30.3.9.7 Common Operation

In this chapter, the operation common to each mode / area option communication in section 30.3.9.1. Transmit-Receive/ Transmit in Master Mode to section 30.3.9.6. Receive Only in Slave Mode on Clock Synchronous Operation (3-wire) is explained. When the enable of RSPI communication end interrupt (CENDIE) is 0, at the time of communication completion, a flag of communication end (CENDF) is set and an event of communication end (sp_elccend) is output, but no interrupt is output. However, if the enable of communication end interrupt (CENDIE) is set to 1 before clearing the flag of communication end (CENDF) while the enable of RSPI function (SPE) is 1, the communication end interrupt is output.

3.CENDF标志在RSPCK的第一个边沿被清除以进行下一次传输。或者当向SPSRC.CENDFC位写入1时，CENDF标志为0。

30.3.9.7 常用操作

在本章中，30.3.9.1节中的每个模式区域选项通信的通用操作。发送-接收在主模式下发送到第30.3.9.6节。解释了时钟同步操作（3线）时仅在从模式下接收。当RSPI通信结束中断（CENDIE）使能为0时，通信完成时，设置通信结束标志（CENDF）并输出通信结束事件（sp_elccend），但不输出中断。但是，如果在清除通信结束标志（CENDF）之前将通信结束中断（CENDIE）的使能设置为1，而RSPI功能（SPE）的使能为1，则输出通信结束中断。

   - The communication end interrupt
2. When the enable of RSPI communication end interrupt (CENDIE) is 0, at the time of communication completion, the following two are the same timing, but no interrupt.
   - A flag of communication end (CENDF)
   - An event of communication end (sp_elccend)
3. After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of RSPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt is output after 1 PCLKUSCIx.
4. After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of RSPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt is not output.

30.3.10 Error Detection

In normal SPI serial transfers, data written to the transmit buffer of SPDR is transmitted, and received data can be read from the receive buffer of SPDR. If access is made to SPDR, an abnormal transfer might occur, depending on the status of the transmit or receive buffer or the status of the SPI at the beginning or end of serial transfer.

If an abnormal transfer occurs, the SPI detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 30.9 lists the relationship between non-normal transfer operations and the SPI error detection function.

Table 30.9 Relationship between non-normal transfer operations and SPI error detection (1 of 2)

Operation	Occurrence condition	SPI operation	Error detection
1	SPDR is written while no empty stages in the transmit FIFO.	• The contents of the transmit buffer are kept • Write data is missing	None
2	SPDR is read while no data stored in receive FIFO.	The contents of the receive buffer and previously received data are output.	None
3	Serial transfer is started in slave mode when the SPI is not able to transmit data.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Underrun error
4	Serial transfer ends when data is stored in the receive FIFO for the number of FIFO stages.	• Keeps the contents of the receive FIFO • Missing receive data	Overrun error

2、当RSPI通讯结束中断（CENDIE）使能为0时，通讯完成时，以下两者时序相同，但无中断。

4.(2)后，即使在RSPI功能(SPE)使能或通信结束标志(CENDF)为0时设置通信结束中断(CENDIE)使能，也不输出通信结束中断。

30.3.10 错误检测

在正常的SPI串行传输中，写入SPDR的发送缓冲区的数据被发送，接收到的数据可以从SPDR的接收缓冲区中读取。如果访问SPDR，可能会发生异常传输，具体取决于发送或接收缓冲区的状态或串行传输开始或结束时SPI的状态。

如果发生异常传输，SPI会将事件检测为欠载错误、溢出错误、奇偶校验错误或模式故障错误。
表30.9列出了非正常传输操作和SPI错误检测功能之间的关系。

Table 30.9 非正常传输操作与SPI错误检测之间的关系(1of2)

1	在发送FIFO中没有空阶段时写入SPDR。	• 发送缓冲区的内容被保留 • 写入数据丢失	None
2	SPDR被读取，而没有数据存储在接收中FIFO.	输出接收缓冲区的内容和先前接收的数据。	None
3	当SPI无法传输数据时，串行传输在从模式下启动。	• 串行传输被暂停 • 发送或接收数据丢失 • MIOn输出信号的驱动停止 • SPI功能被禁用	Underrun error
4	当数据存储在接收FIFO中达到FIFO级数时，串行传输结束。	• 保留接收FIFO的内容 • 缺少接收数据	溢出错误

5	An incorrect parity bit is received during full-duplex synchronous serial communication with the parity function enabled in following mode: ● Transmit-receive master mode ● Receive-only master mode ● Transmit-receive slave mode ● Receive-only slave mode	The parity error flag is asserted	Parity error
6	The SSLn0 input signal is asserted when the serial transfer is idle in multi-master mode.	● Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped ● SPI function is disabled	Mode fault error

8	[In the Motorola-SPI case] The SSLn0 input signal is negated during serial transfer in slave mode.	● Serial transfer is suspended ● Transmit or receive data is missing ● Driving of the MISOn output signal is stopped ● SPI function is disabled	Mode fault error
9	[In the TI-SSP case] The SSL0 input signal is asserted during serial transfer in slave mode.	● Serial transfer is suspended ● Transmit or receive data is missing ● Driving of the MISOn output signal is stopped ● SPI function is disabled	Mode fault error
10	After data is stored in the receive FIFO with SPDRES = 1, the number of stored data is less than the threshold value and no receive data is written for the set value of SPDRC [7:0]	Assert the receive data ready flag	Receive data ready

In operation 1 described in Table 30.9, the SPI does not detect an error. To prevent data omission during writes to SPDR, the writes to SPDR must be executed using a transmit buffer empty interrupt request (when the SPSR.SPTEF flag is 1).

Similarly, the SPI does not detect an error in operation 2. To prevent extraneous data from being read, SPDR read must be executed with an SPI receive buffer full interrupt request (when the SPSR.SPRF flag is 1).

For information on the other errors, see the following sections:

- Underrun error, indicated in operation 3, see section 30.3.10.4. Underrun errors
- Overrun error, indicated in operation 4, see section 30.3.10.1. Overrun errors
- Parity error, indicated in operation 5, see section 30.3.10.2. Parity errors
- Mode fault error, indicated in operations 6 to 8, see section 30.3.10.3. Mode fault errors
- For the transmit and receive interrupts, see section 30.3.7. Transmit Buffer Empty and Receive Buffer Full Interrupts.
- For the reception data ready in operations 10, see section 30.3.10.5. Received data ready.

30.3.10.1 Overrun errors

If a serial transfer ends when the receive buffer of SPDR is full, the SPI detects an overrun error and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the SPI does not copy data from the shift register to the receive buffer, so the data prior to the error occurrence is retained in the receive buffer. To set the OVRF flag to 0, issue a system reset or 1 is written to the SPSRC.OVRFC bit.

Figure 30.47 shows an example of operation of the OVRF and SPRF flags. The SPSR and SPDR accesses shown in Figure 30.47 indicate the condition of accesses to the SPSR and SPDR register, where W denotes a write cycle, and R a read cycle. In this example, the SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

10	数据存储在接收FIFO中后SPDRES=1，存储数据个数小于阈值，SPDRC[7:0]设定值不写入接收数据	置位接收数据就绪标志	接收数据就绪

在表30.9中描述的操作1中，SPI未检测到错误。为防止写入SPDR期间数据遗漏，必须使用发送缓冲区空中断请求（当SPSR.SPTEF标志为1时）执行对SPDR的写入。

同样，SPI不会检测到操作2中的错误。为防止读取无关数据，必须使用SPI接收缓冲区满中断请求（当SPSR.SPRF标志为1时）执行SPDR读取。

●欠载错误，在操作3中指示，参见第30.3.10.4节。欠载错误

30.3.10.1 溢出错误

如果串行传输在SPDR的接收缓冲区已满时结束，则SPI检测到溢出错误并将SPSR.OVRF标志设置为1。当OVRF标志为1时，SPI不会将数据从移位寄存器复制到接收缓冲区，因此错误发生之前的数据保留在接收缓冲区中。要将OVRF标志设置为0，请发出系统复位或将1写入SPSRC.OVRFC位。

图30.47显示了OVRF和SPRF标志的操作示例。图30.47所示的SPSR和SPDR访问表示访问SPSR和SPDR寄存器的条件，其中W表示写周期，R表示读周期。在本例中，当SPCMDm.CPHA位为1且SPCMDm.CPOL位为0时，SPI执行8位串行传输。

波形中为RSPCKn给出的数字表示RSPCK周期数，例如传输的位数。

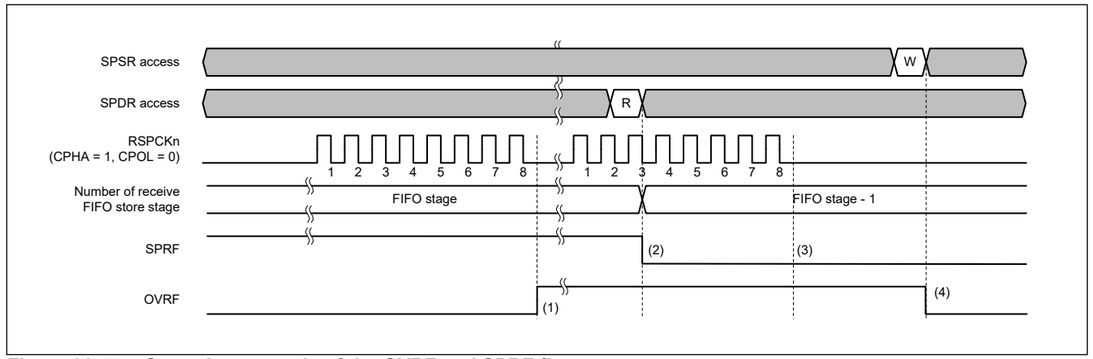

Figure 30.47 Operation example of the OVRF and SPRF flags

The operation of the flags at timings (1) to (4) in Figure 30.47 is as follows:

1. When serial transfer ends while data is stored for the number of FIFO stages, the RSPI detects an overrun error and sets the OVRF flag to 1. The RSPI does not copy shift register data to the receive buffer. The RSPI does not detect a parity error even when SPPE = 1. In master mode, the RSPI copies the value of pointer to the RSPI command register (SPCMDm) to the SPECM[2:0] bits in the RSPI status register (SPSR).
2. When SPDR is read, the SPI outputs the data in the receive buffer. At this time, the SPRF flag is cleared to 0 at the last access when the received data is read from SPDR in one processing routine using DTC / DMAC.
3. If the serial transfer ends with the OVRF flag set to 1 (overrun error occurred), the SPI does not copy data in the shift register to the receive buffer (the SPRF flag does not set to 1). A receive buffer full interrupt is not generated. Even when the SPPE bit is 1, parity errors are not detected. In an overrun error state when the SPI does not copy the received data from the shift register to the receive buffer, on termination of the serial transfer, the SPI determines that the shift register is empty. This enables data transfer from the transmit buffer to the shift register.
4. When 1 is written to the SPSRC.OVRFC bit, the SPSR.OVRF flag is cleared.

The occurrence of an overrun can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. When executing a serial transfer, you must ensure that overrun errors are detected early, for example by reading SPSR immediately after SPDR is read.

If an overrun error occurs and the OVRF flag sets to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled (SPCR.SCKASE = 1) in master mode, an overrun error does not occur. Figure 30.48 and Figure 30.49 show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

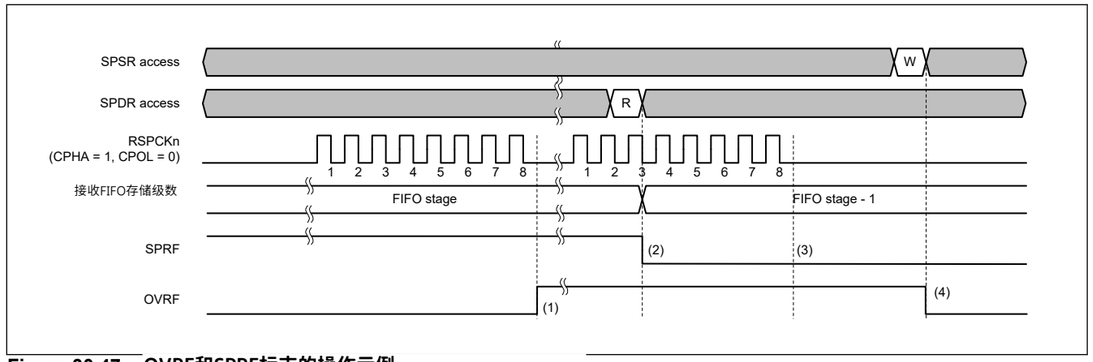

Figure 30.47 OVRF和SPRF标志的操作示例

图30.47中时间(1)到(4)的标志操作如下：

1.当串行传输结束而数据存储到FIFO级数时，RSPI检测到溢出错误并将OVRF标志设置为1。RSPI不会将移位寄存器数据复制到接收缓冲区。即使SPPE=1，RSPI也不会检测到奇偶校验错误。在主模式下，RSPI将指向RSPI命令寄存器(SPCMDm)的指针的值复制到RSPI状态寄存器(SPSR)中的SPECM[2:0]位.

2.读取SPDR时，SPI输出接收缓冲区中的数据。此时，当在一个使用DTCDMAC的处理程序中从SPDR读取接收到的数据时，SPRF标志在最后一次访问时被清除为0。

3.如果串行传输结束时OVRF标志设置为1（发生溢出错误），则SPI不会将移位寄存器中的数据复制到接收缓冲区（SPRF标志不设置为1）。不产生接收缓冲区满中断。即使SPPE位为1，也不会检测到奇偶校验错误。在SPI未将接收到的数据从移位寄存器复制到接收缓冲区的溢出错误状态下，在串行传输终止时，SPI确定移位寄存器为空。这使数据能够从发送缓冲器传输到移位寄存器。

4.当向SPSRC.OVRFC位写入1时，SPSR.OVRF标志被清除。

可以通过读取SPSR或使用SPI错误中断并读取SPSR来检查溢出的发生。
执行串行传输时，必须确保及早检测到溢出错误，例如在读取SPDR后立即读取SPSR。

如果发生溢出错误并且OVRF标志设置为1，则在OVRF标志设置为0之前无法执行正常接收操作。

在主机模式下启用RSPCK自动停止功能(SPCR.SCKASE=1)时，不会发生溢出错误。
图30.48和图30.49显示了在主机模式下接收缓冲器已满时串行传输继续时的时钟停止波形。

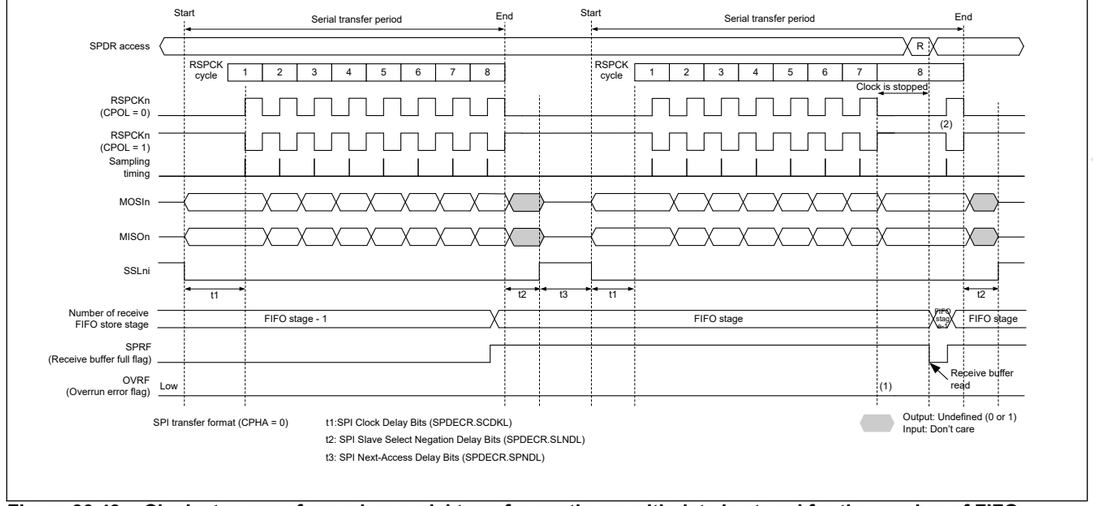

Figure 30.49 Clock stop waveform when serial transfer continues with data is stored for the number of FIFO stages in master mode (CPHA = 0)

The operation of the flags at timings (1) and (2) in Figure 30.48 and Figure 30.49 is as follows:

1. While data is stored in the receive FIFO for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.
2. If SPDR is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts.

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. Figure 30.50 and Figure 30.51 show the clock stop waveform, when there is no delay between frames at burst transfer and the serial transfer continues in the data is stored in the receive FIFO for the number of FIFO stages.

图30.48和图30.49中时序（1）和（2）的标志操作如下：

1.当数据存储在接收FIFO中达到FIFO级数时，RSPCK时钟被禁用并且不会发生溢出错误。

2.如果在时钟停止时读取SPDR，则可以读取接收缓冲区中的数据。RSPCK时钟重新启动。

在主模式下的突发传输期间，如果传输启用RSPCK自动停止功能且帧之间没有延迟，则不会发生溢出错误。图30.50和图30.51显示了时钟停止波形，当突发传输的帧之间没有延迟并且串行传输继续时，数据存储在接收FIFO中的FIFO级数。

The following describes operation of flags at timings (1) and (2) in the figure above.

1. While the data is stored for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.
2. Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read the RSPCK clock restarts.

下面描述在上图中的时间(1)和(2)的标志的操作。

1.当数据按FIFO级数存储时，RSPCK时钟被停用，不会发生溢出错误。

2.在时钟停止时，可以通过读取SPDR来读取接收缓冲数据。读取接收缓冲区数据后，RSPCK时钟重新启动。

30.3.10.2 Parity errors

After transfer in transmit-receive or receive-only master mode, transmit-receive slave mode or receive only slave mode while the SPPE bit in the RSPI control register (SPCR) is 1, the RSPI checks occurrence of a parity error. When the RSPI detects a parity error in received data, the PERF flag in the RSPI status register (SPSR) is set to 1. While the OVRF flag is 1, the RSPI does not copy shift register data to the receive buffer. Therefore, parity error in received data is not detected. To clear the PERF flag in SPSR to 0, issue a system reset or 1 is written to the SPSRC.PERFC bit.

Figure 30.52 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 30.52 indicates the condition of access to the register, where W denotes a write cycle, and R a read cycle. In this example, full-duplex serial communication is performed while the SPCR.SPPE bit is 1. The SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

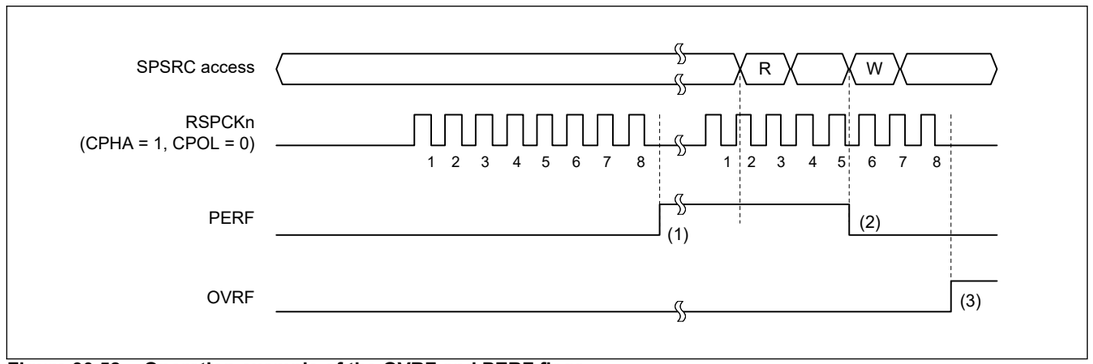

Figure 30.52 Operation example of the OVRF and PERF flags

The operation of the flags at timings (1) to (3) in Figure 30.52 is as follows:

1. When the RSPI does not detect an overrun error and terminates the serial transfer, the RSPI copies shift register data to the receive buffer. When the RSPI checks the received data and detects a parity error at this time, the PERF flag is set to 1. In master mode, the RSPI copies the value of pointer to the RSPI command register (SPCMDm) to the SPECM[2:0] bits in the RSPI Data control register 2 (SPDCR2).
2. When 1 is written to the SPSRC.PERFC bit, then clear the PERF flag.
3. When the SPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The SPI does not perform parity error detection at this time.

Parity errors can be checked for by either reading the SPSR register or using an SPI error interrupt and reading the SPSR register. When executing a serial transfer, such checks are required to ensure early detection of parity errors. When the SPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPDCR2.SPECM[2:0] bits.

30.3.10.3 Mode fault errors

The SPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1.

If the active level is input for the SSL0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of the status of the serial transfer, and sets the SPSR.MODF flag to 1.

On detecting the mode fault error, the SPI copies the value of the pointer to SPCMD to the SPECM[2:0] bits.

The active level of the SSLn0 signal is determined by the SPCR3.SSL0P bit.

When the MSTR bit is 0, the SPI operates in slave mode.

When the RSPI's MODFEN bit = 1 and the SPMS bit = 0 in slave mode, if the SSL0 input signal is negated during the serial transfer period (from valid data drive start to final valid data latch), the RSPI detects a mode fault error, while any of the following 2 conditions is met.

30.3.10.2 奇偶校验错误

当RSPI控制寄存器(SPCR)中的SPPE位为1时，在发送-接收或仅接收主机模式、发送-接收从机模式或仅接收从机模式下传输后，RSPI会检查奇偶校验错误的发生。当RSPI在接收到的数据中检测到奇偶校验错误时，RSPI状态寄存器(SPSR)中的PERF标志设置为1。当OVRF标志为1时，RSPI不会将移位寄存器数据复制到接收缓冲区。因此，未检测到接收数据中的奇偶校验错误。要将SPSR中的PERF标志清除为0，请发出系统复位或将1写入SPSRC.PERFC位。

图30.52显示了OVRF和PERF标志的操作示例。图30.52所示的SPSR访问表示访问寄存器的条件，其中W表示写周期，R表示读周期。在本例中，当SPCR.SPPE位为1时执行全双工串行通信。当SPCMDm.CPHA位为1且SPCMDm.CPOL位为0时，SPI执行8位串行传输。波形表示RSPCK周期数，例如传输的位数。

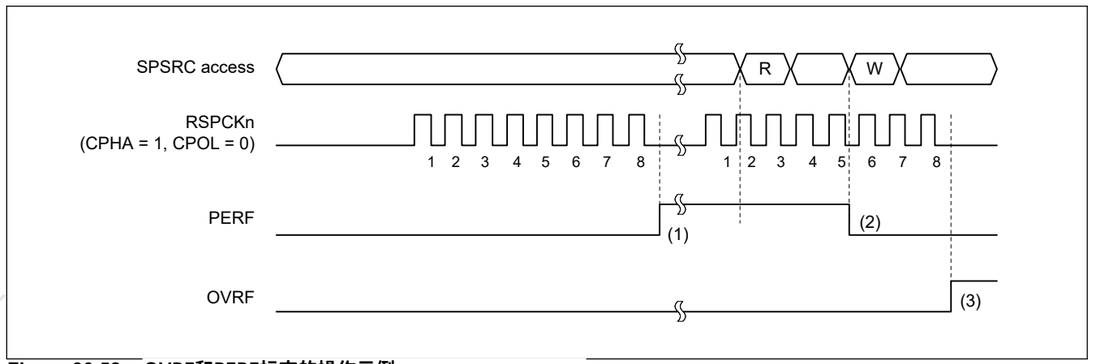

Figure 30.52 OVRF和PERF标志的操作示例

图30.52中时序(1)到(3)的标志操作如下：

1.当RSPI未检测到溢出错误并终止串行传输时，RSPI将移位寄存器数据复制到接收缓冲区。当RSPI此时检查接收到的数据并检测到奇偶校验错误时，PERF标志设置为1。在主机模式下，RSPI将指向RSPI命令寄存器（SPCMDm）的指针的值复制到SPECM[2:0]RSPI数据控制寄存器2(SPDCR2)中的位。

2.当SPSRC.PERFC位写入1时，清除PERF标志。

3.当SPI检测到溢出错误并终止串行传输时，移位寄存器中的数据不会复制到接收缓冲区。此时SPI不执行奇偶校验错误检测。

可以通过读取SPSR寄存器或使用SPI错误中断并读取SPSR寄存器来检查奇偶校验错误。在执行串行传输时，需要进行此类检查以确保及早发现奇偶校验错误。当SPI用于主机模式时，可以通过读取SPDCR2.SPECM[2:0]位来检查发生错误时指向SPCMDm寄存器的指针值。

30.3.10.3 模式故障错误

当SPCR.MSTR位为1、SPCR.SPMS位为0、SPCR.MODFEN位为1时，SPI工作在多主机模式。

如果在多主机模式下为SPI的SSL0输入信号输入有效电平，则无论串行传输的状态如何，SPI都会检测到模式故障错误，并将SPSR.MODF标志设置为1。

在检测到模式故障错误时，SPI将指向SPCMD的指针的值复制到SPECM[2:0]位。

SSLn0信号的有效电平由SPCR3.SSL0P位决定。

当MSTR位为0时，SPI工作在从机模式。

在从机模式下，当RSPI的MODFEN位=1且SPMS位=0时，如果在串行传输期间（从有效数据驱动开始到最终有效数据锁存）否定SSL0输入信号，则RSPI检测到模式故障错误，同时满足以下2个条件中的任何一个。

When the MSTR bit = 1, SPMS bit = 0, and MODFEN bit = 1 in the RSPI control register (SPCR), the RSPI operates in multi-master mode. When an active level is input to the SSL0 input signal of the RSPI in multi-master mode, the RSPI detects a mode fault error regardless of serial transfer status and sets the MODF flag in the RSPI status register (SPSR) to 1. When a mode fault error is detected, the RSPI copies the value of pointer to the RSPI command register (SPCMD) to the SPECM[2:0] bits in the RSPI status register (SPSR). The SSL0 signal active level depends on the SSL0P bit in the RSPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3).

While the MSTR bit is 0, the RSPI operates in slave mode. When the RSPI's MODFEN bit = 1 and the SPMS bit = 0 in slave mode, if the SSL0 input signal is negated during the serial transfer period (from valid data drive start to final valid data latch), the RSPI detects a mode fault error while any of the following 2 conditions is met.

[In the Motorola-SPI case]

When the SSL0 input signal is negated while serial data transfer.

[In the TI-SSP case]

When the SSL0 input signal is asserted while serial data transfer. However, during burst transfer, no error is detected even if the SSL0 input signal is asserted during the last bit of frame.

When the RSPI detects a mode fault error, it stops driving output signals and clears the SPE bit in the SPCR register. When the SPE bit is cleared, the RSPI function is disabled (as described in section 30.3.12. SPI Operation). In a multi-master configuration, the mastership can be released by stopping driving output signals and disabling the RSPI function by using a mode fault error.

Whether a mode fault error is present can be checked by reading SPSR or by reading an RSPI error interrupt and SPSR. To detect a mode fault error without using an RSPI error interrupt, poll SPSR. When the RSPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPECM[2:0] bits in SPSR.

While the MODF flag = 1, the RSPI ignores writing 1 to the SPE bit. To enable the RSPI function after a mode fault error is detected, clear the MODF flag to 0 without fail.

30.3.10.4 Underrun errors

While the SPI is operating in slave mode (SPCR.MSTR bit = 0) and the communication mode select bit (TXMD[1:0]) in the RSPI control register (SPCR) is set to 00b or 01b, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1 (SPI function enabled), the SPI detects an underrun error and sets the SPSR.MODF and SPSR.UDRF flags to 1.

On detecting an underrun error, the SPI stops the driving of output signals and clears the SPCR.SPE bit to 0 (see section 30.3.11. Initializing the SPI).

The occurrence of underrun errors can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting underrun errors without using the SPI error interrupt requires polling of SPSR.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of an underrun error, the MODF flag must be set to 0.

30.3.10.5 Received data ready

When SPCR.TXMD[1:0] = 00b, 01b, or 11b, and SPCR2.SPDRC[7:0] ≠ 0x00, after receiving data in the receive FIFO during communication (SPE = 1), SPDR.SPDRF flag is set to 1 when the received data is not stored even after the number of received FIFOs is equal to or less than ≤ the threshold value and the value set in SPDRC[7:0] has elapsed.

When the receive data ready is detected, the interrupt and event link output can be selected as SPRI or SPEI with the SPCR.SPDRES bit.

Figure 30.53 shows an example of reception data ready detection operation.

当RSPI控制寄存器(SPCR)中的MSTR位=1、SPMS位=0和MODFEN位=1时，RSPI工作在多主机模式。在多主机模式下，当向RSPI的SSL0输入信号输入有效电平时，无论串行传输状态如何，RSPI都会检测到模式故障错误，并将RSPI状态寄存器(SPSR)中的MODF标志设置为1。当检测到模式故障错误时，RSPI将指向RSPI命令寄存器(SPCMD)的指针的值复制到RSPI状态寄存器(SPSR)中的SPECM[2:0]位。SSL0信号有效电平取决于RSPI中的SSL0P位

SSLi信号极性位(SPCR3.SSLiP)(i=0到3)。

当MSTR位为0时，RSPI工作在从机模式。在从机模式下，当RSPI的MODFEN位=1且SPMS位=0时，如果在串行传输期间（从有效数据驱动开始到最终有效数据锁存）否定SSL0输入信号，则RSPI检测到模式故障错误，同时满足以下2个条件中的任何一个。

[In the Motorola-SPI case]

当串行数据传输时SSL0输入信号被否定时。

[In the TI-SSP case]

当SSL0输入信号在串行数据传输时被置位。然而，在突发传输过程中，即使SSL0输入信号在帧的最后一位被置位，也不会检测到错误。

当RSPI检测到模式故障错误时，它会停止驱动输出信号并清除SPCR寄存器中的SPE位。当SPE位清零时，RSPI功能被禁用（如第30.3.12.SPI操作部分所述）。在多主机配置中，可以通过停止驱动输出信号和使用模式故障错误禁用RSPI功能来释放主机权限。

可以通过读取SPSR或读取RSPI错误中断和SPSR来检查是否存在模式故障错误。要在不使用RSPI错误中断的情况下检测模式故障错误，请轮询SPSR。当RSPI用于主机模式时，当出现错误时指向SPCMD的指针值可以通过读取SPSR中的SPECM[2:0]位来检查。

当MODF标志=1时，RSPI忽略将1写入SPE位。要在检测到模式故障错误后启用RSPI功能，请务必将MODF标志清零。

30.3.10.4 Underrun errors

当SPI在从机模式下运行（SPCR.MSTR位=0）并且RSPI控制寄存器(SPCR)中的通信模式选择位(TXMD[1:0])设置为00b或01b时，如果串行传输开始在发送数据输出准备好之前
SPCR.SPE位设置为1（启用SPI功能），SPI检测到欠载错误并将SPSR.MODF和SPSR.UDRF标志设置为1。

检测到欠载错误时，SPI停止驱动输出信号并将SPCR.SPE位清零（参见第30.3.11节。初始化SPI）。

可以通过读取SPSR或使用SPI错误中断并读取
SPSR。在不使用SPI错误中断的情况下检测欠载错误需要轮询SPSR。

当MODF标志为1时，向SPE位写入1会被SPI忽略。要在检测到欠载错误后启用SPI功能，MODF标志必须设置为0。

30.3.10.5 接收数据就绪

当SPCR.TXMD[1:0]=00b、01b或11b且SPCR2.SPDRC[7:0]≠0x00时，在通信期间（SPE=1）接收到接收FIFO中的数据后，设置SPDR.SPDRF标志即使在接收到的FIFO的数量等于或小于≤阈值并且在SPDRC[7:0]中设置的值已经过去后，接收到的数据仍为1。

当检测到接收数据就绪时，中断和事件链接输出可以选择为SPRI或SPEI
SPCR.SPDRES bit.

图30.53显示了接收数据就绪检测操作的示例。

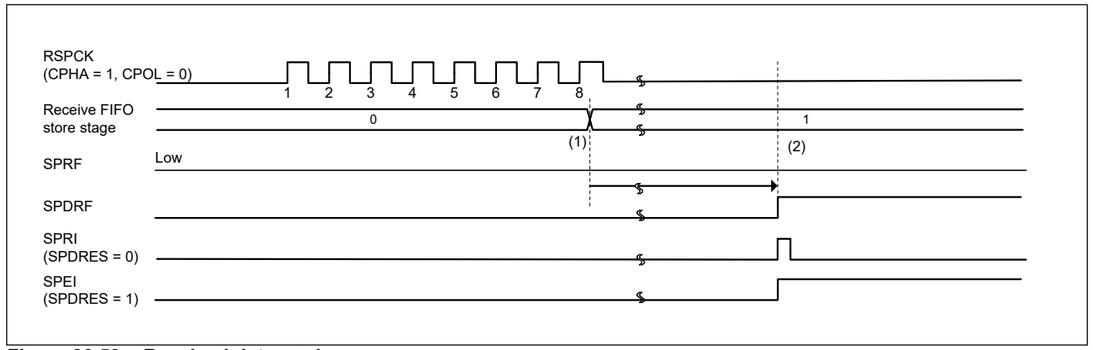

Figure 30.53 Received data ready

The following describes the operation at the timings indicated by (1) and (2) in the figure.

(1) Store the received data in the receive FIFO. SPRF is 0, because receive FIFO store stage ≤ RTRG.

(2) Set SPDRF and assert SPRI or SPEI because there is no writing to the receive FIFO for the amount of SPDRFC [7:0] set from above (1).

30.3.11 Initializing the SPI

If 0 is written to the SPCR.SPE bit or if the SPI sets the SPE bit to 0 because it detected a mode fault error or an underrun error, the SPI disables the SPI function and initializes some of the module functions. When a system reset is generated, the SPI initializes all of the module functions. This section describes initialization by clearing of the SPCR.SPE bit and by a system reset.

30.3.11.1 Initialization by clearing of the SPCR.SPE bit

When the SPCR.SPE bit is set to 0, the SPI initializes by:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the SPI
- Initializing the transmit buffer of the SPI (the SPSR.STEF flag sets to 1)

Initialization by clearing of the SPE bit does not initialize the control bits of the SPI. For this reason, the SPI can be started in the same transfer mode in use prior to initialization when the SPE bit is set to 1 again.

The SPSR.CENDF, SPSR.SPRF, SPSR.OVRF, SPSR.MODF, SPSR.PERF, and SPSR.UDRF flags are not initialized, and the value of the SPDCR2.SPECM[2:0] and SPDCR2.SPCP[2:0] bits are not initialized. Therefore, even after the SPI is initialized, data from the receive buffer can be read to check the communication completion status and the error status during an SPI transfer.

The transmit buffer is initialized to an empty state (the SPSR.SPTEF flag sets to 1). Therefore, if the SPCR.SPTIE bit is set to 1 after SPI initialization, a transmit buffer empty interrupt is generated. To disable any transmit buffer empty interrupts when the SPI is initialized, write 0 to the SPTIE bit simultaneously while writing 0 to the SPE bit.

30.3.11.2 Initialization by system reset

A system reset completely initializes the SPI by initializing all SPI control bits, status bits, and data registers, in addition to meeting the requirements described in section 30.3.11.1. Initialization by clearing of the SPCR.SPE bit.

30.3.12 SPI Operation

30.3.12.1 Master mode operation

The only difference between single- and multi-master mode operation is the use of mode fault error detection (see section 30.3.10. Error Detection). In single-master mode, the SPI does not detect mode fault errors whereas in multi-master mode, it does. This section explains operations that are common to both modes.

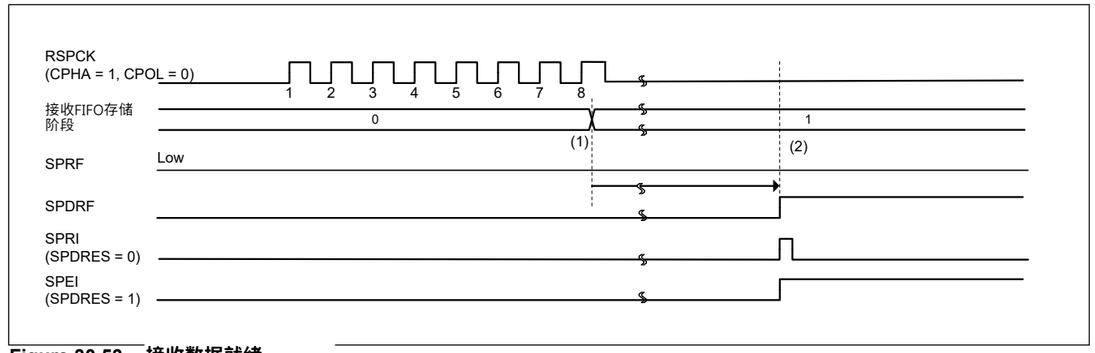

Figure 30.53 接收数据就绪

下面说明图中(1)和(2)所示定时的操作。

(1)将接收到的数据存入接收FIFO。SPRF为0，因为接收FIFO存储阶段≤RTRG。

(2)设置SPDRF并断言SPRI或SPEI，因为对于从上面(1)设置的SPDRFC[7:0]量，没有写入接收FIFO。

30.3.11 初始化SPI

如果将0写入SPCR.SPE位，或者如果SPI由于检测到模式故障错误或欠载错误而将SPE位设置为0，则SPI将禁用SPI功能并初始化一些模块功能。当产生系统复位时，SPI初始化所有模块功能。本节介绍通过清除SPCR.SPE位和系统复位进行的初始化。

30.3.11.1 通过清除SPCR.SPE位进行初始化

当SPCR.SPE位设置为0时，SPI通过以下方式初始化：

●暂停任何正在执行的串行传输

●从机模式下停止驱动输出信号（Hi-Z）

●初始化SPI的内部状态

●初始化SPI的发送缓冲区（SPSR.STEF标志设置为1）

通过清除SPE位进行的初始化不会初始化SPI的控制位。因此，当SPE位再次设置为1时，SPI可以在初始化之前以相同的传输模式启动。

SPSR.CENDF、SPSR.SPRF、SPSR.OVRF、SPSR.MODF、SPSR.PERF和SPSR.UDRF标志未初始化，SPDCR2.SPECM[2:0]和SPDCR2.SPCP[2的值：0]位未初始化。因此，即使在SPI初始化之后，也可以从接收缓冲区读取数据，以检查SPI传输期间的通信完成状态和错误状态。

发送缓冲区初始化为空状态（SPSR.SPTEF标志设置为1）。因此，如果SPCR.SPTIE位在SPI初始化后设置为1，则会产生发送缓冲区空中断。要在SPI初始化时禁用任何发送缓冲区空中断，请同时将0写入SPTIE位，同时将0写入SPE位。

30.3.11.2 通过系统复位初始化

除了满足第30.3.11.1节中描述的要求外，系统复位还通过初始化所有SPI控制位、状态位和数据寄存器来完全初始化SPI。通过清除SPCR.SPE位进行初始化。

30.3.12 SPI操作

30.3.12.1 主模式操作

单主机模式和多主机模式操作之间的唯一区别是使用模式故障错误检测（请参阅第30.3.10节。错误检测）。在单主机模式下，SPI不检测模式故障错误，而在多主机模式下，它可以。本节介绍两种模式共有的操作。

(1) Starting a serial transfer

When data is written to the RSPI data register (SPDR) while the next transfer data is not set in the transmit FIFO, the RSPI updates the transmit buffer (SPTXn,n = 0 to 3) data in SPDR. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR, the SPI copies data from the transmit buffer to the shift register and starts serial transfer. On copying transmit data to the shift register, the SPI changes the status of the shift register to full. On termination of the serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

The polarity of the SSLni output pins depends on the SPCR3.SSLnP (n = 0 to 3) bits settings. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

(2) Terminating a serial transfer

[Except Receive-only in Master Mode]

After the RSPI detects the RSPCK edge corresponding to the final sampling timing regardless of the CPHA bit value in the RSPI command register (SPCMD), the RSPI terminates serial transfer. When the number of data stored in the receive FIFO is less than the number of FIFO stages, data is copied from the shift register to the receive buffer in the RSPI data register (SPDR) after serial transfer.

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[4:0] bit settings. The polarity of the SSLni output pin depends on the SPCR3.SSLnP (n = 0 to 3) bits settings. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

[Receive-only in Master Mode]

When any of the following 2 conditions is met, then RSPI terminating the serial transfer.

- After the RSPI detects the RSPCK edge corresponding to the final sampling timing regardless of the CPHA bit value in the RSPI command register (SPCMD), the RSPI terminates serial transfer.
- When writing SPCR2.RMEDTG = 1 during the serial transfer period, RSPI terminating the serial transfer.

When the number of data stored in the receive FIFO is less than the number of FIFO stages, data is copied from the shift register to the receive buffer in the RSPI data register (SPDR) after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the RSPI in master mode depends on the set value of the SPB[4:0] bits in the RSPI command register (SPCMD). The SSL output signal polarity depends on the set RSPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value. For details about the RSPI transfer format, see section 30.3.5. Transfer Formats.

(3) Sequence control

The transfer format in master mode is determined as follows.

The transfer format used in master mode is determined by the SPCR3, SPCMDm, and SPDECR registers.

The SPCR3.SPSLN[2:0] bits determine the sequence configuration for serial transfers that are executed by the SPI in master mode. The following items are set in the SPCMDm register:

- SSLni pin output signal value
- MSB- or LSB-first
- Data length
- Some of the bit rate settings
- RSPCK polarity and phase
- Whether SPDECR.SCKDL is to be referenced
- Whether SPDECR.SLNDL is to be referenced
- Whether SPDECR.SPNDL is to be referenced

SPCR3.SPBR holds some of the bit rate settings, including SPDECR.SCKDL (SPI clock delay), SPDECR.SLNDL (SSL negation delay), and SPDECR.SPNDL (next-access delay).

Based on the sequence length assigned in SPCR3.SPSLN, the SPI makes up a sequence comprised of a part or all of the SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this

(1) 开始串行传输

当数据写入RSPI数据寄存器(SPDR)而下一次传输数据未设置在发送FIFO中时，RSPI会更新SPDR中的发送缓冲区(SPTXn n=0至3)数据。当SPDCR.SPFC[1:0]位中设置的帧数写入SPDR后移位寄存器为空时，SPI将数据从发送缓冲区复制到移位寄存器并开始串行传输。在将发送数据复制到移位寄存器时，SPI将移位寄存器的状态更改为已满。在串行传输终止时，它将移位寄存器的状态更改为空。无法引用移位寄存器的状态。

SSLni输出引脚的极性取决于SPCR3.SSLnP（n=0到3）位设置。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

(2) 终止串行传输

[除了在主模式下仅接收]

在RSPI检测到与最终采样时序对应的RSPCK边沿后，无论RSPI命令寄存器(SPCMD)中的CPHA位值如何，RSPI都会终止串行传输。当接收FIFO中存储的数据数小于FIFO级数时，串行传输后数据从移位寄存器复制到RSPI数据寄存器(SPDR)中的接收缓冲区。

最终的采样时序根据传输数据的位长而变化。在主机模式下，SPI数据长度取决于SPMDm.SPB[4:0]位设置。SSLni输出引脚的极性取决于SPCR3.SSLnP（n=0到3）位设置。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

[仅在主模式下接收]

当满足以下2个条件中的任何一个时，RSPI将终止串行传输。

●无论RSPI命令寄存器（SPCMD）中的CPHA位值如何，RSPI检测到最终采样时序对应的RSPCK边沿后，RSPI终止串行传输。

●在串行传输期间写入SPCR2.RMEDTG=1时，RSPI终止串行传输。

当接收FIFO中存储的数据数小于FIFO级数时，串行传输后数据从移位寄存器复制到RSPI数据寄存器(SPDR)中的接收缓冲区。

最终的采样时间因传输数据位长而异。主机模式下RSPI的数据长度取决于RSPI命令寄存器(SPCMD)中SPB[4:0]位的设置值。SSL输出信号极性取决于设置的RSPISSLi信号极性位(SPCR3.SSLiP)(i=0to3)值。有关RSPI传输格式的详细信息，请参见30.3.5节。传输格式。

(3) 顺序控制

主机模式下的传输格式如下确定。

主机模式中使用的传输格式由SPCR3、SPCMDm和SPDECR寄存器决定。

SPCR3.SPSLN[2:0]位确定由SPI在主模式下执行的串行传输的序列配置。在SPCMDm寄存器中设置以下项目：

●SSLni管脚输出信号值

- MSB- or LSB-first

●数据长度

●一些比特率设置

●RSPCK极性和相位

●SPDECR.SCKDL是否被引用

●SPDECR.SLNDL是否被引用

●SPDECR.SPNDL是否被引用

SPCR3.SPBR保存一些比特率设置，包括SPDECR.SCKDL（SPI时钟延迟）、SPDECR.SLNDL（SSL否定延迟）和SPDECR.SPNDL（下一次访问延迟）。

根据SPCR3.SPSLN中分配的序列长度，SPI组成一个序列，由部分或全部
SPMDm寄存器。SPI包含一个指向构成序列的SPCMDm寄存器的指针。这个的价值

pointer can be checked by reading the SPDCR2.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command in the sequence, the SPI sets the pointer to SPCMD0, and in this way the sequence is executed repeatedly.

In this section, a frame is the combination of the data in SPDR and the settings in SPCMDm.

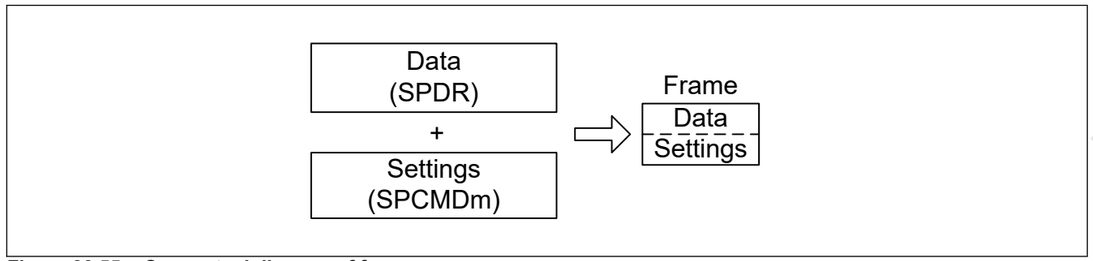

Figure 30.55 Conceptual diagram of frames

Figure 30.56 shows the correspondence between the commands and the transmit and receive buffers in the sequence of operations specified by the settings.

可以通过读取SPDCR2.SPCP[2:0]位来检查指针。当SPCR.SPE位设置为1且SPI功能使能时，SPI加载指向SPCMD0中命令的指针，并在串行传输开始时将SPCMD0设置合并到传输格式中。每次数据传输的下一个访问延迟周期结束时，SPI都会递增指针。在完成对应于序列中最后一个命令的串行传输后，SPI将指针设置为SPCMD0，并以此方式重复执行序列。

(4) 突发传输

本节描述了发送–接收仅发送操作期间的突发传输。

[In the Motorola-SPI case]

If the SPCMDm.SSLKP bit that the SPI references during the current serial transfer is 1, the SPI maintains the SSLni signal level during the serial transfer until the beginning of the SSLni signal assertion for the next serial transfer. If the SSLni signal level for the next serial transfer is the same as the SSLni signal level for the current serial transfer, the SPI can execute continuous serial transfers while keeping the SSLni signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 0.

Figure 30.57 shows an example of an SSLni signal operation for a burst transfer that is implemented using the SPCMD0 and SPCMD1 register settings. This section describes SPI operations (1) to (8) shown in Figure 30.57.

Note: The polarity of the SSLni output signal depends on the SPCR3.SSLnP (n = 0 to 3) bits settings.

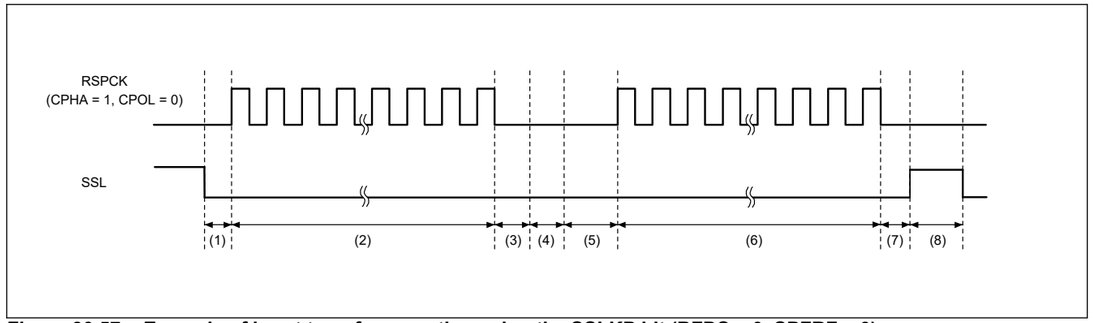

Figure 30.57 Example of burst transfer operation using the SSLKP bit (BFDS = 0, SPFRF = 0)

The SPI operation at times (1) to (8) in the figure is as follows:

1. Based on the SPCMD0 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
2. The SPI executes serial transfers in accordance with the SPCMD0 settings.
3. The SPI inserts an SSL negation delay.
4. Because the SPCMD0.SSLKP bit is 1, the SPI keeps the SSLni signal value specified in SPCMD0. This period additionally continues for 5 TCLK cycles (at minimum) that is the same as the next-access delay time of SPCMD0. If the shift register is empty after the passage of the minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
5. Based on the SPCMD1 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
6. The SPI executes serial transfers in accordance with the SPCMD1 settings.
7. Insert SSL negate delay.
8. Because the SPCMD1.SSLKP bit is 0, the SPI negates the SSLni signal. In addition, a next-access delay is inserted in accordance with SPCMD1.

If the SSLni signal output settings in the SPCMDm register where 1 is assigned to the SSLKP bit are different from the SSLni signal output settings in the SPCMDm register to be used in the next transfer, the SPI switches the SSLni signal status to SSLni signal assertion as shown in (5) in Figure 30.57. This corresponds to the command for the next transfer.

Note: If such an SSLni signal switching occurs, the slaves that drive the MISOn signal compete, and collision of signal levels might occur.

The SPI in master mode references the SSLni signal operation within the module when the SSLKP bit is not used. When the SPCMDm.CPHA bit is 0, the SPI can accurately start serial transfers by using the SSLni signal assertion for the next transfer that is detected internally.

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 1.

Figure 30.58 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 30.58. The SSL output signal polarity depends on the set SPCR3.SSLnP (n = 0 to 3) value.

如果SPI在当前串行传输期间引用的SPCMDm.SSLKP位为1，则SPI在串行传输期间保持SSLni信号电平，直到下一次串行传输的SSLni信号断言开始。如果下一次串行传输的SSLni信号电平与当前串行传输的SSLni信号电平相同，则SPI可以在保持SSLni信号断言状态（突发传输）的同时执行连续串行传输。

●当SPI控制寄存器(SPCR)的突发传输帧之间延迟选择位(BFDS)为0时。

图30.57显示了使用SPCMD0和SPCMD1寄存器设置实现的突发传输的SSLni信号操作示例。本节介绍图30.57所示的SPI操作(1)至(8)。

Note: SSLni输出信号的极性取决于SPCR3.SSLnP（n=0到3）位设置。

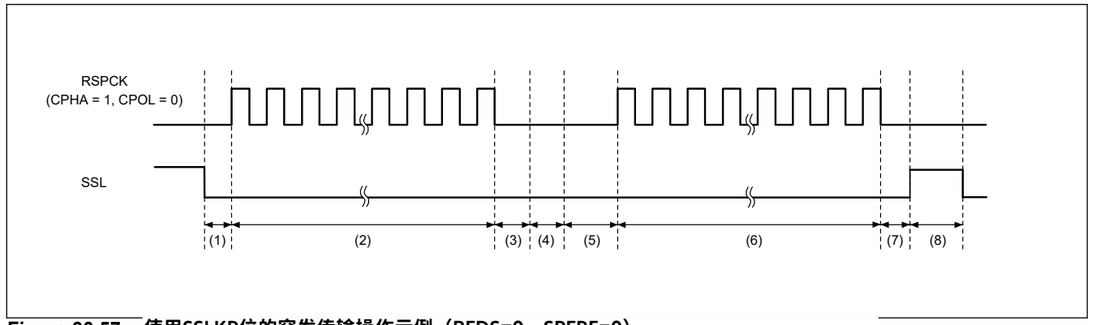

Figure 30.57 使用SSLKP位的突发传输操作示例（BFDS=0，SPFRF=0）

图中（1）到（8）时刻的SPI操作如下：

1.基于SPCMD0设置，SPI断言SSLni信号并插入RSPCK延迟。

2.SPI根据SPMD0设置执行串行传输。

3.SPI插入SSL否定延迟。

4.由于SPCMD0.SSLKP位为1，SPI保持SPCMD0中指定的SSLni信号值。这一时期
额外持续5个TCLK周期（至少），这与SPMD0的下一次访问延迟时间相同。如果在经过最小周期后移位寄存器为空，则该周期一直持续到发送数据存储在移位寄存器中以供下一次传输。

5.基于SPCMD1设置，SPI断言SSLni信号并插入RSPCK延迟。

6.SPI根据SPMD1设置执行串行传输。

7.插入SSL否定延迟。

8.由于SPCMD1.SSLKP位为0，SPI否定SSLni信号。此外，根据SPMD1插入下一个访问延迟。

如果SPCMDm寄存器中的SSLni信号输出设置（其中1分配给SSLKP位）与SPCMDm寄存器中用于下一次传输的SSLni信号输出设置不同，则SPI将SSLni信号状态切换为SSLni信号断言，如下所示如图30.57（5）所示。这对应于下一次传输的命令。

Note: 如果发生这种SSLni信号切换，驱动MISon信号的从机竞争，可能会发生信号电平冲突。

The following shows an example of SSL signal operation and serial data MISO / MOSI when burst transfer is realized using the settings. 3. Final data transfer and SSL assertion are performed simultaneously. If the shift register is empty during the RSPCK negation period between frames, wait for the output of the last clock until the transmission data for the next transfer is stored in the shift register.
4. Perform serial transfer according to SPCMD1.
5. Insert OE negate delay for the last frame.
6. Insert the next access delay according to SPCMD1.

If the SSL signal output setting in SPCMD with the SSLKP bit set to 1 differs from the SSL signal output setting in SPCMD to be used for the next transfer, the RSPI changes the SSL signal state when the SSL signal corresponding to the next-transfer command is asserted ((5)). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

This section describes burst transfer during receive-only operation.

[In the Motorola-SPI case]

When the SSLKP bit in the RSPI command register (SPCMD), which the RSPI references in the current serial transfer, is 1, the RSPI retains the SSL signal level during serial transfer until the SSL signal assertion of the next serial transfer starts. When the SSL signal level in the next serial transfer is the same as the SSL signal level in the current serial transfer, the RSPI can continuously perform serial transfer while holding the SSL signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of RSPI control register (SPCR) is 0.

Figure 30.60 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes RSPI operations of (1) to (8) shown in Figure 30.60. The SSL output signal polarity depends on the set RSPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

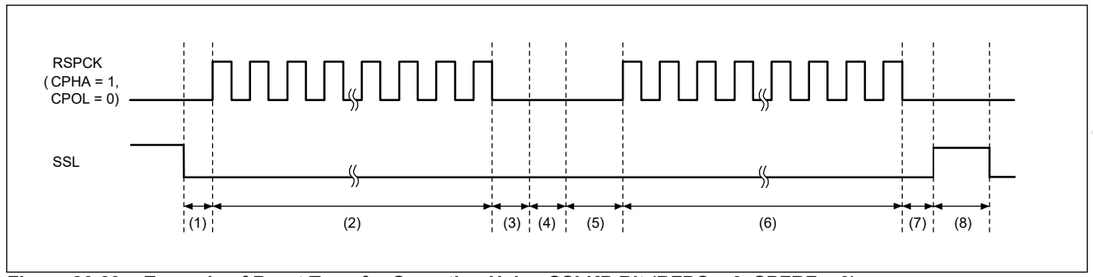

Figure 30.60 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 0, SPFRF = 0)

1. Assert the SSL signal and insert an RSPCK delay according to SPCMD0.
2. Perform serial transfer according to SPCMD0.
3. Insert an SSL negation delay.
4. The SSL signal value in SPCMD0 is retained because the SSLKP bit in SPCMD0 is 1. This period additionally continues for 5 TCLK cycles (at minimum) that is the same as the next-access delay time of SPCMD0.
5. Assert the SSL signal and insert an RSPCK delay according to SPCMD1.
6. Perform serial transfer according to SPCMD1.
7. Insert SSL negate delay.
8. The SSL signal is negated because the SSLKP bit in SPCMD1 is 0. Furthermore, the next-access delay is inserted according to SPCMD1.

If the SSL signal output setting and the SSL signal output setting between SPCMDs used for burst transfer are different, RSPI switches the SSL signal state when the SSL signal corresponding to the next transfer command is asserted ((5)). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

The RSPI in master mode references the SSL signal operation in the module when SSLKP is not used.

3.最终数据传输和SSL断言同时进行。如果在帧之间的RSPCK否定期间移位寄存器为空，则等待最后一个时钟的输出，直到下一次传输的传输数据存储在移位寄存器中。

4.根据SPMD1进行串行传输。

5.为最后一帧插入OE否定延迟。

6.根据SPMD1插入下一个访问延迟。

如果SPCMD中SSLKP位设置为1的SSL信号输出设置与SPCMD中用于下一次传输的SSL信号输出设置不同，则当与nexttransfer命令对应的SSL信号被断言时，RSPI会更改SSL信号状态((5))。请注意，如果发生这样的SSL信号变化，驱动MISO信号的从机可能会相互冲突，从而可能导致信号电平冲突。

本节介绍仅接收操作期间的突发传输。

[In the Motorola-SPI case]

当当前串行传输中RSPI引用的RSPI命令寄存器(SPCMD)中的SSLKP位为1时，RSPI在串行传输期间保持SSL信号电平，直到下一次串行传输的SSL信号断言开始。当下一次串行传输的SSL信号电平与当前串行传输的SSL信号电平相同时，

RSPI可以在保持SSL信号断言状态的同时连续执行串行传输（突发传输）。

●当RSPI控制寄存器(SPCR)的突发传输帧之间延迟选择位(BFDS)为0时。

图30.60显示了使用SPCMD0和SPCMD1的设置实现突发传输时SSL信号操作的示例。下面描述图30.60所示(1)到(8)的RSPI操作。SSL输出信号极性取决于设置的RSPISSLi信号极性位(SPCR3.SSLiP)(i=0to3)值。

8.SSL信号被取反，因为SPCMD1中的SSLKP位为0。此外，根据SPCMD1插入下一个访问延迟。

如果用于突发传输的SPCMD之间的SSL信号输出设置和SSL信号输出设置不同，则当与下一个传输命令对应的SSL信号被断言时，RSPI切换SSL信号状态((5))。请注意，如果发生这样的SSL信号变化，驱动MISO信号的从机可能会相互冲突，从而可能导致信号电平冲突。

不使用SSLKP时，主模式下的RSPI参考模块中的SSL信号操作。

Even when the CPHA bit in SPCMD is 0, the RSPI can accurately start serial transfer by using the nexttransfer SSL signal assertion detected internally. For this reason, burst transfer in master mode is enabled regardless of the set CPHA bit value. (See section 30.3.11. Initializing the SPI.)

- When Between Burst Transfer Frames Delay Select bit (BFDS) of RSPI control register (SPCR) is 1.

Figure 30.61 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes RSPI operations of (1) to (6) shown in Figure 30.61. The SSL output signal polarity depends on the set RSPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

[In the TI-SSP case]

RSPI asserts the SSL signal for one cycle at the start of serial transfer.

Serial transfer can be executed continuously by asserting the SSL signal for one cycle at the start of the next serial transfer (burst transfer).

The following shows an example of SSL signal operation and serial data MISO / MOSI when burst transfer is realized using the settings. The SSL output signal polarity depends on the set RSPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

即使SPCMD中的CPHA位为0，RSPI也可以通过使用内部检测到的nexttransferSSL信号断言准确地启动串行传输。因此，无论设置的CPHA位值如何，都会启用主模式下的突发传输。（参见第30.3.11节。初始化SPI。）

Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

(5) RSPCK delay (t1)

The RSPCK delay value of the SPI in master mode depends on the SPCMDm.SCKDEN bit setting and the SPDECR.SCKDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during a serial transfer by pointer control, and determines an RSPCK delay using the SPCMDm.SCKDEN bit and SPDECR.SCKDL[2:0] bits, as listed in Table 30.10. For a definition of RSPCK delay, see section 30.3.5. Transfer Formats.

RSPCK delay insert to only the first frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay”. (The SPCMD.SSLKP bit is 1 and the SPCR.BFDS bit is 1.)

Note: 最后一帧：当SPCR2.RMFM[4:0]≠00h时，由RMFM[4:0]位设置的帧或者，已接受SPCR2.RMEDTG=1的帧。
如果用于突发传输的SPCMD之间的SSL信号输出设置与SSL信号输出设置不同，则当对应于下一个传输命令的SSL信号被断言时，RSPI切换SSL信号状态(5)。请注意，如果发生这样的SSL信号变化，驱动MISO信号的从机可能会相互冲突，从而可能导致信号电平冲突。

(5) RSPCK delay (t1)

主机模式下SPI的RSPCK延迟值取决于SPMDm.SCKDEN位设置和SPDECR.SCKDL[2:0]位设置。SPI通过指针控制确定串行传输期间要引用的SPCMDm寄存器，并使用SPCMDm.SCKDEN位和SPDECR.SCKDL[2:0]位确定RSPCK延迟，如表30.10中所列。有关RSPCK延迟的定义，请参见第30.3.5节。传输格式。

	101	6 RSPCK	6 RSPCK
	110	7 RSPCK	7 RSPCK
	111	8 RSPCK	8 RSPCK

(6) SSL negation delay (t2)

The SSL negation delay value of the SPI in master mode depends on the SPCMDm.SLNDEN bit setting and the SPDECR.SLNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced by pointer control during a serial transfer, and determines an SSL negation delay using the SPCMDm.SLNDEN bit and SPDECR.SLNDL[2:0] bits, as listed in Table 30.11. For a definition of SSL negation delay, see section 30.3.5. Transfer Formats.

An SSL negation delay is inserted to only the last frame of the burst transmission, that is, transmit without between burst transfer frames delay. (SPCMD.SSLKP bit is 1 and SPCR.BFDS bit is 1).

	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(7) Next-access delay (t3)

The next-access delay value of the SPI in master mode depends on the SPCMDm.SPNDEN bit setting and the SPDECR.SPNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and then determines a next-access delay during serial transfer using the SPCMDm.SPNDEN bit and SPDECR.SPNDL[2:0] bits, as listed in Table 30.12. For a definition of next-access delay, see section 30.3.5. Transfer Formats.

A next-Access delay is inserted to only the last frame of the burst transmission, that is, transmit without between burst transfer frames delay. (SPCMD.SSLKP bit is 1 and SPDR.BFDS bit is 1).

(6) SSL否定延迟(t2)

主模式下SPI的SSL否定延迟值取决于SPMDm.SLNDEN位设置和SPDECR.SLNDL[2:0]位设置。SPI确定串行传输期间指针控制要引用的SPCMDm寄存器，并使用SPCMDm.SLNDEN位和SPDECR.SLNDL[2:0]位确定SSL否定延迟，如表30.11中所列。有关SSL否定延迟的定义，请参阅第30.3.5节。传输格式。

仅在突发传输的最后一帧中插入SSL否定延迟，即在突发传输帧之间没有延迟的传输。（SPCMD.SSLKP位为1，SPCR.BFDS位为1）。

Error processing flow

The SPI detects the following errors:

- Mode fault error
- Underrun error
- Overrun error
- Parity error

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, the SPCR.SPE bit is not cleared and operations for transmission and reception continue. Therefore, Renesas recommends clearing the SPCR.SPE bit to stop operations for errors other than mode fault errors. Not doing so leads to updating of the SPDCR2.SPECM[2:0] bits.

When an error is detected using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

错误处理流程

SPI检测到以下错误：

●模式故障错误
- Underrun error

●超限错误
●奇偶校验错误

当产生模式故障错误时，SPCR.SPE位自动清零，停止发送和接收操作。对于其他来源的错误，SPCR.SPE位不会被清除，发送和接收操作会继续。因此，瑞萨建议清除SPCR.SPE位以停止除模式故障错误以外的错误操作。不这样做会导致更新SPDCR2.SPECM[2:0]位。

当使用中断检测到错误时，清除错误处理例程中的ICU.IELSRn.IR标志。如果不这样做，ICU.IELSRn.IR标志可能会继续指示SPIi_SPTI或SPIi_SPRI中断请求。如果指示了SPIi_SPRI中断请求，则读取接收缓冲区并初始化SPI中的定序器。

30.3.12.2 Slave mode operation

(1) Starting a serial transfer

When the SPCMD0.CPHA bit is 0, if the SPI detects an SSLn0 input signal assertion, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLn0 input signal triggers the start of a serial transfer.

When the CPHA bit is 1, if the SPI detects the first RSPCKn edge in an SSLn0 signal asserted condition, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 1, the first RSPCKn edge in an SSLn0 signal asserted condition triggers the start of a serial transfer.

Regardless of the CPHA bit setting, the SPI drives the MISOn output signal on SSLn0 signal assertion. The data that is output by the SPI is either valid or invalid, depending on the CPHA bit setting.

For details on the SPI transfer format, see section 30.3.5. Transfer Formats. The polarity of the SSLn0 input signal depends on the SPCR3.SSL0P setting.

(2) Terminating a serial transfer

Regardless of the SPCMD0.CPHA bit setting, the SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO is less than the number of FIFO stages, on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR register. On termination of a serial transfer, the SPI changes the status of the shift register to empty, regardless of the

30.3.12.2 从模式操作

(1) 开始串行传输

当SPCMD0.CPHA位为0时，如果SPI检测到SSLn0输入信号断言，它必须将有效数据驱动到MISOn输出信号。因此，当CPHA位为0时，SSLn0输入信号的断言触发串行传输的开始。

当CPHA位为1时，如果SPI在SSLn0信号置位条件下检测到第一个RSPCKn边沿，它必须将有效数据驱动到MISOn输出信号。因此，当CPHA位为1时，SSLn0信号断言条件中的第一个RSPCKn边沿触发串行传输的开始。

无论CPHA位设置如何，SPI都会在SSLn0信号置位时驱动MIOn输出信号。SPI输出的数据是有效还是无效，取决于CPHA位设置。

有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。SSLn0输入信号的极性取决于SPCR3.SSL0P设置。

(2) 终止串行传输

无论SPCMD0.CPHA位设置如何，SPI在检测到对应于最终采样时序的RSPCKn边沿后终止串行传输。当接收FIFO中存储的数据数量小于FIFO级数时，在串行传输终止时，SPI将接收到的数据从移位寄存器复制到SPDR寄存器的接收缓冲区。在串行传输终止时，SPI将移位寄存器的状态更改为空，而不管

receive buffer state. A mode fault error occurs if the SPI detects an SSLn0 input signal negation from the beginning of serial transfer to the end of serial transfer (see section 30.3.10. Error Detection).

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length is determined by the SPCMD0.SPB[4:0] bits setting. The polarity of the SSLn0 input signal is determined by the SPCR3.SSL0P bit setting. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

(3) Notes on single-slave operations

[In the Motorola-SPI case]

If the SPCMD0.CPHA bit is 0, the SPI starts serial transfers when it detects the assertion edge for an SSLn0 input signal. In the configuration shown in Figure 30.8, if the SPI is used in single-slave mode, the SSLn0 signal is fixed at an active state. Therefore, when the CPHA bit is set to 0, the SPI cannot correctly start a serial transfer. For the SPI to correctly execute transmit and receive operations in slave mode when the SSLn0 input signal is fixed at an active state, the CPHA bit must be set to 1. Do not fix the SSLn0 input signal if there is a requirement for setting the CPHA bit to 0.

[In the TI-SSP case]

When RSPI is used as a single slave in the configuration shown in the Figure 30.7, the SSL0 input signal is always fixed to the inactive state, so the SPI cannot start the serial transfer.

When using a single slave, use the configuration shown in the example in Figure 30.6.

(4) Burst transfer

[In the Motorola-SPI case]

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLn0 input signal. When the CPHA bit is 1, the serial transfer period is the period from the first RSPCKn edge to the sampling timing for the reception of the final bit in an SSLn0 signal active state. Even when the SSLn0 input signal remains at the active level, the SPI can accommodate burst transfers, because it can detect the start of an access.

When the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

[In the TI-SSP case]

In serial transfer, data transfer starts after the SSL input signal is asserted for RSPCK 1 cycle. Since frame transfer starts from the SSL input signal, SSL must be asserted between frames.

(5) Initialization flow

Figure 30.68 shows an example of initialization flow for SPI operation when the SPI is in slave mode. For a description of how to set up the ICU, DTC, and I/O ports, see the descriptions given in the individual blocks.

接收缓冲区状态。如果SPI从串行传输开始到串行传输结束检测到SSLn0输入信号取反，则会发生模式故障错误（请参阅第30.3.10节。错误检测）。

最终的采样时序根据传输数据的位长而变化。在从机模式下，SPI数据长度由SPCMD0.SPB[4:0]位设置决定。SSLn0输入信号的极性由SPCR3.SSL0P位设置决定。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

(3) 单从操作注意事项

[In the Motorola-SPI case]

如果SPCMD0.CPHA位为0，则SPI在检测到SSLn0输入信号的断言边沿时开始串行传输。在图30.8所示的配置中，如果SPI用于单从模式，则SSLn0信号固定在激活状态。因此，当CPHA位设置为0时，SPI无法正确启动串行传输。当SSLn0输入信号固定为活动状态时，为了使SPI在从模式下正确执行发送和接收操作，CPHA位必须设置为1。如果需要设置CPHA，请不要固定SSLn0输入信号位为0。

[In the TI-SSP case]

在图30.7所示的配置中，当RSPI用作单从机时，SSL0输入信号始终固定为非活动状态，因此SPI无法启动串行传输。

使用单从机时，请使用图30.6示例中所示的配置。

(4) 突发传输

[In the Motorola-SPI case]

如果SPCMD0.CPHA位为1，则可以执行连续串行传输（突发传输），同时保持SSLn0输入信号的断言状态。当CPHA位为1时，串行传输周期是从第一个RSPCKn边沿到SSLn0信号有效状态下接收最后一个位的采样时序的周期。即使SSLn0输入信号保持在有效电平，SPI也可以适应突发传输，因为它可以检测访问的开始。

当CPHA位为0时，突发传输期间的第二次和后续串行传输无法正确执行。

[In the TI-SSP case]

在串行传输中，数据传输在SSL输入信号被断言为RSPCK1个周期后开始。由于帧传输从SSL输入信号开始，因此必须在帧之间断言SSL。

Error processing flow

In slave mode operation, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the state of the SSLn0 pin.

When an error is detected by using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

30.3.13 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the SPI. In clock synchronous operation, the SSLni pin is not used, and the RSPCKn, MOSIn, and MISOn pins handle communications. All SSLni pins are available as I/O port pins.

Although clock synchronous operation does not require the use of the SSLni pin, operation of the module is the same as in SPI operation. In both master mode and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected, because the SSLni pin is not used.

Additionally, do not perform operation if clock synchronous operation is enabled when the SPCMDm.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).

30.3.13.1 Master mode operation

(1) Starting serial transfer

When data is written to the RSPI data register (SPDR) while the next transfer data is not set in the transmit FIFO, the RSPI updates the transmit buffer (SPTXn, n = 0 to 3) data in SPDR.While the shift register is empty, the RSPI copies transmit buffer data to the shift register to start serial transfer. After the RSPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the RSPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the RSPI transfer format, see section 30.3.5. Transfer Formats. In clock synchronous operation, however, the SSL0 output signal is not used for communication.

30.3.13 时钟同步操作

将SPCR.SPMS位设置为1可选择SPI的时钟同步操作。在时钟同步操作中，不使用SSLni引脚，而RSPCKn、MOSIn和MISOn引脚处理通信。所有SSLni引脚都可用作IO端口引脚。

虽然时钟同步操作不需要使用SSLni引脚，但模块的操作与SPI操作相同。在主模式和从模式操作中，可以使用与在相同的流程中执行通信
SPI操作。但是，未检测到模式故障错误，因为未使用SSLni引脚。

此外，如果在从模式(SPCR.MSTR=0)下SPCMDm.CPHA位设置为0时使能时钟同步操作，则不要执行操作。

30.3.13.1 主模式操作

(1) 开始串行传输

当数据写入RSPI数据寄存器(SPDR)而下一次传输数据未设置在发送FIFO中时，RSPI更新SPDR中的发送缓冲区(SPTXn n=0到3)数据。而移位寄存器为空，RSPI将传输缓冲区数据复制到移位寄存器以开始串行传输。RSPI将发送数据复制到移位寄存器后，将移位寄存器状态更改为满。串行传输完成后，RSPI将移位寄存器状态更改为空。无法监控移位寄存器状态。

有关RSPI传输格式的详细信息，请参见30.3.5节。传输格式。然而，在时钟同步操作中，SSL0输出信号不用于通信。

(2) Terminating serial transfer

The SPI terminates the serial transfer after transmitting an RSPCKn edge corresponding to the sampling timing. If the number of data stored in the receive FIFO < the number of FIFO stages, on termination of serial transfer, the SPI copies data from the shift register to the receive buffer of the SPI Data Register (SPDR).

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[4:0] bits setting. Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

(3) Sequence control

The transfer format used in master mode is determined by the SPCR3, SPCMDm, and SPDECR registers. Although the SSLni signals are not output in clock synchronous operation, these settings are valid.

The SPCR3.SPSLN[2:0] bits determine the sequence configuration for serial transfers that are executed by the SPI in master mode. The following parameters are specified in the SPCMDm register:

- SSLni output signal value
- MSB or LSB first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPDECR.SCKDL is to be referenced
- Whether SPDECR.SLNDL is to be referenced
- Whether SPDECR.SPNDL is to be referenced

SPCR3.SPBR holds some of the bit rate settings such as SPDECR.SCKDL, an SPI clock delay value, SPDECR.SLNDL, an SSL negation delay, and SPDECR.SPNDL, a next-access delay value.

Based on the sequence length that is assigned to SPCR3, the SPI makes up a sequence comprised of a part or all of SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPDCR2.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command comprising the sequence, the SPI sets the pointer to the SPCMD0 register, and in this manner the sequence is executed repeatedly.

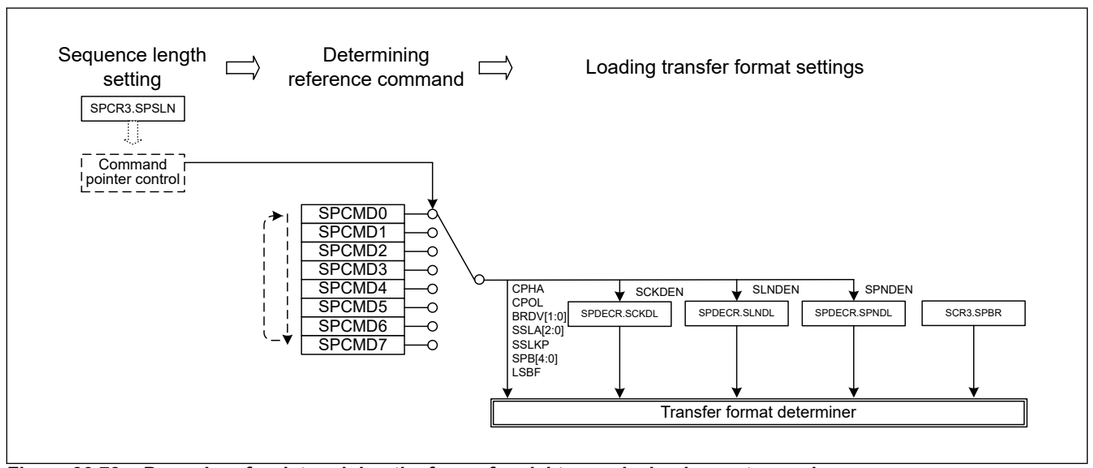

Figure 30.73 Procedure for determining the form of serial transmission in master mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

(2) 终止串行传输

SPI在发送对应于采样时序的RSPCKn边沿后终止串行传输。如果接收FIFO中存储的数据数量<FIFO级数，则在串行传输终止时，SPI将数据从移位寄存器复制到SPI数据寄存器(SPDR)的接收缓冲区。

最终的采样时序根据传输数据的位长而变化。在主模式下，SPI数据长度取决于SPMDm.SPB[4:0]位设置。在没有SSLn0输出信号的情况下进行时钟同步操作的传输。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

(3) 顺序控制

主机模式中使用的传输格式由SPCR3、SPCMDm和SPDECR寄存器决定。虽然
时钟同步操作中不输出SSLni信号，这些设置有效。

SPCR3.SPSLN[2:0]位确定由SPI在主模式下执行的串行传输的序列配置。SPCMDm寄存器中指定了以下参数：

- SSLni输出信号值
- MSB或LSB在前
- 数据长度
- 一些比特率设置
- RSPCKn极性和相位
- SPDECR.SCKDL是否被引用
- SPDECR.SLNDL是否被引用
- SPDECR.SPNDL是否被引用

SPCR3.SPBR保存一些比特率设置，例如SPDECR.SCKDL，一个SPI时钟延迟值，SPDECR.SLNDL，一个SSL否定延迟和SPDECR.SPNDL，下一次访问延迟值。

根据分配给SPCR3的序列长度，SPI组成一个由部分或全部组成的序列
SPMDm寄存器。SPI包含一个指向构成序列的SPCMDm寄存器的指针。该指针的值可以通过读取SPDCR2.SPCP[2:0]位来检查。当SPCR.SPE位设置为1且SPI功能使能时，SPI将指针加载到SPCMD0寄存器中的命令，并在串行传输开始时将SPCMD0寄存器设置合并到传输格式中。每次数据传输的下一个访问延迟周期结束时，SPI都会递增指针。在完成对应于包含序列的最终命令的串行传输后，SPI将指针设置为SPMD0寄存器，并以这种方式重复执行序列。

30.3.13.2 Slave mode operation

(1) Starting serial transfer

When the SPCR.SPMS bit is 1, the first RSPCKn edge triggers the start of a serial transfer in the SPI, and the SPI drives the MISOn output signal. The SSL0 input signal is not used in clock synchronous operation. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

(2) Terminating serial transfer

The SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO < the number of FIFO stages, on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR register. On termination of a serial transfer, the SPI changes the status of the shift register to empty regardless of the receive buffer.

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length depends on the SPCMD0.SPB[4:0] bits setting. For details on the SPI transfer format, see section 30.3.5. Transfer Formats.

(3) Initialization flow

Figure 30.77 shows an example of initialization flow for clock synchronous operation when the SPI is used in slave mode. For a description of how to set up the ICU, DTC, and I/O ports, see the descriptions given in the individual blocks.

30.3.13.2 从模式操作

(1) 开始串行传输

当SPCR.SPMS位为1时，第一个RSPCKn边沿触发SPI中串行传输的开始，并且SPI驱动MISon输出信号。SSL0输入信号不用于时钟同步操作。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

(2) 终止串行传输

SPI在检测到对应于最终采样时序的RSPCKn边沿后终止串行传输。当接收FIFO中存储的数据数<FIFO级数时，在串行传输终止时，SPI将接收到的数据从移位寄存器复制到SPDR寄存器的接收缓冲区。在串行传输终止时，SPI将移位寄存器的状态更改为空，而与接收缓冲区无关。

最终的采样时序根据传输数据的位长而变化。在从机模式下，SPI数据长度取决于SPCMD0.SPB[4:0]位设置。有关SPI传输格式的详细信息，请参见第30.3.5节。传输格式。

(4) Software processing flow

Software processing during clock synchronous slave operation is the same as that for SPI slave operation. For details, see (6)Software processing flow. Mode fault errors do not occur in clock synchronous mode.

30.3.14 Loopback Mode

When 1 is written to the SPCR2.SPLP2 bit or SPCR2.SPLP bit, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, or between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0, and connects the input and output paths of the shift register, establishing a loopback mode. The SPI does not shut off the path between the MOSIn pin and the shift register if the SPCR.MSTR bit is 1, or between the MISOn pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the SPI or the reversed transmit data becomes the received data for the SPI.

(4) 软件处理流程

时钟同步从机操作期间的软件处理与SPI从机操作相同。详见（6）软件处理流程。时钟同步模式下不会发生模式故障错误。

30.3.14 Loopback Mode

当SPCR2.SPLP2位或SPCR2.SPLP位写入1时，如果SPCR.MSTR位为1，则SPI关闭MISOn引脚和移位寄存器之间的路径，或者如果SPCR.MSTR位为0，连接移位寄存器的输入和输出路径，建立环回模式。如果SPCR.MSTR位为1，SPI不关闭MOSIn引脚和移位寄存器之间的路径，如果SPCR.MSTR位为0，则SPI不关闭MISOn引脚和移位寄存器之间的路径。这称为环回模式。当在环回模式下执行串行传输时，SPI的发送数据或反向发送数据将成为SPI的接收数据。

30.3.15 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. To detect defects in the parity bit adding unit and error detecting unit, the parity circuit performs self-diagnosis as shown in Figure 30.79.

- Communication-end

The DMAC or DTC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Because the vector address for the SPIi_SPEI (SPI error interrupt) is allocated to interrupt requests on mode-fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the SPI are listed in Table 30.14. An interrupt is generated on satisfaction of one of the interrupt conditions in Table 30.14. Clear the receive buffer full and transmit buffer empty sources through a data transfer.

When using the DMAC or DTC to perform data transmission and reception, you must first set up the DMAC or DTC to be in a transfer-enabled status before setting the SPI. For information on setting up the DMAC or DTC, see section 15, DMA Controller (DMAC) and section 16, Data Transfer Controller (DTC).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt occur while the ICU.IELSRn.IR flag is 1, the interrupt is not output as a request for the ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IELSRn.IR flag becomes 0. A retained interrupt request is automatically discarded when it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be set to 0.

Table 30.14 SPI interrupt sources

Interrupt source	Symbol	Interrupt condition	DTC/DMAC activation
Receive buffer full	SPIi_SPRI	The receive buffer becomes full (SPSR.SPRF flag is 1) while the SPCR.SPRIE bit is 1 or The receive data become ready (SPSR.SPDRF flag is 1) while the SPCR.SPDRES bit is 0	Possible
Transmit buffer empty	SPIi_SPTI	The transmit buffer becomes empty (SPSR.SPTEF flag is 1) while the SPCR.SPTIE bit is 1	Possible
SPI error (mode-fault, underrun, overrun, or parity error)	SPIi_SPEI	The SPSR.MODF, OVRF,or PERF flag sets to 1, or the SPSR.SPDRES and SPDRF flag set to 1 while the SPCR.SPEIE bit is 1	Impossible
SPI idle	SPIi_SPII	The SPSR.IDLNF flag sets to 0 while the SPCR.SPIIE bit is 1	Impossible
Communication-end	SPIi_SPCEND	CENDIE = 1 and CENDF = 1	Impossible

30.4 Event Link Controller Event Output

The Event Link Controller (ELC) can produce the following event output signals:

- Receive buffer full event output
- Transmit buffer empty event output
- Mode-fault, underrun, overrun, or parity error event output
- SPI idle event output
- Transmission-completed event output

The event link output signal is output regardless of the interrupt enable bit setting.

30.4.1 Receive Buffer Full Event Output

When the number of data stored in the receive FIFO > the threshold value, or when the number of data stored in the receive FIFO ≤ the threshold value and SPDRES = 0 has elapsed after writing to the receive FIFO, and the SPDRC [7:0] has elapsed outputs an event.

30.4.2 Transmit Buffer Empty Event Output

An event is output when the number of empty transmission FIFO stage > the threshold or when the SPCR.SPE bit changes from 0 to 1.

●SPI错误（模式故障、欠载、溢出或奇偶校验错误）

●SPI空闲

- Communication-end

DMAC或DTC可由接收缓冲区满或发送缓冲区空中断激活以执行数据传输。

由于SPIi_SPEI（SPI错误中断）的向量地址分配给模式错误、欠载、溢出和奇偶校验错误的中断请求，因此必须根据标志确定实际中断源。表30.14列出了SPI的中断源。满足表30.14中的中断条件之一时会产生中断。通过数据传输清除接收缓冲区满和发送缓冲区空源。

使用DMAC或DTC进行数据收发时，必须先将DMAC或DTC设置为传输使能状态，然后再设置SPI。有关设置DMAC或DTC的信息，请参阅第15节，DMA控制器(DMAC)和第16节，数据传输控制器(DTC)。

如果在ICU.IELSRn.IR标志为1时发生发送缓冲区空或接收缓冲区满中断的条件，则该中断不会作为对ICU的请求输出，而是在内部保留（保留容量为每个请求一个请求）资源）。当ICU.IELSRn.IR标志变为0时，输出保留中断请求。当作为实际中断请求输出时，自动丢弃保留中断请求。内部保留中断请求的中断使能位（SPCR.SPTIE或SPCR.SPRIE位）也可以设置为0。

Table 30.14 SPI中断源

中断源	Symbol	中断条件	DTC/DMAC activation
接收缓冲区已满	SPIi_SPRI	SPCR.SPRIE位为1时接收缓冲器变满（SPSR.SPRF标志为1）或SPCR.SPDRES位为0时接收数据准备好（SPSR.SPDRF标志为1）	Possible
发送缓冲区为空	SPIi_SPTI	当SPCR.SPTIE位为1时，发送缓冲区变为空（SPSR.SPTEF标志为1）	Possible
SPI错误（模式错误、欠载、溢出或奇偶校验错误）	SPIi_SPEI	SPSR.MODF、OVRF或PERF标志设置为1，或者SPSR.SPDRES和SPDRF标志设置为1，而SPCR.SPEIE位为1	Impossible
SPI空闲	SPIi_SPII	SPSR.IDLNF标志设置为0，而SPCR.SPIIE位为1	Impossible
Communication-end	SPIi_SPCEND	CENDIE = 1 and CENDF = 1	Impossible

30.4 事件链接控制器事件输出

事件链接控制器(ELC)可以产生以下事件输出信号：

●接收缓冲区满事件输出

●发送缓冲区空事件输出

●模式故障、欠载、溢出或奇偶校验错误事件输出

●SPI空闲事件输出

●传输完成事件输出

无论中断允许位设置如何，都会输出事件链接输出信号。

30.4.1 接收缓冲区满事件输出

当接收FIFO中存储的数据数量>阈值时，或者当接收中存储的数据数量FIFO≤阈值且SPDRES=0在写入接收FIFO后已过，并且SPDRC[7:0]已过输出事件。

30.4.2 发送缓冲区空事件输出

当空传输FIFO级数>阈值或SPCR.SPE位从0变为1时，输出事件。

30.4.3 Mode-Fault, Underrun, Overrun, Parity Error, or received data ready Event Output

This event signal is output when mode-fault, underrun, overrun, or parity error is detected. See section 30.5.4. Constraints on Mode-Fault, Underrun, Overrun, Parity Error, or Receive Data Ready Event Output if using this event signal.

(1) Mode-fault

Table 30.15 lists the conditions for occurrence of a mode-fault event.

Table 30.15 Conditions for mode-fault occurrence

SPI mode	SPCR.MODFEN bit	SSLn0 pin	Remarks
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0) Motorola (SPCR.SPFRF = 0)	1	Not active	Event is output only when the SSLn0 pin is deactivated during transmission
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0) Motorola (SPCR.SPFRF = 1)	1	active	Event is output only when the SSLn0 pin is activated during transmission

(2) Underrun

This event signal is output in response to an underrun when a serial transfer starts while the transmission data is not ready, and the value of the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1. Under these conditions, the MODF and UDRF flags are set to 1.

(3) Overrun

This event signal is output in response to an overrun when a serial transfer completes while the receive buffer contains unread data and the value of the SPCR.TXMD[1:0] bits are 00b, 10b, or 11b. Under these conditions, the OVRF flag is set to 1.

(4) Parity error

This event signal is output in response to a parity error detected on completion of a serial transfer while the value of the SPPE bit in SPCR is 1.

(5) Receive Data Ready

When TXMD[1:0] of SPCR = 00b or 10b and SPDRES = 1 as the receive data ready event output condition, the number of data stored in the receive FIFO is received after writing the receive FIFO. An event will be output when the set value of SPDRC[7:0] has elapsed while the number is less than the FIFO threshold.

30.4.4 SPI Idle Event Output

(1) In master mode

In Transmit-Receive / Transmit-only master mode, an event is output when the IDLNF flag in SPSR changes from 1 to 0.

The IDLNF flag changes from 1 to 0 only when either of the conditions 1) and 2) below is met.

1. The SPE bit in SPCR is cleared to 0 (RSPI initialized) during transmission.
2. All of the following three conditions are met.
   - The transmit buffer (SPTXn, n = 0 to 3) is empty (next transfer data has not been set).
   - The SPSR bit in SPCR is 000 (at the start of sequence control).
   - Operation completed until the next access delay (when the master main state machine transitions to the idle state).

In receive only master mode

Any of the following 2 conditions is met.

1. SPE bit of SPCR is 0 (RSPI initialization)
2. When any of the following is met
   - When RMFM [4:0] = 0x0, after writing 1 to RMEDTG, operation completed until the next access delay (when the master main state machine transitions to the idle state).

30.4.3 模式故障、欠载、溢出、奇偶校验错误或接收数据就绪事件输出

当检测到模式故障、欠载、溢出或奇偶校验错误时，输出此事件信号。请参阅第30.5.4节。如果使用此事件信号，则限制模式故障、欠载、溢出、奇偶校验错误或接收数据就绪事件输出。

(1) Mode-fault

表30.15列出了模式故障事件发生的条件。

Table 30.15 模式故障发生的条件

SPI模式	SPCR.MODFEN bit	SSLn0 pin	Remarks
SPI操作(SPMS=0)从机(SPCR.MSTR=0) Motorola (SPCR.SPFRF = 0)	1	不活跃	只有在传输过程中禁用SSLn0引脚时才会输出事件
SPI操作(SPMS=0)从机(SPCR.MSTR=0) Motorola (SPCR.SPFRF = 1)	1	active	只有在传输过程中激活SSLn0引脚时才会输出事件

(2) Underrun

当串行传输开始而传输数据尚未准备好，并且SPCR.MSTR位的值为0且SPCR.SPE位为1时，输出此事件信号以响应欠载。在这些条件下，MODF和UDRF标志设置为1。

(3) Overrun

当串行传输完成而接收缓冲区包含未读数据且SPCR.TXMD[1:0]位的值为00b、10b或11b时，输出此事件信号以响应溢出。在这些条件下，OVRF标志设置为1。

(4) 奇偶校验错误

该事件信号是响应在串行传输完成时检测到的奇偶校验错误而输出的，而
SPCR中的SPPE位为1。

(5) 接收数据就绪

当SPCR的TXMD[1:0]=00b或10b且SPDRES=1作为接收数据就绪事件输出条件时，在写入接收FIFO后接收存储在接收FIFO中的数据数量。当SPDRC[7:0]的设置值已过且数量小于FIFO阈值时，将输出事件。

30.4.4 SPI空闲事件输出

(1) 在主模式

在Transmit-ReceiveTransmit-onlymaster模式下，当SPSR中的IDLNF标志从1变为0时输出事件。

仅当满足以下条件1)和2)中的任何一个时，IDLNF标志才会从1变为0。

1.SPCR中的SPE位在传输过程中被清零（RSPI初始化）。

2.满足以下三个条件。

- ●发送缓冲区（SPTXn，n=0到3）为空（未设置下一次传输数据）。
- ●SPCR中的SPSR位为000（序列控制开始时）。
- ●操作完成，直到下一次访问延迟（当主主状态机转换到空闲状态时）。

在仅接收主模式下

满足以下2个条件中的任何一个。

1.SPCR的SPE位为0（RSPI初始化）

2.满足以下任何一项时

- ●当RMFM[4:0]=0x0时，向RMEDTG写1后，操作完成，直到下一次访问延迟（当主主状态机转换到空闲状态时）。

- When RMFM [4:0] ≠ 0x0, after writing 1 to RMEDTG, operation completed until the next access delay (when the master main state machine transitions to the idle state).
- When RMFM [4:0] ≠ 0x0, the RSPI internal sequencer transitions to the idle state after operation completed until the next access delay (when the master main state machine transitions to the idle state).

(2) In slave mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (SPI is initialized).

30.4.5 Communication End Event Output

In master mode, an event is output when the IDLNF flag (RSPI idle flag) changes from 1 to 0. In slave mode, an event occurs with conditions shown in Table 30.16 and Table 30.17

Table 30.16 Communication End Event Generating Conditions (transmit-receive/transmit slave mode)

	Transmit Buffer Status	Shift Register Status	Others
SPI operation (SPMS = 0, SPFRF = 0)	Empty	Empty	SSL0 input is negated
SPI operation (SPMS = 0, SPFRF = 1)	Empty	Empty	SSL negation delay completed
Clock synchronous operation (SPMS = 1)	Empty	Empty	The last even edge of RSPCK of last data was detected (CPHA = 1)

Table 30.17 Communication End Event Generating Conditions (receive only slave mode)

	Others
SPI operation (SPMS = 0, SPFRF = 0)	After storing the frames corresponding to the SPFC setting value in the receive buffer, negate SSL0 input.
SPI operation (SPMS = 0, SPFRF = 1)	After storing the frames corresponding to the SPFC setting value in the receive buffer, SSL negation delay completed
Clock synchronous operation (SPMS = 1)	RSPCK last even edge detection when receiving the last frame for the SPFC set value (CPHA = 1)

Regardless of master mode or slave mode, no event is output when 0 is written to the SPCR.SPE bit during transmission or when the SPCR.SPE bit is cleared due to a mode fault error or an underrun error.

A communication end event is output at the following timing. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

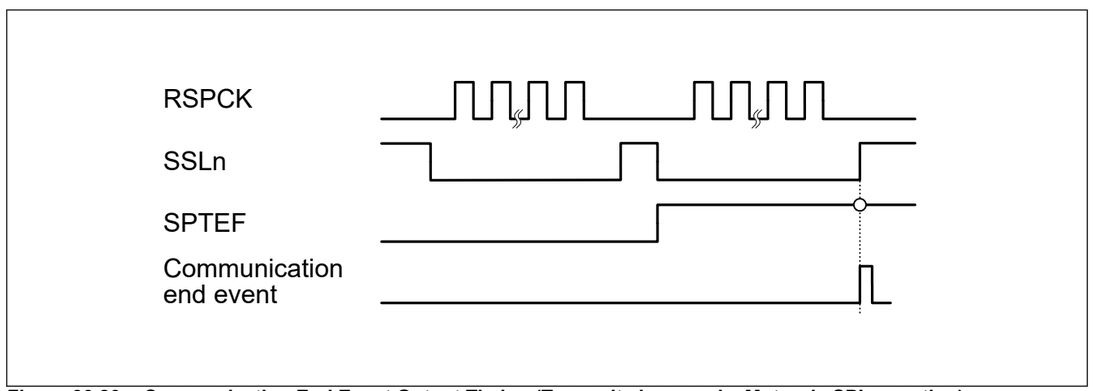

Figure 30.80 Communication End Event Output Timing (Transmit slave mode, Motorola SPI operation)

●当RMFM[4:0]≠0x0时，向RMEDTG写入1后，操作完成，直到下一次访问延迟（当主主状态机转换到空闲状态时）。

●当RMFM[4:0]≠0x0时，RSPI内部定序器在操作完成后转换到空闲状态，直到下一次访问延迟（当主主状态机转换到空闲状态时）。

(2) 在从模式

在从机模式下，当SPCR.SPE位设置为0（SPI初始化）时，会输出一个事件。

30.4.5 通讯结束事件输出

在主机模式下，当IDLNF标志（RSPI空闲标志）从1变为0时输出事件。在从机模式下，事件发生的条件如表30.16和表30.17所示

Table 30.16 通信结束事件发生条件（发送-接收发送从模式）

	发送缓冲区状态	移位寄存器状态	Others
SPI操作（SPMS=0，SPFRF = 0)	Empty	Empty	SSL0输入被否定
SPI操作（SPMS=0，SPFRF = 1)	Empty	Empty	SSL否定延迟已完成
时钟同步操作(SPMS=1)	Empty	Empty	检测到最后一个数据的RSPCK的最后一个偶边沿(CPHA=1)

Table 30.17 通信结束事件发生条件（仅接收从模式）

	Others
SPI操作（SPMS=0，SPFRF=0）	将与SPFC设置值对应的帧存储到接收缓冲区后，否定SSL0输入。
SPI操作（SPMS=0，SPFRF=1）	将对应于SPFC设置值的帧存储到接收缓冲区后，SSL否定延迟完成
时钟同步操作(SPMS=1)	当接收到SPFC设定值的最后一帧时，RSPCK最后一个偶边沿检测(CPHA=1)

无论主模式还是从模式，在传输过程中向SPCR.SPE位写入0或由于模式故障错误或欠载错误而清除SPCR.SPE位时，不输出任何事件。

在以下定时输出通信结束事件。主操作中的通信结束事件输出时序被省略，因为它与空闲事件在相同的时序输出。

30.4.6 Synchronization bypass function

This IP has an internal clock (PCLK) and an operation clock (TCLK), and each has its own operation circuit. Therefore, a synchronization circuit is inserted between the signals between different clocks, and a signal delay between different clocks requires a synchronization delay time (2 to 3 PCLK or 2 to 3 TCLK).

However, the synchronization circuit can be bypassed by the BPEN = 1 of the RSPI control register (SPCR) only when the same clock is input as the internal bus clock and the operation clock. In this case, the synchronization delay time is excluded, and responsiveness is improved.

In addition, this IP has a synchronization circuit between the communication clock (RSPCK) and the operation clock (TCLK), but this synchronization circuit cannot be bypassed.

30.5 Usage Notes

30.5.1 Settings for the Module-Stop State

The Module Stop Control Register B (MSTPCRB) can enable or disable the SPI operation. The SPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details on the Module Stop Control Register B, see section 10, Low Power Modes.

30.5.2 Constraint on Low-Power Functions

When using the module-stop function and entering a low-power mode other than Sleep mode, set the SPCR.SPE bit to 0 before completing communication.

30.5.3 Constraints on Starting Transfer

If the ICU.IELSRn.IR flag is 1 when transfer starts, the interrupt request is internally retained, which can lead to unanticipated behavior of the ICU.IELSRn.IR flag.

To prevent this, use the following procedure to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1):

1. Confirm that transfer stopped (the SPCR.SPE bit is 0).
2. Set the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.
3. Read the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IELSRn.IR flag to 0.

30.5.4 Constraints on Mode-Fault, Underrun, Overrun, Parity Error, or Receive Data Ready Event Output

Using the mode-fault, underrun, overrun, parity error, or receive data ready event is prohibited if the SPI is in multi-master mode (when the SPCR.SPMS bit is 0, the SPCR.MSTR bit is 1, and the SPCR.MODFEN bit is 1).

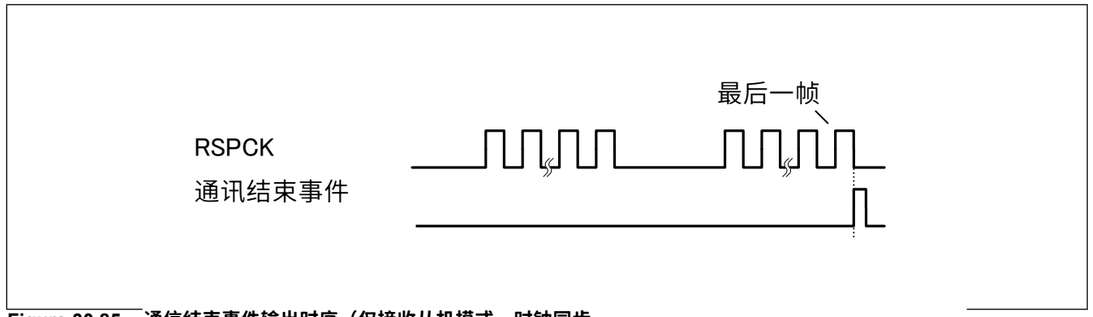

Figure 30.85 通信结束事件输出时序（仅接收从机模式，时钟同步 Operation)

30.4.6 同步旁路功能

这个IP有一个内部时钟（PCLK）和一个操作时钟（TCLK），每个都有自己的操作电路。因此，在不同时钟之间的信号之间插入同步电路，不同时钟之间的信号延迟需要同步延迟时间（2到3个PCLK或2到3个TCLK）。

但是，只有当输入与内部总线时钟和操作时钟相同的时钟时，才能通过RSPI控制寄存器(SPCR)的BPEN=1绕过同步电路。在这种情况下，排除了同步延迟时间，提高了响应性。

另外，这个IP在通信时钟（RSPCK）和工作时钟（TCLK）之间有一个同步电路，但是这个同步电路是不能绕过的。

30.5 使用说明

30.5.1 模块停止状态的设置

模块停止控制寄存器B(MSTPCRB)可以启用或禁用SPI操作。SPI在复位后最初停止。释放模块停止状态可以访问寄存器。有关模块停止控制寄存器B的详细信息，请参见第10节，低功耗模式。

30.5.2 对低功耗功能的限制

当使用模块停止功能并进入除睡眠模式以外的低功耗模式时，在完成通信之前将SPCR.SPE位设置为0。

30.5.3 开始传输的限制

如果ICU.IELSRn.IR标志在传输开始时为1，则内部保留中断请求，这可能导致ICU.IELSRn.IR标志的意外行为。

为防止这种情况发生，请使用以下程序在使能操作之前清除中断请求（通过将SPCR.SPE位设置为1）：

1.确认传输停止（SPCR.SPE位为0）。

2.将相关的中断使能位（SPCR.SPTIE位或SPCR.SPRIE位）设置为0。

3.读取相关的中断使能位（SPCR.SPTIE位或SPCR.SPRIE位）并确认其值为0。

4.将ICU.IELSRn.IR标志设置为0。

30.5.4 模式故障、欠载、溢出、奇偶校验错误或接收数据的约束就绪事件输出

如果SPI处于多主模式（当SPCR.SPMS位为0，SPCR.MSTR位为1，并且SPCR.MODFEN位为1)。

30.5.5 Constraints on the SPSR.SPRF and SPSR.SPTEF Flags

If the polling flags, SPRF and SPTEF, are used, using the interrupts is prohibited, and you must set the SPCR.SPRIE and SPCR.SPTIE bits to 0. Either the interrupts or the flags can be used, but not both.

30.5.5 SPSR.SPRF和SPSR.SPTEF标志的约束

如果使用轮询标志SPRF和SPTEF，则禁止使用中断，您必须设置SPCR.SPRIE和SPCR.SPTIE位为0。可以使用中断或标志，但不能同时使用。

31. Cyclic Redundancy Check (CRC)

31.1 Overview

The Cyclic Redundancy Check (CRC) generates CRC codes to detect errors in the data. The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication. Additionally, various CRC-generation polynomials are available. The snoop function allows to monitor the access to specific addresses. This function is useful in applications that require CRC code to be generated automatically in certain events, such as monitoring writes to the serial transmit buffer and reads from the serial receive buffer.

Table 31.1 lists the CRC calculator specifications and Figure 31.1 shows a block diagram.

31.3 Operation

31.3.1 Basic Operation

The CRC calculator generates CRC codes for use in LSB-first or MSB-first transfer.

The following examples show CRC code generation for input data (0xF0) using the 16-bit CRC-CCITT generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before CRC calculation.

When an 8-bit CRC (with the polynomial $X^8 + X^2 + X + 1$) is in use, the valid bits of the CRC code are obtained in CRCDOR_BY. When a 32-bit CRC is in use, the valid bits of the CRC code are obtained in CRCDOR.

Figure 31.2 and Figure 31.3 show the LSB-first and MSB-first data transmission examples respectively. Figure 31.4 and Figure 31.5 show the LSB-first and MSB-first data reception examples.

31.3 Operation

31.3.1 基本操作

CRC计算器生成用于LSB优先或MSB优先传输的CRC代码。

以下示例显示了使用16位CRC-CCITT生成多项式(X16+X12+X5+1)为输入数据(0xF0)生成CRC码。在这些示例中，CRC数据输出寄存器(CRCDOR_HA)的值在CRC计算之前被清除。

当使用8位CRC（多项式X8+X2+X+1）时，CRC码的有效位在CRCDOR_BY。使用32位CRC时，在CRCDOR中获取CRC码的有效位。

图31.2和图31.3分别显示了LSB-first和MSB-first数据传输示例。图31.4和图31.5显示了LSB优先和MSB优先的数据接收示例。

31.3.2 CRC Snoop Function

The CRC snoop function monitors reads from and writes to a specific register and performs CRC calculation on the monitored data automatically. Because the CRC snoop function recognizes writes to and reads from a specific register address as a trigger to automatically perform CRC calculation, there is no need to write data to the CRCDIR register. All I/O register specified in the section 31.2.5. CRCSAR : Snoop Address Register are subject to the CRC snoop. The CRC snoop is useful in monitoring writes to the SCIn.TDR (n = 0 to 4, 9) register, and reads from the SCIn.RDR (n = 0 to 4, 9) register.

To use this function, write the lower address 14 bits of a specific register to bits CRCSA13 to CRCSA0 in the CRCSAR register, and set CRCSEN bit in the CRCCR1 register to 1. Then, set the CRCSWR bit in the CRCCR1 register to 1 to enable snooping on writes to the target register, or set the CRCSWR bit in the CRCCR1 register to 0 to enable snooping on reads from the target register. It is possible that access to a target I/O register may be executed before the CRCSWR bit write completed. In this case, the data is not stored in the CRCDIR register. To avoid this issue, before accessing I/O register, read back the CRCSWR bit that was written to confirm that the write completed.

When both the CRCSEN and CRCSWR bits are set to 1, and data is written to a target register in a bus master module such as the CPU, DMAC, and DTC, the CRC calculator stores the data in the CRCDIR register and performs CRC calculation. Similarly, when the CRCSEN bit is set to 1, CRCSWR bit to 0, and data is read from a target register in a bus master

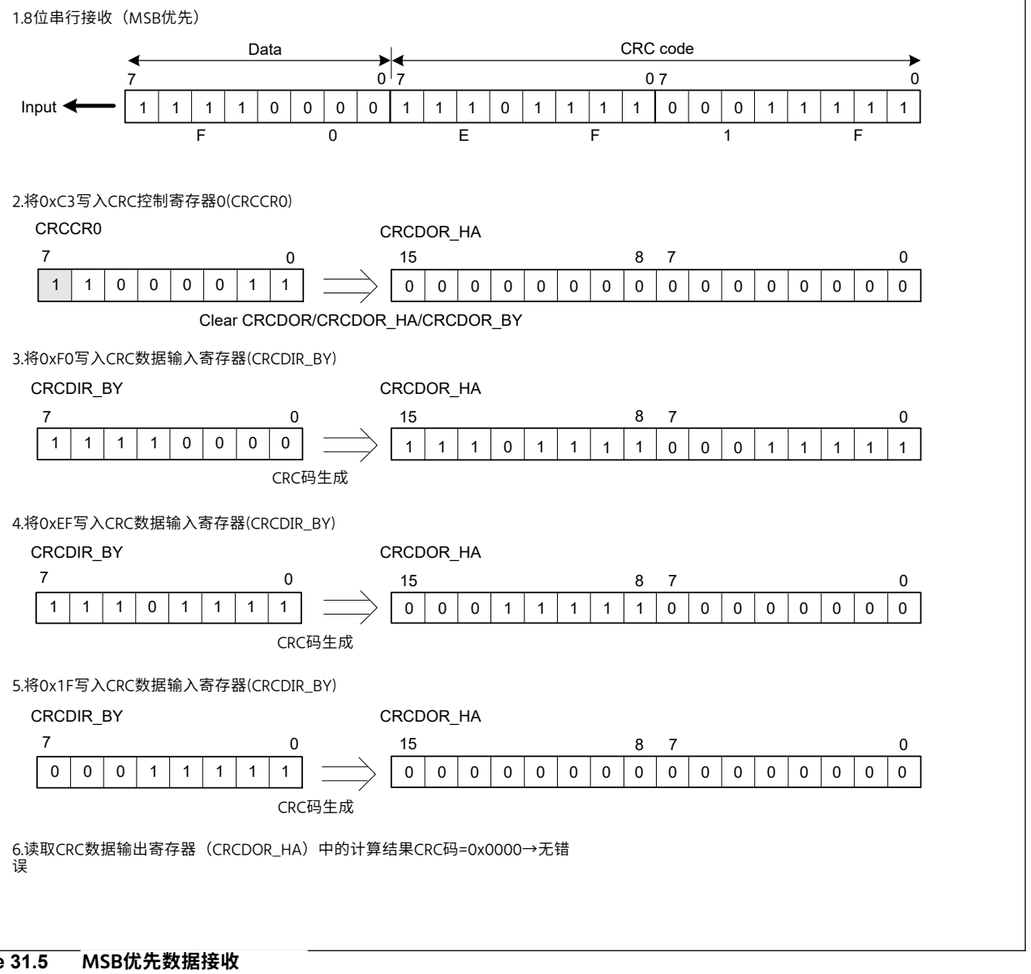

Figure 31.5 MSB优先数据接收

31.3.2 CRC监听功能

CRCsnoop功能监视对特定寄存器的读取和写入，并自动对监视的数据执行CRC计算。由于CRCsnoop功能将特定寄存器地址的写入和读取识别为触发以自动执行CRC计算，因此无需将数据写入CRCDIR寄存器。第31.2.5节中指定的所有IO寄存器。CRCSAR:SnoopAddressRegister受CRCsnoop影响。CRCsnoop在监视对SCIn.TDR(n=0到4 9)寄存器的写入以及从SCIn.RDR(n=0到4 9)寄存器中读取时很有用。

要使用此功能，将特定寄存器的低地址14位写入CRCSAR寄存器中的位CRCSA13到CRCSA0，并将CRCCR1寄存器中的CRCSEN位设置为1。然后，将CRCCR1寄存器中的CRCSWR位设置为1以启用对目标寄存器的写入进行监听，或者将CRCCR1寄存器中的CRCSWR位设置为0以启用对目标寄存器读取的监听。可能在CRCSWR位写入完成之前执行对目标IO寄存器的访问。在这种情况下，数据不存储在CRCDIR寄存器中。为避免此问题，在访问IO寄存器之前，请回读已写入的CRCSWR位以确认写入已完成。

当CRCSEN和CRCSWR位都设置为1，并且数据被写入总线主模块（如CPU、DMAC和DTC）中的目标寄存器时，CRC计算器将数据存储在CRCDIR寄存器中并执行CRC计算。类似地，当CRCSEN位设置为1时，CRCSWR位设置为0，并且从总线主机中的目标寄存器读取数据

module such as the CPU, DMAC, and DTC, the CRC calculator stores the data in the CRCDIR register and performs CRC calculations.

When the CRC code is generated by using CRC-8, CRC-16, and CRC-CCITT generating polynomial, the target register is accessed in 1 byte (8 bits). Similarly, when the CRC code is generated by using CRC-32 and CRC-32C generating polynomial, the target register is accessed in words (32 bits).

When CPU is halted, CRC snoop operation is invalid.

31.4 Usage Notes

31.4.1 Settings for the Module-Stop State

The Module Stop Control Register C (MSTPCRC) can enable or disable CRC calculator operation. The CRC calculator is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

31.4.2 Note on Transmission

The transmission sequence for the CRC code differs based on whether the transmission is LSB-first or MSB-first. Figure 31.6 shows an LSB-first and MSB-first data transmission.

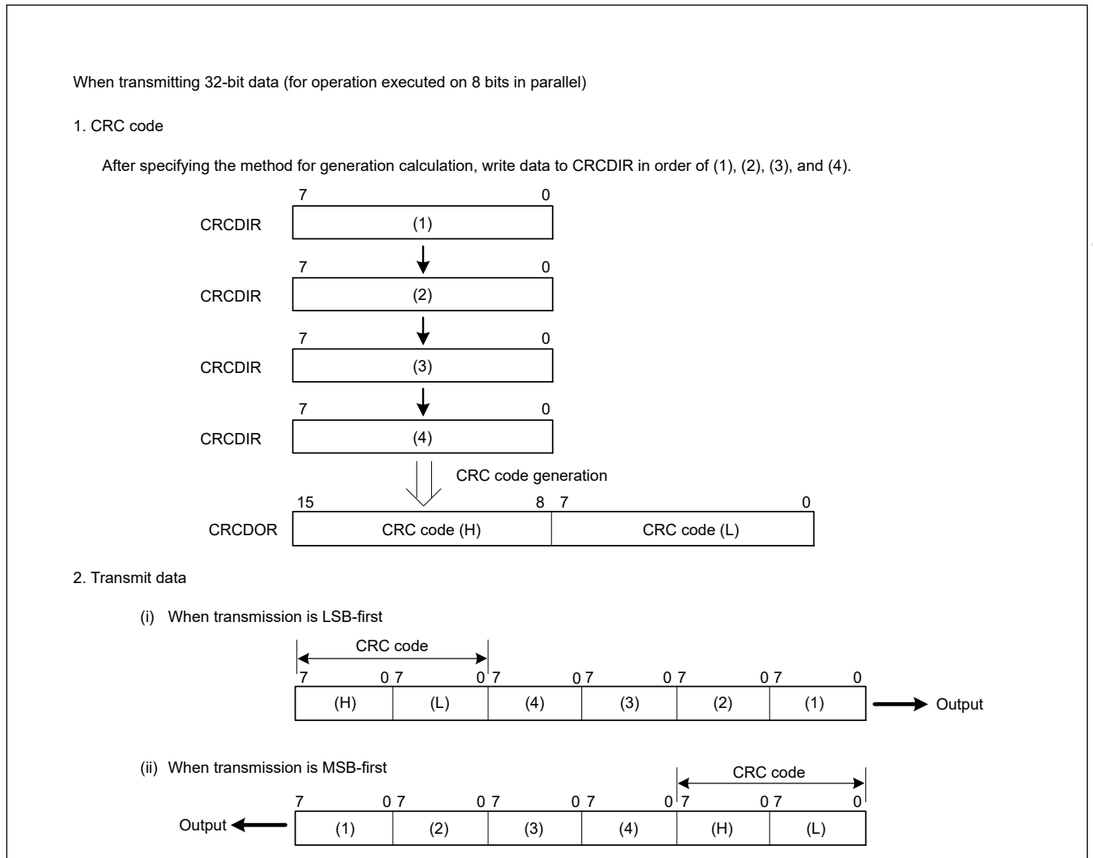

Figure 31.6 LSB-first and MSB-first data transmission

CPU、DMAC和DTC等模块，CRC计算器将数据存储在CRCDIR寄存器中并执行CRC计算。

当使用CRC-8、CRC-16和CRC-CCITT生成多项式生成CRC码时，以1个字节（8位）访问目标寄存器。类似地，当使用CRC-32和CRC-32C生成多项式生成CRC码时，以字（32位）访问目标寄存器。

当CPU停止时，CRCsnoop操作无效。

31.4 使用说明

31.4.1 模块停止状态的设置

模块停止控制寄存器C(MSTPCRC)可以启用或禁用CRC计算器操作。CRC计算器在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

31.4.2 传输注意事项

CRC码的传输顺序根据传输是LSB在先还是MSB在先而有所不同。图31.6显示了LSB优先和MSB优先的数据传输。

31:0	STGSEL[31:0]	Stage selection bit The stage to be used for channel n is selected. Bit 0 corresponds to stage 0, bit 1 to stage 1, ..., and bit 31 to stage 31. 0: The corresponding stage is not used for channel n. 1: The corresponding stage is used for channel n.	R/W

This register selects the stage to use for channel n.

Set the stage to be used using this register before starting the channel processing. Operation is not guaranteed when the channel processing of channel n is started with the setting that does not use any stage, that is, the value of this register is 0.

When multiple stages are selected, the cascade connected biquad IIR filter operation is performed for the selected stages. In this case, the operation of the stages is performed in ascending order of stage number.

Note:
- Writing 1 to the bit corresponding to the stage used for another channel is ignored. The stage with the same number cannot be used between different channels.
- Whether 1 is written to the bit corresponding to the stage used for another channel can be determined by reading the IIRCHnCNT immediately after writing to the IIRCHnCNT and checking whether the written value matches with the read value. When not matched, this means that 1 is written to the bit corresponding to the stage used for another channel.
- Do not rewrite the corresponding IIRCHnCNT register during the channel processing of channel n. Operation is not guaranteed if the bit is rewritten.

33.2.1.15 IIRCHnINT : Channel n Interrupt Enable Register (n = 0 to 15)

Base address: IIRFA = 0x4002_0000

Offset address: 0x10C + 0x10 × n

该寄存器选择用于通道n的阶段。

在开始通道处理之前使用该寄存器设置要使用的阶段。当通道n的通道处理以不使用任何阶段的设置启动时，不保证操作，即该寄存器的值为0。

选择多个阶段时，将对所选阶段进行级联连接的BiquadIIR滤波器操作。在这种情况下，阶段的操作按阶段编号的升序执行。

Note:
- ●将1写入对应于用于另一个通道的阶段的位将被忽略。不同通道之间不能使用相同编号的阶段。
- ●是否将1写入对应于用于另一个通道的阶段的位可通过以下方式确定
  写入IIRCHnCNT后立即读取IIRCHnCNT，并检查写入的值是否与读取的值匹配。当不匹配时，这意味着将1写入与用于另一个通道的阶段相对应的位。
- 在通道n的通道处理过程中，不要重写相应的IIRCHnCNT寄存器。如果该位被重写，则无法保证操作。

33.3 Operation

33.3.1 Overview

IIRFA has a cascade connected biquad IIR (Infinite Impulse Response) filter operation function.

The formula for the transfer function of cascade connected M biquad IIR filters is as follows:

$$H(z) = \prod_{m=1}^{M} \frac{b_0^m + b_1^m z^{-1} + b_2^m z^{-2}}{1 - a_1^m z^{-1} - a_2^m z^{-2}}$$

b_0^m , b_1^m , and b_2^m , are feed-forward coefficients, and a a_1^m and a_2^m are feed-back coefficients.

The operation for each biquad IIR filter is defined by the following difference equation:

$$y(n) = b_0x(n) + b_1x(n-1) + b_2x(n-2) + a_1y(n-1) + a_2y(n-2)$$

$x(n)$ is input data, $y(n)$ is output data, $x(n-1)$ and $y(n-1)$ are input data and output data of 1 sample period delay, and $x(n-2)$ and $y(n-2)$ are input data and output data of 2 sample period delay.

IIRFA performs the cascade connected Direct form II transposed biquad IIR filter operation shown in Figure 33.2.

One biquad IIR filter operation is called a stage. Any number of stages up to 32 stages that are cascade connected are called channels.

33.3 Operation

33.3.1 Overview

IIRFA具有级联双二阶IIR（InfiniteImpulseResponse）滤波器运算功能。

级联M个双二阶IIR滤波器的传递函数公式如下：

$$H(z) = \prod_{m=1}^{M} \frac{b_0^m + b_1^m z^{-1} + b_2^m z^{-2}}{1 - a_1^m z^{-1} - a_2^m z^{-2}}$$

b_0^m Lb_1^m L　　b^m 是前馈系数，aa1　　a^m是反馈系数。

每个双二阶IIR滤波器的操作由以下差分方程定义：

$$y(n) = b_0x(n) + b_1x(n-1) + b_2x(n-2) + a_1y(n-1) + a_2y(n-2)$$

x(n)是输入数据，y(n)是输出数据，x(n−1)和y(n−1)是1个采样周期延迟的输入数据和输出数据，x(n−2)和y(n−2)是2个采样周期延迟的输入数据和输出数据。

IIRFA执行图33.2所示的级联直接形式II转置双二阶IIR滤波器操作。

一个双二阶IIR滤波器操作称为阶段。级联连接的多达32个级的任意数量的级称为通道。

The stages to be cascade connected can be selected for each channel. In addition, the coefficient (a_1, a_2, b_0, b_1, b_2) and delay data (D_0, D_1) can be set for each stage.

Figure 33.3 shows an example of stage selection for each channel. In this example, channel 0 performs the cascade connected biquad IIR filter operation for stage 0, stage 2, and stage 3. For the operation, see section 33.3.2. Channel Processing Operation.

enabled (IIRECCCNT.ECCMD = 1), an error that has occurred in the data in the coefficient/delay data storage area can be detected and corrected. For details on the ECC error, see section 33.3.4. Operation on ECC Error Detection.

The I/O data, stage coefficient/delay data are retained in the single precision floating-point format specified in the IEEE754 standard. For details on the single precision floating-point, see Figure 33.4.

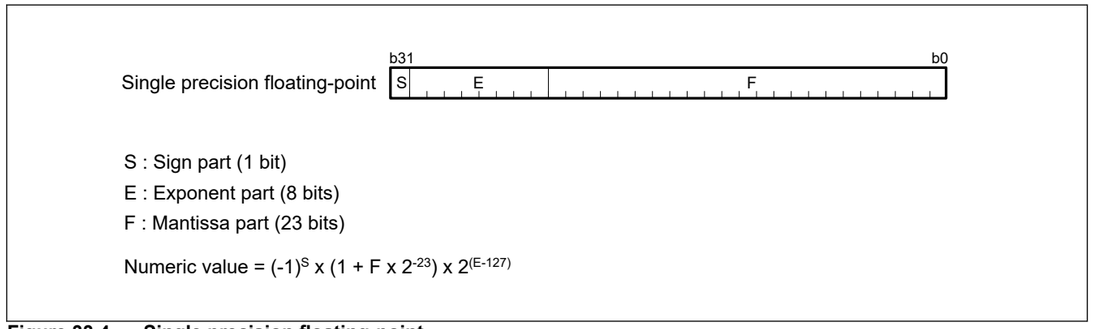

Figure 33.4 Single precision floating-point

The single precision floating-point format supports the following values:

- 0 < E < 255 (normal numbers)
- E = 0 and F = 0 (signed zero)
- E = 0 and F > 0 (denormalized numbers)
- E = 255 and F = 0 (infinity)
- E = 255 and F > 0 (NaN: Not a Number)
  MSB of F is 0. (SNaN: Signaling NaN)
  MSB of F is 1. (QNaN: Quiet NaN)

IIRFA treats the input as +0 if a positive denormalized number is input, −0 if a negative denormalized number is input, and infinity if a NaN (Not a Number) is input.

IIRFA performs addition and multiplication of single precision floating-points multiple times in the cascade connected biquad IIR filter operation. If the result of each addition and multiplication is a positive denormalized number, it is treated as +0. If the result is a negative denormalized number, it is treated as -0. If the result is a NaN (Not a Number), it is treated as infinity. In addition, the rounding mode for each addition and multiplication result can be selected by IIROPCNT.

Note: The output data of channel n may be infinity depending on the channel processing. At this time, an operation error occurs. For details on the operation error, see section 33.3.3. Operation When an Operation Error Occurs.

33.3.2 Channel Processing Operation

Channel processing is a series of operations that are executed when a write access is performed to the input register of a channel. Operations for all stages used by the channel are performed sequentially during the channel processing. If the output data operation is completed in the middle of the channel processing (before the IIRCHnSTS.CPRFF flag is 1), the IIRCHnSTS.ORDYF flag is 1 and the output data (IIRCHnOUT register) can be read.

Figure 33.5 shows an example of channel processing operation.

1. Input data is written.
   When input data is written to the IIR channel n input register (IIRCHnINP), the IIR filter operation is performed in accordance with the setting of the IIR channel n control register (IIRCHnCNT). At this time, the IIRCHnSTS.CPRCS bit is 1. In addition, the delay data registers for stage m (IIRSTGmD0, IIRSTGmD1) used for the operation are updated by the operation result.
2. Operation of the output data is completed.
   When the operation of the output data is completed, the IIRCHnSTS.ORDYF flag is 1 and the operation result is stored to the IIR channel n output register (IIRCHnOUT).
3. Output data is read.
   When the value is read from the IIRCHnOUT register, the IIRCHnSTS.ORDYF flag is 0.

启用（IIRECCCNT.ECCMD=1），可以检测和纠正系数延迟数据存储区域中的数据中发生的错误。有关ECC错误的详细信息，请参阅第33.3.4节。ECC错误检测操作。

IO数据、级系数延迟数据以IEEE754标准中规定的单精度浮点格式保留。有关单精度浮点的详细信息，请参见图33.4。

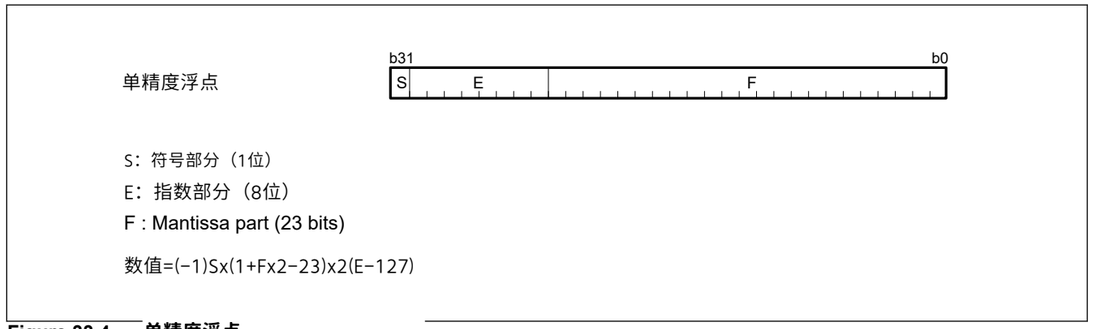

Figure 33.4 单精度浮点

单精度浮点格式支持以下值：

- 0 < E < 255 (normal numbers)
- E = 0 and F = 0 (signed zero)
- E = 0 and F > 0 (denormalized numbers)
- E = 255 and F = 0 (infinity)
- ●E=255且F>0（NaN：非数字）
  F的MSB为0。(SNaN:SignalingNaN)
  F的MSB为1。（QNaN：安静的NaN）

如果输入一个正的非规范化数字，则IIRFA将输入视为+0，如果输入一个负的非规范化数字，则将输入视为−0，如果输入NaN（非数字），则将其视为无穷大。

IIRFA在级联双二阶IIR滤波器操作中多次执行单精度浮点的加法和乘法。如果每次加法和乘法的结果是正的非规格化数，则将其视为+0。如果结果是负的非规范化数字，则将其视为−0。如果结果是NaN（不是数字），则将其视为无穷大。此外，可以通过IIROPCNT选择每个加法和乘法结果的舍入模式。

Note: 取决于通道处理，通道n的输出数据可能是无穷大的。此时，发生操作错误。有关操作错误的详细信息，请参阅第33.3.3节。发生操作错误时的操作。

33.3.2 通道处理操作

通道处理是在对通道的输入寄存器执行写访问时执行的一系列操作。通道使用的所有阶段的操作在通道处理期间顺序执行。如果输出数据操作在通道处理过程中完成（在IIRCHnSTS.CPRFF标志为1之前），则IIRCHnSTS.ORDYF标志为1，并且可以读取输出数据（IIRCHnOUT寄存器）。

图33.5显示了通道处理操作的示例。

1.写入输入数据。
当输入数据写入IIR通道n输入寄存器(IIRCHnINP)时，将根据IIR通道n控制寄存器(IIRCHnCNT)的设置执行IIR滤波器操作。此时，IIRCHnSTS.CPRCS位为1。另外，用于运算的阶段m的延迟数据寄存器（IIRSTGmD0，IIRSTGmD1）由运算结果更新。

2.输出数据的操作完成。
当输出数据的运算完成时，IIRCHnSTS.ORDYF标志为1，运算结果存入IIR通道n输出寄存器（IIRCHnOUT）。

3.读取输出数据。
当从IIRCHnOUT寄存器读取值时，IIRCHnSTS.ORDYF标志为0。

4. Channel processing is completed.
   When the channel processing is completed, the IIRCHnSTS.CPRCFF flag is 1. In addition, the IIRCHnSTS.CPRCS bit is 0.

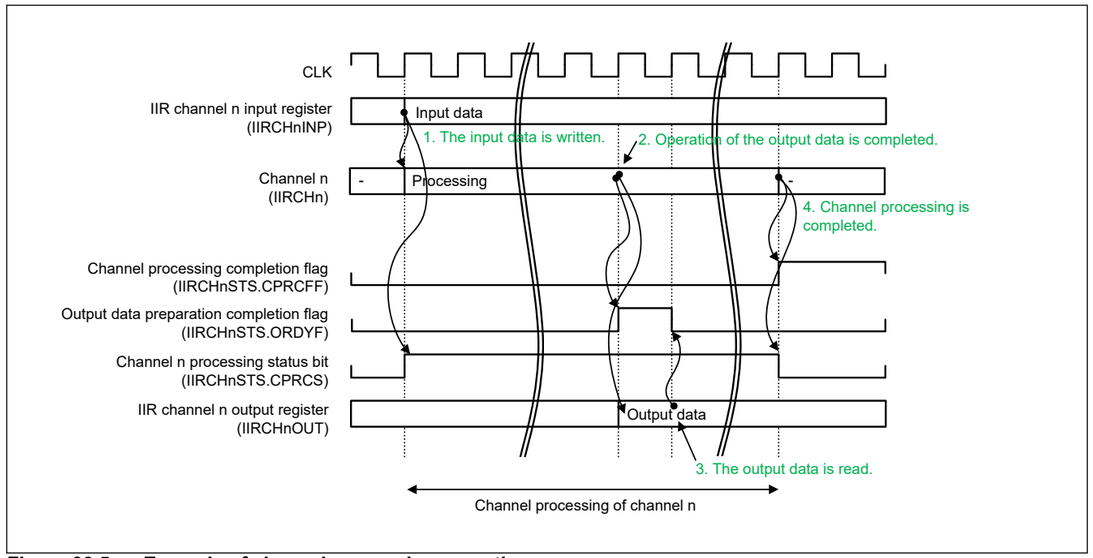

Figure 33.5 Example of channel processing operation

Note: The maximum number of channels that can be processed at the same time is 1. If a write access to the IIRCHnINP register is performed during the channel processing of any channel, bus access is forced to wait until the channel processing that is being performed is completed.

33.3.3 Operation When an Operation Error Occurs

An operation error shows that the result of the cascade connected biquad IIR filter operation is infinity. If the value of the IIR channel n output register (IIRCHnOUT) is positive or negative infinity, an operation error occurs at the same time as when the output data preparation is completed. If an operation error occurs, the IIRCHnSTS.CERRF flag is 1.

A positive infinity and a negative infinity are collectively referred to as infinity or ∞. In addition, +∞ indicates positive infinity and −∞ indicates negative infinity.

The value of the IIRCHnOUT register is the value that is obtained by performing the addition and multiplication of single precision floating-points multiple times. When the result of any addition or multiplication is infinity, this value is propagated and the value of the IIRCHnOUT register ultimately becomes infinity.

The following examples show the conditions in which the result of the addition and multiplication becomes infinity.

(1) An overflow occurs in the addition or multiplication.

If the result of addition or multiplication exceeds the maximum finite value represented by a single precision floating-point, an overflow occurs. If an overflow occurs, the result of the relevant addition or multiplication becomes infinity.

(2) The input value of the addition or multiplication includes SNaN, QNaN, or infinity.

When the input value of the addition or multiplication includes SNaN, QNaN, or infinity, the result of the relevant addition or multiplication becomes infinity.

Table 33.3 and Table 33.4 show the calculation results for input values at the time of addition and multiplication.

4.通道处理完成。
当通道处理完成时，IIRCHnSTS.CPRCFF标志为1。此外，IIRCHnSTS.CPRCS位为0。

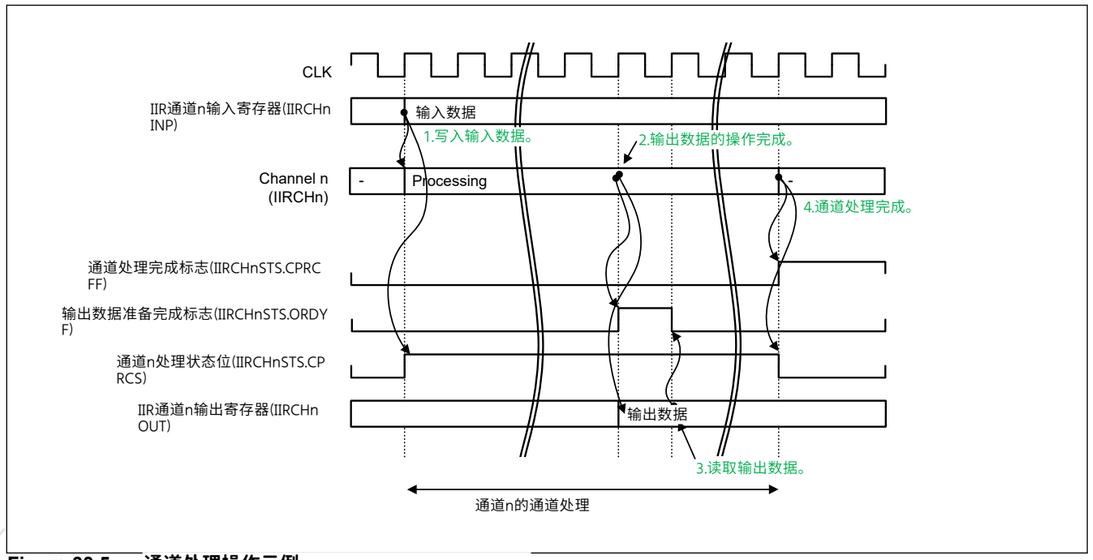

Figure 33.5 通道处理操作示例

Note: 可同时处理的最大通道数为1。如果在任何通道的通道处理过程中对IIRCHnINP寄存器进行写访问，总线访问将被强制等待，直到正在执行的通道处理完成.

33.3.3 发生操作错误时的操作

运算错误表明级联双二阶IIR滤波器运算的结果为无穷大。如果IIR通道n输出寄存器(IIRCHnOUT)的值为正或负无穷大，则在输出数据准备完成的同时发生操作错误。如果发生操作错误，则IIRCHnSTS.CERRF标志为1。

正无穷大和负无穷大统称为无穷大或∞。此外，+∞表示正无穷大，−∞表示负无穷大。

IIRCHnOUT寄存器的值是单精度浮点数多次加法和乘法得到的值。当任何加法或乘法的结果为无穷大时，该值被传播，IIRCHnOUT寄存器的值最终变为无穷大。

以下示例显示了加法和乘法的结果变为无穷大的条件。

(1)加法或乘法发生溢出。

如果加法或乘法的结果超过单精度浮点表示的最大有限值，则会发生溢出。如果发生溢出，相关加法或乘法的结果将变为无穷大。

(2)加法或乘法的输入值包括SNaN、QNaN或无穷大。

当加法或乘法的输入值包括SNaN、QNaN或无穷大时，相关加法或乘法的结果变为无穷大。

表33.3和表33.4显示了加法和乘法时输入值的计算结果。

33.3.4 Operation on ECC Error Detection

The coefficient/delay data storage area has an ECC error detection/correction function and a corrected data write-back function.

The ECC specification is SEC-DED (Single-Error Correction/Double-Error Detection). A 7-bit ECC code is generated for one coefficient/delay data (32-bit data).

(1) ECC error detection function

This ECC error detection function detects the ECC error (ECC 1-bit error, ECC 2-bit error) if an error occurs in the data in the coefficient/delay data storage area. An ECC error is detected when a read access to the coefficient/delay data register is performed and when the coefficient/delay data is used during the channel processing.

An ECC error may be detected multiple times during one channel processing. Table 33.5 shows the conditions for detecting an ECC error.

Table 33.5 Conditions for detecting an ECC error

	2 bits	An ECC 2-bit error is detected.
	3 bits or more	Whether an ECC error is detected is undefined.

33.3.4 ECC错误检测操作

系数延迟数据存储区具有ECC错误检测校正功能和校正数据回写功能。

ECC规范是SEC-DED（单纠错双错误检测）。为一个系数延迟数据（32位数据）生成一个7位ECC码。

(1) ECC错误检测功能

此ECC错误检测功能在系数延迟数据存储区域中的数据发生错误时检测ECC错误（ECC1位错误、ECC2位错误）。当执行对系数延迟数据寄存器的读取访问以及在通道处理期间使用系数延迟数据时，检测到ECC错误。

在一个通道处理期间，可能会多次检测到ECC错误。表33.5显示了检测ECC错误的条件。

Table 33.5 检测ECC 错误的条件

ECC错误检测校正功能	发生错误的位数	ECC error
Enable (IIRECCCNT.ECCMD = 1)	0 bits	未检测到ECC错误。
	1 bit	检测到ECC1位错误。
	2 bits	检测到ECC2位错误。
	3位或更多	是否检测到ECC错误未定义。
Disable (IIRECCCNT.ECCMD = 0)	Don't Care	未检测到ECC错误。

When an ECC 1-bit error is detected, the IIRECCEF.ESEF flag is 1. When an ECC 2-bit error is detected, the IIRECCEF.EDEF flag is 1.

(2) ECC error correction function

The ECC error correction function corrects errors in the values read from the coefficients/delayed data register or the data used for the operation. When an ECC 1-bit error is detected, the error correction is performed.

(3) Corrected data write-back function

The corrected data write-back function writes back the value after an ECC error correction to the data in the coefficient/ delay data storage area. If the ECC error correction is performed when the corrected data write-back function is enabled (IIRECCCNT.ECCWBDIS = 0), the corrected data is written back.

When the ECC error correction is performed during the channel processing, the channel processing continues using the data after ECC error correction. At this time, the number of channel processing cycles is not extended.

When the corrected data is written back during the channel processing, the channel processing continues. At this time, the number of channel processing cycles is extended in accordance with the number of write-back times.

33.3.5 Operating Procedure

33.3.5.1 Initial Settings

Perform the initial settings of IIRFA before use. Table 33.6 shows an example of the initial setting procedure.

When the ECC error detection/correction function is enabled (IIRECCCNT.ECCMD = 1), write the initial values to all coefficient/delay data registers of all stages. The data in the coefficient/delay data storage area is undefined when the power is turned on. Therefore, when the ECC error detection/correction function is enabled (IIRECCCNT.ECCMD = 1), if the data is read from the coefficient/delay data storage area without initializing or if the channel processing is started without initializing, an ECC error occurs.

Table 33.6 Example of initialization procedures

Step	Description	Register to be set
1	Set the ECC function of the coefficient/delay data storage area.	IIRECCCNT
2	Set what stages are to be cascade connected for use in each channel.	IIRCHnCNT
3	Set the initial values (single precision floating-points) to the coefficient/ delay data registers.	IIRSTGmB0, IIRSTGmB1, IIRSTGmB2,IIRSTGmA1, IIRSTGmA2, IIRSTGmD0, IIRSTGmD1
4	Enable or disable the ECC error interrupt and channel n interrupt.	IIRECCINT IIRCHnINT

33.3.5.2 Procedure for Channel Processing Execution

This section shows an example procedure of the channel process execution.

There are three methods to execute the channel processing. The difference between the three methods is the procedure for output data reading after the channel processing starts.

Table 33.7 shows the procedure for output data reading of each method.

Table 33.7 Procedure for output data reading of each method

	Single data processing	Multiple data processing
Method 1	Read without waiting for output data preparation completion.	
Method 2	Read after polling the output data preparation completion flag.	Read after polling the channel processing completion flag.
Method 3	Read after accepting the output data preparation completion interrupt.	Read after accepting the channel processing completion interrupt.

The single data processing and multiple data processing classify the channel processing procedure in accordance with the number of data to be processed. Single data processing means that the channel processing is performed for one input value

当检测到ECC1位错误时，IIRECCEF.ESEF标志为1。当检测到ECC2位错误时，IIRECCEF.EDEF标志为1。

(2) ECC纠错功能

ECC纠错功能纠正从系数延迟数据寄存器读取的值或用于操作的数据中的错误。当检测到ECC1位错误时，执行纠错。

(3) 修正数据回写功能

修正数据回写功能将ECC纠错后的值回写到系数延迟数据存储区域的数据中。如果在启用更正数据回写功能时执行ECC纠错（IIRECCCNT.ECCWBDIS=0），则回写更正数据。

当在信道处理过程中进行ECC纠错时，信道处理继续使用ECC纠错后的数据。此时，通道处理周期数不延长。

当在通道处理期间写回校正数据时，通道处理继续。此时，通道处理周期数根据回写次数而延长。

33.3.5 运作程序

33.3.5.1 初始设置

使用前执行IIRFA的初始设置。表33.6显示了初始设置过程的示例。

当ECC错误检测校正功能使能时（IIRECCCNT.ECCMD=1），将初始值写入所有阶段的所有系数延迟数据寄存器。上电时系数延迟数据存储区中的数据未定义。因此，当启用ECC错误检测校正功能时（IIRECCCNT.ECCMD=1），如果在未初始化的情况下从系数延迟数据存储区读取数据，或者如果在未初始化的情况下启动通道处理，则会发生ECC错误。

Table 33.6 初始化程序示例

Step	Description	要设置的注册
1	设置系数延迟数据存储区的ECC功能。	IIRECCCNT
2	设置要级联连接的级以在每个通道中使用。	IIRCHnCNT
3	将初始值（单精度浮点）设置到系数延迟数据寄存器。	IIRSTGmB0, IIRSTGmB1, IIRSTGmB2,IIRSTGmA1, IIRSTGmA2, IIRSTGmD0, IIRSTGmD1
4	启用或禁用ECC错误中断和通道n中断。	IIRECCINT IIRCHnINT

33.3.5.2 通道处理执行程序

本节显示了通道处理执行的示例过程。

有三种方法来执行通道处理。三种方法的区别在于通道处理开始后读取输出数据的过程。

表33.7显示了每种方法的输出数据读取过程。

Table 33.7 各方法的输出数据读取步骤

	单一数据处理	多数据处理
Method 1	无需等待输出数据准备完成即可读取。	
Method 2	轮询输出数据准备完成标志后读取。	轮询通道处理完成标志后读取。
Method 3	接受输出数据准备完成中断后读取。	接受通道处理完成中断后读取。

单数据处理和多数据处理根据要处理的数据数量对通道处理过程进行分类。单数据处理是指对一个输入值进行通道处理

and no other channel processing is performed after the processing is completed. Multiple data processing means that the channel processing is performed consecutively for multiple input values.

Method 2 and method 3 have different procedures for single data processing and multiple data processing. IIRFA completes the output data preparation before the channel processing is completed. Therefore, to reduce the number of cycles, the procedure for single data processing is to read the output data when the output data preparation is completed, instead of when the channel processing is completed.

Points to note for methods 1, 2, and 3 are as follows:

- Method 1
  - Since the flag determination processing is not required, the overhead is small.
  - When a read access to the IIRCHnOUT register is performed, bus access is forced to wait until the output data preparation is completed.
  - The input value can be written to the IIRCHnINP register and a read access to the IIRCHnOUT register can be performed with DMA.
- Method 2
  - Since the flag determination processing is required, the overhead is large.
  - When a read access to the IIRCHnOUT register is performed, bus access is not forced to wait.
- Method 3
  - The overhead is relatively large due to processing at the time of interrupt acceptance.
  - When a read access to the IIRCHnOUT register is performed, bus access is not forced to wait.
  - After the channel processing starts, the CPU can perform other process until the output data preparation completion interrupt or the channel processing completion interrupt occurs.

In accordance with the number of stages used for the channel processing, the number of cycles increases from the start of the channel processing to the completion of output data preparation and channel processing. Therefore, the recommended method may vary depending on the number of stages to be used.

Method 1 is recommended when the number of stages used for the channel processing is small. When this method is used, the bus is occupied until the output data preparation is completed. Therefore, bus access to other bus master that uses the same bus is forced to wait. In addition, the CPU does not accept any interrupt while the bus access is waited.

Methods 2 and 3 are recommended when the number of stages used for the channel processing is large. When these methods are used, the overhead is large due to the flag determination processing or interrupt processing. Therefore, when the number of stages used for the channel processing is small, the effect of the overhead is large.

Figure 33.6, Table 33.7, and Figure 33.8 show an example procedure for each method.

处理完成后不进行其他通道处理。多数据处理是指对多个输入值连续进行通道处理。

方法2和方法3对单数据处理和多数据处理的过程不同。IIRFA在通道处理完成之前完成输出数据准备。因此，为了减少周期数，单个数据处理的过程是在输出数据准备完成时读取输出数据，而不是在通道处理完成时读取。

方法一、二、三的注意事项如下：

- Method 1

  由于不需要标志确定处理，因此开销很小。

  当对IIRCHnOUT寄存器执行读访问时，总线访问被强制等待，直到输出数据准备完成。

  可以将输入值写入IIRCHnINP寄存器，并且可以使用DMA执行对IIRCHnOUT寄存器的读取访问。

- Method 2

  由于需要标志确定处理，因此开销很大。

  当对IIRCHnOUT寄存器执行读访问时，总线访问不会被强制等待。

- Method 3

  由于接受中断时的处理，开销比较大。

  当对IIRCHnOUT寄存器执行读访问时，总线访问不会被强制等待。

  通道处理开始后，CPU可以进行其他处理，直到输出数据准备完成中断或通道处理完成中断发生。

根据用于通道处理的阶段数，从通道处理开始到输出数据准备和通道处理完成的周期数增加。因此，推荐的方法可能会根据要使用的阶段数而有所不同。

当用于通道处理的阶段数较少时，建议使用方法1。使用这种方法时，总线一直被占用，直到输出数据准备完成。因此，对使用同一总线的其他总线主机的总线访问被迫等待。此外，在等待总线访问期间，CPU不接受任何中断。

当用于通道处理的阶段数较大时，建议使用方法2和3。当使用这些方法时，由于标志确定处理或中断处理，开销很大。因此，当用于信道处理的级数较少时，开销的影响较大。

图33.6、表33.7和图33.8显示了每种方法的示例过程。

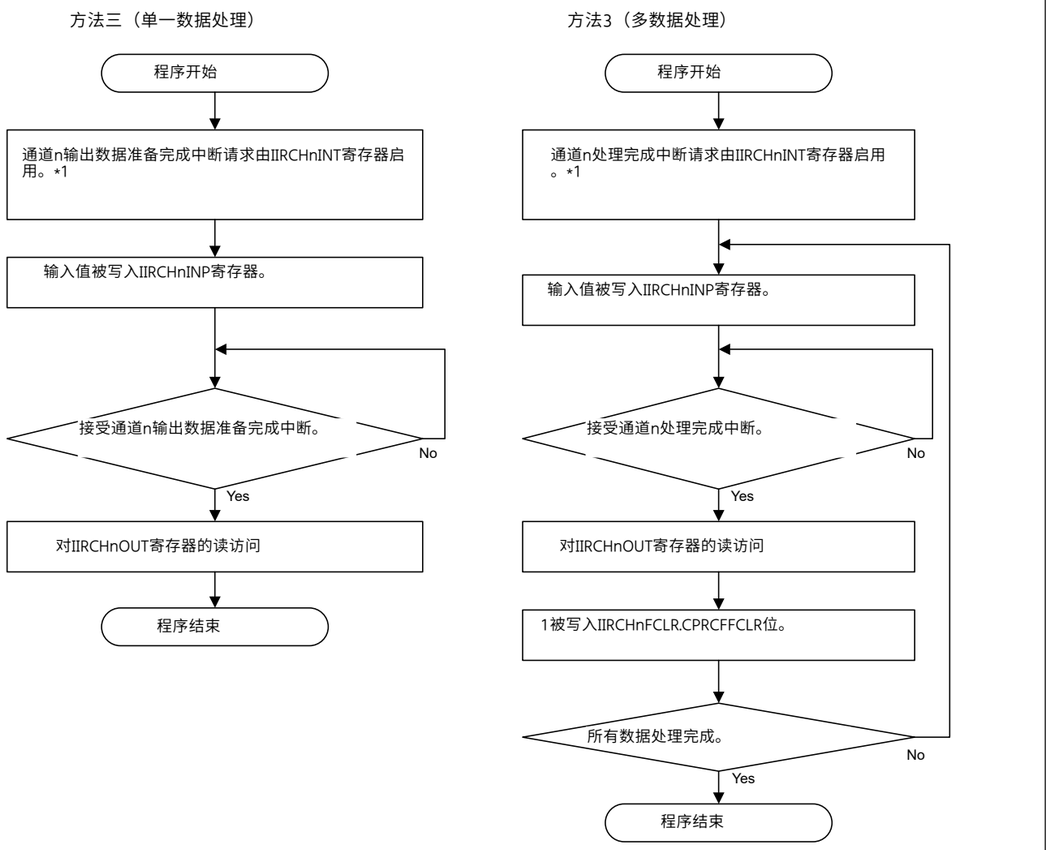
33.3.5.3 Procedure for Intentionally Detecting ECC Errors

This section describes the procedure for intentionally detecting ECC errors (ECC 1-bit error, ECC 2-bit error). To check the behavior of a software routine after an ECC error is detected, perform these procedures.

If the ECC error detection/correction function is disabled (IIRECCCNT.ECCMD = 0), any data can be written to the coefficient/delay data register without updating the ECC code when data is written to the coefficient/delay data register. Therefore, the data error occurrence status of the coefficient/delay data storage area can be reproduced by reversing an appropriate bit of the coefficient/delay data. After the corrupted data has been generated, a read access to the coefficient/delay data register is performed to detect an ECC 1-bit error or ECC 2-bit error in accordance with the number of reversed bits.

The following steps show an example procedure.

1. Perform the initial settings with the ECC error detection/correction function enabled (IIRECCCNT.ECCMD = 1).
2. Write any data to a coefficient/delay data register in any stage.
3. Disable the ECC error detection/correction function (IIRECCCNT.ECCMD = 0).
4. Write a value to detect an ECC 1-bit error or ECC 2-bit error to the address to which data is written in step 2.



注1.当中断请求已经使能时，此步骤可以省略。

Figure 33.8 通道处理的示例程序：方法3

33.3.5.3 有意检测ECC错误的过程

本节介绍有意检测ECC错误（ECC1位错误、ECC2位错误）的过程。要在检测到ECC错误后检查软件例程的行为，请执行以下过程。

如果禁用ECC错误检测校正功能（IIRECCCNT.ECCMD=0），则在将数据写入系数延迟数据寄存器时，可以将任何数据写入系数延迟数据寄存器而无需更新ECC代码。因此，可以通过反转系数延迟数据的适当位来再现系数延迟数据存储区的数据错误发生状态。在生成损坏数据后，对系数延迟数据寄存器执行读取访问，以根据反转的位数检测ECC1位错误或ECC2位错误。

以下步骤显示了一个示例过程。

1.在启用ECC错误检测校正功能(IIRECCCNT.ECCMD=1)的情况下执行初始设置。

2.在任何阶段将任何数据写入系数延迟数据寄存器。

3.禁用ECC错误检测校正功能（IIRECCCNT.ECCMD=0）。

4.将检测ECC1位错误或ECC2位错误的值写入步骤2中写入数据的地址。

Example: When 0x00000000 is written in step 2, writing 0x00000001 reproduces a state where a 1-bit error occurs in the coefficient/delay data and writing 0x00000003 reproduces a state where a 2-bit error occurs in the coefficient/delay data.

5. Enable the ECC error detection/correction function (IIRECCCNT.ECCMD = 1).
6. Read the data from the address to which data is written in steps 2 and 4.
   At this time, an ECC 1-bit error or ECC 2-bit error is detected depending on the value of the data written in steps 2 and 4.

33.4 Interrupt Sources

Table 33.8 shows a list of interrupt sources.

	An ECC 2-bit error has occurred.	IIRECCEF.EDEF	IIRECCEF.EDEF = 1 and IIRECCINT.EDEIE = 1

示例：当在步骤2中写入0x00000000时，写入0x00000001会再现在系数延迟数据中出现1位错误的状态，写入0x00000003会再现在系数延迟数据中出现2位错误的状态。

5.启用ECC错误检测校正功能（IIRECCCNT.ECCMD=1）。

6.从步骤2和4中写入数据的地址读取数据。
此时，根据在步骤2和4中写入的数据值检测ECC1位错误或ECC2位错误。

The JTIDR register data is output from the TDO pin when the IDCODE instruction is executed. After a reset release, the DID[31:0] of JTIDR changes into the Arm® debug code. See the *Arm® CoreSight™ SoC-400 Technical Reference Manual* (ARM DDI 0480F).

34.2.3 JTBPR : Bypass Register

The JTBPR register is a 1-bit register and is connected between the TDI and TDO pins when the JTIR register is set to BYPASS mode. The JTBPR register cannot be read from or written to by the CPU.

34.2.4 JTBSR : Boundary Scan Register

The JTBSR register is a shift register for controlling the external input and output pins of this device, and is distributed across the pads. To apply the JTBSR register in boundary-scan testing, issue the EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ instructions. The BSDL file describes the associations between the JTBSR register bits and the pins of this device. The value after reset is undefined.

34.3 Operation

During a reset, the JTAG ports, TCK, TMS, TDI, and TDO, are assigned as default pin functions. The TCK, TMS, and TDI pins are pulled up by the pull-up resistors. Boundary scan testing can be executed after the setup time elapses when POR is negated and RES is driven low.

34.2.4 JTBSR:边界扫描寄存器

JTBSR寄存器是一个移位寄存器，用于控制该器件的外部输入和输出引脚，分布在各个焊盘上。要在边界扫描测试中应用JTBSR寄存器，请发出EXTEST、SAMPLEPRELOAD、CLAMP和HIGHZ指令。BSDL文件描述了JTBSR寄存器位和该器件引脚之间的关联。复位后的值未定义。

34.3 Operation

在复位期间，JTAG端口、TCK、TMS、TDI和TDO被分配为默认引脚功能。TCK、TMS和TDI引脚由上拉电阻上拉。当POR被否定并且RES被驱动为低电平时，可以在设置时间过去后执行边界扫描测试。

图34.2显示了TAP控制器的状态转换图。所有转换都由TMS信号控制。

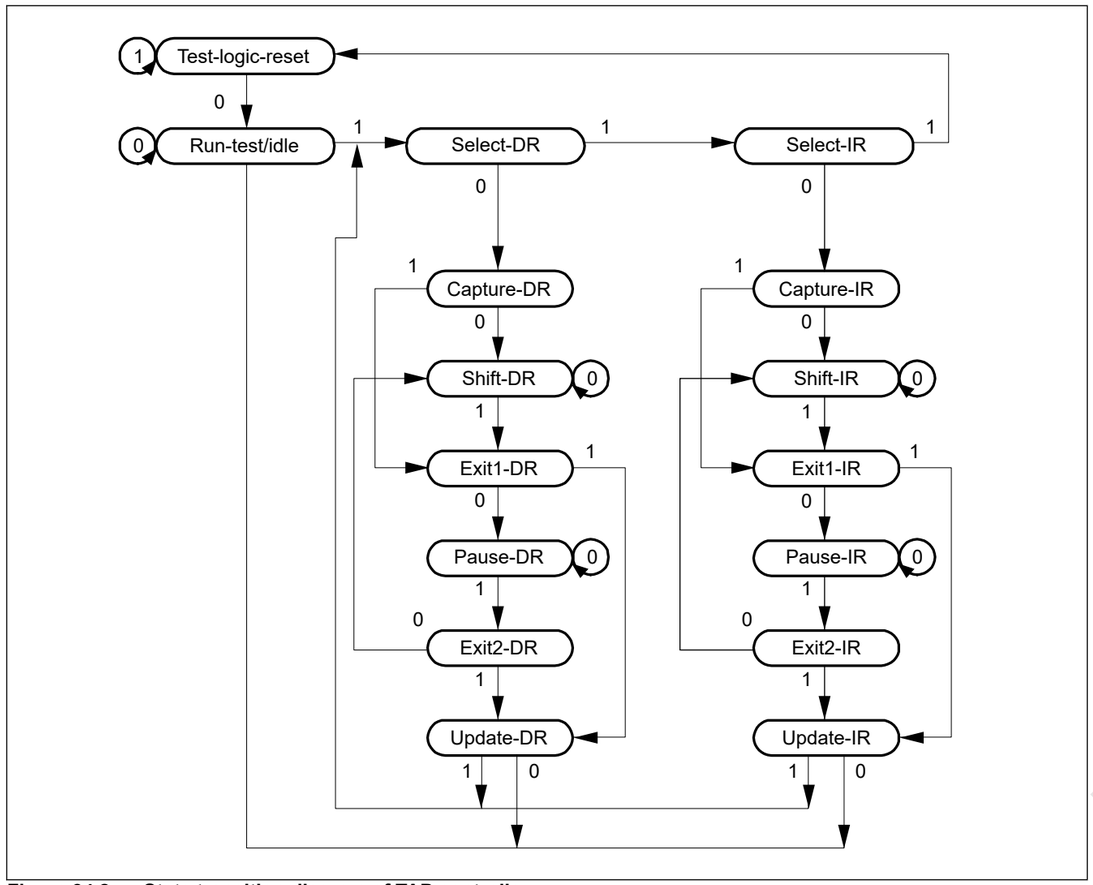

Figure 34.2 State transition diagram of TAP controller

34.3.2 Commands

(1) BYPASS

The BYPASS instruction drives the Bypass Register (JTBPR). This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed circuit board at higher speeds. While this instruction is being executed, the test circuit has no effect on the system circuits.

The JTBPR register is connected between the TDI and TDO pins. Bypass operation is initiated from the Shift-DR operation. The TDO is low in the first clock cycle in the Shift-DR state. In the subsequent clock cycles, values input to the TDI pin are output from the TDO pin.

(2) EXTEST

The EXTEST instruction is used to test external circuits when this device is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified in the SAMPLE/PRELOAD instruction) from the Boundary Scan Register (JTBSR) to the other devices, and input pins are used to input the test result.

(3) SAMPLE/PRELOAD

The SAMPLE/PRELOAD instruction is used to input data from the internal circuits of this device to the JTBSR register, output data from the scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to this device and output signals are also directly output to the external circuits. This device system circuit is not affected by this instruction.

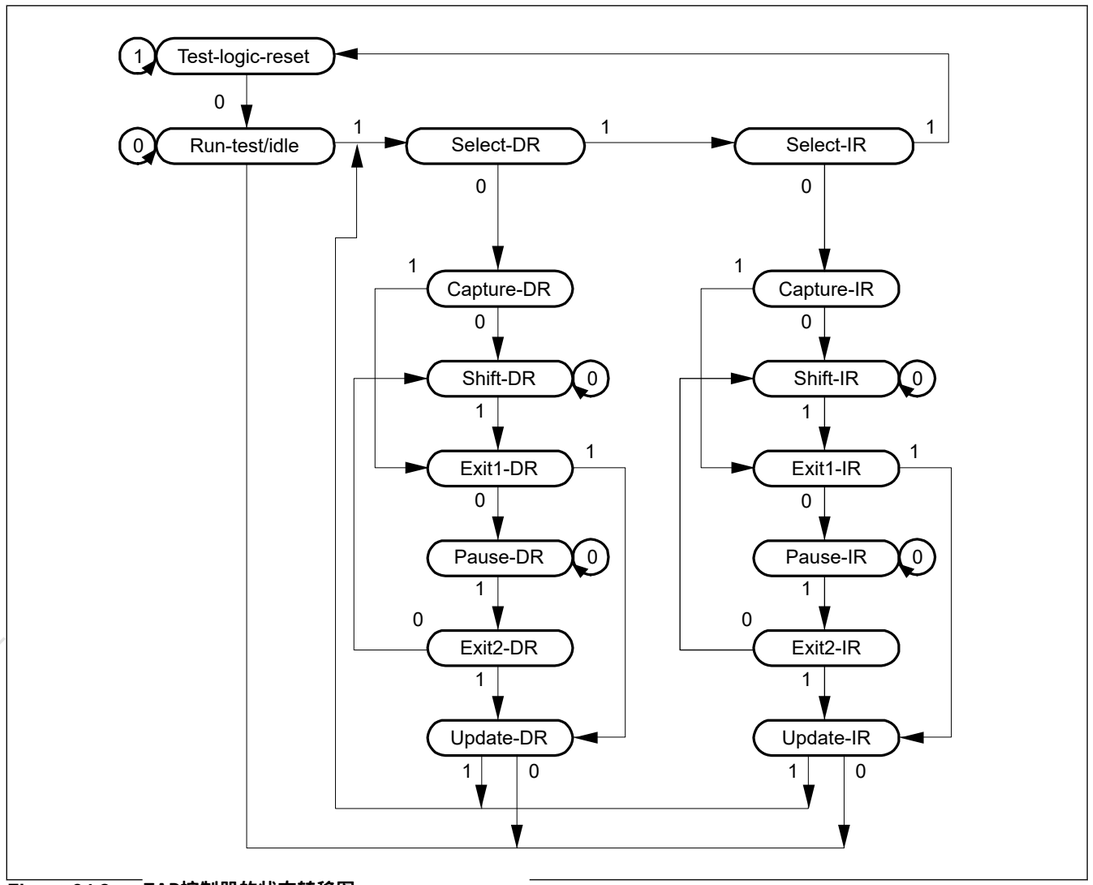

Figure 34.2 TAP控制器的状态转移图

34.3.2 Commands

(1) BYPASS

BYPASS指令驱动旁路寄存器(JTBPR)。该指令缩短了移位路径，便于将串行数据以更高的速度传输到印刷电路板上的其他LSI。在执行该指令时，测试电路对系统电路没有影响。

JTBPR寄存器连接在TDI和TDO引脚之间。旁路操作从Shift-DR操作开始。TDO在Shift-DR状态的第一个时钟周期内为低电平。在随后的时钟周期中，输入到TDI引脚的值从TDO引脚输出。

(2) EXTEST

当本设备安装在印刷电路板上时，EXTEST指令用于测试外部电路。如果执行该指令，输出引脚用于将测试数据（在SAMPLEPRELOAD指令中指定）从边界扫描寄存器(JTBSR)输出到其他设备，输入引脚用于输入测试结果。

(3) SAMPLE/PRELOAD

SAMPLEPRELOAD指令用于将数据从本器件内部电路输入到JTBSR寄存器，从扫描路径输出数据，并将数据重新加载到扫描路径。执行该指令时，输入信号直接输入到本设备，输出信号也直接输出到外部电路。本设备系统电路不受本指令影响。

In SAMPLE operation, the JTBSR register latches a snapshot of the data transferred from the input pins to the internal circuit or data transferred from the internal circuit to the output pins. The latched data is read from the scan path. The JTBSR register latches the data snapshot on the rising edge of the TCK pin in the Capture-DR state. The data snapshot is only transferred from the internal circuit to the output pins during a reset.

In PRELOAD operation, the initial value is written from the scan path to the parallel output latch of the JTBSR register prior to the EXTEST instruction execution. If EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In the EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE

When the IDCODE instruction is selected, the ID Code Register (JTIDR) value is output to the TDO pin in the Shift-DR state of the TAP controller. In this case, the JTIDR register value is output LSB-first. During this instruction execution, the test circuit does not affect the system circuit.

(5) CLAMP

When the CLAMP instruction is selected, output pins output the JTBSR register value that was specified in the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of the JTBSR register is maintained regardless of the TAP controller state.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

(6) HIGHZ

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the JTBSR register is maintained regardless of the state of the TAP controller.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

34.4 Usage Notes

The boundary scan function is subject to the following constraints:

- The boundary scan must be executed when the RES pin is driven low
- Serial data input/output is in LSB order, as shown in Figure 34.3

在SAMPLE操作中，JTBSR寄存器锁存从输入引脚传输到内部电路的数据或从内部电路传输到输出引脚的数据的快照。从扫描路径读取锁存的数据。在Capture-DR状态下，JTBSR寄存器在TCK引脚的上升沿锁存数据快照。数据快照仅在复位期间从内部电路传输到输出引脚。

在PRELOAD操作中，在执行EXTEST指令之前，将初始值从扫描路径写入JTBSR寄存器的并行输出锁存器。如果在不执行此PRELOAD操作的情况下执行EXTEST，则从EXTEST序列的开头到结尾（传输到输出锁存器）输出未定义的值。（在EXTEST指令中，输出并行锁存器始终输出到输出引脚。）

(4) IDCODE

WhentheIDCODEinstructionisselected theIDCodeRegister(JTIDR)valueisoutputtotheTDOpinintheShift-DRstateoftheTAPcontroller.在这种情况下，JTIDR寄存器值首先输出LSB。在该指令执行期间，测试电路不影响系统电路。

(5) CLAMP

选择夹具指令时，输出引脚输出样品中指定的JTBSR寄存器值
预先PRELOAD指令。选择CLAMP指令时，无论TAP控制器状态如何，都将保持JTBSR寄存器的状态。

JTBPR寄存器连接在TDI和TDO引脚之间，导致与选择BYPASS指令时相同的操作。

(6) HIGHZ

选择Highz指令时，所有输出引脚都输入高阻抗状态。选择HIGHZ指令时，无论TAP控制器的状态如何，都会保持JTBSR寄存器。

JTBPR寄存器连接在TDI和TDO引脚之间，导致与选择BYPASS指令时相同的操作。

34.4 使用说明

35. Secure Cryptographic Engine (SCE5)

This is the SCE5_B version of the SCE5 peripheral module.

SCE5_B is referred to as SCE5 in this chapter.

35.1 Overview

The Secure Cryptographic Engine (SCE5) consists of the access management circuit, encryption engine, and random number generation circuit. In combination with the SCE5 library, the SCE5 can prevent eavesdropping (to maintain confidentiality), falsification of information (to ensuret integrity), and impersonation (to verify authenticity).

Because key information required for encryption and decryption is stored only in the SCE5 and all accesses from the outside can be blocked, SCE5 enables building a more robust security system.

Table 35.1 lists the SCE5 specifications. Figure 35.1 shows the SCE5 block diagram.

Table 35.1 SCE5 specifications

Parameter	Specifications
Access control	Access management circuit • In case of irregular access to the SCE5 due to a tampered program or CPU runaway, this circuit blocks all subsequent accesses and stops data output from the SCE5
Encryption engine	AES: Compliant with NIST FIPS PUB 197 • Key length: 128 or 256 bits • Data block size: 128 bits • Encryption usage modes ECB, CBC, CTR: Compliant with NIST SP 800-38A CMAC: Compliant with NIST SP 800-38B GCM: Compliant with NIST SP 800-38D XTS: Compliant with NIST SP 800-38E GCTR • Throughput for 128-bit data 44 PCLKA cycles for 128-bit key 61 PCLKA cycles for 256-bit key*1 AES-GCM • AES-GCM is realized by combining AES-GCTR and GHASH. Key management • Wrapped keys are only valid within the SCE5
Random number generation	32-bit true random number generation circuit
Hardware Unique Key	• A read-only, 128-bit Hardware Unique Key (HUK). • Key derivation functions (KDFs) combine the Hardware Unique Key with the key generation information. The derived keys implement the key wrapping for user key secure storage. • The HUK uniqueness prevents the illicit cloning and copying of keys to another MCU of the MCU group. • The HUK itself is stored in wrapped (encrypted, non-plain) format in an isolated memory area. Therefore it is protected from illicit access and copy.
Unique ID	• A read-only, 128-bit ID unique to an MCU (Unique ID) is accessible from the access management circuit. • Key derivation functions (KDFs) combine the Unique ID with the key generation information. Such derived keys are used to unwrap the HUK within the SCE boundary.
Low power consumption	Setting of the module-stop state is possible

Note 1. This does not include the overhead of calling SCE5 library functions.

35.2.2 Encryption and Decryption

Follow the procedure below to encrypt and decrypt the data:

3. Read the converted data.

The encryption engine has input and output buffers, and can perform encryption/decryption in parallel with data input/output.

35.2.2 加密和解密

请按照以下步骤对数据进行加密和解密：

1.将密钥生成信息输入SCE5，恢复密钥数据。

35.3 Usage Notes

35.3.1 Software Standby Mode

When the software standby mode is entered while the encryption engine is in process, proper processing cannot be resumed after the software standby mode is exited. The software standby mode should therefore be entered while the encryption engine is not running.

35.3.2 Module-Stop Function Setting

SCE5 operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The SCE5 module is initially stopped after reset. Releasing the module-stop state enables access to the registers.

35.3 使用说明

35.3.1 软件待机模式

当加密引擎正在运行时进入软件待机模式时，退出软件待机模式后无法恢复正常处理。因此，应在加密引擎未运行时进入软件待机模式。

35.3.2 模块停止功能设置

可以使用模块停止控制寄存器C(MSTPCRC)禁用或启用SCE5操作。SCE5模块在复位后最初停止。释放模块停止状态可以访问寄存器。

Note 1. Do not convert the same signal source from both A/D converter Unit 0 and Unit 1.
Note 2. Only when the Programmable Gain Amplifier (PGA) is disabled and PGA is set to single-ended input, the ANx can be used for A/D conversion as an analogue input channel. When PGA is enabled, it works as PGAVSS pin; Do not perform A/D conversion of ANx. Regardless of the PGA enable/disable setting, when the PGA is set to a pseudo-differential input, A/D conversion of the ANx is not possible.
Note 3. The one Channel-dedicated Sample-and-Hold Circuit is shared from the two analog channels.

If SGSEL[4:0] is set to other than 0x00, the channel selected by CNVCS[6:0] is available for A/D conversion in the scan operation of the scan group corresponding to the setting value.

Up to 8 A/D conversion channels can be assigned per scan group. Do not assign more than 9 A/D conversion channCNVCS[6:0]els per scan group.

CNVCS[6:0] bits (A/D Conversion Channel Selection)

CNVCS[6:0] bits select the analog signal source for the A/D conversion. CNVCS[6:0] bits should be set for the channel number corresponding to the Analog Input or the Extended Analog function.

Otherwise, the AINMD bit should be set to 0.

SSTSEL[3:0] bits (Sampling State Table Selection)

The ADSGDCRn register controls the diagnosis function at the scanning operation of scan group n.

DIAGVAL[2:0] bits (Self-diagnosis Mode Selection)

DIAGVAL[2:0] bits select the self-diagnosis mode for A/D converter.

DIAGVAL[2:0]bits must be set to 000b when the scan group n is not included any virtual channel that selected the self-diagnosis channel. DIAGVAL[2:0] bits must be set to 100b, 101b or 110b when the scan group n is including the virtual channel that selected the self-diagnosis channel.

ADDISEN bit (Disconnection Detection Assist Enable)

ADDISEN bit enables/disables the disconnection detection assist function. When ADDISEN bit is set to 0, the disconnection detection assist operation is not performed. When ADDISEN bit is set to 1, the disconnection detection assist operation according to the setting of ADDISP bit and ADDISN bit is performed at the scanning operation of scan group n.

ADDISP bit / ADDISN bit (Disconnection Detection Assist Mode Selection)

ADDISP bit and ADDISN bit select the discharge/precharge operation for the disconnection detection.

ADDISP bit selects the discharge/precharge operation for the even-numbered analog channel.

ADDISN bit selects the discharge/precharge operation for the odd-numbered analog channel.

ADNDIS[3:0] bits (Disconnection Detection Assist Period)

ADNDIS[3:0] bits select the discharge/precharge period. When the disconnection detection assist function is disabled (ADDISEN = 0), ADNDIS[3:0] should be set to 0x0. When the disconnection detection assist function is enabled (ADDISEN = 1),ADNDIS[3:0] should be set to a number between 0x3 and 0xF as the number of state for the discharge/precharge period.

31:14	—	These bits are read as 0. The write value should be 0.	R/W

The ADCNVSTR register specifies the A/D successive approximation time, which required by the A/D converter Unit 0 or Unit 1 to convert the sampled analog input to the digital value, in the number of cycles based on A/D conversion clock (ADCLK). The A/D successive approximation time does not include the sampling time of the analog input.

The A/D successive approximation time must be set to meet the value specified in section 46, Electrical Characteristics. If the successive approximation time is set to a value over the range specified for the electrical characteristics, the A/D conversion result is not guaranteed. In addition, the A/D successive approximation time for each A/D converter should be set to be the same. (Set the same value to CST0[5:0] bits and CST1[5:0] bits).

ADCNVSTR寄存器指定AD逐次逼近时间，这是AD转换器单元0或
单元1将采样的模拟输入转换为数字值，其周期数基于AD转换时钟(ADCLK)。AD逐次逼近时间不包括模拟输入的采样时间。

AD逐次逼近时间必须设置为满足第46节“电气特性”中规定的值。如果将逐次逼近时间设置为超出电气特性指定范围的值，则无法保证AD转换结果。此外，每个AD转换器的AD逐次逼近时间应设置为相同。（将相同的值设置为CST0[5:0]位和CST1[5:0]位）。

31:11	—	The write value should be 0.	W

Note 1. To perform a calibration operation, write 1 to each of the calibration start bits simultaneously.

The ADCALSTR register controls the start of the Self-calibration for each A/D converter.

ADCALSTm[2:0] bits (A/D converter Unit m (ADCm) Self-calibration Start Control bits) (m = 0, 1)

ADCALSTm[2:0] bits control the start of the Self-calibration operation of the A/D converter Unit m. When any bit of ADCALSTm[2:0] is set to 1, the Self-calibration operation corresponding to each bit is started. When multiple bits of ADCALSTm[2:0] are set to 1 simultaneously, each self-calibration operation is performed in the order as following:

1. Internal circuit calibration
2. A/D converter gain/offset calibration
3. Channel-specific sample and hold circuit gain/offset calibration

Note: The Self-calibration operation corresponding to the bits set to 0 in ADCALSTm[2:0] is skipped.

ADCALSTm[2:0] bits must be written when all A/D converters are stopped (ADSR.ADACTm = 0 and ADSR.CALACTm = 0);

Writing to ADCALSTm[2:0] bits are prohibited when A/D converters are operating.

注1.要执行校准操作，请同时向每个校准起始位写入1。

ADCALSTR寄存器控制每个AD转换器自校准的开始。

ADCALSTm[2:0]位（AD转换器单元m(ADCm)自校准启动控制位） （m=0 1）

ADCALSTm[2:0]位控制AD转换器单元m的自校准操作的开始。当ADCALSTm[2:0]的任何一位设置为1时，将启动每个位对应的自校准操作。当多个位
ADCALSTm[2:0]同时置1，每次自校准操作按如下顺序执行：

1.内部电路校准

2.AD转换器增益偏移校准

3.通道特定的采样保持电路增益偏移校准

Note: 与ADCALSTm[2:0]中设置为0的位对应的自校准操作被跳过。

当所有AD转换器停止时（ADSR.ADACTm=0和ADSR.CALACTm=0），必须写入ADCALSTm[2:0]位；

当AD转换器工作时，禁止写入ADCALSTm[2:0]位。

The ADSTOPR register forces each A/D converter to stop the operation. When the A/D converter is stopped with this register, the A/D conversion results with that A/D converter are not guaranteed.

ADSTOP0 bit (A/D Converter Unit 0 Force Stop bit)

ADSTOP0 bit forces the A/D converter unit 0 to stop the A/D conversion operation. Setting 0 to ADSTOP0 bit has no effect on the operation. When ADSTOP0 is set to 1, the A/D converter unit 0 is forced to stop the operation. If the A/D converter unit 0 is forced to stop, the A/D conversion results with the A/D converter unit 0 are not guaranteed.

ADSTOP1 bit (A/D Converter Unit 1 Force Stop bit)

ADSTOP1 bit forces the A/D converter unit 1 to stop the A/D conversion operation. Setting 0 to ADSTOP1 bit has no effect on the operation. When ADSTOP1 is set to 1, the A/D converter unit 1 is forced to stop the operation. If the A/D converter unit 1 is forced to stop, the A/D conversion results with the A/D converter unit 1 are not guaranteed.

Note: n = 0 to 8

The ADFIFOERSR register indicates the status of the FIFO. Each flag can be cleared in ADFIFOERSCR.

FIFOOVFn bit (Scan Group n FIFO Overflow Flag)

FIFOOVFn bit indicates whether the overflow occurred in the FIFO of the scan group n.

When FIFOOVFn bit is 0, an overflow is not detected in the FIFO. When FIFOOVFn is 1, an overflow occurred in the FIFO and the A/D conversion result cannot be stored to the FIFO. FIFOOVFn can be cleared in ADFIFOERSCR.

FIFOFLFn bit (Scan Group n FIFO Data Read Request Flag)

FIFOFLFn indicates whether a FIFO data read request in scan group n has been detected. The setting and clearing conditions of FIFOFLFn are shown as follows:

[Setting condition]

When the condition of ADFIFOSRm.FIFOSTn[3:0] ≤ ADFIFOINTLRm.FIFOILVn[3:0] is detected.

[Clearing condition]

When ADFIFOERSCR.FIFOFLCn is written to 1 under the condition of ADFIFOSRm.FIFOSTn[3:0] > ADFIFOINTLRm.FIFOILVn[3:0].

When the condition of ADFIFOSRm.FIFOSTn[3:0] > ADFIFOINTLRm.FIFOILVn[3:0] is occurred by the read access to ADFIFODRn register with DMAC or DTC.

36.3 Operation

A/D conversion clock (ADCLK) is the operation clock of ADC. The A/D converters (ADC0 and ADC1) are operated and controlled by ADCLK as the basic clock. Figure 36.4 shows clock structure of ADC.

ADCLK is generated from the clock source and the division ratio selected in ADCLKCR register. The frequency of ADCLK should be set so that PCLKA ≥ ADCLK. Also, the frequency of ADCLK should be set so that it is within the guaranteed operating range specified in the electrical characteristics. For more details, refer to section 46, Electrical Characteristics.

36.3 Operation

36.3.1 AD转换时钟

D转换时钟(ADCLK)是ADC的操作时钟。AD转换器（ADC0和ADC1）由作为基本时钟的ADCLK操作和控制。图36.4显示了ADC的时钟结构。

ADCLK由时钟源和在ADCLKCR寄存器中选择的分频比生成。ADCLK的频率应设置为PCLKA≥ADCLK。此外，ADCLK的频率应设置在电气特性规定的保证工作范围内。有关详细信息，请参阅第46节，电气特性。

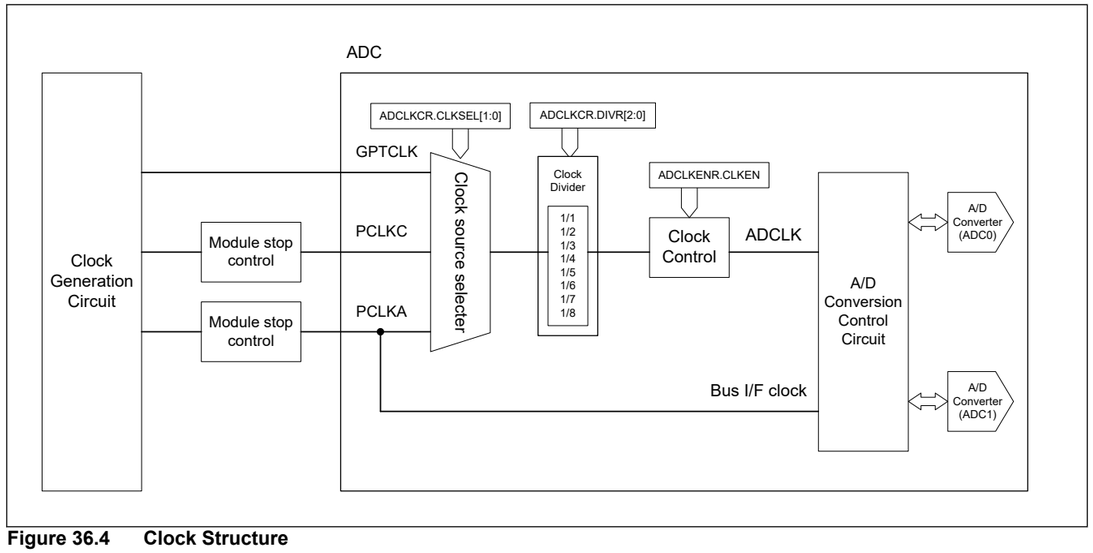

Figure 36.4 Clock Structure

36.3.2 Analog Channel

The analog channel is the source of the analog signal that is targeted for A/D conversion. The analog channels consist of the following elements:

- Analog input channels: A/D conversion channels for the analog input from MCU's I/O pin as the signal source.
- Extended analog channels: A/D conversion channels for the source of the analog signal inside the MCU.

To perform A/D conversion for the analog channels, assignments to the virtual channel and scan group are required. For each element, refer to each item.

36.3.3 Virtual Channel

The virtual channel is a group of registers that stores the A/D conversion configurations for a single analog channel. The virtual channels can be specified the analog channels for A/D conversion, the settings for A/D conversion, the data processing method, the assignment to scan groups, and so on.

To perform the A/D conversion of the analog channel, the analog channel should be assigned to any of the virtual channels. Then that virtual channel should be assigned to one of the scan groups. Refer to Figure 36.5 for the relationship between the analog channels and the virtual channels and scan groups. Figure 36.6 shows the A/D conversion order in Figure 36.5 settings.

The virtual channel can be assigned to only one scan group. When performing the A/D conversion on one analog channel in the different scan group, or when performing the A/D conversion several times within the same scan group, assign several virtual channels to one analog channel.

When performing the A/D conversion more than once using more than one virtual channel within the same scan group for the same analog channel, use the FIFO function in combination. When the FIFO function is not used, the A/D data register (ADDRn (n = 0 to 28)) or the A/D extended analog data register (ADEXDRm (m = 0 to2, 5 to 8)) stores only the data of the last A/D conversion in a scanning operation.

36.3.2 模拟频道

模拟通道是AD转换目标的模拟信号源。模拟通道由以下元素组成：

●模拟输入通道：单片机IO引脚作为信号源的模拟输入的AD转换通道。

●扩展模拟通道：MCU内部模拟信号源的D转换通道。

要对模拟通道执行AD转换，需要分配到虚拟通道和扫描组。对于每个元素，请参阅每个项目。

36.3.3 虚拟通道

虚拟通道是一组寄存器，用于存储单个模拟通道的AD转换配置。虚拟通道可以指定用于AD转换的模拟通道、AD转换的设置、数据处理方法、扫描组的分配等。

要执行模拟通道的AD转换，应将模拟通道分配给任何虚拟通道。然后应该将该虚拟通道分配给扫描组之一。模拟通道与虚拟通道和扫描组的关系见图36.5。图36.6显示了图36.5中的AD转换顺序设置。

虚拟通道只能分配给一个扫描组。对不同扫描组中的1个模拟通道进行AD转换时，或在同一扫描组内进行多次AD转换时，将多个虚拟通道分配给1个模拟通道。

使用同一扫描组内的多个虚拟通道对同一模拟通道进行多次AD转换时，请组合使用FIFO功能。不使用FIFO功能时，AD数据寄存器（ADDRn(n=0to28)）或AD扩展模拟数据寄存器（ADEXDRm(m=0to2 5to8)）只存储最后一个AD的数据扫描操作中的转换。

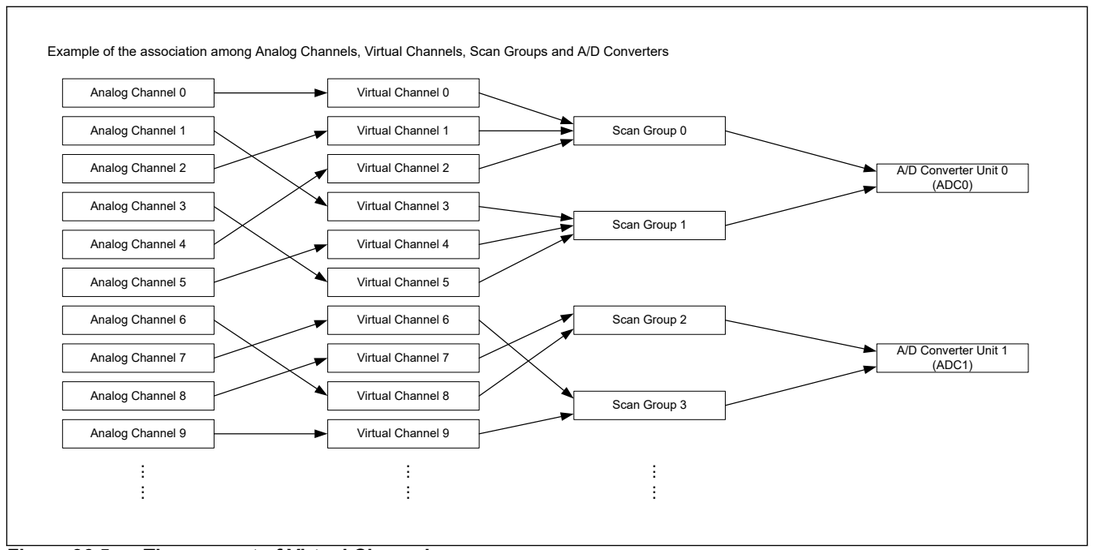

Figure 36.5 The concept of Virtual Channel

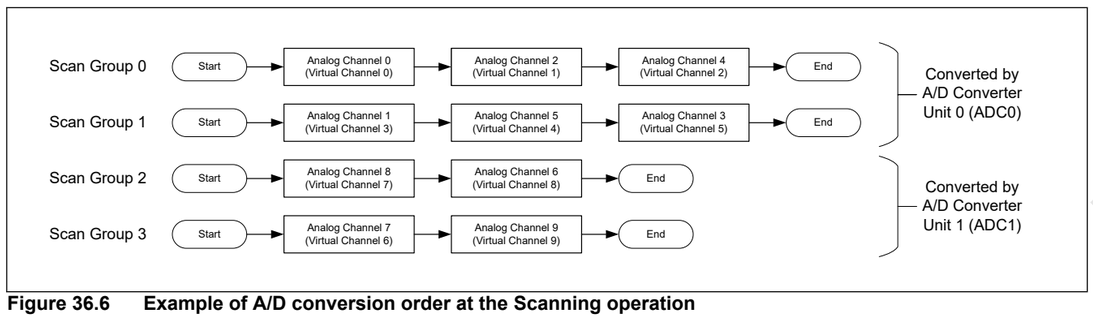

Figure 36.6 Example of A/D conversion order at the Scanning operation

36.3.4 Scan Group

The scan group is a group of the analog channels where the A/D conversions are performed on one scanning operation. To perform the A/D conversion using the scan group, configure the following steps:

- Assign the analog channel for the A/D conversion to the virtual channel.
- Assign the virtual channel to the scan group.
- Assign the scan group to A/D Converter.

Refer to Figure 36.5 and Figure 36.6 for the relationship among the analog channels, the virtual channels, and the scan groups.

A scan group can be assigned up to 8 virtual channels. If more than 9 virtual channels are assigned to a scan group, the 1st to 8th virtual channels in ascending order of the virtual channel number are targeted for A/D conversion, and the 9th and subsequent channels are not targeted for A/D conversion.

Notes on the scan groups

The virtual channels assigned to one scan group should be assigned the analog channels that can be converted by the same A/D converter. If any analog channels cannot be converted by the specified A/D converter are included, the A/D conversion result of those channels are undefined.

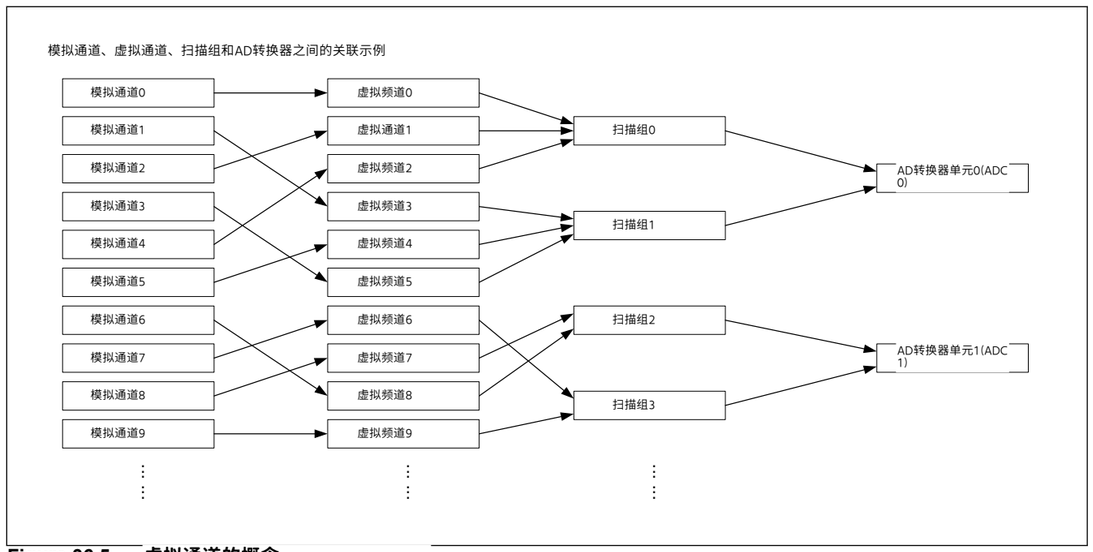

Figure 36.5 虚拟通道的概念

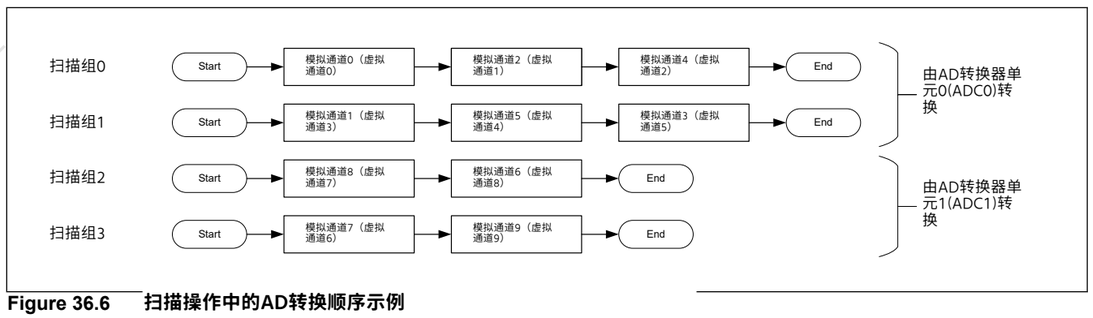

Figure 36.6 扫描操作中的AD转换顺序示例

36.3.4 扫描组

扫描组是一组模拟通道，其中对一次扫描操作执行AD转换。要使用扫描组执行AD转换，请配置以下步骤：

●将AD转换的模拟通道分配给虚拟通道。
●将虚拟通道分配给扫描组。
●将扫描组分配给模数转换器。

模拟通道、虚拟通道和扫描组之间的关系请参见图36.5和图36.6。

一个扫描组最多可以分配8个虚拟通道。如果为扫描组分配了9个以上的虚拟通道，则按虚拟通道编号升序排列的第1到第8个虚拟通道将成为AD转换的目标，而第9和后续通道将不作为AD转换的目标。

关于扫描组的说明

分配给一个扫描组的虚拟通道应分配可以由同一扫描组转换的模拟通道
一个D转换器。如果包含指定的AD转换器不能转换的模拟通道，则这些通道的AD转换结果是不确定的。

36.3.5 Scanning Operation

The scanning operation is the operation of sequential A/D conversion for the analog channels. The modes of the scanning operation are the followings:

- Single Scan mode
  - In single scan mode, one scan group is scanned once for each A/D converter start trigger input.
  - Each time an A/D conversion start trigger is input, A/D conversion is performed once for each analog channel assigned to that scan group.
- Continuous Scan mode
  - The continuous scan mode repeats the scanning operation of one scan group.
  - When an A/D conversion start trigger is input, A/D conversion of each analog channel assigned to that scan group is repeated until A/D conversion stop processing is performed.

The scanning operations are performed on a scan group basis. When the scanning operation is started, A/D conversion is performed for each analog channel based on the virtual channel setting. If 2 or more scan group assigned to the same A/D Converter are started at the same time, the scanning operation of the group with the smallest scan group number is started.

The A/D conversion order of the analog channel in the scanning operation is the ascending order of the virtual channel numbers assigned to the scan group. (The channels with the lowest virtual channel numbers are performed the A/D conversion at the forward end of the scan group. The channels with larger virtual channel numbers are performed the A/D conversion at the backward of the scan group.)

Refer to Figure 36.5 and Figure 36.6 for the relationship of the conversion order of the respective analog channel in the scanning operation.

36.3.5.1 Single Scan mode

Table 36.5 and Figure 36.7 show the operation example in Single Scan mode.

Table 36.5 Example of the scanning operation in Single Scan mode

Step	Operation
1	When a software trigger or a trigger from a peripheral module is input, the scanning operation of the scan group corresponding to the trigger is started.
2	Each time an A/D conversion of one analog channel is completed, A/D conversion result is stored to the data register (ADDRi (i = 0 to 28), ADEXDRj (j = 0 to 2, 5 to 8)). If FIFO is used, the A/D conversion result is also stored to the FIFO data register (ADFIFODRk (k = 0 to 8)).
3	If the Scan End Interrupt is enabled, the Scan End Interrupt corresponding to that scan group is generated when the A/D conversion of all virtual channels assigned to that scan group is completed.
4	During the scanning operation, ADGRSR.ACTGRn (n = 0 to 8) bit corresponding to that scan group is set to 1. ADSR.ADACTm (m = 0, 1) bit corresponding to the A/D Converter performing the A/D conversion is also set to 1. When scanning operation is complete, each bit is cleared to 0 and A/D Converter enters standby.

36.3.5 扫描操作

扫描操作是模拟通道的顺序AD转换操作。扫描操作的模式如下：

●单次扫描模式

在单次扫描模式下，每个AD转换器启动触发输入扫描一个扫描组一次。

每次输入AD转换开始触发时，对分配给该扫描组的每个模拟通道执行一次AD转换。

●连续扫描模式

连续扫描模式重复一个扫描组的扫描操作。

当输入AD转换开始触发时，将重复分配给该扫描组的每个模拟通道的AD转换，直到执行AD转换停止处理。

扫描操作以扫描组为基础进行。当开始扫描操作时，根据虚拟通道设置对每个模拟通道进行AD转换。如果同时启动分配给同一AD转换器的2个或多个扫描组，则开始扫描组号最小的组的扫描操作。

扫描操作中模拟通道的AD转换顺序是分配给扫描组的虚拟通道号的升序。（虚拟通道号最小的通道在扫描组的前端进行AD转换。虚拟通道号较大的通道在扫描组的后端进行AD转换。）

扫描操作中各模拟通道的转换顺序关系请参考图36.5和图36.6。

36.3.5.1 单次扫描模式

表36.5和图36.7显示了单次扫描模式下的操作示例。

Table 36.5 单次扫描模式下的扫描操作示例

Step	Operation
1	当输入软件触发或来自外围模块的触发时，触发对应的扫描组的扫描操作开始。
2	每次完成一个模拟通道的AD转换，AD转换结果被存储到数据寄存器（ADDRi（i=0到28）、ADEXDRj（j=0到2、5到8））。如果使用FIFO，AD转换结果也存储到FIFO数据寄存器（AFIFODRk(k=0to8)）。
3	如果启用了扫描结束中断，则当分配给该扫描组的所有虚拟通道的AD转换完成时，将产生与该扫描组对应的扫描结束中断。
4	在扫描操作期间，对应于该扫描组的ADGRSR.ACTGRn（n=0到8）位设置为1。 对应于执行AD转换的AD转换器的ADSR.ADACTm(m=0 1)位也设置为1。 扫描操作完成后，每个位都被清零，AD转换器进入待机状态。

Step	Operation

When scanning operation starts, ADGRSR.ACTGRn (n = 0 to 8) corresponding to that scan group is set to 1. ADSR.ADACTm (m = 0, 1) bit corresponding to the A/D Converter performing the A/D conversion is also set to 1.
2	Each time an A/D conversion of one analog channel is completed, A/D conversion result is stored to the data register (ADDRi (i = 0 to 28), ADEXDRj (j = 0 to 2, 5 to 8)). If FIFO is used, the A/D conversion result is also stored to the FIFO data register (ADFIFODRk (k = 0 to 8)).
3	If the Scan End Interrupt is enabled, the Scan End Interrupt corresponding to that scan group is generated when the A/D conversion of all virtual channels assigned to that scan group is completed.
4	Step 2 and Step 3 are repeated until the A/D conversion stop process is performed, and scanning operation continues. To stop A/D conversion, follow section 36.5.4. Force stops the A/D conversion operation.

Note 2. Enable all Channel-dedicated sample-and-hold circuits connected to ADCm (m = 0, 1).
Note 3. When the Self-Calibration the channel-dedicated sample-and-hold circuitry, the number of sampling states at the Self-Calibration of the A/D converter (ADCALSTCR.CALASSST[9:0] bits) may also need to be changed. Set the value that satisfies the electrical characteristics.
Note 4. If the A/D Converter Error is detected by the Self-Calibration, it may be set outside the operation guaranteed range specified in the electric characteristics. Check the operation setting.

36.3.6.3 Restrictions on Self-Calibration

(1) Prohibition of the scanning operation during Self-Calibration

Do not start the scanning operation during Self-Calibration. When performing the scanning operation, start the scanning operation after Self-Calibration is completed. Operation is not guaranteed when the scanning operation is started during Self-Calibration.

(2) Prohibition of additional writes to the ADCALSTR register during Self-Calibration

After the Self-Calibration is started, writing to ADCALSTR register is prohibited until Self-Calibration is completed. Write to ADCALSTR register after Self-Calibration is completed. Operation is not guaranteed if this restriction is violated.

(3) Prohibition of forcibly stop during Self-Calibration

Do not force stop with the ADSTOPR register during Self-Calibration. Even if the A/D conversion operation is to be stopped forcibly due to a system error or exception handling, be sure to wait until the Self-Calibration is complete. Operation is not guaranteed when forced to stop during Self-Calibration.

(4) Restrictions on Self-Calibration for Channel-dedicated sample-and-hold circuit

To perform the Self-Calibration for the Channel-dedicated sample-and-hold circuit, all Channel-dedicated sample-and-hold circuits connected to the A/D converter should be enabled as follows.

- For ADC0: Set 1 for ADSHCR0.SHEN0 to SHEN2 bit
- For ADC1: Set 1 for ADSHCR1.SHEN4 to SHEN6 bit

If there is a Channel-dedicated sample-and-hold circuit that is not used, set it to disabled (ADSHCRm.SHENn = 0 (m = 0, 1. n = 0 to 2, 4 to 6) after Self-Calibration completes.

Operation is not guaranteed when the Self-Calibration for the Channel-dedicated sample-and-hold circuit is performed while any Channel-dedicated sample-and-hold circuit are disabled.

(5) Restrictions on the Self-Calibration

Self-calibration should be performed for the A/D converters one by one. During the Self-Calibration operation, the other A/D converters should be in idle (not in scan operation or Self-Calibration operation).

注1.如果不使用通道专用的采样保持电路，则不需要。
注2.使能所有连接到ADCm的通道专用采样保持电路(m=0 1)。
注3.当对通道专用的采样保持电路进行自校准时，ADC转换器的自校准时的采样状态数（ADCALSTCR.CALASSST[9:0]位）可能也需要更改.设置满足电气特性的值。

注4.如果通过自校准检测到AD转换器错误，则可能设置在电气特性规定的操作保证范围之外。检查操作设置。

36.3.6.3 自校准的限制

(1) 自校准期间禁止扫描操作

请勿在自校准期间启动扫描操作。执行扫描操作时，请在自校准完成后开始扫描操作。在自校准期间开始扫描操作时，无法保证操作。

(2) 在自校准期间禁止对ADCALSTR寄存器进行额外的写入

自校准开始后，在自校准完成之前，禁止写入ADCALSTR寄存器。自校准完成后写入ADCALSTR寄存器。如果违反此限制，则无法保证操作。

(3) 自校准期间禁止强行停止

在自校准期间不要使用ADSTOPR寄存器强制停止。即使由于系统错误或异常处理而强制停止AD转换操作，也请务必等到自校准完成。在自校准期间强制停止时无法保证操作。

(4) 通道专用采样保持电路自校准的限制

要对通道专用采样保持电路执行自校准，连接到AD转换器的所有通道专用采样保持电路应启用如下。

●对于ADC0：将ADSHCR0.SHEN0到SHEN2位设置为1
●对于ADC1：将ADSHCR1.SHEN4到SHEN6位设置为1

如果有一个未使用的通道专用采样保持电路，则在自校准完成后将其设置为禁用(ADSHCRm.SHENn=0(m=0 1.n=0to2 4to6).

在禁用任何通道专用采样和保持电路的情况下执行通道专用采样保持电路的自校准时，不能保证操作。

(5) 自校准的限制

应对AD转换器一一进行自校准。在自校准操作期间，其他AD转换器应处于空闲状态（不在扫描操作或自校准操作中）。

If this restriction is violated, the A/D conversion accuracy will be degraded due to noise during the self-calibration operation. In this case, the A/D Converter characteristics are not guaranteed.

In addition, in order to enhance the effect of Self-Calibration, Self-Calibration operation should be performed under conditions with as little noise as possible.

(6) Restrictions on setting of the number of status for Self-Calibration

The number of states to be set in the ADCALSTCR and ADCALSHCR registers should be set to satisfy the values specified in the Electrical Characteristics. In addition, the number of states involved in Self-calibration should be set to satisfy the following restrictions.

If these restrictions are violated, A/D conversion results are not guaranteed.

[Restrictions on setting of ADCALSTCR register]

- ADCALSTCR.CALADSST[9:0] bits
  - According to the type of Self-Calibration, set the values to satisfy those specified in the electrical characteristics.
  - If the setting value differs according to the type of Self-Calibration, change the register setting value for each Self-Calibration.
- ADCALSTCR.CALADCST[5:0] bits
  - Set the same value as ADCNVSTR.CSTm[5:0] (m = 0, 1) bits.
    (ADCALSTCR.CALADCST[9:0] = ADCNVSTR.CSTm[5:0])

[Restrictions on setting of ADCALSHCR register] (only when Channel-dedicated sample-and-hold circuit is used)

- ADCALSHCR.CALSHSST[7:0] bits
  - Set the value equal to the value of the ADSHSTRm.SHSST[7:0] bits plus 1 (m = 0, 1).
    (ADCALSHCR.CALSHSST[7:0] = ADSHSTRm.SHSST[7:0] + 1)
  - If the setting values of ADSHSTR0.SHSST[7:0] and ADSHSTR1.SHSST[7:0] are different, change the register setting values of CALSHSST[7:0] for each Self-Calibration of ADC0 (SH0 to SH2) and ADC1 (SH4 to SH6).
- ADCALSHCR.CALSHHST[2:0] bits
  - Set the same value as ADSHSTRm.SHHST[2:0] (m = 0, 1) bits.

36.3.7 Analog Input Channel

For the correspondence between the analog input pins and the analog channel numbers, the A/D converters, Programmable Gain Amplifier, and Channel-dedicated sample-and-hold circuit, refer to Table 36.3.

36.3.8 Extended Analog Function

Extended Analog Function performs A/D conversion on the internal signal source of MCU. The available sources for Extended Analog Function are shown in the following:

- Self-diagnosis voltage
- Internal Reference Voltage
- Temperature Sensor
- D/A Converter Output (Internal Output Path to ACMPHS)

36.3.9 Self-diagnosis Function

This A/D converter has a built-in self-diagnosis function. The self-diagnosis function inputs the self-diagnosis voltage to the A/D converter and performs A/D conversion. The A/D conversion result of the self-diagnosis voltage can be used to confirm that the A/D converter is operating normally.

36.3.9.1 Self-diagnosis Configuration

The procedure for self-diagnosis of the A/D converter is shown in the following:

如果违反此限制，则AD转换精度将因自校准操作期间的噪声而降低。在这种情况下，不能保证AD转换器的特性。

此外，为了增强自校准的效果，自校准操作应在噪声尽可能小的条件下进行。

(6) 自校准状态数设置限制

在ADCALSTCR和ADCALSHCR寄存器中设置的状态数应设置为满足电气特性中指定的值。此外，Self-calibration中涉及的状态数应设置为满足以下限制。

如果违反这些限制，则无法保证AD转换结果。

[ADCALSTCR寄存器的设置限制]

- ADCALSTCR.CALADSST[9:0] bits
  根据自校准的类型，设置值以满足电气特性中规定的值。
  如果设置值因Self-Calibration类型而异，请更改每个SelfCalibration的寄存器设置值。
- ADCALSTCR.CALADCST[5:0] bits
  设置与ADCNVSTR.CSTm[5:0](m=0 1)位相同的值。（ADCALSTCR.CALADCST[9:0]=ADCNVSTR.CSTm[5:0]）

[ADCALSHCR寄存器的设置限制]（仅当使用通道专用采样保持电路时）

- ADCALSHCR.CALSHSST[7:0] bits
  将该值设置为等于ADSHSTRm.SHSST[7:0]位的值加1(m=0 1)。（ADCALSHCR.CALSHSST[7:0]=ADSHSTRm.SHSST[7:0]+1）
  如果ADSHSTR0.SHSST[7:0]和ADSHSTR1.SHSST[7:0]的设置值不同，请更改每次ADC0自校准（SH0至SH2）的CALSHSST[7:0]寄存器设置值和ADC1（SH4至SH6）。
- ADCALSHCR.CALSHHST[2:0] bits
  设置与ADSHSTRm.SHHST[2:0](m=0 1)位相同的值。

36.3.9 Self-diagnosis Function

该AD转换器具有内置自诊断功能。自诊断功能将自诊断电压输入到AD转换器并执行AD转换。自诊断电压的AD转换结果可用于确认AD转换器工作正常。

36.3.9.1 Self-diagnosis Configuration

AD转换器的自诊断程序如下所示：

1. Assign the self-diagnosis channel to one of the virtual channels and configure the virtual channel.
2. Assign the virtual channel for which the self-diagnosis channel has been selected to one of the scan groups.
3. Set the self-diagnosis voltage in the ADSGDCRn.DIAGVAL[2:0] (n = 0 to 8) bits corresponding to the scan group assigned in 2. above.
4. When the scan group to which the self-diagnosis channel is assigned is started the scanning and A/D conversion of the self-diagnosis channel is started, the self-diagnosis operation is executed.

Table 36.9 shows the operation setting when the self-diagnosis function is used. When using the self-diagnosis function, follow the settings in Table 36.9. If self-diagnosis operation is performed with the settings other than those shown in Table 36.9, the self-diagnosis result (A/D conversion result) is not guaranteed.

Table 36.9 Operation setting and expected value when self-diagnosis function is used

Note 2. The A/D conversion data is the value when 16-bit data format (ADDOPCRn.ADPRC[1:0] = 00b) is selected.
Note 3. The expected value of A/D conversion is the signed data. The A/D conversion result becomes 0x0001 (+1) or more when a positive accuracy error occurs in A/D conversion, and becomes 0xFFFF (-1) or less when a negative accuracy error occurs.
Note 4. When an accuracy error occurs in A/D conversion, the A/D conversion result is a value greater than or equal to 0x8000.
Note 5. When an accuracy error occurs in A/D conversion, the A/D conversion result is less than or equal to 0x7FFF.

36.3.9.2 Notes on self-diagnosis function

(1) Notes on performing the Self-Diagnosis

The data register (ADEXDR0) to store the self-diagnosis result is shared by all A/D converters. When performing the self-diagnosis, ADEXDR0 register is overwritten by the result of the later self-diagnosis operation. If self-diagnosis operations of ADC0 and ADC1 are performed simultaneously, a conflict occurs when the self-diagnosis result is stored in ADEXDR0 register, and the self-diagnosis result of either ADC0 or ADC1 is lost. In addition, the value in the ADEXDR0 register cannot distinguish the data has been converted by which A/D converter.

To avoid this problem, it is recommended to perform self-diagnosis in one of the following methods:

[Recommended operation when self-diagnosis function is used]

- Perform self-diagnosis for each A/D converter one by one.
  - In order to distinguish which A/D converter's self-diagnosis result when reading the data register, please schedule the self-diagnosis operation of each A/D converter to be exclusive.
- Use FIFO function for scan groups that include self-diagnosis channels.
  - By using FIFO, it is possible to distinguish indirectly the A/D conversion result for that scan group was converted by which A/D converter. This mechanism makes it possible to distinguish which A/D converter's self-diagnosis result.

(2) Notes on data format during self-diagnosis

When self-diagnosis is performed, if a data format other than 16-bit length is set, an overflow occurs due to A/D conversion data rounding, and the A/D conversion data error is detected. To perform self-diagnosis, select the 16-bit data format.

36.3.10 Internal Reference Voltage

ADC can perform A/D conversion of Internal Reference Voltage. Internal Reference Voltage outputs a constant voltage that is independent of the power supply voltage (VCC, VSS, AVCC, AVSS, VREFH0 and VREFL0). The monitoring of Internal

1.将自诊断通道分配给其中一个虚拟通道并配置虚拟通道。
2.将已选择自诊断通道的虚拟通道分配给其中一个扫描组。
3.在ADSGDCRn.DIAGVAL[2:0](n=0到8)位中设置自诊断电压，对应于上面2.中分配的扫描组。
4.当分配自诊断通道的扫描组开始扫描并开始自诊断通道的A/D转换时，执行自诊断操作。

表36.9显示了使用自诊断功能时的操作设置。使用自诊断功能时，请按照表36.9中的设置。如果以表36.9所示设置以外的设置执行自诊断操作，则不能保证自诊断结果（AD转换结果）。

Table 36.9 使用自诊断功能时的动作设定及期望值

	ADSGDCRx	ADCHCRy		ADDOPCRCy	
	DIAGVAL[2:0]	CNVCS[6:0]	AINMD	SIGNSEL

注2.AD转换数据是选择16位数据格式(ADDOPCRn.ADPRC[1:0]=00b)时的值。
注3.AD转换的期望值是有符号数据。当AD转换出现正精度误差时，AD转换结果变为0x0001(+1)或更大，而当出现负精度误差时，AD转换结果变为0xFFFF(−1)或更小。
注4.当AD转换出现精度误差时，AD转换结果为大于等于0x8000的值。
注5.当AD转换出现精度误差时，AD转换结果小于等于0x7FFF。

36.3.9.2 自诊断功能注意事项

(1) 执行自诊断的注意事项

存储自诊断结果的数据寄存器（ADEXDR0）由所有AD转换器共享。执行自诊断时，ADEXDR0寄存器被后面的自诊断操作的结果覆盖。如果同时进行ADC0和ADC1的自诊断操作，则在ADEXDR0寄存器中存储自诊断结果时会发生冲突，ADC0或ADC1的自诊断结果会丢失。另外，ADEXDR0寄存器中的值无法区分数据是由哪个A/D转换器转换的。

为避免此问题，建议通过以下方法之一进行自诊断：

[使用自诊断功能时的推荐操作]

●对每个AD转换器逐一进行自诊断。

为了在读取数据寄存器时区分哪个AD转换器的自诊断结果，请将每个AD转换器的自诊断操作安排为独占。

●对包含自诊断通道的扫描组使用FIFO功能。

通过使用FIFO，可以间接区分该扫描组的AD转换结果是由哪个AD转换器转换的。这种机制可以区分哪个AD转换器的自诊断结果。

(2) 自诊断时数据格式的注意事项

执行自诊断时，如果设置了16位长度以外的数据格式，则由于AD转换数据舍入而发生溢出，并检测到AD转换数据错误。要执行自诊断，请选择16位数据格式。

36.3.10 内部参考电压

ADC可以对内部参考电压进行AD转换。内部参考电压输出与电源电压（VCC、VSS、AVCC、AVSS、VREFH0和VREFL0）无关的恒定电压。内部监控

Reference Voltage can be used to detect variations in the analog reference supply voltage (VREFH0 and VREFL0) and abnormalities or faults in the system.

When performing A/D conversion of Internal Reference Voltage, it is required to set the Internal Reference Voltage Monitor Enable Register (ADREFCR) and assign the analog channel of Internal Reference Voltage to any of the virtual channels. Refer to Table 36.4 for the correspondence between Internal Reference Voltage function and the analog channels. For the sampling time when A/D conversion of Internal Reference Voltage is performed, refer to section 46, Electrical Characteristics.

36.3.11 Temperature Sensor

When A/D conversion of Temperature Sensor is performed, Temperature Sensor should be configured and the analog channel of Temperature Sensor should be assigned to any of the virtual channels. Refer to Table 36.4 for the correspondence between Temperature Sensor and analog channels. For the sampling time when A/D conversion of Temperature Sensor is performed, refer to section 46, Electrical Characteristics.

When the output of the D/A converter is used for the reference input voltage of High-Speed Analog Comparator (ACMPHS), this function can be used to monitor the output voltage of the D/A converter. For details of the D/A converter function, refer to section 37, 12-Bit D/A Converter (DAC12).

When A/D conversion is performed on the output of D/A converter (DA0 to DA3) (output to ACMPHS), the D/A converter should be configured and the analog channel of the D/A converter should be assigned to one of the virtual channels. For the sampling time when A/D conversion is performed on the D/A converter output voltage, refer to section 46, Electrical Characteristics.

36.3.13 Programmable Gain Amplifier

ADC has built-in Programmable Gain Amplifier (PGA). The PGA amplifies an external analog input signal and outputs it to A/D converter, Channel-dedicated sample-and-hold circuit, and High-Speed Analog Comparator (ACMPHS).

36.3.13.1 Configuration and Operation of PGA

The PGAs are able to select the single-ended input or the pseudo-differential input per unit. Figure 36.9 shows the internal configuration of the PGA in the single-ended input mode and the pseudo differential input mode.

(1) Single-ended input

In single-ended input mode, PGA amplifies the input from PGAIN pin with the specified gain. The gain is set with ADPGACRn.PGAGAIN[3:0] (n = 0 to 3) bits. Settable gains are ×2.000 to ×13.333. Table 36.10 shows the calculation formula of PGA output voltage.

When operating the PGA in single-ended input mode, PGAIN should be connected to the signal source and PGAVSS should be connected to the analog ground (AVSS0). The input voltage to PGAIN must not exceed the range specified in the Electrical Characteristics.

(2) Pseudo-differential input

In pseudo differential input mode, PGA amplifies the difference between PGAIN pin and PGAVSS pin with the specified gain and output the voltage obtained by adding the offset of AVCC×0.5 level. The gain is set by ADPGACRn.PGAGAIN[3:0] (n = 0 to 3) bits and ADPGACRn.PGADG[1:0] (n = 0 to 3) bits. Settable gains are ×1.500, ×2.333, ×4.000, and ×5.667. Set the same gain value to PGAGAIN[3:0] bits and PGADG[1:0] bits. Table 36.10 shows the calculation formula of PGA output voltage.

When operating the PGA in Pseudo Differential Input Mode, PGAIN should be connected to the signal source, and PGAVSS should be connected to the reference ground of the signal source. The inputs to PGAIN and PGAVSS pins must not exceed the range specified in the Electrical Characteristics.

参考电压可用于检测模拟参考电源电压（VREFH0和VREFL0）的变化以及系统中的异常或故障。

Restrictions on the PGA Output Monitoring Function

The PGA output monitor function (hereinafter referred to as this function) is an auxiliary function for the purpose of program development, debugging, checking operation, and analysis of the MCU, and is not intended to be used in normal operation. When this function is used, the PGA characteristics may deteriorate and unintentional operation may occur due to the effects of load or external noise caused by the terminal output, etc. For these reasons, functions, characteristics, and reliability are not guaranteed when this function is used. When using this function, be sure to give sufficient consideration to the safety of the customer's equipment and system before using it. Also, after the development of your equipment or system is completed, be sure to use the product with this function disabled (no PGA output to the pins).

36.3.13.4 Restrictions on PGA

When using a PGA, observe the following constraints:

(1) Limitations of the analog input path to which PGAIN and PGAVSS are assigned

When PGA is used, the analog input pin assigned to PGAVSS pin cannot be input to A/D conversion or Channel-dedicated sample-and-hold circuit.

Regardless of the PGA is enabled or disabled, if the PGA is set to Pseudo Differential Input Mode, the analog inputs to which PGAIN and PGAVSS are assigned cannot be used by the A/D converter or Channel-dedicated sample-and-hold circuit bypassing the PGA.

(2) Restrictions of the input-voltage range to pins to which PGAIN and PGAVSS are assigned

The inputs to the pins to which PGAIN and PGAVSS are connected must not exceed the range specified in the Electrical Characteristics.

要将PGA的内部输出输出到引脚，需要ADPGAMONCR寄存器设置和分配PGAOUT功能的引脚配置。有关引脚配置的更多详细信息，请参阅第18节，IO端口。

PGA输出监控功能的限制

PGA输出监控功能（以下简称该功能）是用于单片机的程序开发、调试、检查运行和分析的辅助功能，不打算在正常运行时使用。使用本功能时，由于负载的影响或端子输出引起的外部噪声等的影响，PGA特性可能会劣化，可能会发生误动作。因此，不保证本功能时的功能、特性和可靠性。用过的。使用此功能时，请务必充分考虑客户设备和系统的安全后再使用。此外，在您的设备或系统开发完成后，请务必使用禁用此功能的产品（无PGA输出到引脚）。

36.3.13.4 对PGA的限制

使用PGA时，请注意以下限制：

(1) 分配PGAIN和PGAVSS的模拟输入路径的限制

使用PGA时，分配给PGAVSS引脚的模拟输入引脚不能输入到AD转换或通道专用采样保持电路。

无论PGA是启用还是禁用，如果PGA设置为伪差分输入模式，则分配了PGAIN和PGAVSS的模拟输入不能被AD转换器或绕过PGA的通道专用采样保持电路使用.

36.3.14.3 Restrictions on Channel-dedicated sample-and-hold circuit

When using Channel-dedicated sample-and-hold circuit, observe the following restrictions:

(1) Operating Modes in which channel-dedicated sample-and-hold circuits can be used

Channel-dedicated sample-and-hold circuit is only available in Single Scan mode. Cannot be used in Continuous Scan mode.

(2) Restrictions on Self-Calibration Operation of Channel-dedicated sample-and-hold circuit

Self-Calibration operation is required when Channel-dedicated sample-and-hold circuit is used. For more details on Self-Calibration procedures for Channel-dedicated sample-and-hold circuit and the restrictions on it, refer to section 36.3.6. Self-Calibration.

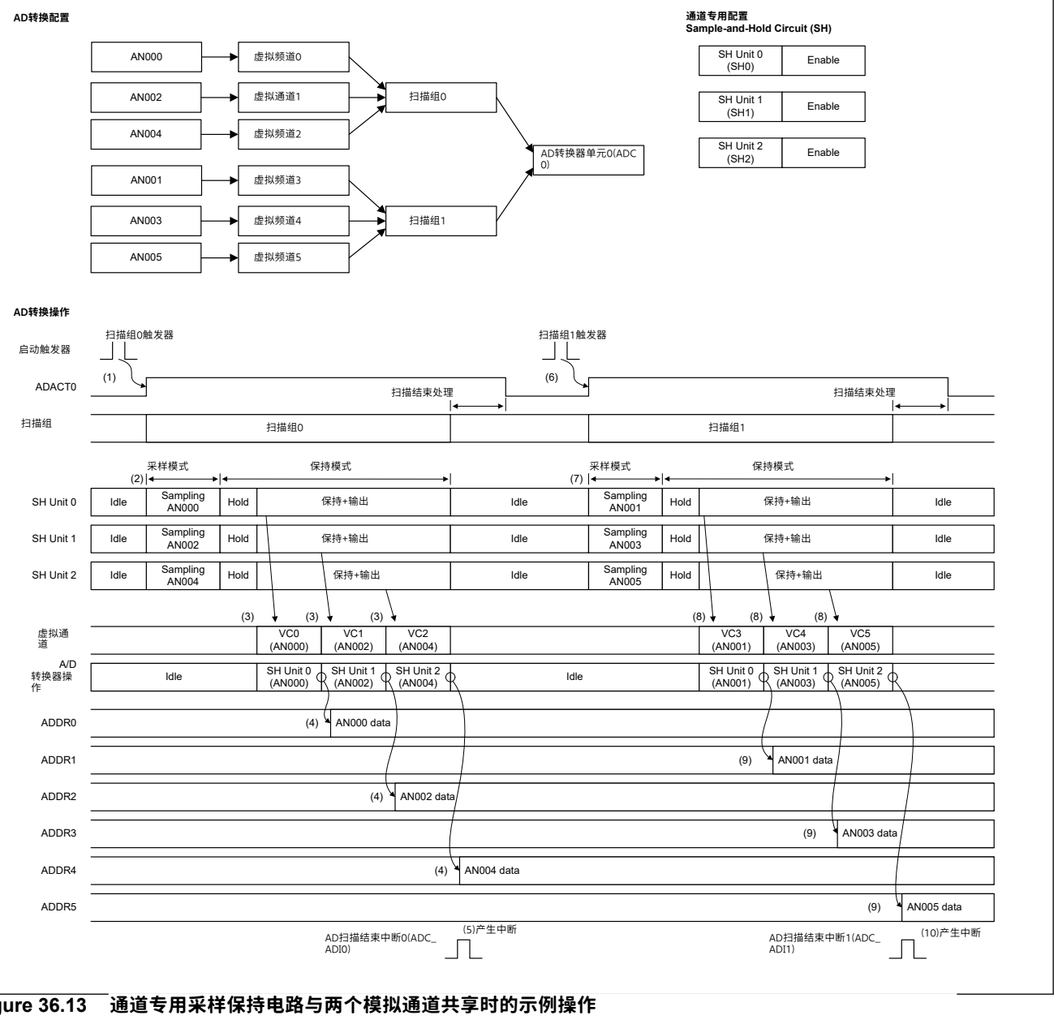

Figure 36.13 通道专用采样保持电路与两个模拟通道共享时的示例操作

36.3.14.3 通道专用采样保持电路的限制

使用通道专用采样保持电路时，请遵守以下限制：

(1) 可以使用通道专用采样保持电路的工作模式

通道专用的采样保持电路仅在单次扫描模式下可用。不能在连续扫描模式下使用。

(2) 通道专用采样保持电路自校准操作的限制

当使用通道专用的采样保持电路时，需要进行自校准操作。有关自我的更多详细信息
通道专用采样保持电路的校准程序及其限制，请参阅第36.3.6节。自己
Calibration.

(3) Restrictions on assigning Virtual Channels and Scan Groups

For analog channels using Channel-dedicated sample-and-hold circuit, assign them to virtual channels so that A/D conversion is performed at the front of the scan group. Specifically, assign an analog channel that uses Channel-dedicated sample-and-hold circuit from the virtual channel that has the smallest virtual channel number among the virtual channels assigned to that scan group. (Assign the analog channels of Channel-dedicated sample-and-hold circuit to the front virtual channels in ascending order of the virtual channel number.)

If this restriction is violated, the operation of Channel-dedicated sample-and-hold circuit and A/D converter is not guaranteed.

(4) Restrictions on analog paths when using Channel-dedicated sample-and-hold circuit

When Channel-dedicated sample-and-hold circuit is enabled, both the even analog channels and the odd-numbered analog channels connected to Channel-dedicated sample-and-hold circuit are performed the A/D conversion with Channel-dedicated sample-and-hold circuit. A/D conversion cannot be performed by bypassing Channel-dedicated sample-and-hold circuit for only one of the analog channels.

Refer also the next restriction related to this restriction.

(5) Prohibition of multiple assignments of Channels Using the Same Channel-dedicated sample-and-hold circuit in the same scan group

It is prohibited to assign more than one virtual channel that uses the same Channel-dedicated sample-and-hold circuit to a single scan group. Specific restrictions are the followings:

[Restrictions]

- The virtual channel whose signal source is selected as the even analog channel connected to Channel-dedicated Sample-and-Hold Circuit and the virtual channel whose signal source is selected as the odd-numbered analog channel must not be assigned to the same scan group.
- It is prohibited to assign the even analog channels or odd-numbered analog channels connected to Channel-dedicated Sample-and-Hold Circuit to multiple virtual channels, and assign them to the same scan group.

Operation is not guaranteed if this restriction is violated.

To avoid this restriction, assign virtual channels that use the same Channel-dedicated Sample-and-Hold Circuit to separate scan groups. This restriction can be avoided by preventing A/D conversion from occurring more than once for the same Channel-dedicated Sample-and-Hold Circuit during one scanning operation.

(6) Restrictions on Group Priority Operation

Channel-dedicated Sample-and-Hold Circuit is not available in Group Priority Operation.

36.3.15 Disconnection Detection Assist Function

Disconnection Detection Assist Function is the function that fixes the charges of the sampling capacitance of the A/D converter to a specified condition prior to starting A/D conversion. This function can be used to detect the wiring disconnection connected to analog input.

Figure 36.14 shows an example operation of A/D conversion when Disconnection Detection Assist Function is used. Figure 36.15 shows an example of the disconnection detection when precharge is selected, and Figure 36.16 shows an example of the disconnection detection when discharge is selected.

(3) 分配虚拟通道和扫描组的限制

对于使用通道专用采样保持电路的模拟通道，将它们分配给虚拟通道，以便在扫描组的前面执行AD转换。具体而言，从分配给该扫描组的虚拟通道中虚拟通道编号最小的虚拟通道分配一个使用通道专用采样保持电路的模拟通道。（将通道专用采样保持电路的模拟通道按虚拟通道编号的升序分配到前面的虚拟通道。）

如果违反此限制，则不能保证通道专用采样保持电路和AD转换器的操作。

(4) 使用通道专用采样保持电路时对模拟路径的限制

当通道专用采样保持电路使能时，连接到通道专用采样保持电路的偶数模拟通道和奇数模拟通道都与通道专用采样保持电路进行模数转换。仅对一个模拟通道绕过通道专用的采样保持电路，无法执行D转换。

另请参阅与此限制相关的下一个限制。

(5) 禁止在同一扫描组中使用同一通道专用采样和保持电路的多个通道分配

禁止将使用同一通道专用采样保持电路的多个虚拟通道分配给单个扫描组。具体限制如下：

[Restrictions]

●信号源选择为偶数模拟通道连接到通道专用采样保持电路的虚拟通道和信号源选择为奇数模拟通道的虚拟通道不能分配到同一个扫描组。

●禁止将连接到通道专用采样保持电路的偶数模拟通道或奇数模拟通道分配给多个虚拟通道，并将它们分配到同一个扫描组中。

如果违反此限制，则无法保证操作。

为避免此限制，请将使用相同通道专用采样保持电路的虚拟通道分配给单独的扫描组。可以通过防止在一次扫描操作期间为同一通道专用采样保持电路多次发生AD转换来避免这种限制。

(6) 群组优先操作限制

通道专用的采样保持电路在组优先操作中不可用。

36.3.15 断线检测辅助功能

断线检测辅助功能是在开始AD转换之前将AD转换器的采样电容的电荷固定到指定条件的功能。此功能可用于检测连接到模拟输入的接线断开。

图36.14显示了使用断线检测辅助功能时AD转换的示例操作。图36.15显示了选择预充电时的断线检测示例，图36.16显示了选择放电时的断线检测示例。

36.3.16 Group Priority Operation

The priority of scan groups is group 0 > group 1 > … > group 8.

Table 36.12 shows the conditions when Group Priority Operation can be used and the corresponding register settings. Set the operation according to Table 36.12.

36.3.16.1 Group Priority Operation in Single Scan mode

In Group Priority Operation in Single Scan mode, the single scanning operation is performed for a scan group according to the scan group's priority.

If an A/D conversion start trigger for the high priority group is input during a scanning operation of the low priority group, the scanning operation of the low priority group is interrupted, and the scanning operation of the high priority group is started. After the scanning operation of the high priority group is completed, the scanning operation of the low priority group is resumed.

When an A/D conversion start trigger of the low priority group during a scanning operation of the high priority group is input, the scanning operation of the low priority group is performed after the scanning operation of the high priority group is completed.

Example of the Group Priority Operation in Single Scan mode

Table 36.13 and Figure 36.17 show the example of Group Priority Operation in Single Scan mode when analog channel 0 (AN000) is assigned to scan group 0 (high priority) and analog channel 1 to 3 (AN001 to AN003) are assigned to scan group 1 (low priority).

Table 36.13 Example of the Group Priority Operation in Single Scan mode (2 Groups)

Step	Operation
1	The scanning operation of scan group 1 starts when a trigger for scan group 1 is input.
2	When A/D conversion of each channel in scan group 1 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
3	If a trigger for scan group 0 is input during A/D conversion for scan group 1, the scanning operation of scan group 1 is suspended and the scanning operation of scan group 0 is started. *1
4	When A/D conversion of each channel in scan group 0 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
5	If Scan End Interrupt in scan group 0 is set to enabled, an Scan End Interrupt occurs.
6	The scanning operation of scan group 1 is resumed after scanning of scan group 0 is completed. The scanning operation is resumed from the A/D conversion incomplete channel. *1
7	When A/D conversion of each channel in scan group 1 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
8	If Scan End Interrupt for scan group 1 is set to enable, an Scan End Interrupt occurs.
9	When all scanning operations are completed, ADSR.ADACTm (m = 0, 1) bits are cleared and the A/D converter enters the standby status.

Note 1. The timing of interruption and restart of scanning operation depends on the operating conditions. For more details, refer to section 36.3.16.3. Restrictions on Group Priority Operation.

36.3.16.1 单次扫描模式下的组优先操作

在单次扫描模式下的组优先操作中，根据扫描组的优先级对一个扫描组执行单次扫描操作。

如果在低优先级组的扫描操作期间输入高优先级组的AD转换开始触发，则低优先级组的扫描操作被中断，并且高优先级组的扫描操作开始。高优先级组的扫描操作完成后，重新开始低优先级组的扫描操作。

当在高优先级组的扫描操作期间输入低优先级组的AD转换开始触发时，在高优先级组的扫描操作完成之后执行低优先级组的扫描操作。

单次扫描模式下的组优先操作示例

表36.13和图36.17显示了当模拟通道0(AN000)分配给扫描组0（高优先级）并且模拟通道1到3（AN001到AN003）分配给扫描组1时，单次扫描模式下的组优先级操作示例（低优先级）。

2	当扫描组1中各通道的A/D转换完成后，A/D转换结果存入对应的A/D数据寄存器n(ADDRn)。
3	如果在扫描组1的AD转换期间输入了扫描组0的触发信号，则扫描组1的扫描操作暂停，扫描组0的扫描操作开始。*1
4	当扫描组0中各通道的AD转换完成后，AD转换结果存入对应的AD数据寄存器n(ADDRn)。
5	如果扫描组0中的扫描结束中断设置为启用，则会发生扫描结束中断。
6	扫描组0的扫描完成后，扫描组1的扫描操作将恢复。扫描操作从AD转换未完成通道重新开始。*1
7	当扫描组1中各通道的A/D转换完成后，A/D转换结果存入对应的A/D数据寄存器n(ADDRn)。
8	如果扫描组1的扫描结束中断设置为启用，则会发生扫描结束中断。
9	当所有扫描操作完成后，ADSR.ADACTm(m=0 1)位被清零，AD转换器进入待机状态。

注1.扫描操作的中断和重新启动时间取决于操作条件。有关详细信息，请参阅第36.3.16.3节。限制组优先操作。

36.3.16.2 Group Priority Operation in Continuous Scan mode

In Group Priority Operation in Continuous Scan mode, the continuous scanning operation is performed for the scan group (continuous-scan group) in which scanning operation was first started. If an A/D conversion start trigger of another scan group (interrupt-scan group) is input during the continuous scanning operation of the continuous-scan group, the following operations are performed according to the priority of the interrupt-scan group.

1. Priority: When Interrupt-scan group (high) > Continuous-scan group (low)
   - The scanning operation of the continuous-scan group is interrupted, and the single scanning operation of the interrupt-scan group is started.
   - The continuous scanning operation of the continuous-scan group is restarted after the single scanning operation of the interrupt-scan group is completed.
2. Priority: When Continuous-scan group (high) > Interrupt-scan group (low)
   - This operation is prohibited. Operation is not guaranteed.

   In case 1. above, if an A/D conversion start trigger for another scan group (interrupt-scan group B) is input during the single scanning operation of the interrupt-scan group (interrupt-scan group A), the following operation is performed according to the priority of interrupt-scan group B.
3. Priority: When Interrupt-scan group B (high) > Interrupt-scan group A (middle) > Continuous-scan group (low)

36.3.16.2 连续扫描模式下的组优先操作

在连续扫描模式下的组优先操作中，对首先开始扫描操作的扫描组（连续扫描组）执行连续扫描操作。如果在连续扫描组的连续扫描操作期间输入另一个扫描组（中断扫描组）的AD转换开始触发，则根据中断扫描组的优先级执行以下操作。

1.优先级：当中断扫描组（高）>连续扫描组（低）

- ●连续扫描组的扫描操作被中断，中断扫描组的单次扫描操作开始。
- ●连续扫描组的连续扫描操作在中断扫描组的单次扫描操作完成后重新开始。

2.优先级：当连续扫描组（高）>中断扫描组（低）

- ●禁止该操作。不保证操作。

在上述情况1.中，如果在中断扫描组（中断扫描组A）的单次扫描操作期间输入另一个扫描组（中断扫描组B）的AD转换开始触发，则根据以下操作执行以下操作中断扫描组B的优先级。

3.优先级：当中断扫描组B（高）>中断扫描组A（中）>连续扫描组（低）

- The single scanning operation of interrupt-scan group A is suspended, and the single scanning operation of interrupt-scan group B is started.
- After the single scanning operation of interrupt-scan group B is completed, the single scanning operation of interrupt-scan group A is resumed.
- After the scanning operation of interrupt-scan group A is completed, the continuous scanning operation of the continuous-scan group is resumed.

4. Priority: When interrupt-scan group A (high) > interrupt-scan group B (medium) > continuous-scan group (low)
   - After the single scanning operation of interrupt-scan group A is completed, the single scanning operation of interrupt-scan group B is started.
   - After the single scanning operation of interrupt-scan group B is completed, the continuous scanning operation of the continuous-scan group is resumed.
5. Priority: When interrupt-scan group A (high) > continuous-scan group (medium) > interrupt-scan group (low)
   - This operation is prohibited. Operation is not guaranteed.

Example operations are shown in the followings:

(1) Example of Two-group Priority Operation in Continuous Scan mode

36.3.16.3 Restrictions on Group Priority Operation

(1) Channel-dedicated sample-and-hold circuit Restrictions

Channel-dedicated sample-and-hold circuit is prohibited in Group Priority Operation.

(2) Restrictions on the operation mode and operation setting of the A/D converter

Group Priority Operation in Single Scan mode prohibits the use of three or more scan groups for a single A/D converter. In this case, the operation is not guaranteed.

When using three or more scan groups for one A/D converter in Group Priority Operation, use the A/D converter in Continuous Scan mode.

For more details, refer to Table 36.12.

Note: SG：扫描组VC：虚拟通道

Figure 36.19 组优先操作示例（连续扫描模式）（3组）

36.3.16.3 群组优先操作限制

(1) 通道专用采样保持电路限制

在组优先操作中禁止使用通道专用的采样保持电路。

(2) AD转换器的操作模式和操作设置的限制

单扫描模式下的组优先操作禁止对单个AD转换器使用三个或更多扫描组。在这种情况下，无法保证操作。

当在组优先操作中为一个AD转换器使用三个或更多扫描组时，在组优先操作中使用AD转换器连续扫描模式。

更多详细信息，请参见表36.12。

(3) Restrictions on Group Priority Operation in Continuous Scan mode

In Group Priority Operation in Continuous Scan mode, do not input A/D conversion start triggers for scan groups that have a lower priority than the scan group that started continuous scanning operation. If this restriction is violated, the operation is not guaranteed.

(4) Restrictions on Trigger Input for the Same Scan Group

Input the A/D converter start triggers for the same scan group in Group Priority Operation for the following periods.

[When Synchronous Operation is disabled (ADSYCR.ADSYDISm = 1)]

- 2 ADCLK + 2 PCLK cycles after the scan end flag is set *1

[When Synchronous Operation is enabled (ADSYCR.ADSYDISm = 0)]

- Synchronous Operation Period cycle × 2 after the scan end flag is set *1

Note: m = 0, 1

Note 1. ADSCANENDSR.SCANENDFn = 1 (n = 0 to 8)

If A/D conversion start triggers are input without waiting for the above period, the A/D conversion start triggers may be lost. To accept A/D conversion start triggers reliably, input triggers at the intervals described above.

(5) Restrictions on Suspend and Resume for Scanning operation of Low-Priority Groups

When an A/D conversion start trigger for the high priority group is input during scanning of the low priority group in Group Priority Operation, the scanning operation of the low priority group is interrupted at the timing shown in the following:

[Scan interruption timing of low priority group]

- When Synchronous Operation is enabled
  - After the A/D converter start trigger of the high-priority group is accepted, the scanning operation of the low-priority group is suspended after waiting until the next Synchronous Operation Period timing.
- When Synchronous Operation is disabled
  - The scanning operation of the low-priority group is immediately suspended after the A/D conversion start trigger of the high-priority group is accepted.

If A/D conversion is being performed on channels for which A/D-Converted Value Addition/Averaging Function is to be used at the timing of scan interruption of a low-priority group, the midway result of A/D-converted value addition/average value at that time is discarded. When the scanning operation of the low-priority group is resumed, A/D conversion is performed again for the number of times specified by A/D-Converted Value Addition/Averaging Function from the beginning.

If the scanning operation is suspended by Group Priority Operation, ADGRSR.ACTGRn (n = 0 to 8) bit of the scanning group remains set to 1.

36.3.17 Synchronous Operation

Synchronous Operation is the function that controls the operations of multiple A/D converters so that they are synchronized.

36.3.17.1 Synchronous Operation Examples

(1) Basic Synchronous Operation

The basic operation of Synchronous Operation is shown in the following.

[Operation example]

- A/D converter Unit 0 (ADC0)
  - Single Scan mode
  - Assign analog channel 0 to 2 (AN000 to AN002) to scan group 0 and perform A/D conversion. (each analog channel allocates virtual channel 0 to 2)

(3) 连续扫描模式下组优先操作的限制

在连续扫描模式下的组优先操作中，对于优先级低于开始连续扫描操作的扫描组的扫描组，不要输入AD转换开始触发。如果违反此限制，则无法保证操作。

(4) 同一扫描组的触发输入限制

在以下时段中，在GroupPriorityOperation中输入同一扫描组的AD转换器启动触发器。

[禁用同步操作时(ADSYCR.ADSYDISm=1)]

●设置扫描结束标志后的2个ADCLK+2个PCLK周期*1

[启用同步操作时(ADSYCR.ADSYDISm=0)]

●设置扫描结束标志后的同步操作周期周期×2*1

Note: m = 0, 1

注1.ADSCANENDSR.SCANENDFn=1（n=0到8）

如果在未等待上述时间的情况下输入AD转换启动触发器，则可能会丢失AD转换启动触发器。要可靠地接受AD转换开始触发，请按上述间隔输入触发。

(5) 低优先级组扫描操作暂停和恢复的限制

在Group中的低优先级组扫描期间输入高优先级组的AD转换启动触发时PriorityOperation，低优先级组的扫描操作在如下所示的时序被中断：

[低优先级组的扫描中断时机]

●启用同步操作时

高优先级组的AD转换器启动触发被接受后，低优先级组的扫描操作在等待下一个SynchronousOperationPeriod时序后暂停。

●当同步操作被禁用时

在接受高优先级组的AD转换开始触发后，立即暂停低优先级组的扫描操作。

如果在低优先级组的扫描中断时对要使用AD转换值相加平均功能的通道执行AD转换，则此时的AD转换值相加平均值的中间结果被丢弃。当低优先级组的扫描操作重新开始时，AD转换从头开始重新执行AD-ConvertedValueAdditionAveragingFunction指定的次数。

如果扫描操作被GroupPriorityOperation暂停，扫描组的ADGRSR.ACTGRn（n=0到8）位保持设置为1。

36.4.1 Internal data processing flow

Figure 36.22 shows the internal processing-flow of A/D conversion data.

The A/D conversion data output from the A/D converter is temporarily stored in the data buffer. At this time, A/D conversion data is bit-extended to 16-bit length data for subsequent data processing. (12-bit length data is shifted left by 4 bits and extended to 16-bit length data.) And then, various data processing is performed based on the register setting. If the function that corresponds to each data processing is not used, its data processing is skipped.

本节介绍AD转换数据的内部处理。关于AD转换的操作，请参阅36.3节。手术。

36.4.1 内部数据处理流程

图36.22显示了AD转换数据的内部处理流程。

AD转换器输出的AD转换数据暂时存储在数据缓冲器中。此时，AD转换数据被位扩展为16位长度的数据，用于后续的数据处理。（12位长度数据左移4位，扩展为16位长度数据。）然后，根据寄存器设置执行各种数据处理。如果不使用每个数据处理对应的函数，则跳过其数据处理。

36.4.2 Calibration and Adjustment

In this process, the following processing is performed for the results output from the A/D converter.

1. Calibrate Gain Error and Offset Error
2. Adjust User's Gain
3. Adjust User's Offset

For details on each process, refer to the each item.

36.4.2 校准和调整

在此过程中，对从AD转换器输出的结果执行以下处理。

1.校准增益误差和偏移误差

2.调整用户增益

3.调整用户的偏移量

有关每个过程的详细信息，请参阅每个项目。

36.4.2.1 Gain Error and Offset Error Calibration

This process calibrates the A/D converter's Gain Error and Offset Error due to by chip-by-chip characteristic variations.

Calibration for the A/D converter's Gain Error and Offset Error is performed by calculation based on error data measured inside the ADC by Self-Calibration operation.

36.4.2.2 User's Gain Adjustment

User's Gain adjusting function multiplies the A/D conversion data by an arbitrary coefficient value.

The coefficient value of User's Gain is set in ADUGTRn.UGAIN[23:0] (n = 0 to 7). User's Gain can be set for each virtual channel. The User's Gain Table to be used is selected in ADDOPCRAm.GAINSEL[3:0] (m = 0 to 36). The coefficient value of User's Gain is the sum of the gain corresponding to the bits that are set to 1 in ADUGTRn.UGAIN[23:0]. Table 36.16 shows the gain factors corresponding to the respective bits in ADUGTRn.UGAIN[23:0]. An example of setting User's Gain is shown in Table 36.17. Figure 36.23 shows the relationship between before adjustment (input) and after adjustment (output) to the A/D conversion result when User's Gain adjustment function is used.

The overflow of A/D conversion data may occur when User's Gain adjusting function is used.

36.4.2.1 增益误差和失调误差校准

该过程校准因芯片特性变化而导致的AD转换器的增益误差和偏移误差。

AD转换器的增益误差和失调误差的校准是根据通过自校准操作在ADC内部测量的误差数据进行计算的。

36.4.2.2 用户增益调整

用户的增益调整功能将AD转换数据乘以任意系数值。

用户增益的系数值在ADUGTRn.UGAIN[23:0]（n=0到7）中设置。可以为每个虚拟通道设置用户增益。要使用的用户增益表在ADDOPCRAm.GAINSEL[3:0]（m=0到36）中选择。用户增益的系数值是ADUGTRn.UGAIN[23:0]中设置为1的位对应的增益之和。表36.16显示了对应于ADUGTRn.UGAIN[23:0]中各个位的增益因子。设置用户增益的示例如表36.17所示。图36.23显示了使用用户增益调整功能时调整前（输入）和调整后（输出）与AD转换结果的关系。

使用用户增益调整功能时，可能会出现AD转换数据溢出。

36.4.2.3 User's Offset Adjustment

User's Offset adjustment function adds or subtracts any constant value to or from the A/D conversion data.

The constant value of User's Offset is set in ADUOFTRn.UOFSET[15:0] (n = 0 to 7). User's Offset can be set for each virtual channel. User's Offset Table to be used is selected in ADDOPCRAm.OFSETSEL[3:0] (m = 0 to 36). Table 36.18 shows the relationship between the register setting value of User's Offset and the offset value. Figure 36.24 shows the relationship between before adjustment (input) and after adjustment (output) to the A/D conversion result when User's Offset adjustment function is used.

36.4.2.3 用户偏移调整

用户的偏移调整功能可以在AD转换数据中添加或减去任何常数值。

用户偏移的常数值在ADUOFTRn.UOFSET[15:0]中设置（n=0到7）。可以为每个虚拟通道设置用户偏移量。要使用的用户偏移表在ADDOPCRAm.OFSETSEL[3:0]（m=0到36）中选择。表36.18显示了用户偏移的寄存器设置值和偏移值之间的关系。图36.24显示了使用User'sOffset调整功能时调整前（输入）和调整后（输出）与AD转换结果的关系。

使用User'sOffset调整功能时，可能会发生AD转换数据溢出。

36.4.3 A/D-Converted Value Addition/Average Function

A/D-Converted Value Addition Function and A/D-Converted Value Averaging Function perform A/D conversion on analog channels continuously for the specified number of times, and calculates the total or the average value of the A/D conversion data.

The A/D-converted value addition/averaging function can be set for each virtual channel in ADDOPCRBn.AVEMD[1:0] (n = 0 to 36) and ADDOPCRBn.ADC[3:0] (n = 0 to 36). When A/D-converted value addition/averaging function is used, the A/D converter repeats A/D conversion of the target analog channels continuously for the specified number of times. After A/D conversion of the number of times specified in ADDOPCRBn.ADC[3:0] bits is completed, the calculated result of the total value or average value is output.

Note: When the A/D-converted value addition/average function is used, overflow of the A/D conversion data may occur. However, in certain conditions, A/D conversion data overflow may not be detected. For details about A/D conversion data overflow, refer to section 36.6.2. A/D conversion overflow.

36.4.4 Limiter Clip Function

Limiter Clip Function is the function to set the upper and lower limits of A/D conversion data. When the A/D conversion data exceeds the specified upper limit value, it is clipped to the upper limit value. If the A/D conversion data falls below the specified lower limit, it is clipped to the lower limit value. Figure 36.25 shows an example of Limiter Clip Function operation.

The upper and lower limits of Limiter Clip Function can be specified in ADLIMTRn.LIMU[15:0] (n = 0 to 7) and ADLIMTRn.LIML[15:0] (n = 0 to 7). The Limiter Clip Function can be selected use or not (enable or disable) for each virtual channel in ADDOPCRCm.LIMTBLS[3:0] (m = 0 to 36).

Limiter Clip Function is processed by 16-bit length. When 14-/12-/10-bit is selected as the data length of the A/D conversion data (when ADDIOCRCm.ADPRC[1:0] = 01b, 10b, or 11b), the rounding to the specified data length is performed after the clipping by Limiter Clip Function. For more details, refer to section 36.4.5. Data Formatting process.

For Limiter Clip Function, the upper limit value should be greater than the lower limit value (ADLIMTRn.LIMU[15:0] > ADLIMTRn.LIML[15:0] (n = 0 to 7)). When the upper limit value is less than or equal to the lower limit value, the A/D conversion data is always 0x0000.

If a limiter clip occurs, the flags are set in the following status registers:

- ADLIMGRSR: The flag is set to the bit corresponding to the scan group where the limiter clip occurred.
- ADLIMCHSR0: If a limiter clip occurs during A/D conversion of an analog input channel, the flag is set to the corresponding bit.
- ADLIMEXSR: If a limiter clip occurs during A/D conversion of Extended Analog Function, the flag is set to the corresponding bit.

36.4.3 一个D转换的增值平均函数

D-ConvertedValueAdditionFunction和AD-ConvertedValueAveragingFunction在模拟通道上连续执行AD转换指定次数，并计算AD转换数据的总和或平均值。

可以在ADDOPCRBn.AVEMD[1:0]（n=0到36）和ADDOPCRBn.ADC[3:0]（n=0到36）中为每个虚拟通道设置AD转换值加法平均功能。使用AD转换值加法平均功能时，AD转换器连续重复目标模拟通道的AD转换指定次数。完成ADDOPCRBn.ADC[3:0]位中指定次数的AD转换后，输出总值或平均值的计算结果。

Note: 使用AD转换值加法平均功能时，可能会发生AD转换数据溢出。
但是，在某些情况下，可能无法检测到AD转换数据溢出。关于AD转换数据溢出的详细内容，请参阅36.6.2节。AD转换溢出。

36.4.4 限制器剪辑功能

限制器剪辑功能是设置AD转换数据的上限和下限的功能。当AD转换数据超过指定的上限值时，将被剪裁到上限值。如果AD转换数据低于指定的下限，则将其裁剪为下限值。图36.25显示了限制器削波功能操作的示例。

限制器削波功能的上限和下限可以在ADLIMTRn.LIMU[15:0]（n=0到7）中指定，并且ADLIMTRN.LIML[15:0]（n=0到7）。可以为ADDOPCRCm.LIMTBLS[3:0](m=0到36)中的每个虚拟通道选择使用或不使用限制器剪辑功能（启用或禁用）。

限制器剪辑功能按16位长度处理。When14-12-10-bitisselectedasthedatalengthoftheADconversiondata(whenADDIOCRCm.ADPRC[1:0]=01b 10b or11b) theroundingtothespecifieddatalengthisperformedaftertheclipping通过限制器剪辑功能。有关详细信息，请参阅第36.4.5节。数据格式化过程。

对于限制器削波功能，上限值应大于下限值(ADLIMTRn.LIMU[15:0]>ADLIMTRn.LIML[15:0](n=0to7))。当上限值小于或等于下限值时，AD转换数据始终为0x0000。

如果发生限制器剪辑，则在以下状态寄存器中设置标志：

- ADLIMGRSR：该标志设置为与发生限制器剪辑的扫描组对应的位。
- ADLIMCHSR0：如果在模拟输入通道的AD转换过程中出现限幅器削波，则将该标志设置为相应的位。
- ADLIMEXSR：如果在扩展模拟功能的AD转换过程中出现限幅器削波，则将该标志设置为相应的位。

To clear the flags in the status registers, write 1 to the corresponding bit in ADLIMGRSCR, ADLIMCHSCR0, ADLIMEXSCR.

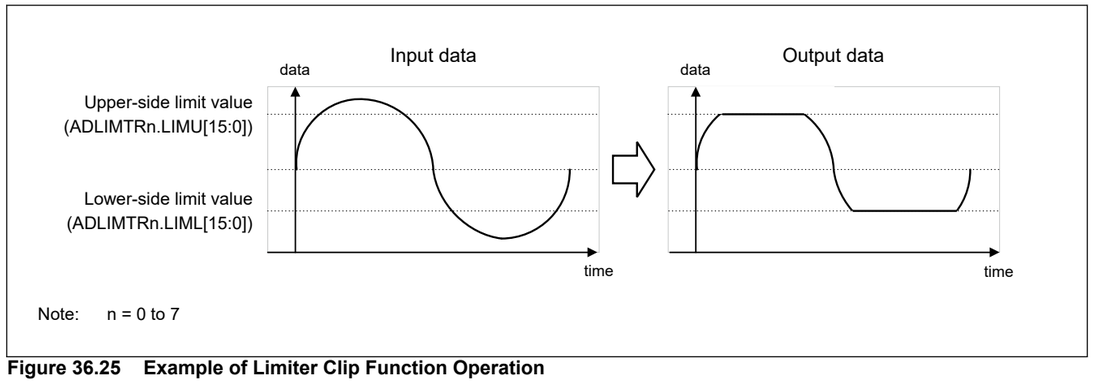

Figure 36.25 Example of Limiter Clip Function Operation

36.4.5 Data Formatting process

This process rounds and formats the A/D conversion data to the specified data format. The data processed in this process is stored to DATA[15:0] bits in A/D data register (ADDRi (i = 0 to 28)), Extended A/D data register (ADEXDRj (j = 0 to 2, 5 to 8)), and FIFO data register (ADFIFODRk (k = 0 to 8)) as the A/D conversion results.

Rounding and formatting of A/D conversion data is performed as the following based on ADDOPCRCn.ADPRC[1:0] (n = 0 to 36) bits setting.

- When 14-/12-/10-bit data format is selected (ADPRC[1:0] = 01b, 10b, 11b)
  - The lower bits are cut based on ADDOPCRCn.ADPRC[1:0] setting.
  - The most significant bit of the digit to be cut is rounded. (round down if 0, round up if 1)
- When 16-bit format is selected (ADPRC[1:0] = 00b)
  - Data length is not rounded.

For more details about the data format that has been processed by this process, refer to section 36.4.6. Data Format.

36.4.6 Data Format

The data format of the A/D conversion result stored to DATA[15:0] bits in A/D data register (ADDRi (i = 0 to 28)), Extended A/D data register (ADEXDRj (j = 0 to 2, 5 to 8)), and FIFO data register (ADFIFODRk (k = 0 to 8)) is described in the following.

Note: The A/D converter in ADC is the 12-bit A/D converter. When 16-bit or 14-bit data format is selected, the lower 4 bits or lower 2 bits of the A/D conversion result are extended bits for data processing. These bits are bit-extended and used internally for error calibration (Self-Calibration) of the A/D converter, User's Gain/offset adjusting function, and A/D-Converted Value Averaging Function.

Even if 16-bit or 14-bit data format is selected, the resolution and accuracy of the A/D converter is not guaranteed.

(1) 16-bits data length format

Table 36.19 shows the alignment of A/D conversion data on 16-bit data format. Figure 36.26 shows the data range for 16-bit data format.

For 16-bit data format, the analog input-voltage (VREFL0 to VREFH0) is A/D-converted within 0x0000 to 0xFFFF.

要清除状态寄存器中的标志，请将1写入ADLIMGRSCR、ADLIMCHSCR0、ADLIMEXSCR.

36.4.5 数据格式化过程

此过程将AD转换数据四舍五入并格式化为指定的数据格式。此过程中处理的数据存储到AD数据寄存器(ADDRi(i=0to28))、扩展AD数据寄存器(AdexDRj(j=0to2 5to8))中的DATA[15:0]位，和FIFO数据寄存器(AFIFODRk(k=0to8))作为AD转换结果。

基于ADDOPCRCn.ADPRC[1:0]（n=0到36）位设置，AD转换数据的舍入和格式化如下所示。

●选择14-12-10位数据格式（ADPRC[1：0]=01B，10B，11B）

根据ADDOPCRCn.ADPRC[1:0]设置切割低位。

要剪切的数字的最高位被四舍五入。（0向下取整，1向上取整）

●选择16位格式时(ADPRC[1:0]=00b)

数据长度未四舍五入。

关于该进程处理的数据格式的更多详细信息，请参见第36.4.6节。数据格式。

36.4.6 数据格式

AD转换结果的数据格式存储到AD数据寄存器(ADDRi(i=0to28))中的DATA[15:0]位，
扩展AD数据寄存器(ATEXDRj(j=0to2 5to8))和FIFO数据寄存器(AFIFODDRk(k=0to8))描述如下。

Note: ADC中的AD转换器是12位AD转换器。When16-bitor14-bitdataformatisselected thelower4bitsorlower2bitsoftheADconversionresultareextendedbitsfordataprocessing.这些位经过位扩展并在内部用于AD转换器的误差校准（自校准）、用户增益偏移调整功能和AD转换值平均功能。

即使选择16位或14位数据格式，也不能保证AD转换器的分辨率和精度。

36.4.7 Compare Match Function

36.4.7.1 Compare match

The compare match function compares the A/D conversion result with the reference value set in the compare match table register (ADCMPTBRn (n = 0 to 7). The compare match function compares the A/D conversion data after the data formatting process.

(1) Compare match mode

The comparison mode for detecting the compare match is selected in ADCMPMDRm.CMPMDn[1:0] (m = 0, 1. n = 0 to 7). The comparison mode can be selected from the following four modes.

1. Compare match is detected when the A/D conversion value is greater than or equal to the specified upper limit value.
2. Compare match is detected when the A/D conversion value is less than or equal to the specified lower limit.
3. Compare match is detected when the A/D conversion value is greater than or equal to the specified upper limit value, or less than or equal to the lower limit value.
4. Compare match is detected when the A/D conversion value is within the specified upper and lower limit values (when the value is lower than or equal to the upper limit value and greater than or equal to the lower limit value).

Figure 36.30 shows an example of compare match detection.

36.4.7 比较匹配函数

36.4.7.1 比较匹配

比较匹配功能将AD转换结果与比较匹配表寄存器(ADCMPTBRn(n=0to7))中设置的参考值进行比较。比较匹配 功能将经过数据格式化处理后的AD转换数据进行比较。

(1) 比较匹配模式

检测比较匹配的比较模式在ADCMPMDRm.CMPMDn[1:0](m=0 1.n=0to7)中选择。
比较模式可以从以下四种模式中选择。

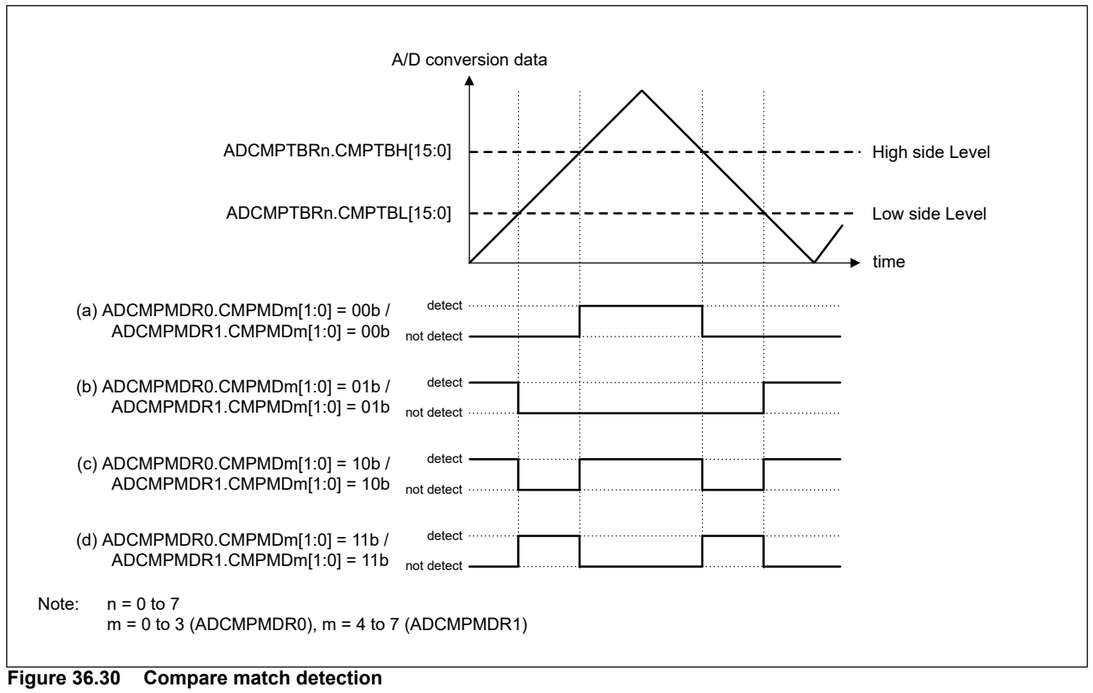
1.当AD转换值大于或等于指定的上限值时，检测到比较匹配。

2.当AD转换值小于或等于指定的下限时，检测到比较匹配。

3.当AD转换值大于或等于指定的上限值或小于或等于下限值时，检测到比较匹配。

4.当AD转换值在指定的上下限值范围内（小于等于上限值且大于等于下限值）时，检测到比较匹配。

图36.30显示了比较匹配检测的示例。



Note: n = 0 to 7
m = 0 to 3 (ADCMPMDR0), m = 4 to 7 (ADCMPMDR1)

Figure 36.30 Compare match detection

(2) Compare match detection

To use the compare match function, enable the compare match table used in ADCMPENR register, and select the compare match table in ADDOPCRBn.CMPTBLEm (n = 0 to 36, m = 0 to 7) for each virtual channel.

When A/D conversion is performed on a virtual channel for which the compare match function is enabled, a compare match is judged based on the A/D conversion result of its channel.

When a compare match is detected, the flags are set in the following status registers:

- ADCMPTBSR: The flag is set to the bit corresponding to the compare match table used when a compare match is detected.
- ADCMPCHSR0: The flag is set to the bit corresponding to the analog input channel that detected the compare match.
- ADCMPEXSR: The flag is set to the bit corresponding to Extended Analog Function where a compare match is detected.

To clear the flag of each status register, write 1 to the corresponding bit of ADCMPTBSCR, ADCMPCHSCR0, ADCMPEXSCR.

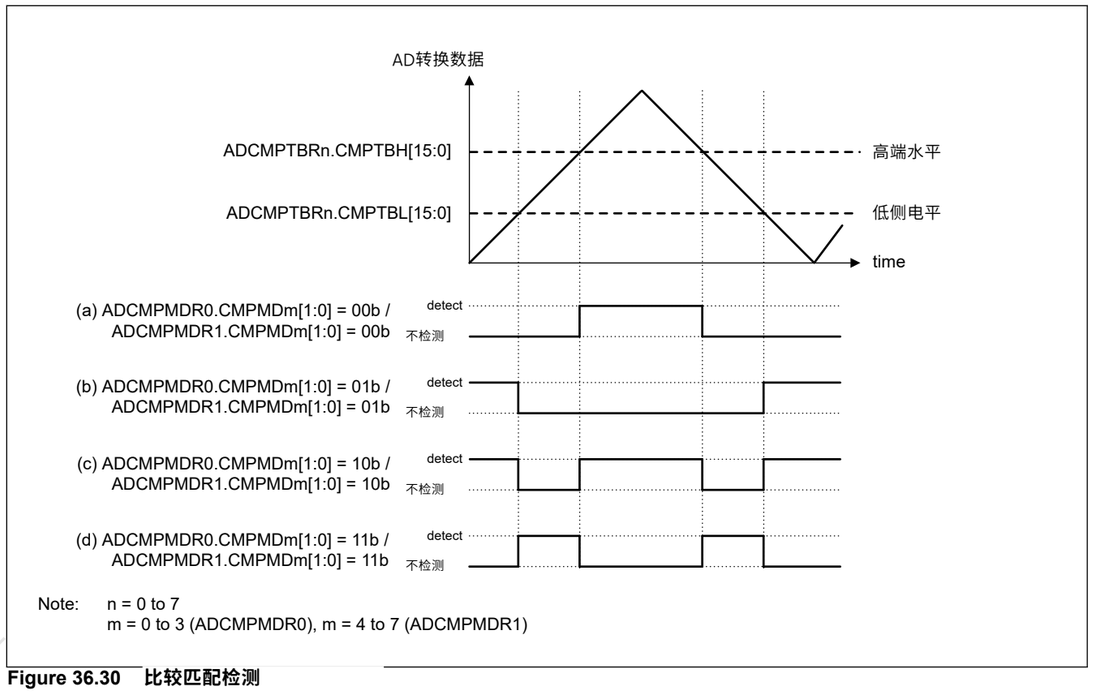
If Compare Match interrupt is enabled in ADCMPINTCR register and a compare match using compare match table 0 to 3 is detected, the corresponding interrupt is generated. Check the compare match of compare match table 4 to 7 in ADCMPTBSR register.

36.4.7.2 Composite Compare Match

The composite compare match function generates interrupts and ELC events by combining the comparison results of multiple compare match tables. The combination and condition of the compare match table for the composite compare match function is set in ADCCMPCR0 or ADCCMPCR1.

Composite Compare Match interrupt is generated when a compare match is detected that matches the specified condition.

Figure 36.31 shows the relationship between composite compare match and compare match function. Table 36.23 shows the relationship between the composite compare match function and the control register.



Note: n = 0 to 7
m = 0 to 3 (ADCMPMDR0), m = 4 to 7 (ADCMPMDR1)

Figure 36.30 比较匹配检测

(2) 比较匹配检测

要使用比较匹配功能，请启用ADCMPENR寄存器中使用的比较匹配表，并在ADDOPCRBn.CMPTBLEm（n=0到36，m=0到7）中为每个虚拟通道选择比较匹配表。

当对启用了比较匹配功能的虚拟通道进行AD转换时，将根据其通道的AD转换结果判断比较匹配。

当检测到比较匹配时，会在以下状态寄存器中设置标志：

●ADCMPTBSR：该标志设置为与检测到比较匹配时使用的比较匹配表对应的位。

●ADCMPCHSR0：该标志设置为与检测到比较匹配的模拟输入通道对应的位。

●ADCMPEXSR：该标志设置为与检测到比较匹配的扩展模拟功能对应的位。

要清除每个状态寄存器的标志，将1写入ADCMPTBSCR的相应位ADCMPCHSCR0，ADCMPEXSCR.

如果在ADCMPINTCR寄存器中使能了比较匹配中断，并且检测到使用比较匹配表0到3的比较匹配，则产生相应的中断。检查ADCMPTBSR寄存器中比较匹配表4到7的比较匹配。

36.4.7.2 复合比较匹配

复合比较匹配功能通过组合多个比较匹配表的比较结果来生成中断和ELC事件。复合比较匹配功能的比较匹配表的组合和条件在ADCCMPCR0或ADCCMPCR1中设置。

当检测到与指定条件匹配的比较匹配时，将产生复合比较匹配中断。

图36.31显示了复合比较匹配和比较匹配函数之间的关系。表36.23显示了复合比较匹配函数和控制寄存器之间的关系。

36.4.8 Data Registers

A/D data register (ADDRi (i = 0 to 28)) and Extended A/D data register (ADEXDRj (j = 0 to 2, 5 to 8)) store the A/D conversion data of the analog channels corresponding to each register. These registers are updated (overwritten) when A/D conversion for the analog channel corresponding to each register is completed.

36.4.9 FIFO Function

FIFO consists of 8-stage registers and can hold up to 8 A/D conversion data. One FIFO is implemented for each scan group. The A/D conversion data stored in FIFO can be read from ADFIFODRn register (n = 0 to 8).

FIFO acts as a ring buffer. Writing and reading A/D conversion data to and from FIFO is controlled by the write pointer and read pointer inside FIFO. The block diagram of FIFO is shown in Figure 36.32.

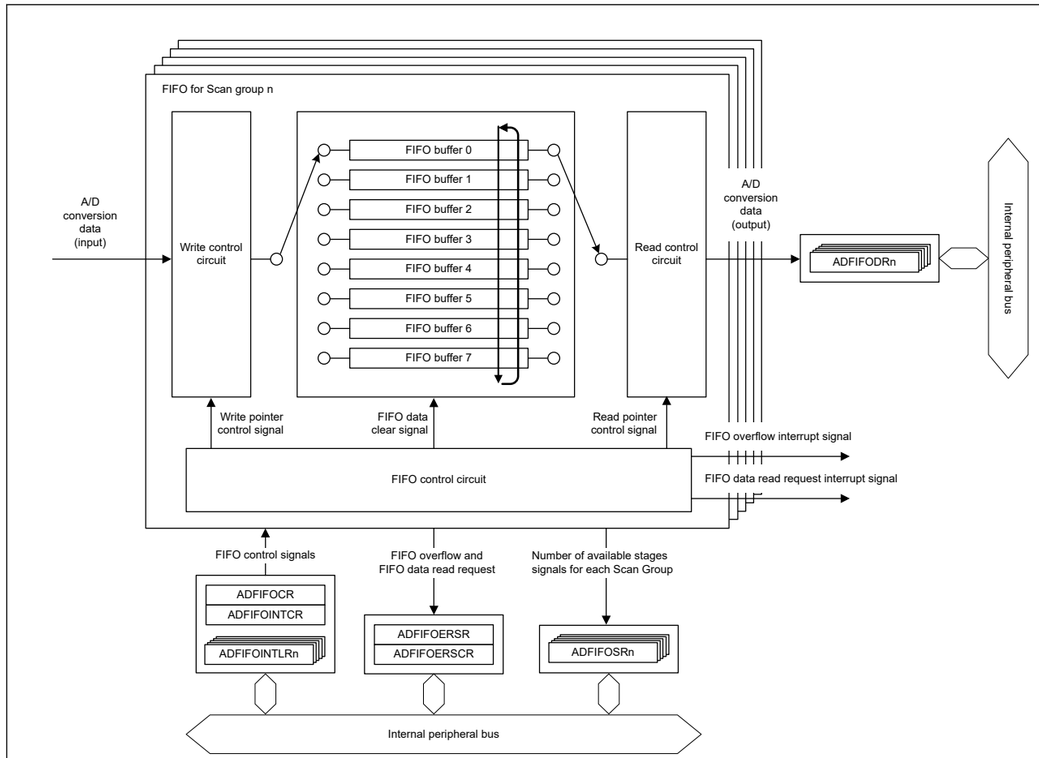
36.4.8 数据寄存器

AD数据寄存器(ADDRi(i=0到28))和扩展AD数据寄存器(ADXDRj(j=0到2 5到8))存储每个寄存器对应的模拟通道的AD转换数据。当每个寄存器对应的模拟通道的AD转换完成时，这些寄存器将被更新（覆盖）。

36.4.9 FIFO Function

FIFO由8级寄存器组成，最多可保存8个AD转换数据。每个扫描组实现一个FIFO。
存储在FIFO中的AD转换数据可以从ADFIFODRn寄存器（n=0到8）中读取。

FIFO充当环形缓冲区。向FIFO写入和读取AD转换数据由FIFO内部的写指针和读指针控制。FIFO的框图如图36.32所示。



Note: n = 0 to 8

Figure 36.32 The block diagram of FIFO

36.4.9.1 Operation when A/D conversion data is read from FIFO

The A/D conversion data is stored sequentially to the register pointed by the write pointer. When A/D conversion data is written to a register in FIFO, the write pointer is switched to the next register. (Write pointer value is increased 1). At this time, the number of available stages (ADFIFOSRm.FIFOSTn[3:0] (m = 0 to 4, n = 0 to 8) bits) is decreased 1.

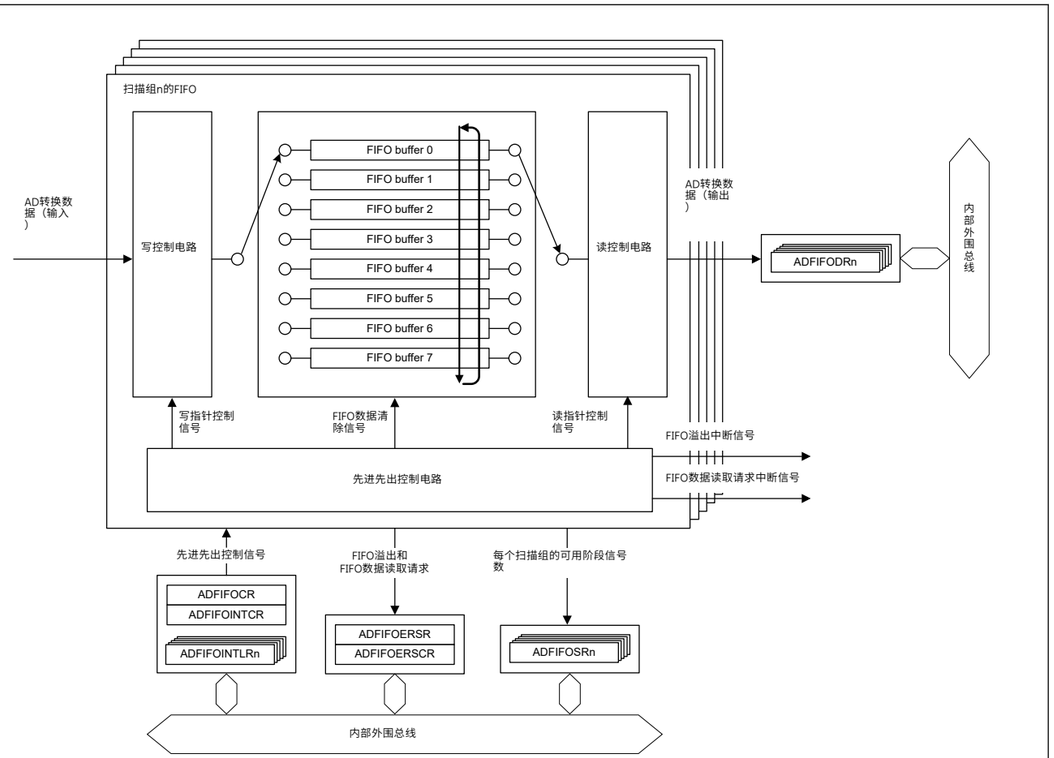
A FIFO overflow occurs when ADFIFOSRm.FIFOSTn[3:0] bits are 0000b and an additional A/D conversion data is written to FIFO. When a FIFO overflow occurs, the A/D converter data is not written and the write pointer does not change.

36.4.9.2 Operation when A/D conversion data is read from FIFO

When A/D conversion data is read from FIFO data register (ADFIFODRn (n = 0 to 8)), the data in the register pointed to by FIFO read pointer is read. When A/D conversion data is read from FIFO, the read pointer is switched to the next register (the read pointer is increased 1). At this time, the number of available stages in FIFO (ADFIFOSRm.FIFOSTn[3:0] (m = 0 to 4, n = 0 to 8) bits) is increased 1.

If FIFO is empty (ADFIFOSRm.FIFOSTn[3:0] bits are 1111b) and the reading from the FIFO is occurred, an invalid data is read. (If FIFO is read after a reset or after FIFO data is cleared, 0x00000000 is read. If data had been written to register in FIFO, the previous data is read.) In addition, the read pointer does not change in the read operation when FIFO is empty.

Read A/D conversion data from FIFO data register (ADFIFODRn) by 32-bit access. For more details, refer to section 36.4.9.5. Usage Notes on FIFO.



Note: n = 0 to 8

Figure 36.32 先进先出的框图

36.4.9.1 从FIFO读取AD转换数据时的操作

AD转换数据依次存储到写指针指向的寄存器中。当AD转换数据写入FIFO中的一个寄存器时，写指针切换到下一个寄存器。（写指针值增加1）。此时，可用级数（ADFIFOSRm.FIFOSTn[3:0]（m=0到4，n=0到8）位）减少1。

当ADFIFOSRm.FIFOSTn[3:0]位为0000b且额外的AD转换数据写入FIFO时，发生FIFO溢出。当发生FIFO溢出时，AD转换器数据不被写入，写指针也不改变。

36.4.9.2 从FIFO读取AD转换数据时的操作

当从FIFO数据寄存器(ADFIFODRn(n=0to8))读取AD转换数据时，寄存器中的数据由FIFO读指针被读取。当从FIFO中读取AD转换数据时，读指针切换到下一个寄存器（读指针加1）。此时，FIFO（ADFIFOSRm.FIFOSTn[3:0]（m=0到4，n=0到8）位）中的可用级数增加1。

如果FIFO为空（ADFIFOSRm.FIFOSTn[3:0]位为1111b）并且发生从FIFO的读取，则读取无效数据。（如果在复位或清除FIFO数据后读取FIFO，则读取0x00000000。如果数据已写入FIFO中的寄存器，则读取之前的数据。）此外，在读取操作时读取指针不会改变FIFO为空。

通过32位访问从FIFO数据寄存器(ADFIFODRn)读取AD转换数据。有关详细信息，请参阅第36.4.9.5节。关于FIFO的使用说明。

36.4.9.3 FIFO data read request and overflow

When A/D conversion data is written to or read from FIFO, the write pointer or read pointer changes. Depending on the state of the write pointer and the read pointer, the number of available stages in FIFO is reflected in ADFIFOSRm.FIFOSTn[3:0] (m = 0 to 4, n = 0 to 8).

FIFO data read request flag is set (ADFIFOERSR.FIFOFLFn = 1) when the number of available stages become less than or equal to the value specified in ADFIFOINTLRm.FIFOLVn[3:0] (m = 0 to 4, n = 0 to 8) bit. If a FIFO data read request occurs, FIFO data read request interrupt can be generated.

When FIFO is full (ADFIFOSRm.FIFOSTn[3:0] bits are 0000b) and additional A/D converter data are written, FIFO overflow error flag is set (ADFIFOERSROOEOOVFn = 1). If a FIFO overflow occurs, FIFO data overflow interrupt can be generated.

36.4.9.4 Clearing FIFO data

The data stored in the registers in FIFO can be cleared by writing to ADFIFODCR.FIFODCn (n = 0 to 8) bit. When writing 1 to ADFIFODCR.FIFODCn bit, the registers, read pointer, and write pointer in FIFO of the scan group corresponding to FIFODCn bit are initialized. Clearing FIFO data should be performed while A/D conversion is not being performed.

36.4.9.5 Usage Notes on FIFO

Reading the A/D conversion data from the FIFO data register (ADFIFODRn (n = 0 to 8)) should be performed with a single 32-bit access; access to each bit of ADFIFODRn, 16-bit read access, and 8-bit read access are prohibited.

Whenever a 32-bit read access is performed from the internal bus to ADFIFODRn, the FIFO reads out the data and changes the FIFO read pointer. If reading access to each bit of ADFIFODRn is performed, the read pointer may advance unintentionally, resulting in loss of A/D conversion data. Also, if 16-bit or 8-bit access is performed, the read pointer will not change and correct data may not be read.

36.4.10 A/D Conversion Data Error detection

The ERR bit in A/D data register (ADDRi (i = 0 to 28)), Extended A/D data register (ADEXDRj (j = 0 to 2, 5 to 8)), and FIFO data register (ADFIFODRk (k = 0 to 8)) is a flag that indicates an A/D conversion data error. An A/D conversion data error indicates that an invalid A/D conversion data has been detected. If an A/D conversion data error occurs (ERR = 1), the A/D conversion data cannot be guaranteed.

A/D conversion data error is generated by the following factors.

- A/D converter error
- A/D conversion overflow

For more details about these errors, refer to section 36.6. Error Detection.

36.5 Start and Stop control of A/D conversion

36.5.1 Software Trigger

A/D conversion of scan group n can be started by writing 1 to ADSTRn.ADST (n = 0 to 8) bit or ADSYSTR.ADSYSTn (n = 0 to 8) bit.

ADSTRn.ADST bit is used to start A/D conversion individually for each scan group. ADSYSTR.ADSYSTn bit is used to start A/D conversion on the scan group assigned to ADC0 or ADC1 at the same time.

Except when Group Priority Operation, if ADC0 or ADC1 is already performing A/D conversion operation for a scan group, writing to ADSTRn.ADST bit or ADSYSTR.ADSYSTn bit to an another scan group that uses that A/D converter is ignored.

36.5.2 Peripheral module Triggers

A/D conversion can be started by triggers from the peripheral modules listed in the followings.

- ELC Trigger
- GPT Trigger

36.4.9.3 FIFO数据读取请求和溢出

当AD转换数据写入FIFO或从FIFO读取时，写指针或读指针会发生变化。根据写指针和读指针的状态，FIFO中可用的级数反映在ADFIFOSRm.FIFOSTn[3:0]（m=0到4，n=0到8）中。

当可用阶段数小于或等于ADFIFOINTLRm.FIFOLVn[3:0]（m=0到4，n=0到8）中指定的值时，设置FIFO数据读取请求标志(ADFIFOERSR.FIFOFLFn=1)）少量。如果发生FIFO数据读取请求，则会产生FIFO数据读取请求中断。

当FIFO已满（ADFIFOSRm.FIFOSTn[3:0]位为0000b）并写入额外的AD转换器数据时，设置FIFO溢出错误标志（ADFIFOERSROOEOOVFn=1）。如果发生FIFO溢出，会产生FIFO数据溢出中断。

36.4.9.4 清除FIFO数据

FIFO寄存器中存储的数据可以通过写入ADFIFODCR.FIFODCn(n=0to8)位来清除。当向ADFIFODCR.FIFODCn位写入1时，初始化FIFODCn位对应的扫描组的FIFO中的寄存器、读指针和写指针。未执行AD转换时应执行清除FIFO数据。

36.4.9.5 先进先出的使用说明

从FIFO数据寄存器(AFIFODRn(n=0to8))读取AD转换数据应使用单个32位访问；禁止访问ADFIFODRn的每一位、16位读访问和8位读访问。

每当从内部总线对AFIFODRn执行32位读取访问时，FIFO都会读取数据并更改FIFO读取指针。如果对ADFIFODDRn的每一位进行读访问，读指针可能会意外前进，导致AD转换数据丢失。此外，如果执行16位或8位访问，则读指针不会改变，并且可能无法读取正确的数据。

36.4.10 AD转换数据错误检测

AD数据寄存器(ADDRi(i=0to28))、扩展AD数据寄存器(AdexDRj(j=0to2 5to8))中的ERR位，以及FIFO数据寄存器(ADFIFODRk(k=0to8))是指示AD转换数据错误的标志。AD转换数据错误表示检测到无效的AD转换数据。如果发生AD转换数据错误(ERR=1)，则无法保证AD转换数据。

D转换数据错误由以下因素产生。

- ●AD转换器错误
- ●AD转换溢出

有关这些错误的更多详细信息，请参阅第36.6节。错误检测。

36.5 AD转换的启动和停止控制

36.5.1 软件触发

可以通过将1写入ADSTRn.ADST（n=0到8）位或ADSYSTR.ADSYSTn（n=0到8）位来启动扫描组n的D转换。

ADSTRn.ADST位用于为每个扫描组单独启动AD转换。ADSYSTR.ADSYSTn位用于同时启动分配给ADC0或ADC1的扫描组的AD转换。

除组优先操作外，如果ADC0或ADC1已经对一个扫描组执行AD转换操作，则忽略向另一个使用该AD转换器的扫描组写入ADSTRn.ADST位或ADSYSTR.ADSYSTn位。

36.5.2 外设模块触发器

D转换可以通过来自下列外围模块的触发器来启动。

- ELC Trigger
- GPT Trigger

- External Trigger (I/O port)

To perform A/D conversion by a trigger from a peripheral module, configure the trigger for each scan group and enable the trigger input from the peripheral module in ADTRGENR register.

36.5.2.1 ELC Trigger

A/D conversion can be started by an event (ELC event) from Event Link Controller. To start A/D conversion using an ELC event, configure the scan group using the ELC event in ADTRGELCn (n = 0 to 8) register and enable the A/D conversion start trigger in ADTRGENR register. Table 36.24 shows the correspondence between ADTRGELCn register and ELC event.

36.5.2.2 GPT Trigger

A/D conversion can be started by an interrupt source from the general-purpose PWM Timer (GPT). To start A/D conversion using an interrupt source from the GPT, configure the scan group using the GPT interrupt source in ADTRGGPTn (n = 0 to 8) register and enable the A/D conversion start trigger in ADTRGENR register. Table 36.25 shows the correspondence between ADTRGGPTn register and GPT interrupt sources.

●外部触发（IO端口）

要通过来自外设模块的触发执行AD转换，请为每个扫描组配置触发，并在ADTRGENR寄存器中启用来自外设模块的触发输入。

36.5.2.1 ELC Trigger

D转换可以通过来自EventLinkController的事件（ELC事件）启动。要使用ELC事件启动AD转换，请使用ADTRGELCn(n=0至8)寄存器中的ELC事件配置扫描组，并在ADTRGENR寄存器中启用AD转换启动触发器。ADTRGELCn寄存器与ELC事件的对应关系如表36.24所示。

36.5.2.2 GPT Trigger

D转换可由通用PWM定时器(GPT)的中断源启动。要使用来自GPT的中断源启动AD转换，请使用ADTRGGPTn(n=0至8)寄存器中的GPT中断源配置扫描组，并在ADTRGENR寄存器中启用AD转换启动触发器。ADTRGGPTn寄存器与GPT中断源的对应关系如表36.25所示。

36.5.2.3 External Trigger

A/D conversion can be started by the input from the external trigger pin (ADTRG0 and ADTRG1). To start A/D conversion using an external trigger, configure the scan group using the external trigger in ADTRGEXTn (n = 0 to 8) register and enable the A/D conversion start trigger in ADTRGENR register.

External trigger is active low. Therefore, before using an external trigger (ADTRG0 and ADTRG1), configure the I/O port and input the High level to the external trigger pin.

36.5.3 Trigger Delay

The trigger delay function adds a delay to the A/D conversion start trigger in order to adjust the A/D conversion start timing for each scan group. This function adds a delay to the internal trigger for each scan group generated by accepting an external trigger, ELC trigger or GPT trigger. This function cannot be used to add a delay to a software trigger.

The delay value to be added to the internal trigger is set for each scan group in ADTRGDLRi (i = 0 to 4) register. The delay value to be added is the register setting value × A/D Conversion clock (ADCLK) cycle.

36.5.4 Force stops the A/D conversion operation

The scanning operation of the A/D converter can be forcibly stopped by writing 1 to ADSTOPR.ADSTOPm (m = 0, 1) bit during scanning operation. If the scanning operation is forcibly stopped, the A/D conversion data is not guaranteed.

36.5.4.1 Forced stop procedure

Table 36.26 shows the procedure for forced stop of A/D conversion operation. Observe Table 36.26 when performing the forced stop. If this procedure is violated, the A/D converter may not be able to stop and then it may not operate normally. In that case, a reset is required for recovery.

Table 36.26 Procedure for Forced Stop of A/D conversion operation

No.	Step Name	Description
1	Disable trigger input	Disables the trigger input from the peripheral module. (Write ADTRGENR.STTRGENn = 0)
2	Waiting time	After setting the above Step 1, a wait time is required to safely stop the A/D converter. Proceed to the next processing after the specified waiting time has elapsed. For details on the wait time, refer to section 36.5.4.2. Waiting time after disabling trigger input for forced stop processing.
3	Checking the A/D converter status	Check if the A/D converter is operating after the waiting time of the above Step 2 has elapsed. If the A/D converter is running (ADSR.ADACTm = 1), proceed to Step 4. If the A/D converter is stopped (ADSR.ADACTm = 0), no further processing is required (proceed to Step 6).
4	Forced stop of A/D converter	Forcibly stop the A/D converter by ADSTOPR register. *1 (Write ADSTOPR.ADSTOPm = 1)
5	Waiting for A/D converter to stop	Wait until the A/D converter stops. (ADSR.ADACTm = 0)
6	End	Processing of forced stop is completed.

Note: m = 0, 1, n = 0 to 8
Do not write to ADSYSTR register or ADSTRn register while this forced stop procedure is in progress.
Note 1. Forced stopping during Self-Calibration operation is prohibited. For more details, refer to section 36.3.6. Self-Calibration.

36.5.4.2 Waiting time after disabling trigger input for forced stop processing

In the forced stop procedure shown in Table 36.26, after disabling the trigger input from the peripheral module, a wait time is required to perform the forced stop (Step 2 of Table 36.26). This wait time is the time that must be secured to perform a forced stop safely.

电阻位	活动名称
ADTRGGPTn.TRGGPTB9	GPT9_ADTRGB

Note: n = 0 to 8

36.5.2.3 外部触发

通过来自外部触发引脚（ADTRG0和ADTRG1）的输入可以启动D转换。要使用外部触发启动AD转换，请使用ADTRGEXTn(n=0至8)寄存器中的外部触发配置扫描组，并在ADTRGENR寄存器中启用AD转换启动触发。

外部触发低电平有效。因此，在使用外部触发（ADTRG0和ADTRG1）之前，配置IO端口并将高电平输入到外部触发引脚。

36.5.3 触发延迟

触发延迟功能将延迟添加到AD转换开始触发，以便调整每个扫描组的AD转换开始时序。此功能为通过接受外部触发、ELC触发或GPT触发而生成的每个扫描组的内部触发添加延迟。此功能不能用于向软件触发添加延迟。

在ADTRGDLRi(i=0to4)寄存器中为每个扫描组设置要添加到内部触发的延迟值。要添加的延迟值是寄存器设置值×AD转换时钟(ADCLK)周期。

36.5.4 强制停止AD转换操作

在扫描操作期间，通过向ADSTOPR.ADSTOPm(m=0 1)位写入1可以强制停止AD转换器的扫描操作。如果强制停止扫描操作，则无法保证AD转换数据。

36.5.4.1 强制停止程序

表36.26显示了AD转换操作的强制停止程序。执行强制停止时请遵守表36.26。如果违反此程序，AD转换器可能无法停止，然后可能无法正常运行。在这种情况下，需要重置以进行恢复。

Table 36.26 强制停止AD转换操作的步骤

No.	步骤名称	Description
1	禁用触发输入	禁用来自外围模块的触发输入。（写ADTRGENR.STTRGENn=0）
2	等待的时间	设置上述步骤1后，需要等待一段时间才能安全停止AD转换器。经过指定的等待时间后，继续进行下一个处理。有关等待时间的详细信息，请参阅第36.5.4.2节。 强制停止处理禁用触发输入后的等待时间。
3	检查AD转换器状态	在经过上述步骤2的等待时间后，检查AD转换器是否正在运行。如果AD转换器正在运行（ADSR.ADACTm=1），则继续执行步骤4。如果AD转换器停止（ADSR.ADACTm=0），则不需要进一步处理（继续执行步骤6）。
4	AD转换器的强制停止	通过ADSTOPR寄存器强制停止AD转换器。*1 (Write ADSTOPR.ADSTOPm = 1)
5	等待AD转换器停止	等到AD转换器停止。(ADSR.ADACTm=0)
6	End	强制停止处理完成。

Note: m=0 1 n=0到8在此强制停止过程正在进行时不要写入ADSYSTR寄存器或ADSTRn寄存器。

注1.自校准操作期间禁止强制停止。有关详细信息，请参阅第36.3.6节。自校准。

36.5.4.2 强制停止处理的触发输入无效后的等待时间

在表36.26所示的强制停止过程中，在禁用来自外围模块的触发输入后，执行强制停止需要等待时间（表36.26的步骤2）。该等待时间是必须确保安全执行强制停止的时间。

The wait time after disabling the trigger input for forced stop processing is calculated as follows.

[Waiting time after disabling trigger input in forced stop processing]

- When Synchronous Operation is enabled (ADSYCR.ADSYDISm = 0)
  - (ADTRGDLRi.TRGDLYn[7:0] setting value + ADSYCR.ADCSYCYC[10:0] setting value × 2) × t_{ADCLK}
- When Synchronous Operation is disabled (ADSYCR.ADSYDISm = 1)
  - (4 + ADTRGDLRi.TRGDLYn[7:0] setting value) × t_{ADCLK}

Note: i = 0 to 4, n = 0 to 8, m = 0, 1 t_{ADCLK}: ADCLK period

Proceed to the Step 3 process in Table 36.26after the waiting time calculated by the above expressions has elapsed using various timer functions, etc. When the above-mentioned wait time is generated without using the timer function, a wait time can also be generated by reading the status register, etc. multiple times. The number of register reads required is expressed by the following equation:

[Wait time generating by register read]

N_{RD} = (Wait time after disabling trigger input ÷ (t_{PCLK} × N_{RDCYC})) + 1

N_{RD}: Number of register reads required to generate the trigger input disable wait time (truncate after the decimal point)

t_{PCLK}: The period of the Bus I/F clock (PCLKA)

N_{RDCYC}: Minimum number of register read access cycles

For more details, refer to section Appendix 3, I/O Registers.

36.6 Error Detection

36.6.1 A/D converter error

An A/D converter error is detected when an abnormal operation of the A/D converter occurs. If an A/D converter error is detected, the A/D conversion result is not guaranteed.

An A/D converter error occurs in the following cases: However, depending on the operating state of the device, an A/D converter error may not be detected even under the following conditions.

[A/D Converter Error Generation Conditions]

- When A/D conversion is performed without Self-calibration.
- When the operating frequency of ADCLK exceeds the guaranteed operating frequency specified in the electric characteristics.
- When the successive approximation time of the A/D converter exceeds the guaranteed operating range specified in the electric characteristics.
- When an accidental abnormal operation occurs in the A/D converter due to external factors.

If an A/D converter error is detected, the flag is set in ADERSR.ADERFn (n = 0, 1) bit. To clear the A/D converter error flag, write 1 to the corresponding bit in ADERSCR register.

Notes on A/D Converter Error

The A/D converter error is an auxiliary function used to detect abnormal operation of the A/D converter. It does not guarantee reliable operation error detection or normal operation. Even under the A/D converter error occurrence conditions described above, an A/D converter error may not be detected depending on the operating status of the device.

36.6.2 A/D conversion overflow

A/D conversion overflow is detected when A/D conversion data exceeds the range that can be handled in the specified data format. When A/D conversion overflow occurs, the A/D conversion data at that time becomes the upper or lower limit value of the specified data format. For the range that can be handled as A/D conversion data, refer to section 36.4.6. Data Format.

A/D conversion overflow is detected in the following cases:

强制停止处理的触发输入无效后的等待时间计算如下。

[强制停止处理中触发输入无效后的等待时间]

●启用同步操作时(ADSYCR.ADSYDISm=0)

(ADTRGDLRi.TRGDLYn[7:0]设置值+ADSYCR.ADCSYCYC[10:0]设置值×2)×tADCLK

●禁用同步操作时(ADSYCR.ADSYDISm=1)

- (4 + ADTRGDLRi.TRGDLYn[7:0] setting value) × t_{ADCLK}

Note: i=0到4 n=0到8 m=0 1tADCLK:ADCLK周期

使用各种计时器函数等，在通过上述表达式计算的等待时间过去后，继续执行表36.26中的步骤3处理。当不使用计时器函数生成上述等待时间时，也可以通过以下方式生成等待时间多次读取状态寄存器等。所需的寄存器读取次数由以下等式表示：

[通过寄存器读取产生的等待时间]

NRD=(禁用触发输入后的等待时间÷(tPCLK×NRDCYC))+1

NRD：生成触发输入禁用等待时间所需的寄存器读取次数（小数点后截断）

tPCLK:总线IF时钟(PCLKA)的周期

NRDCYC:寄存器读取访问周期的最小数量

有关详细信息，请参阅附录3，IO寄存器部分。

36.6 错误检测

36.6.1 AD转换器错误

当AD转换器发生异常操作时，检测到AD转换器错误。如果检测到AD转换器错误，则无法保证AD转换结果。

在以下情况下会发生AD转换器错误：但是，根据设备的操作状态，即使在以下情况下也可能无法检测到AD转换器错误。

[AD转换器错误产生条件]

●在没有自校准的情况下进行AD转换时。

●ADCLK的工作频率超过电气特性中规定的保证工作频率时。

●AD转换器的逐次逼近时间超过电气特性中规定的保证工作范围时。

●当AD转换器由于外部因素发生意外异常操作时。

如果检测到AD转换器错误，则在ADERSR.ADERFn(n=0 1)位中设置该标志。要清除AD转换器错误标志，将1写入ADERSCR寄存器中的相应位。

AD转换器错误的注意事项

AD转换器错误是用于检测AD转换器异常操作的辅助功能。它不保证可靠的操作错误检测或正常操作。即使在上述AD转换器错误发生条件下，根据设备的操作状态，也可能无法检测到AD转换器错误。

36.6.2 AD转换溢出

当AD转换数据超出指定数据格式可以处理的范围时，将检测到D转换溢出。当发生AD转换溢出时，此时的AD转换数据变为指定数据格式的上限值或下限值。关于可作为AD转换数据处理的范围，请参阅36.4.6项。数据格式。

在以下情况下会检测到D转换溢出：

- When the input to the A/D converter exceeds VREFH0 or falls below VREFL0
- When overflow occurs by the internal processing (calculation) for the A/D conversion data shown in the following:
  - Gain Error and Offset Error Calibration
  - User's Gain/User's Offset adjustment function
  - When using A/D-Converted Value Addition/Averaging Function
  - Data Formatting Process

When an A/D conversion overflow is detected, the flag is set in the following status register:

- ADOVFERSR: The flag is set to the bit corresponding to the A/D converter that detected the A/D conversion overflow.
- ADOVFCHSR0: The flag is set to the bit corresponding to the analog input channel on which A/D conversion overflow is detected.
- ADOVFEXSR: The flag is set to the bit corresponding to the Extended Analog channel on which A/D conversion overflow is detected.

To clear the flags in the status registers, write 1 to the corresponding bit in ADOVFERSCR, ADOVFCHSCR0, ADOVFEXSCR.

Restrictions on A/D conversion overflow

When A/D-Converted Value Addition/Averaging Function is used, A/D conversion overflow is not detected under the following conditions.

- Leading channel of scan group
- Restart channel of the interrupted group in Group Priority Operation

To detect that the A/D conversion data is illegal under these conditions, use Limiter Clip Function or Compare match function.

36.6.3 FIFO overflow

If A/D-converted data is written (added) to FIFO while FIFO is full, a FIFO overflow is detected. For more details about FIFO overflow, refer to section 36.4.9. FIFO Function.

36.7 Procedure for setting up and changing

36.7.1 Initial setup procedure

Table 36.27 shows the initial setup procedure.

Table 36.27 Initial setup procedure (1 of 2)

No.	Step	Description

2	I/O port Configuration	Set ASEL bit of the pin used as analog input to 1.
3	Synchronous Operation Configuration	Set the Synchronous operation function. The synchronous operation function is enabled at the initial value of the register after reset release. If the synchronous operation function is not used, be sure to disable the synchronous operation function (ADSYCR.ADSYDISm = 1 (m = 0, 1)).
4	ADCLK Configuration	Set the clock source and division ratio for ADCLK. Then, set ADCLKENR.CKEN bit to 1, and wait for ADCLK to supply (ADCLKSR.CLKSR = 1).
5	A/D conversion configuration	Perform various settings for A/D conversion.
6	Wait for operation stabilization	Wait until the various operating stabilization times specified in the Electrical Characteristics have elapsed.

●当AD转换器的输入超过VREFH0或低于VREFL0时

●当AD转换数据的内部处理（计算）发生溢出时，如下所示：

增益误差和偏移误差校准

–用户增益用户偏移调整功能

使用D转换的增值平均功能时

数据格式化过程

当检测到AD转换溢出时，在以下状态寄存器中设置标志：

●ADOVFERSR：该标志设置为与检测到AD转换溢出的AD转换器对应的位。

●ADOVFCHSR0：该标志设置为与检测到AD转换溢出的模拟输入通道对应的位。

●ADOVFEXSR：该标志设置为与检测到AD转换溢出的扩展模拟通道对应的位。

要清除状态寄存器中的标志，请将1写入ADOVFERSCR、ADOVFCHSCR0、ADOVFEXSCR.

AD转换溢出的限制

使用AD转换值加法平均功能时，在以下条件下不会检测到AD转换溢出。

●扫描组主通道

●GroupPriorityOperation中中断组的重启通道

要在这些条件下检测AD转换数据是非法的，请使用限制器剪辑功能或比较匹配功能。

36.6.3 FIFO overflow

如果在FIFO已满时将AD转换数据写入（添加）到FIFO，则检测到FIFO溢出。有关更多详细信息FIFO溢出，请参阅第36.4.9节。先进先出功能。

(1) AD转换器错误中断

当检测到AD转换器错误时，可以生成D转换器错误中断。

当ADERINTCR.ADEIEm(m=0 1)位为1且
ADERSR.ADERFm(m=0 1)位为1。

(2) A/D Converter Self-Calibration End Interrupt

A/D converter Self-Calibration End interrupt can be generated at the end of A/D converter Self-Calibration operation.

A/D converter Self-Calibration End interrupt (ADC_CALENDm (m = 0, 1)) is generated when ADCALINTCR.CALENDIEm (m = 0, 1) bit is 1 and ADCALENDSR.CALENDFm (m = 0, 1) bit is 1.

(3) A/D scan End interrupt

A/D Scan End interrupt can be generated at the end of scanning operation of scan group n (n = 0 to 8).

A/D Scan End interrupt for scan group 0 to 4 (ADC_ADI0 to ADC_ADI4) are generated when ADINTCR.ADIEn (n = 0 to 4) bit is set to 1 and ADSCANENDSR.SCENDFn (n = 0 to 4) bit is set to 1.

A/D Scan End interrupt for scan group 5 to 8 (ADC_ADI5678) is generated when ADINTCR.ADIEn (n = 5 to 8) bit is set to 1 and ADSCANENDSR.SCENDFn (n = 5 to 8) bit is set to 1 is satisfied in any of the scan group 5 to 8.

However, A/D Scan End interrupt is not generated when A/D conversion operation (scanning operation) is forcibly stopped by ADSTOPR register.

(4) Limitter Clip interrupt

Limiter Clip interrupt (ADC_LIMCLPI) can be generated when a limiter clip with limiter table i (i = 0 to 7) is detected.

Limiter Clip interrupt is generated when either ADLIMINTCR.LIMIEi (i = 0 to 7) bit is 1 and ADLIMGRSR.LIMGRFi (i = 0 to 7) bit is 1 is satisfied.

(5) A/D Conversion Overflow interrupt

A/D Conversion Overflow interrupt can be generated when A/D Conversion overflow in the A/D conversion result using ADCm (m = 0, 1) is detected. For details about A/D Conversion overflow, refer to section 36.6.2. A/D conversion overflow.

A/D Conversion Overflow interrupt (ADC_RESOVFm (m = 0, 1)) is generated when ADOVFINTCR.ADOVFIEm (m = 0, 1) bit is 1 and ADOVFERSR.ADOVFEFm (m = 0, 1) bit is 1.

(6) Compare Match interrupt

Compare Match interrupt can be generated when a compare match is detected.

Compare Match interrupt (ADC_CMPIj (j = 0 to 3)) is generated when ADCMPINTCR.CMPIEj (j = 0 to 3) bit is 1 and ADCMPTBSR.CMPTBFj (j = 0 to 3) bit is 1.

There are no interrupts corresponding to the compare match tables 4 to 7.

(7) Composite Compare Match interrupt

Composite Compare Match interrupt (ADC_CCMPMk (k = 0, 1)) can be generated by combining the comparison results of two or more compare match tables. For details about composite compare match, refer to section 36.4.7.2. Composite Compare Match.

(8) FIFO data read request interrupt

FIFO data read request interrupt can be generated when the number of available stages in FIFO become less than or equal to the specified value.

FIFO data read request interrupt for scan group 0 to 4 (ADC_FIFOREQ0 to ADC_FIFOREQ4) are generated when ADFIFOINTCR.FIFOIEn (n = 0 to 4) is set to 1 and ADFIFOSRm.FIFOSTn[3:0] ≤ ADFIFOINTLRm.FIFOLVn[3:0] (m = 0 to 3, n = 0 to 4).

FIFO data read request interrupt for scan group 5 to 8 (ADC_FIFOREQ5678) are generated when the following condition is satisfied in any FIFO for scan group 5 to 8: ADFIFOINTCR.FIFOIEn (n = 5 to 8) is set to 1 and ADFIFOSRm.FIFOSTn[3:0] ≤ ADFIFOINTLRm.FIFOLVn[3:0] (m = 3 to 4, n = 5 to 8)

However, FIFO read request interrupt is not generated while the ADFIFOERSR.FIFOFLFn (n = 0 to 8) bit corresponding to its interrupt source is set to 1.

(9) FIFO data overflow interrupt

FIFO data overflow interrupt (ADC _FIFOOVF) can be generated when a FIFO overflow is detected in any of FIFO in scan groups 0 to 8.

(2) AD转换器自校准结束中断

AD转换器自校准结束中断可以在AD转换器自校准操作结束时产生。

D转换器自校准结束中断(ADC_CALENDm(m=0 1))在以下情况下产生
ADCALINTCR.CALENDIEm(m=0 1)位为1，ADCALENDSR.CALENDFm(m=0 1)位为1。

(3) AD扫描结束中断

在扫描组n（n=0到8）的扫描操作结束时可以产生D扫描结束中断。

当ADINTCR.ADIEn(n=0到4)位设置为1且ADSCANENDSR.SCENDFn(n=0到4)位设置为1时，将生成扫描组0到4（AD C_ADI0到ADC_ADI4）的D扫描结束中断。

当ADINTCR.ADIEn(n=5到8)位设置为1且ADSCANENDSR.SCENDFn(n=5到8)位设置为1时，将产生扫描组5到8(AD C_ADI5678)的D扫描结束中断扫描组5到8中的任何一个。

但是，当ADSTOPR寄存器强制停止AD转换操作（扫描操作）时，不会产生AD扫描结束中断。

(4) 限制器剪辑中断

当检测到带有限制器表i（i=0到7）的限制器剪辑时，可以生成限制器剪辑中断(ADC_LIMCLPI)。

当ADLIMINTCR.LIMIEi(i=0至7)位为1且ADLIMGRSR.LIMGRFi(i=0至7)位为1时，产生限制器剪辑中断。

(5) AD转换溢出中断

当AD转换结果中的AD转换溢出时，可以产生AD转换溢出中断
ADCm(m=0 1)被检测到。关于AD转换溢出的详细内容，请参阅36.6.2节。AD转换溢出。

当ADOVFINTCR.ADOVFIEm(m=0 1)位为1且ADOVFERSR.ADOVFEFm(m=0 1)位为1时，产生D转换溢出中断(ADC_ RESOVFm(m=0 1))。

(6) 比较匹配中断

当检测到比较匹配时，可以产生比较匹配中断。

当ADCMPINTCR.CMPIEj(j=0to3)位为1且
ADCMPTBSR.CMPTBFj(j=0到3)位为1。

没有对应于比较匹配表4到7的中断。

(7) 复合比较匹配中断

综合比较匹配中断(ADC_CCMPMk(k=0 1))可以通过组合两个或多个比较匹配表的比较结果来产生。有关复合比较匹配的详细信息，请参阅第36.4.7.2节。复合比较匹配。

(8) FIFO数据读取请求中断

当FIFO中的可用级数小于或等于指定值时，会产生FIFO数据读取请求中断。

扫描组0到4（ADC_FIFOREQ0到ADC_FIFOREQ4）的FIFO数据读取请求中断在以下情况下产生
ADFIFOINTCR.FIFOIEn（n=0到4）设置为1，并且ADFIFOSRm.FIFOSTn[3:0]≤ADFIFOINTLRm.FIFOLVn[3:0]（m=0到3，n=0到4）。

当扫描组5到8的任何FIFO满足以下条件时，将生成扫描组5到8的FIFO数据读取请求中断(ADC_FIFOREQ5678)：ADFIFOINTCR.FIFOIEn(n=5到8)设置为1且ADFIFOSRm.FIFOSTn[3:0]≤ADFIFOINTLRm.FIFOLVn[3:0]（m=3到4，n=5到8）

但是，当其中断源对应的ADFIFOERSR.FIFOFLFn(n=0至8)位设置为1时，不会产生FIFO读请求中断。

(9) FIFO数据溢出中断

当在扫描组0到8中的任何FIFO中检测到FIFO溢出时，可以生成FIFO数据溢出中断(ADC_FIFOOVF)。

FIFO data overflow interrupt is generated when ADFIFOINTCR.FIFOIEn (n = 0 to 8) bit is 1 and ADFIFOERSR.FIFOOVFn (n = 0 to 8) bit is 1.

36.10 Usage Notes

36.10.1 Prohibitation of changing the operation settings during A/D conversion operation

The registers related to the operation setting of the A/D converter should be set while all A/D converters are stopped (ADSR.ADACTm = 0 and ADSR.CALACTm = 0 (m = 0, 1)). Changing (writing) of registers except for those listed below is prohibited during A/D conversion. If the operation setting is changed during A/D conversion, operation is not guaranteed.

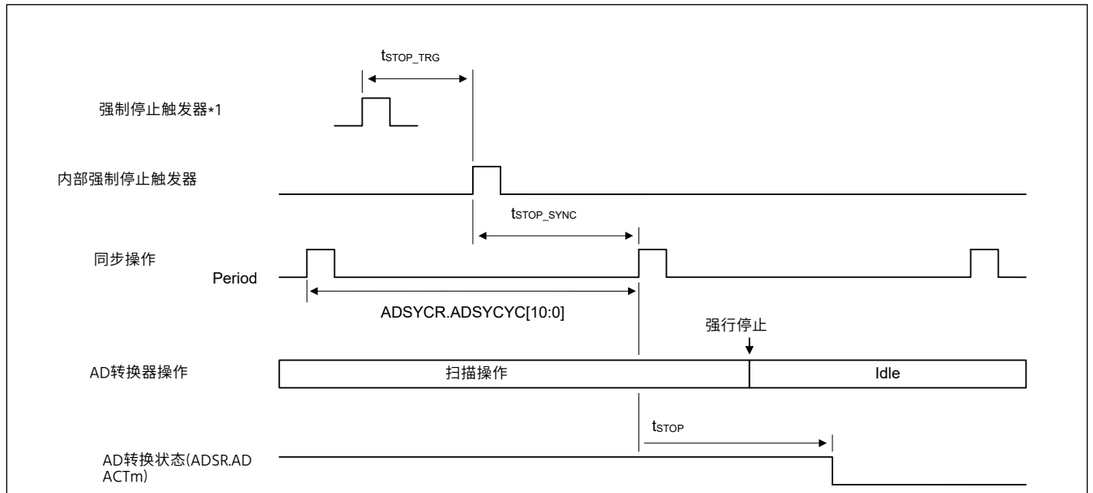
[Registers that can be written while the A/D converter is operating]

- Status Clear Registers
  - Status clear registers related to A/D converter operation (ADERSCR, ADCALSCR, ADCALENDSCR, ADSCANENDSCR)
  - A/D Conversion Overflow Status Clear Registers (ADOVFERSCR, ADOVFCHSCR0, ADOVFEXSCR)
  - Limiter Clip Status Clear Register (ADLIMGRSCR, ADLIMCHSCR0, ADLIMEXSCR)
  - Compare Match Status Clear Register (ADCMPTBSCR, ADCMPCHSCR0, ADCMPEXSCR)
  - FIFO Error Status Clear Register (ADFIFOERSCR)
- Software Trigger Register (ADSYSTR, ADSTRn (n = 0 to 8))
- A/D Converter Stop Register (ADSTOPR)
- A/D Converter Start Trigger Enable Register (ADTRGENR) *1

Note 1. Writing during operation is only permitted for disabling the trigger input (ADTRGENR.STTRGENn = 0 (n = 0 to 8)) in order to stop the A/D conversion. To avoid unintended operation, do not change the trigger input to Enable (ADTRGENR.STTRGENn = 1) during operation.

36.10.2 Usage Notes on Forced Stop of A/D Conversion

If you want to forcibly stop the A/D conversion operation, follow the procedure in section 36.5.4. Force stops the A/D conversion operation.



注1.它是通过写入ADSTOPR.ADSTROPm=1生成的。(m=0 1)

Figure 36.37 强制停止处理时间

36.10 使用说明

36.10.1 禁止在AD转换操作期间更改操作设置

与AD转换器的操作设置相关的寄存器应在所有AD转换器停止时设置（ADSR.ADACTm=0和ADSR.CALACTm=0(m=0 1)）。在AD转换过程中，禁止更改（写入）除以下列出的寄存器之外的寄存器。如果在AD转换期间更改操作设置，则无法保证操作。

[可以在AD转换器运行时写入的寄存器]

●状态清除寄存器

与AD转换器操作相关的状态清除寄存器
(ADERSCR, ADCALSCR, ADCALENDSCR, ADSCANENDSCR)

AD转换溢出状态清除寄存器
(ADOVFERSCR, ADOVFCHSCR0, ADOVFEXSCR)

限制器剪辑状态清除寄存器
(ADLIMGRSCR, ADLIMCHSCR0, ADLIMEXSCR)

比较匹配状态清除寄存器
(ADCMPTBSCR, ADCMPCHSCR0, ADCMPEXSCR)

FIFO错误状态清除寄存器(ADFIF OERSCR)

●软件触发寄存器(ADSYSTR ADSTRn(n=0to8))

●AD转换器停止寄存器(ADSTOPR)

●AD转换器启动触发使能寄存器(ADTRGENR)*1

注1.操作期间写入仅允许禁用触发输入(ADTRGENR.STTRGENn=0(n=0至8))以停止AD转换。为避免意外操作，请勿在操作期间将触发输入更改为启用(ADTRGENR.STTRGENn=1)。

36.10.2 强制停止AD转换的使用说明

如果要强制停止AD转换操作，请按照第36.5.4节中的步骤进行操作。强制停止AD转换操作。

36.10.3 Usage Notes on A/D data registers

When A/D conversion is performed multiple times on the same analog channel, A/D data register (ADDRn (n = 0 to 28) or A/D extended analog data register m (m = 0 to 2, 5 to 8) corresponding to that analog channel is overwritten at the later A/D conversion.

If you intend to keep the data for each A/D conversion for the same analog channel, perform one of the following methods.

- Read out data from registers at each scanning operation
  - At the end of scanning each scan group, read out the A/D conversion data of the analog channel that was subject to A/D conversion from ADDRn or ADEXDRm.
  - This method is effective if A/D conversion of the same analog channel is not performed more than once in the same scan group, and A/D conversion data can be read from the registers before the next scanning operation.
- Use FIFO function to hold data for each A/D conversion
  - By using FIFO, multiple A/D conversion data for the same analog channel can be kept.
  - Read out the A/D conversion data before FIFO overflow.

36.10.4 Settings for the Module-Stop Function

The Module Stop Control Register can enable or disable ADC operation. The ADC is initially stopped after a reset. The registers become accessible on release from the module-stop state.

Also refer to section 36.10.5. Restrictions on Entering and Releasing the Low-Power States in connection with this usage note.

36.10.5 Restrictions on Entering and Releasing the Low-Power States

Before entering the module-stop state or Software Standby mode, be sure to stop A/D conversion. In Addition, configure the A/D conversion not to start during the entering to the low power state.

To operate the A/D converter after the module-stop state or software standby mode is released, wait for the operation stabilization time specified in the Electrical Characteristics, execute Self-Calibration operation, and then start A/D conversion.

Also, when releasing the module-stop state again after entering to the module-stop state, make sure the shutdown time specified in the Electrical Characteristics has elapsed before releasing the module stop state.

Operations are not guaranteed if these restriction are violated.

36.10.6 Notes on board design

(1) Protection Circuit

To prevent the analog input pins from being destroyed by abnormal voltage such as excessive surge, take the following measures.

- Insert a capacitor between AVCC0 and AVSS0 and between VREFH0 and VREFL0.
- Connect a protection circuit to protect the analog input pins.

An example of a protection circuit is shown in Figure 36.38.

(2) Board design to ensure A/D conversion accuracy

In order to ensure the accuracy of A/D conversion, design the board considering the following:

- Analog circuits and digital circuits should be separated from each other as far as possible.
- Analog circuit signal lines and digital circuit signal lines should not intersect or be placed near each other.
- The analog input, analog reference power supply (VREFH0), analog reference ground (VREFL0), and analog power supply (AVCC0) should be separated from digital circuits using the analog ground (AVSS0).
- The analog ground (AVSS0) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

36.10.3 AD数据寄存器的使用注意事项

当对同一模拟通道进行多次AD转换时，对应于该模拟通道的AD数据寄存器(ADDRn(n=0到28)或AD扩展模拟数据寄存器m(m=0到2、5到8)将被覆盖在后来的AD转换。

如果您打算为同一模拟通道保留每次AD转换的数据，请执行以下方法之一。

●在每次扫描操作时从寄存器中读取数据

在每个扫描组扫描结束时，从ADDRn或ADXDRm中读出经过AD转换的模拟通道的AD转换数据。

此方法在同一扫描组中对同一模拟通道的AD转换不超过一次时有效，并且可以在下一次扫描操作之前从寄存器中读取AD转换数据。

●使用FIFO功能保存每次AD转换的数据

通过使用FIFO，可以保存同一模拟通道的多个AD转换数据。

在FIFO溢出之前读出AD转换数据。

36.10.4 模块停止功能的设置

模块停止控制寄存器可以启用或禁用ADC操作。ADC在复位后最初停止。寄存器在从模块停止状态释放时变得可访问。

另请参阅第36.10.5节。与本使用说明有关的进入和释放低功耗状态的限制。

36.10.5 进入和释放低功耗状态的限制

在进入模块停止状态或软件待机模式之前，请务必停止AD转换。此外，配置进入低功耗状态期间不启动AD转换。

要在模块停止状态或软件待机模式解除后操作AD转换器，请等待电气特性中指定的操作稳定时间，执行自校准操作，然后开始AD转换。

另外，在进入模块停止状态后再次解除模块停止状态时，请确保在解除模块停止状态之前已经过了电气特性中指定的关闭时间。

如果违反这些限制，则无法保证操作。

36.10.6 电路板设计注意事项

(1) 保护电路

为防止模拟输入引脚因过大浪涌等异常电压而损坏，请采取以下措施。

●在AVCC0和AVSS0之间以及VREFH0和VREFL0之间插入一个电容。

●连接保护电路以保护模拟输入引脚。

保护电路示例如图36.38所示。

(2) 板卡设计保证AD转换精度

为了保证AD转换的准确性，设计板子时考虑以下几点：

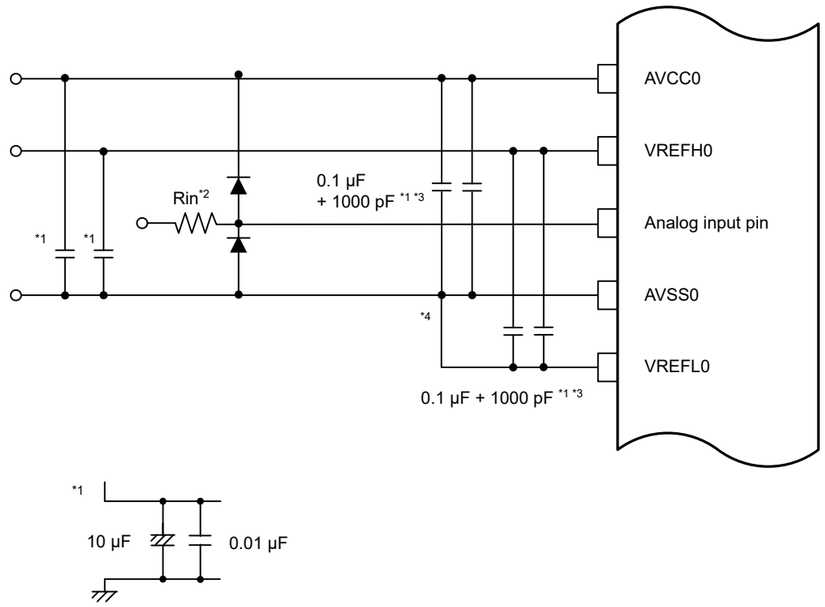
●模拟电路和数字电路应尽量分开。

●模拟电路信号线和数字电路信号线不能交叉或靠近。

●模拟输入、模拟参考电源（VREFH0）、模拟参考地（VREFL0）和模拟电源（AVCC0）应与使用模拟地（AVSS0）的数字电路分开。

●模拟地（AVSS0）应连接到板上稳定的数字地（VSS）（单点地平面连接）。

- Place a capacitor for noise filters between AVCC0 pin and AVSS0 pin and between VREFH0 pin and VREFL0 pin close to the pin and connect them. Also, connect AVSS0 and VREFL0 pins to the analog ground on the board as close to the pins as possible. An example of connection is shown in Figure 36.38.



Note 1. The values shown here are for reference only.
The appropriate values depend on your board design, operating conditions, etc.
Note 2. Rin: Signal source impedance
Note 3. To ensure the better A/D conversion accuracy, these capacitors must be place as close as possible to the appropriate pins.
Note 4. Connect to the analog ground of the board at the position as close as possible to the capacitor for noise filtering that ensure the A/D conversion accuracy.

Figure 36.38 Example of protection circuit and noise prevention

36.10.7 Notes on using analog channels to which the PGA is connected

When using an analog input pin to which a PGA is connected, refer to section 36.3.13.2. PGA operation setting.

36.10.8 Notes on Synchronous Operation

Synchronous Operation function is enabled in the initial state after reset released. If using Synchronous Operation function, follow the restrictions described in section 36.3.17. Synchronous Operation. If Synchronous Operation function is not used, disable Synchronous Operation in ADSYCR register.

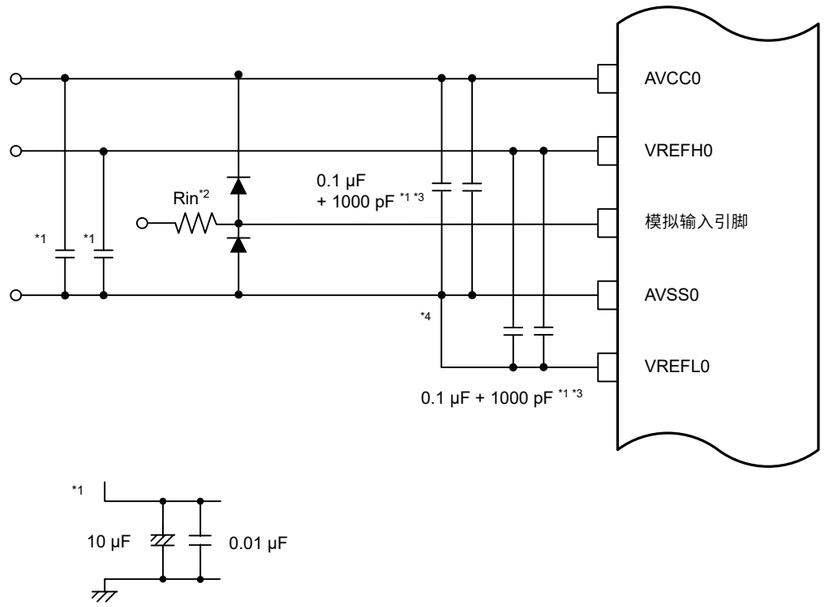
36.10.9 Notes on Channel-dedicated sample-and-hold circuit

When using Channel-dedicated sample-and-hold circuit, follow the restrictions. For more details, refer to section 36.3.14. Channel-Dedicated Sample-and Hold Circuit.

36.10.10 Prohibition of A/D conversions from multiple A/D converter to the same analogue signal source

To avoid degradation of the accuracy of the A/D conversion result, A/D conversion of the same analog channel (same analog signal source) from both ADC0 and ADC1 is prohibited, except for the self-diagnosis channel.

●在AVCC0引脚和AVSS0引脚之间以及VREFH0引脚和VREFL0引脚之间放置一个用于噪声滤波器的电容器靠近引脚并连接它们。此外，将AVSS0和VREFL0引脚连接到电路板上的模拟地，使其尽可能靠近引脚。连接示例如图36.38所示。



注1.此处显示的数值仅供参考。
适当的值取决于您的电路板设计、操作条件等。
注2.Rin：信号源阻抗
注3.为确保更好的AD转换精度，这些电容必须尽可能靠近相应的引脚放置。

注4.在尽可能靠近电容器的位置连接到电路板的模拟地，以确保AD转换精度的噪声过滤。

36.10.7 使用连接PGA的模拟通道的注意事项

使用连接PGA的模拟输入引脚时，请参阅第36.3.13.2节。PGA操作设置。

36.10.8 同步操作注意事项

同步操作功能在复位释放后的初始状态下启用。如果使用同步操作功能，请遵循第36.3.17节中描述的限制。同步操作。如果不使用同步操作功能，请禁用ADSYCR寄存器中的同步操作。

36.10.9 通道专用采样保持电路注意事项

使用通道专用采样保持电路时，请遵守限制条件。有关详细信息，请参阅第36.3.14节。
通道专用采样保持电路。

36.10.10 禁止从多个AD转换器到同一个模拟信号源的AD转换

为避免AD转换结果精度下降，除自诊断通道外，禁止ADC0和ADC1对同一模拟通道（同一模拟信号源）进行AD转换。

If this restriction is violated, the A/D conversion results are not guaranteed because the A/D conversion accuracy of the target analog channel may deteriorate significantly.

36.10.11 Notes on A/D Conversion Start Trigger

A/D conversion start triggers for the same scan group are not accepted until scanning operation of the scan group is completed (in this case, A/D converter start triggers are ignored).

An A/D conversion trigger for the same scan group should be input after the scanning operation of its scan group is completed (ADSCANENDSR.SCANENDFn = 1 (n = 0 to 8)) and after a 6 PCLKA clock cycles or more has elapsed.

36.10.12 Notes on Self-Calibration

Observe the restrictions on Self-Calibration function. For more details, refer to section 36.3.6. Self-Calibration.

36.10.13 Notes on Group Priority Operation

Observe the restrictions when using Group Priority Operation. For more details, refer to section 36.3.16. Group Priority Operation.

36.10.14 Notes on PGA Output Monitor Function

There are restrictions when using the PGA output monitor function. For more details, refer to section 36.3.13. Programmable Gain Amplifier.

如果违反此限制，则无法保证AD转换结果，因为目标模拟通道的AD转换精度可能会显着下降。

36.10.11 AD转换开始触发注意事项

在扫描组的扫描操作完成之前，不接受同一扫描组的AD转换启动触发器（在这种情况下，忽略AD转换器启动触发器）。

在其扫描组的扫描操作完成（ADSCANENDSR.SCANENDFn=1（n=0至8））并且经过6个或更多PCLKA时钟周期后，应输入同一扫描组的AD转换触发。

36.10.12 自校准注意事项

遵守自校准功能的限制。有关详细信息，请参阅第36.3.6节。自校准。

36.10.13 群组优先操作注意事项

37.2.1 DADRn : D/A Data Register n (n = 0, 1)

Base address: DAC12m = 0x4017_2000 + 0x0100 × m (m = 0, 1)

Offset address: 0x00 + 0x02 × n

Bit position:	15															0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DADRn register is 16-bit read/write registers that store data for D/A conversion. When an analog output is enabled, the values in DADRn are converted and output to the analog output pins.

12-bit data can be formatted as left- or right-justified in the DADPR.DPSEL bit setting. In right-justified format (DADPR.DPSEL = 0), the lower 12 bits, [11:0], are valid. In left-justified format (DADPR.DPSEL = 1), the upper 12 bits, [15:4], are valid.

37.2.2 DACR : D/A Control Register

Note 1. When analog output is disabled, the analog output signal is placed in the Hi-Z state.

DAE bit (D/A Enable)

The DAE bit controls D/A conversion, amplifier operation, and analog output in combination with the DAOEi bit (i = 0, 1) and the DAAMPCR.DAAMPi bit (i = 0, 1). See Table 37.5.

DAOEi bit (D/A Output Enable i)

The DAOEi bit (i = 0, 1) controls D/A conversion, amplifier operation, and analog output in combination with the DAE bit and DAAMPCR.DAAMPi bit (i = 0, 1). See Table 37.5.

When both the DAOEi bit (i = 0, 1) and DAE bit are 0, D/A conversion of channel i (i = 0, 1) is not processed, and no conversion result is output.

The event link function can be used to set the DAOEi bit to 1. The DAOE0 bit is set to 1 when the event specified in the ELSR12 register of the ELC (ELC_DA0 event) occurs, and output of the D/A conversion results starts. The DAOE1 bit is set to 1 when the event specified in the ELSR13 register of the ELC (ELC_DA1 event) occurs, and output of the D/A conversion results starts.

D/A conversions for channel 2 and 3 are controled by same bits in the register for the address when m = 1.

The setting of the ELC functions for channel 2 and 3 is possible in same manner too.

The event specified in the ELSR28 register of the ELC triggers the set of DAOE0 bit for address of m = 1 and the output of the D/A conversion for channel 2. The event specified in the ELSR29 triggers the set of DAOE1 bit and the output of the D/A conversion for channel 3.

注1.当模拟输出禁用时，模拟输出信号置于Hi-Z状态。

DAE位（DA启用）

DAE位与DAOEi位(i=0 1)和DAAMPCR.DAAMPi位(i=0 1)一起控制DA转换、放大器操作和模拟输出。见表37.5。

DAOEi位（DA输出使能i）

DAOEi位(i=0 1)与DAE位和DAAMPCR.DAAMPi位(i=0 1)一起控制DA转换、放大器操作和模拟输出。见表37.5。

当DAOEi位(i=0 1)和DAE位均为0时，通道i(i=0 1)的DA转换不进行处理，也不输出转换结果。

事件链接功能可用于将DAOEi位设置为1。当在
发生ELC（ELC_DA0事件）的ELSR12寄存器，开始输出DA转换结果。当发生ELC的ELSR13寄存器中指定的事件（ELC_DA1事件）时，DAOE1位设置为1，并开始输出DA转换结果。

当m=1时，通道2和3的DA转换由地址寄存器中的相同位控制。

通道2和3的ELC功能的设置也可以以相同的方式进行。

ELC的ELSR28寄存器中指定的事件触发地址m=1的DAOE0位的设置和通道2的DA转换的输出。ELSR29中指定的事件触发DAOE1位的设置和通道2的输出D通道3的转换。

The DAAMPCR register selects D/A output with or without using the amplifier.

DAAMP0 bit (Amplifier Control 0)

When the DAAMP0 bit is 0, analog values are output for D/A output of channel 0 (m = 0) and channel 2 (m = 1) without using the amplifier. When the DAAMP0 bit is 1, analog values are output for D/A output of channel 0 (m = 0) and channel 2 (m = 1) through the amplifier.

When both the DACR.DAE and DACR.DAOE0 bits are 0, the amplifier is not used regardless of the setting of the DAAMP0 bit. See Table 37.5 for details.

DAAMP1 bit (Amplifier Control 1)

When the DAAMP1 bit is 0, analog values are output for D/A output of channel 1 (m = 0) and channel 3 (m = 1) without using the amplifier. When the DAAMP1 bit is 1, analog values are output for D/A output of channel 1 (m = 0) and channel 3 (m = 1) through the amplifier.

When both the DACR.DAE and DACR.DAOE1 bits are 0, the amplifier is not used regardless of the setting of the DAAMP1 bit. See Table 37.5 for details.

The DAASWCR register controls D/A output with the output amplifier or D/A output for internal modules. This register is used in the initialization procedure to wait for stabilization of the D/A output amplifier. Each bit in DAASWCR should be set to 1 when both the DACR.DAE bit and the DACR.DAOEi (i = 0, 1) bit are 0. See section 37.6.5. Initialization Procedure with the Output Amplifier.

DAASWCR寄存器通过输出放大器控制DA输出或用于内部模块的DA输出。该寄存器在初始化过程中用于等待DA输出放大器的稳定。当DACR.DAE位和DACR.DAOEi(i=0 1)位均为0时，DAASWCR中的每个位都应设置为1。请参见第37.6.5节。输出放大器的初始化程序。

DAASW0 bit (D/A Amplifier Stabilization Wait 0)

Set the DAASW0 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 0 and 2 output amplifier. When DAASW0 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 0 to the DA0 pin (m = 0) and channel 2 to the DA2 pin (m = 1). When the DAASW0 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 0 (m = 0) and channel 2 (m = 1) is output through the output amplifier to the DA0 pin (m = 0) and DA2 pin (m = 1). When the amplifier is not used (DAAMPCR.DAAMP0 bit is 0) and DAASW0 is set to 1, D/A conversion result of channel 0 (m = 0) and channel 2 (m = 1) is output to the internal modules.

DAASW1 bit (D/A Amplifier Stabilization Wait 1)

Set the DAASW1 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 1 and 3 output amplifier. When DAASW1 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 1 to the DA1 pin (m = 0) and channel 3 to the DA3 pin (m = 1). When the DAASW1 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 1 (m = 0) and channel 3 (m = 1) is output through the output amplifier to the DA1 pin (m = 0) and DA3 pin (m = 1). When the amplifier is not used (DAAMPCR.DAAMP1 bit is 0) and DAASW1 is set to 1, D/A conversion result of channel 1 (m = 0) and channel 3 (m = 1) is output to the internal modules.

37.3 Operation

The DAC12 includes D/A conversion circuits for four channels, each of which can operate independently. When the DAOEn bit (n = 0, 1) in DACR is set to 1, DAC12 is enabled and the conversion result is output.

This following example shows D/A conversion on channel 0. Figure 37.2 shows the timing of this operation.

To process D/A conversion on channel 0:

1. Set the data for D/A conversion in the DADR0 register and the data format in the DADPR.DPSEL bit.
2. Set the DACR.DAOE0 bit to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time t_{DCONV} elapses. The conversion result continues to be output until DADR0 is written to again or the DAOE0 bit is set to 0. The output value (reference) is expressed by the following formula:

$$\frac{\text{Setting in DADR0}}{4096} \times AVCC0$$

3. To start conversion again, write another value to DADR0. The conversion result is output after the conversion time t_{DCONV} elapses.
4. To disable analog output, set the DAOE0 bit to 0.

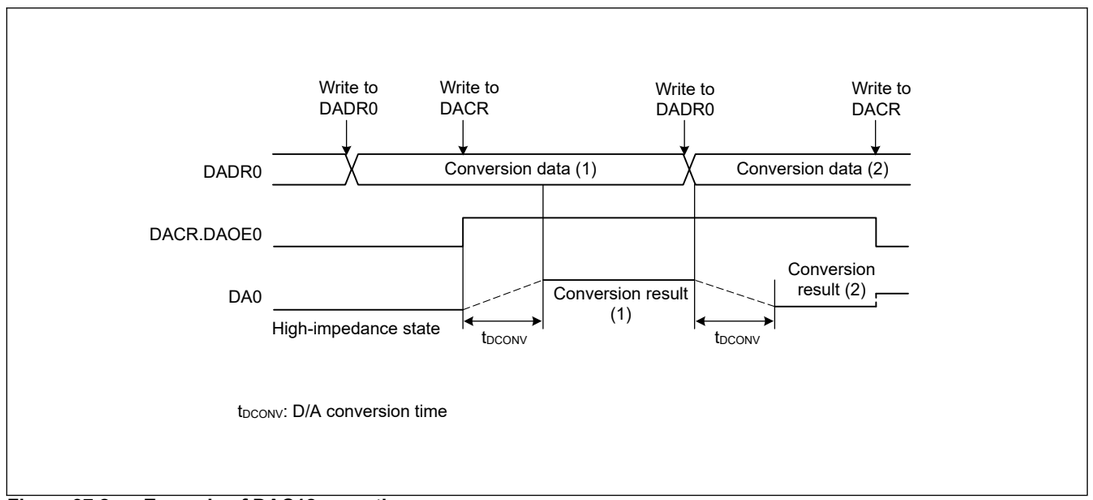

Figure 37.2 Example of DAC12 operation

DAASW0位（DA放大器稳定等待0）

在初始化过程中将DAASW0位设置为1，以等待DA通道0和2输出放大器稳定。当DAASW0设置为1时，DA转换操作，但DA的转换结果不从通道0输出到DA0引脚（m=0）和通道2到DA2引脚（m=1）。当DAASW0位为0时，稳定等待时间停止，通道0（m=0）和通道2（m=1）的DA转换结果通过输出放大器输出到DA0引脚（m=0）和DA2引脚（m=1）。当不使用放大器（DAAMPCR.DAAMP0位为0）且DAASW0设置为1时，将通道0（m=0）和通道2（m=1）的DA转换结果输出到内部模块。

DAASW1位（DA放大器稳定等待1）

在初始化过程中将DAASW1位设置为1，以等待DA通道1和3输出放大器稳定。当DAASW1设置为1时，DA转换操作，但DA的转换结果不从通道1输出到DA1引脚（m=0）和通道3输出到DA3引脚（m=1）。当DAASW1位为0时，稳定等待时间停止，通道1（m=0）和通道3（m=1）的DA转换结果通过输出放大器输出到DA1引脚（m=0）和DA3引脚（m=1）。当不使用放大器（DAAMPCR.DAAMP1位为0）且DAASW1设置为1时，通道1（m=0）和通道3（m=1）的DA转换结果输出到内部模块。

37.3 Operation

DAC12包括四个通道的DA转换电路，每个通道都可以独立工作。当。。。的时候
DACR中的DAOEn位(n=0 1)设置为1，使能DAC12并输出转换结果。

以下示例显示了通道0上的DA转换。图37.2显示了此操作的时序。

在通道0上处理DA转换：

1.在DADR0寄存器中设置用于DA转换的数据，在DADPR.DPSEL位中设置数据格式。

2.将DACR.DAOE0位设置为1以启动DA转换。经过转换时间tDCONV后，转换结果从模拟输出引脚DA0输出。转换结果继续输出，直到再次写入DADR0或将DAOE0位设置为0。输出值（参考值）由以下公式表示：

$$\frac{\text{DADR04096中的设置}}{4096} \times AVCC0$$

3.要再次开始转换，向DADR0写入另一个值。在经过转换时间tDCONV后输出转换结果。

4.要禁用模拟输出，请将DAOE0位设置为0。

37.6 Usage Notes

37.6.1 Settings for the Module-Stop Function

DAC12 operation can be disabled or enabled using the Module Stop Control Register. The DAC12 is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

37.6.2 DAC12 Operation in the Module-Stop State

When the MCU enters the module-stop state with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in the module-stop state, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

37.6.3 DAC12 Operation in Software Standby Mode

When the MCU enters Software Standby mode with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in Software Standby mode, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

37.6.4 Constraint on Entering Deep Software Standby Mode

When the MCU enters Deep Software Standby mode with D/A conversion enabled, the outputs of the DAC12 are placed in a high impedance state.

37.6.5 Initialization Procedure with the Output Amplifier

Use the following initialization procedures with the output amplifier. The example shows the case for channel 0.

3. Set the DAAMPCR.DAAMP0 bit to 1.
4. Set the DACR.DAE bit or the DACR.DAOE0 bit to 1 to start operation of the amplifier.
5. Clear the DAASWCR.DAASW0 bit to 0 after waiting for the duration of D/A conversion time t_{DCONV}.
6. Write the value to be converted in the DADR0 register.

Temperature sensor calibration data is stored in the lower 12 bits of the TSCDR register.

38.3 Using the Temperature Sensor

The temperature sensor outputs a voltage that varies with the temperature. This voltage is converted to a digital value by the 12-bit A/D converter. To obtain the die temperature, convert this value into the temperature.

38.3.1 Preparation for Using the Temperature Sensor

The ambient temperature (T) is proportional to the temperature sensor voltage output (Vs), so ambient temperature is calculated with the following formula:

T = (Vs - V1) / slope + T1

- T: Ambient temperature of MCU as calculation result (°C)
- Vs: Voltage output by the temperature sensor on temperature measurement (V)
- T1: Temperature experimentally measured at one point (°C)
- V1: Voltage output by the temperature sensor on measurement of T1 (V)
- T2: Temperature experimentally measured at a second point (°C)
- V2: Voltage output by the temperature sensor on measurement of T2 (V)
- Slope: Temperature gradient of the temperature sensor (V / °C), slope = (V2 - V1) / (T2 -T1)

Characteristics vary between sensors, so Renesas recommends measuring two different sample temperatures as follows:

1. Use the 12-bit A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1.
2. Again use the 12-bit A/D converter to measure the voltage V2 output by the temperature sensor at a different temperature T2.
3. Obtain the temperature gradient (slope = (V2 - V1) / (T2 - T1)) from these results.
4. Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic (T = (Vs - V1) / slope + T1).

If you are using the temperature gradient given in section 46, Electrical Characteristics, use the A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1, then calculate the temperature characteristic using the following formula:

T = (Vs - V1) / slope + T1

Note: This method produces less accurate temperatures than measurement at two points.

In this MCU, the TSCDR register stores the temperature value (CAL127) of the temperature sensor measured under the condition Ta = Tj = 127°C and AVCC0 = VREFH0 = 3.3 V. If you use this value as the sample measurement result at the first point, you can omit the preparation before using the temperature sensor.

V1 is calculated from CAL127:

V1 = 3.3 × CAL127 / 4096 [V] (In case of 12 bit accuracy)

Using this value, the measured temperature can be calculated according to the following formula:

T = (Vs - V1) / slope + 127 [°C]

- T: Ambient temperature of MCU as calculation result (°C)
- Vs: Voltage output by the temperature sensor when the temperature is measured (V)
- V1: Voltage output by the temperature sensor when Ta = Tj = 127°C and AVCC0 = VREFH0 = 3.3 V (V)
- Slope: Temperature gradient of the temperature sensor*1 / 1000 (V/°C)

Note 1. See section 46, Electrical Characteristics

38.3.2 Procedures for Using the Temperature Sensor

Figure 38.2 shows the procedure for using the TSN.

温度传感器校准数据存储在TSCDR寄存器的低12位中。

38.3 使用温度传感器

温度传感器输出随温度变化的电压。该电压由12位AD转换器转换为数字值。要获得芯片温度，请将该值转换为温度。

38.3.1 使用温度传感器的准备工作

环境温度(T)与温度传感器电压输出(Vs)成正比，因此使用以下公式计算环境温度：

T = (Vs - V1) / slope + T1

- T：作为计算结果的MCU的环境温度（°C）
- Vs：温度传感器测温时的电压输出（V）
- T1：在某一点实验测量的温度(°C)
- V1：温度传感器在测量T1（V）时输出的电压
- T2：在第二点实验测量的温度(°C)
- V2：温度传感器在测量T2（V）时输出的电压
- 斜率：温度传感器的温度梯度（V°C），斜率=（V2V1）（T2−T1）

传感器的特性各不相同，因此瑞萨电子建议测量两种不同的样品温度，如下所示：

1、使用12位AD转换器测量温度T1时温度传感器输出的电压V1。

2.再次使用12位AD转换器测量温度传感器在不同温度T2下输出的电压V2。

3.从这些结果中获得温度梯度（斜率=(V2V1)(T2T1)）。

4.随后，通过将斜率代入温度特性公式(T=(VsV1)斜率+T1)来获得温度。

如果您使用第46节“电气特性”中给出的温度梯度，请使用AD转换器测量温度传感器在温度T1下输出的电压V1，然后使用以下公式计算温度特性：

T = (Vs - V1) / slope + T1

Note: 这种方法产生的温度不如两点测量准确。

在此MCU中，TSCDR寄存器存储在Ta=Tj=127°C和AVCC0=VREFH0=3.3V条件下测量的温度传感器的温度值(CAL127)。如果您使用此值作为第一次的样本测量结果点，您可以省略使用温度传感器之前的准备工作。

V1由CAL127计算得出：

V1=3.3×CAL1274096[V]（在12位精度的情况下）

使用该值，可根据以下公式计算测得的温度：

T = (Vs - V1) / slope + 127 [°C]

- T：作为计算结果的MCU的环境温度（°C）
- Vs：测温时温度传感器输出的电压（V）

39. High-Speed Analog Comparator (ACMPHS)

39.1 Overview

The High-Speed Analog Comparator (ACMPHS) can be used to compare a test voltage with a reference voltage and to provide a digital output based on the result of conversion. Both the test voltage and the reference voltage can be provided to the ACMPHS from internal sources (D/A converter output, Programable Gain Amplifire (PGA) output) and an external source. Such flexibility is useful in applications that require go/no-go comparisons to be performed between analog signals without necessarily requiring A/D conversion.

Table 39.1 lists the ACMPHS specifications, Figure 39.1 shows a block diagram, and Table 39.2 shows the input source configurations.

Table 39.1 ACMPHS specifications

Parameter	Specifications
Number of channels	4 channels: ACMPHSn (n = 0 to 3)
Analog input voltage	• Output from internal PGA • Input from internal A/D converter input pin (one selectable)
Reference voltage	• Output from internal D/A converter • Input from internal A/D converter input pin (one selectable)
ACMPHS output	• Comparison result • Generation of ELC event output • Monitor output from register
Interrupt request signal	• Interrupt request generated on valid edge detection from comparison result • Selectable to rising edge, falling edge, or both edges
Digital filter function	• Selectable to one of three sampling frequencies • Not using the filter function is selectable

39. 高速模拟比较器(ACMPHS)

39.1 Overview

高速模拟比较器(ACMPHS)可用于将测试电压与参考电压进行比较，并根据转换结果提供数字输出。测试电压和参考电压都可以从内部源（数模转换器输出、可编程增益放大器(PGA)输出）和外部源提供给ACMPHS。这种灵活性在需要在模拟信号之间执行go-no-go比较而不一定需要AD转换的应用中很有用。

表39.1列出了ACMPHS规范，图39.1显示了框图，表39.2显示了输入源配置。

1	COE	Comparator Output Enable 0: Disable comparator output (output signal is low level) 1: Enable comparator output	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
4:3	CEG[1:0]	Selection of Valid Edge (Edge Selector) 0 0: Do not detect edge 0 1: Detect rising edge 1 0: Detect falling edge 1 1: Detect both edges	R/W
6:5	CDFS[1:0]	Noise Filter Selection *1 *2 *3 0 0: Do not use noise filter 0 1: Use noise filter sampling frequency of PCLKB/2^3 1 0: Use noise filter sampling frequency of PCLKB/2^4 1 1: Use noise filter sampling frequency of PCLKB/2^5	R/W

Note 1. Disable the ACMPHS output (COE= 0) before changing the CDFS[1:0] and CINV bits.
Note 2. If the CDFS[1:0] and CINV bits are changed, an ACMPHS interrupt request and an ELC event might be generated. Before changing these bits, set the ELSRn register to 0 (the ACMPHS output is not linked). After changing these bits, clear the IR flag in the IELSRn register to 0 to clear the interrupt status.
Note 3. If the CDFS[1:0] bits are changed from 00b (noise filter not used) to a value other than 00b (noise filter used), perform sampling four times and update the filter output, and then use the ACMPHS interrupt request or the ELC event.
Note 4. A stabilization wait time is required to permit ACMPHS operation after enabling it (HCMPON = 1). The operation stabilization wait time for ACMPHS is 300 ns.

Note: Set this register before setting registers in the POEG when using comparator output as a POEG source.

注3.如果CDFS[1:0]位从00b（未使用噪声滤波器）更改为00b以外的值（使用噪声滤波器），执行四次采样并更新滤波器输出，然后使用ACMPHS中断请求或ELC事件。
注4.启用ACMPHS后需要稳定等待时间以允许其运行(HCMPON=1)。ACMPHS的操作稳定等待时间为300ns。

Note: 当使用比较器输出作为POEG源时，在设置POEG中的寄存器之前设置该寄存器。

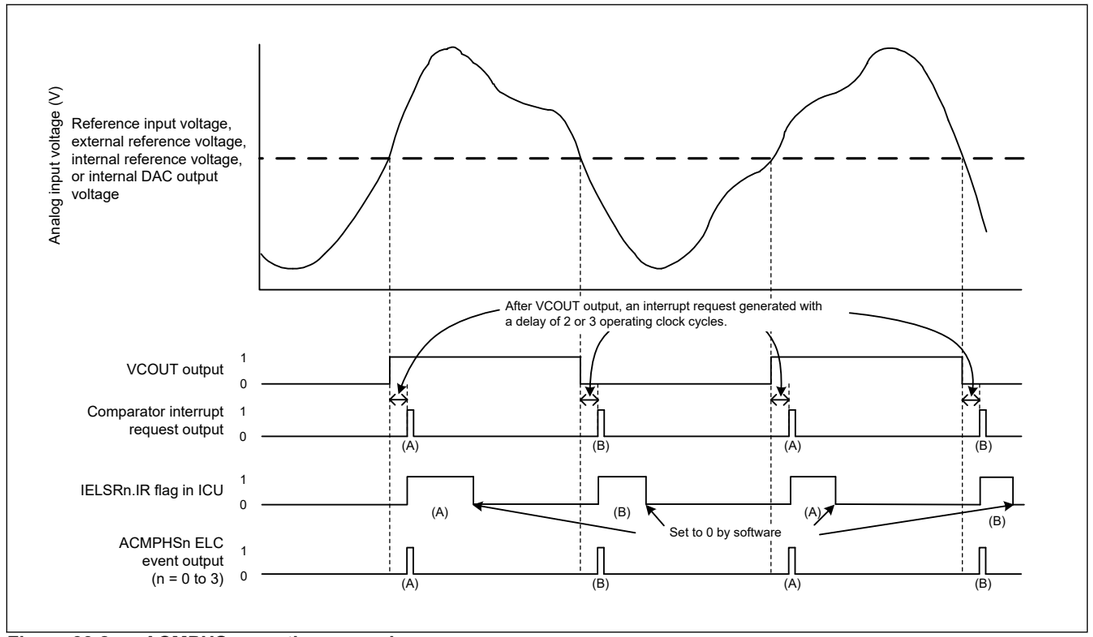

Figure 39.2 ACMPHS operation example

Figure 39.2 applies when CPOE = 1 (pin output enabled), CDFS[1:0] = 00b (filter not used), and CEG1 = CEG0 = 1 (both-edge detection selected). When CINV = 0, CEG0 = 1, and CEG1 = 0 (rising-edge detection selected for non-inversion output signal from the ACMPHS), the IELSR.IR flag changes as shown by (A) only. When CINV = 0, CEG0 = 0, and CEG1 = 1 (falling-edge detection selected for non-inversion output signal from the ACMPHS), the IR flag changes as shown by (B) only.

39.4 Noise Filter

The ACMPHS contains a noise filter. The sampling clock can be selected in the CMPCTL.CDFS[1:0] bits. The comparator output signal is sampled every sampling clock, and if the same value is sampled three times, the noise filter output at the next sampling clock cycle is used as the ACMPHS output.

Figure 39.3 shows the configuration of the noise filter and edge detector, and Figure 39.4 shows an example of noise filter and interrupt operation.

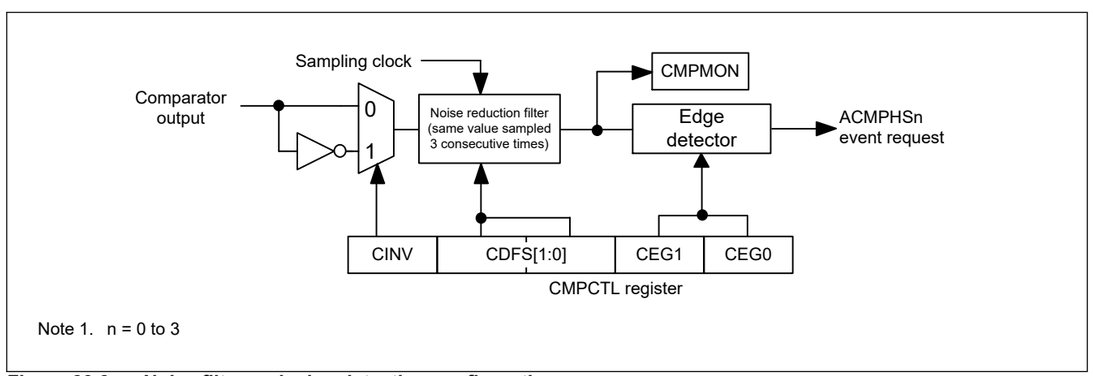

Figure 39.3 Noise filter and edge detection configuration

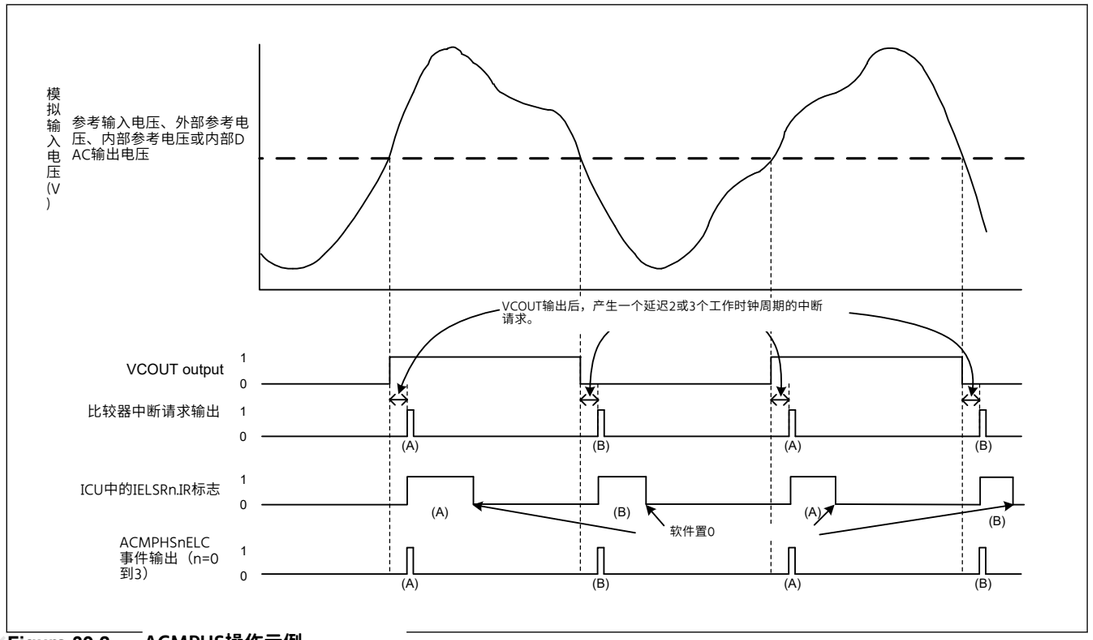

Figure 39.2 ACMPHS操作示例

图39.2适用于CPOE=1（使能引脚输出）、CDFS[1:0]=00b（未使用滤波器）和CEG1=CEG0=1（选择双沿检测）时。当CINV=0、CEG0=1和CEG1=0（为来自ACMPHS的非反相输出信号选择上升沿检测）时，IELSR.IR标志仅如(A)所示变化。当CINV=0、CEG0=0和CEG1=1（为来自ACMPHS的非反相输出信号选择下降沿检测）时，IR标志仅如(B)所示变化。

39.4 噪声过滤器

ACMPHS包含一个噪声滤波器。可以在CMPCTL.CDFS[1:0]位中选择采样时钟。每个采样时钟对比较器输出信号进行采样，如果采样3次相同的值，则将下一个采样时钟周期的噪声滤波器输出作为ACMPHS输出。

图39.3显示了噪声滤波器和边缘检测器的配置，图39.4显示了噪声滤波器和中断操作的示例。

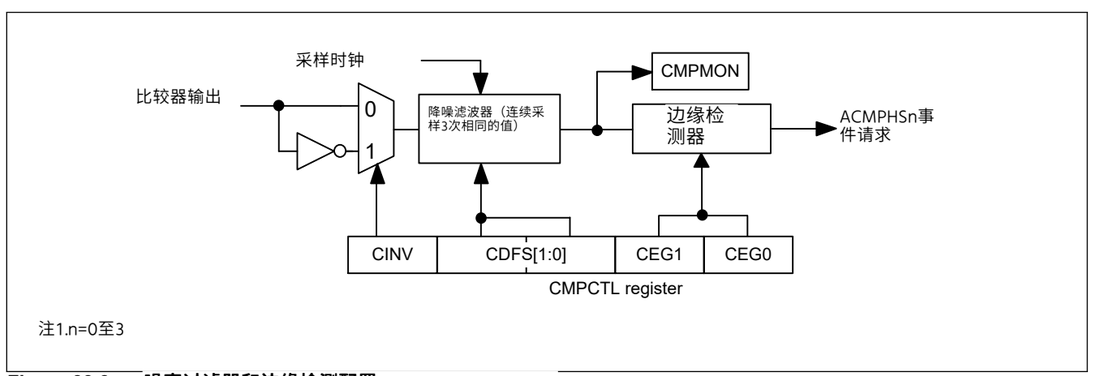

Figure 39.3 噪声过滤器和边缘检测配置

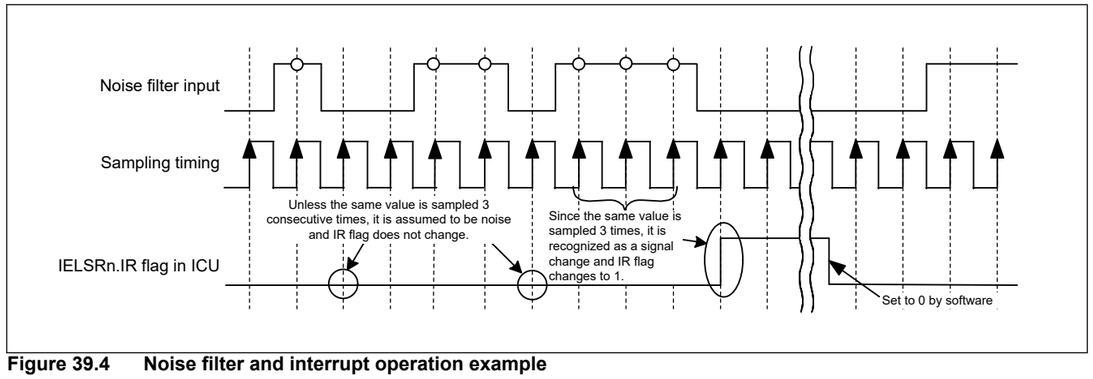

Figure 39.4 Noise filter and interrupt operation example

The operation example in Figure 39.4 applies when the CMPCTL.CDFS[1:0] bits are 01b, 10b, or 11b (noise filter used).

39.5 ACMPHS Interrupts

The ACMPHS generates three interrupt requests from sources ACMPHSn (n = 0 to 3). To use an ACMPHS interrupt, select it in the IELSR register in the Interrupt Controller Unit (ICU).

When using the ACMPHS interrupt through the edge selector, set at least one of the CMPCTL.CEG0 and CMPCTL.CEG1 bits to 1 (to a value other than 00b for no edge selection).

For details on the register settings related to ACMPHS interrupt requests, see section 39.2.1. CMPCTL : Comparator Control Register.

39.6 ACMPHS Output to the Event Link Controller (ELC)

The ELC uses the ACMPHS interrupt request signal as an ELC event signal, enabling link operation for the preset module. To use the ACMPHS ELC event, select them in the ELSR register in the ELC. When using the ELC event request, set at least one of the CMPCTL.CEG0 and CMPCTL.CEG1 bits to 1 (to a value other than 00b for no edge selection).

39.7 ACMPHS Pin Output

The comparison result from the ACMPHS can be output to external pins. Use the CMPCTL.CINV and CPIOC.CPOE bits to set the output polarity (non-inverted or inverted output) and enable or disable output. To output the ACMPHS comparison result to the CMPOUTn (n = 0 to 3), VCOUT and CMPOUT012 output pins, set the associated port mn pin function control register (PmnPFS) in the I/O register. The CMPOUT0 to CMPOUT3 compare outputs are bundled with the VCOUT pin. The CMPOUT0 to CMPOUT2 compare outputs are bundled with the CMPOUT012 pin too.

39.8 Usage Notes

39.8.1 Settings for the Module-Stop Function

ACMPHS operation can be disabled or enabled using the Module Stop Control Register. The ACMPHS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

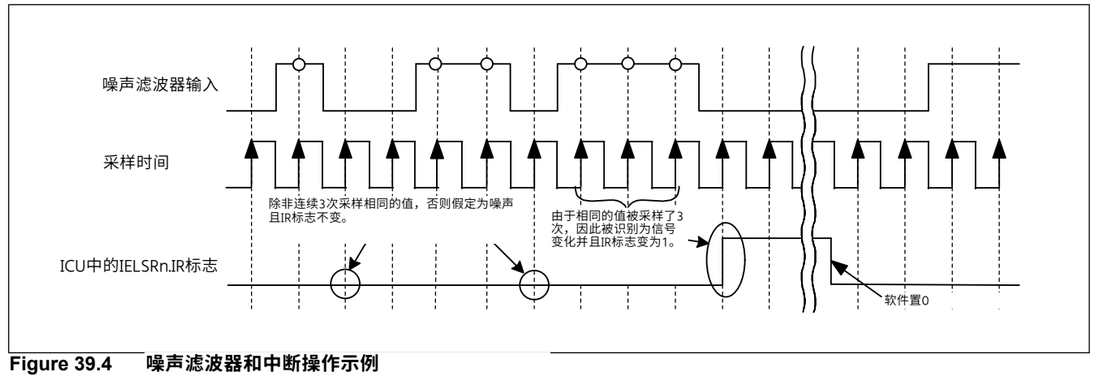

Figure 39.4 噪声滤波器和中断操作示例

图39.4中的操作示例适用于CMPCTL.CDFS[1:0]位为01b、10b或11b（使用噪声滤波器）时。

39.5 ACMPHS Interrupts

ACMPHS从源ACMPHSn（n=0到3）产生三个中断请求。要使用ACMPHS中断，请在中断控制器单元(ICU)的IELSR寄存器中选择它。

通过边沿选择器使用ACMPHS中断时，将CMPCTL.CEG0和CMPCTL.CEG1位中的至少一个设置为1（设置为00b以外的值表示不选择边沿）。

有关与ACMPHS中断请求相关的寄存器设置的详细信息，请参见第39.2.1节。CMPCTL:比较器控制寄存器。

39.6 ACMPHS输出到事件链接控制器(ELC)

ELC使用ACMPHS中断请求信号作为ELC事件信号，为预设模块启用链接操作。
要使用ACMPHSELC事件，请在ELC的ELSR寄存器中选择它们。使用ELC事件请求时，将CMPCTL.CEG0和CMPCTL.CEG1位中的至少一个设置为1（设置为00b以外的值以表示无边沿选择）。

39.7 ACMPHS引脚输出

ACMPHS的比较结果可以输出到外部引脚。使用CMPCTL.CINV和CPIOC.CPOE位设置输出极性（非反相或反相输出）并启用或禁用输出。要将ACMPHS比较结果输出到CMPOUTn（n=0至3）、VCOUT和CMPOUT012输出引脚，请在IO寄存器中设置相关的端口mn引脚功能控制寄存器（PmnPFS）。CMPOUT0到CMPOUT3比较输出与VCOUT引脚捆绑在一起。CMPOUT0到CMPOUT2比较输出也与CMPOUT012引脚捆绑在一起。

39.8 使用说明

39.8.1 模块停止功能的设置

可以使用模块停止控制寄存器禁用或启用ACMPHS操作。ACMPHS在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

以下是数据操作的位宽为32位时的操作示例。

1. Writing 00b to the DOCR.OMS[1:0] bits selects data comparison mode, and setting the DOCR.DCSEL[2:0] to selects detection condition.
2. The 32-bit reference data is set in DODSR0 and DODSR1.*1
3. 32-bit data for comparison is written to DODIR.
4. If a value written to DODIR match the detection condition set by DOCR.DCSEL[2:0], the DOCR.DOPCF flag is set to 1 and an ELC event is generated. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

Note: The comparison operation is executed only by writing to the DODIR

Note 1. The DODSR1 register setting is required only when window comparison is selected. Set a value greater than DODSR0 (DODSR1 > DODSR0).

3. 32-bit data to be added is written to DODIR. The result of the operation is stored in DODSR0.
4. Writing of 32-bit data continues until all data for addition have been written to DODIR.
5. If the result of an operation is greater than 0xFFFF_FFFF, the DOSR.DOPCF flag is set to 1 and an ELC event is generated. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

3.将要添加的32位数据写入DODIR。运算结果存储在DODSR0中。

4.继续写入32位数据，直到所有要加法的数据都写入DODIR。

5.如果操作结果大于0xFFFF_FFFF，则DOSR.DOPCF标志设置为1，并生成ELC事件。当DOCR.DOPCIE位为1时，也会产生数据操作电路中断。

注1.仅通过写入DODIR来执行加法。

3. 32-bit data to be subtracted is written to DODIR. The result of the operation is stored in DODSR0.
4. Writing of 32-bit data continues until all data for subtraction have been written to DODIR.
5. If the result of an operation is less than 0x0000_0000, the DOSR.DOPCF flag is set to 1 and an ELC event is generated. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

Note 1. Subtraction is executed only by writing to the DODIR.

40.4 Interrupt Source

The data operation circuit generates the data operation circuit interrupt (DOC_DOPCI) as an interrupt request. When an interrupt source is generated, the data operation circuit flag corresponding to the interrupt is set to 1, when the data operation circuit interrupt enable bit is enabled, interrupt request signal is generated. Table 40.2 describes the interrupt request.

Table 40.2 Interrupt request from DOC

Interrupt request	Status flag	Interrupt source
DOC interrupt	DOPCF	• The compared values match the detection condition. • The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1). • The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1).

40.5 Event Link Output

The DOC outputs event signals for the event link controller (ELC) under the following conditions, and these can be used to initiate operations by other modules selected in advance.

- The compared values match the detection condition
- The data addition result is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)
- The data subtraction result is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)

40.6 Interrupt Handling and Event Linking

The DOC has a bit to enable or disable interrupts. An interrupt request signal is output for the CPU when an interrupt source is generated while the corresponding enable bit is enabled.

1.向DOCR.OMS[1:0]位写入10b选择数据减法模式。

2.在DODSR0寄存器中设置32位数据作为初始值。

3.将要减去的32位数据写入DODIR。运算结果存储在DODSR0中。

4.继续写入32位数据，直到所有减法数据都已写入DODIR。

5.如果操作结果小于0x0000_0000，则DOSR.DOPCF标志设置为1，并生成ELC事件。当DOCR.DOPCIE位为1时，也会产生数据操作电路中断。

注1.减法只能通过写入DODIR来执行。

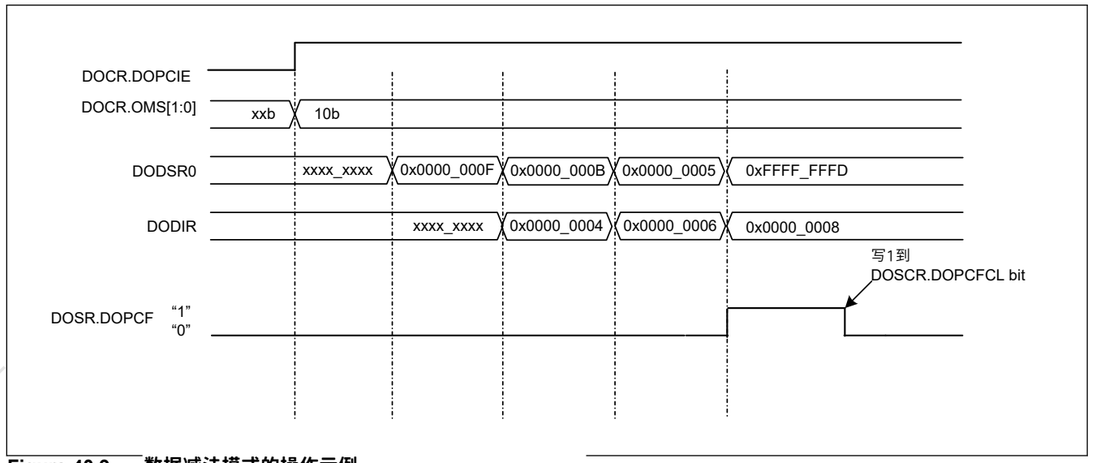

Figure 40.9 数据减法模式的操作示例

40.4 中断源

数据运算电路产生数据运算电路中断(DOC_DOPCI)作为中断请求。当产生中断源时，中断对应的数据运算电路标志置1，当数据运算电路中断使能位使能时，产生中断请求信号。表40.2描述了中断请求。

Table 40.2 来自DOC的中断请求

中断请求	状态标志	中断源
文档中断	DOPCF	• 比较值与检测条件匹配。 • 数据相加的结果大于0xFFFF(DOCR.DOBW=0)或0xFFFF_FFFF(DOCR.DOBW=1)。 • 数据减法的结果小于0x0000(DOCR.DOBW=0)或0x0000_0000(DOCR.DOBW=1)。

40.5 事件链接输出

DOC在以下条件下为事件链接控制器(ELC)输出事件信号，这些信号可用于启动预先选择的其他模块的操作。

- ●比较值符合检测条件
- ●数据相加结果大于0xFFFF（DOCR.DOBW=0）或0xFFFF_FFFF（DOCR.DOBW=1）
- ●数据减法结果小于0x0000（DOCR.DOBW=0）或0x0000_0000（DOCR.DOBW=1）

40.6 中断处理和事件链接

DOC有一个位来启用或禁用中断。当相应的使能位使能时产生中断源时，向CPU输出中断请求信号。

In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

40.7 Usage Notes

40.7.1 Settings for the Module-Stop State

The module Stop Control Register C (MSTPCRC) can enable or disable DOC operation. The DOC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

相反，当产生中断源时，事件链接输出信号作为事件信号通过ELC发送到其他模块，而不管相应中断使能位的设置如何。

40.7 使用说明

40.7.1 模块停止状态的设置

模块停止控制寄存器C(MSTPCRC)可以启用或禁用DOC操作。DOC在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

ECCPRCR2 bit (Register Write Control)

The ECCPRCR2 bit controls the write mode of the ECCETST register. When the ECCPRCR2 bit is set to 1, writes to the ECCETST register is enabled. When writing to this bit, write 0x78 to the KW2[6:0] bits at the same time.

KW[6:0]位（写入密钥代码）

KW[6:0]位启用或禁用对ECPCRR位的写入。写入ECCPRCR位时，同时向KW[6:0]位写入0x78。当向KW[6:0]位写入0x78以外的值时，不会更新ECPCRR位。KW[6:0]位总是被读取为0x00。

The ECC Protection Register 2 (ECCPRCR2) protects this register against writes. Before writing to this bit, set the ECCPRCR2 bit in the ECCPRCR2 register to 1 (write protection disabled). Do not write to the ECCETST register while accessing the SRAM.

TSTBYP bit (ECC Bypass Select)

The TSTBYP bit enables direct access to the ECC code by bypassing the ECC function. When the ECC bypass function is used, the ECCMOD[1:0] bits in the ECCMODE register are set to 00b. The ECC must be accessed in 32 bits using the same address for 32-bit data. The ECC code is assigned to the lower 7 bits of the 32-bit data. When writing the ECC code, the upper 25 bits are ignored. When reading the ECC code, the upper 25 bits are undefined.

Note: For details of ECC test, see section 41.3.4. ECC Decoder Testing.

41.2.11 ECCOAD : SRAM ECC Error Operation After Detection Register

Base address: SRAM = 0x4000_2000

Offset address: 0xD8

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation After Detection 0: Non-maskable interrupt 1: Reset	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The ECC Protection Register (ECCPRCR) protects this register against writes. Before writing to this bit, set the ECCPRCR bit in the ECCPRCR register to 1 (write protection disabled). Do not write to the ECCOAD register while accessing the SRAM.

OAD bit (Operation After Detection)

The OAD bit selects whether to generate a reset or a non-maskable interrupt when an ECC error is detected. The OAD bit in the ECCOAD register is used for SRAM0.

41.3 Operation

41.3.1 Module Stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

SRAM0 is controlled by SRAM0 bit in MSTPCRA register and, in the case of 1, SRAM0 becomes the clock stop state.

The SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The SRAM operates after a reset.

SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to SRAM is in progress.

Access to the SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see section 10, Low Power Modes.

ECC保护寄存器2(ECCPRCR2)保护该寄存器不被写入。在写入该位之前，将ECPCRR2寄存器中的ECPCRR2位为1（写保护禁用）。访问SRAM时不要写入ECCETST寄存器。

TSTBYP位（ECC旁路选择）

TSTBYP位允许通过绕过ECC功能直接访问ECC代码。使用ECC旁路功能时，ECCMODE寄存器中的ECCMOD[1:0]位设置为00b。必须使用32位数据的相同地址以32位访问ECC。ECC代码分配给32位数据的低7位。写入ECC代码时，忽略高25位。读取ECC码时，高25位未定义。

Note: 有关ECC测试的详细信息，请参见第41.3.4节。ECC解码器测试。

41.2.11 ECCOAD：检测寄存器后的SRAMECC错误操作

Base address: SRAM = 0x4000_2000

Offset address: 0xD8

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD
重置后的值：	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	检测后的操作 0：不可屏蔽中断1：复位	R/W
7:1	—	这些位被读取为0。写入值应为0。	R/W

Note: 如果安全属性配置为安全：●
允许安全访问和非安全读取访问
- 忽略非安全写入访问，不会生成TrustZone访问错误。

如果安全属性配置为非安全：●
允许安全和非安全访问。

ECC保护寄存器(ECCPRCR)保护该寄存器不被写入。在写入该位之前，将ECPCRR寄存器中的ECPCRR位设置为1（禁用写保护）。访问SRAM时不要写入ECCOAD寄存器。

OAD位（检测后操作）

OAD位选择在检测到ECC错误时是否产生复位或不可屏蔽中断。ECCOAD寄存器中的OAD位用于SRAM0。

41.3 Operation

41.3.1 模块停止功能

通过设置模块停止控制寄存器A(MSTPCRA)停止向SRAM提供时钟信号，可以降低功耗。

SRAM0由MSTPCRA寄存器中的SRAM0位控制，在为1的情况下，SRAM0变为时钟停止状态。

因此，通过停止提供时钟信号，SRAM被置于模块停止状态。SRAM在复位后运行。

如果SRAM处于模块停止状态，则无法访问。在访问SRAM的过程中，不应转换到模块停止状态。

禁止在模块停止状态下访问SRAM。如果尝试访问，则无法保证正确操作。

有关MSTPCRA寄存器的详细信息，请参见第10节，低功耗模式。

41.3.2 Correction of ECC errors

Enabling and disabling of ECC error correction can be selected through ECCMODE register setting. In the initial state, ECC error correction is disabled. The ECC check type is SEC-DED (Single-Error Correction and Double-Error Detection Code).

When ECC function is enabled, 7-bit check bits are appended to 32-bit data for writing. For reading, 39-bit (data: 32 bits, check bits: 7 bits) data is read out from the SRAM.

When ECC function is enabled and error checking is selected by setting ECCMOD[1:0] in the ECCMODE register to 00b, error correction is done if a 1-bit error occurs and the ECC1ERR bit in the ECC1STS register is set to 1 if the E1STSEN bit in the ECC1STSEN register is 1. If a 2-bit error occurs, error detection is done and the ECC2ERR bit in the ECC2STS register is set to 1, though error correction is not performed.

When ECC function is enabled and the error checking is disable, error correction is done if a 1-bit error occurs but ECC1ERR bit in the ECC1STS register is not updated although E1STSEN bit in the ECC1STSEN register is 1. If a 2-bit error occurs, this error is detected but the ECC2ERR bit in the ECC2STS register is not updated, and error correction is not performed.

When ECC function is disable, neither error correction nor error detection is done although 1-bit or 2-bit error occur.

So ECC1ERR bit and ECC2ERR bit are not updated.

There is no way to confirm the location where the error was found. Therefore, when after the occurrence of an error, update all the data.

When updating all the data after the occurrence of an error, the only support of 32 bit data writing.

Since the SRAM data is undefined after power on and release from deep software standby mode, accessing the SRAM when ECC function is enabled and error checking is selected causes an ECC error to occur. Therefore, before using ECC function, initial writing with 32bit data size to the area to be used in the SRAM should be done.

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, please do not perform the read access in a row after the write access.

41.3.3 ECC Error Interrupt Function

When ECC function is enabled and error checking is applied to the SRAM, an ECC error occurs when either the ECC2ERR bit in the ECC2STS register or the ECC1ERR bit in the ECC1STS register becomes 1 to indicate that ECC checking revealed a 2-bit error or a 1-bit error, respectively.

An ECC erroris output with a pulse width of ICLK.When the ECC 1-bit error is to be masked, set the ECC1STSEN.E1STSEN bit to 0 to disable updating of the ECC1ERR bit. An ECC error will not be generated while ECC function is disabled or when ECC function is enabled but error checking is not selected.

ECC error can choose non maskable interrupt or reset by ECCOAD register. When set 1 in the OAD bit of the ECCOAD register, ECC error is output to the Reset function. When set 0 in the OAD bit of the ECCOAD register, ECC Error interrupt is output to the ICU as non-maskable interrupt.

41.3.4 ECC Decoder Testing

Figure 41.1 shows the ECC decoder testing.

41.3.2 纠正ECC错误

可以通过ECCMODE寄存器设置来选择ECC纠错的启用和禁用。在初始状态下，ECC纠错被禁用。ECC校验类型为SEC-DED（单纠错双错误检测码）。

当ECC功能使能时，7位校验位被附加到32位数据中进行写入。读取时，从SRAM中读出39位（数据：32位，校验位：7位）数据。

当ECC功能使能并且通过将ECCMODE寄存器中的ECCMOD[1:0]设置为00b来选择错误检查时，如果发生1位错误，则进行纠错，并且ECC1STS寄存器中的ECC1ERR位设置为1，如果ECC1STSEN寄存器中的E1STSEN位为1。如果发生2位错误，则进行错误检测并将ECC2STS寄存器中的ECC2ERR位设置为1，但不执行错误纠正。

当启用ECC功能且禁用错误检查时，如果发生1位错误，则进行错误纠正，但尽管ECC1STSEN寄存器中的E1STSEN位为1，但ECC1STS寄存器中的ECC1ERR位不更新。如果发生2位错误，则会检测到该错误，但不会更新ECC2STS寄存器中的ECC2ERR位，也不执行纠错。

当ECC功能被禁用时，即使发生1位或2位错误，也不会进行纠错或错误检测。

因此ECC1ERR位和ECC2ERR位不会更新。

无法确认发现错误的位置。因此，当发生错误后，更新所有数据。

发生错误后更新所有数据时，仅支持32位数据写入。

由于上电并从深度软件待机模式释放后SRAM数据未定义，因此在启用ECC功能并选择错误检查时访问SRAM会导致发生ECC错误。因此，在使用ECC功能之前，应先将32位数据大小的数据写入SRAM中要使用的区域。

在写访问之后连续执行读访问时，优先执行读访问。因此，在初始化过程中，请不要在写访问之后连续进行读访问。

41.3.3 ECC错误中断功能

当ECC功能使能并对SRAM应用错误检查时，当ECC2STS寄存器中的ECC2ERR位或ECC1STS寄存器中的ECC1ERR位变为1时，将发生ECC错误，表示ECC检查发现2位错误或分别为1位错误。

脉冲宽度为ICLK的ECC错误输出。当要屏蔽ECC1位错误时，设置ECC1STSEN.E1STSEN位为0以禁用ECC1ERR位的更新。禁用ECC功能或启用ECC功能但未选择错误检查时，不会产生ECC错误。

ECC错误可以选择不可屏蔽中断或通过ECCOAD寄存器复位。当ECCOAD寄存器的OAD位设置为1时，ECC错误输出到复位功能。当ECCOAD寄存器的OAD位设置为0时，ECC错误中断作为不可屏蔽中断输出到ICU。

41.3.4 ECC解码器测试

图41.1显示了ECC解码器测试。

41.3.5 TrustZone Filter function

There are two types of TrustZone Filter function for SRAM.

- TrustZone Filter for SRAM register protection
- TrustZone Filter for SRAM memory protection

41.3.5.1 TrustZone Filter for SRAM register protection

SRAM registers can be protected with a Security Attribution (SA) from Non-secure access. When SA indicates that SRAM registers are secure status, non-secure access can not overwrite them because TrustZone Filter detects finds an error and protects the write access. SA for SRAM registers is just one to be used commonly among SRAM registers.

41.3.5 TrustZone过滤器功能

SRAM有两种TrustZoneFilter功能。

●用于SRAM寄存器保护的TrustZone过滤器

●用于SRAM内存保护的TrustZone过滤器

41.3.5.1 用于SRAM寄存器保护的TrustZone过滤器

可以使用安全属性(SA)保护SRAM寄存器免受非安全访问。当SA指示SRAM寄存器处于安全状态时，非安全访问无法覆盖它们，因为TrustZoneFilter检测到发现错误并保护写访问。SRAM寄存器的SA只是SRAM寄存器中常用的一种。

Table 41.2 Register protection

SA	Access status	Write access	Read access
Secure	Secure	Permit	Permit
	Non-secure	TrustZone Filter error Protected	Permit
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

When TrustZone Filter error for SRAM register access occurs, no error notification and no error response occurs.

41.3.5.2 TrustZone Filter for SRAM memory protection

SRAM memory can be divided into Secure/Non secure callable/Non secure status with Memory Security Attribution (MSA) and can be protected from Non-secure access. When MSA indicates that SRAM memory region are Secure or Non secure callable status, Non-secure access can't overwrite them.

Table 41.3 Memory protection

SA	Access status	Write access	Read access
Secure / Non secure callable	Secure	Permit	Permit
	Non-secure	TrustZone Filter error • Protected • Error response occurs	TrustZone Filter error • Read data is 0 • Error response occurs
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

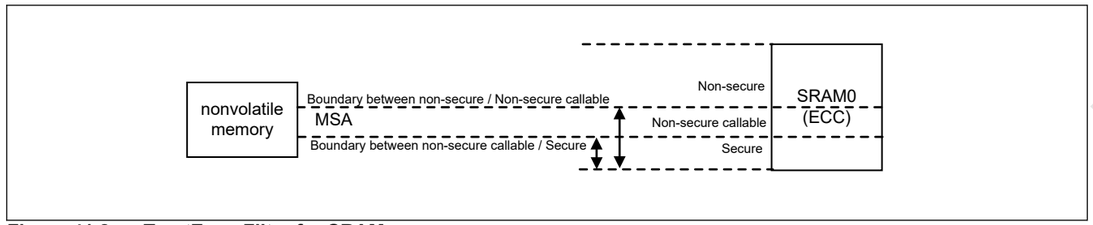

Figure 41.2 TrustZone Filter for SRAM memory

When TrustZone Filter error for SRAM memory access occurs, an error notification which become Reset request or NMI request occurs. See section 45.2. Arm TrustZone Security .

41.3.6 Interrupt Source

The SRAM interrupt source includes an ECC error and TrustZone filter error. ECC error can choose non-maskable interrupt or reset by OAD bit. When the debugger is connected, reset and non-maskable interrupt are maskable. Also, if these masks are set by the debugger, each status register is not set even if an ECC error occurs. For details on the debug mode, see section 2, CPU.

41.3.5.2 用于SRAM内存保护的TrustZone过滤器

SRAM内存可分为SecureNonsecurecallableNonsecurestatuswithMemorySecurityAttribution(MSA)并且可以防止非安全访问。当MSA指示SRAM内存区域为安全或非安全可调用状态时，非安全访问无法覆盖它们。

41.3.6 中断源

SRAM中断源包括ECC错误和TrustZone过滤器错误。ECC错误可以选择不可屏蔽中断或通过OAD位复位。当调试器连接时，复位和不可屏蔽中断都是可屏蔽的。此外，如果调试器设置了这些掩码，则即使发生ECC错误，也不会设置每个状态寄存器。有关调试模式的详细信息，请参见第2节CPU。

NSBSTBR[3:0] bit (Security attributes of each region for Standby RAM)

Standby RAM is divided into 8 regions. Each region can be set as Secure or Non-secure state with NSBSTBR[3:0]

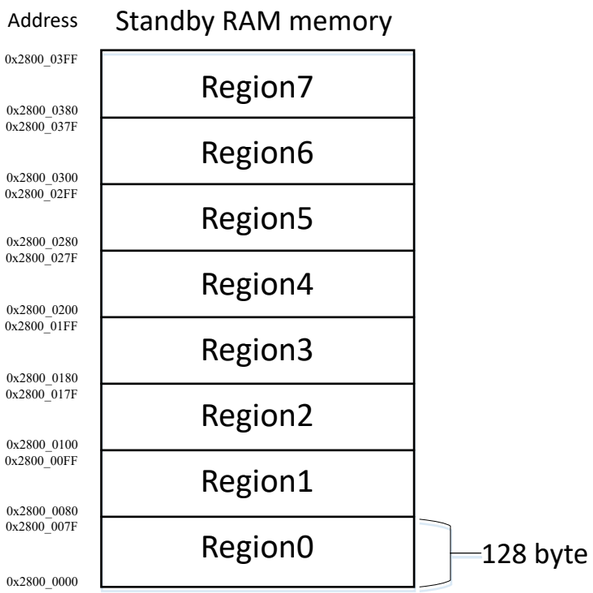

Figure 42.1 Standby RAM regions

42.3 Operation

42.3.1 Data Retention

The power supply to the Standby SRAM in Deep Software Standby mode is enabled by the DPSBYCR.DEEPCUT[1:0] bits. If the DPSBYCR.DEEPCUT[1:0] bits are set to 00b, data in the Standby SRAM is retained in Deep Software Standby mode. See section 10, Low Power Modes, for details on the DPSBYCR.DEEPCUT[1:0] bits.

42.3.2 Setting for the Module-stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

If the Standby SRAM bit in MSTPCRA is set to 1, supply of the clock signal to the Standby SRAM is stopped.

The Standby SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The Standby SRAM operates after a reset.

The Standby SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to the standby SRAM is in progress.

For details on the MSTPCRA register, see section 10, Low Power Modes.

NSBSTBR[3:0]位（StandbyRAM每个区域的安全属性）

备用RAM分为8个区域。每个区域都可以通过NSBSTBR[3:0]设置为安全或非安全状态

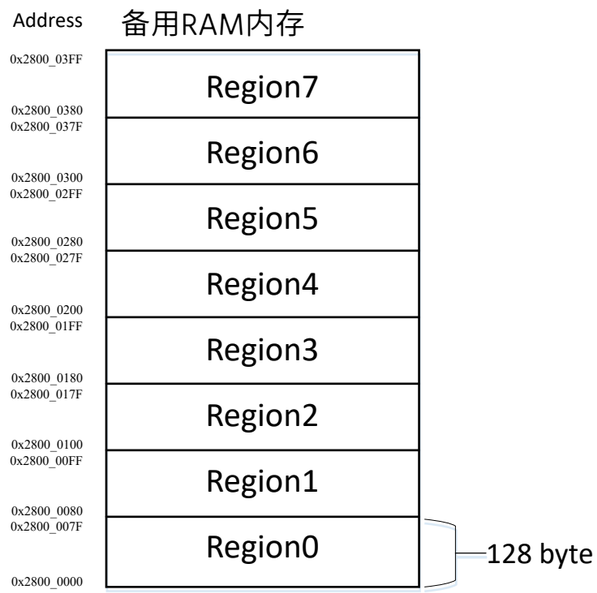

Figure 42.1 备用RAM区域

42.3 Operation

42.3.1 数据保留

深度软件待机模式下的待机SRAM电源由DPSBYCR.DEEPCUT[1:0]位启用。如果DPSBYCR.DEEPCUT[1:0]位设置为00b，则待机SRAM中的数据将保留在深度软件待机模式中。有关DPSBYCR.DEEPCUT[1:0]位的详细信息，请参见第10节，低功耗模式。

42.3.2 模块停止功能的设置

通过设置模块停止控制寄存器A(MSTPCRA)停止向SRAM提供时钟信号，可以降低功耗。

如果MSPCRA中的StandbySRAM位设置为1，则停止向StandbySRAM提供时钟信号。
因此，通过停止提供时钟信号，备用SRAM进入模块停止状态。待机SRAM在复位后运行。

如果处于模块停止状态，则无法访问备用SRAM。在访问备用SRAM的过程中，不应转换到模块停止状态。

有关MSTPCRA寄存器的详细信息，请参见第10节，低功耗模式。

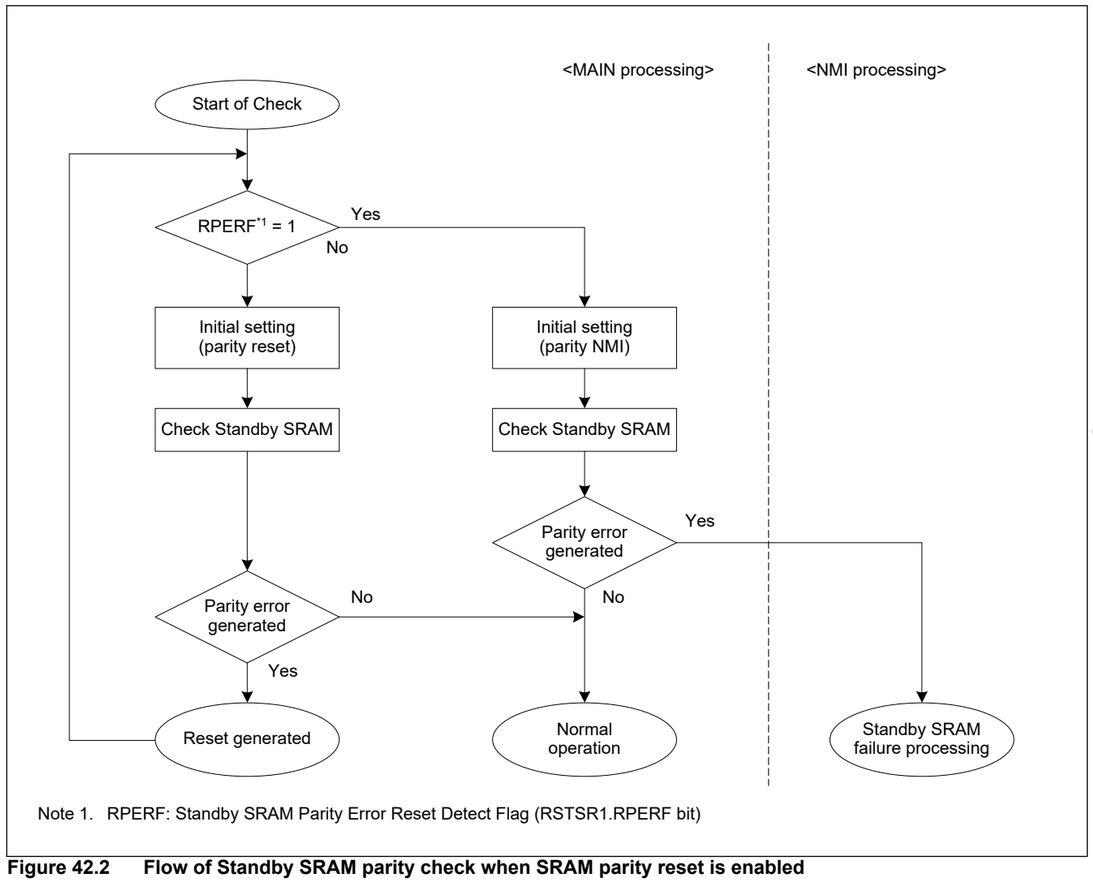
42.3.3 Parity Calculation Function

The IEC60730 standard requires the checking of SRAM data. When data is written, a parity bit is added to every 8-bit data in the Standby SRAM which has 32-bit data width, and when data is read, the parity is checked. When a parity error occurs, a parity error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the SRAM.PARIOAD register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

Parity errors often occur because of noise. To confirm whether the cause of the parity error is noise or corruption, follow the parity check flows shown in Figure 42.2 and Figure 42.3.

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.



Note 1. RPERF: Standby SRAM Parity Error Reset Detect Flag (RSTSR1.RPERF bit)

Figure 42.2 Flow of Standby SRAM parity check when SRAM parity reset is enabled

42.3.3 奇偶校验计算功能

IEC60730标准要求检查SRAM数据。写入数据时，在32位数据宽度的StandbySRAM中每8位数据添加一个奇偶校验位，读取数据时检查奇偶校验位。当发生奇偶校验错误时，会生成奇偶校验错误通知。此功能也可用于触发复位。

奇偶校验错误通知可以指定为不可屏蔽中断或SRAM.PARIOAD寄存器的OAD位中的复位。当OAD位设置为1时，奇偶校验错误输出到复位功能。当OAD位设置为0时，奇偶校验错误作为不可屏蔽中断输出到ICU。

奇偶校验错误经常因噪声而发生。要确认奇偶校验错误的原因是噪声还是损坏，请遵循图42.2和图42.3所示的奇偶校验流程。

在写访问之后连续执行读访问时，优先执行读访问。因此，在初始化过程中，不要在写访问之后连续执行读访问。

Note 1. RPEST: SRAM Parity Error Interrupt Status Flag (NMISR.RPEST bit)

42.3.4 TrustZone Filter function

There is only one type of TrustZone Filter function for Standby SRAM and that is, TrustZone Filter for SRAM memory protection

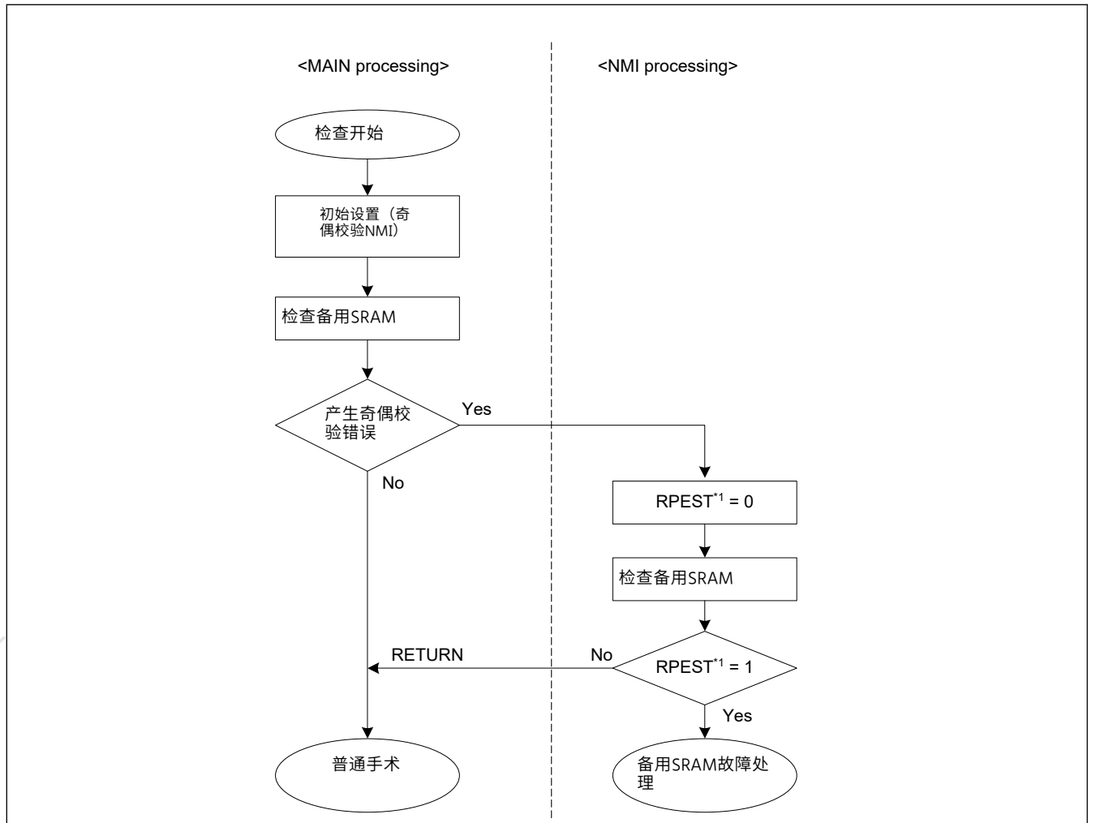
42.3.4.1 TrustZone Filter for Standby SRAM Memory Protection

Standby SRAM memory can be divided into 8 regions, 128 bytes each with a Security Attribution (SA) to be protected from Non-secure access. When SA indicates that the region in Standby SRAM is secure status, non-secure access can not overwrite them because TrustZone Filter detects finds an error and protects the write access.

Table 42.2 Security Attribution and Access status

SA	Access status	Write access	Read access
Secure	Secure	Permit	Permit
	Non-secure	TrustZone Filter error - Protected	TrustZone Filter error - Read data is 0
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

When TrustZone Filter error for Standby SRAM access occurs, no error notification and no error response occurs.



注1.RPEST：SRAM奇偶校验错误中断状态标志（NMISR.RPEST位）

Figure 42.3 启用SRAM奇偶校验中断时的待机SRAM奇偶校验流程

42.3.4 TrustZone过滤器功能

StandbySRAM只有一种TrustZoneFilter功能，即用于SRAM内存保护的TrustZoneFilter

42.3.4.1 用于备用SRAM内存保护的TrustZone过滤器

备用SRAM存储器可分为8个区域，每个128字节具有安全属性(SA)
非安全访问。当SA指示StandbySRAM中的区域为安全状态时，非安全访问无法覆盖它们，因为TrustZone Filter检测发现错误并保护写访问。

Table 42.2 安全属性和访问状态

SA	访问状态	写访问	读取权限
Secure	Secure	Permit	Permit
	Non-secure	TrustZone过滤器错误受保护	TrustZone过滤器错误读取数据为0
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

当StandbySRAM访问的TrustZoneFilter错误发生时，不会发生错误通知和错误响应。

42.3.5 Access Cycle

Number of cycles from the CPU.

For Standby SRAM, cache always has non-cacheable access.

Table 42.3 Standby SRAM (Parity Area 0x2800_0000 to 0x2800_03FF)

	Read cycle		Write cycle	
	Word access	Half-word/Byte access	Word access	Half-word/Byte access
ICLK ≥ PCLKB	Min.: 2 ICLK + 2 PCLKB Max.: (n + 1) ICLK + 2 PCLKB		Min.: 1 ICLK + 1 PCLKB Max.: n ICLK + 1 PCLKB	

Note: When the frequency ratio of ICLK : PCLKB is n : 1

42.4 Usage Notes

42.4.1 Instruction Fetch from the Standby SRAM Area

When using Standby SRAM to operate a program, initialize the Standby SRAM area so that the CPU can correctly prefetch data. A parity error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 4-byte boundary. Renesas recommends using the NOP instruction for data initialization.

42.3.5 访问周期

CPU的周期数。

对于备用SRAM，缓存始终具有不可缓存的访问权限。

Table 42.3 备用SRAM（奇偶校验区0x2800_0000至0x2800_03FF）

	读周期		写周期	
	字访问	Half-word/Byte access	字访问	Half-word/Byte access
ICLK ≥ PCLKB	Min.: 2 ICLK + 2 PCLKB Max.: (n + 1) ICLK + 2 PCLKB		Min.: 1 ICLK + 1 PCLKB Max.: n ICLK + 1 PCLKB	

Note: 当ICLK:PCLKB的频率比为n:1时

42.4 使用说明

42.4.1 从备用SRAM区域取指令

使用StandbySRAM操作程序时，初始化StandbySRAM区域，以便CPU可以正确预取数据。如果CPU从未初始化的区域预取，则可能发生奇偶校验错误。用4字节边界从程序的结束地址初始化额外的12字节区域。瑞萨推荐使用NOP指令进行数据初始化。

FSADDR[31:0]位（FACI命令处理的起始地址）

FSADDR[31:0]位指定FACI命令处理的起始地址。在代码闪存的FACI命令处理中忽略位[31:24]。在数据闪存的FACI命令处理中忽略位[31:17]。与低于表43.4中列出的地址边界的地址位相关的位也被忽略。

43.4.13 FEADDR : FACI Command End Address Register

Base address: FACI = 0x407F_E000

Offset address: 0x34

Bit position:	31																													0
Bit field:	FEADDR[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FEADDR[31:0]	End Address for FACI Command Processing	R/W*1

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that bit [0] and bit [1] are read-only.

The FEADDR register specifies the end address of the target area for Multi Block Erase and Blank Check command processing. When incremental mode is selected as the addressing mode for Blank Checking (when FBCCNT.BCDIR = 0), the address specified in the FSADDR register should be equal to or smaller than the address in the FEADDR register. Conversely, the address in the FSADDR register should be equal to or larger than the address in the FEADDR register when decremental mode is selected as the addressing mode for Blank Check (i.e. when FBCCNT.BCDIR = 1). If the BCDIR, FSADDR, and FEADDR bit settings are inconsistent with the specified rules, the flash sequencer enters the command-locked state (see section 43.11.2. Error Protection).

The FEADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

FEADDR[31:0] bits (End Address for FACI Command Processing)

The FEADDR[31:0] bits specify the end address for Multi Block Erase and Blank Check command processing. In command processing, bits 31 to 17 and any bits that do not reach the address boundaries listed in the section 43.4.12. FSADDR : FACI Command Start Address Register are ignored.

For information on the addresses of the flash memory, see section 43.2. Structure of Memory.

15:8	KEY[7:0]	Key Code	W*3

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while the FRDY bit = 0 is ignored.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY bits is D9h.
Note 3. Written values are not retained by these bits (always read as 0x00).
Note 4. Only secure access can write to this register. Both secure access and non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is note generated.

ESUSPMD bit (Erasure Suspend Mode)

The ESUSPMD bit selects the erasure suspension mode when a P/E suspend command is issued while the flash sequencer is executing erasure processing (see section 43.9.3.10. P/E Suspend Command). This bit should be set before issuing Block Erase or Multi Block Erase command.

43.4.26 FPCKAR : Flash Sequencer Processing Clock Notification Register

Base address: FACI = 0x407F_E000

Offset address: 0xE4

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								PCKA[7:0]

15:8	KEY[7:0]	Key Code	W*3

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x1E.
Note 3. Written values are not retained by these bits (always read 0x00).

FPCKAR specifies the operating frequency of the flash sequencer while processing FACI commands. The highest operating frequency for the given product is set as the initial value.

PCKA[7:0] bits (Flash Sequencer Operating Clock Notification)

The PCKA[7:0] bits specify the operating frequency of the flash sequencer while processing FACI commands. Set the desired frequency for these bits before issuing an FACI command. Specifically, convert the frequency in MHz to a binary number and set it for these bits.

Example:

Frequency is 35.9 MHz (PCKA = 0x24)

Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics cannot be guaranteed. If the value set in these bits is greater than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics can be guaranteed but the FACI command processing time such as the time programming/erasure takes will increase. The minimum FACI command processing time is obtained when the operating frequency of the flash sequencer is the same as the PCKA value.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the PCKA bit.

当闪存定序器正在执行擦除处理时发出PE暂停命令时，ESUSPMD位选择擦除暂停模式（请参阅第43.9.3.10节。PE暂停命令）。该位应在发出块擦除或多块擦除命令之前设置。

43.4.26 FPCKAR:闪存定序器处理时钟通知寄存器

15:8	KEY[7:0]	关键代码	W*3

注1.当FSTATR寄存器中的FRDY位为1时可以写入该位。当FRDY位为0时忽略写入该位。
注2.仅当写入16位且写入KEY[7:0]位的值为0x1E时，才能写入这些位。
注3.这些位不保留写入的值（始终读取0x00）。

FPCKAR在处理FACI命令时指定闪存定序器的工作频率。将给定产品的最高工作频率设置为初始值。

PCKA[7:0]位（闪存定序器工作时钟通知）

PCKA[7:0]位指定闪存定序器在处理FACI命令时的工作频率。在发出FACI命令之前为这些位设置所需的频率。具体来说，将以MHz为单位的频率转换为二进制数并为这些位设置它。

Example:

频率为35.9MHz(PCKA=0x24)

将35.9MHz的第一个小数位四舍五入为整数(=36)并将其转换为二进制数。

如果这些位中设置的值小于闪存定序器的实际工作频率，则无法保证闪存编程擦除特性。如果这些位中设置的值大于闪存定序器的实际工作频率，则可以保证闪存编程擦除特性，但FACI命令处理时间（例如编程擦除所花费的时间）会增加。当闪存定序器的工作频率与PCKA值相同时，得到最小FACI命令处理时间。

KEY[7:0] bits (Key Code)

KEY[7:0]位控制对PCKA位的写入权限。

1. Access size to this register is 16 bits
2. The value of KEY[7:0] is 0x66
3. The FSPR bit is 1.

Note 2. Written values are not retained by these bits (always read 0x00).

Note 3. Only secure access can write to this register. Both secure access and non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is note generated.

Offset address: 0x40

Bit position:	7	6	5	4	3	2	1	0

Value after reset:	0	0	1	1	1	1	0	0

Bit	Symbol	Function	R/W
7:0	FCKMHZ[7:0]	Data Flash Access Frequency Register These bits optimize the speed of reading the data flash memory.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

This register optimizes the speed of reading the data flash memory.

Set the frequency of the peripheral module clock (FCLK) of internal peripheral bus which is the clock for access to the data flash memory, in MHz units. For example, 35.9 MHz should be rounded up and set the frequency to 36. Number of cycles required for access to the data flash memory are inserted according to the frequency. When changing the frequency of the FCLK, follow the procedure below to modify the value of the data flash access frequency register (FCKMHZ) in either of the following ways according to whether operation is at a lower frequency before or after the change.

- When changing the speed from low to high: Modify FCKMHZ. After confirming the change by reading FCKMHZ, change the frequency.
- When changing the speed from high to low: Change the frequency. After the frequency is changed, modify FCKMHZ.

该寄存器优化了数据闪存的读取速度。

设置内部外围总线的外围模块时钟(FCLK)的频率，它是访问数据闪存的时钟，以MHz为单位。例如，35.9MHz应向上取整，并将频率设置为36。根据频率插入访问数据闪存所需的周期数。当改变FCLK的频率时，根据改变之前或之后是在较低频率下操作，按照以下步骤，通过以下任一方式修改数据闪存访问频率寄存器(FCKMHZ)的值。

●转速由低变高时：修改FCKMHZ。通过读取FCKMHZ确认更改后，更改频率。

●速度由高变低时：改变频率。频率改变后，修改FCKMHZ。

43.7 Overview of Functions

By using a dedicated flash-memory programmer to program the flash memory through a serial interface (serial programming) or JTAG/SWD interface (on-chip debug mode), the device can be rewritten regardless of whether this is before or after it is mounted on the target system.

Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties.

Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations. Table 43.10 lists the overview of the methods of programming and the corresponding operating modes.

Table 43.10 Programming methods

Programming method	Functional overview	Operating mode
Serial programming	A dedicated flash-memory programmer through the SCI interface enables on-board programming of the flash memory after the device is mounted on the target system.	Serial programming mode
	A dedicated flash-memory programmer through the SCI interface and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	
Self-programming	A user program written to memory in advance of serial programming execution can also program the flash memory. The background operation capability makes it possible to fetch instructions or otherwise read data from the code flash memory while the data flash memory is programmed. As a result, a program resident in the code flash memory is able to program the data flash memory. For background operations that are not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while the code flash memory is being programmed by self-programming. In such cases, a program for programming from the internal SRAM must be transferred in advance and executed.	Normal operating mode
JTAG or SWD programming	A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD enables on-board programming of the flash memory after the device is mounted on the target system. A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system. 43.7 功能概述

通过使用专用闪存编程器通过串行接口（串行编程）或JTAGSWD接口（片上调试模式）对闪存进行编程，无论是在安装之前还是之后，都可以重写设备目标系统。

此外，内置了禁止重写或读取写入闪存的用户程序的安全功能，这可以防止第三方篡改和非法读取程序。

用户程序编程（自编程）适用于目标系统上的应用程序在制造或发货后可能需要更新的应用程序。还集成了用于安全重写闪存的保护功能。此外，支持自编程期间的中断处理，因此可以与外部通信处理等同时进行编程，这在各种情况下都是如此。表43.10列出了编程方法和相应操作模式的概述。

43.8 Operating Modes of the Flash Sequencer

The flash sequencer has three operating modes as shown in Figure 43.6. Transitions between modes are initiated by changing the value of the FENTRYR register.

When the value of the FENTRYR register is 0x0000, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. The code flash memory and data flash memory are both readable.

When the value of the FENTRYR register is 0x0001, the flash sequencer is in code flash P/E mode where the code flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is readable.

When the value of the FENTRYR register is 0x0080, the flash sequencer is in data flash P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

43.9 FACI命令

本节介绍有关FACI命令的信息，表43.13列出了FACI命令。

The FACI commands are issued by writing to the FACI command-issuing area (see Table 43.3). When write access as shown in Table 43.14 proceeds in the specified state, the flash sequencer executes the processing associated with the given command (see section 43.9.2. Relationship between the Flash Sequencer State and FACI Commands).

Table 43.14 FACI command formats

FACI commands	Number of write access	Write data to the FACI command-issuing area

Configuration set N = 8	11	0x40	0x08 (=N)	WD1 to WD8	0xD0

Note: WDN (N = 1, 2, …): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY bit to 0 at the start of a command processing other than the Status Clear command, and sets this bit to 1 on completion.

If the FRDYIE.FRDYIE bit setting is 1, a flash ready (FRDY) interrupt is generated when the FSTATR.FRDY bit is set to 1.

43.9.2 Relationship between the Flash Sequencer State and FACI Commands

The FACI commands are accepted according to the mode/state of the flash sequencer. FACI commands should be issued after transitioning of the flash sequencer to the code flash P/E mode or data flash P/E mode and after checking the state of the flash sequencer.

Use the FSTATR and FASTAT registers to check the state of the flash sequencer. In addition, the occurrence of errors in general can be checked by reading the CMDLK bit in the FASTAT register. The value of the CMDLK bit is the logical OR of the following bits in the FSTATR register:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR
- FLWEERR.

Table 43.15 lists the available FACI commands in each operating mode.

FACI命令通过写入FACI命令发布区域来发布（参见表43.3）。当表43.14所示的写访问在指定状态下进行时，闪存定序器执行与给定命令相关的处理（请参阅第43.9.2节。闪存定序器状态和FACI命令之间的关系）。

Table 43.14 FACI命令格式

配置集 N = 8	11	0x40	0x08 (=N)	WD1 to WD8	0xD0

Note: WDN(N=1 2 …)：要编程的第N个16位数据。

闪存定序器在除状态清除命令之外的命令处理开始时将FSTATR.FRDY位清除为0，并在完成时将此位设置为1。

如果FRDYIE.FRDYIE位设置为1，则当FSTATR.FRDY位设置为1时会产生闪存就绪(FRDY)中断。

43.9.2 FlashSequencerState和FACI命令之间的关系

根据闪存定序器的模式状态接受FACI命令。FACI命令应在闪存定序器转换到代码闪存PE模式或数据闪存PE模式并检查闪存定序器的状态之后发出。

使用FSTATR和FASTAT寄存器检查闪存序列器的状态。此外，一般可以通过读取FASTAT寄存器中的CMDLK位来检查错误的发生。CMDLK位的值是FSTATR寄存器中以下位的逻辑或：

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR
- FLWEERR.

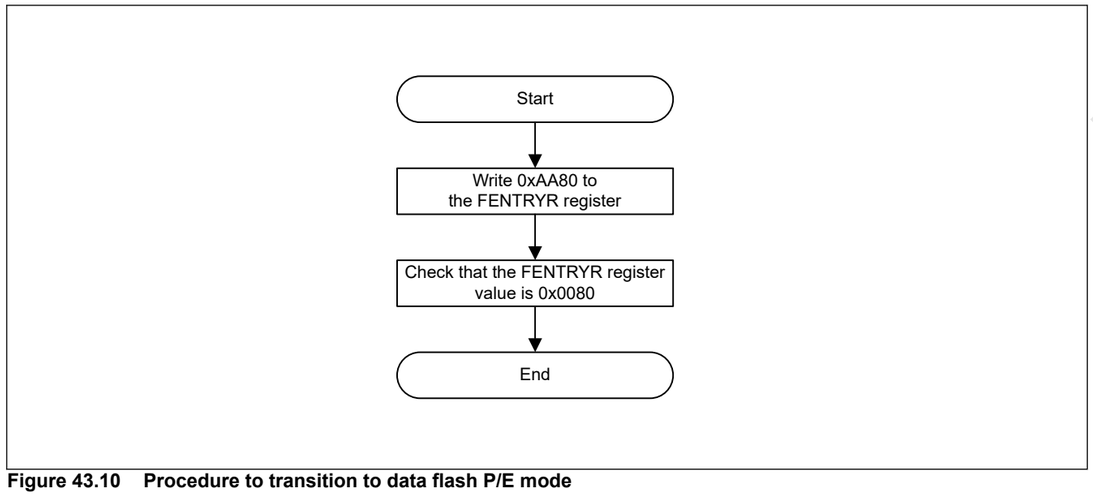

Figure 43.10 Procedure to transition to data flash P/E mode

43.9.3.5 Transition to Read Mode

To read the flash memory, a transition to read mode is required by setting the FENTRYR register to 0x0000. The transition to read mode should be made after the flash sequencer completes the processing and while operation is not in the command-locked state.

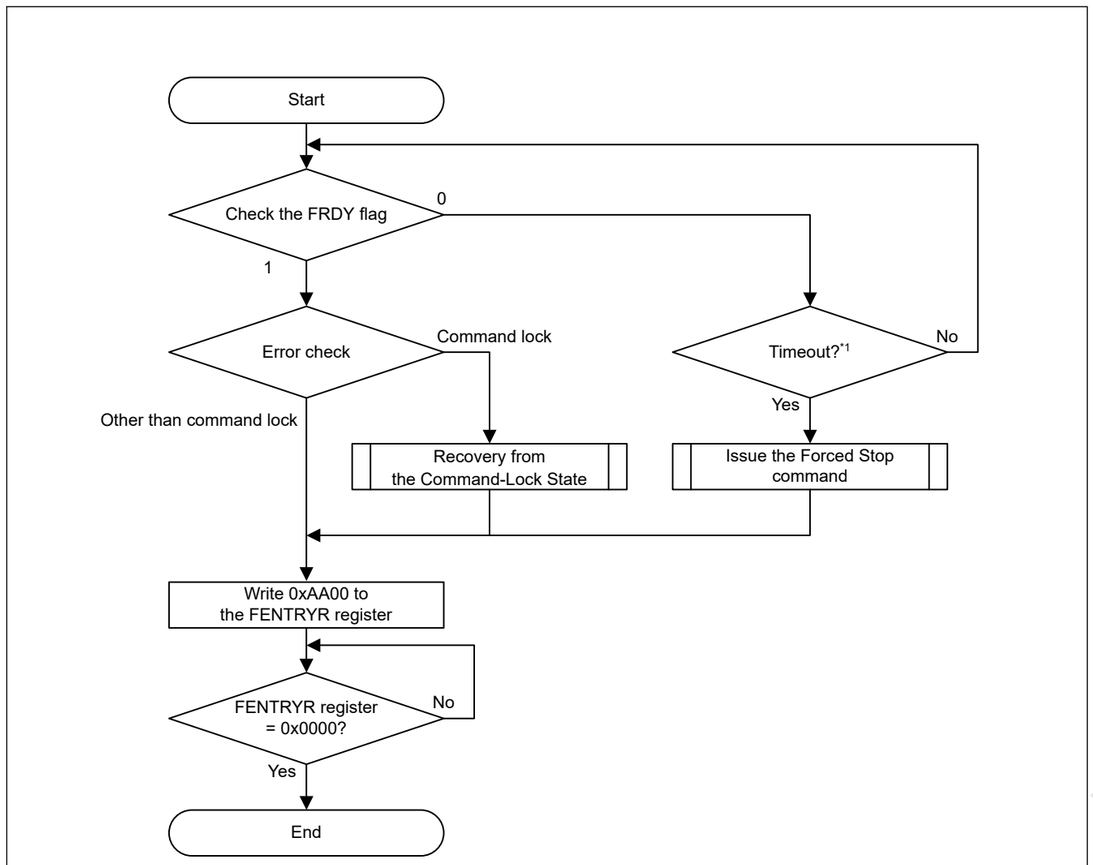
43.9.3.5 过渡到阅读模式

要读取闪存，需要通过将FENTRYR寄存器设置为0x0000转换到读取模式。闪存定序器完成处理后且操作未处于命令锁定状态时，应转换到读取模式。

图43.11显示了转换到读取模式的过程。



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (see section 46, Electrical Characteristics)

Figure 43.11 Procedure to transition to read mode

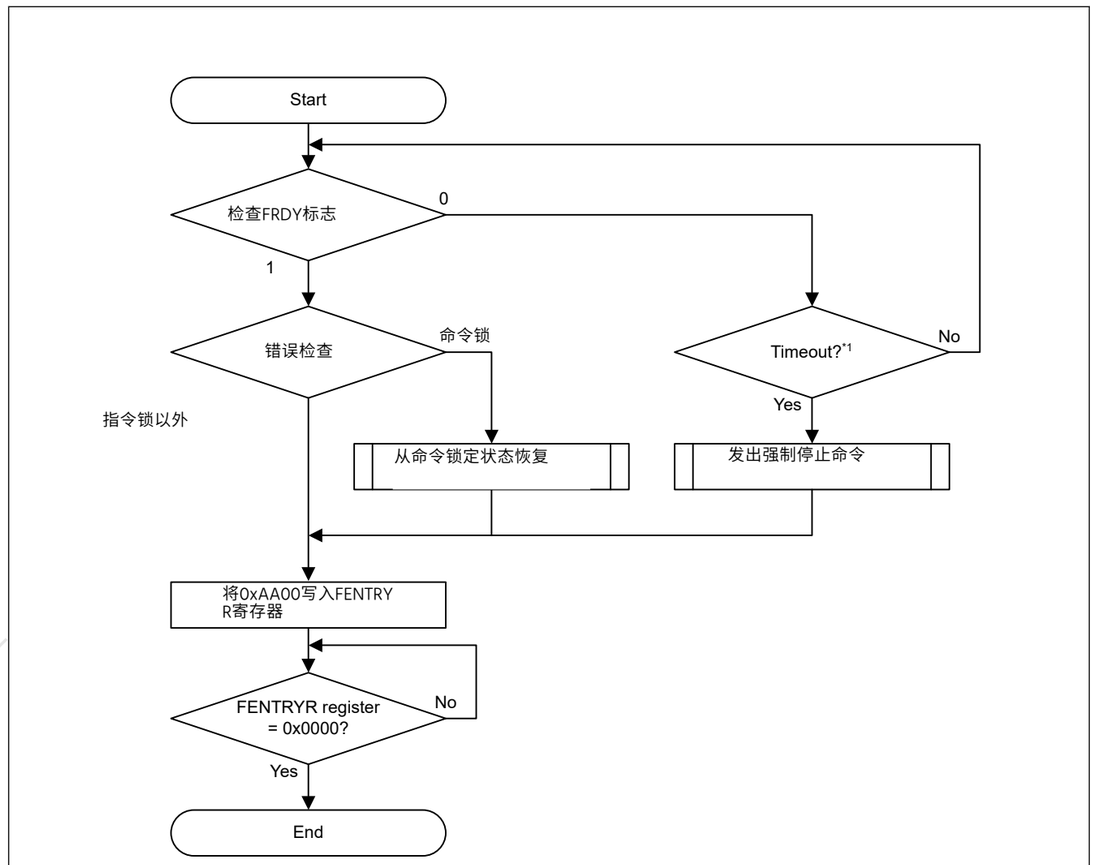
43.9.3.6 Recovery from the Command-Locked State

When the flash sequencer enters the command-locked state, FACI commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, forced stop command, or FASTAT register.

When the command-locked state is detected by checking for an error before issuing the P/E suspend command, the FRDY bit in the FSTATR register might be 0 even though command processing has not completed. If processing is not complete by the maximum programming/erasure time specified in the electrical characteristics, this is a timeout and the flash sequencer must be stopped with the forced stop command.

The FLWEERR bit in the FSTATR register does not change from 1 to 0 with the status clear command. When these bits are set to 1, use the forced stop command to release from the command-locked state. Bits other than FRDY and FLWEERR in FSTATR register that indicate the command-locked state can be changed from 1 to 0 with the status clear or forced stop command.

Figure 43.12 shows the recovery flow from the command-locked state.



注1.超时的判断是基于1.1倍的FACI命令处理正在进行的最长时间（见第46节，电气特性）

Figure 43.11 转换到阅读模式的过程

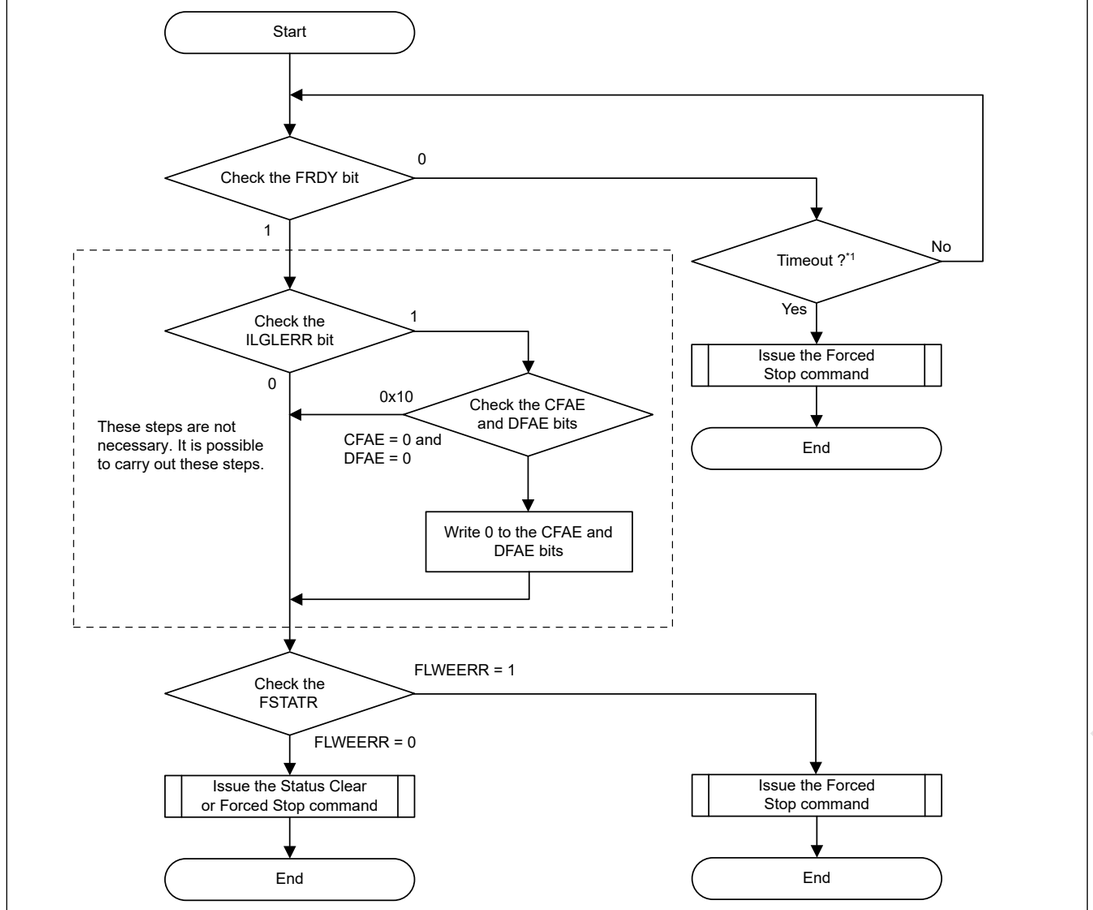
43.9.3.6 从命令锁定状态恢复

当闪存定序器进入命令锁定状态时，无法接受FACI命令。要从命令锁定状态释放定序器，请使用状态清除命令、强制停止命令或FASTAT寄存器。

当通过在发出PE挂起命令之前检查错误来检测命令锁定状态时，即使命令处理尚未完成，FSTATR寄存器中的FRDY位也可能为0。如果在电气特性中指定的最大编程擦除时间未完成处理，则这是一个超时，并且必须使用强制停止命令停止闪存定序器。

FSTATR寄存器中的FLWEERR位不会随着状态清除命令从1变为0。当这些位设置为1时，使用强制停止命令从命令锁定状态中释放。FSTATR寄存器中除FRDY和FLWEERR以外的位指示命令锁定状态可以通过状态清除或强制停止命令从1更改为0。

图43.12显示了从命令锁定状态的恢复流程。



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (see section 46, Electrical Characteristics)

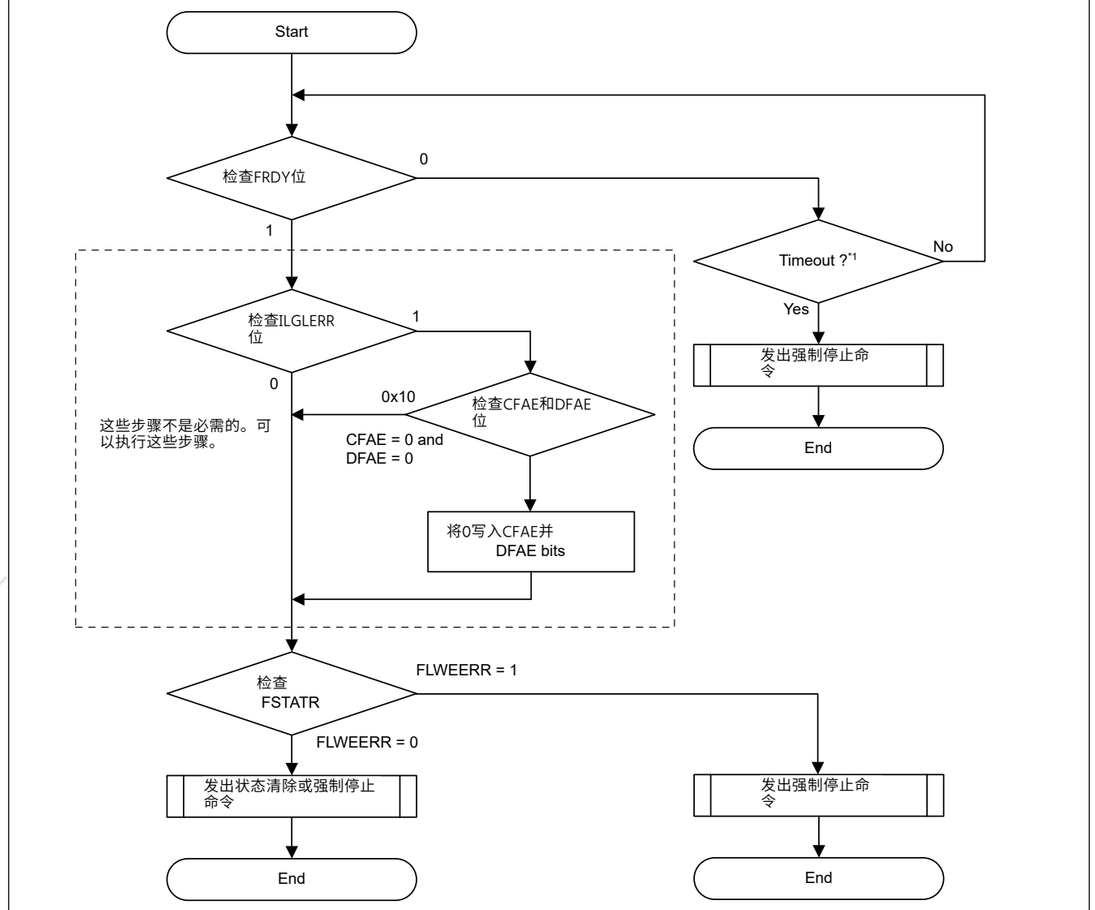
Figure 43.12 Recovery flow from the command-locked state

43.9.3.7 Program Command

The program command is used for writing to the user area and data area. Before issuing the FACI program command, set the first address of the target block in the FSADDR register. Writing 0xD0 at the final access of the FACI command-issuing area starts the program command processing. If the target area of program command processing contains area that are not for writing, write 0xFFFF to the corresponding area.

Issuing the program command while the FACI internal data buffer is full leads to a wait on the peripheral bus that might affect communications performance of other peripheral modules. To avoid a wait, set the DBFULL bit in the FSTATR register to 0 when issuing the FACI command. Writing to the data area does not lead to the data buffer becoming full.

Figure 43.13 shows the usage of the program command.



注1.超时的判断是基于1.1倍的FACI命令处理正在进行的最长时间（见第46节，电气特性）

Figure 43.12 从命令锁定状态恢复流程

43.9.3.7 程序命令

程序命令用于写入用户区和数据区。在发出FACI程序命令之前，在FSADDR寄存器中设置目标块的首地址。在最终访问FACI命令发布区域时写入0xD0开始程序命令处理。如果程序命令处理的目标区域包含非写入区域，则将0xFFFF写入相应区域。

在FACI内部数据缓冲区已满时发出程序命令会导致外围总线等待，这可能会影响其他外围模块的通信性能。为避免等待，请在发出FACI命令时将FSTATR寄存器中的DBFULL位设置为0。写入数据区不会导致数据缓冲区变满。

图43.13显示了程序命令的用法。

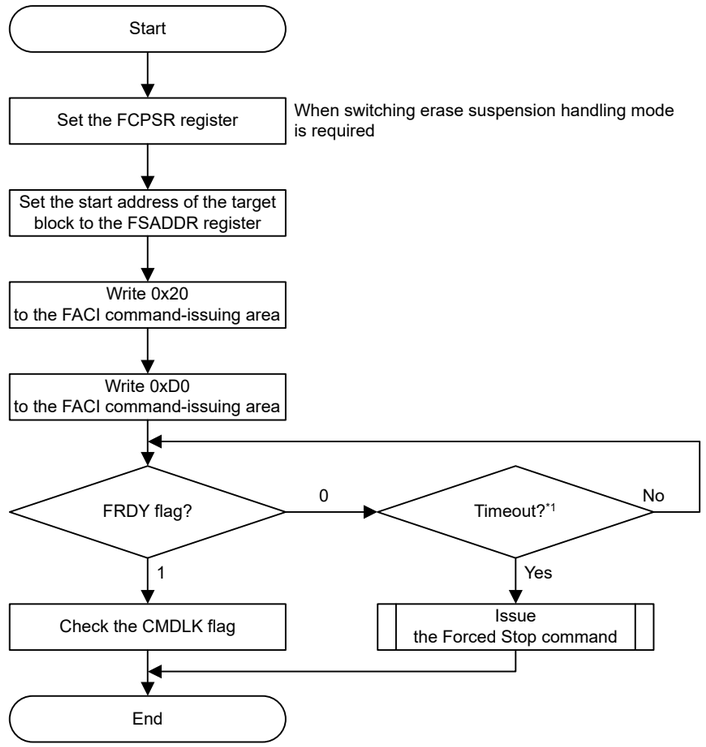
43.9.3.8 Block Erase Command

The block erase command is used for erasing user area or data area. The erase unit is one block. Before issuing a block erase command, set the first address of the target block to FSADRR register. Writing 0xD0 at the second write access of the FACI command triggers the FACI to start the block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

Figure 43.14 shows the usage of the block erase command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of erasure. See section 46, Electrical Characteristics.

Figure 43.14 Usage flow of the block erase command

43.9.3.9 Multi Block Erase Command

The multi block erase command is used for erasing data area. The erase unit is 64, 128, or 256 bytes. Before issuing the multi block erase command, set the start address to FSADRR register and the end address to FEADDR register. Writing 0xD0 at the second write access of the FACI command triggers FACI to start the multi block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

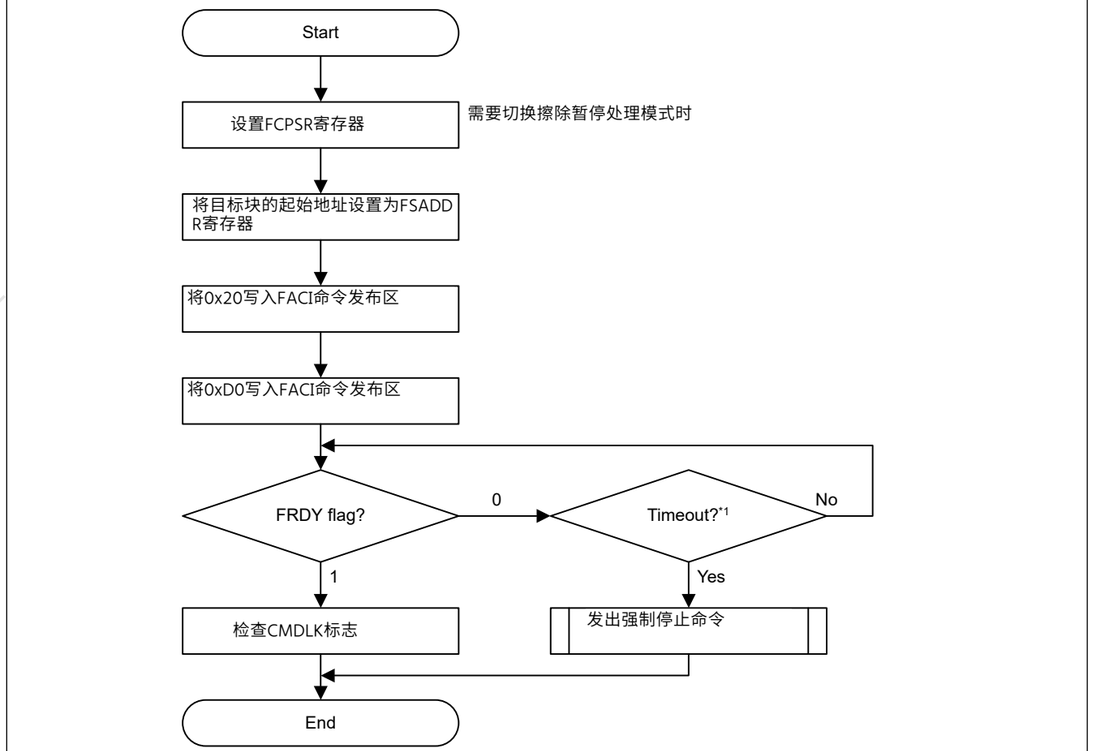
Set the FCPSR registers before issuing the multi block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

43.9.3.8 块擦除命令

块擦除命令用于擦除用户区或数据区。擦除单位是一个块。在发出块擦除命令之前，将目标块的首地址设置为FSADRR寄存器。在FACI命令的第二次写访问时写入0xD0会触发FACI开始块擦除命令处理。命令处理的完成可以通过FSTATR寄存器的FRDY位来确认。

在发出块擦除命令之前设置FCPSR寄存器。此外，当要切换擦除暂停模式时，必须设置FCPSR。

图43.14显示了块擦除命令的用法。



注1.超时的判断是基于最大擦除时间的1.1倍。
参见第46节，电气特性。

Figure 43.14 块擦除命令的使用流程

43.9.3.9 多块擦除命令

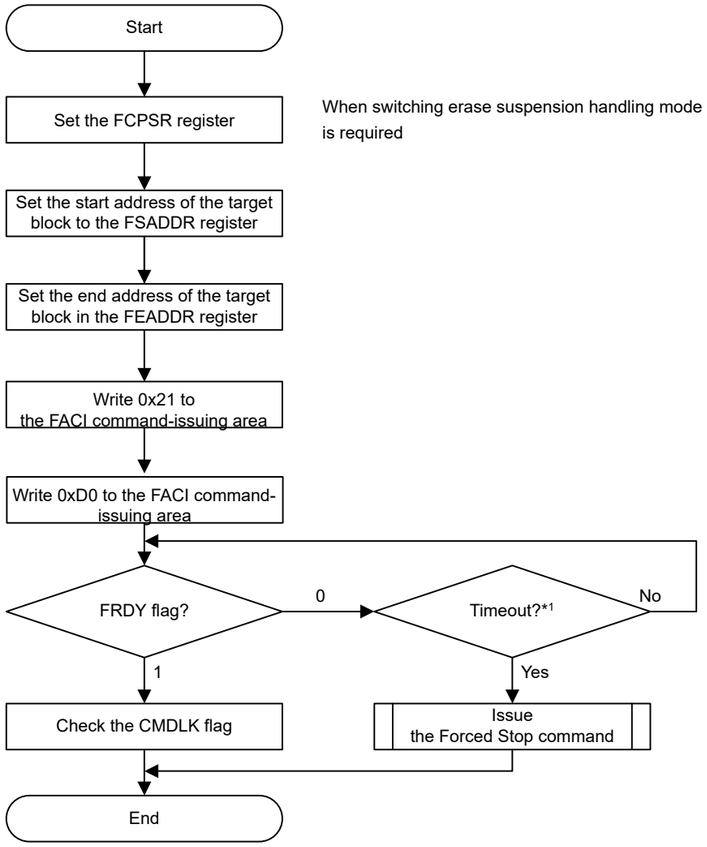
多块擦除命令用于擦除数据区域。擦除单元为64、128或256字节。在发出多块擦除命令之前，将起始地址设置为FSADRR寄存器，将结束地址设置为FEADDR寄存器。在FACI命令的第二次写访问时写入0xD0会触发FACI开始多块擦除命令处理。命令处理的完成可以通过FSTATR寄存器的FRDY位来确认。

在发出多块擦除命令之前设置FCPSR寄存器。此外，当要切换擦除暂停模式时，必须设置FCPSR。

The erase size is specified by both the FSADDR and FEADDR settings. Table 43.17 describes how to set the FSADDR and FEADDR.

Table 43.17 Settings for the erase size

Erase size	FSADDR	FEADDR
64 bytes	FSA0 to FSA5 = 0 (64 byte-boundary)	FSADDR + 0x3C
128 bytes	FSA0 to FSA6 = 0 (128 byte-boundary)	FSADDR + 0x7C
256 bytes	FSA0 to FSA7 = 0 (256 byte-boundary)	FSADDR + 0xFC



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of erasure. See section 46, Electrical Characteristics.

Figure 43.15 Usage flow of the multi block command

43.9.3.10 P/E Suspend Command

The P/E suspend command is used to suspend programming/erasure. Before issuing a P/E suspend command, check that the CMDLK bit in the FASTAT register is 0, and that the execution of programming/erasure is performed normally. To confirm that the P/E suspend command can be received, check that the SUSRDY bit in the FSTATR register is 1. After issuing a P/E suspend command, read the CMDLK bit to confirm that no error occurs.

If an error occurs during programming/erasure, the CMDLK bit is set to 1. When programming/erasure processing has finished from the time when the SUSRDY bit is 1 to when the P/E suspend command is received, no error occurs and the

43.9.3.10 PE挂起命令

PE暂停命令用于暂停编程擦除。在发出PE挂起命令之前，请检查FASTAT寄存器中的CMDLK位是否为0，并且编程擦除的执行是否正常执行。要确认可以接收到PE挂起命令，请检查FSTATR寄存器中的SUSRDY位是否为1。发出PE挂起命令后，读取CMDLK位以确认没有错误发生。

如果在编程擦除过程中发生错误，则将CMDLK位设置为1。从SUSRDY位为1到接收到PE暂停命令时，当编程擦除处理完成时，不会发生错误，并且

suspended state is not entered (the FRDY bit in the FSTATR register is 1 and the ERSSPD and PRGSPD bits in FSTATR are 0).

When a P/E suspend command is received and the programming/erasure suspend processing finishes normally, the flash sequencer enters the suspended state, the FRDY bit is set to 1, and the ERSSPD or PRGSPD bit is 1. After issuing a P/E suspend command, check that the ERSSPD or PRGSPD bit is 1 and the suspended state is entered, then proceed with the subsequent flow. If a P/E resume command is issued in the subsequent flow even when the suspended state is not entered, an illegal command error occurs and the flash sequencer shifts to the command-locked state (see section 43.11.2. Error Protection).

If the erasure suspended state is entered, programming to blocks other than an erasure target block can be performed. Additionally, the programming and erasure suspended states can shift to read mode by clearing the FENTRYR register.

Figure 43.16 shows the usage of the P/E suspend command.

未进入挂起状态（FSTATR寄存器中的FRDY位为1，FSTATR中的ERSSPD和PRGSPD位为0）。

当接收到PE挂起命令并且编程擦除挂起处理正常完成时，闪存定序器进入挂起状态，FRDY位设置为1，ERSSPD或PRGSPD位为1。发出PE挂起命令后，检查是否ERSSPD或PRGSPD位为1，进入挂起状态，然后进行后续流程。如果在后续流程中发出PEresume命令，即使没有进入挂起状态，也会发生非法命令错误，并且闪存定序器会切换到命令锁定状态（请参阅第43.11.2节。错误保护）。

如果进入擦除暂停状态，则可以执行对擦除目标块以外的块的编程。
此外，通过清除FENTRYR寄存器，编程和擦除暂停状态可以转换为读取模式。

图43.16显示了PE挂起命令的用法。

When issuing a P/E suspend command during flash memory programming, the flash sequencer suspends programming processing. Figure 43.17 shows the suspend programming operation. Figure 43.16 PE挂起命令的使用流程

(1) 编程期间暂停

在闪存编程期间发出PE暂停命令时，闪存定序器暂停编程处理。图43.17显示了挂起编程操作。当接收到编程相关命令时，flashsequencer将FSTATR寄存器中的FRDY位清0以开始编程。如果闪存定序器进入状态

in which the P/E suspend command can be received after programming starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0. If the flash sequencer receives a P/E suspend command while a programming pulse is applied, the flash sequencer continues with the pulse. After the specified pulse application time, the flash sequencer finishes pulse application, starts the programming suspend processing, and sets the PRGSPD bit in the FSTATR register to 1.

When a suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the programming suspended state. When receiving a P/E resume command in the programming suspended state, the flash sequencer clears the FRDY and PRGSPD bits to 0 and resumes programming.

Figure 43.17 shows the timing for suspension during programming.

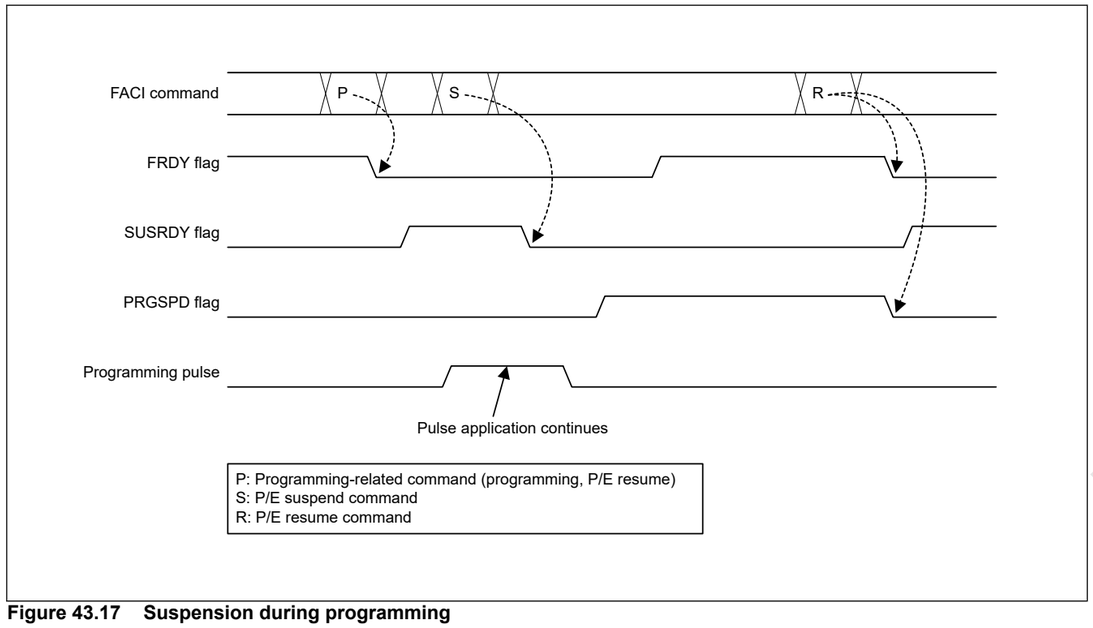

Figure 43.17 Suspension during programming

(2) Suspension during Erasure (Suspension Priority Mode)

The flash sequencer has a suspension priority mode for the suspension of erasure. Figure 43.18 shows the suspend operation of erasure when the erasure suspend mode is set to the suspension priority mode (the ESUSPMD bit in the FCPSR register is 0).

When receiving an erasure-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start erasure. If the flash sequencer enters the state in which the P/E suspend command can be received after erasure starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0.

When receiving a suspend command during erasure, the flash sequencer starts the suspend processing and sets the ERSSPD bit in the FSTATR register to 1 even when it is applying an erasure pulse. When the suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the erasure suspended state. When receiving a P/E resume command in the erasure suspended state, the flash sequencer clears the FRDY and ERSSPD bits to 0 and resumes erasure. Operations of the FRDY, SUSRDY, and ERSSPD bits at the suspension and resumption of erasure are the same, regardless of the erasure suspend mode.

The setting of the erasure suspend mode affects the control method of erasure pulses. In suspension priority mode, when receiving a P/E suspend command while erasure pulse A that has not been previously suspended is being applied, the flash sequencer suspends the application of erasure pulse A and enters the erasure suspended state. When receiving a P/E suspend command while reapplying erasure pulse A after erasure is resumed with a P/E resume command, the flash sequencer

在编程开始后可以接收PE挂起命令的情况下，它将FSTATR寄存器中的SUSRDY位设置为1。

当发出PE暂停命令时，闪存定序器接收该命令并将SUSRDY位清除为0。如果在施加编程脉冲时闪存定序器接收到PE暂停命令，则闪存定序器继续执行该脉冲。在指定的脉冲施加时间之后，闪存序列器完成脉冲施加，开始编程暂停处理，并将FSTATR寄存器中的PRGSPD位设置为1。

当暂停处理完成时，闪存定序器将FRDY位设置为1以进入编程暂停状态。当在编程暂停状态下接收到PEresume命令时，闪存定序器将FRDY和PRGSPD位清除为0并恢复编程。

图43.17显示了编程期间暂停的时序。

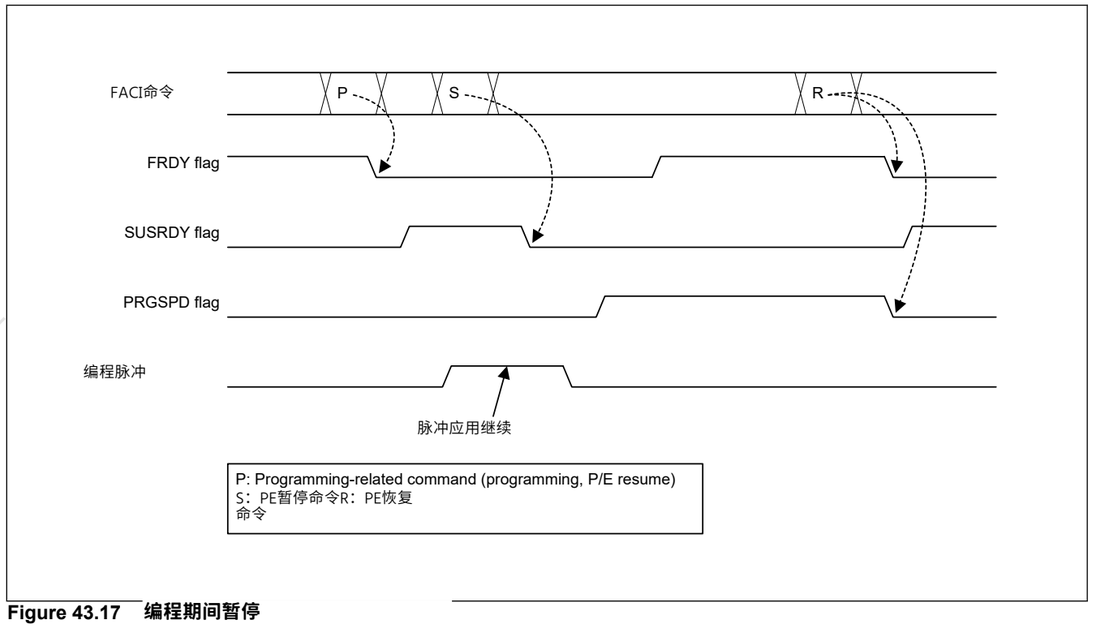

Figure 43.17 编程期间暂停

(2) 擦除期间暂停（暂停优先模式）

闪存定序器具有用于暂停擦除的暂停优先模式。图43.18显示了擦除挂起模式设置为挂起优先模式（FCPSR寄存器中的ESUSPMD位为0）时的擦除挂起操作。

当接收到擦除相关命令时，闪存定序器将FSTATR寄存器中的FRDY位清零以开始擦除。如果闪存序列器在擦除开始后进入可以接收PE挂起命令的状态，它会将FSTATR寄存器中的SUSRDY位设置为1。

当发出PE挂起命令时，闪存定序器接收该命令并将SUSRDY位清除为0。

在擦除期间接收到挂起命令时，闪存定序器启动挂起处理并将FSTATR寄存器中的ERSSPD位设置为1，即使它正在施加擦除脉冲。当挂起处理完成时，闪存定序器将FRDY位设置为1以进入擦除挂起状态。当在擦除暂停状态下接收到PE恢复命令时，闪存定序器将FRDY和ERSSPD位清除为0并恢复擦除。无论擦除暂停模式如何，FRDY、SUSRDY和ERSSPD位在擦除暂停和恢复时的操作都是相同的。

擦除暂停模式的设置会影响擦除脉冲的控制方法。在挂起优先模式下，当在施加先前未被挂起的擦除脉冲A的同时接收到PE挂起命令时，闪存定序器挂起擦除脉冲A的施加并进入擦除挂起状态。在使用PE恢复命令恢复擦除后，在重新应用擦除脉冲A的同时接收到PE暂停命令时，闪存定序器

continues to apply erasure pulse A. After the specified pulse application time, the flash sequencer finishes erasure pulse application and enters the erasure suspended state.

When the flash sequencer receives a P/E resume command next and erasure pulse B is being applied, the flash sequencer receives a P/E suspend command again, and the application of erasure pulse B is then suspended. In suspension priority mode, delays due to suspension can be minimized because the application of an erasure pulse is suspended once per pulse, and priority is given to the suspend processing.

If the interval of suspension after resume is longer than t_{REST1} (Resume time: priority on suspension, resume after the 1st suspend for the same pulse), suspend delay will be always t_{SESD1} (Suspend delay: priority on suspension, the 1st suspend for the same pulse).

If the interval of suspension after resume is shorter than t_{REST1}, suspend delay becomes either t_{SESD1} or t_{SESD2} (Suspend delay: priority on suspension, the 2nd suspend for the same pulse).

(The value of t_{REST1} / t_{SESD1} / t_{SESD2}, see section 46, Electrical Characteristics.)

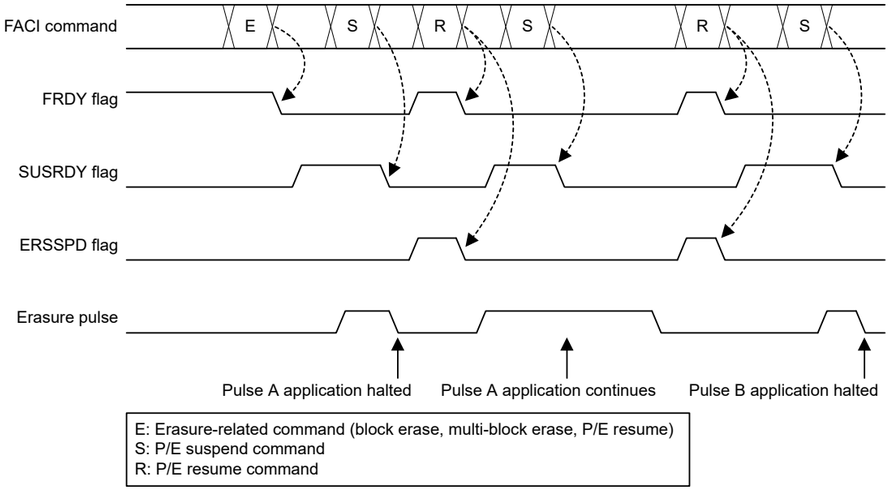

Figure 43.18 Suspension during erasure (suspension priority mode)

(3) Suspension during Erasure (Erasure Priority Mode)

The flash sequencer has an erasure priority mode for the suspension of erasure. Figure 43.19 shows the suspend operation of erasure when the erasure suspend mode is set to the erasure priority mode (the ESUSPMD bit in the FCPSR register is 1). The control method of erasure pulses in erasure priority mode is the same as that of programming pulses for the programming suspend processing.

If the flash sequencer receives a P/E suspend command while an erasure pulse is applied, the flash sequencer continues to apply the pulse. In this mode, the required time for the erasure processing can be reduced compared to the suspension priority mode because the re-application of erasure pulses does not occur when a P/E resume command is issued.

继续施加擦除脉冲A。在指定的脉冲施加时间之后，闪存定序器完成擦除脉冲施加并进入擦除暂停状态。

当闪存定序器接下来接收到PE恢复命令并且正在施加擦除脉冲B时，闪存定序器再次接收到PE暂停命令，然后暂停擦除脉冲B的施加。在挂起优先模式中，由于擦除脉冲的施加在每个脉冲中挂起一次，因此挂起引起的延迟可以被最小化，并且挂起处理具有优先权。

如果恢复后挂起的时间间隔大于tREST1（恢复时间：挂起优先，相同脉冲第一次挂起后恢复），挂起延迟将始终为tSESD1（挂起延迟：挂起优先，第一次挂起相同的脉冲）。

如果恢复后的暂停间隔小于tREST1，则暂停延迟变为tSESD1或tSESD2（暂停延迟：暂停优先，相同脉冲的第2次暂停）。

（tREST1tSESD1tSESD2的值，请参见第46节，电气特性。）

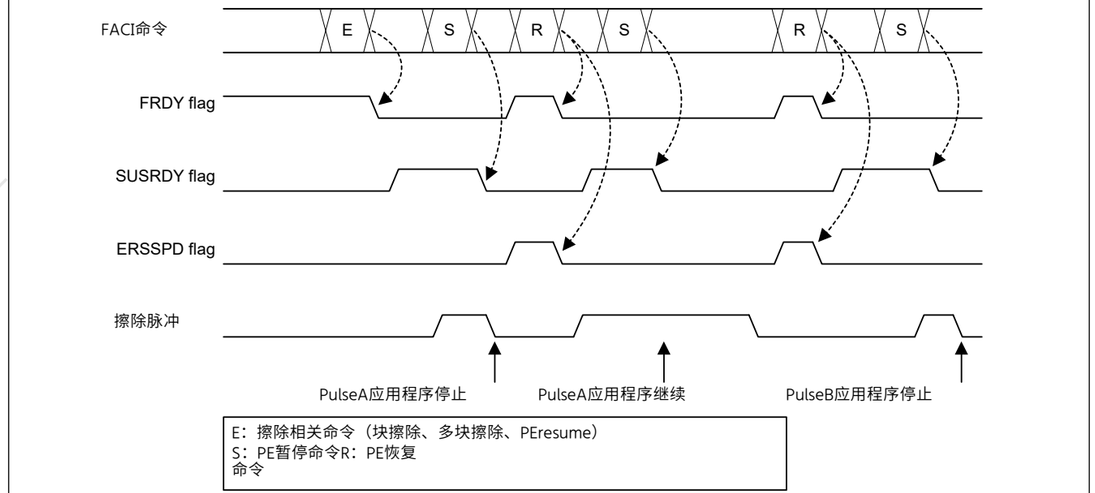

Figure 43.18 擦除期间暂停（暂停优先模式）

(3) 擦除期间暂停（擦除优先模式）

闪存定序器具有用于暂停擦除的擦除优先模式。图43.19显示了擦除挂起模式设置为擦除优先模式时的擦除挂起操作（FCPSR寄存器中的ESUSPMD位为1）。擦除优先模式中擦除脉冲的控制方法与用于编程暂停处理的编程脉冲的控制方法相同。

如果在施加擦除脉冲时闪存定序器接收到PE暂停命令，则闪存定序器继续施加脉冲。在这种模式下，与暂停优先模式相比，擦除处理所需的时间可以减少，因为当发出PE恢复命令时不会发生擦除脉冲的重新施加。

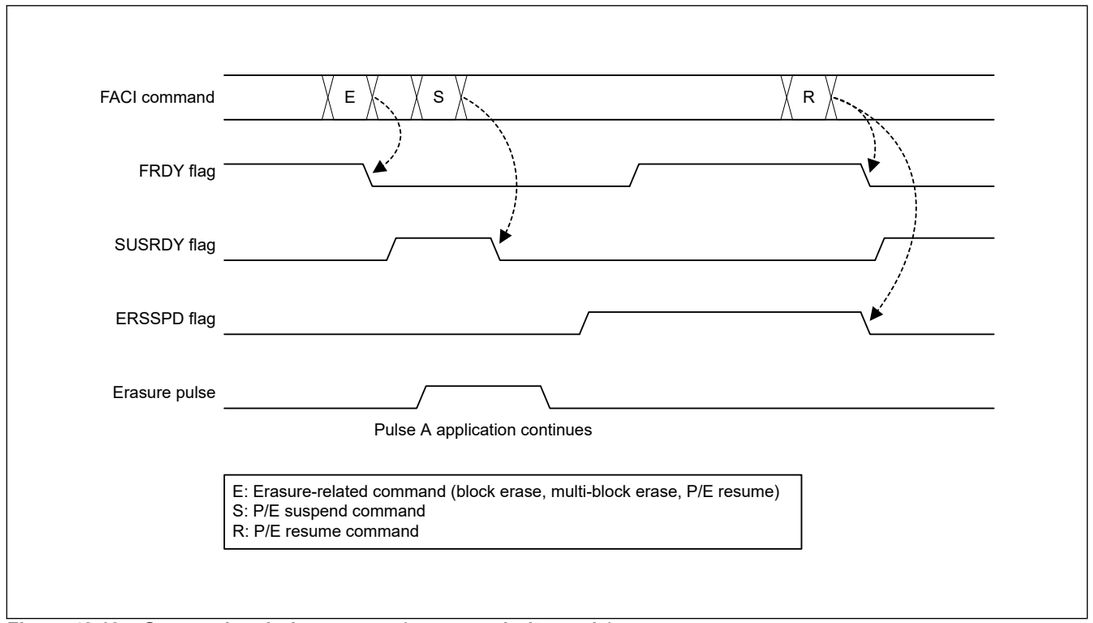

Figure 43.19 Suspension during erasure (erasure priority mode)

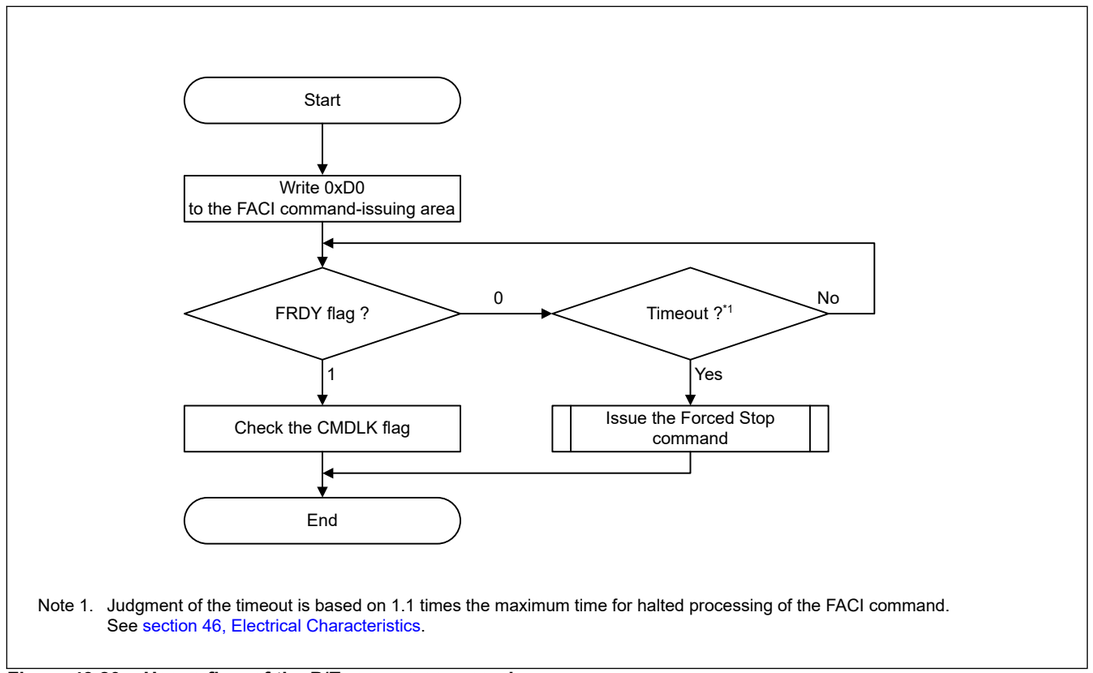
43.9.3.11 P/E Resume Command

The P/E resume command is used to resume suspended programming or erasure. If the FENTRYR setting has been modified during suspension, issue a P/E resume command only after resetting FENTRYR to the previous value that was held before the P/E suspend command was issued. Figure 43.20 shows usage of the P/E resume command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for halted processing of the FACI command. See section 46, Electrical Characteristics.

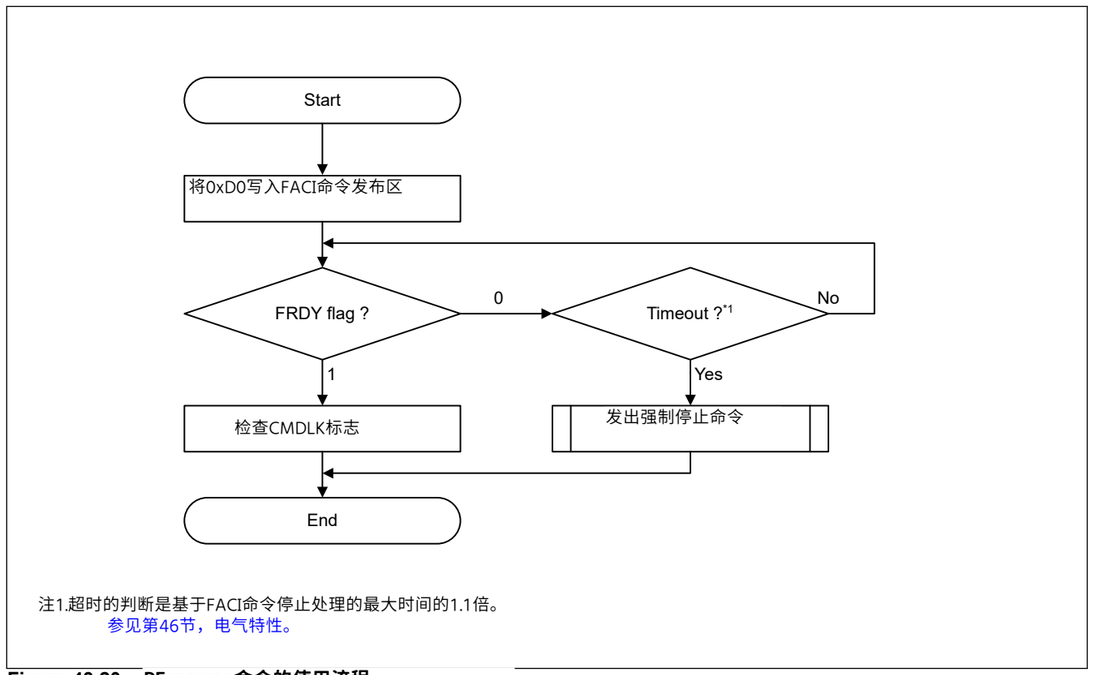
43.9.3.11 PE恢复命令

PEresume命令用于恢复暂停的编程或擦除。如果在挂起期间修改了FENTRYR设置，则仅在将FENTRYR重置为发出PE挂起命令之前保持的先前值之后才发出PEresume命令。图43.20显示了PEresume命令的用法。



注1.超时的判断是基于FACI命令停止处理的最大时间的1.1倍。
参见第46节，电气特性。

43.9.3.12 Status Clear Command

The status clear command is used to clear the command-locked state (see section 43.9.3.6. Recovery from the Command-Locked State).

You can use the status clear command to clear the following bits in the FSTATR register in the command-locked state:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR

Figure 43.21 shows usage of the status clear command.

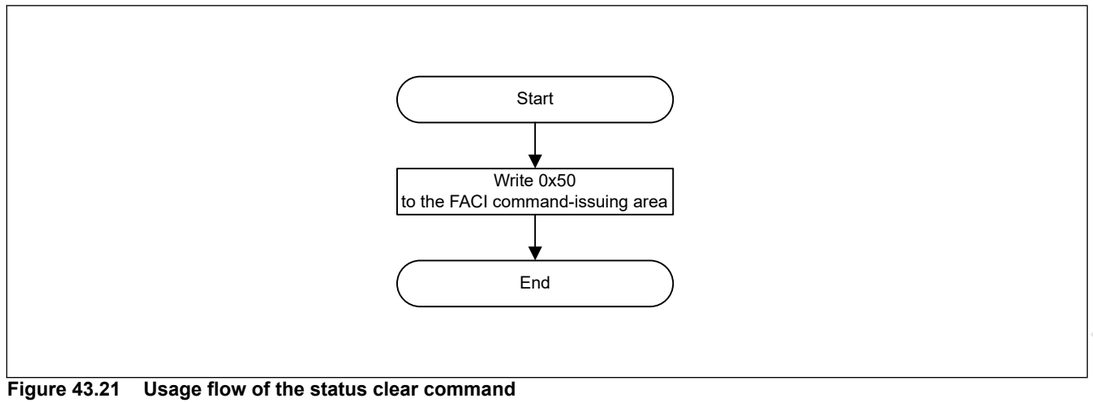

Figure 43.21 Usage flow of the status clear command

43.9.3.13 Forced Stop Command

The forced stop command is used to forcibly end command processing by the flash sequencer. Although this command halts command processing more quickly than the P/E suspension command, values from the programming or erasure that are in progress are not guaranteed. Additionally, resumption of processing is not possible. Processing of programming or erasure that is halted by the forced stop command is also defined as one programming round.

Executing the forced stop command also initializes part of the FACI, the whole FCU, the FSTATR and FASTAT registers. This command can be used in the procedure for recovery from the command-locked state and for processing in response to a timeout of the flash sequencer (see section 43.9.3.6. Recovery from the Command-Locked State).

Figure 43.22 shows usage of the forced stop command.

43.9.3.12 状态清除命令

statusclear命令用于清除命令锁定状态（参见第43.9.3.6节。从命令中恢复锁定状态）。

在命令锁定状态下，您可以使用statusclear命令清除FSTATR寄存器中的以下位：

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR

图43.21显示了statusclear命令的用法。

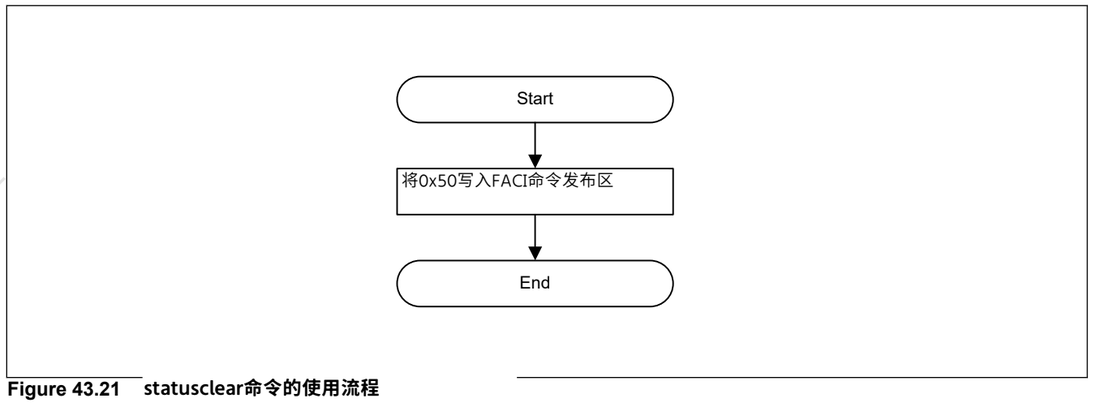

Figure 43.21 statusclear命令的使用流程

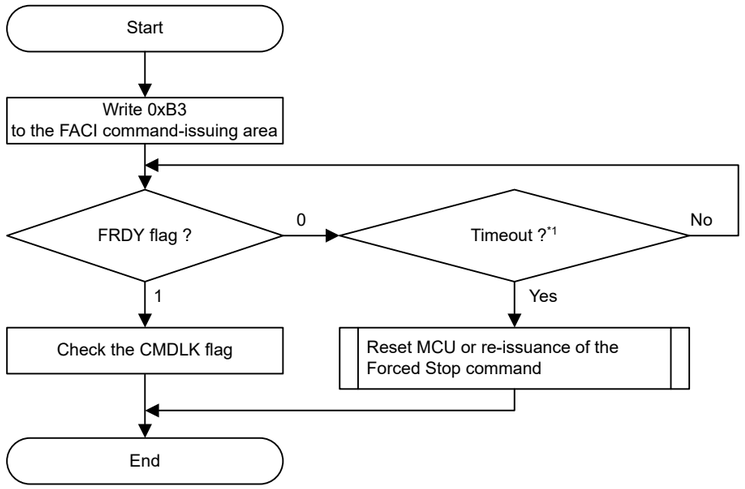
43.9.3.13 强制停止命令

强制停止命令用于强制结束闪存定序器的命令处理。尽管此命令比PE暂停命令更快地停止命令处理，但不能保证正在进行的编程或擦除的值。此外，无法恢复处理。由强制停止命令停止的编程或擦除的处理也被定义为一轮编程。

执行强制停止命令还会初始化部分FACI、整个FCU、FSTATR和FASTAT寄存器。
此命令可用于从命令锁定状态恢复的过程以及用于响应闪存定序器超时的处理（请参阅第43.9.3.6节。从命令锁定状态恢复）。

图43.22显示了强制停止命令的用法。



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of the Forced Stop command latency.
See section 46, Electrical Characteristics.

Figure 43.22 Usage flow of the forced stop command

(1) Notes on Using the Forced Stop Command during Command Issue

When using the forced stop command at the timeout occurrence by DBFULL bit of the program command, writing in the FACI command-issuing area is sometimes processed as writing in data of the program command. See Table 43.3 in section 43.3. Address Space for information on the FACI command-issuing area to force a command lock. Then issue a forced stop command with return method from the command lock status (see Figure 43.13). Locking commands is possible in any case where the unit for reading the FACI command issuing area is 8, 16, or 32 bits.

43.9.3.14 Blank Check Command

The blank check command is used to confirm that an area is in the non-programmed state. Values read from the data flash memory that have been erased but not yet programmed again that is in the non-programmed state, are undefined.

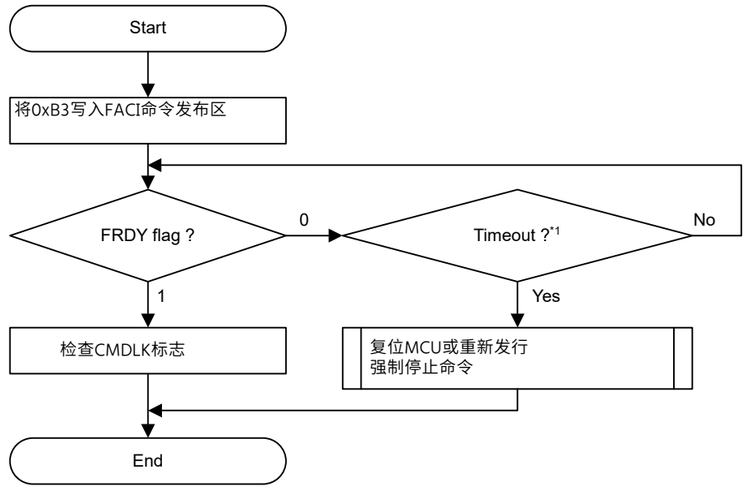
Before issuing the Blank Check command, set addressing mode, start address, and end address of the target area for Blank Check to the FBCCNT, FSADDR, and FEADDR registers. When Blank Check addressing mode is set to decremental mode (i.e. FBCCNT.BCDIR = 1), address specified in FSADDR should be equal to or larger than address in FEADDR.

On the other hand, the address in FSADDR should be equal to or smaller than address in FEADDR when Blank Check addressing mode is set to incremental mode (i.e. FBCCNT.BCDIR = 0).

If the settings of the BCDIR bit, FSADDR, and FEADDR are inconsistent, the flash sequencer enters the command-locked state. The size of the target area for Blank Check is in the range from 4 bytes to the data flash memory capacity and is set in units of 4 bytes.

Write 0x71 and 0xD0 to the FACI command-issuing area to start Blank Check. Completion of processing can be confirmed by the FRDY bit of the FSTATR register. At the end of processing, the result of Blank Check is stored in the BCST bit in the FBCSTAT register. If non-programmed data exists within the target area for Blank Check, flash sequencer stops Blank Check command operation. In this case, address of non-programmed data is indicated to FPSADDR register.

Figure 43.23 shows usage of the blank check command.



注1.超时的判断基于强制停止命令延迟的最大时间的1.1倍。
参见第46节，电气特性。

Figure 43.22 强制停止命令的使用流程

(1) 命令发出期间使用强制停止命令的注意事项

通过程序命令的DBFULL位在超时发生时使用强制停止命令时，写入
FACI命令发布区域有时被处理为写入程序命令的数据。请参见第43.3节中的表43.3。FACI命令发布区域信息的地址空间以强制命令锁定。然后从命令锁定状态发出带返回方法的强制停止命令（见图43.13）。在读取FACI命令发布区域的单位为8、16或32位的任何情况下，锁定命令都是可能的。

43.9.3.14 空白检查命令

空白检查命令用于确认某个区域处于非编程状态。从处于未编程状态的已擦除但尚未再次编程的数据闪存读取的值未定义。

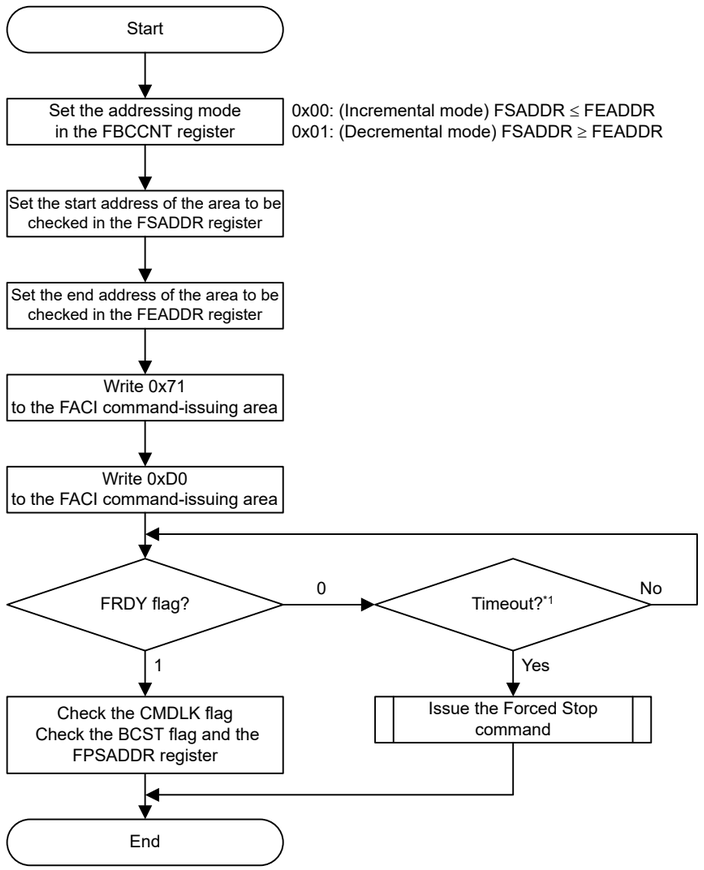
在发出空白检查命令之前，设置空白目标区域的寻址方式、起始地址和结束地址
检查FBCCNT、FSADDR和FEADDR寄存器。当空白检查寻址模式设置为递减模式（即FBCCNT.BCDIR=1）时，FSADDR中指定的地址应等于或大于FEADDR中的地址。

另一方面，当空白检查寻址模式设置为增量模式（即FBCCNT.BCDIR=0）时，FSADDR中的地址应等于或小于FEADDR中的地址。

如果BCDIR位、FSADDR和FEADDR的设置不一致，则flashsequencer进入command-locked状态。BlankCheck的目标区域大小在4字节到数据闪存容量的范围内，以4字节为单位设置。

将0x71和0xD0写入FACI命令发出区域以启动空白检查。可通过FSTATR寄存器的FRDY位确认处理完成。处理结束时，空白检查的结果存储在FBCSTAT寄存器的BCST位中。如果空白检查的目标区域内存在未编程的数据，闪存定序器将停止空白
检查命令操作。在这种情况下，非编程数据的地址被指示到FPSADDR寄存器。

图43.23显示了空白检查命令的用法。



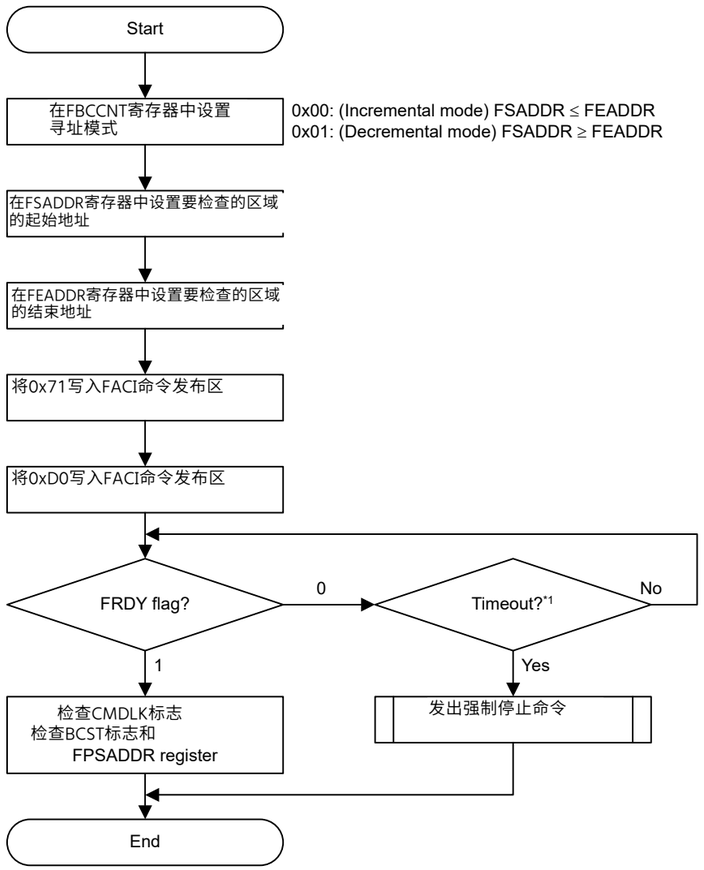
Note 1. Judgment of the timeout is based on 1.1 times the maximum time of Blank Checking for the whole target range. See section 46, Electrical Characteristics.

Figure 43.23 Usage flow of the blank check command

43.9.3.15 Configuration Set Command

The Configuration set command is used to set option-setting memory. Before issuing the Configuration set command, set the specified address (shown in Table 43.18) in the FSADDR register. Writing 0xD0 to the FACI command-issuing area in the final access for issuing the FACI command starts FACI processing of the Configuration set command.

Figure 43.24 shows usage of the configuration set command.



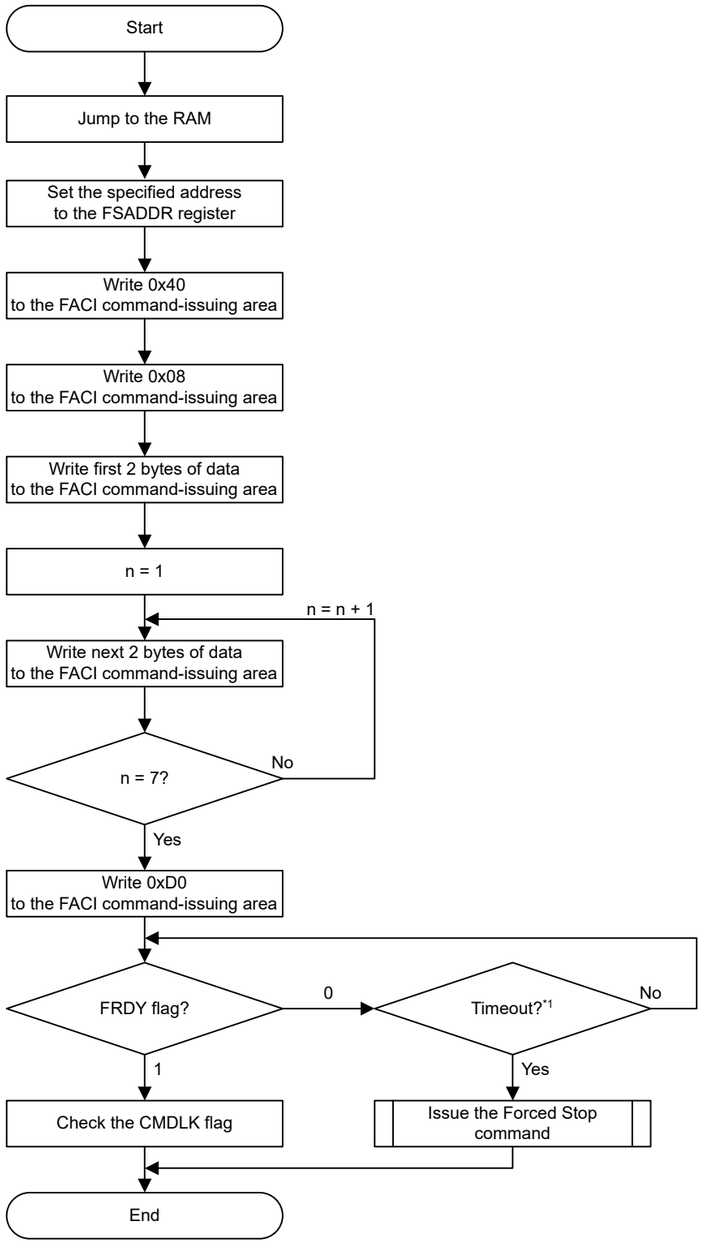
注1.超时的判断是基于1.1倍的整个目标范围的BlankChecking最大时间。看第46节，电气特性。

Figure 43.23 空白检查命令的使用流程

43.9.3.15 配置集命令

Configurationset命令用于设置选项设置内存。在发出配置设置命令之前，在FSADDR寄存器中设置指定的地址（如表43.18所示）。在发出FACI命令的最终访问中将0xD0写入FACI命令发出区域，开始配置设置命令的FACI处理。

图43.24显示了配置集命令的用法。



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of programing in option-setting memory. See section 46, Electrical Characteristics.

注1.超时的判断是基于选项设置内存中最大编程时间的1.1倍。参见第46节，电气特性。

Figure 43.24 配置集命令使用流程

The correspondence between the possible target data for configuration setting and the address value set in the FSADDR register is shown in Table 43.18. For details, see section 43.4.12. FSADDR : FACI Command Start Address Register.

Table 43.18 Address Used by Configuration Set Command

Address	FSADDR Register Value	Setting Data	Operation of additional writing		Timing when the Setting is Enabled

0x0100_A2C0	0x0100_A2C0	Block Protect Setting Register Select (BPS_SEL)	Writable	Writable	At a reset

Note 1. The SAS.FSPR bit cannot be restored to 1 by using the Configuration set command once it is set to 0. Therefore, setting the start-up area select flags again becomes impossible. (when the Configuration set command is issued to the address of 0x0100A134, the command is locked.) Exercise extra caution when handling the SAS.FSPRbit.
Note 2. Once PBPS[n] bit is set to 0, the BPS[n] bit cannot be restored to 1 by using the Configuration set command.
Note 3. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS[n] bit can not be set to 0 by using the Configuration set command when the BPS[n] bit is 1.
Note 4. Once PBPS_SEC[n] bit is set to 0, the BPS_SEC[n] bit cannot be restored to 1 by using the Configuration set command.
Note 5. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS_SEC[n] bit cannot be set to 0 by using the Configuration set command when the BPS_SEC[n] bit is 1.

43.10 Suspend Operation

Reading from the flash memory is not possible during programming or erasure if the conditions for background operation given in Table 43.29 are not satisfied. When a P/E suspend command is issued to suspend the programming or erasure of the flash memory, reading from the flash memory is enabled. Regarding P/E suspend commands, there are one suspend command mode for programming and two suspend command modes for erasure (suspension priority mode and erasure priority mode). To resume suspended programming or erasure, the P/E resume command is available. See details on the suspend operation, refer to Figure 43.16.

43.11 Protection Function

43.11.1 Software Protection

Software protection disables programming and erasure of the code flash memory through the settings of control registers and block protect setting in the user area. If an attempt is made to issue an FACI command against software protection, the flash sequencer enters the command-locked state.

43.11.1.1 Protection through FWEPROR

Unless the FWEPROR.FLWE[1:0] bits are set to 01b, programming cannot proceed in any mode.

配置设置的可能目标数据与FSADDR寄存器中设置的地址值的对应关系如表43.18所示。详见43.4.12节。FSADDR：FACI命令起始地址寄存器。

0x0100_A2C0	0x0100_A2C0	块保护设置寄存器 Select (BPS_SEL)	Writable	Writable	复位时

注1.SAS.FSPR位一旦设置为0，就无法通过Configurationset命令恢复为1。因此，再次设置启动区域选择标志变得不可能。（当向0x0100A134地址发出Configurationset命令时，该命令被锁定。）处理SAS.FSPRbit时要格外小心。

注2.一旦PBPS[n]位设置为0，BPS[n]位不能通过使用配置设置命令恢复为1。
注3.一旦这些位设置为0，就不能使用配置设置命令将这些位恢复为1。当BPS[n]位为1时，不能使用配置设置命令将PBPS[n]位设置为0。

注4.一旦PBPS_SEC[n]位设置为0，则BPS_SEC[n]位无法通过使用配置设置命令恢复为1。
注5.一旦这些位设置为0，就不能使用配置设置命令将这些位恢复为1。当BPS_SEC[n]位为1时，无法使用配置设置命令将PBPS_SEC[n]位设置为0。

43.10 暂停操作

如果不满足表43.29中给出的后台操作条件，则在编程或擦除期间无法从闪存读取。当发出PE暂停命令以暂停闪存的编程或擦除时，将启用从闪存读取。关于PE挂起命令，有一种用于编程的挂起命令模式和两种用于擦除的挂起命令模式（挂起优先模式和擦除优先模式）。要恢复暂停的编程或擦除，可以使用PEresume命令。参见挂起操作的详细信息，参见图43.16。

43.11 保护功能

43.11.1 软件保护

软件保护通过控制寄存器的设置和用户区的块保护设置禁用代码闪存的编程和擦除。如果尝试针对软件保护发出FACI命令，则闪存定序器进入命令锁定状态。

43.11.1.1 通过FWEPROR进行保护

除非FWEPROR.FLWE[1:0]位设置为01b，否则无法在任何模式下进行编程。

43.11.1.2 Protection by FENTRYR

When the FENTRYR register is set to 0x0000, the flash sequencer enters read mode. In read mode, FACI commands cannot be accepted. If an attempt is made to issue an FACI command in read mode, the flash sequencer enters the command-locked state.

43.11.1.3 Protection by Block Protect Setting

Each block in user area has the block protect setting (BPS or BPS_SEC). When the FBPROT0 or FBPROT1 register is 0x0000 and the block protect bit is 0, issuing the Program or Block Erase command to user area of the code flash causes the command-locked state. To program or erase the block whose block protect bit is 0, set the FBPROT0 or FBPROT1 register to 0x0001.

The block protect setting can be locked by the permanent block protect setting (PBPS or PBPS_SEC). When the permanent block protect setting and the block protect setting are 0, issuing a Program or Block erase command to user area of the code flash causes the flash sequencer to enter the command-locked state regardless of the FBPROT0 and FBPROT1 register settings.

Valid block protect setting (BPS or BPS_SEC) depends on the Block Protect Select bit (BPS_SEL).

See section 43.12.2. Permanent Block Protect Setting for details of the block protect setting and permanent block protect setting. See section 43.4.15. FBPROT0 : Flash Block Protection Register and section 43.4.16. FBPROT1 : Flash Block Protection for Secure Register for more information.

For details of block protect setting (BPS or BPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

The protected area by the block protect setting is always determined by the address of the FSADDR register setting regardless of the address swapping function setting (the startup area select). Table 43.19 to Table 43.20 show the relation of user area and the block protect setting in each function setting.

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of user area (for example, address is 0x00_0000 to the last block address).
- BPS[0]/BPS_SEC[0] and BPS[1]/BPS_SEC[1] are assigned to the block of user area depending on the startup area select setting (SAS.BTFLG bit). (See section 43.11.3. Start-Up Program Protection).

Table 43.19 shows the block protect setting when the startup area select is disabled (not swapping).

Table 43.20 show example of the block protect setting when the address conversion function is used.

Table 43.19 Example of Block Protect setting when SAS.BTFLG is 1

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes

43.11.1.2 FENTRYR的保护

当FENTRYR寄存器设置为0x0000时，闪存定序器进入读取模式。在读取模式下，无法接受FACI命令。如果尝试在读取模式下发出FACI命令，则闪存定序器进入命令锁定状态。

43.11.1.3 通过块保护设置进行保护

用户区的每个块都有块保护设置（BPS或BPS_SEC）。当FBPROT0或FBPROT1寄存器为0x0000且块保护位为0时，向代码闪存的用户区发出Program或BlockErase命令会导致命令锁定状态。要编程或擦除块保护位为0的块，请将FBPROT0或FBPROT1寄存器设置为0x0001。

块保护设置可以通过永久块保护设置（PBPS或PBPS_SEC）锁定。当永久块保护设置和块保护设置为0时，无论FBPROT0和FBPROT1寄存器设置如何，向代码闪存的用户区发出程序或块擦除命令都会使闪存定序器进入命令锁定状态。

有效的块保护设置（BPS或BPS_SEC）取决于块保护选择位（BPS_SEL）。

请参见第43.12.2节。永久块保护设置有关块保护设置和永久块保护设置的详细信息。请参见第43.4.15节。FBPROT0：闪存块保护寄存器和第43.4.16节。FBPROT1：安全寄存器的闪存块保护了解更多信息。

有关块保护设置（BPS或BPS_SEC）和块保护选择（BPS_SEL）的详细信息，请参阅第6节，选项设置Memory.

块保护设置的保护区域始终由FSADDR寄存器设置的地址决定，与地址交换功能设置（启动区域选择）无关。表43.19至表43.20显示了每个功能设置中用户区和块保护设置的关系。

●BPS[0]到BPS[n]或BPS_SEC[0]到BPS_SEC[n]分配给用户区的块（例如，地址是0x00_0000到最后一个块地址）。

●BPS[0]BPS_SEC[0]和BPS[1]BPS_SEC[1]根据启动区选择设置（SAS.BTFLG位）分配给用户区块。（参见第43.11.3节。启动程序保护）。

表43.19显示了禁用启动区域选择（不交换）时的块保护设置。

表43.20显示了使用地址转换功能时的块保护设置示例。

43.11.2 Error Protection

Error protection detects the issuing of illegal FACI commands, illegal access, and flash sequencer malfunction. FACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue the Status Clear or Forced Stop command. The Status Clear command can only be used while the FRDY bit in the FSTATR register is 1. The Forced Stop command can be used regardless of the value of the FRDY bit. While the CMDLKIE bit in the FAEINT register is 1, a flash access error (FIFERR) interrupt is generated if the flash sequencer enters the command-locked state (the CMDLK bit in the FASTAT register is set to 1).

If the flash sequencer enters the command-locked state in response to a command other than the P/E suspend command during programming or erasure processing, the flash sequencer continues the processing for programming or erasure. In this state, the P/E suspend command cannot be used to suspend the processing for programming or erasure. If a command is issued in the command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set from previous error detection.

Table 43.21 shows the error protection types and status bit values after error detections.

43.11.2 错误保护

错误保护检测非法FACI命令的发出、非法访问和闪存定序器故障。FACI命令接受被禁用（命令锁定状态）以响应检测到这些错误。闪存定序器处于命令锁定状态时，无法对闪存进行编程或擦除。要从命令锁定状态释放，请发出状态清除或强制停止命令。状态清除命令只能在FSTATR寄存器中的FRDY位为1时使用。无论FRDY位的值如何，都可以使用强制停止命令。当FAEINT寄存器中的CMDLKIE位为1时，如果闪存定序器进入命令锁定状态（FASTAT寄存器中的CMDLK位设置为1），则会产生闪存访问错误(FIFERR)中断。

如果闪存定序器在编程或擦除处理期间响应于除了PE暂停命令之外的命令而进入命令锁定状态，则闪存定序器继续进行编程或擦除处理。在这种状态下，PE挂起命令不能用于挂起编程或擦除处理。如果在命令锁定状态下发出命令，则ILGLERR位变为1，其他位保留先前错误检测设置的值。

表43.21显示了错误检测后的错误保护类型和状态位值。

43.11.3 Start-Up Program Protection

Protection of the startup program is for protection of the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.

The startup area is 8 Kbytes in size and is assigned to the user area in the code flash memory. This function uses the values of the SAS.BTFLG bit and the FSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see Figure 43.25 to Figure 43.28).

In protection of the startup program, the state of the selection of the startup area can be fixed by the FSPR bit. However, the SAS.FSPR bit never be restored to 1 once the flag is set to 0. Exercise extra caution when handling the SAS.FSPR bit.

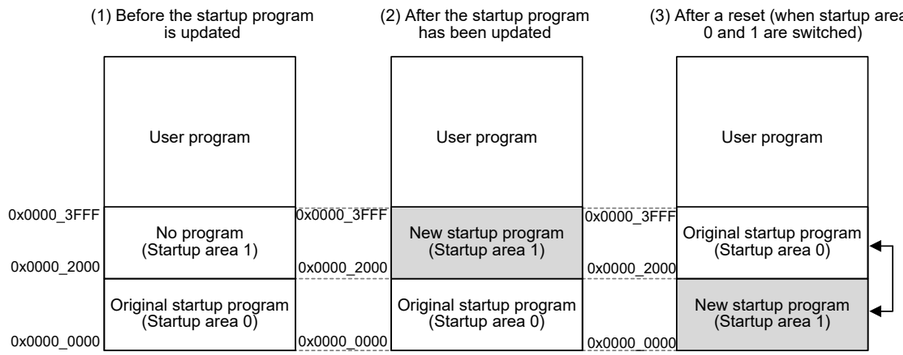
注2.关于FWEPROR寄存器的详细信息，请参阅第43.4.8节。FWEPROR：闪存PE保护寄存器。

43.11.3 启动程序保护

启动程序的保护是为了保护复位后要启动的程序（启动程序）。此功能提供了一种在复位期间暂停重写时安全更新启动程序的方法。

启动区大小为8KB，分配给代码闪存中的用户区。该函数使用SAS.BTFLG位和FSUACR.SAS[1:0]位的值来改变以块为单位存储启动程序的区域（见图43.25至图43.28）。

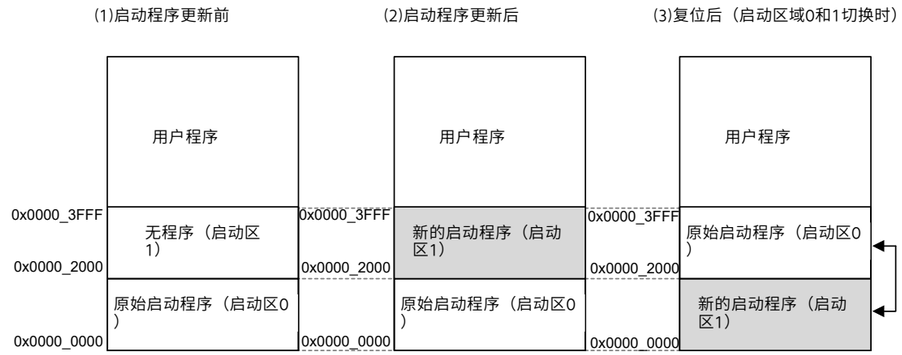
在启动程序的保护中，启动区域的选择状态可以通过FSPR位来固定。但是，那一旦标志设置为0，SAS.FSPR位永远不会恢复为1。处理SAS.FSPR位时要格外小心。



Note: The addresses are used for reading, programming, and erasure. Startup area 0 is erased when Block Erase command is issued for the address 0x00000000 with allocation shown under 3.

1. Before the startup program is updated
   When the SAS.BTFLG bit is 1 and the FSUACR.SAS[1:0] bits are 0xb, the address range from 0x00002000 to 0x00003FFF is selected as startup area 1 and the address range from 0x00000000 to 0x00001FFF is selected as startup area 0.
2. After the startup program has been updated
   A new startup program can be written to startup area 1. At this time, startup area 0 will still contain the previous startup program, so rewriting by starting up from startup area 0 remains possible if rewriting to the startup area 1 fails.
3. After a reset (when startup areas 0 and 1 are switched)
   When rewriting startup area 1 is successfully completed, switch the assignment of startup areas 0 and 1 by rewriting the startup area selection bit (the SAS.BTFLG bit) with Configuration set command. Afterwards, the program is started up from startup area 1 after a reset.

Figure 43.25 Concept of Protection of the Startup Program



Note: 这些地址用于读取、编程和擦除。当对地址0x00000000发出块擦除命令时，启动区域0被擦除，分配如下3所示。1.更新启动程序之前

当SAS.BTFLG位为1且FSUACR.SAS[1:0]位为0xb时，选择0x00002000到0x00003FFF的地址范围作为启动区1，选择从0x00000000到0x00001FFF的地址范围作为启动区0。2.启动程序更新后

可以将新的启动程序写入启动区1。此时启动区0仍会包含之前的启动程序，因此如果对启动区1的重写失败，仍然可以从启动区0启动进行重写。3.复位后（启动区域0和1切换时）

当重写启动区1成功完成时，通过使用Configurationset命令重写启动区选择位（SAS.BTFLG位）来切换启动区0和1的分配。之后，程序在复位后从启动区1启动。

43.12 Security Function

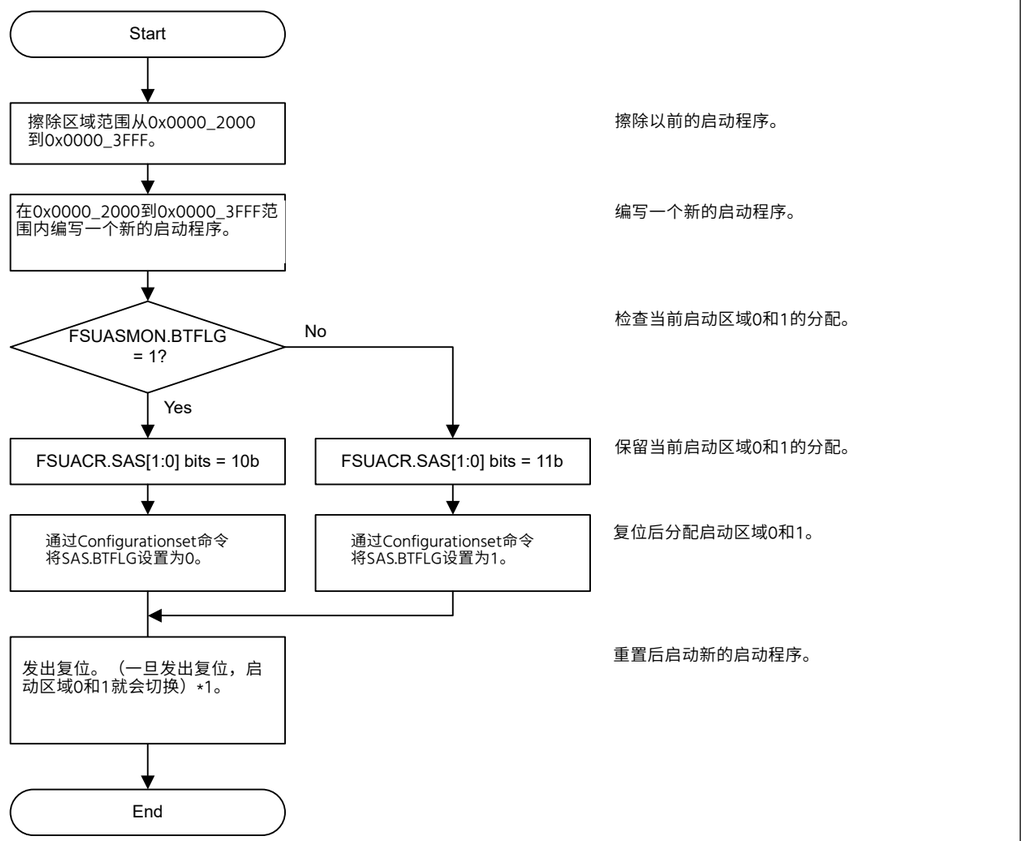
The flash sequencer supports the following security functions:

- Security flag for startup area
- Permanent block protect setting
- Flash memory protection for TrustZone

43.12.1 Security Flag for Startup Area Select

The security flag (SAS.FSPR) for the startup area is located in the option-setting memory.

When the SAS.FSPR bit is 0, issuing the configuration set command to change the SAS.BTFLG bit causes the flash sequencer to be in the command-locked state. Also, when the SAS.FSPR bit is 0, it is invalid to write to the Startup Area Select bits SAS[1:0] in the FSUACR register. The SAS.FSPR bit enables protection.



注1.详见图43.26和图43.27。

Figure 43.28 保护启动程序的概念

43.12 安全功能

闪存定序器支持以下安全功能：

●启动区安全标志

●永久封锁保护设置

●TrustZone的闪存保护

43.12.1 启动区域选择的安全标志

启动区域的安全标志(SAS.FSPR)位于选项设置内存中。

当SAS.FSPR位为0时，发出配置设置命令来更改SAS.BTFLG位会导致闪存定序器处于命令锁定状态。此外，当SAS.FSPR位为0时，写入FSUACR寄存器中的启动区域选择位SAS[1:0]无效。SAS.FSPR位启用保护。

43.12.2 Permanent Block Protect Setting

The permanent block protect setting is the clear protection for the block protection setting. User area cannot be permanently updated by the FACI command when the permanent block protect setting is enabled. See section 43.11.1.3. Protection by Block Protect Setting for more details.

The block protect setting and the permanent block protect setting have the write/clear protection against the configuration set command. The flash sequencer does not detect an error when the configuration set command is issued to the write/clear protected settings.

Figure 43.29 and Table 43.22 show the write/clear protection against the block protect setting (BPS[n]) and the permanent protect setting (PBPS[n]). Figure 43.30 and Table 43.23 show the write/clear protection against the block protect setting for secure (BPS_SEC[n]) and permanent protect setting for secure (PBPS_SEC[n]).

Effective permanent block protect setting (PBPS or PBPS_SEC) depends on block protect select (BPS_SEL). For details of permanent block protect setting (PBPS or PBPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

43.12.2 永久块保护设置

永久块保护设置是对块保护设置的明确保护。启用永久块保护设置后，FACI命令无法永久更新用户区域。请参阅第43.11.1.3节。通过块保护设置进行保护以获取更多详细信息。

块保护设置和永久块保护设置具有针对配置集命令的写清除保护。向写清除保护设置发出配置设置命令时，闪存定序器不会检测到错误。

图43.29和表43.22显示了针对块保护设置(BPS[n])和永久保护设置(PBPS[n])的写清除保护。图43.30和表43.23显示了针对安全的块保护设置(BPS_SEC[n])和安全的永久保护设置(PBPS_SEC[n])的写清除保护。

有效的永久块保护设置（PBPS或PBPS_SEC）取决于块保护选择（BPS_SEL）。有关永久块保护设置（PBPS或PBPS_SEC）和块保护选择（BPS_SEL）的详细信息，请参见第6节，选项设置存储器。

43.12.3 Flash Memory Protection for TrustZone

Information in this section focuses on the flash sequencer operation.

The flash memory provides the following types of protect function against non-secure access:

- Protection for flash memory area (P/E)
- Protection for flash memory area (read)
- Protection for registers
- Protection during FACI command operation
- Code flash P/E mode entry protection

43.12.3.1 Protection for Flash Memory Area (P/E)

This function protects the secure region of the code flash and data flash from FACI commands of non-secure access. The condition of protection depends on the FACI command, the access attribution, and the memory boundary setting.

For details of secure region, see section 45, Security Features .

43.12.3 TrustZone的闪存保护

本节中的信息侧重于闪存定序器的操作。

闪存提供以下类型的保护功能以防止非安全访问：

- ●保护闪存区（PE）
- ●保护闪存区域（读取）
- ●寄存器保护
- ●FACI命令操作期间的保护
- ●CodeflashPE模式进入保护

43.12.3.1 对闪存区域(PE)的保护

此功能保护代码闪存和数据闪存的安全区域免受非安全访问的FACI命令的影响。保护条件取决于FACI命令、访问属性和内存边界设置。

有关安全区域的详细信息，请参阅第45节，安全功能。

有关保护闪存区域(PE)的信息，请参见表43.24。

When the target area of FACI command is the user area of code flash, the flash sequencer compares the FSADDR register setting with the memory boundary setting of the code flash and determines whether the target area is in the secure region.

The memory boundary can be set to 0x0000_0000 to 0x00FF_8000 in 32 KB unit.

Figure 43.31 shows details of the non-secure/secure attribute of user area in the code flash.

When the target area of the issuing FACI command is the data area of data flash, the flash sequencer compares the FSADDR/FEADDR register setting with the memory boundary setting of the data flash and determines whether the target area is in secure region. The memory boundary can be set to 0x0800_0000 to 0x0800_FC00 in 1 KB unit. Figure 43.32 shows details of the non-secure/secure attribute of data area in the data flash.

- X indicates read/write access is not possible by the non-secure access. Write data is ignored and read data is always 0.

Note 1. The FACI command issued by the non-secure access is not allowed.

Code flash programming/erasure can be protected by the FMEPROT register of secure function. Therefore, it does not assume that secure function issues P/E suspend command during code flash programming/erasure of non-secure function.

Data flash programming/erasure of non-secure can be suspended by secure function. If secure function issues P/E suspend command during data flash programming/erasure of non-secure function, secure function should issue P/E resume command. When secure function issues P/E resume command, secure function should notify non-secure function that data flash programming/erasure is complete and return to non-secure function. See Figure 43.35 and Figure 43.36 in example of issuing P/E suspend of secure function during programming/erasure of non-secure function.

注1.非安全访问发出的FACI命令是不允许的。

代码闪存编程擦除可以通过安全功能的FMEPROT寄存器进行保护。因此，不假设安全功能在非安全功能的代码闪存编程擦除期间发出PE挂起命令。

非安全的数据闪存编程擦除可以通过安全功能暂停。如果在非安全功能的数据闪存编程擦除期间安全功能发出PE暂停命令，安全功能应发出PE恢复命令。当安全功能发出PEresume命令时，安全功能应通知非安全功能数据闪存编程擦除完成并返回到非安全功能。在对非安全功能进行编程擦除时发出PE暂停安全功能的示例请参见图43.35和图43.36。

43.12.3.5 Code Flash P/E Mode Entry Protection

The flash sequencer has protection function of code flash P/E by the FMEPROT register for the secure developer. Secure function can prevent disturbance of reading code flash memory by this protection function. See section 43.4.14. FMEPROT : Flash P/E Mode Entry Protection Register.

For applications that do not require non-secure region programming/erasure other than from secure function, it is recommended to always disable non-secure function of code flash programming/erasure by enabling the protection function of FMEPROT register.

See Figure 43.37 in details of the code flash P/E sequence example by non-secure function.

43.12.3.5 CodeFlashPE模式进入保护

闪存定序器通过FMEPROT寄存器为安全开发人员提供代码闪存PE的保护功能。安全功能可以通过此保护功能防止读取代码闪存的干扰。请参阅第43.4.14节。FMEPROT：FlashPE模式进入保护寄存器。

对于除安全功能外不需要非安全区域编程擦除的应用，建议始终通过启用FMEPROT寄存器的保护功能来禁用代码闪存编程擦除的非安全功能。

有关非安全功能的代码闪存PE序列示例的详细信息，请参见图43.37。

Pin Name	I/O	Mode to be Used	Use

Tool connection time*1	Up to 1 second	Up to 2 seconds	Up to 3 seconds

Note 1. See the boot firmware manual for the detail connection time.

43.13.1 Boot Mode (for the SCI Interface)

In boot mode (for the SCI interface), the host sends control commands and data for programming, and the flash memory is programmed or erased accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When this MCU is activated in boot mode (for the SCI interface), the program on the dedicated area the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.

Figure 43.38 shows the system configuration for operations in boot mode (for the SCI interface).

43.14 Using the Serial Programmer for Rewriting

A serial programmer can be used to rewrite flash memory in boot mode.

(1) Serial Programming

This MCU is mounted on the system board at the time of serial programming. Providing a connector to the board enables rewriting of this MCU by the serial programmer to proceed.

43.13.1 引导模式（用于SCI接口）

在引导模式下（针对SCI接口），主机发送控制命令和数据进行编程，相应地对闪存进行编程或擦除。片上SCI以异步模式处理主机和该MCU之间的传输。主机中必须准备好用于传输控制命令和编程数据的工具。

当这个MCU在启动模式下被激活时（对于SCI接口），在MCU的专用区域上的程序被执行。
引导程序通过接收来自主机的控制命令自动调整SCI的比特率并控制编程擦除。

图43.38显示了引导模式下操作的系统配置（对于SCI接口）。

43.14 使用串行编程器进行重写

串行编程器可用于在引导模式下重写闪存。

(1) 串行编程

该MCU在串行编程时安装在系统板上。为电路板提供连接器可以让串行编程器重写该MCU以继续进行。

43.14.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU with data are described below.

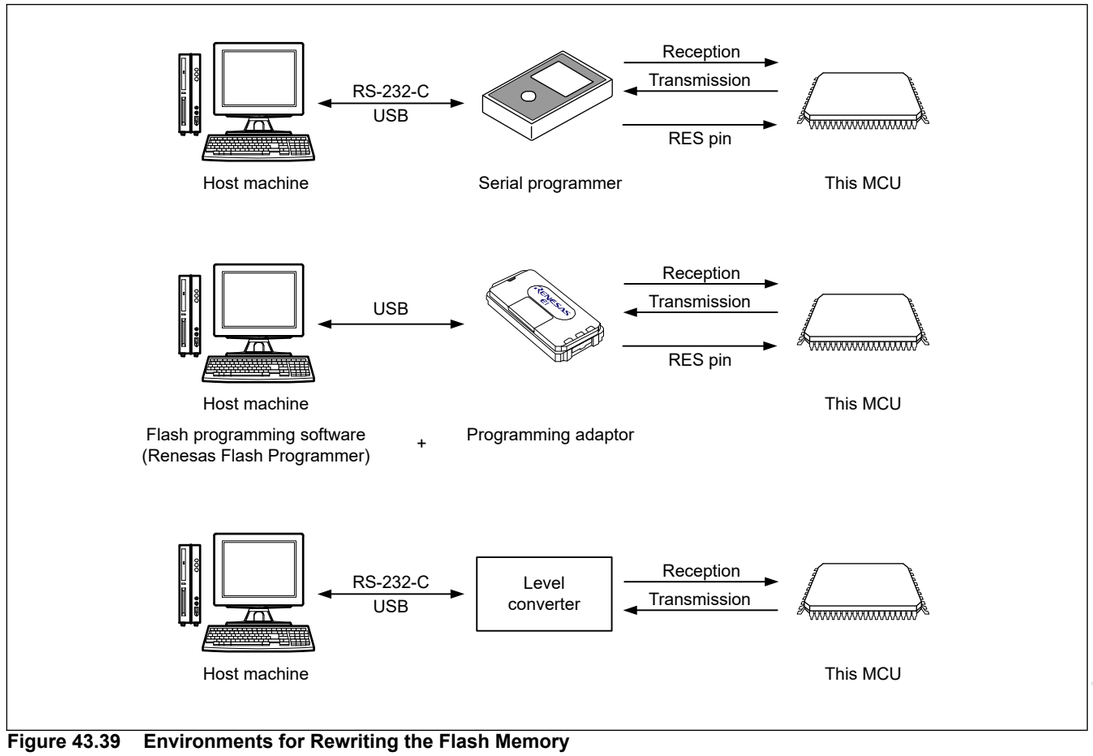

Figure 43.39 Environments for Rewriting the Flash Memory

43.15 Programming through Self-Programming

43.15.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACI commands can be used with user programs for writing to the flash memory. This allows upgrading of user programs and rewriting of constant data fields.

The program for rewriting must be transferred to the internal RAM in advance when the BGO is not available or when rewriting the option-setting memory.

43.14.1 串行编程环境

使用数据重写MCU的闪存的推荐环境如下所述。

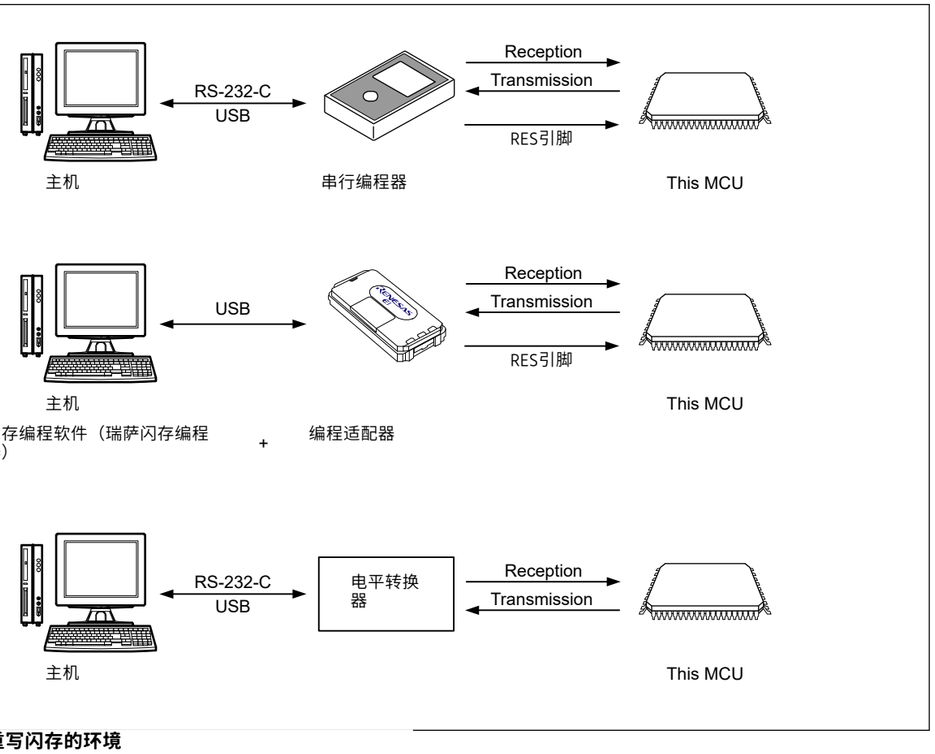

Figure 43.39 重写闪存的环境

43.15 通过自编程进行编程

43.15.1 Overview

该MCU支持用户程序本身对闪存进行编程。FACI命令可与用户程序一起用于写入闪存。这允许升级用户程序和重写常量数据字段。

当BGO不可用或重写选项设置存储器时，必须提前将重写程序传送到内部RAM。

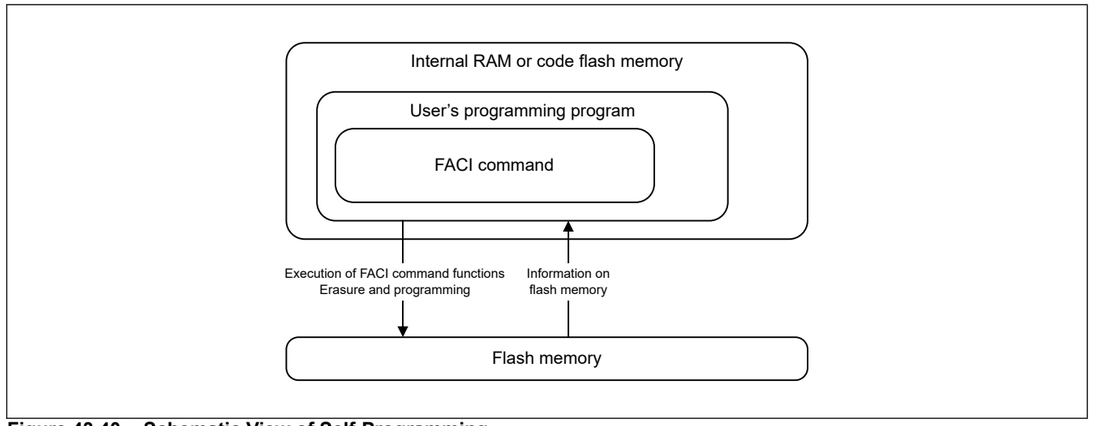

Figure 43.40 Schematic View of Self-Programming

For comprehensive information on the self-programming, refer to section 43.9. FACI Commands

43.15.2 Background Operation

The background operation (BGO) can be used to execute the flash rewrite routine on the code flash memory when the data flash memory is rewritten.

Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed below.

Table 43.29 Conditions under which Background Operation is Usable

	Range for rewriting	Range for reading
Common	Code flash memory	Data flash memory
	Data flash memory	Code flash memory

43.16 Reading Flash Memory

43.16.1 Reading Code Flash Memory

Special settings are not required to read code flash memory after release from the reset state. Data can simply be read out through access to addresses in the code flash memory.

When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

43.16.2 Reading Data Flash Memory

Special settings are not required to read data flash memory after release from the reset state. Data can simply be read out through access to addresses in the data flash memory.

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

43.16.3 Access Cycle

When the CPU cache is hit, access is one cycle.

For the CPU cache is missed while CPU cache operation is enabled, or CPU cache is disabled. (This operation only guarantees the first read access of a wrapping burst in AHB protocol. Otherwise, access wait occurs until the CPU cache is filled.)

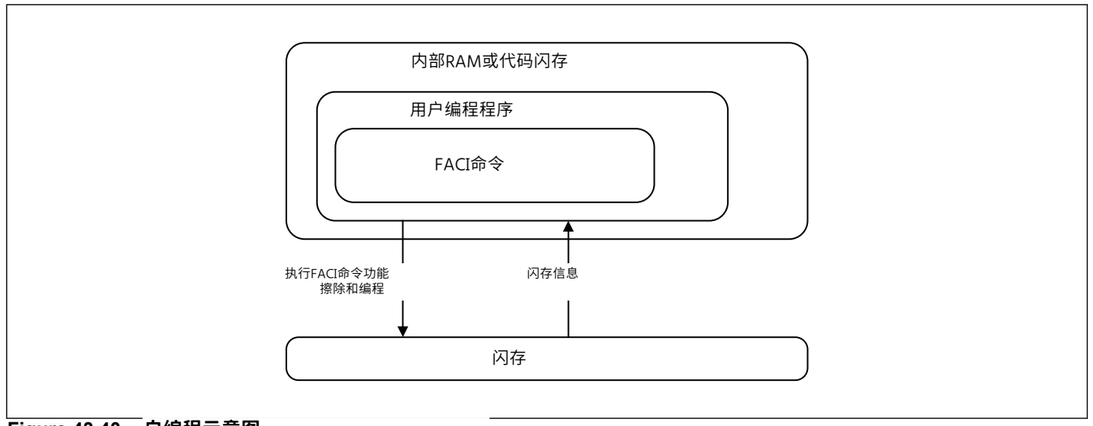

Figure 43.40 自编程示意图

有关自编程的全面信息，请参阅第43.9节。FACI命令

43.15.2 后台操作

当数据闪存被重写时，后台操作（BGO）可用于在代码闪存上执行闪存重写例程。

当用于重写的闪存和用于读取的闪存的组合为下列任何一种时，可以使用后台操作。

Table 43.29 后台操作可用的条件

	重写范围	读取范围
Common	代码闪存	数据闪存
	数据闪存	代码闪存

43.16 读取闪存

43.16.1 读码闪存

从复位状态释放后，读取代码闪存不需要特殊设置。可以通过访问代码闪存中的地址来简单地读取数据。

当读取已擦除但尚未再次编程的代码闪存时（即处于未编程状态），所有位都被读取为1。

43.16.2 读取数据闪存

从复位状态释放后读取数据闪存不需要特殊设置。通过访问数据闪存中的地址可以简单地读取数据。

从已擦除但尚未再次编程（即处于未编程状态）的数据闪存中读取的值未定义。当您需要确认某个区域处于非编程状态时，请使用空白检查。

43.16.3 访问周期

当CPU缓存被命中时，访问为一个周期。

启用CPU缓存操作或禁用CPU缓存时CPU缓存丢失。（此操作仅保证AHB协议中包装突发的第一次读取访问。否则，将等待访问，直到CPU缓存被填满。）

43.17 Usage Notes

(1) Reading Area Where Programming/Erasure was Interrupted and Area Targeted for Suspension

The data stored in the area where programming or erasure has been suspended or the area where programming or erasure has been suspended by using the suspend command are undefined. To avoid faulty operation caused by reading undefined data, take care not to fetch instructions or read data from areas where programming or erasure was suspended and where programming or erasure was suspended by using the suspend command.

(2) Suspension During Programming/Erasure

When processing of programming/erasure is stopped by issuing the P/E suspend command, the programming/erasure processing can be resumed by issuing the P/E resume command. If the flash sequencer enters the command-locked state for any reason and issues the forced stop command after the suspended processing is normally completed and the ERSSPD flag or PRGSPD flag is set to 1, the suspended processing cannot be resumed. In addition, the values in the area where the processing was suspended are not guaranteed. Erase that area

(3) Prohibition of Additional Programming

Programming a given area of the code flash memory or data flash memory twice is not possible. To program the code flash memory or data flash memory where has been programed, erase the target area. Programming can be added to the option-setting memory.

(4) Resets During Programming/Erasure, or Blank Checking

In the case of a reset due to the signal on the RES pin during programming/erasure, or blank checking of the flash memory, wait for at least t_{RESW} (see section 46, Electrical Characteristics) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics, then release the device from the reset state.

(5) Allocation of Vectors for Interrupts and Other Exceptions During Programming/Erasure

Generation of an interrupt or other exception during programming/erasure may lead to fetching of the vector from the code flash memory. Under conditions where BGO cannot be used, set the address of the vector to an address that is not in the

43.17 使用说明

(1) 编程擦除被中断的阅读区域和暂停的目标区域

存储在已暂停编程或擦除的区域或已使用suspend命令暂停编程或擦除的区域中的数据是未定义的。为避免因读取未定义数据而导致错误操作，请注意不要从暂停编程或擦除的区域以及使用暂停命令暂停编程或擦除的区域获取指令或读取数据。

(2) 编程擦除期间的暂停

当通过发出PE暂停命令停止编程擦除处理时，可以通过发出PE恢复命令来恢复编程擦除处理。如果闪存定序器由于任何原因进入命令锁定状态并在挂起处理正常完成并且ERSSPD标志或PRGSPD标志设置为1后发出强制停止命令，则无法恢复挂起的处理。此外，不能保证处理暂停的区域中的值。擦除该区域

(3) 禁止额外编程

不能对代码闪存或数据闪存的给定区域进行两次编程。要对已编程的代码闪存或数据闪存进行编程，请擦除目标区域。可以将编程添加到选项设置存储器中。

(4) 在编程擦除或空白检查期间复位

如果在编程擦除期间由于RES引脚上的信号而导致复位，或者闪存的空白检查，一旦工作电压为在电气特性规定的范围内，然后将设备从复位状态释放。

(5) 在编程擦除期间为中断和其他异常分配向量

在编程擦除期间产生中断或其他异常可能会导致从代码闪存中获取向量。在无法使用BGO的情况下，将向量的地址设置为不在

code flash memory. Alternatively, make sure that no handling of interrupts or exceptions proceeds during programming/erasure.

(6) Items Prohibited During Programming/Erasure, or Blank Checking

High voltage is applied to the flash memory during programming/erasure, or blank checking. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0]bits.
- Change the OPCCR.OPCM[2:0] bits.
- Change the SCKDIVCR.FCK[2:0]bits.
- Change the SCKSCR.CKSEL[2:0]bits.
- Transition to the software standby mode, or deep software standby mode.

(7) Programming/Erasure in Low-Speed Modes

Do not programming/erasure the flash memory when low-speed mode is selected with the operating power control register (OPCCR).

(8) Emulator Connection

Renesas provides the emulator which supports both debugging using SWD or JTAG communication and serial programming using SCI communication. This emulator makes it easy to switch between debugging and serial programming.

Table 43.32 shows the pinout of 10 pin or 20 pin socket pinouts when using this emulator. The pinout of SWD and JTAG is ARM standard, and MD, TXD, RXD pins are added for the serial programming using SCI communication.

The serial programming interface must be used to program the TrustZone IDAU boundary register settings.

It is recommended to connect PA14/SWCLK/TCK and P201/MD pins using wired OR circuit on the board to use both debugging and serial programming

代码闪存。或者，确保在编程擦除期间不处理中断或异常。

(6) 编程擦除或空白检查期间禁止的项目

在编程擦除或空白检查期间向闪存施加高电压。为防止损坏闪存，请勿执行以下操作。

- 电源的工作电压是否超出允许范围。
- 改变FWEPROR.FLWE[1:0]位。
- 更改OPCCR.OPCM[2:0]位。
- 更改SCKDIVCR.FCK[2:0]位。
- 更改SCKSCR.CKSEL[2:0]位。
- 转换到软件待机模式或深度软件待机模式。

(7) 低速模式下的编程擦除

当使用操作电源控制寄存器(OPCCR)选择低速模式时，不要对闪存进行编程擦除。

(8) 仿真器连接

瑞萨电子提供的仿真器支持使用SWD或JTAG通信进行调试和使用SCI通信进行串行编程。该仿真器可以轻松地在调试和串行编程之间切换。

表43.32显示了使用该仿真器时10针或20针插座的引脚排列。SWD和JTAG的管脚是ARM标准，并增加了MD、TXD、RXD引脚用于使用SCI通信的串行编程。

必须使用串行编程接口对TrustZoneIDAU边界寄存器设置进行编程。

建议使用板上的有线或电路连接PA14SWCLKTCK和P201MD引脚，以同时使用调试和串行编程

44. Internal Voltage Regulator

44.1 Overview

The MCU includes one internal voltage regulator:

45.2 Arm TrustZone Security

45.2.1 Arm TrustZone Technology

Arm TrustZone technology divides the system and the application into Secure and Non-secure domains. Secure application can access both Secure and Non-secure memory and resources. Non-secure application can only access Non-secure memory and resources.

The system starts up in Secure state by default. The security state of CPU can be either Secure or Non-secure.

45.2.2 Memory Security Attribution

The code flash, the data flash, and the SRAM are divided into Secure (S), Non-secure (NS) and Non-secure callable (NSC) regions. These memory security attributions are set into the nonvolatile memory by the serial programming command when the device lifecycle is SSD state. These memory security attributions are loaded into the IDAU and the memory controller before application execution. These memory security attributions cannot be updated by application but can be through the dedicated registers.

The code flash can be divided in up to three regions. The data flash can be divided in up to two regions. The SRAM can be divided in up to three regions. Figure 45.1 shows the memory mapping. Table 45.1 shows the size of memory region.

45.2 ArmTrustZone安全

45.2.1 ArmTrustZone技术

ArmTrustZone技术将系统和应用程序划分为安全和非安全域。安全应用程序可以访问安全和非安全内存和资源。非安全应用程序只能访问非安全内存和资源。

系统默认以安全状态启动。CPU的安全状态可以是Secure或Non-secure。

45.2.2 内存安全归属

代码闪存、数据闪存和SRAM分为安全(S)、非安全(NS)和非安全可调用(NSC)区域。当设备生命周期为SSD状态时，这些内存安全属性由串行编程命令设置到非易失性内存中。这些内存安全属性在应用程序执行之前被加载到IDAU和内存控制器中。这些内存安全属性不能由应用程序更新，但可以通过专用寄存器来更新。

代码闪存最多可分为三个区域。数据闪存最多可分为两个区域。SRAM最多可分为三个区域。图45.1显示了内存映射。表45.1显示了内存区域的大小。

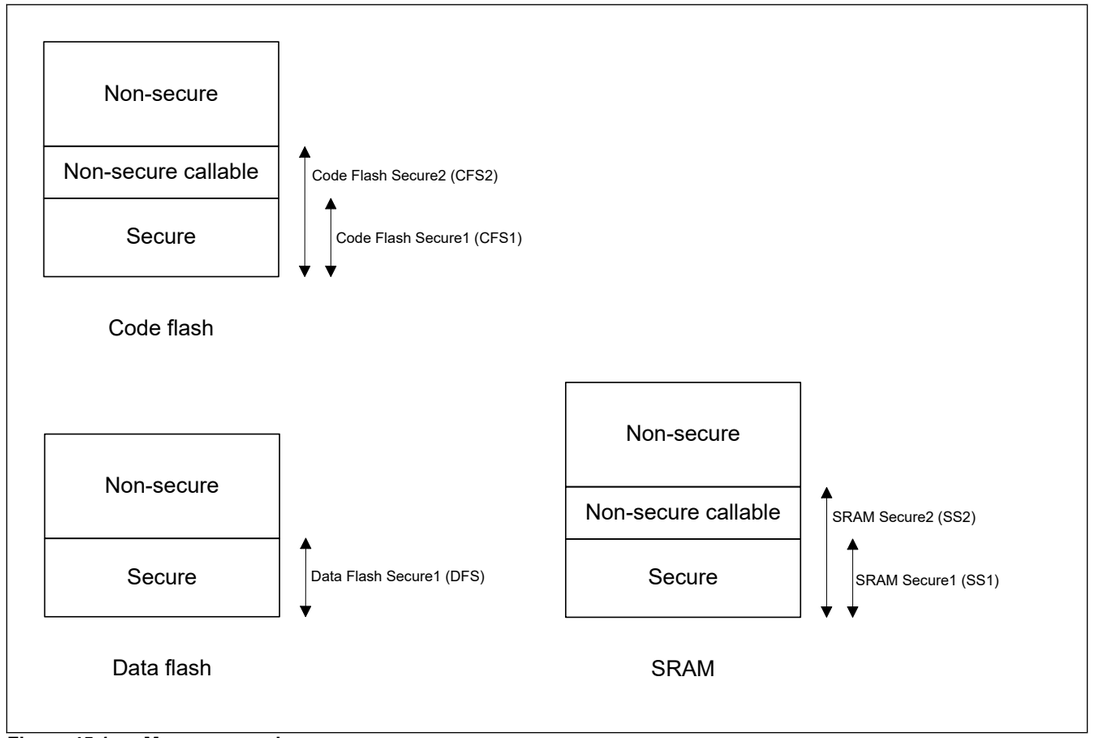

Figure 45.1 Memory mapping

Table 45.1 Memory Region Size

Memory Region	Start Address	Size
Code flash secure	0x0000_0000	CFS1 × 1 KB
Code flash non-secure callable	CFS1 × 1 KB	CFS2 × 32 KB - CFS1 × 1 KB
Code flash non-secure	CFS2 × 32 KB	Code flash size - CFS2 × 32 KB
Data flash secure	0x0800_0000	DFS × 1 KB

SRAM non-secure	0x2000_0000 + SS2 × 8 KB	SRAM size - SS2 × 8 KB

The Standby SRAM is divided 8 regions. Security attribution can be set for each region, but both secure region and non-secure region must be contiguous. In other words, the Standby SRAM can have one contiguous secure region and one contiguous non-secure region. The Standby SRAM security attribution is set to the dedicated register by the secure application. See section 42, Standby SRAM for the details.

备用SRAM分为8个区域。可以为每个区域设置安全属性，但安全区域和非安全区域必须是连续的。换言之，StandbySRAM可以有一个连续的安全区域和一个连续的非安全区域。备用SRAM安全属性由安全应用程序设置到专用寄存器。有关详细信息，请参见第42节，备用SRAM。

45.2.3 Peripheral Security Attribution

Each peripheral can be configured to be Secure or Non-secure.

Peripherals are divided into two types.

Type-1 peripherals has the one security attribution. Access to all registers is controlled by one security attribution. Type-1 peripheral security attribution is set to the PSARx (x = B to E) register by the secure application.

Type-2 peripherals has the security attribution for each register or for each bit. Access to each register or bit field is controlled according to these security attributions. Type-2 peripheral security attribution is set to the Security Attribution register in each module by the secure application. For the Security Attribution register, see sections in the user manual for each peripheral.

Table 45.3 shows the classification of peripheral type.

45.2.3 外围安全属性

每个外围设备都可以配置为安全或非安全。

外设分为两种。

Type-1外围设备具有唯一的安全属性。对所有寄存器的访问由一个安全属性控制。类型1外设安全属性由安全应用程序设置到PSARx（x=B到E）寄存器。

Type-2外设对每个寄存器或每个位都有安全属性。根据这些安全属性控制对每个寄存器或位字段的访问。类型2外围安全属性由安全应用程序设置到每个模块中的安全属性寄存器。对于安全属性寄存器，请参阅每个外设的用户手册中的部分。

45.3.1 更改生命周期状态

使用串行编程命令更改设备生命周期状态。有关命令的详细信息，请参见启动固件应用说明。生命周期不能由应用程序更新，但可以通过专用寄存器读取。

As shown in Figure 45.2, there are three types lifecycle transition.

The first one is to change to lower debug access level or restrict the serial programming mode. This change can be done with no restriction.

Note: The debug interface is permanently disabled in LCK_DBG. After changed to LCK_DBG, the debug interface cannot be used forever.

Note: The debug interface and serial programming interface are permanently disabled in LCK_BOOT. After changed to LCK_BOOT, the debug interface and the serial programming interface cannot be used forever.

The second one is to change to higher debug access level or request for RMA. This change needs key authentication. The key length is 128 bits. The secure developer needs to inject two keys when the lifecycle is SSD state. One is "SECDBG_KEY" which is used to authentication to change the lifecycle from NSECSD to SSD. Other one is "RMA_KEY" which is used to authentication to change the lifecycle from SSD or DPL to RMA_REQ. The non-secure developer needs to inject one key when the lifecycle is NSECSD state. This is "NONSECDBG_KEY" which is used to authentication to change the lifecycle from DPL to NSECSD. See section 45.4. Key Injection for the detail of how to inject the key. The key authentication uses a challenge and response authentication or authentication using the unique ID. The authentication using the unique ID is available only transition to RMA_REQ. The following is the process of how to calculate the response, challenge and response authentication, or the authentication code using unique ID.

Response = AES128-CMAC (KEY, 128bits challenge)

Authentication code = AES128-CMAC (KEY, 128bits unique ID)

Note: In case the key is not injected, these lifecycle changes cannot be done.

Note: In the lifecycle transition from NSECSD to SSD or form DPL to NSECSD, the contents on the flash memory are not erased.

Note: MCU does not respond after changing to higher debug access level or RMA_REQ. If you continue to use the serial programming commands, need to re-enter the boot mode after a reset. See the boot firmware application note for the detail.

Note: In the lifecycle transition to RMA_REQ, the contents on the flash memory except permanently locked block or setting or BPS_SEL register are erased. The contents in the permanently locked block or register can be read by Renesas at failure analysis. Permanently locked block means the block which programming and erasure is disabled permanently by PBPS, PBPS_SEC and BPS_SEL register. Permanently locked register means SAS register which programming and erasure is disabled permanently by FSPR bit.

The third one is all erase. This is done by an initialize command unless an initialize command itself is disabled. The lifecycle is back to SSD and the contents on the flash memory is erased. If there is permanently locked block or register, an initialize command does not execute. In case of the all bits of PBPS and PBPS_SEC register are 1 and FSPR bit is1, an initialize command is executable.

Note: The initialize command can be issued by everyone, so contents on the flash memory are easily erased. Developers who do not want this can invalidate the initialize command permanently by parameter setting command.

Note: MCU does not respond after executing the initialize command. If you continue to use the serial programming commands, need to re-enter the boot mode after a reset. See the boot firmware application note for the detail.

45.3.2 Debug access level

There are three debug access levels, and the debug access level changes according to the lifecycle state.

- DBG2: The debugger connection is allowed, and no restriction to access memories and peripherals
- DBG1: The debugger connection is allowed, and restricted to access only non-secure memory regions and peripherals
- DBG0: The debugger connection is not allowed

45.3.3 Serial Programming

Whether a serial programmer can be connected and the range of flash memory that can be accessed depends on the lifecycle state as shown in Table 45.8. And the accepted serial programming command differs depending on the lifecycle state. See the boot firmware application note for the detail of command.

如图45.2所示，生命周期转换分为三种。

第一个是更改为降低调试访问级别或限制串行编程模式。这种改变可以不受限制地进行。

Note: 调试接口在LCK_DBG中被永久禁用。改成LCK_DBG后，调试接口就不能一直使用了。

Note: 调试接口和串行编程接口在LCK_BOOT中永久禁用。改成之后
LCK_BOOT、调试接口和串行编程接口不能永远使用。

第二个是更改为更高的调试访问级别或请求RMA。此更改需要密钥身份验证。密钥长度为128位。当生命周期为SSD状态时，安全开发人员需要注入两个密钥。一种是"SECDBG_KEY"，用于身份验证以将生命周期从NSECSD更改为SSD。另一种是"RMA_KEY"，用于身份验证以将生命周期从SSD或DPL更改为RMA_REQ。当生命周期为NSECSD状态时，非安全开发者需要注入一个密钥。这是"NONSECDBG_KEY"，用于身份验证以将生命周期从DPL更改为NSECSD。见第45.4节。KeyInjection有关如何注入密钥的详细信息。密钥身份验证使用质询和响应身份验证或使用唯一ID的身份验证。使用唯一ID的身份验证只能转换到RMA_REQ。以下是如何计算响应、挑战和响应身份验证或使用唯一ID的身份验证码的过程。

Response = AES128-CMAC (KEY, 128bits challenge)

认证码=AES128-CMAC(KEY 128bitsuniqueID)

Note: 如果未注入密钥，则无法完成这些生命周期更改。

Note: 在从NSECSD到SSD或从DPL到NSECSD的生命周期转换中，闪存上的内容不会被擦除。

Note: 更改为更高的调试访问级别或RMA_REQ后，MCU没有响应。如果继续使用串口编程命令，需要复位后重新进入开机模式。有关详细信息，请参阅启动固件应用说明。

Note: 在到RMA_REQ的生命周期转换中，闪存上的内容除了永久锁定的块或设置或BPS_SEL寄存器外被擦除。瑞萨在故障分析时可以读取永久锁定的块或寄存器中的内容。永久锁定块是指被PBPS、PBPS_SEC和BPS_SEL寄存器永久禁用编程和擦除的块。永久锁定寄存器是指通过FSPR位永久禁用编程和擦除的SAS寄存器。

第三个是全部擦除。这由初始化命令完成，除非初始化命令本身被禁用。生命周期回到SSD，闪存上的内容被擦除。如果存在永久锁定的块或寄存器，则不会执行初始化命令。如果PBPS和PBPS_SEC寄存器的所有位为1，FSPR位为1，则可执行初始化命令。

Note: 每个人都可以发出初始化命令，因此闪存上的内容很容易被擦除。不希望这样的开发者可以通过参数设置命令使初始化命令永久无效。

Note: 执行初始化命令后MCU没有响应。如果继续使用串口编程命令，需要复位后重新进入开机模式。有关详细信息，请参阅启动固件应用说明。

45.3.2 调试访问级别

共有三个调试访问级别，调试访问级别根据生命周期状态而变化。

- DBG2：允许调试器连接，不限制访问内存和外设
- DBG1：允许调试器连接，但仅限于访问非安全内存区域和外围设备
- DBG0：不允许调试器连接

45.3.3 串行编程

是否可以连接串行编程器以及可以访问的闪存范围取决于生命周期状态，如表45.8所示。并且接受的串行编程命令根据生命周期状态而有所不同。有关命令的详细信息，请参见启动固件应用说明。

45.3.4 Lifecycle changing example

The following is a typical lifecycle changing example.

Secure developer

- Change the lifecycle from CM to SSD by using the serial programming command.
- Set the memory security attribution of the code flash, data flash and SRAM by using the serial programming command.
- Program the secure application by using the serial programming interface and debug the secure application. Debug is possible if the lifecycle is CM, but it is impossible to set the memory security attribution in CM state. If the memory security attribution is not set, all area of the code flash, data flash and SRAM is Secure.

Note: Need to configure the registers listed in Table 45.10 as Non-secure only in NSECSD state. See section 45.6.1. Restrictions on setting the security attribution for details.

- Inject SECDBG_KEY and RMA_KEY by using the serial programming command (if need).
- Disable the all erase by using the serial programming command (if need).
- Change the lifecycle from SSD to NSECSD by using the serial programming command.

Non-secure developer

- Program the Non-secure application by using the serial programming interface and debug the Non-secure application.
- Inject NONSECDBG_KEY by using the serial programming command (if need).
- Disable the all erase by using the serial programming command (if need).
- Change the lifecycle to DPL by using the serial programming command.

45.3.5 Failure analysis

If the customer requests the failure analysis to Renesas, it is necessary to send the device after changing the lifecycle to RMA_REQ. If the lifecycle is not RMA_REQ, Renesas can not do the failure analysis. Because RMA_REQ is permanent state, it can not back to the another state after changing to RMA_REQ. It is assumed to change to SSD or NSECSD and analyze before changing to RMA_REQ.

Devices sent to Renesas will not be returned to customers. The device will be discarded.

Note: As described in the section 45.3.1. Changing the Lifecycle State, RMA_KEY is needed to change the lifecycle to RMA_REQ. If the customer forgets the RMA_KEY, Renesas can not do the failure analysis.

45.4 Key Injection

There are three steps required to inject a user key into the MCU.

First, the customer needs to create the 128 bits installation key. This key is called User Factory Programming Key (UFPK) and used to encrypt a user key. The customer gets the key of the wrapped version (W-UFPK) through the Renesas Key Wrapping Service.

Second the customer encrypts the user key using UFPK as the AES key.

Last the customer sends W-UFPK and the encrypted user key to the MCU by using serial programming interface. The sent user key is decrypted, wrapped with the hardware unique key, and then stored in the nonvolatile memory.

Figure 45.3 is the illustration of key injection. Table 45.9 shows the keys that can be injected by serial programming interface.

User Key is used for authentication during the life cycle transition.

45.3.4 生命周期更改示例

以下是一个典型的生命周期更改示例。

安全开发人员

●使用串行编程命令将生命周期从CM更改为SSD。

●使用串行编程命令设置codeflash、dataflash和SRAM的内存安全属性。

●使用串行编程接口对安全应用程序进行编程并调试安全应用程序。如果生命周期是CM，则可以调试，但无法在CM状态下设置内存安全属性。如果未设置内存安全属性，则代码闪存、数据闪存和SRAM的所有区域都是安全的。

Note: 仅在NSECSD状态下需要将表45.10中列出的寄存器配置为非安全。请参见第45.6.1节。设置安全属性的限制以获取详细信息。

●使用串行编程命令（如果需要）注入SECDBG_KEY和RMA_KEY。

●使用串行编程命令禁用全部擦除（如果需要）。

●使用串行编程命令将生命周期从SSD更改为NSECSD。

Non-secure developer

●使用串行编程接口对非安全应用程序进行编程并调试非安全应用程序。

●使用串行编程命令（如果需要）注入NONSECDBG_KEY。

●使用串行编程命令禁用全部擦除（如果需要）。

●使用串行编程命令将生命周期更改为DPL。

45.3.5 故障分析

如果客户要求对瑞萨进行故障分析，则需要在将生命周期更改为RMA_REQ后发送设备。如果生命周期不是RMA_REQ，瑞萨将无法进行故障分析。因为RMA_REQ是永久状态，所以在更改为RMA_REQ后不能回到另一个状态。假设更改为SSD或NSECSD并在更改为RMA_REQ之前进行分析。

发送给瑞萨的设备将不会退还给客户。该设备将被丢弃。

Note: 如第45.3.1节所述。更改LifecycleState，需要RMA_KEY才能将生命周期更改为RMA_REQ。如果客户忘记了RMA_KEY，瑞萨将无法进行故障分析。

45.4 密钥注入

将用户密钥注入MCU需要三个步骤。

首先，客户需要创建128位安装密钥。此密钥称为用户工厂编程密钥(UFPK)，用于加密用户密钥。客户通过RenesasKeyWrappingService获得打包版本(W-UFPK)的密钥。

其次，客户使用UFPK作为AES密钥对用户密钥进行加密。

最后客户通过串行编程接口将W-UFPK和加密的用户密钥发送给MCU。发送的用户密钥被解密，用硬件唯一密钥包装，然后存储在非易失性存储器中。

图45.3是密钥注入的示意图。表45.9显示了可以通过串行编程接口注入的密钥。

用户密钥用于生命周期过渡期间的身份验证。

45.6 使用说明

45.6.1 Restrictions on setting the security attribution

To set the software breakpoint, the debugger need to re-program the flash. Table 45.10 shows the registers that the debugger sets to re-program the flash. If the security attribution of the register listed in Table 45.10 is configured as secure, the debugger can not set the software breakpoint in NSECSD state because the debugger can not change the register setting. Secure developper need to configure the registers listed in Table 45.10 as non-secure only in NSECSD state.

Table 45.10 The registers that the debugger sets to re-program the flash

Function name	Register name
Clock Generation Circuit	SCKDIVCR, SCKCR, PLLCCR, PLLCR, HOCOCR, MOCOCR
Low-Power modes	OPCCR

45.6.2 SAU setting

After reset, all of address space is marked as Secure by SAU default setting. SAU_CTRL register should be set to 0x2 to enable the IDAU security attribution. That is, after setting SAU_CTRL register to 0x2, the address space security attribution becomes as shown in Table 45.6.

45.6.3 Non-secure exception during the setting of FACI registers

As shown in Table 45.5, the registers related to FACI are protected from non-secure access only during programming/erasure or during suspend programming/erasure. Outside of this state, the access from non-secure region is not protected. For example, when programming by the secure user, the non-secure user can rewrite the FSADDR if a non-secure exception occurs immediately after “Set the start address of the target block to the FSADDR register” flow in Figure 43.13. If the FACI command is issued after the non-secure exception processing is completed and the CPU state returns to the secure state, data will be programmed to an address not intended by the secure user.

To prevent such a things, secure user needs to set not to accept the non-secure exception during the following period.

- Set not to accept the non-secure exeption before setting FWEPROR to 01h or setting FENTRYR to other than 0000h, that is before lereasing the protection of FWEPROR or FENTRYR.
- Set to accept the non-secure exception after all write access to the FACI command-issuing area is completed.

45.6.4 FCU interrupt usage

It is recommended that secure users do not use the FCU interrupts, but rather use the register polling. Because non-secure users can program/erase the data flash without calling the secure gateway, if secure user uses FCU interrupts, the unintentional exception handliing may be exeuted when data flash is programmed/erased by a non-secure user.

45.6.1 设置安全属性的限制

要设置软件断点，调试器需要重新编程闪存。表45.10显示了调试器为重新编程闪存而设置的寄存器。如果表45.10中列出的寄存器的安全属性配置为安全，则调试器无法在NSECSD状态下设置软件断点，因为调试器无法更改寄存器设置。仅在NSECSD状态下，安全开发人员需要将表45.10中列出的寄存器配置为非安全。

Table 45.10 调试器设置的用于重新编程闪存的寄存器

函数名称	注册名称
时钟产生电路	SCKDIVCR, SCKCR, PLLCCR, PLLCR, HOCOCR, MOCOCR
Low-Power modes	OPCCR

45.6.2 SAU设置

复位后，SAU默认设置将所有地址空间标记为安全。SAU_CTRL寄存器应设置为0x2以启用IDAU安全属性。即设置SAU_CTRL寄存器为0x2后，地址空间安全属性变为如表45.6所示。

45.6.3 FACI寄存器设置期间的非安全异常

如表45.5所示，与FACI相关的寄存器仅在编程擦除或挂起编程擦除期间受到保护，不会受到非安全访问。在此状态之外，来自非安全区域的访问不受保护。例如，当由安全用户编程时，如果在图43.13中的“将目标块的起始地址设置为FSADDR寄存器”流程之后立即发生非安全异常，则非安全用户可以重写FSADDR。如果在非安全异常处理完成后发出FACI命令并且CPU状态返回到安全状态，则数据将被编程到安全用户不打算使用的地址。

为了防止这样的事情发生，安全用户需要在接下来的时间段内设置不接受非安全异常。

- ●在将FWEPROR设置为01h或将FENTRYR设置为0000h以外的值之前，即在解除对FWEPROR或FENTRYR的保护之前，设置不接受非安全例外。
- ●设置为在对FACI命令发布区域的所有写访问完成后接受非安全异常。

45.6.4 FCU中断使用

建议安全用户不要使用FCU中断，而是使用寄存器轮询。由于非安全用户可以在不调用安全网关的情况下对数据闪存进行编程擦除，因此如果安全用户使用FCU中断，则在数据闪存被非安全用户编程擦除时可能会执行意外异常处理。

46.2.7 Thermal Characteristics

Maximum value of junction temperature (Tj) must not exceed the value of section 46.2.1. Tj/Ta Definition.

Tj is calculated by either of the following equations.

- Tj = Ta + θja × Total power consumption
- Tj = Tt + Ψjt × Total power consumption
  - Tj : Junction Temperature (°C)
  - Ta : Ambient Temperature (°C)
  - Tt : Top Center Case Temperature (°C)
  - θja : Thermal Resistance of "Junction"-to-"Ambient" (°C/W)
  - Ψjt : Thermal Resistance of "Junction"-to-"Top Center Case" (°C/W)
- Total power consumption = Voltage × (Leakage current + Dynamic current)
- Leakage current of IO = Σ (I_{OL} × V_{OL}) /Voltage + Σ (|I_{OH}| × |VCC – V_{OH}|) /Voltage
- Dynamic current of IO = Σ IO (C_{in} + C_{load}) × IO switching frequency × Voltage
  - C_{in}: Input capacitance
  - C_{load}: Output capacitance

Regarding θja and Ψjt, refer to Table 46.11.

46.2.7 热特性

结温最大值(Tj)不得超过第46.2.1节的值。TjTa定义。

Tj通过以下任一公式计算。

●Tj=Ta+θja×总功耗

●Tj=Tt+Ψjt×总功耗

Tj：结温(°C)

Ta：环境温度 (°C)

Tt：顶部中心外壳温度(°C)

θja："结"到"环境"的热阻(°CW)

Ψjt："结"到"顶部中心外壳"的热阻(°CW)

●总功耗=电压×（漏电流+动态电流）

●IO漏电流=Σ(IOL×VOL)电压+Σ(IOH×VCC VOH)电压

●IO的动态电流=ΣIO(Cin+Cload)×IO开关频率×电压

Cin:输入电容

C负载：输出电容

关于θja和Ψjt，请参阅表46.11。

●IOL=1mA，VOL=0.5V，12路输出

●Cin=8pF，16个引脚，输入频率=10MHz

- C_{load} = 30 pF, 16 pins, Output frequency = 10 MHz

Leakage current of IO = Σ (V_{OL} × I_{OL}) / Voltage + Σ ((VCC - V_{OH}) × I_{OH}) / Voltage
= (20 mA × 1 V) × 8 / 3.5 V + (1 mA × 0.5 V) × 12 / 3.5 V + ((VCC - (VCC - 0.5 V)) × 1 mA) × 12 / 3.5 V

Note 1. The recovery time is determined by the system clock source. When multiple oscillators are active, the recovery time can be determined with the following equation:
Total recovery time = recovery time for an oscillator as the system clock source + the longest tSBYOSCWT in the active oscillators - tSBYOSCWT for the system clock + 2 LOCO cycles (when LOCO is operating)
Note 2. When the frequency of the crystal is 24 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 1.
Note 3. When the frequency of PLL is 240 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 4.
Note 4. When the frequency of the external clock is 24 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 1.
Note 5. When the frequency of PLL is 240 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 4.
Note 6. The LOCO frequency is 32.768 kHz and the greatest value of the internal clock division setting is 1.
Note 7. The HOCO frequency is 20 MHz and the greatest value of the internal clock division setting is 1.
Note 8. The PLL frequency is 240 MHz and the greatest value of the internal clock division setting is 4.
Note 9. The MOCO frequency is 8 MHz and the greatest value of the internal clock division setting is 1.
Note 10. When the SNZCR.RXDREQEN bit is set to 0, the following time is added as the power supply recovery time: 16 µs (typical), 48 µs (maximum).
Note 11. The recovery time can be calculated with the equation of tSBYOSCWT + tSBYSEQ. And they can be determined with the following value and equation. For n, the greatest value is selected from among the internal clock division settings.

Wakeup time	TYP		MAX		Unit

Note 1. This skew applies when the same driver I/O is used. If the I/O of the middle and high drivers is mixed, operation is not guaranteed.
Note 2. Constraints on input cycle:
When not switching the source clock: $t_{Pcyc} \times 2 < t_{ACYC}$ should be satisfied.
When switching the source clock: $t_{Pcyc} \times 6 < t_{ACYC}$ should be satisfied.

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.
Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.
Note 3. This result is obtained from reliability testing.
Note 4. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 10,000), erasing can be performed n times for each block. For example, when 128-byte programming is performed 64 times for different addresses in 8-KB blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. Overwriting is prohibited.
Note 5. Time for resumption includes time for reapplying the erasing pulse (up to one full pulse) that was cut off at the time of suspension.
Note 6. The reference value at VCC = 3.3V and room temperature.

注1.这是重新编程后保证所有特性的最少次数。保证范围是从1到最小值。
注2.这表示在指定范围内执行重新编程时特性的最小值。
注3：此结果来自可靠性测试。
注4.重新编程擦除周期是每个块的擦除次数。当重新编程擦除周期为n次（n=10 000）时，可以对每个块执行n次擦除。例如，当对8KB块中的不同地址执行64次128字节编程，然后擦除整个块时，重新编程擦除周期计为1。但是，不能将同一地址多次编程为一次擦除。禁止覆盖。

注5.恢复时间包括重新应用暂停时切断的擦除脉冲（最多1个完整脉冲）的时间。

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.
Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.
Note 3. This result is obtained from reliability testing.
Note 4. The reference value at VCC = 3.3 V and room temperature.

注1.重新编程擦除周期是每个块的擦除次数。当重新编程擦除周期为n次（n=125 000）时，可以对每个块执行n次擦除。例如，当对64字节块中的不同地址执行16次4字节编程，然后擦除整个块时，重新编程擦除周期计为1。但是，不能将同一地址多次编程为一次擦除。禁止覆盖。
注2.这是重新编程后保证所有特性的最少次数。保证范围是从1到最小值。
注3.这表示在指定范围内执行重新编程时特性的最小值。
注4：此结果来自可靠性测试。
注5.恢复时间包括重新应用暂停时切断的擦除脉冲（最多1个完整脉冲）的时间。

Keep: Pin states are retained during periods in Software Standby mode.

Note 1. Retains the I/O port state until the DPSBYCR.IOKEEP bit is cleared to 0.
Note 2. Input is enabled if the pin is specified as the Software Standby canceling source while it is used as an external interrupt pin.
Note 3. Input is enabled if the pin is specified as the Deep Software Standby canceling source.
Note 4. The built-in pull-up is turned on to protect the circuit from negative potential inputs.
Note 5. Regardless of whether the PGA is enabled or disabled, when the PGA is set to pseudo-differential mode, the built in pull-up is turned on to protect the circuit from negative potential inputs. To turn off the built-in pull-up, turn off the PGA's pseudo-differential mode and set it to single mode.

注1.保持IO端口状态直到DPSBYCR.IOKEEP位被清除为0。
注2.如果引脚被指定为软件待机取消源，同时它被用作外部中断引脚，则输入被启用。
注3.如果引脚被指定为深度软件待机取消源，则启用输入。
注4.内置上拉电阻打开以保护电路免受负电位输入的影响。
注5.无论PGA启用还是禁用，当PGA设置为伪差分模式时，内置上拉电阻会打开以保护电路免受负电位输入的影响。要关闭内置上拉，关闭PGA的伪差分模式并将其设置为单模式。

3.2 Access Cycles

This section provides access cycle information for the I/O registers described in this manual.

- Registers are grouped by associated module.
- The number of access cycles indicates the number of cycles based on the specified reference clock.
- In the internal I/O area, reserved addresses that are not allocated to registers must not be accessed, otherwise operations cannot be guaranteed.
- The number of I/O access cycles depends on bus cycles of the internal peripheral bus, divided clock synchronization cycles, and wait cycles of each module. Divided clock synchronization cycles differ depending on the frequency ratio between ICLK and PCLK.
- When the frequency of ICLK is equal to that of PCLK, the number of divided clock synchronization cycles is always constant.
- When the frequency of ICLK is greater than that of PCLK, at least 1 PCLK cycle is added to the number of divided clock synchronization cycles.
- The number of write access cycles indicates the number of cycles obtained by non-bufferable write access.

Note: This applies to the number of cycles when access from the CPU does not conflict with bus access from other bus masters such as DTC or DMAC.

3.2 访问周期

本节提供本手册中描述的IO寄存器的访问周期信息。

●寄存器按相关模块分组。

●访问周期数是指基于指定参考时钟的周期数。

●在内部IO区，不能访问未分配给寄存器的保留地址，否则无法保证操作。

●IO访问周期数取决于内部外设总线的总线周期、分频时钟同步周期和每个模块的等待周期。分频时钟同步周期取决于ICLK和PCLK之间的频率比。

●当ICLK的频率等于PCLK的频率时，分频的时钟同步周期数始终是恒定的。

●当ICLK频率大于PCLK频率时，分频时钟同步周期数至少增加1个PCLK周期。

●写访问周期数是指非缓冲写访问所获得的周期数。

Note: 这适用于当来自CPU的访问与来自其他总线主控器（例如DTC或DMAC）的总线访问不冲突时的周期数。

Table 3.2 Access cycles (3 of 3)

Peripherals	Address		Number of access cycles				Cycle Unit	Related function
			ICLK = FCLK		ICLK > FCLK*1			
	From	To	Read	Write	Read	Write		
FLAD, FACI	0x407F_C000	0x407F_EFFF	5	4	2 to 5	2 to 4	FCLK	Data Flash, Flash Application Command Interface

Note 1. If the number of PCLK or FCLK cycles is non-integer (for example 1.5), the minimum value is without the decimal point, and the maximum value is rounded up to the decimal point. For example, 1.5 to 2. 5 is 1 to 3.

Table 3.2 访问周期（3个，共3个）

Peripherals	Address		访问周期数				Cycle Unit	相关功能
			ICLK = FCLK		ICLK > FCLK*1			
	From	To	Read	Write	Read	Write		
FLAD, FACI	0x407F_C000	0x407F_EFFF	5	4	2 to 5	2 to 4	FCLK	数据闪存、闪存应用命令 Interface

注1.如果PCLK或FCLK周期数为非整数（例如1.5），则最小值不带小数点，最大值四舍五入到小数点。例如，1.5到2。5是1到3。
