21.3.5 Count Direction Changing Function

The count direction of the GTCNT counter can be changed by modifying the UD bit in GTUDDTYC.

In saw-wave mode, if the UD bit in GTUDDTYC is modified during count operation, the count direction is changed at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the GTUDDTYC.UD bit is modified while the count operation stops and the GTUDDTYC.UDF bit is 0, the GTUDDTYC.UD bit modification is not reflected at the start of counting and the count direction is changed at an overflow or an underflow. If the UDF bit is set to 1 while the count operation stops, the GTUDDTYC.UD bit value at that time is reflected at the start of counting.

In triangle-wave mode, the count direction does not change even though the UD bit in GTUDDTYC is modified during the count operation. Similarly, even though the GTUDDTYC.UD bit is modified while the count operation stops and GTUDDTYC.UDF bit is 0, the GTUDDTYC.UD bit value is not reflected to the count operation. If the GTUDDTYC.UDF bit is set to 1 while the count operation is stopped, the GTUDDTYC.UD bit value at that time is reflected at the start of counting.

If the count direction changes during a saw-wave count operation, the GTPR value after the start of up-counting is reflected in the count cycle during up-counting and the GTPR value after the start of down-counting is reflected in the count cycle during down-counting.

Figure 21.28 shows an example of count direction changing function operation.

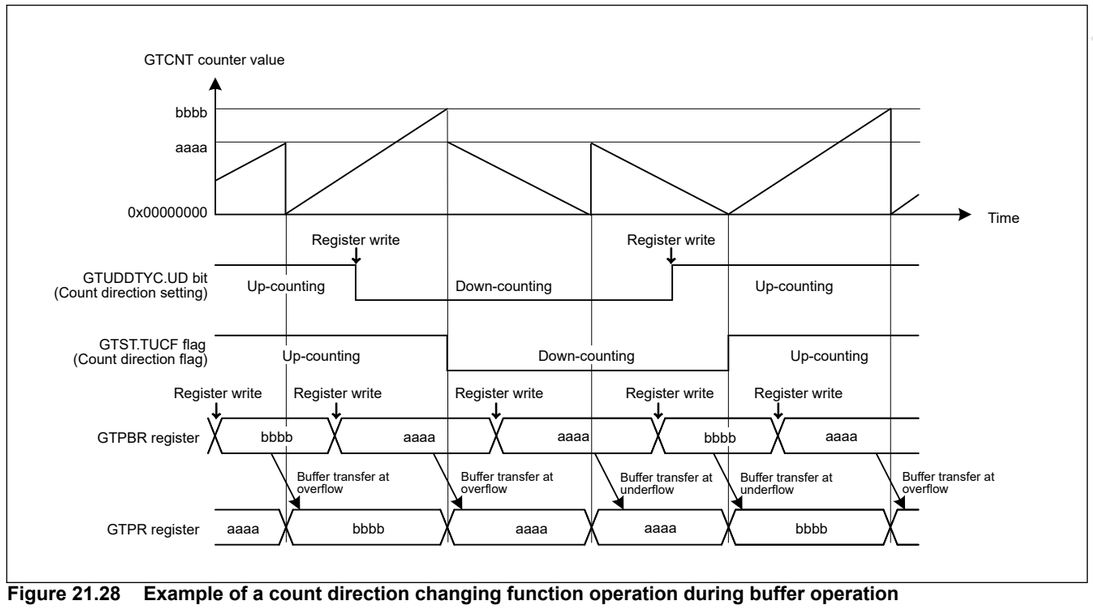

Figure 21.28 Example of a count direction changing function operation during buffer operation

21.3.6 Function of Output Duty 0% and 100%

The output duty of the GTIOCnA pin and the GTIOCnB pin (n = 0 to 9) are set to 0% or 100% by changing the GTUDDTYC.OADTY bit or GTUDDTYC.OBDTY bit.

Note: n: 0 to 9
m: A, B

21.3.5 计数方向改变功能

GTCNT计数器的计数方向可以通过修改GTUDDTYC中的UD位来改变。

在锯齿波模式下，如果在计数操作期间修改GTUDDTYC中的UD位，则计数方向会在溢出（在向上计数期间修改时）或下溢（在向下计数期间修改时）改变。如果在计数操作停止时修改GTUDDTYC.UD位且GTUDDTYC.UDF位为0，则GTUDDTYC.UD位的修改不会反映在计数开始时，并且计数方向会在上溢或下溢时改变。如果在计数操作停止时UDF位设置为1，则此时的GTUDDTYC.UD位值将反映在计数开始时。

在三角波模式下，即使在计数操作期间修改GTUDDTYC中的UD位，计数方向也不会改变。同样，即使在计数操作停止且GTUDDTYC.UDF位为0时修改GTUDDTYC.UD位，GTUDDTYC.UD位的值也不会反映到计数操作中。如果在计数操作停止时将GTUDDTYC.UDF位设置为1，则此时的GTUDDTYC.UD位值将反映在计数开始时。

如果在锯齿波计数操作期间计数方向发生变化，则加计数开始后的GTPR值反映在加计数期间的计数周期中，而减计数开始后的GTPR值反映在计数周期中在向下计数期间。

图21.28显示了计数方向改变功能操作的示例。

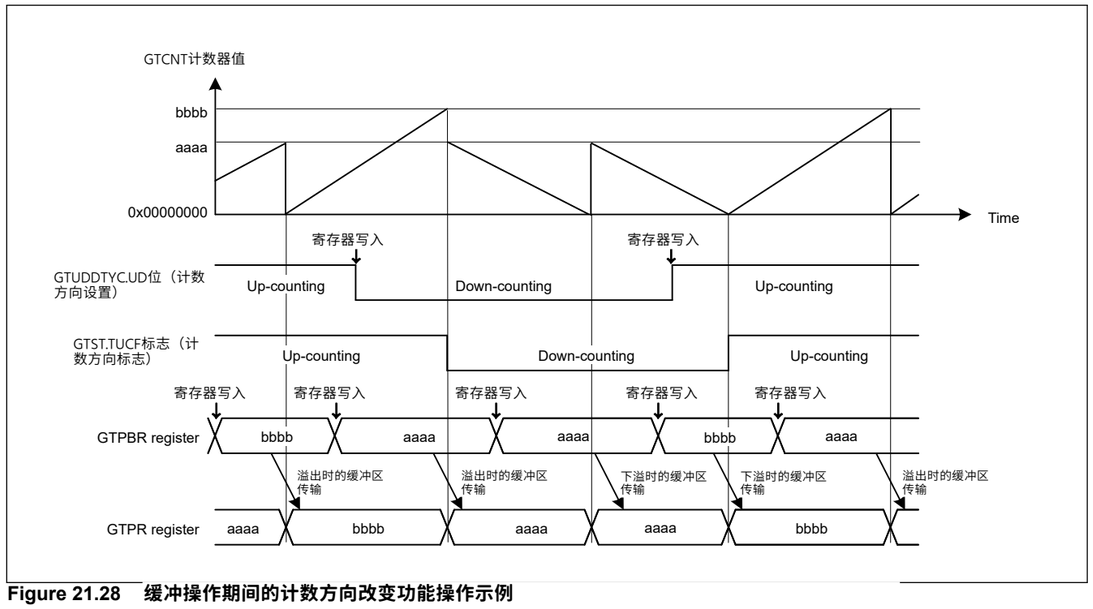

Figure 21.28 缓冲操作期间的计数方向改变功能操作示例

21.3.6 输出占空比0%和100%的功能

GTIOCnA引脚和GTIOCnB引脚（n=0至9）的输出占空比通过更改GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位。

In saw-wave mode, if the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified during the count operation, the output duty setting is reflected at an overflow (when modified during up-counting) or an underflow (when modified during down-counting). If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF or the GTUDDTYC.OBDTYF bit is 0, the output duty modification is not reflected at the start of counting. The output duty changes at an overflow or an underflow. If the GTUDDTYC.OADTYF or the GTUDDTYC.OBDTYF bit is set to 1 while the count operation is stopped, the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit value at that time is reflected at the start of counting.

In triangle-wave mode, if the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified during the count operation, the output duty setting is reflected an underflow.

If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation is stopped and the GTUDDTYC.OADTYF or the GTUDDTYC.OBDTYF bit is 0, the output duty modification is not reflected at the start of counting. The output duty changes at an underflow. If the GTUDDTYC.OADTY bit or the GTUDDTYC.OBDTY bit is modified while the count operation stops and the GTUDDTYC.OADTYF or the GTUDDTYC.OBDTYF bit is 1, the output duty modification is reflected at the start of counting.

In performing 0% or 100% duty operation, GPT internally continues to:

- Perform compare match operation
- Set compare match flag
- Output interrupt
- Perform buffer operation.

When the control is changed from 0% or 100% duty setting to compare match, the output value of GTIOCnA pin at cycle end is decided by GTIOR.GTIOA[3:2] and GTUDDTYC.OADTYR. The output value of GTIOCnB pin at cycle end is decided by GTIOR.GTIOB[3:2] and GTUDDTYC.OBDTYR.

When GTIOR.GTIOA[3:2] and GTIOR.GTIOB[3:2] are set to 01b, the output pins output low at cycle end. When GTIOR.GTIOA[3:2] and GTIOR.GTIOB[3:2] are set to 10b, the output pins output high at cycle end.

GTUDDTYC.OADTYR selects the value that is the object of output retained/toggled at cycle end, when GTIOR.GTIOm[3:2] are set to 00b (output retained at cycle end) or when GTIOR.GTIOm[3:2] are set to 11b (output toggled at cycle end). Table 21.23 shows the values of GTIOCnA and GTIOCnB pin output at cycle end.

00 (output retained at cycle end)	0	0	0	1	0
	1	0	1	1	1
01 (low output at cycle end)	—	0	0	0	0
10 (high output at cycle end)	—	1	1	1	1
11 (output toggled at cycle end)	0	1	1	0	1
	1	1	0	0	0

Figure 21.29 shows an example of output duty 0% and 100% function.

在锯齿波模式下，如果在计数操作期间修改GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位，则输出占空比设置反映在溢出（在向上计数期间修改时）或下溢（在向下期间修改时-数数）。如果在计数操作停止且GTUDDTYC.OADTYF或GTUDDTYC.OBDTYF位为0时修改GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位，则在计数开始时不反映输出占空比修改。输出占空比在上溢或下溢时发生变化。如果在计数操作停止时GTUDDTYC.OADTYF或GTUDDTYC.OBDTYF位设置为1，则

GTUDDTYC.OADTY位或当时的GTUDDTYC.OBDTY位值反映在计数开始时。

在三角波模式下，如果在计数操作期间修改GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位，则输出占空比设置反映为下溢。

如果在计数操作停止且GTUDDTYC.OADTYF或GTUDDTYC.OBDTYF位为0时修改GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位，则在计数开始时不反映输出占空比修改。输出占空比在下溢时发生变化。如果在计数操作停止且GTUDDTYC.OADTYF或GTUDDTYC.OBDTYF位为1时修改了GTUDDTYC.OADTY位或GTUDDTYC.OBDTY位，则输出占空比修改将反映在计数开始时。

在执行0%或100%占空比操作时，GPT在内部继续：

- ●执行比较匹配操作
- ●设置比较匹配标志
- ●输出中断
- ●执行缓冲操作。

当控制从0%或100%占空比设置更改为比较匹配时，周期结束时GTIOCnA引脚的输出值由GTIOR.GTIOA[3:2]和GTUDDTYC.OADTYR决定。周期结束时GTIOCnB引脚的输出值由GTIOR.GTIOB[3:2]和GTUDDTYC.OBDTYR决定。

当GTIOR.GTIOA[3:2]和GTIOR.GTIOB[3:2]设置为01b时，输出引脚在周期结束时输出低电平。什么时候GTIOR.GTIOA[3:2]和GTIOR.GTIOB[3:2]设置为10b，输出引脚在周期结束时输出高电平。

GTUDDTYC.OADTYR当GTIOR.GTIOm[3:2]设置为00b（在循环结束时保持输出）或GTIOR.GTIOm[3:2]设置时，选择作为在循环结束时切换的输出保留对象的值到11b（输出在循环结束时切换）。表21.23显示了循环结束时GTIOCnA和GTIOCnB引脚输出的值。

21.3.8.1 Synchronized operation by software

The GTCNT counters can be started, stopped, and cleared on multiple channels by setting the associated GTSTR, GTSTP, or GTCLR bits simultaneously to 1.

Count start with a phase difference is possible by setting the initial value in the GTCNT counter and setting the associated GTSTR bits simultaneously to 1.

21.3.10 Period Count Function

By setting the GTPC register, the end of period can be counted.

The number of period to be counted should be set into the GTPC.PCNT counter when the GTPC.PCEN bit is 0. When the PCEN bit is 1, the PCNT counter can be read, but writing is disabled. When the PCEN bit is 1, down-counting is perfoemed at the end of period. When the PCNT counter is 1 at the end of period, it becomes 0 and counting is stopped to finish the period count function. At that time, the GTST.PCF flag is set, and the period count function finish interrupt request GPTn_PC is generated. When the GTPC.ASTP bit is 1, the GTCNT counter is also stopped at the same time that the period count function is finished.

When the GTCNT counter is stopped while period count function is enabled, the PCNT counter keeps its value. When the GTCNT counter restarts counting and the PCEN bit is 1, the PCNT counter restarts down-counting from the hold value.

When the PCEN bit is changed from 0 to 1 while the PCNT counter is 0 and the ASTP bit is 1, the GTCNT counter is stopped at the count clock immidiately after that.

When either GTSECR.SPCE bit or GTSECR.SPCD bit is set to 1, the PCEN bit in the channels set to 1 by the GTSECSR register is simultaneously set the value to enable or disable the period count function for multiple channels.

Figure 21.45 and Figure 21.46 show examples of PWM cycle count function.

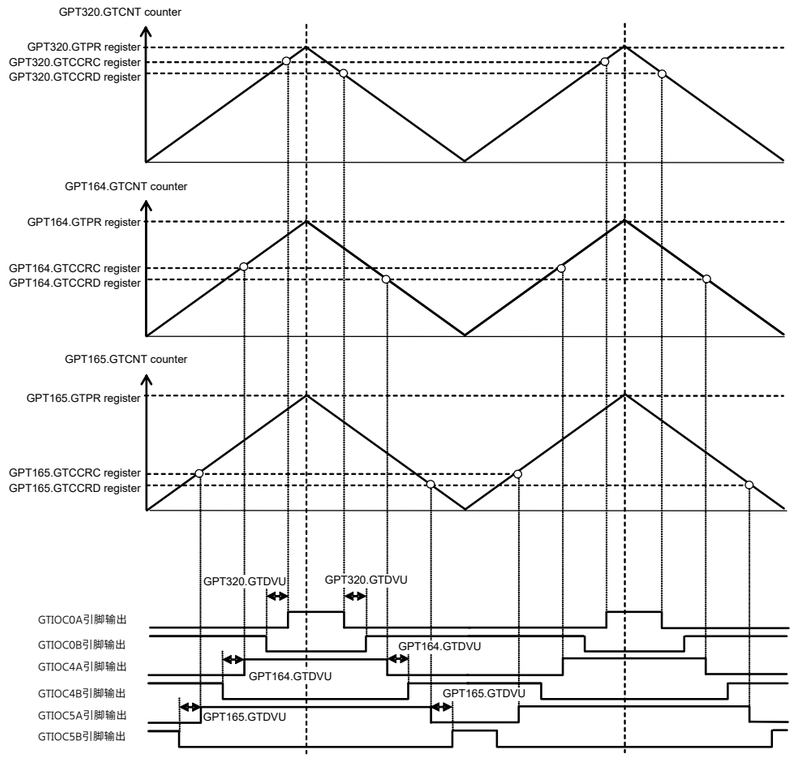

Figure 21.44 具有自动死区时间设置的三相不对称三角波互补PWM输出示例

21.3.10 周期计数功能

通过设置GTPC寄存器，可以计算周期结束。

当GTPC.PCEN位为0时，要计数的周期数应设置到GTPC.PCNT计数器中。当PCEN位为1，可以读取PCNT计数器，但禁止写入。当PCEN位为1时，在周期结束时进行递减计数。当PCNT计数器在周期结束时为1时，它变为0并停止计数以完成周期计数功能。此时，GTST.PCF标志置位，产生周期计数功能完成中断请求GPTn_PC。当GTPC.ASTP位为1时，GTCNT计数器也在周期计数功能完成的同时停止。

当GTCNT计数器停止而周期计数功能使能时，PCNT计数器保持其值。当。。。的时候GTCNT计数器重新开始计数且PCEN位为1，PCNT计数器重新从保持值开始向下计数。

当PCNT计数器为0且ASTP位为1时PCEN位从0变为1时，GTCNT计数器立即停止在计数时钟处。

当GTSECR.SPCE位或GTSECR.SPCD位设置为1时，通过GTSECSR寄存器设置为1的通道中的PCEN位同时设置该值以启用或禁用多个通道的周期计数功能。

图21.45和图21.46显示了PWM周期计数功能的示例。

21.3.11 Phase Counting Function

The phase difference between the GTIOCnA and GTIOCnB pin (n = 0 to 9) inputs is detected and the associated GTCNT counts up or counts down. The detectable phase difference is available in any combination with the relationship between the edge and the level of GTIOCnA and GTIOCnB pin inputs being set in the GTUPSR and GTDNSR registers. For details on count operation, see section 21.3.1.1. Counter operation.

21.3.11 相位计数功能

检测到GTIOCnA和GTIOCnB引脚（n=0到9）输入之间的相位差，并且相关的GTCNT向上计数或向下计数。可检测的相位差可与在GTUPSR和GTDNSR寄存器中设置的GTIOCnA和GTIOCnB引脚输入的边沿和电平之间的关系进行任何组合。有关计数操作的详细信息，请参阅第21.3.1.1节。柜台操作。

21.3.12 Output Phase Switching (GPT_OPS)

GPT_OPS provides a function for easy control of brushless DC motor operation using the Output Phase Switching Control Register (OPSCR).

GPT_OPS outputs a PWM signal to be used for chopper control or level signal for each phase (U-positive phase/negative phase, V-positive phase/negative phase, W-positive phase/negative phase) of the 6-phase motor control. This function uses a soft setting value (OPSCR.UF, VF, WF) set by software or external signals detected by the Hall element, a PWM waveform of GPT320.GTIOC0A.

Figure 21.57 shows the conceptual diagram of GPT_OPS control flow.

GPT_OPS输出用于斩波控制的PWM信号或6相电机控制的每一相（U正相负相、V正相负相、W正相负相）的电平信号。该功能使用软件设置的软设置值（OPSCR.UF、VF、WF）或霍尔元件检测到的外部信号，GPT320.GTIOC0A的PWM波形。

21.3.12.1 Input selection and synchronization of external input signal

In the GPT_OPS control flow conceptual diagram shown in Figure 21.57, (1) is a selection of input phase from the software settings and external input by the OPSCR.FB bit.

When OPSCR.FB bit is 0, select the external input. Enable the input signal after synchronization with the GPT core clock (PCLKD). After carrying out noise filtering (optional), set the external input to the input phase of PWM (PWM of GPT320.GTIOC0A) using falling edge sampling with OPSCR.ALIGN bit set to 1.

When OPSCR.FB bit is 1, select the soft setting (OPSCR.UF, VF, WF) with the value of the input phase of PWM (PWM of GPT320.GTIOC0A) using falling edge sampling with OPSCR.ALIGN bit set to 1.

When OPSCR.ALIGN bit is 0, GPT_OPS operates with the input phase of PCLKD synchronization with either OPSCR.FB bit set to 0 or OPSCR.FB bit set to 1. However, there are cases where the PWM pulse width of the output U/V/W phases (PWM output mode) of switch timing (just before/just after) is shortened.

Table 21.39 shows the input selection process and setting of associated OPSCR bits.

21.3.12.1 外部输入信号的输入选择和同步

在图21.57所示的GPT_OPS控制流程概念图中，(1)是通过OPSCR.FB位从软件设置和外部输入中选择输入相位。

当OPSCR.FB位为0时，选择外部输入。与GPT内核时钟(PCLKD)同步后启用输入信号。执行噪声过滤（可选）后，使用下降沿采样将外部输入设置为PWM的输入相位（GPT320.GTIOC0A的PWM），并将OPSCR.ALIGN位设置为1。

当OPSCR.FB位为1时，选择软设置（OPSCR.UF、VF、WF）与PWM的输入相位值（PWM的GPT320.GTIOC0A)使用下降沿采样，并将OPSCR.ALIGN位设置为1。

当OPSCR.ALIGN位为0时，GPT_OPS以PCLKD同步的输入相位运行，其中OPSCR.FB位设置为0或OPSCR.FB位设置为1。但是，输出UVW相位的PWM脉冲宽度存在某些情况（PWM输出模式）的开关时间（就在之前）被缩短了。

表21.39显示了输入选择过程和相关OPSCR位的设置。

21.3.12.2 Input sampling

The OPSCR.U, V, W bits indicate the PCLKD sampling results of the input selected in the OPSCR.FB bit.

When OPSCR.FB bit is 0 and after synchronization with the GPT core clock (PCLKD) and noise filtering (optional), OPSCR.U, V, W bits indicate the sampling results of the external input. When OPSCR.FB bit is 1, OPSCR.U, V, W bits are the value (OPSCR.UF, VF, WF) of the soft setting.

21.3.12.3 Input phase decode

In the GPT_OPS control flow conceptual diagram shown in Figure 21.57, (3) enables the 6-phase signals by decoding the input phase selected in the OPSCR.FB bit.

Table 21.40 shows the decode table of input phase when OPSCR.RV bit is 0.

21.3.12.4 Rotation Direction Control

In the GPT_OPS control flow conceptual diagram shown in Figure 21.57, (2) controls the direction of rotation of a 3-phase motor using the OPSCR.RV bit.

When the rotation direction is reverse (RV bit = 1), the input phase is inverted.

Table 21.42 shows the assigned output phases based on the OPSCR.RV bit setting (before and after rotation direction control).

21.3.12.5 Output selection control

In the GPT_OPS control flow conceptual diagram in Figure 21.57, (4) represents the selection of the output waveform by setting the OPSCR register bit.

For output selection, the following bits are relevant:

- The OPSCR.EN bit controls whether to output the 6-phase output, or to stop
- The OPSCR.P and OPSCR.N bits can select from the level signal or PWM signal (chopper output) for the output phase
- The polarity of the output phase can be set to a positive logic or negative logic by the OPSCR. INV bit.

Table 21.43 and Table 21.44 show the output selection control method using the OPSCR register bit.

21.3.12.4 旋转方向控制

在图21.57所示的GPT_OPS控制流程概念图中，(2)使用OPSCR.RV位控制三相电机的旋转方向。

当旋转方向为反向时（RV位=1），输入相位反转。

表21.42显示了基于OPSCR.RV位设置（旋转方向控制之前和之后）分配的输出相位。

21.3.12.5 输出选择控制

在图21.57的GPT_OPS控制流程概念图中，(4)表示通过设置OPSCR寄存器位来选择输出波形。

对于输出选择，以下位是相关的：

- ●OPSCR.EN位控制是输出6相输出，还是停止
- ●OPSCR.P和OPSCR.N位可以选择输出相位的电平信号或PWM信号（斩波器输出）
- ●输出相的极性可以通过OPSCR设置为正逻辑或负逻辑。INV位。

21.3.12.6 Output selection control (group output disable function)

When OPSCR.GODF is 1 and the signal value selected by the OPSCR.GRP bit is high (output disable request), the group output-disable function asynchronously sets the output to Hi-Z. When an output-disable request is generated, the OPSCR.EN bit is cleared to 0. For the return, set the OPSCR.EN bit to 1 after clearing the output disable request by software.

To ensure output-disable control, use the POEG_GROUPn (n = A to D) interrupt to clear the flag in the POE or check that the OPSCR.EN bit is 0 and then clear the flag. For an example of the operation of group output disable control, see Figure 21.60.

21.3.12.6 输出选择控制（组输出禁用功能）

当OPSCR.GODF为1且OPSCR.GRP位选择的信号值为高电平（输出禁用请求）时，组输出禁用功能异步将输出设置为Hi-Z。产生输出禁止请求时，OPSCR.EN位清零。返回时，请在软件清除输出禁止请求后将OPSCR.EN位设置为1。

为确保输出禁用控制，请使用POEG_GROUPn（n=A到D）中断清除POE中的标志或检查OPSCR.EN位是否为0，然后清除标志。组输出禁用控制的操作示例见图21.60。

21.3.12.7 Event Link Controller (ELC) output

In the GPT_OPS control flow conceptual diagram shown in Figure 21.57, (5) outputs the Hall sensor input signal edge to the ELC.

The Hall sensor input edge signal is the logical OR of the rising and falling edge signals of each U-phase/V-phase/W-phase input sampled at PCLKD. That is, if the high period of each of the U-phase/V-phase/W-phase of the input phase is short in duration, the Hall sensor edge input signal is not output at that time.

When the OPSCR.FB bit is 0, the Hall sensor input edge signal is the logical OR of the edge signals of the external input phase sampled at PCLKD.

When OPSCR.FB bit is 1, the Hall sensor input edge signal is the logical OR of the edge of the soft setting (OPSCR.UF, VF, WF) sampled at PCLKD.

See Figure 21.58 to Figure 21.60 for examples of the output signal to the ELC.

21.3.12.8 GPT_OPS start operation setting flow

Table 21.45 Example setting of GPT_OPS start operation

No.	Step Name	Description

2	Counting of GPT320	Start the count operation of GPT320, and outputs a PWM waveform.
3	GPT_OPS input data set (only software setting is selected)	Set software setting to OPSCR.UF, VF, and WF bits.
4	Noise filter settings of GPT_OPS external input (only external input is selected)	When using a noise filter, set the sampling clock of the noise filter by OPSCR.NFCS[1:0] bits. Then the noise filter is enabled if OPSCR.NFEN = 1.
5	GPT_OPS input phase selection setting/input phase alignment setting	Select the input phase from the external input or software setting by OPSCR.FB bit. Select the alignment of the input phase by OPSCR.ALIGN bit.
6	Setting the GPT_OPS output phase	Set the level output/PWM output of the positive/negative phase output by OPSCR.P/OPSCR.N bit. Set the positive logic/negative logic of the output phase by OPSCR.INV bit. Set the rotation direction by OPSCR.RV bit
7	GPT_OPS setting the group output disable function	Set the selection of output disable source by OPSCR.GRP bit. Perform the setting of on/off of the group output disable function by OPSCR.GODF bit.
8	GPT_OPS Working	Setting the OPSCR.EN = 1 outputs the 6-phase output to drive the brushless DC motor from the GPT_OPS.

21.3.13 Inter Channel Logical Operation Function

The logical operation function between compare match outputs can be performed.

Figure 21.61 shows the block diagram of inter channel logical operation.

To prevent hazard to the GPT output, the signal after logical operation is latched with PCLKD. After latching, the output disable control is performed.

When the logical operation function which causes the delay of 1 PCLKD is selected, the output enable signal is also delayed with 1 PCLKD and input to the output disable control.

When the same signal (C = A or D = B) to operate logical function AND, OR, EXOR and NOR is selected, C or D is treated as 1. In the case of GTIOCnA pin output, when A of same channel is selected for C, the result of AND is A, the result of OR is 1, the result of EXOR is NOT A, and the result of NOR is 0.

21.3.12.7 事件链接控制器(ELC)输出

在图21.57所示的GPT_OPS控制流程概念图中，(5)将霍尔传感器输入信号沿输出到ELC。

霍尔传感器输入边沿信号是在PCLKD采样的每个U相V相W相输入的上升沿和下降沿信号的逻辑或。也就是说，如果输入相的U相V相W相中的每一个的高电平时段持续时间短，则此时不输出霍尔传感器边沿输入信号。

当OPSCR.FB位为0时，霍尔传感器输入边沿信号为在PCLKD采样的外部输入相位边沿信号的逻辑或。

当OPSCR.FB位为1时，霍尔传感器输入边沿信号为软设置边沿的逻辑或（OPSCR.UF，VF，WF）在PCLKD采样。

有关ELC的输出信号示例，请参见图21.58至图21.60。

21.4 Interrupt Sources

21.4.1 Interrupt Sources

The GPT provides the following interrupt sources:

- GTCCR input capture/compare match
- GTCNT counter overflow (GTPR compare match)/underflow.
- period count function finish

Each interrupt source has its own status flag. When an interrupt source signal is generated, the associated status flag in GTST is set to 1. The associated status flag in GTST can be cleared by writing 0. If flag set and flag clear occur at the same time, flag clear takes priority over flag set. These flags are automatically updated by the internal state. The Interrupt Controller Unit can change the relative channel priorities. However, the priority within a channel is fixed. For details, see section 13, Interrupt Controller Unit (ICU).

Table 21.46 lists the GPT interrupt sources.

Table 21.46 Interrupt sources

21.4 中断源

21.4.1 中断源

GPT提供以下中断源：

●GTCCR输入捕捉比较匹配

●GTCNT计数器上溢（GTPR比较匹配）下溢。

●周期计数功能完成

每个中断源都有自己的状态标志。当一个中断源信号产生时，相关的状态标志在GTST设置为1。GTST中相关的状态标志可以通过写入0来清除。如果标志设置和标志清除同时发生，标志清除优先于标志设置。这些标志由内部状态自动更新。中断控制器单元可以改变相关的通道优先级。但是，通道内的优先级是固定的。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

表21.46列出了GPT中断源。

21.5 Operations Linked by ELC

21.5.1 Event Signal Output to ELC

- Generation of compare match F interrupt (GPTn_CMPF)
- Generation of overflow interrupt (GPTn_OVF)
- Generation of underflow interrupt (GPTn_UDF)
- Finish of period count function (GPTm_PC)

Note: n = 0 to 9
m = 0, 1, 4 to 6

21.5.2 Event Signal Inputs from ELC

The GPT can perform the following operations in response to a maximum of 8 events from the ELC:

- Start counting, stop counting, clear counting
- Up-counting, down-counting
- Input capture.

See section 18, Event Link Controller (ELC) for the connection between the ELC and the event signal input.

21.6 Noise Filter Function

Each pin for use in input capture and Hall sensor input to the GPT is equipped with a noise filter. The noise filter samples input signals at the sampling clock and removes the pulses whose length is less than 3 sampling cycles.

DMAC和DTC可以通过每个通道中的中断来激活。有关详细信息，请参见第13节，中断控制器单元(ICU)，第16节，DMA控制器(DMAC)，和第17节，数据传输控制器(DTC)。

21.5 由ELC链接的操作

21.5.1 事件信号输出到ELC

当GPT的中断请求信号被事件链接控制器(ELC)用作事件信号时，GPT可以执行与预先设置的另一个模块链接的操作。

21.5.2 来自ELC的事件信号输入

GPT可以执行以下操作以响应来自ELC的最多8个事件：

●开始计数、停止计数、清计数
- Up-counting, down-counting
●输入捕捉。

有关ELC和事件信号输入之间的连接，请参见第18节，事件链接控制器(ELC)。

21.6 噪音过滤功能

用于GPT的输入捕捉和霍尔传感器输入的每个引脚都配备了噪声滤波器。噪声滤波器以采样时钟对输入信号进行采样，并去除长度小于3个采样周期的脉冲。

The noise filter functionality includes enabling and disabling the noise filter for each pin and setting of the sampling clock for each channel.

Figure 21.63 shows the timing of noise filtering.

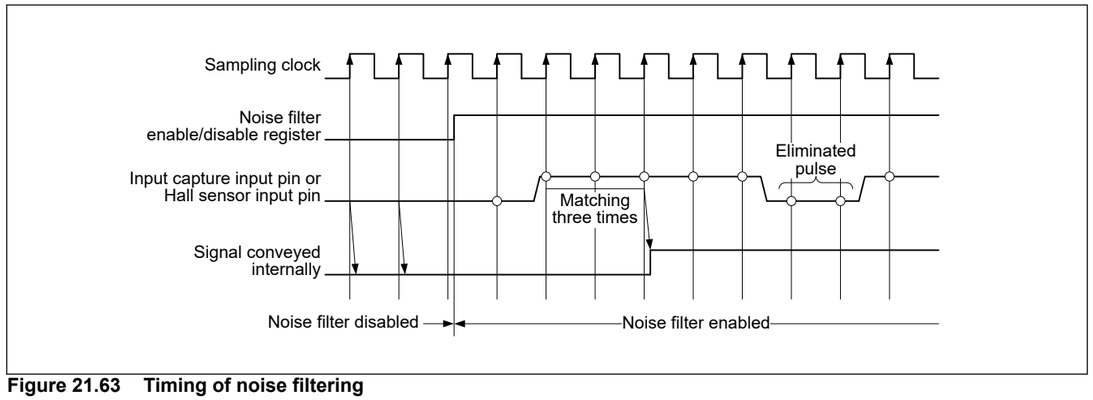

Figure 21.63 Timing of noise filtering

If noise filtering is enabled, the input capture operation or output phase switching operation is performed on the edges of the noise filtered signal after a delay of a sampling interval × 2 + PCLKD at the shortest. This is due to the noise filtering for the input capture input or hall sensor input.

21.7 Protection Function

21.7.1 Write-Protection for Registers

To prevent registers from being accidentally modified, registers can be write-protected in channel units by setting GTWP.WP. Write-protection can be set for the following registers:

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTDTCR, GTDVU, GTICLF, GTPC.

Every bit in registers GTSTR, GTSTP and GTCLR which can update the corresponding registers in other channels and can be updated by any of the corresponding registers in other channels conversely, can be protected by setting the GTWP.STRWP, STPWP, and CLRWP bits, respectively, per channel.

Likewise, writing to the GTSECSR and GTSECR registers, which can control all channels by writing to the GTSECSR and GTSECR registers of a given channel, can by enabled or disabled by the setting of the GTWP.CMNWP bit.

Protection using the GTWP register is only for write operations by the CPU. This protection does not cover updates to registers that occur in association with CPU writes.

21.7.2 Disabling of Buffer Operation

If the timing of the buffer register write is delayed relative to the timing for the buffer transfer, buffer operation can be suspended with the GTBER.BD[1] and BD[0] bit settings. Specifically, buffer transfer can be temporarily disabled even though a buffer transfer condition is generated during buffer register write.

0 can be set simultaneously by setting the GTSECR register for multiple channels which were set by the GTSECSR register.

Figure 21.64 shows an example of operation for disabling buffer operation.

噪声过滤器功能包括为每个引脚启用和禁用噪声过滤器以及为每个通道设置采样时钟。

图21.63显示了噪声过滤的时序。

如果噪声过滤使能，输入捕捉操作或输出相位切换操作在最短采样间隔×2+PCLKD的延迟后对噪声过滤信号的边沿执行。这是由于输入捕捉输入或霍尔传感器输入的噪声过滤。

21.7 保护功能

21.7.1 寄存器的写保护

为了防止寄存器被意外修改，可以通过设置以通道为单位对寄存器进行写保护
GTWP.WP。可以为以下寄存器设置写保护：

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTDTCR, GTDVU, GTICLF, GTPC.

寄存器GTSTR、GTSTP和GTCLR中的每个位可以更新其他通道中的相应寄存器，反之也可以由其他通道中的任何相应寄存器更新，可以分别通过设置GTWP.STRWP、STPWP和CLRWP位来保护 每个频道。

同样，写入GTSECSR和GTSECR寄存器，它们可以通过写入GTSECSR和
给定通道的GTSECR寄存器可以通过设置GTWP.CMNWP位来启用或禁用。

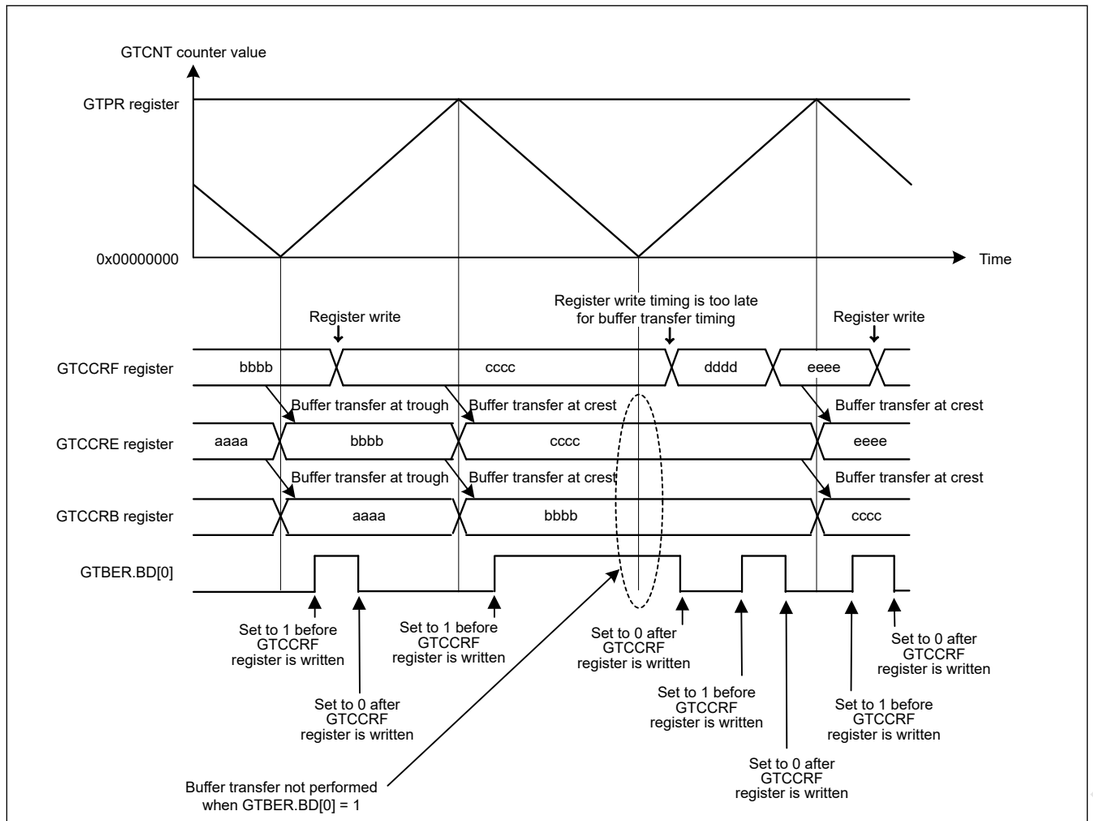
使用GTWP寄存器的保护仅适用于CPU的写操作。此保护不涵盖与CPU写入相关的寄存器更新。

21.7.2 禁用缓冲区操作

如果缓冲寄存器写入的时序相对于缓冲传输的时序延迟，则可以通过GTBER.BD[1]和BD[0]位设置暂停缓冲操作。具体来说，即使在缓冲寄存器写入期间产生了缓冲传送条件，也可以暂时禁用缓冲传送。

0可以通过设置GTSECSR寄存器为由GTSECSR寄存器设置的多个通道同时设置。

图21.64显示了禁用缓冲区操作的操作示例。



Note: The base address of registers are the same.

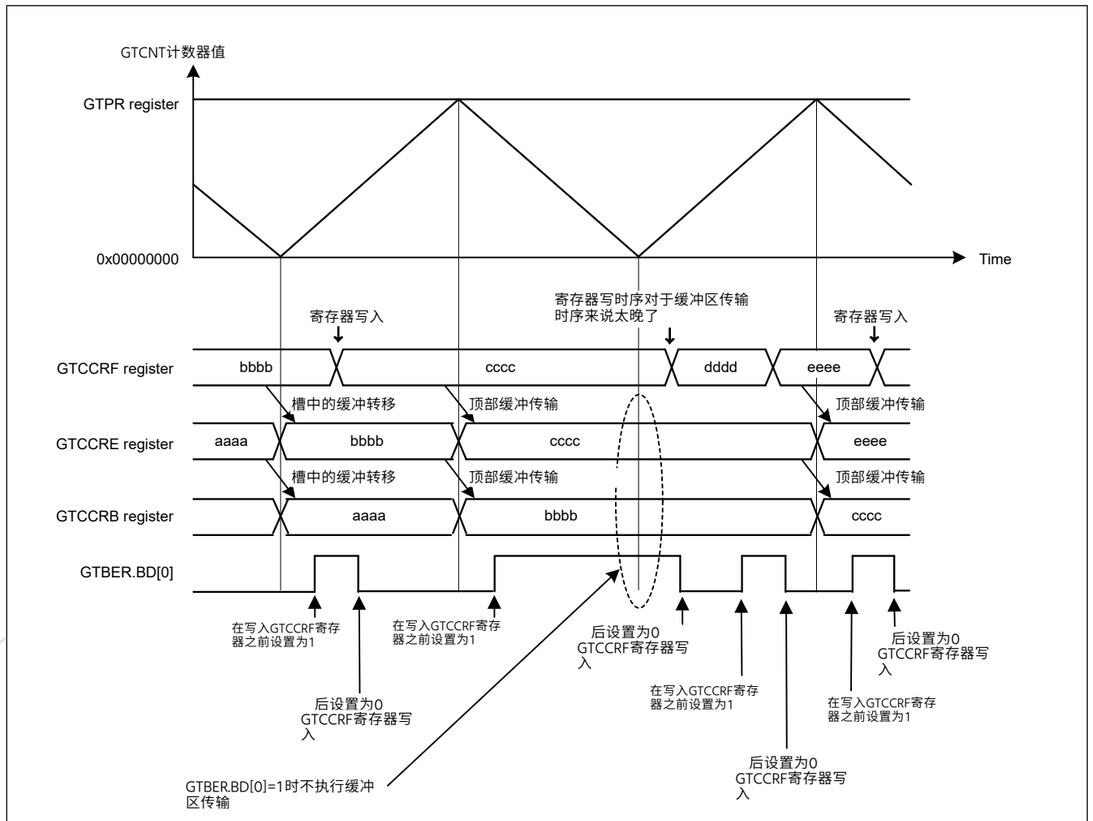
21.7.2.1 Simultaneous Control of Buffer Operations of Multiple Channels

The GTBER.BD bit can be set by writing directly to the GTBER register per channel or by making settings in the GTSECR register for multiple channels that have already set in the GTSECSR register.

Follow the procedure below to simultaneously set the GTBER.BD bits of multiple channels.

1. Select the channels for simultaneously setting by the GTSECSR register
   Set the GTSECSR register so that the values at the bit positions for the corresponding channels for simultaneously setting of the GTBER.BD bits become 1. All GTSECSR registers can be updated by writing to the GTSECSR register of any channel.
2. Simultaneously set the GTBER.BD bits by updating the GTSECR register
   In the GTSECR register, set the operation of the GTBER.BD bits (enabling or disabling of buffer operation) which are to be simultaneously set. Writing to a GTSECR register from any channel updates the GTBER.BD bits in all channels corresponding to the bits set as 1 in the GTSECSR register, in accordance with the value of the GTSECR register.

Figure 21.65 show examples of simultaneously controlling the enabling or disabling of buffer operation for multiple channels.



Note: 寄存器的基地址相同。

Figure 21.64 三角波缓冲操作、双缓冲操作、波谷和波峰缓冲转移的禁用操作示例

21.7.2.1 多通道缓冲操作的同时控制

GTBER.BD位可以通过直接写入每个通道的GTBER寄存器或通过在GTSECR寄存器中为已在GTSECSR寄存器中设置的多个通道进行设置来设置。

按照以下步骤同时设置多个通道的GTBER.BD位。

1.通过GTSECSR寄存器选择同时设置的通道
设置GTSECSR寄存器，使用于同时设置GTBER.BD位的相应通道的位位置的值变为1。通过写入任何通道的GTSECSR寄存器，可以更新所有GTSECSR寄存器。

2.通过更新GTSECR寄存器同时设置GTBER.BD位
在GTSECR寄存器中，设置要同时设置的GTBER.BD位的操作（启用或禁用缓冲区操作）。根据GTSECR寄存器的值，从任何通道写入GTSECR寄存器会更新与GTSECSR寄存器中设置为1的位相对应的所有通道中的GTBER.BD位。

图21.65显示了同时控制多个通道的缓冲区操作的启用或禁用的示例。

21.7.3 GTIOCnm Pin Output Negate Control (n = 0 to 9, m = A, B)

For protection from system failure, the output disable control that changes the GTIOCnm pin output value forcibly is provided for GTIOCnm pin output by the request of output disable from POEG. Output protection is required when the same output level being on the GTIOCnA and GTIOCnB pins is detected. GPT detects this condition and generates output disable requests to POEG according to the setting of the output disable request permission bits, such as GTINTAD.GRPABH, GTINTAD.GRPABL. After the POEG receives output disable requests from each channel and calculates external input using an OR operation, the POEG generates output disable requests to GPT.

One output disable signal (representing the shared output disable request signal of the GTIOCnA pin and the GTIOCnB pin) out of 4 output disable requests generated by the POEG is selected by setting GTINTAD.GRP[1:0]. The status of the selected disable output request is monitored by reading the GTST.ODF bit. The output level during output disable is set based on the GTIOR.OADF[1:0] bits for the GTIOCnA pin and the GTIOR.OBDF[1:0] setting for the GTIOCnB pin.

The change to the output disable state is performed asynchronously by generating the output disable request from the POEG. The release of the output disable state is performed at end of cycle by terminating the output disable request.

When event count is performed or when the output disable state should be released immediately without waiting for end of cycle, GTIOR.OADF[1:0] should be set to 00b (for GTIOCnA pin) or GTIOR.OBDF[1:0] should be set to 00b (for the GTIOCnB pin).

Figure 21.66 shows an example of the GTIOCnm pin output disable control operation.（n = 0 to 9, m = A, B）

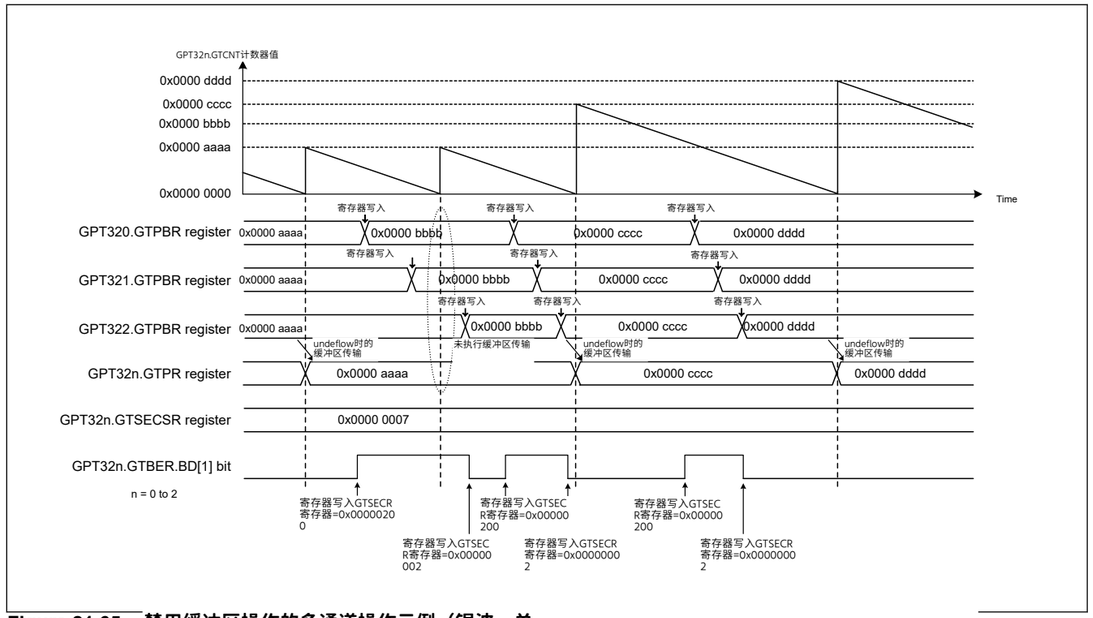

Figure 21.65 禁用缓冲区操作的多通道操作示例（锯波，单Buffer Operation)

21.7.3 GTIOCnm引脚输出负控制（n=0到9，m=A，B）

为防止系统故障，根据POEG的输出禁用请求，为GTIOCnm引脚输出提供强制改变GTIOCnm引脚输出值的输出禁用控制。当检测到GTIOCnA和GTIOCnB引脚上的输出电平相同时，需要输出保护。GPT检测到这种情况并根据输出禁用请求许可位的设置，如GTINTAD.GRPABH、GTINTAD.GRPABL向POEG生成输出禁用请求。在POEG接收到来自每个通道的输出禁用请求并使用OR运算计算外部输入后，POEG向GPT生成输出禁用请求。

通过设置GTINTAD.GRP[1:0]，在POEG产生的4个输出禁止请求中选择一个输出禁止信号（代表GTIOCnA引脚和GTIOCnB引脚的共享输出禁止请求信号）。通过读取GTST.ODF位来监控所选禁用输出请求的状态。输出禁用期间的输出电平根据GTIOCnA引脚的GTIOR.OADF[1:0]位和GTIOCnB引脚的GTIOR.OBDF[1:0]设置来设置。

通过从POEG生成输出禁用请求异步执行对输出禁用状态的更改。通过终止输出禁用请求，在循环结束时执行输出禁用状态的释放。

当执行事件计数或应立即释放输出禁用状态而不等待周期结束时，应将GTIOR.OADF[1:0]设置为00b（对于GTIOCnA引脚）或GTIOR.OBDF[1:0]应设置为设置为00b（对于GTIOCnB引脚）。

图21.66显示了GTIOCnm引脚输出禁用控制操作的示例。（n=0到9，m=A，B）

21.8 Initialization Method of Output Pins

21.8.1 Pin Settings after Reset

The GPT registers are initialized at a reset. Start counting after selecting the port pin function with the PmnPFS register, setting GTIOR.OAE and GTIOR.OBE bits, and outputting the GPT function to external pins.

21.8.1 复位后的引脚设置

GPT寄存器在复位时被初始化。通过PmnPFS寄存器选择端口引脚功能，设置GTIOR.OAE和GTIOR.OBE位，并将GPT功能输出到外部引脚后开始计数。

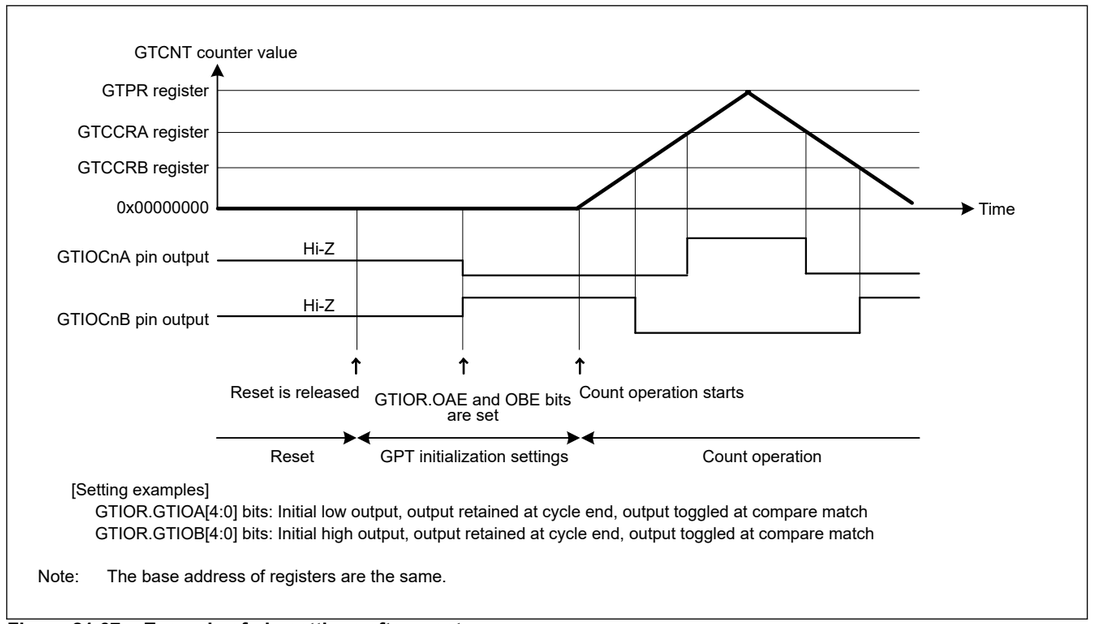

Figure 21.67 Example of pin settings after reset

21.8.2 Pin Initialization Due to Error during Operation

If an error occurs during GPT operation, the following four types of pin processing can be performed before pin initialization:

- Set the OAHLD and OBHLD bits in GTIOR to 1 and retain the outputs at count stop
- Set the OAHLD and OBHLD bits in GTIOR to 0, specify arbitrary output values at OADFLT and OBDFLT in GTIOR, and output the arbitrary values at count stop
- Set the pin to output an arbitrary value as a general output port by setting the PDR, PODR registers and PmnPFS.PMR bit of the I/O port in advance. Set the OAE and OBE bits in GTIOR to 0, and the control bit associated with the pin in the PMR to 0 to allow arbitrary values to be output from the pin set as a general output port when an error occurs.
- Drive the output to a high impedance state using the POEG function.

If the automatic dead time setting is made, clear the GTDTCR.TDE bit to 0 after counting stops. When counting stops, only the values of registers that are changed by a GPT external source change. If counting is resumed, operation continues from where it stopped. If counting is stopped, the registers must be initialized before counting starts.

21.9 Usage Notes

21.9.1 Module-Stop Function Setting

The Module Stop Control Register can enable or disable GPT operation. The GPT is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

21.9.2 GTCCRn Settings during Compare Match Operation (n = A to F)

(1) When automatic dead time setting is made in triangle-wave PWM mode

The GTCCRA register must satisfy all of the following conditions:

- GTDVU < GTCCRA
- 0 < GTCCRA < GTPR

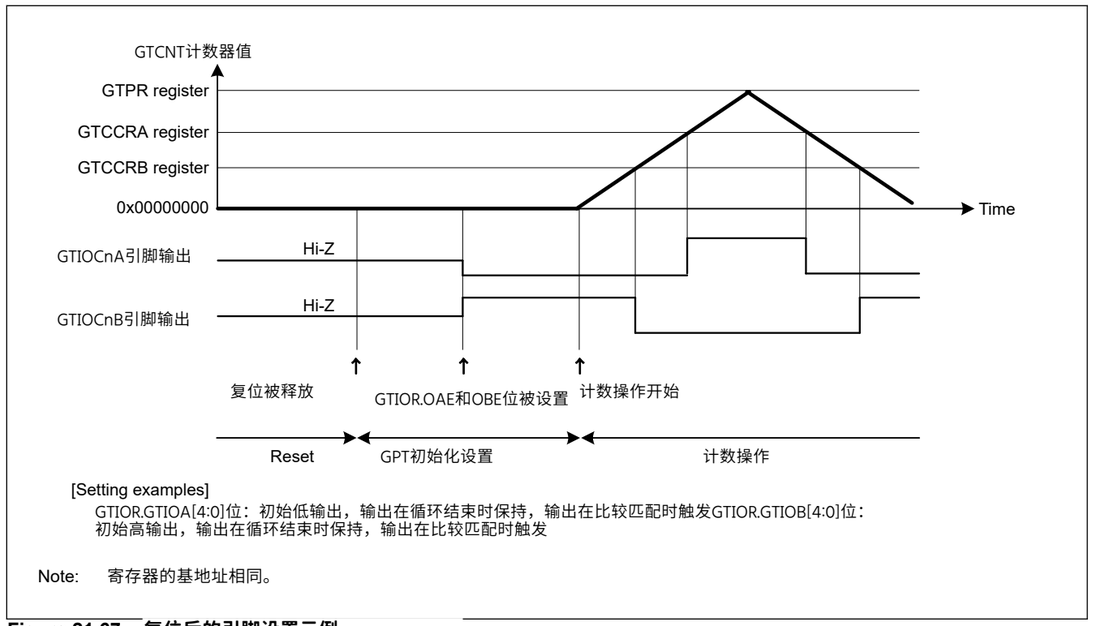

Figure 21.67 复位后的引脚设置示例

21.8.2 由于操作过程中的错误而导致的引脚初始化

如果在GPT操作过程中发生错误，可以在引脚初始化之前进行以下四种引脚处理：

●将GTIOR中的OAHLD和OBHLD位设置为1，并在计数停止时保留输出

●将GTIOR中的OAHLD和OBHLD位设置为0，在GTIOR中的OADFLT和OBDFLT指定任意输出值，并在计数停止时输出任意值

●通过预先设置IO端口的PDR、PODR寄存器和PmnPFS.PMR位，将引脚设置为输出任意值作为通用输出端口。将GTIOR中的OAE和OBE位设置为0，并将与PMR中的引脚相关的控制位设置为0，以允许在发生错误时从设置为通用输出端口的引脚输出任意值。

●使用POEG功能将输出驱动为高阻抗状态。

如果进行了自动死区时间设置，则在计数停止后将GTDTCR.TDE位清零。当计数停止时，只有被GPT外部源改变的寄存器的值会改变。如果重新开始计数，则从停止处继续操作。如果停止计数，则必须在计数开始前初始化寄存器。

21.9 使用说明

21.9.1 模块停止功能设置

模块停止控制寄存器可以启用或禁用GPT操作。GPT在重置后最初停止。
释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

21.9.2 比较匹配操作期间的GTCCRn设置（n=A到F）

(1) 在三角波PWM模式下进行自动死区时间设置时

GTCCRA寄存器必须满足以下所有条件：

- GTDVU < GTCCRA
- 0 < GTCCRA < GTPR

(2) When automatic dead time setting is not made in triangle-wave PWM mode

The GTCCRA register must be set within the range of 0 < GTCCRA < GTPR. If GTCCRA = 0 or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0 or GTCCRA = GTPR is satisfied. When GTCCRA > GTPR, no compare match occurs.

Similarly, GTCCRB must be set within the range of 0 < GTCCRB < GTPR. If GTCCRB = 0 or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB is 0 or GTCCRB = GTPR is satisfied. When GTCCRB > GTPR, no compare match occurs.

(3) When automatic dead time setting is made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, the correct output waveforms with secured dead time may not be obtained.

- In up-counting: GTCCRC < GTCCRD, GTCCRC > GTDVU, GTCCRD < GTPR - GTDVU
- In down-counting: GTCCRC > GTCCRD, GTCCRC < GTPR - GTDVU, GTCCRD > GTDVU

(4) When automatic dead time setting is not made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRC < GTCCRD < GTPR
- In down-counting: GTPR > GTCCRC > GTCCRD > 0

Similarly, GTCCRE and GTCCRF must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRE < GTCCRF < GTPR
- In down-counting: GTPR > GTCCRE > GTCCRF > 0.

(5) In saw-wave PWM mode

The GTCCRA register must be set with the range of 0 < GTCCRA < GTPR. If GTCCRA = 0 or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0 or GTCCRA = GTPR is satisfied. If GTCCRA > GTPR is set, no compare match occurs.

Similarly, GTCCRB must be set with the range of 0 < GTCCRB < GTPR. If GTCCRB = 0 or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB = 0 or GTCCRB = GTPR is satisfied. If GTCCRB > GTPR is set, no compare match occurs.

21.9.3 Setting Range for GTCNT Counter

The GTCNT counter register must be set with the range of 0 ≤ GTCNT ≤ GTPR.

21.9.4 Starting and Stopping the GTCNT Counter

The control timing of starting and stopping the GTCNT counter by the GTCR.CST bit synchronizes the count clock that is selected in GTCR.TPCS[3:0]. When GTCR.CST is updated, the GTCNT counter starts/stops after a count clock that is selected in GTCR.TPCS[3:0]. Therefore, an event generated before the GTCNT counter actually starts is ignored, resulting in situations in which an event is accepted or an interrupt occurs after GTCR.CST is set to 0.

21.9.5 Priority Order of Each Event

(1) GTCNT register

Table 21.47 shows a priority order of events updating the GTCNT register.

(2) 在三角波PWM模式下未进行自动死区时间设置时

GTCCRA寄存器必须设置在0<GTCCRA<GTPR的范围内。如果设置了GTCCRA=0或GTCCRA=GTPR，则仅当满足GTCCRA=0或GTCCRA=GTPR时，才会在周期内发生比较匹配。当GTCCRA>GTPR时，不发生比较匹配。

同样，GTCCRB必须设置在0<GTCCRB<GTPR的范围内。如果设置了GTCCRB=0或GTCCRB=GTPR，则仅当GTCCRB为0或GTCCRB=GTPR满足时，才会在周期内发生比较匹配。当GTCCRB>GTPR时，不发生比较匹配。

(3) 在锯波单发脉冲模式下进行自动死区时间设置时

GTCCRC和GTCCRD寄存器必须设置为满足以下限制。如果不满足这些限制，则可能无法获得具有安全死区时间的正确输出波形。

- In up-counting: GTCCRC < GTCCRD, GTCCRC > GTDVU, GTCCRD < GTPR - GTDVU
- In down-counting: GTCCRC > GTCCRD, GTCCRC < GTPR - GTDVU, GTCCRD > GTDVU

(4) 在锯波单发脉冲模式下未进行自动死区时间设置时

GTCCRC和GTCCRD寄存器必须设置为满足以下限制。如果不满足限制，则不会发生两个比较匹配，并且无法执行脉冲输出。

- In up-counting: 0 < GTCCRC < GTCCRD < GTPR
- In down-counting: GTPR > GTCCRC > GTCCRD > 0

同样，必须设置GTCCRE和GTCCRF以满足以下限制。如果不满足限制，则不会发生两个比较匹配，并且无法执行脉冲输出。

- In up-counting: 0 < GTCCRE < GTCCRF < GTPR
- In down-counting: GTPR > GTCCRE > GTCCRF > 0.

(5) 在锯齿波PWM模式下

GTCCRA寄存器必须设置为0<GTCCRA<GTPR。如果设置了GTCCRA=0或GTCCRA=GTPR，则仅当满足GTCCRA=0或GTCCRA=GTPR时，才会在周期内发生比较匹配。如果设置了GTCCRA>GTPR，则不会发生比较匹配。

类似地，GTCCRB必须设置在0<GTCCRB<GTPR的范围内。如果设置了GTCCRB=0或GTCCRB=GTPR，则仅当满足GTCCRB=0或GTCCRB=GTPR时，才会在周期内发生比较匹配。如果设置了GTCCRB>GTPR，则不会发生比较匹配。

21.9.3 GTCNT计数器的设置范围

GTCNT计数器寄存器的设置范围必须为0≤GTCNT≤GTPR。

21.9.4 启动和停止GTCNT计数器

通过GTCR.CST位启动和停止GTCNT计数器的控制时序与在GTCR.TPCS[3:0]中选择的计数时钟同步。当GTCR.CST更新时，GTCNT计数器在GTCR.TPCS[3:0]中选择的计数时钟后开始停止。因此，在GTCNT计数器实际启动之前产生的事件将被忽略，从而导致在GTCR.CST设置为0之后接受事件或发生中断的情况。

21.9.5 每个事件的优先顺序

(1) GTCNT register

表21.47显示了更新GTCNT寄存器的事件的优先顺序。

Table 21.47 Priority order of sources updating GTCNT

Source updating GTCNT	Priority order
Writing by CPU (writing to GTCNT/GTCLR)	High
Clear by hardware sources set in GTCSR	↑
Count up or down by hardware sources set in GTUPSR/GTDNSR	↑
Count operation	Low

If up-counting and down-counting by hardware sources occur at the same time, the GTCNT counter value does not change. When there is a conflict between updating the GTCNT register and reading by the CPU, pre-update data is read.

(2) GTCR.CST bit

When there is a conflict between starting/stopping by hardware sources set in the GTSSR/GTPSR registers and writing by the CPU (writing to GTCR/GTSTR/GTSTP registers), the writing by CPU has priority over the starting/stopping by hardware sources.

In case that stop by the period count function conflicts with start by the CPU writing (GTCR register writing/GTSTR register writing), the period count function is finished with setting the GTST.PCF flag. The CST bit is not changed and the GTCNT continues to count.

When there is a conflict between starting by hardware sources set in the GTSSR register and stopping by hardware sources set in GTPSR register, the GTCR.CST bit value does not change. When there is a conflict between updating the GTCR.CST bit and reading by the CPU (reading from GTCR/GTSTR/GTSTP registers), pre-update data is read.

(3) GTCCRm registers (m = A to F)

When there is a conflict between input capture/buffer transfer operation and writing to the GTCCRm registers, the writing to GTCCRm registers has priority over input capture/buffer transfer operation. When there is a conflict between input capture and writing to the counter register by the CPU or updating the counter register by hardware sources, the pre-update counter value is captured. When there is a conflict between updating the GTCCRm registers and reading by the CPU, pre-update data is read.

(4) GTPR registers

When there is a conflict between buffer transfer operation and writing to the GTPR register, writing to GTPR register has priority over buffer transfer operation. When there is a conflict between updating GTPR register and reading by the CPU, pre-update data is read.

Table 21.47 更新GTCNT的源的优先顺序

源更新GTCNT	优先顺序
CPU写入（写入GTCNTGTCLR）	High
由GTCSR中设置的硬件源清除	↑
通过GTUPSRGTDNSR中设置的硬件源进行向上或向下计数	↑
计数操作	Low

如果硬件源的递增计数和递减计数同时发生，GTCNT计数器值不会改变。
当更新GTCNT寄存器和CPU读取之间存在冲突时，会读取更新前的数据。

(2) GTCR.CST bit

当GTSSRGTPSR寄存器中设置的硬件源启动停止与CPU写入（写入GTCRGTSTRGTSTP寄存器）发生冲突时，CPU写入优先于硬件源启动停止。

如果周期计数功能停止与CPU写入启动（GTCR寄存器写入GTSTR寄存器写入）发生冲突，则周期计数功能通过设置GTST.PCF标志结束。CST位不变，GTCNT继续计数。

当GTSSR寄存器中设置的硬件源启动和GTPSR寄存器中设置的硬件源停止之间存在冲突时，GTCR.CST位的值不会改变。当更新GTCR.CST位与CPU读取（从GTCRGTSTRGTSTP寄存器读取）之间存在冲突时，将读取更新前数据。

(3) GTCCRm寄存器（m=A到F）

当输入捕捉缓冲区传输操作与写入GTCCRm寄存器之间存在冲突时，写入GTCCRm寄存器优先于输入捕捉缓冲区传输操作。当输入捕获与CPU写入计数器寄存器或硬件源更新计数器寄存器之间存在冲突时，将捕获更新前的计数器值。当更新GTCCRm寄存器和CPU读取之间存在冲突时，会读取更新前的数据。

(4) GTPR registers

当缓冲区传输操作与写入GTPR寄存器之间存在冲突时，写入GTPR寄存器优先于缓冲区传输操作。当更新GTPR寄存器与CPU读取发生冲突时，读取更新前的数据。

22.2 Register Descriptions

22.2.1 AGT : AGT Counter Register

Base address: AGTn = 0x400E_8000 + 0x0100 × n (n = 0 to 5)

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	n/a	16-bit counter and reload register Setting range : 0x0000 to 0xFFFF	R/W

AGTn.AGT is a 16-bit register. The write value is written to the reload register and the read value is read from the counter.

The states of the reload register and the counter change according to the TSTART bit in the AGTCR register and TCMEA/TCMEB bit in the AGTCMSR register. For details, see section 22.3.1. Reload Register and Counter Rewrite Operation.

When 1 is written to the TSTOP bit in the AGTCR register, AGT counter is forcibly stopped and set to 0xFFFF.

When the TCK[2:0] bits setting in the AGTMR1 register are a value other than 001b (PCLKB/8) or 011b (PCLKB/2), if the AGT register is set to 0x0000, a request signal to the ICU, the DTC, the DMAC, and the ELC is generated once immediately after the count starts. The AGTOn, AGTIOn pin output are toggled.

When the AGT register is set to 0x0000 in event counter mode, regardless of the value of TCK[2:0] bits, a request signal to the ICU, the DTC, the DMAC, and the ELC is generated once immediately after the count starts.

In addition, the AGTOn pin output is toggled even during a period other than the specified count period. When the AGT register is set to 0x0001 or more, a request signal is generated each time AGT underflows.

22.2.2 AGTCMA : AGT Compare Match A Register

Base address: AGTn = 0x400E_8000 + 0x0100 × n (n = 0 to 5)

Offset address: 0x02

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W

Note 1. Set the AGTCMA register to 0xFFFF when compare match A is not used.

The **AGTCMA** register is a read/write register to set a value for compare match with the AGT counter. The states of the reload register and compare register A change according to the TSTART bit in the AGTCR register. For details, see section 22.3.2. Reload Register and AGT Compare Match A/B Register Rewrite Operation.

22.2 注册说明

22.2.1 AGT:AGT计数器寄存器

Base address: AGTn = 0x400E_8000 + 0x0100 × n (n = 0 to 5)

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
重置后的值：	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	n/a	16位计数器和重载寄存器设置范 围：0x0000到0xFFFF	R/W

AGTn.AGT是一个16位寄存器。写入值写入重载寄存器，读取值从计数器中读取。

重载寄存器和计数器的状态根据AGTCR寄存器和TCMEA中的TSTART位改变
AGTCMSR寄存器中的TCMEB位。详见22.3.1节。重载寄存器和计数器重写操作。

当AGTCR寄存器的TSTOP位写入1时，AGT计数器被强制停止并设置为0xFFFF。

当AGTMR1寄存器中的TCK[2:0]位设置为001b(PCLKB8)或011b(PCLKB2)以外的值时，如果
AGT寄存器设置为0x0000，在计数开始后立即生成一次对ICU、DTC、DMAC和ELC的请求信号。AGTO
n、AGTIOn引脚输出被切换。

当AGT寄存器在事件计数器模式下设置为0x0000时，无论TCK[2:0]位的值如何，都会在计数开始后立即生成一次对ICU、DTC、DMAC和ELC的请求信号.

此外，即使在指定计数周期以外的周期内，AGTOn引脚输出也会切换。当AGT寄存器设置为0x0001或更大时，每次AGT下溢时都会产生一个请求信号。

When the TSTART bit is set to 1 (count starts), the TCSTF flag is set to 1 (count in progress) in synchronization with the count source. Also, after 0 is written to the TSTART bit, the TCSTF flag is set to 0 (count stops) in synchronization with the count source. For details, see section 22.4.1. Count Operation Start and Stop Control.

TCSTF flag (AGT Count Status Flag)

The TCSTF flag indicates the AGT count status.

[Setting condition]

Note: Write access to the AGTMR1 register initializes the output from the AGTOn, AGTIOn, AGTOAn, and AGTOBn. For details on the output level at initialization, see section 22.2.7. AGTIOC : AGT I/O Control Register.

Note 1. When event counter mode is selected, the external input pin (AGTIOn) is selected as the count source regardless of the setting of TCK[2:0] bits.

Note 2. Do not switch count sources during count operation. Only switch count sources when both the TSTART bit and TCSTF flag in the AGTCR register are set to 0 (count stops).

Note 3. The operating mode can only be changed when the count is stopped while both the TSTART bit and TCSTF flag in the AGTCR register are set to 0 (count is stopped). Do not change the operating mode during count operation.

Note 4. The TEDGPL bit is enabled only in event counter mode.

Note 5. To run AGT in Software Standby and Deep Software Standby mode, select AGTLCLK or AGTSCLK (TCK[2:0] = 100b, 110b).

Note 6. AGTn (n = 0, 2, 4) cannot use AGTn (n = 0, 2, 4) underflow (setting prohibited). AGTn (n = 1, 3, 5) uses the AGTn (n = 0, 2, 4) underflow.

Note 7. Do not change the TCK[2:0] bits when the CKS[2:0] bits in the AGTMR2 register is not 000b. First, change the CKS[2:0] bits in the AGTMR2 register to 000b. Then change the TCK[2:0] bits and wait for one cycle of the count source.

注意1.选择事件计数器模式时，无论设置如何

注2.在计数操作期间不要切换计数源。只有当TSTART位和TCSTF标志都在
AGTCR寄存器设置为0（计数停止）。

注3.只有在AGTCR寄存器中的TSTART位和TCSTF标志都设置为0（计数停止）时停止计数才能更改操作模式。请勿在计数操作期间更改操作模式。

注4.TEDGPL位仅在事件计数器模式下启用。

注5.要在软件待机和深度软件待机模式下运行AGT，请选择AGTLCLK或AGTSCLK(TCK[2:0]=100b 110b)。注6.AGTn(n=0 2 4)不能使用AGTn(n=0 2 4)下溢（禁止设置）。AGTn(n=1 3 5)使用AGTn(n=0 2 4)下溢。

注7.当AGTMR2寄存器中的CKS[2:0]位不是000b时，不要更改TCK[2:0]位。首先，更改CKS[2:0]位

Note 1. Do not rewrite the CKS[2:0] bits during count operation. Only rewrite the CKS[2:0] bits when both the TSTART bit and TCSTF flag in the AGTCR register are set to 0 (count stops).
Note 2. When count source is AGTLCLK or AGTSCLK, the switch of CKS[2:0] bits is valid.
Note 3. Do not switch the TCK[2:0] bits in the AGTMR1 register when CKS[2:0] bits are not 000b. Switch the TCK[2:0] bits in the AGTMR1 register after CKS[2:0] bits are set to 000b, and wait for 1 cycle of the count source.

CKS[2:0] bit (AGTLCLK or AGTSCLK Count Source Clock Frequency Division Ratio)

CKS[2:0] bits select the Count Source Clock Frequency Division Ratio for AGTLCLK or AGTSCLK.

LPM bit (Low Power Mode)

The LPM bit sets the low power operation, which impacts access to certain AGT registers. Set this bit to 1 to operate in low power.

When this bit is 1, access to the following registers is prohibited:

- AGT/AGTCMA/AGTCMB/AGTCR.

After this bit is switched from 1 to 0, the first access to the register is constrained as follows:

- When reading from the AGT register, read AGT register twice. Only the second reading of data is valid.
- When writing to the AGT, AGTCMA, AGTCMB, and AGTCR register, allow at least 2 cycles of the count source clock when writing to the register.
- When confirm the value written to the AGT, AGTCMA, AGTCMB, and AGTCR registers.
  - When the count operation is stopped; after writing data, it can be read in the next cycle.
  - When the count operation is operating; after writing data, it can be written 4 cycles after the count source clock.

注1.在计数操作期间不要重写CKS[2:0]位。仅当AGTCR寄存器中的TSTART位和TCSTF标志都设置为0（计数停止）时才重写CKS[2:0]位。

注2.当计数源为AGTLCLK或AGTSCLK时，CKS[2:0]位的切换有效。
注3.当CKS[2:0]位不是000b时，不要切换AGTMR1寄存器中的TCK[2:0]位。在CKS[2:0]位设置为000b后，切换AGTMR1寄存器中的TCK[2:0]位，并等待计数源的1个周期。

CKS[2:0]位（AGTLCLK或AGTSCLK计数源时钟分频比）

CKS[2:0]位选择AGTLCLK或AGTSCLK的计数源时钟分频比。

LPM位（低功耗模式）

LPM位设置低功耗操作，这会影响对某些AGT寄存器的访问。将此位设置为1以在低功耗下运行。

该位为1时，禁止访问以下寄存器：

- AGT/AGTCMA/AGTCMB/AGTCR.

该位由1变为0后，对寄存器的第一次访问受到如下约束：

●读取AGT寄存器时，读取AGT寄存器两次。只有第二次读取数据是有效的。

●写入AGT、AGTCMA、AGTCMB和AGTCR寄存器时，写入寄存器时至少允许计数源时钟的2个周期。

●确认写入AGT、AGTCMA、AGTCMB、AGTCR寄存器的值时。
当计数操作停止时；写入数据后，可以在下一个周期读取。
当计数操作正在运行时；写入数据后，可在计数源时钟后4个周期写入。

22.3 Operation

22.3.1 Reload Register and Counter Rewrite Operation

Regardless of the operating mode, the timing of the rewrite operation to the reload register and the counter differs depending on the value of the TSTART bit in the AGTCR register and of the TCMEA or TCMEB bit in the AGTCMSR register. When the TSTART bit is 0 (count stops), the count value is directly written to the reload register and the counter. When the TSTART bit is 1 (count starts) and the TCMEA bit and TCMEB bit are 0 (AGT compare match A/B register are invalid), the value is written to the reload register in synchronization with the count source, and then to the counter in synchronization with the next count source. When the TSTART bit is 1 (count starts) and the TCMEA bit or the TCMEB bit is 1 (AGT compare match A register or compare match B register is valid), the value is written to the reload register in synchronization with the count source, and then to the counter in synchronization with the underflow of the counter.

22.3 Operation

22.3.1 重载寄存器和计数器重写操作

无论操作模式如何，对重载寄存器和计数器的重写操作的时序根据AGTCR寄存器中的TSTART位和AGTCMSR寄存器中的TCMEA或TCMEB位的值而有所不同。当TSTART位为0（计数停止）时，计数值直接写入重载寄存器和计数器。当TSTART位为1（计数开始）且TCMEA位和TCMEB位为0（AGT比较匹配AB寄存器无效）时，将值与计数源同步写入重载寄存器，然后写入计数器与下一个计数源同步。当TSTART位为1（计数开始）且TCMEA位或TCMEB位为1（AGT比较匹配A寄存器或比较匹配B寄存器有效）时，值与计数源同步写入重载寄存器，然后与计数器的下溢同步到计数器。

图22.3和图22.4显示了使用TSTART位值和TCMEATCMEB位值进行重写操作的时序。

22.3.2 Reload Register and AGT Compare Match A/B Register Rewrite Operation

Regardless of the operating mode, the timing of the rewrite operation to the reload register and AGT compare register A/B depends on the value of the TSTART bit in the AGTCR register. When the TSTART bit is 0 (count stops), the count value is directly written to the reload register and AGT compare register A/B. When the TSTART bit is 1 (count starts), the value is written to the reload register in synchronization with the count source, and then to the compare register in synchronization with the underflow of the counter.

Figure 22.5 shows the timing of rewrite operation with TSTART bit value for compare register A. AGT Compare register B is of the same timing as AGT compare register A.

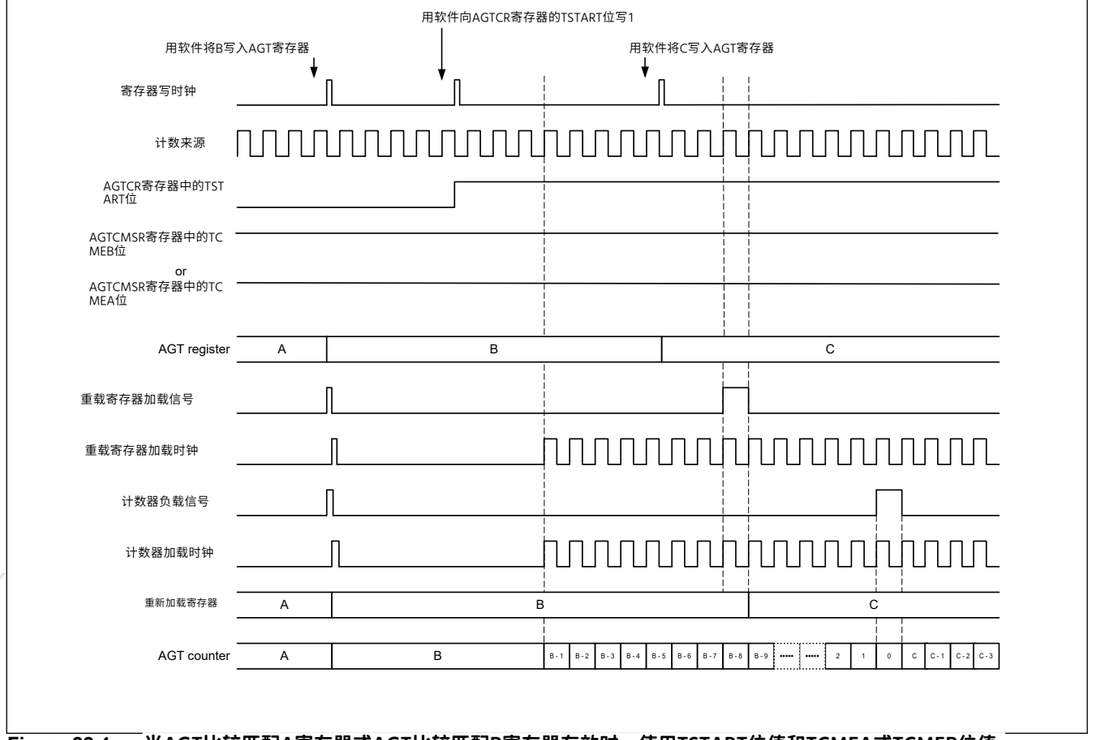

Figure 22.4 当AGT比较匹配A寄存器或AGT比较匹配B寄存器有效时，使用TSTART位值和TCMEA或TCMEB位值进行重写操作的时序

22.3.2 重载寄存器和AGT比较匹配AB寄存器重写操作

不管操作模式如何，对重载寄存器和AGT比较寄存器AB的重写操作的时序取决于AGTCR寄存器中TSTART位的值。当TSTART位为0（计数停止）时，计数值直接写入重载寄存器和AGT比较寄存器AB。当TSTART位为1（计数开始）时，该值同步写入重载寄存器计数源，然后与计数器的下溢同步到比较寄存器。

图22.5显示了比较寄存器A的TSTART位值的重写操作时序。AGT比较寄存器B与AGT比较寄存器A的时序相同。

22.3.3 Timer Mode

In this mode, the AGT counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register. In timer mode, the count value is decremented by 1 on each rising edge of the count source. When the count value reaches 0x0000 and the next count source is input, an underflow occurs and an interrupt request is generated.

22.3.3 定时器模式

在此模式下，AGT计数器按AGTMR1寄存器中的TCK[2:0]位选择的计数源递减。
在定时器模式下，计数值在计数源的每个上升沿减1。当计数值达到0x0000并输入下一个计数源时，发生下溢并产生中断请求。

图22.6显示了定时器模式下的操作示例。

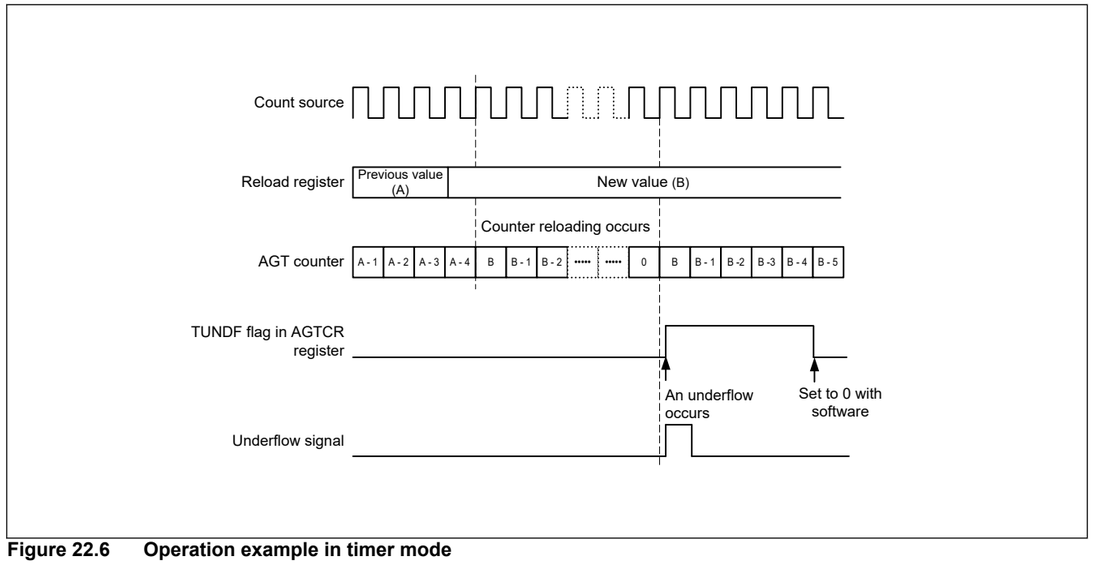

Figure 22.6 Operation example in timer mode

22.3.4 Pulse Output Mode

In pulse output mode, the counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register, and the output level of the AGTIOn and AGTOn pins inverted each time an underflow occurs.

In pulse output mode, the count value is decremented by 1 on each rising edge of the count source. When the count value reaches 0x0000 and the next count source is input, an underflow occurs and an interrupt request is generated. In addition, a pulse can be output from the AGTIOn and AGTOn pins. The output level is inverted each time an underflow occurs. The pulse output from the AGTOn pin can be stopped with the TOE bit in the AGTIOC register. The output level can be selected with the TEDGSEL bit in the AGTIOC register.

Figure 22.7 shows the operation example in pulse output mode.

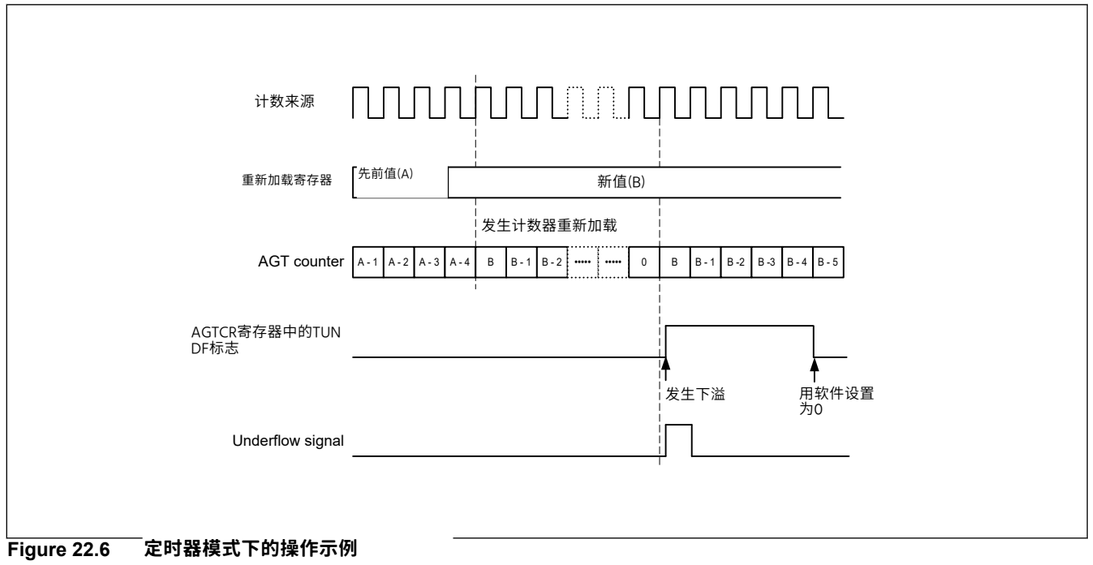

Figure 22.6 定时器模式下的操作示例

22.3.4 脉冲输出方式

在脉冲输出模式下，计数器由AGTMR1寄存器中的TCK[2:0]位选择的计数源递减，并且每次发生下溢时反转AGTIOn和AGTOn引脚的输出电平。

在脉冲输出模式下，计数值在计数源的每个上升沿减1。当计数值达到0x0000并输入下一个计数源时，发生下溢并产生中断请求。此外，可以从AGTIOn和AGTOn引脚输出脉冲。每次发生下溢时，输出电平都会反转。AGTOn引脚的脉冲输出可通过AGTIOC寄存器中的TOE位停止。可以通过AGTIOC寄存器中的TEDGSEL位选择输出电平。

图22.7显示了脉冲输出模式下的操作示例。

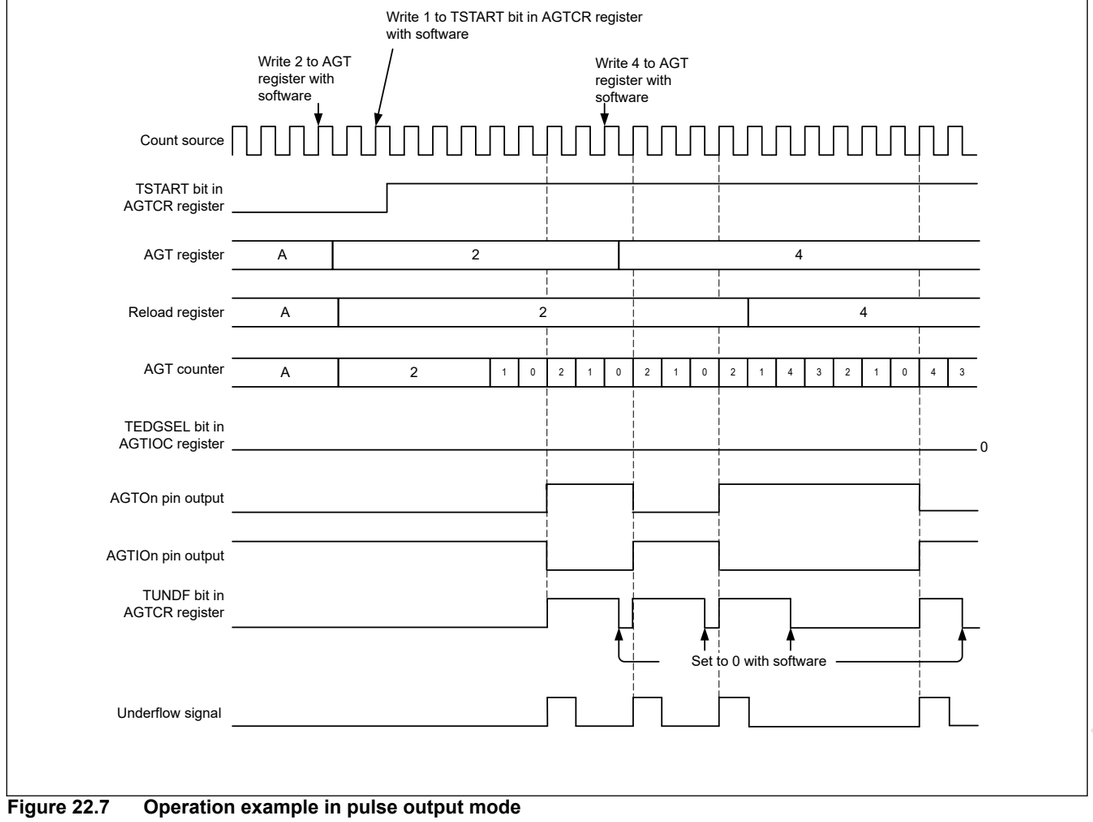

Figure 22.7 Operation example in pulse output mode

22.3.5 Event Counter Mode

In event counter mode, the counter is decremented by an external event signal (count source) input to the AGTIOn pin. Various periods for counting events can be set with the TIOGT[1:0] bits in the AGTIOC register and AGTISR registers. In addition, the filter function for theAGTIOn pin input can be specified with bits TIPF[1:0] in the AGTIOC register. The output from the AGTOn pin can be toggled even in event counter mode.

Figure 22.8 shows the operation example in event counter mode.

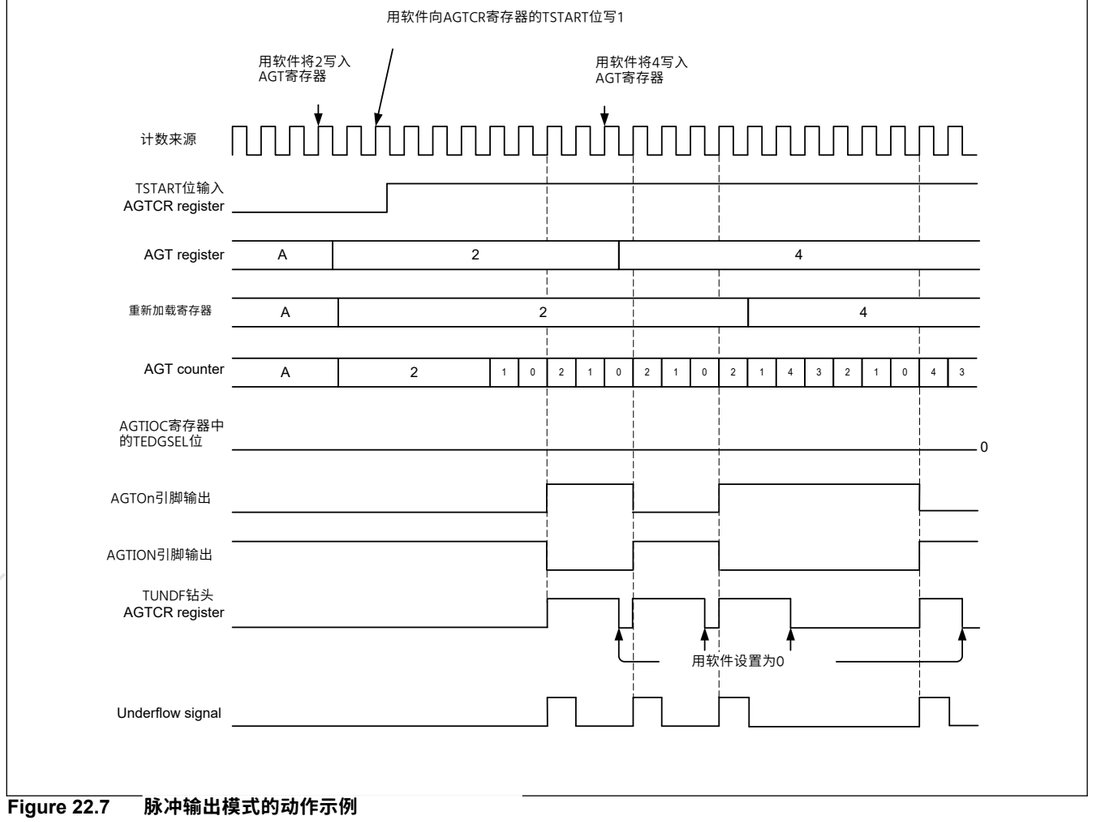

Figure 22.7 脉冲输出模式的动作示例

22.3.5 事件计数器模式

在事件计数器模式下，计数器由输入到AGTIOn引脚的外部事件信号（计数源）递减。可以使用AGTIOC寄存器和AGTISR寄存器中的TIOGT[1:0]位设置计数事件的各种周期。此外，AGTIOn引脚输入的过滤功能可通过AGTIOC寄存器中的位TIPF[1:0]指定。即使在事件计数器模式下，也可以切换AGTOn引脚的输出。

图22.8显示了事件计数器模式下的操作示例。

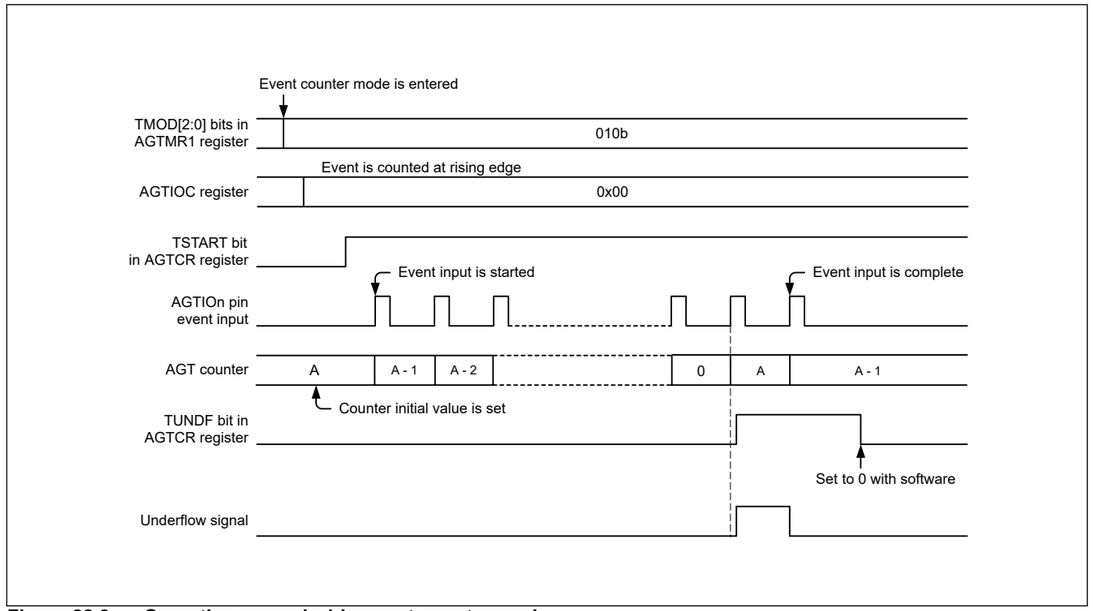

Figure 22.8 Operation example 1 in event counter mode

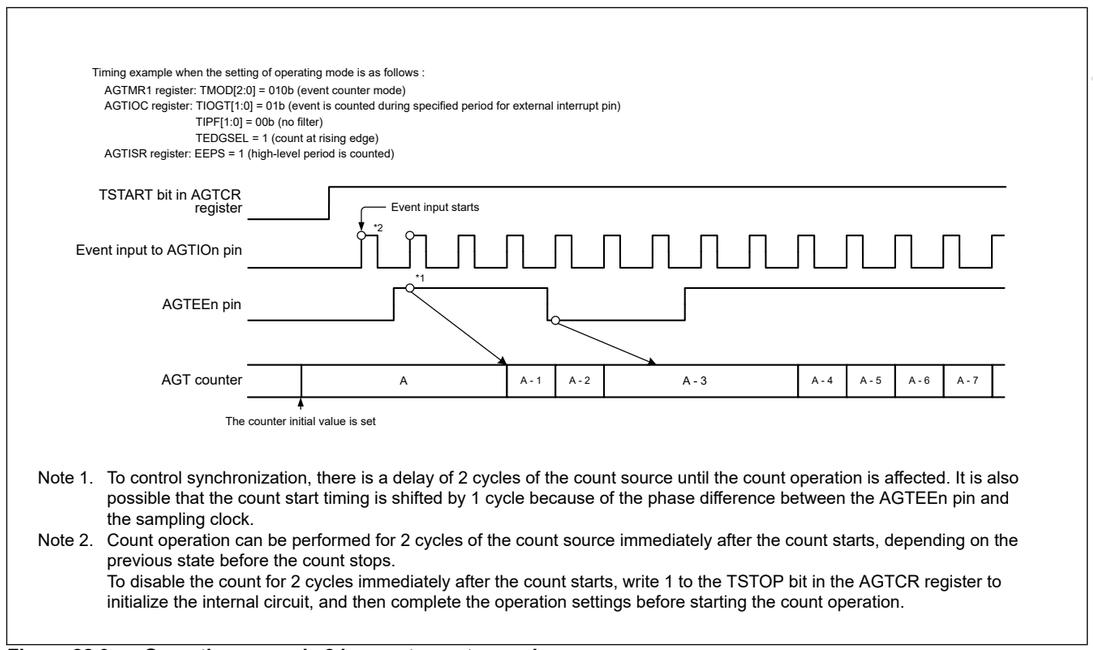
Figure 22.9 shows an operation example for counting during the specified period in event counter mode (TIOGT[1:0] bits in the AGTIOC register are set to 01b).



Note 1. To control synchronization, there is a delay of 2 cycles of the count source until the count operation is affected. It is also possible that the count start timing is shifted by 1 cycle because of the phase difference between the AGTEEn pin and the sampling clock.

Note 2. Count operation can be performed for 2 cycles of the count source immediately after the count starts, depending on the previous state before the count stops.
To disable the count for 2 cycles immediately after the count starts, write 1 to the TSTOP bit in the AGTCR register to initialize the internal circuit, and then complete the operation settings before starting the count operation.

Figure 22.9 Operation example 2 in event counter mode

22.3.6 Pulse Width Measurement Mode

In pulse width measurement mode, the pulse width of an external signal input to the AGTIOn pin is measured. When the level specified by the TEDGSEL bit in the AGTIOC register is input to the AGTIOn pin, the counter is decremented by the

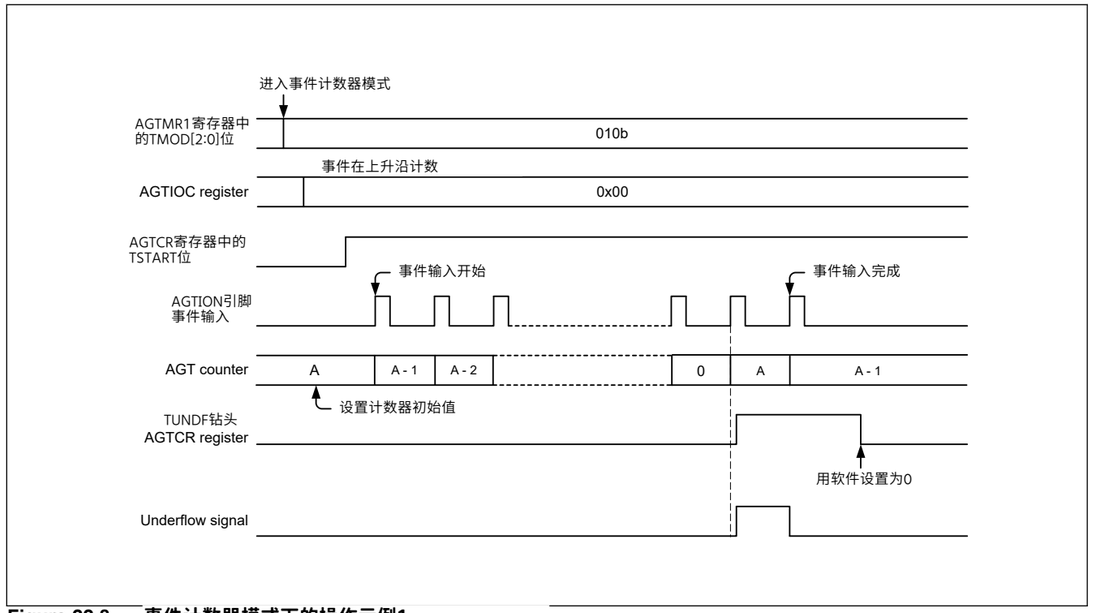


Figure 22.8 事件计数器模式下的操作示例1

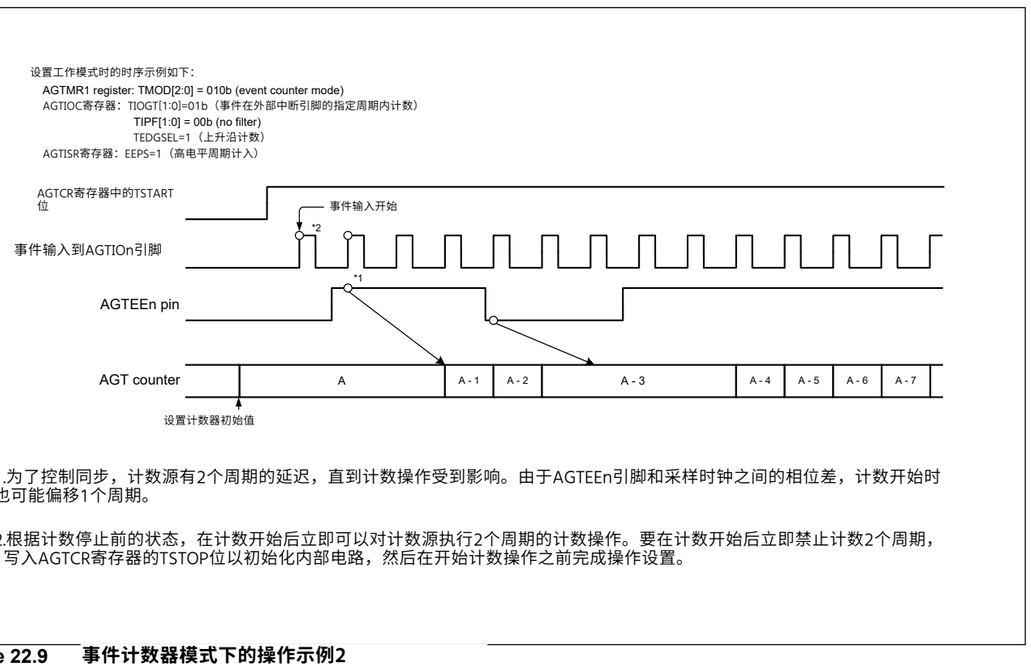
图22.9显示了在事件计数器模式下在指定周期内进行计数的操作示例（AGTIOC寄存器中的TIOGT[1:0]位设置为01b）。



注1.为了控制同步，计数源有2个周期的延迟，直到计数操作受到影响。由于AGTEEn引脚和采样时钟之间的相位差，计数开始时间也可能偏移1个周期。

注2.根据计数停止前的状态，在计数开始后立即可以对计数源执行2个周期的计数操作。要在计数开始后立即禁止计数2个周期，将1写入AGTCR寄存器的TSTOP位以初始化内部电路，然后在开始计数操作之前完成操作设置。

count source selected with the TCK[2:0] bits in the AGTMR1 register. When the specified level on the AGTIOn pin ends, the counter is stopped, the TEDGF bit in the AGTCR register is set to 1 (active edge received), and an interrupt request is generated. The measurement of pulse width data is performed by reading the count value while the counter is stopped. Also, when the counter underflows during measurement, the TUNDF bit in the AGTCR register is set to 1 and an interrupt request is generated.

Figure 22.10 shows the operation example in pulse width measurement mode.

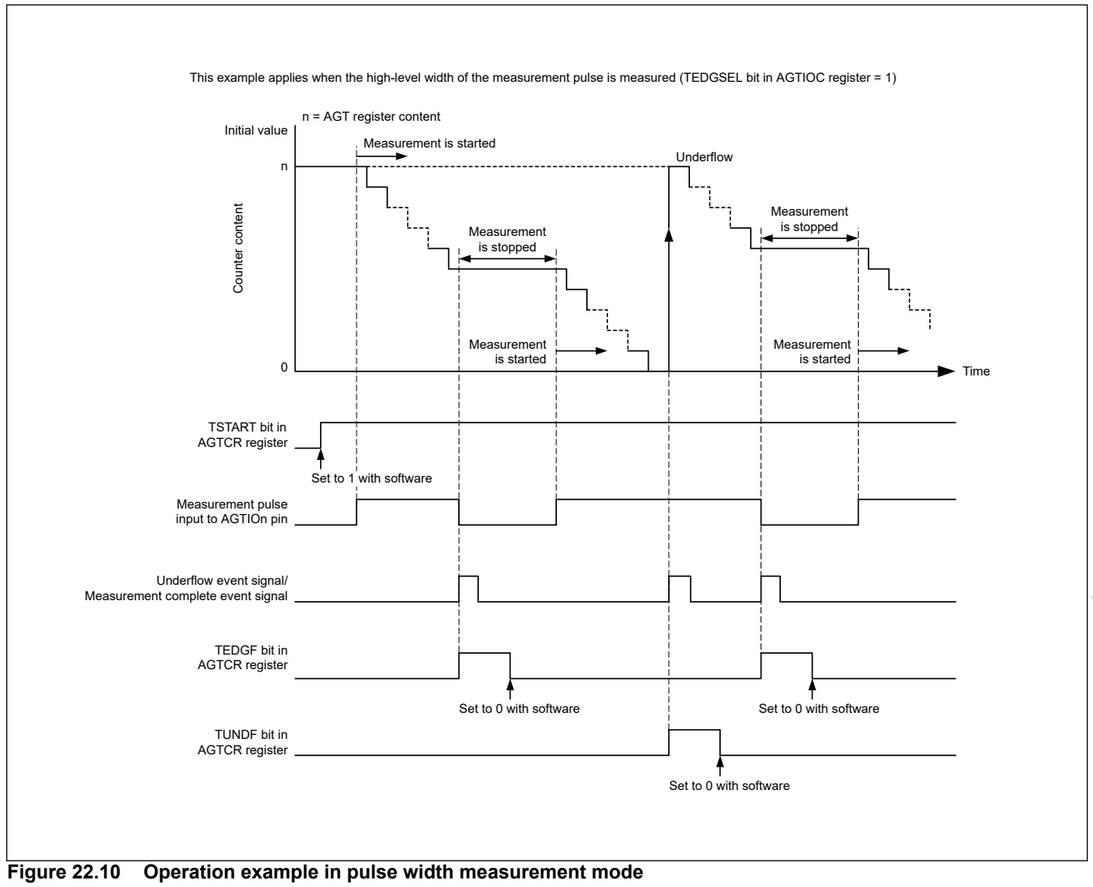

Figure 22.10 Operation example in pulse width measurement mode

22.3.7 Pulse Period Measurement Mode

In pulse period measurement mode, the pulse period of an external signal input to the AGTIOn pin is measured. The counter is decremented by the count source selected with TCK[2:0] bits in the AGTMR1 register. When a pulse with the period specified by the TEDGSEL bit in the AGTIOC register is input to the AGTIOn pin, the count value is transferred to the read-out buffer on the rising edge of the count source. The value in the reload register is loaded to the counter at the next rising edge. Simultaneously, the TEDGF flag in the AGTCR register is set to 1 (active edge received) and an interrupt request is generated. The read-out buffer (AGT register) is read at this time and the difference from the reload value (see section 22.4.6. How to Calculate Event Number, Pulse Width, and Pulse Period) is the period data of the input pulse. The period data is retained until the read-out buffer is read. When the counter underflows, the TUNDF flag in the AGTCR register is set to 1 (underflow) and an interrupt request is generated.

Figure 22.11 shows the operation example in pulse period measurement mode.

Only input pulses with a period longer than twice the period of the count source are measured. Also, the low-level and high-level widths must both be longer than the period of the count source. If a pulse period shorter than these conditions is input, the input might be ignored.

通过AGTMR1寄存器中的TCK[2:0]位选择计数源。当AGTIOn引脚上的指定电平结束时，计数器停止，AGTCR寄存器中的TEDGF位设置为1（接收到有效沿），并产生中断请求。通过在计数器停止时读取计数值来执行脉冲宽度数据的测量。此外，当测量期间计数器下溢时，AGTCR寄存器中的TUNDF位设置为1，并产生中断请求。

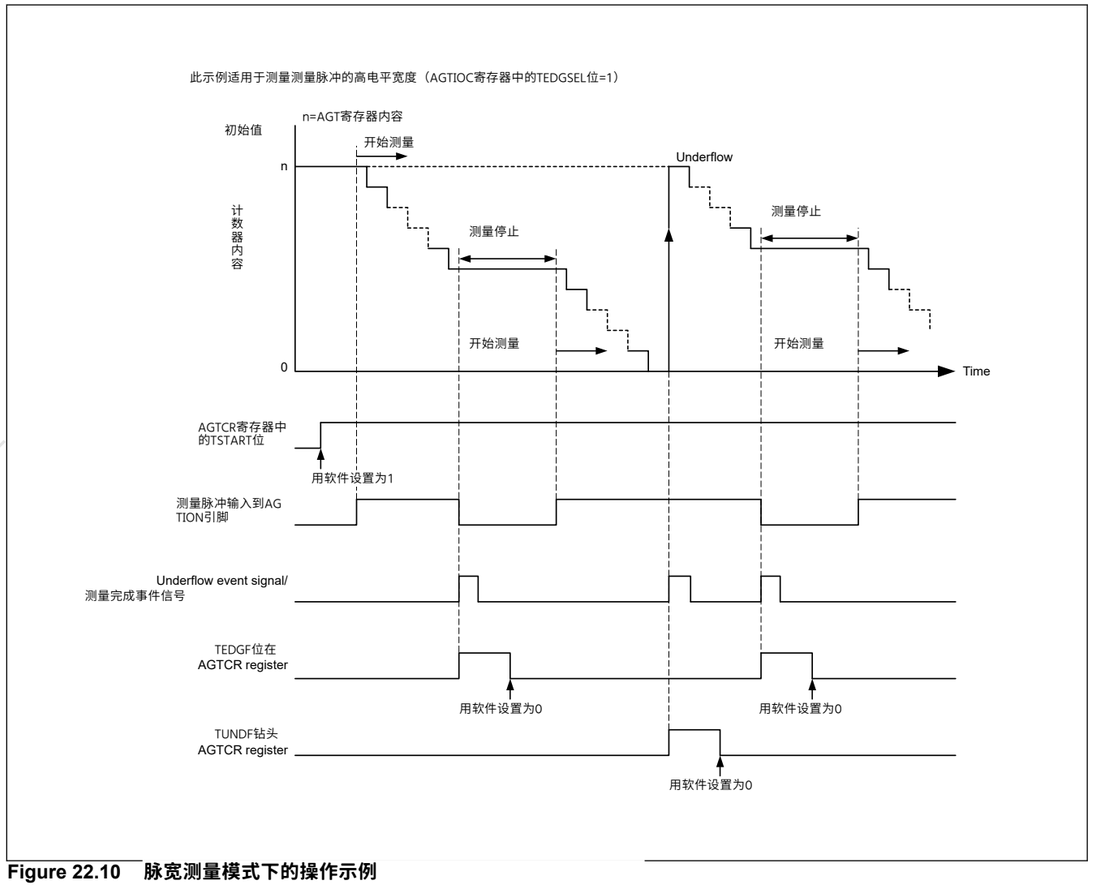

Figure 22.10 脉宽测量模式下的操作示例

22.3.7 脉冲周期测量模式

在脉冲周期测量模式下，测量输入到AGTIOn引脚的外部信号的脉冲周期。计数器由AGTMR1寄存器中的TCK[2:0]位选择的计数源递减。当AGTIOC寄存器中TEDGSEL位指定周期的脉冲输入到AGTIOn引脚时，计数值在计数源的上升沿传送到读出缓冲器。重载寄存器中的值在下一个上升沿加载到计数器。同时，AGTCR寄存器中的TEDGF标志设置为1（接收到有效沿）并产生中断请求。此时读取读出缓冲器（AGT寄存器），与重载值的差值（见22.4.6.如何计算事件数、脉冲宽度和脉冲周期）是输入脉冲的周期数据。周期数据被保留，直到读出缓冲器被读取。当计数器下溢时，AGTCR寄存器中的TUNDF标志设置为1（下溢）并产生中断请求。

图22.11显示了脉冲周期测量模式下的操作示例。

仅测量周期长于计数源周期两倍的输入脉冲。此外，低电平和高电平宽度都必须长于计数源的周期。如果输入比这些条件短的脉冲周期，输入可能会被忽略。

This example applies when the initial value of the AGT register is set to A, the TEDGSEL bit in the AGTIOC register is set to 0, and the period from one rising edge to the next edge of the measurement pulse is measured.

Note 1. Reading from the AGT register must be performed during the period from when the TEDGF flag is set to 1 (active edge received) until the next active edge is input. The content of the read-out buffer is retained until the AGT register is read. If it is not read before the active edge is input, the measurement result of the previous period is retained.
Note 2. When the AGT register is read in pulse period measurement mode, the content of the read-out buffer is read.
Note 3. When the active edge of the measurement pulse is input and then the set edge of an external pulse is input, the TEDGF flag in the AGTCR register is set to 1 (active edge received).
Note 4. To set to 0 with software, write 0 to the TEDGF flag in the AGTCR register with an 8-bit memory manipulation instruction.
Note 5. To set to 0 with software, write 0 to the TUNDF flag in the AGTCR register with an 8-bit memory manipulation instruction.

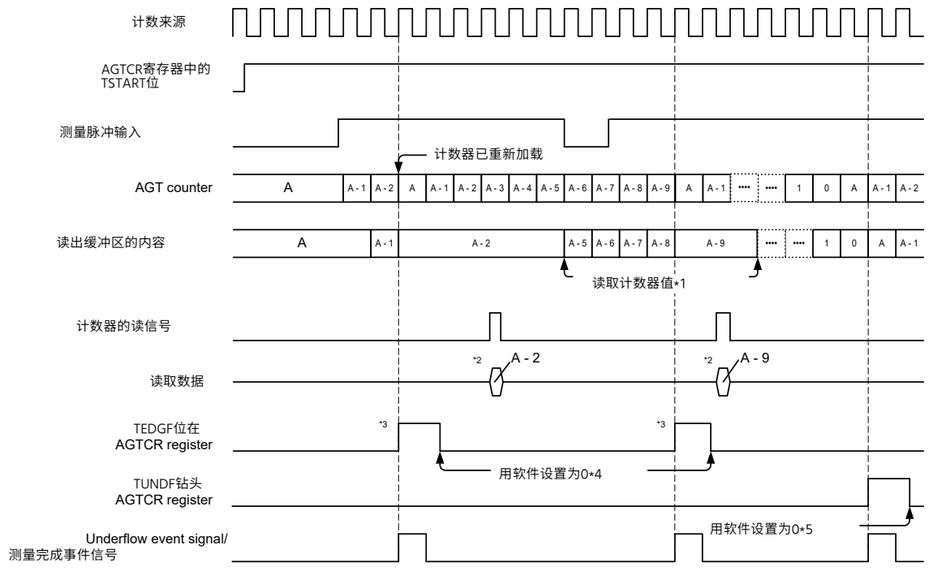
Figure 22.11 Operation example in pulse period measurement mode

22.3.8 Compare Match function

The compare match function detects matches (compare match) between the content of the AGTCMA or AGTCMB register and the content of the AGT register. This function is enabled when the TCMEA or TCMEB bit in the AGTCMSR register is 1 (compare match A register or compare match B register is valid). The counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register, and when the values of AGT and AGTCMA or AGTCMB match, the TCMAF/TCMBF flag in the AGTCR register is set to 1 (match), and an interrupt request is generated.

When the compare match function is enabled, the timing of the rewrite operation to the reload register and the counter differs. See section 22.3.1. Reload Register and Counter Rewrite Operation for details. In addition, the output level of the AGTOAn, AGTOBn pins is inverted by the match and by the underflow. The output level can be selected with the TOPOLA or TOPOLB bit in the AGTCMSR register.

Figure 22.12 shows the operation example in compare match mode.



此示例适用于将AGT寄存器的初始值设置为A，将AGTIOC寄存器中的TEDGSEL位设置为0，并测量从一个上升沿到下一个测量脉冲沿的周期。

注1.从TEDGF标志设置为1（接收到有效边沿）到输入下一个有效边沿期间，必须执行从AGT寄存器的读取。读出缓冲器的内容一直保留到AGT寄存器被读取。如果在输入有效边沿之前未读取，则保留前一周期的测量结果。

注2.在脉冲周期测量模式下读取AGT寄存器时，会读取读出缓冲区的内容。
注3.当输入测量脉冲的有效边沿，然后输入外部脉冲的设置边沿时，AGTCR寄存器中的TEDGF标志设置为1（接收到有效边沿）。

注4.要使用软件设置为0，请使用8位存储器操作指令将0写入AGTCR寄存器中的TEDGF标志。注5.要通过软件设置为0，请使用8位存储器操作指令将0写入AGTCR寄存器中的TUNDF标志。

Figure 22.11 脉冲周期测量模式下的操作示例

22.3.8 比较匹配功能

比较匹配功能检测AGTCMA或AGTCMB寄存器的内容与AGT寄存器的内容之间的匹配（比较匹配）。该功能在AGTCMSR寄存器中的TCMEA或TCMEB位为1时使能（比较匹配A寄存器或比较匹配B寄存器有效）。计数器按AGTMR1寄存器中TCK[2:0]位选择的计数源递减，当AGT和AGTCMA或AGTCMB的值匹配时，AGTCR寄存器中的TCMAFTCMBF标志设置为1（匹配），并产生中断请求。

当比较匹配功能启用时，对重载寄存器和计数器的重写操作的时序不同。请参阅第22.3.1节。重载寄存器和计数器重写操作了解详情。此外，AGTOAn、AGTOBn引脚的输出电平通过匹配和下溢反转。输出电平可以选择与

AGTCMSR寄存器中的TOPOLA或TOPOLB位。

22.4 Usage Notes

22.4.1 Count Operation Start and Stop Control

- When the operating mode (see Table 22.1) is set to other than the event counter mode, or the count source is set to other than AGTn underflow event signal (TCK[2:0] = 101b):
  - After 1 (count starts) is written to the TSTART bit in the AGTCR register while the count is stopped, the TCSTF flag in the AGTCR register remains 0 (count stops) for 3 cycles of the count source. Do not access the registers associated with AGT other than the TCSTF flag until this bit is set to 1 (count in progress).
  - After 0 (count stops) is written to the TSTART bit during a count operation, the TCSTF flag remains 1 for 3 cycles of the count source. When the TCSTF flag is set to 0, the count is stopped. Do not access the registers associated with AGT. Other than the TCSTF flag until this bit is set to 0.

- When the operating mode (see Table 22.1) is set to event counter mode, or the count source is set to AGT1 underflow event signal (TCK[2:0] = 101b):
  - After 1 (count starts) is written to the TSTART bit in the AGTCR register while the count is stopped, the TCSTF flag in the AGTCR register remains 0 (count stops) for 2 PCLKB cycles. Do not access the registers associated with AGT other than the TCSTF flag until this bit is set to 1 (count in progress).
  - After 0 (count stops) is written to the TSTART bit during a count operation, the TCSTF flag remains 1 for 2 PCLKB cycles. When the TCSTF flag is set to 0, the count is stopped. Do not access the registers associated with AGT other than the TCSTF flag until this bit is set to 0.

22.4.2 Access to Counter Register

When the TSTART bit and TCSTF flag in the AGTCR register are both 1 (count starts), allow at least 3 cycles of the count source clock between writes when writing to the AGT register successively.

22.4.3 When Changing Mode

The registers associated with AGT operating mode (AGTMR1, AGTMR2, AGTIOC, AGTISR, AGTCMSR and AGTIOC) can be changed only when the count is stopped with both the TSTART bit and TCSTF flag set to 0 (count stops). Do not change these registers during count operation.

When the registers associated with AGT operating mode are changed, the values of TEDGF, TUNDF, TCMAF, and TCMBF flags are undefined. Before starting the count, write 0 to the following flags:

- TEDGF (no active edge received)
- TUNDF (no underflow)
- TCMAF (no match)
- TCMBF (no match).

22.4.4 Output pin setting

When using the AGTOn, AGTIOn, AGTOAn, or AGTOBn as an output pin, set up the Operation and determine the initial output values. Then set an output mode in the port register.

When using the AGTIOn as an input pin in pulse width measurement mode or pulse period measurement mode, set up the Operation and start count operation. Then start to enter external events from the AGTIOn pin. Invalidate the first measurement and validate the second and later completed measurements.

22.4.5 Digital Filter

When using the digital filter, do not start the timer operation for 5 cycles of the digital filter clock after setting TIPF[1:0] bits and when the TEDGSEL bit in the AGTIOC register changes.

22.4.6 How to Calculate Event Number, Pulse Width, and Pulse Period

- In event counter mode, event number is expressed mathematically as follows:
  Event number = initial value of counter [AGT register] - counter value of active event end

22.4 使用说明

22.4.1 计数操作启动和停止控制

●当操作模式（见表22.1）设置为非事件计数器模式，或计数源设置为非AGTn下溢事件信号（TCK[2:0]=101b）时：

在计数停止期间将1（计数开始）写入AGTCR寄存器中的TSTART位后，AGTCR寄存器中的TCSTF标志在计数源的3个周期内保持为0（计数停止）。在此位设置为1（正在进行计数）之前，不要访问与AGT相关的寄存器，而不是TCSTF标志。

在计数操作期间将0（计数停止）写入TSTART位后，TCSTF标志在计数源的3个周期内保持为1。当TCSTF标志设置为0时，停止计数。不要访问与AGT关联的寄存器。除TCSTF标志外，直到该位设置为0。

●当工作模式（见表22.1）设置为事件计数器模式，或计数源设置为AGT1下溢事件信号（TCK[2:0]=101b）时：

在停止计数时将1（计数开始）写入AGTCR寄存器中的TSTART位后，AGTCR寄存器中的TCSTF标志在2个PCLKB周期内保持为0（计数停止）。在此位设置为1（正在进行计数）之前，不要访问与AGT相关的寄存器，而不是TCSTF标志。

在计数操作期间将0（计数停止）写入TSTART位后，TCSTF标志保持1持续2
PCLKB周期。当TCSTF标志设置为0时，停止计数。不要访问与相关的寄存器
AGT不是TCSTF标志，直到该位设置为0。

22.4.2 访问计数器寄存器

当AGTCR寄存器中的TSTART位和TCSTF标志都为1（计数开始）时，连续写入AGT寄存器时，在两次写入之间至少允许计数源时钟的3个周期。

22.4.3 更改模式时

与AGT操作模式相关的寄存器（AGTMR1、AGTMR2、AGTIOC、AGTISR、AGTCMSR和AGTIOC）只有在TSTART位和TCSTF标志都设置为0（计数停止）时停止计数时才能更改。在计数操作期间不要更改这些寄存器。

当与AGT工作模式相关的寄存器发生变化时，TEDGF、TUNDF、TCMAF和
TCMBF标志未定义。在开始计数之前，将0写入以下标志：

●TEDGF（未收到有效边沿）

- TUNDF (no underflow)
- TCMAF (no match)
- TCMBF (no match).

22.4.4 输出引脚设置

当使用AGTOn、AGTIOn、AGTOAn或AGTOBn作为输出引脚时，设置操作并确定初始输出值。然后在端口寄存器中设置一个输出模式。

在脉冲宽度测量模式或脉冲周期测量模式下使用AGTIOn作为输入引脚时，设置
操作并开始计数操作。然后开始从AGTIOn引脚输入外部事件。使第一次测量无效并验证第二次和以后
完成的测量。

22.4.5 数字滤波器

使用数字滤波器时，在设置TIPF[1:0]位后以及AGTIOC寄存器中的TEDGSEL位发生变化时，在数字滤波器时钟的5个周期内不要启动定时器操作。

22.4.6 如何计算事件编号、脉冲宽度和脉冲周期

●在事件计数器模式下，事件编号以数学方式表示如下：
事件编号=计数器的初始值[AGT寄存器]活动事件结束的计数器值

- In pulse width measurement mode, pulse width is expressed mathematically as follows:
  Pulse width = counter value of stopping measurement - counter value of next stopping measurement
- In pulse period measurement mode, input pulse period is expressed mathematically as follows:
  Period of input pulse = (initial value of counter [AGT register] - reading value of the read-out buffer) + 1.

22.4.7 When Count is Forcibly Stopped by TSTOP Bit

After the counter is forcibly stopped by the TSTOP bit in the AGTCR register, do not access the following I/O registers for 1 cycle of the count source:

- AGT
- AGTCMA
- AGTCMB
- AGTCR
- AGTMR1
- AGTMR2.

22.4.8 When Selecting AGTn (n = 0, 2, 4) Underflow as the Count Source

Operate according to the following procedures described in this section when selecting the underflow event signal as the count source.

(1) Procedure for starting operation

1. Set AGT.
2. Start the count operation of AGTn (n = 1, 3, 5).
3. Start the count operation of AGTn (n = 0, 2, 4).

(2) Procedure for stopping operation

1. Stop the count operation of AGTn (n = 0, 2, 4).
2. Stop the count operation of AGTn (n = 1, 3, 5).
3. Stop the count source clock of AGTn (n = 1, 3, 5) (write 000b in the AGTMR1.TCK[2:0] bits).

22.4.9 Module-stop function

AGT operation can be disabled or enabled using Module Stop Control Register D (MSTPCRD) and Module Stop Control Register E (MSTPCRE). The AGT module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes

22.4.10 When Switching Source Clock

When switching a clock source by changing SCKSCR.CKSEL[2:0], the clock output from the selector stops for 4 cycles of the switched clock. Therefore, when using the AGTIO, AGTEE, or both input as external event input, the clock source should not be switched. If switching the clock source while using the external event input, extend the input pulse width by 4 clock cycles of the switched source clock cycles.

●在脉冲宽度测量模式下，脉冲宽度以数学方式表示如下：
脉冲宽度=停止测量的计数器值下一个停止测量的计数器值

●在脉冲周期测量模式下，输入脉冲周期的数学表达式如下：
输入脉冲周期=（计数器初始值[AGT寄存器]读出缓冲器的读取值）+1。

22.4.7 当计数被TSTOP位强制停止时

计数器被AGTCR寄存器中的TSTOP位强制停止后，在计数源的1个周期内不要访问以下IO寄存器：

- AGT
- AGTCMA
- AGTCMB
- AGTCR
- AGTMR1
- AGTMR2.

22.4.8 选择AGTn(n=0 2 4)下溢作为计数源时

选择下溢事件信号作为计数源时，请按照本节所述的以下步骤进行操作。

(1) 开始运行的步骤

1. Set AGT.
2.启动AGTn(n=1 3 5)的计数操作。
3.启动AGTn(n=0 2 4)的计数操作。

(2) 停止运行的步骤

1.停止AGTn(n=0 2 4)的计数操作。
2.停止AGTn(n=1 3 5)的计数操作。
3.停止AGTn(n=1 3 5)的计数源时钟（将000b写入AGTMR1.TCK[2:0]位）。

22.4.9 Module-stop function

可以使用模块停止控制寄存器D(MSTPCRD)和模块停止控制来禁用或启用AGT操作
寄存器E(MSTPCRE)。AGT模块在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式

22.4.10 切换源时钟时

当通过改变SCKSCR.CKSEL[2:0]来切换时钟源时，选择器的时钟输出在切换时钟的4个周期内停止。因此，当使用AGTIO、AGTEE或两者输入作为外部事件输入时，不应切换时钟源。如果在使用外部事件输入时切换时钟源，请将输入脉冲宽度延长4个切换源时钟周期的时钟周期。

23. Realtime Clock (RTC)

23.1 Overview

The realtime clock (RTC) has two counting modes, calendar count mode and binary count mode, that are used by switching register settings. For calendar count mode, the RTC has a 100-year calendar from 2000 to 2099 and automatically adjusts dates for leap years. For binary count mode, the RTC counts seconds and retains the information as a serial value. Binary count mode can be used for calendars other than the Gregorian (Western) calendar.

The sub-clock oscillator or LOCO can be selected as the count source of the time counters. The RTC uses a 128-Hz clock acquired by dividing the count source by a prescaler. Year, month, date, day-of-week, a.m. /p.m. (in 12-hour mode), hour, minute, second, or 32-bit binary is counted by 1/128 second.

Table 23.1 lists the RTC specifications, Figure 23.1 shows a block diagram, and Table 23.2 lists the I/O pins.

Table 23.1 RTC specifications

23. 实时时钟(RTC)

23.1 Overview

实时时钟(RTC)有两种计数模式，日历计数模式和二进制计数模式，通过切换寄存器设置使用。对于日历计数模式，RTC有一个从2000年到2099年的100年日历，并自动调整闰年的日期。对于二进制计数模式，RTC会计算秒数并将信息保留为序列值。二进制计数模式可用于公历（西方）以外的日历。

可以选择子时钟振荡器或LOCO作为时间计数器的计数源。RTC使用一个128-Hz时钟，通过预分频器将计数源分频获得。年、月、日、星期、上午、下午（在12小时模式下）时、分、秒或32位二进制按1128秒计数。

表23.1列出了RTC规格，图23.1显示了框图，表23.2列出了IO引脚。

23.2 Register Descriptions

Write or read from the RTC registers as described in section 23.6.5. Notes on Writing to and Reading from Registers.

If the value in an RTC register after a reset is given as x (undefined bits) in the list, it is not initialized by a reset. When RTC enters the reset state or a low power state during counting operations, for example, while the RCR2.START bit is 1, the year, month, day of the week, date, hours, minutes, seconds, and 64-Hz counters continue to operate.

Note: A reset generated while writing to a register might destroy the register value. In addition, do not allow the MCU to enter Software Standby or Deep Software Standby mode immediately after setting any of these registers. For details, see section 23.6.4. Transitions to Low Power Modes after Setting Registers.

23.2 注册说明

如第23.6.5节所述，从RTC寄存器写入或读取。关于写入和读取寄存器的注意事项。

如果复位后RTC寄存器中的值在列表中以x（未定义位）的形式给出，则它不会被复位初始化。当RTC在计数操作期间进入复位状态或低功耗状态时，例如，当RCR2.START位为1时，年、月、星期、日期、小时、分钟、秒和64-Hz计数器继续经营。

Note: 写入寄存器时产生的复位可能会破坏寄存器值。此外，不要让MCU在设置任何这些寄存器后立即进入软件待机或深度软件待机模式。详见23.6.4节。设置寄存器后转换到低功耗模式。

If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, you must stop the count operation using the START bit in RCR2. The PM bit is only enabled when the RCR2.HR24 bit is 0.

Otherwise, the setting in the PM bit has no effect. To read this counter, follow the procedure in section 23.3.5. Reading 64-Hz Counter and Time.

7:6	—	These bits are read as 0. The write value should be 0.	R/W

The RDAYCNT counter is used in calendar count mode to set and count the BCD-coded date value. It counts the carries generated once per day in the hour counter. When specifying a value, the range of specifiable days depends on the month and whether the year is a leap year. Before writing to this register, you must stop the count operation using the START bit in RCR2. To read this counter, follow the procedure in section 23.3.5. Reading 64-Hz Counter and Time.

RTCOS bit (RTCOUT Output Select)

The RTCOS bit selects the RTCOUT output period. The RTCOS bit must be rewritten while the count operation is stopped (RCR2.START = 0) and the RTCOUT output is disabled (RCR2.RTCOE = 0). When RTCOUT is output to an external pin, the RCR2.RTCOE bit must be enabled.

PES[3:0] bits (Periodic Interrupt Select)

RA生态工作室

The RCR2 register is related to hours mode, automatic adjustment function, enabling RTCOUT output, 30-second adjustment, RTC software reset, and controlling count operation.

START bit (Start)

The START bit stops or restarts the prescaler or time counter operation. This bit is updated in synchronization with the next cycle of the count source. When the START bit is modified, check that the bit is updated before proceeding.

RESET bit (RTC Software Reset)

The RESET bit initializes the prescaler and registers to be reset by RTC software. When 1 is written to this bit, initialization starts in synchronization with the count source. When the initialization is complete, the RESET bit is automatically set to 0. Check that this bit is 0 before proceeding.

ADJ30 bit (30-Second Adjustment)

The ADJ30 bit is for 30-second adjustment.

When 1 is written to the ADJ30 bit, the RSECCNT value of 30 seconds or less is rounded down to 00 second and the value of 30 seconds or more is rounded up to 1 minute.

The 30-second adjustment is performed in synchronization with the count source. When 1 is written to this bit, the ADJ30 bit is automatically set to 0 after the 30-second adjustment completes. If 1 is written to the ADJ30 bit, check that the bit is 0 before proceeding. When the 30-second adjustment is performed, the prescaler and R64CNT are also reset. The ADJ30 bit is set to 0 by an RTC software reset.

RTCOE bit (RTCOUT Output Enable)

The RTCOE bit enables output of a 1-Hz/64-Hz clock signal from the RTCOUT pin.

Use the START bit to stop counting before changing the value of the RTCOE bit. Do not stop counting (write 0 to the START bit) and change the value of the RTCOE bit at the same time.

When RTCOUT is to be output from an external pin, enable the RTCOE bit and set up the port control for the pin.

AADJE bit (Automatic Adjustment Enable)

The AADJE bit controls (enables or disables) automatic adjustment.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJE bit.

The AADJE bit is set to 0 by an RTC software reset.

AADJP bit (Automatic Adjustment Period Select)

The AADJP bit selects the automatic-adjustment period.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJP bit.

The AADJP bit is set to 0 by an RTC software reset.

HR24 bit (Hours Mode)

The HR24 bit specifies whether the RTC operates in 12- or 24-hour mode.

Use the START bit to stop counting before changing the value of the HR24 bit. Do not stop counting (write 0 to the START bit) and change the value of the HR24 bit at the same time.

CNTMD bit (Count Mode Select)

The CNTMD bit specifies whether the RTC count mode operates in calendar count mode or in binary count mode.

When setting the count mode, execute an RTC software reset and start again from the initial settings. This bit is updated in synchronization with the count source. However, the count mode switches only after the RTC software reset. (Bit switches before RTC reset, mode switches after RTC reset.)

For details on initial settings, see section 23.3.1. Outline of Initial Settings of Registers after Power On.

RCR2寄存器与小时模式、自动调整功能、启用RTCOUT输出、30秒调整、RTC软件复位和控制计数操作有关。

开始位（开始）

START位停止或重新启动预分频器或时间计数器操作。该位与计数源的下一个周期同步更新。修改START位后，请在继续之前检查该位是否已更新。

RESET位（RTC软件复位）

RESET位初始化预分频器和寄存器以由RTC软件复位。当向该位写入1时，初始化与计数源同步开始。初始化完成后，RESET位自动设置为0。在继续之前检查该位是否为0。

ADJ30 bit (30-Second Adjustment)

ADJ30位用于30秒调整。

向ADJ30位写入1时，30秒以下的RSECCNT值向下舍入为00秒，30秒以上的值向上舍入为1分钟。

30秒调整与计数源同步进行。向该位写入1时，30秒调整完成后ADJ30位自动设置为0。如果将1写入ADJ30位，请在继续之前检查该位是否为0。当执行30秒调整时，预分频器和R64CNT也被复位。RTC软件复位将ADJ30位设置为0。

RTCOE位（RTCOUT输出使能）

RTCOE位使能从RTCOUT引脚输出1-Hz64-Hz时钟信号。

在更改RTCOE位的值之前，使用START位停止计数。不要停止计数（将0写入START位）并同时更改RTCOE位的值。

当RTCOUT要从外部引脚输出时，使能RTCOE位并设置引脚的端口控制。

ADJE位（自动调整使能）

AADJE位控制（启用或禁用）自动调整。

在更改ADJE位的值之前，将正负位(RADJ.PMADJ[1:0])设置为00b（不执行调整）。

RTC软件复位将ADJE位设置为0。

AADJP位（自动调整周期选择）

AADJP位选择自动调整周期。

在更改AADJP位的值之前，将正负位(RADJ.PMADJ[1:0])设置为00b（不执行调整）。

AADJP位通过RTC软件复位设置为0。

HR24 bit (Hours Mode)

HR24位指定RTC是在12小时还是24小时模式下运行。

在更改HR24位的值之前，使用START位停止计数。不要停止计数（将0写入START位）并同时更改HR24位的值。

CNTMD位（计数模式选择）

CNTMD位指定RTC计数模式是在日历计数模式还是二进制计数模式下运行。

设置计数模式时，执行RTC软件复位并从初始设置重新开始。该位与计数源同步更新。但是，计数模式仅在RTC软件复位后切换。（RTC复位前位切换，RTC复位后模式切换。）

有关初始设置的详细信息，请参阅第23.3.1节。上电后寄存器的初始设置概要。

Note 4. When rewriting this bit, confirm that the value has been rewritten before performing the following processing.

RCR2 in the binary count mode is a register related to the automatic correction function, RTCOUT output enable, RTC software reset, and count mode control.

START bit (Start)

The START bit stops or restarts the prescaler or counter (clock) operation. This bit is updated in synchronization with the count source. When the START bit is modified, check that the bit is updated before proceeding.

RESET bit (RTC Software Reset)

The RESET bit initializes the prescaler and registers to be reset by RTC software. When 1 is written to this bit, initialization starts in synchronization with the count source. When the initialization is complete, the RESET bit is automatically set to 0. When 1 is written to the RESET bit, check that the bit is 0 before proceeding.

RTCOE bit (RTCOUT Output Enable)

The RTCOE bit enables output of a 1-Hz/64-Hz clock signal from the RTCOUT pin.

Use the START bit to stop counting before changing the value of the RTCOE bit. Do not stop counting (write 0 to the START bit) and change the value of the RTCOE bit at the same time. When an RTCOUT signal is to be output from an external pin, enable the port control in addition to setting this bit.

注4.改写该位时，请确认该值已被改写，然后再进行以下处理。

二进制计数模式下的RCR2是与自动校正功能、RTCOUT输出使能、RTC软件复位和计数模式控制相关的寄存器。

开始位（开始）

START位停止或重新启动预分频器或计数器（时钟）操作。该位与计数源同步更新。修改START位后，请在继续之前检查该位是否已更新。

RESET位（RTC软件复位）

RESET位初始化预分频器和寄存器以由RTC软件复位。当向该位写入1时，初始化与计数源同步开始。初始化完成后，RESET位自动设置为0。当向RESET位写入1时，在继续之前检查该位是否为0。

RTCOE位（RTCOUT输出使能）

RTCOE位使能从RTCOUT引脚输出1-Hz64-Hz时钟信号。

在更改RTCOE位的值之前，使用START位停止计数。不要停止计数（将0写入START位）并同时更改RTCOE位的值。当要从外部引脚输出RTCOUT信号时，除了设置该位外，还启用端口控制。

AADJE bit (Automatic Adjustment Enable)

The AADJE bit controls (enables or disables) automatic adjustment.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJE bit. The AADJE bit is set to 0 by an RTC software reset.

AADJP bit (Automatic Adjustment Period Select)

The AADJP bit selects the automatic-adjustment period.

Correction period can be selected from 32 second units or 8 second units in binary count mode.

Set the plus-minus bits (RADJ.PMADJ[1:0]) to 00b (adjustment is not performed) before changing the value of the AADJP bit. The AADJP bit is set to 0 by an RTC software reset.

CNTMD bit (Count Mode Select)

The CNTMD bit specifies whether the RTC count mode operates in calendar count mode or in binary count mode.

When setting the count mode, execute an RTC software reset and start again from the initial settings. This bit is updated in synchronization with the count source. However, the count mode switches only after the RTC software reset. (Bit switches before RTC reset, mode switches after RTC reset.)

For details on initial settings, see section 23.3.1. Outline of Initial Settings of Registers after Power On .

23.2.25 RCR4 : RTC Control Register 4

Base address: RTC = 0x4008_3000

Offset address: 0x28

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	RCKSEL
Value after reset:	0	0	0	0	0	0	0	x

0	RCKSEL	Count Source Select 0: Sub-clock oscillator is selected 1: LOCO is selected	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

The RCR4 register is used in both calendar count mode and binary count mode.

RCKSEL bit (Count Source Select)

The RCKSEL bit selects the count source from the sub-clock oscillator and LOCO.

The RCKSEL bit is only used in normal operation mode. When the RCKSEL bit is set to 0, the time is counted with the sub-clock oscillator. When the bit is set to 1, the time is counted with LOCO.

For details on count source setting, see section 23.3.1. Outline of Initial Settings of Registers after Power On and section 23.3.2. Clock and Count Mode Setting Procedure. The count source must be selected only once before specifying the initial settings of the RTC registers at power on.

ADJE位（自动调整使能）

AADJE位控制（启用或禁用）自动调整。

在更改ADJE位的值之前，将正负位(RADJ.PMADJ[1:0])设置为00b（不执行调整）。RTC软件复位将ADJE位设置为0。

AADJP位（自动调整周期选择）

AADJP位选择自动调整周期。

在二进制计数模式下，校正周期可以从32秒单位或8秒单位中选择。

在更改AADJP位的值之前，将正负位(RADJ.PMADJ[1:0])设置为00b（不执行调整）。AADJP位通过RTC软件复位设置为0。

CNTMD位（计数模式选择）

CNTMD位指定RTC计数模式是在日历计数模式还是二进制计数模式下运行。

设置计数模式时，执行RTC软件复位并从初始设置重新开始。该位与计数源同步更新。但是，计数模式仅在RTC软件复位后切换。（RTC复位前位切换，RTC复位后模式切换。）

有关初始设置的详细信息，请参阅第23.3.1节。上电后寄存器的初始设置概要。

23.2.26 RFRL:频率寄存器L

Base address: RTC = 0x4008_3000

Offset address: 0x2C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Symbol	Function	R/W
15:0	RFC[15:0]	Frequency Comparison Value Write 0x00FF to this register when using the LOCO.	R/W

RFRL is a register for controlling the prescaler when LOCO is selected.

The RTC time counter operates on a 128-Hz clock signal as the base clock. Therefore, when LOCO is selected, LOCO is divided by the prescaler to generate a 128-Hz clock signal. Set the frequency comparison value in the RFC[15:0] bits to generate a 128-Hz clock from the LOCO frequency. Before writing to RFC[15:0] after a cold start, write 0x0000 to the RFRH register.

A value from 0x0007 through 0x01FF can be specified as the frequency comparison value. If a value outside of this range is specified, the RTC does not operate correctly. Before writing to this register, be sure to stop the count operation through the setting of the START bit in RCR2. The operating frequency of the peripheral module clock and the LOCO should be such that the peripheral module clock is ≥ LOCO.

Calculation method of frequency comparison value:

RFC[15:0] = (LOCO clock frequency) / 128 - 1

When the LOCO frequency is 32.768 kHz, the RFRL register should be set to 0x00FF.

RFRL是一个寄存器，用于在选择LOCO时控制预分频器。

RTC时间计数器以128-Hz时钟信号作为基本时钟运行。Therefore whenLOCOisselected LOCOisdividedbythepr escalertogeneratea128-Hzclocksignal.设置RFC[15:0]位中的频率比较值以从LOCO频率生成128-Hz时钟。在冷启动后写入RFC[15:0]之前，将0x0000写入RFRH寄存器。

从0x0007到0x01FF的值可以指定为频率比较值。如果指定的值超出此范围，则RTC将无法正确运行。在写入该寄存器之前，请务必通过设置RCR2中的START位来停止计数操作。外围模块时钟和LOCO的工作频率应使外围模块时钟≥LOCO。

频率比较值的计算方法：

RFC[15:0] = (LOCO clock frequency) / 128 - 1

当LOCO频率为32.768kHz时，RFRL寄存器应设置为0x00FF。

23.2.28 RADJ:时间误差调整寄存器

7:6	PMADJ[1:0]	Plus-Minus 00：不进行调整。01：通过预分频器1的加法进行调整0：通过预分频器1的减法进行调整1：禁止设置。	R/W

RADJ寄存器用于日历计数模式和二进制计数模式。通过对预分频器或64-Hz计数器进行加法或减法来执行调整。如果自动调整启用(RCR2.AADJE)位为0，则调整

is performed when writing to the RADJ. If the RCR2.AADJE bit is 1, adjustment is performed in the interval specified in the Automatic Adjustment Period Select (RCR2.AADJP) bit.

The current adjustment by software (disabling automatic adjustment) may be invalid if the following adjustment value is specified within 320 cycles of the count source after the register setting. To perform adjustment consecutively, wait for 320 cycles or more of the count source after the register setting, then specify the next adjustment value.

RADJ is updated in synchronization with the count source. When RADJ is modified, check that all the bits are updated before continuing with more processing. This register is set to 0x00 by an RTC software reset. The setting of this register is enabled only when the sub-clock oscillator is selected. When LOCO is selected, adjustment is not performed.

ADJ[5:0] bits (Adjustment Value)

The ADJ[5:0] bits specify the adjustment value (number of sub-clock cycles) from the prescaler.

PMADJ[1:0] bits (Plus-Minus)

The PMADJ[1:0] bits select whether the clock is set ahead or back depending on the error-adjustment value set in the ADJ[5:0] bits.

23.2.29 RTCCRn : Time Capture Control Register n (n = 0 to 2)

7	TCEN	Time Capture Event Input Pin Enable 0: Disable the RTCICn pin as the time capture event input pin 1: Enable the RTCICn pin as the time capture event input pin	R/W

Note 1. Indicates that an event is detected. Writing 1 to this bit has no effect. Writing 0 sets this bit to 0.

The RTCCRn register is used both in calendar count mode and in binary count mode. RTCCR0, RTCCR1, and RTCCR2 control the RTCIC0, RTCIC1, and RTCIC2 pins, respectively.

RTCCRn is updated in synchronization with the count source. When RTCCRn is modified, check that all the bits except the TCST bit are updated before continuing with additional processing. This register is cleared to 0x00 by an RTC software reset. When RTCICm is used as the time capture pin, VBTICTLR.VCHnIEN (n = 0 to 2) must be set to 1.

TCCT[1:0] bits (Time Capture Control)

The TCCT[1:0] bits control the edge detection of the time capture event input pins, RTCIC0, RTCIC1, and RTCIC2. The detection edge is selectable. The TCCT[1:0] bits must be set while the VBTICTLR.VCHnIEN bit is 1.

在写入RADJ时执行。如果RCR2.AADJE位为1，则在自动调整周期选择(RCR2.AADJP)位指定的间隔内执行调整。

如果在寄存器设置后的计数源的320个周期内指定了以下调整值，则通过软件进行的当前调整（禁用自动调整）可能无效。要连续执行调整，请在寄存器设置后等待计数源的320个或更多周期，然后指定下一个调整值。

RADJ与计数源同步更新。修改RADJ后，在继续进行更多处理之前检查所有位是否已更新。该寄存器通过RTC软件复位设置为0x00。该寄存器的设置仅在选择了副时钟振荡器时启用。选择LOCO时，不进行调整。

ADJ[5:0] bits (Adjustment Value)

ADJ[5:0]位指定来自预分频器的调整值（子时钟周期数）。

7	TCEN	时间捕捉事件输入引脚使能 0：禁止RTCICn引脚作为时间捕捉事件输入引脚1：使能RTCICn 引脚作为时间捕捉事件输入引脚	R/W

注1.表示检测到事件。向该位写入1无效。写入0将该位设置为0。

RTCCRn寄存器用于日历计数模式和二进制计数模式。RTCCR0、RTCCR1和RTCCR2分别控制RTCIC0、RTCIC1和RTCIC2引脚。

RTCCRn与计数源同步更新。当RTCCRn被修改时，检查除
TCST位在继续进行附加处理之前被更新。RTC软件复位将该寄存器清零为0x00。当RTCICm用作时间捕捉引脚时，VBTICTLR.VCHnIEN(n=0to2)必须设置为1。

TCCT[1:0]位（时间捕捉控制）

TCCT[1:0]位控制时间捕捉事件输入引脚RTCIC0、RTCIC1和RTCIC2的边沿检测。检测边缘是可选的。当VBTICTLR.VCHnIEN位为1时，必须设置TCCT[1:0]位。

TCST bit (Time Capture Status)

The TCST bit indicates that an event on the time capture event input pins, RTCIC0, RTCIC1, and RTCIC2, was detected. When the TCST bit is 0, no event is detected. When the TCST bit is 1, this bit indicates that an event was detected on the associated pin and the capture register is valid. When multiple events are detected, the capture time for the first event is retained.

The event is detected only during count operation (RCR2.START bit = 1). Before reading the capture register, make sure that this bit is set to 1.

Set the TCST bit while the TCCT[1:0] bits are 00b (no event is detected). The TCST bit is set to 0 in synchronization with the count source. When the TCST bit is set to 0, check that the bit is updated before continuing with additional processing.

TCNF[1:0] bits (Time Capture Noise Filter Control)

The TCNF[1:0] bits control the noise filter of the time capture event input pins (RTCIC0, RTCIC1, and RTCIC2).

When the noise filter is on, the count source divided by 1 or divided by 32 is selectable. In this case, when the input level on the time capture event input pin matches three consecutive times at the set sampling period, the input level is determined.

Set the TCNF[1:0] bits while the TCCT[1:0] bits are 00b (no event is detected). When the noise filter is used, set the TCNF[1:0] bits, wait for 3 cycles of the specified sampling period, then set the TCCT[1:0] bits. Set the TCNF[1:0] bits when the VBTICTLR.VCHnIEN bit is 1.

TCEN bit (Time Capture Event Input Pin Enable)

The TCEN bit enables or disables the time capture event input pins RTCIC0, RTCIC1, and RTCIC2. When the functions of the time capture event input pins are multiplexed, set VBTICTLR first. If the TCEN bit is set to 0, also set the TCCT[1:0] bits to 00b.

section 23.2.29. RTCCRn : Time Capture Control Register n (n = 0 to 2) lists the conditions for enabling the RTCICn pin. Before setting this bit to 1, be sure to set the count source setting bit (RCR4.RCKSEL), RTC time capture event enable bit (RCPE.RTCEN), port control setting bits (PmnPFS.PDR, and PmnPFS.PMR). For details on the port control setting bits (PmnPFS.PDR and PmnPFS.PMR), see section 19, I/O Ports.

23.2.30 RSECCPn : Second Capture Register n (n = 0 to 2) (in Calendar Count Mode)

Base address: RTC = 0x4008_3000

Offset address: 0x52 + 0x10 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	SEC10[2:0]			SEC1[3:0]			
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
3:0	SEC1[3:0]	1-Second Capture Capture value for the ones place of seconds.	R
6:4	SEC10[2:0]	10-Second Capture Capture value for the tens place of seconds.	R
7	—	The read value is undefined.	R

RSECCPn is a read-only register that captures the RSECCNT value when a time capture event is detected.

The event detection times detected by the RTCIC0, RTCIC1, and RTCIC2 pins are stored in the RSECCP0, RSECCP1, and RSECCP2 registers, respectively. This register is cleared to 0x00 by an RTC software reset. Before reading from this register, the time capture event detection should be stopped using the RTCCRn.TCCT[1:0] bits.

TCST位（时间捕捉状态）

TCST位指示检测到时间捕捉事件输入引脚RTCIC0、RTCIC1和RTCIC2上的事件。当TCST位为0时，未检测到任何事件。当TCST位为1时，该位表示在相关引脚上检测到事件并且捕捉寄存器有效。当检测到多个事件时，将保留第一个事件的捕获时间。

仅在计数操作期间检测到事件（RCR2.START位=1）。在读取捕获寄存器之前，请确保该位设置为1。

当TCCT[1:0]位为00b（未检测到事件）时，设置TCST位。TCST位与计数源同步设置为0。当TCST位设置为0时，在继续进行其他处理之前检查该位是否已更新。

TCNF[1:0]位（时间捕捉噪声滤波器控制）

TCNF[1:0]位控制时间捕捉事件输入引脚（RTCIC0、RTCIC1和RTCIC2）的噪声滤波器。

当噪声滤波器打开时，计数源除以1或除以32是可选的。在这种情况下，当时间捕捉事件输入引脚上的输入电平在设置的采样周期内连续匹配3次时，确定输入电平。

当TCCT[1:0]位为00b（未检测到事件）时，设置TCNF[1:0]位。使用噪声滤波器时，设置TCNF[1:0]位，等待指定采样周期的3个周期，然后设置TCCT[1:0]位。当VBTICTLR.VCHnIEN位为1时，设置TCNF[1:0]位。

TCEN位（时间捕捉事件输入引脚使能）

TCEN位启用或禁用时间捕捉事件输入引脚RTCIC0、RTCIC1和RTCIC2。当时间捕捉事件输入引脚的功能复用时，首先设置VBTICTLR。如果TCEN位设置为0，也将TCCT[1:0]位设置为00b。

第23.2.29节。RTCCRn：时间捕捉控制寄存器n（n=0到2）列出了启用RTCICn引脚的条件。在将此位设置为1之前，请务必设置计数源设置位(RCR4.RCKSEL)、RTC时间捕捉事件使能位(RCPE.RTCEN)、端口控制设置位(PmnPFS.PDR和PmnPFS.PMR)。有关端口控制设置位（PmnPFS.PDR和PmnPFS.PMR）的详细信息，请参阅第19节，IO端口。

23.3.6 Alarm Function

Figure 23.7 shows how to use the alarm function.

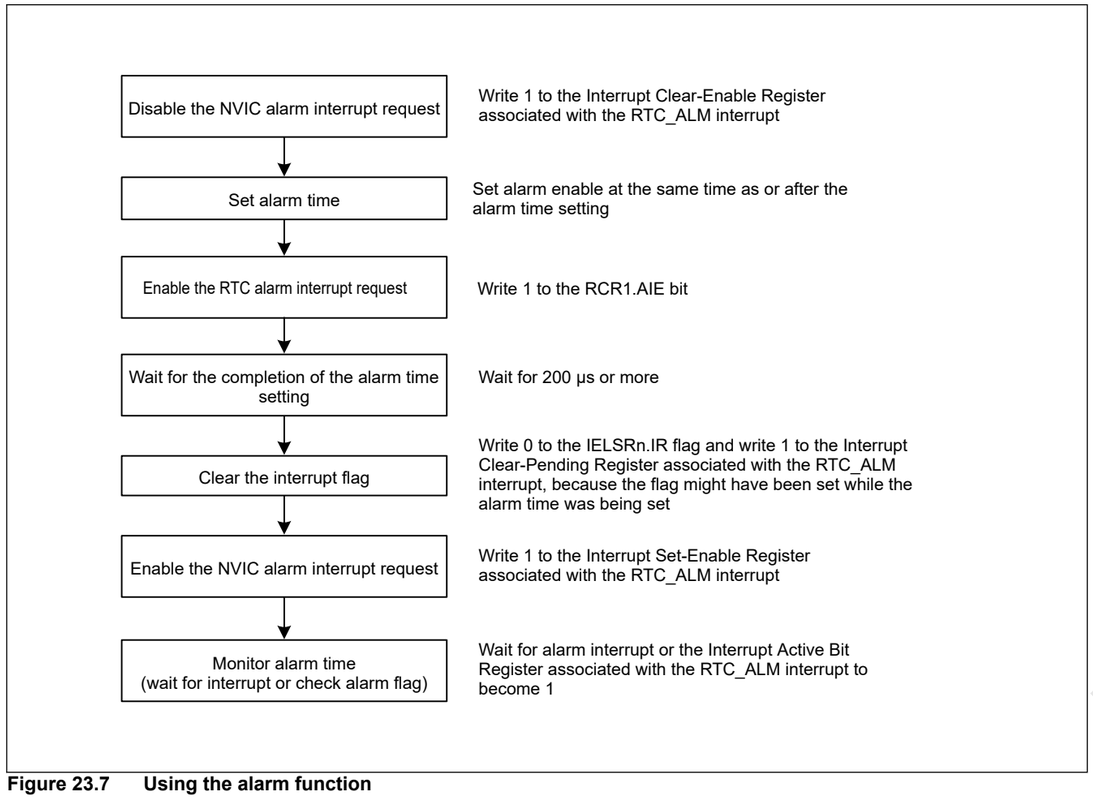

Figure 23.7 Using the alarm function

In calendar count mode, an alarm can be generated by any one of year, month, date, day-of-week, hour, minute or second, or any combination of those. Write 1 to the ENB bit in the alarm registers involved in the alarm setting, and set the alarm time in the lower bits. Write 0 to the ENB bit in registers not involved in the alarm setting.

In binary count mode, an alarm can be generated in any bit combination of 32 bits. Write 1 to the ENB bit of the Alarm Enable register associated with the target bit of the alarm, and set the alarm time in the alarm register. For bits that are not the target of the alarm, write 0 to the ENB bit of the Alarm Enable register.*1

For any of the ENB[31:0] bits that are set to 1, the bits in the corresponding positions in the binary counter (BCNT[31:0]) are compared with the values of the corresponding bits in the binary alarm registers*1. When all such bits match, the IR flag associated with the RTC_ALM interrupt is set to 1 and the corresponding bits in the Interrupt Set-Pending/Clear-Pending Registers are set to 1. Alarm detection can be confirmed by reading the Interrupt Set-Pending Register associated with the RTC_ALM interrupt, but an interrupt should be used in most cases. If 1 is set in the Interrupt Set-Enable Register associated with the RTC_ALM interrupt, an alarm interrupt is generated in the event of the alarm, enabling the alarm to be detected.

Writing 0 sets the IELSRn.IR flag associated with the RTC_ALM interrupt to 0. If interrupt is enabled, the Interrupt Set-Pending/Clear-Pending Register associated with the RTC_ALM interrupt is cleared automatically after exiting the interrupt handler. Otherwise, write 1 to the Interrupt Clear-Pending Register associated with the RTC_ALM interrupt to clear it.

When the counter and the alarm time match in a low power state, the MCU returns from the low power state.

Note 1. For any bits in the ENB bits that are set to 1, the values in the corresponding positions in the alarm registers from the following registers are compared with the corresponding bits of the counted values.

Counter registers: RSECCNT, RMINCNT, RHRCNT, RWKCNT, RDAYCNT, RMONCNT, RYRCNT

Alarm registers: RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, RYRAREN

23.3.6 报警功能

图23.7显示了如何使用报警功能。

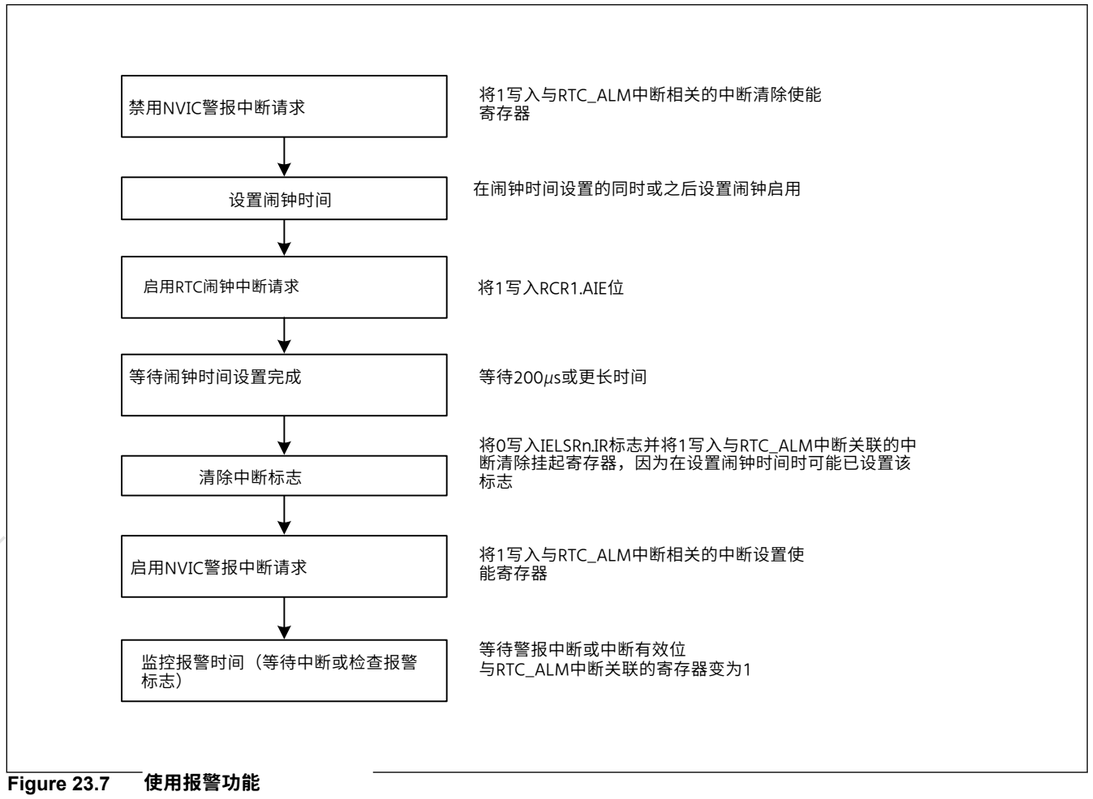

Figure 23.7 使用报警功能

在日历计数模式下，可以通过年、月、日、星期、小时、分钟或秒中的任何一个或它们的任意组合来生成警报。将1写入涉及闹钟设置的闹钟寄存器的ENB位，并在低位设置闹钟时间。将0写入与报警设置无关的寄存器中的ENB位。

在二进制计数模式下，可以以32位的任意位组合产生报警。将1写入闹钟的ENB位与报警的目标位相关联的使能寄存器，并在报警寄存器中设置报警时间。对于不是警报目标的位，将0写入警报启用寄存器的ENB位。*1

对于任何设置为1的ENB[31:0]位，二进制计数器(BCNT[31:0])中相应位置的位与二进制报警寄存器中相应位的值进行比较*1.当所有这些位匹配时，与RTC_ALM中断相关的IR标志设置为1，并且中断设置挂起清除挂起寄存器中的相应位设置为1。可以通过读取中断设置挂起寄存器来确认警报检测与RTC_ALM中断相关联，但在大多数情况下应使用中断。如果在与RTC_ALM中断相关的中断设置使能寄存器中设置为1，则在发生警报时会产生警报中断，从而能够检测到警报。

写入0将与RTC_ALM中断关联的IELSRn.IR标志设置为0。如果启用中断，则中断设置与RTC_ALM中断关联的PendingClear-Pending寄存器在退出中断处理程序后自动清除。否则，将1写入与RTC_ALM中断相关的中断清除挂起寄存器以将其清除。

当计数器和闹钟时间在低功耗状态下匹配时，MCU从低功耗状态返回。

注1.对于设置为1的ENB位中的任何位，将以下寄存器中警报寄存器中相应位置的值与计数值的相应位进行比较。

Counter registers: RSECCNT, RMINCNT, RHRCNT, RWKCNT, RDAYCNT, RMONCNT, RYRCNT

Alarm registers: RSECAR, RMINAR, RHRAR, RWKAR, RDAYAR, RMONAR, RYRAREN

23.3.7 Procedure for Disabling Alarm Interrupt

Figure 23.8 shows the procedure for disabling the enabled alarm interrupt request.

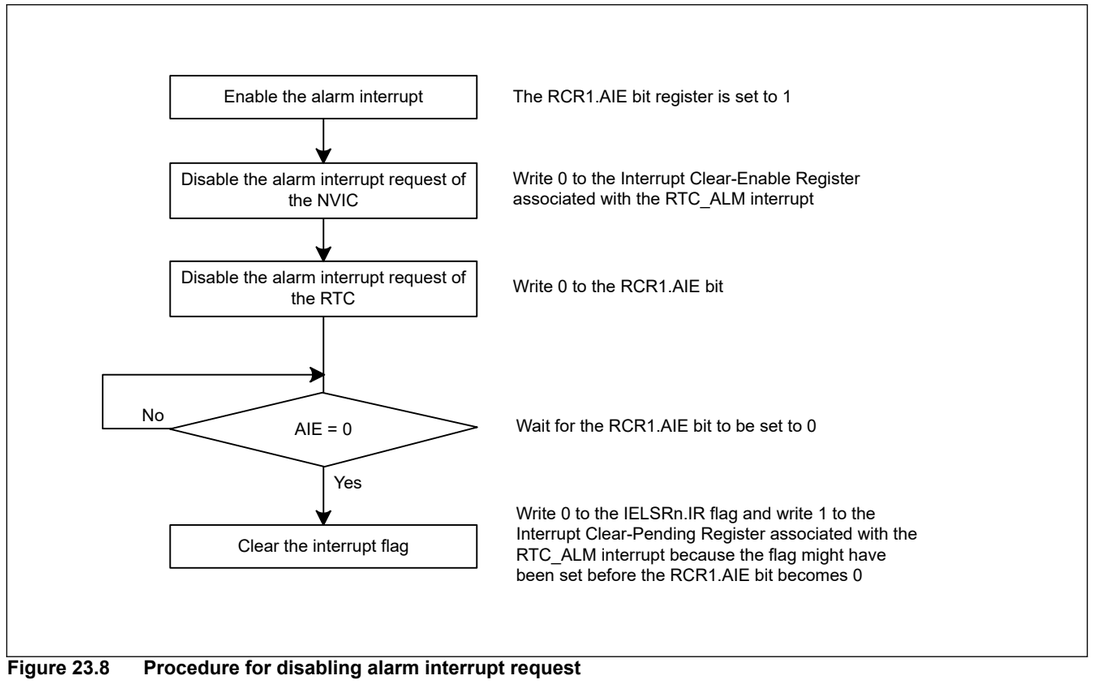

Figure 23.8 Procedure for disabling alarm interrupt request

23.3.8 Time Error Adjustment Function

The time error adjustment function is used to correct errors, running fast or slow, in the time caused by variation in the precision of oscillation by the sub-clock oscillator. Because 32768 cycles of the sub-clock oscillator constitute 1 second of operation when the sub-clock oscillator is selected, the clock runs fast if the sub-clock frequency is high and slow if the sub-clock frequency is low.

The time error adjustment functions include:

- Automatic adjustment
- Adjustment by software

Use the RCR2.AADJE bit to select automatic adjustment or adjustment by software.

23.3.8.1 Automatic adjustment

Enable automatic adjustment by setting the RCR2.AADJE bit to 1.

Automatic adjustment is the addition or subtraction of the value counted by the prescaler to or from the value in the RADJ register every time the adjustment period selected by the RCR2.AADJP bit elapses.

(1) Example 1: Sub-clock oscillator running at 32.769 kHz

Adjustment procedure

When the sub-clock oscillator is running at 32.769 kHz, 1 second elapses every 32769 clock cycles. The RTC is meant to run at 32768 clock cycles, so the clock runs fast by 1 clock cycle every second. The time on the clock is fast by 60 clock cycles per minute, so adjustment can take the form of setting the clock back by 60 cycles every minute.

23.3.7 禁用警报中断的步骤

图23.8显示了禁用启用的警报中断请求的过程。

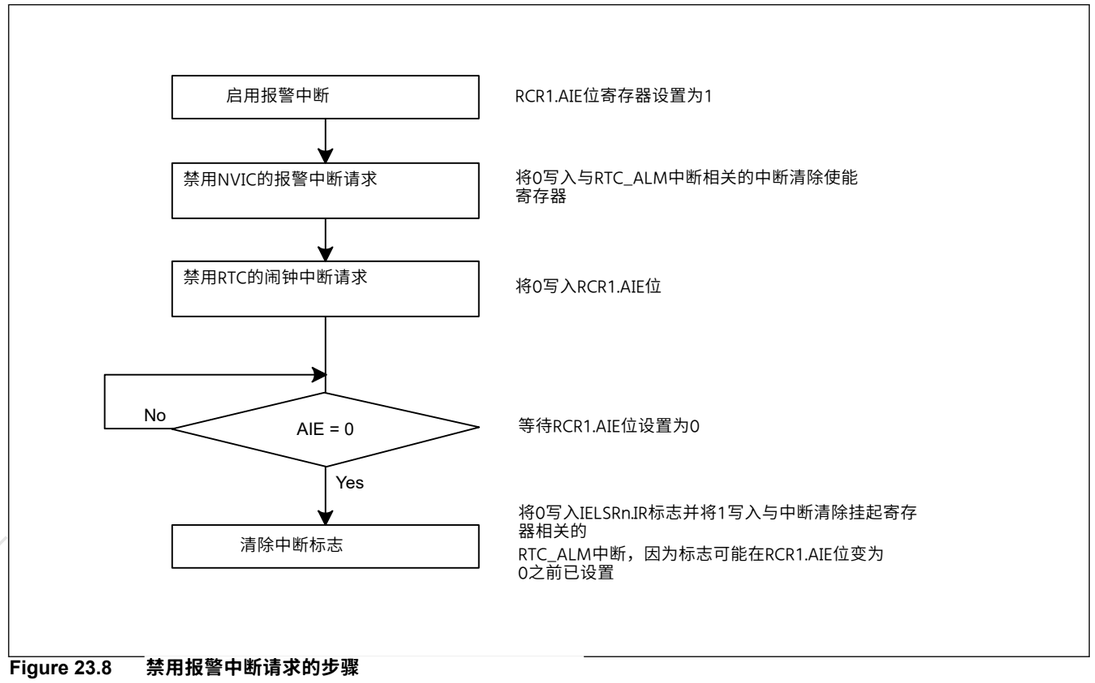

Figure 23.8 禁用报警中断请求的步骤

23.3.8 时间误差调整功能

时间误差调整功能用于校正子时钟振荡器振荡精度变化引起的时间误差，运行速度快或慢。由于在选择子时钟振荡器时，子时钟振荡器的32768个周期构成1秒的操作，因此如果子时钟频率高，则时钟运行快，如果子时钟频率低，则时钟运行慢。

时间误差调整功能包括：

- 自动调整
- 软件调整

使用RCR2.AADJE位选择自动调整或软件调整。

23.3.8.1 自动调整

通过将RCR2.AADJE位设置为1来启用自动调整。

自动调整是每次经过RCR2.AADJP位选择的调整周期后，将预分频器计数的值与RADJ寄存器中的值相加或相减。

(1) 示例1：运行在32.769kHz的子时钟振荡器

调整程序

当副时钟振荡器以32.769kHz运行时，每32769个时钟周期经过1秒。RTC旨在以32768个时钟周期运行，因此时钟以每秒1个时钟周期的速度运行。时钟上的时间每分钟快60个时钟周期，因此调整可以采取将时钟每分钟调回60个周期的形式。

Register settings when RCR2.CNTMD = 0:

- RCR2.AADJP = 0 (adjustment every minute)
- RADJ.PMADJ[1:0] = 10b (adjustment is performed by the subtraction from the prescaler)
- RADJ.ADJ[5:0] = 60 (0x3C)

(2) Example 2: Sub-clock oscillator running at 32.766 kHz

Adjustment procedure

When the sub-clock oscillator is running at 32.766 kHz, 1 second elapses every 32766 clock cycles. The RTC is meant to run at 32768 clock cycles, so the clock runs slow by 2 clock cycles every second. The time on the clock is slow by 20 clock cycles every 10 seconds, so adjustment can take the form of setting the clock forward by 20 cycles every 10 seconds.

Register settings when RCR2.CNTMD = 0:

- RCR2.AADJP = 1 (adjustment every 10 seconds)
- RADJ.PMADJ[1:0] = 01b (adjustment is performed by the addition to the prescaler)
- RADJ.ADJ[5:0] = 20 (0x14)

(3) Example 3: Sub-clock oscillator running at 32.764 kHz

Adjustment procedure

When the sub-clock oscillator is running at 32.764 kHz, 1 second elapses on 32764 clock cycles. Because the RTC operates for 32768 clock cycles as 1 second, the clock is delayed for 4 clock cycles per second. In 8 seconds, the delay is 32 clock cycles, therefore correction can be made by advancing the clock 32 clock cycles every 8 seconds.

Register settings when RCR2.CNTMD = 1:

- RCR2.AADJP = 1 (adjustment every 8 seconds)
- RADJ.PMADJ[1:0] = 01b (adjustment is performed by the addition to the prescaler)
- RADJ.ADJ[5:0] = 32 (0x20)

23.3.8.2 Adjustment by software

Enable adjustment by software by setting the RCR2.AADJE bit to 0. Adjustment by software is the addition or subtraction of the value counted by the prescaler to or from the value in the RADJ register on execution of a write instruction to the RADJ register.

(1) Example 1: Sub-clock oscillator running at 32.769 kHz

Adjustment procedure

When the sub-clock oscillator is running at 32.769 kHz, 1 second elapses every 32769 clock cycles. The RTC is meant to run at 32768 clock cycles, so the clock runs fast by 1 clock cycle every second. The time on the clock is fast by 1 clock cycle per second, so adjustment can take the form of setting the clock back by 1 cycle every second.

Register settings

- RADJ.PMADJ[1:0] = 10b (adjustment is performed by the subtraction from the prescaler)
- RADJ.ADJ[5:0] = 1 (0x10)
  This is written to the RADJ register once per 1-second interrupt.

23.3.8.3 Procedure to change the mode of adjustment

When changing the mode of adjustment, change the value of the AADJE bit in RCR2 after setting the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).

To change adjustment by software to automatic adjustment:

1. Set the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).
2. Set the RCR2.AADJE bit to 1 (automatic adjustment is enabled).

RCR2.CNTMD=0时的寄存器设置：

- RCR2.AADJP = 0 (adjustment every minute)
- ●RADJ.PMADJ[1:0]=10b（通过预分频器的减法进行调整）
- RADJ.ADJ[5:0] = 60 (0x3C)

(2) 示例2：以32.766kHz运行的子时钟振荡器

调整程序

当子时钟振荡器以32.766kHz运行时，每32766个时钟周期经过1秒。RTC旨在以32768个时钟周期运行，因此时钟每秒运行2个时钟周期。时钟上的时间每10秒慢20个时钟周期，因此调整可以采取将时钟每10秒向前设置20个周期的形式。

RCR2.CNTMD=0时的寄存器设置：

- RCR2.AADJP = 1 (adjustment every 10 seconds)
- ●RADJ.PMADJ[1:0]=01b（通过加到预分频器进行调整）
- RADJ.ADJ[5:0] = 20 (0x14)

(3) 示例3：以32.764kHz运行的子时钟振荡器

调整程序

当副时钟振荡器以32.764kHz运行时，32764个时钟周期经过1秒。由于RTC以1秒为单位运行32768个时钟周期，因此时钟每秒延迟4个时钟周期。在8秒内，延迟为32个时钟周期，因此可以通过每8秒将时钟提前32个时钟周期来进行校正。

RCR2.CNTMD=1时的寄存器设置：

- RCR2.AADJP = 1 (adjustment every 8 seconds)
- ●RADJ.PMADJ[1:0]=01b（通过加到预分频器进行调整）
- RADJ.ADJ[5:0] = 32 (0x20)

23.3.8.2 软件调整

通过将RCR2.AADJE位设置为0来启用软件调整。软件调整是在对RADJ寄存器执行写指令时，将预分频器计数的值与RADJ寄存器中的值相加或相减。

(1) 示例1：运行在32.769kHz的子时钟振荡器

调整程序

当副时钟振荡器以32.769kHz运行时，每32769个时钟周期经过1秒。RTC旨在以32768个时钟周期运行，因此时钟以每秒1个时钟周期的速度运行。时钟上的时间每秒快1个时钟周期，因此调整可以采取将时钟每秒调回1个周期的形式。

注册设置

- ●RADJ.PMADJ[1:0]=10b（通过预分频器的减法进行调整）
- RADJ.ADJ[5:0] = 1 (0x10)
  每1秒中断一次将其写入RADJ寄存器。

23.3.8.3 更改调整模式的程序

改变调整模式时，将RADJ.PMADJ[1:0]位设置为00b后改变RCR2中的AADJE位的值（不进行调整）。

将软件调整改为自动调整：

1.将RADJ.PMADJ[1:0]位设置为00b（不进行调整）。

2.将RCR2.AADJE位设置为1（启用自动调整）。

3. Use the RCR2.AADJP bit to select the period of adjustment.
4. In RADJ, set the PMADJ[1:0] bits for addition or subtraction and the ADJ[5:0] bits to the value for use in time error adjustment.

To change automatic adjustment to adjustment by software:

1. Set the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).
2. Set the RCR2.AADJE bit to 0 (adjustment by software is enabled).
3. Proceed with the adjustment by setting the RADJ.PMADJ[1:0] bits for addition or subtraction and the RADJ.ADJ[5:0] bits to the value for use in time error adjustment at the wanted time. After that, the time is adjusted every time a value is written to the RADJ register.

23.3.8.4 Procedure to stop adjustment

Stop the adjustment by setting the RADJ.PMADJ[1:0] bits to 00b (adjustment is not performed).

23.3.9 Capturing the time

The RTC is capable of storing the month, date, hour, minute and second/binary counters 3 to 0 by detecting an edge of a signal on a time capture event input pin in calendar count mode or binary count mode .

A noise filter can also be used on a time capture event input pin. If the noise filter is enabled, the RTCCRn.TCST bit is set to 1 when the input level on the pin matches three times.

The noise filter can be switched on or off for each of the time capture event input pins.Set VBTICTLR.VCHnIEN (n = 0 to 2) to 1 to enable the RTCICn input. Operation when the noise filter is off is shown in Figure 23.9 and operation when the noise filter is on is shown in Figure 23.10.

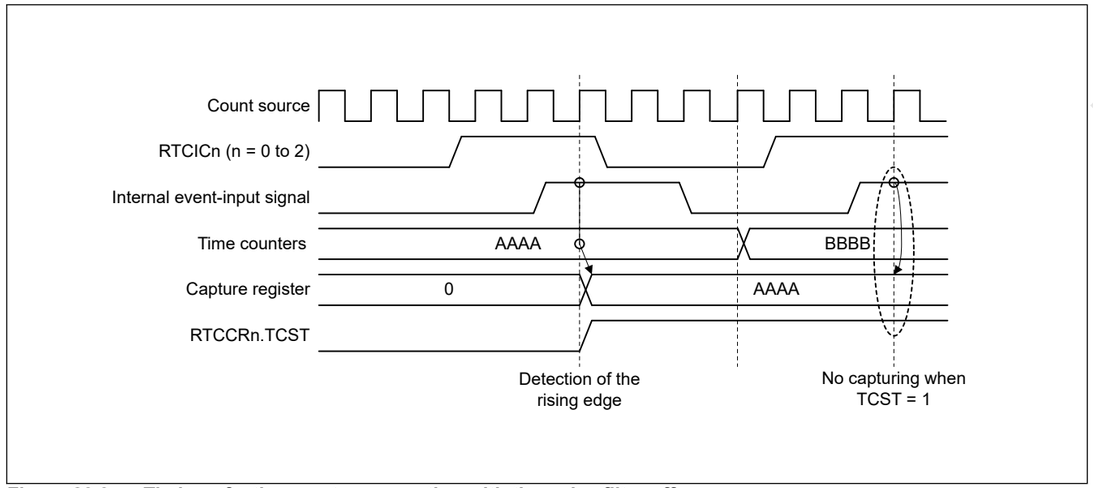

Figure 23.9 Timing of a time capture operation with the noise filter off

3.使用RCR2.AADJP位选择调整周期。

4.在RADJ中，将PMADJ[1:0]位设置为加法或减法，并将ADJ[5:0]位设置为用于时间误差调整的值。

将自动调整更改为软件调整：

1.将RADJ.PMADJ[1:0]位设置为00b（不进行调整）。

2.将RCR2.AADJE位设置为0（启用软件调整）。

3.通过将RADJ.PMADJ[1:0]位设置为加法或减法并将RADJ.ADJ[5:0]位设置为在所需时间用于时间误差调整的值，继续进行调整。之后，每次将值写入RADJ寄存器时都会调整时间。

23.3.8.4 停止调整的程序

通过将RADJ.PMADJ[1:0]位设置为00b来停止调整（不执行调整）。

23.3.9 捕捉时间

通过在日历计数模式或二进制计数模式下检测时间捕捉事件输入引脚上的信号沿，RTC能够存储月、日、小时、分钟和秒二进制计数器3到0。

噪声滤波器也可用于时间捕捉事件输入引脚。如果启用噪声滤波器，则当引脚上的输入电平匹配3次时，RTCCRn.TCST位设置为1。

可以为每个时间捕捉事件输入引脚打开或关闭噪声滤波器。将VBTICTLR.VCHnIEN（n=0到2）设置为1以启用RTCICn输入。噪声滤波器关闭时的操作如图23.9所示，噪声滤波器打开时的操作如图23.10所示。

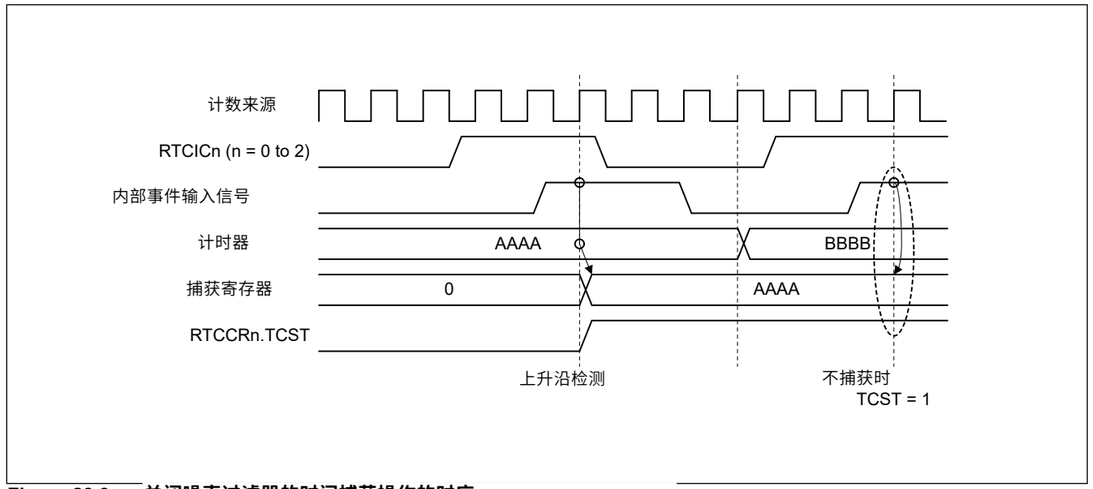

Figure 23.9 关闭噪声过滤器的时间捕获操作的时序

23.4 Interrupt Sources

The RTC has three interrupt sources, as listed in Table 23.3.

Table 23.3 RTC interrupt sources

Name	Interrupt source
RTC_ALM	Alarm interrupt
RTC_PRD	Periodic interrupt
RTC_CUP	Carry interrupt

(1) Alarm interrupt (RTC_ALM)

This interrupt is generated based on the comparison result between the alarm registers and RTC counters. For details, see section 23.3.6. Alarm Function.

Because there is a possibility that the interrupt flag might be set to 1 when the settings of the alarm registers match the clock counters, wait for the alarm time settings to be confirmed and clear the IELSRn.IR flag and the interrupt Set-Pending Register associated with the RTC_ALM interrupt to 0 again after modifying values of the alarm registers. After the interrupt flag for the alarm interrupt is set to 1 and the state is returned to mismatching of the alarm registers and clock counters, the flag is not 1 again until there is another match or the values of the alarm registers are modified again.

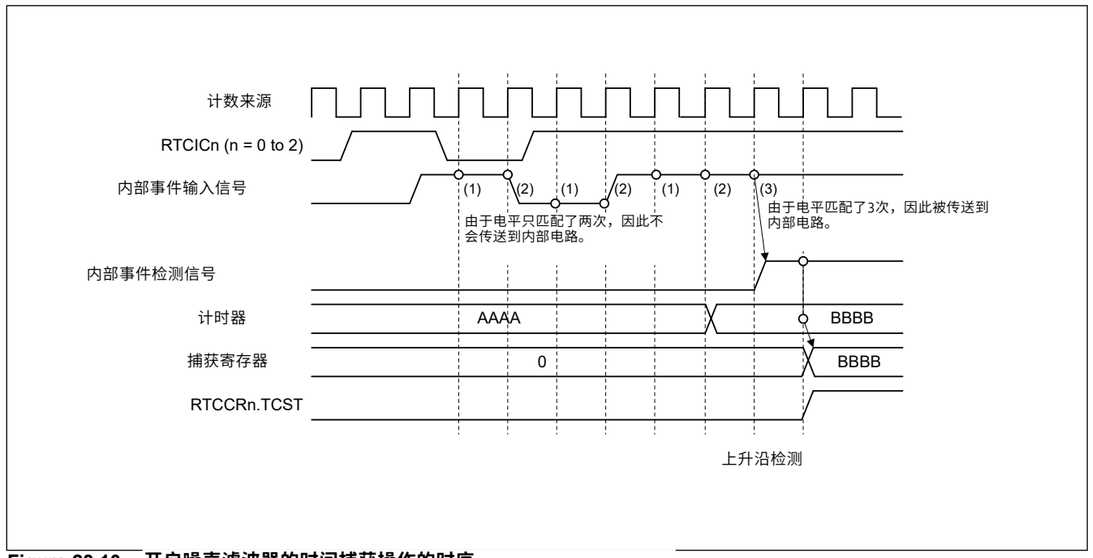

Figure 23.10 开启噪声滤波器的时间捕获操作的时序

23.4 中断源

RTC具有三个中断源，如表23.3中所列。

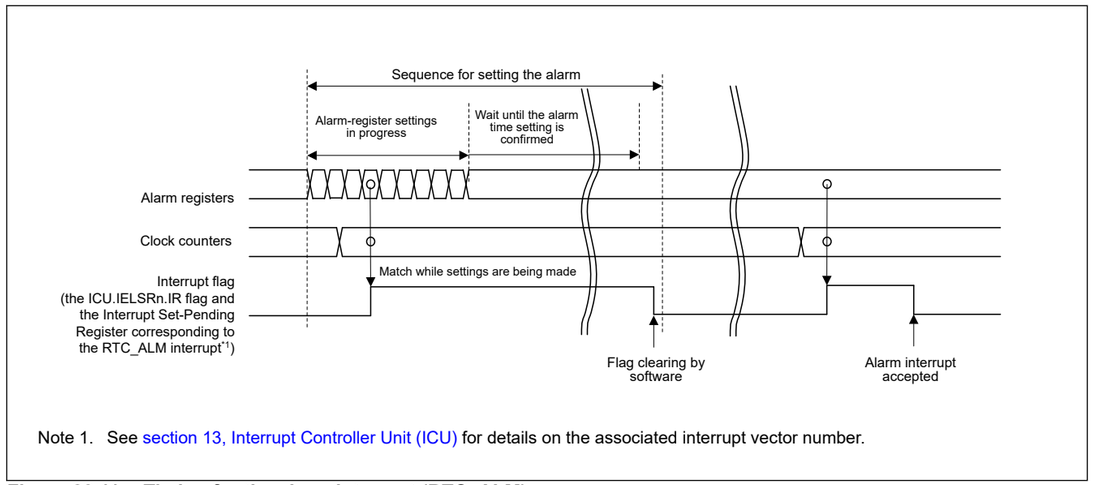
Table 23.3 RTC中断源

Name	中断源
RTC_ALM	报警中断
RTC_PRD	周期性中断
RTC_CUP	进位中断

(1) 闹钟中断(RTC_ALM)

该中断是根据闹钟寄存器和RTC计数器之间的比较结果产生的。详见23.3.6节。报警功能。

因为当闹钟寄存器的设置与时钟计数器匹配时中断标志可能被设置为1，请等待闹钟时间设置被确认并清除IELSRn.IR标志和相关的中断设置挂起寄存器修改闹钟寄存器的值后，RTC_ALM中断再次为0。报警中断的中断标志置1并返回报警寄存器和时钟计数器不匹配状态后，该标志不再为1，直到再次匹配或再次修改报警寄存器的值。



Note 1. See section 13, Interrupt Controller Unit (ICU) for details on the associated interrupt vector number.

Figure 23.11 Timing for the alarm interrupt (RTC_ALM)

(2) Periodic interrupt (RTC_PRD)

This interrupt is generated at intervals of 2 seconds, 1 second, 1/2 second, 1/4 second, 1/8 second, 1/16 second, 1/32 second, 1/64 second, 1/128 second, or 1/256 second. The interrupt interval can be selected in the RCR1.PES[3:0] bits.

(3) Carry interrupt (RTC_CUP)

This interrupt is generated when a carry to the second counter/binary counter 0 occurred or a carry to the R64CNT counter occurred during read access to the 64-Hz counter.

Figure 23.12 shows the timing of the carry interrupt (RTC_CPU).

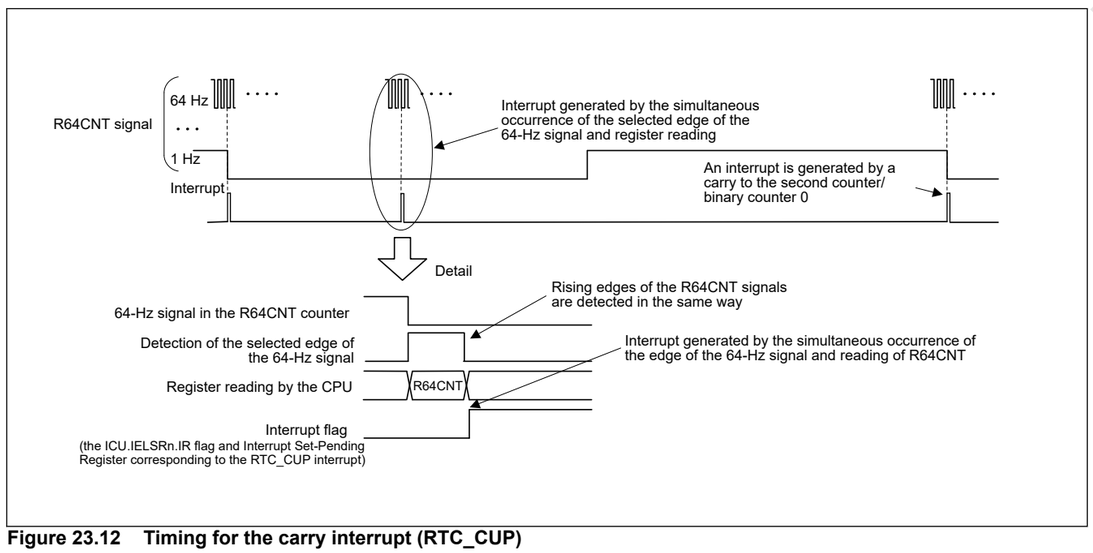


Figure 23.12 Timing for the carry interrupt (RTC_CUP)

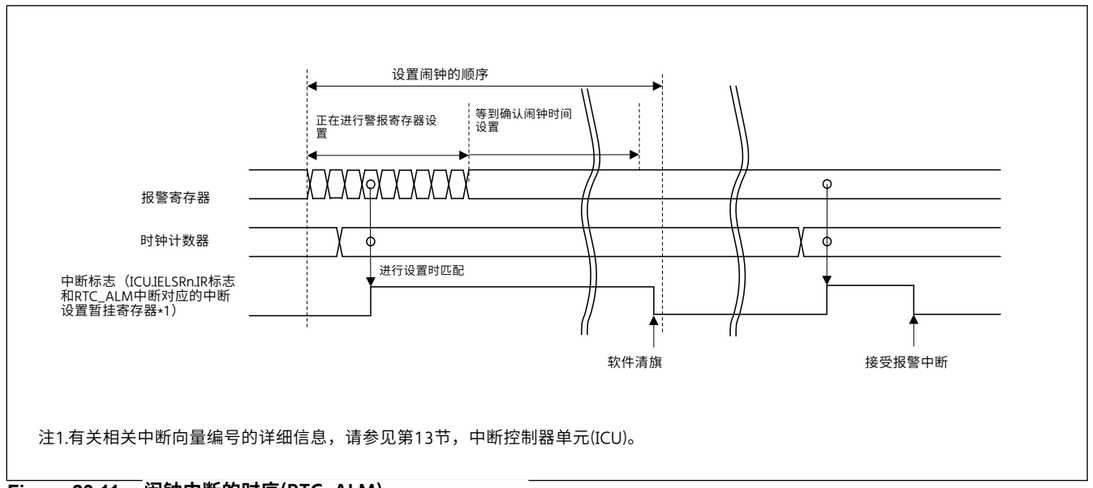
23.5 Event Link Output

The RTC generates periodic event output (RTC_PRD) event signal for the ELC that can be used to initiate operations by other modules selected in advance.



注1.有关相关中断向量编号的详细信息，请参见第13节，中断控制器单元(ICU)。

Figure 23.11 闹钟中断的时序(RTC_ALM)

(2) 周期性中断(RTC_PRD)

此中断以2秒、1秒、12秒、14秒、18秒、116秒、132秒、164秒、1128秒或1256秒的间隔生成。可以在RCR1.PES[3:0]位中选择中断间隔。

(3) 进位中断(RTC_CUP)

当第二个计数器二进制计数器0的进位发生或在对64-Hz计数器的读访问期间发生对R64CNT计数器的进位时，将产生此中断。

图23.12显示了进位中断(RTC_CPU)的时序。

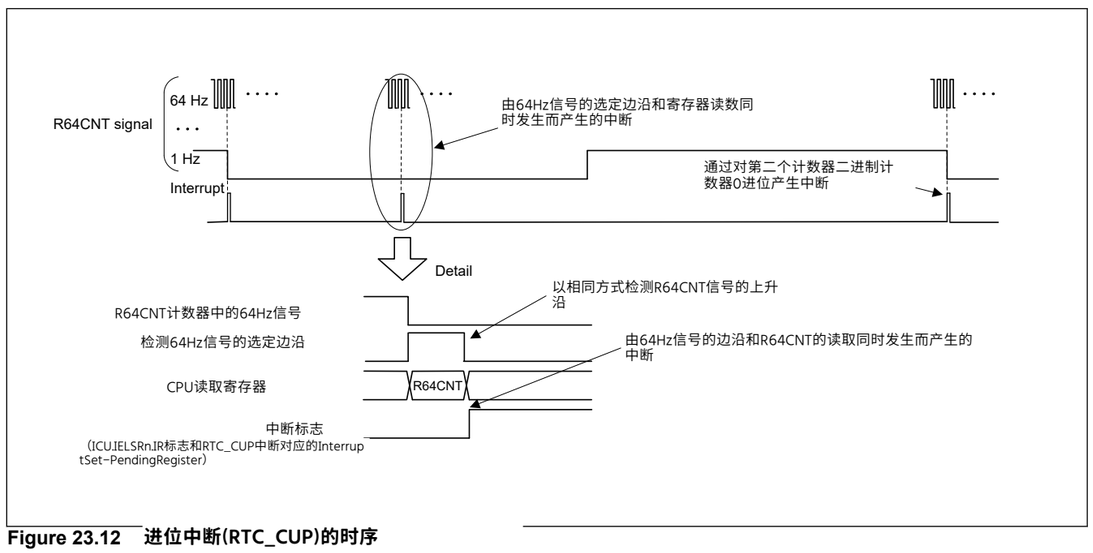


Figure 23.12 进位中断(RTC_CUP)的时序

23.5 事件链接输出

RTC为ELC生成周期性事件输出(RTC_PRD)事件信号，该信号可用于启动预先选择的其他模块的操作。

The periodic event signal is output at the interval selected from 1/256, 1/128, 1/64, 1/32, 1/16, 1/8, 1/4, 1/2, 1, and 2 seconds by setting the RCR1.PES[3:0] bits.

The event generation period immediately after the event generation is selected is not guaranteed.

Note: If event linking from the RTC is used, only set the ELC after setting the RTC, for example initialization and time settings. Setting the RTC after the ELC can lead to output of unexpected event signals.

23.5.1 Interrupt Handling and Event Linking

The RTC has a bit to enable or disable periodic interrupts. An interrupt request signal is output to the CPU when an interrupt source is generated while the associated enable bit is enabled.

In contrast, an event link output signal is sent to other modules as an event signal through the ELC when an interrupt source is generated, regardless of the setting of the associated interrupt enable bit.

Note: Although alarm and periodic interrupts can still be output during Software Standby or Deep Software Standby mode, the periodic event signals for the ELC are not output.

23.6 Usage Notes

23.6.1 Register Writing during Counting

The following registers should not be written to during counting, that is, while the RCR2.START bit is 1:

- RSECCNT/BCNT0
- RMINCNT/BCNT1
- RHRCNT/BCNT2
- RDAYCNT
- RWKCNT/BCNT3
- RMONCNT
- RYRCNT
- RCR1.RTCOS
- RCR2.RTCOE
- RCR2.HR24
- RFRL

The counter should be stopped before writing to any of these registers.

23.6.2 Use of Periodic Interrupts

Figure 23.13 shows the procedure for using periodic interrupts.

The generation and period of the periodic interrupt can be changed by setting the RCR1.PES[3:0] bits. However, because the prescaler R64CNT and RSECCNT/BCNT0 are used to generate interrupts, the interrupt period is not guaranteed immediately after setting the RCR1.PES[3:0] bits.

In addition, any of the following operation can affect the interrupt period:

- Stopping/restarting or resetting counter operation
- Reset by RTC software
- 30-second adjustment by changing the RCR2 value

When the time error adjustment function is used, the interrupt generation period after adjustment is added or subtracted based on the adjustment value.

通过设置RCR1.PES[3:0，以从1256、1128、164、132、116、18、14、12、1和2秒中选择的间隔输出周期性事件信号]位。

不保证选择事件生成后的事件生成周期。

Note: 如果使用来自RTC的事件链接，请仅在设置RTC后设置ELC，例如初始化和时间设置。在ELC之后设置RTC会导致意外事件信号的输出。

23.5.1 中断处理和事件链接

RTC有一个位来启用或禁用周期性中断。当相关使能位使能时产生中断源时，将向CPU输出中断请求信号。

相反，当产生中断源时，事件链接输出信号作为事件信号通过ELC发送到其他模块，而不管相关中断使能位的设置如何。

Note: 尽管在软件待机或深度软件待机模式下仍可输出警报和周期性中断，但不会输出ELC的周期性事件信号。

23.6 使用说明

23.6.1 计数期间的寄存器写入

计数期间不应写入以下寄存器，即RCR2.START位为1时：

- RSECCNT/BCNT0
- RMINCNT/BCNT1
- RHRCNT/BCNT2
- RDAYCNT
- RWKCNT/BCNT3
- RMONCNT
- RYRCNT
- RCR1.RTCOS
- RCR2.RTCOE
- RCR2.HR24
- RFRL

在写入任何这些寄存器之前，应停止计数器。

23.6.2 使用周期性中断

图23.13显示了使用周期性中断的过程。

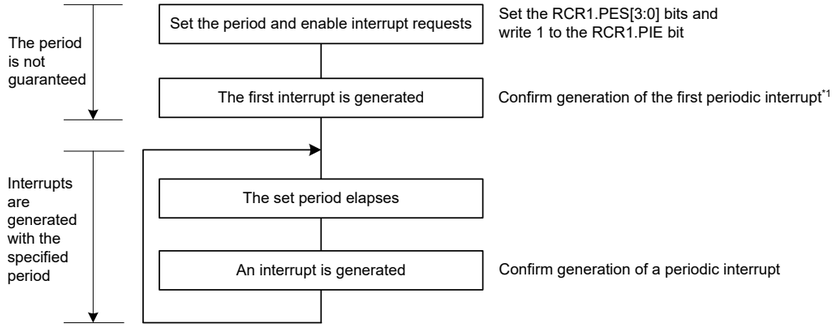
可以通过设置RCR1.PES[3:0]位来更改周期性中断的产生和周期。但是，因为预分频器R64CNT和RSECCNTBCNT0用于产生中断，所以在设置RCR1.PES[3:0]位后不能立即保证中断周期。

此外，以下任何操作都会影响中断周期：

- ●停止重新启动或重置计数器操作
- ●RTC软件复位
- ●通过改变RCR2值进行30秒调整

使用时间误差调整功能时，根据调整值加减调整后的中断产生周期。

RA生态工作室



Note 1. When an interrupt generation period changes while the periodic interrupt is used, an interrupt might be generated at the completion of the setting. If the interrupt is generated immediately after the setting, the period is not guaranteed for two interrupts including the current interrupt.

Figure 23.13 Using the periodic interrupt function

23.6.3 RTCOUT (1-Hz/64-Hz) Clock Output

Stopping/restarting or resetting counter operation, reset by RTC software, and the 30-second adjustment by changing the RCR2 value affects the period of RTCOUT (1-Hz/64-Hz) output. When the time error adjustment function is used, the period of RTCOUT (1-Hz/64-Hz) output after adjustment is added or subtracted based on the adjustment value.

23.6.4 Transitions to Low Power Modes after Setting Registers

A transition to a low power state (Software Standby mode, Deep Software Standby mode, or battery backup state) during a write to an RTC register might corrupt the value of the register. After setting the register, confirm that the setting is in place before initiating a transition to a low power state.

23.6.5 Notes on Writing to and Reading from Registers

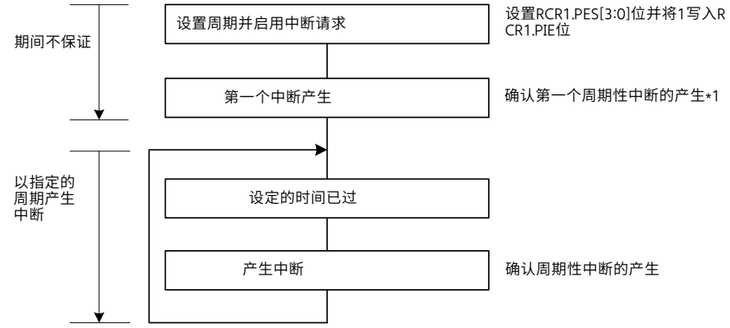
- When reading a counter register such as the second counter after writing to the counter register, follow the procedure in section 23.3.5. Reading 64-Hz Counter and Time.
- The value written to the count registers, alarm registers, year alarm enable register, bits RCR2.AADJE, AADJP, and HR24, RCR4 register, or frequency register is reflected when fourth read operations are performed after writing.
- The values written to the RCR1.CIE, RCR1.RTCOS, and RCR2.RTCOE bits can be read immediately after writing.
- To read the value from the timer counter after returning from a reset or a period in Software Standby mode, Deep Software Standby mode, or battery backup state, wait for 1/128 second while the clock is operating (RCR2.START bit = 1).
- After a reset is generated, write to the RTC register after 6 cycles of the count source clock have elapsed.

23.6.6 Changing the Count Mode

When changing the count mode (calendar count mode/binary count mode), set the RCR2.START bit to 0, stop the counting operation, then start it again from the initial setting. For details on the initial setting, see section 23.3.1. Outline of Initial Settings of Registers after Power On.

23.6.7 Initialization Procedure When the RTC Is Not to Be Used

Registers in the RTC are not initialized by a reset. Depending on the initial state, the generation of an unintentional interrupt request or operation of the counter might lead to increased power consumption.



注1.当使用周期性中断时中断产生周期发生变化时，可能会在设置完成时产生中断。如果设置后立即产生中断，则不保证包括当前中断在内的两次中断的周期。

Figure 23.13 使用周期性中断功能

23.6.3 RTCOUT(1-Hz64-Hz)时钟输出

停止重新启动或重置计数器操作，通过RTC软件重置，并通过更改30秒调整RCR2值影响RTCOUT(1-Hz64-Hz)输出的周期。使用时间误差调整功能时，调整后的RTCOUT（1-Hz64-Hz）输出的周期根据调整值加减。

23.6.4 设置寄存器后转换到低功耗模式

在写入RTC寄存器期间转换到低功耗状态（软件待机模式、深度软件待机模式或电池备份状态）可能会损坏寄存器的值。设置寄存器后，在开始转换到低功耗状态之前确认设置到位。

23.6.5 关于写入和读取寄存器的注意事项

●在写入计数器寄存器后读取第二个计数器等计数器寄存器时，请按照第23.3.5节。读取64-Hz计数器和时间。

●写入计数寄存器、报警寄存器、年报警使能寄存器、RCR2.AADJE、AADJP位和HR24、RCR4寄存器或频率寄存器的值在写入后执行第四次读操作时反映。

●写入RCR1.CIE、RCR1.RTCOS和RCR2.RTCOE位的值可在写入后立即读取。

●要在软件待机模式下从复位或一段时间返回后从定时器计数器读取值，Deep软件待机模式或电池备份状态在时钟运行时等待1128秒（RCR2.START位=1）。

●产生复位后，经过6个计数源时钟周期后写入RTC寄存器。

23.6.6 更改计数模式

当改变计数模式（日历计数模式二进制计数模式）时，将RCR2.START位设置为0，停止计数操作，然后从初始设置重新开始。有关初始设置的详细信息，请参阅第23.3.1节。上电后寄存器的初始设置概要。

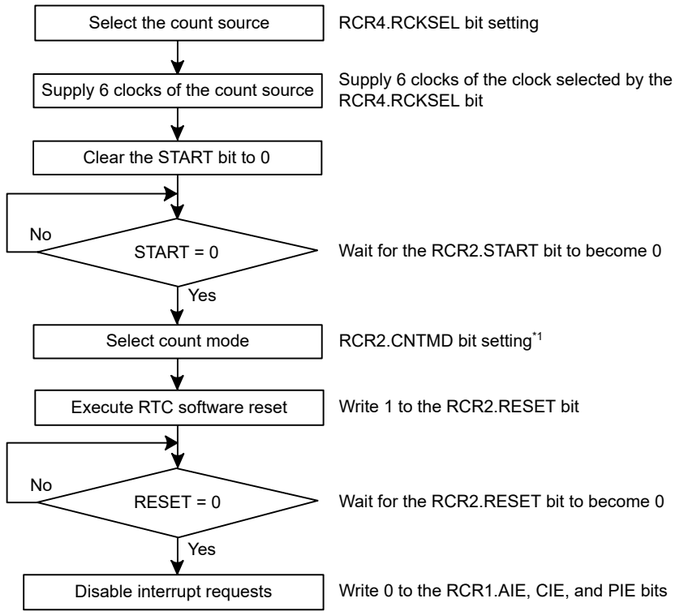
23.6.7 不使用RTC时的初始化程序

RTC中的寄存器不会因复位而初始化。根据初始状态，意外中断请求的生成或计数器的操作可能会导致功耗增加。

For applications that do not require a realtime clock, initialize the registers by following the initialization procedure shown in Figure 23.14.

Alternatively, when the sub-clock oscillator is not used as the system clock or realtime clock, the counter can be stopped by writing 0 (sub-clock oscillator is selected) to the RCR4.RCKSEL bit and stopping the sub-clock oscillator. To stop the sub-clock oscillator, write 1 to the SOSCCR.SOSTP bit.

For details on the setting of the SOSCCR.SOSTP bit, see section 8, Clock Generation Circuit.



Note 1. This step is not necessary if the count mode is concurrently set by setting the START bit to 0.

Figure 23.14 Initialization procedure

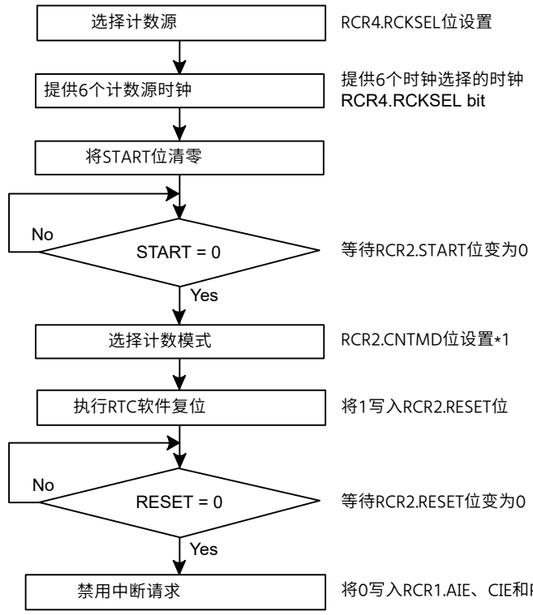
23.6.8 When Switching Source Clock

When switching a clock source by changing SCKSCR.CKSEL[2:0], the clock output from the selector stops for 4 cycles of the switched clock. If the RTC periodical interrupt or RTC periodical event output was generated at this time, the interrupt or event is invalid.

对于不需要实时时钟的应用程序，按照图23.14所示的初始化过程初始化寄存器。

或者，当副时钟振荡器不用作系统时钟或实时时钟时，可以通过向RCR4.RCKSEL位写入0（选择副时钟振荡器）并停止副时钟振荡器来停止计数器。要停止副时钟振荡器，向SOSCCR.SOSTP位写入1。

有关SOSCCR.SOSTP位设置的详细信息，请参见第8节，时钟生成电路。



注1.如果通过将START位设置为0同时设置计数模式，则不需要此步骤。

Figure 23.14 初始化程序

23.6.8 切换源时钟时

当通过改变SCKSCR.CKSEL[2:0]来切换时钟源时，选择器的时钟输出在切换时钟的4个周期内停止。如果此时产生了RTC周期性中断或RTC周期性事件输出，则该中断或事件无效。

24.2.1 WDTRR : WDT Refresh Register

Base address: WDT = 0x4008_3400

Offset address: 0x00

Bit position:	7							0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	n/a	The down-counter is refreshed by writing 0x00 and then writing 0xFF to this register.	R/W

The WDTRR register refreshes the down-counter of the WDT.

The down-counter of the WDT is refreshed by writing 0x00 and then writing 0xFF to WDTRR register (refresh operation) within the refresh-permitted period.

After the down-counter is refreshed, it starts counting down from the value selected by setting the WDT Timeout Period Select bits (OFS0.WDTTOPS[1:0]) in the Option Function Select Register 0 in auto start mode. In register start mode, counting down starts from the value selected by setting the Timeout Period Select bits (WDTCR.TOPS[1:0]) in the WDT Control Register.

When 0x00 is written, the read value is 0x00. When a value other than 0x00 is written, the read value is 0xFF. For details of the refresh operation, see section 24.3.3. Refresh Operation.

WDT的递减计数器通过在允许刷新期间内写入0x00然后将0xFF写入WDTRR寄存器（刷新操作）来刷新。

递减计数器刷新后，在自动启动模式下，它从通过设置选项功能选择寄存器0中的WDT超时周期选择位(OFS0.WDTTOPS[1:0])选择的值开始递减计数。在寄存器启动模式下，倒计时从通过设置WDT控制寄存器中的超时周期选择位(WDTCR.TOPS[1:0])选择的值开始。

写入0x00时，读取值为0x00。写入0x00以外的值时，读取的值为0xFF。有关刷新操作的详细信息，请参阅第24.3.3节。刷新操作。

The WDTCR register is used to set the clock division ratio, and window start and end positions for refresh, and the timeout period until the down-counter underflows in register start mode.

Some constraints apply to writes to the WDTCR register. For details, see section 24.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the settings in the WDTCR register are disabled, and the settings in the Option Function Select Register 0 (OFS0) are enabled. The settings for the WDTCR register can also be made in the OFS0 register. For details, see section 24.3.8. Association between Option Function Select Register 0 (OFS0) and WDT Registers.

TOPS[1:0] bits (Timeout Period Select)

The TOPS[1:0] bits select the timeout period, the period until the down-counter underflows, from 1024, 4096, 8192, and 16384 cycles, taking the divided clock specified in the CKS[3:0] bits as 1 cycle. After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the number of PCLKB cycles until the counter underflows.

Table 24.2 lists the relationship between the CKS[3:0] and TOPS[1:0] bit settings, the timeout period, and the number of PCLKB cycles.

WDTCR寄存器用于设置时钟分频比、刷新的窗口开始和结束位置，以及在寄存器开始模式下直到递减计数器下溢的超时时间。

一些限制适用于写入WDTCR寄存器。详见24.3.2节。控制对WDTCR的写入，WDTRCR和WDTCSTPR寄存器。

在自动启动模式下，禁用WDTCR寄存器中的设置，启用选项功能选择寄存器0(OFS0)中的设置。WDTCR寄存器的设置也可以在OFS0寄存器中进行。详见24.3.8节。选项功能选择寄存器0(OFS0)和WDT寄存器之间的关联。

TOPS[1:0]位（超时周期选择）

TOPS[1:0]位从1024、4096、8192和16384个周期中选择超时周期，直到递减计数器下溢的周期，以CKS[3:0]位中指定的分频时钟为1个周期.向下计数器刷新后，CKS[3:0]和TOPS[1:0]位的组合决定了PCLKB周期数，直到计数器下溢。

表24.2列出了CKS[3:0]和TOPS[1:0]位设置、超时时间和
PCLKB cycles.

	11b		16384	134217728

CKS[3:0] bits (Clock Division Ratio Select)

The CKS[3:0] bits specify the division ratio of the clock used for the down-counter. The division ratio can be selected from the PCLKB divided by 4, 64, 128, 512, 2048, and 8192. Combined with the TOPS[1:0] bit setting, this allows the WDT to be configured to a count period between 4096 and 134217728 PCLKB clock cycles.

RPES[1:0] bits (Window End Position Select)

The RPES[1:0] bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. Set the window end position to a value less than the value for the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.

RPSS[1:0] bits (Window Start Position Select)

The RPSS[1:0] bits specify the window start position that indicates the refresh-permitted period. 100%, 75%, 50%, or 25% of the timeout period can be selected for the window start position. Set the window start position to a value greater than the value for the window end position. If the window start position is set to a value less than or equal to the window end position, the window end position is set to 0%.

Table 24.3 lists the counter values for the window start and end positions, and Figure 24.2 shows the refresh-permitted period set in the RPSS[1:0], RPES[1:0], and TOPS[1:0] bits.

	11b		16384	134217728

CKS[3:0]位（时钟分频比选择）

CKS[3:0]位指定用于递减计数器的时钟的分频比。分频比可以从PCLKB除以4、64、128、512、2048和8192中选择。结合TOPS[1:0]位设置，这允许将WDT配置为4096和134217728个PCLKB时钟周期。

RPES[1:0]位（窗口结束位置选择）

RPES[1:0]位指定指示刷新允许周期的窗口结束位置。可以为窗口结束位置选择75%、50%、25%或0%的超时时间。将窗口结束位置设置为小于窗口起始位置的值（窗口起始位置>窗口结束位置）。如果窗口结束位置大于窗口起始位置，则仅启用窗口起始位置设置。

RPSS[1:0]位（窗口起始位置选择）

RPSS[1:0]位指定指示允许刷新周期的窗口起始位置。可以为窗口起始位置选择100%、75%、50%或25%的超时时间。将窗口开始位置设置为大于窗口结束位置的值。如果窗口开始位置设置为小于或等于窗口结束位置的值，则窗口结束位置设置为0%。

表24.3列出了窗口开始和结束位置的计数器值，图24.2显示了在RPSS[1:0]、RPES[1:0]和TOPS[1:0]位中设置的允许刷新周期。

Base address: WDT = 0x4008_3400

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Symbol	Function	R/W
15	REFEF	Refresh Error Flag 0: No refresh error occurred 1: Refresh error occurred	R/W*1

Note 1. Only 0 can be written to clear the flag.

The WDTSR register indicates the counter value of the down-counter and the status of whether an underflow or refresh error occurred in the down-counter.

CNTVAL[13:0] bits (Down-Counter Value)

Read the CNTVAL[13:0] bits to confirm the value of the down-counter. The read value might differ from the actual count by 1.

UNDFF flag (Underflow Flag)

Read the UNDFF flag to confirm whether an underflow occurred in the counter. A value of 1 indicates that the down counter underflowed. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N+1) PCLKB cycles. In addition, clearing of the flag is ignored for (N+1) PCLKB cycles after an underflow. N is specified in the WDTCR.CKS[3:0] bits as follows:

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

REFEF flag (Refresh Error Flag)

Read the REFEF flag to confirm whether a refresh error occurred, indicating that a refresh operation was performed during a prohibited period. A value of 1 indicates that a refresh error occurred. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the REFEF flag takes (N+1) PCLKB cycles. In addition, clearing of the flag is ignored for (N+1) PCLKB cycles after a refresh error. N is specified in the WDTCR.CKS[3:0] bits as follows:

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

24.2.4 WDTRCR : WDT Reset Control Register

Bit	Symbol	Function	R/W
15	REFEF	刷新错误标志 0：未发生刷新错误1：发生刷新错误	R/W*1

注1.只能写入0来清除标志。

WDTSR寄存器指示递减计数器的计数值以及递减计数器是否发生下溢或刷新错误的状态。

CNTVAL[13:0] bits (Down-Counter Value)

读取CNTVAL[13:0]位以确认递减计数器的值。读取的值可能与实际计数相差1。

UNDFF flag (Underflow Flag)

读取UNDFF标志以确认计数器是否发生下溢。值1表示递减计数器下溢。将0写入标志以将值设置为0。写入1无效。

清除UNDFF标志需要(N+1)个PCLKB周期。此外，在下溢后的(N+1)个PCLKB周期内忽略标志的清除。N在WDTCR.CKS[3:0]位中指定如下：

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

REFEF标志（刷新错误标志）

读取REFEF标志，确认是否发生刷新错误，表示在禁止期间进行了刷新操作。值1表示发生了刷新错误。将0写入标志以将值设置为0。写入1无效。

清除REFEF标志需要(N+1)个PCLKB周期。此外，在刷新错误后的(N+1)个PCLKB周期内，标志的清除将被忽略。N在WDTCR.CKS[3:0]位中指定如下：

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

24.2.4 WDTRCR:WDT复位控制寄存器

Some constraints apply to writes to the WDTRCR register. For details, see section 24.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the WDTRCR register settings are disabled, and the settings in the Option Function Select register 0 (OFS0) are enabled. The settings for the WDTRCR register can also be made for the OFS0 register. For details, see section 24.3.8. Association between Option Function Select Register 0 (OFS0) and WDT Registers.

24.2.5 WDTCSTPR : WDT Count Stop Control Register

Base address: WDT = 0x4008_3400

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0

6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	SLCSTP	WDT Count Stop Control Register 0: Disable count stop 1: Stop count on transition to Sleep mode	R/W

The WDTCSTPR register controls whether to stop the WDT counter in a low power mode. Some constraints apply to writes to the WDTCSTPR register. For details, see section 24.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the WDTCSTPR register settings are disabled, and the settings in the Option Function Select register 0 (OFS0) are enabled. The settings for the WDTCSTPR register can also be made for the OFS0 register. For details, see section 24.3.8. Association between Option Function Select Register 0 (OFS0) and WDT Registers.

SLCSTP bit (WDT Count Stop Control Register)

The SLCSTP bit selects whether to stop counting on transition to Sleep mode, Snooze, or Software Standby mode.

24.2.6 Option Function Select Register 0 (OFS0)

For information on the OFS0 register, see section 24.3.8. Association between Option Function Select Register 0 (OFS0) and WDT Registers.

24.3 Operation

24.3.1 Count Operation in each Start Mode

The WDT has two start modes:

- Auto start mode, in which counting automatically starts after a release from the reset state
- Register start mode, in which counting starts with a refresh by writing to the register.

In auto start mode, counting automatically starts after a release from the reset state according to the settings in the Option Function Select register 0 (OFS0) in the flash.

In register start mode, counting starts with a refresh by writing to the WDTRR register after the respective registers are set after a release from the reset state.

一些限制适用于写入WDTRCR寄存器。详见24.3.2节。控制写入WDTCR、WDTRCR和WDTCSTPR寄存器。

在自动启动模式下，WDTRCR寄存器设置被禁用，而选项功能选择寄存器0(OFS0)中的设置被启用。WDTRCR寄存器的设置也可以对OFS0寄存器进行。详见24.3.8节。选项功能选择寄存器0(OFS0)和WDT寄存器之间的关联。

在自动启动模式下，WDTCSTPR寄存器设置被禁用，而选项功能选择寄存器0(OFS0)中的设置被启用。也可以对OFS0寄存器进行WDTCSTPR寄存器的设置。详见24.3.8节。选项功能选择寄存器0(OFS0)和WDT寄存器之间的关联。

SLCSTP位（WDT计数停止控制寄存器）

SLCSTP位选择在转换到休眠模式、贪睡或软件待机模式时是否停止计数。

24.2.6 选项功能选择寄存器0(OFS0)

有关OFS0寄存器的信息，请参见第24.3.8节。选项功能选择寄存器0(OFS0)和WDT寄存器之间的关联。

24.3 Operation

24.3.1 每种启动模式下的计数操作

WDT有两种启动模式：

●自动启动模式，从复位状态释放后自动开始计数

●寄存器启动模式，通过写入寄存器，从刷新开始计数。

在自动启动模式下，根据选项中的设置从复位状态释放后自动开始计数
功能选择闪存中的寄存器0(OFS0)。

在寄存器启动模式下，在从复位状态释放后，在设置各个寄存器后，通过写入WDTRR寄存器，从刷新开始计数。

Select auto start mode or register start mode by setting the WDT Start Mode Select bit (OFS0.WDTSTRT) in the OFS0 register.

When the auto start mode is selected, the settings in the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are disabled while the settings in the OFS0 register are enabled.

When the register start mode is selected, the setting for the OFS0 register is disabled while the settings for the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are enabled.

24.3.1.1 Register start mode

When the WDT Start Mode Select bit (OFS0.WDTSTRT) is 1, register start mode is selected and the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are enabled.

After the reset state is released, set the following to Sleep mode in the WDTCSTPR register:

- Clock division ratio
- Window start and end positions
- Timeout period in the WDTCR register
- Reset output or interrupt request output in the WDTRCR register
- Counter stop control during transitions to Sleep mode in the WDTCSTPR register

Refresh the down-counter to start counting down from the value set in the Timeout Period Selection bits (WDTCR.TOPS[1:0]).

Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and counting down continues. The WDT does not output the reset signal as long as counting continues. However, if the down-counter underflows because the down-counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the WDT outputs the reset signal or a non-maskable interrupt request/interrupt request (WDT_NMIUNDF). Reset output or interrupt request output can be selected in the WDT Reset Interrupt Request Select bit (WDTRCR.RSTIRQS). Non-maskable interrupt requests or interrupt requests can be selected in the WDT Underflow/Refresh Error Interrupt Enable bit (NMIER.WDTEN).

Figure 24.3 shows an example of operation under the following conditions:

- Register start mode (OFS0.WDTSTRT = 1)
- Reset output is enabled (WDTRCR.RSTIRQS = 1)
- The window start position is 75% (WDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (WDTCR.RPES[1:0] = 10b)

通过设置OFS0寄存器中的WDT启动模式选择位(OFS0.WDTSTRT)来选择自动启动模式或寄存器启动模式。

选择自动启动模式后，WDT控制寄存器（WDTCR）中的设置，WDTRESET控制寄存器（WDTRCR）和WDT计数停止控制寄存器（WDTCSTPR）在启用OFS0寄存器中的设置时被禁用。

选择寄存器启动模式时，在WDT控件的设置时禁用OFS0寄存器的设置
使能寄存器(WDTCR)、WDT复位控制寄存器(WDTRCR)和WDT计数停止控制寄存器(WDTCSTPR)。

24.3.1.1 注册启动模式

当WDT启动模式选择位(OFS0.WDTSTRT)为1时，选择寄存器启动模式并启用WDT控制寄存器(WDTCR)、WDT复位控制寄存器(WDTRCR)和WDT计数停止控制寄存器(WDTCSTPR)。

释放复位状态后，在WDTCSTPR寄存器中将以下内容设置为休眠模式：

- ●时钟分频比
- ●窗口开始和结束位置
- ●WDTCR寄存器中的超时时间
- ●WDTRCR寄存器中的复位输出或中断请求输出
- ●WDTCSTPR寄存器中转换到休眠模式期间的计数器停止控制

刷新递减计数器以从超时周期选择位(WDTCR.TOPS[1:0])中设置的值开始递减计数。

When the WDT Start Mode Select bit (OFS0.WDTSTRT) in the Option Function Select Register 0 (OFS0) is 0, auto start mode is selected, the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are disabled, and the settings in the OFS0 register are enabled.

Within the reset state, the setting values for the following in the Option Function Select Register 0 (OFS0) are set in the WDT registers:

- Clock division ratio
- Window start and end positions
- Timeout period
- Reset output or interrupt request
- Counter stop control during transition to Sleep mode

When the reset state is released, the down-counter automatically starts counting down from the value set in the WDT Timeout Period Select bits (OFS0.WDTTOPS[1:0]).

Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and counting down continues. The WDT does not output the reset signal as long as the counting continues. However, if the down-counter underflows because refreshing of the down-counter is not possible due to a

runaway program or if a refresh error occurs due to refreshing outside the refresh-permitted period, the WDT outputs the reset signal or non-maskable interrupt request/interrupt request (WDT_NMIUNDF).

After the reset signal or non-maskable interrupt request/interrupt request is generated, the counter reloads the timeout period after counting for 1 cycle. The value of the timeout period is set in the down-counter and counting restarts.

Reset output or interrupt request output can be selected by setting the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS). Non-maskable interrupt request or interrupt request can be selected in the WDT Underflow/ Refresh Error Interrupt Enable bit (NMIER.WDTEN).

Figure 24.4 shows an example of operation (non-maskable interrupt) under the following conditions:

- Auto start mode (OFS0.WDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.WDTRSTIRQS = 0)
- The window start position is 75% (OFS0.WDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.WDTRPES[1:0] = 10b)

24.3.2 Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers

Writing to the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), or WDT Count Stop Control Register (WDTCSTPR) is possible once between the release from the reset state and the first refresh operation.

如果程序失控或由于刷新允许刷新周期之外的刷新而发生刷新错误，则WDT输出复位信号或不可屏蔽中断请求中断请求(WDT_NMIUNDF)。

复位信号或不可屏蔽中断请求中断请求产生后，计数器在计数1个周期后重新加载超时周期。超时时间的值在递减计数器中设置并重新开始计数。

通过设置WDT复位中断请求选择位(OFS0.WDTRSTIRQS)可以选择复位输出或中断请求输出。可以在WDT下溢刷新错误中断 允许位(NMIER.WDTEN)中选择不可屏蔽的中断请求或中断请求。

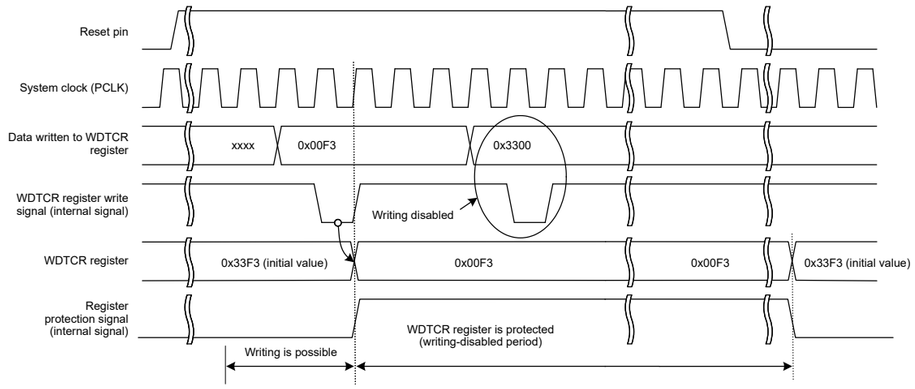
After a refresh (counting starts) or a write to WDTCR, WDTRCR or WDTCSTPR register, the protection signal in the WDT becomes 1 to protect WDTCR, WDTRCR and WDTCSTPR register against subsequent write attempts. This protection is released by the reset source of the WDT. With other reset sources, the protection is not released.

Figure 24.5 shows control waveforms produced in response to writing to the WDTCR.



Note: PCLK = PCLKB
Reset pin = RES

Figure 24.5 Control waveforms produced in response to writes to the WDTCR register

24.3.3 Refresh Operation

The down-counter is refreshed and starts counting operation on a write of the values 0x00 and 0xFF to the WDT Refresh Register (WDTRR). If a value other than 0xFF is written after 0x00, the down-counter is not refreshed. If an invalid value is written, correct refreshing resumes on a write of 0x00 and 0xFF to the WDTRR register.

Correct refreshing is also performed when a register other than WDTRR is accessed or WDTRR is read between writing 0x00 and writing 0xFF to WDTRR. Writes to refresh the counter must be made within the refresh-permitted period, and this is determined by the 0xFF write. For this reason, correct refreshing is performed even when 0x00 is written outside the refresh-permitted period.

[Example write sequences that are valid for refreshing the counter]

- 0x00 → 0xFF
- 0x00 ((n–1)th time) → 0x00 (nth time) → 0xFF
- 0x00 → access to another register or read from WDTRR → 0xFF

[Example write sequences that are invalid for refreshing the counter]

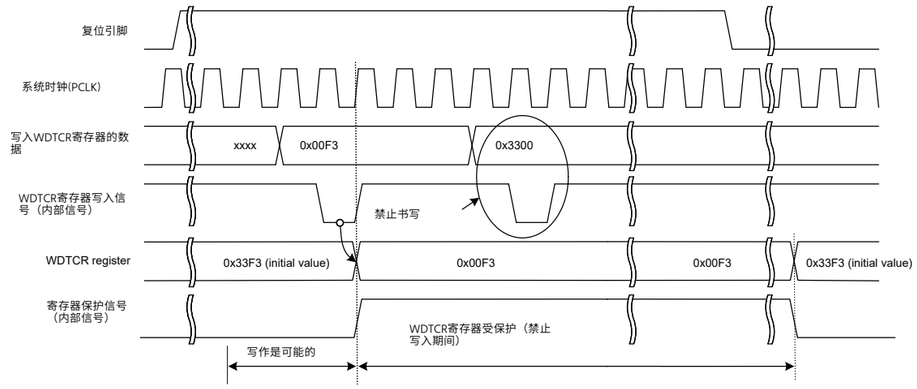
- 0x23 (a value other than 0x00) → 0xFF
- 0x00 → 0x54 (a value other than 0xFF)
- 0x00 → 0xAA (0x00 and a value other than 0xFF) → 0xFF

After 0xFF is written to the WDT Refresh Register (WDTRR), refreshing the down-counter requires up to 4 cycles of the signal for counting. To meet this requirement, complete writing 0xFF to WDTRR 4 count cycles before the down-counter underflows.

Figure 24.6 shows the WDT refresh-operation waveforms when the clock division ratio is PCLKB/64.

在刷新（计数开始）或写入WDTCR、WDTRCR或WDTCSTPR寄存器后，WDT变为1以保护WDTCR、WDTRCR和WDTCSTPR寄存器免受后续写入尝试。该保护由WDT的复位源解除。使用其他复位源时，不会解除保护。

图24.5显示了响应写入WDTCR产生的控制波形。



Note: PCLK=PCLKB复位引脚=RES

Figure 24.5 响应写入WDTCR寄存器而产生的控制波形

24.3.3 刷新操作

向下计数器刷新并在将值0x00和0xFF写入WDT刷新时开始计数操作寄存器(WDTRR)。如果在0x00之后写入0xFF以外的值，则不刷新递减计数器。如果写入无效值，则在向WDTRR寄存器写入0x00和0xFF时会恢复正确刷新。

在写入0x00和写入0xFF到WDTRR之间访问WDTRR以外的寄存器或读取WDTRR时，也会执行正确刷新。刷新计数器的写入必须在允许刷新的周期内进行，这由0xFF写入决定。因此，即使在可刷新期间外写入0x00，也会执行正确的刷新。

[对刷新计数器有效的示例写入序列]

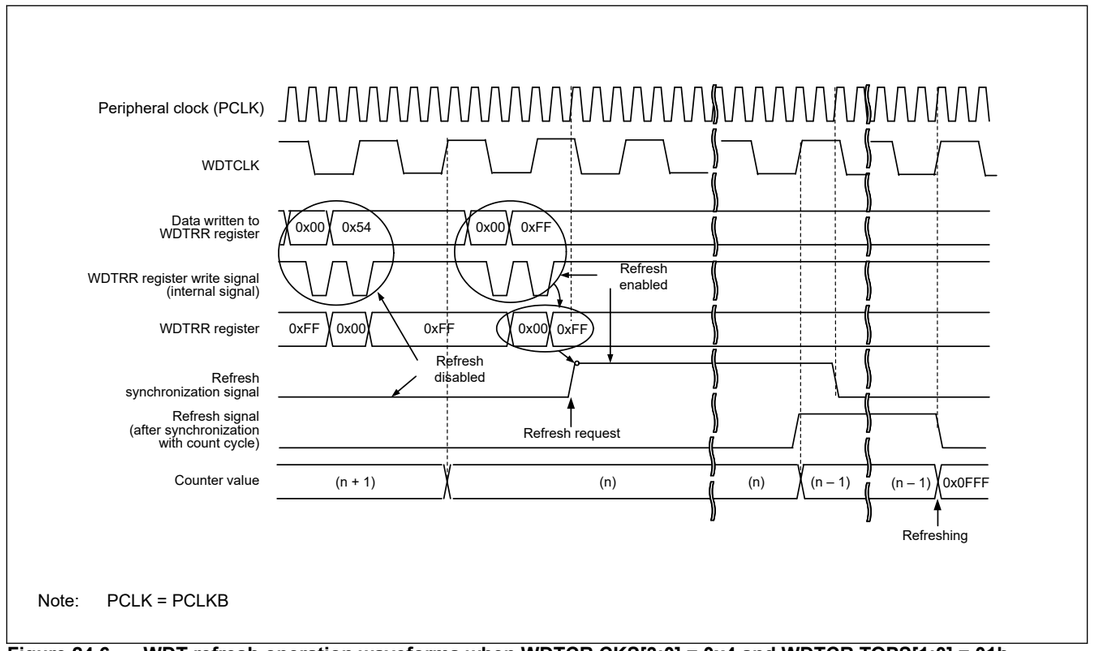
- 0x00 → 0xFF
- 0x00 ((n–1)th time) → 0x00 (nth time) → 0xFF
- ●0x00→访问另一个寄存器或从WDTRR读取→0xFF

[对刷新计数器无效的示例写入序列]

- ●0x23（0x00以外的值）→0xFF
- ●0x00→0x54（0xFF以外的值）
- ●0x00→0xAA（0x00和0xFF以外的值）→0xFF

将0xFF写入WDT刷新寄存器(WDTRR)后，刷新递减计数器最多需要4个信号周期进行计数。为满足此要求，请在递减计数器下溢之前的4个计数周期内将0xFF写入WDTRR。

图24.6显示了时钟分频比为PCLKB64时的WDT刷新操作波形。



Note: PCLK = PCLKB

Figure 24.6 WDT refresh operation waveforms when WDTCR.CKS[3:0] = 0x4 and WDTCR.TOPS[1:0] = 01b

Note: When setting the refresh time, consider the oscillation accuracy of the clock sources of the PCLKB and WDTCLK. Set values which ensure that refreshing is possible even when the frequency varies in the range of error of the oscillation accuracy.

24.3.4 Status Flags

The refresh error (WDTSR.REFEF) and underflow (WDTSR.UNDFF) flags retain the source of the interrupt request from the WDT. After a release from the interrupt request generation, read the WDTSR.REFEF and WDTSR.UNDFF flags to check for the interrupt source. For each flag, writing 0 clears the bit. Writing 1 has no effect. Leaving the status flags unchanged does not affect operation. If the flags are not cleared at the next interrupt request from the WDT, the earlier interrupt source is cleared and the new interrupt source is written. For the time period between when 0 is written in each flag and when its value is reflected, see section 24.2.3. WDTSR : WDT Status Register.

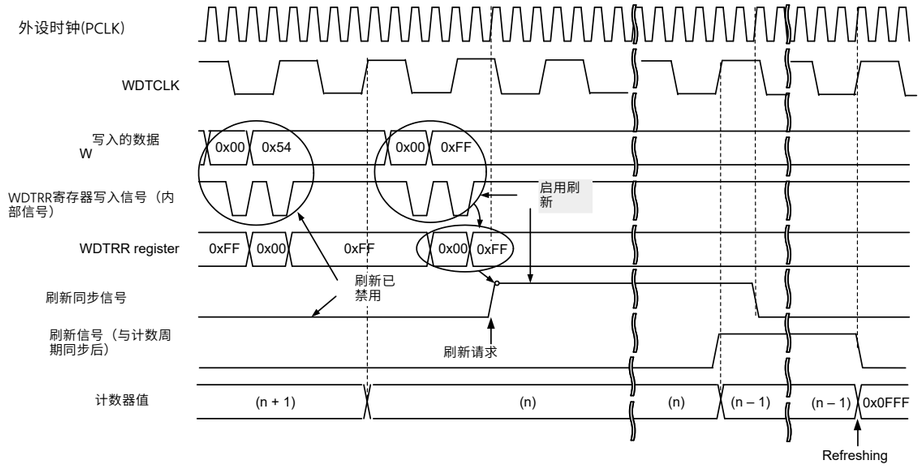
24.3.5 Reset Output

When the Reset Interrupt Select bit (WDTRCR.RSTIRQS) is set to 1 in register start mode, or when the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 1 in auto start mode, a reset signal is output for 1 cycle count when an underflow in the down-counter or a refresh error occurs.

In register start mode, the down-counter is initialized (all bits set to 0) and stopped in that state after output of a reset signal. After the reset state is released and the program is restarted, the counter is set up again and counting down starts again with a refresh. In auto start mode, counting down starts automatically after the reset state is released.

24.3.6 Interrupt Sources

When the Reset Interrupt Select bit (WDTRCR.RSTIRQS) is set to 0 in register start mode or when the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 0 in auto start mode, an interrupt (WDT_NMIUNDF) signal is generated when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or an interrupt. For details, see section 13, Interrupt Controller Unit (ICU).



Note: PCLK = PCLKB

Figure 24.6 WDTCR.CKS[3:0]=0x4和WDTCR.TOPS[1:0]=01b时的WDT刷新操作波形

Note: 设置刷新时间时，要考虑PCLKB和WDTCLK时钟源的振荡精度。设定即使频率在振荡精度的误差范围内变化也能进行刷新的值。

24.3.4 状态标志

刷新错误(WDTSR.REFEF)和下溢(WDTSR.UNDFF)标志保留来自WDT的中断请求源。释放中断请求生成后，读取WDTSR.REFEF和WDTSR.UNDFF标志以检查中断源。对于每个标志，写入0会清除该位。写1无效。保持状态标志不变不会影响操作。如果在WDT发出下一个中断请求时未清除标志，则清除较早的中断源并写入新的中断源。关于从各标志写入0到反映其值的时间段，请参阅第24.2.3节。WDTSR：WDT状态寄存器。

24.3.5 复位输出

当复位中断选择位(WDTRCR.RSTIRQS)在寄存器启动模式下设置为1时，或当WDT复位时在自动启动模式下，选项功能选择寄存器0(OFS0)中的中断请求选择位(OFS0.WDTRSTIRQS)设置为1，当递减计数器中的下溢或刷新错误发生时，在1个周期计数内输出复位信号.

在寄存器启动模式下，递减计数器被初始化（所有位设置为0）并在输出复位信号后停止在该状态。复位状态解除并重新启动程序后，再次设置计数器，并通过刷新再次开始倒计时。在自动启动模式下，复位状态解除后自动开始倒计时。

24.3.6 中断源

当在寄存器启动模式下复位中断选择位(WDTRCR.RSTIRQS)设置为0或WDT复位时在自动启动模式下，选项功能选择寄存器0(OFS0)中的中断请求选择位(OFS0.WDTRSTIRQS)设置为0，当计数器下溢或发生刷新错误时，将产生中断(WDT_NMIUNDF)信号。此中断可用作不可屏蔽中断或中断。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

24.3.7 Reading the Down-Counter Value

The WDT stores the counter value in the down-counter value bits (WDTSR.CNTVAL[13:0]) of the WDT Status Register. Check these bits to obtain the counter value. The read value of the down-counter might differ from the actual count by one.

24.4 Output to the Event Link Controller (ELC)

The WDT is capable of a link operation for the previously specified module when interrupt request signal is used as an event signal by the ELC. The event signal is output by the counter underflow and refresh error. An event signal is output regardless of the setting of the Reset Interrupt Request Select bit (WDTRCR.RSTIRQS) in register start mode or auto start mode. An event signal can also be output when the next interrupt source is generated while the Refresh Error flag (WDTSR.REFEF) or Underflow flag (WDTSR.UNDFF) is 1. For details, see section 18, Event Link Controller (ELC).

24.5 Usage Notes

24.5.1 ICU Event Link Setting Register n (IELSRn) Setting

Setting 0x53 to ICU Event Link Setting Register n (ICU.IELSRn) is prohibited when enabling the WDT reset assertion (OFS0.WDTRSTIRQS = 0 or WDTRCR.RSTIRQS = 0) or when enabling event link operation (ELSRn.ELS[8:0] = 0x53).

24.4 输出到事件链接控制器(ELC)

当ELC将中断请求信号用作事件信号时，WDT能够对先前指定的模块进行链接操作。事件信号由计数器下溢和刷新错误输出。在寄存器启动模式或自动启动模式下，无论复位中断请求选择位(WDTRCR.RSTIRQS)的设置如何，都会输出事件信号。当刷新错误标志(WDTSR.REFEF)或下溢标志(WDTSR.UNDFF)为1时，也可以在产生下一个中断源时输出事件信号。有关详细信息，请参阅第18节，事件链接控制器(ELC)。

24.5.1 ICU事件链接设置寄存器n(IELSRn)设置

当启用WDT复位断言(OFS0.WDTRSTIRQS=0或WDTRCR.RSTIRQS=0)或启用事件链接操作(ELSRn.ELS[8:0])时，禁止将0x53设置为ICU事件链接设置寄存器n(ICU.IELSRn)=0x53)。

25. Independent Watchdog Timer (IWDT)

25.1 Overview

The Independent Watchdog Timer (IWDT) consists of a 14-bit down counter that must be serviced periodically to prevent counter underflow. The IWDT provides functionality to reset the MCU or to generate a non-maskable interrupt or an underflow interrupt. Because the timer operates with an independent, dedicated clock source, it is particularly useful in returning the MCU to a known state as a fail-safe mechanism when the system runs out of control. The IWDT can be triggered automatically by a reset, underflow, refresh error, or a refresh of the count value in the registers.

The IWDT functions differ from those of the WDT in the following respects:

- The divided IWDT-dedicated clock (IWDTCLK) is used as the count source (not affected by PCLKB)
- IWDT does not support register start mode

Table 25.1 lists the IWDT specifications and Figure 25.1 shows a block diagram.

Table 25.1 IWDT specifications

Parameter	Description
Count source*1	IWDT-dedicated clock (IWDTCLK)
Clock division ratio	Division by 1, 16, 32, 64, 128, or 256
Counter operation	Counting down using a 14-bit down-counter
Condition for starting the counter	• Counting automatically starts after a reset • Only secure developer can start the IWDT
Conditions for stopping the counter	• Reset (the down-counter and other registers return to their initial values) • A counter underflows or a refresh error is generated (counting restarts automatically).
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods)
Reset output sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error).
Non-maskable interrupt/interrupt sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error).
Reading the counter value	The down-counter value can be read by the IWDTSR register
Event link function	• Down-counter underflow event output • Refresh error event output.
Output signal (internal signal)	• Reset output • Interrupt request output • Sleep-mode count stop control output.
Auto start mode	Configurable to the following triggers: • Clock frequency division ratio after a reset (OFS0.IWDTCKS[3:0] bits) • Timeout period of the Independent Watchdog Timer (OFS0.IWDTTOPS[1:0] bits) • Window start position in the Independent Watchdog Timer (OFS0.IWDTRPSS[1:0] bits) • Window end position in the Independent Watchdog Timer (OFS0.IWDTRPES[1:0] bits) • Reset output or interrupt request output (OFS0.IWDTRSTIRQS bit) • Down-count stop function at transition to Sleep mode, Software Standby mode, or Snooze mode (OFS0.IWDTSTPCTL bit).

Note 1. Satisfy the frequency of the peripheral module clock (PCLKB) ≥ 4 × (the frequency of the count clock source after division).

The bus interface and registers operate with PCLKB, and the 14-bit counter and control circuits operate with IWDTCLK.

25. 独立看门狗定时器(IWDT)

25.1 Overview

独立看门狗定时器(IWDT)包含一个14位递减计数器，必须定期对其进行服务以防止计数器下溢。IWDT提供复位MCU或生成不可屏蔽中断或下溢中断的功能。由于定时器使用独立的专用时钟源运行，因此当系统失控时，它在将MCU作为故障安全机制返回到已知状态时特别有用。IWDT可以通过复位、下溢、刷新错误或寄存器中的计数值的刷新来自动触发。

IWDT的功能与WDT的功能有以下不同：

●分频IWDT专用时钟（IWDTCLK）用作计数源（不受PCLKB影响）

●IWDT不支持寄存器启动方式

表25.1列出了IWDT规范，图25.1显示了框图。

The IWDTRR register refreshes the down-counter of the IWDT. The down-counter of the IWDT is refreshed by writing 0x00 and then writing 0xFF to IWDTRR (refresh operation) within the refresh-permitted period. After the down-counter is refreshed, it starts counting down from the value selected in the IWDT Timeout Period Select bits (OFS0.IWDTTOPS[1:0]) in the Option Function Select Register 0 (OFS0).

When 0x00 is written, the read value is 0x00. When a value other than 0x00 is written, the read value is 0xFF. For details of the refresh operation, see section 25.3.2. Refresh Operation.

13:0	CNTVAL[13:0]	Down-counter Value Value counted by the down-counter	R
14	UNDFF	Underflow Flag 0: No underflow occurred 1: Underflow occurred	R/W*1
15	REFEF	Refresh Error Flag 0: No refresh error occurred 1: Refresh error occurred	R/W*1

Note 1. Only 0 can be written to clear the flag.

The IWDTSR register indicates the counter value of the down-counter and whether an underflow or refresh error occurred in the down-counter.

CNTVAL[13:0] bits (Down-counter Value)

Read the CNTVAL[13:0] bits to confirm the value of the down-counter. The read value might differ from the actual count by 1.

UNDFF flag (Underflow Flag)

Read the UNDFF flag to confirm whether an underflow occurred in the down-counter. The value 1 indicates that the down-counter underflowed. Write 0 to the UNDFF flag to set the value to 0. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N + 2) IWDTCLK cycles and 2 PCLKB cycles. In addition, clearing of this flag is ignored for (N + 2) IWDTCLK cycles after an underflow. N is specified in the IWDTCKS[3:0] bits as follows:

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128
- When OFS0.IWDTCKS[3:0] = 0x5, N = 256.

REFEF flag (Refresh Error Flag)

Read the REFEF flag to confirm whether a refresh error occurred. This indicates that a refresh operation was performed during a prohibited period. The value 1 indicates that a refresh error occurred. Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

Clearing of the REFEF flag takes (N + 2) IWDTCLK cycles and 2 PCLKB cycles. In addition, clearing of this flag is ignored for (N + 2) IWDTCLK cycles following a refresh error. N is specified in the IWDTCKS[3:0] bits as follows:

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128

IWDTSR寄存器指示递减计数器的计数值以及递减计数器是否发生下溢或刷新错误。

CNTVAL[13:0] bits (Down-counter Value)

读取UNDFF标志以确认递减计数器中是否发生下溢。值1表示递减计数器下溢。将0写入UNDFF标志以将值设置为0。写入1无效。

清除UNDFF标志需要(N+2)个IWDTCLK周期和2个PCLKB周期。此外，在下溢后的(N+2)个IWDTCLK周期内，该标志的清除将被忽略。N在IWDTCKS[3:0]位中指定如下：

IWDTTOPS[1:0] bits (IWDT Timeout Period Select)

The IWDTTOPS[1:0] bits select the timeout period, that is, the period until the down-counter underflows, from 128, 512, 1024, or 2048 cycles, taking the divided clock specified in the IWDTCKS[3:0] bits as 1 cycle.

After the down-counter is refreshed, the combination of the IWDTCKS[3:0] and IWDTTOPS[1:0] bits determines the number of IWDTCLK cycles until the counter underflows.

Table 25.2 lists the relationship between the IWDTCKS[3:0] and IWDTTOPS[1:0] bit settings, the timeout period, and the number of IWDTCLK cycles.

IWDTCKS[3:0] bits (IWDT-Dedicated Clock Frequency Division Ratio Select)

The IWDTCKS[3:0] bits specify the division ratio of the clock used for the down-counter. The division ratio can be selected from the IWDT-dedicated clock (IWDTCLK) divided by 1, 16, 32, 64, 128, and 256. Combined with the IWDTTOPS[1:0] bit setting, the IWDT can be configured to a count period between 128 and 524,288 IWDTCLK cycles.

- When OFS0.IWDTCKS[3:0] = 0x5, N = 256.

IWDTTOPS[1:0]位（IWDT超时周期选择）

IWDTTOPS[1:0]位选择超时周期，即从128、512、1024或2048个周期到递减计数器下溢的周期，采用IWDTCKS[3:0]位中指定的分频时钟作为1个周期。

向下计数器刷新后，IWDTCKS[3:0]和IWDTTOPS[1:0]位的组合决定了在计数器下溢之前的IWDTCLK周期数。

表25.2列出了IWDTCKS[3:0]和IWDTTOPS[1:0]位设置、超时周期和IWDTCLK周期数之间的关系。

IWDTCKS[3:0]位（IWDT专用时钟分频比选择）

IWDTCKS[3:0]位指定用于递减计数器的时钟分频比。分频比可以从IWDT专用时钟(IWDTCLK)除以1、16、32、64、128和256中选择。结合IWDTTOPS[1:0]位设置，可以将IWDT配置为计数128到524 288个IWDTCLK周期之间的周期。

IWDTRPES[1:0] bits (IWDT Window End Position Select)

The IWDTRPES[1:0] bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. Set the window end position to a value less than the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.

IWDTRPSS[1:0] bits (IWDT Window Start Position Select)

The IWDTRPSS[1:0] bits specify the window start position that indicates the refresh-permitted period. 100%, 75%, 50%, or 25% of the timeout period can be selected for the window start position. Set the window start position to a value greater than the window end position. If the window start position is less than or equal to the window end position, the window end position is set to 0%.

Table 25.3 lists the counter values for the window start and end positions, and Figure 25.2 shows the refresh-permitted period set in the IWDTRPSS[1:0], IWDTRPES[1:0], and IWDTTOPS[1:0] bits.

IWDTSTPCTL bit (IWDT Stop Control)

The IWDTSTPCTL bit selects whether to stop counting on transition to Sleep, Snooze, or Software Standby mode.

25.3 Operation

25.3.1 Auto Start Mode

When the IWDT Start Mode Select bit (OFS0.IWDTSTRT) in the Option Function Select Register 0 is 0, auto start mode is selected, otherwise the IWDT is disabled.

Within the reset state, the setting values for the following in the Option Function Select Register 0 (OFS0) are set in the IWDT registers:

- Clock division ratio (OFS0.IWDTCKS[3:0])
- Window start and end positions (OFS0.IWDTRPSS[1:0], OFS0.IWDTRPES[1:0])
- Timeout period (OFS0.IWDTTOPS[1:0])
- Reset output or interrupt request (OFS0.IWDTRSTIRQS)

When the reset state is released, the counter automatically starts counting down from the value selected in the IWDT Timeout Period Select bits (OFS0.IWDTTOPS[1:0]).

After that, as long as the program continues normal operation and the counter is refreshed within the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and down-counting continues. The IWDT does not output the reset signal as long as this procedure continues. However, if the counter underflows because the program crashed or because a refresh error occurred when an attempt is made to refresh outside the refresh-permitted period, the IWDT asserts the reset signal or non-maskable interrupt request/interrupt request (IWDT_NMIUNDF).

After the reset signal or non-maskable interrupt request/interrupt request is generated, the counter reloads the timeout period after counting for 1 cycle, the value of the timeout period is set in the down-counter and counting starts. The reset output or interrupt request output can be selected with the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS). Non-maskable interrupt request or interrupt request can be selected with the IWDT Underflow/Refresh Error Interrupt Enable bit (NMIER.IWDTEN).

Figure 25.3 shows an example of operation under the following conditions:

- Auto start mode (OFS0.IWDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.IWDTRSTIRQS = 0)
- The window start position is 75% (OFS0.IWDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.IWDTRPES[1:0] = 10b).

IWDTSTPCTL位（IWDT停止控制）

IWDTSTPCTL位选择在转换到休眠、贪睡或软件待机模式时是否停止计数。

25.3 Operation

25.3.1 自动启动模式

当IWDT启动模式选择位置（OFS0.IWDTSTRT）中的选项函数选择寄存器0为0时，选择了自动启动模式，否则IWDT将被禁用。

在复位状态下，选项功能选择寄存器0(OFS0)中的以下设置值在
IWDT registers:

- ●时钟分频比（OFS0.IWDTCKS[3:0]）
- ●窗口开始和结束位置（OFS0.IWDTRPSS[1:0]、OFS0.IWDTRPES[1:0]）
- ●超时周期（OFS0.IWDTOPS[1:0]）
- ●复位输出或中断请求（OFS0.IWDTRSTIRQS）

解除复位状态后，计数器自动从IWDT中选择的值开始倒计时
超时周期选择位(OFS0.IWDTOPS[1:0])。

之后，只要程序继续正常运行，并且在允许刷新的时间内刷新计数器，每次刷新计数器并继续递减计数时，计数器中的值都会被复位。只要此过程继续，IWDT就不会输出复位信号。但是，如果由于程序崩溃或在刷新允许周期之外尝试刷新时发生刷新错误而导致计数器下溢，则IWDT将置位复位信号或不可屏蔽中断请求中断请求(IWDT_NMIUNDF)。

在产生复位信号或不可屏蔽中断请求中断请求后，计数器在计数1个周期后重新加载超时周期，超时周期的值设置在递减计数器中并开始计数。可以通过IWDT复位中断请求选择位(OFS0.IWDTRSTIRQS)选择复位输出或中断请求输出。可以使用IWDT下溢刷新错误中断 允许位(NMIER.IWDTEN)选择不可屏蔽的中断请求或中断请求。

图25.3显示了以下条件下的操作示例：

- ●自动启动模式（OFS0.IWDTSTRT=0）
- ●使能不可屏蔽中断请求输出（OFS0.IWDTRSTIRQS=0）
- ●窗口起始位置为75%(OFS0.IWDTRPSS[1:0]=10b)
- ●窗口结束位置为25%(OFS0.IWDTRPES[1:0]=10b)。

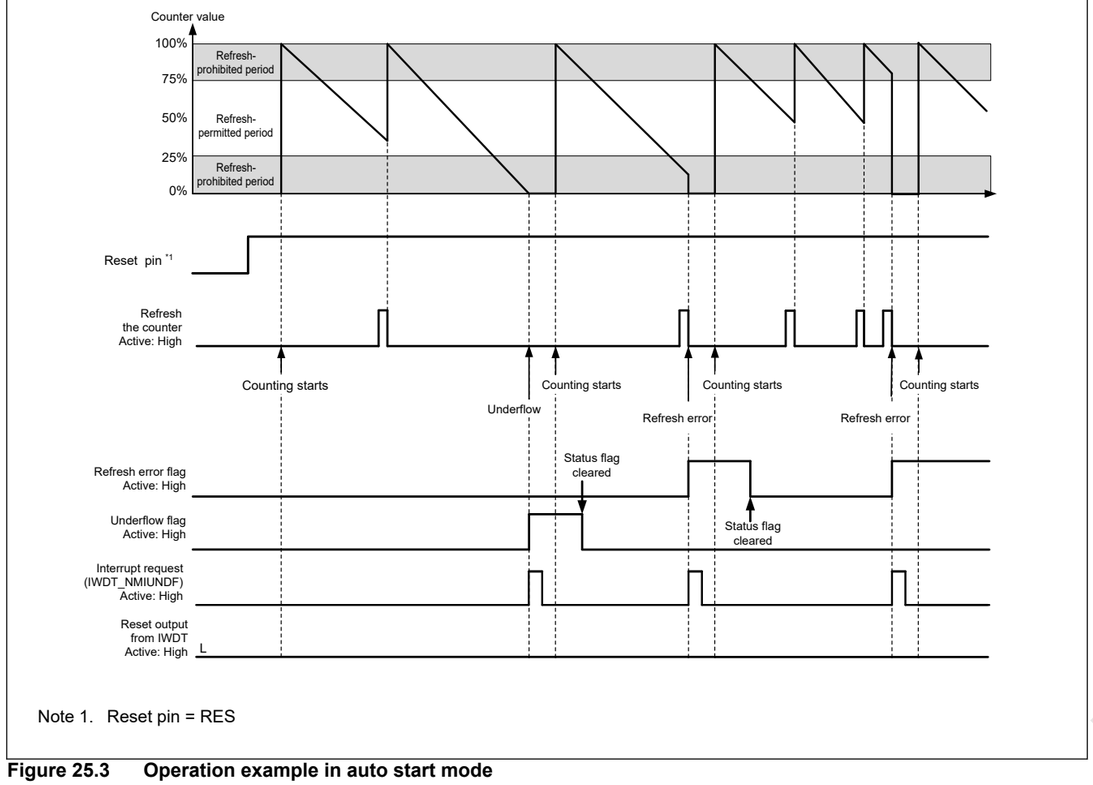

Figure 25.3 Operation example in auto start mode

25.3.2 Refresh Operation

The down-counter is refreshed and operation starts (counting is started by refreshing) by writing the values 0x00 and 0xFF to the IWDT Refresh Register (IWDTRR). If a value other than 0xFF is written after 0x00, the down-counter is not refreshed. If an invalid value is written, correct refreshing resumes on a write of 0x00 and 0xFF to the IWDTRR.

When writes are made in the order of 0x00 (first time) → 0x00 (second time), and if 0xFF is written after that, the writing order 0x00 → 0xFF is satisfied. Writing 0x00 ((n - 1)th time) →0x00 (nth time) → 0xFF is valid, and the refresh is performed correctly. Even when the first value written before 0x00 is not 0x00, correct refreshing is performed as long as the operation contains the write sequence of 0x00 → 0xFF.

Correct refreshing is also performed regardless of whether a register other than IWDTRR is accessed or IWDTRR is read between writing 0x00 and writing 0xFF to IWDTRR. Writes to refresh the counter must be made within the refresh-permitted period. Whether writing is done within the refresh-permitted period is determined when 0xFF is written. For this reason, correct refreshing is performed even when 0x00 is written outside the refresh-permitted period.

[Example write sequences that are valid to refresh the counter]

- 0x00 → 0xFF
- 0x00 ((n - 1)th time) → 0x00 (nth time) → 0xFF
- 0x00 → access to another register or read from IWDTRR → 0xFF.

[Example write sequences that are not valid to refresh the counter]

- 0x23 (a value other than 0x00) → 0xFF
- 0x00 → 0x54 (a value other than 0xFF)

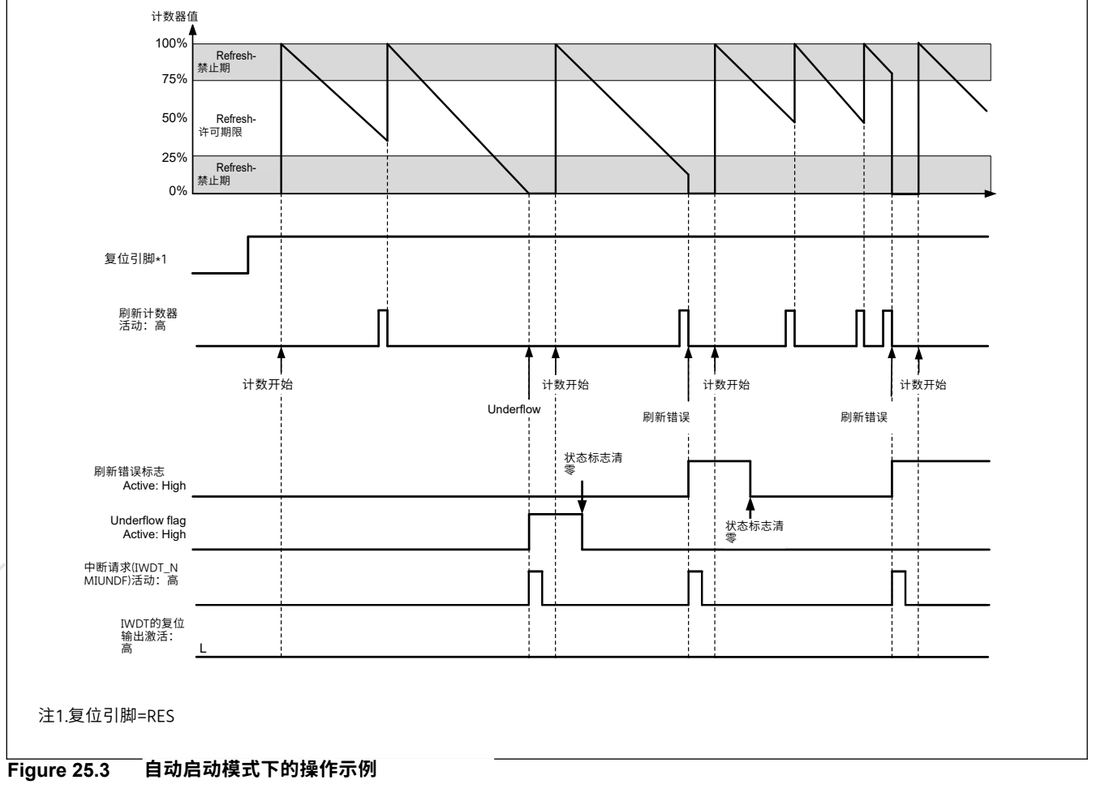

Figure 25.3 自动启动模式下的操作示例

25.3.2 刷新操作

通过将值0x00和0xFF写入IWDT刷新寄存器(IWDTRR)来刷新递减计数器并开始操作（通过刷新开始计数）。如果在0x00之后写入0xFF以外的值，则不刷新递减计数器。如果写入无效值，则在向IWDTRR写入0x00和0xFF时会恢复正确刷新。

当以0x00（第一次）→0x00（第二次）的顺序进行写入时，如果在此之后写入0xFF，则满足写入顺序0x00→0xFF。写入0x00((n1)次)→0x00(n次)→0xFF有效，刷新正确。即使在0x00之前写入的第一个值不是0x00时，只要操作包含0x00→0xFF的写入序列，就会执行正确的刷新。

无论在写入0x00和写入0xFF到IWDTRR之间是否访问IWDTRR以外的寄存器或读取IWDTRR，也会执行正确刷新。刷新计数器的写入必须在允许刷新的期限内进行。在写入0xFF时确定是否在可刷新周期内完成写入。因此，即使在可刷新期间外写入0x00，也会执行正确的刷新。

[对刷新计数器有效的示例写入序列]

- 0x00 → 0xFF
- 0x00 ((n - 1)th time) → 0x00 (nth time) → 0xFF
- ●0x00→访问另一个寄存器或从IWDTRR读取→0xFF。

[对刷新计数器无效的示例写入序列]

- ●0x23（0x00以外的值）→0xFF
- ●0x00→0x54（0xFF以外的值）

- 0x00 → 0xAA (0x00 and a value other than 0xFF) → 0xFF.

After 0xFF is written to the IWDTRR register, refreshing the counter requires up to 4 cycles of the signal for counting (the IWDT-Dedicated Clock Frequency Division Ratio Select bits (OFS0.IWDTCKS[3:0]) to determine how many cycles of the IWDT-dedicated clock (IWDTCLK) make up 1 cycle for counting. To meet this requirement, writing 0xFF to the IWDTRR must be completed 4 count cycles before the end of the refresh-permitted period or a down-counter underflow. The value of the counter can be checked with the counter bits (IWDTSR.CNTVAL[13:0]).

[Example refreshing timings]

- When the window start position is set to 0x1FFF, even if 0x00 is written to IWDTRR before 0x1FFF is reached at (0x2002, for example), refreshing occurs if 0xFF is written to IWDTRR after the value of the IWDTSR.CNTVAL[13:0] bits reaches 0x1FFF
- When the window end position is set to 0x1FFF, refreshing occurs if 0x2003 (4 count cycles before 0x1FFF) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 0x00 → 0xFF to IWDTRR
- When the refresh-permitted period continues until count 0x0000, refreshing can be performed immediately before an underflow. In this case, if 0x0003 (4 count cycles before an underflow) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 0x00 → 0xFF to IWDTRR, no underflow occurs and refreshing is performed.

Figure 25.4 shows the IWDT refresh-operation waveforms when PCLKB > IWDTCLK and the clock division ratio is IWDTCLK.

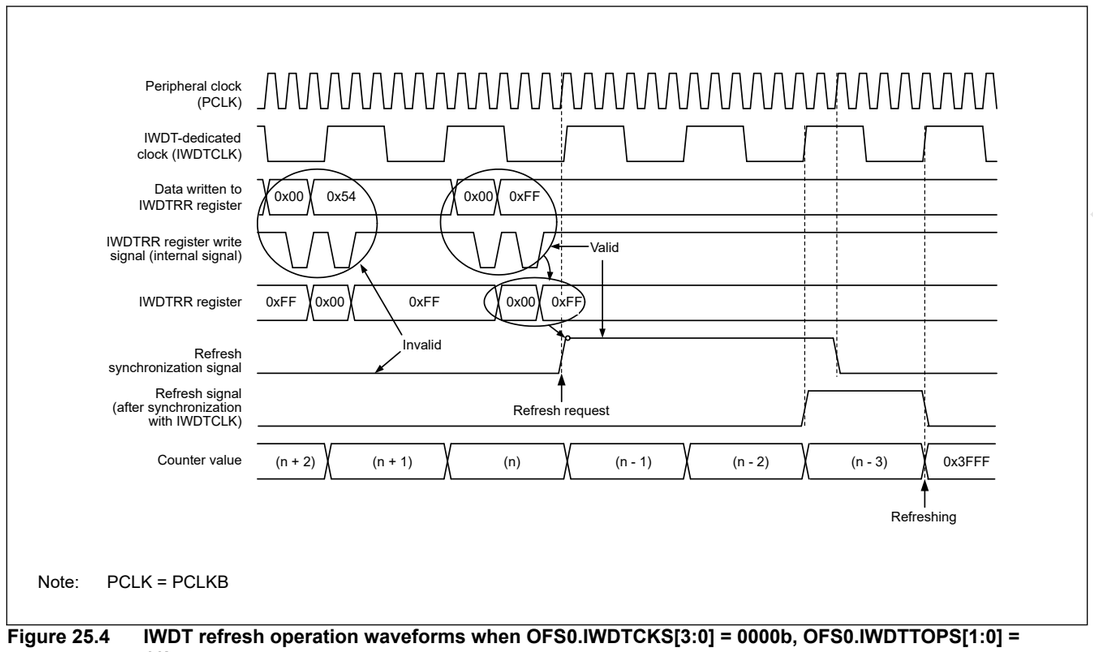

Figure 25.4 IWDT refresh operation waveforms when OFS0.IWDTCKS[3:0] = 0000b, OFS0.IWDTTOPS[1:0] = 11b

25.3.3 Status Flags

The refresh error (IWDTSR.REFEF) and underflow (IWDTSR.UNDFF) flags retain the source of the interrupt request from the IWDT. Therefore, after a release from the interrupt request generation, read the IWDTSR.REFEF and UNDFF flags to check for the interrupt source. For each flag, writing 0 clears the bit and writing 1 has no effect.

Leaving the status flags unchanged does not affect operation. If the flags are not cleared at the time of the next interrupt request from the IWDT, the earlier interrupt source is cleared and the new interrupt source is written. For the time period between when 0 is written in each flag and when its value is reflected, see section 25.2.2. IWDTSR : IWDT Status Register.

●0x00→0xAA（0x00和0xFF以外的值）→0xFF。

将0xFF写入IWDTRR寄存器后，刷新计数器需要最多4个周期的信号计数（IWDT专用时钟分频比选择位（OFS0.IWDTCKS[3:0]）来确定IWDT专用时钟(IWDTCLK)占1个周期用于计数。为满足此要求，必须在刷新允许周期结束或递减计数器下溢之前4个计数周期完成向IWDTRR写入0xFF。可以使用计数器位(IWDTSR.CNTVAL[13:0])检查计数器。

[Example refreshing timings]

●当窗口起始位置设置为0x1FFF时，即使在到达0x1FFF之前将0x00写入IWDTRR（例如0x2002），如果在IWDTSR.CNTVAL[13:0]位的值达到0x1FFF后将0xFF写入IWDTRR，则会发生刷新

●当窗口结束位置设置为0x1FFF时，如果在将0x00→0xFF写入IWDTRR后立即从IWDTSR.CNTVAL[13:0]位读取0x2003（0x1FFF之前的4个计数周期）或更大的值，则会发生刷新

●当刷新允许周期持续到计数0x0000时，可以在下溢之前立即执行刷新。在这种情况下，如果在将0x00→0xFF写入IWDTRR后立即从IWDTSR.CNTVAL[13:0]位读取0x0003（下溢前的4个计数周期）或更大的值，则不会发生下溢并执行刷新。

IWDTCLK.

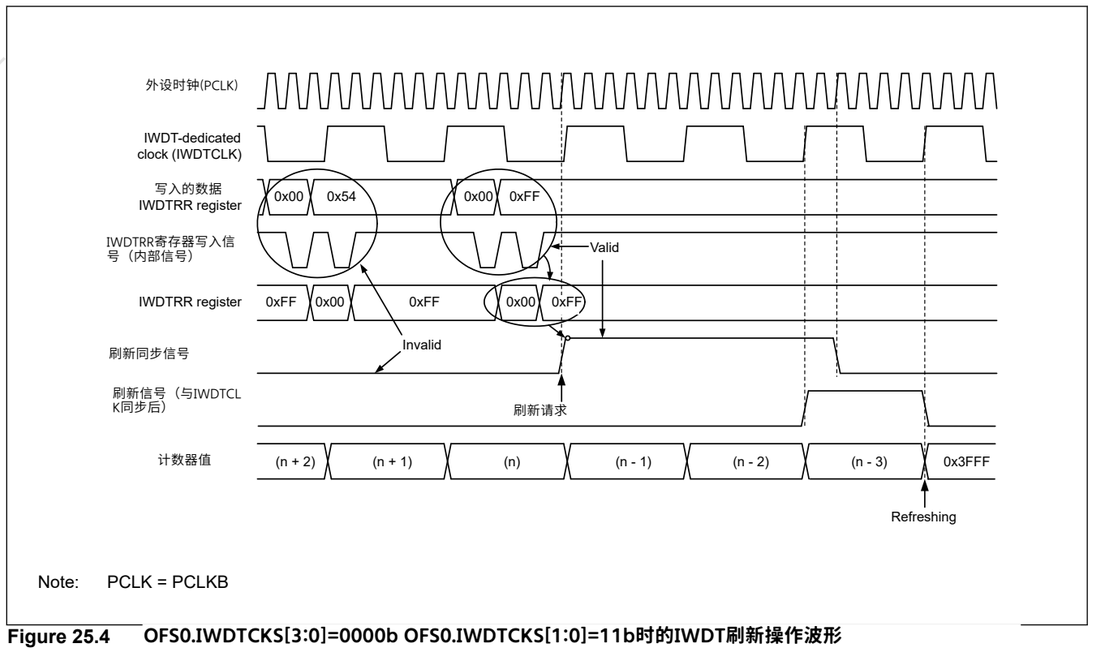

Figure 25.4 OFS0.IWDTCKS[3:0]=0000b OFS0.IWDTCKS[1:0]=11b时的IWDT刷新操作波形

25.3.3 状态标志

刷新错误(IWDTSR.REFEF)和下溢(IWDTSR.UNDFF)标志保留来自IWDT的中断请求源。因此，在中断请求生成释放后，读取IWDTSR.REFEF和UNDFF标志以检查中断源。对于每个标志，写入0清除该位，写入1无效。

保持状态标志不变不会影响操作。如果在IWDT发出下一个中断请求时未清除标志，则清除较早的中断源并写入新的中断源。关于从各标志写入0到反映其值的时间段，请参阅第25.2.2节。IWDTSR：IWDT状态寄存器。

25.3.4 Reset Output

When the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 1, a reset signal is output when an underflow in the counter or a refresh error occurs. Counting down automatically starts after the reset output.

25.3.5 Interrupt Sources

When the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 0, an interrupt (IWDT_NMIUNDF) signal occurs when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or an interrupt. For details, see section 13, Interrupt Controller Unit (ICU).

Table 25.4 IWDT interrupt source

Name	Interrupt source	Interrupt to CPU	Start DMAC or DTC
IWDT_NMIUNDF	• Down-counter underflow • Refresh error	Possible	Not possible

25.3.6 Reading the Down-Counter Value

As the counter is a IWDT-dedicated clock (IWDTCLK), the counter value cannot be read directly. The IWDT synchronizes the counter value with the peripheral clock (PCLKB) and stores it in the down-counter value bits (IWDTSR.CNTVAL[13:0]) of the IWDT Status Register. Check these bits to obtain the counter value indirectly.

Reading the counter value requires multiple PCLKB clock cycles (up to 4 clock cycles), and the read counter value might differ from the actual counter value by a value of one count.

Figure 25.5 shows the processing for reading the IWDT counter value when PCLKB > IWDTCLK and the clock division ratio is IWDTCLK.

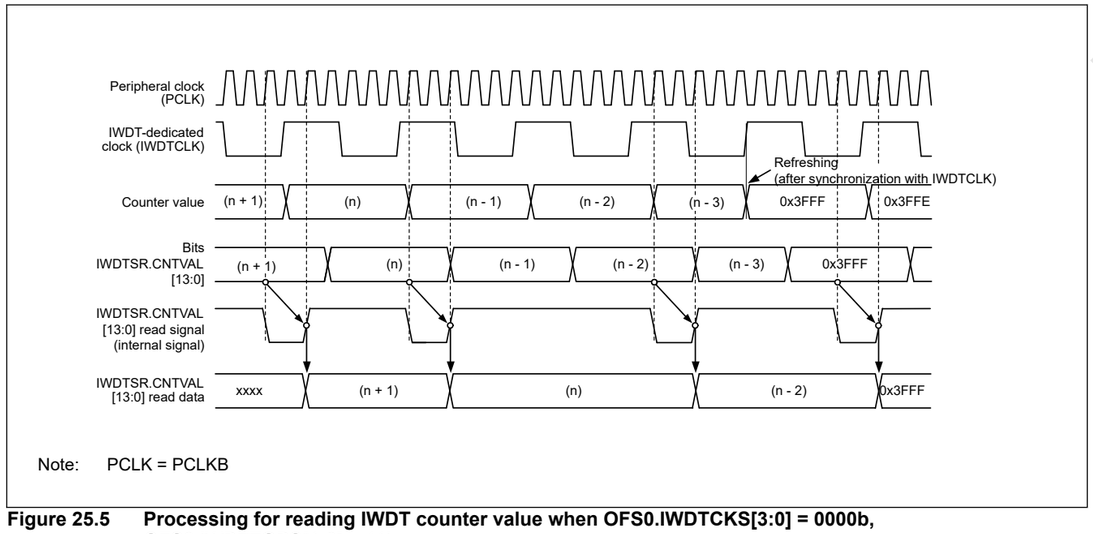

Figure 25.5 Processing for reading IWDT counter value when OFS0.IWDTCKS[3:0] = 0000b, OFS0.IWDTTOPS[1:0] = 11b

25.4 Output to the Event Link Controller (ELC)

The IWDT is capable of link operation for a specified module when the interrupt request signal is used as an event signal by the event link controller (ELC). The event signal is output by the counter underflow or refresh error.

An event signal is output regardless of the setting of the OFS0.IWDTRSTIRQS bit. An event signal can also be output at generation of the next interrupt source while the Refresh Error flag (IWDTSR.REFEF) or Underflow flag (IWDTSR.UNDFF) is 1. For details, see section 18, Event Link Controller (ELC).

25.3.4 复位输出

当IWDT重置中断请求选择位置（OFS0.IWDTRSTIRQS）中的选项函数选择寄存器0（OFS0）的位置为1时，当计数器中的下流或刷新错误发生时，将输出重置信号。复位输出后自动开始倒计时。

25.3.5 中断源

当IWDT重置中断请求选择位置（OFS0.IWDTRSTIRQS）中的选项函数选择寄存器0（OFS0）设置为0时，当计数器中的下流或刷新错误发生时，会发生中断（IWDT_NMIUNDF）信号。此中断可用作不可屏蔽中断或中断。有关详细信息，请参阅第13节，中断控制器单元(ICU)。

Table 25.4 IWDT中断源

Name	中断源	对CPU的中断	启动DMAC或DTC
IWDT_NMIUNDF	• Down-counter underflow • 刷新错误	Possible	不可能

25.3.6 读取递减计数器值

由于计数器是IWDT专用时钟(IWDTCLK)，因此无法直接读取计数器值。IWDT将计数器值与外设时钟(PCLKB)同步，并将其存储在IWDT状态寄存器的递减计数器值位(IWDTSR.CNTVAL[13:0])中。检查这些位以间接获得计数器值。

读取计数器值需要多个PCLKB时钟周期（最多4个时钟周期），读取的计数器值可能与实际计数器值相差一个计数值。

图25.5显示了当PCLKB>IWDTCLK且时钟分频比为IWDTCLK时读取IWDT计数器值的处理。

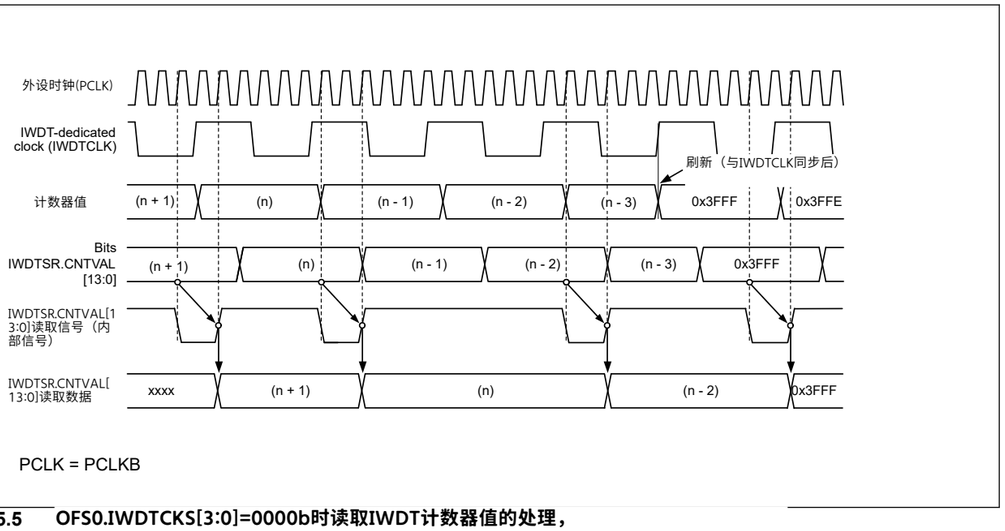

Figure 25.5 OFS0.IWDTCKS[3:0]=0000b时读取IWDT计数器值的处理，OFS0.IWDTTOPS[1:0] = 11b

25.4 输出到事件链接控制器(ELC)

当中断请求信号被事件链接控制器(ELC)用作事件信号时，IWDT能够对指定模块进行链接操作。事件信号由计数器下溢或刷新错误输出。

无论OFS0.IWDTRSTIRQS位的设置如何，都会输出事件信号。当刷新错误标志(IWDTSR.REFEF)或下溢标志(IWDTSR.UNDFF)为1时，也可以在生成下一个中断源时输出事件信号。有关详细信息，请参阅第18节，事件链接控制器(ELC)。

25.5 Usage Notes

25.5.1 Refresh Operations

While configuring the refresh time, consider variations in the range of errors given the accuracy of PCLKB and IWDTCLK. Set values that ensure refreshing is possible.

25.5.2 Clock Division Ratio Setting

Satisfy the frequency of the peripheral module clock (PCLKB) ≥ 4 × (the frequency of the count clock source after division).

25.5.3 Constraints on the ICU Event Link Setting Register n (IELSRn) Setting

Setting 0x52 to ICU Event Link Setting Register n (IELSRn.IELS[8:0]) is prohibited when enabling the IWDT reset assertion (OFS0.IWDTRSTIRQS = 0) or when enabling event link operation (ELSRn.ELS[8:0] = 0x52).

25.5 使用说明

25.5.1 刷新操作

在配置刷新时间时，请考虑给定PCLKB和IWDTCLK精度的误差范围的变化。
设置确保可以刷新的值。

25.5.2 时钟分频比设置

满足外设模块时钟（PCLKB）的频率≥4×（分频后的计数时钟源的频率）。

25.5.3 ICU事件链接设置寄存器n(IELSRn)设置的约束

当启用IWDT复位断言(OFS0.IWDTRSTIRQS=0)或启用事件链接操作(ELSRn.ELS[8:0]=0x52）。

The ECMR register controls ETHERC operation. Except for the TE and RE bits, set the bits in this register during initialization after a reset. When rewriting this register outside the initialization process, set the EDMAC0.EDMR.SWR bit to 1 to reset the EDMAC and ETHERC, then set this register again.

PRM bit (Promiscuous Mode)

When the PRM bit is set to 1, the ETHERC operates in promiscuous mode, where all Ethernet frames are received. In promiscuous mode, the ETHERC receives all valid frames regardless of whether the address matches the destination or broadcast address, and regardless of the multicast bit setting.

RTM bit (Bit Rate)

The RTM bit sets the bit rate when the RMII is selected.

ILB bit (Internal Loopback Mode)

When the ILB bit is set to 1, transmit frames can be looped back in the MCU. Set the DM bit to 1 (full-duplex mode) to perform a loopback test.

TE bit (Transmission Enable)

When the TE bit is set to 1, the ETHERC transmit function is enabled. When the TE bit is set to 0, the transmit function is disabled after the frame being processed is completely transmitted.

RE bit (Reception Enable)

When the RE bit is set to 1, the ETHERC receive function is enabled. When the RE bit is set to 0, the receive function is disabled after the frame being processed is completely received.

PRCEF bit (CRC Error Frame Receive Mode)

When the PRCEF bit is set to 1, the EDMAC is not notified that a CRC error has occurred even when the error is detected in a receive frame. Accordingly, the EDMAC0.EESR.CERF flag and RFS0 bit in receive descriptor 0 (RD0) do not set to 1.

ZPF bit (0 Time PAUSE Frame Enable)

When the ZPF bit is 1, a PAUSE frame with a pause_time parameter of 0 is transmitted when a PAUSE frame transmit request is canceled before the PAUSE time of the previously transmitted PAUSE frame has elapsed. After the PAUSE frame containing the pause_time parameter of 0 is received, the ETHERC is ready for transmission.

When the ZPF bit is 0, even if the PAUSE frame transmit request from the receive FIFO is canceled, the next PAUSE frame is not transmitted until the PAUSE time of the previously transmitted PAUSE frame has elapsed. When a PAUSE frame containing a pause_time parameter of 0 is received, it is discarded.

Bit	Symbol	Function	R/W
18	PFR	PAUSE帧接收模式 0：不向EDMAC传输PAUSE帧1：向EDMAC传输PAUSE帧。	R/W
19	ZPF	0时间PAUSE帧启用 0：不使用包含pause_time参数为0的PAUSE帧1：使用包含pause_time参数为0的PAUSE帧。	R/W
20	TPC	PAUSE帧发送 0：即使在PAUSE期间也发送PAUSE帧1：在PAUSE期间不发送PAUSE帧。	R/W
31:21	—	这些位被读取为0。写入值应为0。	R/W

ECMR寄存器控制ETHERC操作。除TE和RE位外，在复位后初始化期间设置此寄存器中的位。在初始化过程之外重写该寄存器时，将EDMAC0.EDMR.SWR位设置为1以复位EDMAC和ETHERC，然后再次设置该寄存器。

PRM bit (Promiscuous Mode)

当PRM位设置为1时，ETHERC以混杂模式运行，其中接收所有以太网帧。在混杂模式下，ETHERC接收所有有效帧，无论地址是否匹配目标地址或广播地址，也无论多播位设置如何。

RTM bit (Bit Rate)

选择RMII时，RTM位设置了比特率。

ILB bit (Internal Loopback Mode)

当ILB位设置为1时，发送帧可以在MCU中环回。将DM位设置为1（全双工模式）以执行环回测试。

TE位（传输使能）

当TE位设置为1时，使能ETHERC发送功能。当TE位设置为0时，正在处理的帧发送完毕后，发送功能被禁用。

RE位（接收使能）

当RE位设置为1时，使能ETHERC接收功能。当RE位设置为0时，接收功能在正在处理的帧被完全接收后被禁用。

PRCEF位（CRC错误帧接收模式）

当PRCEF位设置为1时，即使在接收帧中检测到错误，也不通知EDMAC发生CRC错误。因此，接收描述符0(RD0)中的EDMAC0.EESR.CERF标志和RFS0位不会设置为1。

ZPF位（0时间暂停帧启用）

当ZPF位为1时，如果在先前发送的PAUSE帧的PAUSE时间过去之前取消PAUSE帧发送请求，则发送一个pause_time参数为0的PAUSE帧。在接收到包含pause_time参数为0的PAUSE帧后，ETHERC准备好传输。

当ZPF位为0时，即使来自接收FIFO的PAUSE帧发送请求被取消，直到前一个发送的PAUSE帧的PAUSE时间过去后，下一个PAUSE帧才会发送。当接收到包含pause_time参数为0的PAUSE帧时，将其丢弃。

11:0	RFL[11:0]	Receive Frame Maximum Length The set value becomes the maximum frame length. The minimum value that can be set is 1,518 bytes, and the maximum value that can be set is 2,048 bytes. Values less than 1,518 bytes are regarded as 1,518 bytes, and values larger than 2,048 bytes are regarded as 2,048 bytes.	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The RFLR register specifies the maximum frame length that can be received by the MCU. Set the length in bytes. Do not rewrite this register while the ECMR.RE bit is 1 (receive function enabled).

RFL[11:0] bits (Receive Frame Maximum Length)

The RFL[11:0] bits set the frame length to be checked. The frame length is the number of bytes in a field, extending from the destination address to the frame check sequence [FCS] of the received frame. When this length exceeds the RFL[11:0] bit value, the EDMAC is notified of a frame-too-long error, and the excess data is discarded.

RFL[11:0]位（接收帧最大长度）

RFL[11:0]位设置要检查的帧长度。帧长度是一个字段中的字节数，从目标地址延伸到接收帧的帧校验序列[FCS]。当此长度超过RFL[11:0]位值时，EDMAC会收到帧太长错误的通知，并丢弃多余的数据。

Note 1. Write 1 to clear the flag.

The ECSR register indicates the status of the ETHERC. When any flag in the ECSR register is set to 1 while the associated bit in the ECSIPR register is 1 (interrupt enabled), the EDMAC0.EESR.ECI flag is set to 1.

ICD flag (False Carrier Detect Flag)

The ICD flag indicates that the PHY-LSI has detected a false carrier on the line. The flag is set to 1 when a receive error signal shown in Figure 26.11 is received from the PHY-LSI. The information might not be correct when signals input from the PHY-LSI change faster than software recognizes the change. Check the timing of the PHY-LSI.

LCHNG flag (Link Signal Change Flag)

The LCHNG flag indicates that the ET0_LINKSTA signal input from the PHY-LSI has changed from high to low, or from low to high. Check the PSR.LMON flag for the current link status. See section 26.5.1. Preventing the LCHNG Flag from Erroneously Setting to 1 for more information.

PSRTO flag (PAUSE Frame Retransmit Over Flag)

The PSRTO flag indicates that the number of retransmissions reached the value set in the TPAUSER register when retransmitting a PAUSE frame while automatic PAUSE frame transmission is enabled.

ICD标志（错误载波检测标志）

ICD标志表示PHY-LSI检测到线路上的错误载波。当从PHY-LSI接收到图26.11所示的接收错误信号时，该标志设置为1。当来自PHY-LSI的信号输入变化快于软件识别变化的速度时，该信息可能不正确。检查PHY-LSI的时序。

LCHNG标志（链路信号变化标志）

LCHNG标志表示从PHY-LSI输入的ET0_LINKSTA信号已由高变为低，或由低变为高。检查当前链接状态的PSR.LMON标志。请参阅第26.5.1节。防止LCHNG标志错误地设置为1以获取更多信息。

26.3 Operation

This section provides an overview of the ETHERC operations. ETHERC supports the flow control compliant with IEEE802.3x, and can transmit and receive PAUSE frames.

26.3.1 Transmission

The ETHERC transmitter assembles the transmit data into a frame and outputs it to the MII or RMII when a transmit request is received from the EDMAC. The frame transmitted through the MII or RMII is transmitted on the line by the PHY-LSI.

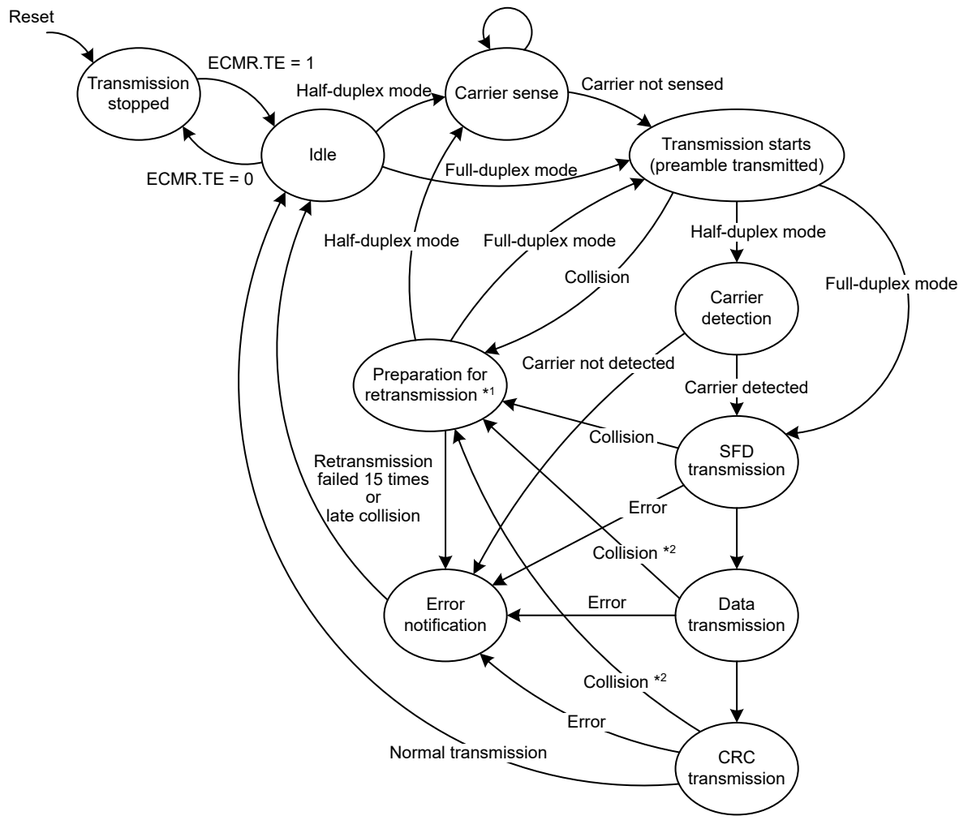
26.3 Operation

本节概述了ETHERC操作。ETHERC支持符合以下标准的流量控制IEEE802.3x，可收发PAUSE帧。

26.3.1 Transmission

ETHERC发送器将发送数据组装成一个帧，并在收到来自EDMAC的发送请求时将其输出到MII或RMII。通过MII或RMII传输的帧由PHYLSI在线路上传输。

图26.4显示了ETHERC发送器的状态转换。



Note 1. Preparation for retransmission after a collision is detected includes transmitting a jam signal and adjusting transmission time intervals using the backoff algorithm.
Note 2. Preparation for retransmission is performed only when a collision is detected within 512 bit times after preamble transmission starts. When a collision is detected after 512 bit times, only a jam signal is transmitted and processing using the backoff algorithm is not performed.

Figure 26.4 ETHERC transmitter state transitions

The ETHERC transmitter state transitions are as follows:

1. When the ECMR.TE bit is set to 1, the ETHERC enters the transmit idle state.
2. When a transmit request is received from the EDMAC, the ETHERC enters the carrier sense state. The ETHERC waits for the interpacket gap and then transmits a preamble to the MII or RMII. When full-duplex mode is selected, carrier sensing is not required, so the ETHERC transmits a preamble immediately after receiving a transmit request from the EDMAC.
3. The ETHERC transmits the Start Frame Delimiter (SFD), transmit data, and CRC sequentially. When the transmission completes successfully, the ETHERC notifies the EDMAC of successful completion, and the EDMAC sets the EDMAC0.EESR.TC flag to 1. When a late collision or loss of carrier is detected during data transmission, the ETHERC stops the transmission and notifies the EDMAC of the error.
4. After the time specified as the interpacket gap has elapsed, the ETHERC enters the idle state and continues the transmission when transmit data remains.

注2.只有在前导码后512比特时间内检测到冲突时，才进行重传准备
传输开始。当在512位时间后检测到冲突时，仅传输阻塞信号，并且不执行使用退避算法的处理。

Figure 26.4 ETHERC发送器状态转换

ETHERC发送器状态转换如下：

1.当ECMR.TE位设置为1时，ETHERC进入发送空闲状态。

2.当收到来自EDMAC的发送请求时，ETHERC进入载波侦听状态。ETHERC等待包间间隙，然后将前同步码发送到MII或RMII。Whenfull-duplexmodeisselected carriersensingisnotrequired sotheETHERCtransmitsapreambleimmediatelyafterreceivingatransmitrequestfromtheEDMAC.

3.ETHERC依次传输起始帧定界符（SFD）、传输数据和CRC。当传输成功完成时，ETHERC通知EDMAC成功完成，EDMAC将EDMAC0.EESR.TC标志设置为1。当在数据传输过程中检测到延迟冲突或载波丢失时，ETHERC停止传输并通知错误的EDMAC。

4.指定的包间间隙时间过去后，ETHERC进入空闲状态，并在传输数据剩余时继续传输。

26.3.2 Reception

The ETHERC receiver separates the frame input from the MII or RMII into the preamble, SFD, receive data, and CRC, and transmits only the receive data (destination address, source address, type/length, data/LLC). Figure 26.5 shows the state transitions of the ETHERC receiver.

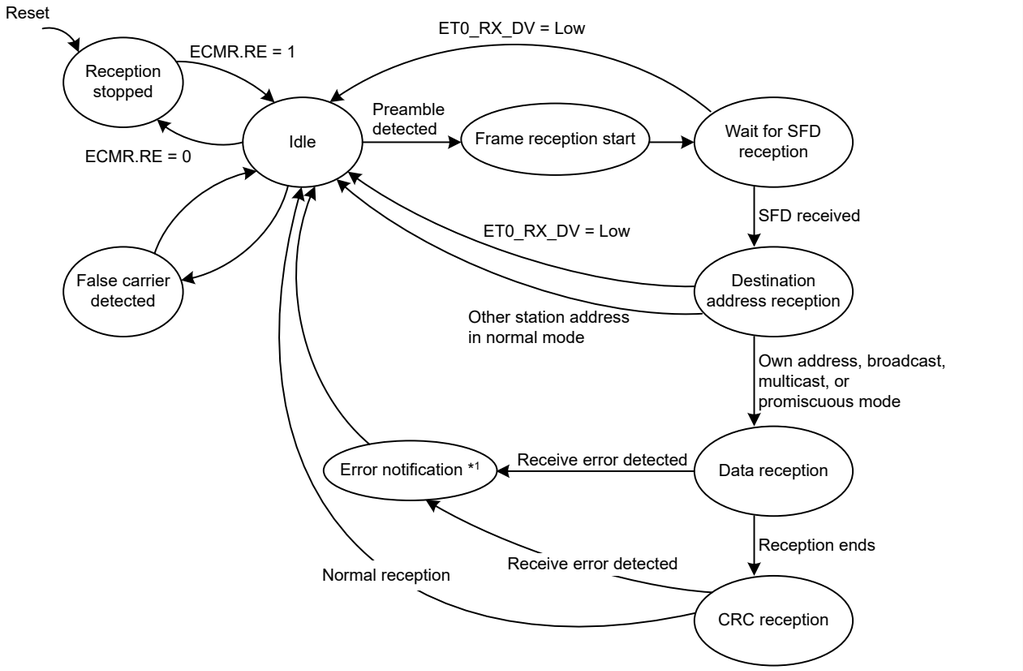

Figure 26.5 ETHERC receiver state transitions

The ETHERC receiver state transitions are as follows:

1. When the ECMR.RE bit is set to 1, the ETHERC enters the receive idle state.
2. When the SFD following the preamble of the receive packet is detected, the ETHERC starts reception. If the received SFD is invalid, the ETHERC discards the frame.
3. In normal mode, the ETHERC starts data reception when the destination address of the receive frame is the address of the MCU or the receive frame is a broadcast or multicast frame. In promiscuous mode, the ETHERC starts data reception regardless of the receive frame type.
4. After receiving data from the MII or RMII, the ETHERC performs a CRC check. The ETHERC notifies the EDMAC of the CRC check result. After the received data is transferred to the receive buffer, the CRC check result is written back to the receive descriptor as status. The result is also reflected in the EDMAC0.EESR.CERF flag.
5. When the ECMR.RE bit is 1 after one frame is received, the ETHERC prepares to receive the next frame.

26.3.2 Reception

ETHERC接收器将从MII或RMII输入的帧分离为前导码、SFD、接收数据和CRC，并仅发送接收数据（目标地址、源地址、类型长度、数据LLC）。图26.5显示了ETHERC接收器的状态转换。

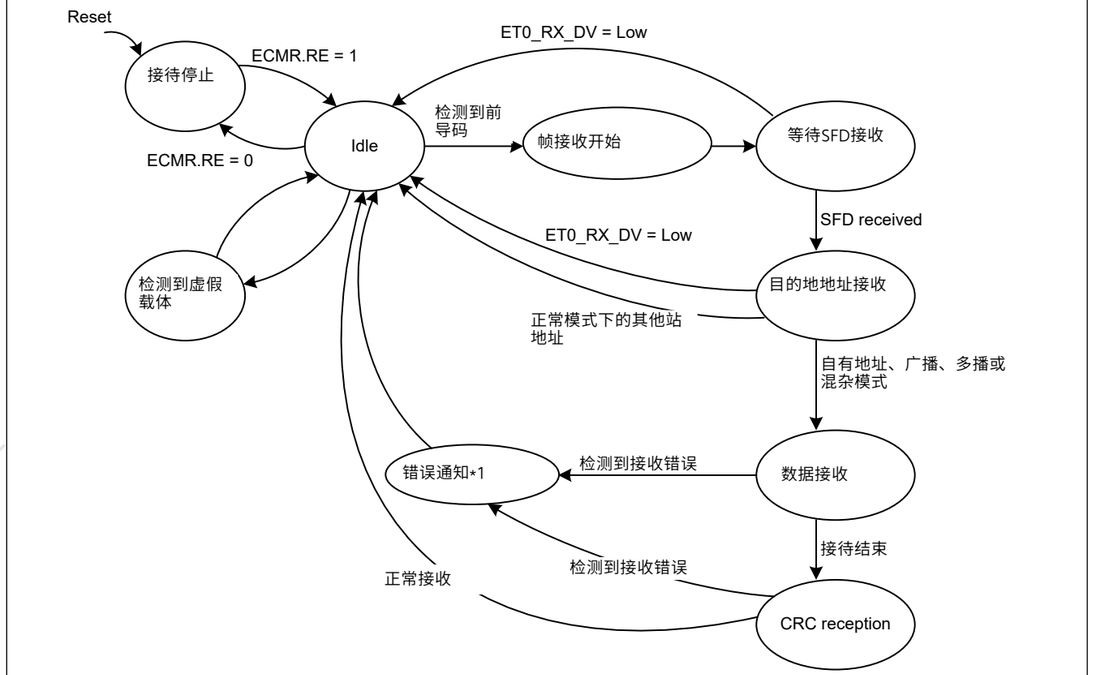

Figure 26.5 ETHERC接收器状态转换

ETHERC接收器状态转换如下：

1.当ECMR.RE位设置为1时，ETHERC进入接收空闲状态。

2.当检测到接收包前导码后面的SFD时，ETHERC开始接收。如果接收到的SFD无效，则ETHERC丢弃该帧。

3.普通模式下，当接收帧的目的地址为MCU地址或接收帧为广播或组播帧时，ETHERC开始数据接收。在混杂模式下，无论接收帧类型如何，ETHERC都会开始数据接收。

4.ETHERC接收到来自MII或RMII的数据后，进行CRC校验。ETHERC将CRC校验结果通知给EDMAC。接收到的数据传送到接收缓冲区后，CRC校验结果作为状态写回接收描述符。结果也反映在EDMAC0.EESR.CERF标志中。

5.当接收到一帧后ECMR.RE位为1时，ETHERC准备接收下一帧。

26.3.4 Accessing the MII and RMII Registers

Use the PIR register to access the MII and RMII registers in the PHY-LSI. Serial data in the MII and RMII management frame format is transmitted and received through the ET0_MDC and ET0_MDIO pins controlled by software.

26.3.4.1 MII and RMII management frame format

Table 26.3 lists the MII and RMII management frame formats.

26.3.4.1 MII和RMII管理帧格式

Note: PRE（前导码）：发送32个连续的1。
ST（帧开始）：发送01b。
OP（操作码）：发送10b读或01b写。
PHYAD（PHY地址）：一个MAC最多可以连接32个PHY-LSI。使用这5位选择PHY-LSI。当PHY LSI地址为1，发送0x01。

REGAD (register address): One register is selected from up to 32 registers in the PHY-LSI. When the register address is 1, send 0x01.
TA (turnaround): Use 2-bit turnaround time to avoid contention between the register address and data during a read operation. Send 10b during a write operation. Release the bus for 1 bit during a read operation (Z is output).

DATA (data): 16-bit data. Sequentially send or receive starting from the MSB.
IDLE (IDLE condition): Wait time before inputting the next MII or RMII management format. Release the bus during a write operation (Z is output). No control is required, because a bus was already released during a read operation.

26.3.4.2 MII and RMII register access procedure

Access to the MII and RMII registers includes writing data in 1-bit units, reading data in 1-bit units, and releasing the bus. Figure 26.15 to Figure 26.18 show examples of the MII and RMII register access timing. The access timing differs with the PHY-LSI type.

REGAD（寄存器地址）：从PHY-LSI的最多32个寄存器中选择一个寄存器。当寄存器地址为1时，发送0x01。TA（周转）：使用2位周转时间来避免读取操作期间寄存器地址和数据之间的争用。在写操作期间发送10b。在读操作期间释放总线1位（Z为输出）。（这表示为Z0，因为在下一个时钟周期从PHY-LSI输出0。）DATA（数据）：16位数据。从MSB开始顺序发送或接收。

IDLE（IDLE条件）：输入下一个MII或RMII管理格式前的等待时间。在写操作期间释放总线（Z为输出）。不需要控制，因为在读取操作期间总线已被释放。

26.3.5 Magic Packet Detection

The ETHERC supports Wake-on-LAN (WOL). WOL is a function to detect a Magic Packet transmitted from a host device or other device, and to wake the MCU from a low power mode such as Sleep. When the ETHERC detects a Magic Packet, it outputs high on the ET0_WOL pin. Write 1 to the EDMAC0.EDMR.SWR bit to drive the ET0_WOL pin low.

Because a Magic Packet is transmitted in broadcast mode, it is received regardless of the destination MAC address selected in the format. The ETHERC outputs high on the ET0_WOL pin only when the destination MAC address matches its own MAC address. See the technical documentation provided by Advanced Micro Devices, Inc., for details on the Magic Packet.

To use WOL in the MCU, use the procedure in the following example:

1. Configure the ICU to disable ETHER_EINT0 interrupt requests.
2. Set the ECMR.MPDE bit to 1 to enable Magic Packet detection, and set the ECMR.RE bit to 1 to enable reception.
3. Set the ECSIPR.MPDIP bit to 1 to enable notification of Magic Packet detection interrupts.
4. Set the EDMAC0.EESIPR.ECIIP bit to 1 to enable ETHERC status register source interrupts.
5. Configure the ICU to enable ETHER_EINT0 interrupt requests.
6. Change the CPU operating mode to Sleep mode or place unused peripherals in the module-stop state, as required.
7. When a Magic Packet is detected, an interrupt request is sent to the CPU. High is output on the ET0_WOL pin to notify peripheral devices that the Magic Packet was detected.

26.3.5.1 Constraints on Magic Packet detection

The ETHERC receives packets, including broadcast packets, even when waiting to receive a Magic Packet. This means that receive data might already be stored in the receive FIFO of the EDMAC when a Magic Packet is detected. Also, flags in the ECSR and EDMAC0.EESR registers might have changed. When returning to normal operation after detecting a Magic Packet, set the EDMAC0.EDMR.SWR bit to 1 to reset the ETHERC and EDMAC.

26.3.6 Adjusting Transmission Efficiency by Changing the IPG

The IPG is a non-transmit period between transmit frames. The ETHERC can change the value of the IPG to increase or decrease transmission efficiency based on the value set in the IPGR register. Typical values are specified in the IEEE802.3 standard. When changing the setting, confirm that all devices in the same network operate normally.

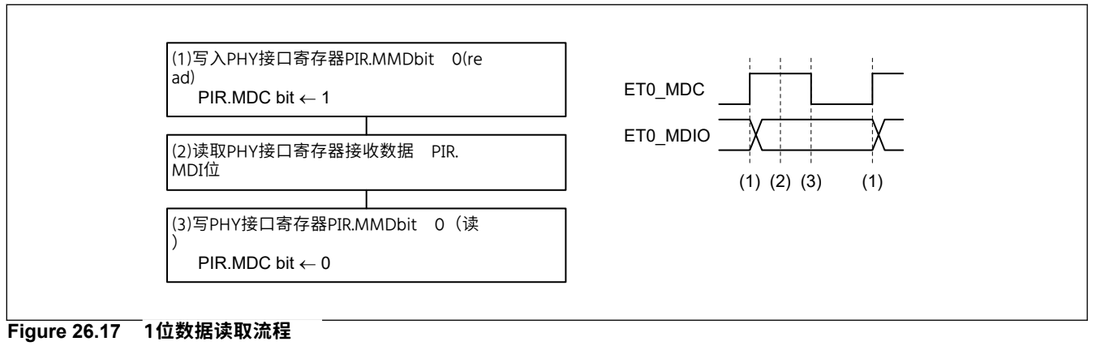

Figure 26.17 1位数据读取流程

Figure 26.18 总线释放流程，IDLE写操作见表26.3

26.3.5 魔术包检测

ETHERC支持网络唤醒(WOL)。WOL是一种检测从主机设备或其他设备发送的魔术包，并将MCU从低功耗模式（例如睡眠）唤醒的功能。当ETHERC检测到一个魔术包时，它在ET0_WOL引脚上输出高电平。将1写入EDMAC0.EDMR.SWR位以将ET0_WOL引脚驱动为低电平。

因为MagicPacket以广播模式传输，所以无论格式中选择的目标MAC地址如何，都会接收到它。仅当目标MAC地址与其自己的MAC地址匹配时，ETHERC才会在ET0_WOL引脚上输出高电平。有关MagicPacket的详细信息，请参阅AdvancedMicroDevices Inc.提供的技术文档。

要在MCU中使用WOL，请使用以下示例中的过程：

1.将ICU配置为禁用ETHER_EINT0中断请求。

2.将ECMR.MPDE位设置为1以启用魔术包检测，并将ECMR.RE位设置为1以启用接收。

3.将ECSIPR.MPDIP位设置为1以启用魔术包检测中断通知。

4.将EDMAC0.EESIPR.ECIIP位设置为1以启用ETHERC状态寄存器源中断。

5.配置ICU以启用ETHER_EINT0中断请求。

6.根据需要将CPU工作模式更改为休眠模式或将未使用的外设置于模块停止状态。

7.当检测到MagicPacket时，向CPU发送中断请求。ET0_WOL引脚上输出高电平以通知外围设备检测到魔术包。

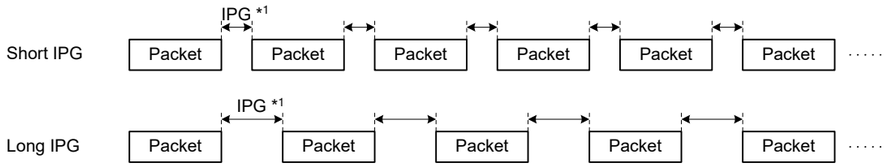
26.3.5.1 魔术包检测的约束

ETHERC接收数据包，包括广播数据包，即使在等待接收魔术数据包时也是如此。这意味着当检测到魔术包时，接收数据可能已经存储在EDMAC的接收FIFO中。此外，ECSR和EDMAC0.EESR寄存器中的标志可能已更改。检测到魔法后恢复正常运行时

数据包，将EDMAC0.EDMR.SWR位设置为1以复位ETHERC和EDMAC。

26.3.6 改变IPG调整传输效率

IPG是传输帧之间的非传输周期。ETHERC可以根据IPGR寄存器中设置的值改变IPG的值来提高或降低传输效率。典型值在IEEE802.3标准中指定。更改设置时，请确认同一网络中的所有设备都正常运行。



Note 1. The IPG may be longer than the set value depending on the condition of the line or system bus.

Figure 26.19 Differences in transmission efficiency based on changes in the IPG

26.3.7 Flow Control

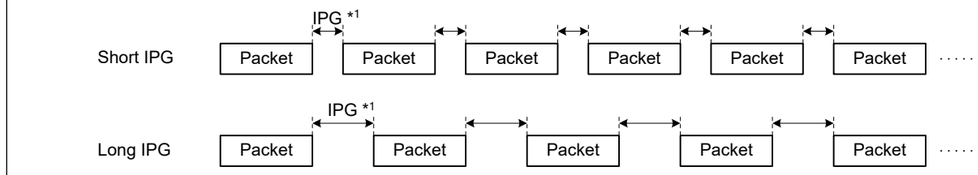
The ETHERC can perform flow control compliant with IEEE802.3x in full-duplex mode, and the receiver and transmitter can be set independently. PAUSE frames can be transmitted automatically or manually.

26.3.7.1 Automatic PAUSE frame transmission

When the ECMR.TXF bit is set to 1, automatic PAUSE frame transmission is enabled. A PAUSE frame is automatically transmitted by a PAUSE frame transmit request from the EDMAC. The APR.AP[15:0] bit value is used for the pause_time parameter of the PAUSE frame.

When a PAUSE frame is transmitted, if the EDMAC is still requesting PAUSE frame transmission after the PAUSE time elapses, a PAUSE frame is transmitted again. The maximum number of PAUSE frame retransmissions can be set in the TPAUSER.TPAUSE[15:0] bits. If the maximum number of retransmissions is reached, subsequent PAUSE frames are not transmitted.

Figure 26.20 shows the procedure for setting up automatic PAUSE frame transmission.



Note 1. 根据线路或系统总线的情况，IPG可能会比设定值长。

Figure 26.19 基于IPG变化的传输效率差异

26.3.7 流量控制

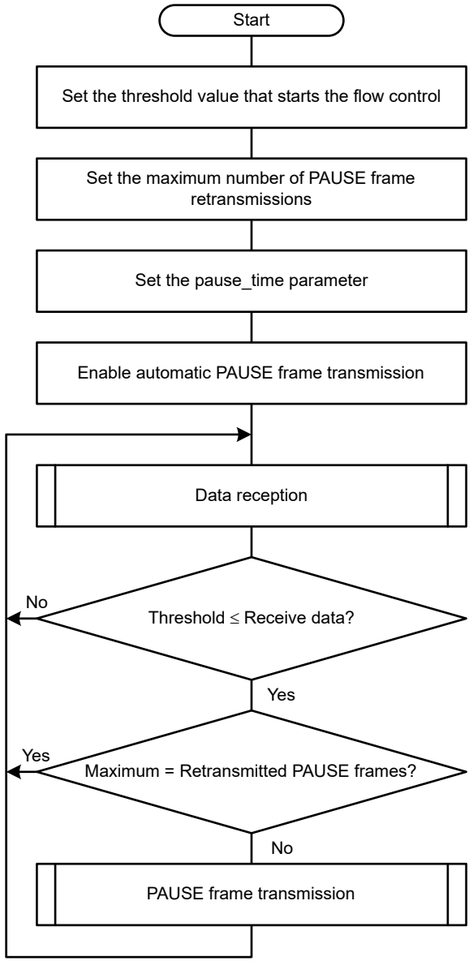
ETHERC可以在全双工模式下进行符合IEEE802.3x的流量控制，接收端和发送端可以独立设置。PAUSE帧可以自动或手动传输。

26.3.7.1 自动暂停帧传输

当ECMR.TXF位设置为1时，启用自动暂停帧传输。PAUSE帧由来自EDMAC的PAUSE帧发送请求自动发送。APR.AP[15:0]位值用于PAUSE帧的pause_time参数。

当发送暂停帧时，如果在暂停时间过去后EDMAC仍在请求暂停帧发送，则再次发送暂停帧。PAUSE帧重传的最大次数可以在TPAUSER.TPAUSE[15:0]位中设置。如果达到最大重传次数，则不传输后续PAUSE帧。

图26.20显示了设置自动暂停帧传输的过程。

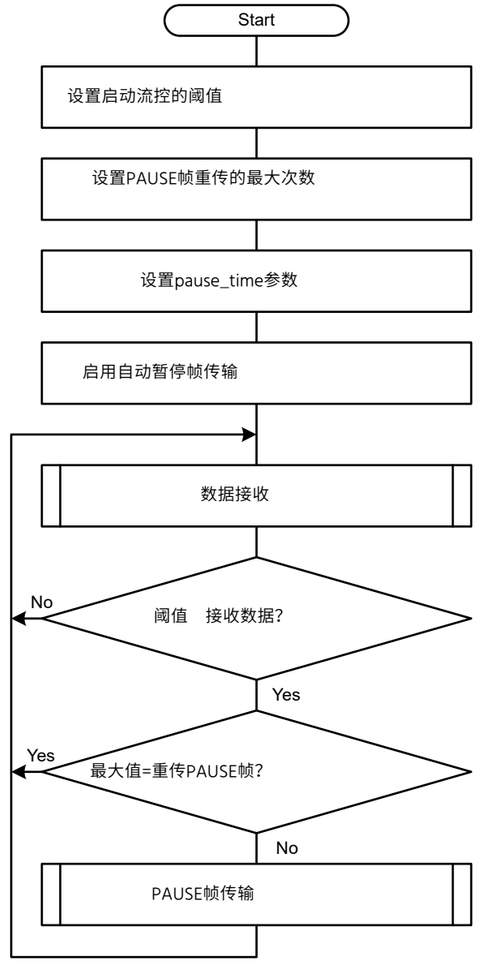


1. Set the threshold value in the EDMAC0.FCFTR.RFDO[2:0] bits or EDMAC0.FCFTR.RFFO[2:0] bits.
2. Set the maximum number of automatic PAUSE frame retransmissions in the TPAUSER.TPAUSE[15:0] bits.
3. Set the pause_time parameter of the automatic PAUSE frame in the APR.AP[15:0] bits.
4. Set the ECMR.TXF bit to 1.
5. Set the ECMR.RE bit to 1.
6. Check whether the amount of receive FIFO data or the number of received frames reached the threshold.
7. Check whether the number of automatic PAUSE frame retransmissions reached the threshold.

Figure 26.20 Example procedure for setting up automatic PAUSE frame transmission

26.3.7.2 Manual PAUSE frame transmission

A PAUSE frame can be manually transmitted at any time. When the software writes the pause_time parameter of the PAUSE frame to the MPR.MP[15:0] bits, the ETHERC transmits a PAUSE frame once. To transmit a PAUSE frame more than once, write to the MPR.MP[15:0] bits for each transmission.



1.在EDMAC0.FCFTR.RFDO[2:0]位或EDMAC0.FCFTR.RFFO[2:0]位中设置阈值。2.在TPAUSER.TPAUSE[15:0]位中设置自动暂停帧重传的最大次数。3.在APR.AP[15:0]位中设置自动PAUSE帧的pause_time参数。4.将ECMR.TXF位设置为1。5.将ECMR.RE位设置为1。6.检查接收FIFO数据量或接收帧数是否达到阈值。7.检查自动暂停帧重传次数是否达到阈值。

Figure 26.20 设置自动暂停帧传输的示例过程

26.3.7.2 手动暂停帧传输

PAUSE帧可以随时手动发送。当软件写入的pause_time参数
PAUSE帧到MPR.MP[15:0]位，ETHERC发送一个PAUSE帧一次。要多次传输PAUSE帧，请在每次传输时写入MPR.MP[15:0]位。

26.3.7.3 PAUSE frame reception

When the ECMR.RXF bit is set to 1, PAUSE frame detection is enabled. After a PAUSE frame is received, the ETHERC completes transmission of the current frame and waits for the PAUSE time of the received PAUSE frame to elapse before it can transmit the next frame. The ETHERC also increments the RFCF.RPAUSE[7:0] bit value.

However, while waiting for the PAUSE time to elapse, if a PAUSE frame that contains a pause_time parameter of 0 is received and the ECMR.ZPF bit is 1, the ETHERC becomes ready to transmit immediately.

26.4 Interrupts

When a flag in the ECSR register sets to 1 and the associated bit in the ECSIPR register is 1, the ETHERC notifies the EDMAC of the interrupt source status. After receiving the notification, the EDMAC sets the EDMAC0.EESR.ECI flag to 1. When the EDMAC0.EESIPR.ECIIP bit is 1, the EDMAC sends an ETHER_EINT0 interrupt request to the CPU.

For details, see section 27, Ethernet DMA Controller (EDMAC).

26.5 Usage Notes

26.5.1 Preventing the LCHNG Flag from Erroneously Setting to 1

The ECSR.LCHNG flag might set to 1 even when the input level of the ET0_LINKSTA pin remains the same. In this case, high level is input to the ET0_LINKSTA pin when setting the PFS.PmnPFS register to assign the ET0_LINKSTA signal to a port, or when releasing the ETHERC and EDMAC software reset using the EDMAC0.EDMR.SWR bit. The ECSR.LCHNG flag is sets to 1 because the ET0_LINKSTA signal in the ETHERC is fixed low level regardless of the input level to the external pin if the MPC does not assign the ET0_LINKSTA signal or during an ETHERC and EDMAC software reset.

To avoid erroneously generating a link signal change interrupt, clear the ECSR.LCHNG flag, and then set the ECSIPR.LCHNGIP bit to 1.

26.5.2 Input to RMII0_RX_ER Pin While RMII Is Selected

When the width of a reception error signal received from the PHY-LSI is only 1 cycle of the REF50CK0 clock (50 MHz) while the RMII is selected, the signal is not recognized as an error signal.

26.5.3 Collision Occurrence in Half-Duplex Mode

Transmission might start and communication might collide within 21 clock cycles (50 MHz) from reception in halfduplex mode.

26.3.7.3 暂停帧接收

当ECMR.RXF位设置为1时，启用PAUSE帧检测。接收到PAUSE帧后，ETHERC完成当前帧的传输，并等待接收到的PAUSE帧的PAUSE时间过去，然后才能传输下一帧。ETHERC还会增加RFCF.RPAUSE[7:0]位的值。

然而，在等待PAUSE时间过去时，如果接收到包含pause_time参数为0的PAUSE帧并且ECMR.ZPF位为1，则ETHERC立即准备好发送。

26.4 Interrupts

当ECSR寄存器中的标志设置为1并且ECSIPR寄存器中的相关位为1时，ETHERC通知中断源状态的EDMAC。收到通知后，EDMAC将EDMAC0.EESR.ECI标志设置为1。
当EDMAC0.EESIPR.ECIIP位为1时，EDMAC向CPU发送一个ETHER_EINT0中断请求。

有关详细信息，请参阅第27节，以太网DMA控制器(EDMAC)。

26.5 使用说明

26.5.1 防止LCHNG标志错误设置为1

即使ET0_LINKSTA引脚的输入电平保持不变，ECSR.LCHNG标志也可能设置为1。在这种情况下，当设置PFS.PmnPFS寄存器以将ET0_LINKSTA信号分配给端口时，或使用EDMAC0.EDMR.SWR位释放ETHERC和EDMAC软件复位时，高电平输入到ET0_LINKSTA引脚。ECSR.LCHNG标志设置为1，因为如果MPC未分配ET0_LINKSTA信号或在ETHERC和EDMAC软件复位期间，无论外部引脚的输入电平如何，ETHERC中的ET0_LINKSTA信号都是固定的低电平。

为避免错误地生成链接信号更改中断，请清除ECSR.LCHNG标志，然后设置ECSIPR.LCHNGIP位为1。

26.5.2 选择RMII时输入到RMII0_RX_ER引脚

选择RMII时，如果从PHY-LSI接收到的接收错误信号的宽度仅为REF50CK0时钟(50MHz)的1个周期，则该信号不会被识别为错误信号。

26.5.3 半双工模式下的冲突发生

在半双工模式下，从接收开始的21个时钟周期(50MHz)内，传输可能会开始并且通信可能会发生冲突。

27. Ethernet DMA Controller (EDMAC)

27.1 Overview

The MCU provides one channel for the Ethernet DMA Controller (EDMAC) for the Ethernet Controller (ETHERC) .

The EDMAC controls most of the transmit and receive buffer management for communications. This reduces the load on the CPU and allows efficient data transmission and reception. The data transfers are controlled according to the information referred to as descriptors, in memory. EDMAC0 controls data transmission and reception for ETHERC0.

Table 27.1 lists the EDMAC specifications and Figure 27.1 shows the configuration. Figure 27.2 shows the configuration of descriptors and the transmit and receive buffers in memory.

Table 27.1 EDMAC specifications

Parameter	Specifications
Data transmission and reception	• Controls data transmission and reception according to descriptors • Supports single buffer frame transmission and reception (1 buffer per frame) and multi-buffer frame transmission and reception (multiple buffers per frame)
Functions	• Minimizes system bus occupancy time using block transfer (32-byte units) • Writes back the transmit or receive frame state to descriptors • Inserts padding in receive data
Module-stop function	Module-stop state can be set to reduce power consumption

27. 以太网DMA控制器(EDMAC)

27.1 Overview

MCU为以太网控制器(ETHERC)的以太网DMA控制器(EDMAC)提供一个通道。

EDMAC控制大部分用于通信的发送和接收缓冲区管理。这减少了CPU的负载并允许高效的数据传输和接收。数据传输是根据内存中称为描述符的信息进行控制的。EDMAC0控制ETHERC0的数据传输和接收。

表27.1列出了EDMAC规范，图27.1显示了配置。图27.2显示了描述符的配置以及内存中的发送和接收缓冲区。

31:7	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. This setting applies to data for the transmit and receive buffers. It does not apply to transmit and receive descriptors and registers.

The EDMR register controls EDMAC operation. Set the EDMR register during initialization process after a reset. When rewriting this register outside of the initialization process, set the SWR bit to 1 to reset the EDMAC and ETHERC, then set this register again. If the ETHERC and EDMAC are reset during data transmission or reception, abnormal data might be sent on the line. Do not rewrite this register while the ETHERC transmit or receive function is enabled. It takes 64 cycles of the peripheral module clock (PCLKA) to initialize the ETHERC and EDMAC. Complete the initialization before accessing registers in the ETHERC and EDMAC.

27.2.2 EDTRR : EDMAC Transmit Request Register

Base address: EDMAC0 = 0x4011_4000

Offset address: 0x08

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TR	Transmit Request When 1 is written, the EDMAC reads the associated descriptor and transmits frames where the TD0.TACT bit is 1. The TR bit clears to 0 after all the valid frames are transmitted. Writing 0 to this bit has no effect.	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

The EDTRR register controls EDMAC transmission. After the EDMAC transmits one frame, it reads the next descriptor. When the TD0.TACT bit in the descriptor is 1, the EDMAC continues transmission. When the TD0.TACT bit is 0, the EDMAC sets the TR bit to 0 and stops transmission.

27.2.3 EDRRR : EDMAC Receive Request Register

Base address: EDMAC0 = 0x4011_4000

Offset address: 0x10

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RR	Receive Request 0: Disable the receive function*1 1: Read receive descriptor and enable the receive function.	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. If the receive function is disabled during frame reception, write-back to the receive descriptor is not performed successfully. Subsequent pointers for reading a receive descriptor become abnormal and the EDMAC cannot operate normally. In this case, to enable the EDMAC receive function again, execute a software reset by setting the EDMR.SWR bit to 1. To disable the EDMAC receive function without resetting the EDMAC, set the ETHERC0.ECMR.RE bit to 0. After the EDMAC completes reception and write-back to the receive descriptor is confirmed, set the RR bit to 0.

The EDRRR register controls EDMAC reception. When the RR bit sets to 1, the EDMAC reads the receive descriptor.

Bit	Symbol	Function	R/W
6	DE	大端模式小端模式*1 0：大端模式1：小端模式。	R/W
31:7	—	这些位被读取为0。写入值应为0。	R/W

注1.此设置适用于发送和接收缓冲区的数据。它不适用于发送和接收描述符和寄存器。

EDMR寄存器控制EDMAC操作。在复位后的初始化过程中设置EDMR寄存器。在初始化过程之外重写该寄存器时，将SWR位设置为1以复位EDMAC和ETHERC，然后再次设置该寄存器。如果ETHERC和EDMAC在数据传输或接收过程中被复位，可能会在线路上发送异常数据。在启用ETHERC发送或接收功能时不要重写该寄存器。初始化ETHERC和EDMAC需要64个外围模块时钟(PCLKA)周期。在访问ETHERC和EDMAC中的寄存器之前完成初始化。

27.2.2 EDTRR:EDMAC发送请求寄存器

Base address: EDMAC0 = 0x4011_4000

31:1	—	这些位被读取为0。写入值应为0。	R/W

EDTRR寄存器控制EDMAC传输。EDMAC传输一帧后，读取下一个描述符。
当描述符中的TD0.TACT位为1时，EDMAC继续传输。当TD0.TACT位为0时，
EDMAC将TR位设置为0并停止传输。

27.2.3 EDRRR:EDMAC接收请求寄存器

Offset address: 0x10

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RR
重置后的值：	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RR	接收请求 0：关闭接收功能*1 1：读取接收描述符并启用接收功能。	R/W
31:1	—	这些位被读取为0。写入值应为0。	R/W

注1.如果在帧接收期间禁用接收功能，则无法成功执行对接收描述符的回写。
后续读取接收描述符的指针异常，EDMAC不能正常工作。在这种情况下，要再次启用EDMAC接收功能，通过将EDMR.SWR位设置为1来执行软件复位。要禁用EDMAC接收功能而不重置EDMAC，请将ETHERC0.ECMR.RE位设置为0。EDMAC完成接收并确认回写到接收描述符，将RR位设置为0。

EDRRR寄存器控制EDMAC接收。当RR位设置为1时，EDMAC读取接收描述符。

When the RD0.RACT bit is 1, the EDMAC waits for a receive request from the ETHERC. When the EDMAC has received data for the receive buffer size, it reads the next descriptor and waits to receive a frame. If the RD0.RACT bit is 0, the EDMAC sets the RR bit to 0 and stops reception.

27.2.4 TDLAR : Transmit Descriptor List Start Address Register

当RD0.RACT位为1时，EDMAC等待来自ETHERC的接收请求。当EDMAC接收到接收缓冲区大小的数据时，它会读取下一个描述符并等待接收帧。如果RD0.RACT位为0，则EDMAC将RR位设置为0并停止接收。

Note 1. The ECI flag is read-only. When the source in the ECSR register is cleared, the ECI flag is also cleared.
Note 2. When an address error is detected, the EDMAC halts the process. To resume operation, set the EDMR.SWR bit to 1 (resetting the EDMAC and ETHERC), and then reconfigure the EDMAC and ETHERC.

The EESR register indicates the ETHERC and EDMAC communication status. Each flag in the EESR register can be output as an interrupt request signal (ETHER_EINT0) from the EDMAC. Writing 1 clears all of the flags except ECI to 0. Writing 0 does not affect any of the flag values. The interrupt sources are enabled by setting the associated bits in the EESIPR register.

CERF flag (CRC Error Flag)

The CERF flag sets to 1 when an error is detected while checking the frame check sequence (FCS) field of the receive frame.

PRE flag (PHY-LSI Receive Error Flag)

The PRE flag indicates that the RX_ER signal output from the PHY-LSI is high.

RTSF flag (Frame-Too-Short Error Flag)

The RTSF flag indicates that a received frame is less than 64 bytes.

RTLF flag (Frame-Too-Long Error Flag)

The RTLF flag indicates that a received frame is greater than the upper limit of the receive frame length set in the ETHERC0.RFLR register. The excess data is discarded.

注1.ECI标志是只读的。当ECSR寄存器中的源被清零时，ECI标志也被清零。
注2.当检测到地址错误时，EDMAC停止该过程。要恢复操作，请将EDMR.SWR位设置为1（复位
EDMAC和ETHERC），然后重新配置EDMAC和ETHERC。

EESR寄存器指示ETHERC和EDMAC通信状态。EESR寄存器中的每个标志都可以作为中断请求信号（ETHER_EINT0）从EDMAC输出。写入1会将除ECI之外的所有标志清除为0。写入0不会影响任何标志值。通过设置ESIPR寄存器中的相关位来启用中断源。

CERF标志（CRC错误标志）

当在检查接收帧的帧校验序列(FCS)字段时检测到错误时，CERF标志设置为1。

PRE标志（PHY-LSI接收错误标志）

PRE标志表示从PHY-LSI输出的RX_ER信号为高电平。

ETHERC0.RFLR寄存器。多余的数据被丢弃。

RA生态工作室

RRF flag (Alignment Error Flag)

The RRF flag indicates that a frame is not an integral number of octets. The last word that is not an integral number of octets is not transferred.

RMAF flag (Multicast Address Frame Receive Flag)

The RMAF flag indicates that a multicast frame was received.

TRO flag (Transmit Retry Over Flag)

The TRO flag indicates that a collision occurred again during the 15th retry of frame transmission.

CD flag (Late Collision Detect Flag)

The CD flag indicates that a late collision was detected during frame transmission.

DLC flag (Loss of Carrier Detect Flag)

The DLC flag indicates that a loss of carrier was detected during frame transmission.

CND flag (Carrier Not Detect Flag)

The CND flag sets to 1 when a carrier is not detected during preamble transmission.

RFOF flag (Receive FIFO Overflow Flag)

The RFOF flag indicates that the receive FIFO overflowed during frame reception.

RDE flag (Receive Descriptor Empty Flag)

The RDE flag indicates that the read receive descriptor is invalid. When this flag sets to 1, set the RD0.RACT bit in the receive descriptor to 1 and set the EDRRR.RR bit to 1 to resume reception.

FR flag (Frame Receive Flag)

The FR flag indicates that a frame was received and the receive descriptor was updated. The FR flag sets to 1 every time a frame is received.

TFUF flag (Transmit FIFO Underflow Flag)

The TFUF flag indicates that no data remains in the transmit FIFO during frame transmission. Incomplete data is sent to the line.

TDE flag (Transmit Descriptor Empty Flag)

The TDE flag indicates that the TD0.TACT bit of the transmit descriptor is 0 while the previous transmit descriptor indicates that the frame is not complete (TD0.TFP[1:0] bits are 10b or 00b) in multi-buffer frame transmission. As a result, an incomplete frame might be sent.

When this flag sets to 1, perform a software reset and then set the EDTRR.TR bit to 1 to resume transmission. Transmission starts from the address stored in the TDLAR register.

TC flag (Frame Transfer Complete Flag)

The TC flag indicates that all the data specified in the transmit descriptor was transmitted from the ETHERC. This flag is set to 1 when one frame was transmitted in a single-buffer frame transmission or when the last data of a frame is transmitted in multi-buffer frame transmission and the TD0.TACT bit in the next transmit descriptor is 0. After frame transmission is complete, the EDMAC writes the transfer status back to the descriptor.

ECI flag (ETHERC Status Register Source Flag)

The ECI flag is set to 1 when an interrupt request is generated by the ECSR register.

ADE flag (Address Error Flag)

The ADE flag indicates that the memory address that the EDMAC tried to use for transfer is invalid.

RFCOF flag (Receive Frame Counter Overflow Flag)

The RFCOF flag indicates that the next frame reception started while the number of frames stored in the receive FIFO reached the maximum number of frames (16 frames). The received frame is discarded while the RFCOF flag is 1.

RRF标志（对齐错误标志）

RRF标志表明一个帧不是整数个八位字节。不是整数八位字节的最后一个字不被传送。

RMAF标志（多播地址帧接收标志）

RMAF标志指示接收到多播帧。

TRO标志（传输重试结束标志）

TRO标志表示在第15次帧传输重试期间再次发生冲突。

CD标志（后期碰撞检测标志）

CD标志表示在帧传输期间检测到后期冲突。

DLC标志（载波丢失检测标志）

DLC标志表示在帧传输期间检测到载波丢失。

CND标志（载波未检测标志）

当在前导码传输期间未检测到载波时，CND标志设置为1。

RFOF标志（接收FIFO溢出标志）

RFOF标志表示接收FIFO在帧接收期间溢出。

RDE标志（接收描述符空标志）

RDE标志指示读取的接收描述符无效。当该标志设置为1时，将接收描述符中的RD0.RACT位设置为1，并将EDRRR.RR位设置为1以恢复接收。

FR标志（帧接收标志）

FR标志表示接收到一个帧并且接收描述符已更新。每次接收到一帧时，FR标志设置为1。

TFUF flag (Transmit FIFO Underflow Flag)

TFUF标志表示在帧传输期间没有数据保留在传输FIFO中。不完整的数据被发送到线路。

TDE标志（传输描述符空标志）

TDE标志表示发送描述符的TD0.TACT位为0，而前一个发送描述符表示在多缓冲帧传输中该帧未完成（TD0.TFP[1:0]位为10b或00b）。因此，可能会发送不完整的帧。

当该标志设置为1时，执行软件复位，然后将EDTRR.TR位设置为1以恢复传输。传输从存储在TDLAR寄存器中的地址开始。

TC标志（帧传输完成标志）

TC标志表示发送描述符中指定的所有数据都是从ETHERC发送的。当在单缓冲帧传输中传输一帧或在多缓冲帧传输中传输一帧的最后一个数据并且下一个传输描述符中的TD0.TACT位为0时，此标志设置为1。传输完成后，EDMAC将传输状态写回描述符。

ECI标志（ETHERC状态寄存器源标志）

当ECSR寄存器产生中断请求时，ECI标志设置为1。

ADE标志（地址错误标志）

ADE标志表示EDMAC尝试用于传输的内存地址无效。

RFCOF标志（接收帧计数器溢出标志）

RFCOF标志表示在接收FIFO中存储的帧数达到最大帧数（16帧）时开始下一帧接收。当RFCOF标志为1时，接收到的帧被丢弃。

RABT flag (Receive Abort Detect Flag)

The RABT flag indicates that the ETHERC aborted frame reception because of a CRC error, PHY-LSI receive error, frame-too-short error, frame-too-long error, or other errors.

TABT flag (Transmit Abort Detect Flag)

The TABT flag indicates that the ETHERC aborted frame transmission because of transmit retry over, loss of carrier, no carrier detection, or other errors.

TWB flag (Write-Back Complete Flag)

The TWB flag indicates the EDMAC completed writing back to the descriptor after frame transmission. This flag is set to 1 after each frame transmission when the TRIMD.TIM bit is 0. It only sets to 1 when the TRIMD.TIS bit is 1.

31:8	—	These bits are read as 0. The write value should be 0.	R/W

The TRSCER register selects whether the receive status indicated in the EESR.RMAF and RRF flags is reflected in the RFE bit of the receive descriptor as a summary. The bits in this register are associated with bits in the EESR register that have the same number. When the RMAFCE or RRFCE bit is set to 0, the associated receive status is reflected in the RFE bit. When the RMAFCE or RRFCE bit is set to 1, the associated receive status is not reflected.

27.2.9 RMFCR : Missed-Frame Counter Register

Base address: EDMAC0 = 0x4011_4000

Offset address: 0x40

Bit position:	31	15	0
Bit field:	—	MFC[15:0]	
Value after reset:	0	0	0

Bit	Symbol	Function	R/W
15:0	MFC[15:0]	Missed-Frame Counter These bits indicate the number of frames that are discarded and not transferred to the receive buffer during reception.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The RMFCR register indicates that the number of frames that could not be stored in the receive FIFO and so were discarded during reception. When the receive FIFO overflows, it stops receiving data, and the rest of frames are discarded. At the same time, the RMFCR register value is incremented. When the RMFCR register value reaches 0xFFFF, count-up is halted. Writing any value to the RMFCR register clears the counter value to 0.

For frames that are not completely received, after data in the receive FIFO is transferred to the receive buffer, the RACT bit in the receive descriptor 0 (RD0) clears to 0 (descriptor disabled), the RFS9 bit sets to 1 (receive FIFO overflowed), and the EESR.RFOF flag is set to 1 (overflow detected).

27.2.8 TRSCER：ETHERCEDMAC发送接收状态复制使能寄存器

31:8	—	这些位被读取为0。写入值应为0。	R/W

TRSCER寄存器选择是否将EESR.RMAF和RRF标志中指示的接收状态作为摘要反映在接收描述符的RFE位中。该寄存器中的位与EESR寄存器中具有相同编号的位相关联。当RMAFCE或RRFCE位设置为0时，相关的接收状态反映在RFE位中。当RMAFCE或RRFCE位设置为1时，不反映相关的接收状态。

27.2.9 RMFCR:漏帧计数器寄存器

Base address: EDMAC0 = 0x4011_4000

Offset address: 0x40

Bit position:	31	15	0
Bit field:	—	MFC[15:0]	
重置后的值：	0	0	0

Bit	Symbol	Function	R/W
15:0	MFC[15:0]	Missed-Frame Counter 这些位指示在接收期间被丢弃且未传输到接收缓冲区的帧数。	R/W
31:16	—	这些位被读取为0。写入值应为0。	R/W

RMFCR寄存器指示无法存储在接收FIFO中并因此在接收期间被丢弃的帧数。当接收FIFO溢出时，它停止接收数据，其余帧被丢弃。同时，RMFCR寄存器值递增。当RMFCR寄存器值达到0xFFFF时，停止向上计数。向RMFCR寄存器写入任何值都会将计数器值清零。

对于未完全接收的帧，接收FIFO中的数据传输到接收缓冲区后，接收描述符0（RD0）中的RACT位清为0（描述符禁用），RFS9位设置为1（接收FIFO溢出），并且EESR.RFOF标志设置为1（检测到溢出）。

27.2.10 TFTR : Transmit FIFO Threshold Register

31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: When starting transmission before one frame data is completely written, take care to prevent an underflow. To prevent a transmit underflow, Renesas recommends using the initial value (store-and-forward mode).

The TFTR register specifies the transmit FIFO threshold at which the first transmission starts. The actual threshold is the set value multiplied by 4.

The ETHERC starts transmission when the amount of data in the transmit FIFO exceeds the number of bytes set in this register, when the transmit FIFO is full, or when one frame of data is completely written. Set the TFTR register while the EDTRR.TR bit is 0.

TFTR寄存器指定第一次发送开始时的发送FIFO阈值。实际阈值是设定值乘以4。

当发送FIFO中的数据量超过此寄存器中设置的字节数、发送FIFO已满或一帧数据被完全写入时，ETHERC开始发送。当EDTRR.TR位为0时设置TFTR寄存器。

27.2.11 FDR：FIFO深度寄存器

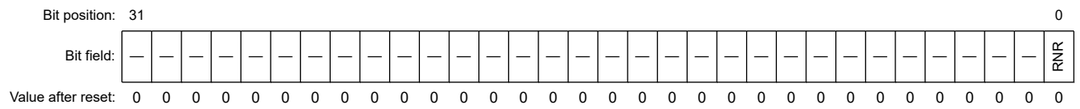
The FDR register specifies the transmit and receive FIFO depths. Set this register to 0x0000_070F before starting transmission and reception.

27.2.12 RMCR : Receive Method Control Register

Base address: EDMAC0 = 0x4011_4000

Offset address: 0x58



Bit	Symbol	Function	R/W
0	RNR	Receive Request Reset 0: EDRRR.RR bit (receive request bit) is cleared to 0 when one frame is received 1: EDRRR.RR bit (receive request bit) is not cleared to 0 when one frame is received.	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

The RMCR register specifies how to control the EDRRR.RR bit when receiving a frame. When the RNR bit is 0, the EDRRR.RR bit clears to 0 when one frame is received, so it must be set to 1 by software to receive the subsequent frame. When the RNR bit is 1, the EDRRR.RR bit does not clear to 0 when one frame is received, and the EDMAC reads the next receive descriptor and continues frame reception. Renesas recommends setting the RNR bit to 1 when receiving data continuously. Set the RMCR register while the EDRRR.RR bit is 0.

RMCR寄存器指定接收帧时如何控制EDRRR.RR位。当RNR位为0时，
EDRRR.RR位在接收到一帧后清为0，因此必须通过软件设置为1才能接收后续帧。
当RNR位为1时，接收到一帧时EDRRR.RR位不清为0，EDMAC读取下一个接收描述符并继续帧接收。Renesas建议在连续接收数据时将RNR位设置为1。当EDRRR.RR位为0时设置RMCR寄存器。

Bit	Symbol	Function	R/W
31:0	n/a	The TDFAR register indicates the start address of the last fetched transmit descriptor when the EDMAC is fetching the descriptor information from the transmit descriptor.	R

The TDFAR register indicates the start address of the last fetched transmit descriptor when the EDMAC is fetching the descriptor information from the transmit descriptor. Check the contents of this register to identify which transmit descriptor information the EDMAC is using for active processing. The address of transmit descriptor that the EDMAC fetches might not match the read value of the TDFAR register. The TDFAR is read only. Do not write to this register.

27.3 Operation

The EDMAC transfers data according to the information written in the descriptor. Two descriptors are provided: transmit and receive. A descriptor includes the buffer size, address, and transmit or receive status. The EDMAC transmits or receives data continuously by using sequentially arranged descriptors.

27.3.1 Descriptor Lists and Data Buffers

To transfer data using the EDMAC, create the transmit and receive descriptor lists in memory, set the start address of the transmit descriptor list in the TDLAR register, and set the start address of the receive descriptor list in the RDLAR register. Also, the transmit and receive buffers associated with each descriptor are required.

Align the descriptor list on the appropriate address boundary according to the descriptor length set in the EDMR.DL[1:0] bits. The transmit buffer can be aligned on a word boundary, halfword boundary, or byte boundary. When the valid transmit buffer size is 16 bytes or less, align it on a 32-byte boundary. When the valid transmit buffer size is larger than 16bytes, the transmit buffer setting on not aligned 32-byte boundary is permitted. However EDMAC0 might read the transmit buffer aligned on 32-byte boundary, therefore, initialize the transmit buffer area at the beginning of 32 byte-boundary where the transmit buffer set in. Align the receive buffer on a 32-byte boundary. Set different addresses for the transmit and receive descriptors and buffers for EDMAC0.

27.3.1.1 Transmit descriptor

Figure 27.3 shows the relationship between a transmit descriptor and transmit buffer. A transmit descriptor consists of TD0 to TD2. The transmit frame and transmit buffer configuration can be specified as one buffer per frame (single-buffer frame transmission) or multiple buffers per frame (multi-buffer frame transmission) by setting the transmit descriptor.

27.3 Operation

EDMAC根据描述符中写入的信息传输数据。提供了两个描述符：发送和接收。描述符包括缓冲区大小、地址和发送或接收状态。EDMAC通过使用顺序排列的描述符连续发送或接收数据。

27.3.1 描述符列表和数据缓冲区

要使用EDMAC传输数据，在内存中创建发送和接收描述符列表，在TDLAR寄存器中设置发送描述符列表的起始地址，在RDLAR寄存器中设置接收描述符列表的起始地址。此外，还需要与每个描述符关联的发送和接收缓冲区。

根据在EDMR.DL[1:0]位中设置的描述符长度将描述符列表对齐在适当的地址边界上。发送缓冲区可以在字边界、半字边界或字节边界上对齐。当有效发送缓冲区大小为16字节或更少时，将其对齐在32字节边界上。当有效传输缓冲区大小大于16字节时，允许在未对齐的32字节边界上设置传输缓冲区。然而，EDMAC0可能会读取对齐在32字节边界上的传输缓冲区，因此，在设置传输缓冲区的32字节边界的开头初始化传输缓冲区。将接收缓冲区对齐在32字节边界上。为EDMAC0的发送和接收描述符和缓冲区设置不同的地址。

27.3.1.1 传输描述符

图27.3显示了发送描述符和发送缓冲区之间的关系。发送描述符由TD0到TD2组成。通过设置传输描述符，可以将传输帧和传输缓冲区配置指定为每帧一个缓冲区（单缓冲区帧传输）或每帧多个缓冲区（多缓冲区帧传输）。

Bit	Symbol	Function	R/W
15:0	RFL	Receive Frame Length Specifies the length (number of bytes) of the receive frame stored in the buffer. This does not include the number of bytes for padding set in the RPADIR register. These bits are written back to the descriptor associated with the end of a frame.	R/W
31:16	RBL	Receive Buffer Length Specifies the byte length of the associated receive buffer. Set an integral multiple of 32 as the buffer length.	R/W

Note: Bits for write-back are underlined.

RD1 specifies the receive buffer length. When reception is complete, the receive frame length is written back.

(3) Receive descriptor 2 (RD2)

Bit	Symbol	Function	R/W
31:0	RBA	Receive Buffer Address Specifies the start address of the receive buffer. Align the buffer address on a 32-byte boundary.	R/W

RD2 specifies the start address of the receive buffer.

27.3.2 Transmission

When the EDTRR.TR bit is set to 1 while the ETHERC0.ECMR.TE bit is 1, the EDMAC reads the descriptor following the previously used descriptor in the transmit descriptor list (or the descriptor indicated in the TDLAR register after a reset). When the TACT bit is 1 in the transmit descriptor (TD0), the EDMAC sequentially reads transmit data from the start address of the transmit buffer indicated in transmit descriptor 2 (TD2) and transfers it to the ETHERC through the transmit FIFO. The ETHERC creates a transmit frame and starts transmission to the MII or RMII. When all data indicated in the TD1.TBL bit is transferred, write-back is performed based on the TD0.TFP[1:0] bit setting as follows:

- When the TD0.TFP[1:0] bits are 00b or 10b (frame is incomplete), the TD0.TACT bit is written back
- When the TD0.TFP[1:0] bits are 01b or 11b (frame is complete), the TD0.TACT, TD0.TFS, and TD0.TFE bits are written back.

When the TD0.TACT bit in the read descriptor is 1, the EDMAC continues reading descriptors and transmit frames. When the TD0.TACT bit in the read descriptor is 0, the EDMAC sets the EDTRR.TR bit to 0 and stops transmission.

(2) 接收描述符1(RD1)

Bit	Symbol	Function	R/W
15:0	RFL	接收帧长度 指定存储在缓冲区中的接收帧的长度（字节数）。这不包括RPADIR寄存器中设置的填充字节数。这些位被写回与帧结束相关的描述符。	R/W
31:16	RBL	接收缓冲区长度 指定相关接收缓冲区的字节长度。设置32的整数倍作为缓冲区长度。	R/W

Note: 用于回写的位带有下划线。

RD1指定接收缓冲区长度。当接收完成时，接收帧长度被写回。

(3) 接收描述符2(RD2)

Bit	Symbol	Function	R/W
31:0	RBA	接收缓冲区地址 指定接收缓冲区的起始地址。在32字节边界上对齐缓冲区地址。	R/W

RD2指定接收缓冲区的起始地址。

27.3.2 Transmission

当EDTRR.TR位设置为1而ETHERC0.ECMR.TE位为1时，EDMAC读取发送描述符列表中先前使用的描述符之后的描述符（或复位后TDLAR寄存器中指示的描述符）。当发送描述符(TD0)中的TACT位为1时，EDMAC从发送描述符2(TD2)中指示的发送缓冲区的起始地址顺序读取发送数据，并通过发送FIFO将其传输到ETHERC。ETHERC创建一个传输帧并开始传输到MII或RMII。当所有数据显示在

传输TD1.TBL位，根据TD0.TFP[1:0]位设置执行回写，如下所示：

●当TD0.TFP[1:0]位为00b或10b（帧不完整）时，TD0.TACT位被回写

●当TD0.TFP[1:0]位为01b或11b（帧完成）时，TD0.TACT、TD0.TFS和TD0.TFE位被写回。

当读取描述符中的TD0.TACT位为1时，EDMAC继续读取描述符并发送帧。当读描述符中的TD0.TACT位为0时，EDMAC将EDTRR.TR位设置为0并停止传输。

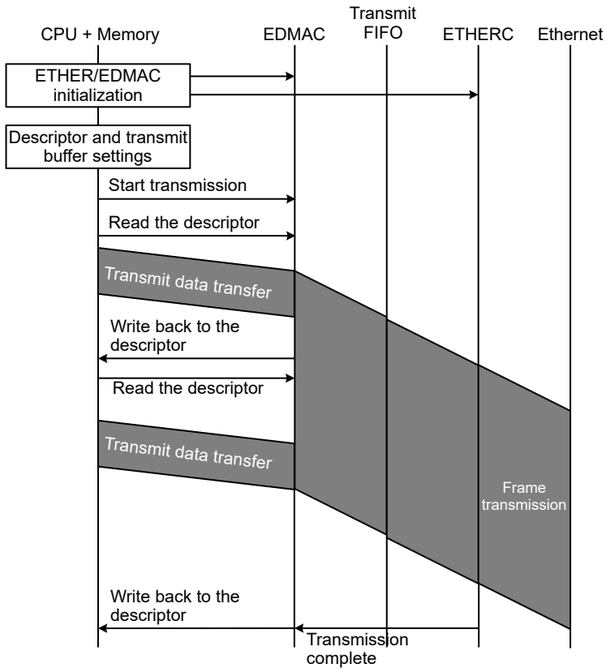

Figure 27.5 Example of transmission flow

27.3.3 Reception

When the EDRRR.RR bit is set to 1 while the ETHERC0.ECMR.RE bit is 1, the EDMAC reads the receive descriptor following the previously used descriptor (or the descriptor indicated in the RDLAR register after a reset) and then waits for reception. When the RD0.RACT bit is 1, if the data stored in the receive FIFO is 32 bytes or more, or if the end byte of the frame is stored in the receive buffer, the EDMAC transfers data from the receive FIFO to the receive buffer indicated in receive descriptor 2 (RD2).

If the data length of the received frame is longer than the buffer length set in the RBL bit in receive descriptor 1 (RD1), the EDMAC writes back 10b or 00b to the RD0.RFP[1:0] bits and 0 to the RD0.RACT bit when the receive buffer becomes full, and then the EDMAC reads the next data. After that, the EDMAC transfers data to another receive buffer.

When the frame reception is complete or when the frame reception is aborted by an error, the EDMAC writes back 11b or 01b to the RD0.RFP[1:0] bits, 0 to the RD0.RACT bit, and the receive frame length to the RD1.RFL bit. When the RMCR.RNR bit is 1, the EDMAC reads the next descriptor and waits for reception. When the RNR bit is 0, the EDMAC sets the EDRRR.RR bit to 0 and stops reception.

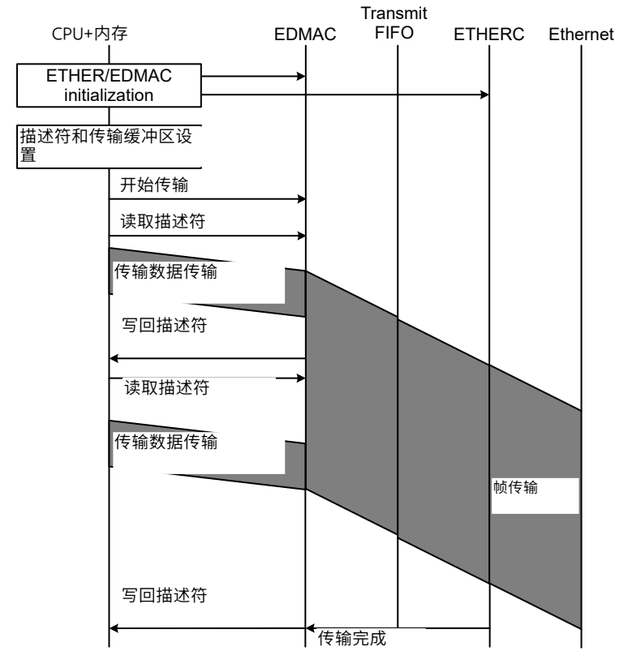

Figure 27.5 传输流程示例

27.3.3 Reception

当EDRRR.RR位设置为1而ETHERC0.ECMR.RE位为1时，EDMAC读取先前使用的描述符（或复位后RDLAR寄存器中指示的描述符）之后的接收描述符，然后等待接收.当RD0.RACT位为1时，如果接收FIFO中存储的数据为32字节或更多，或者如果帧的结束字节存储在接收缓冲区中，则EDMAC将数据从接收FIFO传输到接收缓冲区在接收描述符2(RD2)中指示。

如果接收帧的数据长度大于接收描述符1(RD1)中RBL位中设置的缓冲区长度，则
当接收缓冲器变满时，EDMAC将10b或00b写回RD0.RFP[1:0]位，并将0写回RD0.RACT位，然后EDMAC读取下一个数据。之后，EDMAC将数据传输到另一个接收缓冲区。

当帧接收完成或帧接收因错误而中止时，EDMAC将11b或01b写回RD0.RFP[1:0]位，将0写回RD0.RACT位，并将接收帧长度写入RD1.RFL位。当RMCR.RNR位为1时，EDMAC读取下一个描述符并等待接收。当RNR位为0时，EDMAC将EDRRR.RR位设置为0并停止接收。

27.3.4 Multi-Buffer Frame Transmission

27.3.4.1 Error processing while transmitting multi-buffer frame

If an error occurs during multi-buffer frame transmission, the EDMAC performs the processing shown in Figure 27.7. In the figure, when the TACT bit of transmit descriptor 0 (TD0) is 0, the descriptor indicates that all data in the buffer is successfully transmitted. When the TACT bit is 1, the descriptor indicates that data in the buffer is not yet transmitted. If a frame transmit error*1 occurs in the head or at the middle of the frame while the TD0.TACT bit is 1, the EDMAC stops data transmission from the transmit FIFO and EDMAC data transfer, and sets the TD0.TACT bit to 0.

After that, the EDMAC reads the next descriptor to see if the descriptor indicates the middle of the frame (TD0.TFP[1:0] bits are 00b) or the end of the frame (TD0.TFP[1:0] bits are 01b). When the descriptor indicates the middle of the frame, the EDMAC sets the TD0.TACT bit to 0 and reads the next descriptor. When the descriptor indicates the end of the frame, in addition to setting the TD0.TACT bit to 0, the EDMAC also writes back to the TD0.TFE and TD0.TFS bits.

After an error occurs, data in the buffer is not transmitted until write-back to the descriptor for the end of the frame. When the associated transmit error interrupt is enabled in the EESIPR register, an interrupt request is generated immediately after write-back to the descriptor for the end of the frame.

Note 1. A transmit retry-over condition, late collision, or loss of carrier is detected, or a carrier is not detected.

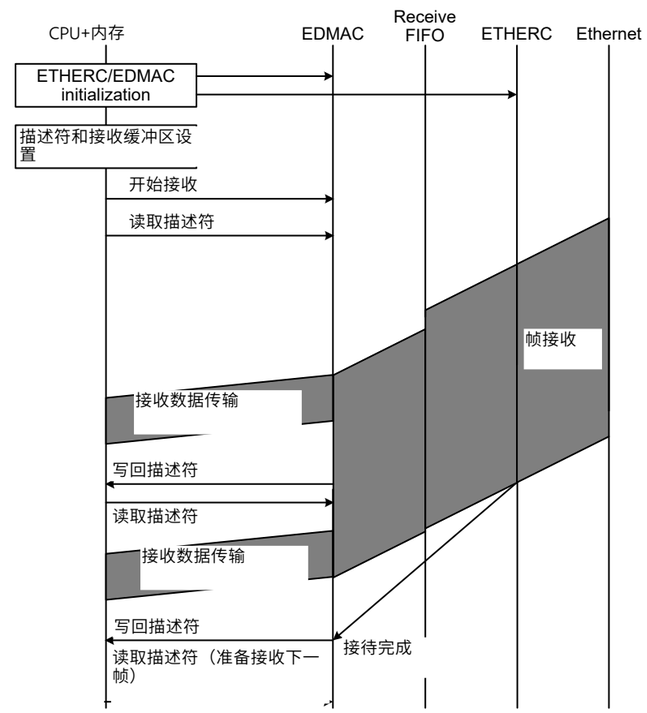

Figure 27.6 接收流程示例

27.3.4 多缓冲区帧传输

27.3.4.1 传输多缓冲帧时的错误处理

如果在多缓冲帧传输过程中发生错误，EDMAC将执行图27.7所示的处理。图中，当发送描述符0（TD0）的TACT位为0时，描述符表示缓冲区中的所有数据都发送成功。当TACT位为1时，描述符指示缓冲区中的数据尚未传输。如果在TD0.TACT位为1时在帧的开头或中间发生帧发送错误*1，则EDMAC停止从发送FIFO和EDMAC数据传输的数据传输，并将TD0.TACT位设置为0.

之后，EDMAC读取下一个描述符，看描述符是表示帧中间（TD0.TFP[1:0]位为00b）还是帧结束（TD0.TFP[1:0]位为01b)。当描述符指示帧的中间时，EDMAC将TD0.TACT位设置为0并读取下一个描述符。当描述符指示帧结束时，除了将TD0.TACT位设置为0外，EDMAC还写回TD0.TFE和TD0.TFS位。

发生错误后，缓冲区中的数据不会传输，直到写回帧结束的描述符。当在ESIPR寄存器中使能相关的发送错误中断时，在帧结束写回描述符后立即生成中断请求。

注1.检测到传输重试条件、延迟冲突或载波丢失，或未检测到载波。

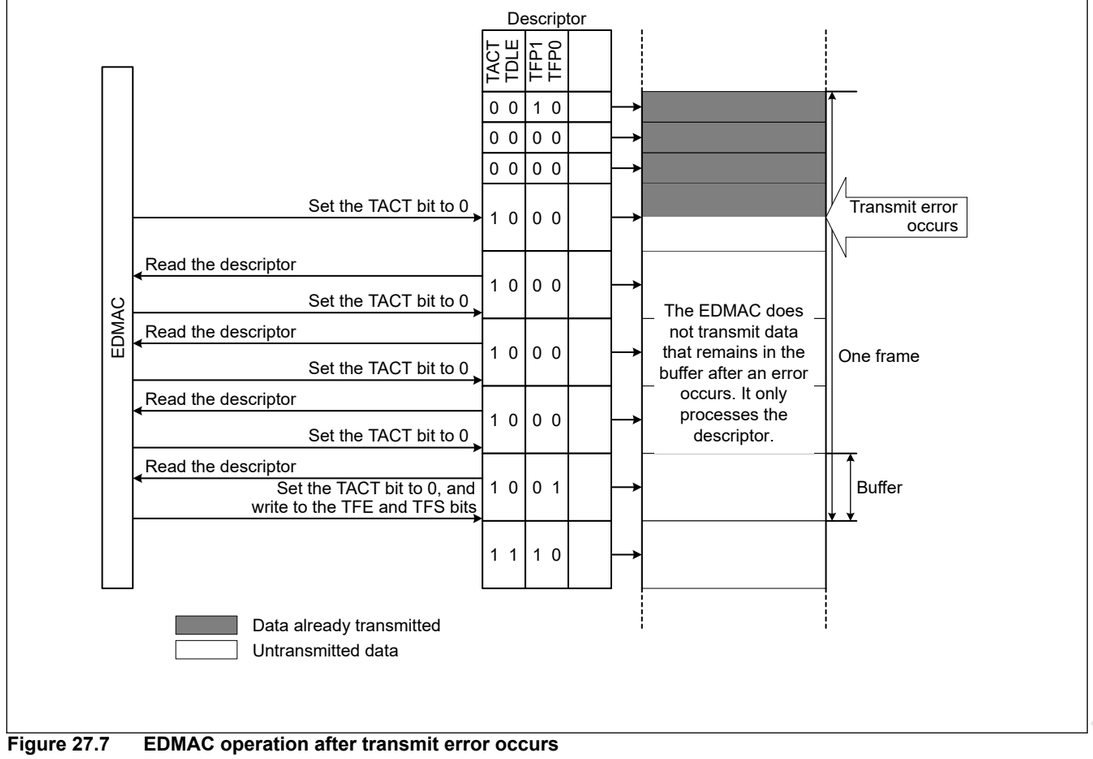

Figure 27.7 EDMAC operation after transmit error occurs

27.3.4.2 Error processing while receiving multi-buffer frame

If an error occurs during multi-buffer frame reception, the EDMAC performs the processing shown in Figure Figure 27.8. In the figure, when the RACT bit of receive descriptor 0 (RD0) is 0, the descriptor indicates that data was successfully received in the buffer. When the RACT bit is 1, the descriptor indicates that data is not yet received in the buffer. If a frame receive error*1 occurs, the EDMAC stops receiving new data, but it transfers data that is already stored in the receive FIFO to the receive buffer.

When the receive buffer becomes full during transfer, the EDMAC sets the RACT bit to 0 and the RFP[1:0] bits to 10b or 00b and reads the next descriptor. After all data in the receive FIFO is transferred, the EDMAC writes back the status to the descriptor.

When the associated receive error interrupt is enabled in the EESIPR register, an interrupt request is generated immediately after write-back to the descriptor. When there is a request to receive a new frame, the EDMAC continues reception using the descriptor following the descriptor where the error occurred.

Note 1. A CRC error, PHY-LSI receive error, frame-too-short error, frame-too-long error, or alignment error is detected.

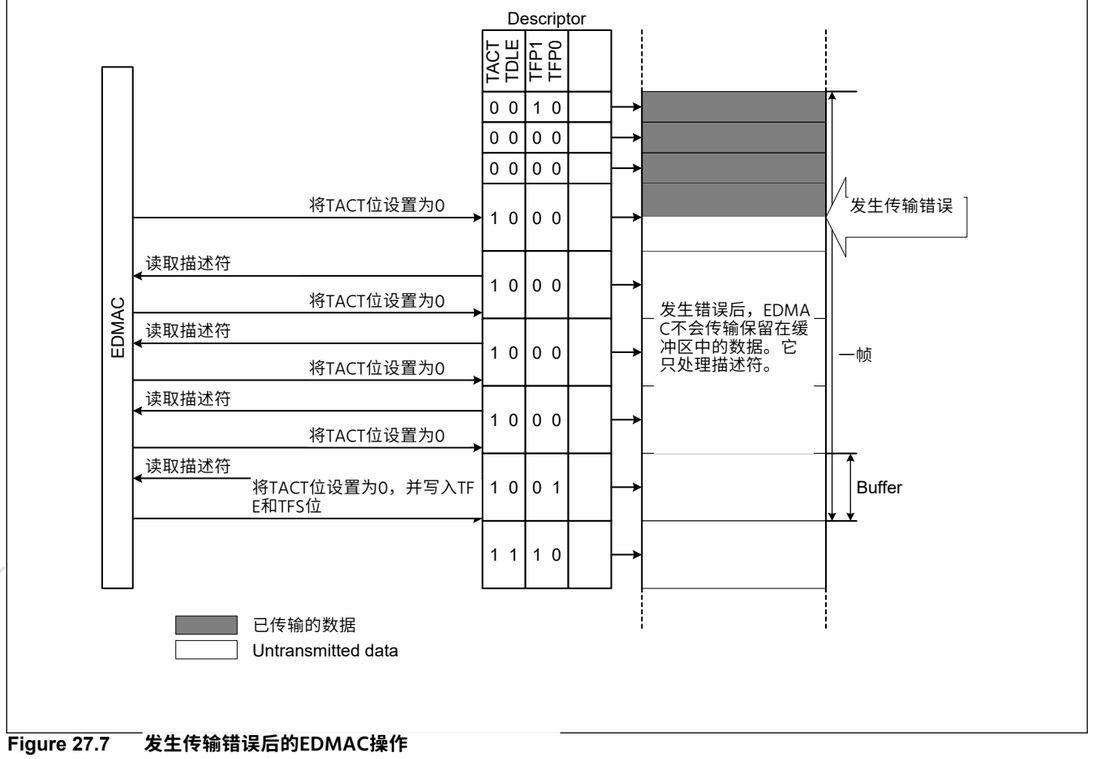

Figure 27.7 发生传输错误后的EDMAC操作

27.3.4.2 接收多缓冲帧时的错误处理

如果在多缓冲区帧接收过程中发生错误，EDMAC将执行图27.8所示的处理。图中，当接收描述符0（RD0）的RACT位为0时，描述符表示缓冲区成功接收到数据。当RACT位为1时，描述符指示缓冲区中尚未接收到数据。如果发生帧接收错误*1，EDMAC将停止接收新数据，但会将已存储在接收FIFO中的数据传输到接收缓冲区。

当接收缓冲区在传输过程中变满时，EDMAC将RACT位设置为0，并将RFP[1:0]位设置为10b或00b并读取下一个描述符。接收FIFO中的所有数据传输完毕后，EDMAC将状态写回描述符。

当在ESIPR寄存器中启用相关的接收错误中断时，在写回描述符后立即生成中断请求。当有接收新帧的请求时，EDMAC使用发生错误的描述符之后的描述符继续接收。

注1.检测到CRC错误、PHY-LSI接收错误、帧太短错误、帧太长错误或对齐错误。

27.3.5 Bus Transfer Error

Bus transfer error occurs with the slave TrustZone filter error, the master MPU error, the slave bus error or the illegal address access error. When the bus transfer error is detected, the EDMAC halts the process and EESR.ADE bit is set to 1.

Bus transfer error can be output as an interrupt request signal (ETHER_EINT0). The slave TrustZone error and the master MPU error can be output as NMI. When ETHER_EINT0 and NMI are generated, NMI always responds first. Figure 27.9 and Figure 27.10 show the processing for the bus error in NMI handler and ETHER_EINT0 handler.

27.3.5 总线传输错误

总线传输错误与从属TrustZone过滤器错误、主控MPU错误、从属总线错误或非法地址访问错误一起发生。当检测到总线传输错误时，EDMAC将停止该过程并将EESR.ADE位设置为1。

总线传输错误可以作为中断请求信号(ETHER_EINT0)输出。从站TrustZone错误和主站MPU错误可以作为NMI输出。当ETHER_EINT0和NMI生成时，NMI总是首先响应。图27.9和图27.10显示了NMI处理程序和ETHER_EINT0处理程序中的总线错误处理。

27.4 Interrupts

When any of the status flags in the EESR register sets to 1 while the associated interrupt request enable bit in the EESIPR register is 1, EDMAC0 issues an ETHER_EINT0 interrupt request.

27.5 Usage Notes

27.5.1 Settings for the Module-Stop Function

The following bit in Module Stop Control Register B (MSTPCRB) enables or disables EDMAC module operation:

- The MSTPB15 bit in enables or disables ETHERC0 and EDMAC0 operation

The modules are initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

27.4 Interrupts

当EESR寄存器中的任何状态标志设置为1且ESIPR寄存器中相关的中断请求使能位为1时，EDMAC0发出ETHER_EINT0中断请求。

27.5 使用说明

27.5.1 模块停止功能的设置

模块停止控制寄存器B(MSTPCRB)中的以下位启用或禁用EDMAC模块操作：

●MSTPB15位启用或禁用ETHERC0和EDMAC0操作

模块在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

27.5.2 Stopping the EDMAC during Operation

When stopping EDMAC operation by using a Software Standby mode or the module-stop function while the EDMAC is running, confirm that the EDTRR.TR and EDRRR.RR bits are 0. If the EDMAC is stopped while the EDTRR.TR or EDRRR.RR bit is 1, data for the frame that is being transmitted or received might not be complete, and EDMAC operation after exiting Software Standby mode or the module-stop state is not guaranteed.

27.5.2 在运行期间停止EDMAC

在EDMAC运行时使用软件待机模式或模块停止功能停止EDMAC操作时，请确认EDTRR.TR和EDRRR.RR位为0。如果在EDTRR.TR或EDRRR.RR时停止EDMAC位为1，正在发送或接收的帧的数据可能不完整，并且无法保证退出软件待机模式或模块停止状态后的EDMAC操作。

Note: After writing 1 to the SCKE bit, read it to confirm that it is set to 1.

USBE bit (USBFS Operation Enable)

The USBE bit enables or disables operation of the USBFS.

Changing the USBE bit from 1 to 0 initializes the bits listed in Table 28.3. Only change this bit while the SCKE bit is 1. In host controller mode, this bit must be set to 1 after setting the DRPD bit to 1, eliminating SYSSTS0.LNST[1:0] flags chattering, and confirming that the USB bus state is stable.

DPRPU bit (D+ Line Resistor Control)

The DPRPU bit enables or disables pulling up the D+ line in device controller mode.

When the DPRPU bit is set to 1 in device controller mode, the USBFS pulls up the D+ line to notify the USB host that it attached. Changing the DPRPU bit from 1 to 0 releases the pull-up, thereby notifying the USB host that it detached.

Set this bit to 1 in device controller mode and to 0 in host controller mode.

USBE位（USBFS操作使能）

USBE位启用或禁用USBFS的操作。

将USBE位从1更改为0会初始化表28.3中列出的位。仅在SCKE位为1时更改该位。在主机控制器模式下，必须在将DRPD位设置为1后将该位设置为1，消除SYSSTS0.LNST[1:0]标志抖动，并确认USB总线状态是稳定的。

当DPRPU位在设备控制器模式下设置为1时，USBFS拉高D+线以通知USB主机它已连接。将DPRPU位从1更改为0会释放上拉电阻，从而通知USB主机它已分离。

在设备控制器模式下将此位设置为1，在主机控制器模式下设置为0。

DRPD bit (D+/D– Line Resistor Control)

TheDRPD bit enables or disables pulling down D+ and D– lines in host controller mode.

Set this bit to 1 in host controller mode and to 0 in device controller mode.

The DCFM bit selects the host or device function of the USBFS.

Only change this bit when the DPRPU and DRPD bits are both 0.

SCKE bit (USB Clock Enable)

The SCKE bit stops or enables the 48-MHz clock supply to the USBFS.

When this bit is 0, only SYSCFG is permitted to be read from and written to; the other registers related to the USB should not be read from or written to.

SOFEA bit (Active Monitor When the Host Controller Is Selected)

The SOFEA bit is used in host controller mode to check whether the output of the last SOF is complete when the USBFS is suspended because of a 0 setting to the DVSTCTR0.UACT bit.

In host controller mode, check that both the HTACT and SOFEA bits are 0 before setting the SYSCFG.USBE bit to 0 to stop the USBFS or setting the SYSCFG.SCKE bit to 0 to stop the clock signal supply during communication.

HTACT bit (USB Host Sequencer Status Monitor)

The HTACT bit is set to 0 when the host sequencer of the USBFS is completely stopped.

In host controller mode, check that the HTACT bit is 0 before setting the DVSTCTR0.UACT bit to 0 to place the USBFS in the suspended state or setting the SCKE bit to 0 to stop the clock signal supply during communication.

OVCMON[1:0] bits (External USB_OVRCURA/ USB_OVRCURB Input Pin Monitor)

SOFEA位（选择主机控制器时的主动监视器）

SOFEA位在主机控制器模式下用于检查当USBFS由于DVSTCTR0.UACT位设置为0而暂停时最后一个SOF的输出是否完成。

在主机控制器模式下，在将SYSCFG.USBE位设置为0以停止USBFS或将SYSCFG.SCKE位设置为0以在通信期间停止时钟信号供应之前，请检查HTACT和SOFEA位是否都为0。

HTACT位（USB主机定序器状态监视器）

当USBFS的主机定序器完全停止时，HTACT位设置为0。

在主机控制器模式下，在将DVSTCTR0.UACT位设置为0以将USBFS置于挂起状态或将SCKE位设置为0以在通信期间停止时钟信号供应之前，请检查HTACT位是否为0。

OVCMON[1:0]位（外部USB_OVRCURAUSB_OVRCURB输入引脚监视器）

15:12	—	These bits are read as 0. The write value should be 0.	R/W

The USBFS controller does not support low-speed connections in device controller mode. When this value is read, abnormal connection processing must be executed in higher level application software.

RHST[2:0] bits (USB Bus Reset Status)

RHST[2:0] bits indicate the status of the USB bus reset.

In host controller mode, writing 1 to the USBRST bit causes the RHST[2:0] bits to set to 100b. When 0 is written to the USBRST bit and the USBFS ends the SE0 state, the RHST[2:0]bits update to a new value.

In device controller mode, if the USBFS detects a USB bus reset, the RHST[2:0] bits indicate 010b if the DPRPU bit is 1, and a DVST interrupt is generated.

UACT bit (USB Bus Enable)

When set to 1 in host controller mode, the UACT bit enables USB bus operation by controlling SOF packet transmission to the USB bus in addition to data and reception. The USBFS starts SOF packet output within one frame period after the UACT bit is set to 1. When UACT is set to 0, the USBFS enters the idle state after the SOF packet output.

The USBFS sets the UACT bit to 0 on any of the following conditions:

- A DTCH interrupt is detected during communication (when UACT = 1)
- An EOFERR interrupt is detected during communication (when UACT = 1)

Always write 1 to the UACT bit at the end of the USB bus reset processing (writing 0 to the USBRST bit) or at the end of resume processing from the suspended state (writing 0 to the RESUME bit).

In device controller mode, always set this bit to 0.

RESUME bit (Resume Output)

The RESUME bit controls the resume signal output in host controller mode.

When this bit is set to 1, the USBFS drives the USB port to the K-state and outputs the resume signal. The USBFS sets the bit to 1 on detection of a remote wakeup signal while the RWUPE bit is 1 and in the USB Suspend state.

The USBFS continues outputting the K-state while the RESUME bit is 1, until the bit is cleared to 0 by software. The RESUME bit must be 1 (resume period) for the time defined in the USB 2.0 specification. Only set this bit to 1 while the interface is in the Suspend state. Write 1 to the UACT bit simultaneously with the end of the resume processing (writing 0 to the RESUME bit).

Always set this bit to 0 in device controller mode.

USBRST bit (USB Bus Reset Output)

The USBRST bit controls the output of the USB bus signal in host controller mode. When this bit set to 1, the USBFS drives the USB port to the SE0 state to reset the USB bus. The USBFS continues outputting SE0 while the USBRST bit is 1, until the bit is cleared to 0 by software. The USBRST bit must be 1 (USB bus reset period) for the time defined in the USB 2.0 specification. Writing 1 to the USBRST bit during communication (UACT = 1) or during resume processing (RESUME

15:12	—	这些位被读取为0。写入值应为0。	R/W

USBFS控制器不支持设备控制器模式下的低速连接。当读取此值时，必须在更高级别的应用软件中执行异常连接处理。

RHST[2:0]位（USB总线复位状态）

RHST[2:0]位指示USB总线复位的状态。

在主机控制器模式下，将1写入USBRST位会导致RHST[2:0]位设置为100b。当0被写入USBRST位和USBFS结束SE0状态，RHST[2:0]位更新为新值。

在设备控制器模式下，如果USBFS检测到USB总线复位，如果DPRPU位为1，则RHST[2:0]位指示010b，并产生DVST中断。

UACT位（USB总线使能）

在主机控制器模式下设置为1时，UACT位通过控制向USB总线发送SOF数据包以及数据和接收来启用USB总线操作。USBFS在UACT位设置为1后的一帧周期内开始SOF数据包输出。当UACT设置为0时，USBFS在SOF数据包输出后进入空闲状态。

USBFS在以下任何条件下将UACT位设置为0：

●通信期间检测到DTCH中断（当UACT=1时）

●通信期间检测到EOFERR中断（当UACT=1时）

在USB总线复位处理结束（将0写入USBRST位）或从挂起状态恢复处理结束（将0写入RESUME位）时，始终向UACT位写入1。

在设备控制器模式下，始终将此位设置为0。

RESUME位（恢复输出）

RESUME位控制主机控制器模式下的恢复信号输出。

当该位设置为1时，USBFS将USB端口驱动到K状态并输出恢复信号。当RWUPE位为1且处于USB挂起状态时，USBFS在检测到远程唤醒信号时将该位设置为1。

当RESUME位为1时，USBFS继续输出K状态，直到该位被软件清除为0。这在USB2.0规范中定义的时间内，RESUME位必须为1（恢复周期）。仅当接口处于挂起状态时将此位设置为1。在恢复处理结束的同时向UACT位写入1（向RESUME位写入0）。

在设备控制器模式下始终将此位设置为0。

USBRST位（USB总线复位输出）

USBRST位控制主机控制器模式下USB总线信号的输出。当该位设置为1时，USBFS将USB端口驱动到SE0状态以复位USB总线。当USBRST位为1时，USBFS继续输出SE0，直到该位被软件清零。在USB2.0规范中定义的时间内，USBRST位必须为1（USB总线复位周期）。通信期间(UACT=1)或恢复处理期间(RESUME)向USBRST位写入1

= 1) prevents the USBFS from starting USB bus reset processing until both the UACT and RESUME bits become 0. Write 1 to the UACT bit simultaneously with the end of the USB bus reset processing (writing 0 to the USBRST bit).

Always set this bit to 0 in device controller mode.

RWUPE bit (Wakeup Detection Enable)

The RWUPE bit enables or disables remote wakeup signals (resume signals) from downstream peripheral devices in host controller mode. When this bit is set to 1, the USBFS detects a remote wakeup signal (K-state for 2.5 µs) from a downstream peripheral device, and performs resume processing, driving the K-state. When the RWUPE bit is set to 0, the USBFS ignores remote wakeup signals (K-states) from peripheral devices connected to the USB port.

Do not stop the internal clock when the RWUPE bit is 1, even in the Suspend state (SYSCFG.SCKE bit must be set to 1).

Always set this bit to 0 in device controller mode.

WKUP bit (Wakeup Output)

The WKUP bit enables or disables remote wakeup signals (resume signals) to the USB bus in device controller mode.

The USBFS controls the output timing of the remote wakeup signals. When this bit is set to 1, the USBFS clears it to 0 after outputting the K-state for 10 ms. The USB 2.0 specification specifies that the USB bus idle state must be kept for 5 ms or longer before a remote wakeup signal is sent. If the USBFS writes 1 to the WKUP bit immediately after detecting the Suspend state, the K-state is output after 2 ms.

Only write 1 to the WKUP bit when the device is in the Suspend state (INTSTS0.DVSQ[2:0] = 1xxb) and the USB host enables the remote wakeup signal (RWUPE = 1). Do not stop the internal clock while this bit is 1, even in the Suspend state (SYSCFG.SCKE bit must be set to 1).

Always set this bit to 0 in host controller mode.

HNPBTOA bit (Host Negotiation Protocol (HNP) Control)

TheHNPBTOA bit is used when switching from device B to device A while in OTG mode.

If the HNPBTOA bit is 1, the internal function control maintains the Suspend state until HNP processing ends, even if the SYSCFG.DPRPU bit is set to 0 or the SYSCFG.DCFM bit is set to 1. Resume interrupts (RESM) are not generated even if a falling edge of D+ is detected.

The HNP processing ends when a host attach event is detected, because of a pull-up by the initiating party, or the HNPBTOA bit is cleared to 0 by software because the HNP processing times out.

Note 1. The valid bits depend on the MBW settings (CFIFOSEL.MBW) and BIGEND settings (CFIFOSEL.BIGEND) in the associated port selection register. See Table 28.5 and Table 28.6.

Three FIFO ports are available:

=1)防止USBFS开始USB总线复位处理，直到UACT和RESUME位都变为0。在USB总线复位处理结束的同时向UACT位写入1（向USBRST位写入0）。

在设备控制器模式下始终将此位设置为0。

RHUPE位（唤醒检测使能）

在主机控制器模式下，RWUPE位启用或禁用来自下游外围设备的远程唤醒信号（恢复信号）。当该位设置为1时，USBFS检测到来自下游外围设备的远程唤醒信号（K状态持续2.5µs），并执行恢复处理，驱动K状态。当RHUPE位设置为0时，USBFS忽略来自连接到USB端口的外围设备的远程唤醒信号（K状态）。

当RHUPE位为1时不要停止内部时钟，即使处于挂起状态（SYSCFG.SCKE位必须设置为1）。

在设备控制器模式下始终将此位设置为0。

WKUP bit (Wakeup Output)

WKUP位在设备控制器模式下启用或禁用到USB总线的远程唤醒信号（恢复信号）。

USBFS控制远程唤醒信号的输出时序。当该位设置为1时，USBFS在输出K状态10ms后将其清除为0。USB2.0规范规定，在发送远程唤醒信号之前，USB总线空闲状态必须保持5ms或更长时间。如果USBFS在检测到Suspend状态后立即向WKUP位写入1，则在2ms后输出K-state。

仅当设备处于挂起状态（INTSTS0.DVSQ[2:0]=1xxb）且USB主机使能远程唤醒信号（RWUPE=1）时向WKUP位写入1。当该位为1时不要停止内部时钟，即使处于挂起状态（SYSCFG.SCKE位必须设置为1）。

在主机控制器模式下始终将此位设置为0。

HNPBTOA位（主机协商协议(HNP)控制）

在OTG模式下从设备B切换到设备A时使用HNPBTOA位。

如果HNPBTOA位为1，内部功能控制保持暂停状态直到HNP处理结束，即使SYSCFG.DPRPU位设置为0或SYSCFG.DCFM位设置为1。不产生恢复中断(RESM)即使检测到D+的下降沿。

当检测到主机连接事件时，HNP处理结束，因为发起方的上拉，或者
由于HNP处理超时，HNPBTOA位由软件清零。

Each FIFO port is configured with:

- A port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that selects the pipe assigned to the FIFO port
- A port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR)

Each FIFO port has the following constraints:

- Access to the FIFO buffer for DCP control transfers is through the CFIFO port
- Access to the FIFO buffer for DMA or DTC transfers is through the D0FIO or D1FIFO port

Do not change the pipe number while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (CFIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number to use for reading or writing data through the CFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

启用DMA或DTC传输时不要更改管道编号。

CURPIPE[3:0]位（CFIFO端口访问管道规范）

CURPIPE[3:0]位指定用于通过CFIFO端口读取或写入数据的管道编号。写入这些位后，读取它们以检查写入的值是否与读取的值一致，然后再进行下一个过程。不要为CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位设置相同的管道编号。

RA生态工作室

During FIFO buffer access, even when an attempt is made to change the CURPIPE[3:0] setting, the current access setting is retained until access is complete.

ISEL bit (CFIFO Port Access Direction When DCP Is Selected)

After writing a new value to the ISEL bit with the DCP as the selected pipe, read the ISEL bit to check that the written value agrees with the read value before proceeding to the next process. Set the ISEL and CURPIPE[3:0] bits simultaneously.

MBW bit (CFIFO Port Access Bit Width)

The MBW bit specifies the bit width for accessing the CFIFO port.

When the selected pipe is receiving, set the CURPIPE[3:0] and MBW bits simultaneously. After a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read.

When the selected pipe is transmitting, the bit width cannot be changed from 8-bit to 16-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double buffering, this setting enables re-reading of the currently-read FIFO buffer plane from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the REW bit to 1, be sure to check that the FRDY bit is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

在FIFO缓冲区访问期间，即使尝试更改CURPIPE[3:0]设置，当前访问设置也会保留，直到访问完成。

ISEL位（选择DCP时的CFIFO端口访问方向）

在以DCP作为选定管道的情况下将新值写入ISEL位后，读取ISEL位以检查写入的值是否与读取的值一致，然后再进行下一个过程。同时设置ISEL和CURPIPE[3:0]位。

MBW位（CFIFO端口访问位宽度）

MBW位指定访问CFIFO端口的位宽。

当所选管道正在接收时，同时设置CURPIPE[3:0]和MBW位。在写入这些位开始从FIFO缓冲区读取数据后，在读取所有数据之前不要更改这些位。

当所选管道正在传输时，位宽不能从8位更改为16位，同时数据正在写入FIFO缓冲区。

即使选择了16位宽度，也可以通过字节访问控制写入奇数个字节。

REW位（缓冲区指针倒带）

REW位指定是否倒回缓冲区指针。

当所选管道正在接收时，在读取FIFO缓冲区时将此位设置为1允许从第一个数据重新读取FIFO缓冲区。在双缓冲中，此设置允许从第一个条目重新读取当前读取的FIFO缓冲区平面。

请勿在同时更改CURPIPE[3:0]位时将此位设置为1。在将REW位设置为1之前，请务必检查FRDY位是否为1。

要从传输管道的第一个数据重写FIFO缓冲区，请使用BCLR位。

The same pipe must not be specified in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected. The pipe number must not be changed while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number to use for reading or writing data through the DnFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, even when an attempt is made to change the CURPIPE[3:0] setting, the current access setting is retained until access is complete.

MBW bit (FIFO Port Access Bit Width)

The MBW bit specifies the bit width for accessing the DnFIFO port.

When the selected pipe is receiving, after a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read. Set the CURPIPE[3:0] and MBW bits simultaneously.

When the selected pipe is transmitting, the bit width cannot be changed from 8-bit to 16-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16-bit width is selected.

DREQE bit (DMA/DTC Transfer Request Enable)

The DREQE bit enables or disables issuing of DMA or DTC transfer requests. To enable DMA or DTC transfer requests, set this bit to 1 after setting the CURPIPE[3:0] bits. To change the CURPIPE[3:0] setting, first set this bit to 0.

DCLRM bit (Auto Buffer Memory Clear Mode Accessed after Specified Pipe Data is Read)

The DCLRM bit enables or disables automatic FIFO buffer clearing after data in the selected pipe is read.

When this bit is set to 1, on receiving a zero-length packet while the FIFO buffer assigned to the selected pipe is empty, or when reading of a received short packet is complete while the PIPECFG.BFRE bit is 1, the USBFS sets the BCLR bit in the FIFO port control register to 1.

When using the USBFS with the SOFCFG.BRDYM bit set to 1, set this bit to 0.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double buffering, this setting enables re-reading of the currently-read FIFO buffer plane from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the bit to 1, be sure to check that the FRDY bit is 1.

不能在CFIFOSEL、D0FIFOSEL和D1FIFOSEL寄存器的CURPIPE[3:0]位中指定相同的管道。当D0FIFOSEL和D1FIFOSEL寄存器中的CURPIPE[3:0]位设置为0000b时，不选择管道。启用DMA或DTC传输时，不得更改管道编号。

CURPIPE[3:0]位（FIFO端口访问管道规范）

CURPIPE[3:0]位指定用于通过DnFIFO端口读取或写入数据的管道编号。写入这些位后，读取它们以检查写入的值是否与读取的值一致，然后再进行下一个过程。不要为CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位设置相同的管道编号。

在FIFO缓冲区访问期间，即使尝试更改CURPIPE[3:0]设置，当前访问设置也会保留，直到访问完成。

MBW位（FIFO端口访问位宽度）

MBW位指定访问DnFIFO端口的位宽。

当所选管道正在接收时，在写入这些位后开始从FIFO缓冲区读取数据，在读取所有数据之前不要更改这些位。同时设置CURPIPE[3:0]和MBW位。

当所选管道正在传输时，位宽不能从8位更改为16位，同时数据正在写入FIFO缓冲区。

即使选择了16位宽度，也可以通过字节访问控制写入奇数个字节。

DREQE位（DMADTC传输请求使能）

DREQE位启用或禁用DMA或DTC传输请求的发出。要启用DMA或DTC传输请求，请在设置CURPIPE[3:0]位后将此位设置为1。要更改CURPIPE[3:0]设置，首先将该位设置为0。

DCLRM位（读取指定管道数据后访问的自动缓冲存储器清除模式）

在读取所选管道中的数据后，DCLRM位启用或禁用自动FIFO缓冲区清除。

当该位设置为1时，在分配给所选管道的FIFO缓冲区为空时接收到零长度数据包，或在PIPECFG.BFRE位为1时完成读取接收到的短数据包时，USBFS设置FIFO端口控制寄存器中的BCLR位为1。

当使用SOFCFG.BRDYM位设置为1的USBFS时，将此位设置为0。

REW位（缓冲区指针倒带）

REW位指定是否倒回缓冲区指针。

当所选管道正在接收时，在读取FIFO缓冲区时将此位设置为1允许从第一个数据重新读取FIFO缓冲区。在双缓冲中，此设置允许从第一个条目重新读取当前读取的FIFO缓冲区平面。

请勿在同时更改CURPIPE[3:0]位时将此位设置为1。在将该位设置为1之前，请务必检查FRDY位是否为1。

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

RCNT bit (Read Count Mode)

The RCNT bit specifies the read mode for the value in the CFIFOCTR.DTLN bit. When accessing DnFIFO with the PIPECFG.BFRE bit set to 1, set the RCNT bit to 0.

28.2.8 CFIFOCTR : CFIFO Port Control Register

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[8:0] bits (Receive Data Length)

The DTLN[8:0] bits indicate the length of the receive data.

While the FIFO buffer is being read, the DTLN[8:0] bits indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1), as follows:

- RCNT = 0

  The USBFS sets the DTLN[8:0] bits to indicate the length of the receive data until the CPU or DMA/DTC has read all of the received data from a single FIFO buffer plane.

  While the PIPECFG.BFRE bit = 1, the USBFS retains the length of the receive data until the BCLR bit is set to 1, even after all the data is read.

- RCNT = 1

  The USBFS decrements the value indicated in the DTLN[8:0] bits each time data is read from the FIFO buffer. The value is decremented by 1 when MBW = 0, and by 2 when MBW = 1.

  The USBFS sets these bits to 0 when all the data is read from one FIFO buffer plane. In double buffer mode, if data is received in one FIFO buffer plane before all of the data is read from the other plane, the USBFS sets these bits to indicate the length of the receive data in the former plane when all of the data is read from the latter plane.

FRDY bit (FIFO Port Ready)

The FRDY bit indicates whether the FIFO port can be accessed by the CPU or DMA/DTC.

In the following cases, the USBFS sets the FRDY bit to 1 but data cannot be read through the FIFO port because there is no data to be read:

要从传输管道的第一个数据重写FIFO缓冲区，请使用BCLR位。

RCNT位（读取计数模式）

RCNT位指定CFIFOCTR.DTLN位中值的读取模式。当使用DnFIFO访问PIPECFG.BFRE位设置为1，将RCNT位设置为0。

15	BVAL	缓冲存储器有效标志 0：无效（写入0无效）1：写入结束	R/W

CFIFOCTR、D0FIFOCTR和D1FIFOCTR寄存器对应于CFIFO、D0FIFO和D1FIFO缓冲区。

DTLN[8:0]位（接收数据长度）

DTLN[8:0]位指示接收数据的长度。

在读取FIFO缓冲区时，DTLN[8:0]位指示不同的值，具体取决于DnFIFOSEL.RCNT位(n=0 1)，如下所示：

- RCNT = 0

  USBFS设置DTLN[8:0]位以指示接收数据的长度，直到CPU或DMADTC从单个FIFO缓冲区平面读取所有接收数据。

  当PIPECFG.BFRE位=1时，USBFS将保留接收数据的长度，直到BCLR位设置为1，即使在读取所有数据之后也是如此。

- RCNT = 1

  每次从FIFO缓冲区读取数据时，USBFS都会递减DTLN[8:0]位中指示的值。当MBW=0时该值减1，当MBW=1时该值减2。

  当从一个FIFO缓冲平面读取所有数据时，USBFS将这些位设置为0。在双缓冲模式下，如果在一个FIFO缓冲平面中的数据在从另一个平面读取所有数据之前接收到数据，则USBFS设置这些位以指示在读取所有数据时在前一个平面中接收数据的长度从后一个平面。

FRDY位（FIFO端口就绪）

FRDY位指示FIFO端口是否可以被CPU或DMADTC访问。

在以下情况下，USBFS将FRDY位设置为1，但由于没有数据可读取，因此无法通过FIFO端口读取数据：

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit = 1

In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

BCLR bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU side for the selected pipe.

When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USBFS clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the DCP is the selected pipe, setting the BCLR bit to 1 allows the USBFS to clear the FIFO buffer regardless of whether the CPU or SIE has access rights. To clear the buffer when the SIE has access rights, set the DCPCTR.PID[1:0] bits to 00b (NAK response) before setting the BCLR bit to 1.

When the selected pipe is transmitting, if 1 is written to the BVAL flag and the BCLR bit simultaneously, the USBFS clears the data that is already written, enabling transmission of a zero-length packet.

When the selected pipe is not the DCP, only write 1 to the BCLR bit while the FRDY bit in the FIFO port control register is 1 (set by the USBFS).

BVAL flag (Buffer Memory Valid Flag)

Set the BVAL flag to 1 when data is completely written to the FIFO buffer on the CPU side for the pipe selected in CURPIPE[3:0].

When the selected pipe is transmitting, set this flag to 1 in the following cases:

- To transmit a short packet, set this flag to 1 after data is written
- To transmit a zero-length packet, set this flag to 1 before data is written to the FIFO buffer

The USBFS then switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When data of the maximum packet size is written for the pipe in continuous transfer mode, the USBFS sets the BVAL flag to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

Only write 1 to the BVAL flag while the FRDY bit is 1 (set by the USBFS). When the selected pipe is receiving, do not set the BVAL flag to 1.

28.2.9 DnFIFOCTR : DnFIFO Port Control Register (n = 0, 1)

Base address: USBFS = 0x4009_0000

Offset address: 0x02A + 0x4 × n

Bit	Symbol	Function	R/W
8:0	DTLN[8:0]	Receive Data Length Indicates the receive data length. The meaning of the values differs depending on the RCNT bit setting in the port select register. For details, see the description of the DTLN[8:0] bits.	R
12:9	—	These bits are read as 0. The write value should be 0.	R/W
13	FRDY	FIFO Port Ready 0: FIFO port access disabled 1: FIFO port access enabled	R

●当分配给所选管道的FIFO缓冲区为空时，接收到一个长度为零的数据包

●PIPECFG.BFRE位=1时接收到一个短数据包并完全读取数据

在这些情况下，将BCLR位设置为1以清除FIFO缓冲区，并启用下一个数据的发送和接收。

BCLR位（CPU缓冲区清除）

将BCLR位设置为1以清除所选管道的CPU端的FIFO缓冲区。

当分配给所选管道的FIFO缓冲区设置为双缓冲区模式时，USBFS仅清除
即使两个平面都已启用读取，也有FIFO缓冲区。

当DCP为选定管道时，将BCLR位设置为1允许USBFS清除FIFO缓冲区，而不管CPU或SIE是否具有访问权限。要在SIE具有访问权限时清除缓冲区，请将DCPCTR.PID[1:0]位设置为00b（NAK响应），然后再将BCLR位设置为1。

当所选管道正在传输时，如果同时向BVAL标志和BCLR位写入1，则USBFS会清除已写入的数据，从而可以传输零长度数据包。

当所选管道不是DCP时，仅在FIFO端口控制寄存器中的frdy位为1（由USBF设置）时，仅将1个写入BCLR位。

BVAL标志（缓冲存储器有效标志）

当数据完全写入CPU端的FIFO缓冲区时，将BVAL标志设置为1，用于在
CURPIPE[3:0].

当所选管道正在传输时，在以下情况下将此标志设置为1：

●要发送一个短包，在数据写入后将此标志设置为1

●要发送零长度数据包，请在数据写入FIFO缓冲区之前将此标志设置为1

然后USBFS将FIFO缓冲区从CPU端切换到SIE端，从而启用传输。

当在连续传输模式下为管道写入最大数据包大小的数据时，USBFS将BVAL标志设置为1，并将FIFO缓冲区从CPU侧切换到SIE侧，从而启用传输。

仅在FRDY位为1（由USBFS设置）时将1写入BVAL标志。当所选管道正在接收时，不要将BVAL标志设置为1。

Note 1. Only 0 can be read.

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[8:0] bits (Receive Data Length)

The DTLN[8:0] bits indicate the length of the receive data.

While the FIFO buffer is being read, the DTLN[8:0] bits indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1), as follows:

- RCNT = 0

  The USBFS sets the DTLN[8:0] bits to indicate the length of the receive data until the CPU or DMA/DTC has read all of the received data from a single FIFO buffer plane.

  While the PIPECFG.BFRE bit = 1, the USBFS retains the length of the receive data until the BCLR bit is set to 1, even after all the data is read.

- RCNT = 1

  The USBFS decrements the value indicated in the DTLN[8:0] bits each time data is read from the FIFO buffer. The value is decremented by 1 when MBW = 0, and by 2 when MBW = 1.

  The USBFS sets these bits to 0 when all the data is read from one FIFO buffer plane. In double buffer mode, if data is received in one FIFO buffer plane before all of the data is read from the other plane, the USBFS sets these bits to indicate the length of the receive data in the former plane when all of the data is read from the latter plane.

FRDY bit (FIFO Port Ready)

The FRDY bit indicates whether the FIFO port can be accessed by the CPU or DMA/DTC.

In the following cases, the USBFS sets the FRDY bit to 1 but data cannot be read through the FIFO port because there is no data to be read:

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit = 1

In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

BCLR bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU side for the selected pipe.

When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USBFS clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the DCP is the selected pipe, setting the BCLR bit to 1 allows the USBFS to clear the FIFO buffer regardless of whether the CPU or SIE has access rights. To clear the buffer when the SIE has access rights, set the DCPCTR.PID[1:0] bits to 00b (NAK response) before setting the BCLR bit to 1.

When the selected pipe is transmitting, if 1 is written to the BVAL flag and the BCLR bit simultaneously, the USBFS clears the data that is already written, enabling transmission of a zero-length packet.

When the selected pipe is not the DCP, only write 1 to the BCLR bit while the FRDY bit in the FIFO port control register is 1 (set by the USBFS).

BVAL flag (Buffer Memory Valid Flag)

Set the BVAL flag to 1 when data is completely written to the FIFO buffer on the CPU side for the pipe selected in CURPIPE[3:0].

When the selected pipe is transmitting, set this flag to 1 in the following cases:

- To transmit a short packet, set this flag to 1 after data is written

Bit	Symbol	Function	R/W
15	BVAL	缓冲存储器有效标志 0：无效（写入0无效）1：写入结束	R/W

注1.只能读取0。

CFIFOCTR、D0FIFOCTR和D1FIFOCTR寄存器对应于CFIFO、D0FIFO和D1FIFO缓冲区。

DTLN[8:0]位（接收数据长度）

DTLN[8:0]位指示接收数据的长度。

在读取FIFO缓冲区时，DTLN[8:0]位指示不同的值，具体取决于DnFIFOSEL.RCNT位(n=0 1)，如下所示：

- RCNT = 0

  USBFS设置DTLN[8:0]位以指示接收数据的长度，直到CPU或DMADTC从单个FIFO缓冲区平面读取所有接收数据。

  当PIPECFG.BFRE位=1时，USBFS将保留接收数据的长度，直到BCLR位设置为1，即使在读取所有数据之后也是如此。

- RCNT = 1

  每次从FIFO缓冲区读取数据时，USBFS都会递减DTLN[8:0]位中指示的值。当MBW=0时该值减1，当MBW =1时该值减2。

  当从一个FIFO缓冲平面读取所有数据时，USBFS将这些位设置为0。在双缓冲模式下，如果在一个FIFO缓冲平面中的数据在从另一个平面读取所有数据之前接收到数据，则USBFS设置这些位以指示在读取所有数据时在前一个平面中接收数据的长度从后一个平面。

FRDY位（FIFO端口就绪）

FRDY位指示FIFO端口是否可以被CPU或DMADTC访问。

在以下情况下，USBFS将FRDY位设置为1，但由于没有数据可读取，因此无法通过FIFO端口读取数据：

●当分配给所选管道的FIFO缓冲区为空时，接收到一个长度为零的数据包

●PIPECFG.BFRE位=1时接收到一个短数据包并完全读取数据

在这些情况下，将BCLR位设置为1以清除FIFO缓冲区，并启用下一个数据的发送和接收。

BCLR位（CPU缓冲区清除）

将BCLR位设置为1以清除所选管道的CPU端的FIFO缓冲区。

当分配给所选管道的FIFO缓冲区设置为双缓冲区模式时，USBFS仅清除
即使两个平面都已启用读取，也有FIFO缓冲区。

当DCP为选定管道时，将BCLR位设置为1允许USBFS清除FIFO缓冲区，而不管CPU或SIE是否具有访问权限。要在SIE具有访问权限时清除缓冲区，请将DCPCTR.PID[1:0]位设置为00b（NAK响应），然后再将BCLR位设置为1。

当所选管道正在传输时，如果同时向BVAL标志和BCLR位写入1，则USBFS会清除已写入的数据，从而可以传输零长度数据包。

当所选管道不是DCP时，仅在FIFO端口控制寄存器中的frdy位为1（由USBF设置）时，仅将1个写入BCLR位。

BVAL标志（缓冲存储器有效标志）

当数据完全写入CPU端的FIFO缓冲区时，将BVAL标志设置为1，用于在
CURPIPE[3:0].

当所选管道正在传输时，在以下情况下将此标志设置为1：

●要发送一个短包，在数据写入后将此标志设置为1

- To transmit a zero-length packet, set this flag to 1 before data is written to the FIFO buffer

The USBFS then switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When data of the maximum packet size is written for the pipe in continuous transfer mode, the USBFS sets the BVAL flag to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

Only write 1 to the BVAL flag while the FRDY bit is 1 (set by the USBFS). When the selected pipe is receiving, do not set the BVAL flag to 1.

●要发送零长度数据包，请在数据写入FIFO缓冲区之前将此标志设置为1

然后USBFS将FIFO缓冲区从CPU端切换到SIE端，从而启用传输。

当在连续传输模式下为管道写入最大数据包大小的数据时，USBFS将BVAL标志设置为1，并将FIFO缓冲区从CPU侧切换到SIE侧，从而启用传输。

Set this bit to 1 when a low-speed device is connected. The bit is only valid in host controller mode. Set this bit to 0 in device controller mode.

在主机控制器模式下，CTSQ[2:0]位的读取值无效。

RA生态工作室

VALID bit (USB Request Reception)

In host controller mode, the read value of the VALID bit is invalid.

DVSQ[2:0] bits (Device State)

The DVSQ[2:0] bits are initialized by a USB bus reset. In host controller mode, the read value is invalid.

BRDY flag (Buffer Ready Interrupt Status)

The BRDY flag indicates the BRDY interrupt status.

The USBFS sets the BRDY bit to 1 when it detects a BRDY interrupt status (PIPEnBRDY = 1, n = 0 to 9) on at least one pipe for which BRDY interrupts are enabled (BRDYENB.PIPEnBRDYE = 1).

For the conditions that cause the PIPEnBRDY status to be asserted, see section 28.3.3.1. BRDY interrupt.

The USBFS sets the BRDY bit to 0 when the software writes 0 to all of the PIPEnBRDY bits associated with the PIPEnBRDYE bits that are set to 1. Writing 0 to the BRDY flag in the software does not clear the flag.

NRDY flag (Buffer Not Ready Interrupt Status)

The NRDY flag indicates the NRDY interrupt status.

The USBFS sets the NRDY bit to 1 when it detects a NRDY interrupt status (PIPEnNRDY = 1, n = 0 to 9) on at least one pipe for which NRDY interrupts are enabled (NRDYENB.PIPEnNRDYE = 1).

For the conditions that cause the PIPEnNRDY status to be asserted, see section 28.3.3.2. NRDY interrupt.

The USBFS sets the NRDY bit to 0 when the software writes 0 to all of the PIPEnNRDY bits associated with the PIPEnNRDYE bits that are set to 1. Writing 0 to the NRDY flag in the software does not clear the flag.

BEMP flag (Buffer Empty Interrupt Status)

The BEMP flag indicates the BEMP interrupt status.

The USBFS sets the BEMP bit to 1 when it detects a BEMP interrupt status (PIPEnBEMP = 1, n = 0 to 9) on at least one pipe for which BEMP interrupts are enabled (BEMPENB.PIPEnBEMPE = 1).

For the conditions that cause the PIPEnBEMP status to be asserted, see section 28.3.3.3. BEMP interrupt.

The USBFS sets the BEMP bit to 0 when the software writes 0 to all of the PIPEnBEMP bits associated with the PIPEnBEMPE bits that are set to 1. Writing 0 to the BEMP flag in the software does not clear the flag.

CTRT flag (Control Transfer Stage Transition Interrupt Status)

In device controller mode, the USBFS updates the value of the CTSQ[2:0] bits and sets the CTRT flag to 1 on detecting a transition in the control transfer stage. When a control transfer stage transition interrupt occurs, clear the CTRT flag before the USBFS detects the next control transfer stage transition.

Values read from the CTRT flag in host controller mode are invalid.

DVST flag (Device State Transition Interrupt Status)

In device controller mode, the USBFS updates the value of the DVSQ[2:0] bits and sets the DVST flag to 1 on detecting a change in the device state. When a device state transition interrupt occurs, clear theDVST flag before the USBFS detects the next device state transition.

Values read from the DVST flag in host controller mode are invalid.

SOFR flag (Frame Number Refresh Interrupt Status)

In host controller mode, the USBFS sets the SOFR flag to 1 on updating the frame number when the DVSTCTR0.UACT bit is set to 1 by software. A SOFR interrupt is detected every 1 ms.

In device controller mode, the USBFS sets the SOFR flag to 1 on updating the frame number. A frame number refresh interrupt is detected every 1 ms.

The USBFS can detect an SOFR interrupt through the internal interpolation function even when a corrupted SOF packet is received from the USB host.

有效位（USB请求接收）

当USBFS在至少一个启用了BRDY中断(BRDYENB.PIPEnBRDYE=1)的管道上检测到BRDY中断状态(PIPEnBRDY=1 n=0到9)时，将BRDY位设置为1。

有关导致PIPEnBRDY状态被断言的条件，请参见第28.3.3.1节。BRDY中断。

当软件将0写入与
设置为1的PIPEnBRDYE位。在软件中将0写入BRDY标志不会清除该标志。

NRDY标志指示NRDY中断状态。

当USBFS在至少一个启用了NRDY中断(NRDYENB.PIPEnNRDYE=1)的管道上检测到NRDY中断状态(PIPEnNRDY=1 n=0到9)时，将NRDY位设置为1。

有关导致PIPEnNRDY状态被断言的条件，请参见第28.3.3.2节。NRDY中断。

USBFS将NRDY位设置为0，当软件将0写入与
设置为1的PIPEnNRDYE位。在软件中将0写入NRDY标志不会清除该标志。

BEMP标志（缓冲区空中断状态）

BEMP标志指示BEMP中断状态。

当USBFS在至少一个启用了BEMP中断(BEMPENB.PIPEnBEMPE=1)的管道上检测到BEMP中断状态(PIPEnBEMP=1 n=0到9)时，将BEMP位设置为1。

有关导致PIPEnBEMP状态被断言的条件，请参见第28.3.3.3节。BEMP中断。

当软件将0写入与
PIPEnBEMPE位设置为1。在软件中将0写入BEMP标志不会清除该标志。

在设备控制器模式下，USBFS更新CTSQ[2:0]位的值，并在检测到控制传输阶段的转换时将CTRT标志设置为1。当控制传输阶段转换中断发生时，在USBFS检测到下一个控制传输阶段转换之前清除CTRT标志。

在主机控制器模式下从CTRT标志读取的值无效。

DVST标志（设备状态转换中断状态）

在设备控制器模式下，USBFS更新DVSQ[2:0]位的值，并在检测到设备状态发生变化时将DVST标志设置为1。当设备状态转换中断发生时，在USBFS检测到下一个设备状态转换之前清除DVST标志。

在主机控制器模式下从DVST标志读取的值无效。

SOFR标志（帧号刷新中断状态）

在主机控制器模式下，当软件将DVSTCTR0.UACT位设置为1时，USBFS在更新帧号时将SOFR标志设置为1。每1ms检测一次SOFR中断。

在设备控制器模式下，USBFS在更新帧号时将SOFR标志设置为1。每1ms检测一次帧号刷新中断。

即使从USB主机接收到损坏的SOF数据包，USBFS也可以通过内部插值功能检测SOFR中断。

RESM flag (Resume Interrupt Status)

In device controller mode, the USBFS sets the RESM flag to 1 on detecting the falling edge of the signal on the USB_DP pin in the Suspend state (DVSQ[2:0] = 1xxb). Values read from the RESM flag in host controller mode are invalid.

VBINT flag (VBUS Interrupt Status)

The USBFS sets the VBINT flag to 1 on detecting a level change (high to low or low to high) in the USB_VBUS pin input value. The USBFS sets the VBSTS flag to indicate the USB_VBUS pin input value. When a VBUS interrupt occurs, eliminate transient elements by reading the VBSTS flag at least three times through software processing and check that the values read are the same.

Note 1. The USBFS detects a change in the status in the PDDETINT, OVRCR or BCHG bit even when the clock supply is stopped (SYSCFG.SCKE = 0), and it requests the interrupt when the associated interrupt request bit is 1. RA生态工作室

clearing the status through the software. No other interrupts can be detected while the clock supply is stopped (SYSCFG.SCKE bit = 0).

INTSTS1 is used to confirm the status of each interrupt in host controller mode. Only enable the status change interrupts indicated in the bits in INTSTS1 in host controller mode.

PDDETINT flag (PDDET Detection Interrupt Status Flag)

The USBFS sets the PDDETINT flag to 1 on detecting a level change (high to low or low to high) in the PDDET pin input value. When the PDDETINT interrupt is generated, perform debouncing by reading the BCCTRL1.PDDETSTS flag at least three times through software processing and checking that the values read are the same.

SACK flag (Setup Transaction Normal Response Interrupt Status)

The SACK flag indicates the status of the setup transaction normal response interrupt in host controller mode.

The USBFS detects the SACK interrupt and sets this flag to 1 when an ACK response is returned from a peripheral device during the setup transactions issued by the USBFS. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

Values read from the SACK flag in device controller mode are invalid.

SIGN flag (Setup Transaction Error Interrupt Status)

The SIGN flag indicates the status of setup transaction error interrupts in host controller mode.

The USBFS detects the SIGN interrupt and sets this flag to 1 when an ACK response is not returned from a peripheral device three consecutive times during the setup transactions issued by the USBFS. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS detects the SIGN interrupt when any of the following response conditions occur for three consecutive setup transactions:

- Timeout is detected by the USBFS when the peripheral device has returned no response
- A corrupted ACK packet is received
- A handshake other than ACK (NAK, NYET, or STALL) is received

Values read from the SIGN flag in device controller mode are invalid.

EOFERR flag (EOF Error Detection Interrupt Status)

The EOFERR flag indicates the status of EOF error detection interrupts in host controller mode.

The USBFS detects the EOFERR interrupt and sets this flag to 1 on detecting that communication did not complete at the EOF2 timing defined in the USB 2.0 specification. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

After detecting the EOFERR interrupt, the USBFS controls the hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt was detected to 0
- Puts the port in which the EOFERR interrupt occurred into the idle state

The software must terminate all pipes in which communications are being carried out and re-enumerate the USB port.

Values read from the EOFERR flag in device controller mode are invalid.

ATTCH flag (ATTCH Interrupt Status)

The ATTCH flag indicates the status of USB attach detection interrupts in host controller mode.

The USBFS detects the ATTCH interrupt and sets this flag to 1 on detecting a J- or K-state on the full- or low-speed signal level for 2.5 µs. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS detects the ATTCH interrupt on any of the following conditions.

- K-state, SE0, or SE1 changes to J-state, and J-state continues for 2.5 µs
- J-state, SE0, or SE1 changes to K-state, and K-state continues for 2.5 µs

Values read from the ATTCH flag in device controller mode are invalid.

通过软件清除状态。停止提供时钟（SYSCFG.SCKE位=0）时，不会检测到其他中断。

INTSTS1用于确认主机控制器模式下每个中断的状态。仅在主机控制器模式下启用INTSTS1位中指示的状态更改中断。

PDDETINT标志（PDDET检测中断状态标志）

USBFS在检测到PDDET引脚输入值的电平变化（从高到低或从低到高）时将PDDETINT标志设置为1。当产生PDDETINT中断时，通过软件处理至少3次读取BCCTRL1.PDDETSTS标志并检查读取的值是否相同来执行去抖动。

SACK标志（设置事务正常响应中断状态）

SACK标志指示主机控制器模式下设置事务正常响应中断的状态。

在USBFS发出的设置事务期间，当外围设备返回ACK响应时，USBFS检测到SACK中断并将该标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

在设备控制器模式下从SACK标志读取的值无效。

SIGN标志（设置事务错误中断状态）

SIGN标志指示主机控制器模式下设置事务错误中断的状态。

在USBFS发出的设置事务期间，如果外围设备连续3次没有返回ACK响应，则USBFS检测到SIGN中断并将该标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

当三个连续的设置事务发生以下任何响应条件时，USBFS检测到SIGN中断：

●当外围设备没有返回响应时，USBFS检测到超时
●收到损坏的ACK数据包
●收到ACK（NAK、NYET或STALL）以外的握手

在设备控制器模式下从SIGN标志读取的值无效。

EOFERR标志（EOF错误检测中断状态）

EOFERR标志指示主机控制器模式下EOF错误检测中断的状态。

USBFS检测到EOFERR中断，并在检测到通信未在USB2.0规范中定义的EOF2时序完成时将该标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

检测到EOFERR中断后，USBFS对硬件进行如下控制，而不考虑相关的中断使能位设置：

●将检测到EOFERR中断的端口的DVSTCTR0.UACT位设置为0
●将发生EOFERR中断的端口置于空闲状态

软件必须终止正在执行通信的所有管道并重新枚举USB端口。

在设备控制器模式下从EOFERR标志读取的值无效。

ATTCH标志（ATTCH中断状态）

ATTCH标志指示主机控制器模式下USB连接检测中断的状态。

USBFS检测到ATTCH中断，并在检测到全速或低速信号电平上的JorK状态持续2.5µs时将此标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

USBFS在以下任何条件下检测ATTCH中断。

●K-state、SE0或SE1变为J-state，J-state持续2.5µs
●J-state、SE0或SE1变为K-state，K-state持续2.5µs

在设备控制器模式下从ATTCH标志读取的值无效。

DTCH flag (USB Disconnection Detection Interrupt Status)

The DTCH flag indicates the status of USB disconnection detection interrupts in host controller mode.

The USBFS detects the DTCH interrupt and sets this flag to 1 on detecting a USB bus detach event. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS detects bus detach events based on the USB 2.0 specification.

After detecting the DTCH interrupt, the USBFS controls hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt was detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state

The software must terminate all pipes in which communications are being carried out and invoke the wait state for attaching to the USB port (waiting for ATTCH interrupt generation).

Values read from the DTCH flag in device controller mode are invalid.

BCHG flag (USB Bus Change Interrupt Status)

The BCHG flag indicates the status of USB bus change interrupts in host controller mode.

The USBFS detects the BCHG interrupt and sets this flag to 1 when a change in the full- or low-speed signal level occurs on the USB port. This includes any change from J-state, K-state, or SE0 to J-state, K-state, or SE0. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

The USBFS sets the LNST[1:0] flags to indicate the input state of the USB port. When a BCHG interrupt occurs, eliminate transient elements by repeat reading the LNST[1:0] flags by software until the same value is read at least three times.

Change in the USB bus state can be detected while the internal clock is stopped.

Values read from the BCHG flag in device controller mode are invalid.

OVRCR flag (Overcurrent Input Change Interrupt Status)

The OVRCR flag indicates the status of USB_OVRCURA and USB_OVRCURB input pin change interrupts.

The USBFS detects the OVRCR interrupt and sets this flag to 1 when a change (high to low or low to high) occurs in at least one of the input values to the USB_OVRCURA and USB_OVRCURB pins. If the associated interrupt enable bit is set to 1 by software, the USBFS generates the interrupt.

DTCH标志（USB断线检测中断状态）

DTCH标志指示主机控制器模式下USB断开检测中断的状态。

USBFS检测到DTCH中断并在检测到USB总线分离事件时将此标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

USBFS根据USB2.0规范检测总线分离事件。

检测到DTCH中断后，USBFS对硬件进行如下控制，而不管相关的中断使能位设置如何：

●将检测到DTCH中断的端口的DVSTCTR0.UACT位设置为0

●将发生DTCH中断的端口置于空闲状态

软件必须终止正在执行通信的所有管道并调用等待状态以连接到USB端口（等待ATTCH中断生成）。

在设备控制器模式下从DTCH标志读取的值无效。

BCHG标志（USB总线更改中断状态）

BCHG标志指示主机控制器模式下USB总线更改中断的状态。

当USB端口上发生全速或低速信号电平变化时，USBFS检测到BCHG中断并将该标志设置为1。这包括从J-state、K-state或SE0到J-state、K-state或SE0的任何更改。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

USBFS设置LNST[1:0]标志以指示USB端口的输入状态。当发生BCHG中断时，通过软件重复读取LNST[1:0]标志来消除瞬态元素，直到至少读取相同的值3次。

当内部时钟停止时，可以检测到USB总线状态的变化。

在设备控制器模式下从BCHG标志读取的值无效。

OVRCR标志（过流输入变化中断状态）

OVRCR标志指示USB_OVRCURA和USB_OVRCURB输入引脚变化中断的状态。

当USB_OVRCURA和USB_OVRCURB引脚的至少一个输入值发生变化（从高到低或从低到高）时，USBFS检测到OVRCR中断并将该标志设置为1。如果相关的中断使能位由软件设置为1，则USBFS产生中断。

Note 1. To clear the status, write 0 only to the bits to be cleared. Write 1 to the other bits.

FRNM[10:0] flags (Frame Number)

The USBFS sets the FRNM[10:0] flags to indicate the latest frame number, which is updated every 1 ms, when an SOF packet is issued or received.

CRCE flag (Receive Data Error)

The CRCE flag sets to 1 when a CRC error or bit stuffing error occurs during isochronous transfer. On detecting a CRC error in host controller mode, the USBFS generates an internal NRDY interrupt.

To clear the CRCE flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

OVRN flag (Overrun/Underrun Detection Status)

The OVRN flag sets to 1 when an overrun or underrun error occurs during isochronous transfer. To clear the flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

In host controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the time to issue an OUT token comes before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the time to issue an IN token comes when no FIFO buffer planes are empty

In device controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the IN token is received before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the OUT token is received when no FIFO buffer planes are empty

FRNM[10:0] flags (Frame Number)

USBFS设置FRNM[10:0]标志以指示最新的帧号，该帧号每1ms更新一次，当发出或接收SOF数据包时。

CRCE标志（接收数据错误）

当同步传输期间发生CRC错误或位填充错误时，CRCE标志设置为1。在主机控制器模式下检测到CRC错误时，USBFS会生成内部NRDY中断。

要清除CRCE标志，向其写入0，同时向FRMNUM寄存器中的其他位写入1。

OVRN标志（溢出欠载检测状态）

当同步传输期间发生溢出或欠载错误时，OVRN标志设置为1。要清除该标志，请向其写入0，同时向FRMNUM寄存器中的其他位写入1。

在主机控制器模式下，OVRN标志在以下任何条件下设置为1：

●对于传输同步管道，发出OUT令牌的时间是在所有传输数据写入FIFO缓冲区之前

●对于接收同步管道，在没有FIFO缓冲平面为空时发出IN令牌

在设备控制器模式下，OVRN标志在以下任何条件下设置为1：

●对于传输同步管道，在所有传输数据写入FIFO缓冲区之前接收到IN令牌

●对于接收同步管道，当没有FIFO缓冲平面为空时接收OUT令牌

In host controller mode, the USBADDR[6:0] bits are invalid.

STSRECOV[3:0] bits (Status Recovery)

Use the STSRECOV[3:0] bits to resume the state of the internal sequencer on recovering from USB power shut-off. For details, see section 28.3.1.5. Release from deep software standby mode because of USB suspend/resume interrupts.

Writing to these bits is enabled while the DVCHGR.DVCHG bit is set to 1.

Note 1. Only set this bit while the PID is NAK. Before setting this bit, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

DIR bit (Transfer Direction)

In host controller mode, the DIR bit sets the transfer direction of the data stage and status stage for control transfers. In device controller mode, set the DIR bit to 0.

SHTNAK bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to change PID to NAK on transfer end when the selected pipe is receiving. It is only valid when the selected pipe is receiving.

When the SHTNAK bit is 1, the USBFS changes the DCPCTR.PID[1:0] bits for the DCP to NAK on determining that a transfer has ended. The USBFS determines transfer end on the following condition:

- A short packet, including a zero-length packet, is successfully received.

28.2.29 DCPMAXP : DCP Maximum Packet Size Register

Base address: USBFS = 0x4009_0000

Note 1. Only set the MXPS[6:0] bits while PID is NAK. Before setting these bits, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary. After the MXPS[6:0] bits are set and the DCP is set to the CURPIPE[3:0] bits in a port select register, clear the buffer by setting the BCLR bit in the port control register to 1.
Note 2. Only set the DEVSEL[3:0] bits while PID is NAK and the DCPCTR.SUREQ bit is 0. Before setting these bits, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

MXPS[6:0] bits (Maximum Packet Size)

The MXPS[6:0] bits specify the maximum data payload (maximum packet size) for the DCP. The initial value is 0x40 (64 bytes). Set the bits to a USB 2.0-compliant value. Do not write to the FIFO buffer or set PID = BUF whileMXPS[6:0] is set to 0.

注1.仅当PID为NAK时设置该位。在设置该位之前，请检查DCPCTR.PBUSY位是否为0，然后更改DCPCTR.PID[1:0]位用于DCP从BUF到NAK。如果PID[1:0]位被USBFS更改为NAK，则无需通过软件检查PBUSY位。

DIR位（传输方向）

在主机控制器模式下，DIR位设置控制传输的数据阶段和状态阶段的传输方向。在设备控制器模式下，将DIR位设置为0。

SHTNAK位（传输结束时禁用管道）

SHTNAK位指定当所选管道正在接收时，是否在传输结束时将PID更改为NAK。仅在所选管道正在接收时有效。

当SHTNAK位为1时，USBFS在确定传输已结束时将DCPCR.PID[1:0]位更改为DCP为NAK。USBFS在以下条件下确定传输结束：

●成功接收到短报文，包括零长度报文。

28.2.29 DCPMAXP:DCP最大数据包大小寄存器

注1.仅在PID为NAK时设置MXPS[6:0]位。在设置这些位之前，请检查DCPCTR.PBUSY位是否为0，然后将DCP的DCPCTR.PID[1:0]位从BUF更改为NAK。如果PID[1:0]位被USBFS更改为NAK，则无需通过软件检查PBUSY位。在设置MXPS[6:0]位并将DCP设置为端口选择寄存器中的CURPIPE[3:0]位后，通过将端口控制寄存器中的BCLR位设置为1来清除缓冲区。

注2.仅在PID为NAK且DCPCTR.SUREQ位为0时设置DEVSEL[3:0]位。在设置这些位之前，请检查DCPCTR.PBUSY位为0，然后将DCPCR.PID[1:0]位从BUF更改为NAK。如果PID[1:0]位被USBFS更改为NAK，则无需通过软件检查PBUSY位。

MXPS[6:0]位（最大数据包大小）

MXPS[6:0]位指定DCP的最大数据有效载荷（最大数据包大小）。初始值为0x40（64字节）。将这些位设置为符合USB2.0的值。当MXPS[6:0]设置为0时，不要写入FIFO缓冲区或设置PID=BUF。

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target peripheral device for a control transfer. Set up the device address in the associated DEVADDn (n = 0 to 5) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0010b, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0000b.

DEVSEL[3:0] bits (Device Select)

在主机控制器模式下，DEVSEL[3:0]位指定目标外围设备的地址以进行控制传输。首先在相关的DEVADDn（n=0到5）寄存器中设置设备地址，然后将这些位设置为相应的值。例如，要将DEVSEL[3:0]位设置为0010b，首先要设置DEVADD2寄存器中的地址。

在设备控制器模式下，将这些位设置为0000b。

Note 1. This bit is read as 0.
Note 2. Only set the SQSET and SQCLR bits while PID is NAK. Before setting these bits, check that the PBUSY bit is 0, and then change the PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

PID[1:0] bits (Response PID)

The PID[1:0] bits control the USB response type during control transfers.

In host controller mode, to change the PID[1:0] setting from NAK to BUF:

- When the transmitting direction is set:
  a. Write all of the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  b. Set PID[1:0] bits to 01b (BUF).
     The USBFS then executes the OUT transaction.
- When the receiving direction is set:
  a. Check that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  b. Set PID[1:0] bits to 01b (BUF).
     The USBFS then executes the IN transaction.

The USBFS changes the PID[1:0] setting as follows:

- When the PID[1:0] bits are set to BUF (01b) by software and the USBFS has received data exceeding MaxPacketSize, the USBFS sets the PID[1:0] to STALL (11b)
- When a reception error, such as a CRC error, is detected three times consecutively, the USBFS sets thePID[1:0] bits to NAK (00b)
- On receiving the STALL handshake, the USBFS sets PID[1:0] to STALL (11b)

In device controller mode, the USBFS changes the PID[1:0] setting as follows:

- On receiving a setup packet, the USBFS sets PID[1:0] to NAK (00b). The USBFS then sets the INTSTS0.VALID flag to 1, and the PID[1:0] setting cannot be changed until the software clears the VALID flag to 0.
- When the PID[1:0] bits are set to BUF (01b) by software and the USBFS has received data exceeding MaxPacketSize, the USBFS sets PID[1:0] to STALL (11b)
- On detecting a control transfer sequence error, the USBFS sets PID[1:0] to STALL (1xb)
- On detecting a USB bus reset, the USBFS sets PID[1:0] to NAK

The USBFS does not check the PID[1:0] setting while processing a SET_ADDRESS request.

The PID[1:0] bits are initialized by a USB bus reset.

CCPL bit (Control Transfer End Enable)

In device controller mode, setting the CCPL bit to 1 enables the status stage of the control transfer to be completed. When the bit is set to 1 by software while the associated PID[1:0] bits are set to BUF, the USBFS completes the control transfer status stage.

During control read transfers, the USBFS transmits the ACK handshake in response to the OUT transaction from the USB host. During control write or no-data control transfers, it transmits the zero-length packet in response to the IN transaction from the USB host. On detecting a SET_ADDRESS request, the USBFS operates in auto response mode from the setup stage up to status stage completion regardless of the CCPL bit setting.

The USBFS changes the CCPL bit from 1 to 0 on receiving a new setup packet. The software cannot write 1 to the bit while the INTSTS0.VALID bit is 1. The bit is initialized by a USB bus reset.

In host controller mode, always write 0 to the CCPL bit.

PBUSY bit (Pipe Busy)

The PBUSY bit indicates whether DCP is used for the transaction when USBFS changes the PID[1:0] bits from BUF to NAK. The USBFS changes the PBUSY bit from 0 to 1 on start of a USB transaction for the selected pipe. It changes the PBUSY bit from 1 to 0 on completion of one transaction.

注1.该位读为0。
注2.仅在PID为NAK时设置SQSET和SQCLR位。在设置这些位之前，请检查PBUSY位是否为0，然后将DCP的PID[1:0]位从BUF更改为NAK。如果PID[1:0]位被USBFS更改为NAK，则无需通过软件检查PBUSY位。

PID[1:0] bits (Response PID)

PID[1:0]位在控制传输期间控制USB响应类型。

在主机控制器模式下，要将PID[1:0]设置从NAK更改为BUF：

●设置传输方向时：

a. 当DVSTCTR0.UACT位为1且PID为NAK时，将所有发送数据写入FIFO缓冲区。

湾。将PID[1:0]位设置为01b(BUF)。

然后USBFS执行OUT事务。

●设置接收方向时：

a. 在DVSTCTR0.UACT位为1且PID为NAK时检查FIFO缓冲区是否为空（或清空缓冲区）。

湾。将PID[1:0]位设置为01b(BUF)。

然后USBFS执行IN事务。

USBFS更改PID[1:0]设置如下：

●当PID[1:0]位被软件设置为BUF(01b)并且USBFS接收到超过MaxPacketSize的数据时，USBFS将PID[1:0]设置为STALL(11b)

●当连续3次检测到接收错误（例如CRC错误）时，USBFS将PID[1:0]位设置为NAK(00b)

●在接收到STALL握手时，USBFS将PID[1:0]设置为STALL(11b)

在设备控制器模式下，USBFS将PID[1:0]设置更改如下：

●在接收到设置数据包时，USBFS将PID[1:0]设置为NAK(00b)。然后USBFS将INTSTS0.VALID标志设置为1，并且在软件将VALID标志清除为0之前无法更改PID[1:0]设置。

●当PID[1:0]位被软件设置为BUF(01b)并且USBFS接收到超过MaxPacketSize的数据时，USBFS将PID[1:0]设置为STALL(11b)

●在检测到控制传输序列错误时，USBFS将PID[1:0]设置为STALL(1xb)

●在检测到USB总线复位时，USBFS将PID[1:0]设置为NAK

USBFS在处理SET_ADDRESS请求时不检查PID[1:0]设置。

PID[1:0]位由USB总线复位初始化。

CCPL位（控制传输结束使能）

在设备控制器模式下，将CCPL位设置为1可以完成控制传输的状态阶段。当该位由软件设置为1且相关的PID[1:0]位设置为BUF时，USBFS完成控制传输状态阶段。

在控制读取传输期间，USBFS发送ACK握手以响应来自USB主机的OUT事务。在控制写入或无数据控制传输期间，它传输零长度数据包以响应来自USB主机的IN事务。在检测到SET_ADDRESS请求时，USBFS从设置阶段到状态阶段完成以自动响应模式运行，无论CCPL位设置如何。

USBFS在接收到新的设置数据包时将CCPL位从1更改为0。当INTSTS0.VALID位为1时，软件无法向该位写入1。该位由USB总线复位初始化。

在主机控制器模式下，始终将0写入CCPL位。

PBUSY bit (Pipe Busy)

PBUSY位指示当USBFS将PID[1:0]位从BUF更改为NAK时是否使用DCP进行事务处理。USBFS在所选管道的USB事务开始时将PBUSY位从0更改为1。它改变了

PBUSY位在一个事务完成时从1变为0。

After PID is set to NAK by software, the value in the PBUSY bit indicates whether changes to pipe settings can proceed.

For details, see section 28.3.4.1. Pipe control register switching procedures.

SQMON bit (Sequence Toggle Bit Monitor)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

The USBFS toggles the bit on normal completion of the transaction. It does not toggle the bit, however, when a DATAPID mismatch occurs during a transfer in the receiving direction.

In device controller mode, the USBFS sets the SQMON bit to 1 (specifies DATA1 as the expected value) on successful reception of the setup packet.

In device controller mode, the USBFS does not reference this bit during IN or OUT transactions at the status stage, and it does not toggle the bit on normal completion.

SQSET bit (Sequence Toggle Bit Set)

The SQSET bit specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SQCLR bit (Sequence Toggle Bit Clear)

The SQCLR bit specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer. It is read as 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SUREQCLR bit (SUREQ Bit Clear)

In host controller mode, setting the SUREQCLR bit to 1 clears the SUREQ bit to 0. The bit is read as 0.

If transfer stops while the SUREQ bit is set to 1 in a setup transaction, set the SUREQCLR bit to 1 by software. This is not necessary at the end of a normal setup transaction, because the USBFS automatically clears the SUREQ bit to 0.

Only control the SUREQ bit through the SUREQCLR bit while the DVSTCTR0.UACT bit is 0. When UACT is 0, communication is halted or no transfer is occurring because a bus disconnection was detected.

In device controller mode, always write 0 to this bit.

SUREQ bit (Setup Token Transmission)

In host controller mode, setting the SUREQ bit to 1 triggers the USBFS to transmit the setup packet. After completing the setup transaction process, the USBFS generates either the SACK or SIGN interrupt and clears the SUREQ bit to 0. The USBFS also clears the SUREQ bit to 0 when the software sets the SUREQCLR bit to 1.

Before setting the SUREQ bit to 1, set the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, and USBLENG appropriately to transmit the target USB request in the setup transaction. Also check that the PID[1:0] bits for the DCP are set to NAK. After setting the SUREQ bit to 1, do not change the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, or USBLENG until the setup transaction is complete (SUREQ bit = 1). Write 1 to the SUREQ bit only when transmitting the setup token. Otherwise, write 0.

In device controller mode, always write 0 to this bit.

BSTS flag (Buffer Status)

The BSTS flag indicates the status of access to the DCP FIFO buffer. The meaning of this flag varies as follows depending on the CFIFOSEL.ISEL setting:

- When ISEL = 0, the bit indicates whether receive data can be read from the buffer
- When ISEL = 1, the bit indicates whether transmit data can be written to the buffer

在软件将PID设置为NAK后，PBUSY位中的值指示是否可以继续对管道设置进行更改。

详见28.3.4.1节。管道控制寄存器切换程序。

SQMON位（序列切换位监视器）

SQMON位指示DCP传输期间下一个事务的序列切换位的预期值。

USBFS在事务正常完成时切换该位。但是，当在接收方向的传输过程中发生DATAPID不匹配时，它不会切换该位。

在设备控制器模式下，USBFS在成功接收到设置数据包时将SQMON位设置为1（指定DATA1作为预期值）。

在设备控制器模式下，USBFS在状态阶段的IN或OUT事务期间不引用该位，并且它不会在正常完成时切换该位。

SQSET位（序列切换位设置）

SQSET位将DATA1指定为DCP传输期间下一个事务的序列切换位的预期值。

不要同时将SQCLR和SQSET位设置为1。

SQCLR位（序列翻转位清除）

SQCLR位将DATA0指定为DCP传输期间下一个事务的序列切换位的预期值。读为0。

不要同时将SQCLR和SQSET位设置为1。

SUREQCLR bit (SUREQ Bit Clear)

在主机控制器模式下，将SUREQCLR位设置为1会将SUREQ位清除为0。该位被读取为0。

如果在设置事务中将SUREQ位设置为1时传输停止，则通过软件将SUREQCLR位设置为1。这在正常设置事务结束时不是必需的，因为USBFS会自动将SUREQ位清除为0。

当DVSTCTR0.UACT位为0时，仅通过SUREQCLR位控制SUREQ位。当UACT为0时，由于检测到总线断开，通信停止或没有传输发生。

在设备控制器模式下，始终向该位写入0。

SURESQ位（设置令牌传输）

在主机控制器模式下，将SUREQ位设置为1会触发USBFS发送设置数据包。完成设置事务处理后，USBFS产生SACK或SIGN中断并将SUREQ位清零。当软件将SUREQCLR位设置为1时，USBFS也将SUREQ位清零。

在将SUREQ位设置为1之前，将DCPMAXP.DEVSEL[3:0]位、USBREQ、USBVAL、USBINDX和USBLENG适当地在设置事务中传输目标USB请求。还要检查DCP的PID[1:0]位是否设置为NAK。将SUREQ位设置为1后，在设置事务完成（SUREQ位=1）之前，不要更改DCPMAXP.DEVSEL[3:0]位、USBREQ、USBVAL、USBINDX或USBLENG。仅在发送设置令牌时向SUREQ位写入1。否则，写0。

在设备控制器模式下，始终向该位写入0。

BSTS flag (Buffer Status)

BSTS标志指示访问DCPFIFO缓冲区的状态。根据CFIFOSEL.ISEL设置，该标志的含义如下：

- ISEL=0时，该位指示是否可以从缓冲区读取接收数据
- ISEL=1时，该位指示发送数据是否可以写入缓冲区

Set pipes 1 to 9 using the PIPESEL, PIPECFG, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN registers (n = 0 to 9).

After selecting the pipe in the PIPESEL register, pipe functions must be set in the associated PIPECFG, PIPEMAXP, and PIPEPERI registers. PIPEnCTR, PIPEnTRE, and PIPEnTRN can be set independently of the pipe selection in this register.

PIPESEL[3:0] bits (Pipe Window Select)

The PIPESEL[3:0] bits select the pipe number associated with the PIPECFG, PIPEMAXP, and PIPEPERI registers used for data writing and reading. Selecting a pipe number in the PIPESEL[3:0] bits allows writing to and reading from PIPECFG, PIPEMAXP, and PIPEPERI associated with the selected pipe number.

When PIPESEL[3:0] = 0000b, 0 is read from all of the bits in PIPECFG, PIPEMAXP, and PIPEPERI. Writing to these bits has no effect.

PIPESEL[3:0]位（管道窗口选择）

PIPESEL[3:0]位选择与用于数据写入和读取的PIPECFG、PIPEMAXP和PIPEPERI寄存器相关的管道编号。在PIPESEL[3:0]位中选择一个管道编号允许写入和读取与所选管道编号相关的PIPECFG、PIPEMAXP和PIPEPERI。

当PIPESEL[3:0]=0000b时，从PIPECFG、PIPEMAXP和PIPEPERI中的所有位读取0。写入这些位无效。

Note 1. Only set the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 2. Only set the BFRE, DBLB, and DIR bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 3. To change the BFRE, DBLB, or DIR bits after completing USB communication on the selected pipe, in addition to the constraints described in Note 2, write 1 and 0 to the PIPEnCTR.ACLRM bit continuously through the software and clear the FIFO buffer assigned to the pipe.

PIPECFG specifies the transfer type, FIFO buffer access direction, and endpoint numbers for pipes 1 to 9. It also selects single or double buffer mode, and whether to continue or disable pipe operation at the end of transfer.

EPNUM[3:0] bits (Endpoint Number)

The EPNUM[3:0] bits specify the endpoint number for the selected pipe. Setting 0000b indicates the pipe not used.

Set these bits so that the combination of the DIR and EPNUM[3:0] settings is different from those for other pipes. The EPNUM[3:0] bits can be set to 0000b for all pipes.

DIR bit (Transfer Direction)

The DIR bit specifies the transfer direction for the selected pipe.

When the software sets this bit to 0, the USBFS uses the selected pipe for receiving. When the software sets this bit to 1, the USBFS uses the selected pipe for transmitting.

SHTNAK bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to change the PIPEnCTR.PID[1:0] bits to 00b (NAK) at the end of transfer when the selected pipe is set in the receiving direction. The bit is valid for pipes 1 to 5 in the receiving direction.

When the software sets this bit to 1 for a receiving pipe, the USBFS changes the associated PIPEnCTR.PID[1:0] bits to 00b (NAK) on determining the transfer end. The USBFS determines that the transfer has ended on the following conditions:

- A short packet data (including a zero-length packet) was successfully received
- The transaction counter is used and the number of packets specified for the transaction counter are successfully received

注1.PID为NAK时，仅设置TYPE[1:0]、SHTNAK和EPNUM[3:0]位。在设置这些位之前，请检查PIPEnCTR.PBUSY位为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

注2.仅在PID为NAK且在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置BFRE、DBLB和DIR位。在设置这些位之前，请检查PIPEnCTR.PBUSY位是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

注3.要在选定管道上完成USB通信后更改BFRE、DBLB或DIR位，除了注2中描述的约束外，通过软件连续向PIPEnCTR.ACLRM位写入1和0并清除FIFO分配给管道的缓冲区。

PIPECFG指定管道1到9的传输类型、FIFO缓冲区访问方向和端点编号。它还选择单缓冲区或双缓冲区模式，以及在传输结束时是继续还是禁用管道操作。

EPNUM[3:0] bits (Endpoint Number)

EPNUM[3:0]位指定所选管道的端点号。设置0000b表示管道未使用。

设置这些位，以便DIR和EPNUM[3:0]设置的组合不同于其他管道的设置。这对于所有管道，EPNUM[3:0]位可以设置为0000b。

DIR位（传输方向）

DIR位指定所选管道的传输方向。

当软件将此位设置为0时，USBFS使用所选管道进行接收。当软件将该位设置为1时，USBFS使用选定的管道进行传输。

SHTNAK位（传输结束时禁用管道）

SHTNAK位指定当所选管道设置为接收方向时，是否在传输结束时将PIPEnCTR.PID[1:0]位更改为00b(NAK)。该位对接收方向的管道1到5有效。

当软件将该位设置为1用于接收管道时，USBFS在确定传输结束时将相关的PIPEnCTR.PID[1:0]位更改为00b(NAK)。USBFS在以下条件下确定传输已结束：

- 成功接收短包数据（包括零长度包）
- 使用事务计数器，成功接收事务计数器指定的包数

DBLB bit (Double Buffer Mode)

The DBLB bit selects either single or double buffer mode for the FIFO buffer used by the selected pipe. The bit is valid for pipes 1 to 5.

BFRE bit (BRDY Interrupt Operation Specification)

The BFRE bit specifies the BRDY interrupt generation timing from the USBFS to the CPU for the selected pipe.

When the software sets the BFRE bit to 1 and the selected pipe is in the receiving direction, the USBFS detects the transfer completion and generates the BRDY interrupt on reading the packet.

When a BRDY interrupt is generated with this setting, the software must write 1 to the BCLR bit in the port control register. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to the BCLR bit.

When the BFRE bit is set to 1 by software and the selected pipe is in the transmitting direction, the USBFS does not generate the BRDY interrupt. For details, see section 28.3.3.1. BRDY interrupt.

TYPE[1:0] bits (Transfer Type)

The TYPE[1:0] bits specify the transfer type for the pipe selected in the PIPESEL.PIPESEL[3:0] bits. Before setting PID to BUF and starting USB communication on the selected pipe, set the TYPE[1:0] bits to a value other than 00b.

Note: The value of the MXPS[8:0] bits is 0x000 when no pipe is selected in the PIPESEL.PIPESEL[3:0] bits and 0x040 when a pipe is selected.

Note 1. Only set the MXPS[8:0] bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 2. Only set the DEVSEL[3:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00b (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

PIPEMAXP specifies the maximum packet size for pipes 1 to 9.

DBLB位（双缓冲模式）

DBLB位为所选管道使用的FIFO缓冲区选择单缓冲区模式或双缓冲区模式。该位对管道1到5有效。

BFRE位（BRDY中断操作规范）

BFRE位为所选管道指定从USBFS到CPU的BRDY中断生成时序。

当软件将BFRE位设置为1且所选管道处于接收方向时，USBFS检测到传输完成并在读取数据包时产生BRDY中断。

当使用该设置产生BRDY中断时，软件必须将1写入端口控制寄存器中的BCLR位。
在将1写入BCLR位之前，分配给所选管道的FIFO缓冲区不会用于接收。

当BFRE位由软件设置为1且所选管道处于发送方向时，USBFS不会产生BRDY中断。详见28.3.3.1节。BRDY中断。

TYPE[1:0] bits (Transfer Type)

TYPE[1:0]位指定在PIPESEL.PIPESEL[3:0]位中选择的管道的传输类型。设置PID之前BUF并在所选管道上启动USB通信，将TYPE[1:0]位设置为00b以外的值。

注1.仅在PID为NAK且在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置MXPS[8:0]位。
在设置这些位之前，请检查PIPEnCTR.PBUSY位是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

注2.仅在PID为NAK时设置DEVSEL[3:0]位。在设置这些位之前，请检查PIPEnCTR.PBUSY位是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00b(NAK)，则无需通过软件检查PBUSY位。

PIPEMAXP指定管道1到9的最大数据包大小。

MXPS[8:0] bits (Maximum Packet Size)

The MXPS[8:0] bits specify the maximum data payload (maximum packet size) for the selected pipe.

Set these bits to the appropriate value for each transfer type based on the USB 2.0 specification. When MXPS[8:0] = 0, do not write to the FIFO buffer or set PID to BUF. These writes have no effect.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target device for USB communication. Set up the device address in the associated DEVADDn (n = 0 to 5) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0x2, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0x0.

28.2.34 PIPEPERI : Pipe Cycle Control Register

Base address: USBFS = 0x4009_0000

12	IFIS	Isochronous IN Buffer Flush 0: Do not flush buffer 1: Flush buffer	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only set the IITV[2:0] bits while PID is NAK. Before setting these bits, check that the PBUSY bit is 0, and then change the PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

PIPEPERI selects whether the buffer is flushed or not when an interval error occurred during isochronous IN transfers, and sets the interval error detection interval for pipes 1 to 9.

IITV[2:0] bits (Interval Error Detection Interval)

To change the IITV[2:0] bits to another value after they are set and USB communication is performed, set the PIPEnCTR.PID[1:0] bits to 00b (NAK) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer.

The IITV[2:0] bits are not provided for pipes 3 to 5. Write 000b to bit positions of the IITV[2:0] bits associated with pipes 3 to 5.

IFIS bit (Isochronous IN Buffer Flush)

The IFIS bit specifies whether to flush the buffer when the pipe selected in the PIPESEL.PIPESEL[3:0] bits is used for isochronous IN transfers.

In device controller mode when the selected pipe is for isochronous IN transfers, the USBFS automatically clears the FIFO buffer if the USBFS fails to receive the IN token from the USB host within the interval set in theIITV[2:0] bits in terms of frames.

When double buffering is specified (PIPECFG.DBLB = 1), the USBFS only clears the data in the previously used plane.

The USBFS clears the FIFO buffer on receiving the SOF packet immediately after the frame in which the USBFS expected to receive the IN token. Even if the SOF packet is corrupted, the FIFO buffer is cleared at the time the SOF packet is expected to be received by using the internal interpolation function.

In host controller mode, set the IITV[2:0] bits to 000b.

MXPS[8:0]位（最大数据包大小）

MXPS[8:0]位指定所选管道的最大数据有效负载（最大数据包大小）。

根据USB2.0规范将这些位设置为每种传输类型的适当值。当MXPS[8:0]=0时，不要写入FIFO缓冲区或将PID设置为BUF。这些写入没有效果。

DEVSEL[3:0] bits (Device Select)

在主机控制器模式下，DEVSEL[3:0]位指定USB通信的目标设备的地址。首先在相关的DEVADDn（n=0到5）寄存器中设置设备地址，然后将这些位设置为相应的值。例如，要将DEVSEL[3:0]位设置为0x2，首先设置DEVADD2寄存器中的地址。

在设备控制器模式下，将这些位设置为0x0。

28.2.34 PIPEPERI:管道循环控制寄存器

12	IFIS	同步IN缓冲区刷新 0：不刷新缓冲区1： 刷新缓冲区	R/W

注1.仅在PID为NAK时设置IITV[2:0]位。在设置这些位之前，请检查PBUSY位是否为0，然后将PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

PIPEPERI选择在同步IN传输期间发生间隔错误时是否刷新缓冲区，并设置管道1到9的间隔错误检测间隔。

IITV[2:0]位（间隔错误检测间隔）

要在设置IITV[2:0]位并在执行USB通信后将其更改为另一个值，请设置PIPEnCTR.PID[1:0]位为00b(NAK)，然后将PIPEnCTR.ACLRM位设置为1以初始化间隔定时器。

不为管道3到5提供IITV[2:0]位。将000b写入与管道3到5相关联的IITV[2:0]位的位位置。

IFIS位（同步IN缓冲区刷新）

IFIS位指定当在PIPESEL.PIPESEL[3:0]位中选择的管道用于同步IN传输时是否刷新缓冲区。

在设备控制器模式下，当所选管道用于同步IN传输时，如果USBFS未能在IITV[2:0]位（以帧为单位）设置的间隔内从USB主机接收IN令牌，则USBFS自动清除FIFO缓冲区.

当指定双缓冲时（PIPECFG.DBLB=1），USBFS只清除先前使用的平面中的数据。

在USBFS预期接收IN令牌的帧之后，USBFS在接收到SOF数据包后立即清除FIFO缓冲区。即使SOF数据包损坏，FIFO缓冲区也会在预期接收SOF数据包时使用内部插值功能清除。

在主机控制器模式下，将IITV[2:0]位设置为000b。

Note 2. Only set the ATREPM bit or write 1 to the SQCLR or SQSETbit while PID is NAK. Before setting these bits, check that the PBUSY bit is 0, and then change the PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00 (NAK) by the USBFS, checking the PBUSYbit through the software is not necessary.

Note 3. Only set the ACLRM bit while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting this bit, check that the PBUSY bit is 0, and then change the PID[1:0] bits from 01b (BUF) to 00b (NAK). PIPEnCTR can be set for any pipe selection in the PIPESEL register.

注3.仅在PID为NAK且在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置ACLRM位。在设置该位之前，请检查PBUSY位是否为0，然后将PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00(NAK)，则无需通过软件检查PBUSY位。

PIPEnCTR可以为PIPESEL寄存器中的任何管道选择设置。

PID[1:0] bits (Response PID)

The PID[1:0]bits specify the response type for the next transaction on the selected pipe.

The default PID[1:0] setting is NAK. Change the PID[1:0] setting to BUF to use the associated pipe for USB transfer. Table 28.9 and Table 28.10 show the basic operations of the USBFS (when there are no errors in the communication packets) based on the PID[1:0] bit setting.

After changing the PID[1:0] setting from BUF to NAK through the software during USB communication on the selected pipe, check that the PBUSY bit is 1 to see if USB transfer on the pipe has actually entered the NAK state. If the USBFS changes the PID[1:0] bits to NAK, checking the PBUSY bit through the software is not necessary.

The USBFS changes the PIPEnCTR.PID[1:0] setting in the following cases:

- The USBFS sets PID to NAK on recognizing completion of the transfer when the selected pipe is in the receiving direction and the PIPECFG.SHTNAK bit for the selected pipe is set to 1 by software
- The USBFS sets PID to STALL (11b) on receiving a data packet with a payload exceeding the maximum packet size of the selected pipe
- The USBFS sets PID to NAK on detecting a USB bus reset in device controller mode
- The USBFS sets PID to NAK on detecting a reception error, such as a CRC error, three consecutive times in host controller mode
- The USBFS sets PID to STALL (11b) on receiving the STALL handshake in host controller mode

To specify the response type, set the PID[1:0] bits as follows:

- To transition from NAK (00b) to STALL, set 10b
- To transition from BUF (01b) to STALL, set 11b
- To transition from STALL (11b) to NAK, set 10b and then 00b
- To transition from STALL to BUF, set 00b (NAK) and then 01b (BUF)

PID[1:0] bits (Response PID)

PID[1:0]位指定所选管道上下一个事务的响应类型。

默认PID[1:0]设置为NAK。将PID[1:0]设置更改为BUF以使用关联的管道进行USB传输。表28.9和表28.10显示了基于PID[1:0]位设置的USBFS的基本操作（当通信数据包中没有错误时）。

在选定管道上进行USB通信期间，通过软件将PID[1:0]设置从BUF更改为NAK后，检查PBUSY位是否为1，以查看管道上的USB传输是否真正进入了NAK状态。如果USBFS将PID[1:0]位更改为NAK，则无需通过软件检查PBUSY位。

USBFS在以下情况下更改PIPEnCTR.PID[1:0]设置：

- 当所选管道处于接收方向并且所选管道的PIPECFG.SHTNAK位由软件设置为1时，USBFS在识别到传输完成时将PID设置为NAK
- USBFS在接收到负载超过所选管道的最大数据包大小的数据包时将PID设置为STALL(11b)
- USBFS在设备控制器模式下检测到USB总线复位时将PID设置为NAK
- USBFS在主机控制器模式下连续3次检测到接收错误（例如CRC错误）时将PID设置为NAK
- USBFS在主机控制器模式下接收到STALL握手时将PID设置为STALL(11b)

要指定响应类型，请按如下方式设置PID[1:0]位：

- 要从NAK(00b)转换到STALL，设置10b
- 要从BUF(01b)转换到STALL，设置11b
- 要从STALL(11b)转换为NAK，请设置10b，然后设置00b
- 要从STALL转换到BUF，请设置00b(NAK)，然后设置01b(BUF)

PID[1:0] value	Transfer type	Transfer direction (DIR bit)	USBFS operation
01b (BUF)	Bulk	Receiving direction (DIR = 0)	Receives data and returns ACK in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception

	Isochronous	Receiving direction (DIR = 0)	Receives data in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, discards the data.
	Isochronous	Transmitting direction (DIR = 1)	Transmits data in response to the token from the USB host if the associated FIFO buffer is ready for transmission. Otherwise, transmits a zero-length packet.
10b (STALL) or 11b (STALL)	Bulk or interrupt	Does not depend on the setting	Returns STALL in response to the token from the USB host
	Isochronous	Does not depend on the setting	Returns nothing in response to the token from the USB host

PBUSY bit (Pipe Busy)

The PBUSY bit indicates whether the selected pipe is being used for the current transaction.

The USBFS changes the PBUSY bit from 0 to 1 on start of the USB transaction for the selected pipe, and changes the PBUSY bit from 1 to 0 on completion of one transaction.

Reading the PBUSY bit by software after PID is set to NAK allows you to check whether changing the pipe setting is possible. For details, see section 28.3.4.1. Pipe control register switching procedures.

SQMON bit (Sequence Toggle Bit Confirmation)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.

When the selected pipe is not the isochronous transfer type, the USBFS toggles the SQMON flag on successful completion of the transaction. However, the USBFS does not toggle the SQMON flag when a DATA-PID mismatch occurs during transfer in the receiving direction.

SQSET bit (Sequence Toggle Bit Set)

Setting the SQSET bit to 1 through the software causes the USBFS to set DATA1 as the expected value of the sequence toggle bit for the next transaction on the selected pipe. The USBFS clears the SQSET bit to 0.

SQCLR bit (Sequence Toggle Bit Clear)

Setting the SQCLR bit to 1 through the software causes the USBFS to clear the expected value of the sequence toggle bit for the next transaction on the selected pipe to DATA0. The USBFS clears the SQCLR bit to 0.

ACLRM bit (Auto Buffer Clear Mode)

The ACLRM bit enables or disables auto buffer clear mode for the selected pipe. To completely clear the data in the FIFO buffer allocated to the selected pipe, write 1 and then 0 to the ACLRM bit continuously.

Table 28.11 shows the data cleared by writing 1 and 0 to the ACLRM bit continuously and the cases in which this processing is required.

Table 28.11 Data cleared by the USBFS when ACLRM = 1 (1 of 2)

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear

	Isochronous	不依赖于设置	响应来自USB主机的令牌，不返回任何内容

PBUSY bit (Pipe Busy)

PBUSY位指示所选管道是否正在用于当前事务。

USBFS在所选管道的USB事务开始时将PBUSY位从0更改为1，并更改PBUSY位在一个事务完成时从1变为0。

在PID设置为NAK后，通过软件读取PBUSY位可以检查是否可以更改管道设置。详见28.3.4.1节。管道控制寄存器切换程序。

SQMON位（序列切换位确认）

SQMON位指示所选管道的下一个事务的序列切换位的预期值。

当所选管道不是同步传输类型时，USBFS在事务成功完成时切换SQMON标志。但是，当在接收方向的传输过程中发生DATA-PID不匹配时，USBFS不会切换SQMON标志。

SQSET位（序列切换位设置）

通过软件将SQSET位设置为1会导致USBFS将DATA1设置为所选管道上下一个事务的序列切换位的预期值。USBFS将SQSET位清0。

SQCLR位（序列翻转位清除）

通过软件将SQCLR位设置为1会导致USBFS将所选管道上下一个事务的序列切换位的预期值清除为DATA0。USBFS将SQCLR位清0。

ACLRM位（自动缓冲区清除模式）

ACLRM位启用或禁用所选管道的自动缓冲区清除模式。要完全清除分配给所选管道的FIFO缓冲区中的数据，请向ACLRM位连续写入1和0。

表28.11显示了通过向ACLRM位连续写入1和0来清除的数据以及需要进行此处理的情况。

Table 28.11 当ACLRM=1(1of2)时USBFS清除的数据

Number	通过设置ACLRM位清除数据	需要数据清楚的情况

2	Interval count value when the selected pipe is the isochronous transfer type	When resetting the interval count value

4	FIFO buffer toggle control	When changing the PIPECFG.DBLB setting
5	Internal flags related to the transaction count	When forcing the transaction count function to terminate

ATREPM bit (Auto Response Mode)

The ATREPM bit enables or disables auto response mode for the selected pipe.

This bit can be set to 1 in device controller mode when the selected pipe is the bulk transfer type. When the bit is set to 1, the USBFS responds to the token from the USB host as follows:

- When the selected pipe is set for bulk IN transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 1):
  a. When the ATREPM bit = 1 and PID = BUF, the USBFS transmits a zero-length packet in response to the IN token.
  b. The USBFS updates (allows toggling of) the sequence toggle bit (DATA-PID) each time the USBFS receives ACK from the USB host. In a single transaction, the IN token is received, a zero-length packet is transmitted, and then ACK is received. The USBFS does not generate the BRDY or BEMP interrupt.
- When the selected pipe is set for bulk OUT transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 0):
  When the ATREPM bit = 1 and PID = BUF, the USBFS returns NAK in response to the OUT token and generates an NRDY interrupt.

For USB communication in auto response mode, set the ATREPM bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode. When the selected pipe uses isochronous transfer, always set this bit to 0.

In host controller mode, always set the ATREPM bit to 0.

INBUFM bit (Transmit Buffer Monitor)

The INBUFM bit indicates the FIFO buffer status for the selected pipe in the transmitting direction.

When the selected pipe is set in the transmitting direction (PIPECFG.DIR = 1), the USBFS sets this bit to 1 when the CPU or DMA/DTC completes writing data to at least one FIFO buffer plane.

The USBFS sets this bit to 0 when the USBFS completes transmission of the data from the FIFO buffer plane to which all the data is written. In double buffer mode (PIPECFG.DBLB = 1), the USBFS sets the INBUFM bit to 0 when the USBFS completes transmission of the data from the two FIFO buffer planes before the CPU or DMA/DTC completes writing data to one FIFO buffer plane.

The INBUFM bit indicates the same value as the BSTS bit when the selected pipe is in the receiving direction (PIPECFG.DIR = 0).

BSTS bit (Buffer Status)

The BSTS bit indicates the FIFO buffer status for the selected pipe.

The meaning of the BSTS bit depends on the PIPECFG.DIR, PIPECFG.BFRE, and DnFIFOSEL.DCLRM settings, as shown in Table 28.12.

5	与事务计数相关的内部标志	强制事务计数函数终止时

ATREPM位（自动响应模式）

ATREPM位启用或禁用所选管道的自动响应模式。

当所选管道为批量传输类型时，该位可以在设备控制器模式下设置为1。当该位设置为1时，USBFS响应来自USB主机的令牌，如下所示：

●Whentheselectedpipeissetforbulk INtransfers(PIPECFG.TYPE[1:0]=01bandPIPECFG.DIR=1):

a. 当ATREPM位=1且PID=BUF时，USBFS发送一个长度为零的数据包以响应IN令牌。

湾。每次USBFS从USB主机接收到ACK时，USBFS都会更新（允许切换）序列切换位(DATA-PID)。在单个事务中，收到IN令牌，发送零长度数据包，然后收到ACK。USBFS不会产生BRDY或BEMP中断。

●当所选管道设置为批量OUT传输时（PIPECFG.TYPE[1:0]=01b和PIPECFG.DIR=0）：

当ATREPM位=1且PID=BUF时，USBFS返回NAK以响应OUT令牌并生成一个
NRDY interrupt.

对于自动响应模式下的USB通信，当FIFO缓冲区为空时，将ATREPM位设置为1。在自动响应模式下的USB通信期间不要写入FIFO缓冲区。当所选管道使用同步传输时，始终将此位设置为0。

在主机控制器模式下，始终将ATREPM位设置为0。

INBUFM位（发送缓冲区监视器）

INBUFM位指示发送方向上所选管道的FIFO缓冲区状态。

当所选管道设置为发送方向(PIPECFG.DIR=1)时，当CPU或DMADTC完成将数据写入至少一个FIFO缓冲区平面时，USBFS将该位设置为1。

当USBFS完成从写入所有数据的FIFO缓冲区平面传输数据时，USBFS将该位设置为0。在双缓冲模式(PIPECFG.DBLB=1)下，当USBFS在CPU或DMADTC完成将数据写入一个FIFO缓冲层之前完成从两个FIFO缓冲层的数据传输时，USBFS将INBUFM位设置为0。

当所选管道处于接收方向时（PIPECFG.DIR=0），INBUFM位指示与BSTS位相同的值。

BSTS bit (Buffer Status)

BSTS位指示所选管道的FIFO缓冲区状态。

BSTS位的含义取决于PIPECFG.DIR、PIPECFG.BFRE和DnFIFOSEL.DCLRM设置，如表28.12所示。

Table 28.12 BSTS bit operation

Note 1. Only write 1 to the SQCLR or SQSET bit while PID is NAK. Before setting these bits, check that the PBUSY bit is 0, and then change the PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00b (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

Note 2. Only set the ACLRM bit while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting this bits, check that the PIPEnCTR.PBUSY bit is 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PID[1:0] bits are changed to 00b (NAK) by the USBFS, checking the PBUSY bit through the software is not necessary.

PID[1:0] bits (Response PID)

The PID[1:0]bits specify the response type for the next transaction of the selected pipe.

The default PID[1:0] setting is NAK. Change the PID[1:0] setting to BUF to use the associated pipe for USB transfer. Table 28.9 and Table 28.10 show the basic operation (when there are no errors in the transmitted and received packets) of the USBFS depending on the PID[1:0] setting.

After changing the PID[1:0] setting from BUF to NAK through the software during USB communication on the selected pipe, check that the PBUSY bit is 1 to see if USB transfer on the selected pipe has actually entered the NAK state. If the USBFS changes the PID[1:0] bits to NAK, checking the PBUSY bit through the software is not necessary.

The USBFS changes the PIPEnCTR.PID[1:0] setting in the following cases:

- The USBFS sets PID to STALL (11b) on receiving a data packet with a payload exceeding the maximum packet size of the selected pipe
- The USBFS sets PID to NAK on detecting a USB bus reset in device controller mode
- The USBFS sets PID to NAK on detecting a reception error, such as a CRC error, three consecutive times in host controller mode
- The USBFS sets PID to STALL (11b) on receiving the STALL handshake in host controller mode

To specify each response type, set the PID[1:0] bits as follows:

- To transition from NAK (00b) to STALL, set 10b
- To transition from BUF (01b) to STALL, set 11b
- To transition from STALL (11b) to NAK, set 10b and then 00b
- To transition from STALL to BUF, set 00b (NAK) and then 01b (BUF)

PBUSY bit (Pipe Busy)

The PBUSY bit indicates whether the selected pipe is being used for the current transaction.

The USBFS changes the PBUSY bit from 0 to 1 on start of the USB transaction for the selected pipe, and changes the PBUSY bit from 1 to 0 on completion of one transaction.

Reading the PBUSY bit by software after PID is set to NAK allows you to check whether changing the pipe setting is possible.

SQMON bit (Sequence Toggle Bit Confirmation)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.

The USBFS toggles the SQMON bit on successful completion of the transaction. However, the USBFS does not toggle the SQMON bit when a DATA-PID mismatch occurs during transfer in the receiving direction.

SQSET bit (Sequence Toggle Bit Set)

Setting the SQSET bit to 1 through the software causes the USBFS to set DATA1 as the expected value of the sequence toggle bit for the next transaction on the selected pipe. The USBFS sets the SQSET bit to 0.

SQCLR bit (Sequence Toggle Bit Clear)

Setting the SQCLR bit to 1 through the software causes the USBFS to clear the expected value of the sequence toggle bit for the next transaction on the selected pipe to DATA0. The USBFS sets the SQCLR bit to 0.

ACLRM bit (Auto Buffer Clear Mode)

The ACLRM bit enables or disables auto buffer clear mode for the selected pipe. To completely clear the data in the FIFO buffer allocated to the selected pipe, write 1 and then 0 to the ACLRM bit continuously.

注1.PID为NAK时，仅向SQCLR或SQSET位写入1。在设置这些位之前，请检查PBUSY位是否为0，然后将PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00b(NAK)，则无需通过软件检查PBUSY位。

注2.仅在PID为NAK时和在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置ACLRM位。在设置该位之前，请检查PIPEnCTR.PBUSY位是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PID[1:0]位被USBFS更改为00b(NAK)，则无需通过软件检查PBUSY位。

PID[1:0] bits (Response PID)

PID[1:0]位指定所选管道的下一个事务的响应类型。

默认PID[1:0]设置为NAK。将PID[1:0]设置更改为BUF以使用关联的管道进行USB传输。表28.9和表28.10显示了取决于PID[1:0]设置的USBFS的基本操作（在发送和接收的数据包中没有错误时）。

在选定管道上进行USB通信期间，通过软件将PID[1:0]设置从BUF更改为NAK后，检查PBUSY位是否为1，以查看选定管道上的USB传输是否真正进入了NAK状态。如果USBFS将PID[1:0]位更改为NAK，则无需通过软件检查PBUSY位。

USBFS在以下情况下更改PIPEnCTR.PID[1:0]设置：

●USBFS在接收到负载超过所选管道的最大数据包大小的数据包时将PID设置为STALL(11b)

●USBFS在设备控制器模式下检测到USB总线复位时将PID设置为NAK

●USBFS在主机控制器模式下连续3次检测到接收错误（例如CRC错误）时将PID设置为NAK

●USBFS在主机控制器模式下接收到STALL握手时将PID设置为STALL(11b)

要指定每种响应类型，请按如下方式设置PID[1:0]位：

●要从NAK(00b)转换到STALL，设置10b

●要从BUF(01b)转换到STALL，设置11b

●要从STALL(11b)转换为NAK，请设置10b，然后设置00b

●要从STALL转换到BUF，请设置00b(NAK)，然后设置01b(BUF)

PBUSY bit (Pipe Busy)

PBUSY位指示所选管道是否正在用于当前事务。

USBFS在所选管道的USB事务开始时将PBUSY位从0更改为1，并更改PBUSY位在一个事务完成时从1变为0。

在PID设置为NAK后，通过软件读取PBUSY位可以检查是否可以更改管道设置。

SQMON位（序列切换位确认）

SQMON位指示所选管道的下一个事务的序列切换位的预期值。

USBFS在事务成功完成时切换SQMON位。但是，USBFS不会切换SQMON位，当在接收方向的传输过程中发生DATA-PID不匹配时。

SQSET位（序列切换位设置）

通过软件将SQSET位设置为1会导致USBFS将DATA1设置为所选管道上下一个事务的序列切换位的预期值。USBFS将SQSET位设置为0。

SQCLR位（序列翻转位清除）

通过软件将SQCLR位设置为1会导致USBFS将所选管道上下一个事务的序列切换位的预期值清除为DATA0。USBFS将SQCLR位设置为0。

ACLRM位（自动缓冲区清除模式）

ACLRM位启用或禁用所选管道的自动缓冲区清除模式。要完全清除分配给所选管道的FIFO缓冲区中的数据，请向ACLRM位连续写入1和0。

Table 28.13 shows the data cleared by writing 1 and 0 continuously to the ACLRM bit and the cases in which this processing is required.

Table 28.13 Data cleared by the USBFS when ACLRM = 1

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear
1	All data in the FIFO buffer allocated to the selected pipe	When initializing the selected pipe
2	Interval count value when the selected pipe is the isochronous transfer type	When resetting the interval count value
3	Internal flags related to the PIPECFG.BFRE bit	When changing the PIPECFG.BFRE setting
4	Internal flags related to the transaction count	When forcing the transaction count function to terminate

BSTS bit (Buffer Status)

The BSTS bit indicates the FIFO buffer status for the selected pipe.

The meaning of the BSTS bit depends on the PIPECFG.DIR, PIPECFG.BFRE, and DnFIFOSEL.DCLRM settings, as shown in Table 28.12.

28.2.37 PIPEnTRE : PIPEn Transaction Counter Enable Register (n = 1 to 5)

15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: Set each bit in PIPEnTRE while PID is NAK. Before setting these bits after changing the PIPEnCTR.PID[1:0] bits for the selected pipe from BUF to NAK, check that the PIPEnCTR.PBUSY bit is 0. However, if the PID[1:0] bits are changed to NAK by the USBFS, checking the PBUSY bit through the software is not necessary.

TRCLR bit (Transaction Counter Clear)

When the TRCLR bit sets to 1, the USBFS clears the value of the transaction counter associated with the selected pipe and then sets the TRCLR bit to 0.

TRENB bit (Transaction Counter Enable)

The TRENB bit enables or disables the transaction counter.

For receiving pipes, setting the TRENB bit to 1 after setting the total number of the packets to be received in the PIPEnTRN.TRNCNT[15:0] bits through the software allows the USBFS to control hardware on having received the number of packets equal to the TRNCNT[15:0] setting, as follows:

- When the PIPECFG.SHTNAK bit is 1, the USBFS changes the PID bits to NAK for the associated pipe on having received the number of packets equal to the TRNCNT[15:0] setting
- When the PIPECFG.BFRE bit is 1, the USBFS asserts the BRDY interrupt on having received the number of packets equal to the TRNCNT[15:0] setting and then reading the last received data

表28.13显示了通过向ACLRM位连续写入1和0来清除的数据以及需要进行此处理的情况。

BSTS bit (Buffer Status)

BSTS位指示所选管道的FIFO缓冲区状态。

BSTS位的含义取决于PIPECFG.DIR、PIPECFG.BFRE和DnFIFOSEL.DCLRM设置，如表28.12所示。

Note: 当PID为NAK时，设置PIPEnTRE中的每个位。在将所选管道的PIPEnCTR.PID[1:0]位从BUF更改为NAK之后设置这些位之前，请检查PIPEnCTR.PBUSY位是否为0。但是，如果PID[1:0]位更改为NAK通过USBFS，无需通过软件检查PBUSY位。

TRCLR位（事务计数器清零）

当TRCLR位设置为1时，USBFS清除与所选管道关联的事务计数器的值，然后将TRCLR位设置为0。

TRENB位（事务计数器使能）

TRENB位启用或禁用事务计数器。

对于接收管道，在设置接收管道的总包数后，将TRENB位设置为1 PIPEnTRN.TRNCNT[15:0]位通过软件允许USBFS在接收到等于TRNCNT[15:0]设置的数据包数量时控制硬件，如下所示：

●当PIPECFG.SHTNAK位为1时，USBFS在接收到等于TRNCNT[15:0]设置的数据包数时将关联管道的PID位更改为NAK

●当PIPECFG.BFRE位为1时，USBFS在接收到等于TRNCNT[15:0]设置的数据包数量并读取最后接收到的数据时断言BRDY中断

For transmitting pipes, set the TRENB bit to 0.

When the transaction counter is not used, set this bit to 0. When the transaction counter is used, set the TRNCNT[15:0] bits before setting this bit to 1. Set this bit to 1 before receiving the first packet to be counted by the transaction counter.

28.2.38 PIPEnTRN : PIPEn Transaction Counter Register (n = 1 to 5)

Bit	Symbol	Function	R/W
15:0	TRNCNT[15:0]	Transaction Counter When written to, this bit specifies the total packets (number of transactions) to be received by the selected pipe. When read from, when PIPEnTRE.TRENB is 0, this bit indicates the specified number of transactions. When PIPEnTRE.TRENB is 1, this bit indicates the current transaction count.	R/W

The PIPEnTRN registers retain their settings during a USB bus reset.

TRNCNT[15:0] bits (Transaction Counter)

The USBFS increments the value of the TRNCNT[15:0] bits by 1 when all of the following conditions are satisfied on receiving the packet:

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value ≠ current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[9:0] setting

The USBFS clears the value of the TRNCNT[15:0] bits to 0 when any of the following conditions are satisfied:

All of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value = current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[9:0] setting

Both of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The USBFS received a short packet

Both of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The PIPEnTRE.TRCLR bit was set to 1 by software

For transmitting pipes, set the TRNCNT[15:0] bits to 0. When the transaction counter is not used, set the TRNCNT[15:0] bits to 0.

Setting the number of transactions to be transferred to the TRNCNT[15:0] bits is only enabled when the PIPEnTRE.TRENB bit is 0. To set the number of transactions to be transferred, set the TRCLR bit to 1 to clear the current counter value before setting the PIPEnTRE.TRENB bit to 1.

对于传输管道，将TRENB位设置为0。

当不使用事务计数器时，将该位设置为0。当使用事务计数器时，将该位设置为1之前设置TRNCNT[15:0]位。在接收第一个要计数的数据包之前将该位设置为1由交易柜台。

TRNCNT[15:0] bits (Transaction Counter)

当接收到数据包时满足以下所有条件时，USBFS将TRNCNT[15:0]位的值加1：

●PIPEnTRE.TRENB位=1

●(TRNCNT[15:0]设定值≠当前计数器值+1)收到数据包

●接收数据包的有效载荷与PIPEMAXP.MXPS[9:0]设置一致

当满足以下任一条件时，USBFS将TRNCNT[15:0]位的值清零：

满足以下所有条件：

●PIPEnTRE.TRENB位=1

●(TRNCNT[15:0]setvalue=currentcountervalue+1)收到数据包

●接收数据包的有效载荷与PIPEMAXP.MXPS[9:0]设置一致

满足以下两个条件：

●PIPEnTRE.TRENB位=1

●USBFS收到一个短数据包

满足以下两个条件：

●PIPEnTRE.TRENB位=1

●PIPEnTRE.TRCLR位由软件设置为1

对于传输管道，将TRNCNT[15:0]位设置为0。当不使用事务计数器时，将TRNCNT[15:0]位设置为0。

仅当PIPEnTRE.TRENB位为0时才使能将要传输的事务数设置到TRNCNT[15:0]位。要设置要传输的事务数，请将TRCLR位设置为1以清除当前计数器将PIPEnTRE.TRENB位设置为1之前的值。

15:8	—	These bits are read as 0. The write value should be 0.	R/W

The DEVADDn register specifies the transfer speed of the peripheral device that is the communication target for pipes 0 to 9.

In host controller mode, set all DEVADDn bits before starting communication to any pipes. Only change the bits in DEVADDn when no valid pipes are using the bit settings. A valid pipe is defined as one that satisfies both of the following conditions:

- DEVADDn is selected in the DEVSEL[3:0] bits
- The PID[1:0] bits are set to BUF for the selected pipe, or the selected pipe is the DCP with the DCPCTR.SUREQ bit set to 1

In device controller mode, set all bits in this register to 0.

USBSPD[1:0] bits (Transfer Speed of Communication Target Device)

TheUSBSPD[1:0] bits specify the USB transfer speed of the target peripheral device. Set these bits to 10b when a full-speed device is connected through the hub. In host controller mode, the USBFS generates packets based on the USBSPD[1:0] setting. In device controller mode, set these bits to 00b.

DEVADDn寄存器指定作为管道0到9的通信目标的外围设备的传输速度。

在主机控制器模式下，在开始与任何管道通信之前设置所有DEVADDn位。仅更改中的位DEVADDn当没有有效管道使用位设置时。有效管道被定义为同时满足以下两个条件的管道：

●DEVADDn在DEVSEL[3:0]位中选择

●所选管道的PID[1:0]位设置为BUF，或者所选管道是DCPCTR.SUREQ位设置为1的DCP

在设备控制器模式下，将此寄存器中的所有位设置为0。

USBSPD[1:0]位（通信目标设备的传输速度）

USBSPD[1:0]位指定目标外围设备的USB传输速度。当通过集线器连接全速设备时，将这些位设置为10b。在主机控制器模式下，USBFS根据USBSPD[1:0]设置生成数据包。在设备控制器模式下，将这些位设置为00b。

28.3 Operation

28.3.1 System Control

This section describes register settings required for initializing the USBFS and controlling power consumption.

28.3.1.1 Setting data to the USBFS registers

Setting the SYSCFG.USBE bit to 1 after starting the clock supply (SYSCFG.SCKE bit = 1) enables and starts USBFS operation.

28.3.1.2 Selecting the controller function

The USBFS can operate as either a host or device controller.

Use the SYSCFG.DCFM bit to select one of these USBFS functions. The DCFM bit must be changed in the initial settings immediately after a reset or in the D+ pull-up-disabled state (SYSCFG.DPRPU bit = 0) and D+ and D– pull-down-disabled state (SYSCFG.DRPD bit = 0).

28.3.1.3 Controlling the USB data bus using resistors

The USBFS provides pull-up and pull-down resistors for the D+ and D– lines. Pull these lines up or down by setting the SYSCFG.DPRPU and DRPD bits.

In device controller mode, confirm that connection to the USB host is made, and then set the SYSCFG.DPRPU bit to 1 and pull up the D+ line (in full-speed communication).

When the SYSCFG.DPRPU bit is set to 0 during communication with a PC, the USBFS disables the pull-up resistor of the USB data line, thereby notifying the USB host of disconnection.

In host controller mode, set the SYSCFG.DRPD bit to 1 to pull down the D+ and D– lines.

Table 28.14 USB data bus resistor control

SYSCFG register settings		USB data bus control		
DRPD bit	DPRPU bit	D–	D+	Function
0	0	Open	Open	When resistors not used
0	1	Open	Pull-up	When operating as a device controller at full-speed
1	0	Pull-down	Pull-down	When operating as a host controller
1	1	—	—	Setting prohibited

28.3.1.4 Example external connection circuits

Figure 28.2 shows an example OTG connection in the self-powered system. The USBFS controls the pull-up resistor of the D+ line and the pull-down resistor of D+ and D- lines. Select pull-up and pull-down for the lines in the SYSCFG.DPRPU

DOVRCRA0位（USBOVRCURA中断源恢复）

由于USBFS的OVRCURA输入，DOVRCRA0位指示系统已从深度软件待机模式返回。此恢复仅在DOVRCRAE0位为1时启用。当此位为1时向DOVRCRAE0位写入0会将该位清除为0。

DOVRCRB0位（USBOVRCURB中断源恢复）

DOVRCRB0位指示由于USBFS的OVRCURB输入，系统已从深度软件待机模式返回。此恢复仅在DOVRCRBE0位为1时启用。当此位为1时向DOVRCRBE0位写入0会将该位清除为0。

DVBINT0位（USBVBUS中断源恢复）

由于USBFS的VBUS输入，DVBINT0位指示系统已从深度软件待机模式返回。此恢复仅在DVBSE0位为1时启用。当该位为1时将0写入DVBSE0位可将该位清除为0。

28.3 Operation

28.3.1 系统控制

本节介绍初始化USBFS和控制功耗所需的寄存器设置。

28.3.1.1 将数据设置到USBFS寄存器

启动时钟供应（SYSCFG.SCKE位=1）后将SYSCFG.USBE位设置为1启用并启动USBFS操作。

28.3.1.2 选择控制器功能

USBFS可以作为主机或设备控制器运行。

使用SYSCFG.DCFM位选择这些USBFS功能之一。DCFM位必须在复位后立即更改为初始设置或在D+上拉禁用状态（SYSCFG.DPRPU位=0）和D+和D 下拉禁用状态（SYSCFG.DRPD位=0））。

28.3.1.3 使用电阻控制USB数据总线

USBFS为D+和D−线提供上拉和下拉电阻。通过设置
SYSCFG.DPRPU和DRPD位。

在设备控制器模式下，确认与USB主机的连接已建立，然后将SYSCFG.DPRPU位设置为1并拉高D+线（全速通信）。

当SYSCFG.DPRPU位在与PC通信期间设置为0时，USBFS禁用上拉电阻
USB数据线，从而通知USB主机断开。

在主机控制器模式下，将SYSCFG.DRPD位设置为1以拉低D+和D−线。

Table 28.14 USB数据总线电阻控制

SYSCFG寄存器设置		USB数据总线控制		
DRPD bit	DPRPU bit	D–	D+	Function
0	0	Open	Open	不使用电阻时
0	1	Open	Pull-up	作为设备控制器全速运行时
1	0	Pull-down	Pull-down	作为主机控制器运行时
1	1	—	—	禁止设定

28.3.1.4 外部连接电路示例

和SYSCFG.DRPD位。在设备控制器模式下，如果在与USB主机通信时将SYSCFG.DPRPU位设置为0，则禁用USB数据线的上拉电阻。USBFS可以使用它来通知USB主机设备断开连接。

28.3.1.5 Release from deep software standby mode because of USB suspend/resume interrupts

Deep Software Standby mode can be canceled by a USB suspend/resume interrupt. USB suspend/resume interrupts are detected by the USB resume detecting unit, which controls and monitors the USB I/O pins to detect the interrupts.

Figure 28.7 shows a schematic diagram of the connection between the USB resume detecting unit and the USB I/O pins.

28.3.1.5 由于USB挂起恢复中断而从深度软件待机模式中释放

深度软件待机模式可以通过USB挂起恢复中断来取消。USB暂停恢复中断由USB恢复检测单元检测，该单元控制和监视USBIO引脚以检测中断。

图28.7显示了USB恢复检测单元与USBIO引脚之间的连接示意图。

28.3.3 Interrupt Descriptions

28.3.3.1 BRDY interrupt

The BRDY interrupt is generated in both host and device controller modes. This section describes the conditions in which the USBFS sets the associated bit in BRDYSTS to 1. Under these conditions, the USBFS generates a BRDY interrupt if the software has set the bit in BRDYENB associated with the given pipe to 1 and the INTENB0.BRDYE bit to 1.

The conditions for generating and clearing the BRDY interrupt depend on the SOFCFG.BRDYM and PIPECFG.BFRE settings for each pipe as follows:

(1) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.

On any of the following conditions, the USBFS generates an internal BRDY interrupt request trigger and sets the BRDYSTS.PIPEnBRDY bit associated with the selected pipe to 1.

For transmitting pipes

- When the DIR bit is changed from 0 to 1 by software
- When packet transmission is complete for a pipe while write-access from the CPU to the FIFO buffer for the pipe is disabled (when the BSTS bit is read as 0)
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is complete
- When the hardware flushes the buffer of the pipe for isochronous transfers
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to transition from the write-disabled to write-enabled state

No request trigger is generated for the DCP, that is, during data transmission for control transfers.

For receiving pipes

- When packet reception is successfully complete, enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the given pipe is disabled (when the BSTS bit is read as 0). No request trigger is generated for transactions in which a DATA-PID mismatch has occurred.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode. No request trigger is generated until completion of reading data from the currently-read FIFO buffer, even if reception by the other FIFO buffer is complete.

In device controller mode, the BRDY interrupt is not generated in the status stage of control transfers. The PIPEBRDY interrupt status of the selected pipe can be set to 0 by writing 0 to the associated PIPEnBRDY bit through software. In this case, the other PIPEBRDY bit should be set to 1.

Clear the BRDY status before accessing the FIFO buffer.

28.3.3 中断说明

28.3.3.1 BRDY interrupt

在主机和设备控制器模式下都会产生BRDY中断。本节描述USBFS将BRDYSTS中的相关位设置为1的条件。在这些条件下，如果软件将BRDYENB中与给定管道相关的位设置为1并且INTENB0.BRDYE位，USBFS将生成BRDY中断为1。

产生和清除BRDY中断的条件取决于每个管道的SOFCFG.BRDYM和PIPECFG.BFRE设置，如下所示：

(1) 当SOFCFG.BRDYM=0且PIPECFG.BFRE=0时

通过这些设置，BRDY中断指示FIFO端口可访问。

在以下任何一种情况下，USBFS都会产生一个内部BRDY中断请求触发器并设置BRDYSTS.PIPEnBRDY位与所选管道相关联为1。

用于传输管道

●DIR位由软件从0变为1时

●当一个管道的数据包传输完成而从CPU到该管道的FIFO缓冲区的写访问被禁用时（当BSTS位被读取为0时）

●双缓冲模式下，当一个FIFO缓冲区完成向另一个FIFO缓冲区写入数据时为空时

●直到向当前写入的FIFO缓冲区写入数据完成，才会产生请求触发，即使传输到另一个FIFO缓冲区已完成

●当硬件刷新管道缓冲区以进行同步传输时

●当PIPEnCTR.ACLRM位写入1时，导致FIFO缓冲区从写禁止状态转变为写使能状态

没有为DCP生成请求触发，即在控制传输的数据传输期间。

用于接收管道

●当数据包接收成功完成时，允许读取FIFO缓冲区，同时禁止CPU对给定管道的FIFO缓冲区的读取访问（当BSTS位被读取为0时）。对于发生DATA-PID不匹配的事务，不会生成请求触发器。

●当一个FIFO缓冲区在双缓冲区模式下从另一个FIFO缓冲区读取数据完成后使能读取。在从当前读取的FIFO缓冲区读取数据完成之前，不会生成请求触发，即使其他FIFO缓冲区的接收已完成。

在设备控制器模式下，在控制传输的状态阶段不会产生BRDY中断。通过软件将0写入相关的PIPEnBRDY位，可以将所选管道的PIPEBRDY中断状态设置为0。在这种情况下，另一个PIPEBRDY位应设置为1。

在访问FIFO缓冲区之前清除BRDY状态。

(2) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 1

With these settings, the USBFS generates a BRDY interrupt on completion of reading all data for a single transfer using the receiving pipe, and sets the bit in BRDYSTS associated with the pipe to 1.

On any of the following conditions, the USBFS determines that the last data for a single transfer was received.

- When a short packet including a zero-length packet is received
- When the PIPEn transaction counter register (PIPEnTRN) is used and the number of packets specified in the PIPEnTRN.TRNCNT[15:0] bits are completely received

When the data is completely read after any of these conditions is satisfied, the USBFS determines that all data for a single transfer is completely read.

When a zero-length packet is received while the FIFO buffer is empty, the USBFS determines that all data for a single transfer is completely read when the FRDY bit in the FIFO port control register is 1 and the DTLN[8:0] bits are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the associated port control register through the software. With these settings, the USBFS does not detect a BRDY interrupt for the transmitting pipe.

The PIPEBRDY interrupt status of a pipe can be set to 0 by writing 0 to the associated BRDYSTS.PIPEnBRDY bit through the software. In this case, 1s must be written to the PIPEBRDY bits for the other pipes.

In this mode, do not change the PIPECFG.BFRE bit setting until all data for a single transfer is processed. When it is necessary to change the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pipe must be cleared using the PIPEnCTR.ACLRM bit.

(3) When SOFCFG.BRDYM = 1 and PIPECFG.BFRE = 0

With these settings, the BRDYSTS.PIPEnBRDY values are linked to the BSTS bit setting for each pipe. In other words, the BRDY interrupt status bits (PIPEBRDY) are set to 1 or 0 by the USB depending on the FIFO buffer status.

For transmitting pipes

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for write access, and are set to 0 when it is not ready. The BRDY interrupt is not generated for the DCP in the transmitting direction even when it is ready for write access.

For receiving pipes

The BRDY interrupt status bits set to 1 when the FIFO buffer is ready for read access, and set to 0 when all data is read (not ready for read access).

When a zero-length packet is received while the FIFO buffer is empty, the associated bit is set to 1 and the BRDY interrupt is continuously generated until the software writes 1 to BCLR. With this setting, the PIPEnBRDY bit cannot be set to 0 by software.

When the SOFCFG.BRDYM bit is set to 1, set the PIPECFG.BFRE bit for all pipes to 0.

Figure 28.12 shows the timing of BRDY interrupt generation.

(2) 当SOFCFG.BRDYM=0且PIPECFG.BFRE=1时

使用这些设置，USBFS在完成使用接收管道读取单次传输的所有数据时生成BRDY中断，并将BRDYSTS中与管道关联的位设置为1。

在以下任何一种情况下，USBFS都会确定已接收到单次传输的最后一个数据。

●收到包含零长度包的短包时

●当使用PIPEn事务计数器寄存器(PIPEnTRN)并且完全接收到PIPEnTRN.TRNCNT[15:0]位中指定的数据包数量时

当满足其中任何一个条件后数据被完全读取时，USBFS确定单次传输的所有数据都被完全读取。

当FIFO缓冲区为空时接收到零长度数据包时，当FIFO端口控制寄存器中的FRDY位为1且DTLN[8:0]位为0.在这种情况下，要开始下一次传输，通过软件向相关端口控制寄存器中的BCLR位写入1。使用这些设置，USBFS不会检测到传输管道的BRDY中断。

通过软件将0写入相关的BRDYSTS.PIPEnBRDY位，可以将管道的PIPEBRDY中断状态设置为0。在这种情况下，必须将1写入其他管道的PIPEBRDY位。

在此模式下，在处理完单次传输的所有数据之前，不要更改PIPECFG.BFRE位设置。当需要在处理完成之前更改PIPECFG.BFRE位时，必须使用PIPEnCTR.ACLRM位清除管道的所有FIFO缓冲区。

(3) 当SOFCFG.BRDYM=1且PIPECFG.BFRE=0时

通过这些设置，BRDYSTS.PIPEnBRDY值链接到每个管道的BSTS位设置。换句话说，BRDY中断状态位(PIPEBRDY)由USB设置为1或0，具体取决于FIFO缓冲区状态。

用于传输管道

当FIFO缓冲区准备好进行写访问时，BRDY中断状态位设置为1，当它未准备好时设置为0。发送方向上的DCP不会产生BRDY中断，即使它已准备好进行写访问。

用于接收管道

当FIFO缓冲区准备好进行读取访问时，BRDY中断状态位设置为1，并在读取所有数据（未准备好进行读取访问）时设置为0。

当FIFO缓冲区为空时接收到零长度数据包时，相关位设置为1，并且持续产生BRDY中断，直到软件将1写入BCLR。使用此设置，PIPEnBRDY位不能通过软件设置为0。

当SOFCFG.BRDYM位设置为1时，将所有管道的PIPECFG.BFRE位设置为0。

图28.12显示了BRDY中断产生的时序。

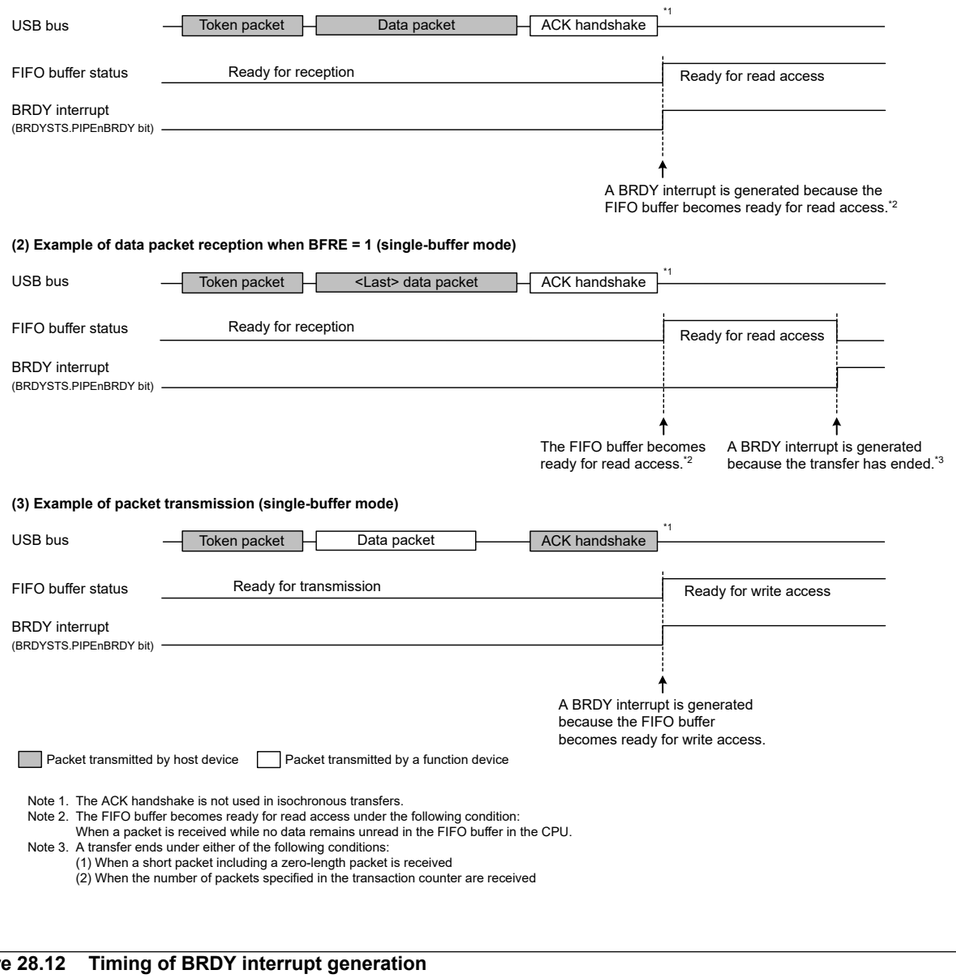

Figure 28.12 Timing of BRDY interrupt generation

The condition for clearing the INTSTS0.BRDY bit depends on the SOFCFG.BRDYM bit setting, as shown in Table 28.18.

0	The USBFS clears the BRDY bit to 0 when all bits in BRDYSTS are set to 0 by software.
1	The USBFS clears the BRDY bit to 0 when the BSTS bits for all pipes have cleared to 0.

28.3.3.2 NRDY interrupt

On generating an internal NRDY interrupt request for the pipe whose PID bits are set to BUF by software, the USBFS sets the associated PIPEnNRDY bit in NRDYSTS to 1. If the associated bit in NRDYENB is set to 1 by software, the USBFS sets the INTSTS0.NRDY bit to 1 and generates a USBFS interrupt.

This section describes the conditions in which the USBFS generates the internal NRDY interrupt request for a given pipe.

The internal NRDY interrupt request is not generated during setup transaction execution in host controller mode. During setup transactions in host controller mode, the SACK or SIGN interrupt is detected.

28.3.3.2 NRDY interrupt

在为PID位由软件设置为BUF的管道生成内部NRDY中断请求时，USBFS将NRDYSTS中的相关PIPEnNRDY位设置为1。如果NRDYENB中的相关位由软件设置为1，则USBFS设置INTSTS0.NRDY位为1并产生USBFS中断。

本节描述USBFS为给定管道生成内部NRDY中断请求的条件。

内部NRDY中断请求在主控制器模式下的设置事务执行期间不会产生。在主机控制器模式下的设置事务期间，检测到SACK或SIGN中断。

The internal NRDY interrupt request is not generated during status stage execution of the control transfer in device controller mode.

(1) In host controller mode

For transmitting pipes

On any of the following conditions, the USBFS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBFS transmits a zero-length packet following the OUT token and sets the associated NRDYSTS.PIPEnNRDY bit and the FRMNUM.OVRN bit to 1.
- During communications other than setup transactions on pipes not used for isochronous transfers, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device
  - An error is detected in the packet from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the associated PID[1:0] setting for the pipe to NAK
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the PID[1:0] setting for the associated pipe to STALL (11b).

For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBFS discards the received data for the IN token and sets the PIPEnNRDY bit associated with the pipe and the OVRN bit to 1. When a packet error is detected in the received data for the IN token, the USBFS also sets the FRMNUM.CRCE bit to 1.
- For non-isochronous transfer pipes, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device for the IN token issued by the USBFS (when timeout is detected before detection of the DATA packet from the peripheral device)
  - An error is detected in the packet from the peripheral device. In this case, the USBFS sets the associated PIPEnNRDY bit to 1 and changes the associated PID[1:0] setting for the pipe to NAK
- For isochronous transfer pipes, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe to 1. The PID[1:0] setting for the pipe is not changed.
- For isochronous transfer pipes, when a CRC error or a bit stuffing error is detected in the received data packet. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe and the CRCE bit to 1.
- When the STALL handshake is received. In this case, the USBFS sets the PIPEnNRDY bit associated with the pipe to 1 and changes the PID[1:0] setting for the associated pipe to STALL.

(2) In device controller mode

For transmitting pipes

- When an IN token is received while there is no data to be transmitted in the FIFO buffer. In this case, the USBFS generates a NRDY interrupt request on reception of the IN token and sets the NRDYSTS.PIPEnNRDY bit to 1. For an isochronous transfer pipe in which an interrupt is generated, the USBFS transmits a zero-length packet and sets the FRMNUM.OVRN bit to 1.

For receiving pipes

- When an OUT token is received but there is no space available in the FIFO buffer. For an isochronous transfer pipe in which an interrupt is generated, the USBFS generates a NRDY interrupt request on reception of the OUT token and sets the PIPEnNRDY bit to 1 and OVRN bit to 1. For a non-isochronous transfer pipe in which an interrupt is generated, the USBFS generates a NRDY interrupt request when a NAK handshake is transferred after the data following the OUT token is received, and sets the PIPEnNRDY bit to 1. The NRDY interrupt request is not generated during retransmission

在设备控制器模式下控制传输的状态阶段执行期间，不会产生内部NRDY中断请求。

(1) 在主机控制器模式下

用于传输管道

在以下任何一种情况下，USBFS都会检测到NRDY中断：

●对于同步传输管道，当FIFO缓冲区中没有要传输的数据时发出OUT令牌的时间到来。在这种情况下，USBFS在OUT令牌之后发送一个长度为零的数据包，并将相关的NRDYSTS.PIPEnNRDY位和FRMNUM.OVRN位设置为1。

●在不用于同步传输的管道上的设置事务以外的通信期间，当以下两种情况的任意组合连续发生3次时：

外围设备没有返回响应（当在检测到来自外围设备的握手包之前检测到超时

在来自外围设备的数据包中检测到错误。在这种情况下，USBFS将相关的PIPEnNRDY位设置为1，并将管道的相关PID[1:0]设置更改为NAK

●在设置事务以外的通信期间，当从外围设备接收到STALL握手时。在这种情况下，USBFS将相关的PIPEnNRDY位设置为1，并将相关管道的PID[1:0]设置更改为STALL(11b)。

用于接收管道

●对于同步传输管道，当发出IN令牌的时间到来但FIFO中没有可用空间时
缓冲。在这种情况下，USBFS丢弃接收到的IN令牌数据，并将与管道关联的PIPEnNRDY位和OVRN位设置为1。当在接收到的IN令牌数据中检测到数据包错误时，USBFS也会设置FRMNUM.CRCE位为1。

●对于非等时传输管道，当以下两种情况的任意组合连续出现3次时：

USBFS发出的IN令牌没有从外围设备返回响应（当在检测到来自外围设备的DATA数据包之前检测到超时时）

在来自外围设备的数据包中检测到错误。在这种情况下，USBFS将相关的PIPEnNRDY位设置为1，并将管道的相关PID[1:0]设置更改为NAK

●对于同步传输管道，当外围设备没有返回对IN令牌的响应时（在检测到来自外围设备的DATA数据包之前检测到超时）或在外围设备的数据包中检测到错误。在这种情况下，USBFS将与管道关联的PIPEnNRDY位设置为1。管道的PID[1:0]设置不会更改。

●对于同步传输管道，当在接收到的数据包中检测到CRC错误或比特填充错误时。在这种情况下，USBFS将与管道关联的PIPEnNRDY位和CRCE位设置为1。

●收到STALL握手时。在这种情况下，USBFS将与管道关联的PIPEnNRDY位设置为1，并将关联管道的PID[1:0]设置更改为STALL。

(2) 在设备控制器模式下

用于传输管道

●当接收到一个IN令牌而FIFO缓冲区中没有要传输的数据时。在这种情况下，USBFS
在接收到IN令牌时生成NRDY中断请求并将NRDYSTS.PIPEnNRDY位设置为1。对于产生中断的同步传输管道，USBFS发送一个长度为零的数据包并将FRMNUM.OVRN位设置为1.

用于接收管道

●当接收到OUT令牌但FIFO缓冲区中没有可用空间时。对于产生中断的同步传输管道，USBFS在接收到OUT令牌时产生一个NRDY中断请求，并将PIPEnNRDY位设置为1，并将OVRN位设置为1。USBFS在接收到OUT令牌之后的数据后，在传输NAK握手时产生NRDY中断请求，并将PIPEnNRDY位设置为1。重传期间不产生NRDY中断请求

because of a DATA-PID mismatch. In addition, the NRDY interrupt request is not generated if an error occurs in the DATA packet.

- For isochronous transfer pipes, when a token is not received successfully within an interval frame. In this case, the USBFS generates an NRDY interrupt request when the SOF is received, and sets the PIPEnNRDY bit to 1.

Figure 28.13 shows the timing of NRDY interrupt generation in device controller mode.

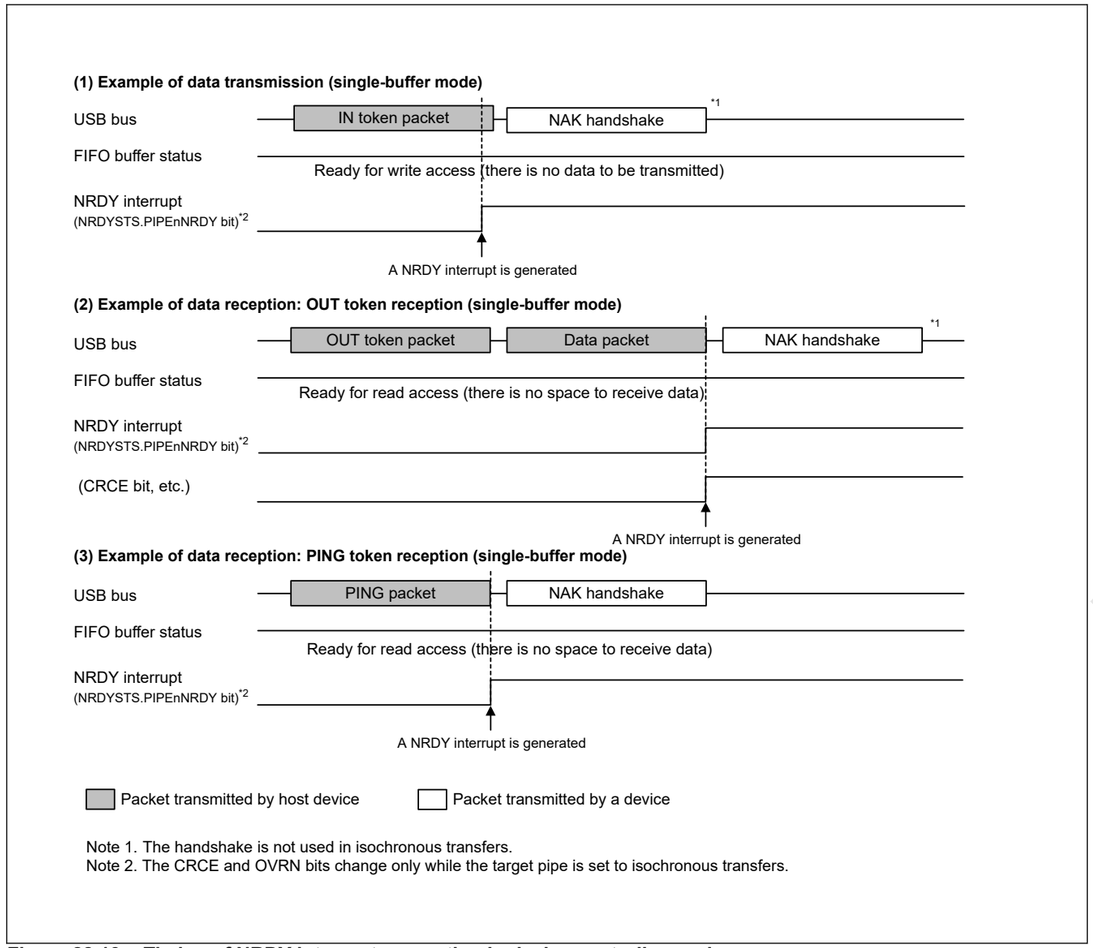

Figure 28.13 Timing of NRDY interrupt generation in device controller mode

28.3.3.3 BEMP interrupt

On detecting a BEMP interrupt for the pipe whose PID bits are set to BUF by software, the USBFS sets the associated BEMPSTS.PIPEnBEMP bit to 1. If the associated bit in BEMPENB is set to 1 by software, the USBFS sets the INTSTS0.BEMP bit to 1 and generates a USBFS interrupt. This section describes the conditions in which the USBFS generates an internal BEMP interrupt request.

(1) For transmitting pipes

When the FIFO buffer of the associated pipe is empty on completion of transmission, including zero-length packet transmission, and in single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for a non-DCP pipe. The internal BEMP interrupt request is not generated in any of the following conditions:

因为DATA-PID不匹配。此外，如果DATA包发生错误，则不会产生NRDY中断请求。

●对于同步传输管道，当在间隔帧内没有成功接收到令牌时。在这种情况下，USBFS在接收到SOF时产生一个NRDY中断请求，并将PIPEnNRDY位设置为1。

图28.13显示了设备控制器模式下NRDY中断产生的时序。

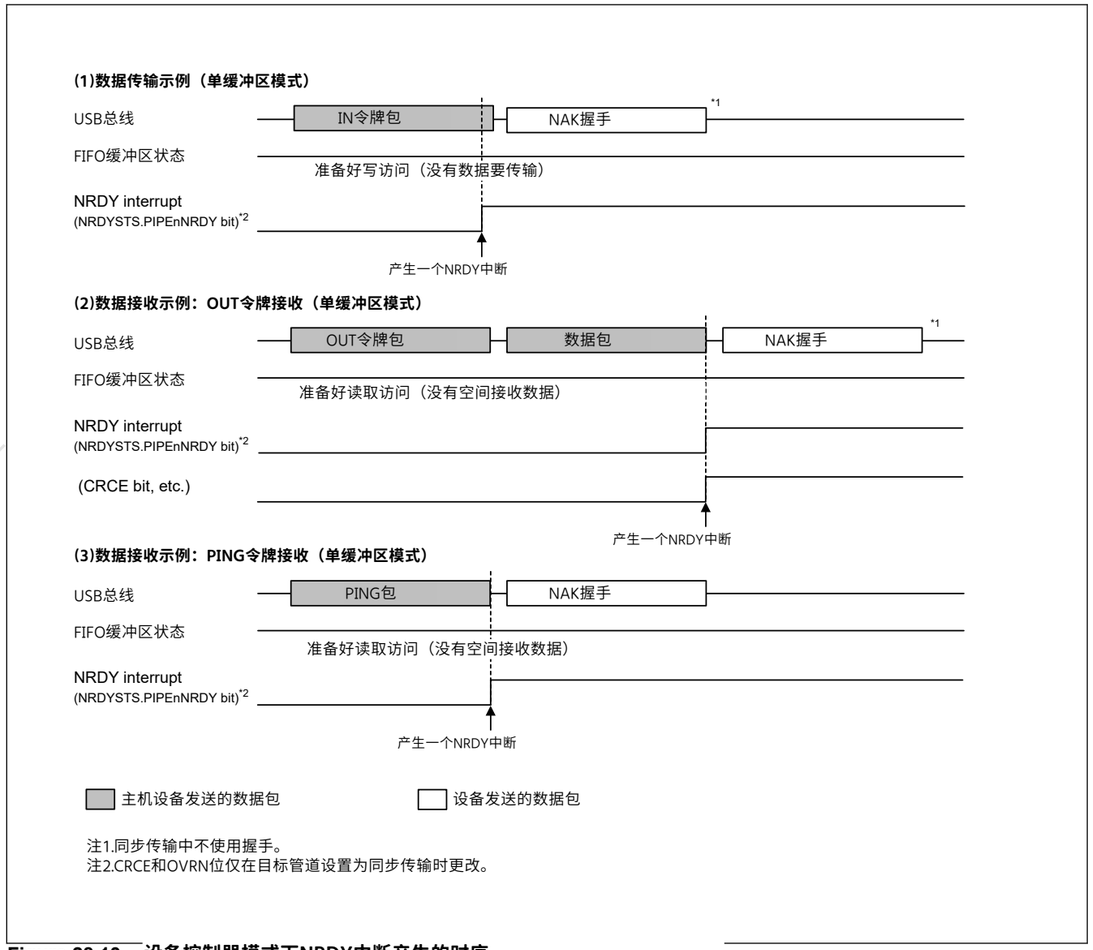

Figure 28.13 设备控制器模式下NRDY中断产生的时序

28.3.3.3 BEMP interrupt

在检测到PID位被软件设置为BUF的管道的BEMP中断时，USBFS将相关的BEMPSTS.PIPEnBEMP位设置为1。如果BEMPENB中的相关位被软件设置为1，USBFS将设置INTSTS0.BEMP位为1并产生USBFS中断。本节介绍USBFS产生内部BEMP中断请求的条件。

(1) 用于传输管道

当相关管道的FIFO缓冲区在传输完成时为空时，包括零长度数据包传输，并且在单缓冲区模式下，内部BEMP中断请求与非DCP管道的BRDY中断同时生成。在以下任何一种情况下都不会产生内部BEMP中断请求：

- When the CPU or DMA/DTC has already started writing data to the FIFO buffer of the CPU on completion of transmitting data from one FIFO buffer in double buffer mode
- When the buffer is cleared (emptied) by setting the PIPEnCTR.ACLRM or the BCLR bit to 1 in the port control register
- When an IN transfer (zero-length packet transmission) is performed during the control transfer status stage in device controller mode

(2) For receiving pipes

When a successfully-received data packet size exceeds the specified maximum packet size. In this case, the USBFS generates a BEMP interrupt request, sets the associated BEMPSTS.PIPEnBEMP bit to 1, discards the received data, and changes the associated PID[1:0] setting for the pipe to STALL (11b). The USBFS returns no response in host controller mode, and returns STALL response in device controller mode.

The internal BEMP interrupt request is not generated in any of the following conditions:

- When a CRC error or a bit stuffing error is detected in the received data
- When a setup transaction is being performed:
  - Writing 0 to the BEMPSTS.PIPEnBEMP bit clears the status
  - Writing 1 to the BEMPSTS.PIPEnBEMP bit has no effect

Figure 28.14 shows the timing of BEMP interrupt generation in device controller mode.

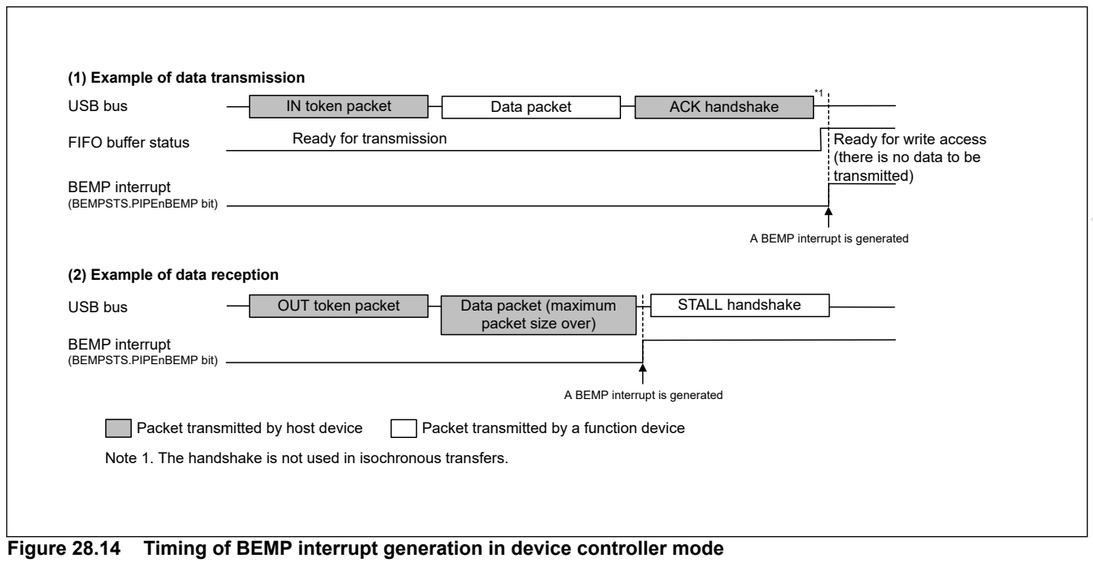

Figure 28.14 Timing of BEMP interrupt generation in device controller mode

28.3.3.4 Device state transition interrupt (device controller mode)

Figure 28.15 shows a diagram of the USBFS device state transitions. The USBFS controls device states and generates device state transition interrupts. However, recovery from the Suspend state (resume signal detection) is detected by means of the resume interrupt. Device state transition interrupts can be enabled or disabled independently in INTENB0. Devices whose states have changed can be checked in the INTSTS0.DVSQ[2:0] bits.

When a transition is made to the default state, a device state transition interrupt is generated after a USB bus reset is detected.

The USBFS controls device states, and device state transition interrupts can be generated, only in device controller mode.

●当CPU或DMADTC在双缓冲模式下从一个FIFO缓冲区完成数据传输后已经开始向CPU的FIFO缓冲区写入数据时

●通过将端口控制寄存器中的PIPEnCTR.ACLRM或BCLR位设置为1来清除（清空）缓冲区时

●在设备控制器模式的控制传输状态阶段进行IN传输（零长度包传输）时

(2) 用于接收管道

当成功接收的数据包大小超过指定的最大包大小时。在这种情况下，USBFS生成一个BEMP中断请求，将相关的BEMPSTS.PIPEnBEMP位设置为1，丢弃接收到的数据，并将管道的相关PID[1:0]设置更改为STALL(11b)。USBFS在主机控制器模式下不返回响应，在设备控制器模式下返回STALL响应。

在以下任何一种情况下都不会产生内部BEMP中断请求：

●在接收到的数据中检测到CRC错误或位填充错误时

●执行设置事务时：

将0写入BEMPSTS.PIPEnBEMP位可清除状态

向BEMPSTS.PIPEnBEMP位写入1无效

Figure 28.16 shows a diagram of the control transfer stage transitions of the USBFS. The USBFS controls the control transfer sequence and generates control transfer stage transition interrupts. Control transfer stage transition interrupts can be enabled or disabled independently in INTENB0. Transfer stages that have transitioned can be checked in the INTSTS0.CTSQ[2:0] bits.

(1) Control read transfer errors

- An OUT token is received but no data is transferred in response to the IN token at the data stage
- An IN token is received at the status stage
- A data packet with DATAPID = DATA0 is received at the status stage

(2) Control write transfer errors

- An IN token is received but no ACK is returned in response to the OUT token at the data stage
- A data packet with DATAPID = DATA0 is received as the first data packet at the data stage
- An OUT token is received at the status stage

(3) Control write no data transfer errors

- An OUT token is received at the status stage

At the control write transfer data stage, if the receive data length exceeds the wLength value of the USB request, it is not recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (INTSTS0.CTRT = 1), the CTSQ[2:0] = 110b value is saved until the CTRT bit is set to 0, clearing the interrupt status. While CTSQ[2:0] = 110b is being saved, no CTRT interrupt for ending the setup stage is generated, even if a new USB request is received. The USBFS saves the setup stage completion status, and it generates a CTRT interrupt after the interrupt status is cleared by software.

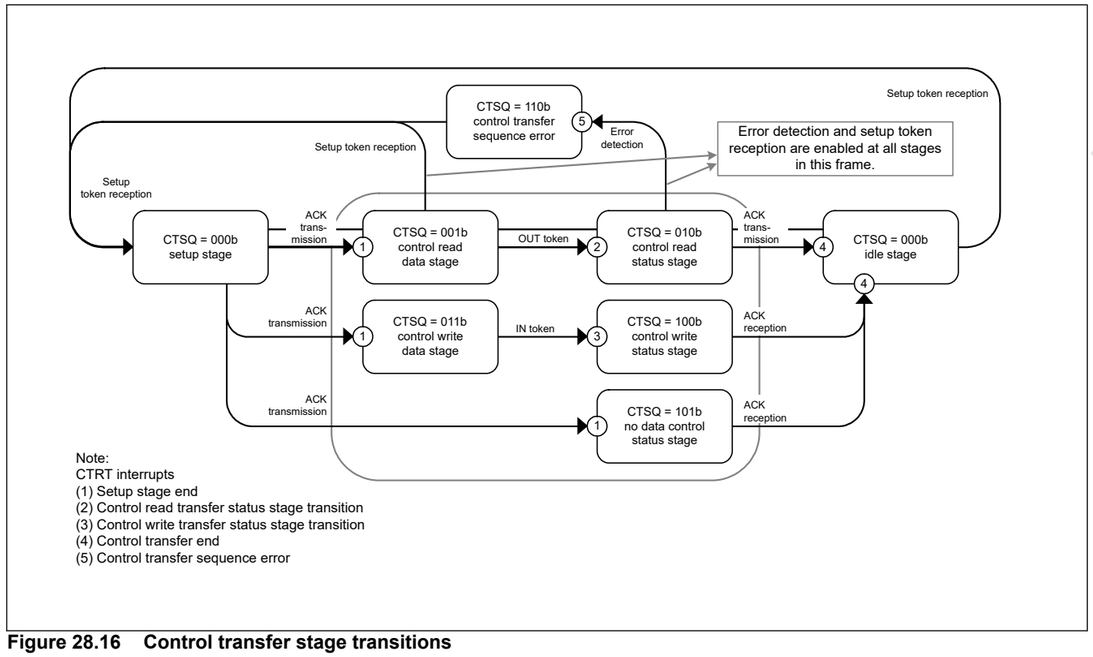

Figure 28.16 Control transfer stage transitions

28.3.3.6 Frame update interrupt

In host controller mode, an interrupt is generated when the frame number is updated.

In device controller mode, an SOFR interrupt is generated when the frame number is updated. The USBFS updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation.

(1) 控制读取传输错误

●在数据阶段收到一个OUT令牌，但没有传输数据以响应IN令牌

●在状态阶段收到一个IN令牌

●在状态阶段接收到DATAPID=DATA0的数据包

(2) 控制写入传输错误

●在数据阶段收到一个IN令牌，但没有返回ACK响应OUT令牌

●DATAPID=DATA0的数据包作为数据阶段的第一个数据包被接收

●在状态阶段收到一个OUT令牌

(3) 控制写入无数据传输错误

●在状态阶段收到一个OUT令牌

在控制写入传输数据阶段，如果接收数据长度超过USB请求的wLength值，则不被识别为控制传输序列错误。
在控制读取传输状态阶段，除了零长度数据包之外的数据包被一个ACK响应接收并且传输正常结束。

当响应序列错误（INTSTS0.CTRT=1）而发生CTRT中断时，将保存CTSQ[2:0]=110b值，直到CTRT位设置为0，清除中断状态。在保存CTSQ[2:0]=110b时，不会产生用于结束设置阶段的CTRT中断，即使收到新的USB请求也是如此。USBFS保存设置阶段完成状态，软件清除中断状态后产生CTRT中断。

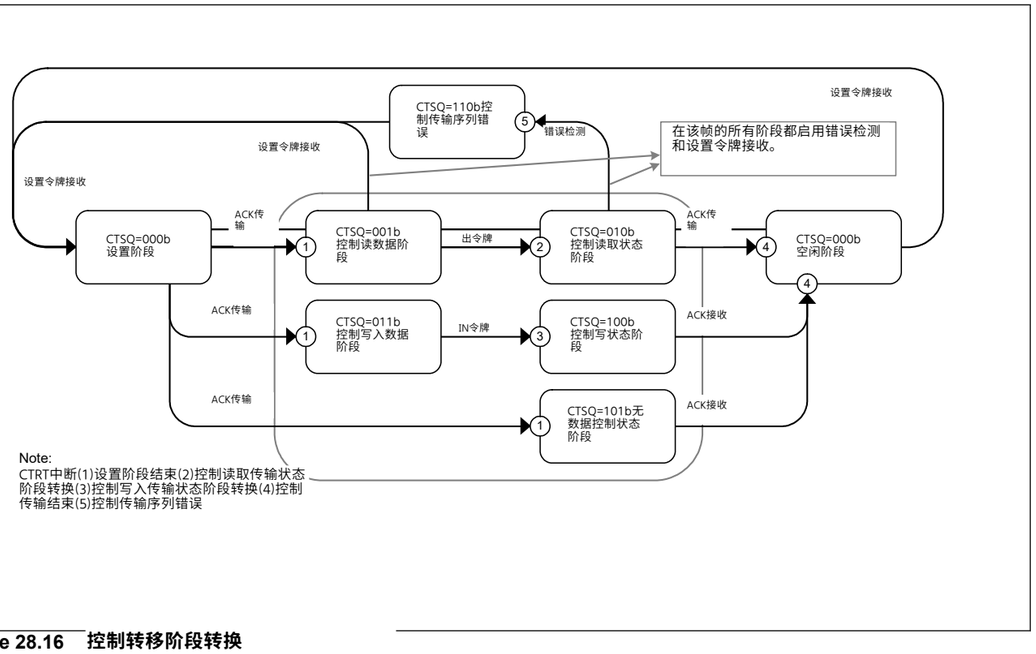

Figure 28.16 控制转移阶段转换

28.3.3.6 帧更新中断

在主机控制器模式下，更新帧号时会产生中断。

在设备控制器模式下，更新帧号时会产生SOFR中断。如果USBFS在全速运行期间检测到新的SOF数据包，则USBFS会更新帧号并生成SOFR中断。

28.3.3.7 VBUS interrupt

When the USB_VBUS pin level changes, a VBUS interrupt is generated. The level of the USB_VBUS pin can be checked with the INTSTS0.VBSTS bit. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. If the system is activated with the host controller connected, the first VBUS interrupt is not generated, because there is no change in the USB_VBUS pin level.

28.3.3.8 Resume interrupt

In device controller mode, a resume interrupt is generated when the device state is the Suspend state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the Suspend state is detected by means of the resume interrupt.

In host controller mode, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

28.3.3.9 OVRCR interrupt

An OVRCR interrupt is generated when the USB_OVRCURA or USB_OVRCURB pin level has changed. The levels of the USB_OVRCURA and USB_OVRCURB pins can be checked in the SYSSTS0.OVCMON[1:0] flags. The external power supply IC can check whether overcurrent is detected using the OVRCR interrupt.

For OTG connections, the OVRCR interrupt allows you to check whether a change is detected in the VBUS comparator.

28.3.3.10 BCHG interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether a peripheral device is connected and can also be used to detect a remote wakeup in host controller mode. The BCHG interrupt is generated in both host and device controller modes.

28.3.3.11 DTCH interrupt

A DTCH interrupt occurs when a USB bus disconnect is detected in host controller mode. The USBFS detects bus disconnects in compliance with the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software. The pipes enter the wait state for a bus connection to the port, waiting for an ATTCH interrupt to occur. Regardless of the value set in the associated interrupt enable bit, the USBFS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt is detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state

28.3.3.12 SACK interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet is received from the peripheral device in host controller mode. The SACK interrupt can be used to confirm that the setup transaction is successfully complete.

28.3.3.13 SIGN interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet is not correctly received from the peripheral device three consecutive times in host controller mode. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

28.3.3.14 ATTCH interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5 µs in host controller mode. To be more specific, an ATTCH interrupt is detected on any of the following conditions:

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5 µs
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5 µs

28.3.3.7 VBUS interrupt

当USB_VBUS引脚电平改变时，会产生VBUS中断。USB_VBUS引脚的电平可以通过INTSTS0.VBSTS位检查。主控制器是连接还是断开可以使用VBUS中断来确认。如果系统在连接主机控制器的情况下激活，则不会产生第一个VBUS中断，因为USB_VBUS引脚电平没有变化。

28.3.3.8 恢复中断

在设备控制器模式下，当设备状态为Suspend状态且USB总线状态发生变化（从J-state到K-state，或从J-state到SE0）时，会产生恢复中断。通过恢复中断检测从挂起状态的恢复。

在主机控制器模式下，不会产生恢复中断。使用BCHG中断来检测USB总线状态的变化。

28.3.3.9 OVRCR interrupt

当USB_OVRCURA或USB_OVRCURB引脚电平发生变化时，会产生OVRCR中断。的水平USB_OVRCURA和USB_OVRCURB引脚可以在SYSSTS0.OVCMON[1:0]标志中检查。外部电源IC可以使用OVRCR中断检查是否检测到过电流。

对于OTG连接，OVRCR中断允许您检查是否在VBUS比较器中检测到变化。

28.3.3.10 BCHG interrupt

当USB总线状态改变时会产生BCHG中断。BCHG中断可用于检测是否连接了外围设备，也可用于检测主机控制器模式下的远程唤醒。BCHG中断在主机和设备控制器模式下产生。

28.3.3.11 DTCH interrupt

当在主机控制器模式下检测到USB总线断开连接时，会发生DTCH中断。USBFS检测符合USB2.0规范的总线断开连接。

在检测到中断时，为相关端口执行通信的所有管道必须由软件终止。管道进入等待状态，等待总线连接到端口，等待ATTCH中断发生。无论相关中断使能位中设置的值如何，USBFS硬件：

- 将检测到DTCH中断的端口的DVSTCTR0.UACT位设置为0
- 将发生DTCH中断的端口置于空闲状态

28.3.3.12 SACK中断

当在主机控制器模式下从外围设备接收到对发送的设置数据包的ACK响应时，将产生SACK中断。SACK中断可用于确认设置事务成功完成。

28.3.3.13 标志中断

在主机控制器模式下，如果连续三次未从外围设备正确接收到已发送的设置数据包的ACK响应，则会产生SIGN中断。SIGN中断可用于检测没有从外围设备发送的ACK响应或ACK数据包的损坏。

28.3.3.14 ATTCH interrupt

在主机控制器模式下，当在USB端口上检测到全速信号电平的J状态或K状态持续2.5µs时，将产生ATTCH中断。更具体地说，在以下任何条件下都会检测到ATTCH中断：

- 当K-state、SE0或SE1变为J-state时，J-state持续2.5µs
- J-state、SE0或SE1变为K-state时，K-state持续2.5µs

28.3.3.15 EOFERR interrupt

An EOFERR interrupt occurs when the USBFS detects that communication is not complete at the EOF2 timing defined in the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software, and the port must be re-enumerated. Regardless of the value set in the associated interrupt enable bit, the USBFS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt is detected to 0
- Puts the port in which the EOFERR interrupt is generated into the idle state

28.3.3.16 Portable Device Detection Interrupt

The USBFS sets the INTSTS1.PDDETINT flag to 1 on detecting a portable device and generates the portable device detection interrupt. When the portable device detection interrupt is generated, use software to repeat reading the BCCTRL1.PDDETSTS flag until the same value is read three or more times, and perform debounce processing.

28.3.4 Pipe Control

Table 28.19 lists the pipe settings for the USBFS. USB data transfer is performed through logical pipes that the software associates with endpoints. The USBFS provides 10 pipes that are used for data transfer. Set up the pipes based on your system specifications.

28.3.3.15 EOFERR interrupt

当USBFS检测到在USB2.0规范中定义的EOF2时序未完成通信时，将发生EOFERR中断。

在检测到中断时，所有为相关端口执行通信的管道必须由软件终止，并且必须重新枚举该端口。无论相关中断使能位中设置的值如何，USBFS硬件：

- 将检测到EOFERR中断的端口的DVSTCTR0.UACT位设置为0
- 将产生EOFERR中断的端口置于空闲状态

28.3.3.16 便携式设备检测中断

USBFS在检测到便携式设备时将INTSTS1.PDDETINT标志设置为1，并生成便携式设备检测中断。当便携式设备检测中断产生时，使用软件重复读取BCCTRL1.PDDETSTS标志，直到读取相同的值3次或更多次，并进行去抖动处理。

28.3.4 管道控制

表28.19列出了USBFS的管道设置。USB数据传输是通过软件与端点关联的逻辑管道执行的。USBFS提供了10个用于数据传输的管道。根据您的系统规格设置管道。

Table 28.19 Pipe settings (2 of 2)

Register name	Bit name	Setting	Notes
PIPEnTRE	TRENB	Transaction counter enable	Pipes 1 to 5: Settable
	TRCLR	Current transaction counter clear	Pipes 1 to 5: Settable
PIPEnTRN	TRNCNT	Transaction counter	Pipes 1 to 5: Settable

28.3.4.1 Pipe control register switching procedures

The following bits in the pipe control registers can be changed only when USB communication is prohibited (PID = NAK).

Do not change the following registers and bits when USB communication is enabled (PID = BUF):

- Bits in DCPCFG and DCPMAXP
- SQCLR and SQSET bits in DCPCTR
- Bits in PIPECFG, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPEnCTR
- Bits in PIPEnTRE and PIPEnTRN

To set these bits when USB communication is enabled (PID = BUF):

1. A request to change the bits in the pipe control register occurs.
2. Set the PID[1:0] bits associated with the pipe to NAK.
3. Wait until the associated PBUSY bit clears to 0.
4. Set the bits in the pipe control register.

The following bits in the pipe control registers can be changed only when the selected pipe information is not set in the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Do not set the following registers when the CURPIPE[3:0] bits are set:

- Bits in DCPCFG and DCPMAXP
- Bits in PIPECFG, PIPEMAXP and PIPEPERI

To change pipe information, you must set the CURPIPE[3:0] bits in the port select registers to a pipe other than the one to be changed. For the DCP, the buffer must be cleared using the BCLR bit in the Port Control Register after the pipe information is changed.

28.3.4.2 Transfer types

The PIPECFG.TYPE[1:0] bits specify the following transfer types for each pipe:

- DCP: No setting is necessary (fixed at control transfer)
- Pipes 1 and 2: Set to bulk or isochronous transfer
- Pipes 3 to 5: Set to bulk transfer
- Pipes 6 to 9: Set to interrupt transfer

28.3.4.3 Endpoint number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to 15.

- DCP: No setting is necessary (fixed at endpoint 0)
- Pipes 1 to 9: Select and set the endpoint numbers from 1 to 15 so that the combination of the PIPECFG.DIR and EPNUM[3:0] bits is unique

Table 28.19 管道设置(2of2)

注册名称	位名称	Setting	Notes
PIPEnTRE	TRENB	事务计数器启用	管道1至5：可设置
	TRCLR	当前交易柜台清零	管道1至5：可设置
PIPEnTRN	TRNCNT	交易柜台	管道1至5：可设置

28.3.4.1 管道控制寄存器切换程序

只有当USB通信被禁止(PID=NAK)时，管道控制寄存器中的以下位才能更改。

当启用USB通信(PID=BUF)时，请勿更改以下寄存器和位：

●DCPCFG和DCPMAXP中的位

●DCPCTR中的SQCLR和SQSET位

●PIPECFG、PIPEMAXP和PIPEPERI中的位

●PIPEnCTR中的ATREPM、ACLRM、SQCLR和SQSET位

●PIPEnTRE和PIPEnTRN中的位

要在启用USB通信(PID=BUF)时设置这些位：

1.发生更改管道控制寄存器中的位的请求。

2.将与管道关联的PID[1:0]位设置为NAK。

3.等到相关的PBUSY位清除为0。

4.设置管道控制寄存器中的位。

管道控制寄存器中的以下位只有在所选管道信息未设置时才能更改CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位。

设置CURPIPE[3:0]位时不要设置以下寄存器：

●DCPCFG和DCPMAXP中的位

●PIPECFG、PIPEMAXP和PIPEPERI中的位

要更改管道信息，您必须将端口选择寄存器中的CURPIPE[3:0]位设置为要更改的管道以外的管道。对于DCP，必须在管道信息更改后使用端口控制寄存器中的BCLR位清除缓冲区。

28.3.4.2 传输类型

PIPECFG.TYPE[1:0]位为每个管道指定以下传输类型：

●DCP：无需设置（控制转移时固定）

●管道1和2：设置为批量或同步传输

●管道3到5：设置为批量传输

●管道6到9：设置为中断传输

28.3.4.3 端点编号

PIPECFG.EPNUM[3:0]位用于设置每个管道的端点编号。DCP固定在端点0。其他管道可以设置从端点1到15。

●DCP：无需设置（固定在端点0）

●管道1到9：从1到15选择和设置端点编号，以便PIPECFG.DIR和EPNUM[3:0]位的组合是唯一的

28.3.4.4 Maximum packet size setting

Specify the maximum packet size for each pipe in the DCPMAXP.MXPS[6:0] and PIPEMAXP.MXPS[9:0] bits. The DCP and pipes 1 to 5 can be set to any of the maximum pipe sizes defined in the USB 2.0 specification. For pipes 6 to 9, the maximum packet size is 64 bytes. Set the maximum packet size as follows before starting a transfer (PID = BUF):

- DCP: Set to 8, 16, 32, or 64
- Pipes 1 to 5: Set to 8, 16, 32, or 64 for bulk transfers
- Pipes 1 and 2: Set between 1 and 256 for isochronous transfers
- Pipes 6 to 9: Set between 1 and 64

28.3.4.5 Transaction counter for pipes 1 to 5 in the receiving direction

When the specified number of transactions is complete in the data packet receiving direction, the USBFS recognizes that the transfer ended. Two transaction counters are provided: one is the PIPEnTRN register, which specifies the number of transactions to be executed, and the other is the current counter, which internally counts the number of executed transactions. If the PIPECFG.SHTNAK bit is set to 1, when the current counter value matches the specified number of transactions, the associated PIPEnCTR.PID[1:0] bits are set to NAK and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The data read from PIPEnTRN differs depending on the PIPEnTRE.TRENB setting as follows:

- The TRENB bit = 0: Specified transaction counter value can be read
- The TRENB bit = 1: Current counter value indicating the internally counted number of executed transactions can be read

The following constraints apply when working with the TRCLR bit:

- If the transactions are being counted and PID = BUF, the current counter cannot be cleared
- If there is any data left in the buffer, the current counter cannot be cleared

28.3.4.6 Response PID

Specify the response PID for each pipe in the PID[1:0] bits in DCPCTR and PIPEnCTR. This section describes the USBFS operation with different response PID settings.

(1) Software response PID settings in host controller mode

Select the response PID to specify the execution of transactions as follows:

- NAK setting: Using pipes is disabled and no transactions are executed
- BUF setting: Transactions are executed based on the FIFO buffer state:
  - OUT direction: An OUT token is issued if the FIFO buffer contains transmit data.
  - IN direction: An IN token is issued if the FIFO buffer is not full and can receive data.
- STALL setting: Using pipes is disabled and no transactions are executed

Note: Use the DCPCTR.SUREQ bit to execute setup transactions for the DCP.

(2) Software response PID settings in device controller mode

Select the response PID to respond as follows to transactions from the host:

- NAK setting: A NAK response is returned to all generated transactions
- BUF setting: A response is returned to transactions based on the FIFO buffer
- STALL setting: A STALL response is returned to all generated transactions

Note: For setup transactions, an ACK response is always returned, regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

28.3.4.4 最大数据包大小设置

在DCPMAXP.MXPS[6:0]和PIPEMAXP.MXPS[9:0]位中指定每个管道的最大数据包大小。DCP和管道1到5可以设置为USB2.0规范中定义的任何最大管道尺寸。对于管道6到9，最大数据包大小为64字节。在开始传输之前设置最大数据包大小如下（PID=BUF）：

●DCP：设置为8、16、32或64

●管道1到5：设置为8、16、32或64以进行批量传输

●管道1和2：设置在1和256之间，用于同步传输

●管道6到9：设置在1到64之间

28.3.4.5 接收方向上管道1到5的事务计数器

当在数据包接收方向完成指定数量的事务时，USBFS识别传输结束。提供了两个事务计数器：一个是PIPEnTRN寄存器，指定要执行的事务数，另一个是当前计数器，内部统计执行的事务数。如果PIPECFG.SHTNAK位设置为1，则当当前计数器值与指定的事务数匹配时，相关的PIPEnCTR.PID[1:0]位将设置为NAK，并禁用后续传输。通过PIPEnTRE.TRCLR位初始化事务计数器功能的当前计数器，事务可以从头开始重新计数。从PIPEnTRN读取的数据因PIPEnTRE.TRENB设置而异，如下所示：

●TRENB位=0：可以读取指定的事务计数器值

●TRENB位=1：表示内部计数的已执行事务数的当前计数器值可被读取

使用TRCLR位时适用以下约束：

●如果正在对事务进行计数且PID=BUF，则无法清除当前计数器

●如果缓冲区中还有数据，则无法清除当前计数器

28.3.4.6 响应PID

在DCPCTR和PIPEnCTR的PID[1:0]位中指定每个管道的响应PID。本节介绍具有不同响应PID设置的USBFS操作。

(1) 主机控制器模式下的软件响应PID设置

选择响应PID来指定事务的执行，如下所示：

●NAK设置：禁用使用管道，不执行任何事务

●BUF设置：根据FIFO缓冲区状态执行事务：

OUT方向：如果FIFO缓冲区包含发送数据，则发出OUT令牌。

IN方向：如果FIFO缓冲区未满并且可以接收数据，则发出IN令牌。

●STALL设置：禁止使用管道，不执行任何事务

Note: 使用DCPCTR.SUREQ位执行DCP的设置事务。

(2) 设备控制器模式下的软件响应PID设置

选择响应PID以对来自主机的事务进行如下响应：

●NAK设置：对所有生成的事务返回NAK响应

●BUF设置：根据FIFO缓冲区向事务返回响应

●STALL设置：向所有生成的事务返回STALL响应

Note: 对于设置事务，无论PID[1:0]位设置如何，始终返回ACK响应，并且USB请求存储在寄存器中。

Sections (3) and (4) describe situations in which the USBFS writes to the PID[1:0] bits because of specific transaction results.

(3) Hardware response PID settings in host controller mode

- NAK setting: PID = NAK is set in the following cases, and issuing of tokens is automatically stopped:
  - When a non-isochronous transfer is performed and an NRDY interrupt is generated
    (For details, see section 28.3.3.2. NRDY interrupt.)
  - If a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
  - If transaction counting ends when the SHTNAK bit is set to 1 for bulk transfers
- BUF setting: The USBFS does not write this setting.
- STALL setting: PID = STALL is set in the following cases, and issuing of tokens is automatically stopped:
  - When STALL is received in response to a transmitted token
  - When a received data packet exceeds the maximum packet size

(4) Hardware response PID settings in device controller mode

- NAK setting: PID = NAK is set in the following cases, and a NAK response is returned to transactions:
  - When the setup token is received normally (DCP only)
  - If transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
- BUF setting: There is no BUF writing by the USBFS.
- STALL setting: PID = STALL is set in the following cases, and a STALL response is returned to transactions:
  - When a received data packet exceeds the maximum packet size
  - When a control transfer sequence error is detected (DCP only)

28.3.4.7 Data PID sequence bit

The USBFS automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON bit in DCPCTR and PIPEnCTR. When data is transmitted, the sequence bit toggles on ACK handshake reception. When data is received, the sequence bit toggles on ACK handshake transmission. The SQCLR bit in DCPCTR and the SQSET bit in PIPEnCTR can be used to change the data PID sequence bit.

In device controller mode when control transfers are used, the USBFS automatically sets the sequence bit for stage transitions. DATA1 is returned when the setup stage ends. The sequence bit is not referenced and PID = DATA1 is returned in the status stage. Therefore, no software settings are required. However, in host controller mode when control transfers are used, the sequence bit must be set by software for the stage transitions.

For ClearFeature requests for transmission or reception, the data PID sequence bit must be set by software in both host and device controller modes.

28.3.4.8 Response PID = NAK function

The USBFS provides a function for disabling pipe operation (PID response = NAK) when the final data packet of a transaction is received. The USBFS automatically distinguishes this based on reception of a short packet or the transaction counter. Enable this function by setting the PIPECFG.SHTNAK bit to 1.

When the double buffer mode is being used for the FIFO buffer, using this function enables reception of data packets in transfer units. If pipe operation is disabled, the software must enable the pipe again (PID response = BUF).

The response PID = NAK function can be used only for bulk transfers.

第(3)和(4)节描述了USBFS由于特定事务结果而写入PID[1:0]位的情况。

(3) 主机控制器模式下的硬件响应PID设置

●NAK设置：PID=NAK在以下情况下设置，令牌自动停止发行：
当执行非同步传输并产生NRDY中断时
（有关详细信息，请参阅第28.3.3.2节。NRDY中断。）
如果在PIPECFG.SHTNAK位设置为1以进行批量传输时接收到短数据包
如果在SHTNAK位设置为1以进行批量传输时事务计数结束

●BUF设置：USBFS不写入此设置。

●STALL设置：PID=STALL在以下情况下设置，并且自动停止发行令牌：
当接收到STALL以响应传输的令牌时
当接收到的数据包超过最大包大小时

(4) 设备控制器模式下的硬件响应PID设置

●NAK设置：PID=NAK在以下情况下设置，并向事务返回NAK响应：
正常接收到设置令牌时（仅DCP）
当PIPECFG.SHTNAK位设置为1以进行批量传输时，如果事务计数结束或收到短数据包

●BUF设置：USBFS不写入BUF。

●STALL设置：PID=STALL在以下情况下设置，并向事务返回STALL响应：
当接收到的数据包超过最大包大小时
当检测到控制传输序列错误时（仅限DCP）

28.3.4.7 数据PID序列位

当数据在控制传输数据阶段、批量传输和中断传输成功传输时，USBFS会自动切换数据PID中的序列位。下一个要发送的数据PID的序列位可以通过DCPCTR和PIPEnCTR中的SQMON位来确认。发送数据时，序列位在ACK握手接收时切换。当接收到数据时，序列位在ACK握手传输上切换。DCPCTR中的SQCLR位和PIPEnCTR中的SQSET位可用于更改数据PID序列位。

在使用控制传输的设备控制器模式下，USBFS自动设置阶段转换的序列位。DATA1在设置阶段结束时返回。不引用序列位，在状态阶段返回PID=DATA1。因此，不需要任何软件设置。但是，在使用控制传输的主机控制器模式下，必须由软件设置序列位以进行阶段转换。

对于发送或接收的ClearFeature请求，数据PID序列位必须由软件在主机和设备控制器模式下设置。

28.3.4.8 响应PID=NAK功能

USBFS提供了在接收到事务的最终数据包时禁用管道操作（PID响应=NAK）的功能。USBFS根据收到的短数据包或事务计数器自动区分这一点。通过将PIPECFG.SHTNAK位设置为1来启用此功能。

当FIFO缓冲区使用双缓冲区模式时，使用此功能可以接收以传输为单位的数据包。如果管道操作被禁用，软件必须再次启用管道（PID响应=BUF）。

响应PID=NAK函数只能用于批量传输。

28.3.4.9 Auto response mode

For bulk transfer pipes (1 to 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (PIPECFG.DIR = 0), OUT-NAK mode is invoked, and during an IN transfer (DIR = 1), null auto response mode is invoked.

28.3.4.10 OUT-NAK mode

For bulk OUT transfer pipes, NAK is returned in response to an OUT token, and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To transition from normal mode to OUT-NAK mode, specify OUT-NAK mode while pipe operation is disabled (PID[1:0] = 00b for NAK response). Next enable pipe operation (PID[1:0] = 01b for BUF response), on which OUT-NAK mode becomes valid. If an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To transition from OUT-NAK mode to normal mode, cancel OUT-NAK mode while pipe operation is disabled (NAK). Next enable pipe operation (BUF). In normal mode, reception of OUT data is enabled.

28.3.4.11 Null auto response mode

For bulk IN transfer pipes, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To transition from normal mode to null auto response mode, specify null auto response mode while pipe operation is disabled (response PID = NAK). Next enable pipe operation (response PID = BUF) on which null auto response mode becomes valid. Before setting null auto response mode, check that PIPEnCTR.INBUFM = 0, because the mode can be set only when the buffer is empty. If the INBUFM bit is 1, empty the buffer using the PIPEnCTR.ACLRM bit. Do not write data from the FIFO port while a transition to null auto response mode is being made.

To transition from null auto response mode to normal mode, keep pipe operation disabled (response PID = NAK) for the period of the zero-length packet transmission (about 10 µs) before canceling the null auto response mode. In normal mode, data can be written from the FIFO port, so packet transmission to the host is enabled by enabling pipe operation (response PID = BUF).

28.3.5 FIFO Buffer

The USBFS provides a FIFO buffer for data transfers, and it manages the memory area used for each pipe. The FIFO buffer has two states depending on whether the access right is assigned to the system (CPU side) or the USBFS (SIE side).

(1) Buffer status

Table 28.20 and Table 28.21 show the buffer status in the USBFS. The FIFO buffer status can be confirmed using the DCPCTR.BSTS and PIPEnCTR.INBUFM bits. The transfer direction for the FIFO buffer can be specified in either the PIPECFG.DIR or CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM bit is valid for pipes 0 to 5 in the transmitting direction.

When a transmitting pipe uses double buffering, the software can read the BSTS bit to monitor the FIFO buffer status on the CPU side and the INBUFM bit to monitor the FIFO buffer status on the SIE side. When write access to the FIFO port by the CPU or DMA/DTC is slow and the buffer empty status cannot be determined using the BEMP interrupt, the software can use the INBUFM bit to confirm the end of transmission.

Table 28.20 Buffer status indicated in the BSTS bit

ISEL or DIR	BSTS	FIFO buffer status
0 (receiving direction)	0	There is no received data, or data is being received. Reading from the FIFO port is disabled.
0 (receiving direction)	1	There is received data, or a zero-length packet is received. Reading from the FIFO port is allowed. When a zero-length packet is received, reading is not possible and the buffer must be cleared.
1 (transmitting direction)	0	Transmission has not completed. Writing to the FIFO port is disabled.
1 (transmitting direction)	1	Transmission is complete. CPU write is allowed.

28.3.4.9 自动响应模式

对于批量传输管道（1到5），当PIPEnCTR.ATREPM位设置为1时，将转换到自动响应模式。在OUT传输期间(PIPECFG.DIR=0)，将调用OUT-NAK模式，在IN传输期间(DIR=1)，将调用空自动响应模式。

28.3.4.10 OUT-NAK mode

对于批量OUT传输管道，NAK响应OUT令牌返回，并且当PIPEnCTR.ATREPM位设置为1。要从正常模式转换到OUT-NAK模式，请在禁用管道操作时指定OUT-NAK模式（对于NAK响应，PID[1:0]=00b）。接下来启用管道操作（PID[1:0]=01b用于BUF响应），此时OUT-NAK模式变为有效。如果在禁用管道操作之前立即收到OUT令牌，则正常接收令牌数据，并向主机返回ACK。

要从OUT-NAK模式转换到正常模式，请在禁用管道操作(NAK)时取消OUT-NAK模式。接下来启用管道操作(BUF)。在正常模式下，可以接收OUT数据。

28.3.4.11 空自动响应模式

对于批量IN传输管道，当PIPEnCTR.ATREPM位设置为1时，将连续传输零长度数据包。

要从正常模式转换为空自动响应模式，请在禁用管道操作时指定空自动响应模式（响应PID=NAK）。接下来启用空自动响应模式有效的管道操作（响应PID=BUF）。在设置空自动响应模式之前，请检查PIPEnCTR.INBUFM=0，因为只有在缓冲区为空时才能设置模式。如果INBUFM位为1，则使用PIPEnCTR.ACLRM位清空缓冲区。在转换到空自动响应模式时，不要从FIFO端口写入数据。

要从空值自动响应模式转换到正常模式，在取消空值自动响应模式之前，在零长度数据包传输期间（约10µs）保持管道操作禁用（响应PID=NAK）。在正常模式下，可以从FIFO端口写入数据，因此通过启用管道操作（响应PID=BUF）来启用到主机的数据包传输。

28.3.5 FIFO Buffer

USBFS为数据传输提供FIFO缓冲区，并管理用于每个管道的内存区域。根据访问权限是分配给系统（CPU端）还是USBFS（SIE端），FIFO缓冲区有两种状态。

(1) 缓冲状态

表28.20和表28.21显示了USBFS中的缓冲区状态。FIFO缓冲区状态可以使用确认DCPCTR.BSTS和PIPEnCTR.INBUFM位。FIFO缓冲区的传输方向可以在任一pipecfg.dir或cfifoselisel位（选择DCP时）。

INBUFM位对传输方向的管道0到5有效。

当传输管道使用双缓冲时，软件可以读取BSTS位来监控CPU侧的FIFO缓冲区状态，以及读取INBUFM位来监控SIE侧的FIFO缓冲区状态。当写访问FIFO端口由CPU或DMADTC较慢且无法使用BEMP中断确定缓冲区空状态，软件可以使用INBUFM位确认传输结束。

Table 28.20 BSTS位中指示的缓冲区状态

ISEL或DIR	BSTS	FIFO缓冲区状态
0 (receiving direction)	0	没有接收到数据，或正在接收数据。 禁止从FIFO端口读取。
0 (receiving direction)	1	有接收数据，或接收到零长度数据包。 允许从FIFO端口读取。 当接收到零长度数据包时，无法读取，必须清除缓冲区。
1 (transmitting direction)	0	传输尚未完成。 禁止写入FIFO端口。
1 (transmitting direction)	1	传输完成。 允许CPU写入。

Table 28.21 Buffer status indicated in the INBUFM bit

DIR	INBUFM	FIFO buffer status
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	Transmission is complete. There is no data waiting to be transmitted.
1 (transmitting direction)	1	The FIFO port has written data to the buffer. There is data to be transmitted.

28.3.6 FIFO Buffer Clearing

Table 28.22 shows the methods for clearing the FIFO buffer. The FIFO buffer can be cleared using BCLR bit in the port control register, DnFIFOSEL.DCLRM, or the PIPEnCTR.ACLRM bit.

Single or double buffering can be selected for pipes 1 to 5 in the PIPECFG.DBLB bit.

Table 28.22 Buffer clearing methods

FIFO buffer clearing mode	Clearing FIFO buffer on the CPU side	Mode for automatically clearing the FIFO buffer after reading the specified pipe data	Auto buffer clear mode for discarding all received packets
Register used	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Bit used	BCLR	DCLRM	ACLRM
Clearing condition	Cleared by writing 1	1: Mode valid 0: Mode invalid	1: Mode valid 0: Mode invalid

(1) Auto buffer clear mode function

The USBFS discards all received data packets if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet is received, the ACK response is returned to the host controller. The auto buffer clear mode function can only be set in the FIFO buffer reading direction.

Setting the ACLRM bit to 1 and then to 0 clears the FIFO buffer of the selected pipe regardless of the access direction. An access cycle of at least 100 ns is required for the internal hardware sequence processing between ACLRM = 1 and ACLRM = 0.

28.3.7 FIFO Port Functions

Table 28.23 shows the settings for the FIFO port functions. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, set the BVAL flag in the port control register to end writing. To send a zero-length packet, use the BCLR bit to clear the buffer, and then set the BVAL flag to end writing.

In reading, reception of new packets is automatically enabled when all data is read. Data cannot be read when a zero-length packet is received (DTLN[8:0] = 0), so the buffer must be cleared with the BCLR bit. The length of the receive data can be confirmed in the DTLN[8:0] bits in the port control register.

Table 28.23 FIFO port function settings (1 of 2)

Register name	Bit name	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	Selects DTLN[11:0] read mode
	REW	FIFO buffer rewind (re-read, rewrite)
	DCLRM	Automatically clears receive data for a specified pipe after the data is read (only for DnFIFO)
	DREQE	Enables DMA/DTC transfers (only for DnFIFO)
	MBW	FIFO port access bit width
	BIGEND	Selects FIFO port endian
	ISEL	FIFO port access direction (only for DCP)
	CURPIPE	Selects the current pipe

Table 28.21 INBUFM位中指示的缓冲区状态

DIR	INBUFM	FIFO缓冲区状态
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	传输完成。 没有等待传输的数据。
1 (transmitting direction)	1	FIFO端口已将数据写入缓冲区。 有数据要传输。

28.3.6 FIFO缓冲区清除

表28.22显示了清除FIFO缓冲区的方法。可以使用端口控制寄存器中的BCLR位、DnFIFOSEL.DCLRM或PIPEnCTR.ACLRM位清除FIFO缓冲区。

可以在PIPECFG.DBLB位中为管道1到5选择单缓冲或双缓冲。

Table 28.22 缓冲区清除方法

FIFO缓冲区清除模式	清除FIFO缓冲区 CPU端	读取指定管道数据后自动清除FIFO缓冲区的模式	自动缓冲区清除模式，用于丢弃所有接收到的数据包
注册使用	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
使用的位	BCLR	DCLRM	ACLRM
清算条件	通过写1清除	1：模式有效0 ：模式无效	1：模式有效0 ：模式无效

(1) 自动缓冲清除模式功能

如果PIPEnCTR.ACLRM位设置为1，USBFS将丢弃所有接收到的数据包。如果接收到正确的数据包，则向主机控制器返回ACK响应。自动缓冲区清除模式功能只能在FIFO缓冲区读取方向设置。

无论访问方向如何，将ACLRM位设置为1，然后设置为0都会清除所选管道的FIFO缓冲区。ACLRM=1和ACLRM=0之间的内部硬件序列处理需要至少100ns的访问周期。

28.3.7 FIFO端口功能

表28.23显示了FIFO端口功能的设置。在写访问中，在达到最大数据包大小之前写入数据会自动启用数据传输。要在达到最大数据包大小之前启用传输，请设置端口控制寄存器中的BVAL标志以结束写入。要发送零长度数据包，请使用BCLR位清除缓冲区，然后设置BVAL标志以结束写入。

在读取中，当所有数据被读取时，自动启用新数据包的接收。接收到零长度数据包时（DTLN[8:0]=0）无法读取数据，因此必须使用BCLR位清除缓冲区。接收数据的长度可以在端口控制寄存器的DTLN[8:0]位中确认。

Table 28.23 FIFO端口功能设置(1of2)

	DCLRM	读取数据后自动清除指定管道的接收数据（仅适用于DnFIFO）
	DREQE	启用DMADTC传输（仅适用于DnFIFO）
	MBW	FIFO端口访问位宽
	BIGEND	选择FIFO端口字节序
	ISEL	FIFO端口访问方向（仅适用于DCP）
	CURPIPE	选择当前管道

Table 28.23 FIFO port function settings (2 of 2)

Register name	Bit name	Description
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	Ends writing to the FIFO buffer
	BCLR	Clears the FIFO buffer on the CPU side
	DTLN	Checks the length of receive data

(1) FIFO port selection

Table 28.24 shows the pipes that can be selected with the different FIFO ports. The pipe to be accessed must be selected in the CURPIPE[3:0] bits in the port select register. After the pipe is selected, the software must check whether the written value can be read correctly from the CURPIPE[3:0] bits. (If the previous pipe number is read, it indicates that the USBFS is modifying the pipe.) Next, the software checks that the FRDY bit in the port control register is 1.

In addition, the software must specify the bus width to be accessed in the MBW bit in the port select register. The FIFO buffer access direction conforms to the PIPECFG.DIR setting. For the DCP only, the ISEL bit in the port select register determines the direction.

Table 28.24 FIFO port access by pipe

Pipe	Access method	Ports that can be used
DCP	CPU access	CFIFO port register
Pipes 1 to 9	CPU access	• CFIFO port register • D0FIFO/D1FIFO port register
	DMA/DTC access	D0FIFO/D1FIFO port register

(2) REW bit

It is possible to temporarily stop access to a pipe currently being accessed, access a different pipe, and then continue processing for the first pipe again. The REW bit in the port select register is used for this processing.

If a pipe is selected in the CURPIPE[3:0] bits in the port select register with the REW bit set to 1, the pointer used for reading from and writing to the FIFO buffer is reset, and reading or writing can be carried out from the first byte. If a pipe is selected with 0 set for the REW bit, data can be read and written in continuation from the previous selection, without the pointer being reset.

To access the FIFO port, the software must check that the FRDY bit in the port control register is 1 after selecting a pipe.

28.3.8 DMA Transfers (D0FIFO and D1FIFO Ports)

(1) Overview of DMA transfers

For pipes 1 to 9, the FIFO port can be accessed using the DMAC. When buffer access for a pipe targeted for DMA transfer is enabled, a DMA transfer request is issued.

Select the unit of transfer to the FIFO port in the DnFIFOSEL.MBW bit, and select the pipe targeted for the DMA transfer in the DnFIFOSEL.CURPIPE[3:0] bits. Do not change the selected pipe during the DMA transfer.

(2) DnFIFO auto clear mode (D0FIFO and D1FIFO port reading direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USBFS automatically clears the FIFO buffer of the selected pipe when reading of data from the FIFO buffer is complete.

Table 28.25 shows the packet reception and FIFO buffer clearing processing by software for each of the settings. As shown in the table, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA transfers without involving software.

The DnFIFO auto clear mode can only be set in the FIFO buffer reading direction.

Table 28.23 FIFO端口功能设置(2of2)

注册名称	位名称	Description
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	结束写入FIFO缓冲区
	BCLR	清除CPU端的FIFO缓冲区
	DTLN	检查接收数据的长度

(1) 先进先出端口选择

表28.24显示了可以使用不同FIFO端口选择的管道。必须在端口选择寄存器的CURPIPE[3:0]位中选择要访问的管道。选择管道后，软件必须检查是否可以从CURPIPE[3:0]位正确读取写入的值。（如果读取了之前的管道号，则表明USBFS正在修改管道。）接下来，软件检查端口控制寄存器中的FRDY位是否为1。

此外，软件必须在端口选择寄存器的MBW位中指定要访问的总线宽度。FIFO缓冲区访问方向符合PIPECFG.DIR设置。仅对于DCP，端口选择寄存器中的ISEL位决定方向。

Table 28.24 通过管道访问FIFO端口

Pipe	访问方法	可以使用的端口
DCP	CPU访问	CFIFO端口寄存器
管道1至9	CPU访问	• CFIFO端口寄存器 • D0FIFOD1FIFO端口寄存器
	DMA/DTC access	D0FIFOD1FIFO端口寄存器

(2) REW位

可以暂时停止对当前正在访问的管道的访问，访问不同的管道，然后再次继续处理第一个管道。端口选择寄存器中的REW位用于此处理。

如果在端口选择寄存器的CURPIPE[3:0]位中选择了一个管道，并且REW位设置为1，则用于读取和写入FIFO缓冲区的指针复位，可以进行读取或写入从第一个字节开始。如果在REW位设置为0的情况下选择管道，则可以从先前的选择继续读取和写入数据，而无需重置指针。

要访问FIFO端口，软件必须在选择管道后检查端口控制寄存器中的FRDY位是否为1。

28.3.8 DMA传输（D0FIFO和D1FIFO端口）

(1) DMA传输概述

对于管道1到9，可以使用DMAC访问FIFO端口。当启用以DMA传输为目标的管道的缓冲区访问时，将发出DMA传输请求。

在DnFIFOSEL.MBW位中选择传输到FIFO端口的单位，并在DnFIFOSEL.CURPIPE[3:0]位中选择DMA传输的目标管道。在DMA传输期间不要更改选定的管道。

(2) DnFIFO自动清除模式（D0FIFO和D1FIFO端口读取方向）

如果DnFIFOSEL.DCLRM位设置为1，USBFS会在从FIFO缓冲区读取数据完成时自动清除所选管道的FIFO缓冲区。

表28.25显示了针对每个设置通过软件进行的数据包接收和FIFO缓冲区清除处理。如表所示，缓冲区清除条件取决于PIPECFG.BFRE位中设置的值。使用DnFIFOSEL.DCLRM位无需在任何需要清除缓冲区的情况下通过软件清除缓冲区。这可以在不涉及软件的情况下实现DMA传输。

DnFIFO自动清除模式只能设置在FIFO缓冲区读取方向。

28.3.9 Control Transfers Using the DCP

The DCP is used for data transfers in the control transfer data stage. The FIFO buffer of the DCP is a 64-byte single buffer with a fixed area for both control reads and control writes. The FIFO buffer can be accessed only through the CFIFO port.

28.3.9.1 Control transfers in host controller mode

(1) Setup stage

The USQREQ, USBVAL, USBINDX, and USBLENG registers are used to transmit USB requests for setup transactions. Writing the setup packet data to the registers and then writing 1 to the DCPCTR.SUREQ bit transmits the specified data for the setup transaction. On completion of the transaction, the SUREQ bit clears to 0. Do not change these USB request registers while SUREQ = 1.

When an attached function device is detected, the software must issue the first setup transaction for the device using this sequence with the DCPMAXP.DEVSEL[3:0] bits cleared to 0 and the DEVADD0.USBSPD[1:0] bits set appropriately.

When an attached function device is shifted to the Address state, the software must issue setup transactions using this sequence with the assigned USB address set in the DEVSEL[3:0] bits and the bits in DEVADDn corresponding to the specified USB address set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in DEVADD2. When PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in DEVADD5.

When the setup transaction data is sent, an interrupt request is generated based on the response from the peripheral device (SIGN or SACK bit in INTSTS1). This interrupt request allows the software to check the setup transaction result.

A DATA0 data packet (USB request) for the setup transaction is always transmitted regardless of the status of the DCPCTR.SQMON bit.

(2) Data stage

The data stage is used to transfer data using the DCP FIFO buffer.

Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit. Specify the transfer direction in the DCPCFG.DIR bit.

For the first data packet of the data stage, the data PID must be transferred as DATA1. Set data PID = DATA1 in the DCPCTR.SQSET bit and set the PID bits = BUF. Completion of data transfer is detected using the BRDY or BEMP interrupt.

For control write transfers, when the number of data bytes to be sent is an integer multiple of the maximum packet size, the software must send a zero-length packet at the end.

(3) Status stage

The status stage is used for zero-length packet data transfers in the reverse direction of the data stage. As in the data stage, data is transfered using the DCP FIFO buffer. Transactions are executed using the same procedure as the data stage.

Data packets in the status stage must be transmitted and received with the data PID set to DATA1 using the DCPCTR.SQSET bit.

When a zero-length packet is received, check the receive-data length in the CFIFOCTR.DTLN[8:0] bits after a BRDY interrupt is generated, and then clear the FIFO buffer using the BCLR bit.

28.3.9 使用DCP进行控制传输

DCP用于控制传输数据阶段的数据传输。DCP的FIFO缓冲区是一个64字节的单缓冲区，具有用于控制读取和控制写入的固定区域。FIFO缓冲区只能通过CFIFO端口访问。

28.3.9.1 主机控制器模式下的控制传输

(1) 设置阶段

USQREQ、USBVAL、USBINDX和USBLENG寄存器用于传输设置事务的USB请求。
将设置数据包数据写入寄存器，然后向DCPCTR.SUREQ位写入1，以传输设置事务的指定数据。事务完成后，SUREQ位清除为0。在SUREQ=1时不要更改这些USB请求寄存器。

当检测到连接的功能器件时，软件必须使用此序列为器件发出第一个设置事务，其中DCPMAXP.DEVSEL[3:0]位清零，DEVADD0.USBSPD[1:0]位适当设置。

当连接的功能器件转移到地址状态时，软件必须使用此序列发出设置事务，其中指定的USB地址设置在DEVSEL[3:0]位中，并且DEVADDn中的位对应于指定的USB地址设置适当。例如，当PIPEMAXP.DEVSEL[3:0]=0010b时，在DEVADD2中进行适当的设置。当PIPEMAXP.DEVSEL[3:0]=0101b时，在DEVADD5中进行适当的设置。

发送设置事务数据时，根据外围设备的响应（INTSTS1中的SIGN或SACK位）生成中断请求。该中断请求允许软件检查设置事务结果。

一个DATA0数据包（USB请求）用于设置事务总是被传输，无论状态如何
DCPCTR.SQMON bit.

(2) 数据阶段

数据级用于使用DCPFIFO缓冲区传输数据。

在访问DCPFIFO缓冲区之前，请在CFIFOSEL.ISEL位中指定访问方向。在DCPCFG.DIR位中指定传输方向。

对于数据阶段的第一个数据包，数据PID必须作为DATA1传输。在DCPCTR.SQSET位中设置数据PID=DATA1，并设置PID位=BUF。使用BRDY或BEMP中断检测数据传输的完成。

对于控制写传输，当要发送的数据字节数是最大数据包大小的整数倍时，软件必须在最后发送一个长度为零的数据包。

(3) 状态阶段

状态阶段用于在数据阶段的相反方向上进行零长度分组数据传输。与数据阶段一样，使用DCPFIFO缓冲区传输数据。事务使用与数据阶段相同的过程执行。

状态阶段的数据包必须在数据PID设置为DATA1的情况下使用
DCPCTR.SQSET bit.

当接收到零长度数据包时，在产生BRDY中断后检查CFIFOCTR.DTLN[8:0]位中的接收数据长度，然后使用BCLR位清除FIFO缓冲区。

28.3.9.2 Control transfers in device controller mode

(1) Setup stage

The USBFS sends an ACK response to a normal setup packet for the USBFS. The USBFS operates in the setup stage as follows:

On receiving a new setup packet, the USBFS sets the following bits:

- Sets the INTSTS0.VALID bit to 1
- Sets the DCPCTR.PID[1:0] bits to NAK
- Sets the DCPCTR.CCPL bit to 0

When the USBFS receives a data packet following a setup packet, it stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Before performing the response processing for a control transfer, set the VALID flag to 0. When the VALID bit = 1, PID = BUF cannot be set, and the data stage cannot be terminated.

Using the VALID bit function, the USBFS can suspend a request being processed when it receives a new USB request during a control transfer and return a response to the latest request.

In addition, the USBFS automatically detects the direction bit (bmRequestType bit [8]) and the request data length (wLength) in the received USB request. It distinguishes between control read transfers, control write transfers, and no-data control transfers, and it controls stage transitions. For an incorrect sequence, a sequence error occurs in the control transfer stage transition interrupt, and the interrupt is reported to the software. For a diagram of the stage control by the USBFS, see Figure 28.16.

(2) Data stage

The DCP must be used to execute data transfers for received USB requests. Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit.

If the transfer data is larger than the size of the DCP FIFO buffer, execute the data transfer using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

(3) Status stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to BUF.

After this setting is made, the USBFS automatically executes the status stage based on the data transfer direction determined at the setup stage. The procedure is as follows:

- For control read transfers

  The USBFS receives a zero-length packet from the USB host and transmits an ACK response.
- For control write transfers and no-data control transfers

  The USBFS transmits a zero-length packet and receives an ACK response from the USB host.

(4) Control transfer auto response function

The USBFS automatically responds to a correct SET_ADDRESS request. If any of the following errors occurs in the SET_ADDRESS request, a response from the software is necessary.

- bmRequestType is not 00h: Any transfer other than a control write transfer
- wIndex is not 00h: Request error
- wLength is not 00h: Any transfer other than a no-data control transfer
- wValue is larger than 7Fh: Request error
- INTSTS0.DVSQ[2:0] are 011b (Configured state): Control transfer of a device state error

For all requests other than the SET_ADDRESS request, a response is required from the corresponding software.

28.3.9.2 设备控制器模式下的控制传输

(1) 设置阶段

USBFS向USBFS的正常设置数据包发送ACK响应。USBFS在设置阶段运行如下：

在接收到新的设置数据包时，USBFS设置以下位：

- ●将INTSTS0.VALID位设置为1
- ●将DCPCTR.PID[1:0]位设置为NAK
- ●将DCPCTR.CCPL位设置为0

当USBFS在setup数据包之后接收到数据包时，它会将USB请求参数存储在USBREQ中，
USBVAL, USBINDX, and USBLENG.

在执行控制传输的响应处理之前，将VALID标志设置为0。当VALID位=1时，PID=
BUF不能设置，数据阶段不能终止。

使用VALID位功能，USBFS可以在控制传输期间接收到新的USB请求时暂停正在处理的请求，并返回对最新请求的响应。

此外，USBFS会自动检测接收到的USB请求中的方向位（bmRequestTypebit[8]）和请求数据长度（wLength）。它区分控制读取传输、控制写入传输和无数据控制传输，并控制阶段转换。对于不正确的序列，在控制转移阶段转换中断中发生序列错误，并将中断报告给软件。USBFS的阶段控制图见图28.16。

(2) 数据阶段

DCP必须用于执行接收到的USB请求的数据传输。在访问DCPFIFO缓冲区之前，请在CFIFOSEL.ISEL位中指定访问方向。

如果传输数据大于DCPFIFO缓冲区的大小，则使用控制写传输的BRDY中断和控制读传输的BEMP中断执行数据传输。

(3) 状态阶段

通过将DCPCTR.CCPL位设置为1而将DCPCTR.PID[1:0]位设置为BUF来终止控制传输。

完成此设置后，USBFS根据设置阶段确定的数据传输方向自动执行状态阶段。程序如下：

- ●用于控制读取传输

  USBFS从USB主机接收零长度数据包并发送ACK响应。
- ●用于控制写传输和无数据控制传输

  USBFS发送一个长度为零的数据包并接收来自USB主机的ACK响应。

(4) 控制转移自动响应功能

USBFS自动响应正确的SET_ADDRESS请求。如果出现以下任何错误
SET_ADDRESS请求，需要软件的响应。

- ●bmRequestType不是00h：控制写入传输以外的任何传输
- ●wIndexisnot00h：请求错误
- ●wLength不是00h：除无数据控制传输之外的任何传输
- ●wValue大于7Fh：请求错误
- ●INTSTS0.DVSQ[2:0]为011b（已配置状态）：设备状态错误的控制传输

对于除SET_ADDRESS请求之外的所有请求，都需要相应软件的响应。

28.3.10 Bulk Transfers (Pipes 1 to 5)

The FIFO buffer usage (single/double buffer setting) is configurable for bulk transfers. The USBFS provides the following functions for bulk transfers:

- BRDY interrupt function (PIPECFG.BFRE bit), see section 28.3.3.1. BRDY interrupt
- Transaction count function (PIPEnTRE.TRENB, TRCLR, and PIPEnTRN.TRNCNT[15:0] bits), see section 28.3.4.5. Transaction counter for pipes 1 to 5 in the receiving direction
- Response PID = NAK function (PIPECFG.SHTNAK bit), see section 28.3.4.8. Response PID = NAK function
- Auto response mode (PIPEnCTR.ATREPM bit), see section 28.3.4.9. Auto response mode

28.3.11 Interrupt Transfers (Pipes 6 to 9)

In device controller mode, the USBFS performs interrupt transfers based on the timing dictated by the host controller.

In host controller mode, the software can set the timing for issuing tokens using the interval counter.

28.3.11.1 Interval counter for interrupt transfers in host controller mode

Specify the transaction interval for interrupt transfers in the PIPEPERI.IITV[2:0] bits. The USBFS issues interrupt transfer tokens based on this interval.

(1) Counter initialization

The USBFS initializes the interval counter under the following conditions:

- Power-on reset

  This initializes the IITV[2:0] bits.
- FIFO buffer initialization using the PIPEnCTR.ACLRM bit:

  This does not initialize the IITV[2:0] bits, but does initialize the count value. Setting the PIPEnCTR.ACLRM bit to 0 starts counting from the value set in IITV[2:0].

The interval counter is not initialized in the following case:

- USB bus reset or USB suspended

  The IITV[2:0] bits are not initialized. Setting 1 to the DVSTCTR0.UACT bit starts counting from the value saved before entering the USB bus reset state or USB suspend state.

(2) Operation when tokens cannot be transmitted or received even on token generation

No token is generated in the following cases even at token generation time. In these cases, the USBFS tries to execute the transaction in the next interval.

- When the PID is set to NAK or STALL
- When the FIFO buffer is full at token transmit time in the receiving (IN) direction
- When there is no data to be transmitted in the FIFO buffer at token transmit time in the transmitting (OUT) direction

28.3.12 Isochronous Transfers (Pipes 1 and 2)

The USBFS provides the following functions for isochronous transfers:

- Notification of isochronous transfer error
- Interval counter specified in the PIPEPERI.IITV[2:0] bits
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function specified in the PIPEPERI.IFIS bit

28.3.10 批量传输（管道1到5）

FIFO缓冲区使用（单双缓冲区设置）可配置为批量传输。USBFS为批量传输提供以下功能：

●BRDY中断功能（PIPECFG.BFRE位），见28.3.3.1节。BRDY中断

●事务计数函数（PIPEnTRE.TRENB、TRCLR和PIPEnTRN.TRNCNT[15:0]位），参见第28.3.4.5节。接收方向上管道1到5的事务计数器

●响应PID=NAK功能（PIPECFG.SHTNAK位），参见第28.3.4.8节。响应PID=NAK功能

●自动响应模式（PIPEnCTR.ATREPM位），参见第28.3.4.9节。自动响应模式

28.3.11 中断传输（管道6到9）

在设备控制器模式下，USBFS根据主机控制器规定的时序执行中断传输。

在主机控制器模式下，软件可以使用间隔计数器设置发布令牌的时间。

28.3.11.1 主机控制器模式下中断传输的间隔计数器

在PIPEPERI.IITV[2:0]位中指定中断传输的事务间隔。USBFS基于此间隔发出中断传输令牌。

(1) 计数器初始化

USBFS在以下条件下初始化间隔计数器：

- Power-on reset

  这将初始化IITV[2:0]位。

●使用PIPEnCTR.ACLRM位初始化FIFO缓冲区：

这不会初始化IITV[2:0]位，但会初始化计数值。将PIPEnCTR.ACLRM位设置为0从IITV[2:0]中设置的值开始计数。

在以下情况下不初始化间隔计数器：

●USB总线复位或USB挂起

IITV[2:0]位未初始化。将DVSTCTR0.UACT位置1从进入USB总线复位状态或USB挂起状态之前保存的值开始计数。

(2) 即使在生成令牌时也无法发送或接收令牌时的操作

在以下情况下，即使在生成令牌时也不会生成令牌。在这些情况下，USBFS会尝试在下一个时间间隔执行事务。

●当PID设置为NAK或STALL时

●接收(IN)方向的令牌发送时FIFO缓冲区已满时

●在发送（OUT）方向的令牌发送时间，FIFO缓冲区中没有要发送的数据时

28.3.12 同步传输（管道1和2）

USBFS为同步传输提供以下功能：

●同步传输错误通知

●PIPEPERI.IITV[2:0]位中指定的间隔计数器

●同步IN传输数据设置控制（IDLY功能）

●PIPEPERI.IFIS位中指定的同步IN传输缓冲区刷新功能

28.3.12.1 Error detection in isochronous transfers

The USBFS provides a function for detecting the errors described in this section, so that when errors occur in isochronous transfers, they can be controlled by software. Table 28.26 and Table 28.27 show the priority order for errors detected by the USBFS and the associated interrupts.

PID errors

- The PID value of the received packet is invalid.

CRC errors and bit stuffing errors

- A CRC error is found in a received packet or the bit stuffing is illegal.

Maximum packet size exceeded

- The data size of the received packet exceeds the specified maximum packet size.

Overrun and underrun errors

In host controller mode:

- The FIFO buffer is full at token transmit time in the IN (receiving) direction
- There is no data to be sent in the FIFO buffer at token transmit time in the OUT (transmitting) direction

In device controller mode:

- There is no data to be sent in the FIFO buffer at token receive time in the IN (transmitting) direction
- The FIFO buffer is full at token receive time in the OUT (receiving) direction

Interval errors

In device controller mode, the following cases are treated as an interval error:

- Failure to receive an IN token in the interval frame during an isochronous IN transfer
- Failure to receive an OUT token in the interval frame during an isochronous OUT transfer

Table 28.26 Error detection for token transmission and reception

Detection priority	Error	Generated interrupt and status
1	PID error	No interrupts are generated in either host or device controller mode (ignored as a corrupted packet)
2	CRC or bit stuffing error	No interrupts are generated in either host or device controller mode (ignored as a corrupted packet)
3	Overrun or underrun error	An NRDY interrupt is generated to set the FRMNUM.OVRN bit to 1 in both host and device controller modes. In device controller mode, a zero-length packet is transmitted in response to an IN token. No data packets are received in response to OUT token.
4	Interval error	An NRDY interrupt is generated in device controller mode. No interrupt is generated in host controller mode.

Table 28.27 Error detection for data packet reception

Detection priority	Error	Generated interrupt and status
1	PID error	No interrupts are generated (ignored as a corrupted packet)
2	CRC or bit stuffing error	An NRDY interrupt is generated and the FRMNUM.CRCE bit sets to 1 in both host and device controller modes
3	Maximum packet size exceeded error	A BEMP interrupt is generated and the PID[1:0] bits set to STALL in both host and device controller modes

28.3.12.1 同步传输中的错误检测

USBFS提供了检测本节所述的错误的功能，以便在同步传输中发生错误时，可以通过软件进行控制。表28.26和表28.27显示了USBFS检测到的错误和相关中断的优先级顺序。

PID错误

●接收报文的PID值无效。

CRC错误和位填充错误

●收到的报文发现CRC错误或比特填充不合法。

超出最大数据包大小

●接收到的数据包的数据大小超过了指定的最大数据包大小。

溢出和欠载错误

在主机控制器模式下：

●在IN（接收）方向发送令牌时，FIFO缓冲区已满

●在OUT（发送）方向的令牌发送时间，FIFO缓冲区中没有要发送的数据

在设备控制器模式下：

●在IN（发送）方向的令牌接收时间，FIFO缓冲区中没有要发送的数据

●在OUT（接收）方向的令牌接收时间，FIFO缓冲区已满

间隔错误

在设备控制器模式下，以下情况被视为间隔错误：

●等时IN传输期间在间隔帧中接收IN令牌失败

●在等时OUT传输期间未能在间隔帧中接收到OUT令牌

Table 28.26 令牌发送和接收的错误检测

检测优先级	Error	产生的中断和状态
1	PID错误	在主机或设备控制器模式下都不会产生中断（被忽略为损坏的数据包）
2	CRC或位填充错误	在主机或设备控制器模式下都不会产生中断（被忽略为损坏的数据包）
3	溢出或欠载错误	在主机和设备控制器模式下，都会产生一个NRDY中断来将FRMNUM.OVRN位设置为1。在设备控制器模式下，发送一个零长度数据包以响应IN令牌。 没有接收到响应OUT令牌的数据包。
4	间隔误差	在设备控制器模式下会产生一个NRDY中断。在主机控制器模式下不产生中断。

Table 28.27 数据包接收错误检测

检测优先级	Error	产生的中断和状态
1	PID错误	不产生中断（作为损坏的数据包被忽略）
2	CRC或位填充错误	在主机和设备控制器模式下都会产生一个NRDY中断并且FRMNUM.CRCE位设置为1
3	超出最大数据包大小错误	在主机和设备控制器模式下都会产生BEMP中断并且PID[1:0]位设置为STALL

28.3.12.2 DATA-PID

In device controller mode, the USBFS responds to a received PID as follows:

(1) IN direction

- DATA0: Transmitted as data packet PID
- DATA1: Not transmitted
- DATA2: Not transmitted
- mDATA: Not transmitted

(2) OUT direction

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets ignored
- mDATA: Packets ignored

28.3.12.3 Interval counter

The isochronous transfer interval can be set in the PIPEPERI.IITV[2:0] bits. In device controller mode, the interval counter enables the functions as shown in Table 28.28. In host controller mode, the USBFS generates the token issuance timing, and the interval counter operation is the same as that for interrupt transfers.

Table 28.28 Interval counter functions in device controller mode

Transfer direction	Function	Conditions for detection
IN	Transmit buffer flush	Failure to receive an IN token successfully in the interval frame during an isochronous IN transfer.
OUT	Notification of no reception of token	Failure to receive an OUT token successfully in the interval frame during an isochronous OUT transfer.

The interval count is performed when an SOF is received or for interpolated SOFs, so the isochronism can be maintained even if an SOF is corrupt. The frame interval can be set to 2^{IITV} frames.

(1) Counter initialization in device controller mode

The USBFS initializes the interval counter under the following conditions:

- Power-on reset

  This initializes the PIPEPERI.IITV[2:0] bits.
- FIFO buffer initialization using the ACLRM bit

  This does not initialize the IITV[2:0] bits, but does initialize the count value.

After the interval counter is initialized, the interval count starts under one of the following conditions when a packet is transferred successfully:

- An SOF is received after data is transmitted in response to an IN token when PID = BUF
- An SOF is received after data is received in response to an OUT token when PID = BUF

The interval counter is not initialized in the following conditions:

- When the PID[1:0] bits are set to NAK or STALL

  This does not stop the interval timer. The USBFS attempts the transaction in the next interval.
- When the USB bus is reset or USBFS is suspended

  This does not initialize the IITV[2:0] bits. When an SOF is received, the interval counter starts counting from the value set before SOF was received.

28.3.12.2 DATA-PID

在设备控制器模式下，USBFS响应接收到的PID如下：

(1) 在方向

●DATA0：作为数据包PID发送
●DATA1：未发送
●DATA2：未传输
●mDATA：不传输

(2) 出方向

●DATA0：作为数据包PID正常接收
●DATA1：作为数据包PID正常接收
●DATA2：忽略的数据包
●mDATA：忽略的数据包

28.3.12.3 间隔计数器

同步传输间隔可以在PIPEPERI.IITV[2:0]位中设置。在设备控制器模式下，间隔计数器启用如表28.28所示的功能。在主机控制器模式下，USBFS产生令牌发布时序，间隔计数器操作与中断传输相同。

Table 28.28 设备控制器模式下的间隔计数器功能

转移方向	Function	检测条件
IN	发送缓冲区刷新	在同步IN传输期间未能在间隔帧中成功接收IN令牌。
OUT	未收到令牌的通知	在同步OUT传输期间未能在间隔帧中成功接收OUT令牌。

间隔计数在接收到SOF时执行或对插值SOF执行，因此即使SOF损坏也可以保持等时性。帧间隔可以设置为2个IITV帧。

(1) 设备控制器模式下的计数器初始化

USBFS在以下条件下初始化间隔计数器：

- Power-on reset

  这将初始化PIPEPERI.IITV[2:0]位。
●使用ACLRM位初始化FIFO缓冲区

  这不会初始化IITV[2:0]位，但会初始化计数值。

间隔计数器初始化后，当数据包传输成功时，间隔计数在以下条件之一开始：

●当PID=BUF时，响应IN令牌传输数据后收到SOF
●当PID=BUF时，接收到响应OUT令牌的数据后接收到SOF

间隔计数器在以下情况下不会初始化：

●当PID[1:0]位设置为NAK或STALL时

  这不会停止间隔计时器。USBFS在下一个间隔尝试事务。
●USB总线复位或USBFS挂起时

  这不会初始化IITV[2:0]位。当接收到SOF时，间隔计数器从接收到SOF之前设置的值开始计数。

(2) Interval counting and transfer control in host controller mode

The USBFS controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bits settings. Specifically, the USBFS issues a token for a selected pipe once every 2^{IITV} frames.

The USBFS starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits are set to BUF by software.

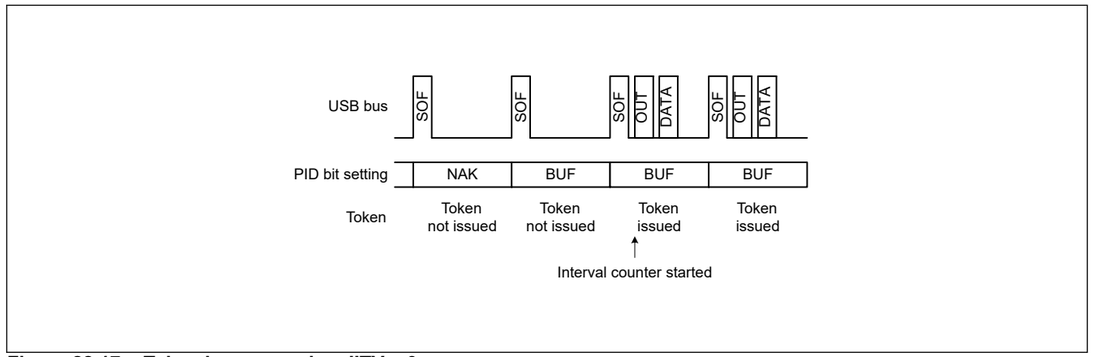

Figure 28.17 Token issuance when IITV = 0

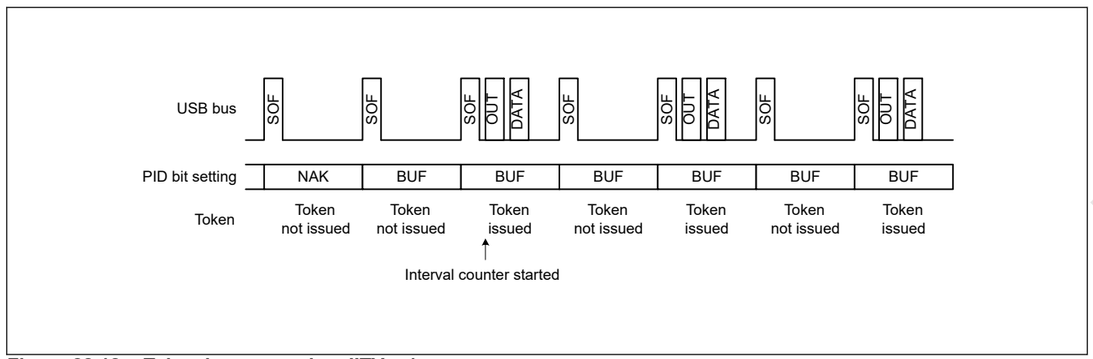

Figure 28.18 Token issuance when IITV = 1

When the selected pipe is set for isochronous transfers, the USBFS performs the following operation in addition to controlling the token issuance interval. The USBFS issues a token even when the NRDY interrupt generation condition is satisfied.

When the selected pipe is for isochronous IN transfers

The USBFS generates an NRDY interrupt when the USBFS issues an IN token but does not successfully receive a packet from a peripheral device (no response or packet error).

The USBFS sets the FRMNUM.OVRN bit to 1, generating an NRDY interrupt, when the time to issue an IN token occurs while the USBFS cannot receive data because the FIFO buffer is full, because the CPU or DMAC/DTC is too slow in reading data from the FIFO buffer.

When the selected pipe is for isochronous OUT transfers

The USBFS sets the OVRN bit to 1, generating an NRDY interrupt and transmitting a zero-length packet, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer, or because the CPU or DMAC/DTC is too slow in writing data to the FIFO buffer.

The token issuance interval is reset on any of the following conditions:

- When the USBFS is reset through a reset pin

  This initializes the IITV[2:0] bits.

(2) 主机控制器模式下的间隔计数和传输控制

USBFS根据PIPEPERI.IITV[2:0]位设置控制令牌发布操作之间的间隔。
具体来说，USBFS每2个IITV帧为所选管道发布一次令牌。

USBFS在PID[1:0]位设置为的帧之后的帧开始计算令牌发布间隔
BUF通过软件。

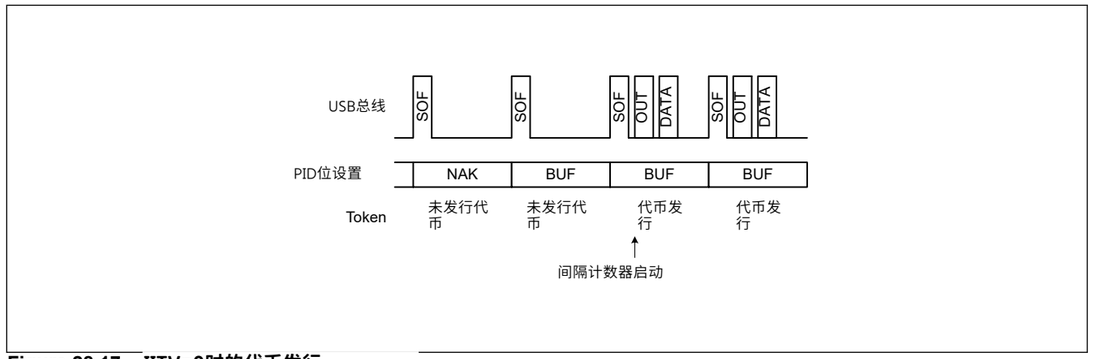

Figure 28.17 IITV=0时的代币发行

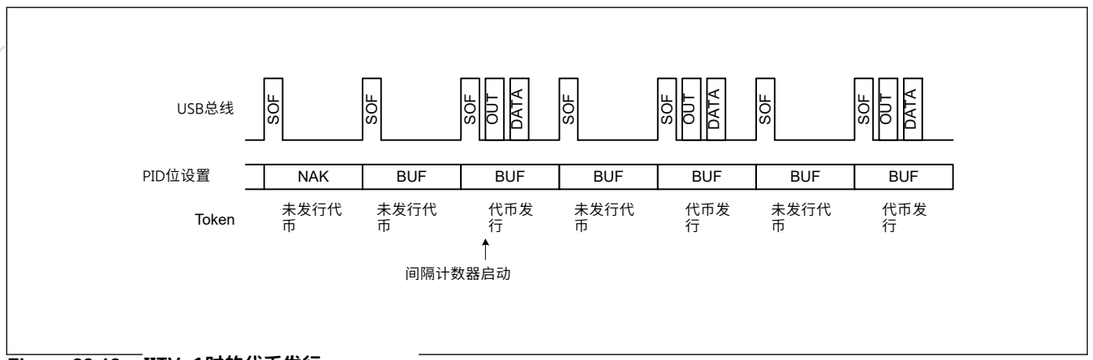

Figure 28.18 IITV=1时的代币发行

当所选管道设置为同步传输时，USBFS除了控制令牌发布间隔外，还执行以下操作。即使满足NRDY中断生成条件，USBFS也会发出令牌。

当所选管道用于同步IN传输时

当USBFS发出IN令牌但未成功接收到来自外围设备的数据包（无响应或数据包错误）时，USBFS会生成NRDY中断。

USBFS将FRMNUM.OVRN位设置为1，产生一个NRDY中断，此时发生发出IN令牌的时间，而USBFS无法接收数据，因为FIFO缓冲区已满，因为CPU或DMACDTC读取数据太慢从FIFO缓冲区。

当所选管道用于同步OUT传输时

USBFS将OVRN位设置为1，产生一个NRDY中断并发送一个长度为零的数据包，当发出OUT令牌的时间到来而FIFO缓冲区中没有要发送的数据时，或者因为CPU或DMACDTC将数据写入FIFO缓冲区太慢。

令牌发行间隔在以下任何条件下重置：

●USBFS通过复位引脚复位时

这将初始化IITV[2:0]位。

- When the PIPEnCTR.ACLRM bit is set to 1 by software

(3) Interval counting and transfer control in device controller mode

When the selected pipe is for isochronous OUT transfers

The USBFS generates an NRDY interrupt when it fails to receive a data packet within the interval set in the PIPEPERI.IITV[2:0] bits.

The USBFS also generates an NRDY interrupt when it fails to receive data because of a CRC error or other errors contained in the data packet or because the FIFO buffer is full.

The NRDY interrupt is generated on SOF packet reception. Even if the SOF packet is corrupted, internal interpolation allows the interrupt to be generated when the SOF packet is received. However, when the IITV bits are set to a value other than 0, the USBFS generates an NRDY interrupt on receiving an SOF packet for every interval after interval counting starts.

When the PID[1:0] bits are set to NAK by software after starting the interval timer, the USBFS does not generate an NRDY interrupt on receiving an SOF packet.

The timing for starting interval counting depend on the IITV[2:0] setting as follows:

- When the IITV[2:0] bits = 0:

  Interval counting starts at the next frame after the software changes the PID[1:0] bits of the selected pipe to BUF.

- When the IITV[2:0] bits ≠ 0:

  Interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe are changed to BUF.

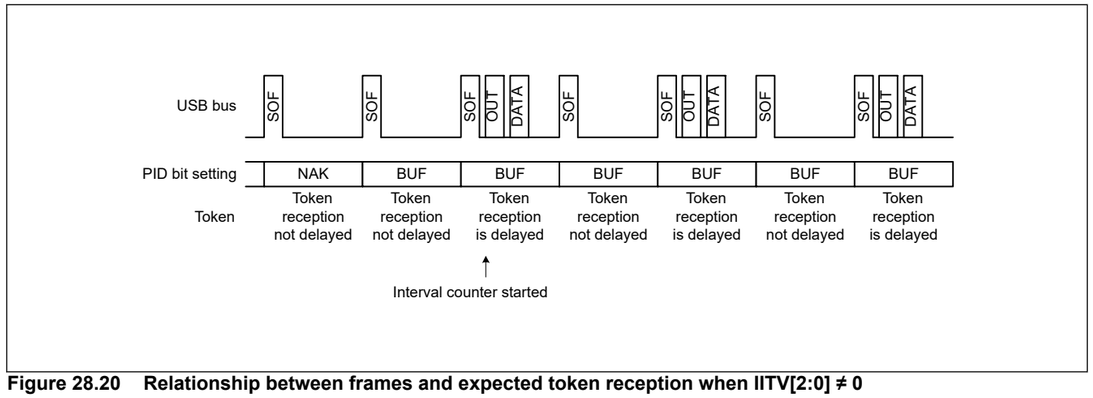

Figure 28.20 Relationship between frames and expected token reception when IITV[2:0] ≠ 0

●PIPEnCTR.ACLRM位由软件设置为1时

(3) 设备控制器模式下的间隔计数和传输控制

当所选管道用于同步OUT传输时

当USBFS在设置的时间间隔内没有接收到数据包时，会产生一个NRDY中断。
PIPEPERI.IITV[2:0] bits.

当由于数据包中包含的CRC错误或其他错误或FIFO缓冲区已满而无法接收数据时，USBFS也会产生NRDY中断。

NRDY中断在SOF数据包接收时产生。即使SOF数据包损坏，内部插值也允许在接收到SOF数据包时产生中断。但是，当IITV位设置为0以外的值时，USBFS会在间隔计数开始后的每个间隔接收到SOF数据包时产生NRDY中断。

当PID[1:0]位在启动间隔定时器后被软件设置为NAK时，USBFS在接收到SOF数据包时不会产生NRDY中断。

开始间隔计数的时间取决于IITV[2:0]设置，如下所示：

●当IITV[2:0]位=0时：

软件将所选管道的PID[1:0]位更改为BUF后，间隔计数从下一帧开始。

●当IITV[2:0]位≠0时：

在所选管道的PID[1:0]位更改为BUF后，成功接收第一个数据包后，间隔计数开始。

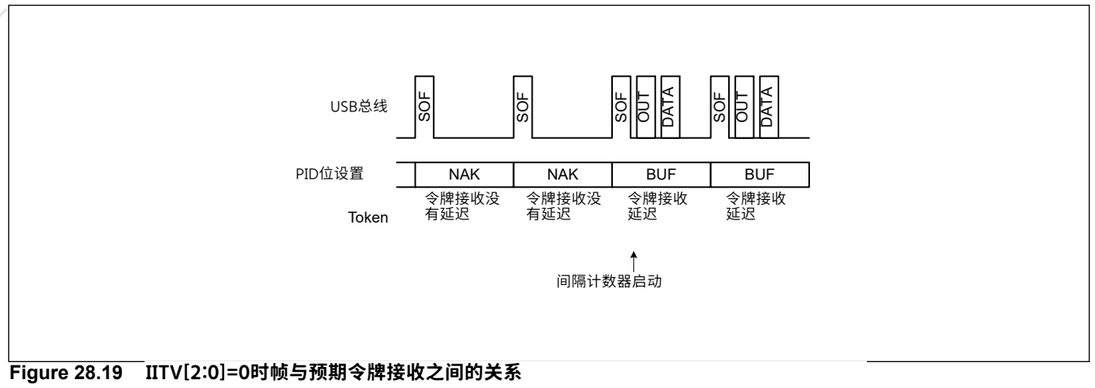

Figure 28.19 IITV[2:0]=0时帧与预期令牌接收之间的关系

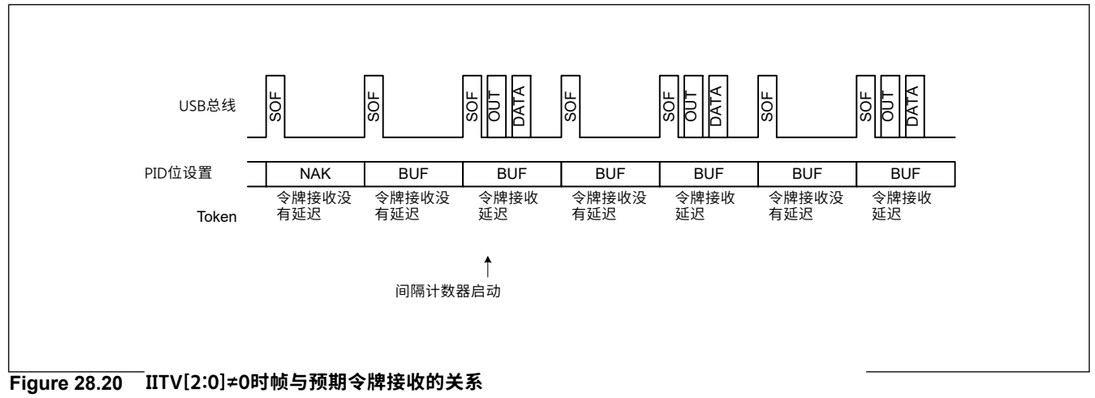

Figure 28.20 IITV[2:0]≠0时帧与预期令牌接收的关系

When the selected pipe is for isochronous IN transfers

The PIPEPERI.IFIS bit must be 1 for this use case. When IFIS = 0, the USBFS transmits a data packet in response to a received IN token regardless of the PIPEPERI.IITV[2:0] setting.

When IFIS is 1 and there is data to be transmitted in the FIFO buffer, the USBFS clears the FIFO buffer when it fails to receive an IN token in the frame at the interval set in the IITV[2:0] bits.

The USBFS also clears the FIFO buffer when it fails to receive an IN token successfully because of a bus error, such as a CRC error, contained in the IN token.

The FIFO buffer is cleared on SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the FIFO buffer to be cleared when the SOF packet is received.

The timing to start interval counting depends on the IITV[2:0] setting, as with OUT transfers.

The interval is counted on any of the following conditions in device controller mode:

- When a hardware reset is applied to the USBFS (which also sets the IITV[2:0] bits to 000b)
- When the PIPEnCTR.ACLRM bit is set to 1 by software
- When the USBFS detects a USB bus reset

(4) Transmit data setup for isochronous transfers in device controller mode

With isochronous data transmission using the USBFS in device controller mode, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the SOF packet is detected. This isochronous transfer transmit data setup function can identify the frame that started transmission.

When the double buffering is used, transmission is only enabled for the buffer where data writing was completed first, even after the data write to both buffers is complete. Accordingly, even if multiple IN tokens are received, only the one packet of FIFO buffer data is transmitted.

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transferred and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

Figure 28.21 shows an example transmission using the isochronous transfer transmission data setup function when IITV = 0 (every frame) is set.

当所选管道用于同步IN传输时

对于此用例，PIPEPERI.IFIS位必须为1。当IFIS=0时，无论PIPEPERI.IITV[2:0]设置如何，USBFS都会发送一个数据包以响应接收到的IN令牌。

当IFIS为1且FIFO缓冲区中有数据要发送时，如果USBFS在IITV[2:0]位设置的时间间隔内未能接收到帧中的IN令牌，则清除FIFO缓冲区。

当USBFS由于总线错误（例如
CRC错误，包含在IN令牌中。

FIFO缓冲区在SOF数据包接收时被清除。即使SOF数据包损坏，内部插值也允许在接收到SOF数据包时清除FIFO缓冲区。

开始间隔计数的时间取决于IITV[2:0]设置，与OUT传输一样。

在设备控制器模式下，根据以下任何条件计算间隔：

- 当对USBFS应用硬件复位时（也将IITV[2:0]位设置为000b）
- PIPEnCTR.ACLRM位由软件设置为1时
- 当USBFS检测到USB总线复位时

(4) 设备控制器模式下同步传输的传输数据设置

在设备控制器模式下使用USBFS进行同步数据传输，数据写入FIFO缓冲区后，可在检测到SOF包后的第一帧发送数据包。此同步传输传输数据设置功能可以识别开始传输的帧。

使用双缓冲时，仅对先完成数据写入的缓冲区启用传输，即使在两个缓冲区的数据写入完成后也是如此。因此，即使接收到多个IN令牌，也仅发送一包FIFO缓冲器数据。

当接收到IN令牌时，当FIFO缓冲区准备好传输数据时，将传输数据并返回正常响应。但是，如果FIFO缓冲区无法传输数据，则会传输零长度数据包并发生欠载错误。

图28.21显示了在设置IITV=0（每帧）时使用同步传输传输数据设置功能的示例传输。

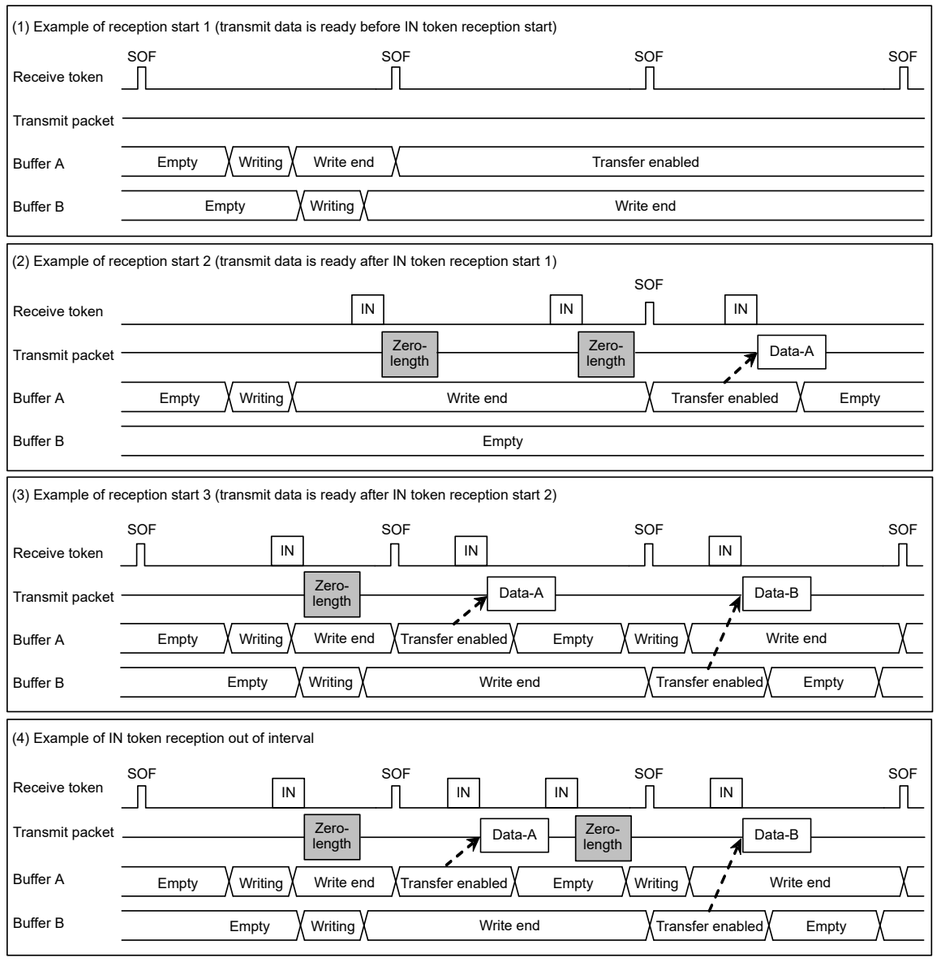

Figure 28.21 Example data setup operation

(5) Transmit buffer flush for isochronous transfers in device controller mode

In device controller mode during isochronous data transmission, if the USBFS receives an SOF packet for the next frame without receiving an IN token in the interval frame, it operates as if the IN token is corrupt and clears the buffer that is enabled for transmission, putting that buffer in the writing enabled state.

When double buffering is used and writing to both buffers is complete, the cleared FIFO buffer is assumed to be the one where the data was transmitted in the interval frame, and transmission is enabled for the FIFO buffer that was not cleared on SOF packet reception.

The timing of the buffer flush function depends on the PIPEPERI.IITV[2:0] setting as follows:

- When IITV = 0:

  The buffer flush operation starts from the first frame after the pipe is enabled.
- When IITV ≠ 0:

  The buffer flush operation starts after the first normal transaction.

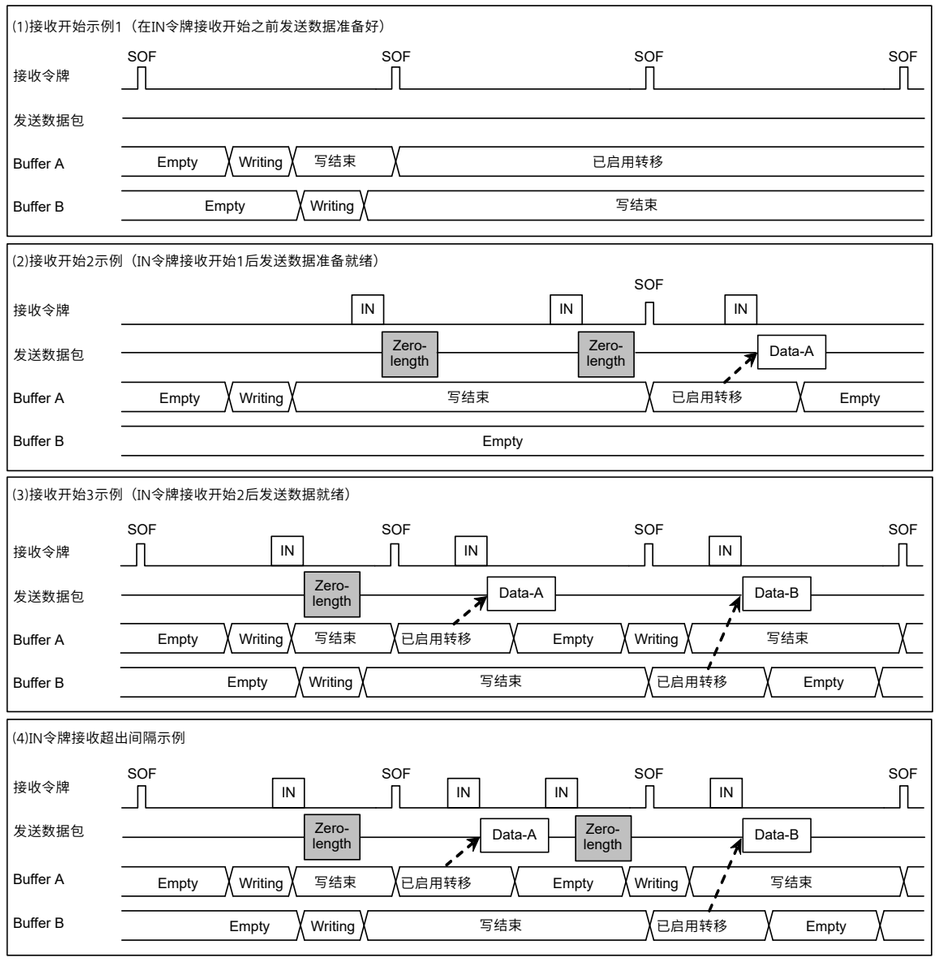

Figure 28.21 示例数据设置操作

(5) 设备控制器模式下同步传输的传输缓冲区刷新

在同步数据传输期间的设备控制器模式下，如果USBFS接收到下一帧的SOF数据包，而在间隔帧中没有接收到IN令牌，则它会像IN令牌损坏一样操作并清除启用传输的缓冲区，将该缓冲区处于写入启用状态。

当使用双缓冲并完成对两个缓冲区的写入时，已清除的FIFO缓冲区被假定为在间隔帧中传输数据的缓冲区，并为接收SOF数据包时未清除的FIFO缓冲区启用传输。

缓冲区刷新功能的时间取决于PIPEPERI.IITV[2:0]设置，如下所示：

- When IITV = 0:

  缓冲区刷新操作从启用管道后的第一帧开始。
- When IITV ≠ 0:

  缓冲区刷新操作在第一个正常事务之后开始。

Figure 28.22 shows an example buffer flush. When an unanticipated token is received before the interval frame, the USBFS sends the write data or a zero-length packet as an underrun error, depending on the data setup status.

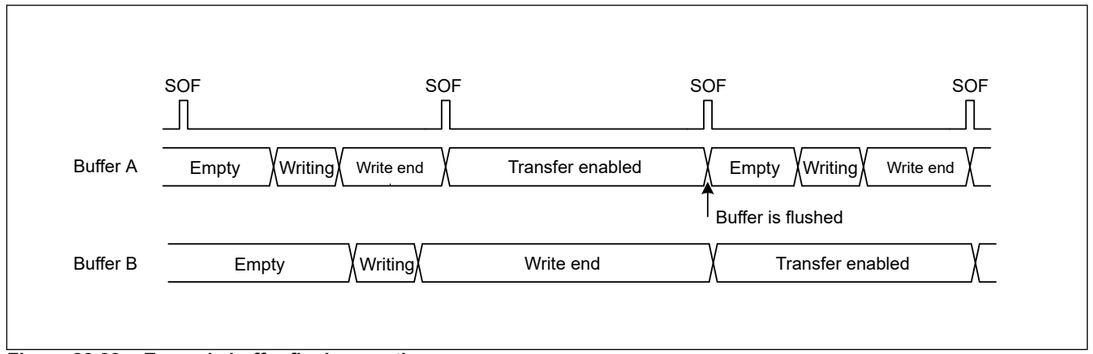

Figure 28.22 Example buffer flush operation

Figure 28.23 shows an example interval error occurrence. There are five types of interval errors, as shown in the figure. An interval error occurs at timing (A), and the buffer flush function is activated.

If an interval error occurs during an IN transfer, the buffer flush function is activated. If it occurs during an OUT transfer, an NRDY interrupt is generated. Use the FRMNUM.OVRN bit to distinguish between this and NRDY interrupts triggered by received packet errors and overrun errors.

For tokens that are shaded in the figure, responses are returned based on the FIFO buffer status.

- IN direction:
  - If the buffer is ready to transfer data, the data is transferred and a normal response is returned
  - If the buffer is not ready to transfer data, a zero-length packet is transmitted and an underrun error occurs
- OUT direction:
  - If the buffer is ready to receive data, the data is received and a normal response is returned
  - If the buffer is not ready to receive data, the received data is discarded and an overrun error occurs

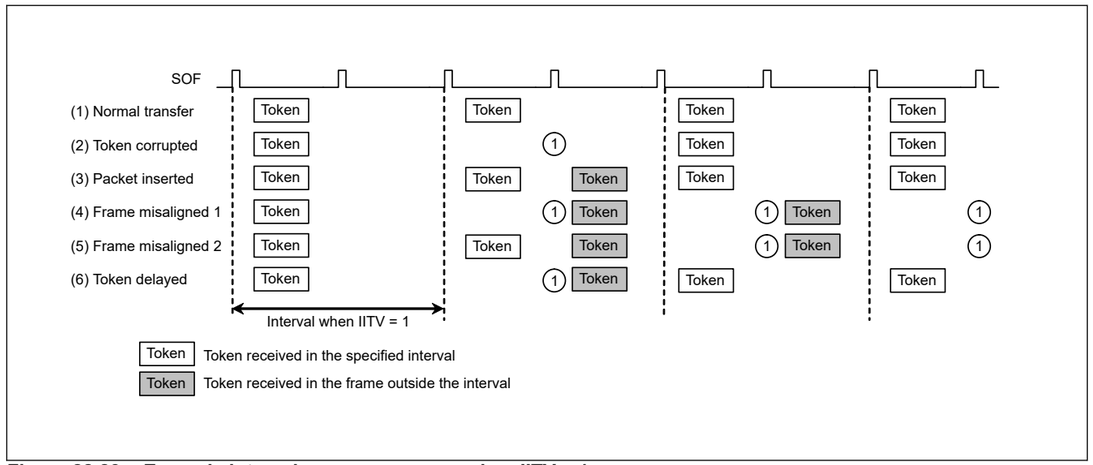

Figure 28.23 Example interval error occurrence when IITV = 1

28.3.13 SOF Interpolation Function

In device controller mode, if packet reception is disabled at intervals of 1 ms because the SOF packet is corrupted or missing, the USBFS interpolates the SOF. SOF interpolation begins when the USBE and SCKE bits in SYSCFG are set to 1 and an SOF packet is received.

图28.22显示了一个示例缓冲区刷新。当在间隔帧之前接收到意外令牌时，USBFS将根据数据设置状态发送写数据或零长度数据包作为欠载错误。

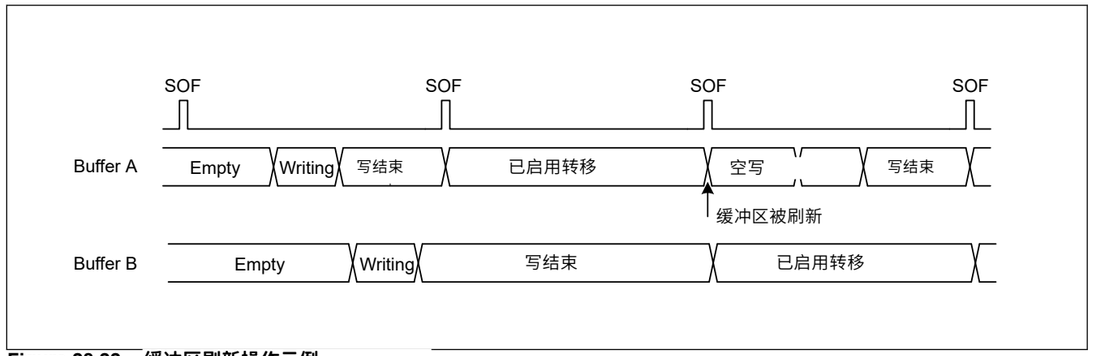

Figure 28.22 缓冲区刷新操作示例

图28.23显示了一个发生间隔错误的示例。如图所示，有五种区间误差。在时间（A）发生间隔错误，缓冲刷新功能被激活。

如果在IN传输期间发生间隔错误，则会激活缓冲区刷新功能。如果它发生在OUT传输期间，则NRDY中断产生。使用FRMNUM.OVRN位来区分此中断和由接收数据包错误和溢出错误触发的NRDY中断。

对于图中带阴影的令牌，根据FIFO缓冲区状态返回响应。

- IN direction:
  如果缓冲区准备好传输数据，则传输数据并返回正常响应
  如果缓冲区未准备好传输数据，则传输零长度数据包并发生欠载错误
- OUT direction:
  如果缓冲区准备好接收数据，则接收数据并返回正常响应
  如果缓冲区没有准备好接收数据，则丢弃接收到的数据并发生溢出错误

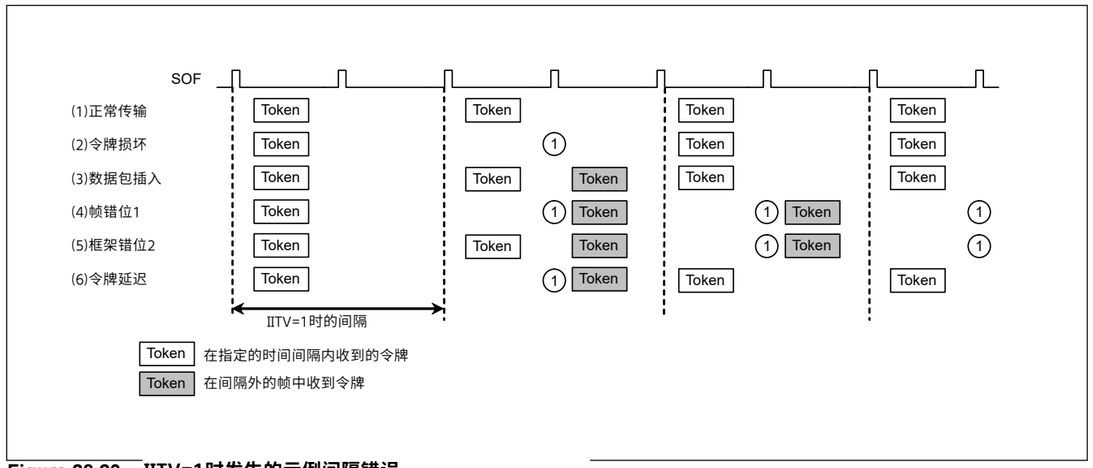

Figure 28.23 IITV=1时发生的示例间隔错误

28.3.13 SOF插值函数

在设备控制器模式下，如果由于SOF数据包损坏或丢失而每隔1ms禁用数据包接收，则USBFS会内插SOF。当SYSCFG中的USBE和SCKE位设置为1并且接收到SOF数据包时，SOF内插开始。

The interpolation function is initialized under the following conditions:

- MCU reset
- USB bus reset
- Suspend state detection

The SOF interpolation operates as follows:

- The interpolation function is not activated until an SOF packet is received
- When the first SOF packet is received, interpolation is performed by counting 1 ms on the 48-MHz internal clock
- When the second and subsequent SOF packets are received, interpolation is performed at the previous reception interval
- Interpolation is not performed in the Suspend state or on reception of a USB bus reset

The USBFS supports the following functions controlled by SOF packet reception. These functions operate normally with SOF interpolation if the SOF packet is missing:

- Updating of the frame number
- SOFR interrupt timing
- Isochronous transfer interval count

If an SOF packet is missing during full-speed operation, the FRMNUM.FRNM[10:0] bits are not updated.

28.3.14 Pipe Schedule

28.3.14.1 Conditions for generating transactions

In host controller mode and when the DVSTCTR0.UACT bit is set to 1, the USBFS generates transactions under the conditions shown in Table 28.29.

Table 28.29 Conditions for generating transactions

Transaction	Conditions for generation				
	DIR	PID	IITV0	Buffer state	SUREQ
Setup	—*1	—*1	—*1	—*1	1 setting
Control transfer data stage, status stage, bulk transfer	IN	BUF	Invalid	Receive area exists	—*1
	OUT	BUF	Invalid	Transmit data exists	—*1
Interrupt transfer	IN	BUF	Valid	Receive area exists	—*1
	OUT	BUF	Valid	Transmit data exists	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

Note 1. An em dash (—) in the table indicates that the condition is unrelated to the generating of tokens. “Valid” indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter. “Invalid” indicates that a transaction is generated regardless of the interval counter.
Note 2. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.
Note 3. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

28.3.14.2 Transfer schedule

This section describes the transfer scheduling within a frame of the USBFS. After the USBFS sends an SOF, the transfer is carried out in the following sequence:

1. Execution of periodic transfers:

插值函数在以下条件下初始化：

- MCU reset
- ●USB总线复位
- ●暂停状态检测

SOF插值操作如下：

- ●直到收到SOF数据包才激活插值功能
- ●当接收到第一个SOF数据包时，通过在48-MHz内部时钟上计数1ms执行插值
- ●当接收到第二个和后续的SOF数据包时，按照之前的接收间隔进行插值
- ●在挂起状态或接收到USB总线复位时不执行插值

USBFS支持以下由SOF数据包接收控制的功能。这些功能正常运行
如果SOF数据包丢失，则SOF插值：

- ●更新帧号
- ●SOFR中断时序
- ●同步传输间隔计数

如果在全速运行期间丢失SOF数据包，则不会更新FRMNUM.FRNM[10:0]位。

28.3.14 管道计划

28.3.14.1 产生交易的条件

在主机控制器模式下，当DVSTCTR0.UACT位设置为1时，USBFS在表28.29所示的条件下生成事务。

Table 28.29 产生交易的条件

Transaction	生成条件				
	DIR	PID	IITV0	缓冲状态	SUREQ
Setup	—*1	—*1	—*1	—*1	1 setting
控制传输数据阶段、状态阶段、批量传输	IN	BUF	Invalid	接收区存在	—*1
	OUT	BUF	Invalid	传输数据存在	—*1
中断传输	IN	BUF	Valid	接收区存在	—*1
	OUT	BUF	Valid	传输数据存在	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

注1.表中的破折号(—)表示该条件与令牌的生成无关。“有效”表示，对于中断传输和同步传输，事务仅在基于间隔计数器的传输帧中生成。“无效”表示无论间隔计数器如何都生成事务。

注2.这表示无论是否有接收区域，都会生成一个事务。但是，如果没有接收区域，则丢弃接收到的数据。

注3.这表示无论是否有任何数据要传输，都会产生交易。然而，如果没有要传输的数据，则传输零长度数据包。

28.3.14.2 转移时间表

本节介绍USBFS帧内的传输调度。USBFS发送SOF后，按以下顺序进行传输：

1.定期转账的执行：

A pipe is searched for in the order of pipe 1 → pipe 2 → pipe 6 → pipe 7 → pipe 8 → pipe 9, and then if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.

2. Setup transactions for control transfers:

   The DCP is checked, and if a setup transaction is possible, it is sent.

3. Execution of bulk transfers, control transfer data stages, and control transfer status stages:

   A pipe is searched for in the order of DCP → pipe 1 → pipe 2 → pipe 3 → pipe 4 → pipe 5, and then if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.

   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

28.3.14.3 Enabling USB communication

Setting the DVSTCTR0.UACT bit to 1 initiates an SOF transmission, and transaction generation is enabled. Setting the UACT bit to 0 stops SOF transmission and the Suspend state is invoked. If the UACT setting is changed from 1 to 0, processing stops after the next SOF is sent.

28.3.15 Battery Charging Detection Processing

The USBFS provides control over the data contact detection processing (D+ line contact checking), primary detection processing (charger detection processing), and secondary detection processing (charger determination processing) as defined in the Battery Charging Specification.

28.3.15.1 Processing in device controller mode

To operate a function device as a battery charging portable device:

1. Start primary detection processing after detecting contact with the D+ and D- lines. The Battery Charging Specification describes two processing methods for Data Contact Detection. The USBFS supports both methods as follows:

   - Software processing

     After a VBINT interrupt or polling of the VBSTS flag indicates a change in the state of the USBFS_VBUS input pin, software controls a wait from 300 to 900 ms. The BCCTRL1.VDPSRCE and CHGDETE bits are then both set to 1 to start primary detection processing.

   - Hardware Processing

     Apply 7 to 13 µA of current to the D+ line to hold the D+ line at the logical high level. This is done to detect the D+ and D- lines going to the logical low level because of pull-down resistors on the host device side when the D+ and D- lines come in contact with those of the host. Monitor the SYSSTS0.LNST[1:0] flags while the PHYSECTRL.CNEN bit, BCCTRL1.RPDME and IDPSRCE bit are set to 1 to see when the level on the D+ line changes from high to low. After detecting a low level on the D+ line, clear the PHYSECTRL.CNEN bit, BCCTRL1.RPDME and IDPSRCE bit to 0 and set both the BCCTRL1.VDPSRCE and CHGDETE bits to 1 to start primary detection processing. The VDPSRCE and CHGDETE bits must be set to 1 simultaneously.

2. After the start of primary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL1.CHGDETSTS flag. A value of 1 indicates detection of a charger, and secondary detection processing starts.*1

3. To start secondary detection processing, clear the BCCTRL1.VDPSRCE bit to 0, then clear the BCCTRL1.CHGDETE bits to 0 after a software-controlled wait of 20 ms. Next, set both the BCCTRL1.VDMSRCE and PDDETE bits to 1.

4. After the start of secondary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL1.PDDETSTS flag, and determine the result of the secondary detection processing.

Note 1. In primary detection processing, detection of a voltage above the range from 0.25 to 0.4 V and below the range from 0.8 to 2.0 V on the D-Line indicates that the other device is a host device that supports battery charging (charging downstream port). The BCCTRL1.CHGDETSTS flag in the PHY block only indicates whether the voltage on the D- line is higher than the range from 0.25 to 0.4 V, so add processing as required to read the SYSSTS0.LNST[1:0] flags and confirm that the voltage on the D- line is also below the range from 0.8 to 2.0 V.

Figure 28.24 shows the process flow.

按照管道1→管道2→管道6→管道7→管道8→管道9的顺序查找管道，如果有管道可以生成等时或中断传输事务，则生成事务.

2.为控制转移设置交易：

DCP被检查，如果设置事务是可能的，它被发送。

3、批量传输、控制传输数据阶段、控制传输状态阶段的执行：

按照DCP→管道1→管道2→管道3→管道4→管道5的顺序搜索管道，然后如果有管道需要进行批量传输、控制传输数据阶段或可以生成控制转移状态阶段，生成事务。

生成事务时，无论来自外围设备的响应是ACK还是NAK，处理都会转移到下一个管道事务。如果帧内有时间进行传输，则重复步骤3。

28.3.14.3 启用USB通信

将DVSTCR0.UACT位设置为1启动SOF传输，并启用事务生成。设置
UACT位为0停止SOF传输并调用暂停状态。如果UACT设置从1更改为0，则在发送下一个SOF后处理停止。

28.3.15 电池充电检测处理

USBFS提供对电池充电规范中定义的数据接触检测处理（D+线路接触检查）、一次检测处理（充电器检测处理）和二次检测处理（充电器确定处理）的控制。

28.3.15.1 设备控制器模式下的处理

将功能设备作为电池充电便携式设备操作：

1.检测到与D+和Dlines的接触后开始初级检测处理。电池充电规范描述了数据接触检测的两种处理方法。USBFS支持以下两种方法：

●软件处理

在VBINT中断或VBSTS标志的轮询指示USBFS_VBUS输入引脚的状态发生变化后，软件控制从300到900ms的等待。然后将BCCTRL1.VDPSRCE和CHGDETE位都设置为1以启动主要检测处理。

●硬件处理

向D+线施加7到13µA的电流，以将D+线保持在逻辑高电平。这样做是为了检测D+和Dlines进入逻辑低电平，因为当D+和Dlines与主机的那些接触时，由于主机设备侧的下拉电阻器。在PHYSECTRL.CNEN位、BCCTRL1.RPDME和IDPSRCE位设置为1时监控SYSSTS0.LNST[1:0]标志，以查看D+线上的电平何时从高变为低。检测到D+线上的低电平后，将PHYSECTRL.CNEN位、BCCTRL1.RPDME和IDPSRCE位清除为0，并将BCCTRL1.VDPSRCE和CHGDETE位都设置为1，以启动初级检测处理。VDPSRCE和CHGDETE位必须同时设置为1。

2.主要检测处理开始后，软件控制等待40毫秒后，检查
BCCTRL1.CHGDETSTS标志。值为1表示检测到充电器，并开始二次检测处理。*1

3.要启动二次检测处理，将BCCTRL1.VDPSRCE位清零，然后在软件控制的20ms等待后将BCCTRL1.CHGDETE位清零。接下来，将BCCTRL1.VDMSRCE和PDDETE位都设置为1。

4.二次检测处理开始后，软件控制等待40ms，检查BCCTRL1.PDDETSTS标志，确定二次检测处理的结果。

注1.在初级检测处理中，在D-Line上检测到高于0.25至0.4V范围且低于0.8至2.0V范围的电压表示其他设备是支持电池充电的主机设备（充电下游港口）。PHY模块中的BCCTRL1.CHGDETSTS标志位仅指示Dline上的电压是否高于0.25到0.4V的范围，因此根据需要添加处理以读取SYSSTS0.LNST[1:0]标志位并确认电压Dline上的电压也低于0.8至2.0V的范围。

图28.24显示了处理流程。

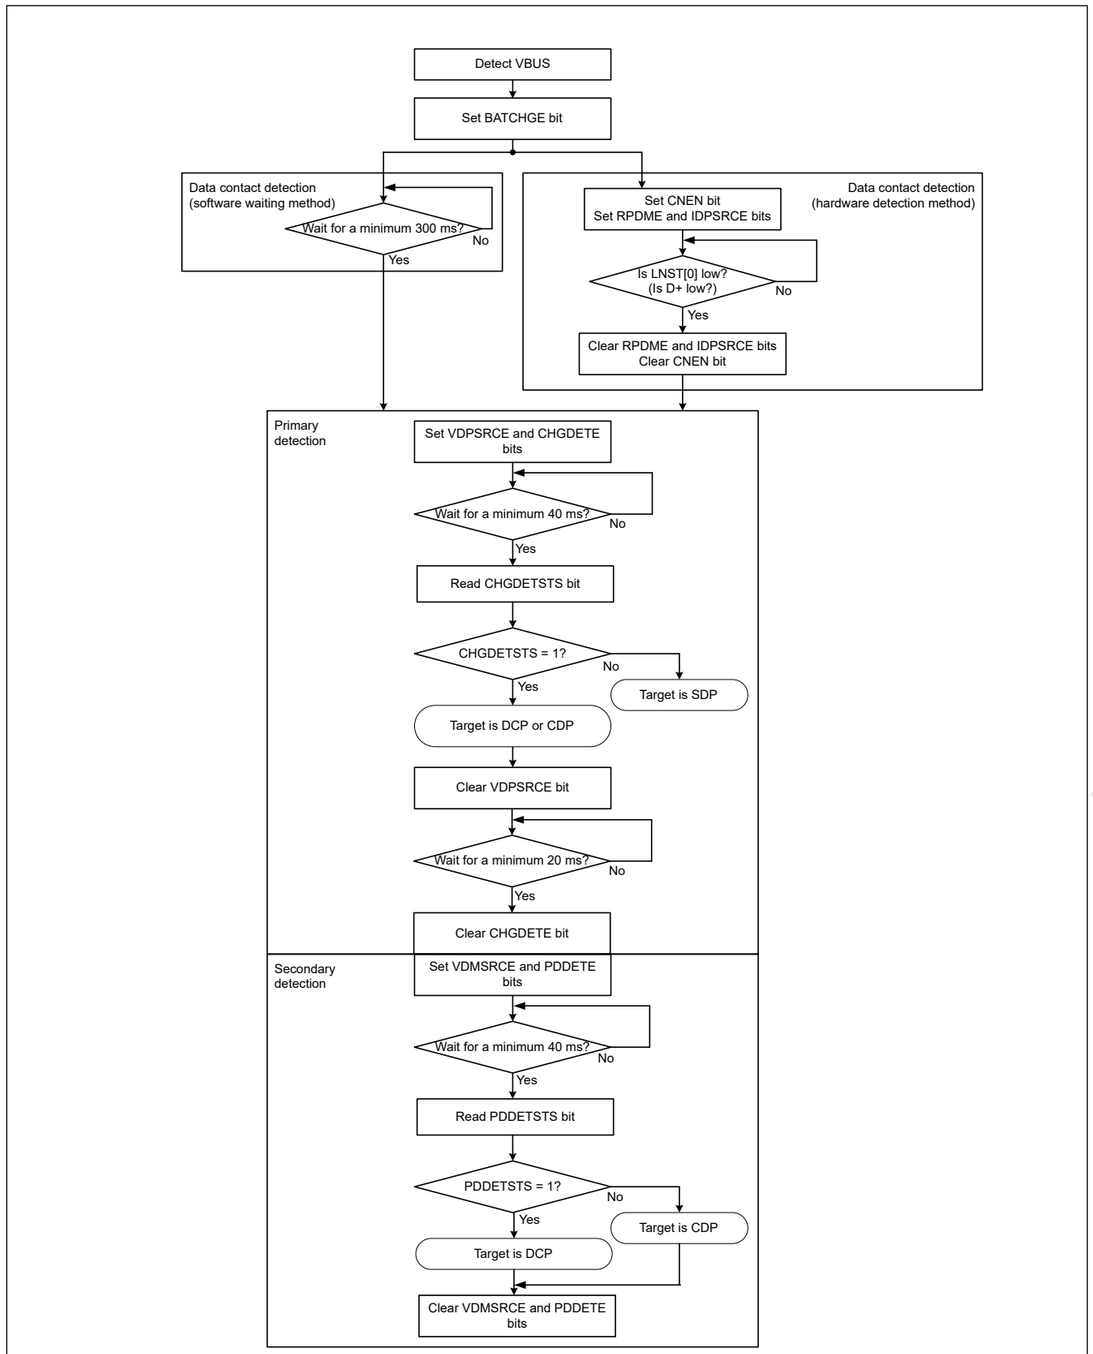

Figure 28.24 Processing flow as portable device

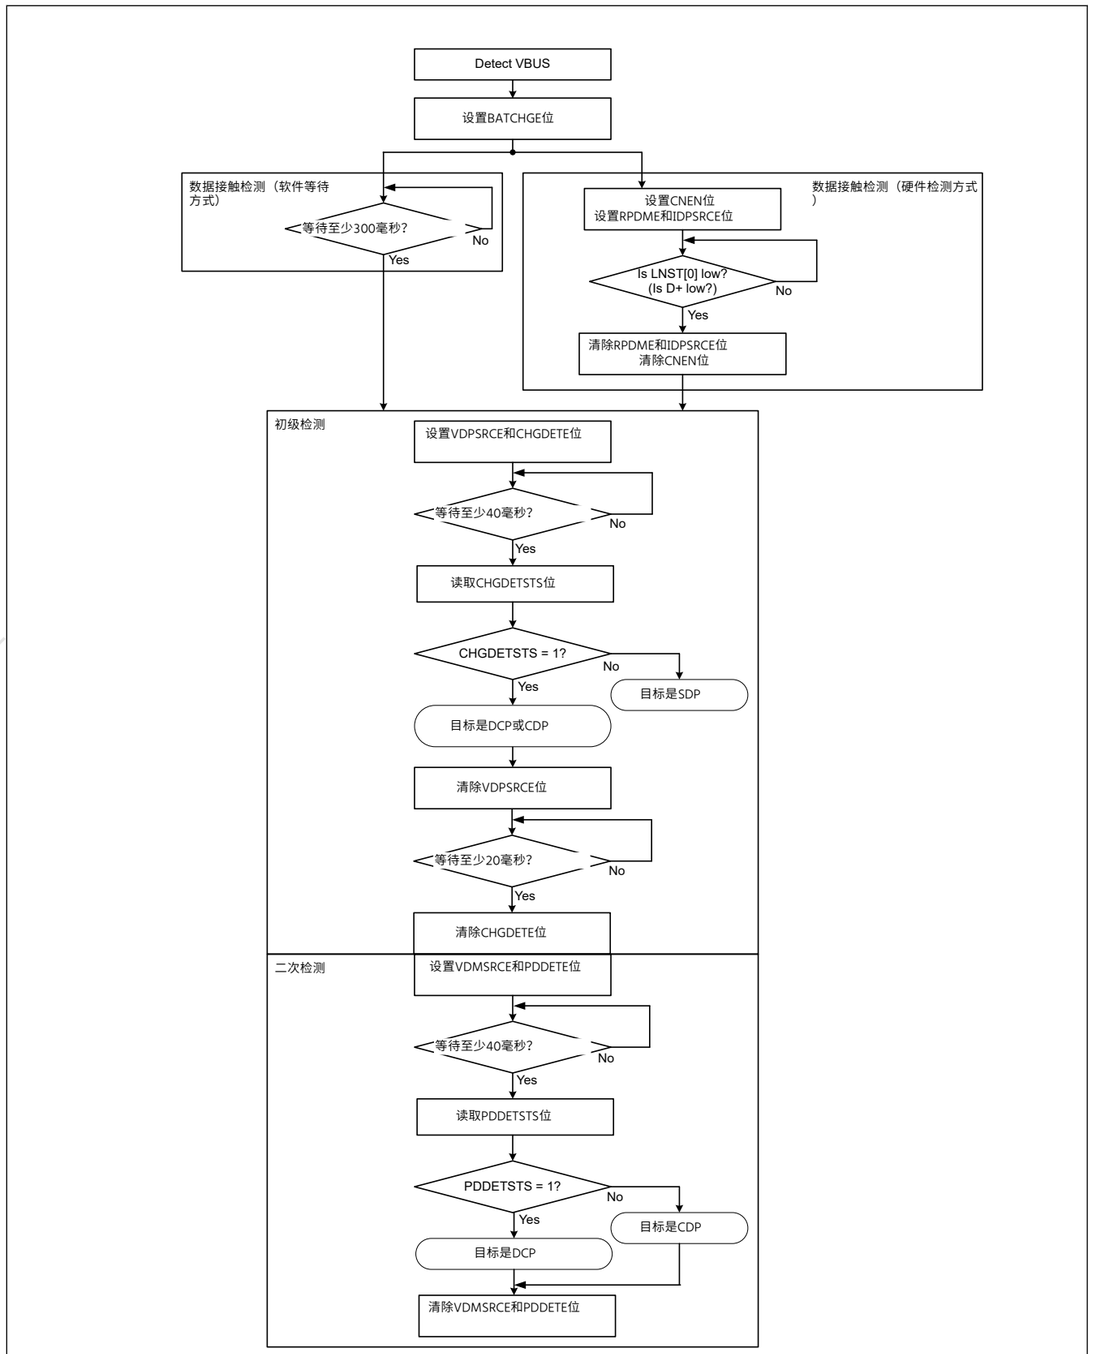

Figure 28.24 作为便携式设备的处理流程

28.3.15.2 Processing in host controller mode

In host controller mode, driving the D- line is required for a portable device to perform primary detection. The USBFS supports the following two primary detection methods:

When using the Portable Device detection function

The D- line is driven when a Portable Device is detected.

1. Start driving the VBUS.
2. Set the BCCTRL1.PDDETE bit to 1 to enable the portable device detection circuit.
3. Monitor the portable device detection signal and start driving the D- line when the level of the portable device detection signal is high.*1
4. Stop driving the D- line when the portable device detection signal is at the low level.*1

Note 1. The PDDETINT interrupt indicates a change in the level of the portable device detection signal, and the current level can be obtained by reading the PDDETSTS flag.

When not using the Portable Device detection function

Regardless of whether or not a Portable Device was detected, drive the D- line after device disconnection is detected, and leave the D- line open after connection is detected. Software handles the timing of a and b.

a. After disconnection is detected, start driving the D- line within 200 ms.

b. After connection is detected, stop driving the D- line within 10 ms.

Figure 28.25 shows the process flow for steps 1. to 4. and Figure 28.26 shows the process flow for steps a. and b., respectively.

28.3.15.2 主机控制器模式下的处理

在主机控制器模式下，便携式设备需要驱动Dline才能执行初级检测。USBFS支持以下两种主要检测方法：

使用便携式设备检测功能时

当检测到便携式设备时驱动Dline。

1.开始驱动VBUS。

2.将BCCTRL1.PDDETE位设置为1以启用便携式设备检测电路。

3.监测便携设备检测信号，当便携设备检测信号为高电平时开始驱动Dline。*1

4、当便携设备检测信号为低电平时，停止驱动Dline。*1

注1.PDDETINT中断表示便携式设备检测信号电平的变化，当前电平可通过读取PDDETSTS标志获得。

不使用便携设备检测功能时

无论是否检测到便携式设备，在检测到设备断开后驱动Dline，在检测到连接后保持Dline处于打开状态。软件处理a和b的时序。

a. 检测到断线后，在200ms内开始驱动Dline。

湾。检测到连接后，请在10ms内停止驱动Dline。

图28.25显示了步骤1.至4.的处理流程，图28.26显示了步骤a的处理流程。和b.，分别。

28.4 Usage Notes

28.4.1 Settings for the Module-Stop State

USBFS operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The USBFS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

28.4.2 Clearing the Interrupt Status Register on Exiting Software Standby Mode

Because the input buffer is always enabled in Software Standby mode, an unexpected interrupt might occur under the following conditions:

- When the interrupt is enabled in Normal mode
- When the interrupt is disabled in Software Standby mode
- When the input level of the pin that cancels software standby is changed in Software Standby mode

These conditions might cause the associated interrupt flag in the Interrupt Status Register to set unexpectedly. After the MCU exits the Software Standby mode, the unexpected interrupt might be sent to the interrupt controller. To avoid this, always clear the INTSTS0 and INTSTS1 registers in the canceling sequence.

28.4.3 Clearing the Interrupt Status Register after Setting Up the Port Function

The input buffer is disabled before the PmnPFS.PSEL and PmnPFS.PMR port is set up, so the internal signal is fixed high or low. The input buffer is enabled after the port is set so that the external pin state is propagated to the MCU. An unexpected interrupt might occur at this time, causing the VBINT and OVRCR bits in INTSTS0 and INTSTS1, or other

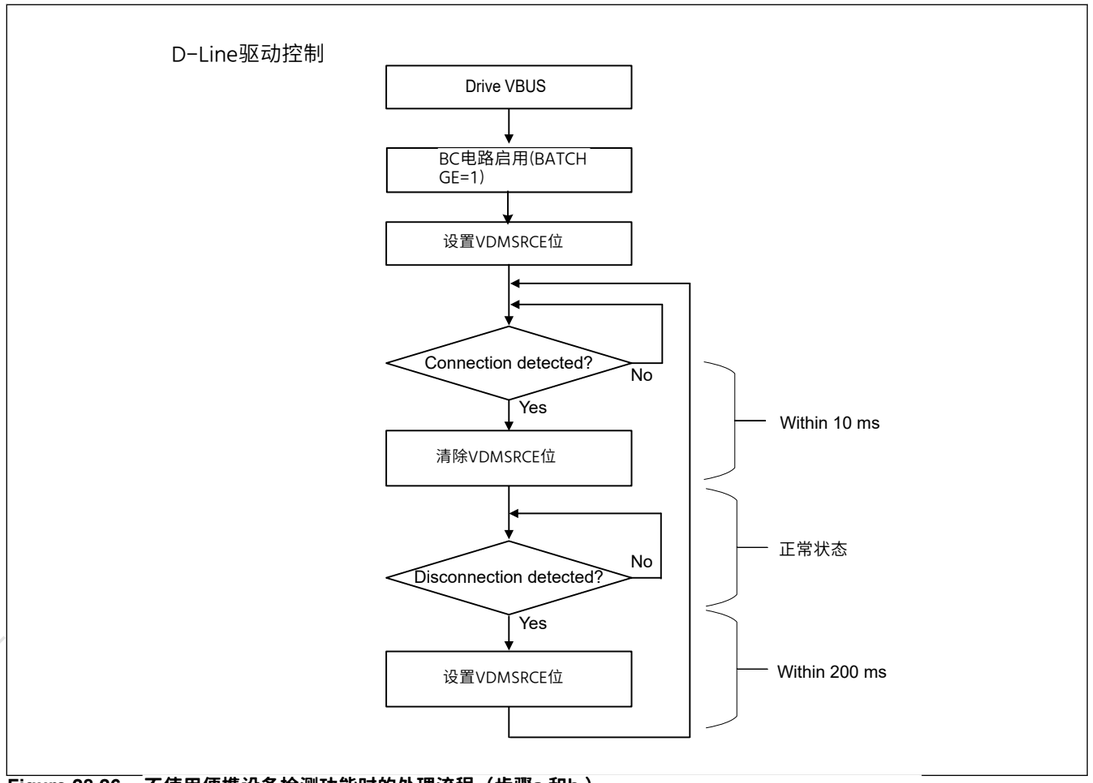

Figure 28.26 不使用便携设备检测功能时的处理流程（步骤a.和b.）

28.4 使用说明

28.4.1 模块停止状态的设置

可以使用模块停止控制寄存器B(MSTPCRB)禁用或启用USBFS操作。USBFS在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

28.4.2 退出软件待机模式时清除中断状态寄存器

由于在软件待机模式下始终启用输入缓冲区，因此在以下情况下可能会发生意外中断：

- 在正常模式下使能中断时
- 在软件待机模式下禁用中断时
- 在软件待机模式下，取消软件待机的引脚的输入电平发生变化时

这些情况可能会导致中断状态寄存器中的相关中断标志意外设置。MCU退出软件待机模式后，可能会向中断控制器发送意外中断。为避免这种情况，请始终在取消序列中清除INTSTS0和INTSTS1寄存器。

28.4.3 设置端口功能后清除中断状态寄存器

在设置PmnPFS.PSEL和PmnPFS.PMR端口之前，输入缓冲器被禁用，因此内部信号固定为高电平或低电平。设置端口后启用输入缓冲器，以便将外部引脚状态传播到MCU。此时可能会发生意外中断，导致INTSTS0和INTSTS1中的VBINT和OVRCR位，或其他

interrupt status flags to set to 1. To avoid a malfunction, always clear the INTSTS0 and INTSTS1 registers after setting up the port.

中断状态标志设置为1。为避免故障，请在设置端口后始终清除INTSTS0和INTSTS1寄存器。

Writing to the SYSCFG register can proceed while the PHY clock is stopped. However, written values are only reflected in the SYSCFG register after the PHY clock is oscillating again.

USBE bit (USBHS Operation Enable)

The USBE bit enables or disables operation of USBHS.

Changing the USBE bit from 1 to 0 initializes the bits listed in Table 29.3. Only change this bit after specifying the input clock in the PHYSET.CLKSEL[1:0] bits and confirming that the PLLSTA.PLLLOCK flag is 1. In CL-only mode, change the USBE bit after setting the PHYSET.HSEB bit to 1. At that time, the USBCLK must be set to 48 MHz and USB60CLK must be set to 60 MHz. For the clock settings, see section 29.3.3. Supplying the Clock.

In host controller mode, always set this bit to 1 after setting the DRPD bit to 1, eliminating SYSSTS0.LNST[1:0] bit chattering, and confirming that the USB bus state is stable.

当PHY时钟停止时，可以继续写入SYSCFG寄存器。但是，写入的值仅在PHY时钟再次振荡后才会反映在SYSCFG寄存器中。

USBE位（USBHS操作使能）

USBE位启用或禁用USBHS的操作。

将USBE位从1更改为0会初始化表29.3中列出的位。仅在PHYSET.CLKSEL[1:0]位中指定输入时钟并确认PLLSTA.PLLLOCK标志为1后更改该位。在CL-only模式下，将PHYSET.HSEB位设置为1后更改USBE位.此时USBCLK必须设置为48MHz，USB60CLK必须设置为60MHz。有关时钟设置，请参阅第29.3.3节。提供时钟。

在主机控制器模式下，在将DRPD位设置为1后始终将此位设置为1，消除SYSSTS0.LNST[1:0]位抖动，并确认USB总线状态稳定。

DPRPU bit (D+ Line Resistor Control)

The DPRPU bit enables or disables pulling up the D+ line in device controller mode.

When the DPRPU bit is set to 1 in device controller mode, the USBHS pulls up the D+ line to notify the USB host that it attached. Changing the DPRPU bit from 1 to 0 releases the pull-up, thereby notifying the USB host that it detached.

Set this bit to 1 in device controller mode and to 0 in host controller mode.

DRPD bit (D+/D- Line Resistor Control)

The DRPD bit enables or disables pulling down D+ and D- lines in host controller mode.

Set this bit to 1 in host controller mode. Set it to 0 when OTG is not used in device controller mode.

DCFM bit (Controller Operation Select)

The DCFM bit selects the host or device function of the USBHS.

Only change this bit when the DPRPU and DRPD bits are both 0.

HSE bit (High-Speed Operation Enable)

The HSE bit enables or disables high-speed operation.

When this bit is 1, the USBHS operates in high- or full-speed based on the results of the reset handshake.

In host controller mode, setting this bit to 0 allows the USBHS to operate in low- or full-speed. If the DVSTCTR0.RHST[2:0] flags indicate that a low-speed device has attached, set the HSE bit to 0.

In host controller mode, setting this bit to 1 allows the USBHS to operate in high- or full-speed based on the results of the reset handshake. Change the HSE bit after detection of an attach event (ATTCH interrupt) and before the USB bus reset (when DVSTCTR0.USBRST = 1), or after detection of a detach event.

In device controller mode, setting this bit to 0 allows the USBHS to operate in full-speed. Setting the bit to 1 allows the USBHS to perform the reset handshake and then operate in high-speed or full-speed, based on the results.

In device controller mode, only change this bit when the DPRPU bit is 0.

CNEN bit (Single-ended Receiver Enable)

Setting the CNEN bit to 1 enables single-ended receiver operation and selects monitoring of the D+ and D- line states in the SYSSTS0.LNST[1:0] flags. Use this bit to prevent through-current damage that might otherwise be caused during single-ended receiver operation, where the terminals are floating while the USBHS is detached.

In host controller mode, set this bit to 1 after confirming that the PHY clock is being supplied. In device controller mode, set this bit to 1 when the VBUS is detected because of a VBUS interrupt, and set it to 0 when the VBUS line is removed.

DPRPU位（D+线路电阻控制）

DPRPU位启用或禁用在设备控制器模式下上拉D+线。

当DPRPU位在设备控制器模式下设置为1时，USBHS拉高D+线以通知USB主机它已连接。将DPRPU位从1更改为0会释放上拉电阻，从而通知USB主机它已分离。

在设备控制器模式下将此位设置为1，在主机控制器模式下设置为0。

DRPD位（D+DLine电阻控制）

DRPD位在主机控制器模式下启用或禁用下拉D+和Dlines。

在主机控制器模式下将此位设置为1。在设备控制器模式下不使用OTG时将其设置为0。

DCFM位（控制器操作选择）

DCFM位选择USBHS的主机或设备功能。

仅当DPRPU和DRPD位都为0时更改该位。

HSE位（高速操作使能）

HSE位启用或禁用高速操作。

当该位为1时，USBHS根据复位握手的结果以高速或全速运行。

在主机控制器模式下，将该位设置为0允许USBHS以低速或全速运行。如果DVSTCTR0.RHST[2:0]标志表示已连接低速设备，将HSE位设置为0。

在主机控制器模式下，将此位设置为1允许USBHS根据复位握手的结果以高速或全速运行。在检测到附加事件（ATTCH中断）和USB总线复位之前（当DVSTCTR0.USBRST=1时）或检测到分离事件之后，更改HSE位。

在设备控制器模式下，将该位设置为0允许USBHS全速运行。将该位设置为1允许USBHS根据结果执行复位握手，然后以高速或全速运行。

在设备控制器模式下，仅当DPRPU位为0时更改该位。

CNEN位（单端接收器使能）

将CNEN位设置为1可启用单端接收器操作并选择监控D+和Dline状态SYSSTS0.LNST[1:0]标志。使用该位可防止在单端接收器操作期间可能造成的直通电流损坏，其中在USBHS分离时端子处于浮动状态。

在主机控制器模式下，在确认提供PHY时钟后将该位设置为1。在设备控制器模式下，当由于VBUS中断而检测到VBUS时将该位设置为1，并在移除VBUS线时将其设置为0。

BWAIT[3:0] bits (CPU Bus Access Wait Specification)

The BWAIT[3:0] bits specify the wait time for access to the USBHS registers.

When accessing the registers at addresses in the range beginning at 0x4011_1004, set the cycle time for consecutive access to at least 40.8 ns. The initial value is 0xF (17 cycles), but Renesas recommends that you satisfy this condition by setting the best wait time for the frequency of the CPU clock in your application.

This setting is the same as the wait time for accesses to the FIFO port register. The maximum speed of access to the FIFO port is as follows:

- MBW[1:0] = 10b (32-bit width): Maximum 60 MB/s
- MBW[1:0] = 01b (16-bit width): Maximum 30 MB/s
- MBW[1:0] = 00b (8-bit width): Maximum 15 MB/s

BWAIT[3:0]位（CPU总线访问等待规范）

BWAIT[3:0]位指定访问USBHS寄存器的等待时间。

访问从0x4011_1004开始的地址范围内的寄存器时，将连续访问的周期时间设置为至少40.8ns。初始值为0xF（17个周期），但瑞萨建议您通过在应用程序中为CPU时钟频率设置最佳等待时间来满足此条件。

该设置与访问FIFO端口寄存器的等待时间相同。访问FIFO端口的最大速度如下：

- MBW[1:0] = 10b (32-bit width): Maximum 60 MB/s
- MBW[1:0] = 01b (16-bit width): Maximum 30 MB/s
- MBW[1:0] = 00b (8-bit width): Maximum 15 MB/s

LNST[1:0] flags (USB Data Line Status Monitor Flag)

The LNST[1:0] flags indicate the state of the USB data lines, D+ and D-. For details, see Table 29.4.

In device controller mode, read the LNST[1:0] flags after setting the SYSCFG.CNEN and SYSCFG.USBE bits to 1. In host controller mode, read them after setting the SYSCFG.DRPD bit to 1.

When you are checking hardware contacts for the battery charging function in device controller mode, read the LNST[1:0] flags after setting the SYSCFG.DRPD, SYSCFG.CNEN, and BCCTRL.IDPSRCE bits to 1. For details, see section 29.3.15. Battery charging detection processing.

SOFEA flag (SOF Active Monitor Flag While Host Controller Operation Is Selected)

The SOFEA flag is used in host controller mode to check whether the output of the last SOF is complete when the USBHS is suspended because of a 0 setting to the DVSTCTR0.UACT bit.

In host controller mode, check that both the HTACT and SOFEA flags are 0 before setting the SYSCFG.USBE bit to 0 to stop the USBHS or setting the LPSTS.SUSPENDM bit to 0 to stop the clock signal supply during communication.

HTACT flag (Host Sequencer Status Monitor Flag)

The HTACT flag clears to 0 when the host sequencer of the USBHS is completely stopped.

In host controller mode, check that the HTACT flag is 0 before setting the DVSTCTR0.UACT bit to 0 to place the USBHS in the Suspend state or setting the LPSTS.SUSPENDM bit to 0 to stop the clock signal supply during communication.

OVCMON[1:0] flags (External USBHS_OVRCURA/USBHS_O VRCURB Input Pin Monitor Flag)

The OVCMON[1:0] flags indicate the status of the overcurrent signals from an external power supply IC.

LNST[1:0]标志指示USB数据线D+和D−的状态。详见表29.4。

在设备控制器模式下，将SYSCFG.CNEN和SYSCFG.USBE位设置为1后读取LNST[1:0]标志。在主机控制器模式下，将SYSCFG.DRPD位设置为1后读取它们。

当您在设备控制器模式下检查电池充电功能的硬件触点时，在将SYSCFG.DRPD、SYSCFG.CNEN和BCCTRL.IDPSRCE位设置为1后读取LNST[1:0]标志。有关详细信息，请参阅第29.3节.15.电池充电检测处理。

在主机控制器模式下，在将SYSCFG.USBE位设置为0以停止USBHS或将LPSTS.SUSPENDM位设置为0以在通信期间停止时钟信号供应之前，请检查HTACT和SOFEA标志是否为0。

HTACT标志（主机定序器状态监视器标志）

当USBHS的主机定序器完全停止时，HTACT标志清零。

在主机控制器模式下，在将DVSTCTR0.UACT位设置为0以将USBHS置于暂停状态或将LPSTS.SUSPENDM位设置为0以在通信期间停止时钟信号供应之前，请检查HTACT标志是否为0。

OVCMON[1:0]标志（外部USBHS_OVRCURAUSBHS_OVRCURB输入引脚监控标志）

15:12	—	The read values are undefined. The write value should be 0.	R/W

RHST[2:0] flags (USB Bus Reset Status Flag)

The RHST[2:0] flags indicate the USB bus reset status.

In host controller mode, writing 1 to the USBRST bit causes the RHST[2:0] flags to set to 100b. When 0 is written to the USBRST bit and the USBHS ends the SE0 state, the RHST[2:0] flags update to a new value.

In device controller mode, if the USBHS detects a USB bus reset, the RHST[2:0] flags set to 010b if an attach event occurs while the DPRPU bit is 1, and a DVST interrupt is generated.

UACT bit (USB Bus Operation Enable for the Host Controller Operation)

When set to 1 in host controller mode, the UACT bit enables USB bus operation by controlling SOF packet transmission to the USB bus in addition to data and reception. The USBHS starts SOF packet output within one frame period after the this bit is set to 1. If UACT is set to 0, the USBHS enters the idle state after the SOF packet output.

The USBHS sets the bit to 0 on any of the following conditions:

- A DTCH interrupt is detected during communication (while UACT = 1)
- An EOFERR interrupt is detected during communication (while UACT = 1)

Always write 1 to the UACT bit at the end of the USB bus reset processing (on a 0 write to the USBRST bit) or at the end of resume processing from the Suspend state (on a 0 write to the RESUME bit).

The USBHS clears the UACT bit to 0 if it receives an ACK response to an LPM token while the HL1CTRL1.L1REQ bit is set to 1. The USBHS sets the UACT bit to 1 when it finishes resume processing from the L1 state.

In device controller mode, always set this bit to 0.

RESUME bit (Resume Signal Output for the Host Controller Operation)

The RESUME bit controls the resume signal output in host controller mode.When this bit is set to 1, the USBHS drives the USB port to the K-state and outputs the resume signal. The USBHS sets the bit to 1 on detection of a remote wakeup signal while the RWUPE bit is 1 and in the USB suspend state. The USBHS continues outputting the K-state while the RESUME bit is 1, until the bit is cleared to 0 by software. The RESUME bit must be 1 (= resume period) for the time defined in the USB 2.0 specification. Only set this bit to 1 while the interface is in the Suspend state. Write 1 to the UACT bit simultaneously with the end of the resume processing (0 write to the RESUME bit).

Setting the RESUME bit to 1 during transition to the L1 state allows the USBHS to drive the USB port to the K-state and output the resume signal. The USBHS clears the RESUME bit to 0 at the end of the resume period, the value set in the HL1CTRL2.HIRD[3:0] bits.

Always set this bit to 0 in device controller mode.

RHST[2:0]标志（USB总线复位状态标志）

RHST[2:0]标志指示USB总线复位状态。

在主机控制器模式下，将1写入USBRST位会导致RHST[2:0]标志设置为100b。当0被写入USBRST位和USBHS结束SE0状态，RHST[2:0]标志更新为新值。

在设备控制器模式下，如果USBHS检测到USB总线复位，如果在DPRPU位为1时发生连接事件并产生DVST中断，则RHST[2:0]标志设置为010b。

UACT位（主机控制器操作的USB总线操作使能）

在主机控制器模式下设置为1时，UACT位通过控制向USB总线发送SOF数据包以及数据和接收来启用USB总线操作。USBHS在该位设置为1后的一帧周期内开始SOF数据包输出。如果UACT设置为0，则USBHS在SOF数据包输出后进入空闲状态。

USBHS在以下任何条件下将该位设置为0：

- ●在通信期间检测到DTCH中断（当UACT=1时）
- ●通信期间检测到EOFERR中断（当UACT=1时）

在USB总线复位处理结束时（向USBRST位写入0）或从挂起状态恢复处理结束时（向RESUME位写入0），始终向UACT位写入1。

如果USBHS在HL1CTRL1.L1REQ位设置为1时接收到对LPM令牌的ACK响应，则将UACT位清除为0。USBHS在完成从L1状态恢复处理时将 UACT位设置为1。

在设备控制器模式下，始终将此位设置为0。

RESUME位（主机控制器操作的恢复信号输出）

RESUME位控制主机控制器模式下的恢复信号输出。当该位设置为1时，USBHS将USB端口驱动到K状态并输出恢复信号。当RUPE位为1且处于USB挂起状态时，USBHS在检测到远程唤醒信号时将该位设置为1。当RESUME位为1时，USBHS继续输出K状态，直到该位被软件清零。在USB2.0规范中定义的时间内，RESUME位必须为1（=恢复周期）。仅当接口处于挂起状态时将此位设置为1。在恢复处理结束的同时向UACT位写入1（向RESUME位写入0）。

在转换到L1状态期间将RESUME位设置为1允许USBHS将USB端口驱动到K状态并输出恢复信号。USBHS在恢复周期结束时将RE SUME位清除为0，该值在HL1CTRL2.HIRD[3:0]位中设置。

在设备控制器模式下始终将此位设置为0。

USBRST bit (USB Bus Reset Output for the Host Controller Operation)

The USBRST bit controls the output of the USB bus signal in host controller mode. When this bit set to 1, the USBHS drives the USB port to the SE0 state to reset the USB bus. The USBHS continues outputting SE0 while the USBRST bit is 1, until the bit is cleared to 0 by software. The USBRST bit must be 1 (= USB bus reset period) for the time defined in the USB 2.0 specification. Writing 1 to the USBRST bit during communication (UACT bit = 1) or during resume processing (RESUME bit = 1) prevents the USBHS from starting USB bus reset processing until both the UACT and RESUME bits clear to 0. Write 1 to the UACT bit simultaneously with the end of the USB bus reset processing (0 write to the USBRST bit).

Always set this bit to 0 in device controller mode.

RWUPE bit (Remote Wakeup Detection Enable for the Host Controller Operation)

The RWUPE bit enables or disables remote wakeup signals (resume signals) from downstream peripheral devices in host controller mode. When this bit is set to 1, the USBHS detects a remote wakeup signal (K-state for 2.5 µs) from a downstream peripheral device, and it performs resume processing, driving the K-state. When the RWUPE bit is set to 0, the USBHS ignores remote wakeup signals (K-states) from peripheral devices connected to the USB port.

Do not stop the PHY clock while the RWUPE bit is 1, even in the Suspend state (the LPSTS.SUSPENDM bit must be set to 1). Also, do not reset the USB bus (setting USBRST to 1) from the Suspend state. This is prohibited in the USB 2.0 specification.

The RWUPE bit is also used to enable or disable detection of a remote wakeup signal during transition to the L1 state.

Always set this bit to 0 in device controller mode.

WKUP bit (Remote Wakeup Output for the Device Controller Operation)

The WKUP bit enables or disables remote wakeup signals (resume signals) to the USB bus in device controller mode.

The USBHS controls the output timing of the remote wakeup signals. When this bit is set to 1, the USBHS clears it to 0 after outputting the K-state for 10 ms. The USB 2.0 specification dictates that the USB bus idle state must be maintained for 5 ms or longer before a remote wakeup signal is sent. If the USBHS writes 1 to the WKUP bit immediately after detecting the Suspend state, the K-state is output after 2 ms.

Only write 1 to the WKUP bit when the device is in the Suspend state (the PL1CTRL1.DVSQ[3:0] flags are 01xxb) and the USB host enables the remote wakeup signal (RWUPE = 1). Do not stop the PHY clock while this bit is 1, even in the Suspend state (the LPSTS.SUSPENDM bit must be set to 1).

If the WKUP bit is set to 1 during transition to the L1 state, the USBHS outputs the K-state for 50 µs and then clears the bit to 0. Before writing 1 to the bit during the L1 state, check that the PL1CTRL1.DVSQ[3:0] flags are 10xxb.

Always set this bit to 0 in host controller mode.

HNPBTOA bit (Host Negotiation Protocol (HNP) Control)

The HNPBTOA bit is used when switching from device B to device A while in OTG mode.

If the HNPBTOA bit is 1, the internal function control maintains the Suspend state until HNP processing ends, even if the SYSCFG.DPRPU bit is set to 0 or the SYSCFG.DCFM bit is set to 1. Resume interrupts (RESM) are not generated even if a falling edge of D+ is detected.

The HNP processing ends when a host attach event is detected, because of a pull-up by the initiating party, or the HNPBTOA bit is cleared to 0 by software because the HNP processing times out.

29.2.6 TESTMODE : USB Test Mode Register

Base address: USBHS = 0x4011_1000

Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

USBRST位（用于主机控制器操作的USB总线复位输出）

USBRST位控制主机控制器模式下USB总线信号的输出。当该位设置为1时，USBHS将USB端口驱动到SE0状态以复位USB总线。当USBRST位为1时，USBHS继续输出SE0，直到该位被软件清零。在USB2.0规范中定义的时间内，USBRST位必须为1（=USB总线复位周期）。在通信期间（UACT位=1）或恢复处理期间（RESUME位=1）向USBRST位写入1可防止USBHS开始USB总线复位处理，直到UACT和RESUME位都清零。向UACT位写入1同时结束USB总线复位处理（0写入USBRST位）。

在设备控制器模式下始终将此位设置为0。

RHUPE位（主机控制器操作的远程唤醒检测使能）

在主机控制器模式下，RWUPE位启用或禁用来自下游外围设备的远程唤醒信号（恢复信号）。当该位设置为1时，USBHS检测到来自下游外围设备的远程唤醒信号（K状态持续2.5µs），并执行恢复处理，驱动K状态。当RWUPE位设置为0时，USBHS忽略来自连接到USB端口的外围设备的远程唤醒信号（K状态）。

当RHUPE位为1时不要停止PHY时钟，即使处于挂起状态（LPSTS.SUSPENDM位必须设置为1）。此外，不要将USB总线（将USBRST设置为1）从挂起状态复位。这在USB2.0规范中是禁止的。

RWUPE位还用于在转换到L1状态期间启用或禁用远程唤醒信号的检测。

在设备控制器模式下始终将此位设置为0。

WKUP位（设备控制器操作的远程唤醒输出）

WKUP位在设备控制器模式下启用或禁用到USB总线的远程唤醒信号（恢复信号）。

USBHS控制远程唤醒信号的输出时序。当该位设置为1时，USBHS在输出K状态10ms后将其清除为0。USB2.0规范规定，在发送远程唤醒信号之前，USB总线空闲状态必须保持5ms或更长时间。如果USBHS在检测到Suspend状态后立即向WKUP位写入1，则在2ms后输出K状态。

仅当设备处于挂起状态（PL1CTRL1.DVSQ[3:0]标志为01xxb）时向WKUP位写入1，并且USB主机使能远程唤醒信号(RWUPE=1)。当该位为1时不要停止PHY时钟，即使在挂起状态（LPSTS.SUSPENDM位必须设置为1）。

如果在转换到L1状态期间WKUP位设置为1，则USBHS输出K状态50µs，然后将该位清除为0。在L1状态期间向该位写入1之前，请检查PL1CTRL1.DVSQ[3:0]标志为10xxb。

在主机控制器模式下始终将此位设置为0。

HNPBTOA位（主机协商协议(HNP)控制）

在OTG模式下从设备B切换到设备A时使用HNPBTOA位。

如果HNPBTOA位为1，内部功能控制保持暂停状态直到HNP处理结束，即使SYSCFG.DPRPU位设置为0或SYSCFG.DCFM位设置为1。不产生恢复中断(RESM)即使检测到D+的下降沿。

当检测到主机连接事件时，HNP处理结束，因为发起方的上拉，或者由于HNP处理超时，HNPBTOA位由软件清零。

UTST[3:0] bits (Test Mode)

Writing values to the UTST[3:0] bits allows the USBHS to output USB test signals in high-speed operation mode. Table 29.5 shows the test mode operation settings.

Table 29.5 Test mode operation settings

Test mode	UTST[3:0] bit setting

Test_Packet	0x4	0xC
Test_Force_Enable	—	0xD
Reserved	0x5 to 0x7	0xE to 0xF

Host controller mode

In host controller mode, these bits can be set after setting the SYSCFG.DRPD bit to 1. After the UTST[3:0] bits are set, the USBHS outputs waveforms to the USB port by setting the DVSTCTR0.UACT bit to 1. The USBHS also performs high-speed termination for the USB port by setting these bits in host controller mode.

To set the UTST[3:0] bits in host controller mode:

1. Reset the hardware.
2. Start supplying the PHY clock, and then set the LPSTS.SUSPENDM bit to 1.
3. Set the SYSCFG.DCFM and SYSCFG.DRPD bits to 1. (Setting the SYSCFG.HSE bit to 1 is not required.)
4. Set the SYSCFG.USBE bit to 1.
5. Set the UTST[3:0] bits based on the test requirements.
6. Set the DVSTCTR0.UACT bit to 1.

Assuming the initial steps (1) to (6) are already complete, to change the UTST[3:0] bits in host controller mode:

1. Set the DVSTCTR0.UACT and SYSCFG.USBE bits to 0.
2. Set the SYSCFG.USBE bit to 1.
3. Set the UTST[3:0] bits based on the test requirements.
4. Set the DVSTCTR0.UACT bit to 1.

When the UTST[3:0] bits are set to 1011b (Test_SE0_NAK), the USBHS does not output SOF packets to ports for which the DVSTCTR0.UACT bit is set to 1.

When the UTST[3:0] bits are set to 1101b (Test_Force_Enable), the USBHS outputs SOF packets to ports for which the DVSTCTR0.UACT bit is set to 1. In this test mode, the USBHS does not control the hardware related to attach detection, even if it detects a high-speed detach event (DTCH interrupt).

Before setting the UTST[3:0] bits, set the PID[1:0] bits of all pipe control registers to 00b (NAK response). To return to normal USB communication after setting a test mode, issue a hardware reset.

UTST[3:0] bits (Test Mode)

将值写入UTST[3:0]位允许USBHS在高速操作模式下输出USB测试信号。表29.5显示了测试模式操作设置。

Table 29.5 测试模式操作设置

主机控制器模式

在主机控制器模式下，可以在将SYSCFG.DRPD位设置为1后设置这些位。设置UTST[3:0]位后，USBHS通过将DVSTCTR0.UACT位设置为1将波形输出到USB端口。USBHS还通过在主机控制器模式下设置这些位来执行USB端口的高速端接。

在主机控制器模式下设置UTST[3:0]位：

1.重置硬件。

2.开始提供PHY时钟，然后将LPSTS.SUSPENDM位设置为1。

3.将SYSCFG.DCFM和SYSCFG.DRPD位设置为1。（不需要将SYSCFG.HSE位设置为1。）

4.将SYSCFG.USBE位设置为1。

5.根据测试要求设置UTST[3:0]位。

6.将DVSTCTR0.UACT位设置为1。

假设初始步骤(1)到(6)已经完成，在主机控制器模式下更改UTST[3:0]位：

1.将DVSTCTR0.UACT和SYSCFG.USBE位设置为0。

2.将SYSCFG.USBE位设置为1。

3.根据测试要求设置UTST[3:0]位。

4.将DVSTCTR0.UACT位设置为1。

当UTST[3:0]位设置为1011b(Test_SE0_NAK)时，USBHS不会将SOF数据包输出到DVSTCTR0.UACT位设置为1的端口。

当UTST[3:0]位设置为1101b(Test_Force_Enable)时，USBHS将SOF数据包输出到DVSTCTR0.UACT位设置为1。在此测试模式下，USBHS不控制与连接检测相关的硬件，即使它检测到高速分离事件（DTCH中断）。

在设置UTST[3:0]位之前，将所有管道控制寄存器的PID[1:0]位设置为00b（NAK响应）。要在设置测试模式后返回正常USB通信，请发出硬件复位。

Device controller mode

In device controller mode, set these bits using a SetFeature request from the USB host during high-speed communication. The USBHS does not enter the Suspend state while these bits are 0001b to 0100b. To return to normal USB communication after setting a test mode, issue a hardware reset.

Bit	Symbol	Function	R/W
31:0	FIFOPORT[31:0]*1	Read receive data from the FIFO buffer or write transmit data to the FIFO buffer by accessing these bits.	R/W

Note 1. The valid bits depend on the MBW[1:0] and BIGEND settings in the associated port selection register.

Three FIFO ports are provided:

- CFIFO
- D0FIFO
- D1FIFO

Each FIFO port is configured with:

- A port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer and writing of data to the FIFO buffer
- A port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that selects the pipe assigned to the FIFO port
- A port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR)

Each FIFO port has the following constraints:

- Access to the FIFO buffer for DCP control transfers is through the CFIFO port
- Access to the FIFO buffer for DMA or DTC transfers is through the D0FIFO or D1FIFO port
- The D0FIFO and D1FIFO ports can also be accessed by the CPU
- When using functions specific to the FIFO port, such as the DMA or DTC transfer function, you cannot change the pipe number selected in the CURPIPE[3:0] bits of the Port Selection Register
- Registers configuring one FIFO port do not affect other FIFO ports
- The same pipe must not be assigned to two or more FIFO ports
- There are two FIFO buffer states, one giving access rights to the CPU and the other to the serial interface engine (SIE). When the SIE has access rights, the FIFO buffer cannot be accessed by the CPU

FIFOPORT bits (FIFOPORT[31:0])

When the FIFOPORT bits is accessed, the USBHS reads the received data from the FIFO buffer or writes the transmission data to the FIFO buffer. The FIFO port register can be accessed only when the FRDY flag in the associated port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is 1.

设备控制器模式

在设备控制器模式下，在高速通信期间使用来自USB主机的SetFeature请求设置这些位。
当这些位为0001b至0100b时，USBHS不会进入暂停状态。要在设置测试模式后返回正常USB通信，请发出硬件复位。

注1.有效位取决于相关端口选择寄存器中的MBW[1:0]和BIGEND设置。

提供了三个FIFO端口：

- CFIFO
- D0FIFO
- D1FIFO

每个FIFO端口配置有：

●一个端口寄存器（CFIFO、D0FIFO或D1FIFO），用于处理从FIFO缓冲区读取数据并将数据写入FIFO缓冲区

●端口选择寄存器（CFIFOSEL、D0FIFOSEL或D1FIFOSEL），用于选择分配给FIFO端口的管道

●一个端口控制寄存器（CFIFOCTR、D0FIFOCTR或D1FIFOCTR）

每个FIFO端口具有以下约束：

●通过CFIFO端口访问DCP控制传输的FIFO缓冲区

●通过D0FIFO或D1FIFO端口访问DMA或DTC传输的FIFO缓冲区

●D0FIFO和D1FIFO端口也可以被CPU访问

●当使用特定于FIFO端口的功能时，例如DMA或DTC传输功能，您无法更改端口选择寄存器的CURPIPE[3:0]位中选择的管道编号

●配置一个FIFO端口的寄存器不会影响其他FIFO端口

●不能将同一管道分配给两个或多个FIFO端口

●有两种FIFO缓冲区状态，一种授予CPU访问权限，另一种授予串行接口引擎(SIE)。当SIE有访问权限时，CPU不能访问FIFO缓冲区

FIFOPORT bits (FIFOPORT[31:0])

当访问FIFOPORT位时，USBHS从FIFO缓冲区读取接收数据或将发送数据写入FIFO缓冲区。只有当相关端口控制寄存器（CFIFOCTR、D0FIFOCTR或D1FIFOCTR）中的FRDY标志为1时，才能访问FIFO端口寄存器。

Do not specify the same pipe number in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.

Do not change the pipe number while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number used to read or write data through the CFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, the pipe specification is maintained until the access is complete, even if the software attempts to change the CURPIPE[3:0] setting. Access continues after the current value is written back to the CURPIPE[3:0] bits.

ISEL bit (FIFO Port Access Direction when DCP Is Selected)

After writing a new value to the ISEL bit while the DCP is the selected pipe, read this bit to check that the written value agrees with the read value before proceeding to the next process. Set the ISEL and CURPIPE[3:0] bits simultaneously.

BIGEND bit (FIFO Port Endian Control)

Use the BIGEND bit to set the byte endian order of the CFIFO port to be the same as that selected in the endian selection register (MDE).

MBW[1:0] bits (CFIFO Port Access Bit Width)

The MBW[1:0] bits specify the bit width for accessing the CFIFO port.

不要在CFIFOSEL、D0FIFOSEL和D1FIFOSEL寄存器的CURPIPE[3:0]位中指定相同的管道编号。

启用DMA或DTC传输时不要更改管道编号。

CURPIPE[3:0]位（FIFO端口访问管道规范）

CURPIPE[3:0]位指定用于通过CFIFO端口读取或写入数据的管道号。写入这些位后，读取它们以检查写入的值是否与读取的值一致，然后再进行下一个过程。不要为CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位设置相同的管道编号。

在FIFO缓冲区访问期间，管道规范一直保持到访问完成，即使软件尝试更改CURPIPE[3:0]设置。将当前值写回CURPIPE[3:0]位后继续访问。

ISEL位（选择DCP时的FIFO端口访问方向）

在DCP为选定管道时向ISEL位写入新值后，读取该位以检查写入的值是否与读取的值一致，然后再进行下一个过程。同时设置ISEL和CURPIPE[3:0]位。

BIGEND位（FIFO端口字节序控制）

使用BIGEND位将CFIFO端口的字节字节序设置为与在字节序选择寄存器(MDE)中选择的相同。

MBW[1:0]位（CFIFO端口访问位宽度）

MBW[1:0]位指定访问CFIFO端口的位宽。

RA生态工作室

When the selected pipe is receiving, after a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read. When reading the FIFO buffer, read with the access size set in MBW.

When the selected pipe is transmitting, set the CURPIPE[3:0] and MBW[1:0] bits simultaneously. The bit width cannot be changed from 8-bit to 16- or 32-bit, or from 16-bit to 32-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16- or 32-bit width is selected.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether or not to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double-buffering when reading is already in progress, this setting enables reading either FIFO buffer from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the bit to 1, always check that the FRDY flag is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

RCNT bit (Read Count Mode)

When the RCNT bit set to 0, the USBHS clears the CFIFOCTR.DTLN[11:0] flags to 0 on finishing reading all of the received data in the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits, or after reading a single plane in double buffer mode.

With this bit set to 1, the USBHS decrements the value in the CFIFOCTR.DTLN[11:0] flags each time it reads data received from the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits.

当所选管道正在接收时，在写入这些位后开始从FIFO缓冲区读取数据，在读取所有数据之前不要更改这些位。读取FIFO缓冲区时，读取以MBW为单位设置的访问大小。

当所选管道正在传输时，同时设置CURPIPE[3:0]和MBW[1:0]位。当数据写入FIFO缓冲区时，位宽不能从8位更改为16位或32位，或从16位更改为32位。

即使选择了16位或32位宽度，也可以通过字节访问控制写入奇数个字节。

REW位（缓冲区指针倒带）

REW位指定是否回绕缓冲区指针。

当所选管道正在接收时，在读取FIFO缓冲区时将此位设置为1允许从第一个数据重新读取FIFO缓冲区。在读取已经在进行时的双缓冲中，此设置允许从第一个条目读取任一FIFO缓冲区。

请勿在同时更改CURPIPE[3:0]位时将此位设置为1。在将该位设置为1之前，请始终检查FRDY标志是否为1。

要从传输管道的第一个数据重写FIFO缓冲区，请使用BCLR位。

RCNT位（读取计数模式）

当RCNT位设置为0时，USBHS在完成读取分配给CURPIPE[3:0]位指定的管道的FIFO缓冲区中的所有接收数据后，将CFIFOCTR.DTLN[11:0]标志清除为0，或在双缓冲模式下读取单个平面后。

该位设置为1时，USBHS每次读取从分配给CURPIPE[3:0]位指定的管道的FIFO缓冲区接收的数据时都会递减CFIFOCTR.DTLN[11:0]标志中的值。

Do not specify the same pipe number in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

Do not change the pipe number while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number used to read or write data through the DnFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, the pipe specification is maintained until the access is complete, even if the software attempts to change the CURPIPE[3:0] setting. Access continues after the current value is written back to the CURPIPE[3:0] bits.

BIGEND bit (FIFO Port Endian Control)

Use the BIGEND bit to set the byte endian order of the D0FIFO or D1FIFO port to be the same as that selected in the endian selection register (MDE).

MBW[1:0] bits (FIFO Port Access Bit Width)

The MBW[1:0] bits specify the bit width for accessing the DnFIFO port.

When the selected pipe is receiving, after a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read. When reading the FIFO buffer, read with the access size set in MBW.

When the selected pipe is transmitting, set the CURPIPE[3:0] and MBW[1:0] bits simultaneously. The bit width cannot be changed from 8-bit to 16- or 32-bit, or from 16-bit to 32-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16- or 32-bit width is selected.

DREQE bit (DMA/DTC Transfer Request Enable)

The DREQE bit enables or disables issuing of DMA or DTC transfer requests. Only change the settings of DREQE bit when the CURPIPE[3:0] bits are 0x0.

To enable DMA or DTC transfer requests, set this bit to 1 after setting the CURPIPE[3:0] bits to 0x0, and then set the CURPIPE[3:0] bits to the PIPE number for the transfer.

DCLRM bit (Auto FIFO Buffer Clear Mode after Specified Pipe is Read)

The DCLRM bit enables or disables automatic FIFO buffer clearing after data in the selected pipe is read.

When this bit is set to 1, on receiving a zero-length packet while the FIFO buffer assigned to the selected pipe is empty, or when reading of a received short packet is complete while the PIPECFG.BFRE bit is 1, the USBHS sets the BCLR bit in the FIFO port control register to 1.

When using the USBHS with the SOFCFG.BRDYM bit set to 1, set this bit to 0.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether or not to rewind the buffer pointer.

不要在CFIFOSEL、D0FIFOSEL和D1FIFOSEL寄存器的CURPIPE[3:0]位中指定相同的管道编号。
当D0FIFOSEL和D1FIFOSEL寄存器中的CURPIPE[3:0]位设置为0000b时，不选择管道。

启用DMA或DTC传输时不要更改管道编号。

CURPIPE[3:0]位（FIFO端口访问管道规范）

CURPIPE[3:0]位指定用于通过DnFIFO端口读取或写入数据的管道编号。写入这些位后，读取它们以检查写入的值是否与读取的值一致，然后再进行下一个过程。不要为CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位设置相同的管道编号。

在FIFO缓冲区访问期间，管道规范一直保持到访问完成，即使软件尝试更改CURPIPE[3:0]设置。将当前值写回CURPIPE[3:0]位后继续访问。

BIGEND位（FIFO端口字节序控制）

使用BIGEND位将D0FIFO或D1FIFO端口的字节字节序设置为与在字节序选择寄存器(MDE)中选择的相同。

MBW[1:0]位（FIFO端口访问位宽）

MBW[1:0]位指定访问DnFIFO端口的位宽。

当所选管道正在接收时，在写入这些位后开始从FIFO缓冲区读取数据，在读取所有数据之前不要更改这些位。读取FIFO缓冲区时，读取以MBW为单位设置的访问大小。

当所选管道正在传输时，同时设置CURPIPE[3:0]和MBW[1:0]位。当数据写入FIFO缓冲区时，位宽不能从8位更改为16位或32位，或从16位更改为32位。

即使选择了16位或32位宽度，也可以通过字节访问控制写入奇数个字节。

DREQE位（DMADTC传输请求使能）

DREQE位启用或禁用DMA或DTC传输请求的发出。仅当CURPIPE[3:0]位为0x0时更改DREQE位的设置。

要启用DMA或DTC传输请求，请在将CURPIPE[3:0]位设置为0x0后将此位设置为1，然后将CURPIPE[3:0]位到用于传输的PIPE编号。

DCLRM位（读取指定管道后自动FIFO缓冲区清除模式）

在读取所选管道中的数据后，DCLRM位启用或禁用自动FIFO缓冲区清除。

当该位设置为1时，在分配给所选管道的FIFO缓冲区为空时接收到零长度数据包，或在PIPECFG.BFRE位为1时完成读取接收到的短数据包时，USBHS设置FIFO端口控制寄存器中的BCLR位为1。

当使用SOFCFG.BRDYM位设置为1的USBHS时，将此位设置为0。

REW位（缓冲区指针倒带）

REW位指定是否回绕缓冲区指针。

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double-buffering when reading is already in progress, this setting enables reading either FIFO buffer from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the bit to 1, always check that the FRDY flag is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

RCNT bit (Read Count Mode)

When the RCNT bit set to 0, the USBHS clears the DnFIFOCTR.DTLN[11:0] flags (n = 0, 1) to 0 on finishing reading all of the received data in the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits, or after reading a single plane in double buffer mode.

With this bit set to 1, the USBHS decrements the value in the CFIFOCTR.DTLN[11:0] flags each time it reads data received from the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits. When accessing DnFIFO with the PIPECFG.BFRE bit set to 1, set the RCNT bit to 0.

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[11:0] flags (Receive Data Length Flag)

The DTLN[11:0] flags indicate the length of the receive data.

While the FIFO buffer is being read, the DTLN[11:0] bits indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1), as follows:

- RCNT = 0:
  The USBHS sets the DTLN[11:0] flags to indicate the length of the receive data until the CPU or DMA/DTC has read all of the received data in the FIFO buffer (or until it has read a single plane in double buffer mode).
  While the PIPECFG.BFRE bit is 1, the USBHS retains the length of the receive data until the BCLR bit is set to 1, even after all the data is read.
- RCNT = 1:

当所选管道正在接收时，在读取FIFO缓冲区时将此位设置为1允许从第一个数据重新读取FIFO缓冲区。在读取已经在进行时的双缓冲中，此设置允许从第一个条目读取任一FIFO缓冲区。

请勿在同时更改CURPIPE[3:0]位时将此位设置为1。在将该位设置为1之前，请始终检查FRDY标志是否为1。

要从传输管道的第一个数据重写FIFO缓冲区，请使用BCLR位。

RCNT位（读取计数模式）

当RCNT位设置为0时，USBHS将DnFIFOCTR.DTLN[11:0]标志(n=0 1)清除为0，完成读取分配给CURPIPE中指定管道的FIFO缓冲区中的所有接收数据[3:0]位，或在双缓冲模式下读取单个平面后。

该位设置为1时，USBHS每次读取从分配给CURPIPE[3:0]位指定的管道的FIFO缓冲区接收的数据时都会递减CFIFOCTR.DTLN[11:0]标志中的值。当PIPECFG.BFRE位设置为1访问DnFIFO时，将RCNT位设置为0。

CFIFOCTR、D0FIFOCTR和D1FIFOCTR寄存器对应于CFIFO、D0FIFO和D1FIFO缓冲区。

DTLN[11:0]标志（接收数据长度标志）

DTLN[11:0]标志指示接收数据的长度。

在读取FIFO缓冲区时，DTLN[11:0]位指示不同的值，具体取决于DnFIFOSEL.RCNT位(n=0 1)，如下所示：

- RCNT = 0:
  USBHS设置DTLN[11:0]标志以指示接收数据的长度，直到CPU或DMADTC已读取FIFO缓冲区中的所有接收数据（或直到它在双缓冲区模式下读取单个平面）.当PIPECFG.BFRE位为1时，USBHS将保留接收数据的长度，直到BCLR位设置为1，即使在读取所有数据之后也是如此。
- RCNT = 1:

The USBHS decrements the value indicated in the DTLN[11:0] flags each time the CPU or DMA/DTC reads the receive data from the FIFO buffer. (The value is decremented by 1 when MBW[1:0] = 00b, by 2 when MBW[1:0] = 01b, and by 4 when MBW[1:0] = 10b.)
The USBHS sets these flags to 0 when all the data is read from the FIFO buffer. In double buffer mode, if data is received in one FIFO buffer plane before all of the data is read from the other plane, the USBHS sets these bits to indicate the length of the receive data in the latter plane when all of the data is read from the former plane.
When the RCNT bit is 1, reading the DTLN[11:0] flags while the FIFO buffer is being read returns the latest value within 150 ns after the FIFO port read cycle.

FRDY flag (FIFO Port Ready Flag)

The FRDY flag indicates whether the FIFO port can be accessed by the CPU or DMA/DTC.

In the following cases, the USBHS sets the FRDY flag to 1 but data cannot be read through the FIFO port because there is no data to be read:

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit is 1

In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

BCLR bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU for the selected pipe.

When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USBHS clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the DCP is the selected pipe, setting the BCLR bit to 1 allows the USBHS to clear both sets of FIFO buffers regardless of whether the CPU or SIE has access rights. To clear the buffer when the SIE has access rights, set the DCPCTR.PID[1:0] bits to 00b (NAK response) before setting the BCLR bit to 1.

When the selected pipe is not the DCP, only write 1 to the BCLR bit while the FRDY flag in the FIFO port control register is 1 (set by the USBHS).

BVAL bit (FIFO Buffer Valid Flag)

Set the BVAL bit to 1 when data is completely written to the FIFO buffer on the CPU for the pipe selected in CURPIPE[3:0].

When the selected pipe is transmitting, set this bit to 1 in the following cases:

- To transmit a short packet, set this bit to 1 after data is written
- To transmit a zero-length packet, set this bit to 1 before data is written to the FIFO buffer
- Set this bit to 1 after the specified number of data bytes is written for the pipe in continuous transfer mode, where the number is a natural integer multiple of the maximum packet size and less than the buffer size

The USBHS then switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When the selected pipe is in use for transmission, simultaneously setting the BVAL flag and the BCLR bit to 1 causes the USBHS to clear the data that is already written and enables transmission of a zero-length packet. When data of the maximum packet size is written for the pipe in non-continuous transfer mode, the USBHS sets this bit to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

Only write 1 to the BVAL flag while the FRDY bit is 1 (set by the USBHS). When the selected pipe is receiving, do not set the BVAL flag to 1.

每次CPU或DMADTC从FIFO缓冲区读取接收数据时，USBHS都会递减DTLN[11:0]标志中指示的值。（当MBW[1:0]=00b时该值减1，当MBW[1:0]=01b时减2，当MBW[1:0]=10b时减4。）USBHS将这些标志设置为0当从FIFO缓冲区中读取所有数据时。在双缓冲模式下，如果在一个FIFO缓冲平面中的数据在从另一个平面读取所有数据之前接收到数据，则USBHS设置这些位以指示在读取所有数据时后一个平面中接收数据的长度从前飞机。当RCNT位为1时，在读取FIFO缓冲区时读取DTLN[11:0]标志会在FIFO端口读取周期后150ns内返回最新值。

FRDY标志（FIFO端口就绪标志）

FRDY标志指示CPU或DMADTC是否可以访问FIFO端口。

在以下情况下，USBHS将FRDY标志设置为1，但由于没有数据可读取，因此无法通过FIFO端口读取数据：

●当分配给所选管道的FIFO缓冲区为空时，接收到一个长度为零的数据包

●PIPECFG.BFRE位为1时，接收到一个短数据包并完全读取数据

在这些情况下，将BCLR位设置为1以清除FIFO缓冲区，并启用下一个数据的发送和接收。

BCLR位（CPU缓冲区清除）

将BCLR位设置为1以清除CPU上所选管道的FIFO缓冲区。

当分配给所选管道的FIFO缓冲区设置为双缓冲区模式时，USBHS仅清除
即使两个平面都已启用读取，也有FIFO缓冲区。

当DCP为选定管道时，将BCLR位设置为1允许USBHS清除两组FIFO缓冲区，而不管CPU或SIE是否具有访问权限。要在SIE具有访问权限时清除缓冲区，请将DCPCTR.PID[1:0]位设置为00b（NAK响应），然后再将BCLR位设置为1。

当所选管道不是DCP时，仅在FIFO端口控制寄存器中的Frdy标志为1（由USBH设置）时，仅将1个写入BCLR位。

BVAL位（FIFO缓冲区有效标志）

当数据完全写入CPU上的FIFO缓冲区时，将BVAL位设置为1，用于
CURPIPE[3:0].

当所选管道正在传输时，在以下情况下将此位设置为1：

●发送短数据包，写入数据后将该位设置为1

●要发送零长度数据包，请在数据写入FIFO缓冲区之前将此位设置为1

●在连续传输模式下为管道写入指定数量的数据字节后，将此位设置为1，其中该数字是最大数据包大小的自然整数倍，并且小于缓冲区大小

然后USBHS将FIFO缓冲区从CPU侧切换到SIE侧，从而启用传输。

当所选管道用于传输时，同时将BVAL标志和BCLR位设置为1会导致
USBHS清除已写入的数据并启用零长度数据包的传输。当在非连续传输模式下为管道写入最大数据包大小的数据时，USBHS将该位设置为1，并将FIFO缓冲区从CPU侧切换到SIE侧，从而启用传输。

仅在FRDY位为1（由USBHS设置）时将1写入BVAL标志。当所选管道正在接收时，不要将BVAL标志设置为1。

Note 3. When setting the BRDYM bit to 1, set the INTL bit to 1.
Note 4. The setting in the TRNENSEL bit is only valid in host controller mode. Even in host controller mode, the setting of this bit has no effect on the transaction-enabled time during high-speed communication.

EDGESTS flag (Interrupt Edge Processing Status Flag)

The EDGESTS flag indicates 1 during the edge processing of an edge interrupt output signal. Confirm that this flag is 0 before stopping the PHY clock.

BRDYM bit (PIPEBRDY Interrupt Status Clear Timing)

The BRDYM bit specifies how the BRDY interrupt status flags for the pipes are cleared.

TRNENSEL bit (Transaction-Enabled Time Select)

When the USB port is in use for full- or low-speed communications, the TRNENSEL bit specifies the timing with which the USBHS issues tokens in a frame (transaction-enabled time).

Set this bit to 1 when a low-speed device is connected through a hub. The bit is only valid in host controller mode. Set this bit to 0 when the interface is in use as a device controller.

注3.将BRDYM位设置为1时，将INTL位设置为1。
注4.TRNENSEL位的设置仅在主机控制器模式下有效。即使在主机控制器模式下，该位的设置也不会影响高速通信期间的事务使能时间。

EDGESTS标志（中断边缘处理状态标志）

EDGESTS标志在边沿中断输出信号的边沿处理期间指示为1。在停止PHY时钟之前确认该标志为0。

BRDYM位（PIPEBRDY中断状态清除时序）

BRDYM位指定如何清除管道的BRDY中断状态标志。

TRNENSEL位（事务使能时间选择）

当USB端口用于全速或低速通信时，TRNENSEL位指定USBHS在一个帧中发布令牌（事务启用时间）。

当通过集线器连接低速设备时，将此位设置为1。该位仅在主机控制器模式下有效。当接口用作设备控制器时，将此位设置为0。

CLKSEL[1:0] bits (Input System Clock Frequency)

The CLKSEL[1:0] bits select the transfer clock source for the USBHS.

For the transfer clock generated in the USB-PHY internal PLL, these bits set the input clock frequency. To input the clock source from the EXTAL pin, the USB 2.0 clock specification must be strictly followed.

Writing to the CKSEL[1:0] bits is invalid in CL-only mode because the internal PLL is stopped (see the description for HSEB bit (CL-only mode)). For the clock settings, see section 29.3.3. Supplying the Clock.

HSEB bit (CL-only mode)

The HSEB bit selects whether the USBHS operates in CL-only mode. High-speed transfer by the USBHS requires the use of internal high-speed analog circuits including the PLL, clock, and data recovery (CDR) circuit in the USB-PHY block.

CL-only mode limits the transfer to the USB 1.1 specification (full- and low-speed transfer only). Power consumption can be reduced by stopping the internal PLL of the PHY module and other high-speed analog circuits.

CLKSEL[1:0]位（输入系统时钟频率）

CLKSEL[1:0]位选择USBHS的传输时钟源。

对于USB-PHY内部PLL中生成的传输时钟，这些位设置输入时钟频率。要从EXTAL引脚输入时钟源，必须严格遵循USB2.0时钟规范。

在CL-only模式下写入CKSEL[1:0]位无效，因为内部PLL已停止（请参见HSEB位（仅限CL模式））。有关时钟设置，请参阅第29.3.3节。提供时钟。

HSEB bit (CL-only mode)

HSEB位选择USBHS是否工作在CL-only模式。USBHS的高速传输需要使用内部高速模拟电路，包括USB-PHY模块中的PLL、时钟和数据恢复(CDR)电路。

仅CL模式将传输限制为USB1.1规范（仅限全低速传输）。通过停止PHY模块的内部PLL和其他高速模拟电路可以降低功耗。

In CL-only mode, the USBHS requires supply clocks of 48 MHz and 60 MHz, generated in the Clock Generation Circuit. For the clock supply method, see section 8, Clock Generation Circuit.

Note 1. The CTSQ[2:0], VALID, and DVSQ[2:0] flags are only valid in device controller mode.
Note 2. The status of the CTRT, DVST, and RESM flags are changed only in device controller mode. Set the associated interrupt enable bits to 0 (disabled) in host controller mode.
Note 3. To clear the CTRT, DVST, SOFR, RESM, or VBINT flags, write 0 only to the flags to be cleared. Write 1 to the other flags. Do not write 0 to the status flags indicating 0.
Note 4. The USBHS detects a change in the status in the RESM or VBINT flag even while the clock supply is stopped (LPSTS.SUSPENDM = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply before clearing the status by software.

BRDY flag (BRDY Interrupt Status Flag)

The BRDY flag indicates the BRDY interrupt state. For the conditions that cause the flag to be set, see section 29.2.13. BRDYENB : BRDY Interrupt Enable Register.

The USBHS clears the BRDY flag to 0 when 0 is written to the BRDYSTS.PIPEBRDYn (n = 0 to 9) flags for all pipes for which the BRDY interrupt is enabled (BRDYENB.PIPEBRDYEn bits). Writing 0 to the BRDY flag in the software does not clear the flag.

NRDY flag (NRDY Interrupt Status Flag)

The NRDY flag indicates the NRDY interrupt state. For the conditions that cause the flag to be set, see section 29.2.14. NRDYENB : NRDY Interrupt Enable Register.

The USBHS clears the NRDY flag to 0 when 0 is written to the NRDYSTS.PIPENRDYn (n = 0 to 9) flags for all pipes for which the NRDY interrupt is enabled (NRDYENB.PIPENRDYEn bits). Writing 0 to the NRDY flag in the software does not clear the flag.

BEMP flag (BEMP Interrupt Status Flag)

The BEMP indicates the BEMP interrupt state. For the conditions that cause the flag to be set, see section 29.2.15. BEMPENB : BEMP Interrupt Enable Register.

The USBHS clears the BEMP flag to 0 when 0 is written to the BEMPSTS.PIPEBEMPn (n = 0 to 9) flags for all pipes for which the BEMP interrupt is enabled (BEMPENB.PIPEBEMPEn bits). Writing 0 to the BEMP flag in the software does not clear the flag.

CTRT flag (Control Transfer Stage Transition Interrupt Status Flag)

In device controller mode, the USBHS updates the value of the CTSQ[2:0] bits and sets the CTRT flag to 1 on detecting a transition in the control transfer stage. When a control transfer stage transition interrupt occurs, clear the CTRT flag before the USBHS detects the next control transfer stage transition.

Values read from the CTRT flag in host controller mode are invalid.

DVST flag (Device State Transition Interrupt Status Flag)

In device controller mode, the USBHS updates the value of the PL1CTRL1.DVSQ[3:0] bits and sets the DVST flag to 1 on detecting a change in the device state. When a device state transition interrupt occurs, clear the DVST flag before the USBHS detects the next device state transition.

Values read from the DVST flag in host controller mode are invalid.

SOFR flag (Frame Number Refresh Interrupt Status Flag)

In host controller mode, the USBHS sets the SOFR flag to 1 on updating the frame number when the DVSTCTR0.UACT bit is set to 1 by software. An SOFR interrupt is detected every 1 ms.

In device controller mode, the USBHS sets the SOFR flag to 1 on updating the frame number. An SOFR interrupt is detected every 1 ms. The USBHS can detect an SOFR interrupt through the SOF complementation function even when a corrupted SOF packet is received from the USB host. See section 29.3.13. SOF Complementation Function.

注1.CTSQ[2:0]、VALID和DVSQ[2:0]标志仅在设备控制器模式下有效。
注2.CTRT、DVST和RESM标志的状态仅在设备控制器模式下更改。在主机控制器模式下，将相关的中断使能位设置为0（禁用）。

注3.要清除CTRT、DVST、SOFR、RESM或VBINT标志，只需将0写入要清除的标志。将1写入其他标志。不要将0写入指示0的状态标志。

注4.即使在时钟供应停止(LPSTS.SUSPENDM=0)时，USBHS也会检测到RESM或VBINT标志的状态变化，并在相关中断请求位为1时请求中断。启用时钟供应在通过软件清除状态之前。

BRDY标志（BRDY中断状态标志）

BRDY标志指示BRDY中断状态。有关导致设置标志的条件，请参阅第29.2.13节。
BRDYENB：BRDY中断允许寄存器。

当0写入BRDYSTS.PIPEBRDYn（n=0到9）标志时，USBHS将BRDY标志清除为0，用于所有启用了BRDY中断的管道（BRDYENB.PIPEBRDYEn位）。在软件中将0写入BRDY标志不会清除该标志。

NRDY标志（NRDY中断状态标志）

NRDY标志指示NRDY中断状态。有关导致设置标志的条件，请参阅第29.2.14节。
NRDYENB：NRDY中断允许寄存器。

当0写入所有启用了NRDY中断的管道（NRDYENB.PIPENRDYEn位）的NRDYSTS.PIPENRDYn（n=0到9）标志时，USBHS将NRDY标志清除为0。在软件中将0写入NRDY标志不会清除该标志。

BEMP标志（BEMP中断状态标志）

BEMP指示BEMP中断状态。有关导致设置标志的条件，请参阅第29.2.15节。
BEMPENB：BEMP中断使能寄存器。

当0写入所有启用了BEMP中断的管道（BEMPENB.PIPEBEMPEn位）的BEMPSTS.PIPEBEMPn（n=0到9）标志时，USBHS将BEMP标志清除为0。在软件中将0写入BEMP标志不会清除该标志。

CTRT标志（控制传输阶段转换中断状态标志）

在设备控制器模式下，USBHS更新CTSQ[2:0]位的值并将CTRT标志设置为1检测到控制传输阶段的转换。当控制传输阶段转换中断发生时，在USBHS检测到下一个控制传输阶段转换之前清除CTRT标志。

在主机控制器模式下从CTRT标志读取的值无效。

DVST标志（设备状态转换中断状态标志）

在设备控制器模式下，USBHS更新PL1CTRL1.DVSQ[3:0]位的值并将DVST标志设置为1，以检测设备状态的变化。当设备状态转换中断发生时，在USBHS检测到下一个设备状态转换之前清除DVST标志。

在主机控制器模式下从DVST标志读取的值无效。

SOFR标志（帧号刷新中断状态标志）

在主机控制器模式下，当DVSTCTR0.UACT位被软件设置为1时，USBHS在更新帧号时将SOFR标志设置为1。每1ms检测一次SOFR中断。

在设备控制器模式下，USBHS在更新帧号时将SOFR标志设置为1。每1ms检测一次SOFR中断。即使从USB主机接收到损坏的SOF数据包，USBHS也可以通过SOF补充功能检测SOFR中断。请参阅第29.3.13节。SOF互补函数。

RESM flag (Resume Interrupt Status Flag)

In device controller mode, the USBHS sets the RESM flag to 1 on detecting the falling edge of the signal on the USBHS_DP pin in the Suspend state (PL1CTRL1.DVSQ[3:0] = 01xxb).

Values read from the RESM flag in host controller mode are invalid.

VBINT flag (VBUS Interrupt Status Flag)

The USBHS sets the VBINT flag to 1 on detecting a level change (high to low or low to high) in the USBHS_VBUS pin input value. The USBHS sets the VBSTS flag to indicate the USBHS_VBUS pin input value. When a VBINT interrupt occurs, eliminate transient elements by reading the VBSTS flag at least three times through software processing and check that the values read are the same.

RESM标志（恢复中断状态标志）

在设备控制器模式下，USBHS在检测到信号的下降沿时将RE SM标志设置为1
USBHS_DP引脚处于挂起状态(PL1CTRL1.DVSQ[3:0]=01xxb)。

在主机控制器模式下从RESM标志读取的值无效。

VBINT标志（VBUS中断状态标志）

USBHS在检测到USBHS_VBUS引脚输入值的电平变化（从高到低或从低到高）时将VBINT标志设置为1。USBHS设置VBSTS标志以指示USBHS_VBUS引脚输入值。当发生VBINT中断时，通过软件处理至少3次读取VBSTS标志来消除瞬态元素，并检查读取的值是否相同。

Bit	Symbol	Function	R/W
15	OVRCR	OVRCR Interrupt Status Flag*1 0: No OVRCR interrupt occurred 1: OVRCR interrupt occurred	R/W*2

Note: Only enable the status change interrupts indicated in the flags in INTSTS1 in host controller mode, except for the PDDET detection interrupt.

Note 1. The USBHS detects a change in the status in the PDDETINT, BCHG, or OVRCR flag even while the clock supply is stopped (LPSTS.SUSPENDM = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply before clearing the status by software. No other interrupts can be detected while the clock supply is stopped (LPSTS.SUSPENDM = 0).

Note 2. To clear the flags in INTSTS1, write 0 only to the flags to be cleared. Write 1 to the other bits.

PDDETINT flag (PDDET Detection Interrupt Status Flag)

The USBHS sets the PDDETINT flag to 1 on detecting a level change (high to low or low to high) in the PDDET pin input value. When the PDDETINT interrupt is generated, perform debouncing by reading the PDDETSTS flag at least three times through software processing and checking that the values read are the same.

SACK flag (Setup Transaction Normal Response Interrupt Status Flag)

The SACK flag indicates the status of the setup transaction normal response interrupt in host controller mode.

The USBHS detects the SACK interrupt and sets this bit to 1 when an ACK response is returned from a peripheral device during the setup transactions issued by the USBHS. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

Values read from the SACK flag in device controller mode are invalid.

SIGN flag (Setup Transaction Error Interrupt Status Flag)

The SIGN flag indicates the status of setup transaction error interrupts in host controller mode.

The USBHS detects the SIGN interrupt and sets this bit to 1 when an ACK response is not returned from a peripheral device three consecutive times during the setup transactions issued by the USBHS. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS detects the SIGN interrupt when any of the following response conditions occur for three consecutive setup transactions:

- Timeout is detected by the USBHS when the peripheral device has returned no response
- A corrupted ACK packet is received
- A handshake other than ACK (NAK, NYET, or STALL) is received

Values read from the SIGN flag in device controller mode are invalid.

EOFERR flag (EOF Error Detection Interrupt Status Flag)

The EOFERR flag indicates the status of EOF error detection interrupts in host controller mode.

The USBHS detects the EOFERR interrupt and sets this bit to 1 on detecting that communication did not complete at the EOF2 timing defined in the USB 2.0 specification. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

After detecting the EOFERR interrupt, the USBHS controls the hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt was detected to 0
- Puts the port in which the EOFERR interrupt occurred into the idle state

The software must terminate all pipes in which communications are being carried out and re-enumerate the USB port.

Values read from the EOFERR flag in device controller mode are invalid.

LPMEND flag (LPM Transaction End Interrupt Status Flag)

The PLPMEND flag indicates the status of LPM transaction end interrupts in host controller mode.

Bit	Symbol	Function	R/W
15	OVRCR	OVRCR中断状态标志*1 0：未发生OVRCR中断1：发生OVRCR中断	R/W*2

Note: 仅在主机控制器模式下启用INTSTS1中标志指示的状态更改中断，PDDET检测中断除外。

注1.即使在时钟供应停止(LPSTS.SUSPENDM=0)时，USBHS也会检测到PDDETINT、BCHG或OVRCR标志的状态变化，并在相关中断请求位为1时请求中断。使能通过软件清除状态之前的时钟供应。停止提供时钟(LPSTS.SUSPENDM=0)时无法检测到其他中断。

注2.要清除INTSTS1中的标志，只需将0写入要清除的标志。将1写入其他位。

PDDETINT标志（PDDET检测中断状态标志）

USBHS在检测到PDDET引脚输入值的电平变化（从高到低或从低到高）时将PDDETINT标志设置为1。当产生PDDETINT中断时，通过软件处理至少3次读取PDDETSTS标志并检查读取的值是否相同来执行去抖动。

SACK标志（设置事务正常响应中断状态标志）

SACK标志指示主机控制器模式下设置事务正常响应中断的状态。

在USBHS发出的设置事务期间，当外围设备返回ACK响应时，USBHS检测到SACK中断并将该位设置为1。如果相关的中断使能位由软件设置为1，则USBHS产生中断。

在设备控制器模式下从SACK标志读取的值无效。

SIGN标志（设置事务错误中断状态标志）

SIGN标志指示主机控制器模式下设置事务错误中断的状态。

在USBHS发出的设置事务期间，如果外围设备连续3次没有返回ACK响应，则USBHS检测到SIGN中断并将该位设置为1。如果相关的中断使能位由软件设置为1，则USBHS产生中断。

当三个连续的设置事务发生以下任何响应条件时，USBHS检测到SIGN中断：

- ●当外围设备没有返回响应时，USBHS检测到超时
- ●收到损坏的ACK数据包
- ●收到ACK（NAK、NYET或STALL）以外的握手

在设备控制器模式下从SIGN标志读取的值无效。

EOFERR标志（EOF错误检测中断状态标志）

EOFERR标志指示主机控制器模式下EOF错误检测中断的状态。

USBHS检测到EOFERR中断并在检测到通信未完成时将该位设置为1
USB2.0规范中定义的EOF2时序。如果相关的中断使能位由软件设置为1，则USBHS产生中断。

检测到EOFERR中断后，USBHS对硬件进行如下控制，而不考虑相关的中断使能位设置：

- ●将检测到EOFERR中断的端口的DVSTCTR0.UACT位设置为0
- ●将发生EOFERR中断的端口置于空闲状态

软件必须终止正在执行通信的所有管道并重新枚举USB端口。

在设备控制器模式下从EOFERR标志读取的值无效。

LPMEND标志（LPM事务结束中断状态标志）

PLPMEND标志指示主机控制器模式下LPM事务结束中断的状态。

When the HL1CTRL1.L1REQ bit sets to 1, the USBHS sends an LPM token. When the LPM transaction is ended because a response from the function device or a timeout is detected, the USBHS sets this flag to 1.

Values read from the LPMEND flag in device controller mode are invalid.

L1RSMEND flag (L1 Resume End Interrupt Status Flag)

The L1RSMEND flag indicates the status of L1 resume end interrupts in host controller mode.

When performing resume processing after transitioning to the L1 state because an ACK was received in response to an LPM token, the USBHS sets this flag to 1.

Values read from the L1RSMEND flag in device controller mode are invalid.

ATTCH flag (USB Connection Detection Interrupt Status Flag)

The ATTCH flag indicates the status of USB attach detection interrupts in host controller mode.

The USBHS detects the ATTCH interrupt and sets this bit to 1 on detecting a J- or K-state on the full- or low-speed signal level for 2.5 µs. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS detects the ATTCH interrupt on any of the following conditions:

- K-state, SE0, or SE1 changes to J-state, and J-state continues for 2.5 µs
- J-state, SE0, or SE1 changes to K-state, and K-state continues for 2.5 µs

Values read from the ATTCH flag in device controller mode are invalid.

DTCH flag (USB Disconnection Detection Interrupt Status Flag)

The DTCH flag indicates the status of USB detach detection interrupts in host controller mode.

The USBHS detects the DTCH interrupt and sets this bit to 1 on detecting a USB bus detach event. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS detects bus detach events based on the USB 2.0 specification.

After detecting the DTCH interrupt, the USBHS controls hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt was detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state

The software must terminate all pipes in which communications are being carried out and invoke the wait state for attaching to the USB port (waiting for ATTCH interrupt generation).

Values read from the DTCH flag in device controller mode are invalid.

BCHG flag (USB Bus Change Interrupt Status Flag)

The BCHG flag indicates the status of USB bus change interrupts in host controller mode.

The USBHS detects the BCHG interrupt and sets this bit to 1 when a change in the full-speed signal level occurs on the USB port. This includes any change from J-state, K-state, or SE0 to J-state, K-state, or SE0. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS sets the SYSSTS0.LNST[1:0] flags to indicate the input state of the USB port. When a BCHG interrupt occurs, eliminate transient elements by repeat reading the LNST[1:0] bits by software until the same value is read at least three times.

Changes in the USB bus state can be detected while the PHY clock is stopped.

Values read from the BCHG flag in device controller mode are invalid.

OVRCR flag (OVRCR Interrupt Status Flag)

The OVRCR flag indicates the input status on the USBHS_OVCUR0A pin or changes on the USBHS_OVCUR0B pin. If the INTENB1.OVRCRE bit sets to 1, the USBHS requests the interrupt.

The USBHS sets the SYSSTS0.OVCMON[1:0] flags to indicate the input state of the USBHS_OVCUR0A and USBHS_OVCUR0B pins.

当HL1CTRL1.L1REQ位设置为1时，USBHS发送一个LPM令牌。当LPM事务因检测到来自功能设备的响应或超时而结束时，USBHS将此标志设置为1。

在设备控制器模式下从LPMEND标志读取的值无效。

L1RSMEND标志（L1恢复结束中断状态标志）

L1RSMEND标志指示主机控制器模式下L1恢复结束中断的状态。

在转换到L1状态后执行恢复处理时，因为接收到响应LPM令牌的ACK，USBHS将此标志设置为1。

在设备控制器模式下从L1RSMEND标志读取的值无效。

ATTCH标志（USB连接检测中断状态标志）

ATTCH标志指示主机控制器模式下USB连接检测中断的状态。

USBHS检测到ATTCH中断，并在检测到全速或低速信号电平上的JorK状态持续2.5µs时将该位设置为1。如果相关的中断使能位由软件设置为1，则USBHS产生中断。

USBHS在以下任何条件下检测ATTCH中断：

- K-state、SE0或SE1变为J-state，J-state持续2.5µs
- J-state、SE0或SE1变为K-state，K-state持续2.5µs

在设备控制器模式下从ATTCH标志读取的值无效。

DTCH标志（USB断开检测中断状态标志）

DTCH标志指示主机控制器模式下USB分离检测中断的状态。

USBHS检测到DTCH中断并在检测到USB总线分离事件时将该位设置为1。如果相关的中断使能位由软件设置为1，则USBHS产生中断。

USBHS根据USB2.0规范检测总线分离事件。

检测到DTCH中断后，USBHS对硬件进行如下控制，而不管相关的中断使能位设置如何：

- 将检测到DTCH中断的端口的DVSTCTR0.UACT位设置为0
- 将发生DTCH中断的端口置于空闲状态

软件必须终止正在执行通信的所有管道并调用等待状态以连接到USB端口（等待ATTCH中断生成）。

在设备控制器模式下从DTCH标志读取的值无效。

BCHG标志（USB总线更改中断状态标志）

BCHG标志指示主机控制器模式下USB总线更改中断的状态。

当全速信号电平发生变化时，USBHS检测到BCHG中断并将该位设置为1。
USB端口。这包括从J-state、K-state或SE0到J-state、K-state或SE0的任何更改。如果相关的中断使能位由软件设置为1，则USBHS产生中断。

USBHS设置SYSSTS0.LNST[1:0]标志以指示USB端口的输入状态。当发生BCHG中断时，通过软件重复读取LNST[1:0]位来消除瞬态元素，直到至少读取3次相同的值。

当PHY时钟停止时，可以检测到USB总线状态的变化。

在设备控制器模式下从BCHG标志读取的值无效。

OVRCR标志（OVRCR中断状态标志）

OVRCR标志指示USBHS_OVCUR0A引脚上的输入状态或USBHS_OVCUR0B引脚上的变化。如果INTENB1.OVRCRE位设置为1，则USBHS请求中断。

USBHS设置SYSSTS0.OVCMON[1:0]标志以指示USBHS_OVCUR0A的输入状态和
USBHS_OVCUR0B pins.

These pins allow overcurrent detection by software in host controller mode. To implement this function, connect the overcurrent signal from the external power supply IC that supplies VBUS to connected USB devices to the OVCUR0A or OVCUR0B pin. On detection of an OVRCR interrupt, eliminate transients by repeatedly reading the OVCMON[1:0] flags through the software until the same value is read at least three times.

这些引脚允许在主机控制器模式下通过软件进行过流检测。要实现此功能，请将来自为所连接的USB设备提供VBUS的外部电源IC的过流信号连接到OVCUR0A或OVCUR0B引脚。在检测到OVRCR中断时，通过软件重复读取OVCMON[1:0]标志来消除瞬变，直到至少读取相同的值3次。

Note 1. The OVRN flag is for debugging. Design the timing so that no overrun or underrun occurs in the system.

FRNM[10:0] flags (Frame Number Flag)

The USBHS sets the FRNM[10:0] flags to indicate the latest frame number, which is updated every 1 ms, when an SOF packet is issued or received.

CRCE flag (CRC Error Detection Status Flag)

The CRCE flag sets to 1 when a CRC error or bit stuffing error occurs during isochronous transfer. On detecting a CRC error, the USBHS generates an internal NRDY interrupt.

To clear the CRCE flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

29.2.22 BEMPSTS:BEMP中断状态寄存器

FRNM[10:0]标志（帧号标志）

USBHS设置FRNM[10:0]标志以指示最新的帧号，该帧号每1ms更新一次，当发出或接收SOF数据包时。

CRCE标志（CRC错误检测状态标志）

当同步传输期间发生CRC错误或位填充错误时，CRCE标志设置为1。在检测到CRC错误时，USBHS产生一个内部NRDY中断。

要清除CRCE标志，向其写入0，同时向FRMNUM寄存器中的其他位写入1。

OVRN flag (Overrun/Underrun Detection Status Flag)

The OVRN flag sets to 1 when an overrun or underrun error occurs during isochronous transfer. To clear the flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

In host controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the time to issue an OUT token comes before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the time to issue an IN token comes when no FIFO buffer planes are empty

In device controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the IN token is received before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the OUT token is received when no FIFO buffer planes are empty

Read these bits repeatedly until the same value is read twice.

29.2.25 USBADDR : USB Address Register

DIR位（传输方向）

在主机控制器模式下，DIR位设置控制传输的数据阶段和状态阶段的传输方向。在设备控制器模式下，将DIR位设置为0。

SHTNAK bit (Pipe Blocking on End of Transfer)

The SHTNAK bit specifies whether to change PID to NAK on transfer end when the selected pipe is receiving. It is only valid when the selected pipe is receiving.

When the SHTNAK bit is 1, the USBHS changes the DCPCTR.PID[1:0] bits for the DCP to NAK on determining that a transfer has ended. The USBHS determines transfer end on the following condition:

- A short packet, including a zero-length packet, is successfully received

CNTMD bit (Continuous Transfer Mode)

The CNTMD bit indicates whether transfer through the default control pipe is in continuous transfer mode.

Note 1. Only set the MXPS[6:0] bits while PID is NAK. Before setting this bit, check that the CSSTS and PBUSY bits are 0, and then change the DCPCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK), and the CFIFOSEL.CURPIPE[3:0] bits to 0000b. If the DCPCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY bits through software is not necessary. After the MXPS[6:0] bits are set and the DCP is set to the CURPIPE[3:0] bits in a port select register, clear the buffer by setting the BCLR bit the port control register to 1.

Note 2. Only set the DEVSEL[3:0] bits while PID is NAK and the DCPCTR.SUREQ bits are 0. Before setting these bits, check that the CSSTS and PBUSY flags are 0, and then change the DCPCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK), and the DCPCTR.SUREQ[3:0] bits to 0. If the DCPCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY bits through software is not necessary.

MXPS[6:0] bits (Maximum Packet Size)

The MXPS[6:0] bits specify the maximum data payload (maximum packet size) for the DCP. The initial value is 0x40 (64 bytes). Set the bits to a USB 2.0-compliant value. Do not write to the FIFO buffer or set PID = BUF while MXPS[6:0] is set to 0.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target peripheral device for a control transfer. Set up the device address in the associated DEVADDn (n = 0 to A) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0010b, for example, first set the address in the DEVADD2 register. In device controller mode, set these bits to 0000b.

SHTNAK位（传输结束时的管道阻塞）

SHTNAK位指定当所选管道正在接收时，是否在传输结束时将PID更改为NAK。仅在所选管道正在接收时有效。

当SHTNAK位为1时，USBHS在确定传输已经结束时将DCPCR.PID[1:0]位更改为NAK。USBHS在以下条件下确定传输结束：

●成功接收短包，包括零长度包

CNTMD位（连续传输模式）

CNTMD位指示通过默认控制管道的传输是否处于连续传输模式。

注1.仅在PID为NAK时设置MXPS[6:0]位。在设置该位之前，检查CSSTS和PBUSY位是否为0，然后将DCPCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)，以及CFIFOSEL.CURPIPE[3:0]位到0000b。如果DCPCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查CSSTS和PBUSY位。在设置MXPS[6:0]位并将DCP设置为端口选择寄存器中的CURPIPE[3:0]位后，通过将端口控制寄存器的BCLR位设置为1来清除缓冲区。

注2.仅在PID为NAK且DCPCTR.SUREQ位为0时设置DEVSEL[3:0]位。在设置这些位之前，请检查CSSTS和PBUSY标志为0，然后将DCPCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)，然后DCPCTR.SUREQ[3:0]位为0。如果DCPCTR.PID[1:0]位被USBHS更改为00b(NAK)，请检查CSSTS和不需要通过软件进行PBUSY位。

MXPS[6:0]位（最大数据包大小）

MXPS[6:0]位指定DCP的最大数据有效载荷（最大数据包大小）。初始值为0x40（64字节）。将这些位设置为符合USB2.0的值。当MXPS[6:0]设置为0时，不要写入FIFO缓冲区或设置PID=BUF。

DEVSEL[3:0] bits (Device Select)

在主机控制器模式下，DEVSEL[3:0]位指定目标外围设备的地址以进行控制传输。首先在相关的DEVADDn（n=0到A）寄存器中设置设备地址，然后将这些位设置为相应的值。例如，要将DEVSEL[3:0]位设置为0010b，首先要设置DEVADD2寄存器中的地址。在设备控制器模式下，将这些位设置为0000b。

PID[1:0] bits (Response PID)

The PID[1:0] bits control the USB response type during control transfers.

In host controller mode, to change the PID[1:0] setting from NAK to BUF:

- When the transmitting direction is set:
  a. Write all of the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  b. Set PID[1:0] bits to 01b (BUF).
  The USBHS then executes the OUT transaction (or PING transaction)
- When the receiving direction is set:
  a. Check that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  b. Set PID[1:0] bits to 01b (BUF).
  The USBHS then executes the IN transaction.

The USBHS changes the PID[1:0] setting as follows:

- When the PID[1:0] bits are set to BUF (01b) by software and the USBHS has received data exceeding MaxPacketSize, the USBHS sets PID[1:0] to STALL (11b)
- When a reception error, such as a CRC error, is detected three times consecutively, the USBHS sets PID[1:0] to NAK (00b)
- On receiving the STALL handshake, the USBHS sets PID[1:0] to STALL (11b)

In device controller mode, the USBHS changes the PID[1:0] setting as follows:

- On receiving a setup packet, the USBHS sets PID[1:0] to NAK (00b). The USBHS then sets the INTSTS0.VALID flag to 1, and the PID[1:0] setting cannot be changed until the software clears the VALID flag to 0.
- When the PID[1:0] bits are set to BUF (01b) by software and the USBHS has received data exceeding MaxPacketSize, the USBHS sets PID[1:0] to STALL (11b)
- On detecting a control transfer sequence error, the USBHS sets PID[1:0] to STALL (1xb)
- On detecting a USB bus reset, the USBHS sets PID[1:0] to NAK

The USBHS does not check the PID[1:0] setting while processing a SET_ADDRESS request.

CCPL bit (Control Transfer End Enable)

In device controller mode, setting the CCPL bit to 1 enables the status stage of the control transfer to be completed. When the bit is set to 1 by software while the associated PID[1:0] bits are set to BUF, the USBHS completes the control transfer status stage.

During control read transfers, the USBHS transmits the ACK handshake in response to the OUT transaction from the USB host. During control write or no-data control transfers, it transmits the zero-length packet in response to the IN transaction from the USB host. On detecting a SET_ADDRESS request, the USBHS operates in auto response mode from the setup stage up to status stage completion regardless of the CCPL bit setting.

The USBHS changes the CCPL bit from 1 to 0 on receiving a new setup packet. The software cannot write 1 to the bit while the INTSTS0.VALID bit is 1. The bit is initialized by a USB bus reset.

In host controller mode, always write 0 to the CCPL bit.

PINGE bit (PING Token Issue Enable)

In host controller mode, when the software sets the PINGE bit to 1, the USBHS issues a PING token for transfer in the transmitting direction, which triggers the transfer to start. If an ACK handshake is detected in the PING transaction, the OUT transaction is executed in the next transaction. If a NAK or NYET handshake is detected in the OUT transaction, the PING transaction is executed in the next transaction.

If the software sets this bit to 0, the USBHS issues no PING token for transfer in the transmitting direction. All transfers in the transmitting direction are executed in the OUT transaction.

PID[1:0] bits (Response PID)

PID[1:0]位在控制传输期间控制USB响应类型。

在主机控制器模式下，要将PID[1:0]设置从NAK更改为BUF：

●设置传输方向时：

a. 当DVSTCTR0.UACT位为1且PID为NAK时，将所有发送数据写入FIFO缓冲区。

湾。将PID[1:0]位设置为01b(BUF)。
然后USBHS执行OUT事务（或PING事务）

●设置接收方向时：

a. 在DVSTCTR0.UACT位为1且PID为NAK时检查FIFO缓冲区是否为空（或清空缓冲区）。

湾。将PID[1:0]位设置为01b(BUF)。
然后USBHS执行IN事务。

USBHS将PID[1:0]设置更改如下：

●当PID[1:0]位被软件设置为BUF(01b)并且USBHS接收到超过MaxPacketSize的数据时，USBHS将PID[1:0]设置为STALL(11b)

●当连续3次检测到接收错误（例如CRC错误）时，USBHS将PID[1:0]设置为NAK(00b)

●在接收到STALL握手时，USBHS将PID[1:0]设置为STALL(11b)

在设备控制器模式下，USBHS将PID[1:0]设置更改如下：

●在接收到一个设置数据包时，USBHS将PID[1:0]设置为NAK(00b)。然后USBHS将INTSTS0.VALID标志设置为1，并且在软件将VALID标志清除为0之前无法更改PID[1:0]设置。

●当PID[1:0]位被软件设置为BUF(01b)并且USBHS接收到超过MaxPacketSize的数据时，USBHS将PID[1:0]设置为STALL(11b)

●在检测到控制传输序列错误时，USBHS将PID[1:0]设置为STALL(1xb)

●在检测到USB总线复位时，USBHS将PID[1:0]设置为NAK

USBHS在处理SET_ADDRESS请求时不检查PID[1:0]设置。

CCPL位（控制传输结束使能）

在设备控制器模式下，将CCPL位设置为1可以完成控制传输的状态阶段。当该位由软件设置为1且相关的PID[1:0]位设置为BUF时，USBHS完成控制传输状态阶段。

在控制读取传输期间，USBHS发送ACK握手以响应来自USB主机的OUT事务。在控制写入或无数据控制传输期间，它传输零长度数据包以响应来自USB主机的IN事务。在检测到SET_ADDRESS请求时，USBHS从设置阶段到状态阶段完成以自动响应模式运行，无论CCPL位设置如何。

USBHS在接收到新的设置数据包时将CCPL位从1更改为0。当INTSTS0.VALID位为1时，软件无法向该位写入1。该位由USB总线复位初始化。

在主机控制器模式下，始终将0写入CCPL位。

PINGE位（PING令牌发布启用）

在主机控制器模式下，当软件将PINGE位设置为1时，USBHS会发出一个PING令牌以进行传输方向的传输，从而触发传输开始。如果在PING事务中检测到ACK握手，则在 下一个事务中执行OUT事务。如果在OUT事务中检测到NAK或NYET握手，则

PING事务在下一个事务中执行。

如果软件将此位设置为0，则USBHS不会发出PING令牌以进行传输方向的传输。发送方向的所有传输都在OUT事务中执行。

PBUSY flag (Pipe Busy Flag)

The PBUSY bit indicates whether DCP is used for the transaction when USBHS changes the PID[1:0] bits from BUF to NAK. The USBHS changes the PBUSY flag from 0 to 1 on start of a USB transaction for the selected pipe. It changes the PBUSY flag from 1 to 0 on completion of one transaction.

After PID is set to NAK by software, the value in the PBUSY flag indicates whether changes to pipe settings can proceed.

For details, see section 29.3.7.1. Pipe control register switching procedures.

SQMON flag (Sequence Toggle Bit Monitor Flag)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

The USBHS toggles the bit on normal completion of the transaction. It does not toggle the bit, however, when a DATAPID mismatch occurs during a transfer in the receiving direction.

In device controller mode, the USBHS sets the SQMON bit to 1 (specifies DATA1 as the expected value) on successful reception of the setup packet.

In device controller mode, the USBHS does not reference this bit during IN or OUT transactions at the status stage, and it does not toggle the bit on normal completion.

SQSET bit (Sequence Toggle Bit Set)

The SQSET bit specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SQCLR bit (Sequence Toggle Bit Clear)

The SQCLR bit specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer. It is read as 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SUREQCLR bit (SUREQ Bit Clear)

In host controller mode, setting the SUREQCLR bit to 1 clears the SUREQ bit to 0. The bit is read as 0.

If transfer stops while the SUREQ bit is set to 1 in a setup transaction, set the SUREQCLR bit to 1 through software. This is not necessary at the end of a normal setup transaction, because the USBHS automatically clears the SUREQ bit to 0.

Only control the SUREQ bit through the SUREQCLR bit while the DVSTCTR0.UACT bit is 0. When UACT is 0, communication is halted or no transfer is occurring because a bus disconnection was detected.

In device controller mode, always write 0 to the SUREQCLR bit.

CSSTS flag (CSSTS Status Flag)

In host controller mode, the CSSTS flag indicates the complete-split state in split transactions for pipes that are not isochronous. The USBHS sets the CSSTS flag to 1 at the beginning of a complete-split transaction and sets the flag back to 0 when it detects transaction completion.

Values read from the CSSTS flag in device controller mode are invalid.

CSCLR bit (CSSTS Status Flag Clear)

In host controller mode, setting the CSCLR bit to 1 clears the CSSTS bit to 0.

Set this bit to 1 through software when forcing the next transfer to restart from start-split in transfers using split transactions. This is not necessary at the end of a successful complete-split transaction in a normal split transaction, because the USBHS automatically clears the CSSTS flag to 0.

Only control the CSSTS flag through the CSCLR bit while the DVSTCTR0.UACT bit is 0. When UACT is 0, communication is halted or no transfer is occurring because a port disconnection was detected. Writing 1 to this bit while the CSSTS flag is 0 has no effect; the flag remains 0.

In device controller mode, always write 0 to this bit.

PBUSY标志（管道忙标志）

当USBHS将PID[1:0]位从BUF更改为
纳克。USBHS在所选管道的USB事务开始时将PBUSY标志从0更改为1。它改变了
PBUSY标志在一个事务完成时从1变为0。

软件将PID设置为NAK后，PBUSY标志中的值指示是否可以继续对管道设置进行更改。

详见29.3.7.1节。管道控制寄存器切换程序。

SQMON标志（序列切换位监控标志）

SQMON位指示DCP传输期间下一个事务的序列切换位的预期值。

USBHS在事务正常完成时切换该位。但是，当在接收方向的传输过程中发生DATAPID不匹配时，它不会切换该位
。

在设备控制器模式下，USBHS在成功接收到设置数据包时将SQMON位设置为1（指定DATA1作为预期值）。

在设备控制器模式下，USBHS在状态阶段的IN或OUT事务期间不参考该位，并且在正常完成时不切换该位。

SQSET位（序列切换位设置）

SQSET位将DATA1指定为DCP传输期间下一个事务的序列切换位的预期值。

不要同时将SQCLR和SQSET位设置为1。

SQCLR位（序列翻转位清除）

SQCLR位将DATA0指定为DCP传输期间下一个事务的序列切换位的预期值。读为0。

不要同时将SQCLR和SQSET位设置为1。

SUREQCLR bit (SUREQ Bit Clear)

在主机控制器模式下，将SUREQCLR位设置为1会将SUREQ位清除为0。该位被读取为0。

如果在设置事务中将SUREQ位设置为1时传输停止，则通过软件将SUREQCLR位设置为1。这在正常设置事务结束
时不是必需的，因为USBHS会自动将SUREQ位清除为0。

当DVSTCTR0.UACT位为0时，仅通过SUREQCLR位控制SUREQ位。当UACT为0时，由于检测到总线断开，
通信停止或没有传输发生。

在设备控制器模式下，始终将0写入SUREQCLR位。

CSSTS标志（CSSTS状态标志）

在主机控制器模式下，CSSTS标志指示非同步管道的拆分事务中的完全拆分状态。USBHS在完全拆分事务开始时
将CSSTS标志设置为1，并在检测到事务完成时将该标志设置回0。

在设备控制器模式下从CSSTS标志读取的值无效。

CSCLR位（CSSTS状态标志清除）

在主机控制器模式下，将CSCLR位设置为1会将CSSTS位清零。

在使用拆分事务的传输中强制下一次传输从start-split重新启动时，通过软件将此位设置为1。
在正常拆分事务中成功完成拆分事务结束时，这不是必需的，因为USBHS会自动将CSSTS标志清除为0。

仅当DVSTCTR0.UACT位为0时，通过CSCLR位控制CSSTS标志。当UACT为0时，由于检测到端口断开，通信停
止或不发生传输。CSSTS标志为0时向该位写入1无效；标志保持为0。

在设备控制器模式下，始终向该位写入0。

SUREQ bit (SETUP Token Transmission)

In host controller mode, setting the SUREQ bit to 1 triggers the USBHS to transmit the setup packet. After completing the setup transaction process, the USBHS generates either the SACK or SIGN interrupt and clears the SUREQ bit to 0. The USBHS also clears the SUREQ bit to 0 when the software sets the SUREQCLR bit to 1.

Before setting the SUREQ bit to 1, set the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, and USBLENG appropriately to transmit the wanted USB request in the setup transaction. Also check that the PID[1:0] bits for the DCP are set to NAK. After setting the SUREQ bit to 1, do not change the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, or USBLENG until the setup transaction is complete (SUREQ bit = 1). Write 1 to the SUREQ bit only when transmitting the setup token. Otherwise, write 0.

In device controller mode, always write 0 to this bit.

BSTS flag (Buffer Status Flag)

The BSTS flag indicates the status of access to the DCP FIFO buffer. The meaning of this flag varies as follows depending on the CFIFOSEL.ISEL setting:

- When ISEL = 0, the bit indicates whether receive data can be read from the buffer
- When ISEL = 1, the bit indicates whether transmit data can be written to the buffer

Set pipes 1 to 9 using the PIPESEL, PIPECFG, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN registers (n = 0 to 9).

After selecting the pipe in the PIPESEL register, pipe functions must be set in the associated PIPECFG, PIPEMAXP, and PIPEPERI registers. PIPEnCTR, PIPEnTRE, and PIPEnTRN can be set independently of the pipe selection in this register.

PIPESEL[3:0] bits (Pipe Window Select)

The PIPESEL[3:0] bits select the pipe number associated with the PIPECFG, PIPEMAXP, and PIPEPERI registers used for data writing and reading. Selecting a pipe number in the PIPESEL[3:0] bits allows writing to and reading from PIPECFG, PIPEMAXP, and PIPEPERI associated with the selected pipe number.

When PIPESEL[3:0] = 0x0, 0 is read from all of the bits in PIPECFG, PIPEMAXP, and PIPEPERI. Writing to these bits has no effect.

SURESQ位（SETUP令牌传输）

在主机控制器模式下，将SUREQ位设置为1会触发USBHS发送设置数据包。完成设置事务处理后，USBHS产生SACK或SIGN中断并将SUREQ位清零。当软件将SUREQCLR位设置为1时，USBHS也将SUREQ位清零。

在将SUREQ位设置为1之前，将DCPMAXP.DEVSEL[3:0]位、USBREQ、USBVAL、USBINDX和USBLENG在设置事务中适当地传输所需的USB请求。还要检查DCP的PID[1:0]位是否设置为NAK。将SUREQ位设置为1后，在设置事务完成（SUREQ位=1）之前，不要更改DCPMAXP.DEVSEL[3:0]位、USBREQ、USBVAL、USBINDX或USBLENG。仅在发送设置令牌时向SUREQ位写入1。否则，写0。

在设备控制器模式下，始终向该位写入0。

BSTS标志（缓冲区状态标志）

BSTS标志指示访问DCPFIFO缓冲区的状态。根据CFIFOSEL.ISEL设置，该标志的含义如下：

- ISEL=0时，该位指示是否可以从缓冲区读取接收数据
- ISEL=1时，该位指示发送数据是否可以写入缓冲区

使用PIPESEL、PIPECFG、PIPEMAXP、PIPEPERI、PIPEnCTR、PIPEnTRE和PIPEnTRN寄存器（n=0到9）设置管道1到9。

在PIPESEL寄存器中选择管道后，必须在相关的PIPECFG、PIPEMAXP和PIPEPERI寄存器。PIPEnCTR、PIPEnTRE和PIPEnTRN可以独立于该寄存器中的管道选择进行设置。

PIPESEL[3:0]位（管道窗口选择）

PIPESEL[3:0]位选择与用于数据写入和读取的PIPECFG、PIPEMAXP和PIPEPERI寄存器相关的管道编号。在PIPESEL[3:0]位中选择一个管道编号允许写入和读取与所选管道编号相关的PIPECFG、PIPEMAXP和PIPEPERI。

当PIPESEL[3:0]=0x0时，从PIPECFG、PIPEMAXP和PIPEPERI中的所有位读取0。写入这些位无效。

Note 1. Only set the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY flags through the software is not necessary.

Note 2. Only set the BFRE, DBLB, and DIR bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

Note 3. To change the BFRE, DBLB, or DIR bit after completing USB communication on the selected pipe, in addition to the constraints described in note 2, write 1 and 0 to the PIPEnCTR.ACLRM bit continuously through software and clear the FIFO buffer assigned to the pipe.

EPNUM[3:0] bits (Endpoint Number)

The EPNUM[3:0] bits specify the endpoint number for the selected pipe. Setting 0000b indicates the pipe not used.

Set these bits so that the combination of the DIR and EPNUM[3:0] settings is different from those for other pipes. (The EPNUM[3:0] bits can be set to 0000b for all pipes.)

DIR bit (Transfer Direction)

The DIR bit specifies the transfer direction for the selected pipe.

注1.PID为NAK时，仅设置TYPE[1:0]、SHTNAK和EPNUM[3:0]位。在设置这些位之前，请检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PIPEnCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查CSSTS和PBUSY标志。

注2.仅在PID为NAK且在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置BFRE、DBLB和DIR位。在设置这些位之前，请检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PIPEnCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查PBUSY标志。

注3.在选定管道上完成USB通信后更改BFRE、DBLB或DIR位，除了约束
如注2所述，通过软件连续向PIPEnCTR.ACLRM位写入1和0，并清除分配给管道的FIFO缓冲区。

EPNUM[3:0] bits (Endpoint Number)

EPNUM[3:0]位指定所选管道的端点号。设置0000b表示管道未使用。

设置这些位，以便DIR和EPNUM[3:0]设置的组合不同于其他管道的设置。（这所有管道的EPNUM[3:0]位都可以设置为0000b。）

DIR位（传输方向）

DIR位指定所选管道的传输方向。

When the software sets this bit to 0, the USBHS uses the selected pipe for receiving. When the software sets this bit to 1, the USBHS uses the selected pipe for transmitting.

SHTNAK bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to change the PIPEnCTR.PID[1:0] bits to 00b (NAK) at the end of transfer when the selected pipe is set in the receiving direction. The bit is valid for pipes 1 to 5 in the receiving direction.

When the software sets this bit to 1 for a receiving pipe, the USBHS changes the associated PIPEnCTR.PID[1:0] bits to 00b (NAK) on determining the transfer end. The USBHS determines that the transfer has ended on the following conditions:

- Short packet data (including a zero-length packet) was successfully received
- The transaction counter is used and the number of packets specified for the transaction counter were successfully received

CNTMD bit (Continuous Transfer Mode)

The CNTMD bit specifies whether to operate the selected pipe in continuous transfer mode. The bit is valid for pipes 1 to 5 of the bulk transfer type.

Based on this bit setting, the USBHS determines the completion of transmission or reception for the FIFO buffer allocated to the selected pipe as shown in Table 29.9.

Table 29.9 Relationship between the CNTMD setting and methods for determining completion of FIFO buffer transmission or reception

CNTMD bit setting	Methods for determining readable state and transmittable state
0	Condition for FIFO buffer readable state in receiving direction (DIR = 0): ● The USBHS received one packet
	Conditions for FIFO buffer transmittable state in transmitting direction (DIR = 1): When one of the following is satisfied: 1. Software (or DMAC/DTC) wrote data of the maximum packet size to the FIFO buffer 2. Software (or DMAC/DTC) wrote data of the short packet size (including 0 bytes) to the FIFO buffer and set the BVAL flag in the port control register to 1
1	Condition for FIFO buffer readable state in receiving direction (DIR = 0): 1. The byte count of data received in the FIFO buffer allocated to the selected pipe is equal to the allocated byte count ((BUFSIZE + 1) × 64). 2. The USBHS received a short packet, other than a zero-length packet. 3. The USBHS received a zero-length packet when data was already contained in the FIFO buffer allocated to the selected pipe. 4. Software received the number of packets specified for the transaction counter set for the selected pipe.
	Conditions for FIFO buffer transmittable state in transmitting direction (DIR = 1): When one of the following is satisfied. 1. The amount of data written by software (or DMAC/DTC) is equal to the size of the FIFO buffer allocated to the selected pipe. 2. The software (or DMAC/DTC) wrote data of smaller size than that of the FIFO buffer allocated to the selected pipe (including 0 bytes) and set the BVAL flag in the port control register to 1. 3. The software (or DMAC/DTC) wrote data of smaller size than that of one FIFO buffer allocated to the selected pipe (including 0 bytes) and asserted the DENDx_N signal on the last write.

DBLB bit (Double Buffer Mode)

The DBLB bit selects either single or double buffer mode for the FIFO buffer used by the selected pipe. The bit is valid for pipes 1 to 5.

When the software sets this bit to 1, the USBHS allocates twice the FIFO buffer size specified in the PIPEBUF.BUFSIZE[5:0] bits for the selected pipe. The FIFO buffer size that the USBHS allocates to the selected pipe is as follows:

(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

BFRE bit (BRDY Interrupt Operation Specification)

The BFRE bit specifies the BRDY interrupt generation timing from the USBHS to the CPU for the selected pipe.

When the software sets the BFRE bit to 1 and the selected pipe is in the receiving direction, the USBHS detects the transfer completion and generates the BRDY interrupt on reading the packet.

当软件将此位设置为0时，USBHS使用所选管道进行接收。当软件将该位设置为1时，USBHS使用选定的管道进行传输。

SHTNAK位（传输结束时禁用管道）

SHTNAK位指定当所选管道设置为接收方向时，是否在传输结束时将PIPEnCTR.PID[1:0]位更改为00b(NAK)。该位对接收方向的管道1到5有效。

当软件将该位设置为1用于接收管道时，USBHS在确定传输结束时将相关的PIPEnCTR.PID[1:0]位更改为00b(NAK)。USBHS在以下条件下确定传输已结束：

●成功接收短包数据（包括零长度包）

●使用事务计数器，并且成功接收了为事务计数器指定的数据包数

CNTMD位（连续传输模式）

CNTMD位指定是否在连续传输模式下操作选定的管道。该位对批量传输类型的管道1到5有效。

根据该位设置，USBHS确定分配给所选管道的FIFO缓冲区的发送或接收是否完成，如表29.9所示。

Table 29.9 CNTMD设置与确定FIFO缓冲区发送或接收完成的方法之间的关系

CNTMD位设置	确定可读状态和可传输状态的方法
0	接收方向（DIR=0）FIFO缓冲区可读状态的条件：● USBHS收到一个数据包
	发送方向(DIR=1)的FIFO缓冲区可发送状态的条件： 当满足以下条件之一时：1.软件（或DMACDTC）将最大数据包大小的数据写入FIFO缓冲区2.软件（或DMACDTC）将短数据包大小（包括0字节）的数据写入FIFO缓冲区并将端口控制寄存器中的BVAL标志设置为1
1	接收方向（DIR=0）FIFO缓冲区可读状态的条件：1.分配给所选管道的FIFO缓冲区中接收到的数据字节数等于分配的字节数（（BUFSIZE+1）×64）。2.USBHS收到一个短数据包，而不是零长度数据包。3.当数据已经包含在分配给所选管道的FIFO缓冲区中时，USBHS接收到一个长度为零的数据包。4.软件接收到为选定管道设置的事务计数器指定的数据包数量。
	发送方向(DIR=1)的FIFO缓冲区可发送状态的条件： 满足以下条件之一时。1.软件（或DMACDTC）写入的数据量等于分配给所选管道的FIFO缓冲区的大小。2.软件（或DMACDTC）写入小于分配给所选管道的FIFO缓冲区大小的数据（包括0字节），并将端口控制寄存器中的BVAL标志设置为1。3.软件（或DMACDTC)写入的数据小于分配给所选管道的一个FIFO缓冲区的数据（包括0字节），并在最后一次写入时置位DENDx_N信号。

DBLB位（双缓冲模式）

DBLB位为所选管道使用的FIFO缓冲区选择单缓冲区模式或双缓冲区模式。该位对管道1到5有效。

当软件将该位设置为1时，USBHS分配两倍于所选管道的PIPEBUF.BUFSIZE[5:0]位。USBHS分配给所选管道的FIFO缓冲区大小如下：

(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

BFRE位（BRDY中断操作规范）

BFRE位为所选管道指定从USBHS到CPU的BRDY中断生成时序。

当软件将BFRE位设置为1且所选管道处于接收方向时，USBHS检测到传输完成并在读取数据包时产生BRDY中断。

RA生态工作室

When a BRDY interrupt is generated with this setting, the software must write 1 to the BCLR bit in the port control register. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to the BCLR bit.

When the BFRE bit is set to 1 by software and the selected pipe is in the transmitting direction, the USBHS does not generate the BRDY interrupt. For details, see section 29.3.6.1. BRDY interrupt.

TYPE[1:0] bits (Transfer Type)

The TYPE[1:0] bits specify the transfer type for the pipe selected in the PIPESEL.PIPESEL[3:0] bits. Before setting PID to BUF and starting USB communication on the selected pipe, set the TYPE[1:0] bits to a value other than 00b.

29.2.35 PIPEBUF : Pipe Buffer Register

15	—	The read value is undefined. The write value should be 0.	R/W

Note: Only set the bits in the PIPEBUF register while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY flags through the software is not necessary.

BUFNMB[7:0] bits (Buffer Number)

The BUFNMB[7:0] bits specify the first block number of the FIFO buffer to be allocated to the selected pipe.

The USBHS allocates the FIFO buffer blocks to the selected pipe as follows:

Block number: BUFNMB to block number: BUFNMB + (BUFSIZE + 1) × (DBLB + 1) - 1

Set a value within the memory size range for these bits (0 [0x00] to 8640 [0x87] for 8.5 KB), while observing the following conditions:

- 0x00 is for DCP only
- 0x04 is for pipe 6 only, but is available for other pipes when pipe 6 is not used. When pipe 6 is selected, writes to these bits are disabled. The USBHS automatically allocates 0x04 to the BUFNMB bits for pipe 6.
- 0x05 is for pipe 7 only, but is available for other pipes when pipe 7 is not used. When pipe 7 is selected, writes to these bits are disabled. The USBHS automatically allocates 0x05 to the BUFNMB bits for pipe 7.
- 0x06 is for pipe 8 only, but is available for other pipes when pipe 8 is not used. When pipe 8 is selected, writes to these bits are disabled. The USBHS automatically allocates 0x06 to the BUFNMB bits for pipe 8.
- 0x07 is for pipe 9 only, but is available for other pipes when pipe 9 is not used. When pipe 9 is selected, writes to these bits are disabled. The USBHS automatically allocates 0x07 to the BUFNMB bits for pipe 9.

BUFSIZE[4:0] bits (Buffer Size)

The BUFSIZE[4:0] bits specify the FIFO buffer size (number of blocks) to be allocated to the selected pipe. One block is 64 bytes.

当使用该设置产生BRDY中断时，软件必须将1写入端口控制寄存器中的BCLR位。
在将1写入BCLR位之前，分配给所选管道的FIFO缓冲区不会用于接收。

当BFRE位由软件设置为1且所选管道处于发送方向时，USBHS不会产生BRDY中断。详见29.3.6.1节。BRDY中断。

TYPE[1:0] bits (Transfer Type)

TYPE[1:0]位指定在PIPESEL.PIPESEL[3:0]位中选择的管道的传输类型。设置PID之前BUF并在所选管道上启动USB通信，将TYPE[1:0]位设置为00b以外的值。

29.2.35 PIPEBUF:管道缓冲寄存器

14:10	BUFSIZE[4:0]	缓冲区大小 0x00: 64 bytes 0x01: 128 bytes ⋮ 0x1F: 2 KB	R/W
15	—	读取值未定义。写入值应为0。	R/W

Note: 仅在PID为NAK时以及在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置PIPEBUF寄存器中的位。在设置这些位之前，请检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PIPEnCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查CSSTS和PBUSY标志。

BUFNMB[7:0] bits (Buffer Number)

BUFNMB[7:0]位指定要分配给所选管道的FIFO缓冲区的第一个块号。

USBHS将FIFO缓冲区块分配给所选管道，如下所示：

块号：BUFNMB到块号：BUFNMB+(BUFSIZE+1)×(DBLB+1)1

为这些位设置一个内存大小范围内的值（0[0x00]到8640[0x87]，对于8.5KB），同时遵守以下条件：

●0x00仅用于DCP

●0x04仅适用于管道6，但在不使用管道6时可用于其他管道。选择管道6时，将这些位写入这些位。USBHS自动将0x04分配给管道6的BUFNMB位。

●0x05仅适用于管道7，但在管道7不使用时可用于其他管道。选择管道7时，将这些位写入这些位。USBHS自动将0x05分配给管道7的BUFNMB位。

●0x06仅用于管道8，但在不使用管道8时可用于其他管道。选择管道8时，将这些位写入这些位。USBHS自动将0x06分配给管道8的BUFNMB位。

●0x07仅适用于管道9，但在不使用管道9时可用于其他管道。选择管道9时，将这些位写入这些位。USBHS自动将0x07分配给管道9的BUFNMB位。

BUFSIZE[4:0] bits (Buffer Size)

BUFSIZE[4:0]位指定要分配给所选管道的FIFO缓冲区大小（块数）。一个块是64字节。

When the software sets the DBLB bit to 1, the USBHS allocates twice the FIFO buffer size specified in these bits to the selected pipe. The DBLB = 1 setting is valid for pipes 1 to 5.

The USBHS allocates the FIFO buffer blocks to the selected pipe as follows:

(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

Set the value within the following range:

- For pipes 1 to 5, set a value from 0x00 to 0x1F (up to 2 KB)
- For pipes 6 to 9, only set a value of 0x00 (64 bytes)

29.2.36 PIPEMAXP : Pipe Maximum Packet Size Register

Note 1. The initial value of the MXPS[10:0] bits is 0x00 when no pipe is selected in the PIPESEL.PIPESEL[3:0] bits and 0x40 when a pipe is selected.

Note 2. Only set the MXPS[10:0] bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY flags through the software is not necessary.

Note 3. Only set the DEVSEL[3:0] bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

MXPS[10:0] bits (Maximum Packet Size)

The MXPS[10:0] bits specify the maximum data payload (maximum packet size) for the selected pipe.

Set these bits to the appropriate value for each transfer type based on the USB 2.0 specification. When MXPS[10:0] = 0, do not write to the FIFO buffer or set PID to BUF. These writes have no effect.

To communicate on an isochronous pipe using a split transaction, set the value in the MXPS[10:0] bits to 188 bytes or less.

当软件将DBLB位设置为1时，USBHS将这些位中指定的两倍FIFO缓冲区大小分配给所选管道。DBLB=1设置对管道1到5有效。

USBHS将FIFO缓冲区块分配给所选管道，如下所示：

(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

将值设置在以下范围内：

●对于管道1到5，设置一个从0x00到0x1F的值（最大2KB）

●对于管道6到9，仅设置值0x00（64字节）

注1.在PIPESEL.PIPESEL[3:0]位中未选择管道时，MXPS[10:0]位的初始值为0x00，选择管道时为0x40。

注2.仅在PID为NAK且在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置MXPS[10:0]位。
在设置这些位之前，检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志是否为0，然后更改PIPEnCTR.PID[1:0]位从01b(BUF)到00b(NAK)。如果PIPEnCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查CSSTS和PBUSY标志。

注3.仅在PID为NAK且在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置DEVSEL[3:0]位。
在设置这些位之前，检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志是否为0，然后更改PIPEnCTR.PID[1:0]位从01b(BUF)到00b(NAK)。如果PIPEnCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查PBUSY标志。

MXPS[10:0]位（最大数据包大小）

MXPS[10:0]位指定所选管道的最大数据有效负载（最大数据包大小）。

根据USB2.0规范将这些位设置为每种传输类型的适当值。当MXPS[10:0]=0时，不要写入FIFO缓冲区或将PID设置为BUF。这些写入没有效果。

要使用拆分事务在同步管道上进行通信，请将MXPS[10:0]位中的值设置为188字节或更少。

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target device for USB communication. Set up the device address in the associated DEVADDn (n = 0 to A) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0x2, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0x0.

29.2.37 PIPEPERI : Pipe Cycle Control Register

Base address: USBHS = 0x4011_1000

Offset address: 0x06E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]

Bit	Symbol	Function	R/W
2:0	IITV[2:0]*1	Interval Error Detection Interval Specifies the interval error detection timing for the selected pipe as the n-th power of 2 of the frame timing.	R/W
11:3	—	These bits are read as 0. The write value should be 0.	R/W
12	IFIS	Isochronous IN Buffer Flush 0: Do not flush buffer 1: Flush buffer	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only set the IITV[2:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

PIPEPERI selects whether the buffer is flushed or not when an interval error occurred during isochronous IN transfers, and sets the interval error detection interval for pipes 1 to 9.

IITV[2:0] bits (Interval Error Detection Interval)

To change the IITV[2:0] bits to another value after they are set and USB communication is performed, set the PIPEnCTR.PID[1:0] bits to 00b (NAK) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer.

The IITV[2:0] bits are not provided for pipes 3 to 5. Write 000b to bit positions of the IITV[2:0] bits associated with pipes 3 to 5.

IFIS bit (Isochronous IN Buffer Flush)

The IFIS bit specifies whether to flush the buffer when the pipe specified in the PIPESEL.PIPESEL[3:0] bits is used for isochronous IN transfers.

In device controller mode when the selected pipe is for isochronous IN transfers, the USBHS automatically clears the FIFO buffer if the USBHS fails to receive the IN token from the USB host within the interval set in the IITV[2:0] bits in terms of frames.

When double buffering is specified (PIPECFG.DBLB = 1), the USBHS only clears the data in the previously used plane.

The USBHS clears the FIFO buffer on receiving the SOF packet immediately after the frame in which the USBHS expected to receive the IN token. Even if the SOF packet is corrupted, the FIFO buffer is cleared at the time the SOF packet is expected to be received by using the internal complementation function.

In host controller mode, set the IITV[2:0] bits to 000b.

Set the IITV[2:0] bits to 000b when the selected pipe is not used for isochronous transfers.

DEVSEL[3:0] bits (Device Select)

在主机控制器模式下，DEVSEL[3:0]位指定USB通信的目标设备的地址。首先在相关的DEVADDn（n=0到A）寄存器中设置设备地址，然后将这些位设置为相应的值。例如，要将DEVSEL[3:0]位设置为0x2，首先设置DEVADD2寄存器中的地址。

在设备控制器模式下，将这些位设置为0x0。

29.2.37 PIPEPERI:管道循环控制寄存器

Base address: USBHS = 0x4011_1000

Offset address: 0x06E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

11:3	—	这些位被读取为0。写入值应为0。	R/W
12	IFIS	同步IN缓冲区刷新 0：不刷新缓冲区1： 刷新缓冲区	R/W
15:13	—	这些位被读取为0。写入值应为0。	R/W

注1.仅在PID为NAK时设置IITV[2:0]位。在设置这些位之前，请检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY flags为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PIPEnCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查PBUSY标志。

PIPEPERI选择在同步IN传输期间发生间隔错误时是否刷新缓冲区，并设置管道1到9的间隔错误检测间隔。

IITV[2:0]位（间隔错误检测间隔）

要在设置IITV[2:0]位并在执行USB通信后将其更改为另一个值，请设置PIPEnCTR.PID[1:0]位为00b(NAK)，然后将PIPEnCTR.ACLRM位设置为1以初始化间隔定时器。

不为管道3到5提供IITV[2:0]位。将000b写入与管道3到5相关联的IITV[2:0]位的位位置。

IFIS位（同步IN缓冲区刷新）

IFIS位指定当PIPESEL.PIPESEL[3:0]位中指定的管道用于同步IN传输时是否刷新缓冲区。

在设备控制器模式下，当所选管道用于同步IN传输时，如果USBHS在IITV[2:0]位设置的时间间隔内未能从USB主机接收到IN令牌，则USBHS自动清除FIFO缓冲区帧。

当指定双缓冲时（PIPECFG.DBLB=1），USBHS仅清除先前使用的平面中的数据。

在USBHS预期接收IN令牌的帧之后，USBHS在接收到SOF数据包后立即清除FIFO缓冲区。即使SOF数据包已损坏，FIFO缓冲区也会在预期接收SOF数据包时使用内部补充功能清除。

在主机控制器模式下，将IITV[2:0]位设置为000b。

当所选管道不用于同步传输时，将IITV[2:0]位设置为000b。

Note 1. Only set the ATREPM bit while PID is NAK. Before setting this bit, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

Note 2. Only set the ACLRM bit while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting this bit, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

注1.仅当PID为NAK时设置ATREPM位。在设置该位之前，检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PIPEnCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查PBUSY标志。

注2.仅在PID为NAK时和在端口选择寄存器的CURPIPE[3:0]位中选择管道之前设置ACLRM位。在设置该位之前，检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志是否为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PIPEnCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查PBUSY标志。

Note 3. The ATREPM bit and the INBUFM flag in the PIPE6CTR to PIPE9CTR registers are reserved. The read value is undefined. The write value must be 0.

PID[1:0] bits (Response PID)

The PID[1:0] bits specify the response type for the next transaction on the selected pipe.

The default PID[1:0] setting is NAK. Change the PID[1:0] setting to BUF to use the associated pipe for USB transfer. Table 29.10 and Table 29.11 show the basic operations of the USBHS (when there are no errors in the communication packets) based on the PID[1:0] bit setting.

After changing the PID[1:0] setting from BUF to NAK through the software during USB communication on the selected pipe, check that the PBUSY bit is 1 to see if USB transfer on the selected pipe has actually entered the NAK state. If the USBHS changes the PID[1:0] bits to NAK, checking the PBUSY bit through the software is not necessary.

The USBHS changes the PIPEnCTR.PID[1:0] setting in the following cases:

- The USBHS sets PID to NAK on recognizing completion of the transfer when the selected pipe is in the receiving direction and the PIPECFG.SHTNAK bit for the selected pipe is set to 1 by software
- The USBHS sets PID to STALL (11b) on receiving a data packet with a payload exceeding the maximum packet size of the selected pipe
- The USBHS sets PID to NAK on detecting a USB bus reset in device controller mode
- The USBHS sets PID to NAK on detecting a reception error, such as a CRC error, three consecutive times in host controller mode
- The USBHS sets PID to STALL (11b) on receiving the STALL handshake in host controller mode

To specify the response type, set the PID[1:0] bits as follows:

- To transition from NAK (00b) to STALL, set 10b
- To transition from BUF (01b) to STALL, set 11b
- To transition from STALL (11b) to NAK, set 10b and then 00b
- To transition from STALL to BUF, set 00b (NAK) and then 01b (BUF)

Table 29.10 Operation of the USBHS based on the PIPEnCTR.PID[1:0] setting in host controller mode

PID[1:0] value	Transfer type (TYPE[1:0] value)	Transfer direction (DIR value)	USBHS operation
00b (NAK)	Does not depend on the setting	Does not depend on the setting	Does not issue tokens
01b (BUF)	Bulk or Interrupt	Does not depend on the setting	Issues tokens when the DVSTCTR0.UACT bit is 1 and the FIFO buffer associated with the selected pipe is ready for transmission and reception. Does not issue tokens when the DVSTCTR0.UACT bit is 0 or the FIFO buffer associated with the selected pipe is not ready for transmission or reception.
	Isochronous	Does not depend on the setting	Issues tokens when the DVSTCTR0.UACT bit is 1, regardless of the state of the FIFO buffer associated with the selected pipe. Does not issue tokens when UACT = 0.
10b (STALL) or 11b (STALL)	Does not depend on the setting	Does not depend on the setting	Does not issue tokens.

注3.PIPE6CTR至PIPE9CTR寄存器中的ATREPM位和INBUFM标志被保留。读取值未定义。写入值必须为0。

PID[1:0] bits (Response PID)

PID[1:0]位指定所选管道上下一个事务的响应类型。

默认PID[1:0]设置为NAK。将PID[1:0]设置更改为BUF以使用关联的管道进行USB传输。表29.10和表29.11显示了基于PID[1:0]位设置的USBHS的基本操作（通信数据包中没有错误时）。

在选定管道上进行USB通信期间，通过软件将PID[1:0]设置从BUF更改为NAK后，检查PBUSY位是否为1，以查看选定管道上的USB传输是否真正进入了NAK状态。如果USBHS将PID[1:0]位更改为NAK，则无需通过软件检查PBUSY位。

USBHS在以下情况下更改PIPEnCTR.PID[1:0]设置：

●USBHS设置为NAK，以识别所选管道处于接收方向和PIPECFG.SHTNAK位时，将所选管道设置为1bySoffate

●USBHS在接收到负载超过所选管道最大数据包大小的数据包时将PID设置为STALL(11b)

●USBHS在设备控制器模式下检测到USB总线复位时将PID设置为NAK

●USBHS在主机控制器模式下连续3次检测到接收错误（例如CRC错误）时将PID设置为NAK

●USBHS在主机控制器模式下接收到STALL握手时将PID设置为STALL(11b)

要指定响应类型，请按如下方式设置PID[1:0]位：

●要从NAK(00b)转换到STALL，设置10b

●要从BUF(01b)转换到STALL，设置11b

●要从STALL(11b)转换为NAK，请设置10b，然后设置00b

●要从STALL转换到BUF，请设置00b(NAK)，然后设置01b(BUF)

PBUSY flag (Pipe Busy Flag)

The PBUSY flag indicates whether the selected pipe is being used for the current transaction.

The USBHS changes the PBUSY bit from 0 to 1 on start of the USB transaction for the selected pipe, and changes the PBUSY bit from 1 to 0 on completion of one transaction.

Reading the PBUSY bit by software after PID is set to NAK allows you to check whether changing the pipe setting is possible. For details, see section 29.3.7.1. Pipe control register switching procedures.

	Isochronous	不依赖于设置。	响应来自USB主机的令牌，不返回任何内容

PBUSY标志（管道忙标志）

PBUSY标志指示所选管道是否正在用于当前事务。

USBHS在所选管道的USB事务开始时将PBUSY位从0更改为1，并更改PBUSY位在一个事务完成时从1变为0。

在PID设置为NAK后，通过软件读取PBUSY位可以检查是否可以更改管道设置。详见29.3.7.1节。管道控制寄存器切换程序。

SQMON flag (Sequence Toggle Bit Monitor Flag)

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.

When the selected pipe is not the isochronous transfer type, the USBHS toggles the SQMON flag on successful completion of the transaction. However, the USBHS does not toggle the SQMON flag when a DATA-PID mismatch occurs during transfer in the receiving direction.

SQSET bit (Sequence Toggle Bit Set)

Setting the SQSET bit to 1 through the software causes the USBHS to set DATA1 as the expected value of the sequence toggle bit for the next transaction on the selected pipe.

SQCLR bit (Sequence Toggle Bit Clear)

Setting the SQCLR bit to 1 through the software causes the USBHS to clear the expected value of the sequence toggle bit for the next transaction on the selected pipe to DATA0.

In host controller mode, when this bit is set to 1 for a bulk OUT transfer pipe, the USBHS starts the next transfer for the selected pipe from a PING token.

ACLRM bit (Auto Buffer Clear Mode)

The ACLRM bit enables or disables auto buffer clear mode for the selected pipe. To completely clear the data in the FIFO buffer allocated to the selected pipe, write 1 and then 0 to the ACLRM bit continuously.

Table 29.12 shows the data cleared by writing 1 and 0 continuously to the ACLRM bit and the cases in which this processing is required.

Table 29.12 Data cleared by the USBHS when ACLRM = 1

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear
1	All data in the FIFO buffer allocated to the selected pipe (two FIFO buffers in double buffer mode)	When clearing all data in the FIFO buffer allocated to the selected pipe
2	Interval count value when the selected pipe is the isochronous transfer type	When resetting the interval count value

ATREPM bit (Auto Response Mode)

The ATREPM bit enables or disables auto response mode for the selected pipe.

This bit can be set to 1 in device controller mode when the selected pipe is the bulk transfer type. When the bit is set to 1, the USBHS responds to the token from the USB host as follows:

- When the selected pipe is set for bulk IN transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 1):
  - When the ATREPM bit = 1 and PID = BUF, the USBHS transmits a zero-length packet in response to the IN token.
  - The USBHS updates (allows toggling of) the sequence toggle bit (DATA-PID) each time the USBHS receives ACK from the USB host. In a single transaction, the IN token is received, a zero-length packet is transmitted, and then ACK is received. The USBHS does not generate the BRDY or BEMP interrupt.
- When the selected pipe is set for bulk OUT transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 0):
  When the ATREPM bit = 1 and PID = BUF, the USBHS returns NAK in response to the OUT token or PING token and generates an NRDY interrupt.

For USB communication in auto response mode, set the ATREPM bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode. When the selected pipe uses isochronous transfer, always set this bit to 0.

In host controller mode, always set the ATREPM bit to 0.

CSSTS flag (CSSTS Status Flag)

In host controller mode, the CSSTS flag indicates the complete-split status of a split transaction. It is valid for pipes that are not the isochronous transfer type.

The USBHS sets the CSSTS flag to 1 at the beginning of the complete-split transaction, and sets the CSSTS flag to 0 on detecting completion of the complete-split transaction. If a detach event is detected during the transaction, the CSSTS flag might stay set to 1. In this case, clear the CSSTS flag by setting the CSCLR bit to 1.

SQMON标志（序列切换位监控标志）

SQMON标志指示所选管道的下一个事务的序列切换位的预期值。

当所选管道不是同步传输类型时，USBHS在事务成功完成时切换SQMON标志。但是，当在接收方向的传输过程中发生DATA-PID不匹配时，USBHS不会触发SQMON标志。

SQSET位（序列切换位设置）

通过软件将SQSET位设置为1会导致USBHS将DATA1设置为所选管道上下一个事务的序列切换位的预期值。

SQCLR位（序列翻转位清除）

通过软件将SQCLR位设置为1会导致USBHS将所选管道上下一个事务的序列切换位的预期值清除为DATA0。

在主机控制器模式下，当该位为批量OUT传输管道设置为1时，USBHS从PING令牌开始选定管道的下一次传输。

ACLRM位（自动缓冲区清除模式）

ACLRM位启用或禁用所选管道的自动缓冲区清除模式。要完全清除分配给所选管道的FIFO缓冲区中的数据，请向ACLRM位连续写入1和0。

表29.12显示了通过向ACLRM位连续写入1和0来清除的数据以及需要进行此处理的情况。

Table 29.12 当ACLRM=1时USBHS清除的数据

Number	通过设置ACLRM位清除数据	需要数据清楚的情况
1	FIFO缓冲区中的所有数据分配给所选管道（双缓冲区模式下的两个FIFO缓冲区）	清除分配给所选管道的FIFO缓冲区中的所有数据时
2	选择管道为等时传输类型时的间隔计数值	重置间隔计数值时

ATREPM位（自动响应模式）

ATREPM位启用或禁用所选管道的自动响应模式。

当所选管道为批量传输类型时，该位可以在设备控制器模式下设置为1。当该位设置为1时，USBHS响应来自USB主机的令牌，如下所示：

●Whentheselectedpipeissetforbulk INtransfers(PIPECFG.TYPE[1:0]=01bandPIPECFG.DIR=1):

当ATREPM位=1且PID=BUF时，USBHS发送一个长度为零的数据包以响应IN令牌。

每次USBHS从USB主机接收到ACK时，USBHS都会更新（允许切换）序列切换位(DATA-PID)。在单个事务中，收到IN令牌，发送零长度数据包，然后收到ACK。USBHS不会产生BRDY或BEMP中断。

●当所选管道设置为批量OUT传输时（PIPECFG.TYPE[1:0]=01b和PIPECFG.DIR=0）：
当ATREPM位=1且PID=BUF时，USBHS返回NAK以响应OUT令牌或PING令牌并产生NRDY中断。

对于自动响应模式下的USB通信，当FIFO缓冲区为空时，将ATREPM位设置为1。在自动响应模式下的USB通信期间不要写入FIFO缓冲区。当所选管道使用同步传输时，始终将此位设置为0。

在主机控制器模式下，始终将ATREPM位设置为0。

CSSTS标志（CSSTS状态标志）

在主机控制器模式下，CSSTS标志指示拆分事务的完全拆分状态。它对非同步传输类型的管道有效。

USBHS在完成拆分事务开始时将CSSTS标志设置为1，并在检测到完成拆分事务完成时将CSSTS标志设置为0。如果在事务期间检测到分离事件，CSSTS标志可能保持设置为1。在这种情况下，通过将CSCLR位设置为1来清除CSSTS标志。

Values read from the CSSTS flag in device controller mode are invalid.

CSCLR bit (CSPLIT Status Clear)

In host controller mode, if the software sets the CSCLR bit to 1, the USBHS clears the CSSTS flag to 0. In split transactions, set the CSCLR bit to 1 by software to force the next transfer to restart from start-split. Because the USBHS automatically clears the CSSTS flag to 0 at the end of a successful complete-split transaction in a normal split transaction, clearing the flag through software is not required. Only clear the CSSTS flag using the CSCLR bit when the DVSTCTR0.UACT bit is set to 0 or when no transfer was made after a detach detect. If the CSCLR bit is set to 1 while the CSSTS flag is 0, the CSSTS flag remains 0.

In device controller mode, always write 0 to the CSCLR bit.

INBUFM flag (Transmit Buffer Monitor Flag)

The INBUMFM flag indicates the FIFO buffer status for the selected pipe in the transmitting direction.

When the selected pipe is set in the transmitting direction (PIPECFG.DIR = 1), the USBHS sets this bit to 1 when the CPU or DMA/DTC completes writing data to at least one FIFO buffer plane.

The USBHS sets this bit to 0 when the USBHS completes transmission of data from the FIFO buffer plane to which all the data is written. In double buffer mode (PIPECFG.DBLB = 1), the USBHS sets the INBUFM flag to 0 when the USBHS completes transmission of data from the two FIFO buffer planes before the CPU or DMA/DTC completes writing data to one FIFO buffer plane.

The INBUFM flag indicates the same value as the BSTS flag when the selected pipe is in the receiving direction (PIPECFG.DIR = 0).

BSTS flag (Buffer Status Flag)

The BSTS flag indicates the FIFO buffer status for the selected pipe. The meaning of the BSTS flag depends on the PIPECFG.DIR, PIPECFG.BFRE, and DnFIFOSEL.DCLRM settings, as shown in Table 29.13.

Table 29.13 BSTS flag operation

DIR value	BFRE value	DCLRM value	Meaning of BSTS flag
0	0	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read
		1	Setting prohibited
	1	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 when the software sets the BCLR bit in the port control register to 1 after the data read is complete
		1	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read
1	0	0	Sets to 1 when transmit data can be written to the FIFO buffer, and clears to 0 on completion of data write

	1	0	Setting prohibited

Value after reset:	x	x	x	x	x	x	0	0	x	x	x	x	x	x	x	x

在设备控制器模式下从CSSTS标志读取的值无效。

CSCLR位（CSPLIT状态清除）

在主机控制器模式下，如果软件将CSCLR位设置为1，则USBHS将CSSTS标志清除为0。在拆分事务中，通过软件将CSCLR位设置为1，以强制下一次传输从start-split重新开始。由于USBHS在正常拆分事务中成功完成拆分事务结束时会自动将CSSTS标志清零，因此不需要通过软件清除该标志。仅当DVSTCTR0.UACT位设置为0或在分离检测后未进行传输时，才使用CSCLR位清除CSSTS标志。如果CSCLR位设置为1，而

CSSTS标志为0，CSSTS标志保持为0。

在设备控制器模式下，始终将0写入CSCLR位。

INBUFM标志（发送缓冲区监控标志）

INBUMFM标志指示发送方向上所选管道的FIFO缓冲区状态。

当所选管道设置为发送方向(PIPECFG.DIR=1)时，当CPU或DMADTC完成将数据写入至少一个FIFO缓冲区平面时，USBHS将该位设置为1。

当USBHS完成从写入所有数据的FIFO缓冲区平面的数据传输时，USBHS将该位设置为0。在双缓冲模式(PIPECFG.DBLB=1)中，当USBHS在CPU或DMADTC完成将数据写入一个FIFO缓冲平面之前完成从两个FIFO缓冲平面的数据传输时，USBHS将INBUFM标志设置为0。

当所选管道处于接收方向时（PIPECFG.DIR=0），INBUFM标志表示与BSTS标志相同的值。

BSTS标志（缓冲区状态标志）

BSTS标志指示所选管道的FIFO缓冲区状态。BSTS标志的含义取决于PIPECFG.DIR、PIPECFG.BFRE和DnFIFOSEL.DCLRM设置，如表29.13所示。

Table 29.13 BSTS标志操作

方向值	BFRE value	DCLRM value	BSTS标志的含义

		1	当接收数据可以从FIFO缓冲区读取时设置为1，并在数据读取完成时清除为0
1	0	0	当发送数据可以写入FIFO缓冲区时设置为1，并在数据写入完成时清除为0
		1	禁止设定
	1	0	禁止设定

29.2.39 PIPEnTRE:管道n事务计数器启用寄存器(n=1到5)

9	TRENB	Transaction Counter Enable 0: Disable transaction counter 1: Enable transaction counter	R/W
15:10	—	The read values are undefined. The write value should be 0.	R/W

Note: Only change the PIPEnTRE register settings while the PIPEnCTR.CSSTS flag is 0 and the PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY and PIPEnCTR.CSSTS flags is 0. However, software processing to check the PIPEnCTR.PBUSY flag is not required if the USBHS has changed the PID[1:0] bits to 00b (NAK response).

TRCLR bit (Transaction Counter Clear)

When the TRCLR bit sets to 1, the USBHS clears the count value of the transaction counter associated with the selected pipe and then clears the TRCLR bit to 0.

TRENB bit (Transaction Counter Enable)

The TRENB bit enables or disables the transaction counter.

For receiving pipes, setting the TRENB bit to 1 after setting the total number of the packets to be received in the PIPEnTRN.TRNCNT[15:0] bits through the software allows the USBHS to control hardware on having received the number of packets equal to the TRNCNT[15:0] setting as follows:

- When the PIPECFG.SHTNAK bit is 1, the USBHS changes the PID bits to NAK for the associated pipe on having received the number of packets equal to the TRNCNT[15:0] setting
- When the PIPECFG.BFRE bit is 1, the USBHS asserts the BRDY interrupt on having received the number of packets equal to the TRNCNT[15:0] setting and then reading the last received data.

For transmitting pipes, set the TRENB bit to 0.

When the transaction counter is not used, set this bit to 0. When the transaction counter is used, set the TRNCNT[15:0] bits before setting this bit to 1. Set this bit to 1 before receiving the first packet to be counted by the transaction counter.

29.2.40 PIPEnTRN : Pipe n Transaction Counter Register (n = 1 to 5)

When PIPEnTRE.TRENB is 1, indicates the current transaction count.	R/W

Note 1. Only set the TRNCNT[15:0] bits while PID is NAK and PIPEnTRE.TRENB is 0. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

The PIPEnTRN registers retain their settings during a USB bus reset.

TRCLR位（事务计数器清零）

当TRCLR位设置为1时，USBHS清除与所选管道关联的事务计数器的计数值，然后将TRCLR位清除为0。

TRENB位（事务计数器使能）

TRENB位启用或禁用事务计数器。

对于接收管道，在设置接收管道的总包数后，将TRENB位设置为1
PIPEnTRN.TRNCNT[15:0]位通过软件允许USBHS在接收到等于TRNCNT[15:0]设置的数据包数量时控制硬件，如下所示：

●当PIPECFG.SHTNAK位为1时，USBHS在接收到等于TRNCNT[15:0]设置的数据包数量时将关联管道的PID位更改为NAK

●当PIPECFG.BFRE位为1时，USBHS在接收到等于TRNCNT[15:0]设置的数据包数量并读取最后接收到的数据时触发BRDY中断。

对于传输管道，将TRENB位设置为0。

当不使用事务计数器时，将该位设置为0。当使用事务计数器时，将该位设置为1之前设置TRNCNT[15:0]位。在接收第一个要计数的数据包之前将该位设置为1由交易柜台。

注1.仅当PID为NAK且PIPEnTRE.TRENB为0时设置TRNCNT[15:0]位。在设置这些位之前，请检查PIPEnCTR.CSSTS和PIPEnCTR.PBUSY标志为0，然后将PIPEnCTR.PID[1:0]位从01b(BUF)更改为00b(NAK)。如果PIPEnCTR.PID[1:0]位被USBHS更改为00b(NAK)，则无需通过软件检查PBUSY标志。

PIPEnTRN寄存器在USB总线复位期间保留其设置。

TRNCNT[15:0] bits (Transaction Counter)

The USBHS increments the value of the TRNCNT[15:0] bits by one when all of the following conditions are satisfied on receiving the packet:

- The PIPEnTRE.TRENB bit is 1
- (TRNCNT[15:0] set value ≠ current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[8:0] setting

The USBHS clears the value of the TRNCNT[15:0] bits to 0 when any of the following conditions is satisfied.

All of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value = current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[8:0] setting

Both the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The USBHS received a short packet

Both the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The PIPEnTRE.TRCLR bit was set to 1 by software

For transmitting pipes, set the TRNCNT[15:0] bits to 0. When the transaction counter is not used, set the TRNCNT[15:0] bits to 0.

Setting the number of transactions to be transferred to the TRNCNT[15:0] bits is enabled only when the PIPEnTRE.TRENB bit is 0. To set the number of transactions to be transferred, set the TRCLR bit to 1 to clear the current counter value before setting the PIPEnTRE.TRENB bit to 1.

当接收到数据包时满足以下所有条件时，USBHS将TRNCNT[15:0]位的值加一：

●PIPEnTRE.TRENB位为1
●(TRNCNT[15:0]设定值≠当前计数器值+1)收到数据包
●接收数据包的有效载荷与PIPEMAXP.MXPS[8:0]设置一致

当满足以下任一条件时，USBHS将TRNCNT[15:0]位的值清零。

满足以下所有条件：

●PIPEnTRE.TRENB位=1
●(TRNCNT[15:0]setvalue=currentcountervalue+1)收到数据包
●接收数据包的有效载荷与PIPEMAXP.MXPS[8:0]设置一致

满足以下两个条件：

●PIPEnTRE.TRENB位=1
●USBHS收到一个短数据包

满足以下两个条件：

●PIPEnTRE.TRENB位=1
●PIPEnTRE.TRCLR位由软件设置为1

对于传输管道，将TRNCNT[15:0]位设置为0。当不使用事务计数器时，将TRNCNT[15:0]位设置为0。

仅当PIPEnTRE.TRENB位为0时才使能将要传输的事务数设置到TRNCNT[15:0]位。要设置要传输的事务数，请将TRCLR位设置为1以清除当前计数器将PIPEnTRE.TRENB位设置为1之前的值。

The DEVADDn register specifies the transfer speed of the peripheral device that is the communication target for pipes 0 to 9.

In host controller mode, set all DEVADDn bits before starting communication to any pipes. Only change the bits in DEVADDn when no valid pipes are using the bit settings. A valid pipe is defined as one that satisfies both of the following conditions:

- DEVADDm is selected in the DEVSEL[3:0] bits
- The PID[1:0] bits are set to BUF for the selected pipe, or the selected pipe is the DCP with the DCPCTR.SUREQ bit set to 1

In device controller mode, set all bits in this register to 0.

USBSPD[1:0] bits (Transfer Speed of Communication Target Device)

The USBSPD[1:0] bits specify the USB transfer speed of the target peripheral device. In host controller mode, the USBHS generates packets based on the USBSPD[1:0] setting. In device controller mode, set these bits to 00b.

HUBPORT[2:0] bits (Communication Target Connecting Hub Port)

In host controller mode, the USBHS generates packets based on the HUBPORT[2:0] setting when performing a split transaction.

UPPHUB[3:0] bits (Communication Target Connecting Hub Register)

In host controller mode, the USBHS generates packets based on the UPPHUB[3:0] setting when performing a split transaction.

HWUPM bit (Resume Return Mode Setting)

The HWUPM bit specifies whether to enable hardware processing for return from low power mode even while the CPU clock is inactive.

In device controller mode, processing for return from low power mode on detecting Resume is enabled even while the CPU clock is inactive.

This bit specifies whether to detect Resume while the CPU clock is inactive. The PL1CTRL1.L1EXTMD bit controls whether to make a hardware return. To make a hardware return from the LPM L1 low power state while the CPU clock is inactive, set this bit and the PL1CTRL1.L1EXTMD bit to 1.

DEVADDn寄存器指定作为管道0到9的通信目标的外围设备的传输速度。

在主机控制器模式下，在开始与任何管道通信之前设置所有DEVADDn位。仅更改中的位DEVADDn当没有有效管道使用位设置时。有效管道被定义为同时满足以下两个条件的管道：

- DEVADDm在DEVSEL[3:0]位中选择
- 所选管道的PID[1:0]位设置为BUF，或者所选管道是DCPCTR.SUREQ位设置为1的DCP

在设备控制器模式下，将此寄存器中的所有位设置为0。

USBSPD[1:0]位（通信目标设备的传输速度）

USBSPD[1:0]位指定目标外围设备的USB传输速度。在主机控制器模式下，USBHS根据USBSPD[1:0]设置生成数据包。在设备控制器模式下，将这些位设置为00b。

HUBPORT[2:0]位（通信目标连接集线器端口）

在主机控制器模式下，USBHS在执行拆分事务时根据HUBPORT[2:0]设置生成数据包。

UPPHUB[3:0]位（通信目标连接集线器寄存器）

在设备控制器模式下，即使CPU时钟处于非活动状态，也会启用在检测到Resume时从低功耗模式返回的处理。

该位指定是否在CPU时钟不活动时检测Resume。PL1CTRL1.L1EXTMD位控制是否进行硬件返回。要在CPU时钟不活动时使硬件从LPML1低功耗状态返回，设置该位和PL1CTRL1.L1EXTMD位为1。

SUSPENDM bit (UTMI SuspendM Control)

The SUSPENDM bit controls the SuspendM signal to be sent to the PHY designed under the UTMI specification. The initial value is 0 with the UTMI is in suspension mode.

Set this bit to 1 to supply the PHY clock to operate the USB2.0 host or device controller.

In compliance with the UTMI specification, clock output is normally controlled by the SuspendM signal. When the SUSPENDM bit is 0, the clock to LINK is stopped. Because the PHY in this MCU follows the UTMI specification, setting the SUSPENDM bit to 1 is required to supply the PHY clock. For the clock settings, see section 29.3.3. Supplying the Clock.

When the SUSPENDM bit is 0, the USBHS cannot be written to but can be read from. The registers listed in Table 29.14 are writable even when the SUSPENDM bit is 0.

Table 29.14 Registers that can be written to by software when SUSPENDM = 0

Address	Register or bit name
0x4006_0000	SYSCFG register
0x4006_0002	BUSWAIT register
0x4006_0032	INTENB1.PDDETINTE bit
0x4006_0100	LPCTRL register
0x4006_0102	LPSTS register
0x4006_0140	BCCTRL register

The value written to the SYSCFG register while the PHY clock is inactive is updated only after the PHY clock begins oscillating. The PHY clock oscillates in the following cases described in this section.

When SUSPENDM bit is set to 1, the PLLSTA.PLLLOCK flag is set to 1 after the predetermined time has passed. The USB-PHY internal PLL is stopped when the SUSPENDM bit is set to 0.

For details on CL-only mode, see section 29.2.17. PHYSET : PHY Setting Register.

SUSPENDM bit (UTMI SuspendM Control)

SUSPENDM位控制要发送到根据UTMI规范设计的PHY的SuspendM信号。初始值为0，UTMI处于暂停模式。

将此位设置为1以提供PHY时钟以操作USB2.0主机或设备控制器。

根据UTMI规范，时钟输出通常由SuspendM信号控制。当。。。的时候
SUSPENDM位为0，LINK时钟停止。由于该MCU中的PHY遵循UTMI规范，因此需要将SUSPENDM位设置为1以提供PHY时钟。有关时钟设置，请参阅第29.3.3节。提供时钟。

当SUSPENDM位为0时，USBHS不能被写入但可以被读取。即使SUSPENDM位为0，表29.14中列出的寄存器也是可写的。

Note 2. In device controller mode, set the IDPSRCE, IDMSINKE, VDPSRCE, IDPSINKE, and VDMSRCE bits to 1 after setting the SYSCFG.DRPD bit to 0.

IDPSRCE bit (IDPSRC Control)

In device controller mode, set the IDPSRCE bit to 1 to perform data contact detection.

The Battery Charging Standard provides two ways to handle data contact detection, one through the software and one using hardware to contact the data line. The IDPSRE bit uses the hardware method.

When the IDPSRE bit is set to 1, the USBHS enables the IDP_SRC circuit and, at the same time, controls D- pull-down.

(D- pull-down is controlled with the VUH_DMPULLDOWN signal.)

IDMSINKE bit (IDMSINK Control)

In device controller mode, set the IDMSINKE bit to 1 to perform primary detection.

如果PL1CTRL1.L1EXTMD位为0，则该位的设置或清除由软件控制。如果PL1CTRL1.L1EXTMD位为1，则转换到该位的L1或L2状态由软件控制，从L1或L2状态恢复由硬件控制。

IDPSRCE bit (IDPSRC Control)

在设备控制器模式下，将IDPSRCE位设置为1以执行数据接触检测。

电池充电标准提供了两种处理数据接触检测的方法，一种是通过软件，另一种是通过硬件接触数据线。IDPSRE位使用硬件方法。

当IDPSRE位设置为1时，USBHS使能IDP_SRC电路，同时控制Dpull-down。

（Dpull-down由VUH_DMPULLDOWN信号控制。）

IDMSINKE bit (IDMSINK Control)

在设备控制器模式下，将IDMSINKE位设置为1以执行主要检测。

The CHGDETSTS flag indicates the charger port detection state.

PDDETSTS flag (PDDET Status Flag)

The PDDETSTS flag indicates the following states based on the controller mode:

- In host controller mode: PD detection state
- In device controller mode: DCP detection state

L1RESPEN bit (L1 Response Enable)

If the USBHS receives an LPM token while the L1RESPEN bit is 0, it returns no response. If the USBHS receives an LPM token while this bit is 1, it returns a response based on the L1RESPMD[1:0] setting.

L1RESPMD[1:0] bits (L1 Response Mode)

When the L1RESPEN bit is set to 1, the USBHS returns a response to the LPM token based on the setting in the L1RESPMD[1:0] bits.

L1NEGOMD bit (L1 Response Negotiation Control)

The L1NEGOMD bit specifies the negotiation function for the HIRD value.

HIRDTHR[3:0] bits (L1 Response Negotiation Threshold Value)

The HIRDTHR[3:0] bits specify the HIRD threshold value used for L1NEGOMD. The format of the set value is the same as the HIRD field in HL1CTRL.

L1EXTMD bit (PHY Control Mode at L1 Return)

The L1EXTMD bit specifies the LPSTS.SUSPENDM bit control method when a host K signal is received in the L1 state while the LPSTS.SUSPENDM bit is 0 and the PHY is inactive.

Similar to the Suspend constraints, because the minimum host K period is 50 µs, the PHY might not recover within the host K period specified for software settings on return. The initial value is within software control, so set this bit to 1 during the initialization process when the L1 state is supported.

The LPSTS.SUSPENDM bit is controlled by software on transition to the L1 state regardless of the setting in this bit. It is not cleared by hardware.

When this bit is set to 1, the LPSTS.SUSPENDM bit is also set to 1 on return from L2.

L1RESPEN位（L1响应使能）

如果USBHS在L1RESPEN位为0时接收到LPM令牌，则它不返回任何响应。如果USBHS在该位为1时接收到LPM令牌，它会根据L1RESPMD[1:0]设置返回响应。

L1RESPMD[1:0]位（L1响应模式）

当L1RESPEN位设置为1时，USBHS根据
L1RESPMD[1:0] bits.

L1NEGOMD位（L1响应协商控制）

L1NEGOMD位指定HIRD值的协商功能。

HIRDTHR[3:0]位（L1响应协商阈值）

HIRDTHR[3:0]位指定用于L1NEGOMD的HIRD阈值。设置值的格式与HL1CTRL中的HIRD字段相同。

L1EXTMD位（L1返回时的PHY控制模式）

L1EXTMD位指定LPSTS.SUSPENDM位在L1状态下接收到主机K信号而LPSTS.SUSPENDM位为0且PHY处于非活动状态时的LPSTS.SUSPENDM位控制方法。

与挂起约束类似，由于最小主机K周期为50µs，因此PHY可能无法在返回时为软件设置指定的主机K周期内恢复。初始值在软件控制范围内，因此在支持L1状态的初始化过程中将此位设置为1。

LPSTS.SUSPENDM位在转换到L1状态时由软件控制，无论该位的设置如何。它不会被硬件清除。

当该位设置为1时，LPSTS.SUSPENDM位在从L2返回时也设置为1。

L1RWE bit (LPM Token L1 RemoteWake Enable)

The L1RWE bit specifies the value to be set in the RWE field of the LPM token that the USBHS transmits when the HL1CTRL1.L1REQ bit is set to 1.

The USBHS does not control detection of the remote wakeup signal in the L1 state with this bit. The remote wakeup signal is controlled by the DVSTCTR0.RWUPE bit, as with Suspend.

BESL bit (BESL & Alternate HIRD)

The BESL bit selects the K-state drive period on L1 Resume. For details, see the description of the HIRD bits.

L1ADDR[3:0]位（LPM令牌设备地址）

L1ADDR[3:0]位指定要在LPM令牌的ADDR字段中设置的值，当USBHS发送HL1CTRL1.L1REQ位设置为1。

HIRD[3:0]位（LPM令牌HIRD）

HIRD[3:0]位指定要在USBHS发送的LPM令牌的HIRD字段中设置的值。HL1CTRL1.L1REQ位设置为1。表29.15显示了HIRD设置和HIRD字段值之间的关系。

L1RWE位（LPM令牌L1远程唤醒启用）

L1RWE位指定在USBHS发送的LPM令牌的RWE字段中设置的值。HL1CTRL1.L1REQ位设置为1。

29.3 Operation

29.3.1 System Control

This section describes register settings required for initializing the USBHS and controlling power consumption.

29.3.1.1 Setting data to the USBHS registers

Setting the SYSCFG.USBE bit to 1 after starting the PHY clock supply enables and starts USBHS operation. For information on how to supply the PHY clock, see section 29.3.3. Supplying the Clock.

29.3.1.2 Selecting the controller function

The USBHS can operate as a host or device controller.

Use the SYSCFG.DCFM bit to select one of these USBHS functions. The DCFM bit must be changed in the initial settings immediately after a reset or in the D+ pull-up-disabled state (SYSCFG.DPRPU bit = 0) and D+ and D- pulldown- disabled state (SYSCFG.DRPD bit = 0).

29.3.2 Controlling the USB data bus using resistorss

The USBHS provides pull-up and pull-down resistors for the D+ and D- lines. Pull these lines up or down by setting the SYSCFG.DPRPU and DRPD bits.

In device controller mode, confirm that connection to the USB host is made, and then set the SYSCFG.DPRPU bit to 1 and pull up the D+ line (in full-speed communication).

When the SYSCFG.DPRPU bit is set to 0 during communication with a PC, the USBHS disables the pull-up resistor for the USB data line, thereby notifying the USB host of disconnection.

Table 29.16 shows the settings for controlling the resistors for the USB data bus. Control the USB data bus appropriately for your system using the DRPD and DPRPU bit settings.

Table 29.16 Control settings for the USB data bus resistors (excluding OTG operation)

0	0	Open	Open	When resistors not used
0	1	Open	Pull-Up	When operating as a device controller at full-speed
1	0	Pull-Down	Pull-Down	When operating as a host controller

29.3 Operation

29.3.1 系统控制

本节介绍初始化USBHS和控制功耗所需的寄存器设置。

29.3.1.1 将数据设置到USBHS寄存器

启动PHY时钟电源后将SYSCFG.USBE位设置为1使能并启动USBHS操作。有关如何提供PHY时钟的信息，请参阅第29.3.3节。提供时钟。

29.3.1.2 选择控制器功能

USBHS可以作为主机或设备控制器运行。

使用SYSCFG.DCFM位选择这些USBHS功能之一。DCFM位必须在复位后立即更改为初始设置或在D+上拉禁用状态（SYSCFG.DPRPU位=0）和D+和Dpulldown禁用状态（SYSCFG.DRPD位=0）。

29.3.2 使用电阻控制USB数据总线

USBHS为D+和Dlines提供上拉和下拉电阻。通过设置SYSCFG.DPRPU和DRPD位。

在设备控制器模式下，确认与USB主机的连接已建立，然后将SYSCFG.DPRPU位设置为1并拉高D+线（全速通信）。

当SYSCFG.DPRPU位在与PC通信期间设置为0时，USBHS禁用上拉电阻USB数据线，从而通知USB主机断开。

表29.16显示了用于控制USB数据总线电阻器的设置。使用DRPD和DPRPU位设置为您的系统适当控制USB数据总线。

Table 29.16 USB数据总线电阻的控制设置（不包括OTG操作）

0	1	Open	Pull-Up	作为设备控制器全速运行时
1	0	Pull-Down	Pull-Down	作为主机控制器运行时

29.3.3 提供时钟

表29.17显示了USBHS所需的两个输入时钟。

Table 29.17 Input clocks

Input clock name	Description
PCLKA	Peripheral module clock A input. There is no constraint on the frequency of the PCLKA input.
PHY clock	PHY clock generated from external input or internal supply ● External input: The clock is generated by the USB-PHY internal PLL based on a 12-MHz, 20-MHz, or 24-MHz clock supplied to the EXTAL pin from outside the MCU. For the external clock specifications, especially the jitter characteristics, strictly follow the specifications of ±50 ppm. ● Internal supply: The clock is generated by supplying 48 MHz and 60 MHz to the USB-PHY module and selecting CL-only mode (PHYSET.HSEB). High-speed operation is not supported with this mode.

Figure 29.2 illustrates the PHY clock settings.

29.3.4 Constraints on Stopping the Clock

PCLKA and PHY clock can be stopped during disconnection or suspension. However, to stop any of these clocks while the USB is suspended in device controller mode, the stopped clock must be resupplied using the resume interrupt. The PHY clock must be resupplied within 5.5 ms after the resume interrupt is generated.

29.3.4 停止时钟的限制

PCLKA和PHY时钟可以在断开或挂起期间停止。然而，要停止任何这些时钟，而USB在设备控制器模式下暂停，必须使用恢复中断重新提供停止的时钟。PHY时钟必须在产生恢复中断后的5.5 ms内重新提供。

29.3.6 Interrupt Descriptions

29.3.6.1 BRDY interrupt

The BRDY interrupt is generated in both host and device controller modes. This section describes the conditions in which the USBHS sets the associated bit in BRDYSTS to 1. Under these conditions, the USBHS generates a BRDY interrupt if the software sets the bit in BRDYENB associated with the given pipe to 1 and INTENB0.BRDYE bit to 1.

The conditions for generating and clearing the BRDY interrupt depend on the SOFCFG.BRDYM and PIPECFG.BFRE settings for each pipe as follows:

(1) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.

On any of the following conditions, the USBHS generates an internal BRDY interrupt request trigger and sets the BRDYSTS.PIPEBRDY flag associated with the pipe to 1.

For transmitting pipes

- When the DIR bit is changed from 0 to 1 by software
- When writing by the CPU to the FIFO buffer is disabled for a pipe (when the BSTS flag is read as 0) and the USBHS has completed packet transmission. In continuous transfer, a BRDY interrupt is generated on completion of the transmission of data from one FIFO buffer.
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is complete
- When the hardware flushes the buffer of the pipe for isochronous transfers
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to transition from the write-disabled to write-enabled state.

No request trigger is generated for the DCP, that is, during data transmission for control transfers.

For receiving pipes

- When packet reception is successfully complete, enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the given pipe is disabled (when the BSTS flag is read as 0). No request trigger is generated for transactions in which DATA-PID mismatch has occurred. In continuous transmission or reception mode, the request trigger is not generated when the data is of the specified maximum packet size and the buffer has available space. When a short packet is received, the request trigger is generated even if the FIFO buffer has available space. When the transaction counter is used, the request trigger is generated on receiving the specified number of packets. In this case, the request trigger is generated even if the FIFO buffer has available space.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode. No request trigger is generated until completion of reading data from the currently-read FIFO buffer, even if reception by the other FIFO buffer is complete.
  In device controller mode, the BRDY interrupt is not generated in the status stage of control transfers. The PIPEBRDY interrupt status of the selected pipe can be set to 0 by writing 0 to the associated PIPEBRDY flag through the software. In this case, 1s must be written to the associated bits for the other pipes. Clear the BRDY status before accessing the FIFO buffer.

29.3.6 中断说明

29.3.6.1 BRDY interrupt

在主机和设备控制器模式下都会产生BRDY中断。本节描述USBHS将BRDYSTS中的相关位设置为1的条件。在这些条件下，如果软件将与给定管道相关的BRDYENB中的位设置为1，并且将INTENB0.BRDYE位设置为1，USBHS将生成BRDY中断.

产生和清除BRDY中断的条件取决于每个管道的SOFCFG.BRDYM和PIPECFG.BFRE设置，如下所示：

(1) 当SOFCFG.BRDYM=0且PIPECFG.BFRE=0时

通过这些设置，BRDY中断指示FIFO端口可访问。

在以下任何一种情况下，USBHS产生一个内部BRDY中断请求触发并设置与管道关联的BRDYSTS.PIPEBRDY标志为1。

用于传输管道

●DIR位由软件从0变为1时

●当CPU对FIFO缓冲区的写操作禁止管道时（当BSTS标志读为0时）且USBHS已完成数据包传输。在连续传输中，一个FIFO缓冲区的数据传输完成时会产生一个BRDY中断。

●双缓冲模式下，当一个FIFO缓冲区完成向另一个FIFO缓冲区写入数据时为空时

●直到向当前写入的FIFO缓冲区写入数据完成，才会产生请求触发，即使传输到另一个FIFO缓冲区已完成

●当硬件刷新管道缓冲区以进行同步传输时

●当PIPEnCTR.ACLRM位写入1时，会导致FIFO缓冲区从写禁止状态转变为写使能状态。

没有为DCP生成请求触发，即在控制传输的数据传输期间。

用于接收管道

●当数据包接收成功完成时，允许读取FIFO缓冲区，同时禁止从CPU对给定管道的FIFO缓冲区的读取访问（当BSTS标志被读取为0时）。对于发生DATA-PID不匹配的事务，不会生成请求触发器。在连续发送或接收模式下，当数据达到指定的最大数据包大小且缓冲区有可用空间时，不会生成请求触发。当接收到一个短数据包时，即使FIFO缓冲区有可用空间，也会生成请求触发。当使用事务计数器时，在接收到指定数量的数据包时生成请求触发器。在这种情况下，即使FIFO缓冲区有可用空间，也会生成请求触发。

●当一个FIFO缓冲区在双缓冲区模式下从另一个FIFO缓冲区读取数据完成后使能读取。在从当前读取的FIFO缓冲区读取数据完成之前，不会生成请求触发，即使其他FIFO缓冲区的接收已完成。在设备控制器模式下，在控制传输的状态阶段不会产生BRDY中断。通过软件将0写入相关的PIPEBRDY标志，可以将所选管道的PIPEBRDY中断状态设置为0。在这种情况下，必须将1写入其他管道的相关位。在访问之前清除BRDY状态

FIFO buffer.

(2) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 1

With these settings, the USBHS generates a BRDY interrupt on completion of reading all data for a single transfer using the receiving pipe, and sets the bit in BRDYSTS associated with the pipe to 1.

On any of the following conditions, the USBHS determines that the last data for a single transfer was received:

- When a short packet including a zero-length packet is received
- When the PIPEnTRN register is used and the number of packets specified in the PIPEnTRN.TRNCNT[15:0] bits are completely received

When the data is completely read after any of these conditions is satisfied, the USBHS determines that all data for a single transfer is completely read.

When a zero-length packet is received while the FIFO buffer is empty, the USBHS determines that all data for a single transfer is completely read when the FRDY flag in the FIFO port control register is 1 and the DTLN[11:0] flags are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the associated port control register through software. With these settings, the USBHS does not detect a BRDY interrupt for the transmitting pipe.

The PIPEBRDY interrupt status of a pipe can be set to 0 by writing 0 to the associated BRDYSTS.PIPEBRDY flag through the software. In this case, 1s must be written to the PIPEBRDY bits for the other pipes.

In this mode, do not change the PIPECFG.BFRE bit setting until all data for a single transfer is processed. When it is necessary to change the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pipe must be cleared using the PIPEnCTR.ACLRM bit.

(3) When SOFCFG.BRDYM = 1 and PIPECFG.BFRE = 0

With these settings, the BRDYSTS.PIPEBRDY flag values are linked to the BSTS flag setting for each pipe. In other words, the BRDY interrupt status bits are set to 1 or 0 by the USBHS depending on the FIFO buffer status.

For transmitting pipes

The BRDY interrupt status bits are set to 1 when the FIFO port is ready for write access, and are set to 0 when it is not ready. The BRDY interrupt is not generated for the DCP in the transmitting direction even when it is ready for write access.

For receiving pipes

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for read access, and are set to 0 when all data is read (not ready for read access).

When a zero-length packet is received while the FIFO buffer is empty, the associated bit is set to 1 and the BRDY interrupt is continuously generated until the software writes 1 to BCLR. With this setting, the PIPEBRDY flag cannot be set to 0 by software.

When the SOFCFG.BRDYM bit is set to 1, set the PIPECFG.BFRE bit for all pipes to 0, and the SOFCFG.INTL bit to 1 for level detection.

Figure 29.5 shows the timing of BRDY interrupt generation.

(2) 当SOFCFG.BRDYM=0且PIPECFG.BFRE=1时

使用这些设置，USBHS在完成使用接收管道读取一次传输的所有数据时生成BRDY中断，并将BRDYSTS中与管道相关的位设置为1。

在以下任何一种情况下，USBHS都会确定接收到单次传输的最后一个数据：

- 收到包含零长度包的短包时
- 当使用PIPEnTRN寄存器并且PIPEnTRN.TRNCNT[15:0]位中指定的数据包数量被完全接收时

当满足这些条件中的任何一个后数据被完全读取时，USBHS确定单次传输的所有数据都被完全读取。

当FIFO缓冲区为空时接收到零长度数据包时，当FIFO端口控制寄存器中的FRDY标志为1且DTLN[11:0]标志为0.在这种情况下，要开始下一次传输，通过软件向相关端口控制寄存器中的BCLR位写入1。使用这些设置，USBHS不会检测到传输管道的BRDY中断。

通过软件将0写入相关的BRDYSTS.PIPEBRDY标志可以将管道的PIPEBRDY中断状态设置为0。在这种情况下，必须将1写入其他管道的PIPEBRDY位。

在此模式下，在处理完单次传输的所有数据之前，不要更改PIPECFG.BFRE位设置。当需要在处理完成之前更改PIPECFG.BFRE位时，必须使用PIPEnCTR.ACLRM位清除管道的所有FIFO缓冲区。

(3) 当SOFCFG.BRDYM=1且PIPECFG.BFRE=0时

通过这些设置，BRDYSTS.PIPEBRDY标志值链接到每个管道的BSTS标志设置。换言之，BRDY中断状态位由USBHS设置为1或0，具体取决于FIFO缓冲区状态。

用于传输管道

当FIFO端口准备好进行写访问时，BRDY中断状态位设置为1，当它未准备好时设置为0。发送方向上的DCP不会产生BRDY中断，即使它已准备好进行写访问。

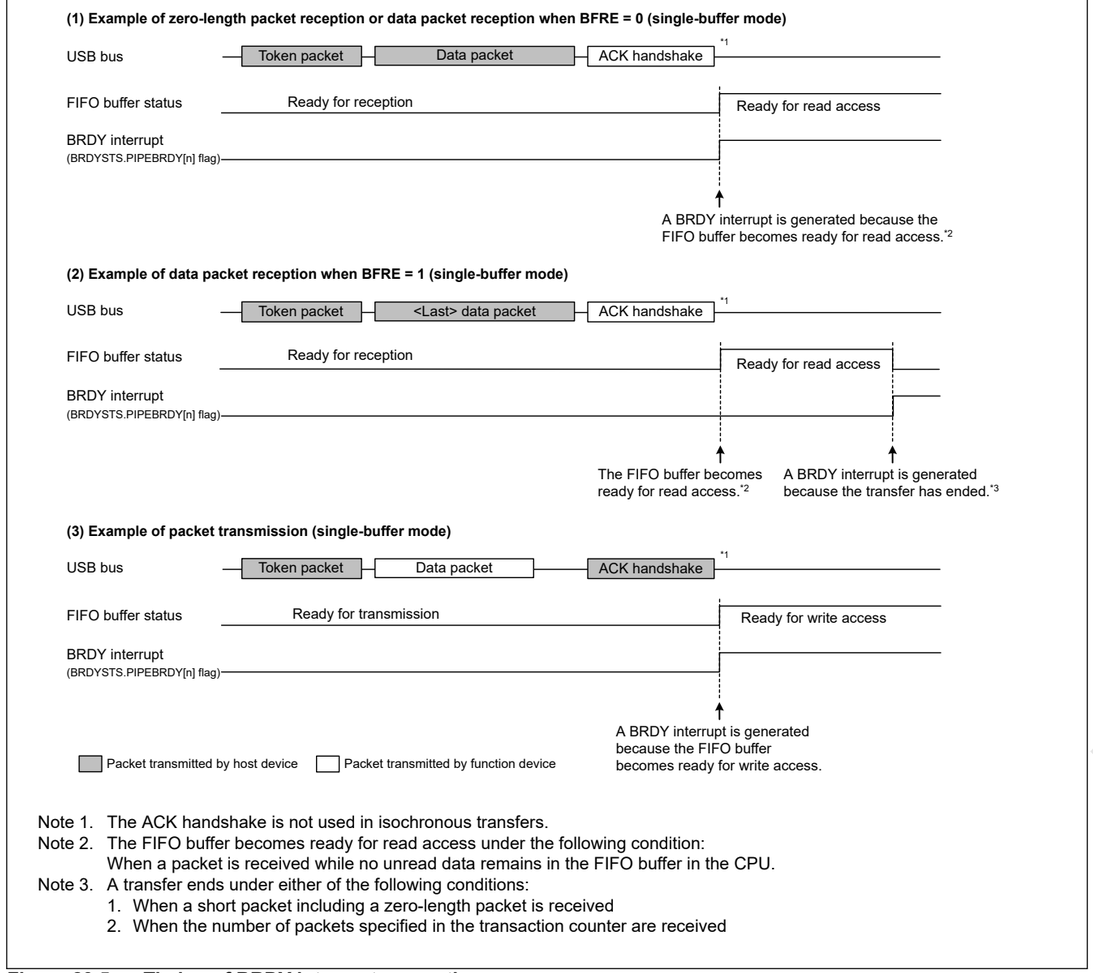
用于接收管道

当FIFO缓冲区准备好进行读取访问时，BRDY中断状态位设置为1，当读取所有数据（未准备好进行读取访问）时设置为0。

当FIFO缓冲区为空时接收到零长度数据包时，相关位设置为1，并且持续产生BRDY中断，直到软件将1写入BCLR。使用此设置，PIPEBRDY标志不能由软件设置为0。

当SOFCFG.BRDYM位设置为1时，将所有管道的PIPECFG.BFRE位设置为0，并将SOFCFG.INTL位设置为1以进行电平检测。

图29.5显示了BRDY中断产生的时序。



Note 1. The ACK handshake is not used in isochronous transfers.
Note 2. The FIFO buffer becomes ready for read access under the following condition:
When a packet is received while no unread data remains in the FIFO buffer in the CPU.
Note 3. A transfer ends under either of the following conditions:
1. When a short packet including a zero-length packet is received
2. When the number of packets specified in the transaction counter are received

Figure 29.5 Timing of BRDY interrupt generation

The condition for clearing the INTSTS0.BRDY flag depends on the SOFCFG.BRDYM bit setting value, as shown in Table 29.21

Table 29.21 Conditions for clearing the BRDY flag

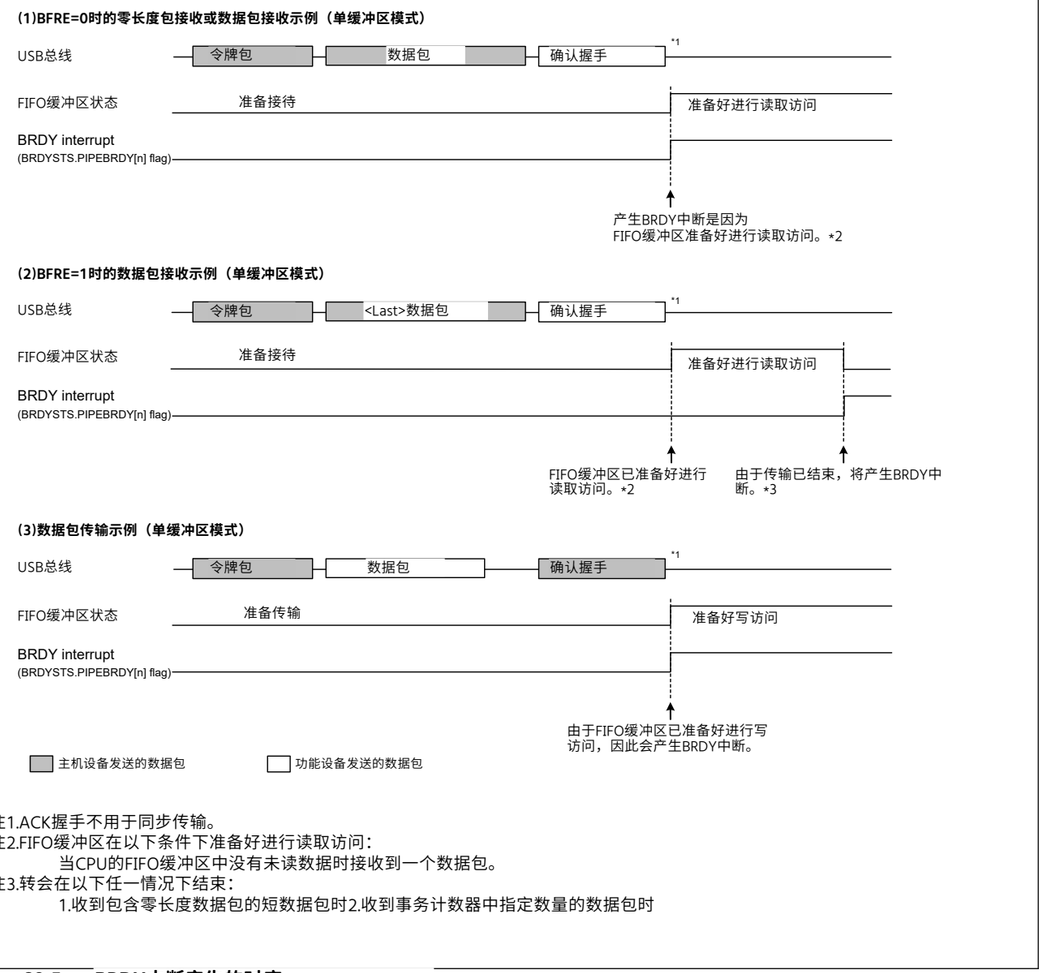
BRDYM bit	Condition for clearing BRDY flag
0	The USBHS clears the BRDY flag to 0 when all bits in BRDYSTS are set to 0 by software
1	The USBHS clears the BRDY flag to 0 when the BSTS flags for all pipes have cleared to 0

29.3.6.2 NRDY interrupt

On generating an internal NRDY interrupt request for the pipe whose PID[1:0] bits are set to 01b (BUF response) by software, the USBHS sets the associated NRDYSTS.PIPENRDY flag to 1. If the associated bit in NRDYENB is set to 1 by software, the USBHS sets the INTSTS0.NRDY flag to 1 and generates a USBHS interrupt.

This section describes the conditions in which the USBHS generates the internal NRDY interrupt request for a given pipe.

The internal NRDY interrupt request is not generated during setup transaction execution in host controller mode. During setup transactions in host controller mode, the SACK or SIGN interrupt is detected.



注1.ACK握手不用于同步传输。
注2.FIFO缓冲区在以下条件下准备好进行读取访问：

29.3.6.2 NRDY interrupt

在为PID[1:0]位由软件设置为01b（BUF响应）的管道生成内部NRDY中断请求时，USBHS将相关的NRDYSTS.PIPENRDY标志设置为1。如果NRDYENB中的相关位设置为通过软件置1，USBHS将INTSTS0.NRDY标志设置为1并产生USBHS中断。

本节描述USBHS为给定管道生成内部NRDY中断请求的条件。

内部NRDY中断请求在主控制器模式下的设置事务执行期间不会产生。在主机控制器模式下的设置事务期间，检测到SACK或SIGN中断。

The internal NRDY interrupt request is not generated during status stage execution of the control transfer in device controller mode

(1) In host controller mode when no split transactions occur in the connection

For transmitting pipes

On any of the following conditions, the USBHS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS transmits a zero-length packet following the OUT token and sets the associated NRDYSTS.PIPENRDY flag and the FRMNUM.OVRN flag to 1.
- During communications other than setup transactions on pipes not used for isochronous transfers, when any combination of the following two conditions occurs three consecutive times:
  - No response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device
  - An error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the PID[1:0] setting for the associated pipe to 00b (NAK response)
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device (includes STALL for both OUT and PING). In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the PID[1:0] setting for the associated pipe to 11b (STALL response).

For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBHS discards the received data for the IN token and sets the associated PIPENRDY flag and the OVRN flag to 1. When a packet error is detected in the received data for the IN token, the USBHS also sets the FRMNUM.CRCE flag to 1.
- For non-isochronous transfer pipes, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device for the IN token issued by the USBHS (when timeout is detected before detection of the DATA packet from the peripheral device)
  - An error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response).
- For isochronous transfer pipes, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1. The PID[1:0] setting for the pipe is not changed.
- For isochronous transfer pipes, when a CRC error or a bit stuffing error is detected in the received data packet. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe and the CRCE flag to 1.
- When the STALL handshake is received. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1 and changes the PID[1:0] setting for the associated pipe to STALL.

(2) In host controller mode when split transactions occur in the connection

For transmitting pipes

On any of the following conditions, the USBHS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS sets the associated RDYSTS.PIPENRDY flag for the given pipes to 1 on issuing a start-split transaction and sets the FRMNUM.OVRN flag to 1. The USBHS also transmits a zero-length packet following the OUT token.
- For non-isochronous transfer pipes, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for start-split and complete-split transactions (when timeout is detected before detection of the handshake packet from the hub)

在设备控制器模式下控制传输的状态阶段执行期间不产生内部NRDY中断请求

(1) 在主机控制器模式下，连接中没有发生拆分事务

用于传输管道

在以下任何一种情况下，USBHS都会检测到NRDY中断：

●对于同步传输管道，当FIFO缓冲区中没有要传输的数据时发出OUT令牌的时间到来。在这种情况下，USBHS在OUT令牌之后发送一个长度为零的数据包，并将相关的NRDYSTS.PIPENRDY标志和FRMNUM.OVRN标志设置为1。

●在不用于同步传输的管道上的设置事务以外的通信期间，当以下两种情况的任意组合连续发生3次时：

外围设备没有返回响应（当在检测到来自外围设备的握手包之前检测到超时时

在来自外围设备的数据包中检测到错误。在这种情况下，USBHS将关联的PIPENRDY标志设置为1，并将关联管道的PID[1:0]设置更改为00b（NAK响应）

●在设置事务以外的通信期间，当从外围设备接收到STALL握手时（包括OUT和PING的STALL）。在这种情况下，USBHS将关联的PIPENRDY标志设置为1，并将关联管道的PID[1:0]设置更改为11b（STALL响应）。

用于接收管道

●对于同步传输管道，当发出IN令牌的时间到来但FIFO中没有可用空间时
缓冲。在这种情况下，USBHS丢弃IN令牌的接收数据并将相关的PIPENRDY标志和OVRN标志设置为1。当在IN令牌的接收数据中检测到数据包错误时，USBHS也会设置FRMNUM.CRCE标志为1。

●对于非等时传输管道，当以下两种情况的任意组合连续出现3次时：

USBHS发出的IN令牌没有从外围设备返回响应（当在检测到来自外围设备的DATA包之前检测到超时时）

在来自外围设备的数据包中检测到错误。在这种情况下，USBHS将相关的PIPENRDY标志设置为1，并将管道的相关PID[1:0]设置更改为00b（NAK响应）。

●对于同步传输管道，当外围设备没有返回对IN令牌的响应时（在检测到来自外围设备的DATA数据包之前检测到超时）或在外围设备的数据包中检测到错误。在这种情况下，USBHS将每个管道的相关NRDYSTS.PIPENRDY标志设置为1。管道的PID[1:0]设置不会更改。

●对于同步传输管道，当在接收到的数据包中检测到CRC错误或比特填充错误时。在这种情况下，USBHS为每个管道设置相关的NRDYSTS.PIPENRDY标志，并将CRCE标志设置为1。

●收到STALL握手时。在这种情况下，USBHS将每个管道的相关NRDYSTS.PIPENRDY标志设置为1，并将相关管道的PID[1:0]设置更改为STALL。

(2) 在连接中发生拆分事务时处于主机控制器模式

用于传输管道

在以下任何一种情况下，USBHS都会检测到NRDY中断：

●对于同步传输管道，当FIFO缓冲区中没有要传输的数据时发出OUT令牌的时间到来。在这种情况下，USBHS在发出开始分割事务时将给定管道的相关RDYSTS.PIPENRDY标志设置为1，并将FRMNUM.OVRN标志设置为1。USBHS还在OUT令牌之后传输零长度数据包。

●对于非等时传输管道，当以下两种情况的任意组合连续出现3次时：

集线器没有响应开始拆分和完成拆分事务（在检测到来自集线器的握手包之前检测到超时）

– An error is detected in the packet from the hub. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response).When an NRDY interrupt is detected on complete-split issuance, the USBHS clears the CSSTS flag to 0.

- When a STALL handshake is received for the complete-split transaction. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, changes the associated PID[1:0] setting for the pipe to 11b (STALL response), and clears the CSSTS flag to 0. An interrupt is not detected during setup transaction.

For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the given pipe and the FRMNUM.OVRN flag to 1 on start-split issuance. The USBHS discards the received data for the IN token.
- During bulk-pipe transfers or transfers other than setup transactions with the DCP, when any combination of the following two cases occurs three consecutive times:
  – No response is returned from the hub for the IN token the USBHS issued on issuance of the start-split or complete-split transactions (when timeout is detected before detection of the data packet from the hub)
  – An error is detected in the packet from the hub. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response). When this condition occurs during complete-split, the USBHS clears the CSSTS flag to 0.
- During a complete-split transaction for isochronous transfer or interrupt transfer pipes, when any combination of the following two cases occurs three consecutive times:
  – No response is returned from the hub for the IN token issued by the USBHS (when a timeout is detected before detection of the DATA packet from the hub)
  – An error is detected in the packet from the hub. On generating this condition for an interrupt transfer pipe, the USBHS sets the associated NRDYSTS.PIPENRDY flag to 1, changes the associated PID[1:0] setting for the pipe to 00b (NAK response), and clears the CSSTS flag to 0. On generating this condition for the pipe for isochronous transfers, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, CRCE flag to 1, and clears the CSSTS bit to 0. It does not change the PID[1:0] setting.
- During a complete-split transaction, when the STALL handshake is received for a non-isochronous transfer pipe. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, changes the associated PID[1:0] setting for the pipe to 11b (STALL response), and clears the CSSTS flag to 0.
- During a complete-split transaction, when the NYET handshake is received for an isochronous transfer or interrupt transfer pipe for the microframe number = 4. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1 and the CRCE flag to 1, and clears the CSSTS flag to 0. It does not change the PID[1:0] setting.

(3) In device controller mode

For transmitting pipes

- When an IN token is received while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS generates an NRDY interrupt request on reception of the IN token and sets the NRDYSTS.PIPENRDY flag to 1. For an isochronous transfer pipe in which an interrupt is generated, the USBHS transmits a zero-length packet and sets the FRMNUM.OVRN flag to 1.

For receiving pipes

- When an OUT token is received but there is no space available in the FIFO buffer. For an isochronous transfer pipe in which an interrupt is generated, the USBHS generates an NRDY interrupt request on reception of the OUT token and sets the NRDYSTS.PIPENRDY flag to 1 and the FRMNUM.OVRN flag to 1. For a non-isochronous transfer pipe in which an interrupt is generated, the USBHS generates an NRDY interrupt request when an NAK handshake is transferred after the data following the OUT token is received, and sets the NRDYSTS.PIPENRDY flag to 1. The NRDY interrupt request is not generated during retransmission because of a DATA-PID mismatch. In addition, the NRDY interrupt request is not generated if an error occurs in the DATA packet.
- On receiving a PING token when there is no space available in the FIFO buffer. The USBHS generates an NRDY interrupt request on reception of the PING token, setting the NRDYSTS.PIPENRDY flag to 1.

在来自集线器的数据包中检测到错误。在这种情况下，USBHS将管道的相关NRDYSTS.PIPENRDY标志设置为1，并将管道的相关PID[1:0]设置更改为00b（NAK响应）。当在发出完全拆分时检测到NRDY中断时，USBHS将CSSTS标志清零。

●当为完全拆分事务接收到STALL握手时。在这种情况下，USBHS将管道的相关NRDYSTS.PIPENRDY标志设置为1，将管道的相关PID[1:0]设置更改为11b（STALL响应），并将CSSTS标志清除为0。中断是在设置事务期间未检测到。

用于接收管道

●对于同步传输管道，当发出IN令牌的时间到来但FIFO缓冲区中没有可用空间时。在这种情况下，USBHS将给定管道的相关NRDYSTS.PIPENRDY标志和FRMNUM.OVRN标志设置为1在开始拆分发布时。USBHS丢弃接收到的IN令牌数据。

●在批量管道传输或与DCP的设置事务以外的传输过程中，当以下两种情况的任意组合发生连续3次时：

没有从集线器返回对USBHS在发出start-split或completesplit事务时发出的IN令牌的响应（当在检测到来自集线器的数据包之前检测到超时时）

在来自集线器的数据包中检测到错误。在这种情况下，USBHS将管道的相关NRDYSTS.PIPENRDY标志设置为1，并将管道的相关PID[1:0]设置更改为00b（NAK响应）。如果在完全拆分期间发生这种情况，USBHS会将CSSTS标志清除为0。

●在等时传输或中断传输管道的完全拆分事务中，当以下两种情况的任意组合连续发生3次时：

对于USBHS发出的IN令牌，集线器没有返回响应（当在检测到来自集线器的DATA数据包之前检测到超时时）

在来自集线器的数据包中检测到错误。在为中断传输管道生成此条件时，
USBHS将关联的NRDYSTS.PIPENRDY标志设置为1，将管道的关联PID[1:0]设置更改为00b（NAK响应），并将CSSTS标志清除为0。在为同步传输的管道生成此条件时，USBHS将管道的相关NRDYSTS.PIPENRDY标志设置为1，CRCE标志设置为1，并将CSSTS位清除为0。它不会更改PID[1:0]设置。

●在完全拆分事务期间，当接收到非同步传输管道的STALL握手时。在这种情况下，USBHS将管道的相关NRDYSTS.PIPENRDY标志设置为1，将管道的相关PID[1:0]设置更改为11b（STALL响应），并将CSSTS标志清除为0。

●在完全拆分事务期间，当接收到同步传输或中断的NYET握手时
微帧编号的传输管道=4。在这种情况下，USBHS将每个管道的相关NRDYSTS.PIPENRDY标志设置为1，CRCE标志设置为1，并将CSSTS标志清除为0。它不会更改PID[1:0]设置。

(3) 在设备控制器模式下

用于传输管道

●当接收到一个IN令牌而FIFO缓冲区中没有要传输的数据时。在这种情况下，USBHS
在接收到IN令牌时生成NRDY中断请求并将NRDYSTS.PIPENRDY标志设置为1。对于产生中断的同步传输管道，USBHS发送一个长度为零的数据包并将FRMNUM.OVRN标志设置为1.

用于接收管道

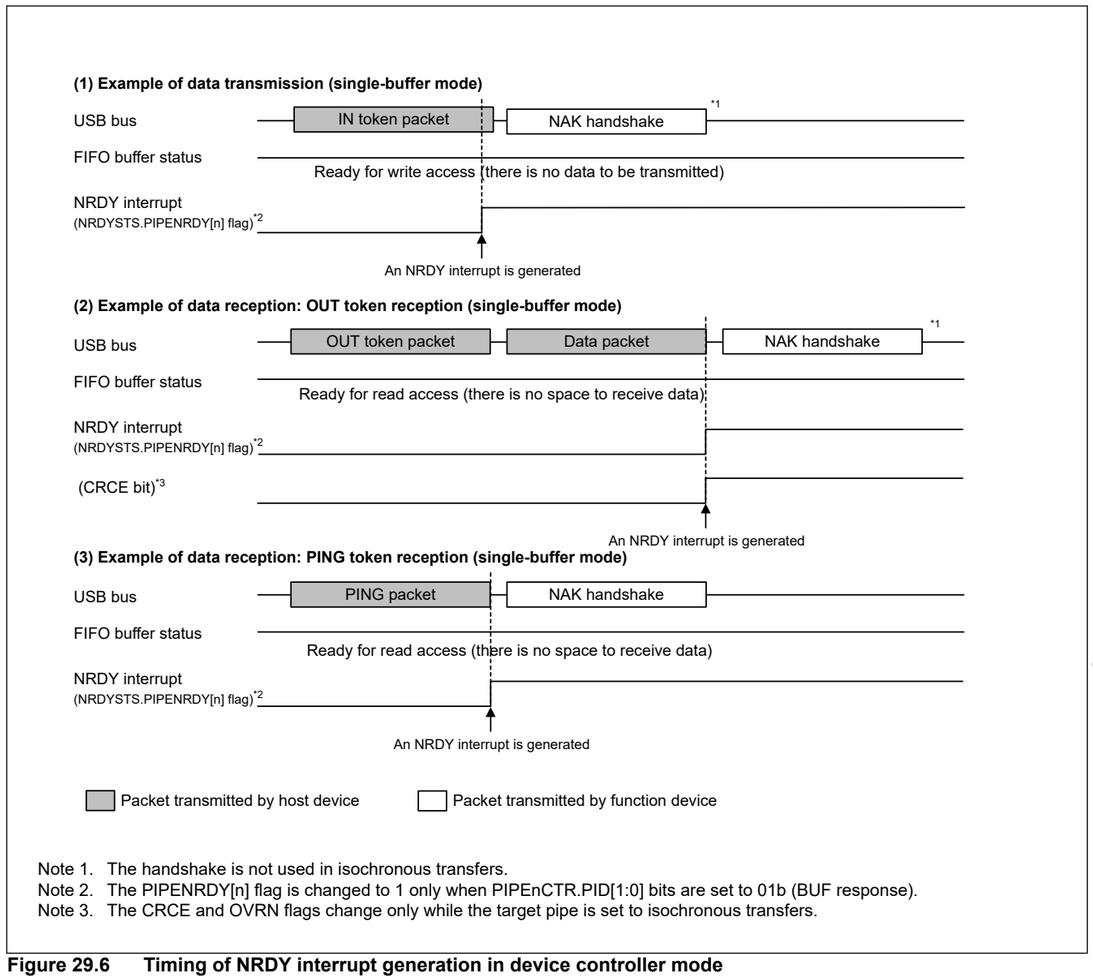
●当接收到OUT令牌但FIFO缓冲区中没有可用空间时。对于产生中断的同步传输管道，USBHS在接收到OUT令牌时产生一个NRDY中断请求，并将NRDYSTS.PIPENRDY标志设置为1，将FRMNUM.OVRN标志设置为1。对于非同步传输管道在产生中断时，USBHS在接收到OUT令牌之后的数据后传输NAK握手时产生NRDY中断请求，并将NRDYSTS.PIPENRDY标志设置为1。在重传期间不会产生NRDY中断请求，因为DATA-PID不匹配。除此之外

如果DATA包中发生错误，则不会产生NRDY中断请求。

●在FIFO缓冲区中没有可用空间时接收PING令牌。USBHS在接收到PING令牌时生成一个NRDY中断请求，将NRDYSTS.PIPENRDY标志设置为1。

- For isochronous transfer pipes, when a token is not received successfully within an interval frame. In this case, the USBHS generates an NRDY interrupt request when the SOF is received, and sets the NRDYSTS.PIPENRDY flag to 1.

Figure 29.6 shows the timing of NRDY interrupt generation in device controller mode.



Note 1. The handshake is not used in isochronous transfers.
Note 2. The PIPENRDY[n] flag is changed to 1 only when PIPEnCTR.PID[1:0] bits are set to 01b (BUF response).
Note 3. The CRCE and OVRN flags change only while the target pipe is set to isochronous transfers.

Figure 29.6 Timing of NRDY interrupt generation in device controller mode

29.3.6.3 BEMP interrupt

On detecting a BEMP interrupt for the pipe whose PID[1:0] bits in the pipe control register are set to 01b (BUF response) by software, the USBHS sets the associated BEMPSTS.PIPEBEMP flag to 1. If the associated BEMPENB bit is set to 1 by software, the USBHS sets the INTSTS0.BEMP flag to 1 and generates a USB interrupt. This section describes the conditions in which the USBHS generates an internal BEMP interrupt request.

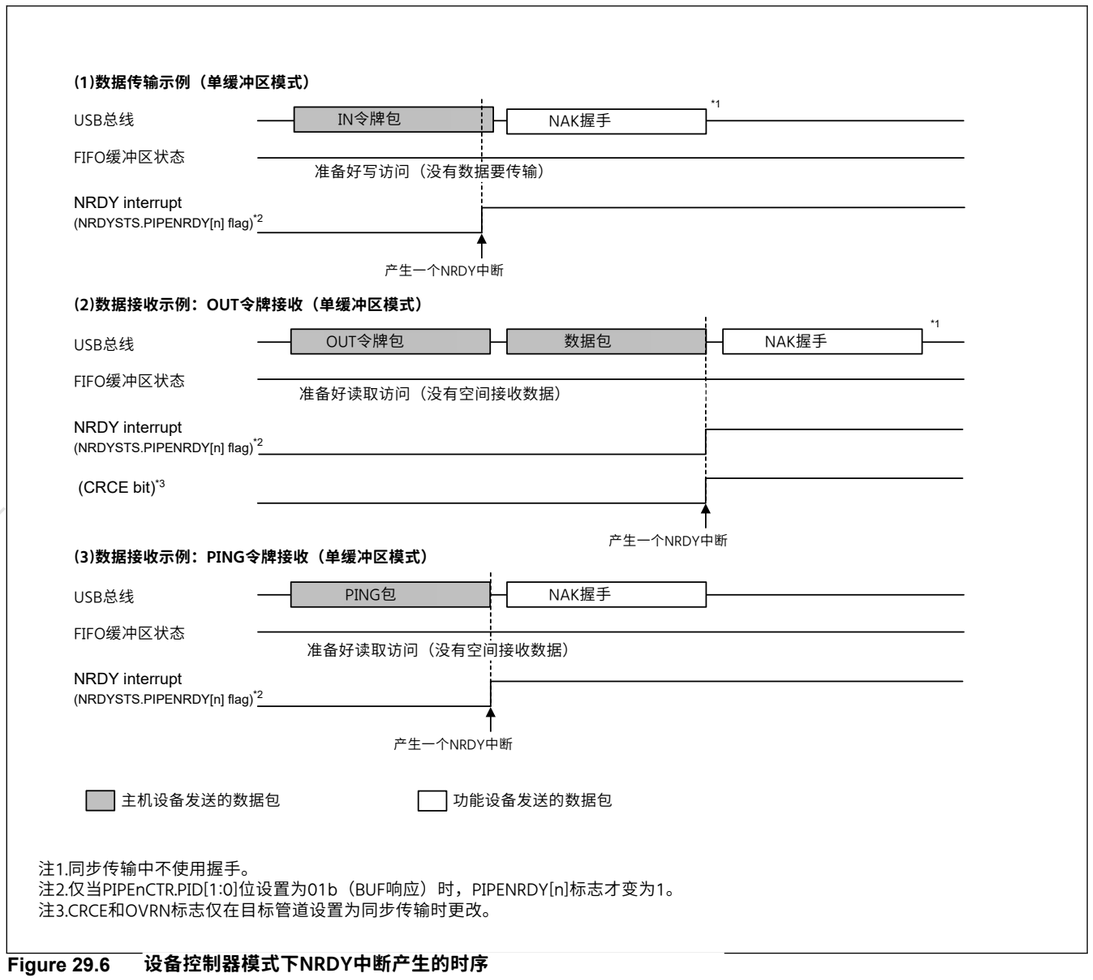
(1) For transmitting pipes

When the FIFO buffer of the associated pipe is empty on completion of transmission, including zero-length packet transmission, and in single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for a non-DCP pipe. The internal BEMP interrupt request is not generated in any of the following conditions:

- When the CPU or DMA/DTC has already started writing data to the FIFO buffer of the CPU on completion of transmitting data from one FIFO buffer in double buffer mode
- When the buffer is cleared (emptied) by setting 1 to the PIPEnCTR.ACLRM or the BCLR bit in the port control register

●对于同步传输管道，当在间隔帧内没有成功接收到令牌时。在这种情况下，
USBHS在接收到SOF时产生一个NRDY中断请求，并将NRDYSTS.PIPENRDY标志设置为1。

图29.6显示了设备控制器模式下NRDY中断产生的时序。



注1.同步传输中不使用握手。
注2.仅当PIPEnCTR.PID[1:0]位设置为01b（BUF响应）时，PIPENRDY[n]标志才变为1。
注3.CRCE和OVRN标志仅在目标管道设置为同步传输时更改。

Figure 29.6 设备控制器模式下NRDY中断产生的时序

29.3.6.3 BEMP interrupt

在检测到管道控制寄存器中的PID[1:0]位被软件设置为01b（BUF响应）的管道的BEMP中断时，USBHS将相关的BEMPSTS.PIPEBEMP标志设置为1。如果相关的BEMPENB位是由软件设置为1，USBHS将INTSTS0.BEMP标志设置为1并产生USB中断。本节介绍USBHS产生内部BEMP中断请求的条件。

(1) 用于传输管道

当相关管道的FIFO缓冲区在传输完成时为空时，包括零长度数据包传输，并且在单缓冲区模式下，内部BEMP中断请求与非DCP管道的BRDY中断同时生成。在以下任何一种情况下都不会产生内部BEMP中断请求：

●当CPU或DMADTC在双缓冲模式下从一个FIFO缓冲区完成数据传输后已经开始向CPU的FIFO缓冲区写入数据时

●当通过将PIPEnCTR.ACLRM或端口控制寄存器中的BCLR位设置为1来清除（清空）缓冲区时

- When an IN transfer (zero-length packet transmission) is performed during the control transfer status stage in device controller mode

(2) For receiving pipes

When a successfully-received data packet size exceeds the specified maximum packet size. In this case, the USBHS generates a BEMP interrupt request, sets the associated BEMPSTS.PIPEBEMP flag to 1, discards the received data, and changes the associated PID[1:0] setting for the pipe to STALL (11b). The USBHS returns no response in host controller mode, and returns STALL response in device controller mode.

The internal BEMP interrupt request is not generated in any of the following conditions:

- When a CRC error or a bit stuffing error is detected in the received data
- When a setup transaction is being performed:
  - Writing 0 to the BEMPSTS.PIPEBEMP flag clears the status
  - Writing 1 to the BEMPSTS.PIPEBEMP flag has no effect

Figure 29.7 shows the timing of BEMP interrupt generation in device controller mode.

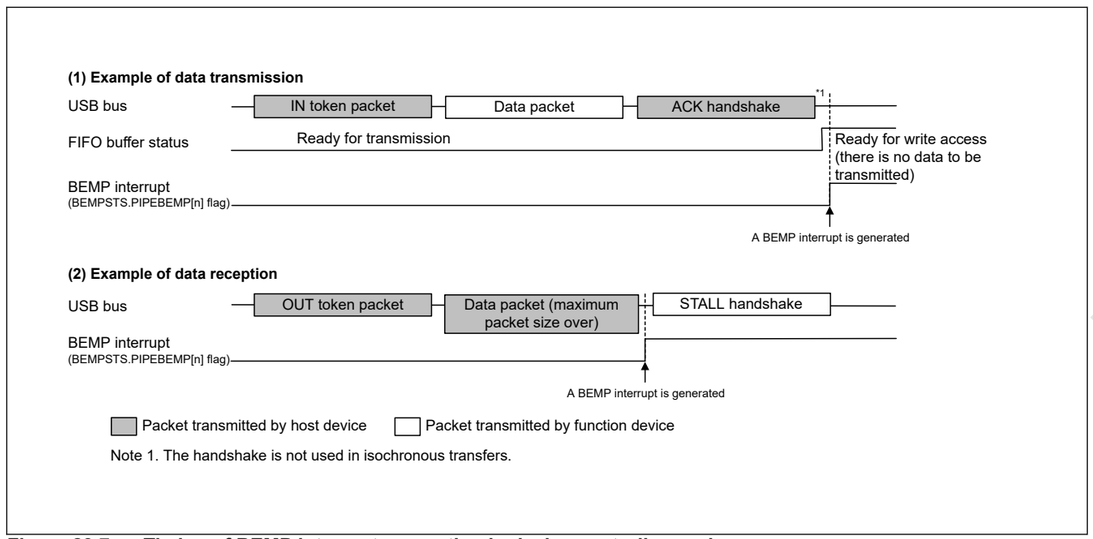


Figure 29.7 Timing of BEMP interrupt generation in device controller mode

29.3.6.4 Device state transition interrupt (device controller mode)

Figure 29.8 shows a diagram of the USBHS device state transitions. The USBHS controls device states and generates device state transition interrupts. However, recovery from the Suspend state (resume signal detection) is detected by means of the resume interrupt. Device state transition interrupts can be enabled or disabled independently in INTENB0. Devices whose states have changed can be checked in the PL1CTRL.DVSQ[3:0] flags.

When a transition is made to the default state, a device state transition interrupt is generated after a USB bus reset is detected.

The USBHS controls device states, and device state transition interrupts can be generated, only in device controller mode.

●在设备控制器模式的控制传输状态阶段进行IN传输（零长度包传输）时

(2) 用于接收管道

当成功接收的数据包大小超过指定的最大包大小时。在这种情况下，USBHS生成一个BEMP中断请求，将相关的BEMPSTS.PIPEBEMP标志设置为1，丢弃接收到的数据，并将管道的相关PID[1:0]设置更改为STALL(11b)。USBHS在主机控制器模式下不返回响应，在设备控制器模式下返回STALL响应。

在以下任何一种情况下都不会产生内部BEMP中断请求：

●在接收到的数据中检测到CRC错误或位填充错误时

●执行设置事务时：

将0写入BEMPSTS.PIPEBEMP标志清除状态

向BEMPSTS.PIPEBEMP标志写入1无效

29.3.6.4 设备状态转换中断（设备控制器模式）

图29.8显示了USBHS设备状态转换的示意图。USBHS控制设备状态并产生设备状态转换中断。但是，从挂起状态的恢复（恢复信号检测）是通过恢复中断来检测的。可以在INTENB0中独立启用或禁用设备状态转换中断。可以在PL1CTRL.DVSQ[3:0]标志中检查状态已更改的设备。

当转换到默认状态时，检测到USB总线复位后会产生设备状态转换中断。

USBHS控制设备状态，并且只能在设备控制器模式下产生设备状态转换中断。

29.3.6.5 Control transfer stage transition interrupt (device controller mode)

Figure 29.9 shows a diagram of the control transfer stage transitions of the USBHS. The USBHS controls the control transfer sequence and generates control transfer stage transition interrupts. Control transfer stage transition interrupts can be enabled or disabled independently in INTENB0. Transfer stages that have transitioned can be checked in the INTSTS0.CTSQ[2:0] bits.

Control transfer stage transition interrupts are generated only in device controller mode. This section describes control transfer sequence errors. When an error occurs, the DCPCTR.PID[1:0] bits are set to 1xb (STALL response).

- Control read transfer errors
  - An OUT token or PING token is received but no data is transferred in response to the IN token at the data stage
  - An IN token is received at the status stage

29.3.6.5 控制转移阶段转换中断（设备控制器模式）

图29.9显示了USBHS的控制传输阶段转换图。USBHS控制控制传输序列并产生控制传输阶段转换中断。控制转移阶段转换中断可以在INTENB0中独立启用或禁用。可以在INTSTS0.CTSQ[2:0]位中检查已转换的传输阶段。

控制转移阶段转换中断仅在设备控制器模式下产生。本节描述控制传输序列错误。发生错误时，DCPCTR.PID[1:0]位设置为1xb（STALL响应）。

- 控制读取传输错误
  - 接收到OUT令牌或PING令牌，但在数据阶段没有响应IN令牌传输数据
  - 在状态阶段收到一个IN令牌

- A data packet with DATAPID = DATA0 is received at the status stage

- Control write transfer errors
  - An IN token is received but no ACK returned in response to the OUT token in the data stage
  - A data packet with DATAPID = DATA0 is received as the first data packet at the data stage
  - An OUT token or PING token is received in the status stage

- Control write no data transfer errors
  - An OUT token or PING token is received at the status stage

At the control write transfer data stage, if the receive data length exceeds the wLength value of the USB request, it is not recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (INTSTS0.CTRT flag = 1), the CTSQ[2:0] = 110b value is saved until CTRT flag clears to 0, clearing the interrupt status. While CTSQ[2:0] bits = 110b is being saved, no CTRT interrupt for ending the setup stage is generated, even if a new USB request is received. The USBHS saves the setup stage completion status, and it generates a CTRT interrupt after the interrupt status is cleared by software.

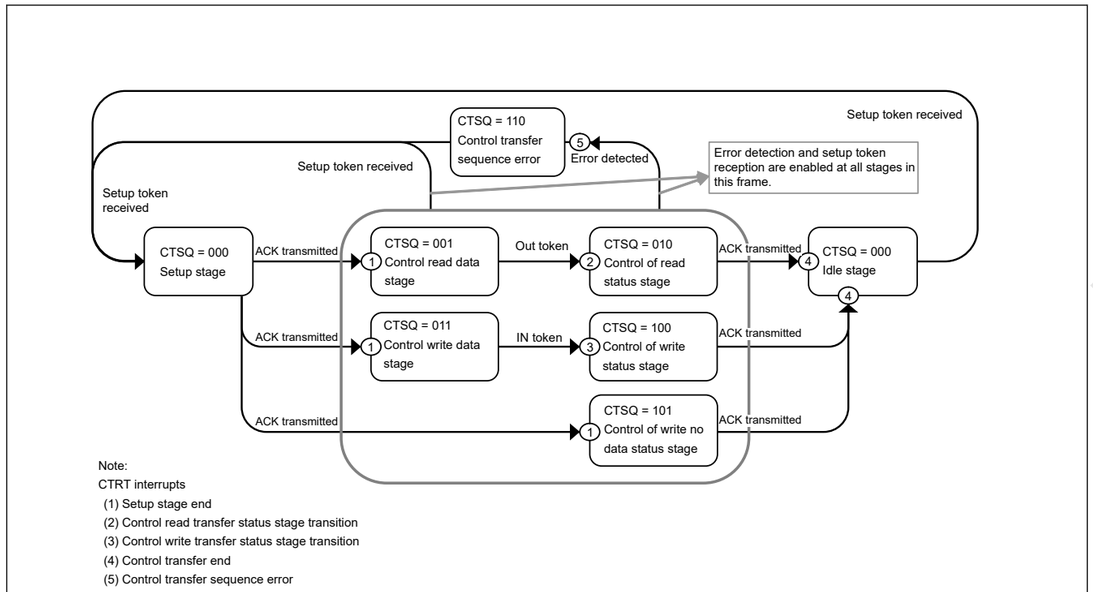

Figure 29.9 Control transfer stage transitions

29.3.6.6 Frame update interrupt

In host controller mode, an interrupt is generated when the frame number is updated.

In device controller mode, an SOFR interrupt is generated when the frame number is updated. The USBHS updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation.

29.3.6.7 VBUS interrupt

When the USBHS_VBUS pin level changes, a VBUS interrupt is generated. The level of the USBHS_VBUS pin can be checked in the INTSTS0.VBSTS flag. Whether the host controller is connected or disconnected can be confirmed using the

在状态阶段接收到DATAPID=DATA0的数据包

●控制写入传输错误

在数据阶段接收到一个IN令牌但没有返回ACK以响应OUT令牌

DATAPID=DATA0的数据包作为数据阶段的第一个数据包被接收

在状态阶段收到OUT令牌或PING令牌

●控制写入无数据传输错误

在状态阶段收到OUT令牌或PING令牌

在控制写入传输数据阶段，如果接收数据长度超过USB请求的wLength值，则不被识别为控制传输序列错误。在控制读取传输状态阶段，除了零长度数据包之外的数据包被一个ACK响应接收并且传输正常结束。

当CTRT中断响应序列错误（INTSTS0.CTRT标志=1）时，CTSQ[2:0]=110b值被保存，直到CTRT标志清除为0，清除中断状态。在保存CTSQ[2:0]位=110b时，不会产生用于结束设置阶段的CTRT中断，即使收到新的USB请求也是如此。USBHS保存建立阶段完成状态，软件清除中断状态后产生CTRT中断。

29.3.6.6 帧更新中断

在主机控制器模式下，更新帧号时会产生中断。

在设备控制器模式下，更新帧号时会产生SOFR中断。如果在全速运行期间检测到新的SOF数据包，USBHS会更新帧号并生成SOFR中断。

29.3.6.7 VBUS interrupt

当USBHS_VBUS引脚电平改变时，会产生VBUS中断。USBHS_VBUS引脚的电平可以在INTSTS0.VBSTS标志中检查。上位控制器是否连接或断开可以使用确认

RA生态工作室

VBUS interrupt. If the system is activated with the host controller connected, the first VBUS interrupt is not generated, because there is no change in the USBHS_VBUS pin level.

29.3.6.8 Resume interrupt

In device controller mode, a resume interrupt is generated when the device is in the Suspend state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the Suspend state is detected by means of the resume interrupt.

In host controller mode, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

29.3.6.9 OVRCR interrupt

An OVRCR interrupt is generated when the USBHS_OVRCURA or USBHS_OVRCURB pin level has changed. The levels of the USBHS_OVRCURA and USBHS_OVRCURB pins can be checked in the SYSSTS0.OVCMON[1:0] flags. The external power supply IC can check whether overcurrent is detected using the OVRCR interrupt.

For OTG connections, the OVRCR interrupt allows you to check whether a change is detected in the VBUS comparator.

29.3.6.10 BCHG interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether a peripheral device is connected. It can also be used to detect a remote wakeup in host controller mode. The BCHG interrupt is generated in both host and device controller modes.

29.3.6.11 DTCH interrupt

A DTCH interrupt occurs when a USB bus disconnect is detected in host controller mode. The USBHS detects bus disconnects in compliance with the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software. The pipes enter the wait state for a bus connection to the port, waiting for an ATTCH interrupt to occur. Regardless of the value set in the associated interrupt enable bit, the USBHS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt is detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state

29.3.6.12 SACK interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet is received from the peripheral device in host controller mode. The SACK interrupt can be used to confirm that the setup transaction is successfully complete.

29.3.6.13 SIGN interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet is not correctly received from the peripheral device three consecutive times in host controller mode. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

29.3.6.14 ATTCH interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5 µs in host controller mode. To be more specific, an ATTCH interrupt is detected in any of the following conditions:

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5 µs
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5 µs

29.3.6.15 EOFERR interrupt

An EOFERR interrupt occurs when the USBHS detects that communication is not complete at the EOF2 timing defined in the USB 2.0 specification.

VBUS中断。如果系统在连接主机控制器的情况下激活，则不会产生第一个VBUS中断，因为USBHS_VBUS引脚电平没有变化。

29.3.6.8 恢复中断

在设备控制器模式下，当设备处于Suspend状态并且USB总线状态发生变化（从J-state到K-state，或从J-state到SE0）时，会产生一个恢复中断。通过恢复中断检测从挂起状态的恢复。

在主机控制器模式下，不会产生恢复中断。使用BCHG中断来检测USB总线状态的变化。

29.3.6.9 OVRCR interrupt

当USBHS_OVRCURA或USBHS_OVRCURB引脚电平发生变化时，会产生OVRCR中断。USBHS_OVRCURA和USBHS_OVRCURB引脚的电平可以在SYSSTS0.OVCMON[1:0]标志中检查。外部电源IC可以使用OVRCR中断检查是否检测到过电流。

对于OTG连接，OVRCR中断允许您检查是否在VBUS比较器中检测到变化。

29.3.6.10 BCHG interrupt

当USB总线状态改变时会产生BCHG中断。BCHG中断可用于检测是否连接了外围设备。它还可用于检测主机控制器模式下的远程唤醒。BCHG中断在主机和设备控制器模式下产生。

29.3.6.11 DTCH interrupt

当在主机控制器模式下检测到USB总线断开连接时，会发生DTCH中断。USBHS检测符合USB2.0规范的总线断开连接。

在检测到中断时，为相关端口执行通信的所有管道必须由软件终止。管道进入等待状态，等待总线连接到端口，等待ATTCH中断发生。无论相关中断使能位中设置的值如何，USBHS硬件：

- 将检测到DTCH中断的端口的DVSTCTR0.UACT位设置为0
- 将发生DTCH中断的端口置于空闲状态

29.3.6.12 SACK中断

当在主机控制器模式下从外围设备接收到对发送的设置数据包的ACK响应时，将产生SACK中断。SACK中断可用于确认设置事务成功完成。

29.3.6.13 标志中断

在主机控制器模式下，如果连续三次未从外围设备正确接收到已发送的设置数据包的ACK响应，则会产生SIGN中断。SIGN中断可用于检测没有从外围设备发送的ACK响应或ACK数据包的损坏。

29.3.6.14 ATTCH interrupt

在主机控制器模式下，当在USB端口上检测到全速信号电平的J状态或K状态持续2.5µs时，将产生ATTCH中断。更具体地说，在以下任何一种情况下都会检测到ATTCH中断：

- 当K-state、SE0或SE1变为J-state时，J-state持续2.5µs
- J-state、SE0或SE1变为K-state时，K-state持续2.5µs

29.3.6.15 EOFERR interrupt

当USBHS检测到在USB2.0规范中定义的EOF2时序未完成通信时，将发生EOFERR中断。

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software, and the port must be re-enumerated. Regardless of the value set in the associated interrupt enable bit, the USBHS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt is detected to 0
- Puts the port in which the EOFERR interrupt is generated into the idle state

29.3.6.16 PDDETINT interrupt

The USBHS sets the INTSTS1.PDDETINT flag to 1 on detecting a level change (high to low or low to high) in the PDDET pin input value and generates the PDDETINT interrupt. When the PDDETINT interrupt is generated, use software to repeatedly read the BCCTRL.PDDETSTS flag until the same value is read three or more times, and perform debounce processing.

29.3.6.17 LPMEND interrupt

When the LPM transaction ends because a response from the peripheral device or a timeout is detected, the INTSTS1.LPMEND flag sets to 1 and the LPMEND interrupt is generated.

29.3.6.18 L1RSMEND interrupt

When performing resume processing when the USBHS has transitioned to the L1 state because an ACK is received in response to an LPM token, the USBHS sets the INTSTS1.L1RSMEND flag to 1 on completion of the resume processing.

29.3.7 Pipe Control

Table 29.22 lists the pipe settings for the USBHS. USB data transfer is performed through logical pipes that the software associates with endpoints. The USBHS provides 10 pipes for data transfer. Set up the pipes based on your system specifications.

	IITV[2:0]	Interval counter	Pipes 1, 2: Settable only for isochronous transfers Pipes 3 to 5: Setting disabled Pipes 6 to 9: Settable only in host controller mode

在检测到中断时，所有为相关端口执行通信的管道必须由软件终止，并且必须重新枚举该端口。无论相关中断使能位中设置的值如何，USBHS硬件：

- 将检测到EOFERR中断的端口的DVSTCTR0.UACT位设置为0
- 将产生EOFERR中断的端口置于空闲状态

29.3.6.16 PDDETINT interrupt

USBHS在检测到PDDET引脚输入值的电平变化（从高到低或从低到高）时将INTSTS1.PDDETINT标志设置为1，并产生PDDETINT中断。当PDDETINT中断产生时，用软件反复读取BCCTRL.PDDETSTS标志，直到读取3次以上相同的值，并进行去抖动处理。

29.3.6.17 LPMEND interrupt

当LPM事务由于检测到来自外围设备的响应或超时而结束时，
INTSTS1.LPMEND标志设置为1并产生LPMEND中断。

29.3.6.18 L1RSMEND interrupt

当USBHS由于接收到响应LPM令牌的ACK而转换到L1状态时执行恢复处理时，USBHS在恢复处理完成时将INTSTS1.L1RSMEND标志设置为1。

29.3.7 管道控制

表29.22列出了USBHS的管道设置。USB数据传输是通过软件与端点关联的逻辑管道执行的。USBHS提供了10个用于数据传输的管道。根据您的系统规格设置管道。

29.3.7.1 管道控制寄存器切换程序

只有当USB通信被禁止时（PID[1:0]位为00b（NAK响应））才能更改管道控制寄存器中的以下位。图29.10显示了启用USB通信时的管道控制寄存器切换过程（PID[1:0]位为00b（BUF响应））。

启用USB通信时，请勿更改以下寄存器和位（PID[1:0]位为01b(BUFresponse)）：

- DCPCFG和DCPMAXP中的位
- DCPCTR中的SQCLR和SQSET位
- PIPECFG、PIPEBUF、PIPEMAXP和PIPEPERI中的位
- PIPEnCTR中的ATREPM、ACLRM、SQCLR和SQSET位
- PIPEnTRE和PIPEnTRN中的位
- DEVADDn中的位（n=0到A）

要设置CSCLR位和DEVADDn中的位（n=0到A），请遵循第29.2节中描述的程序。登记 Descriptions.

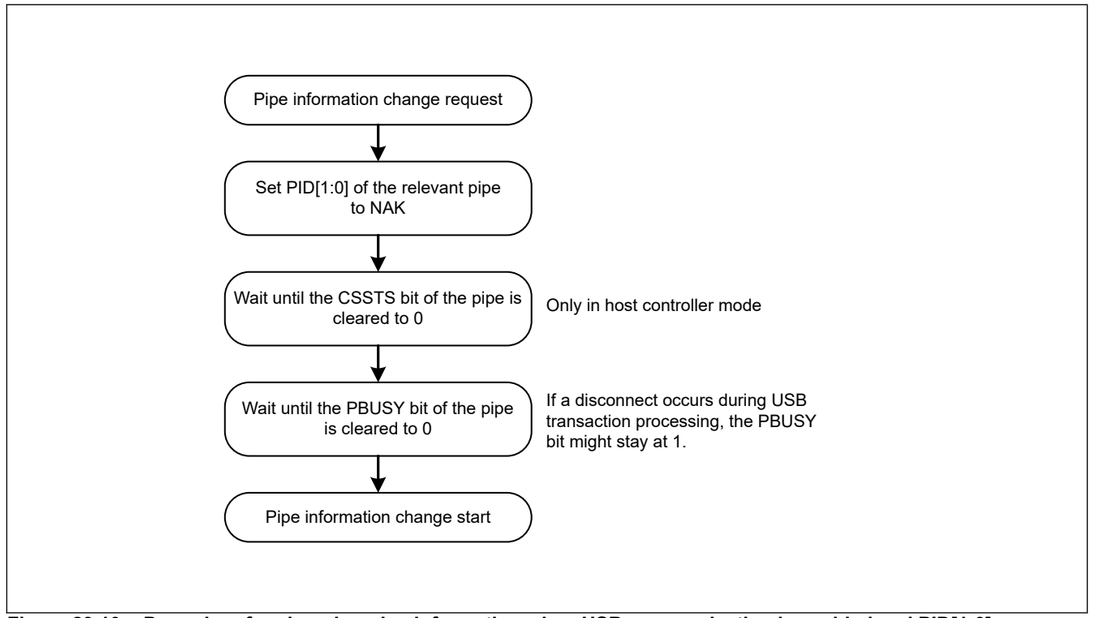

Figure 29.10 Procedure for changing pipe information when USB communication is enabled and PID[1:0] bits are 01b (BUF response)

The following bits in the pipe control registers can be changed only when the selected pipe information is not set in the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Do not set the following registers while the CURPIPE[3:0] bits are set:

- Bits in DCPCFG and DCPMAXP
- Bits in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- PIPEnCTR and ACLRM bits

To change pipe information, you must set the CURPIPE[3:0] bits to a pipe other than the one to be changed. For the DCP, the buffer must be cleared using the BCLR bit after the pipe information is changed.

29.3.7.2 Transfer types

The PIPECFG.TYPE[1:0] bits specify the following transfer types for each pipe:

- DCP: No setting necessary (fixed at control transfer)
- Pipes 1 and 2: Set to bulk transfer or isochronous transfer
- Pipes 3 to 5: Set to bulk transfer
- Pipes 6 to 9: Set to interrupt transfer

29.3.7.3 Endpoint number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to 15.

- DCP: No setting is necessary (fixed at endpoint 0)
- Pipes 1 to 9: Select and set the endpoint numbers from 1 to 15 so that the combination of the PIPECFG.DIR and EPNUM[3:0] bits is unique

29.3.7.4 Maximum packet size setting

Specify the maximum packet size for each pipe in the MXPS bits in DCPMAXP and PIPEMAXP. The DCP and pipes 1 to 5 can be set to any of the maximum pipe sizes defined in the USB 2.0 specification. For pipes 6 to 9, the maximum packet

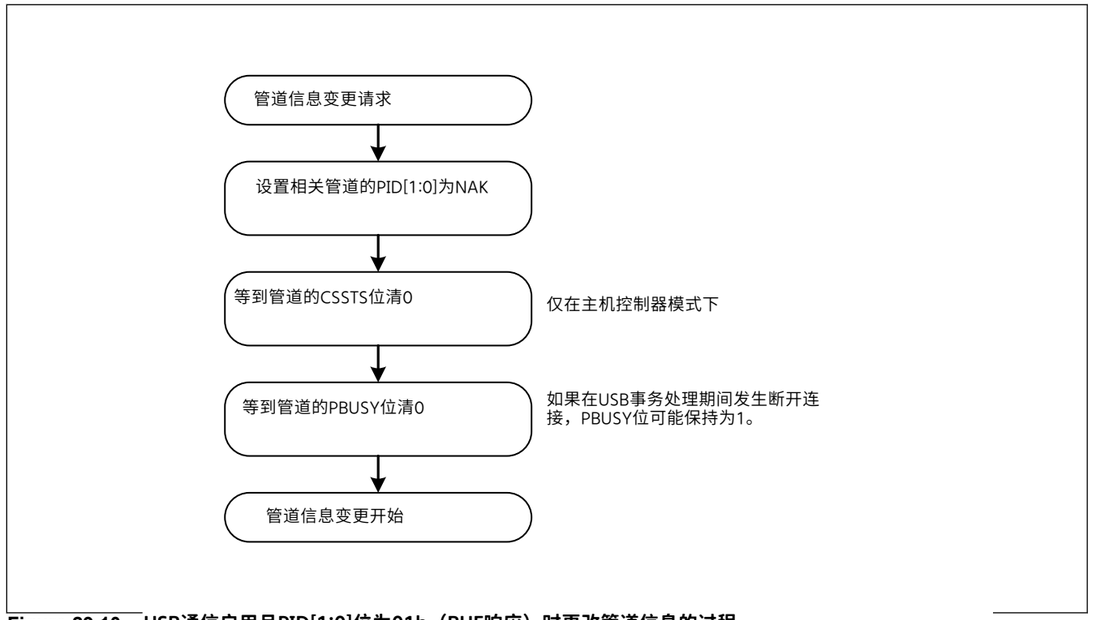

Figure 29.10 USB通信启用且PID[1:0]位为01b（BUF响应）时更改管道信息的过程

管道控制寄存器中的以下位只有在所选管道信息未设置时才能更改CFIFOSEL、D0FIFOSEL和D1FIFOSEL中的CURPIPE[3:0]位。

设置CURPIPE[3:0]位时不要设置以下寄存器：

●DCPCFG和DCPMAXP中的位

●PIPECFG、PIPEBUF、PIPEMAXP和PIPEPERI中的位

●PIPEnCTR和ACLRM位

要更改管道信息，您必须将CURPIPE[3:0]位设置为要更改的管道以外的管道。对于DCP，必须在管道信息更改后使用BCLR位清除缓冲区。

29.3.7.2 传输类型

PIPECFG.TYPE[1:0]位为每个管道指定以下传输类型：

●DCP：无需设置（控制转移时固定）

●管道1和2：设置为批量传输或同步传输

●管道3到5：设置为批量传输

●管道6到9：设置为中断传输

29.3.7.3 端点编号

PIPECFG.EPNUM[3:0]位用于设置每个管道的端点编号。DCP固定在端点0。其他管道可以设置从端点1到15。

●DCP：无需设置（固定在端点0）

●管道1到9：从1到15选择和设置端点编号，以便PIPECFG.DIR和EPNUM[3:0]位的组合是唯一的

29.3.7.4 最大数据包大小设置

在DCPMAXP和PIPEMAXP的MXPS位中指定每个管道的最大数据包大小。DCP和管道1到5可以设置为USB2.0规范中定义的任何最大管道尺寸。对于管道6到9，最大数据包

size is 64 bytes. Set the maximum packet size as follows before starting a transfer (PID[1:0] bits are set to 01b (BUF response)):

- DCP: Set to 64 for high-speed operation
- DCP: Set to 8, 16, 32, or 64 for full-speed operation
- Pipes 1 to 5: Set to 512 for high-speed bulk transfers
- Pipes 1 to 5: Set to 8, 16, 32, or 64 for full-speed bulk transfers
- Pipes 1, 2: Set between 1 and 1024 for high-speed isochronous transfers
- Pipes 1, 2: Set between 1 and 1023 for full-speed isochronous transfers
- Pipes 6 to 9: Set between 1 and 64

High-bandwidth interrupt transfers and isochronous transfers are not supported.

29.3.7.5 Transaction counter for pipes 1 to 5 in the receiving direction

When the specified number of transactions is complete in the data packet receiving direction, the USBHS recognizes that the transfer has ended. Two transaction counters are provided. One is the PIPEnTRN register, which specifies the number of transactions to be executed, and the other is the current counter, which internally counts the number of executed transactions. If the PIPECFG.SHTNAK bit is set to 1, when the current counter value matches the specified number of transactions, the associated PIPEnCTR.PID[1:0] bits are set to 00b (NAK response) and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The data read from PIPEnTRN differs depending on the PIPEnTRE.TRENB setting as follows:

- The TRENB bit = 0: Specified transaction counter value can be read
- The TRENB bit = 1: Current counter value indicating the internally counted number of executed transactions can be read.

The following constraints apply when working with the TRCLR bit:

- If the transactions are being counted and the PIPEnCTR.PID[1:0] bits are set to 01b (BUF response), the current counter cannot be cleared
- If there is any data left in the buffer, the current counter cannot be cleared

29.3.7.6 Response PID

Specify the response PID for each pipe in the PID[1:0] bits in DCPCTR and PIPEnCTR. This section describes the USBHS operation with different response PID settings.

Software response PID settings in host controller mode

Select the response PID to specify the execution of transactions as follows:

- NAK setting: Using pipes is disabled and no transactions are executed
- BUF setting: Transactions are executed based on the FIFO buffer state:
  OUT direction: An OUT token is issued if the FIFO buffer contains transmit data.
  IN direction: An IN token is issued if the FIFO buffer is not full and can receive data.
- STALL setting: Using pipes is disabled and no transactions are executed

Note: Use the SUREQ bit to execute setup transactions for the DCP.

Software response PID settings in device controller mode

Select the response PID to respond as follows to transactions from the host:

- NAK setting: A NAK response is returned to all generated transactions
- BUF setting: A response is returned to transactions based on the FIFO buffer
- STALL setting: A STALL response is returned to all generated transactions

大小为64字节。在开始传输之前设置最大数据包大小如下（PID[1:0]位设置为01b（BUF响应））：

●DCP：设置为64用于高速运行
●DCP：设置为8、16、32或64以实现全速运行
●管道1到5：设置为512用于高速批量传输
●管道1到5：设置为8、16、32或64以实现全速批量传输
●管道1、2：设置在1到1024之间，用于高速同步传输
●管道1、2：设置在1和1023之间，用于全速同步传输
●管道6到9：设置在1到64之间

不支持高带宽中断传输和同步传输。

29.3.7.5 接收方向上管道1到5的事务计数器

当在数据包接收方向完成指定数量的事务时，USBHS识别传输已结束。提供了两个交易柜台。一个是PIPEnTRN寄存器，它指定要执行的事务数，另一个是当前计数器，它在内部对执行的事务数进行计数。如果PIPECFG.SHTNAK位设置为1，则当当前计数器值与指定的事务数匹配时，相关的PIPEnCTR.PID[1:0]位设置为00b（NAK响应）并禁用后续传输。通过PIPEnTRE.TRCLR位初始化事务计数器功能的当前计数器，事务可以从头开始重新计数。从PIPEnTRN读取的数据因PIPEnTRE.TRENB设置而异，如下所示：

●TRENB位=0：可以读取指定的事务计数器值
●TRENB位=1：当前计数器值表示内部计数的已执行事务数可以被读取。

使用TRCLR位时适用以下约束：

●如果正在对事务进行计数且PIPEnCTR.PID[1:0]位设置为01b（BUF响应），则无法清除当前计数器

●如果缓冲区中还有数据，则无法清除当前计数器

29.3.7.6 响应PID

在DCPCTR和PIPEnCTR的PID[1:0]位中指定每个管道的响应PID。本节介绍具有不同响应PID设置的USBHS操作。

主机控制器模式下的软件响应PID设置

选择响应PID来指定事务的执行，如下所示：

●NAK设置：禁用使用管道，不执行任何事务
●BUF设置：根据FIFO缓冲区状态执行事务：
  OUT方向：如果FIFO缓冲区包含发送数据，则发出OUT令牌。
  IN方向：如果FIFO缓冲区未满并且可以接收数据，则发出IN令牌。
●STALL设置：禁止使用管道，不执行任何事务

注意：使用SUREQ位执行DCP的设置事务。

设备控制器模式下的软件响应PID设置

选择响应PID以对来自主机的事务进行如下响应：

●NAK设置：对所有生成的事务返回NAK响应
●BUF设置：根据FIFO缓冲区向事务返回响应
●STALL设置：向所有生成的事务返回STALL响应

Note: For setup transactions, an ACK response is always returned, regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

Hardware response PID settings in host controller mode and Hardware response PID settings in device controller mode describe situations in which the USBHS writes to the PID[1:0] bits because of specific transaction results.

Hardware response PID settings in host controller mode

- NAK setting: The PID[1:0] bits are set to 00b (NAK response) in the following cases, and issuing of tokens is automatically stopped:
  - When a non-isochronous transfer is performed and an NRDY interrupt is generated. For details, see section 29.3.6.2. NRDY interrupt
  - If a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
  - If transaction counting ends when the SHTNAK bit is set to 1 for bulk transfers
- BUF setting: The USBHS does not write this setting
- STALL setting: The PID[1:0] bits are set to STALL in the following cases, and issuing of tokens is automatically stopped:
  - When STALL is received in response to a transmitted token
  - When a received data packet exceeds the maximum packet size

Hardware response PID settings in device controller mode

- NAK setting: The PID[1:0] bits are set to 00b (NAK response) in the following cases, and a NAK response is returned to transactions:
  - When the setup token is received normally (DCP only)
  - If transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
- BUF setting: The USBHS does not write this setting
- STALL setting: The PID[1:0] bits are set to STALL in the following cases, and a STALL response is returned to transactions:
  - When a received data packet exceeds the maximum packet size
  - When a control transfer sequence error is detected

29.3.7.7 Data PID sequence bit

The USBHS automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON bit in DCPCTR and PIPEnCTR. When data is transmitted, the sequence bit toggles on ACK handshake reception. When data is received, the sequence bit toggles on ACK handshake transmission. The SQCLR bit in DCPCTR and the SQSET bit in PIPEnCTR can be used to change the data PID sequence bit.

In device controller mode when control transfers are used, the USBHS automatically sets the sequence bit for stage transitions. DATA1 is returned when the setup stage ends. The sequence bit is not referenced and PID = DATA1 is returned in the status stage. Therefore, no software settings are required. However, in host controller mode when control transfers are used, the sequence bit must be set by software for the stage transitions.

For ClearFeature requests for transmission or reception, the data PID sequence bit must be set by software in both host and device controller modes.

29.3.7.8 Response PID = NAK function

The USBHS provides a function for disabling pipe operation (PID[1:0] bits are set to 00b (NAK response)) when the final data packet of a transaction is received. The USBHS automatically distinguishes this based on reception of a short packet or the transaction counter. Enable this function by setting the PIPECFG.SHTNAK bit to 1.

Note: 对于设置事务，无论PID[1:0]位设置如何，始终返回ACK响应，并且USB请求存储在寄存器中。

主机控制器模式下的硬件响应PID设置和设备控制器模式下的硬件响应PID设置描述了USBHS由于特定事务结果而写入PID[1:0]位的情况。

主机控制器模式下的硬件响应PID设置

●NAK设置：在以下情况下，PID[1:0]位设置为00b（NAK响应），令牌自动停止发行：

当执行非同步传输并产生NRDY中断时。详见29.3.6.2节。NRDY中断

如果在PIPECFG.SHTNAK位设置为1以进行批量传输时接收到短数据包

如果在SHTNAK位设置为1以进行批量传输时事务计数结束

●BUF设置：USBHS不写入此设置

●STALL设置：PID[1:0]位在以下情况下设置为STALL，令牌的发行自动停止：

当接收到STALL以响应传输的令牌时

当接收到的数据包超过最大包大小时

设备控制器模式下的硬件响应PID设置

●NAK设置：在以下情况下，PID[1:0]位设置为00b（NAK响应），并向事务返回NAK响应：

正常接收到设置令牌时（仅DCP）

当PIPECFG.SHTNAK位设置为1以进行批量传输时，如果事务计数结束或收到短数据包

●BUF设置：USBHS不写入此设置

●STALL设置：PID[1:0]位在以下情况下设置为STALL，并向事务返回STALL响应：

当接收到的数据包超过最大包大小时

当检测到控制传输序列错误时

29.3.7.7 数据PID序列位

当数据在控制传输数据阶段、批量传输和中断传输中成功传输时，USBHS会自动切换数据PID中的序列位。下一个要发送的数据PID的序列位可以通过DCPCTR和PIPEnCTR中的SQMON位来确认。发送数据时，序列位在ACK握手接收时切换。当接收到数据时，序列位在ACK握手传输上切换。DCPCTR中的SQCLR位和PIPEnCTR中的SQSET位可用于更改数据PID序列位。

在使用控制传输的设备控制器模式下，USBHS自动设置阶段转换的序列位。DATA1在设置阶段结束时返回。不引用序列位，在状态阶段返回PID=DATA1。因此，不需要任何软件设置。但是，在使用控制传输的主机控制器模式下，必须由软件设置序列位以进行阶段转换。

对于发送或接收的ClearFeature请求，数据PID序列位必须由软件在主机和设备控制器模式下设置。

29.3.7.8 响应PID=NAK功能

USBHS提供了在接收到事务的最终数据包时禁用管道操作（PID[1:0]位设置为00b（NAK响应））的功能。USBHS根据收到的短数据包或事务计数器自动区分这一点。通过将PIPECFG.SHTNAK位设置为1来启用此功能。

When the double buffer mode is being used for the FIFO buffer, using this function enables reception of data packets in transfer units. If pipe operation is disabled, software must enable the pipe again (PID[1:0] bits are set to 01b (BUF response)).

The response PID = NAK function can be used only for bulk transfers.

29.3.7.9 Auto response mode

For bulk transfer pipes (1 to 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode.

During an OUT transfer (PIPECFG.DIR = 0), OUT-NAK mode is invoked, and during an IN transfer (DIR = 1), null auto response mode is invoked.

29.3.7.10 OUT-NAK mode

For bulk OUT transfer pipes, NAK is returned in response to an OUT token, and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To transition from normal mode to OUT-NAK mode, specify OUT-NAK mode while pipe operation is disabled (PID[1:0] = 00b for NAK response). Next, enable pipe operation (PID[1:0] = 01b for BUF response), on which OUT-NAK mode becomes valid. If an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To transition from OUT-NAK mode to normal mode, cancel OUT-NAK mode while pipe operation is disabled (NAK).

Next enable pipe operation (BUF). In normal mode, reception of OUT data is enabled.

29.3.7.11 Null auto response mode

For bulk IN transfer pipes, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To transition from normal mode to null auto response mode, specify null auto response mode while pipe operation is disabled (PID[1:0] bits are set to 00b (NAK response)). Next, enable pipe operation (PID[1:0] bits are set to 01b (BUF response)), on which null auto response mode becomes valid. Before setting null auto response mode, check that PIPEnCTR.INBUFM = 0, because the mode can be set only when the buffer is empty. If the INBUFM bit is 1, empty the buffer using the PIPEnCTR.ACLRM bit. Do not write data from the FIFO port while a transition to null auto response mode is being made.

To transition from null auto response mode to normal mode, keep pipe operation disabled (PID[1:0] bits are set to 00b (NAK response)) for the period of the zero-length packet transmission (about 10 µs) before canceling the null auto response mode. In normal mode, data can be written from the FIFO port, so packet transmission to the host is enabled by enabling pipe operation (PID[1:0] bits are set to 01b (BUF response)).

29.3.8 FIFO Buffer

The USBHS provides a FIFO buffer for data transfers, and it manages the memory area used for each pipe. The FIFO buffer has two states depending on whether the access right is assigned to the system (CPU side) or the USBHS (SIE side).

29.3.8.1 Buffer status

Table 29.23 and Table 29.24 show the buffer status in the USBHS. The FIFO buffer status can be confirmed using the DCPCTR.BSTS and PIPEnCTR.INBUFM bits. The transfer direction for the FIFO buffer can be specified in the PIPECFG.DIR or CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM bit is valid for pipes 1 to 5 in the transmitting direction.

When a transmitting pipe uses double buffering, the software can read the BSTS bit to monitor the FIFO buffer status on the CPU side and the INBUFM bit to monitor the FIFO buffer status on the SIE side. When write access to the FIFO port by the CPU or DMA/DTC is slow and the buffer empty status cannot be determined using the BEMP interrupt, the software can use the INBUFM bit to confirm the end of transmission.

Table 29.23 Buffer status indicated in the BSTS flag (1 of 2)

ISEL or DIR	BSTS	FIFO buffer status
0 (receiving direction)	0	There is no received data, or data is being received. Reading from the FIFO port is disabled.

当FIFO缓冲区使用双缓冲区模式时，使用此功能可以接收以传输为单位的数据包。如果禁用管道操作，软件必须再次启用管道（PID[1:0]位设置为01b（BUF响应））。

响应PID=NAK函数只能用于批量传输。

29.3.7.9 自动响应模式

对于批量传输管道（1到5），当PIPEnCTR.ATREPM位设置为1时，将转换到自动响应模式。

在OUT传输期间(PIPECFG.DIR=0)，将调用OUT-NAK模式，在IN传输期间(DIR=1)，将调用空自动响应模式。

29.3.7.10 OUT-NAK mode

对于批量OUT传输管道，NAK响应OUT令牌返回，并且当PIPEnCTR.ATREPM位设置为1。要从正常模式转换到OUT-NAK模式，请在禁用管道操作时指定OUT-NAK模式（对于NAK响应，PID[1:0]=00b）。接下来，启用管道操作（PID[1:0]=01b用于BUF响应），此时OUT-NAK模式变为有效。如果在禁用管道操作之前立即收到OUT令牌，则正常接收令牌数据，并向主机返回ACK。

要从OUT-NAK模式转换到正常模式，请在禁用管道操作(NAK)时取消OUT-NAK模式。

接下来启用管道操作(BUF)。在正常模式下，可以接收OUT数据。

29.3.7.11 空自动响应模式

对于批量IN传输管道，当PIPEnCTR.ATREPM位设置为1时，将连续传输零长度数据包。

要从正常模式转换为空自动响应模式，请在禁用管道操作时指定空自动响应模式（PID[1:0]位设置为00b（NAK响应））。接下来，启用管道操作（PID[1:0]位设置为01b（BUF响应）），此时空自动响应模式变为有效。在设置空自动响应模式之前，请检查PIPEnCTR.INBUFM=0，因为只有在缓冲区为空时才能设置模式。如果INBUFM位为1，则使用PIPEnCTR.ACLRM位清空缓冲区。在转换到空自动响应模式时，不要从FIFO端口写入数据。

要从空自动响应模式转换到正常模式，请在零长度数据包传输期间（约10μs）保持管道操作禁用（PID[1:0]位设置为00b（NAK响应）），然后再取消空自动响应模式。在正常模式下，数据可以从FIFO端口写入，因此通过启用管道操作（PID[1:0]位设置为01b（BUF响应））来启用到主机的数据包传输。

29.3.8 FIFO Buffer

USBHS为数据传输提供FIFO缓冲区，并管理用于每个管道的内存区域。FIFO缓冲区有两种状态，具体取决于访问权限是分配给系统（CPU端）还是USBHS（SIE端）。

29.3.8.1 缓冲状态

表29.23和表29.24显示了USBHS中的缓冲区状态。FIFO缓冲区状态可以使用确认DCPCTR.BSTS和PIPEnCTR.INBUFM位。FIFO缓冲区的传输方向可以在pipecfg.dir或cfifoselisel位（选择DCP时）。

INBUFM位对传输方向的管道1到5有效。

当传输管道使用双缓冲时，软件可以读取BSTS位来监控CPU侧的FIFO缓冲区状态，以及读取INBUFM位来监控SIE侧的FIFO缓冲区状态。当写访问FIFO端口由CPU或DMADTC较慢且无法使用BEMP中断确定缓冲区空状态，软件可以使用INBUFM位确认传输结束。

Table 29.23 BSTS标志中指示的缓冲区状态（2个中的1个）

ISEL或DIR	BSTS	FIFO缓冲区状态
0 (receiving direction)	0	没有接收到数据，或正在接收数据。 禁止从FIFO端口读取。

ISEL or DIR	BSTS	FIFO buffer status
0 (receiving direction)	1	There is received data, or a zero-length packet is received. Reading from the FIFO port is allowed. When a zero-length packet is received, reading is not possible and the buffer must be cleared.
1 (transmitting direction)	0	Transmission is not complete. Writing to the FIFO port is disabled.
1 (transmitting direction)	1	Transmission is complete. CPU write is allowed.

1 (transmitting direction)	0	Transmission is complete. There is no data waiting to be transmitted.
1 (transmitting direction)	1	The FIFO port has written data to the buffer. There is data to be transmitted.

29.3.8.2 FIFO buffer clearing

Table 29.25 shows the methods for clearing the FIFO buffer. The FIFO buffer can be cleared using the BCLR bit in the port control register, DnFIFOSEL.DCLRM, or the PIPEnCTR.ACLRM bit.

Single or double buffering can be selected for pipes 1 to 5 in the PIPECFG.DBLB bit.

Table 29.25 Buffer clearing methods

Bit used	BCLR	DCLRM	ACLRM
Clearing condition	Cleared by writing 1	1: Mode valid 0: Mode invalid	1: Mode valid 0: Mode invalid

Auto buffer clear mode function

The USBHS discards all received data packets if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet is received, the ACK response is returned to the host controller. The auto buffer clear mode function can only be set in the FIFO buffer reading direction.

Setting the ACLRM bit to 1 and then to 0 clears the FIFO buffer of the selected pipe regardless of the access direction. An access cycle of at least 100 ns is required for the internal hardware sequence processing between ACLRM = 1 and ACLRM = 0.

29.3.8.3 FIFO port functions

Table 29.26 shows the settings for the FIFO port functions. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, set the BVAL flag in the port control register to end writing. To send a zero-length packet, use the BCLR bit to clear the buffer, and then set the BVAL flag to end writing.

In reading, reception of new packets is automatically enabled when all data is read. Data cannot be read when a zerolength packet is received (DTLN[11:0] = 0), so the buffer must be cleared with the BCLR bit. The length of the receive data can be confirmed in the DTLN[11:0] flags in the port control register.

Table 29.23 BSTS标志中指示的缓冲区状态（2个中的2个）

ISEL或DIR	BSTS	FIFO缓冲区状态
0 (receiving direction)	1	有接收数据，或接收到零长度数据包。 允许从FIFO端口读取。 当接收到零长度数据包时，无法读取，必须清除缓冲区。
1 (transmitting direction)	0	传输未完成。 禁止写入FIFO端口。
1 (transmitting direction)	1	传输完成。 允许CPU写入。

0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	传输完成。 没有等待传输的数据。

29.3.8.2 FIFO缓冲区清除

表29.25显示了清除FIFO缓冲区的方法。可以使用端口控制寄存器中的BCLR位、DnFIFOSEL.DCLRM或PIPEnCTR.ACLRM位清除FIFO缓冲区。

可以在PIPECFG.DBLB位中为管道1到5选择单缓冲或双缓冲。

Table 29.25 缓冲区清除方法

FIFO缓冲区清除模式	清除FIFO缓冲区 CPU端	自动清除模式 读取指定管道数据后的FIFO缓冲区	自动缓冲区清除模式，用于丢弃所有接收到的数据包
注册使用	• CFIFOCTR • DnFIFOCTR	DnFIFOSEL	PIPEnCTR
使用的位	BCLR	DCLRM	ACLRM
清算条件	通过写1清除	1：模式有效0 ：模式无效	1：模式有效0 ：模式无效

自动缓冲清除模式功能

如果PIPEnCTR.ACLRM位设置为1，USBHS将丢弃所有接收到的数据包。如果接收到正确的数据包，则向主机控制器返回ACK响应。自动缓冲区清除模式功能只能在FIFO缓冲区读取方向设置。

无论访问方向如何，将ACLRM位设置为1，然后设置为0都会清除所选管道的FIFO缓冲区。ACLRM=1和ACLRM=0之间的内部硬件序列处理需要至少100ns的访问周期。

29.3.8.3 先进先出端口功能

表29.26显示了FIFO端口功能的设置。在写访问中，在达到最大数据包大小之前写入数据会自动启用数据传输。要在达到最大数据包大小之前启用传输，请设置端口控制寄存器中的BVAL标志以结束写入。要发送零长度数据包，请使用BCLR位清除缓冲区，然后设置BVAL标志以结束写入。

在读取中，当所有数据被读取时，自动启用新数据包的接收。接收到零长度数据包时（DTLN[11:0]=0）无法读取数据，因此必须使用BCLR位清除缓冲区。接收数据的长度可以在端口控制寄存器中的DTLN[11:0]标志中确认。

Table 29.26 FIFO port function settings

Register name	Bit name	Description

	REW	FIFO buffer rewind (re-read, rewrite)
	DCLRM	Automatically clears receive data for a specified pipe after the data is read (only for DnFIFO)
	DREQE	Enables DMA/DTC transfers (only for DnFIFO)
	MBW[1:0]	FIFO port access bit width
	BIGEND	Selects FIFO port endian
	ISEL	FIFO port access direction (only for DCP)
	CURPIPE[3:0]	Selects the current pipe
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	Ends writing to the FIFO buffer
	BCLR	Clears the FIFO buffer on the CPU side
	DTLN[11:0]	Checks the length of receive data

FIFO port selection

Table 29.27 shows the pipes that can be selected with the different FIFO ports. The pipe to be accessed must be selected in the CURPIPE[3:0] bits in the port selection register. After a pipe is selected, the software must check whether the written value can be correctly read from the CURPIPE[3:0] bits. (If the previous pipe number is read, it indicates that the USBHS is modifying the pipe.) Next, the software checks that the FRDY flag in the port control register is 1.

In addition, the software must specify the bus width to be accessed in the MBW[1:0] bits in the port selection register.

The FIFO buffer access direction conforms to the PIPECFG.DIR setting. For the DCP only, the ISEL bit in the port selection register determines the direction.

Table 29.27 FIFO port access by pipe

Pipe	Access Method	Port that can be used
DCP	CPU access	CFIFO port register
Pipes 1 to 9	CPU access	CFIFO port register D0FIFO/D1FIFO port register
	DMA/DTC access	D0FIFO/D1FIFO port register

REW bit

It is possible to temporarily stop access to a pipe being accessed, access a different pipe, and then continue processing for the first pipe again. The REW bit in the port selection register is used for this processing.

If a pipe is selected in the CURPIPE[3:0] bits in the port selection register with the REW bit set to 1, the pointer used for reading from and writing to the FIFO buffer is reset, and reading or writing can be carried out from the first byte. If a pipe is selected with the REW bit set to 0, data can be read and written in continuation from the previous selection, without the pointer being reset.

To access the FIFO port, the software must check that the FRDY bit in the port control register is 1 after selecting a pipe.

29.3.8.4 DMA/DTC transfers (D0FIFO and D1FIFO ports)

Overview of DMA/DTC transfer

For pipes 1 to 9, the FIFO port can be accessed using the DMAC/DTC. When buffer access for the pipe targeted for DMA/DTC transfer is enabled, a DMA/DTC transfer request is issued.

Select the unit of transfer to the FIFO port in the DnFIFOSEL.MBW[1:0] bits, and select the pipe targeted for the DMA/DTC transfer in the DnFIFOSEL.CURPIPE[3:0] bits. Do not change the selected pipe during the DMA transfer.

Table 29.26 FIFO端口功能设置

注册名称	位名称	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	选择DTLN[11:0]读取模式
	REW	FIFO缓冲区倒带（重新读取、重写）
	DCLRM	读取数据后自动清除指定管道的接收数据（仅适用于DnFIFO）
	DREQE	启用DMADTC传输（仅适用于DnFIFO）
	MBW[1:0]	FIFO端口访问位宽
	BIGEND	选择FIFO端口字节序
	ISEL	FIFO端口访问方向（仅适用于DCP）
	CURPIPE[3:0]选择当前管道	
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	结束写入FIFO缓冲区
	BCLR	清除CPU端的FIFO缓冲区
	DTLN[11:0]	检查接收数据的长度

先进先出端口选择

表29.27显示了可以使用不同FIFO端口选择的管道。必须在端口选择寄存器的CURPIPE[3:0]位中选择要访问的管道。选择管道后，软件必须检查是否可以从CURPIPE[3:0]位正确读取写入的值。（如果读取到之前的管道号，则表明USBHS正在修改管道。）接下来，软件检查端口控制寄存器中的FRDY标志为1。

此外，软件必须在端口选择寄存器的MBW[1:0]位中指定要访问的总线宽度。

FIFO缓冲区访问方向符合PIPECFG.DIR设置。仅对于DCP，端口选择寄存器中的ISEL位决定方向。

Table 29.27 通过管道访问FIFO端口

Pipe	访问方法	可以使用的端口
DCP	CPU访问	CFIFO端口寄存器
管道1到9	CPU访问	CFIFO端口寄存器 D0FIFOD1FIFO端口寄存器
	DMADTC访问	D0FIFOD1FIFO端口寄存器

REW位

可以暂时停止对正在访问的管道的访问，访问不同的管道，然后再次继续处理第一个管道。端口选择寄存器中的REW位用于此处理。

如果在端口选择寄存器的CURPIPE[3:0]位中选择了一个管道，并且REW位设置为1，则用于读取和写入FIFO缓冲区的指针复位，可以进行读取或写入从第一个字节开始。如果在REW位设置为0的情况下选择了管道，则可以从先前的选择继续读取和写入数据，而无需重置指针。

要访问FIFO端口，软件必须在选择管道后检查端口控制寄存器中的FRDY位是否为1。

29.3.8.4 DMADTC传输（D0FIFO和D1FIFO端口）

DMADTC传输概述

对于管道1到9，可以使用DMACDTC访问FIFO端口。当对目标管道进行缓冲区访问时启用DMADTC传输，发出DMADTC传输请求。

在DnFIFOSEL.MBW[1:0]位中选择传输到FIFO端口的单位，并选择目标管道DnFIFOSEL.CURPIPE[3:0]位中的DMADTC传输。在DMA传输期间不要更改选定的管道。

DnFIFO auto clear mode (D0FIFO and D1FIFO port reading direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USBHS automatically clears the FIFO buffer of the selected pipe when reading of data from the FIFO buffer is complete.

Table 29.28 shows the packet reception and FIFO buffer clearing processing by software for each of the different settings. As shown in the table, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA/DTC transfers without involving software.

The DnFIFO auto clear mode can only be set in the FIFO buffer reading direction.

Table 29.28 Packet reception and FIFO buffer clearing processing by software

	Register setting			
	DCLRM = 0		DCLRM = 1

29.3.8.5 Allocating the FIFO buffer

Figure 29.11 shows an example of a memory map of the FIFO buffer. The FIFO buffer is an area shared by the USBHS and the control CPU of the application. There are two situations for the FIFO buffer: (1) access rights are given to the application (CPU side), and (2) access rights are given to the USBHS (SIE side).

An independent area is set for the FIFO buffer for each pipe. A memory area is determined by the first block number and the number of blocks (specified in the BUFNMB[7:0] and BUFSIZE[4:0] bits in PIPEBUF), where 64 bytes is regarded as one block. When the continuous transfer mode is selected in the CNTMD bit in PIPECFG, set the BUFSIZE[4:0] bits to an integral multiple of the maximum packet size. When double buffering is selected in the DBLB bit in PIPECFG, twice the memory area specified in the BUFSIZE[4:0] bits in PIPEBUF is allocated to the same pipe.

Three FIFO ports are used to access (read data from and write data to) the FIFO buffer. Specify the number of the pipe to be allocated to the FIFO port in the CURPIPE[3:0] bits in C/DnFIFOSEL.

The FIFO buffer status of each pipe can be checked in the DCPCTR.BSTS, PIPEnCTR, and INBUFM bits. The FIFO port access rights can be checked in the FRDY flag in C/DnFIFOCTR.

DnFIFO自动清除模式（D0FIFO和D1FIFO端口读取方向）

如果DnFIFOSEL.DCLRM位设置为1，USBHS会在从FIFO缓冲区读取数据完成时自动清除所选管道的FIFO缓冲区。

表29.28显示了软件对每个不同设置的数据包接收和FIFO缓冲区清除处理。如表所示，缓冲区清除条件取决于PIPECFG.BFRE位中设置的值。使用

DnFIFOSEL.DCLRM位消除了在需要清除缓冲区的任何情况下通过软件清除缓冲区的需要。这可以在不涉及软件的情况下实现DMADTC传输。

DnFIFO自动清除模式只能设置在FIFO缓冲区读取方向。

Table 29.28 通过软件进行数据包接收和FIFO缓冲区清除处理

	注册设置			
	DCLRM = 0		DCLRM = 1

29.3.8.5 分配FIFO缓冲区

图29.11显示了FIFO缓冲区的内存映射示例。FIFO缓冲区是由USBHS和应用程序的控制CPU共享的区域。FIFO缓冲区有两种情况：（1）访问权限给应用程序（CPU端），（2）访问权限给USBHS（SIE端）。

为每个管道的FIFO缓冲区设置一个独立的区域。一个内存区域由第一个块号和块数（在PIPEBUF中的BUFNMB[7:0]和BUFSIZE[4:0]位指定）确定，其中64个字节被视为一个块。在PIPECFG的CNTMD位中选择连续传输模式时，将BUFSIZE[4:0]位设置为最大数据包大小的整数倍。当在PIPECFG的DBLB位中选择双缓冲时，PIPEBUF中的BUFSIZE[4:0]位指定的内存区域的两倍将分配给同一管道。

三个FIFO端口用于访问（读取数据和写入数据）FIFO缓冲区。在CDnFIFOSEL的CURPIPE[3:0]位中指定要分配给FIFO端口的管道编号。

可以在DCPCTR.BSTS、PIPEnCTR和INBUFM位中检查每个管道的FIFO缓冲区状态。可以在CDnFIFOCTR中的FRDY标志中检查FIFO端口访问权限。

29.3.9 Control Transfers Using the DCP

The Default Control Pipe (DCP) is used for data transfers in the control transfer data stage. The FIFO buffer of the DCP is a 64-byte single buffer with a fixed area for both control reads and control writes. The FIFO buffer can be accessed only through the CFIFO port.

29.3.9.1 Control transfers in host controller mode

Setup stage

The USBREQ, USBVAL, USBINDX, and USBLENG registers are used to transmit USB requests for setup transactions. Writing the setup packet data to the register and then writing 1 to the DCPCTR.SUREQ bit transmits the specified data for the setup transaction. On completion of the transaction, the SUREQ bit clears to 0. Do not change these USB request registers while SUREQ = 1.

When an attached function device is detected, the software must issue the first setup transaction for the device using this sequence with the DCPMAXP.DEVSEL[3:0] bits cleared to 0 and the DEVADD0.USBSPD[1:0] bits set appropriately.

When an attached function device is shifted to the Address state, the software must issue setup transactions using this sequence with the assigned USBAddress set in the DEVSEL[3:0] bits and the bits in DEVADDn (n = 0 to A) corresponding to the specified USBAddress set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in DEVADD2. When PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in DEVADD5.

When the setup transaction data is sent, an interrupt request is generated based on the response from the peripheral device (SIGN or SACK bit in INTSTS1). This interrupt request allows the software to check the setup transaction result.

The DATA0 data packet (USB request) for the setup transaction is always transmitted regardless of the status of the DCPCTR.SQMON flag.

29.3.9 使用DCP进行控制传输

默认控制管道(DCP)用于控制传输数据阶段的数据传输。DCP的FIFO缓冲区是一个64字节的单缓冲区，具有用于控制读取和控制写入的固定区域。FIFO缓冲区只能通过CFIFO端口访问。

29.3.9.1 主机控制器模式下的控制传输

设置阶段

USBREQ、USBVAL、USBINDX和USBLENG寄存器用于传输设置事务的USB请求。
将设置数据包数据写入寄存器，然后向DCPCTR.SUREQ位写入1，以传输设置事务的指定数据。事务完成后，SUREQ位清除为0。在SUREQ=1时不要更改这些USB请求寄存器。

当检测到连接的功能器件时，软件必须使用此序列为器件发出第一个设置事务，其中DCPMAXP.DEVSEL[3:0]位清零，DEVADD0.USBSPD[1:0]位适当设置。

当连接的功能器件转移到地址状态时，软件必须使用此序列发出设置事务，其中指定的USBAddress设置在DEVSEL[3:0]位和DEVADDn中的位（n=0到A）对应于指定的USBAddress设置得当。例如，当PIPEMAXP.DEVSEL[3:0]=0010b时，在DEVADD2中进行适当的设置。当PIPEMAXP.DEVSEL[3:0]=0101b时，在DEVADD5中进行适当的设置。

发送设置事务数据时，根据外围设备的响应（INTSTS1中的SIGN或SACK位）生成中断请求。该中断请求允许软件检查设置事务结果。

用于设置事务的DATA0数据包（USB请求）始终被传输，无论
DCPCTR.SQMON flag.

Data stage

The data stage is used to transfer data using the DCP FIFO buffer.

Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit. Specify the transfer direction in the DCPCFG.DIR bit.

For the first data packet of the data stage, the data PID must be transferred as DATA1. Set data PID to DATA1 in the DCPCTR.SQSET bit and set the PID[1:0] bits to 01b (BUF response). Completion of data transfer is detected using the BRDY or BEMP interrupt.

Data transfer of multiple packets is enabled in continuous transfer mode. However, when continuous transfer is specified in the receiving direction, the BRDY interrupt is not generated unless the buffer becomes full or a short packet is received (for 256 bytes or less, which is an integral multiple of the maximum packet size). If the transmit data size is an integral multiple of the maximum packet size, control the control write transfer through the software to transmit a zerolength packet last.

Status stage

The status stage is used for zero-length packet data transfers in the reverse direction of the data stage. As in the data stage, data is transfered using the DCP FIFO buffer. Transactions are executed using the same procedure as the data stage.

Data packets in the status stage must be transmitted and received with the data PID set to DATA1 using the DCPCTR.SQSET bit.

When a zero-length packet is received, check the receive-data length in the CFIFOCTR.DTLN[11:0] flags after a BRDY interrupt is generated, and then clear the FIFO buffer using the BCLR bit.

29.3.9.2 Control transfers in device controller mode

Setup stage

The USBHS returns an ACK response to a normal setup packet for the USBHS. The USBHS operates in the setup stage as follows:

On receiving a new setup packet, the USBHS sets the following bits:

- Sets the INTSTS0.VALID flag to 1
- Sets the DCPCTR.PID[1:0] bits to 00b (NAK response)
- Sets the DCPCTR.CCPL bit to 0

When the USBHS receives a data packet following a setup packet, it stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Before performing the response processing for a control transfer, set the VALID flag to 0. When the VALID flag = 1, the PID[1:0] bits cannot be set to 01b (BUF response), and the data stage cannot be terminated.

Using the VALID flag function, the USBHS can suspend a request being processed when it receives a new USB request during a control transfer and return a response to the latest request.

In addition, the USBHS automatically detects the direction bit (bmRequestType bit 8) and the request data length (wLength) in the received USB request. It distinguishes between control read transfers, control write transfers, and nodata control transfers, and it controls stage transitions. For an incorrect sequence, a sequence error occurs in the control transfer stage transition interrupt, and the interrupt is reported to the software. For a diagram of the stage control by the USBHS, see Figure 29.9.

Data stage

The DCP must be used to execute data transfers for received USB requests. Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit.

If the transfer data is larger than the size of the DCP FIFO buffer, execute the data transfer using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

In high-speed control write transfers, a NYET handshake response is returned based on the FIFO buffer status.

数据阶段

数据级用于使用DCPFIFO缓冲区传输数据。

在访问DCPFIFO缓冲区之前，请在CFIFOSEL.ISEL位中指定访问方向。在DCPCFG.DIR位中指定传输方向。

对于数据阶段的第一个数据包，数据PID必须作为DATA1传输。将数据PID设置为DATA1 DCPCTR.SQSET位并将PID[1:0]位设置为01b（BUF响应）。使用检测到数据传输的完成 BRDY或BEMP中断。

在连续传输模式下启用多个数据包的数据传输。但是，当在接收方向指定连续传输时，除非缓冲区变满或接收到短数据包（256字节或更少，这是最大数据包大小的整数倍），否则不会产生BRDY中断。如果传输数据大小是最大数据包大小的整数倍，则通过软件控制控制写入传输，最后传输一个零长度数据包。

状态阶段

状态阶段用于在数据阶段的相反方向上进行零长度分组数据传输。与数据阶段一样，使用DCPFIFO缓冲区传输数据。事务使用与数据阶段相同的过程执行。

状态阶段的数据包必须在数据PID设置为DATA1的情况下使用 DCPCTR.SQSET bit.

当接收到零长度数据包时，在产生BRDY中断后检查CFIFOCTR.DTLN[11:0]标志中的接收数据长度，然后使用BCLR位清除FIFO缓冲区。

29.3.9.2 设备控制器模式下的控制传输

设置阶段

USBHS向USBHS的正常设置数据包返回ACK响应。USBHS在设置阶段运行如下：

在接收到新的设置数据包时，USBHS设置以下位：

●将INTSTS0.VALID标志设置为1

●将DCPCTR.PID[1:0]位设置为00b（NAK响应）

●将DCPCTR.CCPL位设置为0

当USBHS在设置包之后接收到数据包时，它会将USB请求参数存储在USBREQ中， USBVAL, USBINDX, and USBLENG.

在执行控制传输的响应处理之前，将VALID标志设置为0。当VALID标志=1时， PID[1:0]位不能设置为01b（BUF响应），并且不能终止数据阶段。

使用VALID标志功能，USBHS可以在控制传输期间接收到新的USB请求时暂停正在处理的请求，并返回对最新请求的响应。

此外，USBHS会自动检测接收到的USB请求中的方向位（bmRequestTypebit8）和请求数据长度（wLength）。它区分控制读取传输、控制写入传输和无数据控制传输，并控制阶段转换。对于不正确的序列，在控制转移阶段转换中断中发生序列错误，并将中断报告给软件。USBHS的舞台控制图见图29.9。

数据阶段

DCP必须用于执行接收到的USB请求的数据传输。在访问DCPFIFO缓冲区之前，请在CFIFOSEL.ISEL位中指定访问方向。

如果传输数据大于DCPFIFO缓冲区的大小，则使用控制写传输的BRDY中断和控制读传输的BEMP中断执行数据传输。

在高速控制写入传输中，根据FIFO缓冲区状态返回NYET握手响应。

Status stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to 01b (BUF response).Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to 01b (BUF response).

After this setting is made, the USBHS automatically executes the status stage based on the data transfer direction determined at the setup stage. The status stage is executed as follows:

- For control read transfers:
  The USBHS receives a zero-length packet from the USB host and transmits an ACK response
- For control write transfer and no data control transfer:
  The USBHS transmits a zero-length packet and receives an ACK response from the USB host.

Control transfer auto response function

The USBHS automatically responds to a normal SET_ADDRESS request. If the SET_ADDRESS request contains any of the following errors, a response must be returned by software.

- When bmRequestType is not 00h: except control write transfer
- When wIndex is not 00h: request error
- When wLength is not 00h: except no data control transfer
- When wValue is larger than 7Fh: request error
- When PL1CTRL.DVSQ[3:0] flags are 0011b (Configured): control transfer of device state error

A response by the corresponding software is required to all requests other than SET_ADDRESS.

29.3.10 Bulk Transfers (Pipes 1 to 5)

The FIFO buffer usage (setting of single buffer/double buffer or continuous/discontinuous transfer mode) is configurable for bulk transfers. The FIFO buffer size can be set up to 2 KB. The USBHS manages the FIFO buffer state and automatically responds to the PING packet and the NYET handshake.

29.3.10.1 PING packet control in host controller mode

In the OUT direction, a PING packet is automatically transmitted by the USBHS. The USBHS starts communication in the transmitting direction beginning with the PING packet. When it receives an ACK handshake in response to the PING packet, the USBHS transmits an OUT packet. The USBHS returns to the PING transmission state on receiving a NAK or NYET response during an OUT transaction. The procedure is as follows:

Starting OUT data transmission

(1) Transmit PING packet
(2) Receive NAK handshake
(3) Transmit PING packet
(4) Receive ACK handshake
(5) Transmit OUT data packet
(6) Receive ACK handshake
(7) Transmit OUT data packet
⋮
(8) Return to (1) on receiving a NAK/NYET handshake

The USBHS returns to the PING packet transmission state when a hardware reset is issued, the NYET or NAK handshake is received, the sequence toggle bit is cleared (SQCLR), or the buffer clear bit (ACLRM) is set.

29.3.10.2 NYET handshake control in device controller mode

Table 29.29 lists responses to received tokens during bulk and control transfers. The USBHS returns a NYET response when an available area for only one packet is left in the FIFO buffer when the USBHS has received an OUT token during a bulk or control transfer. When the USBHS receives a short packet, however, it returns an ACK response instead of NYET even when this condition occurs.

状态阶段

通过将DCPCTR.CCPL位设置为1而将DCPCTR.PID[1:0]位设置为01b（BUF响应）来终止控制传输。通过在DCPCTR时将DCPCTR.CCPL位设置为1来终止控制传输。PID[1:0]位设置为01b（BUF响应）。

完成此设置后，USBHS根据设置阶段确定的数据传输方向自动执行状态阶段。状态阶段执行如下：

- 对于控制读取传输：
  USBHS接收来自USB主机的零长度数据包并发送ACK响应
- 对于控制写传输和无数据控制传输：
  USBHS发送一个长度为零的数据包并接收来自USB主机的ACK响应。

控制转移自动响应功能

USBHS自动响应正常的SET_ADDRESS请求。如果SET_ADDRESS请求包含以下任何错误，则必须由软件返回响应。

- bmRequestType不为00h时：控制写入传输除外
- wIndex不为00h时：请求错误
- wLength不为00h时：无数据控制传输除外
- wValue大于7Fh时：请求错误
- 当PL1CTRL.DVSQ[3:0]标志为0011b（已配置）时：设备状态错误的控制传输

除SET_ADDRESS之外的所有请求都需要相应软件的响应。

29.3.10 批量传输（管道1到5）

FIFO缓冲区使用（设置单缓冲区双缓冲区或连续不连续传输模式）可配置为批量传输。FIFO缓冲区大小可设置为2 KB。USBHS管理FIFO缓冲区状态并自动响应PING数据包和NYET握手。

29.3.10.1 主机控制器模式下的PING包控制

在OUT方向，USBHS自动发送一个PING数据包。USBHS从PING数据包开始在传输方向上开始通信。当它接收到响应PING数据包的ACK握手时，USBHS发送一个OUT数据包。USBHS在OUT事务期间收到NAK或NYET响应后返回PING传输状态。程序如下：

开始OUT数据传输

(1) 发送PING数据包接收NA
(2) K握手发送PING数据包
(3)
(4) 接收ACK握手发送OUT数
(5) 据包接收ACK握手发送OU
(6) T数据包
(7)
⋮
(8) 收到NAKNYET握手后返回(1)

当发出硬件复位、接收到NYET或NAK握手、清除序列切换位(SQCLR)或设置缓冲区清除位(ACLRM)时，USBHS将返回PING数据包传输状态。

29.3.10.2 设备控制器模式下的NYET握手控制

表29.29列出了在批量和控制传输期间对接收到的令牌的响应。当USBHS在批量或控制传输期间接收到OUT令牌时，如果FIFO缓冲区中只剩下一个数据包的可用区域，则USBHS将返回NYET响应。但是，当USBHS接收到一个短数据包时，即使发生这种情况，它也会返回ACK响应而不是NYET。

Table 29.29 Responses to received tokens

PID[1:0] bit setting	FIFO buffer state	Received token	Response	Note
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY	OUT/PING	ACK	When OUT token is received, data packet is received.*1
	RCV-BRDY	OUT	NYET	Data packet is received*2
	RCV-BRDY	OUT (Short)	ACK	Data packet is received*2
	RCV-BRDY	PING	ACK	*2
	RCV-NRDY	OUT/PING	NAK	—
	TRN-BRDY	IN	DATA0/1	Data packet is transmitted
	TRN-NRDY	IN	NAK	—

Note 1. RCV-BRDY: An available area for two packets is left in the FIFO buffer when an OUT token or a PING token is received.
Note 2. RCV-BRDY: An available area for only one packet is left in the FIFO buffer when an OUT token is received.
RCV-NRDY: No available area is left in the FIFO buffer when a PING token is received.
TRN-BRDY: The FIFO buffer contains transmit data when an IN token is received.
TRN-NRDY: The FIFO buffer contains no transmit data when an IN token is received.

29.3.11 Interrupt Transfers (Pipes 6 to 9)

In device controller mode, the USBHS performs interrupt transfers based on the timing dictated by the host controller. In the interrupt transfer, the USBHS ignores PING packets (no response) and does not transmit the NYET handshake, but returns an ACK, NAK, or STALL response.

In host controller mode, the software can set the timing for issuing tokens using the interval counter. The USBHS does not issue a PING token but issues an OUT token, including for transfers in the OUT direction.

The USBHS does not support high-bandwidth interrupt transfers.

29.3.11.1 Interval counter for interrupt transfers in host controller mode

Specify the transaction interval for interrupt transfers in the PIPEPERI.IITV[2:0] bits. The USBHS issues interrupt transfer tokens based on this interval.

(1) Initializing the counter

The USBHS initializes the interval counter under the following conditions:

- Power-on reset:
  This initializes the IITV[2:0] bits
- FIFO buffer initialization using the PIPEnCTR.ACLRM bit:
  This does not initialize the IITV[2:0] bits, but does initialize the count value. Setting the PIPEnCTR.ACLRM bit to 0 starts counting from the value set in IITV[2:0].

(2) Operation when tokens cannot be transmitted or received even on token generation

No token is generated in the following cases even at token generation time. In these cases, the USBHS tries to execute the transaction in the next interval.

- When the PID[1:0] bits are set to NAK or STALL
- When the FIFO buffer is full at token transmit time in the receiving (IN) direction
- When there is no data to be transmitted in the FIFO buffer at token transmit time in the transmitting (OUT) direction

29.3.12 Isochronous Transfers (Pipes 1 and 2)

The USBHS does not support high-bandwidth isochronous transfers but provides the following functions for isochronous transfers:

Table 29.29 对收到的令牌的响应

PID[1:0]位设置	FIFO缓冲区状态	接收到的令牌	响应	Note
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY	OUT/PING	ACK	当接收到OUT令牌时，接收到数据包。*1
	RCV-BRDY	OUT	NYET	接收数据包*2
	RCV-BRDY	OUT (Short)	ACK	接收数据包*2
	RCV-BRDY	PING	ACK	*2
	RCV-NRDY	OUT/PING	NAK	—
	TRN-BRDY	IN	DATA0/1	传输数据包
	TRN-NRDY	IN	NAK	—

注1.RCV-BRDY：当接收到OUT令牌或PING令牌时，两个数据包的可用区域留在FIFO缓冲区中。
注2.RCV-BRDY：当接收到OUT令牌时，FIFO缓冲区中只剩下一个可用于一个数据包的区域。
RCV-NRDY：接收到PING令牌时，FIFO缓冲区中没有可用区域。
TRN-BRDY：接收到IN令牌时，FIFO缓冲区包含发送数据。
TRN-NRDY：接收到IN令牌时，FIFO缓冲区不包含发送数据。

29.3.11 中断传输（管道6到9）

在设备控制器模式下，USBHS根据主机控制器规定的时序执行中断传输。在中断传输中，USBHS忽略PING数据包（无响应）并且不发送NYET握手，而是返回ACK、NAK或STALL响应。

在主机控制器模式下，软件可以使用间隔计数器设置发布令牌的时间。USBHS不会发出PING令牌，但会发出OUT令牌，包括用于OUT方向的传输。

USBHS不支持高带宽中断传输。

29.3.11.1 主机控制器模式下中断传输的间隔计数器

在PIPEPERI.IITV[2:0]位中指定中断传输的事务间隔。USBHS基于此间隔发出中断传输令牌。

(1) 初始化计数器

USBHS在以下条件下初始化间隔计数器：

- Power-on reset:
  这将初始化IITV[2:0]位

●使用PIPEnCTR.ACLRM位初始化FIFO缓冲区：
这不会初始化IITV[2:0]位，但会初始化计数值。将PIPEnCTR.ACLRM位设置为0从IITV[2:0]中设置的值开始计数。

(2) 即使在生成令牌时也无法发送或接收令牌时的操作

在以下情况下，即使在生成令牌时也不会生成令牌。在这些情况下，USBHS尝试在下一个时间间隔执行事务。

●当PID[1:0]位设置为NAK或STALL时
●接收(IN)方向的令牌发送时FIFO缓冲区已满时
●在发送（OUT）方向的令牌发送时间，FIFO缓冲区中没有要发送的数据时

29.3.12 同步传输（管道1和2）

USBHS不支持高带宽同步传输，但为同步传输提供以下功能：

- Notification of isochronous transfer error
- Interval counter (specified in the PIPEPERI.IITV[2:0] bits)
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function (specified in the PIPEPERI.IFIS bit)
- SOF pulse output function

29.3.12.1 Error detection in isochronous transfers

The USBHS provides a function for detecting the errors described in this section, so that when errors occur in isochronous transfers, they can be controlled by software. Table 29.30 and Table 29.31 show the priority order for errors detected by the USBHS and the associated interrupts.

PID errors

- The PID value of the received packet is invalid

CRC errors and bit stuffing errors

- A CRC error is found in a received packet or the bit stuffing is illegal

Maximum packet size exceeded

- The data size of the received packet exceeds the specified maximum packet size

Overrun and underrun errors

In host controller mode:

- The FIFO buffer is full at token transmit time in the IN (receiving) direction
- There is no data to be sent in the FIFO buffer at token transmit time in the OUT (transmitting) direction

In device controller mode:

- There is no data to be sent in the FIFO buffer at token receive time in the IN (transmitting) direction
- The FIFO buffer is full at token receive time in the OUT (receiving) direction

Interval error

In device controller mode, the following cases are treated as an interval error:

- Failure to receive an IN token in the interval frame during an isochronous IN transfer
- Failure to receive an OUT token in the interval frame during an isochronous OUT transfer

Table 29.30 Error detection for token transmission and reception

Detection priority	Error type	Interrupt generated at error detection and status
1	PID error	No interrupts are generated in either host or device controller mode. (Ignored as a corrupted packet.)
2	CRC or bit stuffing error	No interrupts are generated in either host or device controller mode. (Ignored as a corrupted packet.)
3	Overrun or underrun error	An NRDY interrupt is generated to set the OVRN flag to 1 in both host and device controller modes. In device controller mode, a zero-length packet is transmitted in response to an IN token. No data packets are received in response to the OUT token.
4	Interval error	An NRDY interrupt is generated in device controller mode. No interrupt is generated in host controller mode.

1	PID error	No interrupt is generated. (Ignored as a corrupted packet.)

●同步传输错误通知
●间隔计数器（在PIPEPERI.IITV[2:0]位中指定）
●同步IN传输数据设置控制（IDLY功能）
●同步IN传输缓冲区刷新功能（在PIPEPERI.IFIS位中指定）
●SOF脉冲输出功能

29.3.12.1 同步传输中的错误检测

USBHS提供了检测本节描述的错误的功能，因此当同步传输中出现错误时，可以通过软件进行控制。表29.30和表29.31显示了USBHS检测到的错误和相关中断的优先级顺序。

PID错误

●接收报文的PID值无效

CRC错误和位填充错误

●收到的报文发现CRC错误或比特填充不合法

超出最大数据包大小

●接收包的数据大小超过了指定的最大包大小

溢出和欠载错误

在主机控制器模式下：

●在IN（接收）方向发送令牌时，FIFO缓冲区已满
●在OUT（发送）方向的令牌发送时间，FIFO缓冲区中没有要发送的数据

在设备控制器模式下：

●在IN（发送）方向的令牌接收时间，FIFO缓冲区中没有要发送的数据
●在OUT（接收）方向的令牌接收时间，FIFO缓冲区已满

间隔误差

在设备控制器模式下，以下情况被视为间隔错误：

●等时IN传输期间在间隔帧中接收IN令牌失败
●在等时OUT传输期间未能在间隔帧中接收到OUT令牌

Table 29.30 令牌发送和接收的错误检测

检测优先级	错误类型	错误检测和状态产生的中断
1	PID错误	在主机或设备控制器模式下都不会产生中断。（作为损坏的数据包被忽略。）
2	CRC或位填充错误	在主机或设备控制器模式下都不会产生中断。（作为损坏的数据包被忽略。）
3	溢出或欠载错误	在主机和设备控制器模式下，都会产生一个NRDY中断来将OVRN标志设置为1。在设备控制器模式下，发送一个零长度数据包以响应IN令牌。 没有接收到响应OUT令牌的数据包。
4	间隔误差	在设备控制器模式下会产生一个NRDY中断。在主机控制器模式下不产生中断。

Detection priority	Error type	Interrupt generated at error detection and status
2	CRC or bit stuffing error	An NRDY interrupt is generated and the FRMNUM.CRCE bit sets to 1 in both host and device controller modes.
3	Maximum packet size exceeded error	A BEMP interrupt is generated and the PID[1:0] bits set to STALL in both host and device controller modes.

29.3.12.2 DATA PID

The USBHS does not support high-bandwidth transfers. In device controller mode, the USBHS responds as follows to a received PID:

IN direction

- DATA0: Transmitted as data packet PID
- DATA1: Not transmitted
- DATA2: Not transmitted
- mDATA: Not transmitted

OUT direction (full-speed operation)

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets ignored
- mDATA: Packets ignored

OUT direction (high-speed operation)

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Received normally as data packet PID
- mDATA: Received normally as data packet PID

29.3.12.3 Interval counter

The isochronous transfer interval can be set in the PIPEPERI.IITV[2:0] bits. In device controller mode, the interval counter enables functions as shown in Table 29.32. In host controller mode, the USBHS generates the token issuance timing, and the interval counter operation is the same as that for interrupt transfers.

Table 29.32 Interval counter functions in device controller mode

Transfer direction	Function	Conditions for detection
IN	Transmit buffer flush	Failure to receive an IN token successfully in the interval frame during an isochronous IN transfer
OUT	Notification of no reception of token	Failure to receive an OUT token successfully in the interval frame during an isochronous OUT transfer

The interval count is performed when an SOF is received or for complemented SOFs, so the isochronism can be maintained even if an SOF is corrupt. The frame interval can be set to 2IITV (μ) frames.

(1) Counter initialization in device controller mode

The USBHS initializes the interval counter under the following conditions:

- Power-on reset:
  This initializes the PIPEPERI.IITV[2:0] bits
- FIFO buffer initialization using the ACLRM bit:
  This does not initialize the IITV[2:0] bits, but does initialize the count value.

Table 29.31 数据包接收错误检测(2of2)

检测优先级	错误类型	错误检测和状态产生的中断
2	CRC或位填充错误	在主机和设备控制器模式下，都会产生一个NRDY中断并且FRMNUM.CRCE位设置为1。
3	超出最大数据包大小错误	在主机和设备控制器模式下，都会产生BEMP中断并且PID[1:0]位设置为STALL。

29.3.12.2 数据PID

USBHS不支持高带宽传输。在设备控制器模式下，USBHS对接收到的PID做出如下响应：

在方向

●DATA0：作为数据包PID发送
●DATA1：未发送
●DATA2：未传输
●mDATA：不传输

OUT方向（全速运行）

●DATA0：作为数据包PID正常接收
●DATA1：作为数据包PID正常接收
●DATA2：忽略的数据包
●mDATA：忽略的数据包

OUT方向（高速运转）

●DATA0：作为数据包PID正常接收
●DATA1：作为数据包PID正常接收
●DATA2：作为数据包PID正常接收
●mDATA：作为数据包PID正常接收

29.3.12.3 间隔计数器

同步传输间隔可以在PIPEPERI.IITV[2:0]位中设置。在设备控制器模式下，间隔计数器启用表29.32中所示的功能。在主机控制器模式下，USBHS产生令牌发布时序，间隔计数器操作与中断传输相同。

Table 29.32 设备控制器模式下的间隔计数器功能

转移方向	Function	检测条件
IN	发送缓冲区刷新	在等时IN传输期间未能在间隔帧中成功接收IN令牌
OUT	未收到令牌的通知	在等时OUT传输期间未能在间隔帧中成功接收OUT令牌

间隔计数是在接收到SOF时执行的，或者是针对补充的SOF执行的，因此即使SOF损坏也可以保持等时性。帧间隔可以设置为2IITV(μ)帧。

(1) 设备控制器模式下的计数器初始化

USBHS在以下条件下初始化间隔计数器：

- Power-on reset:
  这将初始化PIPEPERI.IITV[2:0]位
●使用ACLRM位初始化FIFO缓冲区：
  这不会初始化IITV[2:0]位，但会初始化计数值。

After the interval counter is initialized, the interval count starts under either of the following conditions when a packet is transferred successfully:

- An SOF is received after data is transmitted in response to an IN token, with the PID[1:0] bits set to 01b (BUF response)
- An SOF is received after data is received in response to an OUT token, with PID[1:0] bits set to 01b (BUF response)

The interval counter is not initialized under the following conditions:

- When the PID[1:0] bits are set to NAK or STALL
  This does not stop the interval timer. The USBHS attempts the transaction in the next interval.
- USB bus reset and USB suspension
  This does not initialize the IITV[2:0] bits. When an SOF is received, the interval counter starts counting from the value set before SOF was received.

(2) Interval counting and transfer control in host controller mode

The USBHS controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bit settings. Specifically, the USBHS issues a token for a selected pipe once every 2IITV frames.

The USBHS starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits are set to 01b (BUF response) by software.

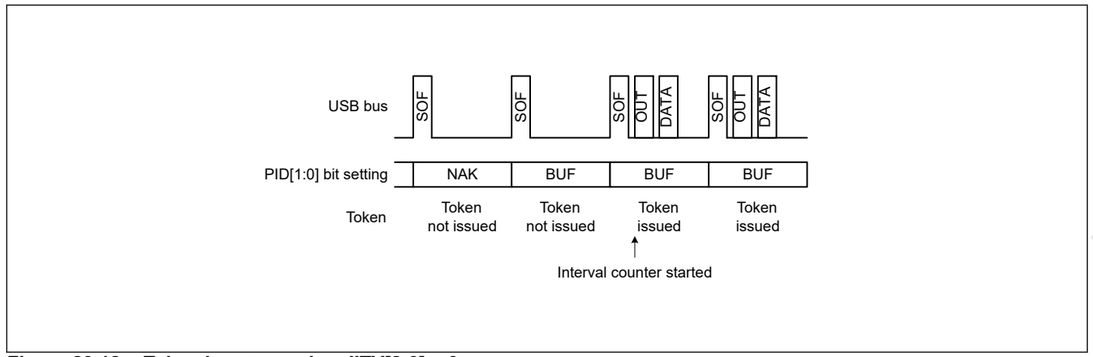

Figure 29.12 Token issuance when IITV[2:0] = 0

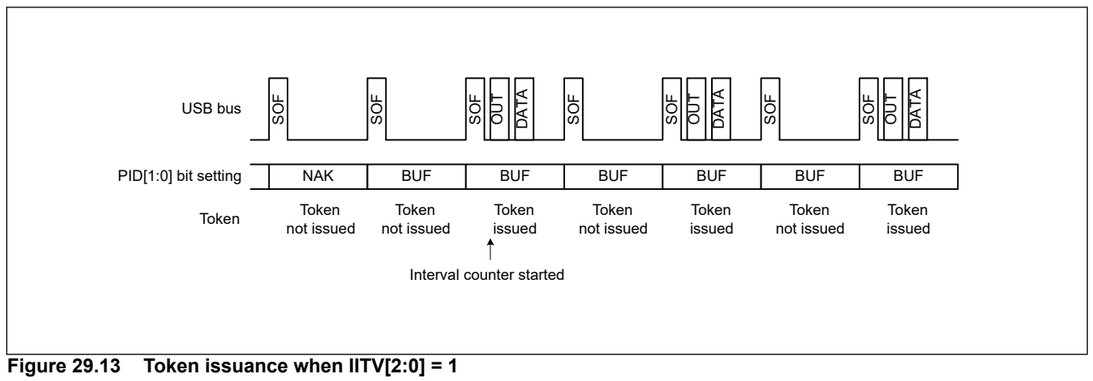

Figure 29.13 Token issuance when IITV[2:0] = 1

When the selected pipe is set for isochronous transfers, the USBHS carries out the following operation in addition to controlling the token issuance interval. The USBHS issues a token even when the NRDY interrupt generation condition is satisfied.

间隔计数器初始化后，当数据包传输成功时，间隔计数在以下任一条件下开始：

●在发送数据以响应IN令牌后收到SOF，PID[1:0]位设置为01b（BUF响应）

●接收到响应OUT令牌的数据后接收SOF，PID[1:0]位设置为01b（BUF响应）

间隔计数器在以下情况下不会初始化：

●当PID[1:0]位设置为NAK或STALL时
这不会停止间隔计时器。USBHS在下一个时间间隔尝试事务。

●USB总线复位和USB挂起
这不会初始化IITV[2:0]位。当接收到SOF时，间隔计数器从接收到SOF之前设置的值开始计数。

(2) 主机控制器模式下的间隔计数和传输控制

USBHS根据PIPEPERI.IITV[2:0]位设置控制令牌发布操作之间的间隔。
具体来说，USBHS每2IITV帧为选定管道发布一次令牌。

USBHS在软件将PID[1:0]位设置为01b（BUF响应）的帧之后的帧开始计算令牌发布间隔。

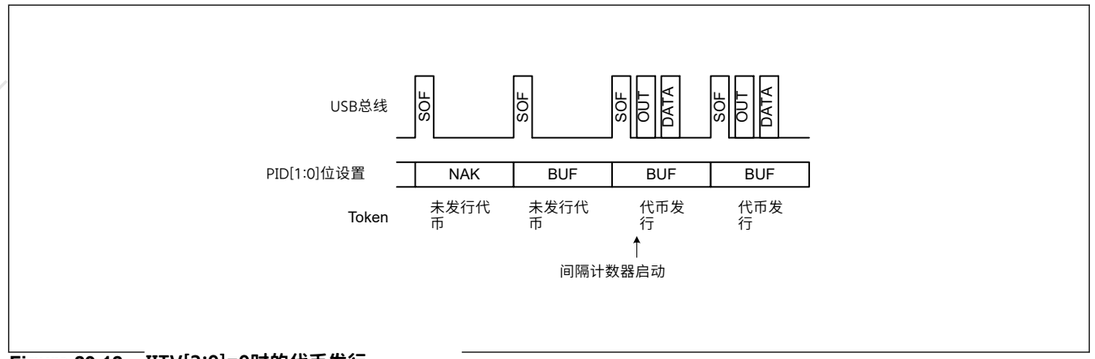

Figure 29.12 IITV[2:0]=0时的代币发行

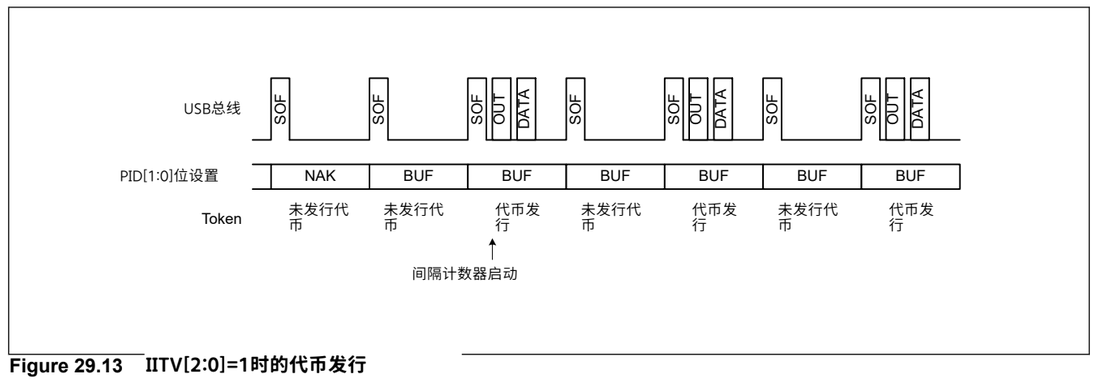

Figure 29.13 IITV[2:0]=1时的代币发行

当所选管道设置为同步传输时，USBHS除了控制令牌发布间隔外，还会执行以下操作。即使满足NRDY中断产生条件，USBHS也会发出一个令牌。

When the selected pipe is for isochronous IN transfers

The USBHS generates an NRDY interrupt when the USBHS issues an IN token but does not receive a packet successfully from a peripheral device (no response or packet error).

When the selected pipe is for isochronous OUT transfers

The USBHS sets the OVRN flag to 1, generating an NRDY interrupt and transmitting a zero-length packet, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer, because the CPU or DMA/DTC is too slow in writing data to the FIFO buffer.

The token issuance interval is reset on any of the following conditions:

- When the MCU is reset
  This initializes the IITV[2:0] bits
- When the PIPEnCTR.ACLRM bit is set to 1 by software

(3) Interval counting and transfer control in device controller mode

When the selected pipe is for isochronous OUT transfers

The USBHS generates an NRDY interrupt when it fails to receive a data packet within the interval set in the PIPEPERI.IITV[2:0] bits.

The USBHS also generates an NRDY interrupt when it fails to receive data because of a CRC error or other errors contained in the data packet or because of the FIFO buffer is full.

The NRDY interrupt is generated on SOF packet reception. Even if the SOF packet is corrupted, internal complementation allows the interrupt to be generated when the SOF packet is received. However, when the IITV[2:0] bits are set to a value other than 0, the USBHS generates an NRDY interrupt on receiving an SOF packet for every interval after interval counting starts.

When the PID[1:0] bits are set to 00b (NAK response) by software after starting the interval timer, the USBHS does not generate an NRDY interrupt on receiving an SOF packet.

The timing for starting interval counting depend on the IITV[2:0] setting as follows:

- When the IITV[2:0] bits = 0:
  The interval counting starts when the PID[1:0] bits of the selected pipe are changed to BUF
- When the IITV[2:0] bits ≠ 0:
  The interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe are changed to 01b (BUF response)

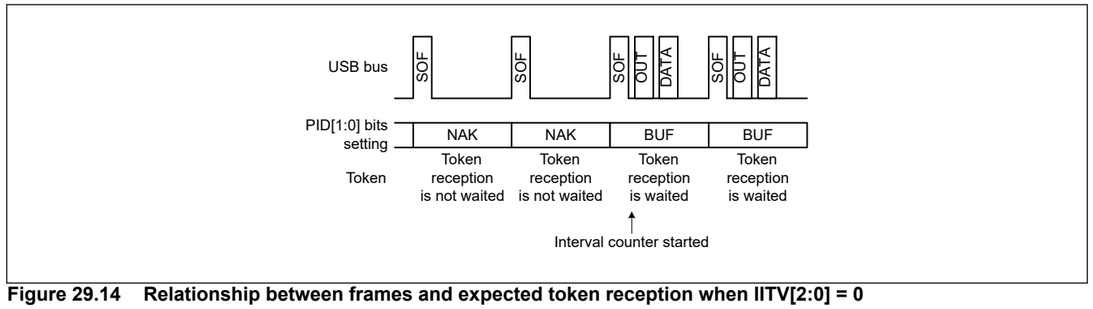

Figure 29.14 Relationship between frames and expected token reception when IITV[2:0] = 0

当所选管道用于同步IN传输时

当USBHS发出IN令牌但未成功接收到来自外围设备的数据包（无响应或数据包错误）时，USBHS生成NRDY中断。

当所选管道用于同步OUT传输时

USBHS将OVRN标志设置为1，产生一个NRDY中断并发送一个长度为零的数据包，当发出OUT令牌的时间到来而FIFO缓冲区中没有要发送的数据时，因为CPU或DMADTC是将数据写入FIFO缓冲区太慢。

令牌发行间隔在以下任何条件下重置：

- ●MCU复位时
  这将初始化IITV[2:0]位
- ●PIPEnCTR.ACLRM位由软件设置为1时

(3) 设备控制器模式下的间隔计数和传输控制

当所选管道用于同步OUT传输时

当USBHS在设置的时间间隔内未能接收到数据包时，会产生一个NRDY中断。
PIPEPERI.IITV[2:0] bits.

当由于数据包中包含的CRC错误或其他错误或由于FIFO缓冲区已满而无法接收数据时，USBHS也会产生NRDY中断。

NRDY中断在SOF数据包接收时产生。即使SOF数据包损坏，内部补码也允许在接收到SOF数据包时产生中断。但是，当IITV[2:0]位设置为0以外的值时，USBHS会在间隔计数开始后的每个间隔接收到SOF数据包时产生NRDY中断。

当PID[1:0]位在启动间隔定时器后由软件设置为00b（NAK响应）时，USBHS在接收到SOF数据包时不会产生NRDY中断。

开始间隔计数的时间取决于IITV[2:0]设置，如下所示：

- ●当IITV[2:0]位=0时：
  当所选管道的PID[1:0]位更改为BUF时，间隔计数开始
- ●当IITV[2:0]位≠0时：
  在所选管道的PID[1:0]位更改为01b（BUF响应）后，第一个数据包的成功接收完成后，间隔计数开始

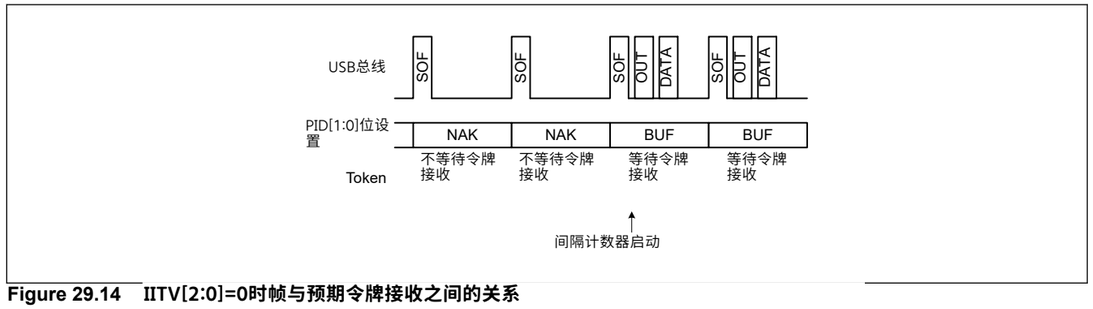

Figure 29.14 IITV[2:0]=0时帧与预期令牌接收之间的关系

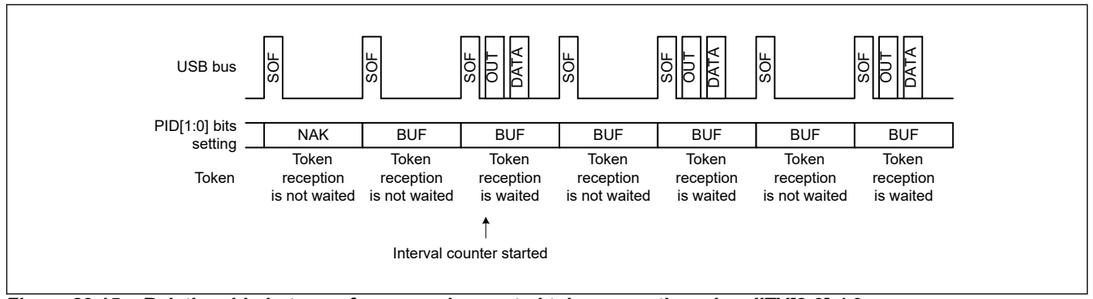

Figure 29.15 Relationship between frames and expected token reception when IITV[2:0] ≠ 0

When the selected pipe is for isochronous IN transfers

The PIPEPERI.IFIS bit must be 1 for this use case. When the IFIS bit is cleared to 0, the USBHS transmits a data packet in response to a received IN token, regardless of the PIPEPERI.IITV[2:0] setting.

When IFIS is 1 and there is data to be transmitted in the FIFO buffer, the USBHS clears the FIFO buffer when it fails to receive an IN token in the frame at the interval set in the IITV[2:0] bits.

The USBHS also clears the FIFO buffer when it fails to receive an IN token successfully because of a bus error, such as a CRC error, contained in the IN token.

The FIFO buffer is cleared on SOF packet reception. Even if the SOF packet is corrupted, the internal complementation allows the FIFO buffer to be cleared when the SOF packet is received.

The timing to start interval counting depends on the IITV[2:0] setting, as with OUT transfers.

The interval is counted on any of the following conditions in device controller mode:

- When a hardware reset is applied to the USBHS (which also sets the IITV[2:0] bits to 000b)
- When the PIPEnCTR.ACLRM bit is set to 1 by software
- When the USBHS detects a USB bus reset

(4) Transmit data setup for isochronous transfers in device controller mode

With isochronous data transmission using the USBHS in device controller mode, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the SOF packet is detected. This isochronous transfer transmit data setup function can identify the frame that started transmission.

When the double buffering is used, transmission is only enabled for the buffer in which data writing was completed first, even after the data write to both buffers is complete. Accordingly, even if multiple IN tokens are received, only the one packet of FIFO buffer data is transmitted.

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transferred and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

Figure 29.16 shows an example of transmission using the isochronous transfer transmit data setup function when the IITV[2:0] bits are set to 0 (every frame).

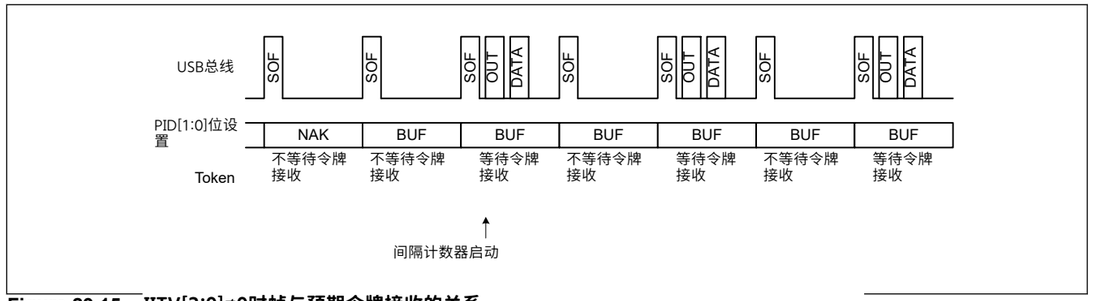

Figure 29.15 IITV[2:0]≠0时帧与预期令牌接收的关系

当所选管道用于同步IN传输时

对于此用例，PIPEPERI.IFIS位必须为1。当IFIS位清0时，USBHS发送数据包以响应接收到的IN令牌，无论PIPEPERI.IITV[2:0]设置如何。

当IFIS为1且FIFO缓冲区中有数据要发送时，USBHS会在其未能按照IITV[2:0]位设置的时间间隔接收帧中的IN令牌时清除FIFO缓冲区。

当USBHS由于总线错误（例如
CRC错误，包含在IN令牌中。

FIFO缓冲区在SOF数据包接收时被清除。即使SOF数据包损坏，内部补码也允许在接收到SOF数据包时清除FIFO缓冲区。

开始间隔计数的时间取决于IITV[2:0]设置，与OUT传输一样。

在设备控制器模式下，根据以下任何条件计算间隔：

●当对USBHS应用硬件复位时（也将IITV[2:0]位设置为000b）

●PIPEnCTR.ACLRM位由软件设置为1时

●当USBHS检测到USB总线复位时

(4) 设备控制器模式下同步传输的传输数据设置

在设备控制器模式下使用USBHS进行等时数据传输，数据写入FIFO缓冲区后，可在检测到SOF包后的第一帧发送数据包。此同步传输传输数据设置功能可以识别开始传输的帧。

当使用双缓冲时，即使在两个缓冲区的数据写入都完成之后，也只对首先完成数据写入的缓冲区启用传输。因此，即使接收到多个IN令牌，也仅发送一包FIFO缓冲器数据。

当接收到IN令牌时，当FIFO缓冲区准备好传输数据时，将传输数据并返回正常响应。但是，如果FIFO缓冲区无法传输数据，则会传输零长度数据包并发生欠载错误。

图29.16显示了使用同步传输传输数据设置功能的传输示例，当
IITV[2:0]位设置为0（每帧）。

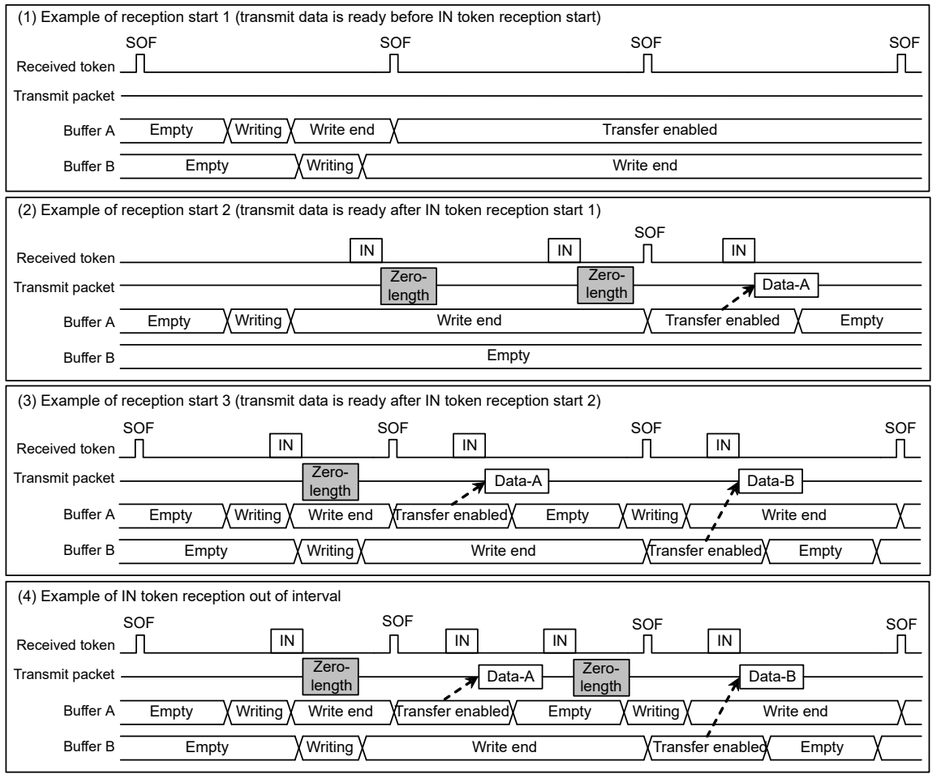

Figure 29.16 Example data setup operation

(5) Isochronous transfer transmit buffer flush in device controller mode

In device controller mode during isochronous data transmission, if the USBHS receives an SOF packet for the next frame without receiving an IN token in the interval frame, it operates as if the IN token is corrupt and clears the buffer that is enabled for transmission, putting that buffer in the writing enabled state.

When double buffering is used and writing to both buffers is complete, the cleared FIFO buffer is assumed to be the one where the data was transmitted in the interval frame, and transmission is enabled for the FIFO buffer that was not cleared on SOF packet reception.

The timing of the buffer flush function depends on the PIPEPERI.IITV[2:0] setting as follows:

- When IITV[2:0] = 0:
  The buffer flush operation starts from the first frame after the pipe is enabled
- When IITV[2:0] ≠ 0:
  The buffer flush operation starts after the first normal transaction

Figure 29.17 shows an example buffer flush. When an unanticipated token is received before the interval frame, the USBHS sends the write data or a zero-length packet as an underrun error, depending on the data setup status.

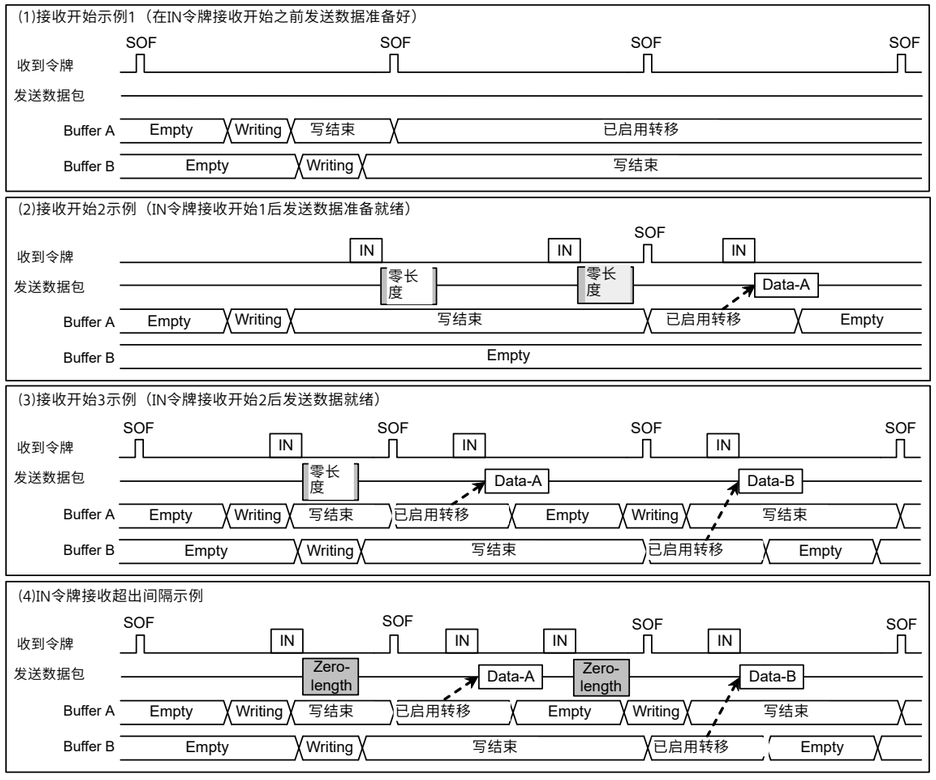

Figure 29.16 示例数据设置操作

(5) 设备控制器模式下的同步传输发送缓冲区刷新

在同步数据传输期间的设备控制器模式下，如果USBHS接收到下一帧的SOF数据包而没有在间隔帧中接收到IN令牌，则它会像IN令牌损坏一样操作并清除启用传输的缓冲区，将该缓冲区处于写入启用状态。

当使用双缓冲并完成对两个缓冲区的写入时，已清除的FIFO缓冲区被假定为在间隔帧中传输数据的缓冲区，并为接收SOF数据包时未清除的FIFO缓冲区启用传输。

缓冲区刷新功能的时间取决于PIPEPERI.IITV[2:0]设置，如下所示：

- When IITV[2:0] = 0:
  缓冲区刷新操作从启用管道后的第一帧开始
- When IITV[2:0] ≠ 0:
  缓冲区刷新操作在第一个正常事务之后开始

图29.17显示了一个示例缓冲区刷新。当在间隔帧之前接收到意外令牌时，USBHS将根据数据设置状态发送写数据或零长度数据包作为欠载错误。

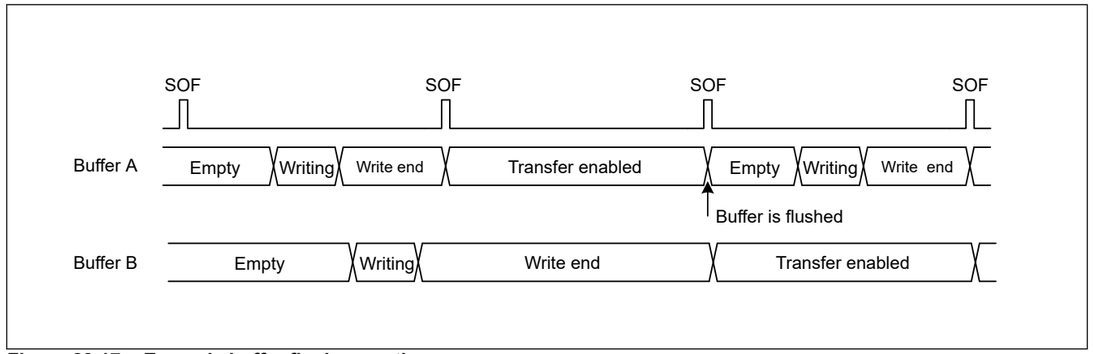

Figure 29.17 Example buffer flush operation

Figure 29.18 shows an example interval error occurrence. There are five types of interval errors, as shown in the figure. An interval error occurs at timing ①, and the buffer flush function is activated.

If an interval error occurs during an IN transfer, the buffer flush function is activated. If it occurs during an OUT transfer, an NRDY interrupt is generated. Use the FRMNUM.OVRN bit to distinguish between this and NRDY interrupts triggered by received packet errors and overrun errors.

For tokens that are shaded in the figure, responses are returned based on the FIFO buffer status.

- IN direction:
  - If the buffer is ready to transfer data, the data is transferred and a normal response is returned
  - If the buffer is not ready to receive data, a zero-length packet is transmitted and an underrun error occurs
- OUT direction:
  - If the buffer is ready to receive data, the data is received and a normal response is returned
  - If the buffer is not ready to receive data, the received data is discarded and an overrun error occurs

29.3.13 SOF Complementation Function

In device controller mode, if packet reception is disabled at intervals of 1 ms in full-speed mode or 125 µs in high-speed mode because the SOF packet is missing or corrupted, the USBHS complements the SOF. SOF complementation begins when the SYSCFG.USBE and LPSTS.SUSPENDM bits are set to 1 and an SOF packet is received. The complementation function is initialized under the following conditions:

- Power-on reset

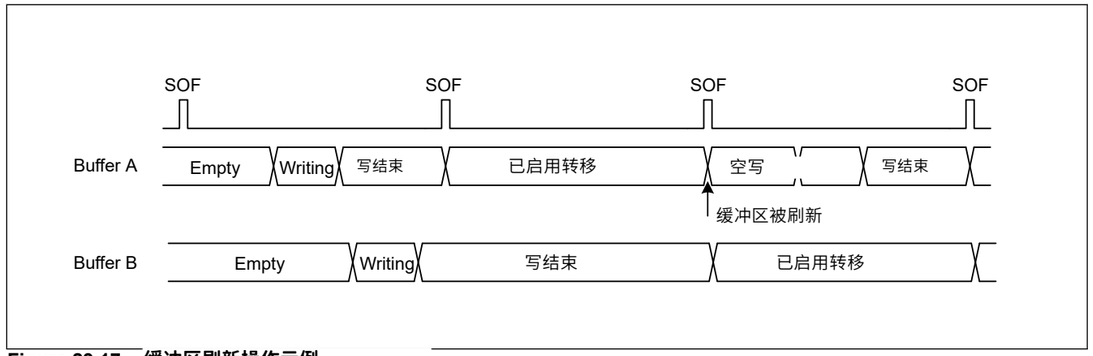

Figure 29.17 缓冲区刷新操作示例

图29.18显示了一个发生间隔错误的示例。如图所示，有五种区间误差。在时间①发生间隔错误，缓冲刷新功能被激活。

如果在IN传输期间发生间隔错误，则会激活缓冲区刷新功能。如果它发生在OUT传输期间，则NRDY中断产生。使用FRMNUM.OVRN位来区分此中断和由接收数据包错误和溢出错误触发的NRDY中断。

对于图中带阴影的令牌，根据FIFO缓冲区状态返回响应。

- IN direction:
  - 如果缓冲区准备好传输数据，则传输数据并返回正常响应
  - 如果缓冲区未准备好传输数据，则传输零长度数据包并发生欠载错误
- OUT direction:
  - 如果缓冲区准备好接收数据，则接收数据并返回正常响应
  - 如果缓冲区没有准备好接收数据，则丢弃接收到的数据并发生溢出错误

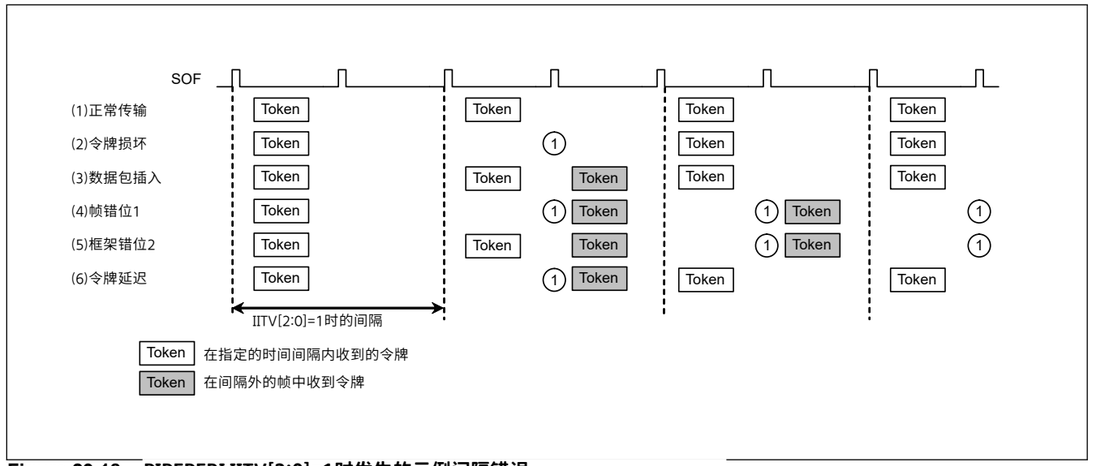

Figure 29.18 PIPEPERI.IITV[2:0]=1时发生的示例间隔错误

29.3.13 SOF互补函数

在设备控制器模式下，如果在全速模式下每隔1ms或在高速模式下每隔125µs禁用数据包接收，因为SOF数据包丢失或损坏，USBHS会补充SOF。当SYSCFG.USBE和LPSTS.SUSPENDM位设置为1并且接收到SOF数据包时，SOF补码开始。补码函数在以下条件下初始化：

- Power-on reset

- USB bus reset
- Suspend state detection

The SOF complementation function operates as follows:

- The frame interval (125 µs or 1 ms) is determined by the reset handshake protocol result
- The complementation function is not activated until an SOF packet is received
- When the first SOF packet is received, complementation is performed by counting 125 µs or 1 ms on the 48-MHz internal clock
- When the second or subsequent SOF packets are received, complementation is performed at the previous reception interval
- Complementation is not performed in the Suspend state or on reception of a USB bus reset. During high-speed operation, complementation continues for 3 ms from the last packet on transition to the Suspend state

The USBHS supports the following functions controlled by SOF packet reception. These functions operate normally with SOF complementation if the SOF packet is missing:

- Updating of the frame number and micro frame number
- SOFR interrupt and micro-SOF lock
- SOF pulse output
- Isochronous transfer interval count

If an SOF packet is missing during full-speed operation, the FFRMNUM.FRNM[10:0] flags are not updated. If a micro-SOF packet is missing during high-speed operation, the URMNUM.UFRNM[2:0] bits are updated.

However, if a micro-SOF packet is missing while the UFRNM[2:0] bits are set to 000b, the FRNM bits are not updated. In this case, even if a subsequent micro-SOF packet with a value other than UFRNM[2:0] bits = 000b is received successfully while UFRNM[2:0] bits are set to the value other than 000b, the FRNM bits are not updated.

29.3.14 Pipe Schedule

29.3.14.1 Conditions for generating transactions

In host controller mode and when the DVSTCTR0.UACT bit is set to 1, the USBHS generates transactions under the conditions as shown in Table 29.33.

Table 29.33 Conditions for generating transactions

Transaction	Conditions for generation				
	DIR	PID[1:0]	IITV0	Buffer state	SUREQ
Setup	—*1	—*1	—*1	—*1	1 setting
Control transfer data stage, status stage, bulk transfer	IN	BUF	—*1	Receive area exists	—*1
	OUT	BUF	—*1	Transmit data exists	—*1
Interrupt transfer	IN	BUF	Valid*2	Receive area exists	—*1
	OUT	BUF	Valid*2	Transmit data exists	—*1
Isochronous transfer	IN	BUF	Valid*2	*3	—*1
	OUT	BUF	Valid*2	*4	—*1

Note 1. An em dash (—) in the table indicates that the condition is unrelated to the generating of tokens.
Note 2. "Valid" indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter.
Note 3. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.
Note 4. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

●USB总线复位
●暂停状态检测

SOF互补函数的操作如下：

●帧间隔（125μs或1ms）由复位握手协议结果决定
●直到收到SOF报文才激活补码功能
●当接收到第一个SOF数据包时，通过在48-MHz内部时钟上计数125μs或1ms来执行补码
●当接收到第二个或后续的SOF数据包时，按照前一个接收间隔进行补码
●在挂起状态或接收到USB总线复位时不执行补码。在高速运行期间，从最后一个数据包转换到暂停状态时，互补会持续3ms

USBHS支持以下由SOF数据包接收控制的功能。这些功能正常运行
如果SOF数据包丢失，则SOF补充：

●更新帧号和微帧号
●SOFR中断和micro-SOF锁定
●SOF脉冲输出
●同步传输间隔计数

如果在全速操作期间丢失SOF数据包，则FFRMNUM.FRNM[10:0]标志不会更新。如果一个微SOF数据包在高速运行期间丢失，URMNUM.UFRNM[2:0]位被更新。

但是，如果在UFRNM[2:0]位设置为000b时缺少micro-SOF数据包，则不会更新FRNM位。在这种情况下，即使在将UFRNM[2:0]位设置为000b以外的值时成功接收到具有非UFRNM[2:0]位=000b的值的后续micro-SOF数据包，FRNM位仍为未更新。

29.3.14 管道计划

29.3.14.1 产生交易的条件

在主机控制器模式下，当DVSTCTR0.UACT位设置为1时，USBHS在表29.33所示的条件下生成事务。

Table 29.33 产生交易的条件

Transaction	生成条件				
	DIR	PID[1:0]	IITV0	缓冲状态	SUREQ
Setup	—*1	—*1	—*1	—*1	1 setting

	OUT	BUF	—*1	传输数据存在	—*1
中断传输	IN	BUF	Valid*2	接收区存在	—*1
	OUT	BUF	Valid*2	传输数据存在	—*1
Isochronous transfer	IN	BUF	Valid*2	*3	—*1
	OUT	BUF	Valid*2	*4	—*1

注1.表中的破折号(—)表示该条件与令牌的生成无关。
注2."有效"表示，对于中断传输和同步传输，事务仅在基于间隔计数器的传输帧中生成。

注3.这表示无论是否有接收区域，都会生成一个事务。但是，如果没有接收区域，则丢弃接收到的数据。

注4.这表示无论是否有任何数据要传输，都会产生交易。然而，如果没有要传输的数据，则传输零长度数据包。

29.3.14.2 Transfer schedule

This section describes the transfer scheduling within a frame of the USBHS. After the USBHS sends an SOF, the transfer is carried out in the following sequence:

1. Execution of periodic transfers:
   A pipe is searched for in the order of pipe 1 → pipe 2 → pipe 6 → pipe 7 → pipe 8 → pipe 9, and then if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.
2. Setup transactions for control transfers:
   The DCP is checked, and if a setup transaction is possible, it is sent.
3. Execution of bulk transfers, control transfer data stages, and control transfer status stages:
   A pipe is searched for in the order of DCP → pipe 1 → pipe 2 → pipe 3 → pipe 4 → pipe 5, and then if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.
   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

29.3.14.3 Enabling USB communication

Setting the DVSTCTR0.UACT bit to 1 initiates an SOF transmission, and transaction generation is enabled. Setting the UACT bit to 0 stops SOF transmission, and the Suspend state is invoked. If the UACT setting is changed from 1 to 0, processing stops after the next SOF is sent.

29.3.15 Battery charging detection processing

The USBHS provides control over the data contact detection processing (D+ line contact checking), primary detection processing (charger detection processing), and secondary detection processing (charger determination processing) as defined in the Battery Charging Specification.

This section describes operations required in device and host controller modes.

29.3.15.1 Processing in device controller mode

To operate a function device as a battery charging portable device:

1. Start primary detection processing after detecting contact with the D+ and D- lines. The Battery Charging Specification describes two processing methods for Data Contact Detection. The USBHS supports both methods as follows:
   - Software processing
     After a VBINT interrupt or polling of the VBSTS flag indicates a change in the state of the USBHS_VBUS input pin, software controls a wait from 300 to 900 ms. The BCCTRL.VDPSRCE and IDMSINKE bits are then both set to 1, enabling the VDP_SRC and IMP_SINK circuits, respectively, to start primary detection processing.
   - Hardware processing
     Apply 7 to 13 µA of current to the D+ line to hold the D+ line at the logical high level. This is done to detect the D+ and D- lines going to the logical low level because of pull-down resistors on the host device side when the D+ and D- lines come in contact with those of the host. Monitor the SYSSTS0.LNST[1:0] flags while the BCCTRL.IDPSRCE bit is set to 1, enabling the IDP_SRC circuit, to see when the level on the D+ line changes from high to low. After detecting a low level on the D+ line, clear the BCCTRL.IDPSRCE bit to 0, disabling the IDP_SRC circuit, and set both the BCCTRL.VDPSRCE and IDMSINKE bits to 1, enabling the VDP_SRC and IDM_SINK circuits, respectively, to start primary detection processing. The VDPSRCE and IDMSINKE bits must be set to 1 simultaneously.
2. After the start of primary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL.CHGDETSTS flag. A value of 1 indicates detection of a charger, and secondary detection processing starts.*1
3. To start secondary detection processing, clear both the BCCTRL.VDPSRCE and IDMSINKE bits to 0, disabling the VDP_SRC and IDM_SINK circuits, respectively. Next, set both the BCCTRL.VDMSRCE and IDPSINKE bits to 1, enabling the VDM_SRC and IDP_SINK circuits, respectively.
4. After the start of secondary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL.PDDETSTS flag. A value of 1 indicates that secondary detection processing is complete.

29.3.14.2 转移时间表

本节介绍USBHS帧内的传输调度。USBHS发送SOF后，按以下顺序进行传输：

1.定期转账的执行：
按照管道1→管道2→管道6→管道7→管道8→管道9的顺序查找管道，如果有管道可以产生等时或中断传输事务，则产生该事务.

2.为控制转移设置交易：
DCP被检查，如果设置事务是可能的，它被发送。

3、批量传输、控制传输数据阶段、控制传输状态阶段的执行：
按照DCP→管道1→管道2→管道3→管道4→管道5的顺序搜索管道，然后如果有管道需要进行批量传输、控制传输数据阶段或可以生成控制转移状态阶段，生成事务。生成事务时，无论来自外围设备的响应是ACK还是NAK，处理都会转移到下一个管道事务。如果帧内有时间进行传输，则重复步骤3。

29.3.14.3 启用USB通信

将DVSTCR0.UACT位设置为1启动SOF传输，并启用事务生成。设置
UACT位为0停止SOF传输，并调用暂停状态。如果UACT设置从1更改为0，则在发送下一个SOF后处理停止
。

29.3.15 电池充电检测处理

USBHS提供对电池充电规范中定义的数据接触检测处理（D+线路接触检查）、一次检测处理（充电器检测处理）和二次检测处理（充电器确定处理）的控制。

本节介绍设备和主机控制器模式所需的操作。

29.3.15.1 设备控制器模式下的处理

将功能设备作为电池充电便携式设备操作：

1.检测到与D+和Dlines的接触后开始初级检测处理。电池充电规范描述了数据接触检测的两种处理方法。USBHS支持以下两种方法：

●软件处理
在VBINT中断或轮询VBSTS标志指示USBHS_VBUS输入引脚的状态发生变化后，软件控制从300到900ms的等待。然后BCCTRL.VDPSRCE和IDMSINKE位都设置为1，分别使VDP_SRC和IMP_SINK电路开始主要检测处理。

●硬件加工
向D+线施加7到13µA的电流，以将D+线保持在逻辑高电平。这样做是为了检测D+和Dlines进入逻辑低电平，因为当D+和Dlines与主机的那些接触时，由于主机设备侧的下拉电阻器。监控SYSSTS0.LNST[1:0]标志，而

BCCTRL.IDPSRCE位设置为1，启用IDP_SRC电路，以查看D+线上的电平何时从高变为低。检测到D+线上的低电平后，将BCCTRL.IDPSRCE位清除为0，禁用IDP_SRC电路，并将BCCTRL.VDPSRCE和IDMSINKE位都设置为1，启用VDP_SRC和

IDM_SINK电路分别启动初级检测处理。VDPSRCE和IDMSINKE位必须同时设置为1。

2.主要检测处理开始后，软件控制等待40毫秒后，检查
BCCTRL.CHGDETSTS标志。值为1表示检测到充电器，并开始二次检测处理。*1

3.要开始二次检测处理，请将BCCTRL.VDPSRCE和IDMSINKE位都清零，分别禁用VDP_SRC和IDM_SINK电路。接下来，将BCCTRL.VDMSRCE和IDPSINKE位都设置为1，分别启用VDM_SRC和IDP_SINK电路。

4.二次检测处理开始后，软件控制等待40毫秒后，检查BCCTRL.PDDETSTS标志。值为1表示二次检测处理完成。

Note 1. In primary detection processing, detection of a voltage above the range from 0.25 to 0.4 V and below the range from 0.8 to 2.0 V on the D-Line indicates that the other device is a host device that supports battery charging (charging downstream port). The BCCTRL.CHGDETSTS flag in the PHY block only indicates whether the voltage on the D-line is higher than the range from 0.25 to 0.4 V, so add processing as required to read the SYSSTS0.LNST[1:0] flags and confirm that the voltage on the D- line is also below the range from 0.8 to 2.0 V.

Figure 29.19 illustrates this processing flow.

注1.在初级检测处理中，在D-Line上检测到高于0.25至0.4V范围且低于0.8至2.0V范围的电压表示其他设备是支持电池充电的主机设备（充电下游港口）。PHY块中的BCCTRL.CHGDETSTS标志位仅指示Dline上的电压是否高于0.25至0.4V的范围，因此根据需要添加处理以读取SYSSTS0.LNST[1:0]标志并确认电压Dline上的电压也低于0.8至2.0V的范围。

图29.19说明了这个处理流程。

29.3.15.2 Processing in host controller mode

In host controller mode, driving the D- line is required for a portable device to perform primary detection. The USBHS supports the following two primary detection methods:

- When the hardware has a portable device detection function
- When the hardware does not have the function or the function is present but not used

Figure 29.20 and Figure 29.21 show the processing flows for these methods.

(1) When the hardware has a portable device detection function

a. Start driving the USBHS_VBUS input pin.

b. Set the BCCTRL.IDMSINKE bit to 1 to enable the portable device detection circuit.

c. Monitor the portable device detection signal and start driving the D-line when the level of the portable device detection signal is high*1.

d. Stop driving the D-line when the portable device detection signal is at the low level*1.

Note 1. The PDDETINT interrupt indicates a change in the level of the portable device detection signal (EUH_CPDDET), and the current level can be obtained by reading the PDDETSTS flag.

(2) When the hardware does not have a portable device detection function or the function is not used

Software handles the timing of steps a. and b.

a. After a disconnect is detected, start driving the D-line within 200 ms.

b. After a connect is detected, stop driving the D-line within 10 ms.

29.3.15.2 主机控制器模式下的处理

在主机控制器模式下，便携式设备需要驱动Dline才能执行初级检测。USBHS支持以下两种主要检测方法：

●当硬件具有便携设备检测功能时

●当硬件不具备该功能或该功能存在但未使用时

图29.20和图29.21显示了这些方法的处理流程。

(1) 当硬件具有便携设备检测功能时

湾。将BCCTRL.IDMSINKE位设置为1以启用便携式设备检测电路。

c. 监视便携设备检测信号，当便携设备检测信号为高电平时开始驱动D线*1。

d。便携设备检测信号为低电平时停止驱动D线*1。

注1.PDDETINT中断表示便携式设备检测信号（EUH_CPDDET）的电平发生变化，通过读取PDDETSTS标志可以获得当前电平。

(2) 硬件不具备便携设备检测功能或未使用该功能时

29.3.16 Link Power Management Processing

The Link Power Management standard defines the existing Suspend state as the L2 state and also defines the L1 state as a state that allows transition and return with lower latency than the L2 state (Suspend). Table 29.34 provides a comparison between the L2 (Suspend) and L1 states.

29.3.16.1 Processing in device controller mode

(1) Descriptor contents

In device controller mode, the USBHS must return its descriptor on receiving the GetDescriptor command.

Change the content of the descriptor to be returned depending on whether the transition to and return from the L1 state corresponds to the processing for the LPM transaction. The following table shows the relationship between LPM correspondence and the descriptor.

Table 29.35 Relationship between LPM correspondence and descriptor

Correspondence with LPM	bcdUSB field	USB2.0 extension descriptor		Response to received LPM request	Notes
		Provided/ not provided	Value of LPM bit		
Does not correspond	0200h	Not provided	—	No response	Normal operation when the LPM is not supported
	0201h	Provided	0	STALL	Setting for clear non-correspondence to LPM. In this case, a STALL response must be returned.
Corresponds	0201h	Provided	1	ACK or NYET	Normal operation when the LPM is supported

Declare whether to correspond to the transition to and return from L1 in the LPM bit in the USB 2.0 extension descriptor. To provide the USB2.0 extension descriptor, the bcdUSB field of the device descriptor must be set to a value of 0201h or larger.

When the LPM is not supported, the USB2.0 extension descriptor is not provided and the bcdUSB field value must be 0200h. If an LPM token is received in this case, it must be ignored. It is also possible to set the bcdUSB field value to 0201h and the LPM bit in the USB2.0 extension descriptor to 0 (LPM tokens not supported). In this case, the LPM token cannot be ignored and a STALL response must be returned.

When the LPM token is supported, set the bcdUSB field value to 0201h and set the LPM bit in the USB 2.0 extension descriptor to 1 (LPM tokens supported). This allows acknowledgment when returning a NYET or ACK response to the LPM token.

(2) Processing during LPM token reception

Transition to and return from the L1 state in device controller mode is as follows:

a. When the USBHS receives an LPM token from the host, the L1RESPEN, L1RESPMD[1:0], and L1NEGOMD settings in PL1CTRL1 determine whether a response packet is sent or the token is ignored and, if a response is to be sent, whether it is an ACK, NYET, or STALL packet.

b. If an ACK response to the LPM token is sent and the host does not transmit another LPM token in 8 µs, the USBHS enters the L1 state. The USBHS handles detection of the newly transmitted packet and the transition to the L1 state. The DVST interrupt can be used to detect the transition.

29.3.16.1 设备控制器模式下的处理

(1) 描述符内容

在设备控制器模式下，USBHS必须在接收到GetDescriptor命令时返回其描述符。

根据L1状态的转换和返回是否对应于LPM事务的处理，更改要返回的描述符的内容。下表显示了LPM对应关系和描述符之间的关系。

Table 29.35 LPM对应与描述符的关系

与LPM的通信	bcdUSB field	USB2.0扩展描述符		收到的回复 LPM request	Notes
		提供未提供	LPM位的值		
不对应	0200h	不提供	—	没有反应	不支持LPM时的正常操作
	0201h	Provided	0	STALL	设置明确不对应 LPM。在这种情况下，必须返回一个STALL响应。
Corresponds	0201h	Provided	1	ACK或NYET	支持LPM时的正常操作

在USB2.0扩展描述符中的LPM位中声明是否对应于L1的转换和返回。要提供USB2.0扩展描述符，设备描述符的bcdUSB字段必须设置为0201h或更大的值。

不支持LPM时，不提供USB2.0扩展描述符，bcdUSB字段值必须为0200h。如果在这种情况下接收到LPM令牌，则必须将其忽略。也可以将bcdUSB字段值设置为0201h，并将USB2.0扩展描述符中的LPM位设置为0（不支持LPM令牌）。在这种情况下，不能忽略LPM令牌并且必须返回STALL响应。

当支持LPM令牌时，将bcdUSB字段值设置为0201h，并将USB2.0扩展描述符中的LPM位设置为1（支持LPM令牌）。这允许在向LPM令牌返回NYET或ACK响应时进行确认。

(2) LPM令牌接收期间的处理

设备控制器模式下L1状态的转换和返回如下：

a. 当USBHS从主机接收到LPM令牌时，PL1CTRL1中的L1RESPEN、L1RESPMD[1:0]和L1NEGOMD设置确定是发送响应包还是忽略令牌，如果要发送响应，是否是ACK、NYET或STALL数据包。

湾。如果发送了对LPM令牌的ACK响应并且主机在8µs内没有发送另一个LPM令牌，则USBHS进入L1状态。USBHS处理新传输数据包的检测和向L1状态的转换。DVST中断可用于检测转换。

c. Two types of processing can return the USBHS from the L1 state:

- When the host drives the D-line in the K-state:
  The function device detects the K-state and starts processing the return from the L1 state in response to an RESM interrupt request
- When the function device outputs a remote wakeup signal:
  If the software on the function device sets the DVSTCTR0.WKUP bit to 1, it sends a remote wakeup signal to the host

The software clears the DVSTCTR0.WKUP bit to 0 on returning from the L2 (Suspend) state, and the USBHS clears the DVSTCTR0.WKUP bit to 0 for return from the L1 state.

(3) HIRD field value negotiation function

The HIRD field value included in the LPM token indicates the host K-drive period on return from the L1 state. The HIRD field value can be adjusted according to the requirements of the target system. For example, a small HIRD field value is better for systems focusing on higher transfer efficiency, while a large HIRD field value is better for systems focusing on low power consumption.

Based on the L1NEGOMD and HIRDTHR[3:0] settings in PL1CTRL1, an ACK response is returned when the received HIRD field value is in the expected range, and otherwise a NYET response is returned, requesting the host to change the HIRD field value.

Note: This HIRD field value negotiation function at the host must also support negotiation processing.

29.3.16.2 Processing in host controller mode

(1) Processing during LPM token transmission

Transition to and return from the L1 state in host controller mode is as follows:

a. When the HL1CTRL.L1REQ bit is set to 1, an LPM token is sent to the function device from the host device.

b. If an ACK response is received from the function device, a transition to the L1 state starts within 10 µs and is complete within 50 µs. If a transaction error is detected, another LPM token is transmitted within 8 µs. Retransmission can proceed up to two times. The USBHS handles all of this processing.

c. Two types of processing can return the USBHS from the L1 state:

- When the host drives the D-line for the K state:
  When the DVSTCTR0.RESUME bit is set to 1, the host device starts driving the D-line for the K-state and starts processing the return
- When the function device generates a remote wakeup signal:
  When the host device detects a remote wakeup signal from the function device, it sets the DVSTCTR0.RESUME bit to 1 and starts driving the D-line for the K-state

Unlike when returning from the Suspend (L2) state, the USBHS clears the DVSTCTR0.RESUME bit to 0. After clearing the RESUME bit, it sets the DVSTCTR0.UACT bit to 1 and issues an L1RSMEND interrupt request.

29.3.17 Release from Deep Software Standby Mode Because of USB Suspend/Resume Interrupts

Deep Software Standby mode can be canceled by a USB suspend/resume interrupt. USB suspend/resume interrupts are detected by the USB resume detecting unit, which controls and monitors the USB I/O pins to detect the interrupts.

Figure 29.22 shows the flow for setting the USBHS when entering Deep Software Standby mode from either host or device controller mode. Figure 29.23 and Figure 29.24 show the flows for setting the USBHS when canceling Deep Software Standby mode from host controller mode. Figure 29.25 shows the flow for setting the USBHS when canceling Deep Software Standby mode from device controller mode.

c. 两种类型的处理可以使USBHS从L1状态返回：

●当主机在K态驱动D线时：
功能设备检测到K状态并开始处理从L1状态返回以响应RESM中断请求

●当功能设备输出远程唤醒信号时：
如果功能设备上的软件将DVSTCTR0.WKUP位设置为1，它会向主机发送远程唤醒信号

软件在从L2（挂起）状态返回时将DVSTCTR0.WKUP位清除为0，并且USBHS清除
DVSTCTR0.WKUP位为0表示从L1状态返回。

(3) HIRD字段值协商功能

LPM令牌中包含的HIRD字段值指示从L1状态返回的主机K-drive周期。HIRD字段值可以根据目标系统的要求进行调整。例如，较小的HIRD字段值更适合专注于更高传输效率的系统，而较大的HIRD字段值更适合专注于低功耗的系统。

根据PL1CTRL1中的L1NEGOMD和HIRDTHR[3:0]设置，当接收到的HIRD字段值在预期范围内时返回ACK响应，否则返回NYET响应，请求主机更改
HIRD字段值。

Note: 主机上的这个HIRD字段值协商功能也必须支持协商处理。

29.3.16.2 主机控制器模式下的处理

(1) LPM令牌传输期间的处理

主机控制器模式下L1状态的转换和返回如下：

a. 当HL1CTRL.L1REQ位设置为1时，LPM令牌从主机设备发送到功能设备。

湾。如果从功能设备接收到ACK响应，则在10µs内开始转换到L1状态，并在50µs内完成。如果检测到事务错误，则会在8µs内发送另一个LPM令牌。重传最多可以进行两次。USBHS处理所有这些处理。

c. 两种类型的处理可以使USBHS从L1状态返回：

●当主机驱动D线为K状态时：
当DVSTCTR0.RESUME位设置为1时，主机设备开始驱动D线为K状态并开始处理返回

●当功能设备产生远程唤醒信号时：
当主机设备检测到来自功能设备的远程唤醒信号时，它会将DVSTCTR0.RESUME位设置为1，并开始驱动D线为K状态

与从挂起(L2)状态返回时不同，USBHS将DVSTCTR0.RESUME位清除为0。清除RESUME位后，将DVSTCTR0.UACT位设置为1并发出L1RSMEND中断请求。

29.3.17 由于USB挂起恢复而从深度软件待机模式中释放 Interrupts

深度软件待机模式可以通过USB挂起恢复中断来取消。USB暂停恢复中断由USB恢复检测单元检测，该单元控制和监视USBIO引脚以检测中断。

图29.22显示了从主机或设备控制器模式进入深度软件待机模式时设置USBHS的流程。图29.23和图29.24显示了从主机控制器模式取消深度软件待机模式时设置USBHS的流程。图29.25显示取消Deep时设置USBHS的流程

29.4 Usage Notes

29.4.1 Settings for the Module-Stop Function

USBHS operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The USBHS is initially stopped after reset. Releasing the module-stop state enables access to the registers. After releasing module stop, make settings required to activate the PHY circuit, including the input system clock frequency setting, and then clear the PHYSET.DIRPD bit to 0. For details, see section 10, Low Power Modes .

29.4.2 Setup for Transitioning to Deep Software Standby Mode

Before transitioning to Deep Software Standby mode, clear the DVSTCTR0.VBUSEN bit to 0.

29.4.3 Clearing the Interrupt Status Register on Exiting Software Standby Mode

Because the input buffer is always enabled in Software Standby mode, an unexpected interrupt might occur under the following conditions:

- When the interrupt is enabled in Normal mode

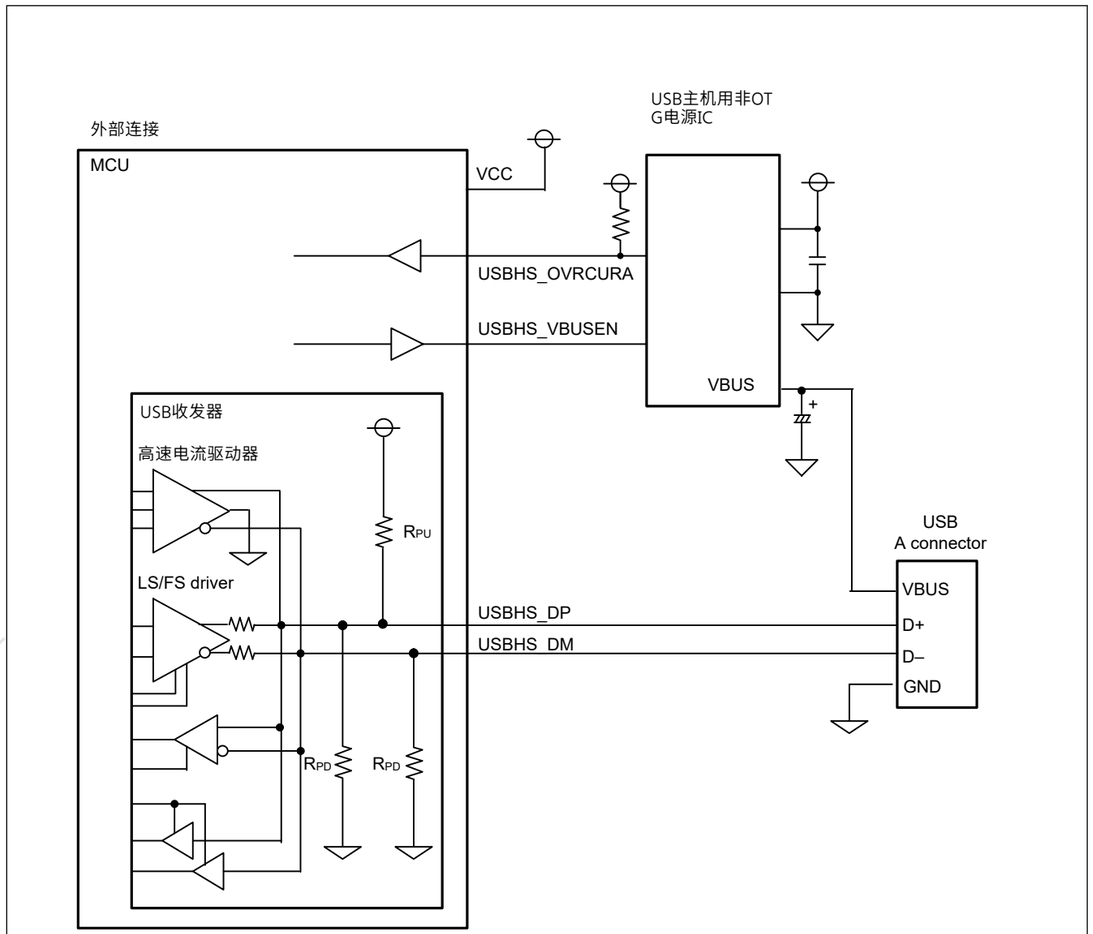

Figure 29.30 示例USB主机连接

29.4 使用说明

29.4.1 模块停止功能的设置

可以使用模块停止控制寄存器B(MSTPCRB)禁用或启用USBHS操作。USBHS在复位后最初停止。释放模块停止状态可以访问寄存器。解除模块停止后，进行激活PHY电路所需的设置，包括输入系统时钟频率设置，然后将PHYSET.DIRPD位清为0。详细信息请参见第10节，低功耗模式。

29.4.2 转换到深度软件待机模式的设置

在转换到深度软件待机模式之前，将DVSTCTR0.VBUSEN位清零。

29.4.3 退出软件待机模式时清除中断状态寄存器

由于在软件待机模式下始终启用输入缓冲区，因此在以下情况下可能会发生意外中断：

●在正常模式下使能中断时

RA生态工作室

- When the interrupt is disabled in Software Standby mode
- When the input level of the pin that cancels Software Standby is changed in Software Standby mode

These conditions might cause the associated interrupt flag in the Interrupt Status Register to set unexpectedly. After the MCU exits the Software Standby mode, the unexpected interrupt might be sent to the interrupt controller. To avoid this, always clear the INTSTS0 and INTSTS1 registers in the canceling sequence.

29.4.4 Clearing the Interrupt Status Register after Setting Up the Port Function

The input buffer is disabled before the PmnPFS.PSEL and PmnPFS.PMR ports are set up, so the internal signal is fixed high or low. The input buffer is enabled after the port is set so that the external pin state is propagated to the MCU. An unexpected interrupt might occur at this time, causing the VBINT and OVRCR bits in INTSTS0 and INTSTS1, or other interrupt status flags to set to 1. To avoid a malfunction, always clear the INTSTS0 and INTSTS1 registers after setting up the port.

●在软件待机模式下禁用中断时

●在软件待机模式下，取消软件待机的引脚的输入电平发生变化时

这些情况可能会导致中断状态寄存器中的相关中断标志意外设置。MCU退出软件待机模式后，可能会向中断控制器发送意外中断。为避免这种情况，请始终在取消序列中清除INTSTS0和INTSTS1寄存器。

29.4.4 设置端口功能后清除中断状态寄存器

在设置PmnPFS.PSEL和PmnPFS.PMR端口之前，输入缓冲器被禁用，因此内部信号固定为高或低。设置端口后启用输入缓冲器，以便将外部引脚状态传播到MCU。此时可能会发生意外中断，导致INTSTS0和INTSTS1中的VBINT和OVRCR位或其他中断状态标志设置为1。为避免故障，请务必在设置端口后清除INTSTS0和INTSTS1寄存器。

30.2 Register Descriptions

30.2.1 RSR : Receive Shift Register

RSR is a shift register that receives serial data input from the RXDn pin and converts it into parallel data. When one frame of data is received, the data is automatically transferred to the RDR, RDRHL, or the receive FIFO register. The RSR register cannot be directly accessed by the CPU.

30.2.2 RDR : Receive Data Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 3 to 9)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

RDR is an 8-bit register that stores received data. When one frame of serial data is received, it is transferred from RSR to RDR, and the RSR register can receive more data. Because RSR and RDR function as a double buffer, continuous received operations can be performed.

Read the RDR only once after a receive data full interrupt (SCIn_RXI) occurs.

Note: If the next frame of data is received before reading the received data from RDR, an overrun error occurs. The CPU cannot write to the RDR.

30.2.3 RDRHL : Receive Data Register for Non-Manchester mode (MMR.MANEN = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 3 to 9)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x10

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	RDAT[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	RDAT[8:0]	Serial Receive Data	R
15:9	—	These bits are read as 0.	R

RDRHL is a 16-bit register that stores received data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of RDRHL are the shadow register of RDR, so access to RDRHL affects the RDR register. Access to the RDRHL register is prohibited if 7-bit or 8-bit data length is selected.

After one frame of data is received, the received data is transferred from the RSR register to the RDR/RDRHL registers, allowing the RSR register to receive more data.

The RSR and RDRHL registers form a double-buffered structure to enable continuous reception. RDRHL should be read only when a receive data full interrupt (SCIn_RXI) request is issued. An overrun error occurs when the next frame of data is received before the received data is read from RDRHL. The CPU cannot write to the RDRHL register.

30.2.1 RSR:接收移位寄存器

RSR是一个移位寄存器，它接收从RXDn引脚输入的串行数据并将其转换为并行数据。当接收到一帧数据时，数据会自动传输到RDR、RDRHL或接收FIFO寄存器。CPU不能直接访问RSR寄存器。

RDR是一个8位寄存器，用于存储接收到的数据。当接收到一帧串行数据时，将其从RSR传输到RDR，而RSR寄存器可以接收更多的数据。由于RSR和RDR用作双缓冲器，因此可以执行连续接收操作。

在接收数据完全中断(SCIn_RXI)发生后，仅读取一次RDR。

Note: 如果在从RDR读取接收到的数据之前接收到下一帧数据，则会发生溢出错误。CPU无法写入RDR。

RDRHL_MAN is a 16-bit register that stores received data. Use this register when asynchronous mode and 9-bit data length are selected. The lower 8 bits of RDRHL_MAN are the shadow register of RDR, so access to RDRHL_MAN affects the RDR register. Access to the RDRHL_MAN register is prohibited if 7-bit or 8-bit data length is selected.

After one frame of data is received, the received data is transferred from the RSR register to the RDR/RDRHL_MAN registers, allowing the RSR register to receive more data.

The RSR and RDRHL_MAN registers form a double-buffered structure to enable continuous reception.

RDRHL_MAN should be read only when a receive data full interrupt (SCIn_RXI) request is issued. An overrun error occurs when the next frame of data is received before the received data is read from RDRHL_MAN.

The CPU cannot write to the RDRHL_MAN register.

15	—	This bit is read as 0.	R

Note 1. If this flag is read, it indicates the same value as that read from the SSR_FIFO register. Write 0 to the SSR_FIFO register to clear the flag.

FRDRHL is a 16-bit register that consists of the 8-bit FRDRH and FRDRL registers. FRDRH is assigned to the FRDRHL[15:8] bits, and allocated to the same address as FRDRHL. FRDRL is assigned to the FRDRHL[7:0] bits, and allocated to (the address of FRDRHL + 1) address.

FRDRH and FRDRL constitute a 16-stage FIFO register that stores serial receive data and related status information readable by software. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

The SCI completes reception of one frame of serial data by transferring the received data from the Receive Shift Register (RSR) into FRDRH and FRDRL for storage. Continuous reception is executed until 16 stages are stored. If data is read when there is no received data in FRDRH and FRDRL, the value is undefined. When FRDRH and FRDRL are full, subsequent serial receive data is lost. The CPU can read from the FRDRH and FRDRL registers but cannot write to them.

Reading 1 from the RDF, ORER, or DR flags of the FRDRH register is the same as reading from those bits in the SSR_FIFO register. When writing 0 to clear a flag in the SSR_FIFO register after reading the FRDRH register, write 0 only to the flag that is to be cleared and write 1 to the other flags.

When reading both the FRDRH and FRDRL registers, read in order from FRDRH to FRDRL. The FRDRHL register can be accessed in 16-bit units.

12	FER	成帧错误标志 0：FRRDH和FRDRL的第一个数据没有发生帧错误1：FRRDH和FRDRL的第一个数据发生了帧错误	R
13	ORER	溢出错误标志 该标志与SSR_FIFO.ORER相同。 0：未发生溢出错误1：发生溢出错误	R*1
14	RDF	接收FIFO数据满标志 该标志与SSR_FIFO.RDF相同。 0：FRRDH和FRRDL写入的接收数据量小于指定的接收触发数 1：写入FRRDH和FRRDL的接收数据量等于或大于指定的接收触发数	R*1
15	—	该位读为0。	R

注1.如果读取该标志，则表示与从SSR_FIFO寄存器读取的值相同。将0写入SSR_FIFO寄存器以清除标志。

FRDRHL是一个16位寄存器，由8位FRDRH和FRDRL寄存器组成。FRDRH被分配到FRDRHL[15:8]位，并分配到与FRDRHL相同的地址。FRDRL分配给FRDRHL[7:0]位，并分配给（FRDRHL+1的地址）地址。

FRDRH和FRDRL构成一个16级FIFO寄存器，用于存储串行接收数据和软件可读的相关状态信息。该寄存器仅在异步模式下有效，包括多处理器模式或时钟同步模式。

SCI通过将接收到的数据从接收移位寄存器（RSR）传送到FRDRH和FRDRL中进行存储，从而完成一帧串行数据的接收。执行连续接收，直到存储16个阶段。如果在FRDRH和FRDRL中没有接收到数据时读取数据，则该值未定义。当FRDRH和FRDRL已满时，后续的串行接收数据会丢失。CPU可以读取FRDRH和FRDRL寄存器，但不能写入它们。

从FRDRH寄存器的RDF、ORER或DR标志读取1与从SSR_FIFO寄存器。在读取FRDRH寄存器后写入0以清除SSR_FIFO寄存器中的标志时，仅将0写入要清除的标志，将1写入其他标志。

读取FRDRH和FRDRL寄存器时，按从FRDRH到FRDRL的顺序读取。FRDRHL寄存器可以以16位为单位进行访问。

TDR is an 8-bit register that stores transmit data.

When the SCI detects that the TSR register is empty, it transfers the transmit data written in the TDR register to the TSR register and starts transmission.

The double-buffered structure of the TDR and TSR registers enables continuous serial transmission. If the next transmit data is already written to TDR when one frame of data is transmitted, the SCI transfers the written data to the TSR register to continue transmission.

The CPU can read from or write to TDR at any time. Only write transmit data to TDR once after each instance of the transmit data empty interrupt (SCIn_TXI).

When empty space is detected in the TSR register, the transmit data stored in the TDRHL registers is transferred to TSR and transmission starts.

The TSR and TDRHL registers have a double-buffered structure to support continuous transmission. When the next data to be transmitted is stored in TDRHL after one frame of data is transmitted, the transmitting operation continues by transferring the data to the TSR register.

The CPU can read and write to the TDRHL register. Bits [15:9] in TDRHL are fixed to 1. These bits are read as 1. The write value should be 1.

Write transmit data to theTDRHL register only once when a transmit data empty interrupt (SCIn_TXI) request is issued.

TDRHL_MAN is a 16-bit register that stores transmit data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of TDRHL_MAN are the shadow register of TDR, so access to TDRHL_MAN affects the TDR register. Access to the TDRHL_MAN register is prohibited if 7-bit or 8-bit data length is selected.

When empty space is detected in the TSR register, the transmit data stored in the TDRHL_MAN registers is transferred to TSR and transmission starts.

The TSR and TDRHL_MAN registers have a double-buffered structure to support continuous transmission. When the next data to be transmitted is stored in TDRHL_MAN after one frame of data is transmitted, the transmitting operation continues by transferring the data to the TSR register.

Write transmit data to theTDRHL_MAN register only once when a transmit data empty interrupt (SCIn_TXI) request is issued.

TDAT[8:0] bit (Serial transmit data)

This register sets serial transmission data.

MPBT bit (Multi-processor transfer bit flag)

Selects the multi processor bit of transmit frame.

TSYNC bit (Transmit SYNC data bit)

When Manchester mode and MMR.SBSEL = "1" and MMR.SYNSEL = "1",the type of SYNC selected according to this bit becames the Start Bit of the transmission frame.

9	MPBT	Multi-Processor Transfer Bit Flag Specifies the multi-processor bit in the transmission frame. 15:10	—	The write value should be 1.	W

FTDRHL is a 16-bit register that consists of the 8-bit FTDRH and FTDRL registers. FTDRH is assigned to the FTDRHL[15:8] bits, and allocated to the same address as FTDRHL. FTDRL is assigned to the FTDRHL[7:0] bits, and allocated to (the address of FTDRHL + 1) address.

FTDRH and FTDRL constitute a 16-stage FIFO register that stores data for serial transmission and a multi-processor transfer bit. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

When the SCI detects that the Transmit Shift Register (TSR) is empty, it transfers data written in the FTDRH and FTDRL registers to the TSR register and starts serial transmission. Continuous serial transmission is executed until no transmit data is left in FTDRH and FTDRL. When FTDRHL is full of transmit data, no more data can be written. If writing new data is attempted, the data is ignored. The CPU can write to the FTDRH and FTDRL registers but cannot read them.

When writing to both the FTDRH and FTDRL registers, write in order from FTDRH to FTDRL.

TDAT[8:0] bits (Serial transmit data)

The TDAT[8:0] bits set the serial transmission data. This is valid only when FIFO is selected in asynchronous mode (including multiprocessor) or clock synchronous mode.

MPBT flag (Multi-Processor Transfer Bit Flag)

The MPBT flag specifies the value of the multi-processor bit of the transmit frame. When FCR.FM = 1, SSR.MPBT is invalid.

30.2.10 TSR : Transmit Shift Register

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first automatically transfers transmit data from TDR, TDRHL, or transmit FIFO to TSR, then sends the data to the TXDn pin. The CPU cannot directly access the TSR.

30.2.9 FTDRHLFTDRHFTDRL:发送FIFO数据寄存器

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 3 to 9)

Offset address: 0x0E (FTDRHL/FTDRH)
0x0F (FTDRL)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	MPBT	TDAT[8:0]								
重置后的值:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
8:0	TDAT[8:0]	串行传输数据 指定串行传输数据。 仅在异步模式下有效，包括多处理器模式和时钟同步模式，并且选择了FIFO。	W
9	MPBT	多处理器传输位标志 指定传输帧中的多处理器位。仅在异步模式和SMR.MP=1且选择FIFO时有效。仅在异步模式下有效，包括多处理器模式和时钟同步模式，并选择FIFO。 0：数据发送周期1：ID发送周期	W
15:10	—	写入值应为1。	W

FTDRHL是一个16位寄存器，由8位FTDRH和FTDRL寄存器组成。FTDRH分配给FTDRHL[15:8]位，并分配到与FTDRHL相同的地址。FTDRL分配给FTDRHL[7:0]位，并分配给（FTDRHL的地址+1）地址。

FTDRH和FTDRL构成一个16级FIFO寄存器，用于存储串行传输的数据和一个多处理器传输位。该寄存器仅在异步模式下有效，包括多处理器模式或时钟同步模式。

当SCI检测到传输移位寄存器(TSR)为空时，它将写入FTDRH和FTDRL寄存器的数据传输到TSR寄存器并开始串行传输。执行连续串行传输，直到在FTDRH和FTDRL中没有剩余传输数据。当FTDRHL充满传输数据时，不能再写入数据。如果尝试写入新数据，则忽略该数据。CPU可以写入FTDRH和FTDRL寄存器，但不能读取它们。

当同时写入FTDRH和FTDRL寄存器时，按照从FTDRH到FTDRL的顺序写入。

TDAT[8:0]位（串行发送数据）

TDAT[8:0]位设置串行传输数据。这仅在异步模式（包括多处理器）或时钟同步模式下选择FIFO时有效。

MPBT标志（多处理器传输位标志）

MPBT标志指定发送帧的多处理器位的值。FCR.FM=1时，SSR.MPBT无效。

30.2.10 TSR：发送移位寄存器

TSR是传送串行数据的移位寄存器。为了进行串行数据传输，SCI首先自动将发送数据从TDR、TDRHL或发送FIFO传输到TSR，然后将数据发送到TXDn引脚。CPU不能直接访问TSR。

30.2.11 SMR : Serial Mode Register for Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 3 to 9)

Note 3. When writing a new value to a bit other than the MPIE bit of this register in multi-processor mode (SMR.MP bit = 1), write 0 to the MPIE bit using the store instruction to avoid accidentally setting the MPIE bit to 1 by a read-modify-write operation when using a bit manipulation instruction.

CKE[1:0] bits (Clock Enable)

RA生态工作室

TEIE bit (Transmit End Interrupt Enable)

The TEIE bit enables or disables SCIn_TEI interrupt requests. Set TEIE to 0 to disable an SCIn_TEI interrupt request.

In simple IIC mode, SCIn_TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STIn). In this case, the TEIE bit can be used to enable or disable the STI.

MPIE bit (Multi-Processor Interrupt Enable)

When the MPIE bit is set to 1 and data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags RDRF, ORER, FER, RDF, and DR in SSR/SSR_FIFO to 1 is disabled. When data with the multi-processor bit set to 1 is received, the MPIE bit is automatically set to 0, and normal reception resumes. For details, see section 30.4. Multi-Processor Communication Function.

When the MPB bit in the SSR register is 0, the receive data is not transferred from the RSR register to the RDR register, a receive error is not detected, and setting the flags ORER and FER to 1 is disabled.

When the MPB bit is set to 1, the MPIE bit is automatically set to 0, SCIn_RXI and SCIn_ERI interrupt requests are enabled (if the RIE bit in SCR is set to 1), and setting of the ORER and FER flags to 1 is enabled.

Set MPIE to 0 if the multi-processor communications function is not used.

RE bit (Receive Enable)

The RE bit enables or disables serial reception. When the RE bit is set to 1, serial reception starts by detecting the start bit in asynchronous mode or the synchronous clock input in clock synchronous mode. Set the reception format in the SMR register before setting the RE bit to 1.

In non-FIFO operation, when reception is halted by setting the RE bit to 0, the RDRF, ORER, FER, and PER flags in the SSR register are not affected, and the previous values are retained.

When FIFO operation is selected and reception is halted by setting the RE bit to 0, the RDF, ORER, FER, PER, and DR flags in SSR_FIFO are not affected and the previous values are retained.

TE bit (Transmit Enable)

The TE bit enables or disables serial transmission.

When the TE bit is set to 1, serial transmission is started by writing transmit data to the TDR register. Set the transmission format in the SMR register before setting the TE bit to 1.

RIE bit (Receive Interrupt Enable)

The RIE bit enables or disables SCIn_RXI and SCIn_ERI interrupt requests.

SCIn_RXI and SCIn_ERI interrupt requests are disabled by setting the RIE bit to 0.

An SCIn_ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in SSR/SSR_FIFO then setting the flag to 0, or by setting the RIE bit to 0.

TIE bit (Transmit Interrupt Enable)

The TIE bit enables or disables SCIn_TXI interrupt requests. SCIn_TXI interrupt requests are disabled by setting the TIE bit to 0.

Note: To switch the TIE bit value from 0 to 1 in FIFO mode, set the TIE and TE bits to 1 simultaneously or set the TIE bit to 1 when TE = 1. When TE = 0 in FIFO mode, setting the TIE bit to 1 is prohibited.

TEIE位（发送结束中断允许）

TEIE位启用或禁用SCIn_TEI中断请求。将TEIE设置为0以禁用SCIn_TEI中断请求。

在简单IIC模式下，SCIn_TEI在完成发出启动、重新启动或停止条件(STIn)时分配给中断。
在这种情况下，TEIE位可用于启用或禁用STI。

MPIE位（多处理器中断允许）

当MPIE位设置为1并且接收到多处理器位设置为0的数据时，不读取数据并且将SSRSSR_FIFO中的状态标志RDRF、ORER、FER、RDF和DR设置为1被禁用。当接收到多处理器位设置为1的数据时，MPIE位自动设置为0，并恢复正常接收。有关详细信息，请参阅第30.4节。多处理器通信功能。

当SSR寄存器的MPB位为0时，接收数据不会从RSR寄存器传送到RDR寄存器，不会检测到接收错误，并且将标志ORER和FER设置为1被禁止。

当MPB位设置为1时，MPIE位自动设置为0，允许SCIn_RXI和SCIn_ERI中断请求（如果SCR中的RIE位设置为1），并且允许设置ORER和FER标志为1.

如果不使用多处理器通信功能，则将MPIE设置为0。

RE位（接收使能）

RE位启用或禁用串行接收。当RE位设置为1时，串行接收通过检测异步模式下的起始位或时钟同步模式下的同步时钟输入来启动。在将RE位设置为1之前，在SMR寄存器中设置接收格式。

在非FIFO操作中，当通过将RE位设置为0来停止接收时，RDRF、ORER、FER和PER标志
SSR寄存器不受影响，保留之前的值。

WhenFIFOoperationisselectedandreceptionishaltedbysettingtheREbitto0 theRDF ORER FER PER andDRflagsin SSR_FIFOarenotaffectedandthepreviousvaluesareretained.

TE位（发送使能）

TE位启用或禁用串行传输。

当TE位设置为1时，通过将发送数据写入TDR寄存器开始串行发送。在将TE位设置为1之前，在SMR寄存器中设置传输格式。

RIE位（接收中断允许）

RIE位启用或禁用SCIn_RXI和SCIn_ERI中断请求。

通过将RIE位设置为0来禁用SCIn_RXI和SCIn_ERI中断请求。

SCIn_ERI中断请求可以通过从SSRSSR_FIFO中的ORER、FER或PER标志读取1然后将该标志设置为0或通过将RIE位设置为0来取消。

TIE位（发送中断允许）

TIE位启用或禁用SCIn_TXI中断请求。通过将TIE位设置为0来禁用SCIn_TXI中断请求。

Note: 要在FIFO模式下将TIE位值从0切换为1，请将TIE和TE位同时设置为1，或者在TE=1时将TIE位设置为1。在FIFO模式下，当TE=0时，将TIE位设置为1是禁止。

Note 1. Only 0 can be written to clear the flag after reading 1.

The SSR register provides SCI status flags and transmission and reception multi-processor bits.

MPBT bit (Multi-Processor Bit Transfer)

The MPBT bit sets the value of the multi-processor bit in the transmit frame.

MPB bit (Multi-Processor)

The MPB bit holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

TEND flag (Transmit End Flag)

The TEND flag indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled) and the FCR.FM bit is set to 0 (non-FIFO selected). When the SCR.TE bit is set to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated on transmission of the tail-end bit of a character being transmitted.

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR.TE bit is 1
- When 0 is written to TDRE after reading TDRE = 1 while the SCR.TE bit is 1

PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

  Although receive data is transferred to the RDR register when the parity error occurs, no SCIn_RXI interrupt request occurs. When the PER flag is set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to PER after reading PER = 1. After writing 0 to the PER flag, read the PER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

The FER flag indicates that a framing error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When 0 is sampled as the stop bit during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

  In 2-stop-bit mode, only the first stop bit is checked. The second stop bit is not checked. Although receive data is transferred to the RDR register when the framing error occurs, no SCIn_RXI interrupt request occurs. When the FER flag is to 1, the subsequent receive data is not transferred to the RDR register.

Bit	Symbol	Function	R/W
6	RDRF	接收数据满标志 0：RDR寄存器中没有接收到数据1： RDR寄存器中接收到数据	R/(W)*1
7	TDRE	传输数据空标志 0：在TDR寄存器中发送数据1：在T DR寄存器中不发送数据	R/(W)*1

注1.读1后只能写0清除标志。

SSR寄存器提供SCI状态标志和发送和接收多处理器位。

MPBT bit (Multi-Processor Bit Transfer)

MPBT位设置发送帧中多处理器位的值。

MPB bit (Multi-Processor)

MPB位保存接收帧中多处理器位的值。当SCR.RE位为0时，该位不变。

TEND标志（发送结束标志）

TEND标志表示传输完成。

[Setting conditions]

●当SCR.TE位设置为0（禁用串行传输）且FCR.FM位设置为0（选择非FIFO）时。当SCR.TE位设置为1时，TEND标志不受影响并保持值1。

●TDR寄存器未在发送字符的尾端位时更新时。

[Clearing conditions]

●当SCR.TE位为1时将发送数据写入TDR寄存器

●当SCR.TE位为1时，读取TDRE=1后向TDRE写入0

PER标志（奇偶校验错误标志）

PER标志表示在异步模式接收过程中发生奇偶校验错误，接收异常结束。

[Setting condition]

●当地址匹配功能被禁用（DCCR.DCME=0）时，在异步模式接收期间检测到奇偶校验错误。

尽管发生奇偶校验错误时接收数据被传送到RDR寄存器，但不会发生SCIn_RXI中断请求。当PER标志设置为1时，后续接收数据不会传送到RDR寄存器。

[Clearing condition]

●读取PER=1后向PER写入0时。将0写入PER标志后，读取PER标志以检查它是否实际设置为0。

当SCR.RE位设置为0（禁用串行接收）时，PER标志不受影响并保留其先前的值。

FER标志（帧错误标志）

FER标志表示在异步模式下接收过程中发生了帧错误，并且接收异常结束。

[Setting condition]

●当地址匹配功能被禁用（DCCR.DCME=0）时，在异步模式接收期间采样0作为停止位时。

在2停止位模式下，仅检查第一个停止位。不检查第二个停止位。虽然发生帧错误时接收数据被传输到RDR寄存器，但不会发生SCIn_RXI中断请求。当FER标志为1时，后续接收数据不传送到RDR寄存器。

[Clearing condition]

- When 0 is written to FER after reading FER = 1. After writing 0 to the FER flag, read the FER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error and a framing error is read from the RDR register.

  The data received before an overrun error occurred is saved in the RDR register, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register. In clock synchronous mode, serial transmission and reception are stopped.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1. After writing 0 to the ORER flag, read the ORER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing conditions]

- When 0 is written to RDRF after reading RDRF = 1

The TDRE flag indicates the presence of transmit data in the TDR register.

[Setting conditions]

- When the SCR.TE bit is 0
- When data is transmitted from the TDR register to the TSR register

[Clearing conditions]

- When 0 is written to TDRE after reading TDRE = 1
- When the SCR.TE bit is 1 and data is written to the TDR register

[Clearing condition]

●当读取FER=1后向FER写入0时。将0写入FER标志后，读取FER标志以检查它是否实际设置为0。

当SCR.RE位设置为0（禁用串行接收）时，FER标志不受影响并保留其先前的值。

ORER标志（溢出错误标志）

ORER标志表示接收期间发生溢出错误，接收异常结束。

[Setting condition]

●在接收没有奇偶校验错误和帧错误的数据之前接收下一个数据时，从RDR寄存器中读取。

溢出错误发生前接收到的数据保存在RDR寄存器中，但错误发生后接收到的数据丢失。
当ORER标志设置为1时，接收数据不转发到RDR寄存器。在时钟同步模式下，串行发送和接收停止。

[Clearing condition]

●读取ORER=1后向ORER写入0时。向ORER标志写入0后，读取ORER标志以检查它是否实际设置为0。

当SCR.RE位设置为0（禁用串行接收）时，ORER标志不受影响并保留其先前的值。

TDRE标志表示TDR寄存器中存在发送数据。

[Setting conditions]

●当数据从TDR寄存器传送到TSR寄存器时

[Clearing conditions]

7	TDFE	Transmit FIFO Data Empty Flag 0: The amount of transmit data written in FTDRHL exceeds the specified transmit triggering number 1: The amount of transmit data written in FTDRHL is equal to or less than the specified transmit triggering number	R/W*1

Note 1. Only 0 can be written, to clear the flag after reading 1.

The SSR_FIFO register provides the SCI with FIFO mode status flags.

DR flag (Receive Data Ready Flag)

The DR flag indicates that the amount of data stored in the Receive FIFO Data Register (FRDRHL) falls below the specified receive triggering number, and that no next data is received after 15 ETUs (elementary time units) from the last stop bit in asynchronous mode. This flag is valid only in asynchronous mode, including multi-processor mode, when FIFO operation is selected.

In clock synchronous mode, the DR flag is not set to 1.

[Setting condition]

- When FRDRHL contains less data than the specified receive triggering number, and no next data is received after 15 ETUs*1 from the last stop bit, and the SSR_FIFO.FER and SSR_FIFO.PER flags are 0.

[Clearing conditions]

- When 1 is read from DR, after all received data is read
- When the FCR.FM bit is changed from 0 to 1

Note 1. This is equivalent to 1.5 frames in the 8-bit format with one stop bit.
The DR flag is only set to 1 when FIFO is selected in asynchronous mode, including multi-processor mode. It is not set to 1 in other operation modes.

TEND flag (Transmit End Flag)

The TEND flag indicates that FTDRHL does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

Bit	Symbol	Function	R/W
0	DR	接收数据就绪标志 0：接收中，或者接收成功后FRDRHL中没有接收到的数据（接收FIFO为空） 1：正常接收完成后一段时间内没有接收到下一个接收数据，此时FIFO中存储的数据量等于或小于接收触发数	R/W*1
1	—	读取值未定义。写入值应为1。	R/W
2	TEND	发送结束标志 0：字符传输中1：字符传输完成	R/W*1
3	PER	奇偶校验错误标志 0：未发生奇偶校验错误1：发生奇偶校验错误	R/W*1
4	FER	成帧错误标志 0：未发生帧错误1：发生帧错误	R/W*1
5	ORER	溢出错误标志 0：未发生溢出错误1：发生溢出错误	R/W*1
6	RDF	接收FIFO数据满标志 0：写入FRDRHL的接收数据量小于指定的接收触发数 1：写入FRDRHL的接收数据量等于或大于指定的接收触发数	R/W*1
7	TDFE	发送FIFO数据空标志 0：写入FTDRHL的发送数据量超过指定的发送触发数 1：写入FTDRHL的发送数据量等于或小于指定的发送触发数	R/W*1

注1.只能写入0，读取1后清除标志。

SSR_FIFO寄存器为SCI提供FIFO模式状态标志。

DR标志（接收数据就绪标志）

DR标志表示存储在接收FIFO数据寄存器(FRDRHL)中的数据量低于指定的接收触发数，并且在异步模式下从最后一个停止位开始15个ETU（基本时间单位）后没有接收到下一个数据.此标志仅在选择FIFO操作时在异步模式下有效，包括多处理器模式。

在时钟同步模式下，DR标志不设置为1。

[Setting condition]

●当FRDRHL包含的数据少于指定的接收触发数，并且从最后一个停止位开始15个ETU*1后没有接收到下一个数据，并且SSR_FIFO.FER和SSR_FIFO.PER标志为0。

[Clearing conditions]

●从DR读取1时，在读取所有接收到的数据后

●当FCR.FM位由0变为1时

注1.这相当于8位格式的1.5帧，带有一位停止位。
只有在异步模式（包括多处理器模式）下选择FIFO时，DR标志才设置为1。在其他操作模式下不设置为1。

TEND标志（发送结束标志）

TEND标志表明FTDRHL在发送串行字符的最后一位时不包含有效数据，因此暂停发送。

[Setting condition]

- When FTDRHL does not contain transmit data when the last bit of a 1-byte serial character is transmitted.

[Clearing conditions]

- When transmit data is written to FTDRHL*1 while the SCR.TE bit is 1
- When 0 is written to TEND after 1 is read from TEND, when the SCR.TE bit is 1
- When the FCR.FM bit is changed from 0 to 1

Note 1. Do not use the TEND bit as a transmit end flag when the DTC writes data to FTDRHL in response to an SCIn_TXI interrupt request.

PER flag (Parity Error Flag)

The PER flag indicates whether there is a parity error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When data is received and a parity error is detected, when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to PER after reading PER = 1.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a parity error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

The FER flag indicates whether there is a framing error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When 0 is sampled as the stop bit during reception when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to FER after reading FER = 1.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a framing error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

The ORER flag indicates that the receive operation stopped abnormally because an overrun error occurred.

[Setting condition]

- When the next serial reception completes while the receive FIFO is full with 16-byte receive data.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1.

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.

RDF flag (Receive FIFO Data Full Flag)

The RDF flag indicates that receive data was transferred to the FRDRHL register, and the amount of data in FRDRHL is equal to or exceeds the specified receive triggering number. When RTRG is set to 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0.

[Setting condition]

- When the amount of receive data equal to or greater than the specified receive triggering number is stored in FRDRHL,*1 and the FIFO is not empty.

●当FTDRHL不包含发送数据时，发送1字节串行字符的最后一位。

[Clearing conditions]

●当SCR.TE位为1时将发送数据写入FTDRHL*1

●从TEND读取1后，向TEND写入0时，SCR.TE位为1时

●当FCR.FM位由0变为1时

注1.当DTC将数据写入FTDRHL以响应SCIn_TXI中断请求时，请勿使用TEND位作为发送结束标志。

PER标志（奇偶校验错误标志）

PER标志指示在禁用地址匹配功能（DCCR.DCME=0）时，异步模式下从FRDRHL寄存器读取的数据是否存在奇偶校验错误。

[Setting condition]

●当接收到数据并检测到奇偶校验错误时，当地址匹配功能被禁用时（DCCR.DCME=0）。

[Clearing condition]

●读取PER=1后向PER写入0时。

接收操作是连续的，接收数据存储在FRDRHL寄存器中，即使在接收过程中发生奇偶校验错误。

当SCR.RE位设置为0（禁用串行接收）时，PER标志不受影响并保留其先前的值。

FER标志（帧错误标志）

FER标志指示在禁用地址匹配功能（DCCR.DCME=0）时，异步模式下从FRDRHL寄存器读取的数据是否存在帧错误。

[Setting condition]

●当地址匹配功能被禁用（DCCR.DCME=0）时，在接收期间采样0作为停止位时。

[Clearing condition]

●读取FER=1后向FER写入0时。

接收操作是连续的，接收数据存储在FRDRHL寄存器中，即使在接收过程中发生帧错误。

当SCR.RE位设置为0（禁用串行接收）时，FER标志不受影响并保留其先前的值。

ORER标志（溢出错误标志）

ORER标志指示接收操作由于发生溢出错误而异常停止。

[Setting condition]

●当接收FIFO已满16字节接收数据时，下一次串行接收完成时。

[Clearing condition]

●读取ORER=1后向ORER写入0时。

当SCR.RE位设置为0（禁用串行接收）时，ORER标志不受影响并保留其先前的值。

RDF标志（接收FIFO数据满标志）

RDF标志表示接收数据已传送到FRDRHL寄存器，并且FRDRHL中的数据量等于或超过指定的接收触发数。当RTRG设置为0时，即使接收FIFO中的数据量等于0，RDF标志也不会设置。

[Setting condition]

●当FRDRHL中存储了等于或大于指定接收触发数的接收数据量时，*1且FIFO不为空。

[Clearing conditions]

- When 0 is written to RDF after reading RDF = 1
- When FRDRHL is read by the DTC, but only when the block transfer is the last transmission
- When the setting and clearing conditions occur at the same time, the RDF bit is set to 0. After that, when the amount of data stored in the FRDRHL register is the same as or greater than the RTRG value, RDF is set to 1 after 1 PCLK.

Note 1. Because FRDRHL is a 16-stage FIFO register, the maximum amount of data that can be read when RDF is 1 is equivalent to the specified receive triggering number. If an attempt is made to read after all the data in FRDRHL is read, the data is undefined.

TDFE flag (Transmit FIFO Data Empty Flag)

The TDFE flag indicates that data is transferred from the FTDRHL register into the TSR register, the amount of data in FTDRHL is below the specified transmit triggering number, and writing of transmit data to FTDRHL is enabled.

[Setting conditions]

- When the TE bit in SCR is 0
- When the amount of transmit data written in FTDRHL is equal to or less than the specified transmit triggering number*1

[Clearing conditions]

- When writing to FTDRHL is executed on the last transmission while the DTC is activated
- When 0 is written to the TDFE flag after reading TDFE = 1.*2
  The setting conditions are given priority when TE = 0. When the setting condition and clearing condition occur at the same time, the TDFE flag is set to 0. After that, when the amount of data stored in the FTDRHL register is equal to or less than the TTRG value, TDFE is set to 1 after 1 PCLK.

Note 1. Because the FTDRHL register is a 16-stage FIFO register, when the TDFE flag is 1, the maximum amount of data that can be written to the FTDRHL register is 16 minus FDR.T[4:0] bytes. If more data is written, data is discarded.
Note 2. Do not clear the TDFE flag during block transfer processing by the DTC.

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 3 to 9)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x04

3	PER	Parity Error Flag 0: No parity error occurred 1: Parity error occurred	R/W*1
4	ERS	Error Signal Status Flag 0: No low error signal response 1: Low error signal response occurred	R/W*1

[Clearing conditions]

●读取RDF=1后向RDF写入0时

●当DTC读取FRDRHL时，但仅当块传输是最后一次传输时

●当设置和清除条件同时发生时，RDF位被设置为0。之后，当FRDRHL寄存器中存储的数据量等于或大于RTRG值时，RDF被设置为1在1个PCLK之后。

注1.因为FRDRHL是16级FIFO寄存器，所以当RDF为1时可以读取的最大数据量等于指定的接收触发数。如果在读取FRDRHL中的所有数据后尝试读取，则数据未定义。

TDFE标志（发送FIFO数据空标志）

TDFE标志表示数据从FTDRHL寄存器传送到TSR寄存器，在
FTDRHL低于指定的发送触发数，并且允许将发送数据写入FTDRHL。

[Setting conditions]

●当SCR的TE位为0时

●当写入FTDRHL的发送数据量等于或小于指定的发送触发数时*1

[Clearing conditions]

●当DTC激活时，在最后一次传输上执行写入FTDRHL时

●读取TDFE=1后向TDFE标志写入0时。*2
  当TE=0时，设置条件优先。当设置条件和清除条件同时发生时，TDFE标志设置为0。之后，当FTDRHL寄存器中存储的数据量等于或小于比TTRG值，TDFE在1个PCLK后设置为1。

注1.由于FTDRHL寄存器为16级FIFO寄存器，因此当TDFE标志为1时，可写入FTDRHL寄存器的最大数据量为16减去FDR.T[4:0]字节。如果写入更多数据，则丢弃数据。
注2.在DTC的块传输处理过程中，不要清除TDFE标志。

7	TDRE	Transmit Data Empty Flag 0: Transmit data in TDR register 1: No transmit data in TDR register	R/W*1

Note 1. Only 0 can be written, to clear the flag after reading 1.

The SSR_SMCI register provides the SCI with smart card interface mode status flags.

TEND flag (Transmit End Flag)

When there is no error signal from the receiving side, the TEND flag is set to 1 when more data for transfer is ready to be transferred to the TDR register.

[Setting conditions]

- When the SCR_SMCI.TE bit = 0 (serial transmission is disabled).
  When the SCR_SMCI.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period elapses after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated.

  The set timing is determined by the following register settings:
  - When SMR_SMCI.GM = 0 and SMR_SMCI.BLK = 0, 12.5 ETUs after the start of transmission
  - When SMR_SMCI.GM = 0 and SMR_SMCI.BLK = 1, 11.5 ETUs after the start of transmission
  - When SMR_SMCI.GM = 1 and SMR_SMCI.BLK = 0, 11.0 ETUs after the start of transmission
  - When SMR_SMCI.GM = 1 and SMR_SMCI.BLK = 1, 11.0 ETUs after the start of transmission

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR_SMCI.TE bit is 1
- When 0 is written to TDRE after reading TDRE = 1 while the SCR_SMCI.TE bit is 1

PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception. Although receive data is transferred to RDR when a parity error occurs, no SCIn_RXI interrupt request occurs. After the PER flag is set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to PER after reading PER = 1. After writing 0 to the PER flag, read the flag to check that it is actually set to 0.

When the RE bit in SCR_SMCI is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

ERS flag (Error Signal Status Flag)

[Setting condition]

- When a low error signal is sampled.

[Clearing condition]

Bit	Symbol	Function	R/W
5	ORER	溢出错误标志 0：未发生溢出错误1：发生溢出错误	R/W*1
6	RDRF	接收数据满标志 0：RDR寄存器中没有接收到数据1：RDR寄存器中接收到数据	R/W*1
7	TDRE	传输数据空标志 0：在TDR寄存器中发送数据1：在TDR寄存器中不发送数据	R/W*1

注1.只能写入0，读取1后清除标志。

SSR_SMCI寄存器为SCI提供智能卡接口模式状态标志。

TEND标志（发送结束标志）

当接收端没有错误信号时，当更多数据准备好传输到TDR寄存器时，TEND标志设置为1。

[Setting conditions]

- 当SCR_SMCI.TE位=0时（禁用串行传输）。
  当SCR_SMCI.TE位从0变为1时，TEND标志不受影响并保持值1。
- 在最后一次发送1个字节后经过指定时间后，ERS标志为0，并且不更新TDR寄存器。

  设置时序由以下寄存器设置确定：
  - 当SMR_SMCI.GM=0且SMR_SMCI.BLK=0时，传输开始后12.5ETU
  - 当SMR_SMCI.GM=0和SMR_SMCI.BLK=1时，传输开始后11.5ETU
  - 当SMR_SMCI.GM=1和SMR_SMCI.BLK=0时，传输开始后11.0ETU
  - 当SMR_SMCI.GM=1且SMR_SMCI.BLK=1时，传输开始后11.0ETU

[Clearing conditions]

- 当SCR_SMCI.TE位为1时将发送数据写入TDR寄存器
- 当SCR_SMCI.TE位为1时，读取TDRE=1后向TDRE写入0

PER标志（奇偶校验错误标志）

PER标志表示在异步模式接收过程中发生奇偶校验错误，接收异常结束。

[Setting condition]

- 在接收过程中检测到奇偶校验错误时。尽管发生奇偶校验错误时将接收数据传输到RDR，但不会发生SCIn_RXI中断请求。PER标志设置为1后，后续接收数据不会传输到RDR。

[Clearing condition]

- 读取PER=1后向PER写入0时。将0写入PER标志后，读取该标志以检查它是否实际设置为0。

当SCR_SMCI中的RE位设置为0（禁用串行接收）时，PER标志不受影响并保留其先前的值。

ERS标志（错误信号状态标志）

[Setting condition]

- 采样低误差信号时。

[Clearing condition]

- When 0 is written to ERS after reading ERS = 1.

ORER flag (Overrun Error Flag)

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error is read from the RDR register. The data received before an overrun error occurred is saved in the RDR, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1. After writing 0 to the ORER flag, read the flag to check that it is actually set to 0.

When the RE bit in SCR_SMCI is set to 0, the ORER flag is not affected and retains its previous value.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing conditions]

MER flag (Manchester Error Flag)

When data is received in Manchester mode, Manchester error is detected and it is displayed.

[Setting conditions]

- When receiving in Manchester mode and detecting Manchester code error in data area of received frame.
  Received data when an error occurs is transferred to the RDR register, but the RXI interrupt request is not generatedand the ERI interrupt request is generated.
  When the Manchester error flag is set to “1”, subsequent receive data is not transferred to the RDR register.
  For details on Manchester error, see section 30.5.11. Errors in Manchester Mode.

[Clearing conditions]

- When 0 is written to MER after reading MER = 1 (after writing 0 to it, read the MER bit to check that it has actually been set to 0.)
  Even when the RE bit in SCR is set to 0 (serial reception is disabled), the MER flag is not affected and retains its previous value.

MPB flag (Multi-Processor)

Holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

TEND flag (Transmit End Flag)

Indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled) and FCR.FM bit is set to 0 (non-FIFO selected).
  When the SCR.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at the time of transmission of the tail-end bit of a character being transmitted

[Clearing conditions]

- When transmit data are written to the TDR register while the SCR.TE bit is 1.

7	TDRE	传输数据空标志 0：发送数据在TDR寄存器1：没有发送数据在TDR寄存器	R/(W)*1

注1.该位只能写入0，确认（读取）后清除标志，标志设置为1。

SSR由SCI的状态标志和接收多处理器位构成。

MER标志（曼彻斯特错误标志）

在曼彻斯特模式下接收数据时，检测到曼彻斯特错误并显示出来。

[Setting conditions]

●曼彻斯特模式接收时，检测接收帧数据区的曼彻斯特码错误。
发生错误时接收到的数据被传送到RDR寄存器，但不产生RXI中断请求，产生ERI中断请求。当曼彻斯特错误标志设置为“1”时，后续接收数据不会传输到RDR寄存器。

有关曼彻斯特错误的详细信息，请参阅第30.5.11节。曼彻斯特模式中的错误。

[Clearing conditions]

●读MER=1后向MER写入0时（向其写入0后，读取MER位以检查它是否已实际设置为0。）即使SCR中的RE位设置为0（串行接收是禁用），MER标志不受影响并保留其先前的值。

MPB flag (Multi-Processor)

保存接收帧中多处理器位的值。当SCR.RE位为0时，该位不变。

TEND标志（发送结束标志）

表示传输完成。

[Setting conditions]

●当SCR.TE位设置为0（禁用串行传输）且FCR.FM位设置为0（选择非FIFO）时。当SCR.TE位从0变为1时，TEND标志不受影响并保持值1。

●发送字符尾端位时，TDR寄存器未更新时

[Clearing conditions]

●当SCR.TE位为1时将发送数据写入TDR寄存器。

- When 0 is written to TDRE after reading TDRE = 1 while the SCR.TE bit is 1.

PER flag (Parity Error Flag)

Indicates that a parity error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When a parity error is detected during reception in Asynchronous Mode and the state of Address Match function invalidity (DCCR.DCME = 0).
  Although receive data when the parity error occurs is transferred to RDR, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to PER after reading PER = 1 (after writing 0 to it, read the PER bit to check that it has actually been set to 0.)

Even when the RE bit in SCR is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

Indicates that a framing error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When “0” is sampled as the stop bit during reception in Asynchronous Mode and the state of Address Match function invalidity (DCCR.DCME = 0).
  In 2-stop-bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked. Note that although receive data when the framing error occurs is transferred to RDR, no RXI interrupt request occurs. In addition, when the FER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to FER after reading FER = 1 (after writing 0 to it, read the FER bit to check that it has actually been set to 0.)
  .

Even when the RE bit in SCR is set to 0, the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

[Setting condition]

- When the next data is received before receive data is read from RDR which don’t have any valid reception error.
  In RDR, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, reception data isn’t forwarded to RDR register. Note that, in clock synchronous mode, serial transmission and reception will be stop.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1 (after writing 0 to it, read the ORER bit to check that it has actually been set to 0.)

Even when the RE bit in SCR is set to 0, the ORER flag is not affected and retains its previous value.

RDRF flag (Receive Data Full Flag)

Indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register

[Clearing conditions]

- When it’s written to “0" after the state of “1" is read

[Clearing condition]

●读取PER=1后向PER写入0时（写入0后，读取PER位以检查其是否已实际设置为0。）

即使SCR中的RE位设置为0（禁用串行接收），PER标志也不受影响并保持其先前的值。

FER标志（帧错误标志）

表示异步模式接收时出现帧错误，接收异常结束。

[Setting condition]

●当在异步模式接收期间采样“0”作为停止位和地址匹配功能无效状态（DCCR.DCME=0）。在2-stop-bit模式下，只检查第一个停止位是否为1，不检查第二个停止位。请注意，虽然发生帧错误时的接收数据被传输到RDR，但不会发生RXI中断请求。此外，当FER标志设置为1时，后续接收数据不会传输到RDR。

[Clearing condition]

●读取FER=1后向FER写入0时（写入0后，读取FER位以检查其是否已实际设置为0。）

.

即使SCR中的RE位设置为0，FER标志也不受影响并保持其先前的值。

ORER标志（溢出错误标志）

表示接收过程中发生溢出错误，接收异常结束。

[Setting condition]

●在接收数据从没有任何有效接收错误的RDR读取之前接收到下一个数据时。在RDR中，保留发生溢出错误之前的接收数据，但发生溢出错误之后接收的数据会丢失。当ORER标志设置为1时，接收数据不转发到RDR寄存器。请注意，在时钟同步模式下，串行发送和接收将停止。

[Clearing condition]

●读ORER=1后向ORER写入0时（写入0后，读取ORER位以检查其是否已实际设置为0。）

[Clearing conditions]

- When it’s written to “0" after the state of “1" is read
- When the SCR.TE bit is 1, it’s written to the TDR register

Note: RDRF and TDRE should not be cleared by SSR register access unless communication is interrupted.

Note 1. Writable only when the TE and RE bits in SCR/SCR_SMCI are 0 (both serial transmission and reception are disabled).
Note 2. The setting is invalid and a fixed data length of 8 bits is used in modes other than asynchronous mode.
Note 3. LSB-first must be selected and the value of the MSB (bit [7]) in TDR cannot be transmitted.

The SCMR register selects the smart card interface and communication format.

SMIF bit (Smart Card Interface Mode Select)

Setting the SMIF bit to 1 selects smart card interface mode. Setting it to 0 selects all other modes:

- Asynchronous mode, including multi-processor mode
- Clock synchronous mode
- Simple SPI mode
- Simple IIC mode

SINV bit (Transmitted/Received Data Invert)

The SINV bit inverts the transmit and receive data logic level. It does not affect the logic level of the parity bit. To invert the parity bit, invert the PM bit in SMR or SMR_SMCI.

CHR1 bit (Character Length 1)

The CHR1 bit selects the data length of transmit and receive data in combination with the CHR bit in the SMR register. A fixed data length of 8 bits is used in modes other than asynchronous mode.

BCP2 bit (Base Clock Pulse 2)

The BCP2 bit selects the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set this bit in combination with the SMR_SMCI.BCP[1:0] bits.

Table 30.5 Combinations of the SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits

将SMIF位设置为1选择智能卡接口模式。将其设置为0会选择所有其他模式：

- ●异步模式，包括多处理器模式
- ●时钟同步模式
- ●简单SPI模式
- ●简单IIC模式

SINV位（发送接收数据反转）

SINV位反转发送和接收数据逻辑电平。它不影响奇偶校验位的逻辑电平。要反转奇偶校验位，请反转SMR或SMR_SMCI中的PM位。

CHR1位（字符长度1）

CHR1位结合SMR寄存器中的CHR位选择发送和接收数据的数据长度。在异步模式以外的模式中使用8位的固定数据长度。

BCP2位（基本时钟脉冲2）

BCP2位选择智能卡接口模式下1位数据传输时间内的基本时钟周期数。将该位与SMR_SMCI.BCP[1:0]位一起设置。

BRR is an 8-bit register that adjusts the bit rate.

As each SCI channel has independent baud rate generator control, different bit rates can be set for each channel. Table 30.6 shows the relationship between the setting (N) in the BRR and the bit rate (B) for normal asynchronous mode, multi-processor transfer, clock synchronous mode, smart card interface mode, simple SPI mode, and simple IIC mode.

The initial value of the BRR register is 0xFF. The BRR register can be read by the CPU, but it can be written to only when the TE and RE bits in SCR/SCR_SMCI are 0.

Table 30.10 and Table 30.11 list examples of BRR (N) settings in normal asynchronous mode. Table 30.12 lists the maximum bit rate settable for each operating frequency. Table 30.16 lists examples of BRR (N) settings in smart card interface mode.

In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, see section 30.7.4. Receive Data Sampling Timing and Reception Margin. Table 30.13 and Table 30.15 list the maximum bit rates with external clock input.

When either the Asynchronous Mode Base Clock Select bit (ABCS) or the Baud Rate Generator Double-speed Mode Select bit (BGDM) in the Serial Extended Mode Register (SEMR) is set to 1 in asynchronous mode, the bit rate becomes twice the value listed in Table 30.17. When both of those registers are set to 1, the bit rate becomes four times the listed value.

Note: Space: Setting prohibited.
—: Can be set, but an error occurs.

Note 1. Continuous transmission or reception is not possible. After transmitting or receiving one frame of data, a 1-bit period elapses before starting to transmit or receive the next frame of data. The output of the synchronization clock is stopped for a 1-bit period. Therefore, it takes 9 bits worth of time to transfer one frame (8 bits) of data, and the average transfer rate is 8/9 times the bit rate. When the FIFO is selected, this setting (BRR = 00h and SMR.CKS[1:0] = 00b) is not available.

Note: 空格：禁止设置。—：可以设置，
但发生错误。

注1.不能连续发送或接收。在发送或接收一帧数据后，在开始发送或接收下一帧数据之前会经过1位周期。同步时钟的输出停止1位周期。因此，传输一帧（8位）数据需要9位的时间，平均传输速率为89倍的位速率。

选择FIFO时，此设置（BRR=00h且SMR.CKS[1:0]=00b）不可用。

30.2.21 MDDR : Modulation Duty Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 3 to 9)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

MDDR corrects the bit rate adjusted by the BRR register.

When the BRME bit in SEMR is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected using the settings in MDDR (M/256). Table 30.20 shows the relationship between the MDDR setting (M) and the bit rate (B).

The initial value of MDDR is 0xFF. Bit [7] in this register is fixed to 1.

The CPU can read the MDDR register, but this register is only writable when the TE and RE bits in SCR/SCR_SMCI are 0.

30.2.21 MDDR：调制占空比寄存器

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 3 to 9)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
重置后的值：	1	1	1	1	1	1	1	1

MDDR校正由BRR寄存器调整的比特率。

当SEMR中的BRME位设置为1时，片上波特率发生器生成的比特率使用MDDR(M256)中的设置进行均匀校正。表30.20显示了MDDR设置(M)和比特率(B)之间的关系。

MDDR的初始值为0xFF。该寄存器中的位[7]固定为1。

CPU可以读取MDDR寄存器，但该寄存器只有在SCRSCR_SMCI中的TE和RE位为0时才可写。

Table 30.20 Relationship between MDDR setting (M) and bit rate (B) when bit rate modulation function is used

B: Bit rate (bps)
M: MDDR setting (128 ≤ MDDR ≤ 256)
N: BRR setting for baud rate generator (0 ≤ N ≤ 255)
PCLK: Operating frequency (MHz)

The SEMR register selects the clock source for the 1-bit period in asynchronous mode.

ACS0 bit (Asynchronous Mode Clock Source Select)

Selects the clock source in the asynchronous mode.

The ACS0 bit is valid in asynchronous mode (SMR.CM bit = 0) and when an external clock input is selected (SCR.CKE[1:0] bits = 10b or 11b). This bit is used to select an external clock input or the logical AND of compare matches output from the internal GPT.

Set the ACS0 bit to 0 in other than asynchronous mode.

For SCI1 and SCI2, the GTIOCnA output (n = 3, 4, 6, 7) of GPT can be set as the serial transfer base clock. Refer to Table 30.23 for details.

These bits for the other SCI channels than SCI1 and SCI2 are reserved. The write values to these bits for other than SCI1 and SCI2 should be 0.

Figure 30.3, Figure 30.4 show a setting example of when GTIOC3A and GTIOC4A are selected for output.

This figure shows an example when GPT clock is input to SCI1.

When generating 187.5 kbps of GPT average transfer rate for PCLKD = 32 MHz:

1. Generate a frequency of 4 MHz using GTIOC3A as the base clock.
2. Generate 3/4 clock enable of base clock to set an average transfer rate of 3 MHz/16 = 187.5 kbps using GTIOC4A.

ACS0位在异步模式（SMR.CM位=0）和选择外部时钟输入时（SCR.CKE[1:0]位=10b或11b）有效。该位用于选择外部时钟输入或内部GPT的比较匹配输出的逻辑与。

在非异步模式下将ACS0位设置为0。

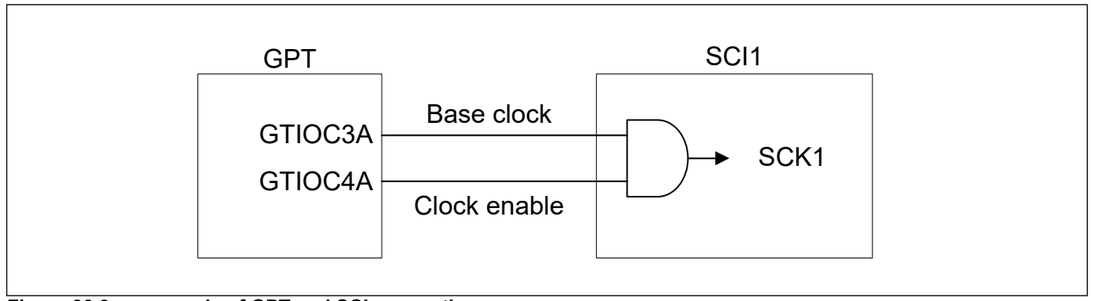

Figure 30.3 example of GPT and SCI connection

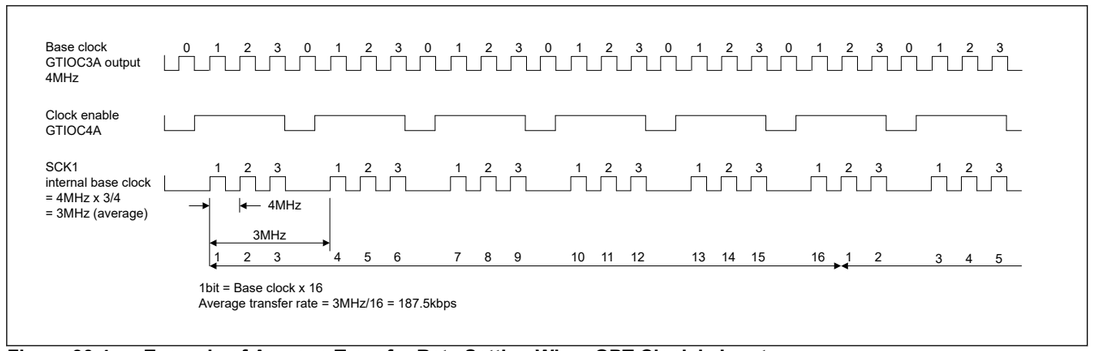

Figure 30.4 Example of Average Transfer Rate Setting When GPT Clock is Input

PADIS bit (Preamble function Disable)

In asynchronous mode, select enable / disable of preamble function. In Manchester mode, preamble is not output regardless of this bit setting

BRME bit (Bit Rate Modulation Enable)

The BRME bit enables or disables the bit rate modulation function. The bit rate generated by the on-chip baud rate generator is evenly corrected when this function is enabled. Set to 0 in Manchester mode.

ABCSE bit (Asynchronous Mode Extended Base Clock Select 1)

The ABCSE bit sets the pulse number for the base clock in a 1-bit period to 6, and the double-frequency clock is output from the baud rate generator. When the bit rate is set to 6 while dividing the bus clock frequency, use this bit and set SMR.CKS[1:0] = 00b and BRR = 0.

Set it to "0" in modes other than asynchronous mode. Even in asynchronous mode, set it to "0" when using external clock.

ABCS bit (Asynchronous Mode Base Clock Select)

The ABCS bit selects the number of clock cycles for a 1-bit period.

Set it to "0" in modes other than asynchronous mode and Manchester mode.

NFEN bit (Digital Noise Filter Function Enable)

The NFEN bit enables or disables the digital noise filter function.

When the digital noise filter function is enabled:

- Noise cancellation is applied to the RXDn input signal in asynchronous mode
- Noise cancellation is applied to the SDAn and SCLn input signals in simple I^2C mode

In all other modes, set the NFEN bit to 0 to disable the digital noise filter function. When the function is disabled, input signals are transferred as received.

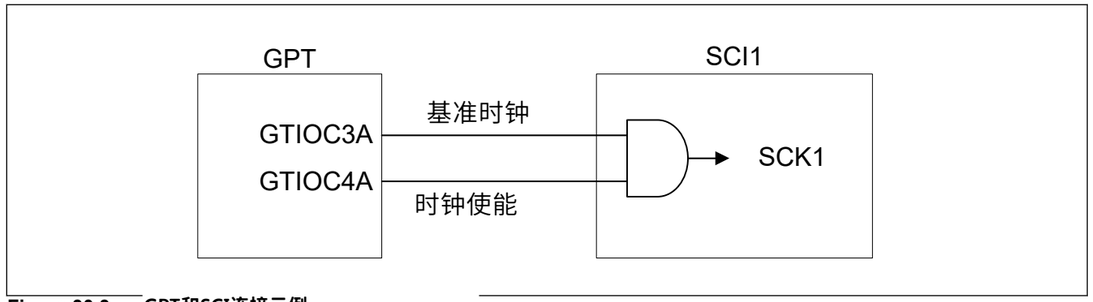

Figure 30.3 GPT和SCI连接示例

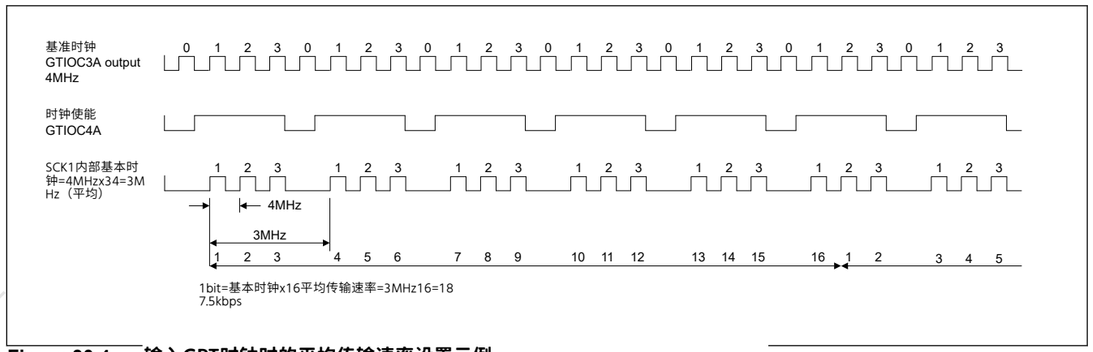

Figure 30.4 输入GPT时钟时的平均传输速率设置示例

PADIS位（前导功能禁用）

在异步模式下，选择enabledisableofpreamble功能。在曼彻斯特模式下，无论该位设置如何，都不会输出前导码

BRME位（比特率调制启用）

BRME位启用或禁用比特率调制功能。该功能使能时，片内波特率发生器产生的比特率得到均匀校正。在曼彻斯特模式下设置为0。

ABCSE位（异步模式扩展基本时钟选择1）

ABCSE位将基本时钟在1位周期内的脉冲数设置为6，并从波特率发生器输出双频时钟。当比特率设置为6并同时分频总线时钟频率时，使用该位并设置SMR.CKS[1:0]=00b和BRR=0。

在异步模式以外的模式下将其设置为“0”。即使在异步模式下，使用外部时钟时也将其设置为“0”。

ABCS位（异步模式基本时钟选择）

ABCS位选择1位周期的时钟周期数。

在异步模式和曼彻斯特模式以外的模式下将其设置为“0”。

NFEN位（数字噪声滤波器功能使能）

NFEN位启用或禁用数字噪声滤波器功能。

启用数字噪声滤波器功能时：

●在异步模式下对RXDn输入信号应用噪声消除

●在简单I2C模式下，对SDAn和SCLn输入信号应用噪声消除

在所有其他模式下，将NFEN位设置为0以禁用数字噪声滤波器功能。禁用该功能时，输入信号按接收到的方式传输。

BGDM bit (Baud Rate Generator Double-Speed Mode Select)

The BGDM bit selects whether or not to double the base clock frequency output from the baud rate generator.

The BGDM bit is valid when the on-chip baud rate generator is selected as the clock source (SCR.CKE[1] = 0) in asynchronous mode (SMR.CM = 0) or Manchester mode (MMR.MANEN = 1). When external clock is selected (SCR.CKE[1] = 1), set it to 0. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.

Set this bit to 0 in modes other than asynchronous mode or Manchester mode.

RXDESEL bit (Asynchronous Start Bit Edge Detection Select)

The RXDESEL bit selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data reception operation depends on the setting of this bit. Set this bit to 1 when reception must be stopped while a break occurs or when reception must be started without keeping the RXDn pin input at the high level for the period of one data frame or longer after completion of the break.

Set this bit to 0 in modes other than asynchronous mode.

Note 1. Writing to these bits is only possible when the RE and TE bits in SCR/SCR_SMCI are 0 (serial reception and transmission disabled).

The SNFR register sets the digital noise filter clock.

NFCS[2:0] bits (Noise Filter Clock Select)

The NFCS[2:0] bits select the sampling clock for the digital noise filter. To use the noise filter in asynchronous mode, set these bits to 000b. In simple I2C mode, when 32 clocks are selected as one bit period in the basic clock selection bits of the SEMR register, set the NFCS [2: 0] bits in the range from 001b to 100b. When any other value is selected for the basic clock selection bit, set the NFCS bit to 001b.

BGDM位（波特率发生器双速模式选择）

BGDM位选择是否将波特率发生器输出的基本时钟频率加倍。

在异步模式(SMR.CM=0)或曼彻斯特模式(MMR.MANEN=1)选择片内波特率发生器作为时钟源(SCR.CKE[1]=0)时，BGDM位有效。选择外时钟（SCR.CKE[1]=1）时，将其设置为0。基本时钟是由BaudRateGenerator的时钟输出生成的。当BGDM位设置为1时，基本时钟周期减半，比特率加倍。

在异步模式或曼彻斯特模式以外的模式下将此位设置为0。

RXDESEL位（异步起始位边沿检测选择）

RXDESEL位选择异步模式下接收起始位的检测方法。发生中断时，数据接收操作取决于该位的设置。如果在发生中断时必须停止接收，或者在中断完成后，RXDn引脚输入在一个数据帧或更长时间内不保持高电平而必须开始接收时，将该位设置为1。

在异步模式以外的模式下将此位设置为0。

IICM bit (Simple IIC Mode Select)

In combination with the SCMR.SMIF bit, the IICM bit selects the operating mode.

IICDL[4:0] bits (SDAn Delay Output Select)

The IICDL[4:0] bits specify an output delay on the SDAn pin relative to the falling edge of the output on the SCLn pin.

The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generator as the base. The signal obtained by frequency-dividing PCLK by the divisor set in SMR.CKS[1:0] is supplied as the clock signal from the on-chip baud rate generator. Set 00000b to IICDL[4:0] bits unless operation is in simple IIC mode. In simple IIC mode, set the bits to a value in the range from 00001b to 11111b.

IICINTM bit (IIC Interrupt Mode Select)

IICCSC bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SCLn clock signal is to be synchronized when the SCLn pin is driven low because a wait was inserted by another other device.

The SCLn clock signal is not synchronized if the IICCSC bit is 0. The SCLn clock signal is generated according to the rate selected in the BRR register regardless of the level being input on the SCLn pin.

Set the IICCSC bit to 1 except during debugging.

注1.仅在检查总线状态并确认总线空闲后才生成启动条件。
注2.检查总线状态并确认总线繁忙后，生成重新启动或停止条件。
注3.在给定时间，不要将IICSTAREQ、IICRSTAREQ和IICSTPREQ位中的一个以上设置为1。
注4.只写0。当写1时，该值被忽略。
注5.在IICSTIF标志的值为0后执行条件生成。
注6.当该位为1时，请勿向该位写入0。当该位为1时，通过向该位写入0来暂停条件的产生。

SIMR3寄存器用于控制简单I2C模式下的启动、重启和停止条件，并将SSDAn和SSCLn引脚保持在固定电平。

●向该位写入1。

[Clearing condition]

●停止条件生成完成时。

IICSTIF flag (Issuing of Start, Restart, or Stop Condition Completed Flag)

After generating a condition, the IICSTIF flag indicates that the condition generation is complete. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.

When the IICSTIF flag is 1 while an interrupt request is enabled by setting the SCR.TEIE bit, an STI request is output.

[Setting condition]

- On completion of a start, restart, or stop condition generation.

  If the setting condition conflicts with any of the clearing conditions for the flag, the clearing condition takes precedence.

[Clearing conditions]

- On writing 0 to the bit. After writing 0 to the IICSTIF bit, read the bit to check that it is actually set to 0.
- On writing 0 to the SIMR1.IICM bit when operation is not in simple IIC mode.
- On writing 0 to the SCR.TE bit.

IICSDAS[1:0] bits (SDAn Output Select)

The IICSDAS[1:0] bits control output from the SDAn pin. Set IICSDAS[1:0] and IICSCLS[1:0]to the same value during normal operations.

IICSCLS[1:0] bits (SCLn Output Select)

The IICSCLS[1:0] bits control output from the SCLn pin. Set IICSDAS[1:0] and IICSCLS[1:0] to the same value during normal operations.

SISR monitors the state in simple IIC mode.

IICACKR flag (ACK Reception Data Flag)

Received ACK and NACK bits can be read from the IICACKR flag. The IICACKR flag is updated on the rising edge of the SCLn clock for the received ACK/NACK bit.

IICSTIF标志（发出启动、重启或停止条件完成标志）

生成条件后，IICSTIF标志指示条件生成完成。使用时
IICSTAREQ、IICRSTAREQ或IICSTPREQ位会导致条件生成，请在将IICSTIF标志设置为0后执行此操作。

当IICSTIF标志为1且通过设置SCR.TEIE位使能中断请求时，输出STI请求。

[Setting condition]

●完成启动、重新启动或停止条件生成时。

如果设置条件与标志的任何清除条件冲突，则清除条件优先。

[Clearing conditions]

●向该位写入0。将0写入IICSTIF位后，读取该位以检查它是否实际设置为0。
●在非简单IIC模式下向SIMR1.IICM位写入0。
●将0写入SCR.TE位。

IICSDAS[1:0]位（SDAn输出选择）

IICSDAS[1:0]位控制SDAn引脚的输出。在正常操作期间将IICSDAS[1:0]和IICSCLS[1:0]设置为相同的值。

IICSCLS[1:0]位（SCLn输出选择）

IICSCLS[1:0]位控制SCLn引脚的输出。在正常操作期间将IICSDAS[1:0]和IICSCLS[1:0]设置为相同的值。

7	CKPH	Clock Phase Select 0: Do not delay clock 1: Delay clock	R/W*1

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).
Note 2. Only 0 can be written to this bit, to clear the flag.

SPMR selects the extension settings in asynchronous and clock synchronous modes.

SSE bit (SSn Pin Function Enable)

Set the SSE bit to 1 to use the SSn pin to control transmission and reception in simple SPI mode. Set this bit to 0 in all other modes. In simple SPI mode, when master mode is selected (SCR.CKE[1:0] = 00b and SPMR.MSS = 0) and there is a single master, the SSn pin on the master side is not required to control reception and transmission. In such a case, set the SSE bit to 0. Do not set both the SSE and CTSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

CTSE bit (CTS Enable)

Set the CTSE bit to 1 if the SSn pin is to be used for inputting the CTS control signal to control transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, and simple IIC mode. Do not set both the CTSE and SSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

MSS bit (Master Slave Select)

The MSS bit selects master or slave operation in simple SPI mode. The functions of the TXDn and RXDn pins are reversed when this bit is set to 1, so that data is received through the TXDn pin and transmitted through the RXDn pin.

注1.只有当SCR寄存器中的RE和TE位为0（串行发送和接收都被禁止）时，才能写入这些位。

注2.该位只能写入0，以清除标志。

SPMR在异步和时钟同步模式下选择扩展设置。

SSE位（SSn引脚功能使能）

将SSE位设置为1以使用SSn引脚控制简单SPI模式下的发送和接收。在所有其他模式下将此位设置为0。在简单的SPI模式下，选择主模式（SCR.CKE[1：0]=00B和SPMR.MSS=0），并且有一个主人，主侧不需要SSNPIN来控制接收和传输.在这种情况下，请将SSE位设置为0。不要将SSE和CTSE位都设置为1。如果进行此设置，则操作与将这些位设置为0时的操作相同。

CTSE bit (CTS Enable)

如果SSn引脚用于输入CTS控制信号以控制发送和接收，请将CTSE位设置为1。该位设置为0时输出RTS信号。在智能卡接口模式、简单SPI模式和简单模式下设置该位为0
IIC模式。不要将CTSE和SSE位都设置为1。如果进行此设置，则操作与将这些位设置为0时的操作相同。

MSS位（主从选择）

MSS位选择简单SPI模式下的主机或从机操作。当该位设置为1时，TXDn和RXDn引脚的功能相反，因此数据通过TXDn引脚接收并通过RXDn引脚发送。

RA生态工作室

Set this bit to 0 in modes other than simple SPI mode.

CSTPEN bit (CTS external pin Enable)

Select the terminals usage method when using the CTS and RTS functions.

MFF flag (Mode Fault Flag)

[Clearing condition]

- On writing 0 to the bit after it is read as 1.

CKPOL bit (Clock Polarity Select)

The CKPOL bit selects the polarity of the clock signal output through the SCKn pin. See Figure 30.99 for details. Set the CKPOL bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

CKPH bit (Clock Phase Select)

The CKPH bit selects the phase of the clock signal output through the SCKn pin. See Figure 30.99 for details. Set the CKPH bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

FM bit (FIFO Mode Select)

When the FM bit is set to 1, FTDRHL and FRDRHL are selected for communication. When the FM bit is set to 0, TDR and RDR, or TDRHL and RDRHL are selected for communication.

RFRST bit (Receive FIFO Data Register Reset)

When the RFRST bit is set to 1, the FRDRHL register is reset and the received data count resets to 0. When 1 is written to the RFRST bit, it clears to 0 after 1 PCLK.

TFRST bit (Transmit FIFO Data Register Reset)

When the TFRST bit is set to 1, the FTDRHL register is reset and the transmit data count resets to 0. When 1 is written to the TFRST bit, it clears to 0 after 1 PCLK.

DRES bit (Receive Data Ready Error Select)

When detecting a receive data ready error, the selection can be made from an SCIn_RXI interrupt request or an SCIn_ERI interrupt request. When starting DTC or DMAC and reading from the FRDRH and FRDRL registers, set the DRES bit to 1.

TTRG[3:0] bits (Transmit FIFO Data Trigger Number)

The TDFE flag is set to 1 when the amount of transmit data in FTDRHL is equal to or less than the transmit triggering number specified in the TTRG[3:0] bits, and software can write data to FTDRHL. If SCR.TIE = 1, an SCIn_TXI interrupt request occurs.

The RDF flag is set to 1 when the amount of receive data in FRDRHL is equal to or greater than the receive triggering number specified in the RTRG[3:0] bits, and software can read data from FRDRHL. If SCR.RIE = 1, an SCIn_RXI interrupt request occurs.

When RTRG[3:0] is 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0, and an SCIn_RXI interrupt does not occur.

RSTRG[3:0] bits (RTS Output Active Trigger Number Select)

When the amount of receive data stored in FRDRHL is equal to or greater than the receive triggering number specified in the RSTRG[3:0] bits, the RTS signal goes high.

When RSTRG[3:0] is 0, the RTS signal does not go high even when the amount of data in FRDRHL is equal to 0.

30.2.30 FDR : FIFO Data Count Register

当RFRST位设置为1时，FRDRHL寄存器复位，接收数据计数复位为0。当向RFRST位写入1时，它在1个PCLK后清除为0。

TFRST位（发送FIFO数据寄存器复位）

当TFRST位设置为1时，FTDRHL寄存器复位并且发送数据计数复位为0。当1写入TFRST位时，它在1个PCLK后清除为0。

DRES位（接收数据就绪错误选择）

当检测到接收数据就绪错误时，可以从SCIn_RXI中断请求或SCIn_ERI中断请求中进行选择。启动DTC或DMAC并读取FRDRH和FRDRL寄存器时，将DRES位设置为1。

TTRG[3:0]位（发送FIFO数据触发编号）

当FTDRHL中的发送数据量等于或小于TTRG[3:0]位中指定的发送触发数时，TDFE标志设置为1，并且软件可以将数据写入FTDRHL。如果SCR.TIE=1，则发生SCIn_TXI中断请求。

RTRG[3:0]位（接收FIFO数据触发编号）

当FRDRHL中的接收数据量等于或大于RTRG[3:0]位中指定的接收触发数时，RDF标志设置为1，并且软件可以从FRDRHL中读取数据。如果SCR.RIE=1，则发生SCIn_RXI中断请求。

当RTRG[3:0]为0时，即使接收FIFO中的数据量等于0，RDF标志也不置位，并且SCIn_RXI中断不发生。

RSTRG[3:0]位（RTS输出有效触发数选择）

当FRDRHL中存储的接收数据量等于或大于RSTRG[3:0]位中指定的接收触发数时，RTS信号变为高电平。

当RSTRG[3:0]为0时，即使FRDRHL中的数据量等于0，RTS信号也不会变高。

Note 1. Only 0 can be written, to clear the flag after reading 1.

The DCCR register controls the address match function.

DCMF flag (Data Compare Match Flag)

The DCMF flag indicates that the SCI detected a receive data match with the comparison data (CDR.CMPD).

[Setting condition]

- On match of the comparison data (CDR.CMPD) with the receive data when DCCR.DCME = 1.

[Clearing condition]

- When 0 is written after 1 is read from DCMF.

Clearing the SCR.RE bit to 0 does not affect the DCMF flag, which retains its previous value.

DPER flag (Data Compare Match Parity Error Flag)

The DPER flag indicates that a parity error occurred on address match detection (receive data match detection).

[Setting condition]

- When a parity error is detected in a frame in which an address match is detected.

[Clearing conditions]

- When 0 is written after 1 is read from DPER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DPER flag is not affected and retains its previous value.

DFER flag (Data Compare Match Framing Error Flag)

The DFER flag indicates that a framing error occurred on address match detection (receive data match detection).

[Setting conditions]

- When a stop bit of a frame in which an address match is detected is 0.

  When in 2-stop-bit mode, only the first bit of the stop bits is checked for a value of 1 (the second stop bit is not checked).

[Clearing conditions]

- When 0 is written after 1 is read from DFER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DFER flag is not affected and retains its previous value.

IDSEL bit (ID Frame Select)

The IDSEL bit selects whether to compare data regardless of the MPB bit value or to compare data only when MPB = 1 (ID frame), when the address match function is enabled.

DCME bit (Data Compare Match Enable)

The DCME bit enables or disables the address match function (data compare match function).

If the SCI detects a match to the comparison data (CDR.CMPD) with the receive data, the DCME bit clears automatically, after which SCI operation mode is in normal receive mode. See section 30.3.6. Address Match (Receive Data Match Detection) Function.

Bit	Symbol	Function	R/W
6	IDSEL	ID帧选择 仅在异步模式下有效，包括多处理器模式。 0：无论MPB位值如何，始终比较数据1：仅当MPB位=1时比较数据（ID帧）	R/W
7	DCME	数据比较匹配启用 仅在异步模式下有效，包括多处理器模式。 0：禁用地址匹配功能1：启用地址匹配功能	R/W

注1.只能写入0，读取1后清除标志。

DCCR寄存器控制地址匹配功能。

DCMF标志（数据比较匹配标志）

DCMF标志表示SCI检测到接收数据与比较数据(CDR.CMPD)匹配。

[Setting condition]

●当DCCR.DCME=1时，比较数据(CDR.CMPD)与接收数据匹配。

[Clearing condition]

●从DCMF读取1后写入0时。

将SCR.RE位清除为0不会影响DCMF标志，它保留其先前的值。

DPER标志（数据比较匹配奇偶校验错误标志）

DPER标志表示在地址匹配检测（接收数据匹配检测）时发生奇偶校验错误。

[Setting condition]

●在检测到地址匹配的帧中检测到奇偶校验错误时。

[Clearing conditions]

●从DPER读取1后写入0时。

当SCR.RE位设置为0（禁用串行接收）时，DPER标志不受影响并保留其先前的值。

DFER标志（数据比较匹配帧错误标志）

DFER标志表示在地址匹配检测（接收数据匹配检测）时发生了帧错误。

[Setting conditions]

●当检测到地址匹配的帧的停止位为0时。

在2停止位模式下，仅检查停止位的第一位是否为1（不检查第二个停止位）。

[Clearing conditions]

●从DFER读取1后写入0时。

当SCR.RE位设置为0（禁用串行接收）时，DFER标志不受影响并保留其先前的值。

IDSEL位（ID帧选择）

IDSEL位选择无论MPB位值如何比较数据，还是仅在MPB=1（ID帧）时比较数据，当地址匹配功能启用时。

DCME位（数据比较匹配使能）

DCME位启用或禁用地址匹配功能（数据比较匹配功能）。

如果SCI检测到比较数据（CDR.CMPD）与接收数据匹配，则DCME位自动清零，此后SCI操作模式进入正常接收模式。请参见第30.3.6节。地址匹配（接收数据匹配检测）功能。

The write value must be 0 for all modes other than asynchronous mode.

Note: 该寄存器仅在启用曼彻斯特模式（MMR.MANEN=1）时有效。

该寄存器用于指定在曼彻斯特模式下是否处理序言错误、接收同步错误或起始位错误作为中断源。如果将这些错误作为中断源处理，则在每个错误发生时都会产生中断请求和事件请求，并且在相应的错误标志被清除之前不会执行下一次接收。

请在MMR.MANEN=“0”时设置该寄存器。并且不要在通信过程中更改该寄存器。

PFEREN位（前言错误使能）

该位指定是否将序言错误作为中断源处理。

当它设置为0时，前言错误不作为中断源处理。当它设置为1时，前言错误作为中断源处理。

SYEREN位（接收同步错误使能）

该位指定是否将接收同步错误作为中断源处理。

当它设置为0时，接收SYNC错误不作为中断源处理。当它设置为1时，接收SYNC错误作为中断源处理。

SBEREN位（启动位错误启用）

该位指定是否将起始位错误作为中断源处理。

当它设置为0时，起始位错误不作为中断源处理。当它设置为1时，起始位错误作为中断源处理。

TWRC bit (Counter Write Control)

This bit determines whether a value written to TPRE or TCNT is written to the reload register only or is written to both the reload register and the counter.

30.2.59 TPRE : Timer Prescaler Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x32

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

TPRE consists of an 8-bit reload register, a read buffer, and a counter, each of which has FFh as its initial value. The counter counts down in synchronization with the counter clock selected by the TMR.TCSS[2:0] bits, and is reloaded with the value in the reload register when it underflows. Underflows of this register provide the clock source to drive counting by the TCNT register. The reload register and read buffer are allocated to the same address. Data is written to the reload register in writing, and the counter value that has been transferred to the read buffer is returned in reading.

It takes one PCLK cycle to load a value from the reload register to the counter.

30.2.60 TCNT : Timer Count Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x33

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

TCNT consists of an 8-bit reload register, a read buffer, and a counter, each of which has FFh as its initial value. This down-counter counts underflows of the TPRE register until the TCNT register underflows, and is then reloaded with the value from the reload register. The reload register and read buffer are allocated to the same address. Data is written to the reload register in writing, and the counter value that has been transferred to the read buffer is returned in reading.

It takes one PCLK cycle to load a value from the reload register to the counter.

30.3 Operation in Asynchronous Mode

Figure 30.6 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit or receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communications line is usually held in the mark state (high level).

注1.仅当定时器停止(TCST=0)时才重写TOMS[1:0]和TCSS[2:0]位。

TWRC位（计数器写控制）

该位确定写入TPRE或TCNT的值是仅写入重载寄存器还是同时写入重载寄存器和计数器。

30.2.59 TPRE：定时器预分频寄存器

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x32

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
重置后的值：	1	1	1	1	1	1	1	1

TPRE由一个8位重载寄存器、一个读缓冲区和一个计数器组成，每个计数器的初始值都为FFh。计数器与TMR.TCSS[2:0]位选择的计数器时钟同步递减计数，并在下溢时重新加载重载寄存器中的值。该寄存器的下溢提供时钟源来驱动TCNT寄存器的计数。重载寄存器和读缓冲区被分配到同一个地址。写入时数据被写入重载寄存器，读取时返回已传送到读缓冲区的计数器值。

将一个值从重载寄存器加载到计数器需要一个PCLK周期。

30.2.60 TCNT：定时器计数寄存器

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x33

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
重置后的值：	1	1	1	1	1	1	1	1

TCNT由一个8位重载寄存器、一个读缓冲区和一个计数器组成，每个计数器的初始值都为FFh。该递减计数器对TPRE寄存器的下溢进行计数，直到TCNT寄存器下溢，然后用重新加载寄存器中的值重新加载。重载寄存器和读缓冲区被分配到同一个地址。写入时数据被写入重载寄存器，读取时返回已传送到读缓冲区的计数器值。

将一个值从重载寄存器加载到计数器需要一个PCLK周期。

30.3 异步模式下的操作

图30.6显示了异步串行通信的一般格式。一帧由起始位（低电平）、发送或接收数据、奇偶校验位和停止位（高电平）组成。在异步串行通信中，通信线路通常保持在标记状态（高电平）。

The SCI monitors the communications line. When the SCI detects a low, it regards that as a start bit and starts serial communication.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and receiver have a double-buffered structure in addition to FIFO mode, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

SCI监控通信线路。当SCI检测到低电平时，将其视为起始位并开始串行通信。

在SCI内部，发射器和接收器是独立的单元，可实现全双工通信。发送器和接收器除了FIFO模式外，都具有双缓冲结构，从而可以在发送或接收过程中读取或写入数据，从而实现数据的连续发送和接收。

30.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate.

In reception, the SCI samples the falling edge of the start bit using the base clock, and performs internal synchronization.*2

Because receive data is sampled on the rising edge of the 8th pulse*1 of the base clock, data is latched at the middle of each bit (when sampling timing does not adjust (SPTR.ASEN = 0)), as shown in Figure 30.7 The reception margin in asynchronous mode is determined by the following formula (1):

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%] \quad \ldots \quad \text{Formula (1)}$$

Note: M: Reception margin
N: Ratio of bit rate to clock
(N = 16 when SEMR.ABCSE = 0 and SEMR.ABCS = 0,
N = 8 when SEMR.ABCS = 1,
N = 6 when SEMR.ABCSE = 1)
D: Duty cycle of clock (D = 0.5 to 1.0)
L: Frame length (L = 9 to 13)
F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined using the following formula:
$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\ \%$

This represents the computed value. Renesas recommends a margin of 20% to 30% in system design.

30.3.2 异步模式下接收数据采样时序和接收余量

在异步模式下，SCI在频率为16倍*1比特率的基本时钟上运行。

在接收时，SCI使用基本时钟对起始位的下降沿进行采样，并执行内部同步。*2

由于接收数据在基本时钟的第8个脉冲*1的上升沿进行采样，因此数据在每个位的中间锁存（当采样时序不调整时(SPTR.ASEN=0)），如图30.7所示异步模式下的接收余量由以下公式（1）确定：

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%] \quad \ldots \quad \text{Formula (1)}$$

Note: M：接收余量
N：比特率与时钟的比率
（当SEMR.ABCSE=0和SEMR.ABCS=0时，N=16，
N = 8 when SEMR.ABCS = 1,
N = 6 when SEMR.ABCSE = 1)
D:时钟占空比(D=0.5to1.0)
L：帧长（L=9到13）
F：时钟频率偏差的绝对值

假设公式（1）中的F=0和D=0.5的值，接收裕量使用以下公式确定：
$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\ \%$

这表示计算值。瑞萨建议在系统设计中留出20%到30%的余量。

Note 1. In this example, the SEMR.ABCS bit is 0 and the SEMR.ABCSE is 0. When the ABCS bit is 1 and the ABCSE bit is 0, a frequency of 8 times the bit rate is used as a base clock, and receive data is sampled on the rising edge of the 4th pulse of the base clock.

When the ABCSE bit is 1, a sextuple frequency of a bit rate is used as a base clock, and receive data is sampled on the rising edge of the 3rd pulse of the base clock.

Note 2. The determination condition of the start bit is as follows.

The function of adjust sampling timing is OFF (ASEN = 0):

The determination condition of a start bit is that Low beyond half bit length continues. It is same as the sampling timing. In Figure 30.7, Low period should be kept over 8-cycles to detect a start bit. If Low period does not keep over 8-cycles, the IP judges this as a noise. So, the IP does not start reception and wait start bit.

The function of adjust samplint timing is ON (ASEN = 1):

The determination condition of a start bit is that Low keeps up until the sampling timing. Adjusting the sampling timing forward (AJD = 1) increases the possibility of erroneously determin-ing a noise as the start bit.

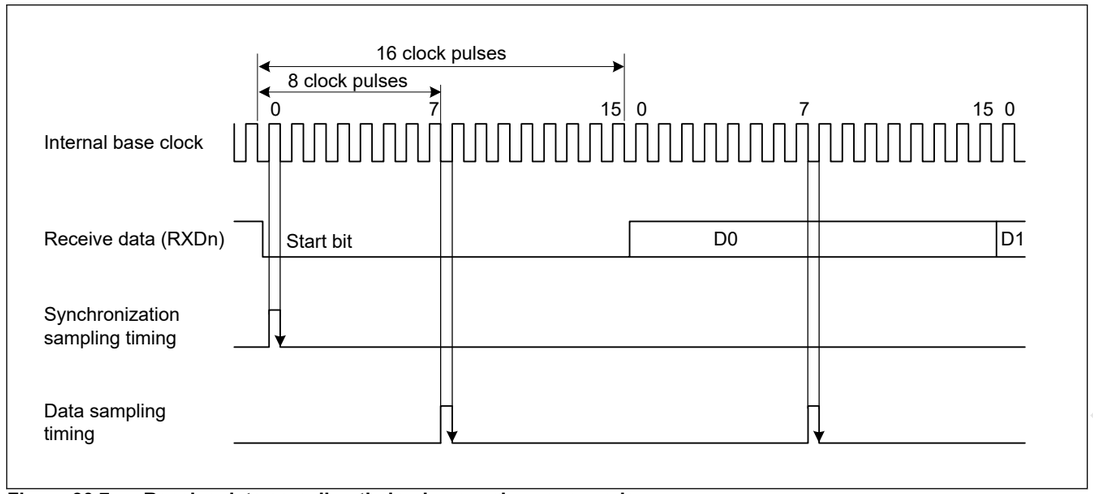

Figure 30.7 Receive data sampling timing in asynchronous mode

30.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the transfer clock of the SCI, based on the SMR.CM and SCR.CKE[1:0] settings.

When an external clock is input to the SCKn pin, the clock frequency must be 16 times the bit rate (when SEMR.ABCS = 0) or 8 times the bit rate (when SEMR.ABCS = 1).

When the SCI uses its internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is configured so that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 30.8.

When clock output is enabled, the clock is output after setting the SCR.TE or SCR.RE bit to 1.

注1.本例中，SEMR.ABCS位为0，SEMR.ABCSE位为0。当ABCS位为1，ABCSE位为0时，使用8倍比特率的频率作为基准时钟，并在基本时钟的第4个脉冲的上升沿对接收数据进行采样。

当ABCSE位为1时，以比特率的六倍频为基准时钟，在基准时钟的第3个脉冲的上升沿对接收数据进行采样。

注2.起始位的判断条件如下。

调整采样定时功能关闭（ASEN=0）：

起始位的确定条件是超过半位长度的Low继续。与采样时间相同。在图30.7中，低电平周期应保持超过8个周期以检测起始位。如果Low周期未保持超过8个周期，则IP将其判断为噪声。因此，IP不开始接收并等待开始位。

调整采样定时功能开启（ASEN=1）：

起始位的确定条件是Low一直保持到采样定时。向前调整采样时序(AJD=1)会增加错误地将噪声确定为起始位的可能性。

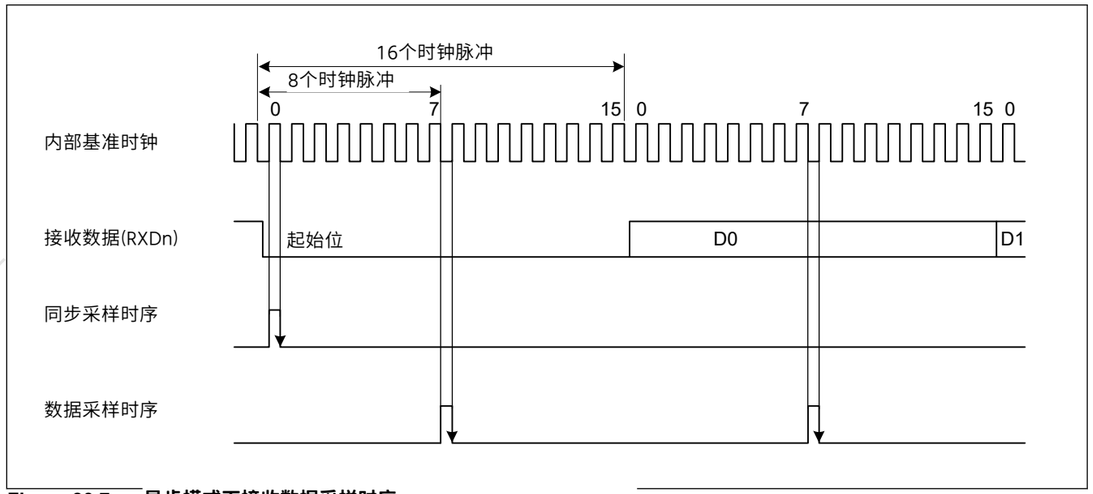

Figure 30.7 异步模式下接收数据采样时序

30.3.3 Clock

根据SMR.CM和SCR.CKE[1:0]设置，可以选择片内波特率发生器产生的内部时钟或输入到SCKn引脚的外部时钟作为SCI的传输时钟。

当外部时钟输入到SCKn引脚时，时钟频率必须为比特率的16倍（SEMR.ABCS=0时）或比特率的8倍（SEMR.ABCS=1时）。

当SCI使用其内部时钟时，时钟可以从SCKn引脚输出。在这种情况下，时钟输出的频率等于比特率，并配置相位，使时钟的上升沿在传输数据的中间，如图30.8所示。

时钟输出使能时，将SCR.TE或SCR.RE位设置为1后输出时钟。

30.3.4 Double-Speed Operation and Frequency of 6 Times the Bit Rate

When the SEMR.ABCS bit is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0. When the SEMR.BGDM bit is set to 1, the cycle of the base clock is half and the bit rate is double that of when BGDM is set to 0. When the SCR.CKE[1] bit is set to 0 and the on-chip baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the SCI to operate at a bit rate four times that when the ABCS and BGDM bits are set to 0.

When the SEMR.ABCSE bit is set to 1, the number of base clock pulses is 6 during a period of 1 bit, and the SCI operates at a bit rate 16/3 times that when SEMR.ABCS = 0, SEMR.BGDM = 0, and SEMR.ABCSE = 0.

As shown by Formula (1) in section 30.3.2. Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, the reception margin decreases when the SEMR.ABCS or SEMR.ABCSE bit is set to 1. Therefore, if the target bit rate can be obtained with ABCS or ABCSE set to 0, it is recommended that you use the SCI with ABCS and ABCSE set to 0.

30.3.5 CTS and RTS Functions

The CTS function uses input on the CTSn_RTSn pin in transmission control. Setting the SPMR.CTSE bit to 1 enables the CTS function. For the functions of CTS and RTS, you can select the alternate setting that uses either function with one terminal and the dedicated setting that uses each function independently with two terminals. This setting is done with the SPMR.CTSPEN bit.

When the CTS function is enabled, placing a low level on the CTSn_RTSn pin causes transmission to start.

Driving the CTSn_RTSn pin high while transmission is in progress does not affect transmission of the current frame.

In the RTS function, which uses output on the CTSn_RTSn pin, a low level is output when reception becomes possible. Conditions for output of the low and high levels are shown in this section.

[Conditions for low level output]

Satisfaction of all conditions are listed in this section.

Non-FIFO selected

- The value of the SCR.RE bit is 1
- Reception is not in progress
- There is no received data yet to be read
- The ORER, FER, and PER flags in the SSR register are all 0

FIFO selected

- The value of the SCR.RE bit is 1
- The amount of receive data written in FRDRHL is equal to or less than the setting value of FCRH.RSTRG[3:0]
- The ORER flag in the SSR_FIFO register (ORER in FRDRH) is 0

[Condition for high level output]

- The conditions for low-level output are not satisfied

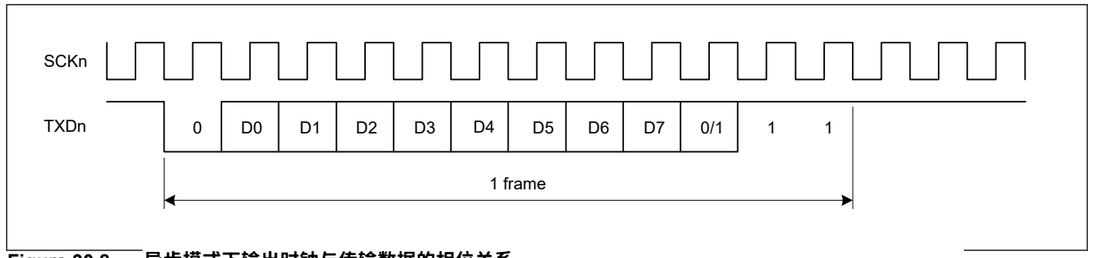

Figure 30.8 异步模式下输出时钟与传输数据的相位关系 SMR.CHR=0，PE=1，MP=0，STOP=1

30.3.4 双倍速操作和6倍比特率的频率

当SEMR.ABCS位设置为1并选择1位周期的8个基本时钟脉冲时，SCI以ABCS设置为0时的两倍比特率运行。当SEMR.BGDM位为设置为1，基本时钟的周期是BGDM设置为0时的一半，比特率是两倍。当SCR.CKE[1]位设置为0并且选择片内波特率发生器时，将ABCS和BGDM位设置为1允许SCI以四倍于ABCS和BGDM位设置为0时的比特率运行。

当SEMR.ABCSE位设置为1时，1位周期内的基本时钟脉冲数为6，SCI以16的比特率运行，是SEMR.ABCS=0时SEMR.BGDM=0时的3倍 和SEMR.ABCSE=0。

如30.3.2节中的公式（1）所示。异步模式下接收数据采样时序和接收裕度，当SEMR.ABCS或SEMR.ABCSE位设置为1时接收裕度减小。因此，如果将ABCS或ABCSE设置为0即可获得目标码率，则为建议您使用SCI，ABCS和ABCSE设置为0。

30.3.5 CTS和RTS函数

CTS功能在传输控制中使用CTSn_RTSn引脚上的输入。将SPMR.CTSE位设置为1可启用CTS功能。对于CTS和RTS的功能，您可以选择在一个端子上使用任一功能的交替设置和在两个端子上独立使用每个功能的专用设置。该设置通过SPMR.CTSPEN位完成。

当CTS功能使能时，将CTSn_RTSn引脚置于低电平会导致传输开始。

在传输过程中将CTSn_RTSn引脚驱动为高电平不会影响当前帧的传输。

在使用CTSn_RTSn引脚输出的RTS功能中，当可以接收时输出低电平。
本节显示了低电平和高电平的输出条件。

本节列出了所有条件的满足情况。

30.3.6 Address Match (Receive Data Match Detection) Function

The address match function can be used only in asynchronous mode.

If the DCCR.DCME bit is set to 1, when one frame of data is received, the SCI compares that received data with the data set in CDR.CMPD. If the SCI detects a match to the comparison data (CDR.CMPD*1) with the received data, the SCI can issue the SCIn_RXI interrupt request.

If the SMR.MP bit is set to 0, comparison occurs only for valid data in receive format. In multi-processor mode (SMR.MP bit = 1), if the DCCR.IDSEL bit is set to 1, receive data where the MPB bit is 1 is subject to comparison for address match and receive data where the MPB bit is 0 is always treated as a non-match.

If the DCCR.IDSEL bit is set to 0, SCI performs address match detection regardless of the MPB bit value of the received data.

Until SCI detects a match to the comparison data (CDR.CMPD*1) with receive data, received data is skipped (discarded), and the SCI cannot detect a parity error or framing error.

When SCI detects a match, the DCCR.DCME bit is automatically cleared, and the DCCR.DCMF flag is set to 1. If the DCCR.IDSEL bit is set to 1, the SCR.MPIE bit is automatically cleared. If DCCR.IDSEL is set to 0, the value of the SCR.MPIE bit is retained. If the SCR.RIE bit is set to 1, the SCI issues an SCIn_RXI interrupt request.

If the SCI detects a framing error in the receive data for which a match is detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag is set to 1. The compared receive data is not stored in the RDR register, and SSR.RDRF remains 0. When FCR.FM = 1, the RDR register indicates the FRDRHL register, and the SSR.RDRF flag indicates the SSR_FIFO.RDF flag.

After the SCI detects a match, and DCCR.DCME is automatically cleared, the SCI receives the next data continuously based on the current register setting.

When the DCCR.DFER or DCCR.DPER flag is set, the address match is not performed. Before enabling the address match function, set the DCCR.DFER and DCCR.DPER flags to 0.

Examples of the address match function are shown in Figure 30.9 and Figure 30.10.

Note 1. This comparative target can select one length of 3 types: CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.

30.3.6 地址匹配（接收数据匹配检测）功能

地址匹配功能只能在异步模式下使用。

如果DCCR.DCME位设置为1，当接收到一帧数据时，SCI会将接收到的数据与CDR.CMPD中设置的数据进行比较。如果SCI检测到比较数据(CDR.CMPD*1)与接收到的数据匹配，则SCI可以发出SCIn_RXI中断请求。

如果SMR.MP位设置为0，则仅对接收格式的有效数据进行比较。在多处理器模式下（SMR.MP位=1），如果DCCR.IDSEL位设置为1，则接收MPB位为1的数据进行地址匹配比较，接收MPB位为0的数据始终被视为不匹配。

如果DCCR.IDSEL位设置为0，SCI执行地址匹配检测，而不管接收数据的MPB位值如何。

在SCI检测到与接收数据的比较数据(CDR.CMPD*1)匹配之前，会跳过（丢弃）接收到的数据，并且SCI无法检测奇偶校验错误或帧错误。

当SCI检测到匹配时，自动清除DCCR.DCME位，并将DCCR.DCMF标志设置为1。如果DCCR.IDSEL位设置为1，SCR.MPIE位自动清零。如果DCCR.IDSEL设置为0，则SCR.MPIE位被保留。如果SCR.RIE位设置为1，则SCI发出SCIn_RXI中断请求。

如果SCI在检测到匹配的接收数据中检测到帧错误，则DCCR.DFER标志设置为1，如果SCI在该帧中检测到奇偶校验错误，则DCCR.DPER标志设置为1。比较后的接收数据不存入RDR寄存器，SSR.RDRF保持为0。当FCR.FM=1时，RDR寄存器指示FRDRHL寄存器，而

SSR.RDRF标志表示SSR_FIFO.RDF标志。

SCI检测到匹配后，DCCR.DCME自动清零，SCI根据当前寄存器设置连续接收下一个数据。

当设置DCCR.DFER或DCCR.DPER标志时，不执行地址匹配。在启用地址匹配功能之前，将DCCR.DFER和DCCR.DPER标志设置为0。

地址匹配函数的例子如图30.9和图30.10所示。

注1.此比较目标可以选择3种长度中的一种：7位长度的CMPD[6:0]、8位长度的CMPD[7:0]和9位长度的CMPD[8:0].

30.3.7 SCI Initialization in Asynchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the SCR register, then continue through the SCI initialization procedure (select non-FIFO or FIFO) shown in Table 30.28 and Table 30.29. Whenever the operating mode or transfer format is to be changed, the SCR register must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied during initialization.

30.3.7 异步模式下的SCI初始化

在发送和接收数据之前，首先将初始值0x00写入SCR寄存器，然后继续执行SCI初始化程序（选择非FIFO或FIFO）如表30.28和表30.29所示。每当要更改操作模式或传输格式时，必须在更改之前初始化SCR寄存器。

在异步模式下使用外部时钟时，请确保在初始化期间提供时钟信号。

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, RDRF, RDF, PER, and DR flags in SSR/SSR_FIFO nor RDR and RDRHL. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: In non-FIFO mode, switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of an SCIn_TXI interrupt request.

30.3.8 Serial Data Transmission in Asynchronous Mode

(1) Non-FIFO selected

Figure 30.11, Figure 30.12, and Figure 30.13 show examples of serial transmission in asynchronous mode.

In serial transmission, the SCI operates as described in this section. When the SCR.TE bit is set to 1, the high level is output to TXDn for one frame. However, when SEMR.PADIS is set to "1", this preamble will not be output. An example of operation when preamble is not output is shown in Figure 30.14.

1. The SCI transfers data from the TDR[*1] register to the TSR register when data is written to TDR[*1] in the SCIn_TXI interrupt handling routine.
   The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the TDR[*1] register to the TSR register. If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to the TDR[*1] register in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR[*1] register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data
   - Parity bit or multi-processor bit (can be omitted depending on the format)
   - Stop bit
4. The SCI checks for update of the TDR register on output of the stop bit.
5. When the TDR register is updated, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from the TDR[*1] register to the TSR register and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register is not updated, the SSR.TEND flag is set to 1, the stop bit is sent, and the mark state is entered, in which 1 is output. If the SCR.TEIE bit is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Note 1. The TDRHL register when 9-bit data length is selected.

30.3.8 异步模式下的串行数据传输

(1)选择非FIFO图30.11、图30.12和图30.13显示了异步模式下串行传输的示例。

在串行传输中，SCI的操作如本节所述。当SCR.TE位设置为1时，高电平输出到TXDn一帧。但是，当SEMR.PADIS设置为“1”时，不会输出此前导码。图30.14显示了不输出前导码时的操作示例。

1.当在SCIn_TXI中断处理程序中将数据写入TDR*1时，SCI将数据从TDR*1寄存器传输到TSR寄存器。当一条指令同时将SCR.TE和SCR.TIE位设置为1时，会在传输开始时产生SCIn_TXI中断请求。

2.在SPMR.CTSE位设置为0（禁用CTS功能）或CTSn_RTSn引脚上的低电平导致数据从TDR*1寄存器传输到TSR寄存器后，传输开始。如果SCR.TIE位为1，则产生SCIn_TXI中断请求。通过在当前发送数据的发送完成之前将下一个发送数据写入SCIn_TXI中断处理程序中的TDR*1寄存器，可以进行连续发送。使用SCIn_TEI中断请求时，在写入最后一个要发送的数据后，将SCR.TIE位设置为0（禁止SCIn_TXI中断请求）并将SCR.TEIE位设置为1（启用SCIn_TEI中断请求）从SCIn_TXI请求的处理例程到TDR*1寄存器。

3.数据按以下顺序从TXDn引脚发送：

- ●起始位
- ●传输数据
- ●奇偶校验位或多处理器位（可根据格式省略）
- ●停止位

4.SCI在停止位输出时检查TDR寄存器的更新。

5.当TDR寄存器更新时，将SPMR.CTSE位设置为0（禁用CTS功能）或CTSn_RTSn引脚上的低电平输入会导致下一个发送数据从TDR*1寄存器传输到TSR寄存器，并且传输停止位，然后开始下一帧的串行传输。

6、如果TDR寄存器没有更新，则将SSR.TEND标志置1，发送停止位，进入标记状态，其中输出1。如果SCR.TEIE位为1，则SSR.TEND标志设置为1，并产生SCIn_TEI中断请求。

Figure 30.16 Data format written to FTDRH and FTDRL with FIFO selected

In serial transmission, the SCI operates as described in this section. When the TE bit is set to 1, the high level is output to TXDn for one frame (preamble).

1. The SCI transfers data from the FTDRL*1 register to the TSR register when data is written to FTDRL*1 in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the FTDRL*1 register to the TSR register. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, SSR_FIFO.TDFE is set to 1. If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to FTDRL*1 in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the FTDRL*1*2 register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data
   - Parity bit or multi-processor bit (can be omitted depending on the format)
   - Stop bit
4. On output of the stop bit, the SCI checks whether non-transmitted data remains in the FTDRL*3 register.
5. When data is set to FTDRL*3, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from FTDRL*1 to TSR and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set in FTDRL*3, the TEND flag in SSR_FIFO is set to 1, the stop bit is sent, and the mark state is entered in which 1 is output. If the SCR.TEIE bit is 1, the SSR_FIFO.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Note 1. Write data not to FTDRL but to the FTDRH and FTDRL registers.
Note 2. Write data in order from FTDRH to FTDRL when 9-bit data length is selected.
Note 3. The SCI only checks for update to the FTDRL register and not the FTDRH register when 9-bit data length is selected.

Figure 30.17 shows an example flow of serial transmission in asynchronous mode with FIFO selected.

Figure 30.16 选择FIFO写入FTDRH和FTDRL的数据格式

在串行传输中，SCI的操作如本节所述。当TE位设置为1时，高电平输出到TXDn一帧（前导码）。

1.当数据写入FTDRL*1时，SCI将数据从FTDRL*1寄存器传输到TSR寄存器

SCIn_TXI中断处理程序。可写入FTDRL的数据量为16减去FDR.T[4:0]字节。当一条指令同时将SCR.TE和SCR.TIE位设置为1时，会在传输开始时产生SCIn_TXI中断请求。

2.在SPMR.CTSE位设置为0（禁用CTS功能）或CTSn_RTSn引脚上的低电平导致数据从FTDRL*1寄存器传输到TSR寄存器后，传输开始。当写入FTDRL的发送数据量等于或小于指定的发送触发数时，SSR_FIFO.TDFE设置为1。如果SCR.TIE位为1，则产生SCIn_TXI中断请求。在当前发送数据的发送完成之前，通过在SCIn_TXI中断处理例程中将下一个发送数据写入FTDRL*1，可以进行连续发送。当使用SCIn_TEI中断请求时，将SCR.TIE位设置为0（禁止SCIn_TXI中断请求）并且

将要发送的最后一个数据写入到SCR.TEIE位为1（启用SCIn_TEI中断请求）FTDRL*1*2寄存器来自SCIn_TXI请求的处理例程。

3.数据按以下顺序从TXDn引脚发送：

- ●起始位
- ●传输数据
- ●奇偶校验位或多处理器位（可根据格式省略）
- ●停止位

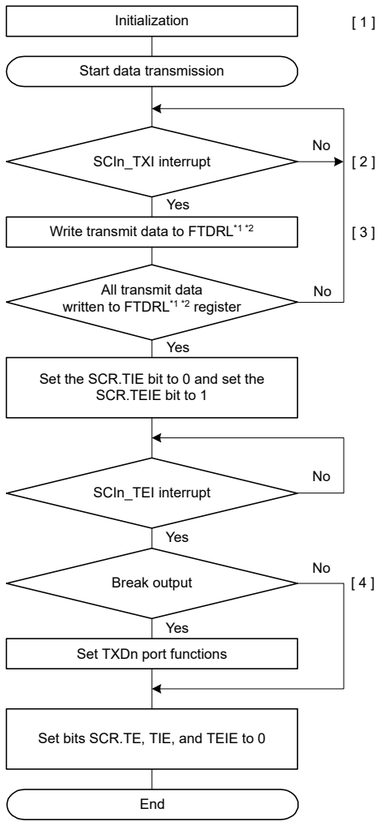
4.在停止位输出时，SCI检查未发送的数据是否保留在FTDRL*3寄存器中。

5.当数据设置为FTDRL*3时，将SPMR.CTSE位设置为0（禁用CTS功能）或CTSn_RTSn引脚上的低电平输入会导致下一个传输数据从FTDRL*1传输到TSR并传输停止位，之后开始下一帧的串行传输。

6.如果FTDRL*3中没有设置数据，则将SSR_FIFO中的TEND标志设置为1，发送停止位，并进入输出1的标记状态。如果SCR.TEIE位为1，则SSR_FIFO.TEND标志设置为1，并产生SCIn_TEI中断请求。

注1.不要将数据写入FTDRL，而是写入FTDRH和FTDRL寄存器。
注2.选择9位数据长度时，按从FTDRH到FTDRL的顺序写入数据。
注意3.SCI仅检查对FTDRL寄存器的更新，而不是选择9位数据长度时的FTDRH寄存器。

图30.17显示了选择FIFO的异步模式下串行传输的示例流程。



[1] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[2] Transmit data write to FTDRL*1 by an SCIn_TXI interrupt request:
When transmit data is transferred from FTDRL to TSR, when the quantity of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL*1 *2 once in the SCIn_TXI interrupt handling routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data to FTDRL using an SCIn_TXI interrupt request and clear the SSR_FIFO.TDFE flag to 0. The number of transmission data it is possible to write in is 16 - (the number of stored transmit FIFO data). Transmit data can also be written to FTDRL by activating the DTC or DMAC. When writing the data to FTDRL by DTC or DMAC, the TDFE flag is cleared automatically, so do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to FTDRL.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXD pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

Note 1. When data length is 9 bits, this refers to FTDRH and FTDRL registers.
Note 2. When data length is 9 bits, write in order from FTDRH to FTDRL.

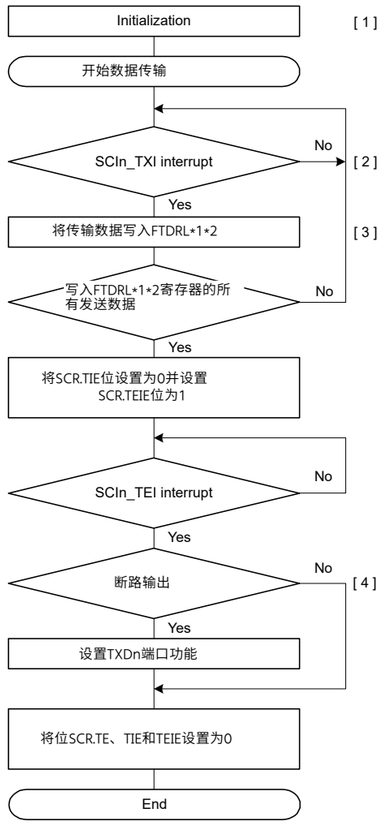
30.3.9 Serial Data Reception in Asynchronous Mode

(1) Non-FIFO selected

Figure 30.18 and Figure 30.19 show an example of the operation for serial data reception in asynchronous mode.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and when it detects a start bit, the SCI performs internal synchronization, stores receive data in RSR.
3. If the multi-processor communication function is enabled (SMR.MP = 1), see section 30.4.2. Multi-Processor Serial Data Reception. If the address match function (data compare match function) is enabled (DCCR.DCME = 1), the SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and comparison data (CDR.CMPD*1).
4. If the SCI detects an address match, the DCCR.DCME bit is automatically cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt*2 request is generated. To enable the generation of an SCIn_RXI interrupt request, set the SCR.RIE bit to 1. The compared receive data are not stored in the RDR register*3. The SSR.RDRF flag remains 0.



[1] SCI initialization:
设置数据传输。
SCR.TE位设置为1后，每帧输出1，并启用传输。

[2] 通过SCIn_TXI中断请求将数据写入FTDRL*1：
当发送数据从FTDRL传输到TSR时，当写入FTDRL的发送数据量等于或小于指定的发送触发数时，将产生发送数据FIFO空中断（SCIn_TXI）请求。在SCIn_TXI中断处理例程中将发送数据写入FTDRL*1*2一次。

[3] 串行传输继续程序：
要继续串行传输，请使用SCIn_TXI中断请求将所有传输数据写入FTDRL，并将SSR_FIFO.TDFE标志清零。可以写入的传输数据数为16（存储的传输FIFO数据数）。也可以通过激活DTC或DMAC将传输数据写入FTDRL。通过DTC或DMAC将数据写入FTDRL时，TDFE标志会自动清除，因此不要写入

TDFE flag.
使用SCIn_TEI中断请求时，将要发送的最后一个数据写入FTDRL后，将SCR.TIE位设置为0，并将SCR.TEIE位设置为1。

[4] 串行传输结束时中断输出：
要在串行传输中输出中断，通过SPTR.SPB2IO和SPTR.SPB2DT位设置TXD引脚的输出状态（低电平输出）后，将SCR.TE位设置为0。

注1.当数据长度为9位时，指的是FTDRH和FTDRL寄存器。
注2.当数据长度为9位时，按照FTDRH到FTDRL的顺序写入。

Figure 30.17 选择FIFO的异步模式下串行传输示例流程

30.3.9 异步模式下的串行数据接收

(1) Non-FIFO selected

图30.18和图30.19显示了异步模式下串行数据接收操作的示例。

在串行数据接收中，SCI操作如下：

1.当SCR.RE位的值变为1时，CTSn_RTSn引脚上的输出信号变为低电平。

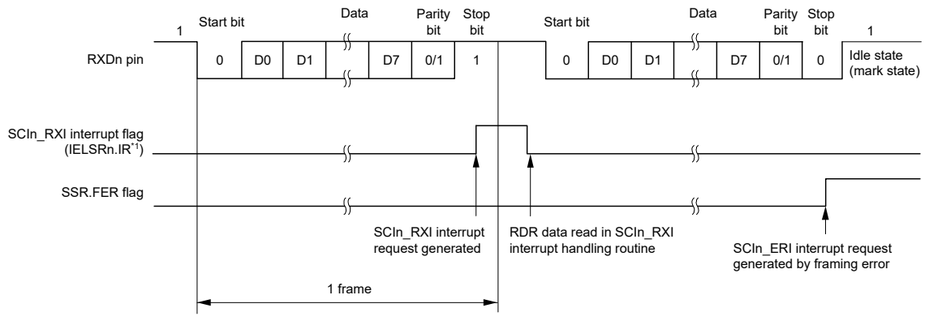
2.SCI监控通信线路，当检测到起始位时，SCI执行内部同步，将接收数据存储在RSR中。

3.如果启用多处理器通信功能（SMR.MP=1），请参见第30.4.2节。多处理器串行数据接收。如果地址匹配功能（数据比较匹配功能）被启用（DCCR.DCME=1），SCI无法检测奇偶校验或帧错误，因为接收数据被跳过（丢弃），直到SCI检测到接收数据和比较之间的匹配数据（CDR.CMPD*1）。

4.如果SCI检测到地址匹配，DCCR.DCME位自动清零，DCCR.DCMF标志变为1，并产生SCIn_AM中断*2请求。要启用SCIn_RXI中断请求的生成，请将SCR.RIE位设置为1。比较的接收数据不存储在RDR寄存器*3中。SSR.RDRF标志保持为0。

5. If the SCI detects a framing error in the receive data for which an address match is detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag becomes 1. To enable the generation of an SCIn_ERI interrupt request, set the SCR.RIE bit to 1.
6. If a framing or a parity error is detected (the DCCR.DFER flag or DCCR.DPER flag is 1) in the SCIn_AM interrupt handling routine, set the DCCR.DFER and DCCR.DPER flags to 0 and set the DCCR.DCME bit to 1 to enable the address match function again. If neither a framing nor a parity error has been detected (the DCCR.DFER and DCCR.DPER flags are both 0), set the DCCR.DCMF flag to 0. See Figure 30.9.
7. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR*3 register.
8. If a parity error is detected, the SSR.PER flag is set to 1 and receive data is transferred to the RDR*3 register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
9. If a framing error is detected, the SSR.FER flag is set to 1 and receive data is transferred to the RDR*3 register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
10. When reception finishes successfully, receive data is transferred to the RDR*3 register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data is complete. Reading the received data that was transferred to the RDR register causes the CTSn_RTSn pin to output low.

Note 1. This scope of comparison is selectable as one of three lengths: CMPD[6:0] is for 7-bit length, CMPD[7:0] is for 8-bit length, and CMPD[8:0] is for 9-bit length.
Note 2. As no interrupt enable bit is assigned to the SCIn_AM interrupt, an interrupt request is generated by setting the DCCR.DCMF to 1.
Note 3. Only read data in the RDRHL register when 9-bit data length is selected.



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.18 Example of SCI operation for serial reception in asynchronous mode (1) when the RTS function is not used, and with 8-bit data, parity bit, and 1 stop bit

5.如果SCI在检测到地址匹配的接收数据中检测到帧错误，则DCCR.DFER标志设置为1，如果SCI在该帧中检测到奇偶校验错误，则DCCR.DPER标志变为1.要启用SCIn_ERI中断请求的生成，请将SCR.RIE位设置为1。

6.如果在SCIn_AM中断处理例程中检测到成帧或奇偶校验错误（DCCR.DFER标志或DCCR.DPER标志为1），则将DCCR.DFER和DCCR.DPER标志设置为0，并设置DCCR.DCME位为1以再次启用地址匹配功能。如果未检测到成帧错误或奇偶校验错误（DCCR.DFER和DCCR.DPER标志均为0），则将DCCR.DCMF标志设置为0。参见图30.9。

7.如果发生溢出错误，则SSR.ORER标志设置为1。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。接收数据不传送到RDR*3寄存器。

8.如果检测到奇偶校验错误，则将SSR.PER标志设置为1，并将接收数据传输到RDR*3寄存器。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。

9.如果检测到帧错误，则将SSR.FER标志设置为1，并将接收数据传输到RDR*3寄存器。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。

10.接收成功后，接收数据被传送到RDR*3寄存器。如果SCR.RIE位为1，则

注1.此比较范围可选择以下三种长度之一：CMPD[6:0]用于7位长度，CMPD[7:0]用于8位长度，CMPD[8:0]用于9位长度。

Table 30.30 lists the states of the flags in the SSR register and receive data handling when a receive error is detected.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER bits to 0 before resuming reception. In addition, be sure to read the RDR or RDRHL register during overrun error processing. When a reception is forced to terminate by setting the SCR.RE bit to 0 during operation, read the RDR or RDRHL register because received data that is not yet read might be left in the RDR or RDRHL.

表30.30列出了SSR寄存器中标志的状态以及检测到接收错误时的接收数据处理。

如果检测到接收错误，则会产生SCIn_ERI中断请求，但不会产生SCIn_RXI中断请求。
当接收错误标志为1时，无法恢复数据接收。因此，在恢复接收之前，请将ORER、FER和PER位设置为0。此外，请务必在溢出错误处理期间读取RDR或RDRHL寄存器。如果在操作期间通过将SCR.RE位设置为0来强制终止接收，请读取RDR或RDRHL寄存器，因为尚未读取的已接收数据可能留在RDR或RDRHL中。

[1] SCI initialization:
Set data reception.

[2][3] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. The error type is identified by reading the ORER, PER, and FER flags in SSR. After performing the appropriate error processing, be sure to set the ORER, PER, and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. For a framing error, a break can be detected by reading the value of the input port associated with the RXDn pin.

[4] Read the receive data in RDR once inthe SCIn_RXI interrupt handling routine.

[5] To continue serial reception, before the stop bit of the current frame is received, read data from RDR in the SCIn_RXI interrupt processing routine. The RDR data can also be read by activating the DMAC or DTC.

Note 1. Do not set RE to 0 before reading RDR.
Note 2. The RDR register becomes the RDRHL register when 9-bit data length is selected.

错误类型通过读取SSR中的ORER、PER和FER标志来识别。执行适当的错误处理后，请务必将ORER、PER和FER标志设置为0。如果这些标志中的任何一个设置为1，则无法恢复接收。对于 帧错误，可以通过读取值来检测中断与RXDn引脚相关的输入端口。

[4]在SCIn_RXI中断处理程序中读取一次RDR中的接收数据。

[5]要继续串行接收，在接收到当前帧的停止位之前，在SCIn_RXI中断处理程序中从RDR中读取数据。RDR数据也可以通过激活DMAC或DTC来读取。

[1] SCI initialization:
Set data reception.

[1-2] Address match cycle:
Set the DCCR.DCME bit to 1 to enable address matching.

[1-3] Comparing receive data and data for comparison (CDR.CMPD):
Compare receive data and data for comparison (CDR.CMPD).
The SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and data for comparison.
If the SCI detects an address match, the DCCR.DCME bit is cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt request is issued.

[1-4] [1-5] Reception error processing:
An error is identified by reading the DFER or DPER flag in DCCR in the SCIn_AM interrupt handling routine.
After appropriate handling of the error, set both the DFER and DPER flags to 0.
If either of these flags is set to 1, address matching cannot be resumed.

[2] [3] Reception error processing and break detection:
When a reception error occurs, the SCIn_ERI interrupt is generated.
The error is identified by reading the ORER, PER, and FER flags in the SSR.
After appropriate handling of the error, set all of the ORER, PER, and FER flags to 0. If any of these flags is set to 1, reception cannot be resumed.
If a framing error occurs, a break can be detected by reading the value of the input port bit corresponding to the RXDn pin.

[4] Read the receive data in the RDR register from within the SCIn_RXI interrupt handling routine.

[5] Procedure for continuing serial reception:
To continue serial reception, read the value of the RDR register in the SCIn_RXI interrupt handling routine before the stop bit is received.
The value of the RDR register can also be read by activating the DMAC or DTC.

Note 1. Be sure to set the RE bit to 0 before reading the RDR register.
Note 2. The RDRHL register is used instead of the RDR register when the 9-bit data length is selected.

[1-2]地址匹配周期：将DCCR.DCME位设置为1以启用地址匹配。

[1-3]比较接收数据和比较数据（CDR.CMPD）：比较接收数据和比较数据（CDR.CMPD）。
SCI无法检测奇偶校验或成帧错误，因为接收数据被跳过（丢弃），直到SCI检测到接收数据和用于比较的数据之间的匹配。如果SCI检测到地址匹配，则DCCR.DCME位被清零，

DCCR.DCMF标志变为1，并发出SCIn_AM中断请求。

SCIn_AM中断处理例程。
正确处理错误后，将DFER和DPER标志都设置为0。如果这些标志中的任何一个设置为1，则无法恢复地址匹配。

[2][3]接收错误处理和中断检测：当发生接收错误时，会产生SCIn_ERI中断。
通过读取SSR中的ORER、PER和FER标志来识别错误。
正确处理错误后，将所有ORER、PER和FER标志设置为0。如果这些标志中的任何一个设置为1，则无法恢复接收。如果发生帧错误，可以通过读取对应于RXDn引脚的输入端口位的值来检测中断。

[4]从SCIn_RXI中断处理程序中读取RDR寄存器中的接收数据。

[5]继续串行接收的过程：要继续串行接收，在接收到停止位之前，在SCIn_RXI中断处理程序中读取RDR寄存器的值。RDR寄存器的值也可以通过激活DMAC或DTC来读取。

注1.务必在读取RDR寄存器之前将RE位设置为0。
注意2。选择9位数据长度时，使用RDRHL寄存器代替RDR寄存器。

Figure 30.25 shows an example of a data format that is written to FRDRH register and FRDRL register in asynchronous mode.

In asynchronous mode, 0 is written to the MPB bit in the FRDRH register. Data that corresponds to the data length is written to FRDRH and FRDRL. Unused bits are written as 0. Read in order from FRDRH to FRDRL. If software reads FRDRL, the

图30.25显示了在异步模式下写入FRDRH寄存器和FRDRL寄存器的数据格式示例。

在异步模式下，将0写入FRDRH寄存器的MPB位。对应于数据长度的数据被写入FRDRH和FRDRL。未使用的位写为0。按从FRDRH到FRDRL的顺序读取。如果软件读取FRDRL，则

SCI updates FER, PER, and receive data (RDAT[8:0]) in the FRDRL register with the next data. The flags RDF, ORER, and DR in the FRDRH register always reflect the associated flags in the SSR_FIFO register.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and, when it detects a start bit, the SCI performs internal synchronization, stores receive data in the RSR register.
3. If the multi-processor communications function is enabled (SMR.MP = 1), see section 30.4.2. Multi-Processor Serial Data Reception. If the address match function (data compare match function) is enabled (DCCR.DCME = 1), the SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and the data for comparison (CDR.CMPD*1).
4. If the SCI detects an address match, the DCCR.DCME bit is automatically cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt*2 request is generated. To enable the generation of an SCIn_RXI interrupt request, set the SCR.RIE bit to 1. The compared receive data are not stored in the RDR register*3. The SSR.RDRF flag remains 0.
5. If the SCI detects a framing error in the receive data for which an address match was detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag becomes 1. To enable the generation of an SCIn_ERI interrupt request, set the SCR.RIE bit to 1.
6. If a framing or a parity error is detected (the DCCR.DFER flag or DCCR.DPER flag is 1) in the SCIn_AM interrupt handling routine, set the DCCR.DFER and DCCR.DPER flags to 0 and set the DCCR.DCME bit to 1 to enable the address match function again. If neither a framing nor a parity error has been detected (the DCCR.DFER and DCCR.DPER flags are 0), set the DCCR.DCMF flag to 0. See Figure 30.9.
7. If an overrun error occurs during normal communications, the SSR_FIFO.ORER flag is set to 1. If the SCR.RIE bit in SCR is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the FRDRL*3 register.
8. If a parity error is detected, the PER flag and receive data are transferred to the FRDRL*3 register. If the SCR.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
9. If a framing error is detected, the FER flag and receive data are transferred to the FRDRL*3 register. If the SCR.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
10. After a framing error is detected and when SCI detects that the continuous receive data is zero for one frame, reception stops.
11. When the amount of data stored in the FRDRL register falls below the specified receive triggering number, and the next data is not received after 15 ETUs from the last stop bit in asynchronous mode, the SSR_FIFO.DR flag is set to 1. When the SCR.RIE bit is 1 and the FCR.DRES bit is 0, the SCI generates an SCIn_RXI interrupt request. When the FCR.DRES bit is 1, SCI generates an SCIn_ERI interrupt request.

SCI使用下一个数据更新FRDRL寄存器中的FER、PER和接收数据(RDAT[8:0])。标志RDF、ORER和FRDRH寄存器中的DR始终反映SSR_FIFO寄存器中的相关标志。

Figure 30.25 存储在FRDRH和FRDRL中的数据格式，选择了FIFO

在串行数据接收中，SCI操作如下：

1.当SCR.RE位的值变为1时，CTSn_RTSn引脚上的输出信号变为低电平。

2.SCI监视通信线路，当它检测到一个起始位时，SCI执行内部同步，将接收数据存储在RSR寄存器中。

3.如果启用了多处理器通信功能（SMR.MP=1），请参见第30.4.2节。多处理器串行数据接收。如果地址匹配功能（数据比较匹配功能）被启用（DCCR.DCME=1），SCI无法检测奇偶校验或帧错误，因为接收数据被跳过（丢弃），直到SCI检测到接收数据与用于比较的数据（CDR.CMPD*1）。

4.如果SCI检测到地址匹配，DCCR.DCME位自动清零，DCCR.DCMF标志变为1，并产生SCIn_AM中断*2请求。要启用SCIn_RXI中断请求的生成，请将SCR.RIE位设置为1。比较的接收数据不存储在RDR寄存器*3中。SSR.RDRF标志保持为0。

5.如果SCI在检测到地址匹配的接收数据中检测到帧错误，则DCCR.DFER标志设置为1，如果SCI在该帧中检测到奇偶校验错误，则DCCR.DPER标志变为1.要启用SCIn_ERI中断请求的生成，请将SCR.RIE位设置为1。

6.如果在SCIn_AM中断处理例程中检测到成帧或奇偶校验错误（DCCR.DFER标志或DCCR.DPER标志为1），则将DCCR.DFER和DCCR.DPER标志设置为0，并设置DCCR.DCME位为1以再次启用地址匹配功能。如果既没有检测到成帧错误也没有检测到奇偶校验错误（DCCR.DFER和DCCR.DPER标志为0），将DCCR.DCMF标志设置为0。参见图30.9。

7.如果在正常通信过程中发生溢出错误，则SSR_FIFO.ORER标志设置为1。如果SCR中的SCR.RIE位为1，则产生SCIn_ERI中断请求。接收数据不传送到FRDRL*3寄存器。

8.如果检测到奇偶校验错误，则将PER标志和接收数据传送到FRDRL*3寄存器。如果SCR.RIE位设置为1，则会产生SCIn_ERI中断请求。

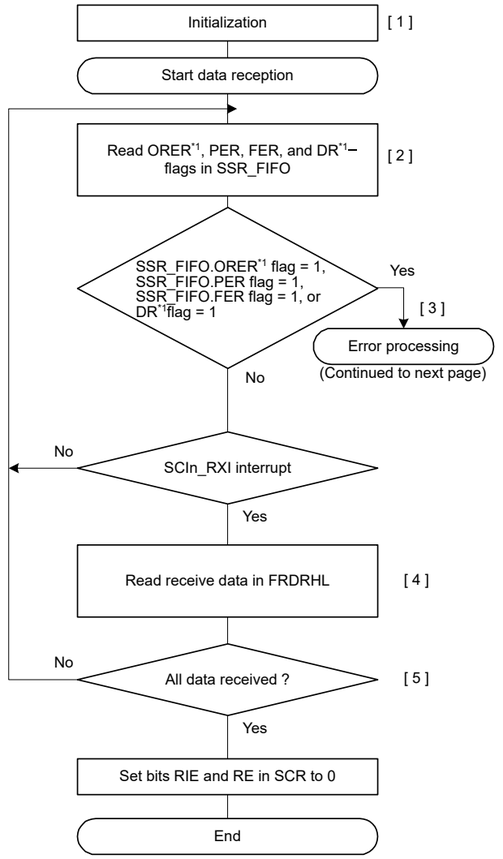
9.如果检测到帧错误，则将FER标志和接收数据传送到FRDRL*3寄存器。如果SCR.RIE位设置为1，则会产生SCIn_ERI中断请求。

10、检测到帧错误后，当SCI检测到连续接收数据一帧为零时，停止接收。

11.当FRDRL寄存器中存储的数据量低于指定的接收触发数，并且在异步模式下从最后一个停止位开始15个ETU后没有接收到下一个数据时，SSR_FIFO.DR标志设置为1。SCR.RIE位为1，FCR.DRES位为0，SCI产生一个SCIn_RXI中断请求。当FCR.DRES位为1时，SCI产生一个SCIn_ERI中断请求。

12. When reception finishes successfully, receive data is transferred to the FRDRL*3 register. The RDF bit is set to 1 when the amount of receive data written to FRDRHL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit in SCR is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the FRDRL*4 register in the SCIn_RXI interrupt handling routine, before an overrun error occurs. If the received data that is transferred to FRDRL*5 is less than the RTS trigger number, the CTSn_RTSn pin outputs low.

Note 1. One of three lengths is selected for the target for comparison: CMPD[6:0] is for 7-bit length, CMPD[7:0] is for 8-bit length, and CMPD[8:0] is for 9-bit length.
Note 2. As no interrupt enable bit is assigned to the SCIn_AM interrupt, an interrupt request is generated by setting the DCCR.DCMF to 1.
Note 3. Only read data in the FRDRH and FRDRL registers when 9-bit data length is selected.
Note 4. Read data in order from FRDRH and FRDRL when 9-bit data length is selected.
Note 5. The SCI only checks for update to the FRDRL register and not to the FRDRH register when 9-bit data length is selected.



[1] SCI initialization:
Set data reception.

[2] [3] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. A break can be detected by reading the SPTR.RXDMON flag. An error is identified by reading the ORER*1, PER, DR*1, and FER flags in SSR_FIFO. After performing the appropriate error processing, be sure to set the ORER*1 flag to 0. Reception cannot be resumed if ORER*1 flag is set to 1. The reception operation is continuous, even if the FER = 1 or PER = 1 or DR*1 = 1.

[4] Read the receive data in FRDRHL in the SCIn_RXI interrupt handling routine. The receive data stored in the FRDRHL register is read until the number of stored data is below the FCR.RTRG value. Confirm the number of the reception data in the FIFO by reading FDR.R.

[5] Serial reception continuation procedure:
To continue serial reception, before an overrun error occurs, read data from FRDRHL in the SCIn_RXI interrupt handling routine and clear RDF flag and DR flag to 0.
The FRDRHL data can also be read by activating the DMA or DTC. The RDF flag is cleared automatically in this case, so do not write to the RDF flag.

Note 1. Can be read in the FRDRHL.ORER and DR flags.

Figure 30.26 Example flow of serial reception in asynchronous mode with FIFO selected and Address Matching Enabled (1)

12.接收成功后，接收数据被传送到FRRDL*3寄存器。当写入FRDRHL的接收数据量等于或大于指定的接收触发数时，RDF位设置为1。如果SCR中的SCR.RIE位为1，则产生SCIn_RXI中断请求。在发生溢出错误之前，通过在SCIn_RXI中断处理程序中读取传输到FRDRL*4寄存器的接收数据来启用连续接收。如果传送到FRDRL*5的接收数据小于RTS触发数，CTSn_RTSn引脚输出低电平。

注1.选择三个长度之一作为目标进行比较：CMPD[6:0]为7位长度，CMPD[7:0]为8位长度，CMPD[8:0]为9位长度。

注2.由于没有为SCIn_AM中断分配中断使能位，因此通过设置
DCCR.DCMF to 1.
注3.选择9位数据长度时，仅读取FRDRH和FRDRL寄存器中的数据。
注4.选择9位数据长度时，按FRDRH和FRDRL的顺序读取数据。

[1]SCI初始化：设置数据接收。

[2][3]接收错误处理和中断检测：如果发生接收错误，则产生SCIn_ERI中断。可以通过读取SPTR.RXDMON标志来检测中断。通过读取SSR_FIFO中的ORER*1、PER、DR*1和FER标志来识别错误。执行适当的错误处理后，请务必将ORER*1标志设置为0。如果ORER*1标志设置为1，则无法恢复接收。接收操作是连续的，即使FER=1或PER=1或DR*1=1。

[4]在SCIn_RXI中断处理程序中读取FRDRHL中的接收数据。读取存储在FRDRHL寄存器中的接收数据，直到存储的数据数量低于FCR.RTRG值。通过读取FDR.R来确认FIFO中接收数据的数量。

[5]串行接收继续程序：
要继续串行接收，在发生溢出错误之前，在SCIn_RXI中断处理程序中从FRDRHL读取数据并将RDF标志和DR标志清除为0。也可以通过激活DMA或DTC来读取FRDRHL数据。在这种情况下，RDF标志会自动清除，因此不要写入RDF标志。

注1.可以在FRDRHL.ORER和DR标志中读取。

The receive sampling timing is adjusted from the middle of bit by following formula. And the adjustable direction is set by ACTR.AJD. You can select forward or backward from the middle of bit. When adjusting backward (ACTR.AJD = 0), substitute AJD = +1 and substitute AJD = -1 when adjusting forward (ACTR.AJD = 1).

Adjusted sampling timing = the middle of bit + AJD * (base clock * the setting calue of ACTR.AST[2:0])

The setting timing is limited by base clock cycles per 1 bit. Please refer to Table 30.31 in detail.

A reception movement image figure of the communication through a photo coupler with this function is shown in Figure 30.31, Figure 30.32 and Figure 30.33, the movement explanation of this function is shown in Figure 30.34.

Please don't use this function when there is no difference between the rising transfer time and the falling transfer time, because there is a possibility of deteriorating the reception margin.

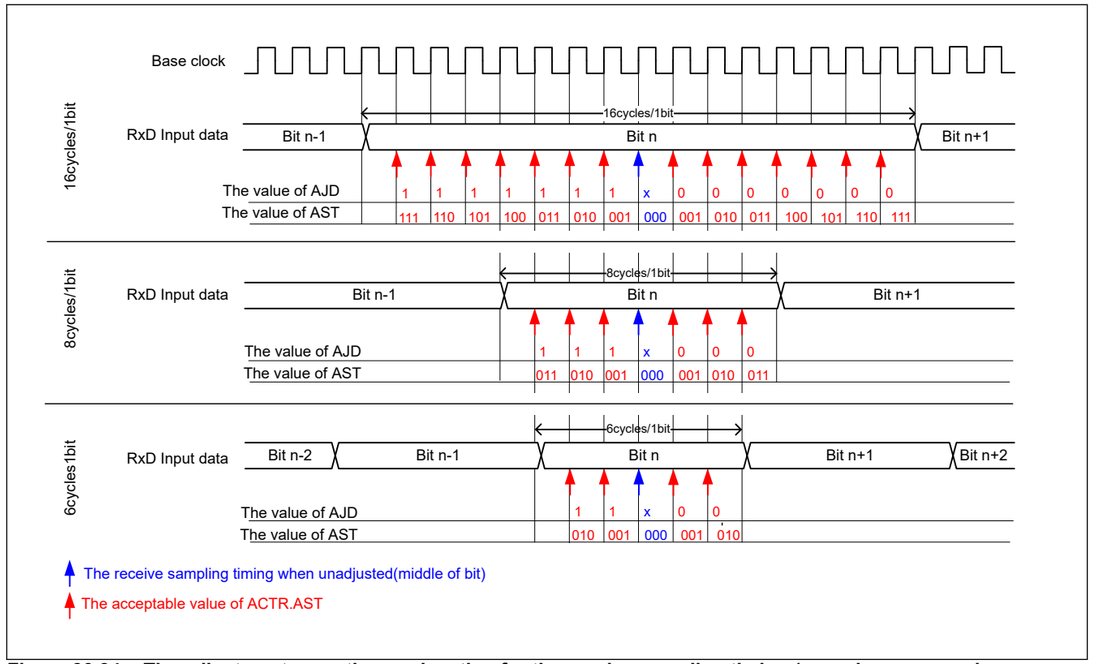

Figure 30.34 The adjustment operation explanation for the receive sampling timing (asynchronous mode using internal clock)

30.3.11 The function of adjust transmit timing (Asynchronous Mode)

In communication via a photo coupler or the like, when either the rising or falling transition time of the TXD output signal is long, then a communication partner receive dulled waveform. In this case, the reception margin may be affected.

In these cases, make a communication partner to be sampling at middle of bit using the function of adjust transmit timing.

When SPTR.ATEN is 1, this function can adjust the edge timing at the timing calculated by the following formula for the edge set with ACTR.AET.

The adjustment edge timing = the base clock * ACTR.ATT[2:0]

In addition, the upper limit of the adjustment edge timing is limited by setting the base clock cycles. Refer to Table 30.32 in details.

A transmission movement image figure of the communication through a photo coupler with this function is shown in Figure 30.35, Figure 30.36 and Figure 30.37, the movement explanation of this function is shown in Figure 30.38 and Figure 30.39.

Please don't use this function when there is not the difference between the rising transfer time and the falling transfer time, there is a possibility of deteriorating the reception margin of a communication partner.

30.3.11 调整发送时间的功能（异步模式）

在经由光电耦合器等的通信中，当TXD输出信号的上升或下降过渡时间较长时，通信伙伴接收到钝化的波形。在这种情况下，接收裕量可能会受到影响。

在这些情况下，使用调整发送时间的功能使通信伙伴在位中间进行采样。

当SPTR.ATEN为1时，该功能可以在ACTR.AET设置的边沿通过以下公式计算的时序调整边沿时序。

调整边沿时序=基准时钟*ACTR.ATT[2:0]

另外，调整边沿时序的上限是通过设置基本时钟周期来限制的。详见表30.32。

图30.35、图30.36、图30.37为具有该功能的光耦通信的传输动作图，该功能的动作说明如图30.38和图30.39所示。

请不要在上升传输时间和下降传输时间之间没有差异时使用此功能，这可能会降低通信伙伴的接收裕度。

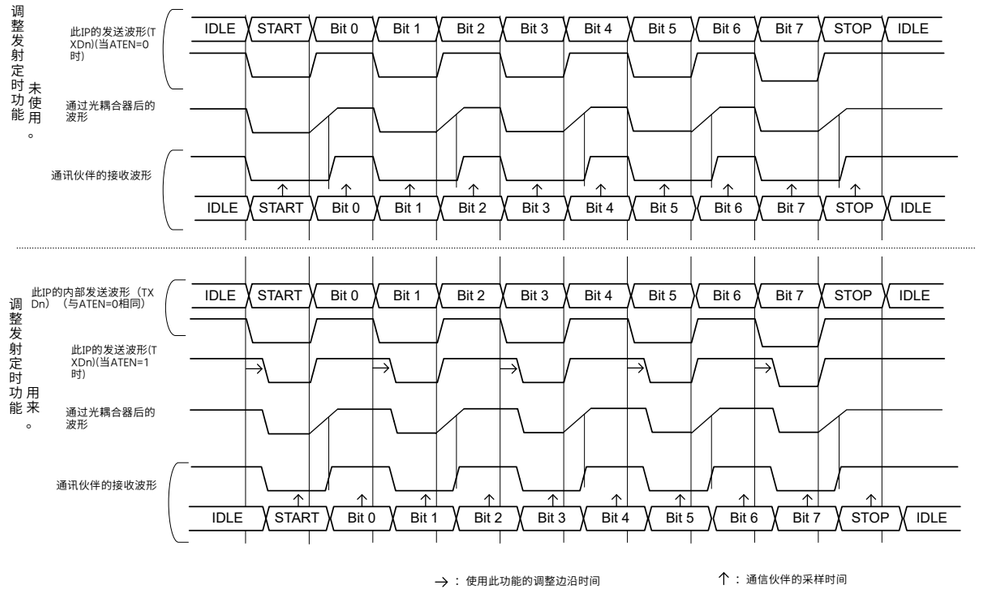

Figure 30.37 通过光电耦合器的发射波形的解释

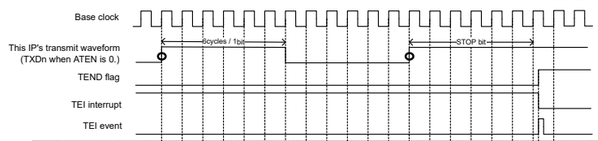
The operation explanation of adjustment the transmit timing

(a) In the case of the falling transfer time >> rising transfer time

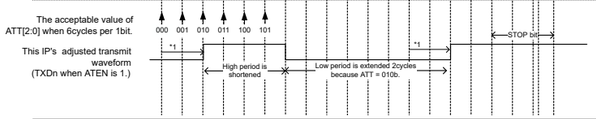
In this case, the high period of a communication partner's reception waveform is made long, and the low period is made short.
Therefore, this IP transmits the waveform with the edge relatively brought forward by adjusting the falling edge timing.
Then adjust value(ATT[2:0]) should be set to make equal the low-period/1bit and high-period/1bit for a communication partner.

This function's operation is explained as an example of 6cycles/1bit.



(a-1) The function of adjust transmit timing OFF (ATEN = 0), AET = x, ATT[2:0] = xxxb

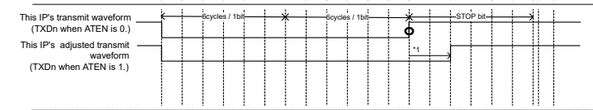
TEND flag is set when stop-bit transmission end.
TEI interrupt and event are output at the same time, too.
Even when ATEN is 1, their timing does not change.



(a-2)The function of adjust transmit timing ON (ATEN = 1), AET = 0, ATT[2:0] = 010b

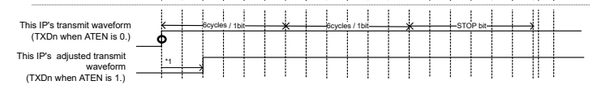
The acceptable value of ATT[2:0] are 000b – 101b when 6cycles per 1bit.

When AET = 0, the rising edge ○ of TxD waveform is adjusted.



(a-3) When the same value continues in the transmission data (0->0)

This function adjust the edge timing of transmit waveform.
So, transmit timing adjustment is not done when the same value continues in the transmission data.
The figure on the left shows the example of ATEN = 1, AET = 0 and ATT[2:0] = 010b.



(a-4)When the same value continues in the transmission data (1->1)

This function adjust the edge timing of transmit waveform.
So, transmit timing adjustment is not done when the same value continues in the transmission data.
The figure on the left shows the example of ATEN = 1, AET = 0 and ATT[2:0] = 010b.

Note 1. Thee rising edge of transmit timing is shifted to back by the setting value of ACTR.ATT[2:0].

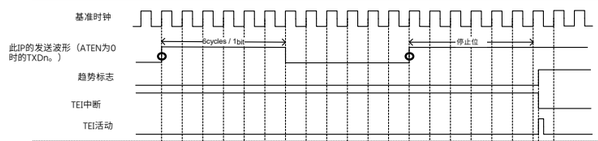
调整发送时间的操作说明

(a)在下降传送时间>>上升传送时间的情况下在这种情况下，通信对方的接收波形的高电平周期变长，而低电平周期变短。因此，该IP通过调整下降沿时序来传输边缘相对提前的波形。

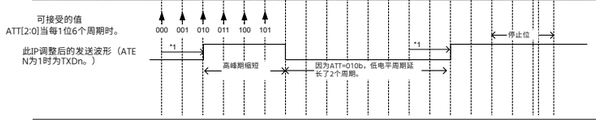
然后调整值（ATT[2:0]）应设置为使通信伙伴的低周期1bit和高周期1bit相等。

该功能的操作以6cycles1bit为例进行说明。



(a-1)调整发送时序的功能OFF(ATEN=0) AET=x ATT[2:0]=xxxb

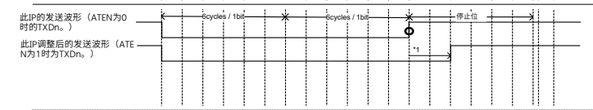
当停止位传输结束时设置TEND标志。
TEI中断和事件也同时输出。
即使ATEN为1，它们的时序也不会改变。



(a-2)调整发送时序的功能ON(ATEN=1) AET=0 ATT[2:0]=010b

ATT[2:0]的可接受值为000b 101b，当每1bit有6个周期时。

当AET=0时，调整TxD波形的上升沿。



(a-3)发送数据中持续相同值时(0->0)
此功能调整发送波形的边沿时序。

因此，当传输数据中继续相同的值时，不进行传输定时调整。左图显示了ATEN=1、AET=0和

因此，当传输数据中继续相同的值时，不进行传输定时调整。左图显示了ATEN=1、AET=0和

30.4 Multi-Processor Communication Function

The multi-processor communication function enables the SCI to transmit and receive data between multiple processors by sharing an asynchronous serial communication line that has an added multi-processor bit. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station.

The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle:

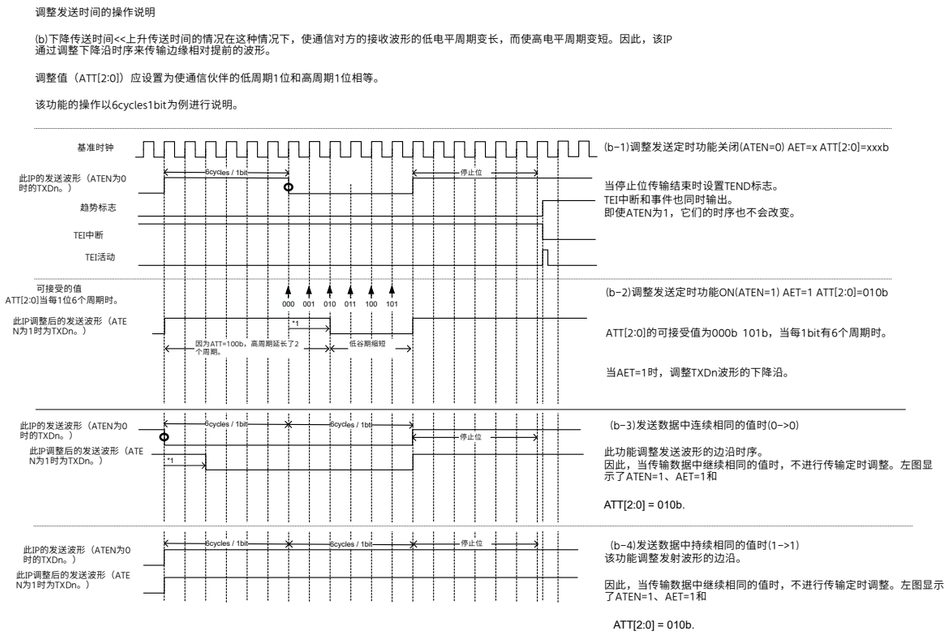
- When the multi-processor bit is set to 1, the transmission cycle is the ID transmission cycle
- When the multi-processor bit is set to 0, the transmission cycle is the data transmission cycle

Figure 30.40 shows an example of communication between processors using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits communication data in which the multi-processor bit set to 0 is added to the transmit data. After receiving communication data with the multi-processor bit set to 1, the receiving station compares the received ID with the ID of the receiving station itself. If the two match, the receiving station receives communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until it receives data in which the multi-processor bit is set to 1.

(1) Non-FIFO selected

To support this function, the SCI provides the SCR.MPIE bit. When the MPIE bit is set to 1, the following operations are disabled until the reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR register (the RDRHL register when 9-bit data length is selected)
- Detection of a receive error



注1.发送时序的下降沿由ACTR.ATT[2:0]的设置值向后移动。

Figure 30.39 AET为1时发射时序调整操作说明

30.4 多处理器通信功能

多处理器通信功能使SCI能够通过共享一条增加了多处理器位的异步串行通信线路在多个处理器之间发送和接收数据。在多处理器通信中，为每个接收站分配一个唯一的ID代码。串行通信周期由指定接收站的ID传输周期和向指定接收站传输数据的数据传输周期组成。

多处理器位用于区分ID传输周期和数据传输周期：

●当多处理器位设置为1时，传输周期为ID传输周期

●当多处理器位设置为0时，传输周期为数据传输周期

图30.40显示了使用多处理器格式的处理器之间的通信示例。首先，发送站发送将设置为1的多处理器位添加到接收站的ID码的通信数据。接着，发送站发送在发送数据中附加了多处理器比特为0的通信数据。接收站接收到多处理器位设置为1的通信数据后，将接收到的ID与接收站自身的ID进行比较。如果两者匹配，则接收站接收随后发送的通信数据。如果接收到的ID与接收站的ID不匹配，则接收站跳过通信数据，直到接收到多处理器位设置为1的数据。

(1) Non-FIFO selected

为了支持这个功能，SCI提供了SCR.MPIE位。当MPIE位设置为1时，以下操作被禁止，直到接收到多处理器位设置为1的数据：

●将接收数据从RSR寄存器传送到RDR寄存器（选择9位数据长度时的RDRHL寄存器）

●接收错误检测

- Setting of the respective RDRF, ORER, and FER status flags in the SSR register

When the SCI receives a character in which the multi-processor bit is set to 1, the SSR.MPBT bit is set to 1 and the SCR.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode. The clock used for the multi-processor communication is the same as the clock used in normal asynchronous mode.

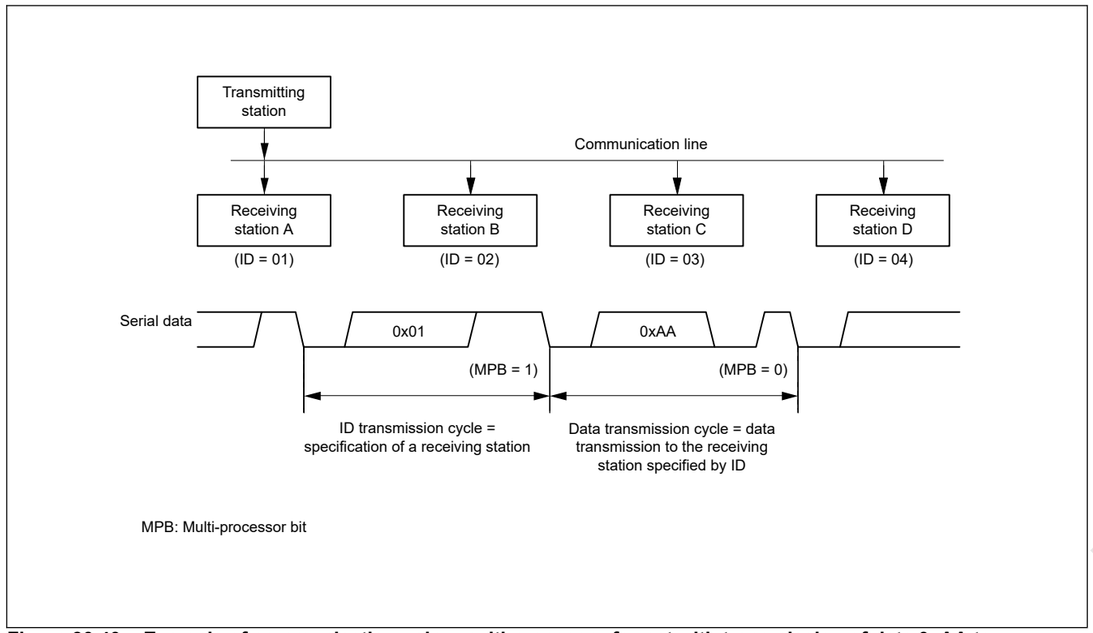


Figure 30.40 Example of communication using multi-processor format with transmission of data 0xAA to receiving station A

(2) FIFO selected

For data transmission, software must write data to FTDRHL.MPBT that corresponds to transmit data in FTDRHL.TDAT. For data reception, the multi-processor bit that is part of the receive data is written to FTDRHL.MPB and receive data is written to FRDRL.

When the MPIE bit is set to 1, the following operations are disabled until reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the FRDRHL register
- Detection of a receive error
- Break
- Setting of the respective RDF, ORER, and FER status flags in the SSR_FIFO register

When the SCI receives an 8-bit character in which the multi-processor bit is set to 1, the FTDRHL.MPB bit is set to 1 and receive data is written to FRDRHL.RDAT. The SCR.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode with FIFO selected.

30.4.1 Multi-Processor Serial Data Transmission

(1) Non-FIFO selected

●在SSR寄存器中设置相应的RDRF、ORER和FER状态标志

当SCI接收到多处理器位设置为1的字符时，SSR.MPBT位设置为1，并且SCR.MPIE位自动清零，使SCI恢复正常接收操作。如果SCR.RIE位设置为1，则SCIn_RXI中断产生。

当指定多处理器格式时，奇偶校验位功能被禁用。除此之外，与正常异步模式下的操作没有区别。用于多处理器通信的时钟与正常异步模式下使用的时钟相同。

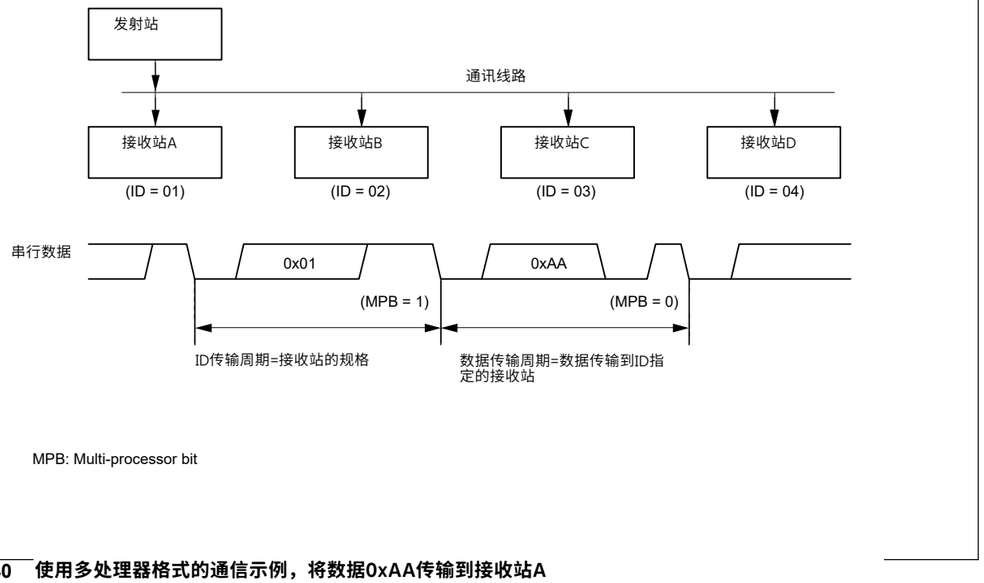

Figure 30.40 使用多处理器格式的通信示例，将数据0xAA传输到接收站A

(2) FIFO selected

对于数据传输，软件必须将数据写入与FTDRHL.TDAT中的传输数据相对应的FTDRHL.MPBT。对于数据接收，作为接收数据一部分的多处理器位被写入FTDRHL.MPB，接收数据被写入FRDRL。

当MPIE位设置为1时，以下操作被禁止，直到接收到多处理器位设置为1的数据：

●将接收数据从RSR寄存器传送到FRDRHL寄存器

●接收错误检测

- Break

●在SSR_FIFO寄存器中设置相应的RDF、ORER和FER状态标志

当SCI接收到多处理器位设置为1的8位字符时，FTDRHL.MPB位设置为1，接收数据写入FRDRHL.RDAT。SCR.MPIE位自动清零，使SCI恢复正常接收操作。如果SCR.RIE位设置为1，则会产生SCIn_RXI中断。

当指定多处理器格式时，奇偶校验位功能被禁用。除此之外，与选择FIFO的正常异步模式下的操作没有区别。

(2) FIFO selected

Figure 30.47 shows an example of a data format that is written to FRDRH and FRDRL in multi-processor mode.

In multi-processor mode, the MPB value that is a part of the receive data is written to the FRDRH.MPB bit. A value of 0 is written to the FRDRH.PER flag. Data is written to FRDRH and FRDRL with the correct data length. Unused bits are written with 0. Read in order from FRDRH to FRDRL. When software reads the FRDRL register, the SCI updates FER, MPB, and receive data (RDAT[8:0]) in FRDRL with the next data. The RDF, ORER and DR flags in the FRDRH register always reflect the associated flags in the SSR_FIFO register.

(2) FIFO selected

图30.47显示了在多处理器模式下写入FRDRH和FRDRL的数据格式示例。

在多处理器模式下，作为接收数据一部分的MPB值被写入FRDRH.MPB位。值0写入FRDRH.PER标志。数据以正确的数据长度写入FRDRH和FRDRL。未使用的位写入0。按从FRDRH到FRDRL的顺序读取。当软件读取FRDRL寄存器时，SCI用下一个数据更新FER、MPB和FRDRL中的接收数据（RDAT[8:0]）。FRDRH寄存器中的RDF、ORER和DR标志始终反映SSR_FIFO寄存器中的相关标志。

The SCR.MPIE bit is automatically cleared and normal reception continues.

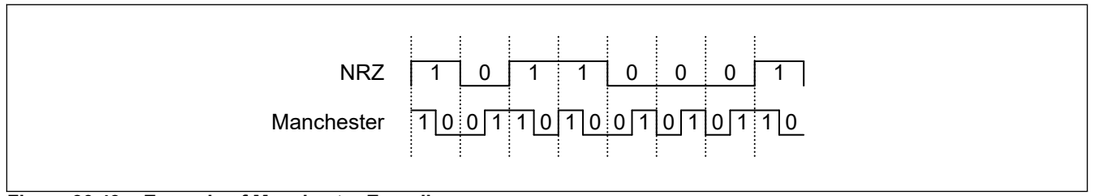

Figure 30.49 Example of Manchester Encoding

In Manchester mode, a preface and a start bit area are added to the transmit data in the register to configure a transmit frame. For transmission, data is encoded in Manchester encoding. When data is received, frames having the same format as transmitted frames are detected and Manchester decoding is performed.

For details on the frame format, see section 30.5.1. Frame Format.

30.5.1 Frame Format

Figure 30.50 shows the frame format in Manchester mode.

In the upper half of the figure, relevant setting registers are shown.

The preface area and the data area are encoded in Manchester encoding.

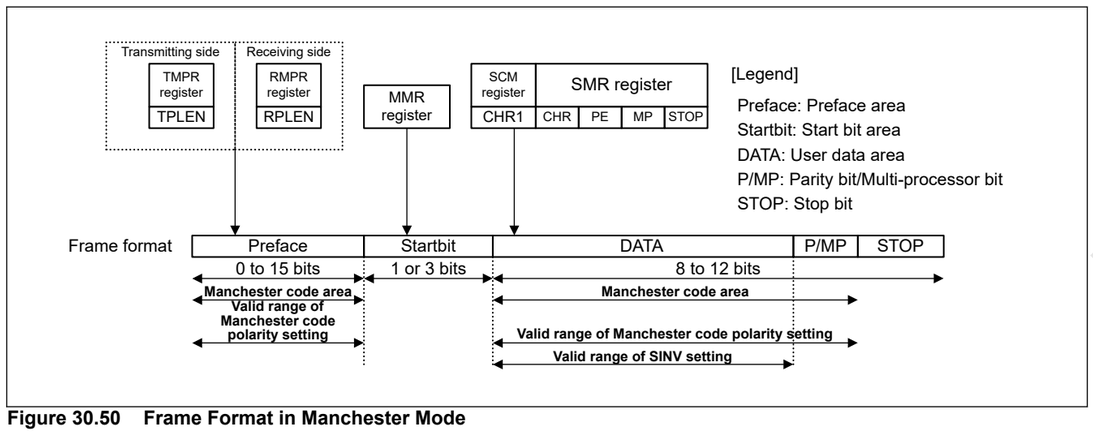

Figure 30.50 Frame Format in Manchester Mode

(1) Preface area

This is a fixed pattern area located at the beginning of each frame.

Different registers are used to set the preface area for transmission and reception. The preface length is determined by setting TMPR.TPLEN[3:0] for transmission. It is determined by setting RMPR.RPLEN[3:0] for reception.

If it is set to 0, the transmit preface is disabled and is not added.

If it is set to 1d to 15d, a preface whose length is determined by this setting is added.

(For example, if it is set to 1d, a 1-bit preface is added. If it is set to 15d, a 15-bit preface is added.)

The preface pattern is set with TMPR.TPPAT[1:0] for transmission and RMPR.RPPAT[1:0] for reception, and is selected from four types of patterns.

Figure 30.51 shows how the preface pattern is set. The preface area and the start bit area are added for each communication frame.

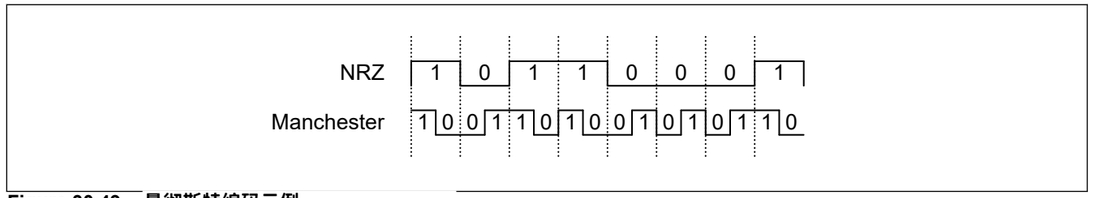

Figure 30.49 曼彻斯特编码示例

在曼彻斯特模式下，前言和起始位区域被添加到寄存器中的发送数据以配置发送帧。对于传输，数据以曼彻斯特编码进行编码。当接收到数据时，检测与传输帧格式相同的帧并执行曼彻斯特解码。

有关帧格式的详细信息，请参见第30.5.1节。帧格式。

30.5.1 帧格式

图30.50显示了曼彻斯特模式下的帧格式。

在图的上半部分，显示了相关的设置寄存器。

前言区和数据区采用曼彻斯特编码。

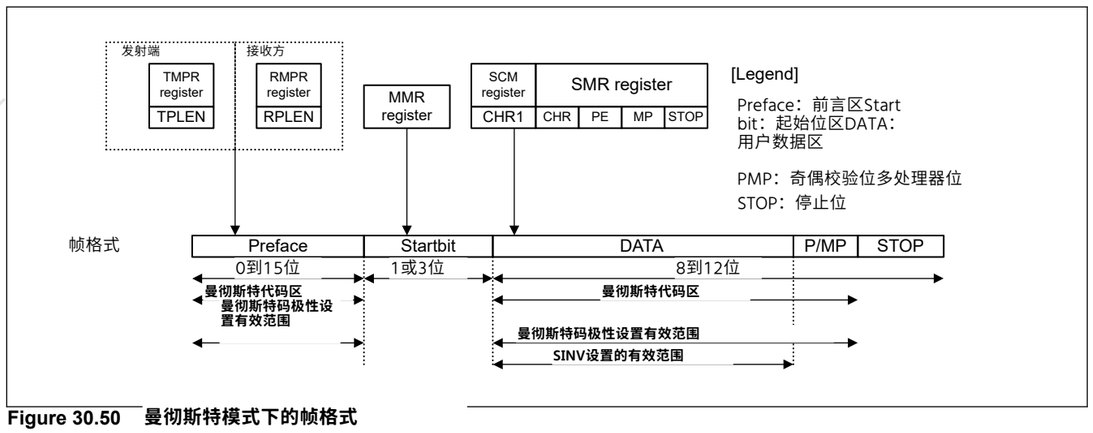

Figure 30.50 曼彻斯特模式下的帧格式

(1) 前言区

这是位于每帧开始处的固定模式区域。

不同的寄存器用于设置发送和接收的前言区域。前言长度通过设置TMPR.TPLEN[3:0]来决定传输。通过设置RMPR.RPLEN[3:0]来确定接收。

如果设置为0，则发送前言被禁用且不添加。

如果设置为1d到15d，则添加一个长度由该设置确定的前言。

（例如，如果设置为1d，则添加1位前言。如果设置为15d，则添加15位前言。）

前言模式设置为发送用TMPR.TPPAT[1:0]，接收用RMPR.RPPAT[1:0]，从四种模式中选择。

图30.51显示了如何设置前言模式。为每个通信帧添加前言区和起始位区。

(2) Start bit area

This is an area indicating the start of valid data in a frame. It is added after the preface area.

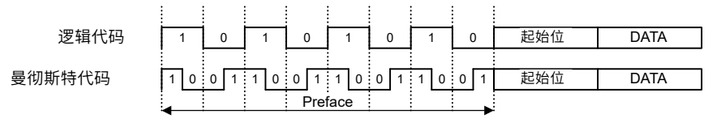
The start bit length is determined by MMR.SBSEL setting. When MMR.SBSEL = “0”, the start bit length is 1 bit.

When MMR.SBSEL = “1”, the start bit length is 3 bits.

When MMR.SBSEL = “1”, the SYNC type can be selected from command SYNC and data SYNC.

Command SYNC means the three start bits are added as a one-to-zero transition.

■ TMPR/RMPR = 10: One-zero pattern
（TPLENRPLEN=8h：前言长度=8位）



■ TMPR/RMPR = 01: Zero-one pattern

(2) 起始位区

这是指示帧中有效数据开始的区域。它添加在前言区域之后。

起始位长度由MMR.SBSEL设置决定。当MMR.SBSEL=“0”时，起始位长度为1位。

当MMR.SBSEL=“1”时，起始位长度为3位。

当MMR.SBSEL=“1”时，SYNC类型可以从命令SYNC和数据SYNC中选择。

命令SYNC意味着三个起始位被添加为一个从1到零的转换。

Data SYNC means the three start bits are added as a zero-to-one transition.

The SYNC type is determined by the MMR.SYNSEL, MMR.SYNVAL and TDRH.TSYNC settings.

(When receiving, the received result is applied to RDRH.RSYNC.)

When MMR.SBSEL = “0”, the start bit is added as a zero-to-one or one-to-zero transition.

The selection is determined by the MMR.SYNVAL setting.

The MMR.SYNSEL bit specifies the destination to be referred to when setting for transmission.

When the MMR.SYNSEL bit is set to 1, the MMR.SYNVAL setting is referred to. When the MMR.SYNSEL bit is set to 0, the TDRH.TSYNC setting is referred to.

Figure 30.52 shows the state of the start bit area according to the settings in the MMR.SYNSEL, MMR.SYNVAL and TDRH.TSYNC registers in the case of transmission. Figure 30.53 shows that in the case of reception.

The start bit(s) is not affected by the MMR.TMPOL or MMR.RMPOL setting.

数据同步意味着三个起始位被添加为一个零到一的转换。

SYNC类型由MMR.SYNSEL、MMR.SYNVAL和TDRH.TSYNC设置确定。

（接收时，将接收到的结果应用到RDRH.RSYNC。）

当MMR.SBSEL=“0”时，添加起始位作为零到一或一到零的转换。

选择由MMR.SYNVAL设置决定。

MMR.SYNSEL位指定发送设置时要参考的目标。

当MMR.SYNSEL位设置为1时，参考MMR.SYNVAL设置。当MMR.SYNSEL位设置为0时，参考TDRH.TSYNC设置。

(3) DATA

Since the format of the data area is the same as that of the asynchronous mode, see section 30.3.1. Serial Data Transfer Format.

As shown in Figure 30.49, Frame Format in Manchester Mode, the stop bit is not included in the Manchester encoding range.

30.5.2 Clock

As the transfer clock in Manchester mode, the clock generated by the on-chip baud rate generator is used by setting the SMR.CKS[1:0] bit.

Also it is possible to set the oversampling (transfer rate of one-bit period) by SEMR.ABCS bit.

When the SMER.ABCS bit is set to 0, oversampling x16 is selected with the one-bit period being 16 cycles of the base clock. When the SMER.ABCS bit is set to 1, oversampling x8 is selected with the one-bit period being 8 cycles of the base clock.

30.5.3 Initialization of the SCI in Manchester Mode

Before transferring data, write the initial value (00h) to the SCR register and initialize the SCI following the example of flowchart shown in Figure 30.54.

Whenever the operating mode or transfer format is changed, the SCR register must be initialized before the change is made.

Note that setting the SCR.RE bit to 0 initializes none of: the ORER, FER, PER, MER, RDRF, and RDF flags in the SSR register, the SYER, PFER and SBER flags in the MESR register, and the RDR, RDRH, and RDRL registers.

Note also that switching the value of SCR.TE from 0 to 1 when SCR.TIE is 1 generates a TXI interrupt request.

(3) DATA

由于数据区的格式与异步模式相同，见30.3.1节。串行数据传输
Format.

如图30.49，曼彻斯特模式下的帧格式，停止位不包含在曼彻斯特编码范围内。

30.5.2 Clock

作为曼彻斯特模式下的传输时钟，片内波特率发生器产生的时钟用于设置
SMR.CKS[1:0] bit.

也可以通过SEMR.ABCS位设置过采样（一位周期的传输率）。

当SMER.ABCS位设置为0时，选择过采样x16，一位周期为基本时钟的16个周期。当SMER.ABCS位设置为1时，选择过采样x8，一位周期为基本时钟的8个周期。

30.5.3 曼彻斯特模式下SCI的初始化

在传输数据之前，将初始值（00h）写入SCR寄存器并按照图30.54所示的流程图示例初始化SCI。

每当改变操作模式或传输格式时，必须在改变之前初始化SCR寄存器。

请注意，将SCR.RE位设置为0不会初始化以下各项：SSR寄存器中的ORER、FER、PER、MER、RDRF和RDF标志，MESR寄存器中的SYER、PFER和SBER标志，以及RDR、RDRH 和RDRL寄存器。

另请注意，当SCR.TIE为1时，将SCR.TE的值从0切换到1会产生TXI中断请求。

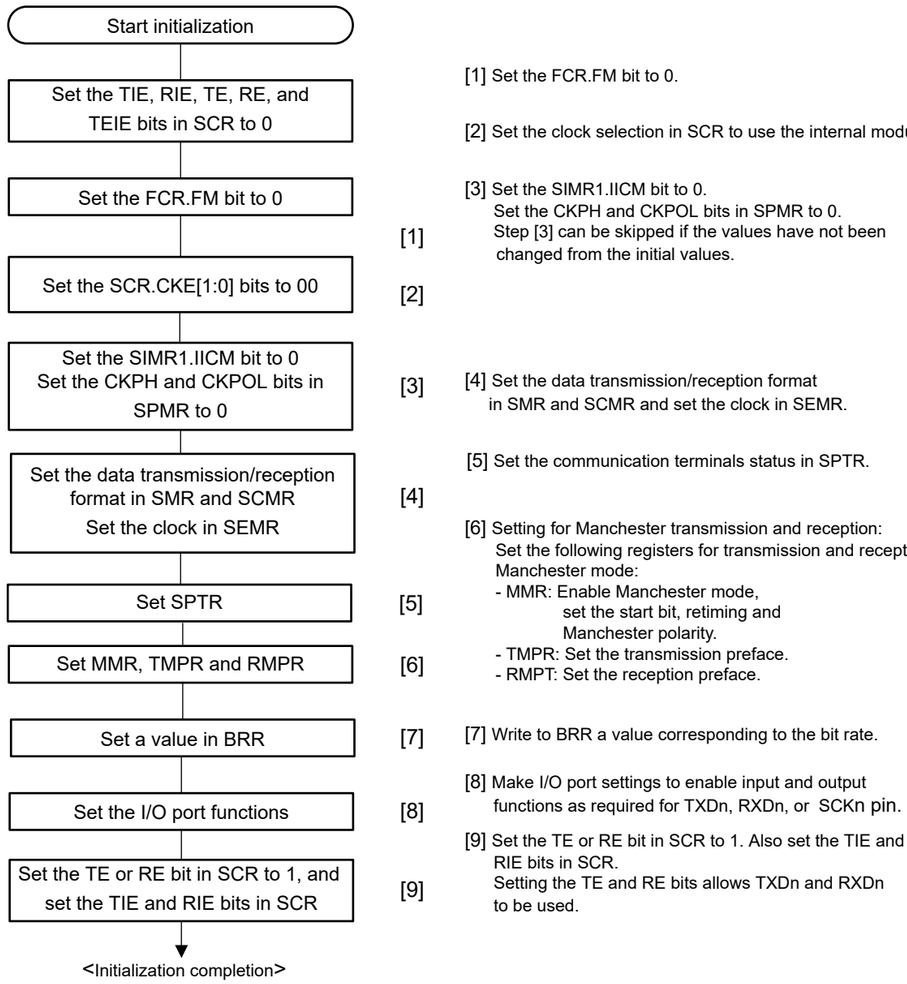

Figure 30.54 SCI Initialization Flow in Manchester Mode

30.5.4 Double-speed operation

When the ABCS bit in SEMR is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the BGDM bit in SEMR is set to 1, the cycle of the base clock is reduced to half and the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the ABCS and the BGDM bits in SEMR are set to 1, the SCI operates on the bit rate four times that of when the ABCS and the BGDM bits in SEMR are set to 0.

30.5.5 CTS and RTS functions

The CTS function uses input on the CTSn_RTSn pin in transmission control. Setting the CTSE bit in SPMR to 1 enables the CTS function. The CTSn_RTSn pin can be set as a multiplexed pin which allows one pin to be used for either function, or as dedicated pins with each pin for a single function. Use the CTSPEN bit in SPMR for this setting.

30.5.4 Double-speed operation

当SEMR中的ABCS位设置为1并选择1位周期的8个基本时钟脉冲时，SCI以ABCS设置为0时的两倍比特率运行。

当SEMR中的BGDM位设置为1时，基本时钟的周期减少到一半，SCI的比特率是ABCS设置为0时的两倍。

当SEMR中的ABCS和BGDM位设置为1时，SCI以四倍的比特率运行。
SEMR中的ABCS和BGDM位设置为0。

30.5.5 CTS和RTS功能

CTS功能在传输控制中使用CTSn_RTSn引脚上的输入。将SPMR中的CTSE位设置为1使能CTS功能。CTSn_RTSn管脚可以设置为多路复用管脚，允许一个管脚用于任一功能，或作为专用管脚，每个管脚用于单一功能。使用SPMR中的CTSPEN位进行此设置。

When the CTS function is enabled, reception starts only when the CTSn_RTSn pin is at the low level.

Applying a high level to the CTSn_RTSn pin after transmission starts does not affect transmission of the current frame, which continues.

The RTS function uses output on the CTSn_RTSn pin to request transmission. When the SCI is ready to receive, it outputs a low level to the CTSn_RTSn pin, Conditions for output of the low level and high level are as follows:

[Conditions for low-level output]

When all conditions listed below are satisfied:

- The value of the RE bit in SCR is 1.
- The SCI is ready to receive.
- There is no received data yet to be read.
- All of the following flags are set to 0: SSR.ORER, FER, PER and MER flags, and MESR.SYER (when SYEREN = 1), PFER (when PFEREN = 1) and SBER flags (when SBEREN = 1).

[Conditions for high-level output]

- When the conditions for low output are not satisfied

30.5.6 Serial data transmission in Manchester mode

The SCI encodes data in Manchester encoding and sends the resultant data in Manchester mode.

When the polarity setting (MR.TMPOL) set to 0, logic 0 is coded as a zero-to-one transition in Manchester code and logic 1 is coded as a one-to-zero transition in Manchester code.

When the polarity setting (MR.TMPOL) set to 1, logic 0 is coded as a one-to-zero transition in Manchester code and logic 1 is coded as a zero-to-one transition in Manchester code.

For this reason, a level transition occurs with the Manchester encoded data in the middle of individual logic data. (See Figure 30.49).

The transmitter constructs transmit frames in a specific format by adding a preface area to data and setting the start bit(s) according to the polarity setting and sends resultant serial data.

For details on the frame format, see section 30.5.1. Frame Format.

Figure 30.55 shows the flowchart in transmission. Figure 30.56, Figure 30.57, and Figure 30.58 show examples of the operation for serial transmission in Manchester mode.

当CTS功能使能时，只有在CTSn_RTSn引脚为低电平时才开始接收。

传输开始后将高电平应用到CTSn_RTSn引脚不会影响当前帧的传输，当前帧会继续传输。

RTS功能使用CTSn_RTSn引脚上的输出来请求传输。当SCI准备好接收时，向CTSn_RTSn管脚输出一个低电平，输出低电平和高电平的条件如下：

[Conditions for low-level output]

当满足下列所有条件时：

●SCR中RE位的值为1。

●SCI已准备好接收。

●没有接收到的数据尚未读取。

●以下所有标志都设置为0：SSR.ORER、FER、PER和MER标志，以及MESR.SYER（当SYEREN=1时）、PFER（当PFEREN=1时）和SBER标志（当SBEREN=1时）。

[Conditions for high-level output]

●不满足低输出条件时

30.5.6 曼彻斯特模式下的串行数据传输

SCI以曼彻斯特编码对数据进行编码，并以曼彻斯特模式发送结果数据。

当极性设置(MR.TMPOL)设置为0时，逻辑0被编码为曼彻斯特代码中的零到一转换，逻辑1被编码为曼彻斯特代码中的一到零转换。

当极性设置(MR.TMPOL)设置为1时，逻辑0被编码为曼彻斯特代码中的一对零转换，逻辑1被编码为曼彻斯特代码中的零到一转换。

出于这个原因，在各个逻辑数据中间的曼彻斯特编码数据会发生电平转换。（看Figure 30.49).

发送器通过向数据添加前言区域并根据极性设置设置起始位来构建特定格式的发送帧，并发送结果串行数据。

有关帧格式的详细信息，请参见第30.5.1节。帧格式。

图30.55显示了传输中的流程图。图30.56、图30.57和图30.58显示了曼彻斯特模式下串行传输的操作示例。

[2] TXI interrupt:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (TXI) request is generated.

When TSYNC is used, also set TDRHL.TYSNC.

[4] Serial transmission continuation procedure:
To continue serial transmission, write the transmit data to TDR once by using an TXI interrupt.
The transmit data can also be written to TDR by activating the DMAC or DTC in the TXI interrupt request.
When TEI interrupt requests are used, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to TDR.

30.5.7 Serial Data Reception in Manchester Mode

In Manchester mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate. Reception starts by sampling the falling edges of received data at the base clock. As shown in Figure 30.59, reception starts at a falling edge of the received data and it continues if the received data keeps low for the duration of 1/4 bit. If the received data goes high within the duration of 1/4 bit, the SCI judges it as an error and waits for a falling edge again.

If a high level is expected in the first half of a bit in the received data, the SCI judges a low level that continues for one base clock cycle as an error and ignores the change to the low level.

Note 1. This is the case when SEMR.ABCS = 0. When SEMR.ABCS = 1, the SCI operates on a base clock with a frequency of 8 times the bit rate.

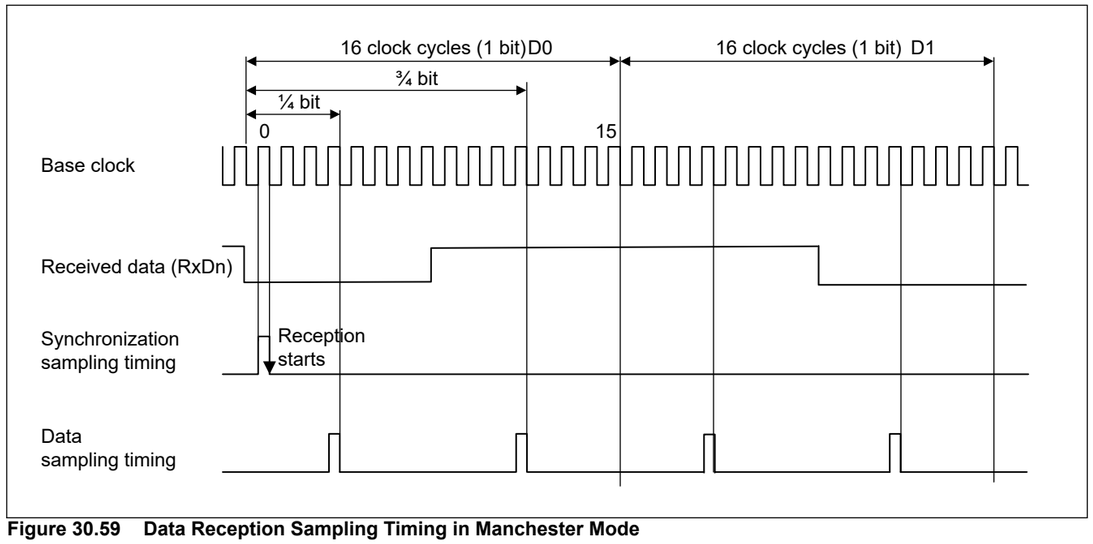

Figure 30.59 Data Reception Sampling Timing in Manchester Mode

In Manchester mode, data reception starts with detection of a preface and start bit area.

The SCI checks the input from the RXDn pin to see whether a preface is added based on the value of RMPR.RPLEN.

If the preface is disabled (RMPR.RPLEN = 0), it moves on to the detection of a start bit area without detecting a preface.

Figure 30.58 曼彻斯特模式下串行传输的传输结束操作示例（使用前言但没有CTS功能）

30.5.7 曼彻斯特模式下的串行数据接收

在曼彻斯特模式下，SCI在频率为16倍*1比特率的基本时钟上运行。接收开始于在基本时钟处对接收到的数据的下降沿进行采样。如图30.59所示，接收在接收数据的下降沿开始，如果接收数据保持低电平持续14位，则继续接收。如果接收到的数据在14bit的时间内变高，则SCI判断为错误，再次等待下降沿。

如果在接收数据的前半个比特中预期为高电平，则SCI将持续一个基本时钟周期的低电平判断为错误，并忽略向低电平的变化。

注1.这是SEMR.ABCS=0时的情况。当SEMR.ABCS=1时，SCI在频率为比特率8倍的基本时钟上运行。

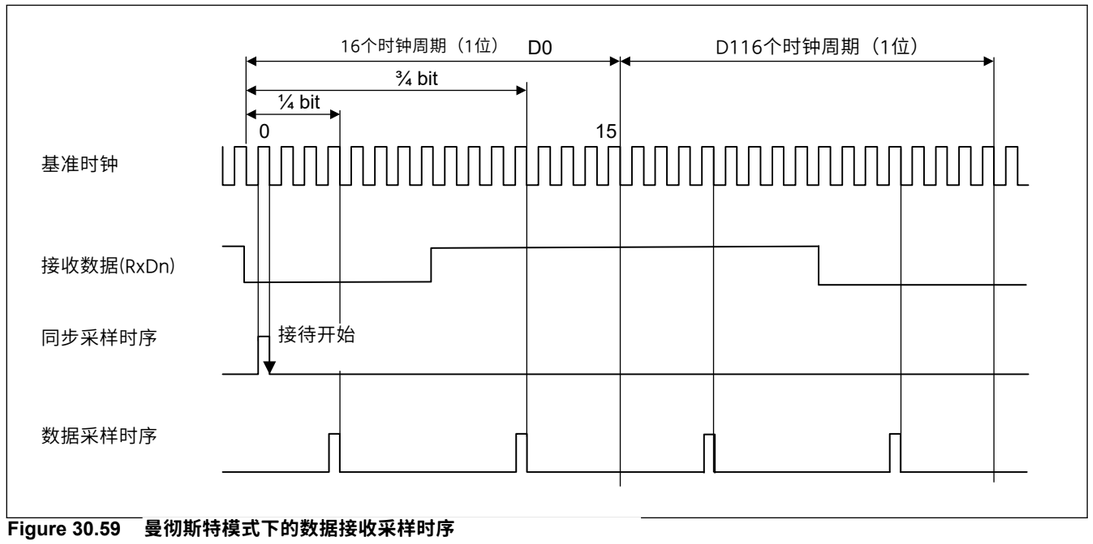

Figure 30.59 曼彻斯特模式下的数据接收采样时序

在曼彻斯特模式下，数据接收从检测前言和起始位区域开始。

SCI检查来自RXDn引脚的输入，以查看是否根据RMPR.RPLEN的值添加了前言。

如果前言被禁用（RMPR.RPLEN=0），它会继续检测起始位区域而不检测前言。

When a preface is enabled, it identifies a preface pattern setting according to the set value in RMPR.RPPAT, and compares it with the RXDn input for a pattern match to detect a preface pattern.

Upon detection of a preface pattern match, it judges it as a normal preface and moves on to the detection of a start bit area.

If detecting a preface pattern mismatch or a Manchester code error in the preface area, it judges it as a preface error and asserts a preface error (PFER).

For start bit detection, the SCI selects an expected value based on the register settings (MMR.SBSEL and SYNVAL), compares it with the RXDn input for a pattern match to detect a start bit area. Upon detection of a start bit pattern match, it judges it as a normal start bit area and moves on to the data processing.

Only when a preface and a start bit area are detected normally, it moves on to the next phase of data reception.

Upon detection of a start bit pattern mismatch, it asserts a start bit error flag (SBER).

In data processing, the SCI shifts the data by the expected received data length based on the register settings (SCMR.CHR1 and SMR.CHR) through the RSR register. If two sampling points in a bit of the received data are identical, the SCI judges this as a Manchester code error.

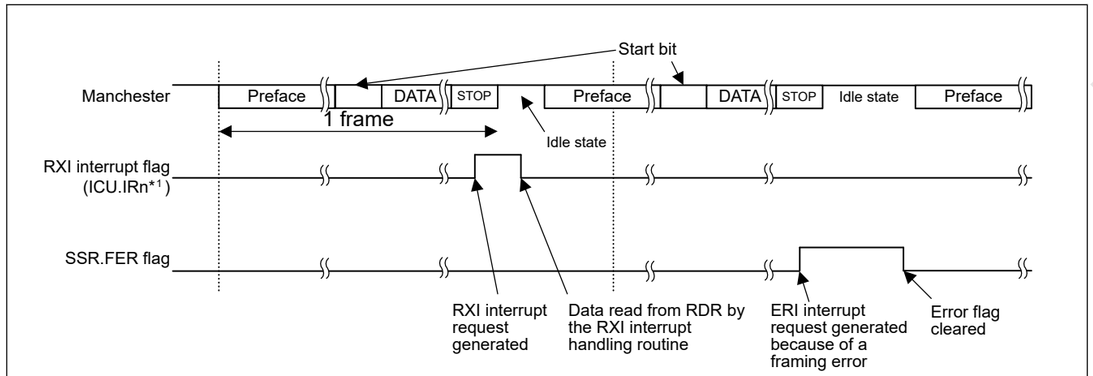
For details, see para. (4) in section 30.5.11. Errors in Manchester Mode.

When the parity function is disabled (SMR.PE = 0), the SCI moves on to the next phase of stop bit detection. When the parity function is enabled (SMR.PE = 1), the SCI performs parity checking. If detecting a parity error, it asserts a parity error flag (PER), and then moves on to stop bit detection.

In stop bit detection, the SCI checks the following in the stop bit area of the received frame:

It has two sampling points in a bit. If both points are at the high level, the bit is recognized as a normal stop bit and the data is stored in the RDR register. At least one low-level point is judged as an abnormal stop bit, causing a framing error flag (FER) to be set. Even when an error is detected, the received data is stored in the RDR register as abnormal data.

Figure 30.60 shows an example of the operation for serial data reception in Manchester mode.



Note 1. For corresponding interrupt numbers, see section 13, Interrupt Controller Unit (ICU).

Figure 30.60 Example of Operation for Serial Data Reception in Manchester mode (with a Preface)

For the state of each status flag in the SSR register and RXDn input processing when a receive error is detected, see section 30.5.11. Errors in Manchester Mode.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated.

Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, PER, MER, SYER*1, PFER*1, and SBER*1 flags to 0 before resuming reception. Also, be sure to read the RDR (or RDRL) register during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR (or the RDRL) register because received data which has not yet been read may be left in the RDR (or the RDRL) register.

Figure 30.61 and Figure 30.62 show examples of serial data reception flowchart in Manchester mode.

Note 1. Effective when the corresponding bit is enabled.

启用前言时，它根据RMPR.RPPAT中的设置值识别前言模式设置，并将其与模式匹配的RXDn输入进行比较，以检测前言模式。

在检测到前言模式匹配时，将其判断为正常前言并继续检测起始位区域。

如果在前言区域检测到前言模式不匹配或曼彻斯特码错误，则将其判断为前言错误并断言前言错误（PFER）。

对于起始位检测，SCI根据寄存器设置（MMR.SBSEL和SYNVAL）选择预期值，将其与模式匹配的RXDn输入进行比较，以检测起始位区域。在检测到起始位模式匹配时，将其判断为正常起始位区域并继续进行数据处理。

只有在正常检测到前言和起始位区域时，才进入下一个数据接收阶段。

在检测到起始位模式不匹配时，它会断言起始位错误标志(SBER)。

在数据处理中，SCI根据寄存器设置（SCMR.CHR1和SMR.CHR）通过RSR寄存器将数据移位预期的接收数据长度。如果接收到的数据位中的两个采样点相同，则SCI判断为曼彻斯特码错误。

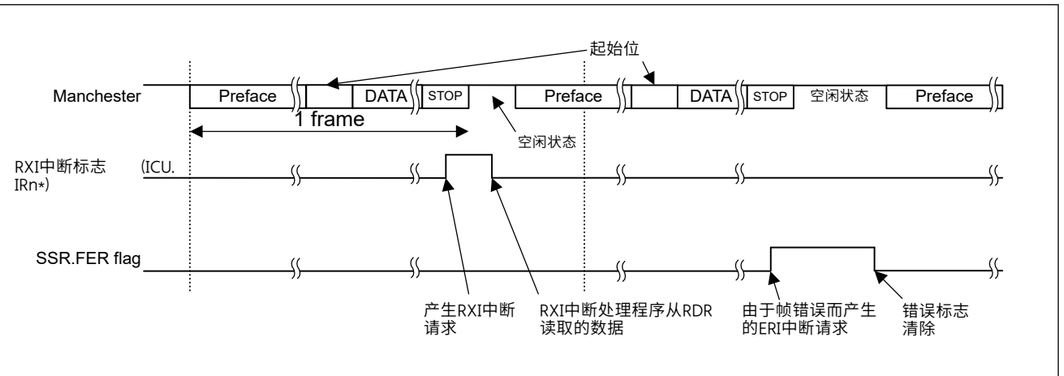
有关详细信息，请参阅段落。(4)在第30.5.11节中。曼彻斯特模式中的错误。

当奇偶校验功能被禁用（SMR.PE=0）时，SCI进入下一个停止位检测阶段。当启用奇偶校验功能时（SMR.PE=1），SCI执行奇偶校验。如果检测到奇偶校验错误，它会置位奇偶校验错误标志(PER)，然后继续进行停止位检测。

在停止位检测中，SCI在接收帧的停止位区域中检查以下内容：

它有两个采样点。如果两个点都处于高电平，则该位被识别为正常停止位，数据存储在RDR寄存器中。至少有一个低电平点被判断为异常停止位，导致设置帧错误标志（FER）。即使检测到错误，接收到的数据也会作为异常数据存储在RDR寄存器中。

图30.60显示了曼彻斯特模式下串行数据接收操作的示例。



注1.有关相应的中断号，请参阅第13节，中断控制器单元(ICU)。

关于SSR寄存器中各状态标志的状态以及检测到接收错误时的RXDn输入处理，请参阅30.5.11节。曼彻斯特模式中的错误。

如果检测到接收错误，则会产生SCIn_ERI中断请求，但不会产生SCIn_RXI中断请求。

当接收错误标志为1时，无法恢复数据接收。因此，在恢复接收之前将ORER、FER、PER、MER、SYER*1、PFER*1和SBER*1标志设置为0。此外，请务必在溢出错误处理期间读取RDR（或RDRL）寄存器。如果在操作期间通过将SCR.RE位设置为0来强制终止接收，请读取RDR（或RDRL）寄存器，因为尚未读取的接收数据可能留在RDR（或RDRL）寄存器中。

请参阅第30.4节。多处理器通信功能(1)曼彻斯特模式下的操作在使用多处理器模式时因为操作是一样的。

A preface and a start bit area are added to the frame format in Manchester mode. See Figure 30.62 for error processing in Manchester mode for the reception flowchart (Figure 30.46). Refer to Table 30.35 for the operation status when detecting various errors.

30.5.9 Receive Retiming

This function corrects the timing for each central edge of the bit, taking advantage of the fact that each bit has an edge in the center in Manchester code.

The receive retiming function can be turned on or off by setting the ERTEN bit in the MMR register.

When the receive retiming function is turned off (MMR.ERTEN = 0), retiming is not performed, causing misalignment between the internal clock and the RXDn input to be accumulated and the receive margin to be reduced.

When the receive retiming function is turned on (MMR.ERTEN = 1), retiming is performed for the preface area, the start bit area*1, and the data area (excluding the stop bit).

Note 1. Retiming is not performed for the start bit area if the preface length is 0 and the start bit length is 3.

As an example, the receive retiming when oversampling x16 is selected is shown below.

When detecting an RXDn input edge two to four cycles before the expected receive cycle, the receive processing is shortened by one sampling CLK cycle.

When detecting a RXDn input edge two to three cycles after the expected receive cycle, the receive processing is extended by one sampling CLK cycle.

(Even if the clock is misaligned with the data by more than two cycles, one cycle is corrected for each bit.)

Figure 30.63 shows the conceptual image of receive retiming range.

When detecting an edge in the tolerance area in the figure, data is received as is without making correction.

When detecting an edge in the SyncJump area in the figure, data is corrected for reception.

When detecting an edge in the SyncError area in the figure, data is received as abnormal data with no correction made.

For a Manchester code error (data matches at the 1/4-phase and 3/4-phase sampling points), the SCI reports a code error.

30.5.9 接收重定时

该函数利用曼彻斯特码中每个位在中心的边缘这一事实，校正位的每个中心边沿的时序。

通过设置MMR寄存器中的ERTEN位可以打开或关闭接收重定时功能。

当接收重定时功能关闭时（MMR.ERTEN=0），不执行重定时，导致内部时钟和RXDn输入之间的错位累积，接收裕量减小。

当接收重定时功能打开时（MMR.ERTEN=1），对前言区、起始位区*1和数据区（不包括停止位）执行重定时。

注1.如果序言长度为0且起始位长度为3，则不对起始位区域执行重定时。

例如，选择过采样x16时的接收重定时如下所示。

当在预期接收周期前2到4个周期检测到RXDn输入边沿时，接收处理将缩短1个采样CLK周期。

当在预期接收周期后两到三个周期检测到RXDn输入边沿时，接收处理将延长一个采样CLK周期。

（即使时钟与数据的偏差超过两个周期，也会为每一位校正一个周期。）

图30.63显示了接收重定时范围的概念图。

在图中的公差范围内检测边缘时，直接接收数据而不进行校正。

当在图中的SyncJump区域检测到边缘时，数据被校正以进行接收。

当在图中的SyncError区域检测到边缘时，数据作为异常数据接收，没有进行校正。

对于曼彻斯特编码错误（数据在1个4相和3个4相采样点匹配），SCI报告编码错误。

30.5.10 Polarity Setting for Manchester Code

The polarity of the Manchester code can be set with the Manchester Mode Register (MMR).

It can be set separately for transmission and reception. Use the MMR.TMPOL bit to set the polarity for transmission and the MMR.RMPOL bit to set the polarity for reception.

The Manchester code polarity setting is valid for the preface area, the data area, and the parity or multi-processor area.

When the initial settings (TMPOL/RMPOL = 0) are used for the polarity of Manchester code, logic 0 is encoded as a zero-to-one transition in Manchester code and logic 1 is encoded as a one-to-zero transition in Manchester code. If the settings are changed to TMPOL/RMPOL = 1, logic 0 is encoded as a one-to-zero transition in Manchester code and logic 1 is encoded as a zero-to-one transition in Manchester code. Figure 30.64 shows the conceptual image of the settings and operation.

Separately from the function above, the transmitted and received data in the data area can be inverted by the transmitted/received data inversion function (SCMR.SINV). Since the polarity of Manchester code (MMR.TMPOL/RMPOL) can be set separately from the transmitted/received data invert function (SCMR.SINV), if both are set to inversion (MMR.TMPOL/RMPOL = 1 and SCMR.SINV = 1), the transmitted and received data are set to initial state (inversion + inversion = normal).

The polarity of the start bit area can be set by a register different from the ones mentioned above.

Since a different register is used, the polarity of the start bit area is not affected by the polarity setting for Manchester code mentioned above.

For details on the setting for the start bit area, see para. (2) in section 30.5.1. Frame Format.

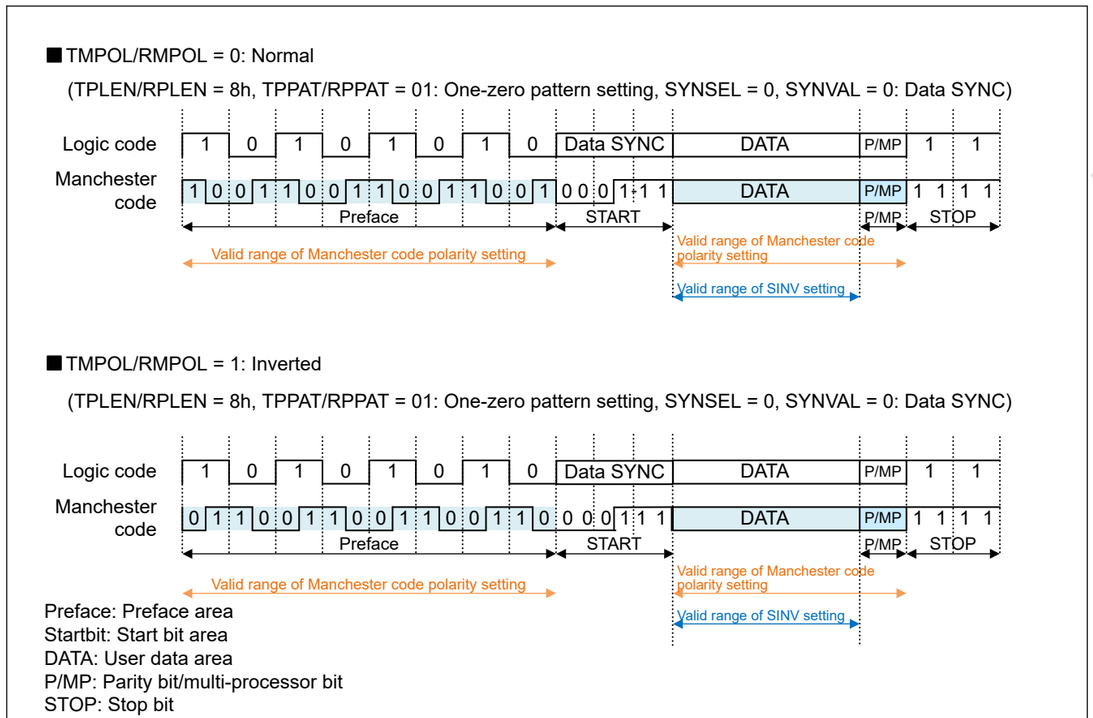

Figure 30.64 Valid Range of the Manchester Code Polarity Setting

30.5.11 Errors in Manchester Mode

There are the following errors in Manchester mode:

30.5.10 曼彻斯特码的极性设置

曼彻斯特码的极性可以通过曼彻斯特模式寄存器(MMR)设置。

可以分别设置发送和接收。使用MMR.TMPOL位设置传输的极性和
MMR.RMPOL位设置接收极性。

曼彻斯特码极性设置对前言区、数据区、奇偶校验或多处理器区有效。

当初始设置(TMPOLRMPOL=0)用于曼彻斯特代码的极性时，逻辑0被编码为曼彻斯特代码中的零到一转换，逻辑1被编码为曼彻斯特代码中的一对零转换。如果设置更改为TMPOLRMPOL=1，则逻辑0被编码为曼彻斯特代码中的一对零转换，逻辑1被编码为曼彻斯特代码中的零到一转换。图30.64显示了设置和操作的概念图。

与上述功能不同，数据区中的发送和接收数据可以通过发送接收数据反转功能(SCMR.SINV)反转。由于曼彻斯特码的极性(MMR.TMPOLRMPOL)可以与发送的接收数据反转功能(SCMR.SINV)分开 设置，如果两者都设置为反转(MMR.TMPOLRMPOL=1和SCMR.SINV=1)，发送和接收的数据设置为初始状态（反转+反转=正常）。

起始位区域的极性可以通过与上述不同的寄存器来设置。

由于使用了不同的寄存器，因此起始位区域的极性不受上述曼彻斯特码极性设置的影响。

有关起始位区域设置的详细信息，请参见第1段。(2)在第30.5.1节中。帧格式。

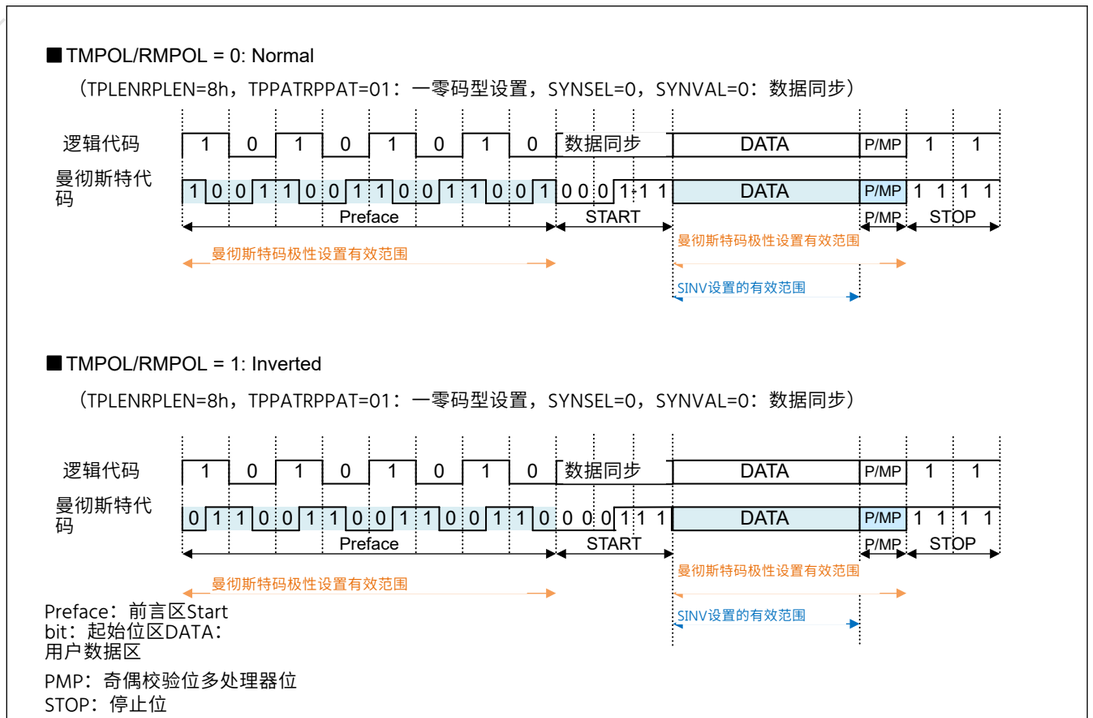

Figure 30.64 曼彻斯特码极性设置的有效范围

30.5.11 曼彻斯特模式中的错误

曼彻斯特模式有以下错误：

1. Parity error
2. Over run error
3. Framing error
4. Manchester error
5. Preface error
6. Start Bit error
7. Receive SYNC error

For errors (1) to (3), see section 30.3.9. Serial Data Reception in Asynchronous Mode (1) because they are the same as in asynchronous mode.

Each errors are judged in each area, but they are reflected on flags and operations at the timing of 3/4-bit sampling of the STOP bit area. If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the previous information.

Table 30.33 lists the states of the serial status register when detecting errors and judgment about whether to store data in the RDR.

Table 30.34 lists the errors that can be detected in each area of a Manchester frame.

If a Preface error or Start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the result of the previous frame reception. Also, if an error is detected in the previous frame, data will not be received, but errors in the pre-face area and start bit area will update that flag. Table 30.35 shows the flags and actions in this case.

(4) Manchester error

A Manchester error is generated when a Manchester code error is detected.

In Manchester code, there must be an edge (transition) in the center of the bit.

In the data area of a received frame (including the parity/multi-processor bit), the values of the 1/4-bit and 3/4-bit sampling points are checked in each received 1-bit data, and a Manchester code error is determined if these two values match.

If a Manchester code error is detected, the Manchester error flag (SSR.MER) is asserted.

If a Manchester error occurs, it is handled as an interrupt source and event source. If a Manchester error is detected, the next reception is not performed until the corresponding error flag is cleared.

(5) Preface error

A preface error is generated when the preface pattern does not match or a Manchester code error is detected in the preface area. If a preface error is detected, the preface error flag (SSR.PFER) is asserted.

It is possible to set whether to use this error flag as an interrupt source with the setting of the MECR register.

When MECR.PFEREN = 1, a preface error is handled as an interrupt source or event source. If a preface error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.PFEREN = 0, a preface error is not handled as an interrupt source or event source, and the next reception is not halted. However, a preface error is notified to MESR.PFER.

(6) Start bit error

A start bit error is generated when a mismatch is detected between the start bit area in the received frame and the preset start bit pattern. Upon detection of a start bit error, a start bit error flag (MESR.SBER) is asserted.

It is possible to set whether to use the start bit error as an interrupt source with the setting of the MECR register.

When MECR.SBEREN = 1, a start bit error is handled as an interrupt source or event source. If a start bit error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.SBEREN = 0, a start bit error is not handled as an interrupt source or event source, and the next reception is not halted. However, a start bit error is notified to MESR.SBER.

(7) Receive SYNC error

When the receive retiming function described in section 30.5.9. Receive Retiming is enabled, the receive retiming operation is performed.

1.奇偶校验错误

2.溢出错误

3.构图错误

4.曼彻斯特错误

5.前言错误

6.起始位错误

7.收到SYNC错误

对于错误(1)至(3)，请参阅第30.3.9节。异步模式下的串行数据接收(1)因为它们与异步模式下相同。

在每个区域中判断每个错误，但它们反映在标志和操作上，在3个4位采样的时间
停止位区域。如果检测到前言错误或起始位错误，则不会接收后续数据。因此，不进行其他错误检测，错误标志保存先前的信息。

表30.33列出了串口状态寄存器在检测错误和判断是否存储数据时的状态
RDR.

表30.34列出了在曼彻斯特帧的每个区域中可以检测到的错误。

如果检测到Preface错误或Startbit错误，则不会接收后续数据。因此，不进行其他错误检测，错误标志保存前一帧接收的结果。此外，如果在前一帧中检测到错误，则不会接收数据，但前脸区域和起始位区域中的错误将更新该标志。表30.35显示了这种情况下的标志和操作。

(4)曼彻斯特错误

当检测到曼彻斯特码错误时，就会产生曼彻斯特错误。

在曼彻斯特码中，位的中心必须有一个边（转换）。

在接收帧的数据区（包括奇偶校验多处理器位），在每个接收的1位数据中检查1个4位和3个4位采样点的值，确定曼彻斯特码错误如果这两个值匹配。

如果检测到曼彻斯特代码错误，则曼彻斯特错误标志(SSR.MER)被置位。

如果发生曼彻斯特错误，则将其作为中断源和事件源进行处理。如果检测到曼彻斯特错误，则在清除相应错误标志之前不会执行下一次接收。

(5)前言错误

当前言模式不匹配或在前言区检测到曼彻斯特码错误时，会产生前言错误。如果检测到前言错误，则断言前言错误标志(SSR.PFER)。

可以通过MECR寄存器的设置来设置是否使用该错误标志作为中断源。

当MECR.PFEREN=1时，前言错误作为中断源或事件源处理。如果检测到前言错误，则在相应的错误标志被清除之前不会执行下一次接收。

当MECR.PFEREN=0时，前言错误不会作为中断源或事件源处理，并且不会停止下一次接收。但是，前言错误会通知给MESR.PFER。

(6)起始位错误

当检测到接收帧中的起始位区域与预设的起始位模式不匹配时，会产生起始位错误。在检测到起始位错误时，将置位起始位错误标志(MESR.SBER)。

可以通过MECR寄存器的设置来设置是否使用起始位错误作为中断源。

当MECR.SBEREN=1时，起始位错误作为中断源或事件源处理。如果检测到起始位错误，则在清除相应错误标志之前不会执行下一次接收。

当MECR.SBEREN=0时，不将起始位错误作为中断源或事件源处理，并且不会停止下一次接收。但是，将向MESR.SBER通知起始位错误。

(7)接收同步错误

当接收重定时功能在第30.5.9节中描述。启用接收重定时，执行接收重定时操作。

If no edges are detected within the receive retiming range (SyncError area in Figure 30.63) when receive timing operation is being performed, a receive SYNC error is generated. Upon detection of a receive SYNC error, a receive SYNC error flag (MESR.SYER) is asserted. In areas not subject to retiming, receive SYNC errors are not detected.

The preface area*1, the start bit area*1,*2, and the data area (excluding the stop bit) for which receive retiming operation is performed are checked.

It is possible to set whether to use the receive SYNC error as an interrupt source with the setting of the MECR register.

When MECR.SYEREN = 1, a receive SYNC error is handled as an interrupt source or event source. If a receive SYNC error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.SYEREN = 0, a receive SYNC error is not handled as an interrupt source or event source, and the next reception is not halted. However, a receive SYNC error is notified to MESR.SYER.

Note 1. In the case of a frame that starts with a pattern that expects the first half of the bit to be High, it is excluded from retiming.
Note 2. In the start bit area, when there is no preface length and 3 bit start bit is set, it is not subject to retiming.
Also, the 1st bit and the 2nd bit in the start bit area when 3 bit start bit is set are not subject to retiming.

Note 2. When MECR.SYEREN = 1, SCIn_ERI interrupt / event is generated by SYER factor.
Note 3. If MECR.PFEREN = 1 or MECR.SBEREN = 1, an SCIn_ERI interrupt / event is generated when the corresponding flag is set.

如果在执行接收定时操作时在接收重定时范围内（图30.63中的SyncError区域）没有检测到边沿，则会产生接收SYNC错误。在检测到接收同步错误时，接收同步错误标志(MESR.SYER)被置位。在不受重定时限制的区域中，不会检测到接收同步错误。

检查执行接收重定时操作的前言区域*1、起始位区域*1、*2和数据区域（不包括停止位）。

可以通过MECR寄存器的设置来设置是否使用接收SYNC错误作为中断源。

当MECR.SYEREN=1时，接收SYNC错误将作为中断源或事件源处理。如果检测到接收SYNC错误，则在清除相应错误标志之前不会执行下一次接收。

当MECR.SYEREN=0时，接收SYNC错误不会作为中断源或事件源处理，并且不会停止下一次接收。但是，接收同步错误会通知给MESR.SYER。

注1.对于以预期位的前半部分为高的模式开始的帧，它被排除在重定时之外。

注2.在起始位区域中，当没有序言长度且设置了3位起始位时，不进行重定时。
此外，当设置3位起始位时，起始位区域中的第1位和第2位不受重定时的影响。

30.6 Operation in Clock Synchronous Mode

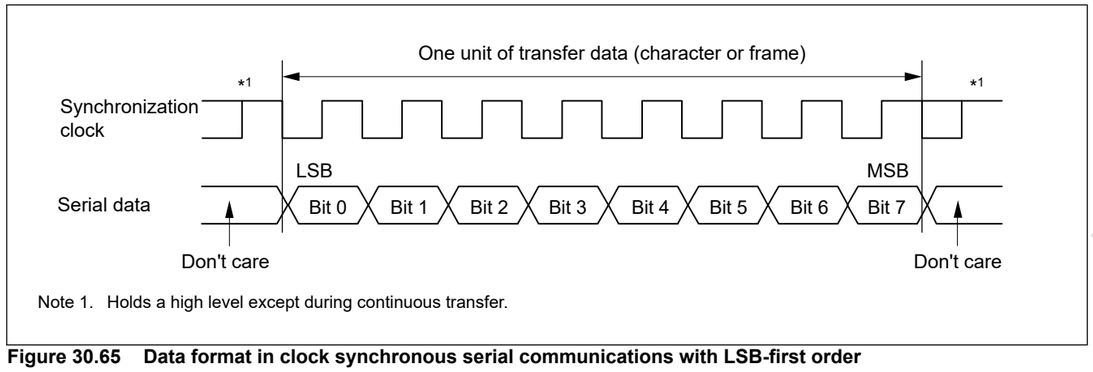
Figure 30.65 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. For single-character data transfer, data consists of 8-bit. In clock synchronous mode, no parity bit can be added.

In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next falling edge. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the last bit as output state. When the SPMR.CKPH bit is 1 in slave mode, the transmission line holds the first bit output state.

Within the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by using a shared clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

However, it is not possible to perform continuous transfer in the fastest bit rate setting (BRR[7:0] = 0x00 and SMR.CKS[1:0] = 00b). Therefore, when the FIFO is selected, this setting (BRR[7:0] = 0x00 and SMR.CKS[1:0] = 00b) is not available.



Note 1. Holds a high level except during continuous transfer.

Figure 30.65 Data format in clock synchronous serial communications with LSB-first order

30.6.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected based on the SCR.CKE[1:0] setting.

When the SCI operates on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character. When no transfer is performed, the clock is held high. However, when only data reception is performed while the CTS function is disabled, the synchronization clock output starts when the SCR.RE bit set to 1. The synchronization clock stops when it goes high*1 and an overrun error occurs or the SCR.RE bit is set to 0.

When only data reception is performed and the CTS function is enabled, the clock output does not start when the SCR.RE bit set to 1 and the CTSn_RTSn pin input is high. The synchronization clock output starts when the SCR.RE bit is set to 1 and the CTSn_RTSn pin input is low. Following that, when the CTSn_RTSn pin input is high on completion of the frame reception, the synchronization clock output stops when it goes high. If the CTSn_RTSn pin input continues to be low, the synchronization clock stops when it goes high*1 and an overrun error occurs or the SCR.RE bit is set to 0.

Note 1. The signal is held high while (SPMR.CKPH = 0 and SPMR.CKPOL = 1) or (SPMR.CKPH = 1 and SPMR.CKPOL = 1). It is held low while (SPMR.CKPH = 0 and SPMR.CKPOL = 1) or (SPMR.CKPH = 1 and SPMR.CKPOL = 0).

注2.如果没有检测到错误，则输出SCIn_RXI中断请求或事件，如果检测到，则输出SCIn_ERI中断请求或事件。

注3.在序言区域或起始位区域中检测到SYER时，根据SYEREN位作为错误处理的行为会发生变化。

30.6 时钟同步模式下的操作

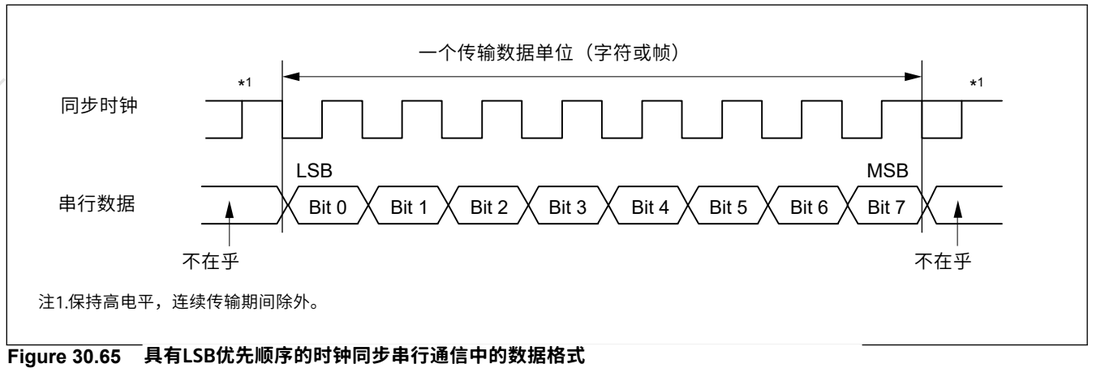
图30.65显示了时钟同步串行数据通信的数据格式。

在时钟同步模式下，数据的发送或接收与时钟脉冲同步。对于单字符数据传输，数据由8位组成。在时钟同步模式下，不能添加奇偶校验位。

在数据传输中，SCI从同步时钟的一个下降沿到下一个下降沿输出数据。在数据接收中，SCI与同步时钟的上升沿同步接收数据。8位数据输出后，传输线保持最后一位作为输出状态。当SPMR.CKPH位在从机模式下为1时，传输线保持第一位输出状态。

在SCI中，发送器和接收器是独立的单元，通过使用共享时钟实现全双工通信。发送端和接收端都具有双缓冲结构，可以在发送时写入下一个发送数据，或者在接收时读取前一个接收数据，实现数据的连续传输。

但是，不可能以最快的比特率设置（BRR[7:0]=0x00和SMR.CKS[1:0]=00b)。Therefore whentheFIFOisselected thissetting(BRR[7:0]=0x00andSMR.CKS[1:0]=00b)isnotavailable.



注1.保持高电平，连续传输期间除外。

Figure 30.65 具有LSB优先顺序的时钟同步串行通信中的数据格式

30.6.1 Clock

可以根据SCR.CKE[1:0]设置选择由片内波特率发生器生成的内部时钟或SCKn引脚上的外部同步时钟输入。

当SCI在内部时钟上运行时，同步时钟从SCKn引脚输出。在一个字符的传输中输出八个同步时钟脉冲。当不执行传输时，时钟保持高电平。但是，当CTS功能禁用时仅执行数据接收时，同步时钟输出会在SCR.RE位设置为1时开始。同步时钟在变为高电平时停止*1并且发生溢出错误或SCR.RE位设置为0。

仅执行数据接收且启用CTS功能时，当SCR.RE位设置为1且CTSn_RTSn引脚输入为高电平时，时钟输出不会启动。当SCR.RE位设置为1且CTSn_RTSn引脚输入为低电平时，同步时钟输出开始。之后，当CTSn_RTSn引脚输入在帧接收完成时为高电平时，同步时钟输出在其变为高电平时停止。如果CTSn_RTSn引脚输入持续为低电平，则同步时钟在变为高电平时停止*1并发生溢出错误或SCR.RE位设置为0。

注1.当(SPMR.CKPH=0且SPMR.CKPOL=1)或(SPMR.CKPH=1且SPMR.CKPOL=1)时，信号保持高电平。它在(SPMR.CKPH=0和SPMR.CKPOL=1)或(SPMR.CKPH=1和SPMR.CKPOL=0)时保持低电平。

30.6.2 CTS and RTS Functions

In the CTS function, the CTSn_RTSn pin input controls the start of data reception or transmission when the clock source is the internal clock. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, setting the CTSn_RTSn pin low causes data reception or transmission to start.

Setting the CTSn_RTSn pin high while the data transmission or reception is in progress does not affect transmission or reception of the current frame.

In the RTS function, the CTSn_RTSn pin output is used to request the start of data reception or transmission when the clock source is an external synchronizing clock. The CTSn_RTSn output goes low when serial communication is enabled. Conditions for output of the CTSn_RTSn low and high are shown as follows:

[Conditions for low output]

Satisfaction of all the following conditions:

Non-FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- Neither transmission nor reception is in progress
- There is no received data available to be read when the SCR.RE bit is 1
- Transmit data is written when the SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR.ORER flag is 0

FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- Neither transmission nor reception is in progress
- The amount of receive data written in FRDRHL is less than the setting value of FCRH.RSTRG[3:0] when SCR.RE = 1
- Data that has not been transmitted is available in FTDRHL when SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR_FIFO.ORER flag is 0

[Condition for high output]

- The conditions for low output are not satisfied

30.6.3 SCI Initialization in Clock Synchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the SCR register, then continue through the SCI initialization procedure given in the sections describing non-FIFO and FIFO selection in section 30.6.2. CTS and RTS Functions. Anytime the operating mode or transfer format is to be changed, the SCR register must be initialized before the change can be made.

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in SSR/SSR_FIFO nor the RDR register. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: In non-FIFO mode, switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 when the SCR.TIE bit is 1 generates an SCIn_TXI interrupt request.

Table 30.37 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (1 of 2)

No.	Step Name	Description
1	Start initialization	
2	Set the SCR.TIE, RIE, TE, RE, and TEIE bits to 0	
3	Set the FCR.FM bit to 0	Set the FCR.FM bit to 0.

30.6.2 CTS和RTS函数

在CTS功能中，当时钟源为内部时钟时，CTSn_RTSn引脚输入控制数据接收或发送的开始。将SPMR.CTSE位设置为1可启用CTS功能。当CTS功能使能时，将CTSn_RTSn引脚设置为低电平会导致数据接收或发送开始。

在数据发送或接收过程中将CTSn_RTSn引脚设置为高电平不会影响当前帧的发送或接收。

在RTS功能中，当时钟源为外部同步时钟时，CTSn_RTSn引脚输出用于请求开始数据接收或发送。当串行通信启用时，CTSn_RTSn输出变为低电平。CTSn_RTSn低电平和高电平的输出条件如下所示：

[低输出的条件]

满足以下所有条件：

满足以下所有条件时选择非FIFO

- ●SCR.RE位或SCR.TE位的值为1
- ●发送和接收都没有进行
- ●当SCR.RE位为1时，没有可读取的接收数据
- ●当SCR.TE位为1且SCR.CKE[1]位为0时写入发送数据
- ●当SCR.TE位为1且SCR.CKE[1]位为1时，TSR寄存器中的数据可用于传输
- ●SSR.ORER标志为0

满足以下所有条件时选择FIFO

- ●SCR.RE位或SCR.TE位的值为1
- ●发送和接收都没有进行
- ●SCR.RE=1时，FRDRHL写入的接收数据量小于FCRH.RSTRG[3:0]的设定值
- ●当SCR.TE位为1且SCR.CKE[1]位为0时，FTDRHL中未发送的数据可用
- ●当SCR.TE位为1且SCR.CKE[1]位为1时，TSR寄存器中的数据可用于传输
- ●SSR_FIFO.ORER标志为0

【高输出条件】

- ●不满足低输出条件

30.6.3 时钟同步模式下的SCI初始化

在发送和接收数据之前，首先将初始值0x00写入SCR寄存器，然后继续执行第30.6.2节中描述非FIFO和FIFO选择的部分中给出的SCI初始化过程。CTS和RTS功能。每当要更改操作模式或传输格式时，必须先初始化SCR寄存器，然后才能进行更改。

Note: 将SCR.RE位设置为0既不会初始化SSRSSR_FIFO中的ORER、FER和PER标志，也不会初始化RDR寄存器。当TE位设置为0时，所选FIFO缓冲区的TEND标志未初始化。

Note: 在非FIFO模式下，当SCR.TIE位为1时，将SCR.TE位的值从1切换为0或从0切换为1会产生SCIn_TXI中断请求。

30.6.4 Serial Data Transmission in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 30.66, Figure 30.67, and Figure 30.68 show examples of serial transmission in clock synchronous mode.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. The SCIn_TXI interrupt request at the beginning of transmission is generated when the TE bit is set to 1 but only after the TIE bit in the SCR is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data finishes. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks for update to the TDR register on output of the last bit.
5. When the TDR register is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame starts.
6. If TDR is not updated, the SSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Figure 30.66, Figure 30.67, and Figure 30.68 show examples of serial data transmission.

Transmission does not start while a receive error flag (ORER, FER, or PER in SSR) is set to 1. Always set the receive error flags to 0 before starting transmission.

Note: Setting the SCR.RE bit to 0 does not clear the receive error flags.

30.6.4 时钟同步模式下的串行数据传输

(1) Non-FIFO selected

图30.66、图30.67和图30.68显示了时钟同步模式下的串行传输示例。

在串行数据传输中，SCI操作如下：

1.当数据在SCIn_TXI中断处理程序中写入TDR时，SCI将数据从TDR寄存器传输到TSR寄存器。发送开始时的SCIn_TXI中断请求在TE位设置为1且仅在SCR中的TIE位也设置为1或当这两个位通过一条指令同时设置为1时产生。

2.将数据从TDR传输到TSR后，SCI开始传输。当SCR.TIE位设置为1时，会产生SCIn_TXI中断请求。在当前发送数据发送完成之前，通过在SCIn_TXI中断处理例程中将下一个发送数据写入TDR来启用连续发送。使用SCIn_TEI中断请求时，在SCIn_TXI请求的处理例程中将要发送的最后一个数据写入TDR寄存器后，将SCR.TIE位设置为0，并将SCR.TEIE位设置为1。

3.指定时钟输出模式时，与输出时钟同步，指定使用外部时钟时，与输入时钟同步，从TXDn引脚发送8位数据。当SPMR.CTSE位为1时，时钟信号的输出被暂停，直到输入CTS信号为低电平。

4.SCI在最后一位输出时检查对TDR寄存器的更新。

5.TDR寄存器更新后，下一个发送数据从TDR传送到TSR，开始下一帧的串行发送。

6.如果TDR未更新，则SSR.TEND标志设置为1。TXDn引脚保持最后一位的输出状态。如果SCR.TEIE位为1，则产生SCIn_TEI中断请求并且SCKn引脚保持高电平。

图30.66、图30.67和图30.68显示了串行数据传输的示例。

当接收错误标志（SSR中的ORER、FER或PER）设置为1时，发送不会开始。在开始发送之前，请务必将接收错误标志设置为0。

Note: 将SCR.RE位设置为0不会清除接收错误标志。

[1] [1]SCI initialization:
Set data transmission.

[2] [2]Writing transmit data write to TDR by an SCIn_TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated.
Transmit data is written to TDR once from the handling routine for SCIn_TXI requests.

[3] [3]Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR upon accepting a transmit data empty interrupt (SCIn_TXI) request. Transmit data can also be written to TDR by activating the DMAC or DTC by theSCIn_TXI interrup trequest.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to theTDR

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

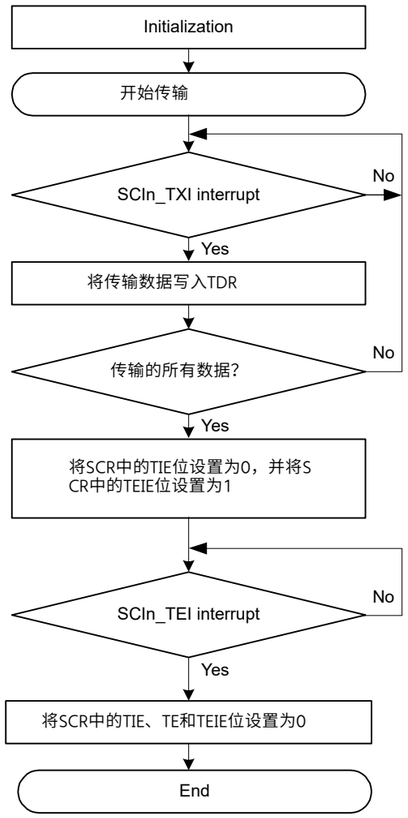
Figure 30.69 Example flow of serial transmission in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 30.70 shows an example of serial transmission in clock synchronous mode with FIFO selected.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the FTDRL[*1] register to the TSR register when data is written to FTDRL[*1] in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 but only after the SCR.TIE bit is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from FTDRL to TSR, the SCI starts transmission. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, the SSR_FIFO.TDFE is set to 1. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to FTDRL in the SCIn_TXI interrupt handling routine before transmission of the current transmit data has finished. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks whether non-transmitted data remains in FTDRL on output of the stop bit.



[1] [1]SCI初始化：设置数据传输。

[2] [2]通过SCIn_TXI中断请求将发送数据写入TDR：当发送数据从TDR传输到TSR时，会产生发送数据空中断(SCIn_TXI)请求。传输数据从SCIn_TXI请求的处理例程中写入一次TDR。

[3] [3]串行传输继续程序：要继续串行传输，在接受传输数据空中断（SCIn_TXI）请求后将传输数据写入TDR。发送数据也可以通过SCIn_TXI中断请求激活DMAC或DTC写入TDR。当SCIn_TEI中断请求正在使用时，设置

将要传输的最后一个数据写入TDR后，SCR.TIE位为0，SCR.TEIE位为1

Note: 当使用外部时钟时（SCR.CKE[1:0]位的值为10b或11b），SCKn引脚上最后一位的上升沿将SSR.TEND标志设置为1。设置SCR.TE位在这之后立即变为0可能会导致接收端接收数据保持时间不足。

Figure 30.69 选择非FIFO的时钟同步模式下的串行传输示例流程

(2)选择FIFO图30.70显示了在时钟同步模式下选择FIFO的串行传输示例。

在串行数据传输中，SCI操作如下：

1.当数据写入FTDRL*1时，SCI将数据从FTDRL*1寄存器传输到TSR寄存器
SCIn_TXI中断处理程序。可写入FTDRL的数据量为16减去FDR.T[4:0]字节。发送开始时的SCIn_TXI中断请求在SCR.TE位设置为1时产生，但仅在SCR.TIE位也设置为1或当这两个位通过一条指令同时设置为1时产生。

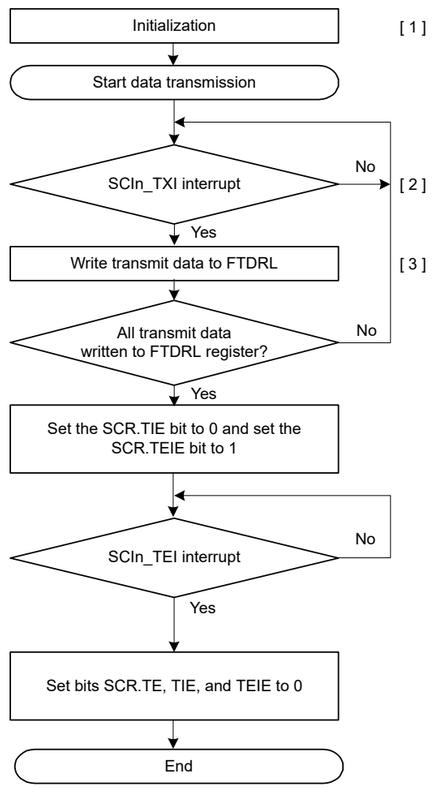
2.将数据从FTDRL传输到TSR后，SCI开始传输。当写入FTDRL的发送数据量等于或小于指定的发送触发数时，SSR_FIFO.TDFE设置为1。当
SCR.TIE位设置为1，产生SCIn_TXI中断请求。在当前发送数据的发送完成之前，通过在SCIn_TXI中断处理例程中将下一个发送数据写入FTDRL来启用连续发送。当使用SCIn_TEI中断请求时，在SCIn_TXI请求的处理例程中将要发送的最后一个数据写入FTDRL后，将SCR.TIE位设置为0，并将SCR.TEIE位设置为1。

3.指定时钟输出模式时，与输出时钟同步，指定使用外部时钟时，与输入时钟同步，从TXDn引脚发送8位数据。当SPMR.CTSE位为1时，时钟信号的输出被暂停，直到输入CTS信号为低电平。

4.SCI在停止位输出时检查未传输的数据是否保留在FTDRL中。

5. When FTDRL is updated, the next transmit data is transferred from FTDRL to TSR and serial transmission of the next frame starts.
6. If FTDRL is not updated, the SSR_FIFO.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Note 1. In clock synchronous mode, FTDRH is not used.



[1]SCI initialization:
Set data transmission.
After the TE bit in SCR is set to 1, 1 is output for a frame, and transmission is enabled.

[2]Transmit data write to FTDRL by an SCIn_TXI interrupt request:
For transmission data from FTDRL to TSR, when the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL once in the SCIn_TXI interrupt handling routine.

[3]Serial transmission continuation procedure:
To continue serial transmission, write the next transmit data to FTDRL in this SCIn_TXI interrupt handling routine and clear the SSR_FIFO.TDFE flag to 0 before transmission of the current transmit data finishes.
Transmit data can also be written to FTDRL by activating the DMAC or DTC. The TDFE flag is cleared automatically in this case. Do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL.

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR_FIFO.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

Figure 30.70 Example flow of serial transmission in clock synchronous mode with FIFO selected

30.6.5 Serial Data Reception in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 30.71 and Figure 30.72 show examples of SCI operation for serial reception in clock synchronous mode.

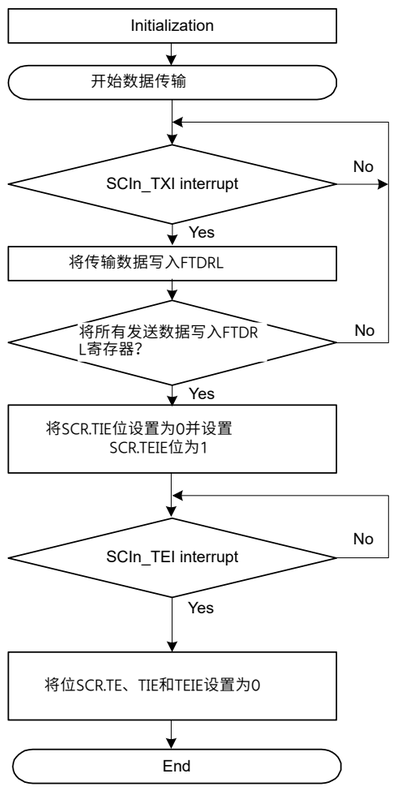
In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.

5.当FTDRL更新时，下一个传输数据从FTDRL传输到TSR并开始下一帧的串行传输。

6.如果FTDRL未更新，则SSR_FIFO.TEND标志设置为1。TXDn引脚保持最后一位的输出状态。如果SCR.TEIE位为1，则产生SCIn_TEI中断请求并且SCKn引脚保持高电平。

注1.在时钟同步模式下，不使用FTDRH。



[1]SCI初始化：设置数据传输。
SCR中的TE位设置为1后，每帧输出1，使能传输。

[2]通过SCIn_TXI中断请求向FTDRL发送数据写入：对于从FTDRL到TSR的发送数据，当写入FTDRL的发送数据量等于或小于指定的发送触发数时，发送数据FIFO空中断（SCIn_TXI)请求被生成。在SCIn_TXI中断处理例程中将发送数据写入FTDRL一次。

[3]串行传输继续程序：要继续串行传输，在这个SCIn_TXI中断处理程序中将下一个传输数据写入FTDRL并清除

在当前传输数据传输完成之前，SSR_FIFO.TDFE标志为0。发送数据也可以通过激活

DMAC或DTC。在这种情况下，TDFE标志会自动清除。
不要写入TDFE标志。
当SCIn_TEI中断请求正在使用时，设置
在将要传输的最后一个数据写入FTDRL后，SCR.TIE位为0，SCR.TEIE位为1。

Note: 当使用外部时钟时（SCR.CKE[1:0]位的值为10b或11b），SCKn引脚上最后一位的上升沿将SSR_FIFO.TEND标志设置为1。设置SCR.TE位在这之后立即变为0可能会导致接收端接收数据保持时间不足。

30.6.5 时钟同步模式下的串行数据接收

(1) Non-FIFO selected

图30.71和图30.72显示了时钟同步模式下串行接收的SCI操作示例。

在串行数据接收中，SCI操作如下：

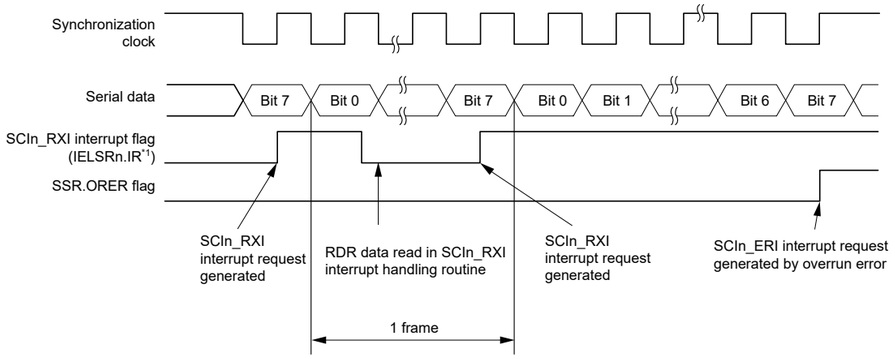
1.当SCR.RE位的值变为1时，CTSn_RTSn引脚变为低电平。

2.SCI执行内部初始化，并与同步时钟输入或输出同步开始接收数据，并将接收数据存储在RSR寄存器中。

3.如果发生溢出错误，则SSR.ORER标志设置为1。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。接收数据不传送到RDR寄存器。

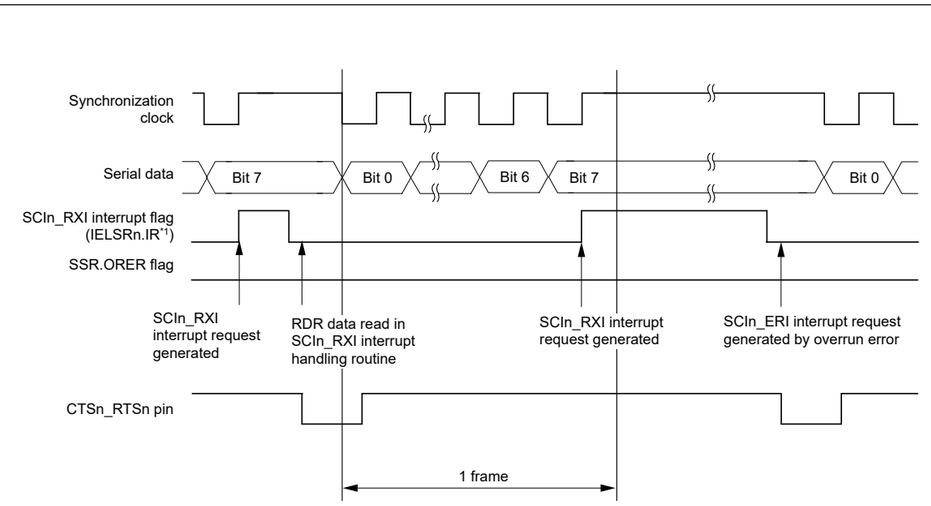
RA生态工作室

4. When reception completes successfully, receive data is transferred to the RDR register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the received data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that is transferred to RDR causes the CTSn_RTSn pin to output low.



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.71 Example operation for serial reception in clock synchronous mode (1) when the RTS function is not used

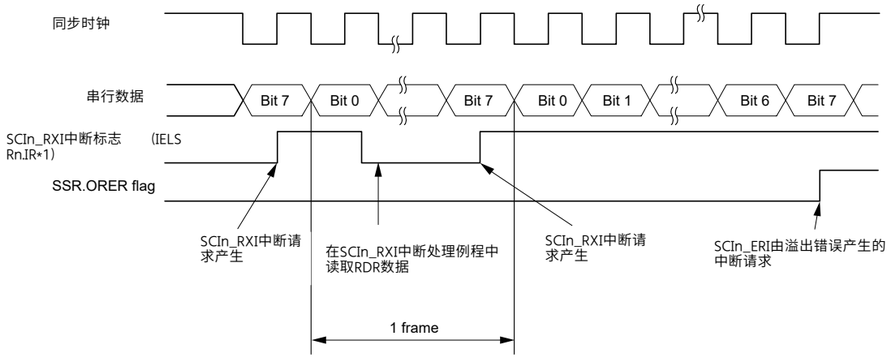


Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.72 Example operation for serial reception in clock synchronous mode (2) when RTS function is used

Data transfer cannot resume while the receive error flag is 1. Therefore, clear the ORER, FER, and PER flags in the SSR register to 0 before resuming data reception. Additionally, always read the RDR register during overrun error processing. When a data reception is forced to terminate by a 0 write to the SCR.RE bit during operation, read the RDR register because received data that is not yet read might be left in the RDR register.

4.当接收成功完成时，接收数据被传送到RDR寄存器。如果SCR.RIE位为1，则SCIn_RXI中断请求产生。连续接收是通过读取接收到的数据传输到在接收下一个接收数据完成之前，SCIn_RXI中断处理程序中的RDR寄存器。读取传输到RDR的接收数据会导致CTSn_RTSn引脚输出低电平。



注1.有关相应中断事件编号的信息，请参见第13节，中断控制器单元(ICU)。

Figure 30.72 使用RTS功能时时钟同步模式下串行接收的示例操作(2)

接收错误标志为1时无法恢复数据传输。因此，在恢复数据接收之前，将SSR寄存器中的ORER、FER和PER标志清除为0。此外，在溢出错误处理期间始终读取RDR寄存器。如果在操作期间通过向SCR.RE位写入0来强制终止数据接收，请读取RDR寄存器，因为尚未读取的已接收数据可能会留在RDR寄存器中。

(2) FIFO selected

Figure 30.74 shows an example of serial reception in clock synchronous mode with FIFO selected.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.

(2)选择FIFO图30.74显示了在时钟同步模式下选择FIFO的串行接收示例。

在串行数据接收中，SCI操作如下：

1.当SCR.RE位的值变为1时，CTSn_RTSn引脚变为低电平。

2.SCI执行内部初始化，并与同步时钟输入或输出同步开始接收数据，并将接收数据存储在RSR寄存器中。

3. If an overrun error occurs, the SSR_FIFO.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Received data is not transferred to the FRDRL[*1] register.
4. When data reception completes successfully, the receive data is transferred to the FRDRL[*1] register. The RDF flag is set to 1 when the amount of the receive data stored in FRDRL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous data reception is enabled by reading the receive data transferred to FRDRL[*2] in the SCIn_RXI interrupt handling routine before an overrun error occurs. If the amount of received data that is transferred to FRDRL is less than the RTS trigger number, the CTSn_RTSn pin goes low.

Note 1. In clock synchronous mode, FRDRH is not used.
Note 2. Read data in order from FRDRH to FRDRL when RDF and ORER are read with receive data.

3.如果发生溢出错误，则SSR_FIFO.ORER标志设置为1。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。接收到的数据不传送到FRDRL*1寄存器。

4.当数据接收成功完成时，接收数据被传送到FRDRL*1寄存器。当存储在FRDRL中的接收数据量等于或大于指定的接收触发数时，RDF标志设置为1。如果SCR.RIE位为1，则产生SCIn_RXI中断请求。在发生溢出错误之前，通过在SCIn_RXI中断处理程序中读取传输到FRDRL*2的接收数据来启用连续数据接收。如果传输到FRDRL的接收数据量小于RTS触发数，则CTSn_RTSn引脚变为低电平。

注1.在时钟同步模式下，不使用FRDRH。
注2.RDF和ORER与接收数据一起读取时，按FRDRH到FRDRL的顺序读取数据。

If a receive error occurs, read the ORER flag in SSR_FIFO, perform the relevant error processing, then set the SSR_FIFO.ORER flag to 0. Data reception cannot resume while the ORER flag is 1.

[4]The receive data stored in FRDRL register is read until the amount of stored data is less than the FCR.RTRG[3:0] value. Software can check readable data in FDR.R[4:0].

[5]Serial reception continuation procedure:

30.7 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

30.7.1 Example Connection

Figure 30.77 shows an example connection between a smart card (IC card) and the MCU. As shown in Figure 30.77, because the MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

Setting the SCR_SMCI.TE and SCR_SMCI.RE bits to 1 with an IC card disconnected enables closed-loop transmission or reception, allowing self-diagnosis. To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.

An output port of the MCU can be used to output a reset signal.

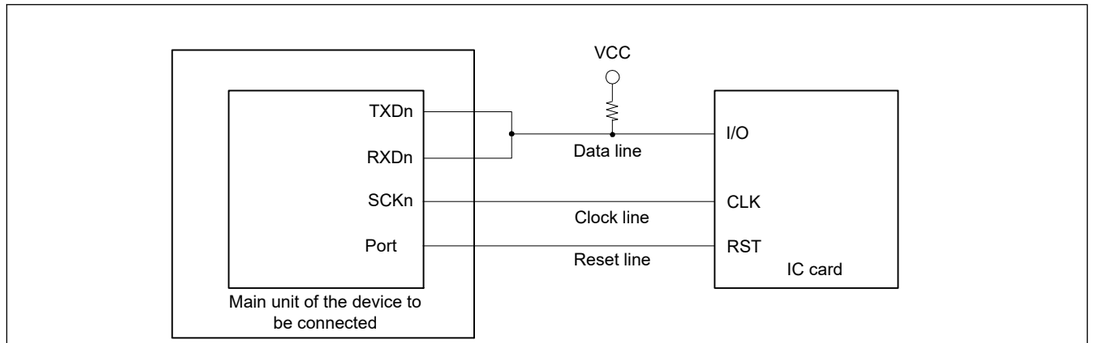

Figure 30.77 Example connection with a smart card (IC card)

30.7.2 Data Format (Except in Block Transfer Mode)

Figure 30.78 shows the data transfer formats in smart card interface mode:

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 ETUs (elementary time unit – the time required for transferring 1 bit) is set as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low error signal is output for 1 ETU after 10.5 ETUs elapse from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 ETUs.

30.7 智能卡接口模式下的操作

SCI支持符合ISOIEC7816-3（识别卡标准）的智能卡（IC卡）接口，作为SCI的扩展功能。

可以使用适当的寄存器选择智能卡接口模式。

30.7.1 示例连接

图30.77显示了智能卡（IC卡）和MCU之间的示例连接。如图30.77所示，由于MCU使用单条传输线与IC卡通信，因此将TXDn和RXDn引脚互连，并使用电阻将数据传输线上拉到VCC。

在断开IC卡的情况下将SCR_SMCI.TE和SCR_SMCI.RE位设置为1可启用闭环发送或接收，从而实现自诊断。要将SCI产生的时钟脉冲提供给IC卡，请将SCKn引脚输出输入到IC卡的CLK引脚。

MCU的输出端口可用于输出复位信号。

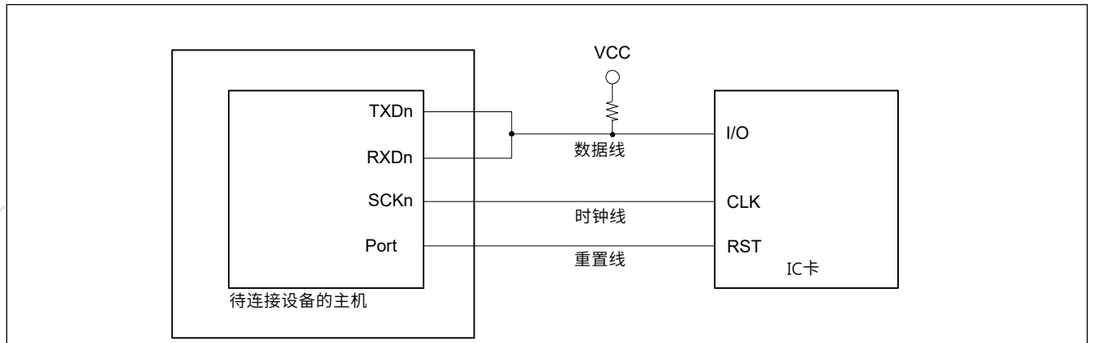

Figure 30.77 与智能卡（IC卡）的连接示例

30.7.2 数据格式（块传输模式除外）

图30.78显示了智能卡接口模式下的数据传输格式：

- 一帧由8位数据和一个异步模式的奇偶校验位组成。
- 在传输过程中，至少设置2个ETU（基本时间单位——传输1位所需的时间）作为从奇偶校验位结束到下一帧开始的保护时间。
- 如果在接收过程中检测到奇偶校验错误，则在从起始位经过10.5ETU后输出1ETU的低错误信号。
- 如果在传输过程中对错误信号进行采样，相同的数据会在至少2个ETU后自动重传。

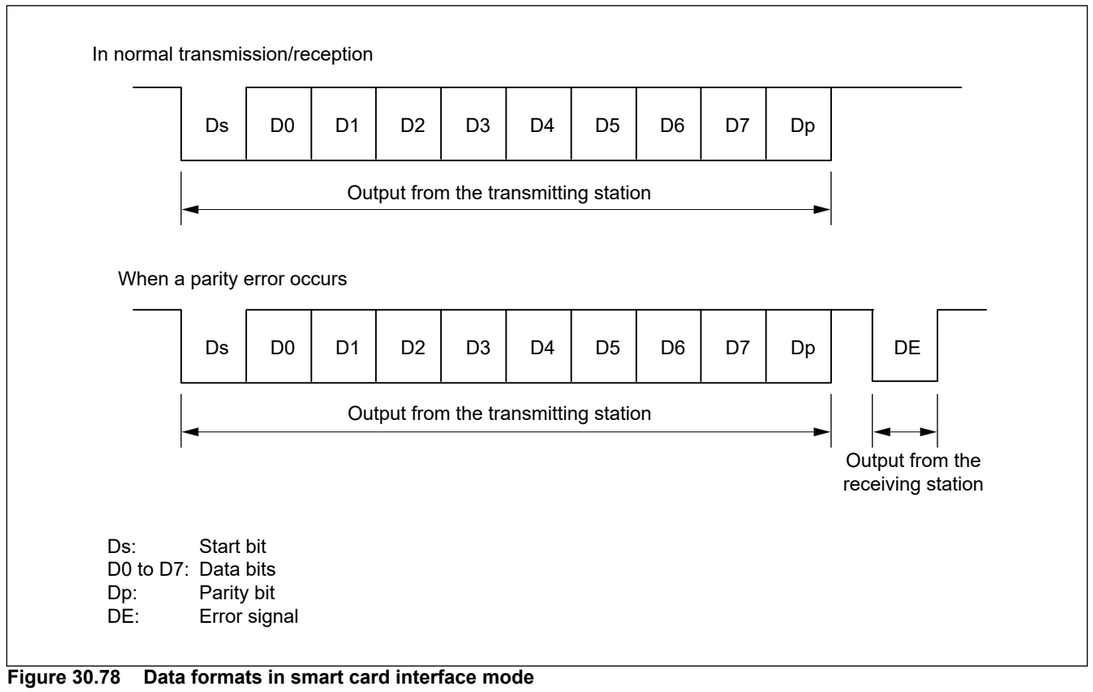

Figure 30.78 Data formats in smart card interface mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedures in this section.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 indicate the Z and A states, respectively, and data is transferred with LSB-first for the start character, as shown in Figure 30.79. Therefore, data in the start character in the figure is 0x3B.

When using the direct convention type, write 0 to both the SCMR.SDIR and SCMR.SINV bits. Write 0 to the SMR_SMCI.PM bit to use even parity, which is prescribed by the smart card standard.

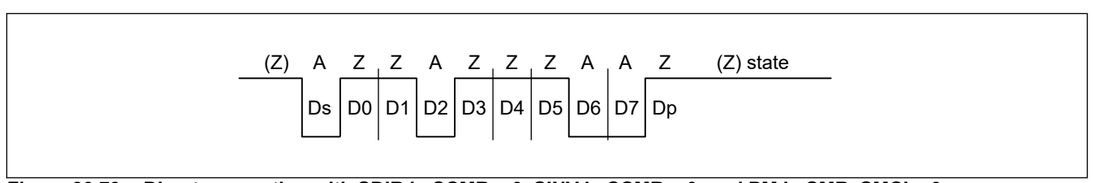

Figure 30.79 Direct convention with SDIR in SCMR = 0, SINV in SCMR = 0, and PM in SMR_SMCI = 0

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 indicate the A and Z states, respectively, and data is transferred with MSB-first for the start character, as shown in Figure 30.80. Therefore, data in the start character in the figure is 0x3F.

When using the inverse convention type, write 1 to both the SCMR.SDIR and SCMR.SINV bits. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to the Z state. Because the SINV bit of the MCU only inverts data bits D7 to D0, write 1 to the PM bit in SMR_SMCI to invert the parity bit for both transmission and reception.

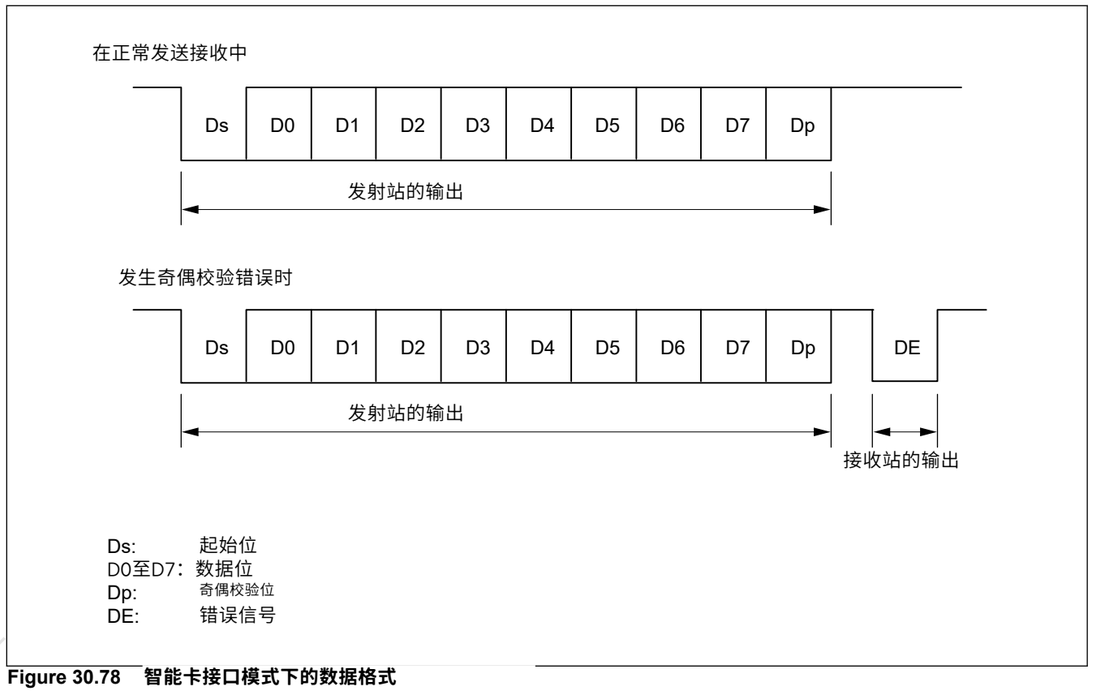

Figure 30.78 智能卡接口模式下的数据格式

与直接约定型和逆约定型IC卡进行通信时，请按照本节的步骤进行。

(1) 直接约定型

对于直接约定类型，逻辑电平1和0分别表示Z和A状态，数据通过LSB-first为起始字符，如图30.79所示。因此，图中起始字符中的数据为0x3B。

使用直接约定类型时，将0写入SCMR.SDIR和SCMR.SINV位。将0写入SMR_SMCI.PM位使用智能卡标准规定的偶校验。

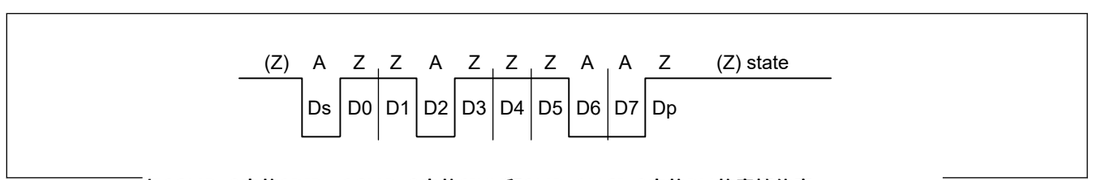

Figure 30.79 与SCMR=0中的SDIR、SCMR=0中的SINV和SMR_SMCI=0中的PM的直接约定

(2) 逆约定型

对于逆约定类型，逻辑电平1和0分别表示A和Z状态，数据通过MSB-first为起始字符，如图30.80所示。因此，图中起始字符中的数据为0x3F。

使用逆约定类型时，将1写入SCMR.SDIR和SCMR.SINV位。奇偶校验位为逻辑电平0，产生偶校验，这是智能卡标准规定的，对应于Z状态。由于MCU的SINV位仅将数据位D7反转为D0，因此向SMR_SMCI中的PM位写入1以反转发送和接收的奇偶校验位。

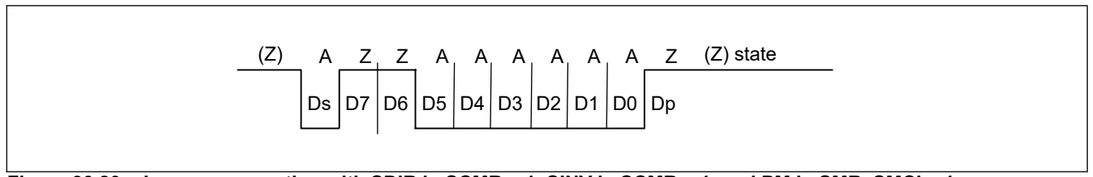

Figure 30.80 Inverse convention with SDIR in SCMR = 1, SINV in SCMR = 1, and PM in SMR_SMCI = 1

30.7.3 Block Transfer Mode

Block transfer mode differs from normal smart card interface mode as follows:

- Even if a parity error is detected during reception, no error signal is output. Because the PER flag in SSR_SMCI is set by error detection, clear the PER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 ETU is set as a guard time from the end of the parity bit until the start of the next frame
- Because the same data is not retransmitted, the TEND flag in SSR_SMCI is set to 11.5 ETUs after transmission starts
- In block transfer mode, the ERS flag in SSR_SMCI indicates the error signal status as in normal smart card interface mode, but the flag is read as 0 because no error signal is transferred

30.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate set up in the SCMR.BCP2 and the SMR_SMCI.BCP[1:0] bits. The frequency is always 16 times the bit rate in normal asynchronous mode.

For data reception, the falling edge of the start bit is sampled with the base clock to perform internal synchronization.

Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 30.81. The reception margin is determined by the following formula:

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%]$$

M: Reception margin (%)

N: Ratio of bit rate to clock ($N = 32, 64, 372, 256$)

D: Duty cycle of clock ($D = 0$ to 1.0)

L: Frame length ($L = 10$)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the specified formula, the reception margin is determined using the following formula:

$$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\ \%$$

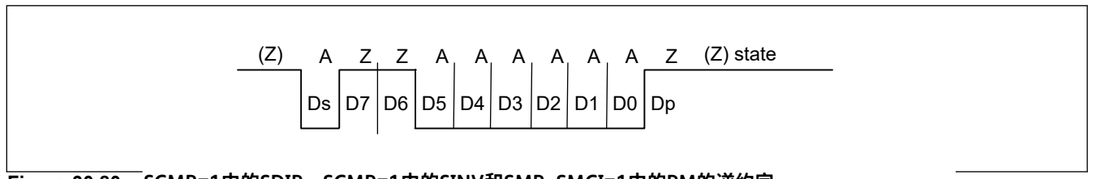

Figure 30.80 SCMR=1中的SDIR、SCMR=1中的SINV和SMR_SMCI=1中的PM的逆约定

30.7.3 块传输模式

块传输模式与普通智能卡接口模式的区别如下：

●即使在接收过程中检测到奇偶校验错误，也不会输出错误信号。因为SSR_SMCI中的PER标志是由错误检测设置的，所以在接收下一帧的奇偶校验位之前清除PER标志。

●在传输过程中，从奇偶校验位结束到下一帧开始至少设置1个ETU作为保护时间

●由于没有重传相同的数据，所以在传输开始后，SSR_SMCI中的TEND标志设置为11.5ETU

●在块传输模式下，SSR_SMCI中的ERS 标志指示错误信号状态，与普通智能卡接口模式一样，但该标志被读取为0，因为没有传输错误信号

30.7.4 接收数据采样时序和接收裕量

只有片内波特率发生器产生的内部时钟可以用作智能卡接口模式下的传输时钟。

在这种模式下，SCI可以在频率为SCMR.BCP2和SMR_SMCI.BCP[1:0]位。在正常异步模式下，频率始终是比特率的16倍。

对于数据接收，起始位的下降沿用基准时钟进行采样，以进行内部同步。

接收数据在基本时钟的第16、32、186、128、46、64、93和256个上升沿进行采样，以便在每个位的中间锁存，如图30.81所示。接收余量由以下公式确定：

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%]$$

M：接收余量（%）

N：比特率与时钟的比率（N=32、64、372、256）

D：时钟的占空比（D=0到1.0）

L：帧长（L=10）

F：时钟频率偏差的绝对值

假设指定公式中的F=0、D=0.5和N=372的值，则使用以下公式确定接收余量：

$$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\ \%$$

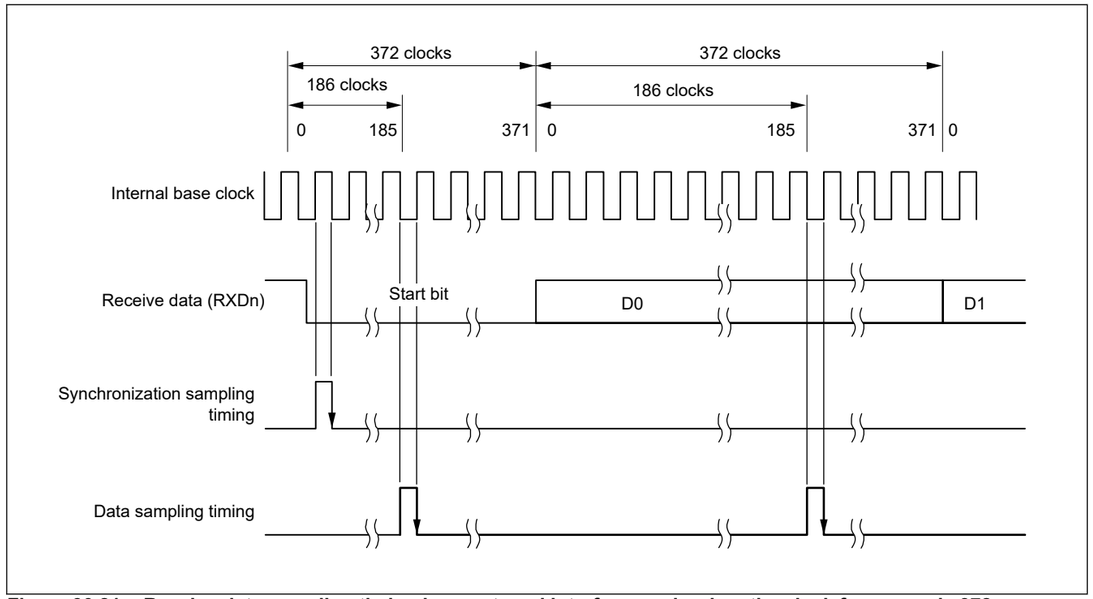

Figure 30.81 Receive data sampling timing in smart card interface mode when the clock frequency is 372 times the bit rate

30.7.5 SCI Initialization (Smart Card Interface Mode)

Before transmitting and receiving data, write the initial value 0x00 in the SCR_SMCI register and initialize the SCI following the example flow shown in Table 30.39.

Always set the initial value in the TIE, RIE, TE, RE, TEIE bits in the SCR_SMCI register before switching from transmission to reception mode or from reception to transmission mode. When SCR_SMCI.RE is set to 0, the RDR register is not initialized.

To change from reception mode to transmission mode, first check that reception has completed, then initialize the SCI. At the end of initialization, set SCR_SMCI.TE = 1 and SCR_SMCI.RE = 0. Reception completion can be verified by reading the SCIn_RXI request, ORER, or PER flag in SSR_SMCI.

To change transmission mode to reception mode, first check that transmission has completed, then initialize the SCI. At the end of initialization, set SCR_SMCI.TE = 0 and SCR_SMCI.RE = 1. Transmission completion can be verified by reading the TEND flag in SSR_SMCI.

30.7.5 SCI初始化（智能卡接口模式）

在发送和接收数据之前，将初始值0x00写入SCR_SMCI寄存器并按照表30.39所示的示例流程初始化SCI。

在从发送模式切换到接收模式或从接收模式切换到发送模式之前，请务必在SCR_SMCI寄存器中的TIE、RIE、TE、RE、TEIE位中设置初始值。当SCR_SMCI.RE设置为0时，RDR寄存器未初始化。

要从接收模式更改为发送模式，首先检查接收是否完成，然后初始化SCI。在初始化结束时，设置SCR_SMCI.TE=1和SCR_SMCI.RE=0。可以通过读取SSR_SMCI中的SCIn_RXI请求、ORER或PER标志来验证接收完成。

要将传输模式更改为接收模式，首先检查传输是否完成，然后初始化SCI。在初始化结束时，设置SCR_SMCI.TE=0和SCR_SMCI.RE=1。可以通过读取SSR_SMCI中的TEND标志来验证传输完成。

30.7.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode) is different from that in non-smart card interface mode, in that an error signal is sampled and data can be re-transmitted in smart card mode. Figure 30.82 shows the data re-transfer operation during transmission.

1. When an error signal from the receiver end is sampled after 1-frame data is transmitted, the SSR_SMCI.ERS flag is set to 1. If the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
2. For a frame in which an error signal is received, the SSR_SMCI.TEND flag is not set. Data is re-transferred from TDR to TSR, allowing automatic data retransmission.
3. If no error signal is returned from the receiver, the ERS flag is not set to 1.
4. In this case, the SCI determines that transmission of 1-frame data, including the re-transfer, is complete, and the TEND flag is set. If the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated. Write transmit data to the TDR to start transmission of the next data.

Figure 30.84 shows an example flow of serial transmission. All the processing steps are automatically performed using an SCIn_TXI interrupt request to activate the DTC or DMAC.

When the SSR_SMCI.TEND flag is set to 1 in transmission and when the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated.

The DTC or DMAC is activated by an SCIn_TXI interrupt request if the SCIn_TXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission when an error occurs. Because the ERS flag is not automatically cleared, set the RIE bit to 1 before enabling an SCIn_ERI interrupt request to be generated if an error occurs, and clear the ERS flag to 0.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings.

For DTC or DMAC settings, see section 17, Data Transfer Controller (DTC), section 16, DMA Controller (DMAC).

30.7.6 串行数据传输（块传输模式除外）

智能卡接口模式下的串行数据传输（块传输模式除外）与非智能卡接口模式下的串行数据传输不同之处在于，在智能卡模式下对错误信号进行采样，数据可以重新传输。图30.82显示了传输过程中的数据重传操作。

1.发送1帧数据后，在接收端采样到错误信号时，SSR_SMCI.ERS标志置1。如果SCR_SMCI.RIE位为1，则产生SCIn_ERI中断请求。在采样下一个奇偶校验位之前将ERS 标志清零。

2.对于接收到错误信号的帧，不设置SSR_SMCI.TEND标志。数据从TDR重新传输到TSR，允许自动数据重新传输。

3.如果接收器没有返回错误信号，则ERS 标志不设置为1。

4.在这种情况下，SCI确定1帧数据的传输（包括重新传输）已完成，并设置TEND标志。如果SCR_SMCI.TIE位为1，则产生SCIn_TXI中断请求。将传输数据写入TDR以开始传输下一个数据。

图30.84显示了串行传输的示例流程。所有处理步骤都使用一个自动执行SCIn_TXI中断请求以激活DTC或DMAC。

当发送中SSR_SMCI.TEND标志设置为1且SCR_SMCI.TIE位为1时，将产生SCIn_TXI中断请求。

如果先前将SCIn_TXI中断请求指定为DTC或DMAC激活源，则DTC或DMAC由SCIn_TXI中断请求激活，从而允许传输发送数据。当DTC或DMAC传输数据时，TEND标志自动设置为0。

如果发生错误，SCI会自动重新传输相同的数据。在此重传期间，TEND标志保持为0，并且DTC或DMAC未激活。因此，SCI和DTC或DMAC会自动传输指定的字节数，包括发生错误时的重传。因为ERS 标志不会自动清零，所以如果发生错误，在使能SCIn_ERI中断请求之前将RIE位设置为1，并将ERS 标志清零。

使用DTC或DMAC发送或接收数据时，请务必在进行SCI设置之前启用DTC或DMAC。

对于DTC或DMAC设置，请参阅第17节，数据传输控制器(DTC)，第16节，DMA控制器(DMAC)。

30.7.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 30.85 shows the data re-transfer operation in reception mode.

1. If a parity error is detected in the receive data, the SSR_SMCI.PER flag is set to 1. When the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no SCIn_RXI interrupt is generated.
3. When no parity error is detected, the SCR_SMCI.PER flag is not set to 1.
4. In this case, data is determined to be received successfully. When the SCR_SMCI.RIE bit is 1, an SCIn_RXI interrupt request is generated.

Figure 30.86 shows an example flow of serial data reception. All the processing steps are automatically performed using an SCIn_RXI interrupt request to activate the DTC or DMAC.

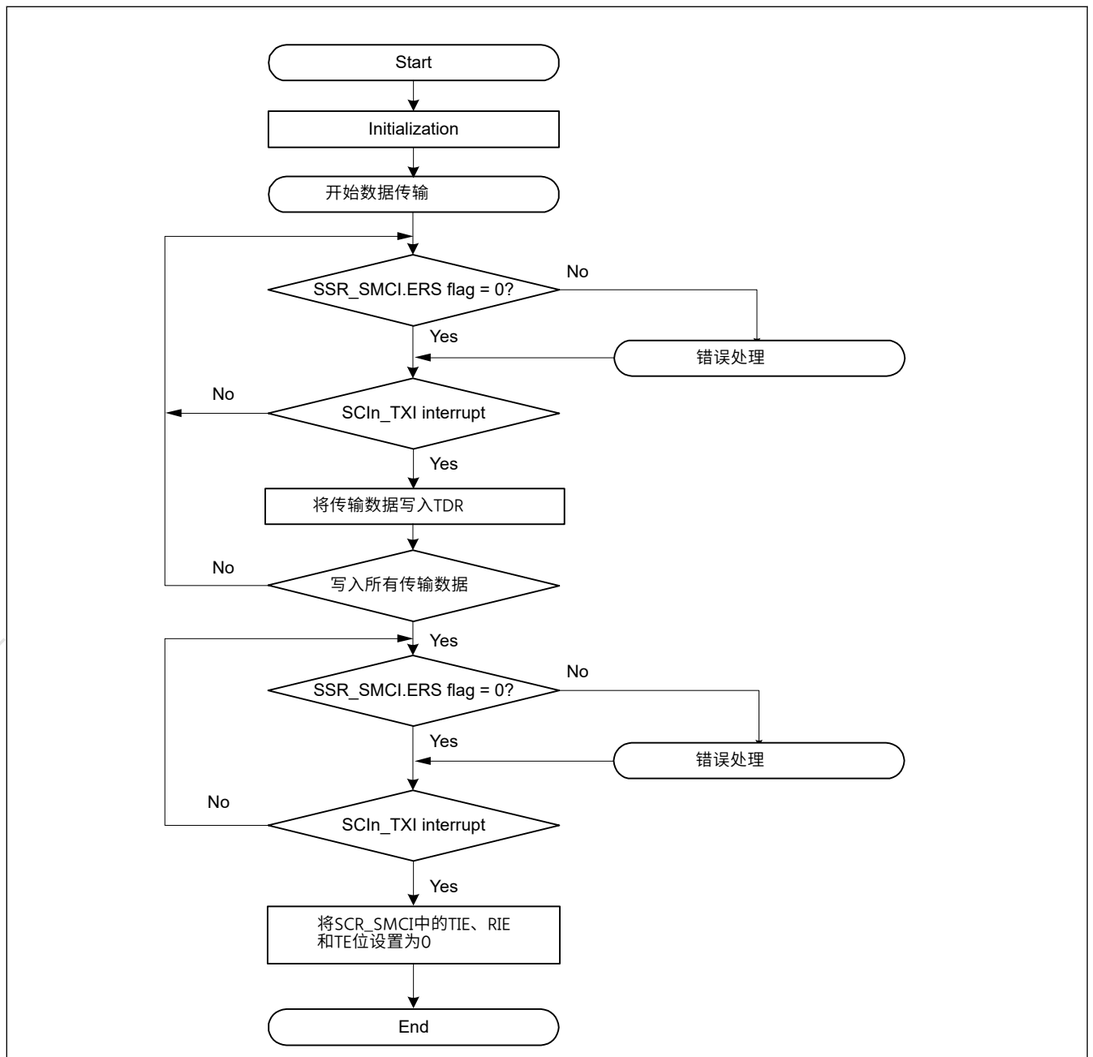

Figure 30.84 智能卡接口传输示例流程

30.7.7 串行数据接收（块传输模式除外）

智能卡接口模式下的串行数据接收与非智能卡接口模式下的串行数据接收类似。图30.85显示了接收模式下的数据重传操作。

1.如果在接收数据中检测到奇偶校验错误，则SSR_SMCI.PER标志设置为1。当SCR_SMCI.RIE位为1时，产生SCIn_ERI中断请求。在采样下一个奇偶校验位之前将PER标志清零。

2.对于检测到奇偶校验错误的帧，不产生SCIn_RXI中断。

3.未检测到奇偶校验错误时，SCR_SMCI.PER标志不设置为1。

4、在这种情况下，确定数据接收成功。当SCR_SMCI.RIE位为1时，产生SCIn_RXI中断请求。

图30.86显示了串行数据接收的示例流程。所有处理步骤都使用一个自动执行SCIn_RXI中断请求以激活DTC或DMAC。

RA生态工作室

In reception, setting the RIE bit to 1 allows an SCIn_RXI interrupt request to be generated. The DTC or DMAC is activated by an SCIn_RXI interrupt request if the SCIn_RXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in SSR_SMCI is set to 1, a receive error interrupt (SCIn_ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.

If a parity error occurs and the PER flag is set to 1 during reception, the receive data is transferred to RDR, allowing the data to be read.

When a reception is forced to terminate by setting SCR_SMCI.RE to 0 during operation, read the RDR register because the received data that is not yet read might be left in the RDR.

Note: For operations in block transfer mode, see section 30.3.9. Serial Data Reception in Asynchronous Mode.

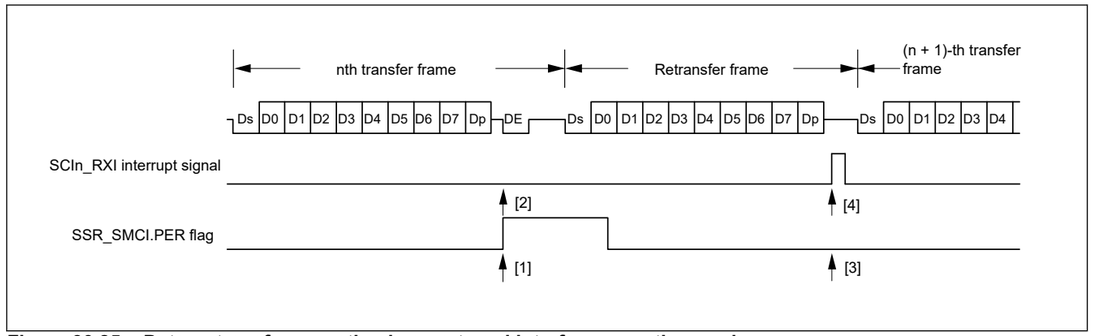

Figure 30.85 Data re-transfer operation in smart card interface reception mode

在接收时，将RIE位设置为1允许产生SCIn_RXI中断请求。如果先前将SCIn_RXI中断请求指定为DTC或DMAC激活源，则DTC或DMAC由SCIn_RXI中断请求激活，从而允许传输接收数据。

如果接收期间发生错误并且SSR_SMCI中的ORER或PER标志设置为1，则会生成接收错误中断(SCIn_ERI)请求。错误发生后清除错误标志。如果发生错误，则不会激活DTC或DMAC并跳过接收数据。因此，将传输DTC或DMAC中指定的接收数据字节数。

如果在接收过程中发生奇偶校验错误并且PER标志设置为1，则接收数据将传输到RDR，从而可以读取数据。

如果在操作期间通过将SCR_SMCI.RE设置为0来强制终止接收，请读取RDR寄存器，因为尚未读取的已接收数据可能留在RDR中。

Note: 关于块传输模式下的操作，请参见第30.3.9节。异步模式下的串行数据接收。

30.7.8 Clock Output Control

When the GM bit in SMR_SMCI is set to 1, the clock output can be controlled by the CKE[1:0] bits in SCR_SMCI. For details on the CKE[1:0] bits, see section 30.2.12. SMR_SMCI : Serial Mode Register for Smart Card Interface Mode (SCMR.SMIF = 1). When setting the clock output, the base clock described in section 30.7.4. Receive Data Sampling Timing and Reception Margin is applied.

Figure 30.87 shows an example timing for the clock output control when the CKE[1] bit in SCR_SMCI is set to 0 and the CKE[0] bit in SCR_SMCI is controlled.

When the GM bit in SMR_SMCI is 0, output control by the CKE[0] bit in SCR_SMCI is immediately reflected on the SCKn pin, so there is a possibility that pulses with an unintended width may be output from the SCKn pin.

When the GM bit in SMR_SMCI is 1, the clock with the same pulse width as the base clock is output even if the CKE[0] bit in SCR_SMCI is changed.

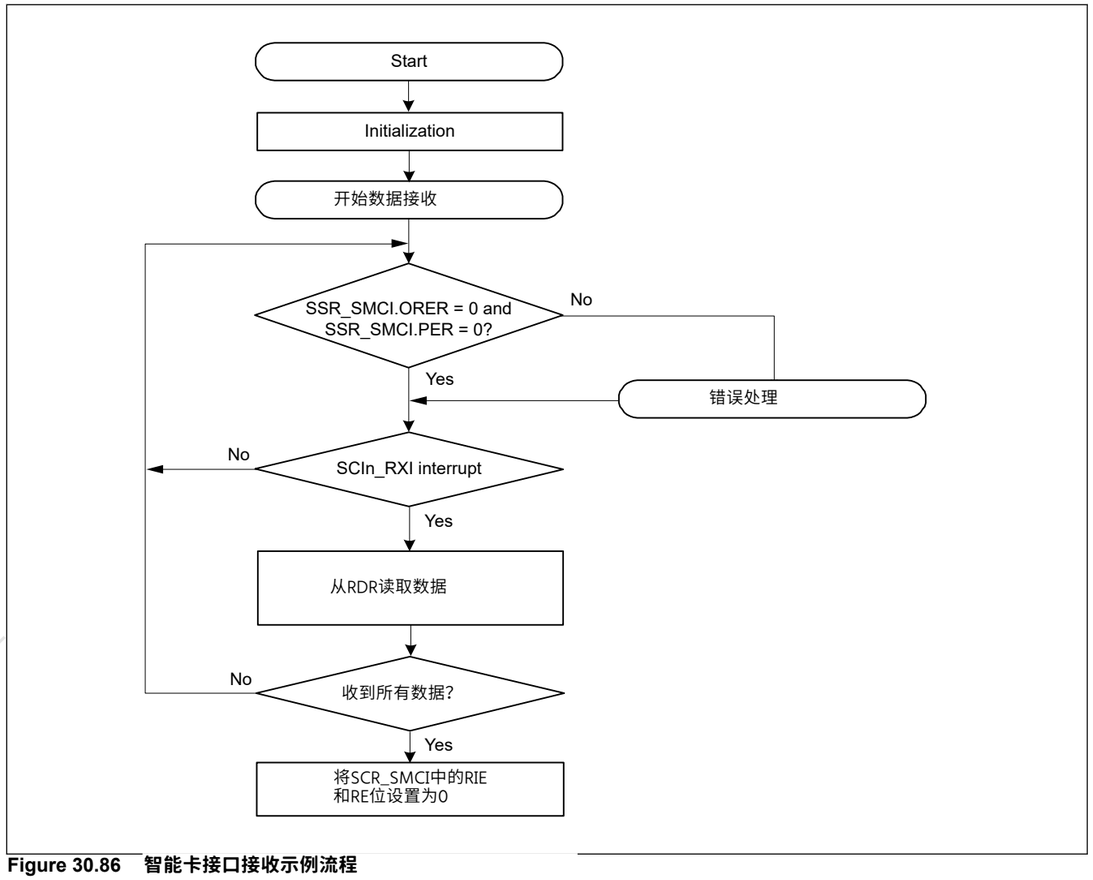

Figure 30.86 智能卡接口接收示例流程

30.7.8 时钟输出控制

当SMR_SMCI中的GM位设置为1时，时钟输出可以由SCR_SMCI中的CKE[1:0]位控制。有关CKE[1:0]位的详细信息，请参见第30.2.12节。SMR_SMCI：智能卡接口模式的串行模式寄存器(SCMR.SMIF=1)。设置时钟输出时，使用第30.7.4节中描述的基本时钟。应用接收数据采样时序和接收裕度。

图30.87显示了当SCR_SMCI中的CKE[1]位设置为0且控制SCR_SMCI中的CKE[0]位。

当SMR_SMCI中的GM位为0时，SCR_SMCI中CKE[0]位的输出控制立即反映在SCKn引脚，因此有可能会从SCKn引脚输出具有意外宽度的脉冲。

当SMR_SMCI中的GM位为1时，即使SCR_SMCI中的CKE[0]位发生变化，也会输出与基本时钟脉冲宽度相同的时钟。

30.8 Operation in Simple IIC Mode

Simple IIC mode format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device can specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8 data bits in all frames are transmitted in order from the MSB.

The I^2C bus format and timing of the I^2C bus are shown in Figure 30.88 and Figure 30.89.

30.8 简单IIC模式下的操作

简单IIC模式格式由8个数据位和一个确认位组成。通过在启动条件或重新启动条件之后继续进入从地址帧，主设备可以指定从设备作为通信伙伴。当前指定的从设备保持有效，直到指定新的从设备或满足停止条件。所有帧中的8个数据位从MSB开始按顺序传输。

I2C总线格式和I2C总线时序如图30.88和图30.89所示。

30.8.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the SIMR3.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept in the released state
- The hold time for the start condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the IICSTAREQ bit in SIMR3 is set to 0, and a start-condition generated interrupt is output

Writing 1 to the IICRSTAREQ bit in SIMR3 causes the generation of a restart condition. The generation of a restart condition proceeds through the following operations:

- The SDAn line is released and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SDAn line falls (from the high level to the low level)
- The hold time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the SIMR3.IICRSTAREQ bit is set to 0, and a restart-condition generated interrupt is output

Writing 1 to the SIMR3.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)

30.8.1 启动、重启和停止条件的生成

将1写入SIMR3.IICSTAREQ位会导致产生启动条件。开始条件的生成通过以下操作进行：

●SDAn线上的电平下降（从高电平到低电平），SCLn线保持在释放状态

●开始条件的保持时间设置为比特周期的一半，比特率由BRR设置确定

●SCLn线上的电平下降（从高电平到低电平），SIMR3中的IICSTAREQ位设置为0，并输出一个起始条件产生的中断

将1写入SIMR3中的IICRSTAREQ位会导致产生重启条件。重新启动条件的生成通过以下操作进行：

●SDAn线释放，SCLn线保持低电平

●SCLn线的低电平周期设置为比特周期的一半，比特率由BRR设置确定

●SCLn线被释放（由低电平转变为高电平）

●当在SCLn线上检测到高电平时，重新启动条件的建立时间设置为BRR设置确定的比特率的半个比特周期

●SDAn线上的电平下降（从高电平到低电平）

●重启条件的保持时间设置为比特周期的一半，比特率由BRR设置确定

●SCLn线上的电平下降（从高电平变为低电平），SIMR3.IICRSTAREQ位设置为0，并输出重启条件产生的中断

将1写入SIMR3.IICSTPREQ位会导致产生停止条件。停止条件的生成通过以下操作进行：

●SDAn线上的电平下降（从高电平到低电平），SCLn线保持在低电平

●SCLn线的低电平周期设置为比特周期的一半，比特率由BRR设置确定

●SCLn线被释放（由低电平转变为高电平）

- When a high level is detected on the SCLn line, the setup time for the stop condition is set as half of a bit period at the bit rate determined by the BRR setting
- The SDAn line is released (transition from the low to the high level), the SIMR3.IICSTPREQ bit is set to 0, and a stop-condition generated interrupt is output

Figure 30.90 shows the timing of operations in the generation of start, restart, and stop conditions.

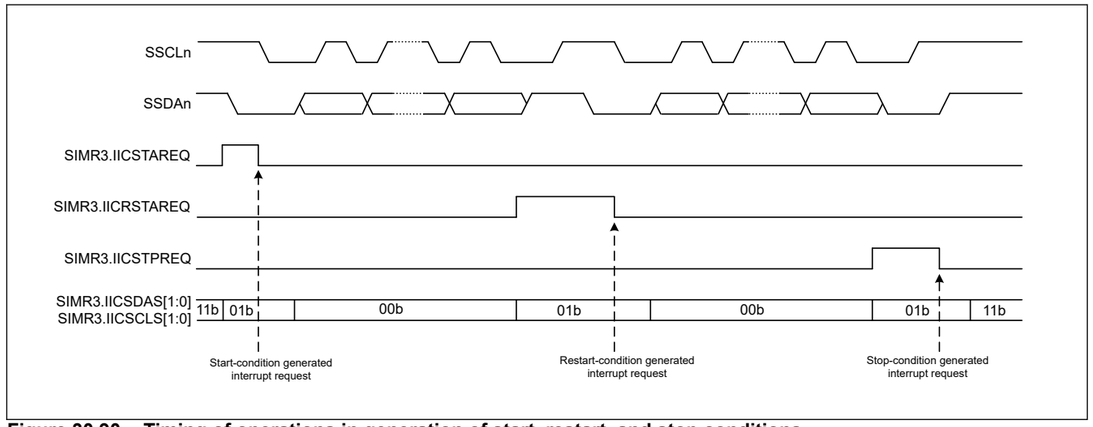

Figure 30.90 Timing of operations in generation of start, restart, and stop conditions

30.8.2 Clock Synchronization

The SCLn line can be driven low if a wait is inserted by a slave device at the other side of the transfer. Setting the SIMR2.IICCSC bit to 1 applies control to obtain synchronization when a difference arises between the levels of the internal SCLn clock signal and the level being input on the SCLn pin.

When the SIMR2.IICCSC bit is set to 1, the level of the internal SCLn clock signal changes from low to high. Counting to determine the period at a high level stops while the low level is being input on the SCLn pin. Counting to determine the period at a high level starts after the transition of the input on the SCLn pin to the high level.

The interval from this time until counting to determine the period at high level starts on the transition of the SCLn pin to the high level, is the total of the delay of SCLn output, delay for noise filtering of the input on the SCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLK). The period at high level of the internal SCLn clock is extended even when other devices do not place the low level on the SCLn line.

If the SIMR2.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SCLn pin and the internal SCLn clock. If the SIMR2.IICCSC bit is 0, synchronization with the internal SCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a wait period into the interval until the transition of the internal SCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a wait period after the transition of the internal SCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the waiting period, generation of the condition itself is not guaranteed.

Figure 30.91 shows an example operation for synchronizing the clocks.

●当在SCLn线上检测到高电平时，停止条件的建立时间设置为比特周期的一半，比特率由BRR设置确定

●SDAn线被释放（从低电平转换为高电平），SIMR3.IICSTPREQ位设置为0，并输出停止条件生成中断

图30.90显示了生成启动、重新启动和停止条件的操作时序。

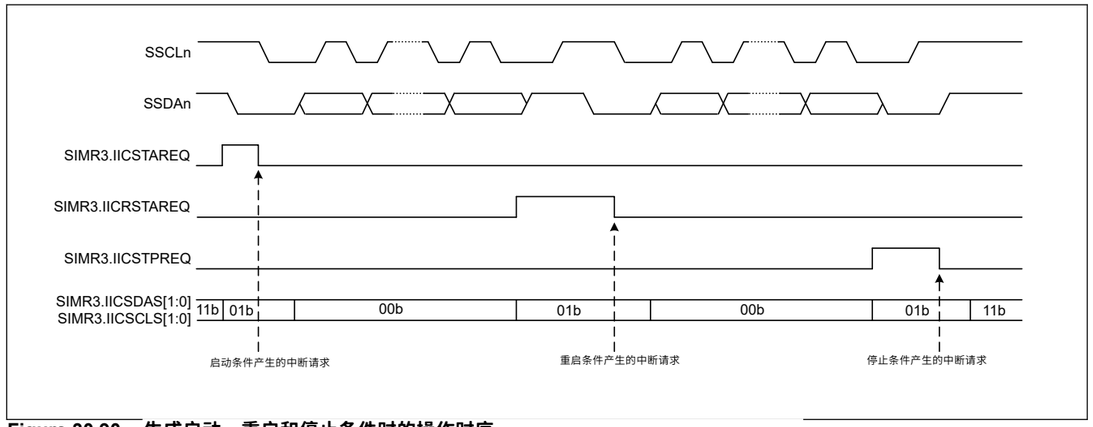

Figure 30.90 生成启动、重启和停止条件时的操作时序

30.8.2 时钟同步

如果从设备在传输的另一侧插入等待，则可以将SCLn线驱动为低电平。设置
当内部电平之间出现差异时，SIMR2.IICCSC位为1应用控制以获得同步
SCLn时钟信号和输入到SCLn引脚的电平。

当SIMR2.IICCSC位设置为1时，内部SCLn时钟信号的电平由低变为高。当SCLn引脚输入低电平时，停止计数以确定高电平周期。在SCLn引脚上的输入转换为高电平后，开始计数以确定高电平的周期。

从这个时间到从SCLn引脚转变为高电平开始计数确定高电平周期的时间间隔是SCLn输出延迟的总和，SCLn引脚上输入的噪声过滤延迟（2或3个周期的采样时钟用于噪声滤波器），以及延迟用于内部处理（1或2个PCLK周期）。即使其他设备没有将低电平置于SCLn线上，内部SCLn时钟的高电平周期也会延长。

如果SIMR2.IICCSC位为1，则通过取逻辑数据的发送和接收来获得同步
SCLn引脚上的输入与内部SCLn时钟的与。如果SIMR2.IICCSC位为0，则与内部SCLn时钟同步以进行数据的发送和接收。

如果从设备在发出启动、重启或停止条件的生成请求后，在内部SCLn时钟信号从低电平转变为高电平之前的间隔中插入一个等待周期，则直到生成的时间为延长了那个时期。

如果从设备在内部SCLn时钟信号从低电平转变为高电平之后插入等待周期，尽管在不停止等待周期的情况下发出生成完成中断，但不能保证条件本身的生成。

图30.91显示了同步时钟的示例操作。

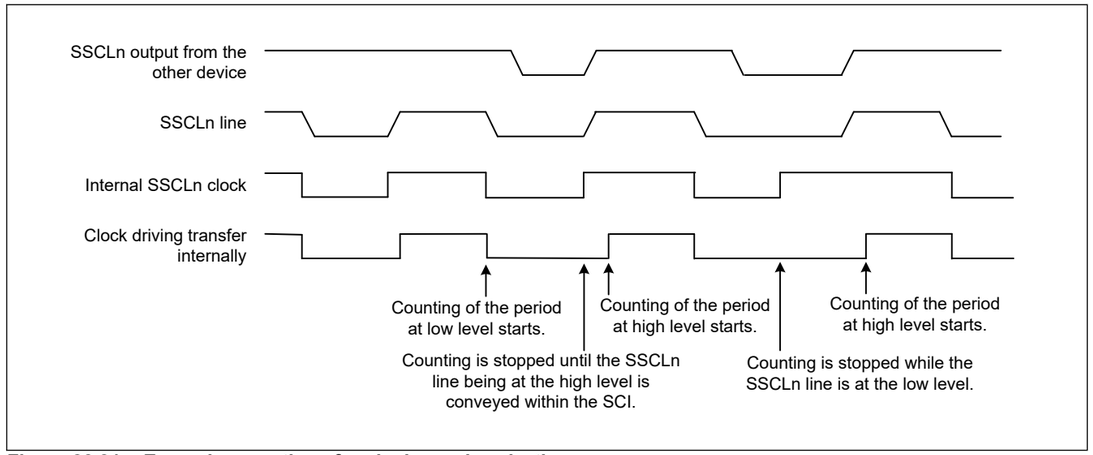

Figure 30.91 Example operations for clock synchronization

30.8.3 SDAn Output Delay

The SIMR1.IICDL[4:0] bits can be used to set a delay for output on the SDAn pin relative to falling edges of output on the SCLn pin. Delay settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, PCLK, by the divisor selected in the SMR.CKS[1:0] bits). A delay for output on the SDAn pin applies to the start condition/restart condition/stop condition signal, 8-bit transmit data, and acknowledge bit.

If the SDAn output delay is shorter than the time for the level on the SCLn pin to fall, the change of the output on the SDAn pin starts while the output level on the SCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SDAn pin specify times greater than the time output on the SCLn pin takes to fall (300 ns for IIC in normal mode and fast mode).

Figure 30.92 shows the timing of delays in SDAn output.

30.8.4 SCI Initialization in Simple IIC Mode

Before transferring data, write the initial value 0x00 to SCR and initialize the interface following the example shown in Table 30.40.

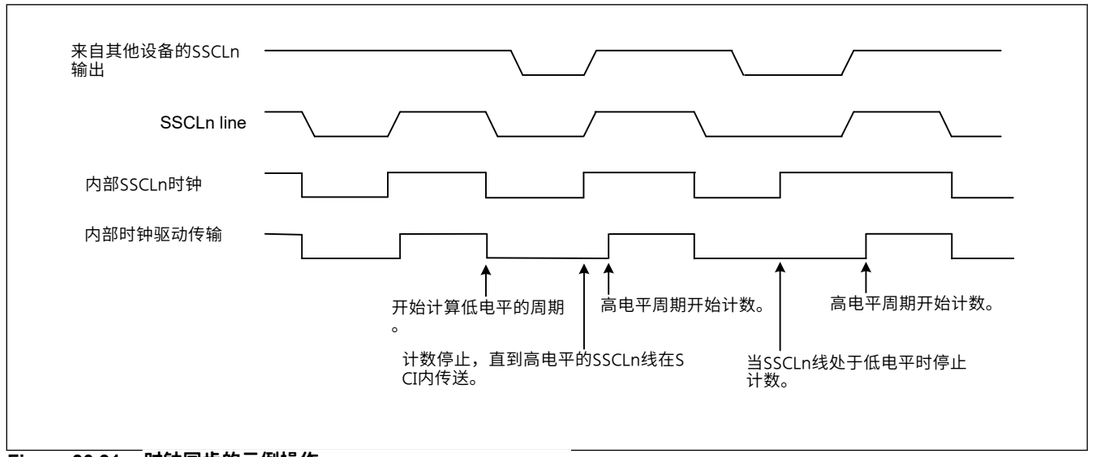

Figure 30.91 时钟同步的示例操作

30.8.3 SDAn输出延迟

SIMR1.IICDL[4:0]位可用于设置SDAn引脚输出相对于输出下降沿的延迟。
SCLn引脚。从0到31的延迟设置是可选的，表示来自片上波特率发生器的时钟信号的相应周期数的周期（通过在SMR.CKS中选择的除数对基本时钟PCLK进行分频得出[1:0]位）。SDAn引脚上的输出延迟适用于启动条件重启条件停止条件信号、8位发送数据和确认位。

如果SDAn输出延迟小于SCLn引脚电平下降的时间，则SDAn引脚上的输出变化会在SCLn引脚上的输出电平下降时开始，从而产生从设备错误操作的可能性.确保SDAn引脚上的输出延迟设置指定的时间大于SCLn引脚上输出的下降时间（IIC在正常模式和快速模式下为300ns）。

图30.92显示了SDAn输出中的延迟时序。

30.8.4 简单IIC模式下的SCI初始化

在传输数据之前，将初始值0x00写入SCR并按照中所示的示例初始化接口
Table 30.40.

Before making any changes to the operating mode or transfer format, be sure to set SCR to its initial value. In simple IIC mode, the open-drain setting for the communication ports should be made on the port side.

30.8.5 Operation in Master Transmission in Simple IIC Mode

Figure 30.93 and Figure 30.94 show examples of master transmission and Figure 30.95 shows an example flow of data transmission.

Figure 30.93 shows the operation example when SIMR2.IICINTM bit is 1 (use reception and transmission interrupts) and the value of the SCR.RIE bit is assumed to be 0 (SCIn_RXI and SCIn_ERI interrupt requests are disabled).

See Table 30.45 for more information on the STI interrupt.

Figure 30.95 shows a flow chart in the case of SIMR2.IICINTM is 1 and address transmission by CPU and data transmission by DTC or DMAC. When 10-bit slave addresses are in use, steps [3] and [4] are repeated twice.

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.

在对操作模式或传输格式进行任何更改之前，请务必将SCR设置为其初始值。在简单IIC模式下，通信端口的开漏设置应在端口侧进行。

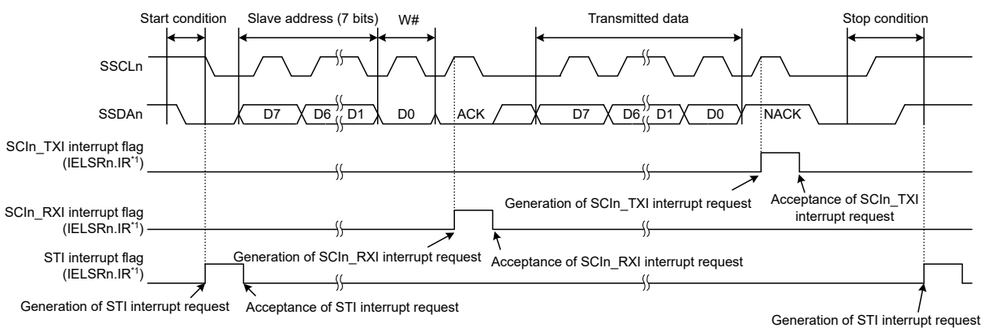
Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.93 Example 1 of operations for master transmission in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts

When the SIMR2.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and required number of data bytes are transmitted. When the NACK is received, error processing such as transmission stop and retransmission is performed using the NACK interrupt as the trigger.

To restart communication for some reason after writing data in the TDR register, use the following procedure:

1. Set the TE and RE bits in the SCR register to 0 to stop communication.
2. Set 0xF0 in the SIMR3 register, release the IIC bus, and clear the generation of a condition.
3. If the RDRF flag in the SSR register is set to 1, clear it.
4. Set the TE and RE bits in the SCR register to 1 and start the next communication.



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

当在主机传输期间SIMR2.IICINTM位设置为0（使用ACKNACK中断）时，DTC或DMAC由ACK中断作为触发器激活并传输所需的数据字节数。接收到NACK时，以NACK中断为触发进行发送停止、重发等错误处理。

要在将数据写入TDR寄存器后出于某种原因重新启动通信，请使用以下过程：

1.将SCR寄存器中的TE和RE位设置为0以停止通信。

2.将SIMR3寄存器中的0xF0置位，释放IIC总线，并清除条件的产生。

3.如果SSR寄存器中的RDRF标志设置为1，则清除它。

4.将SCR寄存器中的TE和RE位设置为1，开始下一次通信。

The value of the SIMR2.IICINTM bit is assumed to be 1 (use reception and transmission interrupts).

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.

30.9 简单SPI模式下的操作

作为一项扩展功能，SCI支持简单的SPI模式，可处理一个或多个主设备与多个从设备之间的传输。

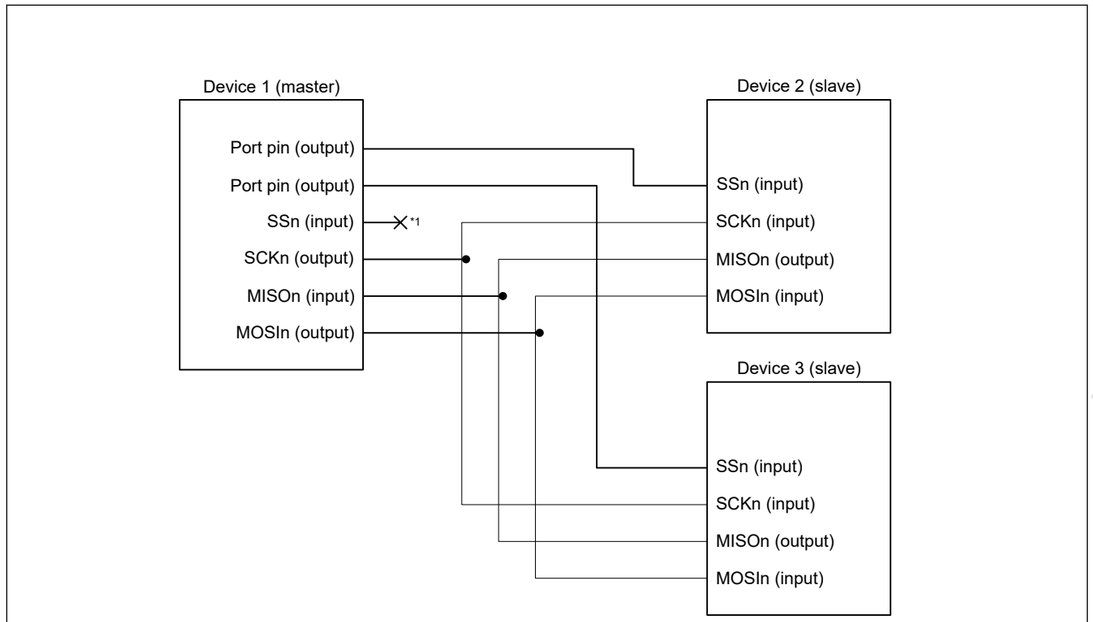
RA生态工作室

Using the settings for clock synchronous mode (SCMR.SMIF = 0, SIMR1.IICM = 0, SMR.CM = 1) and setting the SPMR.SSE bit to 1 place the SCI in simple SPI mode. However, the SSn pin function on the master side is not required for connection of the device used as the master in simple SPI mode when the configuration only has a single master. Therefore, set the SPMR.SSE bit to 0 in such cases.

Figure 30.98 shows an example of connections for simple SPI mode. Control a general port pin to produce the SSn output signal from the master.

In simple SPI mode, data is transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended. The data can be inverted by setting the SCMR.SINV bit to 1.

Because the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a shared clock signal. Additionally, because both the transmitter and receiver have a buffered structure, writing the next transmit data while transmission is in progress and reading previously received data while reception is in progress are both possible. This enables continuous transfer.



Note 1. The SSn pin input is not required in a single-master system (the interface is used with the setting SPMR.SSE = 0).

Figure 30.98 Example connections using simple SPI mode in single master mode with SPMR.SSE bit = 0

30.9.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (SCR.CKE[1:0] bits = 00b or 01b and SPMR.MSS bit = 0) or slave (SCR.CKE[1:0] bits = 10b or 11b and SPMR.MSS bit = 1).

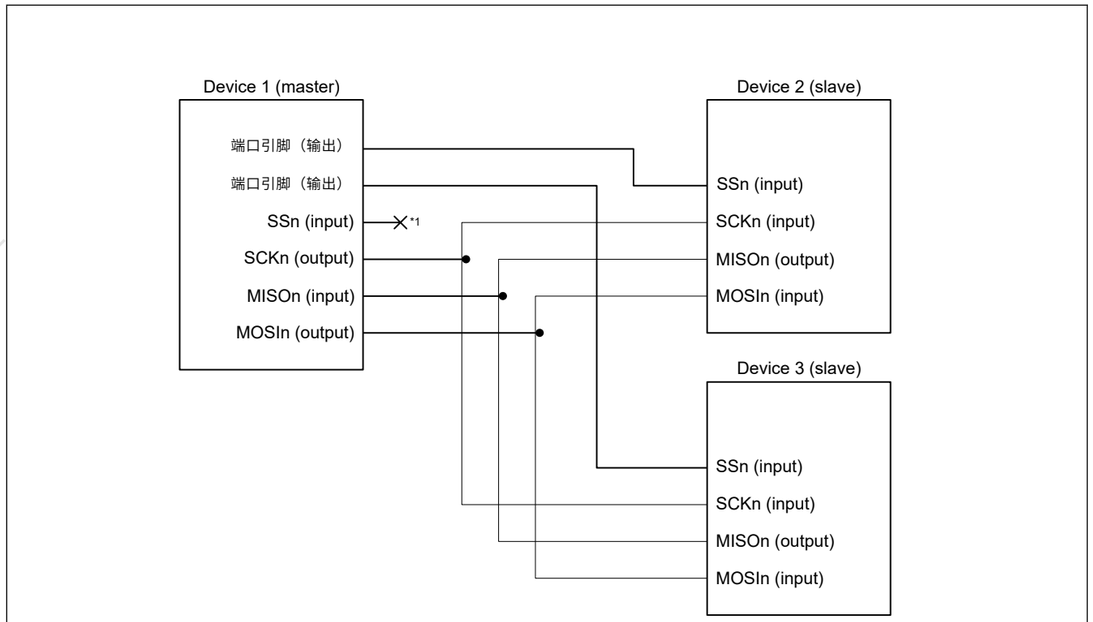
Table 30.41 lists the relationship between the pin states, mode, and level on the SSn pin.

使用时钟同步模式的设置(SCMR.SMIF=0 SIMR1.IICM=0 SMR.CM=1)并设置SPMR.SSE位为1将SCI置于简单SPI模式。但是，当配置只有一个主控时，在简单SPI模式下连接用作主控的设备不需要主控侧的SSn引脚功能。因此，在这种情况下，将SPMR.SSE位设置为0。

图30.98显示了简单SPI模式的连接示例。控制一个通用端口引脚以产生来自主机的SSn输出信号。

在简单SPI模式下，数据与时钟脉冲同步传输，方式与时钟同步模式相同。1个字符的传输数据由8位数据组成，不能附加奇偶校验位。可以通过将SCMR.SINV位设置为1来反转数据。

由于接收器和发送器在SCI模块中彼此独立，因此可以使用共享时钟信号进行全双工通信。此外，由于发送器和接收器都具有缓冲结构，因此在发送过程中写入下一个发送数据和在接收过程中读取先前接收到的数据都是可能的。这使得连续传输成为可能。



注1.在单主机系统中不需要SSn引脚输入（该接口在设置SPMR.SSE=0时使用）。

Figure 30.98 在SPMR.SSE位=0的单主模式下使用简单SPI模式的示例连接

30.9.1 主从模式下的引脚状态

简单SPI模式接口的引脚方向（输入或输出）根据设备是主设备（SCR.CKE[1:0]位=00b或01b且SPMR.MSS位=0）还是从设备（SCR.CKE[1:0]位=10b或11b且SPMR.MSS位=1)。

表30.41列出了SSn引脚上的引脚状态、模式和电平之间的关系。

Table 30.41 States of pins by mode and input level on SSn pin

Mode	Input on SSn pin	State of MOSIn pin	State of MISOn pin	State of SCKn pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance
Slave mode	High level (transfer cannot proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer can proceed)	Input for received data	Output for data transmission	Clock input

Note 1. When there is only a single master (SPMR.SSE = 0), transfer is possible regardless of the input level on the SSn pin. This is equivalent to input of a high level on the SSn pin.
Note 2. The MOSIn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE bit = 0).
Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE bit =0 andSCRRE bit = 0) in a multi-master configuration (SPMR.SSE = 1).

30.9.2 SS Function in Master Mode

Setting the CKE[1:0] bits in the SCR to 00b or 01b and the MSS bit in the SPMR to 0 selects master mode operation. The SSn pin is not used in single-master configurations (SPMR.SSE = 0), so transmission or reception can proceed regardless of the value of the SSn pin.

When the level on the SSn pin is high in a multi-master configuration (SPMR.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission.

When the level on the SSn pin is low in a multi-master configuration (SPMR.SSE = 1), there are other masters, and a transmission or reception is in progress. The MOSIn output and SCKn pins are placed in the high-impedance state and starting transmission or reception is not possible. In addition, the value of the SPMR.MFF bit is 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading SPMR.MFF flag. If a mode fault error occurs while transmission or reception is in progress, transmission or reception does not stop, but the MOSIn and SCKn outputs are in the high-impedance state after completion of the transfer.

Use a general port pin to produce the SS output signal from the master.

30.9.3 SS Function in Slave Mode

Setting the SCR.CKE[1:0] bits to 10b or 11b and the SPMR.MSS bit to 1 selects slave operation. When the SSn pin is high, the MISOn output pin is in the high-impedance state and clock input through the SCKn pin is ignored. When the SSn pin is low, clock input through the SCKn pin is valid and transmission or reception can proceed.

If the input on the SSn pin changes from low to high during transmission or reception, the MISOn output pin is placed in the high-impedance state. Meanwhile, the internal processing for transmission or reception continues at the rate of the clock input through the SCKn pin until processing for the character being transmitted or received is complete, after which it stops, and the appropriate interrupt (SCIn_TXI, SCIn_RXI, or SCIn_TEI) is generated.

30.9.4 Relationship between Clock and Transmit/Receive Data

The CKPOL and CKPH bits in the SPMR register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in Figure 30.99. The relation is the same for both master and slave operation. This is the same as when the level on the SSn pin is high.

Table 30.41 SSn引脚上的模式和输入电平的引脚状态

Mode	SSn引脚上的输入	MOSIn管脚状态	MISon引脚的状态	SCKn引脚状态
主模式*1	高电平（可以进行转移）	数据传输用输出*2	接收数据的输入	时钟输出*3
	低电平（传输无法进行）	High-impedance	接收数据的输入（但禁用）	High-impedance
从机模式	高电平（传输无法进行）	接收数据的输入（但禁用）	High-impedance	时钟输入（但禁用）
	低电平（可以继续传输）	接收数据的输入	数据传输输出	时钟输入

注1.当只有一个主机(SPMR.SSE=0)时，无论SSn引脚上的输入电平如何，都可以进行传输。这相当于在SSn引脚上输入高电平。

注2.当串行传输被禁用（SCR.TE位=0）时，MOSIn引脚输出处于高阻抗状态。
注3.在多主机配置(SPMR.SSE=1)中禁用串行传输(SCR.TE位=0和SCRRE位=0)时，SCKn引脚输出处于高阻抗状态。

30.9.2 主控模式下的SS功能

将SCR中的CKE[1:0]位设置为00b或01b并将SPMR中的MSS位设置为0选择主机模式操作。这SSn引脚不用于单主机配置(SPMR.SSE=0)，因此无论SSn引脚的值如何，都可以进行发送或接收。

在多主机配置（SPMR.SSE=1）中，当SSn引脚上的电平为高电平时，主机设备在开始发送或接收之前从SCKn引脚输出时钟信号，以指示没有其他主机或另一个主机在进行接收或发送。

在多主机配置（SPMR.SSE=1）中，当SSn引脚上的电平为低电平时，存在其他主机，并且正在进行发送或接收。MOSIn输出和SCKn引脚处于高阻状态，无法开始发送或接收。此外，SPMR.MFF位的值为1，表示模式故障错误。在多主机配置中，通过读取SPMR.MFF标志开始错误处理。如果在发送或接收过程中发生模式故障错误，则发送或接收不会停止，但MOSIn和SCKn输出在传输完成后处于高阻抗状态。

使用通用端口引脚从主机产生SS输出信号。

30.9.3 从模式下的SS功能

将SCR.CKE[1:0]位设置为10b或11b并将SPMR.MSS位设置为1选择从机操作。当SSn引脚为高电平时，MIOn输出引脚处于高阻状态，通过SCKn引脚输入的时钟被忽略。当SSn引脚为低电平时，通过SCKn引脚输入的时钟有效，可以进行发送或接收。

如果SSn引脚上的输入在发送或接收期间从低电平变为高电平，则MISOn输出引脚处于高阻抗状态。同时，发送或接收的内部处理以通过SCKn引脚输入的时钟速率继续进行，直到对正在发送或接收的字符的处理完成，之后它停止，并出现适当的中断（SCIn_TXI、SCIn_RXI或SCIn_TEI）生成。

30.9.4 时钟与发送接收数据的关系

SPMR寄存器中的CKPOL和CKPH位可用于以四种不同的方式设置用于发送和接收的时钟。时钟信号与数据收发的关系如图30.99所示。主从操作的关系是相同的。这与SSn引脚上的电平为高电平时相同。

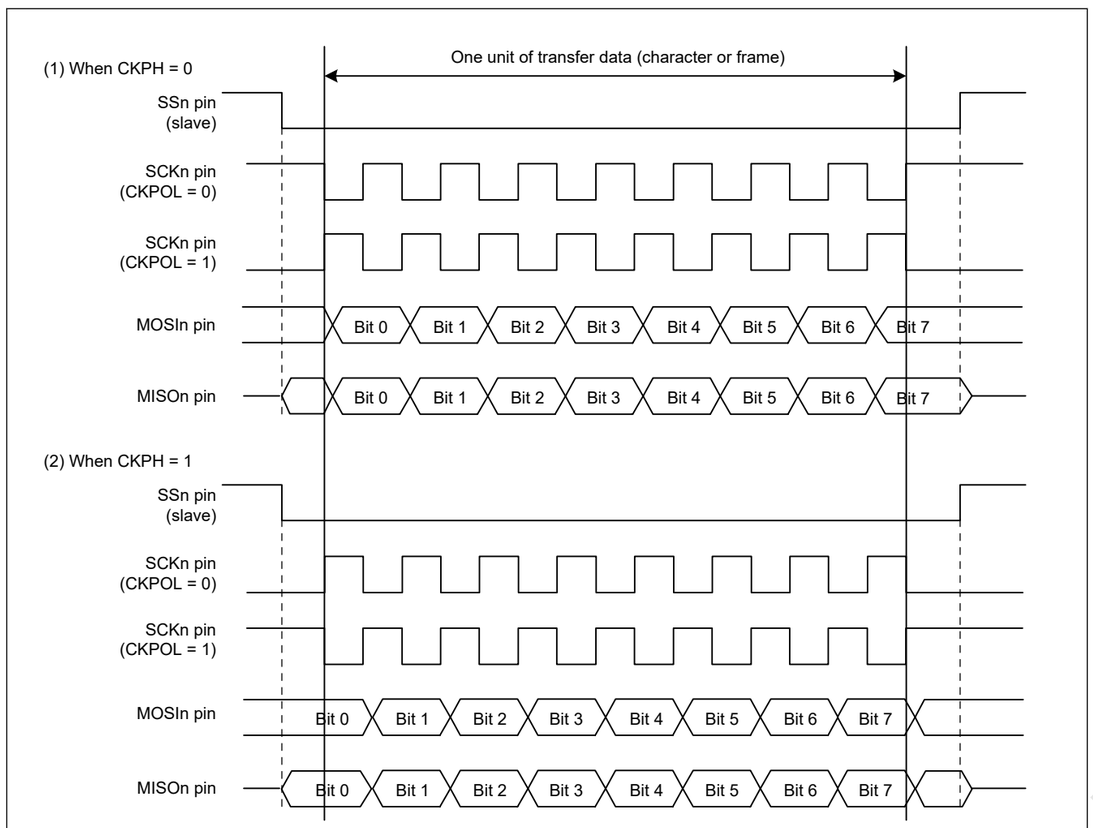


Figure 30.99 Relation between clock signal and transmit or receive data in simple SPI mode

30.9.5 SCI Initialization in Simple SPI Mode

Initialization in simple SPI mode is the same as in clock synchronous mode. See section 30.6.3. SCI Initialization in Clock Synchronous Mode for an example initialization flow. The CKPOL and CKPH bits in the SPMR register must be set to ensure that the clock signal is suitable for both master and slave devices.

Always initialize the SCR register before making any changes to the operating mode or transfer format.

Note: Only the RE bit is set to 0. The SSR.ORER, FER, PER, and RDR flags are not initialized.

Changing the value of the TE bit from 1 to 0 or from 0 to 1 when the TIE bit in the SCR register is 1 at the same time, leads to the generation of a transmit data empty interrupt (SCIn_TXI).

30.9.6 Transmission and Reception of Serial Data in Simple SPI Mode

In master operation, ensure that the SSn pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. Otherwise, the procedures are the same as in clock synchronous mode.

30.10 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be evenly corrected using the number specified in the MDDR register among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in SMR/SMR_SMCI.

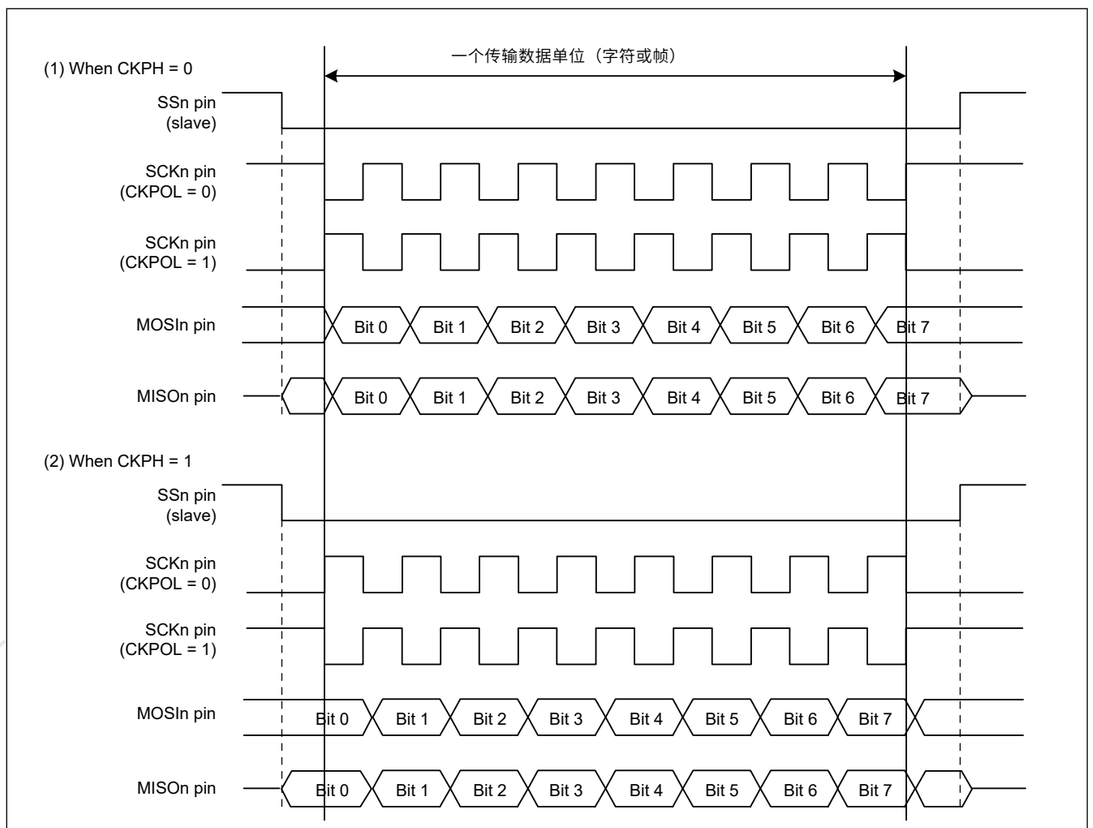

Figure 30.99 简单SPI模式下时钟信号与发送或接收数据的关系

30.9.5 简单SPI模式下的SCI初始化

简单SPI模式的初始化与时钟同步模式相同。请参阅第30.6.3节。时钟中的SCI初始化
示例初始化流程的同步模式。必须设置SPMR寄存器中的CKPOL和CKPH位，以确保时钟信号适用于主设备和从设备。

在对操作模式或传输格式进行任何更改之前，始终初始化SCR寄存器。

Note: 只有RE位设置为0。SSR.ORER、FER、PER和RDR标志未初始化。

当SCR寄存器中的TIE位同时为1时，将TE位的值从1更改为0或从0更改为1，会导致产生发送数据空中断（SCIn_TXI）。

30.9.6 简单SPI模式下串行数据的发送和接收

在主机操作中，确保传输另一侧的从设备的SSn管脚在开始传输前为低电平，在传输完成时为高电平。否则，过程与时钟同步模式相同。

30.10 比特率调制功能

使用比特率调制功能，可以在SMRSMR_SMCI中的CKS[1:0]位选择的内部时钟的256个时钟周期中，使用MDDR寄存器中指定的数量均匀地校正比特率。

Figure 30.100 shows an example where the PCLK is selected in the CKS[1:0] bits in SMR/SMR_SMCI, the BRR bit is set to 0, and the MDDR is set to 160 in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256).

Note: Enabling an internal clock causes bias, and expansion and contraction are generated in the pulse width of the internal base clock.

Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

30.11 Extended Serial Mode Control Section: Description of Operation

30.11.1 Serial Transfer Protocol

In conjunction with the SCIg module, the extended serial mode control section of the SCIh module can realize the serial transfer protocol composed of Start Frames and Information Frames that is shown in Figure 30.101.

A Start Frame is composed of a Break Field, Control Field 0, and Control Field 1. An Information Frame is composed of a number of Data Fields, a CRC16 Upper Field, and a CRC16 Lower Field.

图30.100显示了一个示例，其中在SMRSMR_SMCI的CKS[1:0]位中选择PCLK，BRR位设置为0，异步模式下MDDR设置为160。在这个例子中，基本时钟的周期被均匀地校正（256160）并且比特率也被校正（160256）。

Note: 启用内部时钟会导致偏差，并且会在内部基本时钟的脉冲宽度中产生扩展和收缩。

不要在时钟同步模式和简单SPI模式的最高速度设置（SMR.CKS[1:0]=00b，SCR.CKE[1]=0和BRR=0）中使用此功能。

30.11 扩展串行模式控制部分：操作说明

30.11.1 串行传输协议

结合SCIg模块，SCIh模块的扩展串行模式控制部分可以实现由StartFrames和InformationFrames组成的串行传输协议，如图30.101所示。

起始帧由中断字段、控制字段0和控制字段1组成。信息帧由多个数据字段、CRC16上字段和CRC16下字段组成。

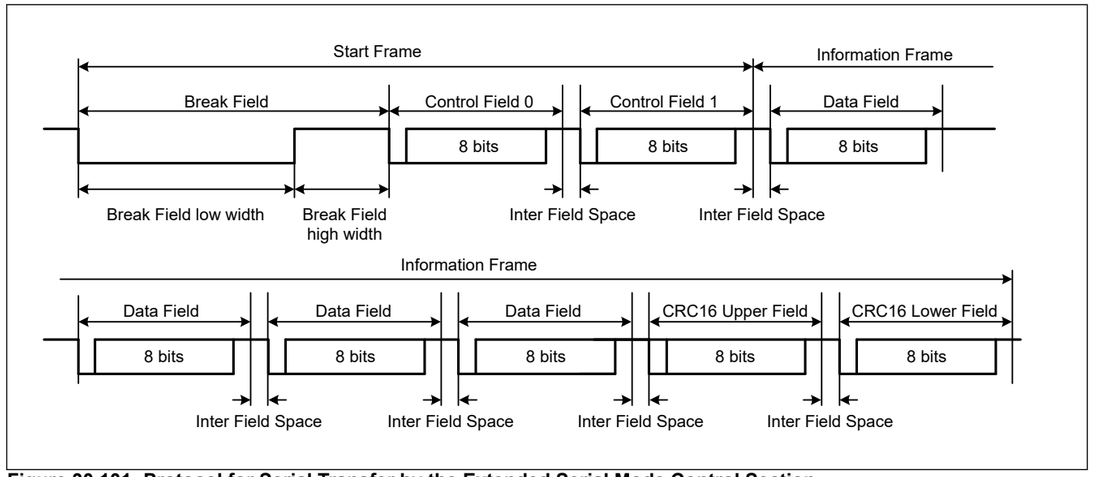

Figure 30.101 Protocol for Serial Transfer by the Extended Serial Mode Control Section

30.11.2 Transmitting a Start Frame

Figure 30.102 shows an example of operations to transmit a Start Frame, which is composed of the Break Field low width, Control Field 0, and Control Field 1. Figure 30.103 and Figure 30.104 are flowcharts for the transmission of a Start Frame.

Operations when the extended serial mode control section is to be used to transmit a Start Frame are as listed below. Be sure to use the SCIn (n = 1, 2) in asynchronous mode.

1. With Break Field low width output mode as the operating mode for the timer, writing 1 to the TCR.TCST bit starts counting by the timer, and the low level will be output from the TXDXn (n = 1, 2) pin over the period corresponding to registers TCNT and TPRE settings.
2. The output on the TXDXn pin is inverted when the timer counter underflows, and the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.
3. Write 0 to the TCR.TCST bit to stop counting by the timer, and send the data for Control Field 0 by using SCIn. After the Break Field low width output, stop counting before the next underflow occurs.
4. When the data for Control Field 0 have been transmitted, send the data for Control Field 1.
5. When the data for Control Field 1 have been transmitted, send an Information Frame.

Omit the Break Field and Control Field 0 to suit the structure of the Start Frame.

30.11.2 发送起始帧

图30.102显示了发送起始帧的操作示例，起始帧由中断字段低宽度、控制字段0和控制字段1组成。图30.103和图30.104是发送起始帧的流程图。

使用扩展串行模式控制部分发送起始帧时的操作如下所列。请务必在异步模式下使用SCIn(n=1 2)。

1.以中断场低宽度输出模式作为定时器的工作模式，开始向TCR.TCST位写入1
由定时器计数，在对应于寄存器TCNT和TPRE设置的周期内，低电平将从TXDXn(n=1 2)引脚输出。

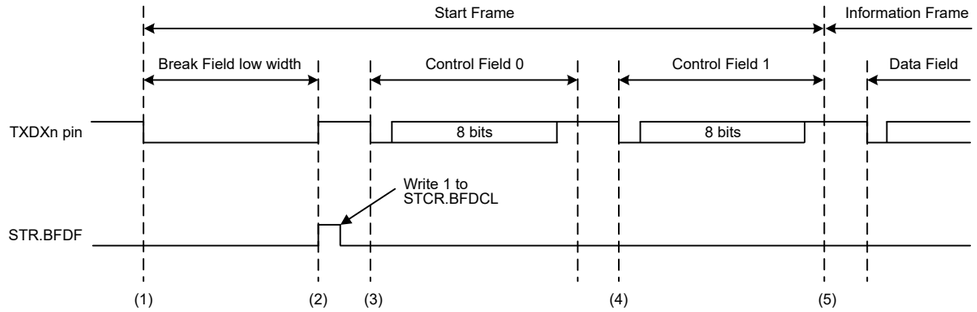
2.当定时器计数器下溢时，TXDXn引脚的输出反相，STR.BFDF标志设置为1。如果ICR.BFDIE位的值为1，也会产生SCIX0中断。

3.将0写入TCR.TCST位以停止定时器计数，并使用SCIn发送控制字段0的数据。在BreakField低宽度输出之后，在下一次下溢发生之前停止计数。

4.当控制字段0的数据传输完毕后，发送控制字段1的数据。

5.当控制字段1的数据传输完毕后，发送一个信息帧。

省略BreakField和ControlField0以适应起始帧的结构。



The above diagram assumes the following:

ESMER: ESME = 1
PCR: TXDXPS = 0
ICR: BFDIE = 1
TMR: TOMS[1:0] = 10b

Note: n = 1, 2

Figure 30.106 shows an example of operations to receive a Start Frame, which is composed of the Break Field low width, Control Field 0, and Control Field 1. Figure 30.107 and Figure 30.108 are flowcharts for the reception of a Start Frame, and Figure 30.109 is a state transition diagram for the extended serial mode control section.

Operations when the extended serial mode control section is to be used to receive a Start Frame are as listed below. Be sure to use the SCIn (n = 1, 2) in asynchronous mode.

1. With Break Field low width detection mode as the operating mode for the timer, writing 1 to the CR3.SDST bit enables detection of the Break Field low width. RXDXn input to the SCIn is disabled at this time.
2. Low-level input on the RXDXn pin continuing over a period longer than that corresponding to the settings of registers TCNT and TPRE is detected as the Break Field low width. At this time, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.
3. When the input from the RXDXn pin goes high after the Break Field low width, the CR0.RXDSF flag becomes 0 and reception of Control Field 0 by the SCIn starts.
4. If the data received in Control Field 0 match the data set in the CF0DR register, the STR.CF0MF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.CF0MIE bit is 1. Reception of Control Field 1 by the SCIn starts after that. If the data received in Control Field 0 do not match the data set in the CF0DR register, a transition to the state prior to Break Field low width detection proceeds.
5. If the data received in Control Field 1 match the data set in registers PCF1DR and SCF1DR, the STR.CF1MF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.CF1MIE bit is 1. Transfer of the Information Frame by the SCIn starts after that. If the data received in Control Field 1 do not match the data set in either or both of registers PCF1DR and SCF1DR, a transition to the state prior to Break Field low width detection proceeds.

Omit the Break Field and Control Field 0 to suit the structure of the Start Frame.

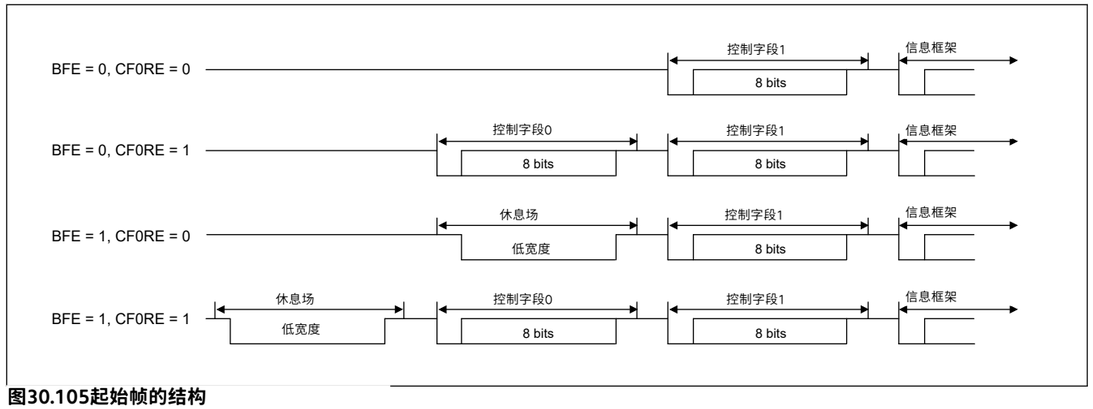

图30.105起始帧的结构

图30.106显示了接收起始帧的操作示例，起始帧由中断字段低宽度组成，控制字段0和控制字段1。图30.107和图30.108是接收起始帧的流程图，以及图30.109是扩展串行模式控制部分的状态转换图。

使用扩展串行模式控制部分接收起始帧时的操作如下所列。请务必在异步模式下使用SCIn(n=1 2)。

1.使用间隔场低宽度检测模式作为定时器的操作模式，向CR3.SDST位写入1可启用间隔场低宽度检测。此时SCIn的RXDXn输入被禁用。

2.RXDXn引脚上的低电平输入持续时间长于对应寄存器TCNT和TPRE的设置的时间被检测为中断场低电平宽度。此时，STR.BFDF标志置1。如果ICR.BFDIE位的值为1，也会产生SCIX0中断。

3.当来自RXDXn引脚的输入在BreakField低电平宽度之后变为高电平时，CR0.RXDSF标志变为0，并且SCIn开始接收ControlField0。

4.如果控制域0中接收的数据与CF0DR寄存器中设置的数据匹配，则STR.CF0MF标志设置为1。如果ICR.CF0MIE位的值为1，也会产生SCIX1中断。接收控制SCIn的字段1在那之后开始。如果在控制字段0中接收到的数据与CF0DR寄存器中设置的数据不匹配，则转换到中断字段低宽度检测之前的状态。

5.如果控制字段1中接收的数据与寄存器PCF1DR和SCF1DR中设置的数据匹配，则STR.CF1MF标志设置为1。如果ICR.CF1MIE位的值为1，也会产生SCIX1中断。SCIn的信息帧在此之后开始。如果在控制字段1中接收到的数据与寄存器PCF1DR和SCF1DR中的一个或两个中设置的数据不匹配，则转换到中断字段低宽度检测之前的状态。

省略BreakField和ControlField0以适应起始帧的结构。

30.11.3.1 Priority Interrupt Bit

Figure 30.110 shows an example of operation in Start Frame reception where a priority interrupt bit is in use. Setting the CR1.PIBE bit to 1 enables the use of a priority interrupt bit.

Operations of the extended serial mode control section in start Frame reception where a priority interrupt bit is in use are as described below.

Steps (1) to (4) are the same as in Figure 30.106, for Start Frame reception.

(5) If the value of the bit selected by the CR1.PIBS[2:0] bits matches the corresponding bit in the PCF1DR register, the STR.PIBDF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.PIBDIE bit is 1. Transfer of the Information Frame by the SCIn (n = 1, 2) starts after that. If the data received in Control Field 1 do not match the data set in either or both of registers PCF1DR and SCF1DR and the priority interrupt bit is not detected, a transition to the state prior to Break Field low width detection proceeds.

在使用优先中断位的开始帧接收中扩展串行模式控制部分的操作如下所述。

步骤(1)到(4)与图30.106中的相同，用于接收起始帧。

(5)如果CR1.PIBS[2:0]位选择的位的值与PCF1DR寄存器中的相应位相匹配，则STR.PIBDF标志设置为1。如果ICR.PIBDIE位为1。

SCIn(n=1 2)的信息帧在此之后开始。如果在控制字段1中接收的数据与寄存器PCF1DR和SCF1DR中的一个或两个中设置的数据不匹配，并且未检测到优先级中断位，则转换到中断字段低宽度检测之前的状态。

30.11.4 Detection of Bus Collisions

Detection of bus collisions operate for cases where output of the Break Field low width and transmission of data by the SCIn (n = 1, 2) are in progress when the ESMER.ESME bit and the SCIn.SCI.TE bit are set to 1.

Figure 30.111 shows an example of operations with bus collision detection. Signals output through TXDXn and input through RXDXn are sampled with the bus collision detection clock set with the CR2.BCCS[1:0] bits as the sampling clock, and the STR.BCDF flag is set to 1 if the signals fail to match three times in a row. An SCIX2 interrupt is also generated if the value of the ICR.BCDIE bit is 1.

30.11.4 总线碰撞检测

总线冲突检测适用于中断字段低宽度的输出和数据传输的情况
当ESMER.ESME位和SCIn.SCI.TE位设置为1时，SCIn(n=1 2)正在进行。

图30.111显示了带有总线冲突检测的操作示例。通过TXDXn输出和通过RXDXn输入的信号以CR2.BCCS[1:0]位设置的总线冲突检测时钟作为采样时钟进行采样，如果信号不匹配三个，则STR.BCDF标志设置为1连续几次。如果ICR.BCDIE位的值为1，也会产生SCIX2中断。

CR2: BCCS[1:0] = 01b
PCR: TXDXPS = 0, RXDXPS = 0
ICR: BCDIE = 1

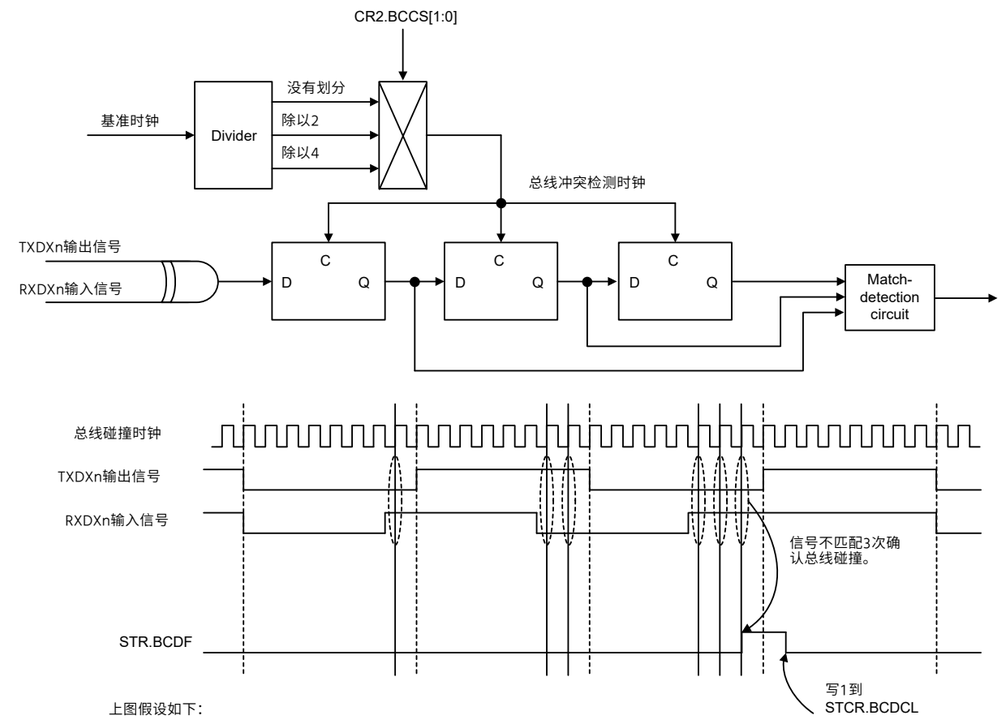
30.11.5 Digital Filter for Input on the RXDXn (n = 1, 2) Pin

Signals input through the RXDXn pin can be passed through a digital filter before they are conveyed to the internal circuits. The digital filter consists of three flip-flop circuit stages connected in series and a match-detecting circuit. The CR2.DFCS[2:0] bits select the sampling clock for the RXDXn pin input signals. If the outputs of all three latches match, the given level is conveyed to subsequent circuits. If the levels do not match, the previous value is retained. In other words, levels are confirmed as being the signal if they are retained for at least three cycles of the sampling clock but judged to be noise rather than changes in the signal level if they change within three cycles of the sampling clock. Figure 30.112 shows an example of operations with the digital filter.



上图假设如下：
ESMER: ESME = 1
CR2: BCCS[1:0] = 01b
PCR: TXDXPS = 0, RXDXPS = 0
ICR: BCDIE = 1

30.11.5 RXDXn(n=1 2)引脚上的输入数字滤波器

通过RXDXn引脚输入的信号在传送到内部电路之前可以通过数字滤波器。数字滤波器由三个串联的触发器电路级和一个匹配检测电路组成。这

CR2.DFCS[2:0]位选择RXDXn引脚输入信号的采样时钟。如果所有三个锁存器的输出都匹配，则将给定电平传送到后续电路。如果级别不匹配，则保留先前的值。换言之，如果电平在采样时钟的至少三个周期内保持，则确认电平为信号，但如果在采样时钟的三个周期内变化，则判断为噪声而不是信号电平的变化。图30.112显示了使用数字滤波器的操作示例。

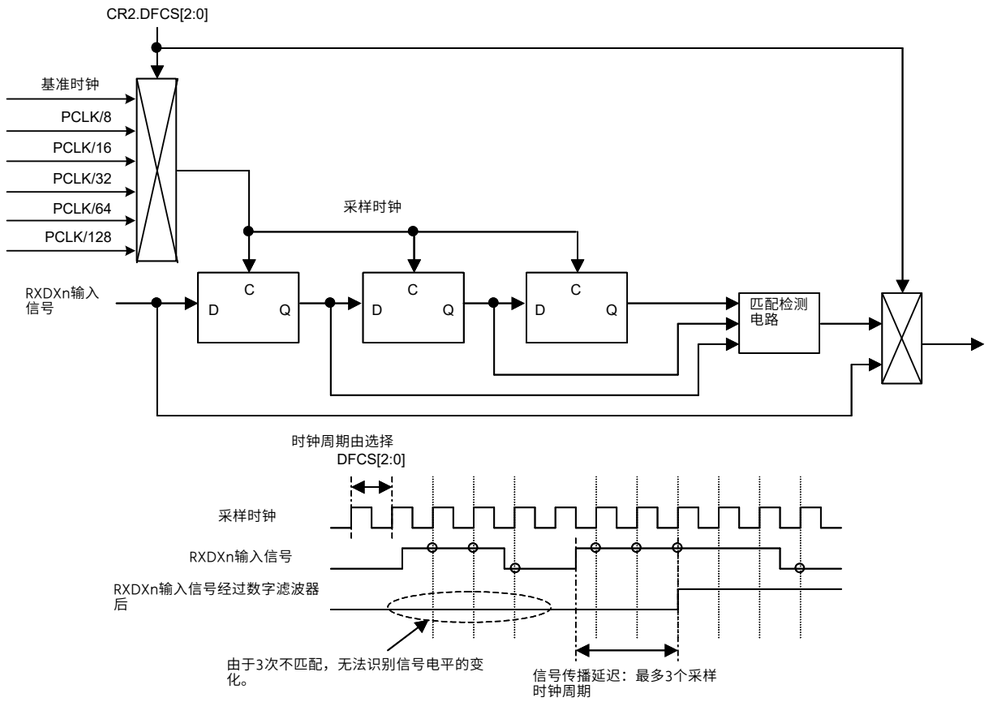
30.11.6 Bit Rate Measurement

The bit rate measurement function measures the intervals between rising and falling edges and between falling and rising edges of the signal input from the RXDXn (n = 1, 2) pin. Figure 30.113 shows an example of operations for bit rate measurement.

1. Writing 1 to the CR0.BRME bit enables bit rate measurement. Only set the BRME bit to 1 when you wish to proceed with bit rate measurement. Furthermore, bit rate measurement will not proceed during a Break Field, even if the BRME bit is set to 1.
2. After detection of the Break Field low width, bit rate measurement starts when the level input on the RXDXn pin becomes high.
3. Once bit rate measurement has started, counter values from the timer are retained in the read buffers on the input of valid edges from the RXDXn pin (rising and falling edges) and the counter is reloaded. An SCIX3 interrupt is also generated if the value of the ICR.AEDIE bit is 1. Retention by registers TCNT and TPRE is released by reading these registers.
4. The bit rate as calculated from the values counted during intervals between valid edges can be used for adjusting the rate by changing the settings of the SCIn. To disable the bit rate measurement after a match with Control Field 1, write 0 to the CR0.BRME bit.



Note: n = 1, 2

30.11.6 比特率测量

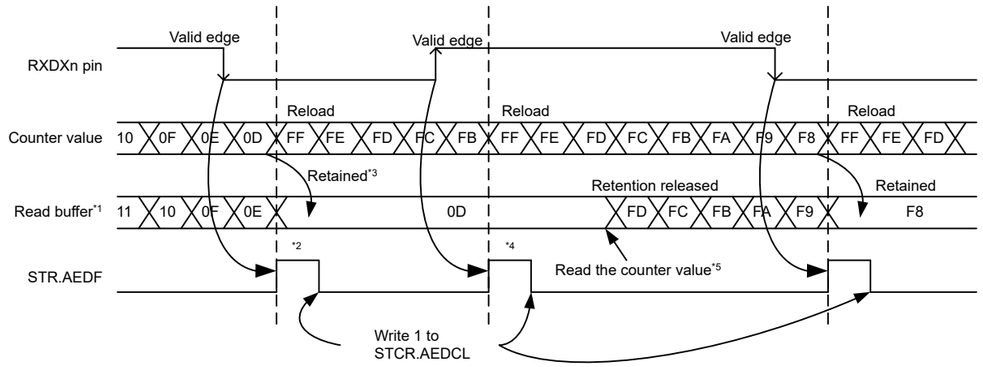
比特率测量功能测量从RXDXn(n=1 2)引脚输入的信号的上升沿和下降沿之间以及下降沿和上升沿之间的间隔。图30.113显示了比特率测量的操作示例。

1.将1写入CR0.BRME位启用比特率测量。仅当您希望继续进行比特率测量时，才将BRME位设置为1。此外，即使BRME位设置为1，在中断字段期间也不会进行比特率测量。

2.检测到BreakField低电平宽度后，当RXDXn引脚上的电平输入变为高电平时开始比特率测量。

3.一旦比特率测量开始，来自定时器的计数器值在来自RXDXn引脚的有效边沿（上升沿和下降沿）的输入上保留在读缓冲器中，并且计数器被重新加载。如果ICR.AEDIE位的值为1，也会产生SCIX3中断。寄存器TCNT和TPRE的保留通过读取这些寄存器来释放。

4.根据有效边沿之间的间隔期间计数的值计算的比特率可用于通过更改SCIn的设置来调整速率。要在与控制字段1匹配后禁用比特率测量，请将0写入CR0.BRME位。



Note: n = 1, 2
Note 1. The TCNT or TPRE register indicates the contents of the read buffers.
Note 2. The STR.AEDF flag becomes 1 on detection of a valid edge.
Note 3. When an effective edge is detected, the current value of the counter is stored in the read buffer.
Note 4. The value retained in the read buffers due to one valid edge is not updated to the new value even if a further valid edge is detected.
Note 5. Retention of a value in a read buffer due to a valid edge is released by reading the TCNT or TPRE register.

30.11.7 Selectable Timing for Sampling Data Received through RXDXn (n = 1, 2)

The extended serial mode control section provides a way of adjusting the timing for the sampling of data received through the RXDXn pin of an SCIn by setting the CR2.RTS[1:0] bits to select the rising edges of 8th, 10th, 12th, or 14th cycle of the SCI base clock. If the value of the SEMR.ABCS bit is 1, the bits select the rising edges of 4th, 5th, 6th, or 7th cycle of the PCLK clock of the SCIn. Figure 30.114 shows timing for the sampling of data received through RXDXn.

30.11.8 Timer

定时器具有以下操作模式。

(1) Break Field Low Width Output Mode

This mode is for output through the TXDXn (n = 1, 2) pin of the low level over the Break Field low width at the transmission of a Start Frame. Setting the TMR.TOMS[1:0] bits to 10b switches operation to Break Field low width output mode. The TMR.TCSS[2:0] bits select the clock source for the counter. When the TCR.TCST bit is set to 1, the output on the TXDXn pin goes to the low level and counting starts. When the timer underflows, the output on the TXDXn pin goes to the high level and the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1. When 0 is written to the TCR.TCST bit, counting stops after reloading of registers TPRE and TCNT. After output of the Break Field low width is completed, stop the timer before it underflows again. Figure 30.115 shows an example of operations in Break Field low width output mode.

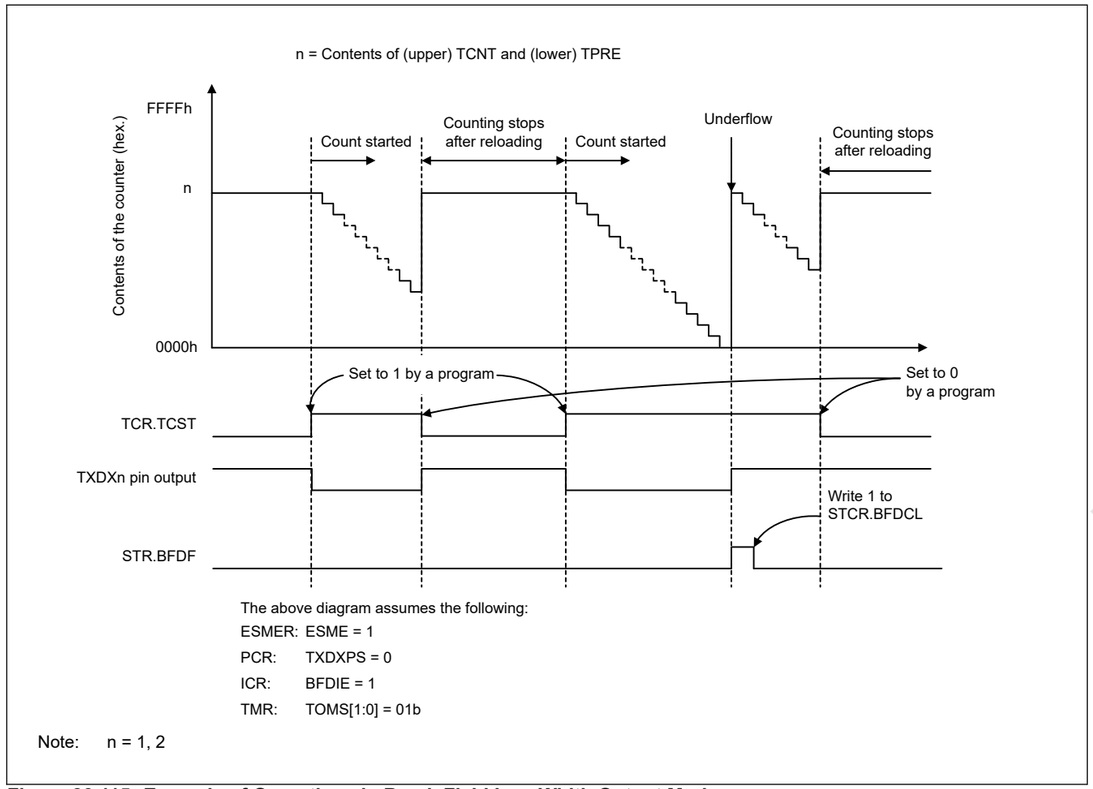

Figure 30.115 Example of Operations in Break Field Low Width Output Mode

(2) Break Field Low Width Determination Mode

This mode is for determining the Break Field low width in the input signal on the RXDXn (n = 1, 2) pin at the reception of a Start Frame. Setting the TMR.TOMS[1:0] bits to 01b switches operation to Break Field low width determination mode. The TMR.TCSS[2:0] bits select the clock source for the counter. When the TCR.TCST bit is set to 1, the interface enters the Break Field low width determinable state. Determination starts when a low level is input from the RXDXn pin. When a high level is then input on the RXDXn pin, registers TPRE and TCNT are reloaded and the interface enters the Break Field low width determinable state. When the timer underflows during Break Field low width determination, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1. If an underflow of the timer during data transfer cause a problem in the form of interrupt generation, stop the timer after Break Field low width determination. Figure 30.116 shows an example of operations in Break Field low width output mode.

(1) 断场低宽度输出模式

此模式用于在传输起始帧时通过中断字段低电平宽度上的低电平TXDXn(n=1 2)引脚输出。将TMR.TOMS[1:0]位设置为10b会将操作切换到BreakField低宽度输出模式。TMR.TCSS[2:0]位选择计数器的时钟源。当TCR.TCST位设置为1时，TXDXn引脚上的输出变为低电平并开始计数。当定时器下溢时，TXDXn引脚上的输出变为高电平，STR.BFDF标志设置为1。如果ICR.BFDIE位的值为1，也会产生SCIX0中断。当写入0时TCR.TCST位，重新加载寄存器TPRE和TCNT后计数停止。BreakField低宽度输出完成后，在定时器再次下溢之前停止定时器。图30.115显示了BreakField低宽度输出模式下的操作示例。

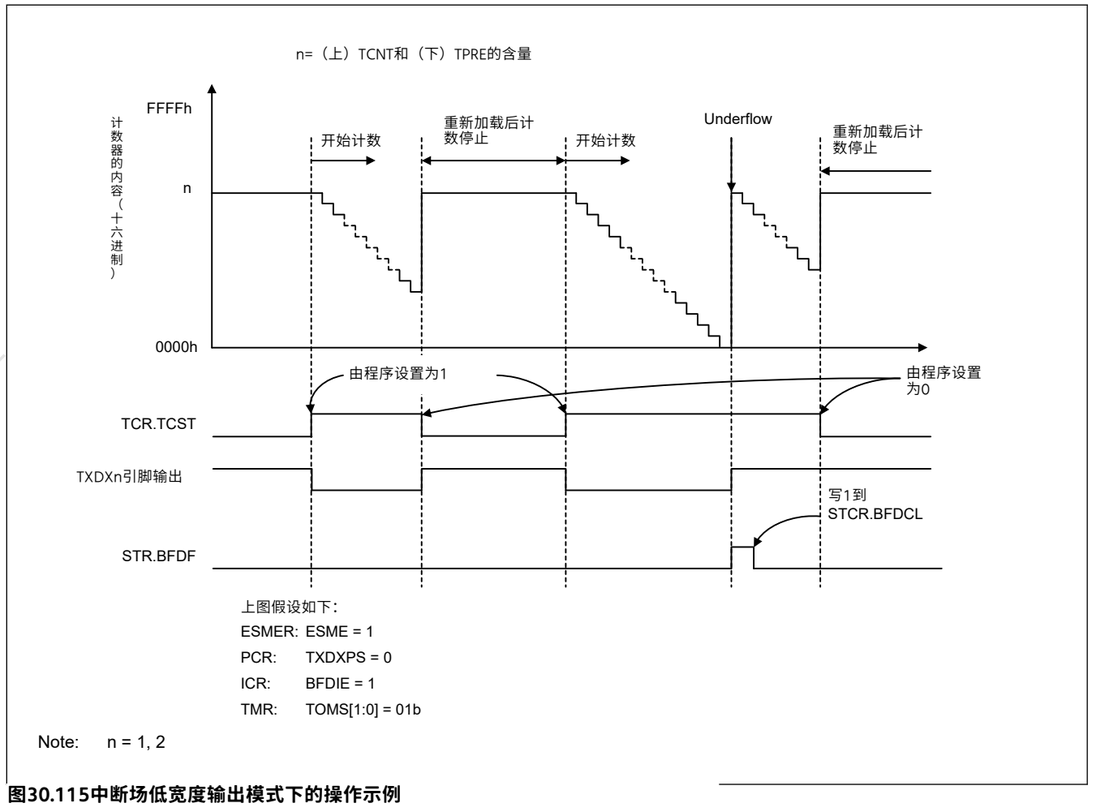

图30.115中断场低宽度输出模式下的操作示例

(2) 断场低宽度测定模式

该模式用于在接收起始帧时确定RXDXn(n=1 2)引脚上的输入信号中的中断场低电平宽度。将TMR.TOMS[1:0]位设置为01b会将操作切换到中断字段低宽度确定模式。TMR.TCSS[2:0]位选择计数器的时钟源。当TCR.TCST位设置为1时，接口进入

BreakField低宽度可确定状态。当从RXDXn引脚输入低电平时开始确定。当RXDXn引脚输入高电平时，寄存器TPRE和TCNT被重新加载，接口进入中断字段低宽度可确定状态。在中断字段低宽度确定期间定时器下溢时，STR.BFDF标志设置为1。如果ICR.BFDIE位的值为1，也会产生SCIX0中断。如果在数据传输期间定时器下溢导致中断产生形式的问题，在BreakField低宽度确定后停止定时器。图30.116显示了BreakField低宽度输出模式下的操作示例。

(3) Timer Mode

This mode is for counting cycles of the internal clock as the clock source. Setting the TMR.TOMS[1:0] bits to 00b switches operation to timer mode. The TMR.TCSS[2:0] bits select the clock source for the counter. Counting starts when 1 is written to the TCR.TCST bit and stops when 0 is written to the TCST bit. Registers TPRE and TCNT both count down. The TPRE register counts cycles of the clock source for counting, and underflows of the TPRE register provide the clock source for counting by the TCNT register. When the timer underflows, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.

(3) 定时器模式

该模式用于计数内部时钟作为时钟源的周期。将TMR.TOMS[1:0]位设置为00b会将操作切换到定时器模式。TMR.TCSS[2:0]位选择计数器的时钟源。将1写入TCR.TCST位时开始计数，将0写入TCST位时停止计数。寄存器TPRE和TCNT都倒计时。TPRE寄存器对时钟源的周期计数进行计数，TPRE寄存器的下溢为TCNT寄存器的计数提供时钟源。当定时器下溢时，STR.BFDF标志设置为1。如果ICR.BFDIE位的值为1，也会产生SCIX0中断。

30.12 Interrupt Sources

30.12 中断源

30.12.1 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (non-FIFO selected)

If the conditions for an SCIn_TXI and SCIn_RXI interrupt are satisfied while the interrupt status flag in the ICU is 1, the ICU does not output the interrupt request but saves it internally with a capacity for retention of one request per source.

When the interrupt status flag in the ICU is set to 0, the interrupt request retained within the ICU is output. The internally retained interrupt request is automatically discarded when the actual interrupt is output. Clearing of the associated interrupt enable bit (the TIE or RIE bit in the SCR/SCR_SMCI) can also be used to discard an internally retained interrupt request.

30.12.1 SCIn_TXI和SCIn_RXI中断的缓冲区操作（选择非FIFO）

如果在ICU中的中断状态标志为1时满足SCIn_TXI和SCIn_RXI中断的条件，则ICU不输出中断请求，而是将其保存在内部，每个源可以保留一个请求。

当ICU中的中断状态标志设置为0时，输出ICU中保留的中断请求。当实际中断输出时，内部保留的中断请求会被自动丢弃。清除相关中断使能位（SCRSCR_SMCI中的TIE或RIE位）也可用于丢弃内部保留的中断请求。

30.12.2 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (FIFO selected)

When an interrupt status flag in the ICU is set to 1, the SCIn_TXI and SCIn_RXI interrupts do not output interrupt requests to the ICU. When an interrupt status flag of the ICU is set to 0, and if the conditions for an SCIn_TXI and SCIn_RXI interrupts are satisfied, an interrupt request is generated.

30.12.2 SCIn_TXI和SCIn_RXI中断的缓冲区操作（选择FIFO）

当ICU中的中断状态标志设置为1时，SCIn_TXI和SCIn_RXI中断不会向ICU输出中断请求。当ICU的中断状态标志设置为0，并且满足SCIn_TXI和SCIn_RXI中断的条件时，将产生中断请求。

30.12.3 Interrupts in Asynchronous, Manchester, Clock Synchronous, and Simple SPI Modes

(1) Non-FIFO selected

Table 30.42 lists interrupt sources in asynchronous mode, Manchester mode, clock synchronous mode, and simple SPI mode.

A different interrupt vector can be assigned to each interrupt source. Individual interrupt sources can be enabled or disabled with the enable bits in the SCR register.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when transmit data is transferred from the TDR or TDRHL register*1 to the TSR register. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TE and SCR.TIE bits to 1 at the same time. An SCIn_TXI interrupt request can activate the DTC or DMAC to handle data transfer.

An SCIn_TXI interrupt request is not generated by setting the SCR.TE bit to 1 when SCR.TIE is 0 or by setting the SCR.TIE bit to 1 when the SCR.TE is 1.*2

When new data is not written by the time of transmission of the last bit of the current transmit data and SCR.TEIE is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated. Additionally, when SCR.TE is 1, the SSR.TEND flag retains the value 1 until more transmit data is written to the TDR or TDRHL register*1, and setting SCR.TEIE to 1 leads to the generation of an SCIn_TEI interrupt request.

Writing data to the TDR or TDRHL register*1 leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the SCIn_TEI interrupt request.

If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated when received data is stored in the RDR register. An SCIn_RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting any of the SSR.ORER, FER, PER and MER*3 flags to 1 when the SCR.RIE bit is 1 leads to the generation of an SCIn_ERI interrupt request.

An SCIn_RXI interrupt request is not generated in this case. Clearing all these flags (ORER, FER, PER, MER*3, SYER*3, PFER*3 and SBER*3) leads to discarding of the SCIn_ERI interrupt request.

Note 1. When asynchronous mode and 9-bit data length are selected.
Note 2. To temporarily prohibit SCIn_TXI interrupts on transmission of the last of the data when a new round of transmission is to be started, after handling the transmission-completed interrupt, control activation of the interrupt by using the interrupt request enable bit in the ICU rather than using the SCR.TIE bit. This approach can prevent the suppression of SCIn_TXI interrupt requests in the transfer of new data.
Note 3. MER, SYER, PFER, and SBER work as a factor of SCIn_ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECR) are set to "1".

(2) FIFO selected

Table 30.43 lists interrupt sources in FIFO selected mode.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when the stored amount of data in the FTDRL register becomes the threshold value indicated in FCR.TTRG or below. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TIE and SCR.TE bits to 1 simultaneously or by setting SCR.TIE to 1 when SCR.TE is 1.

An SCIn_TXI interrupt request is not generated by setting SCR.TE to 1 when SCR.TIE is 0.

If SCR.TEIE is 1 and if the next data is not written to the FTDRL register by the time the last bit of the transmit data is sent, the SSR_FIFO.TEND flag is set to 1 and the SCIn_TEI interrupt request is generated.

If SCR.RIE is 1, the SCIn_RXI interrupt request is generated when the stored amount of data in the FRDRL register is equal to or greater than the threshold value indicated in FCR.RTRG. When RTRG is 0, an SCIn_RXI interrupt does not occur even when the amount of data in the receive FIFO is equal to 0.

If the SCR.RIE bit is 1, when the SSR_FIFO.ORER flag is set to 1 or data with a framing error or a parity error is stored in the FRDRL register, the SCIn_ERI interrupt request is generated. When the amount of data stored in the FRDRL register is at the threshold value or above, the SCIn_RXI interrupt request is also generated. The SCIn_ERI interrupt request can be canceled, in which case SSR_FIFO.ORER, FER, and PER flags are all cleared.

30.12.3 异步、曼彻斯特、时钟同步和简单SPI中的中断 Modes

(1) Non-FIFO selected

表30.42列出了异步模式、曼彻斯特模式、时钟同步模式和简单SPI模式下的中断源。

可以为每个中断源分配不同的中断向量。可以使用SCR寄存器中的启用位启用或禁用各个中断源。

如果SCR.TIE位为1，则当发送数据从TDR传输或
TDRHL寄存器*1到TSR寄存器。也可以使用一条指令同时将SCR.TE和SCR.TIE位设置为1，从而产生SCIn_TXI中断请求。SCIn_TXI中断请求可以激活DTC或DMAC来处理数据传输。

当SCR.TIE为0时将SCR.TE位设置为1或通过设置
当SCR.TE为1时，SCR.TIE位为1。*2

当当前发送数据的最后一位发送时尚未写入新数据且SCR.TEIE为1，则
SSR.TEND标志设置为1并产生SCIn_TEI中断请求。此外，当SCR.TE为1时，SSR.TEND标志保持值1，直到更多的发送数据写入TDR或TDRHL寄存器*1，并且将SCR.TEIE设置为1会导致产生SCIn_TEI中断请求。

将数据写入TDR或TDRHL寄存器*1会导致SSR.TEND标志清零，并在一定时间后丢弃SCIn_TEI中断请求。

如果SCR.RIE位为1，则当接收到的数据存储在RDR寄存器中时会产生SCIn_RXI中断请求。一个
SCIn_RXI中断请求可以激活DTC或DMAC来处理数据传输。

当SCR.RIE位为1时，将任何SSR.ORER、FER、PER和MER*3标志设置为1会导致生成
SCIn_ERI中断请求。

在这种情况下不会产生SCIn_RXI中断请求。清除所有这些标志(ORER FER PER MER*3 SYER*3
PFER*3和SBER*3)导致丢弃SCIn_ERI中断请求。

注意1.选择异步模式和9位数据长度时。
注2.为了在新一轮传输开始时，在传输最后一个数据时暂时禁止SCIn_TXI中断，在处理完传输完成中断后，使用ICU中的中断请求使能位控制中断的激活而不是使用SCR.TIE位。这种方法可以防止在传输新数据时抑制SCIn_TXI中断请求。

注3.MER、SYER、PFER和SBER仅在曼彻斯特模式下作为SCIn_ERI中断的一个因素起作用。SYER、PFER和
SBER也仅在其启用位（MECR中的SYEREN、PFEREN、SBEREN）设置为“1”时才起作用。

(2) FIFO selected

表30.43列出了FIFO选择模式下的中断源。

如果SCR.TIE位为1，当FTDRL寄存器中存储的数据量变为FCR.TTRG中指示的阈值或更低时，将产生SCIn_TXI中断请求。SCIn_TXI中断请求也可以通过使用一条指令同时将SCR.TIE和SCR.TE位设置为1或在SCR.TE为1时将SCR.TIE设置为1来生成。

当SCR.TIE为0时，将SCR.TE设置为1不会产生SCIn_TXI中断请求。

如果SCR.TEIE为1，并且在发送数据的最后一位时下一个数据未写入FTDRL寄存器，则SSR_FIFO.TEND标志设置为1，并产生SCIn_TEI中断请求。

如果SCR.RIE为1，则当FRDRL寄存器中存储的数据量等于或大于FCR.RTRG中指示的阈值时，将产生SCIn_RXI中断请求。当RTRG为0时，即使接收FIFO中的数据量等于0，也不会发生SCIn_RXI中断。

如果SCR.RIE位为1，当SSR_FIFO.ORER标志设置为1或帧错误或奇偶校验错误的数据存储在FRDRL寄存器中时，将产生SCIn_ERI中断请求。当FRDRL寄存器中存储的数据量在阈值或以上时，也会产生SCIn_RXI中断请求。SCIn_ERI中断请求可以被取消，在这种情况下SSR_FIFO.ORER、FER和PER标志都被清除。

SCIn_TXI interrupt request activates the DTC or DMAC, allowing transfer of transmit data if the SCIn_TXI request is previously specified as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission after an error occurrence. However, the SSR_SMCI.ERS flag is not automatically set to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the SCR_SMCI.RIE bit to 1 to enable an SCIn_ERI interrupt request to be generated at error occurrence.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings. For DTC or DMAC settings, see section 17, Data Transfer Controller (DTC), section 16, DMA Controller (DMAC).

In reception, an SCIn_RXI interrupt request is generated when receive data is set to the RDR register. This SCIn_RXI interrupt request activates the DTC or DMAC, allowing transfer of the receive data if the SCIn_RXI request is previously specified as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an SCIn_ERI interrupt request is issued to the CPU instead. The error flag must be cleared.

30.12.5 Interrupts in Simple IIC Mode

Table 30.45 lists the interrupt sources in simple IIC mode. The STI interrupt is allocated to the transmit end interrupt (SCIn_TEI) request. The receive error interrupt (SCIn_ERI) and the address match (SCIn_AM) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple IIC mode.

When the SIMR2.IICINTM bit is 1:

- An SCIn_RXI request is generated on the falling edge of the SCLn signal for the 9th bit. If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.
- An SCIn_TXI request is generated on the falling edge of the SCLn signal for the 9th bit (acknowledge bit). If SCIn_TXI is previously set up as an activation source for the DTC or DMAC, the SCIn_TXI request activates the DTC or DMAC to handle transfer of the transmit data.

When the SIMR2.IICINTM bit is 0:

- An SCIn_RXI request (ACK detection) is generated if the input on the SDAn pin is low on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- An SCIn_TXI request (NACK detection) is generated if the input on the SDAn pin is high on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.

If the DTC or DMAC is used for data transfer in reception or transmission, always set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in SIMR3 are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Table 30.45 SCI interrupt sources

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_RXI (n = 0 to 9)	Reception, ACK detection	—	SCMR.RIE	Possible*1
SCIn_TXI (n = 0 to 9)	Transmission, NACK detection	—	SCMR.TIE	Possible
SCIn_TEI(STIn) (n = 0 to 9)	Completion of generation of a start, restart, or stop condition	SIMR3.IICSTIF	SCMR.TEIE	Not possible

Note 1. Activation of the DTC or DMAC is only possible when the SIMR2.IICINTM bit is 1 (use reception and transmission interrupts)

SCIn_TXI中断请求激活DTC或DMAC，如果之前将SCIn_TXI请求指定为DTC或DMAC激活源，则允许传输数据。当DTC或DMAC传输数据时，TEND标志自动设置为0。

如果发生错误，SCI会自动重新传输相同的数据。在重传期间，TEND标志保持为0，并且DTC或DMAC不被激活。因此，SCI和DTC或DMAC会自动传输指定的字节数，包括发生错误后的重传。但是，发生错误时，SSR_SMCI.ERS标志不会自动设置为0。因此，必须通过预先将SCR_SMCI.RIE位设置为1来清除ERS 标志，以在发生错误时启用SCIn_ERI中断请求。

使用DTC或DMAC发送或接收数据时，请务必在进行SCI设置之前启用DTC或DMAC。对于DTC或DMAC设置，请参阅第17节，数据传输控制器(DTC)，第16节，DMA控制器(DMAC)。

在接收中，当接收数据设置到RDR寄存器时，会产生SCIn_RXI中断请求。该SCIn_RXI中断请求激活DTC或DMAC，如果先前将SCIn_RXI请求指定为DTC或DMAC激活源，则允许传输接收数据。如果发生错误，则设置错误标志。因此，不会激活DTC或DMAC，而是向CPU发出SCIn_ERI中断请求。必须清除错误标志。

30.12.5 简单IIC模式下的中断

表30.45列出了简单IIC模式下的中断源。STI中断分配给发送结束中断(SCIn_TEI)请求。不能使用接收错误中断(SCIn_ERI)和地址匹配(SCIn_AM)请求。

DTC或DMAC也可用于处理简单IIC模式下的传输。

当SIMR2.IICINTM位为1时：

●SCIn_RXI请求在第8位的SCLn信号下降沿产生。如果SCIn_RXI先前设置为DTC或DMAC的激活源，则SCIn_RXI请求将激活DTC或DMAC以处理接收数据的传输。

●SCIn_TXI请求在第9位（确认位）的SCLn信号的下降沿产生。如果SCIn_TXI先前设置为DTC或DMAC的激活源，则SCIn_TXI请求将激活DTC或DMAC以处理传输数据的传输。

当SIMR2.IICINTM位为0时：

●如果SDAn引脚上的输入在第9位（确认位）的SCLn信号的上升沿为低电平，则生成SCIn_RXI请求（ACK检测）

●如果SDAn引脚上的输入在第9位（确认位）的SCLn信号的上升沿为高电平，则生成SCIn_TXI请求（NACK检测）

●如果先前将SCIn_RXI设置为DTC或DMAC的激活源，则SCIn_RXI请求将激活DTC或DMAC以处理接收数据的传输。

如果DTC或DMAC用于接收或传输中的数据传输，请务必在设置SCI之前设置并启用DTC或DMAC。

当SIMR3中的IICSTAREQ、IICRSTAREQ和IICSTPREQ位用于生成开始条件、重新启动条件或停止条件时，生成完成时会发出STI请求。

30.12.6 Interrupt Requests from the Extended Serial Mode Control Section

The extended serial mode control section has a total of six types of interrupt request for generating the SCIX0 interrupt (Break Field low width detected), SCIX1 interrupt (Control Field 0 match, Control Field 1 match, priority interrupt bit detected), SCIX2 interrupt (bus collision detected), and SCIX3 interrupt (valid edge detected). When any of the interrupt factors is generated, the corresponding status flag is set to 1. Details of all of the interrupt requests are listed in Table 30.46.

30.13 Event Linking

By using interrupt request signals as event signals, the SCIn can provide linked operation through the ELC for modules selected in advance.

Event signals can be output regardless of the values of the associated interrupt request enable bits.

- Indicates abnormal termination because of an overrun error during reception
- Indicates detection of the error signal during transmission in smart card interface mode
- The SSR_FIFO.FER and PER flags are 0, and receive data less than the receive FIFO data trigger number is set in a reception FIFO buffer, and it indicates that 15 ETUs elapse when FIFO is selected and the FCR.DRES bit is 1

(2) Receive data full event output (SCIn_RXI, n = 0 to 9)

- Indicates that ACK is detected if the SIMR2.IICINTM bit is 0 in simple IIC mode

30.12.6 来自扩展串行模式控制部分的中断请求

30.13 事件链接

通过使用中断请求信号作为事件信号，SCIn可以通过ELC为预先选择的模块提供联动操作。

无论相关中断请求使能位的值如何，都可以输出事件信号。

- Indicates a match of the comparison data (CDR.CMPD) with one frame of receive data when DCCR.DCME is set to 1 in asynchronous mode, including multi-processor mode.

30.14 Address Non-match Event Output (SCI0_DCUF)

SCI0_DCUF indicates the non-match of comparison data (CDR.CMPD) with receive data that is one frame of the data that is received when DCCR.DCME is set to 1 in asynchronous mode, including multi-processor mode. This event can be used for Snooze end request only. In detail, see section 10, Low Power Modes.

30.15 Noise Cancellation Function

Figure 30.117 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a 2-stage flip-flop circuit and a match detection circuit. When the input signals of the noise filter and the output signals of the 2- stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. When the same level is retained for 3 cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for 3 cycles or shorter is considered as noise, not as a receive signal.

In Asynchronous mode, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The receive level of the RXDn is taken in the flip-flop circuit of the noise filter on the base clock of asynchronous mode.

- When SEMR.ABCS = 0 and SEMR.ABCSE = 0, the cycle is 1/16 of a 1-bit period.
- When SEMR.ABCS = 1 and SEMR.ABCSE = 0, the cycle is 1/8 of a 1-bit period.
- When SEMR.ABCSE = 1, the cycle is 1/6 of a 1-bit period.

In simple IIC mode, this function can be used for each input on SDAn and SCLn. The sampling clock is selected from divided clock of baud rate generator settings SNFR.NFCS[2:0].

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR.TE and SCR.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, the function determines that a level match is detected and the result is conveyed as an internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles.

●SIMR2.IICINTM位在simpleIIC模式下为0表示检测到NACK

●如果SIMR2.IICINTM位在simpleIIC模式下为1，则表示检测到第9位SCLn下降沿

Non-FIFO selected

●表示发送数据从发送数据寄存器（TDR或TDRHL）传送到发送移位寄存器（TSR）。

●禁止使用该事件输出。

(4) 发送结束事件输出（SCIn_TEI，n=0到9）

●表示传输完成

●表示在简单IIC模式下产生启动条件、恢复条件或终止条件

Note: 选择FIFO时，禁止使用该事件输出

(5) 地址匹配事件输出(SCIn_AM n=0 3to9)

●在异步模式下，包括多处理器模式，当DCCR.DCME置1时，表示比较数据（CDR.CMPD）与一帧接收数据匹配。

30.14 地址不匹配事件输出(SCI0_DCUF)

SCI0_DCUF表示比较数据(CDR.CMPD)与接收数据不匹配，接收数据是在异步模式（包括多处理器模式）下DCCR.DCME设置为1时接收到的数据的一帧。此事件仅可用于贪睡结束请求。详细信息，请参见第10节，低功耗模式

30.15 降噪功能

图30.117显示了用于噪声消除的噪声滤波器的配置。噪声滤波器由一个2级触发器电路和一个匹配检测电路组成。当噪声滤波器的输入信号和2级触发器电路的输出信号完全匹配时，匹配的电平作为内部信号传送。除非另有匹配，否则将保留先前的值。当相同电平在噪声滤波器的采样时钟上保持3个周期或更长时间时，它被认为是有效的接收信号。3个周期或更短的脉冲变化被认为是噪声，而不是接收信号。

在异步模式下，可以对输入到RXDn引脚的接收信号应用噪声消除功能。RXDn的接收电平是在异步模式的基本时钟上的噪声滤波器的触发器电路中获取的。

●当SEMR.ABCS=0且SEMR.ABCSE=0时，周期为1位周期的116。

●当SEMR.ABCS=1且SEMR.ABCSE=0时，周期为1位周期的18。

●当SEMR.ABCSE=1时，周期为1位周期的16。

在简单IIC模式下，该功能可用于SDAn和SCLn上的每个输入。采样时钟从波特率发生器设置SNFR.NFCS[2:0]的分频时钟中选择。

如果在启用噪声滤波器的情况下基准时钟停止一次，然后再次重新启动基准时钟输入，则噪声滤波器操作将从时钟停止的状态恢复。当SCR.TE和SCR.RE在基本时钟输入期间设置为0时，所有噪声滤波器触发器值都被初始化为1。因此，如果在接收操作恢复时输入数据为1，则该函数确定一个电平检测到匹配并将结果作为内部信号传送。当输入的电平对应于0时，保留噪声滤波器的初始输出，直到电平在三个连续的采样周期中匹配。

30.16 Usage Notes

30.16.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable SCI operation. The SCI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

30.16.2 SCI Operation during Low Power State

(1) Transmission

When setting the module to the stopped state or in transitions to Software Standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR/SCR_SMCI to 0) after switching the TXDn pin to the general I/O port pin function. When setting I/O port as an SCI connection, the SPTR register can control the state of the TXDn pin. Setting the TE bit to 0 initializes the TSR register and the TEND bit in the SSR/SSR_SMCI is initialized to 1 with non-FIFO selected, and the value is retained, with FIFO selected. Depending on the port settings and SPTR register settings, output pins might output the level before a transition to the low-power state is made after release from the module-stopped state or Software Standby mode. When transitions to these states are made during transmission, the transmitted data becomes indeterminate.

To transmit data in the same transmission mode after cancellation of the low-power state:

1. Set the TE bit to 1.
2. Read SSR/SSR_FIFO/SSR_SMCI.
3. Write data to TDR sequentially to start data transmission.

To transmit data with a different transmission mode, initialize the SCI first.

Figure 30.118 shows an example flow of transition to Software Standby mode during transmission. Figure 30.119 and Figure 30.120 show the port pin states during transition to Software Standby mode.

Before specifying the module-stop state or making a transition to Software Standby mode from the transmission mode using DTC or DMAC transfer, stop the transmit operations (TE = 0). To start transmission after cancellation using the DTC or DMAC, set the TE bit to 1. The SCIn_TXI interrupt flag is set to 1 and transmission starts using the DTC or DMAC.

30.16 使用说明

30.16.1 模块停止功能的设置

模块停止控制寄存器B(MSTPCRB)可以启用或禁用SCI操作。SCI在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

30.16.2 低功耗状态下的SCI操作

(1) Transmission

当将模块设置为停止状态或转换为软件待机时，在将TXDn引脚切换为通用IO端口引脚功能后停止操作（通过将SCRSCR_SMCI中的TIE、TE和TEIE位设置为0）。当设置IO端口为SCI连接时，SPTR寄存器可以控制TXDn引脚的状态。将TE位设置为0初始化TSR寄存器，并且SSRSSR_SMCI中的TEND位在选择非FIFO时初始化为1，而在选择FIFO时保持该值。根据端口设置和SPTR寄存器设置，输出引脚可能会在从模块停止状态或软件待机模式释放后转换到低功耗状态之前输出电平。在传输过程中转换到这些状态时，传输的数据变得不确定。

在取消低功耗状态后以相同的传输模式传输数据：

1.将TE位设置为1。

2. Read SSR/SSR_FIFO/SSR_SMCI.

3.将数据依次写入TDR，开始数据传输。

要以不同的传输模式传输数据，请先初始化SCI。

图30.118显示了传输期间转换到软件待机模式的示例流程。图30.119和
图30.120显示了转换到软件待机模式期间的端口引脚状态。

在指定模块停止状态或从传输模式转换到软件待机模式之前，使用
DTC或DMAC传输，停止传输操作(TE=0)。要在取消后使用DTC或
DMAC，将TE位设置为1。SCIn_TXI中断标志 设置为1，并使用DTC或DMAC开始传输。

(2) Reception

When address match function is not used as wake-up condition

Before specifying the module-stop state or making a transition to Software Standby mode, stop the receive operations (RE = 0 in SCR/SCR_SMCI). If transition is made during data reception, the received data is invalid.

Figure 30.121 shows an example flow of transition to Software Standby mode during reception.

When address match function is used as wake-up condition

Before specifying the module-stop state or making a transition to Software Standby mode:

1. Set the operations after cancellation of the low power state.
2. Set CDR.CMPD and DCCR.DCME to 1.
3. Set the receive operations (RE = 1 in SCR/SCR_SMCI).
4. Set the module-stop state or Software Standby mode.

When SCI transfers to low power mode, if the receive data pin (RXD) is at the low level, set SEMR.RXDESEL = 0.

When setting SEMR.RXDESEL = 1, there is a possibility that a start bit (falling edge of RXD pin) cannot be detected on release of the low power mode.

Figure 30.122 shows an example flow of transition to Software Standby mode during reception with address match.

When using SCI0 in Snooze mode

When using SCI0 in Snooze mode, some restrictions apply, including maximum bit rates. For details, see section 10, Low Power Modes.

(2) Reception

地址匹配功能不用作唤醒条件时

在指定模块停止状态或转换到软件待机模式之前，停止接收操作（SCRSCR_SMCI中的RE=0）。如果在数据接收期间进行转换，则接收到的数据无效。

图30.121显示了接收期间转换到软件待机模式的示例流程。

当地址匹配功能用作唤醒条件时

在指定模块停止状态或转换到软件待机模式之前：

1.设置取消低功耗状态后的操作。

2.将CDR.CMPD和DCCR.DCME设置为1。

3.设置接收操作（在SCRSCR_SMCI中RE=1）。

4.设置模块停止状态或软件待机模式。

当SCI转移到低功耗模式时，如果接收数据引脚(RXD)为低电平，则设置SEMR.RXDESEL=0。

当设置SEMR.RXDESEL=1时，有可能在解除低功耗模式时无法检测到起始位（RXD引脚的下降沿）。

图30.122显示了在地址匹配的接收期间转换到软件待机模式的示例流程。

在贪睡模式下使用SCI0时

在贪睡模式下使用SCI0时，有一些限制，包括最大比特率。有关详细信息，请参阅第10节，低电源模式。

[1] Data being transmitted is lost. Data can be normally transmitted from the CPU by setting the TE bit in SCR/SCR_SMCI to 1, reading SSR/SSR_FIFO/ SSR_SMCI, and writing in Software Standby mode. However, if the DMAC or DTC is activated, the data remaining in the DMAC or DTC is Transmitted when both the TE and TIE bits in SCR/SCR_SMCI are set to 1.

[2] Set the I/O port function and SPTR register settings to switch the TXDn pin to operate as a general I/O port.

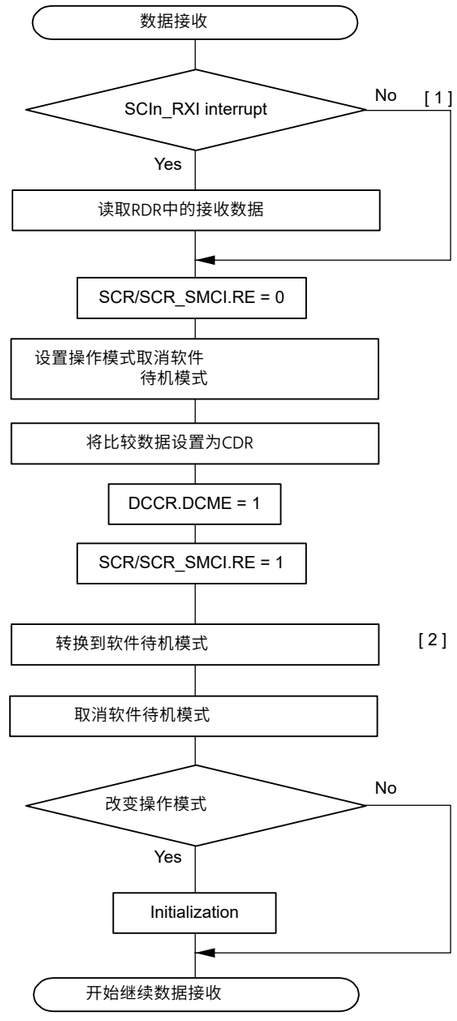
30.16.3 Break Detection and Processing

(1) Non-FIFO selected

When a framing error is detected, a break can be detected by reading the RXDn pin value directly. In a break, the input from the RXDn pin becomes all 0s, and the SSR.FER flag is set to 1 to indicate a framing error, and the SSR.PER flag might also be set to 1 to indicate a parity error. The SCI continues the receive operation even after a break is received. Therefore, even if the FER flag is 0, indicating that no framing error occurred, it is set to 1 again. When the SEMR.RXDESEL bit is 1, the SCI sets the SSR.FER flag to 1 and stops receiving operations until a start bit of the next data frame is detected. If the SSR.FER flag is set to 0, the SSR.FER flag retains 0 during the break.



[1]接收到的数据无效

[2]包括模块停止状态的设置

图30.122在地址匹配的接收期间转换到软件待机模式的示例流程

30.16.3 断裂检测和处理

(1) Non-FIFO selected

当检测到帧错误时，可以通过直接读取RXDn引脚值来检测中断。在中断时，来自RXDn引脚的输入变为全0，并且SSR.FER标志设置为1表示帧错误，SSR.PER标志也可能设置为1表示奇偶校验错误。即使在收到中断后，SCI仍继续接收操作。因此，即使FER标志为0，表示没有发生帧错误，它也会再次设置为1。当SEMR.RXDESEL位为1时，SCI将SSR.FER标志设置为1并停止接收操作，直到检测到下一个数据帧的起始位。如果

SSR.FER标志设置为0，SSR.FER标志在中断期间保持0。

When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit on the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

(2) FIFO selected

After a framing error is detected and when the SCI detects that continuous receive data is 0 for 1 frame, reception stops. When a framing error is detected, a break can be detected by reading the SPTR.RXDMON flag value. After the RXDn signal is in high and the break is finished, data reception to the FRDRHL register resumes.

30.16.4 Mark State and Production of Breaks

When the SCR/SCR_SMCI.TE bit is 0, disabling serial transmission, the state of the TXDn pin can be set using the SPTR.SPB2IO and SPTR.SPB2DT bits. With this approach, a TXDn pin can be placed in the mark state to transmit a break.

Before setting the SCR/SCR_SMCI.TE bit to 1, enabling serial transmission, set the SPB2IO and SPB2DT bits to put the communication line in the mark state (the state of 1), and change the TXDn pin using I/O port function. To output a break on data transmission, after setting the TXDn pin to output 0 by setting the SPB2IO and SPB2DT bits, change the TXDn pin using the I/O port function and set the SCR/SCR_SMCI.TE bit to 0. When the SCR/SCR_SMCI.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

30.16.5 Receive Error Flags and Transmit Operation in Clock Synchronous Mode and Simple SPI Mode

Transmission cannot start when a receive error flag (ORER) in SSR/SSR_FIFO is set to 1, even when data is written to TDR or FTDRL*1. Always set the receive error flags to 0 before starting transmission.

Note: The receive error flags cannot be set to 0 when the RE bit in SCR/SCR_SMCI is set to 0 (serial reception is disabled).

Note 1. Do not use the FTDRH register in simple SPI mode.

30.16.6 Restrictions on Clock Synchronous Transmission in Clock Synchronous Mode and Simple SPI Mode

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

Wait at least the following time from writing transmit data to TDR to the start of the external clock input:

1 PCLK cycle + data output delay time for the slave (t_{DO}) + setup time for the master (t_{SU}). See Figure 30.123.

(2) Continuous transmission

Write the next transmit data to TDR or TDRHL before the falling edge of the transmit clock for bit [7] . See Figure 30.123.

When updating TDR after bit [7] has started to transmit, update TDR while the synchronization clock is in the low-level period, and set the high-level width of the transmit clock (bit [7]) to 4 PCLK cycles or longer. See Figure 30.123.

当RXDn引脚设置为1且中断结束时，在第一个下降沿检测起始位的开始
RXDn引脚允许SCI开始接收操作。

(2) FIFO selected

检测到帧错误后，当SCI检测到1帧连续接收数据为0时，接收停止。当检测到帧错误时，可以通过读取SPTR.RXDMON标志值来检测中断。RXDn信号为高电平且中断完成后，FRDRHL寄存器的数据接收恢复。

30.16.4 标记状态和产生的中断

当SCRSCR_SMCI.TE位为0时，禁用串行传输，TXDn引脚的状态可以使用
SPTR.SPB2IO和SPTR.SPB2DT位。使用这种方法，可以将TXDn引脚置于标记状态以发送中断。

在设置SCRSCR_SMCI.TE位为1，使能串行传输之前，设置SPB2IO和SPB2DT位使通信线处于标记状态（状态为1），并使用IO端口功能改变TXDn引脚。要输出数据传输中断，通过设置SPB2IO和SPB2DT位将TXDn引脚设置为输出0后，使用IO端口功能更改TXDn引脚并将SCRSCR_SMCI.TE位设置为0。当SCRSCR_SMCI.TE位设置为0，无论当前的传输状态如何，都初始化发送器。

30.16.5 在时钟同步模式下接收错误标志和发送操作和简单SPI模式

当SSRSSR_FIFO中的接收错误标志(ORER)设置为1时，传输无法开始，即使数据已写入TDR或FTDRL*1。在开始传输之前，始终将接收错误标志设置为0。

Note: 当SCRSCR_SMCI中的RE位设置为0（禁用串行接收）时，接收错误标志不能设置为0。

注1.不要在简单SPI模式下使用FTDRH寄存器。

30.16.6 时钟同步模式和简单SPI模式下时钟同步传输的限制

当外部时钟源用作同步时钟时，有以下限制。

(1) 传输开始

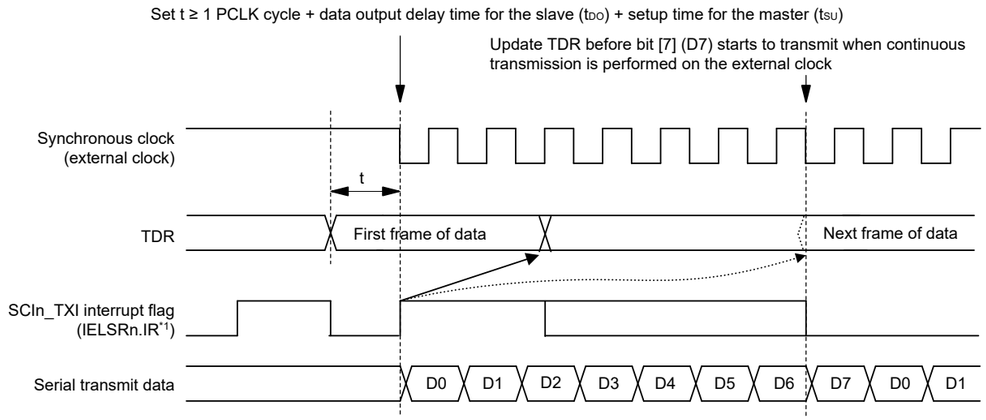
从将发送数据写入TDR到外部时钟输入开始，至少等待以下时间：

1个PCLK周期+从机的数据输出延迟时间(tDO)+主机的建立时间(tSU)。请参见图30.123。

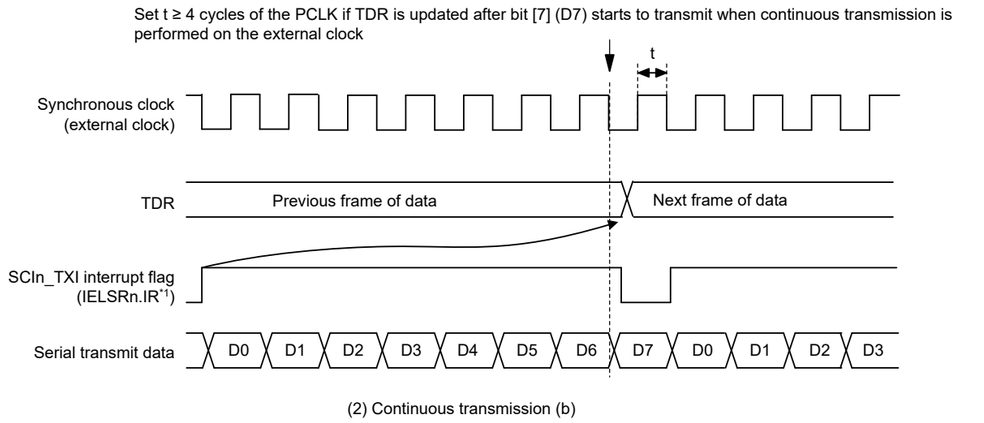
(2) 连续传输

在位[7]的发送时钟下降沿之前将下一个发送数据写入TDR或TDRHL。请参见图30.123。

在bit[7]开始发送后更新TDR时，在同步时钟处于低电平期间更新TDR，并将发送时钟（bit[7]）的高电平宽度设置为4个PCLK周期或更长.请参见图30.123。



(1) Start of transmission and (2) Continuous transmission (a)



(2) Continuous transmission (b)

Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.123 Restraints on use of external clock in clock synchronous transmission

30.16.7 Restrictions on Using DTC or DMAC

During transmission or reception operations using the DTC or DMAC, do not set transfer data for the DTC or DMAC.

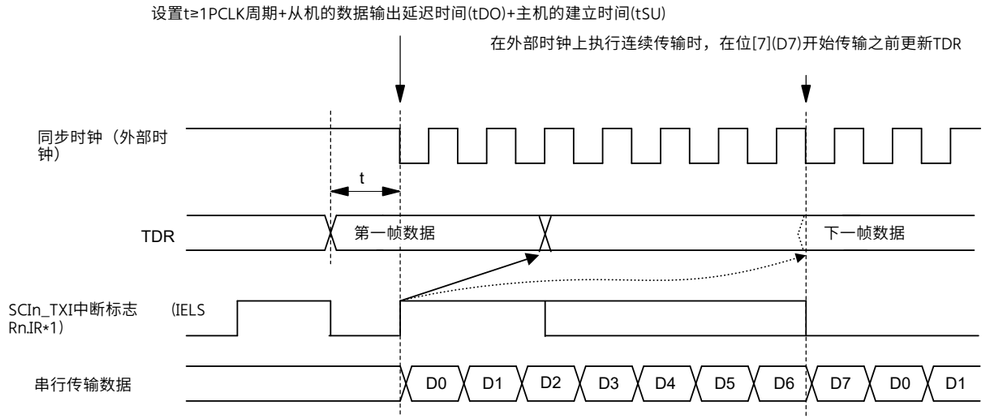
(1) Writing data to TDR (FTDRHL)

Non-FIFO selected

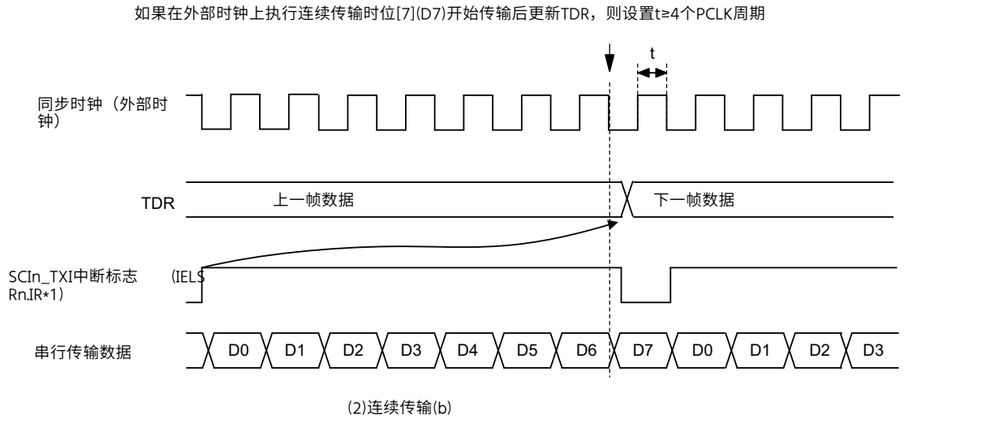
Data can be written to TDR and TDRHL. However, if new data is written to TDR or TDRHL when transmit data remains in TDR or TDRHL, the previous data in TDR and TDRHL is lost because it was not transferred to TSR yet. When using DTC or DMAC, always write transmit data to TDR or TDRHL in the SCIn_TXI interrupt request handling routine.

FIFO selected

It is possible to write data to the FTDRH and FTDRL registers when SCR.TE is 1. Confirm the amount of writable data using the FDR.T[4:0] bits.



(1)传输开始和(2)连续传输(a)



(2)连续传输(b)

注1.有关相应中断事件编号的信息，请参见第13节，中断控制器单元(ICU)。

图30.123时钟同步传输中使用外部时钟的限制

30.16.7 使用DTC或DMAC的限制

在使用DTC或DMAC进行发送或接收操作期间，请勿为DTC或DMAC设置传输数据。

(1) 将数据写入TDR(FTDRHL)

Non-FIFO selected

数据可以写入TDR和TDRHL。但是，如果在发送数据保留在TDR或TDRHL中时将新数据写入TDR或TDRHL，则TDR和TDRHL中的先前数据将丢失，因为它尚未传输到TSR。使用DTC或DMAC时，始终在SCIn_TXI中断请求处理程序中将发送数据写入TDR或TDRHL。

FIFO selected

当SCR.TE为1时，可以将数据写入FTDRH和FTDRL寄存器。使用FDR.T[4:0]位确认可写入的数据量。

(2) Reading data from RDR (FRDRHL)

When using the DTC or DMAC to read RDR and RDRHL, always set the receive data full interrupt (SCIn_RXI) as the activation source of the relevant SCI.

30.16.8 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IELSRn.IR flag) in the ICU is 1, follow the procedure in this section to clear interrupt requests before permitting operations (by setting the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit to 1). For details on the interrupt status flag, see section 13, Interrupt Controller Unit (ICU).

1. Confirm that transfer has stopped (the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit is 0)
2. Set the associated interrupt enable bit (SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit) to 0
3. Read the associated interrupt enable bit (SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit) to check that it actually becomes 0
4. Set the interrupt status flag, IELSRn.IR, in the ICU to 0

30.16.9 External Clock Input in Clock Synchronous Mode and Simple SPI Mode

In clock synchronous mode and simple SPI mode, the external clock SCKn must be input as follows:

High-pulse period, low-pulse period = 2 PCLK cycles or more, period = 6 PCLK cycles or more.

30.16.10 Limitations on Simple SPI Mode

(1) Master mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set in the SPMR.CKPH and CKPOL bits when the SPMR.SSE bit is 1.
  This prevents the clock line from being placed in the high-impedance state when the SCR.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR.TE bit changes from 0 to 1. When the SPMR.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not required because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.
- For the clock delay setting (SPMR.CKPH bit is 1), the receive data full interrupt (SCIn_RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 30.124. If the TE and RE bits in the SCR register become 0 before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Additionally, an SCIn_RXI interrupt might lead to the input signal on the SSn pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, the SCKn pin output goes to high-impedance while the input on the SSn pin is at the low level if a mode fault error occurs while a character is being transferred, stopping supply of the clock signal to the connected slave. Reset the connected slave to avoid misaligned bits when transfer is restarted.

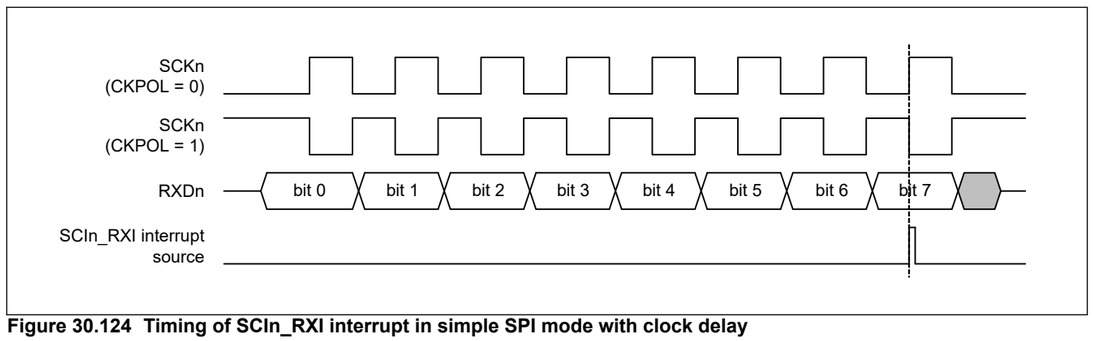


Figure 30.124 Timing of SCIn_RXI interrupt in simple SPI mode with clock delay

(2) 从RDR(FRDRHL)读取数据

使用DTC或DMAC读取RDR和RDRHL时，始终将接收数据满中断（SCIn_RXI）设置为相关SCI的激活源。

30.16.8 开始转移注意事项

在ICU中的中断状态标志（IELSRn.IR标志）为1时开始传输的点，按照本节中的步骤在允许操作之前清除中断请求（通过设置SCRSCR_SMCI.TE或SCRSCR_SMCI.RE位到1)。有关中断状态标志的详细信息，请参见第13节，中断控制器单元(ICU)。

1.确认传输已停止（SCRSCR_SMCI.TE或SCRSCR_SMCI.RE位为0）

2.将相关的中断使能位（SCRSCR_SMCI.TE或SCRSCR_SMCI.RE位）设置为0

3.读取相关的中断使能位（SCRSCR_SMCI.TE或SCRSCR_SMCI.RE位）以检查它是否实际变为0

4.将ICU中的中断状态标志IELSRn.IR设置为0

30.16.9 时钟同步模式和简单SPI模式下的外部时钟输入

在时钟同步模式和简单SPI模式下，外部时钟SCKn必须输入如下：

高脉冲周期，低脉冲周期=2个PCLK周期或更多，周期=6个PCLK周期或更多。

30.16.10 简单SPI模式的限制

(1) 主模式

●当SPMR.SSE位为1时，使用电阻上拉或下拉与SPMR.CKPH和CKPOL位中设置的传输时钟的初始设置相匹配的时钟线。
这可以防止当SCR.TE位设置为0时时钟线处于高阻抗状态，或者当SCR.TE位从0变为1时在时钟线上产生意外边沿。SSE位在单主机模式下为0，不需要上拉或下拉时钟线，因为即使SCR.TE位设置为0，时钟线也不会处于高阻状态。

●对于时钟延迟设置（SPMR.CKPH位为1），接收数据满中断（SCIn_RXI）在SCKn引脚的最后一个时钟沿之前产生，如图30.124所示。如果SCR寄存器中的TE和RE位在SCKn引脚上的时钟信号的最后一个边沿之前变为0，则SCKn引脚处于高阻状态，因此传输时钟的最后一个时钟脉冲的宽度为缩短。此外，SCIn_RXI中断可能会导致所连接从机的SSn引脚上的输入信号在SCKn引脚上的时钟信号的最后一个边沿之前变为高电平，从而导致从机的错误操作。

●在多主机配置中，如果在传输字符时发生模式故障错误，则SCKn引脚输出变为高阻态，而SSn引脚上的输入处于低电平，从而停止向主机提供时钟信号。连接的奴隶。重新启动传输时，重置连接的从机以避免未对齐的位。

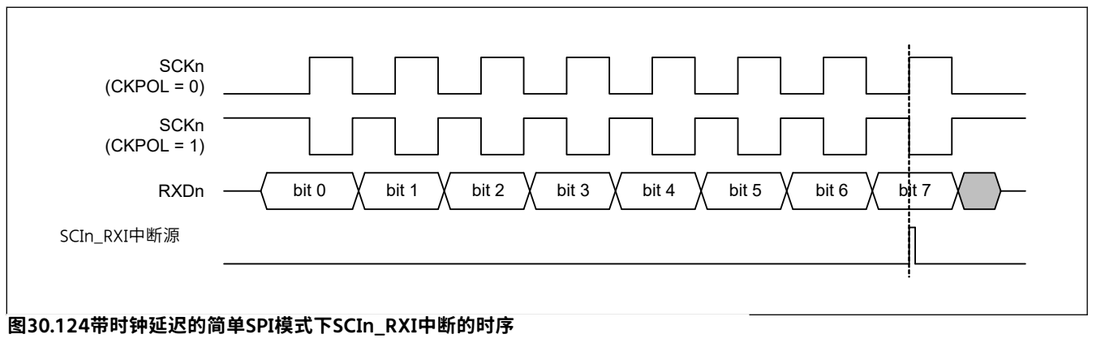

图30.124带时钟延迟的简单SPI模式下SCIn_RXI中断的时序

(2) Slave mode

- Wait at least the following time from writing transmit data in the TDR register to the start of the external clock input.
  1 PCLK cycle + data output delay for the slave (t_{DO}) + setup time for the master (t_{SU})
  Also wait at least 5 PCLK cycles from the input of the low level on the SSn pin to the start of the external clock input.
- Provide an external clock signal to the master the same as the data length for transfer
- Control the input on the SSn pin before the start and after the end of data transfer
- When the input level on the SSn pin is to be changed from low to high while a character is being transferred, set the TE and RE bits in the SCR register to 0 and, after restoring the settings, restart transfer of the first byte

30.16.11 Notes on Transmitt Enable bit (SCR.TE)

In initial register value, when SCR.TE bit is “0”, the terminal as “TXDn” outputs high impedance.

So please make sure that the TXDn line won’t be high impedance by the following one of ways.

1. The pull-up resistance is connected to the TXDn line.
2. Before SCR.TE bit is “0”, the function of the terminal is changed to general-purpose input port or output port. And after SCR.TE bit is “1”, thr function of the terminal is changed to “TXDn”.
3. In asynchronous mode, you can set SPTR and decided level of TXDn terminal during SCR.TE is “0”.

In the Simple SPI mode slave operation, the RXDn terminal operates in the same way as the above TXDn terminal, so please deal with 1 or 2 in the same way. (3 can not be used.)

30.16.12 Limitation 1 on Usage of the Extended Serial Mode Control Section

When the PCR.SHARPS bit is set to 1, output on the TXDXn/RXDXn (n = 1, 2) pin is only possible when the following conditions apply.

- The timer of the SCIh module is in Break Field low width output mode and the value of the TCR.TCST bit is 1 (when the TCST bit is set to 1, the high level continues to be output for up to one cycle of the clock source for counting by the timer counter before output of the low level)
- The value of the SCIn.SCR.TE bit is 1.

30.16.13 Limitation 2 on Usage of the Extended Serial Mode Control Section

An SCIg interrupt request is generated even if the extended serial mode is enabled. However, the SCIg interrupt should not be used during reception of a Start Frame because SCIh uses an SCIg interrupt request.

The two ways of dealing with this are described below. When a receive error is detected, clear the error flag of the SCIg and initialize the control section of the SCIh.

1. Set the SCR.RIE bit of the SCIg to 0 to disable the output of interrupt requests. Check the error flags in the SSR register for SCIg on completion of the reception of a Start Frame, because an ERI interrupt is not generated if a receive error occurs. After reception of the Start Frame is completed, set the SCR.RIE bit of the SCIg to 1 by the time the first byte of the Information Frame is received.
2. Set the SCR.RIE bit of the SCIg to 1 to disable RXI interrupts and enable ERI interrupts for ICU.
   Clear the IRn.IR flag to enable the acceptance of RXI interrupts by ICU by the time the first byte of the Information Frame is received after the completion of Start Frame reception.

(2) 从机模式

●从将发送数据写入TDR寄存器到外部时钟输入开始，至少等待以下时间。
1个PCLK周期+从机的数据输出延迟(tDO)+主机的建立时间(tSU)
还要等待至少5个PCLK周期，从SSn引脚上的低电平输入到外部时钟输入开始。

●向主机提供与传输数据长度相同的外部时钟信号

●在数据传输开始前和结束后控制SSn引脚上的输入

●当在字符传输过程中SSn引脚的输入电平由低变为高时，将SCR寄存器中的TE和RE位设置为0，并在恢复设置后重新开始传输第一个字节

30.16.11 发送使能位(SCR.TE)的注意事项

在初始寄存器值中，当SCR.TE位为“0”时，“TXDn”端输出高阻抗。

所以请通过以下方式之一确保TXDn线不会高阻。

1.上拉电阻连接到TXDn线。

2.SCR.TE位为“0”之前，端子功能变为通用输入端口或输出端口。并且在SCR.TE位为“1”后，终端的thr功能变为“TXDn”。

3.在异步模式下，可以设置SPTR和SCR.TE期间TXDn端子的决定电平为“0”。

在SimpleSPI模式从机操作中，RXDn端子与上述TXDn端子的操作方式相同，因此请按相同方式处理1或2。（3个不能用。）

30.16.12 使用扩展串行模式控制部分的限制1

当PCR.SHARPS位设置为1时，TXDXnRXDXn(n=1 2)引脚上的输出只有在以下条件适用时才可能。

●SCIh模块的定时器处于BreakField低宽度输出模式，TCR.TCST位的值为1（当TCST位设置为1时，最多持续输出高电平一个周期）低电平输出前由定时器计数器计数的时钟源）

●SCIn.SCR.TE位的值为1。

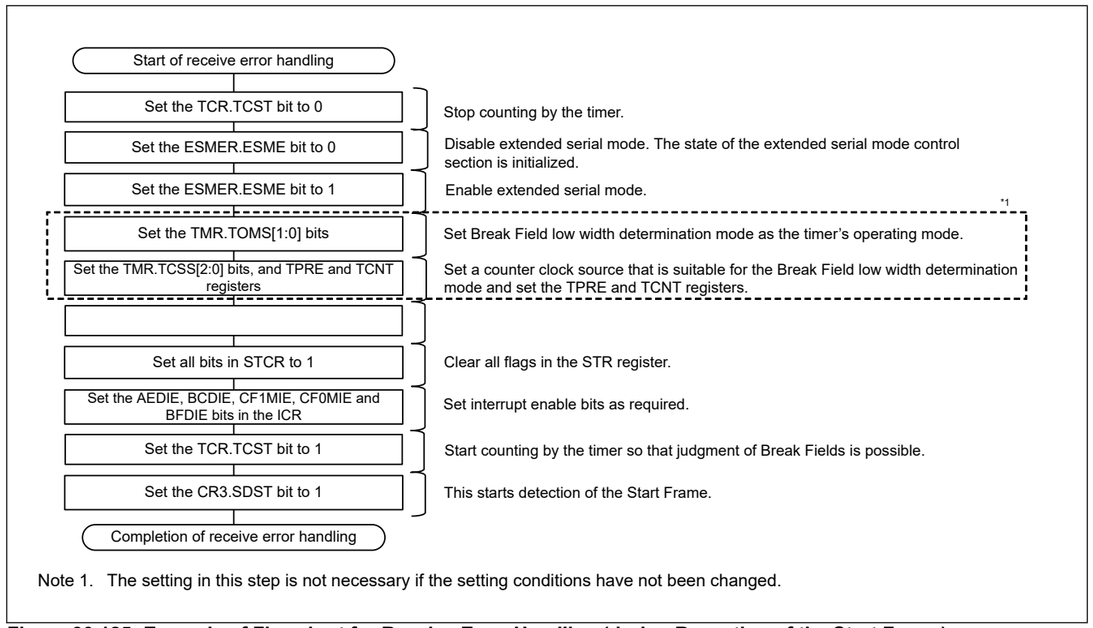
30.16.13 使用扩展串行模式控制部分的限制2

即使启用了扩展串行模式，也会产生SCIg中断请求。但是，在接收起始帧期间不应使用SCIg中断，因为SCIh使用SCIg中断请求。

下面介绍两种处理方法。当检测到接收错误时，清除SCIg的错误标志并初始化SCIh的控制部分。

1.将SCIg的SCR.RIE位设置为0，以禁用中断请求的输出。在完成接收起始帧时检查SSR寄存器中的错误标志是否有SCIg，因为如果发生接收错误，则不会产生ERI中断。开始帧接收完成后，在接收到信息帧的第一个字节时将SCIg的SCR.RIE位设置为1。

2.将SCIg的SCR.RIE位设置为1，以禁用RXI中断并启用ICU的ERI中断。
清除IRn.IR标志以使ICU在信息的第一个字节之前接受RXI中断
开始帧接收完成后接收帧。



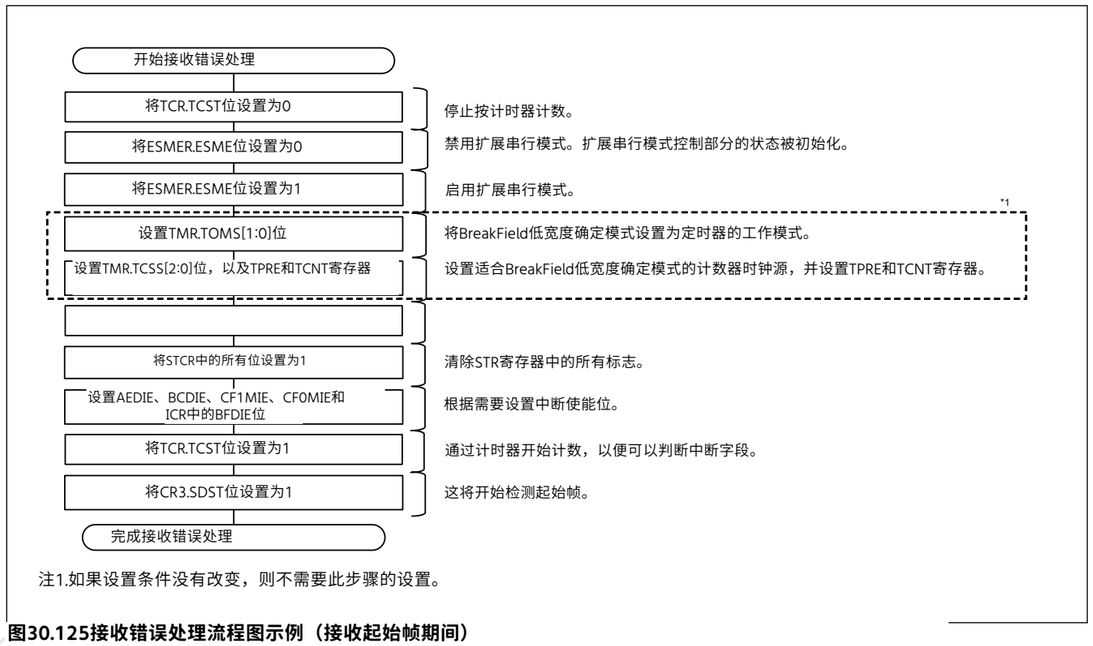
Note 1. The setting in this step is not necessary if the setting conditions have not been changed.

Figure 30.125 Example of Flowchart for Receive Error Handling (during Reception of the Start Frame)

30.16.14 Note on Stopping Reception When Using the RTS Function in Asynchronous Mode

One clock cycle of PCLK is required for the time from setting the SCR.RE bit to 0 to stopping the RTS signal generator in asynchronous mode.

When reading the RDR (or RDRL) register after setting the SCR.RE bit to 0, confirm that the RE bit has been set to 0 before reading the RDR (or RDRL) register to prevent these two processes from being performed consecutively.



注1.如果设置条件没有改变，则不需要此步骤的设置。

图30.125接收错误处理流程图示例（接收起始帧期间）

30.16.14 异步使用RTS函数时停止接收的注意事项 Mode

从将SCR.RE位设置为0到在异步模式下停止RTS信号发生器，需要一个PCLK时钟周期。

在将SCR.RE位设置为0后读取RDR（或RDRL）寄存器时，请在读取RDR（或RDRL）寄存器之前确认RE位已设置为0，以防止这两个过程连续执行。

31. I²C Bus Interface (IIC)

31.1 Overview

The I²C bus interface (IIC) has 3 channels. The IIC module conforms with and provides a subset of the NXP I²C (Inter-Integrated Circuit) bus interface functions.

Table 31.1 lists the IIC specifications, Figure 31.1 shows a block diagram, and Figure 31.2 shows an example of I/O pin connections to external circuits, with an I²C bus configuration. Table 31.2 lists the I/O pins.

SDAO bit (SDA Output Control/Monitor) and SCLO bit (SCL Output Control/Monitor)

The SDAO and SCLO bits directly control the SDAn and SCLn signals output from the IIC. When writing to these bits, also write 0 to the SOWP bit. Setting these bits results in input to the IIC by the input buffer. When slave mode is selected, a start condition might be detected and the bus might be released, depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, transmission, or reception. Operation after rewriting under these conditions is not guaranteed. When reading these bits, the state of signals output from the IIC can be read.

CLO bit (Extra SCL Clock Cycle Output)

The CLO bit allows output of an extra SCL clock cycle for debugging or error processing. Normally, set this bit to 0. Setting the bit to 1 in a normal communication state causes a communication error. For details on this function, see section 31.12.2. Extra SCL Clock Cycle Output Function.

IICRST bit (I^2C Bus Interface Internal Reset)

The IICRST bit initiates an internal state reset of the IIC. Setting this bit to 1 initiates an IIC reset or internal reset. Whether an IIC reset or internal reset is initiated is determined by the settings of this bit in combination with the ICE bit. Table 31.3 lists the IIC resets.

The IIC reset initializes all registers except ICCR1.ICE and ICCR1.IICRST bits and internal states of the IIC. In addition to the internal states of the IIC, the internal reset initializes the following:

- Bit counter (ICMR1.BC[2:0] bits)
- I^2C Bus Shift Register (ICDRS)
- I^2C Bus Status Registers (ICSR1 and ICSR2)
- SDAO and SCLO Output Control/Monitor (ICCR1.SDAO and ICCR1.SCLO bits)

SDAO位（SDA输出控制监视器）和SCLO位（SCL输出控制监视器）

SDAO和SCLO位直接控制IIC输出的SDAn和SCLn信号。写入这些位时，还要向SOWP位写入0。设置这些位会导致输入缓冲器向IIC输入。选择从模式时，可能会检测到启动条件并释放总线，具体取决于位设置。

不要在开始条件、停止条件、重启条件、发送或接收期间重写这些位。不保证在这些条件下重写后的操作。读取这些位时，可以读取IIC输出的信号状态。

CLO位（额外SCL时钟周期输出）

CLO位允许输出额外的SCL时钟周期用于调试或错误处理。通常，将此位设置为0。在正常通信状态下将此位设置为1会导致通信错误。有关此功能的详细信息，请参阅第31.12.2节。额外的SCL时钟周期输出功能。

IICRST位（I2C总线接口内部复位）

IICRST位启动IIC的内部状态复位。将此位设置为1会启动IIC复位或内部复位。是IIC复位还是内部复位由该位的设置和ICE位共同决定。表31.3列出了IIC复位。

IIC复位初始化除ICCR1.ICE和ICCR1.IICRST位和IIC内部状态之外的所有寄存器。除了IIC的内部状态之外，内部复位还会初始化以下内容：

- ●位计数器（ICMR1.BC[2:0]位）
- ●I2C总线移位寄存器(ICDRS)
- ●I2C总线状态寄存器（ICSR1和ICSR2）
- ●SDAO和SCLO输出控制监视器（ICCR1.SDAO和ICCR1.SCLO位）

- I2C Bus Control Register 2 (except ICCR2.BBSY bit)

●I2C总线控制寄存器2（ICCR2.BBSY位除外）

For the reset conditions for each register, see section 31.15. State of Registers When Issuing Each Condition.

关于各寄存器的复位条件，请参阅31.15节。发出每个条件时的寄存器状态。

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the IIC without initializing the port settings and the control and setting registers of the IIC. If the IIC hangs in a low-level output state, resetting the internal states cancels the low-level output state and releases the bus with the SCLn pin and SDAn pin at high impedance.

在操作期间将IICRST位设置为1（ICE位设置为1）启动的内部复位会复位IIC的内部状态，而无需初始化IIC的端口设置以及控制和设置寄存器。如果IIC在低电平输出状态下挂起，复位内部状态会取消低电平输出状态并释放总线，同时SCLn引脚和SDAn引脚处于高阻抗状态。

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up that occurs during communication with the master device in slave mode, the slave and master devices might enter different states, because the bit counter information differs. For this reason, do not initiate an internal reset in slave mode. Initiate recovery processing from the master device. If an internal reset is required because the IIC hangs with the SCLn line in a low-level output state in slave mode, initiate an internal reset, then issue a restart condition from the master device, or issue a stop condition and resume communication from the start condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start or restart condition from the master device, synchronization is lost because the master and slave devices operate asynchronously.

Note: 如果在从模式下与主设备通信期间发生的总线挂断使用IICRST位启动内部复位，则从设备和主设备可能会进入不同的状态，因为位计数器信息不同。因此，不要在从模式下启动内部复位。从主设备启动恢复处理。如果由于IIC在从模式下挂起且SCLn线处于低电平输出状态而需要内部复位，则启动内部复位，然后从主设备发出重新启动条件，或者发出停止条件并从主设备恢复通信开始条件。如果通过仅在从设备中启动复位来重新启动通信，而没有从主设备发出启动或重启条件，则由于主设备和从设备异步操作而失去同步。

ICE bit (I2C Bus Interface Enable)

The ICE bit selects the active or inactive state of the SCLn and SDAn pins. It can also be combined with the IICRST bit to initiate two types of resets. See Table 31.3 for the reset descriptions.

Set the ICE bit to 1 when using the IIC. The SCLn and SDAn pins are placed in the active state when the ICE bit is set to 1. Set the ICE bit to 0 when the IIC is not used. The SCLn and SDAn pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCLn or SDAn pin to the IIC when setting up the pin function control. Slave address comparison is performed if the pins are assigned to the IIC.

ICE位（I2C总线接口使能）

ICE位选择SCLn和SDAn引脚的有效或无效状态。它也可以与IICRST位组合来启动两种类型的复位。复位说明见表31.3。

使用IIC时将ICE位设置为1。当ICE位设置为1时，SCLn和SDAn引脚处于活动状态。不使用IIC时，将ICE位设置为0。当ICE位设置为0时，SCLn和SDAn引脚处于非活动状态。在设置引脚功能控制时，不要将SCLn或SDAn引脚分配给IIC。如果引脚分配给IIC，则执行从地址比较。

Note 1. The MST and TRS bits can be written to when the ICMR1.MTWP bit is set to 1.

ST bit (Start Condition Issuance Request)

The ST bit requests transition to master mode and triggers a start condition. When this bit is set to 1, a start condition is issued when the BBSY flag is set to 0 (bus free state). For details on this function, see section 31.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the ST bit.

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Only set the ST bit to 1 (start condition request) when the BBSY flag is set to 0 (bus free state). Arbitration might be lost if the ST bit is set to 1 (start condition request) when the BBSY flag is 1 (bus busy state).

RS bit (Restart Condition Issuance Request)

The RS bit requests that a restart condition be issued in master mode. When this bit is set to 1 to request a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 31.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the RS bit with the BBSY flag in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Do not set the RS bit to 1 while issuing a stop condition.
Note: If 1 (restart condition request) is written to the RS bit in slave mode, the restart condition is not issued, but the RS bit remains set to 1. If the operating mode changes to master mode without the bit being cleared, a restart condition might be issued.

Bit	Symbol	Function	R/W
3	SP	停止条件发出请求 0：不发出停止条件请求1：发出停止条件请求	R/W
4	—	该位读取为0。写入值应为0。	R/W
5	TRS	Transmit/Receive Mode 0：接收模式1：发送模式	R/W*1
6	MST	Master/Slave Mode 0：从模式1：主模式	R/W*1
7	BBSY	总线忙检测标志 0：I2C总线释放（总线空闲状态）1：I2C总线占用（总线忙状态）	R

注1.当ICMR1.MTWP位设置为1时，可以写入MST和TRS位。

ST位（开始条件发布请求）

ST位请求转换到主模式并触发启动条件。当该位设置为1时，当BBSY标志设置为0（总线空闲状态）时发出启动条件。有关此功能的详细信息，请参阅第31.11节。启动、重启和停止条件发布功能。

[Setting condition]

●ST位写入1时。

[Clearing conditions]

●ST位写入0时

●发出启动条件时（检测到启动条件）

●ICSR2中的AL（仲裁失败）标志设置为1时

●当ICCR1的IICRST位写入1时，应用IIC复位或内部复位。

Note: 仅当BBSY标志设置为0（总线空闲状态）时，才将ST位设置为1（启动条件请求）。如果在BBSY标志为1（总线繁忙状态）时将ST位设置为1（开始条件请求），则仲裁可能会丢失。

RS位（重启条件发布请求）

RS位请求在主机模式下发出重启条件。当该位设置为1以请求重新启动条件时，当BBSY标志设置为1（总线繁忙状态）且MST位设置为1（主模式）时，发出重新启动条件。有关此功能的详细信息，请参阅第31.11节。启动、重启和停止条件发布功能。

[Setting condition]

●当ICCR2中的BBSY标志设置为1时，将1写入RS位。

[Clearing conditions]

●向RS位写入0时

●发出重新启动条件时（检测到启动条件）

●ICSR2中的AL（仲裁失败）标志设置为1时

●当ICCR1的IICRST位写入1时，应用IIC复位或内部复位。

Note: 发出停止条件时不要将RS位设置为1。
Note: 如果在从模式下将1（重新启动条件请求）写入RS位，则不会发出重新启动条件，但RS位保持设置为1。如果操作模式更改为主模式而未清除该位，则重新启动条件可能会发出。

SP bit (Stop Condition Issuance Request)

The SP bit requests that a stop condition be issued in master mode. When this bit is set to 1, a stop condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 31.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the MST bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition is issued (a stop condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Writing to the SP bit is not possible while the BBSY flag is 0 (bus free state).
Note: Do not set the SP bit to 1 while a restart condition is being issued.

TRS bit (Transmit/Receive Mode)

The TRS bit indicates transmit or receive mode. The IIC is in receive mode when the TRS bit is 0 and in transmit mode when the bit is 1. The combination of this bit and the MST bit indicates the IIC operating mode.

The value of the TRS bit automatically changes to 1 for transmit mode or 0 for receive mode when a start condition is issued or detected and the R/W# bit is set. Although writing to the TRS bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When a restart condition is issued normally because of a restart condition request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit appended to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in ICSER, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When the R/W# bit appended to the slave address is set to 1 in master mode
- In slave mode, on a match between the received address and the address enabled in ICSER when the value of the received R/W# bit is 0, including when the received address is the general call address
- In slave mode, when a restart condition is detected (a restart condition is detected with ICCR2.BBSY = 1 and ICCR2.MST = 0)
- When 0 is written to the TRS bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

MST bit (Master/Slave Mode)

The MST bit indicates master or slave mode. The IIC is in slave mode when the MST bit is 0 and is in master mode when the bit is 1. The combination of this bit and the TRS bit indicates the IIC operating mode.

The value of the MST bit automatically changes to 1 for master mode or 0 for slave mode when a start condition is issued or a stop condition is issued or detected. Although writing to the MST bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

SP位（停止条件发布请求）

SP位请求在主机模式下发出停止条件。当该位设置为1时，当BBSY标志设置为1（总线繁忙状态）且MST位设置为1（主模式）时，发出停止条件。有关此功能的详细信息，请参阅第31.11节。启动、重启和停止条件发布功能。

[Setting condition]

●当ICCR2中的BBSY标志和MST位都设置为1时，将1写入SP位。

[Clearing conditions]

●SP位写入0时
●发出停止条件时（检测到停止条件）
●ICSR2中的AL（仲裁失败）标志设置为1时
●检测到启动条件和重启条件时
●当ICCR1的IICRST位写入1时，应用IIC复位或内部复位。

Note: 当BBSY标志为0（总线空闲状态）时，不能写入SP位。
Note: 发出重启条件时不要将SP位设置为1。

TRS bit (Transmit/Receive Mode)

TRS位指示发送或接收模式。TRS位为0时IIC处于接收模式，该位为1时IIC处于发送模式。该位和MST位的组合表示IIC工作模式。

当发出或检测到启动条件并且设置RW#位时，TRS位的值自动更改为1（发送模式）或0（接收模式）。虽然当ICMR1的MTWP位设置为1时可以写入TRS位，但在正常使用期间不需要写入该位。

[Setting conditions]

●因启动条件请求而正常发出启动条件时（ST位设置为1时检测到启动条件时）

●因重新启动条件请求而正常发出重新启动条件时（在RS位设置为1的情况下检测到重新启动条件时）

●在主机模式下，附加在从机地址上的RW#位设置为0时
●从机模式接收到的地址与ICSER中使能的地址匹配时，RW#位设置为1
●当ICMR1中的MTWP位设置为1时将1写入TRS位。

[Clearing conditions]

●检测到停止条件时
●ICSR2中的AL（仲裁失败）标志设置为1时
●在主机模式下，附加在从机地址上的RW#位设置为1时
●从机模式下，当接收到的RW#位的值为0时，接收到的地址与ICSER中使能的地址匹配，包括当接收到的地址是广播地址时
●在从模式下，检测到重启条件时（检测到重启条件时ICCR2.BBSY=1和ICCR2.MST=0）

●当ICMR1中的MTWP位设置为1时，将0写入TRS位时
●当ICCR1的IICRST位写入1时，应用IIC复位或内部复位。

MST bit (Master/Slave Mode)

MST位指示主机或从机模式。当MST位为0时，IIC处于从机模式，当该位为1时，IIC处于主机模式。该位和TRS位的组合表示IIC工作模式。

当发出启动条件或发出或检测到停止条件时，MST位的值自动变为1（主机模式）或0（从机模式）。虽然当ICMR1中的MTWP位设置为1时可以写入MST位，但在正常使用期间不需要写入该位。

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 0 is written to the MST bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

BBSY flag (Bus Busy Detection Flag)

The BBSY flag indicates whether the I^2C bus is occupied (bus busy state) or released (bus free state). The flag is set to 1 when the SDAn line changes from high to low when the SCLn line is high, assuming that a start condition was issued. The flag is set to 0 if a start condition is not detected for the bus free time (ICBRL setting), assuming that a stop condition was issued.

[Setting condition]

- When a start condition is detected.

[Clearing conditions]

- When a start condition is not detected for the bus free time (ICBRL setting) after detecting a stop condition
- When 1 is written to the IICRST bit in ICCR1 with the ICE bit in ICCR1 set to 0 (IIC reset).

BC[2:0] bits (Bit Counter)

The BC[2:0] bits function as a counter indicating the number of bits remaining to be transferred on detection of a rising edge on the SCLn line. Although BC[2:0] are read/write bits, it is not required to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one, for an additional acknowledge bit, between transferred frames when the SCLn line is at a low level. The value in the BC[2:0] bits returns to 000b at the end of a data transfer, including the acknowledge bit, or when a start or restart condition is detected.

Note 1. The setting DLCS = 1 (IICφ/2) is only valid when SCL is low. When SCL is high, the DLCS = 1 setting becomes invalid and the clock source becomes the internal reference clock (IICφ).

TMOS bit (Timeout Detection Time Select)

The TMOS bit selects long or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE = 1). When this bit is set to 0, long mode is selected. When it is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14- bit counter. While the SCLn line is in the state that enables this counter as specified in the TMOH and TMOL bits, the counter

BC[2:0] bits (Bit Counter)

BC[2:0]位用作计数器，指示在检测到SCLn线上的上升沿时要传输的剩余位数。虽然BC[2:0]是读写位，但在正常情况下不需要访问这些位。

要写入这些位，在SCLn线处于低电平时，指定要传输的位数加1，作为附加确认位，在传输的帧之间。BC[2:0]位中的值在数据传输结束时返回到000b，包括确认位，或者当检测到启动或重启条件时。

counts up in synchronization with the internal reference clock (IICφ) as a count source. For details on this function, see section 31.12.1. Timeout Function.

TMOL bit (Timeout L Count Control)

The TMOL bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held low and the timeout function is enabled (ICFER.TMOE = 1).

TMOH bit (Timeout H Count Control)

The TMOH bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held high and the timeout function is enabled (ICFER.TMOE = 1).

SDDL[2:0] bits (SDA Output Delay Counter)

The SDDL[2:0] bits can be used to delay the SDA output. This counter works with the clock source selected in the DLCS bit. This setting can be used for all types of SDA output, including transmission of the acknowledge bit.

Set the SDA output delay to meet the I²C bus standard for the data enable time/acknowledge enable time,*1 or the SMBus standard, within [data hold time (300 ns or more + the SCL clock low-level period) - the data setup time (250 ns)]. If a value outside the standard is set, communication between devices might malfunction or falsely indicate a start or stop condition, depending on the bus state.

For details on this function, see section 31.5. SDA Output Delay Function.

与作为计数源的内部参考时钟(IICφ)同步计数。有关此功能的详细信息，请参阅第31.12.1节。超时功能。

TMOL位（超时L计数控制）

TMOL位启用或禁用超时功能内部计数器的递增计数，同时SCLn线保持低电平且启用超时功能(ICFER.TMOE=1)。

TMOH位（超时H计数控制）

TMOH位启用或禁用超时功能内部计数器的递增计数，同时SCLn线保持高电平且启用超时功能(ICFER.TMOE=1)。

SDDL[2:0]位（SDA输出延迟计数器）

SDDL[2:0]位可用于延迟SDA输出。该计数器与在DLCS位中选择的时钟源一起工作。该设置可用于所有类型的SDA输出，包括确认位的传输。

将SDA输出延迟设置为满足I2C总线标准的数据使能时间确认使能时间，*1或SMBus标准，在[数据保持时间（300 ns或更长+SCL时钟低电平周期）内的数据建立时间（250ns）]。如果设置了超出标准的值，则设备之间的通信可能会发生故障或错误地指示开始或停止条件，具体取决于总线状态。

有关此功能的详细信息，请参阅第31.5节。SDA输出延迟功能。

7	SMBS	SMBus/I2C Bus Select 0: Select I2C Bus 1: Select SMBus	R/W

Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If the application writes 1 to the ACKWP and ACKBT bits at the same time, the ACKBT bit is not set to 1.
Note 2. The WAIT and RDRFS bits are only valid in receive mode (invalid in transmit mode).

NF[1:0] bits (Noise Filter Stage Select)

The NF[1:0] bits select the number of stages in the digital noise filter. For details on this function, see section 31.6. Digital Noise Filter Circuits

Note: Set the noise range to be filtered within a range less than the SCLn line high- or low-level period. If the noise range is set to a value of [SCL clock width: high- or low-level period, whichever is shorter] - [1.5 internal reference clock (IICφ) cycles + analog noise filter: 120 ns (reference values)] or more, the SCL clock is regarded as noise, which might prevent the IIC from operating normally.

ACKBR bit (Receive Acknowledge)

The ACKBR bit stores the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKBT bit (Transmit Acknowledge)

The ACKBT bit sets the acknowledge bit to be sent in receive mode

[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1.

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition request is detected with the SP bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKWP bit (ACKBT Write Protect)

The ACKWP bit controls write enabling of the ACKBT bit.

RDRFS bit (RDRF Flag Set Timing Select)

The RDRFS bit selects the RDRF flag set timing in receive mode and also selects whether to hold the SCLn line low on the falling edge of the 8th SCL clock cycle.

When the RDRFS bit is 0, the SCLn line is not held low on the falling edge of the 8th SCL clock cycle, and the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 on the rising edge of the 8th SCL clock cycle, and the SCLn line is held low on the falling edge of the 8th SCL clock cycle. The low-hold of the SCLn line is released by a write to the ACKBT bit.

After data is received with this setting, the SCLn line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1), based on the receive data.

Bit	Symbol	Function	R/W
6	WAIT	通过读取ICDRR释放低保持。 0：无等待（在第9个时钟周期和第1个时钟周期之间的时间段内，SCLn线不保持低电平。） 1：等待（SCLn线在第9个时钟周期和第1个时钟周期之间保持低电平。）	R/W*2
7	SMBS	SMBusI2C总线选择 0：选择I2C总线1 ：选择SMBus	R/W

注1.仅当ACKWP位已经为1时才写入ACKBT位。如果应用程序同时向ACKWP和ACKBT位写入1，则ACKBT位不会设置为1。

注2.WAIT和RDRFS位仅在接收模式下有效（在发送模式下无效）。

NF[1:0]位（噪声滤波器级选择）

NF[1:0]位选择数字噪声滤波器的级数。关于该功能的详细内容，请参阅31.6节。数字的噪声滤波电路

Note: 将要过滤的噪声范围设置在小于SCLn线高电平或低电平周期的范围内。如果噪声范围设置为[SCL时钟宽度：高电平或低电平周期，以较短者为准][1.5内部参考时钟(IICφ)周期+模拟噪声滤波器：120ns（参考值）]或更大的值，则SCL时钟被视为噪声，可能会妨碍IIC正常工作。

ACKBR bit (Receive Acknowledge)

ACKBR位存储在发送模式下从接收设备接收到的确认位信息。

[Setting condition]

●当ICCR2中的TRS位设置为1接收到1作为确认位时。

[Clearing conditions]

●当ICCR2中的TRS位设置为1接收到0作为确认位时

●当ICCR1中的IICRST位写入1而ICCR1中的ICE位为0时（IIC复位）。

ACKBT bit (Transmit Acknowledge)

ACKBT位设置要在接收模式下发送的确认位

[Setting condition]

●当1写入该位且ACKWP位设置为1时。

[Clearing conditions]

●当0写入该位且ACKWP位设置为1时

●ICCR2的SP位设置为1时检测到停止条件请求时

●当ICCR1中的IICRST位写入1而ICCR1中的ICE位为0时（IIC复位）。

ACKWP位（ACKBT写保护）

ACKWP位控制ACKBT位的写使能。

RDRFS位（RDRF标志设置时序选择）

RDRFS位选择接收模式下的RDRF标志设置时序，并选择是否在第8个SCL时钟周期的下降沿保持SCLn线为低电平。

当RDRFS位为0时，SCLn线在第8个SCL时钟周期的下降沿不保持低电平，并且RDRF标志在第9个SCL时钟周期的上升沿设置为1。

当RDRFS位为1时，RDRF标志在第8个SCL时钟周期的上升沿设置为1，并且SCLn线在第8个SCL时钟周期的下降沿保持低电平。SCLn线的低保持通过写ACKBT位来释放。

使用此设置接收数据后，SCLn线在发送确认位之前自动保持低电平。这使处理能够根据接收数据发送ACK(ACKBT=0)或NACK(ACKBT=1)。

WAIT bit (WAIT)

The WAIT bit controls whether to force a low-hold between the ninth SCL clock cycle and the first SCL clock cycle, until the receive data buffer (ICDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation continues without a low-hold between the ninth and the first SCL clock cycle. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCLn line is held low from the falling edge of the ninth clock cycle until the ICDRR value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When the value of the WAIT bit is to be read, always read ICDRR first.

Note 1. The Fast-mode Plus enable bit (FMPE) is supported by IIC0 (SCL0_A, SDA0_A) and IIC1(SCL1_A, SDA1_A). Bit [7] is the reserved bit in the not supported channel.

TMOE bit (Timeout Function Enable)

The TMOE bit enables or disables the timeout function. For details on this function, see section 31.12.1. Timeout Function.

等待位（等待）

WAIT位控制是否在第9个SCL时钟周期和第一个SCL时钟周期之间强制保持低电平，直到每次在接收模式下接收到单字节数据时完全读取接收数据缓冲区(ICDRR)。

当WAIT位为0时，接收操作继续，在第9个和第一个SCL时钟周期之间没有低电平保持。当RDRFS和WAIT位都为0时，双缓冲器使能连续接收操作。

当WAIT位为1时，SCLn线从第9个时钟周期的下降沿保持低电平，直到每次接收到单字节数据时读取ICDRR值。这启用了以字节为单位的接收操作。

Note: 当要读取WAIT位的值时，总是先读取ICDRR。

SMBS位（SMBusI2C总线选择）

将SMBS位设置为1可选择SMBus并启用ICSER中的HOAE位。

TMOE位（超时功能使能）

TMOE位启用或禁用超时功能。有关此功能的详细信息，请参阅第31.12.1节。超时功能。

MALE bit (Master Arbitration-Lost Detection Enable)

The MALE bit specifies whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

The NALE bit specifies whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode, for example when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with a different number of receive bytes.

SALE bit (Slave Arbitration-Lost Detection Enable)

The SALE bit specifies whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode, for example when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs because of noise.

NACKE bit (NACK Reception Transfer Suspension Enable)

The NACKE bit specifies whether to continue or discontinue the transfer operation when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended. When the NACKE bit is 0, the next transfer operation continues regardless of the received acknowledge content.

For details, see section 31.9.2. NACK Reception Transfer Suspension Function.

SCLE bit (SCL Synchronous Circuit Enable)

The SCLE bit specifies whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCLE bit is set to 0 (no SCL synchronous circuit used), the IIC does not synchronize the SCL clock with the SCL input clock. With this setting, the IIC outputs the SCL clock at the transfer rate set in ICBRH and ICBRL, regardless of the SCLn line state. For this reason, if the bus load of the I^2C bus line is much larger than the specification value, or if the SCL clock output overlaps in multiple masters, a short-cycle SCL clock that does not meet the specification might be output.

When no SCL synchronous circuit is used, it also affects the issuing of the start, restart, and stop conditions, and the continuous output of extra SCL clock cycles.

Do not set this bit to 0 except when checking the output of the set transfer rate.

FMPE bit (Fast-Mode Plus Enable)

The FMPE bit specifies whether to use a slope control circuit for Fast-mode Plus (Fm+).

When this bit is set to 1, a slope control circuit conforming to the I^2C bus Fast-mode Plus (Fm+) standard (tof) is selected.
When this bit is set to 0, a slope control circuit conforming to the I^2C bus Standard-mode (Sm) and Fast-mode (Fm) standards (tof) is selected.

Set this bit to 1 when using transmission rates up to 1 Mbps (Fast-mode Plus (Fm+) standard). Set it to 0 when using other transmission rates (up to 100 kbps (Sm) or up to 400 kbps (Fm)) or for SMBus (10 to 100 kbps).

MALE位（主仲裁丢失检测使能）

MALE位指定是否在主机模式下使用仲裁丢失检测功能。通常，将此位设置为1。

NALE位（NACK传输仲裁丢失检测使能）

NALE位指定在接收模式下发送NACK期间检测到ACK时是否导致仲裁丢失，例如，当总线上存在具有相同地址的从设备时，或者当两个或多个主设备同时选择相同的从设备时接收字节数。

SALE位（从设备仲裁丢失检测使能）

SALE位指定当在从发送模式下在总线上检测到与正在发送的值不同的值时，是否导致仲裁丢失，例如，当总线上存在具有相同地址的从机或与发送数据不匹配时由于噪音而发生。

NACKE位（NACK接收传输暂停使能）

NACKE位指定在发送模式下接收到NACK时是继续还是停止传输操作。通常，将此位设置为1。

当在NACKE位设置为1的情况下接收到NACK时，暂停下一个传输操作。当NACKE位为0时，无论接收到的确认内容如何， 下一次传输操作都会继续进行。

有关详细信息，请参阅第31.9.2节。NACK接收传输暂停功能。

SCLE位（SCL同步电路使能）

SCLE位指定是否将SCL时钟与SCL输入时钟同步。通常，将此位设置为1。

当SCLE位设置为0（不使用SCL同步电路）时，IIC不会将SCL时钟与SCL输入时钟同步。使用此设置，无论SCLn线路状态如何，IIC都以ICBRH和ICBRL中设置的传输速率输出SCL时钟。因此，如果I2C总线的总线负载远大于规格值，或者多个主机的SCL时钟输出重叠，则可能会输出不符合规格的短周期SCL时钟。当不使用SCL同步电路时，也会影响启动、重启和停止条件的发出，以及额外SCL时钟周期的连续输出。

除非检查设置传输速率的输出，否则不要将此位设置为0。

FMPE位（Fast-ModePlusEnable）

FMPE位指定是否对Fast-modePlus(Fm+)使用斜率控制电路。

当该位设置为1时，选择符合I2C总线快速模式加(Fm+)标准(tof)的斜率控制电路。
当该位设置为0时，选择符合I2C总线标准模式(Sm)和快速模式(Fm)标准(tof)的斜率控制电路。

当使用高达1Mbps的传输速率（Fast-modePlus(Fm+)标准）时，将此位设置为1。当使用其他传输速率（最高100kbps(Sm)或最高400kbps(Fm)）或SMBus（10至100kbps）时，将其设置为0。

6	—	This bit is read as 0. The write value should be 0.	R/W
7	HOAE	Host Address Enable 0: Disable host address detection 1: Enable host address detection	R/W

SARyE bit (Slave Address Register y Enable) (y = 0 to 2)

The SARyE bit enables or disables the received slave address and the slave address set in SARLy and SARUy.

When this bit is set to 1, the slave address set in SARLy and SARUy is enabled and is compared with the received slave address. When this bit is set to 0, the slave address set in SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

GCAE bit (General Call Address Enable)

The GCAE bit specifies whether to ignore the general call address (0000 000b + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the IIC recognizes the received slave address as the general call address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the data receive operation. When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

DIDE bit (Device-ID Address Detection Enable)

The DIDE bit specifies whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first frame after a start or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the IIC recognizes that the device-ID address was received. When the next R/W# bit is 0 (W), the IIC recognizes the second and the subsequent frames as slave addresses and continues the receive operation. When this bit is set to 0, the IIC ignores the received first frame even if it matches the device-ID address, and it recognizes the first frame as a normal slave address.

For details on this function, see section 31.7.3. Device-ID Address Detection.

HOAE bit (Host Address Enable)

The HOAE bit specifies whether to ignore the received host address (0001 000b) when the SMBS bit in ICMR3 is 1.

When this bit is set to 1 while the SMBS bit in ICMR3 is 1, if the received slave address matches the host address, the IIC recognizes the received slave address as the host address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the receive operation.

When the SMBS bit in ICMR3 or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

SARyE位（从地址寄存器y使能）（y=0到2）

SARyE位启用或禁用接收到的从机地址和设置在SARLy和SARUy中的从机地址。

当该位设置为1时，设置在SARLy和SARUy中的从机地址被启用，并与接收到的从机地址进行比较。当该位设置为0时，设置在SARLy和SARUy中的从机地址被禁用并被忽略，即使它与接收到的从机地址匹配。

GCAE位（广播呼叫地址使能）

GCAE位指定接收到的广播调用地址（0000000b+0[W]：全0）是否忽略。

当该位设置为1时，如果接收到的从机地址与广播呼叫地址匹配，则IIC将接收到的从机地址识别为广播呼叫地址，而与在SARLy和SARUy中设置的从机地址（y=0到2）无关，并执行数据接收操作。当该位设置为0时，即使接收到的从机地址与广播呼叫地址匹配，也会忽略它。

DIDE位（设备ID地址检测使能）

DIDE位指定在检测到启动或重新启动条件后的第一帧中接收到设备ID(1111100b)时是否识别和执行设备ID地址。

当该位设置为1时，如果接收到的第一个帧与设备ID匹配，则IIC识别出设备ID地址已被接收。当下一个RW#位为0(W)时，IIC将第二个和后续帧识别为从地址并继续接收操作。当该位设置为0时，IIC忽略接收到的第一帧，即使它与设备ID地址匹配，并将第一帧识别为正常的从地址。

有关此功能的详细信息，请参阅第31.7.3节。设备ID地址检测。

HOAE位（主机地址使能）

HOAE位指定当ICMR3中的SMBS位为1时是否忽略接收到的主机地址（0001000b）。

当该位设置为1而ICMR3中的SMBS位为1时，如果接收到的从机地址与主机地址匹配，则IIC将接收到的从机地址识别为主机地址，而与SARLy和SARUy中设置的从机地址无关（y=0到2)并执行接收操作。

当ICMR3中的SMBS位或HOAE位设置为0时，即使接收到的从机地址与主机地址匹配，也会忽略它。

Note 1. Only 0 can be written, to clear the flag.

TMOF flag (Timeout Detection Flag)

The TMOF flag is set to 1 when the IIC detects a timeout because the SCLn line state remains unchanged for the set period.

[Setting condition]

- When the SCLn line state remains unchanged for the period specified in the ICMR2.TMOH, TMOL, and TMOS bits while the ICFER.TMOE bit is 1 (timeout function enabled) in master or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF flag after reading TMOF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

AL flag (Arbitration-Lost Flag)

The AL flag indicates that bus mastership was lost in arbitration because of a bus conflict or some other reason when a start condition was issued or an address and data was transmitted. The IIC monitors the level on the SDAn line during transmission and, if the level on the line does not match the value of the bit being output, is set the value of the AL flag to 1 to indicate that the bus is occupied by another device.

The IIC can also set the AL flag to indicate the detection of arbitration loss during NACK transmission or during data transmission.

[Setting conditions]

When master arbitration-lost detection is enabled (ICFER.MALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock except for the ACK period during data transmission in master transmit mode
- When a start condition is detected while the ST bit in ICCR2 is 1 (start condition requested) or the internal SDA output state does not match the SDAn line level
- When the ST bit in ICCR2 is 1 (start condition requested), with the BBSY flag in ICCR2 set to 1.

When NACK arbitration-lost detection is enabled (ICFER.NALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICFER.SALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock, except for the ACK period during data transmission in slave transmit mode.

[Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

[Setting condition]

●SCLn线路状态在ICMR2.TMOH、TMOL和TMOS位指定的时间段内保持不变，而ICFER.TMOE位在主机或从机模式下为1（使能超时功能）并且接收到的从机地址匹配。

[Clearing conditions]

●读取TMOF=1后向TMOF标志写入0时

●当ICCR1的IICRST位写入1时，应用IIC复位或内部复位。

AL标志（仲裁失败标志）

AL标志表明在发出启动条件或传输地址和数据时，由于总线冲突或其他原因，总线控制权在仲裁中丢失。IIC在传输过程中监视SDAn线上的电平，如果线上的电平与正在输出的位的值不匹配，则将AL标志的值设置为1，以指示总线被另一个设备占用.

IIC还可以设置AL标志以指示在NACK传输或数据传输期间检测到仲裁丢失。

[Setting conditions]

当启用主机仲裁丢失检测时(ICFER.MALE=1)：

●主机传输模式下数据传输期间，除了ACK周期外，当内部SDA输出状态在SCL时钟的上升沿与SDAn线电平不匹配时

●当ICCR2的ST位为1（请求启动条件）或内部SDA输出状态与SDAn线电平不匹配时检测到启动条件

●ICCR2中的ST位为1（请求启动条件）时，ICCR2中的BBSY标志设置为1。

当启用NACK仲裁丢失检测时(ICFER.NALE=1)：

●在接收模式下的NACK传输过程中，当内部SDA输出状态在ACK周期的SCL时钟上升沿与SDAn线电平不匹配时。

当启用从设备仲裁丢失检测时(ICFER.SALE=1)：

●当内部SDA输出状态在SCL时钟的上升沿与SDAn线电平不匹配时，除了在从机传输模式下数据传输期间的ACK周期。

[Clearing conditions]

●读取AL=1后向AL标志写入0时

●当ICCR1的IICRST位写入1时，应用IIC复位或内部复位。

- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1, the IIC suspends data transmission and reception. Writing to ICDRT in transmit mode or reading from ICDRR in receive mode with the NACKF flag set to 1 does not enable data transmit or receive operation. To restart data transmission or reception, set the NACKF flag to 0.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates whether the ICDRR contains receive data.

WUSEN bit (Wakeup Function Synchronous Enable)

The WUSEN bit is used in combination with the WUASYF flag (or WUSYF flag) to switch between the PCLKB synchronous and asynchronous operation, when the wakeup effective function is enabled (ICWUR.WUE = 1).

The PCLKB operation switches from synchronous to asynchronous operation:

When the ICCR2.BBSY flag is 0, if 0 is written to the WUSEN bit while the WUASYF flag is 0. The reception occurs independently of the operation of PCLKB (with PCLKB stopped) after it switches to the PCLKB asynchronous operation, on wakeup event detection.

The PCLKB operation switches from asynchronous to synchronous operation:

- When 1 is written to the WUSEN bit, with the WUASYF flag at 1, when a wakeup event is detected. After writing 1, the WUASYF flag immediately becomes 0.
- When the stop condition is detected with a wakeup event undetected.

WUASYF flag (Wakeup Function Asynchronous Operation Status Flag)

The WUASYF flag can place the IIC in PCLKB asynchronous operation when the wakeup effective function is enabled (ICWUR.WUE = 1).

[Setting condition]

- When the ICCR2.BBSY flag is 0, and the WUSEN bit is set to 0 with the ICWUR.WUE bit set to 1.

[Clearing conditions]

- When 1 is written to the WUSEN bit after detecting the wake-up event with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wake-up event with WUASY flag set to 1 with ICWUR.WUE bit set to 1.
- When you write 1 in the WUSEN bit with the WUASYF flag detected 1 and the wake-up event in the state of ICWUR.WUE = 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

WUSYF flag (Wakeup Function Synchronous Operation Status Flag)

It is shown that IIC is in the PCLKB synchronous operation at wake-up effective function (ICWUR.WUE = 1). This flag is a value in which the WUASYF flag is always reserved.

[Setting conditions]

- When 1 is written to the WUSEN bit after detecting the wake-up event with ICWUR.WUE bit set to 1 with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wake-up event with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

[Clearing condition]

- When the ICCR2.BBSY flag is 0 with the ICWUR.WUE bit set to 1 after writing 0 to the WUSEN bit.

WUSEN位（唤醒功能同步使能）

WUSEN位与WUASYF标志（或WUSYF标志）结合使用，在启用唤醒有效功能（ICWUR.WUE=1）时在PCLKB同步和异步操作之间切换。

PCLKB操作从同步操作切换到异步操作：

当ICCR2.BBSY标志为0时，如果在WUASYF标志为0时将0写入WUSEN位。在唤醒事件切换到PCLKB异步操作后，接收发生独立于PCLKB的操作（PCLKB停止）检测。

PCLKB操作从异步操作切换到同步操作：

●当WUSEN位写入1且WUASYF标志为1时，检测到唤醒事件。写入1后，WUASYF标志立即变为0。

●当检测到停止条件且未检测到唤醒事件时。

WUASYF标志（唤醒功能异步操作状态标志）

WUASYF标志可以在启用唤醒有效功能（ICWUR.WUE=1）时将IIC置于PCLKB异步操作中。

[Setting condition]

●ICCR2.BBSY标志为0且WUSEN位设置为0且ICWUR.WUE位设置为1时。

[Clearing conditions]

●当检测到唤醒事件后将1写入WUSEN位，且ICWUR.WUE位设置为1。

●在检测到WUASY标志设置为1且ICWUR.WUE位设置为1的唤醒事件之前检测到WUSEN位设置为1的停止条件时。

●当您在WUSEN位写入1时，检测到WUASYF标志为1，并且唤醒事件处于ICWUR.WUE=1的状态。

- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

WUSYF标志（唤醒功能同步操作状态标志）

表明IIC在唤醒有效功能(ICWUR.WUE=1)时处于PCLKB同步操作。此标志是WUASYF标志始终保留的值。

[Setting conditions]

●当检测到唤醒事件后将1写入WUSEN位时，将ICWUR.WUE位设置为1，将WUSYF标志设置为0，并将ICWUR.WUE位设置为1。

●在检测到WUSYF标志设置为0且ICWUR.WUE位设置为1的唤醒事件之前检测到WUSEN位设置为1的停止条件时。

- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

[Clearing condition]

●当ICCR2.BBSY标志为0且ICWUR.WUE位在WUSEN位写入0后设置为1时。

7:1	SVA[6:0]	7-bit Address/10-bit Address Lower Bits Slave address setting.	R/W

SVA0 bit (10-bit Address LSB)

When the 10-bit address format is selected (SARUy.FS = 1), the SVA0 bit functions as the LSB of a 10-bit address and is combined with the SVA[6:0] bits to form the lower 8 bits of a 10-bit address.

This bit is valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in this bit is ignored.

SVA[6:0] bits (7-bit Address/10-bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS = 0), the SVA[6:0] bits function as a 7-bit address. When the 10- bit address format is selected (SARUy.FS = 1), these bits combine with the SVA0 bit to form the lower 8 bits of a 10-bit address.

When the SARyE bit in ICSER is 0, the setting in these bits is ignored.

31.2.14 SARUy : Slave Address Register Uy (y = 0 to 2)

When the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the SVA[1:0] and SARLy settings are valid.

When the SARyE bit in ICSER is 0 (SARLy and SARUy disabled), the SARUy.FS setting is invalid.

7:5	—	These bits are read as 1. The write value should be 1.	R/W

BRL[4:0] bits (Bit Rate Low-Level Period)

The BRL[4:0] bits set the low-level period of the SCL clock. ICBRL counts the low-level period with the internal reference clock source (IICφ) specified by the CKS[2:0] bits in ICMR1. ICBRL also generates the data setup time for automatic SCL low-hold operation, see section 31.9. Automatic Low-Hold Function for SCL. When the IIC is used in slave mode, the BRL[4:0] bits must be set to a value longer than the data setup time*1.

If the digital noise filter is enabled (NFE bit in ICFER is 1), set the BRL[4:0] bits to a value at least one greater than the number of stages in the noise filter. For details on the number of stages, see the description of the NF[1:0] bits in section 31.2.5. ICMR3 : I2C Bus Mode Register 3.

BRH[4:0] bits (Bit Rate High-Level Period)

The BRH[4:0] bits set the high-level period of SCL clock. BRH[4:0] bits are valid in master mode. If the IIC is used only in slave mode, do not set the BRH[4:0] bits.

BRL[4:0]位（比特率低电平周期）

BRL[4:0]位设置SCL时钟的低电平周期。ICBRL使用由ICMR1中的CKS[2:0]位指定的内部参考时钟源(IICφ)对低电平周期进行计数。ICBRL还为自动SCL低保持操作生成数据建立时间，请参见第31.9节。SCL的自动低保持功能。当IIC在从机模式下使用时，BRL[4:0]位必须设置为比数据建立时间*1更长的值。

如果启用了数字噪声滤波器（ICFER中的NFE位为1），请将BRL[4:0]位设置为至少比噪声滤波器中的级数大1的值。关于阶段数的详细信息，请参见第31.2.5节中对NF[1:0]位的描述。ICMR3：I2C总线模式寄存器3。

BRH[4:0]位（比特率高电平周期）

BRH[4:0]位设置SCL时钟的高电平周期。BRH[4:0]位在主机模式下有效。如果IIC仅用于从机模式，则不要设置BRH[4:0]位。

ICBRH counts the high-level period with the internal reference clock source (IICφ) specified in the CKS[2:0] bits in ICMR1.

If the digital noise filter is enabled (the NFE bit in ICFER is 1), set these bits to a value at least one greater than the number of stages in the noise filter. For the number of stages in the noise filter, see the description of the NF[1:0] bits in section 31.2.5. ICMR3 : I²C Bus Mode Register 3.

The IIC transfer rate and the SCL clock duty are calculated using the following expressions (1) to (5):

1. ICFER.SCLE = 0
   Transfer rate = 1/[{(BRH + 1) + (BRL + 1)}/IICφ*1 + tr*2 + tf*2]
   Duty cycle = [tr + {(BRH + 1)/IICφ}]/[tr + tf + {(BRH + 1) + (BRL + 1)}/IICφ]
2. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = 1/[{(BRH + 3) + (BRL+ 3)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 3)/IICφ}]/[tr + tf + {(BRH + 3) + (BRL + 3)}/IICφ]
3. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = 1/[{(BRH + 3 + nf*3) + (BRL + 3 + nf)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 3 + nf)/IICφ}]/[tr + tf + {(BRH + 3 + nf) + (BRL + 3 + nf)}/IICφ]
4. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] ≠ 000b
   Transfer rate = 1/[{(BRH + 2) + (BRL + 2)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 2)/IICφ}]/[tr + tf + {(BRH + 2) + (BRL + 2)}/IICφ]
5. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] ≠ 000b
   Transfer rate = 1/[{(BRH + 2 + nf) + (BRL + 2 + nf)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 2 + nf)/IICφ}]/[tr + tf + {(BRH + 2 + nf) + (BRL + 2 + nf)}/IICφ]

Note 1. IICφ = PCLKB × division ratio
Note 2. The SCLn line rise time (tr) and SCLn line fall time (tf) depend on the total bus line capacitance (Cb) and the pull-up resistor (Rp). For details, see the I²C bus standard from NXP Semiconductors.
Note 3. nf = Number of digital noise filters selected in the ICMR3.NF bit.

31.2.17 ICDRT : I2C Bus Transmit Data Register

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

When ICDRT detects a space in the I2C Bus Shift Register (ICDRS), it transfers the transmit data that was written to ICDRT to ICDRS and starts transmitting data in transmit mode. The double-buffer structure of ICDRT and ICDRS allows continuous transmit operation if the next transmit data is written to ICDRT while the ICDRS data is being transmitted.

ICDRT can always be read and written to. Write transmit data to ICDRT once when a transmit data empty interrupt (IICn_TXI) request is generated.

31.2.18 ICDRR : I2C Bus Receive Data Register

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x13

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

When 1 byte of data is received, the received data is transferred from the I2C Bus Shift Register (ICDRS) to ICDRR to enable the next data to be received. The double-buffer structure of ICDRS and ICDRR allows continuous receive operation if the received data is read from ICDRR while ICDRS is receiving data. ICDRR cannot be written to. Read data from ICDRR once when a receive data full interrupt (IICn_RXI) request is generated.

If ICDRR receives the next receive data before the current data is read from ICDRR (while the RDRF flag in ICSR2 is 1), the IIC automatically holds the SCL clock low 1 cycle before the RDRF flag is set to 1 next.

31.2.19 ICDRS : I2C Bus Shift Register

Base address: n/a

Offset address: n/a

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	—	—	—	—	—	—	—	—

ICDRS is an 8-bit shift register for data transmit and receive. During transmission, transmit data is transferred from ICDRT to ICDRS and is transmitted from the SDAn pin. During reception, data is transferred from ICDRS to ICDRR after 1 byte of data is received. ICDRS cannot be accessed directly.

31.3 Operation

31.3.1 Communication Data Format

The I2C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start or restart condition is an address frame that specifies a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 31.3 shows the I2C bus format, and Figure 31.4 shows the I2C bus timing.

31.2.17 ICDRT：I2C总线发送数据寄存器

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
重置后的值：	1	1	1	1	1	1	1	1

当ICDRT检测到I2C总线移位寄存器(ICDRS)中有空间时，它将写入ICDRT的发送数据传输到ICDRS，并开始在发送模式下发送数据。ICDRT和ICDRS的双缓冲结构允许在传输ICDRS数据的同时将下一个传输数据写入ICDRT的连续传输操作。

ICDRT始终可以被读取和写入。当产生发送数据空中断（IICn_TXI）请求时，将发送数据写入ICDRT。

31.2.18 ICDRR:I2C总线接收数据寄存器

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x13

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
重置后的值：	0	0	0	0	0	0	0	0

当接收到1个字节的数据时，接收到的数据会从I2C总线移位寄存器(ICDRS)传输到ICDRR，以便接收下一个数据。如果在ICDRS正在接收数据时从ICDRR读取接收到的数据，ICDRS和ICDRR的双缓冲结构允许连续接收操作。无法写入ICDRR。当产生接收数据完全中断(IICn_RXI)请求时，从ICDRR读取数据一次。

如果ICDRR在从ICDRR读取当前数据之前接收到下一个接收数据（此时ICSR2中的RDRF标志为1），则IIC在下一个RDRF标志设置为1之前自动将SCL时钟保持低1个周期。

31.2.19 ICDRS:I2C总线移位寄存器

Base address: n/a

Offset address: n/a

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
重置后的值：	—	—	—	—	—	—	—	—

ICDRS是一个用于数据发送和接收的8位移位寄存器。在传输期间，传输数据从ICDRT传输到ICDRS，并从SDAn引脚传输。在接收过程中，接收到1个字节的数据后，数据从ICDRS传输到ICDRR。ICDRS不能直接访问。

31.3.2 初始设置

在开始数据发送或接收之前，使用图31.5所示的过程初始化IIC。

1.将ICCR1.ICE位设置为0，将SCLn和SDAn引脚设置为无效状态。

2.将ICCR1.IICRST位设置为1以启动IIC复位。

3.将ICCR1.ICE位设置为1以启动内部复位。

4.设置SARLy、SARUy、ICSER、ICMR1、ICBRH和ICBRL寄存器（y=0到2），并根据需要设置其他寄存器。IIC的初始设置见图31.5。

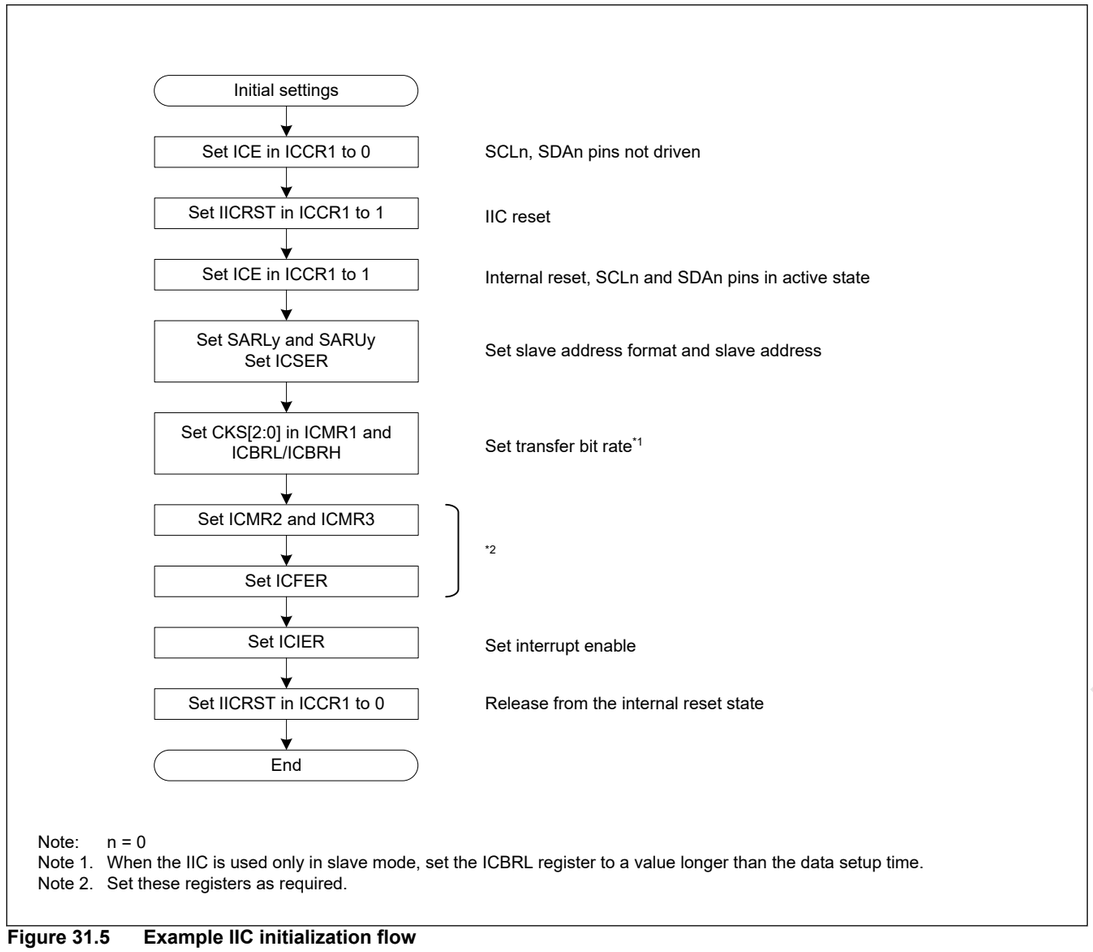
5. When the required register settings are complete, set the ICCR1.IICRST bit to 0 to release the IIC reset.

This procedure is not required if the IIC initialization is already complete.



Note: n = 0
Note 1. When the IIC is used only in slave mode, set the ICBRL register to a value longer than the data setup time.
Note 2. Set these registers as required.

31.3.3 Master Transmit Operation

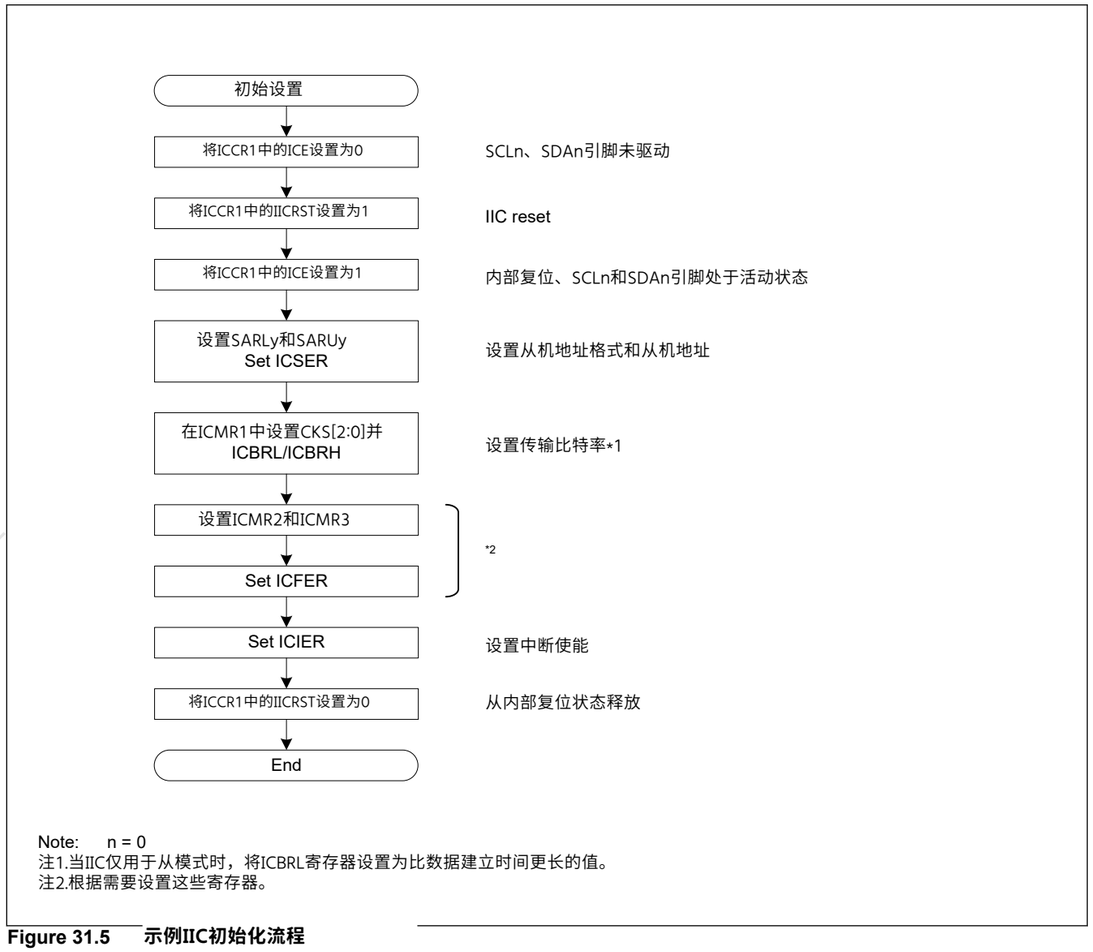
In master transmit operation, the IIC outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 31.6 shows an example of master transmission, and Figure 31.7 to Figure 31.9 show the operation timing in master transmission.

To set up and perform master transmission:

1. Process initial settings. For details, see section 31.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and START flags in ICSR2 automatically set to 1 and the ST bit automatically is set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.

5.完成所需的寄存器设置后，将ICCR1.IICRST位设置为0以释放IIC复位。

如果IIC初始化已经完成，则不需要此过程。



Note: n = 0
注1.当IIC仅用于从模式时，将ICBRL寄存器设置为比数据建立时间更长的值。
注2.根据需要设置这些寄存器。

31.3.3 主发送操作

在主设备发送操作中，IIC作为主设备输出SCL时钟和发送的数据信号，从设备返回确认。图31.6显示了主传输的示例，图31.7至图31.9显示了主传输的操作时序。

设置和执行主传输：

1.处理初始设置。有关详细信息，请参阅第31.3.2节。初始设置。

2.读取ICCR2中的BBSY标志，检查总线是否空闲，然后将ICCR2中的ST位设置为1（启动条件要求）。收到请求后，IIC发出一个开始条件。同时，ICSR2中的BBSY和START标志位自动置1，ST位自动置0。此时，如果检测到启动条件，内部电平为SDA输出状态和当ST位为1时SDAn线匹配，IIC识别出ST位请求的启动条件的发布已成功完成，并且ICCR2中的MST和TRS位自动设置为1，将IIC置于主机发送模式。ICSR2中的TDRE标志也自动设置为1，以响应TRS位设置为1。

3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. After the byte containing the slave address and R/W# bit is transmitted, the value of the TRS bit automatically updates to select master transmit or master receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the IIC continues in master transmit mode. Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For data transmission with an address in the 10-bit format, start by writing 11110b, the 2 higher-order bits of the slave address, and W to ICDRT as the first address transmission. For the second address transmission, write the 8 lower-order bits of the slave address to ICDRT.
4. Check that the TDRE flag in ICSR2 is 1, and then write the transmit data to the ICDRT register. The IIC automatically holds the SCLn line low until the transmit data is ready or a stop condition is issued.
5. After all bytes of transmit data are written to the ICDRT register, wait until the value in the TEND flag in ICSR2 returns to 1, and then set the SP bit in ICCR2 to 1 (stop condition requested). On receiving a stop condition request, the IIC issues the stop condition. Regarding issuing a stop condition, see section 31.11.3. Issuing a Stop Condition.
6. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, it automatically sets the TDRE and TEND flags to 0, and sets the STOP flag in ICSR2 to 1.
7. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

3.检查ICSR2中的TDRE标志是否为1，然后将要发送的值（从机地址和RW#位）写入ICDRT。当发送数据写入ICDRT时，TDRE标志自动设置为0，数据从ICDRT传输到ICDRS，TDRE标志再次设置为1。在发送包含从机地址和RW#位的字节后，TRS位的值会自动更新，以根据发送的RW#位的值选择主机发送或主机接收模式。如果RW#位的值为0，则IIC继续处于主机发送模式。因为此时ICSR2.NACKF标志为1表示没有从设备识别该地址或通信中有错误，所以向ICCR2.SP位写入1以发出停止条件。对于地址为10位格式的数据传输，首先将11110b、从机地址的高2位和W写入ICDRT作为第一个地址传输。对于第二次地址传输，将从地址的低8位写入ICDRT。

4.检查ICSR2中的TDRE标志是否为1，然后将发送数据写入ICDRT寄存器。IIC自动将SCLn线保持为低电平，直到发送数据准备好或发出停止条件。

5.将发送数据的所有字节写入ICDRT寄存器后，等待ICSR2中的TEND标志中的值返回1，然后将ICCR2中的SP位设置为1（请求停止条件）。在收到停止条件请求时，IIC发出停止条件。关于发出停止条件，请参阅第31.11.3节。发出停止条件。

6.在检测到停止条件时，IIC自动将ICCR2中的MST和TRS位设置为00b并进入从机
接收模式。此外，它自动将TDRE和TEND标志设置为0，并将ICSR2中的STOP标志设置为1。

7.检查ICSR2.STOP标志是否为1，然后将ICSR2.NACKF和STOP标志设置为0以进行下一次传输操作。

31.3.4 Master Receive Operation

In master receive operation, the IIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because the IIC must start by sending a slave address to the associated slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 31.10 and Figure 31.11 show examples of master reception (7-bit address format), and Figure 31.12 to Figure 31.14 show the operation timing in master reception.

To set up and perform master reception:

1. Process initial settings. For details, see section 31.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. When the IIC detects the start condition, the BBSY and START flags in ICSR2 automatically set to 1, and the ST bit automatically is set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
