21.3.12 External pulse width measuring function

The pulse width of GTIOCnA pin input (n = 0 to 3), GTIOCnB pin input, and GTETRGA / GTETRGB / GTETRGC / GTETRGD pin inputs can be measured.

The setting to enable or disable count-up of the GTCNT counter and the input pin and level which measured pulse width are selected by the USILVL[3:0] bits of the GTUPSR register.

The setting to enable or disable count-down of the GTCNT counter and the input pin and level which measured pulse width are selected by the DSILVL[3:0] bits of the GTDNSR register.

The setting to enable both count-up and count-down of the GTCNT counter at the same time is prohibited.

The counting operation performs periodic counting with the period of the GTPR register.

If the phase counting function and the pulse width measuring function are enabled at the same time, the pulse width measuring function does not work and the phase counting function works.

Figure 21.129, Figure 21.130 show examples of external pulse width measuring function and Table 21.61 shows example for setting external pulse width measuring function.

21.3.12 外部脉宽测量功能

GTIOCnA引脚输入（n=0至3）、GTIOCnB引脚输入和GTETRGAGTETRGBGTETRGC的脉冲宽度可以测量GTETRGD引脚输入。

通过GTUPSR寄存器的USILVL[3:0]位选择启用或禁用GTCNT计数器的计数以及测量脉冲宽度的输入引脚和电平的设置。

通过GTDNSR寄存器的DSILVL[3:0]位选择启用或禁用GTCNT计数器的倒数计数以及测量脉冲宽度的输入引脚和电平。

禁止同时启用GTCNT计数器的加计数和减计数的设置。

计数操作以GTPR寄存器的周期进行周期性计数。

如果同时开启相位计数功能和脉宽测量功能，则脉宽测量功能不起作用，相位计数功能起作用。

图21.129、图21.130显示了外部脉冲宽度测量功能的示例，表21.61显示了设置外部脉冲宽度测量功能的示例。

21.3.13 Output Phase Switching (GPT_OPS)

GPT_OPS can easily control Brushless DC motor using Output Phase Switching Control Register (OPSCR).

GPT_OPS uses S/W setting value (OPSCR.UF, VF, WF bits) or external signals detected by the Hall element as input signals. GPT_OPS outputs either level signals or chopped signals by GPT320's PWM as the 6-phase (U-positive phase / negative phase, V-positive phase / negative phase, W-positive phase / negative phase) signals to control motor.

Figure 21.131 shows the block diagram of GPT_OPS.

The GPT_UVWEDGE signal is output signal to ELC generated by detecting the edge of input signal.

21.3.13 输出相位切换(GPT_OPS)

GPT_OPS可以使用输出相位切换控制寄存器(OPSCR)轻松控制无刷直流电机。

GPT_OPS使用SW设置值（OPSCR.UF、VF、WF位）或霍尔元件检测到的外部信号作为输入信号。GPT_OPS通过GPT320的PWM输出电平信号或斩波信号作为6相（U正相负相，V正相负相，W正相负相）信号来控制电机。

图21.131显示了GPT_OPS的框图。

GPT_UVWEDGE信号是对ELC的输出信号，通过检测输入信号的边沿产生。

21.3.13.1 Input Selection and Sampling

The FB bit selects either the software setting value or external input for the input signal.

When the FB bit is 0, the GTIU, GTIV, GTIW external input are selected for the input signal to GPT_OPS after synchronization with the GPT core clock (GTCLK) and noise filtering.

When the FB bit is 1, the software setting value (UF,VF,WF bits) are selected for the input signal to GPT_OPS.

The selected input signals are sampled by the method selected by the ALIGN bit, and they are treated as input phase of GPT_OPS.

When the ALIGN bit is 0, the input signals are sampled by GTCLK.

When the ALIGN bit is 1, the input signals are sampled by the falling edge of GTIOC0A pin output.

The signals after sampling can be read by the U, V, W bits.

Table 21.62 shows the input selection by the FB bit and sampling method by the ALIGN bit.

Table 21.62 Input Selection and Sampling Method

OPSCR Register		Input Selection Sampling Method	Input Phase (GPT_OPS internal signal)
FB bit	ALIGN bit		
0	0	GTIU, GTIV, GTIW external input GTCLK sampling	Input U-phase (gtu_sync) Input V-phase (gtv_sync) Input W-phase (gtw_sync)

1	0	Software setting value UF, VF, WF bits GTCLK sampling	
	1	Software setting value UF, VF, WF bits GTIOC0A falling edge sampling	

21.3.13.2 Rotation Direction Control

When the rotation direction is reverse (RV bit = 1), the input phase is inverted.

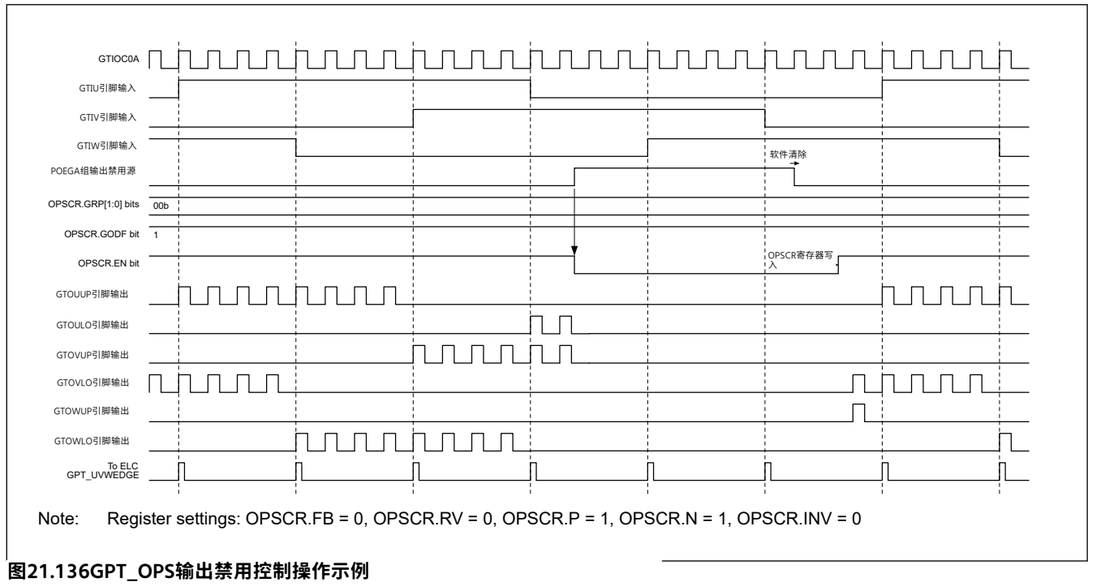

图21.136GPT_OPS输出禁用控制操作示例

21.3.13.1 输入选择和采样

FB位选择输入信号的软件设置值或外部输入。

当FB位为0时，在与GPT内核时钟(GTCLK)同步和噪声过滤后，选择GTIU、GTIV、GTIW外部输入作为GPT_OPS的输入信号。

当FB位为1时，为GPT_OPS的输入信号选择软件设置值（UF、VF、WF位）。

选择的输入信号按照ALIGN位选择的方法进行采样，并将它们视为输入相位GPT_OPS.

当ALIGN位为0时，输入信号由GTCLK采样。

当ALIGN位为1时，输入信号在GTIOC0A引脚输出的下降沿采样。

采样后的信号可以通过U、V、W位读取。

表21.62显示了FB位的输入选择和ALIGN位的采样方法。

Table 21.62 输入选择和采样方法

21.3.13.2 旋转方向控制

当旋转方向为反向时（RV位=1），输入相位反转。

21.3.13.3 Input phase decode

The 6-phase signals by decoding input phase after rotation direction control are generated.

21.3.13.4 Output selection control

The EN, P, N, INV bits select the output wave.

The EN bit enables output of the 6-phase output. When the EN bit is 1, output of the 6-phase output is enabled. When the EN bit is 0, the external pin output is Hi-Z.

The P, N bits select whether chopping positive and negative phase are performed or not. When P, N bits are 1, chopping is performed by GTIOC0A pin output.

When the chopping is performed, there are cases where the PWM width of output is shorter than the width of the PWM used to chop just before or after switching of output phase, depending on the phase difference between the phase output switch timing and the phase of PWM.

The INV bit selects the polarity (either positive logic or negative logic) of phase output.

21.3.13.3 输入相位解码

21.3.13.4 输出选择控制

EN、P、N、INV位选择输出波形。

EN位使能6相输出的输出。EN位为1时，使能6相输出。当。。。的时候
EN位为0，外部引脚输出为Hi-Z。

P、N位选择是否执行斩波正相和反相。当P、N位为1时，由GTIOC0A引脚输出进行斩波。

进行斩波时，输出的PWM宽度有时会比输出相位切换前后的斩波宽度短，这取决于相位输出切换时序和相位之间的相位差。脉宽调制。

INV位选择相位输出的极性（正逻辑或负逻辑）。

21.3.13.5 Output Selection Control (Group Output Disable Function)

When GODF = 1 and signal value selected by the GRP bit is Hi (Output Disable Request), GPT_OPS's output pins are changed to Hi-Z asynchronously and the OPSCR.EN bit is cleared to 0 by the output disable request signal synchronized with GTCLK.

For the return, after clearing the Output Disable Request by software, please set the EN = 1.

The timing of EN bit cleared to 0 is 3 GTCLK cycles after generating the output disable request. In order to perform the output disable control surely, the output disable request flag in POEG should be cleared in the timing that terminating the output disable request is at least 4 GTCLK cycles after generating the output disable request.

The example of the operation of the group output disable control, please refer to the above-mentioned Figure 21.136.

21.3.13.6 Event Link Controller (ELC) Output

The logical sum of the pulse detected by rising and falling edge of U, V, W phase input is output to the event link controller (ELC). When the high level period of input phase is short, there are cases that the detected edge is not transmitted to the ELC correctly because of the logical sum.

21.3.13.5 输出选择控制（组输出禁用功能）

当GODF=1且GRP位选择的信号值为Hi(OutputDisableRequest)时，GPT_OPS的输出引脚异步更改为Hi-Z并且OPSCR.EN位通过与GTCLK同步的输出禁用请求信号清零。

返回时，请在软件清除OutputDisableRequest后，设置EN=1。

EN位清0的时间是产生输出禁止请求后的3个GTCLK周期。为了可靠地执行输出禁用控制，POEG中的输出禁用请求标志应在产生输出禁用请求后至少4个GTCLK周期终止输出禁用请求的时序中清除。

组输出禁用控制的操作示例，请参考上述图21.136。

21.3.13.6 事件链接控制器(ELC)输出

通过U、V、W相输入的上升沿和下降沿检测到的脉冲的逻辑和输出到事件链接控制器(ELC)。当输入相的高电平周期较短时，检测到的边沿有时会因为逻辑和而不能正确传输到ELC。

21.3.14 Inter Channel Logical Operation Function

The logical operation function between compare match outputs can be performed.

Figure 21.137 shows the block diagram of inter channel logical operation.

To prevent hazard to the GPT output, the signal after logical operation is latched with GTCLK. After latching, the output disable control is performed.

When the logical operation function which causes the delay of 1 GTCLK is selected, the output enable signal is also delayed with 1 GTCLK and input to the output disable control.

When the same signal (C = A or D = B) to operate logical function AND, OR, EXOR and NOR is selected, C or D is treated as 1. In the case of GTIOCnA pin output, when A of same channel is selected for C, the result of AND is A, the result of OR is 1, the result of EXOR is NOT A, and the result of NOR is 0.

21.4 Interrupt Sources

21.4.1 Interrupt Sources

The GPT provides the following interrupt sources:

- GTCCR input capture/compare match
- GTADTR compare match
- GTCNT counter overflow (GTPR compare match)/underflow.
- period count function finish

Each interrupt source has its own status flag. When an interrupt source signal is generated, the associated status flag in GTST is set to 1, and an interrupt request is generated. The associated status flag in GTST can be cleared by writing 0. If flag set and flag clear occur at the same time, flag clear takes priority over flag set. These flags are automatically updated by the internal state. The Interrupt Controller Unit can change the relative channel priorities. However, the priority within a channel is fixed. For details, see section 12, Interrupt Controller Unit (ICU).

Table 21.68 lists the GPT interrupt sources.

Table 21.68 Interrupt sources

(1) GPTn_CCMPA interrupt (n = 0 to 9)

An interrupt request is generated under the following conditions:

- When the GTCCRA register functions as a compare match register, the GTCNT counter value (in complementary PWM mode, the GTCNT counter value of master channel) matches with the GTCCRA register
- When the GTCCRA register functions as an input capture register, the input-capture signal causes transfer of the GTCNT counter value to the GTCCRA register. In complementary PWM mode, GTCCRA register does not function as an input capture register.

(2) GPTn_CCMPB interrupt (n = 0 to 9)

An interrupt request is generated under the following conditions:

- When the GTCCRB register functions as a compare match register, the GTCNT counter value matches with the GTCCRB register. In complementary PWM mode, GTCCRB register does not function as a compare match register.
- When the GTCCRB register functions as an input capture register, the input-capture signal causes transfer of the GTCNT counter value to the GTCCRB register. In complementary PWM mode, GTCCRB register does not function as an input capture register.

21.4 中断源

21.4.1 中断源

GPT提供以下中断源：

●GTCCR输入捕捉比较匹配

●GTADTR比较匹配

●GTCNT计数器上溢（GTPR比较匹配）下溢。

●周期计数功能完成

每个中断源都有自己的状态标志。当一个中断源信号产生时，相关的状态标志在GTST设置为1，并产生中断请求。GTST中相关的状态标志可以通过写入0来清除。如果标志设置和标志清除同时发生，标志清除优先于标志设置。这些标志由内部状态自动更新。中断控制器单元可以改变相关的通道优先级。但是，通道内的优先级是固定的。有关详细信息，请参阅第12节，中断控制器单元(ICU)。

表21.68列出了GPT中断源。

Table 21.68 中断源

- GTCR.MD[3:0] = 0110b (triangle-wave PWM mode 3)
- GTBER.CCRB[1:0] = 01b, 10b, 11b (buffer operation with the GTCCRE register).

(6) GPTn_CMPF interrupt (n = 0 to 9)

An interrupt request is generated under the following condition:

- When the GTCCRF register functions as a compare match register, the GTCNT counter value (in complementary PWM mode, the GTCNT counter value of master channel) matches with the GTCCRF register.

A compare match is not performed and therefore, an interrupt is not requested in the following conditions:

- GTCR.MD[3:0] = 0110b (triangle-wave PWM mode 3)
- GTBER.CCRB[1:0] = 10b, 11b (buffer operation with the GTCCRF register).

(7) GPTn_OVF interrupt (n = 0 to 9)

An interrupt request is generated in the following conditions:

- In saw-wave PWM mode 1 and saw-wave one-shot pulse mode, interrupt requests are enabled at overflows (when the GTCNT counter value changes from GTPR to 0 during up-counting)
- In saw-wave PWM mode 2, interrupt requests are enabled at overflows (GTCNT counter value changes from GTCCRm (m = A to F) register value selected with GTCSR.CSCMSC[2:0] bits to 0) or the time when GTCNT counter value matches GTPR register value.
- In triangle-wave mode, interrupt requests are enabled at crests (the GTCNT changes from GTPR to GTPR-1)

(3) GPTn_CMPC中断（n=0到9）

在以下情况下会产生中断请求：

●当GTCCRC寄存器作为比较匹配寄存器时，GTCNT计数器值（在互补PWM模式下，主通道的GTCNT计数器值）与GTCCRC寄存器匹配。

不执行比较匹配，因此在以下情况下不请求中断：

- GTCR.MD[3:0] = 0001b (saw-wave one-shot pulse mode)
- GTCR.MD[3:0] = 0110b (triangle-wave PWM mode 3)

●当GTCCRD寄存器作为比较匹配寄存器时，GTCNT计数器值（在互补PWM模式下，主通道的GTCNT计数器值）与GTCCRD寄存器匹配。

不执行比较匹配，因此在以下情况下不请求中断：

- GTCR.MD[3:0] = 0001b (saw-wave one-shot pulse mode)

●当GTCCRF寄存器作为比较匹配寄存器时，GTCNT计数器值（在互补PWM模式下，主通道的GTCNT计数器值）与GTCCRF寄存器匹配。

不执行比较匹配，因此在以下情况下不请求中断：

- GTCR.MD[3:0] = 0001b (saw-wave one-shot pulse mode)
- GTCR.MD[3:0] = 0110b (triangle-wave PWM mode 3)

●在锯齿波PWM模式2中，中断请求在溢出（GTCNT计数器值从使用GTCSR.CSCMSC[2:0]位选择的GTCCRm（m=A到F）寄存器值变为0）或GTCNT计数器值与GTPR寄存器值匹配。

●在三角波模式下，在波峰处启用中断请求（GTCNT从GTPR变为GTPR-1）

- In complementary PWM mode, interrupt requests are enabled at crests (GTCNT counter value of master channel changes from GTPR register value to GTPR register value minus 1).
- In counting by hardware sources (include external pulse width measuring function), an overflow (GTCNT changes from GTPR to 0 in up count) has occurred.

(8) GPTn_UDF interrupt (n = 0 to 9)

An interrupt request is generated in the following conditions.

- In saw-wave PWM mode 1 and saw-wave one-shot pulse mode, interrupt requests are enabled at underflows (when the GTCNT counter value changes from 0 to GTPR during down-counting)

- In complementary PWM mode, interrupt requests are enabled at troughs (GTCNT counter value of master channel changes from 0 to 1).
- In counting by hardware sources (include external pulse width measuring function), underflow (GTCNT changes from 0 to GTPR in down count) has occurred.

About Interrupt signals and interrupt status flags, see section 21.2.16. GTST : General PWM Timer Status Register.

(9) GPTn_ADTRGA interrupt (n = 0 to 9)

When the GTCNT counter value matches with GTADTRA, an interrupt request is generated under the following condition.

- In Up-counting, the interrupt enable bit (ADTRAUEN) in GTINTAD is 1.
- In Down-counting, the interrupt enable bit (ADTRADEN) in GTINTAD is 1.
  In event count operation performing, this interrupt request isn't generated.

(10) GPTn_ADTRGB interrupt (n = 0 to 9)

When the GTCNT counter value matches with GTADTRB, an interrupt is generated under the following condition.

- In Up-counting, the interrupt enable bit (ADTRBUEN) in GTINTAD is 1.

  In event count operation performing, this interrupt request isn't generated.

(11) GPTn_PC Interrupt (n = 0 to 3)

21.4.2 DMAC and DTC Activation

The DMAC and DTC can be activated by the interrupt in each channel. For details, see section 12, Interrupt Controller Unit (ICU), section 15, DMA Controller (DMAC), and section 16, Data Transfer Controller (DTC).

21.4.3 Interrupt and A/D Conversion Start Request Skipping Function

21.4.3.1 Interrupt Skipping Function by GTITC Register

By setting the GTITC register, the GTCNT counter overflow (GTPR register compare match) interrupt (GPTn_OVF) and underflow interrupt (GPTn_UDF) can be skipped. Other interrupts and A/D conversion start request signals can be skipped in coordination with the GPTn_OVF/GPTn_UDF skipping function. When the interrupt is skipped, the updating of relevant status flag is also skipped. The interrupt skipping is continued even if the status flag is set to 1.

The interrupt skipping function is related only to the GTITC register setting, and is not related to setting of the GTINTAD register interrupt enable bit. The interrupt skipping is continued even if the interrupt is disabled with GTINTAD register setting.

When both troughs and crests are counted and skipped in triangle-wave mode, if the number of times of skipping is odd, GPTn_OVF/GPTn_UDF interrupt requests cannot be generated at troughs only or at crests only depending on the skipping counter start timing. Therefore, in order to count both troughs and crests and generate the GPTn_OVF/GPTn_UDF interrupts at troughs only or crests only in triangle-wave mode, the number of times of skipping should be even.

●在互补PWM模式下，中断请求在波峰处使能（主通道的GTCNT计数器值从GTPR寄存器值变为GTPR寄存器值减1）。

●通过硬件源计数（包括外部脉冲宽度测量功能），发生溢出（GTCNT在向上计数时从GTPR变为0）。

(8) GPTn_UDF中断（n=0到9）

在以下情况下会产生中断请求。

●在锯齿波PWM模式1和锯齿波单发脉冲模式下，下溢时（当向下计数期间GTCNT计数器值从0变为GTPR时）使能中断请求

●在三角波模式下，在波谷处启用中断请求（GTCNT由0变为1）

●在互补PWM模式下，中断请求在波谷处启用（主通道的GTCNT计数器值从0变为1）。

●硬件源计数（包括外部脉宽测量功能）发生下溢（向下计数时GTCNT从0变为GTPR）。

关于中断信号和中断状态标志，请参见第21.2.16节。GTST：通用PWM定时器状态寄存器。

(9) GPTn_ADTRGA中断（n=0到9）

当GTCNT计数器值与GTADTRA匹配时，会在以下条件下产生中断请求。

●在向上计数中，GTINTAD中的中断使能位（ADTRAUEN）为1。

●在递减计数中，GTINTAD中的中断使能位(ADTRADEN)为1。在执行事件计数操作时，不产生该中断请求。

(10)GPTn_ADTRGB中断（n=0到9）

●在向上计数中，GTINTAD中的中断使能位（ADTRBUEN）为1。

●在递减计数中，GTINTAD中的中断使能位（ADTRBDEN）为1。在执行事件计数操作时，不产生该中断请求。

(11)GPTn_PC中断（n=0到3）

21.4.2 DMAC和DTC激活

DMAC和DTC可以通过每个通道中的中断来激活。有关详细信息，请参阅第12节，中断控制器单元(ICU)，第15节，DMA控制器(DMAC)，和第16节，数据传输控制器(DTC)。

21.4.3 中断和AD转换开始请求跳过功能

21.4.3.1 GTITC寄存器的中断跳跃功能

通过设置GTITC寄存器，可以跳过GTCNT计数器溢出（GTPR寄存器比较匹配）中断（GPTn_OVF）和下溢中断（GPTn_UDF）。与GPTn_OVFGPTn_UDF跳过功能配合，可以跳过其他中断和AD转换开始请求信号。当中断被跳过时，相关状态标志的更新也被跳过。即使状态标志设置为1，中断跳过也会继续。

中断跳过功能只与GTITC寄存器的设置有关，与GTINTAD寄存器中断使能位的设置无关。即使通过GTINTAD寄存器设置禁用中断，中断跳过也会继续。

三角波模式下波谷和波峰都计数跳越时，若跳越次数为奇数，
GPTn_OVFGPTn_UDF中断请求不能仅在波谷或波峰产生，具体取决于跳跃计数器的开始时间。因此，为了在三角波模式下同时计算波谷和波峰，并在仅波谷或波峰产生GPTn_OVFGPTn_UDF中断，跳过的次数应该是偶数。

Similarly, in saw-wave mode, when both overflows and underflows are counted and skipped with the count direction changed, GPTn_OVF/GPTn_UDF interrupt requests are sometimes not generated at overflows only or at underflows only. Therefore, in order to count both overflows and underflows with the count direction changed and generate the GPTn_OVF/ GPTn_UDF interrupts at overflows only or underflows only in saw-wave mode, the skipping state should be carefully checked before using.

When changing the skipping count, be sure to release the skipping count setting (GTITC.IVTC[1:0] bits = 00b).

Figure 21.139 to Figure 21.144 show examples of skipping function operation.

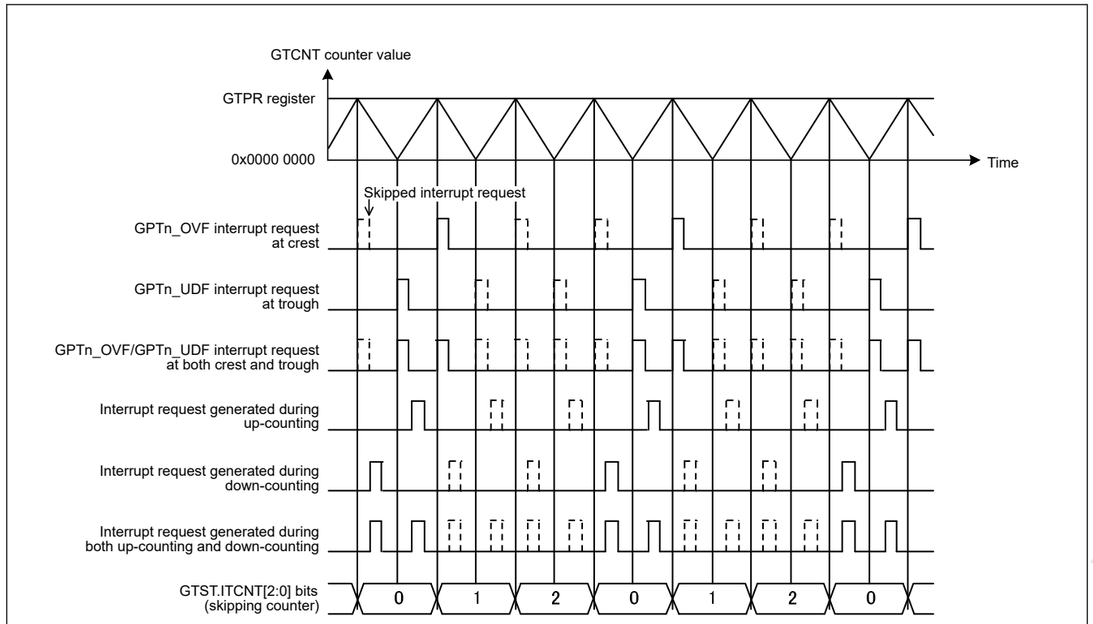

Figure 21.139 Example of Interrupt Skipping Function Operation (Triangle Waves, Counting and Skipping Crests, Skipping Count: 2)

类似地，在锯齿波模式下，当计数方向改变同时计数和跳过上溢和下溢时，GPTn_OVFGPTn_UDF中断请求有时不会仅在上溢或仅在下溢时产生。因此，为了在计数方向改变的情况下计算上溢和下溢并生成GPTn_OVF

GPTn_UDF仅在上溢或仅在锯齿波模式下下溢时中断，使用前应仔细检查跳过状态。

更改跳过计数时，请务必释放跳过计数设置（GTITC.IVTC[1:0]位=00b）。

21.4.3.2 Extended Interrupt Skipping Function

Overflow/underflow interrupt, compare match/input capture interrupt, A/D conversion start request, and buffer transfer can be skipped by counting the GTCNT counter overflow or underflow based on settings of the GTEITC, GTEITLI1, GTEITLI2 and GTEITLB registers.

Overflow/underflow interrupt, compare match/input capture interrupt, A/D conversion start request, and buffer transfer can individually be set for skipping and the skipping period using the GTEITLI1, GTEITLI2, and GTEITLB registers.

The skipping period is set, related to the operation of the two independent extended interrupt skipping counters (EITCNT1[3:0] and EITCNT2[3:0] bits in the GTEITC registers), as a period that either of the counter value for such skipping counters is other than 0 or other than the skipping count. The skipping period can also be set as a period that the both skipping counters are set as other than 0 or other than the skipping count for the counter value.

Figure 21.145 shows the counter operation for interrupt skipping by the GTITC register and extended interrupt skipping.

The counter operation for extended interrupt skipping is set by the GTEITC register.

The EITCNT1[3:0] bits are set for 0 as initial value and then they count the count source (in Figure 21.145, a crest is selected) selected by the extended interrupt counter 1 count source select bit (GTEITC.EIVTC1[1:0] bits), and repeat the count operation which returns to 0 when the skipping count (in Figure 21.145, count is 2) set by the extended interrupt skipping 1 skipping count setting bit (EIVTT1[3:0] bits) is achieved.

The EITCNT2[3:0] bits can be set for the initial value and they count the count source (in Figure 21.145, a trough is selected) selected by the extended interrupt counter 2 count source select bit (EIVTC2[1:0] bits), and repeat the count operation which return to 0 when the skipping count (in Figure 21.145 count is 2) set by the EIVTT2[3:0] bits is achieved. The initial value is set when the GTEITC register is written by the access of upper 16 bits or 32 bits while the setting for the extended interrupt skipping counter 2 is not counted (EIVTC2[1:0] bits are 00b) and when the write value to the EIVTC2[1:0] bits is other than 00b. When the initial value is set, the write value to the extended interrupt skipping counter 2 initial value bits (EITCNT2IV[3:0] bits) are set as the initial value for the EITCNT2[3:0] bits.

The extended interrupt skipping counter starts up-counting at the first count clock after the setting is modified from not counting to counting.

The interrupt skipping count counter (GTST.ITCNT[2:0] bits) for the interrupt skipping function set by the GTITC register is reset to 000b when the GTCNT counter operation is stopped: however, the EITCNT1[3:0] and EITCNT2[3:0] bits for the extended interrupt skipping function retain the value even after the GTCNT counter operation is stopped, and the counting can be resumed from the value before the counter is stopped. When values for the EITCNT1[3:0] and EITCNT2[3:0] bits are to be reset (0000b), set the EIVTC1[1:0] and EIVTC2[1:0] bits to the setting for not counting (not skipping) (00b).

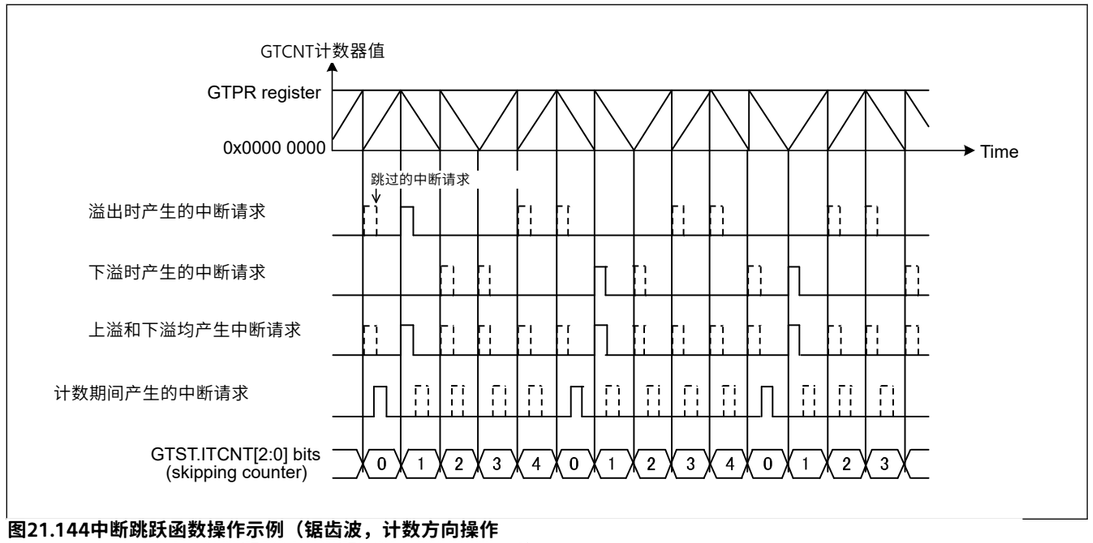

图21.144中断跳跃函数操作示例（锯齿波，计数方向操作更改，计数和跳过上溢和下溢，跳过计数：4）

21.4.3.2 扩展中断跳过功能

根据GTEITC、GTEITLI1、GTEITLI2和GTEITLB寄存器的设置，通过对GTCNT计数器上溢或下溢进行计数，可以跳过上溢下溢中断、比较匹配输入捕捉中断、AD转换开始请求和缓冲区传输。

可以使用GTEITLI1、GTEITLI2和GTEITLB寄存器分别设置上溢下溢中断、比较匹配输入捕捉中断、AD转换开始请求和缓冲区传输以用于跳过和跳过周期。

设置跳过周期，与两个独立的扩展中断跳过计数器（GTEITC寄存器中的EITCNT1[3:0]和EITCNT2[3:0]位）的操作有关，作为此类计数器值中的任何一个的周期跳过计数器不是0或不是跳过计数。也可以将跳过时间段设置为两个跳过计数器设置为0以外的时间段或设置为计数器值的跳过次数以外的时间段。

图21.145显示了通过GTITC寄存器跳过中断和扩展中断跳过的计数器操作。

扩展中断跳过的计数器操作由GTEITC寄存器设置。

EITCNT1[3:0]位设置为0作为初始值，然后对扩展中断计数器1计数源选择位(GTEITC.EIVTC1[1:0]位），并重复计数操作，当达到扩展中断跳过1跳过计数设置位（EIVTT1[3:0]位）设置的跳过计数（在图21.145中，计数为2）时返回0。

EITCNT2[3:0]位可设置为初始值，并对扩展中断计数器2计数源选择位(EIVTC2[1:0]位)，并重复计数操作，当达到EIVTT2[3:0]位设置的跳过计数（在图21.145中计数为2）时返回0。当通过高16位或32位访问写入GTEITC寄存器时设置初始值，而扩展中断跳过计数器2的设置不计数（EIVTC2[1:0]位为00b）以及写入值时到EIVTC2[1:0]位不是00b。设置初始值时，将写入扩展中断跳过计数器2个初始值位（EITCNT2IV[3:0]位）的值设置为EITCNT2[3:0]位的初始值。

扩展中断跳过计数器在设置从不计数修改为计数后的第一个计数时钟开始向上计数。

由GTITC寄存器设置的中断跳过功能的中断跳过计数计数器（GTST.ITCNT[2:0]位）在GTCNT计数器操作停止时复位为000b：但是，EITCNT1[3:0]和EITCNT2[3:0]扩展中断跳过功能位即使在GTCNT计数器操作停止后仍保持该值，并且可以从计数器停止之前的值重新开始计数。当EITCNT1[3:0]和EITCNT2[3:0]位的值要复位(0000b)时，将EIVTC1[1:0]和EIVTC2[1:0]位设置为不计数的设置（不跳过）（00b）。

When the skipping count is to be changed, change the count after stopping the skipping counter operation (set either of the EIVTC1[1:0] bit or the EIVTC2[1:0] bit to 00b).

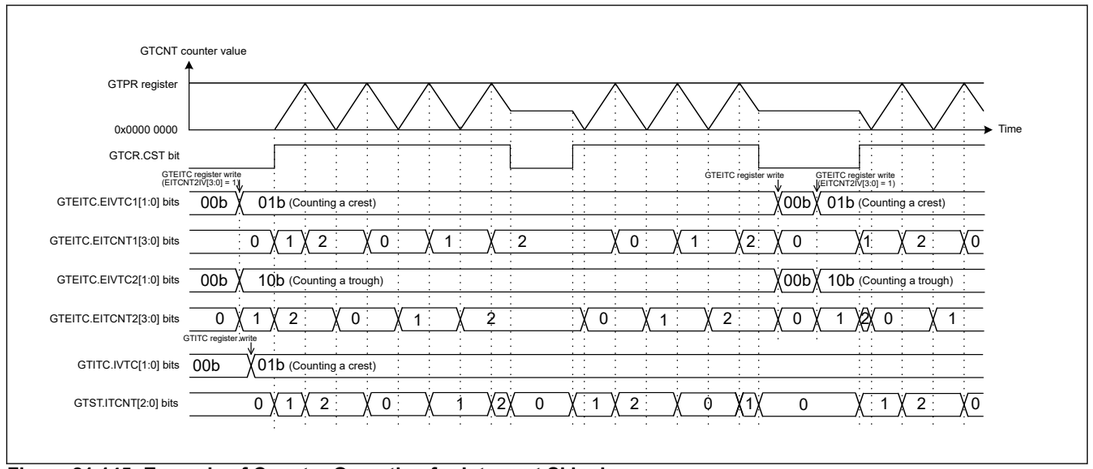

Figure 21.145 Example of Counter Operation for Interrupt Skipping

Interrupt skipping by the GTEITL1 register and A/D conversion start request skipping by the GTEITLI2 register can be performed simultaneously with skipping by the GTITC register or GTADCMSC register. A skipping period in this case is represented by OR-ed skipping periods of respective registers.

Figure 21.146 shows corresponding interrupt skipping operations by different registers are performed simultaneously.

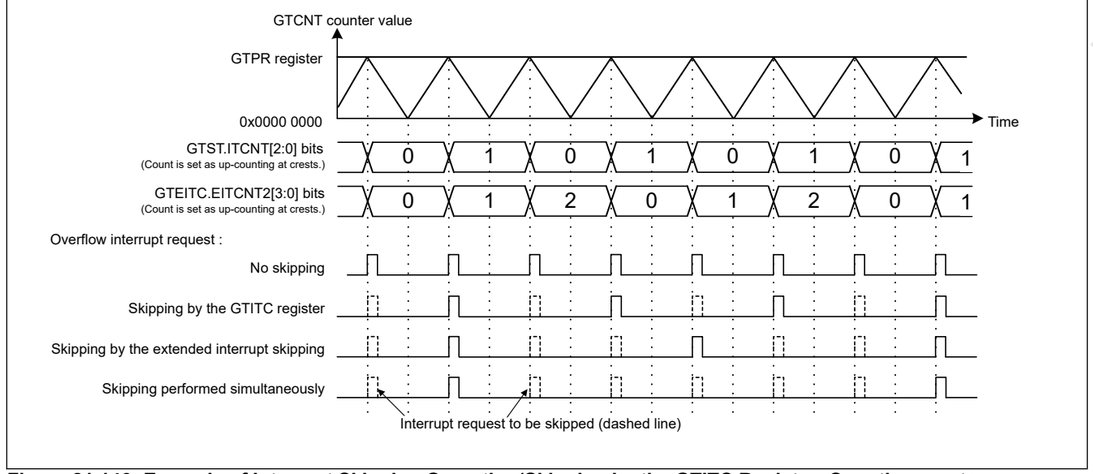

Figure 21.146 Example of Interrupt Skipping Operation(Skipping by the GTITC Register: Counting crests, Extended Interrupt Skipping: EIVTC1[1:0] bits = 00b, EIVTC2[1:0] bits = 01b, EITLV[2:0] bits = 010b)

When the extended interrupt skipping selected by GTEITLI1 is performed, the relevant status flag is also skipped. The skipping function is continued even if the status flag is set to 1.

When A/D conversion start request skipping selected by GTEITLI2 is performed, the relevant status flag is also skipped. The skipping function is continued even if the status flag is set to 1.

Skipping of updating of status flag and ELC event source outputs corresponding to A/D conversion start request for which skipping can be set up in the GTEITLI2 register is only based on the settings of the GTITC register and the extended interrupt skipping register, and has no connection with the setting of A/D conversion start request enable bit in the

如果要更改跳跃计数，请在停止跳跃计数器操作后更改计数（设置任一EIVTC1[1:0]位或EIVTC2[1:0]位到00b）。

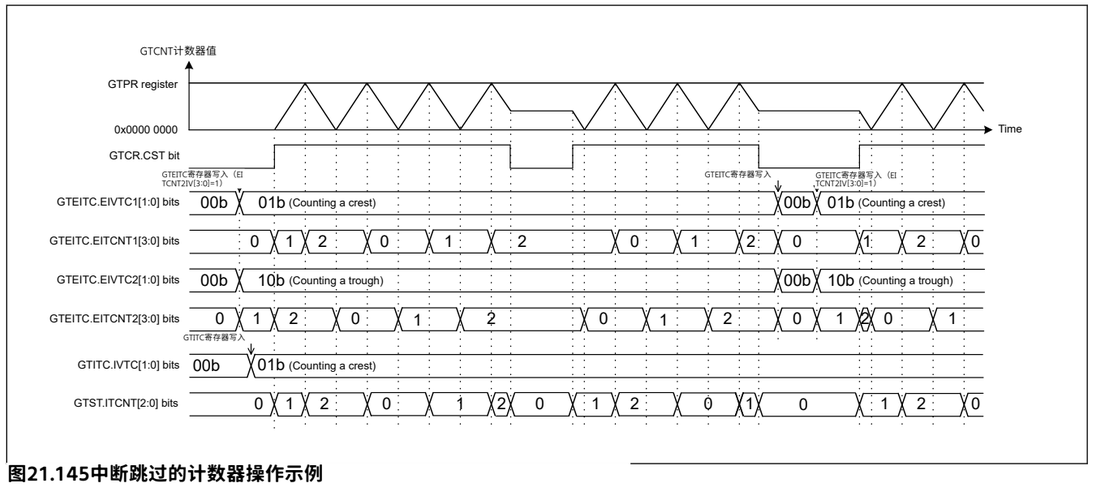

图21.145中断跳过的计数器操作示例

GTEITL1寄存器的中断跳跃和GTEITLI2寄存器的AD转换开始请求跳跃可以与GTITC寄存器或GTADCMSC寄存器的跳跃同时执行。这种情况下的跳跃周期由各个寄存器的或运算跳跃周期表示。

图21.146显示了不同寄存器同时执行相应的中断跳过操作。

A buffer transfer skipping by the GTEITLB register is performed in all of buffer operation which is enabled in the GTBER and GTDTCR registers and GTBER2 register, or all buffer operations performed by saw-wave one-shot pulse mode or triangle-wave PWM mode 3 or complementary PWM mode(excludes buffer transfer from GTCCRC, GTCCRE to GTCCRA).

21.4.3.3 A/D conversion Start Request Compare Match Skipping Function

The A/D conversion start request and GTADTR register buffer transfer can be skipped by counting the compare matches of GTADTRA register and GTADTRB register based on settings of the GTADCMSC register and GTADCMSS register.

The skipping period is set, related to the operation of the two independent A/D conversion start request compare match skipping counters (ADCMSCNT1[3:0] and ADCMSCNT2[3:0] bits in the GTADCMSC register), as a period that either of the counter value for such skipping counters is other than 0 or other than the skipping count. The skipping period can also be set as a period that the both skipping counters are set as other than 0 or other than the skipping count for the counter value.

Figure 21.156 shows the counter operation for A/D conversion start request compare match skipping.

The counter operation for A/D conversion start request compare match skipping is set by the GTADCMSC register.

The ADCMSCNT1[3:0] bits count the count source (in Figure 21.156, a crest is selected) selected by the A/D conversion start request compare match skipping counter 1 count source select bit (GTADCMSC.ADCMSC1[1:0] bits), and repeat the count operation which returns to 0 when the skipping count (in Figure 21.156, count is 2) set by the A/D conversion start request compare match skipping 1 skipping count setting bit (ADCMST1[3:0] bits) is achieved.

The ADCMSCNT2[3:0] bits count the count source (in Figure 21.156, a trough is selected) selected by the A/D conversion start request compare match skipping counter 2 count source select bit (GTADCMSC.ADCMSC2[1:0] bits), and repeat the count operation which returns to 0 when the skipping count (in Figure 21.156, count is 2) set by the A/D conversion start request compare match skipping 2 skipping count setting bit (ADCMST2[3:0] bits) is achieved.

The ADCMSCNTk[3:0] bits (k = 1, 2) can be set for the initial value. The initial value is set when the GTADCMSC register is written by the access of 16 bits or 32 bits while the setting for the A/D conversion start request compare match skipping counter k is not counted (ADCMSCk [1:0] bits are 00b) and the write value to the ADCMSCk[1:0] bits is other than 00b. When the initial value is set, the write value to the A/D conversion start request compare match skipping counter k initial value bits (ADCMSCNTkIV[3:0] bits) are set as the initial value for the ADCMSCNT2[3:0] bits.

The A/D conversion start request compare match skipping counter starts up-counting at the first count clock after the setting is modified from not counting to counting.

The ADCMSCNT1[3:0] and ADCMSCNT2[3:0] bits for the A/D conversion start request compare match skipping function retain the value even after the GTCNT counter operation is stopped, and the counting can be resumed from the value before the counter is stopped. When values for the ADCMSCNT1[3:0] and ADCMSCNT2[3:0] bits are to be reset (0000b), set the ADCMSC1[1:0] and ADCMSC2[1:0] bits to the setting for not counting (not skipping) (00b).

When the skipping count is to be changed, change the count after stopping the skipping counter operation (set either of the ADCMSC1[1:0] bit or the ADCMSC 2[1:0] bit to 00b).

图21.156显示了AD转换开始请求比较匹配跳过的计数器操作。

AD转换开始请求比较匹配跳过的计数器操作由GTADCMSC寄存器设置。

ADCMSCNT1[3:0]位对由AD转换开始请求比较匹配跳过计数器1计数源选择位（GTADCMSC.ADCMSC1[1:0]位）选择的计数源（在图21.156中，选择一个波峰）进行计数，并重复计数操作，当达到由AD转换开始请求比较匹配跳过1跳过计数设置位（ADCMST1[3:0]位）设置的跳过计数（在图21.156中，计数为2）时，计数操作返回0。

ADCMSCNT2[3:0]位计数由AD转换开始请求比较匹配跳过计数器2计数源选择位（GTADCMSC.ADCMSC2[1:0]位）选择的计数源（在图21.156中，选择了一个波谷），并重复计数操作，当达到由AD转换开始请求比较匹配跳过2跳过计数设置位（ADCMST2[3:0]位）设置的跳过计数（在图21.156中，计数为2）时，计数操作返回0。

ADCMSCNTk[3:0]位(k=1 2)可设置为初始值。当通过16位或32位访问写入GTADCMSC寄存器时设置初始值，同时不计算AD转换开始请求比较匹配跳过计数器k的设置（ADCMSCk[1:0]位为00b）并且向ADCMSCk[1:0]位写入的值不是00b。设置初始值时，将写入AD转换开始请求比较匹配跳过计数器k初始值位（ADCMSCNTkIV[3:0]位）的值设置为ADCMSCNT2[3:0]位的初始值。

AD转换开始请求比较匹配跳过计数器在设置从不计数修改为计数后的第一个计数时钟开始向上计数。

AD转换开始请求比较匹配跳过功能的ADCMSCNT1[3:0]和ADCMSCNT2[3:0]位即使在GTCNT计数器操作停止后仍保持该值，并且可以从计数器之前的值恢复计数停了下来。当ADCMSCNT1[3:0]和ADCMSCNT2[3:0]位的值要复位(0000b)时，将ADCMSC1[1:0]和ADCMSC2[1:0]位设置为不计数的设置（不跳过）（00b）。

如果要更改跳跃计数，请在停止跳跃计数器操作后更改计数（设置任一ADCMSC1[1:0]位或ADCMSC2[1:0]位到00b)。

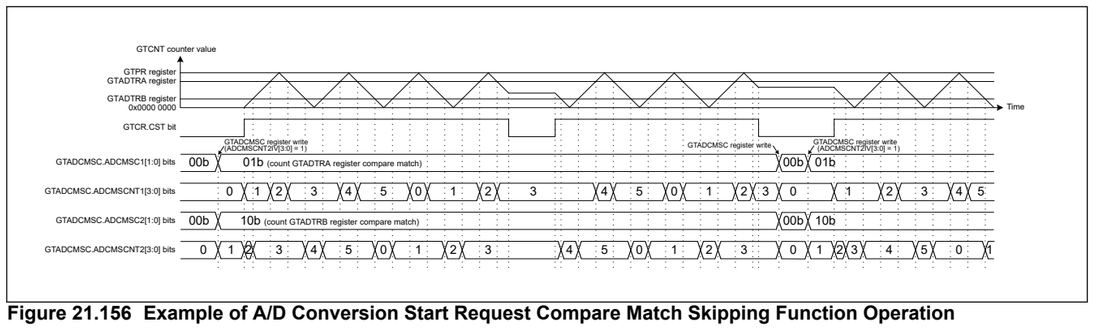

Figure 21.156 Example of A/D Conversion Start Request Compare Match Skipping Function Operation

A/D conversion start request skipping by the ADCMSC register can be performed simultaneously with skipping by the GTITC register or GTEITC register. A skipping period in this case is represented by OR-ed skipping periods of respective registers.

Figure 21.157 shows corresponding interrupt skipping operations and A/D conversion start request skipping operation are performed simultaneously.

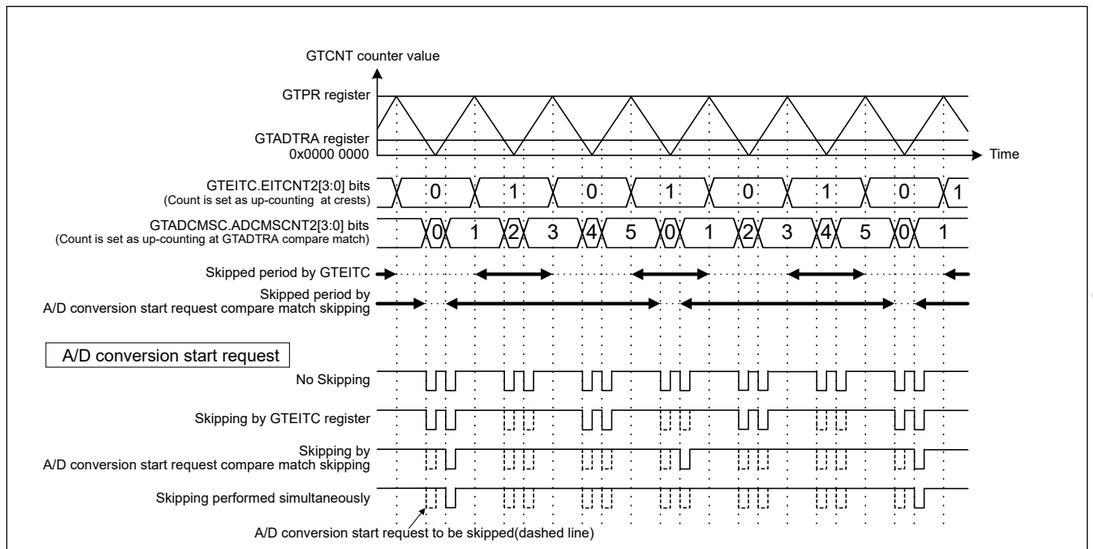

Figure 21.157 Example of A/D Conversion Start Request Compare Match Skipping Function Operation (Extended Interrupt Skipping: EIVTC2[1:0] = 01b, EADTAL[2:0] = 010b, A/D Conversion Start Request Compare Match Skipping: ADCMSC2[1:0] = 01b, ADCMSAL[2:0] = 010b)

When A/D conversion start request skipping which can be set by the GTADCMSS register is performed, updating of status flag and the ELC event output depend on the A/D conversion start request enable bit in the GTINTAD register. All the operations by A/D conversion start request which are set as disable by the GTINTAD register is not performed.

A buffer transfer skipping by the GTADCMSS register is performed in all of buffer operation which is enabled in the GTBER and GTBER2 register, or all buffer operations performed by saw-wave one-shot pulse mode or triangle-wave PWM mode 3 or complementary PWM mode(excludes buffer transfer from GTCCRC, GTCCRE to GTCCRA).

An A/D conversion start request skipping and a buffer transfer skipping are operated individually.

Figure 21.158, Figure 21.159 show examples of extended skipping function operation.

ADCMSC寄存器跳过的D转换开始请求可以与
GTITC寄存器或GTEITC寄存器。这种情况下的跳跃周期由各个寄存器的或运算跳跃周期表示。

图21.157显示了相应的中断跳过操作和AD转换开始请求跳过操作同时执行。

当执行可由GTADCMSS寄存器设置的AD转换开始请求跳过时，状态标志和ELC事件输出的更新取决于GTINTAD寄存器中的AD转换开始请求使能位。由GTINTAD寄存器设置为禁用的AD转换开始请求的所有操作均不执行。

GTADCMSS寄存器的缓冲区传输跳过在所有缓冲区操作中执行，该操作在GTBER和GTBER2寄存器，或由锯齿波单次脉冲模式或三角波PWM模式3或互补PWM模式执行的所有缓冲区操作（不包括从GTCCRC、GTCCRE到GTCCRA的缓冲区传输）。

AD转换开始请求跳过和缓冲区传送跳过是单独操作的。

Table 21.70 shows an example of setting the A/D conversion start request compare match skipping.

The A/D conversion start request compare match skipping counter 2 initial value is set by the written value to the ADCMSCNT2IV[3:0] bits which is applied to change the setting from not counting the extended interrupt skipping counter 2 count source (GTADCMSC.ADCMSC2[1:0] bits = 00b) to counting (ADCMSC2[1:0] bits = other than 00b). Writing to the A/D conversion start request compare match skipping counter 2 initial value bit (ADCMSCNT2IV[3:0] bits) is performed only when the setting of the above mentioned A/D conversion start request compare match skipping counter 2 initial value is written.

3	Set the A/D conversion start request compare match skipping counter k (k = 1, 2)	With the GTADCMSC register, set a count source of the skipping counter, skipping count, and the skipping counter k initial value as the following order. Set the GTADCMSC.ADCMSCk[1:0] bits as value other than 00b, and set the ADCMSTk[3:0] bits as value other than 0000b. Change the ADCMSCk[1:0] bits from 00b to value other than 00b as well as set the ADCMSCNTkIV[3:0] bits to the skipping counter k initial value.
4	Start count operation	Set GTCR.CST to 1 to start count operation.
5	Set buffer value for each cycle	Refer to section 21.3.2. Buffer Operation, section 21.3.3. PWM Output Operating Mode, section 21.5. A/D Conversion Start Request, and so on.

21.5 A/D Conversion Start Request

The A/D conversion start request can be issued at a compare match between the GTCNT counter and the GTADTRA or GTADTRB register. Up-counting only, down-counting only, or both up-counting and down-counting can be specified by setting the GTINTAD register.

In complementary PWM mode, the A/D conversion start request can be issued at a compare match with the GTCNT counter of master channel.

During event count operation, the A/D conversion start request can not be generated.

The A/D conversion start request is output as event signals to ELC.

The GTADTRA and GTADTRB registers each has two buffer registers. Buffer operation with the GTADTRA register used together with the GTADTBRA and GTADTDBRA registers, and buffer operation with the GTADTRB register used together with the GTADTBRB and GTADTDBRB registers can be performed.

The timing of the generation of requests to start A/D conversion can be monitored by an external pin. When the A/D conversion start request signal to be monitored is selected in the GTADSMR.ADSMSk bit (k = 0, 1) and when the output is enabled in the ADSMENk bit, a signal is output synchronized with a cycle frame of the timer used to generate the A/D conversion start request signal, of which the output is driven high at the generation of the A/D conversion start request signal by the GTADSMk pin, or at the end of the cycle of which the output is driven low. When a signal to request the start of A/D conversion is generated at the end of the cycle, the generation of this signal has priority in terms of monitoring output and the output remains at the high level till the end of the next cycle. The registers (GTADTRA and GTADTRB) that are sources of generating the A/D conversion start request signals and their counting directions can be checked by the A/D conversion start request flags (ADTRAUF, ADTRADF, ADTRBUF, and ADTRBDF) in the GTST register. When the output of the same A/D conversion start request signal monitoring output is enabled for multiple channels, ORed signals will be output from the GPT32.

Figure 21.160 shows an example of A/D conversion start request operation, Table 21.71 shows example for setting A/D conversion start request operation.

3	设置AD转换开始请求比较匹配跳过计数器k(k=1 2)	使用GTADCMSC寄存器，按以下顺序设置跳跃计数器的计数源、跳跃计数和跳跃计数器k初始值。 将GTADCMSC.ADCMSCk[1:0]位设置为00b以外的值，并将ADCMSTk[3:0]位设置为0000b以外的值。将ADCMSCk[1:0]位从00b更改为00b以外的值，并设置 ADCMSCNTkIV[3:0]位到跳跃计数器k的初始值。
4	开始计数操作	将GTCR.CST设置为1以启动计数操作。
5	为每个周期设置缓冲区值	请参阅第21.3.2节。缓冲区操作，第21.3.3节。PWM输出操作模式，第21.5节。AD转换开始请求，等等。

21.5 AD转换开始请求

可以在GTCNT计数器与GTADTRA或GTADTRB寄存器之间的比较匹配时发出AD转换开始请求。通过设置GTINTAD寄存器，可以指定仅递增计数、仅递减计数或同时递增计数和递减计数。

在互补PWM模式下，可以在与主通道的GTCNT计数器比较匹配时发出AD转换开始请求。

在事件计数操作期间，不能产生AD转换开始请求。

AD转换开始请求作为事件信号输出到ELC。

GTADTRA和GTADTRB寄存器各有两个缓冲寄存器。可以使用与GTADTBRA和GTADTDBRA寄存器一起使用的GTADTRA寄存器进行缓冲操作，以及使用与GTADTBRB和GTADTDBRB寄存器一起使用的GTADTRB寄存器进行缓冲操作。

可以通过外部引脚监控开始AD转换的请求的生成时间。当在GTADSMR.ADSMSk位(k=0 1)中选择要监视的AD转换开始请求信号并且在ADSMENk位中使能输出时，将输出与用于定时器的周期帧同步的信号。产生AD转换开始请求信号，其输出在GTADSMk引脚产生AD转换开始请求信号时被驱动为高电平，或者在输出被驱动为低电平的周期结束时被驱动为高电平。当在周期结束时产生请求开始AD转换的信号时，该信号的产生在监视输出方面具有优先权，并且输出保持高电平直到下一个周期结束。可以通过GTST寄存器中的AD转换开始请求标志（ADTRAUF、ADTRADF、ADTRBUF和ADTRBDF）检查作为产生AD转换开始请求信号的源的寄存器（GTADTRA和GTADTRB）及其计数方向。当多个通道的相同AD转换开始请求信号监视输出启用时，将从GPT32输出ORed信号。

For double buffer operation, also set the A/D conversion start request point in two cycles after the current cycle (in saw-wave mode or triangle-wave mode with buffer transfer at trough or crest) or one cycle after the current cycle (in triangle-wave mode with buffer transfer at both trough and crest) in the GTADTDBRA and GTADTDBRB registers.

Figure 21.161 shows an example for A/D conversion start request timing operation.

This shows an example of the output of A/D conversion start request A by the ELC as start source 0 (ELC_AD00) for the A/D converter. The A/D conversion start request A signal is output by the ELC in response to a match in comparison with the GTADTRA register.

The same timing applies when the A/D conversion start request A signal from GPT is directly input to ADC without going through ELC.

If GPT is operating with PCLKD and ADC is operating with PCLKA, A/D conversion start request A is passed to ELC on the next rising edge of PCLKA.

If GPT is operating with GPTCLK and ADC is also operating with GPTCLK, A/D conversion start request A is passed to ELC without delay.

For all other clock combinations, A/D conversion start request A is synchronized and passed to ELC.

图21.161显示了AD转换开始请求时序操作的示例。

这显示了ELC作为AD转换器的启动源0(ELC_AD00)输出AD转换启动请求A的示例。AD转换开始请求A信号由ELC输出，以响应与GTADTRA寄存器的比较匹配。

当来自GPT的AD转换开始请求A信号不经过ELC直接输入到ADC时，同样的时序也适用。

如果GPT使用PCLKD运行，而ADC使用PCLKA运行，则AD转换开始请求A在PCLKA的下一个上升沿传递给ELC。

如果GPT使用GPTCLK运行并且ADC也使用GPTCLK运行，则将AD转换启动请求A传递给ELC毫不拖延。

对于所有其他时钟组合，AD转换启动请求A被同步并传递给ELC。

21.6 Operations Linked by ELC

21.6.1 Event Signal Output to ELC

The GPT can perform operation linked with another module set in advance when its interrupt request signal is used as an event signal by the Event Link Controller (ELC).

The A/D conversion start request during up-counting/down-counting can be enabled/disabled individually with the A/D conversion start request enable bit to output events output to ELC.

The GPT has the following ELC event signals:

- Generation of compare match and input capture A interrupt (GPTn_CCMPA)
- Generation of compare match and input capture B interrupt (GPTn_CCMPB)

关于AD转换开始请求的限制，请参阅第17节，事件链接控制器(ELC)和第21.10.6节。
中断请求的间隔。

21.6 由ELC链接的操作

21.6.1 事件信号输出到ELC

当GPT的中断请求信号被事件链接控制器(ELC)用作事件信号时，GPT可以执行与预先设置的另一个模块链接的操作。

向上计数期间的AD转换开始请求可以通过AD转换开始请求使能位单独禁用，以将事件输出到ELC。

GPT具有以下ELC事件信号：

- ●产生比较匹配和输入捕捉A中断(GPTn_CCMPA)
- ●产生比较匹配和输入捕捉B中断(GPTn_CCMPB)

- Generation of compare match C interrupt (GPTn_CMPC)
- Generation of compare match D interrupt (GPTn_CMPD)
- Generation of compare match E interrupt (GPTn_CMPE)
- Generation of compare match F interrupt (GPTn_CMPF)
- Generation of overflow interrupt (GPTn_OVF)
- Generation of underflow interrupt (GPTn_UDF)
- Generation of A/D conversion start request A (GPTn_ADTRGA)
- Generation of A/D conversion start request B (GPTn_ADTRGB)
- Finish of period count function (GPTm_PC)

Note: n = 0 to 9
m = 0 to 3

21.6.2 Event Signal Inputs from ELC

The GPT can perform the following operations in response to a maximum of 8 events from the ELC:

- Start counting, stop counting, clear counting
- Up-counting, down-counting
- Input capture.

See section 17, Event Link Controller (ELC) for the connection between the ELC and the event signal input.

21.7 Noise Filter Function

Each pin for use in input capture and Hall sensor input to the GPT is equipped with a noise filter. The noise filter samples input signals at the sampling clock and removes the pulses whose length is less than 3 sampling cycles.

The noise filter functionality includes enabling and disabling the noise filter for each pin and setting of the sampling clock for each channel.

Figure 21.162 shows the timing of noise filtering.

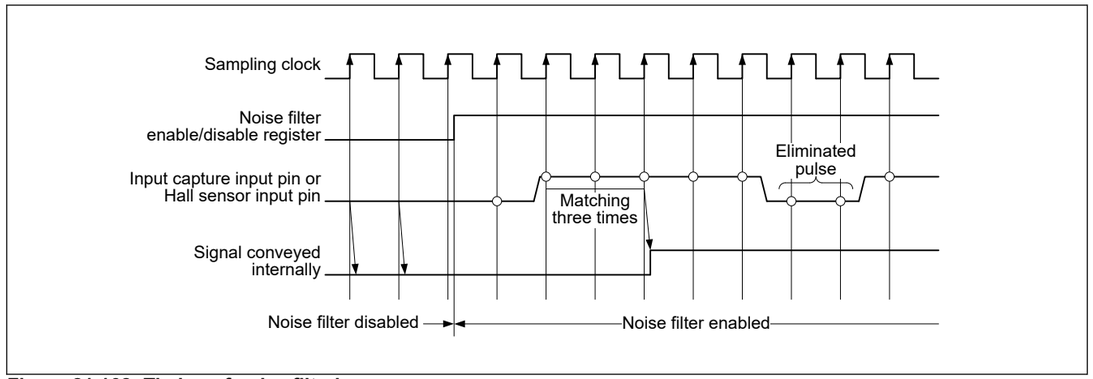

Figure 21.162 Timing of noise filtering

If noise filtering is enabled, the input capture operation or output phase switching operation is performed on the edges of the noise filtered signal after a delay of (sampling interval × 2 + GTCLK) at the shortest. This is due to the noise filtering for the input capture input or hall sensor input.

●产生比较匹配C中断(GPTn_CMPC)
●产生比较匹配D中断(GPTn_CMPD)
●产生比较匹配E中断(GPTn_CMPE)
●产生比较匹配F中断(GPTn_CMPF)
●产生溢出中断（GPTn_OVF）
●产生下溢中断（GPTn_UDF）
●生成AD转换开始请求A(GPTn_ADTRGA)
●生成AD转换开始请求B(GPTn_ADTRGB)
●周期计数功能完成（GPTm_PC）

Note: n = 0 to 9
m = 0 to 3

21.6.2 来自ELC的事件信号输入

GPT可以执行以下操作以响应来自ELC的最多8个事件：

●开始计数、停止计数、清计数
- Up-counting, down-counting
●输入捕捉。

有关ELC和事件信号输入之间的连接，请参见第17节，事件链接控制器(ELC)。

21.7 噪音过滤功能

用于GPT的输入捕捉和霍尔传感器输入的每个引脚都配备了噪声滤波器。噪声滤波器以采样时钟对输入信号进行采样，并去除长度小于3个采样周期的脉冲。

噪声过滤器功能包括为每个引脚启用和禁用噪声过滤器以及为每个通道设置采样时钟。

图21.162显示了噪声过滤的时序。

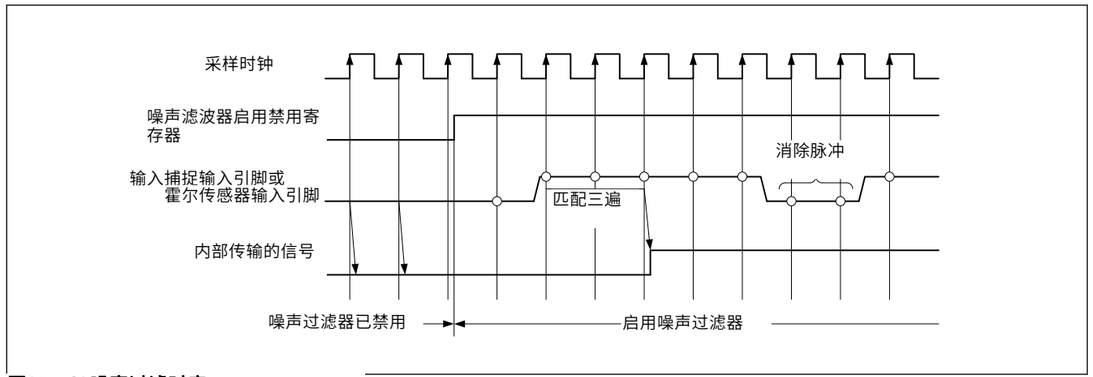

图21.162噪声过滤时序

如果噪声过滤使能，输入捕捉操作或输出相位切换操作在最短延迟（采样间隔×2+GTCLK）后在噪声过滤信号的边缘执行。这是由于输入捕捉输入或霍尔传感器输入的噪声过滤。

21.8 Protection Function

21.8.1 Write-Protection for Registers

To prevent registers from being accidentally modified, registers can be write-protected in channel units by setting GTWP.WP. Write-protection can be set for the following registers:

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTITC, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTPDBR, GTADTRA, GTADTBRA, GTADTDBRA, GTADTRB, GTADTBRB, GTADTDBRB, GTDTCR, GTDVU, GTDVD, GTDBU, GTDBD, GTSOS, GTSOTR, GTADSMR, GTEITC, GTEITLI1, GTEITLI2, GTEITLB, GTICLF, GTPC, GTADCMSC, GTADCMSS, GTBER2, GTOLBR, GTICCR.

Every bit in registers GTSTR, GTSTP and GTCLR which can update the corresponding registers in other channels and can be updated by any of the corresponding registers in other channels conversely, can be protected by setting the GTWP.STRWP, STPWP, and CLRWP bits, respectively, per channel.

Likewise, writing to the GTSECSR and GTSECR registers, which can control all channels by writing to the GTSECSR and GTSECR registers of a given channel, can by enabled or disabled by the setting of the GTWP.CMNWP bit.

Protection using the GTWP register is only for write operations by the CPU. This protection does not cover updates to registers that occur in association with CPU writes.

21.8.2 Disabling of Buffer Operation

If the timing of the buffer register write is delayed relative to the timing for the buffer transfer, buffer operation can be suspended with the GTBER.BD[3], BD[2], BD[1] and BD[0] bits settings. Specifically, buffer transfer can be temporarily disabled even though a buffer transfer condition is generated during buffer register write, by setting the BD[3], BD[2], BD[1] and BD[0] bits to 1 (buffer operation disabled) before buffer register write, and setting the bits to 0 (buffer operation enabled) after completion of writing to all the buffer registers.

The BD[3], BD[2], BD[1] and BD[0] bits can be set on channel basis by writing directly to the GTBER register or it can be set to 0 simultaneously by setting the GTSECR register for multiple channels which were set by the GTSECSR register.

Figure 21.163 shows an example of operation for disabling buffer operation by writing to the GTBER register.

21.8 保护功能

21.8.1 寄存器的写保护

为了防止寄存器被意外修改，可以通过设置以通道为单位对寄存器进行写保护
GTWP.WP。可以为以下寄存器设置写保护：

GTSSR, GTPSR, GTCSR, GTUPSR, GTDNSR, GTICASR, GTICBSR, GTCR, GTUDDTYC, GTIOR, GTINTAD, GTST, GTBER, GTITC, GTCNT, GTCCRA, GTCCRB, GTCCRC, GTCCRD, GTCCRE, GTCCRF, GTPR, GTPBR, GTPDBR, GTADTRA, GTADTBRA, GTADTDBRA, GTADTRB, GTADTBRB, GTADTDBRB, GTDTCR, GTDVU, GTDVD, GTDBU, GTDBD, GTSOS, GTSOTR, GTADSMR, GTEITC, GTEITLI1, GTEITLI2, GTEITLB, GTICLF, GTPC, GTADCMSC, GTADCMSS, GTBER2, GTOLBR, GTICCR.

寄存器GTSTR、GTSTP和GTCLR中的每个位可以更新其他通道中的相应寄存器，反之也可以由其他通道中的任何相应寄存器更新，可以分别通过设置GTWP.STRWP、STPWP和CLRWP位来保护 每个频道。

同样，写入GTSECSR和GTSECR寄存器，它们可以通过写入GTSECSR和
给定通道的GTSECR寄存器可以通过设置GTWP.CMNWP位来启用或禁用。

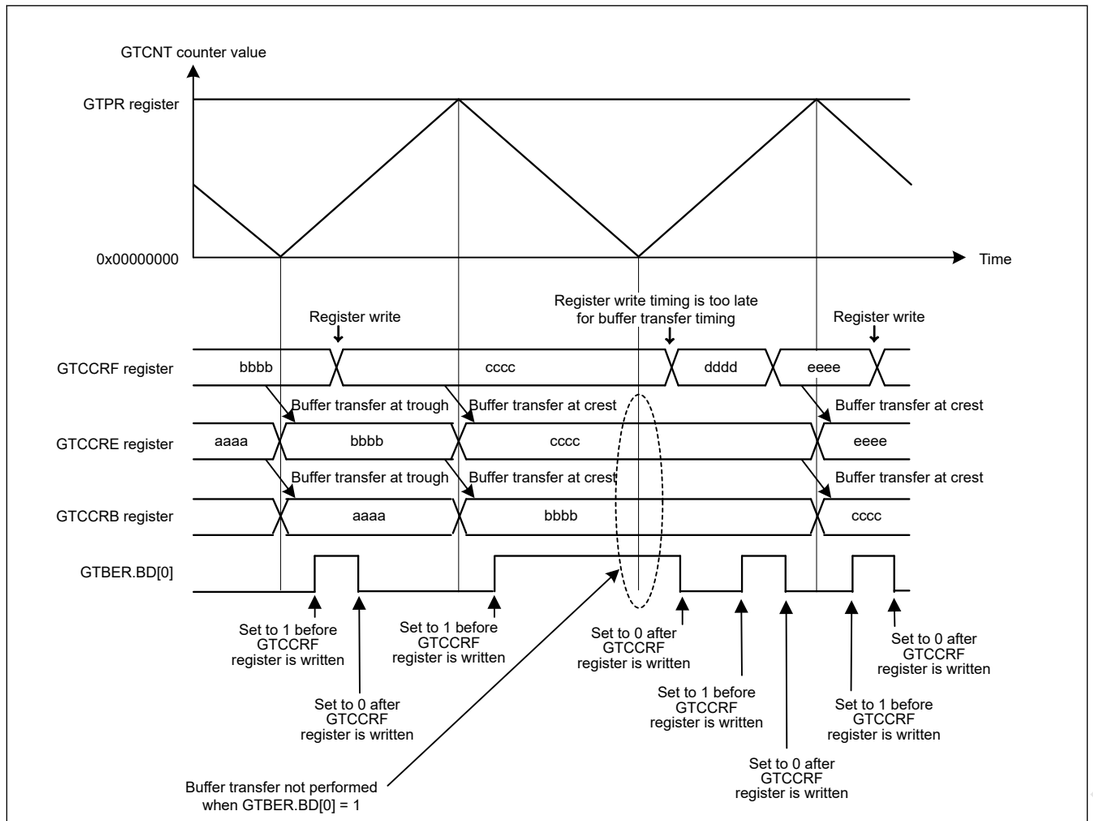
使用GTWP寄存器的保护仅适用于CPU的写操作。此保护不涵盖与CPU写入相关的寄存器更新。

21.8.2 禁用缓冲区操作

如果缓冲寄存器写入的时序相对于缓冲传输的时序延迟，则可以通过GTBER.BD[3]、BD[2]、BD[1]和BD[0]位设置暂停缓冲操作。具体而言，通过将BD[3]、BD[2]、BD[1]和BD[0]位设置为1（禁用缓冲操作)在写入缓冲寄存器之前，并在完成对所有缓冲寄存器的写入后将这些位设置为0（启用缓冲操作）。

BD[3]、BD[2]、BD[1]和BD[0]位可以通过直接写入GTBER寄存器以通道为单位设置，也可以通过为多个通道设置GTSECR寄存器同时设置为0由GTSECSR寄存器设置。

图21.163显示了通过写入GTBER寄存器来禁用缓冲区操作的操作示例。



Note: The base address of registers are the same.

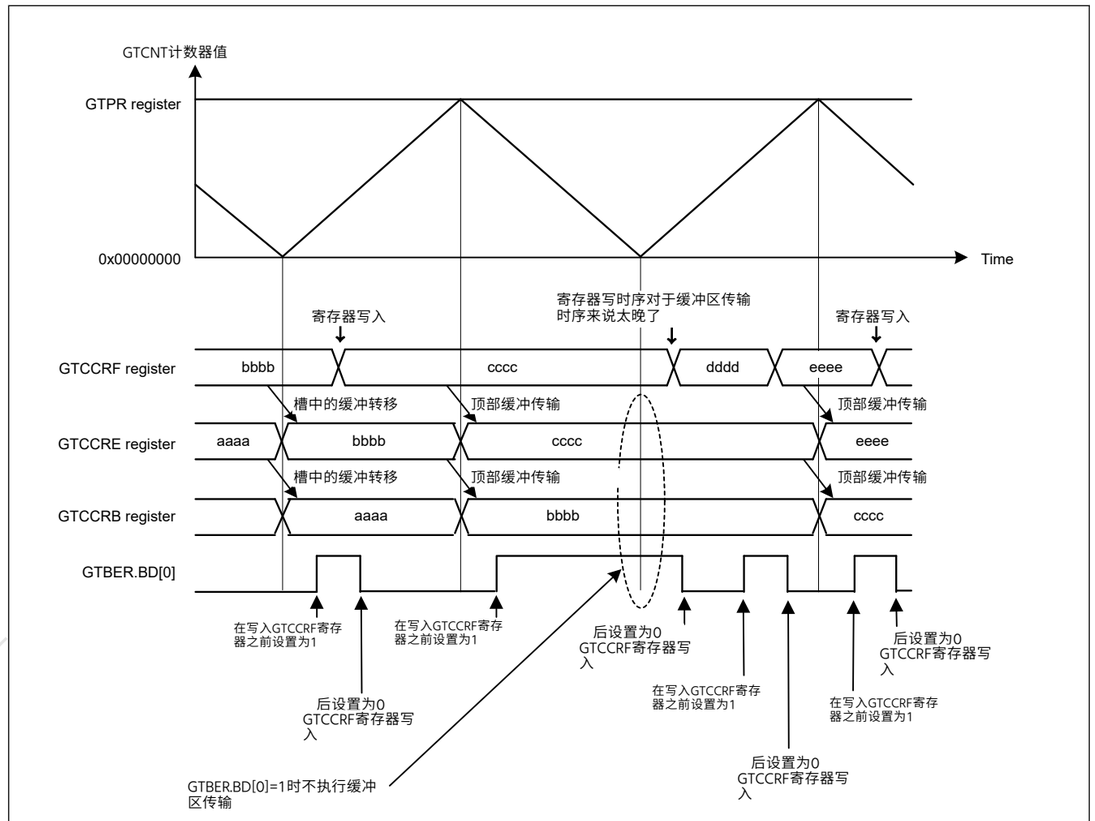
21.8.2.1 Simultaneous Control of Buffer Operations of Multiple Channels

The GTBER.BD bit can be set by writing directly to the GTBER register per channel or by making settings in the GTSECR register for multiple channels that have already set in the GTSECSR register.

Follow the procedure below to simultaneously set the GTBER.BD bits of multiple channels.

1. Select the channels for simultaneously setting by the GTSECSR register
   Set the GTSECSR register so that the values at the bit positions for the corresponding channels for simultaneously setting of the GTBER.BD bits become 1. All GTSECSR registers can be updated by writing to the GTSECSR register of any channel.
2. Simultaneously set the GTBER.BD bits by updating the GTSECR register
   In the GTSECR register, set the operation of the GTBER.BD bits (enabling or disabling of buffer operation) which are to be simultaneously set. Writing to a GTSECR register from any channel updates the GTBER.BD bits in all channels corresponding to the bits set as 1 in the GTSECSR register, in accordance with the value of the GTSECR register.

Figure 21.164 and Figure 21.165 show examples of simultaneously controlling the enabling or disabling of buffer operation for multiple channels.



Note: 寄存器的基地址相同。

图21.163禁用三角波缓冲操作、双缓冲操作和波谷和波峰缓冲传输的操作示例

21.8.2.1 多通道缓冲操作的同时控制

GTBER.BD位可以通过直接写入每个通道的GTBER寄存器或通过在GTSECR寄存器中为已在GTSECSR寄存器中设置的多个通道进行设置来设置。

按照以下步骤同时设置多个通道的GTBER.BD位。

1.通过GTSECSR寄存器选择同时设置的通道
设置GTSECSR寄存器，使用于同时设置GTBER.BD位的相应通道的位位置的值变为1。通过写入任何通道的GTSECSR寄存器，可以更新所有GTSECSR寄存器。

2.通过更新GTSECR寄存器同时设置GTBER.BD位
在GTSECR寄存器中，设置要同时设置的GTBER.BD位的操作（启用或禁用缓冲区操作）。根据GTSECR寄存器的值，从任何通道写入GTSECR寄存器会更新与GTSECSR寄存器中设置为1的位相对应的所有通道中的GTBER.BD位。

图21.164和图21.165显示了同时控制多个通道的缓冲区操作的启用或禁用的示例。

When a GTBER.DBRTECm (m = A, B) bit is set to 1 in saw-wave one-shot pulse mode or triangle-wave PWM mode 3, transfer from the intermediate buffer to the GTCCRm (m = A, B) register is repeated on a cyclic basis even while buffer transfer is disabled by the setting of the GTBER.BD[0] bit or by the buffer transfer extended skipping function.

(1) In saw-wave one-shot pulse mode

In saw-wave one-shot pulse mode, the compare match value for the first half of a waveform is stored in temporary register x (x = C, E) as the intermediate buffer for the GTCCRx (x = C, E) register and the compare match value for the second half of a waveform is stored in temporary register m (m = A, B) as the intermediate buffer for the GTCCRy (y = D, F) register, respectively, for compare match values during repeated buffer operation, and the given values are alternately transferred to the GTCCRm (m = A, B) registers.

Table 21.72 lists the types of buffer transfer of the GTCCR register during counting in saw-wave one-shot pulse mode.

While counting is stopped, the setting of the value in the temporary register is transferred through forcible buffer transfer. In forcible buffer transfer, the values of the GTCCRy (y = D, F) registers are transferred to temporary registers m (m = A, B), and the values of the GTCCRx (x = C, E) are transferred to temporary registers x (x = C, E) when the setting of the corresponding GTBER.DBRTECm (m = A, B) bit is 1, respectively.

When the setting of the GTBER.DBRTECm (m = A, B) bit is 1, values written by the CPU to the GTCCRm (m = A, B) registers are reflected as the values of temporary registers x (x = C, E).

21.8.3 GTIOCnm Pin Output Negate Control (n = 0 to 9, m = A, B)

For protection from system failure, the output disable control that changes the GTIOCnm pin output value forcibly is provided for GTIOCnm pin output by the request of output disable from POEG. Output protection is required when a dead time error or the same output level being on the GTIOCnA and GTIOCnB pins is detected. GPT detects this condition and generates output disable requests to POEG according to the setting of the output disable request permission bits, such as GTINTAD.GRPDTE, GTINTAD.GRPABH, GTINTAD.GRPABL. After the POEG performs the logical OR of the output disable request from each channel and the output disable request from the external input, the POEG generates output disable requests to GPT.

One output disable signal (representing the shared output disable request signal of the GTIOCnA pin and the GTIOCnB pin) out of 4 output disable requests generated by the POEG is selected by setting GTINTAD.GRP[1:0]. The status of the selected disable output request is monitored by reading the GTST.ODF bit. The output level during output disable is set based on the GTIOR.OADF[1:0] bits for the GTIOCnA pin and the GTIOR.OBDF[1:0] setting for the GTIOCnB pin.

The change to the output disable state is performed asynchronously by generating the output disable request from the POEG. The release of the output disable state is performed at end of cycle by terminating the output disable request. It is after 3 GTCLK at shortest when the output disable condition is released after the output disable request becomes no longer satisfied. To reliably control output disabling, clear the flag of POEG for which the condition for the request to disable the output is no longer satisfied after 4 cycles of GTCLK.

When event count is performed or when the operating mode is saw-wave PWM mode 2 or when the output disable state should be released immediately without waiting for end of cycle, GTIOR.OADF[1:0] should be set to 00b (for GTIOCnA pin) or GTIOR.OBDF[1:0] should be set to 00b (for the GTIOCnB pin).

Figure 21.170 shows an example of the GTIOCnm pin output disable control operation. (n = 0 to 9, m = A, B)

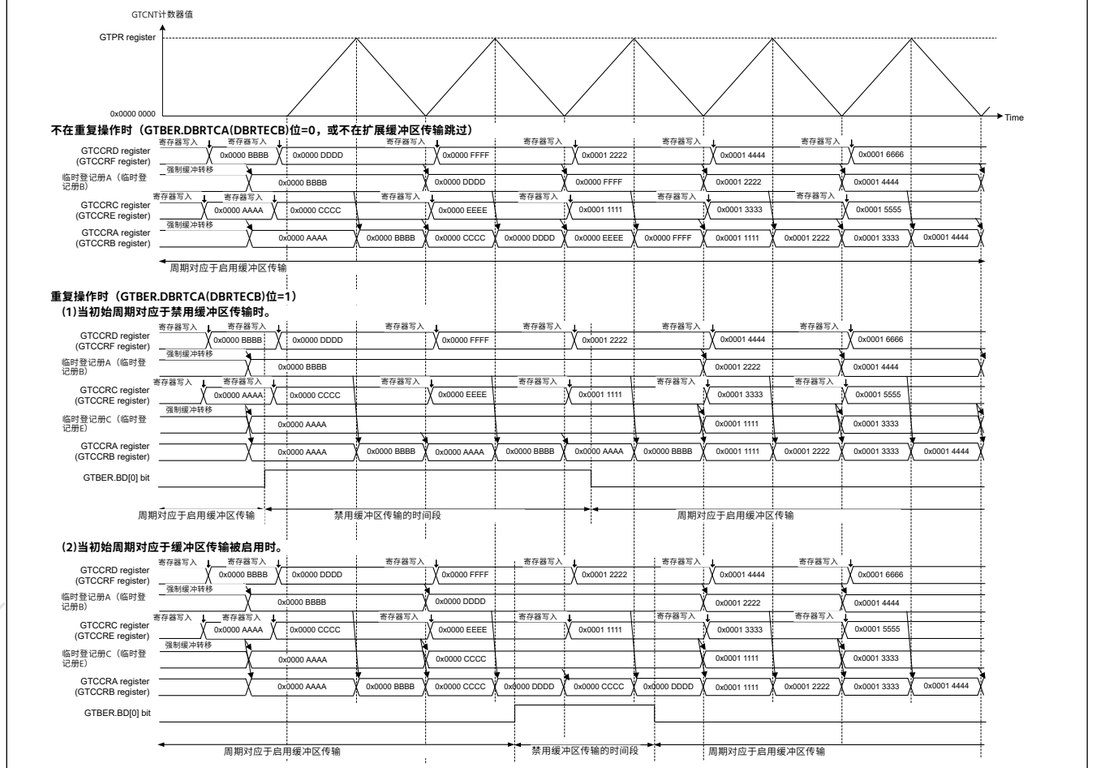

图21.169禁用GTCCR缓冲区传输时重复双缓冲区操作的示例（三角波PWM模式3，更新GTBER.BD[0]位）

21.8.3 GTIOCnm引脚输出负控制（n=0到9，m=A，B）

为防止系统故障，根据POEG的输出禁用请求，为GTIOCnm引脚输出提供强制改变GTIOCnm引脚输出值的输出禁用控制。当检测到死区错误或GTIOCnA和GTIOCnB引脚上的输出电平相同时，需要输出保护。GPT检测到这种情况并根据输出禁用请求许可位的设置，如GTINTAD.GRPDTE、GTINTAD.GRPABH、GTINTAD.GRPABL向POEG生成输出禁用请求。在POEG对来自每个通道的输出禁止请求和来自外部输入的输出禁止请求进行逻辑或运算后，POEG向GPT生成输出禁止请求。

通过设置GTINTAD.GRP[1:0]，在POEG产生的4个输出禁止请求中选择一个输出禁止信号（代表GTIOCnA引脚和GTIOCnB引脚的共享输出禁止请求信号）。通过读取GTST.ODF位来监控所选禁用输出请求的状态。输出禁用期间的输出电平根据GTIOCnA引脚的GTIOR.OADF[1:0]位和GTIOCnB引脚的GTIOR.OBDF[1:0]设置来设置。

对输出禁用状态的更改是通过从
POEG。通过终止输出禁用请求，在循环结束时执行输出禁用状态的释放。输出禁止请求不再满足后，输出禁止条件解除的时间最短为3GTCLK之后。为了可靠地控制输出禁用，在4个GTCLK周期后，清除不再满足禁用输出请求的条件的POEG标志。

当执行事件计数或工作模式为锯齿波PWM模式2或输出禁用状态应立即释放而无需等待周期结束时，GTIOR.OADF[1:0]应设置为00b（对于GTIOCnA引脚）或GTIOR.OBDF[1:0]应设置为00b（对于GTIOCnB引脚）。

21.8.4 Output Protection Function for GTIOCnm Pin Output (n = 0 to 9; m = A, B)

To prepare for a case when an incorrect value (0x0000 0000 or a value greater than or equal to the GTPR register value) is set in the GTCCRA register, the output protection function for the GTIOCnm pin output (disabling function) is activated when the automatic dead time is set (GTDTCR.TDE bit = 1) in triangle-wave PWM mode.

The status of the output protection function can be read from the GTSOS.SOS[1:0] bits.

(4) Restricted Specification of Output Protection Function

Even if an incorrect value (0x0000 0000 or a value greater than or equal to the GTPR register value) is set in the GTCCRA register during count operation, the output protection functions in a specific way such that one of the positive- and negative-phase outputs becomes non-active. However, if the following condition is not satisfied, the output protection does not operate normally.

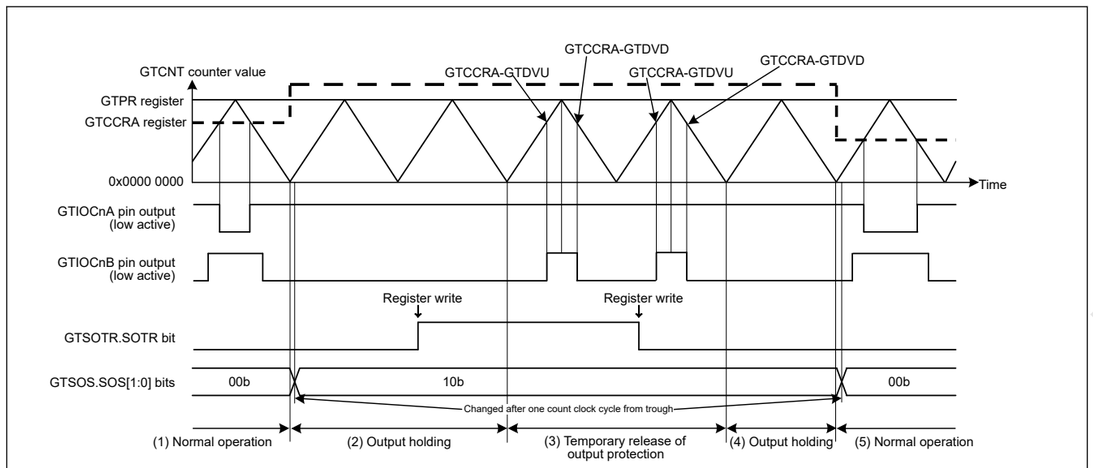
- When the GTCCRA register value at the start of count operation is greater than 0x0000 0000, and less than the setting value of the GTPR register

(5) Temporary Release of Output Protection Function

When the GTSOS.SOS[1:0] bits = 10b (protected state in which GTCCRA register ≥ GTPR register has occurred during transfer at trough), the protected state of the GTIOCnB pin output can be temporarily released by setting the GTSOTR.SOTR bit to 1. The SOS[1:0] bits retain 10b even if the output protection function is released.

When the SOTR bit is set to 0, the GTIOCnB pin output protection can be restarted.

Figure 21.180 shows examples of the operation of temporary release of output protection when the setting of the GTCCRA register ≥ GTPR register during buffer transfer at troughs.



(1) Normal operation period: Toggle output due to a compare match is performed normally.
(2) Output holding period: When GTCCRA ≥ GTPR is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 10b, and the output is held while GTCCRA ≥ GTPR.
Even when the GTSOTR.SOTR bit is set to 1 during the output holding period, the GTIOCnB pin output is held until the first trough after the setting.
(3) Output protection temporary release period: After GTSOTR.SOTR bit is set to 1, the GTIOCnB pin output is performed normally from the first trough after the setting.
Even when the GTSOTR.SOTR bit is set to 0 during the output protection releasing period, the GTIOCnB pin output is held until the first trough after the setting.
(4) Output holding period: The output is held until 0 < GTCCRA < GTPR is detected in the trough.
(5) Normal operation period: When 0 < GTCCRA < GTPR is detected in the trough, the output protection status changes to GTSOS.SOS[1:0] bits = 00b, and toggle output due to a compare match is performed normally.

21.9 Initialization Method of Output Pins

21.9.1 Pin Settings after Reset

The GPT registers are initialized at a reset. Start counting after selecting the port pin function with the PmnPFS register, setting GTIOR.OAE and GTIOR.OBE bits, and outputting the GPT function to external pins.

(4) 输出保护功能限制规格

即使在计数操作期间在GTCCRA寄存器中设置了不正确的值（0x00000000或大于或等于GTPR寄存器值的值），输出保护也会以特定方式起作用，使得正相和负相输出之一变为非积极的。但是，如果不满足以下条件，则输出保护不能正常动作。

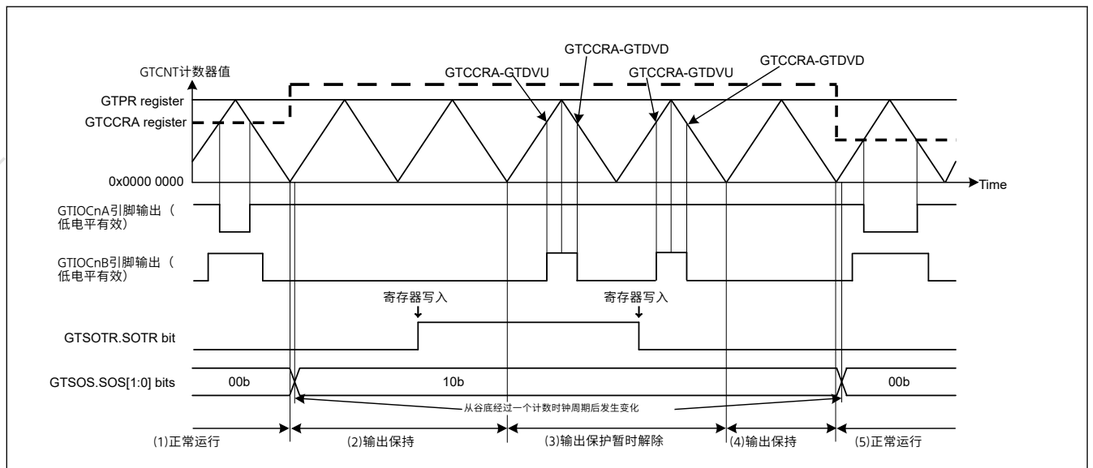
●当计数操作开始时GTCCRA寄存器值大于0x00000000，且小于GTPR寄存器的设置值时

(5) 输出保护功能暂时解除

当GTSOS.SOS[1:0]位=10b时（在低谷传输期间发生GTCCRA寄存器≥GTPR寄存器的保护状态），通过设置GTSOTR.SOTR位可以暂时解除GTIOCnB引脚输出的保护状态为1。即使输出保护功能解除，SOS[1:0]位仍保持10b。

当SOTR位设置为0时，可以重新启动GTIOCnB引脚输出保护。

图21.180显示了在谷底缓冲传输期间，当GTCCRA寄存器的设置≥GTPR寄存器时，输出保护的临时解除操作示例。



(1)正常运营期：由于比较匹配而切换输出正常执行。
(2)输出保持周期：当检测到GTCCRA GTPR处于波谷时，输出保护状态变为GTSOS.SOS[1:0]bits=10b，输出保持同时GTCCRA GTPR。即使在输出保持期间GTSOTR.SOTR位设置为1，GTIOCnB引脚输出也会保持到设置后的第一个波谷。(3)输出保护临时解除周期：GTSOTR.SOTR位设置为1后，GTIOCnB引脚输出从设置后的第一个波谷开始正常进行。即使在输出保护解除期间将GTSOTR.SOTR位设置为0，GTIOCnB引脚输出也会保持到设置后的第一个波谷。

(4)输出保持期：保持输出直到在波谷中检测到0<GTCCRA<GTPR。
(5)正常运营期：当在谷中检测到0<GTCCRA<GTPR时，输出保护状态变为GTSOS.SOS[1:0]位=00b，并且由于比较匹配而正常执行切换输出。

21.9 输出管脚的初始化方法

21.9.1 复位后的引脚设置

GPT寄存器在复位时被初始化。通过PmnPFS寄存器选择端口引脚功能，设置GTIOR.OAE和GTIOR.OBE位，并将GPT功能输出到外部引脚后开始计数。

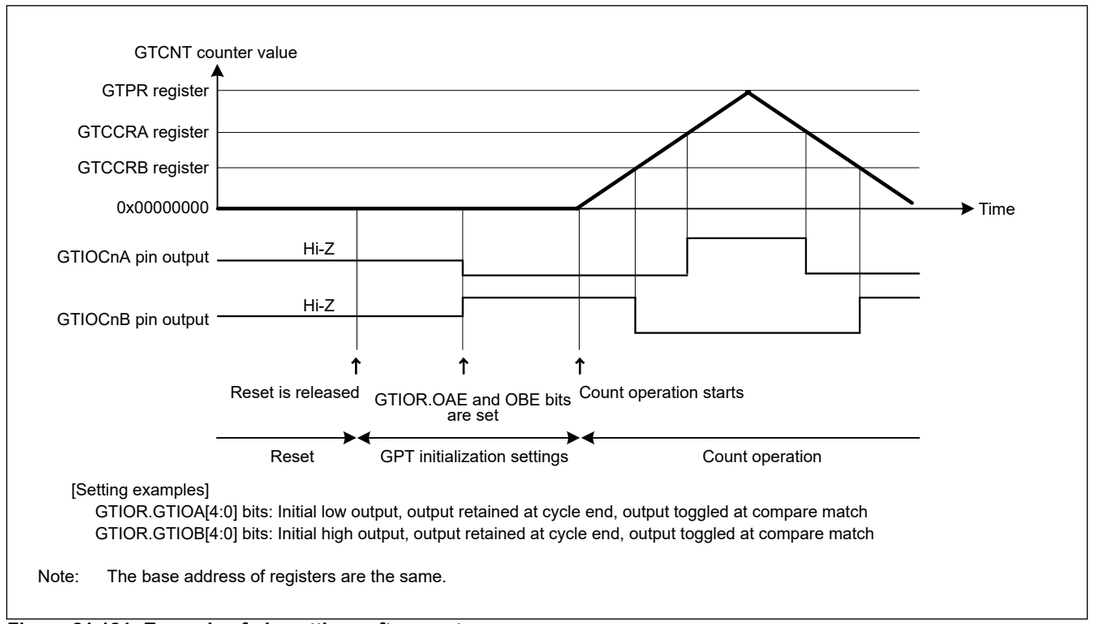

Figure 21.181 Example of pin settings after reset

21.9.2 Pin Initialization Due to Error during Operation

If an error occurs during GPT operation, the following four types of pin control can be performed before pin initialization:

- Set the OAHLD and OBHLD bits in GTIOR to 1 and retain the outputs at count stop
- Set the OAHLD and OBHLD bits in GTIOR to 0, specify arbitrary output values at OADFLT and OBDFLT in GTIOR, and output the arbitrary values at count stop
- Set the pin to output an arbitrary value as a general output port by setting the PDR, PODR registers and PmnPFS.PMR bit of the I/O port in advance. Set the OAE and OBE bits in GTIOR to 0, and the control bit associated with the pin in the PMR to 0 to allow arbitrary values to be output from the pin set as a general output port when an error occurs.
- Drive the output to a high impedance state using the POEG function.

If the automatic dead time setting is made, clear the GTDTCR.TDE bit to 0 after counting stops. When counting stops, only the values of registers that are changed by a GPT external source change. If counting is resumed, operation continues from where it stopped. If counting is stopped, the registers must be initialized before counting starts.

21.10 Usage Notes

21.10.1 Module-Stop Function Setting

The Module Stop Control Register can enable or disable GPT operation. The GPT is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

Set GTCLKCR register before releasing the module-stop state.

21.10.2 GTCCRn Settings during Compare Match Operation (n = A to F)

(1) When automatic dead time setting is made in triangle-wave PWM mode

The GTCCRA register must satisfy all of the following conditions:

- GTDVU < GTCCRA
- GTCCRA > GTDVD
- 0 < GTCCRA < GTPR

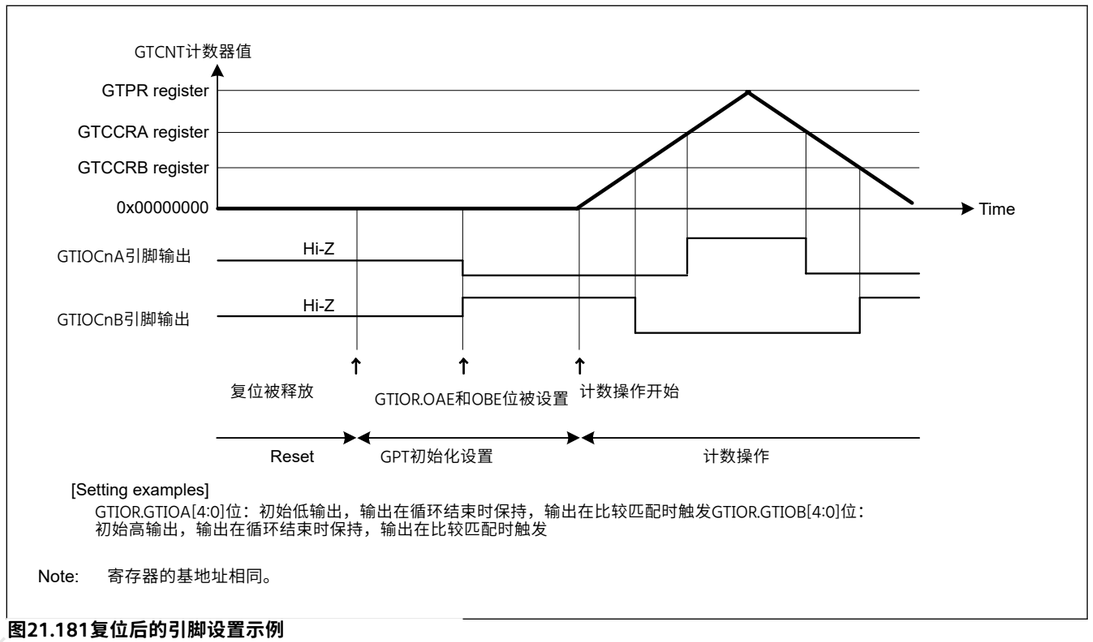

图21.181复位后的引脚设置示例

21.9.2 由于操作过程中的错误而导致的引脚初始化

如果在GPT操作过程中发生错误，可以在引脚初始化之前进行以下四种引脚控制：

●将GTIOR中的OAHLD和OBHLD位设置为1，并在计数停止时保留输出

●将GTIOR中的OAHLD和OBHLD位设置为0，在GTIOR中的OADFLT和OBDFLT指定任意输出值，并在计数停止时输出任意值

●通过预先设置IO端口的PDR、PODR寄存器和PmnPFS.PMR位，将引脚设置为输出任意值作为通用输出端口。将GTIOR中的OAE和OBE位设置为0，并将与PMR中的引脚相关的控制位设置为0，以允许在发生错误时从设置为通用输出端口的引脚输出任意值。

●使用POEG功能将输出驱动为高阻抗状态。

如果进行了自动死区时间设置，则在计数停止后将GTDTCR.TDE位清零。当计数停止时，只有被GPT外部源改变的寄存器的值会改变。如果重新开始计数，则从停止处继续操作。如果停止计数，则必须在计数开始前初始化寄存器。

21.10 使用说明

21.10.1 模块停止功能设置

模块停止控制寄存器可以启用或禁用GPT操作。GPT在重置后最初停止。
释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

在释放模块停止状态之前设置GTCLKCR寄存器。

21.10.2 比较匹配操作期间的GTCCRn设置（n=A到F）

(1) 在三角波PWM模式下进行自动死区时间设置时

GTCCRA寄存器必须满足以下所有条件：

- GTDVU < GTCCRA
- GTCCRA > GTDVD
- 0 < GTCCRA < GTPR

When the setting of GTCCRA = 0 or GTCCRA ≥ GTPR is made for the GTCCRA register during count operation, the output protection function is activated. However, if the following condition is not satisfied, the output protection function does not work normally:

- The value of the GTCCRA register at the start of counting is larger than 0 and less than GTPR.

For details, see section 21.8.4. Output Protection Function for GTIOCnm Pin Output (n = 0 to 9; m = A, B)

(2) When automatic dead time setting is not made in triangle-wave PWM mode

The GTCCRA register must be set within the range of 0 < GTCCRA < GTPR. If GTCCRA = 0 or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0 or GTCCRA = GTPR is satisfied. When GTCCRA > GTPR, no compare match occurs.

Similarly, GTCCRB must be set within the range of 0 < GTCCRB < GTPR. If GTCCRB = 0 or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB is 0 or GTCCRB = GTPR is satisfied. When GTCCRB > GTPR, no compare match occurs.

(3) When automatic dead time setting is made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, the correct output waveforms with secured dead time may not be obtained.

- In up-counting: GTCCRC < GTCCRD, GTCCRC > GTDVU, GTCCRD < GTPR - GTDVD
- In down-counting: GTCCRC > GTCCRD, GTCCRC < GTPR - GTDVU, GTCCRD > GTDVD

(4) When automatic dead time setting is not made in saw-wave one-shot pulse mode

The GTCCRC and GTCCRD registers must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRC < GTCCRD < GTPR
- In down-counting: GTPR > GTCCRC > GTCCRD > 0

Similarly, GTCCRE and GTCCRF must be set to satisfy the following restrictions. If the restrictions are not satisfied, two compare matches do not occur and pulse output cannot be performed.

- In up-counting: 0 < GTCCRE < GTCCRF < GTPR
- In down-counting: GTPR > GTCCRE > GTCCRF > 0.

(5) In saw-wave PWM mode

The GTCCRA register must be set with the range of 0 < GTCCRA < GTPR. If GTCCRA = 0 or GTCCRA = GTPR is set, a compare match occurs within the cycle only when GTCCRA = 0 or GTCCRA = GTPR is satisfied. If GTCCRA > GTPR is set, no compare match occurs.

Similarly, GTCCRB must be set with the range of 0 < GTCCRB < GTPR. If GTCCRB = 0 or GTCCRB = GTPR is set, a compare match occurs within the cycle only when GTCCRB = 0 or GTCCRB = GTPR is satisfied. If GTCCRB > GTPR is set, no compare match occurs.

(6) In Complementary PWM mode 1, 2, 3

The GTCCRn register must be set with the range of 0 ≤ GTCCRn ≤ GTPR + GTDVU.

(7) In Complementary PWM mode 4

In single buffer operation, the GTCCRn register must be set with the range of 0 ≤ GTCCRn ≤ GTPR + GTDVU.

In double buffer operation, the GTCCRn register must be set with the range of GTDVU < GTCCRn < GTPR.

21.10.3 Setting Range for GTCNT Counter

Other than the Saw-wave PWM mode 2 and Complementary PWM mode, the GTCNT counter register must be set with the range of 0 ≤ GTCNT ≤ GTPR.

当在计数操作期间对GTCCRA寄存器设置GTCCRA=0或GTCCRA≥GTPR时，输出保护功能被激活。但是，如果不满足以下条件，则输出保护功能不能正常工作：

●计数开始时GTCCRA寄存器的值大于0小于GTPR。

详见21.8.4节。GTIOCnm引脚输出的输出保护功能（n=0至9；m=A、B）

(2) 在三角波PWM模式下未进行自动死区时间设置时

GTCCRA寄存器必须设置在0<GTCCRA<GTPR的范围内。如果设置了GTCCRA=0或GTCCRA=GTPR，则仅当满足GTCCRA=0或GTCCRA=GTPR时，才会在周期内发生比较匹配。当GTCCRA>GTPR时，不发生比较匹配。

同样，GTCCRB必须设置在0<GTCCRB<GTPR的范围内。如果设置了GTCCRB=0或GTCCRB=GTPR，则仅当GTCCRB为0或GTCCRB=GTPR满足时，才会在周期内发生比较匹配。当GTCCRB>GTPR时，不发生比较匹配。

(3) 在锯波单发脉冲模式下进行自动死区时间设置时

GTCCRC和GTCCRD寄存器必须设置为满足以下限制。如果不满足这些限制，则可能无法获得具有安全死区时间的正确输出波形。

- In up-counting: GTCCRC < GTCCRD, GTCCRC > GTDVU, GTCCRD < GTPR - GTDVD
- In down-counting: GTCCRC > GTCCRD, GTCCRC < GTPR - GTDVU, GTCCRD > GTDVD

(4) 在锯波单发脉冲模式下未进行自动死区时间设置时

GTCCRC和GTCCRD寄存器必须设置为满足以下限制。如果不满足限制，则不会发生两个比较匹配，并且无法执行脉冲输出。

- In up-counting: 0 < GTCCRC < GTCCRD < GTPR
- In down-counting: GTPR > GTCCRC > GTCCRD > 0

同样，必须设置GTCCRE和GTCCRF以满足以下限制。如果不满足限制，则不会发生两个比较匹配，并且无法执行脉冲输出。

- In up-counting: 0 < GTCCRE < GTCCRF < GTPR
- In down-counting: GTPR > GTCCRE > GTCCRF > 0.

(5) 在锯齿波PWM模式下

GTCCRA寄存器必须设置为0<GTCCRA<GTPR。如果设置了GTCCRA=0或GTCCRA=GTPR，则仅当满足GTCCRA=0或GTCCRA=GTPR时，才会在周期内发生比较匹配。如果设置了GTCCRA>GTPR，则不会发生比较匹配。

类似地，GTCCRB必须设置在0<GTCCRB<GTPR的范围内。如果设置了GTCCRB=0或GTCCRB=GTPR，则仅当满足GTCCRB=0或GTCCRB=GTPR时，才会在周期内发生比较匹配。如果设置了GTCCRB>GTPR，则不会发生比较匹配。

(6) 在互补PWM模式1、2、3

GTCCRn寄存器的设置范围必须为0≤GTCCRn≤GTPR+GTDVU。

(7) 在互补PWM模式4

在单缓冲操作中，GTCCRn寄存器必须设置在0≤GTCCRn≤GTPR+GTDVU的范围内。

在双缓冲操作中，GTCCRn寄存器必须设置为GTDVU<GTCCRn<GTPR。

21.10.3 GTCNT计数器的设置范围

除了Saw-wavePWM模式2和互补PWM模式，GTCNT计数器寄存器必须设置为0≤GTCNT≤GTPR的范围。

21.10.4 Starting and Stopping the GTCNT Counter

The control timing of starting and stopping the GTCNT counter by the GTCR.CST bit synchronizes the count clock that is selected in GTCR.TPCS[3:0]. When GTCR.CST is updated, the GTCNT counter starts/stops after a count clock that is selected in GTCR.TPCS[3:0]. Therefore, an event generated before the GTCNT counter actually starts is ignored, resulting in situations in which an event is accepted or an interrupt occurs after GTCR.CST is set to 0.

21.10.5 Priority Order of Each Event

(1) GTCNT register

Table 21.74 shows a priority order of events updating the GTCNT register.

Table 21.74 Priority order of sources updating GTCNT

Source updating GTCNT	Priority order
Writing by CPU (writing to GTCNT/GTCLR)	High
Clear by hardware sources set in GTCSR	↑
Count up or down by hardware sources set in GTUPSR/GTDNSR	↑
Count operation	Low

If up-counting and down-counting by hardware sources occur at the same time, the GTCNT counter value does not change.
When there is a conflict between updating the GTCNT register and reading by the CPU, pre-update data is read.

(2) GTCR.CST bit

When there is a conflict between starting/stopping by hardware sources set in the GTSSR/GTPSR registers and writing by the CPU (writing to GTCR/GTSTR/GTSTP registers), the writing by CPU has priority over the starting/stopping by hardware sources.

In case that stop by the period count function conflicts with start by the CPU writing (GTCR register writing/GTSTR register writing), the period count function is finished with setting the GTST.PCF flag. The CST bit is not changed and the GTCNT continues to count.

When there is a conflict between starting by hardware sources set in the GTSSR register and stopping by hardware sources set in GTPSR register, the GTCR.CST bit value does not change. When there is a conflict between updating the GTCR.CST bit and reading by the CPU (reading from GTCR/GTSTR/GTSTP registers), pre-update data is read.

(3) GTCCRm registers (m = A to F)

When there is a conflict between input capture/buffer transfer operation and writing to the GTCCRm registers, the writing to GTCCRm registers has priority over input capture/buffer transfer operation. When there is a conflict between input capture and writing to the counter register by the CPU or updating the counter register by hardware sources, the pre-update counter value is captured. When there is a conflict between updating the GTCCRm registers and reading by the CPU, pre-update data is read.

(4) GTPR register

When there is a conflict between buffer transfer operation and writing to the GTPR register, writing to GTPR register has priority over buffer transfer operation. When there is a conflict between updating GTPR register and reading by the CPU, pre-update data is read.

(5) GTADTRm registers (m = A, B)

When there is a conflict between buffer transfer operation and writing to GTADTRm register, writing to GTADTRm register has priority over buffer transfer operation.

When there is a conflict between updating the GTADTRm register and reading by the CPU, pre-update data is read.

(6) GTDVm registers (m = U, D)

When there is a conflict between buffer transfer operation and writing to GTDVm register, writing to GTDVm register has priority over buffer transfer operation.

21.10.4 启动和停止GTCNT计数器

通过GTCR.CST位启动和停止GTCNT计数器的控制时序与在GTCR.TPCS[3:0]中选择的计数时钟同步。当GTCR.CST更新时，GTCNT计数器在GTCR.TPCS[3:0]中选择的计数时钟后开始停止。因此，在GTCNT计数器实际启动之前产生的事件将被忽略，从而导致在GTCR.CST设置为0之后接受事件或发生中断的情况。

21.10.5 每个事件的优先顺序

(1) GTCNT register

表21.74显示了更新GTCNT寄存器的事件的优先级顺序。

Table 21.74 更新GTCNT的源的优先顺序

源更新GTCNT	优先顺序
CPU写入（写入GTCNTGTCLR）	High
由GTCSR中设置的硬件源清除	↑
通过GTUPSRGTDNSR中设置的硬件源进行向上或向下计数	↑
计数操作	Low

如果硬件源的递增计数和递减计数同时发生，GTCNT计数器值不会改变。
当更新GTCNT寄存器和CPU读取之间存在冲突时，会读取更新前的数据。

(2) GTCR.CST bit

当GTSSRGTPSR寄存器中设置的硬件源启动停止与CPU写入（写入GTCRGTSTRGTSTP寄存器）发生冲突时，CPU写入优先于硬件源启动停止。

如果周期计数功能停止与CPU写入启动（GTCR寄存器写入GTSTR寄存器写入）发生冲突，则周期计数功能通过设置GTST.PCF标志结束。CST位不变，GTCNT继续计数。

当GTSSR寄存器中设置的硬件源启动和GTPSR寄存器中设置的硬件源停止之间存在冲突时，GTCR.CST位的值不会改变。当更新GTCR.CST位与CPU读取（从GTCRGTSTRGTSTP寄存器读取）之间存在冲突时，将读取更新前数据。

(3) GTCCRm寄存器（m=A到F）

当输入捕捉缓冲区传输操作与写入GTCCRm寄存器之间存在冲突时，写入GTCCRm寄存器优先于输入捕捉缓冲区传输操作。当输入捕获与CPU写入计数器寄存器或硬件源更新计数器寄存器之间存在冲突时，将捕获更新前的计数器值。当更新GTCCRm寄存器和CPU读取之间存在冲突时，会读取更新前的数据。

(4) GTPR register

当缓冲区传输操作与写入GTPR寄存器之间存在冲突时，写入GTPR寄存器优先于缓冲区传输操作。当更新GTPR寄存器与CPU读取发生冲突时，读取更新前的数据。

(5) GTADTRm registers (m = A, B)

当缓冲区传输操作和写入GTADTRm寄存器之间存在冲突时，写入GTADTRm寄存器优先于缓冲区传输操作。

当更新GTADTRm寄存器与CPU读取之间存在冲突时，会读取更新前的数据。

(6) GTDVm registers (m = U, D)

当缓冲区传输操作与写入GTDVm寄存器发生冲突时，写入GTDVm寄存器优先于缓冲区传输操作。

When there is a conflict between updating the GTDVm register and reading by the CPU, pre-update data is read.

(7) GTIOR.GTIOm registers (m = A, B)

When there is a conflict between buffer transfer operation and writing to GTIOR.GTIOm register, writing to GTIOR.GTIOm register has priority over buffer transfer operation.

When there is a conflict between updating the GTIOR.GTIOm and reading by the CPU, pre-update data is read.

21.10.6 Interval of interrupt request

When the core clock of GPT is GPTCLK, interrupt may be lost if the interval between the same interrupt signal is shorter than the following value. However, this restriction does not apply to different interrupt signals.

Interrupt_Interval [ns] = Period_of_GPTCLK [ns] * 6 + Period_of_PCLKA [ns] * 4

For the restriction of event signal, see section 17, Event Link Controller (ELC).

Also, ADC can receive the A/D conversion start request from GPT without going through ELC by setting ADTRGGPTx register (x = 0 to 8).

Again, when the clocks of GPT and ADC are combined as shown in Table 21.75, the A/D conversion start request may be lost if the interval between one A/D conversion start request and the next is less than the following value for the same A/D conversion start request.

However, this restriction does not apply to different A/D conversion start request.

Event_Interval [ns] = Period_of_GPT_core_clock [ns] * 6 + Period_of_ADC_core_clock [ns] * 4

21.10.7 Notes on the GTIOCnm signal input to PWM Delay Generation Circuit (n = 0 to 3, m = A, B)

When controlling the delay of PWM waveform in PWM Delay Generation Circuit, the following limitations exist.

- In saw-wave mode, It is prohibited to change the GTIOCnm signal during the three clock cycles immediately before overflow or underflow.
- In saw-wave mode, it is prohibited to clear the GTCNT register by GTCSR during counting operation.
- In triangle-wave mode, It is prohibited to change the GTIOCnm signal during the three clock cycles immediately before trough.

If the above limitations are not followed, the edge of signal waveform output from PWM Delay Generation Circuit may disappear.

Figure 21.183 shows an example of the change timing of an unacceptable GTIOCnm signal.

当更新GTDVm寄存器与CPU读取之间存在冲突时，会读取更新前的数据。

(7) GTIOR.GTIOm registers (m = A, B)

当缓冲区传输操作和写入GTIOR.GTIOm寄存器之间存在冲突时，写入GTIOR.GTIOm寄存器优先于缓冲区传输操作。

当更新GTIOR.GTIOm和CPU读取之间存在冲突时，读取更新前的数据。

21.10.6 中断请求的间隔

当GPT的核心时钟为GPTCLK时，如果同一中断信号之间的间隔小于以下值，则可能会丢失中断。但是，此限制不适用于不同的中断信号。

Interrupt_Interval [ns] = Period_of_GPTCLK [ns] * 6 + Period_of_PCLKA [ns] * 4

有关事件信号的限制，请参见第17节，事件链接控制器(ELC)。

此外，通过设置ADTRGGPTx寄存器（x=0到8），ADC可以接收来自GPT的AD转换开始请求，而无需通过ELC。

同样，当GPT和ADC的时钟如表21.75所示组合时，如果一个AD转换开始请求和下一个AD转换开始请求之间的间隔小于相同AD转换开始请求的以下值，则可能会丢失AD转换开始请求.

但是，此限制不适用于不同的AD转换启动请求。

Event_Interval [ns] = Period_of_GPT_core_clock [ns] * 6 + Period_of_ADC_core_clock [ns] * 4

21.10.7 GTIOCnm信号输入到PWM延迟发生电路的注意事项（n=0到3，m=A，B）

在PWM延迟发生电路中控制PWM波形的延迟时，存在以下限制。

●在锯齿波模式下，在上溢或下溢之前的三个时钟周期内禁止改变GTIOCnm信号。

●在锯齿波模式下，计数操作期间禁止通过GTCSR清除GTCNT寄存器。

●在三角波模式下，在波谷之前的三个时钟周期内禁止改变GTIOCnm信号。

如果不遵守上述限制，PWM延迟产生电路输出的信号波形边沿可能会消失。

图21.183显示了一个不可接受的GTIOCnm信号的变化时序示例。

The DLYBSn bit selects whether delays are applied to PWM output signals from the GTIOCnA and GTIOCnB pins (n = 0 to 3) by the PWM delay generation circuit or whether the circuit is bypassed.

A signal delayed in the PWM delay generation circuit is output 3 cycles of GPT core clock (GTCLK) later than if it bypasses the PWM delay generation circuit.

DLYENn (n = 0 to 3) bit (PWM Delay Generation Circuit Enable for channel n)

The DLYENn bit selects whether channel n (n = 0 to 3) of PWM delay generation circuit is power on or off. If channel n of the PWM delay generation circuit is not used, set to 1.

If the timing of rising or falling edges in PWM waveforms output from the GTIOCnA and GTIOCnB pins must be adjusted, initialize the PWM generation circuit as shown in the procedure in Figure 22.2.

22.3.1 PWM波形上升沿和下降沿时序的调整

从GTIOCnA和GTIOCnB引脚输出的PWM波形的上升沿和下降沿时序（其中n=通道数）可以延迟到GPT内核时钟(GTCLK)周期的1×32的精度。

如果必须调整GTIOCnA和GTIOCnB引脚输出的PWM波形的上升沿或下降沿时序，请按照图22.2中的步骤初始化PWM生成电路。

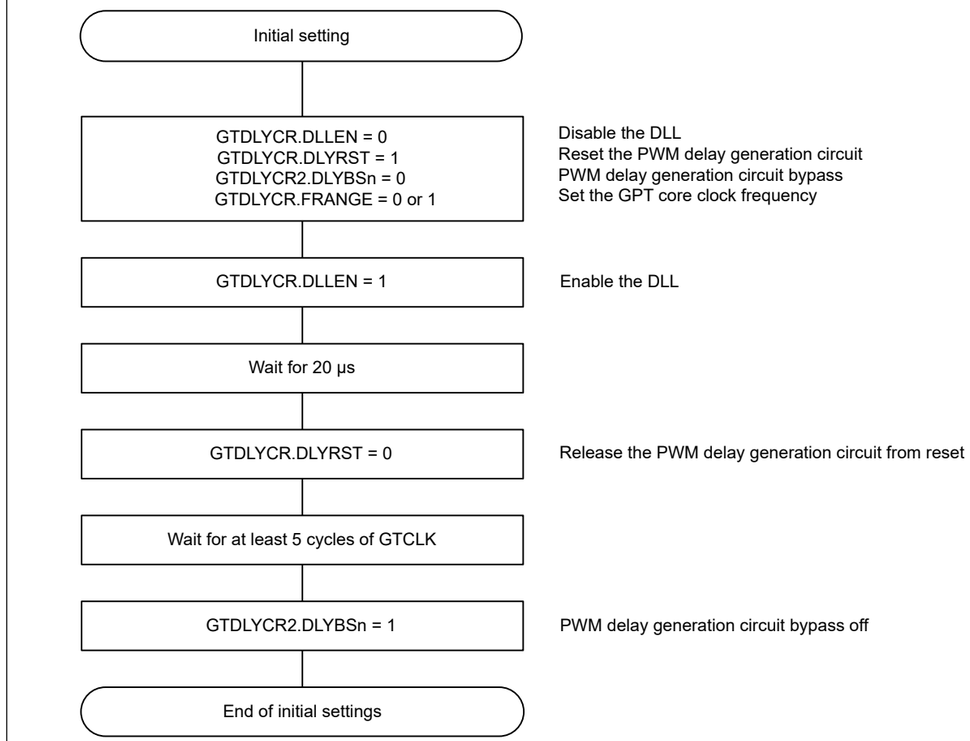

Figure 22.2 Example of initialization flow for the PWM delay generation circuit

In the PWM delay generation circuit, delay can be applied to rising and falling edges of the PWM output to an accuracy of 1/32 of the period of the GPT core clock (GTCLK). This is described in section 21.3.3. PWM Output Operating Mode. Delays associated with the settings are reflected in the PWM output with the timing described in section 22.3.2. Timing for Transfer of GTDLYRnA, GTDLYRnB, GTDLYFnA, and GTDLYFnB Register Settings. When the PWM delay generation circuit is in use, the timing with which a PWM output signal rises and falls can be controlled to an accuracy of 1/32 of the period of the GPT core clock (GTCLK). When this option is not in use, the period of the PWM output waveform is controlled to an accuracy of one period of the input clock for the timer counter, which is GTCLK. With the PWM delay generation circuit, the output can be controlled to an accuracy 32 times better. Additionally,

在PWM延迟生成电路中，可以将延迟应用于PWM输出的上升沿和下降沿，精度为GPT内核时钟(GTCLK)周期的1 32。这在第21.3.3节中进行了描述。PWM输出工作模式。与设置相关的延迟反映在PWM输出中，时序在第22.3. 2节中描述。GTDLYRnA、GTDLYRnB、GTDLYFnA和GTDLYFnB寄存器设置的传输时序。表22.3显示了GTDLYRnA 、GTDLYRnB、GTDLYFnA和GTDLYFnB寄存器与PWM输出之间的关联。

当使用PWM延迟产生电路时，PWM输出信号上升和下降的时序可以控制在GPT内核时钟(GTCLK)周期的1×32精度。不使用此选项时，PWM输出波形的周期被控制为定时器计数器输入时钟的一个周期的精度，即GTCLK。使用PWM延迟产生电路，可以将输出控制精度提高32倍。此外，

the delay settings also control the periods at high and low level for the PWM waveform to the given accuracy. PWM delay generation circuit channels can be individually enabled or disabled.

22.3.2 Timing for Transfer of GTDLYRnA, GTDLYRnB, GTDLYFnA, and GTDLYFnB Register Settings

Settings for the GTDLYRnA, GTDLYRnB, GTDLYFnA, and GTDLYFnB registers are initially transferred to temporary registers, and then reflected in the delay on the GTIOCnA and GTIOCnB (n = 0 to 3) outputs. Transfer of the settings takes place on overflows (in up-counting) or underflows (in down-counting) for saw waves, and in the troughs of triangle waves.

Figure 22.3 and Figure 22.4 show examples of the operation of the GTDLYR0A and GTDLYF0A registers.

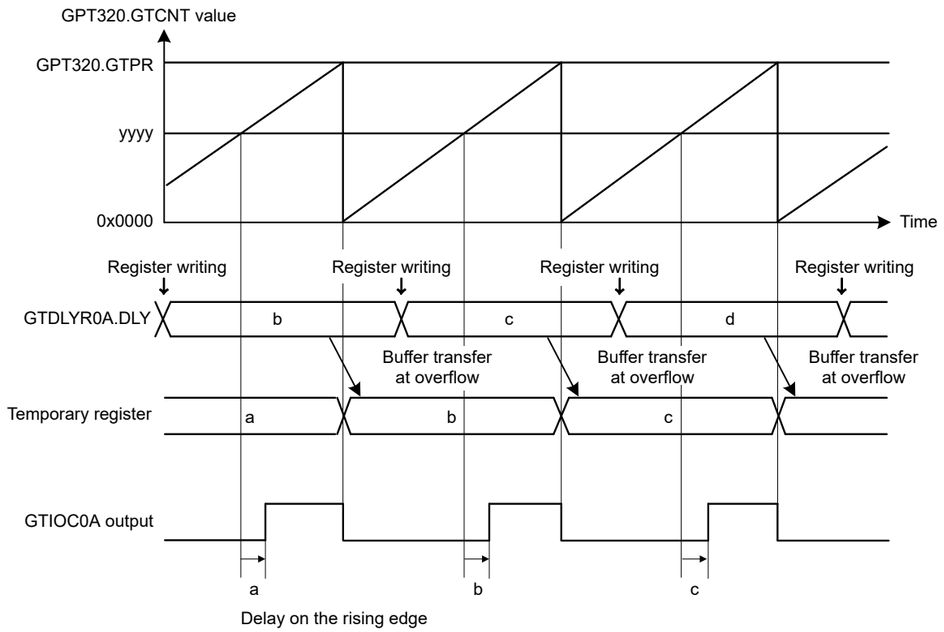

Figure 22.3 Example of GTDLYR0A register operation with PWM saw-wave generation

延迟设置还控制PWM波形的高电平和低电平周期，以达到给定的精度。PWM延迟生成电路通道可以单独启用或禁用。

22.3.2 GTDLYRnA、GTDLYRnB、GTDLYFnA和GTDLYFnB的传输时间注册设置

GTDLYRnA、GTDLYRnB、GTDLYFnA和GTDLYFnB寄存器的设置最初传送到临时寄存器，然后反映在GTIOCnA和GTIOCnB（n=0到3）输出的延迟中。设置的传输发生在锯齿波的上溢（向上计数）或下溢（向下计数）以及三角波的波谷中。

22.4 Usage Notes

22.4.1 Settings for the Module-Stop Function

The Module Stop Control Register D (MSTPCRD) can enable or disable operation of the PWM delay generation circuit. The PWM delay generation circuit is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

22.4.2 Notes on Delay Settings for PWM Delay Generation Circuit

When the PWM delay generation circuit generates delays for a PWM output waveform and the waveform is toggled in response to compare-matches, do not change the settings for delay while the compare-match value is within the ranges listed in Table 22.4. This constraint applies to the GTDLYFnA, GTDLYRnA, GTDLYFnB, and GTDLYRnB registers.

Table 22.4 Constraints on delay settings

Mode	Direction of counting	Compare-match value
Saw-wave mode	Up	GTPR - 2 or above
	Down	2 or below
Triangle-wave mode	Down	2 or below

Figure 22.5 shows an example of how the constraints apply to the timing of setting GTDLYFnA in saw-wave waveform one-shot pulse mode (counting up). Do not change the value set in GTDLYFnA while GTCCRD ≥ GTPR - 2.

22.4 使用说明

22.4.1 模块停止功能的设置

模块停止控制寄存器D(MSTPCRD)可以启用或禁用PWM延迟生成电路的操作。
PWM延迟产生电路在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

22.4.2 PWM延迟产生电路的延迟设置注意事项

当PWM延迟生成电路为PWM输出波形产生延迟并且波形响应比较匹配而切换时，当比较匹配值在表22.4中列出的范围内时，请勿更改延迟设置。此约束适用于GTDLYFnA、GTDLYRnA、GTDLYFnB和GTDLYRnB寄存器。

Table 22.4 延迟设置的限制

Mode	计数方向	Compare-match value
Saw-wave mode	Up	GTPR2或以上
	Down	2或以下
Triangle-wave mode	Down	2或以下

图22.5显示了约束如何应用于在锯波波形单次脉冲模式（向上计数）中设置GTDLYFnA的时序的示例。当GTCCRD≥GTPR2时，请勿更改GTDLYFnA中设置的值。

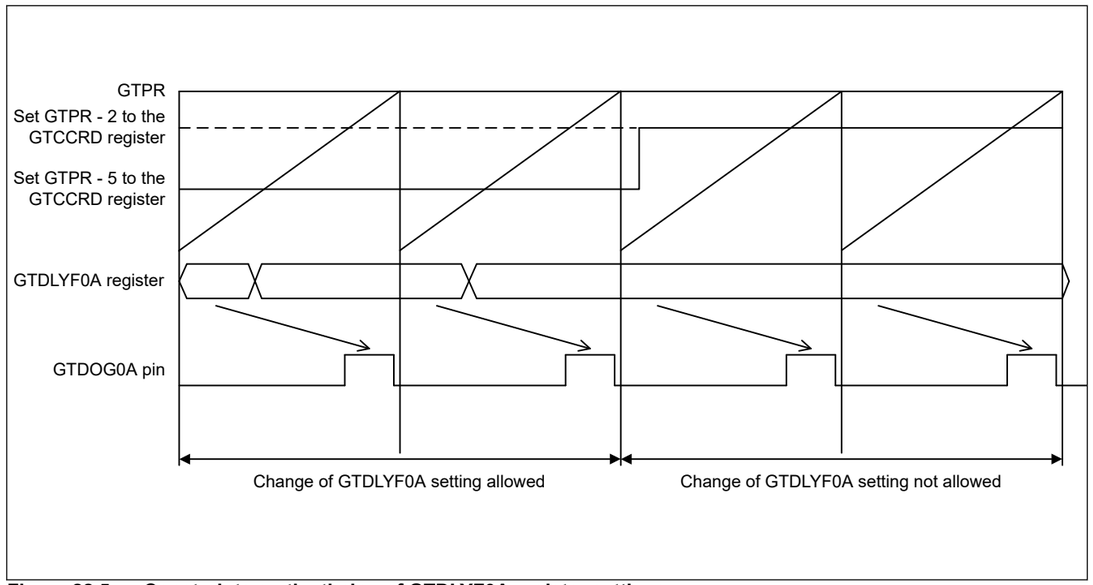

Figure 22.5 Constraints on the timing of GTDLYF0A register settings

Changing the values in the GTDLYFnA, GTDLYRnA, GTDLYFnB, and GTDLYRnB registers during periods where changes to settings are not allowed, might lead to faulty output waveforms such as shifts in the timing of output waveform transitions from the expected values.

22.4.3 Register Write Interval

When GPT core clock is GPTCLK, the writing value may not be reflected if the interval between writing to the GTDLYRnA/GTDLYFnA/GTDLYRnB/GTDLYFnA register is shorter than the following interval time. This restriction only applies to successive writes to the same register.

Write_Interval [ns] = Period_of_PCLKA [ns] × 6 + Period_of_GPTCLK [ns] × 4

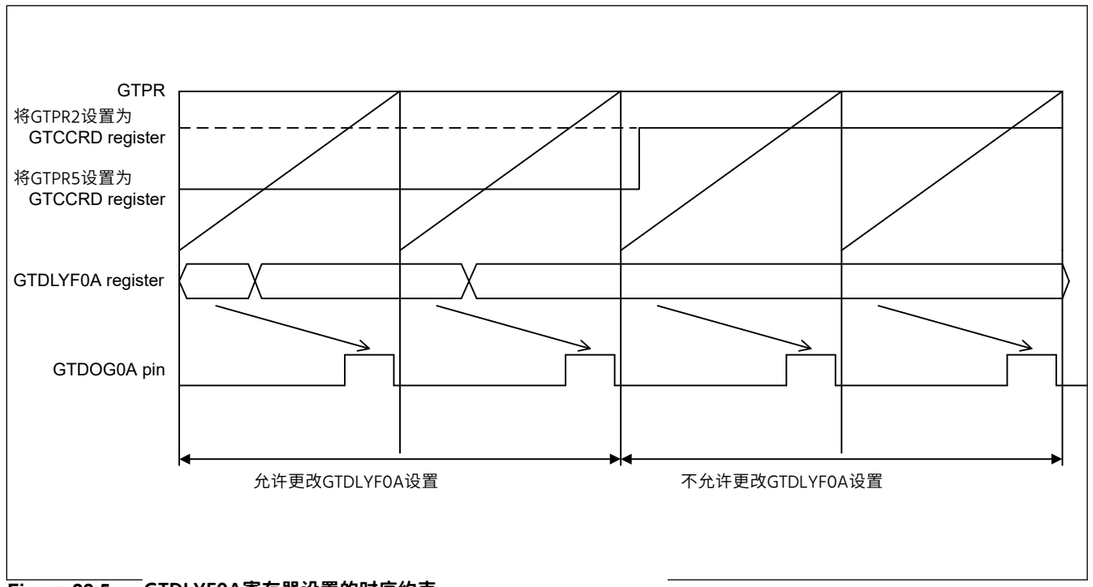

Figure 22.5 GTDLYF0A寄存器设置的时序约束

在不允许更改设置的期间更改GTDLYFnA、GTDLYRnA、GTDLYFnB和GTDLYRnB寄存器中的值可能会导致错误的输出波形，例如输出波形转换的时序偏离预期值。

22.4.3 寄存器写入间隔

当GPT内核时钟为GPTCLK时，如果写入到GTDLYRnAGTDLYFnAGTDLYRnBGTDLYFnA寄存器比以下间隔时间短。此限制仅适用于对同一寄存器的连续写入。

Write_Interval [ns] = Period_of_PCLKA [ns] × 6 + Period_of_GPTCLK [ns] × 4

23. Low Power Asynchronous General Purpose Timer (AGTW)

This is the AGTW_B version of the AGTW peripheral module.

AGTW_B is referred to as AGTW in this chapter.

23.1 Overview

The low power Asynchronous General Purpose Timer (AGT) is a 32-bit timer that can be used for pulse output, external pulse width or period measurement, and counting external events. This timer consists of a reload register and a down counter. The reload register and the down counter are allocated to the same address, and can be accessed with the AGT register.

Table 23.1 lists the AGTW specifications, Figure 23.1 shows a block diagram, and Table 23.2 lists the I/O pins.

23.2 注册说明

23.2.1 AGT:AGT计数器寄存器

Base address: AGTW_Bn = 0x400E_8000 + 0x0100 × n (n = 0, 1)
Offset address: 0x00

Bit position:	31																												0
Bit field:																													
重置后的值:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
31:0	n/a	32-bit counter and reload register Setting range : 0x00000000 to 0xFFFFFFFF	R/W

AGTWn.AGT is a 32-bit register. The write value is written to the reload register and the read value is read from the counter.

The states of the reload register and the counter change according to the TSTART bit in the AGTCR register and TCMEA/TCMEB bit in the AGTCMSR register. For details, see section 23.3.1. Reload Register and Counter Rewrite Operation.

When 1 is written to the TSTOP bit in the AGTCR register, AGT counter is forcibly stopped and set to 0xFFFFFFFF.

When the TCK[2:0] bits setting in the AGTMR1 register are a value other than 001b (PCLKB/8) or 011b (PCLKB/2), if the AGT register is set to 0x00000000, a request signal to the ICU, the DTC, the DMAC, and the ELC is generated once immediately after the count starts. The and AGTWOn, AGTWIOn pin output are toggled.

When the AGT register is set to 0x00000000 in event counter mode, regardless of the value of TCK[2:0] bits, a request signal to the ICU, the DTC, the DMAC, and the ELC is generated once immediately after the count starts.

In addition, the AGTWOn pin output is toggled even during a period other than the specified count period. When the AGT register is set to 0x00000001 or more, a request signal is generated each time AGT underflows.

23.2.2 AGTCMA : AGT Compare Match A Register

Base address: AGTW_Bn = 0x400E_8000 + 0x0100 × n (n = 0, 1)

Note 1. Set the AGTCMA register to 0xFFFFFFFF when compare match A is not used.

The AGTCMA register is a read/write register to set a value for compare match with the AGT counter. The states of the reload register and compare register A change according to the TSTART bit in the AGTCR register. For details, see section 23.3.2. Reload Register and AGT Compare Match A/B Register Rewrite Operation.

Note 1. Set the AGTCMB register to 0xFFFFFFFF when compare match B is not used.

The AGTCMB register is a read/write register to set a value for compare match with the AGT counter. The states of the reload register and compare register B change according to the TSTART bit in the AGTCR register. For details, see section 23.3.2. Reload Register and AGT Compare Match A/B Register Rewrite Operation.

Bit	Symbol	Function	R/W
31:0	n/a	32位计数器和重载寄存器设置范围：0x0000 0000到0xFFFFFFFF	R/W

AGTWn.AGT是一个32位寄存器。写入值写入重载寄存器，读取值从计数器中读取。

重载寄存器和计数器的状态根据AGTCR寄存器和TCMEA中的TSTART位改变
AGTCMSR寄存器中的TCMEB位。详见23.3.1节。重载寄存器和计数器重写操作。

当AGTCR寄存器的TSTOP位写入1时，AGT计数器被强制停止并设置为0xFFFFFFFF。

当AGTMR1寄存器中的TCK[2:0]位设置为001b(PCLKB8)或011b(PCLKB2)以外的值时，如果AGT寄存器设置为0x00000000，计数开始后立即生成一次对ICU、DTC、DMAC和ELC的请求信号。和AGTWOn、AGTWOn引脚输出被切换。

当AGT寄存器在事件计数器模式下设置为0x00000000时，无论TCK[2:0]位的值如何，都会在计数开始后立即生成一次对ICU、DTC、DMAC和ELC的请求信号.

此外，即使在指定计数周期以外的周期内，AGTWOn引脚输出也会切换。当AGT寄存器设置为0x00000001或更大时，每次AGT下溢时都会产生一个请求信号。

Note 1. When 1 (count is forcibly stopped) is written to the TSTOP bit, the TSTART bit and TCSTF flag are initialized at the same time. The pulse output level is also initialized. The read value is 0.
Note 2. For information on using the TSTART bit and TCSTF flag, see section 23.4.1. Count Operation Start and Stop Control.

TSTART bit (AGT Count Start)

The count operation is started by writing 1 to the TSTART bit and stopped by writing 0. When the TSTART bit is set to 1 (count starts), the TCSTF flag is set to 1 (count in progress) in synchronization with the count source. Also, after 0 is written to the TSTART bit, the TCSTF flag is set to 0 (count stops) in synchronization with the count source. For details, see section 23.4.1. Count Operation Start and Stop Control.

TCSTF flag (AGT Count Status Flag)

The TCSTF flag indicates the AGT count status.

- When 1 is written to the TSTOP bit.

TSTOP bit (AGT Count Forced Stop)

When 1 is written to the TSTOP bit, the count is forcibly stopped. The read value is 0.

LPM bit (Low Power Mode)

The LPM bit sets the low power operation, which impacts access to certain AGT registers. Set this bit to 1 to operate in low power.

When this bit is 1, access to the following registers is prohibited:

- AGT/AGTCMA/AGTCMB/AGTCR.

After this bit is switched from 1 to 0, the first access to the register is constrained as follows:

- When reading from the AGT register, read AGT register twice. Only the second reading of data is valid.
- When writing to the AGT, AGTCMA, AGTCMB, and AGTCR register, allow at least 2 cycles of the count source clock when writing to the register.
- When confirm the value written to the AGT, AGTCMA, AGTCMB, and AGTCR registers.
  - When the count operation is stopped; after writing data, it can be read in the next cycle.
  - When the count operation is operating; after writing data, it can be written 4 cycles after the count source clock.

LPM位（低功耗模式）

LPM位设置低功耗操作，这会影响对某些AGT寄存器的访问。将此位设置为1以在低功耗下工作。

该位为1时，禁止访问以下寄存器：

- AGT/AGTCMA/AGTCMB/AGTCR.

该位由1变为0后，对寄存器的第一次访问受到如下约束：

●读取AGT寄存器时，读取AGT寄存器两次。只有第二次读取数据是有效的。

●写入AGT、AGTCMA、AGTCMB和AGTCR寄存器时，写入寄存器时至少允许计数源时钟的2个周期。

●确认写入AGT、AGTCMA、AGTCMB、AGTCR寄存器的值时。

当计数操作停止时；写入数据后，可以在下一个周期读取。

当计数操作正在运行时；写入数据后，可在计数源时钟后4个周期写入。

TEDGSEL bit (I/O Polarity Switch)

The TEDGSEL bit switches the AGTWOn pin output polarity and the AGTWIOn pin input/output edge and polarity.

In pulse output mode, it only controls polarity of the AGTWOn pin output and AGTWIOn pin output. AGTWOn pin output and AGTWIOn pin output are initialized when the AGTMR1 register is written or the TSTOP bit in the AGTCR register is written with 1.

TOE bit (AGTWOn pin Output Enable)

The TOE bit selects whether the AGTOn pin output is disabled or enabled.

TIPF[1:0] bits (Input Filter)

The TIPF[1:0] bits specify the sampling frequency of the AGTIOn pin input filter. When the input to the AGTIOn pin is sampled and the values match three times in succession, the value is regarded as the input value.

TIOGT[1:0] bits (Count Control)

The TIOGT[1:0] bits control the event count.

23.3 Operation

23.3.1 Reload Register and Counter Rewrite Operation

Regardless of the operating mode, the timing of the rewrite operation to the reload register and the counter differs depending on the value of the TSTART bit in the AGTCR register and of the TCMEA or TCMEB bit in the AGTCMSR register. When the TSTART bit is 0 (count stops), the count value is directly written to the reload register and the counter. When the TSTART bit is 1 (count starts) and the TCMEA bit and TCMEB bit are 0 (AGT compare match A/B register are invalid), the value is written to the reload register in synchronization with the count source, and then to the counter in synchronization with the next count source. When the TSTART bit is 1 (count starts) and the TCMEA bit or the TCMEB bit is 1 (AGT compare match A register or compare match B register is valid), the value is written to the reload register in synchronization with the count source, and then to the counter in synchronization with the underflow of the counter.

Figure 23.3 and Figure 23.4 show the timing of rewrite operation with TSTART bit value and TCMEA/TCMEB bit value.

23.3 Operation

23.3.1 重载寄存器和计数器重写操作

无论何种操作模式，对重载寄存器和计数器的重写操作的时序根据AGTCR寄存器中的TSTART位和AGTCMSR寄存器中的TCMEA或TCMEB位的值而有所不同。当TSTART位为0（计数停止）时，计数值直接写入重载寄存器和计数器。当TSTART位为1（计数开始）且TCMEA位和TCMEB位为0（AGT比较匹配AB寄存器无效）时，该值与计数源同步写入重载寄存器，然后写入计数器与下一个计数源同步。当TSTART位为1（计数开始）且TCMEA位或TCMEB位为1（AGT比较匹配A寄存器或比较匹配B寄存器有效）时，值与计数源同步写入重载寄存器，然后与计数器的下溢同步到计数器。

图23.3和图23.4显示了使用TSTART位值和TCMEATCMEB位值进行重写操作的时序。

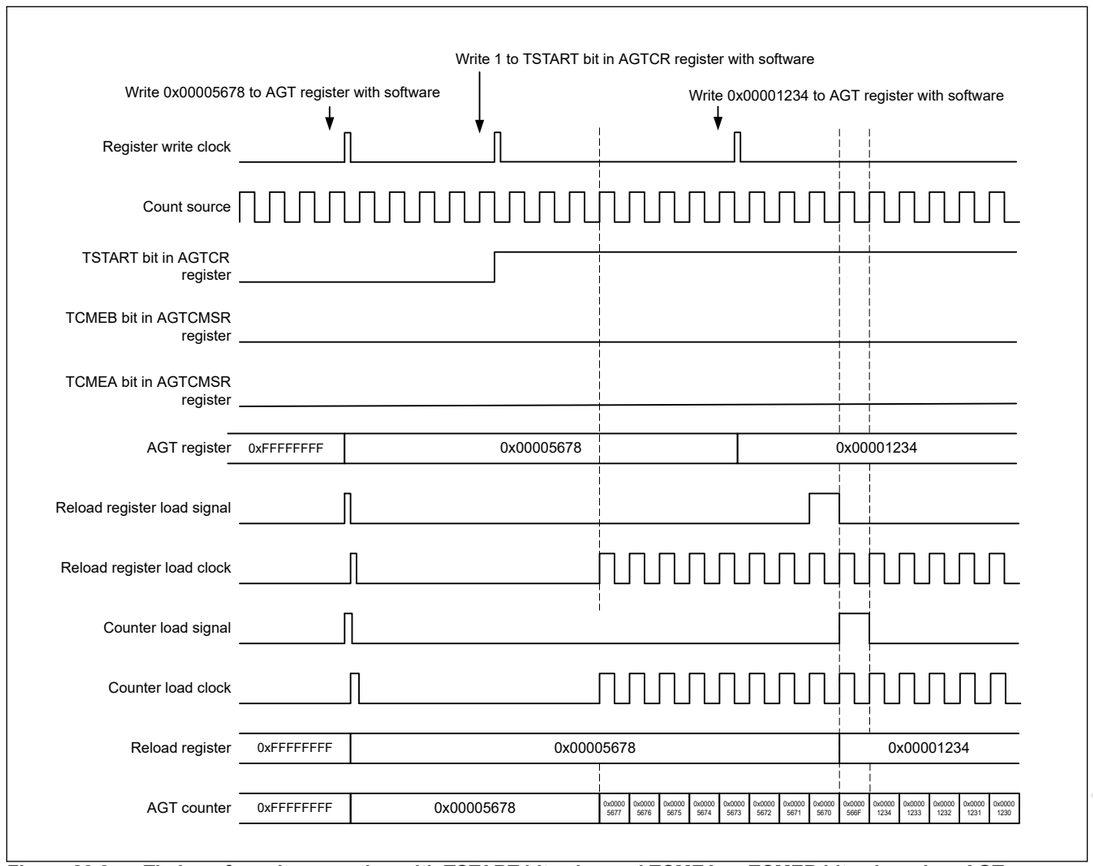

Figure 23.3 Timing of rewrite operation with TSTART bit value and TCMEA or TCMEB bit value when AGT compare match A register or AGT compare match B register is invalid

23.3.2 Reload Register and AGT Compare Match A/B Register Rewrite Operation

Regardless of the operating mode, the timing of the rewrite operation to the reload register and AGT compare register A/B depends on the value of the TSTART bit in the AGTCR register. When the TSTART bit is 0 (count stops), the count value is directly written to the reload register and AGT compare register A/B. When the TSTART bit is 1 (count starts), the value is written to the reload register in synchronization with the count source, and then to the compare register in synchronization with the underflow of the counter.

Figure 23.5 shows the timing of rewrite operation with TSTART bit value for compare register A. AGT Compare register B is of the same timing as AGT compare register A.

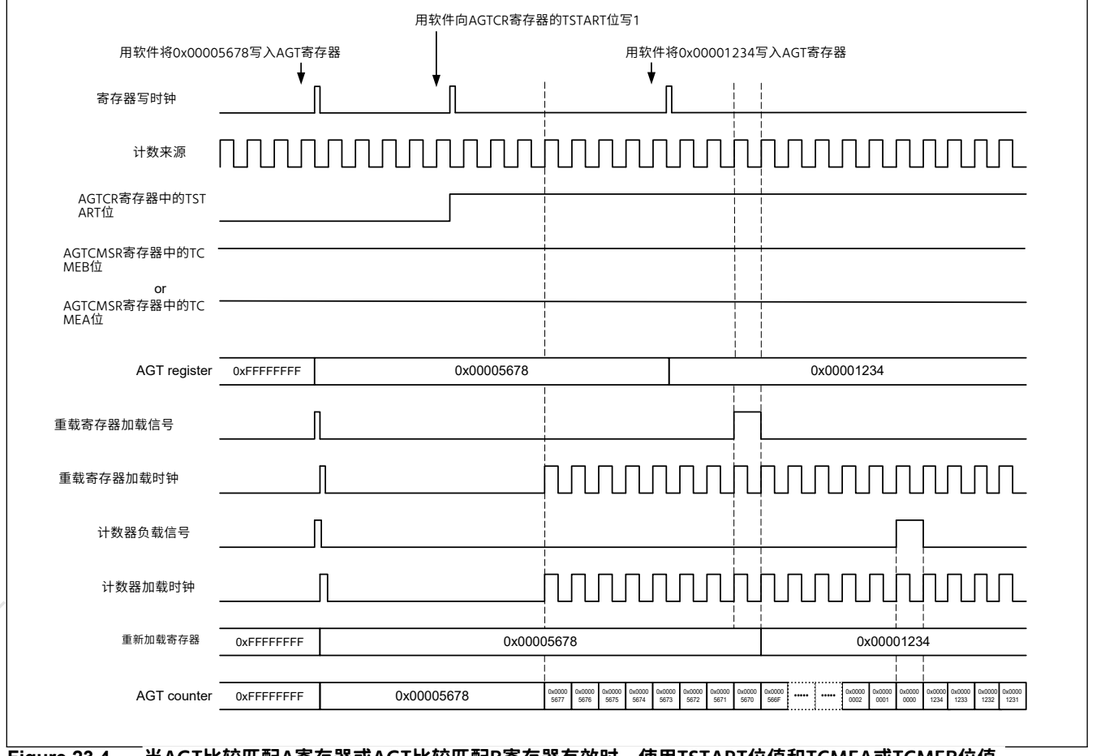

Figure 23.4 当AGT比较匹配A寄存器或AGT比较匹配B寄存器有效时，使用TSTART位值和TCMEA或TCMEB位值进行重写操作的时序

23.3.2 重载寄存器和AGT比较匹配AB寄存器重写操作

不管操作模式如何，对重载寄存器和AGT比较寄存器AB的重写操作的时序取决于AGTCR寄存器中TSTART位的值。当TSTART位为0（计数停止）时，计数值直接写入重载寄存器和AGT比较寄存器AB。当TSTART位为1（计数开始）时，该值同步写入重载寄存器计数源，然后与计数器的下溢同步到比较寄存器。

图23.5显示了比较寄存器A的TSTART位值的重写操作时序。AGT比较寄存器B与AGT比较寄存器A的时序相同。

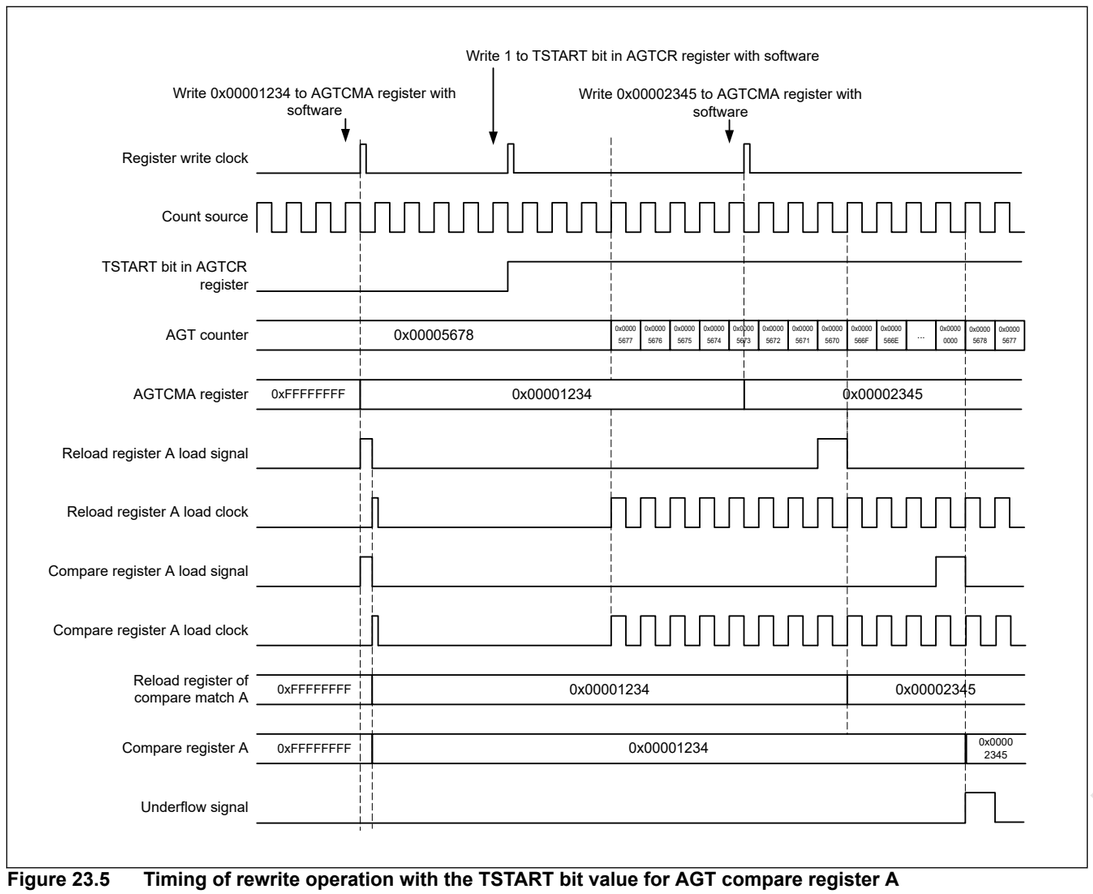

Figure 23.5 Timing of rewrite operation with the TSTART bit value for AGT compare register A

23.3.3 Timer Mode

In this mode, the AGT counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register. In timer mode, the count value is decremented by 1 on each rising edge of the count source. When the count value reaches 0x00000000 and the next count source is input, an underflow occurs and an interrupt request is generated.

Figure 23.6 shows the operation example in timer mode.

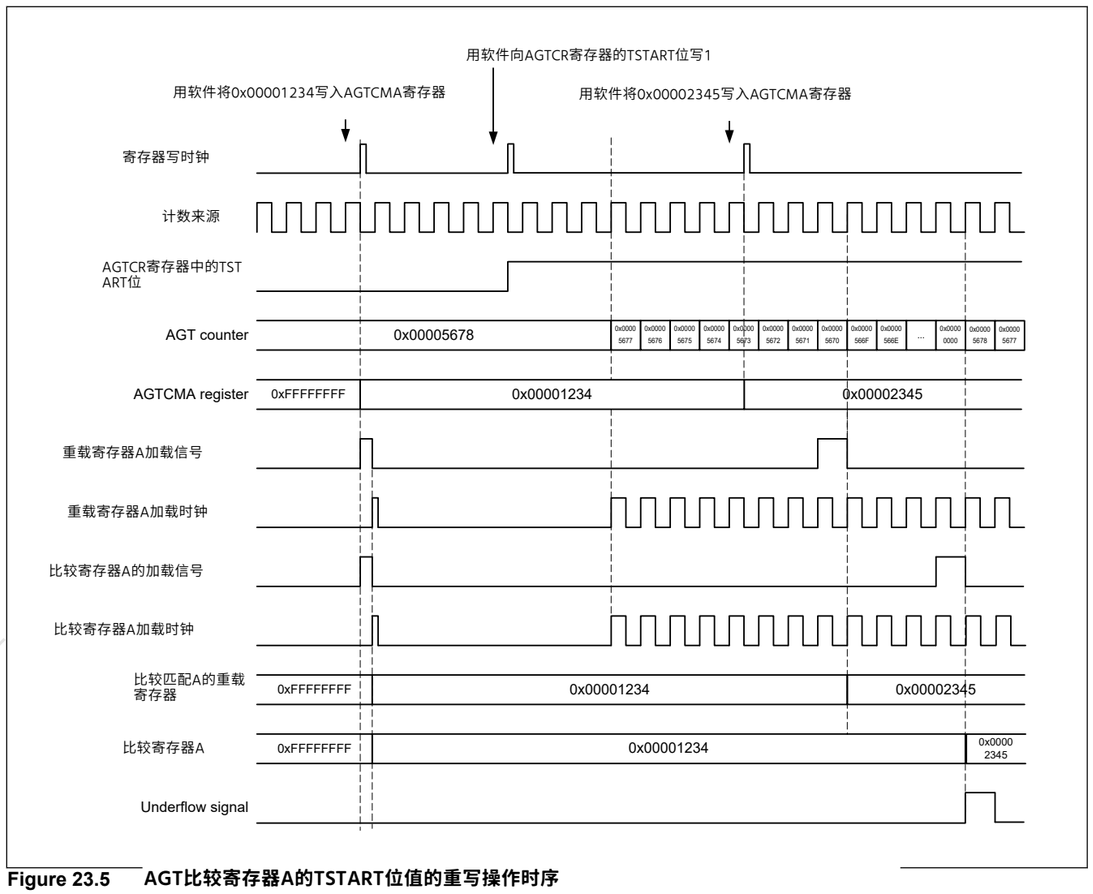

Figure 23.5 AGT比较寄存器A的TSTART位值的重写操作时序

23.3.3 定时器模式

在此模式下，AGT计数器按AGTMR1寄存器中的TCK[2:0]位选择的计数源递减。
在定时器模式下，计数值在计数源的每个上升沿减1。当计数值达到0x00000000并输入下一个计数源时，发生下溢并产生中断请求。

图23.6显示了定时器模式下的操作示例。

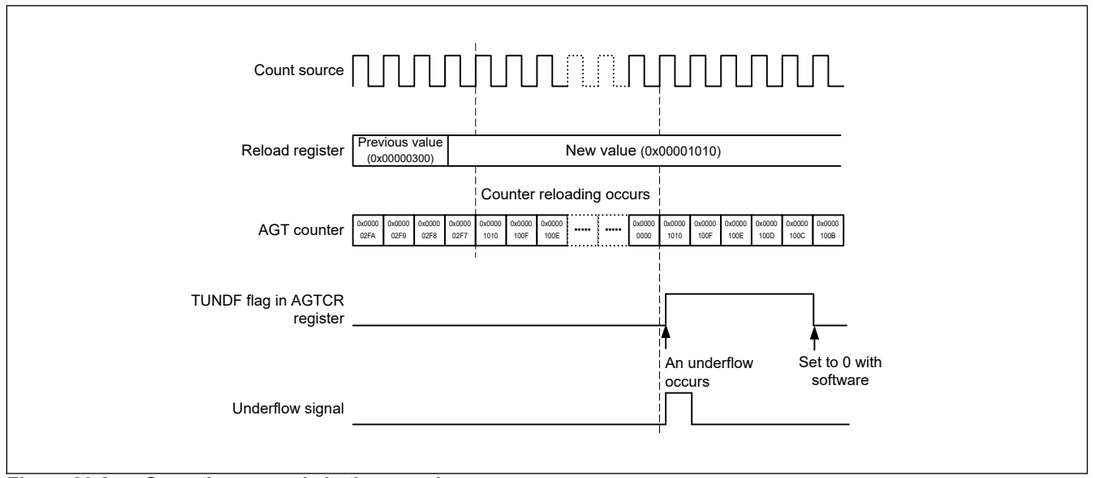

Figure 23.6 Operation example in timer mode

23.3.4 Pulse Output Mode

In pulse output mode, the counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register, and the output level of the AGTWIOn and AGTOn pins inverted each time an underflow occurs.

In pulse output mode, the count value is decremented by 1 on each rising edge of the count source. When the count value reaches 0x00000000 and the next count source is input, an underflow occurs and an interrupt request is generated. In addition, a pulse can be output from the AGTWIOn and AGTOn pins. The output level is inverted each time an underflow occurs. The pulse output from the AGTWOn pin can be stopped with the TOE bit in the AGTIOC register. The output level can be selected with the TEDGSEL bit in the AGTIOC register.

Figure 23.7 shows the operation example in pulse output mode.

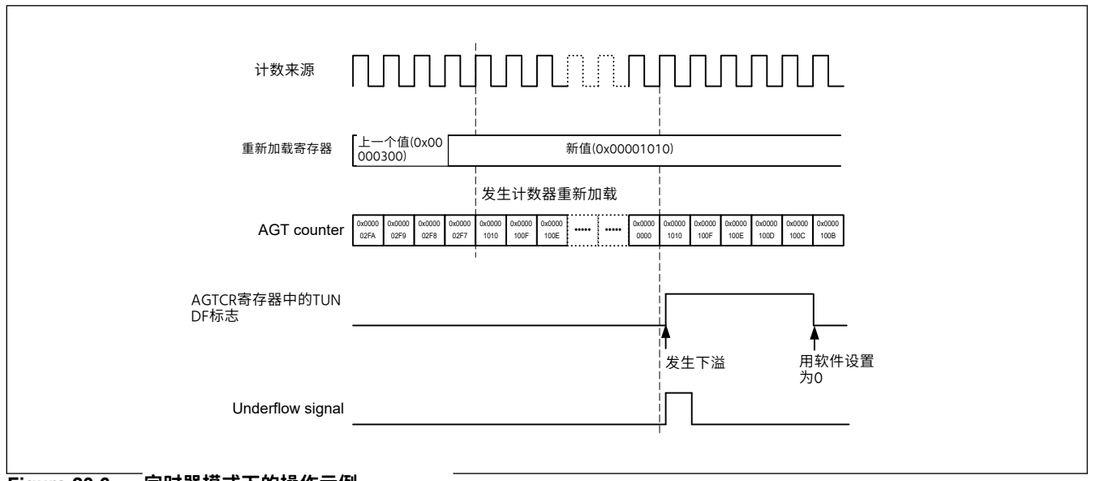

Figure 23.6 定时器模式下的操作示例

23.3.4 脉冲输出方式

在脉冲输出模式下，计数器由AGTMR1寄存器中的TCK[2:0]位选择的计数源递减，每次发生下溢时AGTWIOn和AGTOn引脚的输出电平反转。

在脉冲输出模式下，计数值在计数源的每个上升沿减1。当计数值达到0x00000000并输入下一个计数源时，发生下溢并产生中断请求。此外，可以从AGTWIOn和AGTOn引脚输出脉冲。每次发生下溢时，输出电平都会反转。AGTWOn引脚的脉冲输出可通过AGTIOC寄存器中的TOE位停止。可以通过AGTIOC寄存器中的TEDGSEL位选择输出电平。

图23.7显示了脉冲输出模式下的操作示例。

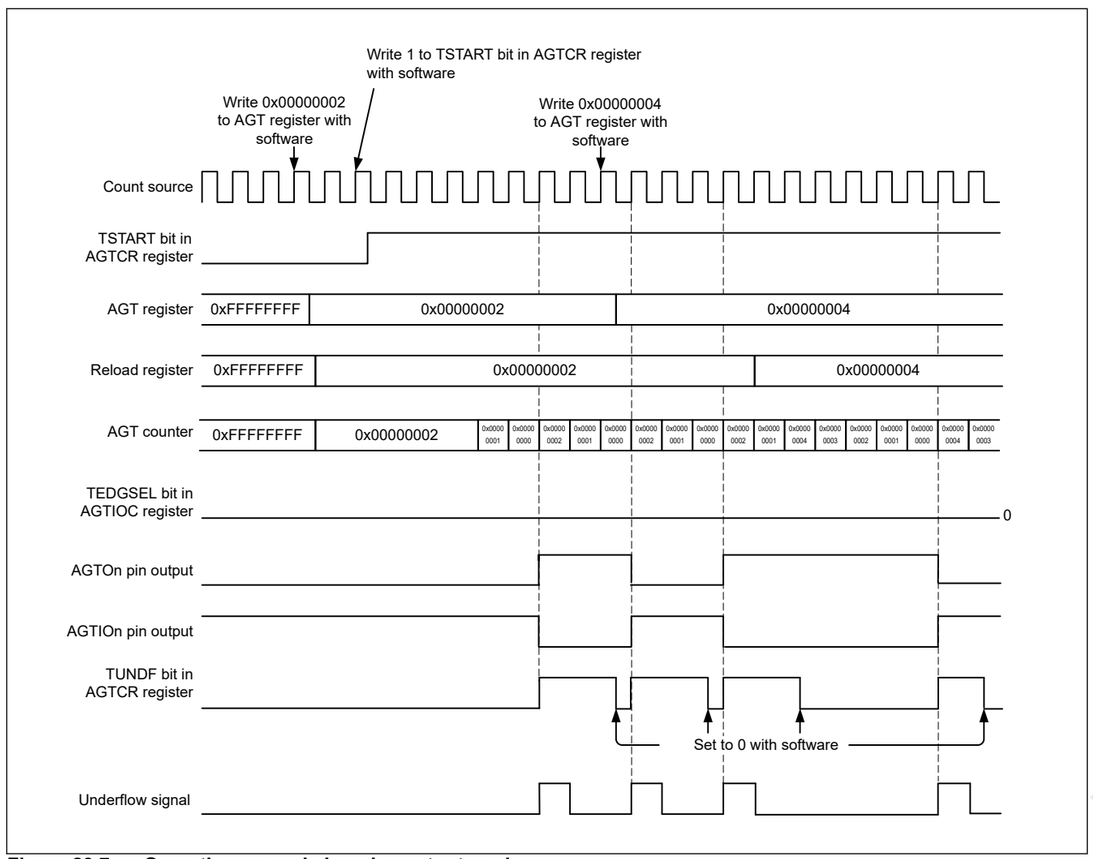

Figure 23.7 Operation example in pulse output mode

23.3.5 Event Counter Mode

In event counter mode, the counter is decremented by an external event signal (count source) input to the AGTWIOn pin. Various periods for counting events can be set with the TIOGT[1:0] bits in the AGTIOC register and AGTISR registers. In addition, the filter function for the AGTWIOn pin input can be specified with bits TIPF[1:0] in the AGTIOC register. The output from the AGTWOn pin can be toggled even in event counter mode.

Figure 23.8 shows the operation example in event counter mode.

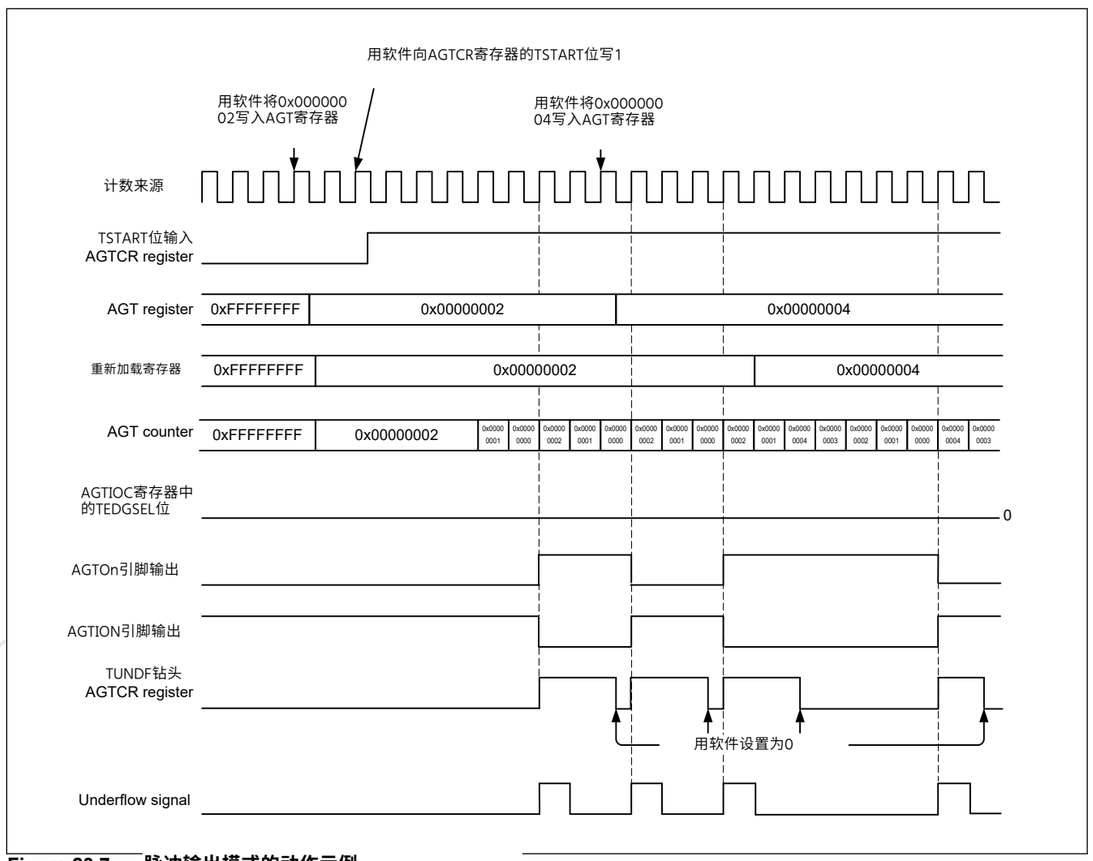

Figure 23.7 脉冲输出模式的动作示例

23.3.5 事件计数器模式

在事件计数器模式下，计数器由输入到AGTWIOn引脚的外部事件信号（计数源）递减。可以使用AGTIOC寄存器和AGTISR寄存器中的TIOGT[1:0]位设置计数事件的各种周期。此外，可以通过AGTIOC寄存器中的位TIPF[1:0]指定AGTWIOn引脚输入的过滤器功能。即使在事件计数器模式下，也可以切换AGTWOn引脚的输出。

图23.8显示了事件计数器模式下的操作示例。

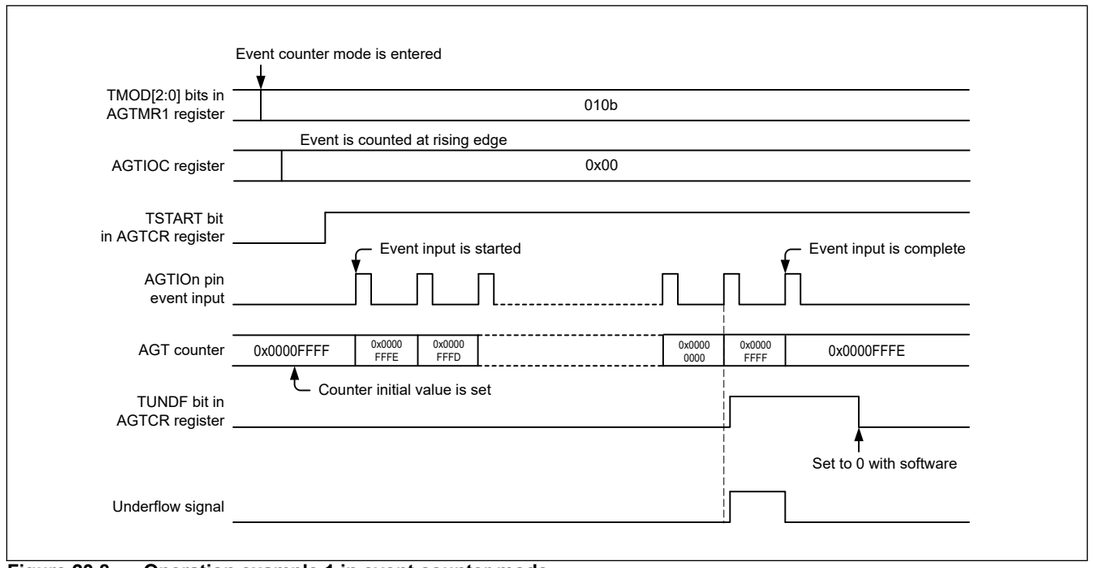

Figure 23.8 Operation example 1 in event counter mode

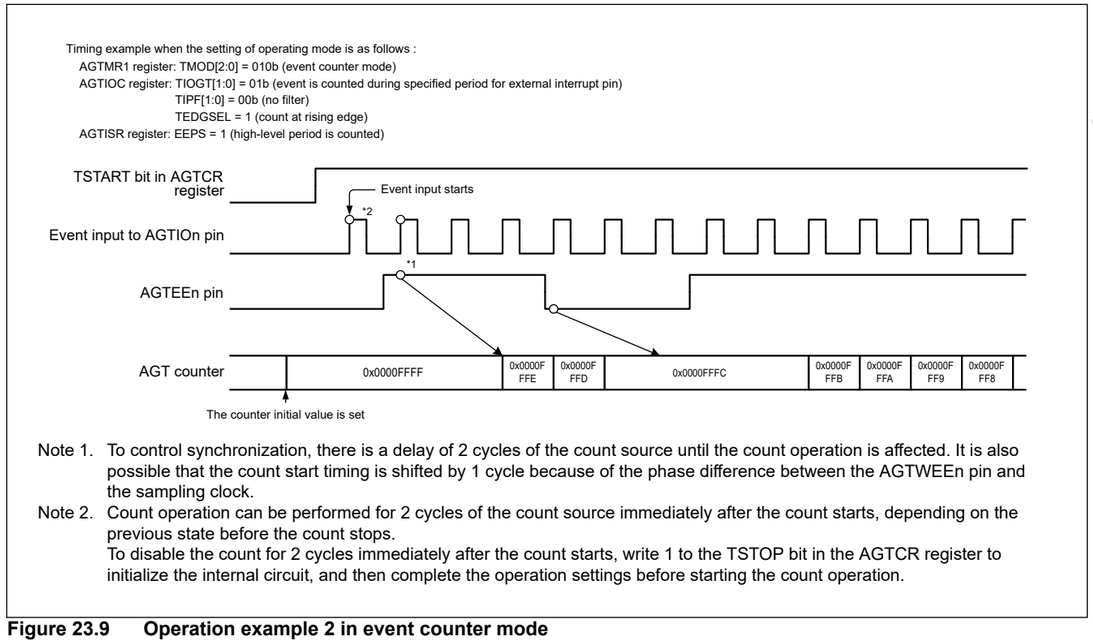
Figure 23.9 shows an operation example for counting during the specified period in event counter mode (TIOGT[1:0] bits in the AGTIOC register are set to 01b).



Note 1. To control synchronization, there is a delay of 2 cycles of the count source until the count operation is affected. It is also possible that the count start timing is shifted by 1 cycle because of the phase difference between the AGTWEEn pin and the sampling clock.

Note 2. Count operation can be performed for 2 cycles of the count source immediately after the count starts, depending on the previous state before the count stops.
To disable the count for 2 cycles immediately after the count starts, write 1 to the TSTOP bit in the AGTCR register to initialize the internal circuit, and then complete the operation settings before starting the count operation.

Figure 23.9 Operation example 2 in event counter mode

23.3.6 Pulse Width Measurement Mode

In pulse width measurement mode, the pulse width of an external signal input to the AGTWIOn pin is measured. When the level specified by the TEDGSEL bit in the AGTIOC register is input to the AGTWIOn pin, the counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register. When the specified level on the AGTWIOn pin ends, the counter is stopped, the TEDGF bit in the AGTCR register is set to 1 (active edge received), and an interrupt request is generated. The measurement of pulse width data is performed by reading the count value while the counter is

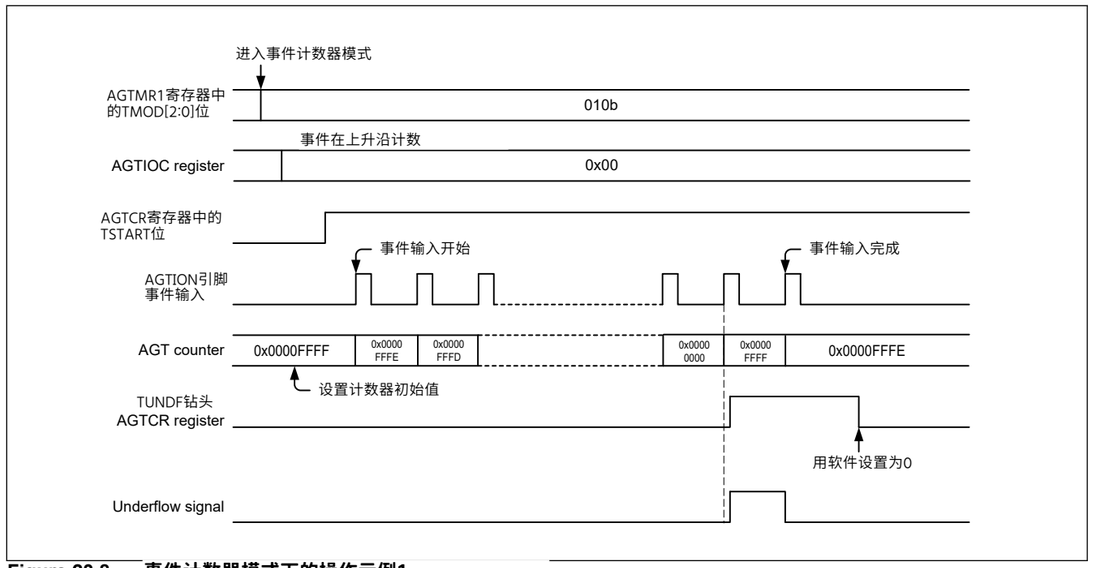


Figure 23.8 事件计数器模式下的操作示例1

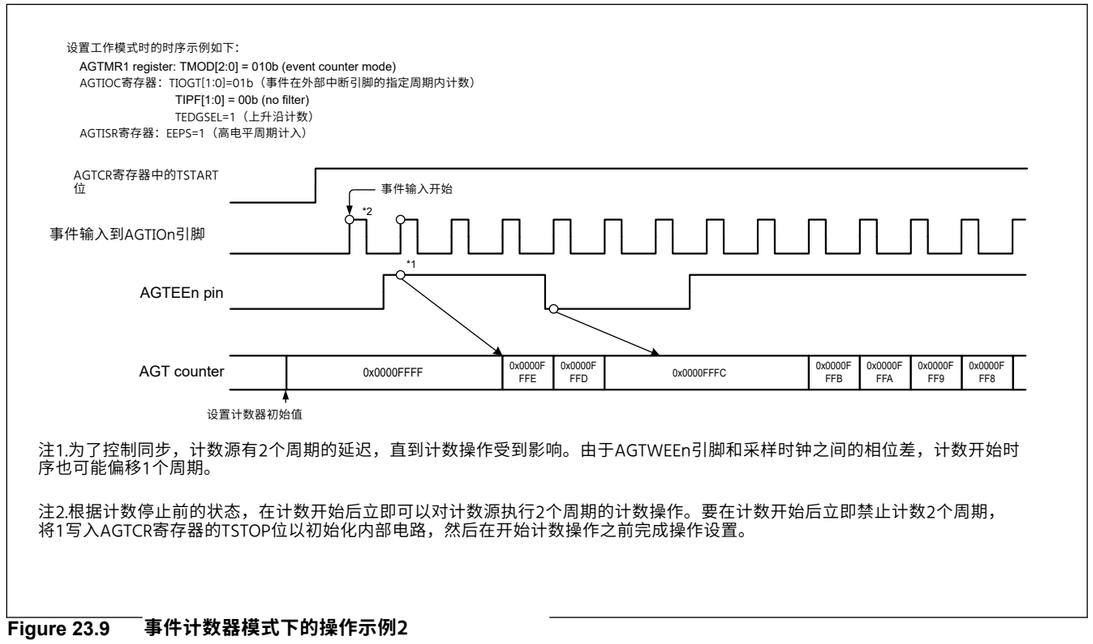
图23.9显示了在事件计数器模式下在指定周期内进行计数的操作示例（AGTIOC寄存器中的TIOGT[1:0]位设置为01b）。



注1.为了控制同步，计数源有2个周期的延迟，直到计数操作受到影响。由于AGTWEEn引脚和采样时钟之间的相位差，计数开始时序也可能偏移1个周期。

注2.根据计数停止前的状态，在计数开始后立即可以对计数源执行2个周期的计数操作。要在计数开始后立即禁止计数2个周期，将1写入AGTCR寄存器的TSTOP位以初始化内部电路，然后在开始计数操作之前完成操作设置。

23.3.6 脉冲宽度测量模式

在脉冲宽度测量模式下，测量输入到AGTWIOn引脚的外部信号的脉冲宽度。当AGTIOC寄存器中的TEDGSEL位指定的电平输入到AGTWIOn引脚时，计数器会根据AGTMR1寄存器中的TCK[2:0]位选择的计数源递减。当AGTWIOn引脚上的指定电平结束时，计数器停止，AGTCR寄存器中的TEDGF位设置为1（接收到有效沿），并产生中断请求。脉冲宽度数据的测量是通过在计数器运行时读取计数值来执行的。

stopped. Also, when the counter underflows during measurement, the TUNDF bit in the AGTCR register is set to 1 and an interrupt request is generated.

Figure 23.10 shows the operation example in pulse width measurement mode.

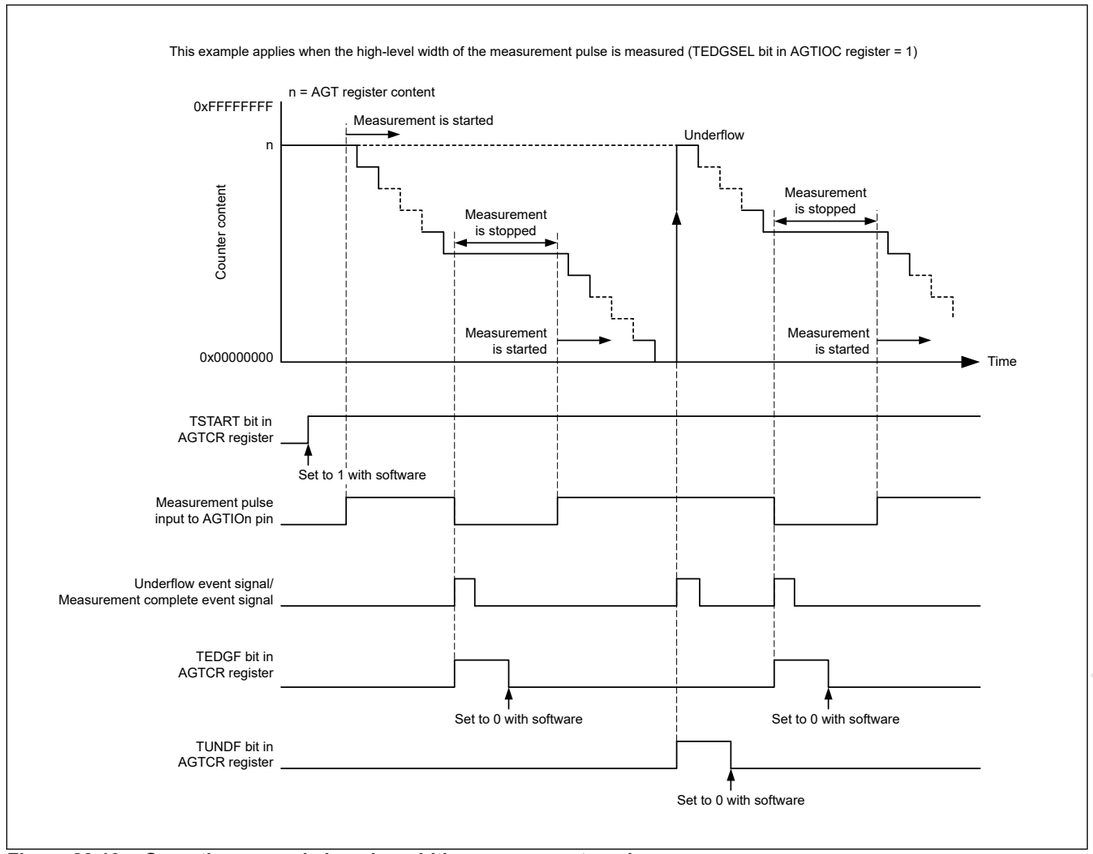

Figure 23.10 Operation example in pulse width measurement mode

23.3.7 Pulse Period Measurement Mode

In pulse period measurement mode, the pulse period of an external signal input to the AGTWIOn pin is measured. The counter is decremented by the count source selected with TCK[2:0] bits in the AGTMR1 register. When a pulse with the period specified by the TEDGSEL bit in the AGTIOC register is input to the AGTWIOn pin, the count value is transferred to the read-out buffer on the rising edge of the count source. The value in the reload register is loaded to the counter at the next rising edge. Simultaneously, the TEDGF flag in the AGTCR register is set to 1 (active edge received) and an interrupt request is generated. The read-out buffer (AGT register) is read at this time and the difference from the reload value (see section 23.4.6. How to Calculate Event Number, Pulse Width, and Pulse Period) is the period data of the input pulse. The period data is retained until the read-out buffer is read. When the counter underflows, the TUNDF flag in the AGTCR register is set to 1 (underflow) and an interrupt request is generated.

Figure 23.11 shows the operation example in pulse period measurement mode.

Only input pulses with a period longer than twice the period of the count source are measured. Also, the low-level and high-level widths must both be longer than the period of the count source. If a pulse period shorter than these conditions is input, the input might be ignored.

停了下来。此外，当测量期间计数器下溢时，AGTCR寄存器中的TUNDF位设置为1，并产生中断请求。

图23.10显示了脉宽测量模式下的操作示例。

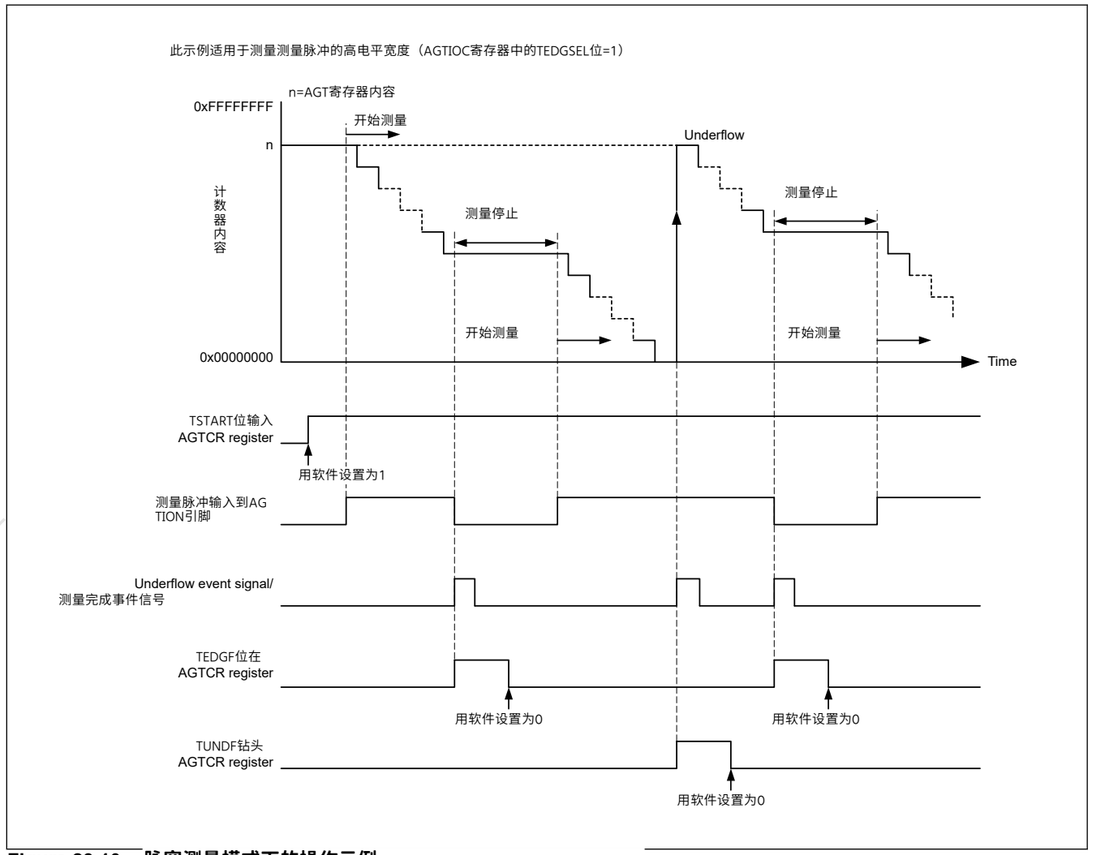

Figure 23.10 脉宽测量模式下的操作示例

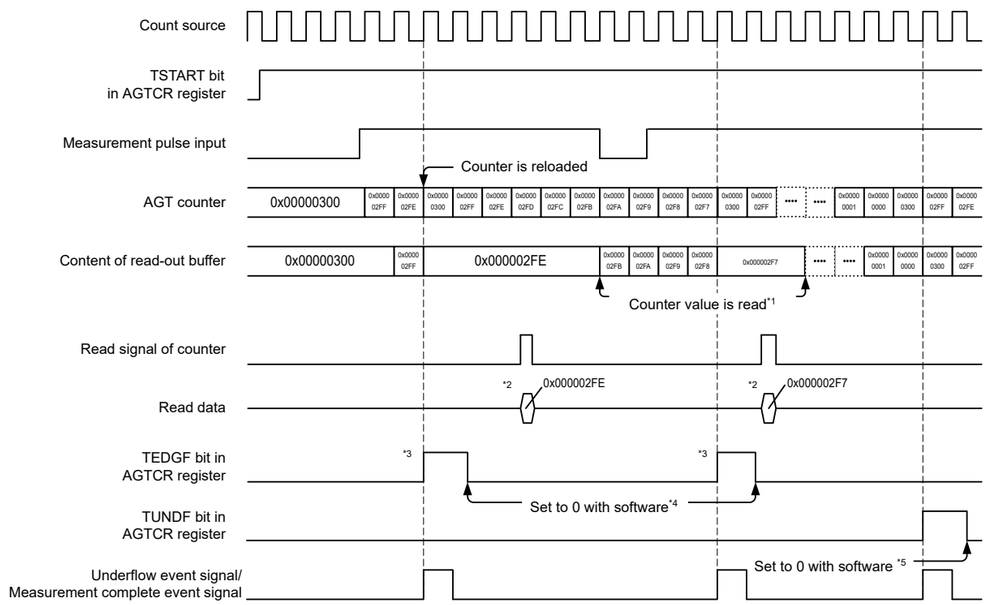
23.3.7 脉冲周期测量模式

在脉冲周期测量模式下，测量输入到AGTWIOn引脚的外部信号的脉冲周期。计数器由AGTMR1寄存器中的TCK[2:0]位选择的计数源递减。当AGTIOC寄存器中的TEDGSEL位指定周期的脉冲输入到AGTWIOn引脚时，计数值在计数源的上升沿传送到读出缓冲器。重载寄存器中的值在下一个上升沿加载到计数器。同时，AGTCR寄存器中的TEDGF标志设置为1（接收到有效沿）并产生中断请求。此时会读取读出缓冲区（AGT寄存器），与重载值的差值（见23.4.6节。如何计算事件数、脉冲宽度和脉冲周期）是输入脉冲的周期数据。周期数据被保留，直到读出缓冲器被读取。当计数器下溢时，AGTCR寄存器中的TUNDF标志设置为1（下溢）并产生中断请求。

图23.11显示了脉冲周期测量模式下的操作示例。

仅测量周期长于计数源周期两倍的输入脉冲。此外，低电平和高电平宽度都必须长于计数源的周期。如果输入比这些条件短的脉冲周期，输入可能会被忽略。



This example applies when the initial value of the AGT register is set to A, the TEDGSEL bit in the AGTIOC register is set to 0, and the period from one rising edge to the next edge of the measurement pulse is measured.

Note 1. Reading from the AGT register must be performed during the period from when the TEDGF flag is set to 1 (active edge received) until the next active edge is input. The content of the read-out buffer is retained until the AGT register is read. If it is not read before the active edge is input, the measurement result of the previous period is retained.
Note 2. When the AGT register is read in pulse period measurement mode, the content of the read-out buffer is read.
Note 3. When the active edge of the measurement pulse is input and then the set edge of an external pulse is input, the TEDGF flag in the AGTCR register is set to 1 (active edge received).
Note 4. To set to 0 with software, write 0 to the TEDGF flag in the AGTCR register with an 8-bit memory manipulation instruction.
Note 5. To set to 0 with software, write 0 to the TUNDF flag in the AGTCR register with an 8-bit memory manipulation instruction.

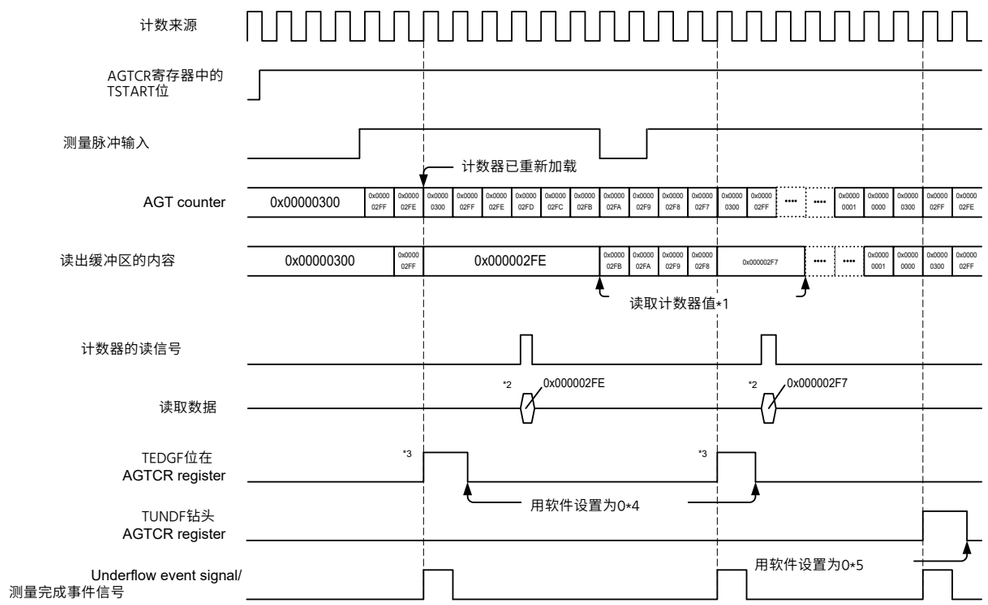
Figure 23.11 Operation example in pulse period measurement mode

23.3.8 Compare Match function

The compare match function detects matches (compare match) between the content of the AGTCMA or AGTCMB register and the content of the AGT register. This function is enabled when the TCMEA or TCMEB bit in the AGTCMSR register is 1 (compare match A register or compare match B register is valid). The counter is decremented by the count source selected with the TCK[2:0] bits in the AGTMR1 register, and when the values of AGT and AGTCMA or AGTCMB match, the TCMAF/TCMBF flag in the AGTCR register is set to 1 (match), and an interrupt request is generated.

When the compare match function is enabled, the timing of the rewrite operation to the reload register and the counter differs. See section 23.3.1. Reload Register and Counter Rewrite Operation for details. In addition, the output level of the AGTWOAn, AGTWOBn pins is inverted by the match and by the underflow. The output level can be selected with the TOPOLA or TOPOLB bit in the AGTCMSR register.

Figure 23.12 shows the operation example in compare match mode.



此示例适用于将AGT寄存器的初始值设置为A，将AGTIOC寄存器中的TEDGSEL位设置为0，并测量从一个上升沿到下一个测量脉冲沿的周期的情况。

注1.从TEDGF标志设置为1（接收到有效边沿）到输入下一个有效边沿期间，必须执行从AGT寄存器的读取。读出缓冲器的内容一直保留到AGT寄存器被读取。如果在输入有效边沿之前未读取，则保留前一周期的测量结果。

注2.在脉冲周期测量模式下读取AGT寄存器时，会读取读出缓冲区的内容。
注3.当输入测量脉冲的有效边沿，然后输入外部脉冲的设置边沿时，AGTCR寄存器中的TEDGF标志设置为1（接收到有效边沿）。

注4.要使用软件设置为0，请使用8位存储器操作指令将0写入AGTCR寄存器中的TEDGF标志。注5.要通过软件设置为0，请使用8位存储器操作指令将0写入AGTCR寄存器中的TUNDF标志。

Figure 23.11 脉冲周期测量模式下的操作示例

23.3.8 比较匹配功能

比较匹配功能检测AGTCMA或AGTCMB寄存器的内容与AGT寄存器的内容之间的匹配（比较匹配）。该功能在AGTCMSR寄存器中的TCMEA或TCMEB位为1时使能（比较匹配A寄存器或比较匹配B寄存器有效）。计数器按AGTMR1寄存器中TCK[2:0]位选择的计数源递减，当AGT和AGTCMA或AGTCMB的值匹配时，AGTCR寄存器中的TCMAFTCMBF标志设置为1（匹配），并产生中断请求。

当比较匹配功能启用时，对重载寄存器和计数器的重写操作的时序不同。请参阅第23.3.1节。重载寄存器和计数器重写操作了解详情。此外，AGTWOAn、AGTWOBn引脚的输出电平通过匹配和下溢反转。输出电平可以选择与

AGTCMSR寄存器中的TOPOLA或TOPOLB位。

23.3.12 Event Signal Output to ELC

The AGTWn (n = 0, 1) uses the Event Link Controller (ELC) to perform a link operation to a specified module using the interrupt request signal as the event signal. The AGTWn (n = 0, 1) outputs compare match A, compare match B, and underflow/measurement complete signals as event signals. For details, see section 17, Event Link Controller (ELC).

23.4 Usage Notes

23.4.1 Count Operation Start and Stop Control

- When the operating mode (see Table 23.1) is set to other than the event counter mode, or the count source is set to other than AGTWn underflow event signal (TCK[2:0] = 101b):
  - After 1 (count starts) is written to the TSTART bit in the AGTCR register while the count is stopped, the TCSTF flag in the AGTCR register remains 0 (count stops) for 3 cycles of the count source. Do not access the registers associated with AGTW other than the TCSTF flag until this bit is set to 1 (count in progress).
  - After 0 (count stops) is written to the TSTART bit during a count operation, the TCSTF flag remains 1 for 3 cycles of the count source. When the TCSTF flag is set to 0, the count is stopped. Do not access the registers associated with AGTW. Other than the TCSTF flag until this bit is set to 0.
- When the operating mode (see Table 23.1) is set to event counter mode, or the count source is set to AGTW1 underflow event signal (TCK[2:0] = 101b):
  - After 1 (count starts) is written to the TSTART bit in the AGTCR register while the count is stopped, the TCSTF flag in the AGTCR register remains 0 (count stops) for 2 PCLKB cycles. Do not access the registers associated with AGTW other than the TCSTF flag until this bit is set to 1 (count in progress).
  - After 0 (count stops) is written to the TSTART bit during a count operation, the TCSTF flag remains 1 for 2 PCLKB cycles. When the TCSTF flag is set to 0, the count is stopped. Do not access the registers associated with AGTW other than the TCSTF flag until this bit is set to 0.

23.4.2 Access to Counter Register

When the TSTART bit and TCSTF flag in the AGTCR register are both 1 (count starts), allow at least 3 cycles of the count source clock between writes when writing to the AGT register successively.

23.4.3 When Changing Mode

The registers associated with AGT operating mode (AGTMR1, AGTMR2, AGTIOC, AGTISR, AGTCMSR and AGTIOC) can be changed only when the count is stopped with both the TSTART bit and TCSTF flag set to 0 (count stops). Do not change these registers during count operation.

When the registers associated with AGT operating mode are changed, the values of TEDGF, TUNDF, TCMAF, and TCMBF flags are undefined. Before starting the count, write 0 to the following flags:

- TEDGF (no active edge received)
- TUNDF (no underflow)
- TCMAF (no match)
- TCMBF (no match).

23.4.4 Output pin setting

When using the AGTWOn, AGTWIOn, AGTWOAn, or AGTWOBn as an output pin, set up the Operation and determine the initial output values. Then set an output mode in the port register.

When using the AGTWIOn as an input pin in pulse width measurement mode or pulse period measurement mode, set up the Operation and start count operation. Then start to enter external events from the AGTWIOn pin. Invalidate the first measurement and validate the second and later completed measurements.

23.3.12 事件信号输出到ELC

AGTWn(n=0 1)使用事件链接控制器(ELC)使用中断请求信号作为事件信号执行到指定模块的链接操作。AGTWn (n=0 1)输出比较匹配A、比较匹配B和下溢测量完成信号作为事件信号。有关详细信息，请参阅第17节，事件链接控制器(ELC)。

23.4 使用说明

23.4.1 计数操作启动和停止控制

●当操作模式（见表23.1）设置为非事件计数器模式，或计数源设置为非AGTWn下溢事件信号（TCK[2:0]=101b）时：

在计数停止期间将1（计数开始）写入AGTCR寄存器中的TSTART位后，AGTCR寄存器中的TCSTF标志在计数源的3个周期内保持为0（计数停止）。在此位设置为1（正在进行计数）之前，不要访问与AGTW相关的寄存器，而不是TCSTF标志。

在计数操作期间将0（计数停止）写入TSTART位后，TCSTF标志在计数源的3个周期内保持为1。当TCSTF标志设置为0时，停止计数。不要访问与AGTW关联的寄存器。除TCSTF标志外，直到该位设置为0。

●当工作模式（见表23.1）设置为事件计数器模式，或计数源设置为AGTW1下溢事件信号（TCK[2:0]=101b）时：

在停止计数时将1（计数开始）写入AGTCR寄存器中的TSTART位后，AGTCR寄存器中的TCSTF标志在2个PCLKB周期内保持为0（计数停止）。在此位设置为1（正在进行计数）之前，不要访问与AGTW相关的寄存器，而不是TCSTF标志。

在计数操作期间将0（计数停止）写入TSTART位后，TCSTF标志保持1持续2
PCLKB周期。当TCSTF标志设置为0时，停止计数。不要访问与相关的寄存器
AGTW不是TCSTF标志，直到该位设置为0。

23.4.2 访问计数器寄存器

当AGTCR寄存器中的TSTART位和TCSTF标志都为1（计数开始）时，连续写入AGT寄存器时，在两次写入之间至少允许计数源时钟的3个周期。

23.4.3 更改模式时

与AGT操作模式相关的寄存器（AGTMR1、AGTMR2、AGTIOC、AGTISR、AGTCMSR和AGTIOC）只有在TSTART位和TCSTF标志都设置为0（计数停止）时停止计数时才能更改。在计数操作期间不要更改这些寄存器。

当与AGT工作模式相关的寄存器发生变化时，TEDGF、TUNDF、TCMAF和
TCMBF标志未定义。在开始计数之前，将0写入以下标志：

●TEDGF（未收到有效边沿）

- TUNDF (no underflow)
- TCMAF (no match)
- TCMBF (no match).

23.4.4 输出引脚设置

使用AGTWOn、AGTWOn、AGTWOAn或AGTWOBn作为输出引脚时，设置操作并确定初始输出值。然后在端口寄存器中设置一个输出模式。

在脉冲宽度测量模式或脉冲周期测量模式下使用AGTWIOn作为输入引脚时，设置
操作并开始计数操作。然后开始从AGTWIOn引脚输入外部事件。使第一次测量无效并验证第二次和以后
完成的测量。

23.4.5 Digital Filter

When using the digital filter, do not start the timer operation for 5 cycles of the digital filter clock after setting TIPF[1:0] bits and when the TEDGSEL bit in the AGTIOC register changes.

23.4.6 How to Calculate Event Number, Pulse Width, and Pulse Period

- In event counter mode, event number is expressed mathematically as follows:
  Event number = initial value of counter [AGT register] - counter value of active event end
- In pulse width measurement mode, pulse width is expressed mathematically as follows:
  Pulse width = counter value of stopping measurement - counter value of next stopping measurement
- In pulse period measurement mode, input pulse period is expressed mathematically as follows:
  Period of input pulse = (initial value of counter [AGT register] - reading value of the read-out buffer) + 1.

23.4.7 When Count is Forcibly Stopped by TSTOP Bit

After the counter is forcibly stopped by the TSTOP bit in the AGTCR register, do not access the following I/O registers for 1 cycle of the count source:

- AGT
- AGTCMA
- AGTCMB
- AGTCR
- AGTMR1
- AGTMR2.

23.4.8 When Selecting AGTW0 Underflow as the Count Source

Operate according to the following procedures described in this section when selecting the underflow event signal as the count source.

(1) Procedure for starting operation

1. Set AGTW.
2. Start the count operation of AGTW1.
3. Start the count operation of AGTW0.

(2) Procedure for stopping operation

1. Stop the count operation of AGTW0.
2. Stop the count operation of AGTW1.
3. Stop the count source clock of AGTW1 (write 000b in the AGTMR1.TCK[2:0] bits).

23.4.9 Module-stop function

AGTW operation can be disabled or enabled using Module Stop Control Register D (MSTPCRD). The AGTW module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes

23.4.10 When Switching Source Clock

When switching a clock source by changing SCKSCR.CKSEL[2:0], the clock output from the selector stops for 4 cycles of the switched clock. Therefore, when using the AGTWIOn, AGTWEEn, or both input as external event input, the clock source should not be switched. If switching the clock source while using the external event input, extend the input pulse width by 4 clock cycles of the switched source clock cycles.

23.4.5 数字滤波器

使用数字滤波器时，在设置TIPF[1:0]位后以及AGTIOC寄存器中的TEDGSEL位发生变化时，在数字滤波器时钟的5个周期内不要启动定时器操作。

23.4.6 如何计算事件编号、脉冲宽度和脉冲周期

●在事件计数器模式下，事件编号以数学方式表示如下：
事件编号=计数器的初始值[AGT寄存器]活动事件结束的计数器值

●在脉冲宽度测量模式下，脉冲宽度以数学方式表示如下：
脉冲宽度=停止测量的计数器值下一个停止测量的计数器值

●在脉冲周期测量模式下，输入脉冲周期的数学表达式如下：
输入脉冲周期=（计数器初始值[AGT寄存器]读出缓冲器的读取值）+1。

23.4.7 当计数被TSTOP位强制停止时

计数器被AGTCR寄存器中的TSTOP位强制停止后，在计数源的1个周期内不要访问以下IO寄存器：

- AGT
- AGTCMA
- AGTCMB
- AGTCR
- AGTMR1
- AGTMR2.

23.4.8 选择AGTW0下溢作为计数源时

选择下溢事件信号作为计数源时，请按照本节所述的以下步骤进行操作。

(1) 开始运行的步骤

1. Set AGTW.

2.启动AGTW1的计数操作。

3.启动AGTW0的计数操作。

(2) 停止运行的步骤

1.停止AGTW0的计数操作。

2.停止AGTW1的计数操作。

3.停止AGTW1的计数源时钟（将000b写入AGTMR1.TCK[2:0]位）。

23.4.9 Module-stop function

可以使用模块停止控制寄存器D(MSTPCRD)禁用或启用AGTW操作。AGTW模块在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式

23.4.10 切换源时钟时

当通过改变SCKSCR.CKSEL[2:0]来切换时钟源时，选择器的时钟输出在切换时钟的4个周期内停止。因此，当使用AGTWIOn、AGTWEn或两者输入作为外部事件输入时，不应切换时钟源。如果在使用外部事件输入时切换时钟源，请将输入脉冲宽度延长4个切换源时钟周期的时钟周期。

24. Watchdog Timer (WDT)

24.1 Overview

The Watchdog Timer (WDT) is a 14-bit down counter that can be used to reset the MCU when the counter underflows because the system has run out of control and is unable to refresh the WDT. In addition, the WDT can be used to generate a non-maskable interrupt or an underflow interrupt.

Table 24.1 lists the WDT specifications and Figure 24.1 shows a block diagram.

24.2 Register Descriptions

24.2.1 WDTRR : WDT Refresh Register

Base address: WDT = 0x4008_3400

Offset address: 0x00

Bit position:	7							0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

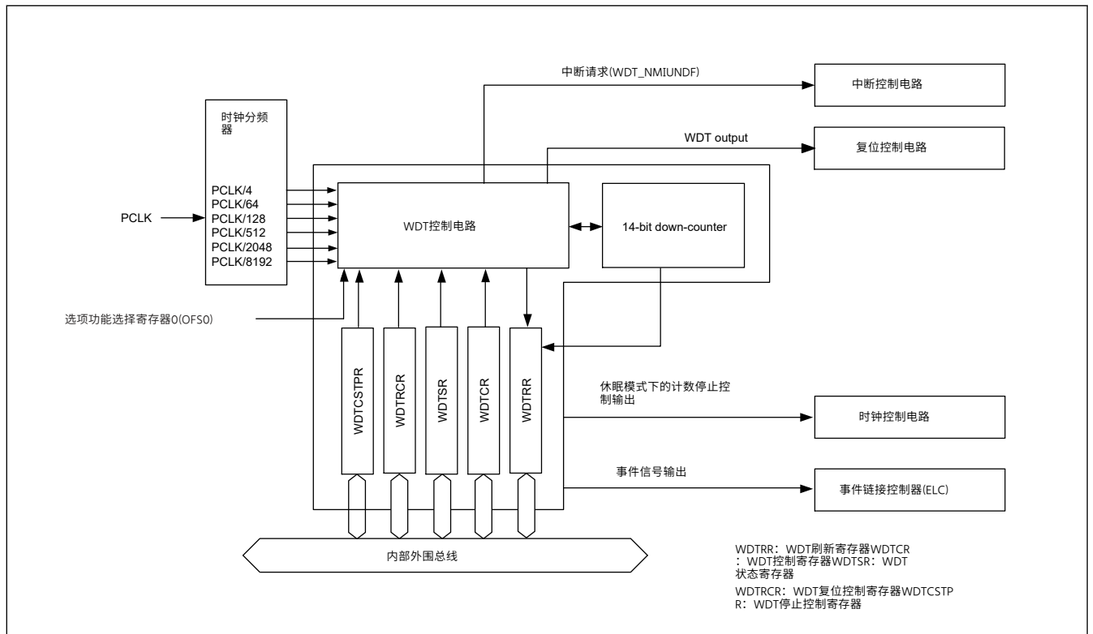
Bit	Symbol	Function	R/W
7:0	n/a	The down-counter is refreshed by writing 0x00 and then writing 0xFF to this register.	R/W

The WDTRR register refreshes the down-counter of the WDT.

The down-counter of the WDT is refreshed by writing 0x00 and then writing 0xFF to WDTRR register (refresh operation) within the refresh-permitted period.

After the down-counter is refreshed, it starts counting down from the value selected by setting the WDT Timeout Period Select bits (OFS0.WDTTOPS[1:0]) in the Option Function Select Register 0 in auto start mode. In register start mode, counting down starts from the value selected by setting the Timeout Period Select bits (WDTCR.TOPS[1:0]) in the WDT Control Register.

When 0x00 is written, the read value is 0x00. When a value other than 0x00 is written, the read value is 0xFF. For details of the refresh operation, see section 24.3.3. Refresh Operation.



Note: PCLK = PCLKB

24.2.1 WDTRR:WDT刷新寄存器

Base address: WDT = 0x4008_3400

Bit position:	7							0
Bit field:								
重置后的值：	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	n/a	通过写入0x00然后将0xFF写入该寄存器来刷新递减计数器。	R/W

WDTRR寄存器刷新WDT的递减计数器。

WDT的递减计数器通过在允许刷新期间内写入0x00然后将0xFF写入WDTRR寄存器（刷新操作）来刷新。

递减计数器刷新后，在自动启动模式下，它从通过设置选项功能选择寄存器0中的WDT超时周期选择位(OFS0.WDTTOPS[1:0])选择的值开始递减计数。在寄存器启动模式下，倒计时从通过设置WDT控制寄存器中的超时周期选择位(WDTCR.TOPS[1:0])选择的值开始。

写入0x00时，读取值为0x00。写入0x00以外的值时，读取的值为0xFF。有关刷新操作的详细信息，请参阅第24.3.3节。刷新操作。

The WDTCR register is used to set the clock division ratio, and window start and end positions for refresh, and the timeout period until the down-counter underflows in register start mode.

Some constraints apply to writes to the WDTCR register. For details, see section 24.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the settings in the WDTCR register are disabled, and the settings in the Option Function Select Register 0 (OFS0) are enabled. The settings for the WDTCR register can also be made in the OFS0 register. For details, see section 24.3.8. Association between Option Function Select Register 0 (OFS0) and WDT Registers.

TOPS[1:0] bits (Timeout Period Select)

The TOPS[1:0] bits select the timeout period, the period until the down-counter underflows, from 1024, 4096, 8192, and 16384 cycles, taking the divided clock specified in the CKS[3:0] bits as 1 cycle. After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the number of PCLKB cycles until the counter underflows.

Table 24.2 lists the relationship between the CKS[3:0] and TOPS[1:0] bit settings, the timeout period, and the number of PCLKB cycles.

WDTCR寄存器用于设置时钟分频比、刷新的窗口开始和结束位置，以及在寄存器开始模式下直到递减计数器下溢的超时时间。

一些限制适用于写入WDTCR寄存器。详见24.3.2节。控制对WDTCR的写入，WDTRCR和WDTCSTPR寄存器。

在自动启动模式下，禁用WDTCR寄存器中的设置，启用选项功能选择寄存器0(OFS0)中的设置。WDTCR寄存器的设置也可以在OFS0寄存器中进行。详见24.3.8节。选项功能选择寄存器0(OFS0)和WDT寄存器之间的关联。

TOPS[1:0]位（超时周期选择）

TOPS[1:0]位从1024、4096、8192和16384个周期中选择超时周期，即递减计数器下溢之前的周期，将CKS[3:0]位中指定的分频时钟作为1个周期.向下计数器刷新后，CKS[3:0]和TOPS[1:0]位的组合决定了PCLKB周期数，直到计数器下溢。

表24.2列出了CKS[3:0]和TOPS[1:0]位设置、超时时间和
PCLKB cycles.

	11b		16384	134217728

CKS[3:0] bits (Clock Division Ratio Select)

The CKS[3:0] bits specify the division ratio of the clock used for the down-counter. The division ratio can be selected from the PCLKB divided by 4, 64, 128, 512, 2048, and 8192. Combined with the TOPS[1:0] bit setting, this allows the WDT to be configured to a count period between 4096 and 134217728 PCLKB clock cycles.

RPES[1:0] bits (Window End Position Select)

The RPES[1:0] bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. Set the window end position to a value less than the value for the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.

RPSS[1:0] bits (Window Start Position Select)

The RPSS[1:0] bits specify the window start position that indicates the refresh-permitted period. 100%, 75%, 50%, or 25% of the timeout period can be selected for the window start position. Set the window start position to a value greater than the value for the window end position. If the window start position is set to a value less than or equal to the window end position, the window end position is set to 0%.

Table 24.3 lists the counter values for the window start and end positions, and Figure 24.2 shows the refresh-permitted period set in the RPSS[1:0], RPES[1:0], and TOPS[1:0] bits.

CKS[3:0]位（时钟分频比选择）

CKS[3:0]位指定用于递减计数器的时钟的分频比。分频比可以从PCLKB除以4、64、128、512、2048和8192中选择。结合TOPS[1:0]位设置，这允许将WDT配置为4096和134217728个PCLKB时钟周期。

RPES[1:0]位（窗口结束位置选择）

RPES[1:0]位指定指示刷新允许周期的窗口结束位置。可以为窗口结束位置选择75%、50%、25%或0%的超时时间。将窗口结束位置设置为小于窗口起始位置的值（窗口起始位置>窗口结束位置）。如果窗口结束位置大于窗口起始位置，则仅启用窗口起始位置设置。

RPSS[1:0]位（窗口起始位置选择）

RPSS[1:0]位指定指示允许刷新周期的窗口起始位置。窗口起始位置可选择100%、75%、50%或25%的超时时间。将窗口开始位置设置为大于窗口结束位置的值。如果窗口开始位置设置为小于或等于窗口结束位置的值，则窗口结束位置设置为0%。

表24.3列出了窗口开始和结束位置的计数器值，图24.2显示了在RPSS[1:0]、RPES[1:0]和TOPS[1:0]位中设置的允许刷新周期。

24.2.3 WDTSR:WDT状态寄存器

Base address: WDT = 0x4008_3400

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	REFEF	UNDF	CNTVAL[13:0]

Bit	Symbol	Function	R/W
15	REFEF	Refresh Error Flag 0: No refresh error occurred 1: Refresh error occurred	R/W*1

Note 1. Only 0 can be written to clear the flag.

The WDTSR register indicates the counter value of the down-counter and the status of whether an underflow or refresh error occurred in the down-counter.

CNTVAL[13:0] bits (Down-Counter Value)

Read the CNTVAL[13:0] bits to confirm the value of the down-counter. The read value might differ from the actual count by 1.

UNDFF flag (Underflow Flag)

Read the UNDFF flag to confirm whether an underflow occurred in the counter. A value of 1 indicates that the down counter underflowed. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N+1) PCLKB cycles. In addition, clearing of the flag is ignored for (N+1) PCLKB cycles after an underflow. N is specified in the WDTCR.CKS[3:0] bits as follows:

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

REFEF flag (Refresh Error Flag)

Read the REFEF flag to confirm whether a refresh error occurred, indicating that a refresh operation was performed during a prohibited period. A value of 1 indicates that a refresh error occurred. Write 0 to the flag to set the value to 0. Writing 1 has no effect.

Clearing of the REFEF flag takes (N+1) PCLKB cycles. In addition, clearing of the flag is ignored for (N+1) PCLKB cycles after a refresh error. N is specified in the WDTCR.CKS[3:0] bits as follows:

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

24.2.4 WDTRCR : WDT Reset Control Register

Bit field:	RSTIRQS	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15	REFEF	刷新错误标志 0：未发生刷新错误1：发生刷新错误	R/W*1

注1.只能写入0来清除标志。

WDTSR寄存器指示递减计数器的计数值以及递减计数器是否发生下溢或刷新错误的状态。

CNTVAL[13:0] bits (Down-Counter Value)

读取CNTVAL[13:0]位以确认递减计数器的值。读取的值可能与实际计数相差1。

UNDFF flag (Underflow Flag)

读取UNDFF标志以确认计数器是否发生下溢。值1表示递减计数器下溢。将0写入标志以将值设置为0。写入1无效。

清除UNDFF标志需要(N+1)个PCLKB周期。此外，在下溢后的(N+1)个PCLKB周期内忽略标志的清除。N在WDTCR.CKS[3:0]位中指定如下：

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

REFEF标志（刷新错误标志）

读取REFEF标志，确认是否发生刷新错误，表示在禁止期间进行了刷新操作。值1表示发生了刷新错误。将0写入标志以将值设置为0。写入1无效。

清除REFEF标志需要(N+1)个PCLKB周期。此外，在刷新错误后的(N+1)个PCLKB周期内，标志的清除将被忽略。N在WDTCR.CKS[3:0]位中指定如下：

- When WDTCR.CKS[3:0] = 0x1, N = 4
- When WDTCR.CKS[3:0] = 0x4, N = 64
- When WDTCR.CKS[3:0] = 0xF, N = 128
- When WDTCR.CKS[3:0] = 0x6, N = 512
- When WDTCR.CKS[3:0] = 0x7, N = 2048
- When WDTCR.CKS[3:0] = 0x8, N = 8192

Some constraints apply to writes to the WDTRCR register. For details, see section 24.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

In auto start mode, the WDTRCR register settings are disabled, and the settings in the Option Function Select register 0 (OFS0) are enabled. 24.3 Operation

24.3.1 Count Operation in each Start Mode

The WDT has two start modes:

- Auto start mode, in which counting automatically starts after a release from the reset state
- Register start mode, in which counting starts with a refresh by writing to the register.

In auto start mode, counting automatically starts after a release from the reset state according to the settings in the Option Function Select register 0 (OFS0) in the flash.

In register start mode, counting starts with a refresh by writing to the WDTRR register after the respective registers are set after a a release from the reset state.

在自动启动模式下，WDTRCR寄存器设置被禁用，而选项功能选择寄存器0(OFS0)中的设置被启用。WDTRCR寄存器的设置也可以对OFS0寄存器进行。详见24.3.8节。选项功能选择寄存器0(OFS0)和WDT寄存器之间的关联。

24.3 Operation

24.3.1 每种启动模式下的计数操作

WDT有两种启动模式：

●自动启动模式，从复位状态释放后自动开始计数

●寄存器启动模式，通过写入寄存器，从刷新开始计数。

在自动启动模式下，根据选项中的设置从复位状态释放后自动开始计数
功能选择闪存中的寄存器0(OFS0)。

在寄存器启动模式下，在从复位状态释放后，在设置各个寄存器后，通过写入WDTRR寄存器，从刷新开始计数。

Select auto start mode or register start mode by setting the WDT Start Mode Select bit (OFS0.WDTSTRT) in the OFS0 register.

When the auto start mode is selected, the settings in the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are disabled while the settings in the OFS0 register are enabled.

When the register start mode is selected, the setting for the OFS0 register is disabled while the settings for the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are enabled.

24.3.1.1 Register start mode

When the WDT Start Mode Select bit (OFS0.WDTSTRT) is 1, register start mode is selected and the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are enabled.

After the reset state is released, set the following to Sleep mode in the WDTCSTPR register:

- Clock division ratio
- Window start and end positions
- Timeout period in the WDTCR register
- Reset output or interrupt request output in the WDTRCR register
- Counter stop control during transitions to Sleep mode in the WDTCSTPR register

Refresh the down-counter to start counting down from the value set in the Timeout Period Selection bits (WDTCR.TOPS[1:0]).

Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and counting down continues. The WDT does not output the reset signal as long as counting continues. However, if the down-counter underflows because the down-counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter was refreshed outside the refresh-permitted period, the WDT outputs the reset signal or a non-maskable interrupt request/interrupt request (WDT_NMIUNDF). Reset output or interrupt request output can be selected in the WDT Reset Interrupt Request Select bit (WDTRCR.RSTIRQS). Non-maskable interrupt requests or interrupt requests can be selected in the WDT Underflow/Refresh Error Interrupt Enable bit (NMIER.WDTEN).

Figure 24.3 shows an example of operation under the following conditions:

- Register start mode (OFS0.WDTSTRT = 1)
- Reset output is enabled (WDTRCR.RSTIRQS = 1)
- The window start position is 75% (WDTCR.RPSS[1:0] = 10b)
- The window end position is 25% (WDTCR.RPES[1:0] = 10b)

通过设置OFS0寄存器中的WDT启动模式选择位(OFS0.WDTSTRT)来选择自动启动模式或寄存器启动模式。

选择自动启动模式后，WDT控制寄存器（WDTCR）中的设置，WDTRESET控制寄存器（WDTRCR）和WDT计数停止控制寄存器（WDTCSTPR）在启用OFS0寄存器中的设置时被禁用。

选择寄存器启动模式时，在WDT控件的设置时禁用OFS0寄存器的设置
使能寄存器(WDTCR)、WDT复位控制寄存器(WDTRCR)和WDT计数停止控制寄存器(WDTCSTPR)。

24.3.1.1 注册启动模式

当WDT启动模式选择位(OFS0.WDTSTRT)为1时，选择寄存器启动模式并启用WDT控制寄存器(WDTCR)、WDT复位控制寄存器(WDTRCR)和WDT计数停止控制寄存器(WDTCSTPR)。

释放复位状态后，在WDTCSTPR寄存器中将以下内容设置为休眠模式：

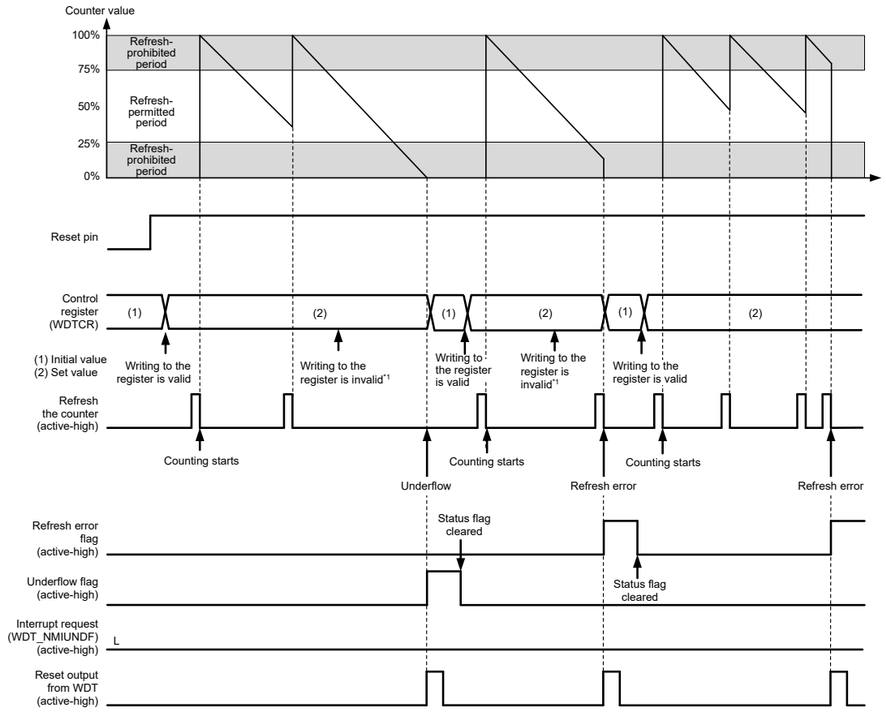
- ●时钟分频比
- ●窗口开始和结束位置
- ●WDTCR寄存器中的超时时间
- ●WDTRCR寄存器中的复位输出或中断请求输出
- ●WDTCSTPR寄存器中转换到休眠模式期间的计数器停止控制

刷新递减计数器以从超时周期选择位(WDTCR.TOPS[1:0])中设置的值开始递减计数。

此后，只要在可刷新期间刷新了计数器，则每次刷新计数器时都会重置计数器中的值，并继续递减计数。只要继续计数，WDT就不会输出复位信号。但是，如果由于程序失控导致递减计数器无法刷新而导致递减计数器下溢，或者由于计数器在刷新允许时间之外刷新而发生刷新错误，则WDT输出复位信号或非可屏蔽中断请求中断请求(WDT_NMIUNDF)。可以在WDT复位中断请求选择位(WDTRCR.RSTIRQS)中选择复位输出或中断请求输出。可以在WDT下溢刷新错误中断 允许位(NMIER.WDTEN)中选择不可屏蔽的中断请求或中断请求。

图24.3显示了以下条件下的操作示例：

- ●寄存器启动模式（OFS0.WDSTSTRT=1）
- ●启用复位输出(WDTRCR.RSTIRQS=1)
- ●窗口起始位置为75%(WDTCR.RPSS[1:0]=10b)
- ●窗口结束位置为25%(WDTCR.RPES[1:0]=10b)



Note: See section 24.3.2. Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.

Figure 24.3 Operation example in register start mode

24.3.1.2 Auto start mode

When the WDT Start Mode Select bit (OFS0.WDTSTRT) in the Option Function Select Register 0 (OFS0) is 0, auto start mode is selected, the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), and WDT Count Stop Control Register (WDTCSTPR) are disabled, and the settings in the OFS0 register are enabled.

Within the reset state, the setting values for the following in the Option Function Select Register 0 (OFS0) are set in the WDT registers:

- Clock division ratio
- Window start and end positions
- Timeout period
- Reset output or interrupt request
- Counter stop control during transition to Sleep mode

When the reset state is released, the down-counter automatically starts counting down from the value set in the WDT Timeout Period Select bits (OFS0.WDTTOPS[1:0]).

Thereafter, as long as the counter is refreshed in the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and counting down continues. The WDT does not output the reset signal as long as the counting continues. However, if the down-counter underflows because refreshing of the down-counter is not possible due to a

24.3.1.2 自动启动模式

当WDT启动模式选择位置（OFS0.WDTSTSTRT）中的选项功能选择寄存器0（OFS0）为0时，选择了自动启动模式，WDT控制寄存器（WDTCR）（WDTCR），WDTRESETRESETCONTROMCONTROL寄存器（WDTRCR）和WDTCountCountCountCountCount停止控制寄存器(WDTCSTPR)被禁用，而OFS0寄存器中的设置被启用。

在复位状态下，选项功能选择寄存器0(OFS0)中的以下设置值在
WDT registers:

- ●时钟分频比
- ●窗口开始和结束位置
- ●超时时间
- ●复位输出或中断请求
- ●转换到睡眠模式期间的计数器停止控制

当复位状态解除时，递减计数器自动从WDT中设置的值开始递减计数
超时周期选择位(OFS0.WDTTOPS[1:0])。

此后，只要在可刷新期间刷新了计数器，则每次刷新计数器时都会重置计数器中的值，并继续递减计数。只要继续计数，WDT就不会输出复位信号。但是，如果递减计数器下溢，因为递减计数器的刷新是不可能的，因为

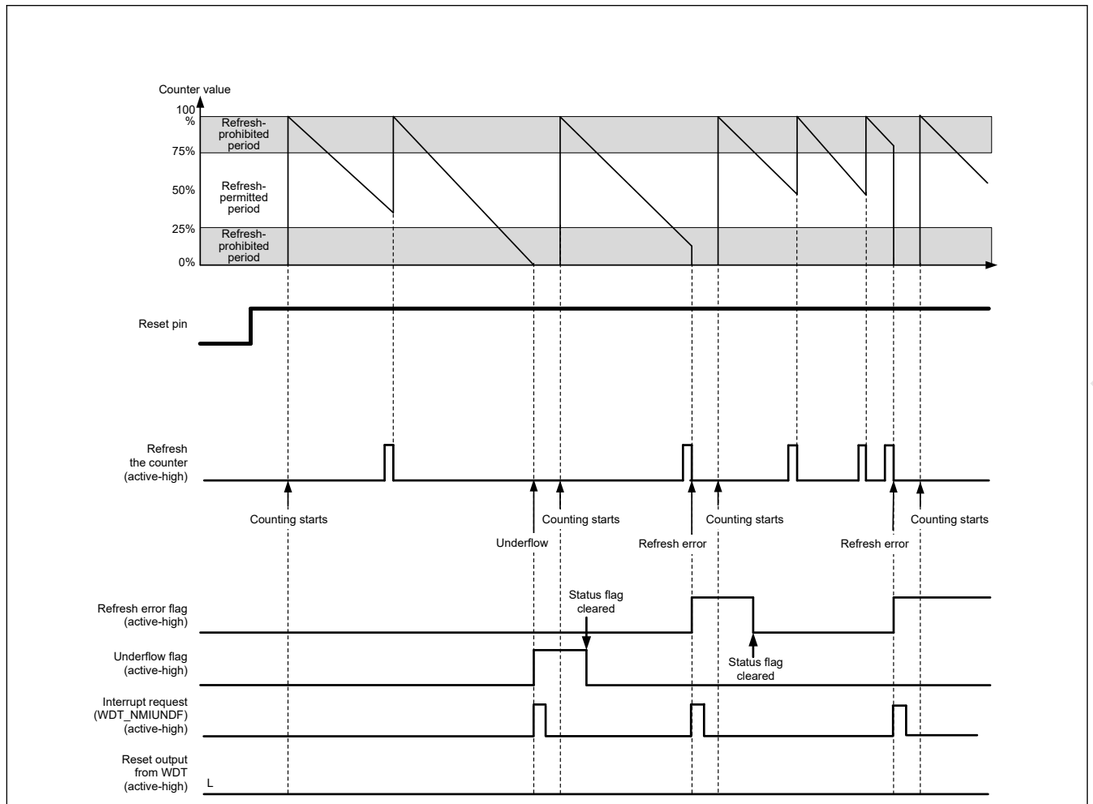
runaway program or if a refresh error occurs due to refreshing outside the refresh-permitted period, the WDT outputs the reset signal or non-maskable interrupt request/interrupt request (WDT_NMIUNDF).

After the reset signal or non-maskable interrupt request/interrupt request is generated, the counter reloads the timeout period after counting for 1 cycle. The value of the timeout period is set in the down-counter and counting restarts.

Reset output or interrupt request output can be selected by setting the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS). Non-maskable interrupt request or interrupt request can be selected in the WDT Underflow/ Refresh Error Interrupt Enable bit (NMIER.WDTEN).

Figure 24.4 shows an example of operation (non-maskable interrupt) under the following conditions:

- Auto start mode (OFS0.WDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.WDTRSTIRQS = 0)
- The window start position is 75% (OFS0.WDTRPSS[1:0] = 10b)
- The window end position is 25% (OFS0.WDTRPES[1:0] = 10b)



Note: Reset pin = RES

24.3.2 Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers

Writing to the WDT Control Register (WDTCR), WDT Reset Control Register (WDTRCR), or WDT Count Stop Control Register (WDTCSTPR) is possible once between the release from the reset state and the first refresh operation.

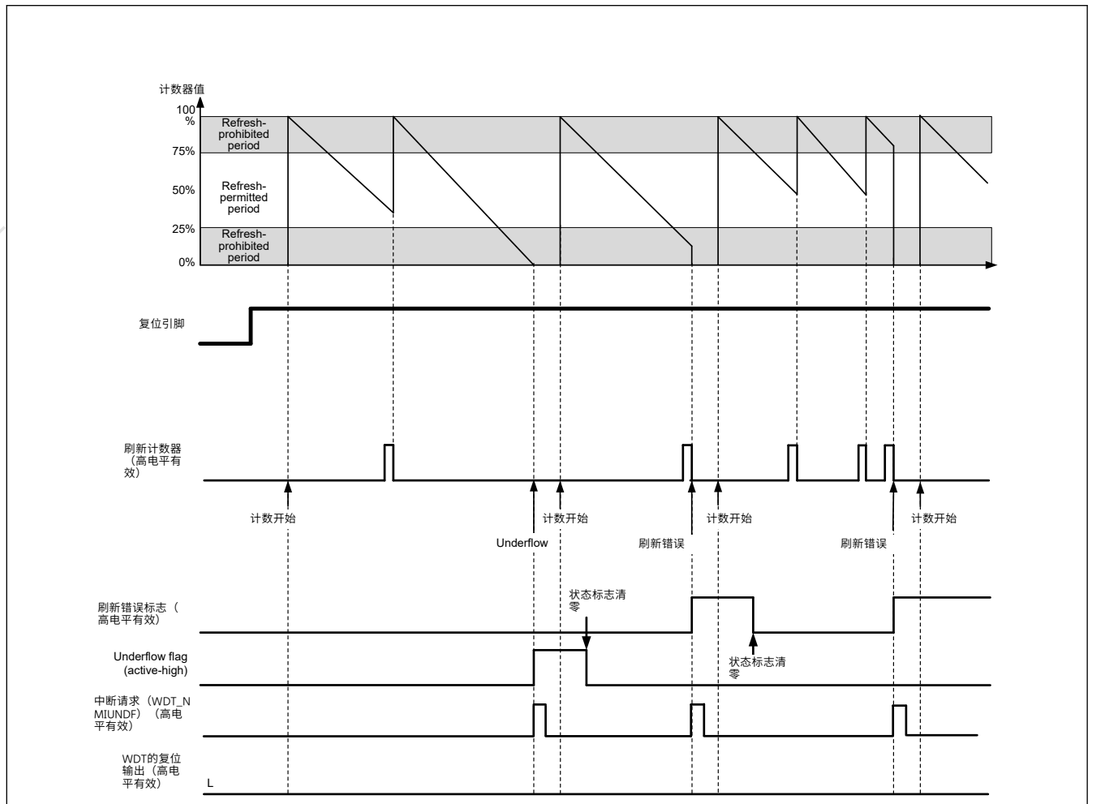
如果程序失控或由于刷新允许刷新期间之外发生刷新错误，则WDT输出复位信号或不可屏蔽中断请求中断请求(WDT_NMIUNDF)。

复位信号或不可屏蔽中断请求中断请求产生后，计数器在计数1个周期后重新加载超时周期。超时时间的值在递减计数器中设置并重新开始计数。

通过设置WDT复位中断请求选择位(OFS0.WDTRSTIRQS)可以选择复位输出或中断请求输出。可以在WDT下溢刷新错误中断 允许位(NMIER.WDTEN)中选择不可屏蔽的中断请求或中断请求。

图24.4显示了以下条件下的操作示例（不可屏蔽中断）：

- ●自动启动模式（OFS0.WDTSTRT=0）
- ●使能不可屏蔽中断请求输出（OFS0.WDTRSTIRQS=0）
- ●窗口起始位置为75%(OFS0.WDTRPSS[1:0]=10b)
- ●窗口结束位置为25%(OFS0.WDTRPES[1:0]=10b)



Note: 复位引脚=RES

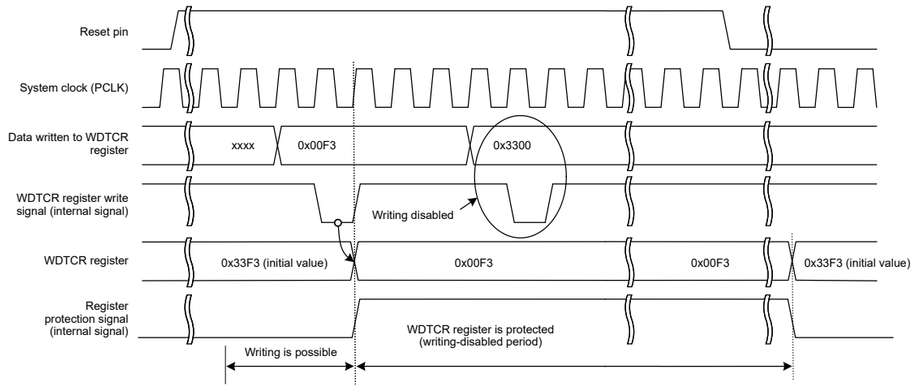
Figure 24.4 自动启动模式下的操作示例

24.3.2 控制对WDTCR、WDTRCR和WDTCSTPR寄存器的写入

写入WDT控制寄存器(WDTCR)、WDT复位控制寄存器(WDTRCR)或WDT计数停止控制在从复位状态释放到第一次刷新操作之间，寄存器(WDTCSTPR)是可能的。

After a refresh (counting starts) or a write to WDTCR, WDTRCR or WDTCSTPR register, the protection signal in the WDT becomes 1 to protect WDTCR, WDTRCR and WDTCSTPR register against subsequent write attempts. This protection is released by the reset source of the WDT. With other reset sources, the protection is not released.

Figure 24.5 shows control waveforms produced in response to writing to the WDTCR.



Note: PCLK = PCLKB
Reset pin = RES

Figure 24.5 Control waveforms produced in response to writes to the WDTCR register

24.3.3 Refresh Operation

The down-counter is refreshed and starts counting operation on a write of the values 0x00 and 0xFF to the WDT Refresh Register (WDTRR). If a value other than 0xFF is written after 0x00, the down-counter is not refreshed. If an invalid value is written, correct refreshing resumes on a write of 0x00 and 0xFF to the WDTRR register.

Correct refreshing is also performed when a register other than WDTRR is accessed or WDTRR is read between writing 0x00 and writing 0xFF to WDTRR. Writes to refresh the counter must be made within the refresh-permitted period, and this is determined by the 0xFF write. For this reason, correct refreshing is performed even when 0x00 is written outside the refresh-permitted period.

[Example write sequences that are valid for refreshing the counter]

- 0x00 → 0xFF
- 0x00 ((n–1)th time) → 0x00 (nth time) → 0xFF
- 0x00 → access to another register or read from WDTRR → 0xFF

[Example write sequences that are invalid for refreshing the counter]

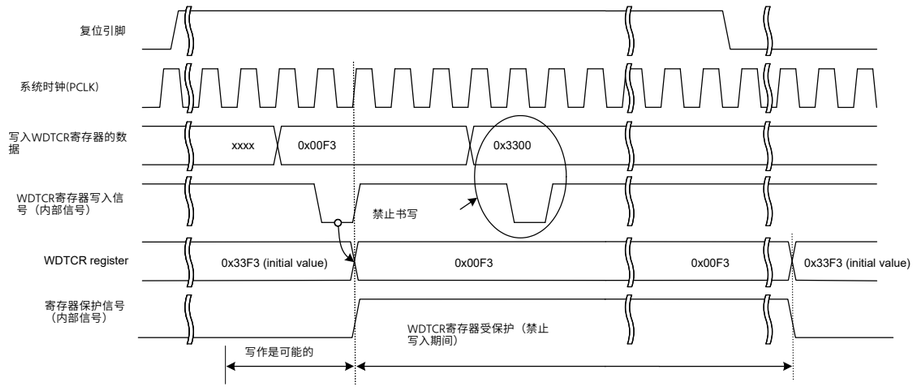
- 0x23 (a value other than 0x00) → 0xFF
- 0x00 → 0x54 (a value other than 0xFF)
- 0x00 → 0xAA (0x00 and a value other than 0xFF) → 0xFF

After 0xFF is written to the WDT Refresh Register (WDTRR), refreshing the down-counter requires up to 4 cycles of the signal for counting. To meet this requirement, complete writing 0xFF to WDTRR 4 count cycles before the down-counter underflows.

Figure 24.6 shows the WDT refresh-operation waveforms when the clock division ratio is PCLKB/64.

在刷新（计数开始）或写入WDTCR、WDTRCR或WDTCSTPR寄存器后，WDT变为1以保护WDTCR、WDTRCR和WDTCSTPR寄存器免受后续写入尝试。该保护由WDT的复位源解除。使用其他复位源时，不会解除保护。

图24.5显示了响应写入WDTCR产生的控制波形。



Note: PCLK=PCLKB复位引脚=RES

Figure 24.5 响应写入WDTCR寄存器而产生的控制波形

24.3.3 刷新操作

向下计数器刷新并在将值0x00和0xFF写入WDT刷新时开始计数操作寄存器(WDTRR)。如果在0x00之后写入0xFF以外的值，则不刷新递减计数器。如果写入无效值，则在向WDTRR寄存器写入0x00和0xFF时会恢复正确刷新。

在写入0x00和写入0xFF到WDTRR之间访问WDTRR以外的寄存器或读取WDTRR时，也会执行正确刷新。刷新计数器的写入必须在允许刷新的周期内进行，这由0xFF写入决定。因此，即使在可刷新期间外写入0x00，也会执行正确的刷新。

[对刷新计数器有效的示例写入序列]

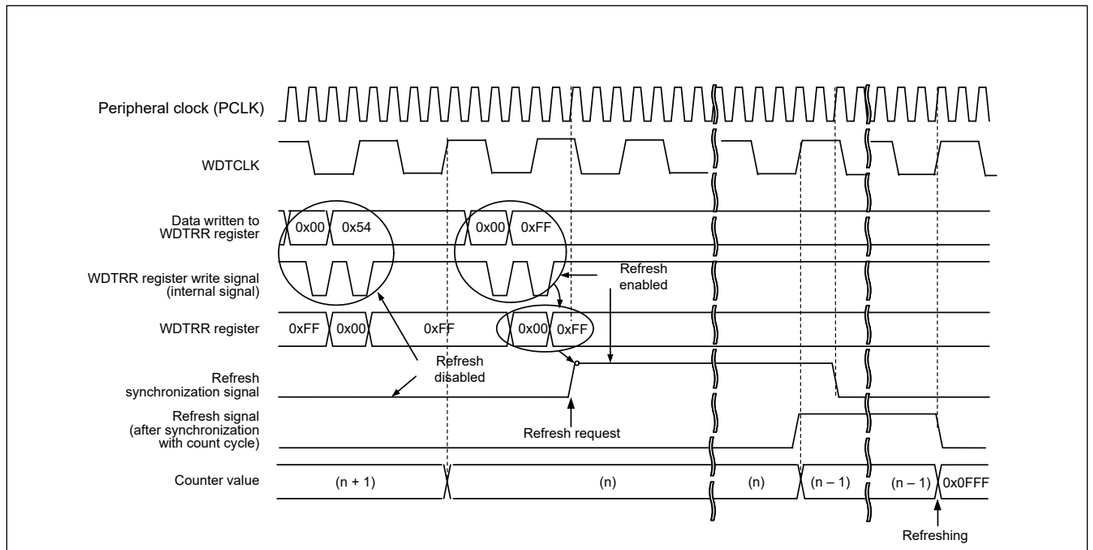
- 0x00 → 0xFF
- 0x00 ((n–1)th time) → 0x00 (nth time) → 0xFF
- ●0x00→访问另一个寄存器或从WDTRR读取→0xFF

[对刷新计数器无效的示例写入序列]

- ●0x23（0x00以外的值）→0xFF
- ●0x00→0x54（0xFF以外的值）
- ●0x00→0xAA（0x00和0xFF以外的值）→0xFF

将0xFF写入WDT刷新寄存器(WDTRR)后，刷新递减计数器最多需要4个信号周期进行计数。为满足此要求，请在递减计数器下溢之前的4个计数周期内将0xFF写入WDTRR。

图24.6显示了时钟分频比为PCLKB64时的WDT刷新操作波形。



Note: PCLK = PCLKB

Figure 24.6 WDT refresh operation waveforms when WDTCR.CKS[3:0] = 0x4 and WDTCR.TOPS[1:0] = 01b

Note: When setting the refresh time, consider the oscillation accuracy of the clock sources of the PCLKB and WDTCLK. Set values which ensure that refreshing is possible even when the frequency varies in the range of error of the oscillation accuracy.

24.3.4 Status Flags

The refresh error (WDTSR.REFEF) and underflow (WDTSR.UNDFF) flags retain the source of the interrupt request from the WDT. After a release from the interrupt request generation, read the WDTSR.REFEF and WDTSR.UNDFF flags to check for the interrupt source. For each flag, writing 0 clears the bit. Writing 1 has no effect. Leaving the status flags unchanged does not affect operation. If the flags are not cleared at the next interrupt request from the WDT, the earlier interrupt source is cleared and the new interrupt source is written. For the time period between when 0 is written in each flag and when its value is reflected, see section 24.2.3. WDTSR : WDT Status Register.

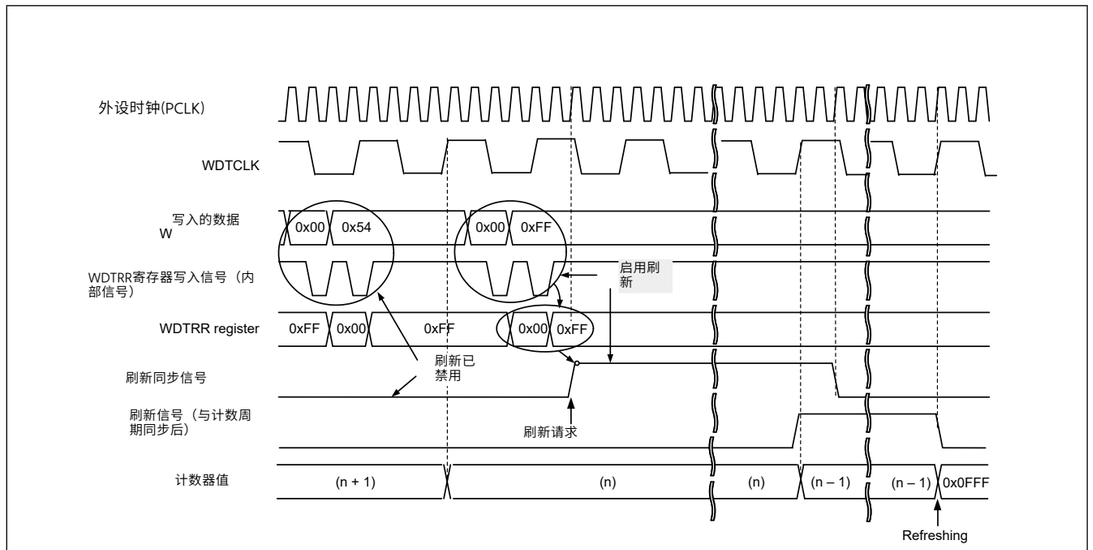
24.3.5 Reset Output

When the Reset Interrupt Select bit (WDTRCR.RSTIRQS) is set to 1 in register start mode, or when the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 1 in auto start mode, a reset signal is output for 1 cycle count when an underflow in the down-counter or a refresh error occurs.

In register start mode, the down-counter is initialized (all bits set to 0) and stopped in that state after output of a reset signal. After the reset state is released and the program is restarted, the counter is set up again and counting down starts again with a refresh. In auto start mode, counting down starts automatically after the reset state is released.

24.3.6 Interrupt Sources

When the Reset Interrupt Select bit (WDTRCR.RSTIRQS) is set to 0 in register start mode or when the WDT Reset Interrupt Request Select bit (OFS0.WDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 0 in auto start mode, an interrupt (WDT_NMIUNDF) signal is generated when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or an interrupt. For details, see section 12, Interrupt Controller Unit (ICU).



Note: PCLK = PCLKB

Figure 24.6 WDTCR.CKS[3:0]=0x4和WDTCR.TOPS[1:0]=01b时的WDT刷新操作波形

Note: 设置刷新时间时，要考虑PCLKB和WDTCLK时钟源的振荡精度。设定即使频率在振荡精度的误差范围内变化也能进行刷新的值。

24.3.4 状态标志

刷新错误(WDTSR.REFEF)和下溢(WDTSR.UNDFF)标志保留来自WDT的中断请求源。释放中断请求生成后，读取WDTSR.REFEF和WDTSR.UNDFF标志以检查中断源。对于每个标志，写入0会清除该位。写1无效。保持状态标志不变不会影响操作。如果在WDT发出下一个中断请求时未清除标志，则清除较早的中断源并写入新的中断源。关于从各标志写入0到反映其值的时间段，请参阅第24.2.3节。WDTSR：WDT状态寄存器。

24.3.5 复位输出

当复位中断选择位(WDTRCR.RSTIRQS)在寄存器启动模式下设置为1时，或当WDT复位时在自动启动模式下，选项功能选择寄存器0(OFS0)中的中断请求选择位(OFS0.WDTRSTIRQS)设置为1，当递减计数器中的下溢或刷新错误发生时，在1个周期计数内输出复位信号.

在寄存器启动模式下，递减计数器被初始化（所有位设置为0）并在输出复位信号后停止在该状态。复位状态解除并重新启动程序后，再次设置计数器，并通过刷新再次开始倒计时。在自动启动模式下，复位状态解除后自动开始倒计时。

24.3.6 中断源

当在寄存器启动模式下复位中断选择位(WDTRCR.RSTIRQS)设置为0或WDT复位时在自动启动模式下，选项功能选择寄存器0(OFS0)中的中断请求选择位(OFS0.WDTRSTIRQS)设置为0，当计数器下溢或发生刷新错误时，将产生中断(WDT_NMIUNDF)信号。此中断可用作不可屏蔽中断或中断。有关详细信息，请参阅第12节，中断控制器单元(ICU)。

24.3.7 Reading the Down-Counter Value

The WDT stores the counter value in the down-counter value bits (WDTSR.CNTVAL[13:0]) of the WDT Status Register. Check these bits to obtain the counter value. The read value of the down-counter might differ from the actual count by one.

Figure 24.7 shows the processing for reading the WDT down-counter value when the clock division ratio is PCLKB/64.

Table 24.5 lists the association between the Option Function Select Register 0 (OFS0) used in auto start mode, and the registers used in register start mode. For details on the Option Function Select Register 0 (OFS0), see section 6.2.1. OFS0 : Option Function Select Register 0.

24.4 Output to the Event Link Controller (ELC)

The WDT is capable of a link operation for the previously specified module when interrupt request signal is used as an event signal by the ELC. The event signal is output by the counter underflow and refresh error. An event signal is output regardless of the setting of the Reset Interrupt Request Select bit (WDTRCR.RSTIRQS) in register start mode or auto start mode. An event signal can also be output when the next interrupt source is generated while the Refresh Error flag (WDTSR.REFEF) or Underflow flag (WDTSR.UNDFF) is 1. For details, see section 17, Event Link Controller (ELC).

24.5 Usage Notes

24.5.1 ICU Event Link Setting Register n (IELSRn) Setting

Setting 0x53 to ICU Event Link Setting Register n (ICU.IELSRn) is prohibited when enabling the WDT reset assertion (OFS0.WDTRSTIRQS = 0 or WDTRCR.RSTIRQS = 0) or when enabling event link operation (ELSRn.ELS[8:0] = 0x53).

24.4 输出到事件链接控制器(ELC)

当ELC将中断请求信号用作事件信号时，WDT能够对先前指定的模块进行链接操作。事件信号由计数器下溢和刷新错误输出。在寄存器启动模式或自动启动模式下，无论复位中断请求选择位(WDTRCR.RSTIRQS)的设置如何，都会输出事件信号。当刷新错误标志(WDTSR.REFEF)或下溢标志(WDTSR.UNDFF)为1时，也可以在产生下一个中断源时输出事件信号。有关详细信息，请参阅第17节，事件链接控制器(ELC)。

24.5 使用说明

24.5.1 ICU事件链接设置寄存器n(IELSRn)设置

当启用WDT复位断言(OFS0.WDTRSTIRQS=0或WDTRCR.RSTIRQS=0)或启用事件链接操作(ELSRn.ELS[8:0])时，禁止将0x53设置为ICU事件链接设置寄存器n(ICU.IELSRn)=0x53)。

25. Independent Watchdog Timer (IWDT)

25.1 Overview

The Independent Watchdog Timer (IWDT) consists of a 14-bit down counter that must be serviced periodically to prevent counter underflow. The IWDT provides functionality to reset the MCU or to generate a non-maskable interrupt or an underflow interrupt. Because the timer operates with an independent, dedicated clock source, it is particularly useful in returning the MCU to a known state as a fail-safe mechanism when the system runs out of control. The IWDT can be triggered automatically by a reset, underflow, refresh error, or a refresh of the count value in the registers.

The IWDT functions differ from those of the WDT in the following respects:

- The divided IWDT-dedicated clock (IWDTCLK) is used as the count source (not affected by PCLKB)
- IWDT does not support register start mode

Table 25.1 lists the IWDT specifications and Figure 25.1 shows a block diagram.

Table 25.1 IWDT specifications

Parameter	Description
Count source*1	IWDT-dedicated clock (IWDTCLK)
Clock division ratio	Division by 1, 16, 32, 64, 128, or 256
Counter operation	Counting down using a 14-bit down-counter
Condition for starting the counter	• Counting automatically starts after a reset • Only secure developer can start the IWDT
Conditions for stopping the counter	• Reset (the down-counter and other registers return to their initial values) • A counter underflows or a refresh error is generated (counting restarts automatically).
Window function	Window start and end positions can be specified (refresh-permitted and refresh-prohibited periods)
Reset output sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error).
Non-maskable interrupt/interrupt sources	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error).
Reading the counter value	The down-counter value can be read by the IWDTSR register
Event link function	• Down-counter underflow event output • Refresh error event output.
Output signal (internal signal)	• Reset output • Interrupt request output • Sleep-mode count stop control output.
Auto start mode	Configurable to the following triggers: • Clock frequency division ratio after a reset (OFS0.IWDTCKS[3:0] bits) • Timeout period of the Independent Watchdog Timer (OFS0.IWDTTOPS[1:0] bits) • Window start position in the Independent Watchdog Timer (OFS0.IWDTRPSS[1:0] bits) • Window end position in the Independent Watchdog Timer (OFS0.IWDTRPES[1:0] bits) • Reset output or interrupt request output (OFS0.IWDTRSTIRQS bit) • Down-count stop function at transition to Sleep, Snooze, or Software Standby mode (OFS0.IWDTSTPCTL bit).
TrustZone Filter	Security attribution can be set

Note 1. Satisfy the frequency of the peripheral module clock (PCLKB) ≥ 4 × (the frequency of the count clock source after division).

The bus interface and registers operate with PCLKB, and the 14-bit counter and control circuits operate with IWDTCLK.

25. 独立看门狗定时器(IWDT)

25.1 Overview

独立看门狗定时器(IWDT)包含一个14位递减计数器，必须定期对其进行服务以防止计数器下溢。IWDT提供复位MCU或生成不可屏蔽中断或下溢中断的功能。由于定时器使用独立的专用时钟源运行，因此当系统失控时，它在将MCU作为故障安全机制返回到已知状态时特别有用。IWDT可以通过复位、下溢、刷新错误或寄存器中的计数值的刷新来自动触发。

IWDT的功能与WDT的功能有以下不同：

●分频IWDT专用时钟（IWDTCLK）用作计数源（不受PCLKB影响）

●IWDT不支持寄存器启动方式

表25.1列出了IWDT规范，图25.1显示了框图。

25.2.1 IWDTRR : IWDT Refresh Register

Base address: IWDT = 0x4008_3200

Offset address: 0x00

Bit position:	7							0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	n/a	The down-counter is refreshed by writing 0x00 and then writing 0xFF to this register	R/W

The IWDTRR register refreshes the down-counter of the IWDT. The down-counter of the IWDT is refreshed by writing 0x00 and then writing 0xFF to IWDTRR (refresh operation) within the refresh-permitted period. After the down-counter is refreshed, it starts counting down from the value selected in the IWDT Timeout Period Select bits (OFS0.IWDTTOPS[1:0]) in the Option Function Select Register 0 (OFS0).

When 0x00 is written, the read value is 0x00. When a value other than 0x00 is written, the read value is 0xFF. For details of the refresh operation, see section 25.3.2. Refresh Operation.

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	REFEF	UNDFF	CNTVAL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
13:0	CNTVAL[13:0]	Down-counter Value Value counted by the down-counter	R
14	UNDFF	Underflow Flag 0: No underflow occurred 1: Underflow occurred	R/W*1
15	REFEF	Refresh Error Flag 0: No refresh error occurred 1: Refresh error occurred	R/W*1

Note 1. Only 0 can be written to clear the flag.

The IWDTSR register indicates the counter value of the down-counter and whether an underflow or refresh error occurred in the down-counter.

CNTVAL[13:0] bits (Down-counter Value)

Read the CNTVAL[13:0] bits to confirm the value of the down-counter. The read value might differ from the actual count by 1.

UNDFF flag (Underflow Flag)

Read the UNDFF flag to confirm whether an underflow occurred in the down-counter. The value 1 indicates that the down-counter underflowed. Write 0 to the UNDFF flag to set the value to 0. Writing 1 has no effect.

Clearing of the UNDFF flag takes (N + 2) IWDTCLK cycles and 2 PCLKB cycles. In addition, clearing of this flag is ignored for (N + 2) IWDTCLK cycles after an underflow. N is specified in the IWDTCKS[3:0] bits as follows:

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128
- When OFS0.IWDTCKS[3:0] = 0x5, N = 256.

REFEF flag (Refresh Error Flag)

Read the REFEF flag to confirm whether a refresh error occurred. This indicates that a refresh operation was performed during a prohibited period. The value 1 indicates that a refresh error occurred. Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

Clearing of the REFEF flag takes (N + 2) IWDTCLK cycles and 2 PCLKB cycles. In addition, clearing of this flag is ignored for (N + 2) IWDTCLK cycles following a refresh error. N is specified in the IWDTCKS[3:0] bits as follows:

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128
- When OFS0.IWDTCKS[3:0] = 0x5, N = 256.

13:0	CNTVAL[13:0]	Down-counter Value 递减计数器计数的值	R
14	UNDFF	Underflow Flag 0：未发生下溢1：发生下溢	R/W*1
15	REFEF	刷新错误标志 0：未发生刷新错误1：发生刷新错误	R/W*1

注1.只能写入0来清除标志。

IWDTSR寄存器指示递减计数器的计数值以及递减计数器是否发生下溢或刷新错误。

CNTVAL[13:0] bits (Down-counter Value)

读取CNTVAL[13:0]位以确认递减计数器的值。读取的值可能与实际计数相差1。

UNDFF flag (Underflow Flag)

读取UNDFF标志以确认递减计数器中是否发生下溢。值1表示递减计数器下溢。将0写入UNDFF标志以将值设置为0。写入1无效。

清除UNDFF标志需要(N+2)个IWDTCLK周期和2个PCLKB周期。此外，在下溢后的(N+2)个IWDTCLK周期内，该标志的清除将被忽略。N在IWDTCKS[3:0]位中指定如下：

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128
- When OFS0.IWDTCKS[3:0] = 0x5, N = 256.

REFEF标志（刷新错误标志）

读取REFEF标志以确认是否发生刷新错误。这表示在禁止期间执行了刷新操作。值1表示发生了刷新错误。将0写入REFEF标志以将值设置为0。写入1无效。

清除REFEF标志需要(N+2)个IWDTCLK周期和2个PCLKB周期。此外，在刷新错误后的(N+2)个IWDTCLK周期内，该标志的清除将被忽略。N在IWDTCKS[3:0]位中指定如下：

- When OFS0.IWDTCKS[3:0] = 0x0, N = 1
- When OFS0.IWDTCKS[3:0] = 0x2, N = 16
- When OFS0.IWDTCKS[3:0] = 0x3, N = 32
- When OFS0.IWDTCKS[3:0] = 0x4, N = 64
- When OFS0.IWDTCKS[3:0] = 0xF, N = 128
- When OFS0.IWDTCKS[3:0] = 0x5, N = 256.

For information on the Option Function Select Register 0 (OFS0), see section 6.2.1. OFS0 : Option Function Select Register 0.

IWDTTOPS[1:0] bits (IWDT Timeout Period Select)

The IWDTTOPS[1:0] bits select the timeout period, that is, the period until the down-counter underflows, from 128, 512, 1024, or 2048 cycles, taking the divided clock specified in the IWDTCKS[3:0] bits as 1 cycle.

After the down-counter is refreshed, the combination of the IWDTCKS[3:0] and IWDTTOPS[1:0] bits determines the number of IWDTCLK cycles until the counter underflows.

Table 25.2 lists the relationship between the IWDTCKS[3:0] and IWDTTOPS[1:0] bit settings, the timeout period, and the number of IWDTCLK cycles.

Table 25.2 Timeout period settings

IWDTCKS[3:0] bits (IWDT-Dedicated Clock Frequency Division Ratio Select)

The IWDTCKS[3:0] bits specify the division ratio of the clock used for the down-counter. The division ratio can be selected from the IWDT-dedicated clock (IWDTCLK) divided by 1, 16, 32, 64, 128, and 256. Combined with the IWDTTOPS[1:0] bit setting, the IWDT can be configured to a count period between 128 and 524,288 IWDTCLK cycles.

有关选项功能选择寄存器0(OFS0)的信息，请参见第6.2.1节。OFS0：选项功能选择寄存器0。

IWDTTOPS[1:0]位（IWDT超时周期选择）

IWDTTOPS[1:0]位选择超时周期，即从128、512、1024或2048个周期开始，直到递减计数器下溢的周期，采用IWDTCKS[3:0]位中指定的分频时钟作为1个周期。

向下计数器刷新后，IWDTCKS[3:0]和IWDTTOPS[1:0]位的组合决定了在计数器下溢之前的IWDTCLK周期数。

表25.2列出了IWDTCKS[3:0]和IWDTTOPS[1:0]位设置、超时周期和IWDTCLK周期数之间的关系。

IWDTCKS[3:0]位（IWDT专用时钟分频比选择）

IWDTCKS[3:0]位指定用于递减计数器的时钟分频比。分频比可以从IWDT专用时钟(IWDTCLK)除以1、16、32、64、128和256中选择。结合IWDTTOPS[1:0]位设置，可以将IWDT配置为计数128到524 288个IWDTCLK周期之间的周期。

IWDTRPES[1:0] bits (IWDT Window End Position Select)

The IWDTRPES[1:0] bits specify the window end position that indicates the refresh-permitted period. 75%, 50%, 25%, or 0% of the timeout period can be selected for the window end position. Set the window end position to a value less than the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is enabled.

IWDTRPSS[1:0] bits (IWDT Window Start Position Select)

The IWDTRPSS[1:0] bits specify the window start position that indicates the refresh-permitted period. 100%, 75%, 50%, or 25% of the timeout period can be selected for the window start position. Set the window start position to a value greater than the window end position. If the window start position is less than or equal to the window end position, the window end position is set to 0%.

Table 25.3 lists the counter values for the window start and end positions, and Figure 25.2 shows the refresh-permitted period set in the IWDTRPSS[1:0], IWDTRPES[1:0], and IWDTTOPS[1:0] bits.

The IWDTRSTIRQS bit specifies the behavior when an underflow or a refresh error occurs. Setting 1 selects reset output. Setting 0 selects non-maskable interrupt or interrupt.

IWDTRPES[1:0]位（IWDT窗口结束位置选择）

IWDTRPES[1:0]位指定指示刷新允许周期的窗口结束位置。可以为窗口结束位置选择75%、50%、25%或0%的超时时间。将窗口结束位置设置为小于窗口开始位置的值（窗口开始位置>窗口结束位置）。如果窗口结束位置大于窗口起始位置，则仅启用窗口起始位置设置。

IWDTRPSS[1:0]位（IWDT窗口起始位置选择）

IWDTRPSS[1:0]位指定指示刷新允许周期的窗口起始位置。窗口起始位置可选择100%、75%、50%或25%的超时时间。将窗口开始位置设置为大于窗口结束位置的值。如果窗口开始位置小于或等于窗口结束位置，则窗口结束位置设置为0%。

表25.3列出了窗口开始和结束位置的计数器值，图25.2显示了在IWDTRPSS[1:0]、IWDTRPES[1:0]和IWDTTOPS[1:0]位中设置的允许刷新周期。

IWDTSTPCTL bit (IWDT Stop Control)

The IWDTSTPCTL bit selects whether to stop counting on transition to Sleep, Snooze, or Software Standby mode.

25.3 Operation

25.3.1 Auto Start Mode

When the IWDT Start Mode Select bit (OFS0.IWDTSTRT) in the Option Function Select Register 0 is 0, auto start mode is selected, otherwise the IWDT is disabled.

Within the reset state, the setting values for the following in the Option Function Select Register 0 (OFS0) are set in the IWDT registers:

- Clock division ratio (OFS0.IWDTCKS[3:0])
- Window start and end positions (OFS0.IWDTRPSS[1:0], OFS0.IWDTRPES[1:0])
- Timeout period (OFS0.IWDTTOPS[1:0])
- Reset output or interrupt request (OFS0.IWDTRSTIRQS)

When the reset state is released, the counter automatically starts counting down from the value selected in the IWDT Timeout Period Select bits (OFS0.IWDTTOPS[1:0]).

After that, as long as the program continues normal operation and the counter is refreshed within the refresh-permitted period, the value in the counter is reset each time the counter is refreshed and down-counting continues. The IWDT does not output the reset signal as long as this procedure continues. However, if the counter underflows because the program crashed or because a refresh error occurred when an attempt is made to refresh outside the refresh-permitted period, the IWDT asserts the reset signal or non-maskable interrupt request/interrupt request (IWDT_NMIUNDF).

After the reset signal or non-maskable interrupt request/interrupt request is generated, the counter reloads the timeout period after counting for 1 cycle, the value of the timeout period is set in the down-counter and counting starts. The reset output or interrupt request output can be selected with the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS). Non-maskable interrupt request or interrupt request can be selected with the IWDT Underflow/Refresh Error Interrupt Enable bit (NMIER.IWDTEN).

Figure 25.3 shows an example of operation under the following conditions:

- Auto start mode (OFS0.IWDTSTRT = 0)
- Non-maskable interrupt request output is enabled (OFS0.IWDTRSTIRQS = 0)
- The window start position is 75% (OFS0.IWDTRPSS[1:0] = 10b)

IWDTSTPCTL位（IWDT停止控制）

IWDTSTPCTL位选择在转换到休眠、贪睡或软件待机模式时是否停止计数。

25.3 Operation

25.3.1 自动启动模式

当IWDT启动模式选择位置（OFS0.IWDTSTRT）中的选项函数选择寄存器0为0时，选择了自动启动模式，否则IWDT将被禁用。

在复位状态下，选项功能选择寄存器0(OFS0)中的以下设置值在
IWDT registers:

- ●时钟分频比（OFS0.IWDTCKS[3:0]）
- ●窗口开始和结束位置（OFS0.IWDTRPSS[1:0]、OFS0.IWDTRPES[1:0]）
- ●超时周期（OFS0.IWDTOPS[1:0]）
- ●复位输出或中断请求（OFS0.IWDTRSTIRQS）

解除复位状态后，计数器自动从IWDT中选择的值开始倒计时
超时周期选择位(OFS0.IWDTOPS[1:0])。

之后，只要程序继续正常运行，并且在允许刷新的时间内刷新计数器，每次刷新计数器并继续递减计数时，计数器中的值都会被复位。只要此过程继续，IWDT就不会输出复位信号。但是，如果由于程序崩溃或在刷新允许周期之外尝试刷新时发生刷新错误而导致计数器下溢，则IWDT将置位复位信号或不可屏蔽中断请求中断请求(IWDT_NMIUNDF)。

复位信号或不可屏蔽中断请求中断请求产生后，计数器在计数1个周期后重新加载超时周期，超时周期的值设置在递减计数器中并开始计数。可以通过IWDT复位中断请求选择位(OFS0.IWDTRSTIRQS)选择复位输出或中断请求输出。可以使用IWDT下溢刷新错误中断　　允许位(NMIER.IWDTEN)选择不可屏蔽的中断请求或中断请求。

图25.3显示了以下条件下的操作示例：

- ●自动启动模式（OFS0.IWDTSTRT=0）
- ●使能不可屏蔽中断请求输出（OFS0.IWDTRSTIRQS=0）
- ●窗口起始位置为75%(OFS0.IWDTRPSS[1:0]=10b)
- ●窗口结束位置为25%(OFS0.IWDTRPES[1:0]=10b)。

25.3.2 Refresh Operation

The down-counter is refreshed and operation starts (counting is started by refreshing) by writing the values 0x00 and 0xFF to the IWDT Refresh Register (IWDTRR). If a value other than 0xFF is written after 0x00, the down-counter is not refreshed. If an invalid value is written, correct refreshing resumes on a write of 0x00 and 0xFF to the IWDTRR.

When writes are made in the order of 0x00 (first time) → 0x00 (second time), and if 0xFF is written after that, the writing order 0x00 → 0xFF is satisfied. Writing 0x00 ((n - 1)th time) →0x00 (nth time) → 0xFF is valid, and the refresh is performed correctly. Even when the first value written before 0x00 is not 0x00, correct refreshing is performed as long as the operation contains the write sequence of 0x00 → 0xFF.

Correct refreshing is also performed regardless of whether a register other than IWDTRR is accessed or IWDTRR is read between writing 0x00 and writing 0xFF to IWDTRR. Writes to refresh the counter must be made within the refresh-permitted period. Whether writing is done within the refresh-permitted period is determined when 0xFF is written. For this reason, correct refreshing is performed even when 0x00 is written outside the refresh-permitted period.

[Example write sequences that are valid to refresh the counter]

- 0x00 → 0xFF
- 0x00 ((n - 1)th time) → 0x00 (nth time) → 0xFF
- 0x00 → access to another register or read from IWDTRR → 0xFF.

[Example write sequences that are not valid to refresh the counter]

- 0x23 (a value other than 0x00) → 0xFF
- 0x00 → 0x54 (a value other than 0xFF)

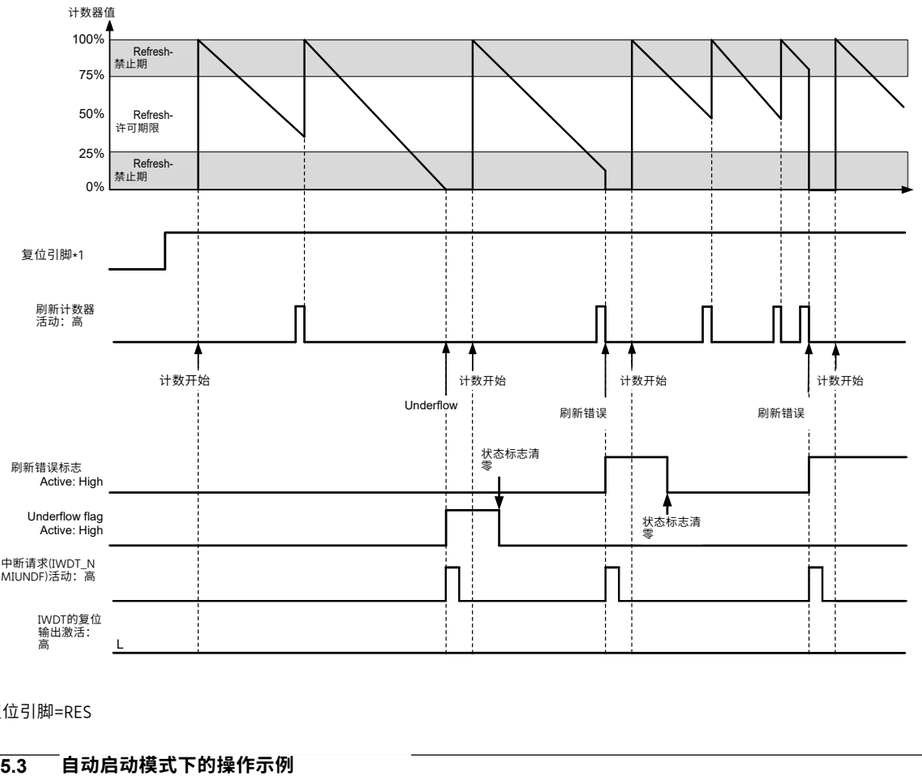

Figure 25.3 自动启动模式下的操作示例

25.3.2 刷新操作

通过将值0x00和0xFF写入IWDT刷新寄存器(IWDTRR)来刷新递减计数器并开始操作（通过刷新开始计数）。如果在0x00之后写入0xFF以外的值，则不刷新递减计数器。如果写入无效值，则在向IWDTRR写入0x00和0xFF时会恢复正确刷新。

当以0x00（第一次）→0x00（第二次）的顺序进行写入时，如果在此之后写入0xFF，则满足写入顺序0x00→0xFF。写入0x00((n1)次)→0x00(n次)→0xFF有效，刷新正确。即使在0x00之前写入的第一个值不是0x00时，只要操作包含0x00→0xFF的写入序列，就会执行正确的刷新。

无论在写入0x00和写入0xFF到IWDTRR之间是否访问IWDTRR以外的寄存器或读取IWDTRR，也会执行正确刷新。刷新计数器的写入必须在允许刷新的期限内进行。在写入0xFF时确定是否在可刷新周期内完成写入。因此，即使在可刷新期间外写入0x00，也会执行正确的刷新。

[对刷新计数器有效的示例写入序列]

- 0x00 → 0xFF
- 0x00 ((n - 1)th time) → 0x00 (nth time) → 0xFF
- ●0x00→访问另一个寄存器或从IWDTRR读取→0xFF。

[对刷新计数器无效的示例写入序列]

- ●0x23（0x00以外的值）→0xFF
- ●0x00→0x54（0xFF以外的值）

- 0x00 → 0xAA (0x00 and a value other than 0xFF) → 0xFF.

After 0xFF is written to the IWDTRR register, refreshing the counter requires up to 4 cycles of the signal for counting (the IWDT-Dedicated Clock Frequency Division Ratio Select bits (OFS0.IWDTCKS[3:0]) to determine how many cycles of the IWDT-dedicated clock (IWDTCLK) make up 1 cycle for counting. To meet this requirement, writing 0xFF to the IWDTRR must be completed 4 count cycles before the end of the refresh-permitted period or a down-counter underflow. The value of the counter can be checked with the counter bits (IWDTSR.CNTVAL[13:0]).

[Example refreshing timings]

- When the window start position is set to 0x1FFF, even if 0x00 is written to IWDTRR before 0x1FFF is reached at (0x2002, for example), refreshing occurs if 0xFF is written to IWDTRR after the value of the IWDTSR.CNTVAL[13:0] bits reaches 0x1FFF
- When the window end position is set to 0x1FFF, refreshing occurs if 0x2003 (4 count cycles before 0x1FFF) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 0x00 → 0xFF to IWDTRR
- When the refresh-permitted period continues until count 0x0000, refreshing can be performed immediately before an underflow. In this case, if 0x0003 (4 count cycles before an underflow) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 0x00 → 0xFF to IWDTRR, no underflow occurs and refreshing is performed.

Figure 25.4 shows the IWDT refresh-operation waveforms when PCLKB > IWDTCLK and the clock division ratio is IWDTCLK.

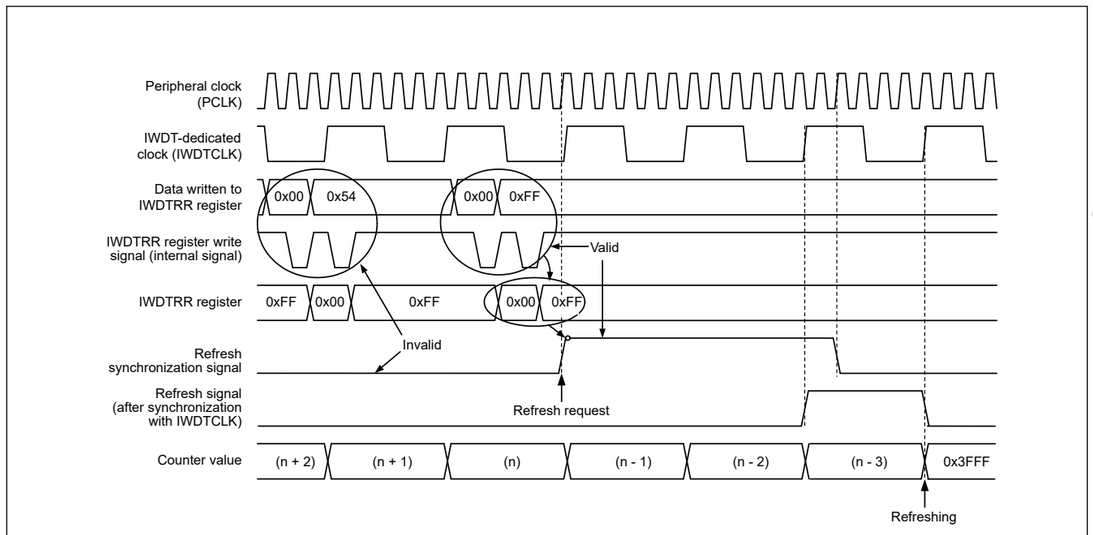

Figure 25.4 IWDT refresh operation waveforms when OFS0.IWDTCKS[3:0] = 0000b, OFS0.IWDTTOPS[1:0] = 11b

25.3.3 Status Flags

The refresh error (IWDTSR.REFEF) and underflow (IWDTSR.UNDFF) flags retain the source of the interrupt request from the IWDT. Therefore, after a release from the interrupt request generation, read the IWDTSR.REFEF and UNDFF flags to check for the interrupt source. For each flag, writing 0 clears the bit and writing 1 has no effect.

Leaving the status flags unchanged does not affect operation. If the flags are not cleared at the time of the next interrupt request from the IWDT, the earlier interrupt source is cleared and the new interrupt source is written. For the time period between when 0 is written in each flag and when its value is reflected, see section 25.2.2. IWDTSR : IWDT Status Register.

●0x00→0xAA（0x00和0xFF以外的值）→0xFF。

将0xFF写入IWDTRR寄存器后，刷新计数器需要最多4个周期的信号计数（IWDT专用时钟分频比选择位（OFS0.IWDTCKS[3:0]）来确定IWDT专用时钟(IWDTCLK)占1个周期用于计数。为满足此要求，必须在刷新允许周期结束或递减计数器下溢之前4个计数周期完成向IWDTRR写入0xFF。可以使用计数器位(IWDTSR.CNTVAL[13:0])检查计数器。

[Example refreshing timings]

●当窗口起始位置设置为0x1FFF时，即使在到达0x1FFF之前将0x00写入IWDTRR（例如0x2002），如果在IWDTSR.CNTVAL[13:0]位的值达到0x1FFF后将0xFF写入IWDTRR，则会发生刷新

●当窗口结束位置设置为0x1FFF时，如果在将0x00→0xFF写入IWDTRR后立即从IWDTSR.CNTVAL[13:0]位读取0x2003（0x1FFF之前的4个计数周期）或更大的值，则会发生刷新

●当刷新允许周期持续到计数0x0000时，可以在下溢之前立即执行刷新。在这种情况下，如果在将0x00→0xFF写入IWDTRR后立即从IWDTSR.CNTVAL[13:0]位读取0x0003（下溢前的4个计数周期）或更大的值，则不会发生下溢并执行刷新。

图25.4显示了当PCLKB>IWDTCLK且时钟分频比为时的IWDT刷新操作波形
IWDTCLK.

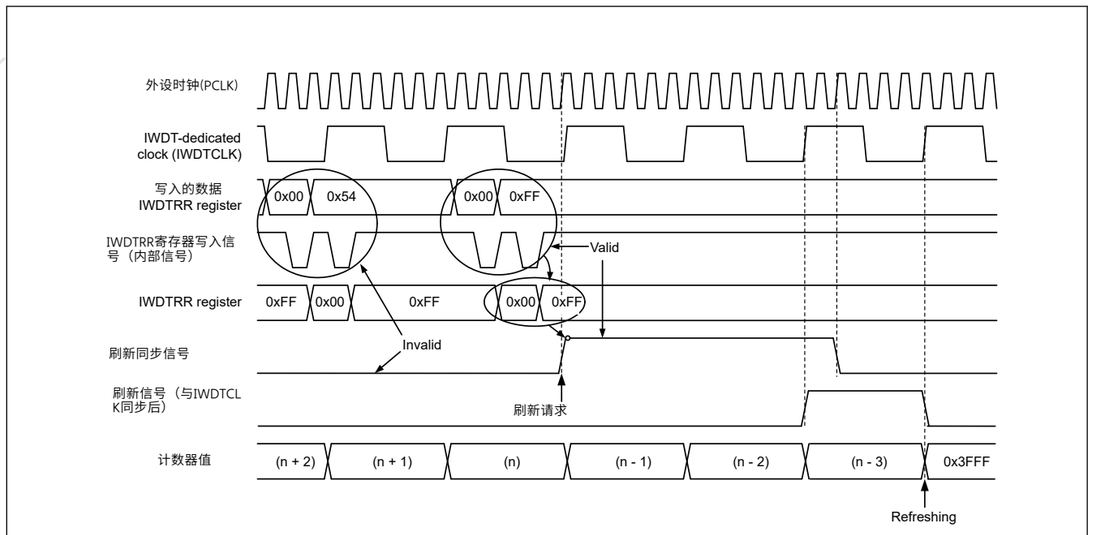

Figure 25.4 OFS0.IWDTCKS[3:0]=0000b OFS0.IWDTCKS[1:0]=11b时的IWDT刷新操作波形

25.3.3 状态标志

刷新错误(IWDTSR.REFEF)和下溢(IWDTSR.UNDFF)标志保留来自IWDT的中断请求源。因此，在中断请求生成释放后，读取IWDTSR.REFEF和UNDFF标志以检查中断源。对于每个标志，写入0清除该位，写入1无效。

保持状态标志不变不会影响操作。如果在IWDT发出下一个中断请求时未清除标志，则清除较早的中断源并写入新的中断源。关于从各标志写入0到反映其值的时间段，请参阅第25.2.2节。IWDTSR：IWDT状态寄存器。

25.3.4 Reset Output

When the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 1, a reset signal is output when an underflow in the counter or a refresh error occurs. Counting down automatically starts after the reset output.

25.3.5 Interrupt Sources

When the IWDT Reset Interrupt Request Select bit (OFS0.IWDTRSTIRQS) in the Option Function Select Register 0 (OFS0) is set to 0, an interrupt (IWDT_NMIUNDF) signal occurs when an underflow in the counter or a refresh error occurs. This interrupt can be used as a non-maskable interrupt or an interrupt. For details, see section 12, Interrupt Controller Unit (ICU).

Table 25.4 IWDT interrupt source

Name	Interrupt source	Interrupt to CPU	Start DMAC or DTC
IWDT_NMIUNDF	• Down-counter underflow • Refresh error	Possible	Not possible

25.3.6 Reading the Down-Counter Value

As the counter is a IWDT-dedicated clock (IWDTCLK), the counter value cannot be read directly. The IWDT synchronizes the counter value with the peripheral clock (PCLKB) and stores it in the down-counter value bits (IWDTSR.CNTVAL[13:0]) of the IWDT Status Register. Check these bits to obtain the counter value indirectly.

Reading the counter value requires multiple PCLKB clock cycles (up to 4 clock cycles), and the read counter value might differ from the actual counter value by a value of one count.

Figure 25.5 shows the processing for reading the IWDT counter value when PCLKB > IWDTCLK and the clock division ratio is IWDTCLK.

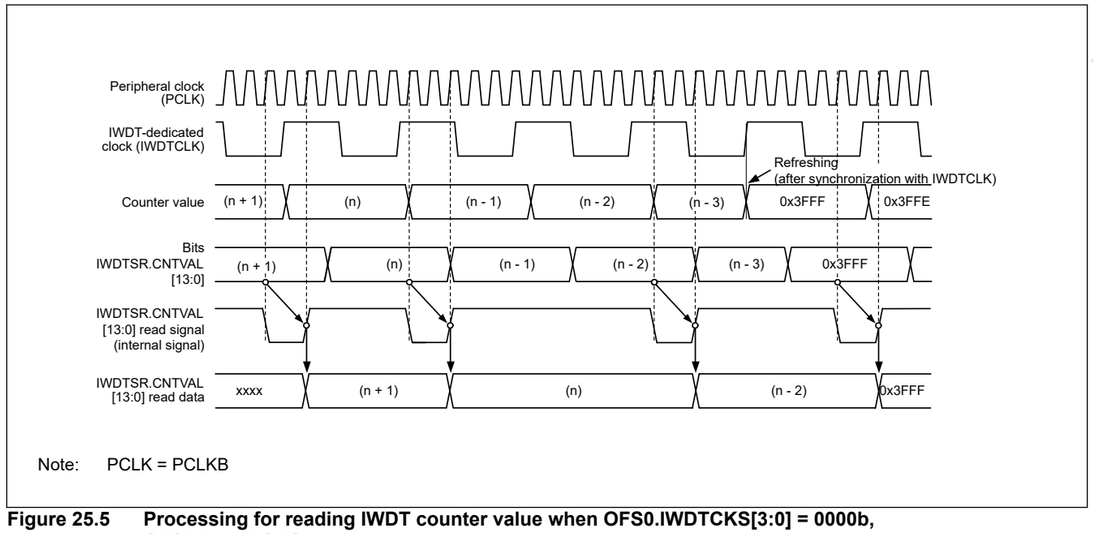

Figure 25.5 Processing for reading IWDT counter value when OFS0.IWDTCKS[3:0] = 0000b, OFS0.IWDTTOPS[1:0] = 11b

25.4 Output to the Event Link Controller (ELC)

The IWDT is capable of link operation for a specified module when the interrupt request signal is used as an event signal by the event link controller (ELC). The event signal is output by the counter underflow or refresh error.

An event signal is output regardless of the setting of the OFS0.IWDTRSTIRQS bit. An event signal can also be output at generation of the next interrupt source while the Refresh Error flag (IWDTSR.REFEF) or Underflow flag (IWDTSR.UNDFF) is 1. For details, see section 17, Event Link Controller (ELC).

25.3.4 复位输出

当IWDT重置中断请求选择位置（OFS0.IWDTRSTIRQS）中的选项函数选择寄存器0（OFS0）的位置为1时，当计数器中的下流或刷新错误发生时，将输出重置信号。复位输出后自动开始倒计时。

25.3.5 中断源

当IWDT重置中断请求选择位置（OFS0.IWDTRSTIRQS）中的选项函数选择寄存器0（OFS0）设置为0时，当计数器中的下流或刷新错误发生时，会发生中断（IWDT_NMIUNDF）信号。此中断可用作不可屏蔽中断或中断。有关详细信息，请参阅第12节，中断控制器单元(ICU)。

Table 25.4 IWDT中断源

Name	中断源	对CPU的中断	启动DMAC或DTC
IWDT_NMIUNDF	• Down-counter underflow • 刷新错误	Possible	不可能

25.3.6 读取递减计数器值

由于计数器是IWDT专用时钟(IWDTCLK)，因此无法直接读取计数器值。IWDT将计数器值与外设时钟(PCLKB)同步，并将其存储在IWDT状态寄存器的递减计数器值位(IWDTSR.CNTVAL[13:0])中。检查这些位以间接获得计数器值。

读取计数器值需要多个PCLKB时钟周期（最多4个时钟周期），读取的计数器值可能与实际计数器值相差一个计数值。

图25.5显示了当PCLKB>IWDTCLK且时钟分频比为IWDTCLK时读取IWDT计数器值的处理。

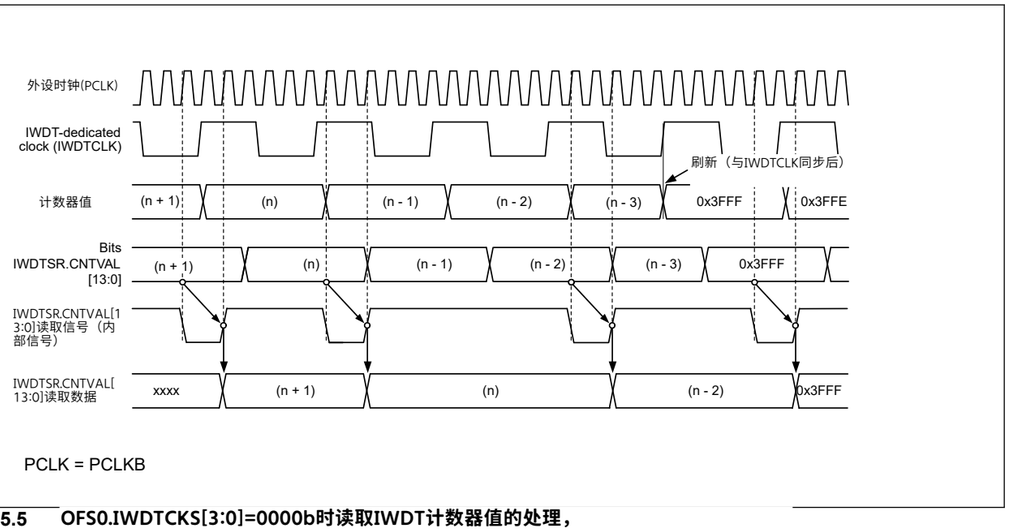

Figure 25.5 OFS0.IWDTCKS[3:0]=0000b时读取IWDT计数器值的处理，OFS0.IWDTTOPS[1:0] = 11b

25.4 输出到事件链接控制器(ELC)

当中断请求信号被事件链接控制器(ELC)用作事件信号时，IWDT能够对指定模块进行链接操作。事件信号由计数器下溢或刷新错误输出。

无论OFS0.IWDTRSTIRQS位的设置如何，都会输出事件信号。当刷新错误标志(IWDTSR.REFEF)或下溢标志(IWDTSR.UNDFF)为1时，也可以在生成下一个中断源时输出事件信号。有关详细信息，请参阅第17节，事件链接控制器(ELC)。

25.5 Usage Notes

25.5.1 Refresh Operations

While configuring the refresh time, consider variations in the range of errors given the accuracy of PCLKB and IWDTCLK. Set values that ensure refreshing is possible.

25.5.2 Clock Division Ratio Setting

Satisfy the frequency of the peripheral module clock (PCLKB) ≥ 4 × (the frequency of the count clock source after division).

25.5.3 Constraints on the ICU Event Link Setting Register n (IELSRn) Setting

Setting 0x52 to ICU Event Link Setting Register n (IELSRn.IELS[8:0]) is prohibited when enabling the IWDT reset assertion (OFS0.IWDTRSTIRQS = 0) or when enabling event link operation (ELSRn.ELS[8:0] = 0x52).

25.5 使用说明

26.2.1 RSR:接收移位寄存器

RSR是一个移位寄存器，它接收从RXDn引脚输入的串行数据并将其转换为并行数据。当接收到一帧数据时，数据会自动传输到RDR寄存器。CPU不能直接访问RSR寄存器。

In FIFO mode (CCR3.FM = 1), this register is 16-stage FIFO buffer configuration.

RDAT[8:0] bit (Serial receive data)

After one frame of data is received, the received data is transferred from the RSR register to this register, thus allowing the RSR register to receive the next data.

The RSR and RDR registers have a double-buffered construction to enable continuous reception.

For Non-FIFO mode, read RDR only once when a receive data full interrupt (SCIn_RXI) request is issued. Without reading received data from RDR, if the next one frame is received, an overrun error occurs.

For FIFO mode, continuous reception is executed until 16 stages are stored. If data is read when there is no received data in the receive-FIFO(RDR), the value is undefined. When the receive-FIFO (RDR) are full of received data, subsequent serial receive data is lost.

The CPU cannot write to RDR.

在FIFO模式（CCR3.FM=1）下，该寄存器为16级FIFO缓冲器配置。

RDAT[8:0]位（串行接收数据）

接收到一帧数据后，将接收到的数据从RSR寄存器传送到该寄存器，从而允许RSR寄存器接收下一个数据。

RSR和RDR寄存器具有双缓冲结构以实现连续接收。

对于非FIFO模式，在发出接收数据完整中断(SCIn_RXI)请求时仅读取一次RDR。如果不从RDR读取接收到的数据，如果接收到下一帧，则会发生溢出错误。

对于FIFO模式，执行连续接收直到存储16个阶段。如果在接收FIFO(RDR)中没有接收到数据时读取数据，则该值未定义。当接收FIFO(RDR)充满接收数据时，后续串行接收数据将丢失。

CPU无法写入RDR。

0 is stored in the bit position which isn't received (RDR.bit8 or RDR.bit7) at the time of 7bit or 8bit communication of Asynchronous and Manchester mode.

MPB bit (Multi-processor flag)

In Asynchronous mode and Manchester mode, during multi-processor communication (CCR3.MP = 1), the value of the multi-processor bit corresponding to the received data (RDAT[8:0]) can be read.

FPER bit (FIFO parity error flag)

Indicates whether the data read from the receive-FIFO has a parity error.

0 is stored for non-FIFO mode.

FFER bit (FIFO framing error flag)

Indicates whether the data read from receive-FIFO has a framing error.

0 is stored for non-FIFO mode.

In FIFO mode (CCR3.FM = 1), this register is 16-stage FIFO buffer configuration.

TDAT[8:0] bit (Serial transmit data)

The TDR is a 9-bit register for storing transmit data.

When empty space is detected in the TSR register, the transmit data stored in the TDR registers is transferred to TSR, and transmitting is started.

在FIFO模式（CCR3.FM=1）下，该寄存器为16级FIFO缓冲器配置。

TDAT[8:0]位（串行发送数据）

TDR是一个9位寄存器，用于存储发送数据。

当在TSR寄存器中检测到空空间时，存储在TDR寄存器中的发送数据被传送到TSR，并开始发送。

The TSR and TDR registers have a double-buffered construction to realize continuous reception. When the next data to be transmitted is stored in TDR after one frame of data has been transmitted, the transmitting operation is continued by transfer to the TSR register.

When the SCI detects that the transmit shift register (TSR) is empty, it transmits data written in the transmit-FIFO (TDR) into TSR and starts serial transmission. Continuous serial transmission is executed until there is no transmit data left in the transmit-FIFO (TDR).

For non-FIFO mode, when a transmit data empty interrupt (SCIn_TXI) request is issued and CCR0.TE is 1, write transmit data to the TDR only once.

For FIFO mode, when transmit-FIFO is full of transmit data 16 frames, no more data can be written. If writing of new data is attempted, the data is ignored.

The TDR register can always be read / written from the CPU. And when byte access, write TDR[15:8] and then write TDR[7:0].

MPBT bit (Multi-processor transfer bit flag)

Selects the multi processor bit of transmit frame.

TSYNC bit (Transmit SYNC data)

When Manchester mode and MCR.SBSEL = 1 and MCR.SYNSEL = 1, the type of SYNC selected according to this bit becomes the Start Bit of the transmission frame.

26.2.4 TSR : Transmit Shift Register

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first automatically transfers transmit data from TDR to TSR, then sends the data to the TXDn pin. The CPU cannot directly access the TSR.

26.2.5 CCR0 : Common Control Register 0

Base address: SCI_Bn = 0x4011_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x08

TSR和TDR寄存器具有双缓冲结构以实现连续接收。在发送一帧数据后，当下一个要发送的数据存储在TDR中时，通过传输到TSR寄存器继续发送操作。

当SCI检测到发送移位寄存器(TSR)为空时，它将写入发送FIFO(TDR)的数据发送到TSR并开始串行发送。执行连续串行传输，直到传输FIFO(TDR)中没有传输数据。

对于非FIFO模式，当发出发送数据空中断(SCIn_TXI)请求且CCR0.TE为1时，仅将发送数据写入TDR一次。

对于FIFO模式，当传输FIFO充满传输数据16帧时，不能再写入数据。如果尝试写入新数据，则忽略该数据。

TDR寄存器总是可以从CPU读取写入。并且当字节访问时，写入TDR[15:8]然后写入TDR[7:0].

MPBT位（多处理器传输位标志）

选择发送帧的多处理器位。

TSYNC位（发送SYNC数据）

当曼彻斯特模式和MCR.SBSEL=1且MCR.SYNSEL=1时，根据该位选择的SYNC类型成为传输帧的起始位。

26.2.4 TSR：发送移位寄存器

TSR是传送串行数据的移位寄存器。为了进行串行数据传输，SCI首先自动将发送数据从TDR传输到TSR，然后将数据发送到TXDn引脚。CPU不能直接访问TSR。

Note 1. In clock-synchronous mode (CCR3.MOD[2:0] = 010b), Simple SPI mode (CCR3.MOD[2:0] = 011b), and Simple IIC mode (CCR3.MOD[2:0] = 100b), 1 can be written only when TE = 0 and RE = 0. After setting TE or RE to 1, only 0 can be written in TE and RE In other mode, writing is enabled under any condition.

Note 2. This bit is a bit that is cleared by hardware. Note that writing to a bit other than this bit with a bit manipulation instruction may cause this bit to be unintentionally set to 1 by a read-modify-write operation.

Note 3. In clock synchronous mode and Simple SPI mode, receive only setting is prohibited in the internal clock (master mode) (TE = 0 and RE = 1 setting prohibited).

RE bit (Receive Enable)

Enables or disables serial receive operation.

When this bit is set to 1, serial reception becomes possible after the synchronization delay time has elapsed in asynchronous mode or the synchronous clock input in clock synchronous mode or the neg-edge of RXDn in manchester mode or start bit in smart-card-interface-mode.

Note that CCR3 should be set prior to setting the RE bit to 1 in order to designate the reception format.

Except smart-card-interface-mode, even if reception is halted by setting the RE bit to 0, the CSR. RDRF, FER, PER, ORER, MSR.MER, SBER, SYER, PFER, FRSR. DR flags are not affected, and the previous values is retained. In smart-card-interface-mode, even if reception is halted by setting the RE bit to 0, the CSR.FER, PER, ORER flags are not affected and the previous value is retained. Also, to stop the reception operation, synchronization delay time will be required from when the RE bit is set to 0 until the reception operation is stopped.

注1.在时钟同步模式(CCR3.MOD[2:0]=010b)、简单SPI模式(CCR3.MOD[2:0]=011b)和简单IIC模式下(CCR3.MOD[2:0]=100b)，只有TE=0和RE=0时才能写1。设置TE或RE为1后，TE和RE只能写0，其他模式下，写为在任何条件下启用。

注2.该位由硬件清零。请注意，使用位操作指令写入该位以外的位可能会导致该位被读取-修改-写入操作无意中设置为1。

注3.在时钟同步模式和简单SPI模式下，内部时钟（主机模式）（TE=0和RE=1禁止设置）。

RE位（接收使能）

启用或禁用串行接收操作。

当此位设置为1时，在异步模式下经过同步延迟时间或时钟同步模式下同步时钟输入或曼彻斯特模式下RXDn的下降沿或智能卡接口中的起始位之后，串行接收变为可能-模式。

请注意，为了指定接收格式，应在将RE位设置为1之前设置CCR3。

除了智能卡接口模式，即使通过将RE位设置为0来停止接收，CSR。RDRF、FER、PER、ORER、MSR.MER、SBER、SYER、PFER、FRSR。DR标志不受影响，并且保留以前的值。在智能卡接口模式下，即使通过将RE位设置为0来停止接收，CSR.FER、PER、ORER标志也不受影响，并且保留之前的值。此外，为了停止接收操作，从RE位设置为0到停止接收操作需要同步延迟时间。

TE bit (Transmit Enable)

Enables or disables serial transmission.

When this bit is set to 1, serial transmission becomes possible after the synchronization delay time has elapsed. After the synchronization delay time, transmission is started by writing transmit data to TDR. Note that CCR3 should be set prior to setting the TE bit to 1 in order to designate the transmission format. In addition, the synchronization delay time is required until the transmission control circuit is stopped after the TE bit is set to 0.

MPIE bit (Multi-Processor Interrupt Enable)

When this bit is set to 1 and the data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags (CSR.RDRF, ORER, FER, FRSR, DR, MSR.MER, SYER, PFER, SBER) are disabled.

When the data with the multi-processor bit set to 1 is received, the MPIE is automatically cleared to 0, and normal reception is resumed. For details, refer to section 26.4. Multi-Processor Communication Function. If you want to continue receiving operation using the multiprocessor function, set this bit to 1 sufficiently earlier than receiving the STOP bit of the next received frame.

When the receive data includes the MPB bit set to 0, the receive data is not transferred from the RSR to the RDR, a receive error is not detected, and setting the flags ORER, FER, MER, SYER, PFER, and SBER to 1 is disabled.

When the receive data includes the MPB bit set to 1, the MPB bit is set to 1, the MPIE bit is automatically cleared to 0, the SCIn_RXI and SCIn_ERI interrupt requests are enabled (if CCR0.RIE is set to 1), and setting the flags ORER, FER, MER, SYER, PFER, and SBER to 1 is enabled.

MPIE should be set to 0 if multi-processor communications function is not to be used.

DCME bit (Data Compare Match Enable)

It can select whether the Address match function (data compare match function) uses or not.

When DCME is 1, if SCI detects the match to the comparison data (CCR4.CMPD) with receive data, DCME is cleared automatically, and after that, SCI operation mode will be receive mode without data compare match function.

Refer to section 26.3.6. Address Match (Receive Data Match Detection) Function.

The write value should be 0 other than asynchronous mode.

IDSEL bit (ID frame select)

It can select whether it is compared in spite of the value of MPB bit or it's compared only the data of MPB bit = 1 (ID frame) when the Address match function is valid. Please set at the same time as DCME.

RIE bit (Receive Interrupt Enable)

Enables or disables SCIn_RXI and SCIn_ERI interrupt requests.

SCIn_RXI and SCIn_ERI interrupt request is disabled by setting the RIE bit to 0.

An SCIn_ERI interrupt request can be canceled by reading 1 from the CSR.ORER, FER, or PER and then setting the flag to 0 or setting the RIE bit to 0.

In the case of Manchester mode, the MER, SYER, PFER and SBER flags are also the cause of SCIn_ERI interrupt request, so the same processing is necessary. For details of these flags, see section 26.2.12. MCR : Manchester Control Register and section 26.2.21. MSR : Manchester Status Register.

TIE bit (Transmit Interrupt Enable)

Enables or disables SCIn_TXI interrupt request.

An SCIn_TXI interrupt request is disabled by setting the TIE bit to 0. At the beginning of transmission, set 1 to CCR0.TE and CCR0.TIE simultaneously. Then the SCIn_TXI interrupt request is generated.

TEIE bit (Transmit End Interrupt Enable)

Enables or disables a SCIn_TEI interrupt request. A SCIn_TEI interrupt request is disabled by setting the TEIE bit to 0.

In simple IIC mode, the SCIn_TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STIn). In this case, the TEIE bit can be used to enable or disable the STIn.

TE位（发送使能）

启用或禁用串行传输。

当该位设置为1时，经过同步延迟时间后可以进行串行传输。在同步延迟时间之后，通过将发送数据写入TDR开始发送。请注意，为了指定传输格式，应在将TE位设置为1之前设置CCR3。此外，在将TE位设置为0后，直到传输控制电路停止为止需要同步延迟时间。

MPIE位（多处理器中断允许）

当该位设置为1并且接收到多处理器位设置为0的数据时，不读取数据并设置状态标志（CSR.RDRF、ORER、FER、FRSR、DR、MSR.MER、SYER PFER SBER)被禁用。

当接收到多处理器位设置为1的数据时，MPIE自动清零，恢复正常接收。详情请参阅26.4节。多处理器通信功能。如果要继续使用多处理器功能进行接收操作，请在接收到下一接收帧的STOP位之前将该位设置为1。

当接收数据包括MPB位设置为0时，接收数据不从RSR传输到RDR，未检测到接收错误，并将标志ORER、FER、MER、SYER、PFER和SBER设置为1被禁用。

当接收数据包括MPB位设置为1时，MPB位设置为1，MPIE位自动清为0，启用SCIn_RXI和SCIn_ERI中断请求（如果CCR0.RIE设置为1），并设置标志ORER、FER、MER，
启用SYER、PFER和SBER为1。

如果不使用多处理器通信功能，则MPIE应设置为0。

DCME位（数据比较匹配使能）

可以选择是否使用地址匹配功能（数据比较匹配功能）。

当DCME为1时，如果SCI检测到比较数据（CCR4.CMPD）与接收数据匹配，则DCME自动清零，之后SCI操作模式将变为无数据比较匹配功能的接收模式。

请参阅第26.3.6节。地址匹配（接收数据匹配检测）功能。

除异步模式外，写入值应为0。

IDSEL位（ID帧选择）

当地址匹配功能有效时，可以选择不管MPB位的值是比较还是只比较MPB位=1（ID帧）的数据。请与DCME同时设置。

RIE位（接收中断允许）

启用或禁用SCIn_RXI和SCIn_ERI中断请求。

通过将RIE位设置为0来禁用SCIn_RXI和SCIn_ERI中断请求。

SCIn_ERI中断请求可以通过从CSR.ORER、FER或PER读取1然后将标志设置为0或将RIE位设置为0来取消。

在曼彻斯特模式的情况下，MER、SYER、PFER和SBER标志也是SCIn_ERI中断请求的原因，因此需要进行相同的处理。有关这些标志的详细信息，请参阅第26.2.12节。MCR：曼彻斯特控制寄存器和第26.2.21节。MSR：曼彻斯特状态寄存器。

TIE位（发送中断允许）

启用或禁用SCIn_TXI中断请求。

通过将TIE位设置为0来禁用SCIn_TXI中断请求。在传输开始时，同时将CCR0.TE和CCR0.TIE设置为1。然后产生SCIn_TXI中断请求。

TEIE位（发送结束中断允许）

启用或禁用SCIn_TEI中断请求。通过将TEIE位设置为0来禁用SCIn_TEI中断请求。

在简单IIC模式下，SCIn_TEI在完成发出启动、重启或停止条件(STIn)时分配给中断。在这种情况下，TEIE位可用于启用或禁用STIn。

SSE bit (SSn Pin Function Enable)

Set this bit to 1 if the SSn pin is to be used in control of transmission and reception (in simple SPI mode).

Set this bit to 0 in any other mode. Do not set both the SSE and CTSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

In the slave mode (CCR3.CKE[1:0] = 10 or 11), SSE should be set 1.

In the master mode (CCR3.CKE[1:0] = 00 or 01) and single-master, the SSn pin on the master side is not required to control reception and transmission, so SSE should be set 0.

SSE位（SSn引脚功能使能）

如果SSn引脚用于控制发送和接收（在简单SPI模式下），则将该位设置为1。

在任何其他模式下将此位设置为0。不要将SSE和CTSE位都设置为使能（即使进行了此设置，操作与这些位设置为0时的操作相同）。

在从机模式下（CCR3.CKE[1:0]=10或11），SSE应设置为1。

在主机模式（CCR3.CKE[1:0]=00或01）和单主机下，主机侧的SSn引脚不需要控制接收和发送，因此SSE应设置为0。

Note 1. Please use this bit in asynchronous mode and manchester mode only. Movement by other mode isn't guaranteed.

CTSE bit (CTS Enable)

Set this bit to 1 if the SSn pin is to be used for inputting of the CTSn control signal to control of transmission and reception. The RTSn signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, Simple LIN mode, and simple IIC mode. Do not set both the CTSE and SSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

CTSPEN bit (CTS external pin Enable)

When CTSE is 1, select the terminals usage method when using the CTS and RTS functions. Set this bit to 1 when assigning the CTS/RTS function to 2 terminals and using them at the same time. Set it to 0 except in Asynchronous and Manchester modes.

注1.请仅在异步模式和曼彻斯特模式下使用该位。不能保证通过其他模式移动。
注2.RINVTINV在智能卡接口模式和简单IIC模式下应设置为0。

CTSE bit (CTS Enable)

如果SSn引脚用于输入CTSn控制信号以控制发送和接收，则将该位设置为1。当该位设置为0时输出RTSn信号。在智能卡接口模式、简单SPI模式、简单LIN模式和简单IIC模式下将该位设置为0。不要将CTSE和SSE位都设置为使能（即使进行了此设置，操作与将这些位设置为0时的操作相同）。

CTSPEN位（CTS外部引脚使能）

CTSE为1时，选择使用CTS和RTS功能时的终端使用方式。当将CTSRTS功能分配给2个端子并同时使用它们时，将此位设置为1。除异步和曼彻斯特模式外，将其设置为0。

Table 26.3 shows the relationship between the CTSE bit and CTSPEN bit settings and the functions of the CTSn_RTSn pin and CTSn pin.

Note: Please set CTSPEN bit = 0 when CTSE bit = 0.

SPB2DT bit (Serial port break data select), SPB2IO bit (Serial port break I/O)

The TXDn terminal status decided by combination of CCR0.TE bit, CCR1.SPB2IO bit and CCR1.SPB2DT bit is indicated in Table 26.4.

0	1	0	Low level output
0	1	1	High level output
1	—	—	Serial transmission data is output.

Note: —: Don't care

PE bit (Parity Enable)

When PE bit to 1, the parity bit is added to transmit data before transmission, and the parity bit is checked in reception. In the multiprocessor format, the parity bit is not added or checked regardless of this bit setting.

PM bit (Parity Mode)

Selects the parity mode for transmission and reception (even or odd). In multi-processor mode, this bit is invalid.

For details on the usage of this bit in smart card interface mode, refer to section 26.7.2. Data Format (Except in Block Transfer Mode).

TINV bit (TXD invert), RINV bit (RXD invert)

The data of RDR is controlled by RINV and CCR3.SINV. And the data from TXDn terminal is controlled by TINV and CCR3.SINV. The control by RINV/TINV are done to communication terminals (RXDn / TXDn), so they can control not only data-bits but also other bits (start bit, stop bit, parity bit). Please refer to Figure 26.3 in detail.

During half-duplex communication and slave operation in simple SPI mode, use the TXDn pin for reception, so set the inversion control of the received data with the TINV bit.

Note: Sentences and a timing chart of the IP operation explanation are mentioned by TINV = 0 and RINV = 0 when TINV's value and RINV's value are not specified.

Note: 当CTSE位=0时，请设置CTSPEN位=0。

SPB2DT位（串口断点数据选择）、SPB2IO位（串口断点IO）

由CCR0.TE位、CCR1.SPB2IO位和CCR1.SPB2DT位组合决定的TXDn端子状态如表26.4所示。

Note: —: Don't care

PE位（奇偶校验使能）

当PE位为1时，发送数据前添加奇偶校验位，接收时校验奇偶校验位。

在多处理器格式中，无论此位设置如何，都不会添加或检查奇偶校验位。

PM bit (Parity Mode)

选择发送和接收的奇偶校验模式（偶数或奇数）。在多处理器模式下，该位无效。

关于该位在智能卡接口模式下的使用详情，请参阅第26.7.2节。数据格式（块中除外 Transfer Mode).

TINV bit (TXD invert), RINV bit (RXD invert)

RDR的数据由RINV和CCR3.SINV控制。来自TXDn端的数据由TINV和CCR3.SINV控制。RINVTINV的控制是对通信终端（RXDnTXDn）进行的，因此它们不仅可以控制数据位，还可以控制其他位（起始位、停止位、奇偶校验位）。详细请参考图26.3。

在简单SPI模式下的半双工通信和从机操作期间，使用TXDn引脚进行接收，因此通过TINV位设置接收数据的反转控制。

Note: 当没有指定TINV的值和RINV的值时，TINV=0和RINV=0提到了IP操作说明的语句和时序图。

Figure 26.3 Example of the receive or transmit data control

SPLP bit (Loopback Control)

When this bit is 1, SCI blocks the input path from RXDn and connects the output path to TXDn to the reception data register.

Transmit data can be inverted and received by combining it with TINV bit.

Clock synchronous mode at slave operation, Asynchronous mode when using an external clock, and Simple LIN mode, set this bit to 0.

SHARPS bit (Half-duplex communication select)

Setting this bit to 1 enables half-duplex communication using the TXDn pin. However, it cannot be used in Simple SPI mode, Simple IIC mode and Smart Card Interface mode.

If this bit is set to 1 and CCR0.TE = 1, CCR0.RE = 0, the TXDn pin becomes communication output. If this bit is set to 1 and CCR0.TE = 0, CCR0.RE = 1, the TXDn pin becomes the communication input. For details, see section 26.18. Half-Duplex communication Function.

Figure 26.3 接收或发送数据控制示例

SPLP bit (Loopback Control)

当该位为1时，SCI阻塞来自RXDn的输入路径，并将输出路径连接到TXDn和接收数据寄存器。

发送数据可以通过与TINV位组合来反转和接收。

从机操作时的时钟同步模式、使用外部时钟时的异步模式和简单LIN模式，将此位设置为0。

SHARPS位（半双工通信选择）

将该位设置为1启用使用TXDn引脚的半双工通信。但是，它不能用于简单SPI模式、简单IIC模式和智能卡接口模式。

如果该位设置为1且CCR0.TE=1，CCR0.RE=0，则TXDn引脚变为通信输出。如果该位设置为1且CCR0.TE=0，CCR0.RE=1，则TXDn引脚变为通信输入。有关详细信息，请参阅第26.18节。半双工通信功能。

NFCS[2:0] bit (Noise Filter Clock Select)

These bits select the sampling clock for the digital noise filter.

To use the noise filter in asynchronous mode, manchester mode and Simple LIN mode set these bits from 000b to 100b. In simple IIC mode, set the bits to a value in the range from 001b to 100b.

NFEN bit (Digital Noise Filter Function Enable)

This bit enables or disables the digital noise filter function. When the function is enabled, noise cancellation is applied to the RXDn input signal in asynchronous mode, manchester mode, Simple LIN mode, and noise cancellation is applied to the SDAn and SCLn input signals in simple IIC mode. In any mode other than above, set the NFEN bit to 0 to disable the digital noise filter function. When the function is disabled, input signals are transferred as is, as internal signals.

BCP[2:0] bit (Base Clock Pulse)

These bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode.

For details, refer to section 26.7.4. Receive Data Sampling Timing and Reception Margin.

BGDM bit (Baud Rate Generator Double-Speed Mode Select)

This bit is valid when the on-chip baud rate generator is selected as the clock source (CCR3.CKE[1] = 0) in asynchronous mode, Manchester mode, clock synchronous mode, Simple SPI mode. When external clock is selected (CCR3.CKE[1] = 1), set it to 0. For the clock output from the baud rate generator, either single or doubled frequency can be selected. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved, and the bit rate is doubled.

Set this bit to 0 in modes other than asynchronous mode or Manchester mode or clock synchronous mode or Simple SPI mode.

ABCS bit (Asynchronous Mode Base Clock Select)

Selects the clock cycles for 1-bit period.

Set it to 0 in modes other than Asynchronous mode, Manchester mode and Simple LIN mode.

ABCSE bit (Asynchronous Mode Extended Base Clock Select)

The pulse number for a base clock at 1-bit period is 6 and the clock of a double frequency is output from baud rate generator. Only when the bit rate is set to 6 dividing frequency of the bus clock, please use this bit and set CCR2.CKS [1:0] = 00b and BRR[7:0] = 0x00.

Set it to 0 in modes other than asynchronous mode. Even in asynchronous mode, set it to 0 when using external clock.

BRR[7:0] bit (Bit rate setting)

BRR is an 8-bit register that adjusts the bit rate.

SCI has independent baud rate generator control, different bit rates can be set for each. Table 26.6 shows the relation-ship between the setting (N) in the BRR and the bit rate (B) for asynchronous mode, multiprocessor transfer, Manchester mode, clock synchronous mode, smart card interface mode, simple SPI mode, and simple IIC mode.

BCP[2:0]位（基本时钟脉冲）

这些位选择智能卡接口模式下1位数据传输时间内的基本时钟周期数。

详情请参阅26.7.4节。接收数据采样时序和接收余量。

BGDM位（波特率发生器双速模式选择）

在异步模式、曼彻斯特模式、时钟同步模式、简单SPI模式选择片内波特率发生器作为时钟源（CCR3.CKE[1]=0）时，该位有效。Whenexternalclockisselected(CCR3.CKE[1]=1) setitto0.Fortheclockoutputfromthebaudrategenerator eithersingleordoubledfrequencycanbeselected.基本时钟由波特率发生器的时钟输出生成。当BGDM位设置为1时，基本时钟周期减半，比特率加倍。

在异步模式或曼彻斯特模式或时钟同步模式或简单SPI模式以外的模式下将此位设置为0。

ABCS位（异步模式基本时钟选择）

选择1位周期的时钟周期。

在异步模式、曼彻斯特模式和简单LIN模式以外的模式下将其设置为0。

ABCSE位（异步模式扩展基本时钟选择）

1位周期的基本时钟脉冲数为6，从波特率发生器输出双频时钟。只有当比特率设置为总线时钟的6分频时，请使用该位并设置CCR2.CKS[1:0]=00b和BRR[7:0]=0x00。

在异步模式以外的模式下将其设置为0。即使在异步模式下，使用外部时钟时也将其设置为0。

Examples of BRR (N) settings in clock synchronous mode and simple SPI mode are listed in Table 26.15. Examples of BRR (N) settings in smart card interface mode are listed in Table 26.17. For details, refer to section 26.7.4. Receive Data Sampling Timing and Reception Margin. Table 26.14 and Table 26.16 list the maximum bit rates with external clock input.

When either the asynchronous mode base clock select bit (ABCS) or the baud rate generator double-speed mode select bit (BGDM) is set to 1 in asynchronous mode and manchester mode, the bit rate becomes twice that listed in Table 26.10 and Table 26.11. When both of those registers are set to 1, the bit rate becomes four times the listed value.

表26.10和表26.11列出了BRR在异步模式和曼彻斯特模式下的N设置示例。表26.12列出了每个工作频率可设置的最大比特率。表26.15列出了时钟同步模式和简单SPI模式下的BRR(N)设置示例。智能卡接口模式下的BRR(N)设置示例在表26.17中列出。简单IIC模式下的BRR(N)设置示例如表26.19所示。在智能卡接口模式下，可以选择1位数据传输时间内的基本时钟周期数S。详情请参阅26.7.4节。接收数据采样时序和接收余量。表26.14和表26.16列出了外部时钟输入的最大比特率。

在异步模式和曼彻斯特模式下，当异步模式基本时钟选择位(ABCS)或波特率发生器双速模式选择位(BGDM)设置为1时，比特率变为表26.10和表26.11中列出的两倍.当这两个寄存器都设置为1时，比特率变为所列值的四倍。

BRME bit (Bit Modulation Enable)

Enables and disables the bit rate modulation function. The bit rate generated by on-chip baud rate generator is evenly corrected when this function is enabled.

Set to 0 in Clock-synchronous mode, Simple SPI mode, Smart Card Interface mode, Manchester mode and Simple LIN mode.

CKS[1:0] bit (Clock Select)

These bits select the clock source for the on-chip baud rate generator.

For the relationship between the settings of these bits and the baud rate, refer to BRR[7:0] bits explanation.

MDDR[7:0] bit (Modulation Duty Setting)

When the BRME bit is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected according to the settings of MDDR (M/256). The relationship between the MDDR setting (M) and the bit rate (B) is given in Table 26.21.

The initial value of MDDR is FFh. Bit 7 in this register is fixed to 1.

BRME位（位调制使能）

启用和禁用比特率调制功能。该功能使能时，片内波特率发生器产生的比特率得到均匀校正。

在时钟同步模式、简单SPI模式、智能卡接口模式、曼彻斯特模式和简单LIN模式下设置为0。

CKS[1:0] bit (Clock Select)

这些位选择片内波特率发生器的时钟源。

这些位的设置与波特率的关系请参考BRR[7:0]位说明。

MDDR[7:0]位（调制占空比设置）

当BRME位设置为1时，片内波特率发生器产生的比特率根据MDDR(M256)的设置进行均匀校正。MDDR设置(M)和比特率(B)之间的关系在表26.21中给出。

MDDR的初始值为FFh。该寄存器的第7位固定为1。

Note 1. In other than asynchronous mode and manchester mode, this bit setting is invalid and a fixed data length of 8 bits is used. In the Simple LIN mode, only the data length of 8 bits can be used, so set it to the initial value.
Note 2. LSB first is fixed and the MSB (bit 7) in TDR is not transmitted in transmission.

CPHA bit (Clock Phase Select)

This bit selects the phase of the clock signal output through the SCKn pin. Refer to Figure 26.97 in details.

Set the bit to 1 in other than simple SPI mode and clock synchronous mode.

CPOL bit (Clock Polarity Select)

This bit selects the polarity of the clock signal output through the SCKn pin. Refer to Figure 26.97 in details.

Set the bit to 1 in other than simple SPI mode and clock synchronous mode.

BPEN bit (Synchronizer bypass enable)

The synchronization circuit can be bypassed by this bit only when the same clock is input to the bus clock and the operation clock (TCLK). Refer to section 26.19. Synchronizer Bypass Function in details.

Usage Notes about this bit setting, please refers to section 26.20.17. Notes on CCR3.BPEN bit setting for more detail.

CHR[1:0] bit (Character Length)

Selects the data length for transmission and reception.

Except of asynchronous mode and manchester mode, a fixed data length of 8 bits is used.

LSBF bit (LSB First select)

Select whether to transmit/receive data in MSB first or LSB first.

SINV bit (Transmitted/Received Data Invert)

SINV can invert the transmit data-bit from TDR to TSR, and can invert the received data from RSR to RDR. This bit does not affect the logic level of the parity bit. To invert the parity bit, invert the CCR1.PM.

STP bit (Stop Bit Length)

Selects the stop bit length in transmission.

In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

In addition, it is used as Break Delimiter length setting when sending Start Frame in simple LIN mode.

RXDESEL bit (Asynchronous Start Bit Edge Detection Select)

Selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data receiving operation depends on the settings of this bit. Set this bit to 1 when reception should be stopped while a break occurs or when reception should be started without retaining the RXDn pin input at high level for the period of one data frame or longer after completion of the break.

Set this bit to 1 in Simple LIN mode. Set this bit to 0 in modes except of asynchronous mode and Simple LIN mode.

MOD[2:0] bit (Communication mode select)

Selects the SCI communication mode.

注1.除异步模式和曼彻斯特模式外，该位设置无效，使用8位固定数据长度。在里面
简易LIN模式，只能使用8位的数据长度，所以设置为初始值。
注2.LSB在前是固定的，TDR中的MSB（第7位）在传输中不传输。

CPHA位（时钟相位选择）

该位选择通过SCKn引脚输出的时钟信号的相位。详见图26.97。

在简单SPI模式和时钟同步模式以外的情况下将该位设置为1。

CPOL位（时钟极性选择）

该位选择通过SCKn引脚输出的时钟信号的极性。详见图26.97。

在简单SPI模式和时钟同步模式以外的情况下将该位设置为1。

BPEN位（同步器旁路使能）

只有当总线时钟和操作时钟（TCLK）输入相同的时钟时，该位才能绕过同步电路。请参阅第26.19节。详细同步器旁路功能。

关于此位设置的使用说明，请参阅第26.20.17节。有关CCR3.BPEN位设置的注释以获取更多详细信息。

CHR[1:0] bit (Character Length)

选择发送和接收的数据长度。

除异步模式和曼彻斯特模式外，使用8位的固定数据长度。

LSBF位（LSB优先选择）

选择是以MSB先还是LSB先发送接收数据。

SINV位（发送接收数据反转）

SINV可以将发送数据位从TDR反转到TSR，并且可以将接收到的数据从RSR反转到RDR。该位不影响奇偶校验位的逻辑电平。要反转奇偶校验位，请反转CCR1.PM。

STP bit (Stop Bit Length)

选择传输中的停止位长度。

在接收中，无论该位设置如何，都只检查第一个停止位。如果第二个停止位为0，则将其视为下一个发送帧的起始位。

此外，在简单LIN模式下发送StartFrame时，它 用作BreakDelimiter长度设置。

RXDESEL位（异步起始位边沿检测选择）

选择异步模式下接收起始位的检测方法。发生中断时，数据接收操作取决于该位的设置。在发生中断时应停止接收或应在中断完成后不将RXDn引脚输入保持在高电平一个数据帧或更长时间的情况下开始接收时，将该位设置为1。

在简单LIN模式下将此位设置为1。在异步模式和简单LIN模式以外的模式下，将此位设置为0。

MOD[2:0]位（通讯模式选择）

选择SCI通信模式。

Note 1. In the bus free state, perform the start condition generation.
Note 2. In the bus busy state, perform restart or stop condition generation when the SCLn pin after acknowledgment described in Figure 26.84 and Figure 26.85 is low level.
Note 3. Do not set more than one from among the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.
Note 4. Execute the generation of a condition after the value of the IICSTIF flag is 0.
Note 5. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

IICDL[4:0] bit (SDA Delay Output Select)

These bits are used to set a delay for output on the SDAn pin relative to the falling edge of the output on the SCLn pin. The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generators the base. The signal obtained by frequency-dividing TCLK by the divisor set in CCR2.CKS[1:0] is supplied as the clock signal from the on-chip baud rate generator.

Set these bits to 00000b unless operation is in simple IIC mode. In simple IIC mode, set the bits to a value in the range from 00001b to 11111b.

IICINTM bit (IIC Interrupt Mode Select)

This bit selects the sources of interrupt requests in Simple IIC mode.

IICCSC bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SCLn clock signal is to be synchronized when the SCLn pin has been placed at the low level in the case of a wait inserted by the other device, etc.

The SCLn clock signal is not synchronized if the IICCSC bit is 0. The SCLn clock signal is generated in accord with the rate selected in the BRR regardless of the level being input on the SCLn pin.

Set the IICCSC bit to 1 except during debugging.

IICACKT bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set this bit to 1 when ACK and NACK bits are received.

IICSTAREQ bit (Start Condition Generation)

When a start condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTAREQ bit to 1.

If you want to generate the start condition after generating the stop condition, start the generation of the start condition with a half cycle period of the bit rate from the stop condition generation interrupt (STI) request output.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the start condition

IICRSTAREQ bit (Restart Condition Generation)

When a restart condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICRSTAREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the restart condition

注1.在总线空闲状态下，执行启动条件生成。
注2.在总线繁忙状态下，当图26.84和图26.85中描述的确认后SCLn引脚为低电平时，执行重新启动或停止条件生成。

注3.在给定时间，不要将IICSTAREQ、IICRSTAREQ和IICSTPREQ位中的一个以上设置为1。
注4.在IICSTIF标志的值为0后执行条件生成。
注5.请勿在该位为1时向其写入0。在该位为1时向该位写入0可暂停条件的产生。

IICDL[4:0]位（SDA延迟输出选择）

这些位用于设置SDAn引脚输出相对于SCLn引脚输出下降沿的延迟。可用的延迟设置范围从无延迟到31个周期，以来自片上波特率发生器的时钟信号为基准。通过在CCR2.CKS[1:0]中设置的除数对TCLK进行分频获得的信号作为来自片上波特率发生器的时钟信号提供。

除非在简单IIC模式下操作，否则将这些位设置为00000b。在简单IIC模式下，将位设置为00001b到11111b范围内的值。

IICINTM位（IIC中断模式选择）

该位选择SimpleIIC模式下的中断请求源。

IICCSC bit (Clock Synchronization)

如果在其他设备插入等待等情况下SCLn引脚已置于低电平时内部生成的SCLn时钟信号要同步，则将IICCSC位设置为1。

如果IICCSC位为0，则SCLn时钟信号不同步。无论SCLn引脚上输入的电平如何，SCLn时钟信号都按照在BRR中选择的速率生成。

除调试期间外，将IICCSC位设置为1。

IICACKT位（ACK传输数据）

传输的数据包含ACK位。当收到ACK和NACK位时，将该位设置为1。

IICSTAREQ位（开始条件生成）

当要产生一个开始条件时，将IICSDAS[1:0]和IICSCLS[1:0]位都设置为01b并设置IICSTAREQ位为1。

如果要在生成停止条件后生成开始条件，请从停止条件生成中断(STI)请求输出开始以比特率的半个周期周期开始生成开始条件。

[设定条件]

●向位写入1

[结算条件]

●开始条件的生成完成

IICRSTAREQ位（重启条件生成）

当要产生重启条件时，将IICSDAS[1:0]和IICSCLS[1:0]位都设置为01b以及将IICRSTAREQ位为1。

[设定条件]

●向位写入1

[结算条件]

When a stop condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTPREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the stop condition

DRES bit (Receive data ready error select bit)

Select whether the detection of receive data ready (FRSR.DR flag = 1) is the cause of SCIn_RXI interrupt request or the cause of SCIn_ERI interrupt request.

TTRG[4:0] bit (Transmit FIFO data trigger number)

The TDFE flag is set to 1 when the quantity of transmit data in the transmit-FIFO(TDR register) is equal to or less than the specified transmit triggering number. If SCR.TIE = 1, SCIn_TXI interrupt request is occurred.

Note: Trigger number have to be set 15. In case the trigger number is set 16 or more, unexpected SCIn_TXI interrupt will occur.

TFRST bit (Transmit FIFO Data Register Reset)

When the TFRST bit is set to 1, the number of the transmission data stored in Transmit-FIFO(TDR register) is made 0.

RTRG[4:0] bit (Receive FIFO data trigger number)

The CSR.RDRF flag is set to 1 when the quantity of receive data in the receive-FIFO(RDR register) is equal to or greater than the specified receive triggering number. If CCR0.RIE = 1, SCIn_RXI interrupt request is occurred. When FCR.RTRG is set to 0, RDRF bit is set if the quantity of data in receive-FIFO is greater than or equal to 1.

Note: Trigger number have to be set to 15. In case the trigger number is set to 16 or more, unexpected SCIn_RXI interrupt will occur.

RFRST bit (Receive FIFO Data Register Reset)

When the RFRST bit is set to 1, the number of the reception data stored in Receive-FIFO(RDR register) is made 0.

RSTRG[4:0] bit (RTS Output Active Trigger Number Select)

When the quantity of receive data stored in the receive-FIFO (RDR register) is equal to or greater than this number, the RTSn signal is in the High state. When FCR.RSTRG is set to 0, RTSn is in the high state if the quantity of data in reveive FIFO is greater than or equal to 1.

Note: Trigger number have to be set 15. In case the trigger number is set 16 or more, RTSn will go to High state at unexpected timing.

31:29	—	这些位被读取为0。写入值应为0。	R/W

DRES位（接收数据就绪错误选择位）

选择检测到接收数据就绪（FRSR.DR标志=1）是SCIn_RXI中断请求的原因还是SCIn_ERI中断请求的原因。

TTRG[4:0]位（发送FIFO数据触发数）

当发送FIFO（TDR寄存器）中的发送数据量等于或小于指定的发送触发数时，TDFE标志设置为1。如果SCR.TIE=1，则发生SCIn_TXI中断请求。

Note: 触发数必须设置为15。如果触发数设置为16或更多，则会发生意外的SCIn_TXI中断。

TFRST位（发送FIFO数据寄存器复位）

当TFRST位设置为1时，存储在Transmit-FIFO（TDR寄存器）中的传输数据数量为0。

RTRG[4:0]位（接收FIFO数据触发数）

当接收FIFO（RDR寄存器）中的接收数据量等于或大于指定的接收触发数时，CSR.RDRF标志设置为1。如果CCR0.RIE=1，则产生SCIn_RXI中断请求。当FCR.RTRG设置为0时，如果接收FIFO中的数据量大于或等于1，则设置RDRF位。

Note: 触发数必须设置为15。如果触发数设置为16或更多，则会发生意外的SCIn_RXI中断。

RFRST位（接收FIFO数据寄存器复位）

当RFRST位设置为1时，存储在Receive-FIFO（RDR寄存器）中的接收数据数量为0。

RSTRG[4:0]位（RTS输出有效触发数选择）

当存储在接收FIFO（RDR寄存器）中的接收数据数量等于或大于该数量时，
RTSn信号处于高电平状态。当FCR.RSTRG设置为0时，如果接收到的数据量大，则RTSn处于高电平状态
FIFO大于或等于1。

Note: 触发数必须设置为15。如果触发数设置为16或更多，RTSn将在意外时间进入高状态。

DEPOL bit (Driver effective polarity select)

Select the active level of the DEn signal.

DEAST[4:0] bit (Driver Assertion Time)

Set the driver assertion time (= time from the activation of the DEn (Driver Enable) signal to the start of the start bit). It is expressed in base clock period.

Driver assertion time

= DEAST [4:0] set value × base clock period + transmission waiting time

Set the driver negation time (= time from the end of the last stop bit of the transmitted message until the DEn (Driver Enable) signal is disabled). It is expressed in base clock period.

Driver negate time

= DENGT[4:0] set value × base clock period

If the transmission data is written during the driver negate time, transmit starting operation is different depends on the writing timing. (The DEn signal remains valid, and transmission of the start bit may start after the transmission wait time has elapsed. Also, the DEn signal may become invalid once, and start bit transmission may start after the Driver assertion time has elapsed.)

BFOIE位（BreakField输出完成中断使能）

选择是否将BreakField输出完成作为SCIn_TXI中断因素包括在内。设置CCR0.TIE=1和CCR3.MOD[1:0]=110b，在BreakField输出完成后输出SCIn_TXI。

BCDIE位（总线冲突检测中断使能）

选择检测到总线冲突时是否输出SCIn_ERI中断。在简单LIN模式下(CCR3.MOD[1:0]=110b)，SCIn_ERI输出控制通过该位执行。当CCR3.MOD[1:0]=110b且BCDIE=1时，即使CCR0.RIE=0，当检测到总线冲突时也会发出SCIn_ERI中断。

[Setting condition]

- When 1 is written to TCST. Start Break Field output from TXDn. Holds 1 during Break Field output.

SDST bit (Start Frame detection enable)

When 1 is written to this bit, Start Frame detection starts. When XCR0.BFE = 1 is set, Break Field can be detected during Start Frame is detected and after Start frame is detected. When XCR0.BFE = 0 is set, Break Field is not detected.

When 0 is written to this bit, Start Frame detection and Break Field detection are stopped. However, if XSR0.RXDSF = 0 at the time of stop, it is not possible to stop data reception of the SCI core with this bit. Write 0 to CCR0.RE to stop the reception operation or perform reception completion processing (CSR.RDRF clear or RDR read) after reception is completed.

BMEN bit (Bit rate measurement enable)

Set this bit to 1 simultaneously with the SDST bit. When this bit is set to 1, the valid edge interval of Control Field 0 and Control Field 1 data is measured.

PCF1D[7:0] bit (Priority compare data for Control Field 1)

Set the priority compare data for Control Field 1.

SCF1D[7:0] bit (Secondary compare data for Control Field 1)

Set the secondary compare data for Control Field 1.

CF1CE[7:0] bit (Control Field 1 compare bit enable)

Select whether to compare bit N of Control Field 1. (N = 0 - 7)

When all of these bits are set to 0 (CF1CE[7:0] = 8'h00), it is always judged that Control Field 1 matches when reception is completed, and XSR0.CF1MF is set. This bit is a comparison enable with PCF1D[7:0] or SCF1D[7:0], and it is not a priority interrupt bit comparison enable.

CF0D[7:0] bit (Control Field 0 compare data)

●当1写入TCST时。从TXDn开始中断字段输出。在BreakField输出期间保持1。

SDST位（起始帧检测使能）

当向该位写入1时，开始帧检测。当XCR0.BFE=1被设置时，BreakField可以被检测到
检测到起始帧并在检测到起始帧之后。当设置XCR0.BFE=0时，不检测中断字段。

当向该位写入0时，开始帧检测和中断字段检测停止。但是，如果停止时XSR0.RXDSF=0，则无法通过该位停止SCI内核的数据接收。将0写入CCR0.RE以停止接收操作或在接收完成后执行接收完成处理（CSR.RDRF清除或RDR读取）。

BMEN位（比特率测量使能）

将此位与SDST位同时设置为1。当该位设置为1时，控制字段0的有效边沿间隔和

CF1CE[7:0]位（控制字段1比较位使能）

选择是否比较控制字段1的位N。(N=07)

当所有这些位都设置为0(CF1CE[7:0]=8'h00)时，在接收完成时总是判断控制字段1匹配，并设置XSR0.CF1MF。该位是与PCF1D[7:0]或SCF1D[7:0]的比较使能，不是优先中断位比较使能。

控制字段0的比较数据。

CF0CE[7:0] bit (Control Field 0 compare bit enable)

When all of these bits are set to 0 (CF0CE[7:0] = 8'h00), it is always judged that Control Field 0 matches when reception is completed, and XSR0.CF0MF is set.

BFLW[15:0] bit (Break Field length setting)

BFLW[15:0] are 16-bit Break Field length setting bits and the initial value is 0xFFFE.

Set the Break Field length to 1 frame or more. The LIN standard stipulates that the Break Field length is 13 bits or more.

When the Break Field sending. Writing 1 to TCST, SCI starts output the Break Field on TXDn. Up-counting is performed with the clock of the timer selected by XCR0.TCSS[1:0]. When the count value matches the value set in this register, up-counting is stopped and Break Field output from TXDn is also stopped.

When the Break Field receiving. Writing 1 to SDST, Start-Frame detection is enabled. SCI starts counting from the negative edge of RXDn. The clock of the timer is selected by XCR0.TCSS[1:0].

When the count value matches the value set in this register, it is determined that a Break Field has been detected. Up-counting continues until the next valid edge or counter overflow.

CF0CE[7:0]位（控制字段0比较位使能）

选择是否比较控制字段0的位N。（N=07）

当所有这些位都设置为0(CF0CE[7:0]=8'h00)时，当接收完成时总是判断控制字段0匹配，并设置XSR0.CF0MF。

BFLW[15:0]位（BreakField长度设置）

BFLW[15:0]是16位间隔字段长度设置位，初始值为0xFFFE。

将中断字段长度设置为1帧或更多。LIN标准规定BreakField长度为13位或更多。

当BreakField发送时。将1写入TCST，SCI开始在TXDn上输出BreakField。通过XCR0.TCSS[1:0]选择的定时器时钟执行递增计数。当计数值与该寄存器中设置的值匹配时，停止向上计数，并且也停止从TXDn输出中断字段。

当BreakField接收时。向SDST写入1，启动帧检测。SCI从RXDn的下降沿开始计数。定时器的时钟由XCR0.TCSS[1:0]选择。

当计数值与此寄存器中设置的值匹配时，确定已检测到中断字段。向上计数一直持续到下一个有效边沿或计数器溢出。

ERS位（错误信号状态标志）

[Setting condition]

●采样错误信号LOW时。

[Clearing condition]

●CFCLR.ERSC写入1时。

DCMF位（数据比较匹配标志）

DCMF位指示SCI检测到比较数据(CCR4.CMPD)与接收数据的匹配。

将CCR0.RE位清为0不会影响DCMF标志，它保持其先前的状态。

[Setting condition]

●与接收数据匹配的比较数据（CCR4.CMPD），同时CCR0.DCME=1。

[Clearing condition]

- When write 1 to CFCLR.DCMFC.

DPER bit (Data Compare Match Parity Error Flag)

The DPER bit indicates that a parity error occurred at Address Match detection (reception data match detection).

Clearing the CCR0.RE bit to 0 does not affect the DPER flag, which retains its previous state.

[Setting condition]

- When a parity error was detected by the frame in which an address match was detected.

[Clearing condition]

- When write 1 to CFCLR.DPERC.

DFER bit (Data Compare Match Framing Error Flag)

The DFER bit indicates that a framing error occurred at Address Match detection (reception data match detection).

Clearing the CCR0.RE bit to 0 does not affect the DFER flag, which retains its previous state.

[Setting condition]

- When a stop bit of the frame in which an Address Match was detected is 0.
  When it is a 2-stop mode, the 1st bit of stop bit judges only whether it's 1 and doesn't check the 2nd bit of stop bit.

[Clearing condition]

- When write 1 to CFCLR.DFERC.

ORER bit (Overrun Error Flag)

The ORER bit indicates that an overrun error has occurred during reception and the reception ends abnormally.

Clearing the CCR0.RE bit to 0 does not affect the ORER flag, which retains its previous state. In Simple IIC mode, this bit is not use.

[Setting condition with Non-FIFO mode (CCR3.FM = 0)]

- When the next data is received before reading out RDR with no-error reception data stored in RDR.
  In RDR, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, reception data isn't forwarded to RDR register.
  Note that, in clock synchronous mode and Simple SPI mode, serial reception will be stop.

[Setting condition with FIFO mode (CCR3.FM = 1)]

- When the next serial reception is completed while the receive FIFO is full of 16receive data.

[Clearing condition]

- When write 1 to CFCLR.ORERC.

MFF bit (Mode Fault Flag)

The MFF bit indicates mode fault errors. In a multi-master configuration, determine the mode fault error occurrence by reading the MFF flag.

[Setting condition]

- Input on the SSn pin being at the low level during master operation (CCR3.CKE[1:0] = 00 or 01) in simple SPI mode.

[Clearing condition]

- When write 1 to CFCLR.MFFC.

PER bit (Parity Error Flag)

The PER bit indicates that a parity error has occurred during reception and the reception ends abnormally.

Clearing the CCR0.RE bit to 0 does not affect the PER flag, which retains its previous state.

[Clearing condition]

●当CFCLR.DCMFC写1时。

DPER位（数据比较匹配奇偶校验错误标志）

DPER位指示在地址匹配检测（接收数据匹配检测）时发生奇偶校验错误。

将CCR0.RE位清除为0不会影响DPER标志，它会保留其先前的状态。

[Setting condition]

●当检测到地址匹配的帧检测到奇偶校验错误时。

[Clearing condition]

●向CFCLR.DPERC写入1时。

DFER位（数据比较匹配帧错误标志）

DFER位指示在地址匹配检测（接收数据匹配检测）时发生帧错误。

将CCR0.RE位清除为0不会影响DFER标志，它保持其先前的状态。

[Setting condition]

●当检测到地址匹配的帧的停止位为0时。
2停止模式时，停止位第1位只判断是否为1，不检查停止位第2位。

[Clearing condition]

●当CFCLR.DFERC写1时。

ORER位（溢出错误标志）

ORER位表示接收过程中发生溢出错误，接收异常结束。

将CCR0.RE位清为0不会影响ORER标志，它保持其先前的状态。在SimpleIIC模式下，该位不使用。

[非FIFO模式的设置条件(CCR3.FM=0)]

●在读取RDR之前接收到下一个数据时，RDR中存储的接收数据无错误。
在RDR中，保留发生溢出错误之前的接收数据，但发生溢出错误之后接收的数据会丢失。当ORER标志设置为1时，接收数据不转发到RDR寄存器。请注意，在时钟同步模式和简单SPI模式下，串行接收将停止。

[FIFO模式的设置条件(CCR3.FM=1)]

●当接收FIFO已满16个接收数据时，下一次串行接收完成时。

[Clearing condition]

●向CFCLR.ORERC写入1时。

MFF位（模式故障标志）

MFF位指示模式故障错误。在多主机配置中，通过读取MFF标志确定模式故障错误发生。

[Setting condition]

●SSn引脚上的输入在简单SPI模式下主机操作期间（CCR3.CKE[1:0]=00或01）为低电平。

[Clearing condition]

●CFCLR.MFFC写1时。

PER位（奇偶校验错误标志）

PER位表示接收过程中发生奇偶校验错误，接收异常结束。

将CCR0.RE位清为0不会影响PER标志，它保持其先前的状态。

In Clock-synchronous mode, Simple SPI mode and Simple IIC mode, this bit not used.

[Setting condition]

- When a parity error is detected during reception. In FIFO select mode, when one or more parity error is detected in receive-FIFO data.
  In non-FIFO mode, although receive data when the parity error occurs is transferred to RDR, no SCIn_RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When write 1 to CFCLR.PERC.

FER bit (Framing Error Flag)

The FER bit indicates that a framing error has occurred during reception and the reception ends abnormally.

Clearing the CCR0.RE bit to 0 does not affect the FER flag, which retains its previous state.

In Clock-synchronous mode, Simple SPI mode and Simple IIC mode, this bit not used.

[Setting condition]

- When 0 is sampled as the stop bit during reception. In FIFO select mode, when one or more framing error is detected in receive-FIFO data. In Manchester mode, when both sampling results (1⁄4 and 3⁄4 sampling points) are not 1 for 1 stop bit. In simple LIN mode, even if a condition that changes to 1 occurs when XCR1.SDST = 1, the FER set timing is delayed up to the Break Field judgment timing at the longest, since it may be a Break Field. If an edge is detected on the RXDn signal before the Break Field judgment timing, FER is detected. If no edge is detected in the RXDn signal before the Break Field judgment timing, Break Field is detected.
  In 2-stop-bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked. In non-FIFO mode, although receive data when the framing error occurs is transferred to RDR, no SCIn_RXI interrupt request occurs. In addition, when the FER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When write 1 to CFCLR.FERC.

TDRE bit (Transmit Data Empty Flag)

[Non-FIFO selected (CCR3.FM = 0)]

The TDRE bit indicates the presence of transmit data in the TDR register.

The condition of CCR0.TE = 0 has priority over the condition of 0.

If other conditions that become 1 and conditions that become 0 are satisfied at the same time, the TDRE flag is set to 0.

[Setting condition]

- When CCR0.TE is 0.
- When data is transmitted from the TDR register to the TSR register.

[Clearing condition]

- When write 1 to CFCLR.TDREC.
- When the transmission data is written to the TDR register during CCR0.TE = 1.

[FIFO selected (CCR3.FM = 1)]

The TDRE bit indicates that data has been transferred from the transmit-FIFO (TDR) into the transmit shift register (TSR), the quantity of data in transmit-FIFO has fallen below the specified transmit triggering number.

When the condition which becomes 1 and the condition which becomes 0 were formed at the same time, TDRE flag will be 0. After that, when the number of data stored in transmit-FIFO is judged, and if that is same or greater than TTRG value, TDRE is set to 1 after 1 PCLK.

[Setting condition]

- When the quantity of transmit data written in transmit-FIFO is equal to or less than the specified transmit triggering number*1.

在时钟同步模式、简单SPI模式和简单IIC模式下，该位未使用。

[Setting condition]

●在接收过程中检测到奇偶校验错误时。在FIFO选择模式下，当在接收FIFO数据中检测到一个或多个奇偶校验错误时。在非FIFO模式下，虽然发生奇偶校验错误时的接收数据会传输到RDR，但不会发生SCIn_RXI中断请求。请注意，当PER标志设置为1时，后续接收数据不会传输到RDR。

[Clearing condition]

●向CFCLR.PERC写入1时。

FER位（帧错误标志）

FER位表示接收过程中发生了帧错误，接收异常结束。

将CCR0.RE位清除为0不会影响FER标志，它保持其先前的状态。

在时钟同步模式、简单SPI模式和简单IIC模式下，该位未使用。

[Setting condition]

●在接收过程中采样0作为停止位时。在FIFO选择模式下，当在接收FIFO数据中检测到一个或多个帧错误时。在曼彻斯特模式下，当两个采样结果（1 4和3 4采样点）对于1个停止位都不是1时。在简单LIN模式下，即使在XCR1.SDST=1时发生变为1的条件，FER设置时序最长也会延迟到BreakField判断时序，因为它可能是一个BreakField。如果在BreakField判断时序之前检测到RXDn信号的边沿，则检测到FER。如果在BreakField判断时序之前在RXDn信号中没有检测到边沿，则检测到BreakField。在2-stop-bit模式下，只检查第一个停止位是否为1，不检查第二个停止位。在非FIFO模式下，虽然发生帧错误时的接收数据被传输到RDR，但不会发生SCIn_RXI中断请求。此外，当FER标志设置为1时，后续接收数据不会传输到RDR。

[Clearing condition]

●CFCLR.FERC写入1时。

TDRE位（发送数据空标志）

[Non-FIFO selected (CCR3.FM = 0)]

TDRE位指示TDR寄存器中存在发送数据。

CCR0.TE=0的条件优先于0的条件。

如果同时满足其他变为1的条件和变为0的条件，则TDRE标志设置为0。

[Setting condition]

●当CCR0.TE为0时。

●当数据从TDR寄存器传送到TSR寄存器时。

[Clearing condition]

●CFCLR.TDREC写入1时。

●在CCR0.TE=1期间将发送数据写入TDR寄存器时。

[FIFO selected (CCR3.FM = 1)]

TDRE位表示数据已从发送FIFO(TDR)传输到发送移位寄存器(TSR)，发送FIFO中的数据量已低于指定的发送触发数。

当变为1的条件和变为0的条件同时形成时，TDRE标志将为0。之后，当判断存储在发送FIFO中的数据数量时，如果相同或大于TTRG值，TDRE在1个PCLK之后设置为1。

[Setting condition]

●当写入到transmit-FIFO中的发送数据量等于或小于指定的发送触发数*1时。

Note 1. The transmit-FIFO is FIFO register of 16 steps, the maximum number of data that can be written when the TDRE flag is 1 is indicated in 0x10 - FTSR.T[5:0]. Even if data any more is written, data is discarded.

[Clearing condition]

- When write 1 to CFCLR.TDREC.
- When the transmission data is written to transmit-FIFO by the DTC or DMAC (the last block transfer when block transfer).

TEND bit (Transmit End Flag)

[Non-FIFO selected (CCR3.FM = 0), and Not Smart card interface mode (CCR3.MOD[2:0] ≠ 001)]

The TEND bit indicates completion of transmission.

[Setting condition]

- When CCR0.TE is 0.
- When the CCR0.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at the time of transmission of the tail-end bit of a character being transmitted.
- When the TDR register is not updated at the end of DE negate time with DE control function enable (CCR3.DEN = 1).
- When Break Field is sending.

[Clearing condition]

- After the synchronization delay time has elapsed since the transmission data was written to the TDR register during CCR0.TE = 1.
- When write 1 to CFCLR.TDREC during CCR0.TE = 1.

[Non-FIFO selected (CCR3.FM = 0), and Smart card interface mode (CCR3.MOD [2:0] = 001)]

With no error signal from the receiving side, this bit is set to 1 when further data for transfer is ready to be transferred to the TDR register.

[Setting condition]

- When CCR0.TE is 0.
- When the CCR0.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period has elapsed after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated. The set timing is determined by register settings as listed below.1
  When GM = 0 and BLK = 0, 12.5etu after the start of transmission
  When GM = 0 and BLK = 1, 11.5etu after the start of transmission
  When GM = 1 and BLK = 0, 11.0etu after the start of transmission
  When GM = 1 and BLK = 1, 11.0etu after the start of transmission

[Clearing condition]

- After the synchronization delay time has elapsed since the transmission data was written to the TDR register during CCR0.TE = 1.
- When write 1 to CFCLR.TDREC during CCR0.TE = 1.

[FIFO selected (CCR3.FM = 1)]

The TEND bit indicates that the transmit-FIFO does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

- TEND is set to 1 when transmit-FIFO does not contain transmit data when the last bit of a one-byte serial character is transmitted.
- When the TDR register is not updated at the end of DE negate time with DE control function enable (CCR3.DEN = 1).

[Clearing condition]

注1.发送FIFO为16步的FIFO寄存器，TDRE标志为1时可写入的最大数据数在0x10FTSR.T[5:0]中指示。即使再写入数据，也会丢弃数据。

[Clearing condition]

●CFCLR.TDREC写入1时。

●当传输数据被DTC或DMAC写入传输FIFO时（块传输时的最后一个块传输）。

TEND位（发送结束标志）

[选择非FIFO(CCR3.FM=0)，且非智能卡接口模式(CCR3.MOD[2:0]≠001)]

TEND位指示传输完成。

[Setting condition]

●当CCR0.TE为0时。

●当CCR0.TE位由0变为1时，TEND标志不受影响，保持值为1。

●TDR寄存器在发送一个字符的尾端位时没有更新。

●当在DE取反时间结束时TDR寄存器没有更新且DE控制功能使能(CCR3.DEN=1)。

●发送中断字段时。

[Clearing condition]

●在CCR0.TE=1期间，自发送数据写入TDR寄存器起，经过同步延迟时间后。

●在CCR0.TE=1期间向CFCLR.TDREC写入1时。

[选择非FIFO(CCR3.FM=0)和智能卡接口模式(CCR3.MOD[2:0]=001)]

在接收端没有错误信号的情况下，当进一步的传输数据准备好传输到接收端时，该位设置为1
TDR register.

[Setting condition]

●当CCR0.TE为0时。

●当CCR0.TE位由0变为1时，TEND标志不受影响，保持值为1。

●在最后一次发送1个字节后经过指定时间后，ERS标志为0，并且不更新TDR寄存器。设置时序由寄存器设置确定，如下所示。1当GM=0和BLK=0时，发送开始后12.5etu当GM=0和BLK=1时，开始发送后11.5etu当GM=1和BLK=0，传输开始后11.0etu当GM=1且BLK=1，传输开始后11.0etu

[Clearing condition]

●在CCR0.TE=1期间，自发送数据写入TDR寄存器起，经过同步延迟时间后。

●在CCR0.TE=1期间向CFCLR.TDREC写入1时。

[FIFO selected (CCR3.FM = 1)]

TEND位表示在发送串行字符的最后一位时，发送FIFO不包含有效数据，因此暂停发送。

[Setting condition]

●当发送一个字节串行字符的最后一位时，当发送FIFO不包含发送数据时，TEND设置为1。

●当在DE取反时间结束时TDR寄存器没有更新且DE控制功能使能(CCR3.DEN=1)。

[Clearing condition]

- After the synchronization delay time has elapsed since the transmission data was written to the TDR register during CCR0.TE = 1.

RDRF bit (Receive Data Full Flag)

[Non-FIFO selected (CCR3.FM = 0)]

The RDRF bit indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing condition]

- When write 1 to CFCLR.RDRFC.
- When the read data is read from the RDR register.

[FIFO selected (CCR3.FM = 1)]

The RDRF bit indicates that receive data has been transferred to the receive FIFO data register (RDR), and the quantity of data in receive-FIFO is equal to or greater than the specified receive triggering number. When FCR.RTRG is set to 0, RDRF is set if the quantity of data in receive-FIFO is greater than or equal to 1.

[Setting condition]

- RDRF is set to 1 when the quantity of receive data in receive-FIFO is equal to or greater than the specified receive triggering number*1.

Note 1. Since the receive-FIFO is 16 stage FIFO register, the maximum quantity of data that can be read when RDF is 1 is equivalent to the specified receive data count number (FDR.R[5:0]). If an attempt is made to read after all the data in receive-FIFO has been read, the data is undefined.

[Clearing condition]

- When write 1 to CFCLR.RDRFC.
- When the reception data is read form receive-FIFO by the DTC or DMAC (the last block transfer when block transfer).

When the condition which becomes 1 and the condition which becomes 0 were formed at the same time, RDRF flag will be 0. After that, when the number of stored data in receive-FIFO is judged, and if that is same or greater than RTRG value, RDRF is set to 1 behind 1 PCLK.

Note: Except when interruption communication, RDRF and TDRE should not be cleared by CFCLR register.

[Clearing condition]

DR bit (Receive Data Ready flag)

The DR bit indicates that the quantity of data stored in the receive FIFO data register (RDR) falls below the specified receive triggering number, and that no next data has been received yet after the elapse of 15 etu from the last stop bit in asynchronous mode. This bit is valid only Asynchronous mode (including multi-processor mode) and FIFO selected. In other mode, this bit does not set to 1.

  - After receive-FIFO(RDR) receives less data than the specified receive triggering number, no next data has been received yet after the elapse of 15 etu*1 from the last stop bit
  - CSR.FER, PER flags are 0.

Note 1. This is equivalent to one and a half (1.5) frames in the 8-bit format with one stop bit (etu: elementary time unit).

[Clearing conditions]

- When all receive data in the receive FIFO (RDR register) is read and 1 is written to FFCLR.DRC.
- When CCR3.FM bit is 0.

PFER bit (Preface Error flag)

This bit indicates that a preface error was detected when receiving frames in Manchester mode.

Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the PFER flag is not affected and retains its previous value.

[Setting condition]

- When detecting a preface error when receiving frames in Manchester mode
  The following operations are performed when a preface error occurs.
  - <When MCR.PFEREN = 1>
    The received data is not transferred to the RDR register and no SCIn_RXI interrupt request occurs. Instead, an SCIn_ERI interrupt request occurs. Note that when the PFER flag is being set to 1, the subsequently received data is not transferred to the RDR register.
  - <When MCR.PFEREN = 0>
    The received data is transferred to the RDR register and an SCIn_RXI interrupt request occurs. An SCIn_ERI interrupt request is not generated. The subsequent receive operations are not affected even with the PFER flag being set to 1.

[Setting condition]

- When detecting a receive SYNC error when receiving frames in Manchester mode
  The following operations are performed when a receive SYNC error occurs.
  - <When MCR.SYEREN = 1>

  - <When MCR.SYEREN = 0>
    The received data is transferred to the RDR register and an SCIn_RXI interrupt request occurs. An SCIn_ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SYER flag being set to 1.

[Clearing condition]

TCNT[15:0] bit (Timer Count Capture value)

Stores the capture value of the 16-bit counter of the Simple LIN module.

- When sending Start Frame
  This register holds the previous value.
- When receiving Start frame with Bit rate measurement disabled
  If a Break Field is detected in the Break Field detection state (refer to Figure 26.79), the Break Field length is captured and held (counter value is captured at the rising edge of RXDn). If a Break Field is detected in a state other than the Break Field detection state, the previous value is retained.
  If the counter overflows, it will not be captured.
- When receiving Start frame with Bit rate measurement enabled
  The count value is captured and held at the valid edge (both RXDn edges). However, in the Break Field detection state, the count value is not captured even if a valid edge occurs. Counter capture value retention is canceled by this register read. Even if a valid edge occurs before reading, the counter value is not captured.

TCNT[15:0]位（定时器计数捕捉值）

存储SimpleLIN模块的16位计数器的捕获值。

●发送起始帧时
该寄存器保存先前的值。

●接收起始帧且比特率测量禁用时
如果在中断字段检测状态下检测到中断字段（参见图26.79），则会捕获并保持中断字段长度（在RXDn的上升沿捕获计数器值）。如果在中断字段检测状态之外的状态下检测到中断字段，则保留先前的值。

如果计数器溢出，则不会被捕获。

●在启用比特率测量的情况下接收起始帧时
计数值被捕获并保持在有效边沿（两个RXDn边沿）。但是，在BreakField检测状态下，即使出现有效边沿，也不会捕获计数值。计数器捕获值保留被此寄存器读取取消。即使在读取之前出现有效边沿，也不会捕获计数器值。

The operation clocks of the communication module and control register can be used asynchronously. Since some control register values are transmitted internally via the synchronization circuit so that they operate correctly even if they are asynchronous, it takes some time for the state to be reflected internally after rewriting the control register.

Communication enable CCR0.TE and CCR0.RE correspond to this register, and when these control bits are set from 1 to 0 to rewrite the control bits for the next communication, the TE and RE signal It is necessary to rewrite the next control bit after the internal state becomes 0. If a very slow clock is used for the communication module clock, the TE and RE bit states will not be reflected slowly internally. At this time, you can check the internal status using this register.

26.3 Operation in Asynchronous Mode

Figure 26.4 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit or receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communications line is usually held in the mark state (high level).

The SCI monitors the communications line. When the SCI detects a start bit, it starts serial communication. The detection condition of the start bit changes according to the CCR3.RXDESEL setting. SCI regards space (Low level) as a start bit when CCR3.RXDESEL is 0. SCI regards a fall edge as a start bit when RXDESEL is 1.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and receiver have a double-buffered structure in addition to FIFO mode, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

通信模块和控制寄存器的操作时钟可以异步使用。由于一些控制寄存器的值是通过同步电路在内部传输的，因此即使它们是异步的，它们也可以正常工作，因此在重写控制寄存器后，需要一些时间才能在内部反映状态。

通信使能CCR0.TE和CCR0.RE对应这个寄存器，当这些控制位被设置为1到0来改写下一次通信的控制位时，TE和RE信号后需要改写下一个控制位内部状态变为0。如果通信模块时钟使用非常慢的时钟，则TE和RE位状态不会在内部缓慢反映。此时，您可以使用该寄存器检查内部状态。

26.3 异步模式下的操作

图26.4显示了异步串行通信的一般格式。一帧由起始位（低电平）、发送或接收数据、奇偶校验位和停止位（高电平）组成。在异步串行通信中，通信线路通常保持在标记状态（高电平）。

SCI监控通信线路。当SCI检测到一个起始位时，它开始串行通信。起始位的检测条件根据CCR3.RXDESEL设置而变化。当CCR3.RXDESEL为0时，SCI将空格（低电平）作为起始位。当RXDESEL为1时，SCI将下降沿视为起始位。

在SCI内部，发射器和接收器是独立的单元，可实现全双工通信。发送器和接收器除了FIFO模式外，都具有双缓冲结构，以便在发送或接收过程中可以读取或写入数据，从而实现数据的连续发送和接收。

26.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate.

In reception, the SCI samples the falling edge of the start bit using the base clock, and performs internal synchronization.*2

Because receive data is sampled on the rising edge of the 8th pulse*1 of the base clock, data is latched at the middle of each bit (when sampling timing does not adjust (CCR4.ASEN = 0 or CCR4.ASEN = 1 and CCR4.AST[2:0] = 000b)), as shown in Figure 26.5 The reception margin in asynchronous mode is determined by the following formula (1):

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%] \quad \ldots \quad \text{Formula (1)}$$

Note: M: Reception margin
N: Ratio of bit rate to clock
(N = 16 when CCR2.ABCSE = 0 and CCR2.ABCS = 0,
N = 8 when CCR2.ABCSE = 0 and CCR2.ABCS = 1,
N = 6 when CCR2.ABCSE = 1)
D: Duty cycle of clock (D = 0.5 to 1.0)
L: Frame length (L = 9 to 13)
F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined using the following formula:
$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\ \%$

This represents the computed value. Renesas recommends a margin of 20% to 30% in system design.

Note 1. In this example, the CCR2.ABCS bit is 0 and the CCR2.ABCSE is 0. When the ABCS bit is 1 and the ABCSE bit is 0, a frequency of 8 times the bit rate is used as a base clock, and receive data is sampled on the rising edge of the 4th pulse of the base clock.
When the ABCSE bit is 1, a sextuple frequency of a bit rate is used as a base clock, and receive data is sampled on the rising edge of the 3rd pulse of the base clock.

Note 2. The determination condition of the start bit is as follows.
The function of adjust sampling timing is OFF (ASEN = 0):

26.3.2 异步模式下接收数据采样时序和接收余量

在异步模式下，SCI在频率为16倍*1比特率的基本时钟上运行。

在接收时，SCI使用基本时钟对起始位的下降沿进行采样，并执行内部同步。*2

因为接收数据在基本时钟的第8个脉冲*1的上升沿进行采样，所以数据在每个位的中间锁存（当采样时序不调整时（CCR4.ASEN=0或CCR4.ASEN=1和CCR4.AST[2:0]=000b)），如图26.5所示异步模式下的接收余量由下式（1）确定：

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%] \quad \ldots \quad \text{Formula (1)}$$

Note: M：接收余量
N：比特率与时钟的比率
（当CCR2.ABCSE=0和CCR2.ABCS=0时，N=16，
当CCR2.ABCSE=0且CCR2.ABCS=1时，N=8，
N = 6 when CCR2.ABCSE = 1)
D:时钟占空比(D=0.5to1.0)
L：帧长（L=9到13）
F：时钟频率偏差的绝对值

假设公式（1）中的F=0和D=0.5的值，接收裕量使用以下公式确定：
$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\ \%$

这表示计算值。瑞萨建议在系统设计中留出20%到30%的余量。

注1.本例中，CCR2.ABCS位为0，CCR2.ABCSE位为0。当ABCS位为1，ABCSE位为0时，使用8倍比特率的频率作为基准时钟，并在基本时钟的第4个脉冲的上升沿对接收数据进行采样。

当ABCSE位为1时，以比特率的六倍频为基准时钟，在基准时钟的第3个脉冲的上升沿对接收数据进行采样。

注2.起始位的判断条件如下。

调整采样定时功能关闭（ASEN=0）：

The determination condition of a start bit is that Low beyond half bit length continues. It is same as the sampling timing. In Figure 26.5, Low period should be kept over 8-cycles to detect a start bit. If Low period does not keep over 8-cycles, the IP judges this as a noise. So, the IP does not start reception and wait start bit.

The function of adjust sampling timing is ON (ASEN = 1):

The determination condition of a start bit is that Low keeps up until the sampling timing. Adjusting the sampling timing forward (AJD = 1) increases the possibility of erroneously determining a noise as the start bit.

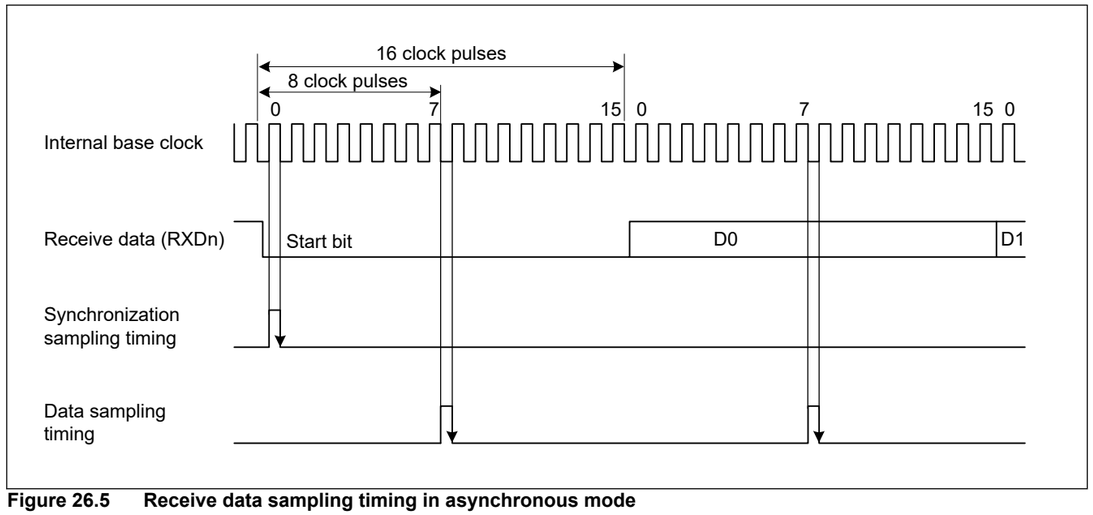

Figure 26.5 Receive data sampling timing in asynchronous mode

26.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the transfer clock of the SCI, based on the CCR3.CKE[1:0] settings.

When an external clock is input to the SCKn pin, the clock frequency must be 16 times the bit rate (when CCR2.ABCS = 0) or 8 times the bit rate (when CCR2.ABCS = 1).

When the SCI uses its internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is configured so that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 26.6.

When the internal clock is selected, the SCKn pin is outputted after setting the CCR0.TE or CCR0.RE bit to 1.

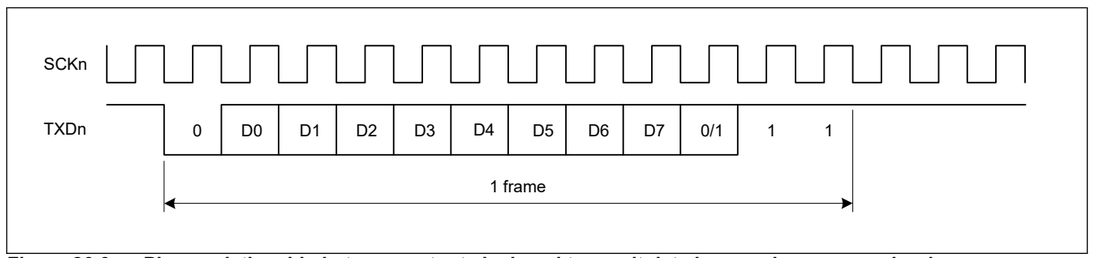

Figure 26.6 Phase relationship between output clock and transmit data in asynchronous mode when CCR1.PE = 1, CCR3.CHR[1:0] = 10b, MP = 0, and STP = 1

26.3.4 Double-Speed Operation and Frequency of 6 Times the Bit Rate

When the CCR2.ABCS bit is set to 1, the SCI operates on the bit rate twice that of when ABCS is set to 0. When the CCR2.BGDM bit is set to 1, the cycle of the base clock is half and the bit rate is double that of when BGDM is set to 0. When the CCR3.CKE[1] bit is set to 0 and the on-chip baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the SCI to operate at a bit rate four times that when the ABCS and BGDM bits are set to 0.

起始位的确定条件是超过半位长度的Low继续。与采样时间相同。在图26.5中，低电平周期应保持超过8个周期以检测起始位。如果Low周期未保持超过8个周期，则IP将其判断为噪声。因此，IP不开始接收并等待开始位。

调整采样定时功能开启（ASEN=1）：

起始位的确定条件是Low一直保持到采样定时。向前调整采样时序(AJD=1)会增加错误地将噪声确定为起始位的可能性。

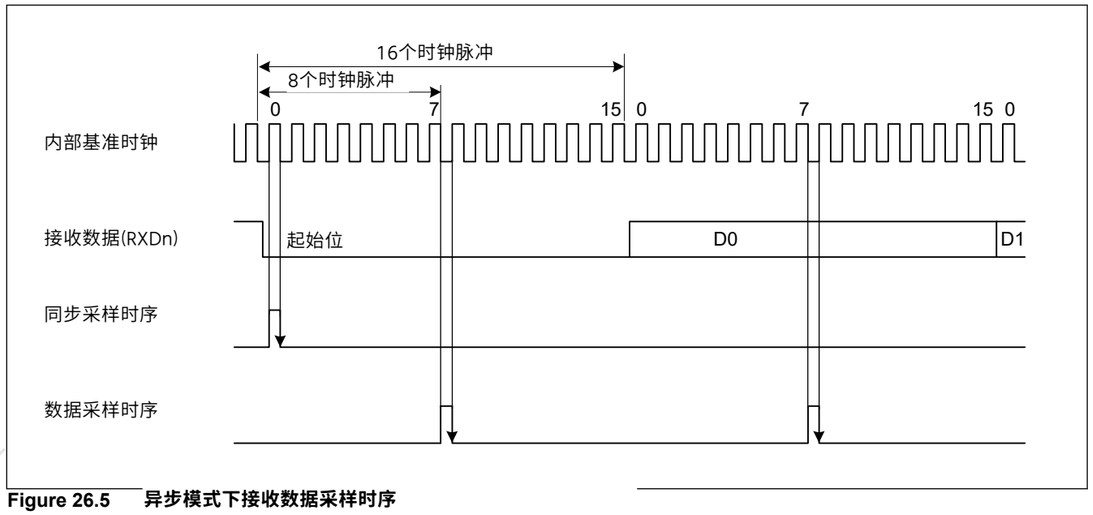

Figure 26.5 异步模式下接收数据采样时序

26.3.3 Clock

根据CCR3.CKE[1:0]的设置，可以选择片内波特率发生器产生的内部时钟或输入到SCKn引脚的外部时钟作为SCI的传输时钟。

当外部时钟输入到SCKn引脚时，时钟频率必须是比特率的16倍（当CCR2.ABCS=0时）或比特率的8倍（当CCR2.ABCS=1时）。

当SCI使用其内部时钟时，时钟可以从SCKn引脚输出。在这种情况下，时钟输出的频率等于比特率，并配置相位，使时钟的上升沿位于发送数据的中间，如图26.6所示。

选择内部时钟时，将CCR0.TE或CCR0.RE位设置为1后输出SCKn引脚。

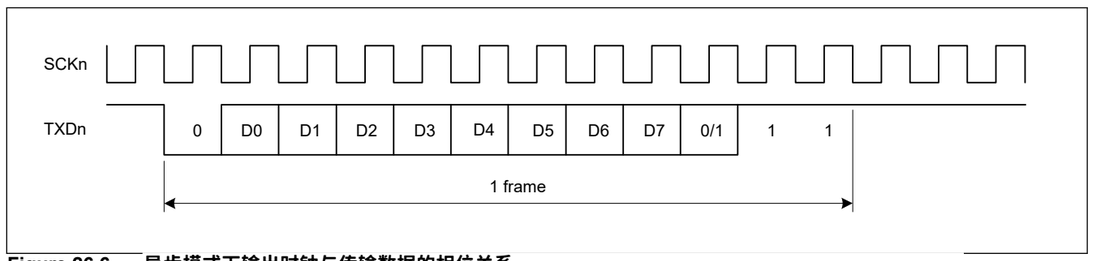

Figure 26.6 异步模式下输出时钟与传输数据的相位关系 CCR1.PE = 1, CCR3.CHR[1:0] = 10b, MP = 0, and STP = 1

26.3.4 双倍速操作和6倍比特率的频率

当CCR2.ABCS位设置为1时，SCI以两倍于ABCS设置为0时的比特率运行。当CCR2.BGDM位设置为1，基本时钟的周期是BGDM设置为0时的一半，比特率是两倍。
当CCR3.CKE[1]位设置为0并选择片内波特率发生器时，将ABCS和BGDM位设置为1允许SCI以四倍于ABCS和BGDM位时的比特率运行设置为0。

When the CCR2.ABCSE bit is set to 1, the number of base clock pulses is 6 during a period of 1 bit, and the base clock frequency is half and the SCI operates at a bit rate 16/3 times that when CCR2.ABCS = 0, CCR2.BGDM = 0, and CCR2.ABCSE = 0.

As shown by Formula (1) in section 26.3.2. Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, the reception margin decreases when the CCR2.ABCS or CCR2.ABCSE bit is set to 1. Therefore, if the target bit rate can be obtained with ABCS or ABCSE set to 0, it is recommended that you use the SCI with ABCS and ABCSE set to 0.

26.3.5 CTS and RTS Functions

The CTS function controls transmission using the CTSn pin input. Setting the CCR1.CTSE bit to 1 enables the CTS function. For the functions of CTS and RTS, you can select the alternate setting to set CTSn_RTSn pin as a multiplexed pin that uses either function with one terminal or the dedicated setting that uses each function independently with two terminals at CTSn pin for CTSn signal and CTSn_RTSn pin for RTSn signal. This setting is done with the CCR1.CTSPEN bit.

When the CTS function is enabled, placing a low level on the CTSn_RTSn pin causes transmission to start.

If FIFO is used and CTSn_RTSn signal is held high before transmission, transmission will not start, so the number of TDR registers written, and the number of data stored are the same (unlike using clock synchronous FIFO).

Driving the CTSn_RTSn pin high while transmission is in progress does not affect transmission of the current frame.

In the RTS function, which uses output on the CTSn_RTSn pin, a low level is output when reception becomes possible. Conditions for output of the low and high levels are shown in this section.

[Conditions for low level output]

Satisfaction of all conditions are listed in this section.

Non-FIFO selected

- The value of the CCR0.RE bit is 1
- When the next reception is possible
  - There are no received data yet to be read and not receiving.
  - CSR.ORER, FER, PER flags are all 0

FIFO selected

- The value of the CCR0.RE bit is 1
- When the next reception is possible
  - When the quantity of receive data written in receive-FIFO(RDR) are less than the setting value of FCR.RSTRG[4:0]
  - CSR.ORER(RDR.ORER) is 0

[Condition for high level output]

- The conditions for low-level output are not satisfied

26.3.6 Address Match (Receive Data Match Detection) Function

The address match function can be used only in asynchronous mode.

If the CCR0.DCME bit is set to 1*2, when one frame of data is received, the SCI compares that received data with the data set in CCR4.CMPD. If the SCI detects a match to the comparison data (CCR4.CMPD*1) with the received data, the SCI can issue the SCIn_RXI interrupt request.

If the CCR3.MP bit is set to 0, comparison occurs only for valid data in receive format. In multi-processor mode (CCR3.MP bit = 1), if the CCR0.IDSEL bit is set to 1, receive data where the MPB bit is 1 is subject to comparison for address match and receive data where the MPB bit is 0 is always treated as a non-match.

If the CCR0.IDSEL bit is set to 0, SCI performs address match detection regardless of the MPB bit value of the received data.

Until SCI detects a match to the comparison data (CCR4.CMPD*1) with receive data, received data is skipped (discarded), and the SCI cannot detect a parity error or framing error.

当CCR2.ABCSE位设置为1时，在1位周期内基本时钟脉冲数为6，基本时钟频率为一半，SCI以16比特率运行，是CCR2.ABCS=时的3倍0，CCR2.BGDM=0，CCR2.ABCSE=0。

如第26.3.2节中的公式（1）所示。异步模式下的接收数据采样时序和接收裕度，当CCR2.ABCS或CCR2.ABCSE位设置为1时，接收裕度减小。因此，如果ABCS或ABCSE设置为0即可获得目标码率，则为建议您使用SCI，ABCS和ABCSE设置为0。

26.3.5 CTS和RTS函数

CTS功能使用CTSn引脚输入控制传输。将CCR1.CTSE位设置为1可启用CTS功能。对于CTS和RTS的功能，您可以选择交替设置，将CTSn_RTSn管脚设置为一个多路复用管脚，使用一个端子的功能或独立使用每个功能的专用设置，在CTSn管脚上为CTSn信号和CTSn_RTSn管脚提供两个端子对于RTSn信号。此设置通过CCR1.CTSPEN位完成。

当CTS功能使能时，将CTSn_RTSn引脚置于低电平会导致传输开始。

如果使用FIFO且CTSn_RTSn信号在发送前保持高电平，则不会开始发送，因此写入的TDR寄存器数量和存储的数据数量相同（与使用时钟同步FIFO不同）。

在传输过程中将CTSn_RTSn引脚驱动为高电平不会影响当前帧的传输。

在使用CTSn_RTSn引脚输出的RTS功能中，当可以接收时输出低电平。
本节显示了低电平和高电平的输出条件。

【低电平输出的条件】

本节列出了所有条件的满足情况。

【高电平输出条件】

26.3.6 地址匹配（接收数据匹配检测）功能

地址匹配功能只能在异步模式下使用。

如果CCR0.DCME位设置为1*2，当接收到一帧数据时，SCI会将接收到的数据与CCR4.CMPD中设置的数据进行比较。如果SCI检测到比较数据(CCR4.CMPD*1)与接收到的数据匹配，则SCI可以发出SCIn_RXI中断请求。

如果CCR3.MP位设置为0，则仅对接收格式的有效数据进行比较。在多处理器模式下（CCR3.MP位=1），如果CCR0.IDSEL位设置为1，则接收MPB位为1的数据进行地址匹配比较，接收MPB位为0的数据始终被视为不匹配。

如果CCR0.IDSEL位设置为0，SCI执行地址匹配检测，而不管接收数据的MPB位值。

在SCI检测到与接收数据的比较数据(CCR4.CMPD*1)匹配之前，将跳过（丢弃）接收到的数据，并且SCI无法检测奇偶校验错误或帧错误。

When SCI detects a match, the CCR0.DCME bit is automatically cleared, and the CSR.DCMF flag is set to 1. If the CCR0.IDSEL bit is set to 1, the CCR0.MPIE bit is automatically cleared. If CCR0.IDSEL is set to 0, the value of the CCR0.MPIE bit is retained. If the CCR0.RIE bit is set to 1, the SCI issues an SCIn_RXI interrupt request.

If the SCI detects a framing error in the receive data for which a match is detected, the CSR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the CSR.DPER flag is set to 1. The compared receive data and MPB bit is not stored in the RDR register, and CSR.RDRF remains 0.

After the SCI detects a match, and CCR0.DCME is automatically cleared, the SCI receives the next data continuously based on the current register setting.

When the CSR.DFER or CSR.DPER flag is set, the address match is not performed. Before enabling the address match function, set the DCCR.DFER and DCCR.DPER flags to 0.

Examples of the address match function are shown in Figure 26.7 and Figure 26.8.

Note 1. This comparative target can select one length of 3 types: CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.

Note 2. Set the CCR0.DCME bit to 1 before receiving the start bit of the received frame that performs address matching.

当SCI检测到匹配时，CCR0.DCME位自动清零，CSR.DCMF标志位设置为1。如果CCR0.IDSEL位设置为1，CCR0.MPIE位自动清零。如果CCR0.IDSEL设置为0，则

CCR0.MPIE位被保留。如果CCR0.RIE位设置为1，则SCI发出SCIn_RXI中断请求。

如果SCI在检测到匹配的接收数据中检测到帧错误，则CSR.DFER标志设置为1，如果SCI在该帧中检测到奇偶校验错误，则CSR.DPER标志设置为1。比较的接收数据和MPB位不存储在RDR寄存器中，CSR.RDRF保持为0。

SCI检测到匹配后，CCR0.DCME自动清零，SCI根据当前寄存器设置连续接收下一个数据。

当设置CSR.DFER或CSR.DPER标志时，不执行地址匹配。在启用地址匹配功能之前，将DCCR.DFER和DCCR.DPER标志设置为0。

地址匹配函数的例子如图26.7和图26.8所示。

注1.此比较目标可以选择3种长度中的一种：7位长度的CMPD[6:0]、8位长度的CMPD[7:0]和9位长度的CMPD[8:0].

注2.在接收到执行地址匹配的接收帧的起始位之前，将CCR0.DCME位设置为1。

26.3.7 SCI Initialization in Asynchronous Mode

Before transmitting and receiving data, start by writing the initial value 0 to the CCR0.TE and CCR0.RE (or writing the initial value to CCR0), then continue through the SCI initialization procedure (select non-FIFO or FIFO) shown in Table 26.26 and Table 26.27. Whenever the operating mode or transfer format is to be changed, the CCR0.TE and CCR0.RE bits must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied during initialization.

26.3.7 异步模式下的SCI初始化

在发送和接收数据之前，首先将初始值0写入CCR0.TE和CCR0.RE（或将初始值写入CCR0），然后继续执行表中所示的SCI初始化程序（选择非FIFO或FIFO）26.26和表26.27。每当要更改操作模式或传输格式时，必须在更改之前初始化CCR0.TE和CCR0.RE位。

在异步模式下使用外部时钟时，请确保在初始化期间提供时钟信号。

Note: Setting the CCR0.RE bit to 0 initializes neither the ORER, FER, RDRF, RDAT, PER, and DR flags in CSR nor RDR. When FIFO selected, even if the TE bit is set as 0, the TEND flag for the selected FIFO buffer is not initialized.

Please be also careful at the time of change in the operation mode.

Note: Switching the value of the CCR0.TE bit from 0 to 1 while the CCR0.TIE bit is 1 leads to the generation of an SCIn_TXI interrupt request.

在改变操作模式时也请小心。

Note 2. If you use an external clock, you do not need to set it.

Figure 26.9 shows an example of the timing when data is transmitted after reset is released, and SCI is set to asynchronous mode according to Table 26.26 or Table 26.27. As shown in the figure, when the pin function is set to the TXDn pin, the CCR0.TE bit is 0, so the pin is high impedance. When transmit data is written after setting the CCR0.TE bit to 1, data transmission starts. There is a transmission wait time from writing TDR to data transmission starts. In asynchronous mode, TXDn is high during this period.

26.3.8 Serial Data Transmission in Asynchronous Mode

(1) Non-FIFO selected

Figure 26.10, Figure 26.11, Figure 26.12 and Figure 26.13 show examples of serial transmission in asynchronous mode.

In serial transmission, the SCI operates as described in this section.

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine.
   The SCIn_TXI interrupt request at the beginning of transmission is generated when the CCR0.TE and CCR0.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the CCR1.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the TDR register to the TSR register. If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to the TDR register in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the CCR0.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the CCR0.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data

图26.9显示了复位释放后发送数据的时序示例，根据表26.26或表26.27将SCI设置为异步模式。如图所示，当引脚功能设置为TXDn引脚时，CCR0.TE位为0，因此引脚为高阻态。将CCR0.TE位设置为1后写入发送数据时，数据发送开始。从写入TDR到数据传输开始有一个传输等待时间。在异步模式下，TXDn在此期间为高电平。

26.3.8 异步模式下的串行数据传输

(1)选择非FIFO图26.10、图26.11、图26.12和图26.13显示了异步模式下的串行传输示例。

在串行传输中，SCI的操作如本节所述。

1.当数据在SCIn_TXI中断处理程序中写入TDR时，SCI将数据从TDR寄存器传输到TSR寄存器。当CCR0.TE和CCR0.TIE位通过一条指令同时设置为1时，会在传输开始时产生SCIn_TXI中断请求。

2.CCR1.CTSE位设置为0（禁用CTS功能）或CTSn_RTSn引脚上的低电平导致数据从TDR寄存器传输到TSR寄存器后开始传输。如果CCR0.TIE位为1，则产生SCIn_TXI中断请求。通过在当前发送数据发送完成之前将下一个发送数据写入SCIn_TXI中断处理程序中的TDR寄存器，可以实现连续发送。使用SCIn_TEI中断请求时，在写入要发送的最后一个数据后，将CCR0.TIE位设置为0（禁止SCIn_TXI中断请求）并将CCR0.TEIE位设置为1（启用SCIn_TEI中断请求）从SCIn_TXI请求的处理例程到TDR寄存器。

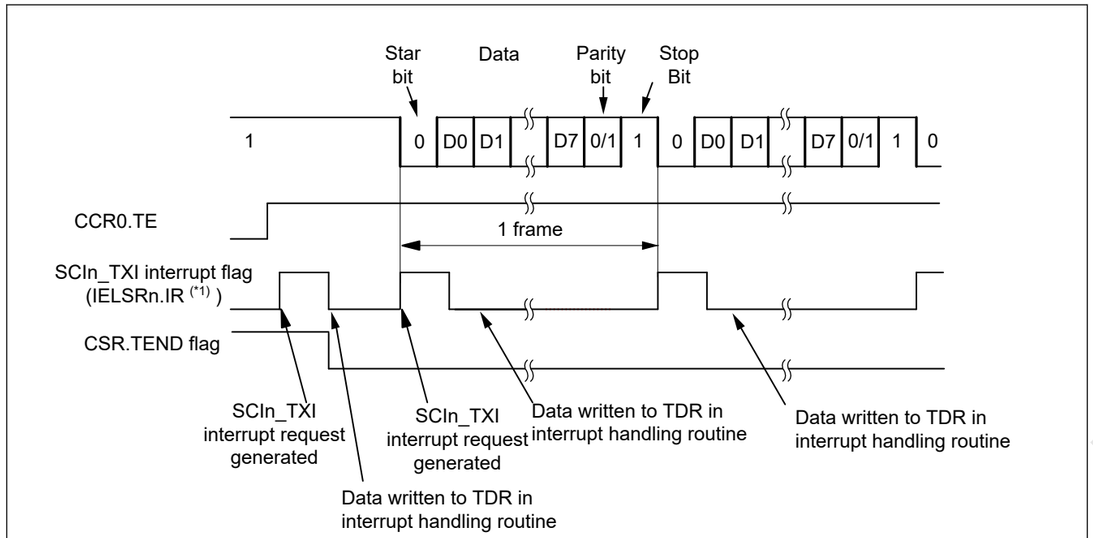
3.数据按以下顺序从TXDn引脚发送：

- 起始位
- 传输数据

- Parity bit or multi-processor bit (can be omitted depending on the format)
- Stop bit

4. The SCI checks for update of the TDR register on output of the stop bit.
5. When the TDR register is updated, setting the CCR1.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from the TDR register to the TSR register and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register is not updated, the CSR.TEND flag is set to 1, the stop bit is sent, and the mark state is entered, in which 1 is output. If the CCR0.TEIE bit is 1, the CSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Figure 26.10, Figure 26.11, Figure 26.12 and Figure 26.13 show examples of serial transmission in asynchronous mode.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

●奇偶校验位或多处理器位（可根据格式省略）
●停止位

4.SCI在停止位输出时检查TDR寄存器的更新。

5.当TDR寄存器更新时，设置CCR1.CTSE位为0（CTS功能被禁用）或低电平输入开启CTSn_RTSn引脚导致下一个发送数据从TDR寄存器传输到TSR寄存器并传输停止位，然后开始下一帧的串行传输。

6、如果TDR寄存器没有更新，则CSR.TEND标志置1，发送停止位，进入标记状态，其中输出1。如果CCR0.TEIE位为1，则CSR.TEND标志设置为1，并产生SCIn_TEI中断请求。

[2] SCIn_TXI interrupt request:
The transmit-data-empty-interrupt(SCIn_TXI) is generated at following conditions.
When set TE and TIE to 0 at same time.
When transmission-data forwards to TSR from TDR.

[3] Serial transmission continuation procedure:
To continue serial transmission write transmit data to TDR*1 once by using a SCIn_TXI.
Transmit data can also be written by activating the DMAC or DTC.

[4] If you use TEI, set TIE = 0 and TEIE = 1 after writing the last-transmit-data to TDR*1 and transmission is started.

[5] Break output at the end of serial transmission:
To output a break, it is necessary to set SPB2IO and SPB2DT, for output status setting when TE is 0.
(If you set these bits at initialization, you can skip this step.)

[6] Set CCR0.TE,TIE,TEIE to 0.

[3]串行传输继续过程：要继续串行传输，使用SCIn_TXI将传输数据写入TDR*1一次。也可以通过激活DMAC或DTC来写入传输数据。[4]

如果使用TEI，在将最后发送数据写入TDR*1并开始发送后，设置TIE=0和TEIE=1。

Figure 26.15 Data format written to transmit-FIFO(TDR) with FIFO selected

In serial transmission, the SCI operates as described in this section.

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. The amount of data that can be written to TDR is 16 minus FTSR.T[5:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the CCR0.TE and CCR0.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the CCR1.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the TDR register to the TSR register. When the amount of transmit data written in TDR is equal to or less than the specified transmit triggering number, CSR.TDFE is set to 1. If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the CCR0.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the CCR0.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data
   - Parity bit or multi-processor bit (can be omitted depending on the format)
   - Stop bit
4. On output of the stop bit, the SCI checks whether non-transmitted data remains in the TDR register.
5. When data is set to transmit-FIFO (TDR), setting the CCR1.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from TDR to TSR and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set in transmit-FIFO (TDR), the TEND flag in CSR is set to 1, the stop bit is sent, and the mark state is entered in which 1 is output. If the CCR0.TEIE bit is 1, the CSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Figure 26.15 在选择FIFO的情况下写入发送FIFO(TDR)的数据格式

在串行传输中，SCI的操作如本节所述。

1.当数据在SCIn_TXI中断处理程序中写入TDR时，SCI将数据从TDR寄存器传输到TSR寄存器。可写入TDR的数据量为16减去FTSR.T[5:0]字节。当CCR0.TE和CCR0.TIE位通过一条指令同时设置为1时，会在传输开始时产生SCIn_TXI中断请求。

2.CCR1.CTSE位设置为0（禁用CTS功能）或CTSn_RTSn引脚上的低电平导致数据从TDR寄存器传输到TSR寄存器后开始传输。当写入TDR的发送数据量等于或小于指定的发送触发数时，CSR.TDFE设置为1。如果CCR0.TIE位为1，则产生SCIn_TXI中断请求。在当前发送数据发送完成之前，通过在SCIn_TXI中断处理例程中将下一个发送数据写入TDR可以实现连续发送。使用SCIn_TEI中断请求时，在写入要发送的最后一个数据后，将CCR0.TIE位设置为0（禁止SCIn_TXI中断请求）并将CCR0.TEIE位设置为1（启用SCIn_TEI中断请求）从SCIn_TXI请求的处理例程到TDR寄存器。

3.数据按以下顺序从TXDn引脚发送：

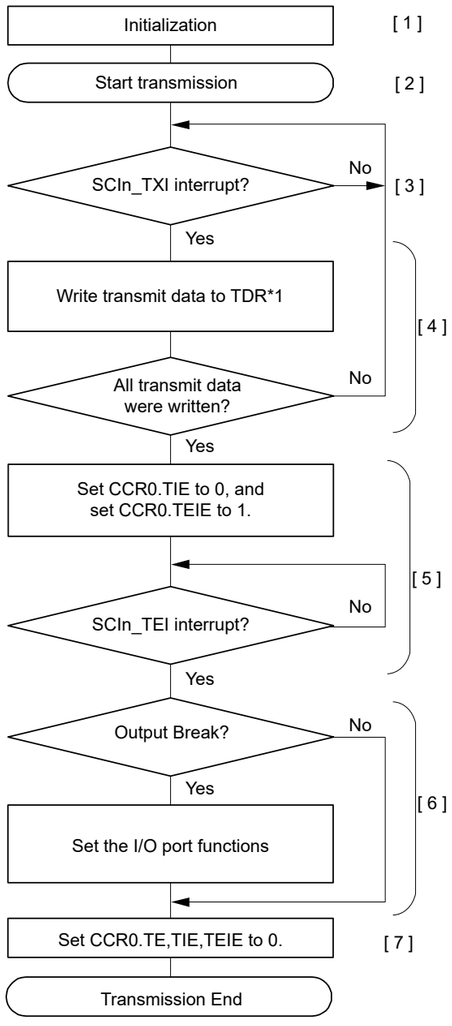
- ●起始位
- ●传输数据
- ●奇偶校验位或多处理器位（可根据格式省略）
- ●停止位

4.在停止位输出时，SCI检查未发送的数据是否保留在TDR寄存器中。

5.当数据设置为发送FIFO（TDR）时，将CCR1.CTSE位设置为0（CTS功能禁用）或低电平CTSn_RTSn引脚上的输入导致下一个传输数据从TDR传输到TSR并传输停止位，然后开始下一帧的串行传输。

6.如果发送FIFO(TDR)中没有设置数据，则CSR中的TEND标志设置为1，发送停止位，进入输出1的标记状态。如果CCR0.TEIE位为1，则CSR.TEND标志设置为1，并产生SCIn_TEI中断请求。

图26.16显示了选择FIFO的异步模式下串行传输的示例流程。



[1] Initialize SCI.
To enable SCIn_TXI interrupt, set TE and TIE to 1 with one instruction at the same time.

[2] Set transmit-data to the transmit-FIFO(TDR).
The number of transmittable data that can be set is16 .

[3] TXI interrupt request:
The transmit-data-empty-interrupt(SCIn_TXI) is generated
when transmission-data forwards to TSR from the transmit-FIFO(TDR) and the number of transmit-data written in the transmit-FIFO is equal to or less than the transmit-FIFO threshold.

[4] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data to the transmit-FIFO(TDR) by using a SCIn_TXI interrupt and clear TDRE flag to 0. (Transmit data can also be written to the transmit- FIFO(TDR) by activating the DMAC or DTC. In this case, the TDRE flag is cleared automatically, so please don't operate the TDRE flag.)
The number of transmission data it's possible to write in is 16 - (the number of stored transmit FIFO data).

[5] If you use SCIn_TEI, set TIE = 0 and TEIE = 1 after writing the last-transmit-data to TDR*1.

[6] Break output at the end of serial transmission:
To output a break, it is necessary to set SPB2IO and SPB2DT, for output status setting when TE is 0.
(If you set these bits at initialization, you can skip this step.)

[7] Set CCR0.TE,TIE,TEIE to 0.

Note 1. In case of byte access with data length 9 bits, write transmit data in order of TDR[15:8] and TDR[7:0].

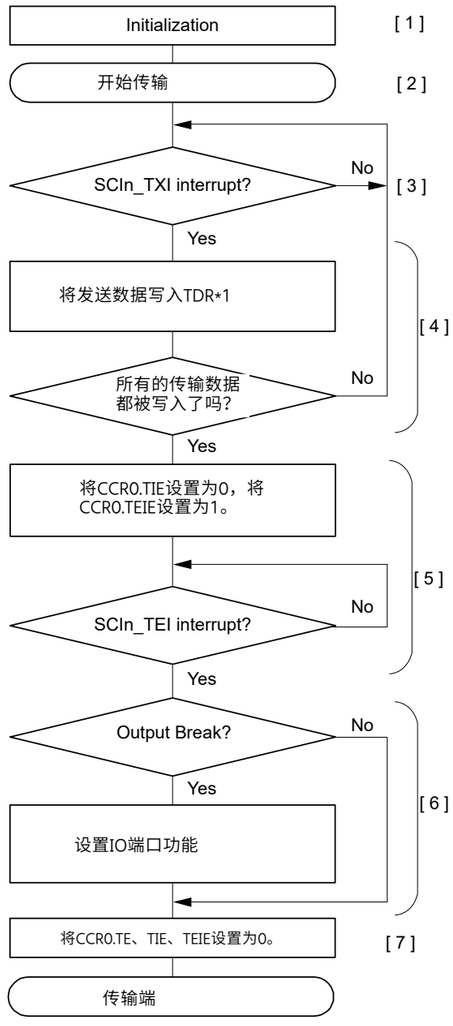
26.3.9 Serial Data Reception in Asynchronous Mode

(1) Non-FIFO selected

Figure 26.17 and Figure 26.18 show an example of the operation for serial data reception in asynchronous mode.

In serial data reception, the SCI operates as follows:

1. When the value of the CCR0.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and when it detects a start bit, the SCI performs internal synchronization, stores receive data in RSR, and checks the parity bit and stop bit.
3. If an overrun error occurs, the CSR.ORER flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.



[1] 初始化SCI。
要启用SCIn_TXI中断，请同时使用一条指令将TE和TIE设置为1。

[2]将发送数据设置到发送FIFO(TDR)。可设置的可发送数据数为16。

[3]TXI中断请求：当传输数据从传输FIFO(TDR)转发到TSR并且写入传输FIFO的传输数据数量相等时，产生传输数据空中断(SCIn_TXI)到或小于发送FIFO阈值。

[4] 串行传输继续过程：
要继续串行发送，请使用SCIn_TXI中断将所有发送数据写入发送FIFO(TDR)，并将TDRE标志清零。（发送数据也可以通过激活DMAC或DTC写入发送FIFO(TDR)。在在这种情况下，TDRE标志会自动清零，因此请不要操作TDRE标志。）
可写入的传输数据数为16（存储的传输FIFO数据数）。

[5]如果您使用SCIn_TEI，请在将最后传输数据写入TDR*1后设置TIE=0和TEIE=1。

[6]串行传输结束时的中断输出：要输出中断，需要设置SPB2IO和SPB2DT，用于TE为0时的输出状态设置。（如果在初始化时设置了这些位，则可以跳过此步骤。）

[7] 将CCR0.TE、TIE、TEIE设置为0。

注1.在数据长度为9位的字节访问情况下，按照TDR[15:8]和TDR[7:0]的顺序写入发送数据。

Figure 26.16 选择FIFO的异步模式下串行传输示例流程

26.3.9 异步模式下的串行数据接收

(1) Non-FIFO selected

图26.17和图26.18显示了异步模式下串行数据接收操作的示例。

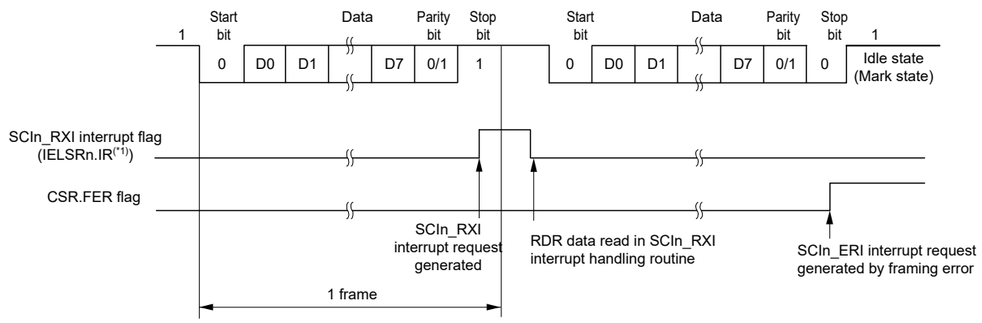
在串行数据接收中，SCI操作如下：

1.当CCR0.RE位的值变为1时，CTSn_RTSn引脚上的输出信号变为低电平。

2.SCI监控通信线路，当检测到起始位时，SCI执行内部同步，将接收数据存储在RSR中，并检查奇偶校验位和停止位。

3.如果发生溢出错误，则CSR.ORER标志设置为1。如果CCR0.RIE位为1，则产生SCIn_ERI中断请求。接收数据不传送到RDR寄存器。

4. If a parity error is detected, the CSR.PER flag is set to 1 and receive data is transferred to the RDR register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
5. If a framing error is detected, the CSR.FER flag is set to 1 and receive data is transferred to the RDR register. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated.
6. When reception finishes successfully, receive data is transferred to the RDR register. If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data is complete. Reading the received data that was transferred to the RDR register causes the CTSn_RTSn pin to output low.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 26.18 Example of SCI operation for serial reception in asynchronous mode (2) when RTS function is used, and with 8-bit data, parity bit, and 1 stop bit

Table 26.28 lists the states of the flags in the CSR status register and receive data handling when a receive error is detected.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER bits to 0 before resuming reception. In addition, be sure to read the RDR register during overrun error processing. When a reception is forced to terminate by setting the CCR0.RE bit to 0 during operation, read the RDR register because received data that is not yet read might be left in the RDR.

Figure 26.19 and Figure 26.20 show example flows of serial data reception.

4.如果检测到奇偶校验错误，则将CSR.PER标志设置为1，并将接收数据传输到RDR寄存器。如果SCR.RIE位为1，则产生SCIn_ERI中断请求。

5.如果检测到帧错误，CSR.FER标志设置为1，接收数据被传送到RDR寄存器。如果CCR0.RIE位为1，则产生SCIn_ERI中断请求。

6.接收成功后，接收数据传送到RDR寄存器。如果CCR0.RIE位为1，则
SCIn_RXI中断请求产生。通过读取传输到的接收数据启用连续接收
在接收下一个接收数据完成之前，SCIn_RXI中断处理程序中的RDR寄存器。
读取传输到RDR寄存器的接收数据会导致CTSn_RTSn引脚输出低电平。

表26.28列出了CSR状态寄存器中标志的状态以及检测到接收错误时的接收数据处理。

如果检测到接收错误，则会产生SCIn_ERI中断请求，但不会产生SCIn_RXI中断请求。
当接收错误标志为1时，无法恢复数据接收。因此，在恢复接收之前，请将ORER、FER和PER位设置为0。此外，请务必在溢出错误处理期间读取RDR寄存器。如果在操作期间通过将CCR0.RE位设置为0来强制终止接收，请读取RDR寄存器，因为尚未读取的接收数据可能会留在RDR中。

[2] Receive error processing and break detection: If a receive error occurs, an SCIn_ERI interrupt is generated. After performing the appropriate error processing, be sure to set the ORER, PER, and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. In the case of a framing error, a break can be detected by reading the value of the input port corresponding to the RXDn pin.

[3] Read the receive data in RDR once in the SCIn_RXI interrupt handling routine.

[4] Serial reception continuation procedure: To continue serial reception, before the stop bit of the current frame is received, read data from RDR in the SCIn_RXI interrupt handling routine. The RDR data can also be read by activating the DMAC or DTC.

In asynchronous mode, 0 is written to the MPB bit in the RDR register. Data that corresponds to the data length is written to RDR. Unused bits are written as 0. If software reads RDR, the SCI updates FER, PER, and receive data (RDAT[8:0]) in the RDR register with the next data. The flags RDF, ORER, and DR in the RDR register always reflect the associated flags in the CSR register.

Figure 26.21 Data format stored in receive-FIFO(RDR) with FIFO selected

Table 26.29 lists the states of the flags in CSR status register and receive data handling when a receive error is detected with FIFO selected. Figure 26.22 and Figure 26.23 show samples of flowcharts for serial data reception with FIFO selected.
In serial data reception, the SCI operates as follows:

1. When the value of the CCR0.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and, when it detects a start bit, the SCI performs internal synchronization, stores receive data in the RSR register.
3. If an overrun error occurs during normal communications, the CSR.ORER flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.
4. If a parity error is detected, the PER flag and receive data are transferred to the RDR register. If the CCR0.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
5. If a framing error is detected, the FER flag and receive data are transferred to the RDR register. If the CCR0.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
6. After a framing error is detected and when SCI detects that the continuous receive data is zero for one frame, reception stops.
7. When the amount of data stored in the RDR register falls below the specified receive triggering number, and the next data is not received after 15 ETUs from the last stop bit in asynchronous mode, the FRSR.DR flag is set to 1. When the CCR0.RIE bit is 1 and the FCR.DRES bit is 0, the SCI generates an SCIn_RXI interrupt request. When the FCR.DRES bit is 1, SCI generates an SCIn_ERI interrupt request.
8. When reception finishes successfully, receive data is transferred to the RDR register. The RDRF bit is set to 1 when the amount of receive data written to RDR is equal to or greater than the specified receive triggering number. If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine, before an overrun error occurs. If the received data that is transferred to RDR is less than the RTS trigger number, the CTSn_RTSn pin outputs low.

Figure 26.21 数据格式存储在接收FIFO(RDR)中并选择了FIFO

表26.29列出了CSR状态寄存器中标志的状态以及当检测到接收错误时的接收数据处理
选择先进先出。图26.22和图26.23显示了选择FIFO的串行数据接收的流程图示例。
在串行数据接收中，SCI操作如下：

1.当CCR0.RE位的值变为1时，CTSn_RTSn引脚上的输出信号变为低电平。

2.SCI监视通信线路，当它检测到一个起始位时，SCI执行内部同步，将接收数据存储在RSR寄存器中。

3.如果在正常通信过程中发生溢出错误，则CSR.ORER标志设置为1。如果CCR0.RIE位为1，则产生SCIn_ERI中断请求。接收数据不传送到RDR寄存器。

4.如果检测到奇偶校验错误，则将PER标志和接收数据传送到RDR寄存器。如果CCR0.RIE位设置为1，则产生SCIn_ERI中断请求。

5.如果检测到帧错误，则将FER标志和接收数据传送到RDR寄存器。如果CCR0.RIE位设置为1，则产生SCIn_ERI中断请求。

6、检测到帧错误后，当SCI检测到连续接收数据一帧为零时，停止接收。

7.当存储在RDR寄存器中的数据量低于指定的接收触发数，并且在异步模式下从最后一个停止位开始15个ETU后没有接收到下一个数据时，FRSR.DR标志设置为1。CCR0.RIE位为1，FCR.DRES位为0，SCI产生一个SCIn_RXI中断请求。当FCR.DRES位为1时，SCI产生一个SCIn_ERI中断请求。

8.接收成功后，接收数据传送到RDR寄存器。当写入RDR的接收数据量等于或大于指定的接收触发数时，RDRF位设置为1。如果CCR0.RIE位为1，则产生SCIn_RXI中断请求。在发生溢出错误之前，通过在SCIn_RXI中断处理例程中读取传输到RDR寄存器的接收数据来启用连续接收。如果接收到的传输到RDR的数据小于RTS触发数，CTSn_RTSn引脚输出低电平。

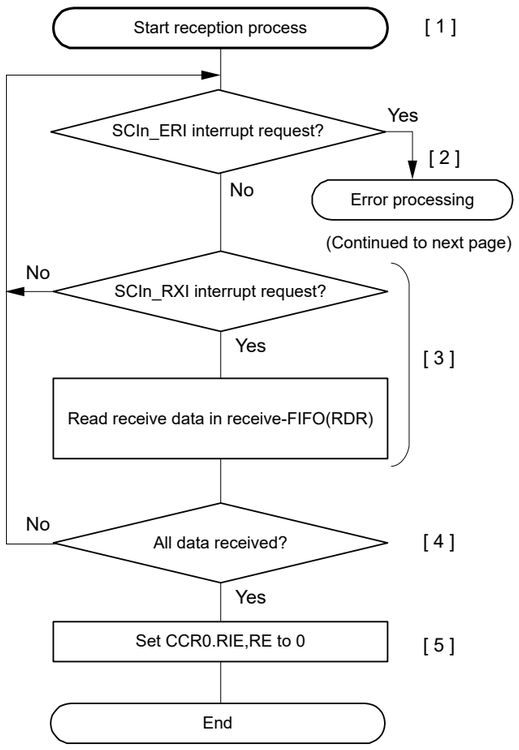
1	0	1	Lost	Overrun error + Parity error
0	1	1	Transferred RDR	Framing error + Parity error
1	0	0	Lost	Overrun error + Framing error + Parity error

Note 1. This flag indicates whether there is an error in received data when reception is completed.



[1] Start reception process

[2] Receive error processing and break detection: If a receive error occurs, an SCIn_ERI interrupt is generated. After performing the appropriate error processing, be sure to set the ORER flags to 0. Reception cannot be resumed if ORER is set to 1. Reception can continue even if PER,FER,DR flags are 1.

[3] Read the receive data in the receive-FIFO(RDR) in the SCIn_RXI interrupt handling routine. The reception data stored in the receive-FIFO(RDR) is read until the number of stored data will be below the FCR.RTRG value at least. You can confirm the number of the reception data in the FIFO by FRSR.R[5:0].

[4] Serial reception continuation procedure: To continue serial reception, before an overrun error occurs, please read data from the receive-FIFO(RDR) in the SCIn_RXI interrupt handling routine and clear CSR.RDRF flag and FRSR.DR flag to 0. The receive-FIFO data can also be read by activating the DMA or DTC. The RDRF flag is cleared automatically in this case, so please don't operate the RDRF flag.

[5] Set CCR0.RIE,RE to 0.

Note 1. Can be read in the RDR.ORER, PER, FER and DR flags.

[2]接收错误处理和中断检测：如果发生接收错误，则产生SCIn_ERI中断。执行适当的错误处理后，请务必将ORER标志设置为0。如果ORER设置为1，则无法恢复接收。即使PER、FER、DR标志为1，也可以继续接收。

[3]在receive中读取接收数据

SCIn_RXI中断处理例程中的FIFO(RDR)。读取存储在接收FIFO(RDR)中的接收数据，直到存储的数据数量至少低于FCR.RTRG值。您可以通过FRSR.R[5:0]确认FIFO中接收数据的数量。

[4]串行接收继续过程：

要继续串行接收，在发生溢出错误之前，请在SCIn_RXI中断处理程序中从接收FIFO(RDR)中读取数据，并将CSR.RDRF标志和FRSR.DR标志清除为0。接收FIFO数据也可以被读取通过激活DMA或DTC。这种情况下RDRF标志会自动清零，因此请不要操作RDRF标志。

[5]将CCR0.RIE RE设置为0。

注1.可以在RDR.ORER、PER、FER和DR标志中读取。

[6] Reception error flag confirmation:
Read CSR and FRSR.
You can identify error by checking flags.

[7] Overrun error processing:
Read the receive-FIFO(RDR) and make space in the receive-FIFO(RDR).

[8] Break processing:
When CCR3.RXDESEL is 0, the latest receive data in the receive-FIFO(RDR) is the break-data which has framing error and all data-bits are 0. So, discard the latest receive data.

[8] Framing error / Parity error processing:
Read all error occurrence data stored in the receive-FIFO(RDR). (You can substitute to write 1 in FCR.RFRST bit and empty the receive-FIFO(RDR).)

[9] DR error process when FCR.DRES is 1.:
Performs error processing required for the system (for example, setting a counter for data number management)

[10] Read all received data in the receive-FIFO(RDR).

[11] Clear the error flag:
Make clear FER, PER, ORER, DR.

[12] Confirming that the error flag is cleared:
Confirm FER,PER,ORER,DR are cleared.

[6]接收错误标志确认：读取CSR和FRSR。
您可以通过检查标志来识别错误。

[7]超限错误处理：
读取接收FIFO(RDR)并在接收FIFO(RDR)中腾出空间。

[8] Break processing:
当CCR3.RXDESEL为0时，receive-FIFO(RDR)中最新接收的数据为有帧错误的中断数据，所有数据位均为0。因此，丢弃最新接收数据。

[8]帧错误奇偶校验错误处理：读取存储在接收FIFO（RDR）中的所有错误发生数据。（您可以替换为在FCR.RFRST位中写入1并清空接收FIFO(RDR)。）

[9]FCR.DRES为1时的DR错误处理：
执行系统所需的错误处理（例如，设置数据编号管理的计数器）

[10]读取接收FIFO(RDR)中的所有接收数据。

[11]清除错误标志：
明确FER、PER、ORER、DR。

[12]确认错误标志已清除：确认FER PER ORER DR已清除。

26.3.10 调整接收采样定时功能（异步模式）

When there is the difference between the rising transfer time and the falling transfer time through a photo coupler, the receive sampling timing at middle of bit affects the reception margin. In this case, the receive sampling timing is able to adjust from the middle of bit to the optimum timing by using this function.

The receive sampling timing is adjusted from the middle of bit by following formula. And the adjustable direction is set by CCR4.AJD. You can select forward or backward from the middle of bit. When adjusting backward (CCR4.AJD = 0), substitute AJD = +1 and substitute AJD = -1 when adjusting forward (CCR4.AJD = 1).

Adjusted sampling timing = the middle of bit + AJD * (base clock * the setting value of CCR4.AST[2:0])

The setting timing is limited by base clock cycles per 1 bit. Please refer to Table 26.30 in detail.

An overview of reception operation of the communication through a photo coupler with this function is shown in Figure 26.24, Figure 26.25 and Figure 26.26, the explanation of operation with this function is shown in Figure 26.27.

Please don't use this function when there is no difference between the rising transfer time and the falling transfer time, because there is a possibility of deteriorating the reception margin.

当通过光电耦合器的上升传输时间和下降传输时间之间存在差异时，位中间的接收采样时间会影响接收裕度。在这种情况下，接收采样时序可以通过使用该功能从比特中间调整到最佳时序。

接收采样定时通过以下公式从位中间调整。可调方向由CCR4.AJD。您可以从位的中间选择向前或向后。向后调整时（CCR4.AJD=0），代入AJD=+1，向前调整时代入AJD=-1（CCR4.AJD=1）。

调整后的采样时序=中间位+AJD*（基准时钟*CCR4.AST[2:0]的设置值）

设置时序受限于每1位的基本时钟周期。详见表26.30。

图26.24、图26.25、图26.26所示为使用该功能的光耦合器通信的接收操作概要，使用该功能的操作说明如图26.27所示。

请不要在上升传输时间和下降传输时间没有差异时使用此功能，因为有可能恶化接收余量。

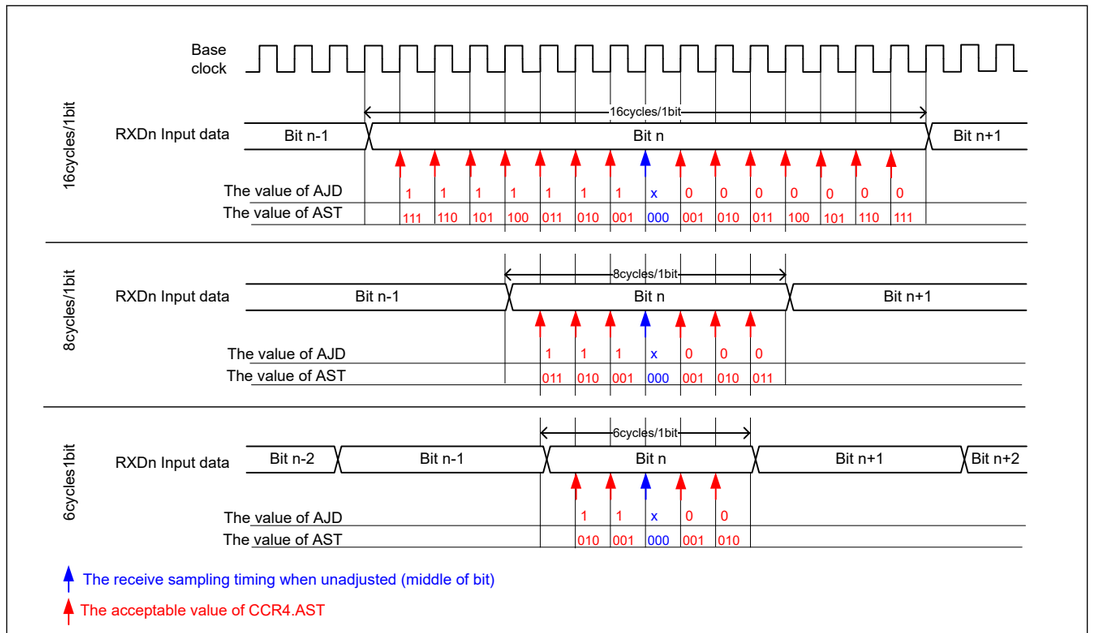

Figure 26.27 Overview of the adjustment operation for the reception sampling timing (asynchronous mode using internal clock)

26.3.11 The function of adjust transmit timing (Asynchronous Mode)

In communication via a photo coupler or the like, when either the rising or falling transition time of the TXDn output signal is long, then a communication partner receive dulled waveform. In this case, the reception margin may be affected.

In these cases, make a communication partner to be sampling at middle of bit using the function of adjust transmit timing.

When CCR4.ATEN is 1, this function can adjust the edge timing at the timing calculated by the following formula for the edge set with CCR4.AET.

The adjustment edge timing = the base clock * CCR4.ATT[2:0]

In addition, the upper limit of the adjustment edge timing is limited by setting the base clock cycles. Refer to Table 26.31 in details.

A transmission movement image figure of the communication through a photo coupler with this function is shown in Figure 26.28, Figure 26.29 and Figure 26.30, the overview of operation with this function is shown in Figure 26.31 and Figure 26.32.

Please don't use this function when there is not the difference between the rising transfer time and the falling transfer time, there is a possibility of deteriorating the reception margin of a communication partner.

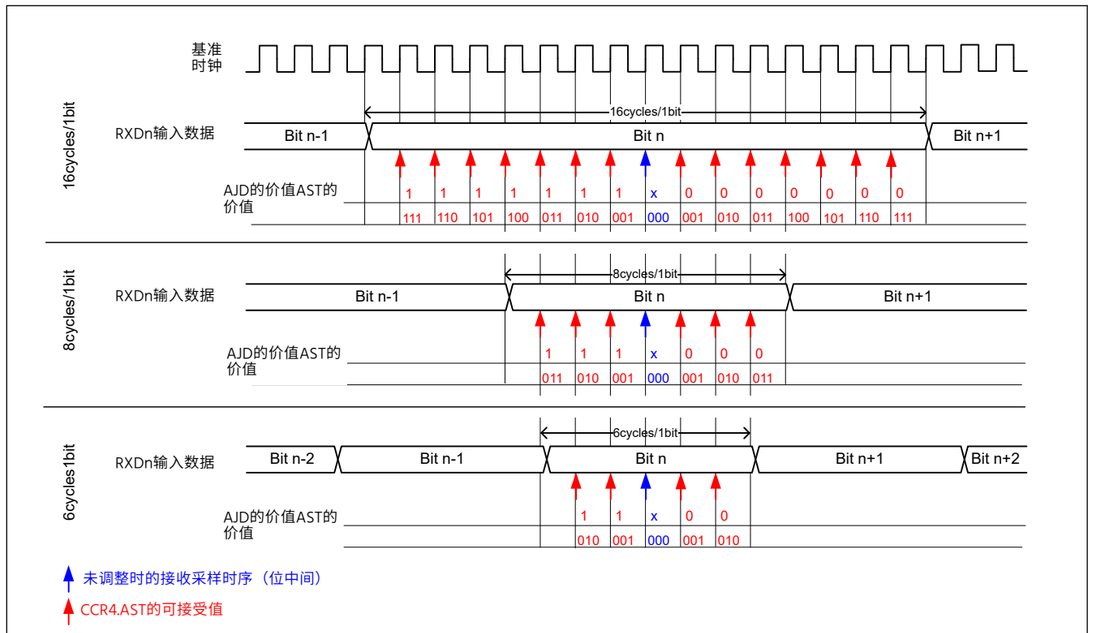

Figure 26.27 接收采样定时调整操作概述（使用内部时钟的异步模式）

26.3.11 调整发送时间的功能（异步模式）

在经由光电耦合器等的通信中，当TXDn输出信号的上升或下降过渡时间较长时，通信伙伴接收到钝化波形。在这种情况下，接收裕量可能会受到影响。

在这些情况下，使用调整发送时间的功能使通信伙伴在位中间进行采样。

当CCR4.ATEN为1时，该功能可以对用CCR4.AET设置的边沿按以下公式计算的时序调整边沿时序。

调整边沿时序=基准时钟*CCR4.ATT[2:0]

另外，调整边沿时序的上限是通过设置基本时钟周期来限制的。详见表26.31。

图26.28、图26.29、图26.30为使用该功能的光耦合器通信的传输动作图，使用该功能的操作概要如图26.31、图26.32所示。

请不要在上升传输时间和下降传输时间之间没有差异时使用此功能，这可能会降低通信伙伴的接收裕度。

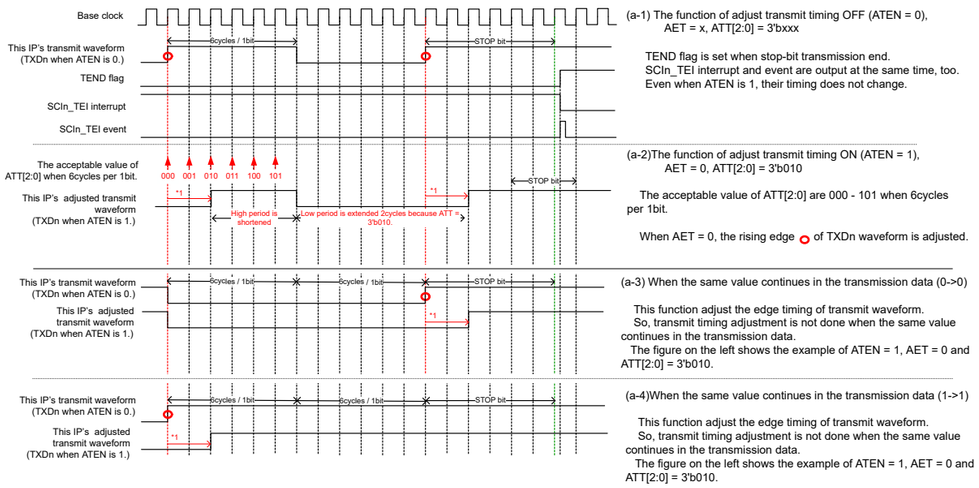
The operation explanation of adjustment the transmit timing

(a) In the case of the falling transfer time >> rising transfer time
In this case, the high period of a communication partner's reception waveform is made long, and the low period is made short.
Therefore, this IP transmits the waveform with the edge relatively brought forward by adjusting the falling edge timing.
Then adjust value(ATT[2:0]) should be set to make equal the low-period/1bit and high-period/1bit for a communication partner.

This function's operation is explained as an example of 6cycles/1bit.



Note 1. The rising edge of transmit timing is shifted to back by the setting value of CCR4.ATT[2:0].

然后调整值（ATT[2:0]）应设置为使通信伙伴的低周期1bit和高周期1bit相等。

该功能的操作以6cycles1bit为例进行说明。

26.4 Multi-Processor Communication Function

The multi-processor communication function enables the SCI to transmit and receive data between multiple processors by sharing an asynchronous serial communication line that has an added multi-processor bit. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station.

The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle:

- When the multi-processor bit is set to 1, the transmission cycle is the ID transmission cycle
- When the multi-processor bit is set to 0, the transmission cycle is the data transmission cycle

Figure 26.33 shows an example of communication between processors using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits communication data in which the multi-processor bit set to 0 is added to the transmit data. After receiving communication data with the multi-processor bit set to 1, the receiving station compares the received ID with the ID of the receiving station itself. If the two match, the receiving station receives communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until it receives data in which the multi-processor bit is set to 1.

RTS control cannot be used at the time of multi-processor communication function use because this is a function corresponding to one-to-many communications.

26.4 多处理器通信功能

多处理器通信功能使SCI能够通过共享一条增加了多处理器位的异步串行通信线路在多个处理器之间发送和接收数据。在多处理器通信中，为每个接收站分配一个唯一的ID代码。串行通信周期由指定接收站的ID传输周期和向指定接收站传输数据的数据传输周期组成。

多处理器位用于区分ID传输周期和数据传输周期：

- 当多处理器位设置为1时，传输周期为ID传输周期
- 当多处理器位设置为0时，传输周期为数据传输周期

图26.33显示了使用多处理器格式的处理器之间的通信示例。首先，发送站发送将设置为1的多处理器位添加到接收站的ID码的通信数据。接着，发送站发送在发送数据中附加了多处理器比特为0的通信数据。接收站接收到多处理器位设置为1的通信数据后，将接收到的ID与接收站自身的ID进行比较。如果两者匹配，则接收站接收随后发送的通信数据。如果接收到的ID与接收站的ID不匹配，则接收站跳过通信数据，直到接收到多处理器位设置为1的数据。

在使用多处理器通信功能时，不能使用RTS控制，因为这是一个对应于一对多通信的功能。

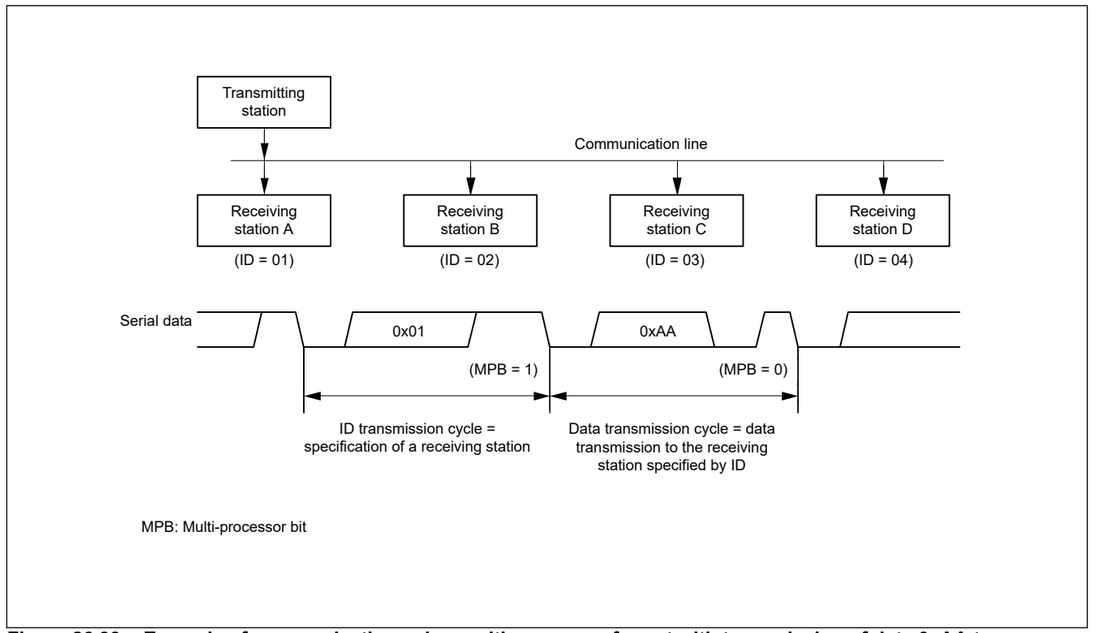

Figure 26.33 Example of communication using multi-processor format with transmission of data 0xAA to receiving station A

(1) Non-FIFO selected

To support this function, the SCI provides the CCR0.MPIE bit. When the MPIE bit is set to 1, the following operations are disabled until the reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR register
- Detection of a receive error
- Setting of the respective RDRF, ORER, and FER status flags in the CSR register

When the SCI receives a character in which the multi-processor bit is set to 1, the RDR.MPB bit is set to 1 and the CCR0.MPIE bit is automatically cleared, returning the SCI to non-multi-processor reception operation. If the CCR0.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in non-multi-processor asynchronous mode. The clock used for the multi-processor communication is the same as the clock used in non-multi-processor asynchronous mode.

(2) FIFO selected

For data transmission, software must write data to TDR.MPBT (Multi-Processor Bit Transfer) that corresponds to transmit data in TDR.TDAT. For data reception, the multi-processor bit that is part of the receive data is written to RDR.MPB and receive data is written to RDR.RDAT.

When the MPIE bit is set to 1, the following operations are disabled until reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR.RDAT register
- Detection of a receive error
- Detection of DR
- Setting of the respective RDRF, ORER, and FER status flags in the CSR register

When the SCI receives a character in which the multi-processor bit is set to 1, the RDR.MPB bit is set to 1 and receive data is written to receive-FIFO(RDR.RDAT). The CCR0.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the CCR0.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

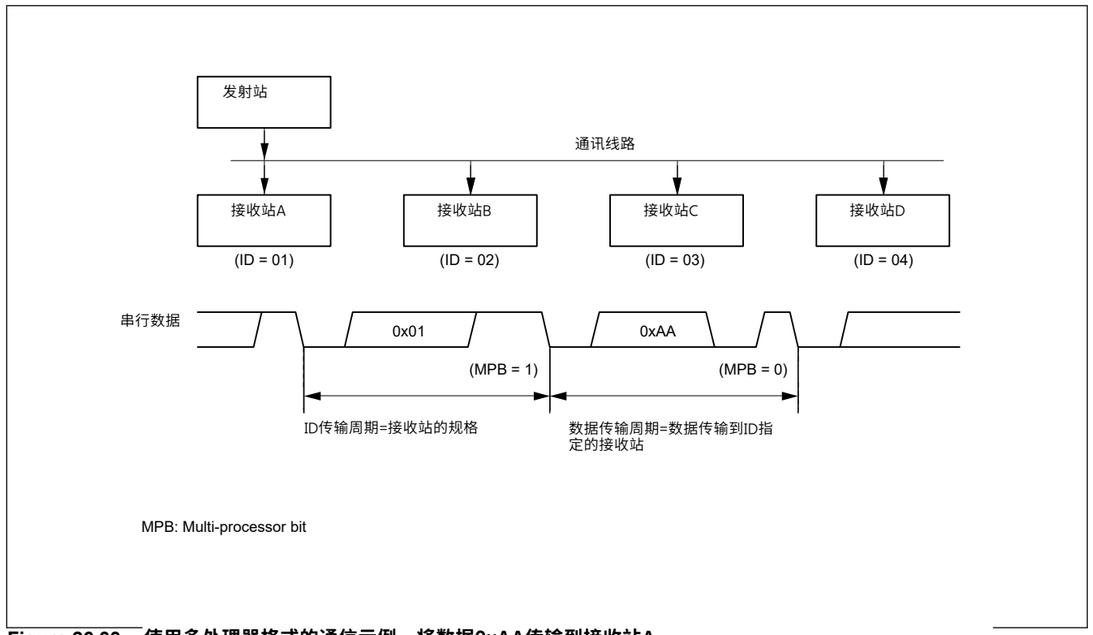

Figure 26.33 使用多处理器格式的通信示例，将数据0xAA传输到接收站A

(1) Non-FIFO selected

为了支持这个功能，SCI提供了CCR0.MPIE位。当MPIE位设置为1时，以下操作被禁止，直到接收到多处理器位设置为1的数据：

- 将接收数据从RSR寄存器传送到RDR寄存器
- 接收错误检测
- 在CSR寄存器中分别设置RDRF、ORER和FER状态标志

当SCI接收到多处理器位设置为1的字符时，RDR.MPB位设置为1，并且
CCR0.MPIE位自动清零，将SCI返回到非多处理器接收操作。如果CCR0.RIE位设置为1，则产生SCIn_RXI中断。

当指定多处理器格式时，奇偶校验位功能被禁用。除此之外，与非多处理器异步模式下的操作没有区别。多处理器通信使用的时钟与非多处理器异步模式使用的时钟相同。

(2) FIFO selected

对于数据传输，软件必须将数据写入对应于TDR.TDAT中传输数据的TDR.MPBT（多处理器位传输）。对于数据接收，作为接收数据一部分的多处理器位写入RDR.MPB，接收数据写入RDR.RDAT。

当MPIE位设置为1时，以下操作被禁止，直到接收到多处理器位设置为1的数据：

- 将接收数据从RSR寄存器传送到RDR.RDAT寄存器
- 接收错误检测
- DR检测
- 在CSR寄存器中分别设置RDRF、ORER和FER状态标志

当SCI接收到一个多处理器位设置为1的字符时，RDR.MPB位设置为1，接收数据写入接收FIFO(RDR.RDAT)。CCR0.MPIE位自动清零，使SCI恢复正常接收操作。如果CCR0.RIE位设置为1，则产生SCIn_RXI中断。

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode with FIFO selected.

26.4.1 Multi-Processor Serial Data Transmission

(1) Non-FIFO selected

Figure 26.34 shows an example flow of multi-processor data transmission. In the ID transmission cycle, the ID must be transmitted with the TDR.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in asynchronous mode.

[2] SCIn_TXI interrupt request:
The transmit-data-empty-interrupt(SCIn_TXI) is generated at following conditions.
When set TE and TIE to 0 at same time.
When transmission-data forwards to TSR from TDR.

[3] Serial transmission continuation procedure:
To continue serial transmission write transmit data and MPBT setting value to TDR*1 once by using a SCIn_TXI. Transmit data and MPBT setting value can also be written by activating the DMAC or DTC.

[4] If you use SCIn_TEI, set TIE = 0 and TEIE = 1 after writing the last-transmit-data to TDR*1 and transmission is started.

[5] Break output at the end of serial transmission:
To output a break, it is necessary to set SPB2IO and SPB2DT, for output status setting when TE is 0. (If you set these bits at initialization, you can skip this step.)

[6] Set CCR0.TE,TIE,TEIE to 0.

Note 1. In case of byte access with data length 9 bits or to write MPBT bit, write transmit data in order of TDR[15:8] and TDR[7:0].

Figure 26.38 and Figure 26.39 are example flows of multi-processor serial reception. When the CCR0.MPIE bit is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to the RDR register, and the SCIn_RXI interrupt request is generated. The rest of the operations are the same as operations in asynchronous mode.

(2) FIFO selected

Figure 26.40 shows an example of a data format that is written to receive-FIFO (RDR) in multi-processor mode.

In multi-processor mode, the MPB value that is a part of the receive data is written to the RDR.MPB bit. A value of 0 is written to the RDR.FPER and PER flags. Data is written to receive-FIFO (RDR) with the correct data length. Unused bits are written with 0. When software reads the receive-FIFO (RDR) register, the SCI updates RDR.FFER, FPER, and MPB flags, and receive data (RDAT[8:0]) in receive-FIFO (RDR) with the next data. The FER, PER, and ORER flags in the receive-FIFO (RDR) register always reflect the associated flags in the CSR and FRSR registers.

[2] ID reception cycle:
Set CCR0.MPIE to 1. and wait for ID reception. If you set this bits at initialization([1]), you can skip this Step.

[3] SCI status confirmation and reception and comparison of ID:
Skip the communication data until the MPB bit receives data 1. When the MPB bit receives data 1, an SCIn_XRI interrupt request is generated. When an SCIn_RXI interrupt request is received, read the data in the receiving FIFO (RDR register) and compare it to the ID of my station. If it is not my station's ID, set the MPIE bit to 1 again and wait for the SCIn_RXI interrupt request. For my station's ID, set the received FIFO threshold to the necessary value.

[4] Data reception at an SCIn_RXI interrupt:
When the number of received data stored in the received FIFO (RDR register) exceeds the received FIFO threshold, the CSR.RDRF bit becomes 1 and an SCIn_RXI interrupt request is generated. In addition, if the number of received data stored in the received FIFO (RDR register) is 1 or more and less than the received FIFO threshold, the FRSR.DR bit becomes 1 after 15 ETU, and an SCIn_RXI interrupt request is generated. The SCIn_RXI interrupt routine reads the data from the received FIFO (RDR register).

[5] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading ORER and FER flags in CSR. After performing the appropriate error processing be sure to clear the ORER and FER flags. In the case of a framing error, a break can be detected by reading the value of the RXDn pin.

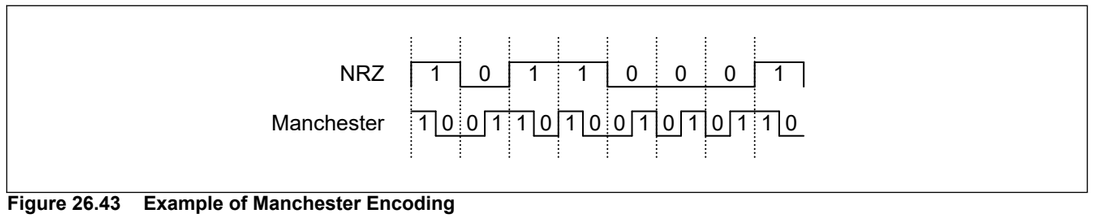

Figure 26.43 Example of Manchester Encoding

In Manchester mode, a preface and a start bit area are added to the transmit data in the register to configure a transmit frame. For transmission, data is encoded in Manchester encoding. When data is received, frames having the same format as transmitted frames are detected and Manchester decoding is performed.

For details on the frame format, see section 26.5.1. Frame Format.

26.5.1 Frame Format

Figure 26.44 shows the frame format in Manchester mode.

In the upper half of the figure, relevant setting registers are shown.

The preface area and the data area are encoded in Manchester encoding.

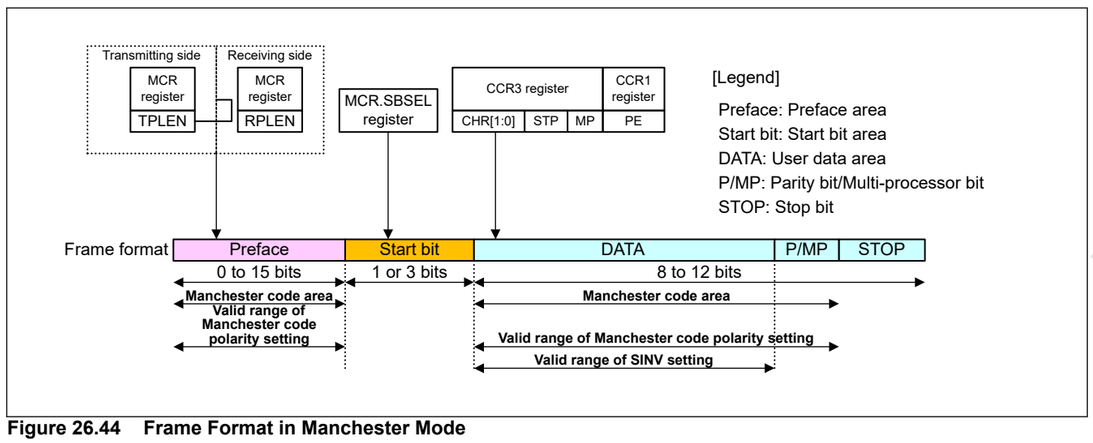

Figure 26.44 Frame Format in Manchester Mode

(1) Preface area

This is a fixed pattern area located at the beginning of each frame.

Different registers are used to set the preface area for transmission and reception. The preface length is determined by setting MCR.TPLEN[3:0] for transmission. It is determined by setting MCR.RPLEN[3:0] for reception.

If it is set to 0, the transmit preface is disabled and is not added.

If it is set to 1d to 15d, a preface whose length is determined by this setting is added.

(For example, if it is set to 1d, a 1-bit preface is added. If it is set to 15d, a 15-bit preface is added.)

The preface pattern is set with MCR.TPPAT[1:0] for transmission and MCR.RPPAT[1:0] for reception, and is selected from four types of patterns.

Figure 26.45 shows how the preface pattern is set. The preface area and the start bit area are added for each communication frame.

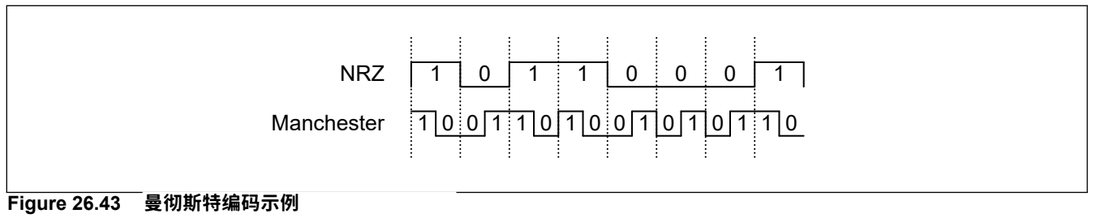

Figure 26.43 曼彻斯特编码示例

在曼彻斯特模式下，前言和起始位区域被添加到寄存器中的发送数据以配置发送帧。对于传输，数据以曼彻斯特编码进行编码。当接收到数据时，检测与传输帧格式相同的帧并执行曼彻斯特解码。

有关帧格式的详细信息，请参见第26.5.1节。帧格式。

26.5.1 帧格式

图26.44显示了曼彻斯特模式下的帧格式。

在图的上半部分，显示了相关的设置寄存器。

前言区和数据区采用曼彻斯特编码。

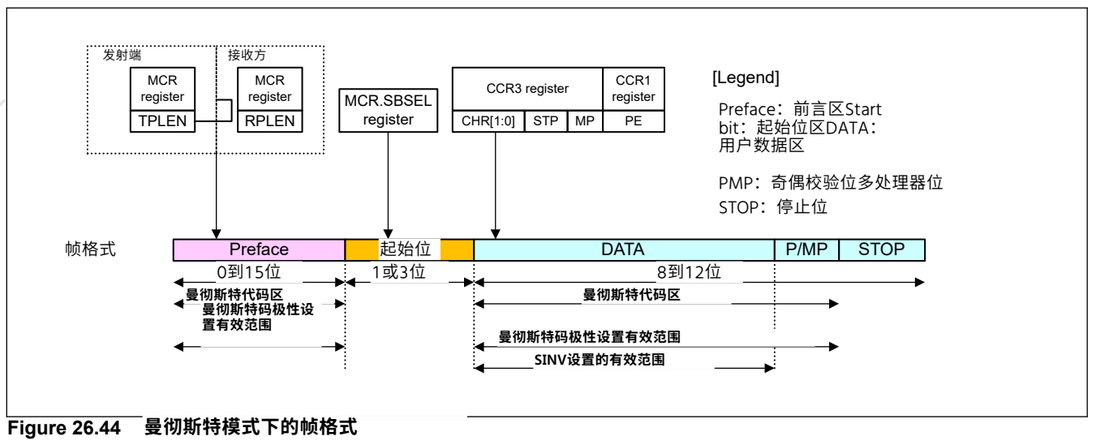

Figure 26.44 曼彻斯特模式下的帧格式

(1) 前言区

这是位于每帧开始处的固定模式区域。

不同的寄存器用于设置发送和接收的前言区域。前言长度通过设置MCR.TPLEN[3:0]来确定传输。通过设置接收的MCR.RPLEN[3:0]来确定。

如果设置为0，则发送前言被禁用且不添加。

如果设置为1d到15d，则添加一个长度由该设置确定的前言。

（例如，如果设置为1d，则添加1位前言。如果设置为15d，则添加15位前言。）

前言模式设置为发送用MCR.TPPAT[1:0]，接收用MCR.RPPAT[1:0]，从四种模式中选择。

图26.45显示了如何设置前言模式。为每个通信帧添加前言区和起始位区。

(2) Start bit area

This is an area indicating the start of valid data in a frame. It is added after the preface area.

The start bit length is determined by MCR.SBSEL setting. When MCR.SBSEL = “0”, the start bit length is 1 bit.

When MCR.SBSEL = “1”, the start bit length is 3 bits.

When MCR.SBSEL = “1”, the SYNC type can be selected from command SYNC and data SYNC.

Command SYNC means the three start bits are added as a one-to-zero transition.

(2) 起始位区

这是指示帧中有效数据开始的区域。它添加在前言区域之后。

起始位长度由MCR.SBSEL设置决定。当MCR.SBSEL=“0”时，起始位长度为1位。

当MCR.SBSEL=“1”时，起始位长度为3位。

当MCR.SBSEL=“1”时，SYNC类型可以从命令SYNC和数据SYNC中选择。

命令SYNC意味着三个起始位被添加为一个从1到零的转换。

Data SYNC means the three start bits are added as a zero-to-one transition.

The SYNC type is determined by the MCR.SYNSEL, MCR.SYNVAL and TDR.TSYNC settings.

(When receiving, the received result is applied to MSR.RSYNC.)

When MCR.SBSEL = “0”, the start bit is added as a zero-to-one or one-to-zero transition.

The selection is determined by the MCR.SYNVAL setting.

The MCR.SYNSEL bit specifies the destination to be referred to when setting for transmission.

When the MCR.SYNSEL bit is set to 1, the MCR.SYNVAL setting is referred to. When the MCR.SYNSEL bit is set to 0, the TDR.TSYNC setting is referred to.

Figure 26.46 shows the state of the start bit area according to the settings in the MCR.SYNSEL, MCR.SYNVAL and TDR.TSYNC registers in the case of transmission. Figure 26.47 shows that in the case of reception.

The start bit(s) is not affected by the MCR.TMPOL or MCR.RMPOL setting.

数据同步意味着三个起始位被添加为一个零到一的转换。

SYNC类型由MCR.SYNSEL、MCR.SYNVAL和TDR.TSYNC设置确定。

（接收时，将接收到的结果应用到MSR.RSYNC。）

当MCR.SBSEL=“0”时，添加起始位作为零到一或一到零的转换。

选择由MCR.SYNVAL设置决定。

MCR.SYNSEL位指定设置传输时要参考的目标。

当MCR.SYNSEL位设置为1时，参考MCR.SYNVAL设置。当MCR.SYNSEL位设置为0时，参考TDR.TSYNC设置。

(3) DATA

由于数据区的格式与异步模式相同，见26.3.1节。串行数据传输
Format.

As shown in Figure 26.43, Frame Format in Manchester Mode, the stop bit is not included in the Manchester encoding range.

26.5.2 Clock

As the transfer clock in Manchester mode, the clock generated by the on-chip baud rate generator is used by setting the CCR2.CKS[1:0] bit.

Also it is possible to set the oversampling (transfer rate of one-bit period) by CCR2.ABCS bit.

When the CCR2.ABCS bit is set to 0, oversampling x16 is selected with the one-bit period being 16 cycles of the base clock. When the CCR2.ABCS bit is set to 1, oversampling x8 is selected with the one-bit period being 8 cycles of the base clock.

26.5.3 Initialization of the SCI in Manchester Mode

Before transferring data, write 0 to CCR0.TE and CCR0.RE (or write the initial value to CCR0 register) and initialize the SCI following the example of flowchart shown in Figure 26.48.

Whenever the operating mode or transfer format is changed, the CCR0 register must be initialized before the change is made.

Note that setting the CCR0.RE bit to 0 initializes none of the ORER, FER, PER, RDRF, and RDF flags in the CSR register, the SYER, PFER, MER and SBER flags in the MSR register, and the RDR registers.

Note also that switching the value of CCR0.TE from 0 to 1 when CCR0.TIE is 1 generates a SCIn_TXI interrupt request.

如图26.43，曼彻斯特模式下的帧格式，停止位不包含在曼彻斯特编码范围内。

26.5.2 Clock

作为曼彻斯特模式下的传输时钟，片内波特率发生器产生的时钟用于设置
CCR2.CKS[1:0] bit.

也可以通过CCR2.ABCS位设置过采样（一位周期的传输率）。

当CCR2.ABCS位设置为0时，选择x16过采样，一位周期为基本时钟的16个周期。当CCR2.ABCS位设置为1时，选择x8过采样，一位周期为基本时钟的8个周期。

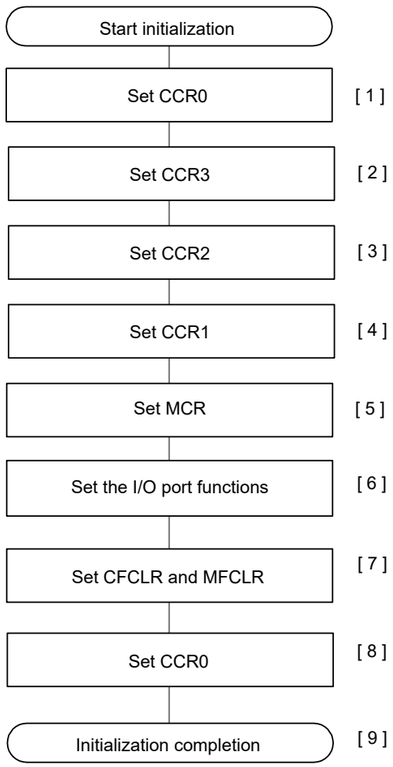
26.5.3 曼彻斯特模式下SCI的初始化

在传输数据之前，将0写入CCR0.TE和CCR0.RE（或将初始值写入CCR0寄存器）并初始化
SCI下面的例子流程图如图26.48所示。

无论何时改变操作模式或传输格式，CCR0寄存器必须在改变之前初始化。

请注意，将CCR0.RE位设置为0不会初始化CSR寄存器中的ORER、FER、PER、RDRF和RDF标志、MSR寄存器中的SYER、PFER、MER和SBER标志以及RDR寄存器。

另请注意，当CCR0.TIE为1时，将CCR0.TE的值从0切换为1会产生SCIn_TXI中断请求。



[1] Set the following bits of CCR0 to 0.
TEIE, TIE, RIE, TE, RE
If you have not changed from the initial settings, you can skip this step.

[2] Set the driver control, Multi-processor communication, the communication mode, transmission/reception format, and Clock enable.
Do not use function bits such as CPOL and CPHA at the initial value.

[3] Set the clock selection, Bit rate setting.
Leave unused function bits at their initial values.(ex. BRME)

[4] Set the noise filter, loopback control, communication terminal status, parity check, and CTS / RTS function.

[5] Set Manchester transmission / reception setting.
Start bit setting, retiming setting, Manchester polarity setting, transmission preface setting, reception preface setting.

[6] Set the I / O port so that the required pin function is valid among the TXDn, RXDn, and SCKn pins.

[7] Set 1 to the following clear bits in the CFCLR and MFCLR registers to clear the target flag.
CFCLR.RDRFC, FERC, PERC, MFC, ORERC, DFERC, DPERC, DCMFC, ERSCMFMFCLR.MERC, SBERC, SYERC, PFERC
This procedure can be omitted for the initial setting after reset.

[9] Set the TE bit or RE bit to 1.
To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time, and multiprocessor function. The TXDn and RXDn pins can be used by setting the TE and RE bits.

Figure 26.48 SCI Initialization Flow in Manchester Mode

26.5.4 Double-speed operation

When the ABCS bit in CCR2 is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0.

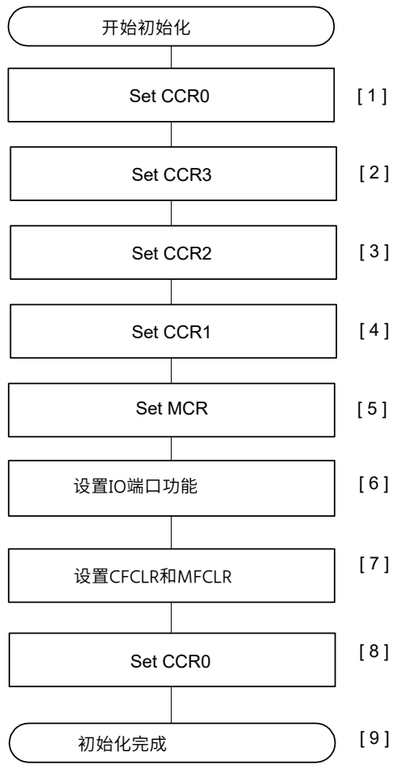
When the BGDM bit in CCR2 is set to 1, the cycle of the base clock is reduced to half and the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the ABCS and the BGDM bits in CCR2 are set to 1, the SCI operates on the bit rate four times that of when the ABCS and the BGDM bits in CCR2 are set to 0.

26.5.5 CTS and RTS functions

The CTS function uses input on the CTSn pin in transmission control. Setting the CTSE bit in CCR1 to 1 enables the CTS function. The CTSn_RTSn pin can be set as a multiplexed pin which allows one pin to be used for either CTS or RTS function, or as dedicated pins with each pin at CTSn pin for CTS function and CTSn_RTSn pin for RTS function. Use the CTSPEN bit in CCR1 for this setting.

When the CTS function is enabled, reception starts only when the CTSn pin is at the low level.



[1]将CCR0的以下位设置为0。
TEIE，领带，RIE，TE，RE
如果您尚未更改初始设置，则可以跳过此步骤。

[2]设置驱动控制、多处理器通信、通信模式、发送接收格式、时钟使能。初始值不要使用CPOL和CPHA等功能位。

[3]设置时钟选择，比特率设置。将未使用的功能位保留为其初始值。（例如BRME）

[4]设置噪声滤波器、环回控制、通信终端状态、奇偶校验、CTSRTS功能。

[5]设置曼彻斯特发射接收设置。起始位设置、重定时设置、曼彻斯特极性设置、发送前言设置、接收前言设置。

[6]设置IO端口，使所需的引脚功能在TXDn、RXDn和SCKn引脚之间有效。

[7]将CFCLR和MFCLR寄存器中的以下清除位设置为1以清除目标标志。CFCLR.RDRFC、FERC、PERC、MFC、ORERC、DFERC、DPERC, DCMFC, ERSCMFMFCLR.MERC, SBERC, SYERC, PFERC
复位后的初始设置可以省略此过程。

[9]将TE位或RE位设置为1。要使能中断，请将TE位和TIE位，以及RE位和RIE位同时设置为1一条指令，以及多处理器功能。通过设置TE和RE位可以使用TXDn和RXDn引脚。

Figure 26.48 曼彻斯特模式下的SCI初始化流程

26.5.4 Double-speed operation

当CCR2中的ABCS位设置为1并选择1位周期的8个基本时钟脉冲时，SCI以ABCS设置为0时的两倍比特率运行。

当CCR2中的BGDM位设置为1时，基本时钟的周期减少到一半，并且SCI以两倍于ABCS设置为0时的比特率运行。

当CCR2中的ABCS和BGDM位设置为1时，SCI以四倍的比特率运行。
CCR2中的ABCS和BGDM位设置为0。

26.5.5 CTS和RTS功能

CTS功能在传输控制中使用CTSn引脚上的输入。将CCR1中的CTSE位设置为1启用CTS功能。CTSn_RTSn引脚可设置为复用引脚，允许一个引脚用于CTS或RTS功能，或作为专用引脚，CTSn引脚用于CTS功能，CTSn_RTSn引脚用于RTS功能。使用CCR1中的CTSPEN位进行此设置。

当CTS功能使能时，只有在CTSn引脚为低电平时才开始接收。

Applying a high level to the CTSn pin after transmission starts does not affect transmission of the current frame, which continues.

The RTS function uses output on the CTSn_RTSn pin to request transmission. When the SCI is ready to receive, it outputs a low level to the CTSn_RTSn pin, Conditions for output of the low level and high level are as follows:

[Conditions for low-level output]

When all conditions listed below are satisfied:

- The value of the RE bit in CCR0 is 1.
- When The SCI is ready to receive next.
  - When there is no received data yet to be read and not receiving
  - All of the following flags are set to 0: CSR.ORER, FER, and PER, MSR.MER, SYER (when SYEREN = 1), PFER (when PFEREN = 1) and SBER flags (when SBEREN = 1).

[Conditions for high-level output]

- When the conditions for low output are not satisfied

26.5.6 Serial data transmission in Manchester mode

The SCI encodes data in Manchester encoding and sends the resultant data in Manchester mode.

When the polarity setting (MCR.TMPOL) set to 0, logic 0 is coded as a zero-to-one transition in Manchester code and logic 1 is coded as a one-to-zero transition in Manchester code.

When the polarity setting (MCR.TMPOL) set to 1, logic 0 is coded as a one-to-zero transition in Manchester code and logic 1 is coded as a zero-to-one transition in Manchester code.

For this reason, a level transition occurs with the Manchester encoded data in the middle of individual logic data. (See Figure 26.43).

The transmitter constructs transmit frames in a specific format by adding a preface area to data and setting the start bit(s) according to the polarity setting and sends resultant serial data.

For details on the frame format, see section 26.5.1. Frame Format.

Figure 26.49 shows the flowchart in transmission. At transmission starts, set the CCR0.TIE and CCR0.TE bits to 1 simultaneously with one instruction. Then, a SCIn_TXI interrupt request is generated. Figure 26.50, Figure 26.51, and Figure 26.52 show examples of the operation for serial transmission in Manchester mode.

传输开始后将高电平施加到CTSn引脚不会影响当前帧的传输，继续传输。

RTS功能使用CTSn_RTSn引脚上的输出来请求传输。当SCI准备好接收时，向CTSn_RTSn管脚输出一个低电平，输出低电平和高电平的条件如下：

[Conditions for low-level output]

当满足下列所有条件时：

●CCR0中RE位的值为1。

●当SCI准备好接收下一个时。

当没有接收到的数据尚未读取且未接收时

以下所有标志都设置为0：CSR.ORER、FER和PER、MSR.MER、SYER（当SYEREN=1时）、PFER（当PFEREN=1时）和SBER标志（当SBEREN=1时）。

[Conditions for high-level output]

●不满足低输出条件时

26.5.6 曼彻斯特模式下的串行数据传输

SCI以曼彻斯特编码对数据进行编码，并以曼彻斯特模式发送结果数据。

当极性设置(MCR.TMPOL)设置为0时，逻辑0被编码为曼彻斯特代码中的零到一转换，逻辑1被编码为曼彻斯特代码中的一到零转换。

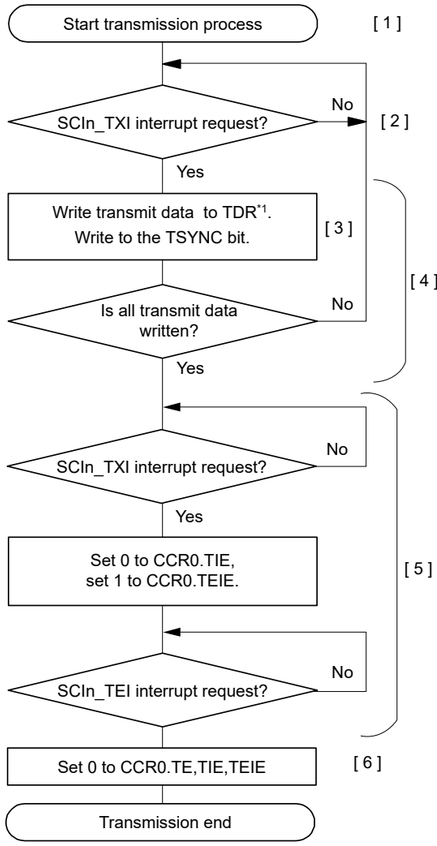
当极性设置(MCR.TMPOL)设置为1时，逻辑0被编码为曼彻斯特代码中的一对零转换，逻辑1被编码为曼彻斯特代码中的零到一转换。

出于这个原因，在各个逻辑数据中间的曼彻斯特编码数据会发生电平转换。（看Figure 26.43）。

发送器通过向数据添加前言区域并根据极性设置设置起始位来构建特定格式的发送帧，并发送结果串行数据。

有关帧格式的详细信息，请参见第26.5.1节。帧格式。

图26.49显示了传输中的流程图。在发送开始时，用一条指令同时将CCR0.TIE和CCR0.TE位设置为1。然后，产生一个SCIn_TXI中断请求。图26.50、图26.51和图26.52显示了曼彻斯特模式下串行传输的操作示例。



[1] Start transmission process

[2] SCIn_TXI interrupt:
A transmit data empty interrupt (SCIn_TXI) request is generated when CCR0.TIE = 1 and TE = 0->1, and when transmit data is transferred from TDR to TSR.

[3] TDR setting:
Write the transmit data to TDR.
When TSYNC is used, also set TDR.TSYNC.

[4] Serial transmission continuation procedure:
To continue serial transmission, write the transmit data to TDR*1 once by using an SCIn_TXI interrupt.
The transmit data can also be written to TDR*1 by activating the DMAC or DTC in the SCIn_TXI interrupt request.

[5] When SCIn_TEI interrupt requests are used, set the CCR0.TIE bit to 0 and the CCR0.TEIE bit to 1 after the last of the data to be transmitted is written to TDR and it' s transmission is started.

[6] Set 0 to CCR0.TE, TIE and TEIE.

Note 1. If TDR[15:8] requires data write and byte access is required, write the transmit data in the order of TDR [15:8] and TDR [7:0].

[4]串行传输继续程序：
要继续串行传输，请将传输数据写入TDR*1使用SCIn_TXI中断一次。
发送数据也可以通过激活TDR*1写入SCIn_TXI中断请求中的DMAC或DTC。

[5]当使用SCIn_TEI中断请求时，将要发送的最后一个数据写入TDR并开始发送后，将CCR0.TIE位设置为0，并将CCR0.TEIE位设置为1。

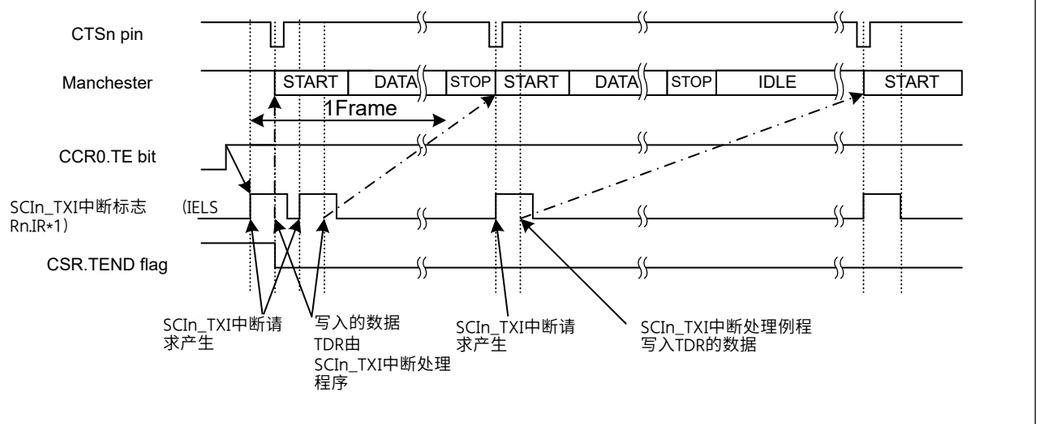
26.5.7 Serial Data Reception in Manchester Mode

In Manchester mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate. Reception starts by sampling the falling edges of received data at the base clock. As shown in Figure 26.53, reception starts at a falling edge of the received data and it continues if the received data keeps low for the duration of 1/4 bit. If the received data goes high within the duration of 1/4 bit, the SCI judges it as an error and waits for a falling edge again.

If a high level is expected in the first half of a bit in the received data, the SCI judges a low level that continues for one base clock cycle as an error and ignores the change to the low level.

Note 1. This is the case when CCR2.ABCS = 0. When CCR2.ABCS = 1, the SCI operates on a base clock with a frequency of 8 times the bit rate.



注1.有关相应的中断号，请参阅第12节，中断控制器单元(ICU)

Figure 26.52 曼彻斯特模式下串行传输的传输结束操作示例（使用前言但没有CTS功能）

26.5.7 曼彻斯特模式下的串行数据接收

在曼彻斯特模式下，SCI在频率为16倍*1比特率的基本时钟上运行。接收开始于在基本时钟处对接收到的数据的下降沿进行采样。如图26.53所示，接收从接收数据的下降沿开始，如果接收数据保持低电平持续14位，接收将继续。如果接收到的数据在14bit的时间内变高，则SCI判断为错误，再次等待下降沿。

如果在接收数据的前半个比特中预期为高电平，则SCI将持续一个基本时钟周期的低电平判断为错误，并忽略向低电平的变化。

注1.当CCR2.ABCS=0时就是这种情况。当CCR2.ABCS=1时，SCI在频率为比特率8倍的基本时钟上运行。

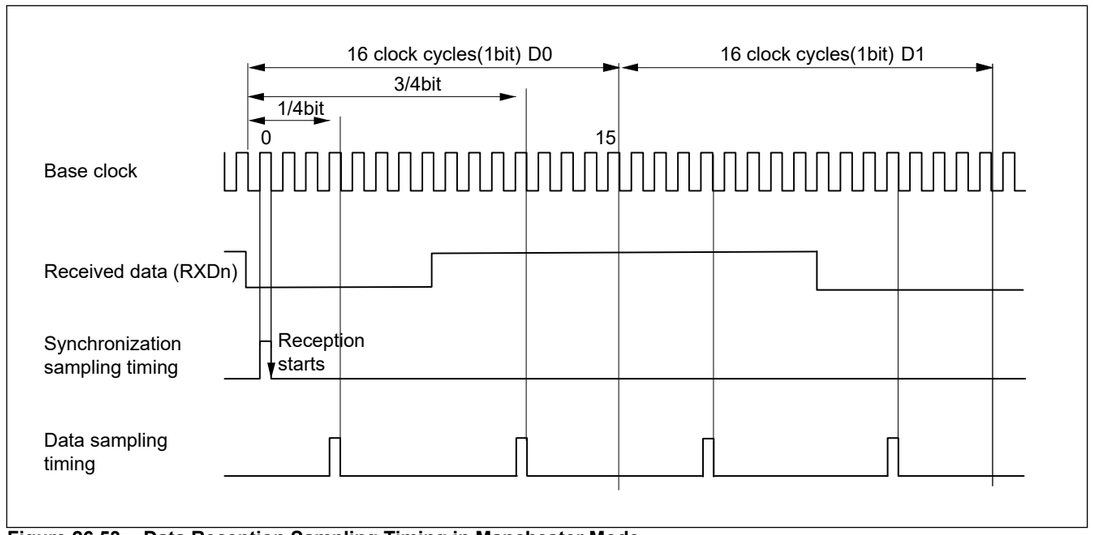

Figure 26.53 Data Reception Sampling Timing in Manchester Mode

In Manchester mode, data reception starts with detection of a preface and start bit area.

The SCI checks the input from the RXDn pin to see whether a preface is added based on the value of MCR.RPLEN.

If the preface is disabled (MCR.RPLEN = 0), it moves on to the detection of a start bit area without detecting a preface.

When a preface is enabled, it identifies a preface pattern setting according to the set value in MCR.RPPAT, and compares it with the RXDn input for a pattern match to detect a preface pattern.

Upon detection of a preface pattern match, it judges it as a normal preface and moves on to the detection of a start bit area.

If detecting a preface pattern mismatch or a Manchester code error in the preface area, it judges it as a preface error and asserts a preface error (PFER).

For start bit detection, the SCI selects an expected value based on the register settings (MCR.SBSEL and SYNVAL), compares it with the RXDn input for a pattern match to detect a start bit area. Upon detection of a start bit pattern match, it judges it as a normal start bit area and moves on to the data processing.

Only when a preface and a start bit area are detected normally, it moves on to the next phase of data reception.

Upon detection of a start bit pattern mismatch, it asserts a start bit error flag (SBER).

In data processing, the SCI shifts the data by the expected received data length based on the register settings (CCR3.CHR[1:0]) through the RSR register. If two sampling points in a bit of the received data are identical, the SCI judges this as a Manchester code error.

For details, see section 26.5.11. Errors in Manchester Mode (4).

When the parity function is disabled (CCR1.PE = 0), the SCI moves on to the next phase of stop bit detection. When the parity function is enabled (CCR1.PE = 1), the SCI performs parity checking. If detecting a parity error, it asserts a parity error flag (PER), and then moves on to stop bit detection.

In stop bit detection, the SCI checks the following in the stop bit area of the received frame:

It has two sampling points in a bit. If both points are at the high level, the bit is recognized as a normal stop bit and the data is stored in the RDR register. At least one low-level point is judged as an abnormal stop bit, causing a framing error flag (FER) to be set. Even when an error is detected, the received data is stored in the RDR register as abnormal data.

Figure 26.54 shows an example of the operation for serial data reception in Manchester mode.

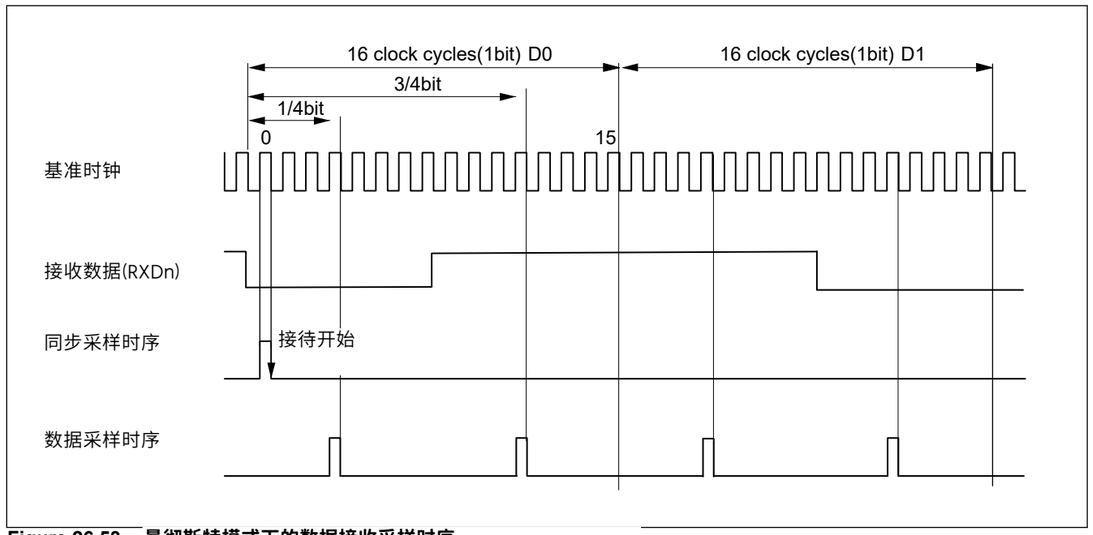

Figure 26.53 曼彻斯特模式下的数据接收采样时序

在曼彻斯特模式下，数据接收从检测前言和起始位区域开始。

SCI检查来自RXDn引脚的输入，以查看是否根据MCR.RPLEN的值添加了前言。

如果前言被禁用（MCR.RPLEN=0），它会继续检测起始位区域而不检测前言。

启用前言时，它根据MCR.RPPAT中的设置值识别前言模式设置，并将其与模式匹配的RXDn输入进行比较，以检测前言模式。

在检测到前言模式匹配时，将其判断为正常前言并继续检测起始位区域。

如果在前言区域检测到前言模式不匹配或曼彻斯特码错误，则将其判断为前言错误并断言前言错误（PFER）。

对于起始位检测，SCI根据寄存器设置（MCR.SBSEL和SYNVAL）选择预期值，将其与模式匹配的RXDn输入进行比较，以检测起始位区域。在检测到起始位模式匹配时，将其判断为正常起始位区域并继续进行数据处理。

只有在正常检测到前言和起始位区域时，才进入下一个数据接收阶段。

在检测到起始位模式不匹配时，它会断言起始位错误标志(SBER)。

在数据处理中，SCI根据寄存器设置(CCR3.CHR[1:0])通过RSR寄存器将数据移位预期的接收数据长度。如果接收到的数据位中的两个采样点相同，则SCI判断为曼彻斯特码错误。

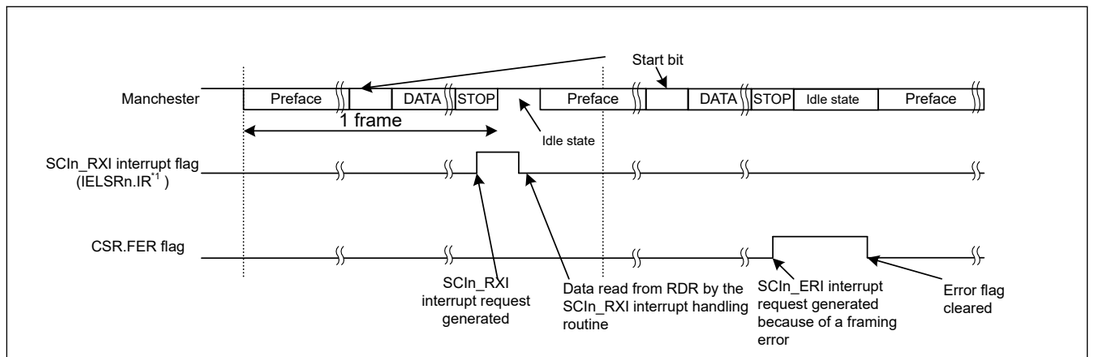
详见26.5.11节。曼彻斯特模式中的错误(4)。

当奇偶校验功能被禁用（CCR1.PE=0）时，SCI进入下一个停止位检测阶段。当启用奇偶校验功能（CCR1.PE=1）时，SCI执行奇偶校验。如果检测到奇偶校验错误，它会置位奇偶校验错误标志(PER)，然后继续进行停止位检测。

在停止位检测中，SCI在接收帧的停止位区域中检查以下内容：

它有两个采样点。如果两个点都处于高电平，则该位被识别为正常停止位，数据存储在RDR寄存器中。至少有一个低电平点被判断为异常停止位，导致设置帧错误标志（FER）。即使检测到错误，接收到的数据也会作为异常数据存储在RDR寄存器中。

图26.54显示了曼彻斯特模式下串行数据接收操作的示例。



Note 1. For corresponding interrupt numbers, see section 12, Interrupt Controller Unit (ICU).

Figure 26.54 Example of Operation for Serial Data Reception in Manchester mode (with a Preface)

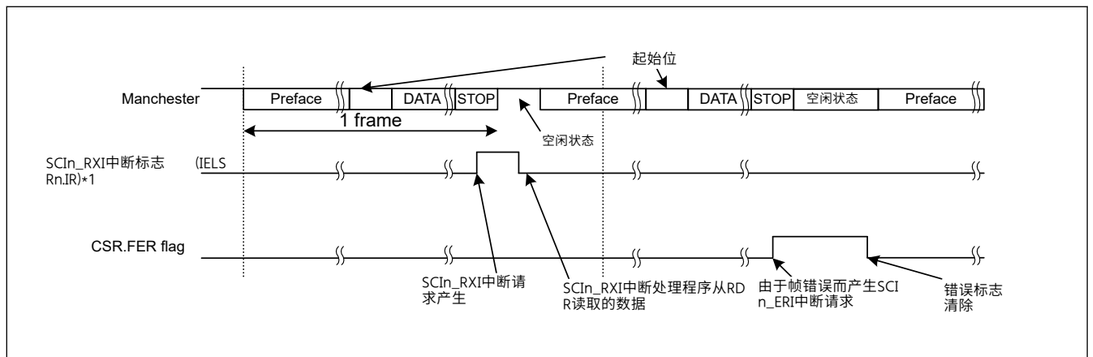
For the state of each status flag in the CCR0 register and RXDn input processing when a receive error is detected, see section 26.5.11. Errors in Manchester Mode.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated.

Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, PER, MER, SYER*1, PFER*1, and SBER*1 flags to 0 before resuming reception. Also, be sure to read the RDR register during overrun error processing. When a reception is forcibly terminated by setting the CCR0.RE bit to 0 during operation, read the RDR register because received data which has not yet been read may be left in the RDR register.

Figure 26.55 and Figure 26.56 show examples of serial data reception flowchart in Manchester mode.

Note 1. Effective when the corresponding bit is enabled.



注1.有关相应的中断号，请参见第12节，中断控制器单元(ICU)。

Figure 26.54 曼彻斯特模式下串行数据接收操作示例（附前言）

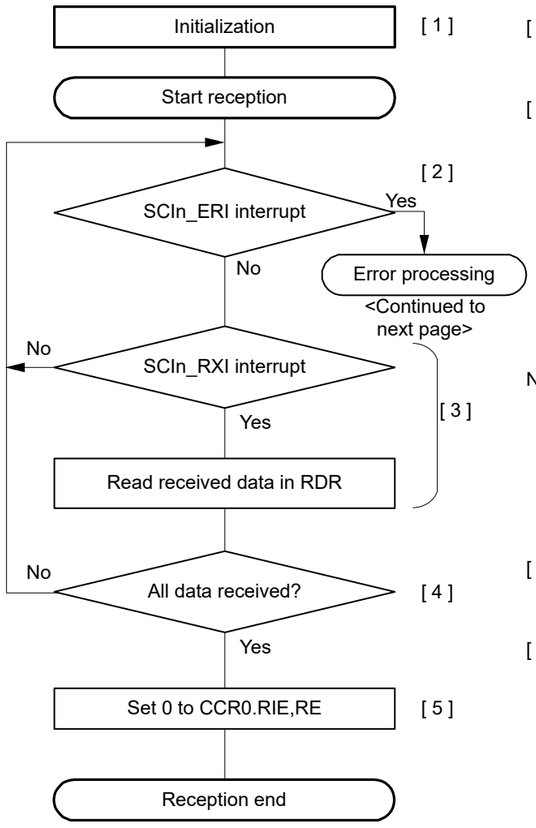
关于检测到接收错误时CCR0寄存器中的每个状态标志的状态和RXDn输入处理，请参阅第26.5.11节。曼彻斯特模式中的错误。

如果检测到接收错误，则会产生SCIn_ERI中断请求，但不会产生SCIn_RXI中断请求。

接收错误标志为1时无法恢复数据接收。因此，请设置ORER、FER、PER、MER、SYER*1，PFER*1和SBER*1在恢复接收之前标志为0。此外，请务必在溢出错误处理期间读取RDR寄存器。如果在操作期间通过将CCR0.RE位设置为0来强制终止接收，请读取RDR寄存器，因为尚未读取的接收数据可能会留在RDR寄存器中。

图26.55和图26.56显示了曼彻斯特模式下的串行数据接收流程图示例。

注1.当相应位使能时有效。



[1] SCI initialization.
(Set CCR0.RE = 1 and RIE = 1)

[2] Receive error processing:
When a receive error occurs, SCI generates an SCIn_ERI interrupt . An error is identified by reading the ORER, PER, FER in CSR and MER, SBER, SYER, PFER in MSR. After performing the appropriate error processing, always set the ORER, PER, FER, MER, SBER, SYER, PFER flags to 0. Reception cannot be resumed if any of these flags is set to 1.

Note: Each of the PFER, SYER, SBER bits in MSR has an enable bit (PFEREN, SYEREN, and SBEREN in MECR). If the corresponding enable bit is set to 0 (disable), the flag value does not affect the communication. Perform error processing as required.

[3] Read the received data in RDR once in the SCIn_RXI interrupt handling routine.

[4] Serial reception continuation procedure:
To continue serial reception, before the stop bit of a frame is received, read data from RDR in the SCIn_RXI interrupt handling routine. The RDR data can also be read by activating the DMAC or DTC.

[5] Write 0 to CCR0.RIE and RE.

（设置CCR0.RE=1和RIE=1）

[2]接收错误处理：
当接收错误发生时，SCI生成一个
SCIn_ERI中断。通过读取CSR中的ORER、PER、FER和MSR中的MER、SBER、SYER、PFER来识别错误。执行适当的错误处理后，请始终将ORER、PER、FER、MER、SBER、SYER、PFER标志设置为0。如果这些标志中的任何一个设置为1，则无法恢复接收。

注意：MSR中的每个PFER、SYER、SBER位都有一个使能位（MECR中的PFEREN、SYEREN和SBEREN）。如果相应的使能位设置为0（禁用），则标志值不影响通信。根据需要进行错误处理。

[3]在SCIn_RXI中断处理程序中读取一次RDR中接收到的数据。

要继续串行接收，在接收到帧的停止位之前，在SCIn_RXI中断处理程序中从RDR读取数据。RDR数据也可以通过激活读取

DMAC or DTC.

26.5.8 Operation When Multi-Processor Bit Is Used

See section 26.4. Multi-Processor Communication Function (1) for the operation in Manchester mode when using multi-processor mode because the operation is the same.

A preface and a start bit area are added to the frame format in Manchester mode. See Figure 26.56 for error processing in Manchester mode for the reception flowchart (Figure 26.39). Refer to Table 26.34 for the operation status when detecting various errors.

26.5.9 Receive Retiming

This function corrects the timing for each central edge of the bit, taking advantage of the fact that each bit has an edge in the center in Manchester code.

The receive retiming function can be turned on or off by setting the ERTEN bit in the MCR register.

When the receive retiming function is turned off (MCR.ERTEN = 0), retiming is not performed, causing misalignment between the internal clock and the RXDn input to be accumulated and the receive margin to be reduced.

When the receive retiming function is turned on (MCR.ERTEN = 1), retiming is performed for the preface area, the start bit area*1, and the data area (excluding the stop bit).

Note 1. Retiming is not performed for the start bit area if the preface length is 0 and the start bit length is 3.

As an example, the receive retiming when oversampling x16 is selected is shown below.

When detecting an RXDn input edge two to four cycles before the expected receive cycle, the receive processing is shortened by one sampling CLK cycle.

When detecting a RXDn input edge two to three cycles after the expected receive cycle, the receive processing is extended by one sampling CLK cycle.

(Even if the clock is misaligned with the data by more than two cycles, one cycle is corrected for each bit.)

Figure 26.57 shows the conceptual image of receive retiming range.

When detecting an edge in the tolerance area in the figure, data is received as is without making correction.

When detecting an edge in the SyncJump area in the figure, data is corrected for reception.

When detecting an edge in the SyncError area in the figure, data is received as abnormal data with no correction made.

For a Manchester code error (data matches at the 1/4-phase and 3/4-phase sampling points), the SCI reports a code error.

26.5.8 使用多处理器位时的操作

请参阅第26.4节。多处理器通信功能(1)曼彻斯特模式下的操作在使用多处理器模式时因为操作是一样的。

曼彻斯特模式的帧格式中添加了前言和起始位区域。接收流程图（图26.39）在曼彻斯特模式下的错误处理见图26.56。检测各种错误时的动作状态见表26.34。

26.5.9 接收重定时

该函数利用曼彻斯特码中每个位在中心的边缘这一事实，校正位的每个中心边沿的时序。

通过设置MCR寄存器中的ERTEN位，可以打开或关闭接收重定时功能。

当接收重定时功能关闭（MCR.ERTEN=0）时，不执行重定时，导致内部时钟和RXDn输入之间的错位被累积，接收裕量减少。

当接收重定时功能打开时（MCR.ERTEN=1），对前言区、起始位区*1和数据区（不包括停止位）执行重定时。

注1.如果序言长度为0且起始位长度为3，则不对起始位区域执行重定时。

例如，选择过采样x16时的接收重定时如下所示。

当在预期接收周期前2到4个周期检测到RXDn输入边沿时，接收处理将缩短1个采样CLK周期。

当在预期接收周期后两到三个周期检测到RXDn输入边沿时，接收处理将延长一个采样CLK周期。

（即使时钟与数据的偏差超过两个周期，也会为每一位校正一个周期。）

图26.57显示了接收重定时范围的概念图。

在图中的公差范围内检测边缘时，直接接收数据而不进行校正。

当在图中的SyncJump区域检测到边缘时，数据被校正以进行接收。

当在图中的SyncError区域检测到边缘时，数据作为异常数据接收，没有进行校正。

对于曼彻斯特编码错误（数据在1个4相和3个4相采样点匹配），SCI报告编码错误。

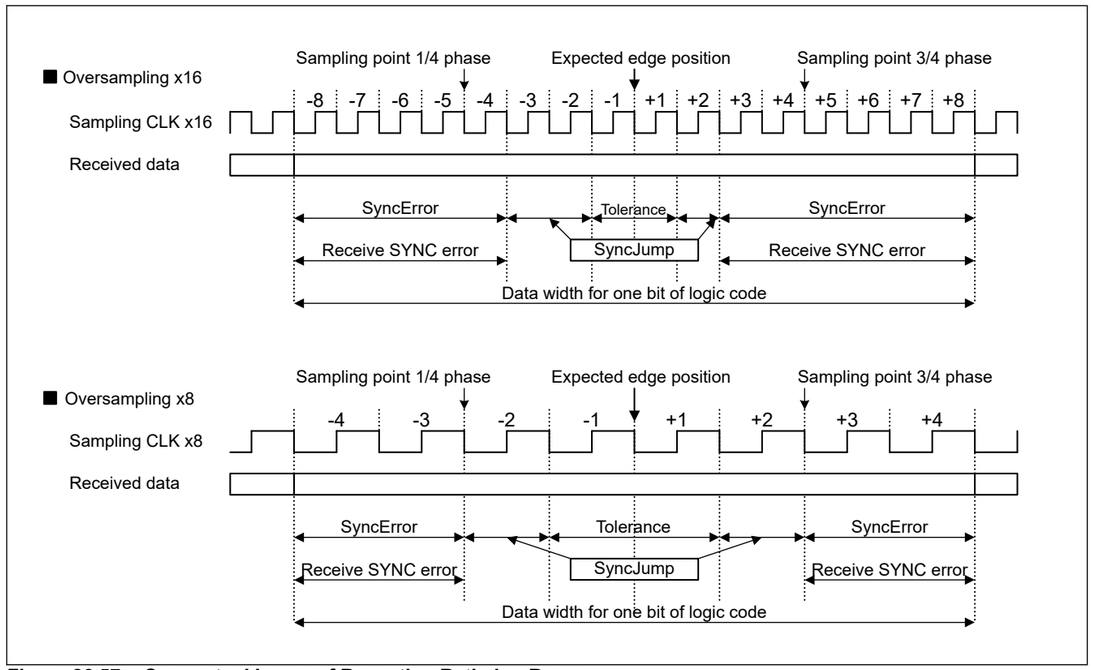

Figure 26.57 Conceptual Image of Reception Retiming Range

26.5.10 Polarity Setting for Manchester Code

The polarity of the Manchester code can be set with the Manchester Control Register (MCR).

It can be set separately for transmission and reception. Use the MCR.TMPOL bit to set the polarity for transmission and the MCR.RMPOL bit to set the polarity for reception.

The Manchester code polarity setting is valid for the preface area, the data area, and the parity or multi-processor area.

When the initial settings (TMPOL/RMPOL = 0) are used for the polarity of Manchester code, logic 0 is encoded as a zero-to-one transition in Manchester code and logic 1 is encoded as a one-to-zero transition in Manchester code. If the settings are changed to TMPOL/RMPOL = 1, logic 0 is encoded as a one-to-zero transition in Manchester code and logic 1 is encoded as a zero-to-one transition in Manchester code. Figure 26.58 shows the conceptual image of the settings and operation.

Separately from the function above, the transmitted and received data in the data area can be inverted by the transmitted/received data inversion function (CCR3.SINV). Since the polarity of Manchester code (MCR.TMPOL/RMPOL) can be set separately from the transmitted/received data invert function (CCR3.SINV), if both are set to inversion (MCR.TMPOL/RMPOL = 1 and CCR3.SINV = 1), the transmitted and received data are set to initial state (inversion + inversion = normal).

The polarity of the start bit area can be set by a register different from the ones mentioned above.

Since a different register is used, the polarity of the start bit area is not affected by the polarity setting for Manchester code mentioned above.

For details on the setting for the start bit area, see section 26.5.1. Frame Format (2).

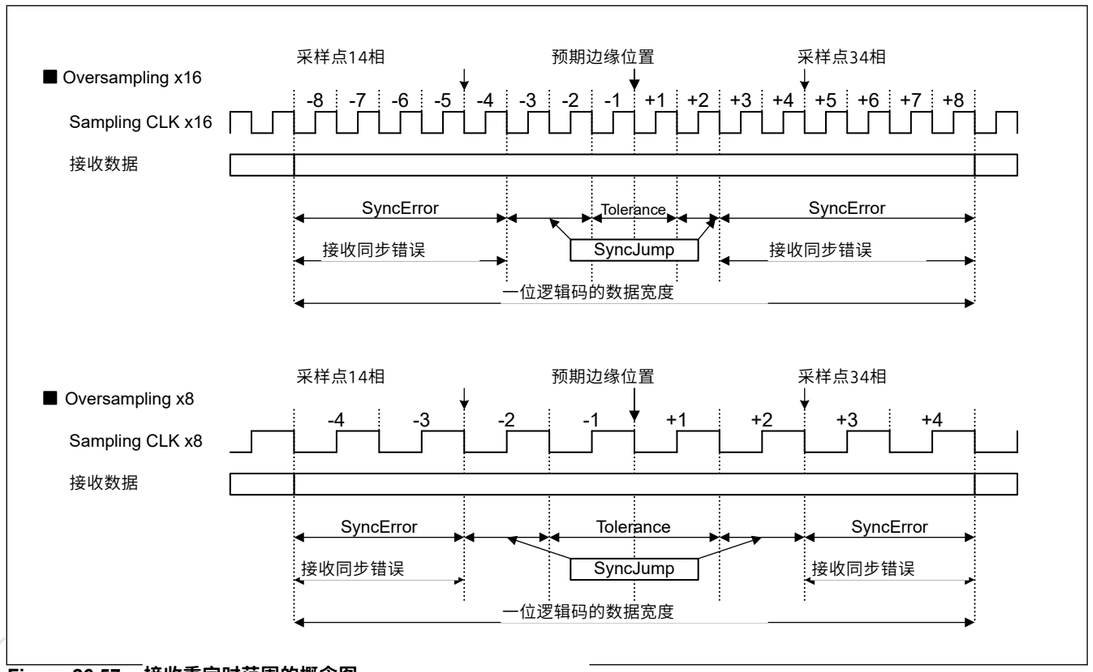

Figure 26.57 接收重定时范围的概念图

26.5.10 曼彻斯特码的极性设置

曼彻斯特码的极性可以通过曼彻斯特控制寄存器(MCR)设置。

可以分别设置发送和接收。使用MCR.TMPOL位设置传输的极性和MCR.RMPOL位设置接收极性。

曼彻斯特码极性设置对前言区、数据区、奇偶校验或多处理器区有效。

当初始设置(TMPOLRMPOL=0)用于曼彻斯特代码的极性时，逻辑0被编码为曼彻斯特代码中的零到一转换，逻辑1被编码为曼彻斯特代码中的一对零转换。如果设置更改为TMPOLRMPOL=1，则逻辑0被编码为曼彻斯特代码中的一对零转换，逻辑1被编码为曼彻斯特代码中的零到一转换。图26.58显示了设置和操作的概念图。

与上述功能不同，数据区中的发送和接收数据可以通过发送接收数据反转功能(CCR3.SINV)反转。由于曼彻斯特码的极性（MCR.TMPOLRMPOL）可以与发送的接收数据反转功能（CCR3.SINV）分开设置，如果两者都设置为反转（MCR.TMPOLRMPOL=1和CCR3.SINV=1），发送和接收的数据设置为初始状态（反转+反转=正常）。

起始位区域的极性可以通过与上述不同的寄存器来设置。

由于使用了不同的寄存器，因此起始位区域的极性不受上述曼彻斯特码极性设置的影响。

关于起始位区域的设置，请参阅26.5.1节。帧格式(2)。

26.5.11 Errors in Manchester Mode

There are the following errors in Manchester mode:

1. Parity error
2. Over run error
3. Framing error
4. Manchester error
5. Preface error
6. Start Bit error
7. Receive SYNC error

For errors (1) to (3), see section 26.3.9. Serial Data Reception in Asynchronous Mode (1) because they are the same as in asynchronous mode.

Each errors are judged in each area, but they are reflected on flags and operations at the timing of 3/4-bit sampling of the STOP bit area. If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the previous information.

Table 26.32 lists the states of the serial status register when detecting errors and judgment about whether to store data in the RDR.

Table 26.33 lists the errors that can be detected in each area of a Manchester frame.

If a Preface error or Start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the result of the previous frame reception. Also, if an error is detected in the previous frame, data will not be received, but errors in the pre-face area and start bit area will update that flag. Table 26.34 shows the flags and actions in this case.

26.5.11 曼彻斯特模式中的错误

曼彻斯特模式有以下错误：

1.奇偶校验错误
2.溢出错误
3.构图错误
4.曼彻斯特错误
5.前言错误
6.起始位错误
7.收到SYNC错误

对于错误(1)至(3)，请参阅第26.3.9节。异步模式下的串行数据接收(1)因为它们与异步模式下相同。

在每个区域中判断每个错误，但它们反映在标志和操作上，在3个4位采样的时间
停止位区域。如果检测到前言错误或起始位错误，则不会接收后续数据。因此，不进行其他错误检测，错误标志保存先前的信息。

RDR.

表26.33列出了可以在曼彻斯特帧的每个区域中检测到的错误。

如果检测到Preface错误或Startbit错误，则不会接收后续数据。因此，不进行其他错误检测，错误标志保存前一帧接收的结果。此外，如果在前一帧中检测到错误，则不会接收数据，但前脸区域和起始位区域中的错误将更新该标志。表26.34显示了这种情况下的标志和操作。

(4) Manchester error

A Manchester error is generated when a Manchester code error is detected.

In Manchester code, there must be an edge (transition) in the center of the bit.

In the data area of a received frame (including the parity/multi-processor bit), the values of the 1/4-bit and 3/4-bit sampling points are checked in each received 1-bit data, and a Manchester code error is determined if these two values match.

If a Manchester code error is detected, the Manchester error flag (MSR.MER) is asserted.

If a Manchester error occurs, it is handled as an interrupt source and event source. If a Manchester error is detected, the next reception is not performed until the corresponding error flag is cleared.

(5) Preface error

A preface error is generated when the preface pattern does not match or a Manchester code error is detected in the preface area. If a preface error is detected, the preface error flag (MSR.PFER) is asserted.

It is possible to set whether to use this error flag as an interrupt source with the setting of the MCR register.

When MCR.PFEREN = 1, a preface error is handled as an interrupt source or event source. If a preface error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MCR.PFEREN = 0, a preface error is not handled as an interrupt source or event source, and the next reception is not halted. However, a preface error is notified to MSR.PFER.

(6) Start bit error

A start bit error is generated when a mismatch is detected between the start bit area in the received frame and the preset start bit pattern. Upon detection of a start bit error, a start bit error flag (MSR.SBER) is asserted.

It is possible to set whether to use the start bit error as an interrupt source with the setting of the MCR register.

When MCR.SBEREN = 1, a start bit error is handled as an interrupt source or event source. If a start bit error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MCR.SBEREN = 0, a start bit error is not handled as an interrupt source or event source, and the next reception is not halted. However, a start bit error is notified to MSR.SBER.

(7) Receive SYNC error

When the receive retiming function described in section 26.5.9. Receive Retiming is enabled, the receive retiming operation is performed.

If no edges are detected within the receive retiming range (SyncError area in Figure 26.57) when receive timing operation is being performed, a receive SYNC error is generated. Upon detection of a receive SYNC error, a receive SYNC error flag (MSR.SYER) is asserted. In areas not subject to retiming, receive SYNC errors are not detected.

The preface area*1, the start bit area*1,*2, and the data area (excluding the stop bit) for which receive retiming operation is performed are checked.

It is possible to set whether to use the receive SYNC error as an interrupt source with the setting of the MCR register.

When MCR.SYEREN = 1, a receive SYNC error is handled as an interrupt source or event source. If a receive SYNC error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MCR.SYEREN = 0, a receive SYNC error is not handled as an interrupt source or event source, and the next reception is not halted. However, a receive SYNC error is notified to MSR.SYER.

Note 1. In the case of a frame that starts with a pattern that expects the first half of the bit to be High, it is excluded from retiming.

Note 2. In the start bit area, when there is no preface length and 3 bit start bit is set, it is not subject to retiming.

Also, the 1st bit and the 2nd bit in the start bit area when 3 bit start bit is set are not subject to retiming.

ORER	FER	PER	MER	SBER*1	PFER*1	SYER		
0	0	0	0	0	0	0	transfer to RDR	No error

(4)曼彻斯特错误

当检测到曼彻斯特码错误时，就会产生曼彻斯特错误。

在曼彻斯特码中，位的中心必须有一个边（转换）。

在接收帧的数据区（包括奇偶校验多处理器位），在每个接收的1位数据中检查1个4位和3个4位采样点的值，确定曼彻斯特码错误如果这两个值匹配。

如果检测到曼彻斯特代码错误，则会置位曼彻斯特错误标志(MSR.MER)。

如果发生曼彻斯特错误，则将其作为中断源和事件源进行处理。如果检测到曼彻斯特错误，则在清除相应错误标志之前不会执行下一次接收。

(5)前言错误

当前言模式不匹配或在前言区检测到曼彻斯特码错误时，会产生前言错误。如果检测到前言错误，则断言前言错误标志(MSR.PFER)。

可以通过MCR寄存器的设置来设置是否将此错误标志用作中断源。

当MCR.PFEREN=1时，前言错误作为中断源或事件源处理。如果检测到前言错误，则在相应的错误标志被清除之前不会执行下一次接收。

当MCR.PFEREN=0时，前言错误不会作为中断源或事件源处理，并且不会停止下一次接收。但是，将向MSR.PFER通知前言错误。

(6)起始位错误

当检测到接收帧中的起始位区域与预设的起始位模式不匹配时，会产生起始位错误。在检测到起始位错误时，将置位起始位错误标志(MSR.SBER)。

可以通过MCR寄存器的设置来设置是否使用起始位错误作为中断源。

当MCR.SBEREN=1时，起始位错误作为中断源或事件源处理。如果检测到起始位错误，则在清除相应错误标志之前不会执行下一次接收。

当MCR.SBEREN=0时，不将起始位错误作为中断源或事件源处理，并且不会停止下一次接收。但是，将向MSR.SBER通知起始位错误。

(7)接收同步错误

当接收重定时功能在第26.5.9节中描述。启用接收重定时，执行接收重定时操作。

如果在执行接收定时操作时在接收重定时范围内（图26.57中的SyncError区域）没有检测到边沿，则会产生接收SYNC错误。在检测到接收同步错误时，接收同步错误标志(MSR.SYER)被置位。在不受重定时限制的区域中，不会检测到接收同步错误。

检查执行接收重定时操作的前言区域*1、起始位区域*1、*2和数据区域（不包括停止位）。

可以通过MCR寄存器的设置来设置是否使用接收SYNC错误作为中断源。

当MCR.SYEREN=1时，接收SYNC错误将作为中断源或事件源处理。如果检测到接收SYNC错误，则在清除相应错误标志之前不会执行下一次接收。

当MCR.SYEREN=0时，接收SYNC错误不会作为中断源或事件源处理，并且不会停止下一次接收。但是，接收SYNC错误会通知给MSR.SYER。

注1.对于以预期位的前半部分为高的模式开始的帧，它被排除在重定时之外。

注2.在起始位区域中，当没有序言长度且设置了3位起始位时，不进行重定时。

此外，当设置3位起始位时，起始位区域中的第1位和第2位不受重定时的影响。

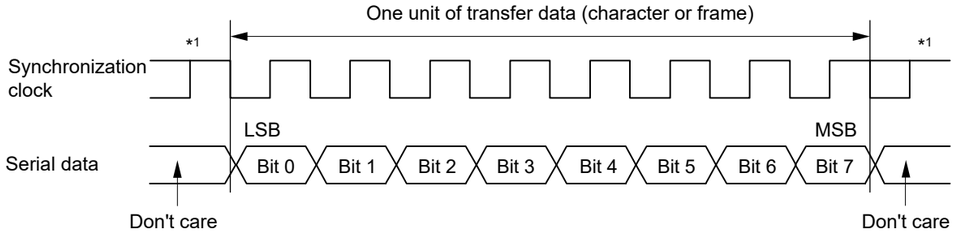
26.6 Operation in Clock Synchronous Mode

Figure 26.59 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. For single-character data transfer, data consists of 8-bit. In clock synchronous mode, no parity bit can be added.

In data transmission when CPHA = 1 and CPOL = 1, the SCI outputs data from one falling edge of the synchronization clock to the next falling edge. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the last bit as output state. When the CPHA bit is 0 in slave mode, the transmission line holds the first bit output state.

Within the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by using a shared a communication clock of the transmitter and the receiver. Furthermore, because both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.



Note 1. Holds a high level except during continuous transfer.

Figure 26.59 Data format in clock synchronous serial communications with LSB-first order

26.6.1 Clock

If the maximum speed of SCK = 1/2TCLK is set in Clock Synchronous and Simple SPI mode, Do not make PCLK less than half the speed of TCLK. If PCLK is made slower than this, malfunction may occur.

1. When the internal clock is selected
   When the SCI operates on an internal clock (CCR3.CKE[1:0] bits are set to 00b or 01b (master mode)), the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output during single-character transmission/reception. When no data transfer is performed, the clock is held at high level.*1 In transmission-only or transmission/reception, the synchronization clock is not output unless transmit data is prepared.
   When the internal clock is selected, the clock with a delay from the SCKn signal is used for the master reception sampling clock. This ensures the data setup time and hold time for high-speed communication.

   Note 1. The signal is held high while (CCR3.CPHA = 0 and CCR3.CPOL = 1) or (CCR3.CPHA = 1 and CCR3.CPOL = 1). It is held low while (CCR3.CPHA = 0 and CCR3.CPOL = 0) or (CCR3.CPHA = 1 and CCR3.CPOL = 0).
2. When the external clock is selected
   When the CCR3.CKE[1:0] bits are set to 10b or 11b (slave mode), data is transmitted and received using the external clock that is input from the SCKn pin.

26.6.2 CTS and RTS Functions

In the CTS function, the CTSn_RTSn pin input controls the start of data reception or transmission when the clock source is the internal clock. Setting the CCR1.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, setting the CTSn_RTSn pin low causes data reception or transmission to start.

Setting the CTSn_RTSn pin high while the data transmission or reception is in progress does not affect transmission or reception of the current frame.

注3.在序言区域或起始位区域中检测到SYER时，根据SYEREN位作为错误处理的行为会发生变化。

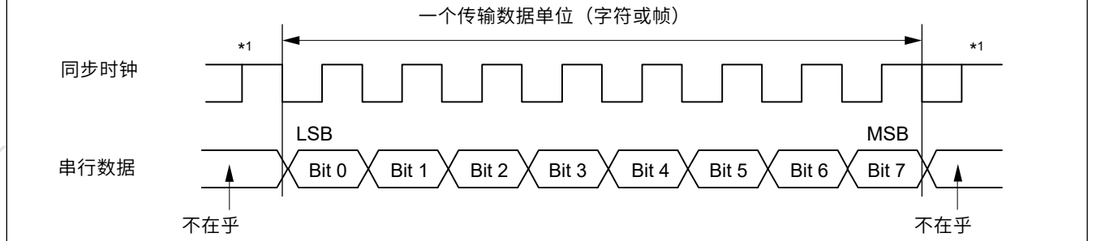
26.6 时钟同步模式下的操作

图26.59显示了时钟同步串行数据通信的数据格式。

在时钟同步模式下，数据的发送或接收与时钟脉冲同步。对于单字符数据传输，数据由8位组成。在时钟同步模式下，不能添加奇偶校验位。

在CPHA=1且CPOL=1时的数据传输中，SCI从同步时钟的一个下降沿到下一个下降沿输出数据。在数据接收中，SCI与同步时钟的上升沿同步接收数据。8位数据输出后，传输线保持最后一位作为输出状态。从机模式下CPHA位为0时，传输线保持第一位输出状态。

在SCI中，发送器和接收器是独立的单元，通过使用发送器和接收器的共享通信时钟来实现全双工通信。此外，由于发送器和接收器都具有双缓冲结构，因此可以在发送过程中写入下一个发送数据，或者在接收过程中读取前一个接收数据，从而实现数据的连续传输。



注1.保持高电平，连续传输期间除外。

Figure 26.59 具有LSB优先顺序的时钟同步串行通信中的数据格式

26.6.1 Clock

如果SCK的最大速度=12TCLK设置在时钟同步和简单SPI模式，不要使PCLK低于TCLK速度的一半。如果PCLK比这慢，可能会发生故障。

1.选择内部时钟时
当SCI在内部时钟上工作时（CCR3.CKE[1:0]位设置为00b或01b（主模式）），同步时钟从SCKn引脚输出。在单字符传输接收期间输出八个同步时钟脉冲。当不进行数据传输时，时钟保持在高电平。*1在仅发送或发送接收中，除非准备好发送数据，否则不会输出同步时钟。选择内部时钟后，将SCKN信号延迟的时钟用于主接收时钟。这确保了高速通信的数据建立时间和保持时间。

注1.当(CCR3.CPHA=0且CCR3.CPOL=1)或(CCR3.CPHA=1且CCR3.CPOL=1)时，信号保持高电平。它在(CCR3.CPHA=0和CCR3.CPOL=0)或(CCR3.CPHA=1和CCR3.CPOL=0)时保持低电平。

2.选择外部时钟时
当CCR3.CKE[1:0]位设置为10b或11b（从模式）时，使用从SCKn引脚输入的外部时钟发送和接收数据。

26.6.2 CTS和RTS函数

在CTS功能中，当时钟源为内部时钟时，CTSn_RTSn引脚输入控制数据接收或发送的开始。将CCR1.CTSE位设置为1可启用CTS功能。当CTS功能使能时，将CTSn_RTSn引脚设置为低电平会导致数据接收或发送开始。

在数据发送或接收过程中将CTSn_RTSn引脚设置为高电平不会影响当前帧的发送或接收。

In the RTS function, the CTSn_RTSn pin output is used to request the start of data reception or transmission when the clock source is an external synchronizing clock. The CTSn_RTSn output goes low when serial communication is enabled. Conditions for output of the CTSn_RTSn low and high are shown as follows:

[Conditions for low output]

Satisfaction of all the following conditions:

Non-FIFO selected when all of the following conditions are satisfied

- The value of the CCR0.RE bit or the CCR0.TE bit is 1
- Next serial communication is enabled.
  - No receive data is present before reading and not receiving. (when CCR0.RE bit = 1)
  - When the transmission data written in TDR is ready for transmission.*1 (when CCR0.TE bit = 1)
- The CSR.ORER flag is 0

Note 1. The CTSn_RTSn pin will be High after starting transmission.

FIFO selected when all of the following conditions are satisfied

- The value of the CCR0.RE bit or the CCR0.TE bit is 1
- Next serial communication is enabled.
  - The number of receive data stored in the receive FIFO (RDR register) is less than the value set in FCR.RSTRG[4:0] (when CCR0.RE bit = 1)
  - When the transmission data written in the transmission FIFO (TDR register) is ready for transmission.*1 (when CCR0.TE bit = 1)
- The CSR.ORER flag is 0

Note 1. The CTSn_RTSn pin will be High after the last data transmission starts.

[Condition for high output]

- The conditions for low output are not satisfied

26.6.3 SCI Initialization in Clock Synchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the CCR0 register, then continue through the SCI initialization procedure given in the sections describing non-FIFO and FIFO selection in section 26.6.2. CTS and RTS Functions. Anytime the operating mode or transfer format is to be changed, the CCR0.TE and CCR0.RE must write to 0 before the change can be made.

Note: Setting the CCR0.RE bit to 0 initializes neither the ORER, FER, PER, and RDRF flags in CSR nor the RDR register. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: Switching the value of the CCR0.TE bit from 1 to 0 when the CCR0.TIE bit is 1 generates an SCIn_TXI interrupt request.

Table 26.36 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (1 of 2)

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set the CCR0.TEIE, TIE, RIE, TE, and RE bits to 0*1. If you have not changed from the initial settings, you can skip this step.
3	Set FCR	Set the TFRST and RFRST to 1 to empty FIFO. Set the DRES, TTRG[4:0], RTRG[4:0], and RSTRG[4:0] bits.

在RTS功能中，当时钟源为外部同步时钟时，CTSn_RTSn引脚输出用于请求开始数据接收或发送。当串行通信启用时，CTSn_RTSn输出变为低电平。CTSn_RTSn低电平和高电平的输出条件如下所示：

[低输出的条件]

满足以下所有条件：

满足以下所有条件时选择非FIFO

●CCR0.RE位或CCR0.TE位的值为1

●启用下一个串行通信。

在读取和未接收之前不存在接收数据。（当CCR0.RE位=1时）

当写入TDR的传输数据准备好传输时。*1（当CCR0.TE位=1时）

●CSR.ORER标志为0

注1.CTSn_RTSn引脚将在开始发送后为高电平。

满足以下所有条件时选择FIFO

●CCR0.RE位或CCR0.TE位的值为1

●启用下一个串行通信。

接收FIFO（RDR寄存器）中存储的接收数据数量小于FCR.RSTRG[4:0]中设置的值（当CCR0.RE位=1时）

当写入发送FIFO（TDR寄存器）的发送数据准备好发送时。*1（当CCR0.TE位=1时）

●CSR.ORER标志为0

注1.CTSn_RTSn引脚将在最后一次数据传输开始后为高电平。

【高输出条件】

●不满足低输出条件

26.6.3 时钟同步模式下的SCI初始化

在发送和接收数据之前，首先将初始值0x00写入CCR0寄存器，然后继续执行第26.6.2节中描述非FIFO和FIFO选择的部分中给出的SCI初始化过程。CTS和RTS功能。每当要更改操作模式或传输格式时，CCR0.TE和CCR0.RE必须先写入0，然后才能进行更改。

Note: 将CCR0.RE位设置为0既不会初始化CSR中的ORER、FER、PER和RDRF标志，也不会初始化RDR寄存器。当TE位设置为0时，所选FIFO缓冲区的TEND标志未初始化。

Note: 当CCR0.TIE位为1时，将CCR0.TE位的值从1切换为0会产生SCIn_TXI中断请求。

Note 4. When using the internal clock (master), the setting of reception only is prohibited.

26.6.4 Serial Data Transmission in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 26.60, Figure 26.61, and Figure 26.62 show examples of serial transmission in clock synchronous mode.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. When starting data transmission, set the CCR0.TIE bit and the CCR0.TE bit to 1 simultaneously by a single instruction. Then a TXI interrupt request is generated.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the CCR0.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data finishes. When SCIn_TEI interrupt requests are in use, set the CCR0.TIE bit to 0 and the CCR0.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the CCR1.CTSE bit is 1 (CTS function enabled).
4. The SCI checks for update to the TDR register on output of the last bit.
5. When the TDR register is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame starts.
6. If TDR is not updated, the CSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the CCR0.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Figure 26.60, Figure 26.61, and Figure 26.62 show examples of serial data transmission.

26.6.4 时钟同步模式下的串行数据传输

(1) Non-FIFO selected

图26.60、图26.61和图26.62显示了时钟同步模式下的串行传输示例。

在串行数据传输中，SCI操作如下：

1.当数据在SCIn_TXI中断处理程序中写入TDR时，SCI将数据从TDR寄存器传输到TSR寄存器。开始数据传输时，通过一条指令同时将CCR0.TIE位和CCR0.TE位设置为1。然后产生一个TXI中断请求。

2.将数据从TDR传输到TSR后，SCI开始传输。当CCR0.TIE位设置为1时，会产生SCIn_TXI中断请求。在当前发送数据发送完成之前，通过在SCIn_TXI中断处理例程中将下一个发送数据写入TDR来启用连续发送。当使用SCIn_TEI中断请求时，在SCIn_TXI请求的处理程序将要发送的最后一个数据写入TDR寄存器后，将CCR0.TIE位设置为0，并将CCR0.TEIE位设置为1。

3.指定时钟输出模式时，与输出时钟同步，指定使用外部时钟时，与输入时钟同步，从TXDn引脚发送8位数据。当CCR1.CTSE位为1（CTS功能使能）时，时钟信号的输出被暂停，直到输入CTS信号为低电平。

4.SCI在最后一位输出时检查对TDR寄存器的更新。

5.TDR寄存器更新后，下一个发送数据从TDR传送到TSR，开始下一帧的串行发送。

6.如果TDR未更新，则CSR.TEND标志设置为1。TXDn引脚保持最后一位的输出状态。如果CCR0.TEIE位为1，则产生SCIn_TEI中断请求且SCKn引脚保持高电平。

图26.60、图26.61和图26.62显示了串行数据传输的示例。

[1] Initialize SCI.
(Set CCR0.TE and TIE to 1.)

[2] Write transmit data to TDR by using SCIn_TXI:
The transmit-data-empty-interrupt(SCIn_TXI) is Generated when transmission-data forwards to TSR from TDR. Write transmit data to TDR once by using a SCIn_TXI.

[3] Serial transmission continuation procedure:
To continue serial transmission write transmit data to TDR by using a SCIn_TXI.
Transmit data can also be written by activating the DMAC or DTC.
If you use SCIn_TEI, set CCR0.TIE = 0 and CCR0.TEIE = 1 after writing the last-transmit-data to TDR.

Note: When the external clock is in use (the value of the CCR3.CKE[1:0] is 10b or 11b), the rising edge on the SCK pin for the last bit sets the CSR.TEND flag to 1. Setting TE to 0 immediately after this, then it may lead to insufficient received data hold time on the receiver side.

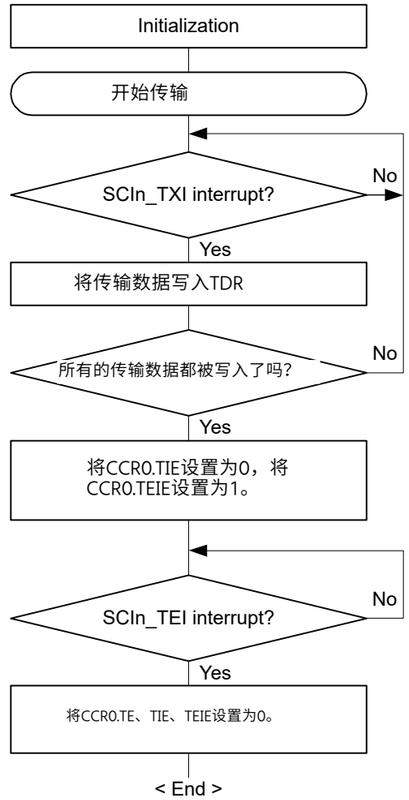
Figure 26.63 Example flow of serial transmission in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 26.64 shows an example of serial transmission in clock synchronous mode with FIFO selected.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the transmit-FIFO (TDR register) to the TSR register when data is written to transmit-FIFO (TDR register) in the SCIn_TXI interrupt handling routine. The amount of data that can be written to transmit-FIFO (TDR register) is 16 - FTSR.T[5:0] bytes. In addition, when starting data transmission, set the CCR0.TIE bit and the CCR0.TE bit to 1 simultaneously by a single instruction. Then a SCIn_TXI interrupt request is generated.
2. After transferring data from transmit-FIFO (TDR register) to TSR, the SCI starts transmission. When the amount of transmit data written in transmit-FIFO (TDR register) is equal to or less than the specified transmit triggering number, the CSR.TDRE is set to 1. When the CCR0.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to transmit-FIFO (TDR register) in the SCIn_TXI interrupt handling routine before transmission of the current transmit data has finished. When SCIn_TEI interrupt requests are in use, set the CCR0.TIE bit to 0 and the CCR0.TEIE bit to 1 after the last of the data to be transmitted is written to the transmit-FIFO (TDR register) from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the CCR1.CTSE bit is 1 (CTS function enabled).
4. The SCI checks whether non-transmitted data remains in transmit-FIFO (TDR register)*1 on output of the stop bit.



[1]初始化SCI。
（将CCR0.TE和TIE设置为1。）

[2]使用SCIn_TXI将发送数据写入TDR：发送数据空中断（SCIn_TXI）是
当传输数据转发到
来自TDR的TSR。使用SCIn_TXI将传输数据写入TDR一次。

[3]串行传输继续程序：要继续串行传输，使用SCIn_TXI将传输数据写入TDR。发送数据也可以通过激活写入
DMAC or DTC.
如果您使用SCIn_TEI，请设置CCR0.TIE=0和CCR0.TEIE=1将最后发送数据写入TDR。

Note: 当使用外部时钟时（CCR3.CKE[1:0]的值为10b或11b），SCK引脚上最后一位的上升沿将CSR.TEND标志设置为1。将TE设置为0在此之后，可能会导致接收端接收数据保持时间不足。

Figure 26.63 选择非FIFO的时钟同步模式下的串行传输示例流程

(2)选择FIFO图26.64显示了在时钟同步模式下选择FIFO的串行传输示例。

在串行数据传输中，SCI操作如下：

1.当数据在SCIn_TXI中断处理程序中写入发送FIFO（TDR寄存器）时，SCI将数据从发送FIFO（TDR寄存器）传输到TSR寄存器。可写入发送FIFO（TDR寄存器）的数据量为16FTSR.T[5:0]字节。此外，在开始数据传输时，通过一条指令同时将CCR0.TIE位和CCR0.TE位设置为1。然后产生一个SCIn_TXI中断请求。

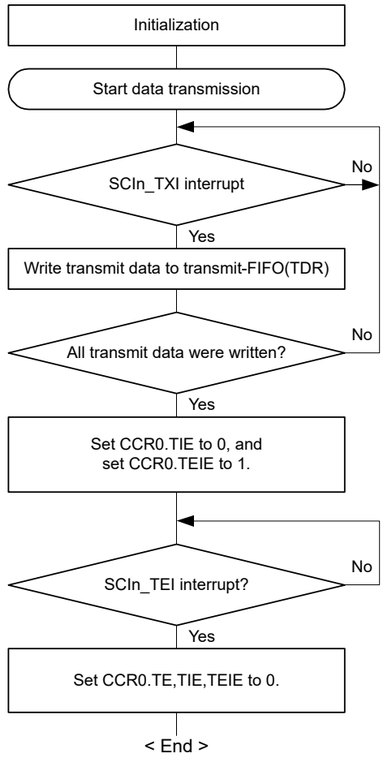
2.将数据从发送FIFO（TDR寄存器）传输到TSR后，SCI开始发送。当写入发送FIFO（TDR寄存器）的发送数据量等于或小于指定的发送触发数时，CSR.TDRE设置为1。当CCR0.TIE位设置为1时，SCIn_TXI中断生成请求。在当前发送数据的发送完成之前，通过在SCIn_TXI中断处理例程中将下一个发送数据写入发送FIFO（TDR寄存器）来启用连续发送。使用SCIn_TEI中断请求时，在SCIn_TXI的处理例程将要发送的最后一个数据写入发送FIFO（TDR寄存器）后，将CCR0.TIE位设置为0并将CCR0.TEIE位设置为1要求。

3.指定时钟输出模式时，与输出时钟同步，指定使用外部时钟时，与输入时钟同步，从TXDn引脚发送8位数据。当CCR1.CTSE位为1（CTS功能使能）时，时钟信号的输出被暂停，直到输入CTS信号为低电平。

4.SCI在停止位输出时检查未发送的数据是否保留在发送FIFO（TDR寄存器）*1中。

5. When data is remaining in the transmit-FIFO (TDR register), the next transmit data is transferred from transmit-FIFO (TDR register) to TSR and serial transmission of the next frame starts.
6. If no data is remaining in the transmit FIFO (TDR register), the CSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the CCR0.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Note 1. The number of unsent transmit data stored in the TDR register (transmit FIFO) can be monitored by reading the FTSR.T[5:0] bits.



[1] [1] Initialize SCI.
(Set CCR0.TE and TIE to 1.)

[2] Write transmit data to transmit-FIFO(TDR) by using SCIn_TXI: The transmit-data-empty-interrupt(SCIn_TXI) is generated when transmission-data forwards to TSR from the transmit-FIFO(TDR) and the number of transmit-data written in the transmit-FIFO is equal to or less than the transmit-FIFO threshold.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to the transmit-FIFO(TDR) by using a SCIn_TXI interrupt and clear CSR.TDRE flag to 0. Transmit data can also be written to the transmit- FIFO(TDR) by activating the DMAC or DTC. In this case, the TDRE flag is cleared automatically, so please don't operate the TDRE flag. If you use SCIn_TEI, set CCR0.TIE = 0 and CCR0.TEIE = 1 after writing the last-transmit-data to TDR.

Note: When the external clock is in use (the value of the CCR3.CKE[1:0] is 10b or 11b), the rising edge on the SCK pin for the last bit sets the CSR.TEND flag to 1. Setting CCR0.TE to 0 immediately after this, then it may lead to insufficient received data hold time on the receiver side.

26.6.5 Serial Data Reception in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 26.65 and Figure 26.66 show examples of SCI operation for serial reception in clock synchronous mode.

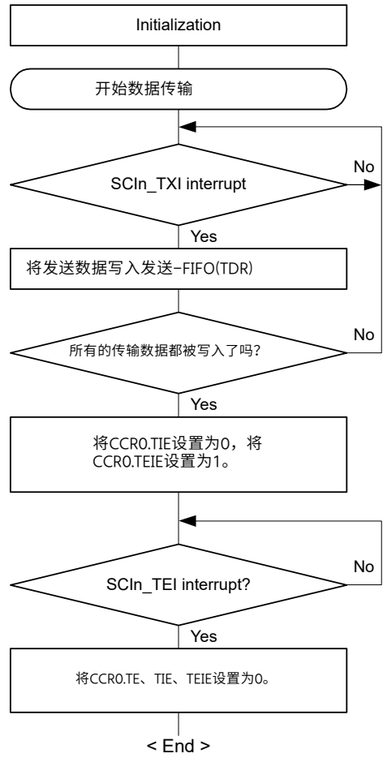
In serial data reception, the SCI operates as follows during serial data reception. Reception-only operation is possible only in slave mode. (In master mode, reception-only operation is prohibited.)

1. When the value of the CCR0.RE bit becomes 1, the CTSn_RTSn pin goes low (when the RTS function is used).
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.

5.当发送FIFO（TDR寄存器）中剩余数据时，下一个发送数据从发送FIFO（TDR寄存器）传送到TSR并开始下一帧的串行发送。

6.如果发送FIFO（TDR寄存器）中没有剩余数据，则CSR.TEND标志设置为1。TXDn引脚保持最后一位的输出状态。如果CCR0.TEIE位为1，则产生SCIn_TEI中断请求且SCKn引脚保持高电平。

注1.存储在TDR寄存器（发送FIFO）中的未发送发送数据的数量可以通过读取
FTSR.T[5:0] bits.



[1] [1]初始化SCI。（将CCR0.TE和TIE设置为1。）

[2]将发送数据写入发送-FIFO(TDR)
通过使用SCIn_TXI：当传输数据从传输FIFO(TDR)转发到TSR并且写入传输FIFO的传输数据数量等于或小于时，产生传输数据空中断(SCIn_TXI)发送FIFO阈值。

[3] 串行传输继续过程：
要继续串行传输，请使用SCIn_TXI中断将传输数据写入传输FIFO(TDR)，并将CSR.TDRE标志清除为0。也可以通过激活DMAC或DTC将传输数据写入传输FIFO(TDR)。在这种情况下，TDRE标志会自动清零，因此请不要操作TDRE标志。如果使用SCIn_TEI，则在将last-transmit-data写入TDR后设置CCR0.TIE=0和CCR0.TEIE=1。

Note: 当使用外部时钟时（CCR3.CKE[1:0]的值为10b或11b），SCK引脚上最后一位的上升沿将CSR.TEND标志设置为1。设置CCR0.TE之后立即为0，则可能导致接收端接收数据保持时间不足。

26.6.5 时钟同步模式下的串行数据接收

(1) Non-FIFO selected

图26.65和图26.66显示了时钟同步模式下串行接收的SCI操作示例。

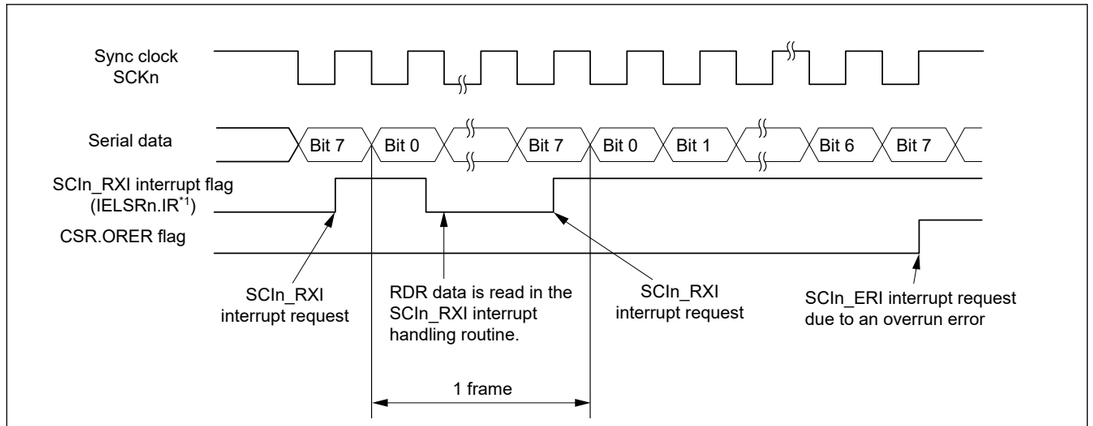
在串行数据接收中，SCI在串行数据接收过程中的操作如下。仅接收操作只能在从模式下进行。（在主模式下，禁止仅接收操作。）

1.当CCR0.RE位的值变为1时，CTSn_RTSn引脚变为低电平（使用RTS功能时）。

2.SCI执行内部初始化，并与同步时钟输入或输出同步开始接收数据，并将接收数据存储在RSR寄存器中。

3. If an overrun error occurs, the CSR.ORER flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.
4. When reception completes successfully, receive data is transferred to the RDR register. If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the received data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that is transferred to RDR causes the CTSn_RTSn pin to output low (when the RTS function is used).

If you want to prevent the CTSn_RTSn pin output from turning low level after the final data is received, clear the CCR0.RE bit to 0 and then read the RDR register.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 26.66 Example operation for serial reception in clock synchronous mode (2) when RTS function is used

3.如果发生溢出错误，则CSR.ORER标志设置为1。如果CCR0.RIE位为1，则产生SCIn_ERI中断请求。接收数据不传送到RDR寄存器。

4.当接收成功完成时，接收数据被传送到RDR寄存器。如果CCR0.RIE位为1，则SCIn_RXI中断请求产生。连续接收是通过读取接收到的数据传输到在接收下一个接收数据完成之前，SCIn_RXI中断处理程序中的RDR寄存器。读取传输到RDR的接收数据会导致CTSn_RTSn引脚输出低电平（使用RTS功能时）。

如果要防止CTSn_RTSn引脚输出在收到最终数据后变为低电平，请将CCR0.RE位清零，然后读取RDR寄存器。

Data transfer cannot resume while the receive error flag is 1. Therefore, clear the ORER, FER, and PER flags in the CSR register to 0 before resuming data reception. Additionally, always read the RDR register during overrun error processing. When a data reception is forced to terminate by a 0 write to the CCR0.RE bit during operation, read the RDR register because received data that is not yet read might be left in the RDR register.

接收错误标志为1时无法恢复数据传输。因此，在恢复数据接收之前，将CSR寄存器中的ORER、FER和PER标志清零。此外，在溢出错误处理期间始终读取RDR寄存器。如果在操作期间通过对CCR0.RE位写入0来强制终止数据接收，请读取RDR寄存器，因为尚未读取的已接收数据可能会留在RDR寄存器中。

[6]溢出错误处理：读取RDR。

[7]清除错误标志：

图26.69显示了时钟同步模式下同时串行发送和接收操作的示例流程。
初始化SCI后，使用以下程序同时进行串行数据发送和接收操作。

从发送模式切换到同时发送和接收模式：

1.通过验证CSR.TEND标志是否设置为1来检查SCI是否完成数据传输。

2. Initialize the CCR0 register, and then set the TIE, RIE, TE, and RE bits in the CCR0 register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data reception.
2. Set the CCR0.TE and RE bits to 0, and then check that the receive error flag (ORER, FER, and PER) in the CSR register is 0.
3. Set the TIE, RIE, TE, and RE bits in the CCR0 register to 1 simultaneously by a single instruction.

When the RTS function is used in the concurrent transmission/reception operation, if you want to prevent the CTSn_RTSn pin output from turning to low after the final data is received as in the reception operation, clear the RE and TE bits in CCR0 to 0 simultaneously, and then read the RDR register.

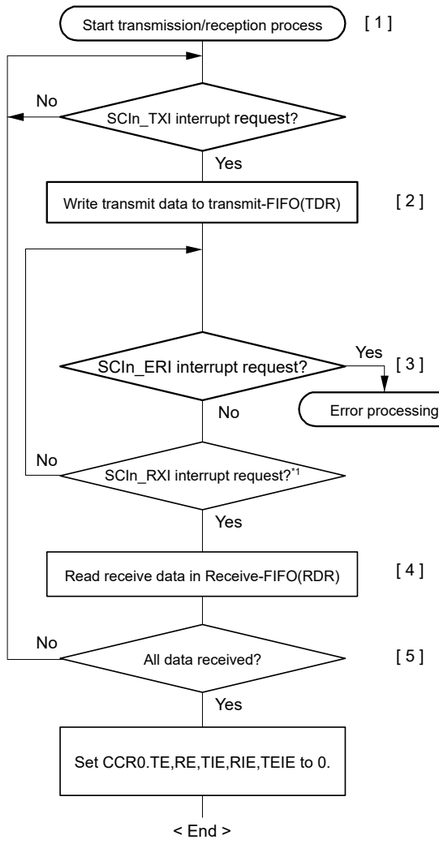
1. Check that the SCI completes the reception.
2. Set the CCR0.TE and RE bits to 0.
3. Check that the receive error flags (ORER, FER, and PER) in the CSR register are 0, and then set the TIE, RIE, TE, and RE bits in the CCR0 register to 1 simultaneously by a single instruction.

Since clock synchronous communication performs transmission and reception at the same time, make sure that the number of data to be transmitted and received is the same.



[1] Start transmission / reception process

[2] Transmit data write:
Write transmit data to Transmit-FIFO(TDR) in the SCIn_TXI Interrupt request handling routine.
Match the number of transmitted data with the FCR.RTRG.

[3] Receive error processing:
If a receive error occurs, after performing the appropriate error processing (Initialization such as stopping communication, reading all received data, clearing CSR.RDRF, etc.), be sure to ORER is 0. Reception cannot be resumed if ORER is 1.

[4] Read receive data:
Read the received data stored in receive-FIFO(RDR) for the number of the FCR.RTRG in the SCIn_RXI interrupt handling routine.

[5] Serial transmission/reception continuation procedure
To continue serial reception, before the overrun error occurs, read data from RDR and clear CSR.RDRF.
To continue serial transmission, write transmit data to the transmit-FIFO(TDR) by using a SCIn_TXI interrupt and clear TDRE flag to 0.
Transmit data can also be written to the transmit- FIFO(TDR) by activating the DMAC or DTC. And The RDR data can also be read by activating the DMAC or DTC. In this case, the TDRE and RDRF are cleared automatically, so please don't operate the TDRE And RDRF.

Note 1. Set all received data to an integer multiple of the receive FIFO threshold. If it is not an integral multiple, return to step [2] and it will become an infinite loop, so set a timeout time separately using a timer etc.

Figure 26.70 Example flow of simultaneous serial transmission and reception in clock synchronous mode with FIFO selected

初始化SCI后，使用以下程序同时进行串行数据发送和接收操作。

从发送模式切换到同时发送和接收模式：

1.通过验证CSR.TEND标志设置为1来检查SCI是否完成传输。

2.初始化CCR0寄存器，然后通过一条指令同时将CCR0寄存器中的TIE、RIE、TE和RE位设置为1。

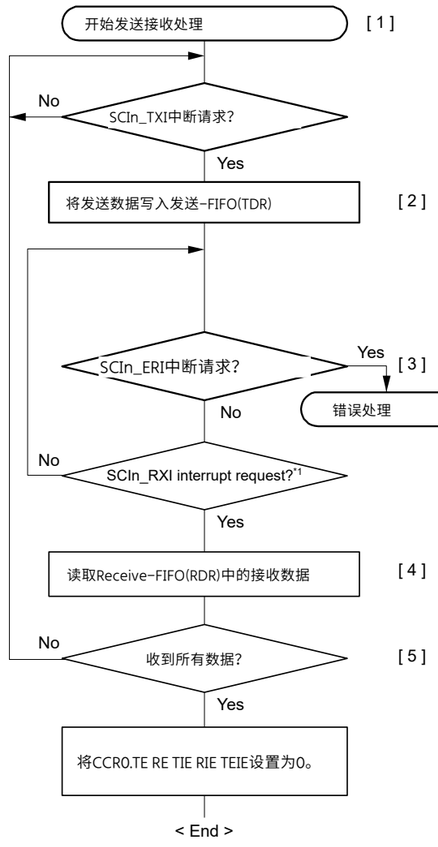
从接收模式切换到同时发送和接收模式：

1.检查SCI是否完成接收。

2.将CCR0.TE和RE位设置为0。

3.检查CSR寄存器中的接收错误标志（ORER、FER和PER）是否为0，然后通过一条指令同时将CCR0寄存器中的TIE、RIE、TE和RE位设置为1。

由于时钟同步通信同时进行发送和接收，请确保要发送和接收的数据数量相同。



[1]开始发送接收处理

[2]发送数据写入：将发送数据写入SCIn_TXI中的Transmit-FIFO(TDR)
中断请求处理例程。
将传输数据的数量与FCR.RTRG匹配。

[3]接收错误处理：
如果发生接收错误，在进行适当的错误处理（如停止通信、读取所有接收数据、清除CSR.RDRF等初始化）后，请确保ORER为0。如果ORER为1，则无法恢复接收。

[4]读取接收数据：在SCIn_RXI中断处理例程中读取存储在接收FIFO(RDR)中的FCR.RTRG编号的接收数据。

[5]串行发送接收继续程序
要继续串行接收，在溢出错误发生之前，从RDR读取数据并清除CSR.RDRF。要继续串行传输，请使用SCIn_TXI中断将传输数据写入传输FIFO(TDR)，并将TDRE标志清零。

发送数据也可以通过激活DMAC或DTC写入发送FIFO(TDR)。并且RDR数据也可以通过激活DMAC或DTC来读取。在这种情况下，TDRE和RDRF会自动清零，所以请不要操作TDRE和RDRF。

注1.将所有接收数据设置为接收FIFO阈值的整数倍。如果不是整数倍，返回步骤[2]会变成死循环，所以用定时器等单独设置超时时间。

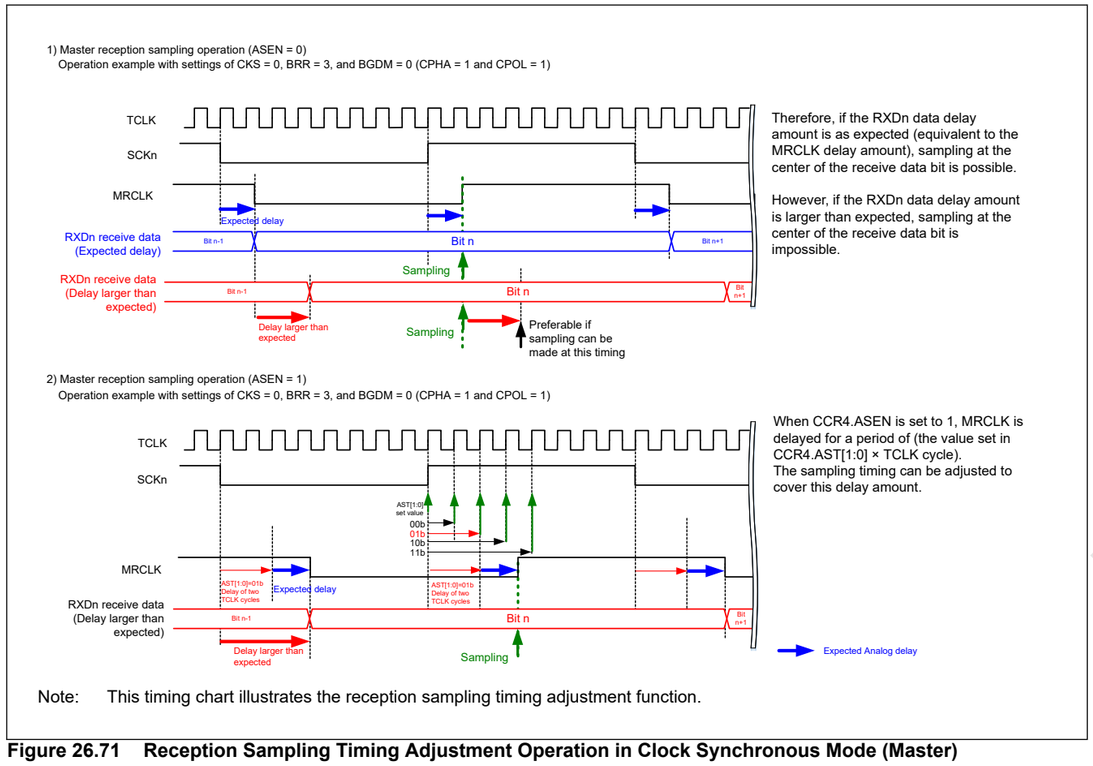
26.6.7 Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with internal clock used

When the clock synchronous internal clock is used (master mode), MRCLK is used as a reception sampling clock.

This function adjusts the reception sampling timing by delaying MRCLK by 1 to 4 TCLK and adding a digital delay. MRCLK's analog delay cannot be adjusted by this function.

Setting the CCR4.ASEN bit to 1 enables this function. The delay value is set in CCR4.AST[1:0].



Note: This timing chart illustrates the reception sampling timing adjustment function.

Figure 26.71 Reception Sampling Timing Adjustment Operation in Clock Synchronous Mode (Master)

26.7 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

26.7.1 Example Connection

Figure 26.72 shows an example connection between a smart card (IC card) and the MCU. As shown in Figure 26.72, because the MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

Setting the CCR0.TE and CCR0.RE bits to 1 with an IC card disconnected enables closed-loop transmission or reception, allowing self-diagnosis. To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.

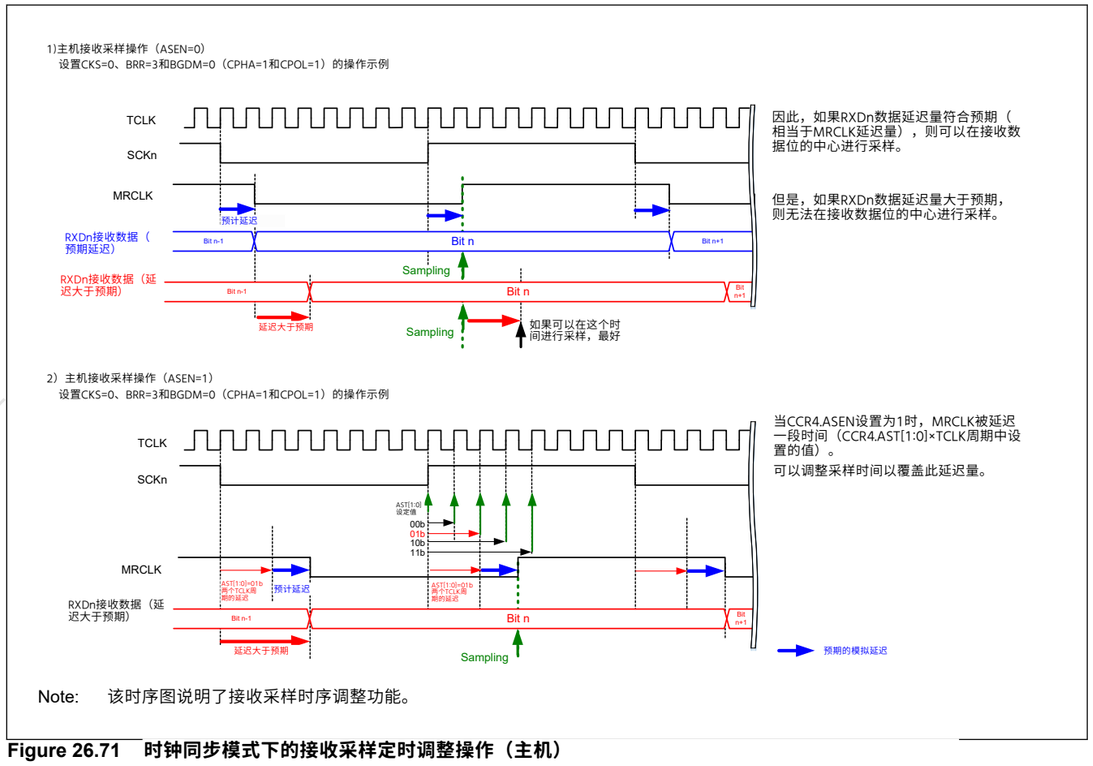
An output port of the MCU can be used to output a reset signal.

26.6.7 使用内部时钟的时钟同步模式下的接收采样定时调整功能

当使用时钟同步内部时钟（主机模式）时，MRCLK用作接收采样时钟。

该函数通过将MRCLK延迟1到4个TCLK并添加数字延迟来调整接收采样时序。
此功能无法调整MRCLK的模拟延迟。

将CCR4.ASEN位设置为1可启用此功能。延迟值在CCR4.AST[1:0]中设置。



Note: 该时序图说明了接收采样时序调整功能。

26.7 智能卡接口模式下的操作

SCI支持符合ISOIEC7816-3（识别卡标准）的智能卡（IC卡）接口，作为SCI的扩展功能。

可以使用适当的寄存器选择智能卡接口模式。

26.7.1 示例连接

图26.72显示了智能卡（IC卡）和MCU之间的示例连接。如图26.72所示，由于MCU使用单条传输线与IC卡通信，因此将TXDn和RXDn引脚互连，并使用电阻将数据传输线上拉到VCC。

在断开IC卡的情况下将CCR0.TE和CCR0.RE位设置为1可启用闭环发送或接收，从而实现自诊断。要将SCI产生的时钟脉冲提供给IC卡，请将SCKn引脚输出输入到IC卡的CLK引脚。

MCU的输出端口可用于输出复位信号。

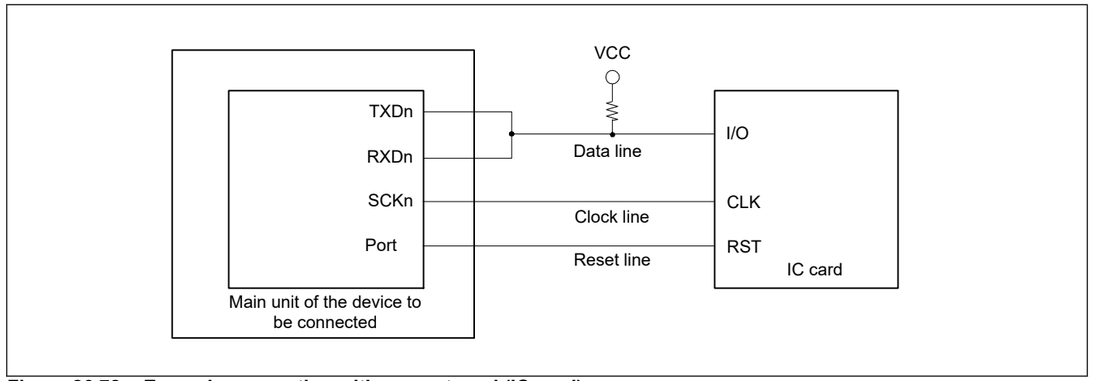

Figure 26.72 Example connection with a smart card (IC card)

26.7.2 Data Format (Except in Block Transfer Mode)

Figure 26.73 shows the data transfer formats in smart card interface mode:

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 ETUs (elementary time unit – the time required for transferring 1 bit) is set as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low error signal is output for 1 ETU after 10.5 ETUs elapse from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 ETUs.

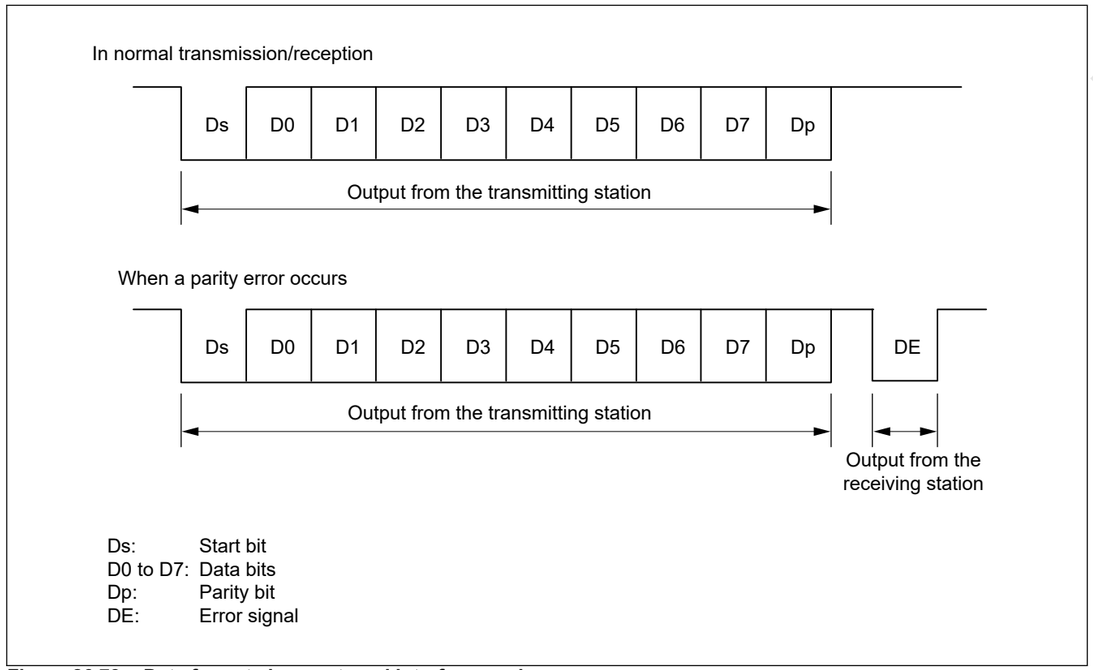

Figure 26.73 Data formats in smart card interface mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedures in this section.

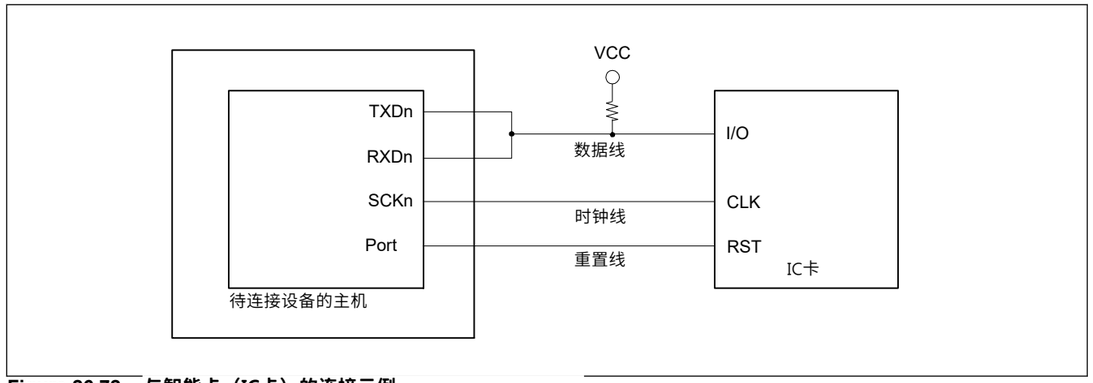

Figure 26.72 与智能卡（IC卡）的连接示例

26.7.2 数据格式（块传输模式除外）

图26.73显示了智能卡接口模式下的数据传输格式：

●一帧由8位数据和一个异步模式的奇偶校验位组成。

●在传输过程中，至少设置2个ETU（基本时间单位——传输1位所需的时间）作为从奇偶校验位结束到下一帧开始的保护时间。

●如果在接收过程中检测到奇偶校验错误，则在从起始位经过10.5ETU后输出1ETU的低错误信号。

●如果在传输过程中对错误信号进行采样，相同的数据会在至少2个ETU后自动重传。

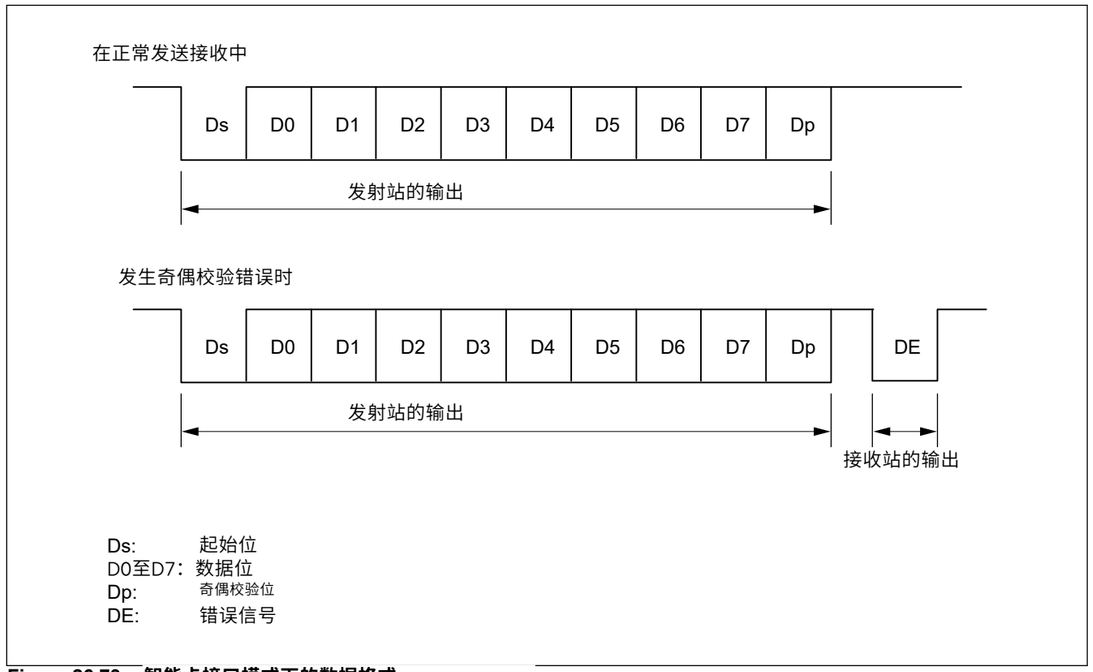

Figure 26.73 智能卡接口模式下的数据格式

与直接约定型和逆约定型IC卡进行通信时，请按照本节的步骤进行。

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 indicate the Z and A states, respectively, and data is transferred with LSB-first for the start character, as shown in Figure 26.74. Therefore, data in the start character in the figure is 0x3B.

When using the direct convention type, write 1 to the CCR3.LSBF and write 0 to the CCR3.SINV. Write 0 to the CCR1.PM bit to use even parity, which is prescribed by the smart card standard.

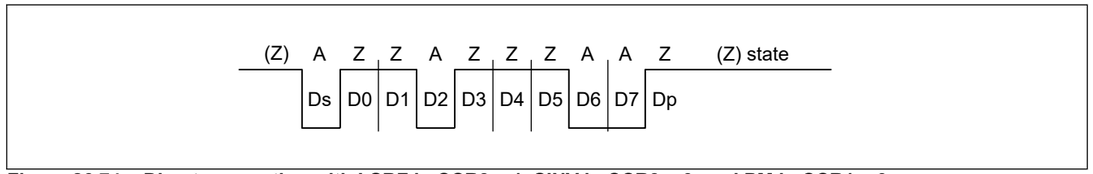

Figure 26.74 Direct convention with LSBF in CCR3 = 1, SINV in CCR3 = 0, and PM in CCR1 = 0

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 indicate the A and Z states, respectively, and data is transferred with MSB-first for the start character, as shown in Figure 26.75. Therefore, data in the start character in the figure is 0x3F.

When using the inverse convention type, write 0 to the CCR3.LSBF and write 1 to the CCR3.SINV. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to the Z state. Because the SINV bit of the MCU only inverts data bits D7 to D0, write 1 to the PM bit in CCR1 to invert the parity bit for both transmission and reception.

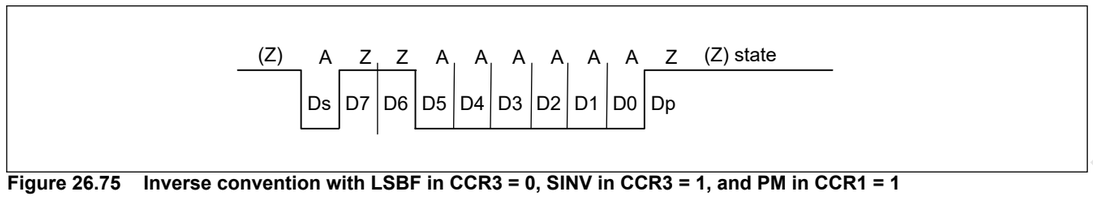

Figure 26.75 Inverse convention with LSBF in CCR3 = 0, SINV in CCR3 = 1, and PM in CCR1 = 1

26.7.3 Block Transfer Mode

Block transfer mode differs from normal smart card interface mode as follows:

- Even if a parity error is detected during reception, no error signal is output. Because the PER flag in CSR is set by error detection, clear the PER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 ETU is set as a guard time from the end of the parity bit until the start of the next frame
- Because the same data is not retransmitted, the TEND flag in CSR is set to 11.5 ETUs after transmission starts
- In block transfer mode, the ERS flag in CSR indicates the error signal status as in normal smart card interface mode, but the flag is read as 0 because no error signal is transferred

26.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate set up in the CCR2.BCP[2:0] bits. The frequency is always 16 times the bit rate in normal asynchronous mode.

For data reception, the falling edge of the start bit is sampled with the base clock to perform internal synchronization.

Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 26.76. The reception margin is determined by the following formula:

(1) 直接约定型

对于直接约定类型，逻辑电平1和0分别表示Z和A状态，数据通过
LSB-first为起始字符，如图26.74所示。因此，图中起始字符中的数据为0x3B。

使用直接约定类型时，向CCR3.LSBF写入1，向CCR3.SINV写入0。将0写入CCR1.PM位以使用智能卡标准规定的偶校验。

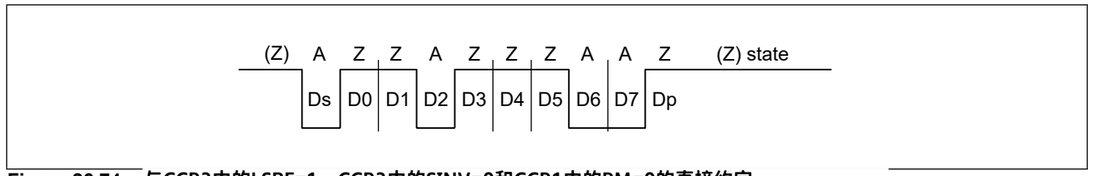

Figure 26.74 与CCR3中的LSBF=1、CCR3中的SINV=0和CCR1中的PM=0的直接约定

(2) 逆约定型

对于逆约定类型，逻辑电平1和0分别表示A和Z状态，数据通过
MSB-first为起始字符，如图26.75所示。因此，图中起始字符中的数据为0x3F。

使用逆约定类型时，向CCR3.LSBF写入0，向CCR3.SINV写入1。奇偶校验位为逻辑电平0，产生偶校验，这是智能卡标准规定的，对应于Z状态。由于MCU的SINV位仅将数据位D7反转为D0，因此向CCR1中的PM位写入1以反转发送和接收的奇偶校验位。

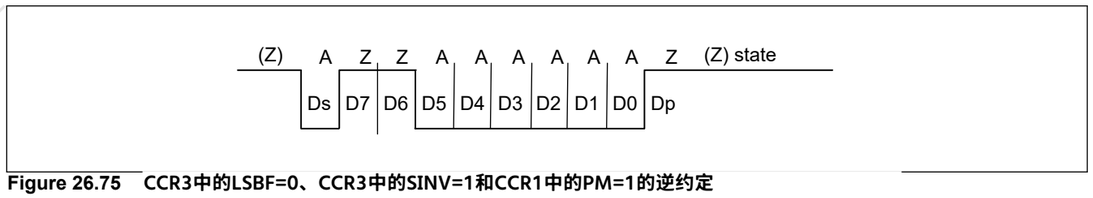

Figure 26.75 CCR3中的LSBF=0、CCR3中的SINV=1和CCR1中的PM=1的逆约定

26.7.3 块传输模式

块传输模式与普通智能卡接口模式的区别如下：

●即使在接收过程中检测到奇偶校验错误，也不会输出错误信号。因为CSR中的PER标志由错误检测设置，所以在接收下一帧的奇偶校验位之前清除PER标志。

●在传输过程中，从奇偶校验位结束到下一帧开始至少设置1个ETU作为保护时间

●由于不重传相同的数据，因此在传输开始后，CSR中的TEND标志设置为11.5ETU

●在块传输模式下，CSR中的ERS 标志指示错误信号状态，与普通智能卡接口模式一样，但该标志被读取为0，因为没有传输错误信号

26.7.4 接收数据采样时序和接收裕量

只有片内波特率发生器产生的内部时钟可以用作智能卡接口模式下的传输时钟。

在这种模式下，SCI可以在频率为CCR2.BCP[2:0]位中设置的比特率的32、64、372、256、93、128、186或512倍的基本时钟上运行。在正常异步模式下，频率始终是比特率的16倍。

对于数据接收，起始位的下降沿用基准时钟进行采样，以进行内部同步。

接收数据在基本时钟的第16、32、186、128、46、64、93和256个上升沿采样，以便在每个位的中间锁存，如图26.76所示。接收余量由以下公式确定：

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%]$$

M: Reception margin (%)

N: Ratio of bit rate to clock ($N = 32, 64, 372, 256$)

D: Duty cycle of clock ($D = 0$ to 1.0)

L: Frame length ($L = 10$)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the specified formula, the reception margin is determined using the following formula:

$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\ \%$

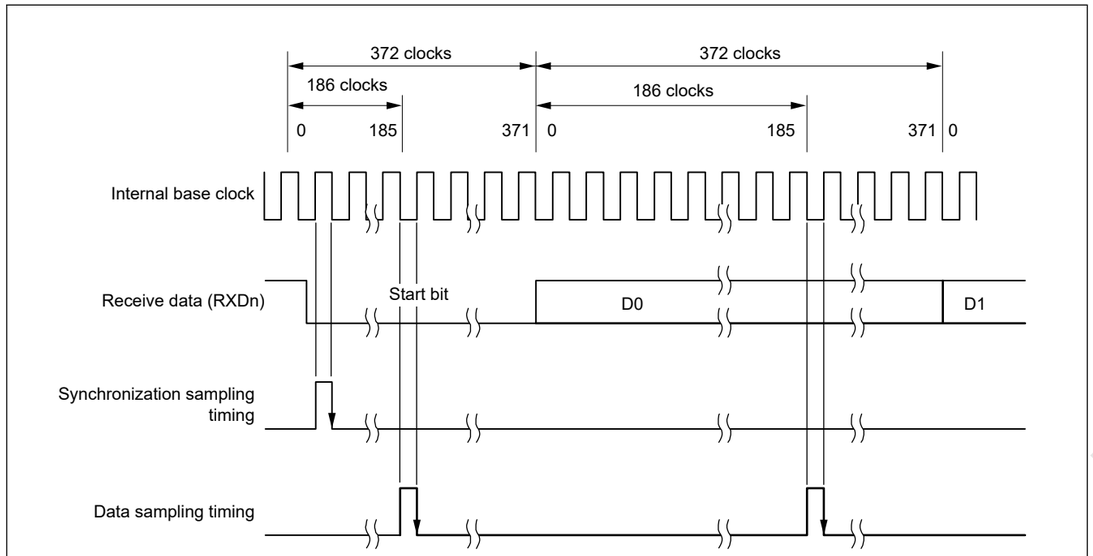

Figure 26.76 Receive data sampling timing in smart card interface mode when the clock frequency is 372 times the bit rate

26.7.5 SCI Initialization (Smart Card Interface Mode)

Before transmitting and receiving data, write the initial value 0x00 in the CCR0 register and initialize the SCI following the example flow shown in Table 26.37.

Always set the initial value in the TIE, RIE, TE, RE, TEIE bits in the CCR0 register before switching from transmission to reception mode or from reception to transmission mode. When CCR0.RE is set to 0, the RDR register is not initialized.

In transmission mode, set 1 to the CCR0.TE bit and CCR0.TIE bit simultaneously, then the SCIn_TXI interrupt request is generated.

To change from reception mode to transmission mode, first check that reception has completed, then initialize the SCI. At the end of initialization, set CCR0.TE = 1 and CCR0.RE = 0. Reception completion can be verified by reading the SCIn_RXI request, ORER, or PER flag in CSR.

To change transmission mode to reception mode, first check that transmission has completed, then initialize the SCI. At the end of initialization, set CCR0.TE = 0 and CCR0.RE = 1. Transmission completion can be verified by reading the TEND flag in CSR.

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%]$$

M：接收余量（%）

N：比特率与时钟的比率（N=32、64、372、256）

D：时钟的占空比（D=0到1.0）

L：帧长（L=10）

F：时钟频率偏差的绝对值

假设指定公式中的F=0、D=0.5和N=372的值，则使用以下公式确定接收余量：

$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\ \%$

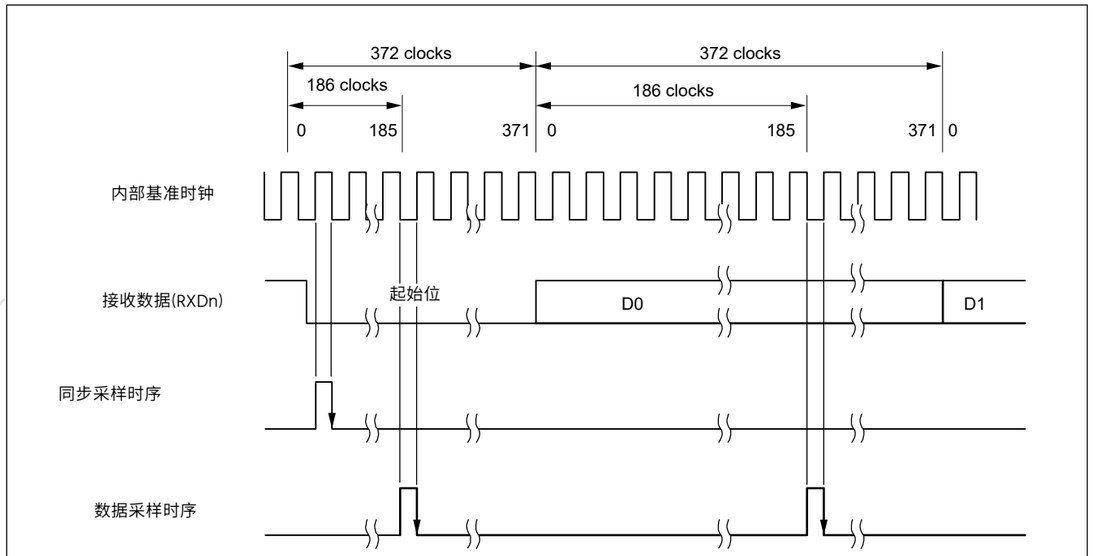

Figure 26.76 时钟频率为372倍比特率时智能卡接口模式下接收数据采样时序

26.7.5 SCI初始化（智能卡接口模式）

在发送和接收数据之前，将初始值0x00写入CCR0寄存器并按照表26.37所示的示例流程初始化SCI。

在从发送模式切换到接收模式或从接收模式切换到发送模式之前，请务必在CCR0寄存器的TIE、RIE、TE、RE、TEIE位中设置初始值。当CCR0.RE设置为0时，RDR寄存器未初始化。

在传输模式下，同时将CCR0.TE位和CCR0.TIE位设置为1，然后产生SCIn_TXI中断请求。

要从接收模式更改为发送模式，首先检查接收是否完成，然后初始化SCI。在初始化结束时，设置CCR0.TE=1和CCR0.RE=0。可以通过读取CSR中的SCIn_RXI请求、ORER或PER标志来验证接收完成。

要将传输模式更改为接收模式，首先检查传输是否完成，然后初始化SCI。在初始化结束时，设置CCR0.TE=0和CCR0.RE=1。可以通过读取CSR中的TEND标志来验证传输完成。

Table 26.37 Example flow of SCI initialization in smart card interface mode

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set CCR0.TEIE, TIE, RIE, TE, RE to 0. If you have not changed from the initial settings, you can skip this step.
3	Set CCR3	Set communication mode (MOD[2:0] = 001b), BLK, GM, and SINV. Leave other bits at their initial values.
4	Set CCR2	Set clock-select and bit-rate. Set BRME to 0.
5	Set CCR1	Set up the loop-back function, communication terminal status. Set NFEN, PE, CTSE to 0 and set PE to 1.
6	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
7	Set CCR3	Set CKE[1:0]. When the CKE[0] bit is set to “1” due on GM setting value, the clock is output from the SCKn pin.
8	Set CFCLR	Write 1 to the following bits and clear the corresponding flag. CFCLR.RDRFC,FERC,PERC,MFFC,ORERC,DFERC,DPERC,DCMFC,ERSC
9	Set CCR0	Set the TE or RE to 1. And set the TIE and RIE. Do not simultaneously set the TE and RE bits to 1 if self-diagnosis in not used.
10	Initialization completed	—

Figure 26.77 is a timing chart when data transmission is performed by making transition to the Smart Card Interface mode according to the above flow chart. The figure shows the case when CCR3.GM bit is 0. As shown in the figure, when the pin function is set to the SCKn pin, the SCKn pin is high impedance because the CCR3.CKE [0] bit is 0. When the TXDn pin is set, the TXDn pin is high impedance because the CCR0.TE bit is 0. Start clock output to the SCKn pin with the clock output setting CCR3.CKE [0] to 1, start data transmission by writing transmit data after setting CCR0.TE to 1.

In the smart card interface mode, even if not communicating at CCR0.TE = 0 and CCR0.RE = 0, the clock is continuously output if the clock output setting is used.

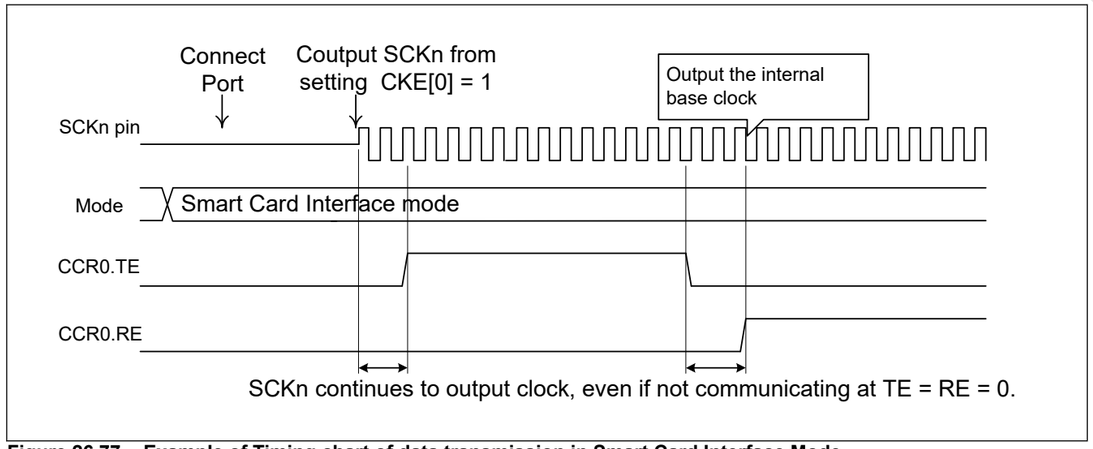

Figure 26.77 Example of Timing chart of data transmission in Smart Card Interface Mode

26.7.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode) is different from that in non-smart card interface mode, in that an error signal is sampled and data can be re-transmitted in smart card mode. Figure 26.78 shows the data re-transfer operation during transmission.

1. When an error signal from the receiver end is sampled after 1-frame data is transmitted, the CSR.ERS flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.

图26.77是按照上述流程图转换到智能卡接口模式进行数据传输时的时序图。图中为CCR3.GM位为0的情况。如图所示，当引脚功能设置为SCKn引脚时，由于CCR3.CKE[0]位为0，SCKn引脚为高阻态。当TXDn引脚置位，TXDn引脚为高阻抗，因为CCR0.TE位为0。时钟输出设置CCR3.CKE[0]为1开始向SCKn引脚输出时钟，设置后通过写入发送数据开始数据传输CCR0.TE为1。

在智能卡接口模式下，即使在CCR0.TE=0和CCR0.RE=0时不通信，如果使用时钟输出设置，时钟也会连续输出。

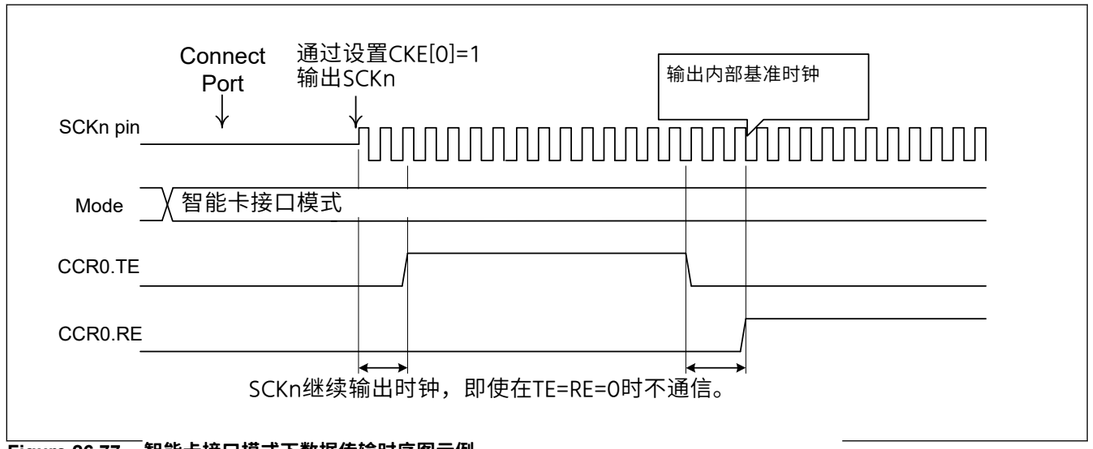

Figure 26.77 智能卡接口模式下数据传输时序图示例

26.7.6 串行数据传输（块传输模式除外）

智能卡接口模式下的串行数据传输（块传输模式除外）与非智能卡接口模式下的串行数据传输不同之处在于，在智能卡模式下对错误信号进行采样，数据可以重新传输。图26.78显示了传输过程中的数据重新传输操作。

1.发送1帧数据后，当从接收端采样到错误信号时，CSR.ERS标志置1。如果CCR0.RIE位为1，则产生SCIn_ERI中断请求。在采样下一个奇偶校验位之前将ERS 标志清零。

2. For a frame in which an error signal is received, the CSR.TEND flag is not set. Data is re-transferred from TDR to TSR, allowing automatic data retransmission.
3. If no error signal is returned from the receiver, the ERS flag is not set to 1.
4. In this case, the SCI determines that transmission of 1-frame data, including the re-transfer, is complete, and the TEND flag is set. If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated. Write transmit data to the TDR to start transmission of the next data.

Figure 26.80 shows an example flow of serial transmission. All the processing steps are automatically performed using an SCIn_TXI interrupt request to activate the DTC or DMAC.

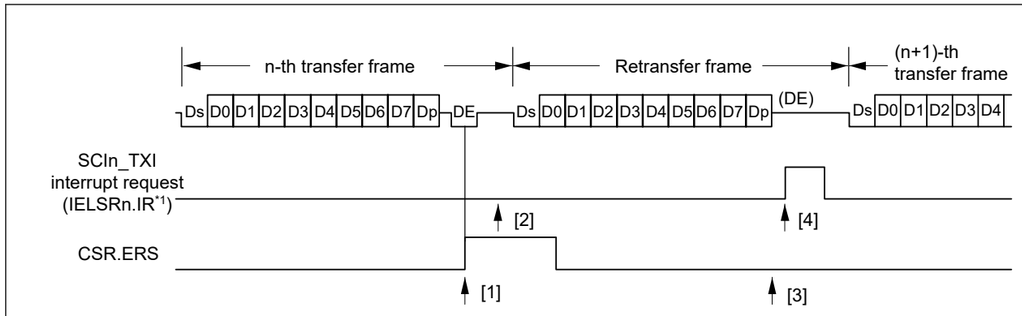
When the CSR.TEND flag is set to 1 in transmission and when the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated.

The DTC or DMAC is activated by an SCIn_TXI interrupt request if the SCIn_TXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission when an error occurs. Because the ERS flag is not automatically cleared, set the RIE bit to 1 before enabling an SCIn_ERI interrupt request to be generated if an error occurs, and clear the ERS flag to 0.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings.

For DTC or DMAC settings, see section 16, Data Transfer Controller (DTC), section 15, DMA Controller (DMAC).



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 26.78 Data re-transfer operation in smart card interface transmission mode

The CSR.TEND flag is set at different timings depending on the CCR3.GM bit setting. Figure 26.79 shows the TEND flag generation timing.

2.对于接收到错误信号的帧，不设置CSR.TEND标志。数据从TDR重新传输到TSR，允许自动数据重新传输。

3.如果接收器没有返回错误信号，则ERS 标志不设置为1。

4.在这种情况下，SCI确定1帧数据的传输（包括重新传输）已完成，并设置TEND标志。如果CCR0.TIE位为1，则产生SCIn_TXI中断请求。将传输数据写入TDR以开始传输下一个数据。

图26.80显示了串行传输的示例流程。所有处理步骤都使用一个自动执行SCIn_TXI中断请求以激活DTC或DMAC。

当CSR.TEND标志在传输中设置为1且CCR0.TIE位为1时，将产生SCIn_TXI中断请求。

如果先前将SCIn_TXI中断请求指定为DTC或DMAC激活源，则DTC或DMAC由SCIn_TXI中断请求激活，从而允许传输发送数据。当DTC或DMAC传输数据时，TEND标志自动设置为0。

如果发生错误，SCI会自动重新传输相同的数据。在此重传期间，TEND标志保持为0，并且DTC或DMAC未激活。因此，SCI和DTC或DMAC会自动传输指定的字节数，包括发生错误时的重传。因为ERS 标志不会自动清零，所以如果发生错误，在使能SCIn_ERI中断请求之前将RIE位设置为1，并将ERS 标志清零。

使用DTC或DMAC发送或接收数据时，请务必在进行SCI设置之前启用DTC或DMAC。

对于DTC或DMAC设置，请参阅第16节，数据传输控制器(DTC)，第15节，DMA控制器(DMAC)。

26.7.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 26.81 shows the data re-transfer operation in reception mode.

1. If a parity error is detected in the receive data, the CSR.PER flag is set to 1. When the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no SCIn_RXI interrupt is generated.
3. When no parity error is detected, the CSR.PER flag is not set to 1.
4. In this case, data is determined to be received successfully. When the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated.

Figure 26.82 shows an example flow of serial data reception. All the processing steps are automatically performed using an SCIn_RXI interrupt request to activate the DTC or DMAC.

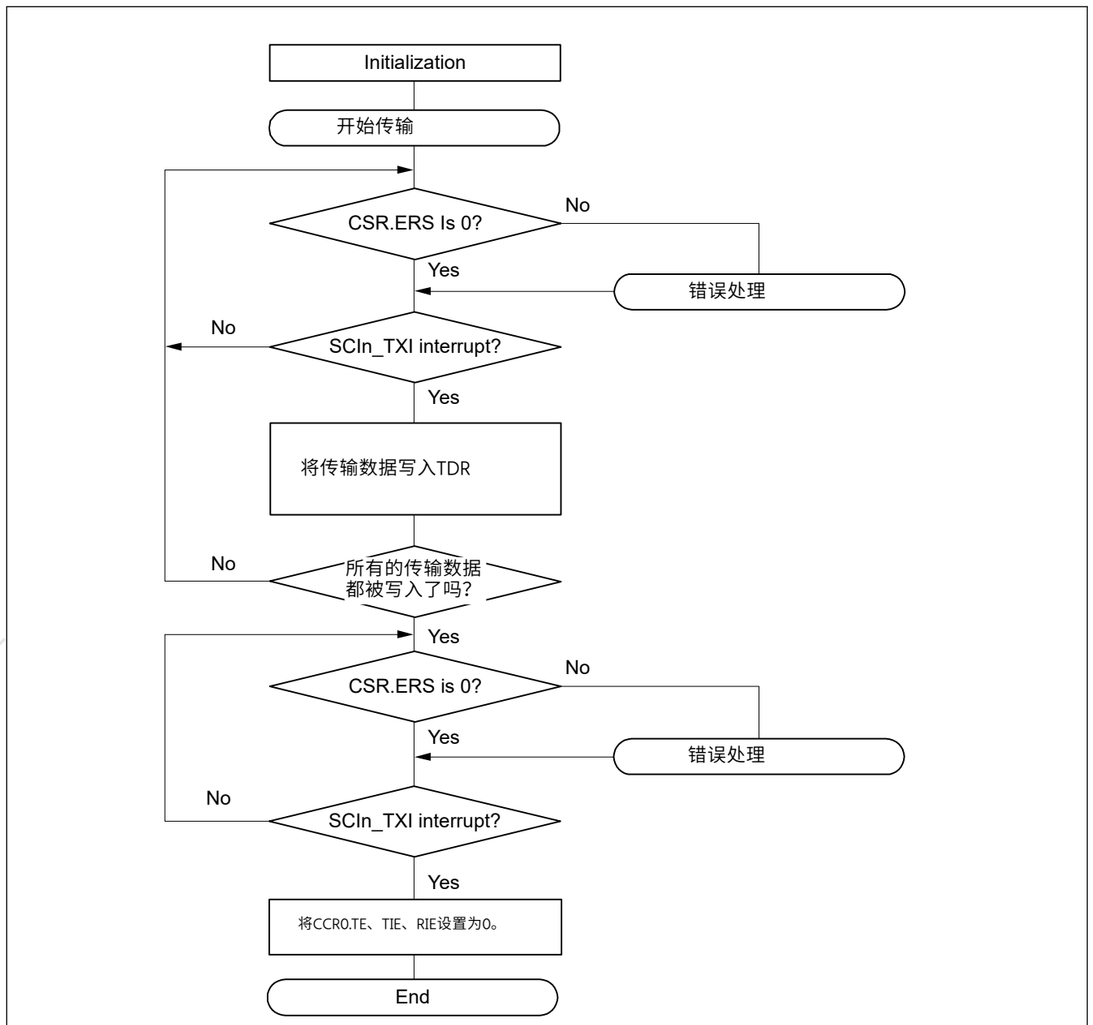

Figure 26.80 智能卡接口传输示例流程

26.7.7 串行数据接收（块传输模式除外）

智能卡接口模式下的串行数据接收与非智能卡接口模式下的串行数据接收类似。图26.81显示了接收模式下的数据重传操作。

1.如果在接收数据中检测到奇偶校验错误，则CSR.PER标志设置为1。当CCR0.RIE位为1时，产生SCIn_ERI中断请求。在采样下一个奇偶校验位之前将PER标志清零。

2.对于检测到奇偶校验错误的帧，不产生SCIn_RXI中断。

3.当没有检测到奇偶校验错误时，CSR.PER标志不设置为1。

4、在这种情况下，确定数据接收成功。当CCR0.RIE位为1时，产生SCIn_RXI中断请求。

图26.82显示了串行数据接收的示例流程。所有处理步骤都使用一个自动执行SCIn_RXI中断请求以激活DTC或DMAC。

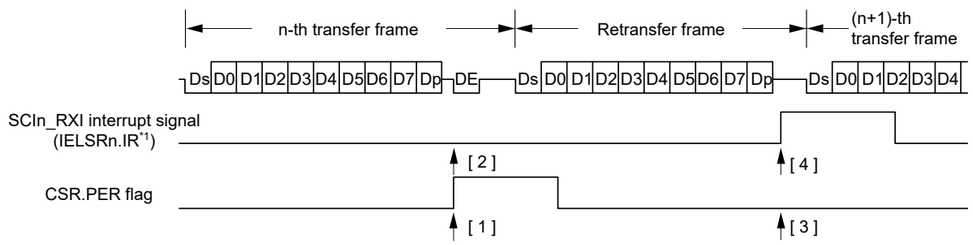
In reception, setting the RIE bit to 1 allows an SCIn_RXI interrupt request to be generated. The DTC or DMAC is activated by an SCIn_RXI interrupt request if the SCIn_RXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in CSR is set to 1, a receive error interrupt (SCIn_ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.

If a parity error occurs and the PER flag is set to 1 during reception, the receive data is transferred to RDR, allowing the data to be read.

When a reception is forced to terminate by setting CCR0.RE to 0 during operation, read the RDR register because the received data that is not yet read might be left in the RDR.

Note: For operations in block transfer mode, see section 26.3.9. Serial Data Reception in Asynchronous Mode.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

在接收时，将RIE位设置为1允许产生SCIn_RXI中断请求。如果SCIn_RXI中断请求先前被指定为DTC或DMAC激活源，则DTC或DMAC由SCIn_RXI中断请求激活，从而允许传输接收数据。

如果在接收期间发生错误并且CSR中的ORER或PER标志设置为1，则会产生接收错误中断(SCIn_ERI)请求。错误发生后清除错误标志。如果发生错误，则不会激活DTC或DMAC并跳过接收数据。因此，将传输DTC或DMAC中指定的接收数据字节数。

如果在接收过程中发生奇偶校验错误并且PER标志设置为1，则接收数据将传输到RDR，从而可以读取数据。

如果在操作期间通过将CCR0.RE设置为0来强制终止接收，请读取RDR寄存器，因为尚未读取的接收数据可能会留在RDR中。

Note: 关于块传输模式下的操作，请参见第26.3.9节。异步模式下的串行数据接收。

26.7.8 Clock Output Control

When the GM bit in CCR3 is set to 1, the clock output can be controlled by the CKE[1:0] bits in CCR3. For details on the CKE[1:0] bits, see section 26.2.8. CCR3 : Common Control Register 3. When setting the clock output, the base clock described in section 26.7.4. Receive Data Sampling Timing and Reception Margin the bit rate is set by CCR2.CKS, CCR2.BCP[2:0] and BRR[7:0].

Figure 26.83 shows an example timing for the clock output control when the CKE[1] bit in CCR3 is set to 0 and the CKE[0] bit in CCR3 is controlled.

When the GM bit in CCR3 is 0, output control by the CKE[0] bit in CCR3 is immediately reflected on the SCKn pin, so there is a possibility that pulses with an unintended width may be output from the SCKn pin.

When the GM bit in CCR3 is 1, the output pulse control by the CCR3.CKE [0] controls the pulse width set to be based on the state of the base clock.

26.7.8 时钟输出控制

当CCR3中的GM位设置为1时，时钟输出可由CCR3中的CKE[1:0]位控制。有关详细信息CKE[1:0]位，参见第26.2.8节。CCR3：公共控制寄存器3。设置时钟输出时，使用第26.7.4节中描述的基本时钟。接收数据采样时序和接收裕度比特率由CCR2.CKS、CCR2.BCP[2:0]和BRR[7:0]设置。

图26.83显示了当CCR3中的CKE[1]位设置为0并控制CCR3中的CKE[0]位时时钟输出控制的示例时序。

当CCR3的GM位为0时，CCR3的CKE[0]位的输出控制立即反映在SCKn引脚上，因此有可能会从SCKn引脚输出不期望宽度的脉冲。

当CCR3中的GM位为1时，由CCR3.CKE[0]控制的输出脉冲控制设置为基于基本时钟状态的脉冲宽度。

26.8 Operation in Simple IIC Mode

Simple IIC mode format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device can specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8 data bits in all frames are transmitted in order from the MSB.

The I^2C bus format and timing of the I^2C bus are shown in Figure 26.84 and Figure 26.85.

26.8 简单IIC模式下的操作

简单IIC模式格式由8个数据位和一个确认位组成。通过在启动条件或重新启动条件之后继续进入从地址帧，主设备可以指定从设备作为通信伙伴。当前指定的从设备保持有效，直到指定新的从设备或满足停止条件。所有帧中的8个数据位从MSB开始按顺序传输。

I2C总线格式和I2C总线时序如图26.84和图26.85所示。

26.8.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the ICR.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept in the released state
- The hold time for the start condition is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The level on the SCLn line falls (from the high level to the low level), the IICSTAREQ bit in ICR is set to 0, and a start-condition generated interrupt is output

Writing 1 to the IICRSTAREQ bit in ICR causes the generation of a restart condition. The generation of a restart condition proceeds through the following operations:

- The SDAn line is released and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the restart condition is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The level on the SDAn line falls (from the high level to the low level)
- The hold time for the restart condition is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The level on the SCLn line falls (from the high level to the low level), the ICR.IICRSTAREQ bit is set to 0, and a restart-condition generated interrupt is output

Writing 1 to the ICR.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the CCR2.BRR setting

26.8.1 启动、重启和停止条件的生成

将1写入ICR.IICSTAREQ位会导致产生启动条件。开始条件的生成通过以下操作进行：

●SDAn线上的电平下降（从高电平到低电平），SCLn线保持在释放状态

●开始条件的保持时间设置为比特周期的一半，比特率由CCR2.BRR设置确定

●SCLn线上的电平下降（从高电平到低电平），ICR中的IICSTAREQ位设置为0，并输出一个startcondition产生的中断

将1写入ICR中的IICRSTAREQ位会导致产生重启条件。重新启动条件的生成通过以下操作进行：

●SDAn线释放，SCLn线保持低电平

●SCLn线的低电平周期设置为比特周期的一半，比特率由CCR2.BRR设置确定

●SCLn线被释放（由低电平转变为高电平）

●当在SCLn线上检测到高电平时，重新启动条件的建立时间设置为比特周期的一半，比特率由CCR2.BRR设置确定

●SDAn线上的电平下降（从高电平到低电平）

●SCLn线上的电平下降（从高电平变为低电平），ICR.IICRSTAREQ位设置为0，并输出重启条件产生的中断

将1写入ICR.IICSTPREQ位会导致产生停止条件。停止条件的生成通过以下操作进行：

●SDAn线上的电平下降（从高电平到低电平），SCLn线保持在低电平

●SCLn线的低电平周期设置为比特周期的一半，比特率由CCR2.BRR设置确定

- When a high level is detected on the SCLn line, the setup time for the stop condition is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The SDAn line is released (transition from the low to the high level), the ICR.IICSTPREQ bit is set to 0, and a stop-condition generated interrupt is output

Figure 26.86 shows the timing of operations in the generation of start, restart, and stop conditions.

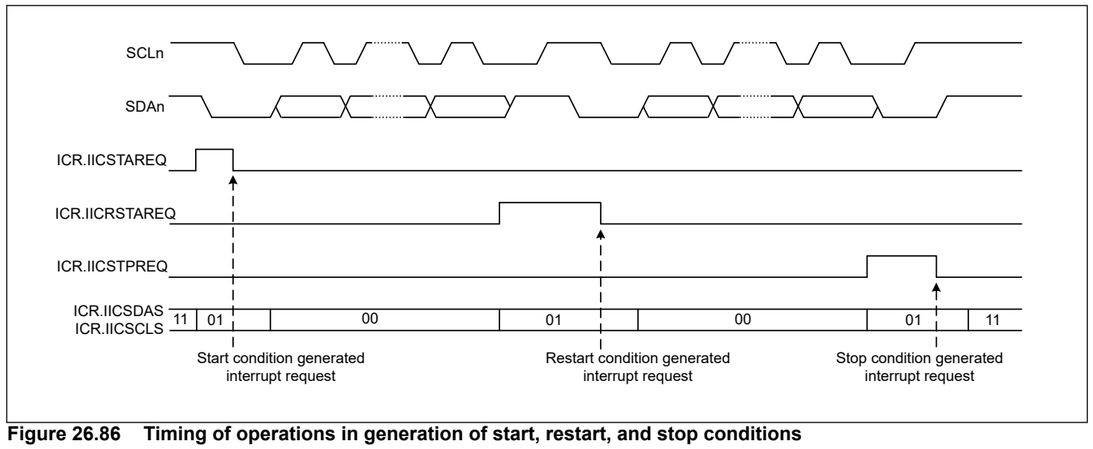

Figure 26.86 Timing of operations in generation of start, restart, and stop conditions

26.8.2 Clock Synchronization

The SCLn line can be driven low if a wait is inserted by a slave device at the other side of the transfer. Setting the ICR.IICCSC bit to 1 applies control to obtain synchronization when a difference arises between the levels of the internal SCLn clock signal and the level being input on the SCLn pin.

When the ICR.IICCSC bit is set to 1, the level of the internal SCLn clock signal changes from low to high. Counting to determine the period at a high level stops while the low level is being input on the SCLn pin. Counting to determine the period at a high level starts after the transition of the input on the SCLn pin to the high level.

The interval from this time until counting to determine the period at high level starts on the transition of the SCLn pin to the high level, is the total time which contains the SCLn input delay, delay for noise filtering of the input on the SCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLK). The period at high level of the internal SCLn clock is extended even when other devices do not place the low level on the SCLn line.

If the ICR.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SCLn pin and the internal SCLn clock. If the ICR.IICCSC bit is 0, synchronization with the internal SCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a wait period into the interval until the transition of the internal SCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a wait period after the transition of the internal SCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the waiting period, generation of the condition itself is not guaranteed.

Figure 26.87 shows an example operation for synchronizing the clocks.

●SCLn线被释放（由低电平转变为高电平）
●当在SCLn线上检测到高电平时，停止条件的建立时间设置为CCR2.BRR设置确定的比特率的半个比特周期

●SDAn线被释放（从低电平转换到高电平），ICR.IICSTPREQ位设置为0，并输出停止条件生成中断

图26.86显示了生成启动、重新启动和停止条件的操作时序。

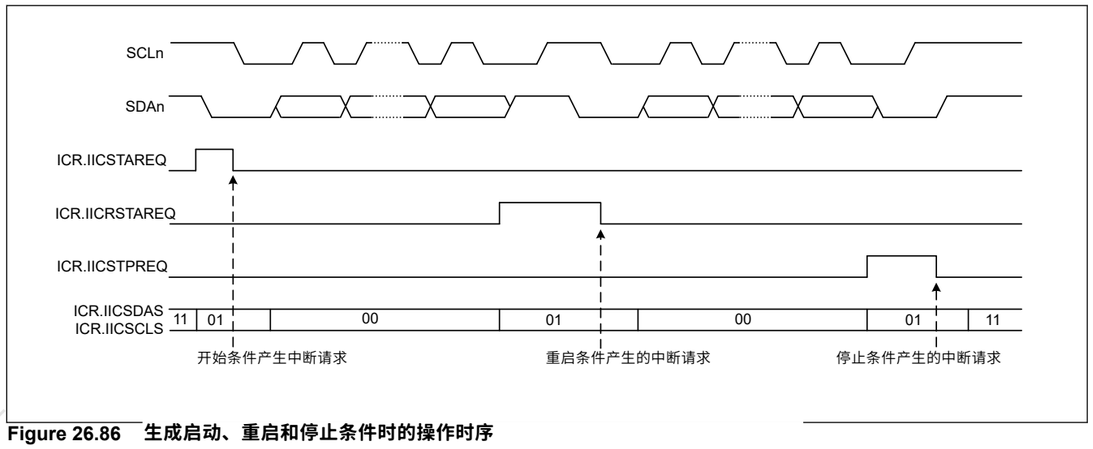

Figure 26.86 生成启动、重启和停止条件时的操作时序

26.8.2 时钟同步

如果从设备在传输的另一侧插入等待，则可以将SCLn线驱动为低电平。设置
当内部电平之间出现差异时，ICR.IICCSC位为1应用控制以获得同步
SCLn时钟信号和输入到SCLn引脚的电平。

当ICR.IICCSC位设置为1时，内部SCLn时钟信号的电平由低变为高。当SCLn引脚输入低电平时，停止计数以确定高电平周期。在SCLn引脚上的输入转换为高电平后，开始计数以确定高电平的周期。

从这个时间到从SCLn引脚转变为高电平开始计数以确定高电平周期的时间间隔是包含SCLn输入延迟、SCLn引脚上输入的噪声过滤延迟的总时间（噪声滤波器的2或3个采样时钟周期）和内部处理的延迟（1或2个PCLK周期）。即使其他设备没有将低电平置于SCLn线上，内部SCLn时钟的高电平周期也会延长。

如果ICR.IICCSC位为1，则通过对SCLn引脚上的输入和内部SCLn时钟进行逻辑与来获得数据发送和接收的同步。如果ICR.IICCSC位为0，则与内部SCLn时钟同步，用于数据的发送和接收。

如果从设备在发出启动、重新启动或停止条件的生成请求后，在内部SCLn时钟信号从低电平转变为高电平之前的间隔中插入一个等待周期，则直到生成的时间为延长了那个时期。

如果从设备在内部SCLn时钟信号从低电平转变为高电平之后插入等待周期，尽管在不停止等待周期的情况下发出生成完成中断，但不能保证条件本身的生成。

图26.87显示了同步时钟的示例操作。

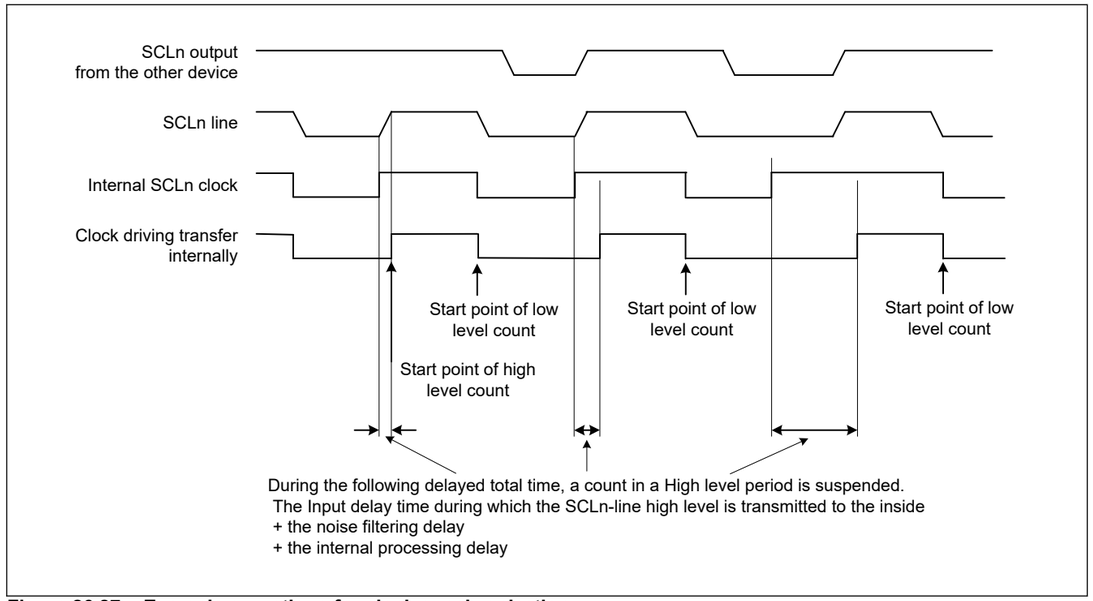

Figure 26.87 Example operations for clock synchronization

26.8.3 SDAn Output Delay

The ICR.IICDL[4:0] bits can be used to set a delay for output on the SDAn pin relative to falling edges of output on the SCLn pin. Delay settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, TCLK, by the divisor selected in the CCR2.CKS[1:0] bits). A delay for output on the SDAn pin applies to the start condition/restart condition/stop condition signal, 8-bit transmit data, and acknowledge bit.

If the SDAn output delay is shorter than the time for the level on the SCLn pin to fall, the change of the output on the SDAn pin starts while the output level on the SCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SDAn pin specify times greater than the time output on the SCLn pin takes to fall (300 ns for IIC in normal mode and fast mode).

Figure 26.88 shows the timing of delays in SDAn output.

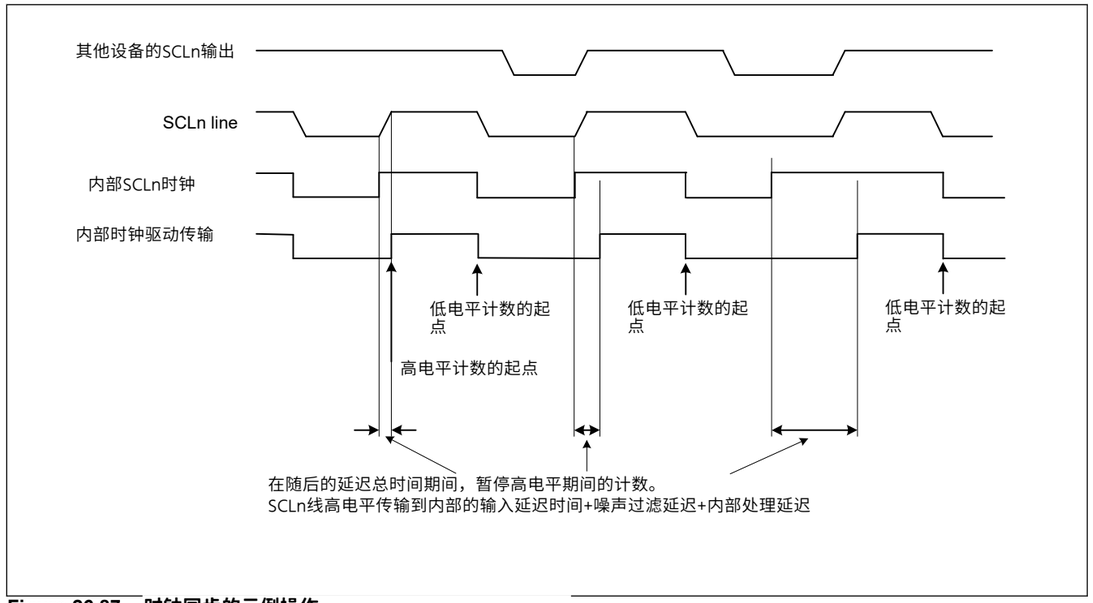

Figure 26.87 时钟同步的示例操作

26.8.3 SDAn输出延迟

ICR.IICDL[4:0]位可用于设置SDAn引脚输出相对于SCLn引脚输出下降沿的延迟。可选择从0到31的延迟设置，表示来自片上波特率发生器的时钟信号的相应周期数的周期（通过将基本时钟TCLK分频得到CCR2.CKS中选择的除数）[1:0]位）。SDAn引脚上的输出延迟适用于启动条件重启条件停止条件信号、8位发送数据和确认位。

如果SDAn输出延迟小于SCLn引脚电平下降的时间，则SDAn引脚上的输出变化会在SCLn引脚上的输出电平下降时开始，从而产生从设备错误操作的可能性.确保SDAn引脚上的输出延迟设置指定的时间大于SCLn引脚上输出的下降时间（IIC在正常模式和快速模式下为300ns）。

图26.88显示了SDAn输出中的延迟时间。

26.8.4 SCI Initialization in Simple IIC Mode

Before transferring data, write the initial value 0x00 to CCR0 and initialize the interface following the example shown in Table 26.38.

Before making any changes to the operating mode or transfer format, be sure to set CCR0 to its initial value. In simple IIC mode, the open-drain setting for the communication ports should be made on the port side.

Table 26.38 Example flow of SCI initialization in simple IIC mode

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set CCR0.TEIE, TIE, RIE, TE, RE to 0. If you have not changed from the initial settings, you can skip this step.
3	Set ICR	Set the IICSDAS[1:0] and IICSCLS[1:0] to 11b. Set the IICDL[4:0] and IICINTM as required. Set the IICACKT and the IICCSC bits to 1.
4	Set CCR3	Set the transmission / reception format as the communication mode (MOD [2:0] = 100b) and CKE [1:0] = 00b.
5	Set CCR2	Set the bit rate modulation function*1, the clock selection, and the bit rate.
6	Set CCR1	Set noise filter, communication pin status, parity check, and CTSn / RTSn function.
7	Set the I/O port functions	Set I/O port settings that allow use (on NMOS open-drain output pins and Hi-Z) of the SCLn and SDAn pin functions.
8	Set CFCLR, ICFCLR	Write 1 to the following bits and clear the corresponding flag. CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC ICFCLR.IICSTIFC
9	Set CCR0 (TE, RE, TIE, RIE)	Set the TE and RE bits to 1. To enable interrupts, set the TE, TIE, RE and RIE bits to 1 with one instruction at the same time (for transmission and when the IICINTM bit is 1, clear the RIE bit). Setting the TE and RE bits to 1 makes the SCLn and SDAn pins functions available.
10	Initialization completed	—

Note: Set the CCR0.TE and RE bits to 0 or 1 at the same time.
Note 1. If you do not use the bit rate modulation function, you do not need to set it.

在传输数据之前，将初始值0x00写入CCR0并按照中所示的示例初始化接口
Table 26.38.

在对操作模式或传输格式进行任何更改之前，请务必将CCR0设置为其初始值。在简单IIC模式下，通信端口的开漏设置应在端口侧进行。

9	设置CCR0（TE、RE、TIE、RIE）	将TE和RE位设置为1。要使能中断，请在一条指令同时将TE、TIE、RE和RIE位设置为1（用于传输且当IICINTM位为1时，清除RIE位）。将TE和RE位设置为1使SCLn和SDAn引脚功能可用。

Note: 同时将CCR0.TE和RE位设置为0或1。
注1.如果不使用码率调制功能，则无需设置。

26.8.5 简单IIC模式下的主传输操作

图26.89和图26.90显示了主机传输的示例，图26.91显示了数据传输的示例流程。

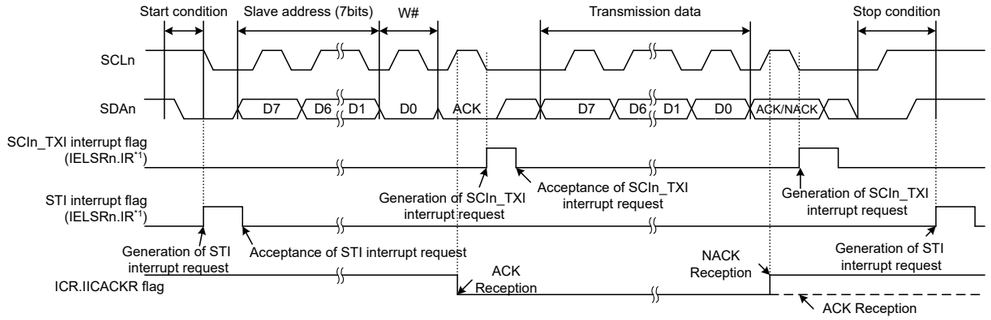
Figure 26.89 shows the operation example when ICR.IICINTM bit is 1 (use reception and transmission interrupts). In this case, you can start DMAC or DTC by SCIn_TXI interrupt. However, if use DMAC or DTC, ACK/NACK can not be confirmed. If you want to confirm ACK/NACK, prepare the transmit data by CPU.

In simple IIC mode, SCIn_TXI interrupt is generated when communication of one frame is completed. And it is not used SCIn_RXI interrupt in master transmission, so the CCR0.RIE set to 0.

See Table 26.43 for more information on the STI interrupt.

Figure 26.91 shows a flow chart in the case of ICR.IICINTM is 1 and address transmission by CPU and data transmission by DTC or DMAC. When 10-bit slave addresses are in use, steps [3] and [4] are repeated twice.

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.



Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 26.89 Example 1 of operations for master transmission in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts (ICR.IICINTM = 1)

When the ICR.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and required number of data bytes are transmitted. When the NACK is received, error processing such as transmission stop and retransmission is performed using the NACK interrupt as the trigger.

To restart communication for some reason after writing data in the TDR register, use the following procedure:

1. Set the TE and RE bits in the CCR0 register to 0 to stop communication.
2. Set ICR.IICSCLS[1:0] and ICR.IICSDAS[1:0] bits to 11b, release the I^2C bus, and clear the generation of a condition.
3. If the RDRF flag in the CSR register is set to 1, the RDR register is read by dummy and the RDRF bit is set to 0.
4. Set the TE and RE bits in the CCR0 register to 1 and start the next communication.

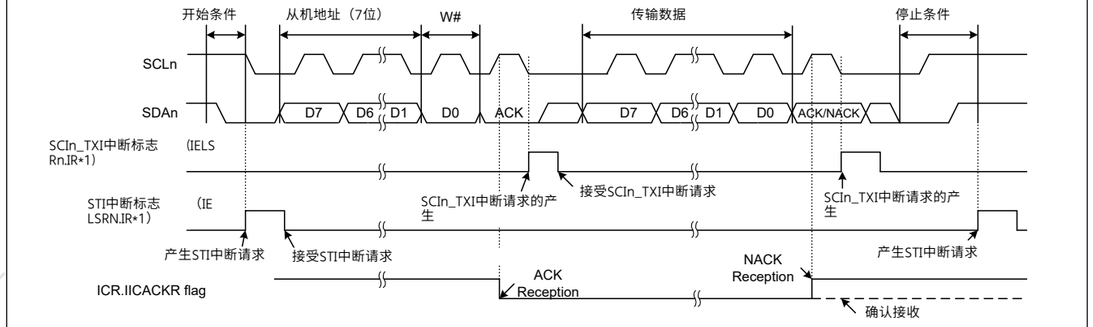
图26.89显示了ICR.IICINTM位为1时的操作示例（使用接收和发送中断）。在这种情况下，您可以通过SCIn_TXI中断启动DMAC或DTC。但是，如果使用DMAC或DTC，则无法确认ACKNACK。如果要确认ACKNACK，请通过CPU准备发送数据。

在简单IIC模式下，SCIn_TXI中断在一帧通信完成时产生。并且没有使用SCIn_RXI在主传输中断，因此CCR0.RIE设置为0。

有关STI中断的更多信息，请参见表26.43。

图26.91是ICR.IICINTM为1，CPU发送地址，DTC或DMAC发送数据时的流程图。当使用10位从地址时，步骤[3]和[4]重复两次。

在简单IIC模式下，与时钟同步传输期间的SCIn_TXI中断请求产生时序不同，当一帧的通信完成时产生发送数据空中断（SCIn_TXI）。



注1.有关相应中断事件编号的信息，请参见第12节，中断控制器单元(ICU)。

Figure 26.89 简单IIC模式下主机发送操作示例1，具有7位从机地址、发送中断和接收中断(ICR.IICINTM =1)

当ICR.IICINTM位在主机传输期间设置为0（使用ACKNACK中断）时，DTC或DMAC由ACK中断作为触发器激活并传输所需的数据字节数。接收到NACK时，以NACK中断为触发进行发送停止、重发等错误处理。

要在将数据写入TDR寄存器后出于某种原因重新启动通信，请使用以下过程：

1.将CCR0寄存器中的TE和RE位设置为0以停止通信。

2.将ICR.IICSCLS[1:0]和ICR.IICSDAS[1:0]位设置为11b，释放I2C总线，并清除条件的产生。

3.如果CSR寄存器中的RDRF标志设置为1，则RDR寄存器被dummy读取并且RDRF位设置为0。

4.将CCR0寄存器中的TE和RE位设置为1，开始下一次通信。

[4] Confirm ACK response from the slave device:
Check the ISR.IICACKR. If its value is 0, it is indicated that the slave device responded with ACK and operations proceed. If its value is 1, it is indicated that there was no response from a slave device. So the next transition is to generation of the stop condition.

[5] Step for continuing with reception:
To proceed with reception, write 0xFF as dummy transmit data to TDR. Other than in the first and last rounds of transmission, a SCIn_TXI request can activate DMAC or DTC to handle writing of data to TDR. Furthermore, except of the last data to be received, a SCIn_RXI request can activate DMAC or DTC to handle reading of data from RDR.

[6] NACK is transmitted in response to the last data.

[7] Generation of a stop condition.

Note: In simple IIC mode, the SCIn_TXI interrupt request is generated when communication is completed.

26.9 Operation in Simple SPI Mode

As an extended function, the SCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Using the settings for Simple SPI mode setting (CCR3.MOD[2:0] bit = 011b) and setting the CCR0.SSE bit to 1 place the SCI in simple SPI mode. However, the SSn pin function on the master side is not required for connection of the device used

26.9 简单SPI模式下的操作

作为一项扩展功能，SCI支持简单的SPI模式，可处理一个或多个主设备与多个从设备之间的传输。

使用简单SPI模式设置(CCR3.MOD[2:0]位=011b)并将CCR0.SSE位设置为1，将SCI处于简单SPI模式。但是，主机侧的SSn引脚功能不需要连接所使用的设备

as the master in simple SPI mode when the configuration only has a single master. Therefore, set the CCR0.SSE bit to 0 in such cases.

Figure 26.96 shows an example of connections for simple SPI mode. Control a general port pin to produce the SSn output signal from the master.

In simple SPI mode, data is transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended. The data can be inverted by setting the CCR3.SINV bit to 1.

Because the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a shared clock signal. Additionally, because both the transmitter and receiver have a buffered structure, writing the next transmit data while transmission is in progress and reading previously received data while reception is in progress are both possible. This enables continuous transfer.

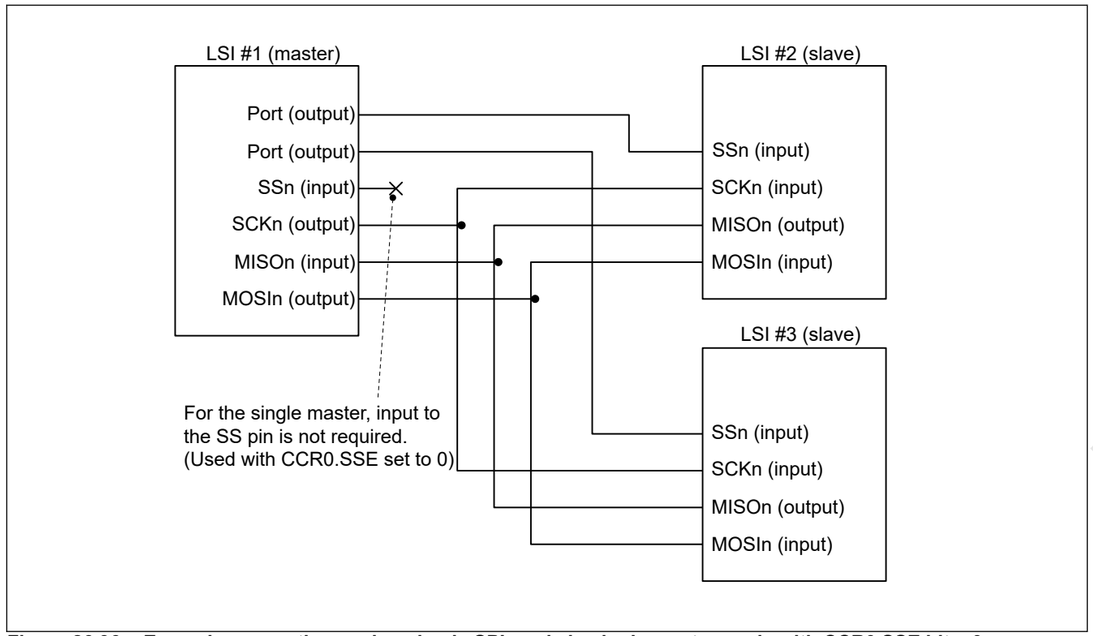

Figure 26.96 Example connections using simple SPI mode in single master mode with CCR0.SSE bit = 0

26.9.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (CCR3.CKE[1:0] = 00b or 01b) or slave (CCR3.CKE[1:0] = 10b or 11b).

Table 26.39 lists the relationship between the pin states, mode, and level on the SSn pin.

Table 26.39 States of pins by mode and input level on SSn pin

Mode	Input on SSn pin	State of MOSIn pin	State of MISOn pin	State of SCKn pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance
Slave mode	High level (transfer cannot proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer can proceed)	Input for received data	Output for data transmission	Clock input

Note 1. When there is only a single master (CCR0.SSE = 0), transfer is possible regardless of the input level on the SSn pin. This is equivalent to input of a high level on the SSn pin. The SSn pin is not used and is available for other purposes.

当配置只有一个主机时，作为简单SPI模式的主机。因此，在这种情况下，将CCR0.SSE位设置为0。

图26.96显示了简单SPI模式的连接示例。控制一个通用端口引脚以产生来自主机的SSn输出信号。

在简单SPI模式下，数据与时钟脉冲同步传输，方式与时钟同步模式相同。1个字符的传输数据由8位数据组成，不能附加奇偶校验位。可以通过将CCR3.SINV位设置为1来反转数据。

由于接收器和发送器在SCI模块中彼此独立，因此可以使用共享时钟信号进行全双工通信。此外，由于发送器和接收器都具有缓冲结构，因此在发送过程中写入下一个发送数据和在接收过程中读取先前接收到的数据都是可能的。这使得连续传输成为可能。

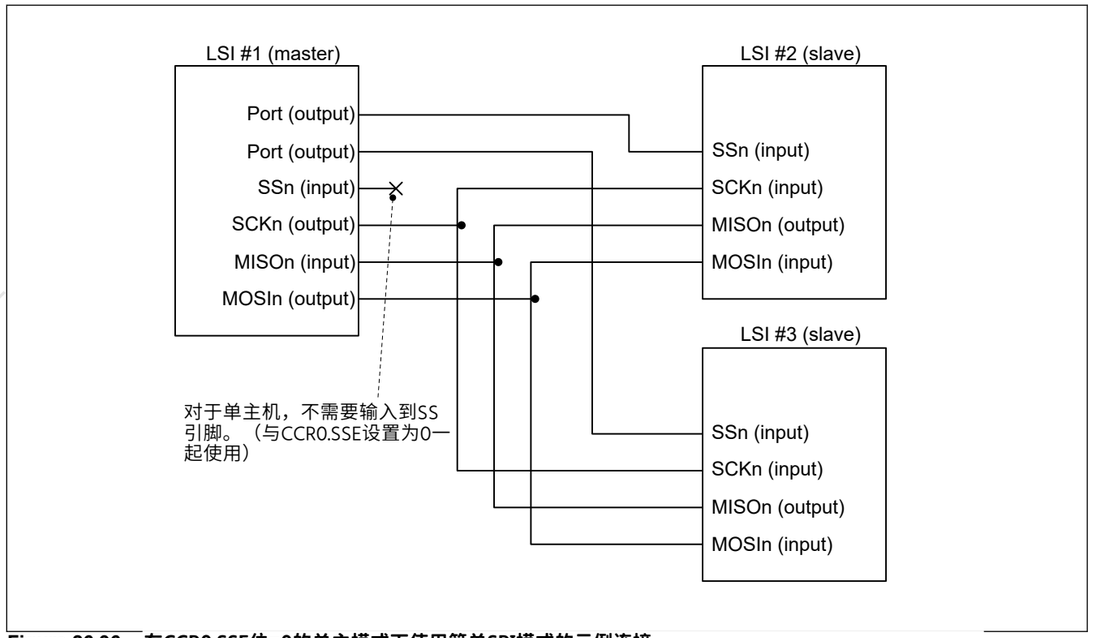

Figure 26.96 在CCR0.SSE位=0的单主模式下使用简单SPI模式的示例连接

26.9.1 主从模式下的引脚状态

简单SPI模式接口的引脚方向（输入或输出）根据设备是主设备（CCR3.CKE[1:0]=00b或01b）还是从设备（CCR3.CKE[1:0]=10b或11b)。

表26.39列出了SSn引脚上的引脚状态、模式和电平之间的关系。

Table 26.39 SSn引脚上的模式和输入电平的引脚状态

Mode	SSn引脚上的输入	MOSIn管脚状态	MISon引脚的状态	SCKn引脚状态
主模式*1	高电平（可以进行转移）	数据传输用输出*2	接收数据的输入	时钟输出*3
	低电平（传输无法进行）	High-impedance	接收数据的输入（但禁用）	High-impedance
从机模式	高电平（传输无法进行）	接收数据的输入（但禁用）	High-impedance	时钟输入（但禁用）
	低电平（可以继续传输）	接收数据的输入	数据传输输出	时钟输入

注1.当只有一个主机(CCR0.SSE=0)时，无论SSn引脚上的输入电平如何，都可以进行传输。这相当于在SSn引脚上输入高电平。SSn引脚未使用，可用于其他用途。

Note 2. The MOSIn pin output is in the high-impedance state when serial transmission is disabled (CCR0.TE bit = 0).
Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (CCR0.TE = 0 and CCR0.RE = 0) in a multi-master configuration (CCR0.SSE = 1).

26.9.2 SS Function in Master Mode

Setting the CKE[1:0] bits in the CCR3 to 00b or 01b selects master mode operation. The SSn pin is not used in single-master configurations (CCR0.SSE = 0), so transmission or reception can proceed regardless of the value of the SSn pin.

When the level on the SSn pin is high in a multi-master configuration (CCR0.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission.

When the level on the SSn pin is low in a multi-master configuration (CCR0.SSE = 1), there are other masters, and a transmission or reception is in progress. The MOSIn output and SCKn pins are placed in the high-impedance state and starting transmission or reception is not possible. In addition, the value of the CSR.MFF bit is 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading CSR.MFF flag. If a mode fault error occurs while transmission or reception is in progress, transmission or reception does not stop, but the MOSIn and SCKn outputs are in the high-impedance state after completion of the transfer.

When the SSn pin input becomes high level, the SCKn pin outputs a clock signal and the MOSIn outputs data. Even if the SCKn pin and the MOSIn pin are in the high impedance state, internal transmission or reception operation continues, but it stops after transmission or reception of a single character is complete. In this case, any of SCIn_TXI, SCIn_RXI, and SCIn_TEI interrupts occurs.

Use a general port pin to produce the SS output signal from the master.

26.9.3 SS Function in Slave Mode

Setting the CCR3.CKE[1:0] bits to 10b or 11b selects slave operation. When the SSn pin is high, the MISOn output pin is in the high-impedance state and clock input through the SCKn pin is ignored. When the SSn pin is low, clock input through the SCKn pin is valid and transmission or reception can proceed.

If the input on the SSn pin changes from low to high during transmission or reception, the MISOn output pin is placed in the high-impedance state. Transmission / reception operation is immediately suspended. If the transmission is in progress, the CSR.TEND flag will not be set, a transmit end interrupt will not be output, and an abnormal stop status will occur. So, do not negate the SSn pin during slave transmission / reception. If an abnormal stop occurs, set CCR0.RE and CCR0.TE to 0 to stop transmission / reception. To resume transmission / reception, set CCR0.RE and CCR0.TE to 1 after at least TCLK × 3 cycles + PCLK × 3 cycles.

26.9.4 Relationship between Clock and Transmit/Receive Data

The CPOL and CPHA bits in the CCR3 register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in Figure 26.97. The relation is the same for both master and slave operation. This is the same as when the level on the SSn pin is high.

注2.当串行传输被禁用（CCR0.TE位=0）时，MOSIn引脚输出处于高阻抗状态。
注3.在多主机配置(CCR0.SSE=1)中禁用串行传输(CCR0.TE=0和CCR0.RE=0)时，SCKn引脚输出处于高阻抗状态。

26.9.2 主控模式下的SS功能

将CCR3中的CKE[1:0]位设置为00b或01b可选择主模式操作。SSn引脚不用于单主机配置(CCR0.SSE=0)，因此无论SSn引脚的值如何，都可以继续发送或接收。

在多主机配置（CCR0.SSE=1）中，当SSn引脚上的电平为高电平时，主机在开始发送或接收之前从SCKn引脚输出时钟信号，以指示没有其他主机或另一个主机在进行接收或发送。

在多主机配置（CCR0.SSE=1）中，当SSn引脚上的电平为低电平时，存在其他主机，并且正在进行发送或接收。MOSIn输出和SCKn引脚处于高阻状态，无法开始发送或接收。此外，CSR.MFF位的值为1，表示模式故障错误。在多主机配置中，通过读取CSR.MFF标志开始错误处理。如果在发送或接收过程中发生模式故障错误，则发送或接收不会停止，但MOSIn和SCKn输出在传输完成后处于高阻抗状态。

当SSn引脚输入变为高电平时，SCKn引脚输出时钟信号，MOSIn输出数据。即使SCKn引脚和MOSIn引脚处于高阻抗状态，内部发送或接收操作仍继续，但在单个字符的发送或接收完成后停止。在这种情况下，任何SCIn_TXI、SCIn_RXI和SCIn_TEI中断都会发生。

使用通用端口引脚从主机产生SS输出信号。

26.9.3 从模式下的SS功能

将CCR3.CKE[1:0]位设置为10b或11b选择从机操作。当SSn引脚为高电平时，MIOn输出引脚处于高阻状态，通过SCKn引脚输入的时钟被忽略。当SSn引脚为低电平时，通过SCKn引脚输入的时钟有效，可以进行发送或接收。

如果SSn引脚上的输入在发送或接收期间从低电平变为高电平，则MISOn输出引脚处于高阻抗状态。发送接收操作立即暂停。如果正在发送，则不会设置CSR.TEND标志，不会输出发送结束中断，并会出现异常停止状态。因此，在从机发送接收期间不要否定SSn引脚。如果发生异常停止，请将CCR0.RE和CCR0.TE设置为0以停止发送接收。要恢复发送接收，至少在TCLK×3个周期+PCLK×3个周期后将CCR0.RE和CCR0.TE设置为1。

26.9.4 时钟与发送接收数据的关系

CCR3寄存器中的CPOL和CPHA位可用于以四种不同的方式设置用于发送和接收的时钟。时钟信号与数据收发的关系如图26.97所示。主从操作的关系是相同的。这与SSn引脚上的电平为高电平时相同。

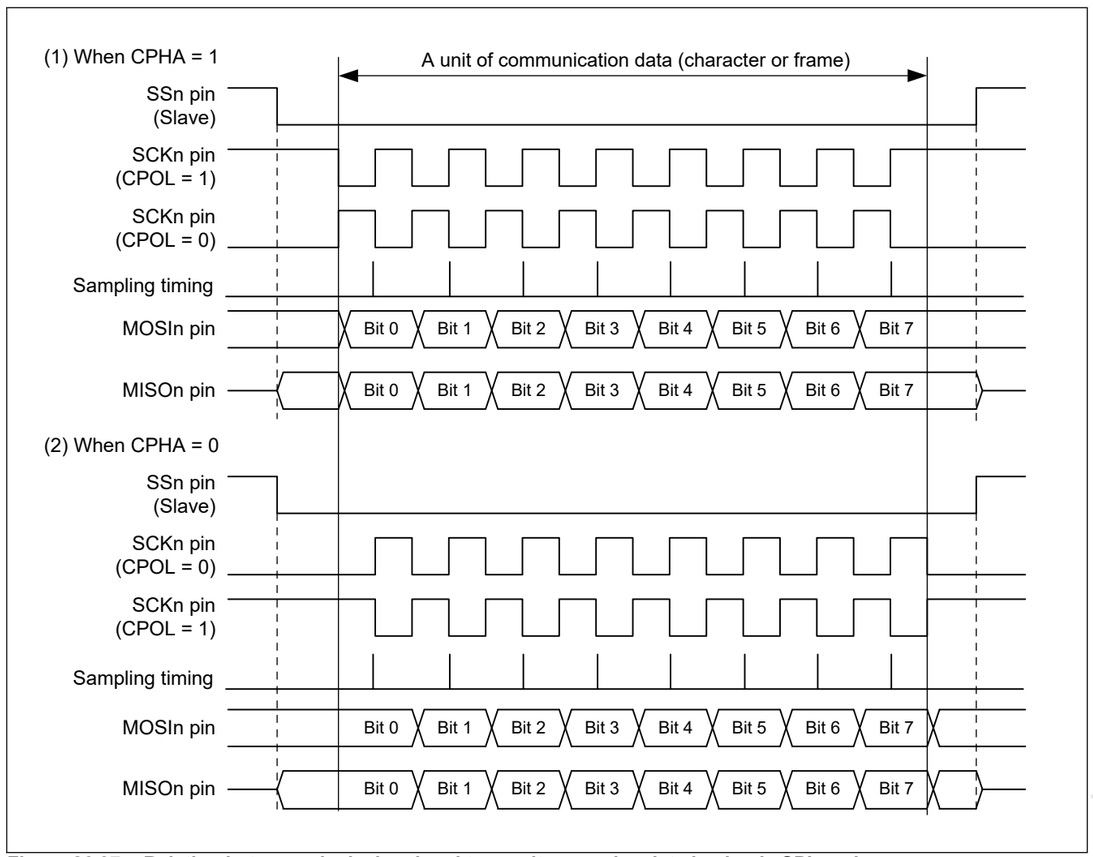

Figure 26.97 Relation between clock signal and transmit or receive data in simple SPI mode

26.9.5 SCI Initialization in Simple SPI Mode

Initialization in simple SPI mode is the same as in clock synchronous mode. See section 26.6.3. SCI Initialization in Clock Synchronous Mode for an example initialization flow. The CPOL and CPHA bits in the CCR3 register must be set to ensure that the clock signal is suitable for both master and slave devices.

Always initialize the CCR0 register before making any changes to the operating mode or transfer format.

Note: Only the RE bit is set to 0. The CSR.ORER, FER, PER, and RDR flags are not initialized.

Changing the value of the TE bit from 1 to 0 or from 0 to 1 when the TIE bit in the CCR0 register is 1 at the same time, leads to the generation of a transmit data empty interrupt (SCIn_TXI).

26.9.6 Transmission and Reception of Serial Data in Simple SPI Mode

In master operation, ensure that the SSn pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. In multiple master operation with CCR0.SSE = 1 even in master mode, a mode fault error will occur if the SSn pin goes low. Therefore, make sure that no mode fault error has occurred before starting communication, and start communication, and make sure that no mode fault error has occurred even after communication ends. If a mode fault error has occurred, communication may be incomplete, so measures such as retransmission are required. Otherwise, the procedures are the same as in clock synchronous mode.

In slave mode, it operates according to the SSn pin input level. Other steps are the same as those of clock synchronous mode.

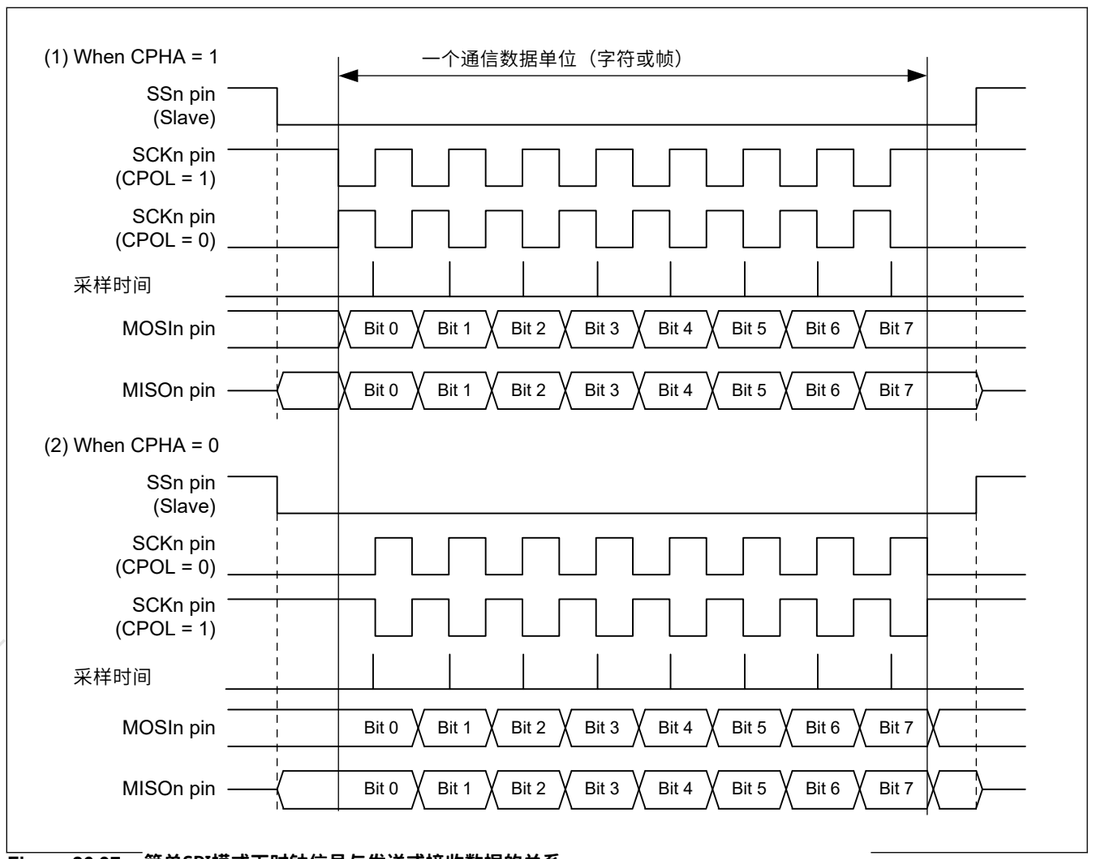

Figure 26.97 简单SPI模式下时钟信号与发送或接收数据的关系

26.9.5 简单SPI模式下的SCI初始化

简单SPI模式的初始化与时钟同步模式相同。请参阅第26.6.3节。时钟中的SCI初始化
示例初始化流程的同步模式。必须设置CCR3寄存器中的CPOL和CPHA位，以确保时钟信号适用于主设备和从设备
。

在对操作模式或传输格式进行任何更改之前，始终初始化CCR0寄存器。

Note: 只有RE位设置为0。CSR.ORER、FER、PER和RDR标志未初始化。

当CCR0寄存器中的TIE位同时为1时，将TE位的值从1更改为0或从0更改为1，会导致产生发送数据空中断（SC
In_TXI）。

26.9.6 简单SPI模式下串行数据的发送和接收

在主机操作中，确保传输另一侧的从设备的SSn管脚在开始传输前为低电平，在传输完成时为高电平。即使在主
机模式下，在CCR0.SSE=1的多主机操作中，如果SSn引脚变为低电平，也会发生模式故障错误。因此，在开始通
讯之前确保没有发生模式故障错误，然后开始通讯，并确保即使在通讯结束后也没有发生模式故障错误。如果发
生模式故障错误，可能会导致通信不完整，因此需要采取重传等措施。否则，过程与时钟同步模式相同。

在从机模式下，它根据SSn引脚输入电平进行操作。其他步骤与时钟同步模式相同。

26.9.7 Reception Sampling Timing Adjustment Function in Simple SPI Mode with internal clock used

The reception sampling timing adjustment function in simple SPI mode is the same as the reception sampling timing adjustment function in clock synchronous mode. For the description of operation, see section 26.6.7. Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with internal clock used.

26.10 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be evenly corrected using the number specified in the MDDR register among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in CCR2.

Figure 26.98 shows an example where the PCLK is selected in the CKS[1:0] bits in CCR2, the BRR bit is set to 0, and the MDDR is set to 160 in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256).

Note: Enabling an internal clock causes bias, and expansion and contraction are generated in the pulse width of the internal base clock.

Do not use this function in clock synchronous mode, simple SPI mode, Smart Card Interface mode, Manchester mode and Simple LIN mode.

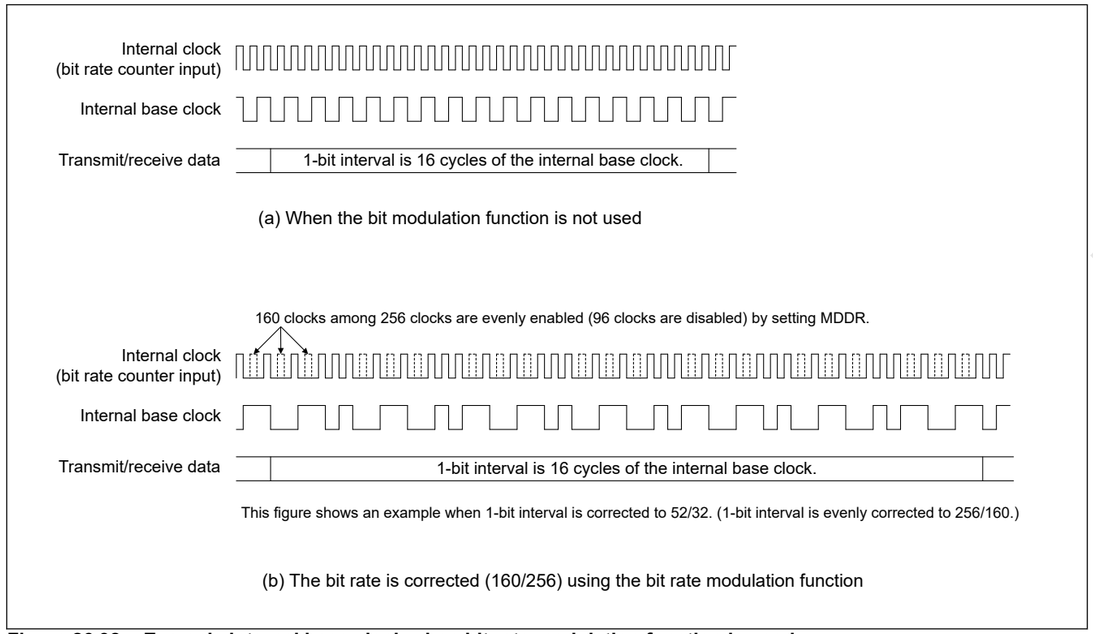

Figure 26.98 Example internal base clock when bit rate modulation function is used

26.11 Simple LIN mode

As an extended function of the SCI, the SCI supports the serial communication protocol (Figure 26.99) consisting of a Start Frame and an Information Frame as Simple LIN. Simple LIN mode is enabled by the CCR3.MOD[2:0] = 110b. Since the simple LIN mode uses the same circuit as the asynchronous mode for transmission / reception control other than Break Field, the basic communication settings required for the asynchronous mode are also required for the simple LIN mode.

(For the setting value when using simple LIN, refer to the explanation in section 26.2. Register Descriptions. In particular, note that CCR3.RXDESEL needs to be changed from the initial value and set to 1.)

The Start Frame consists of a Break Field, Control Field 0, and Control Field 1. The Information Frame can be configured with some Data Fields, a CRC16 Upper Field, and a CRC16 Lower Field.

26.9.7 使用内部时钟的简单SPI模式下的接收采样时序调整功能

简单SPI模式下的接收采样时序调整功能与时钟同步模式下的接收采样时序调整功能相同。操作说明见26.6.7节。使用内部时钟的时钟同步模式下的接收采样定时调整功能。

26.10 比特率调制功能

使用比特率调制功能，可以在由CCR2中的CKS[1:0]位选择的256个内部时钟周期中，使用MDDR寄存器中指定的数量均匀地校正比特率。

图26.98显示了一个示例，其中在CCR2的CKS[1:0]位中选择PCLK，BRR位设置为0，并且在异步模式下MDDR设置为160。在这个例子中，基本时钟的周期被均匀地校正（256160）并且比特率也被校正（160256）。

Note: 启用内部时钟会导致偏差，并且会在内部基本时钟的脉冲宽度中产生扩展和收缩。

不要在时钟同步模式、简单SPI模式、智能卡接口模式、曼彻斯特模式和简单的LIN模式。

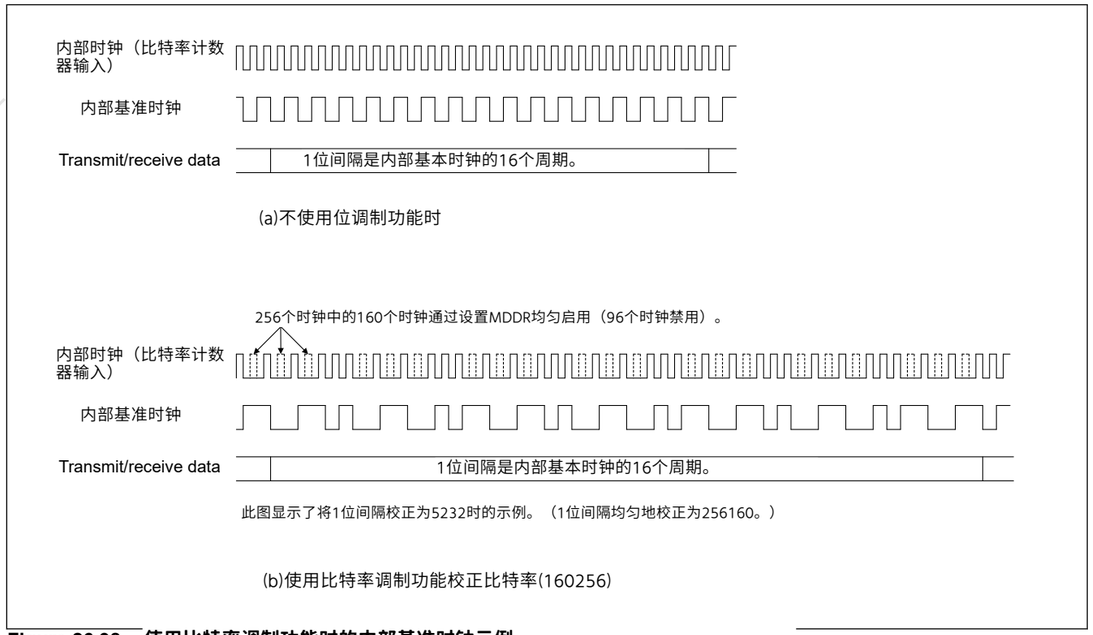

Figure 26.98 使用比特率调制功能时的内部基准时钟示例

26.11 简单LIN模式

作为SCI的扩展功能，SCI支持由Start组成的串行通信协议（图26.99）框架和信息框架作为简单的LIN。简单LIN模式由CCR3.MOD[2:0]=110b启用。由于简单LIN模式使用与异步模式相同的电路进行除BreakField以外的发送接收控制，因此简单LIN模式也需要异步模式所需的基本通信设置。

（使用simpleLIN时的设置值，请参考26.2节寄存器说明。特别注意CCR3.RXDESEL需要从初始值改成1。）

起始帧由中断字段、控制字段0和控制字段1组成。信息帧可以配置一些数据字段、CRC16上字段和CRC16下字段。

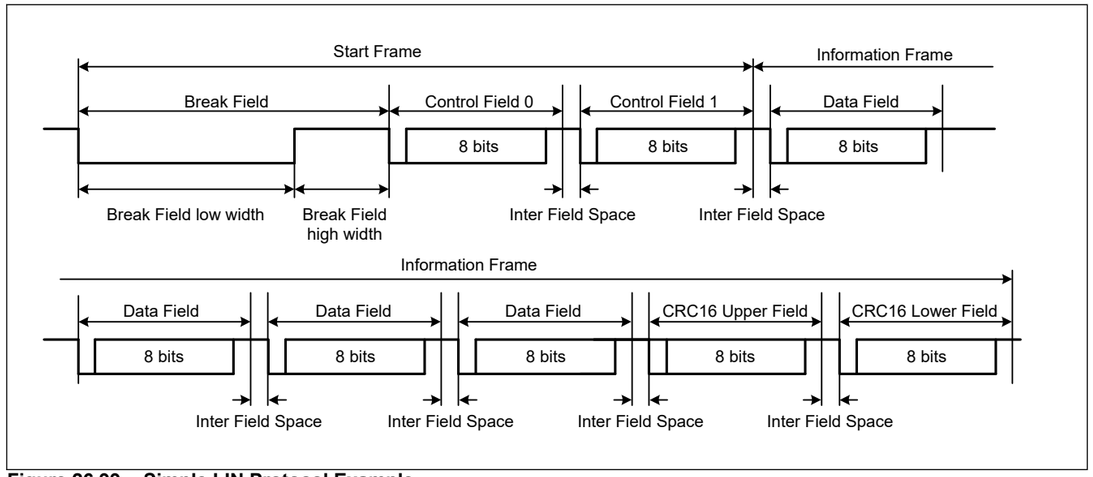

Figure 26.99 Simple LIN Protocol Example

The following describes operations when the Simple LIN is used. In this section, operations are described with the following conditions:

Communication pin (RXDn / TXDn) level inversion function: OFF (RINV = TINV = 0)

When using the simple LIN with the communication pin (RXDn / TXDn) level inversion function enabled, replace the RXDn and TXDn signal levels with their inverted levels.

26.11.1 Simple LIN Start Frame Transmission

Figure 26.100 shows an example of transmission of the Start Frame consisting of a Break Field, Control Field0, and Control Filed1. (Omit Break Field and Control Field0 according to the Start Frame configuration.)

Figure 26.101 shows a flowchart for Start Frame transmission.

The SCI operates as follows during Start Frame transmission.

1. Make the initial settings for the SCI according to the SCI initialization flow (Figure 26.66) in asynchronous mode. In simple LIN mode, do not set CCR0.TE and TIE to 1 at the same time to avoid SCIn_TXI output before the Break Field. Therefore, perform the following two steps sequentially to set the SCI initialization flow (asynchronous mode) procedure [9].
   - Set the bits except CCR0.TIE. (CCR0.TIE = 0, CCR0.TE = 1, and CCR0.RE = 0)
   - Set CCR0.TIE to 1.
2. When 1 is written to TCST, the Break Field output timer starts counting and outputs a low level (Break Field) from the TXDn pin for the period set in XCR2.BFLW[15:0]. A timer count clock source can be selected by XCR0.TCSS[1:0]. Writing 0 to XCR1.TCST suspends output of the Break Field. After the suspension, set CCR0.TE = 0 and turn off the transmission.
3. When the Simple LIN module timer count value matches the set XCR2.BFLW[15:0] value, the timer stops counting and inverts the TXDn pin output level, and the XSR0.BFOF flag is set to 1*1. Furthermore, if XCR0.BFOIE has been set to 1 at this time, a SCIn_TXI interrupt is generated.
4. After the SCIn_TXI interrupt and confirming XSR0.BFOF = 1, write the transmitted data then the Control Field 0 data is transmitted using the SCI*1.

Note: LIN communication requires a Break Delimiter (IDLE period) of 1 bit or more from the end of Break Field output until the next data transmission starts. For this reason, the Break Delimiter length is counted upon completion of Break Field output. If transmit data is written while the Break Delimiter length is being counted, transmission does not start until the Break Delimiter length counting is completed. When transmit data is written after the Break Delimiter length has been counted, transmission starts at the same timing as normal data transmission.
Break Delimiter length count time after Break Field output:
1-bit to 2-bit length (CCR3.STP = 0)

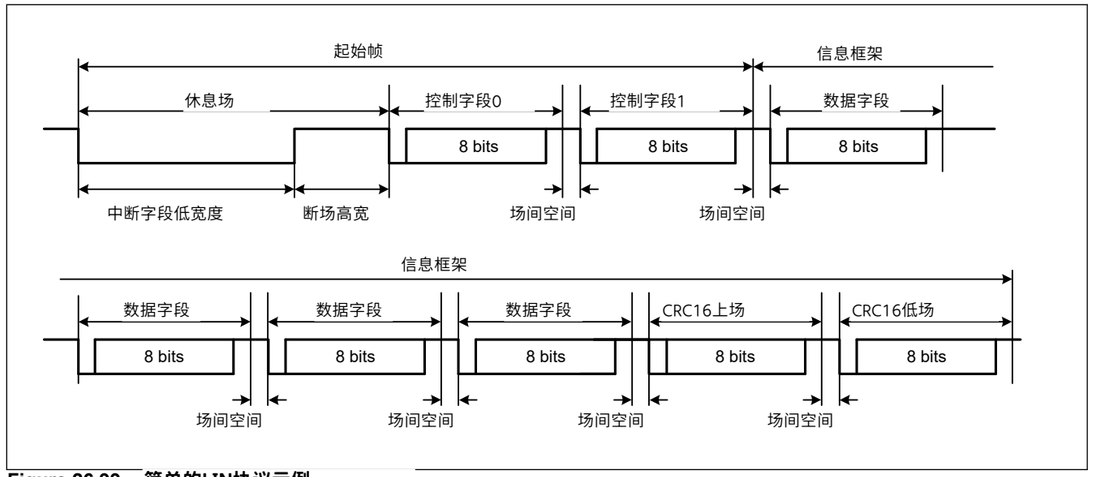

Figure 26.99 简单的LIN协议示例

下面介绍使用SimpleLIN时的操作。在本节中，描述了以下条件的操作：

通讯引脚（RXDnTXDn）电平反转功能：OFF（RINV=TINV=0）

当使用启用了通信引脚（RXDnTXDn）电平反转功能的简单LIN时，更换RXDn和TXDn信号电平及其反相电平。

26.11.1 简单的LIN开始帧传输

图26.100显示了由中断字段、控制字段0和控制组成的起始帧的传输示例归档1。（根据StartFrame配置省略BreakField和ControlField0。）

图26.101显示了起始帧传输的流程图。

SCI在起始帧传输期间操作如下。

1.在异步模式下按照SCI初始化流程（图26.66）对SCI进行初始化设置。在简单LIN模式，不要将CCR0.TE和TIE同时设置为1，以避免在BreakField之前输出SCIn_TXI。因此，依次执行以下两个步骤来设置SCI初始化流程（异步模式）程序[9]。

- ●设置CCR0.TIE以外的位。（CCR0.TIE=0，CCR0.TE=1，CCR0.RE=0）
- ●将CCR0.TIE设置为1。

2.当1写入TCST时，BreakField输出定时器开始计数，并在XCR2.BFLW[15:0]中设置的周期内从TXDn引脚输出低电平（BreakField）。定时器计数时钟源可以通过XCR0.TCSS[1:0]选择。向XCR1.TCST写入0将暂停BreakField的输出。暂停后，设置CCR0.TE=0并关闭传输。

3.当SimpleLIN模块定时器计数值与设置的XCR2.BFLW[15:0]值匹配时，定时器停止计数并反转TXDn引脚输出电平，并将XSR0.BFOF标志设置为1*1。此外，如果此时XCR0.BFOIE已设置为1，则会产生SCIn_TXI中断。

4.SCIn_TXI中断并确认XSR0.BFOF=1后，写入发送的数据，然后使用SCI*1发送控制字段0数据。

Note: LIN通信需要1位或更多的BreakDelimiter（IDLE周期），从BreakField输出结束到下一次数据传输开始。因此，中断分隔符长度在中断字段输出完成时计算。如果在计算间隔分隔符长度时写入发送数据，则在完成间隔分隔符长度计数之前不会开始发送。在计算完间隔分隔符长度后写入发送数据时，发送与正常数据发送的时序相同。

BreakDelimiterlengthcounttimeafterBreakFieldoutput:1位到2位长度(CCR3.STP=0)

2-bit to 3-bit length (CCR3.STP = 1)

5. After the Control Field 0 data has been transmitted, write the Control Field 1 data to TDR. And it is transmitted.
6. After the Control Field 1 data has been transmitted, the Information Frame data is transmitted.

Note 1. After XSR0.BFOF is set to 1, if 1 is written to XCR1.TCST without clearing it, no SCIn_TXI interrupt is output at the end of Break Field transmission. Clear XSR0.BFOF before writing 1 to XCR1.TCST.

6.控制字段1数据传输完毕后，信息帧数据被传输。

注1.XSR0.BFOF设置为1后，如果将1写入XCR1.TCST而不清除它，则在BreakField传输结束时不输出SCIn_TXI中断。在将1写入XCR1.TCST之前清除XSR0.BFOF。

26.11.2 Simple LIN Start Frame Reception

The SCI can detect Start Frames configured as shown in Figure 26.102.

图26.101起始帧传输流程图示例

26.11.2 简单的LIN开始帧接收

SCI可以检测如图26.102所示配置的起始帧。

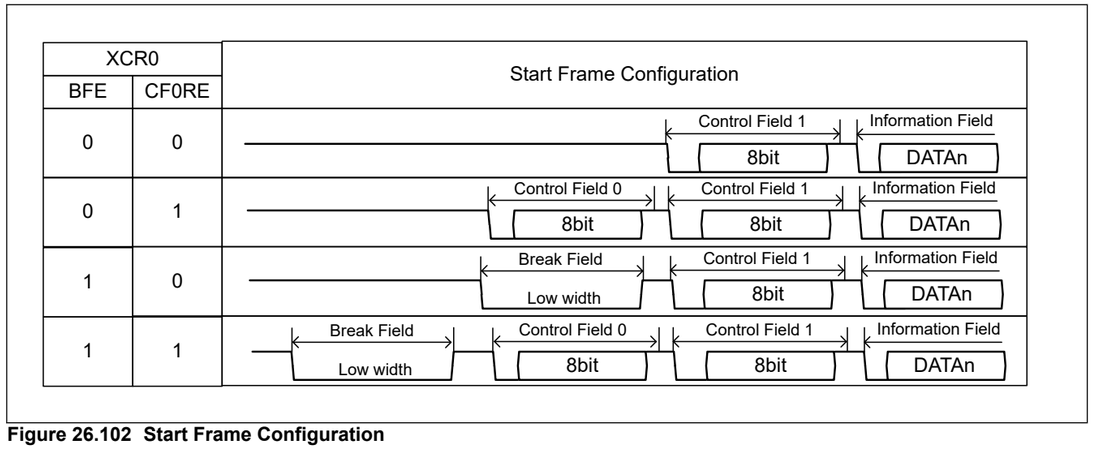

Figure 26.102 Start Frame Configuration

(1) Simple LIN normal reception of Start Frame (PIB not used)

Figure 26.103 shows an example of normal reception of the Start Frame consisting of a Break Field, Control Field0, and Control Field1. Figure 26.104 shows an example of reception to detect the Break Field during Control Field 1. Figure 26.105 shows a flowchart to receive the Start Frame, and Figure 26.106 shows a state transition diagram.

When receiving the Start Frame, the SCI operates as follows. Omit the processing of Break Field and Control Field0 according to the Start Frame configuration.

1. Writing 1 to XCR1.SDST makes it possible to detect the Start Frame. When XCR0.BFE = 1, RXDn input to the SCI core is disabled until the Break Field is detected (because XSR0.RXDSF is set to 1). Once the Break Field is detected, RXDn input can be received to the SCI core (XSR0.RXDSF = 0).
2. When a low level is input from the RXDn pin, the Break Field detection count starts. A timer count clock source can be selected by XCR0.TCSS[1:0].
3. When a low level that is equal to or longer than the period set in XCR2.BFLW[15:0] is input from the RXDn pin, it is determined as Break Field. At this time, XSR0.BFDF is set to 1. If XCR0.BFDIE has been set to 1 at this time, a SCIn_BFD interrupt is generated.
   The timer continues counting until the RXDn rising edge or counter overflow.
4. After the Break Field is detected, when the input level from the RXDn pin becomes high, the count value is captured to XSR1.TCNT[15:0] when BMEN = 0. At this time, XSR0.RXDSF is cleared to 0 and the SCI core starts receiving the RXDn input.
5. The SCI core starts receiving Control Field 0. Because the simple LIN continuously counts the edge interval, it determines a low level that is equal to or longer than the period set in XCR2.BFLW[15:0] as detection of the Break Field. When the Break Field is detected in the Control Field 0 phase, the SCI core waits for reception of Control Field 0 again (Figure 26.104).
6. When Control Field 0 has been received, an SCIn_RXI interrupt is generated and the Control Field 0 data is stored in XSR0.CF0RD[7:0]. When the received data matches the set XCR2.CF0D[7:0] value, XSR0.CF0MF is set to 1. If the received data differs from the set XCR2.CF0D[7:0] value, the SCI transitions to the state before the Break Field is detected.
7. The SCI core starts receiving Control Field 1. When BFE = 1, the Break Field detection function is continuously enabled while SDST = 1 as in the case of Control Field 0. When the Break Field is detected in the Control Field 1 phase, the SCI core waits for reception of Control Field 0 again.
8. When Control Field 1 has been received, an SCIn_RXI interrupt is generated and the Control Field 1 data is stored in XSR0.CF1RD[7:0]. When the received data matches the set XCR1.PCF1D[7:0] value or the set XCR1.SCF1D[7:0] value, XSR0.CF1MF is set to 1. If the received Control Field 1 data matches neither the set XCR1.PCF1D[7:0] value nor the set XCR1.SCF1D[7:0] value, the SCI transitions to the state before the Break Field is detected.
9. The SCI core performs Information Frame communication.
10. When communication is completed, write 0 to XCR1.SDST and 0 to CCR0.RE to stop reception.

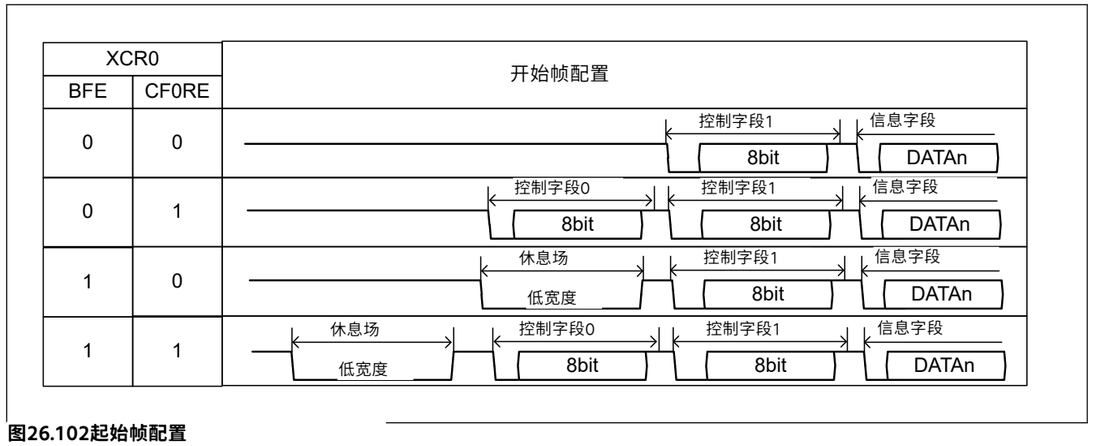

图26.102起始帧配置

(1) 开始帧的简单LIN正常接收（未使用PIB）

图26.103显示了正常接收起始帧的示例，该帧由中断字段、控制字段0和
控制字段1。图26.104显示了在控制域1期间检测中断域的接收示例。图26.105显示了接收起始帧的流程图
，图26.106显示了状态转换图。

当接收到起始帧时，SCI操作如下。根据StartFrame配置省略BreakField和ControlField0的处理。

1.向XCR1.SDST写入1可以检测起始帧。当XCR0.BFE=1时，SCI内核的RXDn输入被禁用，直到检测到中断字段（
因为XSR0.RXDSF设置为1）。一旦检测到中断字段，就可以将RXDn输入接收到SCI内核（XSR0.RXDSF=0）。

2.当从RXDn引脚输入低电平时，BreakField检测计数开始。定时器计数时钟源可以通过XCR0.TCSS[1:0]选择。

3.当等于或长于XCR2.BFLW[15:0]中设置的周期的低电平从RXDn引脚输入时，确定为BreakField。此时，XSR0.B
FDF置1。如果此时XCR0.BFDIE已置1，则产生SCIn_BFD中断。

定时器继续计数，直到RXDn上升沿或计数器溢出。

4.检测到BreakField后，当来自RXDn引脚的输入电平变为高电平时，当BMEN=0时，计数值被捕获到XSR1.TCNT[1
5:0]。此时，XSR0.RXDSF被清除为0和SCI核心开始接收
RXDn input.

5.SCI内核开始接收ControlField0。因为简单的LIN不断地计算边沿间隔，所以它
确定一个等于或长于XCR2.BFLW[15:0]中设置的周期的低电平作为中断字段的检测。当在ControlField0阶段检
测到BreakField时，SCI内核再次等待接收ControlField0（图26.104）。

6.接收到控制字段0后，将产生SCIn_RXI中断，并将控制字段0数据存储在XSR0.CF0RD[7:0]中。当接收到的数据
与设置的XCR2.CF0D[7:0]值匹配时，XSR0.CF0MF设置为1。如果接收到的数据与设置的XCR2.CF0D[7:0]值不同
，则SCI转换到之前的状态检测到中断字段。

7.SCI核开始接收ControlField1，当BFE=1时，BreakField检测功能持续
在SDST=1时启用，与控制字段0的情况一样。当在控制字段1阶段检测到中断字段时，SCI内核再次等待接收控
制字段0。

8.接收到控制字段1后，将产生SCIn_RXI中断，并将控制字段1数据存储在XSR0.CF1RD[7:0]中。当接收到的数据
与设置的XCR1.PCF1D[7:0]值或设置的XCR1.SCF1D[7:0]值匹配时，XSR0.CF1MF设置为1。如果接收到的控制字
段1数据与设置的XCR1都不匹配。PCF1D[7:0]值或设置的XCR1.SCF1D[7:0]值，SCI转换到检测到中断字段之前
的状态。

9.SCI核心执行信息帧通信。

10.通信完成后，向XCR1.SDST写入0，向CCR0.RE写入0，停止接收。

(2) Simple LIN Start Frame reception (using the priority interrupt bit)

Figure 26.107 shows an example of Start Frame reception using the priority interrupt bit. The priority interrupt bit is enabled by setting XCR0.PIBE to 1.

The SCI operates as follows during Start Frame reception using the priority interrupt bit.

Steps (1) to (7) are the same as steps (1) to (7) in the Start Frame reception example in Figure 26.103.

(8) When the value specified in the XCR0.PIBS[2:0] bits matches the set XCR1.PCF1D[7:0] value, XSR0.PIBDF is set to 1 and the SCI core performs communication of the Information Frame. If the data received in Control Field 1 matches neither the set XCR1.PCF1D[7:0] value nor the set XCR1.SCF1D[7:0] value and the priority interrupt bit is not detected, the SCI transitions to the state before the Break Field is detected.

(9) Communicate information frame at the SCI core.

(2) 简单的LIN开始帧接收（使用优先级中断位）

图26.107显示了使用优先中断位接收起始帧的示例。通过将XCR0.PIBE设置为1来启用优先级中断位。

在使用优先中断位接收起始帧期间，SCI操作如下。

步骤(1)到(7)与图26.103的起始帧接收示例中的步骤(1)到(7)相同。

(8)当XCR0.PIBS[2:0]位中指定的值与设置的XCR1.PCF1D[7:0]值匹配时，XSR0.PIBDF设置为1，SCI内核执行信息帧的通信。如果在控制字段1中接收到的数据既不匹配设置的XCR1.PCF1D[7:0]值也不匹配设置的XCR1.SCF1D[7:0]值并且未检测到优先级中断位，则SCI转换到之前的状态检测到中断字段。

26.11.3 Simple LIN Bus Conflict Detection Function

In Simple LIN mode (CCR3MOD[2:0] = 110) when TE = 1, the bus conflict detection function works during Break Field output and during data transmission.

Figure 26.108 shows an operation example of the bus conflict detection function. The TXDn pin output and the RXDn pin input are sampled by the bus conflict detection clock set in XCR0.BCCS[1:0]. When a mismatch occurs three times in a row, XSR0.BCDF is set to 1, and if XCR0.BCDIE has been set to 1 at this time, an SCIn_ERI interrupt is generated.

When an SCIn_ERI interrupt is generated, stop transmission according to Figure 26.109. Check the bus state to decide whether to resume transmission.

26.11.3 简单的LIN总线冲突检测功能

在简单LIN模式(CCR3MOD[2:0]=110)中，当TE=1时，总线冲突检测功能在BreakField输出和数据传输期间工作。

图26.108显示了总线冲突检测功能的操作示例。TXDn引脚输出和RXDn引脚输入由XCR0.BCCS[1:0]中设置的总线冲突检测时钟采样。当连续出现3次不匹配时，XSR0.BCDF置1，如果此时XCR0.BCDIE已经置1，则产生SCIn_ERI中断。

当产生SCIn_ERI中断时，根据图26.109停止传输。检查总线状态以决定是否恢复传输。

26.11.4 Simple LIN Bit Rate Measurement Function

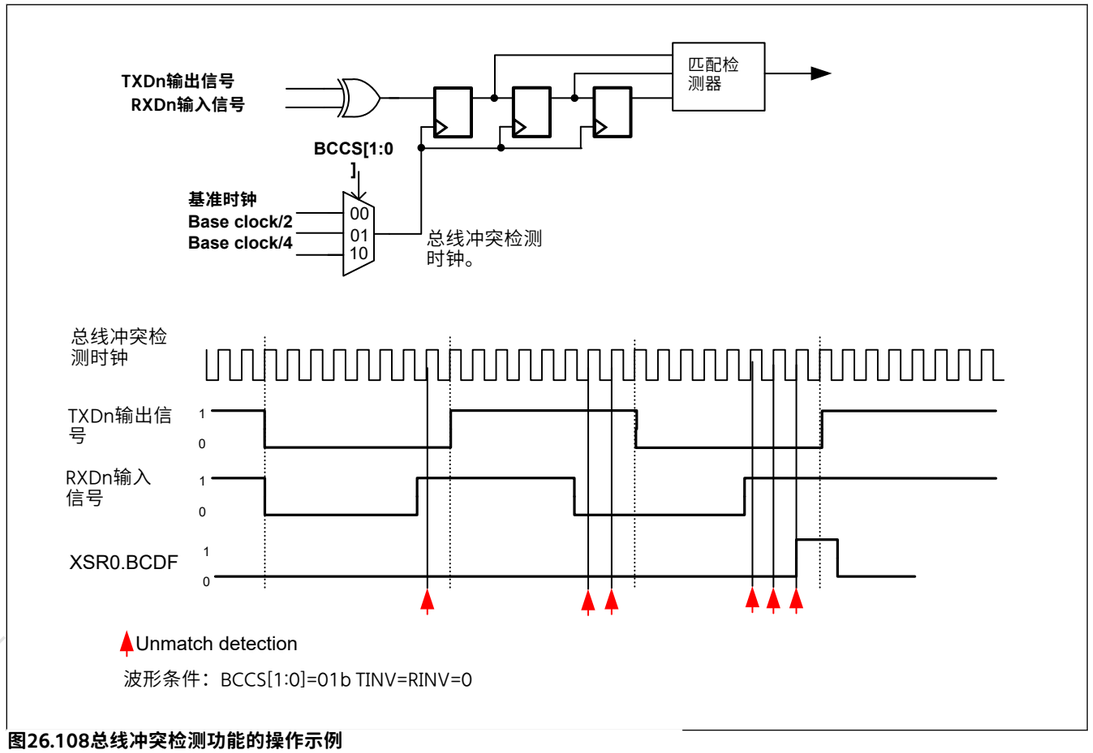

图26.108总线冲突检测功能的操作示例

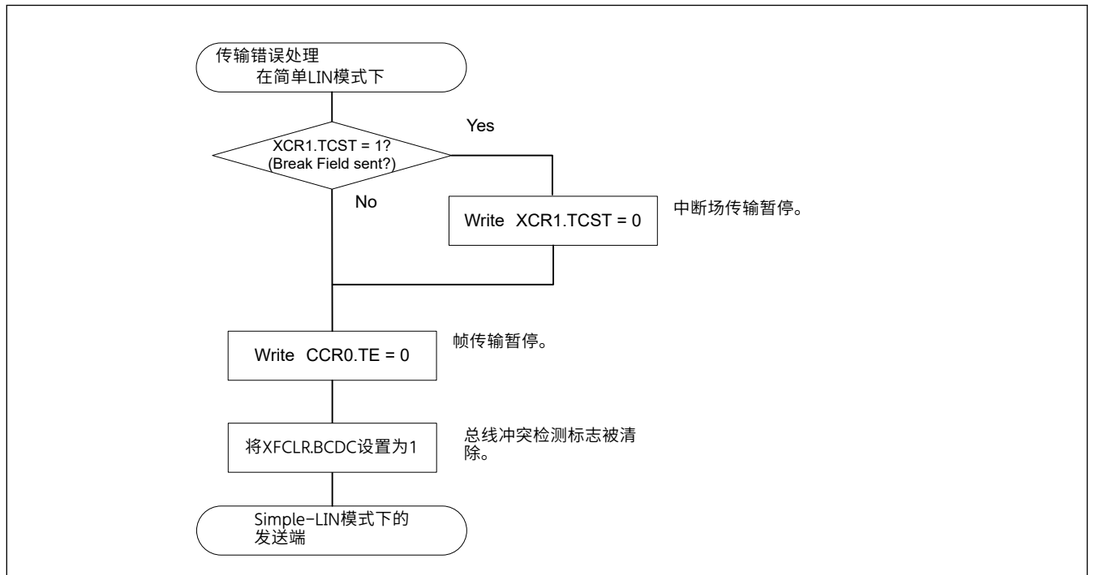

图26.109SCIn_ERI简单LIN模式下传输时的中断处理流程

26.11.4 简单的LIN比特率测量功能

This function measures a bit rate between the effective edges of the input signal from the RXDn pin. Figure 26.110 shows an operation example of the bit rate measurement function.

1. Writing 1 to XCR1.SDST and XCR1.BMEN enables bit rate measurement. When this bit is set to 1, the valid edge interval of Control Field 0 and Control Field 1 data is measured. However, bit rate is not measured between the Break Field and the Break Delimiter. Set XCR1.BMEN and XCR1.SDST to 1 simultaneously, only when measuring bit rate.
2. Because bit rate is not measured in the Break Field, the effective edge detection flag is not set to 1 at the rising edge at the end of the Break Field, and the counter capture value is not stored in XSR1.TCNT[15:0].
3. The counter starts counting from the falling edge of the start bit in Control Field 0. The Break Delimiter count value is not captured in XSR1.TCNT[15:0].
4. The rising edge of the start bit is detected as an effective edge, and then the XSR0.AEDF flag is set to 1. If XCR0.AEDIE has been set to 1 at this time, an SCIn_AED interrupt is output. The start bit count value is stored in XSR1.TCNT[15:0]. The XSR1.TCNT[15:0] value is retained until the effective capture value is read.
5. Even if an effective edge is input from the RXDn input pin, the count value of this effective edge timing is not captured because the XRS1.TCNT[15:0] value has not been read and retention has not been released. In this case, an SCIn_AED interrupt is not output.
6. The XSR1.TCNT[15:0] value is read. Then the retention of XSR1.TCNT[15:0] is released and the XSR0.AEDF flag is cleared by hardware.
7. Because the retention of XSR1.TCNT[15:0] has been released, the count value is captured at the effective edge and is retained. At the same time, the XSR0.AEDF flag is set to 1, and if XCR0.AEDIE has been set to 1, an SCIn_AED interrupt is output. The bit rate can be adjusted by calculating it from the count value between effective edges by software and by changing the SCI settings.
8. To disable bit rate measurement, write 0 to XCR1.BMEN.
9. The XSR0.AEDF value and the XSR1.TCNT[15:0] value remain unchanged at the effective edge timing because the bit rate measurement function is disabled.

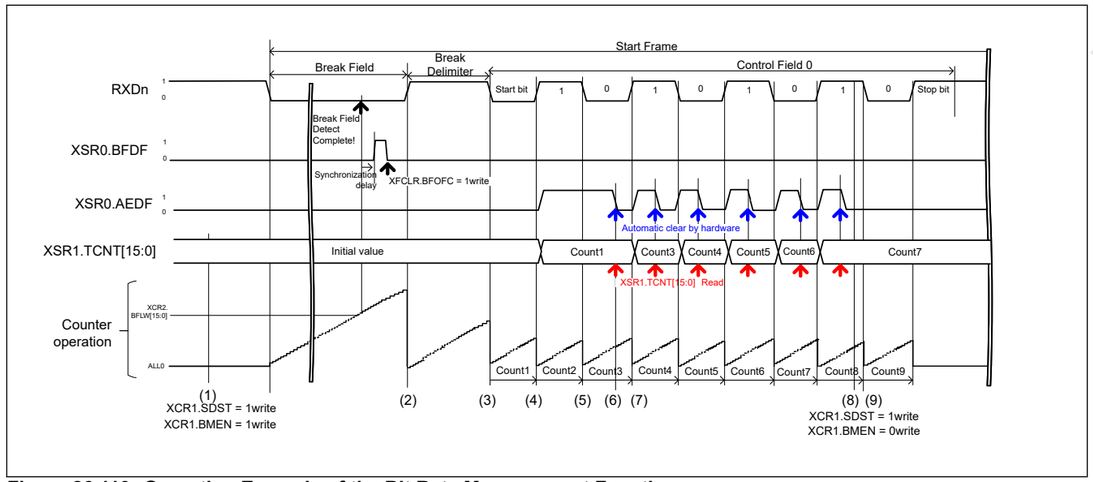

Figure 26.110 Operation Example of the Bit Rate Measurement Function

26.12 Interrupt Sources

26.12.1 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts

If the conditions for an SCIn_TXI and SCIn_RXI interrupt are satisfied while the interrupt status flag in the ICU is 1, the ICU does not output the interrupt request but saves it internally with a capacity for retention of one request per source.

该功能测量来自RXDn引脚的输入信号的有效边沿之间的比特率。图26.110显示了比特率测量功能的操作示例。

1.将1写入XCR1.SDST和XCR1.BMEN启用比特率测量。当该位设置为1时，有效边沿
测量控制字段0和控制字段1数据的间隔。但是，不测量中断字段和中断定界符之间的比特率。仅在测量比特率时同时将XCR1.BMEN和XCR1.SDST设置为1。

2.因为BreakField中没有测量比特率，所以在BreakField结束的上升沿有效边沿检测标志不设置为1，并且计数器捕获值不存储在XSR1.TCNT[15：0]。

3.计数器从控制字段0中起始位的下降沿开始计数。在XSR1.TCNT[15:0]中不捕获间隔分隔符计数值。

4.检测到起始位的上升沿为有效沿，然后将XSR0.AEDF标志置1。如果
此时XCR0.AEDIE已设置为1，输出SCIn_AED中断。起始位计数值存储在
XSR1.TCNT[15:0]。XSR1.TCNT[15:0]值将一直保留到读取有效捕获值为止。

5.即使从RXDn输入引脚输入有效边沿，由于尚未读取XRS1.TCNT[15:0]值且保留尚未解除，因此不会捕获此有效边沿时序的计数值。在这种情况下，不输出SCIn_AED中断。

6.读取XSR1.TCNT[15:0]值。然后XSR1.TCNT[15:0]的保留被释放，XSR0.AEDF标志被硬件清除。

7.因为XSR1.TCNT[15:0]的保留已经被释放，所以计数值在有效边沿被捕获并被保留。同时，XSR0.AEDF标志置1，如果XCR0.AEDIE已经置1，则输出SCIn_AED中断。可以通过软件从有效边沿之间的计数值计算比特率并通过更改SCI设置来调整比特率。

8.要禁用比特率测量，向XCR1.BMEN写入0。

9.XSR0.AEDF值和XSR1.TCNT[15:0]值在有效边沿时序保持不变，因为比特率测量功能被禁用。

26.12 中断源

26.12.1 SCIn_TXI和SCIn_RXI中断的缓冲区操作

如果在ICU中的中断状态标志为1时满足SCIn_TXI和SCIn_RXI中断的条件，则ICU不输出中断请求，而是将其保存在内部，每个源可以保留一个请求。

26.12.2 Interrupts in Asynchronous, Manchester, Clock Synchronous, and Simple SPI Modes

(1) Non-FIFO selected

Table 26.40 lists interrupt sources in asynchronous mode, Manchester mode, clock synchronous mode, and simple SPI mode.

A different interrupt vector can be assigned to each interrupt source. Individual interrupt sources can be enabled or disabled with the enable bits in the CCR0 register.

If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated when transmit data is transferred from the TDR register to the TSR register. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the CCR0.TE and CCR0.TIE bits to 1 at the same time. An SCIn_TXI interrupt request can activate the DTC or DMAC to handle data transfer.

An SCIn_TXI interrupt request is not generated by setting the CCR0.TE bit to 1 when CCR0.TIE is 0 or by setting the CCR0.TIE bit to 1 when the CCR0.TE is 1.*1

When new data is not written by the time of transmission of the last bit of the current transmit data and CCR0.TEIE is 1, the CSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated. Additionally, when CCR0.TE is 1, the CSR.TEND flag retains the value 1 until more transmit data is written to the TDR register, and setting CCR0.TEIE to 1 leads to the generation of an SCIn_TEI interrupt request.

Writing data to the TDR register leads to clearing of the CSR.TEND flag and, after a certain time, discarding of the SCIn_TEI interrupt request.

If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated when received data is stored in the RDR register. An SCIn_RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting any of the CSR.ORER, FER, PER or MSR.MER*2, SYER*2, PFER*2, and SBER*2 flags to 1 when the CCR0.RIE bit is 1 leads to the generation of an SCIn_ERI interrupt request.

An SCIn_RXI interrupt request is not generated in this case. Clearing all these flags (ORER, FER, PER, MER*2, SYER*2, PFER*2 and SBER*2) leads to discarding of the SCIn_ERI interrupt request.

Note 1. To temporarily prohibit SCIn_TXI interrupts on transmission of the last of the data when a new round of transmission is to be started, after handling the transmission-completed interrupt, control activation of the interrupt by using the interrupt request enable bit in the ICU rather than using the CCR0.TIE bit. This approach can prevent the suppression of SCIn_TXI interrupt requests in the transfer of new data.

Note 2. MER, SYER, PFER, and SBER work as a factor of SCIn_ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECR) are set to "1".

(2) FIFO selected

Table 26.41 lists interrupt sources in FIFO selected mode.

If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated when the stored amount of data in the transmit-FIFO (TDR) register becomes the threshold value indicated in FCR.TTRG or below. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the CCR0.TIE and CCR0.TE bits to 1 simultaneously or by setting CCR0.TIE to 1 when CCR0.TE is 1.

An SCIn_TXI interrupt request is not generated by setting CCR0.TE to 1 when CCR0.TIE is 0 or by setting the CCR0.TIE bit to 1 while the setting of the CCR0.TE bit is 1.

If CCR0.TEIE is 1 and if the next data is not written to the transmit-FIFO (TDR) register by the time the last bit of the transmit data is sent, the CSR.TEND flag is set to 1 and the SCIn_TEI interrupt request is generated.

If CCR0.RIE is 1, the SCIn_RXI interrupt request is generated when the stored amount of data in the transmit-FIFO (TDR) register is equal to or greater than the threshold value indicated in FCR.RTRG. When RTRG is 0, an SCIn_RXI interrupt does not occur even when the amount of data in the receive FIFO is equal to 0.

If the CCR0.RIE bit is 1, when the CSR.ORER flag is set to 1 or data with a framing error or a parity error is stored in the transmit-FIFO (TDR) register, the SCIn_ERI interrupt request is generated. When the amount of data stored in the transmit-FIFO (TDR) register is at the threshold value or above, the SCIn_RXI interrupt request is also generated. The SCIn_ERI interrupt request can be canceled, in which case CSR.ORER, FER, and PER flags are all cleared.

26.12.2 异步、曼彻斯特、时钟同步和简单SPI中的中断 Modes

(1) Non-FIFO selected

表26.40列出了异步模式、曼彻斯特模式、时钟同步模式和简单SPI模式下的中断源。

可以为每个中断源分配不同的中断向量。可以使用CCR0寄存器中的启用位启用或禁用各个中断源。

如果CCR0.TIE位为1，则当发送数据从TDR寄存器传输到TSR寄存器时，会产生SCIn_TXI中断请求。也可以使用一条指令同时将CCR0.TE和CCR0.TIE位设置为1，从而产生SCIn_TXI中断请求。SCIn_TXI中断请求可以激活DTC或DMAC来处理数据传输。

当CCR0.TIE为0时将CCR0.TE位设置为1或通过设置
当CCR0.TE为1时，CCR0.TIE位为1。*1

当当前发送数据的最后一位发送时未写入新数据且CCR0.TEIE为1，则
CSR.TEND标志设置为1，并产生SCIn_TEI中断请求。此外，当CCR0.TE为1时，
CSR.TEND标志保持值1，直到更多发送数据写入TDR寄存器，将CCR0.TEIE设置为1会导致产生SCIn_TEI中断请求。

将数据写入TDR寄存器会导致CSR.TEND标志清零，并在一定时间后丢弃
SCIn_TEI中断请求。

如果CCR0.RIE位为1，则当接收到的数据存储在RDR寄存器中时会产生SCIn_RXI中断请求。一个
SCIn_RXI中断请求可以激活DTC或DMAC来处理数据传输。

当CCR0.RIE位为1时，将CSR.ORER、FER、PER或MSR.MER*2、SYER*2、PFER*2和SBER*2标志设置为1会导致产生SCIn_ERI中断请求.

在这种情况下不会产生SCIn_RXI中断请求。清除所有这些标志(ORER FER PER MER*2 SYER*2
PFER*2和SBER*2)导致丢弃SCIn_ERI中断请求。

注1.为了在新一轮传输开始时，在最后一个数据传输时暂时禁止SCIn_TXI中断，在处理完传输完成中断后，使用ICU中的中断请求使能位控制中断的激活而不是使用CCR0.TIE位。这种方法可以防止在传输新数据时抑制SCIn_TXI中断请求。

注2.MER、SYER、PFER和SBER仅在曼彻斯特模式下作为SCIn_ERI中断的一个因素起作用。SYER、PFER和
SBER也仅在其启用位（MECR中的SYEREN、PFEREN、SBEREN）设置为“1”时才起作用。

(2) FIFO selected

表26.41列出了FIFO选择模式下的中断源。

如果CCR0.TIE位为1，则当发送FIFO(TDR)寄存器中存储的数据量变为FCR.TTRG中指示的阈值或更低时，将产生SCIn_TXI中断请求。SCIn_TXI中断请求也可以通过使用一条指令同时将CCR0.TIE和CCR0.TE位设置为1或在CCR0.TE为1时将CCR0.TIE设置为1来产生。

当CCR0.TIE为0时将CCR0.TE设置为1或在CCR0.TE位设置为1时将CCR0.TIE位设置为1不会产生SCIn_TXI中断请求。

如果CCR0.TEIE为1，并且如果在发送数据的最后一位发送时下一个数据未写入到发送FIFO(TDR)寄存器，则CSR.TEND标志设置为1，并且SCIn_TEI中断请求生成。

如果CCR0.RIE为1，则当发送FIFO(TDR)寄存器中存储的数据量等于或大于FCR.RTRG中指示的阈值时，将产生SCIn_RXI中断请求。当RTRG为0时，即使接收FIFO中的数据量等于0，也不会发生SCIn_RXI中断。

如果CCR0.RIE位为1，则当CSR.ORER标志设置为1或有帧错误或奇偶校验错误的数据存储在发送FIFO(TDR)寄存器中时，将产生SCIn_ERI中断请求。当存储在发送FIFO（TDR）寄存器中的数据量在阈值或以上时，也会产生SCIn_RXI中断请求。SCIn_ERI中断请求可以被取消，在这种情况下，CSR.ORER、FER和PER标志都被清除。

26.12.3 Interrupts in Smart Card Interface Mode

Table 26.42 lists interrupt sources in smart card interface mode. A transmit end interrupt (SCIn_TEI) request and an address match (SCIn_AM) request cannot be used in this mode.

	When set TE = 0->1			

Data transmission or reception using the DTC or DMAC is also possible in smart card interface mode, similar to normal SCI mode. In transmission, when the CCR0.TEND flag is set to 1, an SCIn_TXI interrupt request is generated. This SCIn_TXI interrupt request activates the DTC or DMAC, allowing transfer of transmit data if the SCIn_TXI request is previously specified as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission after an error occurrence. However, the CSR.ERS flag is not automatically set to

SCIn_TXI (n = 0 to 4, 9)	传输数据为空	CSR.TEND	CCR0.TIE	Possible
	当设置TE=0->1			

在智能卡接口模式下也可以使用DTC或DMAC进行数据传输或接收，类似于正常SCI模式。在发送过程中，当CCR0.TEND标志设置为1时，会产生一个SCIn_TXI中断请求。这个SCIn_TXI中断请求激活DTC或DMAC，如果之前将SCIn_TXI请求指定为DTC或DMAC激活源，则允许传输数据。当DTC或DMAC传输数据时，TEND标志自动设置为0。

如果发生错误，SCI会自动重新传输相同的数据。在重传期间，TEND标志保持为0，并且DTC或DMAC不被激活。因此，SCI和DTC或DMAC会自动传输指定的字节数，包括发生错误后的重传。但是，CSR.ERS标志不会自动设置为

0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the CCR0.RIE bit to 1 to enable an SCIn_ERI interrupt request to be generated at error occurrence.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings. For DTC or DMAC settings, see section 16, Data Transfer Controller (DTC), section 15, DMA Controller (DMAC).

In reception, an SCIn_RXI interrupt request is generated when receive data is set to the RDR register. This SCIn_RXI interrupt request activates the DTC or DMAC, allowing transfer of the receive data if the SCIn_RXI request is previously specified as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an SCIn_ERI interrupt request is issued to the CPU instead. The error flag must be cleared.

26.12.4 Interrupts in Simple IIC Mode

Table 26.43 lists the interrupt sources in simple IIC mode. The STI interrupt is allocated to the transmit end interrupt (SCIn_TEI) request. The receive error interrupt (SCIn_ERI) and the address match (SCIn_AM) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple IIC mode.

When the ICR.IICINTM bit is 1:

- An SCIn_RXI request is generated on the falling edge of the SCLn signal for the 8th bit. If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.
- An SCIn_TXI request is generated on the falling edge of the SCLn signal for the 9th bit (acknowledge bit). If SCIn_TXI is previously set up as an activation source for the DTC or DMAC, the SCIn_TXI request activates the DTC or DMAC to handle transfer of the transmit data.

When the ICR.IICINTM bit is 0:

- An SCIn_RXI request (ACK detection) is generated if the input on the SDAn pin is low on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- An SCIn_TXI request (NACK detection) is generated if the input on the SDAn pin is high on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.

If the DTC or DMAC is used for data transfer in reception or transmission, always set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in ICR are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

26.12.5 Interrupts in Simple LIN mode

Table 26.44 lists interrupt sources in Simple LIN mode.

发生错误时为0。因此，必须通过预先将CCR0.RIE位设置为1来清除ERS 标志，以使能在错误发生时产生SCIn_ERI中断请求。

使用DTC或DMAC发送或接收数据时，请务必在进行SCI设置之前启用DTC或DMAC。对于DTC或DMAC设置，请参阅第16节，数据传输控制器(DTC)，第15节，DMA控制器(DMAC)。

在接收中，当接收数据设置到RDR寄存器时，会产生SCIn_RXI中断请求。该SCIn_RXI中断请求激活DTC或DMAC，如果先前将SCIn_RXI请求指定为DTC或DMAC激活源，则允许传输接收数据。如果发生错误，则设置错误标志。因此，不会激活DTC或DMAC，而是向CPU发出SCIn_ERI中断请求。必须清除错误标志。

26.12.4 简单IIC模式下的中断

表26.43列出了简单IIC模式下的中断源。STI中断分配给发送结束中断(SCIn_TEI)请求。不能使用接收错误中断(SCIn_ERI)和地址匹配(SCIn_AM)请求。

DTC或DMAC也可用于处理简单IIC模式下的传输。

当ICR.IICINTM位为1时：

●SCIn_RXI请求在第8位的SCLn信号下降沿产生。如果SCIn_RXI先前设置为DTC或DMAC的激活源，则SCIn_RXI请求将激活DTC或DMAC以处理接收数据的传输。

●SCIn_TXI请求在第9位（确认位）的SCLn信号的下降沿产生。如果SCIn_TXI先前设置为DTC或DMAC的激活源，则SCIn_TXI请求将激活DTC或DMAC以处理传输数据的传输。

当ICR.IICINTM位为0时：

●如果SDAn引脚上的输入在第9位（确认位）的SCLn信号的上升沿为低电平，则生成SCIn_RXI请求（ACK检测）

●如果SDAn引脚上的输入在第9位（确认位）的SCLn信号的上升沿为高电平，则生成SCIn_TXI请求（NACK检测）

●如果先前将SCIn_RXI设置为DTC或DMAC的激活源，则SCIn_RXI请求将激活DTC或DMAC以处理接收数据的传输。

如果DTC或DMAC用于接收或传输中的数据传输，请务必在设置SCI之前设置并启用DTC或DMAC。

当ICR中的IICSTAREQ、IICRSTAREQ和IICSTPREQ位用于生成开始条件、重新启动条件或停止条件时，生成完成时会发出STI请求。

26.12.5 简单LIN模式下的中断

表26.44列出了简单LIN模式下的中断源。

	Break Field output completion	XSR0.BFOF		CCR0.TIE, XCR0.BFOIE	
SCIn_TEI (n = 0 to 4, 9)	Transmit end	CSR.TEND	—	CCR0.TEIE	Not Possible
SCIn_BFD (n = 0 to 4, 9)	Break Field Detection	XSR0.BFDF	—	XCR0.BFDIE	Not Possible (Unnecessary)

In Simple LIN mode, in addition to reception errors (ORER, FER, PER), an SCIn_ERI interrupt request is output when a bus conflict is detected during transmission, or when a counter overflow of the Simple LIN module occurs. At this time, a SCIn_RXI interrupt request is not output. The SCIn_ERI interrupt request can be canceled by clearing all the flags.

When transmitting Start Frame, if CCR0.TIE = 1 and XCR0.BFOIE = 1, a SCIn_TXI interrupt request is output when Break Field transmission is completed. When Control Field 0 data is written to the TDR register, data transmission starts. Therefore, transmission using DTC or DMAC is possible.

Set CCR0.TEIE = 1 after writing the last transmit data to the TDR register and transmission starts.

During Start Frame reception (XSR0.SFSF = 1), reception using DTC or DMAC by SCIn_RXI interrupt is not possible. Check the CSR register and XSR0 register, check the reception status (See Figure 26.81), and then clear the flag. Also read the RDR register (if you do not need to check the received data value, clear the RDRF flag without reading the RDR register). When reception of Control Field 1 is completed (XSR0.CF1MF = 1), Start Frame detection is disabled (XSR0.SFSF = 0) and reception using DTC or DMAC is possible. Be sure to read the RDR register.

When Start Frame / Break Field detection is enabled (XCR1.SDST = 1), if a Break Field longer than the period set in XCR2.BFLW [15:0] is received, the BFDF flag is set and a SCIn_BFD interrupt request is output. Then SCI becomes the Start Frame reception state. Clear the BFDF flag.

When Start Frame / Break Field detection is enabled (XCR1.SDST = 1) and the bit rate measurement function is enabled (XCR1.BMEN = 1), an SCIn_AED interrupt factor is output when an active edge is detected. Read the timer count capture value (XSR1.TCNT [15:0]).

26.13 Event Linking

By using interrupt request signals as event signals, the SCIn can provide linked operation through the ELC for modules selected in advance.

Event signals can be output regardless of the values of the associated interrupt request enable bits.

(1) Error event output (receive error or error signal detected) (SCIn_ERI, n = 0 to 4, 9)

- Indicates abnormal termination because of a parity error during reception in asynchronous mode
- Indicates abnormal termination because of a framing error during reception in asynchronous mode
- Indicates abnormal termination because of an overrun error during reception

SCIn_BFD (n = 0 to 4, 9)	断场检测	XSR0.BFDF	—	XCR0.BFDIE	不可能（不必要）

在SimpleLIN模式下，除了接收错误（ORER、FER、PER）外，当在传输过程中检测到总线冲突或发生SimpleLIN模块的计数器溢出时，还会输出SCIn_ERI中断请求。此时，不输出SCIn_RXI中断请求。SCIn_ERI中断请求可以通过清除所有标志来取消。

发送StartFrame时，如果CCR0.TIE=1且XCR0.BFOIE=1，Break时输出SCIn_TXI中断请求现场传输完成。当控制字段0数据写入TDR寄存器时，数据传输开始。因此，可以使用DTC或DMAC进行传输。

将最后一个发送数据写入TDR寄存器并开始发送后，设置CCR0.TEIE=1。

在开始帧接收期间（XSR0.SFSF=1），不能通过SCIn_RXI中断使用DTC或DMAC进行接收。检查CSR寄存器和XSR0寄存器，检查接收状态（见图26.81），然后清除标志。还要读取RDR寄存器（如果不需要检查接收到的数据值，请清除RDRF标志而不读取RDR寄存器）。当控制字段1的接收完成时（XSR0.CF1MF=1），开始帧检测被禁用（XSR0.SFSF=0）并且可以使用DTC或DMAC接收。请务必阅读RDR寄存器。

当启用起始帧中断字段检测(XCR1.SDST=1)时，如果中断字段长于设置的周期接收到XCR2.BFLW[15:0]，设置BFDF标志并输出SCIn_BFD中断请求。那么SCI就变成了开始帧接收状态。清除BFDF标志。

当启动帧中断字段检测启用(XCR1.SDST=1)并启用比特率测量功能(XCR1.BMEN=1)时，当检测到有效边沿时输出SCIn_AED中断因子。读取定时器计数捕获值（XSR1.TCNT[15:0]）。

26.14 Address Non-match Event Output (SCI0_DCUF)

SCI0_DCUF indicates the non-match of comparison data (CCR4.CMPD) with receive data that is one frame of the data that is received when CCR0.DCME is set to 1 in asynchronous mode, including multi-processor mode. This event can be used for Snooze end request only. In detail, see section 10, Low Power Modes.

26.15 Noise Cancellation Function

Figure 26.111 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a 2-stage flip-flop circuit and a match detection circuit. When the input signals of the noise filter and the output signals of the 2- stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. When the same level is retained for 3 cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for 3 cycles or shorter is considered as noise, not as a receive signal.

In asynchronous mode, Manchester and Simple LIN modes, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The sampling period of the noise filter can be selected from the base clock period and the divided clock of the baud rate generator clock source by CCR1.NFCS[2:0].

- When CCR1.NFCS[2:0] = 000b, CCR2.ABCS = 0 and CCR2.ABCSE = 0, the cycle is 1/16 of a 1-bit period.
- When CCR1.NFCS[2:0] = 000b, CCR2.ABCS = 1 and CCR2.ABCSE = 0, the cycle is 1/8 of a 1-bit period.
- When CCR1.NFCS[2:0] = 000b, CCR2.ABCSE = 1, the cycle is 1/6 of a 1-bit period.

In simple IIC mode, this function can be used for each input on SDAn and SCLn. The sampling clock is selected from divided clock of baud rate generator settings by CCR1.NFCS[2:0].

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When CCR0.TE and CCR0.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, the function determines that a level match is detected and the result is conveyed as an internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles.

(6) 主动边缘检测事件输出

●在SimpleLIN模式下，当CCR1.BMEN为1时，表示在RXD输入信号中检测到有效边沿。

26.14 地址不匹配事件输出(SCI0_DCUF)

SCI0_DCUF表示比较数据（CCR4.CMPD）与接收数据不匹配，接收数据是在异步模式（包括多处理器模式）下CCR0.DCME设置为1时接收到的数据的一帧。此事件仅可用于贪睡结束请求。详细信息，请参见第10节，低功耗模式。

26.15 降噪功能

图26.111显示了用于噪声消除的噪声滤波器的配置。噪声滤波器由一个2级触发器电路和一个匹配检测电路组成。当噪声滤波器的输入信号和2级触发器电路的输出信号完全匹配时，匹配的电平作为内部信号传送。除非另有匹配，否则将保留先前的值。当相同电平在噪声滤波器的采样时钟上保持3个周期或更长时间时，它被认为是有效的接收信号。3个周期或更短的脉冲变化被认为是噪声，而不是接收信号。

在异步模式、曼彻斯特模式和简单LIN模式下，噪声消除功能可应用于输入到RXDn引脚的接收信号。噪声滤波器的采样周期可以通过CCR1.NFCS[2:0]从基础时钟周期和波特率发生器时钟源的分频时钟中选择。

●当CCR1.NFCS[2:0]=000b、CCR2.ABCS=0和CCR2.ABCSE=0时，周期为1位周期的116。
●当CCR1.NFCS[2:0]=000b、CCR2.ABCS=1和CCR2.ABCSE=0时，周期为1位周期的18。
●当CCR1.NFCS[2:0]=000b，CCR2.ABCSE=1时，周期为1位周期的16。

在简单IIC模式下，该功能可用于SDAn和SCLn上的每个输入。采样时钟由CCR1.NFCS[2:0]从波特率发生器设置的分频时钟中选择。

如果在启用噪声滤波器的情况下基准时钟停止一次，然后再次重新启动基准时钟输入，则噪声滤波器操作将从时钟停止的状态恢复。当CCR0.TE和CCR0.RE在基本时钟输入期间设置为0时，所有噪声滤波器触发器值都被初始化为1。因此，如果在接收操作恢复时输入数据为1，则该函数确定一个电平检测到匹配并将结果作为内部信号传送。当输入的电平对应于0时，保留噪声滤波器的初始输出，直到电平在三个连续的采样周期中匹配。

26.16 RS-485 Driver Control Function

Setting the DEN bit in the SCI common control register3 (CCR3) to 1 enables the RS-485 driver control function and generates a DEn (Driver Enable) signal that enables the external transceiver transmission mode. The DEn signal outputs a valid level for the period with driver assertion time and driver negate time added before and after data transmission. The DEn signal valid level is set by the DEPOL bit in the driver control register (DCR).

The driver assertion time is the time from when the DEn signal is valid until the start bit starts. Set by DEAST [4:0] of driver control register (DCR).

The driver negate time is the time from the end of the last stop bit of the transmitted message to the invalidation of the DEn signal. Set with DENGT [4:0] of the driver control register (DCR).

DEAST and DENGT are expressed in base clock period (1/8 or 1/16 bit period). For details, refer to section 26.2.13. DCR : Driver Control Register.

When this function is used (CCR3.DEN = 1), the CSR.TEND set timing and SCIn_TEI interrupt output timing are at the end of the driver negation time.

When transmission is completed and the next transmission data is not written before the DEn signal is negated, the DEn signal is negated once. If the timing for writing the next transmit data is not in time, assert the DEn signal after negating it again, insert the driver assertion time, and transmit the next data. If you want to perform the next transmission with the DEn signal asserted, write the next transmission data to the TDR quickly enough in consideration of the synchronization delay time of the register.

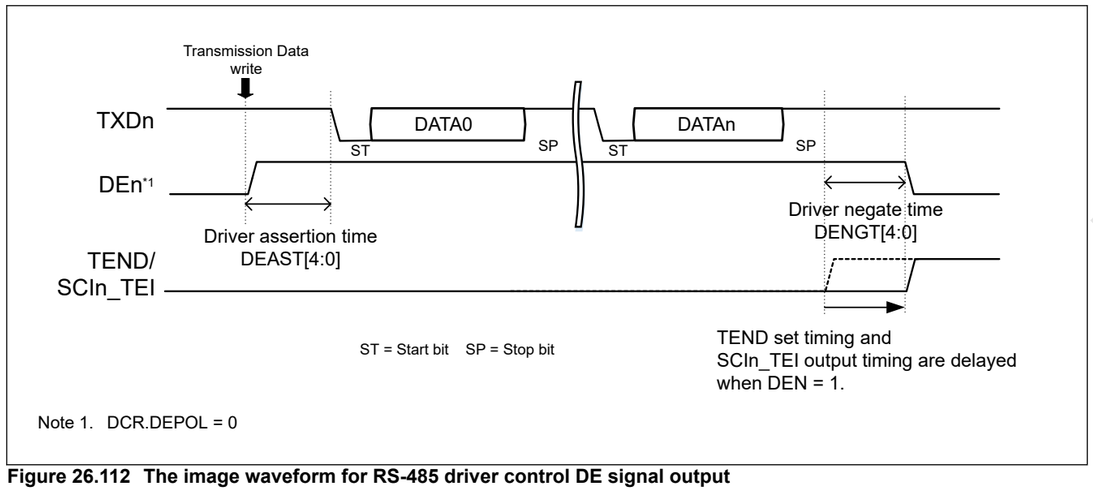

Figure 26.112 The image waveform for RS-485 driver control DE signal output

26.17 Loopback Function

The loopback function can be used in Asynchronous mode with the internal clock, and Manchester mode with the internal clock, and Clock synchronous mode with the internal clock.

When 1 is written to the SPLP bit in the CCR1 register, SCI blocks the external input (RXDn) path and connects the output path of the transmit data register and the input path of the receive data register.

When this function is used with TINV bit = 1, inversion of transmission data becomes reception data. However, this function can be used with TINV = 1 only when operating in clock synchronous mode internal clock.

Table 26.45 shows the relationship between the TINV and SPLP bit settings and the received data.

26.16 RS-485驱动控制功能

将SCI公共控制寄存器3(CCR3)中的DEN位设置为1，启用RS-485驱动器控制功能，并生成启用外部收发器传输模式的DEn(DriverEnable)信号。DEn信号在数据传输前后添加驱动器断言时间和驱动器否定时间的周期内输出有效电平。DEn信号有效电平由驱动控制寄存器(DCR)中的DEPOL位设置。

驱动器断言时间是从DEn信号有效到起始位开始的时间。由驱动控制寄存器(DCR)的DEAST[4:0]设置。

驱动器取反时间是从传输消息的最后一个停止位结束到DEn信号无效的时间。使用驱动控制寄存器(DCR)的DENGT[4:0]设置。

DEAST和DENGT以基本时钟周期（18或116位周期）表示。有关详细信息，请参阅第26.2.13节。直流电阻：驱动程序控制寄存器。

使用此功能时（CCR3.DEN=1），CSR.TEND设置时序和SCIn_TEI中断输出时序在驱动器取反时间结束。

当发送完成并且在DEn信号被取反之前没有写入下一个发送数据时，DEn信号被取反一次。如果写入下一个发送数据的时序不及时，再次取反后置位DEn信号，插入驱动器置位时间，发送下一个数据。如果要在DEn信号置位的情况下执行下一次传输，考虑到寄存器的同步延迟时间，将下一次传输数据足够快地写入TDR。

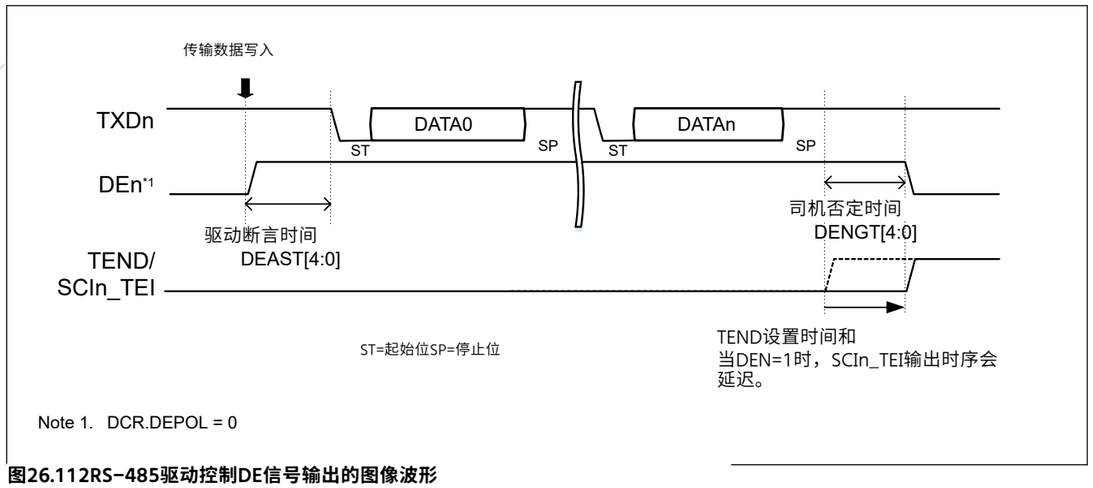

图26.112RS-485驱动控制DE信号输出的图像波形

26.17 Loopback Function

环回功能可用于带内部时钟的异步模式、带内部时钟的曼彻斯特模式和带内部时钟的时钟同步模式。

当向CCR1寄存器中的SPLP位写入1时，SCI会阻塞外部输入(RXDn)路径并连接发送数据寄存器的输出路径和接收数据寄存器的输入路径。

当TINV位=1使用此功能时，发送数据的反相变为接收数据。但是，只有在时钟同步模式内部时钟下运行时，才能在TINV=1时使用此函数。

表26.45显示了TINV和SPLP位设置与接收数据之间的关系。

26.18 Half-Duplex communication Function

Do not use the half-duplex communication function in Simple IIC, Simple SPI and Smart Card Interface modes.

In other communication modes, if the CCR1.SHARPS bit is set to 1, half-duplex communication using the TXDn pin is possible. When half-duplex communication is used, transmission and reception must be performed exclusively. Transmission and reception settings (CCR0.TE = 1 and CCR0.RE = 1) is prohibited.

However, if half-duplex communication is performed as the master reception in clock synchronous mode, perform transmission / reception settings (CCR0.TE = 1 and CCR0.RE = 1) and perform dummy transmission. By dummy transmission (arbitrary transmission data is written to TDR), SCKn is output and reception is enabled. The dummy transmission data is discarded inside the IP and is not actually transmitted.

During half-duplex communication, the only communication port terminal used is the TXDn terminal. Output when CCR0.TE = 1, input when CCR0.TE = 0.

26.19 Synchronizer Bypass Function

The SCI has a bus clock and the operation clock (TCLK). And these have each operating circuit. Therefore, there is a synchronization circuit for signal transfer between different clocks, and synchronization delay time is required for signal propagation between different clocks.

However, the synchronization circuit can be bypassed by the CCR3.BPEN bit only when the same clock is input to the bus clock and the operation clock. In this case, eliminates synchronization delay time and improves responsiveness. Figure 26.114 shows the image waveform of the bypass function.

This IP also has a synchronization circuit between the communication clock (SCKn) and the operation clock (TCLK), but this synchronization circuit cannot be bypassed.

26.18 半双工通信功能

请勿在SimpleIIC、SimpleSPI和SmartCardInterface模式下使用半双工通信功能。

在其他通信模式下，如果CCR1.SHARPS位设置为1，则可以使用TXDn引脚进行半双工通信。当使用半双工通信时，必须专门进行发送和接收。禁止发送和接收设置（CCR0.TE=1和CCR0.RE=1）。

但是，如果在时钟同步模式下作为主机接收执行半双工通信，则执行发送接收设置（CCR0.TE=1和CCR0.RE=1）并执行虚拟发送。通过虚拟传输（将任意传输数据写入TDR），输出SCKn并启用接收。虚拟传输数据在IP内部被丢弃，并不实际传输。

在半双工通信期间，唯一使用的通信端口端子是TXDn端子。输出时CCR0.TE=1，当CCR0.TE=0时输入。

26.19 同步器旁路功能

SCI有一个总线时钟和一个操作时钟（TCLK）。这些都有各自的操作电路。因此，不同时钟之间的信号传输存在同步电路，不同时钟之间的信号传播需要同步延迟时间。

但是，只有在总线时钟和操作时钟输入相同的时钟时，才能通过CCR3.BPEN位绕过同步电路。在这种情况下，消除了同步延迟时间并提高了响应能力。图26.114显示了旁路功能的图像波形。

该IP在通信时钟(SCKn)和操作时钟(TCLK)之间也有一个同步电路，但该同步电路无法绕过。

26.20 Usage Notes

26.20.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable SCI operation. The SCI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

26.20.2 SCI Operation during Low Power State

(1) Transmission

Before using the power consumption reduction function to reduce SCI's power consumption, please do the following to confirm transmission end (CSR.TEND = 1):

- Set the output terminal state after transmission operation is stopped by CCR1.SPB2DT, SPB2IO.
- Stop the transmission (CCR0.TIE = 0, TE = 0, TEIE = 0)

When transitions to these states are made during transmission, the data being transmitted become indeterminate.

To transmit data in the same transmission mode after cancellation of the low power consumption state, set the TE bit to 1, read CSR, and write data to TDR sequentially to start data transmission. To transmit data with a different transmission mode, initialize the SCI first.

26.20 使用说明

26.20.1 模块停止功能的设置

模块停止控制寄存器B(MSTPCRB)可以启用或禁用SCI操作。SCI在复位后最初停止。释放模块停止状态可以访问寄存器。有关详细信息，请参阅第10节，低功耗模式。

26.20.2 低功耗状态下的SCI操作

(1) Transmission

在使用功耗降低功能降低SCI的功耗之前，请执行以下操作以确认发送结束（CSR.TEND=1）：

●通过CCR1.SPB2DT、SPB2IO设置发送操作停止后的输出端子状态。
●停止传输（CCR0.TIE=0，TE=0，TEIE=0）

在传输过程中转换到这些状态时，正在传输的数据变得不确定。

要在取消低功耗状态后以相同的传输模式传输数据，请将TE位设置为1，读取CSR，然后将数据依次写入TDR以开始数据传输。要以不同的传输模式传输数据，请先初始化SCI。

To start transmission using the DMAC/DTC after cancellation from software standby mode, set the CCR0.TE and CCR0.TIE bit to at the same time. Then SCIn_TXI interrupt flag is generated, which causes the DMAC/DTC to write the transmit data, which starts transmission.

Figure 26.115 shows a sample flowchart for transition to software standby mode during transmission. Figure 26.116 and Figure 26.117 show the port pin states during transition to software standby mode.

(2) Reception

When Address match function is non used as condition of resumption (wake-up)

Before specifying the module stop state or making a transition to software standby mode, stop the receive operations (CCR0.RE = 0). If transition is made during data reception, the data being received will be invalid.

Figure 26.118 shows a sample flowchart for reception to software standby mode during reception.

When Address match function is used as condition of resumption (wake-up)

When using the power consumption reduction function to reduce SCI's power consumption, please do the following:

- Set the operation mode to asynchronous mode, after released
- Set the compare data to CCR4.CMPD and set 1 to CCR0.DCME
- Set the receive operation (CCR0.RE = 1)

Please set CCR3.RXDESEL = 0. Because there is a possibility that a start bit (fall edge of RXDn terminal) can't be detected at the time of low power consumption mode release.

After detecting the falling edge of the RXDn terminal and transitioning from standby mode to snooze mode, the operating clock is supplied to SCI and data is received by SCI. The address match function determines the received data, and if it matches, it transitions from snooze mode to normal mode, and if it does not match, it transitions to standby mode again. This operation behaves as if the standby mode is continued until the communication data matching the CMPD is received, and after the standby mode is released, the normal reception operation is continued.

When using this function, the reception speed must be slow enough because it is necessary to perform the transition from the fall detection of the RXDn terminal to the snooze mode, and from the clock supply to the SCI to the reception.

Figure 26.119 shows a sample flowchart for reception to software standby mode during reception.

要在从软件待机模式取消后使用DMACDTC开始传输，请设置CCR0.TE和CCR0.TIE位同时。然后产生SCIn_TXI中断标志 ，使DMACDTC写入发送数据，开始发送。

图26.115显示了传输期间转换到软件待机模式的示例流程图。图26.116和图26.117显示了转换到软件待机模式期间的端口引脚状态。

(2) Reception

不使用地址匹配功能作为恢复条件时（唤醒）

在指定模块停止状态或转换到软件待机模式之前，停止接收操作(CCR0.RE=0)。如果在数据接收过程中进行转换，正在接收的数据将无效。

图26.118显示了在接收期间接收到软件待机模式的示例流程图。

当地址匹配功能用作恢复条件时（唤醒）

使用功耗降低功能降低SCI的功耗时，请执行以下操作：

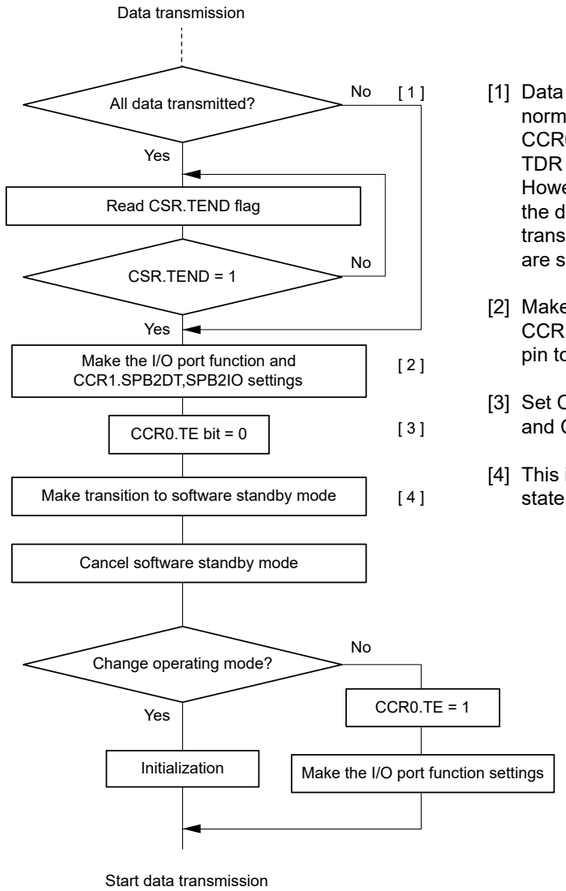
- ●设置操作模式为异步模式，释放后
- ●将比较数据设置为CCR4.CMPD，将1设置为CCR0.DCME
- ●设置接收操作（CCR0.RE=1）

请设置CCR3.RXDESEL=0。因为在低功耗模式释放时可能无法检测到起始位（RXDn端子的下降沿）。

在检测到RXDn端子的下降沿并从待机模式转换到贪睡模式后，工作时钟被提供给SCI，数据由SCI接收。地址匹配功能确定接收到的数据，如果匹配，则从贪睡模式过渡到正常模式，如果不匹配，则再次过渡到待机模式。在接收到与CMPD匹配的通信数据之前，该操作表现为继续待机模式，在解除待机模式后，继续正常接收操作。

使用此功能时，接收速度必须足够慢，因为需要执行从RXDn端子的下降检测到贪睡模式的转换，以及从时钟供应到SCI到接收的转换。

图26.119显示了在接收期间接收到软件待机模式的示例流程图。



[1] Data being transmitted is lost halfway. Data can be normally transmitted from the CPU by setting the CCR0.TE to “1”, reading CSR, and writing data to TDR after canceling software stand by mode. However, if the DMAC or DTC has been activated, the data remaining in the DMAC or DTC will be transmitted when both the TE and TIE bits in CCR0 are set to “1”.

[2] Make the I/O port function and CCR1.SPB2DT,SPB2IO settings to switch the TxDn pin to operate as a general I/O port.

[3] Set CCR0.TE bit to “0”. Set also 0 to CCR0.TIE and CCR0.TEIE if you set these bits were 1.

26.20.3 Break Detection and Processing

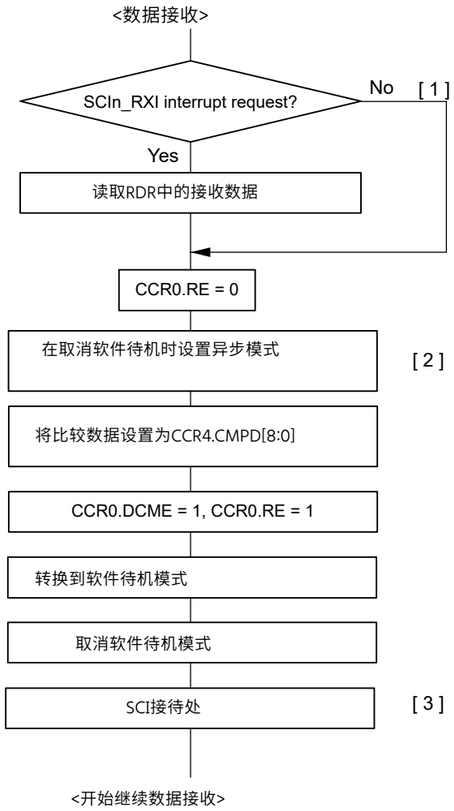
(1) Non-FIFO selected

When a framing error is detected, a break can be detected by reading CSR.RXDMON bit value. In a break, the input from the RXDn pin becomes all 0s, and the CSR.FER flag is set to 1 to indicate a framing error, and the CSR.PER flag might also be set to 1 to indicate a parity error. The SCI continues the receive operation even after a break is received. Therefore, even if the FER flag is 0, indicating that no framing error occurred, it is set to 1 again. When the CCR3.RXDESEL bit is 1, the SCI sets the CSR.FER flag to 1 and stops receiving operations until a start bit of the next data frame is detected. If the CSR.FER flag is set to 0, the CSR.FER flag retains 0 during the break.

When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit on the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

(2) FIFO selected

After a framing error is detected and when the SCI detects that continuous receive data is 0 for 1 frame, reception stops. When a framing error is detected, a break can be detected by reading the CSR.RXDMON flag value. After the RXDn signal is in high and the break is finished, data reception to the receive-FIFO (RDR) register resumes.



[1]正在接收的数据无效。

[2]地址匹配功能仅在异步模式。

[3]地址匹配功能在贪睡模式，当接收到的数据与CCR4.CMPD匹配时，取消待机模式并设置正常接收待机状态。

图26.119在地址匹配的接收期间接收到软件待机模式的流程图示例

26.20.3 断裂检测和处理

(1) Non-FIFO selected

当检测到帧错误时，可以通过读取CSR.RXDMON位的值来检测中断。在中断时，来自RXDn引脚的输入变为全0，并且CSR.FER标志设置为1表示帧错误，CSR.PER标志也可能设置为1表示奇偶校验错误。即使在收到中断后，SCI仍继续接收操作。因此，即使FER标志为0，表示没有发生帧错误，它也会再次设置为1。当CCR3.RXDESEL位为1时，SCI将CSR.FER标志设置为1并停止接收操作，直到检测到下一个数据帧的起始位。如果

CSR.FER标志设置为0，CSR.FER标志在中断期间保持0。

当RXDn引脚设置为1且中断结束时，在第一个下降沿检测起始位的开始
RXDn引脚允许SCI开始接收操作。

(2) FIFO selected

检测到帧错误后，当SCI检测到1帧连续接收数据为0时，接收停止。
当检测到帧错误时，可以通过读取CSR.RXDMON标志值来检测中断。在RXDn信号为高电平且中断完成后，接收FIFO(RDR)寄存器的数据接收恢复。

26.20.4 Mark State and Production of Breaks

When the CCR0.TE bit is 0, disabling serial transmission, the state of the TXDn pin can be set using the CCR1.SPB2IO and CCR1.SPB2DT bits. With this approach, a TXDn pin can be placed in the mark state to transmit a break.

Before setting the CCR0.TE bit to 1, enabling serial transmission, set the SPB2IO and SPB2DT bits to put the communication line in the mark state (the state of 1), and change the TXDn pin using I/O port function. To output a break on data transmission, after setting the TXDn pin to output 0 by setting the SPB2IO and SPB2DT bits, change the TXDn pin using the I/O port function and set the CCR0.TE bit to 0. When the CCR0.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

26.20.5 Receive Error Flags and Transmit Operations (Clock Synchronous Mode and Simple SPI Mode)

Transmission can be start by writing transmit-data to TDR even if CSR.ORER is 1. However, reception cannot be started. Note also that the receive error flags cannot be set to 0 even if the CCR0.RE is set to 0 (serial reception is disabled).

26.20.6 Writing Data to TDR

(1) Non-FIFO selected

Data can be written to TDR anytime when CCR0.TE is 1. However, if new data is written to TDR when transmit data is remaining in TDR, the previous data in TDR is lost because it has not been transferred to TSR yet. If you use DTC or DMAC, be sure to write transmit data to TDR in the SCIn_TXI interrupt request handling routine.

(2) FIFO selected

Data can be written to transmit-FIFO(TDR) when CCR0.TE is 1. Check the number of writable data with the FTSR.T [5:0] bit.

26.20.7 Restrictions on Clock Synchronous Transmission (Clock Synchronous Mode and Simple SPI Mode)

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

Update TDR by the CPU, DMAC, or DTC and wait at least the following time until the start of the external clock input: (See Figure 26.120)

Time taking into account the output AC spec of the MISO terminal of this product and the input AC spec of the master reception + 1 PCLK cycle + synchronization delay.

(2) Continuous transmission

Write the next transmit data to TDR before the falling edge*1 of the transmit clock for bit 7. Please write the transmit data to TDR in consideration of synchronization delay. If the transmit data cannot be written in time, the previous frame data is resent. (See Figure 26.120)

Note 1. When CCR3.CPOL = 1 and CCR3.CPHA = 0, or CCR3.CPOL = 0 and CCR3.CPHA = 1. In the case of CCR3.CPOL = 0 and CCR3.CPHA = 0, or CCR3.CPOL = 1 and CCR3.CPHA = 1, it's the rising edge.

26.20.4 标记状态和产生的中断

当CCR0.TE位为0时，禁用串行传输，TXDn引脚的状态可以使用CCR1.SPB2IO和CCR1.SPB2DT位。使用这种方法，可以将TXDn引脚置于标记状态以发送中断。

在设置CCR0.TE位为1，使能串行传输之前，设置SPB2IO和SPB2DT位使通信线处于标记状态（状态为1），并使用IO端口功能改变TXDn引脚。要输出数据传输中断，通过设置SPB2IO和SPB2DT位将TXDn引脚设置为输出0后，使用IO端口功能更改TXDn引脚并将CCR0.TE位设置为0。当CCR0.TE位为设置为0，无论当前的传输状态如何，都会初始化发送器。

26.20.5 接收错误标志和发送操作（时钟同步模式和简单SPI模式）

即使CSR.ORER为1，也可以通过将发送数据写入TDR来开始发送。但是，无法开始接收。
另请注意，即使CCR0.RE设置为0（禁用串行接收），也不能将接收错误标志设置为0。

26.20.6 将数据写入TDR

(1) Non-FIFO selected

当CCR0.TE为1时，可以随时将数据写入TDR。但是，如果在TDR中剩余发送数据时将新数据写入TDR，则TDR中的先前数据将丢失，因为它尚未传输到TSR。如果您使用DTC或DMAC，请务必在SCIn_TXI中断请求处理程序中将发送数据写入TDR。

(2) FIFO selected

当CCR0.TE为1时，可以将数据写入发送FIFO(TDR)。使用FTSR.T[5:0]位检查可写入数据的数量。

26.20.7 时钟同步传输的限制（时钟同步模式和简单SPI模式）

当外部时钟源用作同步时钟时，有以下限制。

(1) 传输开始

通过CPU、DMAC或DTC更新TDR，并至少等待以下时间，直到外部时钟输入开始：（参见图26.120）

时间考虑了本产品MISO端子的输出AC规格和主机接收的输入AC规格+1PCLK周期+同步延迟。

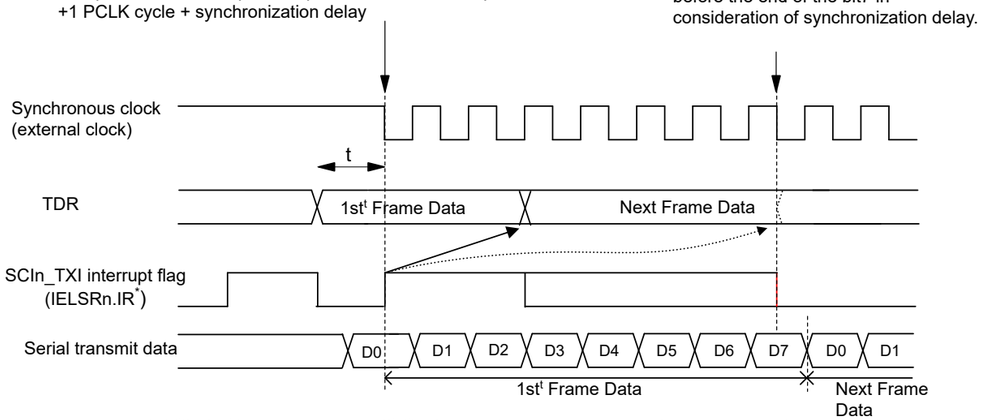
(2) 连续传输

在位7的发送时钟的下降沿*1之前将下一个发送数据写入TDR。请将发送数据写入考虑到同步延迟的TDR。如果发送数据不能及时写入，则重新发送前一帧数据。（见图26.120）

注1.当CCR3.CPOL=1且CCR3.CPHA=0，或CCR3.CPOL=0且CCR3.CPHA=1时。在CCR3.CPOL=0且CCR3.CPHA=0的情况下，或CCR3.CPOL=1且CCR3.CPHA=1，为上升沿。

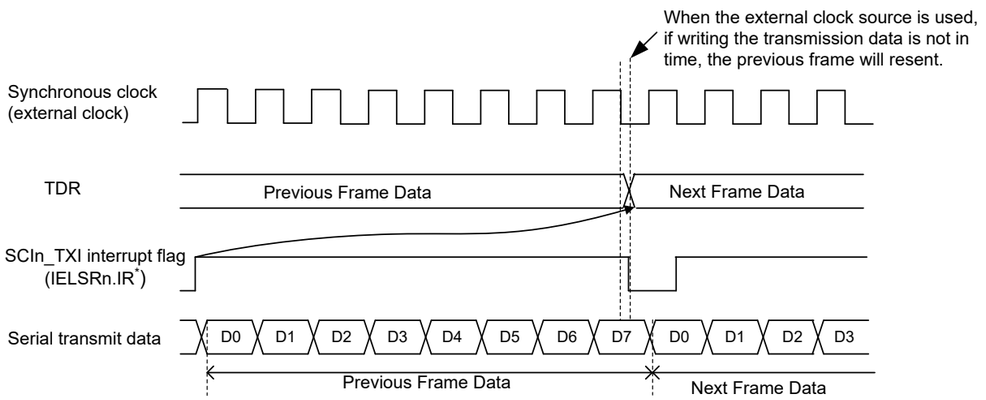
When the external clock source is used, make t more than the following time.
t ≥ Time taking into account the output AC spec of the MISO terminal of this product and the input AC spec of the master reception +1 PCLK cycle + synchronization delay

Write the next transmit data to TDR before the end of the bit7 in consideration of synchronization delay.



(1) Start of transmission and (2) Continuous transmission (When transmission data is in time)

When the external clock source is used, if writing the transmission data is not in time, the previous frame will resent.



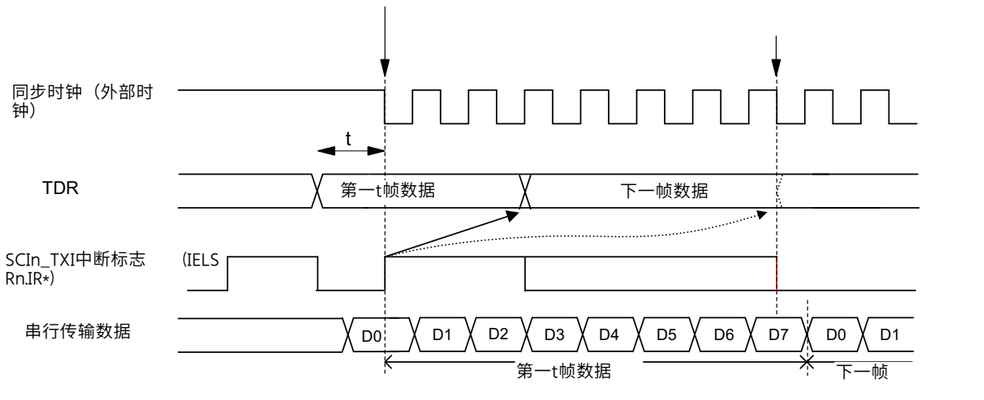
(2) Continuous transmission (When transmission data is not in time)

Note 1. See section 12, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 26.120 Restrictions on Use of External Clock in Clock Synchronous Transmission

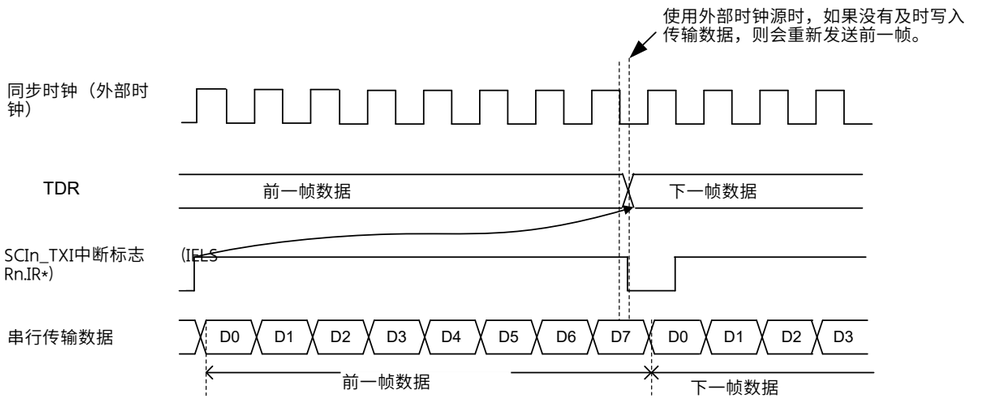
使用外部时钟源时，使t大于以下时间。t≥考虑本产品MISO端子的输出AC规格和主机接收的输入AC规格的时间+1PCLK周期+同步延迟

考虑到同步延迟，在bit7结束之前将下一个发送数据写入TDR。



(1)传输开始和(2)连续传输（传输数据及时）

使用外部时钟源时，如果没有及时写入传输数据，则会重新发送前一帧。



(2)连续传输（传输数据不及时）

注1.有关相应中断事件编号的信息，请参见第12节，中断控制器单元(ICU)。

图26.120时钟同步传输中使用外部时钟的限制

26.20.8 Restrictions on Using DMAC or DTC

When using the DMAC or DTC to read RDR, be sure to set the receive data full interrupt (SCIn_RXI) as the activation source of the relevant SCI.

During the operation in transmission / reception using the DMAC or DTC, it should not set transfer information of DMAC/DTC.

26.20.8 使用DMAC或DTC的限制

使用DMAC或DTC读取RDR时，务必将接收数据满中断（SCIn_RXI）设置为相关SCI的激活源。

在使用DMAC或DTC进行发送接收操作期间，不应设置DMAC的传输信息
DTC.

26.20.9 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IELSRn.IR flag) in the ICU is 1, follow the procedure in this section to clear interrupt requests before permitting operations (by setting the CCR0.TE or CCR0.RE bit to 1). For details on the interrupt status flag, see section 12, Interrupt Controller Unit (ICU).

1. Confirm that transfer has stopped (the CCR0.TE or CCR0.RE bit is 0)

26.20.9 开始转移注意事项

在ICU中的中断状态标志（IELSRn.IR标志）为1时开始传输的点，按照本节中的步骤在允许操作之前清除中断请求（通过将CCR0.TE或CCR0.RE位设置为1）。有关中断状态标志的详细信息，请参见第12节，中断控制器单元(ICU)。

1.确认传输已停止（CCR0.TE或CCR0.RE位为0）

2. Set the associated interrupt enable bit (CCR0.TIE or CCR0.RIE bit) to 0
3. Read the associated interrupt enable bit (CCR0.TIE or CCR0.RIE bit) to check that it actually becomes 0
4. Set the interrupt status flag, IELSRn.IR, in the ICU to 0

26.20.10 Limitations on Simple SPI Mode

(1) Master mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set in the CCR3.CPHA and CPOL bits when the CCR0.SSE bit is 1.

  This prevents the clock line from being placed in the high-impedance state when the CCR0.TE bit is set to 0 or unexpected edges from being generated on the clock line when the CCR0.TE bit changes from 0 to 1. When the CCR0.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not required because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.
- For the clock delay setting (CCR3.CPHA bit is 1), the receive data full interrupt (SCIn_RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 26.121. If the TE and RE bits in the CCR0 register become 0 before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Additionally, an SCIn_RXI interrupt might lead to the input signal on the SSn pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, the SCKn pin output goes to high-impedance while the input on the SSn pin is at the low level if a mode fault error occurs while a character is being transferred, stopping supply of the clock signal to the connected slave. Reset the connected slave to avoid misaligned bits when transfer is restarted.

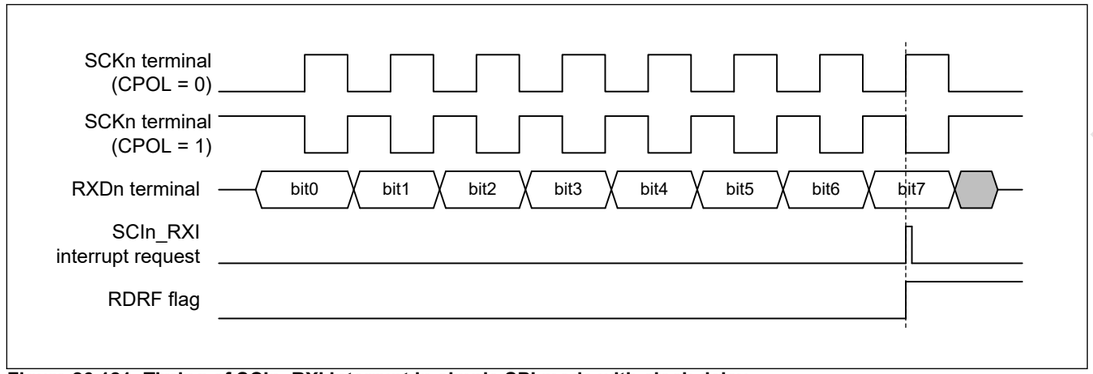


Figure 26.121 Timing of SCIn_RXI interrupt in simple SPI mode with clock delay

(2) Slave mode

- It takes 1PCLK + synchronization delay time + data output delay time (AC spec) from writing the transmit data to the TDR register until the data is output to the RXDn pin. Take these into account when starting external clock input.
- Provide an external clock signal to the master the same as the data length for transfer
- Secure the SSn input setup time (AC spec) from the SSn low-level input to the start of external clock input.
- Control the input on the SSn pin before the start and after the end of data transfer
- When the input level on the SSn pin is to be changed from low to high while a character is being transferred, set the TE and RE bits in the CCR0 register to 0 and, after restoring the settings, restart transfer of the first byte

26.20.11 Notes on Transmit Enable bit (SCR.TE)

In initial register value, when CCR0.TE bit is “0”, the terminal as “TXDn” outputs high impedance.

So please make sure that the TXDn line won’t be high impedance by the following one of ways.

1. The pull-up resistance is connected to the TXDn line.

2.将相关的中断使能位（CCR0.TIE或CCR0.RIE位）设置为0

3.读取相关的中断使能位（CCR0.TIE或CCR0.RIE位），检查它是否真的变为0

4.将ICU中的中断状态标志IELSRn.IR设置为0

26.20.10 简单SPI模式的限制

(1) 主模式

●当CCR0.SSE位为1时，使用电阻上拉或下拉与CCR3.CPHA和CPOL位中设置的传输时钟的初始设置相匹配的时钟线。

这可以防止在CCR0.TE位设置为0时将时钟线置于高阻抗状态或在CCR0.TE位从0变为1时在时钟线上产生意外边沿。SSE位在单主机模式下为0，不需要上拉或下拉时钟线，因为即使SCR.TE位设置为0，时钟线也不会处于高阻状态。

●对于时钟延迟设置（CCR3.CPHA位为1），接收数据满中断（SCIn_RXI）在SCKn引脚的最后一个时钟沿之前产生，如图26.121所示。如果CCR0寄存器中的TE和RE位在SCKn引脚上的时钟信号的最后一个边沿之前变为0，则SCKn引脚处于高阻状态，因此传输时钟的最后一个时钟脉冲的宽度为缩短。此外，SCIn_RXI中断可能会导致所连接从机的SSn引脚上的输入信号在SCKn引脚上的时钟信号的最后一个边沿之前变为高电平，从而导致从机的错误操作。

●在多主机配置中，如果在传输字符时发生模式故障错误，则SCKn引脚输出变为高阻态，而SSn引脚上的输入处于低电平，从而停止向主机提供时钟信号。连接的奴隶。重新启动传输时，重置连接的从机以避免未对齐的位。

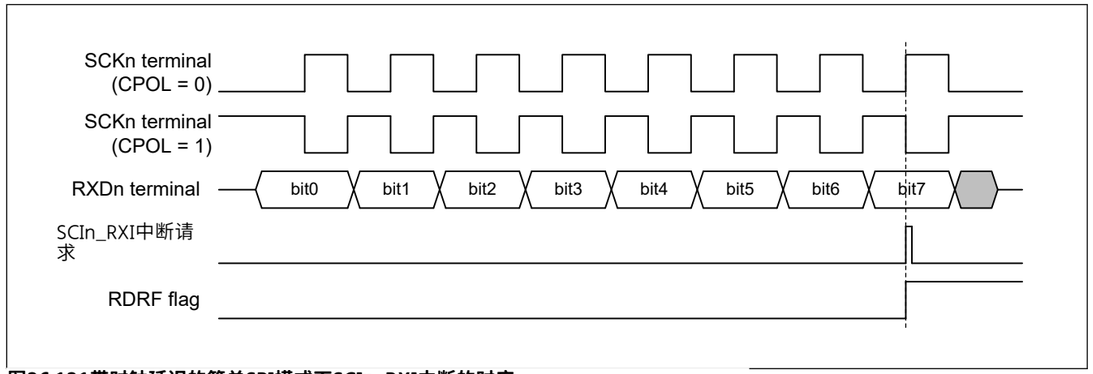

图26.121带时钟延迟的简单SPI模式下SCIn_RXI中断的时序

(2) 从机模式

●从将发送数据写入TDR寄存器到数据输出到RXDn引脚需要1PCLK+同步延迟时间+数据输出延迟时间（AC规格）。在启动外部时钟输入时考虑这些。

●向主机提供与传输数据长度相同的外部时钟信号

●确保从SSn低电平输入到外部时钟输入开始的SSn输入建立时间（AC规格）。

●在数据传输开始前和结束后控制SSn引脚上的输入

●在字符传输过程中，若要将SSn引脚的输入电平从低电平变为高电平，则将CCR0寄存器中的TE和RE位设置为0，并在恢复设置后重新开始传输第一个字节

26.20.11 发送使能位(SCR.TE)的注意事项

在初始寄存器值中，当CCR0.TE位为“0”时，“TXDn”端输出高阻抗。

所以请通过以下方式之一确保TXDn线不会高阻。

1.上拉电阻连接到TXDn线。

2. Before CCR0.TE bit is “0”, the function of the terminal is changed to general-purpose input port or output port. And after CCR0.TE bit is “1”, thr function of the terminal is changed to “TXDn”.
3. In asynchronous mode and Manchester mode, you can set CCR1 and decided level of TXDn terminal during CCR0.TE is “0”.

In the Simple SPI mode slave operation, the RXDn terminal operates in the same way as the above TXDn terminal, so please deal with 1 or 2 in the same way. (3 can not be used.)

26.20.12 Notes on Simple LIN mode

In Simple LIN mode (CCR3.MOD[2:0] = 110), the following functions cannot be used.

- Multi-processor communication function
- Bit Rate Modulation function
- Loopback function
- FIFO buffer

26.20.13 Notes on RS-485 Driver Control function

RS-485 Driver control function is valid only in Asynchronous mode.

When RS-485 Driver control function is active (CCR3.DEN = 1), the CSR.TEND set timing / SCIn_TEI output timing changes as follows. Wait for the SCIn_TEI interrupt and set the CCR0.TE bit in SCI to 0.

When RS-485 Driver control function is inactive: When STOP bit output is completed.

When RS-485 Driver control function is active: At the end of DEn negation time.

26.20.14 Notes on Loopback function

The Loopback function is valid in Asynchronous mode with internal clock, in Manchester mode with internal clock and Clock synchronous mode with internal clock.

26.20.15 Notes regarding register access when operation clock (TCLK) is slower than bus clock (PCLK)

If the operating clock (TCLK) is slower than the bus clock (PCLK), the time until this information is transmitted internally after writing to the CCR0.TE and CCR0.RE registers is slower than the bus access time. In particular, when trying to change the setting register after writing 0 and interrupting communication, do not change the setting register before the signal inside the IP is in the communication stopped state. To prevent this, after setting CCR0.TE and CCR0.RE to 0, check the CESR.TIST and CESR.RIST bits until they are 0 before setting the next register.

26.20.16 Notes on interrupting operation

If 0 is written to CCR0.RE during data reception and the reception operation is interrupted, there is a possibility of an invalid state, so please do not use the received data (RDR register stored value) and the flag value of each status register. To interrupt the reception operation, stop the interrupt or event link reception side and then write 0 to the CCR0.RE bit.

26.20.17 Notes on CCR3.BPEN bit setting

Set the BPEN bit only once when setting the CCR3 register in the SCI initialization flow.

This bit cannot be changed after the initialization.

If you want to change this bit setting, please start from the SCI initialization flow again.

2、在CCR0.TE位为“0”之前，端子功能变为通用输入口或输出口。CCR0.TE位为“1”后，终端的thr功能变为“TXDn”。

3.在异步模式和曼彻斯特模式下，可以设置CCR1和决定CCR0.TE期间TXDn端的电平为“0”。

在SimpleSPI模式从机操作中，RXDn端子与上述TXDn端子的操作方式相同，因此请按相同方式处理1或2。（3个不能用。）

26.20.12 简单LIN模式的注意事项

在简单LIN模式(CCR3.MOD[2:0]=110)下，无法使用以下功能。

●多处理器通讯功能

●比特率调制功能

- Loopback function
- FIFO buffer

26.20.13 RS-485驱动器控制功能注意事项

RS-485驱动器控制功能仅在异步模式下有效。

当RS-485驱动器控制功能激活(CCR3.DEN=1)时，CSR.TEND设置时序SCIn_TEI输出时序变化如下。等待SCIn_TEI中断并将SCI中的CCR0.TE位设置为0。

RS-485驱动器控制功能无效时：STOP位输出完成时。

当RS-485驱动器控制功能激活时：在DEn否定时间结束时。

26.20.14 Loopback功能注意事项

Loopback功能在带内部时钟的异步模式、带内部时钟的曼彻斯特模式和
具有内部时钟的时钟同步模式。

26.20.15 当操作时钟(TCLK)比总线时钟(PCLK)慢时有关寄存器访问的注意事项

如果操作时钟(TCLK)比总线时钟(PCLK)慢，则在写入CCR0.TE和CCR0.RE寄存器之后，直到该信息在内部传输的时间比总线访问时间慢。特别是在写入0并中断通信后尝试更改设置寄存器时，请不要在IP内部的信号处于通信停止状态之前更改设置寄存器。为了防止这种情况发生，在将CCR0.TE和CCR0.RE设置为0后，在设置下一个寄存器之前检查CESR.TIST和CESR.RIST位，直到它们为0。

26.20.16 中断操作注意事项

如果在数据接收过程中向CCR0.RE写入0并中断接收操作，则有可能出现无效状态，因此请不要使用接收到的数据（RDR寄存器存储值）和各状态寄存器的标志值。要中断接收操作，请停止中断或事件链接接收侧，然后将0写入CCR0.RE位。

26.20.17 CCR3.BPEN位设置注意事项

在SCI初始化流程中设置CCR3寄存器时，只需设置一次BPEN位。

该位在初始化后不能更改。

如果要更改此位设置，请重新从SCI初始化流程开始。

31	BUSE	Bus Enable 0: IIC bus operation is disabled. 1: IIC bus operation is enabled.	R/W

BUSE bit (Bus Enable)

Enables or disables the operation on the I^2C Bus by IIC.

Set the BUSE bit to 1 when using IIC. The SCL and SDA pins are placed in the active state when the BUSE bit is set to 1. Set the BUSE bit to 0 when IIC is not to be used. The SCL and SDA pins are placed in the inactive state when the BUSE bit is set to 0.

If the software sets this bit, then it also confirms that initialization is done, and that IIC can use the programmed register values.

Software may disable IIC bus operation while it is active, However:

- When the software reads the value 0 from this field, this indicates that IIC bus operation disable operation has completed.

27.2.3 RSTCTL : Reset Control Register

31	BUSE	总线启用 0：IIC总线操作禁用。1：IIC总线操作使能。	R/W

BUSE bit (Bus Enable)

通过IIC启用或禁用I2C总线上的操作。

使用IIC时将BUSE位设置为1。当BUSE位设置为1时，SCL和SDA引脚处于活动状态。
不使用IIC时将BUSE位设置为0。当BUSE位设置为0时，SCL和SDA引脚处于无效状态。

如果软件设置了这个位，那么它也确认初始化已经完成，并且IIC可以使用编程的寄存器值。

软件可能会在IIC总线处于活动状态时禁用它，但是：

●当软件从该字段读取值0时，表示IIC总线操作禁用操作已完成。

27.2.3 RSTCTL:复位控制寄存器

For details on reset for each register, see section 27.6. Reset Descriptions.

RI2CRST bit (IIC Software Reset)

On Driver setting this bit to 1, IIC shall be reset and disabled.

All registers shall return to their reset values, and the software shall re-initialize IIC.

This field is cleared automatically upon IIC reset completion. This field also resets all Queues in IIC.

Note: Programming this field while it contains a value of 1 may result in undefined behavior.

CRMS bit (Current Master)

表示各操作模式的设置条件和复位条件。

[Clearing conditions]

- When 0 written to the PRSST.CRMS by the software.
- When STOP is issued.
- When Master Arbitration-Lost.

[Setting conditions]

- When 1 written to the PRSST.CRMS by the software.
- When START is issued.

The PRSST register returns IIC current state.

State has two parts: this register which is mandatory, and an additional optional PRSST_DEBUG register intended for debug purposes (see the Debug Capability registers in the Extended Capabilities list).

TRMD bit (Transmit/Receive Mode)

This bit indicates transmit or receive mode.

IIC is in receive mode when the TRMD bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the CRMS bit indicates the operating mode of IIC.

The value of TRMD bit is automatically changed to 1 for transmit mode or 0 for receive mode by issuing or detection of a START condition and setting of the R/W# bit.

[Setting conditions]

- When a START condition is issued normally according to the START condition issuance request (when a START condition is detected with the CNDCTL.STCND bit set to 1).
- When a Repeated START condition is issued normally according to the Repeated START condition issuance request (when a Repeated START condition is detected with the CNDCTL.SRCND bit set to 1).
- When the R/W# bit added to the slave address is set to 0 in master mode.
- When the address received in slave mode matches the address enabled in SVCTL, with the R/W# bit set to 1.

[Clearing conditions]

- When a STOP condition is detected.
- The ALF (arbitration-lost) flag in BST being set to 1.
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended.
- In slave mode, a match between the received address and the address enabled in SVCTL when the value of the received R/W# bit is 0 (including cases where the received address is the general call address).
- In slave mode, a Repeated START condition is detected (a Repeated START condition is detected with BCST.BFREF = 0 and CRMS = 0).

PRSSTWP bit (Present State Write Protect)

PRSSTWP is always 0 when reading.

When writing to PRSST, writing 1 to this bit at the same time enables writing to CRMS bit.

●当软件向PRSST.CRMS写入0时。

●发出STOP时。

●当主仲裁失败时。

[Setting conditions]

●当1被软件写入PRSST.CRMS时。

●发出START时。

PRSST寄存器返回IIC当前状态。

状态有两个部分：该寄存器是强制性的，以及一个额外的可选PRSST_DEBUG寄存器，用于调试目的（请参阅扩展功能列表中的调试功能寄存器）。

TRMD bit (Transmit/Receive Mode)

该位指示发送或接收模式。

当TRMD位设置为0时，IIC处于接收模式，而当该位设置为1时，IIC处于发送模式。该位和CRMS位的组合表示IIC的工作模式。

TRMD位的值自动更改为1（发送模式）或0（接收模式）通过发出或检测到START条件和RW#位的设置。

[Setting conditions]

●根据START条件发出请求正常发出START条件时（当CNDCTL.STCND位设置为1时检测到START条件时）。

●当根据重复启动条件发出请求正常发出重复启动条件时（当CNDCTL.SRCND位设置为1时检测到重复启动条件）。

●在主机模式下，添加到从机地址的RW#位设置为0时。

●从机模式接收到的地址与SVCTL中使能的地址匹配时，RW#位设置为1。

[Clearing conditions]

●检测到停止条件时。

●BST中的ALF（仲裁失败）标志设置为1。

●在主机模式下，接收附加了值为1的RW#位的从机地址。

●从机模式下，当接收到的RW#位的值为0时，接收到的地址与SVCTL中使能的地址匹配（包括接收到的地址是广播地址的情况）。

●在从模式下，检测到重复启动条件（在BCST.BFREF=0和CRMS=0时检测到重复启动条件）。

PRSSTWP位（当前状态写保护）

读取时PRSSTWP始终为0。

写入PRSST时，同时向该位写入1可以写入CRMS位。

MALE bit (Master Arbitration-Lost Detection Enable)

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

MALE位（主仲裁丢失检测使能）

该位用于指定主机模式下是否使用仲裁丢失检测功能。通常，将此位设置为1。

NALE位（NACK传输仲裁丢失检测使能）

该位用于指定在接收模式下发送NACK过程中检测到ACK时是否导致仲裁丢失（例如总线上存在具有相同地址的从设备时，或者当两个或多个主设备同时选择同一个从设备时）不同数量的接收字节）。

SALE bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

SCSYNE bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCSYNE bit set to 0 (no SCL synchronous circuit used), IIC does not synchronize the SCL clock with the SCL input clock. In this setting, IIC outputs the SCL clock with the transfer rate set in STDBR and EXTBR regardless of the SCLn line state. For this reason, if the bus load of the I^2C bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output. When no SCL synchronous circuit uses, it also affects the issuance of a START condition, Repeated START condition, and STOP condition, and the continuous output of extra SCL clock cycles.

This bit must not be set to 0 except for checking the output of the set transfer rate.

FMPE bit (Fast-mode Plus Enable)

This bit is used to specify whether to use a slope control circuit for Fast-mode Plus [Fm+].

When this bit is set to 1, a slope control circuit conforming to the Fast-mode Plus [Fm+] slope control specification (tof) of the IIC-bus is selected. When this bit is set to 0, a slope control circuit conforming to the Standard-mode [Sm] and Fast-mode [fm] slope control specification (tof) of the IIC-bus is selected.

Set this bit to 1 when using the transmission rate within a range up to 1 Mbps (Fast-mode Plus [Fm+]) of the IIC-bus specification. Set this bit to 0 when using the transmission rate at other rates (up to 100 kbps [Sm], up to 400 kbps [Fm]) or for SMBus (10 to 100 kbps).

Note: When communicating in Hs-mode, set as follows.
- Set FMPE to 0 when sending Hs-mode master code (0000 1XXXb) with Fast-mode.
- Set FMPE to 1 when sending Hs-mode master code (0000 1XXXb) with Fast-mode Plus.

HSME bit (High Speed Mode Enable)

This bit is used for communicating in Hs-mode.

When this bit is set to 1, the Hs-mode master code is recognized and Hs-mode communication is possible.

After the START condition is detected, if Hs-mode master code (0000 1XXXb) transmission is recognized, Hs-mode communication starts from Repeated START after receiving the NACK response.

It communicates at the bit rate set in STDBR until the NACK response, and automatically switches from Repeated START condition issuance after receiving the NACK response to the bit rate set in EXTBR.

Hs-mode continues until a STOP condition is detected.

When the STOP condition is detected, the bit rate is automatically switched to the bit rate set in STDBR.

Note: When this bit is set to 1, the BST.NACKDF bit will not be set even if a NACK response is received after sending the Hs-mode master code.

SALE位（从设备仲裁丢失检测使能）

该位用于指定在从机发送模式下，当在总线上检测到与正在发送的值不同的值时（例如，当总线上存在具有相同地址的从机或与发送的值不匹配时，是否导致仲裁丢失由于噪声而发生传输数据）。

SCSYNE位（SCL同步电路使能）

该位用于指定是否将SCL时钟与SCL输入时钟同步。通常，将此位设置为1。

当SCSYNE位设置为0（不使用SCL同步电路）时，IIC不会将SCL时钟与SCL输入时钟同步。在此设置中，IIC以STDBR和EXTBR中设置的传输速率输出SCL时钟，而与SCLn线路状态无关。因此，如果I2C总线的总线负载远大于规格值，或者多个主机的SCL时钟输出重叠，则可能会输出不符合规格的短周期SCL时钟。当没有使用SCL同步电路时，它也会影响START条件、RepeatedSTART条件和

STOP条件，以及额外SCL时钟周期的连续输出。

该位不得设置为0，除非检查设置的传输速率的输出。

FMPE位（Fast-modePlusEnable）

该位用于指定是否对Fast-modePlus[Fm+]使用斜率控制电路。

当该位设置为1时，选择符合IIC总线的Fast-modePlus[Fm+]斜率控制规范(tof)的斜率控制电路。当该位设置为0时，选择符合IIC总线的标准模式[Sm]和快速模式[fm]斜率控制规范(tof)的斜率控制电路。

使用IIC总线规范的高达1Mbps(Fast-modePlus[Fm+])范围内的传输速率时，将此位设置为1。当使用其他速率（最高100kbps[Sm]、最高400kbps[Fm]）或SMBus（10至100kbps）的传输速率时，将此位设置为0。

Note: 在Hs模式下通信时，设置如下。●使用Fast-mode发送Hs-modemastercode(00001XXXb)时将FMPE设置为0。●使用Fast-modePlus发送Hs-mode主码(00001XXXb)时，将FMPE设置为1。

HSME位（高速模式启用）

该位用于在Hs模式下进行通信。

当该位设置为1时，识别Hs模式主代码并且可以进行Hs模式通信。

检测到START条件后，如果识别到Hs-mode主码(00001XXXb)传输，则Hs-mode通信在收到NACK响应后从重复START开始。

在收到NACK响应之前，它以STDBR中设置的比特率进行通信，并在收到NACK响应后自动从重复启动条件发出切换到EXTBR中设置的比特率。

Hs模式一直持续到检测到STOP条件。

当检测到STOP条件时，比特率自动切换到STDBR中设置的比特率。

Note: 当该位设置为1时，即使在发送后收到NACK响应，BST.NACKDF位也不会设置Hs-mode主码。

Note 1. The Hs-mode Master Code Enable bit (HSMCE) is supported by IIC0 (SCL0_A, SDA0_A). Bit[5] is the reserved bit in the not suported channel.

GCAE bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address (0000 000 + 0 (write): All 0) when it is received. When this bit is set to 1, if the received slave address matches the general call address, IIC recognizes the received slave address as the general call address independently of the slave addresses set in the SVDVADy.SVAD[9:0] bits (y = 0 to 2) and performs data receive operation.

When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

HSMCE bit (Hs-mode Master Code Enable)

This bit is used to specify whether to recognize and execute the Hs-mode master code (0000 1XXXb) is received in the first byte after a START condition is detected.

When this bit is set to 1, if the received first byte matches the Hs-mode master code, IIC recognizes that the Hs-mode master code has been received.

注1.IIC0(SCL0_A SDA0_A)支持Hs模式主代码使能位(HSMCE)。Bit[5]是不支持通道中的保留位。

GCAE位（广播呼叫地址使能）

该位用于指定接收到的广播调用地址（0000000+0（写）：全0）是否忽略。当该位设置为1时，如果接收到的从机地址与广播呼叫地址匹配，IIC将接收到的从机地址识别为广播呼叫地址，独立于SVDVADy.SVAD[9:0]位中设置的从机地址（y=0到2)并执行数据接收操作。

当该位设置为0时，即使接收到的从机地址与广播呼叫地址匹配，也会忽略它。

HSMCE位（Hs模式主码启用）

该位用于指定在检测到START条件后的第一个字节中是否识别和执行Hs模式主代码（00001XXXb）。

当该位设置为1时，如果接收到的第一个字节与Hs模式主代码匹配，则IIC识别已接收到Hs模式主代码。

The first byte after Repeated START after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set by SVDVADy.SVAD[9:0].

If the addresses match, the transmission / reception operation continues according to the R/W# bit value.

Hs-mode continues until a STOP condition is detected.

When this bit is set to 0, IIC will ignore the pattern until a STOP condition is detected, even if it matches the Hs-mode master code.

Note: When this bit is set to 1, SCSTRCTL.ACKTWE bit must be set to 0 and SCSTRCTL.RWE bit must be set to 1.

DVIDE bit (Device-ID Address Enable)

This bit is used to specify whether to recognize and execute the Device-ID address when a device ID (1111 100) is received in the first byte after a START condition or Repeated START condition is detected.

When this bit is set to 1, if the received first byte matches the Device-ID, IIC recognizes that the Device-ID address has been received. When the following R/W# bit is 0 (write), IIC recognizes the second and the following bytes as slave addresses and continues the receive operation.

When this bit is set to 0, IIC ignores the received first byte even if it matches the Device ID address and recognizes the first byte as a normal slave address.

For details on the Device-ID address detection, see (3)Device-ID Address Detection .

HOAE bit (Host Address Enable)

This bit is used to specify whether to ignore received host address (0001 000) when the BFCTL.SMBS bit = 1.

When this bit is set to 1 while the SMBS bit = 1, if the received slave address matches the host address, IIC recognizes the received slave address as the host address independently of the slave addresses set in the SVDVADy.SVAD[9:0] bits (y = 0 to 2) and performs the receive operation.

When the SMBS bit or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

SVAEy bits (Slave Address Enable y (y = 0 to 2))

This bit is used to enable or disable the slave address set in the SVDVADy.SVAD[9:0] bits.

When this bit is set to 1, the slave address set in the SVAD[9:0] bits is enabled and is compared with the received slave address.

When this bit is set to 0, the slave address set in the SVAD[9:0] bits is disabled and is ignored even if it matches the received slave address.

27.2.7 REFCKCTL : Reference Clock Control Register

NACK响应Hs模式主机代码后重复START后的第一个字节被识别为从机地址，并与SVDVADy.SVAD[9:0]设置的从机地址进行比较。

如果地址匹配，则根据RW#位值继续发送接收操作。

Hs模式一直持续到检测到STOP条件。

当该位设置为0时，IIC将忽略该模式，直到检测到STOP条件，即使它与Hs模式主代码匹配。

Note: 当该位设置为1时，SCSTRCTL.ACKTWE位必须设置为0，SCSTRCTL.RWE位必须设置为1。

DVIDE位（设备ID地址启用）

该位用于指定在检测到START条件或重复START条件后的第一个字节中接收到设备ID(1111100)时是否识别和执行设备ID地址。

当该位设置为1时，如果接收到的第一个字节与Device-ID匹配，则IIC识别出已接收到Device-ID地址。当后面的RW#位为0（写）时，IIC将第二个和后面的字节识别为从地址并继续接收操作。

当该位设置为0时，IIC忽略接收到的第一个字节，即使它与设备ID地址匹配，并将第一个字节识别为正常的从地址。

关于Device-ID地址检测的详细信息，请参见（3）Device-ID地址检测。

HOAE位（主机地址使能）

该位用于指定当BFCTL.SMBS位=1时是否忽略接收到的主机地址(0001000)。

当该位设置为1且SMBS位=1时，如果接收到的从机地址与主机地址匹配，IIC将接收到的从机地址识别为主机地址，而与SVDVADy.SVAD[9:0]中设置的从机地址无关位（y=0到2）并执行接收操作。

当SMBS位或HOAE位设置为0时，即使接收到的从机地址与主机地址匹配，它也会被忽略。

SVAEy位（从地址启用y（y=0到2））

该位用于启用或禁用SVDVADy.SVAD[9:0]位中设置的从机地址。

当该位设置为1时，SVAD[9:0]位中设置的从机地址被启用，并与接收到的从机地址进行比较。

当该位设置为0时，在SVAD[9:0]位中设置的从地址被禁用并被忽略，即使它与接收到的从地址匹配。

The STDBR register sets the bit rate according to the operating speed (Standard-mode / Fast-mode / Fast-mode plus).

The I²C transfer rate and the SCL clock duty are calculated using the following expression.

Transfer rate = 1 / {[(High-Level Period + α*1) + (Low-Level Period + α)] / IICφ*2 + SCLn line rising time [tr]*3 + SCLn line falling time [tf]*3}

Duty cycle = {SCLn line rising time [tr] + (High-Level Period + α) / IICφ} / {SCLn line falling time [tf] + (Low- Level Period + α) / IICφ}

Note 1. α depend on the number of stages in the noise filter.
Note 2. IICφ = TCLK × Division ratio
Note 3. The SCLn line rising time [tr] and SCLn line falling time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, see the I²C-bus specification from NXP Semiconductors.

SBRLO[7:0] bits (Count value of the Low-level period of SCL clock)

The SBRLO[7:0] bits are used to set the low-level period of SCL clock in Open-Drain mode.

IIC counts the low-level period with the internal reference clock source (IICφ) specified by the REFCKCTL.IREFCKS[2:0] bits. It also works to generate the data setup time for automatic SCL low-hold operation (see section 27.3.1.3.5. Clock Stretching); when IIC is used in I²C slave mode, these bits need to be set to a value longer than the data setup time*1.

If the digital noise filter is enabled (INCTL.DNFE = 1), set the SBRLO[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

STDBR寄存器根据运行速度（标准模式快速模式加快速模式）设置比特率。

I2C传输速率和SCL时钟占空比使用以下表达式计算。

传输速率=1{[(High-LevelPeriod+α*1)+(Low-LevelPeriod+α)]IICφ*2+SCLn线上升时间[tr]*3+SCLn线下降时间[tf]*3

占空比={SCLn线路上升时间[tr]+(High-LevelPeriod+α)IICφ {SCLn线路下降时间[tf]+(LowLevelPeriod+α)IICφ

注1.α取决于噪声滤波器的级数。
注2.IICφ=TCLK×分频比
注3.SCLn线上升时间[tr]和SCLn线下降时间[tf]取决于总总线电容[Cb]和上拉电阻[Rp]。有关详细信息，请参阅NXPSemiconductors的I2C总线规范。

SBRLO[7:0]位（SCL时钟低电平周期的计数值）

SBRLO[7:0]位用于设置开漏模式下SCL时钟的低电平周期。

IIC使用REFCKCTL.IREFCKS[2:0]位指定的内部参考时钟源(IICφ)计算低电平周期。它还可以为自动SCL低保持操作生成数据建立时间（参见第27.3.1.3.5节。时钟拉伸）；在I2C从机模式下使用IIC时，需要将这些位设置为比数据建立时间长*1的值。

如果启用了数字噪声滤波器(INCTL.DNFE=1)，请将SBRLO[7:0]位设置为至少比噪声滤波器中的级数大1的值。关于噪声滤波器的级数，请参见INCTL.DNFS[3:0]位的说明。

10 ns (up to 3.4 Mbps: Hs-mode [HS])

SBRHO[7:0] bits (Count value of the High-level period of SCL clock)

The SBRHO[7:0] bits use to set the high-level period of SCL clock in Open-Drain mode. SBRHO[7:0] bits are valid in master mode. If IIC is used only in I2C slave mode, these bits need not to set the highlevel period.

IIC counts the high-level period with the internal reference clock source (IICφ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1), set the SBRHO[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

DSBRPO bit (Double the Standard Bit Rate Period for Open-Drain)

When DSBRPO = 1, double the high-level period that is set in SBRHO[7:0] and double the low-level period that is set in SBRLO[7:0].

Note 1. The setting SDODCS = 1 (IICφ/2) only becomes valid when SCL is at the low level. When SCL is at the high level, the setting SDODCS = 1 becomes invalid and the clock source becomes the internal reference clock (IICφ).

SDOC bit (SDA Output Control) and SCOC bit (SCL Output Control)

These bits are used to directly control the SDAn and SCLn signals output from this module.

When writing to these bits, also write 1 to the SOCWP bit at the same time.

The result of setting these bits is input to IIC via the input buffer. When slave mode is selected, a START condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a START condition, STOP condition, Repeated START condition, or during transmission or reception. Operation after rewriting under the above conditions is not guaranteed.

EXCYC bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.

Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.

For details on this function, see section 27.3.1.3.6. Port Control , (1)Extra SCL Clock Cycle Output Function.

注1.设置SDODCS=1(IICφ2)仅在SCL为低电平时有效。当SCL为高电平时，设置SDODCS=1无效，时钟源变为内部参考时钟(IICφ)。

SDOC位（SDA输出控制）和SCOC位（SCL输出控制）

这些位用于直接控制从该模块输出的SDAn和SCLn信号。

写入这些位时，也要同时向SOCWP位写入1。

设置这些位的结果通过输入缓冲器输入到IIC。Whenslavemodeisselected aSTARTconditionmaybedetectedandthebusmaybereleaseddependingonthebitsettings.

请勿在START条件、STOP条件、重复START条件或发送或接收期间重写这些位。不保证在上述条件下重写后的操作。

EXCYC位（额外SCL时钟周期输出）

该位用于输出额外的SCL时钟周期，用于调试或错误处理。

通常将该位设置为0。在正常通信状态下将该位设置为1会导致通信错误。

有关此功能的详细信息，请参见第27.3.1.3.6节。端口控制，（1）额外的SCL时钟周期输出功能。

DNFS[3:0] bits (Digital Noise Filter Stage Selection)

These bits are used to select the number of stages in the digital noise filter.

For details on the digital noise filter function, see section 27.3.1.6.3. Digital Noise-Filter Circuits .

In I^2C High Speed mode, the module changes the number of noise filter stage to a quarter of the number of noise filter stage automatically.

Note:
- Set the noise range to be filtered out by the noise filter within a range less than the SCLn line high-level period or low-level period. If the noise range is set to a value of (SCL clock width: high-level period or lowlevel period, whichever is shorter) - [1.5 internal reference clock (IICφ) cycles] or more, the SCL clock is regarded as noise by the noise filter function of IIC, which may prevent IIC from operating normally.
- In I^2C High Speed mode, the lower 2 bits of the DNFS [3:0] bits are ignored, and the number of filter stages for 1 to 4 stages is selected by the upper 2 bits.

DNFS[3:0]位（数字噪声滤波器级选择）

这些位用于选择数字噪声滤波器的级数。

有关数字噪声滤波器功能的详细信息，请参阅第27.3.1.6.3节。数字噪声滤波器电路。

在I2C高速模式下，模块自动将噪声滤波器级数更改为噪声滤波器级数的四分之一。

Note:
- ●将噪声滤波器滤除的噪声范围设置在小于SCLn线高电平周期或低电平周期的范围内。如果噪声范围设置为（SCL时钟宽度：高电平周期或低电平周期，以较短者为准）[1.5个内部参考时钟(IICφ)周期]或更大的值，则SCL时钟被噪声视为噪声IIC的过滤功能，可能会导致IIC无法正常工作。
- ●在I2C高速模式下，DNFS[3:0]位的低2位被忽略，1到4级的滤波器级数由高2位选择。

TODTS[1:0] bits (Timeout Detection Time Selection)

These bits are used to select for the timeout detection time when the timeout function is enabled (BSTE.TODE bit = 1).

When these bits are set to 00b, the timeout detection internal counter functions as a 16-bit counter.

When these bits are set to 01b, the counter functions as a 14-bit counter.

When these bits are set to 10b, the counter functions as a 8-bit counter.

When these bits are set to 11b, the counter functions as a 6-bit counter.

While the SCLn line is in the state that enables this counter as specified by bits TOHCTL and TOLCTL, the counter counts up in synchronization with the internal reference clock (IICφ) as a count source.

For details on the timeout function, see section 27.3.1.4.1. Timeout Error Detection .

TOLCTL bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCLn line is held low when the timeout function is enabled (BSTE.TODE = 1).

TOHCTL bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCLn line is held high when the timeout function is enabled (BSTE.TODE = 1).

当这些位设置为01b时，计数器用作14位计数器。

当这些位设置为10b时，计数器用作8位计数器。

当SCLn线处于启用由位TOHCTL和TOLCTL指定的该计数器的状态时，计数器与作为计数源的内部参考时钟(IICφ)同步计数。

超时功能详见27.3.1.4.1节。超时错误检测。

31:2	—	These bits are read as 0. The write value should be 0.	R/W

ACKTWE bit (Acknowledge Transmission Wait Enable)

This bit is used to select the NTST.RDBFF0 flag set timing in receive mode and also to select whether to hold the SCLn line low at the falling edge of the eighth SCL clock cycle.

When ACKTWE = 0, the SCLn line is not held low at the falling edge of the eighth SCL clock cycle, and the NTST.RDBFF0 flag is set to 1 at the rising edge of the ninth SCL clock cycle.

When ACKTWE = 1, the NTST.RDBFF0 flag is set to 1 at the rising edge of the eighth SCL clock cycle and the SCLn line is held low at the falling edge of the eighth SCL clock cycle. The low-hold of the SCLn line is released by writing a value to the ACKCTL.ACKT bit.

After data is received with this setting, the SCLn line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKCTL.ACKT = 0) or NACK (ACKCTL.ACKT = 1) according to receive data.

●向ACKT位写入1和向ACKTWP位同时写入1时。

[Clearing conditions]

●当0被写入ACKT位和1被同时写入ACKTWP位时。

Note: 在I2C从模式下将ACKT位设置为0。

31:2	—	这些位被读取为0。写入值应为0。	R/W

ACKTWE位（确认发送等待使能）

该位用于选择接收模式下的NTST.RDBFF0标志设置时序，也用于选择是否在第8个SCL时钟周期的下降沿保持SCLn线为低电平。

当ACKTWE=0时，SCLn线在第8个SCL时钟周期的下降沿不保持低电平，并且NTST.RDBFF0标志在第9个SCL时钟周期的上升沿设置为1。

当ACKTWE=1时，NTST.RDBFF0标志在第8个SCL时钟周期的上升沿设置为1，并且SCLn线在第8个SCL时钟周期的下降沿保持低电平。SCLn线的低保持通过向ACKCTL.ACKT位写入一个值来释放。

使用此设置接收数据后，SCLn线在发送确认位之前自动保持低电平。这使得处理能够根据接收数据发送ACK(ACKCTL.ACKT=0)或NACK(ACKCTL.ACKT=1)。

RWE bit (Receive Wait Enable)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the receive data buffer (NTDTBP0) is completely read each time single-byte data is received in receive mode.

When RWE = 0, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the ACKTWE and RWE bits = 0, continuous receive operation is enabled with the double buffer.

When RWE = 1, the SCLn line is held low from the falling edge of the ninth clock cycle until the NTDTBP0 value is read each time single-byte data is received.

This enables receive operation in byte units.

Note: When the value of the RWE bit is to be read, be sure to read the NTDTBP0 beforehand.

STCND bit (START (S) Condition Issuance)

This bit is used to request transition to master mode and issuance of a START condition.

For details on the START condition issuance, see section 27.3.1.3.2. START Condition / Repeated START Condition / STOP Condition Issuing Function .

[Setting condition]

- When 1 is written to the STCND bit

[Clearing conditions]

- When a START condition has been issued (A START condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1

Note: Set the STCND bit to 1 (START condition issuance request) when the BCST.BFREF flag is set to 1 (bus free state).
Note that arbitration may be lost due to a START condition issuance error if the STCND bit is set to 1 (START condition issuance request) when the BFREF flag is set to 0 (bus busy state).

RWE位（接收等待使能）

该位用于控制在接收模式下每次接收单字节数据时，是否将第9个SCL时钟周期和第一个SCL时钟周期之间的周期保持为低电平，直到接收数据缓冲区(NTDTBP0)被完全读取。

当RWE=0时，继续接收操作，而不会将第9个和第一个SCL时钟周期之间的周期保持为低电平。当ACKTWE和RWE位都=0时，双缓冲器使能连续接收操作。

当RWE=1时，SCLn线从第9个时钟周期的下降沿保持低电平，直到每次接收到单字节数据时读取NTDTBP0值。

这启用了以字节为单位的接收操作。

Note: 当要读取RWE位的值时，请务必事先读取NTDTBP0。

31:0	n/a	Normal Transfer Data Buffer Port NTDTBP0 is a 32-bit read/write register. NTDTBP0_BY (NTDTBP0[7:0]) is a 8-bit read/write register.	R/W

32-bit mailbox register NTDTBP0 is a 32-bit bi-directional data transfer register which is used both to read from the Normal Receive Data Buffer, and to write to the Normal Transmit Data Buffer.

In other words, the Normal Receive Data Buffer and the Normal Transmit Data Buffer have the same offset, forming a single bidirectional port for transmitting or receiving IIC data.

Read Operations:

When 1 byte of data has been received, the received data is transferred from the internal shift register to NTDTBP0 to enable the next data to be received. The double-buffer structure of the internal shift register and NTDTBP0 allows continuous receive operation if the received data has been read from NTDTBP0 while the internal shift register is receiving data. Read data from NTDTBP0 once when a receive data full interrupt (IICn_RX) request is generated. If NTDTBP0 receives the next receive data before the current data is read from NTDTBP0 (while the RDBFF0 flag in NTST is 1), this module automatically holds the SCL clock low one cycle before the RDBFF0 flag is set to 1 next. The lower 8 bits of the read 32-bit data are valid as received data.

Write Operations:

When NTDTBP0 detects a space in the internal shift register, it transfers the transmit data that has been written to NTDTBP0 to the internal shift register and starts transmitting data in transmit mode. The double-buffer structure of NTDTBP0 and the internal shift register allows continuous transmit operation if the next transmit data has been written to NTDTBP0 while the the internal shift register data is being transmitted. Write transmit data to NTDTBP0 once when a transmit data empty interrupt (IICn_TX) request is generated. The lower 8 bits of the written 32-bit data are valid as transmission data.

Read Operations:

当接收到1个字节的数据时，接收到的数据会从内部移位寄存器传送到NTDTBP0，以便接收下一个数据。内部移位寄存器和NTDTBP0的双缓冲结构允许在内部移位寄存器接收数据时从NTDTBP0读取接收到的数据时连续接收操作。当产生接收数据完全中断(IICn_RX)请求时，从NTDTBP0读取数据一次。如果NTDTBP0在从NTDTBP0读取当前数据之前接收到下一个接收数据（而NTST中的RDBFF0标志为1），则该模块在RDBFF0标志设置为1之前自动将SCL时钟保持低一个周期。读取的32位数据的低8位作为接收数据有效。

4. When the received slave address matches while the TRMD bit = 1.

[Clearing condition]

- When data is written to NTDTBP0.
- When the TRMD bit in PRSST is set to 0.

Note 1. When the BST.NACKDF flag is set to 1 while the BSTE.NACKDE bit = 1, IIC aborts data transmission/reception. If the TDBEF0 flag = 0 (next transmit data has been written), data is transferred to the Shift Register and the Normal Transmit Data Buffer 0 register becomes empty at the rising edge of the 9th clock cycle, but the TDBEF0 flag is not set to 1.

1. The NTSTE.RDBFE0 bit = 1 (enables Rx0 Data Buffer Full Interrupt Status logging).
2. When receive data is transferred from Shift Register to Normal Receive Data Buffer 0.
   The RDBFF0 flag is set to 1 on the rising edge of the 8th or 9th SCL clock cycle (selected in the ACKTWE bit in SCSTRCTL).
3. When the received slave address matches after a START (or Repeated START) condition is detected with the TRMD bit in PRSST set to 0.

[Clearing condition]

- When data is read from NTDTBP0.

27.3 Operation

27.3.1 功能详情

27.3.1.1 操作模式

IIC有2种操作模式，即主模式操作和从模式操作。

27.3.1.1.1 Master Mode Operation

(1) I2C Master Operation

(a) Data Write Transfer (Single Buffer transfer)

In master transmit operation, IIC outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 27.47 shows an example of usage of master transmission and Figure 27.2 to Figure 27.4 show the timing of operations in master transmission.

The following describes the procedure and operations for master transmission.

1. Initial settings. For details, see section 27.3.2.1. Initial Setting Flow.
2. Read the BCST.BFREF flag to check that the bus is open, and then set the CNDCTL.STCND bit to 1 (START condition issuance request). Upon receiving the request, IIC issues a START condition. At the same time, the BFREF flag bit is automatically set to 0, the BST.STCNDDF flag is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the SDAn line have matched while the STCND bit = 1, IIC recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and bits CRMS and TRMD in the PRSST register are automatically set to 1, placing IIC in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
3. Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the slave address and the R/W# bit) to the NTDTBP0 register. Once the data for transmission are written to the NTDTBP0 register, the TDBEF0 flag is automatically set to 0, the data are transferred from the Normal Transmit Data Buffer 0 to the Shift Register, and the TDBEF0 flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRMD bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, IIC continues in master transmit mode. Because the BST.NACKDF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the CNDCTL.SPCND bit to issue a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1111 0, the 2 higher-order bits of the slave address, and W to the NTDTBP0 register as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to the NTDTBP0 register.
4. After confirming that the NTST.TDBEF0 flag = 1, write the data for transmission to the NTDTBP0 register. IIC automatically holds the SCLn line low until the data for transmission are ready or a STOP condition is issued.
5. After all bytes of data for transmission have been written to the NTDTBP0 register, wait until the value of the BST.TENDF flag returns to 1, and then set the CNDCTL.SPCND bit to 1 (STOP condition issuance request). Upon receiving a STOP condition issuance request, IIC issues the STOP condition.
6. Upon detecting the STOP condition, IIC automatically sets bits CRMS and TRMD in the PRSST register to 00 and enters slave receive mode. Furthermore, it automatically sets the TDBEF0 and TENDF flags to 0, and sets the BST.SPCNDDF flag to 1.
7. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

27.3.1.1.1 主模式操作

(1) I2C主操作

(a)数据写入传输（单缓冲区传输）

在主设备发送操作中，IIC作为主设备输出SCL时钟和发送的数据信号，从设备返回确认。图27.47显示了主传输的使用示例，图27.2至图27.4显示了主传输中的操作时序。

下面介绍主传输的步骤和操作。

1.初始设置。详见27.3.2.1节。初始设定流程。

2.读取BCST.BFREF标志以检查总线是否打开，然后将CNDCTL.STCND位设置为1（开始条件发出请求）。收到请求后，IIC发出START条件。同时，BFREF标志位自动置0，BST.STCNDDF标志位自动置1，STCND位自动置0。此时，如果检测到START条件且内部电平为当SDA输出状态和SDAn线上的电平匹配时，STCND位=1，IIC识别出由STCND位请求的START条件的发布已成功完成，并且PRSST寄存器中的CRMS和TRMD位自动设置为1，将IIC置于主机发送模式。响应TRMD位设置为1，NTST.TDBEF0标志也自动设置为1。

3.检查NTST.TDBEF0标志=1，然后将传输值（从机地址和RW#位）写入NTDTBP0寄存器。一旦要发送的数据写入NTDTBP0寄存器，TDBEF0标志自动设置为0，数据从正常发送数据缓冲区0传输到移位寄存器，并且TDBEF0标志再次设置为1。如果包含从机地址和RW#位已发送，则TRMD位的值会自动更新，以根据发送的RW#位的值选择主机发送或主机接收模式。如果RW#位的值为0，IIC继续在主机发送模式。由于此时BST.NACKDF标志为1表示没有从设备识别该地址或通信中存在错误，因此向CNDCTL.SPCND位写入1以发出STOP条件。对于地址为10位格式的数据传输，首先将11110、从机地址的高2位和W写入NTDTBP0寄存器作为第一个地址传输。然后，作为第二次地址传输，将从机地址的低8位写入NTDTBP0寄存器。

4.确认NTST.TDBEF0标志=1后，将要发送的数据写入NTDTBP0寄存器。IIC自动将SCLn线保持为低电平，直到传输数据准备好或发出STOP条件。

5.待传输数据的所有字节写入NTDTBP0寄存器后，等待
BST.TENDF标志返回1，然后将CNDCTL.SPCND位设置为1（发出停止条件请求）。IIC收到STOP条件发布请求后，发布STOP条件。

6.检测到STOP条件后，IIC自动将PRSST寄存器中的CRMS和TRMD位设置为00，并进入从机接收模式。此外，它自动将TDBEF0和TENDF标志设置为0，并将BST.SPCNDF标志设置为1。

7.检查BST.SPNCDDF标志=1后，将BST.NACKDF和SPCNDDF标志设置为0以进行下一次传输操作。

(b) Data Read Transfer (Single Buffer transfer)

In master receive operation, IIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because IIC must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 27.48 and Figure 27.49 show examples of usage of master reception (7-bit address format) and Figure 27.5 to Figure 27.7 show the timing of operations in master reception.

The following describes the procedure and operations for master reception.

1. Initial settings. For details, see section 27.3.2.1. Initial Setting Flow.
2. Read the BCST.BFREF flag to check that the bus is open, and then set the CNDCTL.STCND bit to 1 (START condition issuance request). Upon receiving the request, IIC issues a START condition. When IIC detects the START condition, the BFREF flag is automatically set to 0 and the BST.STCNDDF flag is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the levels for the SDA output and the levels on the SDAn line have matched while the STCND bit = 1, IIC recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and bits CRMS and TRMD in the PRSST register are automatically set to 1, placing IIC in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
3. Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to the NTDTBP0 register. Once the data for transmission are written to the NTDTBP0 register, the TDBEF0 flag is automatically set to 0, the data are transferred from the Normal Transmit Data Buffer 0 to the Shift Register, and the TDBEF0 flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the PRSST.TRMD bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the TRMD bit is set to 0 on the rising edge of the ninth cycle of SCL clock, placing IIC in master receive mode. At this time, the TDBEF0 flag is set to 0. The NTST.RDBFF0 flag is automatically set to 1 when ACK response is received from the slave device. If the slave device is not recognized or a communication failure occurs, the BST.NACKDF flag will be set to 1. At this time, set 1 to the CNDCTL.SPCND bit to issue a STOP condition. For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a Repeated START condition. After that, transmitting 1111 0, the two higher-order bits of the slave address, and the R bit places IIC in master receive mode.
4. Dummy read the NTDTBP0 register after confirming that the NTST.RDBFF0 flag = 1; this makes IIC start output of the SCL clock and start data reception.
5. After 1 byte of data has been received, the NTST.RDBFF0 flag is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the SCSTRCTL.ACKTWE bit. Reading the NTDTBP0 register at this

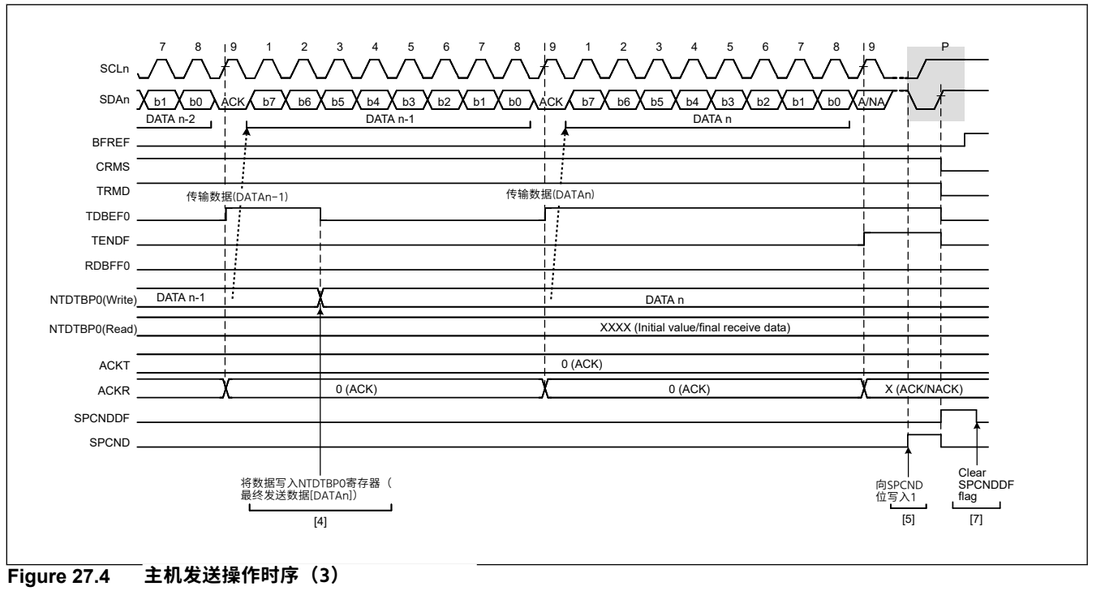

Figure 27.4 主机发送操作时序（3）

(b)数据读取传输（单缓冲区传输）

在主设备接收操作中，IIC作为主设备输出SCL时钟，从从设备接收数据，并返回确认。因为IIC必须先向对应的从设备发送一个从地址开始，所以这部分程序在主发送模式下执行，但后续步骤在主接收模式下进行。

图27.48和图27.49显示了主接收（7位地址格式）的使用示例，图27.5至图27.7显示了主接收中的操作时序。

下面介绍主接收的步骤和操作。

1.初始设置。详见27.3.2.1节。初始设定流程。

2.读取BCST.BFREF标志以检查总线是否打开，然后将CNDCTL.STCND位设置为1（开始条件发出请求）。收到请求后，IIC发出START条件。当IIC检测到START条件时，BFREF标志自动置0，BST.STCNDDF标志自动置1，STCND位自动置0。此时，如果检测到START条件且电平为SDA输出和SDAn线上的电平匹配，而STCND位=1，IIC识别出由STCND位请求的START条件的发出已成功完成，并且PRSST寄存器中的CRMS和TRMD位自动置位为1，将IIC置于主机发送模式。响应TRMD位设置为1，NTST.TDBEF0标志也自动设置为1。

3.检查NTST.TDBEF0标志=1，然后将要发送的值（第一个字节表示从机地址和RW#位的值）写入NTDTBP0寄存器。一旦要发送的数据写入NTDTBP0寄存器，TDBEF0标志自动设置为0，数据从正常发送数据缓冲区0传输到移位寄存器，并且TDBEF0标志再次设置为1。一旦字节包含从地址和

RW#位已发送，PRSST.TRMD位的值会自动更新，以根据发送的RW#位的值选择发送或接收模式。如果RW#位的值为1，则TRMD位在SCL时钟的第9个周期的上升沿设置为0，将IIC置于主机接收模式。此时，TDBEF0标志设置为0。当从从设备接收到ACK响应时，NTST.RDBFF0标志自动设置为1。如果从设备未被识别或发生通信故障，则BST.NACKDF标志将设置为1。此时，将CNDCTL.SPCND位设置为1以发出STOP条件。对于来自具有10位地址的设备的主机接收，首先使用主机发送来发出10位地址，然后发出重复启动条件。之后，发送11110、从机地址的两个高位位和R位将IIC置于主机接收模式。

4、确认NTST.RDBFF0标志=1后，假读NTDTBP0寄存器；这使得IIC开始输出SCL时钟并开始数据接收。

5.接收到1个字节的数据后，NTST.RDBFF0标志在由SCSTRCTL.ACKTWE位选择的SCL时钟（时钟信号）的第8个或第9个周期的上升沿设置为1。此时读取NTDTBP0寄存器

time will produce the received data, and the RDBFF0 flag is automatically set to 0 at the same time. Furthermore, the value of the acknowledgment field received during the ninth cycle of SCL clock is returned as the value set in the ACKCTL.ACKT bit. Furthermore, if the next byte to be received is the next to last byte, set the SCSTRCTL.RWE bit to 1 (for wait insertion) before reading the NTDTBP0 register (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the ACKCTL.ACKT bit to 1 (NACK) in step 6, due to other interrupts, etc., this fixes the SCLn line to the low level on the falling edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a STOP condition is possible.

6. When the SCSTRCTL.ACKTWE bit = 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the ACKCTL.ACKT bit to 1 (NACK).
7. After reading the byte before last from the NTDTBP0 register, if the value of the NTST.RDBFF0 flag is confirmed to be 1, write 1 to the CNDCTL.SPCND bit (STOP condition issuance request) and then read the last byte from the NTDTBP0 register. When 1 is written to the CNDCTL.SPCND bit, IIC is released from the wait state and issues the STOP condition after low-level output in the ninth clock cycle is completed or the SCLn line is released from the low-hold state.
8. Upon detecting the STOP condition, IIC automatically sets bits CRMS and TRMD in the PRSST register to 00 and enters slave receive mode. Furthermore, detection of the STOP condition leads to setting of the BST.SPCNDDF flag to 1.
9. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

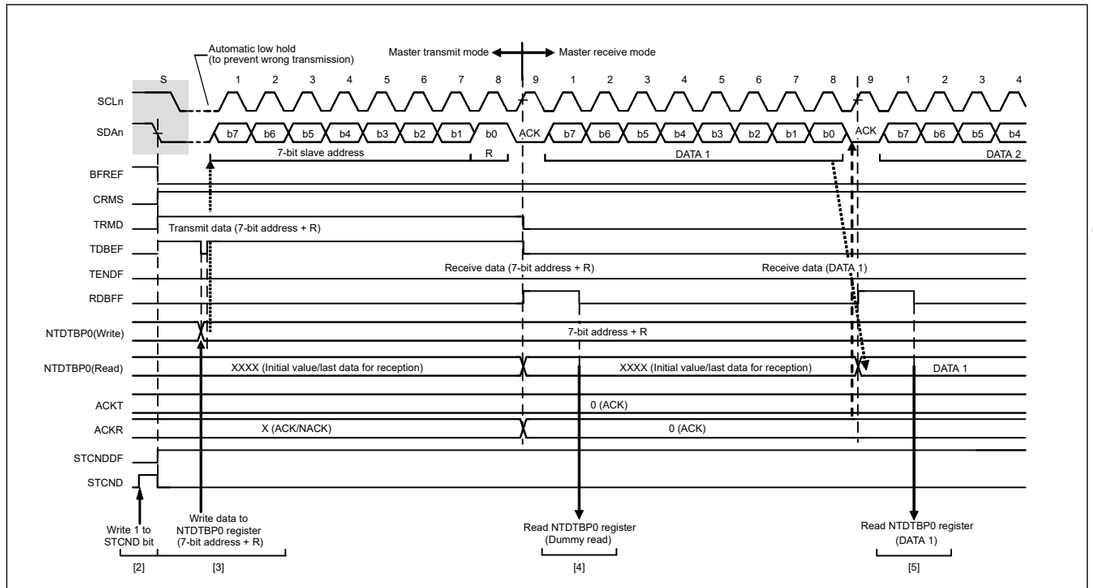

Figure 27.5 Master receive operation timing (1) (7-bit address format, when ACKTWE = 0)

time将产生接收到的数据，同时RDBFF0标志位自动设置为0。此外，在SCL时钟的第9个周期内接收到的确认字段的值作为ACKCTL.ACKT位中设置的值返回。此外，如果要接收的下一个字节是倒数第二个字节，则在读取NTDTBP0寄存器（包含倒数第二个字节）之前将SCSTRCTL.RWE位设置为1（等待插入）。即使在步骤6中将ACKCTL.ACKT位设置为1(NACK)的处理延迟的情况下，由于其他中断等，也可以启用NACK输出，这在下降时将SCLn线固定为低电平在接收最后一个字节时的第9个时钟周期的边沿，因此该状态使得发出STOP条件是可能的。

6.当SCSTRCTL.ACKTWE位=0且必须通知从设备在传输下一个（最终）字节后结束数据接收传输时，将ACKCTL.ACKT位设置为1（NACK）。

7.从NTDTBP0寄存器读取前一个字节后，如果确认NTST.RDBFF0标志的值为1，则将1写入CNDCTL.SPCND位（STOP条件发出请求），然后从NTDTBP0寄存器。当向CNDCTL.SPCND位写入1时，IIC从等待状态中释放并发出

第9个时钟周期的低电平输出完成或SCLn线从低保持状态释放后的STOP条件。

8.检测到STOP条件后，IIC自动将PRSST寄存器中的CRMS和TRMD位设置为00，并且
进入从机接收模式。此外，检测到STOP条件会导致将BST.SPCNDDF标志设置为1。

9.在检查BST.SPNCDDF标志=1后，将BST.NACKDF和SPCNDDF标志设置为0以进行下一次传输操作。

(1) 我2C从操作

(a)数据写入传输（单缓冲区传输）

In slave receive operation, the master device outputs the SCL clock and transmit data, and IIC returns acknowledgments as a slave device.

Figure 27.51 shows an example of usage of slave reception and Figure 1.41 and Figure 1.42 show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

1. Initial settings. For details, see section 27.3.2.1. Initial Setting Flow. After initial settings, IIC will stay in the standby state until it receives a slave address that it matches.
2. After receiving a matching slave address, IIC sets one of the corresponding bits SVST.HOAF, GCAF, and SVAFy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the acknowledge bit (ACK) on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0, IIC continues to place itself in slave receive mode and sets the NTST.RDBFF0 flag to 1.
3. After the BST.SPCNDDF flag is confirmed to be 0 and the NTST.RDBFF0 flag to be 1, dummy read the NTDTBP0 register (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected).
4. When the NTDTBP0 register is read, IIC automatically sets the NTST.RDBFF0 flag to 0. If reading of the NTDTBP0 register is delayed and a next byte is received while the RDBFF0 flag is still set to 1, IIC holds the SCLn line low from one SCL cycle before the timing with which RDBFF0 should be set. In this case, reading the NTDTBP0 register releases the SCLn line from being held at the low level. When the BST.SPCNDDF flag = 1 and the NTST.RDBFF0 flag is also 1, read the NTDTBP0 register until all the data is completely received.
5. Upon detecting the STOP condition, IIC automatically clears bits SVST.HOAF, GCAF, and SVAFy (y = 0 to 2) to 0.
6. After checking that the BST.SPCNDDF flag = 1, set the BST.SPCNDDF flag to 0 for the next transfer operation.

在从机接收操作中，主设备输出SCL时钟并发送数据，IIC作为从设备返回确认。

图27.51显示了从机接收的使用示例，图1.41和图1.42显示了从机接收中的操作时序。

下面描述从属接收的步骤和操作。

1.初始设置。详见27.3.2.1节。初始设定流程。初始设置后，IIC将保持待机状态，直到收到匹配的从地址。

2.接收到匹配的从机地址后，IIC在SCL时钟（时钟信号）的第9个周期的上升沿将相应的位SVST.HOAF、GCAF和SVAFy（y=0到2）之一设置为1，并且在SCL时钟的第9个周期输出确认位(ACK)。如果此时也接收到的RW#位的值为0，则IIC继续将自身置于从接收模式并将NTST.RDBFF0标志设置为1。

3、确认BST.SPCNDDF标志为0，NTST.RDBFF0标志为1后，虚拟读取NTDTBP0寄存器（选择7位地址格式时，虚拟值由从机地址和RW#位组成，或选择10位地址格式时的低8位）。

4.读取NTDTBP0寄存器时，IIC自动将NTST.RDBFF0标志设置为0。如果读取NTDTBP0寄存器延迟并且在RDBFF0标志仍设置为1时接收到下一个字节，IIC将SCLn线保持为低电平从应该设置RDBFF0的时序之前的一个SCL周期开始。在这种情况下，读取NTDTBP0寄存器会解除SCLn线保持在低电平的状态。当BST.SPCNDDF标志=1且NTST.RDBFF0标志也为1时，读取NTDTBP0寄存器，直到所有数据都接收完毕。

5.检测到STOP条件后，IIC自动将位SVST.HOAF、GCAF和SVAFy（y=0至2）清零。

6.检查BST.SPNCDDF标志=1后，将BST.SPCNDDF标志设置为0以进行下一次传输操作。

(b) Data Read Transfer (Single Buffer transfer)

In slave transmit operation, the master device outputs the SCL clock, IIC transmits data as a slave device, and the master device returns acknowledgments.

Figure 27.50 shows an example of usage of slave transmission and Figure 27.10 and Figure 27.11 show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

1. Initial settings. For details, see section 27.3.2.1. Initial Setting Flow.
   After initial settings, IIC will stay in the standby state until it receives a slave address that it matches.
2. After receiving a matching slave address, IIC sets one of the corresponding bits SVST.HOAF, GCAF, and SVAFy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the acknowledge bit (ACK) on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 1, IIC automatically places itself in slave transmit mode by setting both the PRSST.TRMD bit and the NTST.TDBEF0 flag to 1.
3. After the NTST.TDBEF0 flag is confirmed to be 1, write the data for transmission to the NTDTBP0 register. At this time, if IIC does not receive acknowledge from the master device (receives an NACK signal) while the BSTE.NACKDE bit = 1, IIC aborts transfer of the next data.
4. Wait until the following (a) or (b) condition.
   (a) The BST.NACKDF flag is set to 1.
   (b) The BST.TENDF flag is set to 1 while the NTST.TDBEF0 flag = 1, after the last byte for transmission is written to the NTDTBP0 register.

   When the BST.NACKDF flag or the TENDF flag = 1, IIC drives the SCLn line low on the ninth falling edge of SCL clock.
5. When the BST.NACKDF flag or the BST.TENDF flag = 1, dummy read the NTDTBP0 register to complete the processing. This releases the SCLn line.
6. Upon detecting the STOP condition, IIC automatically sets bits SVST.HOAF, GCAF, and SVAFy (y = 0 to 2), flags NTST.TDBEF0 and BST.TENDF, and the PRSST.TRMD bit to 0, and enters slave receive mode.
7. After checking that the BST.SPCNDDF flag = 1, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

(b)数据读取传输（单缓冲区传输）

在从发送操作中，主设备输出SCL时钟，IIC作为从设备发送数据，主设备返回确认。

图27.50显示了从属传输的使用示例，图27.10和图27.11显示了从属传输中的操作时序。

下面介绍从属传输的步骤和操作。

1.初始设置。详见27.3.2.1节。初始设定流程。
初始设置后，IIC将保持待机状态，直到收到匹配的从地址。

2.接收到匹配的从机地址后，IIC在SCL时钟（时钟信号）的第9个周期的上升沿将相应的位SVST.HOAF、GCAF和SVAFy（y=0到2）之一设置为1，并且在SCL时钟的第9个周期输出确认位(ACK)。如果此时也接收到的RW#位的值为1，IIC通过将PRSST.TRMD位和NTST.TDBEF0标志都设置为1自动将自身置于从发送模式。

3.确认NTST.TDBEF0标志为1后，将要发送的数据写入NTDTBP0寄存器。在这
时间，如果IIC在BSTE.NACKDE位=1时没有收到来自主设备的确认（接收到NACK信号），则IIC中止下一个数据的传输。

4.等到以下(a)或(b)条件。

(a) BST.NACKDF标志设置为1。

(b) 在将要发送的最后一个字节写入NTDTBP0寄存器后，BST.TENDF标志设置为1，而NTST.TDBEF0标志=1。

当BST.NACKDF标志或TENDF标志=1时，IIC在SCL时钟的第九个下降沿将SCLn线驱动为低电平。

5.当BST.NACKDF标志或BST.TENDF标志=1时，虚拟读取NTDTBP0寄存器以完成处理。这将释放SCLn线。

6.检测到STOP条件后，IIC自动设置SVST.HOAF、GCAF和SVAFy位（y=0到2），标志NTST.TDBEF0和BST.TENDF，以及PRSST.TRMD位为0，并进入从机接收模式。

7.检查BST.SPNCDDF标志=1后，将BST.NACKDF和SPCNDDF标志设置为0以进行下一次传输操作。

(1) I²C Communication Data Format

The I²C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a START condition or Repeated START condition is an address frame used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a STOP condition is issued.

Figure 27.13 shows the I²C bus format, and Figure 27.14 shows the I²C bus timing.

27.3.1.3.2 START条件重复START条件STOP条件发出 Function

(1) 发出START条件

当CNDCTL.STCND位设置为1时，IIC发出START条件。

当BCST.BFREF标志设置为1（总线空闲状态）时，将STCND位设置为1（开始条件发出请求）。

IIC发出一个START条件。

When a START condition is issued normally, IIC automatically shifts to the master transmit mode. A START condition is issued in the following sequence.

[START condition issuance]

- Drive the SDAn line low (high level to low level).
- Ensure the time set in STDBR.SBRHO[7:0] and the START condition hold time.
- Drive the SCLn line low (high level to low level).
- Detect low level of the SCLn line and ensure the low-level period of SCLn line set in STDBR.SBRLO[7:0].

(2) Issuing a Repeated START Condition

IIC issues a Repeated START condition when the CNDCTL.SRCND bit is set to 1.

When the SRCND bit is set to 1, a Repeated START condition issuance request is made and IIC issues a Repeated START condition when the BCST.BFREF flag = 0 (bus busy state) and the PRSST.CRMS bit = 1 (master mode).

A Repeated START condition is issued in the following sequence.

[Repeated START condition issuance]

- Release the SDAn line.
- Ensure the low-level period of SCLn line set in STDBR.SBRLO[7:0].
- Release the SCLn line (low level to high level).
- Detect a high level of the SCLn line and ensure the time set in STDBR.SBRLO[7:0] and the Repeated START condition setup time.
- Drive the SDAn line low (high level to low level).
- Ensure the time set in STDBR.SBRHO[7:0] and the Repeated START condition hold time.
- Drive the SCLn line low (high level to low level).
- Detect a low level of the SCLn line and ensure the low-level period of SCLn line set in STDBR.SBRLO[7:0].

Note: When issuing Repeated START conditions request, please write the slave address to NTDTBP0 after confirming CNDCTL.SRCND = 0. Data written in the period of CNDCTL.SRCND = 1 is not forwarded because retransmission condition before the occurrence.

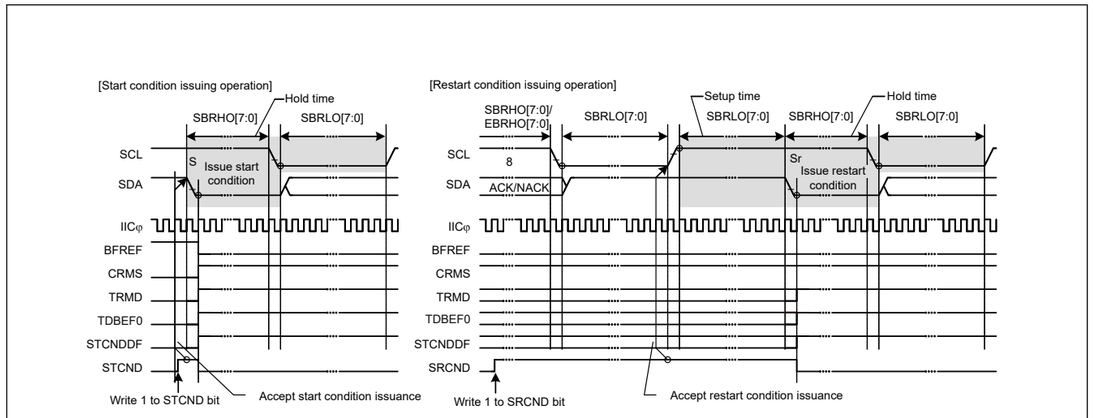

Figure 27.15 START condition / repeated START condition issue timing (STCND and SRCND bits)

Figure 27.16 shows the operation to issue a Repeated START condition after the master transmission.

[Repeated START condition issuance after the master transmission]

- Initial setting. For details, see section 27.3.2.1. Initial Setting Flow.

当START条件正常发出时，IIC自动切换到主机发送模式。START条件按以下顺序发出。

[START condition issuance]

- ●将SDAn线拉低（从高电平到低电平）。
- ●确保STDBR.SBRHO[7:0]中设置的时间和START条件保持时间。
- ●将SCLn线拉低（高电平转低电平）。
- ●检测SCLn线的低电平，保证STDBR.SBRLO[7:0]中设置的SCLn线的低电平周期。

(2) 发出重复的START条件

当CNDCTL.SRCND位设置为1时，IIC发出重复启动条件。

当SRCND位设置为1时，发出重复START条件发出请求，并且IIC在BCST.BFREF标志=0（总线忙状态）和PRSST.CRMS位=1（主机模式）时发出重复START条件。

重复启动条件按以下顺序发出。

[重复START条件发布]

- ●释放SDAn线。
- ●确保STDBR.SBRLO[7:0]中设置的SCLn线的低电平周期。
- ●释放SCLn线（低电平到高电平）。
- ●检测SCLn线的高电平，确保STDBR.SBRLO[7:0]中设置的时间和RepeatedSTART条件建立时间。
- ●将SDAn线拉低（从高电平到低电平）。
- ●确保STDBR.SBRHO[7:0]中设置的时间和RepeatedSTART条件保持时间。
- ●将SCLn线拉低（高电平转低电平）。
- ●检测SCLn线的低电平，保证STDBR.SBRLO[7:0]中设置的SCLn线的低电平周期。

Note: 发出重复启动条件请求时，请在确认后将从机地址写入NTDTBP0 CNDCTL.SRCND=0。在CNDCTL.SRCND=1期间写入的数据不转发，因为发生之前的重传条件。

[主传输后重复START条件发布]

- ●初始设置。详见27.3.2.1节。初始设定流程。

- Read the BFREF flag in BCST to check that the bus is open, and then set the STCND bit in CNDCTL to 1 (START condition issuance request). Upon receiving the request, IIC issues a START condition. At the same time, the BFREF flag is automatically set to 0 and the STCNDDF flag in BST is automatically set to 1 and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the SDAn line have matched while the STCND bit = 1, IIC recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and CRMS and TRMD bits in PRSST is automatically set to 1, placing IIC in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1 in response to setting of the TRMD bit to 1.
- Check that the NTST.TDBEF0 flag = 1, and then write the value for transmission (the slave address and the R/W# bit) to NTDTBP0. Once the data for transmission are written to NTDTBP0, the TDBEF0 flag is automatically set to 0, the data are transferred from NTDTBP0, and the TDBEF0 flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRMD bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, IIC continues in master transmit mode. Since the BST.NACKDF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to CNDCTL.SPCND bit to issue a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1111 0, the 2 higher-order bits of the slave address, and W to NTDTBP0 as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to NTDTBP0.
- After confirming that the NTST.TDBEF0 flag = 1, write the data for transmission to the NTDTBP0 register. IIC automatically holds the SCLn line low until the data for transmission are ready, a Repeated START condition is issued or a STOP condition is issued.
- After all bytes of data for transmission have been written to the NTDTBP0 register, wait until the value of the BST.TENDF flag returns to 1, and then, after check that the BST.STCNDDF flag = 1, set the BST.STCNDDF flag to 0.
- Set the SRCND bit in CNDCTL to 1 (Repeated START condition issuance request). Upon receiving the request, IIC issues a Repeated START condition.
- After check that the BST.STCNDDF flag = 1, write the value for transmission (the slave address and the R/W# bit) to NTDTBP0.

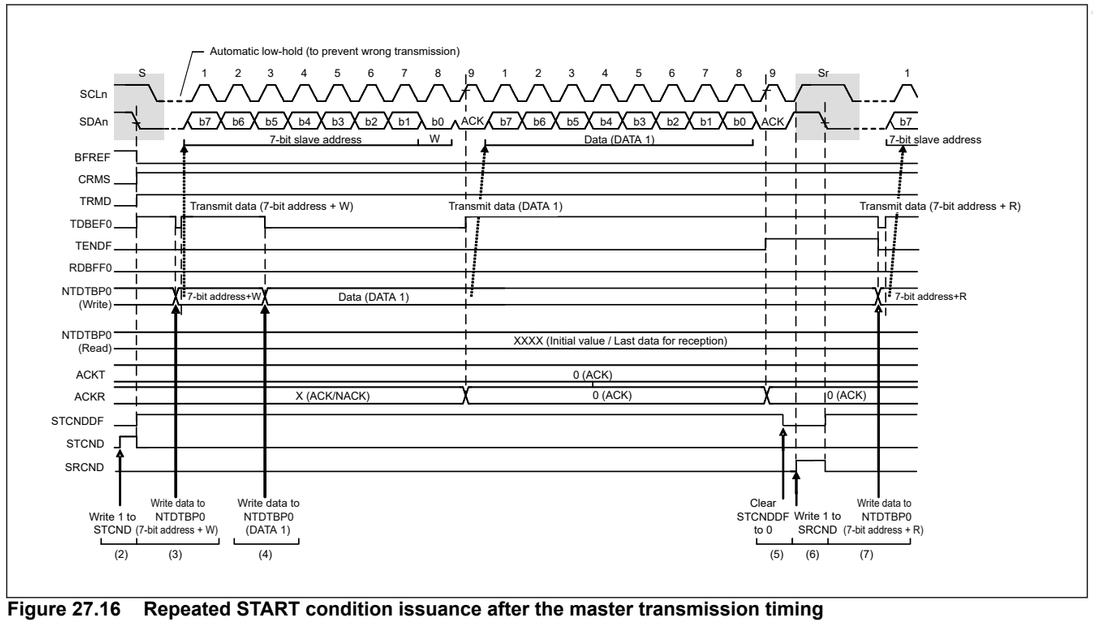

Figure 27.16 Repeated START condition issuance after the master transmission timing

(3) Issuing a STOP Condition

IIC issues a STOP condition when the SPCND bit in CNDCTL is set to 1.

●读取BCST中的BFREF标志以检查总线是否打开，然后将CNDCTL中的STCND位设置为1（START条件发出请求）。收到请求后，IIC发出START条件。同时，BFREF标志位自动置0，BST中的STCNDDF标志位自动置1，STCND位自动置0。此时，如果检测到START条件且内部电平为SDA输出状态和SDAn线上的电平匹配，当STCND位=1时，IIC识别出由STCND位请求的START条件的发布已成功完成，并且PRSST中的CRMS和TRMD位自动设置为1，将IIC置于主发送模式。响应TRMD位设置为1，NTST.TDBEF0标志也自动设置为1。

●检查NTST.TDBEF0标志=1，然后将传输值（从机地址和RW#位）写入NTDTBP0。一旦将要发送的数据写入NTDTBP0，TDBEF0标志自动设置为0，数据从NTDTBP0传输，并且TDBEF0标志再次设置为1。在包含从机地址和RW#位的字节被发送后时，TRMD位的值会自动更新，以根据发送的RW#位的值选择主机发送或主机接收模式。如果RW#位的值为0，IIC继续在主机发送模式。由于此时BST.NACKDF标志为1表示没有从设备识别该地址或通信出现错误，因此向CNDCTL.SPCND位写入1以发出STOP条件。对于地址为10位格式的数据传输，首先将11110、从机地址的高2位和W写入NTDTBP0作为第一个地址传输。然后，作为第二次地址传输，将从机地址的低8位写入NTDTBP0。

●确认NTST.TDBEF0标志=1后，将发送数据写入NTDTBP0寄存器。国际集成电路
自动将SCLn线保持为低电平，直到传输数据准备好、发出重复START条件或发出STOP条件。

●待发送数据的所有字节写入NTDTBP0寄存器后，等待
BST.TENDF标志返回1，然后在检查BST.STCNDDF标志=1后，将BST.STCNDDF标志设置为0。

●将CNDCTL中的SRCND位设置为1（重复START条件发出请求）。收到请求后，IIC发出重复启动条件。

●检查BST.STCNDDF标志=1后，将发送值（从机地址和RW#位）写入NTDTBP0。

(3) 发出停止条件

当CNDCTL中的SPCND位设置为1时，IIC发出STOP条件。

When the SPCND bit is set to 1, a STOP condition issuance request is made and IIC issues a STOP condition when the BCST.BFREF flag = 0 (bus busy state) and the PRSST.MST bit = 1 (master mode).

A STOP condition is issued in the following sequence.

[STOP condition issuance]

- Drive the SDAn line low (high level to low level).
- Ensure the low-level period of SCLn line set in STDBR.SBRLO[7:0].
- Release the SCLn line (low level to high level).
- Detect a high level of the SCLn line and ensure the time set in STDBR.SBRHO[7:0] and the STOP condition setup time.
- Release the SDAn line (low level to high level).
- Ensure the time set in STDBR.SBRLO[7:0] and the bus free time.
- Set the BFREF flag to 1 (to release the bus mastership).

27.3.1.3.3 Address Match Detection

IIC can set three unique slave addresses in addition to the general call address and host address, and also can set 7- bit or 10-bit slave addresses.

(1) Slave-Address Match Detection

IIC can set three unique slave addresses, and has a slave address detection function for each unique slave address.

When the SVCTL.SVAEy bit (y = 0 to 2) is set to 1, the slave addresses set in the SVDVADy register (y = 0 to 2) can be detected.

When IIC detects a match of the set slave address, the corresponding SVST.SVAFy flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the NTST.RDBFF0 flag or the NTST.TDBEF0 flag is set to 1 by the following R/W# bit. This causes a receive data full interrupt (IICn_RX) or transmit data empty interrupt (IICn_TX) to be generated. The SVAFy flag is used to identify which slave address has been specified.

Figure 27.18 to Figure 27.20 show the SVAFy flag set timing in three cases.

当SPCND位设置为1时，发出STOP条件发出请求，当IIC发出STOP条件时BCST.BFREF标志=0（总线繁忙状态）和PRSST.MST位=1（主模式）。

STOP条件按以下顺序发出。

[STOP condition issuance]

●将SDAn线拉低（从高电平到低电平）。

●确保STDBR.SBRLO[7:0]中设置的SCLn线的低电平周期。

●释放SCLn线（低电平到高电平）。

●检测SCLn线的高电平，确保STDBR.SBRHO[7:0]中设置的时间和STOP条件建立时间。

●释放SDAn线（低电平到高电平）。

●确保STDBR.SBRLO[7:0]中设置的时间和总线空闲时间。

●将BFREF标志设置为1（以释放总线控制权）。

27.3.1.3.3 地址匹配检测

IIC除了可以设置广播地址和主机地址外，还可以设置三个唯一的从机地址，也可以设置7bit或10bit的从机地址。

(1) 从地址匹配检测

IIC可以设置三个唯一的从地址，并且对每个唯一的从地址都有从地址检测功能。

当SVCTL.SVAEy位（y=0到2）设置为1时，可以检测SVDVADy寄存器（y=0到2）中设置的从机地址。

当IIC检测到设置的从地址匹配时，对应的SVST.SVAFy标志（y=0到2）在第9个SCL时钟周期的上升沿设置为1，并且NTST.RDBFF0标志或NTST.TDBEF0flag由后面的RW#位设置为1。这会导致产生接收数据满中断(IICn_RX)或发送数据空中断(IICn_TX)。

SVAFy标志用于标识已指定哪个从地址。

(2) Detection of the General Call Address

IIC has a facility for detecting the general call address (0000 000 + 0 (write)). This is enabled by setting the SVCTL.GCAE bit to 1.

If the address received after a START or Repeated START condition is issued is 0000 000 + 1 (read) (start byte), IIC recognizes this as the address of a slave device with an all-zero address but not as the general call address.

When IIC detects the general call address, both the SVST.GCAF flag and the NTST.RDBFF0 flag are set to 1 on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a receive data full interrupt (IICn_RX). The value of the GCAF flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

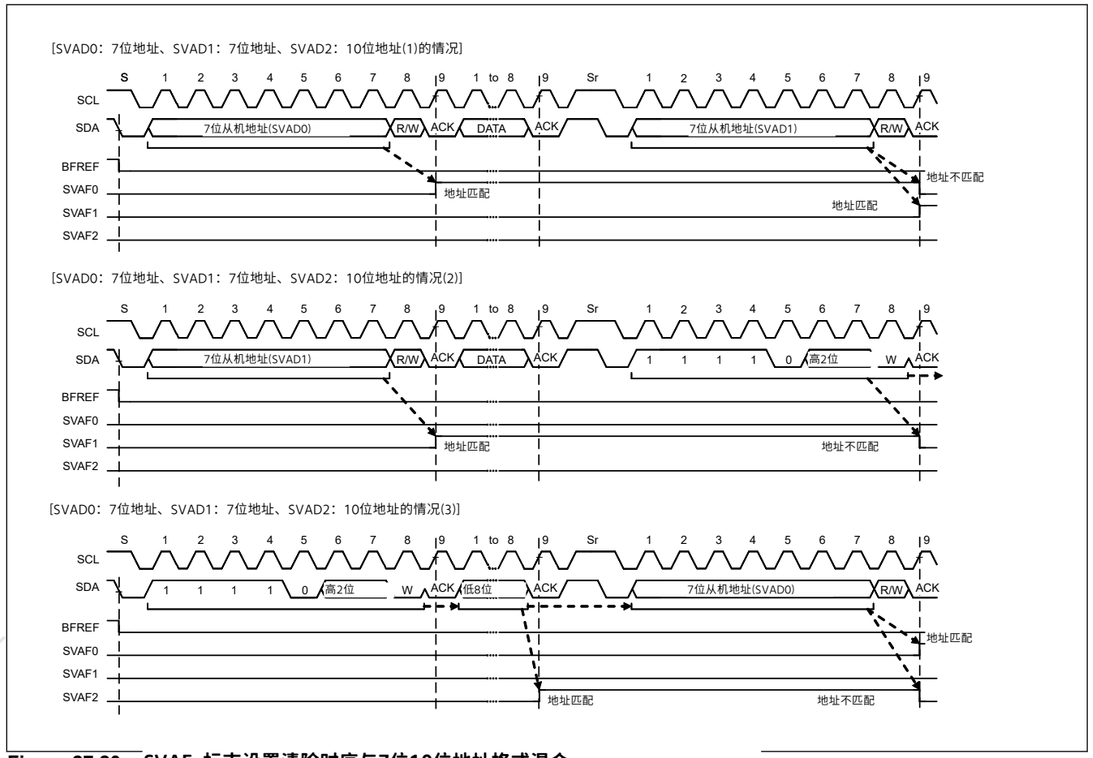

Figure 27.20 SVAFy标志设置清除时序与7位10位地址格式混合

(2) 检测广播呼叫地址

IIC具有检测广播呼叫地址（0000000+0（写入））的功能。这通过将SVCTL.GCAE位设置为1来启用。

如果在发出START或重复START条件后接收到的地址为0000000+1（读取）（起始字节），IIC将其识别为具有全零地址的从设备的地址，但不识别为广播呼叫地址。

当IIC检测到广播呼叫地址时，SVST.GCAF标志和NTST.RDBFF0标志都在SCL时钟的第9个周期的上升沿设置为1。这会导致接收数据完全中断(IICn_RX)的产生。可以确认GCAF标志的值来识别广播呼叫地址已被发送。

检测到广播呼叫地址后的操作与正常的从机接收操作相同。

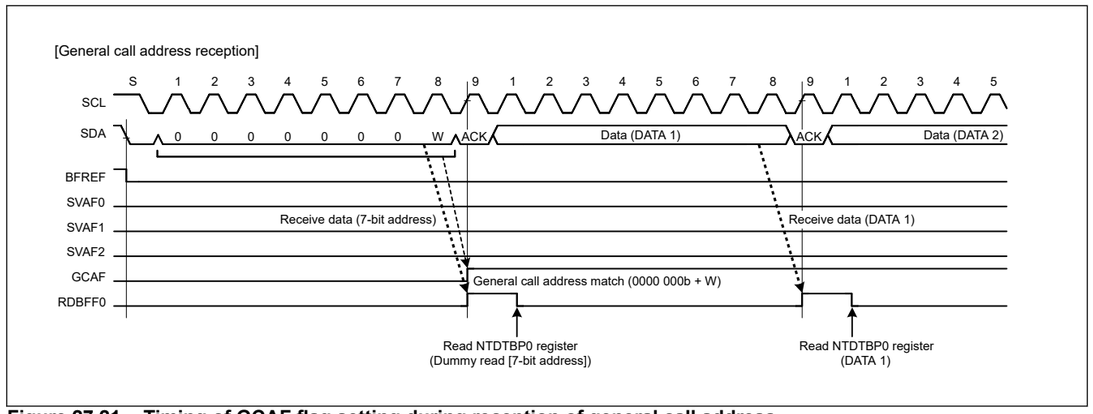

Figure 27.21 Timing of GCAF flag setting during reception of general call address

(3) Device-ID Address Detection

IIC module has a facility for detecting device-ID addresses conformant with the I²C-bus specification (Rev.03). When IIC receives 1111 100 as the first byte after a START condition or Repeated START condition was issued with the SVCTL.DVIDE bit set to 1, IIC recognizes the address as a device ID, sets the SVST.DVIDF flag to 1 on the rising edge of the ninth SCL clock cycle when the following R/W# bit = 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, IIC sets the corresponding SVST.SVAFy flag (y = 0 to 2) to 1.

After that, when the first byte received after a START or Repeated START condition is issued matches the device ID address (1111 100) again and the following R/W# bit = 1, IIC does not compare the second and subsequent bytes and sets the NTST.TDBEF0 flag to 1.

In the device-ID address detection function, IIC sets the DVIDF flag to 0 if a match with IIC's own slave address is not obtained or a match with the device ID address is not obtained after a match with IIC's own slave address and the detection of a Repeated START condition. If the first byte after detection of a START or Repeated START condition matches the device ID address (1111 100) and the R/W# bit = 0, IIC sets the DVIDF flag to 1 and compares the second and subsequent bytes with IIC's slave address. If the R/W# bit = 1, the DVIDF flag holds the previous value and IIC does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DVIDF flag after confirming that TDBEF0 flag = 1.

Furthermore, prepare the device-ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details of the information that must be included in device-ID fields, contact NXP Semiconductors.

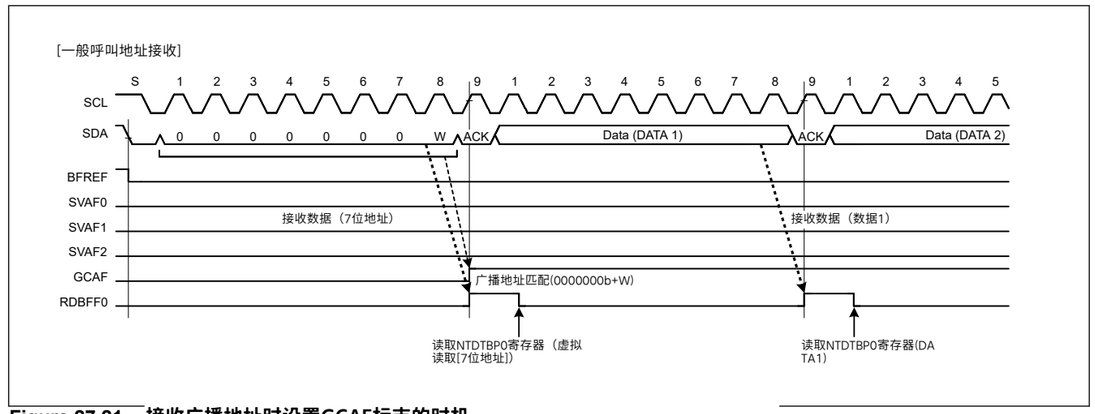

Figure 27.21 接收广播地址时设置GCAF标志的时机

(3) 设备ID地址检测

IIC模块具有用于检测符合I2C总线规范(Rev.03)的设备ID地址的工具。当IIC在发出START条件或重复START条件且SVCTL.DVIDE位设置为1后接收到1111100作为第一个字节时，IIC将地址识别为设备ID，在上升沿将SVST.DVIDF标志设置为1当后面的RW#位=0时，第9个SCL时钟周期，然后将第二个和后续字节与其自己的从地址进行比较。如果地址与从地址寄存器中的值匹配，IIC将相应的SVST.SVAFy标志（y=0到2）设置为1。

之后，当发出START或重复START条件后接收到的第一个字节再次与设备ID地址(1111100)匹配且随后的RW#位=1时，IIC不比较第二个和后续字节并设置NTST。TDBEF0标志为1。

在device-ID地址检测功能中，如果与IIC自己的从机地址匹配没有得到匹配，或者在与IIC自己的从机地址匹配并且检测到没有得到与设备ID地址匹配后，IIC设置DVIDF标志为0。重复启动条件。如果检测到START或重复START条件后的第一个字节与设备ID地址(1111100)匹配并且RW#位=0，则IIC将DVIDF标志设置为1，并将第二个和后续字节与IIC的从地址进行比较。如果RW#位=1，则DVIDF标志保持前一个值，并且IIC不比较第二个和后续字节。因此，在确认TDBEF0标志=1后，可以通过读取DVIDF标志来检查设备ID地址的接收。

此外，准备设备ID字段（3个字节：12位表示制造商+9位表示部件+3位表示版本），在接收到连续的设备ID字段作为正常数据后必须发送到主机传播。有关必须包含在设备ID字段中的信息的详细信息，请联系NXPSemiconductors。

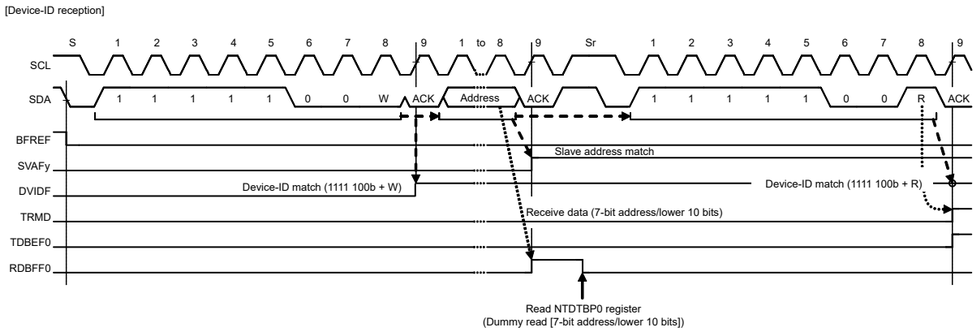

Figure 27.22 SVAFy/DVIDF flag set/clear timing during reception of device-ID

(4) Host Address Detection

IIC has a function to detect the host address while the SMBus is operating. When the SVCTL.HOAE bit is set to 1 while the BFCTL.SMBS bit = 1, IIC can detect the host address (0001 000) in slave receive mode (bits CRMS and TRMD in the PRSST register = 00).

If the bit following the host address (0001 000) is an Rd bit (R/W# bit = 1), IIC can also detect the host address. After the host address is detected, IIC operates in the same manner as normal slave operation.

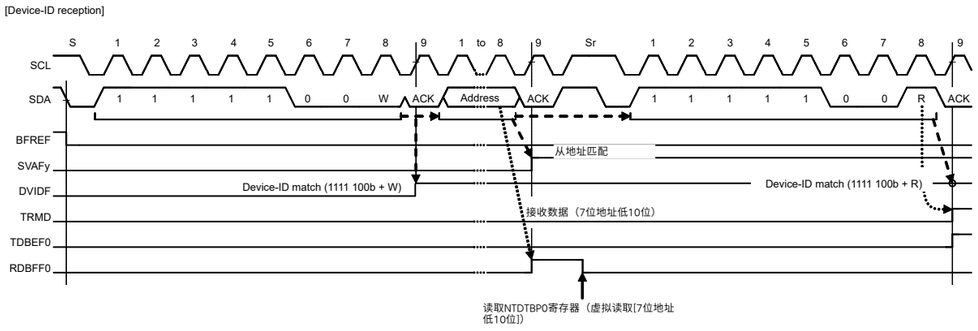

Figure 27.22 SVAFyDVIDF标志在接收设备ID期间设置清除时序

(4) 主机地址检测

IIC具有在SMBus运行时检测主机地址的功能。当SVCTL.HOAE位设置为1而BFCTL.SMBS位=1，IIC可以在从机接收模式下检测主机地址（0001000）（位CRMS和TRMD在PRSST register = 00).

如果主机地址（0001000）后面的位是Rd位（RW#位=1），IIC也可以检测主机地址。检测到主机地址后，IIC以与正常从机操作相同的方式运行。

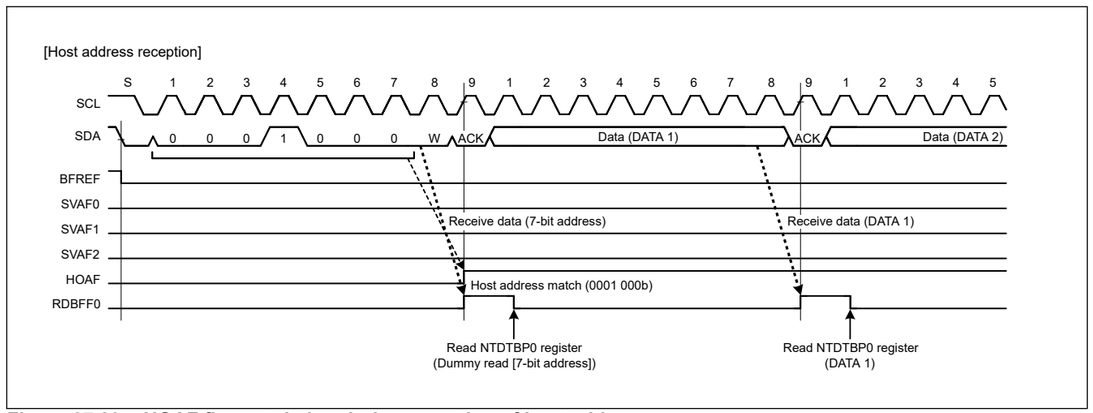

Figure 27.23 HOAF flag set timing during reception of host address

(5) Hs-mode master code Detection

IIC has a facility for detecting the Hs-mode master code (0000 1XXXb). When IIC receives the Hs-mode master code (0000 1XXXb) as the first byte after a START condition was issued with the SVCTL.HSMCE bit set to 1, this module recognizes the address as the Hs-mode master code, sets the SVST.HSMCF flag to 1 on the rising edge of the ninth SCL clock cycle. The first byte after Repeated START after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set by SVDVADy.SVAD[9:0] (y = 0 to 2). When IIC detects a match of the set slave address, the corresponding SVST.SVAFy flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the NTST.RDBFF0 flag or the NTST.TDBEF0 flag is set to 1 by the following R/W# bit. This causes a receive data full interrupt (IICn_RX) or transmit data empty interrupt (IICn_TX) to be generated. The SVAFy flag is used to identify which slave address has been specified. The SVST.HSMCF flag is cleared to 0 when the STOP condition is detected.

Note: If the Hs-mode master code (0000 1XXXb) is received with the SVCTL.HSMCE bit set to 0, other patterns are ignored until the STOP condition is detected.

Note: Hs-mode is supported by IIC0(SCL0_A, SDA0_A).

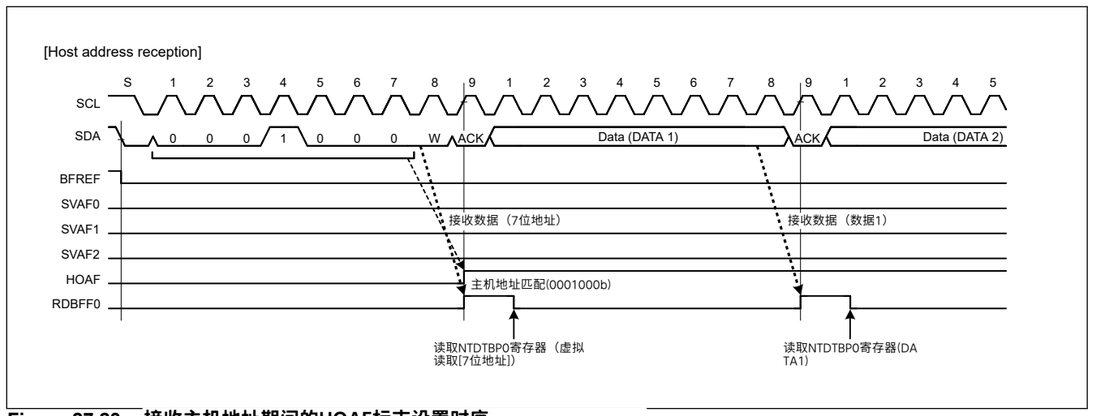

Figure 27.23 接收主机地址期间的HOAF标志设置时序

(5) Hs-mode主码检测

IIC具有检测Hs模式主代码(00001XXXb)的功能。当IIC在SVCTL.HSMCE位设置为1的情况下发出START条件后接收到Hs模式主代码(00001XXXb)作为第一个字节时，该模块将该地址识别为Hs模式主代码，设置SVST。在第9个SCL时钟周期的上升沿，HSMCF标志为1。NACK响应Hs模式主机代码后重复START后的第一个字节被识别为从机地址，并与SVDVADy.SVAD[9:0]设置的从机地址进行比较（y=0到2）。当IIC检测到设置的从地址匹配时，对应的SVST.SVAFy标志（y=0到2）在第9个SCL时钟周期的上升沿设置为1，并且NTST.RDBFF0标志或NTST.TDBEF0flag由后面的RW#位设置为1。这会导致产生接收数据满中断(IICn_RX)或发送数据空中断(IICn_TX)。SVAFy标志用于标识已指定哪个从地址。当检测到STOP条件时，SVST.HSMCF标志清零。

Note: 如果在SVCTL.HSMCE位设置为0的情况下接收到Hs模式主代码(00001XXXb)，则忽略其他模式，直到检测到STOP条件。

Note: IIC0(SCL0_A SDA0_A)支持Hs模式。

27.3.1.3.4 Arbitration-Lost Detection

In addition to the normal arbitration-lost detection function defined by the I^2C-bus specification, the IIC has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmit mode.

(1) Master Arbitration-Lost Detection (MALE Bit)

The IIC drives the SDAn line low to issue a start condition. However, if the SDAn line has already been driven low by another master device issuing a start condition, this module causes arbitration to be lost, so priority is given to transfer by the other master device. Similarly, if the CNDCTL.STCND bit is set to 1 while the BCST.BFREF flag is 0 (bus busy state), arbitration is lost, so priority is given to transfer by the other master device. No start condition is issued in this case.

When a start condition is issued successfully, if the data for transmission including the address bits (the internal SDA output level) and the level on the SDAn line do not match (the high output as the internal SDA output, that is, the SDA0 pin is in the high-impedance state) and the low level is detected on the SDAn line, the IIC loses in arbitration.

IIC detects master arbitration-lost when the following conditions are met while the BSTE.ALE bit = 1 and the BFCTL.MALE bit = 1 (master arbitration-lost detection enabled).

If arbitration of mastership is lost, IIC immediately enters slave receive mode.

If a slave address (including the general call address) matches its own address at this time, IIC continues in slave operation.

[Conditions for master arbitration-lost]

- Non-matching of the internal level for output on SDA and the level on the SDAn line after a START condition was issued by setting the CNDCTL.STCND bit to 1 while the BCST.BFREF flag was set to 1 (erroneous issuing of a START condition)
- Setting of the CNDCTL.STCND bit to 1 (START condition double-issue error) while the BFREF flag is set to 0

Note: IIC does not issue a START condition.

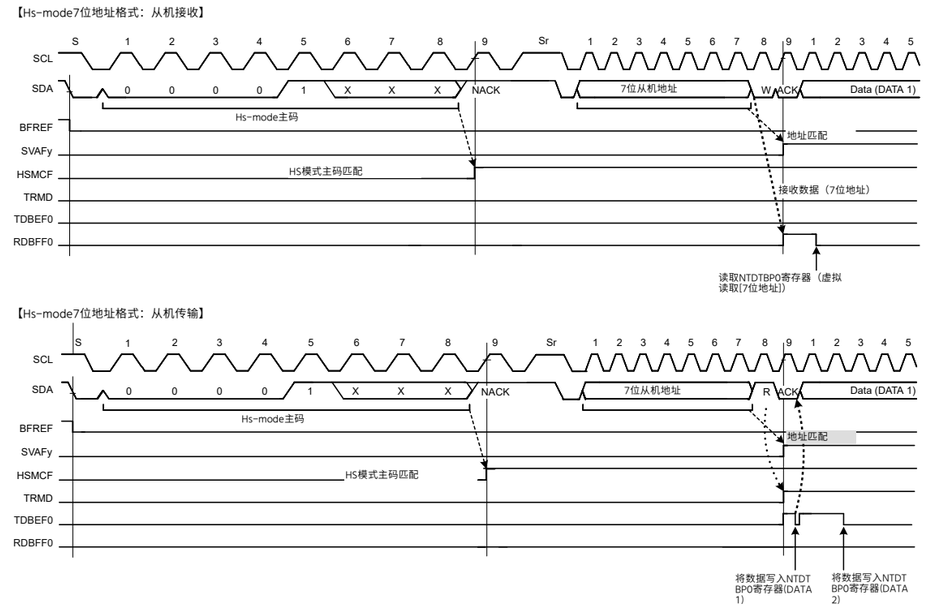

Figure 27.24 接收Hs模式主码期间的SVAFyHSMCF标志设置时序

27.3.1.3.4 Arbitration-Lost Detection

除了I2C总线规范定义的正常仲裁丢失检测功能外，IIC还具有防止重复发出启动条件、在NACK传输期间检测仲裁丢失以及检测从机中的仲裁丢失等功能。传输模式。

(1) 主仲裁丢失检测（MALE位）

IIC将SDAn线驱动为低电平以发出启动条件。但是，如果SDAn线已经被另一个发出启动条件的主设备驱动为低电平，则该模块会导致仲裁丢失，因此优先由另一个主设备进行传输。类似地，如果CNDCTL.STCND位设置为1，而BCST.BFREF标志为0（总线繁忙状态），则仲裁丢失，因此优先由其他主设备传输。在这种情况下不发出启动条件。

启动条件发出成功时，如果发送的数据包括地址位（内部SDA输出电平）与SDAn线上的电平不匹配（高电平输出作为内部SDA输出，即SDA0引脚）处于高阻状态）并且在SDAn线上检测到低电平，则IIC仲裁失败。

当BSTE.ALE位=1且满足以下条件时，IIC检测到主机仲裁丢失
BFCTL.MALE位=1（使能主机仲裁丢失检测）。

如果主控仲裁失败，IIC立即进入从机接收模式。

如果此时从机地址（包括广播地址）与自己的地址匹配，则IIC继续从机操作。

【主仲裁失败的条件】

●将CNDCTL.STCND位设置为1（START条件双发出错误），同时BFREF标志设置为0

(2) Arbitration-Lost Detection during NACK Transmission (NALE Bit)

The IIC has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the SDAn line (the high output as the internal SDA output; i.e. the SDAn pin is in the high-impedance state) and the low level is detected on the SDAn line during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device.

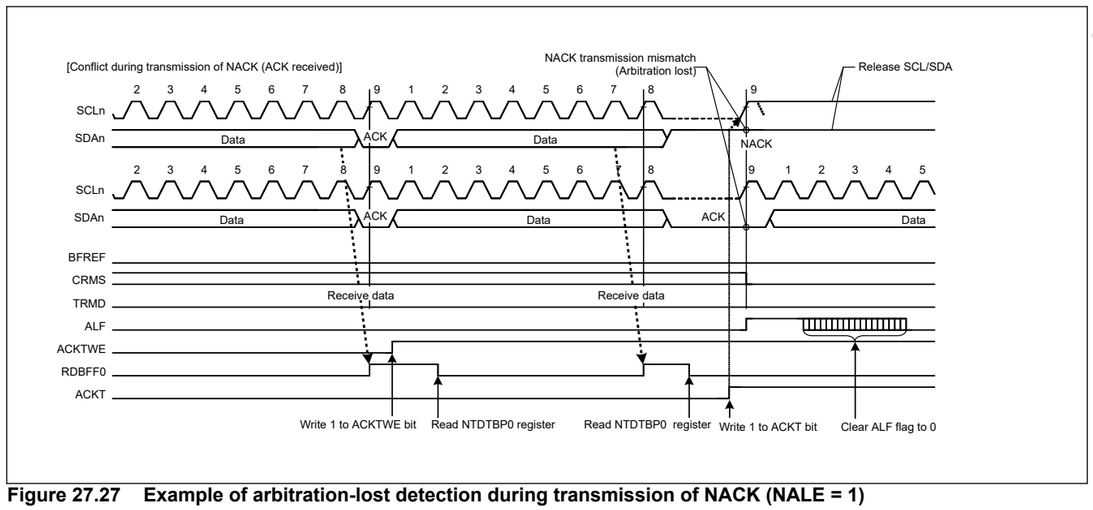

Figure 27.27 Example of arbitration-lost detection during transmission of NACK (NALE = 1)

The following section explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. In this example,, master A sends NACK when it has received 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the necessary 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a

(2) NACK传输期间的仲裁丢失检测（NALE位）

如果内部SDA输出电平与SDAn线上的电平不匹配（高输出作为内部SDA输出；即SDAn引脚处于高阻抗状态），IIC具有导致仲裁丢失的功能，并且在接收模式下发送NACK期间，在SDAn线上检测到低电平。在多主系统中，当两个或多个主设备同时从同一从设备接收数据时，由于NACK传输和ACK传输冲突，导致仲裁丢失。当多个主设备通过单个从设备发送接收相同的信息时，就会发生这种冲突。

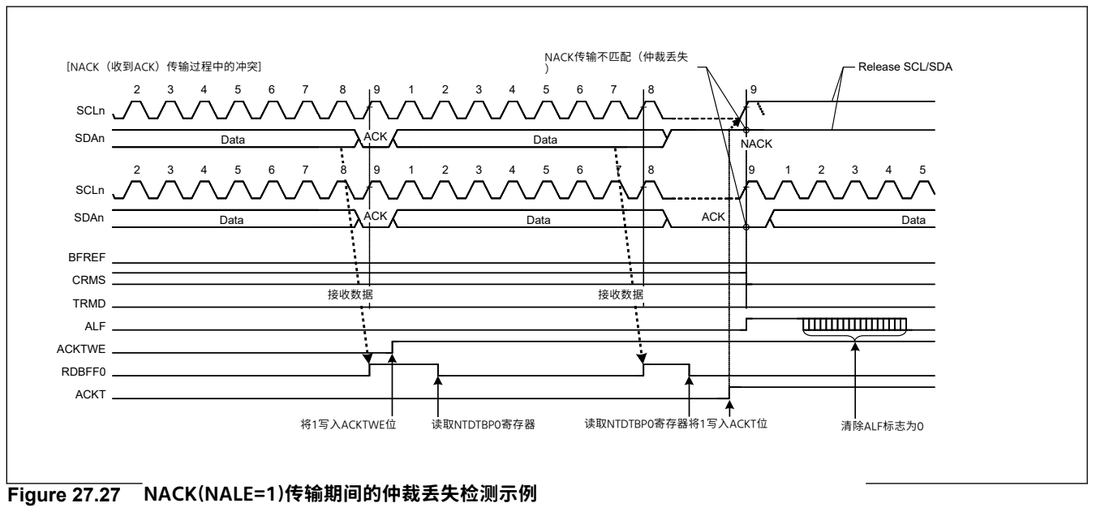

Figure 27.27 NACK(NALE=1)传输期间的仲裁丢失检测示例

以下部分使用两个主设备（主设备A和主设备）的示例解释仲裁丢失检测
B)和单个从设备通过总线连接。在本例中，主设备A从从设备接收2个字节的数据，主设备B从从设备接收4个字节的数据。

如果主设备A和主设备B同时访问从设备，由于从设备地址相同，在访问从设备期间，主设备A和主设备B都不会丢失仲裁。因此，主机A和主机B都承认他们已经获得了总线控制权并照此运行。在此示例中，主设备A在从从设备接收到最后2个字节的数据时发送NACK。同时，masterB发送ACK，因为它没有收到必要的4字节数据。此时，来自masterA的NACK传输和来自masterB的ACK传输冲突。一般来说，如果一个

conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition. Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When this module receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, this module is immediately released from the slave-matched state and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing (such as FFh transmission processing) necessary if the UDID (Unique Device Identifier) of assign address does not match in the Get UDID (general) processing after the Assign Address command.

The IIC detects arbitration-lost during transmission of NACK when the following condition is met while the BSTE.ALE bit = 1 and the BFCTL.NALE bit = 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDAn line (ACK is received) during transmission of NACK (ACKCTL.ACKT bit = 1)

(3) Slave Arbitration-Lost Detection (SALE Bit)

The IIC has a function to cause arbitration to be lost if the data for transmission (the internal SDA output level) and the level on the SDAn line do not match (the high output as the internal SDA output, that is, the SDAn pin is in the high impedance state) and the low level is detected on the SDAn line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

If arbitration is lost during transmission of DATA, this module is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminate subsequent redundant processing (processing for the transmission of 0xFF).

The IIC detects slave arbitration-lost when the following condition is met while the BSTE.ALE bit = 1 and the BFCTL.SALE bit = 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDAn line in slave transmit mode (bits CRMS and TRMD in the PRSST register = 01).

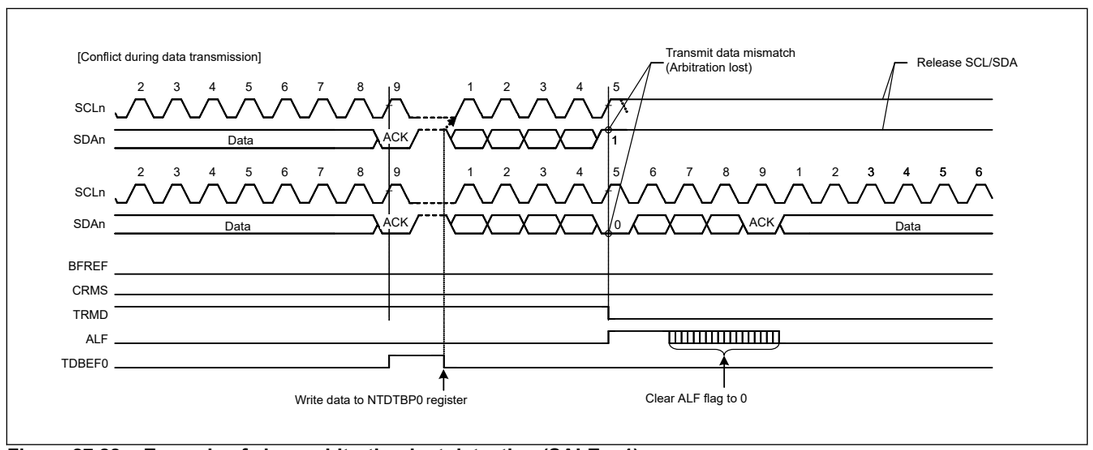

Figure 27.28 Example of slave arbitration-lost detection (SALE = 1)

发生这样的冲突时，masterA无法检测到masterB发送的ACK并发出停止条件。因此，停止条件的发出与主机B的SCL时钟输出相冲突，从而干扰了通信。

当本模块在NACK传输过程中接收到ACK时，它会检测到与其他主设备冲突的失败并导致仲裁丢失。

如果在NACK传输过程中仲裁丢失，该模块立即从从机匹配状态释放并进入从机接收模式。这可以防止发出停止条件，从而防止总线上的通信故障。

同样，在SMBus的ARP命令处理中，如果分配地址的UDID（UniqueDeviceIdentifier），也可以通过检测NACK传输过程中仲裁丢失的功能来消除额外的时钟周期处理（例如FFh传输处理）。在分配地址命令之后的获取UDID（一般）处理中不匹配。

当BSTE.ALE位=1且BFCTL.NALE位=1（启用NACK传输期间仲裁丢失检测）时满足以下条件时，IIC在NACK传输期间检测仲裁丢失。

[在NACK传输期间仲裁丢失的条件]

●在NACK传输期间，当内部SDA输出电平与SDAn线不匹配时（接收到ACK）（ACKCTL.ACKT位=1）

(3) 从设备仲裁丢失检测（SALE位）

IIC有一个功能，如果要发送的数据（内部SDA输出电平）和SDAn线上的电平不匹配（高输出作为内部SDA输出，即SDAn引脚为处于高阻抗状态）并且在从发送模式下在SDAn线上检测到低电平。这种仲裁丢失检测功能主要用于通过SMBus传输UDID（唯一设备标识符）时。

如果在DATA传输过程中仲裁丢失，该模块立即从从机匹配状态释放并进入从机接收模式。该功能可以检测通过SMBus传输UDID期间的数据冲突，并消除后续的冗余处理（传输0xFF的处理）。

当满足以下条件且BSTE.ALE位=1且
BFCTL.SALE位=1（启用从设备仲裁丢失检测）。

27.3.1.3.5 Clock Stretching

(1) Function to Prevent Wrong Transmission of Transmit Data

When data have not been written to the I^2C bus transmit data register (NTDTBP0) with IIC in transmission mode (PRSST.TRMD = 1), the SCLn line is automatically held at the low level over the intervals shown below. This low-hold period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

Master transmit mode

- Low-level interval after a START condition or Repeated START condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

Slave transmit mode

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

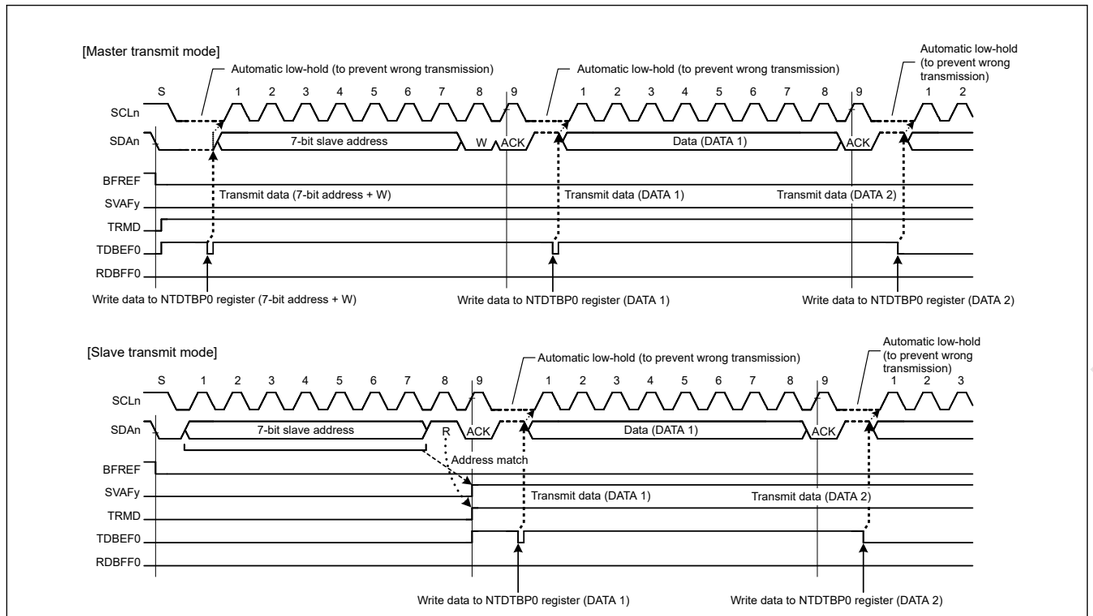

Figure 27.29 Automatic low-hold operation in transmit mode

(2) NACK Reception Transfer Abort Function

IIC has a function to abort transfer operation when NACK is received in transmit mode (PRSST.TRMD = 1). This function is enabled when the BSTE.NACKDE bit is set to 1 (transfer abort enabled). If the next transmit data has already been written (NTST.TDBEF0 = 0) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically aborted. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is aborted by this function (BST.NACKDF = 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to set the NACKDF flag to 0. In master transmit mode, restore operation using either of the methods below:

- After issuing a Repeated START condition, set the NACKDF flag to 0
- After issuing a STOP condition, set the NACKDF flag to 0 and then issue a START condition

27.3.1.3.5 时钟拉伸

(1) 防止传输数据错误传输的功能

当IIC处于传输模式(PRSST.TRMD=1)时尚未将数据写入I2C总线传输数据寄存器(NTDTBP0)时，SCLn线在如下所示的时间间隔内自动保持在低电平。这个低保持期一直延长到要传输的数据已经被写入，这样可以防止错误数据的意外传输。

主传输模式

●发出START条件或RepeatedSTART条件后的低电平间隔

●一次传输的第9个时钟周期与下一次传输的第一个时钟周期之间的低电平间隔

从机发送模式

●一次传输的第9个时钟周期与下一次传输的第一个时钟周期之间的低电平间隔

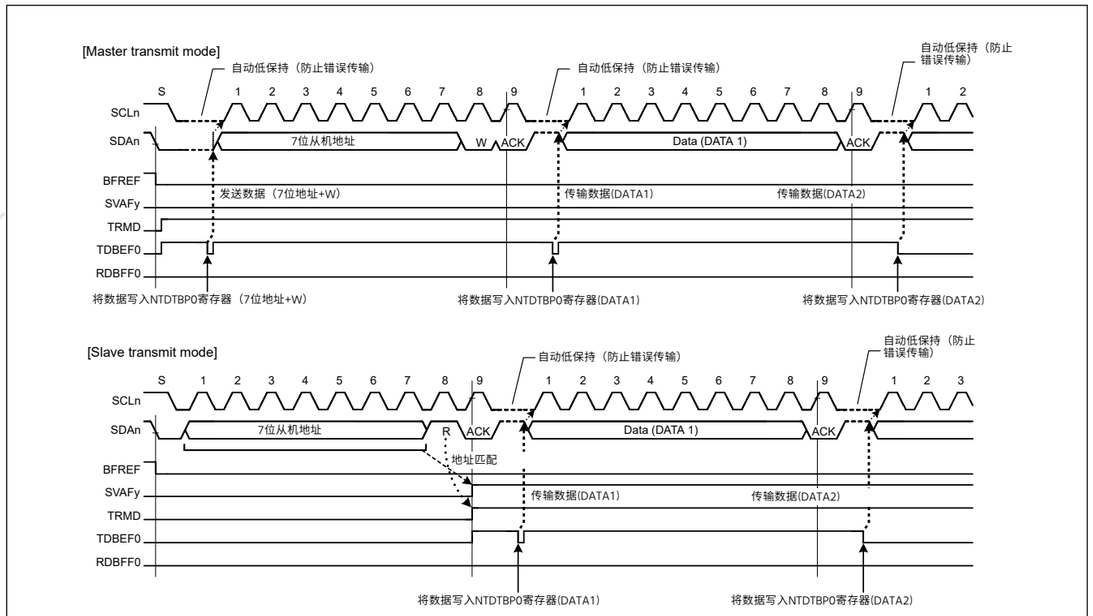

Figure 27.29 发送模式下的自动低保持操作

(2) NACK接收传输中止功能

IIC具有在发送模式下（PRSST.TRMD=1）接收到NACK时中止传输操作的功能。当BSTE.NACKDE位设置为1（使能传输中止）时，该功能被启用。如果在收到NACK时已经写入下一个发送数据（NTST.TDBEF0=0），则在第9个SCL时钟周期的下降沿自动中止下一个数据发送。这可以防止SDAn线路输出电平在下一个发送数据的MSB为0时保持低电平。

如果传输操作被此函数中止（BST.NACKDF=1），发送操作和接收操作将中断。要恢复发送接收操作，请务必将NACKDF标志设置为0。在主发送模式下，使用以下任一方法恢复操作：

●发出重复启动条件后，将NACKDF标志设置为0

●发出STOP条件后，将NACKDF标志设置为0，然后发出START条件

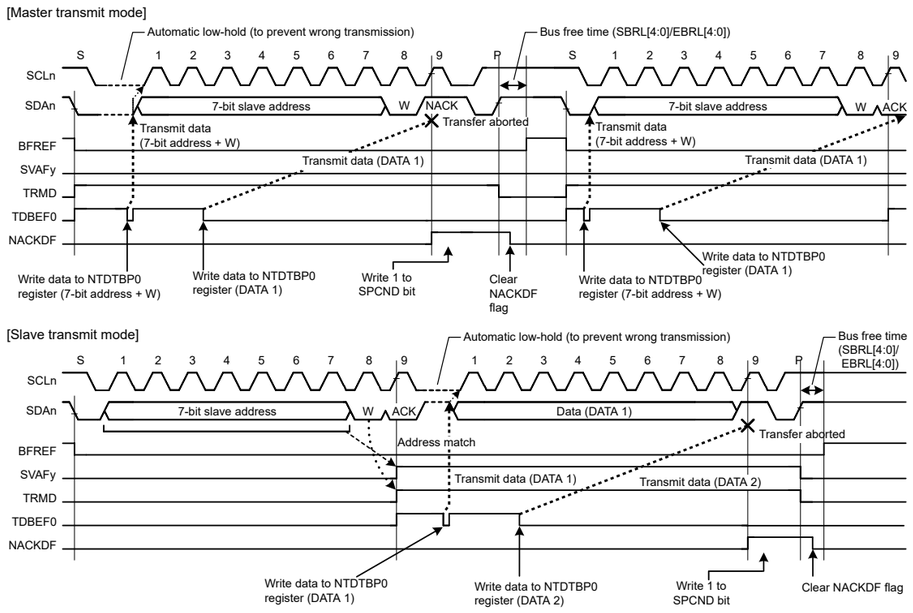

Figure 27.30 Abort of data transfer when NACK is received (NACKE = 1)

(3) Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (NTDTBP0) read is delayed for a period of one transfer frame or more with receive data full (NTST.RDBFF0 = 1) in receive mode (PRSST.TRMD = 0), IIC holds the SCLn line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, IIC's own slave address or another slave address is received after a STOP condition is issued.

Sections in which the SCLn line is held low can be selected with a combination of the RWE and ACKTWE bits in SCSTRCTL.

(a) 1-Byte Receive Operation and Automatic Low-Hold Function Using the RWE Bit

When the SCSTRCTL.RWE bit is set to 1, IIC performs 1-byte receive operation using the RWE bit function.

Furthermore, when the SCSTRCTL.ACKTWE bit = 0, IIC automatically sends the ACKCTL.ACKT bit value for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the SCLn line low at the falling edge of the ninth SCL clock cycle using the RWE bit function. This low-hold is released by reading data from NTDTBP0, which enables bytewise receive operation.

The RWE bit function is enabled for receive frames after a match with IIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

(b) 1-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the ACKTWE Bit

When the SCSTRCTL.ACKTWE bit is set to 1, IIC performs 1-byte receive operation using the ACKTWE bit function.

When the ACKTWE bit is set to 1, the NTST.RDBFF0 flag (receive data full) is set to 1 at the rising edge of the eighth SCL clock cycle, and the SCLn line is automatically held low at the falling edge of the eighth SCL clock cycle. This lowhold is

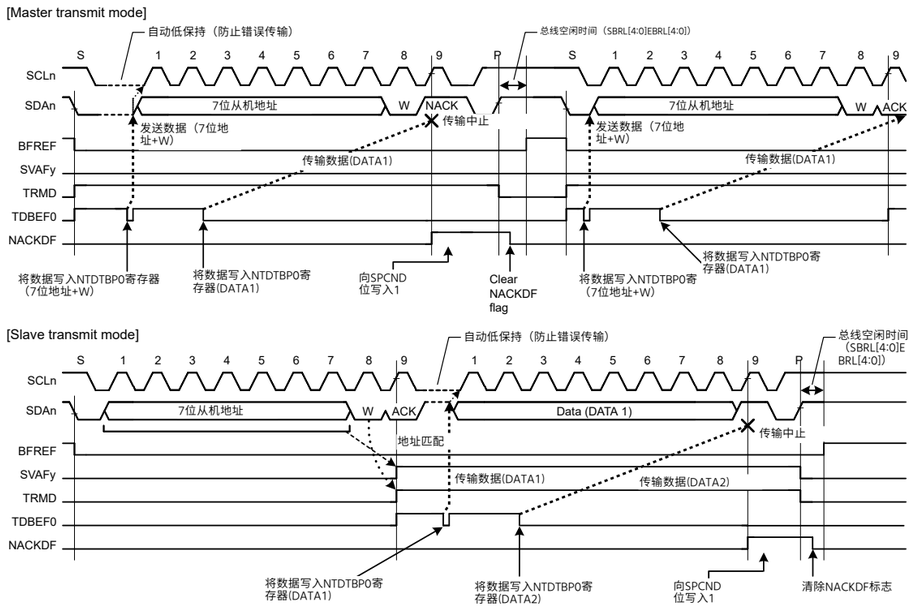

Figure 27.30 收到NACK时中止数据传输(NACKE=1)

(3) 防止数据接收失败的功能

如果在接收模式(PRSST.TRMD=0)下接收数据(NTDTBP0)读取延迟一个传输帧或更长时间且接收数据已满(NTST.RDBFF0=1)时响应处理延迟，则IIC保持SCLn线在接收到下一个数据之前自动拉低，以防止接收数据失败。

即使最终接收数据的读取处理延迟，同时，在STOP条件后接收到IIC自己的从地址或另一个从地址，该功能也启用了使用自动低保持功能防止接收数据失败的功能发出。

SCLn线保持低电平的部分可以通过RWE和ACKTWE位的组合来选择
SCSTRCTL.

(a)1字节接收操作和使用RWE位的自动低保持功能

当SCSTRCTL.RWE位设置为1时，IIC使用RWE位功能执行1字节接收操作。

此外，当SCSTRCTL.ACKTWE位=0时，IIC在第8个SCL时钟周期的下降沿到第9个SCL时钟周期的下降沿期间自动发送ACKCTL.ACKT位值作为确认位，并自动使用RWE位功能在第9个SCL时钟周期的下降沿将SCLn线保持为低电平。该低保持通过从NTDTBP0读取数据来释放，从而启用按字节接收操作。

在主接收模式或从接收模式下，获得与IIC自己的从地址（包括广播地址和主机地址）匹配后的接收帧使能RWE位功能。

(b)1字节接收操作（ACKNACK传输控制）和使用ACKTWE位的自动低保持功能

当SCSTRCTL.ACKTWE位设置为1时，IIC使用ACKTWE位功能执行1字节接收操作。

当ACKTWE位设置为1时，NTST.RDBFF0标志（接收数据已满）在第8个SCL时钟周期的上升沿设置为1，并且SCLn线在第8个SCL的下降沿自动保持为低时钟周期。这个低点是

released by writing a value to the ACKCTL.ACKT bit, but cannot be released by reading data from NTDTBP0, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The ACKTWE bit function is enabled for receive frames after a match with IIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

(1) Extra SCL Clock Cycle Output Function

In master mode, IIC module has a facility for the output of extra SCL clock cycles to release the SDAn line of the slave device from being held at the low level due to the master being out of synchronization with the slave device.

This function is mainly used in master mode to release the SDAn line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from IIC with single cycles of the SCL clock as the unit in the case of a bus error where IIC cannot issue a Repeated START condition or a STOP condition because the slave device is holding the SDAn line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the OUTCTL.EXCYC bit is set to 1, an additional clock pulse at the frequency set by the REFCKCTL.IREFCKS[2:0] bits and the STDBR.SBRHO[7:0] and STDBR.SBRLO[7:0] registers is output from the SCLn pin. After output of this clock pulse, the EXCYC bit automatically becomes 0. After confirming that the EXCYC bit is 0, wait for the setup time of the Repeated START condition or STOP condition, and then confirm the detection of the Repeated START condition or STOP condition. If the Repeated START condition or STOP condition is not detected, consecutive additional clock pulses can be output by writing 1 to the EXCYC bit again.

When IIC module is in master mode and the slave device is holding the SDAn line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a Repeated START condition or a STOP

通过向ACKCTL.ACKT位写入值来释放，但不能通过从NTDTBP0读取数据来释放，这将根据以字节为单位接收到的数据，通过ACKNACK传输控制进行接收操作。

(1) 额外的SCL时钟周期输出功能

在主模式下，IIC模块具有输出额外SCL时钟周期的功能，以释放从设备的SDAn线由于主设备与从设备不同步而保持在低电平。

该功能主要用于主机模式下，以单周期SCL时钟为单位，包含IIC输出的额外SCL周期，使从机的SDAn线从固定状态释放到低电平。IIC无法发出重复启动条件或停止条件的总线错误，因为从设备将SDAn线保持在低电平。请勿在正常情况下使用此设施。在通信正常进行时使用它会导致故障。

当OUTCTL.EXCYC位设置为1时，一个额外的时钟脉冲在由设置的频率REFCKCTL.IREFCKS[2:0]位和STDBR.SBRHO[7:0]和STDBR.SBRLO[7:0]寄存器从SCLn引脚输出。此时钟脉冲输出后，EXCYC位自动变为0。确认EXCYC位为0后，等待重复START条件或STOP条件的建立时间，然后确认检测到重复START条件或STOP条件.如果未检测到重复启动条件或停止条件，则可以通过再次向EXCYC位写入1来输出连续的附加时钟脉冲。

当IIC模块处于主模式并且从设备保持SDAn线为低电平时，因为与从设备的同步由于噪声等的影响而丢失，重复START条件或STOP的输出

condition is not possible. The facility for output of an extra cycle of the SCL clock can be used to output extra cycles of SCL one by one to make the slave device release the SDAn line from being held at the low level, thus recovering the bus from an unusable state. Release of the SDAn line by the slave device can be monitored by reading the SDILV bit in PRSTDBG. After the SDAn line has been released by the slave device, the preset of a Repeated START condition or a STOP condition is issued.

Use this function with the BFCTL.MALE bit set to 0 (master arbitration-lost detection is disabled).

27.3.1.3.7 SMBus Operation

IIC is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the BFCTL.SMBS bit to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus specification, set the REFCKCTL.IREFCKS[2:0] bits, the STDBR.SBRHO[7:0] bits, and the STDBR.SBRLO[7:0] bits. In addition, determine the values of the OUTCTL.SDODCS bit and the OUTCTL.SDOD[2:0] bits to meet the data hold time specification of 300 ns or more. If IIC is used only as an I^2C slave device, the transfer rate setting is not necessary, whereas the STDBR.SBRLO[7:0] bits needs to be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001), use one of the slave device address table basic registers 0 to 2 (SDATBASy.SDSTAD[6:0] bits (y = 0 to 2), and set the corresponding SDATBASy.SDADLS bit (7-bit/10-bit address format select) (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the BFCTL.SALE bit to 1 to enable the slave arbitrationlost detection function.

(1) SMBus Timeout Measurement

(a) Measuring timeout of slave device

The following period (timeout interval: $T_{LOW:SEXT}$) must be measured for slave devices in SMBus communication.

- From START condition to STOP condition

To measure timeout for slave devices, measure the period from START condition detection to STOP condition detection with the GPT timer using a START condition detection interrupt (IICn_EEI) and STOP condition detection interrupt (IICn_EEI) of IIC. The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:SEXT}$: 25 ms (max.) of the SMBus specification.

If the time measured with the GPT exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (min.) of the SMBus specification, the slave device must release the bus by writing 1 to the RSTCTL.INTLRST bit to issue an internal reset of

27.3.1.3.7 SMBus Operation

IIC可用于符合SMBus（2.0版）的数据通信。要执行SMBus通信，请将BFCTL.SMBS位为1。要使用SMBus规范的10kbps到100kbps范围内的传输速率，请将REFCKCTL.IREFCKS[2:0]位、STDBR.SBRHO[7:0]位和STDBR.SBRLO[7:0]位。此外，确定OUTCTL.SDODCS位和OUTCTL.SDOD[2:0]位的值以满足300ns或更长的数据保持时间规范。如果IIC仅用作I2C从设备，则无需设置传输速率，而STDBR.SBRLO[7:0]位需要设置为比数据建立时间(250ns)更长的值。

对于SMBus设备默认地址（1100001），使用从设备地址表基本寄存器0到2之一（SDATBASy.SDSTAD[6:0]位（y=0到2），并设置相应的SDATBASy.SDADLS位（7位10位地址格式选择）（y=0到2）到0（7位地址格式）。

发送UDID（唯一设备标识符）时，将BFCTL.SALE位设置为1，以启用从设备仲裁丢失检测功能。

(1) SMBus超时测量

(a)测量从设备的超时

对于SMBus通信中的从设备，必须测量以下周期（超时间隔：TLOW:SEXT）。

●从START条件到STOP条件

要测量从设备的超时，请使用GPT定时器使用IIC的START条件检测中断(IICn_EEI)和STOP条件检测中断(IICn_EEI)测量从START条件检测到STOP条件检测的周期。测得的超时周期必须在总时钟低电平周期[从设备]TLOW:SEXT:SMBus规范的25毫秒（最大值）内。

如果使用GPT测量的时间超过时钟低电平检测超时TTIMEOUT:SMBus规范的25ms（分钟），从设备必须通过向RSTCTL.INTLRST位写入1来释放总线以发出内部复位的

IIC. When an internal reset is issued, IIC stops driving the bus for the SCLn pin and SDAn pin and make the SCLn/SDAn pin outputs high-impedance, which releases the bus.

(b) Measuring timeout of master device

The following periods (timeout interval: $T_{LOW:MEXT}$) must be measured for master devices in SMBus communication.

- From START condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to STOP condition

To measure timeout for master devices, measure these periods with the GPT timer using a START condition detection interrupt (IICn_EEI), STOP condition detection interrupt (IICn_EEI), and transmit end interrupt (IICn_TEND) or receive data buffer full interrupt (IICn_RX) of IIC. The measured timeout period must be within the total clock lowlevel extended period (master device) $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus specification, and the total of all $T_{LOW:MEXT}$ from START condition to STOP condition must be within $T_{LOW:SEXT}$: 25 ms (max.).

For the ACK receive timing (rising edge of the ninth SCL clock cycle), monitor the BST.TENDF flag in master transmit mode (master transmitter) and the NTST.RDBFF0 flag in master receive mode (master receiver). For this reason, perform bytewise transmit operation in master transmit mode, and hold the SCSTRCTL.ACKTWE bit 0 until the byte just before reception of the final byte in master receive mode. While the ACKTWE bit = 0, the RDBFF0 flag is set to 1 at the rising edge of the ninth SCL clock cycle.

If the period measured with the GPT exceeds the total clock low-level extended period (master device) $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus specification or the total of measured periods exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (min.) of the SMBus specification, the master device must stop the transaction by issuing a STOP condition. In master transmit mode, immediately stop the transmit operation (writing data to NTDTBP0).

(2) Packet Error Code (PEC)

This MCU incorporates a CRC calculator. The CRC calculator enables transmission of a packet error code (PEC) or checking the received data of the SMBus in data communication of IIC. For the CRC generating polynomials of the CRC calculator, see section 31, Cyclic Redundancy Check (CRC).

The PEC data in master transmit mode can be generated by writing all transmit data to the CRC data input register (CRCDIR) in the CRC calculator.

The PEC data in master receive mode can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC data output register (CRCDOR) with the received PEC data.

国际集成电路。当内部复位发出时，IIC停止驱动SCLn引脚和SDAn引脚的总线，并使SCLnSDAn引脚输出高阻态，从而释放总线。

(b)测量主设备超时

对于SMBus通信中的主设备，必须测量以下周期（超时间隔：TLOW:MEXT）。

●从START条件到确认位

●确认位之间

●从确认位到停止条件

要测量主设备的超时，请使用GPT定时器使用IIC的START条件检测中断(IICn_EEI)、STOP条件检测中断(IICn_EEI)和发送结束中断(IICn_TEND)或接收数据缓冲区满中断(IICn_RX)来测量这些周期.测量的超时周期必须在总时钟低电平扩展周期（主设备）TLOW:MEXT：SMBus规范的10毫秒（最大值）内，并且从START条件到STOP条件的所有TLOW:MEXT的总和必须为在TLOW:SEXT内：25毫秒（最大）。

对于ACK接收时序（第9个SCL时钟周期的上升沿），在主机发送模式（主机发送器）和NTST.RDBFF0标志在主机接收模式（主机接收器）监视BST.TENDF标志。因此，在主机发送模式下执行逐字节发送操作，并保持SCSTRCTL.ACKTWE位0直到在主机接收模式下接收到最后一个字节之前的字节。当ACKTWE位=0时，RDBFF0标志在第9个SCL时钟周期的上升沿设置为1。

如果使用GPT测量的周期超过总时钟低电平扩展周期（主设备）TLOW:MEXT:SMBus规范的10ms（最大值）或总测量周期超过时钟低电平检测超时TTIMEOUT：SMBus规范的25ms（分钟），主设备必须通过发出STOP条件来停止事务。在主机发送模式下，立即停止发送操作（向NTDTBP0写入数据）。

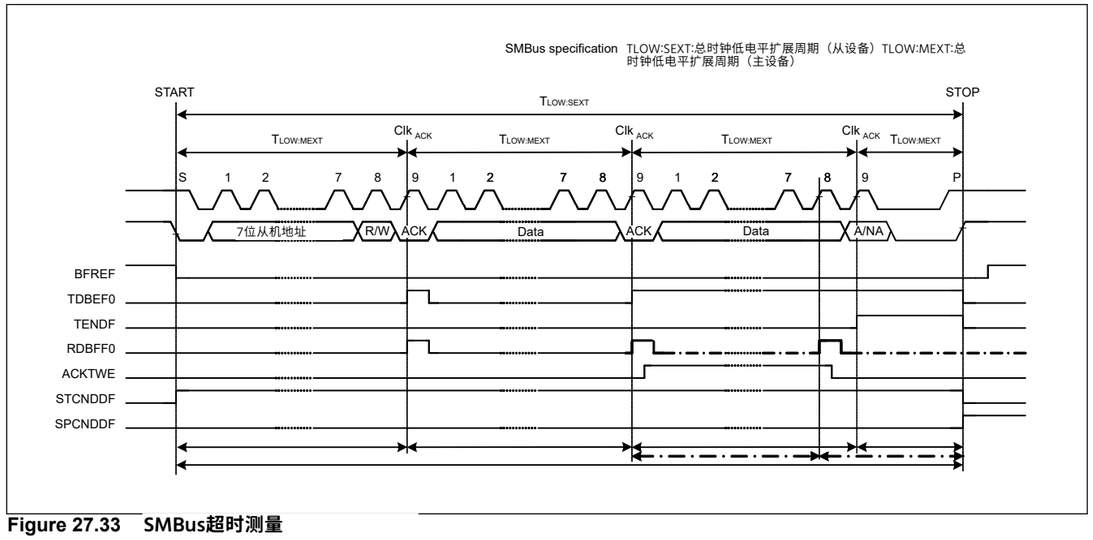

Figure 27.33 SMBus超时测量

(2) 数据包错误代码(PEC)

该MCU包含一个CRC计算器。CRC计算器可以传输数据包错误代码(PEC)或在IIC的数据通信中检查SMBus的接收数据。对于CRC生成多项式CRC计算器，参见第31节，循环冗余校验(CRC)。

主机发送模式下的PEC数据可以通过将所有发送数据写入CRC计算器中的CRC数据输入寄存器(CRCDIR)来生成。

通过将所有接收数据写入CRC计算器中的CRCDIR并将CRC数据输出寄存器(CRCDOR)中获得的值与接收到的PEC数据进行比较，可以检查主机接收模式下的PEC数据。

To send ACK or NACK according to the match or mismatch result when the final byte is received as a result of the PEC code check, set the SCSTRCTL.ACKTWE bit to 1 before the rising edge of the eighth SCL clock cycle during reception of the final byte, and hold the SCLn line low at the falling edge of the eighth clock cycle.

(3) SMBus Host Notification Protocol (Notify ARP Master Command)

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address or to request its own slave address from the SMBus host.

For a product of this MCU to operate as an SMBus host (or ARP master), the host address (0001 000) sent from the slave device must be detected as a slave address, so IIC has a function for detecting the host address. To detect the host address as a slave address, set the BFCTL.SMBS bit and the SVCTL.HOAE bit to 1. Operation after the host address has been detected is the same as normal slave operation.

27.3.1.4 Error Detection

27.3.1.4.1 Timeout Error Detection

IIC includes a timeout function for detecting when the SCLn line has been stuck longer than the predetermined time. IIC can detect an abnormal bus state by monitoring that the SCLn line is stuck low or high for a predetermined time.

The timeout function monitors the SCLn line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the SCLn line changes (rising or falling), but continues to count unless the SCLn line changes. If the internal counter overflows due to no SCLn line change, IIC can detect the timeout and report the bus hung state.

This timeout function is enabled when BSTE.TODE = 1. It detects a hung state that the SCLn line is stuck low or high during the following conditions: (When TMOCTL.TOMDS[1:0] = 00b)

- The bus is busy (BCST.BFREF = 0) in master mode (PRSST.CRMS = 1).
- IIC's own slave address is detected (SVST register is not 0x0000) and the bus is busy (BCST.BFREF = 0) in slave mode (PRSST.CRMS = 0).
- The bus is free (BCST.BFREF = 1) while generation of a START condition is requested (CNDCTL.STCND = 1).

要在接收到作为PEC代码检查的结果的最后一个字节时根据匹配或不匹配结果发送ACK或NACK，请在接收最后一个字节期间在第8个SCL时钟周期的上升沿之前将SCSTRCTL.ACKTWE位设置为1字节，并在第八个时钟周期的下降沿保持SCLn线为低电平。

(3) SMBus主机通知协议（通知ARP主机命令）

在通过SMBus进行通信时，从设备可以临时充当主设备来通知SMBus主机（或ARP主机）它自己的从地址或从SMBus主机请求它自己的从地址。

本MCU的产品要作为SMBus主机（或ARP主机）工作，从机发送的主机地址（0001000）必须被检测为从机地址，所以IIC具有主机地址检测功能。要将主机地址检测为从机地址，请将BFCTL.SMBS位和SVCTL.HOAE位设置为1。检测到主机地址后的操作与正常从机操作相同。

27.3.1.4 错误检测

27.3.1.4.1 超时错误检测

IIC包括一个超时功能，用于检测SCLn线路何时卡住超过预定时间。IIC可以通过监视SCLn线在预定时间内保持低电平或高电平来检测异常总线状态。

超时功能监控SCLn线路状态并使用内部计数器计算低电平周期或高电平周期。每次SCLn线改变（上升或下降）时，超时功能都会复位内部计数器，但除非SCLn线改变，否则会继续计数。如果内部计数器由于SCLn线没有变化而溢出，IIC可以检测到超时并报告总线挂起状态。

此超时功能在BSTE.TODE=1时启用。它在以下情况下检测到SCLn线卡在低电平或高电平的挂起状态：（当TMOCTL.TOMDS[1:0]=00b时）

●在主模式(PRSST.CRMS=1)中，总线繁忙(BCST.BFREF=0)。

●IIC自身的从机地址被检测到（SVST寄存器不是0x0000）并且在从机模式（PRSST.CRMS=0）下总线繁忙（BCST.BFREF=0）。

●总线空闲(BCST.BFREF=1)，同时请求生成START条件(CNDCTL.STCND=1)。

27.3.1.5 Low Power Function

27.3.1.5.1 Wake Up function

IIC is equipped with the Wake-up function that causes the microcomputer to transition from low power consumption mode with system clock is stopped (software standby mode, snooze, etc.) to the normal operation. The Wake-up function is used to generate a Wake-up interrupt signal when the received data matches the address set to Wake-up interrupt factor also receives data in a state where the operating clock (PCLKA/IICCLK) is stopped (PCLKA/IICCLK asynchronous operation). This wake-up interrupt signal causes the microcomputer to transition to the normal operation. After Wake-up interrupt occurs, switch IIC to PCLKA/IICCLK synchronous operation, it will be able to continue the communication operation.

The Wake-up function has four wake-up operation modes (normal WU mode 1, normal WU mode 2, command recovery mode, and EEP response mode). The table below describes the behavior in these four wake-up operation modes.

Table 27.9 Wake-up operation mode (1 of 2)

	ACK response timing	ACK Type responded before recovery to PCLKA/IICCLK synchronous operation	SCL state before recovery to PCLKA/IICCLK synchronous operation
Normal WU mode 1	Before recovery to PCLKA/IICCLK synchronous operation*1	ACK	Fixed to L
Normal WU mode 2	After recovery to PCLKA/IICCLK synchronous operation*2	Before recovery: no response (NACK level retained) After recovery: ACK response	Fixed to L
Command recovery mode	Before recovery to PCLKA/IICCLK synchronous operation*1	ACK	Open

27.3.1.5 低功耗功能

27.3.1.5.1 唤醒功能

IIC配备唤醒功能，使微机在系统时钟停止（软件待机模式、贪睡等）时从低功耗模式转换到正常操作。唤醒功能用于在接收到的数据与设置为唤醒中断因子的地址匹配时生成唤醒中断信号，同时在工作时钟（PCLKAIICCLK）停止（PCLKAIICCLK异步操作）的状态下接收数据）。该唤醒中断信号使微型计算机转变为正常操作。唤醒中断发生后，将IIC切换到PCLKAIICCLK同步操作，即可继续通讯操作。

唤醒功能有四种唤醒操作模式（正常WU模式1、正常WU模式2、命令恢复模式和EEP响应模式）。下表描述了这四种唤醒操作模式下的行为。

Table 27.9 唤醒操作模式(1of2)

	ACK响应时间	ACK类型在恢复到PCLKAIICCLK同步操作之前响应	恢复到PCLKAIICCLK同步操作之前的SCL状态
普通WU模式1	恢复到PCLKA之前IICCLK同步操作*1	ACK	固定为L
普通WU模式2	恢复到PCLKAIICCLK同步操作后*2	恢复前：无响应（保留NACK电平）恢复后：ACK响应	固定为L
命令恢复模式	恢复到PCLKA之前IICCLK同步操作*1	ACK	Open

Table 27.9 Wake-up operation mode (2 of 2)

	ACK response timing	ACK Type responded before recovery to PCLKA/IICCLK synchronous operation	SCL state before recovery to PCLKA/IICCLK synchronous operation
EEP response mode	Before recovery to PCLKA/IICCLK synchronous operation*1	NACK	Open

Note 1. Switching timing from PCLKA/IICCLK asynchronous operation to PCLKA/IICCLK synchronous operation is the fall of the 9th clock of SCL.
Note 2. Switching timing from PCLKA/IICCLK asynchronous operation to PCLKA/IICCLK synchronous operation is the fall of the 8th clock of SCL.

The following is able to select as Wake-Up interrupt factor.

- Host address detection (valid when SVCTL.HOAE = 1)
- General call address detection (valid when SVCTL.GCAE = 1)
- Slave address 0*1 detection (valid when SVCTL.SVAE0 = 1)
- Slave address 1*1 detection (valid when SVCTL.SVAE1 = 1)
- Slave address 2*1 detection (valid when SVCTL.SVAE2 = 1)

Note 1. 7-bit address only can be set. Set SDADLS bit to 0 in SDATBASy.

(1) Normal Wake-Up mode 1

This section describes the behavior, the timing, and a use case of normal WU mode 1.

A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below. Also, the detailed timing is provided in Figure 27.37.

Before wake-up recovery:	ACK is sent in response to the data received with its own slave address.
During wake-up recovery:	ACK response is made at the 9th clock cycle of SCL, and the SCL is held low afterwards.*1
After wake-up recovery:	Normal operation continues.

Note 1. Between ninth clock cycle and first clock cycle during Wake-Up recovery, SCSTRCTL.RWE = 1 does not work.

If the slave address does not match, the SCL line is not held low after the fall of the 9th clock cycle of SCL, and the slave operation continues.

See Figure 27.35 below for a use case.

A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to Figure 27.36.

Table 27.9 唤醒操作模式(2of2)

	ACK响应时间	ACK类型在恢复到PCLKAIICCLK同步操作之前响应	恢复到PCLKAIICCLK同步操作之前的SCL状态

注1.从PCLKAIICCLK异步操作切换到PCLKAIICCLK同步操作的时序是SCL的第9个时钟的下降沿。

注2.从PCLKAIICCLK异步操作切换到PCLKAIICCLK同步操作的时序是SCL的第8个时钟的下降沿。

以下可以选择作为唤醒中断因素。

- ●主机地址检测（SVCTL.HOAE=1时有效）
- ●广播地址检测（SVCTL.GCAE=1时有效）
- ●从机地址0*1检测（SVCTL.SVAE0=1时有效）
- ●从机地址1*1检测（SVCTL.SVAE1=1时有效）
- ●从机地址2*1检测（SVCTL.SVAE2=1时有效）

注1.只能设置7位地址。在SDATBASy中将SDADLS位设置为0。

(1) 正常唤醒模式1

本节介绍正常WU模式1的行为、时序和用例。

从机地址匹配触发的唤醒中断以下述方式转换到正常操作。此外，图27.37中提供了详细的时序。

Before wake-up recovery:	ACK是响应接收到的数据而发送的，带有它自己的从地址。
During wake-up recovery:	在SCL的第9个时钟周期做出ACK响应，之后SCL保持低电平。*1
After wake-up recovery:	正常操作继续。

注1.在唤醒恢复期间的第9个时钟周期和第一个时钟周期之间，SCSTRCTL.RWE=1不起作用。

如果从机地址不匹配，则在SCL的第9个时钟周期下降后，SCL线不保持低电平，从机操作继续。

有关用例，请参见下面的图27.35。

如果转换是由除从地址匹配产生的唤醒中断信号之外的原因（其他恢复原因(IRQ)）触发的，则在转换到正常操作时不会产生唤醒中断。在这种情况下未设置BST.WUCNDDF。按照图27.36进行如下处理。

(2) Normal Wake Up Mode 2

This section describes the behavior, the timing, and a use case of normal WU mode 2.

A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below.

Also, the detailed timing is provided in Figure 27.39.

Before wake-up recovery:	No response to the data received with its own slave address (until 8th SCL cycle end)
During wake-up recovery:	Holding the SCL line low during the 8th and 9th clock cycles
After wake-up recovery:	Returning ACK at the 9th clock cycle of SCL, and continuing the normal operation

If the slave address does not match, the SCL line is not held low after the fall of the 8th SCL v clock cycle. The slave operation continues.

See Figure 27.38 below for a use case.

(2) 正常唤醒模式2

本节介绍正常WU模式2的行为、时序和用例。

从机地址匹配触发的唤醒中断以下述方式转换到正常操作。

此外，图27.39中提供了详细的时序。

Before wake-up recovery:	对接收到的带有自己的从机地址的数据没有响应（直到第8个SCL周期结束）
During wake-up recovery:	在第8和第9个时钟周期内保持SCL线为低电平
After wake-up recovery:	在SCL的第9个时钟周期返回ACK，并继续正常运行

如果从地址不匹配，则在第8个SCLv时钟周期下降后，SCL线不会保持低电平。从操作继续。

有关用例，请参见下面的图27.38。

如果转换是由除从地址匹配产生的唤醒中断信号之外的原因（其他恢复原因(IRQ)）触发的，则在转换到正常操作时不会产生唤醒中断。在这种情况下未设置BST.WUCNDDF。按照图27.36进行如下处理。

(3) Command recovery mode/ EEP response mode (Special Wake Up mode)

In the command recovery mode and EEP response mode, the SCL line is not held low during the wake-up recovery period (after the rise of the 9th clock cycle of SCL), so other I^2C devices can use the I^2C bus during this period. This section describes the behavior, the timing, and use cases of the command recovery mode and the EEP response mode.

A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below. Also, the detailed timing is provided in Figure 27.42.

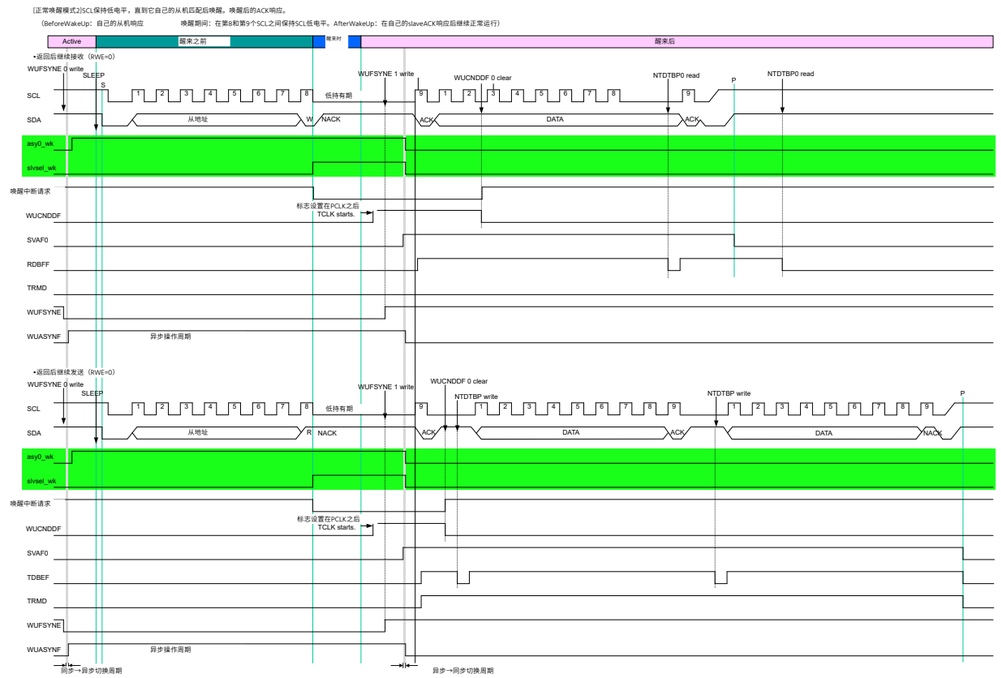
Before wake-up recovery:	In response to the data received with its own slave address, ACK (command recovery mode) or NACK (EEP response mode) is returned.
During wake-up recovery:	The SCL line is not held low.
After wake-up recovery:	Normal operation continues after IIC initial setting.

Note: Because the SCL line is not held low during wake-up recovery, the transmission/reception of the data that follows the slave address is not possible.
Note: The command recovery mode and the EEP response mode are internal reset (RSTCTL.INTLRST = 1) states. Therefore, the match of the slave address does not set the SVST flags (HOAF, GCAF, and SVAF2, SVAF1, SVAF0).

If the slave address does not match, the slave operation continues.

See Figure 27.41 below for a use case.

A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to Figure 27.41.



Note: TCLK = IICCLK
PCLK = PCLKA

Figure 27.39 正常唤醒模式2的时序

(3) 命令恢复模式EEP响应模式（特殊唤醒模式）

在命令恢复模式和EEP响应模式下，SCL线在唤醒恢复期间（SCL第9个时钟周期上升后）不保持低电平，因此其他I2C设备可以使用I2C总线在这段时期。本节介绍命令恢复模式和EEP响应模式的行为、时序和用例。

从机地址匹配触发的唤醒中断以下述方式转换到正常操作。此外，图27.42中提供了详细的时序。

Before wake-up recovery:	以自己的从机地址接收到的数据，返回ACK（命令恢复模式）或NACK（EEP响应模式）。
During wake-up recovery:	SCL线没有保持低电平。
After wake-up recovery:	IIC初始设置后继续正常操作。

Note: 由于在唤醒恢复期间SCL线不保持低电平，因此无法发送接收从地址之后的数据。

Note: 命令恢复模式和EEP响应模式是内部复位(RSTCTL.INTLRST=1)状态。因此，从地址的匹配不会设置SVST标志（HOAF、GCAF和SVAF2、SVAF1、SVAF0）。

如果从机地址不匹配，从机操作继续。

有关用例，请参见下面的图27.41。

如果转换是由除从地址匹配产生的唤醒中断信号之外的原因（其他恢复原因(IRQ)）触发的，则在转换到正常操作时不会产生唤醒中断。在这种情况下未设置BST.WUCNDDF。按照图27.41进行如下处理。

(4) Precautions on the use of the Wake-Up function

Precautions on the use of the Wake-up function is shown below.

- Do not change the registers in IIC except the WUCTL.WUFSYNE bit while the WUST.WUASYNF flag = 1 (while PCLKA/IICCLK asynchronous operation).
- Set WUCTL.WUFE = BSTE.WUCNDDE = BIE.WUCNDDIE = 1 and PRSST.CRMS = PRSST.TRMD = 0 (slave reception mode) before switching PCLKA/IICCLK asynchronous mode.
- Can not select the device ID and the 10-bit slave address for wake-up interrupt factor. Set the DVIDE bit in SVCTL and SDADLS bit in SDATBASy to 0.
- Sets all bits in BIE (TENDIE, NACKDIE, SPCNDDIE, STCNDDIE, ALIE, TODIE) and TDBEIE0 and RDBFIE0 bits in NTIE to 0 (Interrupt disabled) before switching the asynchronous operation.
- Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE = 1).
- Wake-up interrupt is generated while PCLKA/IICCLK asynchronous operation (when WUST.WUASYNF = 1). In case of detecting slave address matching, The case of detect slave address match in PCLKA/IICCLK synchronous mode (WUST.WUASYNF = 0), does not occur Wake-up interrupt, and BST.WUCNDDF flag will be not set also.
- If WUCTL.WUFSYNE bit to 0 write timing and START condition of detecting a conflict, IIC might start the next reception in PCLKA/IICCLK synchronous operation mode. In this case, WUST.WUASYNF flag becomes 1 (switch to PCLKA/IICCLK asynchronous mode) when data communication is finished and detected STOP condition and starts the Wake-up event detection.

(4) 唤醒功能使用注意事项

使用唤醒功能的注意事项如下所示。

●当WUST.WUASYNF标志=1时（当PCLKAIICCLK异步操作时），不要更改IIC中的寄存器，除了WUCTL.WUFSYNE位。

●在切换PCLKAIICCLK异步模式之前设置WUCTL.WUFE=BSTE.WUCNDDE=BIE.WUCNDDIE=1和PRSST.CRMS=PRSST.TRMD=0（从接收模式）。

●唤醒中断因子不能选择设备ID和10位从机地址。将SVCTL中的DVIDE位和SDATBASy中的SDADLS位设置为0。

●在切换异步操作之前，将BIE中的所有位（TENDIE、NACKDIE、SPCNDDIE、STCNDDIE、ALIE、TODIE）和NTIE中的TDBEIE0和RDBFIE0位设置为0（中断禁用）。

●唤醒功能启用时不要使用超时功能（WUCTL.WUFE=1）。

●PCLKAIICCLK异步操作时产生唤醒中断（当WUST.WUASYNF=1时）。在检测从机地址匹配的情况下，在PCLKAIICCLK同步模式（WUST.WUASYNF=0）检测从机地址匹配的情况下，不会发生唤醒中断，也不会设置BST.WUCNDDF标志。

●如果WUCTL.WUFSYNE位为0写入时序和检测到的START条件冲突，IIC可能会启动下一个
在PCLKAIICCLK同步操作模式下接收。在这种情况下，当数据通信完成并检测到STOP条件并启动

唤醒事件检测。

- If you want to switch from PCLKA/IICCLK asynchronous operation to PCLKA/IICCLK synchronous operation without address match detection, it will switch in the STOP condition detection. When the WUCTL.WUFSYNE bit was set to 1 in a bus free state, it is continued PCLKA/IICCLK asynchronous operation (Reception operation: waiting communication frame). WUST.WUASYNF flag becomes to 0 when IIC detect the STOP condition of the next communication frame, and IIC switches to PCLKA/IICCLK synchronous operation.
- After writing 0 to WUFSYNE bit in WUCTL, do not change IIC operation mode setting register (BFCTL, SCSTRCTL, ACKCTL, INCTL, SVCTL, SDATBASy) until switched to the PCLKA/IICCLK asynchronous operation from PCLKA/IICCLK synchronous operation (while WUST.WUASYNF flag = 1). If register value changes by the interrupt processing etc. in this period, IIC might malfunction without succeeding to the setting to the asynchronous operation.
- During PCLKA/IICCLK asynchronous operation (WUST.WUASYNF = 1), do not refer to each flag of SVST, BST, NTST register and BCST.BFREF flag.
- Do not set ACKCTL.ACKT = 1 in order to make an ACK response in the synchronization unit when Wake-up is performed by slave address match in Normal wake-up mode 2.

27.3.1.6 Other

27.3.1.6.1 SCL Synchronization Circuit

In generation of the SCL clock, IIC starts counting out the value for width at high level specified in STDBR.SBRHO[7:0] when it detects a rising edge on the SCLn line and drives the SCLn line low once counting of the width at high level is complete.

When IIC detects the falling edge of the SCLn line, it starts counting out the width at low level period specified in STDBR.SBRLO[7:0], and then stops driving the SCLn line (releases the line) once counting of the width at low level is complete. The SCL clock is thus generated.

If multiple master devices are connected to the I^2C bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, IIC is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When IIC has detected a rising edge on the SCLn line and thus started counting out the width at high level specified in STDBR.SBRHO[7:0], and the level on the SCLn line falls because an SCL signal is being generated by another master device, IIC stops counting when it detects the falling edge, drives the level on the SCLn line low, and starts counting out the width at low level specified in STDBR.SBRLO[7:0]. When IIC finishes counting out the width at low level, it stops driving the SCLn line to the low level (releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in this module, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCLn line has been released. When IIC finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the SCSYNE bit in BFCTL is set to 1.

●如果要从PCLKAIICCLK异步操作切换到PCLKAIICCLK同步操作
如果没有地址匹配检测，它将切换到STOP条件检测。当WUCTL.WUFSYNE位在总线空闲状态设置为1时，继续PCLKAIICCLK异步操作（接收操作：等待通信帧）。当IIC检测到下一个通信帧的STOP条件时，WUST.WUASYNF标志变为0，并且IIC切换到PCLKAIICCLK同步操作。

●将WUCTL中的WUFSYNE位写入0后，不要更改IIC操作模式设置寄存器（BFCTL、SCSTRCTL、ACKCTL、INCTL、SVCTL、SDATBASy），直到从IICCLK异步操作切换到PCLKA
PCLKAIICCLK同步操作（当WUST.WUASYNF标志=1时）。如果在此期间寄存器值因中断处理等而发生变化，则IIC可能会发生故障，而无法成功设置异步操作。

●在PCLKAIICCLK异步操作期间（WUST.WUASYNF=1），不要参考SVST、BST、NTST寄存器的每个标志和BCST.BFREF标志。

●在Normal唤醒模式2中通过从机地址匹配执行唤醒时，不要设置ACKCTL.ACKT=1以便在同步单元中做出ACK响应。

27.3.1.6 Other

27.3.1.6.1 SCL同步电路

在生成SCL时钟时，IIC在检测到SCLn线上的上升沿时开始计算STDBR.SBRHO[7:0]中指定的高电平宽度值，并在计数到高水平完成。

当IIC检测到SCLn线的下降沿时，它开始计数指定的低电平周期的宽度
STDBR.SBRLO[7:0]，然后在低电平宽度计数完成后停止驱动SCLn线（释放线）。这样就生成了SCL时钟。

如果多个主设备连接到I2C总线，由于与另一个主设备的争用，可能会出现SCL信号的冲突。在这种情况下，主设备必须同步它们的SCL信号。由于SCL信号的这种同步必须逐位进行，因此IIC配备了一个设备（SCL同步电路），通过在主机模式下监视SCLn线来获得SCL时钟信号的逐位同步。

当IIC检测到SCLn线上的上升沿并因此开始计算STDBR.SBRHO[7:0]中指定的高电平宽度时，由于另一个主控器正在生成SCL信号，因此SCLn线上的电平下降IIC在检测到下降沿时停止计数，将SCLn线上的电平驱动为低电平，并在STDBR.SBRLO[7:0]中指定的低电平开始计数宽度。当IIC在低电平完成宽度计数时，停止将SCLn线驱动到低电平（释放线）。此时，如果来自其他主设备的SCL时钟信号的低电平宽度大于本模块设置的低电平宽度，则SCL信号的低电平宽度将被扩展。一旦另一个主设备的低电平宽度结束，SCL信号就会上升，因为SCLn线已被释放。当IIC输出完SCL时钟的低电平周期后，SCLn线被释放，SCL时钟上升。即，在来自多个主机的SCL信号竞争的情况下，SCL信号的高电平宽度与宽度较窄的时钟的宽度同步，而SCL信号的低电平宽度与时钟具有更宽的宽度。然而，只有当BFCTL中的SCSYNE位设置为1时，才启用SCL信号的这种同步。

27.3.1.6.2 Facility for Delaying SDA Output

IIC module incorporates a facility for delaying output on the SDA line. The delay can be applied to all output (issuing of the START, Repeated START, and STOP conditions, data, and the ACK and NACK signals) on the SDA line.

With the SDA output delay facility, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL clock is at the low level. Doing this leads to usage with the aim of preventing erroneous operation of communications devices, with the aim of satisfying the 300 ns (minimum) data-hold time requirement of the SMBus specification.

The output delay facility is enabled by setting the SDOD[2:0] bits in OUTCTL to any value other than 000b, and disabled by setting the same bits to 000b.

While the SDA output delay facility is enabled (while the SDOD[2:0] bits in OUTCTL are set to any value other than 000b), the SDODCS bit in OUTCTL selects the clock source for counting by the SDA output delay counter as the internal base clock (IICφ) for IIC module or as a clock signal derived by dividing the frequency of the internal base clock by two (IICφ/2). The counter counts the number of cycles set in the SDOD[2:0] bits in OUTCTL. After counting of the set number of cycles of delay is completed, IIC module places the required output (START, Repeated START, or STOP condition, data, or an ACK or NACK signal) on the SDA line.

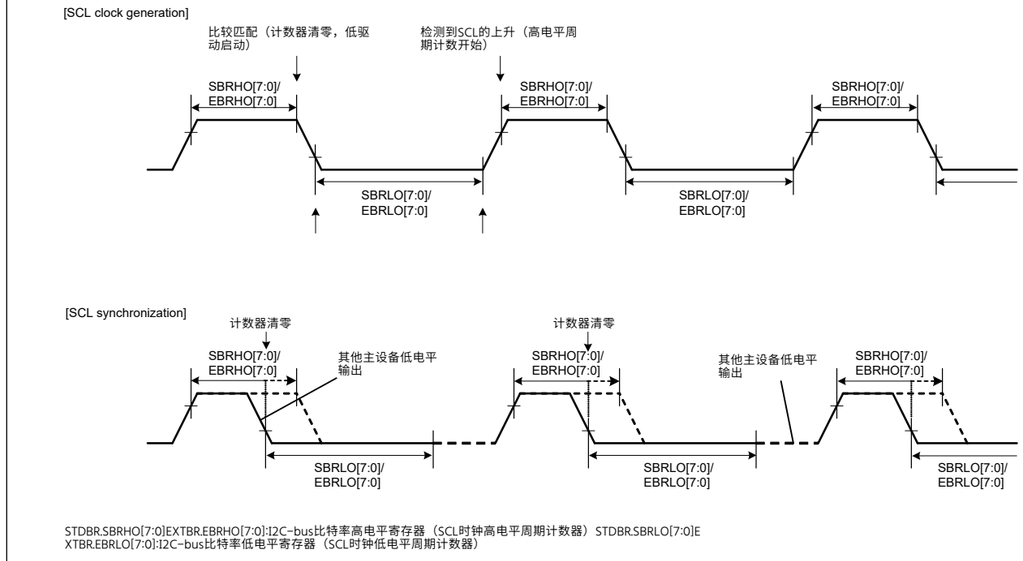

Figure 27.43 SCL信号的生成和同步

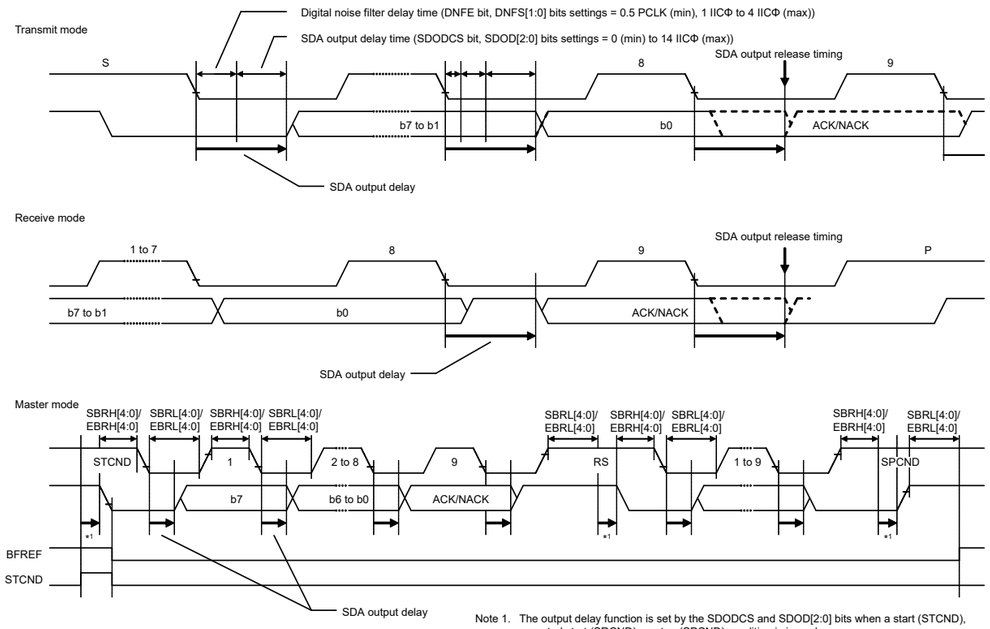
27.3.1.6.2 延迟SDA输出的设备

IIC模块包含一个用于延迟SDA线路上的输出的功能。延迟可以应用于所有输出（发出SDA线上的START、重复START和STOP条件、数据以及ACK和NACK信号。

使用SDA输出延迟功能，SDA输出从检测到SCL信号的下降沿开始延迟，以确保SDA信号在SCL时钟处于低电平的时间间隔内输出。这样做会导致使用目的是防止通信设备的错误操作，目的是满足SMBus规范的300ns（最小）数据保持时间要求。

输出延迟功能通过将OUTCTL中的SDOD[2:0]位设置为000b以外的任何值来启用，并通过将相同位设置为000b来禁用。

当SDA输出延迟功能被使能时（同时OUTCTL中的SDOD[2:0]位设置为000b以外的任何值），OUTCTL中的SDODCS位选择SDA输出延迟计数器计数的时钟源作为内部IIC模块的基本时钟(IICφ)或作为通过将内部基本时钟的频率除以2(IICφ2)得到的时钟信号。计数器计算在OUTCTL的SDOD[2:0]位中设置的周期数。在完成对设定的延迟周期数的计数后，IIC模块将所需的输出（START、RepeatedSTART或STOP条件、数据或ACK或NACK信号）放在SDA线上。



Note 1. The output delay function is set by the SDODCS and SDOD[2:0] bits when a start (STCND), repeated start (SRCND), or stop (SPCND) condition is issued.

27.3.1.6.3 Digital Noise-Filter Circuits

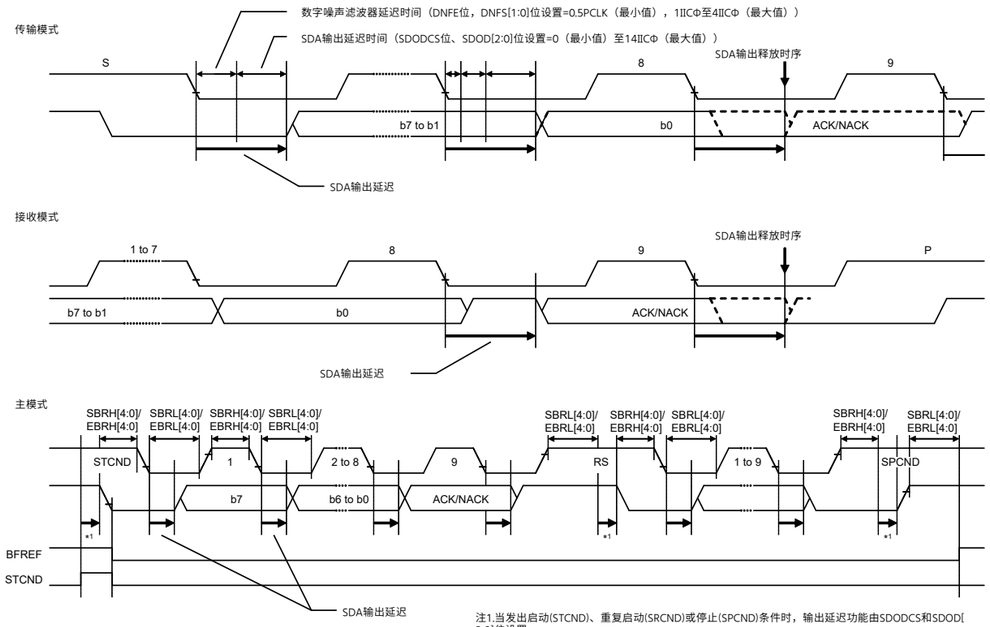
The states of the SCLn and SDAn pins are conveyed to the internal circuitry through digital noise-filter circuits. Figure 27.45 is a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of IIC consists of 16 flip-flop circuit stages connected in series and a match detection circuit. When HS mode is selected, only the first four flip-flop circuits stages are enabled.

The number of effective stages in the digital noise filter is selected by the INCTL.DNFS[3:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to sixteen IICφ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on rising edges of the IICφ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the INCTL.DNFS[3:0] bits, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (IICCLK) and the transfer rate is small (For example, data transfer at 400 kbps with IICCLK = 4 MHz), the characteristics of the digital noise filter may lead to the elimination of needed signals as noise.



注1.当发出启动(STCND)、重复启动(SRCND)或停止(SPCND)条件时，输出延迟功能由SDODCS和SDOD[2:0]位设置。

27.3.1.6.3 数字噪声滤波器电路

SCLn和SDAn引脚的状态通过数字噪声滤波器电路传送到内部电路。图27.45是数字噪声滤波器电路的框图。

IIC的片上数字噪声滤波电路由16个串联的触发器电路级和一个匹配检测电路组成。选择HS模式时，仅启用前四个触发器电路级。

数字噪声滤波器的有效级数由INCTL.DNFS[3:0]位选择。选定的有效级数将噪声过滤能力确定为从1到16个IICφ周期的周期。

SCLn引脚（或SDAn引脚）的输入信号在IICφ信号的上升沿采样。当输入信号电平与由INCTL.DNFS[3:0]位选择的有效触发器电路级数的输出电平匹配时，信号电平被传送到下一级。如果信号电平不匹配，则保留先前的值。

如果内部工作时钟(IICCLK)的频率与传输速率之间的比率很小（例如，数据传输速率为400kbps，IICCLK=4MHz），则数字噪声滤波器的特性可能会导致消除所需的信号作为噪声。

27.3.2 Operation

27.3.2.1 Initial Setting Flow

27.3.2.1.1 I2C Initial Setting Flow (Single Buffer Transfer)

Before starting data transmission and reception, initialize IIC according to the procedure in Figure 27.46.

First, set the BCTL.BUSE bit to 0 (SCLn, SDAn pins not driven).

Next, set the RSTCTL.RI2CRST bit to 1 (IIC reset). This initializes the all registers and internal state. Then, waits for RI2CRST to become 0.

This initializes the various flags and some registers. See Reset Descriptions.

After that, set registers SDATBAS.SDADLS, SDATBAS.SDATAD[9:0], STDBR, INCTL, OUTCTL, TMOCTL, TMOCNT, SCSTRCTL, ACKCTL, and BFCTL, then set the other registers as necessary (for initial settings of IIC, see Figure 27.46).

27.3.2.1 初始设定流程

27.3.2.1.1 I2C初始设置流程（单缓冲区传输）

在开始数据发送和接收之前，按照图27.46中的过程初始化IIC。

首先，将BCTL.BUSE位设置为0（SCLn、SDAn引脚未驱动）。

接下来，将RSTCTL.RI2CRST位设置为1（IIC复位）。这将初始化所有寄存器和内部状态。然后，等待RI2CRST变为0。

这会初始化各种标志和一些寄存器。请参阅重置说明。

之后，设置寄存器SDATBAS.SDADLS、SDATBAS.SDATAD[9:0]、STDBR、INCTL、OUTCTL、TMOCTL、TMOCNT、SCSTRCTL、ACKCTL和BFCTL，然后根据需要设置其他寄存器（有关IIC的初始设置，请参见Figure 27.46）.

27.4.2 Buffer Operation for Buffer Full/Empty Interrupts

If the conditions for generating the each buffer full/empty interrupts are satisfied while the corresponding IR flag is 1, the interrupt request is not output for the ICU but retained internally (the capacity for internal retention is one request per source).

An interrupt request that was being retained within the ICU is output when the value of the ICU.IRn.IR flag becomes 0. Internally retained interrupt requests are automatically cleared under normal conditions of usage. Internally retained interrupt requests can also be cleared by writing 0 to the interrupt enable bit within the given peripheral module.

27.5 Event Link Output

IIC handles event output for the event link controller (ELC) corresponding to the following sources.

(1) Communication event

When a Communication event (arbitration-lost detection, detection of NACK, detection of timeout, detection of a START condition, or detection of a STOP condition) occurs, the corresponding event signal can be output for another module via the ELC.

(2) Receive data full

When a receive data register becomes full, the corresponding event signal can be output for another module via the ELC.

(3) Transmit data empty

When a transmit data register becomes empty, the corresponding event signal can be output for another module via the ELC.

(4) Transmit end

On completion of transfer, the corresponding event signal can be output for another module via the ELC.

27.5.1 Interrupt Handling and Event Linking

IIC module produces four kinds of interrupt: communication event (arbitration-lost detection, detection of NACK, detection of timeout, detection of a START condition, or detection of a STOP condition), receive data full, transmit data empty, and transmit end interrupts. Each of these has an enable bit to control enabling and disabling of the interrupt signal. An interrupt request signal is output for the CPU when an interrupt source condition is satisfied while the setting of the corresponding enable bit is enabled.

The corresponding event link output signals are sent to other modules as event signals via the ELC when the interrupt source conditions are satisfied, regardless of the settings of the interrupt enable bits. For details on interrupt sources, see section 27.4.1. Overview.

27.4.2 缓冲区满空中断的缓冲区操作

如果在相应的IR标志为1时满足产生每个缓冲区满空中断的条件，则该中断请求不输出给ICU，而是在内部保留（内部保留的容量为每个源一个请求）。

当ICU.IRn.IR标志的值变为0时，输出一直保留在ICU内的中断请求。
在正常使用条件下，内部保留的中断请求会自动清除。内部保留的中断请求也可以通过将0写入给定外设模块中的中断使能位来清除。

27.5 事件链接输出

IIC处理与以下源相对应的事件链接控制器(ELC)的事件输出。

(1) 交流活动

当发生通信事件（仲裁丢失检测、NACK检测、超时检测、START条件检测或STOP条件检测）时，可以通过ELC为另一个模块输出相应的事件信号。

(2) 接收数据已满

当接收数据寄存器变满时，可以通过ELC为另一个模块输出相应的事件信号。

(3) 传输数据为空

当发送数据寄存器为空时，可以通过ELC为另一个模块输出相应的事件信号。

(4) 发射端

传输完成后，可以通过ELC为另一个模块输出相应的事件信号。

27.5.1 中断处理和事件链接

IIC模块产生四种中断：通信事件（仲裁丢失检测、NACK检测、超时检测、START条件检测或STOP条件检测）、接收数据满、发送数据空和发送结束中断.其中每一个都有一个启用位来控制中断信号的启用和禁用。当相应的使能位设置为使能时，如果满足中断源条件，则向CPU输出中断请求信号。

当满足中断源条件时，无论中断允许位的设置如何，相应的事件链接输出信号都会通过ELC作为事件信号发送到其他模块。有关中断源的详细信息，请参阅第27.4.1节。概述。

28. CAN with Flexible Data-rate (CANFD)

This is the CANFD_B version of the CANFD peripheral module.

CANFD_B is referred to as CANFD in this chapter.

●消息缓冲区RAM：

This RAM is used to store messages after reception or for transmission using a normal message buffer or a FIFO. Each message entry has an individual ID, data length code, data field, message pointer for upper layer application usage and a time stamp.
This RAM is used to store the message acceptance filtering entries. Each acceptance filter entry has an individual ID, data length code, data field, message pointer for upper layer application usage and message direction pointer.

- Acceptance filter:
  Performs filtering of received messages. The entries in the Acceptance filter list RAM are used for the filtering process.
- Two timers:
  - Reception Timestamp function
  - Transmission separation time for FIFO buffers
- Interrupt generator:
  Generates several types of global and channel interrupts
- CAN Special Function Registers (SFRs):
  Registers associated with CAN. See section 28.2. Register Descriptions.

28.1.2 Clock restriction

For the CAN communication the following restriction for the clocks should be satisfied:

- PCLKA / 2 = PCLKB ≥ CANFDCLK
- PCLKA / 2 = PCLKB ≥ CANMCLK

To avoid missing events the CAN engine clock (CANFDCLK or CANMCLK) frequency must be less than the PCLKB clock frequency.

To avoid loss of CAN message, the PCLKB should be set to a clock with a frequacy depend on the CAN communication Baud Rate. The constraint of a baud rate and a PCLKB clock is shown in Table 28.2.

Table 28.2 Clock restriction

	Baud rate	PCLKB
CANFD	1Mbps Nominal 5Mbps Data	PCLKB ≥ 40MHz
	500Kbps Nominall 5Mbps Data	PCLKB ≥ 32MHz
Classical CAN	1Mbps Data	PCLKB ≥ 32MHz

The frequency of CANFD and CANMCLK depend on the required baud rate. For information how to configure the baud rate, refer to section 28.4.1.3. Baud Rate.

28.2 Register Descriptions

28.2.1 Register Table

The reset value shown for the RAM area, consisting of CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r, CFDRMBCPb, CFDRFMBCPb, CFDCFMBCP0, CFDTMBCPb, CFDTHLACC0, CFDTHLACC1 and CFDRPGACCk is valid after initialization of a hardware reset. See section 28.4.2. CAN Module Configuration after Hardware Reset for details of the initialization process.

If a write access with a size of 8 or 16 bits is performed for the RAM area, then the CANFD module does a read-modify write-access to the RAM location, because the RAM requires a 32-bit access through the ECC module.

For single bit error, the correct data is written back. For multiple bit errors, unknown data is written back.

Do not access the space where the register is not assigned.

The read data from the space where the register is not assigned is unknown.

此RAM用于在接收后存储消息或使用普通消息缓冲区或FIFO进行传输。每个消息条目都有一个单独的ID、数据长度代码、数据字段、供上层应用程序使用的消息指针和时间戳。此RAM用于存储消息接受过滤条目。每个接受过滤器条目都有一个单独的ID、数据长度代码、数据字段、供上层应用程序使用的消息指针和消息方向指针。

- Acceptance filter:
  对收到的消息执行过滤。接受过滤器列表RAM中的条目用于过滤过程。
- Two timers:
  –接收时间戳功能
  FIFO缓冲区的传输分离时间
- Interrupt generator:
  生成多种类型的全局和通道中断
- CAN特殊功能寄存器(SFR):
  与CAN相关的寄存器。请参阅第28.2节。注册说明。

28.1.2 时钟限制

对于CAN通信，应满足以下时钟限制：

- PCLKA / 2 = PCLKB ≥ CANFDCLK
- PCLKA / 2 = PCLKB ≥ CANMCLK

为避免丢失事件，CAN引擎时钟（CANFDCLK或CANMCLK）频率必须低于PCLKB时钟频率。

为避免CAN报文丢失，PCLKB应设置为频率取决于CAN通信的时钟波特率。波特率和PCLKB时钟的约束如表28.2所示。

Table 28.2 时钟限制

	Baud rate	PCLKB
CANFD	1Mbps标称5M bps数据	PCLKB ≥ 40MHz
	500Kbps Nominall 5Mbps Data	PCLKB ≥ 32MHz
经典CAN	1Mbps Data	PCLKB ≥ 32MHz

CANFD和CANMCLK的频率取决于所需的波特率。有关如何配置波特率的信息，请参阅第28.4.1.3节。波特率。

28.2 注册说明

28.2.1 寄存器表

RAM区域的复位值，包括CFDGAFLIDr、CFDGAFLMr、CFDGAFLP0r、CFDGAFLP1r、CFDRMBCPb、CFDRFMBCPb、CFDCFMBCP0、CFDTMBCPb、CFDTHLACC0、CFDTHLACC1和CFDRPGACCk在硬件复位初始化后有效。请参阅第28.4.2节。有关初始化过程的详细信息，请参阅硬件复位后的CAN模块配置。

如果对RAM区域执行大小为8或16位的写访问，则CANFD模块对RAM位置执行读–修改写访问，因为RAM需要通过ECC模块进行32位访问。

对于单位错误，正确的数据被写回。对于多位错误，将写回未知数据。

不要访问未分配寄存器的空间。

从未分配寄存器的空间读取的数据是未知的。

28.2.2 Legend

For all repetitive registers and bits, a lowercase index is used to indicate which slice is being referenced. If an index is being used, it is defined and described in the Register table it is being used in.

There is one global index used across all the registers and bits that need it.

Note: Tq means time quantum.

This register configures the transmission/reception nominal baud rate parameters of the channels.

NBRP[9:0] bits (Channel Nominal Baud Rate Prescaler)

The NBRP[9:0] bits are used to define the peripheral bus clock periods contained in a time quantum.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

NSJW[6:0] bits (Resynchronization Jump Width)

The NSJW[6:0] bits set the synchronization jump width. A value from 1 to 128 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

NTSEG1[7:0] bits (Timing Segment 1)

The NTSEG1[7:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. These bits contain the propagation segment.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

Additionally, configure a Tq value only between 2 and 256, inclusive. See section 28.4.1.2. CAN Bit Timing for more details.

Note 1. These bits are not available in the classical CAN function.

Channel Control register controls the modes of the related channel. It is used to enable generation of interrupts if errors are detected on the CAN bus connected to this channel. It is also used to configure the channel in test mode.

CHMDC[1:0] bits (Channel Mode Control)

The CHMDC[1:0] bits can be used to configure modes of the CAN channel.

CAN mode transitions are described in more details in section 28.3.3. Channel Modes.

Setting CHMDC[1:0] bits to 11b has no effect. When the CANFD module is in GL_HALT mode, these bits can only be set to 10b or 01b. These bits cannot be set in CH_SLEEP mode.

These bits can change automatically when transitioning to Halt mode by the CFDC0CTR.BOM settings.

If CPU write access to CFDC0CTR.CHMDC occurs at the same time when the CAN channel enters Halt mode (at the start of bus-off when CFDC0CTR.BOM = 01b, or at the end of bus-off when CFDC0CTR.BOM = 10b), then the CPU write access has the highest priority.

The CAN channel changes the value of CFDC0CTR.CHMDC within the Channel Control Registers for the specified cases only if the CFDC0CTR.CHMDC value is 00b (Operation mode).

注1.这些位在经典CAN功能中不可用。

通道控制寄存器控制相关通道的模式。如果在连接到此通道的CAN总线上检测到错误，它用于启用中断生成。它还用于在测试模式下配置通道。

CHMDC[1:0]位（通道模式控制）

CHMDC[1:0]位可用于配置CAN通道的模式。

CAN模式转换在第28.3.3节中有更详细的描述。频道模式。

将CHMDC[1:0]位设置为11b无效。当CANFD模块处于GL_HALT模式时，这些位只能设置为10b或01b。这些位不能在CH_SLEEP模式下设置。

当通过CFDC0CTR.BOM设置转换到暂停模式时，这些位可以自动更改。

如果CPU对CFDC0CTR.CHMDC的写访问发生在CAN通道进入Halt模式的同时（当CFDC0CTR.BOM=01b时在总线关闭开始时，或者当CFDC0CTR.BOM=10b时在总线关闭结束时），则CPU写访问的优先级最高。

仅当CFDC0CTR.CHMDC值为00b（操作模式）时，CAN通道才会在指定情况下更改通道控制寄存器中CFDC0CTR.CHMDC的值。

CSLPR bit (Channel Sleep Request)

When the CSLPR bit is 1, a Sleep mode request is generated for the corresponding CAN channel

When this bit is 0, a request to exit Sleep mode is generated for the related CANFD channel.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

RTBO bit (Return from Bus-Off)

When the protocol controller of the CAN channel enters bus-off state, you can force a recovery from bus-off state by setting the RTBO bit in the Channel Control Register to 1.

The error state changes from bus-off state to integrating with a maximum delay of 1 CAN bit time.

When the RTBO bit is set to 1, the REC and TEC registers are initialized and the Bus-Off Status bit (Channel Bus-off Status, CFDC0STS.BOSTS) is set to 0.

Registers other than the REC and TEC registers are not initialized by this command. Even if CFDC0CTR.BORIE is set, a bus-off recovery interrupt is not generated by this recovery from the bus-off state.

The RTBO bit cannot be set in CH_SLEEP mode. Setting this bit in any state other than bus-off state has no effect and the bit is cleared immediately. The read value is always 0.

Return from the Bus-Off command should be used only when CFDC0CTR.BOM is set to 00b.

Only write to this bit when the related CANFD channel is in CH_OPERATION mode. This bit is automatically cleared when set by software.

BEIE bit (Bus Error Interrupt Enable)

When the BEIE and the CFDC0ERFL.BEF bits are both 1, an error interrupt request is generated.

RTBO位（从总线关闭返回）

当CAN通道的协议控制器进入总线关闭状态时，您可以通过将通道控制寄存器中的RTBO位设置为1来强制从总线关闭状态恢复。

错误状态从总线关闭状态变为积分，最大延迟为1个CAN位时间。

当RTBO位设置为1时，REC和TEC寄存器被初始化并且总线关闭状态位（通道总线关闭状态，CFDC0STS.BOSTS)设置为0。

该命令不初始化REC和TEC寄存器以外的寄存器。即使设置了CFDC0CTR.BORIE，从总线关闭状态恢复也不会产生总线关闭恢复中断。

在CH_SLEEP模式下不能设置RTBO位。将该位设置为总线关闭状态以外的任何状态均无效，并且该位立即被清除。读取值始终为0。

只有当CFDC0CTR.BOM设置为00b时，才应使用从总线关闭命令返回。

仅当相关CANFD通道处于CH_OPERATION模式时才写入该位。该位由软件置位时自动清零。

Only write to these bits when the related CANFD channel is in CH_RESET mode.

ERRD bit (Channel Error Display)

The ERRD bit controls the display mode of the error flag bits [14:8] in the Channel Error Flag Register (CFDC0ERFL).

If the ERRD bit is 0 and more than one error occur at the same time, the error flag bits are set for all the errors that occurred at the same time. No further errors are flagged until CFDC0ERFL[14:8] is cleared.

Do not write to the ERRD bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

CTME bit (Channel Test Mode Enable)

Note: 该位在经典CAN功能中不可用。

请勿在CH_SLEEP模式下写入这些位。仅当相关CANFD通道处于CH_RESET模式时才写入这些位。

仅当相关CANFD通道处于CH_RESET模式时才写入这些位。

ERRD位（通道错误显示）

ERRD位控制通道错误标志寄存器(CFDC0ERFL)中错误标志位[14:8]的显示模式。

如果ERRD位为0并且同时发生多个错误，则为同时发生的所有错误设置错误标志位。在清除CFDC0ERFL[14:8]之前不会标记更多错误。

请勿在CH_SLEEP模式下写入ERRD位。仅当相关CANFD通道处于CH_RESET或CH_HALT模式。

CTME位（通道测试模式启用）

CTME位启用通道测试模式。

在CH_SLEEP模式下不要写入该位。仅当相关CANFD通道处于CH_HALT模式时才写入该位。

CTMS[1:0] bits (Channel Test Mode Select)

The CTMS[1:0] bits are used to select the required test mode.

Do not write to these bits in CH_SLEEP or CH_RESET mode. Only write to these bits when the related CANFD channel is in CH_HALT mode.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

BFT bit (Bit Flip Test)

The BFT bit checks the internal CRC generator logic of the protocol controller.

It inverts the first bit (ID bit) of the CAN message data stream being received, so that the internal generated CRC result will not match the received CRC value of the frame. Refer to the bit stuffing rule, when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The internal generated CRC value is always observed in the following registers:

- CFDC0ERFL.CRCREG (Classical CAN frames)
- CFDC0FDCRC.CRCREG (CANFD frames).*1

Note 1. This feature is not available in the classical CAN function.

Some restriction exist when using this bit:

Other CAN node will send a reference message and the receiver node(s) can invert one bit of incoming bit stream.

Note: The transmitter and receiver modes share the same CRC generator, therefore it is not necessary to consider the modes separately when testing.

The Bit Flip test mode is enabled if the BFT (new control signal that inverts the first bit of the bit stream) and CTME bits are both 1 and CFDC0CTR.CTMS is 0x00.

If this function is used by a transmitting node, a bit error or an arbitration lost will occur.

Do not write to the BFT bit in CH_SLEEP mode. Users should not use this function when the Self test mode 1 (Internal Loop back mode). Only write to this bit when the related CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

ROM bit (Restricted Operation Mode)

When the ROM and CTME bits are both 1, the restricted operation mode is enabled. This mode should only be used in basic test mode (CFDC0CTR.CTMS[1:0] = 00b).

The ROM bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. Do not set this bit when in Classical-only mode.

Note: This bit is not available in the classical CAN function.

CTMS[1:0]位（通道测试模式选择）

CTMS[1:0]位用于选择所需的测试模式。

不要在CH_SLEEP或CH_RESET模式下写入这些位。仅当相关CANFD通道处于CH_HALT模式时才写入这些位。

当相关CANFD通道处于CH_RESET模式时，这些位会自动清零。

BFT位（位翻转测试）

BFT位检查协议控制器的内部CRC生成器逻辑。

它将正在接收的CAN报文数据流的第一位（ID位）反转，使得内部生成的CRC结果与接收到的帧的CRC值不匹配。使用此功能时，请参阅位填充规则，因为可能会收到填充错误（由于反转）而不是CRC错误。

内部生成的CRC值始终在以下寄存器中观察：

- CFDC0ERFL.CRCREG (Classical CAN frames)
- CFDC0FDCRC.CRCREG (CANFD frames).*1

注1.此功能在经典CAN功能中不可用。

使用该位时存在一些限制：

其他CAN节点将发送参考消息，并且接收节点可以反转输入比特流的一位。

Note: 发送器和接收器模式共享相同的CRC生成器，因此在测试时无需单独考虑这些模式。

如果BFT（反转位流第一位的新控制信号）和CTME位均为1且CFDC0CTR.CTMS为0x00，则启用位翻转测试模式。

如果发送节点使用此功能，则会发生误码或仲裁丢失。

请勿在CH_SLEEP模式下写入BFT位。自检模式1（内部环回模式）。仅当相关CANFD通道处于CH_HALT模式时才写入该位。

当相关CANFD通道处于CH_RESET模式时，该位自动清零。

ROM位（受限操作模式）

当ROM和CTME位都为1时，限制操作模式被使能。该模式只能用于基本测试模式（CFDC0CTR.CTMS[1:0]=00b）。

在CH_SLEEP模式下不能设置ROM位。仅当相关CANFD通道处于CH_HALT模式时才写入该位。

当相关CANFD通道处于CH_RESET模式时，该位自动清零。不要设置该位时Classical-only mode.

Note: 该位在经典CAN功能中不可用。

Channel Error Flag register shows the status of various error conditions detectable regardless of the setting of the related CAN Channel Error Interrupt Enable Register. It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1) to check when each error condition occurs.

For this register, only a single bit can be cleared by software. Do not use the bit clear instruction to clear the bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Example in assembler language to clear the CFDC0ERFL.BEF bit:

mov.b #0x0FE, CFDC0ERFL ;

BEF bit (Bus Error Flag)

The BEF bit indicates a detection of a CAN channel bus error state, flagged by bits [14:8] in this register.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when a bus error is detected, and is cleared automatically when the related CANFD channel is in CH_RESET mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

EWF bit (Error Warning Flag)

The EWF bit indicates whether an error warning condition has been detected for the CAN channel.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when either TEC or REC exceeds 0x5F.

The setting of this bit only occurs when the TEC or REC initially exceeds 0x5F. Therefore, if the TEC or REC remains > 0x5F and the EWF bit is cleared by software, it is not set again until both the TEC and REC go below 0x60 and either TEC or REC crosses over again from a value 0x5F to a value > 0x5F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

EPF bit (Error Passive Flag)

The EPF bit indicates a detection of a CAN channel error passive state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state becomes error passive state.

Bit	Symbol	Function	R/W

12	B1ERR	位1错误 0：未检测到通道位1错误1：检测到通道位1错误	R/W

15	—	该位读取为0。写入值应为0。	R/W

通道错误标志寄存器显示可检测到的各种错误条件的状态，无论相关设置如何CAN通道错误中断使能寄存器。它还显示CAN通道可检测到的各种总线错误的状态。请参阅CAN规范(ISO11898-1)以检查每个错误情况何时发生。

对于该寄存器，软件只能清零一个位。不要使用位清除指令来清除位。使用MOV指令确保只清除指定位。其他位保持1。

用汇编语言清除CFDC0ERFL.BEF位的示例：

mov.b #0x0FE, CFDC0ERFL ;

BEF位（总线错误标志）

BEF位指示检测到CAN通道总线错误状态，由该寄存器中的位[14:8]标记。

该位通过写入0清零，并且只能由CANFD模块逻辑设置。写1无效。

该位在检测到总线错误时自动置位，并在相关CANFD通道处于CH_RESET模式时自动清零。

如果来自CAN通道的设置与写访问清除同时发生，则该位被设置。

仅当相关CANFD通道处于CH_HALT或CH_OPERATION模式时才写入该位。

EWF位（错误警告标志）

EWF位指示是否检测到CAN通道的错误警告条件。

该位通过写入0清零，并且只能由CANFD模块逻辑设置。写1无效。

当TEC或REC超过0x5F时，该位自动置位。

该位的设置仅在TEC或REC最初超过0x5F时发生。因此，如果TEC或REC保持>0x5F并且EWF位由软件清零，则不会再次设置，直到TEC和REC都低于0x60并且TEC或REC再次从值0x5F跨越到值>0x5F.

如果设置条件与清除条件同时出现，则设置该位。相关时自动清除CANFD通道处于CH_RESET模式。

仅当相关CANFD通道处于CH_HALT或CH_OPERATION模式时才写入该位。

EPF位（错误被动标志）

EPF位指示检测到CAN通道错误被动状态。

该位通过写入0清零，并且只能由CANFD模块逻辑设置。写1无效。

当CAN错误状态变为错误被动状态时，该位自动设置。

The setting of this bit only occurs when the TEC or REC initially exceeds 0x7F. Therefore, if the TEC or REC remains > 0x7F and the bit is cleared by software, it is not set again until both the TEC and REC go below 0x80 and either TEC or REC crosses over again from a value ≤ 0x7F to a value > 0x7F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

BOEF bit (Bus-Off Entry Flag)

The BOEF bit indicates a detection of a CAN channel bus-off entry state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state enters the bus-off state.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, then the bit is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

BORF bit (Bus-Off Recovery Flag)

The BORF bit indicates a detection of a CAN channel bus-off recovery state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically if CAN channel recovers from bus-off state in the following conditions:

- When CFDC0CTR.BOM is 00b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs
- When CFDC0CTR.BOM is 10b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs
- When CFDC0CTR.BOM is 11b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs.

The bit is not set if CAN channel recovers from bus-off state in the following conditions:

- When CAN Reset mode is requested
- When CFDC0CTR.RTBO is set to 1 (the CAN channel returns to error active)
- When CFDC0CTR.BOM is 01b
- When CFDC0CTR.BOM is 11b and a halt request is asserted before the CAN channel reaches the end of the bus-off state.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, the flag is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

OVLF bit (Overload Flag)

The OVLF flag indicates a detection of a CAN channel overload state.

The OVLF bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when an overload condition is detected. If a set condition occurs simultaneously with a clear condition, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

BLF bit (Bus Lock Flag)

The BLF bit indicates a detection of a CAN channel bus lock condition.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when 32 consecutive dominant bits are detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

该位的设置仅在TEC或REC最初超过0x7F时发生。因此，如果TEC或REC保持>0x7F并且该位由软件清除，则不会再次设置，直到TEC和REC都低于0x80并且TEC或REC再次从值≤0x7F跨越到值>0x7F.

如果设置条件与清除条件同时出现，则设置该位。相关时自动清除
CANFD通道处于CH_RESET模式。

仅当相关CANFD通道处于CH_HALT或CH_OPERATION模式时才写入该位。

BOEF位（总线关闭进入标志）

BOEF位指示检测到CAN通道总线关闭进入状态。

该位通过写入0清零，并且只能由CANFD模块逻辑设置。写1无效。

当CAN错误状态进入总线关闭状态时，该位自动置位。

注1.这些位在经典CAN功能中不可用。

通道0CANFD配置寄存器配置计算哪个通信方向（发送器接收器）错误。

EOCCFG[2:0]位（错误发生计数器配置）

EOCCFG[2:0]位选择计算哪种类型的CAN帧配置和方向，包括协议错误。

不要在CH_OPERATION或CH_SLEEP模式下写入这些位。

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

TDCOC bit (Transceiver Delay Compensation Offset Configuration)*1

The TDCOC bit selects which offset is used when defining the position of the secondary sample point (SSP) for the CANFD channel. If the bit is set to 0, the position of the SSP is the measured transceiver delay plus the fixed offset. If the bit is 1, the position of the SSP is defined only by the offset.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical-only mode.

TDCE bit (Transceiver Delay Compensation Enable)*1

The TDCE bit enables the transceiver delay compensation for the CANFD channel.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical-only mode.

ESIC bit (Error State Indication Configuration)*1

The ESIC bit controls the transmission of either the ESI flag information or the message of ESI flag information (CFDCFFDCSTS.CFESI or CFDTMFDCTRb.TMESI).

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical-only mode.

TDCO[7:0] bits (Transceiver Delay Compensation Offset)*1

The TDCO[7:0] bits set the secondary sample point offset. How this value is used, depends on the CFDC0FDCFG.TDCOC setting.

If CFDC0FDCFG.TDCOC = 0, the transceiver delay compensation result is equal to the Trv_Delay (measured delay) + the value in CFDC0FDCFG.TDCO, rounded down to the nearest integer number of time quanta. Otherwise, the result is equal to the value in CFDC0FDCFG.TDCO. See section 28.4.1.5. Transmitter Delay Compensation for details on how CFDC0FDCFG.TDCO is used.

The actual offset value is interpreted as TDCO + 1. For example, if 4 is set in TDCO, the offset is 5 clock cycles. Clock cycle is 1 cycle of CAN channel DLL clock.

Do not write to the TDCO[7:0] bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set to this bit when in Classical-only mode.

FDOE bit (FD-Only Enable)*1

The FDOE bit enables the reception and transmission of CANFD-only frames. If enabled, communication in Classical CAN frame format is disabled. Transmission of Classical CAN frames is not possible because the FDF bit of the message buffer is a don't care (CFDCFFDCSTS.CFFDF/CFDTMFDCTRb.TMFDF).

If messages with Classical CAN frame format are received, the protocol controller treats them as invalid frames and response with error frames. When a Classical CAN frame is configured for transmitting, the FDF bit is sent as recessive, therefore an FD frame is sent. If the data length code (DLC) is configured of greater than 8 bytes, the remaining data bytes are padded with 0xCC.

The FDOE bit cannot be written in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Do not set CFDC0FDCFG.FDOE and CFDC0FDCFG.CLOE simultaneously.

REFE bit (RX Edge Filter Enable)

The REFE bit enables the RX edge filter during the IDLE detection (bus integration). When the bit is enabled, two consecutive dominant time quanta are required to detect a synchronization edge.

仅当相关CANFD通道处于CH_RESET或CH_HALT模式时才写入这些位。

TDCOC位（收发器延迟补偿偏移配置）*1

TDCOC位选择在定义辅助采样点(SSP)的位置时使用哪个偏移量
CANFD通道。如果该位设置为0，则SSP的位置是测量的收发器延迟加上固定偏移。如果该位为1，则SSP的位置仅由偏移量定义。

请勿在CH_OPERATION或CH_SLEEP模式下写入该位。

仅当相关CANFD通道处于CH_RESET或CH_HALT模式时才写入该位。不要设置该位时
Classical-only mode.

TDCE位（收发器延迟补偿启用）*1

TDCE位使能CANFD通道的收发器延迟补偿。

请勿在CH_OPERATION或CH_SLEEP模式下写入该位。

仅当相关CANFD通道处于CH_RESET或CH_HALT模式时才写入该位。不要设置该位时
Classical-only mode.

ESIC位（错误状态指示配置）*1

ESIC位控制ESI标志信息或ESI标志信息消息（CFDCFFDCSTS.CFESI或CFDTMFDCTRb.TMESI）的传输。

请勿在CH_OPERATION或CH_SLEEP模式下写入该位。

仅当相关CANFD通道处于CH_RESET或CH_HALT模式时才写入该位。不要设置该位时
Classical-only mode.

TDCO[7:0]位（收发器延迟补偿偏移）*1

TDCO[7:0]位设置辅助采样点偏移。该值的使用方式取决于CFDC0FDCFG.TDCOC设置。

如果CFDC0FDCFG.TDCOC=0，则收发器延迟补偿结果等于Trv_Delay（测量延迟）+CFDC0FDCFG.TDCO中的值，向下舍入到最接近的时间量子整数。否则，结果等于CFDC0FDCFG.TDCO中的值。请参阅第28.4.1.5节。发送器延迟补偿，了解如何使用CFDC0FDCFG.TDCO的详细信息。

实际偏移值被解释为TDCO+1。例如，如果TDCO设置为4，则偏移为5个时钟周期。时钟周期为CAN通道DLL时钟的1个周期。

请勿在CH_OPERATION或CH_SLEEP模式下写入TDCO[7:0]位。

仅当相关CANFD通道处于CH_RESET或CH_HALT模式时才写入这些位。在仅经典模式下不要设置此位。

FDOE bit (FD-Only Enable)*1

FDOE位使能CANFD-only帧的接收和发送。如果启用，则会禁用经典CAN帧格式的通信。传统CAN帧的传输是不可能的，因为消息缓冲区的FDF位是无关紧要的(CFDCFFDCSTS.CFFDFCFDTMFDCTRb.TMFDF)。

如果接收到具有经典CAN帧格式的消息，协议控制器会将其视为无效帧并以错误帧响应。当经典CAN帧配置为发送时，FDF位作为隐性发送，因此发送FD帧。如果数据长度代码(DLC)配置为大于8个字节，则剩余的数据字节用0xCC填充。

FDOE位不能在CH_OPERATION、CH_HALT或CH_SLEEP模式下写入。

不要同时设置CFDC0FDCFG.FDOE和CFDC0FDCFG.CLOE。

REFE位（RX边沿过滤器使能）

在空闲检测（总线集成）期间，REFE位使能RX边沿滤波器。当该位使能时，需要两个连续的显性时间量来检测同步边沿。

The REFE bit cannot be written in CH_OPERATION, CH_HALT and CH_SLEEP mode. Do not set this bit when in Classical-only mode.

CLOE bit (Classical CAN-Only Enable)*1

The CLOE bit enables the Classical CAN-only mode. If this bit is 1, the protocol controller can only send classical frames and response with a form or CRC error on FD frames.

Do not set CFDC0FDCFG.CLOE and CFDC0FDCFG.FDOE simultaneously.

CFDC0FDCFG.CLOE	CFDC0FDCFG.FDOE	Channel mode
0	0	CANFD mode
0	1	FD-only mode
1	0	Classical CAN-only mode

The CANFD mode is available only for CANFD supported product.

Do not write to this bit in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET mode.

Note 1. These bits are not available in the classical CAN function.

Note 1. These bits are not available in the classical CAN function.

The Channel 0 CANFD Status Register indicates the transceiver compensation delay result and its related FIFO message lost status.

TDCR[7:0] bits (Transceiver Delay Compensation Result)

The TDCR[7:0] bits are set when the transceiver delay has been measured.

The measured delay is a multiple of the CAN channel DLL clock. The result depends on the CFDC0FDCFG.TDCOC configuration and the offset value in CFDC0FDCFG.TDCO. See section 28.4.1.5. Transmitter Delay Compensation for details on how this value is derived.

The TDCR[7:0] bits are updated at the falling edge between FDF and the RES bit when CFDC0FDCFG.TDCOC = 0 and the transceiver delay compensation is enabled (CFDC0FDCFG.TDCE = 1).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

Note: These bits are not available in the classical CAN function.

EOCO bit (Error Occurrence Counter Overflow)

The EOCO bit indicates whether the related CAN channel error occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

TDCR[7:0]位（收发器延迟补偿结果）

TDCR[7:0]位在测量到收发器延迟后置位。

测得的延迟是CAN通道DLL时钟的倍数。结果取决于CFDC0FDCFG.TDCOC配置和CFDC0FDCFG.TDCO中的偏移值。请参阅第28.4.1.5节。TransmitterDelayCompensation了解有关如何得出此值的详细信息。

当CFDC0FDCFG.TDCOC=0并且使能收发器延迟补偿(CFDC0FDCFG.TDCE=1)时，TDCR[7:0]位在FDF和RES位之间的下降沿更新。

当相关CANFD通道处于CH_RESET模式时，这些位会自动清零。

Note: 这些位在经典CAN功能中不可用。

EOCO位（错误发生计数器溢出）

EOCO位指示相关的CAN通道错误发生计数器是否溢出。该位通过写入0清零。写1无效。

This bit is set automatically when CFDC0FDSTS.EOC is 0xFF and a CAN bus error is detected based on the configuration defined in CFDC0FDCFG.EOCCFG.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

SOCO bit (Successful Occurrence Counter Overflow)

The SOCO bit indicates whether the related CAN channel successful occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDC0FDSTS.SOC is 0xFF and a successful message reception or successful message transmission occurs.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Write to this bit only when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

TDCVF bit (Transceiver Delay Compensation Violation Flag)

The CANFD module captures internally the transmitted data bit-by-bit. This data is then compared against the received CAN bus level which is delayed by the transceiver loop delay.

The transceiver delay has some variations depending on the physical parameters such as temperature. The result bit CFDC0FDSTS.TDCR is updated by each message. However, temporary maximum delay violation could be missed. Therefore, the TDCVF bit captures this violation.

This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when the transceiver delay compensation is greater than the maximum delay compensation (6 data bit times - 2 clk_dlc) and the internal bit is overrun.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Note: This bit is not available in the classical CAN function.

EOC[7:0] bits (Error Occurrence Counter)

The EOC[7:0] bits are used together with the SOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

This higher error rate can be detected depending on the configuration of the CFDC0FDCFG.EOCCFG bits.

The EOC[7:0] bits are set only by CANFD module logic. These bits are cleared by writing 1 to CFDC0FDCTR.EOCCLR. Writing any other value has no effect.

These bits are updated when an error occurs, according to the configuration of the CFDC0FDCFG.EOCCFG bits. When the counter reaches the value of 0xFF, the update stops.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

当CFDC0FDSTS.EOC为0xFF并且根据CFDC0FDCFG.EOCCFG中定义的配置检测到CAN总线错误时，该位自动设置。

如果来自CAN通道的设置与写访问清除同时发生，则该位被设置。

当相关CANFD通道处于CH_RESET模式时，该位自动清零。

仅当相关CANFD通道处于CH_HALT或CH_OPERATION模式时才写入该位。

不要使用位清除指令清除该位。使用MOV指令确保只清除指定位。
其他位保持1。

SOCO位（成功发生计数器溢出）

SOCO位指示相关CAN通道成功发生计数器是否溢出。该位通过写入0清零。写1无效。

当CFDC0FDSTS.SOC为0xFF并且成功接收消息或成功发送消息时，该位自动置位。

如果来自CAN通道的设置与写访问清除同时发生，则该位被设置。

当相关CANFD通道处于CH_RESET模式时，该位自动清零。

仅当相关CANFD通道处于CH_HALT或CH_OPERATION模式时才写入该位。

不要使用位清除指令清除该位。使用MOV指令确保只清除指定位。
其他位保持1。

TDCVF位（收发器延迟补偿违规标志）

CANFD模块在内部逐位捕获传输的数据。然后将该数据与接收到的数据进行比较
由收发器环路延迟延迟的CAN总线电平。

收发器延迟有一些变化，具体取决于温度等物理参数。结果位CFDC0FDSTS.TDCR由每个消息更新。但是，可能会错过临时最大延迟违规。
因此，TDCVF位捕获此违规。

该位通过写入0清零。写1无效。

当收发器延迟补偿大于最大延迟补偿（6个数据位乘以2个clk_dlc）并且内部位溢出时，该位自动置位。

如果来自CAN通道的设置与写访问清除同时发生，则该位被设置。

当相关CANFD通道处于CH_RESET模式时，该位自动清零。

仅当相关CANFD通道处于CH_HALT或CH_OPERATION模式时才写入该位。

不要使用位清除指令清除该位。使用MOV指令确保只清除指定位。
其他位保持1。

Note: 该位在经典CAN功能中不可用。

EOC[7:0]位（错误发生计数器）

EOC[7:0]位与SOC[7:0]位一起使用，以支持主机控制的回退到与仲裁比特率相同的有效负载比特率选项，当使用减少的有效负载位长度的消息具有显着性时与其他消息相比，错误率更高。

根据CFDC0FDCFG.EOCCFG位的配置，可以检测到这种较高的错误率。

EOC[7:0]位仅由CANFD模块逻辑设置。这些位通过向CFDC0FDCTR.EOCCLR写入1来清除。
写入任何其他值均无效。

根据CFDC0FDCFG.EOCCFG位的配置，这些位在发生错误时更新。当计数器达到0xFF的值时，更新停止。

当相关CANFD通道处于CH_RESET模式时，这些位会自动清零。

SOC[7:0] bits (Successful occurrence counter)

The SOC[7:0] bits are used together with the EOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

The SOC[7:0] bits are set only by CANFD module logic. Writing any other value has no effect.

These bits are updated when the occurrence of any error-free messages on the bus is detected through reception or transmission. When the counter reaches the value of 0xFF, the update stops.

Note: In Loopback mode, the counter is incremented twice.

These bits are cleared by writing 1 to CFDC0FDCTR.SOCCLR.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

31:28	—	These bits are read as 0. The write value should be 0.	R/W

The Channel 0 CANFD CRC Register holds the CRC value calculated for the CANFD frame.

CRCREG[20:0] bits (CRC Register value)

The CRCREG[20:0] bits contain the CRC value calculated by the CANFD channel logic when the CFDC0CTR.CTME bit is enabled.

The CFDC0FDCRC.CRCREG value is updated in the first bit of the CRC field of the CANFD frame (reception and transmission).

When the CFDC0CTR.CTME bit is 0, the CRCREG[20:0] bits are always read as 0.

When bit 17th of the CRC field is used, CRCREG[20:17] are always read as 0.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

SCNT[3:0] bits (Stuff bit count)

The SCNT[3:0] bits contain the stuff count value of the CANFD frame. These bits indicate the number of inserted stuff bits (modulo 8, Graycoded) for a CANFD frame when the CFDC0CTR.CTME bit is enabled in CFDC0FDCRC.SCNT[3:1]. SCNT[0] is the parity bit.

When the CFDC0CTR.CTME bit is 0, the SCNT[3:0] bits are always read as 0.

The SCNT value is updated in the first bit of CRC field of the CANFD frame (reception and transmission).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

SOC[7:0]位（成功发生计数器）

SOC[7:0]位与EOC[7:0]位一起使用，以支持主机控制的回退到与仲裁比特率相同的有效负载比特率选项，当使用减少的有效负载位长度的消息具有显着与其他消息相比，错误率更高。

SOC[7:0]位仅由CANFD模块逻辑设置。写入任何其他值均无效。

当通过接收或传输检测到总线上出现任何无错误消息时，这些位将被更新。当计数器达到0xFF的值时，更新停止。

Note: 在环回模式下，计数器增加两次。

这些位通过向CFDC0FDCTR.SOCCLR写入1来清除。

当相关CANFD通道处于CH_RESET模式时，这些位会自动清零。

CRCREG[20:0]位（CRC寄存器值）

CRCREG[20:0]位包含在使能CFDC0CTR.CTME位时由CANFD通道逻辑计算的CRC值。

CFDC0FDCRC.CRCREG值在CANFD帧（接收和发送）的CRC字段的第一位更新。

当CFDC0CTR.CTME位为0时，CRCREG[20:0]位总是读为0。

当使用CRC字段的第17位时，CRCREG[20:17]总是读为0。

当相关CANFD通道处于CH_RESET模式时，这些位会自动清零。

SCNT[3:0]位（填充位计数）

The DCE bit enables data length code (DLC) check for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

DRE bit (DLC Replacement Enable)

When the DRE bit is 1 and the DCE is 1, the CANFD stores the configured value (CFDGAFLP0r.GAFLDLC) of the DLC in the destination RX message buffer or FIFO buffer if the DLC check passes. Otherwise, the DLC value in the destination RX message buffer or FIFO buffer is unchanged.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

MME bit (Mirror Mode Enable)

The MME bit enables the Mirror mode for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

DCS bit (Data Link Controller Clock Select)

The DCS bit selects the clock source for CAN communication. Internal clean clock has a smaller clock jitter than the peripheral clock B (PCLKB).

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CANFD module is in GL_RESET mode.

CMPOC bit (CANFD Message Payload Overflow Configuration)

The CMPOC bit controls the message payload acceptance mechanism when the received payload is higher than the message buffer payload size CFDRMNB.RMPLS, CFDRFCCa.RFPLS, and CFDCFCC.CFPLS. The received message payload is always compared with the available message payload size in the message buffer.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CANFD module is in GL_RESET mode.

When this bit is set and payload overflow occurs, the DLC value is stored in the RX message buffer or FIFO buffer unchanged.

Note: This bit is not available in the classical CAN function.

TSP[3:0] bits (Timestamp Prescaler)

The value configured in the TSP[3:0] bits defines the period of the clock source used for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

TSSS bit (Timestamp Source Select)

The TSSS bit allows the selection of the clock source for the timestamp counter.

Note: The bit time clock varies depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

ITRCP[15:0] bits (Interval Timer Reference Clock Prescaler)

The ITRCP[15:0] bits allow the definition of a reference clock for the FIFO interval timer source clock.

When these bits are 0x0000, the timer is disabled.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

消息缓冲区编号优先级不应与TX队列传输一起使用。

DCE位（DLC检查启用）

DCE位启用CAN通道的数据长度代码(DLC)检查。

不要在GL_SLEEP模式下写入该位。仅当CANFD模块处于GL_RESET模式时写入该位。

DRE位（DLC替换启用）

当DRE位为1且DCE为1时，如果DLC检查通过，CANFD将DLC的配置值（CFDGAFLP0r.GAFLDLC）存储在目标RX消息缓冲区或FIFO缓冲区中。否则，目标RX消息缓冲区或FIFO缓冲区中的DLC值不变。

不要在GL_SLEEP模式下写入该位。仅当CANFD模块处于GL_RESET模式时写入该位。

MME位（镜像模式启用）

MME位使能CAN通道的镜像模式。

不要在GL_SLEEP模式下写入该位。仅当CANFD模块处于GL_RESET模式时写入该位。

GL_RESET mode.

CMPOC位（CANFD消息有效负载溢出配置）

当接收到的有效载荷高于消息缓冲区有效载荷大小CFDRMNB.RMPLS、CFDRFCCa.RFPLS和CFDCFCC.CFPLS时，CMPOC位控制消息有效载荷接受机制。接收到的消息负载总是与消息缓冲区中可用的消息负载大小进行比较。

不要在GL_SLEEP或GL_OPERATION模式下写入该位。仅当CANFD模块在时写入该位
GL_RESET mode.

当该位被置位并发生有效载荷溢出时，DLC值不变地存储在RX报文缓冲区或FIFO缓冲区中。

Note: 该位在经典CAN功能中不可用。

The Global Acceptance Filter List Pointer 1 registers are used to configure the FIFO direction pointer fields in each Rule Entry of the Global Acceptance Filter List.

GAFLFDP8, GAFLFDP1, GAFLFDP0 bits (Global Acceptance Filter List FIFO Direction Pointer)

These bits allow the configuration of FIFO Buffers as the target for a received message passing the acceptance check of the related Global Acceptance Filter List entry. Each bit of the GAFLFDP8, GAFLFDP1, GAFLFDP0 is configuring a dedicated FIFO.

Users cannot write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

For storage in Common FIFO, target for reception can only be those Common FIFO Buffers that are configured as RX FIFO.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

Users should only configure up to 2 destination FIFO Buffers or 1 destination FIFO Buffers plus one RX Message Buffer.

RMPLS[2:0] bits (Reception Message Buffer Payload Data Size)

The RMPLS[2:0] bits are used to configure the message buffer payload data size.

Only write to these bits when the CANFD module is in GL_RESET mode.

全局接受过滤器列表指针1寄存器用于配置每个规则中的FIFO方向指针字段
全局接受过滤器列表的条目。

GAFLFDP8、GAFLFDP1、GAFLFDP0位（全局接受过滤器列表FIFO方向指针）

这些位允许将FIFO缓冲区配置为接收到的消息通过相关全局接受过滤器列表条目的接受检查的目标。GAFLFDP8、GAFLFDP1、GAFLFDP0的每一位都在配置一个专用的FIFO。

当CFDGAFLECTR.AFLDAE位为0时，用户不能写入这些位。

对于存储在CommonFIFO中，接收目标只能是那些配置为RX的CommonFIFO缓冲区FIFO.

仅当相关CANFD通道处于CH_RESET或CH_HALT模式时才写入这些位。

用户最多只能配置2个目标FIFO缓冲区或1个目标FIFO缓冲区加上1个RX消息缓冲区。

28.2.25 CFDRMND : RX Message Buffer New Data Register

Base address: CANFD_B = 0x400B_0000

Offset address: 0x0034

Bit position:	31																													0
Bit field:	RMNS[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RMNS[31:0]	RX Message Buffer New Data Status 0: New data not stored in corresponding RX message buffer 1: New data stored in corresponding RX message buffer	R/W

The RX Message Buffer New Data Status Register specifies the new data storage status of the RX message buffers.

RMNS[31:0] bits (RX Message Buffer New Data Status)

The RMNS[31:0] bits indicate the status of new data for the corresponding RX message buffer. RMNS bit [0] corresponds to RX message buffer [0] and so on.

The bit position of CFDRMND corresponds to the buffer number of RXMB.

Do not write to these bits when the CANFD module is in GL_RESET or GL_SLEEP mode. Writing 1 has no effect.

These bits cannot be cleared when message storage in the corresponding RX message buffer is in progress.
Do not use the bit clear instruction to clear these bits. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

These bits are set automatically when storage of new messages are in the corresponding RX message buffer. These bits are cleared by writing 0. These bits are cleared automatically when the CANFD module is in GL_RESET mode.

When CFDRMNB.RMPLS = 000b (maximum 8 bytes payload), the duration of message storage is 6 PCLKB cycles.

When CFDRMNB.RMPLS > 000b, the duration of message storage is 6 PCLKB cycles + 1 for each 4 bytes (maximum of 20 PCLKB cycles for 64 bytes).

Note: This feature is not available in the classical CAN function.

RMNS[31:0]位（RX报文缓冲区新数据状态）

RMNS[31:0]位指示相应RX消息缓冲区的新数据状态。RMNS位[0]对应于RX消息缓冲区[0]等等。

CFDRMND的位位置对应于RXMB的缓冲区号。

当CANFD模块处于GL_RESET或GL_SLEEP模式时，不要写入这些位。写1无效。

当相应RX消息缓冲区中的消息存储正在进行时，这些位不能被清除。
不要使用位清除指令来清除这些位。使用MOV指令确保只清除指定位。其他位保持1。

当新消息存储在相应的RX消息缓冲区中时，这些位会自动设置。这些位通过写0清除。当CANFD模块处于GL_RESET模式时，这些位会自动清除。

当CFDRMNB.RMPLS=000b（最大8字节有效载荷）时，消息存储的持续时间为6个PCLKB周期。

当CFDRMNB.RMPLS>000b时，消息存储的持续时间为6个PCLKB周期+每4个字节1个（64个字节最多20个PCLKB周期）。

Note 1. These bits are not available in the classical CAN function.

The RX FIFO Configuration/Control Registers are used to configure and control the two RX FIFOs.

RFE bit (RX FIFO Enable)

The RFE bit enables the FIFO. When this bit is set to 0, the RX FIFO is cleared to empty.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

This bit can only be set if the configured FIFO depth is greater than 0x000 (CFDRFCCa.RFDC > 0x000) and less than 0x110.

Set the RFE bit with a separate write access to the CFDRFCCa register, after all the other bits in the CFDRFCCa register are set.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

RFIE bit (RX FIFO Interrupt Enable)

The RFIE bit enables generation of the FIFO interrupt.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

注1.这些位在经典CAN功能中不可用。

RXFIFO配置控制寄存器用于配置和控制两个RXFIFO。

RFE bit (RX FIFO Enable)

RFE位使能FIFO。当该位设置为0时，RXFIFO被清空。

仅当CANFD模块处于GL_HALT或GL_OPERATION模式时写入该位。

仅当配置的FIFO深度大于0x000(CFDRFCCa.RFDC>0x000)且小于0x110时，才能设置该位。

在设置CFDRFCCa寄存器中的所有其他位之后，通过对CFDRFCCa寄存器的单独写访问来设置RFE位。

当CANFD模块处于GL_RESET模式时，该位会自动清零。

RFIE位（RXFIFO中断允许）

RFIE位使能FIFO中断的产生。

CANFD模块处于GL_SLEEP模式时不要写入该位。

RFPLS[2:0] bits (Rx FIFO Payload Data Size Configuration)

The RFPLS[2:0] bits define the message data payload allocation in the RAM.

This is the maximum number of bytes which can be received by this FIFO.

Only write to these bits when the CANFD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

RFDC[2:0] bits (RX FIFO Depth Configuration)

The RFDC[2:0] bits select the depth of the FIFO in terms of the number of messages. If the FIFO depth is configured to 0 messages, the FIFO cannot be used.

Only write to these bits when the CANFD module is in GL_RESET mode.

RFIM bit (RX FIFO Interrupt Mode)

The RFIM bit selects the interrupt generation condition for the FIFO.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

Only write to this bit when the CANFD module is in GL_RESET mode.

RFIGCV[2:0] bits (RX FIFO Interrupt Generation Counter Value)

The RFIGCV[2:0] bits select the counter value of the FIFO for generation of FIFO interrupts. These values represent fractions of the FIFO depth for which an interrupt is generated.

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

The setting of the RFIGCV[2:0] bits should be synchronized with the RFDC[2:0] bits.

Only write to these bits when the CANFD module is in GL_RESET mode.

RFPLS[2:0]位（RxFIFO有效负载数据大小配置）

RFPLS[2:0]位定义RAM中的消息数据有效负载分配。

这是该FIFO可以接收的最大字节数。

仅当CANFD模块处于GL_RESET模式时才写入这些位。

Note: 这些位在经典CAN功能中不可用。

RFDC[2:0]位（RXFIFO深度配置）

RFDC[2:0]位根据消息数量选择FIFO的深度。如果FIFO深度配置为0消息，则无法使用FIFO。

仅当CANFD模块处于GL_RESET模式时才写入这些位。

RFIM位选择FIFO的中断产生条件。

CANFD模块处于GL_SLEEP模式时不要写入该位。

仅当CANFD模块处于GL_RESET模式时写入该位。

RFIGCV[2:0]位（RXFIFO中断生成计数器值）

RFIGCV[2:0]位选择FIFO的计数器值以生成FIFO中断。这些值代表产生中断的FIFO深度的分数。

当CANFD模块处于GL_SLEEP模式时，不要写入这些位。

RFIGCV[2:0]位的设置应与RFDC[2:0]位同步。

仅当CANFD模块处于GL_RESET模式时才写入这些位。

13:8	RFMC[5:0]	RX FIFO Message Count Number of messages stored in FIFO	R
31:14	—	These bits are read as 0. The write value should be 0.	R/W

The RX FIFO Status Registers show the status of messages stored in the corresponding FIFO buffers.

RFEMP bit (RX FIFO Empty)

The RFEMP bit is set automatically when:

- The RFMC bit is 0
- RX FIFO is disabled by setting the CFDRFCCa.RFE bit to 0
- The CANFD module is in GL_RESET mode.

The RFEMP bit is cleared automatically when the first message is stored in the RX FIFO buffer.

RFFLL bit (RX FIFO Full)

The RFFLL bit is set automatically when the number of CAN messages stored in the FIFO buffer matches the configured FIFO depth.

The RFFLL is cleared automatically when:

- The number of CAN messages stored in the FIFO buffer is less than the configured FIFO depth
- RX FIFO is disabled by setting the CFDRFCCa.RFE bit to 0
- The CANFD module is in GL_RESET mode.

RFMLT bit (RX FIFO Message Lost)

Only write to the RFMLT bit when CANFD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically whenever a message is lost due to attempted storage when the FIFO buffer is already full. If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode.

RFIF bit (RX FIFO Interrupt Flag)

The RFIF bit is set automatically when the configured interrupt condition is satisfied. This bit is not automatically cleared when the RX FIFO buffer is disabled.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

The bit is cleared by writing 0 to it. The bit is also cleared when CANFD module is in GL_RESET mode.

RFMC[5:0] bits (RX FIFO Message Count)

The RFMC[5:0] bits indicate the number of CAN messages stored in the RX FIFO buffer that can be read by the CPU.

These bits are cleared automatically when the FIFO is disabled and when the CANFD module is in GL_RESET mode.

Bit	Symbol	Function	R/W
13:8	RFMC[5:0]	RXFIFO消息计数 存储在FIFO中的消息数	R
31:14	—	这些位被读取为0。写入值应为0。	R/W

RXFIFO状态寄存器显示存储在相应FIFO缓冲区中的消息的状态。

RFEMP bit (RX FIFO Empty)

RFEMP位在以下情况下自动设置：

●RFMC位为0

●通过将CFDRFCCa.RFE位设置为0来禁用RXFIFO

●CANFD模块处于GL_RESET模式。

当第一条消息存储在RXFIFO缓冲区中时，RFEMP位会自动清零。

RFFLL bit (RX FIFO Full)

当存储在FIFO缓冲区中的CAN报文数量与配置的匹配时，RFFLL位会自动设置
FIFO depth.

RFFLL在以下情况下自动清除：

●FIFO缓冲区中存储的CAN报文数小于配置的FIFO深度

●通过将CFDRFCCa.RFE位设置为0来禁用RXFIFO

●CANFD模块处于GL_RESET模式。

RFMLT位（RXFIFO消息丢失）

仅当CANFD模块处于GL_HALT或GL_OPERATION模式时才写入RFMLT位。写1无效。

不要使用位清除指令清除该位。使用MOV指令确保只清除指定位。
其他位保持1。

当FIFO缓冲区已满时，每当由于尝试存储而导致消息丢失时，该位会自动设置。如果来自CAN通道的设置与写访问清除同时发生，则该位被设置。

该位被清除：

●写入0

●CANFD模块处于GL_RESET模式时。

RFIF位（RXFIFO中断标志 ）

当配置的中断条件满足时，RFIF位自动置位。当RXFIFO缓冲器被禁用时，该位不会自动清除。

仅当CANFD模块处于GL_HALT或GL_OPERATION模式时写入该位。写1无效。

不要使用位清除指令清除该位。使用MOV指令确保只清除指定位。
其他位保持1。

如果来自CAN通道的设置与写访问清除同时发生，则设置该位。

该位通过向其写入0来清除。当CANFD模块处于GL_RESET模式时，该位也会被清除。

RFMC[5:0]位（RXFIFO消息计数）

RFMC[5:0]位指示存储在RXFIFO缓冲区中可供CPU读取的CAN报文数量。

当FIFO被禁用并且CANFD模块处于GL_RESET模式时，这些位会自动清除。

The RX FIFO Pointer Control Registers can be used to increment the read pointer of the corresponding RX FIFO buffers.

RFPC bits (RX FIFO Pointer Control)

When the value 0xFF is written to the RFPC bits, the pointer of the corresponding RX FIFO buffer is moved to the next FIFO entry. Only write 0xFF to these registers when the corresponding RX FIFO buffer is enabled and not empty.

The read value from these bits is always 0x00.

Only write to these bits when the CANFD module is in GL_HALT or GL_OPERATION mode.

Do not write to the RX FIFO Pointer Control registers when DMA is enabled.

注1.这些位在经典CAN功能中不可用。

CFE bit (Common FIFO Enable)

CFE位在设置时启用FIFO。当该位清零时，FIFO被禁用。

当配置为TX模式时，通过清零该位也可用于中止从CommonFIFO发送，或在RX模式下停止接收到CommonFIFO。

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFOs configured as TX FIFO.

This bit can only be set if the configured FIFO depth is greater than 0x000 (CFDCFCC.CFDC > 0x000 and less than 0x110 (0x110 > CFDCFCC.CFDC > 0x000).

Set the CFE bit with a separate write access to the CFDCFCC register, after all the other bits in this register are set.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

This bit is also cleared automatically when the related channel is in CH_RESET mode if the FIFO is configured in TX mode.

CFRXIE bit (Common FIFO RX Interrupt Enable)

The CFRXIE bit enables generation of FIFO interrupts when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CFTXIE bit (Common FIFO TX Interrupt Enable)

The CFTXIE bit enables generation of common FIFO interrupts when the interrupt flag is set after transmission of a frame from the corresponding FIFO buffer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CFPLS[2:0] bits (Common FIFO Payload Data Size Configuration)

The CFPLS[2:0] bits define the message data payload allocation in the RAM. This is the maximum number of bytes which can be received or transmitted by the FIFO buffer.

For details, see section 28.6. FIFO Buffers and Normal Message Buffer Configuration.

Only write to this bit when the CANFD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

CFM bit (Common FIFO Mode)

The CFM bit selects the mode of the FIFO. When a hardware reset is applied, all the Common FIFO buffers are configured in RX FIFO mode.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to these bits when the CANFD module is in GL_RESET mode.

CFITSS bit (Common FIFO Interval Timer Source Select)

The CFITSS bit selects the basic clock source for the Interval Transmission Timer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode. In addition, do not write to this bit when the CFE bit is set to 1.

Do not write 1 to this bit when CANFD communication is used.*1

Note: The bit time clock can vary depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

CFITR bit (Common FIFO Interval Timer Resolution)

The CFITR bit selects the resolution of the reference clock for the Interval Transmission Timer (peripheral clock is the source for the reference clock).

Do not write to this bit when the CANFD module is in GL_SLEEP mode. Also, do not write to this bit when the CFE bit is set to 1.

CFIM bit (Common FIFO Interrupt Mode)

The CFIM bit selects the interrupt generation condition for the FIFO buffer.

Do not write to this bit in GL_SLEEP mode.

仅当CANFD模块处于GL_HALT或GL_OPERATION模式且相关CANFD通道未处于CH_RESET模式（对于配置为TXFIFO的FIFO）时才写入该位。

仅当配置的FIFO深度大于0x000（CFDCFCC.CFDC>0x000且小于0x110（0x110>CFDCFCC.CFDC>0x000）时，才能设置该位。

在设置该寄存器中的所有其他位之后，通过对CFDCFCC寄存器的单独写访问来设置CFE位。

当CANFD模块处于GL_RESET模式时，该位会自动清零。

如果FIFO配置为TX模式，则当相关通道处于CH_RESET模式时，该位也会自动清零。

CFRXIE位（通用FIFORX中断使能）

当在相应的FIFO缓冲区中接收到帧后设置中断标志时，CFRXIE位允许生成FIFO中断。

CANFD模块处于GL_SLEEP模式时不要写入该位。

CFTXIE位（通用FIFOTX中断使能）

当从相应的FIFO缓冲区传输帧后设置中断标志时，CFTXIE位使能通用FIFO中断的生成。

CANFD模块处于GL_SLEEP模式时不要写入该位。

CFPLS[2:0]位（通用FIFO有效负载数据大小配置）

CFPLS[2:0]位定义RAM中的消息数据有效负载分配。这是FIFO缓冲区可以接收或发送的最大字节数。

有关详细信息，请参阅第28.6节。FIFO缓冲区和正常消息缓冲区配置。

仅当CANFD模块处于GL_RESET模式时写入该位。

Note: 这些位在经典CAN功能中不可用。

使用CANFD通信时，请勿向该位写入1。*1

Note: 位时钟可以根据标称和数据速率位配置而变化。

注1.此功能在经典CAN功能中不可用。

CFITR位（通用FIFO间隔定时器分辨率）

CANFD模块处于GL_SLEEP模式时不要写入该位。此外，当CFE位设置为1时，请勿写入该位。

CFIM位（通用FIFO中断模式）

CFIM位选择FIFO缓冲器的中断产生条件。

不要在GL_SLEEP模式下写入该位。

Only write to this bit when the CANFD module is in GL_RESET mode.

CFIGCV[2:0] bits (Common FIFO Interrupt Generation Counter Value)

The CFIGCV[2:0] bits select the message counter value for the generation of FIFO interrupts. These values represent fractions of the FIFO depth at which the interrupt is to be generated.

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

The setting of these bits should be synchronized with the CFDC[2:0] bits.

Only write to these bits when the CANFD module is in GL_RESET mode.

CFTML[1:0] bits (Common FIFO TX Message Buffer Link)

The CFTML[1:0] bits select the normal transmit message buffer position where the TX FIFO is linked to, for transmission scanning.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to this bit when the CANFD module is in GL_RESET mode.

CFDC[2:0] bits (Common FIFO Depth Configuration)

The CFDC[2:0] bits select the depth of the common FIFO in terms of the number of messages. If the FIFO depth is configured to 0 message, the FIFO cannot be used.

Only write to these bits when the CANFD module is in GL_RESET mode.

CFITT[7:0] bits (Common FIFO Interval Transmission Time)

The CFITT[7:0] bits select the delay in the start of transmission for all messages transmitted from this FIFO buffer when configured in TX mode. The delay is a multiple of the basic interval timer clock source period (reference clock × 1, reference clock × 10, or bit time clock of the related CAN channel).

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

Do not write to these bits when the CFE bit is set to 1.

When CFDGCFG.ITRCP[15:0] = 0x0000, set the CFITT[7:0] bits to 0x0000.

CFEMP bit (Common FIFO Empty)

The CFEMP bit is set automatically when:

- The CPU has read all messages from the FIFO configured in RX mode
- All messages have been transmitted from the FIFO configured in TX mode
- The FIFO is disabled by setting the CFE bit to 0
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET when FIFO configured in TX mode.

The CFEMP bit is cleared automatically when:

- The first reception message is stored in the FIFO buffer when configured in RX mode
- The first message to be transmitted is stored in the FIFO buffer when configured in TX mode.

CFFLL bit (Common FIFO Full)

The CFFLL bit is set automatically when the number of CAN messages stored in the FIFO matches the configured FIFO depth.

The CFFLL bit is cleared automatically when:

- The number of CAN messages stored in the FIFO is less than the configured FIFO depth
- The FIFO is disabled by setting the CFE bit to 0
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode when FIFO buffer is configured in TX mode.

CFMLT bit (Common FIFO Message Lost)

The CFMLT bit is set automatically whenever a message is lost due to attempted storage of a new message when FIFO is already full in RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The CFMLT bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode
- When the related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

CFRXIF bit (Common RX FIFO Interrupt Flag)

The CFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

●所有报文均已从配置为TX模式的FIFO发送

●通过将CFE位设置为0来禁用FIFO

●CANFD模块处于GL_RESET模式

●当FIFO配置为TX模式时，相关的CANFD通道处于CH_RESET。

CFEMP位在以下情况下自动清零：

●当配置为RX模式时，第一个接收报文存储在FIFO缓冲区中

●当配置为TX模式时，要发送的第一个报文存储在FIFO缓冲区中。

CFFLL bit (Common FIFO Full)

当存储在FIFO中的CAN报文数量与配置的FIFO深度匹配时，CFFLL位会自动设置。

CFFLL位在以下情况下自动清零：

●FIFO中存储的CAN报文数量小于配置的FIFO深度

●通过将CFE位设置为0来禁用FIFO

●CANFD模块处于GL_RESET模式

●当FIFO缓冲区配置为TX模式时，相关的CANFD通道处于CH_RESET模式。

CFMLT位（通用FIFO消息丢失）

当RX模式下FIFO已满时，由于尝试存储新消息而导致消息丢失，CFMLT位会自动设置。

如果来自CAN通道的设置与写访问清除同时发生，则设置该位。

仅当CANFD模块处于GL_HALT或GL_OPERATION模式并且相关的CANFD通道不处于CH_RESET模式（对于配置为TXFIFO的FIFO）时才写入该位。写1无效。

不要使用位清除指令清除该位。使用MOV指令确保只清除指定位。
其他位保持1。

CFMLT位清零：

●写入0

●CANFD模块处于GL_RESET模式时

●如果FIFO缓冲区配置为TX模式，则相关CANFD通道处于CH_RESET模式时。

CFRXIF位（通用RXFIFO中断标志 ）

如果禁用通用FIFO缓冲区，则CFRXIF位不会自动清除。

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers when configured in RX mode.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The CFRXIF bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode

CFTXIF bit (Common TX FIFO Interrupt Flag)

The CFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO buffer configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers configured in TX mode.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The CFTXIF bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode
- When the related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

CFMC[5:0] bits (Common FIFO Message Count)

The CFMC[5:0] bits indicate the following:

- Number of CAN messages stored by the CPU in the FIFO buffer configured in TX mode pending for transmission
- Number of CAN messages stored in the FIFO buffer configured in RX mode by CANFD module to be read by the CPU

The CFMC[5:0] bits are cleared automatically when:

- The FIFO is disabled
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

The Common FIFO Pointer Control Registers can be used to increment the read or write pointer of the corresponding Common FIFO buffer.

CFPC[7:0] bits (Common FIFO Pointer Control)

When the value 0xFF is written into the CFPC[7:0] bits, the read pointer of the corresponding Common FIFO buffer (when configured in RX mode), or the write pointer of the corresponding Common FIFO buffer (when configured in TX mode) moves to the next FIFO entry.

The read value from these bits is always 0x00.

Only write to these bits when the CANFD module is in GL_HALT or GL_OPERATION mode.

Only write 0xFF to this register when:

- The Common FIFO buffer is enabled and is not empty if configured in RX mode
- The Common FIFO buffer is enabled and is not full if configured in TX mode

Do not write to the Common FIFO Pointer Control registers when DMA is enabled.

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.CFDMAE (see CFDCDTCT.CFDMAE bit in section 28.2.36. CFDCDTCT : DMA Transfer Control Register) is set to 0 while DMA transfer for the corresponding FIFO is on going, the CFDMASTS bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CANFD module is in GL_RESET mode.

The TX Message Buffer Control Registers configure the TX message buffer functions.

TMTR bit (TX Message Buffer Transmission Request)

When the TMTR bit is set, the CANFD module logic tries to transmit the message stored in the corresponding message buffer.

Only write to this bit when the related CANFD module is in CH_HALT or CH_OPERATION mode.

Do not set this bit if the corresponding TX message buffer is linked to a COM FIFO in TX mode or is a part of TX Queue.

This bit cannot be directly cleared by a CPU write access.

This bit can only be set when the Transmission Result flag bits (CFDTMSTSj.TMTRF) in the CFDTMSTSj register corresponding to the message buffer are cleared to 00b.

The TMTR bit is automatically cleared by the:

- CANFD module logic at the end of a successful transmission
- CANFD module logic at the end of a transmission abort, requested by the corresponding CFDTMCi.TMTAR bit
- CANFD module logic when there is a detection of a CAN bus error or arbitration loss if CFDTMCi.TMOM bit is set for the message buffer
- CANFD module logic when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

TMTAR bit (TX Message Buffer Transmission Abort Request)

When the TMTAR bit is set, the CANFD module logic tries to abort the transmission of the frame stored in the corresponding message buffer.

In most cases, transmission cannot be aborted if the internal scan for transmission is complete and the message buffer has already been selected for transmission. In this case, frame may be transmitted successfully from the message buffer. The message buffer selection is released by entering CH_HALT mode.

However, message buffer selected for transmission can be aborted by an abort request when the CAN node detects a new message on the bus (RX pin) before it starts transmission from the selected message buffer.

Only write to the TMTAR bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. This bit can only be set when the related transmit request TMTR bit is set.

The TMTAR bit cannot be cleared by a CPU write access. Clearing of this bit by CANFD has priority over setting by a CPU write access.

The TMTAR bit is automatically cleared by:

- The CANFD module logic at the end of a successful transmission
- The CANFD module logic at the end of a transmission abort
- The CANFD module logic when there is detection of a CAN bus error or arbitration loss
- The CANFD module logic when the CANFD module is in GL_RESET mode or the related channel enters CH_RESET mode.

TMOM bit (TX Message Buffer One-shot Mode)

When the TMOM bit is set, the CANFD module logic tries to transmit the message only once.

If the transmission is successful, the CFDTMSTSj.TMTRF bits are set to 10b or 11b. Otherwise, the transmission is automatically aborted and CFDTMSTSj.TMTRF bits are set to 01b due to a bus error or a bus arbitration lost.

The TMOM bit remains set if the transmission has completed successfully or aborted due to an error or a loss of arbitration.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Set this bit at the same time as the TMTR bit. Clear this bit with a write access.

If a message has already been requested for transmission, do not write to this bit until the message has been successfully transmitted or transmission has been aborted.

7:3	—	这些位被读取为0。写入值应为0。	R/W

TX报文缓冲区控制寄存器配置TX报文缓冲区功能。

TMTR位（TX报文缓冲区传输请求）

当设置TMTR位时，CANFD模块逻辑尝试发送存储在相应消息缓冲区中的消息。

仅当相关CANFD模块处于CH_HALT或CH_OPERATION模式时才写入该位。

如果相应的TX消息缓冲区链接到TX模式下的COMFIFO或者是TX队列的一部分，则不要设置该位。

该位不能通过CPU写访问直接清除。

仅当与消息缓冲区对应的CFDTMSTSj寄存器中的传输结果标志位(CFDTMSTSj.TMTRF)被清除为00b时，才能设置该位。

TMTR位通过以下方式自动清零：

●成功传输结束时的CANFD模块逻辑

●发送中止结束时的CANFD模块逻辑，由相应的CFDTMCi.TMTAR位请求

●如果为消息缓冲区设置了CFDTMCi.TMOM位，则检测到CAN总线错误或仲裁丢失时的CANFD模块逻辑

●CANFD模块处于GL_RESET模式或相关通道处于CH_RESET模式时的CANFD模块逻辑。

TMTAR位（TX报文缓冲区传输中止请求）

当设置TMTAR位时，CANFD模块逻辑尝试中止存储在相应消息缓冲区中的帧的传输。

在大多数情况下，如果内部扫描传输完成并且消息缓冲区已被选择用于传输，则无法中止传输。在这种情况下，可以从消息缓冲区成功传输帧。通过进入CH_HALT模式释放消息缓冲区选择。

但是，当CAN节点在从选定的消息缓冲区开始传输之前检测到总线（RX引脚）上的新消息时，可以通过中止请求中止选择用于传输的消息缓冲区。

仅当相关CANFD通道处于CH_HALT或CH_OPERATION模式时才写入TMTAR位。只有当相关的发送请求TMTR位被置位时，该位才能被置位。

CPU写访问不能清除TMTAR位。CANFD清除该位优先于CPU写访问设置。

TMTAR位通过以下方式自动清零：

●成功传输结束时的CANFD模块逻辑

●传输中止结束时的CANFD模块逻辑

●检测到CAN总线错误或仲裁丢失时的CANFD模块逻辑

●CANFD模块处于GL_RESET模式或相关通道进入CH_RESET模式时的CANFD模块逻辑。

TMOM位（TX消息缓冲区一次性模式）

当TMOM位置位时，CANFD模块逻辑尝试仅发送一次报文。

如果传输成功，CFDTMSTSj.TMTRF位设置为10b或11b。否则，由于总线错误或总线仲裁丢失，传输将自动中止，CFDTMSTSj.TMTRF位设置为01b。

如果传输成功完成或由于错误或仲裁丢失而中止，则TMOM位保持设置。

仅当相关CANFD通道处于CH_HALT或CH_OPERATION模式时才写入该位。

该位与TMTR位同时置位。通过写访问清除该位。

如果已请求发送消息，则在消息成功发送或发送中止之前不要写入该位。

The TMOM bit is automatically cleared by the CANFD module logic when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

- 11: Transmission was successful from the corresponding TX message buffer, but the CFDTMCi.TMTAR bit was set for this TX message buffer.

Only write to these bits when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

The TMTRF[1:0] bits are cleared automatically when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

当CANFD模块处于GL_RESET模式或相关通道处于CH_RESET模式时，TMOM位由CANFD模块逻辑自动清零。

TXQEMP位（TX队列空）

当TX队列被禁用或没有消息存储在TX队列中时，TXQEMP位自动置位。

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CANFD channel is in CH_RESET mode.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CANFD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

TXQMC[2:0][13:8] bits (TX Queue Message Count)

The TXQMC[2:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

The TX Queue Pointer Control Registers are used to confirm storage of a full message in the corresponding TX Queue buffers.

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value 0xFF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 0x00. Do not write to the FIFO control registers when DMA is enabled.

该位在以下情况下自动设置：

●最后一条消息是从TXQueue发送的

●相关CANFD通道处于CH_RESET模式。

当要发送的第一个消息存储在TX队列中时，该位会自动清除。

TXQFLL位（TX队列已满）

当存储在TX队列中的CAN报文数量与配置的匹配时，自动设置TXQFLL位
TX队列深度。

该位在以下情况下自动清零：

●TXQueue中存储的CAN报文数量小于配置的TXQueue深度

●相关CANFD通道处于CH_RESET模式。

TXQTXIF位（TX队列TX中断标志 ）

如果TX队列被禁止，TXQTXIF位不会自动清零。

停止TX队列时，应在禁用TXQE并检查TX队列的空状态后清除该位。

不要使用位清除指令清除该位。使用MOV指令确保只清除指定位。
其他位保持1。写1无效。

当为TX队列配置的中断条件满足时，该位自动置位。

如果来自CAN通道的设置与写访问清除同时发生，则该位被设置。

当相关CANFD通道处于CH_SLEEP或CH_RESET模式时，您无法写入该位。

该位被清除：

●写入0

●当相关CANFD通道处于CH_RESET模式时。

TXQMC[2:0][13:8]位（TX队列消息计数）

TXQMC[2:0]位显示TX队列中的CAN报文数。

THLEMP位（TX历史列表空）

当CPU从TXHistoryList缓冲区读取所有条目时，THLEMP位自动置位。

当第一个条目存储到TX历史列表时，该位自动清零。

该位在以下情况下自动设置：

●TX历史列表被禁用

●相关CANFD通道处于CH_RESET模式。

THLFLL位（TX历史列表已满）

当TX历史列表缓冲区中的条目数与TX历史列表深度匹配时，自动设置THLFLL位。

每个TXHistoryList最多可以存储8个条目。

该位在以下情况下自动清零：

●TX历史列表缓冲区中的条目数小于TX历史列表深度

●TX历史列表被禁用

●相关CANFD通道处于CH_RESET模式。

THLELT bit (TX History List Entry Lost)

The THLELT bit is set when a new entry cannot be stored because the related TX History List buffer is already full.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

THLIF bit (TX History List Interrupt Flag)

The THLIF bit is set when the configured interrupt condition is satisfied.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

The bit is cleared by writing 0 to it.

This bit is automatically cleared in CH_RESET mode.

THLMC[3:0] bits (TX History List Message Count)

The THLMC[3:0] bits show the number of transmitted messages stored in the TX History List.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

RPED bit (RES Bit Protocol Exception Disable)

The RPED bit configures the protocol exception event handling according to ISO 11898-1.

When this bit is enabled, the protocol exception event detection is disabled, and the protocol controller transmits an error frame when the protocol exception event is detected (RES bit is sampled recessive).

Only write to this bit when the CANFD module is in GL_RESET mode.

TSCCFG[1:0] bits (Timestamp Capture Configuration)

The TSCCFG[1:0] bits configure the different capture points of the timestamp for transmission and reception.

- RX Message Buffer Component (CFDRMBCPb[0])
- RX FIFO Access Message Buffer Component (CFDRFMBCPb[0])
- Common FIFO Access Message Buffer Component (CFDCFMBCP0[0])
- TX Message Buffer Component (CFDTMBCPb[0]).

Where b = the Message Buffer component index that has a range that varies based on the type of Message Buffer component.

For a summary of this configuration, see Figure 28.29. For a detailed description of the number of and the different types of message buffers, see section 28.6. FIFO Buffers and Normal Message Buffer Configuration.

As described in section 28.2. Register Descriptions, each Message Buffer component consists of the following registers:

- Identifier (ID)
- Pointer (PTR)
- Data Field (DFp).

Where p = the Data Field register index that has a range that varies based on the type of message buffer component.

Rc is the Message Buffer Component register where c = Message Buffer Component register index that has a range that varies based on the type of Message Buffer component.

A description of the registers, their associated bits and their accessibility are shown below the summary and detailed figures of each component.

In each of the figures, a cell that contains '-' means reserved and has the same behavio as reserved bits for registers in section 28.2.62. Message Buffer Component Structure.

29	—	This bit is read as 0.	R
30	RFRTR	RX FIFO Buffer RTR bit 0: Data frame 1: Remote frame	R
31	RFIDE	RX FIFO Buffer IDE bit 0: STD-ID has been received 1: EXT-ID has been received	R

The RX FIFO Access ID Registers b (b = 0 to 1) store the ID field, IDE bit and RTR bit of the message.

RFID[28:0] bits (RX FIFO Buffer ID Field)

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

Bit	Symbol	Function	R/W

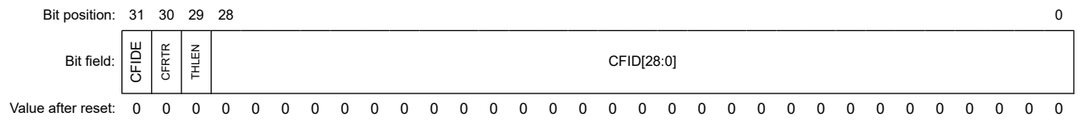
28.2.62.13 CFDCFID : Common FIFO Access ID Register

Base address: CANFD_B = 0x400B_0000

Offset address: 0x05B8



Bit	Symbol	Function	R/W
28:0	CFID[28:0]	Common FIFO Buffer ID Field STD-ID / EXT-ID fields	R/W
29	THLEN	THL Entry enable TX FIFO Mode: 0: Entry will not be stored in THL after successful TX. 1: Entry will be stored in THL after successful TX. RX FIFO Mode: Reserved, this bit is read as 0	R/W
30	CFRTR	Common FIFO Buffer RTR Bit 0: Data Frame 1: Remote Frame	R/W
31	CFIDE	Common FIFO Buffer IDE Bit 0: STD-ID will be transmitted or has been received 1: EXT-ID will be transmitted or has been received	R/W

The Common FIFO Access ID registers store the ID field, IDE bit and RTR bit of the message.

In TX mode, users can read data from the FIFO, only for the current entry based on the write pointer value, not for the other entries.

CFID[28:0] bit (Common FIFO Buffer ID Field)

These are the bits of the STD-ID / EXT-ID fields of the message in the FIFO Buffer.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

THLEN bit (THL Entry enable)

This bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

CFRTR bit (Common FIFO Buffer RTR Bit)

This bit selects whether a Data Frame or a Remote Frame will be transmitted from or was received in the FIFO Buffer.

Note: There are no remote frames in CANFD format. In case a CANFD frame was received (RX mode) the register reflects the state of the received value (RRS bit in FD frame format). In case of CANFD transmission (TX mode CFDCFID.CFFDF =1) the bit is always transmitted dominant (Data Frame).

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

CFIDE bit (Common FIFO Buffer IDE Bit)

This bit selects whether a message with EXT-ID or STD-ID will be transmitted from or was received in the FIFO Buffer.

In TX mode, users can write and read from FIFO buffers.

In RX mode, users can only read data from FIFO buffers.

28.2.62.15 CFDCFFDCSTS:通用FIFO访问CANFD控制状态寄存器

Bit	Symbol	Function	R/W
1	CFBRS*1	Bit Rate Switch bit 0: CANFD frame received or to transmit with no bit rate switch 1: CANFD frame received or to transmit with bit rate switch	R/W
2	CFFDF*1	CAN FD Format bit 0: Non CANFD frame received or to transmit 1: CANFD frame received or to transmit	R/W

9:8	CFIFL[1:0]	COMMON FIFO Buffer Information Label Field	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
31:16	CFPTR[15:0]	Common FIFO Buffer Pointer Field	R/W

Note 1. This bit is not available in the classical CAN function.

The Common FIFO Access CANFD Control/Status Registers show the status of the FDF, BRS and ESI bits, including the pointer of the received CANFD frame or the CANFD frame to transmit.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

CFESI bit (Error State Indicator bit)

In TX mode, you can read and write from FIFO buffers. In this mode, when the CANFD module is not in error passive, the CFESI bit equals the write value. Otherwise, it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFESI bit is updated with the ESI bit value of the CANFD frame when it has been received, indicating the error state of the transmitting node. In RX mode, 0 is stored to this bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFBRS bit (Bit Rate Switch bit)

In TX mode, you can read and write from FIFO buffers. In this mode, the CANFD module either transmits a 0 to indicate no bit rate switch in the frame to be transmitted or a 1 to indicate a bit rate switch in the frame to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFBRS bit is updated with the BRS bit value of the CANFD frame when it has been received, indicating whether there is a bit rate switch (1) or (0) on the CANFD frame.

In RX mode, 0 is stored to the CFBRS bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFFDF bit (CAN FD Format bit)

In TX mode, you can read and write from FIFO buffers. In this mode, the CANFD module either transmits a 0 to indicate a CAN 2.0 frame is to be transmitted or a 1 to indicate a CANFD frame is to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFFDF bit is updated with the FDF bit value of the CAN frame when it has been received, indicating whether it is a CAN 2.0 frame (0) or a CANFD frame (1).

Note: This bit is not available in the classical CAN function.

CFIFL[1:0] bits (COMMON FIFO Buffer Information Label Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTS.CFIFL[1:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The information label value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX mode).

Bit	Symbol	Function	R/W
1	CFBRS*1	比特率切换位 0：接收或发送CANFD帧，无比特率切换1：接收或发送CANFD帧，使用比特率切换	R/W
2	CFFDF*1	CANFD格式位 0：接收或发送非CANFD帧1：接收或发送CANFD帧	R/W
7:3	—	这些位被读取为0。写入值应为0。	R/W
9:8	CFIFL[1:0]	COMMONFIFO缓冲区信息标签字段	R/W
15:10	—	这些位被读取为0。写入值应为0。	R/W
31:16	CFPTR[15:0]	通用FIFO缓冲区指针字段	R/W

注1.该位在经典CAN功能中不可用。

通用FIFO访问CANFD控制状态寄存器显示FDF、BRS和ESI位的状态，包括接收到的CANFD帧或要发送的CANFD帧的指针。

在TX模式下，您可以从FIFO中读取数据，仅针对基于写指针值的当前条目，而不能针对其他条目。

CFESI位（错误状态指示位）

在TX模式下，您可以从FIFO缓冲区读取和写入。在此模式下，当CANFD模块未处于错误被动状态时，CFESI位等于写入值。否则，它是无关紧要的，该位在CAN总线上传输为1，表示这是一个错误被动节点。

在RX模式下，您只能从FIFO缓冲区读取数据。

在RX模式下，CFESI位在接收到CANFD帧时更新为ESI位值，指示发送节点的错误状态。在RX模式下，当接收到的FDF位为0时，将0存储到该位，这意味着接收到CAN2.0帧。

Note: 该位在经典CAN功能中不可用。

CFBRS位（比特率切换位）

在TX模式下，您可以从FIFO缓冲区读取和写入。在这种模式下，CANFD模块要么发送0表示要发送的帧中没有比特率切换，要么发送1表示要发送的帧中的比特率切换。

在RX模式下，您只能从FIFO缓冲区读取数据。

在RX模式下，CFBRS位在接收到CANFD帧时更新为BRS位值，指示CANFD帧上是否存在比特率切换（1）或（0）。

在RX模式下，当接收到的FDF位为0时，将0存储到CFBRS位，这意味着接收到CAN2.0帧。

Note: 该位在经典CAN功能中不可用。

CFFDF位（CANFD格式位）

在TX模式下，您可以从FIFO缓冲区读取和写入。在这种模式下，CANFD模块要么发送一个0来表示一个将发送CAN2.0帧或1表示要发送CANFD帧。

在RX模式下，您只能从FIFO缓冲区读取数据。

在RX模式下，CFFDF位在接收到CAN帧时更新为CAN帧的FDF位值，指示它是CAN2.0帧（0）还是CANFD帧（1）。

Note: 该位在经典CAN功能中不可用。

The pointer value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX mode).

In TX mode, you can read and write from FIFO buffers.

The CFDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*1

Note 1. In RX mode, unused data bytes are filled with 0x00 according to the configured data payload size CFDCFCC.CFPLS, which is a CANFD feature not found in classical CAN.

每个TX报文缓冲区ID寄存器b（b=0到3）用于存储要从相关缓冲区发送的报文的ID、IDE、RTR字段和历史配置。

TMID[28:0] bits (TX Message Buffer ID Field)

The TMID[28:0] bits are bits of the STD-ID/EXT-ID fields of the message stored in this TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

THLEN bit (Tx History List Entry)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMRTR bit (TX Message Buffer RTR bit)

The TMRTR bit selects whether a data frame or remote frame is to be transmitted from this TX message buffer.

Note: There are no remote frames in CANFD format. For a CANFD transmission (CFDTMFDCTRb.CFFDF = 1), this bit is always transmitted dominant (data frame).

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMIDE bit (TX Message Buffer IDE bit)

The TMIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from this TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

Each TX Message Buffer Pointer Register b (b = 0 to 3) is used to store the DLC fields of the message to transmit from the associated buffer.

TMDLC[3:0] bits (TX Message Buffer DLC Field)

The TMDLC[3:0] bits select the number of data bytes to be transmitted from this TX message buffer when the corresponding TMRTR bit is configured as 0.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes to be transmitted.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMID[28:0]位（TX消息缓冲区ID字段）

TMDB_HH[7:0]位将消息的数据字节((p×4)+3)存储在TX消息缓冲区中。

当相关CANFD通道处于CH_SLEEP模式时，请勿写入这些位。

28.3 运作模式

28.3.1 Overview

CANFD模块的模式可分为2组：

●全局模式

●频道模式

28.3.2 Global Modes

These modes are applicable for the complete CANFD module and therefore are called Global modes. The global modes of the CANFD module are:

- Global Sleep
- Global Reset
- Global Halt
- Global Operation.

Figure 28.2 shows the possible transitions between the Global modes.

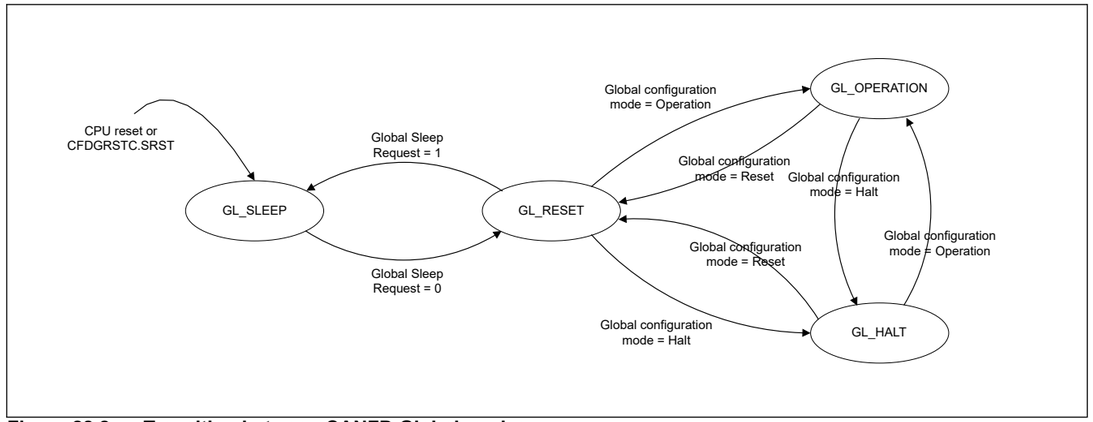

Figure 28.2 Transition between CANFD Global modes

Change in the Global mode can affect the Channel mode. Table 28.14 shows the effect of a Global mode transition on a Channel mode.

Table 28.14 Possible CANFD Channel modes and Global modes

Current Global mode	Target Global mode			
	Sleep	Reset	Halt	Operation
Sleep		Ch-Sleep: Keep Ch-Reset: N/A Ch-Halt: N/A Ch-Oper: N/A		
Reset	Ch-Sleep: Keep Ch-Reset: → Ch-Sleep Ch-Halt: N/A Ch-Oper: N/A		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A
Halt		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: N/A		Ch-Sleep:Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: N/A
Operation		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: → Ch-Reset	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: → Ch-Halt	

28.3.2.1 Global Sleep Mode

After the release of a hardware reset or after setting and clearing a CFDGRSTC.SRST bit, the CANFD module automatically enters Global Sleep mode.

The CANFD module also enters the Global Sleep mode when the Global Sleep Request bit is set while it is in Global Reset mode. This control bit cannot be set in Global Halt mode or Global Operation mode.

28.3.2 全局模式

这些模式适用于完整的CANFD模块，因此称为全局模式。CANFD模块的全局模式有：

●全局睡眠
●全局重置
●全球暂停
●全球运营。

图28.2显示了全局模式之间可能的转换。

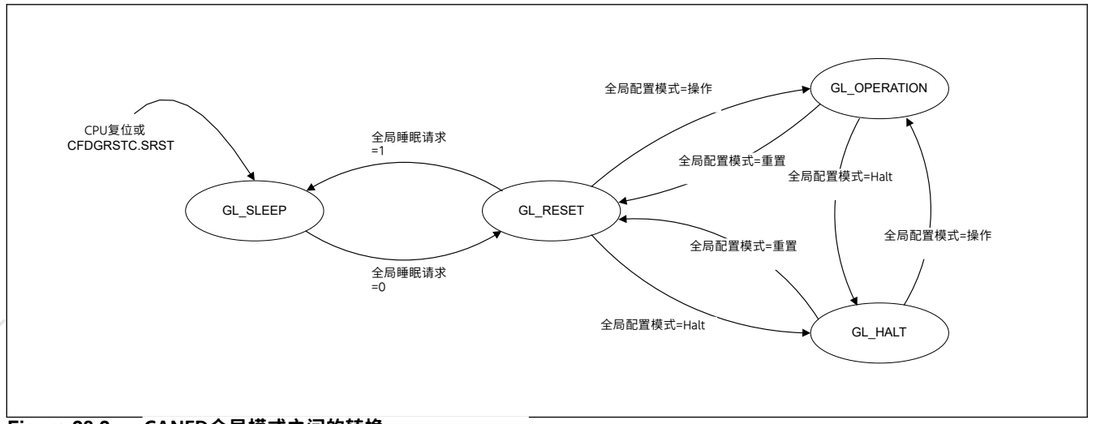

Figure 28.2 CANFD全局模式之间的转换

全局模式的变化会影响通道模式。表28.14显示了全局模式转换对频道模式。

Table 28.14 可能的CANFD通道模式和全局模式

当前全局模式	目标全局模式			
	Sleep	Reset	Halt	Operation
Sleep		Ch-Sleep: Keep Ch-Reset: N/A Ch-Halt: N/A Ch-Oper: N/A		
Reset	Ch-Sleep: Keep Ch-Reset: → Ch-Sleep Ch-Halt: N/A Ch-Oper: N/A		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A
Halt		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: N/A		Ch-Sleep:Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: N/A
Operation		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: → Ch-Reset	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: → Ch-Halt	

28.3.2.1 全局睡眠模式

释放硬件复位或设置和清除CFDGRSTC.SRST位后，CANFD模块自动进入全局休眠模式。

当CANFD模块在全局复位模式下设置全局休眠请求位时，它也会进入全局休眠模式。该控制位不能在GlobalHalt模式或GlobalOperation模式下设置。

Setting the Global Sleep Request bit sets Channel Sleep Request bit and forces the channel into the Channel Sleep mode.

Sleep mode is used for power saving purpose. When CANFD module is in Global Sleep mode, only the clock for CPU write access to the Global Sleep Mode Request bit is active. All other clocks are stopped and all other functions of the CANFD module are suspended.

Read access from all registers is still possible and all register values are preserved.

After setting the Global Sleep Request bit, it is necessary to confirm that the Global Sleep status has been updated, indicating successful transition to Global Sleep mode before the Global Sleep Request bit can be cleared again.

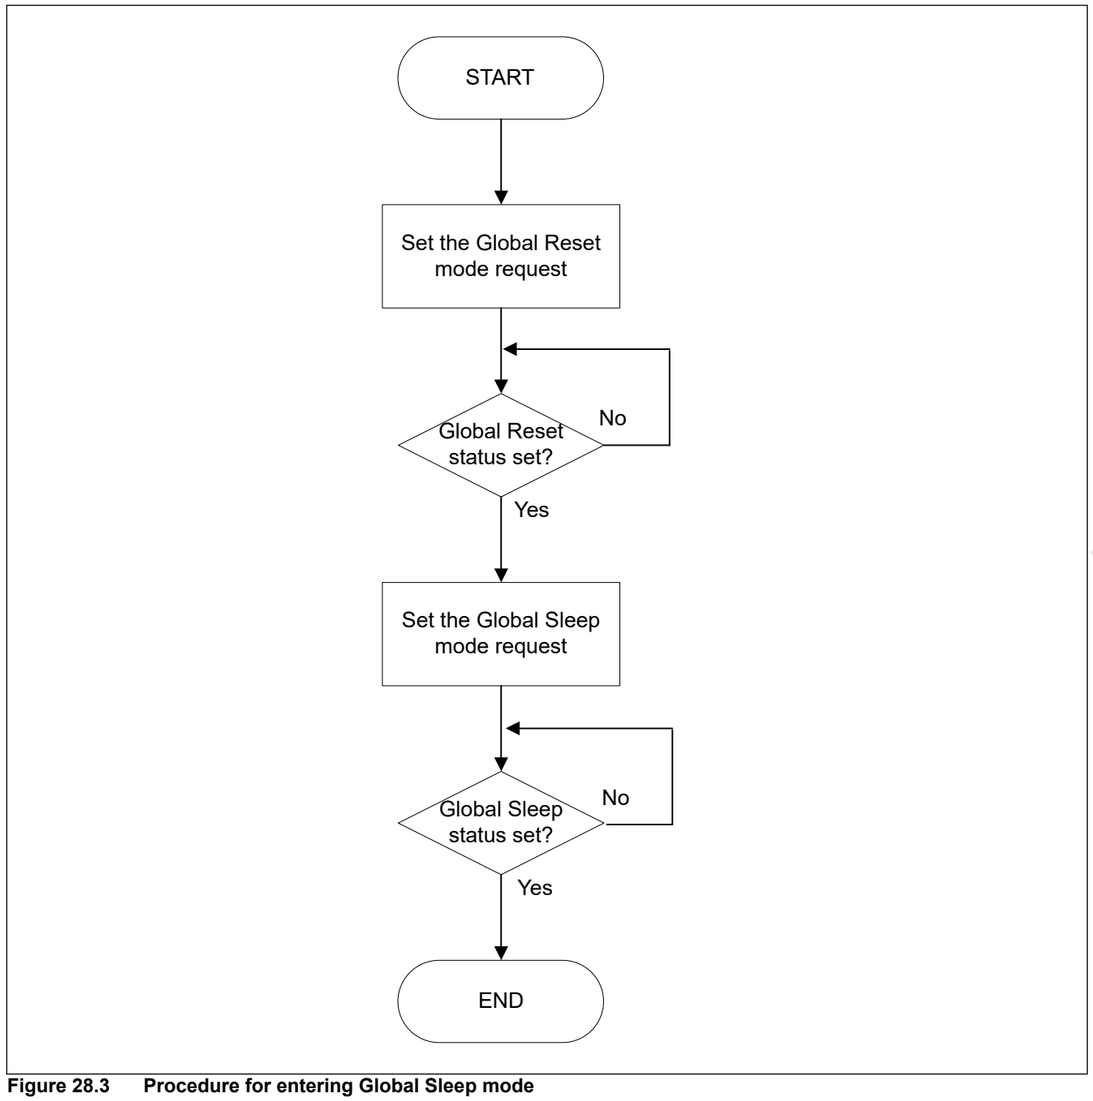

Figure 28.3 Procedure for entering Global Sleep mode

设置全局休眠请求位会设置通道休眠请求位并强制通道进入通道休眠模式。

睡眠模式用于省电目的。当CANFD模块处于全局休眠模式时，只有CPU对全局休眠模式请求位进行写访问的时钟有效。所有其他时钟停止，CANFD模块的所有其他功能暂停。

仍然可以从所有寄存器进行读取访问，并且所有寄存器值都被保留。

设置全局休眠请求位后，需要确认全局休眠状态已更新，表示成功转换到全局休眠模式，然后才能再次清除全局休眠请求位。

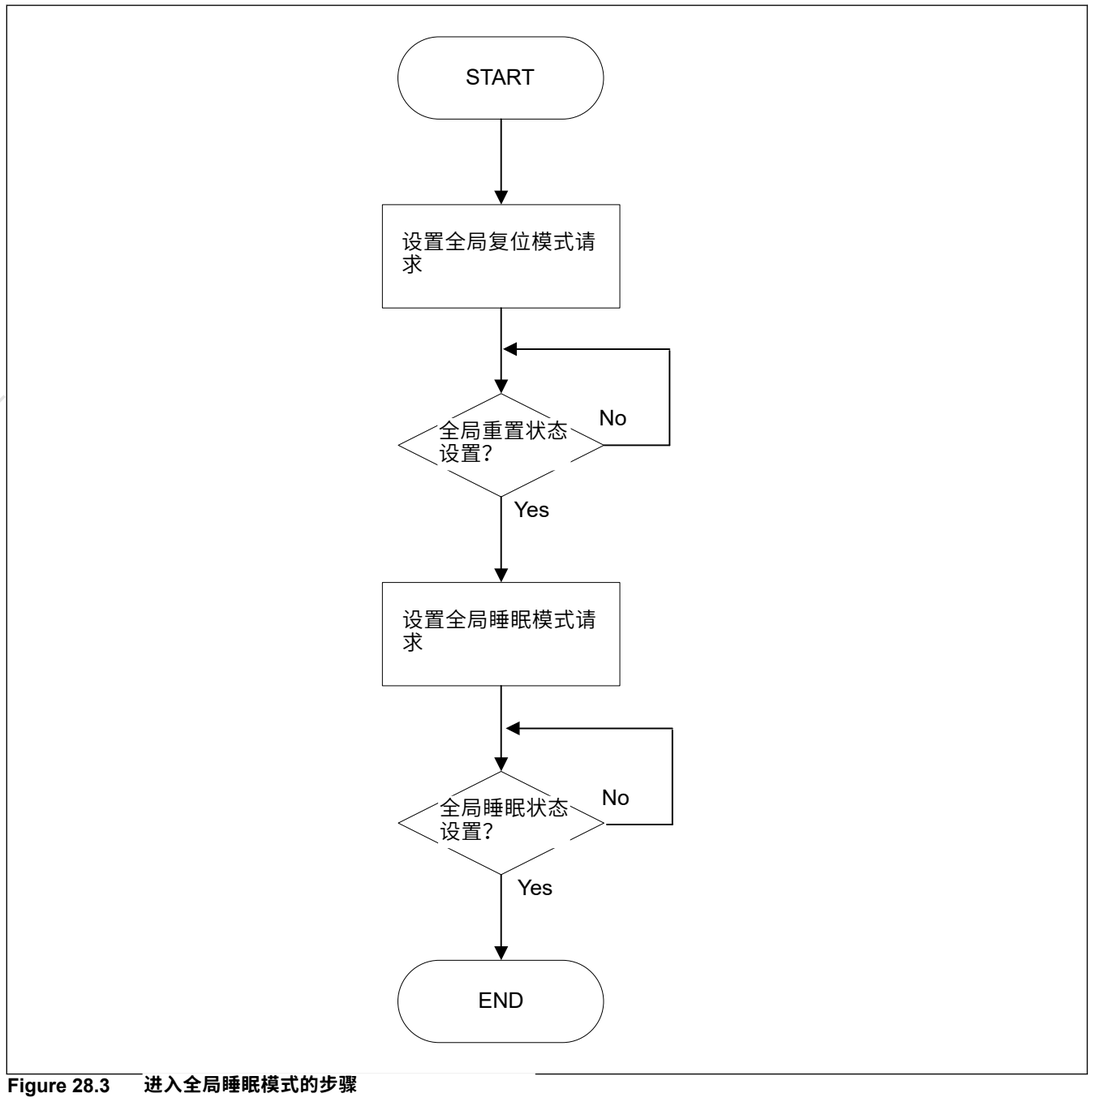

Figure 28.3 进入全局睡眠模式的步骤

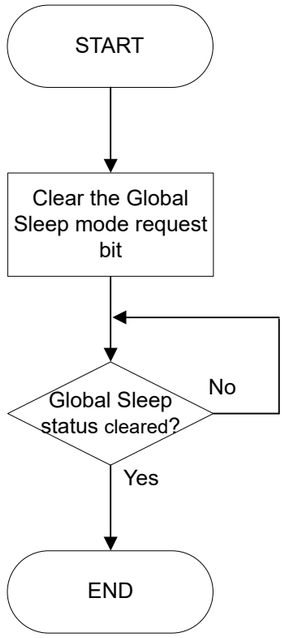

Figure 28.4 Procedure for exiting Global Sleep mode

28.3.2.2 Global Reset Mode

The CANFD module enters this mode in the following ways:

- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Reset mode while the CANFD module is in Global Halt or Global Operation mode
- Global Sleep Mode Request bit is cleared while CANFD module is in Global Sleep mode.

In Global Reset mode, all CANFD module functions are suspended and all status and flag registers are initialized.

Additionally all FIFOs and TX Queues are disabled and transmission control bits are cleared.

Configuration registers (except the test mode registers) are not initialized in this mode to their MCU reset values and the CANFD module can be configured.

See section 28.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Global Reset mode is performed.

Setting the Global mode to Reset by setting the Global Mode Control bits CFDGCTR.GMDC in the Global Control Register to 01b sets Channel Mode Control bits CFDC0CTR.CHMDC in the Channel Control Registers to 01b and forces the channel into the Channel Reset mode.

For channels that are already in Channel Reset mode or Channel Sleep mode, this automatic transition is not performed (CFDC0CTR.CHMDC of related channel already set to 01b).

After setting Global Mode Control bit CFDGCTR.GMDC to Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDGSTS.GRSTSTS in the Global Status Register has been updated, indicating successful transition to Global Reset mode before CFDGCTR.GMDC can be changed again.

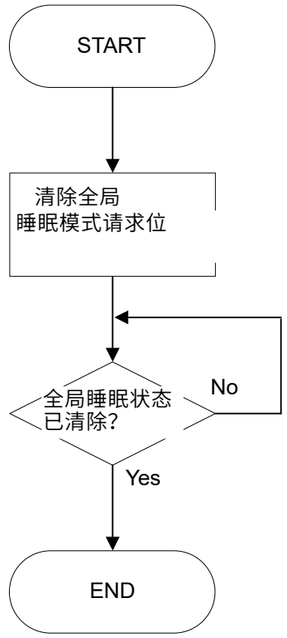

Figure 28.4 退出全局休眠模式的步骤

28.3.2.2 全局重置模式

CANFD模块通过以下方式进入该模式：

●全局控制寄存器中的全局模式控制位CFDGCTR.GMDC配置为全局复位模式，而CANFD模块处于全局暂停或全局操作模式

●CANFD模块处于全局休眠模式时，全局休眠模式请求位被清零。

在全局复位模式下，所有CANFD模块功能都被挂起，所有状态和标志寄存器都被初始化。

此外，所有FIFO和TX队列都被禁用，传输控制位被清除。

配置寄存器（测试模式寄存器除外）在此模式下未初始化为其MCU复位值，并且CANFD模块可以配置。

请参阅第28.3.4节。GlobalModeandChannelModeTransitionInteractions详细描述了当转换到全局复位模式时所有寄存器的行为。

通过设置全局控制中的全局模式控制位CFDGCTR.GMDC将全局模式设置为复位寄存器01b将通道控制寄存器中的通道模式控制位CFDC0CTR.CHMDC设置为01b，并强制通道进入通道复位模式。

对于已经处于通道复位模式或通道休眠模式的通道，不执行此自动转换（相关通道的CFDC0CTR.CHMDC已设置为01b）。

将全局模式控制位CFDGCTR.GMDC设置为复位模式后，需要确认复位模式GlobalStatusRegister中的状态位CFDGSTS.GRSTSTS已更新，表示成功转换到Global可以再次更改CFDGCTR.GMDC之前的复位模式。

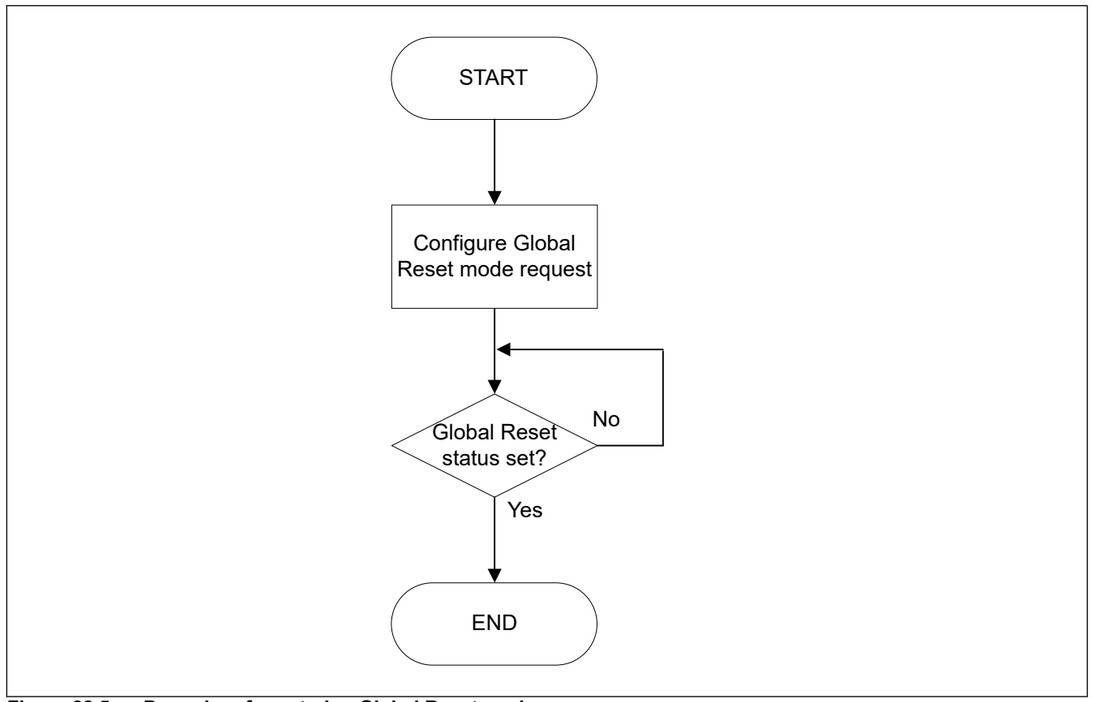

Figure 28.5 Procedure for entering Global Reset mode

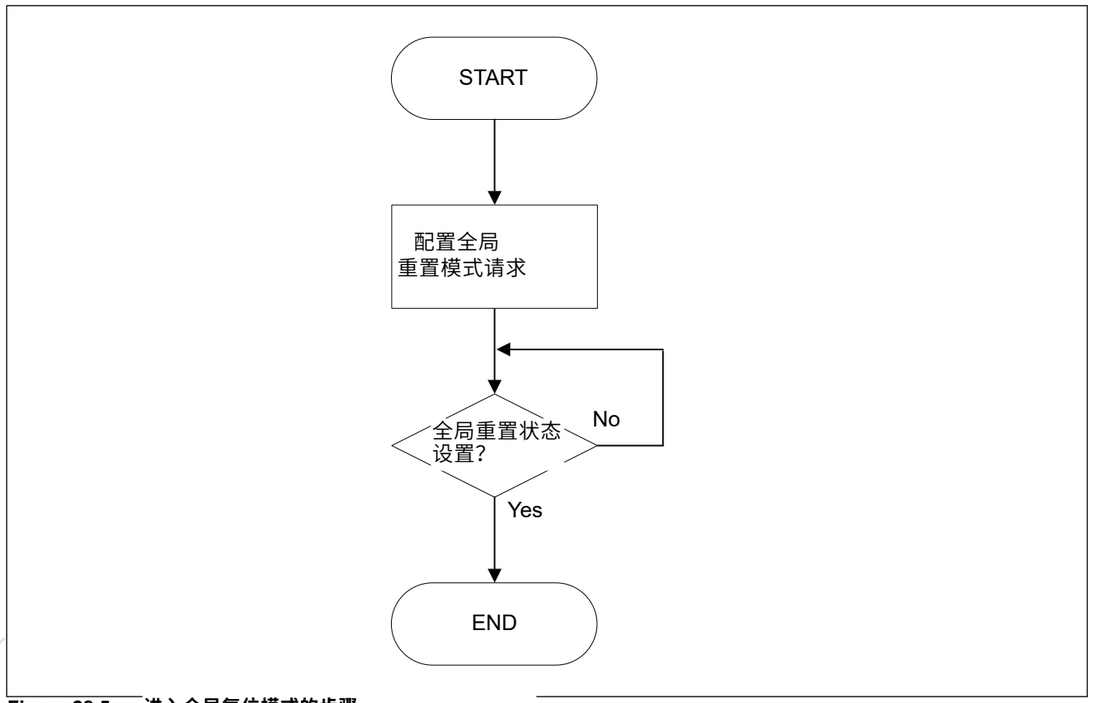

Figure 28.5 进入全局复位模式的步骤

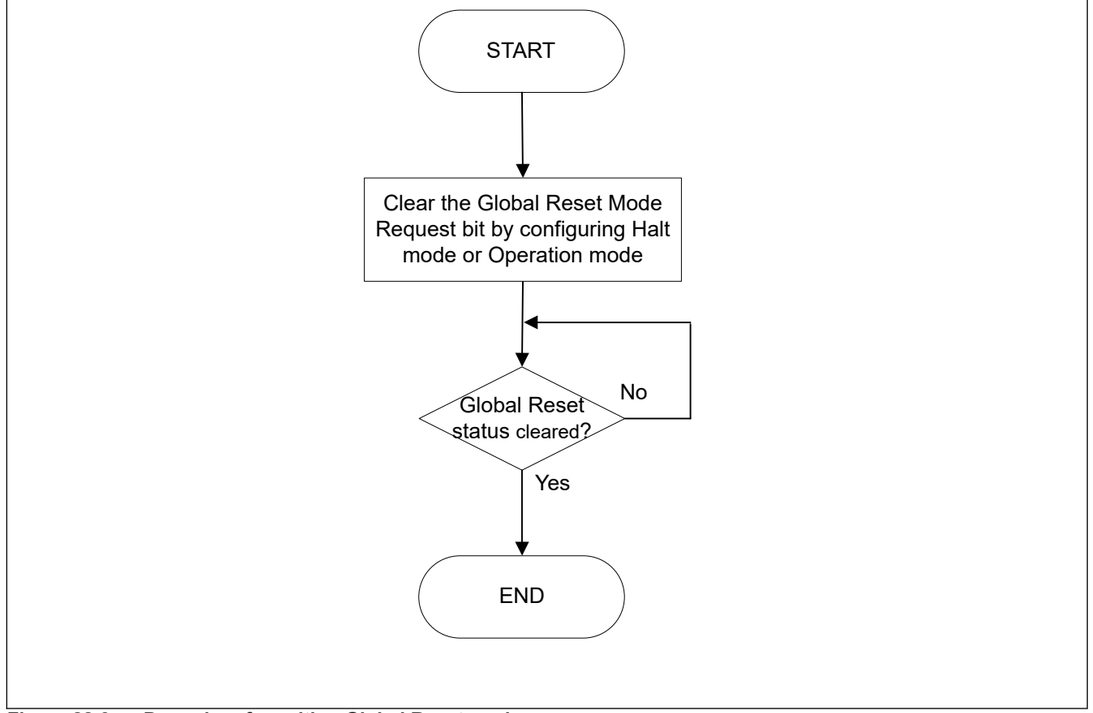

Figure 28.6 Procedure for exiting Global Reset mode

28.3.2.3 Global Halt Mode

The CANFD module enters this mode in the following ways:

- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Halt mode while the CANFD module is in Global Reset mode:
  - the channel is in either Channel Reset or Channel Sleep mode and remains in this mode
- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Halt mode while the CANFD module is in Global Operation mode:
  - the channel in Channel Reset, Channel Halt, or Channel Sleep mode remain in this mode
  - the channel in Channel Operation mode transit to Channel Halt mode
  - Global Halt Mode Status bit is set when the channel have left Channel Operation mode.

If a transmission or reception is ongoing for a channel, the transition to Channel Halt mode is delayed until completion of the communication.

Similarly, if a channel is in bus-off, the full bus-off recovery sequence may be delayed depending on the channel configuration.

In Global Halt mode, all communications are suspended and CANFD logic does not cause any change to the Status and Flag registers (only when a channel is in the bus-off that its REC and TEC values are cleared). Additionally, the test mode configuration and control registers are not initialized in this mode.

The Global Halt mode should be used to configure global module test modes.

See section 28.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Global Halt mode is performed.

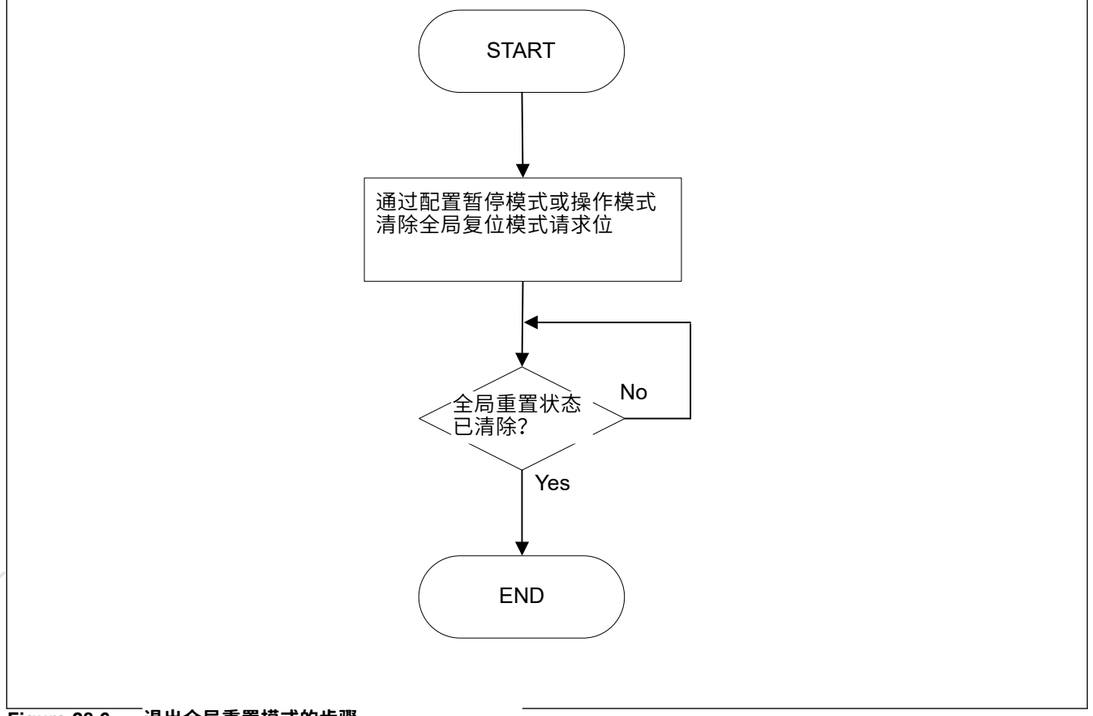

Figure 28.6 退出全局重置模式的步骤

28.3.2.3 全局停止模式

CANFD模块通过以下方式进入该模式：

●当CANFD模块处于全局复位模式时，全局控制寄存器中的全局模式控制位CFDGCTR.GMDC配置为全局暂停模式：

通道处于通道复位或通道休眠模式并保持在该模式

●当CANFD模块处于全局操作模式时，全局控制寄存器中的全局模式控制位CFDGCTR.GMDC配置为全局暂停模式：

处于通道复位、通道暂停或通道休眠模式的通道保持在此模式

通道操作模式中的通道转换到通道暂停模式

当通道离开通道操作模式时，设置全局暂停模式状态位。

如果通道正在进行传输或接收，则延迟到通道暂停模式的转换，直到通信完成。

类似地，如果通道处于总线关闭状态，则完全总线关闭恢复序列可能会延迟，具体取决于通道配置。

在全局暂停模式下，所有通信都暂停，CANFD逻辑不会导致状态和标志寄存器发生任何变化（仅当通道处于总线关闭状态时，其REC和TEC值才会被清除）。此外，测试模式配置和控制寄存器在此模式下未初始化。

GlobalHalt模式应该用于配置全局模块测试模式。

请参阅第28.3.4节。GlobalModeandChannelModeTransitionInteractions详细描述了在转换到全局暂停模式时所有寄存器的行为。

Setting the Global mode to Halt by setting the Global Mode Control bit CFDGCTR.GMDC in the Global Control Register to 10b sets Channel Mode Control bits CFDC0CTR.CHMDC in the Channel Control Registers to 10b for the channel that are in Channel Operation mode and forces these channels into the Channel Halt mode.

For the channel that are already in Channel Reset, Channel Halt, or Channel Sleep mode, this automatic transition is not performed.

Therefore, the Global Halt mode request can be used to shut down all CANFD channel communications without loss of messages and disruption on the related CAN bus (no interruption of reception/transmission processes on the channels).

After setting the Global Mode Control bit CFDGCTR.GMDC to Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register has been updated to indicate a successful transition to Global Halt mode. Do not specify any other SFR setting until confirming CFDGSTS.GHLTSTS is set.

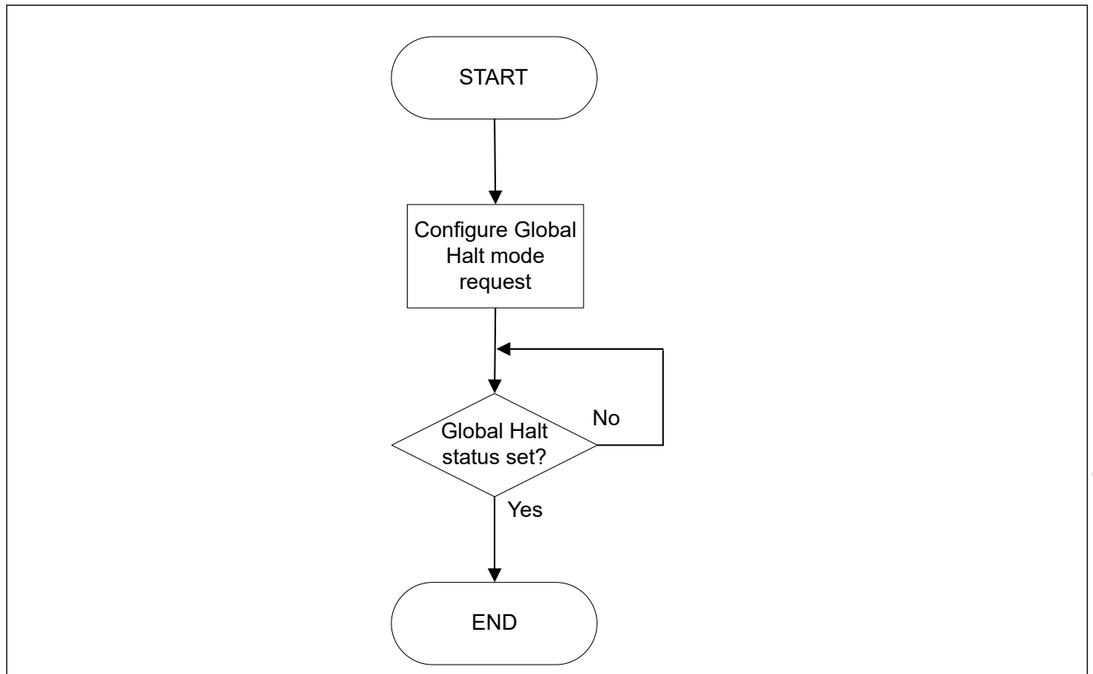

Figure 28.7 Procedure for entering Global Halt mode

通过将全局控制寄存器中的全局模式控制位CFDGCTR.GMDC设置为10b将全局模式设置为暂停，对于处于通道操作模式的通道，将通道控制寄存器中的通道模式控制位CFDC0CTR.CHMDC设置为10b，并强制这些通道进入通道暂停模式。

对于已经处于通道复位、通道暂停或通道休眠模式的通道，不会执行此自动转换。

因此，全局停止模式请求可用于关闭所有CANFD通道通信，而不会丢失消息和中断相关CAN总线（不会中断通道上的接收传输过程）。

将GlobalModeControl位CFDGCTR.GMDC设置为Halt模式后，需要确认HaltMode全局状态寄存器中的状态位CFDGSTS.GHLTTSTS已更新以指示成功转换到全局暂停模式。在确认设置CFDGSTS.GHLTTSTS之前，不要指定任何其他SFR设置。

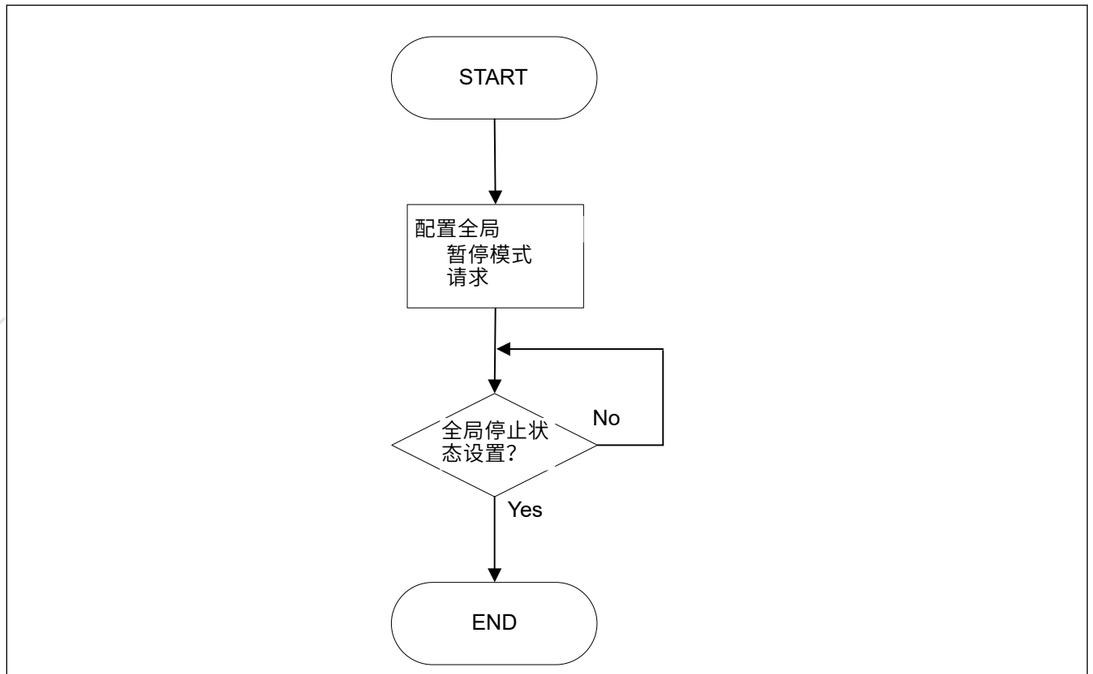

Figure 28.7 进入GlobalHalt模式的步骤

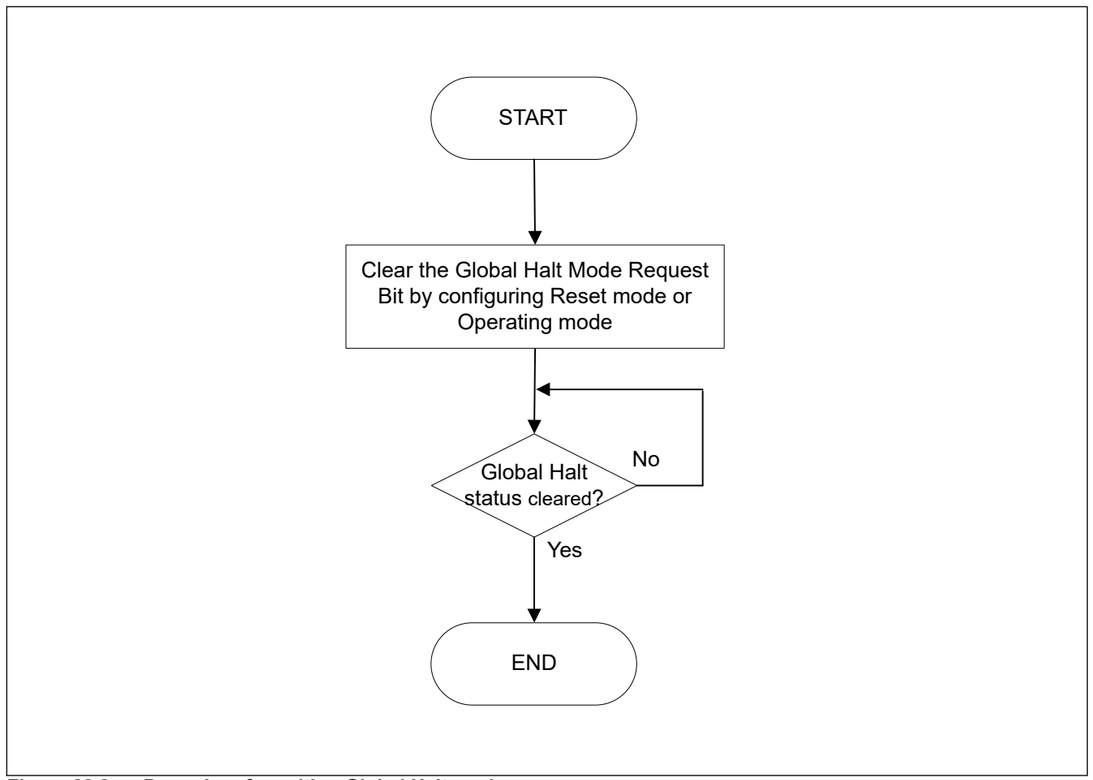

Figure 28.8 Procedure for exiting Global Halt mode

28.3.2.4 Global Operation Mode

The CANFD module enters this mode when the Global Mode Configuration bits are set to Global Operation mode.

The CANFD channel can only be set to Channel Operation mode and start CAN communication when CANFD is in Global Operation mode.

After setting the Global Mode Control bit CFDGCTR.GMDC to Global Operation mode, it is necessary to confirm that the Global Reset Mode Status bit CFDGSTS.GRSTSTS and the Global Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register have been cleared to indicate a successful transition to Global Operation mode before CFDGCTR.GMDC can be modified again.

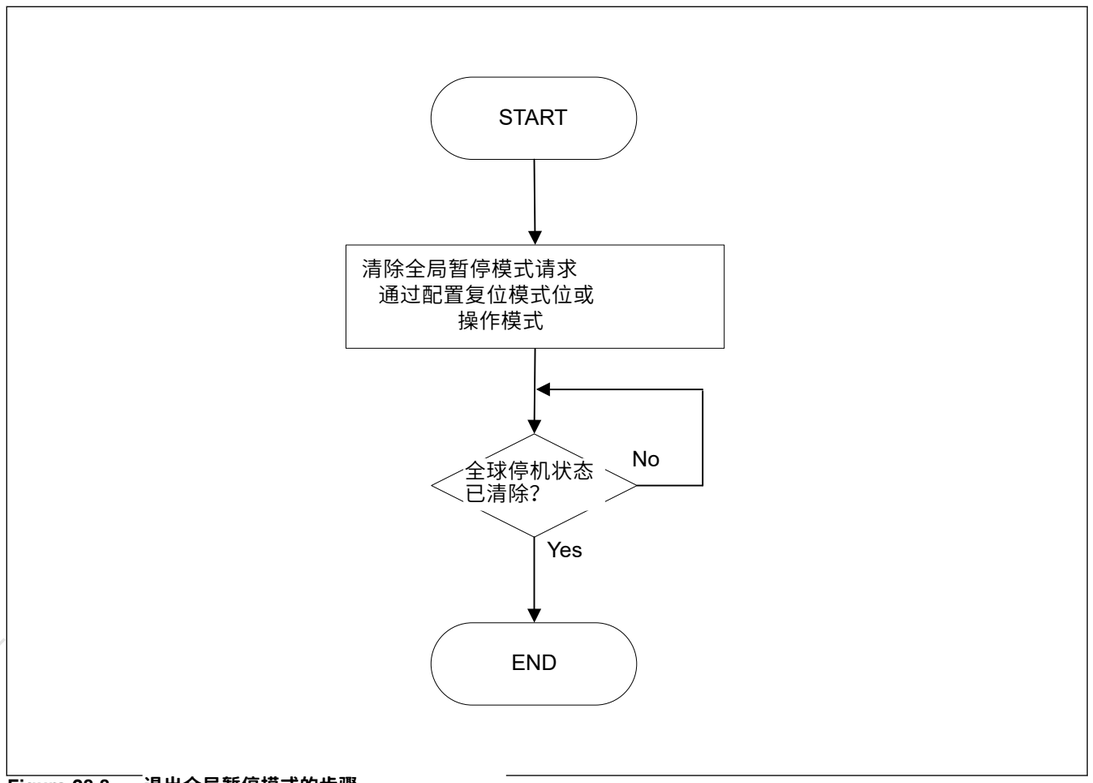

Figure 28.8 退出全局暂停模式的步骤

28.3.2.4 全球运营模式

当全局模式配置位设置为全局操作模式时，CANFD模块进入此模式。

CANFD通道只能设置为ChannelOperation模式并在CANFD处于Global时启动CAN通讯操作模式。

将全局模式控制位CFDGCTR.GMDC设置为全局操作模式后，需要确认
全局复位模式状态位CFDGSTS.GRSTSTS和全局暂停模式状态位CFDGSTS.GHLTSTS在
全局状态寄存器已被清除以指示成功转换到全局操作模式之前
CFDGCTR.GMDC可以再次修改。

28.3.3 Channel Modes

A CAN channel can be in one of the following four channel modes:

- Reset
- Halt
- Operation
- Sleep.

Figure 28.11 shows the possible transitions between the channel modes.

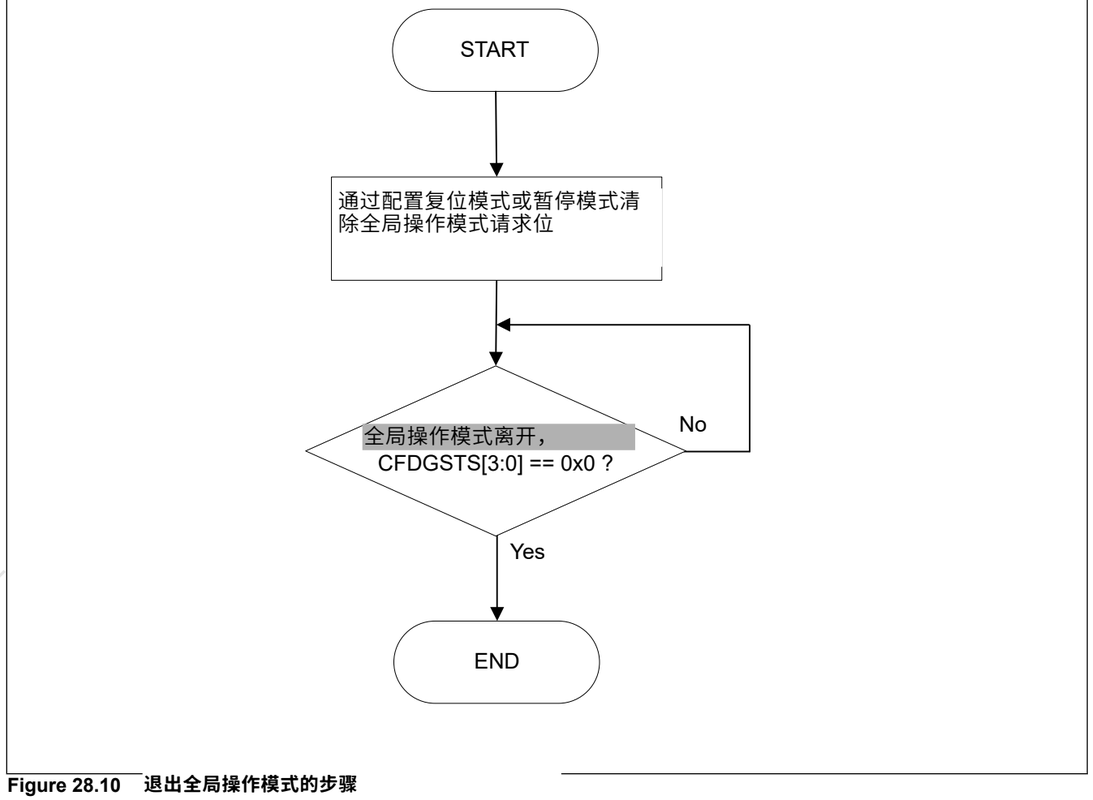

Figure 28.10 退出全局操作模式的步骤

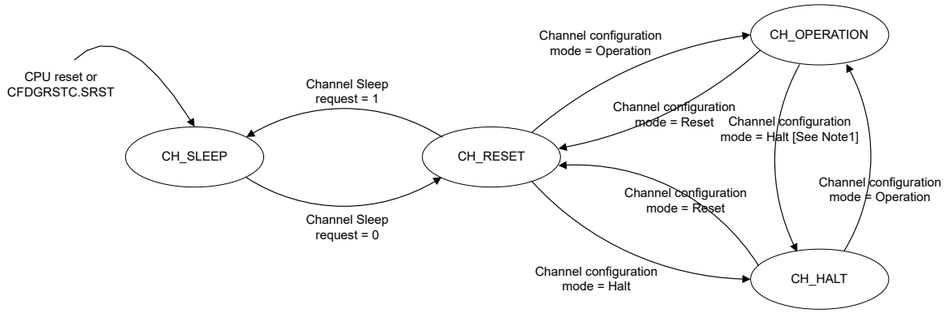
28.3.3 频道模式

CAN通道可以处于以下四种通道模式之一：

- Reset
- Halt
- Operation
- Sleep.

图28.11显示了通道模式之间可能的转换。



Note 1. The transition timing depends on BOM setting in the Channel Configuration Register:
- when BOM = 01b, the state transition timing is immediate after entering bus-off state
- when BOM = 10b, the state transition timing is at the end of bus-off state
- when BOM = 11b, the state transition timing is matching with the setting of CHMDC to Halt mode.

Figure 28.11 Transition between CAN channel modes

28.3.3.1 CAN Channel Sleep Mode

After the release of a hardware reset or after setting and clearing the CFDGRSTC.SRST bit, a CAN channel of the CANFD module automatically enters Channel Sleep mode.

A CAN channel also enters Channel Sleep mode when the related Channel Sleep Mode Request bit is set while the CAN channel is in Channel Reset mode. Do not set this control bit in Channel Halt mode or Channel Operation mode.

Entering the CAN Channel Sleep mode instantly stops the clock supplied to the CAN channel unit and therefore reduces power consumption.

After setting the Channel Sleep Mode Request bit, it is necessary to confirm that the Channel Sleep mode status has been updated to indicate a successful transition to Channel Sleep mode before the Channel Sleep Mode Request bit can be cleared again.

During Channel Sleep mode, do not write to channel related registers. Read operation is still possible.

28.3.3.2 CAN Channel Reset Mode

A CANFD CAN channel enters this mode in the following ways:

- Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers is configured for Channel Reset mode while the related CAN channel is in Channel Halt mode or Channel Operation mode
- Channel Sleep Mode Request bit is cleared while the related CAN channel is in Channel Sleep mode
- Global Mode Control bit CFDGCTR.GMDC is set to Global Reset mode and CAN channel is not in Channel Sleep mode or Channel Reset mode.

In Channel Reset mode, all CAN channel status and flag registers are initialized.

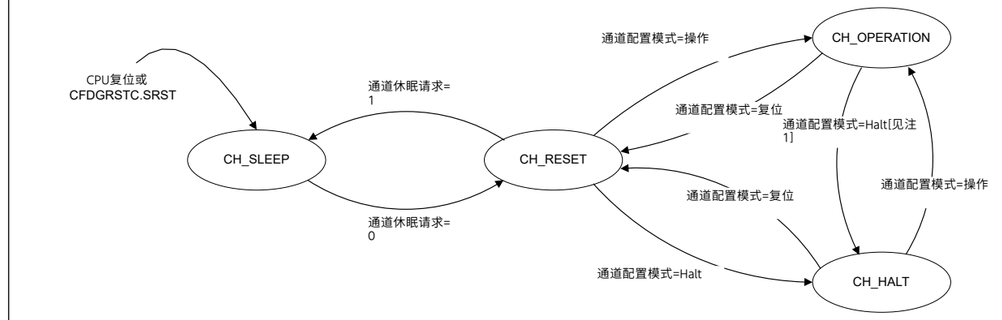
Additionally all channel related transmission control bits are cleared and the channel related TX Queue is disabled.

Configuration registers (except the Channel Test Mode registers) are not initialized in this mode and the CAN channel can be configured for communication.

See section 28.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Channel Reset mode is performed.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDC0STS.CRSTSTS in the related Channel Status Registers has been updated to indicate a successful transition to Channel Reset mode before the related CFDC0CTR.CHMDC bit can be modified again.

See Table 28.15 for the behavior of transitioning to Channel Reset mode while CAN communication is ongoing.



注1.转换时序取决于通道配置寄存器中的BOM设置：●
当BOM=01b时，状态转换时序在进入总线关闭状态后立即进行
- 当BOM=10b时，状态转换时序在总线关闭状态结束时
- 当BOM=11b时，状态转换时序与CHMDC设置为Halt模式相匹配。

Figure 28.11 CAN通道模式之间的转换

28.3.3.1 CAN通道休眠模式

硬件复位释放后或CFDGRSTC.SRST位设置和清零后，CANFD模块的一个CAN通道自动进入通道休眠模式。

当CAN通道处于通道复位模式时相关的通道休眠模式请求位置位，CAN通道也会进入通道休眠模式。不要在ChannelHalt模式或ChannelOperation模式下设置该控制位。

进入CAN通道休眠模式会立即停止提供给CAN通道单元的时钟，从而降低功耗。

设置通道休眠模式请求位后，必须确认通道休眠模式状态已更新以指示成功转换到通道休眠模式，然后才能再次清除通道休眠模式请求位。

在通道休眠模式期间，不要写入通道相关寄存器。仍然可以进行读取操作。

28.3.3.2 CAN通道复位模式

CANFDCAN通道通过以下方式进入此模式：

●通道控制寄存器中的通道模式控制位CFDC0CTR.CHMDC配置为通道复位模式，而相关的CAN通道处于通道暂停模式或通道操作模式

●通道休眠模式请求位在相关CAN通道处于通道休眠模式时清零

●全局模式控制位CFDGCTR.GMDC设置为全局复位模式，CAN通道不处于通道休眠模式或通道复位模式。

在通道复位模式下，所有CAN通道状态和标志寄存器都被初始化。

此外，所有通道相关的传输控制位都被清除，通道相关的TX队列被禁用。

配置寄存器（通道测试模式寄存器除外）在此模式下未初始化，CAN通道可配置为进行通信。

请参阅第28.3.4节。GlobalModeandChannelModeTransitionInteractions详细描述了当转换到通道复位模式时所有寄存器的行为。

将通道模式控制位CFDC0CTR.CHMDC设置为通道复位模式后，需要确认
相关通道状态寄存器中的复位模式状态位CFDC0STS.CRSTSTS已更新，以指示在可以再次修改相关CFDC0CTR.CHMDC位之前成功转换到通道复位模式。

有关在CAN通信进行时转换到通道复位模式的行为，请参见表28.15。

28.3.3.3 CAN Channel Halt Mode

A CANFD CAN channel enters this mode in the following ways:

- Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers is configured for Channel Halt mode while the related CAN channel is in Channel Reset mode or Channel Operation mode
- Global Mode Control bit CFDGCTR.GMDC is set to Global Halt mode and CAN channel is in Channel Operation mode.

In Channel Halt mode, all channel CAN communication is suspended but all status and flag registers remain unchanged during Channel Halt mode entry (except for the bus-off case where REC and TEC values are cleared for this channel).

In addition, the Channel Test Mode Configuration and Control registers are not initialized in this mode.

The Channel Halt mode should be used to configure channel test modes.

See section 28.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Channel Halt mode is performed.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDC0STS.CHLTSTS in the related Channel Status Register has been updated to indicate a successful transition to Channel Halt mode before the related CFDC0CTR.CHMDC can be modified again.

See Table 28.15 for the transition behavior to Channel Halt mode while CAN communication is ongoing.

Table 28.15 Transition behavior in CAN Reset mode and Halt mode

Mode	State		
	Receiver	Transmitter	Bus-Off
CAN Channel Reset mode (CFDC0CTR.CHMDC = 01b)	The CAN channel enters Channel Reset mode without waiting for the completion of the ongoing reception.*1	The CAN channel enters Channel Reset mode without waiting for the completion of the ongoing transmission.*1	The CAN channel enters Channel Reset mode without waiting for the completion of the bus-off recovery.
CAN Channel Halt mode (CFDC0CTR.CHMDC = 10b)	CAN channel enters Channel Halt mode at the end of the ongoing reception or error.*2	CAN channel enters Channel Halt mode after completion of the ongoing transmission.	When CFDC0CTR.BOM is set to 00b, a Channel Halt mode request is accepted only after the completion of the full bus-off recovery sequence. When CFDC0CTR.BOM is set to 10b, the CAN channel transits automatically to Channel Halt mode after waiting for the completion of the bus-off recovery. When CFDC0CTR.BOM is set to 01b, the CAN channel transits automatically to Channel Halt mode without waiting for the completion of the bus-off recovery. When CFDC0CTR.BOM is set to 11b, the CAN channel enters Channel Halt mode as soon as Channel Halt mode is requested (without waiting for the completion of the bus-off recovery).

Note 1. If the entry to Channel Reset mode is required only at the end of an ongoing communication, then Channel Halt mode can be requested first to prevent interruption of CAN communication by direct transition to Channel Reset mode. After the CAN channel enters Channel Halt mode, the Channel Reset mode can be requested.

Note 2. If CAN communication is locked at dominant level after an error flag, software can detect this situation by monitoring the channel related BusLock flag and resolve lock condition by setting the CAN channel to Channel Reset mode.

28.3.3.4 CAN Channel Operation Mode

The Channel Operation mode is activated by setting the CFDC0CTR.CHMDC bits to 00b. If 11 consecutive recessive bits are detected after entering the CAN Operation mode, the CFDC0STS.COMSTS bit is set and the CAN channel:

28.3.3.3 CAN通道暂停模式

CANFDCAN通道通过以下方式进入此模式：

●通道控制寄存器中的通道模式控制位CFDC0CTR.CHMDC配置为通道暂停模式，而相关的CAN通道处于通道复位模式或通道操作模式

●全局模式控制位CFDGCTR.GMDC设置为全局暂停模式，CAN通道处于通道操作模式。

在ChannelHalt模式下，所有通道CAN通信都暂停，但在ChannelHalt模式进入期间所有状态和标志寄存器保持不变（总线关闭情况除外，该通道的REC和TEC值被清除）。

此外，通道测试模式配置和控制寄存器在此模式下未初始化。

通道暂停模式应该用于配置通道测试模式。

请参阅第28.3.4节。GlobalModeandChannelModeTransitionInteractions详细描述了当转换到ChannelHalt模式时所有寄存器的行为。

将通道模式控制位CFDC0CTR.CHMDC设置为通道暂停模式后，需要确认
相关通道状态寄存器中的暂停模式状态位CFDC0STS.CHLTSTS已更新，以指示在可以再次修改相关CFDC0CTR.CHMDC之前成功转换到通道暂停模式。

有关CAN通信正在进行时到通道暂停模式的转换行为，请参见表28.15。

Table 28.15 CAN复位模式和暂停模式下的转换行为

Mode	State		
	Receiver	Transmitter	Bus-Off
CAN通道复位模式(CFDC0CTR.CHMDC=01b)	CAN通道进入 通道复位模式无需等待正在进行的接收完成。*1	CAN通道进入 通道复位模式无需等待正在进行的传输完成。*1	CAN通道进入 通道复位模式无需等待总线关闭恢复完成。
CAN通道暂停模式(CFDC0CTR.CHMDC=10b)	CAN通道在正在进行的接收或错误结束时进入通道暂停模式。*2	CAN通道进入Channel 正在进行的传输完成后暂停模式。	当CFDC0CTR.BOM设置为00b时，仅在完成完整的总线关闭恢复序列后才接受通道暂停模式请求。当CFDC0CTR.BOM设置为10b时，CAN通道在等待总线关闭恢复完成后自动转换到通道暂停模式。当CFDC0CTR.BOM设置为01b时，CAN通道自动转换到通道暂停模式，无需等待总线关闭恢复完成。当CFDC0CTR.BOM设置为11b时，只要请求ChannelHalt模式，CAN通道就会进入ChannelHalt模式（无需等待总线关闭恢复完成）。

注1.如果仅在正在进行的通信结束时需要进入通道复位模式，则通道暂停模式可以是
首先请求通过直接转换到通道复位模式来防止CAN通信中断。CAN通道进入ChannelHalt模式后，可以请求ChannelReset模式。

注2.如果CAN通信在出现错误标志后被锁定在显性电平，软件可以通过监控与通道相关的BusLock标志来检测这种情况，并通过将CAN通道设置为通道复位模式来解决锁定条件。

28.3.3.4 CAN通道操作模式

通道操作模式通过将CFDC0CTR.CHMDC位设置为00b来激活。如果在进入CAN操作模式后检测到11个连续的隐性位，则CFDC0STS.COMSTS位置位并且CAN通道：

- Enables the functions of the channel communication by allowing the channel to become an active node on the CAN network
- Releases the internal fault confinement logic including receive and transmit error counters

At this point, the CAN channel can start transmission and reception of CAN messages.

Within the CAN Channel Operation mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (see Figure 28.12):

- Channel idle: The CAN channel is neither receiving nor transmitting
- Channel receives: The channel is receiving a CAN message sent by another CAN node
- Channel transmits: The channel is transmitting a CAN message

  Note: The channel may receive its own message simultaneously when Self-test mode is enabled.
- Channel is in bus-off state: The CAN channel is cut-off from CAN bus communication.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Operation mode, it is necessary to confirm that the Channel Reset Mode Status bit CFDC0STS.CRSTSTS and the Channel Halt Mode Status bit CFDC0STS.CHLTSTS in the Channel Status Register have been updated to indicate a successful transition to Channel Operation mode before the related CFDC0CTR.CHMDC bit can be changed again.

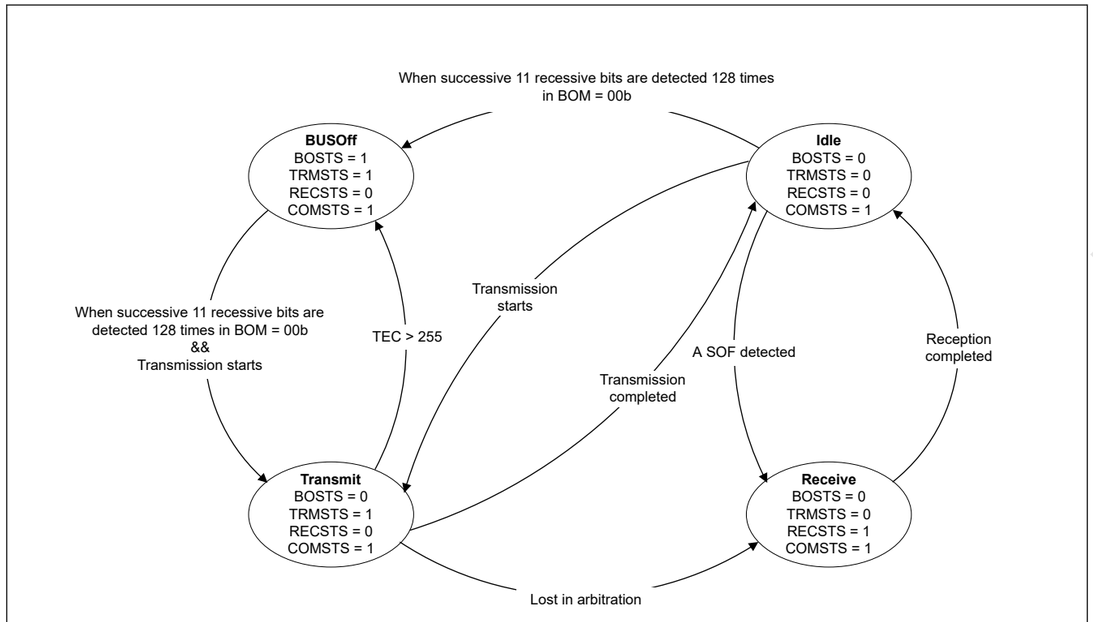


Figure 28.12 Sub-modes of CAN Channel Operation mode (only when BOM = 00b)

28.3.3.5 CAN Channel Bus-Off State

The CAN channel bus-off state is entered according to the fault confinement rules of the CAN specification. The following modes can be configured for returning to the CAN Channel Operation mode from the bus-off state:

- CFDC0CTR.BOM = 00b:
  Bus-Off recovery is compliant to ISO 11898-1, namely the CAN channel re-enters CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. TEC and REC counters are initialized to 0. The Bus-Off Recovery Flag CFDC0ERFL.BORF is set in this case.
- CFDC0CTR.BOM = 01b:

●通过让通道成为CAN网络上的活动节点来启用通道通信的功能

●释放内部故障限制逻辑，包括接收和发送错误计数器

此时，CAN通道就可以开始发送和接收CAN报文了。

在CAN通道操作模式下，通道可能处于四种不同的子模式，具体取决于执行的通信功能类型（参见图28.12）：

●Channelidle：CAN通道既不接收也不发送

●通道接收：通道正在接收另一个CAN节点发送的CAN报文

●通道传输：通道正在传输CAN报文

Note: 启用自检模式后，通道可能会同时收到自己的消息。

●通道处于总线关闭状态：CAN通道与CAN总线通讯中断。

将通道模式控制位CFDC0CTR.CHMDC设置为通道操作模式后，需要确认通道状态寄存器中的通道复位模式状态位CFDC0STS.CRSTSTS和通道暂停模式状态位CFDC0STS.CHLTSTS已更新以指示成功过渡到频道

可以再次更改相关CFDC0CTR.CHMDC位之前的操作模式。

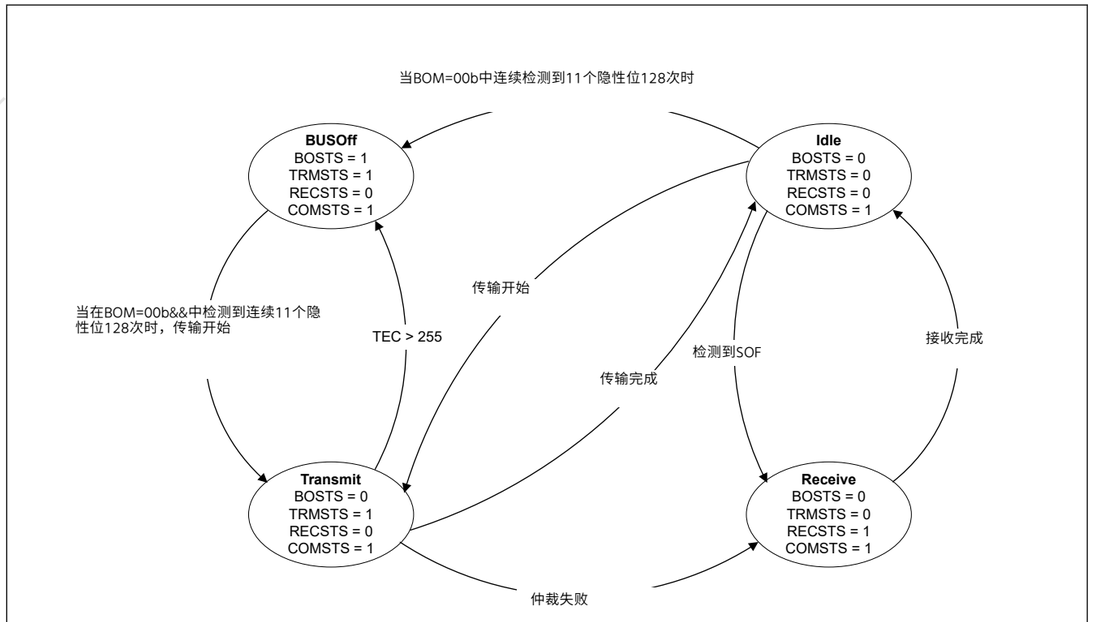

Figure 28.12 CAN通道操作模式的子模式（仅当BOM=00b时）

28.3.3.5 CAN通道总线关闭状态

根据CAN规范的故障限制规则进入CAN通道总线关闭状态。可以配置以下模式以从总线关闭状态返回到CAN通道操作模式：

- CFDC0CTR.BOM = 00b:
  Bus-Off恢复符合ISO11898-1标准，即CAN通道在连续检测到11个隐性位128次后重新进入CAN通信（错误激活状态）。TEC和REC计数器初始化为0。在这种情况下，总线关闭恢复标志CFDC0ERFL.BORF被设置。
- CFDC0CTR.BOM = 01b:

The CAN channel changes the value of the CFDC0CTR.CHMDC bits within the CAN Channel Control Register to 10b and switches immediately to Channel Halt mode automatically after entering bus-off state. TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is not set in this case.

- CFDC0CTR.BOM = 10b:
  The CAN channel changes the value of the CFDC0CTR.CHMDC bits within the CAN Channel Control Register to 10b as soon as it reaches bus-off state and enters Channel Halt mode automatically after the CAN channel has completed the bus-off recovery sequence (after 11 consecutive recessive bits are detected 128 times). TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is set in this case.
- CFDC0CTR.BOM = 11b:
  Bus-off recovery is initiated but CAN channel can immediately enter Channel Halt mode when still in bus-off state if a request is made to enter Channel Halt mode.
  TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is not set.
  Without setting CFDC0CTR.CHMDC [1:0] = 10b and when 11 recessive bits is detected 128 times continuously, transition conditions become the same as CFDC0CTR.BOM = 00b.

Note: If the recovery from bus-off occurs normally in this mode (after waiting for 128 sequences of 11 consecutive recessive bits), and no halt request has been generated during this period, then the Bus-Off Recovery flag CFDC0ERFL.BORF is set.

When software writes to the CFDC0CTR.CHMDC bit at the same time as the CAN channel enters Halt mode (at the start of bus-off when CFDC0CTR.BOM = 01b, or at the end of bus-off when CFDC0CTR.BOM = 10b), the software request has the highest priority.

Note: In the above case, the automatic setting of the CFDC0CTR.CHMDC bit to Channel Halt mode request is performed when the CFDC0CTR.CHMDC bit value is previously 00b (Channel Operation mode).

Additionally, it is possible to force the CAN channel to recover from the bus-off state by setting CFDC0CTR.RTBO to 1. The error state changes from bus-off state to integrating state with a maximum delay of 1 CAN bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The Bus-Off Recovery Flag is not set in this case, and the TEC and REC counters are initialized to 0.

Before setting CFDC0CTR.RTBO to 1, all pending transmissions from the TX message buffers, TX Queues and/or Common FIFO in TX mode should be disabled.

The disable of the pending transmission message buffer, TX Queue or FIFO must be confirmed by the corresponding acknowledge flags.

For the TX message buffer, the acknowledge flags are the Transmission Result Flags (CFDTMSTSj.TMTRF). For the TX Queue, it is the TX Queue Empty flag (CFDTXQSTS.TXQEMP). For the FIFO, it is the FIFO Empty flag (CFDCFSTS.CFEMP).

The CFDC0CTR.RTBO bit should be used for bus-off recovery only when CFDC0CTR.BOM is set to 00b.

Setting this bit in any state other than bus-off has no effect and the bit is cleared immediately.

Table 28.16 shows the settings for the Bus-Off Entry flag CFDC0ERFL.BOEF and the Bus-Off Recovery flag CFDC0ERFL.BORF for the different configurations of CFDC0CTR.BOM.

Table 28.16 Behavior of Bus-off Entry and Recovery flags

BOM	BOEF bit set	BORF bit set
00b	Always (on entry to bus-off)	Always (on exit from bus-off)
00b CFDC0CTR.RTBO set to 1	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software sets CFDC0CTR.RTBO to 1'
01b	Always (on entry to bus-off)	Never
10b	Always (on entry to bus-off)	Always (on exit from bus-off)
11b	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software issues a Halt request

For an efficient software procedure, it is not necessary to wait for the bus-off recovery sequence to end.

CAN通道将CAN通道控制寄存器中的CFDC0CTR.CHMDC位的值更改为10b，并在进入总线关闭状态后立即自动切换到通道暂停模式。在这种情况下，TEC和REC计数器初始化为0，并且总线关闭恢复标志CFDC0ERFL.BORF未设置。

- CFDC0CTR.BOM = 10b:
  CAN通道一旦到达总线关闭状态，就会将CAN通道控制寄存器中的CFDC0CTR.CHMDC位的值更改为10b，并在CAN通道完成总线关闭恢复序列后自动进入ChannelHalt模式（经过11连续的隐性位被检测到128次）。在这种情况下，TEC和REC计数器被初始化为0，并且总线关闭恢复标志CFDC0ERFL.BORF被设置。

- CFDC0CTR.BOM = 11b:
  总线关闭恢复已启动，但如果请求进入通道暂停模式，CAN通道仍处于总线关闭状态时可立即进入通道暂停模式。TEC和REC计数器初始化为0，并且总线关闭恢复标志CFDC0ERFL.BORF未设置。

  不设置CFDC0CTR.CHMDC[1:0]=10b且连续128次检测到11个隐性位时，转换条件与CFDC0CTR.BOM=00b相同。

Note: 如果在此模式下从总线关闭中恢复正常（在等待128个序列的11个连续隐性位之后），并且在此期间没有产生暂停请求，则总线关闭恢复标志CFDC0ERFL.BORF被设置。

当软件在CAN通道进入暂停模式的同时写入CFDC0CTR.CHMDC位（当CFDC0CTR.BOM=01b时在总线关闭开始时，或者当CFDC0CTR.BOM=10b时在总线关闭结束时），软件请求具有最高优先级。

Note: 在上述情况下，当CFDC0CTR.CHMDC位的值先前为00b（通道操作模式）时，会执行将CFDC0CTR.CHMDC位自动设置为通道暂停模式请求。

此外，可以通过将CFDC0CTR.RTBO设置为1来强制CAN通道从总线关闭状态恢复。错误状态从总线关闭状态变为积分状态，最大延迟为1个CAN位时间，并且在检测到11个连续的隐性位后，CAN通信再次成为可能。在这种情况下，不设置总线关闭恢复标志，并且TEC和REC计数器初始化为0。

在将CFDC0CTR.RTBO设置为1之前，来自TX消息缓冲区、TX队列和或TX模式下的通用FIFO应禁用。

未决传输消息缓冲区、TX队列或FIFO的禁用必须由相应的确认标志确认。

对于TX消息缓冲区，确认标志是传输结果标志(CFDTMSTSj.TMTRF)。对于TX Queue，它是TXQueueEmpty标志（CFDTXQSTS.TXQEMP）。对于FIFO，它是FIFO空标志(CFDCFSTS.CFEMP)。

只有当CFDC0CTR.BOM设置为00b时，才应使用CFDC0CTR.RTBO位进行总线关闭恢复。

将该位设置为除总线关闭以外的任何状态均无效，并且该位立即被清除。

表28.16显示了Bus-OffEntry标志CFDC0ERFL.BOEF和Bus-OffRecovery标志的设置CFDC0ERFL.BORF用于CFDC0CTR.BOM的不同配置。

Table 28.16 总线关闭进入和恢复标志的行为

BOM	BOEF位组	BORF位组
00b	总是（在进入巴士下车时）	总是（在巴士下车的出口处）
00bCFDC0CTR.RTBO设置为1	总是（在进入巴士下车时）	只有在软件设置之前发生正常的总线关闭恢复CFDC0CTR.RTBO to 1'
01b	总是（在进入巴士下车时）	Never
10b	总是（在进入巴士下车时）	总是（在巴士下车的出口处）
11b	总是（在进入巴士下车时）	只有在软件发出暂停请求之前发生正常的总线关闭恢复

对于有效的软件程序，不必等待总线关闭恢复序列结束。

It is possible to perform a transmission re-initialization during bus-off recovery. To do this, follow the recommended software flow in Figure 28.13.

28.3.4.1 全局模式变化的时机

全局模式更改的转换时间如下表所示。

Table 28.18 全局模式的最大转换时间（1of2）

From	To	最长过渡时间
GL_SLEEP	GL_RESET	3个外设时钟周期*2
GL_RESET	GL_SLEEP	3个外设时钟周期

GL_RESET	GL_OPERATION	10个外设时钟周期

Table 28.18 Maximum transition time for the global mode (2 of 2)

GL_HALT	GL_RESET	2 CAN bit times
GL_HALT	GL_OPERATION	3 peripheral clock cycles
GL_OPERATION	GL_RESET	2 CAN bit times
GL_OPERATION	GL_HALT	3 CAN frames*1 *3

Note 1. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.
Note 2. Exit GL_SLEEP mode only when CFDGSTS.GRAMINIT is cleared.
Note 3. TQ, CAN frame and CAN bits are related to the individual channels. For the maximum transition time, the channel with the lowest baud rate must be used.

28.3.4.2 Timing of Channel Mode Change

The transition time for the Channel mode changes are shown in the following table.

Table 28.19 Maximum transition time for the channel mode

From	To	max. transition time
CH_SLEEP	CH_RESET	3 peripheral clock cycles
CH_RESET	CH_SLEEP	3 peripheral clock cycles
CH_RESET	CH_HALT	3 CAN bit times
CH_RESET	CH_OPERATION	4 CAN bit times
CH_HALT	CH_RESET	2 CAN bit times
CH_HALT	CH_OPERATION	4 CAN bit times*3
CH_OPERATION	CH_RESET	2 CAN bit times
CH_OPERATION	CH_HALT	2 CAN frames*1 *2

Note 1. The time specified for this transition does not include the case where channel enters bus-off state. For bus-off, the timing depends on the configuration of the CFDC0CTR.BOM[1:0] bits.
Note 2. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.
Note 3. In general, if the baudrate prescaler value CFDC0NCFG.NBRP is changed in CH_HALT mode, the transition time can deviate. The internal prescaler is a free running down counter that creates the TQ clock, and new BRP value is captured when the counter reaches the value 0.

28.4 Initialization

Before joining CAN communications, configure the following settings:

- Clock setting
- Bit timing setting (nominal and data rate)
- Baud Rate setting (nominal and data rate)
- CANFD setting
- Acceptance Filter setting (configuration of Global Acceptance Filter List)
- Reception, Transmission and GW-FIFO setting
- CAN Operation mode setting

注1.给定的转换时间是总线上没有任何错误的时间。如果出现错误情况，转换时间可能会延长到无法计算的结果。对于锁定的RX线或持续的错误情况，转换时间也可能达到卡住状态。
注2.仅当CFDGSTS.GRAMINIT被清除时才退出GL_SLEEP模式。
注3.TQ、CAN帧和CAN位与各个通道相关。对于最大转换时间，必须使用具有最低波特率的通道。

28.3.4.2 频道模式改变的时机

通道模式更改的转换时间如下表所示。

Table 28.19 通道模式的最大转换时间

From	To	最大限度。过渡时间
CH_SLEEP	CH_RESET	3个外设时钟周期
CH_RESET	CH_SLEEP	3个外设时钟周期
CH_RESET	CH_HALT	3CAN位时间
CH_RESET	CH_OPERATION	4个CAN位时间
CH_HALT	CH_RESET	2个CAN位时间
CH_HALT	CH_OPERATION	4CAN位时间*3
CH_OPERATION	CH_RESET	2个CAN位时间
CH_OPERATION	CH_HALT	2个CAN帧*1*2

注1.为该转换指定的时间不包括通道进入总线关闭状态的情况。对于总线关闭，时序取决于CFDC0CTR.BOM[1:0]位的配置。

注2.给定的转换时间是总线上没有任何错误的时间。如果出现错误情况，转换时间可能会延长到无法计算的结果。对于锁定的RX线或持续的错误情况，转换时间也可能达到卡住状态。
注3.一般情况下，如果在CH_HALT模式下改变波特率预分频器值CFDC0NCFG.NBRP，则转换时间可能会发生偏差。内部预分频器是一个自由运行的递减计数器，它创建TQ时钟，当计数器达到值0时，捕获新的BRP值。

28.4 Initialization

在加入CAN通信之前，请配置以下设置：

●时钟设置
●位定时设置（标称和数据速率）
●波特率设置（标称和数据速率）
- CANFD setting
●验收过滤器设置（全局验收过滤器列表的配置）
●接收、发送和GW-FIFO设置
●CAN操作模式设置

TSEG2 = See to (CFDC0NCFG) and (CFDC0DCFG)*1
SJW = See to (CFDC0NCFG) and (CFDC0DCFG)*1

2. Restriction on TSEG1, TSEG2 and SJW
TSEG1(N) > TSEG2(N) ≥ SJW(N)
TSEG1(D) ≥ TSEG2(D) ≥ SJW(D)*1
When only classical frames are used, configure the bit fields TSEG1 and TSEG2 of CFDC0DCFG to valid values.

Note 1. This feature is not available in the classical CAN function.

2.对TSEG1、TSEG2和SJW的限制TSEG1(

TSEG1(D) ≥ TSEG2(D) ≥ SJW(D)*1
当仅使用经典帧时，将CFDC0DCFG的位域TSEG1和TSEG2配置为有效值。

28.4.1.2 CAN Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments that can be configured individually for channel using the related CFDC0NCFG and CFDC0DCFG*1 registers.

Note 1. This register is not available in the classical CAN function.

Figure 28.15 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (TQ), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the baud rate prescaler (nominal and data rate).

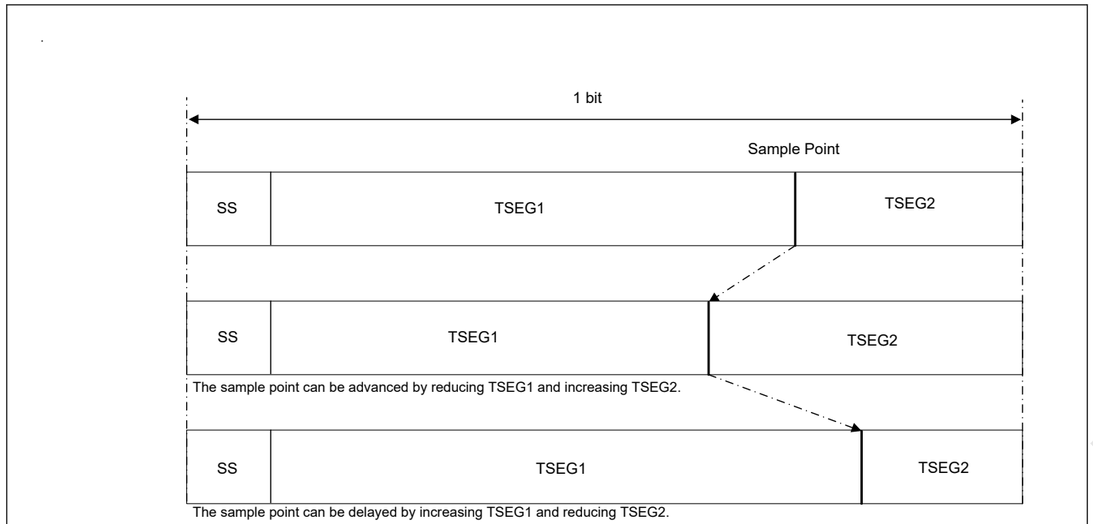

Figure 28.15 Segment composition of a bit and the sample point

1. SS: Synchronization Segment
   This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the interframe space. This comprises of intermission, suspend transmission, bus idle, during bus idle, and all nodes that can start transmission.
2. TSEG1: Time Segment 1
   This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.
3. TSEG2: Time Segment 2
   This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW. While sending or receiving a message, communication frames between some nodes may get out of sync due to a drift in the oscillator frequency or a delay in the transmission path. This is referred to as a phase error.
4. SJW: Resynchronization Jump Width
   This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.

Figure 28.15 shows only one symbolic sample point.

28.4.1.3 Baud Rate

Either the CAN channel system clock (clean clock) or the external oscillator clock can be selected globally as CAN communication clock.

The transfer speed is determined by the DLL clock, the divide-by-N value of the baud rate prescaler, and the number of TQs in one bit.

28.4.1.2 CAN位时序

在CAN协议中，通信帧中的每个位由三个段组成，可以使用相关的CFDC0NCFG和CFDC0DCFG*1寄存器单独配置通道。

注1.该寄存器在经典CAN功能中不可用。

图28.15显示了一个位的分段组成和其中的采样点。

在这些段中，时间段1(TSEG1)和时间段2(TSEG2)用于指定采样点的位置，因此可以通过更改值来更改CAN总线上每个位的采样时序这些细分市场。

此时序的最小分辨率称为时间量子(TQ)，它由提供给CAN通道的时钟频率和波特率预分频器的N分频值（标称和数据速率）决定。

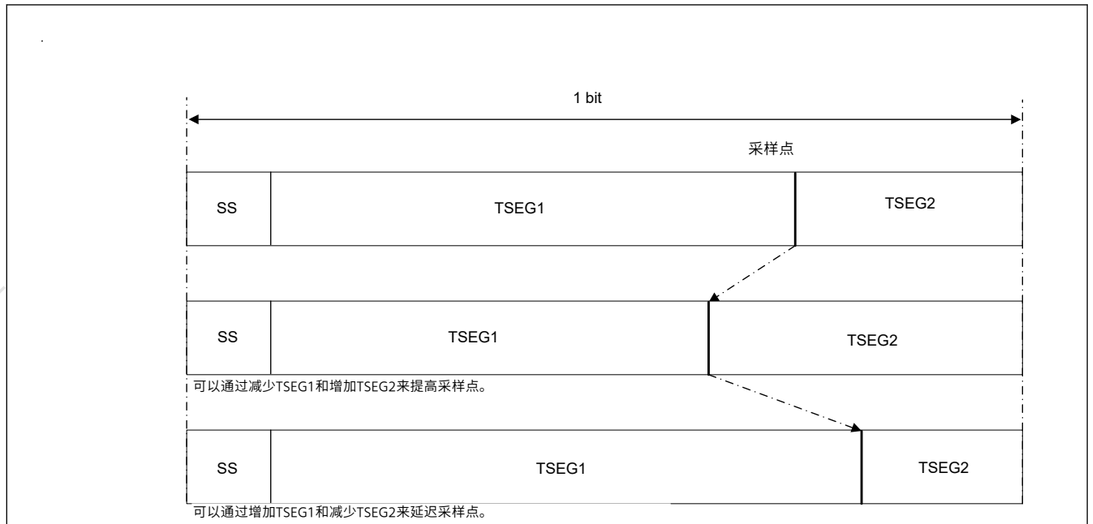

Figure 28.15 位和采样点的段组成

1.SS：同步段
该段用于通过监视帧间空间期间的隐性到显性边缘来同步位。这包括中断、暂停传输、总线空闲、总线空闲期间以及所有可以开始传输的节点。

2.TSEG1：时间段1
该段吸收CAN网络上的物理延迟。网络上的物理延迟是总线延迟、输入比较器延迟和输出驱动器延迟总和的两倍。它可以通过SJW加长。

3.TSEG2：时间段2
该段用于通过执行重新同步来纠正相位误差。它可以被SJW缩短。在发送或接收消息时，某些节点之间的通信帧可能会由于振荡器频率的漂移或传输路径的延迟而失去同步。这被称为相位误差。

4.SJW：再同步跳转宽度
这是由于相位误差而变得不同步的位可以被纠正的最大宽度。

图28.15只显示了一个符号采样点。

28.4.1.3 Baud Rate

CAN通道系统时钟（干净时钟）或外部振荡器时钟均可全局选择作为CAN通信时钟。

传输速度由DLL时钟、波特率预分频器的N分频值和一位TQ的数量决定。

$$\text{baudrate} = \frac{\text{DLL\_Clock}}{(\text{number\_of\_time\_quanta\_per\_bit}) \times (\text{BRP} + 1)}$$

Table 28.22 Baud rate calculation example for nominal and data bit rate CAN communication configurations

Baud rate calculation formula	(DLL clock) (baud rate prescaler divide-by-N value*1) × (number of TQs in one bit)	
	40 MHz	20 MHz
Nominal 1 Mbps Data 5 Mbps	40TQ (1)	20TQ (1)
	8TQ (1)	Not possible
Nominal 500 Kbps Data 2 Mbps	80TQ (1)	40TQ (1)
	20TQ (1)	10TQ (1)

Note: Shown in ( ) are the baud rate prescaler divide-by-N values and this table is not available in the classical CAN function.
Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 - 1023) P: value selected by the BRP bits in the Channel Configuration Registers.

For optimum clock tolerance in networks using the FD frame format, the length of the time quantum should be the same in nominal bit time and in data bit time. This means CFDC0NCFG.NBRP = CFDC0DCFG.DBRP.

Additionally, if transceiver delay compensation is used, do not program the CFDC0DCFG.DBRP bit to be greater than 1, as 1 means divide by 2.

28.4.1.4 Setting of CAN Clock, Bit Timing and Baud Rate

Figure 28.17 shows the procedure for setting the CAN clock and the baud rate for a channel.

These settings should be performed during Channel Reset mode (Configuration mode) for the CAN channels.

Before going to channel communication state, the baud rate must be configured, otherwise the mode does not switch correctly.

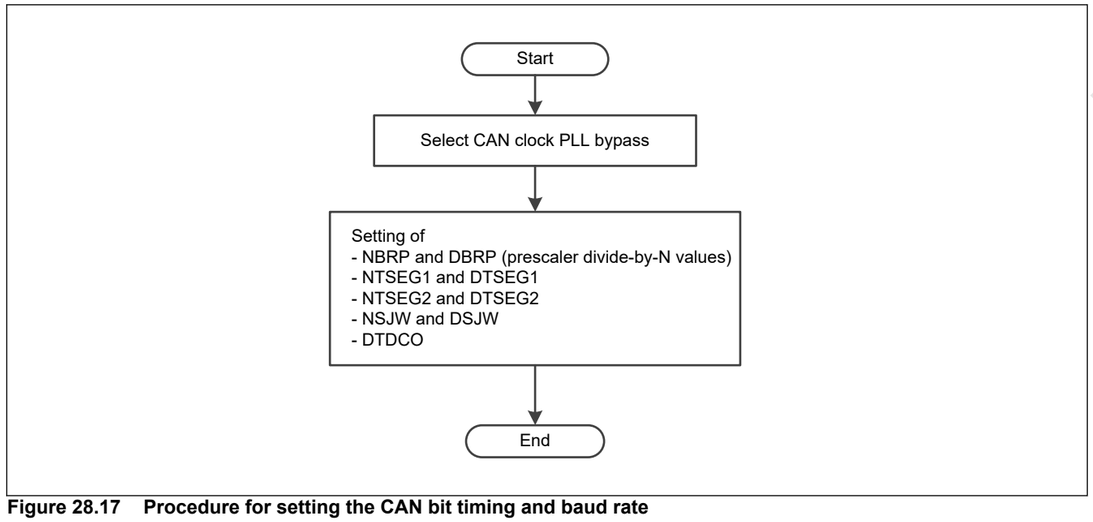

Figure 28.17 Procedure for setting the CAN bit timing and baud rate

28.4.1.5 Transmitter Delay Compensation

This chapter is not valid for classical CAN.

When a high baud rate is used such as 5 Mbps for the data phase, the transmitter delay can become greater than TSEG1. In this case, the transmitter always detects a bit-error in the data phase of the CANFD frame. The TDC compensates for the inability of the transmitter to receive its own transmitted bit at the sample point of that bit.

There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the data phase of CANFD frames. This is derived from the Transceiver Delay Compensation Result bit (CFDC0FDSTS.TDCR) as shown in Figure 28.18.

为了在使用FD帧格式的网络中获得最佳时钟容限，时间片的长度在标称位时间和数据位时间中应该相同。这意味着CFDC0NCFG.NBRP=CFDC0DCFG.DBRP。

此外，如果使用收发器延迟补偿，请勿将CFDC0DCFG.DBRP位编程为大于1，因为1表示除以2。

28.4.1.4 CAN时钟、位时序和波特率的设置

图28.17显示了为通道设置CAN时钟和波特率的过程。

这些设置应在CAN通道的通道复位模式（配置模式）期间执行。

在进入通道通信状态之前，必须配置波特率，否则无法正确切换模式。

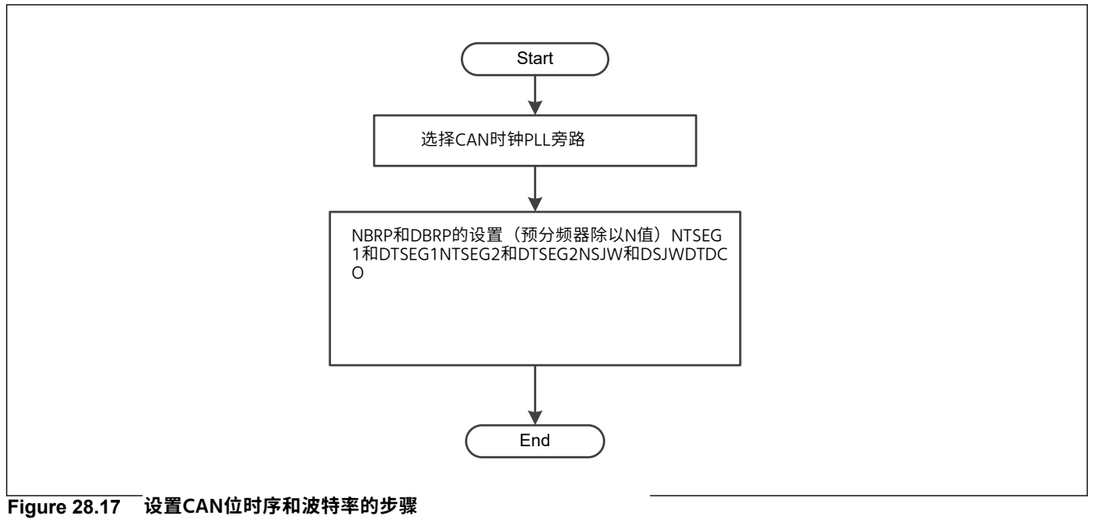

Figure 28.17 设置CAN位时序和波特率的步骤

28.4.1.5 发射机延迟补偿

本章不适用于经典CAN。

当数据阶段使用高波特率（例如5Mbps）时，发送器延迟可能会大于TSEG1。在这种情况下，发送器始终会在CANFD帧的数据阶段检测到位错误。TDC补偿发送器无法在该位的采样点接收其自己的发送位。

还有另一个符号采样点，称为辅助采样点(SSP)，仅在CANFD帧的数据阶段使用。这来自收发器延迟补偿结果位(CFDC0FDSTS.TDCR)，如图28.18所示。

The resolution of the configuration, measured and offset values is based on the CAN channel DLL clock.

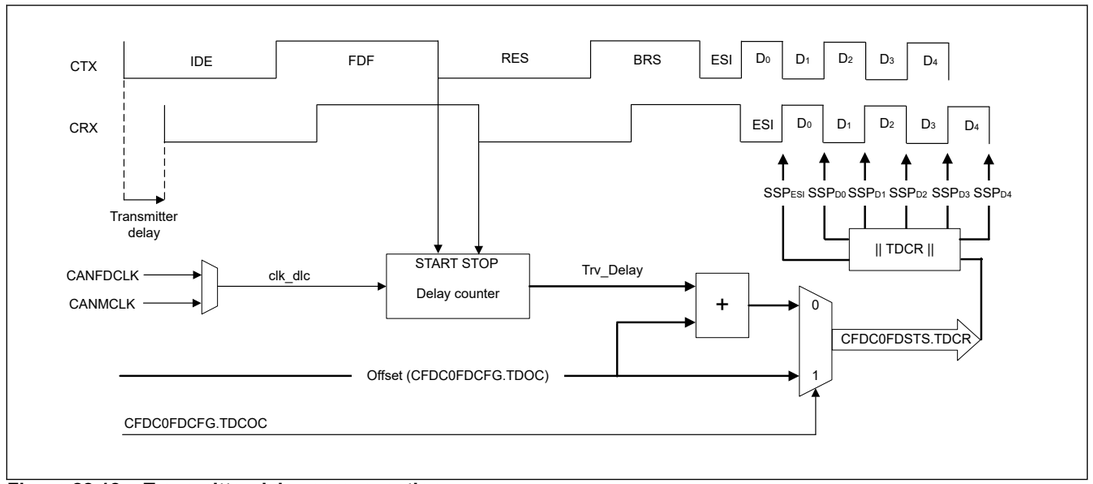

Figure 28.18 Transmitter delay compensation

The measured Trv_Delay is based on the number of clk_dlc clock cycles.The delay is counted up by one for each started clock until the dominant value is seen on CAN_RX. Figure 28.19 shows the measured result. Trv_Delay counted to maximum 127 with a clk_dlc clock.

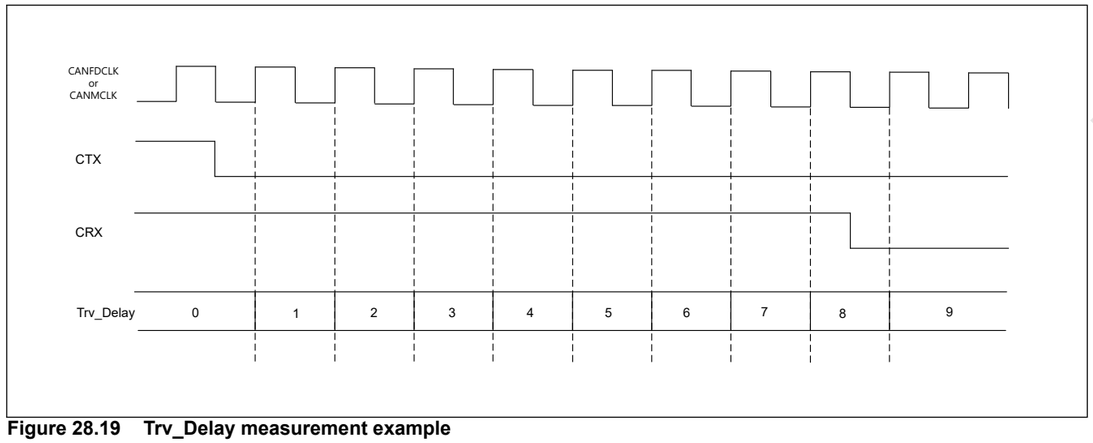

Figure 28.19 Trv_Delay measurement example

The SSP is calculated by taking the result from CFDC0FDSTS.TDCR and rounding the value down to the nearest integer number of data time quanta.

Figure 28.20 shows the positioning of the secondary sample point. When CFDC0FDCFG.TDCOC is equal to 0, the SSP is equal to the Trv_Delay (measured delay) + CFDC0FDCFG.TDCO, rounded down to the nearest integer number of time quanta. Usually, the TDCO value should have the size of (SyncSegmentdata + TSEG1data) to position the SSP to a theoretical location of the sample point.

If the CFDC0FDCFG.TDCOC is equal to 1, the SSP is defined by CFDC0FDCFG.TDCO. If CFDC0DCFG.DBRP is greater than 0, the value is also rounded down to the nearest integer number of time quanta.

配置、测量值和偏移值的分辨率基于CAN通道DLL时钟。

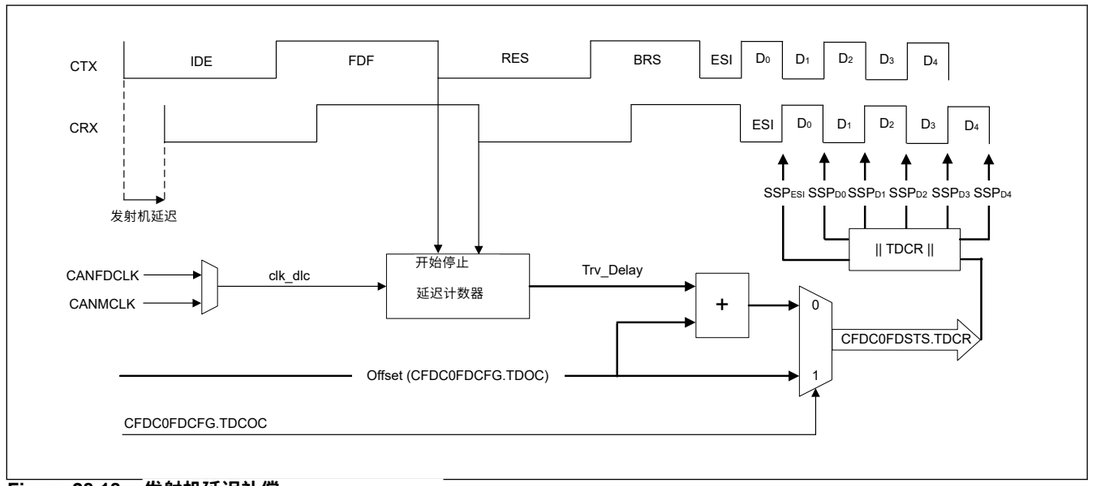

Figure 28.18 发射机延迟补偿

测得的Trv_Delay基于clk_dlc时钟周期数。对于每个启动的时钟，延迟将加一，直到在CAN_RX上看到显性值。图28.19显示了测量结果。使用clk_dlc时钟时，Trv_Delay最大计数为127。

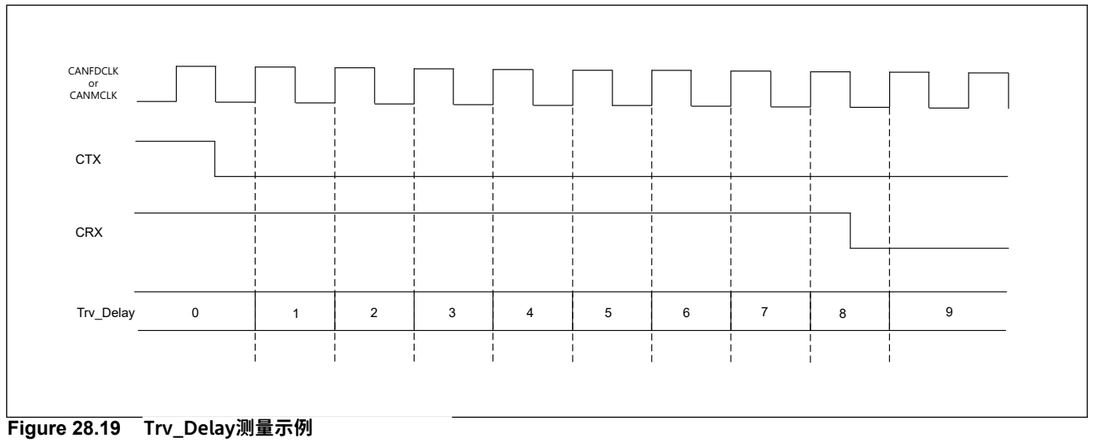

Figure 28.19 Trv_Delay测量示例

SSP是通过从CFDC0FDSTS.TDCR获取结果并将该值向下舍入到最接近的数据时间量整数来计算的。

图28.20显示了辅助采样点的定位。当CFDC0FDCFG.TDCOC等于0时，SSP等于Trv_Delay（测量延迟）+CFDC0FDCFG.TDCO，向下舍入到最接近的整数时间量。通常，TDCO值的大小应为(SyncSegmentdata+TSEG1data)以将SSP定位到采样点的理论位置。

如果CFDC0FDCFG.TDCOC等于1，则SSP由CFDC0FDCFG.TDCO定义。如果CFDC0DCFG.DBRP大于0，则该值也向下舍入到最接近的整数时间量。

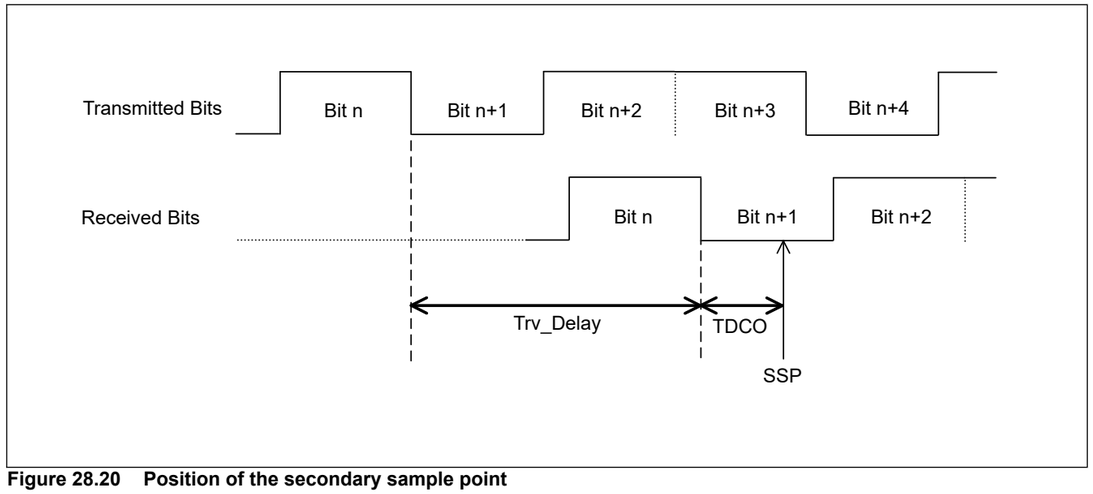

Figure 28.20 Position of the secondary sample point

The maximum delay (Trv_Delay + TDCO) which can be compensated by the CANFD module is (6 data bits - 2clk_dlc).

The ISO 11898-1 allows you to set different values for BRP_data and BRP_nom.

If different values are used for CFDC0NCFG.NBRP and CFDC0DCFG.DBRP, then two CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after sample point of the BRS bit. This condition is shown in Figure 28.21.

The length of the time quantum should be the same in the nominal bit time and in the data bit time. This means CFDC0NCFG.NBRP = CFDC0DCFG.DBRP.

Different bit rates can be achieved by selecting different configuration values for the Time Segments. The nominal bit rate can be configured from 8 to 385 TQs and the data bit rate from 5 to 49 TQs.

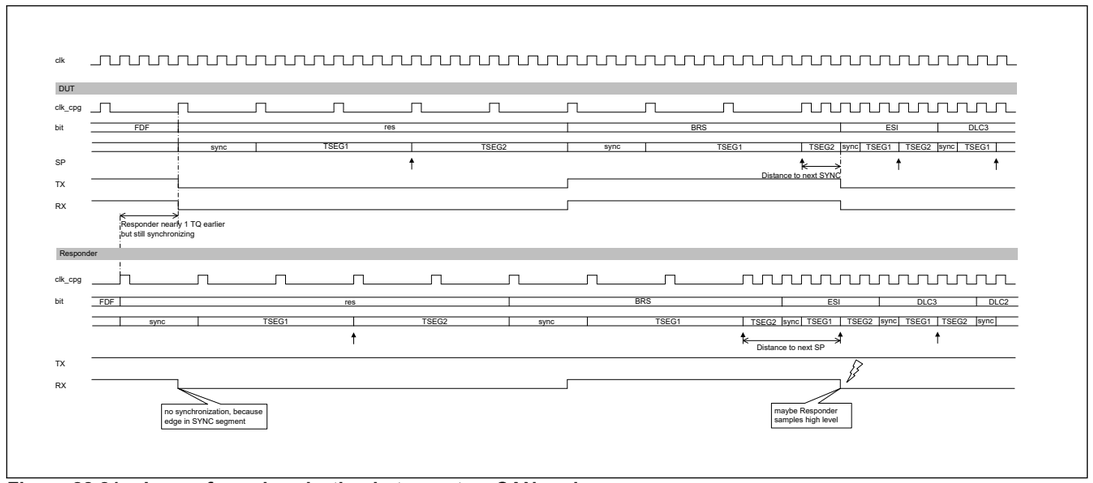

Figure 28.21 Loss of synchronization between two CAN nodes

The transmitter delay compensation measurement result is updated at the falling edge from FDF bit to RES bit when configured accordingly (CFDC0FDCFG.TDCE = 1, CFDC0FDCFG.TDCOC = 0).

Figure 28.22 shows the read flow to get the measured transmitter delay compensation result.

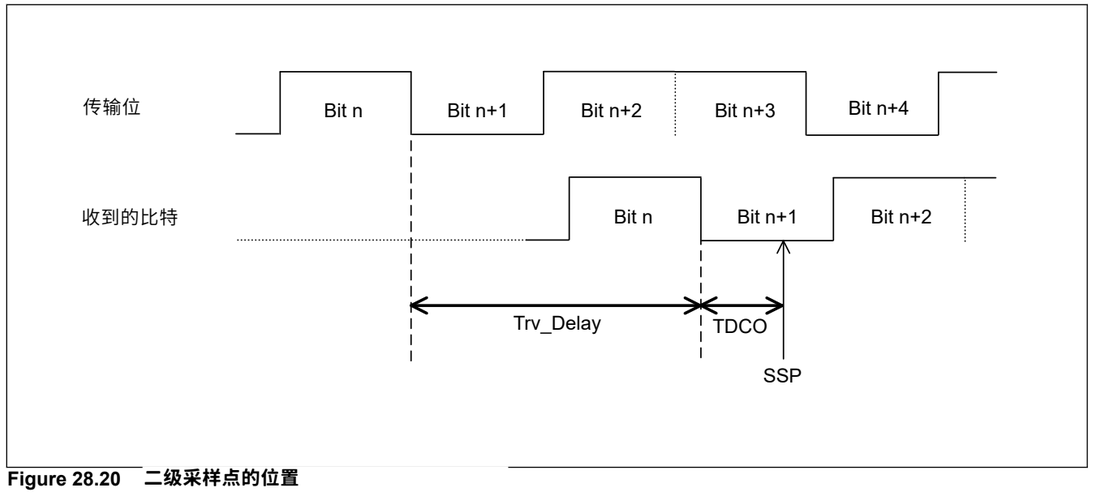

Figure 28.20 二级采样点的位置

CANFD模块可以补偿的最大延迟（Trv_Delay+TDCO）为（6个数据位2clk_dlc）。

ISO11898-1允许您为BRP_data和BRP_nom设置不同的值。

如果CFDC0NCFG.NBRP和CFDC0DCFG.DBRP使用不同的值，则在BRS位采样点之后，当比特率从标称比特率变为数据比特率时，两个CAN节点可能不同步。这种情况如图28.21所示。

时间段的长度在标称位时间和数据位时间中应该相同。这表示
CFDC0NCFG.NBRP = CFDC0DCFG.DBRP.

通过为时间段选择不同的配置值可以实现不同的比特率。标称比特率可配置为8至385TQ，数据比特率可配置为5至49TQ。

28.4.2 CAN Module Configuration after Hardware Reset

After a hardware reset (power on reset) or after setting and clearing a CFDGRSTC.SRST bit, the CANFD module enters Global Sleep mode automatically.

To enable configuration of the CANFD module, you must exit Sleep mode by clearing the Global Sleep Request bit CFDGCTR.GSLPR to 0.

After a hardware reset, the module starts RAM initialization, the CFDGSTS.GRAMINIT bit in the Global Status Register is set automatically to indicate that the CANFD logic is initializing the RAM.

After RAM initialization is complete, this bit is cleared automatically.

RAM initialization is necessary to avoid setting of false ECC error flag after HW reset the random data presented in the RAM.

Do not access registers of CANFD in either read or write until RAM initialization is complete and the CFDGSTS.GRAMINIT bit is cleared.

Before going to communication mode, the Global Acceptance Filter List and message FIFO buffers must be configured. In addition, CAN channel must be configured such as CAN bit timing. For this configuration, CAN channel must be released from Channel Sleep mode and must be configured for communication in Channel Reset mode (Configuration mode).

Figure 28.23 shows the configuration procedure. For details about each step, seesection 28.5. Acceptance Filtering Function using Global Acceptance Filter List (AFL), section 28.6. FIFO Buffers and Normal Message Buffer Configuration, section 28.7. Interrupts and DMA and section 28.4.1.3. Baud Rate.

The CANFD module does not perform the RAM initialization sequence after executing a software reset by setting CFDGRSTC.SRST.

28.4.2 硬件复位后的CAN模块配置

在硬件复位（上电复位）或设置和清除CFDGRSTC.SRST位后，CANFD模块进入全局睡眠模式自动。

要启用CANFD模块的配置，您必须通过清除全局休眠请求位来退出休眠模式CFDGCTR.GSLPR to 0.

硬件复位后，模块开始RAM初始化，全局状态寄存器中的CFDGSTS.GRAMINIT位自动置位，表示CANFD逻辑正在初始化RAM。

RAM初始化完成后，该位自动清零。

RAM初始化是必要的，以避免在硬件重置随机数据后设置错误的ECC错误标志RAM.

在RAM初始化完成之前，不要以读或写方式访问CANFD的寄存器并且CFDGSTS.GRAMINIT位清零。

在进入通信模式之前，必须配置全局接受过滤器列表和消息FIFO缓冲区。此外，CAN通道必须配置如CAN位时序。对于此配置，CAN通道必须从通道休眠模式中释放，并且必须配置为在通道复位模式（配置模式）下进行通信。

图28.23显示了配置过程。有关每个步骤的详细信息，请参阅第28.5节。使用全局接受过滤器列表(AFL)的接受过滤功能，第28.6节。FIFO缓冲区和正常消息缓冲区配置，第28.7节。中断和DMA以及第28.4.1.3节。波特率。

28.5 Acceptance Filtering Function using Global Acceptance Filter List (AFL)

28.5.1 Overview

The CANFD module can handle message acceptance filtering with a global Acceptance Filter List (called AFL). Each element of the AFL defines a filter rule for messages received on a specific channel.

The following actions are performed based on the AFL entries:

- Acceptance filtering based on received CAN Identifier and masking

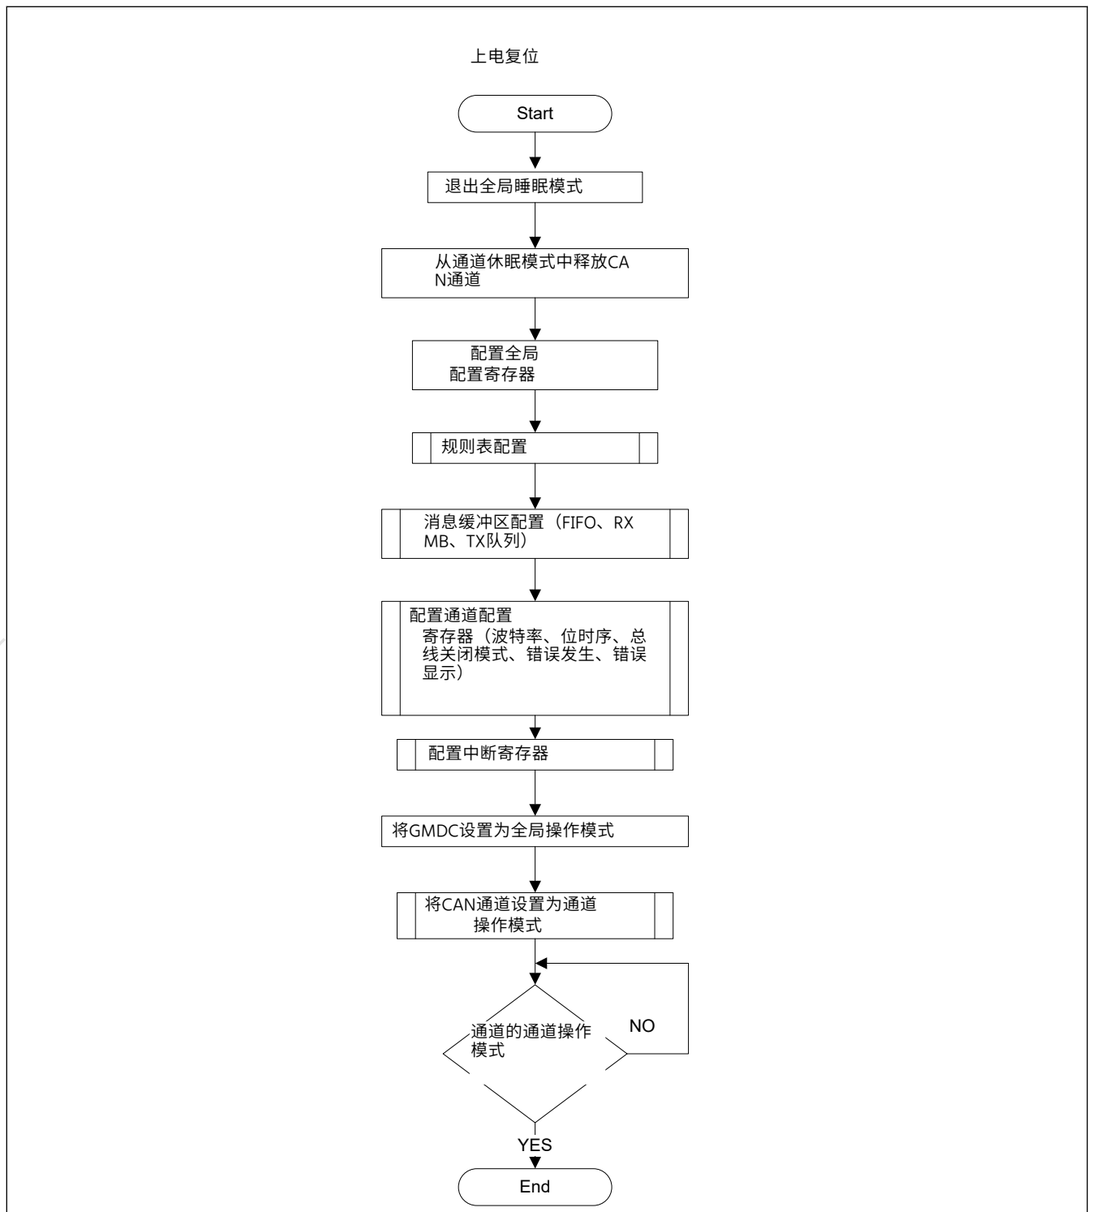

Figure 28.23 硬件复位后的配置过程

28.5 使用全局接受过滤器列表(AFL)的接受过滤功能

28.5.1 Overview

CANFD模块可以使用全局接受过滤器列表（称为AFL）处理消息接受过滤。AFL的每个元素都为在特定通道上接收到的消息定义了一个过滤规则。

根据AFL条目执行以下操作：

- 基于接收到的CAN标识符和掩码的接受过滤

- DLC filtering based on received DLC value
- Message data payload according to the CFDGCFG.CMPOC bit*1
- Storage of accepted messages in the message buffer objects defined in the related AFL entry
- Attaching a 16-bit pointer to the stored messages defined in the related AFL entry, for example to support AUTOSAR applications
- Attaching a 2-bit information label to the stored messages defined in the related AFL entry

Note 1. This feature is not available in the classical CAN function.

The CANFD module allows a maximum of 32 AFL entries.

During acceptance filtering process, each AFL entry in a channel is checked against the received message by the acceptance filter unit. The check starts from the lowest AFL entry number for this channel.

AFL search stops when a match of the received identifier with a configured identifier/mask combination occurs or when the received identifier has been compared against all AFL entries defined for the related channel. If no match occurs, then the received message is rejected. No notification is given to the application in this case.

Additionally, an automatic DLC filtering is performed for each accepted message if DLC check is globally enabled. If the DLC value of the received message is equal to or higher than the configured DLC value in the matching AFL entry, the DLC check is passed.

If DLC replacement (CFDGCFG.DRE bit) is enabled, DLC value configured in the matching AFL entry is greater than 0x0 and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination RXMB or FIFO Buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received on the CAN Bus are not stored in the destination RXMB or FIFO Buffer. These additional data bytes are stored as 0x00 in the destination RXMB or FIFO Buffer.

If DLC replacement is enabled and DLC value of matching AFL entry is 0x0, then the received value of DLC is stored in the destination RX MB or FIFO Buffer.

If DLC replacement (the CFDGCFG.DRE bit) is disabled and DLC check passes, then the received value of DLC on the CAN bus is stored in the destination RXMB or FIFO buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received from the CAN bus are also stored in the destination RXMB or FIFO buffer.

If DLC value of the received message is less than the configured DLC value in the matching AFL entry, then DLC check fails. In this case, the received message is rejected and is not stored in any RXMB or FIFO buffer.

Additionally, DLC check failure is flagged by the DLC Error Flag in the Global Error Flag Register. If configured, an error interrupt is also generated. The DLC replacement configuration has no impact if the DLC check fails.

If a message has passed both acceptance filtering and DLC filtering, it is stored in a single reception message buffer and/or in FIFO buffers configured for reception function.

This message storage target information is also defined in the same AFL entry. Do not set a target at the AFL entry which is not configured.

Each accepted received message can be stored into a maximum of 2 different target destinations (single reception message buffer and/or FIFO buffers).

The programming of more than 2 target destinations is not allowed. If more destinations are programmed, then the internal timing might lead to a race condition that prevents the storage of received messages in the message RAM.. Correct configuration of the numbers of target destination is the responsibility of the application.

Additional protection mechanism is made for the case when a received message contains more data payload Bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

If CFDGCFG.CMPOC = 0, the message is completely rejected and is stored in the target destination. When CFDGCFG.CMPOC = 0 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS), the corresponding CFDFMSTS.RFxMLT or CFDFMSTS.CFxMLT bit is not set to 1, respectively.

●根据接收到的DLC值进行DLC过滤

●根据CFDGCFG.CMPOC位的消息数据有效负载*1

●将接受的消息存储在相关AFL条目中定义的消息缓冲区对象中

●将16位指针附加到相关AFL条目中定义的存储消息，例如以支持AUTOSAR应用程序

●将2位信息标签附加到相关AFL条目中定义的存储消息

注1.此功能在经典CAN功能中不可用。

CANFD模块最多允许32个AFL条目。

在接受过滤过程中，接受过滤单元根据接收到的消息检查通道中的每个AFL条目。检查从该通道的最低AFL条目号开始。

当接收到的标识符与配置的标识符掩码组合发生匹配时，或者当接收到的标识符已与为相关通道定义的所有AFL条目进行比较时，AFL搜索停止。如果不匹配，则拒绝接收到的消息。在这种情况下，不会向应用程序发出通知。

此外，如果全局启用DLC检查，则会对每个接受的消息执行自动DLC过滤。如果
接收到的消息的DLC值等于或高于匹配的AFL条目中配置的DLC值，则
DLC检查通过。

如果启用DLC替换（CFDGCFG.DRE位），匹配AFL条目中配置的DLC值大于0x0并且DLC检查通过，则匹配AFL条目中的DLC配置值存储在目标RXMB或FIFO缓冲区中。

如果接收到的DLC值大于匹配AFL条目中配置的DLC值，则CAN总线上接收到的附加数据字节不会存储在目标RXMB或FIFO缓冲区中。这些额外的数据字节作为0x00存储在目标RXMB或FIFO缓冲区中。

如果启用DLC替换并且匹配AFL条目的DLC值为0x0，则接收到的DLC值存储在目标RXMB或FIFO缓冲区中。

如果DLC替换（CFDGCFG.DRE位）被禁用并且DLC检查通过，则接收到的DLC值在
CAN总线存储在目标RXMB或FIFO缓冲区中。

如果接收到的DLC值大于匹配AFL条目中配置的DLC值，则从CAN总线接收的附加数据字节也将存储在目标RXMB或FIFO缓冲区中。

如果接收到的消息的DLC值小于匹配的AFL条目中配置的DLC值，则DLC检查失败。在这种情况下，接收到的报文被拒绝并且不存储在任何RXMB或FIFO缓冲区中。

此外，DLC检查失败由全局错误标志寄存器中的DLC错误标志标记。如果已配置，还会生成错误中断。如果DLC检查失败，则DLC替换配置没有影响。

如果消息已通过接受过滤和DLC过滤，则将其存储在单个接收消息缓冲区和/或为接收功能配置的FIFO缓冲区中。

该消息存储目标信息也在同一个AFL条目中定义。不要在未配置的AFL条目上设置目标。

每个接受的接收消息最多可以存储到2个不同的目标目的地（单个接收消息缓冲区和/或FIFO缓冲区）。

不允许对超过2个目标目的地进行编程。如果对更多目的地进行了编程，则内部计时可能会导致竞争条件，从而阻止将接收到的消息存储在消息RAM中。正确配置目标目的地的数量是应用程序的责任。

当接收到的消息包含的数据有效负载字节多于目标目的地（CFDRMBB.RMPLS、CFDRFCCa.RFPLS或CFDCFCC.CFPLS）中可能存储的数据时，会采用额外的保护机制。

如果CFDGCFG.CMPOC=0，则消息被完全拒绝并存储在目标目的地中。什么时候
CFDGCFG.CMPOC=0并且RX或CommonFIFOfull（包括接收到的消息）包含的数据有效负载字节数比可能存储在目标目的地（CFDRMNB.RMPLS、CFDRFCCa.RFPLS或CFDCFCC.CFPLS）、相应的CFDFMSTS.RFxMLT或CFDFMSTS中的要多。CFxMLT位不分别设置为1。

When CFDGCFG.CMPOC = 1, the received data bytes greater than CFDRMNB.RMPLS is rejected. When CFDGCFG.CMPOC = 1 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS), the corresponding CFDFMSTS.RFxMLT or CFDFMSTS.CFxMLT bit is set to 1, respectively.

Depending on the CFDGCFG.DRE bit, the original received DLC or the DLC value configured at the AFL entry is stored.

Regardless of the CFDGCFG.CMPOC bit setting, CFDGERFL.CMPOF is set to 1 if a payload overflow condition is detected.

The DLC filtering is performed before the payload overflow function. So for one reception frame, only one flag can be set at the same time with CFDGERFL.DEF or CFDGERFL.CMPOF*1.

Note 1. This bit is not available in the classical CAN function.

28.5.2 Allocation of AFL Entries

The number of AFL entries per channel can be configured using the dedicated field in the related Global Acceptance Filter Configuration Registers (see Figure 28.24).

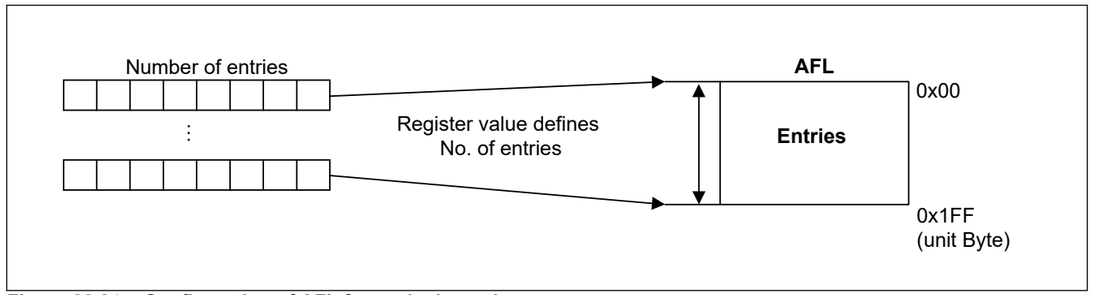

Figure 28.24 Configuration of AFL for each channel

The minimum number of entries for one channel is 0 (no entries defined for the channel) and the maximum number of entries is 32.

All entries are unique for a channel and overlapping or sharing of entries is not supported. Correct configuration of the AFL is the responsibility of the application.

The CANFD module does not flag errors related to the configuration of the AFL.

28.5.3 AFL Entry Description

Each AFL entry consists of 16 bytes. The fields in all entries are identical.

Each entry contains the following information for acceptance filtering and DLC filtering:

- Identifier (11 bits for Standard Frame format, 29 bits for Extended Frame format):
  Acceptance filter unit checks the identifier field of the received message against the identifier field of each AFL entry (full 29 bits masking of identifier bits is possible, see information that follows).
- IDE bit:
  Acceptance filter unit checks the IDE bit of the received message against this bit and selects the relevant part of the identifier field for acceptance filtering (masking of IDE bit is possible, see the information that follows).
- RTR bit:
  Acceptance filter unit only accepts data frames (RTR = 0) or remote frames (RTR = 1) according to the setting of this bit (masking of RTR bit is possible, see the information that follows).
- Loopback Configuration bit:
  This bit can enable or disable the AFL entry depending on the Loopback Configuration or Mirror mode condition.
- Mask for Identifier bits (29 bits):

当CFDGCFG.CMPOC=1时，大于CFDRMNB.RMPLS的接收数据字节被拒绝。什么时候CFDGCFG.CMPOC=1并且RX或CommonFIFOfull（包括接收到的消息）包含的数据有效负载字节数比可能存储在目标目的地（CFDRMNB.RMPLS、CFDRFCCa.RFPLS或CFDCFCC.CFPLS）、相应的CFDFMSTS.RFxMLT或CFDFMSTS中的要多。CFxMLT位分别设置为1。

根据CFDGCFG.DRE位，存储原始接收的DLC或在AFL条目中配置的DLC值。

无论CFDGCFG.CMPOC位设置如何，如果检测到有效负载溢出条件，CFDGERFL.CMPOF将设置为1。

DLC过滤在有效载荷溢出功能之前执行。因此对于一个接收帧，只能使用CFDGERFL.DEF或CFDGERFL.CMPOF*1同时设置一个标志。

注1.该位在经典CAN功能中不可用。

28.5.2 AFL参赛作品的分配

可以使用相关全局接受过滤器中的专用字段配置每个通道的AFL条目数
配置寄存器（见图28.24）。

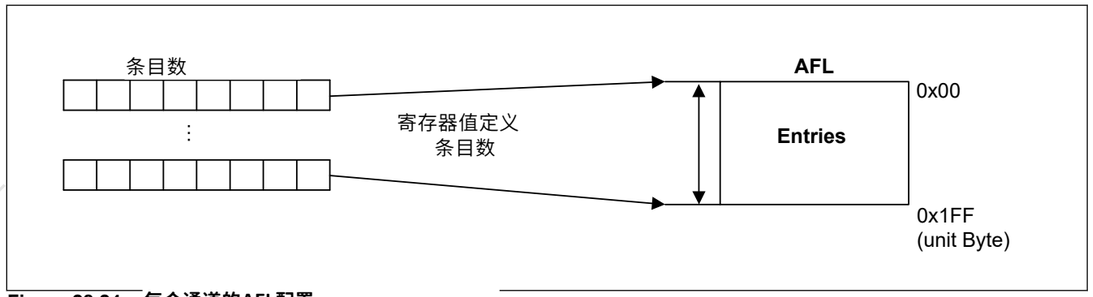

Figure 28.24 每个通道的AFL配置

一个通道的最小条目数为0（没有为通道定义条目），最大条目数为32。

频道的所有条目都是唯一的，不支持条目的重叠或共享。正确配置AFL是应用程序的责任。

CANFD模块不会标记与AFL配置相关的错误。

28.5.3 AFL条目说明

每个AFL条目由16个字节组成。所有条目中的字段都是相同的。

每个条目都包含以下接受过滤和DLC过滤的信息：

●标识符（标准帧格式为11位，扩展帧格式为29位）：
接受过滤器单元根据每个AFL条目的标识符字段检查接收到的消息的标识符字段（标识符位的全29位掩码是可能的，请参阅以下信息）。

- IDE bit:
  接受过滤器单元根据该位检查接收到的消息的IDE位，并选择标识符字段的相关部分进行接受过滤（可以屏蔽IDE位，参见以下信息）。
- RTR bit:
  接受过滤器单元仅根据该位的设置接受数据帧（RTR=0）或远程帧（RTR=1）（RTR位的屏蔽是可能的，参见下面的信息）。
- Loopback Configuration bit:
  该位可以根据环回配置或镜像模式条件启用或禁用AFL条目。

●标识符位掩码（29位）：

Each bit in the identifier mask can mask the corresponding identifier bit in the AFL entry during acceptance filtering, see Figure 28.25.

- Mask for IDE bit:
  If this Mask bit masks the IDE bit of the AFL entry in both Standard Identifier and Extended Identifier format, messages can be accepted by this AFL entry. The identifier of the received message is compared against the Standard Identifier part of the AFL entry for Standard Identifier format messages and against the Extended Identifier part of the AFL entry for Extended Identifier format messages.

- Mask for RTR bit:
  If this Mask bit masks the RTR bit of the AFL entry in both frame formats, data frame and remote frame formats are accepted by this AFL entry.

- Pointer information (16 bits):
  This 16-bit pointer is attached to a received message accepted by the related AFL entry. The pointer is added during message storage in the message buffer area and can be used by application as support function. The pointer information can be used for example to support PDU identifier allocation for the received message in AUTOSAR systems.

- Information label (2 bits):
  This 2-bit label is attached to a received message accepted by the related AFL entry. The label is added during message storage in the message buffer area and can be used by application as support function.

- DLC value for automatic DLC filtering:
  If the DLC value of the received message is equal or higher than the configured DLC value, the DLC check is passed.

If the DLC value in this AFL entry is configured to 0, DLC filtering is effectively disabled for this entry (all accepted messages pass DLC filtering).

Each AFL entry contains the following information for the handling of received messages:

- Message buffer number of one single reception message buffer as target for received message storage
- Single reception message buffer enable bit to configure the single reception message buffer number to be valid or invalid, as target for received message storage
- FIFO direction pointer - each bit of the FIFO direction pointer configures a dedicated FIFO as possible target for a received message

There is no hardware protection against such storage of message. Therefore, the FIFO direction pointer must be configured carefully.

标识符掩码中的每个位都可以在接受过滤期间屏蔽AFL条目中的相应标识符位，见图28.25。

●IDE位掩码：
如果此掩码位以标准标识符和扩展标识符格式屏蔽AFL条目的IDE位，则此AFL条目可以接受消息。接收消息的标识符与标准标识符格式消息的AFL条目的标准标识符部分和扩展标识符部分进行比较

扩展标识符格式消息的AFL条目。

●RTR位掩码：
如果此掩码位在两种帧格式中屏蔽AFL条目的RTR位，则此AFL条目接受数据帧和远程帧格式。

●指针信息（16位）：
这个16位指针附加到相关AFL条目接受的接收消息。该指针是在消息存储过程中在消息缓冲区中添加的，可供应用程序用作支持函数。例如，指针信息可用于支持AUTOSAR系统中接收到的消息的PDU标识符分配。

●信息标签（2位）：
这个2位标签附加到相关AFL条目接受的接收消息。该标签是在消息存储过程中在消息缓冲区中添加的，可供应用程序用作支持功能。

●自动DLC过滤的DLC值：
如果接收到的消息的DLC值等于或大于配置的DLC值，则DLC检查通过。

如果此AFL条目中的DLC值配置为0，则有效禁用此条目的DLC过滤（所有接受的消息都通过DLC过滤）。

每个AFL条目都包含以下用于处理接收到的消息的信息：

●作为接收消息存储目标的单个接收消息缓冲区的消息缓冲区号
●单次接收报文缓冲区使能位，用于配置单次接收报文缓冲区号有效或无效，作为接收报文存储的目标

●FIFO方向指针FIFO方向指针的每一位配置一个专用的FIFO作为接收消息的可能目标

没有针对此类消息存储的硬件保护。因此，必须仔细配置FIFO方向指针。

28.5.4 Entering Entries in the AFL

Application software can enter one full entry into the AFL using the following registers:

- Global AFL ID Entry Register: Part 1 of the AFL entry
- Global AFL Mask Entry Register: Part 2 of the AFL entry
- Global AFL Pointer 0 Entry Register: Part 3 of the AFL entry
- Global AFL Pointer 1 Entry Register: Part 4 of the AFL entry.

16 sets of these registers form a group of AFL entries. Each group can be accessed through a page mechanism. For the CANFD module, 32 of these pages exist to allow access to the whole AFL range. The AFL should only be configured in CH_RESET or CH_HALT mode. Pages are linked to the AFL entries in the following way:

Page 0	Entry 0 — 15
Page 1	Entry 16 — 31

The selection of the AFL access page is done using the Global Acceptance Filter List Entry Control Register (CFDGAFLECTR) (Figure 28.26). This register has the following fields:

- 1 bit to select the AFL page number
- 1 bit to enable or disable the AFL data access to prevent unwanted write access to the AFL.

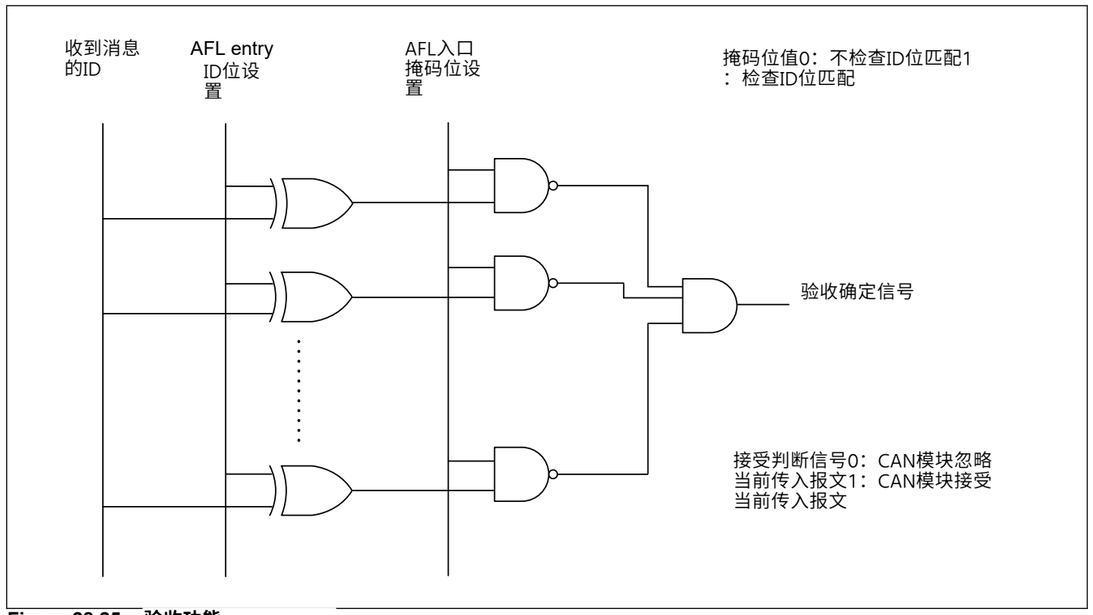

Figure 28.25 验收功能

28.5.4 在AFL中输入条目

应用软件可以使用以下寄存器将一个完整条目输入AFL：

- 全球AFLID条目寄存器：AFL条目的第1部分
- 全局AFL掩码条目寄存器：AFL条目的第2部分
- 全局AFL指针0条目寄存器：AFL条目的第3部分
- 全局AFL指针1条目寄存器：AFL条目的第4部分。

16组这些寄存器形成一组AFL条目。每个组都可以通过页面机制访问。对于CANFD模块，存在32个这样的页面以允许访问整个AFL范围。AFL只能在
CH_RESET或CH_HALT模式。页面通过以下方式链接到AFL条目：

Page 0	Entry 0 — 15
Page 1	Entry 16 — 31

AFL访问页面的选择是使用全局接受过滤器列表条目控制寄存器(CFDGAFLECTR)完成的（图28.26）。该寄存器具有以下字段：

- 1位选择AFL页码
- 1位启用或禁用AFL数据访问，以防止对AFL的不必要的写访问。

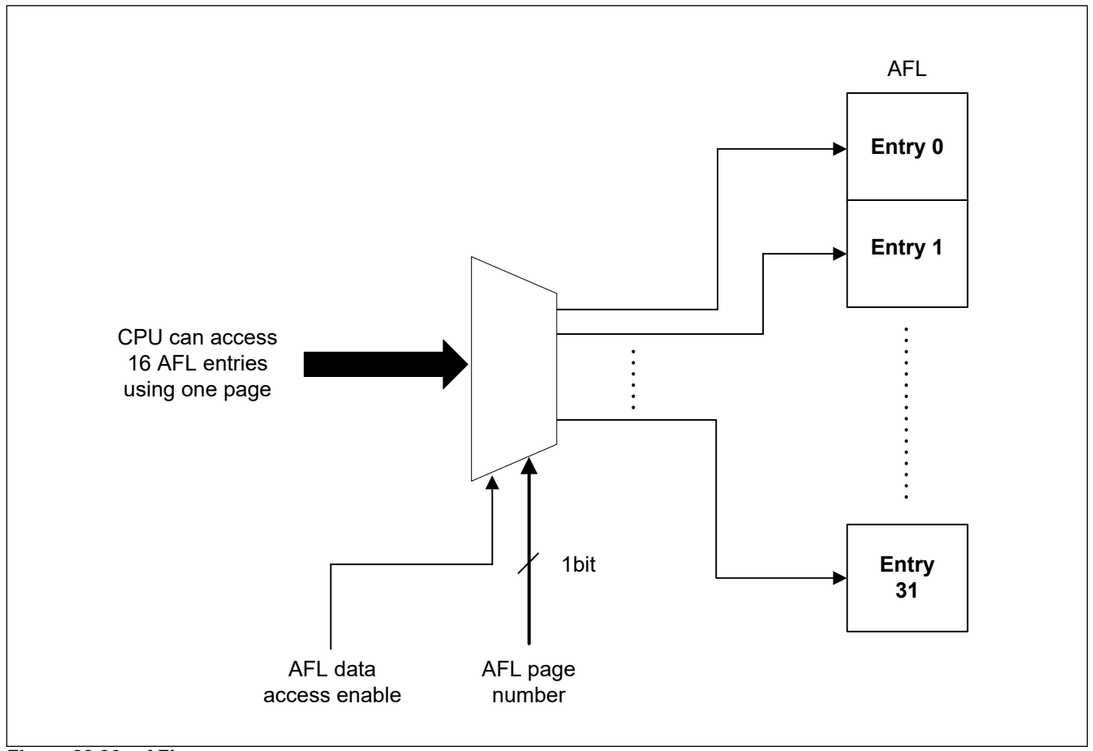

Figure 28.26 AFL page access

Application software should not write numbers higher than 0x1 for the AFL page number.

Follow the configuration shown in Figure 28.27 to program the AFL.

After entering all entries in Configuration mode, locking of the AFL access should be performed to protect unwanted write access to the AFL.

Write protection is active during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION) if the lock bit is set.

Read access to AFL is still possible during all Global modes even when AFL data access is disabled (consistency check of AFL contents is possible during run time).

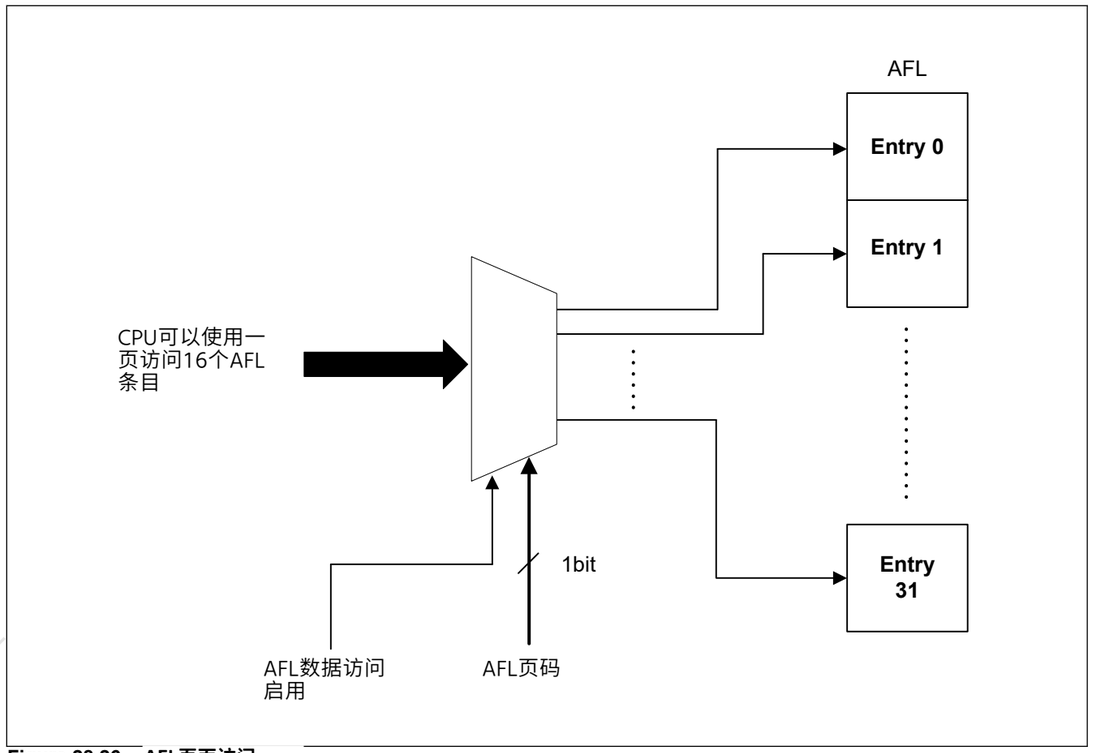

Figure 28.26 AFL页面访问

应用软件不应为AFL页号写入高于0x1的数字。

按照图28.27所示的配置对AFL进行编程。

在配置模式下输入所有条目后，应执行AFL访问锁定以保护对AFL的不需要的写访问。

如果设置了锁定位，则写保护在所有全局模式（GL_RESET、GL_HALT和GL_OPERATION）期间都处于活动状态。

即使禁用AFL数据访问（一致性检查
AFL内容在运行时是可能的）。

28.5.5 Loopback Modes

If the Loopback Configuration bit is set, the AFL entry is only valid in Loopback test mode (Self-test mode 0 or Self-test mode 1) or in mirror mode when receiving messages that were transmitted by the respective CAN channel itself.

The AFL entry is not valid for received messages in loopback mode transmitted by other CAN nodes on the bus. The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID respectively.

If the Loopback Configuration bit is 0, the AFL entry is only valid for:

- Received messages transmitted by other CAN nodes on the bus in normal (non-loopback mode) and mirror modes
- Received messages transmitted by other CAN nodes or the CAN channel itself in Loopback test mode.

The mirror mode can be enabled with the CFDGCFG.MME bit in the Global Configuration Register. If CFDGCFG.MME bit is set, then a successfully transmitted message can be stored back in an RX message buffer or FIFO buffer if a matching entry is configured in the AFL for that channel.

The Loopback Configuration bit in the matching AFL entry must be set to store this frame.

If Mirror mode and Loopback test mode are configured at the same time, the Loopback test mode behavior applies.

Table 28.23 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 28.23 Behavior of acceptance filter based on the loopback configuration setting in AFL entry

Mirror Mode Enable (MME Configuration bit)	Loopback in test mode (Self-test mode 0 or Self-test mode 1)	Channel mode	Loopback Configuration bit in AFL entry	AFL entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

28.5.6 IDE Masking

When the GAFLIDEM bit is 0 in an AFL entry, the IDE bit configured in the AFL entry is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is based on the received IDE bit.

Consider the following example:

- The ID and Mask fields of an AFL entry x is configured as follows:
  - CFDGAFLID [x] = 0xC0553A20 → IDE = 1, RTR = 1, LLB = 0, ID[10:0] = 0x220 / ID[28:0] = 0x00553A20
  - CFDGAFLMr = 0x0000FFFF → IDEM = 0. RTRM = 0, IDM[10:0] = 0x7FF / IDM[28:0] = 0x0000FFFF

28.5.5 Loopback Modes

如果设置了环回配置位，则AFL条目仅在环回测试模式（自测模式0或自测模式1）或在接收由相应CAN通道本身发送的消息时的镜像模式下有效。

AFL条目对于总线上其他CAN节点发送的环回模式下接收到的消息无效。相关条目的表达式有效或无效表示该AFL条目分别与接收到的消息ID进行比较或不进行比较。

如果环回配置位为0，则AFL条目仅对以下情况有效：

- 接收到总线上其他CAN节点在正常（非环回模式）和镜像模式下发送的报文
- Loopback测试模式下接收到其他CAN节点或CAN通道本身发送的报文。

可以使用全局配置寄存器中的CFDGCFG.MME位启用镜像模式。如果设置了CFDGCFG.MME位，则如果在AFL中为该通道配置了匹配条目，则成功传输的消息可以存储回RX消息缓冲区或FIFO缓冲区。

必须设置匹配AFL条目中的环回配置位以存储该帧。

如果同时配置了镜像模式和环回测试模式，则应用环回测试模式行为。

表28.23显示了接收滤波器单元的行为，具体取决于相关输入信号的设置。

Table 28.23 基于AFL条目中环回配置设置的验收过滤器的行为

镜像模式启用（MME配置位）	测试模式环回（自检模式0或自检模式1）	频道模式	AFL条目中的环回配置位	AFL entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: 相关条目的表达式有效或无效表示此AFL条目是否与接收到的消息进行比较身份证，分别。

28.5.6 IDE屏蔽

当AFL条目中的GAFLIDEM位为0时，AFL条目中配置的IDE位不用于ID匹配。在这种情况下，ID[10:0]或ID[28:0]匹配的使用基于接收到的IDE位。

考虑以下示例：

- AFL表项x的ID和Mask字段配置如下：
  - CFDGAFLID [x] = 0xC0553A20 → IDE = 1, RTR = 1, LLB = 0, ID[10:0] = 0x220 / ID[28:0] = 0x00553A20
  - CFDGAFLMr = 0x0000FFFF → IDEM = 0. RTRM = 0, IDM[10:0] = 0x7FF / IDM[28:0] = 0x0000FFFF

- The comparison result for the four different received IDs with AFL entry x is described as follows:
  - If a frame with IDE = 0 and ID = 0x220 is received, this is considered as a match
  - If a frame with IDE = 0 and ID = 0x320 is received, this is not a match
  - If a frame with IDE = 1 and ID = 0x1FFF3A20 is received, this is considered as a match
  - If a frame with IDE = 1 and ID = 0x08803220 is received, this is not a match.

28.5.7 Updating AFL Entry during Communication

You can update the AFL entry without disabling all CAN communications. Choose the entry number to be updated by setting the AFL entry number, and ignore the enable bit.

This entry number is ignored from the AFL matching while the entry is being updated.

Figure 28.28 shows the update flow for an AFL entry.

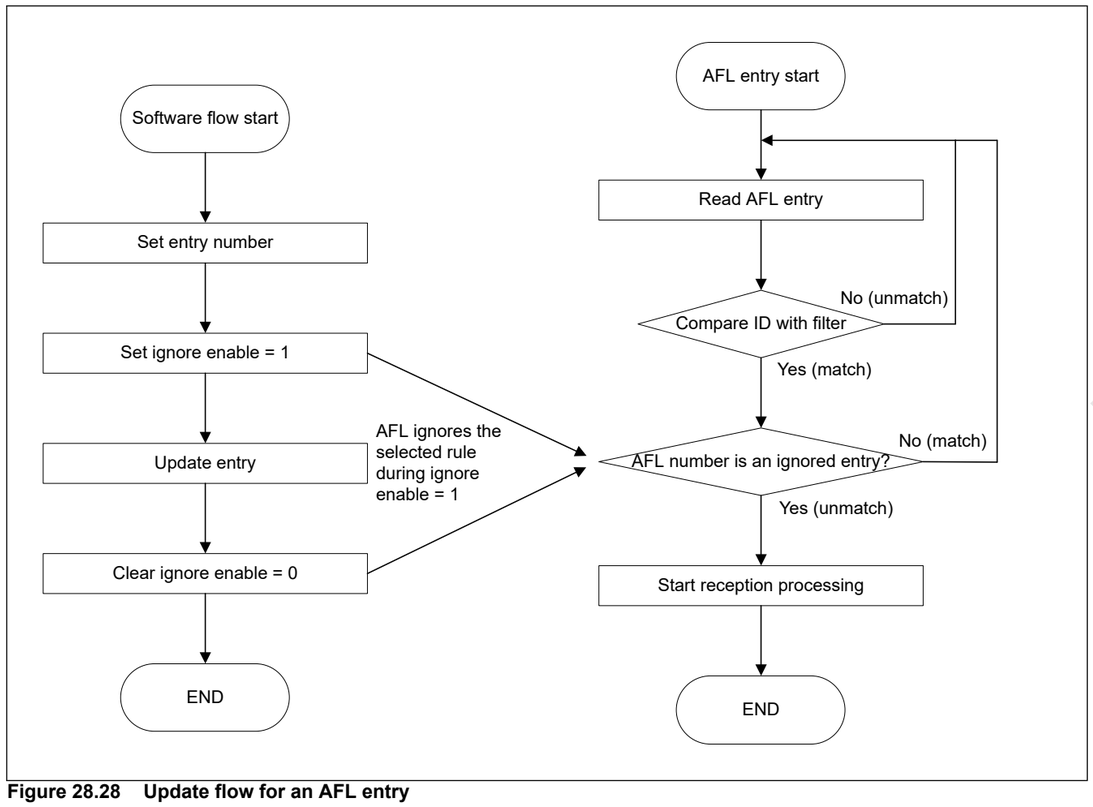

Figure 28.28 Update flow for an AFL entry

The method to update an AFL entry is as follows:

1. Set the entry number to CFDGAFLIGNENT register.
2. Set the value 0xC401 (key code and enable bit) to CFDGAFLIGNCTR register.
3. Set the entry page to CFDGAFLECTR register. This page includes the selected entry. CFDGAFLECTR.AFLDAE is set to 1.
4. Set the new rule to CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r registers.
5. CFDGAFLECTR.AFLDAE is cleared to 0.
6. Set the value 0xC400 (key code and clear enable bit) to CFDGAFLIGNCTR register.

●四种不同的接收ID与AFL条目x的比较结果描述如下：

如果接收到IDE=0且ID=0x220的帧，则视为匹配

如果接收到IDE=0且ID=0x320的帧，则不匹配

如果接收到IDE=1且ID=0x1FFF3A20的帧，则视为匹配

如果接收到IDE=1且ID=0x08803220的帧，则不匹配。

28.5.7 在通信期间更新AFL条目

您可以在不禁用所有CAN通信的情况下更新AFL条目。通过设置AFL条目号来选择要更新的条目号，忽略使能位。

在更新条目时，此条目号会从AFL匹配中忽略。

图28.28显示了AFL条目的更新流程。

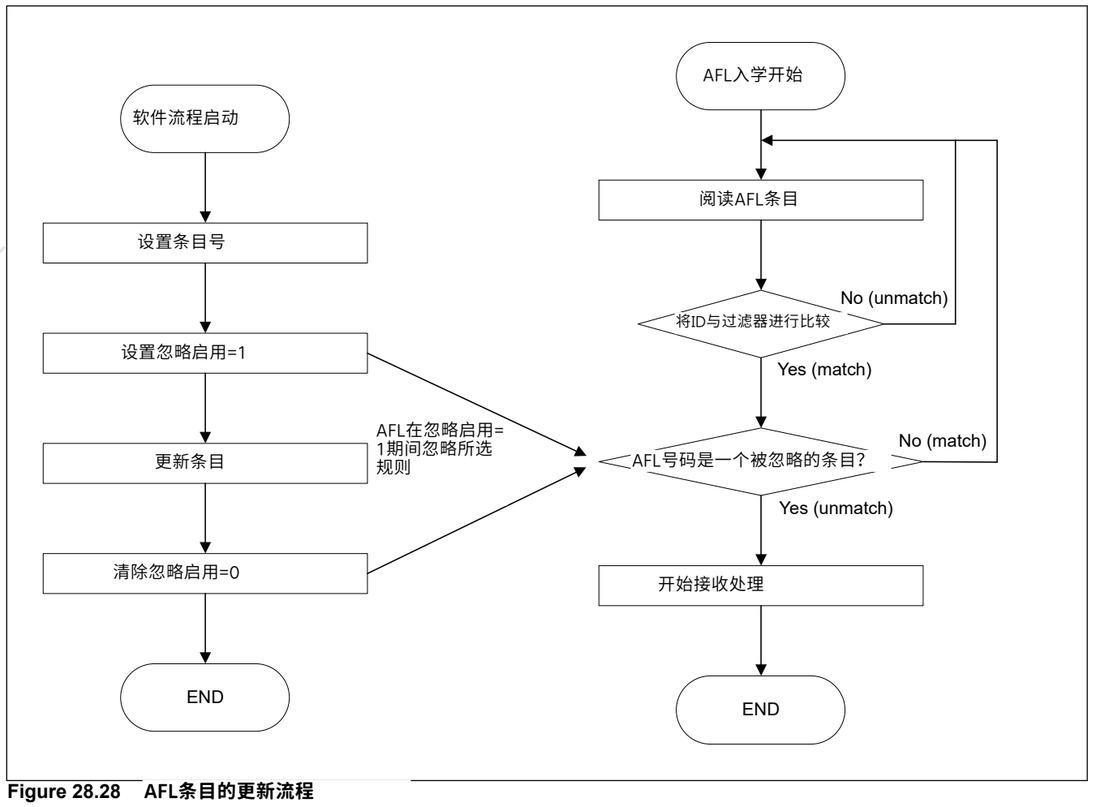

Figure 28.28 AFL条目的更新流程

更新AFL条目的方法如下：

1.将条目号设置为CFDGAFLIGNENT寄存器。

2.将值0xC401（键码和使能位）设置到CFDGAFLIGNCTR寄存器。

3.将入口页面设置为CFDGAFLECTR寄存器。此页面包括所选条目。CFDGAFLECTR.AFLDAE设置为1。

4.为CFDGAFLIDr、CFDGAFLMr、CFDGAFLP0r、CFDGAFLP1r寄存器设置新规则。

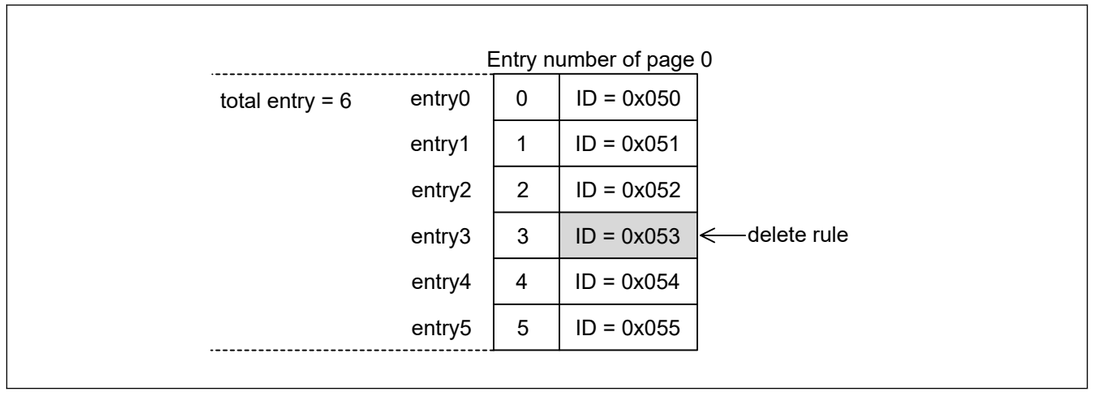
5.CFDGAFLECTR.AFLDAE清零。

6.将值0xC400（键码和清除使能位）设置到CFDGAFLIGNCTR寄存器。

Note: This entry number is ignored during the periods from (2) to (5).

(1) Example 1: Deleting an entry

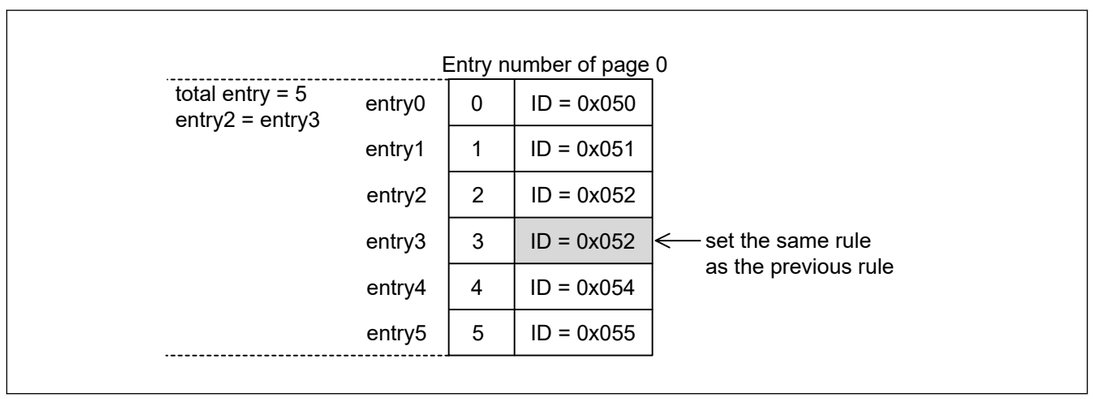
Deleting entry3 when the total number of entries is 6 channel.



How to delete an entry

1. Set 0x00000003 to CFDGAFLIGNENT register.
2. Set 0x0000C401 to CFDGAFLIGNCTR register.
3. Set 0x00000100 to CFDGAFLECTR register.
4. Set the same rule as the previous rule by accessing CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r (r = 3, this is entry3).
5. Set 0x00000000 to CFDGAFLECTR register.
6. Set 0x0000C400 to CFDGAFLIGNCTR register.

Entry3 is now deleted.



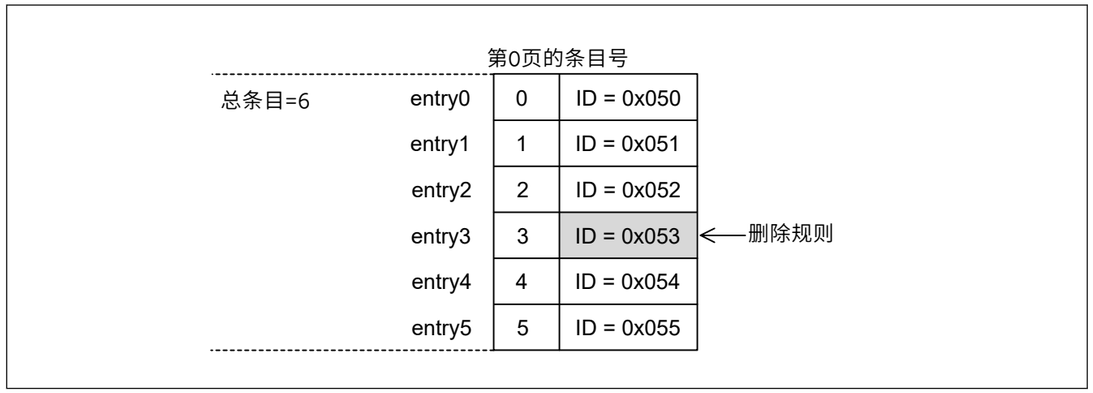
(2) Example 2: Adding an entry

Adding a new entry to entry3 when the total number of entries is 6.

Note: 在从(2)到(5)的期间，该条目号被忽略。

(1) 示例1：删除条目

当条目总数为6个通道时，删除条目3。



如何删除条目

1.将0x00000003设置为CFDGAFLIGNENT寄存器。

2.将0x0000C401设置为CFDGAFLIGNCTR寄存器。

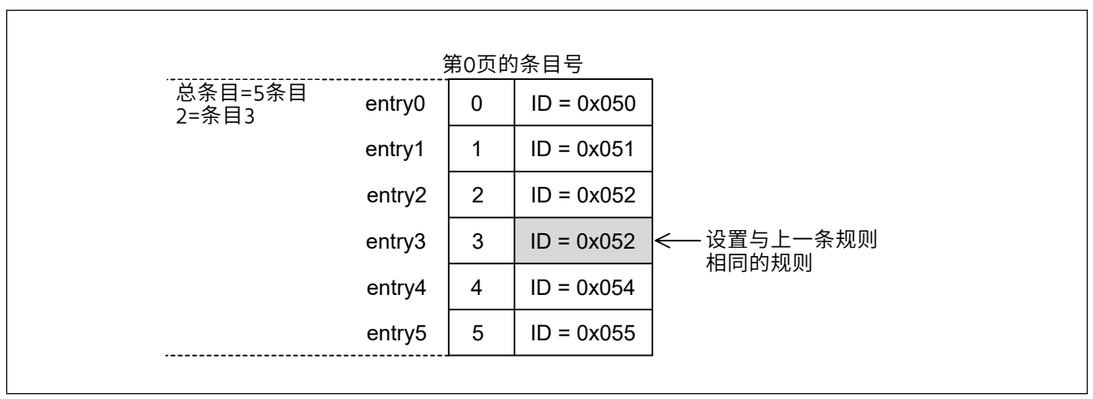
3.将0x00000100设置为CFDGAFLECTR寄存器。

4.通过访问CFDGAFLIDr、CFDGAFLMr、CFDGAFLP0r、CFDGAFLP1r（r=3，这是entry3）设置与上一个规则相同的规则。

5.将0x00000000设置为CFDGAFLECTR寄存器。

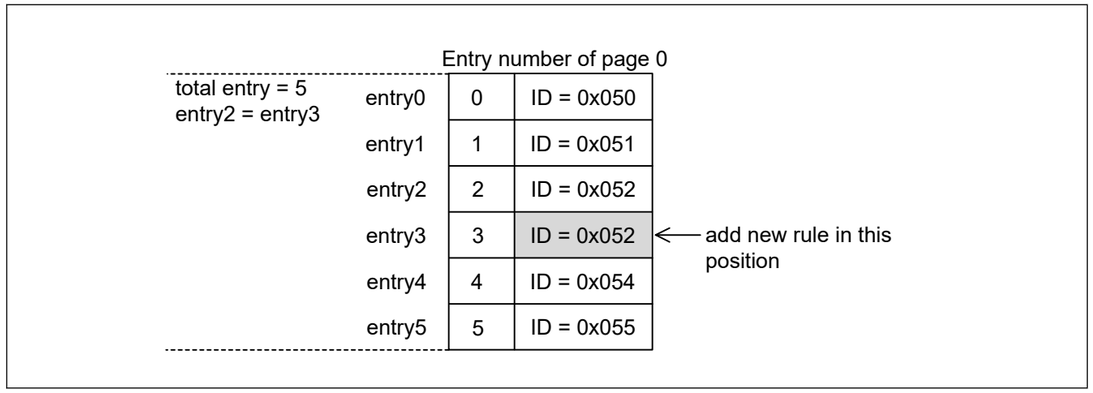
6.将0x0000C400设置为CFDGAFLIGNCTR寄存器。

现在已删除条目3。



(2) 示例2：添加条目

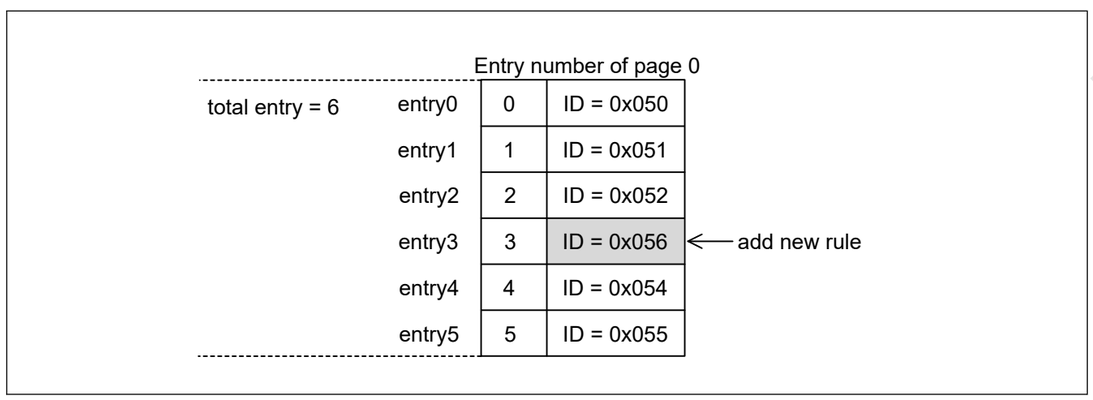
当条目总数为6时，向entry3添加一个新条目。



How to add an entry

1. Set 0x00000003 to CFDGAFLIGNENT register.
2. Set 0x0000C401 to CFDGAFLIGNCTR register.
3. Set 0x00000100 to CFDGAFLECTR register.
4. Set the new rule by accessing CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r (r = 3, this is entry3).
5. Set 0x00000000 to CFDGAFLECTR register.
6. Set 0x0000C400 to CFDGAFLIGNCTR register.

The new entry is now added.



The AFL filter can be used to set CFDGAFLCFG, and addition/deletion of an entry is possible. Therefore, it is necessary to set the maximum number to be used to CFDGAFLCFG.

28.6 FIFO Buffers and Normal Message Buffer Configuration

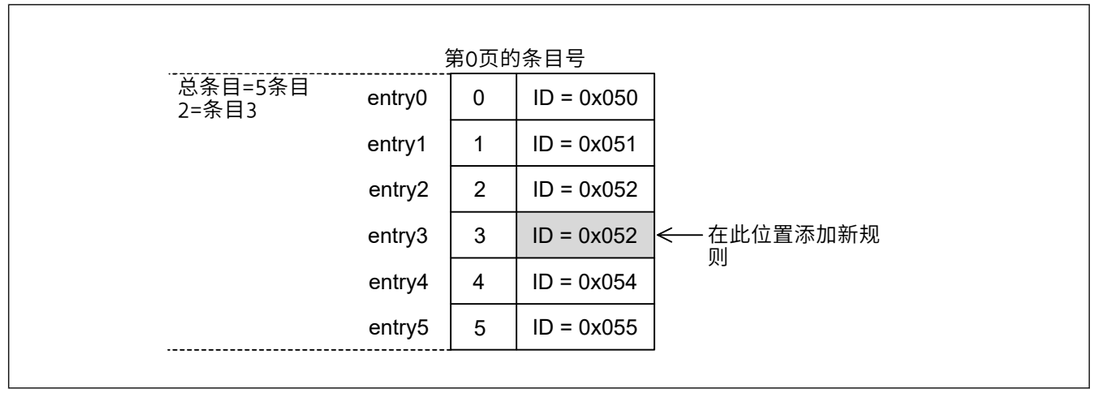
This section describes the process for configuring the number of RX message buffers, the FIFO buffers, and the flat TX message buffers in the CANFD module. The message buffers are mapped as shown in Figure 28.29.

The RX message buffers can be accessed with the RX Message Buffer Registers.

The RX FIFO buffers and the common FIFO buffers configured in RX mode or TX mode can only be accessed with the FIFO Access Registers.

If the common FIFO is configured in TX mode, you can only write data into the FIFO buffer using the FIFO Access registers.

If the common FIFO is configured in RX mode, you can only read data from the FIFO Access Registers.



如何添加条目

1.将0x00000003设置为CFDGAFLIGNENT寄存器。

2.将0x0000C401设置为CFDGAFLIGNCTR寄存器。

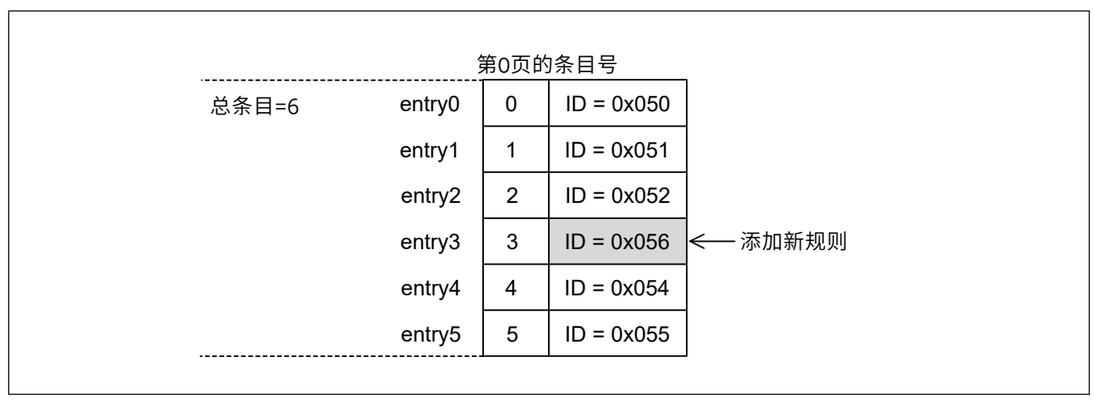
3.将0x00000100设置为CFDGAFLECTR寄存器。

4.通过访问CFDGAFLIDr、CFDGAFLMr、CFDGAFLP0r、CFDGAFLP1r设置新规则（r=3，这是entry3）。

5.将0x00000000设置为CFDGAFLECTR寄存器。

6.将0x0000C400设置为CFDGAFLIGNCTR寄存器。

现在添加了新条目。



AFL过滤器可用于设置CFDGAFLCFG，并且可以添加删除条目。因此，有必要将要使用的最大数量设置为CFDGAF cessary to LCFG。

28.6 FIFO缓冲区和正常消息缓冲区配置

本节介绍在CANFD模块中配置RX报文缓冲区、FIFO缓冲区和平面TX报文缓冲区数量的过程。消息缓冲区的映射如图28.29所示。

RX报文缓冲区可以通过RX报文缓冲区寄存器访问。

RXFIFO缓冲区和配置为RX模式或TX模式的通用FIFO缓冲区只能通过FIFO访问寄存器。

如果普通FIFO配置为TX模式，则只能使用FIFO访问寄存器将数据写入FIFO缓冲区。

如果普通FIFO配置为RX模式，则只能从FIFO访问寄存器中读取数据。

The TX message buffers can be accessed with the TX Message Buffer Registers.

If unused message buffer locations are read, the message buffer locations are read as unknown values.

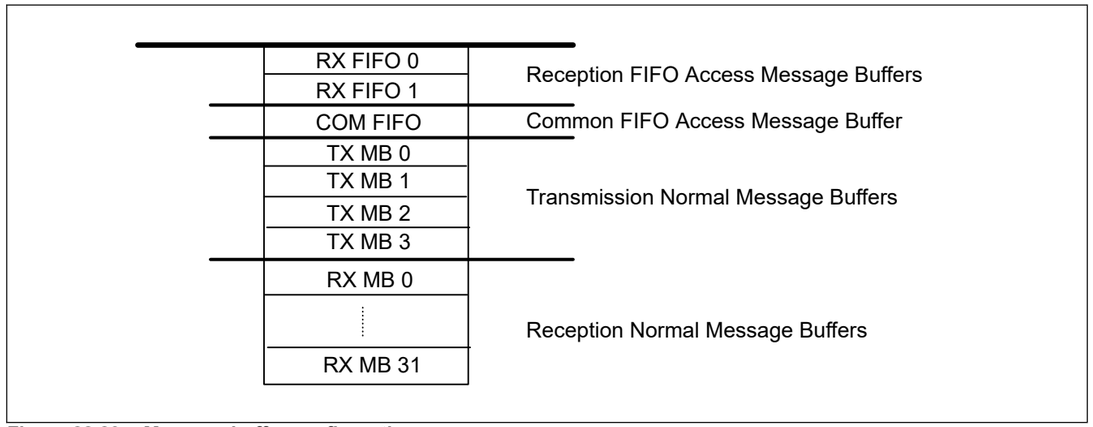


Figure 28.29 Message buffer configuration

28.6.1 Normal RX Message Buffers

In CANFD module, the frames received can be stored in normal RX message buffers based on the configuration of the AFL entries.

Additionally, the number of normal RX message buffers required in the system can be chosen up to a fixed maximum limit.

28.6.1.1 Normal RX Message Buffer Configuration

In CANFD module, the number of normal RX message buffers can be configured by writing to the RX Message Buffer Number Register.

The limiting values for the configuration of number of message buffers are:

- Minimum value = 0x00 (no normal RX MB)
- Maximum value = 0x20

Do not use values outside these limits.

The AFL entries for routing the received messages to normal RX message buffers must be configured to match the requirements of the system.

The AFL entries must also be configured properly, and an AFL entry for normal RX message buffers should not exceed the number of message buffers configured in the RX Message Buffer Number Register.

Note: There is no internal check procedure provided in CANFD module against wrong configuration of the AFL.

The data field size of the RX message buffer can be configured with the CFDRMNB.RMPLS bit. The default size is 8 bytes and the maximum data payload size is 64 bytes.

When the receiving frame exceeds the data field size, then the acceptance depends on the configuration of CFDGCFG.CMPOC (message rejecting or data payload cut).

Note: RMPLS and CMPOC bit is not available in the classical CAN function, so, these feature is not valid for classical CAN.

28.6.2 FIFO Buffers

The CANFD module provides a fixed number of FIFO buffers to support storage of frames for reception and transmission functions .

TX报文缓冲区可以通过TX报文缓冲区寄存器访问。

如果读取未使用的消息缓冲区位置，则将消息缓冲区位置作为未知值读取。

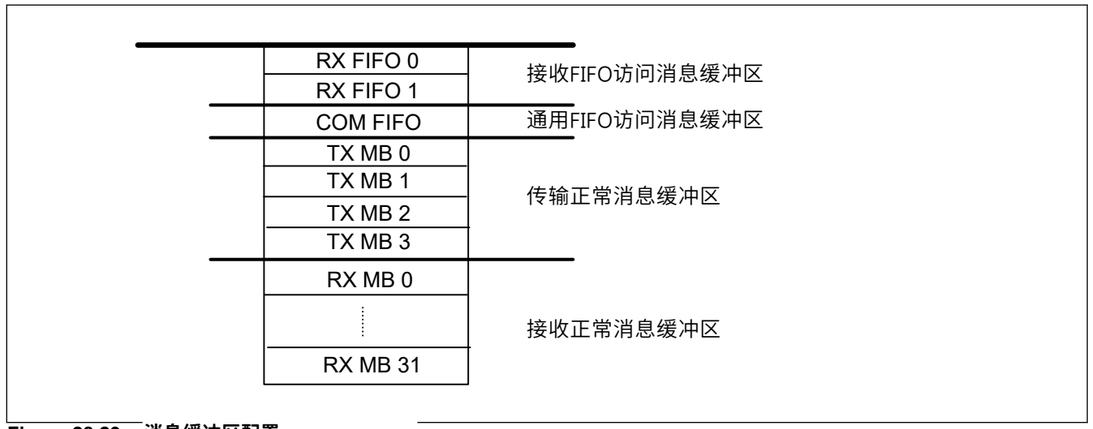

Figure 28.29 消息缓冲区配置

28.6.1 正常RX消息缓冲区

在CANFD模块中，接收到的帧可以根据AFL条目的配置存储在正常的RX消息缓冲区中。

此外，系统所需的正常RX消息缓冲区的数量可以选择为固定的最大限制。

28.6.1.1 正常RX报文缓冲区配置

在CANFD模块中，可以通过写入RX消息缓冲区来配置正常RX消息缓冲区的数量
号码寄存器。

消息缓冲区数量配置的限制值为：

- 最小值=0x00（非正常RXMB）
- 最大值=0x20

不要使用超出这些限制的值。

用于将接收到的消息路由到正常RX消息缓冲区的AFL条目必须配置为匹配系统的要求。

AFL条目也必须正确配置，正常RX消息缓冲区的AFL条目不应超过RX消息缓冲区编号寄存器中配置的消息缓冲区数。

Note: CANFD模块中没有针对AFL的错误配置提供内部检查程序。

RX消息缓冲区的数据字段大小可以通过CFDRMNB.RMPLS位进行配置。默认大小为8字节，最大数据负载大小为64字节。

当接收帧超过数据字段大小时，则接受取决于配置
CFDGCFG.CMPOC（消息拒绝或数据有效负载切断）。

Note: RMPLS和CMPOC位在经典CAN功能中不可用，因此，这些功能对经典CAN功能无效
CAN.

28.6.2 FIFO Buffers

CANFD模块提供固定数量的FIFO缓冲区，以支持存储接收和发送功能的帧。

The number of reception-only FIFO buffers is fixed to 2. However, common FIFO buffer channel can be configured to store messages for transmission or reception function.

These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- Size
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the TX FIFO.

When the receiving frame exceeds the data field size, the acceptance depends on the configuration of the CFDGCFG.CMPOC bit (message rejecting or data payload cut).

28.6.2.1 FIFO Buffers Configuration

In CANFD module, the FIFO buffers can be configured to match the system requirements.

The total number of FIFO buffers = 2 RX FIFO buffers + 1 common FIFO buffer = 3 FIFO buffers.

仅接收FIFO缓冲区的数量固定为2。但是，可以配置通用FIFO缓冲区通道来存储用于发送或接收功能的消息。

可以启用或禁用这些FIFO缓冲区，并且可以配置以下参数以匹配系统要求：

- Size
- ●中断结构
- ●消息丢失机制
- ●FIFO缓冲区的消息覆盖机制
- ●TXFIFO的位置 。

当接收帧超过数据字段大小时，接受取决于配置的
CFDGCFG.CMPOC位（消息拒绝或数据有效负载切断）。

28.6.2.1 FIFO缓冲器配置

在CANFD模块中，可以配置FIFO缓冲区以匹配系统要求。

FIFO缓冲区的总数=2个RXFIFO缓冲区+1个通用FIFO缓冲区=3个FIFO缓冲区。

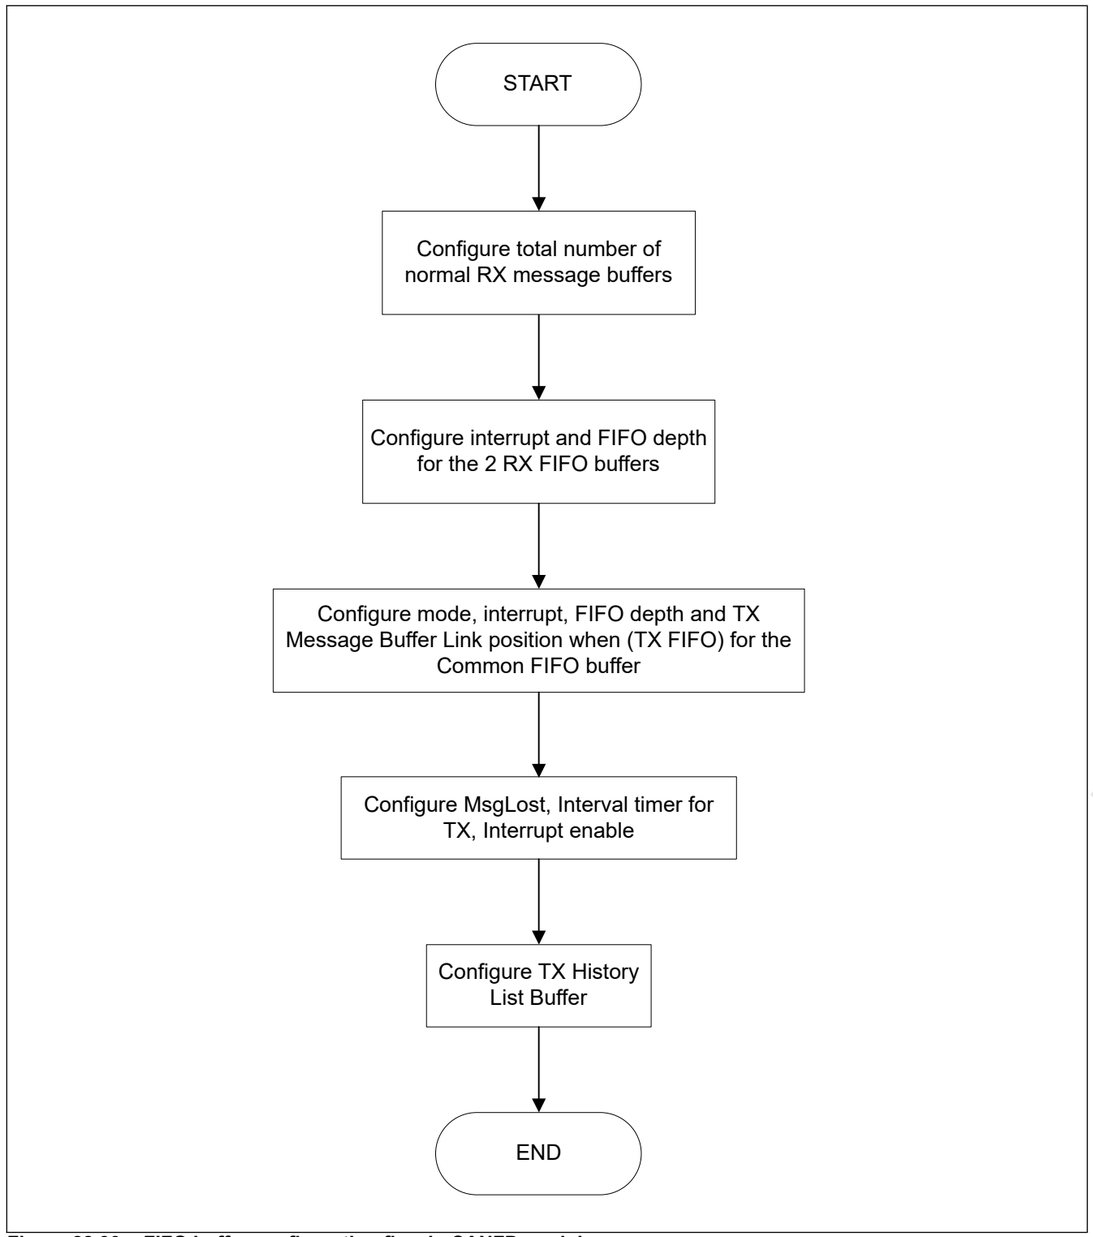

Figure 28.30 FIFO buffer configuration flow in CANFD module

As shown in Figure 28.30, the various FIFO buffers can be configured by writing to the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

For the 2 RX FIFO buffers, the following parameters can be configured:

- Interrupts
- FIFO depth
- FIFO payload data size.

For the common FIFO buffer, the following parameters can be configured:

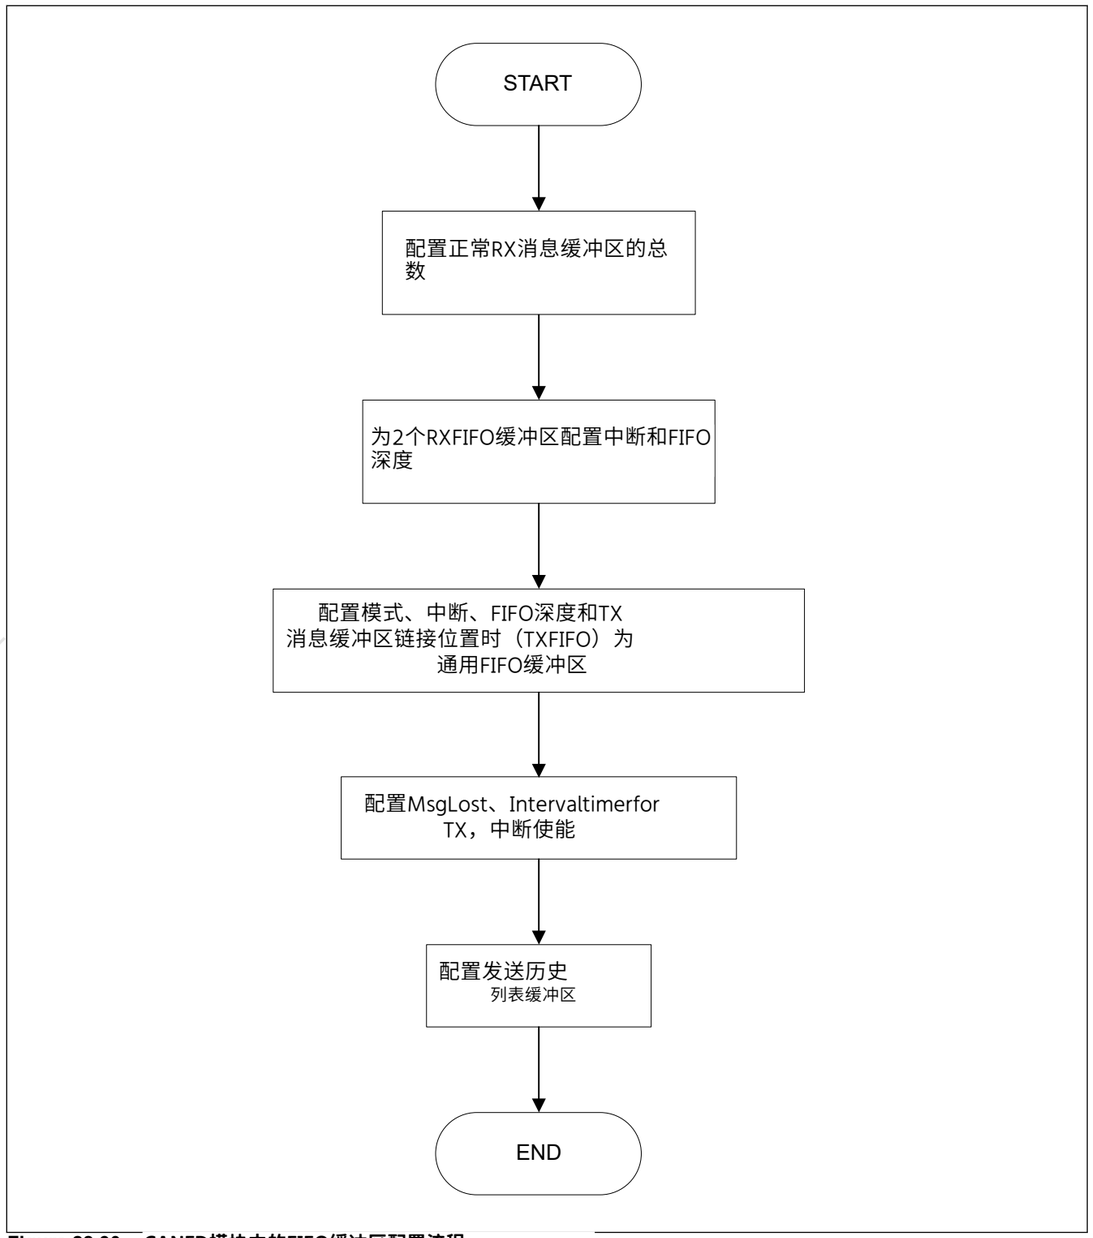

Figure 28.30 CANFD模块中的FIFO缓冲区配置流程

如图28.30所示，可以通过写入RXFIFOConfigurationControl来配置各种FIFO缓冲区寄存器和通用FIFO配置控制寄存器。

对于2个RXFIFO缓冲区，可以配置以下参数：

- Interrupts
- FIFO depth
- FIFO有效负载数据大小。

对于普通的FIFO缓冲区，可以配置以下参数：

- Mode
- Interrupts FIFO depth
- FIFO payload data size
- FIFO TX link position.

(1) FIFO mode configuration of Common FIFO buffer

The mode of the common FIFO buffer can be configured by writing to the CFDCFCC.CFM[1:0] bits in the Common FIFO Configuration/Control Register. The possible modes of configuration for Common FIFO buffer are:

- 0b RX mode (default mode after hardware reset)
- 1b TX mode

Messages can only be read from the RX FIFO buffers and the Common FIFO buffer configured in RX mode. Messages are stored by the CAN module in these FIFO buffers based on the AFL entries.

Messages can be read and written into the Common FIFO buffer configured in TX mode. These messages are transmitted on the appropriate CAN channel.

The pointers can only be incremented when a new message is stored in the FIFO buffer and decremented when a message is transmitted on the corresponding CAN channel by the CANFD module.

After a hardware reset, the Common FIFO buffer is configured in RX mode by default. Only enable the FIFO buffers after configuring the Common FIFO buffer in the required modes.

(2) FIFO TX message buffer link configuration

When the common FIFO is configured as TX FIFO, the FIFO buffer must be linked to a normal TX message buffer to participate in the transmission scan.

Do not write data into a TX message buffer that is linked to a Common FIFO buffer. Also, the TX message buffer linked to a Common FIFO buffer should not be a part of the TX Queue.

The TX message buffer link of each Common FIFO buffer can be configured by writing to the CFDCFCC.CFTML[1:0] bits in the Common FIFO Configuration/Control Registers. Available options for TX message buffer link configuration are:

- 0x00: TX Message Buffer 0
- 0x01: TX Message Buffer 1
- 0x10: TX Message Buffer 2
- 0x11: TX Message Buffer 3

(3) FIFO depth configuration

The depth of each FIFO buffer can be configured by writing to the CFDRFCCa.RFDC[2:0] bits and CFDCFCC.CFDC[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The 6 available options for depth configuration are:

- 0x000: 0 Messages (FIFO buffer cannot be enabled)
- 0x001: 4 Messages
- 0x010: 8 Messages
- 0x011: 16 Messages
- 0x100: 32 Messages
- 0x101: 48 Messages

The RAM allocation for RX message buffers along with FIFO buffers is limited to 16 messages with 64 data bytes. Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CANFD module logic does not check the validity of the configuration.

Note: If the FIFO depth of a common FIFO is 4 messages or more (CFDCFCC.CFDC[2:0] > 000b), then the Common FIFO TX message buffer link is valid when the FIFO is disabled or enabled.

- Mode

●中断FIFO深度

●FIFO有效负载数据大小

●FIFOTX链路位置。

(1) CommonFIFO缓冲区的FIFO模式配置

可通过写入CommonFIFO中的CFDCFCC.CFM[1:0]位来配 置commonFIFO缓冲区的模式
配置控制寄存器。CommonFIFO缓冲区的可能配置模式有：

●0bRX模式（硬件复位后的默认模式）

- 1b TX mode

只能从RXFIFO缓冲区和配置为RX模式的CommonFIFO缓冲区读取消息。CAN模块根据AFL条目将消息存储在这些FIFO缓冲区中。

可以将消息读取和写入在TX模式下配置的CommonFIFO缓冲区。这些消息在适当的CAN通道上传输。

只有当新消息存储在FIFO缓冲区中时，指针才能递增，而当CANFD模块在相应CAN通道上传输消息时，指针才能递减。

硬件复位后，CommonFIFO缓冲区默认配置为RX模式。仅在所需模式下配置CommonFIFO缓冲区后才启用FIFO缓冲区。

(2) FIFOTX消息缓冲区链接配置

当通用FIFO配置为TXFIFO时，FIFO缓冲区必须链接到正常的TX报文缓冲区才能参与传输扫描。

不要将数据写入链接到通用FIFO缓冲区的TX消息缓冲区。此外，链接到通用FIFO缓冲区的TX消息缓冲区不应成为TX队列的一部分。

每个通用FIFO缓冲区的TX报文缓冲区链接可以通过写入通用FIFO配置控制寄存器中的CFDCFCC.CFTML[1:0]位来配置。TX消息缓冲区链路配置的可用选项包括：

●0x00：TX消息缓冲区0

●0x01：TX报文缓冲区1

●0x10：TX消息缓冲区2

●0x11：TX报文缓冲区3

(3) FIFO深度配置

每个FIFO缓冲区的深度可以通过写入RXFIFO配置控制寄存器和通用FIFO配置控制寄存器中的CFDRFCCa.RFDC[2:0]位和CFDCFCC.CFDC[2:0]位来配 置。深度配置的6个可用选项是：

●0x000：0条消息（无法启用FIFO缓冲区）

- 0x001: 4 Messages
- 0x010: 8 Messages
- 0x011: 16 Messages
- 0x100: 32 Messages
- 0x101: 48 Messages

RX消息缓冲区和FIFO缓冲区的RAM分配限制为16条消息和64个数据字节。
不应配置超过此最大限制的RX消息缓冲区以及FIFO缓冲区。

CANFD模块逻辑不检查配置的有效性。

Note: 如果公共FIFO的FIFO深度为4条或更多消息（CFDCFCC.CFDC[2:0]>000b），则公共FIFOTX报文缓冲区链接在FIFO禁用或启用时有效。

If FIFO depth is 0 messages, then the Common FIFO TX message buffer link is not valid when the FIFO is disabled or enabled.

(4) FIFO payload size configuration

The data size of each FIFO buffer can be configured by writing to the CFDRFCCa.RFPLS[2:0] bits and CFDCFCC.CFPLS[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The eight available options for depth configuration are:

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes

The RAM allocation for RX message buffers along with FIFO buffers is limited to 16 messages with 64 data bytes. Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CANFD module logic does not check the validity of the configuration.

Note: This feature is not available in the classical CAN function.

(5) FIFO interrupt configuration

The Interrupt generation conditions for the FIFO buffers can be configured by writing to the CFDRFCCa.RFIM and CFDCFCC.CFIM bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The two available options are:

- 0:
  - RX FIFO mode: Interrupt generated when the Common FIFO counter reaches CFDRFCCa.RFIGCV/ CFDCFCC.CFIGCV value
  - TX FIFO mode: Interrupt generated when the Common FIFO transmits the last message successfully
- 1:
  - RX FIFO mode: Interrupt generated at the end of storage of every received message
  - TX FIFO mode: Interrupt generated for every successfully transmitted message

If the Interrupt Mode bit is 0 for a RX FIFO, then interrupt is generated based on the configuration of the CFDRFCCa.RFIGCV[2:0] bits.

Similarly, if the Interrupt Mode bit is 0 for a Common FIFO configured in RX mode, then interrupt is generated based on the configuration of CFDCFCC.CFIGCV[2:0] bits.

The eight available options for configuring the FIFO counter value for generation of an interrupt are:

- 000b: Interrupt generated when FIFO is 1/8th Full
- 001b: Interrupt generated when FIFO is 1/4th Full
- 010b: Interrupt generated when FIFO is 3/8th Full
- 011b: Interrupt generated when FIFO is 1/2 Full
- 100b: Interrupt generated when FIFO is 5/8th Full
- 101b: Interrupt generated when FIFO is 3/4th Full
- 110b: Interrupt generated when FIFO is 7/8th Full
- 111b: Interrupt generated when FIFO is Full.

如果FIFO深度为0消息，则在禁用或启用FIFO时通用FIFOTX消息缓冲区链接无效。

(4) FIFO有效载荷大小配置

每个FIFO缓冲区的数据大小可以通过写入CFDRFCCa.RFPLS[2:0]位和RXFIFO配置控制寄存器和通用FIFO配置控制中的CFDCFCC.CFPLS[2:0]位寄存器。深度配置的八个可用选项是：

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes

RX消息缓冲区和FIFO缓冲区的RAM分配限制为16条消息和64个数据字节。不应配置超过此最大限制的RX消息缓冲区以及FIFO缓冲区。

CANFD模块逻辑不检查配置的有效性。

Note: 此功能在经典CAN功能中不可用。

(5) FIFO中断配置

FIFO缓冲区的中断生成条件可以通过写入CFDRFCCa.RFIM和RXFIFO配置控制寄存器和通用FIFO配置控制中的CFDCFCC.CFIM位寄存器。两个可用选项是：

- 0:
  RXFIFO模式：CommonFIFO计数器达到CFDRFCCa.RFIGCVCFDCFCC.CFIGCV值时产生中断

  TXFIFO模式：CommonFIFO成功发送最后一条报文时产生中断
- 1:
  RXFIFO模式：在每个接收到的消息存储结束时产生中断
  TXFIFO模式：为每个成功传输的消息生成中断

如果RXFIFO的中断模式位为0，则根据配置生成中断
CFDRFCCa.RFIGCV[2:0] bits.

同样，如果配置为RX模式的CommonFIFO的中断模式位为0，则根据CFDCFCC.CFIGCV[2:0]位的配置生成中断。

配置FIFO计数器值以生成中断的八个可用选项是：

- 000b：FIFO为18thFull时产生的中断
- 001b：FIFO为14thFull时产生中断
- 010b：FIFO为38thFull时产生中断
- 011b：FIFO为12Full时产生中断
- 100b：FIFO为58thFull时产生的中断
- 101b：FIFO为34thFull时产生中断
- 110b：FIFO为78thFull时产生中断
- 111b：FIFO满时产生中断。

In this case, an interrupt is generated when the message count matches the configured value.

However, there are some limitations on the configuration of the CFDRFCCa.RFIGCV[2:0] and CFDCFCC.CFIGCV[2:0] bits depending on the FDC[2:0] bits (FIFO Depth Configuration), see Table 28.24.

28.6.2.2 FIFO Buffers Control

The FIFO interrupt must be enabled by setting any one of the following bits in the RX FIFO Configuration/Control Registers:

- CFDRFCCa.RFIE

In addition, the FIFO interrupt must be enabled by setting any one of the following bits in the Common FIFO Configuration/Control Register:

- CFDCFCC.CFRXIE
- CFDCFCC.CFTXIE

After configuration is complete, each FIFO can be enabled by setting the CFDRFCCa.RFE and CFDCFCC.CFE bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Register to allow transmission and reception of messages.

28.7 Interrupts and DMA

28.7.1 Interrupts

The CANFD module generates several interrupts. The interrupt output, which is connected to the Interrupt Controller Unit (ICU), can be controlled by the corresponding interrupt enable bit.

The status flag is set independent from this enable bit.

The channel transmission interrupt has an additional status flag register. The status bits are set when the corresponding interrupt enables are set.

The status flag register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.

The interrupts in the CANFD module can be classified into two groups, global interrupts and channel interrupts:

- Global interrupts:
  The CANFD module can generate 3 global interrupts:
  - Global interrupt for successful reception into the 2 RX FIFO buffers
  - Global error interrupt.
  - Global Interrupt for successful reception into the 32 RX message buffers
- Channel interrupts:
  Channel of the CANFD module can generate 3 channel interrupts:

在这种情况下，当消息计数与配置值匹配时会产生中断。

但是，CFDRFCCa.RFIGCV[2:0]和CFDCFCC.CFIGCV[2:0]位的配置有一些限制，具体取决于FDC[2:0]位（FIFO深度配置），请参见表28.24。

28.6.2.2 FIFO缓冲器控制

必须通过设置RXFIFO配置控制中的以下任一位来启用FIFO中断
Registers:

- CFDRFCCa.RFIE

此外，必须通过设置CommonFIFO中的以下任一位来启用FIFO中断
Configuration/Control Register:

- CFDCFCC.CFRXIE
- CFDCFCC.CFTXIE

配置完成后，可以通过设置CFDRFCCa.RFE和CFDCFCC.CFE位来使能每个FIFO
RXFIFO配置控制寄存器和通用FIFO配置控制寄存器，以允许发送和接收消息。

28.7 中断和DMA

28.7.1 Interrupts

CANFD模块产生几个中断。连接到中断控制器单元（ICU）的中断输出可由相应的中断使能位控制。

状态标志的设置独立于该使能位。
通道传输中断有一个额外的状态标志寄存器。当相应的中断使能被设置时，状态位被设置。

状态标志寄存器支持识别通道传输的中断源，因为该中断由多个触发源驱动。

CANFD模块中的中断可以分为两类，全局中断和通道中断：

- Global interrupts:
  CANFD模块可以产生3个全局中断：
  成功接收到2个RXFIFO缓冲区的全局中断
  全局错误中断。
  成功接收到32个RX消息缓冲区的全局中断
- Channel interrupts:
  CANFD模块的通道可以产生3个通道中断：

1. Channel transmission
   - Transmission completion from channel
   - Transmission abort from channel
   - Transmission from TX Queue for a channel
   - Channel THL interrupt
   - Successful transmission from a Common FIFO in TX mode for a channel.
2. Channel error interrupt
3. Successful reception in a Common FIFO in RX mode for a channel.

The interrupts are cleared when the corresponding flag bits are cleared or the Interrupt enable bits are cleared.

Table 28.25 gives an overview of interrupt sources for the different interrupt outputs. The interrupt outputs are active-high.

28.7.2 DMA Transfer

The CANFD module has message buffers that can be associated with a DMA channel:

CANFD模块具有可与DMA通道关联的消息缓冲区：

- Reception DMA
  - 2 RX FIFO message buffers
  - Common FIFO Message Buffer

Figure 28.33 shows the potential DMA channels.

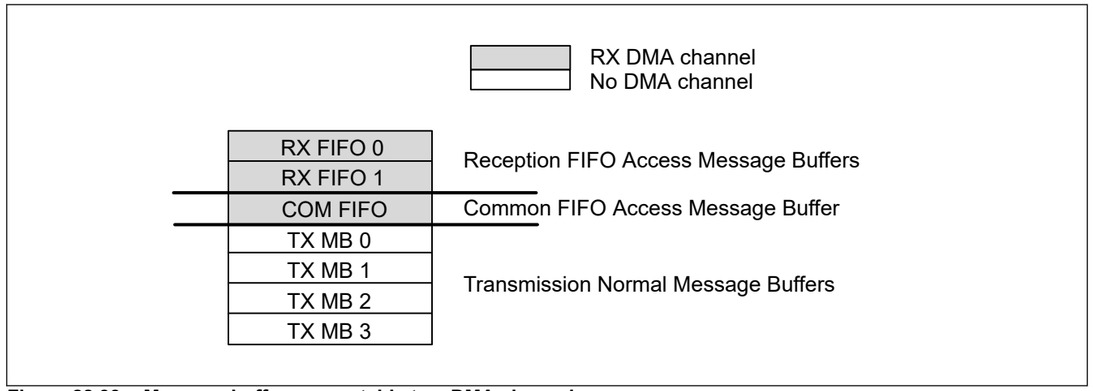

Figure 28.33 Message buffer connectable to a DMA channel

A DMA channel transfer request is generated for each FIFO entry to the DMAC when the related CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE is set to 1 and the belonging FIFO is not empty.

Reception FIFO Interrupt should be disabled for this particular FIFO (CFDRFCCa.RFIE or CFDCFCC.CFRXIE)

Use the regular start address for the DMA access window address. See Figure 28.34.

DMA FIFO pointer decrement is done automatically by reading the last configured data payload byte (CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

Note: The DMA must read the exact length of the configured data payload size (CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

Note: This feature is not available for classical CAN function because CFDRFCCa.RFPLS and CFDCFCC.CFPLS are not in classical CAN.

Do not write to the FIFO control registers when DMA is enabled. The DMA enable of the particular DMA FIFO (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE) can be set at any time. Figure 28.34 shows a configuration flow for an initial setup.

DMAFIFO指针递减是通过读取最后配置的数据有效负载字节（CFDRFCCa.RFPLS或CFDCFCC.CFPLS）自动完成的。

Note: DMA必须读取配置的数据有效负载大小（CFDRFCCa.RFPLS或CFDCFCC.CFPLS).

Note: 此功能不适用于经典CAN功能，因为CFDRFCCa.RFPLS和CFDCFCC.CFPLS不在经典CAN中。

启用DMA时不要写入FIFO控制寄存器。可以随时设置特定DMAFIFO（CFDCDTCT.RFDMAE或CFDCDTCT.CFDMAE）的DMA使能。图28.34显示了初始设置的配置流程。

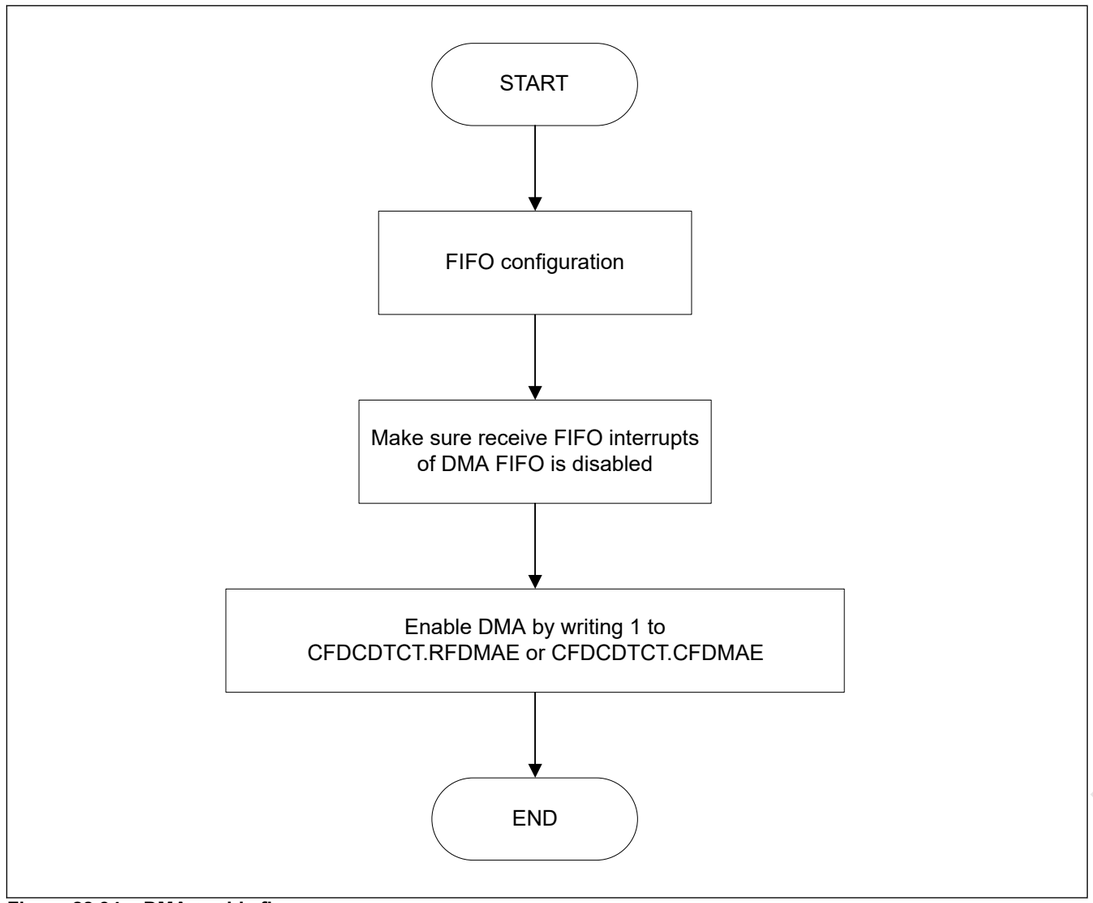

Figure 28.34 DMA enable flow

To disable a DMA transfer request, you must disable the particular DMA enable bit (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE). If the disable is made during an ongoing transfer, then the transfer must be completed first before further action can be taken. The transfer status can be identified by the CFDCDTSTS.RFDMASTS or CFDCDTSTS.CFDMASTS bit. See Figure 28.35 for the DMA disable flow. When the DMA is disabled, consideration should be made for the remaining or new incoming messages to this particular reception FIFO.

When the FIFO is not disabled, reception to the FIFO continues.

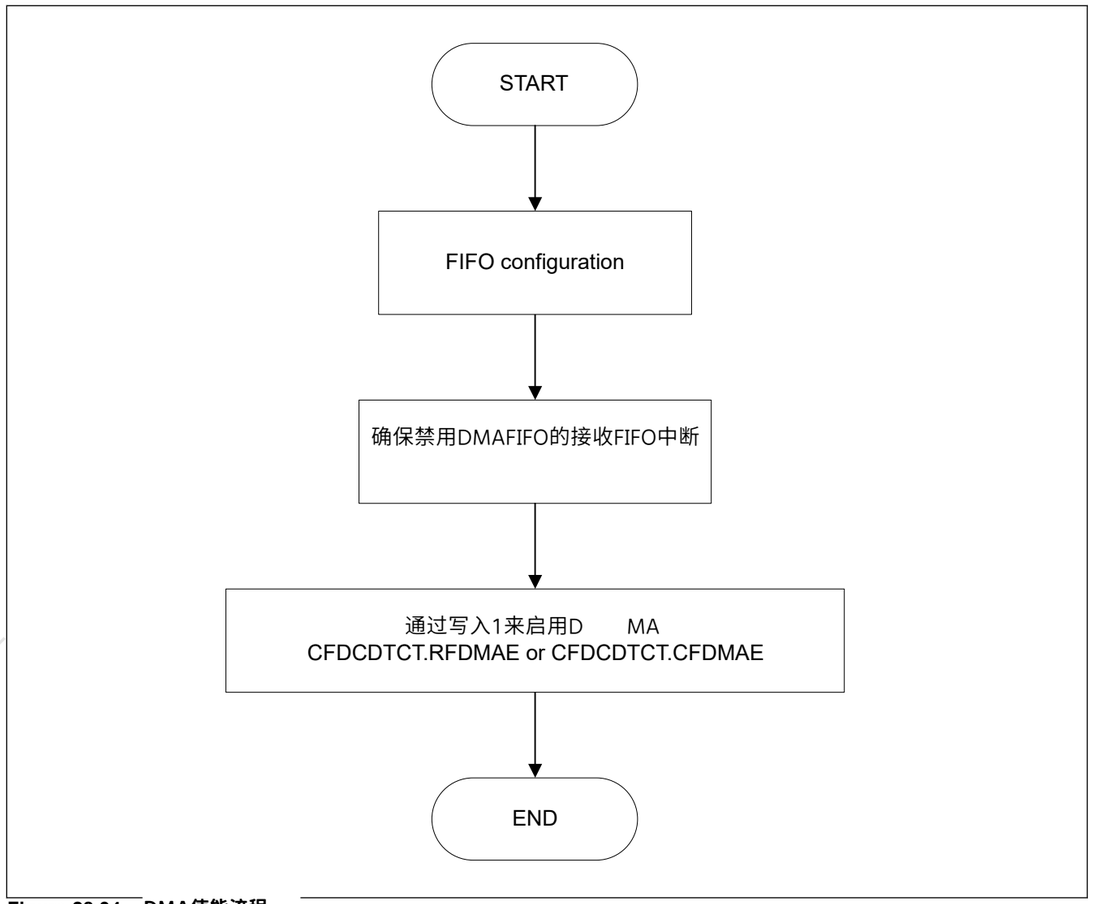

Figure 28.34 DMA使能流程

要禁用DMA传输请求，您必须禁用特定的DMA启用位（CFDCDTCT.RFDMAE或CFDCDTCT.CFDMAE)。如果在正在进行的传输过程中进行了禁用，则必须先完成传输，然后才能采取进一步的操作。传输状态可以通过CFDCDTSTS.RFDMASTS或CFDCDTSTS.CFDMASTS位来识别。有关DMA禁用流程，请参见图28.35。禁用DMA时，应考虑到此特定接收FIFO的剩余或新传入消息。

当FIFO未被禁用时，继续接收FIFO。

28.8 Reception and Transmission

28.8.1 Reception

In the CANFD module, CAN messages received on any of the channels are stored in RX message buffers, RX FIFO buffers, or Common FIFO buffers configured in RX mode depending on the Acceptance Filter List entries.

- Up to 32 RX message buffers can be configured
- 2 RX FIFO buffers available
- 1 Common FIFO Buffer can be configured in RX mode

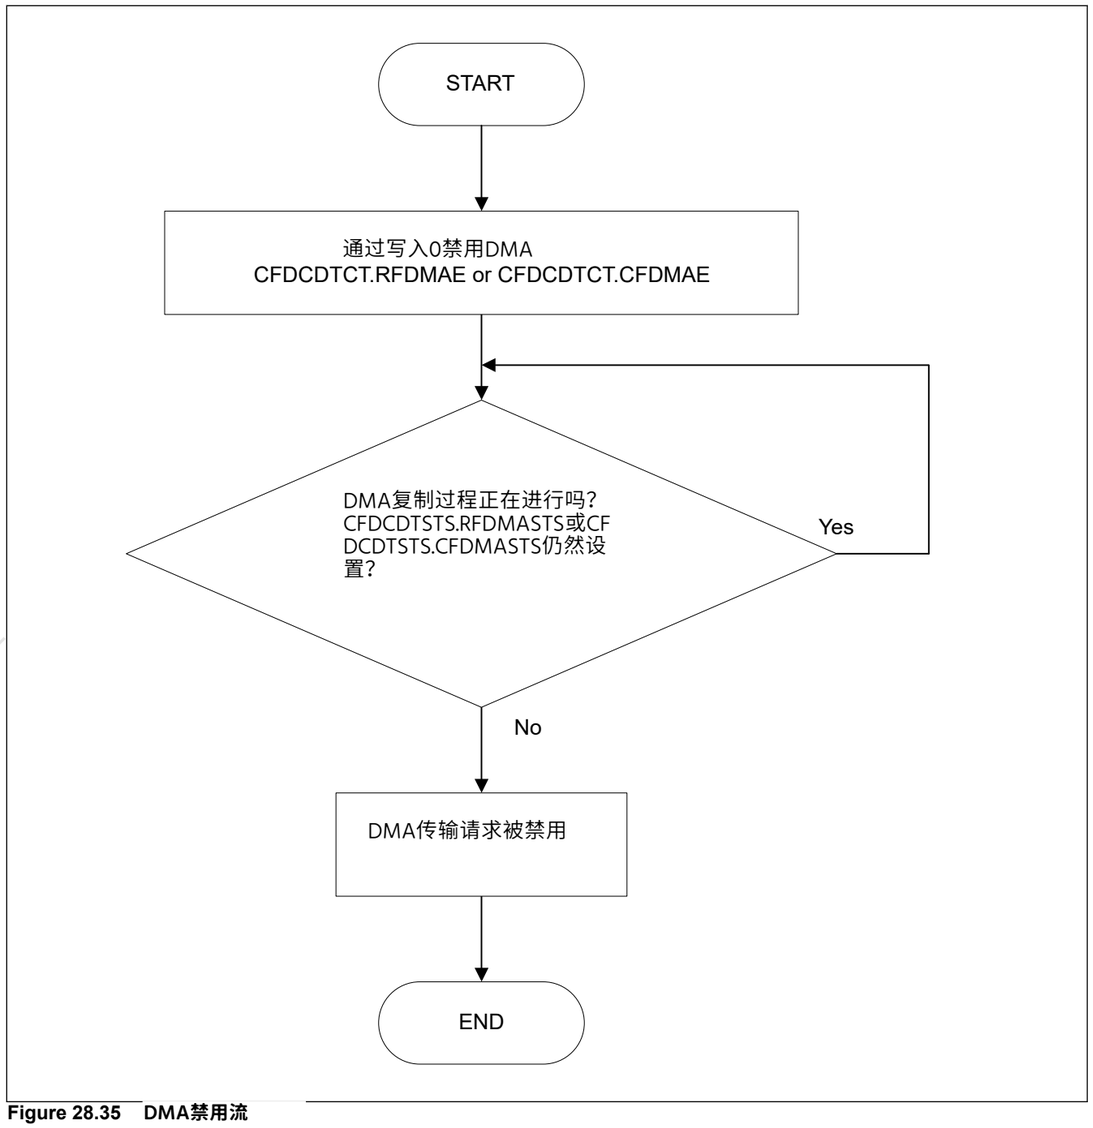

Figure 28.35 DMA禁用流

28.8 接收和传输

28.8.1 Reception

在CANFD模块中，任何通道上接收的CAN报文都存储在RX报文缓冲区、RXFIFO缓冲区或配置为RX模式的Common FIFO缓冲区中，具体取决于AcceptanceFilterList条目。

- ●最多可配置32个RX报文缓冲区
- ●2个RXFIFO缓冲器可用
- ●RX模式下可配置1个CommonFIFOBuffer

28.8.1.1 Message Storage in RX Message Buffers

When a message is successfully received and stored in a RX message buffer, the corresponding New Data flag is set in the RX Message Buffer New Data Register.

The CAN message can be read from the corresponding RX message buffer.

If a new message is stored into a RX message buffer before the previous message in this message buffer can be read, then the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the RX message buffer. If such a loss of messages is not acceptable, then RX FIFO should be used for storing related messages.

Note: Users should do the same processing as the existing software flow also when using interrupt. (see Figure 28.37)

Note: Unused data bytes are filled with 0x00 depending on the DLC value.

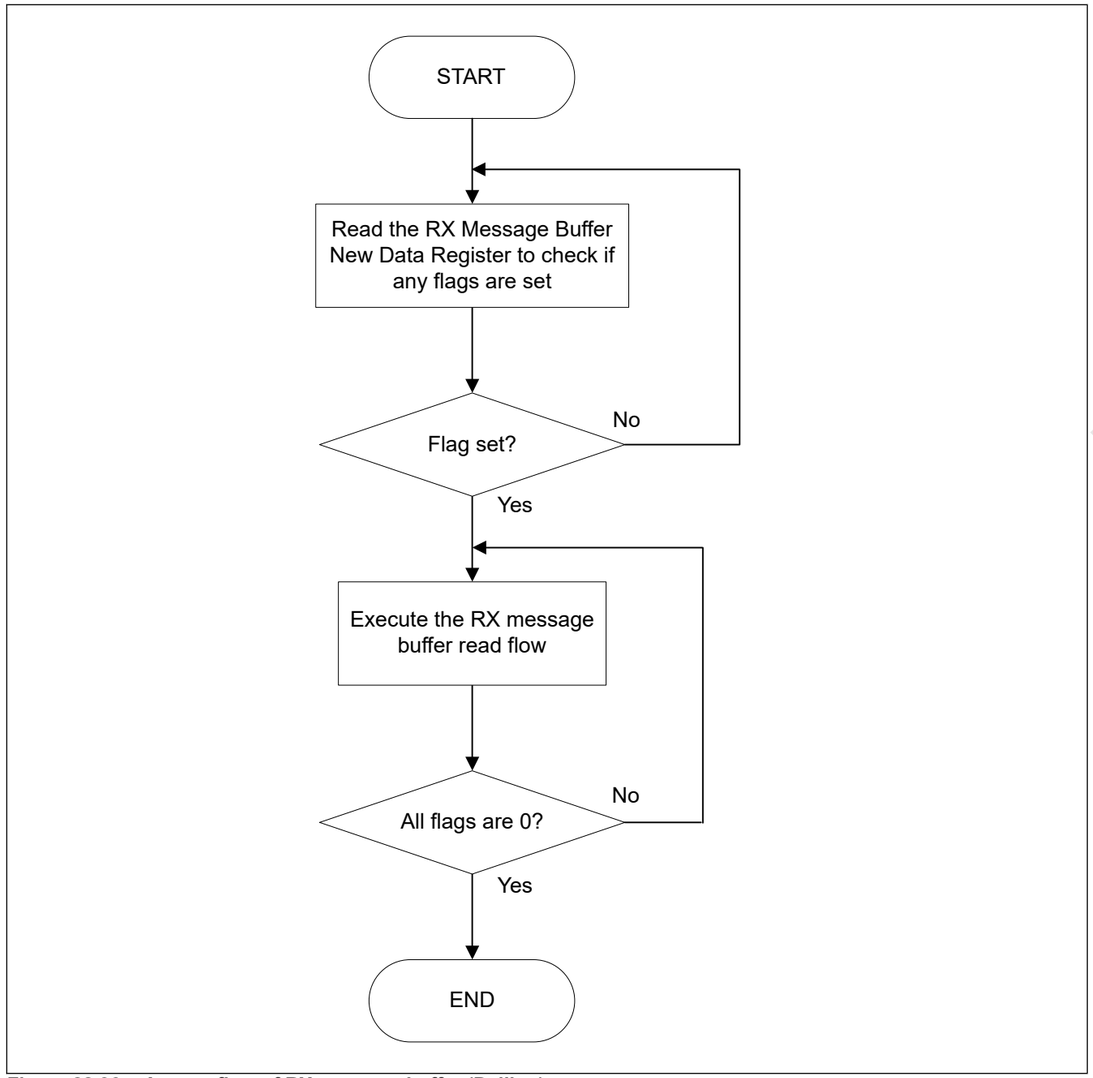

Figure 28.36 Access flow of RX message buffer (Polling)

28.8.1.1 RX消息缓冲区中的消息存储

当消息被成功接收并存储在RX消息缓冲区中时，相应的NewData标志在RX消息缓冲区新数据寄存器。

CAN报文可以从相应的RX报文缓冲区中读取。

如果在可以读取此消息缓冲区中的前一个消息之前将新消息存储到RX消息缓冲区中，则原始消息将被覆盖。没有机制可以防止新消息覆盖RX消息缓冲区中的当前消息。如果这样的消息丢失是不可接受的，则应使用RXFIFO来存储相关消息。

Note: 用户在使用中断时也应与现有软件流程进行相同的处理。（见图28.37）

Note: 未使用的数据字节根据DLC值填充为0x00。

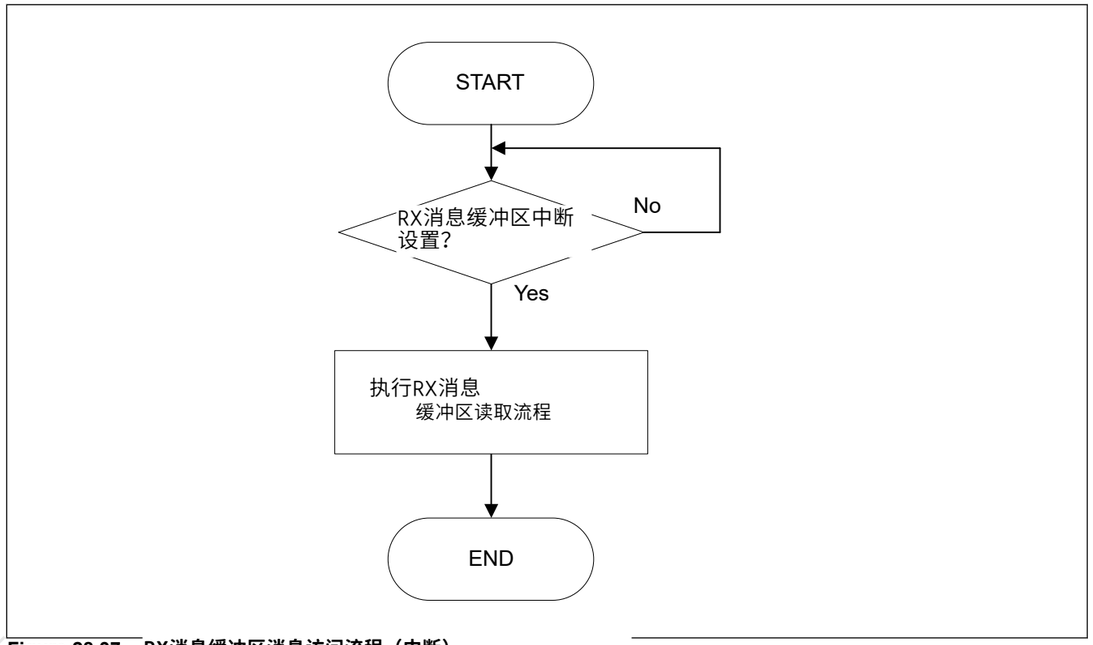

Figure 28.37 RX消息缓冲区消息访问流程（中断）

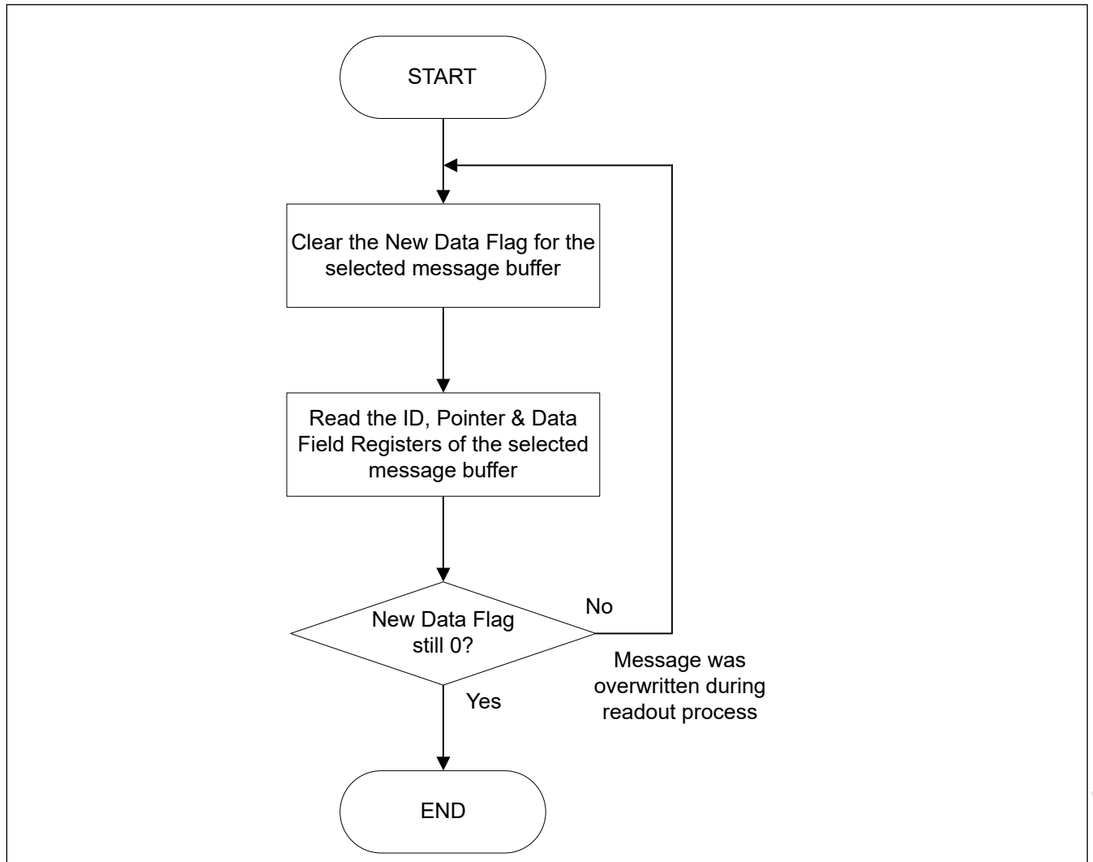

Figure 28.38 Read flow of RX message buffer

28.8.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to RX FIFO buffers or Common FIFO buffer configured in RX mode should be configured based on system requirements.

The CFDGAFLP1r.GAFLFDP[8,1:0] field in the matching AFL entry selects the FIFO buffers to which the related reception message is stored.

When the received message is stored in one or more RX FIFO buffers or Common FIFO buffer configured in RX mode, the message counter value is incremented in the corresponding RX FIFO Status Registers or Common FIFO Status Register.

Depending on the configuration of the FIFO buffers, an interrupt might also be generated.

The message can be read from the corresponding FIFO Access registers.

Note: Because many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, the FIFO Full flag is set.

When the value 0xFF is written to the corresponding FIFO Pointer Control Register, the message count is decremented by 1.

Only write 0xFF to the FIFO Pointer Control register after reading the complete message from the FIFO Access registers of the corresponding FIFO.

When all the messages stored in the FIFO are read, the FIFO Empty flag is set.

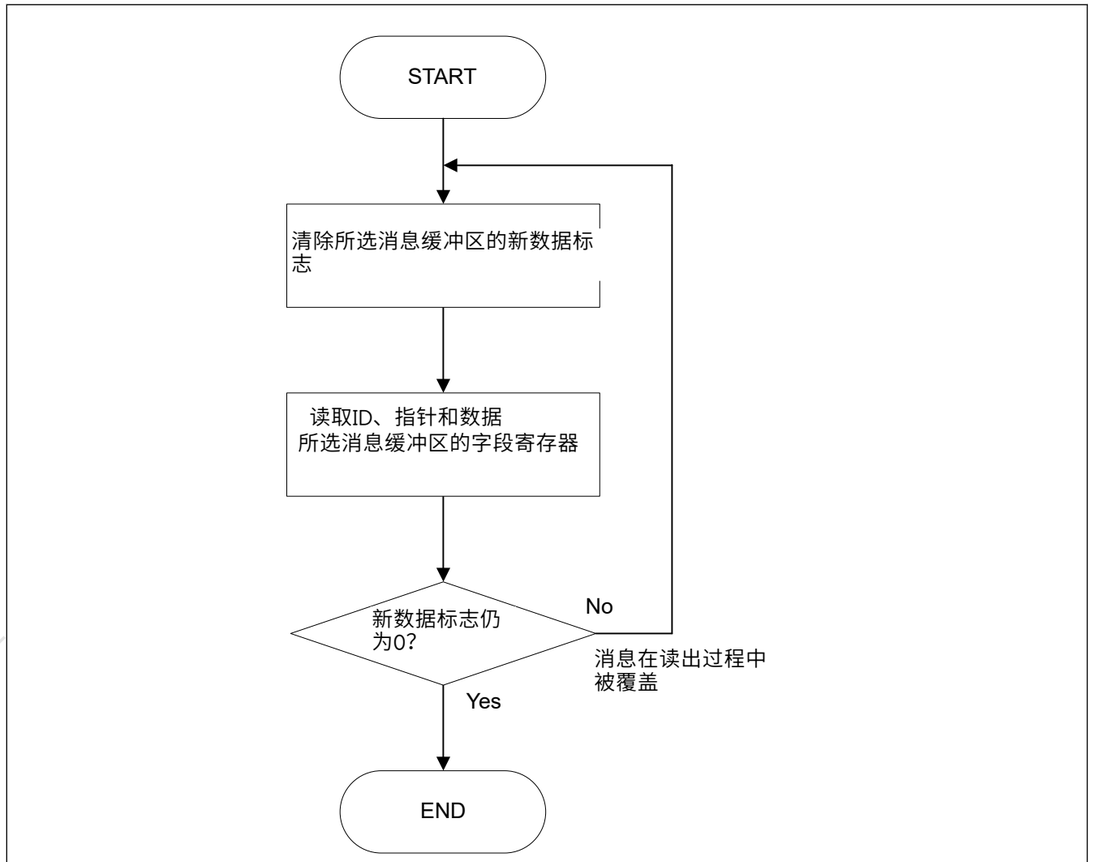

Figure 28.38 读取RX消息缓冲区的流程

28.8.1.2 FIFO缓冲区中的消息存储

将接收到的报文路由到RXFIFO缓冲区或配置为RX模式的CommonFIFO缓冲区的AFL条目应根据系统要求进行配置。

匹配AFL条目中的CFDGAFLP1r.GAFLFDP[8 1:0]字段选择存储相关接收消息的FIFO缓冲区。

当接收到的报文存储在一个或多个配置为RX模式的RXFIFO缓冲区或CommonFIFO缓冲区时，报文计数器值在相应的RXFIFO状态寄存器或CommonFIFO状态寄存器中递增。

根据FIFO缓冲区的配置，也可能会产生中断。

该消息可以从相应的FIFO访问寄存器中读取。

Note: 因为许多消息可以存储在FIFO缓冲区中，所以可能需要读取多个消息才能读取存储在FIFO缓冲区中的最新消息。

如果消息计数值与FIFO深度匹配，则设置FIFO满标志。

当值0xFF写入相应的FIFO指针控制寄存器时，消息计数减1。

仅在从相应FIFO的FIFO访问寄存器中读取完整报文后，将0xFF写入FIFO指针控制寄存器。

当读取存储在FIFO中的所有消息时，设置FIFOEmpty标志。

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

An appropriate value can be configured as warning level to generate an interrupt before the FIFO full condition occurs to avoid loss of a message due to an overrun condition.

Note: The message lost can be set only in RX mode by CAN, and the flag is not set when the CPU is overloading the FIFO buffers.

The RX FIFO buffers and the Common FIFO buffers configured in RX mode can be disabled at any time by clearing the CFDRFCCa.RFE or CFDCFCC.CFE bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

When the CFDRFCCa.RFE or CFDCFCC.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further messages can be stored into the FIFO.

When the RX FIFO buffers or Common FIFO buffer configured in RX mode is assigned as a DMA channel, software should not access the FIFO Access Register of this FIFO buffer or write 0xFF to the FIFO Pointer Control Register (CFDCFPCTR.CFPC or CFDRFPCTRa.RFPC). This can lead to unintended FIFO message decrement. The DMA channel controls the FIFO decrement automatically.

Note: If the interrupt flag is set for a FIFO buffer and then the FIFO is disabled, the interrupt flag is not cleared automatically. The interrupt flag should be cleared before disabling the FIFO.

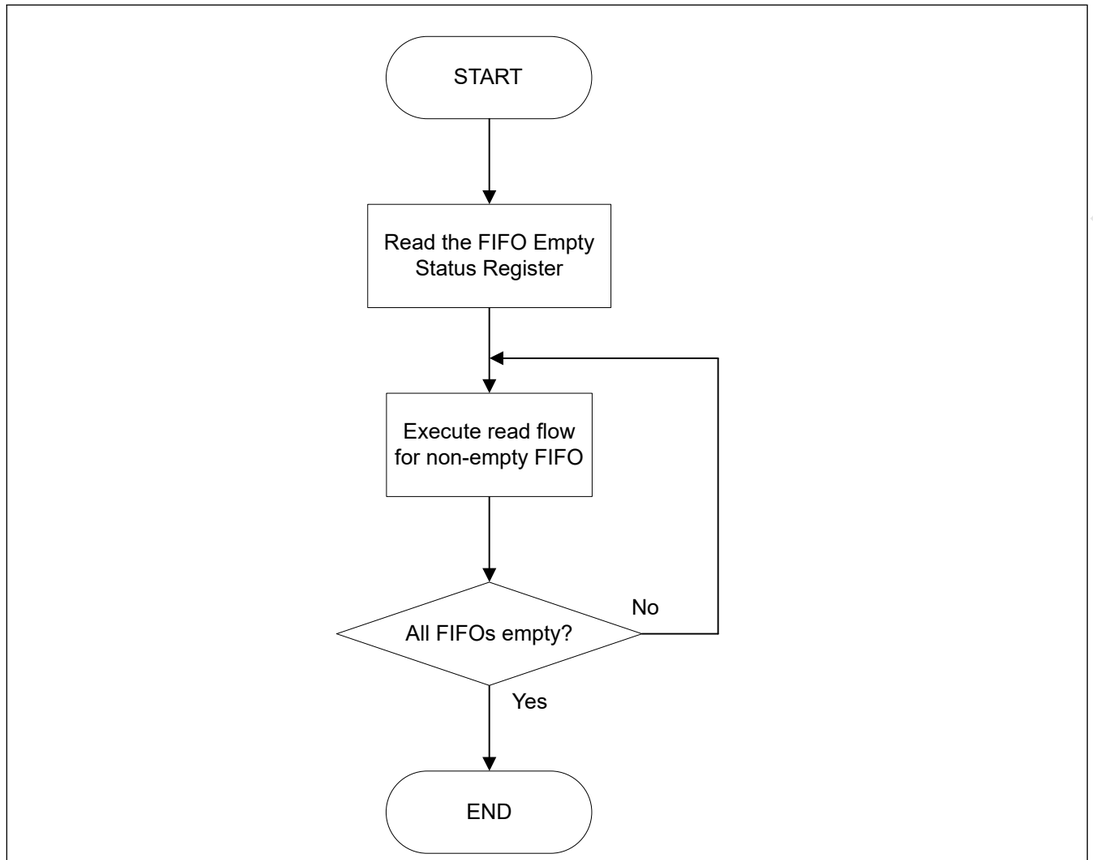

Figure 28.39 Access flow of FIFO buffer message (example for polling case)

如果在FIFO消息计数与FIFO深度匹配（FIFO满状态）时将新消息存储到FIFO，则
FIFO消息丢失标志被设置，新消息丢失（不会覆盖已存储的消息）。

可以将适当的值配置为警告级别，以在FIFO满情况发生之前生成中断，以避免由于溢出情况而丢失消息。

Note: 消息丢失只能在RX模式下由CAN设置，并且在CPU过载时不设置标志
FIFO buffers.

RXFIFO缓冲区和配置为RX模式的通用FIFO缓冲区可以通过清除
RXFIFO配置控制寄存器和通用FIFO中的CFDRFCCa.RFE或CFDCFCC.CFE位
Configuration/Control Registers.

当CFDRFCCa.RFE或CFDCFCC.CFE位清零时，FIFO的报文读写指针被清零，不再处于活动状态。因此，FIFO缓冲区中的所有消息都将丢失，并且无法将更多消息存储到FIFO中。

当RXFIFO缓冲区或配置为RX模式的通用FIFO缓冲区分配为DMA通道时，软件不应访问该FIFO缓冲区的FIFO访问寄存器或将0xFF写入FIFO指针控制寄存器（CFDCFPCTR.CFPC或CFDRFPCTRa.RFPC）.这可能导致意外的FIFO消息递减。DMA通道自动控制FIFO递减。

Note: 如果为FIFO缓冲区设置了中断标志，然后禁用了FIFO，则不会自动清除中断标志。在禁用FIFO之前应清除中断标志。

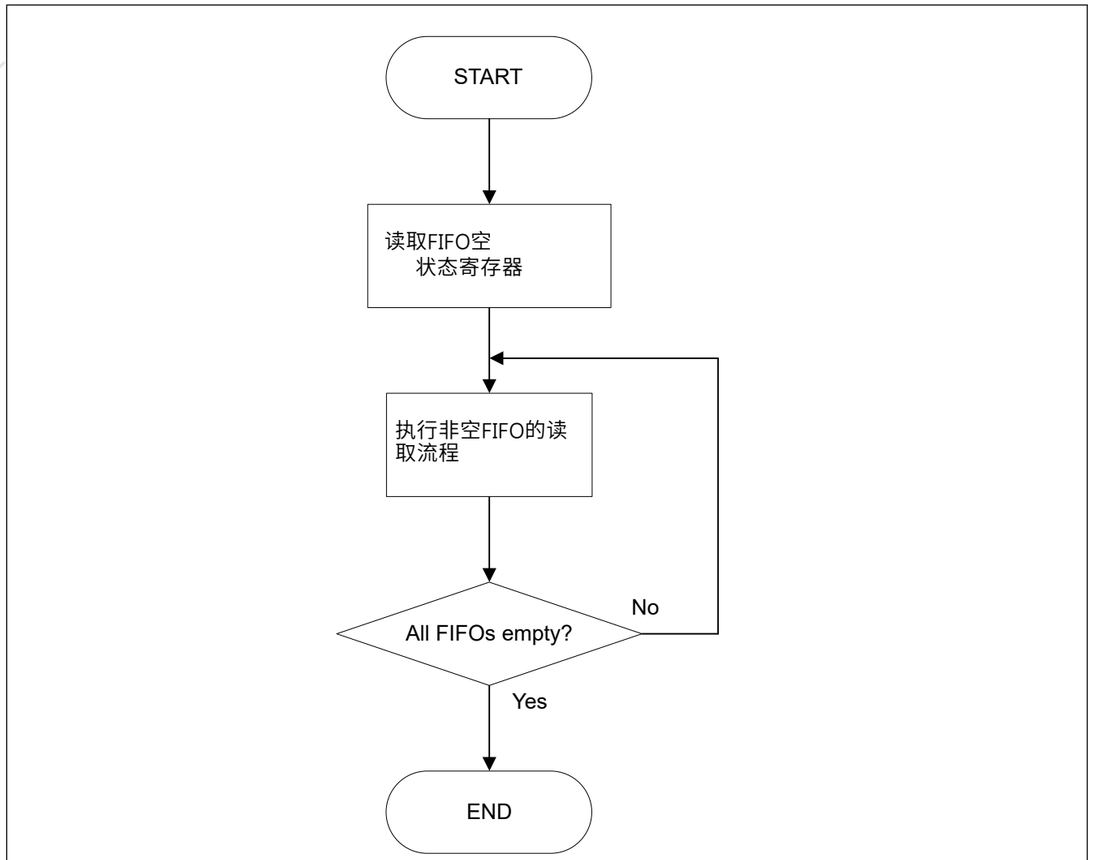

Figure 28.39 FIFO缓冲报文的访问流程（以轮询为例）

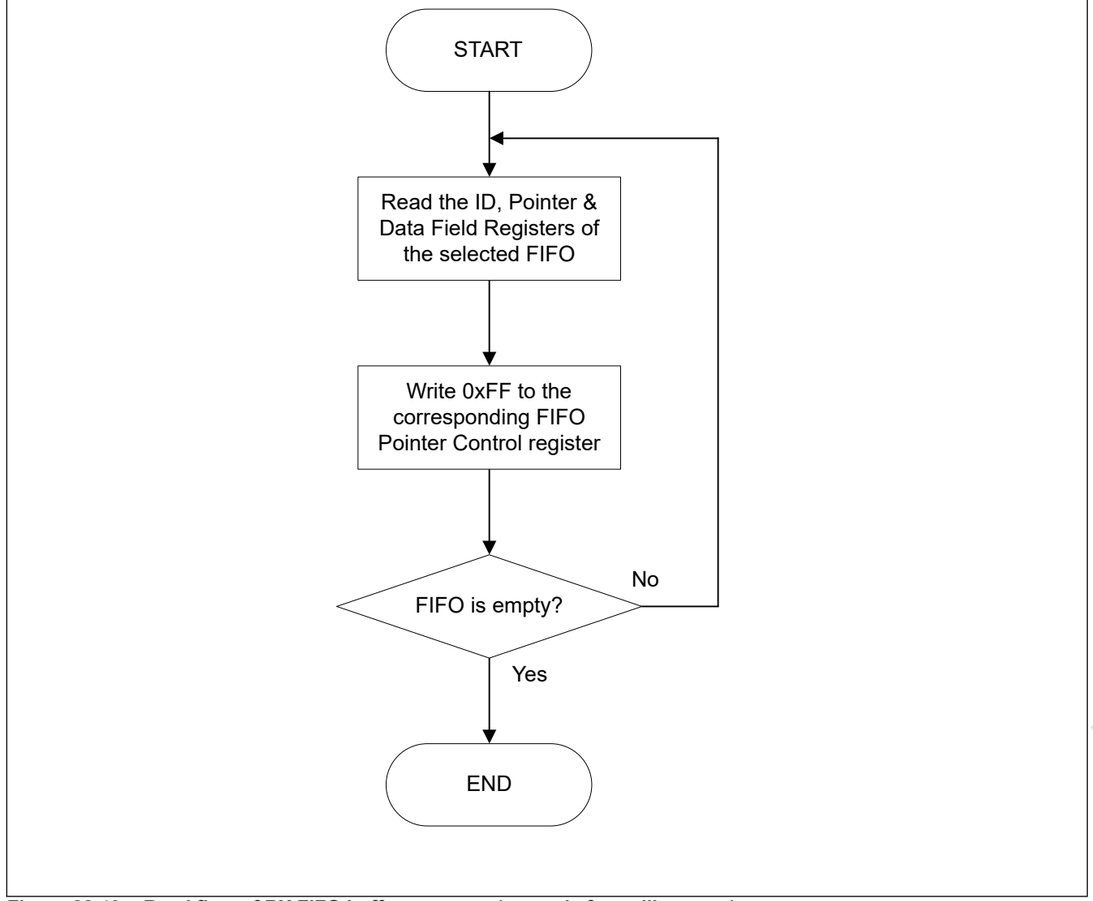

Figure 28.40 Read flow of RX FIFO buffer message (example for polling case)

Note: When the next frame is received before clearing the completion interrupt flag of reception, the completion interrupt of reception is not set again.

Even when an interruption flag is cleared after the completion processing of reception, the already received interrupt flag is not set.

It is necessary to perform the completion processing of reception even before the next completion of frame reception, and to clear an interruption flag.

When processing does not meet the condition, after checking that receiving data is empty, interrupt flag is cleared and it checks that receiving data is empty again.

28.8.1.3 Timestamp

The timestamp counter is a free-running counter that can be used to check reception time of an incoming message or transmission time of successful transmitted messages. The Timestamp counter value is captured based on the CFDGFDCFG.TSCCFG[1:0] configuration (at the sample point of start of frame, point in time when the frame is valid, or for CANFD frames also at the sample point of the RES bit). For reception, it is stored together with the message ID and data into the target RX message buffer or RX FIFO.

For transmit message, the timestamp counter value is stored as part of the TX History List entry.

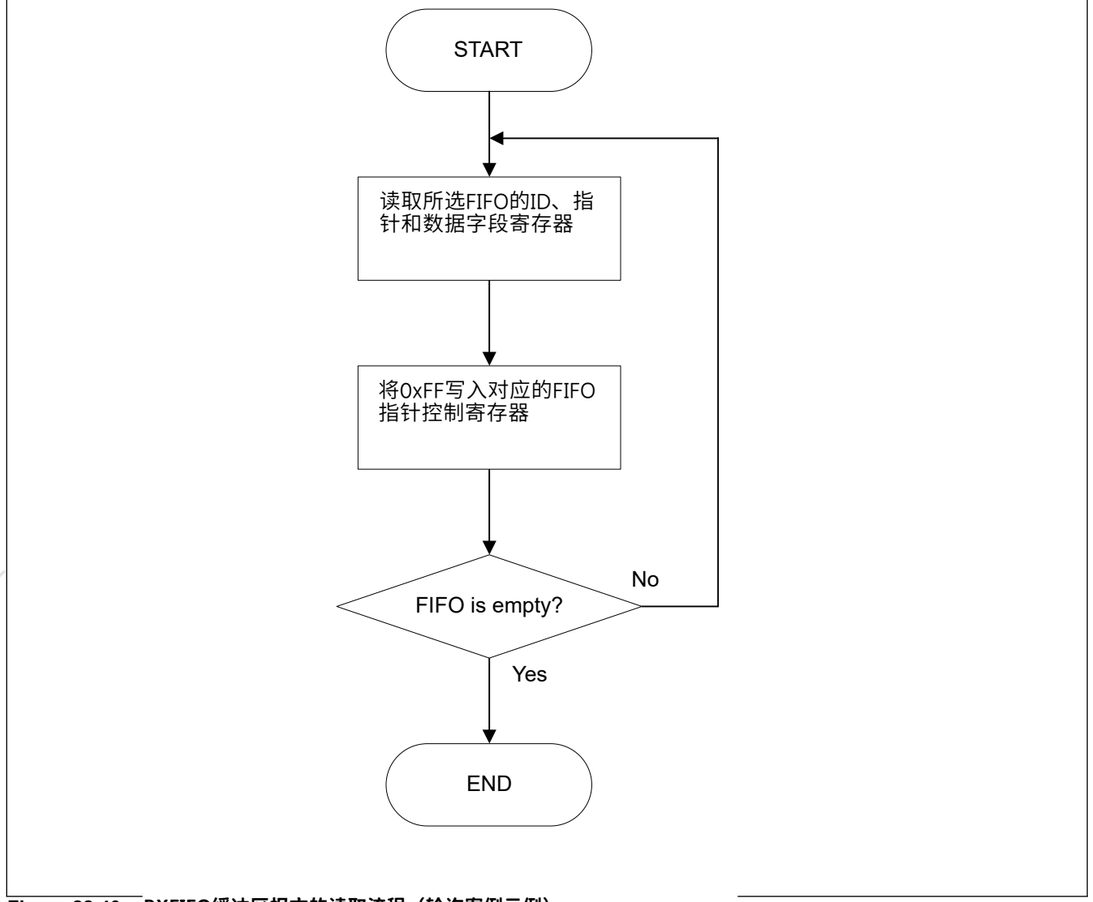

Figure 28.40 RXFIFO缓冲区报文的读取流程（轮询案例示例）

Note: 在清除接收完成中断标志之前接收到下一帧时，不再设置接收完成中断。

即使在接收完成处理后清除中断标志，已接收中断标志也不会置位。

甚至在下一次帧接收完成之前也需要执行接收完成处理，并清除中断标志。

当处理不满足条件时，检查接收数据为空后，清除中断标志，再次检查接收数据是否为空。

28.8.1.3 Timestamp

时间戳计数器是一个自由运行的计数器，可用于检查传入消息的接收时间或成功传输消息的传输时间。Timestamp计数器值是根据CFDGFDCFG.TSCCFG[1:0]配置捕获的（在帧开始的采样点、帧有效的时间点，或者对于CANFD帧也在RES位的采样点）。对于接收，它与消息ID和数据一起存储到目标RX消息缓冲区或RXFIFO中。

对于发送消息，时间戳计数器值存储为TX历史列表条目的一部分。

The counter can be clocked with the peripheral clock or with the CAN channel bit timing clock. The counter source clock can be configured with the CFDGCFG.TSSS bit of the Global Configuration Register. If this bit is 0, the peripheral clock is used. If the bit is 1, the selected CAN channel bit time clock is used.

The channel selection is performed with the CFDGCFG.TSBTCS bit of the Global Configuration Register.

Care must be taken when using selected CAN channel bit time clock as the clock source. When entering Channel Halt mode or Channel Reset node, for this channel, the timestamp counter is stopped. For other CAN channels, the timestamp counter value is not updated.

If peripheral clock is selected as the timestamp counter clock source, Channel modes do not affect the timestamp counter function.

The source clock for the timestamp counter can be divided by a factor defined by the CFDGCFG.TSP bits (timestamp prescaler) in the Global Configuration Register.

The timestamp counter can be reset to 0x0000 with the CFDGCTR.TSRST bit (timestamp reset).

28.8.2 Transmission

There are several possible transmission configurations:

- Normal transmission
- FIFO transmission
- TX Queue transmission
  A fixed number of transmission message buffers (4 TX message buffers) are dedicated. These message buffers are only used for transmission and cannot be configured for reception.
  Additionally transmission from TX Queue or Common FIFO in TX mode can be configured in the following way (see Figure 28.41):
  – TX Queue: Up to four transmission message buffers can be grouped to form a TX Queue with a common access window.
    Upper transmission message buffers are used to form the TXQ.
    TXQ has an access window.
    • TXQ is transmission Message Buffer 0.
- Common FIFO (TX mode): Common FIFO in TX mode is linked to a dedicated channel.
  Channel has a fixed number of one Common FIFO assigned to it. Within the channel, a Common FIFO configured in TX mode, can be freely linked (assigned) between 0 and 3 transmission message buffers (only one FIFO to one transmission message buffer).
  The Common FIFO buffer then replaces the transmission message buffer linked to it.
  Transmission Control and Status registers of these transmission message buffers should not be used.

See Figure 28.29 for information about Common FIFO buffer assignment to related channel.

Note: Common FIFO buffer should not be linked to TX message buffers that are already part of a TX Queue.

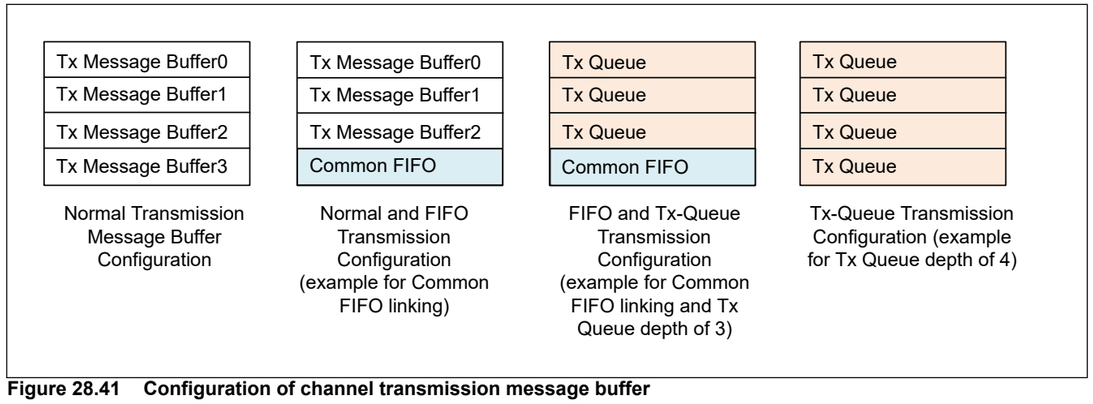

Figure 28.41 Configuration of channel transmission message buffer

计数器可以使用外设时钟或CAN通道位定时时钟进行计时。计数器源时钟可以通过全局配置寄存器的CFDGCFG.TSSS位进行配置。如果该位为0，则使用外设时钟。如果该位为1，则使用选定的CAN通道位时钟。

通道选择通过全局配置寄存器的CFDGCFG.TSBTCS位执行。

使用选定的CAN通道位时钟作为时钟源时必须小心。当进入ChannelHalt模式或ChannelReset节点时，对于该通道，时间戳计数器停止。对于其他CAN通道，时间戳计数器值不会更新。

如果选择外设时钟作为时间戳计数器时钟源，通道模式不影响时间戳计数器功能。

时间戳计数器的源时钟可以除以全局配置寄存器中的CFDGCFG.TSP位（时间戳预分频器）定义的因子。

时间戳计数器可通过CFDGCTR.TSRST位（时间戳复位）复位为0x0000。

28.8.2 Transmission

有几种可能的传输配置：

●正常传输

- FIFO transmission

●TX队列传输
固定数量的传输消息缓冲区（4个TX消息缓冲区）是专用的。这些消息缓冲区仅用于传输，不能配置为接收。
此外，在TX模式下从TXQueue或CommonFIFO进行的传输可以通过以下方式进行配置（请参阅

Figure 28.41):

TXQueue：最多可以将四个传输消息缓冲区分组以形成具有公共访问窗口的TXQueue。上层传输消息缓冲区用于形成TXQ。

TXQ有一个访问窗口。

- TXQ是传输消息缓冲区0。

●CommonFIFO（TX模式）：TX模式下的CommonFIFO链接到一个专用通道。
通道有一个固定数量的分配给它的通用FIFO。在通道内，配置了一个通用FIFO TX模式，可以在0到3个传输报文缓冲区（只有1个FIFO到1个传输报文缓冲区）之间自由链接（分配）。通用FIFO缓冲区然后替换链接到它的传输消息缓冲区。

不应使用这些传输消息缓冲区的传输控制和状态寄存器。

有关分配给相关通道的通用FIFO缓冲区的信息，请参见图28.29。

Note: 公共FIFO缓冲区不应链接到已经是TX队列一部分的TX消息缓冲区。

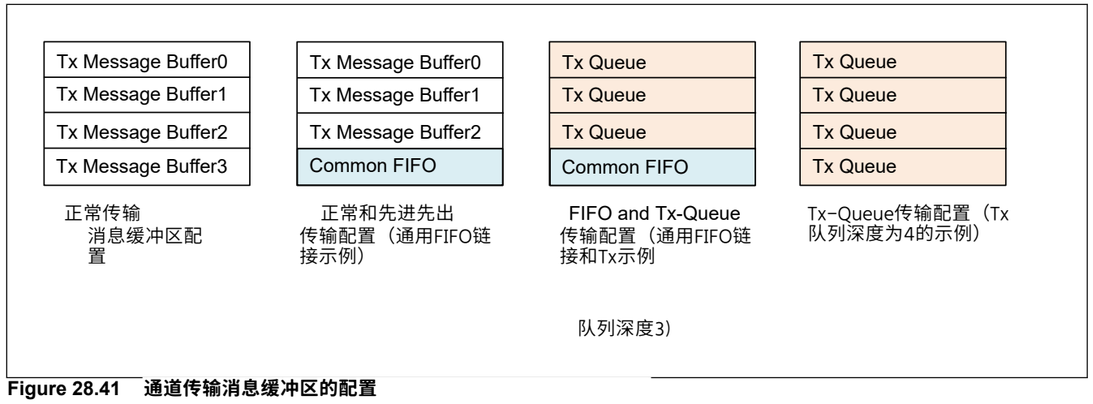

Figure 28.41 通道传输消息缓冲区的配置

28.8.2.1 Transmission Priority

If two or more transmission message buffers of a channel are configured for transmission, then the transmission priority in the CANFD module can be selected from the following two modes:

- CAN ID priority
- Message buffer number priority.

The transmission priority mode is common for all message buffers. It can be configured with the CFDGCFG.TPRI bit in the Global Configuration Register.

For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the TX message buffers linked to the Common FIFO buffer configured in TX mode.

However, message buffer number priority should not be used if TX Queue is enabled.

For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All TX message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the TX message buffers linked to the Common FIFO buffer configured in TX mode and includes the TX Queue message buffers.

If the ID of two or more message buffers is the same, then the smaller message buffer number has higher priority for transmission.

Note: For Common FIFO buffer configured in TX mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.

If the message is being transmitted from the FIFO, then the next pending message within the same FIFO is considered in the transmission arbitration.

In contrast to this, all transmission message buffers of a TX Queue participate in internal transmission arbitration.

Figure 28.42 shows the transmission configuration flow.

28.8.2.1 传输优先级

如果配置了一个通道的两个或多个传输报文缓冲区进行传输，则CANFD模块中的传输优先级可以从以下两种模式中选择：

●CANID优先级

●消息缓冲区编号优先级。

传输优先模式对所有消息缓冲区都是通用的。它可以用CFDGCFG.TPRI位在全局配置寄存器。

对于消息缓冲区号优先传输，具有传输请求的最小消息缓冲区号具有最高传输优先级。这还包括链接到在TX模式下配置的CommonFIFO缓冲区的TX消息缓冲区。

但是，如果启用了TXQueue，则不应使用消息缓冲区编号优先级。

对于CANID优先级传输，ID优先级符合CAN总线仲裁规则（在ISO11898-1规范中指定）。所有TX报文缓冲区都可以进入配置为传输的报文缓冲区的ID优先级比较。这还包括链接到在TX模式下配置的CommonFIFO缓冲区的TX消息缓冲区，并包括TXQueue消息缓冲区。

如果两个或多个消息缓冲区的ID相同，则较小的消息缓冲区号具有较高的传输优先级。

Note: 对于配置为TX模式的CommonFIFO缓冲区，只有FIFO读指针当前指向的报文可以包含在传输仲裁中。

如果消息是从FIFO传输的，则在传输仲裁中考虑同一FIFO中的下一个待处理消息。

与此相反，TXQueue的所有传输消息缓冲区都参与内部传输仲裁。

图28.42显示了传输配置流程。

28.8.2.2 Normal Transmission

Each transmission message buffer has two modes of message transmission:

1. Regular transmission mode
   If the message buffer is placed in regular transmission mode, the data frame or remote frame set in that message buffer can be transmitted.
   Completion of regular transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSj.TMTRF) in the TX Message Buffer Status Registers. These bits are set to 10b or 11b when the regular transmission is successful.

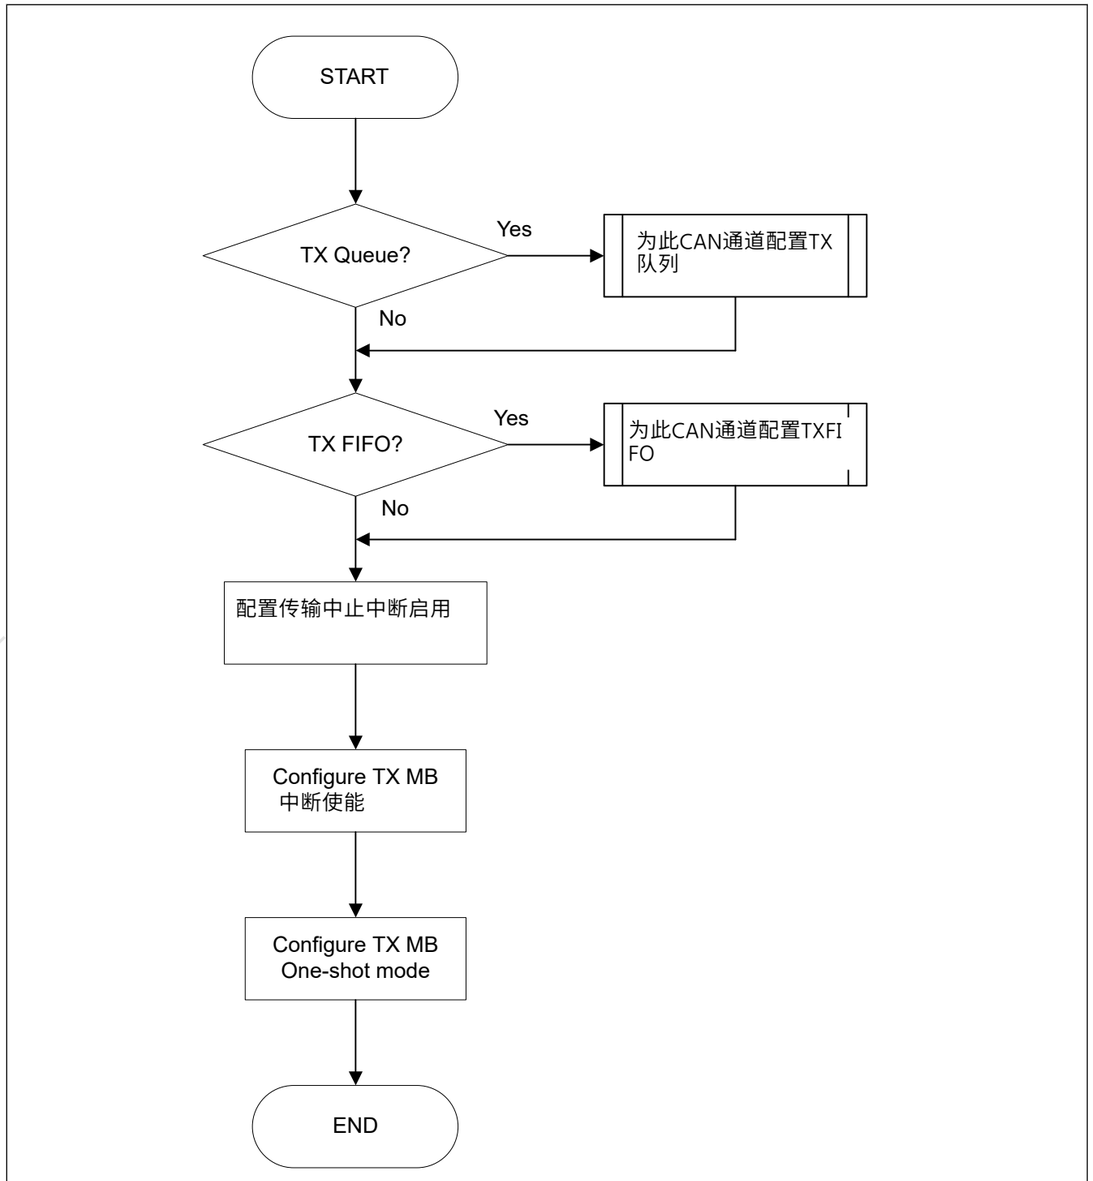

Figure 28.42 传输配置流程

28.8.2.2 正常传输

每个传输消息缓冲区有两种消息传输模式：

1.常规传输方式
如果将消息缓冲区置于常规传输模式，则可以传输该消息缓冲区中设置的数据帧或远程帧。可以通过TX报文缓冲区状态寄存器中相关的TX报文缓冲区传输结果标志位(CFDTMSTSj.TMTRF)来检查是否完成了定期传输。当常规传输成功时，这些位设置为10b或11b。

When arbitration is lost or an error occurs, message transmission is further attempted if no transmission abort request is set for this transmission message buffer.
New internal transmission arbitration for this channel is performed for all message buffers with transmission request.

2. One-shot transmission mode

When the CFDTMCi.TMOM bit of the TX Message Buffer Control Registers is set for a transmission message buffer, the message buffer is placed in One-shot transmission mode and attempts to transmit a message only once.

Completion of One shot transmission can be checked through the related TX Message Buffer Transmission Result Flag bits (CFDTMSTSj.TMTRF) in the TX Message Buffer Status Registers. The CFDTMSTSj.TMTRF bits are set to 10b or 11b when One-shot transmission is successful.

The CFDTMSTSj.TMTRF bits are set to 01b when arbitration is lost or an error occurs during transmission of the related message buffer.

Additional message transmission is not attempted in this case.

The regular transmission request procedure after a configuration is shown in Figure 28.43.

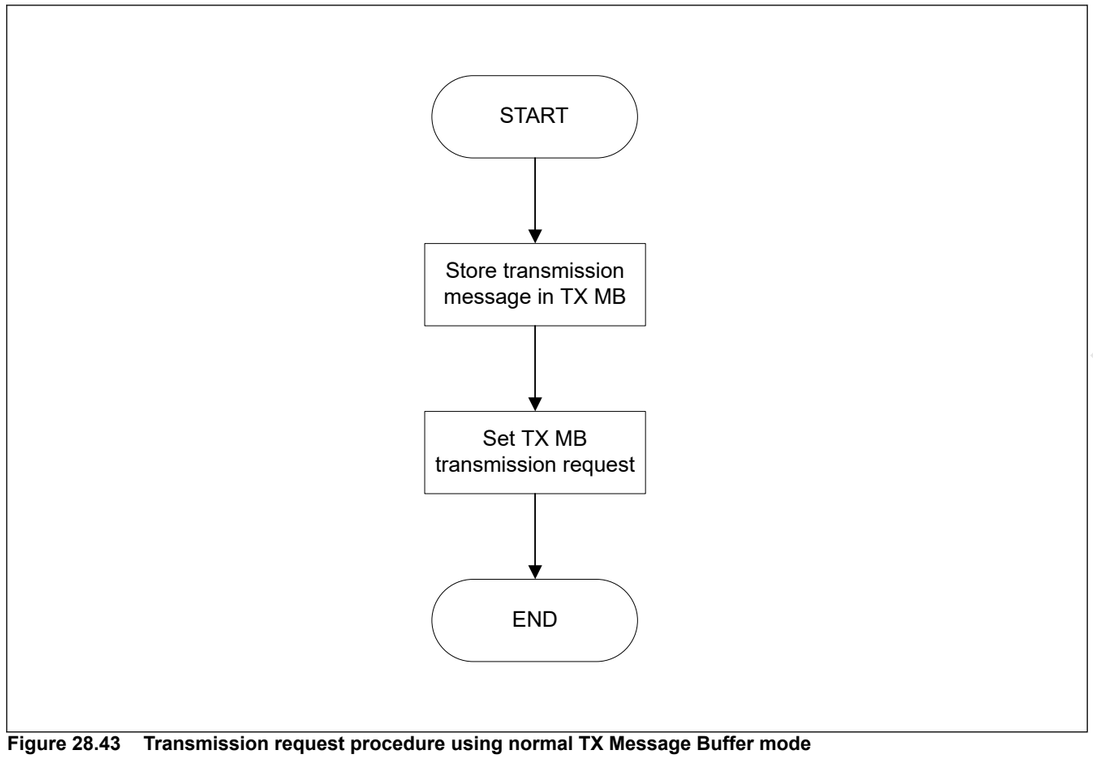

Figure 28.43 Transmission request procedure using normal TX Message Buffer mode

Table 28.27 shows configuration of a normal CAN transmission mode.

Transmission request CFDTMCi.TMTR	Transmission abort request CFDTMCi.TMTAR	One-shot enable CFDTMCi.TMOM	Communication activity
0	0	0	Message buffer disabled
0	0	1	Message buffer disabled

当仲裁丢失或发生错误时，如果没有为此发送消息缓冲区设置发送中止请求，则进一步尝试发送消息。该通道的新内部传输仲裁针对所有具有传输请求的消息缓冲区执行。

2.一键传输模式

当TX报文缓冲区控制寄存器的CFDTMCi.TMOM位设置为发送报文缓冲区时，报文缓冲区被置于一次性发送模式，并且仅尝试发送一次报文。

可以通过TX报文缓冲区状态寄存器中的相关TX报文缓冲区传输结果标志位(CFDTMSTSj.TMTRF)检查Oneshot传输是否完成。当One-shot传输成功时，CFDTMSTSj.TMTRF位设置为10b或11b。

当仲裁丢失或在相关消息缓冲区的传输过程中发生错误时，CFDTMSTSj.TMTRF位设置为01b。

在这种情况下，不会尝试额外的消息传输。

配置后的常规传输请求流程如图28.43所示。

设置状态寄存器（发送发送器），CAN通道开始发送*1。

2.在CRC的第一位，当存在未决的传输请求时，传输扫描程序开始为下一个可能的传输。

Note: The setting point of CFDTMSTSj.TMTSTS is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID due to the synchronization logic implemented for the PLL bypass.

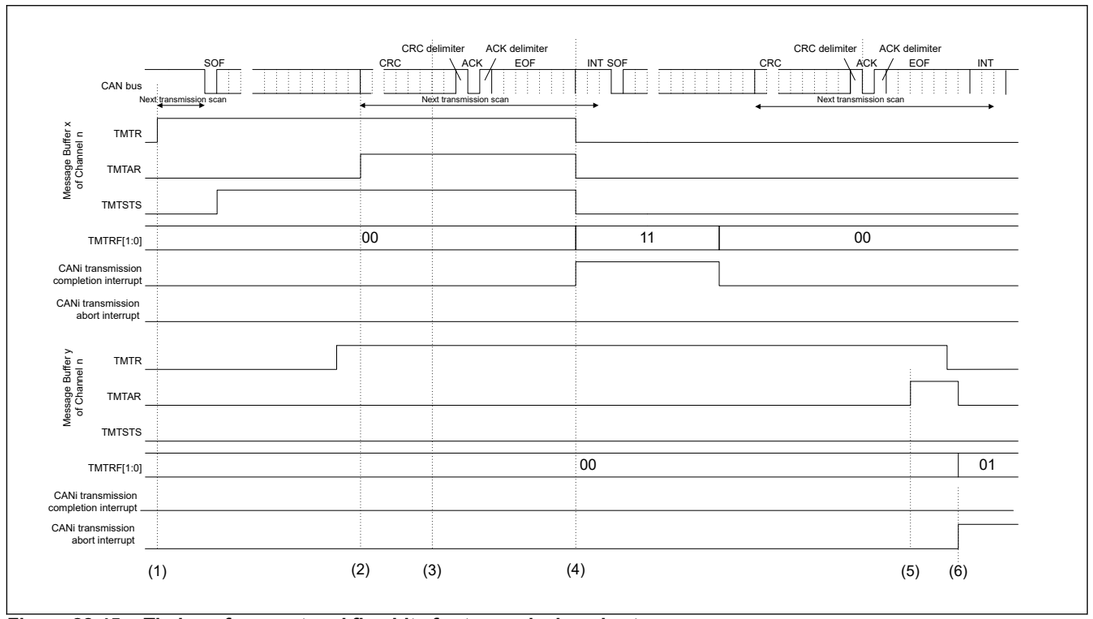

Figure 28.45 Timing of request and flag bits for transmission abort

1. If the CFDTMCi.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, the message buffer scanning procedure determines the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSj.TMTSTS bit in the TX Message Buffer Status Registers is set (transmitting/transmitter), and CAN channel starts the transmission*1.
2. If the CFDTMCi.TMTAR bit is set when the related message buffer is already selected for transmission or currently transmitting, the message is not aborted, if no error occurs or arbitration is lost.
3. At the first CRC bit, the transmission scanning procedure starts for the next transmission. In this example, timing chart message buffer y is not selected as the next transmission message buffer.
4. If the message has been successfully transmitted, the CFDTMSTSj.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 11b and the CFDTMSTSj.TMTSTS and CFDTMCi.TMTR bits are cleared.
   When the TMIE bit in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSj.TMTRF[1:0] bits.
5. Another CAN node is transmitting on the CAN bus (CFDTMSTSj.TMTSTS is not set). If the CFDTMCi.TMTAR bit is set when the related channel is under transmission scan, the transmission request cannot be cleared.
6. After internal processing time, the transmission is aborted and the CFDTMSTSj.TMTRF[1:0] bits are set to 01b.
   If the message buffer is not transmitting or selected as the next transmission message buffer or under transmit scan, then the abort is immediately accepted and the corresponding CFDTMSTSj.TMTRF[1:0] bits in the TX Message Buffer Status Registers are set to 01b.
   In addition, CFDTMCi.TMTR, and CFDTMCi.TMTAR bits are cleared automatically.
   When the transmission abort interrupt enable TAIE bit of the related Channel Control Register is set then an interrupt is generated for successful transmission abort.
   To clear the related interrupt line the CFDTMSTSj.TMTRF[1:0] bits have to be cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSj.TMTSTS bit is cleared.

Note: CFDTMSTSj.TMTSTS的设定点并不总是固定在SOF的开始处。由于为PLL旁路实现的同步逻辑，它可能会延迟到标准ID的开始。

4.如果报文已成功发送，则相应的TX报文缓冲区状态寄存器中的CFDTMSTSj.TMTRF[1:0]位设置为11b，CFDTMSTSj.TMTSTS和CFDTMCi.TMTR位清零。

CAN成功传输中断请求产生。
要清除相关中断线，请清除CFDTMSTSj.TMTRF[1:0]位。

5.另一个CAN节点正在CAN总线上传输（CFDTMSTSj.TMTSTS未设置）。如果CFDTMCi.TMTAR位在相关通道处于发送扫描状态时被置位，则发送请求不能被清除。

6.内部处理时间过后，发送中止，CFDTMSTSj.TMTRF[1:0]位设置为01b。
如果报文缓冲区未发送或未选择作为下一个发送报文缓冲区或正在发送扫描，则立即接受中止并将TX报文缓冲区状态寄存器中的相应CFDTMSTSj.TMTRF[1:0]位设置为01b。

此外，CFDTMCi.TMTR和CFDTMCi.TMTAR位会自动清零。
当相关通道控制寄存器的发送中止中断使能位TAIE置位时，将产生中断以成功发送中止。要清除相关的中断线，必须清除CFDTMSTSj.TMTRF[1:0]位。

注1.如果CAN通道开始传输后仲裁丢失，CFDTMSTSj.TMTSTS位被清零。

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs, either during transmission, or following the loss of arbitration, then during the error frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

28.8.2.3 TX FIFO Transmission

One common FIFO buffer is assigned to CANFD module. The FIFO buffer can be linked to any normal TX message buffer position for this channel with the CFDCFCC.CFTML bits in the Common FIFO Configuration/Control Register if configured in TX mode.

When the transmission scan starts and the FIFO buffer corresponding to this TX message buffer is enabled, the relevant message in the FIFO buffer participates in the transmission scan.

Configuration of a TX message buffer linked to a FIFO buffer configured in TX mode should not be done.

(1) TX FIFO Operation

CAN messages can be written into the TX FIFO by writing to the corresponding FIFO Access registers.

When the value 0xFF is written into the corresponding FIFO Pointer Control Register, the message count of the related FIFO is incremented by 1.

Only write to the FIFO Pointer Control register after writing the complete message to the corresponding FIFO Access registers. If the message count matches the FIFO depth, the FIFO Full flag is set.

The oldest message in the TX FIFO is included in the scan for transmission by the corresponding CANFD module channel logic.

When a message is successfully transmitted from the TX FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the FIFO Empty flag is set.

The interrupt generation conditions for the TX FIFO buffer can be configured by configuring the CFDCFCC.CFIM bit in the corresponding Common FIFO Configuration/Control Register.

If CFDCFCC.CFIM bit is 0, then interrupt is generated when the last message is successfully transmitted from the TX FIFO buffer.

If CFDCFCC.CFIM bit is 1, then interrupt is generated for every successfully transmitted message from the TX FIFO buffer.

The Common FIFO can set interrupt when CAN frame transmission is complete.

The Common FIFO buffer configured in TX Mode can be disabled by clearing the CFDCFCC.CFE bit in the Common FIFO Configuration/Control Register. If this bit is cleared to 0, the FIFO Empty flag is set as follows:

- Immediately if the message from the TX FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX FIFO is already scheduled for transmission or already in transmission.

Note: The Common FIFO buffer is considered as disabled after clearing the CFDCFCC.CFE bit only when the Empty flag is set for the corresponding Common FIFO buffer.

Other possible messages pending from the TX FIFO are lost and their transmission must be requested again. Before CFDCFCC.CFE is set again, ensure that CFDCFSTS.CFEMP bit is set and that there are no pending abort from the TX FIFO.

When the CFDCFCC.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after configuration is shown in Figure 28.46.

再次执行传输扫描程序，以从第一个CRC位的开头搜索最高优先级的传输消息缓冲区。

如果在传输过程中或在仲裁失败之后发生错误，则在错误帧期间，再次执行传输扫描程序以搜索最高优先级的传输消息缓冲区。

28.8.2.3 TX FIFO Transmission

为CANFD模块分配了一个通用FIFO缓冲区。如果配置为TX模式，则FIFO缓冲区可以通过通用FIFO配置控制寄存器中的CFDCFCC.CFTML位链接到该通道的任何正常TX消息缓冲区位置。

当发送扫描开始并且与该TX报文缓冲区对应的FIFO缓冲区使能时，FIFO缓冲区中的相关报文参与发送扫描。

不应配置链接到在TX模式下配置的FIFO缓冲区的TX消息缓冲区。

(1) TX FIFO Operation

通过写入相应的FIFO访问寄存器，可以将CAN消息写入TXFIFO。

当值0xFF被写入对应的FIFO指针控制寄存器时，相关的报文计数
FIFO加1。

仅在将完整消息写入相应的FIFO访问寄存器后才写入FIFO指针控制寄存器。如果消息计数与FIFO深度匹配，则设置FIFO满标志。

TXFIFO中最旧的消息包含在相应CANFD模块通道逻辑的传输扫描中。

当一条消息从TXFIFO成功发送时，消息计数值减1。当FIFO中的所有消息都发送完毕时，FIFO空标志置位。

TXFIFO缓冲区的中断生成条件可以通过配置相应通用FIFO配置控制寄存器中的CFDCFCC.CFIM位来配置。

如果CFDCFCC.CFIM位为0，则当最后一条消息从TXFIFO缓冲区成功发送时，将产生中断。

如果CFDCFCC.CFIM位为1，则从TXFIFO缓冲区中成功发送的每个消息都会产生中断。

当CAN帧传输完成时，CommonFIFO可以设置中断。

在TX模式下配置的CommonFIFO缓冲区可以通过清除Common中的CFDCFCC.CFE位来禁用
FIFO配置控制寄存器。如果该位清0，FIFO空标志设置如下：

●如果来自TXFIFO的消息既没有安排下一次传输也没有在传输中，则立即执行

●传输完成后，检测到CAN总线错误、仲裁丢失或转换到
如果来自TXFIFO的传输已被安排传输或已在传输中，则为通道或全局暂停模式。

Note: 仅当为相应的CommonFIFO缓冲区设置Empty标志时，在清除CFDCFCC.CFE位后，CommonFIFO缓冲区才被视为禁用。

来自TXFIFO的其他可能未决消息丢失，必须再次请求它们的传输。前
再次设置CFDCFCC.CFE，确保设置了CFDCFSTS.CFEMP位并且没有来自TX的挂起中止
FIFO.

当CFDCFCC.CFE位清零时，FIFO的报文读写指针被清零，不再处于活动状态。因此，FIFO缓冲区中的所有消息都将丢失，并且无法将更多消息存储到FIFO中。

配置后的FIFO发送请求流程如图28.46所示。

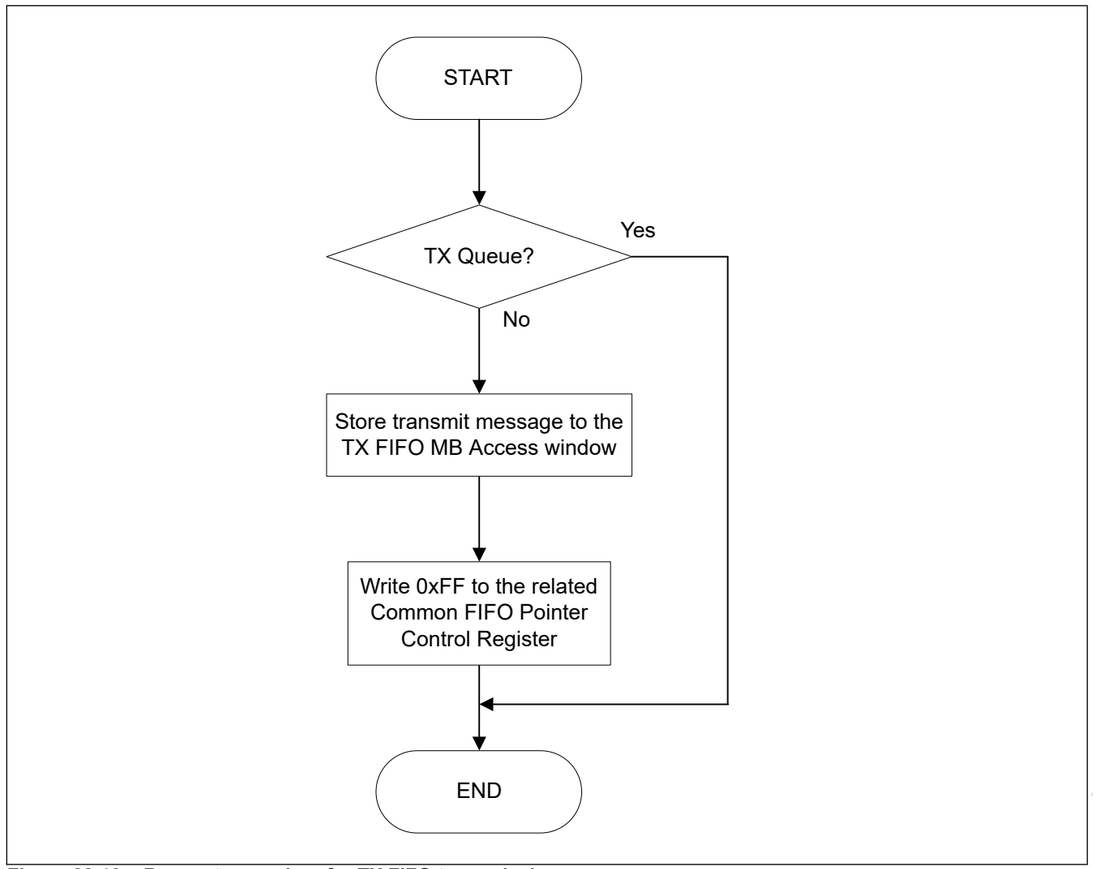

Figure 28.46 Request procedure for TX FIFO transmission

(2) Interval Timer for FIFO Transmission

For each Common FIFO in TX mode, it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFDCFCC.CFE bit is set.

When the Common FIFO in TX mode is enabled, the first message is transmitted without considering this interval time.

The interval timer stops counting when:

- FIFO is disabled by clearing the CFDCFCC.CFE bit.
- CAN channel is in CH_RESET mode.

The interval time is specified by the CFDCFCC.CFITT value from 0 to 255 timer units in the Common FIFO Configuration/ Control Register.

The timer unit can be defined based on two different source clocks for the interval timer. To disable the interval timer for FIFO transmission, select a value of 0.

The timer source can be selected with the configuration bit CFITSS in the Common FIFO Configuration/Control Register.

If CAN channel bit time clock is configured as the clock source, and the CAN channel enters CH_HALT, CH_RESET, or CH_SLEEP mode, the interval timer is stopped for that channel.

If peripheral clock is selected as the interval timer clock source, the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.

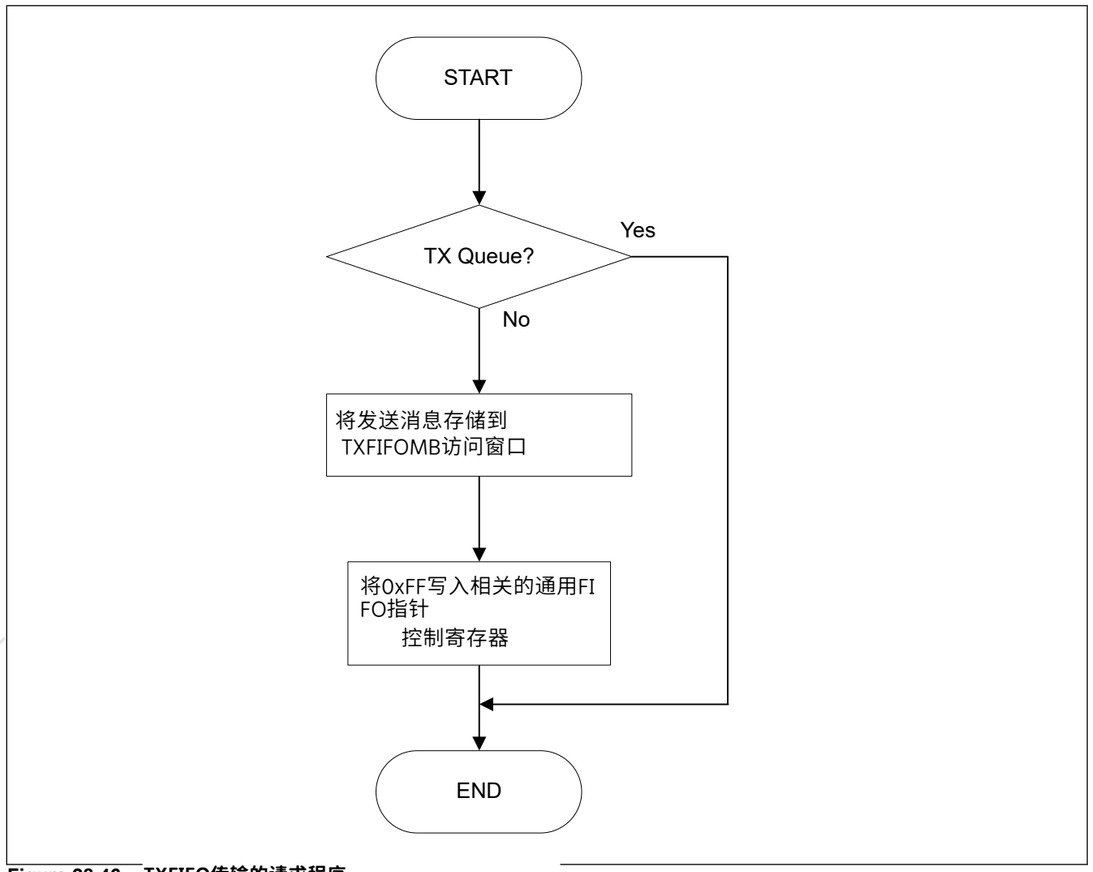

Figure 28.46 TXFIFO传输的请求程序

(2) FIFO传输间隔定时器

对于TX模式下的每个CommonFIFO，可以指定配置为从同一FIFO缓冲区传输的两个连续消息之间的延迟。这种延迟称为间隔时间。在CFDCFCC.CFE位置位后，从FIFO缓冲区成功发送第一条消息后，此间隔时间开始。

当TX模式下的CommonFIFO被使能时，第一个报文被发送而不考虑这个间隔时间。

间隔计时器在以下情况下停止计数：

- 通过清除CFDCFCC.CFE位禁用FIFO。
- CAN通道处于CH_RESET模式。

间隔时间由CommonFIFOConfiguration中的CFDCFCC.CFITT值从0到255个定时器单位指定控制寄存器。

可以根据间隔定时器的两个不同源时钟来定义定时器单元。禁用间隔计时器FIFO传输，选择值0。

定时器源可以通过通用FIFO配置控制寄存器中的配置位CFITSS来选择。

如果CAN通道位时间时钟配置为时钟源，并且CAN通道进入CH_HALT、CH_RESET或CH_SLEEP模式，该通道的间隔定时器停止。

如果选择外设时钟作为间隔定时器时钟源，则间隔定时器只有在CAN通道处于CH_RESET或CH_SLEEP模式时才会停止。

The reference clock can be used to configure the interval time in fixed time units. It is based on the peripheral clock. The reference clock prescaler value CFDGCFG.ITRCP in the Global Configuration Register defines the relation between the peripheral clock frequency/period and the reference clock period.

See Table 28.28 for CFDGCFG.ITRCP configuration values to achieve different reference clock periods based on the peripheral clock frequency and period.

Table 28.28 Configuration example for the reference clock of the FIFO interval timer

Reference clock/Peripheral clock	1 µs	100 µs	500 µs
16 MHz/62.5 ns	16	1600	8000
20 MHz/50 ns	20	2000	10000
32 MHz/31.25 ns	32	3200	16000
50 MHz/20 ns	50	5000	25000

The reference clock resolution can be specified by the interval timer reference clock resolution value CFDCFCC.CFITR in the Common FIFO Configuration/Control Register.

The interval time is based on the reference clock period multiplied by the configured value (x1 or x10). The reference clock based interval timer can be used to satisfy the requirements of the ISO 15765-2 Separation Time. The whole range for the separation time from 100 µs to 127 ms can be covered.

The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).

When the interval time has elapsed, the next transmission request is raised by the related TX FIFO. Therefore, the interval time defines the minimum time between two messages transmitted from one FIFO.

The next message is sent at earliest after this interval time. Figure 28.47 shows an example timing of the internal processing.

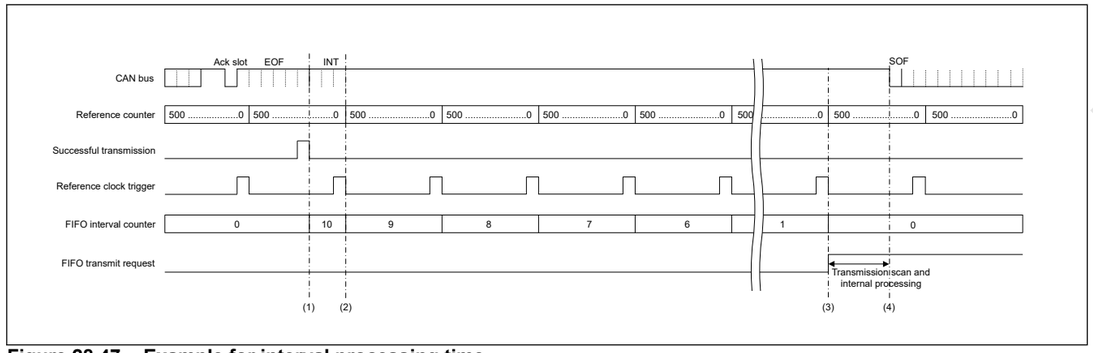

Figure 28.47 Example for interval processing time

The configuration for the timing in Figure 28.47 is as follows:

- Peripheral clock frequency = 50 MHz
- Interval timer reference clock (CFDGCFG.ITRCP) = 500 times
- Reference clock from the settings in Figure 28.47 = 10 µs
- Common FIFO interval timer source selection (CFDCFCC.CFITSS) = 0
- Common FIFO interval timer resolution (CFDCFCC.CFITR) = 0
- Common FIFO interval transmission time (CFDCFCC.CFITT) = 10 times
- Theoretical message separation interval = 100 µs

1. Internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore, the first interval is counting less or equal to 1 reference clock interval.
2. With the next reference clock trigger the FIFO interval timer is decremented.
3. When the FIFO interval timer reached the value 0, the FIFO transmit request is set.

参考时钟可用于以固定时间单位配置间隔时间。它基于外设时钟。全局配置寄存器中的参考时钟预分频器值CFDGCFG.ITRCP定义了外设时钟频率周期和参考时钟周期之间的关系。

有关CFDGCFG.ITRCP配置值，请参见表28.28，以根据外设时钟频率和周期实现不同的参考时钟周期。

Table 28.28 FIFO间隔定时器的参考时钟配置示例

参考时钟外设时钟	1 µs	100 µs	500 µs
16 MHz/62.5 ns	16	1600	8000
20 MHz/50 ns	20	2000	10000
32 MHz/31.25 ns	32	3200	16000
50 MHz/20 ns	50	5000	25000

参考时钟分辨率可以通过通用FIFO配置控制寄存器中的间隔定时器参考时钟分辨率值CFDCFCC.CFITR来指定。

间隔时间基于参考时钟周期乘以配置值（x1或x10）。基于参考时钟的间隔定时器可用于满足ISO15765-2分离时间的要求。可以覆盖从100µs到127ms的整个分离时间范围。

指定的间隔时间在成功传输事件后（在CAN协议的EOF7状态后）开始。

当间隔时间过去时，下一个传输请求由相关的TXFIFO提出。因此，间隔时间定义了从一个FIFO传输的两条消息之间的最短时间。

下一条消息最早在此间隔时间之后发送。图28.47显示了内部处理的示例时序。

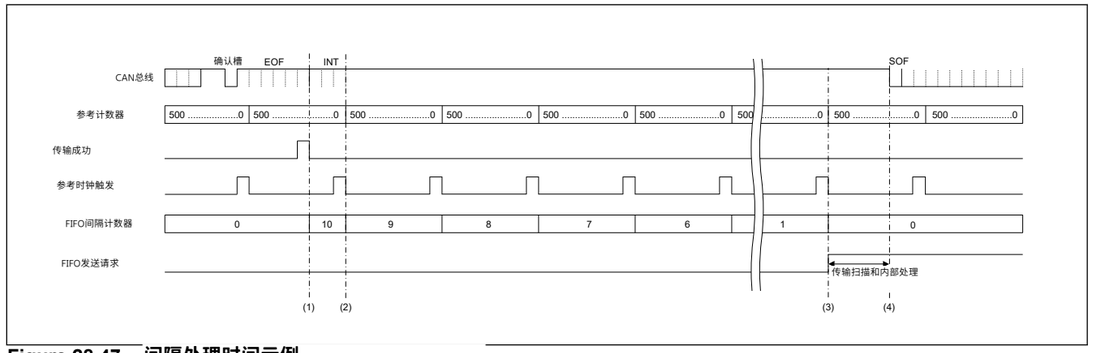

Figure 28.47 间隔处理时间示例

图28.47中的时序配置如下：

- ●外设时钟频率=50MHz
- ●间隔定时器参考时钟(CFDGCFG.ITRCP)=500次
- ●图28.47中设置的参考时钟=10µs
- ●通用FIFO间隔定时器源选择(CFDCFCC.CFITSS)=0
- ●通用FIFO间隔定时器分辨率(CFDCFCC.CFITR)=0
- ●普通FIFO间隔传输时间（CFDCFCC.CFITT）=10次
- ●理论消息分离间隔=100µs

1.内部FIFO间隔定时器随着成功传输结果的出现而重新启动。这次重启不同步到参考时钟触发。因此，第一个间隔计数小于或等于1个参考时钟间隔。

2.随着下一个参考时钟触发，FIFO间隔定时器递减。

3.当FIFO间隔定时器达到值0时，设置FIFO发送请求。

4. When the FIFO is selected for transmission, the transmission starts. Due to internal processing, this usually takes less than 3 CAN bit time, between the internal FIFO transmit request set in step 3. and the actual transmission.

In the worst case when multiple events such as a reception scan, an internal message routing, a transmit scan on all channels occur, it can take up to 126 peripheral clock cycles.

As shown in Figure 28.47, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure CFDCFCC.CFITT to the required minimum value plus 1.

If additional TX message buffers or TX FIFO are configured for transmission of the same channel, the real delay between two messages transmitted from a TX FIFO can be much longer than specified by the interval time. This is due to higher priority message transmission from these TX message buffers or TX FIFO.

Figure 28.48 shows a block diagram of the FIFO interval time generation circuit.

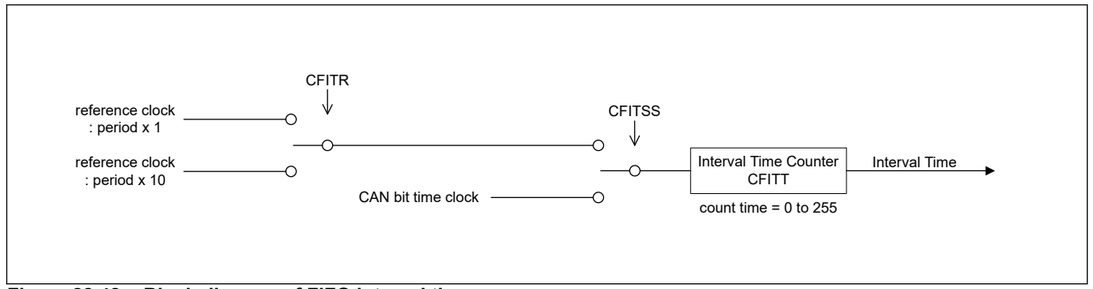

Figure 28.48 Block diagram of FIFO interval timer

28.8.2.4 TX Queue

Each enabled TX Queue for a specific channel consists of three to 4 TX message buffers, which are accessed through one access window.

- The first TX Queue can be configured with a depth of three up to four buffers and uses TX Message Buffer No. 0 as access window (referred to as TXQ)

All the TXQ messages enter the priority comparison for the transmission, which should be only ID Priority (CFDGCFG.TPRI = 0).

The registers for TXQ are:

- CFDTXQCC
- CFDTXQSTS
- CFDTXQPCTR

See related access registers TX Message Buffer ID Registers (TMID[m]), TX Message Buffer Pointer Registers (TMPTR[m]), TX Message Buffer Data Field 0 Registers, and TX Message Buffer Data Field 1 Registers (TMDF[0:1][m]) when access window TXQ0 is used.

The depth of each TXQ buffer can be configured by writing to the CFDTXQCC.TXQDC[1:0] bits of the TX Queue Configuration/Control Register. TXQ can be set from TXMB0 to TXMB3 as a queue buffer at the maximum.

The 4 available options for the depth configuration of TXQ buffer are:

- 0x00: TX Queue disabled
- 0x01: reserved
- 0x10: 3 Messages
- 0x11: 4 Messages

Do not access all the TX message buffers forming the TX Queue directly (except TX Message Buffer No. 0, which act as TX Queue access window).

When a system writes in TXQ, it writes in send data, after checking the state of TXQ.

4.WhentheFIFOisselectedfortransmission thetransmissionstarts.由于内部处理，在步骤3中设置的内部FIFO发送请求和实际发送之间，这通常需要不到3个CAN位时间。

在最坏的情况下，当接收扫描、内部消息路由、所有通道上的发送扫描等多个事件发生时，可能需要多达126个外设时钟周期。

如图28.47所示，不能保证最小间隔总是等于配置的值。如果决不能超过最短时间，请将CFDCFCC.CFITT配置为所需的最小值加1。

如果额外的TX报文缓冲区或TXFIFO配置为传输同一通道，则从TXFIFO传输的两个报文之间的实际延迟可能比间隔时间指定的长得多。这是由于来自这些TX消息缓冲区或TXFIFO的更高优先级的消息传输。

图28.48显示了FIFO间隔时间生成电路的框图。

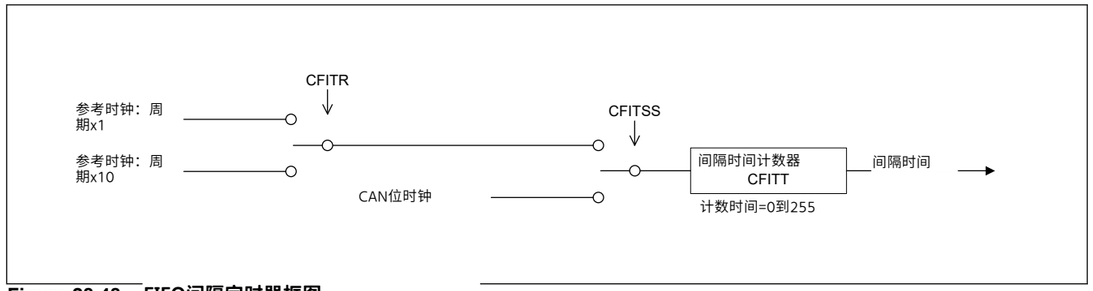

Figure 28.48 FIFO间隔定时器框图

28.8.2.4 TX Queue

为特定通道启用的每个TX队列由3到4个TX消息缓冲区组成，通过一个访问窗口访问这些缓冲区。

●第一个TXQueue可以配置深度为3到4个缓冲区，并使用0号TX消息缓冲区作为访问窗口（简称TXQ）

所有的TXQ消息都进入传输的优先级比较，应该只有ID优先级（CFDGCFG.TPRI=0）。

TXQ的寄存器是：

- CFDTXQCC
- CFDTXQSTS
- CFDTXQPCTR

请参阅相关访问寄存器TX报文缓冲区ID寄存器(TMID[m])、TX报文缓冲区指针寄存器(TMPTR[m])、TX报文缓冲区数据字段0寄存器和TX报文缓冲区数据字段1寄存器(TMDF[0:1][m])当使用访问窗口TXQ0时。

每个TXQ缓冲区的深度可以通过写入TX队列的CFDTXQCC.TXQDC[1:0]位来配置配置控制寄存器。TXQ最大可以设置为TXMB0到TXMB3作为队列缓冲区。

TXQ缓冲区深度配置的4个可用选项是：

●0x00：TX队列禁用

- 0x01: reserved
- 0x10: 3 Messages
- 0x11: 4 Messages

不要直接访问构成TXQueue的所有TX消息缓冲区（除了0号TX消息缓冲区，它充当TX队列访问窗口）。

当系统写入TXQ时，它会在检查TXQ的状态后写入发送数据。

Do not access or configure the related TX Message Buffer Control Registers.

The messages stored to the TX Queue access window are internally stored to a free buffer of the TX Queue.

When the buffer is full, no further access should be done to the queue, until it is no longer full. If access is a software write when the buffer of TXQ is full, send data is overwritten.

The TX Queue can be disabled by clearing the TXQE bit in the TX Queue Configuration/Control Register. If this bit is cleared, the TX Queue Empty flag is set as follows:

- Immediately if the message from the TX Queue is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX Queue is already scheduled for transmission or already in transmission.

Note: The TX Queue is disabled only when the Empty flag is set after clearing the TXQE bit for the corresponding TX Queue.

Other possible messages pending from the TX Queue are lost and their transmission must be requested again.

Before TXQE is set again, ensure that the CFDTXQSTS.TXQEMP bit is set and that there is no pending abort from the TX Queue.

When the TXQE bit is cleared, all messages in the TX Queue buffers are lost and no further message should be stored in the TX Queue.

When a message has been stored to the TX Queue, write 0xFF in the TX Queue Pointer Control Register. This sets the transmit request automatically and changes the internal message buffer pointer to the next free message buffer location of the TX Queue.

Note: If two messages with the same ID are stored in the TX Queue, the order of transmission of these messages can be different from the order in which they were stored in the TX Queue.

To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same ID is stored in the TX Queue.

For the TX Queue, a dedicated interrupt can be enabled by setting the TXQIE bit of the TX Queue Configuration/Control Register.

The interrupt mode can be configured with the CFDTXQCC.TXQIM bit of the same register either to generate an interrupt for every transmitted message or for the last transmitted message.

The TX Queue transmission request procedure after configuration is shown in Figure 28.49.

不要访问或配置相关的TX报文缓冲区控制寄存器。

存储到TXQueue访问窗口的消息在内部存储到TXQueue的空闲缓冲区中。

当缓冲区已满时，不应进一步访问队列，直到它不再满为止。如果在TXQ的缓冲区已满时访问是软件写入，则发送数据将被覆盖。

可以通过清除TX队列配置控制寄存器中的TXQE位来禁用TX队列。如果该位清零，则TXQueueEmpty标志设置如下：

- 如果来自TXQueue的消息既没有安排下一次传输也没有在传输中，则立即执行
- 传输完成后，检测到CAN总线错误、仲裁丢失或转换到
  如果来自TX队列的传输已被安排传输或已在传输中，则通道或全局暂停模式。

Note: 只有在清除相应TX的TXQE位后设置Empty标志时，才会禁用TX队列
Queue.

其他可能从TXQueue挂起的消息丢失，必须再次请求它们的传输。

在再次设置TXQE之前，确保CFDTXQSTS.TXQEMP位已设置并且没有来自TX的挂起中止
Queue.

当TXQE位被清零时，TX队列缓冲区中的所有消息都将丢失，并且不应将更多消息存储在
TX Queue.

当消息已存储到TX队列时，在TX队列指针控制寄存器中写入0xFF。这会自动设置发送请求并将内部消息缓冲区指针更改为TX队列的下一个空闲消息缓冲区位置。

Note: 如果两个具有相同ID的消息存储在TXQueue中，则这些消息的传输顺序可能与它们存储在TXQueue中的顺序不同。

为避免这种情况，重要的是在将具有相同ID的新消息存储到TXQueue之前确认先前具有相同ID的消息已成功传输。

对于TX队列，可以通过设置TX队列配置控制的TXQIE位来启用专用中断
Register.

可以使用同一寄存器的CFDTXQCC.TXQIM位配置中断模式，以便为每个发送的消息或最后发送的消息产生中断。

配置后的TXQueue发送请求流程如图28.49所示。

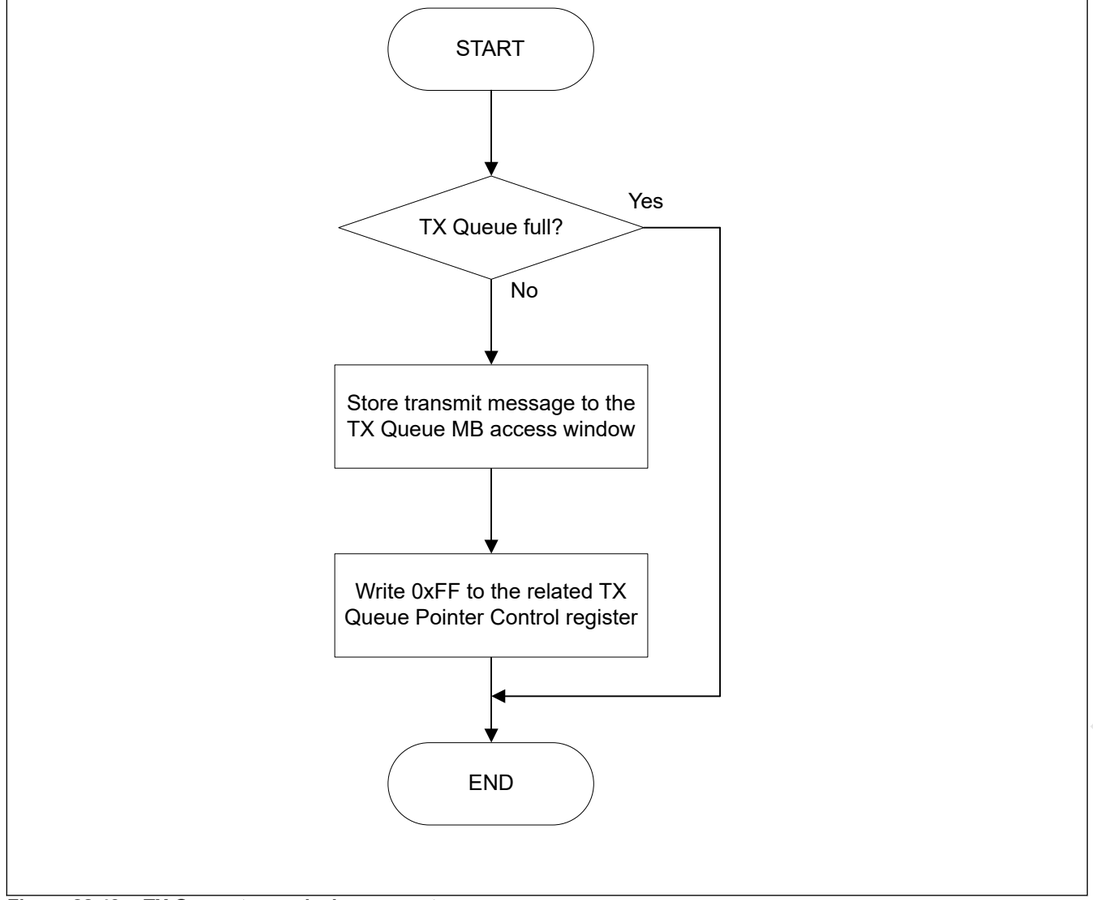

Figure 28.49 TX Queue transmission request

28.8.2.5 TX History List

The TX History List function records the information of the successfully transmitted message in the TX History List Buffers. Two TX History List buffers are provided and THL buffer can store up to 8 TX History List entries.

The CFDTHLCC.THLDTE bit of the TX History List Configuration/Control Register can be used to configure if only message information from TX FIFO or TX Queue is stored, or if all transmit message information from TX Queue, TX FIFO, or normal TX message buffers is stored in the TX History List.

Each transmit message can be individually configured for acceptance to the TX History List with the CFDCFID.THLEN bit in the Message Buffer Pointer Register.

The message information is stored to the TX History List Buffer of a CAN channel after the message is successfully transmitted.

Storing to the list is not synchronized with the status of CFDTMSTSj.TMTRF[1:0] bits in the TX Message Buffer Status Register.

Due to internal processing, the storage to the list can happen with a delay after the successful transmission indication.

Storing the TX History List data can be recognized by the condition that the THLIF is set to 1 when the THLIE bit is configured to 1 or when the TX History List counter CFDTHLSTS.THLMC[5:0] is increased.

In worst case when multi events like reception scan, internal message routing on happen.

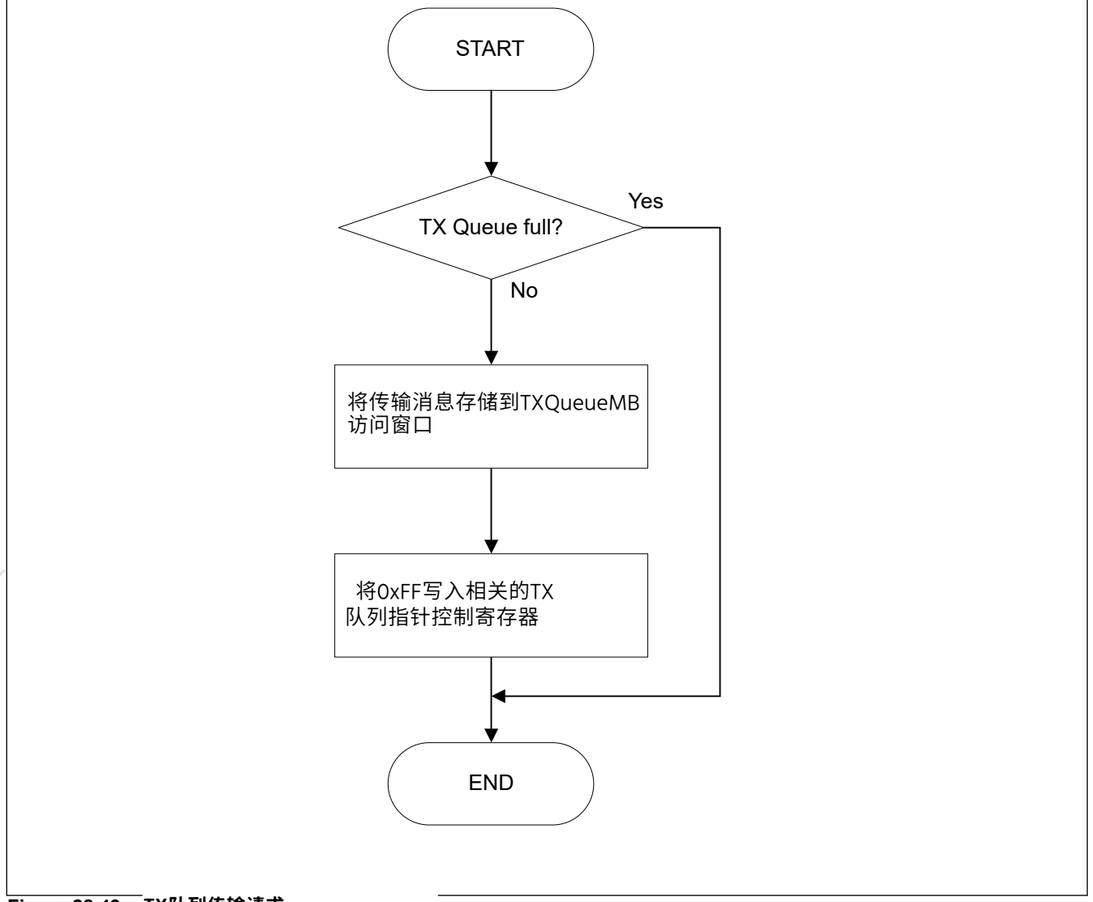

Figure 28.49 TX队列传输请求

28.8.2.5 交易历史列表

TXHistoryList功能将成功发送的报文信息记录在TXHistoryList中缓冲器。提供了两个TX历史列表缓冲区，THL缓冲区可以存储多达8个TX历史列表条目。

TX历史列表配置控制寄存器的CFDTHLCC.THLDTE位可用于配置是否仅存储来自TXFIFO或TX队列的报文信息，或者是否存储了来自TXQueue、TXFIFO或正常TX报文缓冲区的所有发送报文信息存储在TX历史列表中。

可以使用消息缓冲区指针寄存器中的CFDCFID.THLEN位单独配置每个发送消息以接受TX历史列表。

报文发送成功后，报文信息存储到CAN通道的TXHistoryListBuffer中。

存储到列表与TX消息缓冲区状态中CFDTMSTSj.TMTRF[1:0]位的状态不同步
Register.

由于内部处理，在成功传输指示后存储到列表可能会有延迟。

当THLIE位配置为1或TX历史列表计数器CFDTHLSTS.THLMC[5:0]增加时，THLIF设置为1可以识别存储TX历史列表数据。

在最坏的情况下，当接收扫描等多事件发生时，内部消息路由会发生。

- Maximum delay time from setting the CFDTMSTSj.TMTRF to store the TX History List data is 76 peripheral bus clock cycles.

The History list records the following information of a transmitted message:

- Buffer type:
  - 001: TX Message Buffer
  - 010: TX FIFO
  - 100: TX Queue
- Buffer number:
  TX message buffer, TX Queue message buffer or TX message buffer link for the Common FIFO buffer from which transmission occurred. The number depends on the buffer type. See Table 28.29.
- Transmission ID:
  Transmission pointer stored in the transmission message
- Transmit timestamp:
  Message timestamp captured at capture point as configured by CFDGFDCFG.TSCCFG.
- Transmission information label:
  Transmission information label stored in the transmission message.

Table 28.29 TX History List Buffer number entry

Buffer Number	BT[2:0] Buffer Type		
	001b TX Message Buffer	101b TX FIFO	100b TX Queue
00b	Message Buffer 0	Number shown corresponds to the common FIFO. TX Message Buffer Link CFTML of the related Common FIFO configuration	Number shown corresponds to the Message Buffer belonging to the TX Queue which the frame was transmitted
01b	Message Buffer 1		
10b	Message Buffer 2		
11b	Message Buffer 3		

The Transmission ID entry is used to identify which message of a TX FIFO or TX Queue has been successfully transmitted because the TX FIFO or TX Queue number alone is not sufficient.

Therefore, a unique number can be attached to each transmission message stored in a TX FIFO or TX Queue. This unique identification number should be written to the CFDCFFDCSTS.CFPTR[15:0] part of the Common FIFO Access Pointer Register for a TX FIFO or to the CFDTMFDCTRb.TMPTR[15:0] part of the TX Message Buffer Pointer Register of the TX Queue access window message buffer.

When the message is successfully transmitted, this identification number is stored together with the other message related information to the TX History List and can be read using the Transmission ID (TID) of the TX History List Access Register.

Also, for normal TX message buffers, the CFDTMFDCTRb.TMPTR[15:0] part of the TX Message Buffer Pointer Register is stored in the Transmission History List and the information label is the same.

Figure 28.50 shows a transmission preparation flow when TX History List is used.

Read access to the TX History List Access Register is done for every single entry.

After reading one entry, 0xFF must be written to the corresponding TX History List Pointer Control Register to be able to access the next entry until TX History List is empty.

Figure 28.51 shows an example flow for processing the TX History List information.

The TX History Lists have dedicated interrupts, which can be configured with the CFDTHLCC.THLIM bit of the corresponding TX History List Configuration/Control Register and enabled with the CFDTHLCC.THLIE bit of the same

因此，可以将唯一编号附加到存储在TXFIFO或TX队列中的每个传输消息。此唯一标识号应写入TXFIFO的通用FIFO访问指针寄存器的CFDCFFDCSTS.CFPTR[15:0]部分或TXFIFO的TX消息缓冲区指针寄存器的CFDTMFDCTRb.TMPTR[15:0]部分德克萨斯州

当报文成功发送时，该标识号与其他报文相关信息一起存储到TX历史列表中，并可使用TX历史列表访问寄存器的发送ID(TID)读取。

此外，对于普通的TX报文缓冲区，TX报文缓冲区指针寄存器的CFDTMFDCTRb.TMPTR[15:0]部分存储在传输历史列表中，并且信息标签相同。

图28.50显示了使用TXHistoryList时的传输准备流程。

对TX历史列表访问寄存器的读取访问针对每个条目进行。

读取一个条目后，必须将0xFF写入相应的TX历史列表指针控制寄存器，才能访问下一个条目，直到TX历史列表为空。

TX历史列表具有专用中断，可以通过相应的TX历史列表配置控制寄存器的CFDTHLCC.THLIM位进行配置，并通过相同的CFDTHLCC.THLIE位启用

28.8.2.6 TX Data Padding

This chapter is not valid for classical CAN.

If the data length code (DLC) of the transmitting message has a higher number of data bytes than the buffer size, the data bytes beyond the restricted range are replaced by bytes with the value of 0xCC.

This can happen for Common FIFO configured as (TX mode) when the transmit message DLC is higher than the CFDCFCC.CFPLS.

This can also happen in FD only mode, if a Classical frame is configured with a DLC bigger than 8.

28.9 Test Mode

The CANFD module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CANFD module in test modes.

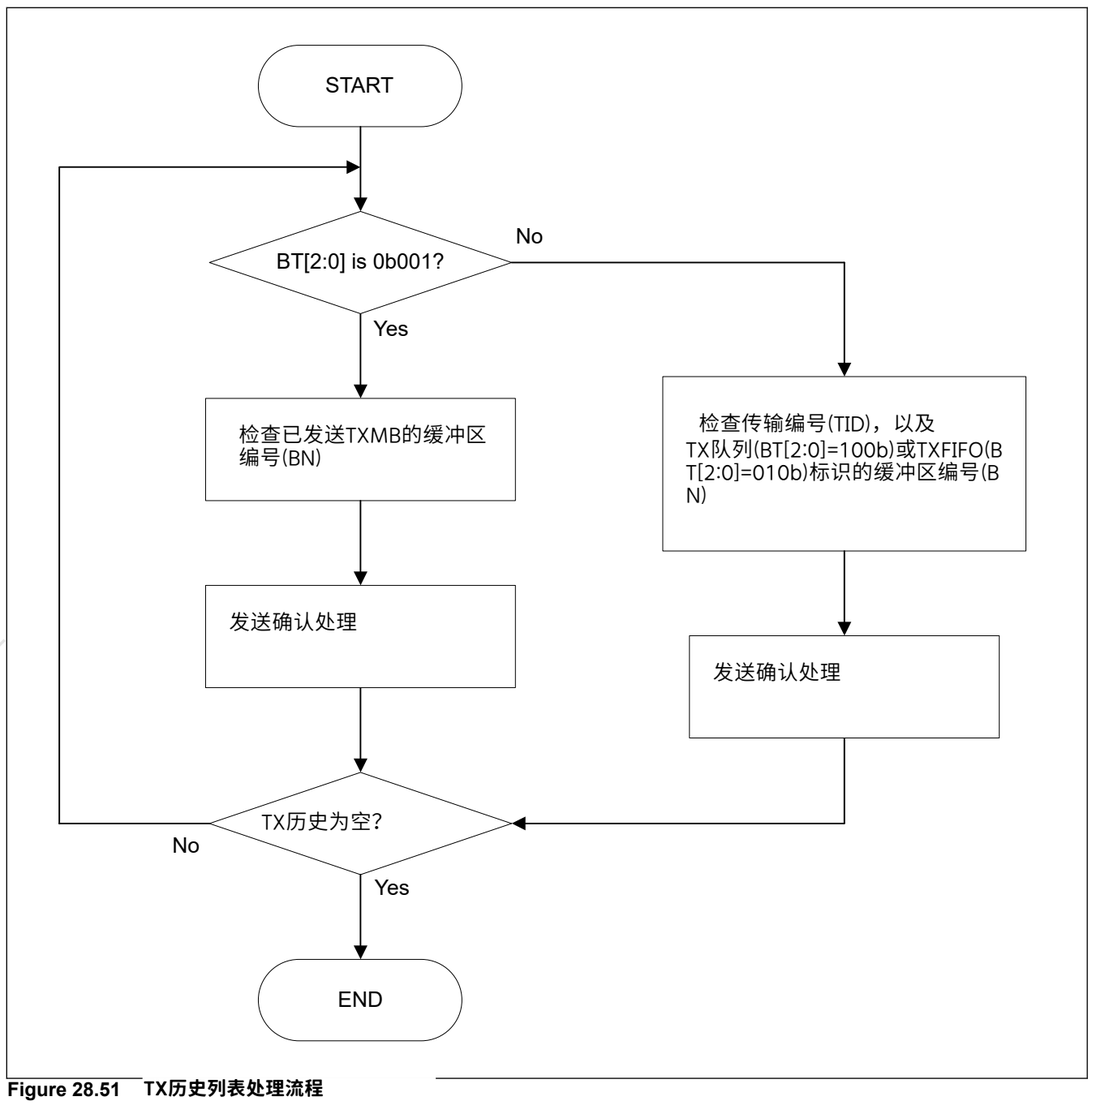

Figure 28.51 TX历史列表处理流程

28.8.2.6 TX数据填充

本章不适用于经典CAN。

如果发送报文的数据长度码(DLC)的数据字节数大于缓冲区大小，则超出限制范围的数据字节将替换为值为0xCC的字节。

当发送消息DLC高于
CFDCFCC.CFPLS.

如果经典帧配置了大于8的DLC，这也可能发生在仅FD模式下。

28.9 测试模式

CANFD模块可以配置为测试模式以允许测试某些功能。这些功能仅用于特殊目的，在测试模式下配置CANFD模块时必须小心。

Note: All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combination of the various test modes specified in this section.

The test modes can be broadly split into 2 groups:

- Channel specific test modes
- Global test modes.

28.9.1 Channel Specific Test Modes

CAN channel can be configured into the following test modes:

- Basic test mode
- Listen-only mode
- Self-test mode 0 (External loop back mode)
- Self-test mode 1 (Internal loop back mode)
- Restricted operation mode.

28.9.1.1 Basic Test Mode

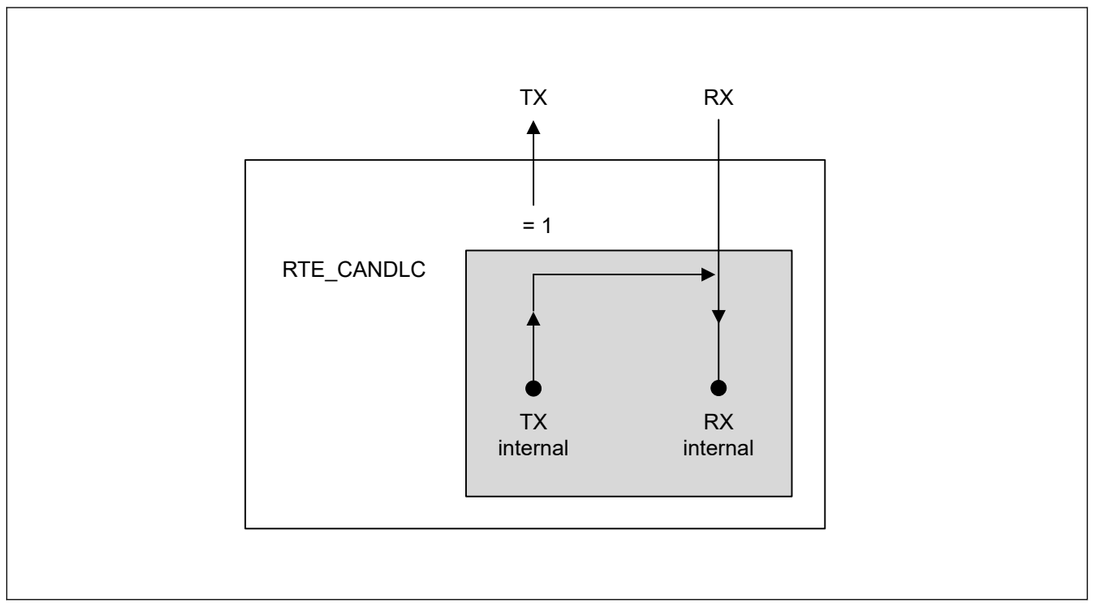
The basic test mode should be used when there is requirement for a particular test setting to be enabled other than when in Listen-only and Self-test modes.

28.9.1.2 Listen-only Mode

The ISO 11898-1 recommends an optional bus-monitoring mode. In this mode, the CAN channel is able to receive valid data frames and valid remote frames. However, it sends only recessive bits on the CAN bus and is not allowed to transmit. If the CAN engine is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is routed internally so that the CAN engine monitors this as dominant. The external TX pin remains in recessive state.

This mode can be used for baud rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.

In this mode, it is not permitted to request transmission from any normal TX message buffer or TX FIFO.



Note: 所有测试模式都是互斥的，除非明确声明某些功能可以跨其他测试模式启用。

不要启用本节中指定的各种测试模式的任何组合。

测试模式可以大致分为两组：

●通道特定的测试模式

●全局测试模式。

28.9.1 通道特定测试模式

CAN通道可配置为以下测试模式：

●基本测试模式

- Listen-only mode

●自检模式0（外部环回模式）

●自检模式1（内部环回模式）

●受限操作模式。

28.9.1.1 基本测试模式

当需要启用特定测试设置时，应使用基本测试模式，而不是在
只听和自测模式。

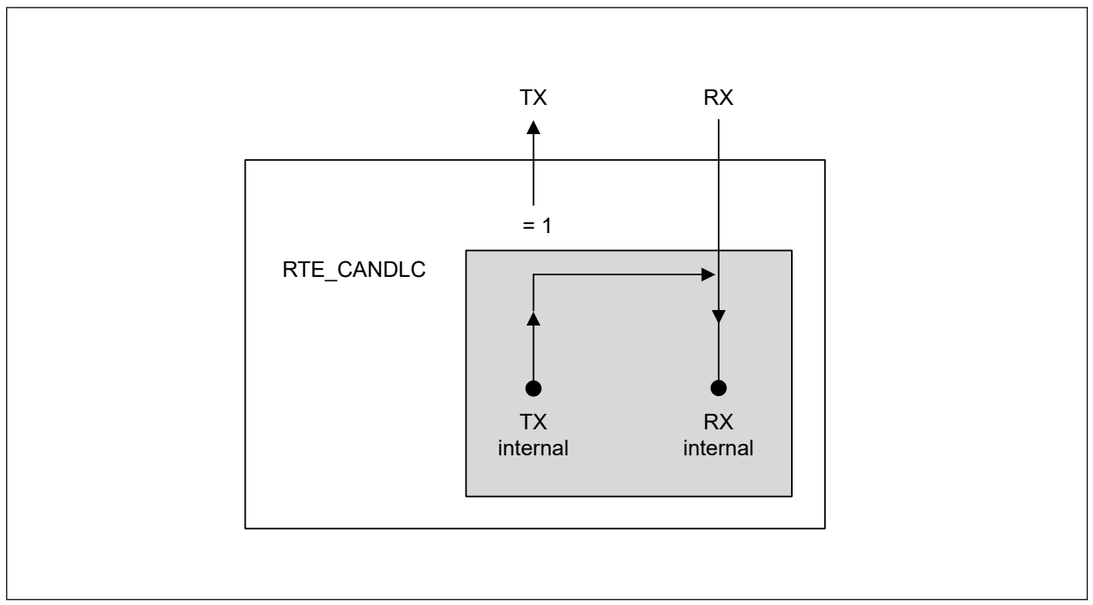
28.9.1.2 Listen-only Mode

ISO11898-1推荐一种可选的总线监控模式。在此模式下，CAN通道能够接收有效的数据帧和有效的远程帧。但是，它只在CAN总线上发送隐性位，不允许发送。

如果CAN引擎需要发送显性位（ACK位、过载标志、活动错误标志），则该位在内部路由，以便CAN引擎将其监控为显性。外部TX引脚保持隐性状态。

该模式可用于波特率检测。在此模式下，如果发生总线错误并启用中断，则会产生错误中断。

在此模式下，不允许从任何正常的TX消息缓冲区或TXFIFO请求传输。

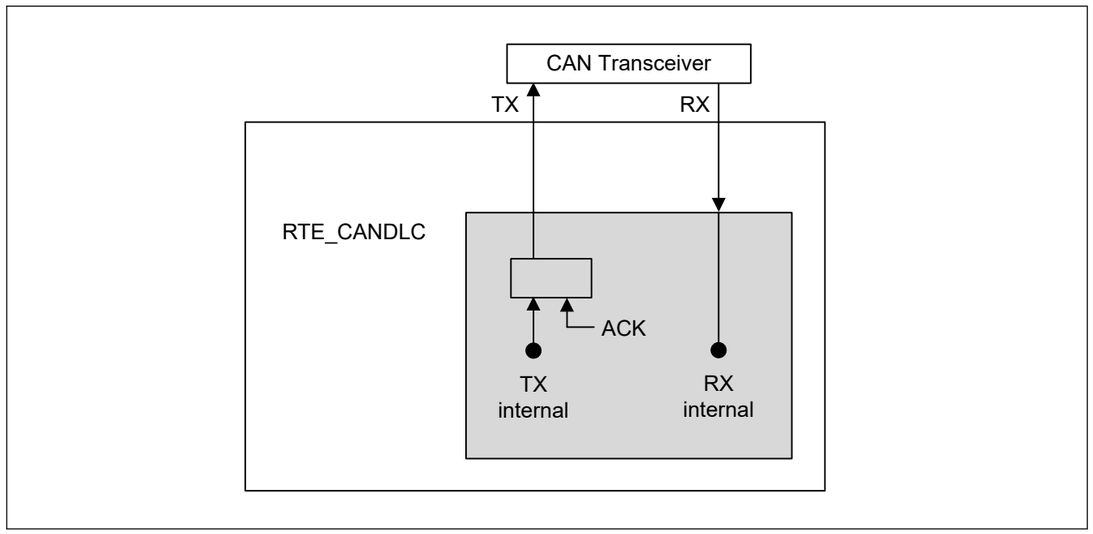


28.9.1.3 Self-test Mode 0 (External loopback mode)

In Self-test mode 0, the CAN engine treats its own transmitted messages as received messages through the CAN transceiver and stores them into its receive message buffers.

To be independent from external stimulation, the engine generates its own Acknowledge bit.

This test can be used for CAN transceiver tests and the RX/TX pins should be connected to the transceiver.



28.9.1.4 Self-test Mode 1 (Internal loopback mode)

In Self-test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent from external stimulation, the CAN engine generates its own Acknowledge bit. In this mode the CAN engine performs an internal feedback from TX internal to RX internal. The actual value of the external RX input is disregarded by the CAN engine.

The external TX pin outputs only recessive bits. The RX/TX pins do not need to be connected to the CAN bus or any external device.

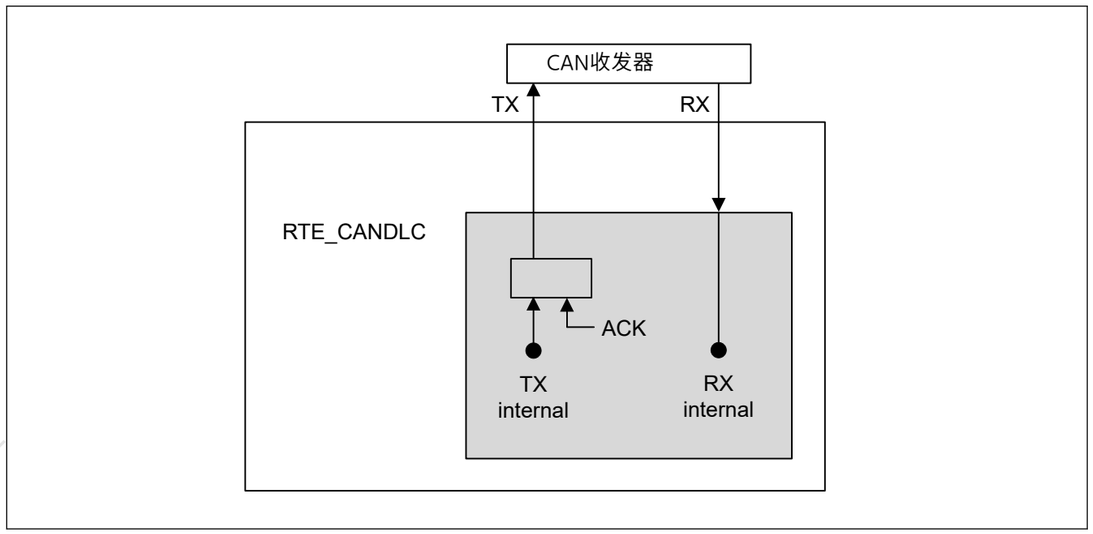
Note: The channel pins are also disconnected from the internal CAN bus communication line.

28.9.1.3 Self-test Mode 0 (External loopback mode)

在自检模式0中，CAN引擎将自己发送的消息视为通过CAN收发器接收到的消息，并将它们存储到其接收消息缓冲区中。

为了独立于外部刺激，引擎会生成自己的确认位。

此测试可用于CAN收发器测试，并且RXTX引脚应连接到收发器。

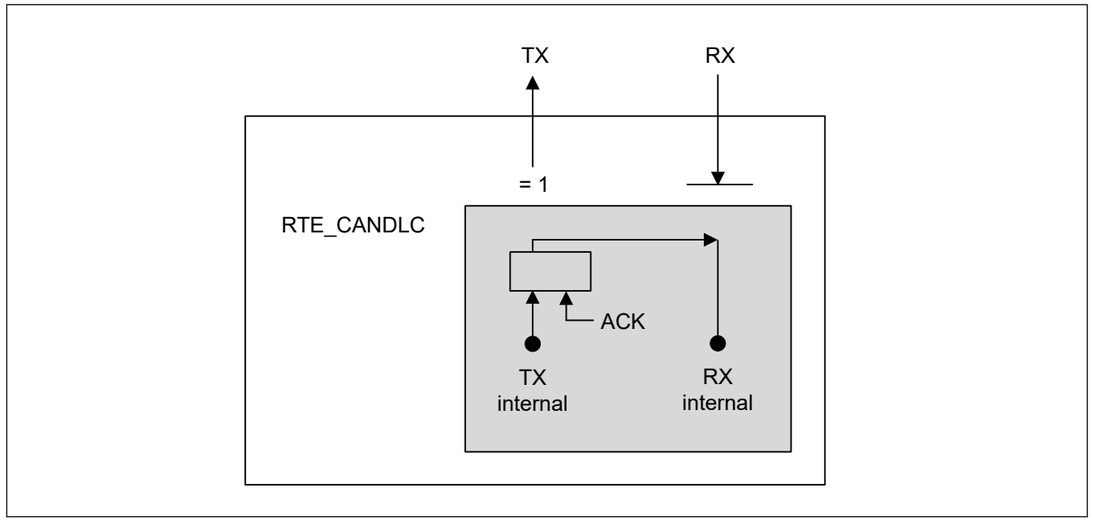


28.9.1.4 Self-test Mode 1 (Internal loopback mode)

在自检模式1中，CAN引擎将自己发送的消息视为接收的消息，并将它们存储到接收缓冲区中。此模式用于自检功能。为了独立于外部刺激，CAN引擎生成自己的确认位。在这种模式下，CAN引擎执行从TX内部到RX内部的内部反馈。CAN引擎忽略外部RX输入的实际值。

外部TX引脚仅输出隐性位。RXTX引脚不需要连接到CAN总线或任何外部设备。

Note: 通道引脚也与内部CAN总线通信线路断开。



28.9.1.5 Restricted Operation Mode

This chapter is not valid for classical CAN.

In Restricted operation mode, the CAN node is able to receive valid data and remote frames generating the Acknowledge bit.

Active error or overload frames cannot be transmitted, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.

Additionally, the Receive and Transmit Error Counter (REC and TEC) are frozen independently from the occurrence of errors. The mode is specified in ISO 11898-1 and the setting of transmit request is permitted.

28.9.2 Global Test Modes

The CANFD module can be configured into the following test modes:

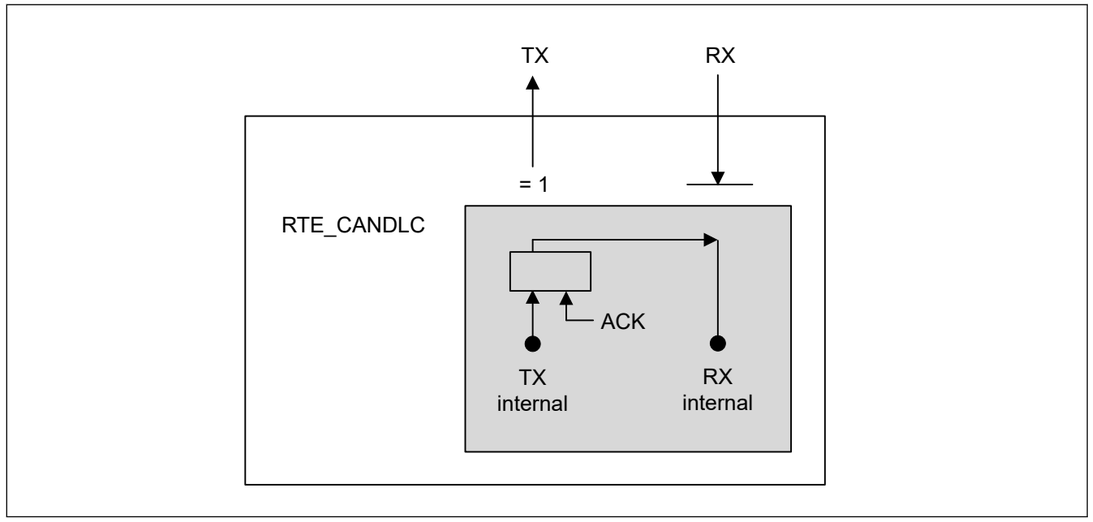
- RAM test mode
- Bit Flip Test

The test modes in the following table are protected by a special software procedure to enable the mode. This software procedure enables write access to the test mode by a specific unlock key as shown in the table.

Test mode	Unlock key 1	Unlock key 2
RAM test mode	0x7575	0x8A8A

If the software sequence of the two consecutive unlock key write accesses (half-word or word access) is interrupted by any other write access to the register or if incorrect data is written to the Global Unlock Key Register, the corresponding test mode cannot be set and the sequence must be restarted.

After the two unlock key write accesses, the next write access should be to set the corresponding test mode enable bit. If this is not followed, the unlock mechanism reset and the test mode enable bit cannot be set and the unlock sequence must be restarted.



28.9.1.5 受限操作模式

本章不适用于经典CAN。

在受限操作模式下，CAN节点能够接收有效数据和生成确认位的远程帧。

无法传输主动错误或过载帧，而是在发生错误或过载情况后等待总线空闲条件的出现以重新同步到CAN通信。

此外，接收和发送错误计数器（REC和TEC）独立于错误发生而被冻结。模式在ISO11898-1中指定，允许设置发送请求。

28.9.2 全局测试模式

CANFD模块可配置为以下测试模式：

- RAM测试模式
- 位翻转测试

下表中的测试模式受特殊软件程序保护以启用该模式。该软件程序允许通过特定的解锁密钥对测试模式进行写访问，如表中所示。

测试模式	解锁钥匙1	解锁钥匙2
RAM测试模式	0x7575	0x8A8A

如果两次连续的解锁密钥写访问（半字或字访问）的软件序列被对寄存器的任何其他写访问中断，或者如果向全局解锁密钥寄存器写入不正确的数据，则无法设置相应的测试模式并且必须重新启动序列。

在两次解锁密钥写访问之后，下一次写访问应该是设置相应的测试模式使能位。如果不遵循，解锁机制复位和测试模式使能位不能设置，解锁序列必须重新启动。

28.9.2.1 RAM Test Mode

The CANFD module can be configured in RAM test mode by setting the CFDGTSTCTR.RTME bit in the Global Test Control Register when the corresponding lock key is previously written. This is a special test mode, in which, the complete RAM area can be accessed.

Note: The actual RAM size is bigger than the RAM area initialized after a hardware reset. Therefore, ECC error flag (of the ECC macro) may be set if CPU reads data from this uninitialized RAM area while CANFD module is in RAM test mode.

In this mode, the RAM area is split into number of pages (pn) of 256 bytes, each which can be accessed with the CFDRPGACCk register.

The page should be selected for read/write access by writing to the CFDGTSTCFG.RTMPS[3:0] bits in the Global Test Control Register. Data can then be read from or written in to the RAM Test Page Access Registers.

Figure 28.53 shows the structure of the pages in the RAM when performing a RAM test mode.

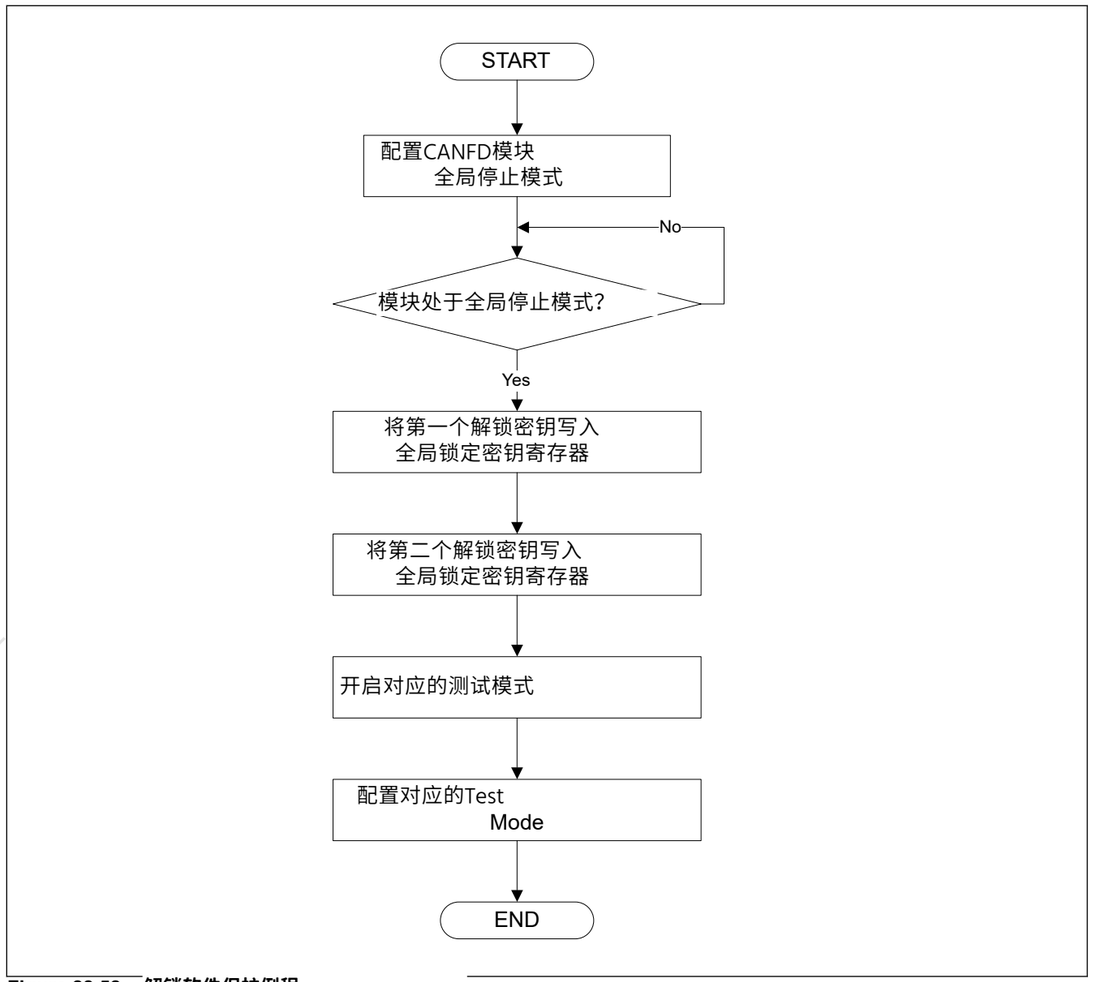

Figure 28.52 解锁软件保护例程

28.9.2.1 RAM测试模式

CANFD模块可通过设置GlobalTest中的CFDGTTSTCTR.RTME位配置为RAM测试模式控制寄存器，当相应的锁定键先前被写入时。这是一种特殊的测试模式，其中，完整的可以访问RAM区域。

Note: 实际RAM大小大于硬件复位后初始化的RAM区域。因此，ECC错误标志（的如果在CANFD模块处于RAM测试模式时CPU从该未初始化的RAM区域读取数据，则可以设置ECC宏。

在这种模式下，RAM区域被分成256字节的页数(pn)，每个页都可以通过CFDRPGACCk register.

应通过写入全局测试中的CFDGTSTCFG.RTMPS[3:0]位来选择该页面进行读写访问控制寄存器。然后可以从RAM测试页访问寄存器读取或写入数据。

图28.53显示了执行RAM测试模式时RAM中的页面结构。

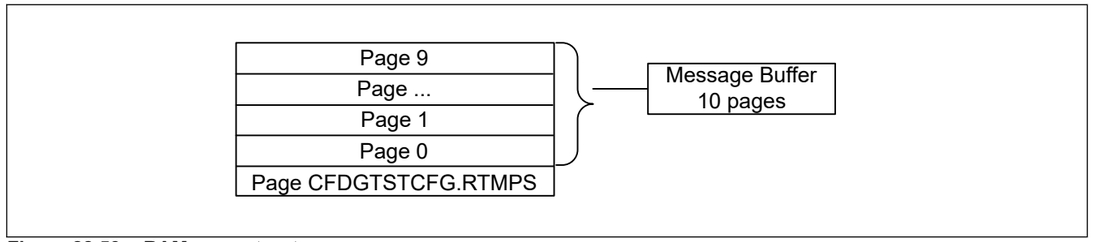

Figure 28.53 RAM page structure

The total available RAM size is 2328 bytes for the Message Buffer RAM.

The pn and CFDGTSTCFG.RTMPS[3:0] values for the MB RAMs are calculated in the following way:

pn = ceil (total RAM size in bytes / number of bytes per page)

- MB RAM:
  pn = ceil (2328 / 256) = 10 pages
  CFDGTSTCFG.RTMPS[3:0] = 0 to 9 inclusive

Figure 28.54 shows the software flow for RAM test mode.

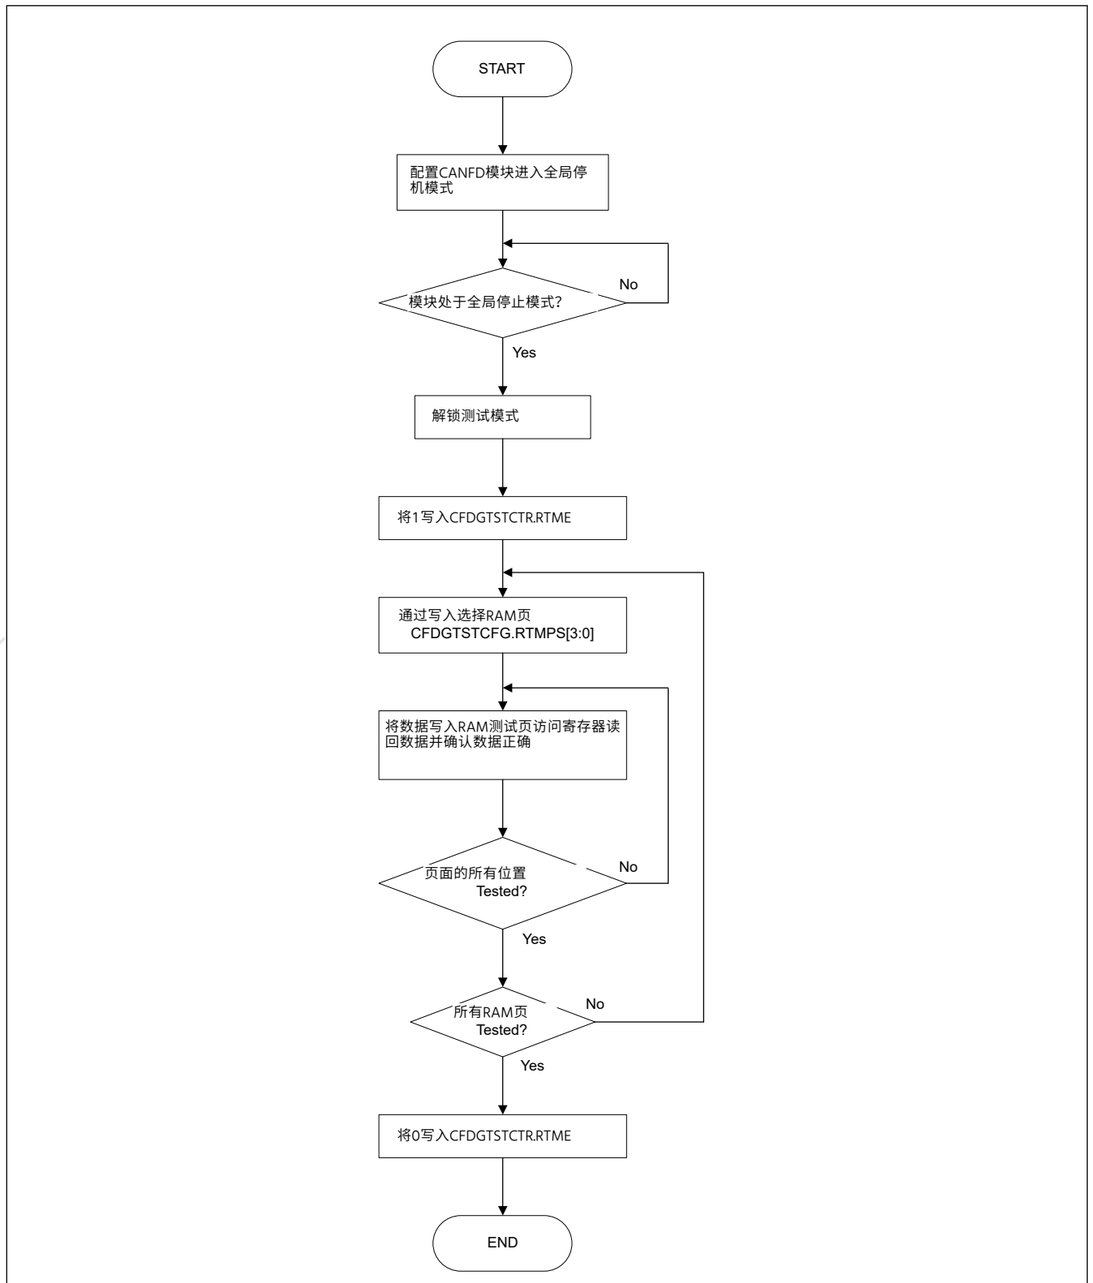
Note 1. Change into the following status before changing to RAMTEST.
- Cancel of a request for transmission.
- Disable of all the FIFO and TXQ.
- Clear of the receiving flag for a receiving buffer.

Figure 28.54 Software flow for RAM test mode

To exit this test mode, the CFDGTSTCTR.RTME bit must be cleared. The CFDGTSTCTR.RTME bit is cleared by writing 0 to it.



注1.更改为RAMTEST之前，请更改为以下状态。
- 取消传输请求。
- 禁用所有FIFO和TXQ。
- 清除接收缓冲区的接收标志。

Figure 28.54 RAM测试模式的软件流程

要退出此测试模式，CFDGTSTCTR.RTME位必须清零。CFDGTSTCTR.RTME位通过向其写入0来清除。

The CFDGTSTCTR.RTME bit is cleared automatically when the CANFD module enters Global Reset mode from the test mode.

28.9.2.2 Bit Flip Test

Bit Flip Test can invert the bit (the 1st bit of ID) of the beginning of the bit stream to receive.

If this function is used by a transmitting node, a bit error or an arbitration lost will occur.

If this function is used by a receiving node, a CRC error or a stuff error will occur.

Users should refer to the bit stuffing rule when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The following sequence should be used to perform CRC Error testing. In the sequence below CANFD module is the receiver.

1. Set the CFDC0CTR.BFT bit to 1'b1, in order to invert the first bit of the incoming bit stream from sending node
2. Wait for the can_cherr_int output signal to set to 1'b1
3. Read either the CFDC0ERFL.CRCREG or the CFDC0FDCRC.CRCREG (depending on the received frame type: Classical or FD). The value should be different from the received CRC value of the reference message from sending node.
4. Check that CFDC0ERFL.CERR is 1'b1

As the CRC generator logic is shared for RX and TX there is no need to create a separate TX CRC Error test.

当CANFD模块从测试模式进入全局复位模式时，CFDGTSTCTR.RTME位会自动清零。

28.9.2.2 位翻转测试

位翻转测试可以反转要接收的位流开始的位（ID的第1位）。

如果发送节点使用此功能，则会发生误码或仲裁丢失。

如果接收节点使用此功能，则会发生CRC错误或填充错误。

用户在使用此功能时应参考比特填充规则，因为可能会收到填充错误（由于反转）而不是CRC错误。

应使用以下序列执行CRC错误测试。在下面的序列中，CANFD模块是接收器。

1.将CFDC0CTR.BFT位设置为1'b1，以反转来自发送节点的传入比特流的第一位

2.等待can_cherr_int输出信号设置为1'b1

3.读取CFDC0ERFL.CRCREG或CFDC0FDCRC.CRCREG（取决于接收到的帧类型：古典或FD）。该值应不同于从发送节点接收到的参考消息的CRC值。

4.检查CFDC0ERFL.CERR是否为1'b1

由于RX和TX共享CRC生成器逻辑，因此无需创建单独的TXCRC错误测试。

29. CANFD ECC (CNECC)

29.1 Overview

MBRAM have ECC function of 2-bit ECC error detection and 1-bit ECC error detection and correction*1. The ECC module adds 7 bits ECC data to 32 bits RAM data.

Note 1. The ECC module cannot detect 3 or more bits error. In this case, the ECC module detects 1-bit or 2-bit error, does not detect errors, or corrects the erroneous bit to erroneous data by setting. When all RAM data are fixed to 0 or 1, it is detected as 2-bit ECC error.

29. CANFD ECC (CNECC)

29.1 Overview

MBRAM具有2位ECC错误检测和1位ECC错误检测和纠正的ECC功能*1。ECC模块将7位ECC数据添加到32位RAM数据中。

注1.ECC模块无法检测3位或更多位错误。在这种情况下，ECC模块检测1位或2位错误，不检测错误，或通过设置将错误位纠正为错误数据。当所有RAM数据固定为0或1时，将被检测为2位ECC错误。

ECEMF bit (ECC Error Message Flag)

The ECEMF bit shows that there is error in present read data bus. This bit is updated by every RAM output data.

When RAM output data is undefined and the ECERVF bit is set to 1, the value of this bit is undefined.

[Setting condition]

There is bit error in present RAM output data under the condition that error judgement is enabled.

[Clearing condition]

- Under the condition that there is no 1-bit error in input data to decode circuit
- When ECC error judgement is disabled (ECERVF = 0).

ECER1F bit (ECC Error Detection and Correction Flag)

The ECER1F bit shows that the bit errors are detected in the one part of RAM read data [38:0] at RAM read access when the error judgment is enabled.

When the 1-bit error interrupt output is enabled, error interrupt is generated by setting this flag.

This bit is read-only, so writing 1 or 0 has no effect.

At clearing, write 1 to the ECER1C bit.

When 1-bit error is detected again under the condition that this bit is set, the interrupt is not generated.

[Setting condition]

When the error judgment is enabled and there is 1-bit error to RAM output data (when not setting ECER1C = 1).

[Clearing condition]

- Writing ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

ECER2F bit (2-bit ECC Error Detection Flag)

The ECER2F bit shows that the bit errors are detected in the two parts of RAM read data [38:0] at RAM read access when the error judgment is enabled.

When the 2-bit error interrupt output is enabled, error interrupt is generated by setting this flag.

This bit is read-only, so writing 1 or 0 has no effect.

At clearing, write 1 to the ECER2C bit.

When 2-bit error is detected again under the condition that this bit is set, the interrupt is not generated.

[Setting condition]

When the error judgment is enabled and there is 2-bit error to RAM output data (when not setting ECER2C = 1).

[Clearing condition]

ECEMF位（ECC错误消息标志）

ECEMF位显示当前读数据总线有错误。该位由每个RAM输出数据更新。

当RAM输出数据未定义且ECERVF位设置为1时，该位的值未定义。

[Setting condition]

在启用错误判断的情况下，当前RAM输出数据存在位错误。

[Clearing condition]

●解码电路的输入数据无1位错误的情况下

●ECC错误判断无效时（ECERVF=0）。

ECER1F位（ECC错误检测和纠正标志）

ECER1F位表示当启用错误判断时，在RAM读取访问时，在RAM读取数据[38:0]的一部分中检测到位错误。

当1位错误中断输出使能时，通过设置该标志产生错误中断。

该位是只读的，因此写入1或0无效。

清零时，将1写入ECER1C位。

在该位置位的情况下再次检测到1位错误时，不会产生中断。

[Setting condition]

启用错误判断且RAM输出数据有1位错误时（未设置ECER1C=1时）。

[Clearing condition]

- Writing ECER1C = 1

●ECC错误判断无效时（ECERVF=0）。

ECER2F位（2位ECC错误检测标志）

ECER2F位表示当错误判断使能时，在RAM读取访问的两部分RAM读取数据[38:0]中检测到位错误。

当2位错误中断输出使能时，通过设置该标志产生错误中断。

该位是只读的，因此写入1或0无效。

清除时，将1写入ECER2C位。

在该位置位的情况下再次检测到2位错误时，不会产生中断。

[Setting condition]

启用错误判断且RAM输出数据有2位错误时（未设置ECER2C=1时）。

[Clearing condition]

- Writing ECER2C = 1
- When ECC error judgement is disabled (ECERVF = 0).

EC1EDIC bit (ECC 1-bit Error Detection Interrupt Control)

The EC1EDIC controls the interrupt output at detecting 1-bit error. By setting 1 to this bit, the 1-bit error interrupt is outputted when 1-bit error detected.

EC2EDIC bit (ECC 2-bit Error Detection Interrupt Control)

The EC2EDIC controls the interrupt output at detecting 2-bit error. By setting 1 to this bit, the 2-bit error interrupt is outputted when 2-bit error detected.

EC1ECP bit (ECC 1-bit Error Correction Permission)

The EC1ECP sets enable or disable to correct the 1-bit error when ECC error detection and correction is valid. By setting 1 to this bit, the non-corrected data is outputted if 1-bit error is detected.

ECERVF bit (ECC Error Judgment Enable Flag)

Setting the ECERVF bit to 1 enables the judgment of error. The correction of output data and the interrupt output depend on setting of the EC1ECP bit, EC2EDIC bit, and EC1EDIC bit.

The write access to this bit is valid when the write value of the EMCA[1:0] is 01b. So only the 16 bits or 32 bits operation command is valid in the case of the write access to this bit.

ECER1C bit (Accumulating ECC Error Detection and Correction Flag Clear)

The ECER1C bit clears the status flag of the ECER1F bit.

The read value is always 0. By writing 0, the internal condition is not changed. When the competition between writing 1 to this bit and setting the ECER1F bit, the former has priority.

The ECER1F bit is cleared by writing 1 to this bit while the ECER1F bit is set. Additionally, the Overflow Detection flag (ECOVFF), ECC Dual Bit Error flag (ECDEDF0) and ECC Single Bit Error flag (ECSEDF0) are also cleared.

ECER2C bit (2-bit ECC Error Detection Flag Clear)

The ECER2C bit clears the status flag of the ECER2F bit.

The read value is always 0. By writing 0, the internal condition is not changed. When the competition between writing 1 to this bit and setting the ECER2F bit, the former has priority.

The ECER2F bit is cleared by writing 1 to this bit while the ECER2F bit is set. Additionally, the Overflow Detection flag (ECOVFF), ECC Dual Bit Error flag (ECDEDF0), and ECC Single Bit Error flag (ECSEDF0) are also cleared.

ECOVFF bit (ECC Overflow Detection Flag)

The ECOVFF bit is set and the overflow interruption is outputted by detecting the new error address under the condition that error address is already captured in the EC710EAD0 register. The overflow interrupt is outputted again when this bit is set and new error is detected.

This bit is read-only, so writing 1 or 0 has no effect.

To clear this bit, write 1 to the ECER2C bit and the ECER1C bit.

[Setting condition]

When new error address is captured under the condition that error address is already captured in the EC710EAD0 register (when not setting ECER2C = 1 or ECER1C = 1).

[Clearing condition]

- Writing ECER2C = 1 or ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

EMCA[1:0] bit (Access Control to ECC Mode Select bit)

The EMCA[1:0] bits are the write trigger reserved bits to the ECERVF bit. The read value is always 0. When the value of these bits is 01b, it is possible to have write access to the ECERVF bit. If these bits are not 01b, write access to the ECERVF bit is ignored and the value is not written.

- Writing ECER2C = 1
- ●ECC错误判断无效时（ECERVF=0）。

EC1EDIC位（ECC1位错误检测中断控制）

EC1EDIC在检测到1位错误时控制中断输出。通过将该位设置为1，当检测到1位错误时输出1位错误中断。

EC2EDIC位（ECC2位错误检测中断控制）

EC2EDIC在检测到2位错误时控制中断输出。通过将此位设置为1，当检测到2位错误时输出2位错误中断。

EC1ECP位（ECC1位纠错权限）

当ECC错误检测和纠正有效时，EC1ECP设置启用或禁用以纠正1位错误。通过将此位设置为1，如果检测到1位错误，则输出未校正的数据。

ECERVF位（ECC错误判断使能标志）

将ECERVF位设置为1可以进行错误判断。输出数据的校正和中断输出取决于EC1ECP位、EC2EDIC位和EC1EDIC位的设置。

当EMCA[1:0]的写值为01b时，对该位的写访问有效。因此在对该位进行写访问的情况下，只有16位或32位操作命令有效。

ECER1C位（累积ECC错误检测和纠正标志清除）

ECER1C位清除ECER1F位的状态标志。

读取值始终为0。通过写入0，内部条件不会改变。当向该位写1与设置ECER1F位竞争时，前者具有优先权。

当ECER1F位置位时，通过向该位写入1来清除ECER1F位。此外，溢出检测标志(ECOVFF)、ECC双比特错误标志(ECDEDF0)和ECC单比特错误标志(ECSEDF0)也被清除。

ECER2C位（2位ECC错误检测标志清除）

ECER2C位清除ECER2F位的状态标志。

读取值始终为0。通过写入0，内部条件不会改变。当向该位写1与设置ECER2F位竞争时，前者具有优先权。

当ECER2F位置位时，通过向该位写入1来清除ECER2F位。此外，溢出检测标志(ECOVFF)、ECC双比特错误标志(ECDEDF0)和ECC单比特错误标志(ECSEDF0)也被清除。

ECOVFF位（ECC溢出检测标志）

在EC710EAD0寄存器中已经捕捉到错误地址的情况下，通过检测新的错误地址，设置ECOVFF位并输出溢出中断。当该位置位并检测到新错误时，溢出中断再次输出。

该位是只读的，因此写入1或0无效。

要清除该位，向ECER2C位和ECER1C位写入1。

[Setting condition]

在EC710EAD0寄存器中已捕获错误地址的情况下捕获新的错误地址时（未设置ECER2C=1或ECER1C=1时）。

[Clearing condition]

- ●写入ECER2C=1或ECER1C=1
- ●ECC错误判断无效时（ECERVF=0）。

EMCA[1:0]位（ECC模式选择位的访问控制）

EMCA[1:0]位是ECERVF位的写触发保留位。读取值始终为0。当这些位的值为01b时，可以对ECERVF位进行写访问。如果这些位不是01b，则忽略对ECERVF位的写访问并且不写入该值。

ECSEDF0 bit (ECC Single bit Error Address Detection Flag)

The ECSEDF0 bit shows that the error is captured in the error address register when error detection is valid. This bit is set by 1-bit error detection.

When 1-bit error is detected after the 2-bit error address is already captured in the EC710EAD0 register, this bit is not updated but the EC710EAD0 register is updated.

This bit is read-only, so writing 1 or 0 has no effect. To clear these bits, write 1 to the ECER1C bit.

[Setting condition]

When there is 1-bit error to RAM output data and error address is captured in EC710EAD0 under the condition that the error judgment is permitted (when not setting ECER1C = 1).

[Clearing condition]

- Writing ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

ECDEDF0 bit (ECC Dual Bit Error Address Detection Flag)

The ECDEDF0 bit shows that the error is captured in the error address register when error detection is valid. This bit is set by 2-bit error detection.

When 2-bit error is detected after the 1-bit error address is already captured in the EC710EAD0 register, this bit is not updated and the EC710EAD0 register is updated.

This bit is read-only, so writing 1 or 0 has no effect. To clear these bits, write 1 to the ECER2C bit.

[Setting condition]

When there is 2-bit error to RAM output data and error address is captured in EC710EAD0 under the condition that the error judgment is permitted (when not setting ECER2C = 1).

[Clearing condition]

- Writing ECER2C = 1
- When ECC error judgement is disabled (ECERVF = 0).

ECSEDF0位（ECC单个位错误地址检测标志）

ECSEDF0位表示当错误检测有效时，错误被捕获到错误地址寄存器中。该位由1位错误检测设置。

当在EC710EAD0寄存器中已捕获2位错误地址后检测到1位错误时，该位不会更新，但EC710EAD0寄存器会更新。

该位是只读的，因此写入1或0无效。要清除这些位，请将1写入ECER1C位。

ECDCS bit (ECC Decode Input Select)

The ECDCS bit selects either the lower 32 bits data value from RAM or value from the internal test register (EDEDB[31:0] in EC710TED) as input signal to decoder.

The write access to this bit is valid under the condition of ECTMCE = 1 (it is possible to set them at the same time.)

This bit is cleared by setting ECTMCE = 0.

ECTMCE bit (ECC Test Mode Control Enable)

The ECTMCE bit selects the access enable or disable to test register and test control bit.

The write access to this bit is valid under the condition that the value of the ETMA[1:0] bits is 10b.

ETMA[1:0] bits (ECC Test Mode Bit Access Control)

The ETMA[1:0] bits are the write trigger reserved bits to the ECTMCE bit. The read value is always 0. When the value of these bits is 10b, it is possible to have write access to the ECTMCE bit. If these bits are not 10b, the write access to the ECTMCE bit is ignored and the value is not written.

ECEDB[31:0] bits (ECC Test Substitute Data)

ECDCS位（ECC解码输入选择）

ECDCS位选择来自RAM的低32位数据值或来自内部测试寄存器（EC710TED中的EEDB[31:0]）的值作为解码器的输入信号。

对该位的写访问在ECTMCE=1的条件下有效（可以同时置位）。

该位通过设置ECTMCE=0清零。

ECTMCE位（ECC测试模式控制使能）

ECTMCE位选择对测试寄存器和测试控制位的访问启用或禁用。

在ETMA[1:0]位的值为10b的情况下，对该位的写访问是有效的。

ETMA[1:0]位（ECC测试模式位访问控制）

ETMA[1:0]位是ECTMCE位的写触发保留位。读取值始终为0。当这些位的值为10b时，可以对ECTMCE位进行写访问。如果这些位不是10b，则忽略对ECTMCE位的写访问并且不写入该值。

ECEAD[10:0] bits (ECC Error Address)

When ECC error is detected for permitting ECC error judgment, RAM address is captured by the detected signal as a trigger and is hold as the error occurring address. The error address is not captured when the error occurred again to the one held by the same factor.

If 2-bit error occurred under the condition that 1-bit error address is already captured, the 2-bit error address is over-written and the ECDEDF0 bit is set to 1.

If 1-bit error occurred under the condition that 2-bit error address is already captured, the 1-bit error address is not overwritten and the ECSEDF0 bit is not set to 1.

29.3 Operation

29.3.1 ECC Function Setting

Figure 29.1 shows a procedure for ECC function setting.

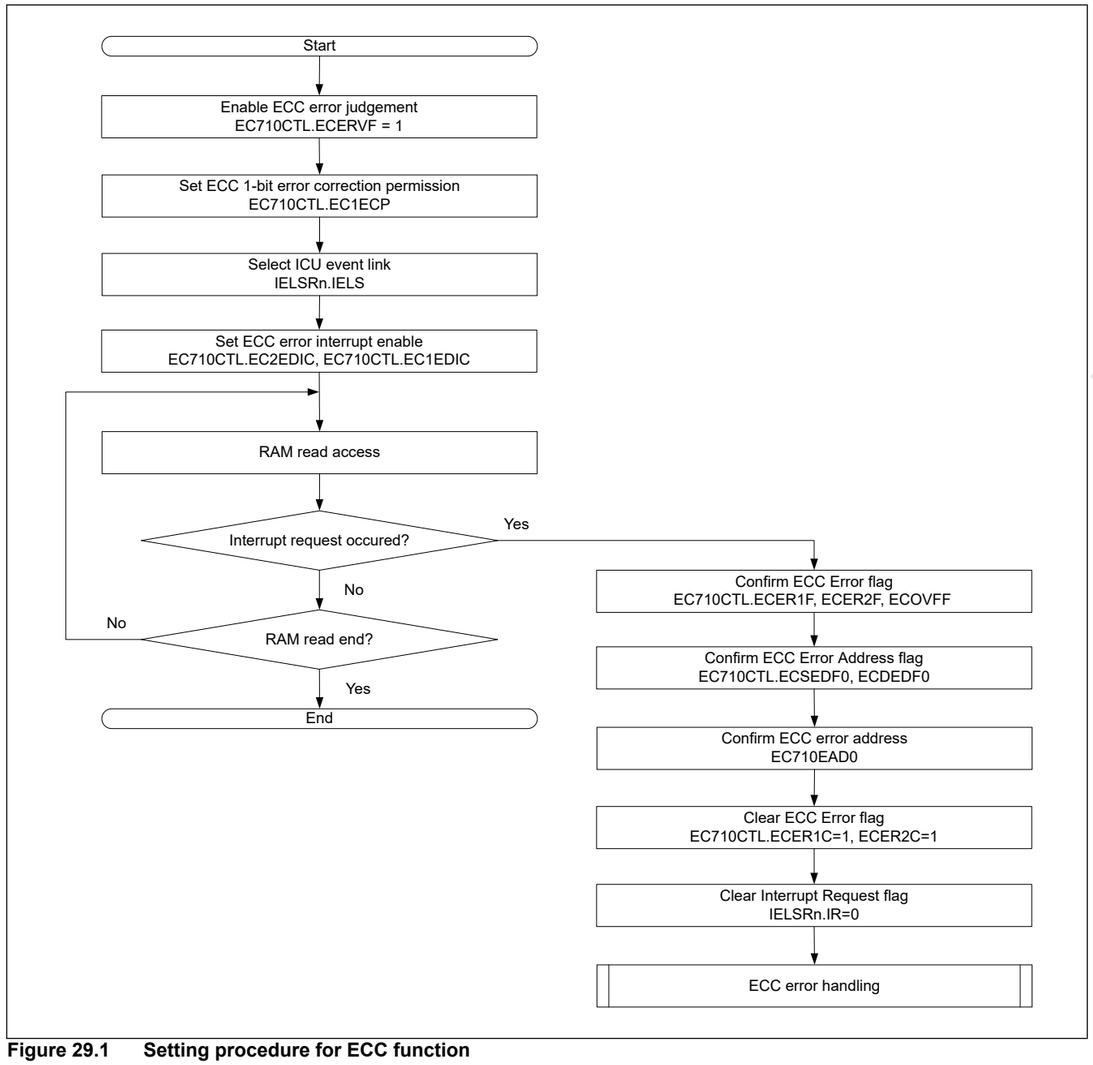

Figure 29.1 Setting procedure for ECC function

ECEAD[10:0]位（ECC错误地址）

当检测到ECC错误以允许ECC错误判断时，RAM地址被检测信号捕获作为触发，并作为错误发生地址保持。当错误再次发生到相同因素持有的地址时，错误地址不会被捕获。

如果在已捕获1位错误地址的情况下发生2位错误，则覆盖2位错误地址并将ECDEDF0位设置为1。

如果在已捕获2位错误地址的情况下发生1位错误，则不会覆盖1位错误地址且ECSEDF0位不会设置为1。

SPDR is the interface with the buffers that hold data for transmission and reception by the SPI. When accessing this register in words, access SPDR. The transmit buffer (SPTX) and receive buffer (SPRX) are independent but both are mapped to SPDR. Figure 30.3 shows the configuration of the SPDR register.

30.2 注册说明

30.2.1 SPDR:RSPI数据寄存器

Base address: SPI_Bn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x00

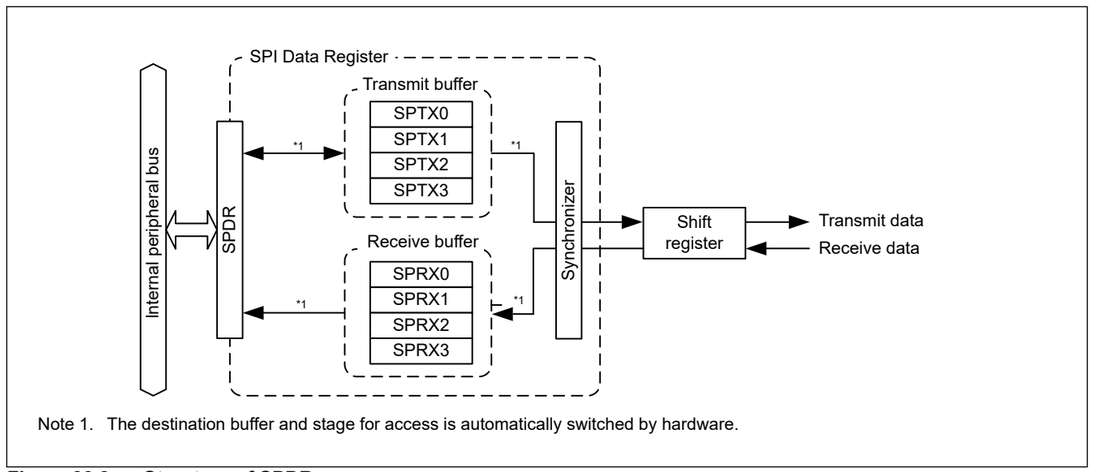
SPDR是与保存数据以供SPI发送和接收的缓冲区的接口。以字访问该寄存器时，访问SPDR。发送缓冲区(SPTX)和接收缓冲区(SPRX)是独立的，但都映射到SPDR。图30.3显示了SPDR寄存器的配置。



Note 1. The destination buffer and stage for access is automatically switched by hardware.

Figure 30.3 Structure of SPDR

32bit × 4 stage transmit FIFO and 32bit × 4 receive FIFO are provided. These 8 stage FIFO are mapped to one address in the SPDR. Transmit buffers (SPTXn, n = 0 to 3) can be written by writing data to SPDR to transmit written data.

Upon completion of receiving data, receive buffers store received data. When an overrun error occurs, data in the receive buffer is not updated.

(1) Bus Interface

The RSPI data register has 32bit x 4 stage transmit FIFO and 32bit x 4 receive FIFO (32 bytes in total). These 32 bytes are mapped to the 4-byte space of SPDR. Write transmit data from the LSB. Received data is stored from the LSB.

SPDR register write operation and read operation are described below.

1. Write
   A transmit buffer write pointer is provided for transmit buffers. When data is written to SPDR, the pointer automatically switches to the next buffer. The following illustrates the structure of the transmit buffer bus interface (write).

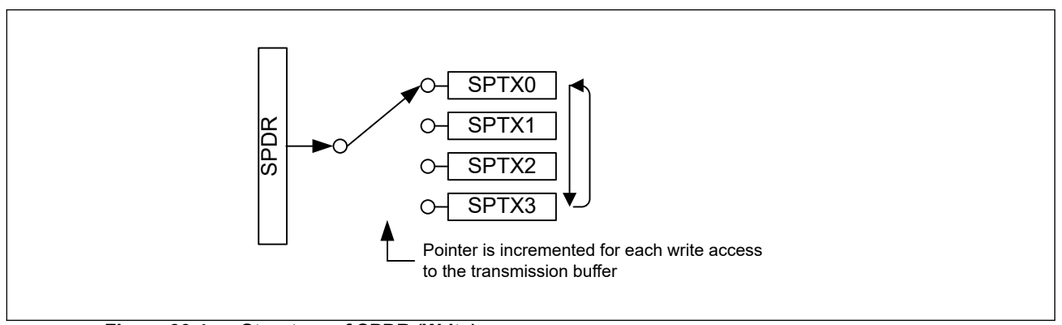


Figure 30.4 Structure of SPDR (Write)

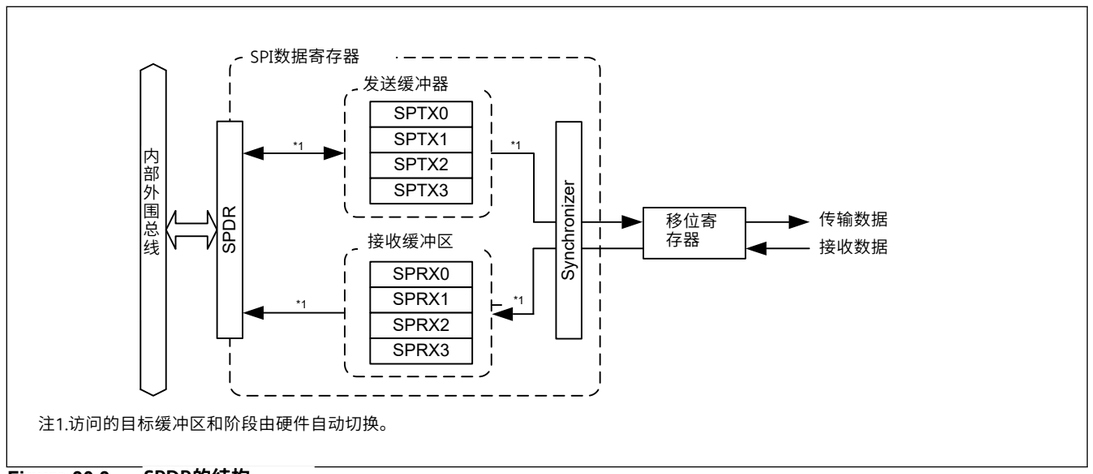
The transmit buffer (SPTX0 to SPTX3) switching order:
SPTX0→SPTX1→SPTX2→SPTX3→SPTX0→SPTX1→…
When writing transmit data to transmit buffers (SPTXn), write transmit data of frames +1 specified by the Transmission FIFO threshold setting bits of RSPI data control register 2 (SPDCR2.TTRG [1: 0]) while an RSPI transmit buffer empty interrupt is present (SPSR.SPTEF flag = 1). Writing to the transmit buffer (SPTXn, n = 0 to 3) in the state where there is no empty stage in the transmit FIFO does not update the buffer value.

2. Read
   Values can be read from receive buffers (SPRXn, n = 0 to 3) or transmit buffers (SPTXn, n = 0 to 3) by reading the SPDR register. Reading a receive buffer or reading a transmit buffer can be selected by the RSPI receive data or transmit data select bit (SPDCR.SPRDTD) in the RSPI data control register.
   The SPDR register is read according to the independent receive buffer read pointer and the transmit buffer read pointer.



注1.访问的目标缓冲区和阶段由硬件自动切换。

Figure 30.3 SPDR的结构

提供32位×4级发送FIFO和32位×4级接收FIFO。这些8级FIFO映射到SPDR中的一个地址。发送缓冲器（SPTXn，n=0到3）可以通过向SPDR写入数据来写入，以发送写入的数据。

接收数据完成后，接收缓冲区存储接收到的数据。发生溢出错误时，接收缓冲区中的数据不会更新。

(1) 总线接口

RSPI数据寄存器有32bitx4级发送FIFO和32bitx4接收FIFO（共32字节）。这32个字节映射到SPDR的4个字节空间。从LSB写入发送数据。接收到的数据从LSB存储。

SPDR寄存器的写操作和读操作如下所述。

1. Write
   为发送缓冲器提供了发送缓冲器写指针。当数据写入SPDR时，指针自动切换到下一个缓冲区。下面说明了发送缓冲区总线接口（写）的结构。

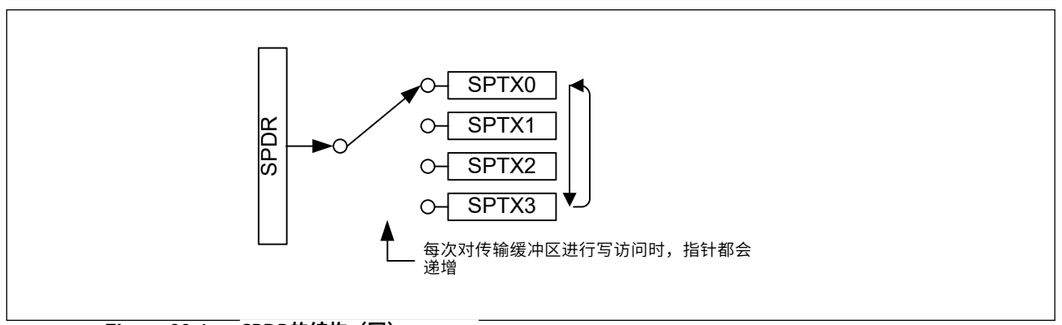


Figure 30.4 SPDR的结构（写）

发送缓冲器（SPTX0到SPTX3）切换顺序：
SPTX0→SPTX1→SPTX2→SPTX3→SPTX0→SPTX1→…
将发送数据写入发送缓冲区(SPTXn)时，写入由RSPI数据控制寄存器2(SPDCR2.TTRG[1:0])的发送FIFO阈值设置位指定的帧+1的发送数据，同时RSPI发送缓冲区空中断存在（SPSR.SPTEF标志=1）。在发送FIFO中没有空级的状态下写入发送缓冲区（SPTXn，n=0到3）不会更新缓冲区值。

2. Read
   通过读取
   SPDR寄存器。可以通过RSPI数据控制寄存器中的RSPI接收数据或发送数据选择位(SPDCR.SPRDTD)来选择读取接收缓冲区或读取发送缓冲区。根据独立的接收缓冲区读指针和发送缓冲区读指针读取SPDR寄存器。

The following illustrates the structure of the receive buffer and transmit buffer bus interface (read).

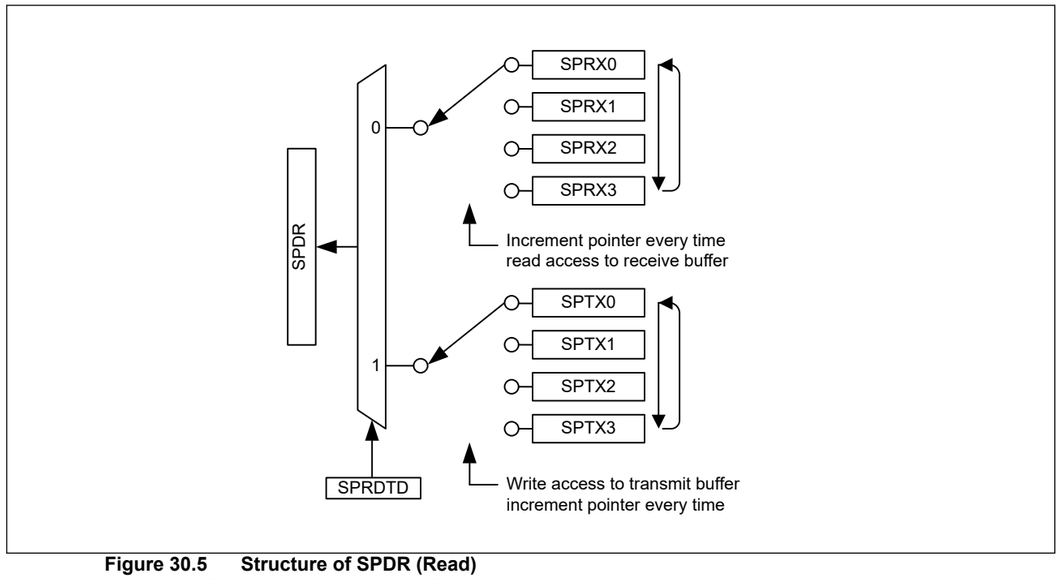

Figure 30.5 Structure of SPDR (Read)

When a receive buffer is read, the receive buffer read pointer automatically switches to the next buffer. The receive buffer read pointer switches in the same order as the transmit buffer write pointer.

The transmit buffer read pointer is updated during the SPDR write access, but it is not updated during the transmit buffer read access. When a transmit buffer is read, the value written to SPDR last can be read.

SCKDL[2:0] bit (RSPCK Delay)

[In the Motorola-SPI case]

The RSPCK delay bits (SCKDL) are used to set the period (RSPCK delay) from SSL signal assertion start until RSPCK oscillates while the SCKDEN bit in the RSPI command register (SPCMD) is 1. If SCKDL is modified while the MSTR bit and the SPE bit in the RSPI control register (SPCR) are 1, subsequent operation is not guaranteed.

To use the RSPI in slave mode, set SCKDL[2:0] bits to 000.

[In the TI-SSP case]

The RSPCK delay bits (SCKDL) are used to set the period (RSPCK delay) from SSL signal assertion start until RSPCK oscillates while the SCKDEN bit in the RSPI command register (SPCMD) is 1. Also that is used to set the period until the SSL signal is negated. If SCKDL is modified while the MSTR bit and the SPE bit in the RSPI control register (SPCR) are 1, subsequent operation is not guaranteed.

To use the RSPI in slave mode, set SCKDL[2:0] bits to 000.

SLNDL[2:0] bit (SSL Negation Delay)

[In the Motorola-SPI case]

The SSL negation delay bits (SLNDL) are used to set the period (SSL negation delay) after the RSPI in master mode sends the final RSPCK edge during serial transfer until it negates the SSL signal while the SLNDEN bit in the RSPI command register (SPCMD) is 1. If SLNDL is modified while the MSTR bit and the SPE bit in the RSPI control register (SPCR) are 1, subsequent operation is not guaranteed.

To use the RSPI in slave mode except TI-SSP, set SLNDL[2:0] bits to 000.

[In the TI-SSP case]

The SSL negation delay bits (SLNDL) are used to set the period (OE negation delay) after the RSPI in master mode sends the final RSPCK edge during serial transfer until it negates the OE signal while the SLNDEN bit in the RSPI command register (SPCMD) is 1. Also, that is used to set the period from when the RSPI in slave mode detects the last RSPCK edge

SCKDL[2:0] bit (RSPCK Delay)

[In the Motorola-SPI case]

RSPCK延迟位(SCKDL)用于设置从SSL信号断言开始到RSPCK振荡的周期（RSPCK延迟），同时RSPI命令寄存器(SPCMD)中的SCKDEN位为1。如果在MSTR位和RSPI控制寄存器（SPCR）中的SPE位为1，不保证后续操作。

要在从机模式下使用RSPI，请将SCKDL[2:0]位设置为000。

[In the TI-SSP case]

RSPCK延迟位(SCKDL)用于设置从SSL信号断言开始到RSPCK振荡的周期（RSPCK延迟），而RSPI命令寄存器(SPCMD)中的SCKDEN位为1。也用于设置周期，直到SSL信号被否定。如果在RSPI控制寄存器(SPCR)中的MSTR位和SPE位为1时修改SCKDL，则无法保证后续操作。

要在从机模式下使用RSPI，请将SCKDL[2:0]位设置为000。

SLNDL[2:0]位（SSL否定延迟）

[In the Motorola-SPI case]

SSL否定延迟位(SLNDL)用于设置在主模式下的RSPI在串行传输期间发送最后一个RSPCK边沿之后的周期（SSL否定延迟），直到它否定SSL信号，而RSPI命令寄存器(SPCMD)中的SLNDEN位)为1。如果在RSPI控制寄存器(SPCR)中的MSTR位和SPE位为1时修改SLNDL，则无法保证后续操作。

要在除TI-SSP之外的从模式下使用RSPI，请将SLNDL[2:0]位设置为000。

[In the TI-SSP case]

SSL否定延迟位(SLNDL)用于设置在主模式下的RSPI在串行传输期间发送最后一个RSPCK边沿之后的周期（OE否定延迟），直到它否定OE信号，而RSPI命令寄存器(SPCMD)中的SLNDEN位)为1。此外，它用于设置从机模式下的RSPI检测到最后一个RSPCK边沿的时间段

of serial transfer to when the OE signal is negated. If SLNDL is modified while the SPE bit in the RSPI control register (SPCR) are 1, subsequent operation is not guaranteed.

SPNDL[2:0] bit (RSPI Next-Access Delay)

The RSPI next-access delay register (SPDECR.SPNDL) is used to set the SSL signal inactive period (next-access delay) after completion of serial transfer while the SPNDEN bit in the RSPI command register (SPCMD) is 1. If SPNDL is modified while the MSTR bit and the SPE bit in the RSPI control register (SPCR) are 1, subsequent operation is not guaranteed.

These bits are used to set the next-access delay value when the SPNDEN bit in SPCMD is 1. To use the RSPI in slave mode, set SPNDL[2:0] bits to 000.

SPNDL[2:0] bit (RSPI Next-Access Delay)

RSPI下一次访问延迟寄存器(SPDECR.SPNDL)用于在RSPI命令寄存器(SPCMD)中的SPNDEN位为1时设置串行传输完成后SSL信号无效周期（下一次访问延迟）。如果SPNDL为当RSPI控制寄存器(SPCR)中的MSTR位和SPE位为1时修改，不保证后续操作。

当SPCMD中的SPNDEN位为1时，这些位用于设置下一次访问延迟值。要在从机模式下使用RSPI，请将SPNDL[2:0]位设置为000。

The RSPI control register (SPCR) is used to set operating mode of the RSPI. If the set BPEN, MSTR, TXMD[1:0], SPFRF, SPMS, MODFEN, BFDS, SCKASE, PTE, SPOE, SPPE bit value is modified while the SPE bit = 1, subsequent operation is not guaranteed.

SPE bit (RSPI Function Enable)

This bit is used to enable or disable RSPI functions. Setting this bit to 1 enables RSPI functions. When the MODF flag in the RSPI status register (SPSR) is 1, the SPE bit is cleared to 0 and the SPE bit cannot be set to 1 until the MODF flag is cleared to 0. (See section 30.3.10. Error Detection) Setting the SPE bit to 0 disables RSPI functions and initializes a part of module functions. (See section 30.3.11. Initializing the SPI)

SPPE bit (Parity Enable)

This bit is used to enable or disable the parity function.

SPOE bit (Parity Mode)

This bit is used to specify even parity or odd parity.

RSPI控制寄存器(SPCR)用于设置RSPI的工作模式。如果设置的BPEN、MSTR、TXMD[1:0]、SPFRF、SPMS、MODFEN、BFDS、SCKASE、PTE、SPOE、SPPE位值在SPE位=1时被修改，则无法保证后续操作。

SPE位（RSPI功能使能）

该位用于启用或禁用RSPI功能。将该位设置为1启用RSPI功能。当RSPI状态寄存器(SPSR)中的MODF标志为1时，SPE位被清除为0，并且在MODF标志被清除为0之前，SPE位不能被设置为1。（参见第30.3.10节错误检测）将SPE位设置为0将禁用RSPI功能并初始化部分模块功能。（参见第30.3.11节。初始化SPI）

SPPE bit (Parity Enable)

该位用于启用或禁用奇偶校验功能。

SPOE bit (Parity Mode)

该位用于指定偶校验或奇校验。

In even parity mode, the parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an even number. In the same way, in odd parity mode, a parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an odd number. The SPOE bit is valid only when the SPPE bit in SPCR is set to 1.

PTE bit (Parity Self-Diagnosis Enable)

This bit is used to enable or disable self-diagnosis of the parity circuit to confirm that the parity function is normal.

SCKASE bit (RSPCK Auto-Stop Function Enable)

This bit is used to enable or disable the RSPCK auto-stop function. When this function is enabled, the RSPCK clock stops immediately before an overrun error occurs during data reception in master mode. For details, see section 30.3.10.1. Overrun errors.

BFDS bit (Between Burst Transfer Frames Delay Select)

This bit controls whether insert the delay time between the burst transfer frames.

Valid in the master mode (SPCR.MSTR = 1) for frames with the SPCMDn.SSLKP bit set to 1.

This bit should be set to 0 in slave mode. The usage of SSL delay control between transfer frames is shown as below. Refer to section 30.3.12.1. Master mode operation in detail.

1. Non-burst transmits
2. Burst transmit with delay between frames
   2-1. From the 1st frame to the last previous frame
   2-2. The last frame
3. Burst transmit with no delay between frames
   3-1. From the 1st frame to the last previous frame
   3-2. The last frame

Note 1. Whether the setting value of following bits are valid or not depends on the setting value of the SPCMD.SPNDEN bit. (Refer to section 30.2.6. SPCMDm : RSPI Command Register (m = 0 to 7).)
The SPDECR.SCKDL[2:0] bits: RSPCK delay
The SPDECR.SLNDL[2:0] bits: SSL negate delay
The SPDECR.SPNDL[2:0] bits: Next access delay

< Setting / operation example > (Motorola SPI, BFDS = 1 Case)

SPCMD0.SSLKP = 1 → Burst transfer / no interframe delay between 0 and 1 (SSL keep active)

SPCMD1.SSLKP = 1 → Burst transfer / no interframe delay between 1 and 2 (SSL keep active)

SPCMD2.SSLKP = 1 → Burst transfer / no interframe delay between 2 and 3 (SSL keep active))

SPCMD3.SSLKP = 1 → Burst transfer / no interframe delay between 3 and 4 (SSL keep active)

SPCMD4.SSLKP = 0 → do not Burst Transfer, and inactive SSL. (BFDS setting is invalid because it does not Burst Transfer.)

SPCMD5.SSLKP = 1 → Burst transfer / no interframe delay between 5 and 6 (SSL keep active)

SPCMD6.SSLKP = 1 → Burst transfer / no interframe delay between 6 and 7 (SSL keep active)

在偶校验模式下，奇偶校验位被确定为1（奇偶校验位+发送字符或接收字符）之和为偶数。同样，在奇校验模式下，奇偶校验位被确定为使得1（奇偶校验位+发送字符或接收字符）之和变为奇数。SPOE位只有在SPCR中的SPPE位设置为1时才有效。

PTE bit (Parity Self-Diagnosis Enable)

该位用于启用或禁用奇偶校验电路的自诊断，以确认奇偶校验功能是否正常。

SCKASE位（RSPCK自动停止功能使能）

该位用于启用或禁用RSPCK自动停止功能。当此功能使能时，RSPCK时钟在主机模式下数据接收期间发生溢出错误之前立即停止。有关详细信息，请参阅第30.3.10.1节。溢出错误。

BFDS位（突发传输帧之间延迟选择）

该位控制是否在突发传输帧之间插入延迟时间。

对于SPCMDn.SSLKP位设置为1的帧，在主模式(SPCR.MSTR=1)下有效。

在从机模式下，该位应设置为0。传输帧之间的SSL延迟控制的使用如下所示。请参阅第30.3.12.1节。详细的主模式操作。

1. Non-burst transmits
2.帧间延迟突发传输
   2-1。从第一帧到最后一帧

SPCMD5.SSLKP=1→Bursttransfernointerframedelaybetween5and6(SSLkeepactive)

SPCMD6.SSLKP=1→Bursttransfernointerframedelaybetween6and7(SSLkeepactive)

SPCMD7.SSLKP = 0 → do not Burst Transfer, and inactive SSL. (BFDS setting is invalid because it does not Burst Transfer.)

MODFEN bit (Mode Fault Error Detection Enable)

This bit is used to enable or disable detection of a mode fault error. (See section 30.3.10. Error Detection.) The RSPI determines SSL0 pin input or output direction according to the combination of the MODFEN and MSTR bits. (See section 30.3.2. Controlling the SPI Pins.)

SPEIE bit (RSPI Error Interrupt Enable)

This bit is used to enable or disable an RSPI error interrupt request when the RSPI detects a mode fault error or an underrun error and sets the MODF flag in the RSPI status register (SPSR) to 1, when the RSPI detects an overrun error and sets the OVRF flag in SPSR to 1, or when the RSPI detects a parity error and sets the PERF flag in SPSR to 1. (See section 30.3.10. Error Detection)

SPRIE bit (RSPI Receive Buffer Full Interrupt Enable)

This bit is used to enable or disable a receive buffer full interrupt request of the RSPI.

SPIIE bit (RSPI Idle Interrupt Enable)

This bit is used to enable or disable an idle interrupt request of the RSPI after the RSPI detects the idle state and sets the IDLNF flag in the RSPI status register (SPSR) to 0.

SPDRES bit (RSPI receive data ready error select)

When a receive data ready is detected (SPSR.SPDRF = 1), select whether to use SPRI interrupt request or SPEI interrupt request.

SPTIE bit (RSPI Transmit Buffer Empty Interrupt Enable)

This bit is used to enable or disable a transmit buffer empty interrupt request of the RSPI.

A transmit buffer empty interrupt request at the beginning of transmission is generated by setting the SPE bit to 1 simultaneously when or after the SPTIE bit is set to 1. Note that a transmit buffer empty interrupt is generated while the SPTIE bit is 1 even though RSPI functions are disabled (SPE bit = 0).

CENDIE bit (RSPI Communication End Interrupt Enable)

This bit controls generation of a communication end interrupt request.

SPMS bit (RSPI Mode Select)

This bit is used to select SPI operation (4-wire) or clock synchronous operation (3-wire).

For clock synchronous operation, the SSL pin is not used but three pins RSPCK, MOSI, and MISO are used for communication. When SPMS = 1 (clock synchronous operation (3-wire)), the setting of the SPFRF bit is invalid.

To perform clock synchronous operation in master mode (SPCR.MSTR = 1), the CPHA bit in the RSPI command register (SPCMD) can be set to 0 or 1. To perform clock synchronous operation in slave mode (SPCR.MSTR = 0), set the CPHA bit to 1. If this bit is set to 0 for clock synchronous operation in slave mode (SPCR.MSTR = 0), subsequent operation is not guaranteed.

The communication status according to the settings of the MSTR bit, TXMD [1:0] bits, SPFRF bit, and SPMS bit of the RSPI control register (SPCR) as follows.

Table 30.4 RSPI Communication Status (1 of 2)

SPCR.MSTR	SPCR.TXMD[1]	SPCR.TXMD[0]	SPCR.SPFRF	SPCR.SPMS	Communication Status	Communication Status No
1	0	0	0	0	Transmit-Receive Master / Motorola SPI / SPI operation (4-wire)	1-(1)
1	0	0	1	0	Transmit-Receive Master / TI-SSP / SPI operation (4-wire)	1-(2)
1	0	0	—	1	Transmit-Receive Master /Clock synchronous operation (3-wire)	1-(3)

1	0	1	1	0	Transmit only Master / TI-SSP / SPI operation (4-wire)	1-(5)

SPCMD7.SSLKP=0→不BurstTransfer，且SSL处于非活动状态。（BFDS设置无效，因为它不Burst Transfer.)

MODFEN位（模式故障错误检测使能）

该位用于启用或禁用模式故障错误检测。（请参阅第30.3.10节。错误检测。）RSPI根据MODFEN和MSTR位的组合确定SSL0引脚的输入或输出方向。（请参阅第30.3.2节。控制SPI引脚。）

SPEIE位（RSPI错误中断使能）

该位用于在RSPI检测到模式故障错误或欠载错误并将RSPI状态寄存器(SPSR)中的MODF标志设置为1时启用或禁用RSPI错误中断请求，当RSPI检测到溢出错误并设置SPSR中的OVRF标志为1，或者当RSPI检测到奇偶校验错误并将SPSR中的PERF标志设置为1时。（参见第30.3.10节。

错误检测）

SPRIE位（RSPI接收缓冲器满中断使能）

该位用于启用或禁用RSPI的接收缓冲区满中断请求。

SPIIE位（RSPI空闲中断允许）

该位用于在RSPI检测到空闲状态并设置RSPI后启用或禁用RSPI的空闲中断请求
RSPI状态寄存器(SPSR)中的IDLNF标志为0。

SPDRES位（RSPI接收数据就绪错误选择）

当检测到接收数据就绪时（SPSR.SPDRF=1），选择是使用SPRI中断请求还是SPEI中断请求。

SPTIE位（RSPI发送缓冲区空中断使能）

该位用于启用或禁用RSPI的发送缓冲区空中断请求。

当SPTIE位设置为1时或之后，同时将SPE位设置为1，可在发送开始时产生发送缓冲区空中断请求。请注意，即使RSPI为1，也会在SPTIE位为1时产生发送缓冲区空中断功能被禁用（SPE位=0）。

CENDIE位（RSPI通信结束中断使能）

该位控制通信结束中断请求的产生。

SPMS位（RSPI模式选择）

该位用于选择SPI操作（4线）或时钟同步操作（3线）。

对于时钟同步操作，不使用SSL引脚，而是使用三个引脚RSPCK、MOSI和MISO进行通信。当SPMS=1（时钟同步操作（3线））时，SPFRF位的设置无效。

要在主机模式下执行时钟同步操作(SPCR.MSTR=1)，可以将RSPI命令寄存器(SPCMD)中的CPHA位设置为0或1。要在从机模式下执行时钟同步操作(SPCR.MSTR=0)，将CPHA位设置为1。如果该位设置为0以在从机模式下进行时钟同步操作（SPCR.MSTR=0），则无法保证后续操作。

根据MSTR位、TXMD[1:0]位、SPFRF位和SPMS位设置的通信状态
RSPI控制寄存器（SPCR）如下。

SPFRF bit (RSPI Frame Format Select)

This bit selects the communication protocol.

The format of the RSPI terminal (RSPCK, SSL0 to 7) can be set according to the set communication protocol.

When SPMS = 1 (clock synchronous operation (3-wire)), this bit is invalid because SSL is not used.

TXMD[1:0] bit (Communication Mode Select)

This bit is used to select the transmit-receive, transmit-only, and receive-only serial communication.

When TXMD[1:0] is set to 01 for communication, transmit-only is performed without reception.

When TXMD[1] is set to 1 for communication, receive-only is performed without transmission.

When TXMD[1:0] is set to 01 for communication, a receive buffer full interrupt request cannot be used.

When TXMD[1] is set to 1 for communication, a transmit buffer empty interrupt request cannot be used.

(See section 30.3.6. Communication Operating Mode.)

MSTR bit (RSPI Master/Slave Mode Select)

This bit is used to select master mode or slave mode of the RSPI. The RSPI determines input/output directions of pins RSPCK, MOSI, MISO, and SSL1 to SSL3 according to the MSTR bit setting.

BPEN bit (Synchronization Circuit Bypass Enable)

This bit selects whether to enable or disable the synchronization bypass function. This bit can be used to bypass the synchronization circuit only when the same clock is input to the bus clock (PCLK) and operation clock (TCLK).

SPFRF位（RSPI帧格式选择）

该位选择通信协议。

RSPI终端的格式（RSPCK，SSL0到7）可以根据设置的通信协议进行设置。

当SPMS=1（时钟同步操作（3线））时，该位无效，因为没有使用SSL。

TXMD[1:0]位（通信模式选择）

该位用于选择发送-接收、仅发送和仅接收串行通信。

当TXMD[1:0]设置为01进行通信时，只执行发送而不接收。

当TXMD[1]设置为1进行通信时，只执行接收而不发送。

当TXMD[1:0]设置为01进行通信时，不能使用接收缓冲区满中断请求。

当TXMD[1]设置为1进行通信时，不能使用发送缓冲区空中断请求。

（参见第30.3.6节。通信操作模式。）

MSTR位（RSPI主从模式选择）

该位用于选择RSPI的主模式或从模式。RSPI确定引脚的输入输出方向
根据MSTR位设置，RSPCK、MOSI、MISO和SSL1到SSL3。

BPEN位（同步电路旁路使能）

该位选择是启用还是禁用同步旁路功能。只有当总线时钟（PCLK）和操作时钟（TCLK）输入相同的时钟时，该位才能用于绕过同步电路。

注1.参考图30.66中的SW流程。

RMFM[4:0]位（仅在主接收中设置帧处理计数）

仅在主接收模式下操作时，可以调整接收帧的数量。仅当主机模式(SPCR.MSTR=1)和通信操作模式选择位(SPCR.TXMD[1:0])为10b时有效。

Only the start bit in master mode reception automatically stops communication after starts frame processing according to the value set in this bit after reception starts.

If the RMFM [4:0] bits are rewritten while the SPE bit of the RSPI control register (SPCR) is 1, subsequent operations are not guaranteed.

RMEDTG bit (End Trigger in Master Receive only)

This bit is used to end reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.TXMD [1:0]) are 10b.

RMSTTG bit (Start Trigger in Master Receive only)

This bit is used to start reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.TXMD [1:0]) are 10b.

Writing 1 to this bit during reception is not accepted. Write again after reception is completed.

SPDRC[7:0] bit (RSPI received data ready detect adjustment)

The receive data ready detection function can be disabled or, if used, the period until detection can be set from 1 to 255 TCLK.

The value set in the SPDRC [7:0] bits is used to 1 set the SPDRF flag. For details, see the description of SPDRF in section 30.2.9. SPSR : SPI Status Register.

If the set value is changed while the SPE bit is 1, subsequent operations are not guaranteed.

SPLP bit (RSPI Loopback)

When the SPLP bit is set to 1, the RSPI shuts down the route between the MISO pin and the shift register (when the MSTR bit in the RSPI control register is 1) or shuts down the route between the MOSI pin and the shift register, inverts the input route value in the shift register, and then connects the route to the output route (when the MSTR bit in the RSPI control register is 0) (loopback mode).

SPLP2 bit (RSPI Loopback 2)

When the SPLP2 bit is set to 1, the RSPI shuts down the route between the MISO pin and the shift register (when the MSTR bit in the RSPI control register is 1) or shuts down the route between MOSI pin and the shift register and then connects the route to the output route without inverting the input route value in the shift register (when the MSTR bit in the RSPI control register is 0) (loopback mode). If this bit is set to 1 together with the SPLP bit, setting this bit takes precedence.

MOIFV bit (MOSI Idle Fixed Value)

This bit is used to select the MOSI pin output value during the SSL negation period (including SSL retention period in burst transfer) when the MOIFE bit is 1 in master mode.

If this bit is modified with the SPE bit in the RSPI control register (SPCR) set to 1, subsequent operation is not guaranteed.

MOIFE bit (MOSI Idle Fixed Value Enable)

This bit is used for the RSPI in master mode to fix the MOSI output value during the SSL negation period (including SSL retention period in burst transfer). When MOIFE bit = 0, the RSPI outputs the last data of the previous serial transfer to MOSI during the SSL negation period. When MOIFE bit = 1, the RSPI outputs the fixed MOIFV bit value to MOSI.

If this bit is modified with the SPE bit in the RSPI control register (SPCR) set to 1, subsequent operation is not guaranteed.

只有主机模式接收的起始位在接收开始后根据该位中设置的值开始帧处理后自动停止通信。

如果在RSPI控制寄存器(SPCR)的SPE位为1时重写RMFM[4:0]位，则无法保证后续操作。

RMEDTG位（仅限主接收中的结束触发）

当主机只接收时，该位用于结束接收。仅当主机模式(SPCR.MSTR=1)和通信模式选择位(SPCR.TXMD[1:0])为10b时有效。

RMSTTG位（仅在主接收中启动触发）

该位用于仅在主机接收时开始接收。仅当主机模式(SPCR.MSTR=1)和通信模式选择位(SPCR.TXMD[1:0])为10b时有效。

接收期间不接受向该位写入1。接收完成后再次写入。

SPDRC[7:0]位（RSPI接收数据就绪检测调整）

可以禁用接收数据就绪检测功能，或者，如果使用，可以将检测前的周期设置为1到255 TCLK.

SPDRC[7:0]位中设置的值用于将SPDRF标志设置为1。详见30.2.9节对SPDRF的描述。SPSR：SPI状态寄存器。

如果在SPE位为1时更改设置值，则无法保证后续操作。

SPLP bit (RSPI Loopback)

当SPLP位设置为1时，RSPI关闭MISO引脚和移位寄存器之间的路由（当RSPI控制寄存器中的MSTR位为1时）或关闭MOSI引脚和移位寄存器之间的路由，将移位寄存器中的输入路由值取反，然后将路由连接到输出路由（当RSPI控制寄存器中的MSTR位为0时）（环回模式）。

SPLP2 bit (RSPI Loopback 2)

当SPLP2位设置为1时，RSPI关闭MISO引脚和移位寄存器之间的路由（当RSPI控制寄存器中的MSTR位为1时）或关闭MOSI引脚和移位寄存器之间的路由，然后将路由连接到输出路由，而不反转移位寄存器中的输入路由值（当RSPI控制寄存器中的MSTR位为0时）（环回模式）。如果该位与SPLP位一起设置为1，则设置该位优先。

MOIFV位（MOSI空闲固定值）

该位用于在主模式下MOIFE位为1时选择SSL否定期间（包括突发传输中的SSL保持期间）的MOSI引脚输出值。

如果将该位修改为将RSPI控制寄存器(SPCR)中的SPE位设置为1，则无法保证后续操作。

MOIFE位（MOSI空闲固定值启用）

该位用于主模式下的RSPI，用于在SSL否定期间（包括突发传输中的SSL保留期间）固定MOSI输出值。当MOIFE位=0时，RSPI在SSL否定期间将上一次串行传输的最后一个数据输出到MOSI。当MOIFE位=1时，RSPI将固定的MOIFV位值输出到MOSI。

如果将该位修改为将RSPI控制寄存器(SPCR)中的SPE位设置为1，则无法保证后续操作。

SSLiP bits (SSL Signal Polarity Bits)

These bits are used to specify the polarity of SSL signals. The set SSLiP bit (i = 3 to 0) values indicate the active polarity of SSLi signals.

If any of these SSLiP bits is modified with the SPE bit in the RSPI control register (SPCR) set to 1, subsequent operation is not guaranteed.

*SSL0 is different from SSL1-SSL3. When slave or multi-master, it functions as an input.

For details, refer to Single Master/Single Slave (This MCU = Slave), and Multi-Master/Multi-Slave (This MCU = Master).

SPBR[7:0] bit (SPI Bit Rate)

The RSPI bit rate bits (SPBR) is used to set the bit rate in master mode. If SPBR is modified while the MSTR bit in the RSPI control register (SPCR) and the MSTR bit are 1, subsequent operation is not guaranteed.

When the RSPI is used in slave mode, the bit rate depends on the input clock bit rate regardless of the SPCMD.BRDV setting. (Specify a bit rate that meets electrical characteristics.).

The bit rate is determined by a combination of the set SPBR value and the set BRDV[1:0] bits value in the RSPI command register (SPCMD0 to SPCMD7).

The bit rate is calculated by the following expression, where n is the set SPBR value (0 to 255) and N is the set BRDV[1:0] bits value (0 to 3).

$$\text{Bit rate} = \frac{f(\text{TCLK})}{2 \times (n+1) \times 2^N}$$

The following table shows an example of correspondence between bit rates and set values of SPBR and BRDV[1:0].

Table 30.5 Corresponding Between Bit Rates and Set Values (Example)

SSLiP位（SSL信号极性位）

这些位用于指定SSL信号的极性。设置SSLiP位（i=3到0）值表示的有效极性
SSLi signals.

如果在将RSPI控制寄存器(SPCR)中的SPE位设置为1的情况下修改了这些SSLiP位中的任何一个，则无法保证后续操作。

*SSL0与SSL1-SSL3不同。当从机或多主机时，它用作输入。

详情请参考单主单从（本MCU=从）和多主多从（本MCU=主）。

SPBR[7:0] bit (SPI Bit Rate)

RSPI比特率位(SPBR)用于设置主机模式下的比特率。如果SPBR被修改，而MSTR位在RSPI控制寄存器（SPCR）和MSTR位为1，不保证后续操作。

当RSPI在从机模式下使用时，比特率取决于输入时钟比特率，与SPCMD.BRDV设置无关。（指定符合电气特性的比特率。）。

比特率由设置的SPBR值和RSPI命令寄存器（SPCMD0到SPCMD7）中设置的BRDV[1:0]位值的组合确定。

比特率通过以下表达式计算，其中n是设置的SPBR值（0到255），N是设置的BRDV[1:0]位值（0到3）。

$$\text{比特率} = \frac{f(\text{TCLK})}{2 \times (n+1) \times 2^N}$$

下表显示了比特率与SPBR和BRDV[1:0]的设置值之间的对应关系示例。

SPSLN[2:0] bit (RSPI Sequence Length)

These bits are used to set the sequence length for the RSPI in master mode to perform sequence operation. According to the sequence length specified by SPSLN[2:0] bits, the RSPI in master mode changes RSPI command registers 0 to 7 (SPCMD0 to SPCMD7) to be referenced and the reference sequence. For details, see section 30.3.13.1. Master mode operation.

The RSPI in slave mode always references SPCMD0

SPSLN[2:0]位（RSPI序列长度）

这些位用于设置RSPI在主模式下执行序列操作的序列长度。根据SPSLN[2:0]位指定的序列长度，主模式下的RSPI更改要参考的RSPI命令寄存器0到7（SPCMD0到SPCMD7）和参考序列。有关详细信息，请参阅第30.3.13.1节。主模式操作。

The RSPI has eight RSPI command registers (SPCMD0 to SPCMD7) that are used to set the transfer format of the RSPI in master mode. Furthermore, some bits in SPCMD0 are used to set the transfer format of the RSPI in slave mode. The RSPI in master mode sequentially references SPCMD0 to SPCMD7 according to the setting of the SPSLN[2:0] bits in the RSPI Control register 3 (SPCR3), and then performs serial transfer specified in the referenced SPCMD.

RSPI set the SPCMD register before setting data to be transmitted by referencing the SPCMD when the transmit buffer is empty (while the next-transfer data has not been set).

The SPCMD referenced by the RSPI in master mode is indicated by SPCP[2:0] in the RSPI status register (SPSR). If SPCMD0 is modified while the RSPI in slave mode is enabled (SPCR.SPE = 1), subsequent operation is not guaranteed.

CPHA bit (RSPCK Phase)

This bit is used to set the RSPCK phase of the RSPI in master mode or slave mode. To perform data communication between RSPI modules, the same RSPCK phase must be set for both modules.

When SPCR.SPMS = 0 and SPCR.SPFRF = 1 (in TI SSP mode), setting CPHA = 0 is invalid.

CPOL bit (RSPCK Polarity)

This bit is used to set the RSPCK polarity of the RSPI in master mode or slave mode. To perform data communication between RSPI modules, the same RSPCK polarity must be set for both modules.

BRDV[1:0] bit (Bit Rate Division)

This register is used to determine the bit rate with a combination of the set values of the BRDV[1:0] bits and the RSPI bit rate register (SPCR3.SPBR). The set SPBR value determines the base bit rate. The set BRDV[1:0] bits value is used to select undivided, 2-divided, 4-divided, or 8-divided base bit rate. SPCMD0 to SPCMD7 enable setting of different BRDV[1:0] values. This makes it possible to perform serial transfer with a different bit rate for each command.

SSLKP bit (SSL Signal Level Hold)

This bit is used to set whether to hold or negate the SSL signal level of the current command during a period from the SSL negation timing for the current command to the SSL assertion timing for the next command when the RSPI in master mode performs serial transfer. Setting this bit to 1 enables burst transfer in SPI operation master mode. For details, see section 30.3.12.1. Master mode operation.

To use the RSPI in slave mode, set SSLKP bit to 0.

LSBF bit (RSPI LSB First)

This bit is used to set the data format of the RSPI in master mode or slave mode to MSB first or LSB first.

RSPI有8个RSPI命令寄存器（SPCMD0到SPCMD7），用于设置主模式下RSPI的传输格式。此外，SPCMD0中的一些位用于设置从机模式下RSPI的传输格式。主机模式下的RSPI根据RSPI控制寄存器3(SPCR3)中SPSLN[2:0]位的设置顺序引用SPCMD0到SPCMD7，然后执行引用的SPCMD中指定的串行传输。

当发送缓冲区为空时（下一次传输数据尚未设置），RSPI在设置要发送的数据之前通过引用SPCMD设置SPCMD寄存器。

RSPI在主模式下引用的SPCMD由RSPI状态寄存器(SPSR)中的SPCP[2:0]指示。如果SPCMD0在从机模式下启用RSPI时修改（SPCR.SPE=1），不能保证后续操作。

CPHA bit (RSPCK Phase)

该位用于设置RSPI在主模式或从模式下的RSPCK相位。要在RSPI模块之间进行数据通信，必须为两个模块设置相同的RSPCK相位。

当SPCR.SPMS=0且SPCR.SPFRF=1（在TISSP模式下）时，设置CPHA=0无效。

CPOL bit (RSPCK Polarity)

该位用于设置RSPI在主模式或从模式下的RSPCK极性。要在RSPI模块之间进行数据通信，必须为两个模块设置相同的RSPCK极性。

BRDV[1:0]位（比特率划分）

该寄存器用于结合BRDV[1:0]位和RSPI比特率寄存器(SPCR3.SPBR)的设置值来确定比特率。设置的SPBR值确定基本比特率。设置的BRDV[1:0]位值用于选择未分频、2分频、4分频或8分频基本比特率。SPCMD0到SPCMD7可以设置不同的BRDV[1:0]值。这使得可以为每个命令以不同的比特率执行串行传输。

SSLKP位（SSL信号电平保持）

该位用于设置在主模式下的RSPI执行串行传输时，从当前命令的SSL否定时序到下一条命令的SSL断言时序期间，是保持还是否定当前命令的SSL信号电平。将此位设置为1可在SPI操作主机模式下启用突发传输。有关详细信息，请参阅第30.3.12.1节。主模式操作。

要在从机模式下使用RSPI，请将SSLKP位设置为0。

LSBF bit (RSPI LSB First)

该位用于设置RSPI在主模式或从模式下的数据格式为MSB优先或LSB优先。

SPNDEN bit (RSPI Next-Access Delay Enable)

This bit is used to set the period (next-access delay) after the RSPI in master mode inactivates the SSL signal at the end of serial transfer until it enables SSL signal assertion of the next access. When SPNDEN bit = 0, the RSPI sets the next-access delay to 1 RSPCK + 5TCLK. When SPNDEN bit = 1, the RSPI inserts the next-access delay in accordance with the RSPI next-access delay register (SPDECR.SPNDL) setting.

To use the RSPI in slave mode, set SPNDEN bit to 0.

SLNDEN bit (SSL Negation Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period (SSL negation delay) after the RSPI in master mode stops RSPCK oscillation until it inactivates the SSL signal. When SLNDEN bit = 0, the RSPI sets the SSL negation delay to 1 RSPCK. When SLNDEN bit = 1, the RSPI negates the SSL signal with the RSPCK delay in accordance with the slave select negation delay register (SPDECR.SLNDL) setting.

To use the RSPI in slave mode, set SLNDEN bit to 0.

[In the TI-SSP case]

This bit is used to set the period from when the master mode RSPI stops RSPCK oscillation to when the OE signal is inactivated, or when the slave mode RSPI detects the last edge of RSPCK and then negates the OE signal. When the SLNDEN bit is 0, the SSL negate delay is 1 RSPCK in master mode and 1 TCLK in slave mode. When SLNDEN bit = 1, the RSPI negates the SSL signal with the RSPCK delay in accordance with the slave select negation delay register (SPDECR.SLNDL) setting.

When using RSPI in slave mode except TI SSP setting, set the SLNDEN bit to 0.

SCKDEN bit (RSPCK Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period (RSPCK delay) after the RSPI in master mode activates the SSL signal until it oscillates RSPCK. When SCKDEN bit = 0, the RSPI sets the RSPCK delay to 1 RSPCK. When SCKDEN bit = 1, the RSPI starts RSPCK oscillation with the RSPCK delay in accordance with the RSPCK delay register (SPDECR.SCKDL) setting.

To use the RSPI in slave mode, set SCKDEN bit to 0.

[In the TI-SSP case]

This bit is used to set the period from the start of assertion of the SSL signal to the RSPCK oscillation (RSPCK delay) and the period of the SSL signal to negation by the RSPI in master mode. When SCKDEN bit = 0, the RSPI does not sets the RSPCK delay. When SCKDEN bit = 1, the RSPI starts RSPCK oscillation with the RSPCK delay in accordance with the RSPCK delay register (SPDECR.SPCKDL) setting.

To use the RSPI in slave mode, set SCKDEN bit to 0.

SPB[4:0] bit (RSPI Data Length)

These bits are used to set the transfer data length of the RSPI in master mode or slave mode.

SSLA[2:0] bit (SSL Signal Assertion)

These bits are used to control SSL signal assertion for the RSPI in master mode to perform serial transfer. The set SSLA[2:0] bits value controls assertion of the SSL3 to SSL0 signals. The signal polarity when the SSL signal is asserted depends on the set value of the RSPI slave select polarity register (SPCR3.SSLiP). When SSLA[2:0] bits are set to 000 in multi-master mode, serial transfer is performed with all SSL signals negated (because SSL0 is input).

To use the RSPI in slave mode, set SSLA[2:0] bits to 000.

SPNDEN位（RSPI下一次访问延迟使能）

该位用于设置在主模式下的RSPI在串行传输结束时停用SSL信号之后的周期（下一次访问延迟），直到它启用下一次访问的SSL信号断言。当SPNDEN位=0时，RSPI将下一次访问延迟设置为1RSPCK+5TCLK。当SPNDEN位=1时，RSPI根据RSPI下一次访问延迟寄存器(SPDECR.SPNDL)的设置插入下一次访问延迟。

要在从机模式下使用RSPI，请将SPNDEN位设置为0。

SLNDEN位（SSL否定延迟设置启用）

[In the Motorola-SPI case]

该位用于设置在主模式下的RSPI停止RSPCK振荡直到它停用SSL信号之后的周期（SSL否定延迟）。当SLNDEN位=0时，RSPI将SSL否定延迟设置为1RSPCK。当SLNDEN位=1时，RSPI根据从机选择否定延迟寄存器(SPDECR.SLNDL)的设置，使用RSPCK延迟否定SSL信号。

要在从机模式下使用RSPI，请将SLNDEN位设置为0。

[In the TI-SSP case]

该位用于设置从主模式RSPI停止RSPCK振荡到OE信号无效，或从模式RSPI检测到RSPCK的最后一个边沿然后取消OE信号的周期。当SLNDEN位为0时，SSL否定延迟在主机模式下为1个RSPCK，在从机模式下为1个TCLK。当SLNDEN位=1时，RSPI根据从机选择否定延迟寄存器(SPDECR.SLNDL)的设置，使用RSPCK延迟否定SSL信号。

在除TISSP设置之外的从模式下使用RSPI时，将SLNDEN位设置为0。

SCKDEN位（RSPCK延迟设置使能）

[In the Motorola-SPI case]

该位用于设置在主模式下的RSPI激活SSL信号之后直到其振荡RSPCK的周期（RSPCK延迟）。当SCKDEN位=0时，RSPI将RSPCK延迟设置为1RSPCK。当SCKDEN位=1时，RSPI启动
根据RSPCK延迟寄存器(SPDECR.SCKDL)设置，具有RSPCK延迟的RSPCK振荡。

要在从机模式下使用RSPI，请将SCKDEN位设置为0。

[In the TI-SSP case]

该位用于设置从SSL信号断言开始到RSPCK振荡（RSPCK延迟）的周期，以及SSL信号在主模式下被RSPI否定的周期。当SCKDEN位=0时，RSPI不设置RSPCK延迟。当SCKDEN位=1时，RSPI根据RSPCK延迟启动RSPCK振荡

RSPCK延迟寄存器(SPDECR.SPCKDL)设置。

要在从机模式下使用RSPI，请将SCKDEN位设置为0。

SPB[4:0]位（RSPI数据长度）

这些位用于设置RSPI在主模式或从模式下的传输数据长度。

SSLA[2:0]位（SSL信号断言）

这些位用于控制主模式下RSPI的SSL信号断言以执行串行传输。套装
SSLA[2:0]位值控制SSL3到SSL0信号的断言。SSL信号有效时的信号极性取决于RSPI从机选择极性寄存器(SPCR3.SSLiP)的设置值。当SSLA[2:0]位在多主机模式下设置为000时，串行传输在所有SSL信号取反的情况下执行（因为输入了SSL0）。

要在从机模式下使用RSPI，请将SSLA[2:0]位设置为000。

The RSPI data control register (SPDCR) controls the data format.

If the value set in this register is changed while the SPE bit is 1, subsequent operations are not guaranteed.

BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. A data after byte swap is different by a data length (setting of SPCMD.SPB[4:0]).

When byte swap, A data length (setting of SPB[4:0]) must be set to 32bit or 16bit. Other case of data length (i.e. 4 to 15, 17 to 31-bit length), byte swap is not guaranteed. For the arrangement of data before and after swapping data lengths of 32 bits and 16 bits, see section 30.3.4.3. Byte Swap Transmission and section 30.3.4.4. Byte Swap Reception.

When the parity function set to valid, the behavior is not guaranteed.

SPRDTD bit (RSPI Receive Data or Transmit Data Select)

This bit is used to select receive buffer or transmit buffer from which the RSPI data register (SPDR) value is read.

When the transmit buffer is read, the value that was written to SPDR immediately before is read.

SINV bit (Serial data invert bit)

This bit is used to invert transmit data and receive data.

When the SINV bit is set to 1, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/reception data.

RSPI数据控制寄存器(SPDCR)控制数据格式。

如果在SPE位为1时更改此寄存器中设置的值，则无法保证后续操作。

BYSW位（字节交换操作模式选择）

它是一个设置位，即以字节为单位交换一个发送接收数据。字节交换后的数据因数据长度不同（SPCMD.SPB[4:0]的设置）。

字节交换时，A数据长度（SPB[4:0]的设置）必须设置为32位或16位。数据长度的其他情况（即4到15、17到31位长度），不保证字节交换。关于交换32位和16位数据长度前后的数据排列，请参见第30.3.4.3节。字节交换传输和第30.3.4.4节。字节交换接收。

当奇偶校验函数设置为有效时，行为不被保证。

SPRDTD位（RSPI接收数据或发送数据选择）

该位用于选择从中读取RSPI数据寄存器(SPDR)值的接收缓冲区或发送缓冲区。

读取发送缓冲区时，会读取之前写入SPDR的值。

SINV位（串行数据反转位）

该位用于反转发送数据和接收数据。

当SINV位设置为1时，发送缓冲器(SPTX)数据反转以反转发送数据和接收数据，然后将反转后的数据存储在接收缓冲器(SPRX)中。奇偶校验位是对应于反转的发送接收数据的值。

The RSPI status register (SPSR) stores flags that indicate RSPI's operating status.

SPCP[2:0] bit (RSPI Command Pointer)

These bits indicate RSPI command registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the current pointer in the RSPI sequence control. For details about the RSPI sequence control, see section 30.3.13.1. Master mode operation.

SPECM[2:0] bit (RSPI Error Command)

These bits indicate RSPI command registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the command pointer (SPCP[2:0] bits) when an error was detected in the RSPI sequence control. The RSPI updates the SPECM[2:0] bits value only when an error is detected. When no error is present (OVRF, MODF, and PERF flags in SPSR are 0), the SPECM[2:0] bits value has no meaning. For the RSPI's error detection function, see section 30.3.10. Error Detection. For the RSPI's sequence control, see section 30.3.13.1. Master mode operation.

SPDRF bit (RSPI Receive Data Ready Flag)

During communication (SPCR.SPE = 1), a certain period of time has elapsed while the number of data stored in the reception FIFO ≤ the reception FIFO threshold.

This bit is set to 0 when the reception operation is not performed (SPCR.TXMD [1:0] = 01b).

[Setting (to 1) condition]

All the following two conditions are met.

- SPCR2.SPDRC[7:0] ≠ 00h.
- After the receive FIFO has been written, when the number of data stored in the receive FIFO ≤ the receive FIFO threshold and the value set by SPDRC [7:0] has elapsed

[Clearing (to 0) condition]

- When 1 is written to the SPSRC.SPDRFC bit.

OVRF bit (Overrun Error Flag)

This flag indicates whether an overrun error is present. When the RSPCK clock auto-stop function is enabled (SPCR.SCKASE bit = 1) in master mode (SPCR.MSTR bit = 1), no overrun error occurs and, therefore, this flag is not set to 1. For details, see section 30.3.10.1. Overrun errors.

[Setting (to 1) condition]

When serial transfer is completed in one of the following two conditions with data stored in the receive FIFO for the number of FIFO stages.

- The SPCR.TXMD[1:0] bits = 00b. (transmit-receive mode)
- The SPCR.TXMD[1:0] bits =10b. (receive only)

[Clearing (to 0) condition]

- When 1 is written to the SPSRC.OVRFC bit.

SPECM[2:0]位（RSPI错误命令）

当在RSPI序列控制中检测到错误时，这些位指示由命令指针（SPCP[2:0]位）指示的RSPI命令寄存器0到7（SPCMD0到SPCMD7）。RSPI仅在检测到错误时更新SPECM[2:0]位的值。当不存在错误时（SPSR中的OVRF、MODF和PERF标志为0），SPECM[2:0]位值没有意义。关于RSPI的错误检测功能，请参见第30.3.10节。错误检测。对于RSPI的序列控制，请参见第30.3.13.1节。主模式操作。

30.3 Operation

在本节中，串行传输周期是指从开始驱动有效数据到获取最终有效数据的周期。

30.3.1 Overview of SPI Operation

The SPI is capable of synchronous serial transfers in the following modes:

- Slave mode (SPI operation)
- Single master mode (SPI operation)
- Multi-master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation)

The SPI mode can be selected by using the MSTR, MODFEN, SPMS, and SPFRF bits in SPCR. Table 30.6 lists the relationship between SPI modes and SPCR settings, and a description of each mode.

30.3.1 SPI操作概述

SPI能够在以下模式下进行同步串行传输：

●从机模式（SPI操作）

●单主模式（SPI操作）

- Multi-master mode (SPI operation)

●从机模式（时钟同步操作）

●主模式（时钟同步操作）

可以使用SPCR中的MSTR、MODFEN、SPMS和SPFRF位选择SPI模式。表30.6列出了SPI模式和SPCR设置之间的关系，以及每种模式的说明。

Table 30.6 SPCR设置和SPI模式之间的关系(1of2)

Note 3. When the SPCR.SPPE bit is 0, parity error detection is not performed.
Note 4. When the SPCR.SCKASE bit is 1, overrun error detection does not proceed.
Note 5. When SPI is receive only slave mode, none of transmit buffer empty and underrun error is detected.
Note 6. CPHA = 0 is invalid in TI SSP mode. (If it is set, the operation is the same as when CPHA = 1.)
Note 7. Supported only in TI SSP mode.

30.3.2 Controlling the SPI Pins

Based on the settings of the MSTR, MODFEN, and SPMS bits in SPCR and the PmnPFS.NCODR bit for I/O Ports, the SPI can switch pin states. Table 30.7 lists the relationship between pin states and bit settings. Setting the PmnPFS.NCODR bit for an I/O port to 0 selects the CMOS output. Setting it to 1 selects the open-drain output. The I/O port settings must follow this relationship.

Table 30.7 Relationship between pin states and bit settings (1 of 2)

Mode	Pin	Pin state*2	
		PmnPFS.NCODR bit for I/O ports = 0	PmnPFS.NCODR bit for I/O ports = 1

注3.当SPCR.SPPE位为0时，不执行奇偶校验错误检测。
注4.当SPCR.SCKASE位为1时，不进行溢出错误检测。
注5.当SPI为仅接收从机模式时，不会检测到发送缓冲区为空和欠载错误。
注6.CPHA=0在TISSP模式下无效。（如果已设置，则操作与CPHA=1时相同。）
注7.仅在TISSP模式下受支持。

30.3.2 控制SPI引脚

根据SPCR中的MSTR、MODFEN和SPMS位以及IO端口的PmnPFS.NCODR位的设置，SPI可以切换引脚状态。表30.7列出了引脚状态和位设置之间的关系。将IO端口的PmnPFS.NCODR位设置为0可选择CMOS输出。将其设置为1选择开漏输出。IO端口设置必须遵循这种关系。

Table 30.7 引脚状态和位设置之间的关系(1of2)

Mode	Pin	引脚状态*2

	SSLn0 to SSLn3*5	Hi-Z*1	Hi-Z*1
	MOSIn	Input	Input
	MISOn	CMOS output	Open-drain output

Note 1. This function is not supported in this mode.
Note 2. SPI settings are not reflected in multiplexed pins for which the SPI function is not selected.
Note 3. Motorola-SPI: When SSLn0 is at the active level, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SPCR3.SSL0P bit.
TI-SSP: From when SSL0 is at the active level until communication is completed, the pin state is Hi-Z under the condition SPCR.SPE = 1.
Note 4. Motorola-SPI: When SSLn0 is at the non-active level or the SPCR.SPE bit is 0, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SPCR3.SSL0P bit.
TI-SSP: When SSL0 is except the communication period or when the SPE bit of SPCR is 0 (assertion after SPE = 1 and communication is completed), the pin status changes to Hi-Z.
Note 5. These pins are available for use as I/O port pins.

The SPI in single-master mode (SPI operation) or multi-master mode (SPI operation) determines the MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) based on the MOIFE and MOIFV bit settings in SPCR2, as listed in Table 30.8.

Table 30.8 MOSI signal value determination during SSL negation

MOIFE bit	MOIFV bit	MOSIn signal value during SSL negation
0	0, 1	Final data from previous transfer
1	0	Low
1	1	High

30.3.3 SPI System Configuration Examples

This configuration example describes that 0 level of SSL0n signals is active level.

When connecting and using in a multi-slave or multi-master mode, the transfer format of the connected device should be unified to either Motorola-SPI or TI-SSP.

30.3.3.1 Single-master/single-slave with the MCU as a master

Figure 30.6 shows a single-master/single-slave SPI system configuration example where the MCU is used as a master. In the single-master/single-slave configuration, the SSLni outputs of the MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in the selected state.*1

Note 1. In the transfer format configured when the SPCMDm.CPHA bit is 0, the SSL signal for some slave devices cannot be fixed to an active level. In this case, always connect the SSLni output of the MCU to the SSL input of the slave device.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

Table 30.7 引脚状态和位设置之间的关系(2of2)

注1.此模式不支持此功能。
注2.SPI设置不反映在未选择SPI功能的复用引脚中。
注3.Motorola-SPI：当SSLn0处于有效电平时，引脚状态为Hi-Z。输入信号是否处于有效电平决定了SPCR3.SSL0P位的设置。TI-SSP：从SSL0处于活动电平到通信完成，引脚状态为Hi-Z条件

SPCR.SPE = 1.
注4.Motorola-SPI：当SSLn0为无效电平或SPCR.SPE位为0时，引脚状态为Hi-Z。输入信号是否处于有效电平决定了SPCR3.SSL0P位的设置。TI-SSP：当SSL0在通信周期之外或SPCR的SPE位为0时（SPE=1后断言，通信完成），引脚状态变为Hi-Z。

注5.这些引脚可用作IO端口引脚。

单主机模式（SPI操作）或多主机模式（SPI操作）下的SPI根据中的MOIFE和MOIFV位设置确定SSL否定期间（包括突发传输期间的SSL保留期间）的MOSI信号值SPCR2，如表30.8中所列。

Table 30.8 SSL否定期间的MOSI信号值确定

MOIFE bit	MOIFV bit	SSL否定期间的MOSIn信号值
0	0, 1	上次传输的最终数据
1	0	Low
1	1	High

30.3.3 SPI系统配置示例

此配置示例描述了SSL0n信号的0电平为活动电平。

在多从机或多主机模式下连接使用时，连接设备的传输格式应统一为Motorola-SPI或TI-SSP。

30.3.3.1 单主单从单片机为主

图30.6显示了单主单从SPI系统配置示例，其中MCU用作主机。在单主单从配置中，不使用MCU（主）的SSLni输出。SPI从机的SSL输入固定为低电平，SPI从机保持在选中状态。*1

注1.在SPCMDm.CPHA位为0时配置的传输格式中，某些从设备的SSL信号不能固定为有效电平。在这种情况下，请始终将MCU的SSLni输出连接到从设备的SSL输入。

MCU（主控）驱动RSPCKn和MOSIn信号。SPI从机驱动MISO信号。

30.3.3.2 Single-master/single-slave with the MCU as a slave

Figure 30.7 shows a single-master/single-slave SPI system configuration example where the MCU is used as a slave. When the MCU operates as a slave, the SSLn0 pin is used as SSL input. The SPI master drives the RSPCK and MOSI signals. The MCU (slave) drives the MISOn signal.*1

Note 1. When SSLn0 is at a non-active level, the pin state is Hi-Z.

In the single-slave configuration when the SPCMDm.CPHA bit is set to 1, the SPCR.SPFRF bit is set to 0, and SPCR.SPMS is set to 0, the SSLn0 input of the MCU (slave) is fixed to the low level and the MCU (slave) is maintained in the selected state. This enables serial transfer execution (Figure 30.8). However, the communication end interrupt does not output when SSL0 input is fixed as Figure 30.8.

在单从配置中，当SPCMDm.CPHA位设置为1时，SPCR.SPFRF位设置为0，并且SPCR.SPMS设置为0，MCU（从机）的SSLn0输入固定为低电平，MCU（从机）保持在选择状态。这将启用串行传输执行（图30.8）。但是，如图30.8那样固定SSL0输入时，不输出通信结束中断。

Figure 30.9 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes the MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The MISO outputs of SPI slaves 0 to 3 are all connected to the MISOn input of the MCU (master). 30.3.3.4 Single-master/multi-slave with the MCU as a slave

Figure 30.10 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a slave. In this example, the SPI system includes an SPI master and two MCUs (slaves X and Y).

The SPCK and MOSI outputs of the SPI master are connected to the RSPCKn and MOSIn inputs of the MCUs (slaves X and Y). The MISOn outputs of the MCUs (slaves X and Y) are all connected to the MISO input of the SPI master. The SSLX and SSLY outputs of the SPI master are connected to the SSLn0 inputs of the MCUs (slaves X and Y, respectively).

The SPI master drives the SPCK, MOSI, SSLX, and SSLY signals. Of the MCUs (slaves X and Y), the slave that receives low-level input into the SSLn0 input drives the MISOn signal.

30.3.3.5 Multi-master/multi-slave with the MCU as a master

Figure 30.11 shows a multi-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes two MCUs (masters X and Y) and two SPI slaves (SPI slaves 1 and 2).

The RSPCKn and MOSIn outputs of the MCUs (masters X and Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOn inputs of the MCUs (masters X and Y). Any generic port Y output from the MCU (master X) is connected to the SSLn0 input of the MCU (master Y). Any generic port X output of the MCU (master Y) is connected to the SSLn0 input of the MCU (master X). The SSLn1 and SSLn2 outputs of the MCUs (masters X and Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, because the system can be comprised solely of SSLn0 input, and SSLn1 and SSLn2 outputs for slave connections, the SSLn3 output of the MCU is not required.

The MCU drives the RSPCKn, MOSIn, SSLn1, and SSLn2 signals when the SSLn0 input level is high. When the SSLn0 input level is low, the MCU detects a mode fault error, sets RSPCKn, MOSIn, SSLn1, and SSLn2 to Hi-Z, and releases the SPI bus directly to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives the MISO signal.

MCU（主机X和Y）的RSPCKn和MOSIn输出连接到SPI从机1和2的RSPCK和MOSI输入。SPI从机1和2的MISO输出连接到MCU（主机X）的MISOn输入和Y)。来自MCU（主X）的任何通用端口Y输出都连接到MCU（主Y）的SSLn0输入。MCU（主设备Y）的任何通用端口X输出都连接到MCU（主设备X）的SSLn0输入。MCU（主机X和Y）的SSLn1和SSLn2输出连接到SPI从机1和2的SSL输入。在此配置示例中，因为系统可以仅由SSLn0输入和SSLn1和SSLn2输出组成从连接，不需要MCU的SSLn3输出。

当SSLn0输入电平为高电平时，MCU驱动RSPCKn、MOSIn、SSLn1和SSLn2信号。当SSLn0输入电平为低时，MCU检测到模式故障错误，将RSPCKn、MOSIn、SSLn1和SSLn2设置为Hi-Z，并将SPI总线直接释放到另一个主控。在SPI从机1和2中，接收到SSL输入的低电平输入的从机驱动MISO信号。

30.3.4 Data Formats

The data format of the SPI depends on the settings in SPI Command Register m (SPCMDm) and the parity enable bit in SPI Control Register (SPCR.SPPE). Regardless of whether the MSB or LSB is first, the SPI treats the range from the LSB bit in the SPI Data Register (SPDR) to the bit associated with the selected data length, as transfer data.

This section shows the format of one frame of data before or after transfer.

Data format with parity disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[4:0]).

当SPCMDm.CPHA位设置为1时，MCU（从机）只能在单从机配置中执行串行传输。

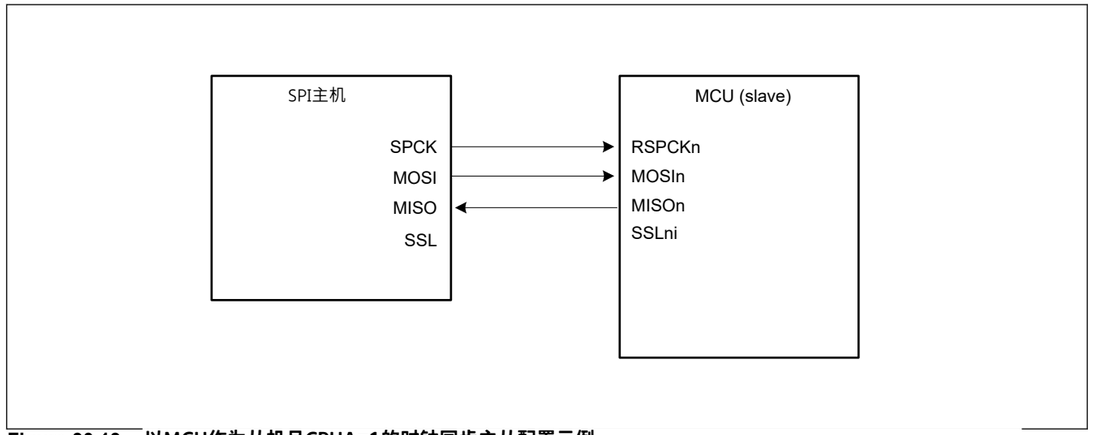

Figure 30.13 以MCU作为从机且CPHA=1的时钟同步主从配置示例

30.3.4 数据格式

SPI的数据格式取决于SPI命令寄存器m(SPCMDm)中的设置和SPI控制寄存器(SPCR.SPPE)中的奇偶校验使能位。无论是MSB还是LSB在前，SPI都会将SPI数据寄存器(SPDR)中的LSB位到与所选数据长度相关的位的范围视为传输数据。

本节显示传输前后一帧数据的格式。

禁用奇偶校验的数据格式

当奇偶校验被禁用时，数据的发送或接收将按照在SPI命令寄存器m(SPCMDm.SPB[4:0])的SPI数据长度设置中选择的位长度进行。

Data format with parity enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[4:0]). In this case, however, the last bit is a parity bit.

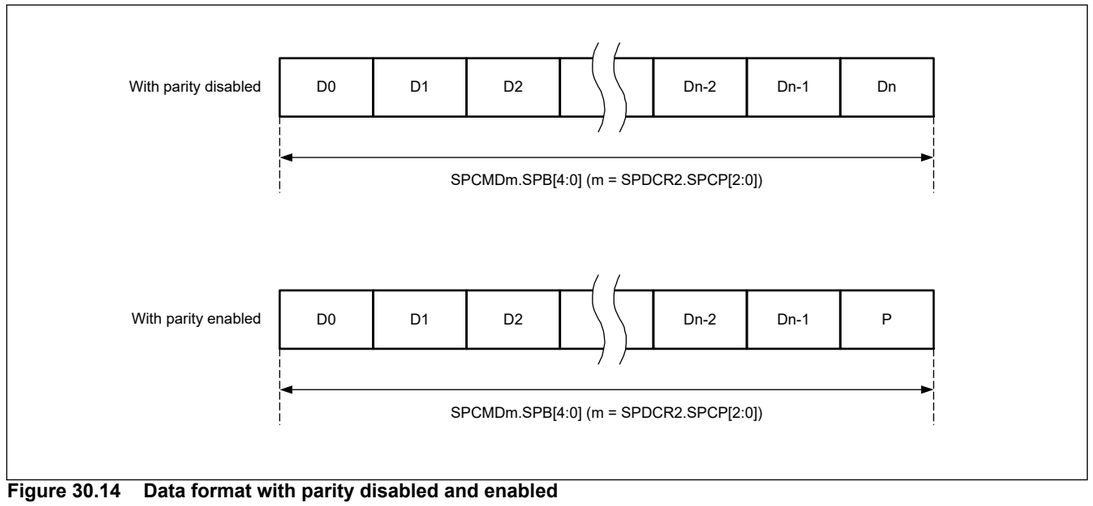

Figure 30.14 Data format with parity disabled and enabled

30.3.4.1 Operation when parity is disabled (SPCR.SPPE = 0)

When parity is disabled, data for transmission is copied to the shift register with no pre-processing. This section describes the connection between the SPI Data Register (SPDR) and the shift register in terms of the combination of MSB- or LSB-first order and data length.

(1) MSB-first transfer with 32-bit data

Figure 30.15 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, a SPI data length of 32 bits, and MSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T31 to T30, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

启用奇偶校验的数据格式

启用奇偶校验时，数据的发送或接收将按照在SPI命令寄存器m(SPCMDm.SPB[4:0])的SPI数据长度设置中选择的位长度进行。然而，在这种情况下，最后一位是奇偶校验位。

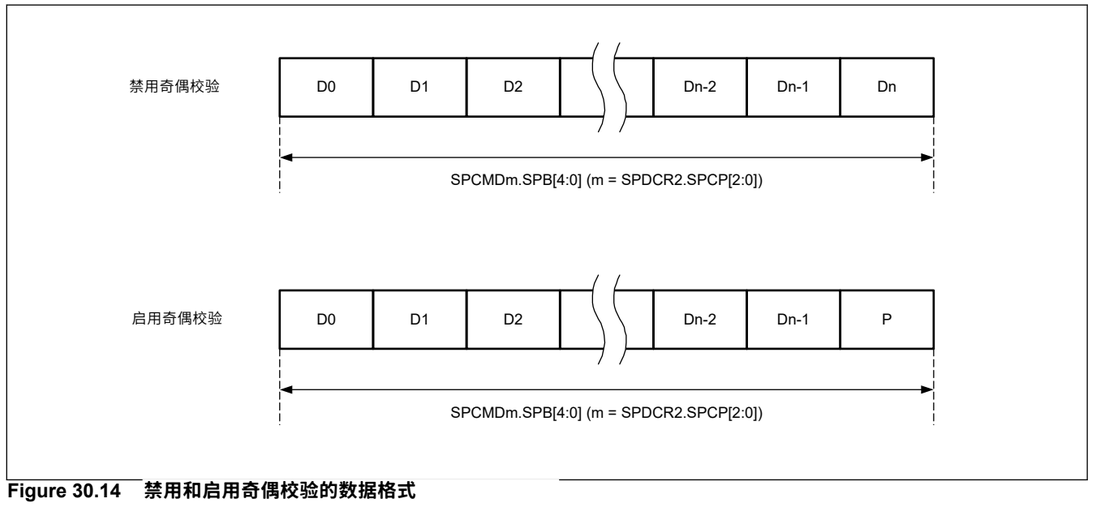

Figure 30.14 禁用和启用奇偶校验的数据格式

30.3.4.1 禁用奇偶校验时的操作(SPCR.SPPE=0)

当奇偶校验被禁用时，用于传输的数据被复制到移位寄存器而不进行预处理。本节从MSB或LSBfirstorder和数据长度的组合来描述SPI数据寄存器(SPDR)和移位寄存器之间的连接。

在接收中，接收到的数据通过移位寄存器的bit[0]逐位移位。在输入所需的RSPCK周期数后收集R31至R00位时，将移位寄存器中的值复制到接收缓冲区。

Figure 30.16 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 24 bits for an example that is not 32 bits, and MSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T23 to T22, and continuing to T00.

Figure 30.19 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and MSB-first selected.

Note: 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length, the behavior is not guaranteed.
2. When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0). If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.
3. Set SPDCR.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

30.3.4.4 Byte Swap Reception

When byte swap is enabled, the data in the shift register, swapped in 8-bit units, is copied to the receive buffer. Figure 30.25 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 32-bit data length, using a combination of MSB / LSB first and with / without byte swap.

(1) MSB-first transfer. (When the byte swap is disabled.)

The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31 → R30 → … → R00.

When necessary RSPCK cycles are input and data is stored from Byte3 [R31 to R24] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.

(2) MSB-first transfer. (When the byte swap is enabled.)

The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08 → R23 → R22 → … → R16 → R31 → R30 → … → R24.

When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte3 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

(3) LSB-first transfer. (When the byte swap is disabled.)

The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00 → R01 → … → R31.

Note: 1.使用字节交换时，将数据长度设置为16位或32位（SPCMDm.SPB[4:0]设置）。如果设置其他长度，则无法保证行为。2.当字节交换有效时，将奇偶校验功能设置为无效（SPCR.SPPE位=0）。如果将奇偶校验功能设置为有效（SPPE位=1），则无法保证行为。3.当SPCR.SPE位为0时，设置SPDCR.BYSW位。如果重写BYSW位，当SPE位为1时，不保证之后的行为。

30.3.4.4 字节交换接收

当字节交换使能时，移位寄存器中的数据以8位为单位进行交换，被复制到接收缓冲区。图30.25显示了在传输32位数据长度的数据时移位寄存器和SPDR（接收缓冲区）之间的关系，使用MSBLSB在前和不进行字节交换的组合。

当输入必要的RSPCK周期并将数据从Byte3[R31到R24]存储到Byte0[R07到R00]时，移位寄存器值被复制到接收缓冲区。

(2) MSB优先传输。（启用字节交换时。）

第一个接收到的数据（R07）存放在移位寄存器的第0位，接收到的数据按照R07→R06→…→R00→R15→R14→…→R08→R23→R22→…→R16→的顺序移位R31→R30→…→R24。

当输入必要的RSPCK周期并将数据从Byte0[R07到R00]到Byte3[R31到R24]存储时，移位寄存器中的字节值以字节为单位反转，并按Byte3[R31的顺序复制到接收缓冲区到R24]到字节0[R07到R00]。

Figure 30.26 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 16-bit data length, using a combination of MSB / LSB first and with / without byte swap.

Note: 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length, the behavior is not guaranteed.
2. When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0). If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.
3. Set SPDCR.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

30.3.5 Transfer Formats

30.3.5.1 When CPHA = 0

Figure 30.27 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Do not perform clock synchronous operation (SPCR.SPMS = 1) when the SPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 30.27, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0, and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI settings. For details, see section 30.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIn and MISOn signals begins at an SSLni signal assertion. The first RSPCKn signal change that occurs after the SSLni signal assertion becomes the first transfer data fetch. After this, data is sampled every 1 RSPCK cycle. The change timing for MOSIn and MISOn signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCK signal operation timing as it only affects the signal polarity.

t1 denotes the RSPCK delay, the period from an SSLni signal assertion to RSPCKn oscillation. t2 denotes the SSL negation delay, the period from the termination of RSPCKn oscillation to an SSLni signal negation. t3 denotes the next-access delay, the period in which SSLni signal assertion is suppressed for the next transfer after the end of serial transfer. t1, t2, and t3 are controlled by a master device running on the SPI system. For a description of t1, t2, and t3 when the SPI is in master mode, see section 30.3.12.1. Master mode operation.

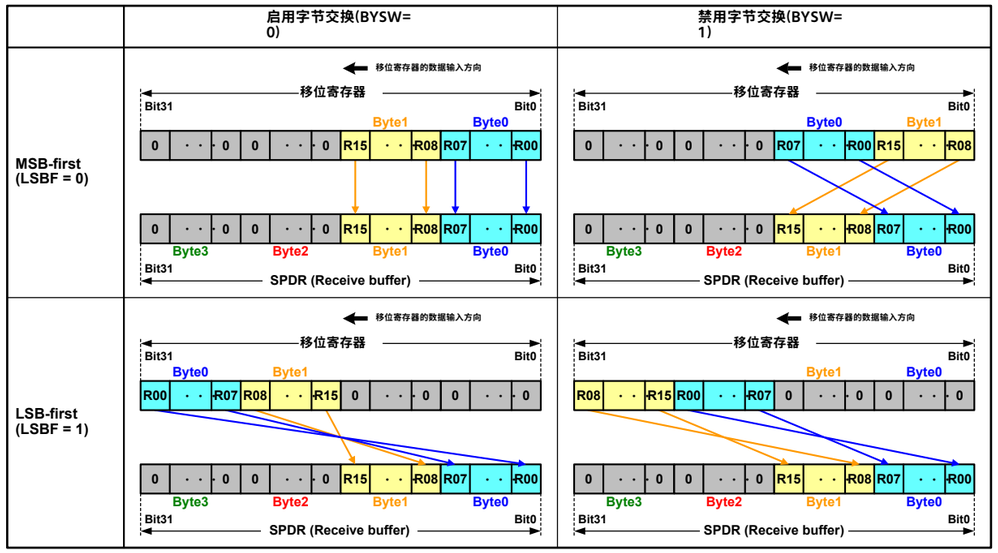

Figure 30.26 带MSBLSB传输的字节交换（16位）

Note: 1.使用字节交换时，将数据长度设置为16位或32位（SPCMDm.SPB[4:0]设置）。如果设置其他长度，则无法保证行为。2.当字节交换有效时，将奇偶校验功能设置为无效（SPCR.SPPE位=0）。如果将奇偶校验功能设置为有效（SPPE位=1），则无法保证行为。3.当SPCR.SPE位为0时，设置SPDCR.BYSW位。如果重写BYSW位，当SPE位为1时，不保证之后的行为。

30.3.5.1 When CPHA = 0

图30.27显示了当SPCMDm.CPHA位为0时串行传输8位数据的示例传输格式。当SPI在从机模式下运行时（SPCR.MSTR=0)且CPHA位为0。在图30.27中，RSPCKn(CPOL=0)表示SPCMDm.CPOL位为0时的RSPCKn信号波形，RSPCKn(CPOL=1)表示CPOL位为0时的RSPCKn信号波形1.采样时序表示SPI将串行传输数据取入移位寄存器的时序。信号的IO方向取决于SPI设置。有关详细信息，请参阅第30.3.2节。控制SPI引脚。

当SPCMDm.CPHA位为0时，将有效数据驱动到MOSIn和MISOn信号开始于SSLni信号断言。在SSLni信号断言之后发生的第一个RSPCKn信号变化成为第一次传输数据获取。此后，每1个RSPCK周期对数据进行采样。MOSIn和MISOn信号的变化时序是传输数据获取时序之后的12RSPCK周期。CPOL位设置不影响RSPCK信号操作时序，因为它只影响信号极性。

t1表示RSPCK延迟，即从SSLni信号断言到RSPCKn振荡的周期。t2表示SSL否定延迟，即从RSPCKn振荡终止到SSLni信号否定的周期。t3表示下一次访问延迟，即在串行传输结束后为下一次传输抑制SSLni信号断言的时间段。t1、t2和t3由在SPI系统上运行的主设备控制。有关SPI处于主模式时的t1、t2和t3的说明，请参见第30.3.12.1节。主模式操作。

30.3.5.2 When CPHA = 1

Figure 30.28 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLni signals are not used, and only the three signals RSPCKn, MOSIn, and MISOn handle communications. In Figure 30.28, RSPCK (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0 and RSPCK (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI mode (master or slave mode). For details, see section 30.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOn signal begins at an SSLni signal assertion. The output of valid data to the MOSIn and MISOn signals begins at the first RSPCKn signal change that occurs after the SSLni signal assertion. After this, data is updated every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKn signal operation timing. It only affects the signal polarity.

t1, t2, and t3 are the same as those when CPHA = 0. For a description of t1, t2, and t3 when the SPI of the MCU is in master mode, see section 30.3.12.1. Master mode operation.

图30.28显示了当SPMDm.CPHA位为1时串行传输8位数据的示例传输格式。
但是，当SPCR.SPMS位为1时，不使用SSLni信号，只有RSPCKn、MOSIn和MISON处理通信。在图30.28中，RSPCK(CPOL=0)表示SPCMDm.CPOL位为0时的RSPCKn信号波形，RSPCK(CPOL=1)表示CPOL位为1时的RSPCKn信号波形。SPI将串行传输数据提取到移位寄存器中。信号的IO方向取决于SPI模式（主模式或从模式）。有关详细信息，请参阅第30.3.2节。控制SPI引脚。

当SPCMDm.CPHA位为1时，将无效数据驱动到MIOn信号开始于SSLni信号断言。在SSLni信号置位后发生的第一个RSPCKn信号变化时，开始向MOSIn和MISOn信号输出有效数据。此后，每1个RSPCK周期更新一次数据。传输数据获取时序是数据更新时序之后的12个RSPCK周期。SPCMDm.CPOL位设置不影响RSPCKn信号操作时序。它只影响信号极性。

30.3.6 Communication Operating Mode

Transmit-Receive serial communication, transmit-only operation, and Receive-only operation are selected by setting the Communication Mode Select bits (TXMD [1:0]) of the RSPI control register (SPCR).

30.3.6.1 Transmit-Receive Serial Communication (TXMD[1:0] = 00b)

Figure 30.30 shows an example of operation when the communication mode select bit (TXMD[1:0]) in the RSPI control register (SPCR) is set to 00b. In the example in Figure 30.30, the RSPI performs 8-bit data serial transfer with the settings of RTRG = FIFO stage - 1, TTRG = 0 in the RSPI data control register 2 (SPDCR2), CPHA in the RSPI command register (SPCMDm) = 1, and CPOL in SPCMD = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

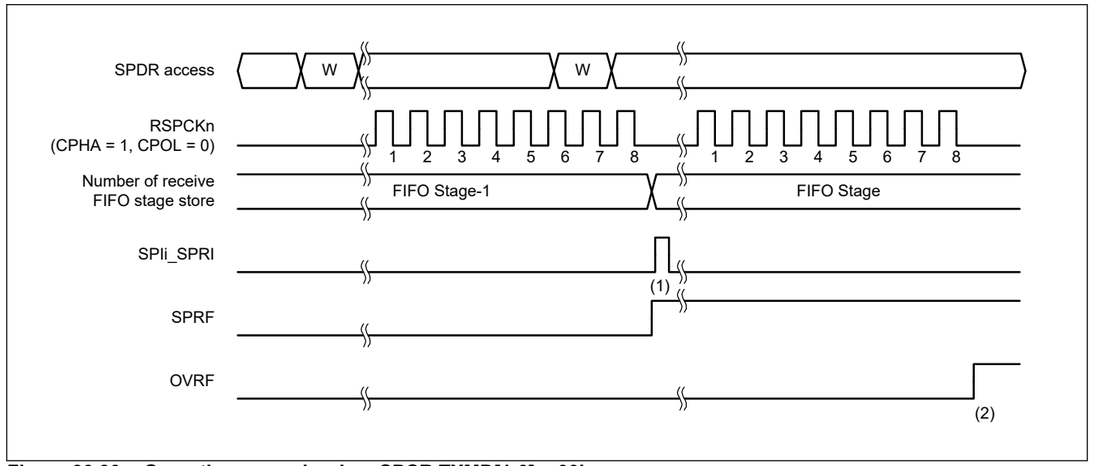

Figure 30.30 Operation example when SPCR.TXMD[1:0] = 00b

The operation of the flags at timings (1) and (2) in Figure 30.30 is as follows:

1. When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request (SPIi_SPRI), the SPI sets the SPSR.SPRF flag to 1, and copies the received data in the shift register to the receive buffer.
2. When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the SPSR.OVRF flag to 1, and discards the received data in the shift register. For details about the operation of the SPSR.OVRF flag, see section 30.3.10.1. Overrun errors.

In Transmit-Receive serial communication (TXMD[1:0] = 00b), transmit data is transmitted and receive data is received. Therefore, the SPRF flag and the OVRF flag are set to 1 at timings (1) and (2) respectively.

30.3.6.2 Transmit-Only Serial Communications (TXMD[1:0] = 01b)

Figure 30.31 shows an example of operation when the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 01b. In this example, the SPI performs an 8-bit serial transfer when the SPDCR2.TTRG is 0, the SPDCR2.RTRG is 0, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

30.3.6.1 发送-接收串行通信（TXMD[1:0]=00b）

图30.30显示了将RSPI控制寄存器(SPCR)中的通信模式选择位(TXMD[1:0])设置为00b时的操作示例。在图30.30的示例中，RSPI执行8位数据串行传输，设置RTRG=FIFO阶段1，RSPI数据控制寄存器2(SPDCR2)中的TTRG=0，RSPI命令寄存器(SPCMDm)中的CPHA=1，SPCMD中的CPOL=0。RSPCK波形下的数字表示RSPCK周期数（传输位数）。

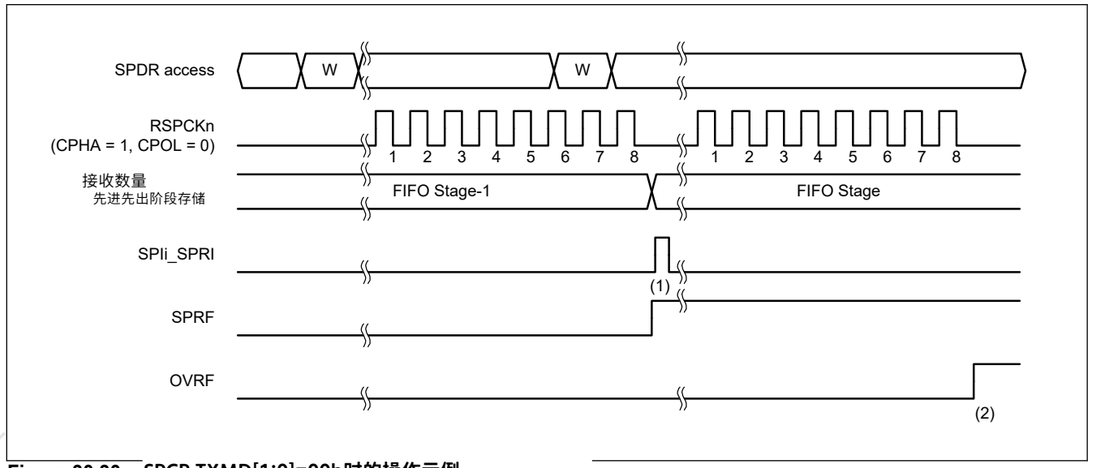

Figure 30.30 SPCR.TXMD[1:0]=00b时的操作示例

图30.30中时间(1)和(2)的标志操作如下：

1.当串行传输结束，而SPDR接收缓冲存储的数量与设置的帧数匹配时
SPDCR2.RTRG，SPI产生接收缓冲区满中断请求（SPIi_SPRI），SPI将SPSR.SPRF标志置1，并将接收到的移位寄存器中的数据复制到接收缓冲区。

2.当串行传输以存储在SPDR接收缓冲区中的FIFO级数的数据结束时，SPI将SPSR.OVRF标志设置为1，并丢弃移位寄存器中的接收数据。有关操作的详细信息
SPSR.OVRF标志，参见第30.3.10.1节。溢出错误。

在发送-接收串行通信(TXMD[1:0]=00b)中，发送数据并接收接收数据。
因此，SPRF标志和OVRF标志分别在时间(1)和(2)被设置为1。

30.3.6.2 仅发送串行通信（TXMD[1:0]=01b）

图30.31显示了当SPI控制寄存器(SPCR)中的通信模式选择位(TXMD[1:0])设置为01b时的操作示例。在本例中，当SPDCR2.TTRG为0、SPDCR2.RTRG为0、SPCMDm.CPHA位为1、SPCMDm.CPOL位为0时，SPI执行8位串行传输。为RSPCKn给出的数字波形中的表示RSPCK周期数，如传输比特数。

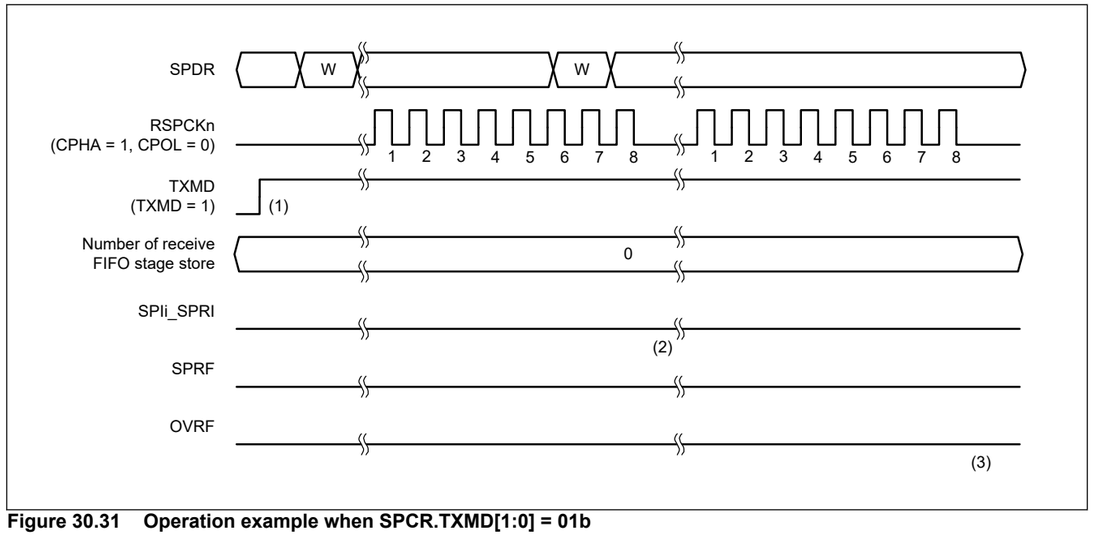

Figure 30.31 Operation example when SPCR.TXMD[1:0] = 01b

The operation of the flags at timings (1) to (3) in Figure 30.31 is as follows:

1. Make sure there is no data left in the receive buffer (the SPSR.SPRF flag is 0) and the SPSR.OVRF flag is 0 before entering transmit-only mode (SPCR.TXMD[1:0] = 01b).
2. When a serial transfer ends without receiving data in the receiving FIFO of SPDR, if the transmit-only mode is selected (SPCR.TXMD[1:0] = 01b), the SPSR.SPRF flag retains the value of 0, and the SPI does not copy the data in the shift register to the receive buffer.
3. Because the receive buffer of SPDR does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

In transmit-only mode (SPCR.TXMD[1:0] = 01b), the SPI transmits data but does not receive data. Therefore, the SPSR.SPRF and SPSR.OVRF flags remain 0 at timings (1) to (3).

30.3.6.3 Receive-Only Serial Communication (TXMD[1:0] = 10b)

Figure 30.32 shows an example of operation when the communication mode select bit (TXMD[1]) in the RSPI control register (SPCR) is set to 1. In the example in Figure 30.32, the SPI performs 8-bit data serial transfer with the settings of TTRG = FIFO stage - 1, RTRG = 0 in the SPI data control register 2 (SPDCR2), CPHA in the SPI command register (SPCMD) = 1, and CPOL in SPCMD = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

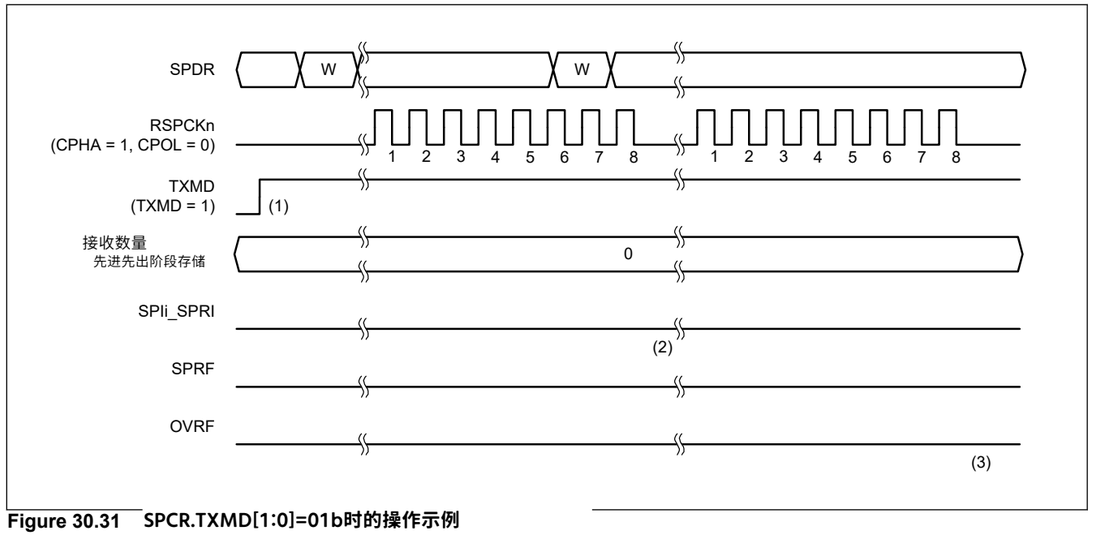

Figure 30.31 SPCR.TXMD[1:0]=01b时的操作示例

图30.31中时间(1)到(3)的标志操作如下：

1.在进入仅发送模式(SPCR.TXMD[1:0]=01b)之前，确保接收缓冲区中没有剩余数据（SPSR.SPRF标志为0）且SPSR.OVRF标志为0。

2.当串行传输结束而在SPDR的接收FIFO中没有接收到数据时，如果选择了仅发送模式（SPCR.TXMD[1:0]=01b），则SPSR.SPRF标志保持值为0，并且SPI不会将移位寄存器中的数据复制到接收缓冲区。

3、因为SPDR的接收缓冲区中没有保存上一次串行传输接收到的数据，所以即使一次串行传输结束，SPSR.OVRF标志保持值0，移位寄存器中的数据不会被复制到接收缓冲区。

在仅发送模式(SPCR.TXMD[1:0]=01b)中，SPI发送数据但不接收数据。因此，SPSR.SPRF和SPSR.OVRF标志在时间(1)到(3)保持为0。

30.3.6.3 仅接收串行通信（TXMD[1:0]=10b）

图30.32显示了将RSPI控制寄存器(SPCR)中的通信模式选择位(TXMD[1])设置为1时的操作示例。在图30.32的示例中，SPI执行8位数据串行传输TTRG=FIFOstage1 RTRG=0intheSPIdatacontrolregister2(SPDCR2) CPHAintheSPIcommandregister(SPCMD)=1 andCPOLinSPCMD=0.RSPCK波形下的数字表示RSPCK周期（传输位数）。

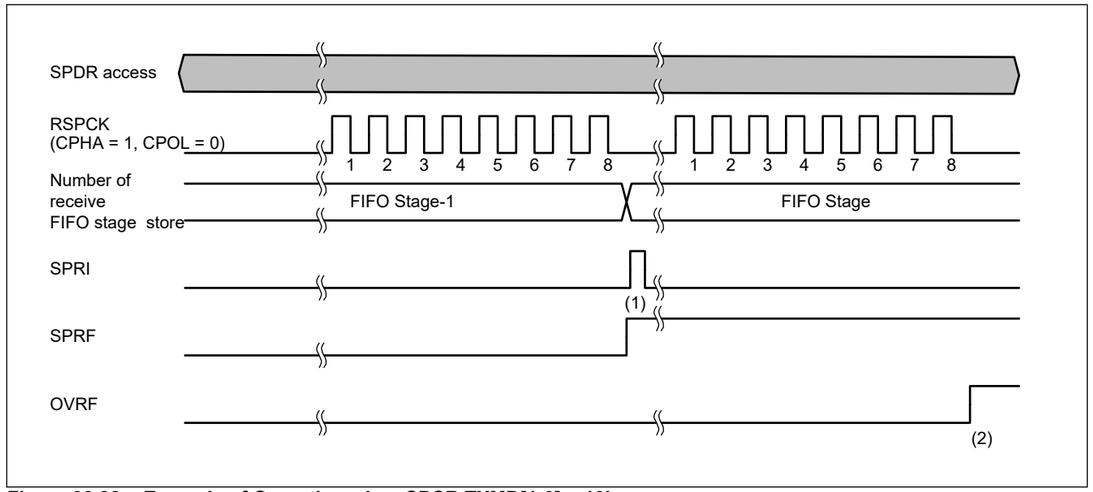

Figure 30.32 Example of Operation when SPCR.TXMD[1:0] = 10b

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer

(2) When serial transfer ends with data for the number of FIFO stages store d in the SPDR receive buffer, the SPI sets the OVRF flag in the SPI status register (SPSR) to 1 and discards the received data in the shift register.

30.3.7 Transmit Buffer Empty and Receive Buffer Full Interrupts

Figure 30.33 show examples of operation of the transmit buffer empty interrupt (SPIi_SPTI) and the receive buffer full interrupt (SPIi_SPRI). The SPDR register accesses shown in these figures indicate the conditions of access to the register, where W denotes a write cycle and R a read cycle. In Figure 30.33, the SPI performs an 8-bit serial transfer when SPCR.TXMD[1:0] bits are 00b, the SPDCR2.TTRG bit is 0, the SPDCR2.RTRG bit is 0, the SPCMDm.CPHA bit is 0, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

The operation of the SPI at timings (1) to (5) in Figure 30.33 is as follows:

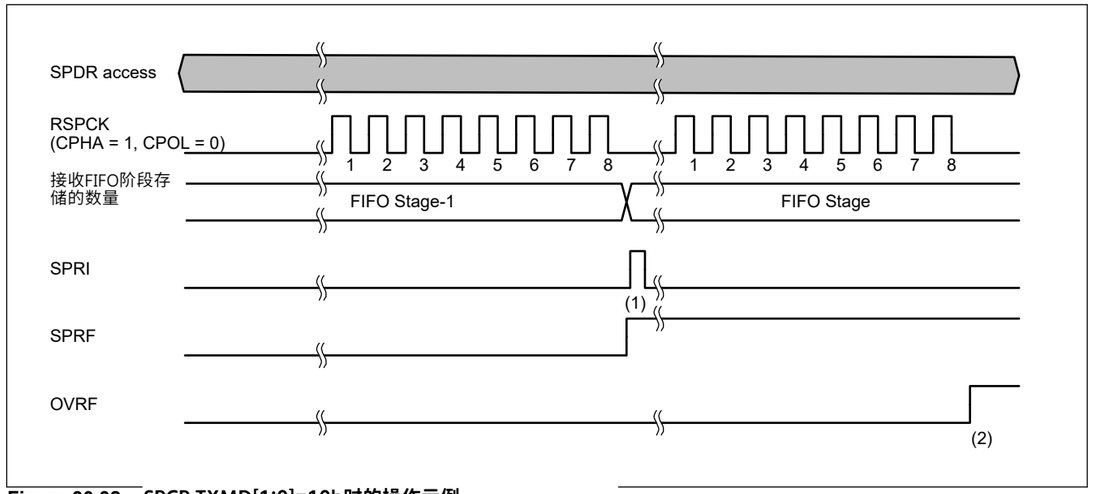

Figure 30.32 SPCR.TXMD[1:0]=10b时的操作示例

下面描述在上图中的时间(1)和(2)的标志的操作。

(1)当串行传输结束而SPDR接收缓冲存储的数量与SPDCR2.RTRG中设置的帧数匹配时，SPI产生一个接收缓冲区满中断请求SPRI（将SPSR.SPRF标志设置为1）并复制接收到的移位寄存器中的数据到接收缓冲区

(2)当串行传输在SPDR接收缓冲区中存储FIFO级数d的数据结束时，SPI将SPI状态寄存器(SPSR)中的OVRF标志设置为1，并丢弃移位寄存器中的接收数据。

30.3.7 发送缓冲区空和接收缓冲区满中断

图30.33显示了发送缓冲区空中断(SPIi_SPTI)和接收缓冲区满中断(SPIi_SPRI)的操作示例。这些图中显示的SPDR寄存器访问表示访问寄存器的条件，其中W表示写周期，R表示读周期。在图30.33中，当SPCR.TXMD[1:0]位为00b、SPDCR2.TTRG位为0、SPDCR2.RTRG位为0、SPCMDm.CPHA位为0时，SPI执行8位串行传输，SPCMDm.CPOL位为0。波形中为RSPCKn给出的数字表示RSPCK周期数，例如传输的位数。

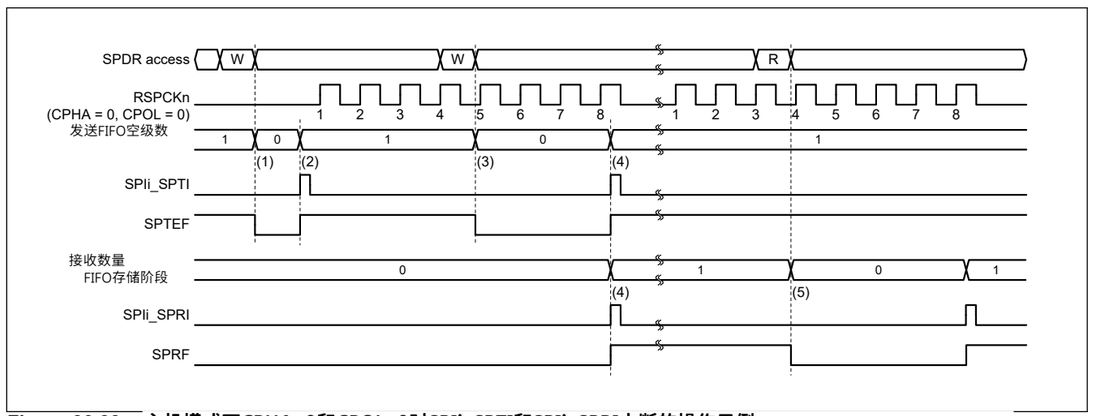

Figure 30.33 主机模式下CPHA=0和CPOL=0时SPIi_SPTI和SPIi_SPRI中断的操作示例

SPI在图30.33中时序(1)到(5)的操作如下：

1. When transmit data is written to SPDR with the transmit buffer of SPDR is before the next transfer data is set, the SPI writes data to the transmit buffer. When transmit data is written to SPDR in one processing routine using DTC / DMAC, the SPSR.SPTEF flag is cleared to 0 at the last access.
2. If the shift register is empty, the SPI copies the data in the transmit buffer to the shift register. At this time, if transmit FIFO empty stage number > TTRG value, then the SPI generates a transmit buffer empty interrupt request (SPIi_SPTI), and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the SPI mode. For details, see section 30.3. Operation, and section 30.3.13. Clock Synchronous Operation.
3. When transmit data is written to SPDR either by the transmit buffer empty interrupt routine, or by the processing of the transmit buffer empty using the SPTEF flag, the SPI writes data to the transmit buffer. When the transmit data is written to SPDR in one processing routine using DTC / DMAC, the SPTEF flag is cleared to 0 at the last access. Because the data being transferred serially is stored in the shift register, the SPI does not copy the data in the transmit buffer to the shift register.
4. When the serial transfer ends with the receive buffer of SPDR > FIFO stage number, the SPI copies the receive data in the shift register to the receive buffer, generates a receive buffer full interrupt request (SPIi_SPRI), and sets the SPRF flag to 1. Because the shift register becomes empty on completion of the serial transfer, if the next transfer data is set in the transmit FIFO before the serial transfer ended, the SPI sets the SPTEF flag to 1 and copies data in the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun error status, on completion of the serial transfer, the SPI determines that the shift register is empty, so data transfer from the transmit buffer to the shift register is enabled.
5. When SPDR is read either by the receive buffer full interrupt routine or processing of the receive buffer full interrupt using the SPRF flag, the receive data can be read. If the received data is read from SPDR in one processing routine using DTC / DMAC, the SPRF flag is cleared to 0 at the last access.

When transmit data is written to the SPDR register while no empty stages in the transmit FIFO, the SPI does not update data in the transmit buffer. When writing to SPDR, always use either a transmit buffer empty interrupt request or check the empty or processing of the transmit buffer empty interrupt using the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1. If the SPI function is disabled (the SPCR.SPE bit is 0), set the SPTIE bit to 0.

When serial transfer ends while data is stored in the receive FIFO for the number of FIFO stages, the SPI does not copy data from the shift register to the receive buffer, and it detects an overrun error (see section 30.3.10. Error Detection). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an SPI receive buffer full interrupt, set the SPCR.SPRIE bit to 1.

Transmission and reception interrupts or the associated IELSRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers.

Similarly, the SPTEF and SPRF flags can be used to confirm the states of the transmit and receive buffers. See section 12, Interrupt Controller Unit (ICU) for the interrupt vector numbers.

30.3.8 Idle Interrupt

The idle interrupt during master mode operation is when the SPCP [2:0] of the RSPI status register (SPSR) becomes 000b (start of sequence control), the IDLNF flag in the RSPI status register (SPSR) is set to 1 and an idle interrupt request is made during master mode operation. An interrupt request is also made by clearing the SPCR.SPE bit to 0.

[In the Motorola-SPI case]

Figure 30.34 shows an example of idle interrupt operation during normal operation.

1.当发送数据写入SPDR时，SPDR的发送缓冲区在下一次传输数据设置之前，SPI将数据写入发送缓冲区。在使用DTCDMAC的一个处理例程中将发送数据写入SPDR时，SPSR.SPTEF标志在最后一次访问时被清除为0。

2.如果移位寄存器为空，SPI将发送缓冲区中的数据复制到移位寄存器中。这时，如果传输FIFO空级数>TTRG值，然后SPI产生一个发送缓冲区空中断请求（SPIi_SPTI），并将SPSR.SPTEF标志设置为1。如何启动串行传输取决于SPI模式。有关详细信息，请参阅第30.3节。操作，以及第30.3.13节。时钟同步操作。

3.当发送数据被发送缓冲区空中断程序写入SPDR时，或者通过使用SPTEF标志处理发送缓冲区空时，SPI将数据写入发送缓冲区。在使用DTCDMAC的一个处理例程中将发送数据写入SPDR时，SPTEF标志在最后一次访问时被清除为0。由于串行传输的数据存储在移位寄存器中，因此SPI不会将发送缓冲区中的数据复制到移位寄存器中。

4.当串行传输以SPDR>FIFO级数的接收缓冲区结束时，SPI将移位寄存器中的接收数据复制到接收缓冲区，产生接收缓冲区满中断请求（SPIi_SPRI），并将SPRF标志设置为1.由于串行传输完成后移位寄存器变为空，如果在串行传输结束前发送FIFO中设置了下一个传输数据，则SPI将SPTEF标志设置为1，并将发送缓冲区中的数据复制到移位登记。即使在溢出错误状态下没有将接收到的数据从移位寄存器复制到接收缓冲区，在串行传输完成时，SPI会确定移位寄存器为空，因此从发送缓冲区到移位寄存器的数据传输是启用。

5.当接收缓冲区满中断程序或接收缓冲区满中断处理读取SPDR时使用SPRF标志，可以读取接收数据。如果在一个使用DTCDMAC的处理例程中从SPDR读取接收到的数据，则SPRF标志在最后一次访问时被清除为0。

当发送数据写入SPDR寄存器且发送FIFO中没有空级时，SPI不会更新发送缓冲区中的数据。写入SPDR时，始终使用发送缓冲区空中断请求或使用SPTEF标志检查发送缓冲区空中断的空或处理。要使用发送缓冲区空中断，请将SPCR中的SPTIE位设置为1。如果禁用SPI功能（SPCR.SPE位为0），请将SPTIE位设置为0。

当串行传输结束而数据存储在接收FIFO中达到FIFO级数时，SPI不会将数据从移位寄存器复制到接收缓冲区，它会检测到溢出错误（参见第30.3.10节。错误检测）.为防止接收数据溢出错误，请在下一次串行传输结束前使用接收缓冲区满中断请求读取接收数据。要使用SPI接收缓冲区满中断，请将SPCR.SPRIE位设置为1。

ICU中的发送和接收中断或相关的IELSRn.IR标志（其中n是中断向量号）可用于确认发送和接收缓冲区的状态。

类似地，SPTEF和SPRF标志可用于确认发送和接收缓冲区的状态。见第12节，用于中断向量编号的中断控制器单元(ICU)。

30.3.8 空闲中断

主机模式操作期间的空闲中断是当RSPI状态寄存器(SPSR)的SPCP[2:0]变为000b（序列控制开始）时，RSPI状态寄存器(SPSR)中的IDLNF标志设置为1，并且空闲中断请求是在主模式操作期间发出的。也可通过将SPCR.SPE位清0来发出中断请求。

[In the Motorola-SPI case]

图30.34显示了正常操作期间的空闲中断操作示例。

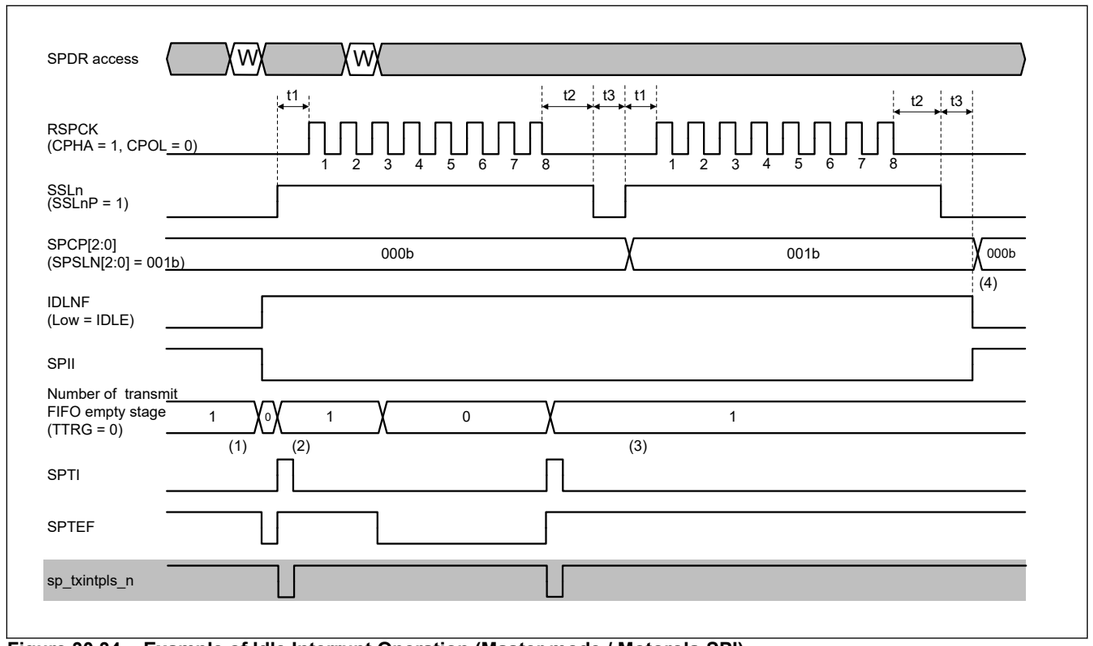

Figure 30.34 Example of Idle Interrupt Operation (Master mode / Motorola-SPI)

1. At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data makes sets the IDLNF flag to 1 (BUSY). When the SPIIE bit in the RSPI control register (SPCR) is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0 before starting transmission.
2. After transmission has started, the IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.
3. The SPCP[2:0] bits change the command to the next command the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.
4. The IDLNF flag is cleared to 0 (IDLE) the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPIIE bit is 1 currently, an SPII interrupt is output.

2.发送开始后，IDLNF标志保持为1(BUSY)，与发送缓冲区状态无关。

3.SPCP[2:0]位在t3周期结束时将命令更改为下一个命令。当下一个命令不是000b时，即使没有写入下一个发送数据，IDLNF标志也保持不变。

4.IDLNF标志在t3周期结束时被清除为0(IDLE)，因为下一个命令是000b并且下一个发送数据不存在。当前SPIIE位为1时，输出SPII中断。

2.CENDF标志在t3周期结束时为1（通信结束），因为下一条命令为000b，没有下一条发送数据，当CENDIE位为1时SPCI中断输出。

3.CENDF标志在下一个发送数据写入发送缓冲区（SPTX）时被清除。或者当向SPSRC.CENDFC位写入1时，CENDF标志为0。

2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. And then the SPCI interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

In slave mode operation, the output timing of the communication end interrupt is deferent due to the value of the SPCR.SPMS bit (RSPI mode select bit), and the clear timing of the communication end interrupt is deferent due to the communication mode (transmit-receive or transmit-only or receive-only).

30.3.9.2 Receive-only in Master Mode

Refer to the description of the CENDF bit in section 30.2.9. SPSR : SPI Status Register for the setting / clearing conditions of the communication completion flag during Receive-only in Master Mode.

3.CENDF标志在下一个发送数据写入发送缓冲区（SPTX）时被清除。或者当向SPSRC.CENDFC位写入1时，CENDF标志为0。

在从模式操作中，通信结束中断的输出时序是不同的，因为SPCR.SPMS位（RSPI模式选择位），通信结束中断的清除时序因通信模式（发送-接收或仅发送或仅接收）而异。
