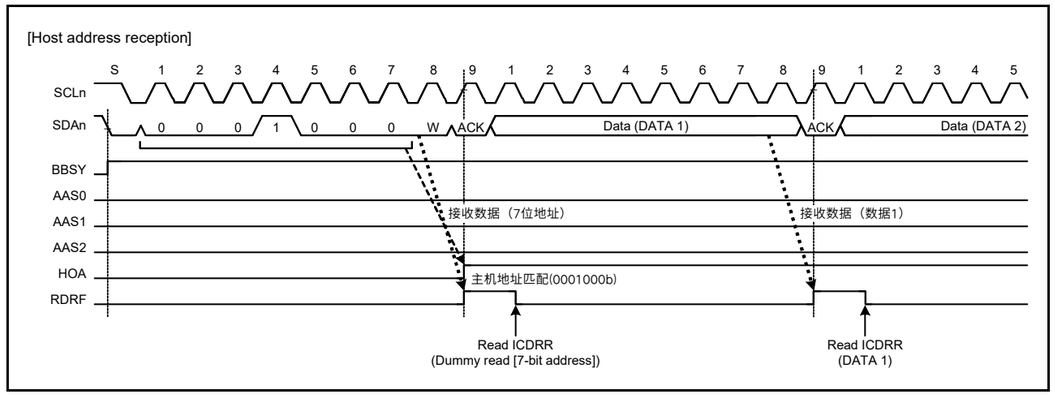

Figure 36.29 接收主机地址期间的HOA标志设置时序

36.8 唤醒功能

IIC提供唤醒功能，使MCU从软件待机模式转换到正常操作。唤醒功能在系统时钟停止时启用数据接收，并在接收到的数据的从地址匹配时产生唤醒中断信号。该中断信号触发返回正常操作。

唤醒功能有四种操作模式：正常唤醒模式1、正常唤醒模式2、命令恢复模式和EEP响应模式。表36.9描述了这些模式下的行为。

Table 36.9 唤醒操作模式

操作模式	ACK响应时间	唤醒前的ACK响应	唤醒期间的SCL状态
正常唤醒模式1	醒来前	ACK	固定低
正常唤醒模式2	醒来后	唤醒前：无响应唤醒后：ACK响应	固定低
命令恢复模式	醒来前	ACK	Open
EEP响应模式	醒来前	NACK	Open

唤醒功能使用注意事项

1. 在唤醒中断触发从软件待机模式到正常操作的转换后，禁用唤醒功能(WUE=0)。
2. 当WUF=0时不要改变IIC寄存器的内容，即使唤醒中断恢复了系统时钟。确认WUF=1后进行寄存器设置。
3. 在进入软件待机模式之前设置WUE=WUIE=1和MST=TRS=0（从接收模式）。
4. 当BBSY=1时不要调用软件待机模式。
5. 唤醒功能支持从地址寄存器SARL0的7位从地址、广播地址和

the host address. 10-bit slave addresses, SARL1 and SARL2, are not supported. Do not use them.

6. When the wakeup function is enabled, disable the interrupt selectable in the ICIER bits (TIE, TEIE, RIE, NAKIE, SPIE, STIE, ALIE, and TMOIE).
7. When the wakeup function is enabled, do not use the timeout function.
8. If the transition from Software Standby mode is triggered by the interrupt (such as IRQn) other than a wakeup interrupt. WUF is not set in this case. Follow the processing shown in Figure 36.31 and Figure 36.36.

36.8.1 Normal Wakeup Mode 1

This section describes the behavior, the timing, and an example operation of normal wakeup mode 1.

1. A wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows. Figure 36.32 provides detailed timing and Figure 36.30 shows an example operation.

   Before wakeup:ACK is sent in response to the data received with the own slave address of the IIC.

   During wakeup:ACK response is made on the ninth clock cycle of SCL, and SCL is held low afterwards.*1

   After wakeup:Normal operation continues.

   If the slave address does not match, the SCL line is not held low after the fall of the ninth clock cycle of SCL, and the slave operation continues.

Note 1. Between the ninth clock cycle and the first clock cycle during wakeup, WAIT = 1 is invalid.

2. If the transition from Software Standby mode is triggered by the interrupt (such as IRQn) other than a wakeup interrupt. WUF is not set in this case. Follow the processing shown in Figure 36.31.

主机地址。不支持10位从机地址SARL1和SARL2。不要使用它们。

6. 启用唤醒功能时，禁用ICIER位（TIE、TEIE、RIE、NAKIE、SPIE, STIE, ALIE, and TMOIE).
7. 启用唤醒功能时，请勿使用超时功能。
8. 如果从软件待机模式的转换是由唤醒中断以外的中断（例如IRQn）触发的。在这种情况下没有设置WUF。按照图36.31和图36.36所示的处理。

36.8.1 正常唤醒模式1

本节介绍正常唤醒模式1的行为、时序和示例操作。

1. 由匹配的从地址触发的唤醒中断启动到正常操作的转换，如下所示。
   图36.32提供了详细的时序，图36.30显示了一个示例操作。

   唤醒前：发送ACK以响应接收到的带有IIC自身从地址的数据。

   唤醒期间：在SCL的第9个时钟周期做出ACK响应，之后SCL保持低电平。*1

   唤醒后：继续正常运行。

   如果从机地址不匹配，则在SCL的第9个时钟周期下降后，SCL线不保持低电平，从机操作继续。

注1.在唤醒期间的第9个时钟周期和第一个时钟周期之间，WAIT=1无效。

2. 如果从软件待机模式的转换是由唤醒中断以外的中断（例如IRQn）触发的。在这种情况下没有设置WUF。按照图36.31所示的处理。

36.8.2 Normal Wakeup Mode 2

This section describes the behavior, the timing, and an example operation of normal wakeup mode 2.

1. A wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows. Figure 36.34 provides detailed timing and Figure 36.33 shows an example operation.

   Before wakeup:No response to the data received with the own slave address of the IIC until the end of the eighth SCL cycle.

   During wakeup:SCL line held low during the eighth and ninth clock cycles.

   After wakeup:ACK returns on the ninth clock cycle of SCL, and normal operation continues.

   If the slave address does not match, the SCL line is not held low after the fall of the eighth SCL clock cycle. The slave operation continues.

2. If the transition from Software Standby mode is triggered by the interrupt (such as IRQn) other than a wakeup interrupt. WUF is not set in this case. Follow the processing shown in Figure 36.31.

36.8.2 正常唤醒模式2

本节介绍正常唤醒模式2的行为、时序和示例操作。

1. 由匹配的从地址触发的唤醒中断启动到正常操作的转换，如下所示。
   图36.34提供了详细的时序，图36.33显示了一个示例操作。

   唤醒前：直到第8个结束，才响应接收到的带有IIC自己从地址的数据SCL cycle.

   在唤醒期间：SCL线在第八和第九个时钟周期保持低电平。

   唤醒后：ACK在SCL的第9个时钟周期返回，继续正常运行。

   如果从机地址不匹配，则在第8个SCL时钟周期下降后，SCL线不会保持低电平。从操作继续。

2. 如果从软件待机模式的转换是由唤醒中断以外的中断（例如IRQn）触发的。在这种情况下没有设置WUF。按照图36.31所示的处理。

36.8.3 Command Recovery Mode and EEP Response Mode (Special Wakeup Modes)

In the command recovery and EEP response modes, the SCL line is not held low during the wakeup period (after the rise of the ninth clock cycle of SCL), so other IIC devices can use the I2C bus during this period.

This section describes the behavior, the timing, and example operations of the command recovery and EEP response modes.

1. A wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows. Figure 36.37 provides detailed timing and Figure 36.35 shows an example operation.

   Before wakeup:In response to the data received with the own slave address of the IIC, ACK (command recovery mode) or NACK (EEP response mode) is returned.

   During wakeup:The SCL line is not held low.

   After wakeup:Normal operation continues after the IIC initial settings.

   If the slave address does not match, the slave operation continues.

Note 1. Because the SCL line is not held low during wakeup, transmission or reception of the data that follows the slave address is not possible.
Note 2. The command recovery and EEP response modes are internal reset states (ICE = IICRST = 1). Therefore, the match of the slave address does not set the ICSR1 flags, HOA, GCA, and ASS0,ASS1,ASS2.

2. If the transition from Software Standby mode is triggered by the interrupt (such as IRQn) other than a wakeup interrupt. WUF is not set in this case. Follow the processing shown in Figure 36.36.

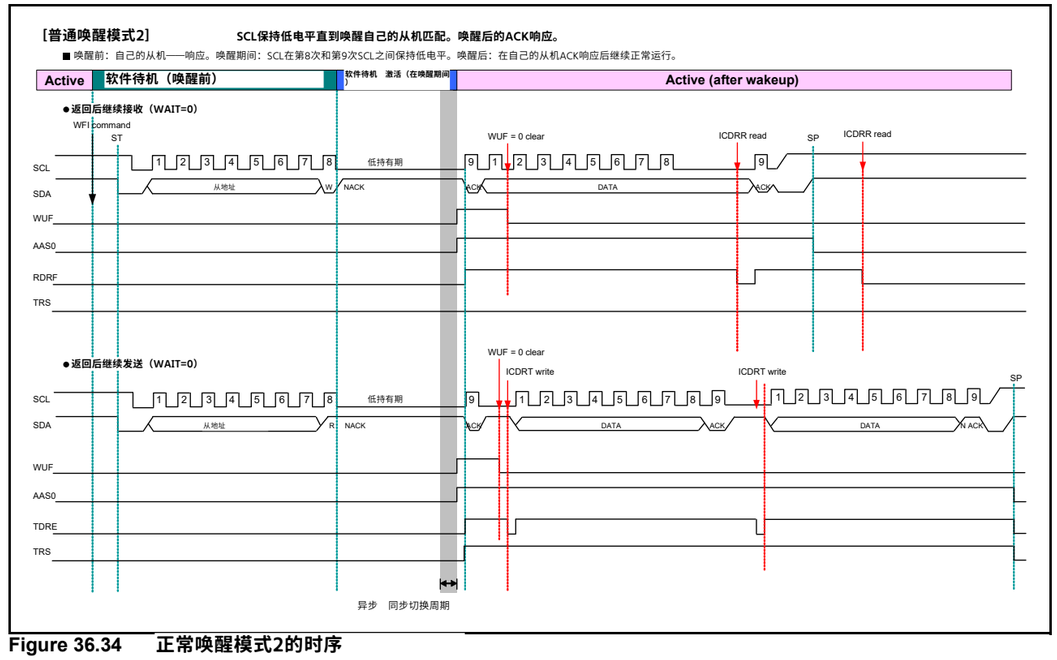

Figure 36.34 正常唤醒模式2的时序

36.8.3 命令恢复模式和EEP响应模式（特殊唤醒模式）

在命令恢复和EEP响应模式下，SCL线在唤醒期间（在SCL的第9个时钟周期上升后）不保持低电平，因此其他IIC设备可以在此期间使用I2C总线。

本节介绍命令恢复和EEP响应模式的行为、时序和示例操作。

1. 由匹配的从地址触发的唤醒中断启动到正常操作的转换，如下所示。
   图36.37提供了详细的时序，图36.35显示了一个示例操作。

   唤醒前：以IIC自己的从机地址接收到的数据，返回ACK（命令恢复模式）或NACK（EEP响应模式）。

   唤醒期间：SCL线不保持低电平。

   唤醒后：IIC初始设置后继续正常运行。

   如果从机地址不匹配，从机操作继续。

注1.由于SCL线在唤醒期间未保持低电平，因此无法发送或接收跟随从地址的数据。注2.命令恢复和EEP响应模式是内部复位状态(ICE=IICRST=1)。因此，从地址的匹配不会设置ICSR1标志、HOA、GCA和ASS0、ASS1、ASS2。

2. 如果从软件待机模式的转换是由唤醒中断以外的中断（例如IRQn）触发的。在这种情况下没有设置WUF。按照图36.36所示的处理。

36.8.4 Precautions for WFI instruction Execution

In the example operations for the wakeup mode shown in Figure 36.30, Figure 36.33, and Figure 36.35, make sure that the start condition is not issued during the period from the setting of BBSY = 0 to the execution of the WFI instruction. When a start condition is issued during this period, NACK is returned after the reception of the first byte of the first data block. Then the detection of the start or restart condition enables the wakeup function.

36.9 Automatic Low-Hold Function for SCL

36.9.1 Function to Prevent Wrong Transmission of Transmit Data

If the I2C Bus Shift Register (ICDRS) is empty and data has not been written to the IIC-Bus Transmit Data Register (ICDRT) with the IIC in transmission mode (TRS bit = 1 in ICCR2), the SCLn line is automatically held low over the subsequent intervals. This low-hold period is extended until the transmit data is written, which prevents the unintended transmission of erroneous data.

Master transmit mode

- Low-level interval after a start or restart condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next.

Slave transmit mode

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next.

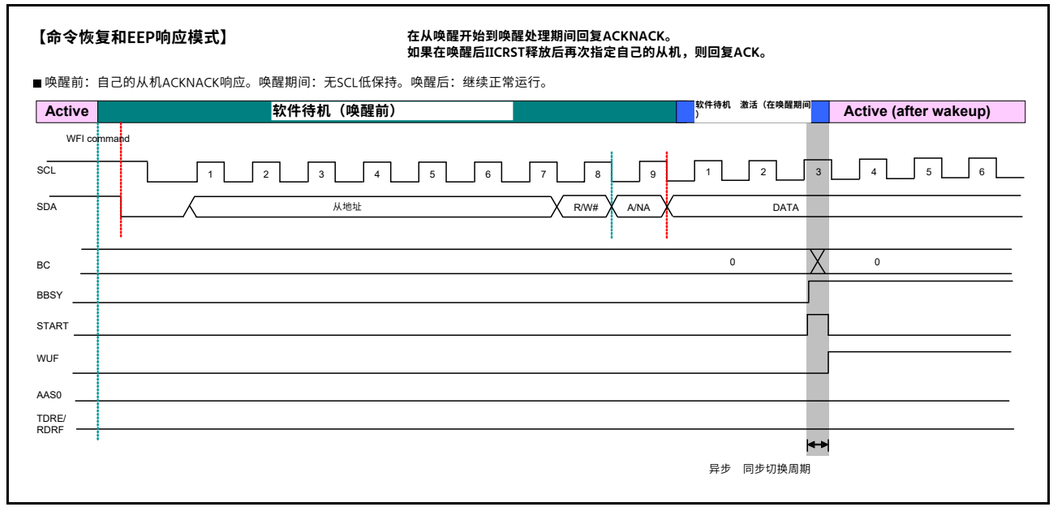

Figure 36.37 命令恢复和EEP响应模式的时序

36.8.4 WFI指令执行注意事项

在图36.30、图36.33和图36.35所示的唤醒模式的示例操作中，请确保从设置BBSY=0到执行WFI指令期间不发出启动条件。如果在此期间发出启动条件，则在接收到第一个数据块的第一个字节后返回NACK。然后检测到启动或重新启动条件启用唤醒功能。

36.9 SCL的自动低保持功能

36.9.1 防止传输数据错误传输的功能

如果I2C总线移位寄存器(ICDRS)为空且数据尚未写入IIC总线发送数据寄存器(ICDRT)且IIC处于传输模式（TRS位=ICCR2中的1），则SCLn线自动在随后的时间间隔内保持低位。这个低保持期一直延长到发送数据被写入，这样可以防止错误数据的意外传输。

主传输模式

- 发出启动或重启条件后的低电平间隔
- 一次传输的第9个时钟周期和下一次传输的第一个时钟周期之间的低电平间隔。

从机发送模式

- 一次传输的第9个时钟周期和下一次传输的第一个时钟周期之间的低电平间隔。

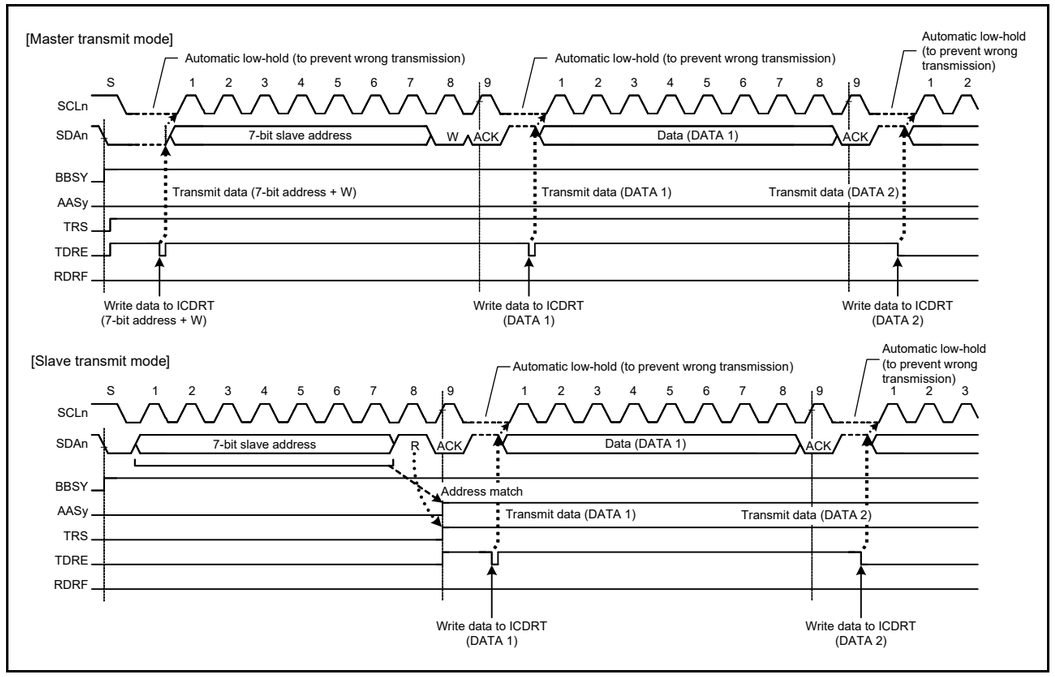

Figure 36.38 Automatic low-hold operation in transmit mode

36.9.2 NACK Reception Transfer Suspension Function

This function suspends transfer operation when NACK is received in transmit mode (TRS bit = 1 in ICCR2). It is enabled when the NACKE bit in ICFER is set to 1. If the next transmit data is already written (TDRE flag = 0 in ICSR2) when NACK is received, the next data transmission on the falling edge of the ninth SCL clock cycle is automatically suspended. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (NACKF flag = 1 in ICSR2), transmit and receive operations are discontinued. To restore transmit or receive operation, you must set the NACKF flag to 0. In master transmit mode, after issue a restart or stop condition, set the NACKF flag to 0, and then issue a start condition again.

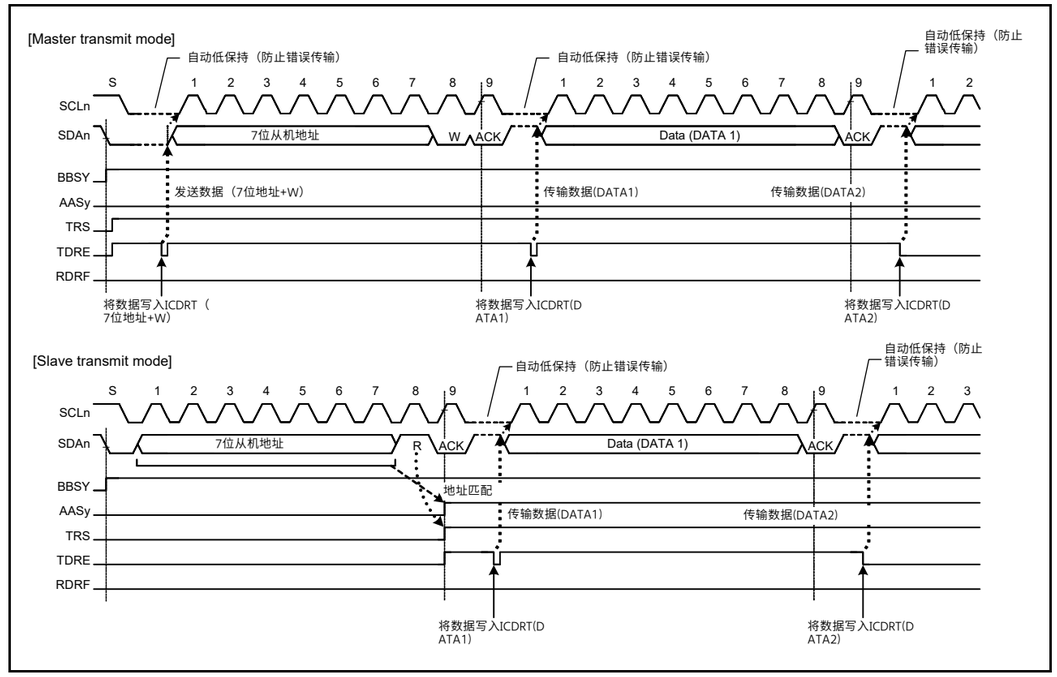

Figure 36.38 发送模式下的自动低保持操作

36.9.2 NACK接收传输暂停功能

当在发送模式下接收到NACK（ICCR2中的TRS位=1）时，该函数暂停传输操作。当ICFER中的NACKE位设置为1时使能。如果在接收到NACK时已经写入下一个发送数据（ICSR2中的TDRE标志=0），则在第9个SCL时钟周期的下降沿进行下一个数据传输自动暂停。这可以防止SDAn线路输出电平在下一个发送数据的MSB为0时保持低电平。

如果传输操作被该函数挂起（ICSR2中的NACKF标志=1），发送和接收操作将中断。要恢复发送或接收操作，必须将NACKF标志设置为0。在主机发送模式下，发出重启或停止条件后，将NACKF标志设置为0，然后再次发出启动条件。

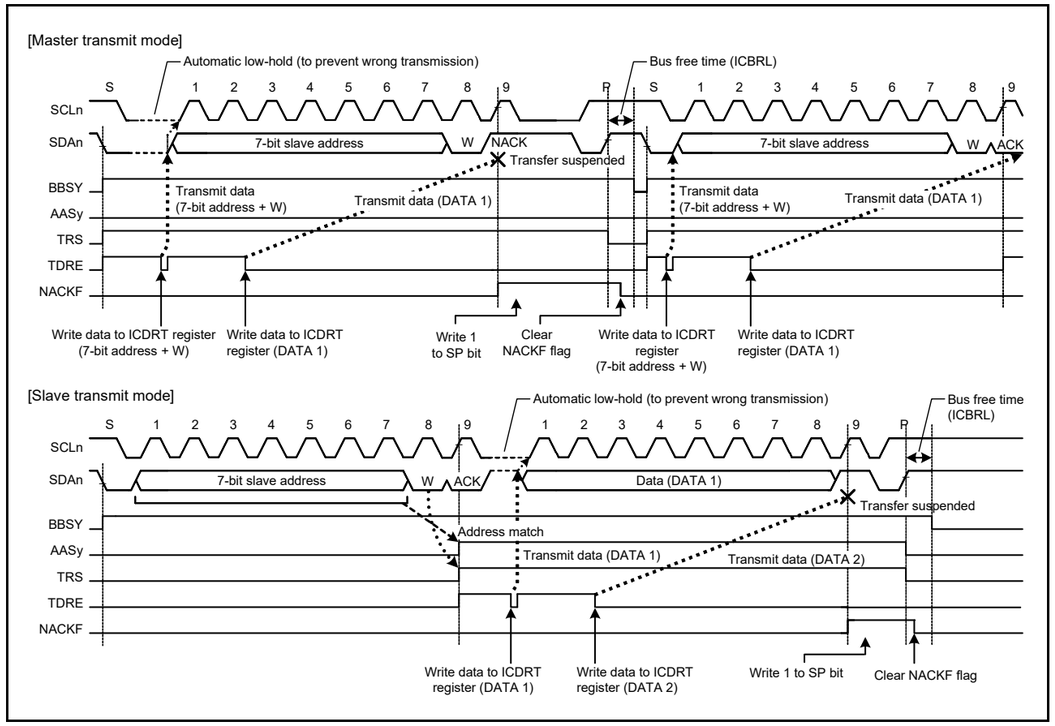

Figure 36.39 Suspension of data transfer when NACK is received, when NACKE = 1

36.9.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer frame or more with receive data full (RDRF flag = 1 in ICSR2) in receive mode (TRS = 0 in ICCR2), the IIC holds the SCLn line low automatically immediately before the next data is received to prevent a failure to receive data.

This function is enabled even if the read processing of the final receive data is delayed and, in the meantime, the IIC slave address is designated after a stop condition is issued. This function does not interfere with other communication because the IIC does not hold the SCLn line low when a mismatch with its own slave address occurs after a stop condition is issued.

Periods in which the SCLn line is held low can be selected with a combination of the WAIT and RDRFS bits in ICMR3.

(1) 1-byte receive operation and automatic low-hold function using the WAIT bit

When the WAIT bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the WAIT bit function. Additionally, when the ICMR3.RDRFS bit is 0, the IIC automatically sends the ACKBT bit value in ICMR3 for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the SCLn line low on the falling edge of the ninth SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from ICDRR, which enables byte-wise receive operation.

The WAIT bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

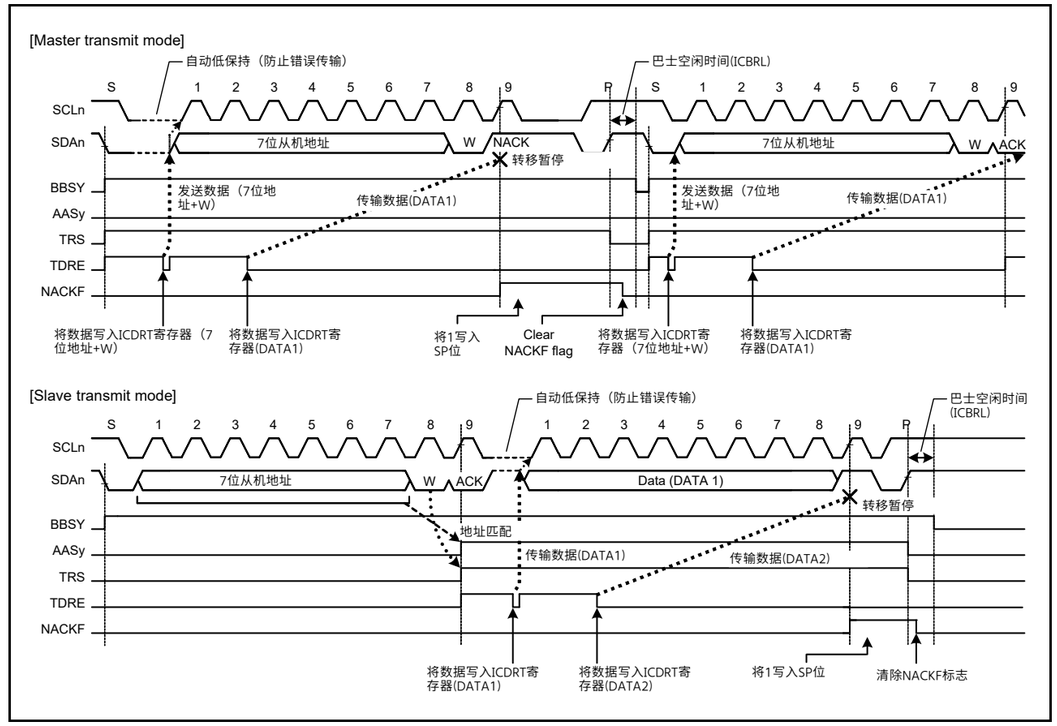

Figure 36.39 接收到NACK时暂停数据传输，当NACKE=1

36.9.3 防止数据接收失败的功能

如果在接收模式（ICCR2中的TRS=0）下接收数据（ICDRR）读取延迟一个传输帧或更长时间且接收数据已满（ICSR2中的RDRF标志=1）时响应处理延迟，则IIC保持在接收到下一个数据之前，SCLn线自动变为低电平，以防止接收数据失败。

即使最终接收数据的读取处理延迟，该功能也有效，同时，在发出停止条件后指定IIC从机地址。此功能不会干扰其他通信，因为在发出停止条件后发生与其自己的从地址不匹配时，IIC不会将SCLn线保持为低电平。

SCLn线保持低电平的周期可以通过ICMR3中的WAIT和RDRFS位的组合来选择。

(1) 使用WAIT位的1字节接收操作和自动低保持功能

当ICMR3中的WAIT位设置为1时，IIC使用WAIT位功能执行1字节接收操作。此外，当ICMR3.RDRFS位为0时，IIC会在第8个SCL时钟周期的下降沿到第9个SCL时钟周期的下降沿期间自动发送ICMR3中的ACKBT位值作为确认位，并且使用WAIT位功能在第9个SCL时钟周期的下降沿自动将SCLn线保持为低电平。该低保持通过从ICDRR读取数据来释放，从而启用逐字节接收操作。

在主机或从机接收模式下获得与IIC从机地址（包括广播地址和主机地址）匹配后的接收帧启用WAIT位功能。

(2) 1-byte receive operation (ACK/NACK transmission control) and automatic low-hold function using the RDRFS bit

When the RDRFS bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the RDRFS bit function. When the RDRFS bit is set to 1, the RDRF flag in ICSR2 is set to 1 (receive data full) on the rising edge of the eighth SCL clock cycle, and the SCLn line is automatically held low on the falling edge of the eighth SCL clock cycle. This low-hold is released by writing a value to the ACKBT bit in ICMR3, but cannot be released by reading data from ICDRR, which enables receive operation through the ACK or NACK transmission control based on the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

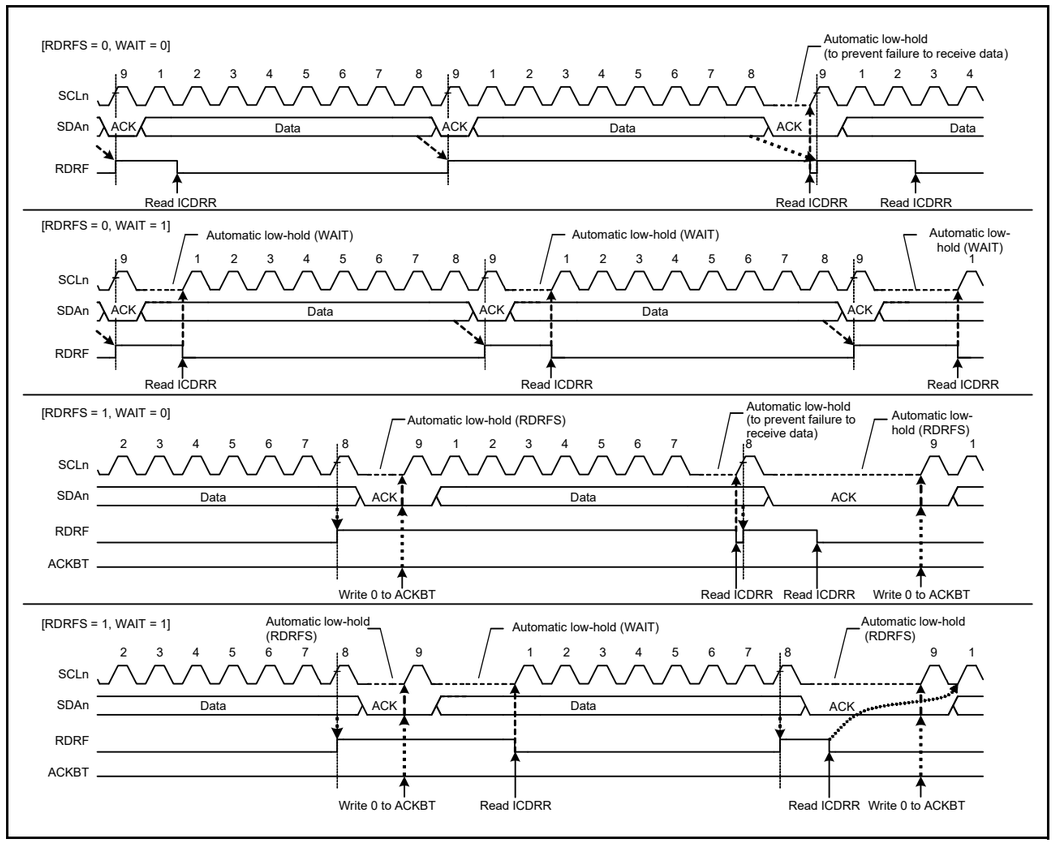

Figure 36.40 Automatic low-hold operation in receive mode using the RDRFS and WAIT bits

(2) 1字节接收操作（ACKNACK传输控制）和使用RDRFS位的自动低保持功能

当ICMR3中的RDRFS位设置为1时，IIC使用RDRFS位功能执行1字节接收操作。当RDRFS位为1时，ICSR2中的RDRF标志位在第8个SCL时钟周期的上升沿置1（接收数据满），并且SCLn线在第8个SCL的下降沿自动保持为低时钟周期。该低保持通过向ICMR3中的ACKBT位写入值来释放，但不能通过从ICDRR读取数据来释放，ICDRR可以根据以字节为单位接收的数据通过ACK或NACK传输控制进行接收操作。

在主机或从机接收模式下获得与IIC从机地址（包括广播地址和主机地址）匹配后的接收帧启用RDRFS位功能。

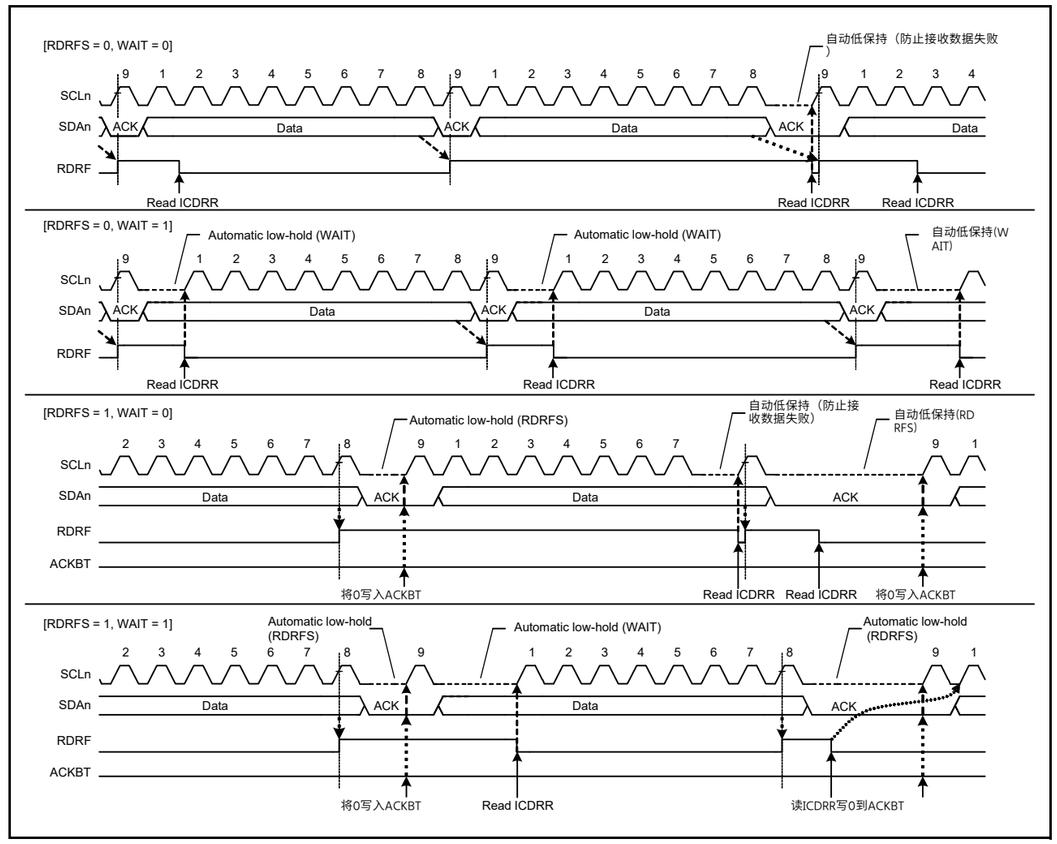

Figure 36.40 使用RDRFS和WAIT位在接收模式下自动保持低电平操作

36.10 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I2C bus standard, the IIC provides functions to prevent double-issue of a start condition, detect arbitration-lost during transmission of NACK, and detect arbitration-lost in slave transmit mode.

36.10.1 Master Arbitration-Lost Detection (MALE Bit)

The IIC drives the SDAn line low to issue a start condition. However, if the SDAn line was already driven low by another master device issuing a start condition, the IIC regards its own start condition as an error and considers this a loss in arbitration. Priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the ST bit in ICCR2 to 1 while the bus is busy (BBSY flag = 1 in ICCR2), the IIC regards this as a double-issuing-of-start-condition error and considers itself to have lost in arbitration. This prevents a failure of transfer resulting from a start condition being issued while transfer is in progress.

When a start condition is issued successfully, if the transmit data including the address bits (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state) and a low level is detected on the SDAn line, the IIC loses in arbitration.

After a loss in arbitration of mastership, the IIC immediately enters slave receive mode. If a slave address, including the general call address, matches its own address at this time, the IIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the MALE bit in ICFER is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Non-matching of the internal level for output on SDA and the level on the SDAn line after a start condition was issued by setting the ST bit in ICCR2 to 1 while the BBSY flag in ICCR2 was set to 0 (erroneous issuing of a start condition)
- Setting of the ST bit in ICCR2 to 1 (start condition double-issue error) while the BBSY flag is 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDAn line in master transmit mode (MST and TRS bits = 11b in ICCR2).

36.10 仲裁丢失检测功能

除了I2C总线标准定义的正常仲裁丢失检测功能外，IIC还提供防止重复发出启动条件、在NACK传输期间检测仲裁丢失以及在从机发送中检测仲裁丢失的功能模式。

36.10.1 主仲裁丢失检测（MALE位）

IIC将SDAn线驱动为低电平以发出启动条件。但是，如果SDAn线已经被另一个发出启动条件的主设备驱动为低电平，则IIC将其自己的启动条件视为错误，并认为这是仲裁失败。其他主设备优先传输。类似地，如果在总线繁忙时通过将ICCR2中的ST位设置为1来请求发出启动条件（ICCR2中的BBSY标志=1），则IIC将此视为双重发出启动条件错误并认为自己在仲裁中败诉。这可以防止由于在传输过程中发出启动条件而导致传输失败。

当启动条件成功发出时，如果发送数据包括地址位（内部SDA输出电平）与SDAn线上的电平不匹配（高输出作为内部SDA输出，意味着SDAn引脚处于高电平）阻抗状态）并且在SDAn线上检测到低电平，则IIC在仲裁中失败。

在主控权仲裁失败后，IIC立即进入从机接收模式。如果此时从机地址（包括广播地址）与自己的地址匹配，则IIC继续从机操作。

当ICFER中的MALE位为1（启用主仲裁丢失检测）时满足以下条件时，检测到主控仲裁丢失。

[Master arbitration-lost conditions]

- 通过将ICCR2中的ST位设置为1，同时ICCR2中的BBSY标志设置为0，发出启动条件后，SDA输出的内部电平与SDAn线上的电平不匹配（错误发出启动条件）
- 当BBSY标志为1时，将ICCR2中的ST位设置为1（启动条件双发错误）
- 当发送数据不包括确认（内部SDA输出电平）与主发送模式下SDAn线上的电平不匹配时（ICCR2中的MST和TRS位=11b）。

36.10.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)
