Table 41.9 Control of A/D conversion operations according to the settings of the ADGSPCR.GBRSCN bit (1 of 2)

A/D conversion operation	Trigger input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group A is in progress	Input of trigger for group A	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group B	Trigger input is ineffective.	A/D conversion is performed on group B after A/D conversion on group A is completed.
	Input of trigger for group C	Trigger input is ineffective.	A/D conversion is performed on group C after A/D conversion on group A is completed.

Table 41.9 Control of A/D conversion operations according to the settings of the ADGSPCR.GBRSCN bit (2 of 2)

A/D conversion operation	Trigger input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group B is in progress	Input of trigger for group A	Conversion for group B that is in progress is discontinued and conversion for group A starts.	• Conversion in progress for group B is discontinued and conversion for group A starts. • Conversion for group B starts after conversion for group A is completed.
	Input of trigger for group B	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group C	Trigger input is ineffective.	A/D conversion is performed on group C after A/D conversion on group B is completed.
When A/D conversion for group C is in progress	Input of trigger for group A	Conversion for group C that is in progress is discontinued and conversion for group A starts.	• Conversion in progress for group C is discontinued and conversion for group A starts. • Conversion for group C starts after conversion for group A is completed.
	Input of trigger for group B	Conversion for group C that is in progress is discontinued and conversion for group B starts.	• Conversion in progress for group C is discontinued and conversion for group B starts. • Conversion for group C starts after conversion for group B is completed.
	Input of trigger for group C	Trigger input is ineffective.	Trigger input is ineffective.

Table 41.10 Group priority operation setting and operation mode for 2 groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 0)

ADGSPCR			Operation mode
GBRSCN	LGRRS	GBRP	
0	—	0	Group priority operation of 2 groups (groups A and B). When the trigger of group A is input, the scan of group B ends (does not re-execute).
1	0	0	Group priority operation of 2 groups (groups A and B). After the scan of group B is interrupted, group B restarts the scan from the beginning of the channel specified by ADANSB0 after the scan of group A is completed.
1	1	0	Group priority operation of 2 groups (groups A and B). After the scan of group B is interrupted, group B resumes the scan from the interrupted channel among the channels specified by ADANSB0 after the scan of group A is completed.
—	0	1	Group priority operation of 2 groups (groups A and B). Group B continuously performs a single scan without inputting a start trigger. After the group B scan is interrupted, the single scan is restarted from the beginning of the channel specified by ADANSB0 after the group A scan is completed.
1	1	1	Group priority operation of 2 groups (groups A and B). Group B continuously performs a single scan without inputting a start trigger. After the scan of group B is interrupted, the single scan is restarted from the interrupted channel among the channels specified by ADANSB0 after the scan of group A is completed.

Table 41.11 Group priority operation setting and operation mode for 3 groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 1) (1 of 2)

ADGSPCR			Operation mode
GBRSCN	LGRRS	GBRP	
0	—	0	Group priority operation of 3 groups (groups A, B, C). When the trigger of group A is input, the scan of group B ends (does not re-execute). When the trigger of group A or group B is input, the scan of group C ends (does not re-execute).

Table 41.11 Group priority operation setting and operation mode for 3 groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 1) (2 of 2)

ADGSPCR			
GBRSCN	LGRRS	GBRP	Operation mode
0	—	1	Group priority operation of 3 groups (groups A, B, C). When the trigger of group A is input, the scan of group B ends (does not re-execute). Group C continuously performs a single scan without inputting a start trigger. After the group C scan is interrupted, the scan is restarted from the beginning of the channel specified by ADANSC0 after the group A/B scan is completed.
1	0	0	Group priority operation of 3 groups (groups A, B, C). After the scan of group B is suspended, the scan restarts from the top channel of the channels specified by ADANSB0 after the group A scan is completed. After the scan of group C is suspended, the scan restarts from the top channel of the channels specified by ADANSC0 after the group A/B scan is completed.
1	1	0	Group priority operation of 3 groups (groups A, B, C). After the scan of group B is suspended, the scan restarts from the interrupted channel of the channels specified by ADANSB0 after the group A scan is completed. After the scan of group C is suspended, the scan restarts from the interrupted channel of the channels specified by ADANSC0 after the group A/B scan is completed.
1	0	1	Group priority operation of 3 groups (groups A, B, C). After the scan of group B is interrupted, the scan is restarted from the beginning of the channel specified by ADANSB0 after the scan of group A is completed. Group C continuously performs a single scan without inputting a start trigger. After the group C scan is interrupted, the single scan is restarted from the beginning of the channel specified by ADANSC0 after the group A/B scan is completed.
1	1	1	Group priority operation of 3 groups (groups A, B, C). After the A/D conversion process of group B is interrupted, the interrupted channel is restarted from the channels specified by ADANSB0 after the scan of group A is completed. Group C continuously performs a single scan without inputting a start trigger. After the group C scan is interrupted, the single scan is restarted from the interrupted channel among the channels specified by ADANSC0 after the group A/B scan is completed.

41.4.5 Compare Function (Window A, Window B)

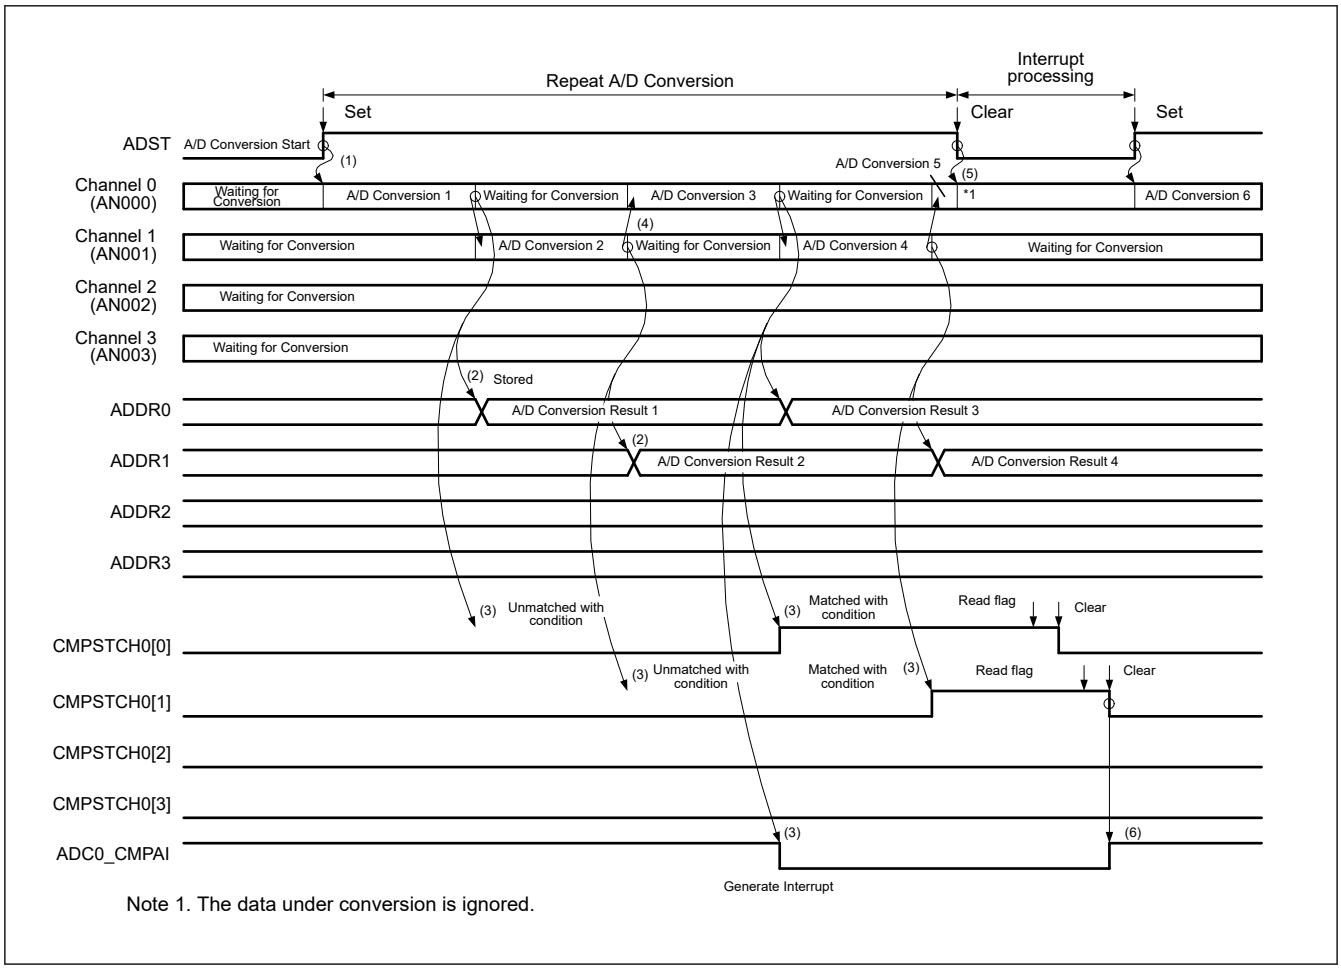
41.4.5.1 Compare Function Window A/B

The compare function is a function that compares the reference value set in the register with the A/D conversion result, and the reference value can be set for each window (A/B). Double trigger mode cannot be used when using the compare function. The major difference between window A and window B is that window B has one selectable channel and different interrupt output signals.

Operation using compare function in combination with continuous scan mode is described below.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by software, synchronous trigger (MTU3, ELC), or asynchronous trigger, A/D conversion of the selected channel is started.
2. When the A/D conversion is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy). When ADCMPCR.CMPAE = 1b, if it is set for window A in the ADCMPANSR0 register, it is compared with the ADCMPDR0 register setting value. When ADCMPCR.CMPBE = 1b, if the ADCMPBNSR register is set for window B, it will be compared with the ADWINULB/ADWINLLB register setting value.
3. As a result of comparison, when the condition set in ADCMPLR0 is matched in window A, the flag (ADCMPSR0. CMPSTCHA0n) bit of the compare function window A is set to 1. At this time, if the ADCMPCR.CMPAIE bit is set to 1, an ADC0_CMPAI interrupt request (level) is generated. Similarly, when window B matches the conditions set in ADCMPBNSR.CMPLB, the compare function window B flag (ADCMPBSR.CMPSTB) bit is set to 1. At this time, if the ADCMPCR.CMPBIE bit is set to 1, an ADC0_CMPBI interrupt request (level) is generated.
4. When all the selected A/D conversions and comparisons are completed, scanning is performed again.
5. After accepting the ADC0_CMPAI/ADC0_CMPBI interrupt, set the ADCSR.ADST bit to 0 (A/D conversion stopped) and execute processing for the channel for which the compare flag is set.

6. When all the compare flags in window A are cleared, the ADC0_CMPAI interrupt request is canceled. Similarly, clearing the compare window B flag cancels the ADC0_CMPBI interrupt request. If you want to perform the compare again, start the A/D conversion again.



Note 1. The data under conversion is ignored.

Figure 41.12 Example of operation of compare function (compare target: AN000-AN003)

41.4.5.2 Event output in Compare Function

For the event output of the compare function, specify the upper and lower reference values for each of windows A/B, compare the A/D conversion value of the selected channel with the upper/lower reference values, and then the event (ADCn_WCMPM/ADCn_WCMPUM) is output according to the event condition (A or B, A and B, A exor B) from the result of satisfying/failing the comparison condition of windows A and B. When using this function, perform A/D conversion in single scan mode.

In window A, any channel of ANn00-ANn15 can be selected. When multiple channels are selected in window A and the comparison condition is satisfied in one of the channels, the comparison condition is satisfied in window A. In window B, one channel of ANn00-ANn15 can be selected.

The setting procedure and setting example when using the event output of the compare function are shown below.

1. ADCSR.ADCS bit must be 00b (single scan mode).
2. Select the channel to be used for window A in the ADCMPANSR0 register, set the comparison condition of the compare function window in the ADCMPLR0 register, and set the upper/lower reference value in the ADCMPDR0/1 register.
3. Select the channel to be used for window B and the comparison condition in the ADCMPBNSR register, and set the upper/lower reference values in the ADWINULB/ADWINLLB registers.
4. In the ADCMPCR register, set the window A/B compound condition, window A/B operation permission, and interrupt output permission.

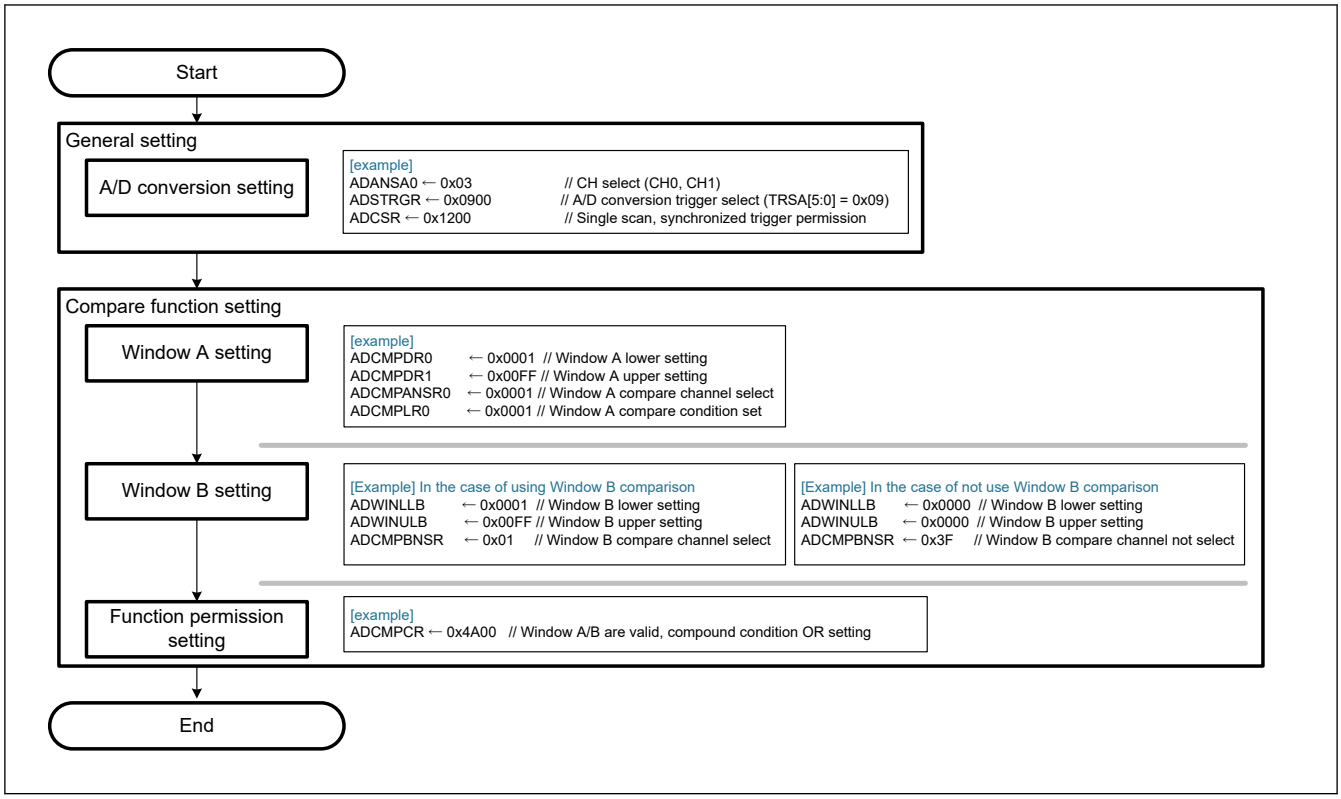


Figure 41.13 Example of setting for using event output of compare function

Precautions when using event output using only window A of the compare function

- Enable both windows A and B. (ADCMPCR.CMPAE = 1, ADCMPCR.CMPBE = 1)
- Set the compound condition setting for windows A and B to "OR condition". (ADCMPCR.CMPAB[1:0] = 00b)
- Set the comparison target channel in window B to "Unselected". (ADCMPBNSR.CMPCHB[5:0] = 111111b).
- Set the comparison condition of window B to 0 < conversion result < 0, which is "always inconsistent". (ADCMPCR.WCMPE = 1, ADWINLLB.CMPLLB[15:0] = ADWINULB.CMPULB[15:0] = 0x0000, ADCMPBNSR.CMPLB = 1)

Figure 41.14 shows example of event output operation of compare function.

The scan end event is output when one single scan ends. Also, depending on the setting of ADCMPCR.CMPAB[1:0], the match/unmatch event (ADCn_WCMPM/ADCn_WCMPUM) is output with a delay of 1 PCLK (Unit 0, 1: PCLKH, Unit 2: PCLKM).

Note: Match/unmatch events are exclusive outputs, and both events are not output at the same time.

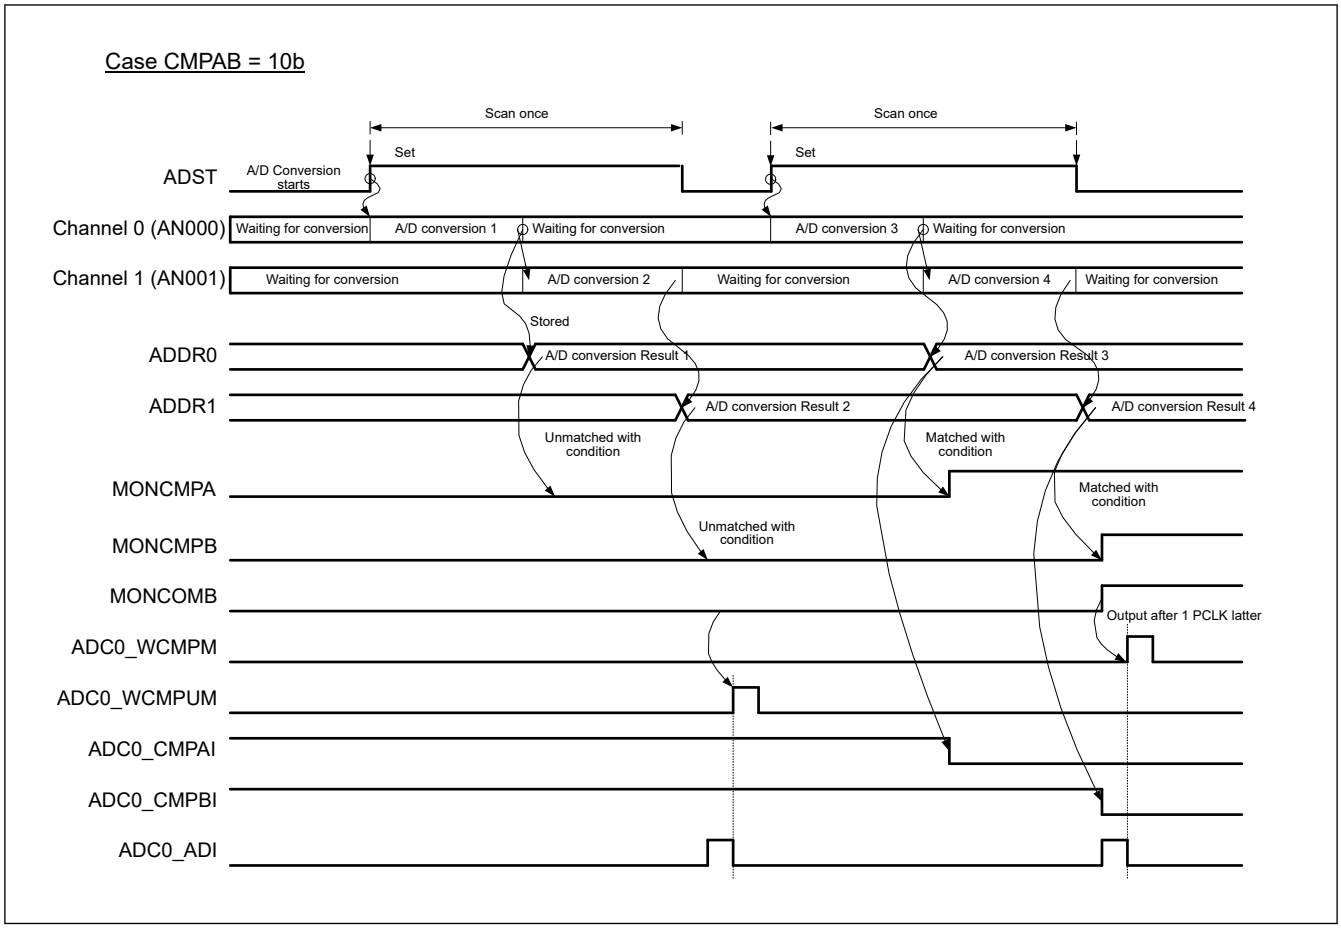

Figure 41.14 Example of operation for event output of compare function

Precautions when using event output of the compare function

The event output of the compare function outputs match/unmatch according to the setting of ADCMPCR.CMPAB[1:0] from the comparison result of window A and the comparison result of window B. The comparison result of window A is the logical sum of the comparison result of the channel to be compared in window A.

The comparison result of window A and the comparison result of window B are updated every A/D conversion of the channel to be compared, and the comparison result is retained even after the single scan is completed. To clear the comparison result (0), set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

41.4.5.3 Compare function constraint

The compare function has the following restrictions.

- Double trigger mode cannot be used together.
  (ADDBLDR, ADDBLDRA, ADDBLDRB are not subject to the compare function.)
- If you want to use match/unmatch event output, set the single scan mode.
- The same CH cannot be set in window A and window B.
- Set so that the upper reference value ≥ the lower reference value.

41.4.6 A/D Data Register Automatic Clearing Function

By setting the ADCER.ACE bit to 1, these are used when the CPU and DMAC read the A/D data registers (ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB). The register can be cleared automatically to 0x0000.

By using this function, it is possible to detect an un-updated failure of the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers. The following is an example when the automatic clear function of the ADDRy register is disabled/enabled.

When the ADCER.ACE bit is 0 (automatic clearing prohibited), the old data (0x0111) becomes the value of the ADDRy register when the A/D conversion result (0x0222) is not written to the ADDRy register for some reason. Furthermore, when the value of this ADDRy register is read to the general-purpose register by using the A/D conversion end interrupt, the old data (0x0111) can be saved in the general-purpose register. However, when checking for un-updated data, it is necessary to check while holding old data in RAM and general-purpose registers one by one.

When the ADCER.ACE bit is 1 (automatic clearing enabled), the ADDRy register is automatically cleared to 0x0000 when ADDRy = 0x0111 is read by the CPU and DMAC. After that, when 0x0222 of the A/D conversion result cannot be transferred to the ADDRy register for some reason, the cleared data (0x0000) remains as the ADDRy register value. If the value of this ADDRy register is read to a general-purpose register by using the A/D conversion end interrupt, 0x0000 is held in the general-purpose register. By simply checking that the read data value is 0x0000, it can be determined that there was an un-updated failure of the ADDRy register.

41.4.7 A/D-converted Value Addition/Average Function

In A/D-converted value addition function, the same channel is A/D-converted two, three, four or sixteen consecutive times and the sum of the converted values is stored in the data register. In A/D-converted value average function, the same channel is A/D-converted two or four consecutive times and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that affect A/D conversion. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition/average mode can be specified when A/D conversion of the analog input of the selected channels is selected.

41.4.8 Starting A/D Conversion with Asynchronous Trigger

The A/D conversion can be started by the input of an asynchronous trigger. To start up the A/D converter by an asynchronous trigger, the A/D conversion start trigger select bits (ADSTRGR.TRSA[5:0]) should be set to 000000b and a low-level signal should be input to the asynchronous trigger (ADTRGn#). Both the ADCSR.TRGE and ADCSR.EXTRG bits then should be set to 1. Figure 41.15 shows a timing of the asynchronous trigger input.

Asynchronous triggers cannot be selected for groups B and C used in group scan mode.

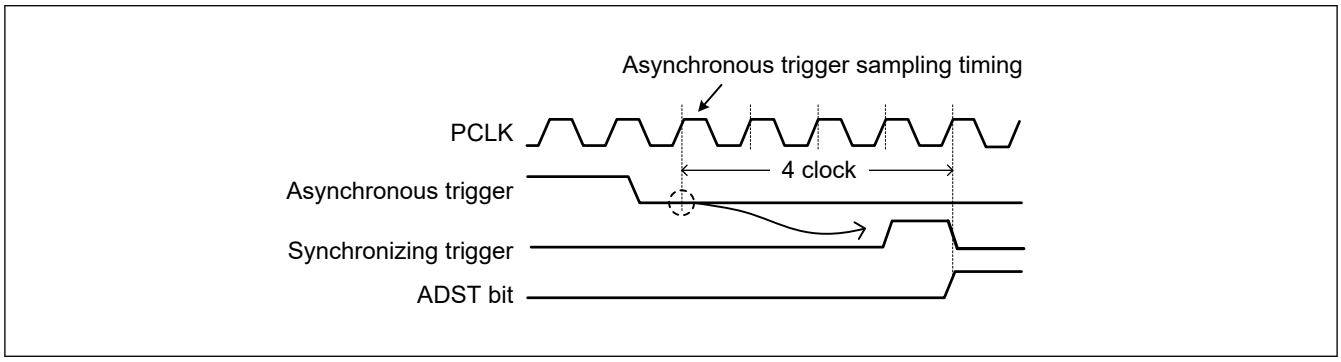

Figure 41.15 Timing of asynchronous trigger input

41.4.9 Starting A/D Conversion with Synchronous Trigger from Peripheral Module

A/D conversion can be started by the synchronization trigger from MTU3 and ELC (1 pulse of "L" in PCLK synchronization). When starting A/D conversion with a synchronous trigger, the ADCSR.TRGE bit is set to 1, the ADCSR.EXTRG bit is set to 0, the ADSTRGR.TRSA[5:0], ADSTRGR.TRSB[5:0], and ADGCTRGR.TRSC[5:0] bits are set to the appropriate trigger factor.

41.4.10 Event Link Function

41.4.10.1 Event output to ELC

ELC can use the ADCn_ADI interrupt request signal as an event signal (ADCn_ADI) to link to a preset module (ADCn_GBADI/ADCn_GCADI interrupt, ADCn_CMPAI/ADCn_CMPBI interrupt cannot be used as an event signal). The event signal can be output regardless of the setting of the corresponding interrupt request permission bit.

The 12-bit A/D converter outputs the scan end event (ADCn_ADI), compare function match event (ADCn_WCMPM), and unmatch event (ADCn_WCMPUM). The scan end event (ADCn_ADI) outputs a "High pulse" for 1 PCLK at the same output timing as the interrupt output (ADCn_ADI) regardless of the setting of ADCSR.ADIE.

The compare match/unmatch event (ADCn_WCMPM/ADCn_WCMPUM) to ELC outputs a "High pulse" for 1 PCLK at a timing delayed by 1 cycle (PCLK) from the interrupt output (ADCn_ADI) regardless of the setting of ADCSR.ADIE. When using the compare match/unmatch event to ELC (ADCn_WCMPM/ADCn_WCMPUM), set it to single scan mode.

41.4.10.2 Starting A/D Conversion with ELC event

The 12-bit A/D converter can start A/D conversion by a preset event by setting ELC_SSEL in ELC.

41.5 Usage Notes

41.5.1 Calibration

After reset is released, need to calibrate A/D Converter before A/D conversion. Calibration flow is the following:

- Release module stop of ADC12.
- Wait for at least 0.5 µs.
- Write ADCCALCTL.CAL bit to 1 to start calibration.
- Poll ADCCALCTL.CAL_RDY bit until it is changed to 1.
- After confirming ADCCALCTL.CAL_RDY is 1, confirm ADCCALCTL.CAL_ERR bit is 0.
- Write ADCCALCTL.CAL bit to 0.

41.5.2 Notes on Reading Data Registers

The A/D data registers, A/D data duplication registers, A/D data duplication register A, A/D data duplication register B, must be read in 16-bit word units, to avoid unmatch from upper value and lower value due to reading by byte units separately.

41.5.3 Notes on Stopping A/D Conversion

41.5.3.1 A/D Conversion Stop Procedure

If using asynchronous or synchronous trigger as the A/D conversion start condition, follow the procedure in the flowchart in Figure 41.16 to stop the A/D conversion.

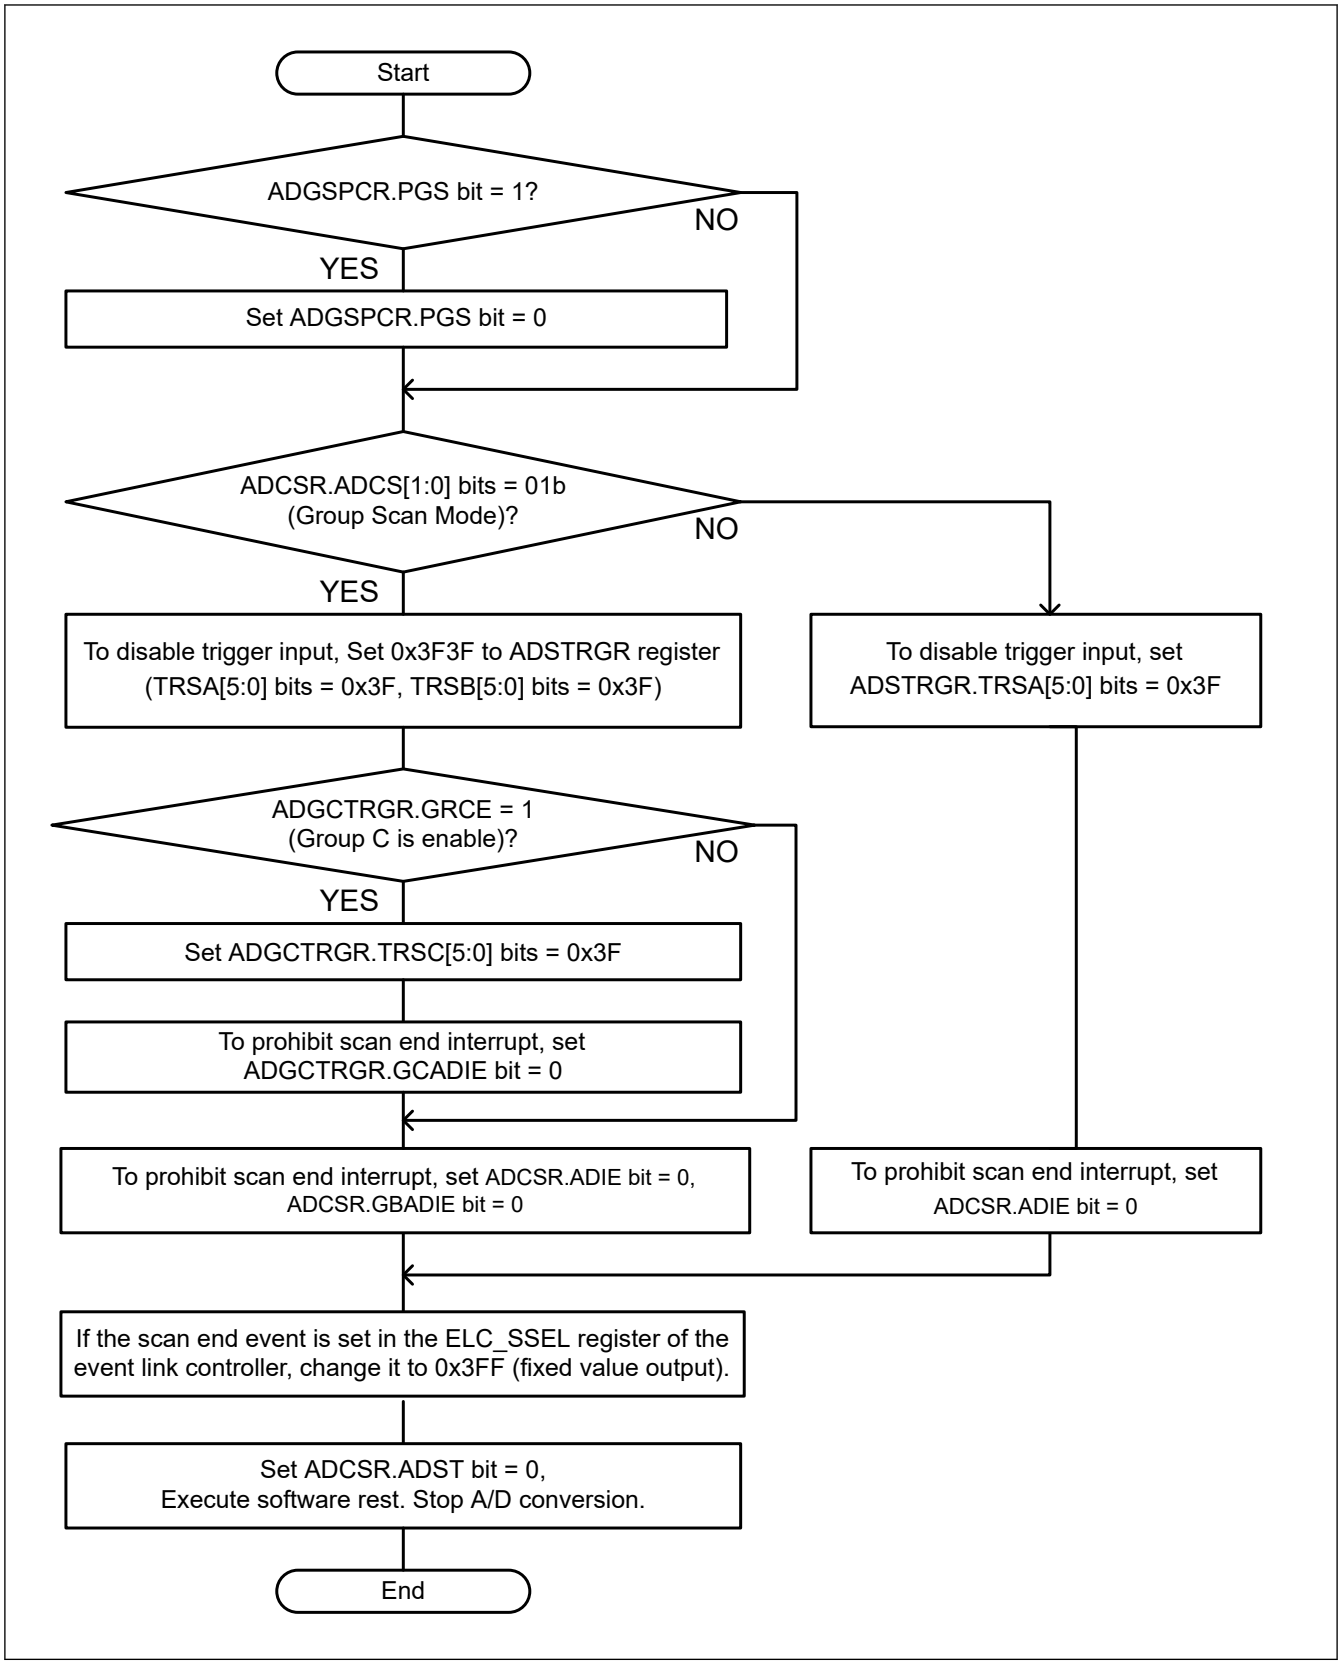

Figure 41.16 A/D Conversion stop procedure

It takes 2 PCLKADC cycles from a software clear until the soft macro stops scanning. If you want to set the following after executing a software clear, enter a wait of 2 PCLKADC cycles or more.

- Scan end interrupt enabled
- Event link controller scan end event valid setting

- Start of A/D conversion by software
- Trigger input valid setting

41.5.3.2 Notes on Mode/Status bits

Initialize or reset the odd/even judgment and monitor bits of the compare function in the double trigger mode as necessary.

- Double trigger mode starts from the first scan operation when ADCSR.DBLE is set from 0 to 1.
- To initialize the monitor bits (MONCMPA, MONCMPB, MONCOMB) of the compare function, set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

41.5.4 A/D conversion forced stop and operation timing at starts

Up to 6 PCLKADCs time is necessary that the A/D converter starts by ADCSR.ADST bit = 1 from stopped status.

When the ADCSR.ADST bit is set to 0 and the A/D conversion is forcibly stopped, the analog part of the 12-bit A/D converter requires a maximum of 2 PCLKADCs to stop operating.

41.5.5 Notes on Scan End Interrupt Processing

When scanning the same analog input twice using any trigger, if the CPU does not complete reading out the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated, the first A/D-converted data is overwritten with the second A/D-converted data and an overwrite error occurs.

41.5.6 Module-Stop Function Setting

Operation of the 12-bit A/D converter can be disabled or enabled using the Module Stop Control register. The initial setting is for operation of the 12-bit A/D converter to be halted. Releasing the module-stop state enables access to the registers. After release from the module-stop state, wait for at least 0.5 µs before starting A/D conversion.

41.5.7 Notes on Entering Low Power Consumption States

When transitioning to module stop mode, stop A/D conversion. When stopping the A/D conversion, it is necessary to secure the time until the analog part of the 12-bit A/D converter stops after setting the ADCSR.ADST bit to 0.

41.5.8 Notes on A/D-converted Value Addition/Average Function

When using channel-dedicated sample-and-hold circuits, it is prohibited to use A/D-converted value addition/average function.

42. Temperature Sensor Unit (TSU)

42.1 Overview

The temperature sensor unit (TSU) indicates the junction temperature as a 12-bit binary digital output code. A temperature sensor unit is used to monitor the LSI junction temperature.

Table 42.1 lists the TSU specifications. Figure 42.1 shows a block diagram of TSU.

Table 42.1 TSU specifications

Item	Description
Number of units	1 unit
Temperature Code Read	• Temperature code averaging function • Comparison with the upper and lower limit settings • Single scan / Continuous scan
Interrupt source	• Conversion Complete • Comparison Result
Low power	• Power down mode

42.3 Register Descriptions

42.3.1 SSUSR : Sensor Suspend Register

Base address: TSU = 0x8008_6000

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	SOC_TS_EN	ADC_PD	EN_TS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Bit	Symbol	Function	R/W
0	EN_TS	Temperature Sensor Enable 0: Temperature Sensor power down 1: Temperature Sensor normal operation	R/W
1	ADC_PD	ADC Power Down 0: Normal operation 1: Power down	R/W
2	SOC_TS_EN	SOC_TS (Start signal of the conversion process) Enable 0: Disable 1: Enable	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

The SSUSR register controls settings related to the power-down of TSU.

42.3.2 STRGR : Sensor Trigger Register

Base address: TSU = 0x8008_6000

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ADEND	ADST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	x	x

Bit	Symbol	Function	R/W
0	ADST	TSU ADC Start Trigger 0: No effect 1: Conversion starts	W
1	ADEND	TSU ADC Stop Trigger 0: No effect 1: conversion ends	W
31:2	—	The write value should be 0.	W

The STRGR register controls a start and an end trigger to ADC in the TSU.

42.3.3 SOSR1 : Sensor Operation Setting 1 Register

Base address: TSU = 0x8008_6000

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	OUTSEL	—	—	—	—	ADCS	—	—	ADCT[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	1

Bit	Symbol	Function	R/W
1:0	ADCT[1:0]	AD Count Setting 0 0: 1 0 1: 2 1 0: 4 1 1: 8	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	—	This bit is read as 1. The write value should be 1.	R/W
4	ADCS	ADC Scan Mode Select 0: Single scan mode 1: Continuous scan mode	R/W
8:5	—	These bits are read as 0. The write value should be 0.	R/W
9	OUTSEL	Select data read from Sensor Code Read register (SCRR) 0: Latest read data 1: Average data	R

Bit	Symbol	Function	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

The SOSR1 register controls the operation setting of ADC.

42.3.4 SCRR : Sensor Code Read Register

Base address: TSU = 0x8008_6000

Offset address: 0x10

Bit position:	31														11															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OUT12BIT_TS[11:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	OUT12BIT_TS[11:0]	Temperature Sensor Code Data	R
31:12	—	These bits are read as 0.	R

The SCRR register is used to read acquired code data.

42.3.5 SSR : Sensor Status Register

Base address: TSU = 0x8008_6000

Offset address: 0x14

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CONV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CONV	TSU Operating Status 0: Conversion is completed. Single scan mode: AD conversion of the number of times needed for average data is completed. Continuous mode: AD conversion of the number of times needed for average data is completed after ADEND is asserted. 1: Conversion is in progress. Set when ADST bit of Sensor Trigger Register is asserted.	R
31:1	—	These bits are read as 0.	R

The SSR register is used to read the TSU operating status.

42.3.6 CMSR : Compare Mode Setting Register

Base address: TSU = 0x8008_6000

Offset address: 0x18

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CMPCOND	CMPEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
0	CMPEN	Compare Enable 0: Disable 1: Enable	R/W
1	CMPCOND	Compare Condition to assert Compare Result Flag 0: Outside of the range Lower Limit (LLILM) > Code Data, or Code Data > Upper Limit (ULIM) 1: Inside of the range Lower Limit (LLILM) < Code Data < Upper Limit (ULIM)	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

The CMSR register controls the compare operation setting.

42.3.7 LLSR : Lower Limit Setting Register

Base address: TSU = 0x8008_6000

Offset address: 0x1C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LLIM[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	LLIM[11:0]	Lower Limit Setting Value	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The LLSR register controls the lower limit value to be compared with acquired code data.

42.3.8 ULSR : Upper Limit Setting Register

Base address: TSU = 0x8008_6000

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ULIM[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	ULIM[11:0]	Upper Limit Setting Value	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The ULSR register controls the upper limit value to be compared with acquired code data.

42.3.9 SISR : Sensor Interrupt Status Register

Base address: TSU = 0x8008_6000

Offset address: 0x30

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CMPF	ADF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ADF	AD Conversion Complete Flag Cleared when ADCLR bit of Sensor Interrupt Clear Register is set to 1. 0: Not completed 1: Completed	R
1	CMPF	Compare Result Flag Cleared when CMPCLR bit of Sensor Interrupt Clear Register is set to 1. 0: Not matched 1: Matched	R
31:2	—	These bits are read as 0.	R

The SISR register is used to monitor the interrupt status.

42.3.10 SIER : Sensor Interrupt Enable Register

Base address: TSU = 0x8008_6000

Offset address: 0x34

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CMPIE	ADIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ADIE	AD Conversion Complete Interrupt Enable 0: Disable 1: Enable	R/W
1	CMPIE	Compare Result Interrupt Enable 0: Disable 1: Enable	R/W

Bit	Symbol	Function	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

The SIER register enables or disables output to the interrupt request output signal (TSUADI, TSUADCMPI).

42.3.11 SICR : Sensor Interrupt Clear Register

Base address: TSU = 0x8008_6000

Offset address: 0x38

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CMPCLR	ADCLR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	x	x

Bit	Symbol	Function	R/W
0	ADCLR	AD Conversion Complete Interrupt Clear 0: No effect 1: Interrupt is cleared.	W
1	CMPCLR	Compare Result Interrupt Clear 0: No effect 1: Interrupt is cleared.	W
31:2	—	The write value should be 0.	W

The SICR register clears the interrupt status.

42.4 Function Description

42.4.1 Acquiring Temperature Code

Conversion starts on reception of the conversion start trigger (when the STRGR.ADST bit is set to 1). When the SCRR.OUT12BIT_TS bit is read after the completion of conversion, a 12-bit temperature code can be acquired.

If the conversion start trigger comes within 120T (internal clock period (320 ns)) after release of the temperature sensor and ADC from the power-down state (setting the sensor suspend register so that the SSUSR.ADC_PD bit is 0 and the SSUSR.EN_TS bit is 1), conversion only starts after 120T has elapsed following release.

42.4.2 Temperature Code Averaging Function

The temperature codes acquired within the TSU are averaged the number of times set by the SOSR1.ADCT[1:0] bits.

42.4.3 Temperature Code Reading Function

The temperature code can be read from the SCRR register through the internal bus. When SOSR1.OUTSEL = 0, the latest converted value is read. When SOSR1.OUTSEL = 1, the average value is read.

42.4.4 Temperature Code Comparison Functions

This function compares the average temperature code and the values set by the LLSR.LLIM[11:0] bits and the ULSR.ULIM[11:0] bits when CMSR.CMPEN = 1.

The temperature code for use in the comparison function is the average temperature code, so the SOSR1.OUTSEL bit should be set to 1 (average data output) when reading the temperature code for use in comparison. When the averaging count setting is 1, however, the latest value is the same as the average value, so the temperature code for use in comparison will be read regardless of the setting of the SOSR1.OUTSEL bit.

The SISR.CMPF bit is set to 1 when the following conditions (1) or (2) is satisfied.

(1) CMSR.CMPCOND = 0 and either one of the below formula is satisfied.

- Acquired data > ULIM setting value of ULSR register
- LLIM setting value of LLSR register > Acquired data

(2) CMSR.CMPCOND = 1 and both two below formulas are satisfied.

- ULIM setting value of ULSR register > Acquired data
- Acquired data > LLIM setting value of LLSR register

42.4.5 Interrupt Output Function

An interrupt is output when conversion is completed and the result of temperature code comparison satisfies the condition. The TSU has two interrupt signals, a conversion complete interrupt (TSUADI) and a comparison result interrupt (TSUADCMPI).

An interrupt enable/disable switching bit, status confirmation bit, and status clearing bit are in place for each of these signals.

42.4.5.1 Conversion Complete Interrupt

A conversion complete interrupt is generated on completion of conversion.

- When the interrupt is enabled (SIER.ADIE = 1)
  - The conversion complete interrupt (TSUADI) is generated on completion of conversion by the TSU.
  - The SISR.ADF bit is set to 1 on completion of conversion by TSU.
  - Writing 1 to the SICR.ADCLR bit sets the SISR.ADF bit to 0 to clear the status flag. The SISR.ADF bit retains the value 1 unless 1 is written to the SICR.ADCLR bit.
- When the interrupt is disabled (SIER.ADIE = 0)
  - The conversion complete interrupt (TSUADI) is not generated on completion of conversion by TSU.
  - The SISR.ADF bit is set to 1 on completion of conversion by TSU.
  - Writing 1 to the SICR.ADCLR bit sets the SISR.ADF bit to 0 to clear the status flag. The SISR.ADF bit retains the value 1 unless 1 is written to the SICR.ADCLR bit.

42.4.5.2 Comparison Result Interrupt

A comparison result interrupt is generated according to the selected condition for comparison when the result of comparison satisfies the condition.

- When the interrupt is enabled (SIER.CMPIE = 1)
  - The comparison result interrupt (TSUADCMPI) is generated when comparison result satisfies the condition in section 42.4.4. Temperature Code Comparison Functions.
  - The SISR.CMPF bit is set to 1 when comparison result satisfies the condition in section 42.4.4. Temperature Code Comparison Functions.
  - Writing 1 to the SICR.CMPCLR bit sets the SISR.CMPF bit to 0 to clear the status flag. The SISR.CMPF bit retains the value 1 unless 1 is written to the SICR.CMPCLR bit.
- When the interrupt is disabled (SIER.CMPIE = 0)
  - The comparison result interrupt (TSUADCMPI) is not generated when comparison result satisfies the condition in section 42.4.4. Temperature Code Comparison Functions.
  - The SISR.CMPF bit is set to 1 when comparison result satisfies the condition in section 42.4.4. Temperature Code Comparison Functions.
  - Writing 1 to the SICR.CMPCLR bit sets the SISR.CMPF bit to 0 to clear the status flag. The SISR.CMPF bit retains the value 1 unless 1 is written to the SCIR.CMPCLR bit.

42.4.6 Single Scan Mode and Continuous Scan Mode

Single scan mode and continuous scan mode are supported. In single scan mode, conversion is only performed once with averaging the number of sampling set by the SOSR1.ADCT[1:0] bits. In continuous scan mode, conversion continues repeatedly until the STRGR.ADEND bit is set to 1. The SOSR1.ADCS bit selects one of the two scan modes. SOSR1.ADCS = 0 is single scan mode and SOSR1.ADCS = 1 is continuous scan mode.

42.5 Operation

The TSU is mainly used in the following two ways.

- Using an interrupt for each completion of the conversion
- Using the comparison result interrupt

42.5.1 Using Interrupt for Each Completion of Conversion

Conversion is started by software and the interrupt is generated on completion of the conversion. After the generation of the interrupt, the temperature code is read.

The comparison function is enabled by default. The upper and lower limit settings for use in comparison are both all 0s by default and the conditions for comparison are not satisfied even while the comparison function is enabled, but the conditions may inadvertently be satisfied if operation proceeds after the upper and lower limits have been set. If the comparison function is not to be used, set the CMSR.CMPEN bit to 0 to disable the comparison function.

Table 42.4 is an example of the procedure for operations when an interrupt is to be used to indicate each completion of the conversion.

Table 42.4 Example of the operation procedure when using interrupt for each completion of the conversion

No	Item	Example of the operation procedure
1	Release from suspended state	Set the SSUSR register to 0x00000005. ● Temperature Sensor is normal operation. ● ADC is normal operation. ● SOC_TS is enabled.
2	Setting of the operating mode	Set 0x0000020B to the SOSR1 register. ● The number of samples for averaging is 8. ● Single scan mode ● Average data output Set SIER register to 0x00000001. ● Enable the conversion complete interrupt. ● Mask the comparison result interrupt.
3	Check the conversion status	Read the SSR.CONV bit. ● Confirm whether conversion is not in progress.
4	Start conversion	Set the STRGR register to 0x00000001. ● Start conversion.
5	Check the interrupt	Read the SISR.ADF bit. ● Confirm AD conversion complete flag is set to 1. Set SICR register to 0x00000001. ● Clear AD conversion complete flag.
6	Check the conversion status	Read the SSR.CONV bit. ● Confirm whether conversion is not in progress.
7	Obtain the temperature code	Read the SCRR register. ● Obtain the temperature code
8	Temperature compensation	Calculate compensated temperature. For details, see section 42.5.3. Temperature Compensation Calculation.

42.5.2 Using Comparison Result Interrupt

Conversion is started by software after the conditions for comparison (within or outside the range, and the upper and lower limits) have been set and the interrupt is generated when the result of comparison with the settings satisfies the conditions. After the generation of the interrupt, the temperature code is read.

Table 42.5 is an example of the procedure for operations when the comparison result interrupt is to be used.

Table 42.5 Example of the operation procedure when using comparison result interrupt

No	Item	Example of the operation procedure
1	Release from suspended state	Set the SSUSR register to 0x00000005. ● Temperature Sensor is normal operation. ● ADC is normal operation. ● SOC_TS is enabled.
2	Setting of the operating mode	Set the SOSR1 register to 0x0000021B. ● The number of samples for averaging is 8. ● Continuous scan mode ● Average data output Set the SIER register to 0x00000002. ● Mask the conversion complete interrupt. ● Enable the comparison result interrupt. Set a lower limit to the LLSR register and an upper limit to the ULSR register. ● Set an upper and lower limit for the temperature. See section 42.5.4. Comparison Setting Value Calculation for the calculation of the setting value.
3	Check the conversion status	Read the SSR.CONV bit. ● Confirm whether conversion is not in progress.
4	Start conversion	Set 0x0000_0001 to STRGR register. ● Start conversion.
5	Check the interrupt	Read the SISR.CMPF bit. ● Confirm comparison result flag is set to 1. Set SICR register to 0x00000002. ● Clear comparison result flag.
6	Check the conversion status	Read the SSR.CONV bit. ● Confirm whether conversion is not in progress.
7	Obtain the temperature code	Read the SCRR register. ● Obtain the temperature code
8	Temperature compensation	Calculate compensated temperature. For details, see section 42.5.3. Temperature Compensation Calculation.

42.5.3 Temperature Compensation Calculation

After acquiring the temperature code data, the compensated temperature T (°C) should be calculated from the value (a) of the SCRR.OUT12BIT_TS bits, the value (b) at −40 (°C) and the value (c) at 125 (°C) stored in OTP.

[Calculation formula]

$$\text{Compensated temperature T (°C)} = \left(\frac{e - d}{c - b}\right) \times (a - b) + d$$

$d = -40, e = 125$

42.5.4 Comparison Setting Value Calculation

The comparison setting value (a) set to the LLSR and ULSR registers should be calculated from each temperature T (°C) you want to set, the value (b) at −40 (°C) and the value (c) at 125 (°C) stored in OTP.

[Calculation formula]

$$\text{Setting value a} = \frac{(T - d) \times (c - b)}{(e - d)} + b$$

42.6 Usage Notes

42.6.1 Release from Power-down

Set the SSUSR.SOC_TS_EN bit to 1 simultaneously or before setting the SSUSR.EN_TS bit to 1 and the SSUSR.ADC_PD bit to 0 to release the TSU from the power-down state.

42.6.2 Conversion Start Trigger

Before starting conversion by the STRGR.ADST bit, check that the SSR.CONV bit is 0.

43. Data Operation Circuit (DOC)

43.1 Overview

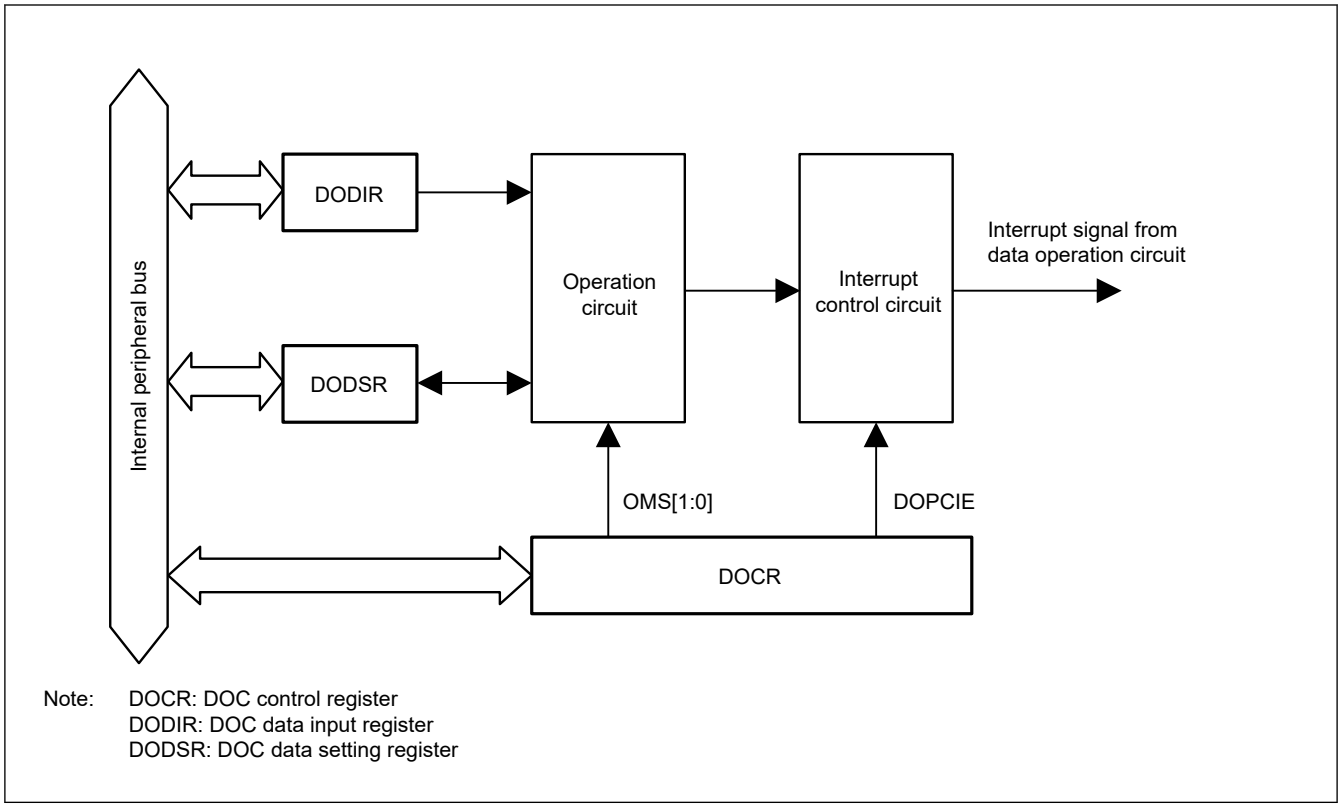
The data operation circuit (DOC) is used to compare, add, and subtract 16-bit data.

Table 43.1 lists the data operation circuit specifications and Figure 43.1 shows a block diagram of the data operation circuit.

- 16-bit data is compared and an interrupt can be generated when a selected condition applies.
- 16-bit data can be added.
- 16-bit data can be subtracted.

Table 43.1 DOC specifications

Parameter	Description
Data operation function	16-bit data comparison, addition, and subtraction
Lower power consumption function	Module-stop state can be set.
Interrupts	An interrupt occurs at the following timings: • The compared values either match or mismatch • The result of data addition is greater than 0xFFFF • The result of data subtraction is less than 0x0000



Note: DOCR: DOC control register
DODIR: DOC data input register
DODSR: DOC data setting register

Figure 43.1 Block diagram of data operation circuit (DOC)

43.2 Register Map

Table 43.2 DOC register map

Address	Register symbol	Register name	Write protection
0x8008_4000	DOCR	DOC Control Register	—

43.3 Register Descriptions

43.3.1 DOCR : DOC Control Register

Base address: DOC = 0x8008_4000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	DOPCFCL	DOPCF	DOPCIE	—	DCSEL	OMS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	OMS[1:0]	Operating Mode Select Selects an operating mode of the data operation circuit. 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited	R/W
2	DCSEL	Detection Condition Select Selects a condition for detecting data comparison result. This bit is valid only in the data comparison mode. 0: Data mismatch is detected. 1: Data match is detected.	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
4	DOPCIE	Data Operation Circuit Interrupt Enable Specifies whether to enable or disable data operation circuit interrupt requests. 0: Disables interrupts from the data operation circuit. 1: Enables interrupts from the data operation circuit.	R/W
5	DOPCF	Data Operation Circuit Flag [Setting conditions] When any of the following is met: ● The condition selected by the DCSEL bit is met. ● A result of data addition is greater than 0xFFFF. ● A result of data subtraction is less than 0x0000. [Clearing condition] Writing 1 to the DOPCFCL bit	R
6	DOPCFCL	DOPCF Flag Clear 0: No effect 1: Clear the DOPCF flag	W
7	—	This bit is read as 0. The write value should be 0.	R/W

43.3.2 DODIR : DOC Data Input Register

Base address: DOC = 0x8008_4000

Offset address: 0x02

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	n/a	The DODIR register is a 16-bit readable/writable register in which 16-bit data for use in operations are stored.	R/W

43.3.3 DODSR : DOC Data Setting Register

Base address: DOC = 0x8008_4000

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	n/a	The DODSR register is a 16-bit readable/writable register. This register stores 16-bit data for use as a reference in data comparison mode. This register also stores the results of operations in data addition and data subtraction modes.	R/W

43.4 Operation

43.4.1 Data Comparison Mode

Figure 43.2 shows an example of the steps involved in data comparison mode operation by the data operation circuit. The following is an example of operation when DCSEL is set to 0 (data mismatch is detected as a result of data comparison).

1. Writing 00b to the DOCR.OMS[1:0] bits selects data comparison mode.
2. The 16-bit reference data is set in DODSR.
3. 16-bit data for comparison is written to DODIR.
4. Writing of 16-bit data continues until all data for comparison have been written to DODIR.
5. If a value written to DODIR does not match that in DODSR, the DOCR.DOPCF flag is set to 1. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

Note: When the DODIR register has the value after reset (0x0000), the DOCR.DOPCF flag does not change to 1 if a value other than 0x0000 is set in the DODSR register. To perform data comparison, set the DODSR register and write a value to the DODIR register. If the DODSR register is set again after data comparison, the value remaining in the DODIR register will not be compared again with the value set in the DODSR register. That is, comparison proceeds in response to writing to the DODIR register but not in response to writing to the DODSR register.

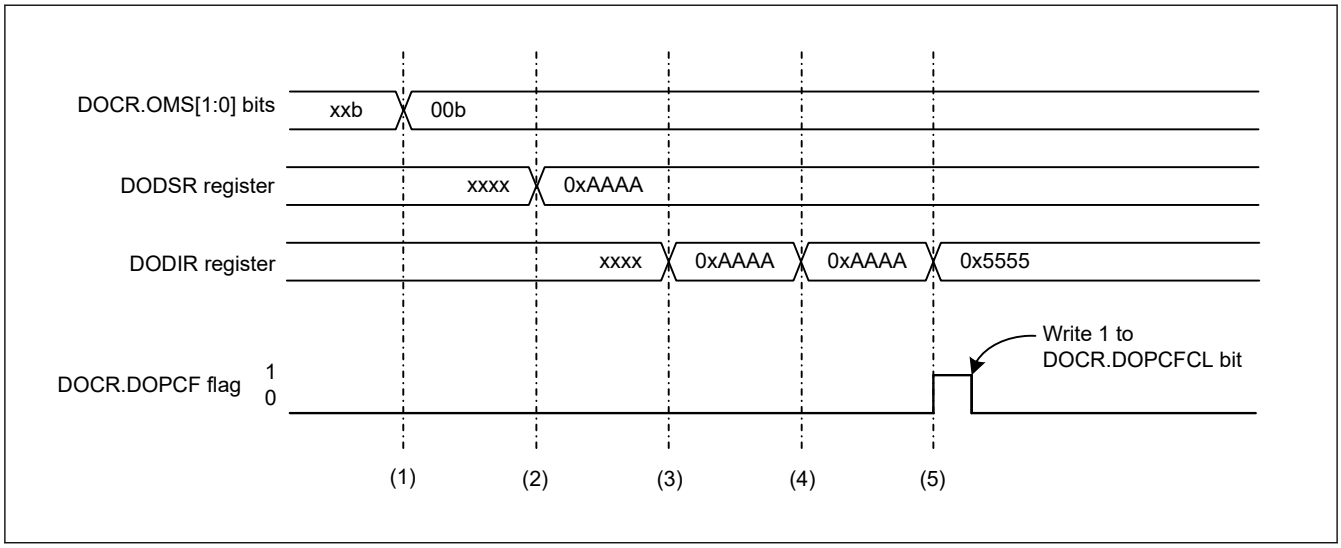

Figure 43.2 Example of operation in data comparison mode

43.4.2 Data Addition Mode

Figure 43.3 shows an example of the steps involved in data addition mode operation by the data operation circuit.

1. Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
2. 16-bit data is set in the DODSR register as the value after reset.
3. 16-bit data to be added is written to DODIR. The result of the operation is stored in DODSR.
4. Writing of 16-bit data continues until all data for addition have been written to DODIR.
5. If the result of an operation is greater than 0xFFFF, the DOCR.DOPCF flag is set to 1. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

Note: When the DODIR register has the value after reset (0x0000), data addition is not performed if a value other than 0x0000 is set in the DODSR register. To perform data addition, set the DODSR register and write a value to be added into the DODIR register. If the DODSR register is set again after data addition, the value remaining in the DODIR register will not be added again to the value set in the DODSR register. That is, addition proceeds in response to writing to the DODIR register but not in response to writing to the DODSR register.

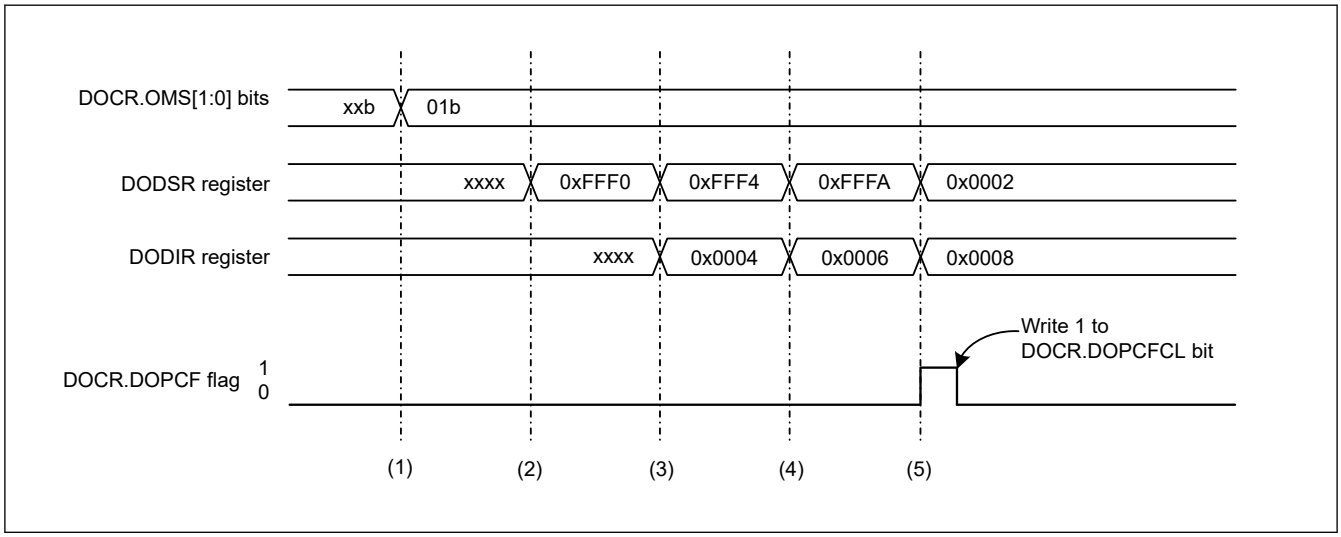

Figure 43.3 Example of operation in data addition mode

43.4.3 Data Subtraction Mode

Figure 43.4 shows an example of the steps involved in data subtraction mode operation by the data operation circuit.

1. Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
2. 16-bit data is set in the DODSR register as the value after reset.
3. 16-bit data to be subtracted is written to DODIR. The result of the operation is stored in DODSR.
4. Writing of 16-bit data continues until all data for subtraction have been written to DODIR.
5. If the result of an operation is less than 0x0000, the DOCR.DOPCF flag is set to 1. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

Note: When the DODIR register has the value after reset (0x0000), data subtraction is not performed if a value other than 0x0000 is set in the DODSR register. To perform data subtraction, set the DODSR register and write a value to be subtracted into the DODIR register. If the DODSR register is set again after data subtraction, the value remaining in the DODIR register will not be subtracted again from the value set in the DODSR register. That is, subtraction proceeds in response to writing to the DODIR register but not in response to writing to the DODSR register.

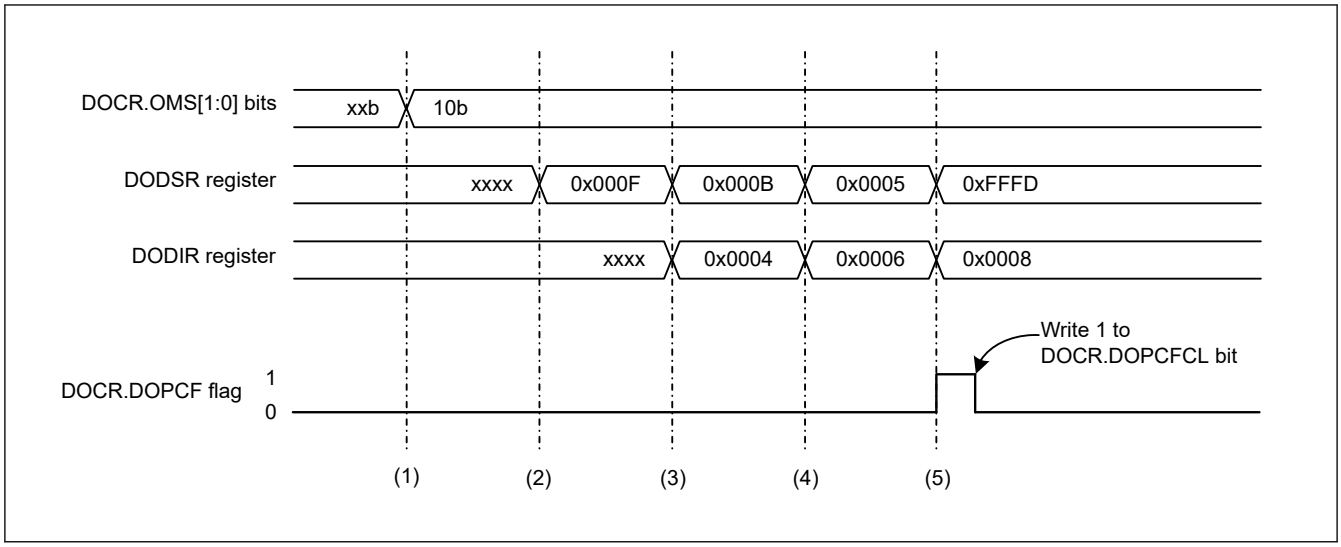

Figure 43.4 Example of operation in data subtraction mode

43.5 Interrupt Requests

The data operation circuit generates the data operation circuit interrupt as an interrupt request. When an interrupt source is generated, the data operation circuit flag (DOCR.DOPCF) corresponding to the interrupt is set to 1. Table 43.4 describes the interrupt request.

Table 43.4 Interrupt request from data operation circuit

Interrupt request	Data operation circuit flag	Interrupt generation timing
Data operation circuit interrupt	DOPCF	• The result of data addition is greater than 0xFFFF • The result of data subtraction is less than 0x0000 • The compared values either match or mismatch

43.6 Usage Note

43.6.1 Module Stop Function Setting

Operation of the data operation circuit can be disabled or enabled using module stop control register D (MSTPCRD). The value after reset indicates that the data operation circuit is in the stop state. Register access is enabled by canceling the module-stop state. For details, see section 9, Low-Power Consumption Function.

44. System SRAM (SYSRAM)

44.1 Overview

The LSI has an on-chip high-speed RAM (with ECC error correction). The RAM, whose capacity is 2.0 MB (512 KB × 4), is installed. Table 44.1 lists the System SRAM (SYSRAM) specifications and Figure 44.1 shows a block diagram of SYSRAM.

Table 44.1 System SRAM specifications

Parameter	Description
RAM capacity	2.0 MB (512 KB × 4)
Operating frequency	250 MHz (PCLKH)
RAM address	SYSRAM0: 0x1000_0000 to 0x1007_FFFF SYSRAM1: 0x1008_0000 to 0x100F_FFFF SYSRAM2: 0x1010_0000 to 0x1017_FFFF SYSRAM3: 0x1018_0000 to 0x101F_FFFF Each RAM module consists of 4 pages of 128 KB
Shortest Latency	• ECC enabled Writing 32/64/96/128-bit transfer: Latency 0 (write to RAM in 1 cycle) 8/16-bit transfer: Latency 2 (write to RAM in 3 cycles) Reading All data transfer: Latency 2 (read from RAM in 3 cycles) • ECC disabled Writing All data transfer: Latency 0 (write to RAM in 1 cycle) Reading All data transfer: Latency 1 (read from RAM in 2 cycles)
Error checking	7-bit ECC data to 32-bit RAM data 1-bit error correction and 2-bit error detection are supported.
Interrupts	3 interrupts are available for each SYSRAMn. They can be used as error events.
Bus error response	SLVERR is returned to the access to the System SRAM. • Write access occurs when write access is disabled by VLWEN bit. • Write or read access occurs when access is disabled by VCEN bit. • Write access occurs when write access is disabled by VRWEN bit to corresponding page. • 2-bit ECC error occurs when read access is done. This response is maskable.
Test function (by error injection)	• Register values can be used as test data to be written to RAM, those in ECEDB[31:0] to the RAM data section and ECERDB[6:0] to the ECC redundancy bit section, respectively. • The ECC redundancy bits included in the RAM data are retained and read as a register value. • The ECC redundancy bits (encoder circuit) generated from the input data and the syndrome code (decoder circuit) can be checked.
Initializing function	Supported

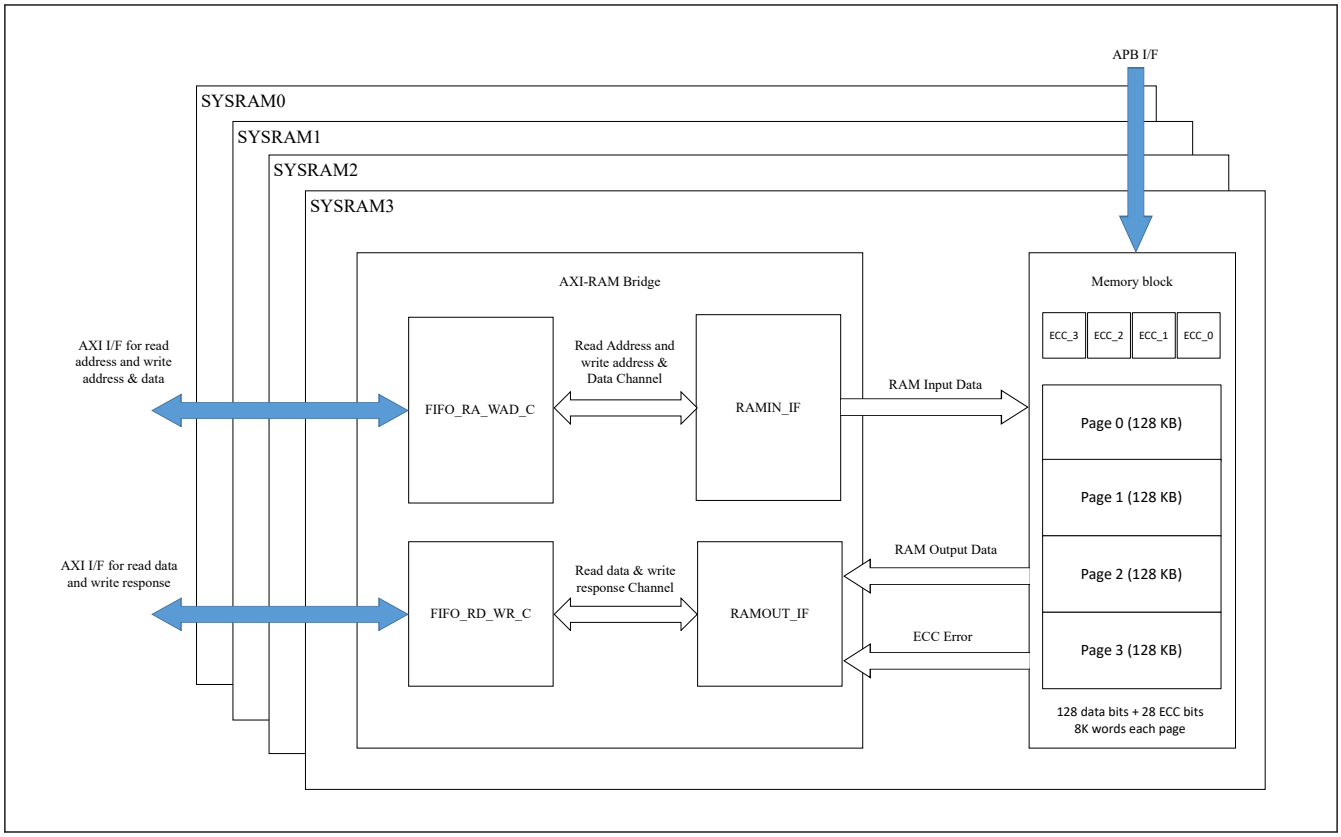

Figure 44.1 Block diagram of System SRAM

44.2 Register Map

Table 44.2 SYSRAM register map

Address	Register symbol	Register name	Write protection
0x8129_3000 + 0x010 × n	SYSRAM_CTRLn	System SRAM Control Register n	PRCRN.PRC3
0x8104_0000 + 0x1000 × i + 0x040 × n (i = 0 to 3, n = 0 to 3)	Wn_EC710CTL	ECC Control Register n	—
0x8104_0004 + 0x1000 × i + 0x040 × n (i = 0 to 3, n = 0 to 3)	Wn_EC710TMC	ECC Test Mode Control Register n	—
0x8104_0008 + 0x1000 × i + 0x040 × n (i = 0 to 3, n = 0 to 3)	Wn_EC710TRC	ECC Redundancy Bit Data Control Test Register n	—
0x8104_000C + 0x1000 × i + 0x040 × n (i = 0 to 3, n = 0 to 3)	Wn_EC710TED	ECC Encode/Decode Input/Output Switchover Test Register n	—
0x8104_0010 + 0x1000 × i + 0x040 × n + 0x004 × m (i = 0 to 3, n = 0 to 3, m = 0 to 7)	Wn_EC710EADm	ECC Error Address m Register n	—

Note: n for SYSRAM_CTRLn and i for the others stand for unit number.

Table 44.3 SYSRAM related system control register

Unit	Module Reset Control Register	Module Stop Control Register	Slave Access Control Register*1
0	—	—	SLVACCCTL6.SYSRAM0_SL
1	—	—	SLVACCCTL6.SYSRAM1_SL
2	—	—	SLVACCCTL6.SYSRAM2_SL
3	—	—	SLVACCCTL6.SYSRAM3_SL

Note 1. Access to memory area is controlled by SLVACCCTL8.TZCSYSRAM_SL.

44.3 Register Descriptions

44.3.1 SYSRAM_CTRLn : System SRAM Control Register n (n = 0 to 3)

Base address: SYSRAM_CTL = 0x8129_3000

Offset address: 0x000 + 0x010 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	MKICCAXIERR	—	—	VLWEN	VCEN	VRWEN[3:0]			
Value after reset:	0	0	0	0	0	0	0	1	0	0	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VECEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	VECEN	Enables or disables error correction with ECC 0: Disabled 1: Enabled	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W
19:16	VRWEN[3:0]	Enables write for each page of RAM The bit n corresponds to the page n (n = 0 to 3). 0: Disabled 1: Enabled	R/W
20	VCEN	Enables access to RAM 0: Disabled 1: Enabled	R/W
21	VLWEN	Enables write for RAM 0: Disabled 1: Enabled	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
24	MKICCAXIERR	Controls AXI-SLVERR issuance for ECC 2-bit errors 0: Issue AXI-SLEVER 1: Do not issue AXI-SLEVER	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

The SYSRAM_CTRLn register is a 32-bit register that controls ECC of the SYSRAMn.

44.3.2 Wn_EC710CTL : ECC Control Register n (n = 0 to 3)

Base address: SYSRAMi = 0x8104_0000 + 0x1000 × i (i = 0 to 3)

Offset address: 0x000 + 0x040 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ECEDF7[1:0]		ECEDF6[1:0]		ECEDF5[1:0]		ECEDF4[1:0]		ECEDF3[1:0]		ECEDF2[1:0]		ECEDF1[1:0]		ECEDF0[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EMCA[1:0]		—	—	ECOVFF	ECER2C	ECER1C	—	ECTHM	ECERVF	EC1ECP	EC2EDIC	EC1EDIC	ECER2F	ECER1F	ECEMF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	ECEMF	ECC Error Indicate Flag Indicates that an error is detected in the current read data. This bit is updated for each 32-bit RAM output data. When ECC error determination is disabled (ECERVF = 0) or the ECC function through mode is set (ECTHM = 1), this bit is always 0. 0: No error is detected in the current read data 1: An error is detected in the current read data	R
1	ECER1F	1-Bit ECC Error Detection/Correction Flag Indicates that a 1-bit error is detected and corrected in the 32-bit read data plus 7 ECC bits (total 39 bits) while the ECC error determination is enabled. 0: 1-bit error has not occurred 1: 1-bit error has occurred*1	R
2	ECER2F	2-Bit ECC Error Detection Flag Indicates that a 2-bit error is detected in the 32-bit read data plus 7 ECC bits (total 39 bits) while the ECC error determination is enabled. 0: 2-bit error has not occurred 1: 2-bit error has occurred*2	R
3	EC1EDIC	1-Bit ECC Error Detection Interrupt Control Enables or disables to output an interrupt signal (SRAMn_IE1) on detection of a 1-bit ECC error. 0: Disables to output an interrupt signal 1: Enables to output an interrupt signal	R/W
4	EC2EDIC	2-Bit ECC Error Detection Interrupt Control Enables or disables to output an interrupt signal (SRAMn_IE2) on detection of a 2-bit ECC error. 0: Disables to output an interrupt signal 1: Enables to output an interrupt signal	R/W
5	EC1ECP	1-Bit ECC Error Correction Enable Enables or disables error correction when a 1-bit ECC error is detected. 0: Error correction is performed on detection of a 1-bit ECC error 1: Error correction is not performed on detection of a 1-bit ECC error	R/W
6	ECERVF	ECC Error Determination Enable To change this bit, it is necessary to write 01b to bits 15 and 14 at the same time to permit writing. 0: The error determination is disabled 1: The error determination is enabled. The ECC function according to EC1EDIC, EC2EDIC, and EC1ECP bits are enabled.	R/W
7	ECTHM	ECC Function Through Mode Enable Enables or disables ECC function Through mode. If Through mode is enabled, no ECC error determination and no error correction is performed. To change this bit, it is necessary to write 01b to bits 15 and 14 at the same time to permit writing. 0: Disables Through mode 1: Enables Through mode. No effect on encoder. Decoder does not determine the error and does not perform error correction.	R/W
8	—	This bit is read as 0. The write value should be 0.	R/W
9	ECER1C	1-Bit ECC Error Detection Clear Clears the 1-bit ECC error detection flag and the error address related flags for the 32-bit read data. Writing 1 to this bit clears the ECER1F, ECOVFF, and ECEDF7[1:0] to ECEDF0[1:0] bits. When a conflict occurs between 1-bit ECC error detection and writing 1 to this bit, writing to this bit is given priority and the 1-bit ECC error detection flag is not set.	R/W
10	ECER2C	2-Bit ECC Error Detection Clear Clears the 2-bit ECC error detection flag and the error address related flags for the 32-bit read data. Writing 1 to this bit clears the ECER2F, ECOVFF, and ECEDF7[1:0] to ECEDF0[1:0] bits. When a conflict occurs between 2-bit ECC error detection and writing 1 to this bit, writing to this bit is given priority and the 2-bit ECC error detection flag is not set.	R/W

Bit	Symbol	Function	R/W
11	ECOVFF	ECC Error Address Capture Overflow Flag Indicates that the error address fails to be stored in the ECC error address register when an ECC error occurs. When an ECC error address capture overflow occurs, SRAMn_OVF interrupt is output. If an ECC error address capture overflow occurs again while this flag is 1, SRAMn_OVF interrupt is output again. 0: ECC error address capture overflow has not occurred 1: ECC error address capture overflow has occurred	R
13:12	—	These bits are read as 0. The write value should be 0.	R/W
15:14	EMCA[1:0]	Access Control to ECC Mode Selection Setting these bits to 01b enables writing to bits 7 and 6 of this register. Otherwise, writing to bits 7 and 6 is ignored. These bits are always read as 00b. 0 1: Writing is enabled Others: Writing is disabled	R/W
17:16	ECEDF0[1:0]	ECC Error Address Capture Flag m (m = 0) Indicates the error address register and the error type. When an ECC error occurs and its error type can be identified, the following value is read from these bits. 0 0: ECC error address is not captured in Wn_EC710EADm 0 1: 1-bit ECC error address is captured in Wn_EC710EADm 1 0: 2-bit ECC error address is captured in Wn_EC710EADm	R
19:18	ECEDF1[1:0]	ECC Error Address Capture Flag m (m = 1) This function is the same as ECEDF0.	R
21:20	ECEDF2[1:0]	ECC Error Address Capture Flag m (m = 2) This function is the same as ECEDF0.	R
23:22	ECEDF3[1:0]	ECC Error Address Capture Flag m (m = 3) This function is the same as ECEDF0.	R
25:24	ECEDF4[1:0]	ECC Error Address Capture Flag m (m = 4) This function is the same as ECEDF0.	R
27:26	ECEDF5[1:0]	ECC Error Address Capture Flag m (m = 5) This function is the same as ECEDF0.	R
29:28	ECEDF6[1:0]	ECC Error Address Capture Flag m (m = 6) This function is the same as ECEDF0.	R
31:30	ECEDF7[1:0]	ECC Error Address Capture Flag m (m = 7) This function is the same as ECEDF0.	R

Note 1. When a 1-bit ECC error is detected while EC1EDIC bit is 1 and ECER1F bit is 0, SRAMn_IE1 interrupt is output. If a 1-bit ECC error is detected while the ECER1F bit is already 1, the SRAMn_IE1 interrupt is not output.

Note 2. When a 2-bit ECC error is detected while EC2EDIC bit is 1 and ECER2F bit is 0, SRAMn_IE2 interrupt is output. If a 2-bit ECC error is detected while the ECER2F bit is already 1, the SRAMn_IE2 interrupt is not output.

The Wn_EC710CTL register indicates operation settings and error status at the time of an ECC error occurrence.

Because RAM block consists of 128-bit data width but ECC is controlled on a 32-bit basis, the highest-order 32 bits are controlled by the W3_EC710CTL register and the lowest-order 32 bits by the W0_EC710CTL register. Do not write to the control bits (bits 7 to 3) of this register while AXI access is in progress.

44.3.3 Wn_EC710TMC : ECC Test Mode Control Register n (n = 0 to 3)

Base address: SYSRAMi = 0x8104_0000 + 0x1000 × i (i = 0 to 3)

Offset address: 0x004 + 0x040 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ETMA[1:0]		—	—	—	—	—	—	ECTMCE	—	—	ECTRRS	ECREOS	ECENS	ECDCS	ECREIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ECREIS	ECC Redundancy Bit Input Data Select Selects whether the ECERDB[6:0] bits value or the ECC data in RAM is to be input to the decoder. This bit is writable only when the ECTMCE bit is 1, and synchronously cleared when the ECTMCE bit becomes 0. 0: ECC data read from RAM is input to the decoder 1: The value of the ECERDB[6:0] bits is input to the decoder	R/W
1	ECDCS	ECC Decode Input Select Selects whether the Wn_EC710TED register value or the RAM output data is to be input to the decoder. This bit is writable only when the ECTMCE bit is 1, and synchronously cleared when the ECTMCE bit becomes 0. 0: RAM output data is input to the decoder 1: The value of the Wn_EC710TED register is input to the decoder	R/W
2	ECENS	ECC Encode Input Select Selects whether the input data to RAM or the Wn_EC710TED register value is to be input to the encoder. This bit is writable only when the ECTMCE bit is 1, and synchronously cleared when the ECTMCE bit becomes 0. 0: Data input to RAM is selected 1: The value of the Wn_EC710TED register is selected	R/W
3	ECREOS	ECC Redundancy Bit Output Data Select Selects whether the ECC encoder output data or the value of the ECERDB[6:0] bits in the Wn_EC710TRC register is to be output as the ECC output. This bit is writable only when the ECTMCE bit is 1, and synchronously cleared when the ECTMCE bit becomes 0. 0: The encoded result of the encoder is output 1: The value of the ECERDB[6:0] bits in the Wn_EC710TRC register is output	R/W
4	ECTRRS	RAM Read Test Mode Select If 1 is set, read value of Wn_EC710TED register is 32-bit output data from RAM and read value of the Wn_EC710TRC.ECERDB[6:0] bits is 7 redundancy bits input to RAM. This bit is writable only when the ECTMCE bit is 1, and synchronously cleared when the ECTMCE bit becomes 0. 0: Read value is the written value for the Wn_EC710TED register and the Wn_EC710TRC.ECERDB[6:0] bits 1: Read value of Wn_EC710TED register is 32-bit output data from RAM and read value of the Wn_EC710TRC.ECERDB[6:0] bits is 7 redundancy bits input to RAM	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	ECTMCE	Test Mode Enable Enables or disables access to the test register and the test control register. When writing to this bit, it is necessary to set bits 15 and 14 of this register to 10b. If bits 15 and 14 are not 10b, writing to this bit is ignored. 0: Disables access to the test mode register and its bits 1: Enables access to the test mode register and its bits	R/W
13:8	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:14	ETMA[1:0]	ECTMCE Write Enable When these bits are 10b, writing to the ECTMCE bit is enabled. Any settings other than 10b disables writing to the ECTMCE bit. These bits are always read as 00b. 1 0: Writing is enabled Others: Writing is disabled	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The Wn_EC710TMC register is used to switch over to and control the ECC function test mode. Do not write to this register while AXI access is in progress.

44.3.4 Wn_EC710TRC : ECC Redundancy Bit Data Control Test Register n (n = 0 to 3)

Base address: SYSRAMi = 0x8104_0000 + 0x1000 × i (i = 0 to 3)

Offset address: 0x008 + 0x040 × n

Bit position:	31	30	24	22	16	14	8	6	0
Bit field:	—	ECSYND[6:0]		—	ECHORD[6:0]	—	ECECRD[6:0]	—	ECERDB[6:0]
Value after reset:	0	0 0 0 0 0 0 0	0	0	0 0 0 0 0 0 0	0	0 0 0 0 0 0 0	0	0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
6:0	ECERDB[6:0]	ECC Redundancy Bit Input/Output Substitute Buffer Register Handling of this register differs according to the setting of the associated register bits as follows: • Wn_EC710TMC.ECTMCE = 1: This register holds the substitute data for use as the value for the redundancy bit. • Wn_EC710TMC.ECREOS = 1: The value in this register substitutes for the redundancy bit value from the encoder and is written to the RAM. • Wn_EC710TMC.ECREIS = 1: The value in this register substitutes for the redundancy bit value from the RAM and is input to the decoder. • Wn_EC710TMC.ECTRRS = 1: The value read from this register is the input data to be supplied to the RAM. The value written in this register is not read.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
14:8	ECECRD[6:0]	ECC Encode Test Register When Wn_EC710TMC.ECTMCE = 1, the redundancy bit value generated in the encoder circuit is read from this register. Note that the read value is that from the encoder as is, for example, the encoded result of the data which was input to the encoder circuit. On the other hand, the value to be written to the RAM is the data output from the encoder circuit with its lower-order 2 bits inverted.	R
15	—	This bit is read as 0. The write value should be 0.	R/W
22:16	ECHORD[6:0]	ECC 7-Redundancy-Bit Data Retain Test Register When Wn_EC710TMC.ECTMCE = 1, 7 redundancy bits read from the RAM are stored in this register at the next clock cycle for the RAM read access. In addition, ECC 7-Redundancy-Bit Data is stored in the next clock cycle when Wn_EC710TED register is read if Wn_EC710TMC.ECTRRS = 1.	R
23	—	This bit is read as 0. The write value should be 0.	R/W
30:24	ECSYND[6:0]	ECC Decode Syndrome Register When Wn_EC710TMC.ECTMCE = 1, the syndrome code generated in the decoder circuit is read from this register. When Wn_EC710TMC.ECTMCE = 0, all 0s are read. The value of this register varies according to changes of decoder input value.	R
31	—	This bit is read as 0. The write value should be 0.	R/W

The Wn_EC710TRC register controls ECC redundancy bits. The value read from this register is valid only when Wn_EC710TMC.ECTMCE = 1, and always 0s when Wn_EC710TMC.ECTMCE = 0.

44.3.5 Wn_EC710TED : ECC Encode/Decode Input/Output Switchover Test Register n (n = 0 to 3)

Base address: SYSRAMi = 0x8104_0000 + 0x1000 × i (i = 0 to 3)

Offset address: 0x00C + 0x040 × n

Bit position:	31																												0
Bit field:	ECEDB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ECEDB[31:0]	32-Bit Data Test Register for ECC Encode/Decode In the test mode, the data of this register is used as the input to the encoder/decoder circuit. When Wn_EC710TMC.ECTRRS = 1, the value read from this register is the value of the data output from RAM. This register is readable and writable when Wn_EC710TMC.ECTMCE = 1. When Wn_EC710TMC.ECTMCE = 0, synchronous clearing occurs.	R/W

The Wn_EC710TED register handles ECC redundancy bits.

44.3.6 Wn_EC710EADm : ECC Error Address m Register n (n = 0 to 3, m = 0 to 7)

Base address: SYSRAMi = 0x8104_0000 + 0x1000 × i (i = 0 to 3)

Offset address: 0x010 + 0x040 × n + 0x004 × m

Bit position:	31															14													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECEAD[14:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
14:0	ECEAD[14:0]	Bit Error Address Retain the address where a 1-bit or 2-bit ECC error was detected.	R
31:15	—	These bits are read as 0.	R

The Wn_EC710EADm registers are read-only registers that retain the values of addresses where ECC errors have occurred.

44.4 Operation

44.4.1 Initialization

RAM initialization function initializes the data and redundancy bit area during reset sequence automatically.

44.4.2 Access Cycle to System SRAM with ECC Function Enabled

Read

Read access cycle when the ECC function is enabled is one cycle longer than the case when the ECC function is disabled regardless of access size.

Write

8/16-bit write access cycle when the ECC function is enabled is two cycles longer than the case when the ECC function is disabled. 32/64/96/128-bit write access cycle when the ECC function is enabled is the same as the case when the ECC function is disabled.

44.4.3 ECC Error Address Calculation Method

An ECC error address is stored as a relative address in the ECC Error Address Register (Wn_EC710EADm). To convert a relative address to an absolute address, follow the calculation formula shown in Table 44.4.

Table 44.4 ECC error address calculation formula

Register	ECC error address calculation formula
W0_EC710EAD0 to W0_EC710EAD7	SYSRAMi start address + (register value × 0x10) + 0x0
W1_EC710EAD0 to W1_EC710EAD7	SYSRAMi start address + (register value × 0x10) + 0x4
W2_EC710EAD0 to W2_EC710EAD7	SYSRAMi start address + (register value × 0x10) + 0x8
W3_EC710EAD0 to W3_EC710EAD7	SYSRAMi start address + (register value × 0x10) + 0xC

Note: i = 0 to 3

44.4.4 Notes on ECC Error Address Register

When 1-bit or 2-bit errors occur, up to 8 addresses where such errors have occurred are saved in the Wn_EC710EAD0 to Wn_EC710EAD7 registers in this order.

If the retained error address is detected again due to the same error cause, it is not retained this time. When the same address is detected due to a different error cause, it is saved if there is an empty register.

If a 2-bit error is detected when all the error address registers are filled with addresses of 1-bit errors, the Wn_EC710EAD7 register is overwritten with the error address where the 2-bit error occurred. At this time, the status register indicating the error flag information is not overwritten.

When storage of 8 or more error addresses is attempted, an overflow interrupt occurs. Clear the flag when the overflow interrupt occurs or every time a 1-bit error occurs.

44.4.5 Notes on ECC Error Detection

When a 1-bit or 2-bit error is detected, information of up to 8 errors can be stored in the ECC error information storage registers Wn_EC710CTL.ECEDFm[1:0] (m = 0 to 7), Wn_EC710CTL.ECOVFF, Wn_EC710CTL.ECER2F, Wn_EC710CTL.ECER1F, and Wn_EC710EADm (m = 0 to 7) in the ascending order of register numbers.

Note that operation differs depending on the storage state of ECC error information.

Note:
1. The ECC error information storage state is determined by every 32 bits. When an ECC error occurs in the least significant 32 bits, ECC error storage state is determined by the W0_EC710CTL register bits and the W0_EC710EADm register. When an ECC error occurs in the most significant 32 bits, ECC error storage state is determined by the W3_EC710CTL register bits and the W3_EC710EADm register.
2. When a 2-bit error is detected, immediately conduct the error processing and operate the ECER2C and ECER1C registers to clear error flags and the registers related to error address.
3. When storage of 8 or more error addresses is attempted, an overflow interrupt occurs. When an overflow interrupt occurs, immediately conduct the error processing and operate the ECER2C and ECER1C registers to clear error flags and the registers related to error address.

(1) When there are empty ECC error information storage registers

The error type and error address are stored in an empty register with the smallest number. At this time, the ECC error occurred causes the 1-bit ECC error detection/correction flag (ECER1F) or the 2-bit ECC error detection flag (ECER2F) to change from 0 to 1, and an interrupt signal to be output if the corresponding Interrupt Control register (EC1EDIC or EC2EDIC) enables interrupt output.

Error type:	Error type is stored in the ECC Error Address Capture flag (ECEDFm[1:0])
Error address:	ECC error address is stored in the ECC Error Address register (Wn_EC710EADm)
Error detection flag:	When 1-bit ECC error is detected: 1-bit ECC Error Detection/Correction flag (ECER1F) is set to 1. When 2-bit ECC error is detected: 2-bit ECC Error Detection flag (ECER2F) is set to 1.

Note: n = 0 to 3, m = 0 to 7.

(2) When there are no empty ECC error information storage registers (when 1-bit ECC error is detected)

When a 1-bit ECC error is detected, only the ECC Error Address Capture Overflow flag (ECOVFF) is set to 1 in the ECC Error Information Storage register.

At this time, the 1-bit ECC error occurred causes an ECC error address capture overflow interrupt to be generated.

Error type:	Error type is not stored in the ECC Error Address Capture flag (ECEDFm[1:0])
Error address:	ECC error address is not stored in the ECC Error Address register (Wn_EC710EADm)
Error detection flag:	ECC Error Address Capture Overflow flag (ECOVFF) is set to 1

Note: n = 0 to 3, m = 0 to 7.

(3) When there are no empty ECC error information storage registers (when 2-bit ECC error is detected)

When a 2-bit ECC error is detected, operation depends on the state of the 2-bit Error Detection flag (ECER2F) at the detection time.

When ECER2F = 0 on detection of a 2-bit ECC error

If the 2-bit ECC Error Detection flag (ECER2F) is 0 when the error is detected, all ECC error information storage registers are full of 1-bit ECC errors. In this case, only the error address is overwritten in the ECC Error Address register (Wn_EC710EADm).

At this time, the 2-bit ECC error occurred causes the following to occur:

- ECC error capture overflow interrupt
- 2-bit ECC error detection interrupt (EC2EDIC = 1: Interrupt output enabled)

Error type:	Error type is not stored in the ECC Error Address Capture flag (ECEDFm[1:0])
Error address:	2-bit ECC error address is overwritten in the ECC Error Address register (Wn_EC710EADm)
Error detection flag:	2-bit ECC Error Detection flag (ECER2F) is set to 1. ECC Error Address Capture Overflow flag (ECOVFF) is set to 1.

When ECER2F = 1 on detection of a 2-bit ECC error

If the 2-bit Error Detection flag (ECER2F) is 1 when the error is detected, only the ECC Error Address Capture Overflow flag (ECOVFF) is set to 1 in the ECC Error Information Storage register.

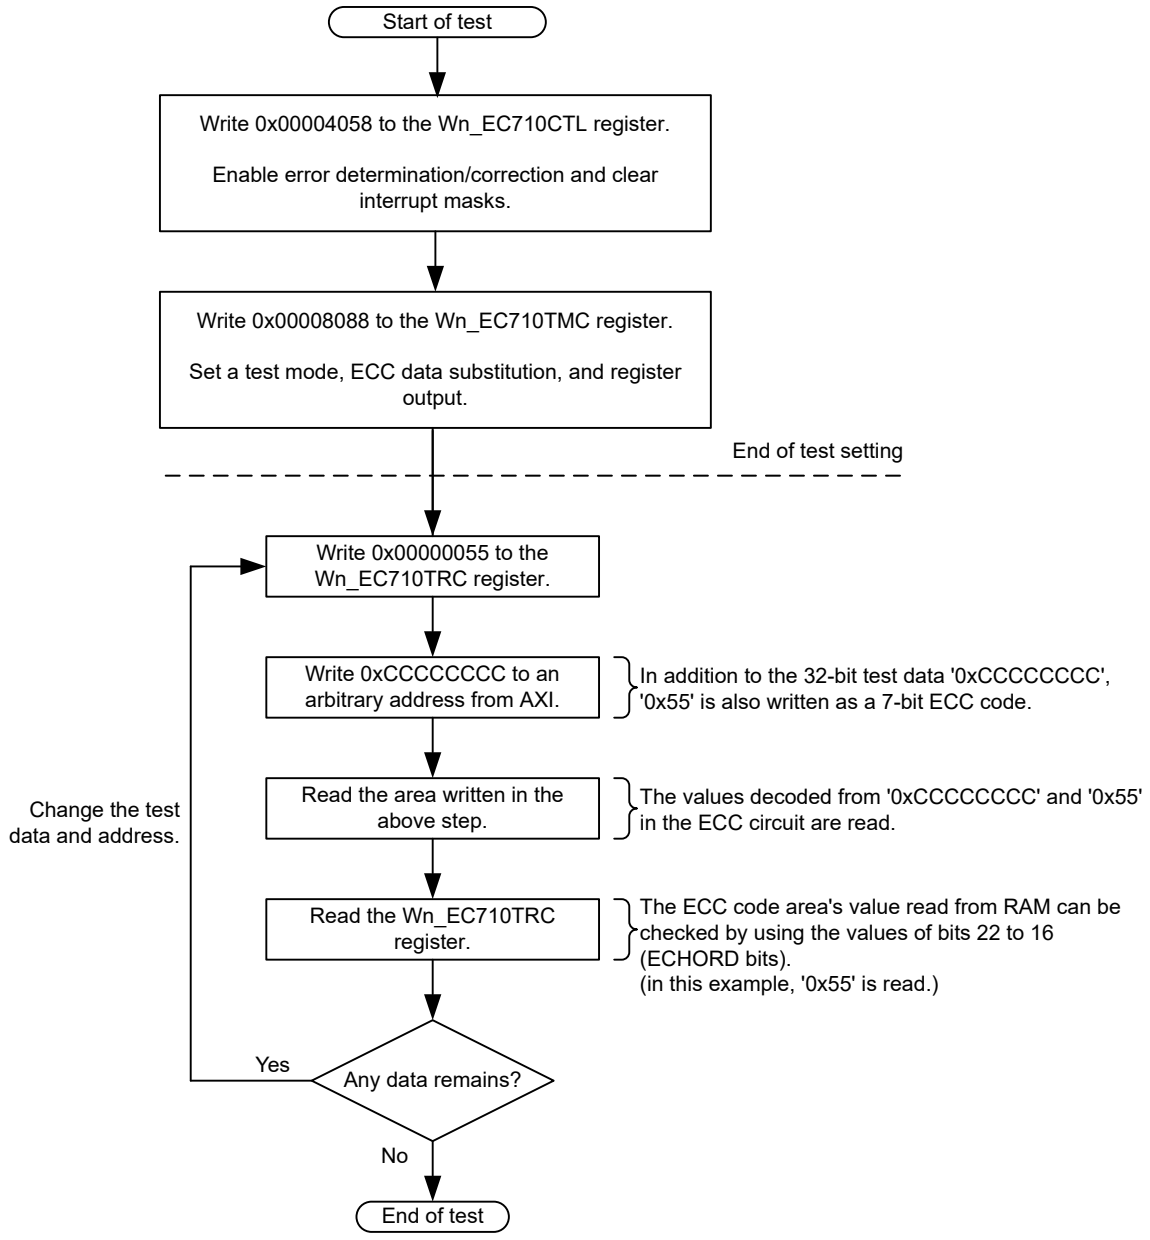
At this time, the 2-bit ECC error occurred causes an ECC error capture overflow interrupt to occur.

Error type:	Error type is not stored in the ECC Error Address Capture flag (ECEDFm[1:0])
Error address:	2-bit ECC error address is not stored in the ECC Error Address register (Wn_EC710EADm)
Error detection flag:	ECC Error Address Capture Overflow flag (ECOVFF) is set to 1

Note: n = 0 to 3, m = 0 to 7.

44.4.6 Test Function (Error Injection)

System SRAM has the error injection function, a facility to test the ECC function. The ECC errors intentionally generated by using the test registers are written to the target RAM area for checking the ECC function without involving the ECC circuit. Figure 44.2 shows an example of test flowchart.



Note: The value of the Wn_EC710CTL register is an example. Use an appropriate value according to the test conditions and purpose.

Figure 44.2 Flowchart example of ECC error injection test

44.4.7 Interrupt

When ECC error occurs, interrupt can be output. Table 44.5 lists the System SRAM interrupt sources. These interrupts are combined to peripheral error interrupts (PERI_ERR0 and PERI_ERR1) as error events with other error interrupts.

Table 44.5 System SRAM interrupt sources

Name	Interrupt sources
SRAMn_IE1	System SRAMn ECC 1 bit error
SRAMn_IE2	System SRAMn ECC 2 bits error
SRAMn_OVF	System SRAMn ECC error address capture overflow

Note: n = 0 to 3

44.5 Usage Notes

44.5.1 Release of Register Write Protection

SYSRAM_CTRLn registers are write protected. These registers are used to release write protection, use the following steps.

1. Write 0x0000A508 to PRCRS register (release write protection by PRC3 bit).
2. Write value to protection register.
3. Write 0x0000A500 to PRCRS register (set write protection by PRC3 bit).

44.5.2 Note on Setting the Register

All bus masters must not access System SRAM while a register of this module is being set.

44.5.3 Access in Bit Size Units

This module performs ECC determination process on a 32-bit basis. If access is made on an 8/16-bit basis, the module performs the following operations:

8/16-bit reading

1. After reading 32 bits of data, this module performs ECC determination.
2. To the read requesting bus master, this module returns 8/16-bit data.

8/16-bit writing

1. This module reads 32 bits of data from the write-target address and performs ECC determination.
2. On the read-out 32 bits, this module overwrites new 8/16-bit data.
3. After attaching ECC data to the write-target 32-bit data of step 2., this module writes them to the System SRAM.

45. One-Time Programmable Memory (OTP)

45.1 Overview

This LSI has one-time programmable memory (OTP). Various information is stored or can be additionally stored in OTP. Data written in OTP can't be overwritten. OTP is shared with product configuration parameters which cannot be accessed by user. Then, all the areas are not accessible from CPU.

Table 45.1 lists the OTP specifications and Figure 45.1 shows a block diagram of the OTP.

Table 45.1 OTP Specifications

Item	Description
Number of units	1 unit
Functionality	• Bit width: 32-bit • Word size: 1024-word • Register I/F to read or write OTP • WORDLOCK available each address (32-bit data) • Overwrite protection • Power down mode support
Available information (Non-security support product)	• Unique ID • JTAG authentication ID and setting • SCI/USB boot setting • Anti-rollback counter • Part number • Product Version • User area

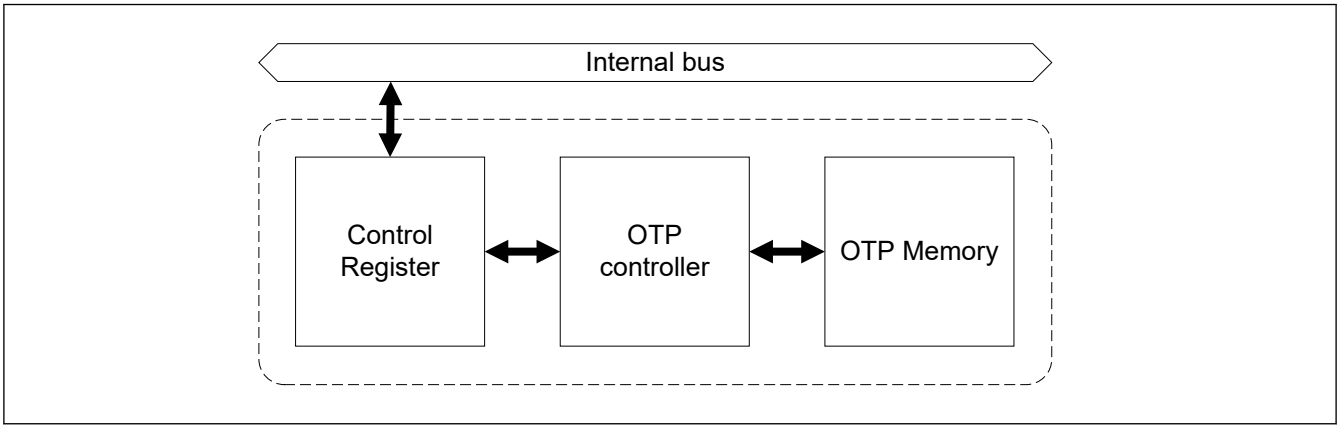


Figure 45.1 OTP Block Diagram

45.2 Register Map

Table 45.2 OTP register map

Address	Register symbol	Register name	Write protection
0x810C_0000	OTPPWR	OTP Power Control Register	—

Table 45.3 OTP related system control register

Unit	Module Reset Control Register	Module Stop Control Register	Slave Access Control Register
All the registers	—	—	SLVACCCTL7.OTP_SL

45.3 Register Descriptions

45.3.1 OTPPWR : OTP Power Control Register

Base address: OTP = 0x810C_0000

Offset address: 0x00

Bit position:	31																										4				0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ACCL	—	—	—	PWR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PWR	OTP power on/off setting When starting OTP access, set PWR bit to 1 regardless of OTP_PWOK bit in OTPSTR register. 0: Power off 1: Power on	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	ACCL	Selects OTP access I/F 0: Not selected 1: Selected	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

OTPPWR register controls the power of OTP and provides a valid access path.

If 0 is written to PWR bit during write access to OTP, OTP powers off after write access is complete. PWR bit cannot be changed during read access to OTP.

When changing ACCL bit to 1, confirm the following:

- PWR bit is 0.
- CMD_RDY bit in OTPSTR register is 0.

When changing ACCL bit to 0, confirm CMD_RDY bit in OTPSTR register is 1.

When OTP access is requested while ACCL bit is 0, the access request is ignored and ERR_RP bit in OTPSTR register is not asserted.

45.3.2 OTPSTR : OTP Access Status Register

Base address: OTP = 0x810C_0000

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	OTP_PWOK	—	—	ERR_RDY_RD	ERR_RDY_WR	—	—	—	ERR_RP	ERR_WP	ERR_WR[1:0]		CMD_RDY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMD_RDY	Indicates whether OTP controller is ready to receive command or not. 0: Not ready 1: Ready	R
2:1	ERR_WR[1:0]	OTP write status Cleared at the start of the next OTP write command. OTP macro is written each 1-bit internally even if multiple bits write. This bit shows the error status each 1-bit write. The status is not reserved and cleared to 0 before next 1-bit write. When multiple bits write, this bit shows the status of the last 1-bit write only. Status of other bits write is not shown. 0 0: PASS 0 1: Fail due to overwrite to the area where WORDLOCK bit is set to 1 1 0: 1 bit write error 1 1: Reserved	R
3	ERR_WP	Write protection error This bit is set to 1 when OTP write access is issued to the write prohibited area. Cleared at the start of the next OTP write command unless the same error condition occurs.	R
4	ERR_RP	Read protection error This bit is set to 1 when OTP read access is issued to the read prohibited area. Cleared at the start of the next OTP read command unless the same error condition occurs.	R
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	ERR_RDY_WR	OTP write command ready error This bit is set to 1 when OTP write access is issued during CMD_RDY = 0. Cleared by writing 0 on this bit. Writing 1 is ignored.	R/W
9	ERR_RDY_RD	OTP read command ready error This bit is set to 1 when OTP read access is issued during CMD_RDY = 0. Cleared by writing 0 on this bit. Writing 1 is ignored.	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
12	OTP_PWOK	Indicates power on/off status of OTP Memory 0: Power Off 1: Power On	R
31:13	—	These bits are read as 0. The write value should be 0.	R/W

OTPSTR register indicates status of command ready and error.

45.3.3 OTPSTAWR : OTP Write Command Register

Base address: OTP = 0x810C_0000

Offset address: 0x08

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STAWR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STAWR	OTP write start By writing 1 to this bit, the OTP write command is issued and writing data to OTP is started. This bit is automatically cleared after the OTP write command is completed. Only 1 can be written to this bit. Writing 0 is ignored.	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

OTPSTAWR register is used to issue the OTP write command.

If OTPSTAWR register is set to 1 while write prohibited area is set in the OTPADRWR register, the STAWR bit does not change to 1 and no OTP write access occurs. In this case, ERR_WP bit in OTPSTR register is set to 1.

45.3.4 OTPADRWR : OTP Write Address Register

Base address: OTP = 0x810C_0000

Offset address: 0x0C

Bit position:	31																				9									0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ADRWR[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	ADRWR[9:0]	OTP write address Set the OTP address where data is written. The address to be set is OTP address in a word (32-bit) unit.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

OTPADRWR register is used to set the write address to OTP.

45.3.5 OTPDATAWR : OTP Write Data Register

Base address: OTP = 0x810C_0000

Offset address: 0x10

Bit position:	31																													0
Bit field:	DATAWR[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DATAWR[31:0]	OTP write data Set the data to be written to the OTP.	R/W

OTPDATAWR register is used to set the write data to OTP.

45.3.6 OTPADRRD : OTP Read Address Register

Base address: OTP = 0x810C_0000

Offset address: 0x14

Bit position:	31																				9									0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ADRRD[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	ADRRD[9:0]	OTP read address Set the OTP address where data is read. The address to be set is OTP address in a word (32-bit) unit. After reading data from the OTP, the address set in this register is automatically incremented. By reading this register, the incremented address can be read. However, if read error (ERR_RP in OTPSTR register) occurs, it will not be incremented. Set a different address.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

OTPADRRD register is used to set the read addresses to OTP.

45.3.7 OTPDATARD : OTP Read Data Register

Base address: OTP = 0x810C_0000

Offset address: 0x18

Bit position:	31																												0
Bit field:	DATARD[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DATARD[31:0]	OTP read data OTP data in address specified by the OTPADRRD register can be read.	R

OTPDATARD register stores read data from OTP.

OTP read access is not performed when the OTPDATARD register is read while read prohibited area is set in the OTPADRRD register. In this case, the ERR_RP bit of the OTPSTR register is set.

45.4 OTP Memory Map

Data width of OTP is 32-bit, and its address is not memory mapped. Dedicated address (0x000 to 0x3FF) is defined to access OTP. Table 45.4 shows OTP memory map in non-security support product. Various information is stored or can be stored in OTP. Address not listed in Table 45.4 is reserved and do not access reserved area.

In OTP, unwritten bit is 0 and written bit is 1. WORDLOCK function is available each address to prevent the area from being overwritten. Control area for WORDLOCK function is assigned in 0x001 to 0x01F. Target area (0x020 to 0x3FF) is protected from overwrite by setting 1 to the corresponding address/bit of the WORDLOCK control area. The relation of target area and corresponding address/bit of the WORDLOCK control area is expressed as following formula.

Address in WORDLOCK control area: Integer part of Target_address / 32

Bit of the address in WORDLOCK control area: Target_address % 32, where % is modulo operation.

Do not write to the corresponding address/bit of WORDLOCK control area for the target area not listed in Table 45.4.

WORDLOCK function for WORDLOCK control area is not available. That means writing to 0x000 is impossible.

Table 45.4 OTP memory map in non-security support product (1 of 2)

Area	Bit width	Start address	End address	WORDLOCK control		Initial property
				Address	Bit	
WORDLOCK control area	1024	0x001	0x01F	—	—	R/W
Unique ID	64	0x0E5	0x0E6	0x007	5 to 6	R
JTAG authentication mode	9	0x0E9	0x0E9	0x007	9	R/W
JTAG authentication level 1 plaintext ID	128	0x0EB	0x0EE	0x007	11 to 14	W
JTAG authentication level 2 plaintext ID	128	0x0EF	0x0F2	0x007	15 to 18	W
SCI/USB boot authentication mode	6	0x1CB	0x1CB	0x00E	11	R/W
SCI/USB boot authentication plaintext ID	128	0x0F3	0x0F6	0x007	19 to 22	W
Anti-rollback counter	320	0x1B1	0x1BA	0x00D	17 to 26	R/W

Product Version	32	0x1DA	0x1DA	0x00E	26	R
Temperature Sensor Code High	12	0x1DC	0x1DC	0x00E	28	R
Temperature Sensor Code Low	12	0x1DD	0x1DD	0x00E	29	R

Table 45.4 OTP memory map in non-security support product (2 of 2)

Area	Bit width	Start address	End address	WORDLOCK control		Initial property
				Address	Bit	
User area	16256	0x204	0x3FF	0x010 to 0x01F	4 to 31 (0x010) 0 to 31 (0x011 to 0x01F)	R/W

45.4.1 Unique ID (UID)

Indicates 64-bit unique ID. This area is read-only.

Address(es): 0x0E5 to 0x0E6

Bit position:	31																												0
Bit field:	ID																												
Value after reset:	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Bit	Symbol	Function	R/W
31:0	ID	64-bit unique ID 0x0E5: Unique ID [31:0] 0x0E6: Unique ID [63:32]	R

Note 1. Value after reset depends on the product variant.

45.4.2 JTAG Authentication Mode (AUTHMODEJ)

Specifies how to authenticate JTAG connection.

Address(es): 0x0E9

Bit position:	31																						8							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MODE[8:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	MODE[8:0]	Specifies JTAG authentication mode Significant bit consists of 3-bit OR. Here, B2 = OR(MODE[8:6]), B1 = OR(MODE[5:3]), B0 = OR(MODE[2:0]). Then, B2 B1 B0: 0 0 0: No authentication 0 0 1: Authentication level 1 (Both EL2 and EL1/EL0 access permission) 0 1 x: Authentication level 2 (Only EL1/EL0 access permission) 1 x x: Permanent prohibition of JTAG connection	R/W
31:9	—	Reserved	—

45.4.3 JTAG Authentication Level 1 Plaintext ID (JID1P)

Specifies plaintext ID for JTAG authentication level 1. This area is write-only. Read value is 0. ID must include at least one '1' programmed bit each 32-bit. It is recommended to set WORDLOCK to this area after writing ID to avoid unintentional ID change.

Address(es): 0x0EB to 0x0EE

Bit position:	31																												0
Bit field:	ID																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ID	128-bit JTAG authentication level 1 plaintext ID 0x0EB: ID [31:0] 0x0EC: ID [63:32] 0x0ED: ID [95:64] 0x0EE: ID [127:96]	W

45.4.4 JTAG Authentication Level 2 Plaintext ID (JID2P)

Specifies plaintext ID for JTAG authentication level 2. This area is write-only. Read value is 0. ID must include at least one '1' programmed bit each 32-bit. It is recommended to set WORDLOCK to this area after writing ID to avoid unintentional ID change.

Address(es): 0x0EF to 0x0F2

Bit position:	31																												0
Bit field:	ID																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ID	128-bit JTAG authentication level 2 plaintext ID 0x0EF: ID [31:0] 0x0F0: ID [63:32] 0x0F1: ID [95:64] 0x0F2: ID [127:96]	W

45.4.5 SCI/USB Boot Authentication Mode (AUTHMODES)

Specifies how to authenticate SCI/USB boot connection.

Address(es): 0x1CB

Bit position:	31																										5			0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MODE[5:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	MODE[5:0]	Specifies SCI/USB boot authentication mode Significant bit consists of 3-bit OR. Here, B1 = OR(MODE[5:3]), B0 = OR(MODE[2:0]). Then, B1 B0: 0 0: No authentication 0 1: Authentication 1 x: Permanent prohibition of SCI/USB boot connection	R/W
31:6	—	Reserved	—

45.4.6 SCI/USB Boot Authentication Plaintext ID (SIDP)

Specifies plaintext ID for SCI/USB boot authentication. This area is write-only. Read value is 0. ID must include at least one '1' programmed bit each 32-bit. It is recommended to set WORDLOCK to this area after writing ID to avoid unintentional ID change.

Address(es): 0x0F3 to 0x0F6

Bit position:	31																												0
Bit field:	ID																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ID	128-bit SCI/USB boot authentication plaintext ID 0x0F3: ID [31:0] 0x0F4: ID [63:32] 0x0F5: ID [95:64] 0x0F6: ID [127:96]	W

45.4.7 Anti-rollback Counter (ARBC)

This area is used as anti-rollback counter. User can freely use this area to control version of their application. For example, five 64-bit counter for version control of five program modules at firmware update.

Address(es): 0x1B1 to 0x1BA

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BIT31	BIT30	BIT29	BIT28	BIT27	BIT26	BIT25	BIT24	BIT23	BIT22	BIT21	BIT20	BIT19	BIT18	BIT17	BIT16	BIT15	BIT14	BIT13	BIT12	BIT11	BIT10	BIT9	BIT8	BIT7	BIT6	BIT5	BIT4	BIT3	BIT2	BIT1	BIT0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	BIT31 to BIT0	Uses as version control	R/W

45.4.8 Part Number (PN)

Indicates part number of the product. This area is read-only.

Address(es): 0x1D9

Bit position:	31																												0
Bit field:	PN																												
Value after reset:	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Bit	Symbol	Function	R/W

Note 1. Depends on part number of the product

45.4.9 Product Version (VER)

Indicates product version. This area is read-only.

Address(es): 0x1DA

Bit position:	31																												0
Bit field:	VER																												
Value after reset:	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Bit	Symbol	Function	R/W
31:0	VER	Product version	R

Note 1. Depends on version of the product

45.4.10 Temperature Sensor Code High (TEMPHI)

Indicates 12-bit temperature sensor code data measured at 125±1°C. This area is read-only.

Address(es): 0x1DC

Bit position:	31																				11										0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSCODE[11:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Bit	Symbol	Function	R/W
11:0	TSCODE[11:0]	Temperature sensor code data measured at 125±1°C	R
31:12	—	Reserved	—

Note 1. Value after reset depends on the product variant.

45.4.11 Temperature Sensor Code Low (TEMPLO)

Indicates 12-bit temperature sensor code data measured at −40±1°C. This area is read-only.

Address(es): 0x1DD

Bit position:	31																				11										0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSCODE[11:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Bit	Symbol	Function	R/W
11:0	TSCODE[11:0]	Temperature sensor code data measured at −40±1℃	R
31:12	—	Reserved	—

Note 1. Value after reset depends on the product variant.

45.4.12 User Area (USERAREA)

This area can be used by user freely. Since WORDLOCK is applied for this area, one time write of 32-bit data is needed each address.

Address(es): 0x204 to 0x3FF

Bit position:	31																												0
Bit field:	AREA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	AREA[31:0]	Free area which user can use.	R/W

45.5 Operation

45.5.1 Write procedure

Table 45.5 Write procedure

Steps	What to do
A	It is assumed that OTP is in a power-down state. Confirm completion of the power-down process by checking that the PWR bit in OTPPWR register is 0 and the CMD_RDY bit in OTPSTR register is 0.
B	Set the PWR and ACCL bits in OTPPWR register to 1. Confirm if CMD_RDY bit in OTPSTR register is 1 after setting.
C	Set the write address to the OTPADRWR register.
D	Set the data to be written to the OTPDATAWR register.
E	Set 1 to the STAWR bit in OTPSTAWR register.
F	OTP controller starts the OTP write process. CMD_RDY bit changes from 1 to 0. If setting the write-prohibited area to OTPADRWR register, the STAWR bit is not set to 1 and the CMD_RDY bit keeps 1. In this case, ERR_WP bit in the OTPSTR register is set to 1.
G	OTP controller writes the value of OTPDATAWR register to OTP. Note) The values of OTPADRWR and OTPDATAWR registers must be retained until this procedure is completed.
H	Poll the STAWR bit until changing to 0 in order to detect the completion of the write command acceptance.
I	Poll the CMD_RDY bit until changing to 1 in order to detect the completion of the write.
J	Once detecting the CMD_RDY bit is 1, confirm that the ERR_WP and ERR_WR bit in the OTPSTR register is not set to 1. Note) If set to 1, OTP write error occurs.
K	When continuing OTP write, repeat step C) and later. When issuing OTP read, refer to step C) and later of Table 45.6. When completing OTP access: • When OTP Read is performed after releasing power down (PWR = 1), dummy read is needed. After dummy OTP Read to the unused user area, set PWR and ACCL bits in the OTPPWR register to 0, and wait until CMD_RDY bit is set to 0. • When OTP Read is not performed after releasing power down (PWR = 1), dummy read is not needed. Set PWR and ACCL bits in the OTPPWR register to 0, and wait until CMD_RDY bit is set to 0. Note) Be sure to power down by this procedure if no more access is needed.

Note: WORDLOCK can be applied for some areas. The OTP write to the WORDLOCK applied area cannot be performed.
For written bits, the bits retain 1 no matter whether they are written with 0 or 1 again.
Reset while writing OTP is prohibited. That operation is not guaranteed.

45.5.2 Read procedure

Table 45.6 Read procedure

Steps	What to do
A	It is assumed that OTP is in a power-down state. Confirm completion of the power-down process by checking that the PWR bit in OTPPWR register is 0 and the CMD_RDY bit in OTPSTR register is 0.
B	Set the PWR and ACCL bits in OTPPWR register to 1. Confirm if CMD_RDY bit in OTPSTR register is 1 after setting.
C	Set the read address to the OTPADRRD register.
D	Read the OTPDATARD register.
E	OTP controller starts the OTP read process. CMD_RDY bit changes from 1 to 0. If setting the read-prohibited area to OTPADRRD register, OTP read process is not performed and the CMD_RDY bit keeps 1. In this case, ERR_RP bit of the OTPSTR register is set to 1.
F	OTP controller reads the data of address set in the OTPADRRD register from OTP. After completion of the process, CPU can receive read data. CMD_RDY bit changes from 0 to 1. Confirm that the ERR_WP bit in the OTPSTR register is not set to 1. If set to 1, OTP read error occurs. Note) Since CPU is waited until completion of the process, polling of CMD_RDY bit is not needed.
G	When continuing OTP read, repeat step C) and later. ● When reading a continuous address (continuous read), repeat step D) and later. The OTPADRRD register is incremented automatically, so no need to change. ● When reading a different address from a continuous address, repeat step C) and later. When issuing OTP write, refer to step C) and later of Table 45.5. When completing OTP access, perform dummy OTP read to the unused user area. Then set PWR and ACCL bits in the OTPPWR registers to 0, and wait until CMD_RDY bit is set to 0. Note) Be sure to power down by this procedure if no more access is needed.

Note: Continuous read is valid for readable areas. If the read address is changed to the read-prohibited area, OTP read process is not performed and the CMD_RDY bit keeps 1. ERR_RP bit of the OTPSTR register is set to 1.

46. Serial Host Interface (SHOSTIF)

46.1 Overview

This LSI has a serial host interface to connect an external host CPU (SPI master) with up to eight input/output pins. The serial host interface allows an external SPI master to access the internal resources (mainly System SRAM) of this LSI directly.

Figure 46.1 shows a block diagram of the SHOSTIF and Table 46.1 lists the serial host interface specifications.

Table 46.1 SHOSTIF specifications

Parameter	Description
Number of units	1 unit
Functionality	• Serial communication is possible in slave mode • Supported interface: – Motorola Serial Peripheral Interface (4-wire SPI) – Enhanced SPI modes with Dual, Quad or Octal SPI. • Serial clock polarity switching • Serial clock phase switching • Transfer mode: – Single data transfer (SDR) supported – No DDR, data strobe nor data mask supported • All the SPI transfer consists of Instruction phase, Address phase and Data phase: – Command phase: 8 bits — Support read/write, transfer type, wait cycles and data length – Address phase: 24 bits — Aligned to 32-bit data boundary – Data phase: 32 bits × burst length up to 64 • Hardware protocol state machine for transfer management • 32 bits × 64 stage FIFO transmit and receive buffers • Serial clock (sclk_in): Up to 40 MHz
Interrupt source	Maskable interrupt sources. All sources are combined to one interrupt. External output pin is available: • SPI master error • AHB error • Transmit FIFO Empty • Transmit FIFO Underflow • Receive FIFO Full • Receive FIFO Overflow
Accessible area	• System SRAM • Mailbox and Semaphore registers • Serial Host Interface registers
Module-stop function	Module-stop state can be set to reduce power consumption

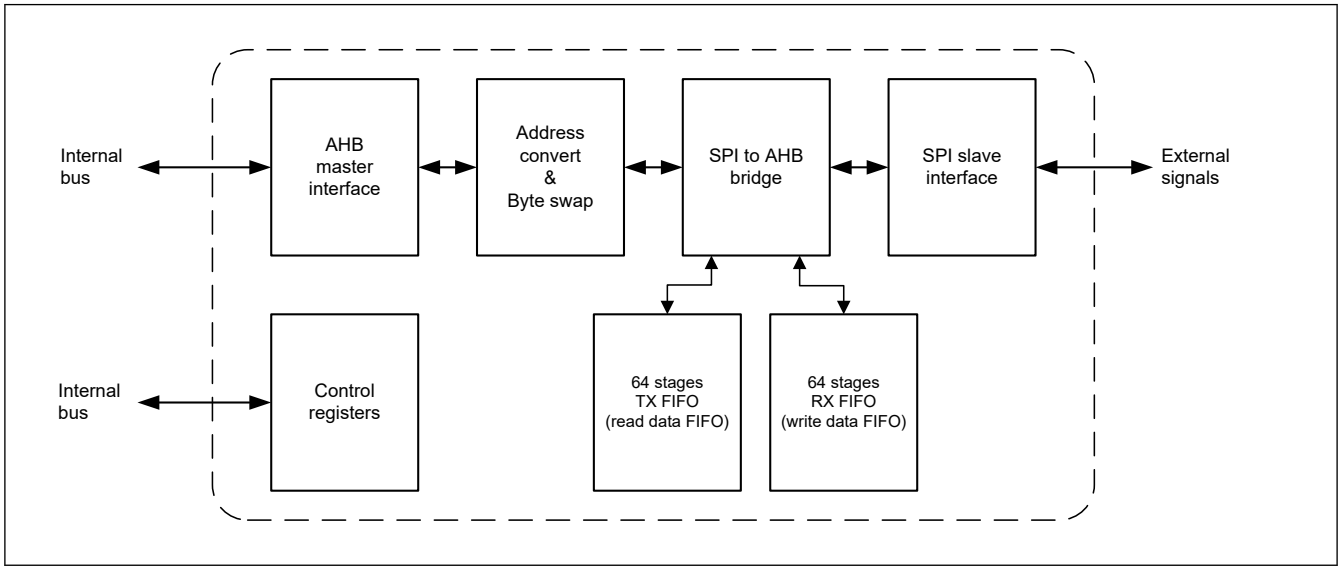

Figure 46.1 SHOSTIF block diagram

Table 46.2 lists the input/output pins of the serial host interface.

Table 46.2 SHOSTIF I/O pins

Name	I/O	Function
HSPI_CK	Input	SHOSTIF Clock input pin
HSPI_CS#	Input	SHOSTIF Chip select input pin
HSPI_IO0	I/O	SHOSTIF Data0 input/output pin
HSPI_IO1	I/O	SHOSTIF Data1 input/output pin
HSPI_IO2	I/O	SHOSTIF Data2 input/output pin
HSPI_IO3	I/O	SHOSTIF Data3 input/output pin
HSPI_IO4	I/O	SHOSTIF Data4 input/output pin
HSPI_IO5	I/O	SHOSTIF Data5 input/output pin
HSPI_IO6	I/O	SHOSTIF Data6 input/output pin
HSPI_IO7	I/O	SHOSTIF Data7 input/output pin
HSPI_INT#	Output	SHOSTIF Interrupt output pin

46.2 Register Map

Table 46.3 SHOSTIF register map

Address*1	Register symbol	Register name	Write protection
0x8024_1000	CTRLR0	Control Register 0	—

0x8129_4000	SHCFG	SHOSTIF Configuration Register	PRCRS.PRC3

Note 1. Address is internal memory address view.

Table 46.4 SHOSTIF related system control register

Unit	Module Reset Control Register	Module Stop Control Register	Slave Access Control Register
0	MRCTLI.MRCTLI01 MRCTLI.MRCTLI02 MRCTLI.MRCTLI03	MSTPCRI.MSTPCRI01	SLVACCCTL7.SHOSTIF_SL

46.3 Register Descriptions

The register base address is different between external SPI master view and internal memory address view except for SHCFG register.

- External SPI master view (8-bit addressing mode) : SHOSTIF_E08 = 0x20_1000

Note: When 32-bit addressing mode is used, please shift 8-bit address (base address + offset address) by 2 bits in the right direction.

- Internal memory address view: SHOSTIF = 0x8024_1000
- Internal memory address view for SHCFG: SHOSTIF_CFG = 0x8129_4000

46.3.1 CTRLR0 : Control Register 0

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SCPOL	SCPH	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	SCPH	Serial Clock Phase Valid when the frame format (FRF) is set to Motorola SPI. The serial clock phase selects the relationship of the serial clock with the slave select signal. When SCPH = 0, data is captured on the first edge of the serial clock. When SCPH = 1, the serial clock toggles for 1 cycle after the slave select line is activated, and data is captured on the second edge of the serial clock. 0: Serial clock toggles in the middle of the first bit 1: Serial clock toggles at the start of the first bit	R/W
9	SCPOL	Serial Clock Polarity Valid when the frame format (FRF) is set to Motorola SPI. Used to select the polarity of the inactive serial clock, which is held inactive when the SPI master is not actively transferring data on the serial bus. 0: Inactive state of the serial clock is low 1: Inactive state of the serial clock is high	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

The CTRLR0 register controls the serial data transfer. It is not possible to write to this register when SHOSTIF is enabled (ENR.ENABLE = 1).

46.3.2 ENR : Enable Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ENABLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ENABLE	SHOSTIF Enable Enables and disables all SHOSTIF operations. When disabled, all serial transfers are halted immediately. Transmit and receive FIFO buffers are cleared when the device is disabled. It is not possible to program some of the SHOSTIF control registers when enabled. When disabled, the SLEEP bit in the SHCFG register is set (after a delay) to inform the system that it is safe to remove the internal clock, thus saving power consumption in the system. 0: Disables SHOSTIF 1: Enables SHOSTIF	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

The ENR register enables or disables the serial host interface.

46.3.3 RXFBTR : Receive FIFO Burst Threshold Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	RXFBTL[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1

Bit	Symbol	Function	R/W
5:0	RXFBTL[5:0]	Receive FIFO Burst Threshold For write operations on SPI slave interface, this register is used to build a burst on AHB master interface. The data is sent in bursts equal to the level specified in this register. If the RXFBTL value is 3 then a burst length of 4 is used for every write transfer. If SHOSTIF receives a burst smaller than the programmed value, then SHOSTIF issues a smaller burst on the AHB interface and completes the transaction. In case of 8-bit addressing mode, do not change from the initial value. In case of 32-bit addressing mode, recommendation value is 0x0F.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

The RXFBTR register controls the burst threshold value for AHB interface from RX FIFO.

46.3.4 TXFTLR : Transmit FIFO Threshold Level Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TFT[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	TFT[5:0]	Transmit FIFO Threshold Controls the level of entries (or below) at which the transmit FIFO controller triggers an interrupt. The FIFO depth is 64. When the number of transmit FIFO entries is less than or equal to this value, the transmit FIFO empty interrupt is triggered.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

The TXFTLR register controls the threshold value for the transmit FIFO memory.

46.3.5 RXFTLR : Receive FIFO Threshold Level Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x01C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	RFT[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	RFT[5:0]	Receive FIFO Threshold Controls the level of entries or above at which the receive FIFO controller triggers an interrupt. The FIFO depth is 64. When the number of receive FIFO entries is greater than or equal to this value + 1, the receive FIFO full interrupt is triggered.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

The RXFTLR register controls the threshold value for the received FIFO memory.

46.3.6 SR : Status Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x028

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BUSY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BUSY	Busy Flag When set, indicates that a serial transfer is in progress. When cleared, indicates that the SHOSTIF is idle or disabled. 0: SHOSTIF is idle or disabled 1: SHOSTIF is actively transferring data	R
31:1	—	These bits are read as 0.	R

The SR register is a read-only register that indicates the current transfer status, FIFO status, and any transmission/reception errors that may have occurred. The Status register may be read at any time. None of the bits in this register request an interrupt.

46.3.7 IMR : Interrupt Mask Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x02C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SPIMEM	AHBEM	TXUIM	—	—	RXFIM	RXOIM	—	—	TXEIM
Value after reset:	0	0	0	0	0	0	1	1	1	0	0	0	1	0	0	1

Bit	Symbol	Function	R/W
0	TXEIM	Transmit FIFO Empty Interrupt Mask 0: txe_intr interrupt is masked 1: txe_intr interrupt is not masked	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	RXOIM	Receive FIFO Overflow Interrupt Mask 0: rxo_intr interrupt is masked 1: rxo_intr interrupt is not masked	R/W
4	RXFIM	Receive FIFO Full Interrupt Mask 0: rxf_intr interrupt is masked 1: rxf_intr interrupt is not masked	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	TXUIM	Transmit FIFO Underflow Mask 0: txu_intr interrupt is masked 1: txu_intr interrupt is not masked	R/W
8	AHBEM	AHB Error Interrupt Mask 0: ahbe_intr interrupt is masked 1: ahbe_intr interrupt is not masked	R/W
9	SPIMEM	SPI Master Error Interrupt Mask 0: spime_intr interrupt is masked 1: spime_intr interrupt is not masked	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

The IMR register masks or enables all interrupts generated by the SHOSTIF. Actual interrupt mask is determined by combination with the SHCFG register.

46.3.8 ISR : Interrupt Status Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x030

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SPIMES	AHBES	TXUIS	—	—	RXFIS	RXOIS	—	—	TXEIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*1

Bit	Symbol	Function	R/W
0	TXEIS	Transmit FIFO Empty Interrupt Status 0: txe_intr interrupt is not active after masking 1: txe_intr interrupt is active after masking	R
2:1	—	These bits are read as 0.	R
3	RXOIS	Receive FIFO Overflow Interrupt Status 0: rxo_intr interrupt is not active after masking 1: rxo_intr interrupt is active after masking	R
4	RXFIS	Receive FIFO Full Interrupt Status 0: rxf_intr interrupt is not active after masking 1: rxf_intr interrupt is active after masking	R
6:5	—	These bits are read as 0.	R
7	TXUIS	Transmit FIFO Underflow Status 0: txu_intr interrupt is not active after masking 1: txu_intr interrupt is active after masking	R
8	AHBES	AHB Error Interrupt Status 0: ahbe_intr interrupt is not active after masking 1: ahbe_intr interrupt is active after masking	R
9	SPIMES	SPI Master Error Interrupt Status 0: spime_intr interrupt is not active after masking 1: spime_intr interrupt is active after masking	R
31:10	—	These bits are read as 0.	R

Note 1. Initial value depends on the setting of ENR register. The value is 0 when ENR.ENABLE = 0 and 1 when ENR.ENABLE = 1.

The ISR register reports the status of the SHOSTIF interrupts after they are masked.

46.3.9 RISR : Raw Interrupt Status Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x034

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SPIMER	AHBER	TXUIR	—	—	RXFIR	RXOIR	—	—	TXEIR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	*1

Bit	Symbol	Function	R/W
0	TXEIR	Transmit FIFO Empty Raw Interrupt Status 0: txe_intr interrupt is not active prior to masking 1: txe_intr interrupt is active prior to masking	R
2:1	—	These bits are read as 0.	R
3	RXOIR	Receive FIFO Overflow Raw Interrupt Status 0: rxo_intr interrupt is not active prior to masking 1: rxo_intr interrupt is active prior to masking	R
4	RXFIR	Receive FIFO Full Raw Interrupt Status 0: rxf_intr interrupt is not active prior to masking 1: rxf_intr interrupt is active prior to masking	R
6:5	—	These bits are read as 0.	R
7	TXUIR	Transmit FIFO Underflow Raw Interrupt Status 0: txu_intr interrupt is not active prior to masking 1: txu_intr interrupt is active prior to masking	R
8	AHBER	AHB Error Raw Interrupt Status This bit indicates whether AHB master interface received an error response. This bit is cleared when the status register is read. 0: ahbe_intr interrupt is not active prior to masking 1: ahbe_intr interrupt is active prior to masking	R
9	SPIMER	SPI Master Error Raw Interrupt Status This bit is set to 1 under the following conditions: • If SPI slave receives a command which does not fall into the command set • If SPI slave receives an out-of-order read command (for example read data before read request in polling mode) • If SPI master writes more data than specified in the instruction phase This bit is cleared when the status register is read. 0: spime_intr interrupt is not active prior to masking 1: spime_intr interrupt is active prior to masking	R
31:10	—	These bits are read as 0.	R

Note 1. Initial value depends on the setting of the ENR register. The value is 0 when ENR.ENABLE = 0 and 1 when ENR.ENABLE = 1.

The RISR register reports the status of the SHOSTIF interrupts before they are masked.

46.3.10 TXUICR : Transmit FIFO Underflow Interrupt Clear Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x038

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXUICR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TXUICR	Clear Transmit FIFO Underflow Interrupt This register reflects the status of the interrupt. A read from this register clears the txu_intr interrupt. Writing to this register has no effect. Read value is the same as TXUIS bit in the ISR register.	R
31:1	—	These bits are read as 0.	R

The TXUICR register is used to clear the txu_intr interrupts.

46.3.11 RXOICR : Receive FIFO Overflow Interrupt Clear Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x03C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RXOICR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RXOICR	Clear Receive FIFO Overflow Interrupt This register reflects the status of the interrupt. A read from this register clears the rxo_intr interrupt. Writing has no effect. Read value is the same as RXOIS bit in the ISR register.	R
31:1	—	These bits are read as 0.	R

The RXOICR register is used to clear the rxo_intr interrupts.

46.3.12 SPIMECR : SPI Master Interrupt Clear Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x040

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPIMECR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPIMECR	Clear SPI Master Error interrupt This register reflects the status of the interrupt. A read from this register clears the spime_intr interrupt. Writing to this register has no effect. Read value is the same as the SPIMES bit in the ISR register.	R
31:1	—	These bits are read as 0.	R

The SPIMECR register is used to clear the spime_intr interrupts.

46.3.13 AHBECR : AHB Error Clear Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x044

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	AHBECR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AHBECR	Clear AHB Error Interrupt This register reflects the status of the interrupt. A read from this register clears the ahbe_intr interrupt. Writing to this register has no effect. Read value is the same as AHBES bit in the ISR register.	R
31:1	—	These bits are read as 0.	R

The AHBECR register is used to clear the ahbe_intr interrupts.

46.3.14 ICR : Interrupt Clear Register

Base address: SHOSTIF = 0x8024_1000
SHOSTIF_E08 = 0x20_1000

Offset address: 0x048

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ICR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ICR	Clear Interrupts This register is set if any of the specified interrupts are active. A read clears the txo_intr, rxu_intr, rxo_intr, ahbe_intr, and the mst_intr interrupts. Writing to this register has no effect. Read value is the same as logical OR of the RXOIS, TXUIS, AHBES, and SPIMES bits in the ISR register.	R
31:1	—	These bits are read as 0.	R

The ICR register is used to clear the txo_intr, rxu_intr, rxo_intr, ahbe_intr, and the mst_intr interrupts.

46.3.15 SHCFG : SHOSTIF Configuration Register

Base address: SHOSTIF_CFG = 0x8129_4000

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	INTMASKE[5:0]						—	—	INTMASKI[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	SLEEP	ADDRESSING	BYTESWAP	SPIMODE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	SPIMODE[1:0]	SPI Frame Format Select Indicates the mode in which the SPI transfer occurs. 0 0: Standard SPI mode 0 1: SPI Dual mode 1 0: SPI Quad mode 1 1: SPI Octal mode	R/W
2	BYTESWAP	Byte Swap Mode Swap data by byte order on AHB bus. 0: No byte swap. Use this setting if byte order of data input by SPI master is [31:24], [23:16], [15:8], or [7:0]. 1: Byte swap. Use this setting if byte order of data input by SPI master is [7:0], [15:8], [23:16], or [31:24].	R/W
3	ADDRESSING	Addressing Mode Specifies unit of the address input by SPI master. 0: 32-bit 1: 8-bit	R/W
4	SLEEP	SHOSTIF Enable Flag Monitor Indicates whether the internal clock can be stopped. Note that when SHOSTIF is reset, this flag does not indicate correct state. 0: Not safe to stop the internal clock 1: Safe to stop the internal clock	R
15:5	—	These bits are read as 0. The write value should be 0.	R/W
21:16	INTMASKI[5:0]	Interrupt Mask Enable for Internal Interrupt (SHOST_INT) Bits correspond to the interrupts: • INTMASKI[0]: Transmit FIFO Empty Interrupt • INTMASKI[1]: Receive FIFO Overflow Interrupt • INTMASKI[2]: Receive FIFO Full Interrupt • INTMASKI[3]: Transmit FIFO underflow Interrupt • INTMASKI[4]: AHB Master interface error Interrupt • INTMASKI[5]: SPI Master interface error Interrupt 0: No masked 1: Masked	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
29:24	INTMASKE[5:0]	Interrupt Mask Enable for External Interrupt (HSPI_INT# signal) Bits correspond to the interrupts: • INTMASKE[0]: Transmit FIFO Empty Interrupt • INTMASKE[1]: Receive FIFO Overflow Interrupt • INTMASKE[2]: Receive FIFO Full Interrupt • INTMASKE[3]: Transmit FIFO Underflow Interrupt • INTMASKE[4]: AHB Master Interface Error Interrupt • INTMASKE[5]: SPI Master Interface Error Interrupt 0: No masked 1: Masked	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

The SHCFG register sets the operation mode and monitors the status of SHOSTIF. This register is not accessible from the external SPI master.

46.4 Operations

The SHOSTIF converts all transfers from SPI to AHB transactions. The external SPI master sends address to SHOSTIF. SHOSTIF takes the address and converts it into an AHB transfer. This enables the external master to access the internal memory directly without any CPU intervention. SHOSTIF can be enabled through boot mode on the reset and load boot program from external master.

All SPI transfers have the following phases:

- Instruction
- Address
- Data

46.4.1 Instruction Phase

Each transfer from the SPI master starts with an 8-bit instruction, which determines the transfer type and process for the rest of the transfer. Table 46.5 shows the instruction field decode.

Table 46.5 Instruction field decode

Bit	Bit name	Description
7	Read/Write	Defines whether the transfer is read or write. 0: Read 1: Write
6:5	Transfer Type	Defines the transfer type. 00: Read/write data 01: Read request 10: Read/write status 11: Read data with dummy
4:3	Wait Cycles	Defines the wait cycles for read transactions. Selects the number of wait cycles for a read transfer. This field is only applicable for read data transfers. When the transfer type is 00, the field decode is as follows: 00: 0 Wait cycles 01: 1 Wait cycle 10: Reserved 11: Reserved When the transfer type is 11, the field decode is as follows: 00: 8 Wait cycles 01: 16 Wait cycles 10: 24 Wait cycles 11: 32 Wait cycles Note: Wait cycles are not applicable for write data operation.
2:0	Data Length	Defines the data to be transmitted in the current transfer. Unit is 32 bits (4 bytes). 000: 1 001: 4 010: 8 011: 16 100: 32 101: 64 110: Prohibited 111: Prohibited

46.4.2 Address Phase

The address phase determines the address from which the data should be read or written on the AHB master interface. Address could be received in the standard, dual, quad, or octal frame format, which is defined by the SPIMODE[1:0] bits in SHCFG register. AHB interface address width is fixed to 32 bits. SPI interface expects to receive 24-bit address, which is sent to the AHB interface. Because the data is always read/written in frame of 32 bits, the address is always word-aligned. The 32-bit output address on the SPI to AHB bridge is dependent on the setting of addressing mode as shown in Table 46.6. Addressing mode is determined by the ADDRESSING bit in SHCFG register.

Table 46.6 Addressing mode

Addressing mode	Data length	Permitted SPI_ADDR*1	Permitted address granularity	SPI to AHB bridge output address
32-bit*2	1/4/8/16/32/64	0x0, 0x1, 0x2, …, 0xFF_FFFF	0x1	{000000b, {SPI_ADDR}, 00b}
8-bit	1	0x0, 0x4, 0x8, …, 0xFF_FFFC	0x4	{00000000b, {SPI_ADDR}}
	4	0x0, 0x10, 0x20, …, 0xFF_FFF0	0x10	
	8	0x0, 0x20, 0x40, …, 0xFF_FFE0	0x20	
	16	0x0, 0x40, 0x80, …, 0xFF_FFC0	0x40	
	32	0x0, 0x80, 0x100, …, 0xFF_FF80	0x80	
	64	0x0, 0x100, 0x200, …, 0xFF_FF00	0x100	

Note 1. SPI_ADDR = 24 bits address received on SPI Interface.
Note 2. Burst transfer across 1 Kbyte boundary is prohibited.

46.4.2.1 Address Conversion

The SPI master cannot access all the memory area in this LSI because the address size is 24-bit address on SPI frame. In this LSI, System SRAM, Mailbox and Semaphore, and SHOSTIF registers are accessible from the external SPI master. Address conversion circuit converts the SPI to AHB bridge output address to the internal address of System SRAM, Mailbox and Semaphore, and SHOSTIF registers. Table 46.7 shows address mapping between SPI address on SPI frame and internal address. Access to reserved area causes an AHB error interrupt.

Table 46.7 Address mapping

Module	SPI address*1	Internal address	Size
System SRAM0 (SYSRAM0)	0x00_0000 to 0x01_FFFF (32-bit) 0x00_0000 to 0x07_FFFC (8-bit)	0x1000_0000 to 0x1007_FFFC	512 KB
System SRAM1 (SYSRAM1)	0x02_0000 to 0x03_FFFF (32-bit) 0x08_0000 to 0x0F_FFFC (8-bit)	0x1008_0000 to 0x100F_FFFC	512 KB
System SRAM2 (SYSRAM2)	0x04_0000 to 0x05_FFFF (32-bit) 0x10_0000 to 0x17_FFFC (8-bit)	0x1010_0000 to 0x1017_FFFC	512 KB
System SRAM3 (SYSRAM3)	0x06_0000 to 0x07_FFFF (32-bit) 0x18_0000 to 0x1F_FFFC (8-bit)	0x1018_0000 to 0x101F_FFFC	512 KB
Mailbox and Semaphore (MBXSEM)	0x08_0000 to 0x08_03FF (32-bit) 0x20_0000 to 0x20_0FFC (8-bit)	0x8024_0000 to 0x8024_0FFC	4 KB
SHOSTIF registers	0x08_0400 to 0x08_07FF (32-bit) 0x20_1000 to 0x20_1FFC (8-bit)	0x8024_1000 to 0x8024_1FFC	4 KB
Reserved	0x08_0800 to 0xFF_FFFC (32-bit) 0x20_2000 to 0xFF_FFFF (8-bit)	Error response	—

Note 1. Depends on the addressing mode.

46.4.3 Data Phase

Data is received or transmitted in frames of 32 bits. The amount of data to be transmitted or received is defined by the Data Length field of Instruction phase.

Data frame is assumed MSB first, which means the byte order is [31:24], [23:16], [15:8], or [7:0]. When the BYTESWAP bit in the SHCFG register is set to 1, the byte order of Data frame can be swapped to [7:0], [15:8], [23:16], or [31:24].

46.4.4 Bridge Operation

The SHOSTIF performs as a bridge between the SPI master and AHB subsystem. The transfers from SPI master are directly converted in AHB read/write operations. The 8-bit instruction defines the characteristics of the transfer and direction of data flow, and SPIMODE[1:0] bits in the SHCFG register define the SPI operating mode. The following sections describe the read and write operations.

46.4.5 Write Operation

46.4.5.1 Write Instruction

The Instruction phase determines the amount of data to be transmitted during write operation. The SPI frame format is derived from SPIMODE[1:0] bits in the SHCFG register. SPI slave supports the instruction opcodes as shown in Table 46.8.

Table 46.8 Instruction set for write data operations

Instruction	Instruction name	Description
0x8i*1 i = 0 to 5	WRITEn n = 1, 4, 8, 16, 32, 64	Write operation
0xC0	WRITESTATUS0	Write Data Status instruction
0xC8	WRITESTATUS1	Write Data Status instruction with 1 wait cycle

Note 1. The lower 3 bits of the instruction determine the amount of data to be fetched by AHB master. For field decode, see Table 46.5.

46.4.5.2 Write Operation

Figure 46.2 shows how SHOSTIF performs write operation.

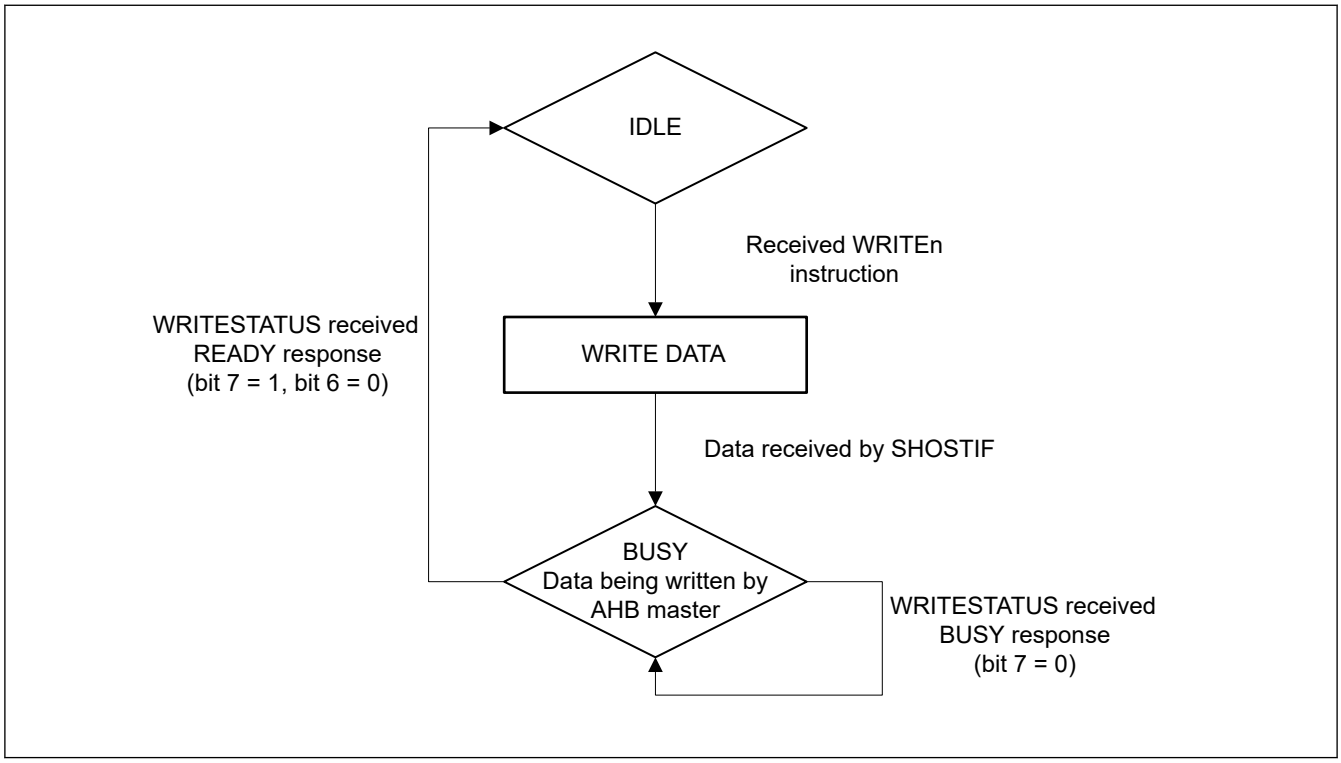

Figure 46.2 Write operation flow

(1) WRITEn (Write Data Instruction)

Data write transaction is always performed in the format specified by SPIMODE[1:0] bits in the SHCFG register. The instruction, data, and address phases are sent in single, dual, quad, or octal format. Write operation from the AHB master interface to the internal slave module starts after the data of length specified in the WRITEn instruction is received in the receive FIFO.

Figure 46.3 shows the write data operation using the WRITEn instruction.

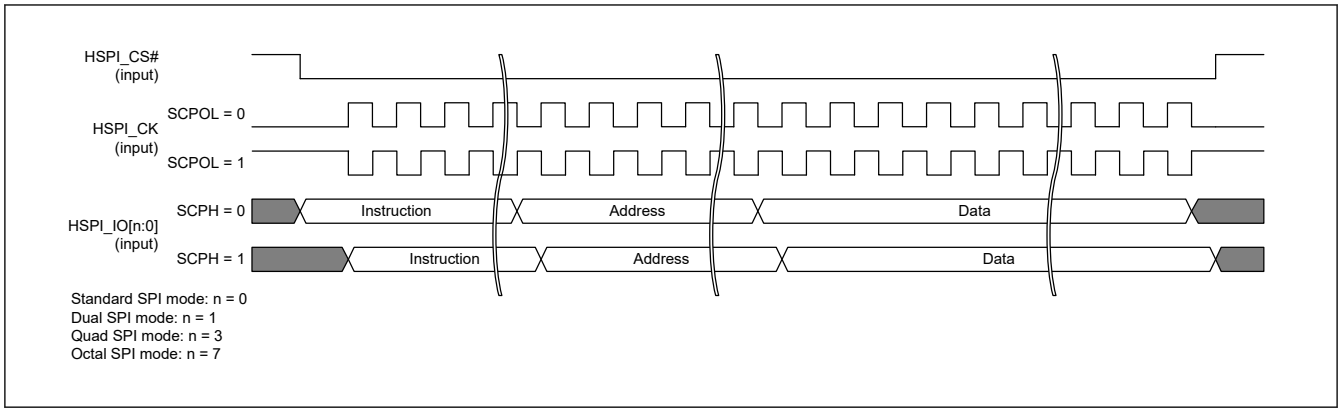

Figure 46.3 WRITEn instruction

(2) WRITESTATUSm (Write Status Instruction)

After the write operation is completed by the master, it should poll for status of the write operation using instruction opcode 0xC0 or 0xC8. Only when the master receives a READY response, it should start a new transfer.

Figure 46.4 shows the write status operation using the WRITESTATUSm instruction.

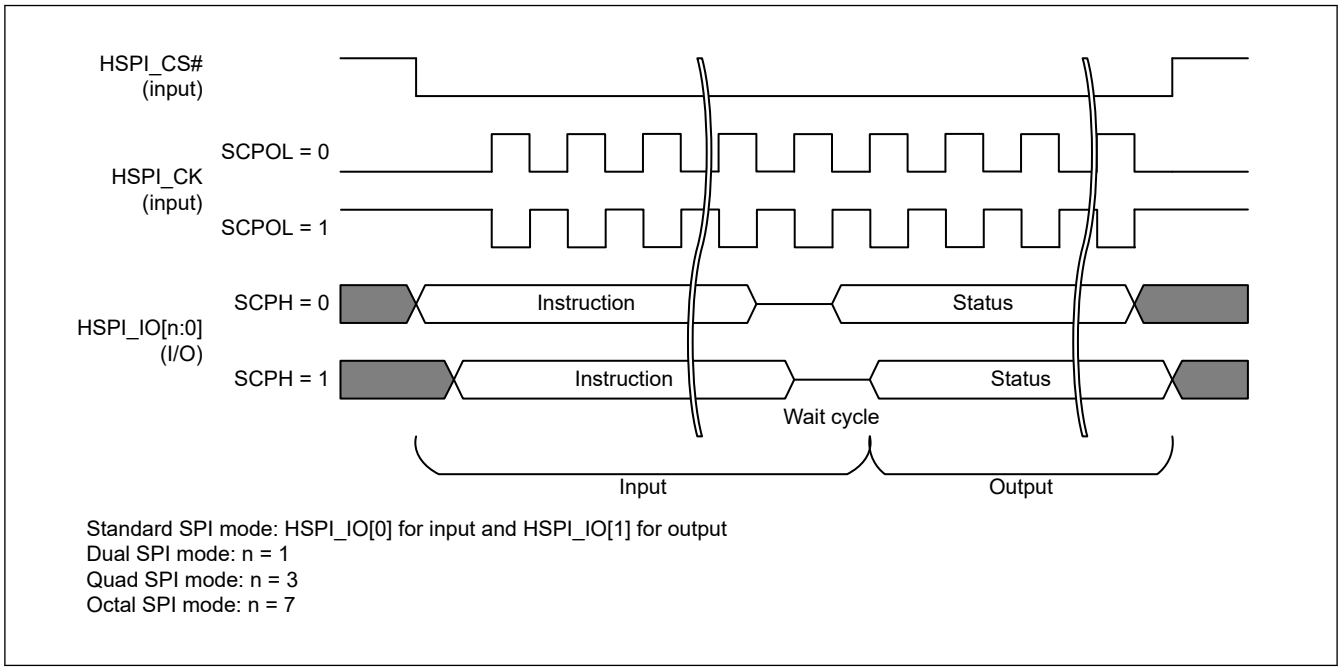

Figure 46.4 WRITESTATUSm instruction (in case of m = 0)

After the SPI master receives a READY response from SHOSTIF, it can move on to the next operation. The AHB interface may get an ERROR response for the write transfer. If the AHB interface gets an ERROR response, the WRITESTATUSm instruction indicates the same by sending a response of 0xC0. The SPI master can then issue a new write transfer or retry the same operation.

Table 46.9 Response field decode

Bit	Name	Description
7	READY	Indicates whether next operation is ready to accept or not. 0: Not ready 1: Ready
6	ERROR	Indicates whether AHB transaction ended with an ERROR response. 0: No error 1: Error
5:0	Reserved	Reserved

46.4.6 Read Operation

46.4.6.1 Read Instruction

In enhanced SPI (Dual/Quad/Octal) modes, all signals are bidirectional. Therefore, the master and slave know when to sample or drive the data on the line. The read instruction set defines the protocol under which the read transactions occur. There are two ways in which the SPI master can read data through SHOSTIF.

(1) Direct Read

In the Direct Read Instruction method, SPI Master initiates a read command and expects the data to be returned in the same command. This way the data is read in the same instruction. Be sure that the data is read on the AHB master interface within the specified cycles (DUMMY cycles).

(2) Read Data in Three Stages (this requires polling)

In some cases, the delay involved during the read operation is such that the read data availability cannot be guaranteed in terms of HSPI_CK cycles due to bus access conflict. To make sure that the data is read in the expected way during the read operation, SHOSTIF provides an alternate approach to divide the read operation into three parts:

- Read request phase
- Wait state
- Read data phase

SPI master requests the read data from SPI slave by sending only the instruction and address during the read request phase. The length of data (1, 4, 8, 16, 32, or 64) to be fetched is also encoded into the instruction. This is converted into an AHB transfer, and data is fetched and stored in the transmit FIFO. After the Read request phase, SPI master checks for availability of data by polling through the READSTATUS instruction. If SPI master receives a positive response for that instruction, then it reads the data using the READn instruction. SHOSTIF then sends all the data received from transmit FIFO to SPI master. Table 46.10 shows all the instructions applicable for read operation.

Table 46.10 Instruction set for read operations

Method	Instruction	Instruction name	Description
Direct Read	0x6i*1 i = 0 to 5	READ8n n = 1, 4, 8, 16, 32, 64	Read Data instruction with 8 wait cycles.
	0x6i*1 i = 8, 9, A, B, C, D	READ16n n = 1, 4, 8, 16, 32, 64	Read Data instruction with 16 wait cycles.
	0x7i*1 i = 0 to 5	READ24n n = 1, 4, 8, 16, 32, 64	Read Data instruction with 24 wait cycles.
	0x7i*1 i = 8, 9, A, B, C, D	READ32n n = 1, 4, 8, 16, 32, 64	Read Data instruction with 32 wait cycles.
3-Stage Read	0x2i*1 i = 0 to 5	READREQn n = 1, 4, 8, 16, 32, 64	Read request.
	0x40	READSTATUS0	Read Data ready instruction without wait cycles.
	0x48	READSTATUS1	Read Data ready instruction with 1 wait cycle.
	0x0i*1 i = 0 to 5	READ0n n = 1, 4, 8, 16, 32, 64	Read Data instruction without wait cycles.
	0x0i*1 i = 8, 9, A, B, C, D	READ1n n = 1, 4, 8, 16, 32, 64	Read Data instruction with 1 wait cycle.

Note 1. The lower 3 bits of the instruction determine the amount of data to be fetched by AHB master. For field decode, see Table 46.5.

46.4.6.2 Direct Read Operation

(1) READmn (Direct Read Data Instruction, m = 8, 16, 24, or 32)

In the direct read approach, only a single instruction is used to fetch the data using AHB interface. After SHOSTIF receives a command with more than or equal to 8 wait cycles (see Table 46.10 for details), SHOSTIF initiates a command on

AHB interface to fetch the required amount of data. After data is received from AHB interface, it is transmitted to the SPI interface after the required amount of wait cycles. Figure 46.5 shows the waveform of the direct read transfer.

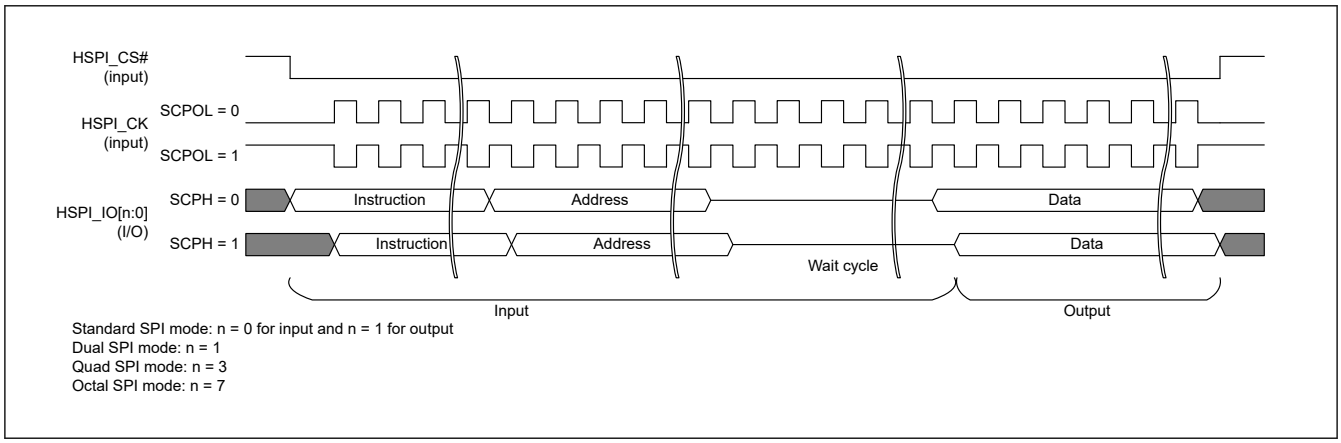

Figure 46.5 READmn instruction (m = 8, 16, 24, or 32)

If SHOSTIF is unable to fetch the data during specific wait cycles, then SHOSTIF indicates this by setting TXE bit in the Status Register (SR) and the Transmit FIFO Underflow Interrupt is asserted.

46.4.6.3 Three Stage Read Operation

When SHOSTIF is idle (the receive/transmit FIFO is empty), and a READREQn instruction is received, it is treated as a read request, and it starts fetching the data from AHB master interface. After the data is available, the READmn instruction returns the read data to SPI master. The SPI master ensures that the data is available before issuing another READmn instruction by polling for data availability. The AHB interface may receive an ERROR response for the read transfer and the READSTATUS instruction indicates this in the response while the SPI master performs the required actions.

Figure 46.6 shows the flow for read operation.

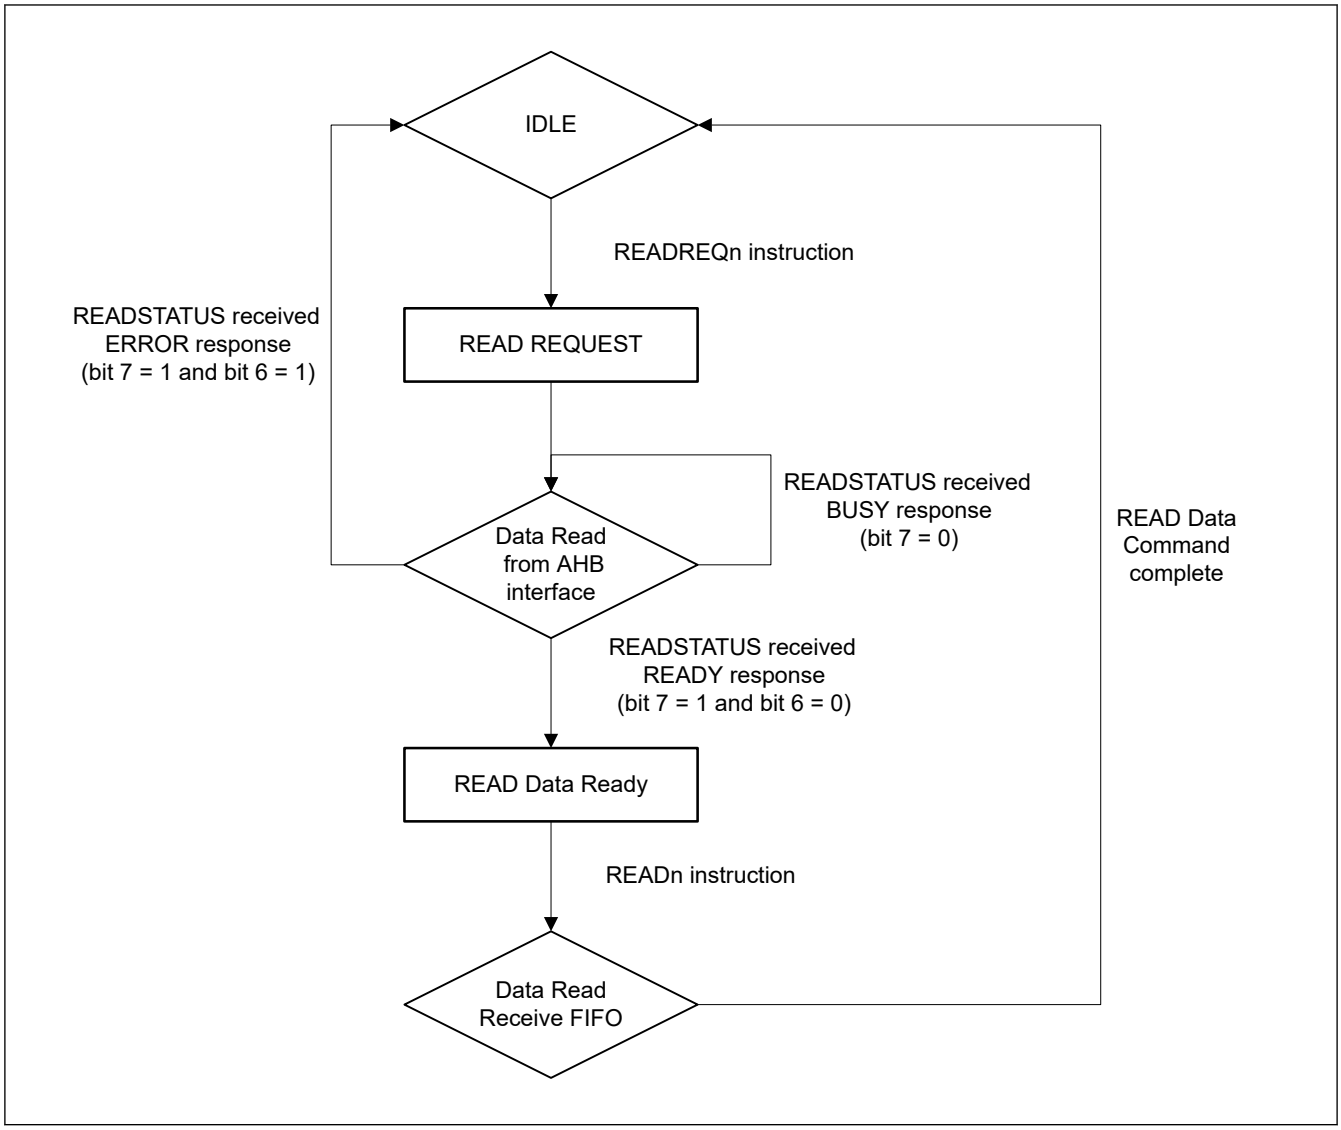

Figure 46.6 Read operation flow for 3-stage operation

(1) READREQn (Read Request Instruction)

Read transaction is always performed in the format specified by SPIMODE[1:0] bits in SHCFG register. This instruction does not require any data transfer and SHOSTIF expects only instruction and address.

Figure 46.7 shows the read request operation using READREQn instruction.

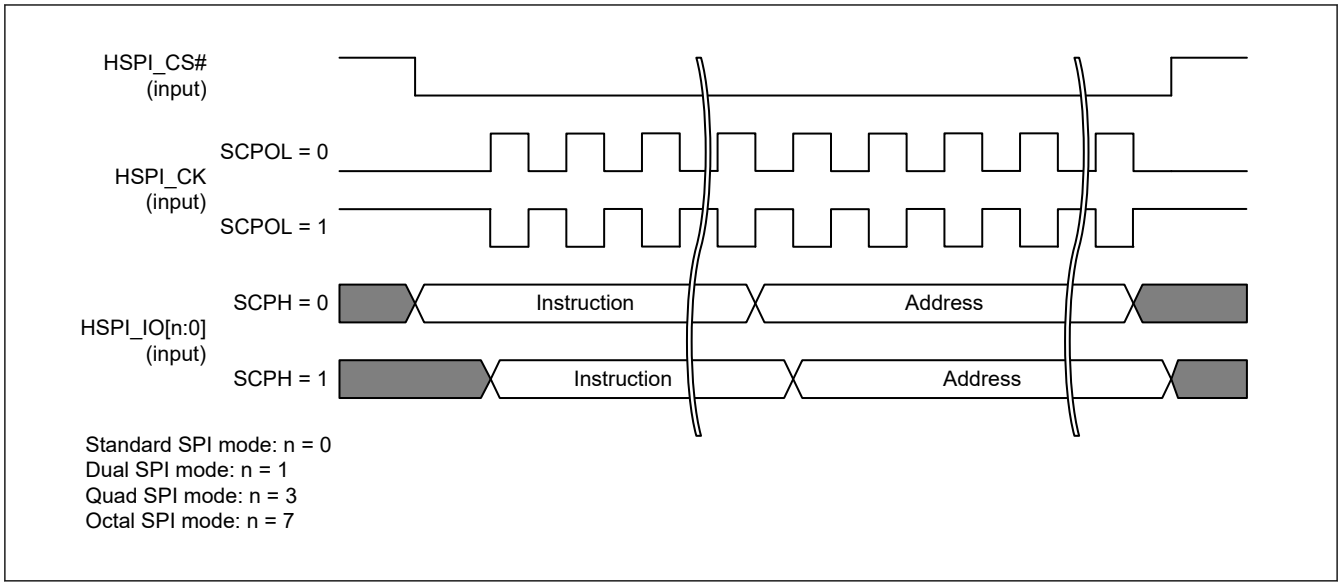

Figure 46.7 READREQn instruction

(2) READSTATUSm (Read Status Instruction, m = 0 or 1)

Read status instruction is used while SHOSTIF fetches the data from AHB interface. The SPI master always polls for data before performing a read data operation, to ensure that data is available for the read operation. SHOSTIF responds to the READSTATUSm command with 8-bit status. The MSB of the status bit indicates whether data is ready or not.

- Response bit 7 = 0 indicates that SHOSTIF is not ready with the data
- Response bit 7 = 1 and bit 6 = 0 indicates that SHOSTIF is ready with the data

Figure 46.8 shows the read status operation using READSTATUSm instruction.

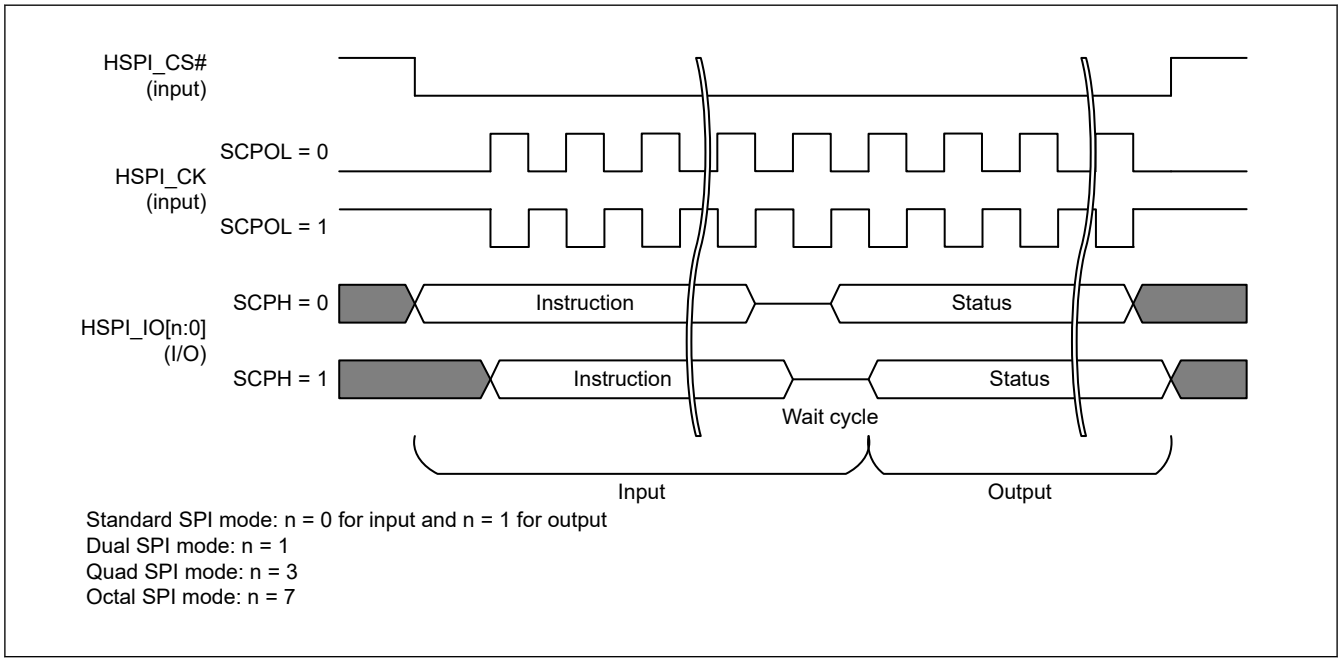

Figure 46.8 READSTATUSm instruction (in case of m = 1)

After the SPI master receives a READY response from SHOSTIF, it performs the read data operation to read the data from SHOSTIF. The AHB interface may get an ERROR response for the read transfer. In that situation, the READSTATUS instruction indicates the same status by sending a response of bit 7 = 1 and bit 6 = 1. SPI master can then issue a new read transfer or retry the same operation.

Table 46.11 Response field decode

Bit	Name	Description
7	READY	Indicates whether data is ready to be fetched from SHOSTIF. 0: Not ready 1: Ready
6	ERROR	Indicates whether AHB transaction ended with an ERROR response or not. 0: No error 1: Error
5:0	Reserved	Reserved

(3) READmn (Read Data Instruction, m = 0 or 1)

After the data is available, READmn instruction is used to read back data from SHOSTIF. This time SHOSTIF does not expect any address to be transmitted by the SPI master. After the instruction is received, the inputs/outputs change direction and revert the data after some wait cycles. Wait cycles can be sent by SHOSTIF depending on the instruction (Table 46.5).

Figure 46.9 shows the read data operation using READmn instruction.

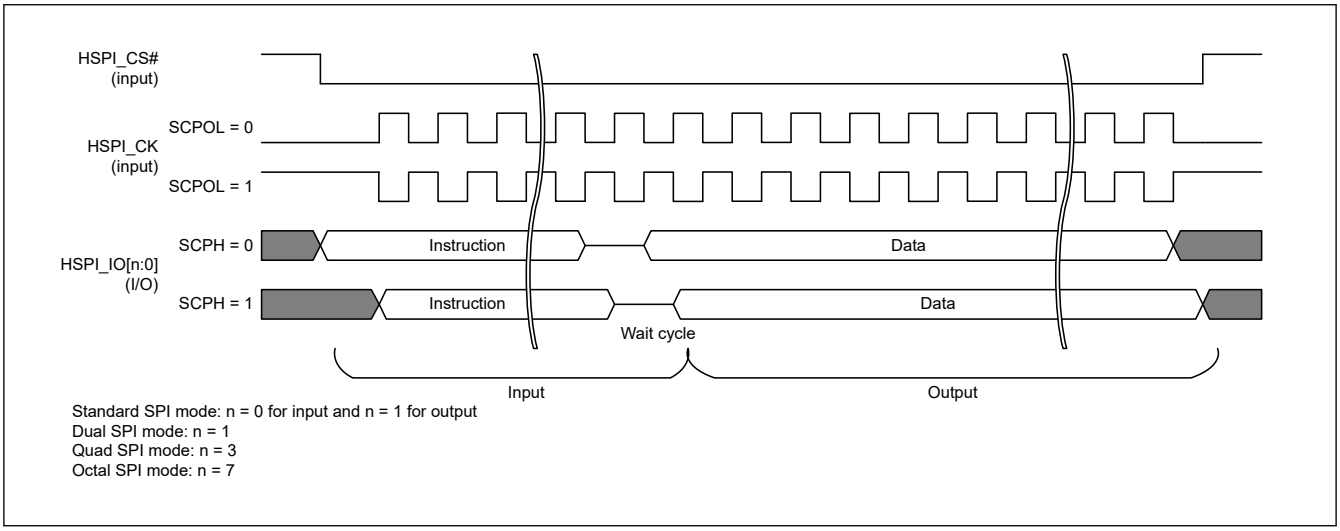

Figure 46.9 READmn instruction (in case of m = 1)

46.4.7 External SPI Master Expectations

The external SPI master must adhere to the flow specified for write and read operations. Any out-of-order operations by SPI master can move SHOSTIF into an undefined state. If SPI master behaves abnormally, then interrupt is sent by SHOSTIF. In such situations, reset SHOSTIF and restart the new transfer.

The following conditions may lead to an error state and the SPIMER bit in RISR register is set for notification.

- SPI master requests for read/write transfer when SHOSTIF is busy with AHB transfer. For example:
  - A read is requested by the SPI master and is followed by a write data transfer while read transfer is still ongoing on the AHB interface.
  - A write transfer is pending on the AHB interface but another read/write data transfer is received by SHOSTIF.
- SPI master reads less amount of data then requested during the Read request phase.
- If the SPI master requested for 16 data frames but it reads only 12 data frames, then the SPIMER bit in RISR register is set and the rest of the data is flushed from the FIFO by performing a soft reset.
- SPI master writes less amount of data than specified in the transfer length.
- If the SPI master requested for 16 data frames but it writes only 12 data frames and deselects the slave early, then the SPIMER bit in the RISR register is set and any of the data left in the FIFO is flushed by performing a soft reset.
- SPI master sends more data for a write, or SPI master read more data then requested.

- If AHB read transfer receives an error response from the slave, then no further transfer is performed for the current request, and data in the FIFO is flushed immediately. If read request transfer receives an error response on AHB interface, SHOSTIF does not expect read data transfer after that because there is no read data available in FIFO. If AHB master still performs a read data transfer, this results in an SPI master error.
- Successful read request transfer is followed by another read request from SPI master.
- A successful read request transfer (which does not receive an error response on the AHB interface) should be followed by read data or read status transfer. If a successful read request transfer is followed by another read request from SPI master, this results in an SPI master error.

46.4.8 AHB Master Interface

The AHB master interface is used as a secondary interface to read or write data for every SPI transfer. The AHB interface address and data width is fixed to 32. The following sections describe how SPI transfers are converted to AHB transactions by SHOSTIF.

46.4.8.1 Write Operation

When SHOSTIF receives a write request (WRITEn command) from SPI master, SHOSTIF saves the address per the rules specified in section 46.4.2. Address Phase. After data is received, it is transmitted as a burst transfer defined by RXFBTR register on AHB interface. This continues until the AHB slave is deselected by the AHB master. If AHB write transfer receives and ERROR response, it is indicated by ahbe_intr interrupt of the ISR and RISR registers. As soon as the error is received on the AHB interface, the rest of the data from SPI interface is discarded and no further transfers are performed for the current operation.

46.4.8.2 Read Operation

When SHOSTIF receives a read request (READmn command) from SPI master, SHOSTIF saves the address per the rules specified in section 46.4.2. Address Phase. SHOSTIF then waits for a burst to complete, and the data to be fully received. The data length is specified in the Data length field of the instruction. For data length of 1, 4, 8, or 16, the corresponding AHB burst type is used to fetch the data. For the burst length of 32 or more, INCR burst type is used to fetch the data.

If any read transfer receives an ERROR response, SHOSTIF aborts the rest of the transfer and indicates the same status in the ISR and RISR registers. When the SPI interface performs a READSTATUS instruction for data ready status, this is indicated to the SPI master with an error response of bit 6 = 1.

46.4.9 Interrupt

Interrupt signal is available in the internal CPU (Cortex-A55 and Cortex-R52) and external host CPU (SPI master). Multiple individual interrupt factors are combined to one signal for internal CPU and external host CPU. Individual interrupt factor can be masked commonly and separately. Figure 46.10 shows a diagram of the interrupt.

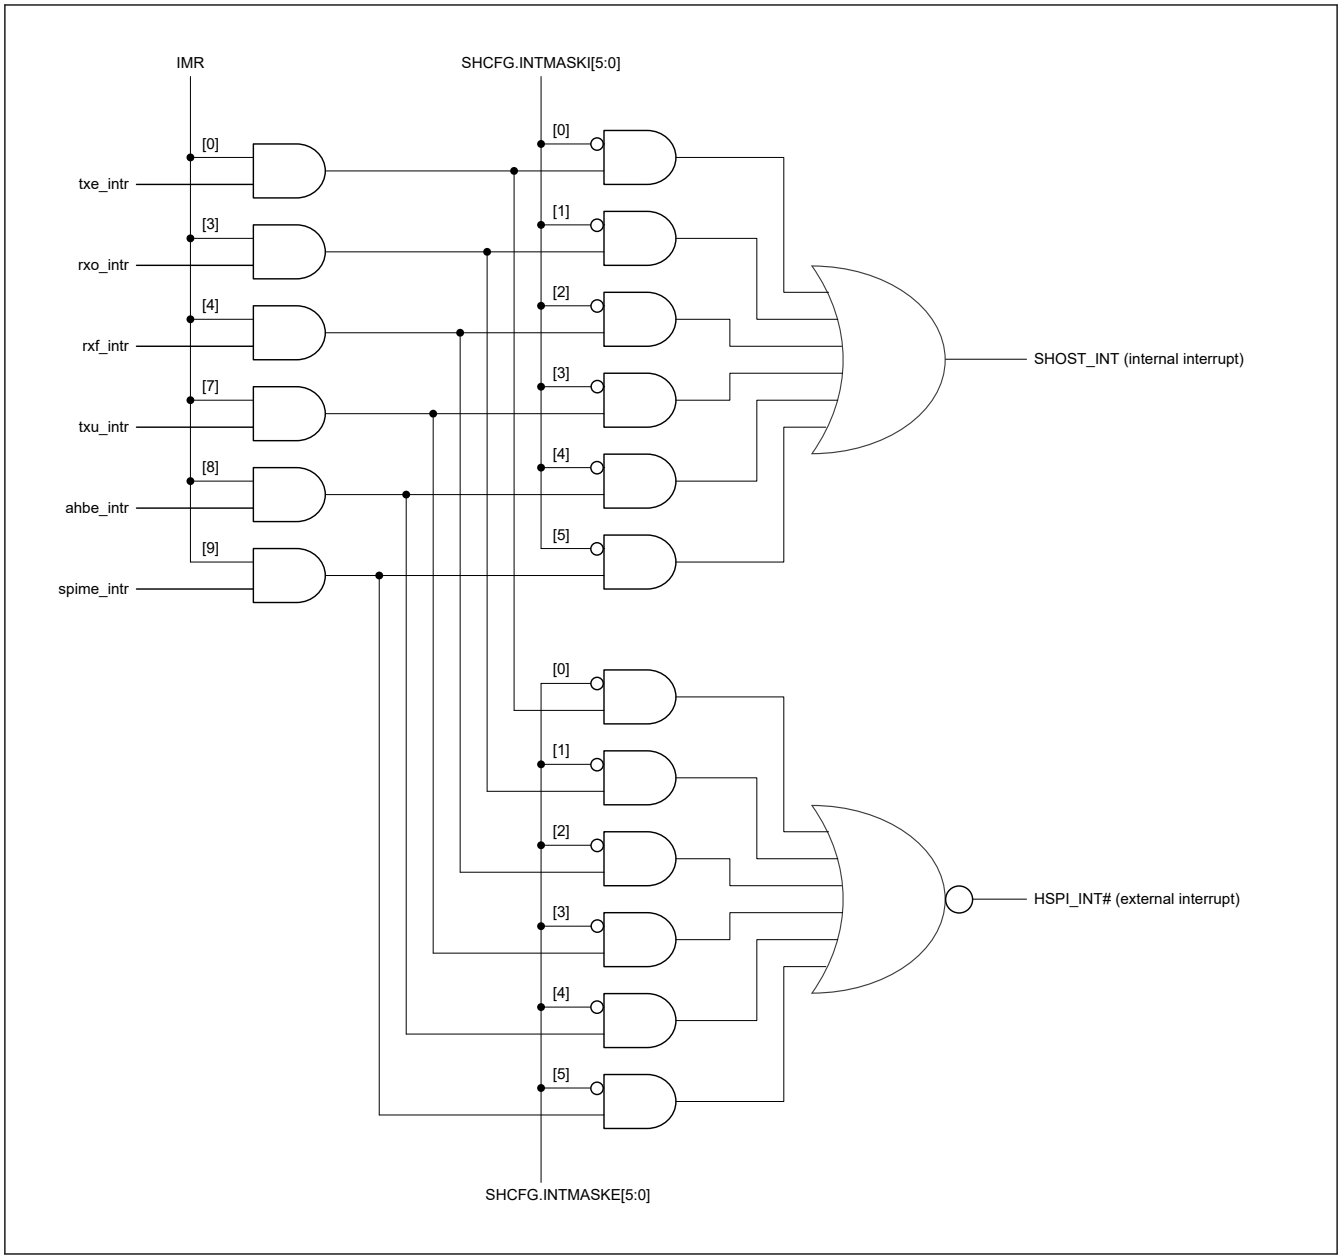

Figure 46.10 Diagram of interrupt signal

Table 46.12 SHOSTIF interrupt source (internal)

Name	Interrupt sources
SHOST_INT	SHOSTIF interrupt (logical OR of all individual interrupts)

Table 46.13 SHOSTIF individual interrupt factor (1 of 2)

Factor name	Description	Interrupt clear	Interrupt mask setting		
			Common	Internal CPU	External host CPU
			IMR register	SHCFG register	
				INTMASKI[5:0] bits	INTMASKE[5:0] bits
txe_intr	Transmit FIFO (read data FIFO) Empty interrupt. When the number of transmit FIFO entries is less than or equal to transmit FIFO threshold level, the interrupt is triggered.	Transmit FIFO entries is greater than threshold	b0	b0	b0

Table 46.13 SHOSTIF individual interrupt factor (2 of 2)

Factor name	Description	Interrupt clear	Interrupt mask setting		
			Common	Internal CPU	External host CPU
			IMR register	SHCFG register	
				INTMASKI[5:0] bits	INTMASKE[5:0] bits
rxo_intr	Receive FIFO (write data FIFO) Overflow interrupt. This interrupt is not triggered if module operates normally.	RXOICR or ICR register read	b3	b1	b1
rxf_intr	Receive FIFO (write data FIFO) Full interrupt. When the number of receive FIFO entries is greater than or equal to receive FIFO threshold level + 1, the interrupt is triggered.	Receive FIFO entries is less than threshold	b4	b2	b2
txu_intr	Transmit FIFO (read data FIFO) Underflow interrupt. The interrupt is triggered in any of the following conditions: ● Data length in READmn is greater than that in READREQn in the 3-stage approach ● Transmission of AHB master interface is not completed within wait cycles specified in READmn in direct read approach	TXUICR or ICR register read	b7	b3	b3
ahbe_intr	AHB Master Interface Error interrupt. When AHB master interface receives an error response, the interrupt is triggered.	AHBECR or ICR register read	b8	b4	b4
spime_intr	SPI Master Interface Error interrupt. The interrupt is triggered in any of the following conditions: ● Illegal instruction code ● Next read or write transaction is issued before the previous transfer is completed	SPEMECR or ICR register read	b9	b5	b5

Note: If Transmit FIFO Underflow interrupt (txu_intr) happens, read access from external bus master may be impossible. Set ENR.ENABLE to 0 once.

46.5 Usage Notes

- When changing the SPI data width, disable SHOSTIF first by setting ENR.ENABLE = 0 during no transmission. Then, change SHCFG.SPIMODE. After changing the SPI data width, enable SHOSTIF again and start transmission.
- During ENR.ENABLE = 0, register access from internal CPU is available but access from external SPI master is ignored. No interrupts occur and read data is undefined.
- Do not change Receive FIFO Burst Threshold Register (RXFBTR) from 0x3F (initial value) in case of 8-bit addressing mode. In case of 32-bit addressing mode, recommendation value is 0x0F.

47. Mailbox and Semaphore (MBXSEM)

47.1 Overview

Mailbox and semaphore are available for controlling exclusive access between internal CPU (Cortex-A55/Cortex-R52) and external host CPU. Table 47.1 shows specification of mailbox and semaphore registers. These registers are accessible from external host CPU via SHOSTIF as well as internal CPU.

Additionally, mailbox and semaphore are available for controlling exclusive access among internal CPUs (Cortex-A55, Cortex-R52 CPU0 and CPU1). Table 1.2 shows specification of mailbox and semaphore registers among internal CPUs.

Table 47.1 Specification of MBXSEM for Host Interface

Semaphore/ Mailbox	Function	Bit size	Number of register	Interrupt generation		Access property*5		
				Cortex-A55/ Cortex-R52	Host CPU	Cortex-A55/ Cortex-R52	Host CPU	Access size
Semaphore	Semaphore	1	8	No	No	R(C)/W	R(C)/W	8, 16, 32
	Read clear enable*1	8	1	No	No	R/W	R/W	8, 16, 32
Mailbox (External Host CPU to Cortex-A55/Cortex-R52)	Mailbox	32	4	No	No	R	R/W	8, 16, 32
	Interrupt Set*2 *3	4	1	Yes (each bit)	No	R	R/W	8, 16, 32
	Interrupt Clear*2 *4	4	1	Cleared (each bit)	No	R/W	R	8, 16, 32
Mailbox (Cortex-A55/ Cortex-R52 to External Host CPU)	Mailbox	32	4	No	No	R/W	R	8, 16, 32
	Interrupt Set*2 *3	4	1	No	Yes (combined)	R/W	R	8, 16, 32
	Interrupt Clear*2 *4	4	1	No	Cleared (when all bits become 0)	R	R/W	8, 16, 32

Note 1. Each bit corresponds to each semaphore register.
Note 2. Each bit represents the interrupt status. When read, same interrupt status can be read through interrupt set and clear registers.
Note 3. When 1 is written to a bit, the corresponding bit is set.
Note 4. When 1 is written to a bit, the corresponding bit is cleared.
Note 5. CoreSight AXI-AP can also access these registers. Access property is same as Cortex-A55/Cortex-R52.

Table 47.2 Specification of MBXSEM among internal CPUs (1 of 2)

Semaphore/ Mailbox	Function	Bit size	Number of register	Interrupt generation		Access property*8 *9		
				Target	Source	Target	Source	Access size
Semaphore	semaphore	1	8	No	No	R(C)/W	R(C)/W	8, 16, 32
	Read clear enable*1	8	1	No	No	R/W	R/W	8, 16, 32
Mailbox Source: Cortex-R52 CPUx Target: Cortex-A55 Corey (x = 0, 1, y = 0 to 3)	Mailbox	32	4 (total 32)	No	No	R	R/W	8, 16, 32
	Interrupt Set*2 *3	4	1 (total 8)	Yes (each reg*5)	No	R	R/W	8, 16, 32
	Interrupt Clear*2 *4	4	1 (total 8)	Cleared (each reg*6)	No	R/W	R	8, 16, 32
Mailbox Source: Cortex-A55 Corey Target: Cortex-R52 CPUx (x = 0, 1, y = 0 to 3)	Mailbox	32	4 (total 32)	No	No	R	R/W	8, 16, 32
	Interrupt Set*2 *3	4	1 (total 8)	Yes (each 4 regs*7)	No	R	R/W	8, 16, 32
	Interrupt Clear*2 *4	16	1 (total 2)	Cleared (each reg*6)	No	R/W	R	8, 16, 32

Table 47.2 Specification of MBXSEM among internal CPUs (2 of 2)

Semaphore/ Mailbox	Function	Bit size	Number of register	Interrupt generation		Access property*8 *9		
				Target	Source	Target	Source	Access size
Mailbox Source: Cortex-R52 CPUx Target: Cortex-R52 CPU|x-1| (x = 0, 1)	Mailbox	32	4 (total 8)	No	No	R	R/W	8, 16, 32
	Interrupt Set*2 *3	4	1 (total 2)	Yes (each reg*5)	No	R	R/W	8, 16, 32
	Interrupt Clear*2 *4	4	1 (total 2)	Cleared (each reg*6)	No	R/W	R	8, 16, 32
Mailbox Source: Cortex-A55 Corex Target: Cortex-A55 Corey (x = 0 to 3, y = 0 to 3 and y ≠ x)	Mailbox	32	4 (total 48)	No	No	R	R/W	8, 16, 32
	Interrupt Set*2 *3	4	1 (total 12)	Yes (each reg*5)	No	R	R/W	8, 16, 32
	Interrupt Clear*2 *4	4	1 (total 12)	Cleared (each reg*6)	No	R/W	R	8, 16, 32

Note 1. Each bit corresponds to each semaphore register.
Note 2. Each bit represents the interrupt status. When read, same interrupt status can be read through send and clear interrupt registers.
Note 3. When 1 is written to a bit, the corresponding bit is set.
Note 4. When 1 is written to a bit, the corresponding bit is cleared.
Note 5. Interrupt is generated when setting more than one bit each corresponding register.
Note 6. Interrupt is cleared when all bits become 0 each corresponding register.
Note 7. Interrupt is generated when setting more than one bit each corresponding 4 registers for Cortex-A55 Core0 to Core3.
Note 8. Access from other CPUs than source and target is always read-only.
Note 9. CoreSight AXI-AP can also access these registers. Access property is same as Cortex-A55 and Cortex-R52 for semaphore and read-only for mailbox.

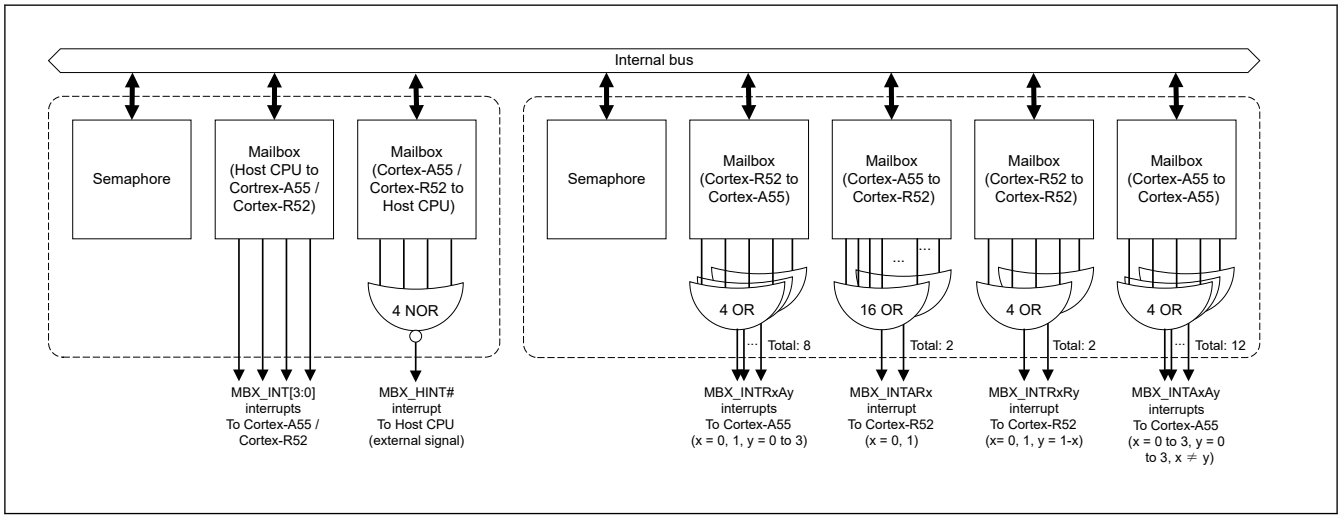

Figure 47.1 MBXSEM Block Diagram

Table 47.3 lists the output pin of the MBXSEM.

Table 47.3 MBXSEM I/O pin

Name	I/O	Function
MBX_HINT#	Output	Mailbox (Cortex-A55/Cortex-R52 to Host CPU) interrupt output pin

0	—	—	SLVACCCTL7.MBXSEM_SL

47.3 Register Descriptions

Register base address is different between external Host CPU view and internal memory address view except.

- External host CPU view : BASE = 0x20_0000

  Note: When 32-bit addressing mode in SHOSTIF is used, please shift the address (base address + offset address) by 2 bits in the right direction.

- Internal CPU view: BASE = 0x8024_0000

Register offset address is described in byte address. Convert it to word address by dividing by 4 if 32-bit addressing mode is used in SHOSTIF.

47.3.1 Semaphore and Mailbox Registers between External Host and Internal CPUs

47.3.1.1 SEMn : Semaphore Register n (n = 0 to 7)

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x00 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SEM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SEM	Semaphore bit 0: Resource being used 1: Resource not being used	R/W*1
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. When read clear function is disabled (SEMRCEN.SEMRCENn = 0), register value is retained after reading the register. When read clear function is enabled (SEMRCEN.SEMRCENn = 1), register is cleared to 0 after reading the register.

SEMn register is used to perform semaphore for synchronization and exclusive control between internal CPU (Cortex-A55/ Cortex-R52/CoreSight) and external host CPU. Resource status can be controlled when the resource is shared between CPUs. Semaphore bit can be cleared when reading this register if SEMRCEN register is enabled.

47.3.1.2 SEMRCEN : Semaphore Read Clear Enable Register

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	SEMRCEN7	SEMRCEN6	SEMRCEN5	SEMRCEN4	SEMRCEN3	SEMRCEN2	SEMRCEN1	SEMRCEN0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SEMRCEN0	Enables or disables SEM0 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
1	SEMRCEN1	Enables or disables SEM1 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
2	SEMRCEN2	Enables or disables SEM2 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
3	SEMRCEN3	Enables or disables SEM3 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
4	SEMRCEN4	Enables or disables SEM4 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
5	SEMRCEN5	Enables or disables SEM5 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
6	SEMRCEN6	Enables or disables SEM6 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
7	SEMRCEN7	Enables or disables SEM7 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

SEMRCEN register enables and disables read clear function of SEMn register.

47.3.1.3 MBXH2Cn : Host to CA55/CR52 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x080 + 0x04 × n

Bit position:	31																												0
Bit field:	MBX[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from external host CPU to internal Cortex-A55/Cortex-R52/CoreSight	R

Note: Only read is available from internal Cortex-A55/Cortex-R52/CoreSight, and read and write are available from external host CPU.

MBXH2Cn register is used as mailbox from external host CPU to internal Cortex-A55/Cortex-R52/CoreSight.

47.3.1.4 MBXISETH2C : Host to CA55/CR52 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x090

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INT3S	MBX_INT2S	MBX_INT1S	MBX_INT0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INT0S	Generates or indicates MBX_INT0 interrupt of mailbox from external host CPU to internal Cortex-A55/Cortex-R52/CoreSight. Write from external host CPU: 0: No operation. MBX_INT0 interrupt status is not changed. 1: MBX_INT0 interrupt is asserted. Read: Indicates MBX_INT0 interrupt status	R
1	MBX_INT1S	Generates or indicates MBX_INT1 interrupt of mailbox from external host CPU to internal Cortex-A55/Cortex-R52/CoreSight. Write from external host CPU: 0: No operation. MBX_INT1 interrupt status is not changed. 1: MBX_INT1 interrupt is asserted. Read: Indicates MBX_INT1 interrupt status	R
2	MBX_INT2S	Generates or indicates MBX_INT2 interrupt of mailbox from external host CPU to internal Cortex-A55/Cortex-R52/CoreSight. Write from external host CPU: 0: No operation. MBX_INT2 interrupt status is not changed. 1: MBX_INT2 interrupt is asserted. Read: Indicates MBX_INT2 interrupt status	R

Bit	Symbol	Function	R/W
3	MBX_INT3S	Generates or indicates MBX_INT3 interrupt of mailbox from external host CPU to internal Cortex-A55/Cortex-R52/CoreSight. Write from external host CPU: 0: No operation. MBX_INT3 interrupt status is not changed. 1: MBX_INT3 interrupt is asserted. Read: Indicates MBX_INT3 interrupt status	R
31:4	—	These bits are read as 0.	R

Note: Only read is available from internal Cortex-A55/Cortex-R52/CoreSight, and read and write are available from external host CPU.

MBXISETH2C register is used to generate mailbox interrupt from external host CPU to internal Cortex-A55/Cortex-R52/CoreSight. Maximum 4 interrupts can be generated.

47.3.1.5 MBXICLRH2C : Host to CA55/CR52 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x094

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INT3C	MBX_INT2C	MBX_INT1C	MBX_INT0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INT0C	Clears or indicates MBX_INT0 interrupt of mailbox from external host CPU to internal Cortex-A55/Cortex-R52/CoreSight. Write from internal Cortex-A55/Cortex-R52/CoreSight: 0: No operation. MBX_INT0 interrupt status is not changed. 1: MBX_INT0 interrupt is cleared. Read: Indicates MBX_INT0 interrupt status	R/W
1	MBX_INT1C	Clears or indicates MBX_INT1 interrupt of mailbox from external host CPU to internal Cortex-A55/Cortex-R52/CoreSight. Write from internal Cortex-A55/Cortex-R52/CoreSight: 0: No operation. MBX_INT1 interrupt status is not changed. 1: MBX_INT1 interrupt is cleared. Read: Indicates MBX_INT1 interrupt status	R/W
2	MBX_INT2C	Clears or indicates MBX_INT2 interrupt of mailbox from external host CPU to internal Cortex-A55/Cortex-R52/CoreSight. Write from internal Cortex-A55/Cortex-R52/CoreSight: 0: No operation. MBX_INT2 interrupt status is not changed. 1: MBX_INT2 interrupt is cleared. Read: Indicates MBX_INT2 interrupt status	R/W
3	MBX_INT3C	Clears or indicates MBX_INT3 interrupt of mailbox from external host CPU to internal Cortex-A55/Cortex-R52/CoreSight. Write from internal Cortex-A55/Cortex-R52/CoreSight: 0: No operation. MBX_INT3 interrupt status is not changed. 1: MBX_INT3 interrupt is cleared. Read: Indicates MBX_INT3 interrupt status	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: Read and write are available from internal Cortex-A55/Cortex-R52/CoreSight, and only read is available from external host CPU.

MBXICLRH2C register is used to clear mailbox interrupt from external host CPU to internal Cortex-A55/Cortex-R52/ CoreSight.

47.3.1.6 MBXC2Hn : CA55/CR52 to Host Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x100 + 0x04 × n

Bit position:	31																													0
Bit field:	MBX[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from internal Cortex-A55/Cortex-R52/CoreSight to external host CPU	R/W

Note: Read and write are available from internal Cortex-A55/Cortex-R52/CoreSight, and only read is available from external host CPU.

MBXC2Hn register is used as mailbox from internal Cortex-A55/Cortex-R52/CoreSight to external host CPU.

47.3.1.7 MBXISETC2H : CA55/CR52 to Host Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x110

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_HINT3S	MBX_HINT2S	MBX_HINT1S	MBX_HINT0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_HINT0S	Generates or indicates MBX_HINT0 interrupt of mailbox from internal Cortex-A55/Cortex-R52/CoreSight to external host CPU. Write from internal Cortex-A55/Cortex-R52/CoreSight: 0: No operation. MBX_INT0 interrupt status is not changed. 1: MBX_HINT0 interrupt is asserted. Read: Indicates MBX_HINT0 interrupt status	R/W
1	MBX_HINT1S	Generates or indicates MBX_HINT1 interrupt of mailbox from internal Cortex-A55/Cortex-R52/CoreSight to external host CPU. Write from internal Cortex-A55/Cortex-R52/CoreSight: 0: No operation. MBX_INT1 interrupt status is not changed. 1: MBX_HINT1 interrupt is asserted. Read: Indicates MBX_HINT1 interrupt status	R/W
2	MBX_HINT2S	Generates or indicates MBX_HINT2 interrupt of mailbox from internal Cortex-A55/Cortex-R52/CoreSight to external host CPU. Write from internal Cortex-A55/Cortex-R52/CoreSight: 0: No operation. MBX_INT2 interrupt status is not changed. 1: MBX_HINT2 interrupt is asserted. Read: Indicates MBX_HINT2 interrupt status	R/W

Bit	Symbol	Function	R/W
3	MBX_HINT3S	Generates or indicates MBX_HINT3 interrupt of mailbox from internal Cortex-A55/Cortex-R52/CoreSight to external host CPU. Write from internal Cortex-A55/Cortex-R52/CoreSight: 0: No operation. MBX_INT3 interrupt status is not changed. 1: MBX_HINT3 interrupt is asserted. Read: Indicates MBX_HINT3 interrupt status	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: Read and write are available from internal Cortex-A55/Cortex-R52/CoreSight, and only read is available from external host CPU.

MBXISETC2H register is used to generate mailbox interrupt from internal Cortex-A55/Cortex-R52/CoreSight to external host CPU. Maximum 4 interrupts can be generated but all the interrupts are combined to one output interrupt signal (MBX_HINT#) by logical NOR.

47.3.1.8 MBXICLRC2H : CA55/CR52 to Host Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000
HOSTIF_E = 0x0018_0000

Offset address: 0x114

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_HINT3C	MBX_HINT2C	MBX_HINT1C	MBX_HINT0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_HINT0C	Clears or indicates MBX_HINT0 interrupt of mailbox from internal Cortex-A55/Cortex-R52/CoreSight to external host CPU. Write from external host CPU: 0: No operation. MBX_HINT0 interrupt status is not changed. 1: MBX_HINT0 interrupt is cleared. Read: Indicates MBX_HINT0 interrupt status	R
1	MBX_HINT1C	Clears or indicates MBX_HINT1 interrupt of mailbox from internal Cortex-A55/Cortex-R52/CoreSight to external host CPU. Write from external host CPU: 0: No operation. MBX_HINT1 interrupt status is not changed. 1: MBX_HINT1 interrupt is cleared. Read: Indicates MBX_HINT1 interrupt status	R
2	MBX_HINT2C	Clears or indicates MBX_HINT2 interrupt of mailbox from internal Cortex-A55/Cortex-R52/CoreSight to external host CPU. Write from external host CPU: 0: No operation. MBX_HINT2 interrupt status is not changed. 1: MBX_HINT2 interrupt is cleared. Read: Indicates MBX_HINT2 interrupt status	R
3	MBX_HINT3C	Clears or indicates MBX_HINT3 interrupt of mailbox from internal Cortex-A55/Cortex-R52/CoreSight to external host CPU. Write from external host CPU: 0: No operation. MBX_HINT3 interrupt status is not changed. 1: MBX_HINT3 interrupt is cleared. Read: Indicates MBX_HINT3 interrupt status	R
31:4	—	These bits are read as 0.	R

Note: Only read is available from internal Cortex-A55/Cortex-R52/CoreSight, and read and write are available from external host CPU.

MBXICLRC2H register is used to clear mailbox interrupt from internal Cortex-A55/Cortex-R52/CoreSight to external host CPU.

47.3.2 Semaphore Registers among Internal CPUs

47.3.2.1 SEMARn : Semaphore Register n among Internal CPUs (n = 0 to 7)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x180 + 0x04 × n

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SEM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SEM	Semaphore bit 0: Resource being used 1: Resource not being used	R/W*1
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. When read clear function is disabled (SEMRCENAR.SEMRCENn = 0), register value is retained after reading the register. When read clear function is enabled (SEMRCENAR.SEMRCENn = 1), register is cleared to 0 after reading the register.

SEMARn register is used to perform semaphore for synchronization and exclusive control among Cortex-A55, Cortex-R52 CPU0 and CPU1. Resource status can be controlled when the resource is shared between CPUs. Semaphore bit can be cleared when reading this register if SEMRCEN register is enabled.

47.3.2.2 SEMRCENAR : Semaphore Read Clear Enable Register among Internal CPUs

Base address: MBXSEM = 0x8024_0000

Offset address: 0x1A0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	SEMR CEN7	SEMR CEN6	SEMR CEN5	SEMR CEN4	SEMR CEN3	SEMR CEN2	SEMR CEN1	SEMR CEN0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SEMRCEN0	Enables or disables SEMAR0 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
1	SEMRCEN1	Enables or disables SEMAR1 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
2	SEMRCEN2	Enables or disables SEMAR2 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
3	SEMRCEN3	Enables or disables SEMAR3 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W

Bit	Symbol	Function	R/W
4	SEMRCEN4	Enables or disables SEMAR4 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
5	SEMRCEN5	Enables or disables SEMAR5 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
6	SEMRCEN6	Enables or disables SEMAR6 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
7	SEMRCEN7	Enables or disables SEMAR7 register read clear function. 0: Disables read clear function 1: Enables read clear function	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

SEMRCENAR register enables and disables read clear function of SEMARn register.

47.3.3 Mailbox Registers from Cortex-R52 to Cortex-A55

47.3.3.1 MBXR0A0n : CR52 CPU0 to CA55 Core0 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x200 + 0x04 × n

Bit position:	31																														0
Bit field:	MBX[31:0]																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-R52 CPU0 to Cortex-A55 Core0	R/W*1

Note 1. Read and write is available from Cortex-R52 CPU0 (Source). Only read is available from Cortex-A55 Core0 (Target). Access from other CPUs except source and target is also read only.

MBXR0A0n register is used as mailbox from Cortex-R52 CPU0 to Cortex-A55 Core0.

47.3.3.2 MBXISETR0A0 : CR52 CPU0 to CA55 Core0 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x210

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR0A0_3S	MBX_INTR0A0_2S	MBX_INTR0A0_1S	MBX_INTR0A0_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR0A0_0S	Sets or indicates interrupt status flag (MBX_INTR0A00) of mailbox 0 from Cortex-R52 CPU0 to Cortex-A55 Core0. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR0A0_1S	Sets or indicates interrupt status flag (MBX_INTR0A01) of mailbox 1 from Cortex-R52 CPU0 to Cortex-A55 Core0. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR0A0_2S	Sets or indicates interrupt status flag (MBX_INTR0A02) of mailbox 2 from Cortex-R52 CPU0 to Cortex-A55 Core0. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR0A0_3S	Sets or indicates interrupt status flag (MBX_INTR0A03) of mailbox 3 from Cortex-R52 CPU0 to Cortex-A55 Core0. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU0 (Source). Only read is available from Cortex-A55 Core0 (Target). Access from other CPUs except source and target is also read only.

MBXISETR0A0 register is used to generate mailbox interrupt from Cortex-R52 CPU0 to Cortex-A55 Core0. MBX_INTR0A0 interrupt is generated as logical OR of MBX_INTR0A00, MBX_INTR0A01, MBX_INTR0A02, or MBX_INTR0A03 status flags.

47.3.3.3 MBXICLRR0A0 : CR52 CPU0 to CA55 Core0 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x214

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR0A0_3C	MBX_INTR0A0_2C	MBX_INTR0A0_1C	MBX_INTR0A0_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR0A0_0C	Clears or indicates interrupt status flag (MBX_INTR0A00) of mailbox 0 from Cortex-R52 CPU0 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1

Bit	Symbol	Function	R/W
1	MBX_INTR0A0_1C	Clears or indicates interrupt status flag (MBX_INTR0A01) of mailbox 1 from Cortex-R52 CPU0 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR0A0_2C	Clears or indicates interrupt status flag (MBX_INTR0A02) of mailbox 2 from Cortex-R52 CPU0 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR0A0_3C	Clears or indicates interrupt status flag (MBX_INTR0A03) of mailbox 3 from Cortex-R52 CPU0 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core0 (Target). Only read is available from Cortex-R52 CPU0 (Source). Access from other CPUs except source and target is also read only.

MBXICLRR0A0 register is used to clear mailbox interrupt from Cortex-R52 CPU0 to Cortex-A55 Core0. MBX_INTR0A0 interrupt is cleared when all the status flags are cleared.

47.3.3.4 MBXR0A1n : CR52 CPU0 to CA55 Core1 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x280 + 0x04 × n

Bit position:	31																												0
Bit field:	MBX[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-R52 CPU0 to Cortex-A55 Core1	R/W*1

Note 1. Read and write is available from Cortex-R52 CPU0 (Source). Only read is available from Cortex-A55 Core1 (Target). Access from other CPUs except source and target is also read only.

MBXR0A1n register is used as mailbox from Cortex-R52 CPU0 to Cortex-A55 Core1.

47.3.3.5 MBXISETR0A1 : CR52 CPU0 to CA55 Core1 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x290

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR0A1_3S	MBX_INTR0A1_2S	MBX_INTR0A1_1S	MBX_INTR0A1_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR0A1_0S	Sets or indicates interrupt status flag (MBX_INTR0A10) of mailbox 0 from Cortex-R52 CPU0 to Cortex-A55 Core1. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR0A1_1S	Sets or indicates interrupt status flag (MBX_INTR0A11) of mailbox 1 from Cortex-R52 CPU0 to Cortex-A55 Core1. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR0A1_2S	Sets or indicates interrupt status flag (MBX_INTR0A12) of mailbox 2 from Cortex-R52 CPU0 to Cortex-A55 Core1. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR0A1_3S	Sets or indicates interrupt status flag (MBX_INTR0A13) of mailbox 3 from Cortex-R52 CPU0 to Cortex-A55 Core1. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU0 (Source). Only read is available from Cortex-A55 Core1 (Target). Access from other CPUs except source and target is also read only.

MBXISETR0A1 register is used to generate mailbox interrupt from Cortex-R52 CPU0 to Cortex-A55 Core1. MBX_INTR0A1 interrupt is generated as logical OR of MBX_INTR0A10, MBX_INTR0A11, MBX_INTR0A12, or MBX_INTR0A13 status flags.

47.3.3.6 MBXICLRR0A1 : CR52 CPU0 to CA55 Core1 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x294

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR0A1_3C	MBX_INTR0A1_2C	MBX_INTR0A1_1C	MBX_INTR0A1_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR0A1_0C	Clears or indicates interrupt status flag (MBX_INTR0A10) of mailbox 0 from Cortex-R52 CPU0 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR0A1_1C	Clears or indicates interrupt status flag (MBX_INTR0A11) of mailbox 1 from Cortex-R52 CPU0 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR0A1_2C	Clears or indicates interrupt status flag (MBX_INTR0A12) of mailbox 2 from Cortex-R52 CPU0 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR0A1_3C	Clears or indicates interrupt status flag (MBX_INTR0A13) of mailbox 3 from Cortex-R52 CPU0 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core1 (Target). Only read is available from Cortex-R52 CPU0 (Source). Access from other CPUs except source and target is also read only.

MBXICLRR0A1 register is used to clear mailbox interrupt from Cortex-R52 CPU0 to Cortex-A55 Core1. MBX_INTR0A1 interrupt is cleared when all the status flags are cleared.

47.3.3.7 MBXR0A2n : CR52 CPU0 to CA55 Core2 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x300 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-R52 CPU0 to Cortex-A55 Core2	R/W*1

Note 1. Read and write is available from Cortex-R52 CPU0 (Source). Only read is available from Cortex-A55 Core2 (Target). Access from other CPUs except source and target is also read only.

MBXR0A2n register is used as mailbox from Cortex-R52 CPU0 to Cortex-A55 Core2.

47.3.3.8 MBXISETR0A2 : CR52 CPU0 to CA55 Core2 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x310

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR0A2_3S	MBX_INTR0A2_2S	MBX_INTR0A2_1S	MBX_INTR0A2_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR0A2_0S	Sets or indicates interrupt status flag (MBX_INTR0A20) of mailbox 0 from Cortex-R52 CPU0 to Cortex-A55 Core2. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR0A2_1S	Sets or indicates interrupt status flag (MBX_INTR0A21) of mailbox 1 from Cortex-R52 CPU0 to Cortex-A55 Core2. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR0A2_2S	Sets or indicates interrupt status flag (MBX_INTR0A22) of mailbox 2 from Cortex-R52 CPU0 to Cortex-A55 Core2. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR0A2_3S	Sets or indicates interrupt status flag (MBX_INTR0A23) of mailbox 3 from Cortex-R52 CPU0 to Cortex-A55 Core2. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU0 (Source). Only read is available from Cortex-A55 Core2 (Target). Access from other CPUs except source and target is also read only.

MBXISETR0A2 register is used to generate mailbox interrupt from Cortex-R52 CPU0 to Cortex-A55 Core2. MBX_INTR0A2 interrupt is generated as logical OR of MBX_INTR0A20, MBX_INTR0A21, MBX_INTR0A22, or MBX_INTR0A23 status flags.

47.3.3.9 MBXICLRR0A2 : CR52 CPU0 to CA55 Core2 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x314

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR0A2_3C	MBX_INTR0A2_2C	MBX_INTR0A2_1C	MBX_INTR0A2_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR0A2_0C	Clears or indicates interrupt status flag (MBX_INTR0A20) of mailbox 0 from Cortex-R52 CPU0 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR0A2_1C	Clears or indicates interrupt status flag (MBX_INTR0A21) of mailbox 1 from Cortex-R52 CPU0 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR0A2_2C	Clears or indicates interrupt status flag (MBX_INTR0A22) of mailbox 2 from Cortex-R52 CPU0 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR0A2_3C	Clears or indicates interrupt status flag (MBX_INTR0A23) of mailbox 3 from Cortex-R52 CPU0 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core2 (Target). Only read is available from Cortex-R52 CPU0 (Source). Access from other CPUs except source and target is also read only.

MBXICLRR0A2 register is used to clear mailbox interrupt from Cortex-R52 CPU0 to Cortex-A55 Core2. MBX_INTR0A2 interrupt is cleared when all the status flags are cleared.

47.3.3.10 MBXR0A3n : CR52 CPU0 to CA55 Core3 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x380 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-R52 CPU0 to Cortex-A55 Core3	R/W*1

Note 1. Read and write is available from Cortex-R52 CPU0 (Source). Only read is available from Cortex-A55 Core3 (Target). Access from other CPUs except source and target is also read only.

MBXR0A3n register is used as mailbox from Cortex-R52 CPU0 to Cortex-A55 Core3.

47.3.3.11 MBXISETR0A3 : CR52 CPU0 to CA55 Core3 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x390

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR0A3_3S	MBX_INTR0A3_2S	MBX_INTR0A3_1S	MBX_INTR0A3_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR0A3_0S	Sets or indicates interrupt status flag (MBX_INTR0A30) of mailbox 0 from Cortex-R52 CPU0 to Cortex-A55 Core3. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR0A3_1S	Sets or indicates interrupt status flag (MBX_INTR0A31) of mailbox 1 from Cortex-R52 CPU0 to Cortex-A55 Core3. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR0A3_2S	Sets or indicates interrupt status flag (MBX_INTR0A32) of mailbox 2 from Cortex-R52 CPU0 to Cortex-A55 Core3. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR0A3_3S	Sets or indicates interrupt status flag (MBX_INTR0A33) of mailbox 3 from Cortex-R52 CPU0 to Cortex-A55 Core3. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU0 (Source). Only read is available from Cortex-A55 Core3 (Target). Access from other CPUs except source and target is also read only.

MBXISETR0A3 register is used to generate mailbox interrupt from Cortex-R52 CPU0 to Cortex-A55 Core3. MBX_INTR0A3 interrupt is generated as logical OR of MBX_INTR0A30, MBX_INTR0A31, MBX_INTR0A32, or MBX_INTR0A33 status flags.

47.3.3.12 MBXICLRR0A3 : CR52 CPU0 to CA55 Core3 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x394

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR0A3_3C	MBX_INTR0A3_2C	MBX_INTR0A3_1C	MBX_INTR0A3_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR0A3_0C	Clears or indicates interrupt status flag (MBX_INTR0A30) of mailbox 0 from Cortex-R52 CPU0 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR0A3_1C	Clears or indicates interrupt status flag (MBX_INTR0A31) of mailbox 1 from Cortex-R52 CPU0 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR0A3_2C	Clears or indicates interrupt status flag (MBX_INTR0A32) of mailbox 2 from Cortex-R52 CPU0 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR0A3_3C	Clears or indicates interrupt status flag (MBX_INTR0A33) of mailbox 3 from Cortex-R52 CPU0 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core3 (Target). Only read is available from Cortex-R52 CPU0 (Source). Access from other CPUs except source and target is also read only.

MBXICLRR0A3 register is used to clear mailbox interrupt from Cortex-R52 CPU0 to Cortex-A55 Core3. MBX_INTR0A3 interrupt is cleared when all the status flags are cleared.

47.3.3.13 MBXR1A0n : CR52 CPU1 to CA55 Core0 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x400 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-R52 CPU1 to Cortex-A55 Core0	R/W*1

Note 1. Read and write is available from Cortex-R52 CPU1 (Source). Only read is available from Cortex-A55 Core0 (Target). Access from other CPUs except source and target is also read only.

MBXR1A0n register is used as mailbox from Cortex-R52 CPU1 to Cortex-A55 Core0.

47.3.3.14 MBXISETR1A0 : CR52 CPU1 to CA55 Core0 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x410

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR1A0_3S	MBX_INTR1A0_2S	MBX_INTR1A0_1S	MBX_INTR1A0_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR1A0_0S	Sets or indicates interrupt status flag (MBX_INTR1A00) of mailbox 0 from Cortex-R52 CPU1 to Cortex-A55 Core0. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR1A0_1S	Sets or indicates interrupt status flag (MBX_INTR1A01) of mailbox 1 from Cortex-R52 CPU1 to Cortex-A55 Core0. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR1A0_2S	Sets or indicates interrupt status flag (MBX_INTR1A02) of mailbox 2 from Cortex-R52 CPU1 to Cortex-A55 Core0. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR1A0_3S	Sets or indicates interrupt status flag (MBX_INTR1A03) of mailbox 3 from Cortex-R52 CPU1 to Cortex-A55 Core0. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU1 (Source). Only read is available from Cortex-A55 Core0 (Target). Access from other CPUs except source and target is also read only.

MBXISETR1A0 register is used to generate mailbox interrupt from Cortex-R52 CPU1 to Cortex-A55 Core0. MBX_INTR1A0 interrupt is generated as logical OR of MBX_INTR1A00, MBX_INTR1A01, MBX_INTR1A02, or MBX_INTR1A03 status flags.

47.3.3.15 MBXICLRR1A0 : CR52 CPU1 to CA55 Core0 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x414

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR1A0_3C	MBX_INTR1A0_2C	MBX_INTR1A0_1C	MBX_INTR1A0_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR1A0_0C	Clears or indicates interrupt status flag (MBX_INTR1A00) of mailbox 0 from Cortex-R52 CPU1 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR1A0_1C	Clears or indicates interrupt status flag (MBX_INTR1A01) of mailbox 1 from Cortex-R52 CPU1 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR1A0_2C	Clears or indicates interrupt status flag (MBX_INTR1A02) of mailbox 2 from Cortex-R52 CPU1 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR1A0_3C	Clears or indicates interrupt status flag (MBX_INTR1A03) of mailbox 3 from Cortex-R52 CPU1 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core0 (Target). Only read is available from Cortex-R52 CPU1 (Source). Access from other CPUs except source and target is also read only.

MBXICLRR1A0 register is used to clear mailbox interrupt from Cortex-R52 CPU1 to Cortex-A55 Core0. MBX_INTR1A0 interrupt is cleared when all the status flags are cleared.

47.3.3.16 MBXR1A1n : CR52 CPU1 to CA55 Core1 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x480 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-R52 CPU1 to Cortex-A55 Core1	R/W*1

Note 1. Read and write is available from Cortex-R52 CPU1 (Source). Only read is available from Cortex-A55 Core1 (Target). Access from other CPUs except source and target is also read only.

MBXR1A1n register is used as mailbox from Cortex-R52 CPU1 to Cortex-A55 Core1.

47.3.3.17 MBXISETR1A1 : CR52 CPU1 to CA55 Core1 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x490

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR1A1_3S	MBX_INTR1A1_2S	MBX_INTR1A1_1S	MBX_INTR1A1_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR1A1_0S	Sets or indicates interrupt status flag (MBX_INTR1A10) of mailbox 0 from Cortex-R52 CPU1 to Cortex-A55 Core1. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR1A1_1S	Sets or indicates interrupt status flag (MBX_INTR1A11) of mailbox 1 from Cortex-R52 CPU1 to Cortex-A55 Core1. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR1A1_2S	Sets or indicates interrupt status flag (MBX_INTR1A12) of mailbox 2 from Cortex-R52 CPU1 to Cortex-A55 Core1. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR1A1_3S	Sets or indicates interrupt status flag (MBX_INTR1A13) of mailbox 3 from Cortex-R52 CPU1 to Cortex-A55 Core1. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU1 (Source). Only read is available from Cortex-A55 Core1 (Target). Access from other CPUs except source and target is also read only.

MBXISETR1A1 register is used to generate mailbox interrupt from Cortex-R52 CPU1 to Cortex-A55 Core1. MBX_INTR1A1 interrupt is generated as logical OR of MBX_INTR1A10, MBX_INTR1A11, MBX_INTR1A12, or MBX_INTR1A13 status flags.

47.3.3.18 MBXICLRR1A1 : CR52 CPU1 to CA55 Core1 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x494

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR1A1_3C	MBX_INTR1A1_2C	MBX_INTR1A1_1C	MBX_INTR1A1_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR1A1_0C	Clears or indicates interrupt status flag (MBX_INTR1A10) of mailbox 0 from Cortex-R52 CPU1 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR1A1_1C	Clears or indicates interrupt status flag (MBX_INTR1A11) of mailbox 1 from Cortex-R52 CPU1 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR1A1_2C	Clears or indicates interrupt status flag (MBX_INTR1A12) of mailbox 2 from Cortex-R52 CPU1 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR1A1_3C	Clears or indicates interrupt status flag (MBX_INTR1A13) of mailbox 3 from Cortex-R52 CPU1 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core1 (Target). Only read is available from Cortex-R52 CPU1 (Source). Access from other CPUs except source and target is also read only.

MBXICLRR1A1 register is used to clear mailbox interrupt from Cortex-R52 CPU1 to Cortex-A55 Core1. MBX_INTR1A1 interrupt is cleared when all the status flags are cleared.

47.3.3.19 MBXR1A2n : CR52 CPU1 to CA55 Core2 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x500 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-R52 CPU1 to Cortex-A55 Core2	R/W*1

Note 1. Read and write is available from Cortex-R52 CPU1 (Source). Only read is available from Cortex-A55 Core2 (Target). Access from other CPUs except source and target is also read only.

MBXR1A2n register is used as mailbox from Cortex-R52 CPU1 to Cortex-A55 Core2.

47.3.3.20 MBXISETR1A2 : CR52 CPU1 to CA55 Core2 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x510

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR1A2_3S	MBX_INTR1A2_2S	MBX_INTR1A2_1S	MBX_INTR1A2_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR1A2_0S	Sets or indicates interrupt status flag (MBX_INTR1A20) of mailbox 0 from Cortex-R52 CPU1 to Cortex-A55 Core2. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR1A2_1S	Sets or indicates interrupt status flag (MBX_INTR1A21) of mailbox 1 from Cortex-R52 CPU1 to Cortex-A55 Core2. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR1A2_2S	Sets or indicates interrupt status flag (MBX_INTR1A22) of mailbox 2 from Cortex-R52 CPU1 to Cortex-A55 Core2. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR1A2_3S	Sets or indicates interrupt status flag (MBX_INTR1A23) of mailbox 3 from Cortex-R52 CPU1 to Cortex-A55 Core2. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU1 (Source). Only read is available from Cortex-A55 Core2 (Target). Access from other CPUs except source and target is also read only.

MBXISETR1A2 register is used to generate mailbox interrupt from Cortex-R52 CPU1 to Cortex-A55 Core2. MBX_INTR1A2 interrupt is generated as logical OR of MBX_INTR1A20, MBX_INTR1A21, MBX_INTR1A22, or MBX_INTR1A23 status flags.

47.3.3.21 MBXICLRR1A2 : CR52 CPU1 to CA55 Core2 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x514

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR1A2_3C	MBX_INTR1A2_2C	MBX_INTR1A2_1C	MBX_INTR1A2_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR1A2_0C	Clears or indicates interrupt status flag (MBX_INTR1A20) of mailbox 0 from Cortex-R52 CPU1 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR1A2_1C	Clears or indicates interrupt status flag (MBX_INTR1A21) of mailbox 1 from Cortex-R52 CPU1 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR1A2_2C	Clears or indicates interrupt status flag (MBX_INTR1A22) of mailbox 2 from Cortex-R52 CPU1 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR1A2_3C	Clears or indicates interrupt status flag (MBX_INTR1A23) of mailbox 3 from Cortex-R52 CPU1 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core2 (Target). Only read is available from Cortex-R52 CPU1 (Source). Access from other CPUs except source and target is also read only.

MBXICLRR1A2 register is used to clear mailbox interrupt from Cortex-R52 CPU1 to Cortex-A55 Core2. MBX_INTR1A2 interrupt is cleared when all the status flags are cleared.

47.3.3.22 MBXR1A3n : CR52 CPU1 to CA55 Core3 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x580 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-R52 CPU1 to Cortex-A55 Core3	R/W*1

Note 1. Read and write is available from Cortex-R52 CPU1 (Source). Only read is available from Cortex-A55 Core3 (Target). Access from other CPUs except source and target is also read only.

MBXR1A3n register is used as mailbox from Cortex-R52 CPU1 to Cortex-A55 Core3.

47.3.3.23 MBXISETR1A3 : CR52 CPU1 to CA55 Core3 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x590

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR1A3_3S	MBX_INTR1A3_2S	MBX_INTR1A3_1S	MBX_INTR1A3_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR1A3_0S	Sets or indicates interrupt status flag (MBX_INTR1A30) of mailbox 0 from Cortex-R52 CPU1 to Cortex-A55 Core3. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR1A3_1S	Sets or indicates interrupt status flag (MBX_INTR1A31) of mailbox 1 from Cortex-R52 CPU1 to Cortex-A55 Core3. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR1A3_2S	Sets or indicates interrupt status flag (MBX_INTR1A32) of mailbox 2 from Cortex-R52 CPU1 to Cortex-A55 Core3. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR1A3_3S	Sets or indicates interrupt status flag (MBX_INTR1A33) of mailbox 3 from Cortex-R52 CPU1 to Cortex-A55 Core3. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU1 (Source). Only read is available from Cortex-A55 Core3 (Target). Access from other CPUs except source and target is also read only.

MBXISETR1A3 register is used to generate mailbox interrupt from Cortex-R52 CPU1 to Cortex-A55 Core3. MBX_INTR1A3 interrupt is generated as logical OR of MBX_INTR1A30, MBX_INTR1A31, MBX_INTR1A32, or MBX_INTR1A33 status flags.

47.3.3.24 MBXICLRR1A3 : CR52 CPU1 to CA55 Core3 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x594

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR1A3_3C	MBX_INTR1A3_2C	MBX_INTR1A3_1C	MBX_INTR1A3_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR1A3_0C	Clears or indicates interrupt status flag (MBX_INTR1A30) of mailbox 0 from Cortex-R52 CPU1 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR1A3_1C	Clears or indicates interrupt status flag (MBX_INTR1A31) of mailbox 1 from Cortex-R52 CPU1 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR1A3_2C	Clears or indicates interrupt status flag (MBX_INTR1A32) of mailbox 2 from Cortex-R52 CPU1 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR1A3_3C	Clears or indicates interrupt status flag (MBX_INTR1A33) of mailbox 3 from Cortex-R52 CPU1 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core3 (Target). Only read is available from Cortex-R52 CPU1 (Source). Access from other CPUs except source and target is also read only.

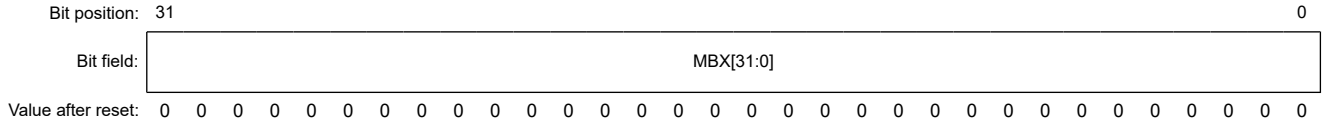
MBXICLRR1A3 register is used to clear mailbox interrupt from Cortex-R52 CPU1 to Cortex-A55 Core3. MBX_INTR1A3 interrupt is cleared when all the status flags are cleared.

47.3.4 Mailbox Registers from Cortex-A55 to Cortex-R52

47.3.4.1 MBXA0R0n : CA55 Core0 to CR52 CPU0 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x600 + 0x04 × n



Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core0 to Cortex-R52 CPU0	R/W*1

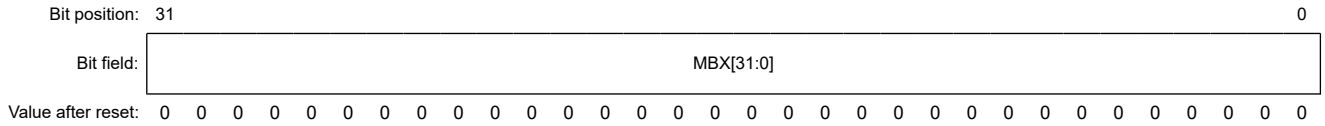
Note 1. Read and write is available from Cortex-A55 Core0 (Source). Only read is available from Cortex-R52 CPU0 (Target). Access from other CPUs except source and target is also read only.

MBXA0R0n register is used as mailbox from Cortex-A55 Core0 to Cortex-R52 CPU0.

47.3.4.2 MBXA1R0n : CA55 Core1 to CR52 CPU0 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x610 + 0x04 × n



Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core1 to Cortex-R52 CPU0	R/W*1

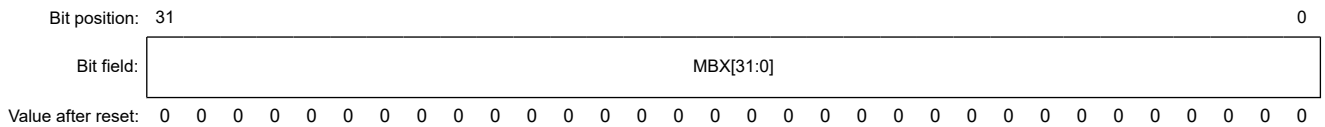
Note 1. Read and write is available from Cortex-A55 Core1 (Source). Only read is available from Cortex-R52 CPU0 (Target). Access from other CPUs except source and target is also read only.

MBXA1R0n register is used as mailbox from Cortex-A55 Core1 to Cortex-R52 CPU0.

47.3.4.3 MBXA2R0n : CA55 Core2 to CR52 CPU0 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x620 + 0x04 × n



Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core2 to Cortex-R52 CPU0	R/W*1

Note 1. Read and write is available from Cortex-A55 Core2 (Source). Only read is available from Cortex-R52 CPU0 (Target). Access from other CPUs except source and target is also read only.

MBXA2R0n register is used as mailbox from Cortex-A55 Core2 to Cortex-R52 CPU0.

47.3.4.4 MBXA3R0n : CA55 Core3 to CR52 CPU0 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x630 + 0x04 × n

Bit position:	31																												0
Bit field:	MBX[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core3 to Cortex-R52 CPU0	R/W*1

Note 1. Read and write is available from Cortex-A55 Core3 (Source). Only read is available from Cortex-R52 CPU0 (Target). Access from other CPUs except source and target is also read only.

MBXA3R0n register is used as mailbox from Cortex-A55 Core3 to Cortex-R52 CPU0.

47.3.4.5 MBXISETA0R0 : CA55 Core0 to CR52 CPU0 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x640

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA0R0_3S	MBX_INTA0R0_2S	MBX_INTA0R0_1S	MBX_INTA0R0_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA0R0_0S	Sets or indicates interrupt status flag (MBX_INTA0R00) of mailbox 0 from Cortex-A55 Core0 to Cortex-R52 CPU0. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA0R0_1S	Sets or indicates interrupt status flag (MBX_INTA0R01) of mailbox 1 from Cortex-A55 Core0 to Cortex-R52 CPU0. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA0R0_2S	Sets or indicates interrupt status flag (MBX_INTA0R02) of mailbox 2 from Cortex-A55 Core0 to Cortex-R52 CPU0. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1

Bit	Symbol	Function	R/W
3	MBX_INTA0R0_3S	Sets or indicates interrupt status flag (MBX_INTA0R03) of mailbox 3 from Cortex-A55 Core0 to Cortex-R52 CPU0. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core0 (Source). Only read is available from Cortex-R52 CPU0 (Target). Access from other CPUs except source and target is also read only.

MBXISETA0R0 register is used to generate mailbox interrupt from Cortex-A55 Core0 to Cortex-R52 CPU0. MBX_INTAR0 interrupt is generated as logical OR of the following 16 status flags.

MBX_INTA0R00, MBX_INTA0R01, MBX_INTA0R02, MBX_INTA0R03 in MBXISETA0R0

MBX_INTA1R00, MBX_INTA1R01, MBX_INTA1R02, MBX_INTA1R03 in MBXISETA1R0

MBX_INTA2R00, MBX_INTA2R01, MBX_INTA2R02, MBX_INTA2R03 in MBXISETA2R0

MBX_INTA3R00, MBX_INTA3R01, MBX_INTA3R02, MBX_INTA3R03 in MBXISETA3R0

47.3.4.6 MBXISETA1R0 : CA55 Core1 to CR52 CPU0 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x644

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA1R0_3S	MBX_INTA1R0_2S	MBX_INTA1R0_1S	MBX_INTA1R0_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA1R0_0S	Sets or indicates interrupt status flag (MBX_INTA1R00) of mailbox 0 from Cortex-A55 Core1 to Cortex-R52 CPU0. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA1R0_1S	Sets or indicates interrupt status flag (MBX_INTA1R01) of mailbox 1 from Cortex-A55 Core1 to Cortex-R52 CPU0. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA1R0_2S	Sets or indicates interrupt status flag (MBX_INTA1R02) of mailbox 2 from Cortex-A55 Core1 to Cortex-R52 CPU0. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1

Bit	Symbol	Function	R/W
3	MBX_INTA1R0_3S	Sets or indicates interrupt status flag (MBX_INTA1R03) of mailbox 3 from Cortex-A55 Core1 to Cortex-R52 CPU0. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core1 (Source). Only read is available from Cortex-R52 CPU0 (Target). Access from other CPUs except source and target is also read only.

MBXISETA1R0 register is used to generate mailbox interrupt from Cortex-A55 Core1 to Cortex-R52 CPU0. MBX_INTAR0 interrupt is generated as logical OR of the following 16 status flags.

MBX_INTA0R00, MBX_INTA0R01, MBX_INTA0R02, MBX_INTA0R03 in MBXISETA0R0

MBX_INTA1R00, MBX_INTA1R01, MBX_INTA1R02, MBX_INTA1R03 in MBXISETA1R0

MBX_INTA2R00, MBX_INTA2R01, MBX_INTA2R02, MBX_INTA2R03 in MBXISETA2R0

MBX_INTA3R00, MBX_INTA3R01, MBX_INTA3R02, MBX_INTA3R03 in MBXISETA3R0

47.3.4.7 MBXISETA2R0 : CA55 Core2 to CR52 CPU0 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x648

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA2R0_3S	MBX_INTA2R0_2S	MBX_INTA2R0_1S	MBX_INTA2R0_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA2R0_0S	Sets or indicates interrupt status flag (MBX_INTA2R00) of mailbox 0 from Cortex-A55 Core2 to Cortex-R52 CPU0. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA2R0_1S	Sets or indicates interrupt status flag (MBX_INTA2R01) of mailbox 1 from Cortex-A55 Core2 to Cortex-R52 CPU0. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA2R0_2S	Sets or indicates interrupt status flag (MBX_INTA2R02) of mailbox 2 from Cortex-A55 Core2 to Cortex-R52 CPU0. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1

Bit	Symbol	Function	R/W
3	MBX_INTA2R0_3S	Sets or indicates interrupt status flag (MBX_INTA2R03) of mailbox 3 from Cortex-A55 Core2 to Cortex-R52 CPU0. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core2 (Source). Only read is available from Cortex-R52 CPU0 (Target). Access from other CPUs except source and target is also read only.

MBXISETA2R0 register is used to generate mailbox interrupt from Cortex-A55 Core2 to Cortex-R52 CPU0. MBX_INTAR0 interrupt is generated as logical OR of the following 16 status flags.

MBX_INTA0R00, MBX_INTA0R01, MBX_INTA0R02, MBX_INTA0R03 in MBXISETA0R0

MBX_INTA1R00, MBX_INTA1R01, MBX_INTA1R02, MBX_INTA1R03 in MBXISETA1R0

MBX_INTA2R00, MBX_INTA2R01, MBX_INTA2R02, MBX_INTA2R03 in MBXISETA2R0

MBX_INTA3R00, MBX_INTA3R01, MBX_INTA3R02, MBX_INTA3R03 in MBXISETA3R0

47.3.4.8 MBXISETA3R0 : CA55 Core3 to CR52 CPU0 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x64C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA3R0_3S	MBX_INTA3R0_2S	MBX_INTA3R0_1S	MBX_INTA3R0_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA3R0_0S	Sets or indicates interrupt status flag (MBX_INTA3R00) of mailbox 0 from Cortex-A55 Core3 to Cortex-R52 CPU0. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA3R0_1S	Sets or indicates interrupt status flag (MBX_INTA3R01) of mailbox 1 from Cortex-A55 Core3 to Cortex-R52 CPU0. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA3R0_2S	Sets or indicates interrupt status flag (MBX_INTA3R02) of mailbox 2 from Cortex-A55 Core3 to Cortex-R52 CPU0. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1

Bit	Symbol	Function	R/W
3	MBX_INTA3R0_3S	Sets or indicates interrupt status flag (MBX_INTA3R03) of mailbox 3 from Cortex-A55 Core3 to Cortex-R52 CPU0. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core3 (Source). Only read is available from Cortex-R52 CPU0 (Target). Access from other CPUs except source and target is also read only.

MBXISETA3R0 register is used to generate mailbox interrupt from Cortex-A55 Core3 to Cortex-R52 CPU0. MBX_INTAR0 interrupt is generated as logical OR of the following 16 status flags.

MBX_INTA0R00, MBX_INTA0R01, MBX_INTA0R02, MBX_INTA0R03 in MBXISETA0R0

MBX_INTA1R00, MBX_INTA1R01, MBX_INTA1R02, MBX_INTA1R03 in MBXISETA1R0

MBX_INTA2R00, MBX_INTA2R01, MBX_INTA2R02, MBX_INTA2R03 in MBXISETA2R0

MBX_INTA3R00, MBX_INTA3R01, MBX_INTA3R02, MBX_INTA3R03 in MBXISETA3R0

47.3.4.9 MBXICLRAR0 : CA55 to CR52 CPU0 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x650

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MBX_INTA3R0_3C	MBX_INTA3R0_2C	MBX_INTA3R0_1C	MBX_INTA3R0_0C	MBX_INTA2R0_3C	MBX_INTA2R0_2C	MBX_INTA2R0_1C	MBX_INTA2R0_0C	MBX_INTA1R0_3C	MBX_INTA1R0_2C	MBX_INTA1R0_1C	MBX_INTA1R0_0C	MBX_INTA0R0_3C	MBX_INTA0R0_2C	MBX_INTA0R0_1C	MBX_INTA0R0_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA0R0_0C	Clears or indicates interrupt status flag (MBX_INTA0R00) of mailbox 0 from Cortex-A55 Core0 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA0R0_1C	Clears or indicates interrupt status flag (MBX_INTA0R01) of mailbox 1 from Cortex-A55 Core0 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA0R0_2C	Clears or indicates interrupt status flag (MBX_INTA0R02) of mailbox 2 from Cortex-A55 Core0 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1

Bit	Symbol	Function	R/W
3	MBX_INTA0R0_3C	Clears or indicates interrupt status flag (MBX_INTA0R03) of mailbox 3 from Cortex-A55 Core0 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
4	MBX_INTA1R0_0C	Clears or indicates interrupt status flag (MBX_INTA1R00) of mailbox 0 from Cortex-A55 Core1 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
5	MBX_INTA1R0_1C	Clears or indicates interrupt status flag (MBX_INTA1R01) of mailbox 1 from Cortex-A55 Core1 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
6	MBX_INTA1R0_2C	Clears or indicates interrupt status flag (MBX_INTA1R02) of mailbox 2 from Cortex-A55 Core1 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
7	MBX_INTA1R0_3C	Clears or indicates interrupt status flag (MBX_INTA1R03) of mailbox 3 from Cortex-A55 Core1 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
8	MBX_INTA2R0_0C	Clears or indicates interrupt status flag (MBX_INTA2R00) of mailbox 0 from Cortex-A55 Core2 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
9	MBX_INTA2R0_1C	Clears or indicates interrupt status flag (MBX_INTA2R01) of mailbox 1 from Cortex-A55 Core2 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
10	MBX_INTA2R0_2C	Clears or indicates interrupt status flag (MBX_INTA2R02) of mailbox 2 from Cortex-A55 Core2 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
11	MBX_INTA2R0_3C	Clears or indicates interrupt status flag (MBX_INTA2R03) of mailbox 3 from Cortex-A55 Core2 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1

Bit	Symbol	Function	R/W
12	MBX_INTA3R0_0C	Clears or indicates interrupt status flag (MBX_INTA3R00) of mailbox 0 from Cortex-A55 Core3 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
13	MBX_INTA3R0_1C	Clears or indicates interrupt status flag (MBX_INTA3R01) of mailbox 1 from Cortex-A55 Core3 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
14	MBX_INTA3R0_2C	Clears or indicates interrupt status flag (MBX_INTA3R02) of mailbox 2 from Cortex-A55 Core3 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
15	MBX_INTA3R0_3C	Clears or indicates interrupt status flag (MBX_INTA3R03) of mailbox 3 from Cortex-A55 Core3 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:16	—	These bits are read as 0. The write value should be 0.	R/W

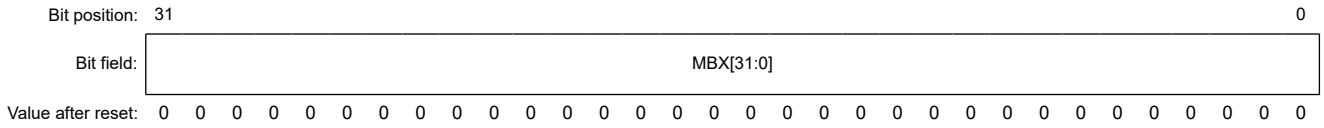
Note 1. Read and write is available from Cortex-R52 CPU0 (Target). Only read is available from Cortex-A55 Core0/1/2/3 (Source). Access from other CPUs except source and target is also read only.

MBXICLRAR0 register is used to clear mailbox interrupt from Cortex-A55 Core0/1/2/3 to Cortex-R52 CPU0. MBX_INTAR0 interrupt is cleared when all the status flags are cleared.

47.3.4.10 MBXA0R1n : CA55 Core0 to CR52 CPU1 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x680 + 0x04 × n



Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core0 to Cortex-R52 CPU1	R/W*1

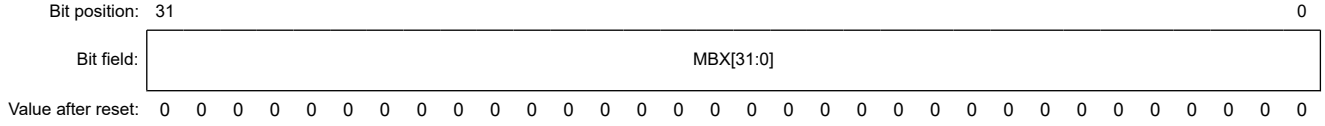
Note 1. Read and write is available from Cortex-A55 Core0 (Source). Only read is available from Cortex-R52 CPU1 (Target). Access from other CPUs except source and target is also read only.

MBXA0R1n register is used as mailbox from Cortex-A55 Core0 to Cortex-R52 CPU1.

47.3.4.11 MBXA1R1n : CA55 Core1 to CR52 CPU1 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x690 + 0x04 × n



Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core1 to Cortex-R52 CPU1	R/W*1

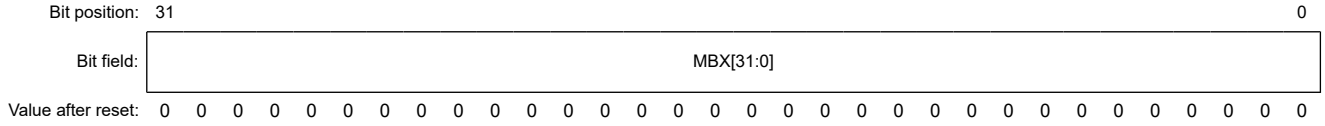
Note 1. Read and write is available from Cortex-A55 Core1 (Source). Only read is available from Cortex-R52 CPU1 (Target). Access from other CPUs except source and target is also read only.

MBXA1R1n register is used as mailbox from Cortex-A55 Core1 to Cortex-R52 CPU1.

47.3.4.12 MBXA2R1n : CA55 Core2 to CR52 CPU1 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x6A0 + 0x04 × n



Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core2 to Cortex-R52 CPU1	R/W*1

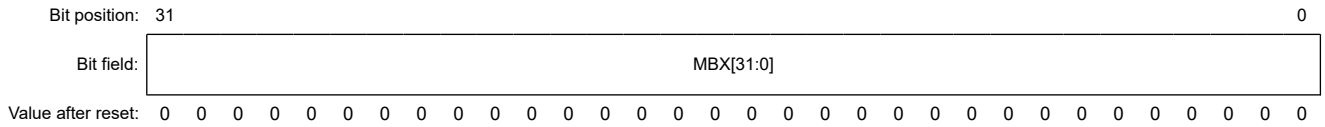
Note 1. Read and write is available from Cortex-A55 Core2 (Source). Only read is available from Cortex-R52 CPU1 (Target). Access from other CPUs except source and target is also read only.

MBXA2R1n register is used as mailbox from Cortex-A55 Core2 to Cortex-R52 CPU1.

47.3.4.13 MBXA3R1n : CA55 Core3 to CR52 CPU1 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x6B0 + 0x04 × n



Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core3 to Cortex-R52 CPU1	R/W*1

Note 1. Read and write is available from Cortex-A55 Core3 (Source). Only read is available from Cortex-R52 CPU1 (Target). Access from other CPUs except source and target is also read only.

MBXA3R1n register is used as mailbox from Cortex-A55 Core3 to Cortex-R52 CPU1.

47.3.4.14 MBXISETA0R1 : CA55 Core0 to CR52 CPU1 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x6C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA0R1_3S	MBX_INTA0R1_2S	MBX_INTA0R1_1S	MBX_INTA0R1_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA0R1_0S	Sets or indicates interrupt status flag (MBX_INTA0R10) of mailbox 0 from Cortex-A55 Core0 to Cortex-R52 CPU1. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA0R1_1S	Sets or indicates interrupt status flag (MBX_INTA0R11) of mailbox 1 from Cortex-A55 Core0 to Cortex-R52 CPU1. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA0R1_2S	Sets or indicates interrupt status flag (MBX_INTA0R12) of mailbox 2 from Cortex-A55 Core0 to Cortex-R52 CPU1. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA0R1_3S	Sets or indicates interrupt status flag (MBX_INTA0R13) of mailbox 3 from Cortex-A55 Core0 to Cortex-R52 CPU1. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core0 (Source). Only read is available from Cortex-R52 CPU1 (Target). Access from other CPUs except source and target is also read only.

MBXISETA0R1 register is used to generate mailbox interrupt from Cortex-A55 Core0 to Cortex-R52 CPU1.
MBX_INTAR1 interrupt is generated as logical OR of the following 16 status flags.

MBX_INTA0R10, MBX_INTA0R11, MBX_INTA0R12, MBX_INTA0R13 in MBXISETA0R1

MBX_INTA1R10, MBX_INTA1R11, MBX_INTA1R12, MBX_INTA1R13 in MBXISETA1R1

MBX_INTA2R10, MBX_INTA2R11, MBX_INTA2R12, MBX_INTA2R13 in MBXISETA2R1

MBX_INTA3R10, MBX_INTA3R11, MBX_INTA3R12, MBX_INTA3R13 in MBXISETA3R1

47.3.4.15 MBXISETA1R1 : CA55 Core1 to CR52 CPU1 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x6C4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA1R1_3S	MBX_INTA1R1_2S	MBX_INTA1R1_1S	MBX_INTA1R1_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA1R1_0S	Sets or indicates interrupt status flag (MBX_INTA1R10) of mailbox 0 from Cortex-A55 Core1 to Cortex-R52 CPU1. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA1R1_1S	Sets or indicates interrupt status flag (MBX_INTA1R11) of mailbox 1 from Cortex-A55 Core1 to Cortex-R52 CPU1. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA1R1_2S	Sets or indicates interrupt status flag (MBX_INTA1R12) of mailbox 2 from Cortex-A55 Core1 to Cortex-R52 CPU1. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA1R1_3S	Sets or indicates interrupt status flag (MBX_INTA1R13) of mailbox 3 from Cortex-A55 Core1 to Cortex-R52 CPU1. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core1 (Source). Only read is available from Cortex-R52 CPU1 (Target). Access from other CPUs except source and target is also read only.

MBXISETA1R1 register is used to generate mailbox interrupt from Cortex-A55 Core1 to Cortex-R52 CPU1.
MBX_INTAR1 interrupt is generated as logical OR of the following 16 status flags.

MBX_INTA0R10, MBX_INTA0R11, MBX_INTA0R12, MBX_INTA0R13 in MBXISETA0R1

MBX_INTA1R10, MBX_INTA1R11, MBX_INTA1R12, MBX_INTA1R13 in MBXISETA1R1

MBX_INTA2R10, MBX_INTA2R11, MBX_INTA2R12, MBX_INTA2R13 in MBXISETA2R1

MBX_INTA3R10, MBX_INTA3R11, MBX_INTA3R12, MBX_INTA3R13 in MBXISETA3R1

47.3.4.16 MBXISETA2R1 : CA55 Core2 to CR52 CPU1 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x6C8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA2R1_3S	MBX_INTA2R1_2S	MBX_INTA2R1_1S	MBX_INTA2R1_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA2R1_0S	Sets or indicates interrupt status flag (MBX_INTA2R10) of mailbox 0 from Cortex-A55 Core2 to Cortex-R52 CPU1. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA2R1_1S	Sets or indicates interrupt status flag (MBX_INTA2R11) of mailbox 1 from Cortex-A55 Core2 to Cortex-R52 CPU1. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA2R1_2S	Sets or indicates interrupt status flag (MBX_INTA2R12) of mailbox 2 from Cortex-A55 Core2 to Cortex-R52 CPU1. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA2R1_3S	Sets or indicates interrupt status flag (MBX_INTA2R13) of mailbox 3 from Cortex-A55 Core2 to Cortex-R52 CPU1. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core2 (Source). Only read is available from Cortex-R52 CPU1 (Target). Access from other CPUs except source and target is also read only.

MBXISETA2R1 register is used to generate mailbox interrupt from Cortex-A55 Core2 to Cortex-R52 CPU1.
MBX_INTAR1 interrupt is generated as logical OR of the following 16 status flags.

MBX_INTA0R10, MBX_INTA0R11, MBX_INTA0R12, MBX_INTA0R13 in MBXISETA0R1

MBX_INTA1R10, MBX_INTA1R11, MBX_INTA1R12, MBX_INTA1R13 in MBXISETA1R1

MBX_INTA2R10, MBX_INTA2R11, MBX_INTA2R12, MBX_INTA2R13 in MBXISETA2R1

MBX_INTA3R10, MBX_INTA3R11, MBX_INTA3R12, MBX_INTA3R13 in MBXISETA3R1

47.3.4.17 MBXISETA3R1 : CA55 Core3 to CR52 CPU1 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x6CC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA3R1_3S	MBX_INTA3R1_2S	MBX_INTA3R1_1S	MBX_INTA3R1_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA3R1_0S	Sets or indicates interrupt status flag (MBX_INTA3R10) of mailbox 0 from Cortex-A55 Core3 to Cortex-R52 CPU1. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA3R1_1S	Sets or indicates interrupt status flag (MBX_INTA3R11) of mailbox 1 from Cortex-A55 Core3 to Cortex-R52 CPU1. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA3R1_2S	Sets or indicates interrupt status flag (MBX_INTA3R12) of mailbox 2 from Cortex-A55 Core3 to Cortex-R52 CPU1. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA3R1_3S	Sets or indicates interrupt status flag (MBX_INTA3R13) of mailbox 3 from Cortex-A55 Core3 to Cortex-R52 CPU1. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core3 (Source). Only read is available from Cortex-R52 CPU1 (Target). Access from other CPUs except source and target is also read only.

MBXISETA3R1 register is used to generate mailbox interrupt from Cortex-A55 Core3 to Cortex-R52 CPU1.
MBX_INTAR1 interrupt is generated as logical OR of the following 16 status flags.

MBX_INTA0R10, MBX_INTA0R11, MBX_INTA0R12, MBX_INTA0R13 in MBXISETA0R1

MBX_INTA1R10, MBX_INTA1R11, MBX_INTA1R12, MBX_INTA1R13 in MBXISETA1R1

MBX_INTA2R10, MBX_INTA2R11, MBX_INTA2R12, MBX_INTA2R13 in MBXISETA2R1

MBX_INTA3R10, MBX_INTA3R11, MBX_INTA3R12, MBX_INTA3R13 in MBXISETA3R1

47.3.4.18 MBXICLRAR1 : CA55 to CR52 CPU1 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x6D0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MBX_INTA3R1_3C	MBX_INTA3R1_2C	MBX_INTA3R1_1C	MBX_INTA3R1_0C	MBX_INTA2R1_3C	MBX_INTA2R1_2C	MBX_INTA2R1_1C	MBX_INTA2R1_0C	MBX_INTA1R1_3C	MBX_INTA1R1_2C	MBX_INTA1R1_1C	MBX_INTA1R1_0C	MBX_INTA0R1_3C	MBX_INTA0R1_2C	MBX_INTA0R1_1C	MBX_INTA0R1_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA0R1_0C	Clears or indicates interrupt status flag (MBX_INTA0R10) of mailbox 0 from Cortex-A55 Core0 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA0R1_1C	Clears or indicates interrupt status flag (MBX_INTA0R11) of mailbox 1 from Cortex-A55 Core0 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA0R1_2C	Clears or indicates interrupt status flag (MBX_INTA0R12) of mailbox 2 from Cortex-A55 Core0 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA0R1_3C	Clears or indicates interrupt status flag (MBX_INTA0R13) of mailbox 3 from Cortex-A55 Core0 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
4	MBX_INTA1R1_0C	Clears or indicates interrupt status flag (MBX_INTA1R10) of mailbox 0 from Cortex-A55 Core1 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
5	MBX_INTA1R1_1C	Clears or indicates interrupt status flag (MBX_INTA1R11) of mailbox 1 from Cortex-A55 Core1 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1

Bit	Symbol	Function	R/W
6	MBX_INTA1R1_2C	Clears or indicates interrupt status flag (MBX_INTA1R12) of mailbox 2 from Cortex-A55 Core1 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
7	MBX_INTA1R1_3C	Clears or indicates interrupt status flag (MBX_INTA1R13) of mailbox 3 from Cortex-A55 Core1 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
8	MBX_INTA2R1_0C	Clears or indicates interrupt status flag (MBX_INTA2R10) of mailbox 0 from Cortex-A55 Core2 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
9	MBX_INTA2R1_1C	Clears or indicates interrupt status flag (MBX_INTA2R11) of mailbox 1 from Cortex-A55 Core2 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
10	MBX_INTA2R1_2C	Clears or indicates interrupt status flag (MBX_INTA2R12) of mailbox 2 from Cortex-A55 Core2 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
11	MBX_INTA2R1_3C	Clears or indicates interrupt status flag (MBX_INTA2R13) of mailbox 3 from Cortex-A55 Core2 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
12	MBX_INTA3R1_0C	Clears or indicates interrupt status flag (MBX_INTA3R10) of mailbox 0 from Cortex-A55 Core3 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
13	MBX_INTA3R1_1C	Clears or indicates interrupt status flag (MBX_INTA3R11) of mailbox 1 from Cortex-A55 Core3 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
14	MBX_INTA3R1_2C	Clears or indicates interrupt status flag (MBX_INTA3R12) of mailbox 2 from Cortex-A55 Core3 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1

Bit	Symbol	Function	R/W
15	MBX_INTA3R1_3C	Clears or indicates interrupt status flag (MBX_INTA3R13) of mailbox 3 from Cortex-A55 Core3 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU1 (Target). Only read is available from Cortex-A55 Core0/1/2/3 (Source). Access from other CPUs except source and target is also read only.

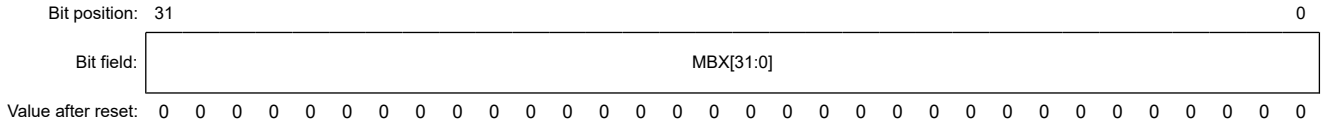
MBXICLRAR1 register is used to clear mailbox interrupt from Cortex-A55 Core0/1/2/3 to Cortex-R52 CPU1. MBX_INTAR1 interrupt is cleared when all the status flags are cleared.

47.3.5 Mailbox Registers between Cortex-R52 CPU0 and CPU1

47.3.5.1 MBXR0R1n : CR52 CPU0 to CR52 CPU1 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x700 + 0x04 × n



Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-R52 CPU0 to Cortex-R52 CPU1	R/W*1

Note 1. Read and write is available from Cortex-R52 CPU0 (Source). Only read is available from Cortex-R52 CPU1 (Target). Access from other CPUs except source and target is also read only.

MBXR0R1n register is used as mailbox from Cortex-R52 CPU0 to Cortex-R52 CPU1.

47.3.5.2 MBXISETR0R1 : CR52 CPU0 to CR52 CPU1 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x710

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR0R1_3S	MBX_INTR0R1_2S	MBX_INTR0R1_1S	MBX_INTR0R1_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR0R1_0S	Sets or indicates interrupt status flag (MBX_INTR0R10) of mailbox 0 from Cortex-R52 CPU0 to Cortex-R52 CPU1. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1

Bit	Symbol	Function	R/W
1	MBX_INTR0R1_1S	Sets or indicates interrupt status flag (MBX_INTR0R11) of mailbox 1 from Cortex-R52 CPU0 to Cortex-R52 CPU1. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR0R1_2S	Sets or indicates interrupt status flag (MBX_INTR0R12) of mailbox 2 from Cortex-R52 CPU0 to Cortex-R52 CPU1. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR0R1_3S	Sets or indicates interrupt status flag (MBX_INTR0R13) of mailbox 3 from Cortex-R52 CPU0 to Cortex-R52 CPU1. Write from Cortex-R52 CPU0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU0 (Source). Only read is available from Cortex-R52 CPU1 (Target). Access from other CPUs except source and target is also read only.

MBXISETR0R1 register is used to generate mailbox interrupt from Cortex-R52 CPU0 to Cortex-R52 CPU1. MBX_INTR0R1 interrupt is generated as logical OR of MBX_INTR0R10, MBX_INTR0R11, MBX_INTR0R12, or MBX_INTR0R13 status flags.

47.3.5.3 MBXICLRR0R1 : CR52 CPU0 to CR52 CPU1 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x714

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR0R1_3C	MBX_INTR0R1_2C	MBX_INTR0R1_1C	MBX_INTR0R1_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR0R1_0C	Clears or indicates interrupt status flag (MBX_INTR0R10) of mailbox 0 from Cortex-R52 CPU0 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR0R1_1C	Clears or indicates interrupt status flag (MBX_INTR0R11) of mailbox 1 from Cortex-R52 CPU0 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1

Bit	Symbol	Function	R/W
2	MBX_INTR0R1_2C	Clears or indicates interrupt status flag (MBX_INTR0R12) of mailbox 2 from Cortex-R52 CPU0 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR0R1_3C	Clears or indicates interrupt status flag (MBX_INTR0R13) of mailbox 3 from Cortex-R52 CPU0 to Cortex-R52 CPU1. Write from Cortex-R52 CPU1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU1 (Target). Only read is available from Cortex-R52 CPU0 (Source). Access from other CPUs except source and target is also read only.

MBXICLRR0R1 register is used to clear mailbox interrupt from Cortex-R52 CPU0 to Cortex-R52 CPU1. MBX_INTR0R1 interrupt is cleared when all the status flags are cleared.

47.3.5.4 MBXR1R0n : CR52 CPU1 to CR52 CPU0 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x780 + 0x04 × n

Bit position:	31																													0
Bit field:	MBX[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-R52 CPU1 to Cortex-R52 CPU0	R/W*1

Note 1. Read and write is available from Cortex-R52 CPU1 (Source). Only read is available from Cortex-R52 CPU0 (Target). Access from other CPUs except source and target is also read only.

MBXR1R0n register is used as mailbox from Cortex-R52 CPU1 to Cortex-R52 CPU0.

47.3.5.5 MBXISETR1R0 : CR52 CPU1 to CR52 CPU0 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x790

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR1R0_3S	MBX_INTR1R0_2S	MBX_INTR1R0_1S	MBX_INTR1R0_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR1R0_0S	Sets or indicates interrupt status flag (MBX_INTR1R00) of mailbox 0 from Cortex-R52 CPU1 to Cortex-R52 CPU0. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTR1R0_1S	Sets or indicates interrupt status flag (MBX_INTR1R01) of mailbox 1 from Cortex-R52 CPU1 to Cortex-R52 CPU0. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR1R0_2S	Sets or indicates interrupt status flag (MBX_INTR1R02) of mailbox 2 from Cortex-R52 CPU1 to Cortex-R52 CPU0. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR1R0_3S	Sets or indicates interrupt status flag (MBX_INTR1R03) of mailbox 3 from Cortex-R52 CPU1 to Cortex-R52 CPU0. Write from Cortex-R52 CPU1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU1 (Source). Only read is available from Cortex-R52 CPU0 (Target). Access from other CPUs except source and target is also read only.

MBXISETR1R0 register is used to generate mailbox interrupt from Cortex-R52 CPU1 to Cortex-R52 CPU0. MBX_INTR1R0 interrupt is generated as logical OR of MBX_INTR1R00, MBX_INTR1R01, MBX_INTR1R02, or MBX_INTR1R03 status flags.

47.3.5.6 MBXICLRR1R0 : CR52 CPU1 to CR52 CPU0 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x794

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTR1R0_3C	MBX_INTR1R0_2C	MBX_INTR1R0_1C	MBX_INTR1R0_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTR1R0_0C	Clears or indicates interrupt status flag (MBX_INTR1R00) of mailbox 0 from Cortex-R52 CPU1 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1

Bit	Symbol	Function	R/W
1	MBX_INTR1R0_1C	Clears or indicates interrupt status flag (MBX_INTR1R01) of mailbox 1 from Cortex-R52 CPU1 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTR1R0_2C	Clears or indicates interrupt status flag (MBX_INTR1R02) of mailbox 2 from Cortex-R52 CPU1 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTR1R0_3C	Clears or indicates interrupt status flag (MBX_INTR1R03) of mailbox 3 from Cortex-R52 CPU1 to Cortex-R52 CPU0. Write from Cortex-R52 CPU0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-R52 CPU0 (Target). Only read is available from Cortex-R52 CPU1 (Source). Access from other CPUs except source and target is also read only.

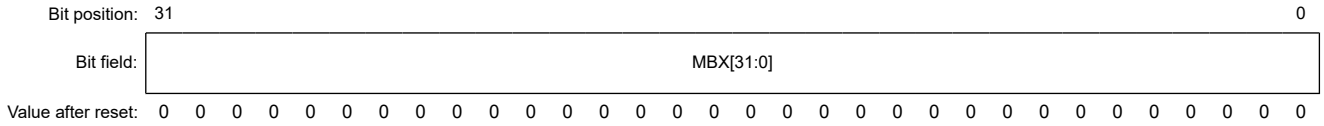
MBXICLRR1R0 register is used to clear mailbox interrupt from Cortex-R52 CPU1 to Cortex-R52 CPU0. MBX_INTR1R0 interrupt is cleared when all the status flags are cleared.

47.3.6 Mailbox Registers among Cortex-A55 Cores

47.3.6.1 MBXA0A1n : CA55 Core0 to CA55 Core1 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x800 + 0x04 × n



Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core0 to Cortex-A55 Core1	R/W*1

Note 1. Read and write is available from Cortex-A55 Core0 (Source). Only read is available from Cortex-A55 Core1 (Target). Access from other CPUs except source and target is also read only.

MBXA0A1n register is used as mailbox from Cortex-A55 Core0 to Cortex-A55 Core1.

47.3.6.2 MBXISETA0A1 : CA55 Core0 to CA55 Core1 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x810

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA0A1_3S	MBX_INTA0A1_2S	MBX_INTA0A1_1S	MBX_INTA0A1_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA0A1_0S	Sets or indicates interrupt status flag (MBX_INTA0A10) of mailbox 0 from Cortex-A55 Core0 to Cortex-A55 Core1. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA0A1_1S	Sets or indicates interrupt status flag (MBX_INTA0A11) of mailbox 1 from Cortex-A55 Core0 to Cortex-A55 Core1. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA0A1_2S	Sets or indicates interrupt status flag (MBX_INTA0A12) of mailbox 2 from Cortex-A55 Core0 to Cortex-A55 Core1. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA0A1_3S	Sets or indicates interrupt status flag (MBX_INTA0A13) of mailbox 3 from Cortex-A55 Core0 to Cortex-A55 Core1. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core0 (Source). Only read is available from Cortex-A55 Core1 (Target). Access from other CPUs except source and target is also read only.

MBXISETA0A1 register is used to generate mailbox interrupt from Cortex-A55 Core0 to Cortex-A55 Core1. MBX_INTA0A1 interrupt is generated as logical OR of MBX_INTA0A10, MBX_INTA0A11, MBX_INTA0A12, or MBX_INTA0A13 status flags.

47.3.6.3 MBXICLRA0A1 : CA55 Core0 to CA55 Core1 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x814

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA0A1_3C	MBX_INTA0A1_2C	MBX_INTA0A1_1C	MBX_INTA0A1_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA0A1_0C	Clears or indicates interrupt status flag (MBX_INTA0A10) of mailbox 0 from Cortex-A55 Core0 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA0A1_1C	Clears or indicates interrupt status flag (MBX_INTA0A11) of mailbox 1 from Cortex-A55 Core0 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA0A1_2C	Clears or indicates interrupt status flag (MBX_INTA0A12) of mailbox 2 from Cortex-A55 Core0 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA0A1_3C	Clears or indicates interrupt status flag (MBX_INTA0A13) of mailbox 3 from Cortex-A55 Core0 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core1 (Target). Only read is available from Cortex-A55 Core0 (Source). Access from other CPUs except source and target is also read only.

MBXICLRA0A1 register is used to clear mailbox interrupt from Cortex-A55 Core0 to Cortex-A55 Core1. MBX_INTA0A1 interrupt is cleared when all the status flags are cleared.

47.3.6.4 MBXA0A2n : CA55 Core0 to CA55 Core2 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x880 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core0 to Cortex-A55 Core2	R/W*1

Note 1. Read and write is available from Cortex-A55 Core0 (Source). Only read is available from Cortex-A55 Core2 (Target). Access from other CPUs except source and target is also read only.

MBXA0A2n register is used as mailbox from Cortex-A55 Core0 to Cortex-A55 Core2.

47.3.6.5 MBXISETA0A2 : CA55 Core0 to CA55 Core2 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x890

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA0A2_3S	MBX_INTA0A2_2S	MBX_INTA0A2_1S	MBX_INTA0A2_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA0A2_0S	Sets or indicates interrupt status flag (MBX_INTA0A20) of mailbox 0 from Cortex-A55 Core0 to Cortex-A55 Core2. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA0A2_1S	Sets or indicates interrupt status flag (MBX_INTA0A21) of mailbox 1 from Cortex-A55 Core0 to Cortex-A55 Core2. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA0A2_2S	Sets or indicates interrupt status flag (MBX_INTA0A22) of mailbox 2 from Cortex-A55 Core0 to Cortex-A55 Core2. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA0A2_3S	Sets or indicates interrupt status flag (MBX_INTA0A23) of mailbox 3 from Cortex-A55 Core0 to Cortex-A55 Core2. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core0 (Source). Only read is available from Cortex-A55 Core2 (Target). Access from other CPUs except source and target is also read only.

MBXISETA0A2 register is used to generate mailbox interrupt from Cortex-A55 Core0 to Cortex-A55 Core2. MBX_INTA0A2 interrupt is generated as logical OR of MBX_INTA0A20, MBX_INTA0A21, MBX_INTA0A22, or MBX_INTA0A23 status flags.

47.3.6.6 MBXICLRA0A2 : CA55 Core0 to CA55 Core2 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x894

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA0A2_3C	MBX_INTA0A2_2C	MBX_INTA0A2_1C	MBX_INTA0A2_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA0A2_0C	Clears or indicates interrupt status flag (MBX_INTA0A20) of mailbox 0 from Cortex-A55 Core0 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA0A2_1C	Clears or indicates interrupt status flag (MBX_INTA0A21) of mailbox 1 from Cortex-A55 Core0 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA0A2_2C	Clears or indicates interrupt status flag (MBX_INTA0A22) of mailbox 2 from Cortex-A55 Core0 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA0A2_3C	Clears or indicates interrupt status flag (MBX_INTA0A23) of mailbox 3 from Cortex-A55 Core0 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core2 (Target). Only read is available from Cortex-A55 Core0 (Source). Access from other CPUs except source and target is also read only.

MBXICLRA0A2 register is used to clear mailbox interrupt from Cortex-A55 Core0 to Cortex-A55 Core2. MBX_INTA0A2 interrupt is cleared when all the status flags are cleared.

47.3.6.7 MBXA0A3n : CA55 Core0 to CA55 Core3 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x900 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core0 to Cortex-A55 Core3	R/W*1

Note 1. Read and write is available from Cortex-A55 Core0 (Source). Only read is available from Cortex-A55 Core3 (Target). Access from other CPUs except source and target is also read only.

MBXA0A3n register is used as mailbox from Cortex-A55 Core0 to Cortex-A55 Core3.

47.3.6.8 MBXISETA0A3 : CA55 Core0 to CA55 Core3 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x910

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA0A3_3S	MBX_INTA0A3_2S	MBX_INTA0A3_1S	MBX_INTA0A3_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA0A3_0S	Sets or indicates interrupt status flag (MBX_INTA0A30) of mailbox 0 from Cortex-A55 Core0 to Cortex-A55 Core3. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA0A3_1S	Sets or indicates interrupt status flag (MBX_INTA0A31) of mailbox 1 from Cortex-A55 Core0 to Cortex-A55 Core3. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA0A3_2S	Sets or indicates interrupt status flag (MBX_INTA0A32) of mailbox 2 from Cortex-A55 Core0 to Cortex-A55 Core3. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA0A3_3S	Sets or indicates interrupt status flag (MBX_INTA0A33) of mailbox 3 from Cortex-A55 Core0 to Cortex-A55 Core3. Write from Cortex-A55 Core0 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core0 (Source). Only read is available from Cortex-A55 Core3 (Target). Access from other CPUs except source and target is also read only.

MBXISETA0A3 register is used to generate mailbox interrupt from Cortex-A55 Core0 to Cortex-A55 Core3. MBX_INTA0A3 interrupt is generated as logical OR of MBX_INTA0A30, MBX_INTA0A31, MBX_INTA0A32, or MBX_INTA0A33 status flags.

47.3.6.9 MBXICLRA0A3 : CA55 Core0 to CA55 Core3 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x914

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA0A3_3C	MBX_INTA0A3_2C	MBX_INTA0A3_1C	MBX_INTA0A3_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA0A3_0C	Clears or indicates interrupt status flag (MBX_INTA0A30) of mailbox 0 from Cortex-A55 Core0 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA0A3_1C	Clears or indicates interrupt status flag (MBX_INTA0A31) of mailbox 1 from Cortex-A55 Core0 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA0A3_2C	Clears or indicates interrupt status flag (MBX_INTA0A32) of mailbox 2 from Cortex-A55 Core0 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA0A3_3C	Clears or indicates interrupt status flag (MBX_INTA0A33) of mailbox 3 from Cortex-A55 Core0 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core3 (Target). Only read is available from Cortex-A55 Core0 (Source). Access from other CPUs except source and target is also read only.

MBXICLRA0A3 register is used to clear mailbox interrupt from Cortex-A55 Core0 to Cortex-A55 Core3. MBX_INTA0A3 interrupt is cleared when all the status flags are cleared.

47.3.6.10 MBXA1A0n : CA55 Core1 to CA55 Core0 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0x980 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core1 to Cortex-A55 Core0	R/W*1

Note 1. Read and write is available from Cortex-A55 Core1 (Source). Only read is available from Cortex-A55 Core0 (Target). Access from other CPUs except source and target is also read only.

MBXA1A0n register is used as mailbox from Cortex-A55 Core1 to Cortex-A55 Core0.

47.3.6.11 MBXISETA1A0 : CA55 Core1 to CA55 Core0 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x990

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA1A0_3S	MBX_INTA1A0_2S	MBX_INTA1A0_1S	MBX_INTA1A0_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA1A0_0S	Sets or indicates interrupt status flag (MBX_INTA1A00) of mailbox 0 from Cortex-A55 Core1 to Cortex-A55 Core0. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA1A0_1S	Sets or indicates interrupt status flag (MBX_INTA1A01) of mailbox 1 from Cortex-A55 Core1 to Cortex-A55 Core0. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA1A0_2S	Sets or indicates interrupt status flag (MBX_INTA1A02) of mailbox 2 from Cortex-A55 Core1 to Cortex-A55 Core0. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA1A0_3S	Sets or indicates interrupt status flag (MBX_INTA1A03) of mailbox 3 from Cortex-A55 Core1 to Cortex-A55 Core0. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core1 (Source). Only read is available from Cortex-A55 Core0 (Target). Access from other CPUs except source and target is also read only.

MBXISETA1A0 register is used to generate mailbox interrupt from Cortex-A55 Core1 to Cortex-A55 Core0. MBX_INTA1A0 interrupt is generated as logical OR of MBX_INTA1A00, MBX_INTA1A01, MBX_INTA1A02, or MBX_INTA1A03 status flags.

47.3.6.12 MBXICLRA1A0 : CA55 Core1 to CA55 Core0 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0x994

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA1A0_3C	MBX_INTA1A0_2C	MBX_INTA1A0_1C	MBX_INTA1A0_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA1A0_0C	Clears or indicates interrupt status flag (MBX_INTA1A00) of mailbox 0 from Cortex-A55 Core1 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA1A0_1C	Clears or indicates interrupt status flag (MBX_INTA1A01) of mailbox 1 from Cortex-A55 Core1 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA1A0_2C	Clears or indicates interrupt status flag (MBX_INTA1A02) of mailbox 2 from Cortex-A55 Core1 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA1A0_3C	Clears or indicates interrupt status flag (MBX_INTA1A03) of mailbox 3 from Cortex-A55 Core1 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core0 (Target). Only read is available from Cortex-A55 Core1 (Source). Access from other CPUs except source and target is also read only.

MBXICLRA1A0 register is used to clear mailbox interrupt from Cortex-A55 Core1 to Cortex-A55 Core0. MBX_INTA1A0 interrupt is cleared when all the status flags are cleared.

47.3.6.13 MBXA1A2n : CA55 Core1 to CA55 Core2 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0xA00 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core1 to Cortex-A55 Core2	R/W*1

Note 1. Read and write is available from Cortex-A55 Core1 (Source). Only read is available from Cortex-A55 Core2 (Target). Access from other CPUs except source and target is also read only.

MBXA1A2n register is used as mailbox from Cortex-A55 Core1 to Cortex-A55 Core2.

47.3.6.14 MBXISETA1A2 : CA55 Core1 to CA55 Core2 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xA10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA1A2_3S	MBX_INTA1A2_2S	MBX_INTA1A2_1S	MBX_INTA1A2_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA1A2_0S	Sets or indicates interrupt status flag (MBX_INTA1A20) of mailbox 0 from Cortex-A55 Core1 to Cortex-A55 Core2. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA1A2_1S	Sets or indicates interrupt status flag (MBX_INTA1A21) of mailbox 1 from Cortex-A55 Core1 to Cortex-A55 Core2. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA1A2_2S	Sets or indicates interrupt status flag (MBX_INTA1A22) of mailbox 2 from Cortex-A55 Core1 to Cortex-A55 Core2. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA1A2_3S	Sets or indicates interrupt status flag (MBX_INTA1A23) of mailbox 3 from Cortex-A55 Core1 to Cortex-A55 Core2. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core1 (Source). Only read is available from Cortex-A55 Core2 (Target). Access from other CPUs except source and target is also read only.

MBXISETA1A2 register is used to generate mailbox interrupt from Cortex-A55 Core1 to Cortex-A55 Core2. MBX_INTA1A2 interrupt is generated as logical OR of MBX_INTA1A20, MBX_INTA1A21, MBX_INTA1A22, or MBX_INTA1A23 status flags.

47.3.6.15 MBXICLRA1A2 : CA55 Core1 to CA55 Core2 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xA14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA1A2_3C	MBX_INTA1A2_2C	MBX_INTA1A2_1C	MBX_INTA1A2_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA1A2_0C	Clears or indicates interrupt status flag (MBX_INTA1A20) of mailbox 0 from Cortex-A55 Core1 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA1A2_1C	Clears or indicates interrupt status flag (MBX_INTA1A21) of mailbox 1 from Cortex-A55 Core1 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA1A2_2C	Clears or indicates interrupt status flag (MBX_INTA1A22) of mailbox 2 from Cortex-A55 Core1 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA1A2_3C	Clears or indicates interrupt status flag (MBX_INTA1A23) of mailbox 3 from Cortex-A55 Core1 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core2 (Target). Only read is available from Cortex-A55 Core1 (Source). Access from other CPUs except source and target is also read only.

MBXICLRA1A2 register is used to clear mailbox interrupt from Cortex-A55 Core1 to Cortex-A55 Core2. MBX_INTA1A2 interrupt is cleared when all the status flags are cleared.

47.3.6.16 MBXA1A3n : CA55 Core1 to CA55 Core3 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0xA80 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core1 to Cortex-A55 Core3	R/W*1

Note 1. Read and write is available from Cortex-A55 Core1 (Source). Only read is available from Cortex-A55 Core3 (Target). Access from other CPUs except source and target is also read only.

MBXA1A3n register is used as mailbox from Cortex-A55 Core1 to Cortex-A55 Core3.

47.3.6.17 MBXISETA1A3 : CA55 Core1 to CA55 Core3 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xA90

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA1A3_3S	MBX_INTA1A3_2S	MBX_INTA1A3_1S	MBX_INTA1A3_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA1A3_0S	Sets or indicates interrupt status flag (MBX_INTA1A30) of mailbox 0 from Cortex-A55 Core1 to Cortex-A55 Core3. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA1A3_1S	Sets or indicates interrupt status flag (MBX_INTA1A31) of mailbox 1 from Cortex-A55 Core1 to Cortex-A55 Core3. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA1A3_2S	Sets or indicates interrupt status flag (MBX_INTA1A32) of mailbox 2 from Cortex-A55 Core1 to Cortex-A55 Core3. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA1A3_3S	Sets or indicates interrupt status flag (MBX_INTA1A33) of mailbox 3 from Cortex-A55 Core1 to Cortex-A55 Core3. Write from Cortex-A55 Core1 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core1 (Source). Only read is available from Cortex-A55 Core3 (Target). Access from other CPUs except source and target is also read only.

MBXISETA1A3 register is used to generate mailbox interrupt from Cortex-A55 Core1 to Cortex-A55 Core3. MBX_INTA1A3 interrupt is generated as logical OR of MBX_INTA1A30, MBX_INTA1A31, MBX_INTA1A32, or MBX_INTA1A33 status flags.

47.3.6.18 MBXICLRA1A3 : CA55 Core1 to CA55 Core3 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xA94

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA1A3_3C	MBX_INTA1A3_2C	MBX_INTA1A3_1C	MBX_INTA1A3_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA1A3_0C	Clears or indicates interrupt status flag (MBX_INTA1A30) of mailbox 0 from Cortex-A55 Core1 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA1A3_1C	Clears or indicates interrupt status flag (MBX_INTA1A31) of mailbox 1 from Cortex-A55 Core1 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA1A3_2C	Clears or indicates interrupt status flag (MBX_INTA1A32) of mailbox 2 from Cortex-A55 Core1 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA1A3_3C	Clears or indicates interrupt status flag (MBX_INTA1A33) of mailbox 3 from Cortex-A55 Core1 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core3 (Target). Only read is available from Cortex-A55 Core1 (Source). Access from other CPUs except source and target is also read only.

MBXICLRA1A3 register is used to clear mailbox interrupt from Cortex-A55 Core1 to Cortex-A55 Core3. MBX_INTA1A3 interrupt is cleared when all the status flags are cleared.

47.3.6.19 MBXA2A0n : CA55 Core2 to CA55 Core0 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0xB00 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core2 to Cortex-A55 Core0	R/W*1

Note 1. Read and write is available from Cortex-A55 Core2 (Source). Only read is available from Cortex-A55 Core0 (Target). Access from other CPUs except source and target is also read only.

MBXA2A0n register is used as mailbox from Cortex-A55 Core2 to Cortex-A55 Core0.

47.3.6.20 MBXISETA2A0 : CA55 Core2 to CA55 Core0 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xB10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA2A0_3S	MBX_INTA2A0_2S	MBX_INTA2A0_1S	MBX_INTA2A0_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA2A0_0S	Sets or indicates interrupt status flag (MBX_INTA2A00) of mailbox 0 from Cortex-A55 Core2 to Cortex-A55 Core0. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA2A0_1S	Sets or indicates interrupt status flag (MBX_INTA2A01) of mailbox 1 from Cortex-A55 Core2 to Cortex-A55 Core0. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA2A0_2S	Sets or indicates interrupt status flag (MBX_INTA2A02) of mailbox 2 from Cortex-A55 Core2 to Cortex-A55 Core0. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA2A0_3S	Sets or indicates interrupt status flag (MBX_INTA2A03) of mailbox 3 from Cortex-A55 Core2 to Cortex-A55 Core0. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core2 (Source). Only read is available from Cortex-A55 Core0 (Target). Access from other CPUs except source and target is also read only.

MBXISETA2A0 register is used to generate mailbox interrupt from Cortex-A55 Core2 to Cortex-A55 Core0. MBX_INTA2A0 interrupt is generated as logical OR of MBX_INTA2A00, MBX_INTA2A01, MBX_INTA2A02, or MBX_INTA2A03 status flags.

47.3.6.21 MBXICLRA2A0 : CA55 Core2 to CA55 Core0 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xB14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA2A0_3C	MBX_INTA2A0_2C	MBX_INTA2A0_1C	MBX_INTA2A0_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA2A0_0C	Clears or indicates interrupt status flag (MBX_INTA2A00) of mailbox 0 from Cortex-A55 Core2 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA2A0_1C	Clears or indicates interrupt status flag (MBX_INTA2A01) of mailbox 1 from Cortex-A55 Core2 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA2A0_2C	Clears or indicates interrupt status flag (MBX_INTA2A02) of mailbox 2 from Cortex-A55 Core2 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA2A0_3C	Clears or indicates interrupt status flag (MBX_INTA2A03) of mailbox 3 from Cortex-A55 Core2 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core0 (Target). Only read is available from Cortex-A55 Core2 (Source). Access from other CPUs except source and target is also read only.

MBXICLRA2A0 register is used to clear mailbox interrupt from Cortex-A55 Core2 to Cortex-A55 Core0. MBX_INTA2A0 interrupt is cleared when all the status flags are cleared.

47.3.6.22 MBXA2A1n : CA55 Core2 to CA55 Core1 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0xB80 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core2 to Cortex-A55 Core1	R/W*1

Note 1. Read and write is available from Cortex-A55 Core2 (Source). Only read is available from Cortex-A55 Core1 (Target). Access from other CPUs except source and target is also read only.

MBXA2A1n register is used as mailbox from Cortex-A55 Core2 to Cortex-A55 Core1.

47.3.6.23 MBXISETA2A1 : CA55 Core2 to CA55 Core1 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xB90

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA2A1_3S	MBX_INTA2A1_2S	MBX_INTA2A1_1S	MBX_INTA2A1_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA2A1_0S	Sets or indicates interrupt status flag (MBX_INTA2A10) of mailbox 0 from Cortex-A55 Core2 to Cortex-A55 Core1. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA2A1_1S	Sets or indicates interrupt status flag (MBX_INTA2A11) of mailbox 1 from Cortex-A55 Core2 to Cortex-A55 Core1. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA2A1_2S	Sets or indicates interrupt status flag (MBX_INTA2A12) of mailbox 2 from Cortex-A55 Core2 to Cortex-A55 Core1. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA2A1_3S	Sets or indicates interrupt status flag (MBX_INTA2A13) of mailbox 3 from Cortex-A55 Core2 to Cortex-A55 Core1. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core2 (Source). Only read is available from Cortex-A55 Core1 (Target). Access from other CPUs except source and target is also read only.

MBXISETA2A1 register is used to generate mailbox interrupt from Cortex-A55 Core2 to Cortex-A55 Core1. MBX_INTA2A1 interrupt is generated as logical OR of MBX_INTA2A10, MBX_INTA2A11, MBX_INTA2A12, or MBX_INTA2A13 status flags.

47.3.6.24 MBXICLRA2A1 : CA55 Core2 to CA55 Core1 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xB94

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA2A1_3C	MBX_INTA2A1_2C	MBX_INTA2A1_1C	MBX_INTA2A1_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA2A1_0C	Clears or indicates interrupt status flag (MBX_INTA2A10) of mailbox 0 from Cortex-A55 Core2 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA2A1_1C	Clears or indicates interrupt status flag (MBX_INTA2A11) of mailbox 1 from Cortex-A55 Core2 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA2A1_2C	Clears or indicates interrupt status flag (MBX_INTA2A12) of mailbox 2 from Cortex-A55 Core2 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA2A1_3C	Clears or indicates interrupt status flag (MBX_INTA2A13) of mailbox 3 from Cortex-A55 Core2 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core1 (Target). Only read is available from Cortex-A55 Core2 (Source). Access from other CPUs except source and target is also read only.

MBXICLRA2A1 register is used to clear mailbox interrupt from Cortex-A55 Core2 to Cortex-A55 Core1. MBX_INTA2A1 interrupt is cleared when all the status flags are cleared.

47.3.6.25 MBXA2A3n : CA55 Core2 to CA55 Core3 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0xC00 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core2 to Cortex-A55 Core3	R/W*1

Note 1. Read and write is available from Cortex-A55 Core2 (Source). Only read is available from Cortex-A55 Core3 (Target). Access from other CPUs except source and target is also read only.

MBXA2A3n register is used as mailbox from Cortex-A55 Core2 to Cortex-A55 Core3.

47.3.6.26 MBXISETA2A3 : CA55 Core2 to CA55 Core3 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xC10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA2A3_3S	MBX_INTA2A3_2S	MBX_INTA2A3_1S	MBX_INTA2A3_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA2A3_0S	Sets or indicates interrupt status flag (MBX_INTA2A30) of mailbox 0 from Cortex-A55 Core2 to Cortex-A55 Core3. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA2A3_1S	Sets or indicates interrupt status flag (MBX_INTA2A31) of mailbox 1 from Cortex-A55 Core2 to Cortex-A55 Core3. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA2A3_2S	Sets or indicates interrupt status flag (MBX_INTA2A32) of mailbox 2 from Cortex-A55 Core2 to Cortex-A55 Core3. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA2A3_3S	Sets or indicates interrupt status flag (MBX_INTA2A33) of mailbox 3 from Cortex-A55 Core2 to Cortex-A55 Core3. Write from Cortex-A55 Core2 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core2 (Source). Only read is available from Cortex-A55 Core3 (Target). Access from other CPUs except source and target is also read only.

MBXISETA2A3 register is used to generate mailbox interrupt from Cortex-A55 Core2 to Cortex-A55 Core3. MBX_INTA2A3 interrupt is generated as logical OR of MBX_INTA2A30, MBX_INTA2A31, MBX_INTA2A32, or MBX_INTA2A33 status flags.

47.3.6.27 MBXICLRA2A3 : CA55 Core2 to CA55 Core3 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xC14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA2A3_3C	MBX_INTA2A3_2C	MBX_INTA2A3_1C	MBX_INTA2A3_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA2A3_0C	Clears or indicates interrupt status flag (MBX_INTA2A30) of mailbox 0 from Cortex-A55 Core2 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA2A3_1C	Clears or indicates interrupt status flag (MBX_INTA2A31) of mailbox 1 from Cortex-A55 Core2 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA2A3_2C	Clears or indicates interrupt status flag (MBX_INTA2A32) of mailbox 2 from Cortex-A55 Core2 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA2A3_3C	Clears or indicates interrupt status flag (MBX_INTA2A33) of mailbox 3 from Cortex-A55 Core2 to Cortex-A55 Core3. Write from Cortex-A55 Core3 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core3 (Target). Only read is available from Cortex-A55 Core2 (Source). Access from other CPUs except source and target is also read only.

MBXICLRA2A3 register is used to clear mailbox interrupt from Cortex-A55 Core2 to Cortex-A55 Core3. MBX_INTA2A3 interrupt is cleared when all the status flags are cleared.

47.3.6.28 MBXA3A0n : CA55 Core3 to CA55 Core0 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0xC80 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core3 to Cortex-A55 Core0	R/W*1

Note 1. Read and write is available from Cortex-A55 Core3 (Source). Only read is available from Cortex-A55 Core0 (Target). Access from other CPUs except source and target is also read only.

MBXA3A0n register is used as mailbox from Cortex-A55 Core3 to Cortex-A55 Core0.

47.3.6.29 MBXISETA3A0 : CA55 Core3 to CA55 Core0 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xC90

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA3A0_3S	MBX_INTA3A0_2S	MBX_INTA3A0_1S	MBX_INTA3A0_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA3A0_0S	Sets or indicates interrupt status flag (MBX_INTA3A00) of mailbox 0 from Cortex-A55 Core3 to Cortex-A55 Core0. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA3A0_1S	Sets or indicates interrupt status flag (MBX_INTA3A01) of mailbox 1 from Cortex-A55 Core3 to Cortex-A55 Core0. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA3A0_2S	Sets or indicates interrupt status flag (MBX_INTA3A02) of mailbox 2 from Cortex-A55 Core3 to Cortex-A55 Core0. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA3A0_3S	Sets or indicates interrupt status flag (MBX_INTA3A03) of mailbox 3 from Cortex-A55 Core3 to Cortex-A55 Core0. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core3 (Source). Only read is available from Cortex-A55 Core0 (Target). Access from other CPUs except source and target is also read only.

MBXISETA3A0 register is used to generate mailbox interrupt from Cortex-A55 Core3 to Cortex-A55 Core0. MBX_INTA3A0 interrupt is generated as logical OR of MBX_INTA3A00, MBX_INTA3A01, MBX_INTA3A02, or MBX_INTA3A03 status flags.

47.3.6.30 MBXICLRA3A0 : CA55 Core3 to CA55 Core0 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xC94

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA3A0_3C	MBX_INTA3A0_2C	MBX_INTA3A0_1C	MBX_INTA3A0_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA3A0_0C	Clears or indicates interrupt status flag (MBX_INTA3A00) of mailbox 0 from Cortex-A55 Core3 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA3A0_1C	Clears or indicates interrupt status flag (MBX_INTA3A01) of mailbox 1 from Cortex-A55 Core3 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA3A0_2C	Clears or indicates interrupt status flag (MBX_INTA3A02) of mailbox 2 from Cortex-A55 Core3 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA3A0_3C	Clears or indicates interrupt status flag (MBX_INTA3A03) of mailbox 3 from Cortex-A55 Core3 to Cortex-A55 Core0. Write from Cortex-A55 Core0 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core0 (Target). Only read is available from Cortex-A55 Core3 (Source). Access from other CPUs except source and target is also read only.

MBXICLRA3A0 register is used to clear mailbox interrupt from Cortex-A55 Core3 to Cortex-A55 Core0. MBX_INTA3A0 interrupt is cleared when all the status flags are cleared.

47.3.6.31 MBXA3A1n : CA55 Core3 to CA55 Core1 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0xD00 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core3 to Cortex-A55 Core1	R/W*1

Note 1. Read and write is available from Cortex-A55 Core3 (Source). Only read is available from Cortex-A55 Core1 (Target). Access from other CPUs except source and target is also read only.

MBXA3A1n register is used as mailbox from Cortex-A55 Core3 to Cortex-A55 Core1.

47.3.6.32 MBXISETA3A1 : CA55 Core3 to CA55 Core1 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xD10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA3A1_3S	MBX_INTA3A1_2S	MBX_INTA3A1_1S	MBX_INTA3A1_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA3A1_0S	Sets or indicates interrupt status flag (MBX_INTA3A10) of mailbox 0 from Cortex-A55 Core3 to Cortex-A55 Core1. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA3A1_1S	Sets or indicates interrupt status flag (MBX_INTA3A11) of mailbox 1 from Cortex-A55 Core3 to Cortex-A55 Core1. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA3A1_2S	Sets or indicates interrupt status flag (MBX_INTA3A12) of mailbox 2 from Cortex-A55 Core3 to Cortex-A55 Core1. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA3A1_3S	Sets or indicates interrupt status flag (MBX_INTA3A13) of mailbox 3 from Cortex-A55 Core3 to Cortex-A55 Core1. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core3 (Source). Only read is available from Cortex-A55 Core1 (Target). Access from other CPUs except source and target is also read only.

MBXISETA3A1 register is used to generate mailbox interrupt from Cortex-A55 Core3 to Cortex-A55 Core1. MBX_INTA3A1 interrupt is generated as logical OR of MBX_INTA3A10, MBX_INTA3A11, MBX_INTA3A12, or MBX_INTA3A13 status flags.

47.3.6.33 MBXICLRA3A1 : CA55 Core3 to CA55 Core1 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xD14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA3A1_3C	MBX_INTA3A1_2C	MBX_INTA3A1_1C	MBX_INTA3A1_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA3A1_0C	Clears or indicates interrupt status flag (MBX_INTA3A10) of mailbox 0 from Cortex-A55 Core3 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA3A1_1C	Clears or indicates interrupt status flag (MBX_INTA3A11) of mailbox 1 from Cortex-A55 Core3 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA3A1_2C	Clears or indicates interrupt status flag (MBX_INTA3A12) of mailbox 2 from Cortex-A55 Core3 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA3A1_3C	Clears or indicates interrupt status flag (MBX_INTA3A13) of mailbox 3 from Cortex-A55 Core3 to Cortex-A55 Core1. Write from Cortex-A55 Core1 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core1 (Target). Only read is available from Cortex-A55 Core3 (Source). Access from other CPUs except source and target is also read only.

MBXICLRA3A1 register is used to clear mailbox interrupt from Cortex-A55 Core3 to Cortex-A55 Core1. MBX_INTA3A1 interrupt is cleared when all the status flags are cleared.

47.3.6.34 MBXA3A2n : CA55 Core3 to CA55 Core2 Mailbox Register n (n = 0 to 3)

Base address: MBXSEM = 0x8024_0000

Offset address: 0xD80 + 0x04 × n

Bit position:	31	0
Bit field:	MBX[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	MBX[31:0]	Mailbox from Cortex-A55 Core3 to Cortex-A55 Core2	R/W*1

Note 1. Read and write is available from Cortex-A55 Core3 (Source). Only read is available from Cortex-A55 Core2 (Target). Access from other CPUs except source and target is also read only.

MBXA3A2n register is used as mailbox from Cortex-A55 Core3 to Cortex-A55 Core2.

47.3.6.35 MBXISETA3A2 : CA55 Core3 to CA55 Core2 Mailbox Interrupt Set Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xD90

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA3A2_3S	MBX_INTA3A2_2S	MBX_INTA3A2_1S	MBX_INTA3A2_0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA3A2_0S	Sets or indicates interrupt status flag (MBX_INTA3A20) of mailbox 0 from Cortex-A55 Core3 to Cortex-A55 Core2. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA3A2_1S	Sets or indicates interrupt status flag (MBX_INTA3A21) of mailbox 1 from Cortex-A55 Core3 to Cortex-A55 Core2. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA3A2_2S	Sets or indicates interrupt status flag (MBX_INTA3A22) of mailbox 2 from Cortex-A55 Core3 to Cortex-A55 Core2. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA3A2_3S	Sets or indicates interrupt status flag (MBX_INTA3A23) of mailbox 3 from Cortex-A55 Core3 to Cortex-A55 Core2. Write from Cortex-A55 Core3 (Source): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is set. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core3 (Source). Only read is available from Cortex-A55 Core2 (Target). Access from other CPUs except source and target is also read only.

MBXISETA3A2 register is used to generate mailbox interrupt from Cortex-A55 Core3 to Cortex-A55 Core2. MBX_INTA3A2 interrupt is generated as logical OR of MBX_INTA3A20, MBX_INTA3A21, MBX_INTA3A22, or MBX_INTA3A23 status flags.

47.3.6.36 MBXICLRA3A2 : CA55 Core3 to CA55 Core2 Mailbox Interrupt Clear Register

Base address: MBXSEM = 0x8024_0000

Offset address: 0xD94

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MBX_INTA3A2_3C	MBX_INTA3A2_2C	MBX_INTA3A2_1C	MBX_INTA3A2_0C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MBX_INTA3A2_0C	Clears or indicates interrupt status flag (MBX_INTA3A20) of mailbox 0 from Cortex-A55 Core3 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
1	MBX_INTA3A2_1C	Clears or indicates interrupt status flag (MBX_INTA3A21) of mailbox 1 from Cortex-A55 Core3 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
2	MBX_INTA3A2_2C	Clears or indicates interrupt status flag (MBX_INTA3A22) of mailbox 2 from Cortex-A55 Core3 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
3	MBX_INTA3A2_3C	Clears or indicates interrupt status flag (MBX_INTA3A23) of mailbox 3 from Cortex-A55 Core3 to Cortex-A55 Core2. Write from Cortex-A55 Core2 (Target): 0: No operation. Interrupt status flag is not changed. 1: Interrupt status flag is cleared. Read: Indicates interrupt status flag	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Read and write is available from Cortex-A55 Core2 (Target). Only read is available from Cortex-A55 Core3 (Source). Access from other CPUs except source and target is also read only.

MBXICLRA3A2 register is used to clear mailbox interrupt from Cortex-A55 Core3 to Cortex-A55 Core2. MBX_INTA3A2 interrupt is cleared when all the status flags are cleared.

47.4 Operation

47.4.1 Semaphore

47.4.1.1 Between external host and internal CPU

SEMn registers are used to perform up to 8 semaphores for synchronization and exclusive control between internal CPU (Cortex-A55/Cortex-R52) and external host CPU.

SEM bit in SEMn register is used to set the status of the resource shared between CPUs to indicate whether the resource is being used or not. Writing 1 to this bit maintains its value. When the read clear function is enabled (SEMRCEN.SEMRCENn bit = 1), reading SEM bit of corresponding SEM register clears its value to 0.

When the SEM0 register is used for semaphore control for a resource A, for example, the following procedure takes place, where CPU0 is Cortex-R52 and CPU1 is external host CPU or vice versa:

1. Use the initialization routine of CPU0 to set the SEMRCEN.SEMRCEN0 bit to 1 (this enables the read clear function for SEM0 register).
2. Set the SEM bit to 1 (resource not being used) in the SEM0 register.
3. For example, when CPU1 attempts to use the resource A, CPU1 reads the SEM0 register repeatedly until 1 is read.
4. When SEM0.SEM = 1 is read, CPU1 confirms that the resource is not being used.
   This operation clears the SEM0.SEM bit to 0.
5. Then CPU1 uses the resource A.
   If CPU0 attempts to use the resource A while CPU1 is using it, 0 is read from the SEM0.SEM bit (resource A being used by CPU1). CPU0 repeats read operation and waits until the resource is released.
6. When CPU1 completes its use of the resource A, 1 is written in the SEM0.SEM bit to indicate that the resource A is released.
7. If CPU0 attempts to use the resource A after the above step (6), it confirms whether the resource is used or not by reading the SEM0.SEM bit. When the SEM0.SEM bit is 1, CPU0 starts to use the resource A. This operation clears the SEM0.SEM bit to 0.

CoreSight AXI-AP can also access these registers. Access property is same as Cortex-A55/Cortex-R52.

47.4.1.2 Among internal CPUs

SEMARn registers are used to perform up to 8 semaphores for synchronization and exclusive control among internal CPUs (Cortex-A55, Cortex-R52 CPU0 and CPU1). Features and usage are same as SEMn registers. CoreSight AXI-AP can also access these registers. Access property is same as CPU.

47.4.2 Mailbox

47.4.2.1 Between external host and internal CPU

MBXH2Cn and MBXC2Hn register are used to perform up to 4 32-bit mailboxes for communication between internal CPU (Cortex-A55/Cortex-R52) and external host CPU. MBXH2Cn registers are mailboxes from external host CPU to Cortex-A55/Cortex-R52 and MBXC2Hn registers are vice versa. CoreSight AXI-AP can also access these registers. Access property is same as Cortex-A55/Cortex-R52.

47.4.2.2 Among internal CPUs

Mailboxes among internal CPUs are available each combination of source and target CPU and core. Table 47.6 lists the mailbox among internal CPUs. Up to 4 32-bit mailboxes are supported each combination. Read and write is available from source CPU. Only read is available from target CPU. Access from other CPUs except source and target is also read only. CoreSight AXI-AP can also access these registers by read only.

Table 47.6 Mailbox among internal CPUs (1 of 2)

Source CPU	Target CPU	Mailbox registers
Cortex-R52 CPU0	Cortex-A55 Core0	MBXR0A0n
	Cortex-A55 Core1	MBXR0A1n
	Cortex-A55 Core2	MBXR0A2n
	Cortex-A55 Core3	MBXR0A3n

Table 47.6 Mailbox among internal CPUs (2 of 2)

Source CPU	Target CPU	Mailbox registers
Cortex-R52 CPU1	Cortex-A55 Core0	MBXR1A0n
	Cortex-A55 Core1	MBXR1A1n
	Cortex-A55 Core2	MBXR1A2n
	Cortex-A55 Core3	MBXR1A3n
Cortex-A55 Core0	Cortex-R52 CPU0	MBXA0R0n
Cortex-A55 Core1		MBXA1R0n
Cortex-A55 Core2		MBXA2R0n
Cortex-A55 Core3		MBXA3R0n
Cortex-A55 Core0	Cortex-R52 CPU1	MBXA0R1n
Cortex-A55 Core1		MBXA1R1n
Cortex-A55 Core2		MBXA2R1n
Cortex-A55 Core3		MBXA3R1n
Cortex-R52 CPU0	Cortex-R52 CPU1	MBXR0R1n
Cortex-R52 CPU1	Cortex-R52 CPU0	MBXR1R0n
Cortex-A55 Core0	Cortex-A55 Core1	MBXA0A1n
	Cortex-A55 Core2	MBXA0A2n
	Cortex-A55 Core3	MBXA0A3n
Cortex-A55 Core1	Cortex-A55 Core0	MBXA1A0n
	Cortex-A55 Core2	MBXA1A2n
	Cortex-A55 Core3	MBXA1A3n
Cortex-A55 Core2	Cortex-A55 Core0	MBXA2A0n
	Cortex-A55 Core1	MBXA2A1n
	Cortex-A55 Core3	MBXA2A3n
Cortex-A55 Core3	Cortex-A55 Core0	MBXA3A0n
	Cortex-A55 Core1	MBXA3A1n
	Cortex-A55 Core2	MBXA3A2n

47.4.3 Interrupt

Interrupt signals are available to internal CPUs and external host CPU (target CPU). Up to 4 interrupt status flags are available related to 4 mailbox registers but can be set independent of use of mailbox. Mailbox interrupt set registers are used to set interrupt status flag by writing 1 to corresponding bit. Writing 0 to corresponding bit is to retain the current interrupt status flag of the bit. Generated interrupt is logical NOR of interrupt status flags for external host CPU and logical OR for among internal CPUs.

Mailbox interrupt clear registers are used to clear interrupt status flag by writing 1 to corresponding bit. Current interrupt status flag can be confirmed by reading these registers. Interrupt is cleared when all the status flags are cleared.

Table 47.7 MBXSEM Interrupt Source from external host to internal CPU

Name	Interrupt sources	Set register	Clear register
MBX_INT0	Mailbox (Host CPU to Cortex-A55/Cortex-R52) interrupt 0	MBXISETH2C	MBXICLRH2C
MBX_INT1	Mailbox (Host CPU to Cortex-A55/Cortex-R52) interrupt 1		
MBX_INT2	Mailbox (Host CPU to Cortex-A55/Cortex-R52) interrupt 2		
MBX_INT3	Mailbox (Host CPU to Cortex-A55/Cortex-R52) interrupt 3		

Table 47.8 MBXSEM Interrupt Source from internal CPU to external host CPU

Name	Interrupt sources	Set register	Clear register
MBX_HINT0	Mailbox (Cortex-A55/Cortex-R52 to Host CPU) interrupt 0	MBXISETC2H	MBXICLRC2H
MBX_HINT1	Mailbox (Cortex-A55/Cortex-R52 to Host CPU) interrupt 1		
MBX_HINT2	Mailbox (Cortex-A55/Cortex-R52 to Host CPU) interrupt 2		
MBX_HINT3	Mailbox (Cortex-A55/Cortex-R52 to Host CPU) interrupt 3		

Note: MBX_HINT[3:0] are combined to one output interrupt signal (MBX_HINT#) by logical NOR.

Table 47.9 MBXSEM Interrupt Source from Cortex-R52 to Cortex-A55

Name	Interrupt sources	Set register	Clear register
MBX_INTR0A0	Mailbox (Cortex-R52 CPU0 to Cortex-A55 Core0) interrupt	MBXISETR0A0	MBXICLRR0A0
MBX_INTR0A1	Mailbox (Cortex-R52 CPU0 to Cortex-A55 Core1) interrupt	MBXISETR0A1	MBXICLRR0A1
MBX_INTR0A2	Mailbox (Cortex-R52 CPU0 to Cortex-A55 Core2) interrupt	MBXISETR0A2	MBXICLRR0A2
MBX_INTR0A3	Mailbox (Cortex-R52 CPU0 to Cortex-A55 Core3) interrupt	MBXISETR0A3	MBXICLRR0A3
MBX_INTR1A0	Mailbox (Cortex-R52 CPU1 to Cortex-A55 Core0) interrupt	MBXISETR1A0	MBXICLRR1A0
MBX_INTR1A1	Mailbox (Cortex-R52 CPU1 to Cortex-A55 Core1) interrupt	MBXISETR1A1	MBXICLRR1A1
MBX_INTR1A2	Mailbox (Cortex-R52 CPU1 to Cortex-A55 Core2) interrupt	MBXISETR1A2	MBXICLRR1A2
MBX_INTR1A3	Mailbox (Cortex-R52 CPU1 to Cortex-A55 Core3) interrupt	MBXISETR1A3	MBXICLRR1A3

Table 47.10 MBXSEM Interrupt Source from Cortex-A55 to Cortex-R52

Name	Interrupt sources	Set register	Clear register
MBX_INTAR0	Mailbox (Cortex-A55 to Cortex-R52 CPU0) interrupt	MBXISETA0R0 MBXISETA1R0 MBXISETA2R0 MBXISETA3R0	MBXICLRAR0

MBX_INTA3A2	Mailbox (CA55 core3 to CA55 core2) interrupt	MBXISETA3A2	MBXICLRA3A2

48. Encoder Interface Subsystem

48.1 Overview

Encoder interface subsystem consists of EnDat 2.2 (ENDAT), BiSS-C (BISS), HIPERFACE DSL (HDSL), and A-format (AFMT). The encoder interface I/O pins are shared with these modules, and one module is statically selected for each unit. Table 48.1 describes the encoder interface subsystem specifications and Figure 48.1 shows a block diagram of the encoder interface subsystem.

Serial communications interface for encoder interface (SCIE) is also used for general encoder interface. It is not included in encoder interface subsystem but its I/O pins are mapped to the same pins as encoder interface I/O.

Interrupts from all the modules including SCIE are shared to ENCIFn_INT[3:0] in interrupt controller (ICU), and interrupts from one module are statically selected for each unit. For details, see section 12.4.1. Event Handling.

Table 48.1 Encoder interface subsystem specifications

Item	Description
Number of units	16 units (12 in LLPP0 and 4 in LLPP1)
Supported encoder interface	• EnDat 2.2 (ENDAT) • BiSS-C (BISS) • HIPERFACE DSL (HDSL) • A-format (AFMT)
Event link	Trigger input
Module-stop function	Module-stop state can be set to reduce power consumption for each module

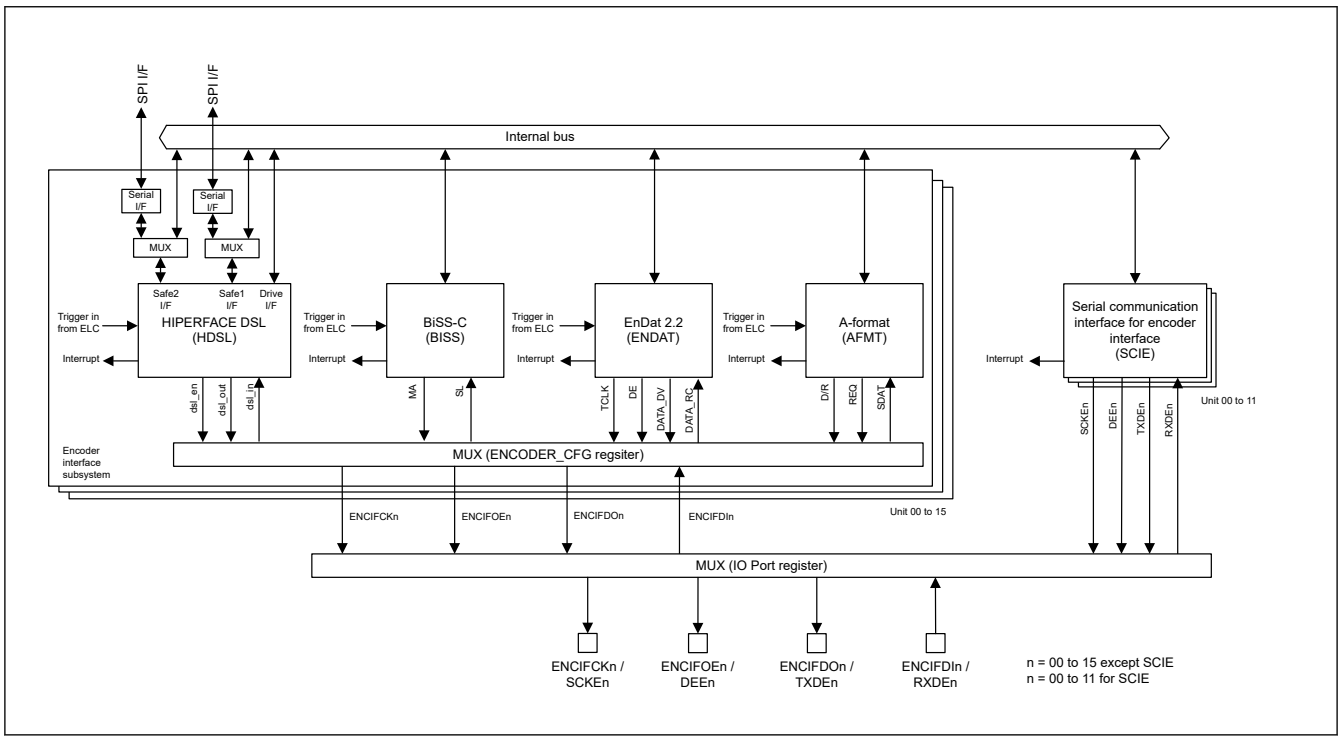

Figure 48.1 Block diagram of encoder interface subsystem

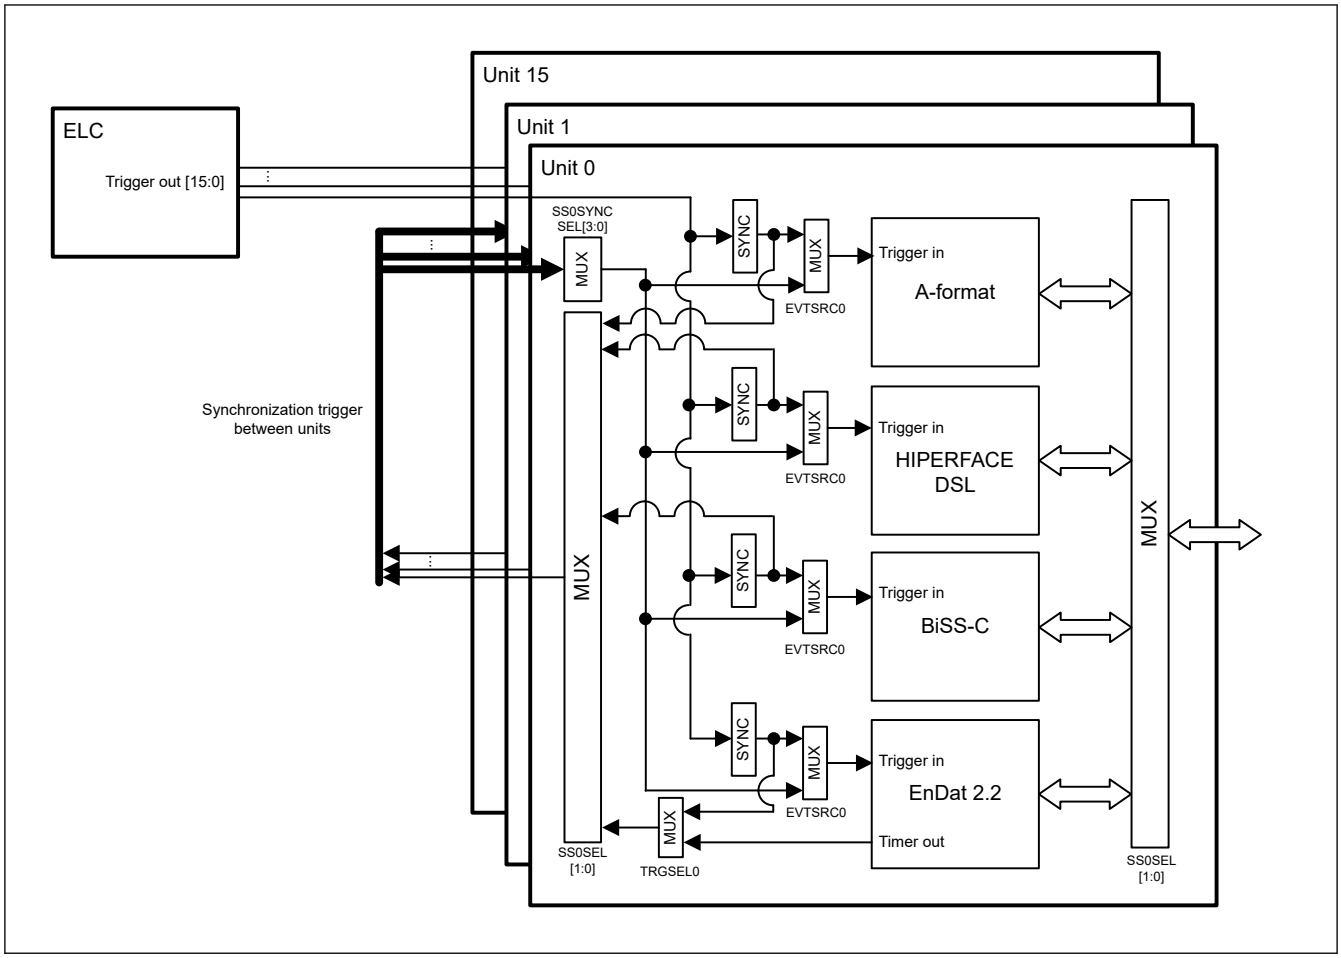

Figure 48.2 Trigger input

Table 48.2 lists the input/output pins of the encoder interface subsystem.

Table 48.2 Pin configuration of the encoder interface subsystem

Unit	Pin name	I/O	Function
Unit n	ENCIFCKn	Output	Encoder interface clock output pin
	ENCIFOEn	Output	Encoder interface data output enable pin
	ENCIFDOn	Output	Encoder interface data output pin
	ENCIFDIn	Input	Encoder interface data input pin

Note: n = 00 to 15

Table 48.3 Encoder interface pin function of each module

Pin name	EnDat 2.2	BiSS-C	HIPERFACE DSL	A-format
ENCIFCKn	TCLK	MA	(N/A)	(N/A)
ENCIFOEn	DE	(N/A)	dsl_en	D/R
ENCIFDOn	DATA_DV	(N/A)	dsl_out	REQ
ENCIFDIn	DATA_RC	SL	dsl_in	SDAT

Note: n = 00 to 15

48.2 Register Map

Table 48.4 ENCSS interface register map

Address	Register symbol	Register name	Write protection
0x8029_1000 + 0x04 × n	ENCODER_CFGn	Encoder IF Configuration Register n (n = 0 to 7)	PRCRN.PRC3
0x8029_1020 + 0x04 × n	BISS_STATn	BiSS-C Status Register n (n = 0 to 7)	—
0x8029_1040 + 0x04 × n	HDSL_STATn	HIPERFACE DSL Status Register n (n = 0 to 7)	—
0x8029_1060 + 0x04 × n	ENDAT_CFGn	EnDat Configuration Register n (n = 0 to 7)	PRCRN.PRC3
0x8029_1080 + 0x04 × n	AFMT_STATn	A-Format Status Register n (n = 0 to 7)	—
0x8029_10A0 + 0x04 × n	HDSLn_OS_D	HIPERFACE_DSL Online Status D Register n (n = 0 to 15)	—
0x8029_10E0 + 0x04 × n	HDSLn_OS_1	HIPERFACE_DSL Online Status 1 Register n (n = 0 to 15)	—
0x8029_1120 + 0x04 × n	HDSLn_OS_2	HIPERFACE_DSL Online Status 2 Register n (n = 0 to 15)	—
0x8029_1160 + 0x04 × n	HDSL_HOSTFn	HIPERFACE_DSL Host F Register n (n = 0, 1)	—

Table 48.5 ENCSS related system control register

Target	Module Reset Control Register	Module Stop Control Register	Slave Access Control Register
All the registers	—	—	SLVACCCTL7.LLPP_SL[*1]

Note 1. Access from Cortex-R52 CPU0 and CPU1 is not protected by TrustZone. This slave access control is applied to access from other masters.

48.3 Register Descriptions

48.3.1 ENCODER_CFGn : Encoder IF Configuration Register n (n = 0 to 7)

Base address: ENCSS = 0x8029_1000

Offset address: 0x000 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	SS1SYNCSEL[3:0]				HF1SAFE2SEL	TRGSEL1	SS1SEL[1:0]		EVTSRC1	HF1SAFE1SEL	HF1ENDIAN
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SS0SYNCSEL[3:0]				HF0SAFE2SEL	TRGSEL0	SS0SEL[1:0]		EVTSRC0	HF0SAFE1SEL	HF0ENDIAN
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	HF0ENDIAN	HIPERFACE DSL Unit 2*n Endian Mode Byte sequence selection for register access 0: Little endian 1: Big endian	R/W
1	HF0SAFE1SEL	HIPERFACE DSL Unit 2*n Safe 1 Interface Select Select the interface mode for safe 1 interface 0: Internal bus interface 1: SPI interface	R/W
2	EVTSRC0	Event Source Select Select the event trigger source for encoder interface subsystem Unit 2*n 0: Trigger out 2*n from ELC 1: Trigger out from other units of encoder interface subsystem. Used unit is selected by SS0SYNCSEL[3:0] bits. The event source unit and triggered unit should be same protocol.	R/W

Bit	Symbol	Function	R/W
4:3	SS0SEL[1:0]	Encoder Interface Port Select Select the encoder interface for Unit 2*n 0 0: HIPERFACE DSL 0 1: BiSS-C 1 0: EnDat 2.2 1 1: A-format	R/W
5	TRGSEL0	EnDat 2.2 Unit 2*n Trigger Output Source Select Select the source of the ENDAT trigger output for other units of encoder interface subsystem 0: Synchronized Trigger out 2*n from ELC 1: Timer output from EnDat 2.2 Unit 2*n	R/W
6	HF0SAFE2SEL	HIPERFACE DSL Unit 2*n Safe 2 Interface Select Select the interface mode for safe 2 interface 0: Internal bus interface 1: SPI interface	R/W
10:7	SS0SYNCSEL[3:0]	Event Source Unit Number Select Specify the unit number of encoder interface subsystem of which trigger output is used as the event source When using own timer output for EnDat 2.2 as event source, specify the same unit number.	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
16	HF1ENDIAN	HIPERFACE DSL Unit 2*n+1 Endian Mode Byte sequence selection for register access 0: Little endian 1: Big endian	R/W
17	HF1SAFE1SEL	HIPERFACE DSL Unit 2*n+1 Safe 1 Interface Select Select the interface mode for safe 1 interface 0: Internal bus interface 1: SPI interface	R/W
18	EVTSRC1	Event Source Select Select the event trigger source for encoder interface subsystem Unit 2*n+1 0: Trigger out 2*n+1 from ELC 1: Trigger out from other units of encoder interface subsystem. Used unit is selected by SS0SYNCSEL[3:0] bits. The event source unit and triggered unit should be same protocol.	R/W
20:19	SS1SEL[1:0]	Encoder Interface Port Select Select the encoder interface for Unit 2*n+1 0 0: HIPERFACE DSL 0 1: BiSS-C 1 0: EnDat 2.2 1 1: A-format	R/W
21	TRGSEL1	EnDat 2.2 Unit 2*n+1 Trigger Output Source Select Select the source of the ENDAT trigger output for other units of encoder interface subsystem 0: Synchronized Trigger out 2*n+1 from ELC 1: Timer output from EnDat 2.2 Unit 2*n+1	R/W
22	HF1SAFE2SEL	HIPERFACE DSL Unit 2*n+1 Safe 2 Interface Select Select the interface mode for safe 2 interface 0: Internal bus interface 1: SPI interface	R/W
26:23	SS1SYNCSEL[3:0]	Event Source Unit Number Select Specify the unit number of encoder interface subsystem of which trigger output is used as the event source When using own timer output for EnDat 2.2 as event source, specify the same unit number.	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

The ENCODER_CFGn register is used to set the encoder interface operating mode. This register should be set before releasing the module stop for each encoder interface module.

48.3.2 BISS_STATn : BiSS-C Status Register n (n = 0 to 7)

Base address: ENCSS = 0x8029_1000

Offset address: 0x020 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	BISS1_EOT	—	—	—	BISS1_ERR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	BISS0_EOT	—	—	—	BISS0_ERR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

Bit	Symbol	Function	R/W
0	BISS0_ERR	BiSS-C Unit 2*n Error 0: External or internal error occurred 1: No error occurred	R
3:1	—	These bits are read as 0.	R
4	BISS0_EOT	End-of-Transmission from BiSS-C Unit 2*n 0: Data transmission active 1: Data transmission inactive	R
15:5	—	These bits are read as 0.	R
16	BISS1_ERR	BiSS-C Unit 2*n+1 Error 0: External or internal error occurred 1: No error occurred	R
19:17	—	These bits are read as 0.	R
20	BISS1_EOT	End-of-Transmission from BiSS-C Unit 2*n+1 0: Data transmission active 1: Data transmission inactive	R
31:21	—	These bits are read as 0.	R

The BISS_STATn register indicates the status of BiSS-C. (n = 0 to 7)

48.3.3 HDSL_STATn : HIPERFACE DSL Status Register n (n = 0 to 7)

Base address: ENCSS = 0x8029_1000

Offset address: 0x040 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	HDSL1_ENCERR	HDSL1_ACTHERR	HDSL1_ACCERR	HDSL1_EDTERR	HDSL1_SPERR	HDSL1_SCHERR	HDSL1_ESTON	—	—	HDSL1_SYNCLKD	HDSL1_LINK
Value after reset:	0	0	0	0	0	0	0	1	1	1	1	1	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	HDSL0_ENCERR	HDSL0_ACTHERR	HDSL0_ACCERR	HDSL0_EDTERR	HDSL0_SPERR	HDSL0_SCHERR	HDSL0_ESTON	—	—	HDSL0_SYNCLKD	HDSL0_LINK
Value after reset:	0	0	0	0	0	0	0	1	1	1	1	1	0	0	0	0

Bit	Symbol	Function	R/W
0	HDSL0_LINK	HIPERFACE-DSL Link Connection indication from HIPERFACE-DSL Unit 2*n 0: Disconnect 1: Connect	R
1	HDSL0_SYNCLCKD	HIPERFACE-DSL Sync Locked Position sampling resolution locked from HIPERFACE-DSL Unit 2*n 0: Unlock 1: Locked	R
3:2	—	These bits are read as 0.	R
4	HDSL0_ESTON	HIPERFACE-DSL Estimator ON Position estimator activated from HIPERFACE-DSL Unit 2*n 0: Inactive 1: Active	R
5	HDSL0_SCHERR	HIPERFACE-DSL Safe Channel Error Transmission error in safe channel 1 from HIPERFACE-DSL Unit 2*n 0: No error 1: Error	R
6	HDSL0_SPERR	HIPERFACE-DSL Safe Position Error Safe position not valid from HIPERFACE-DSL Unit 2*n 0: No error 1: Error	R
7	HDSL0_EDTERR	HIPERFACE-DSL Estimator Deviation Threshold Error Estimator deviation threshold reached from HIPERFACE-DSL Unit 2*n 0: No error 1: Error	R
8	HDSL0_ACCERR	HIPERFACE-DSL Acceleration Error Fast channel/position error from HIPERFACE-DSL Unit 2*n 0: No error 1: Error	R
9	HDSL0_ACTHERR	HIPERFACE-DSL Acceleration Threshold Error Fast channel/position threshold error from HIPERFACE-DSL Unit 2*n 0: No error 1: Error	R
10	HDSL0_ENCERR	HIPERFACE-DSL Encoding Error 8B/10B encoding error in DSL frame transmission from HIPERFACE-DSL Unit 2*n 0: No error 1: Error	R
15:11	—	These bits are read as 0.	R
16	HDSL1_LINK	HIPERFACE-DSL Link Connection indication from HIPERFACE-DSL Unit 2*n+1 0: Disconnect 1: Connect	R
17	HDSL1_SYNCLCKD	HIPERFACE-DSL Sync Locked Position sampling resolution locked from HIPERFACE-DSL Unit 2*n+1 0: Unlock 1: Locked	R
19:18	—	These bits are read as 0.	R
20	HDSL1_ESTON	HIPERFACE-DSL Estimator ON Position estimator activated from HIPERFACE-DSL Unit 2*n+1 0: Inactive 1: Active	R
21	HDSL1_SCHERR	HIPERFACE-DSL Safe Channel Error Transmission error in safe channel 1 from HIPERFACE-DSL Unit 2*n+1 0: No error 1: Error	R

Bit	Symbol	Function	R/W
22	HDSL1_SPERR	HIPERFACE-DSL Safe Position Error Safe position not valid from HIPERFACE-DSL Unit 2*n+1 0: No error 1: Error	R
23	HDSL1_EDTERR	HIPERFACE-DSL Estimator Deviation Threshold Error Estimator deviation threshold reached from HIPERFACE-DSL Unit 2*n+1 0: No error 1: Error	R
24	HDSL1_ACCERR	HIPERFACE-DSL Acceleration Error Fast channel/position error from HIPERFACE-DSL Unit 2*n+1 0: No error 1: Error	R
25	HDSL1_ACTHERR	HIPERFACE-DSL Acceleration Threshold Error Fast channel/position threshold error from HIPERFACE-DSL Unit 2*n+1 0: No error 1: Error	R
26	HDSL1_ENCERR	HIPERFACE-DSL Encoding Error 8B/10B encoding error in DSL frame transmission from HIPERFACE-DSL Unit 2*n+1 0: No error 1: Error	R
31:27	—	These bits are read as 0.	R

The HDSL_STATn register indicates the status of HIPERFACE-DSL. (n = 0 to 7)

48.3.4 ENDAT_CFGn : EnDat Configuration Register n (n = 0 to 7)

Base address: ENCSS = 0x8029_1000

Offset address: 0x060 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	ENDAT1_AXADD[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	ENDAT0_AXADD[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	ENDAT0_AXADD[4:0]	EnDat Unit 2*n Axis Address The component address for EnDat 2.2 Unit 2*n	R/W
15:5	—	These bits are read as 0. The write value should be 0.	R/W
20:16	ENDAT1_AXADD[4:0]	EnDat Unit 2*n+1 Axis Address The component address for EnDat 2.2 Unit 2*n+1	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

The ENDAT_CFGn register is used to set the EnDat 2.2. (n = 0 to 7)

48.3.5 AFMT_STATn : A-Format Status Register n (n = 0 to 7)

Base address: ENCSS = 0x8029_1000

Offset address: 0x080 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	AFMT1_TMOUT	AFMT1_EOT	AFMT1_BUSY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	AFMT0_TMOUT	AFMT0_EOT	AFMT0_BUSY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
0	AFMT0_BUSY	A-format Busy Transmission busy from A-format Unit 2*n 0: Busy 1: Idle	R
1	AFMT0_EOT	A-format End-Of-Frame End-of-transmission from A-format Unit 2*n 0: Data transfer end (cleared by data read) 1: Idle or in-progress	R
2	AFMT0_TMOUT	A-format Timeout Timeout error from A-format Unit 2*n 0: No error 1: Time out error	R
15:3	—	These bits are read as 0.	R
16	AFMT1_BUSY	A-format Busy Transmission busy from A-format Unit 2*n+1 0: Busy 1: Idle	R
17	AFMT1_EOT	A-format End-of-Frame End-of-transmission from A-format Unit 2*n+1 0: Data transfer end (cleared by data read) 1: Idle or in-progress	R
18	AFMT1_TMOUT	A-format Timeout Timeout error from A-format Unit 2*n+1 0: No error 1: Time out error	R
31:19	—	These bits are read as 0.	R

The AFMT_STATn register indicates the status of A-format. (n = 0 to 7)

48.3.6 HDSLn_OS_D : HIPERFACE_DSL Online Status D Register n (n = 0 to 15)

Base address: ENCSS = 0x8029_1000

Offset address: 0x0A0 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	INT	SUM	—	—	POS	—	DTE	PRST	POSTX[1:0]		MIN	ANS	—	QMLW	FREL	—
Value after reset:	0	0	0	1	1	0	1	1	0	0	0	0	0	1	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0.	R
1	FREL	Channel Status for long message 0: The channel for the long message is in use. 1: The channel for the long message is free.	R
2	QMLW	Quality monitoring at Low level 0: Current value of quality monitoring greater than or equal to 14 1: Current value of quality monitoring less than 14	R
3	—	This bit is read as 0.	R
4	ANS	Incorrect Answer Detected 0: No error detected in the last answer to a long message 1: The last answer to a long message was damaged	R
5	MIN	Acknowledgment of Message Initialization 0: Parameter Channel not functioning 1: The DSL encoder sends a figure by which the initialization of the Parameter Channel is acknowledged	R
7:6	POSTX[1:0]	Position Transmission Status 0 0: Position request is transmitted to the DSL encoder 0 1: Safe position 1 was received 1 0: Fast position was received or position newly updated by estimator 1 1: Safe position 2 was received	R
8	PRST	Protocol Reset 0: HDSLn running 1: HDSLn has restarted the protocol	R
9	DTE	Deviation Threshold Error 0: Current value of deviation smaller than the specified maximum 1: Current value of deviation greater than the specified maximum	R
10	—	This bit is read as 0.	R
11	POS	Estimator Turned On 0: No fast position error 1: A source of an error in the fast position was identified or an alignment procedure is currently being carried out. It is probable that the last fast position is invalid. Be aware that the fast position read through drive interface is provided by the estimator.	R
12	—	This bit is read as 1.	R
13	—	This bit is read as 0.	R
14	SUM	Summary Byte 0: The last valid value from MIR_SUM was zero. 1: The last valid value from MIR_SUM was not zero. The importance of this flag depends on the particular error source that leads to a set MIR_SUM.	R

Bit	Symbol	Function	R/W
15	INT	Status of the Interrupt Output 0: Interrupt output on the low level 1: Interrupt output on the high level	R
31:16	—	These bits are read as 0.	R

The HDSLn_OS_D register is used to indicate Online Status D of HIPERFACE_DSL. (n = 0 to 15)

48.3.7 HDSLn_OS_1 : HIPERFACE_DSL Online Status 1 Register n (n = 0 to 15)

Base address: ENCSS = 0x8029_1000

Offset address: 0x0E0 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SINT	SSUM	SCE	—	—	VPOS	—	PRST	POSTX[1:0]		MIN	—	—	QMLW	—	FRES
Value after reset:	0	0	1	1	0	1	0	1	0	0	0	0	0	1	0	0

Bit	Symbol	Function	R/W
0	FRES	Channel Status for the short message 0: The channel for the short message is in use. 1: The channel for the short message is free.	R
1	—	This bit is read as 0.	R
2	QMLW	Quality Monitoring at Low level 0: Current value of quality monitoring greater than or equal to 14 1: Current value of quality monitoring less than 14	R
4:3	—	These bits are read as 0.	R
5	MIN	Acknowledgment of Message Initialization 0: Parameter channel not functioning 1: The DSL encoder sends a figure by which the initialization of the parameter channel is acknowledged.	R
7:6	POSTX[1:0]	Position Transmission Status 0 0: Position request is transmitted to the DSL encoder. 0 1: Safe position 1 was received. 1 0: Fast position was received or position newly updated by estimator. 1 1: Safe position 2 was received.	R
8	PRST	Protocol Reset 0: HDSL0 running 1: HDSL0 has restarted the protocol	R
9	—	This bit is read as 0.	R
10	VPOS	Safe Position Invalid 0: The last safe position received was correct. 1: An error in the safe position was identified. It is expected that the safe position transmitted from the encoder is invalid.	R
11	—	This bit is read as 0.	R
12	—	This bit is read as 1.	R
13	SCE	CRC Error on the Safe Channel 0: The last Safe Channel CRC received was correct. 1: The last Safe Channel CRC received was wrong. It is expected that the last safe position 2 transmitted is invalid.	R

Bit	Symbol	Function	R/W
14	SSUM	Safe Summary Bit 0: The last valid value from SAFE_SUM was zero. 1: The last valid value from SAFE_SUM was not zero. The importance of this flag depends on the particular error source that leads to a set SAFE_SUM.	R
15	SINT	Status of the Interrupt Output 0: Interrupt output on the low level 1: Interrupt output on the high level	R
31:16	—	These bits are read as 0.	R

The HDSLn_OS_1 register is used to indicate Online Status 1 of HIPERFACE_DSL. (n = 0 to 15)

48.3.8 HDSLn_OS_2 : HIPERFACE_DSL Online Status 2 Register n (n = 0 to 15)

Base address: ENCSS = 0x8029_1000

Offset address: 0x120 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	SSUM2	SCE2	—	—	VPOS2	—	PRST	POSTX[1:0]		—	—	—	QMLW	—	—
Value after reset:	0	0	1	1	0	0	0	1	0	0	0	0	0	1	0	0

Bit	Symbol	Function	R/W
1:0	—	This bit is read as 0.	R
2	QMLW	Quality Monitoring at Low level 0: Current value of quality monitoring greater than or equal to 14 1: Current value of quality monitoring less than 14	R
5:3	—	These bits are read as 0.	R
7:6	POSTX[1:0]	Position Transmission Status 0 0: Position request is transmitted to the DSL encoder. 0 1: Safe position 1 was received. 1 0: Fast position was received or position newly updated by estimator. 1 1: Safe position 2 was received.	R
8	PRST	Protocol Reset 0: HDSL0 running 1: HDSL0 has restarted the protocol	R
9	—	This bit is read as 0.	R
10	VPOS2	Safe Position 2 Invalid 0: The last safe position received in channel 2 was correct. 1: A source of an error in the safe position in channel 2 was identified. It is probable that the safe position transmitted from Channel 2 is invalid. Suitable measures must be installed in the user application.	R
11	—	This bit is read as 0.	R
12	—	This bit is read as 1.	R
13	SCE2	Transmission Error Channel 2 0: The last data received in channel 2 was correct. 1: The last safe channel 2 CRC received was wrong. It is expected that the last safe position 2 transmitted is invalid. Suitable measures must be installed in the user application.	R

Bit	Symbol	Function	R/W
14	SSUM2	Summary Bit Channel 2 0: Neither TEST2 nor ERR2 is set. 1: One of the indications TEST2 or ERR2 is set. The error reaction to the flag depends on the meaning of the bit.	R
31:15	—	These bits are read as 0.	R

The HDSLn_OS_2 register is used to indicate Online Status 2 of HIPERFACE_DSL. (n = 0 to 15)

48.3.9 HDSL_HOSTFn : HIPERFACE DSL Host_f Control Register n (n = 0, 1)

Base address: ENCSS = 0x8029_1000

Offset address: 0x160 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

27	—	This bit is read as 0. The write value should be 0.	R/W
28	HOSTD_F7	Drive Interface Register Freeze (hostd_f) for HDSL Unit 8*n+7 0: Not freeze register update 1: Freeze register update	R/W
29	HOST1_F7	Safe 1 Interface Register Freeze (host1_f) for HDSL Unit 8*n+7 0: Not freeze register update 1: Freeze register update	R/W
30	HOST2_F7	Safe 2 Interface Register Freeze (host2_f) for HDSL Unit 8*n+7 0: Not freeze register update 1: Freeze register update	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The HDSL_HOSTFn register is used to control register freeze signals (hostd_f, host1_f, and host2_f). (n = 0, 1)

When it is set to high, no further updates are done for multi-byte registers.

48.4 Usage Notes

48.4.1 Release of Register Write Protection

ENCODER_CFG and ENDAT_CFG registers are write protected. To release write protection, use the following steps:

1. Write 0x0000A508 to PRCRN register (release the write protection by PRC3 bit).
2. Write value to ENCODER_CFG or ENDAT_CFG registers.
3. Write 0x0000A500 to PRCRN register (set the write protection by PRC3 bit).

49. EnDat 2.2 (ENDAT)

49.1 Overview

The MPU includes EnDat 2.2 (ENDAT) master to enable communication between the encoder and EnDat 2.2 interface. Table 49.1 describes the ENDAT specifications and Figure 49.1 shows a block diagram of the ENDAT.

Table 49.1 EnDat 2.2 (ENDAT) specifications

Item	Description
Number of units	16 units (12 in LLPP0 and 4 in LLPP1)
Protocol	EnDat 2.2
Functions	• EnDat 2.2 Basic • Host interface: 32 bits APB • Basic functions of EnDat data transfer: – Clock generator – Data word length – Continuous clock – Error handling – Encoder status – CRC – Cable preparation time – Recovery time II – Recovery time III • Advanced functions of EnDat data transfer – Watchdog – Reset with selected additional information • Strobe source: Hardware, timer and software • Digital filter for data input
Interrupt sources	• Basic interrupt: 1 – Watchdog, receive register updated
Event link	STR input for HW trigger provided from ELC
Module-stop function	Module-stop state can be set to reduce power consumption

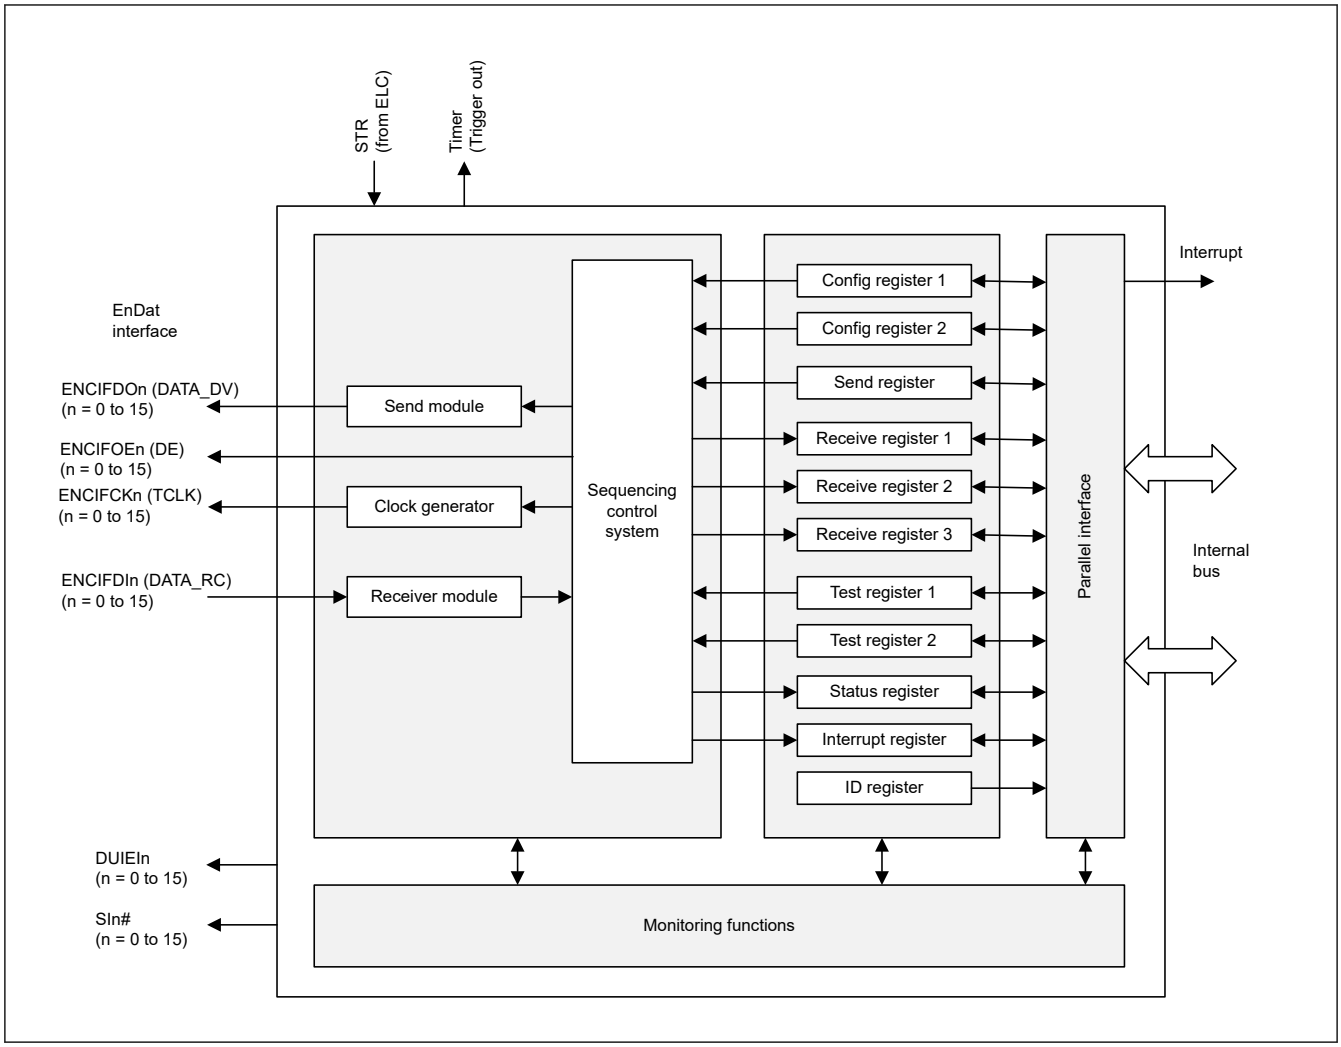

Figure 49.1 Block diagram of EnDat 2.2 (ENDAT)

Table 49.2 lists the input/output pins of the ENDAT.

Table 49.2 Pin configuration of the ENDAT

Unit	Pin name	I/O	Function
ENDATn	ENCIFOEn (DE)	Output	EnDat 2.2 unit n drive enable
	ENCIFDOn (DATA_DV)	Output	EnDat 2.2 unit n data output (drive)
	ENCIFCKn (TCLK)	Output	EnDat 2.2 unit n clock generator output
	ENCIFDIn (DATA_RC)	Input	EnDat 2.2 unit n data input (receive)
	DUEIn	Output	EnDat 2.2 unit n data transfer
	TST_OUTn	Output	EnDat 2.2 unit n data input after internal synchronization
	SIn#	Output	EnDat 2.2 unit n start pulse

Note: n = 0 to 15

Table 49.3 ENDAT interrupt sources

Name	Interrupt sources
ENDATn_INT1	Interrupt output 1

Note: n = 0 to 15

49.2 Register Map

Note 1. Access from Cortex-R52 CPU0 and CPU1 is not protected by TrustZone. This slave access control is applied to access from other masters.

49.3 Register Descriptions

All register access operation should be executed with 32-bit access. It is not possible to write to or read from a single byte or word of a register. Unused bits are filled with zeros.

49.3.1 SEND : Send Register

Base address: ENDATm = 0x9020_4000 + 0x1_0000 × m (m = 0 to 11)
ENDATi = 0x9030_4000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	M[5:0]						A[7:0]								D[15:0]															
Value after reset:	0	0	0	0	0	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	D[15:0]	Parameters, Instructions See Table 49.6.	R/W
23:16	A[7:0]	Memory Range Select (MRS) code, Address, Port address See Table 49.6.	R/W
29:24	M[5:0]	Mode command See Table 49.6.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

The SEND register contains data to be transmitted to the EnDat encoder.

Table 49.6 shows an overview of the supported mode commands with data to be entered into the send register.

Table 49.6 is list of the EnDat master side, however, some commands may not be supported depending on the EnDat encoder that is the EnDat slave side.

Table 49.6 Mode commands

Mode command	M[5:0]	A[7:0]	D[15:0]
Encoder transmit position values	0x07	(Reserved)	(Reserved)
Encoder transmit position values with additional information	0x38	(Reserved)	(Reserved)
Selection of memory area	0x0E	MRS code	(Reserved)
Encoder receive parameters	0x1C	Address	Parameters
Encoder transmit parameters	0x23	Address	(Reserved)
Encoder receive reset	0x2A	Address	(Reserved)
Encoder transmit test values	0x15	(Reserved)	(Reserved)
Encoder receive communication command	0x12	Address	Instruction
Encoder receive test command	0x31	Port address	(Reserved)
Encoder transmit position values with additional information and selection of the memory area	0x09	MRS code	(Reserved)
Encoder transmit position values with additional information and receive parameters	0x1B	Address	Parameters
Encoder transmit position values with additional information and parameters	0x24	Address	(Reserved)
Encoder transmit position values with additional information and receive error reset	0x2D	Address	(Reserved)
Encoder transmit position values with additional information and receive test command	0x36	Port address	(Reserved)

Table 49.7 MRS code

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Request
Additional information 1								
0	1	0	0	0	0	0	0	Send additional info 1 without data contents (NOP)
0	1	0	0	0	0	0	1	Send diagnostic value
0	1	0	0	0	0	1	0	Send position value 2 word 1 LSB
0	1	0	0	0	0	1	1	Send position value 2 word 2
0	1	0	0	0	1	0	0	Send position value 2 word 3 MSB
0	1	0	0	0	1	0	1	Acknowledge memory content LSB
0	1	0	0	0	1	1	0	Acknowledge memory content MSB
0	1	0	0	0	1	1	1	Acknowledge MRS code
0	1	0	0	1	0	0	0	Acknowledge test command
0	1	0	0	1	0	0	1	Send test values word 1 LSB
0	1	0	0	1	0	1	0	Send test values word 2
0	1	0	0	1	0	1	1	Send test values word 3 MSB
0	1	0	0	1	1	0	0	Send temperature 1
0	1	0	0	1	1	0	1	Send temperature 2
0	1	0	0	1	1	1	0	Additional sensors
0	1	0	0	1	1	1	1	Stop sending additional information 1
Additional information 2								
0	1	0	1	0	0	0	0	Send additional information 2 without data contents
0	1	0	1	0	0	0	1	Send commutation
0	1	0	1	0	0	1	0	Send acceleration
0	1	0	1	0	0	1	1	Send commutation and acceleration
0	1	0	1	0	1	0	0	Send limit position signals
0	1	0	1	0	1	0	1	Send limit position signals & acceleration
0	1	0	1	0	1	1	0	Asynchronous position value word 1 LSB
0	1	0	1	0	1	1	1	Asynchronous position value word 2
0	1	0	1	1	0	0	0	Asynchronous position value word 3 MSB
0	1	0	1	1	0	0	1	Operating status error sources
0	1	0	1	—	—	—	—	Not assigned
0	1	0	1	1	1	1	1	Stop sending additional information 2

Note: Data transfer from the send register to the send module occurs only after a completed write cycle and completed transmission cycle to/from encoder.

Only values for the mode commands defined above are entered into the send register. Only EnDat2.2 mode commands are entered in transmission mode 1 (safety mode). This ensures that the most recently entered valid mode command is active if an attempt is made to enter an invalid mode command into the send register.

49.3.2 Receive Registers

The transfer of data from the receive module to the corresponding receive registers occurs at the same time as related status information is updated, directly after the serial-to-parallel conversion.

49.3.2.1 EMPFR1_L : Receive Register 1, Low Double Word

Base address: ENDATm = 0x9020_4000 + 0x1_0000 × m (m = 0 to 11)
ENDATi = 0x9030_4000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x04

Bit position:	31																												0
Bit field:	RDATA_L[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RDATA_L[31:0]	Received data, bit 31 to bit 0 See Table 49.8.	R

49.3.2.2 EMPFR1_H : Receive Register 1, High Double Word

Base address: ENDATm = 0x9020_4000 + 0x1_0000 × m (m = 0 to 11)
ENDATi = 0x9030_4000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	POS1	IF2	F1	CRC[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RDATA_H[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RDATA_H[15:0]	Received data, bit 47 to bit 32 See Table 49.8.	R
20:16	CRC[4:0]	Received CRC	R
21	F1	Safety-relevant error bit F1 0: No error occurred 1: Error occurred or if forced dynamic sampling is active	R
22	IF2	Safety-relevant error bit F2 inversion 0: Error occurred or if forced dynamic sampling is active 1: No error occurred	R
23	POS1	Absolute position value 1 This bit marks Pos1, to which the following additional information with Pos2 belongs. 0: No Pos1 1: Pos1	R
31:24	—	These bits are read as 0.	R

Depending on the transmitted type 2.1 mode command, EMPFR1_L/EMPFR1_H registers contain different data. With EnDat type 2.2 mode commands, the position value is always entered into FMPFR1_L/EMPFR1_H.

Table 49.8 Received data (1 of 2)

Entry	RDATA_H[15:8]	RDATA_H[7:0]	RDATA_L[31:24]	RDATA_L[23:16]	RDATA_L[15:8]	RDATA_L[7:0]
EnDat position value	MSB*3	…	…	…	…	D[7:0]
MRS code*1	(Invalid)	(Invalid)	(Invalid)	MRS code	D[15:8]	D[7:0]

Table 49.8 Received data (2 of 2)

Entry	RDATA_H[15:8]	RDATA_H[7:0]	RDATA_L[31:24]	RDATA_L[23:16]	RDATA_L[15:8]	RDATA_L[7:0]
Address and parameter*1	(Invalid)	(Invalid)	(Invalid)	Address	D[15:8]	D[7:0]
Port address and data*1	(Invalid)	(Invalid)	(Invalid)	Port Address	D[15:8]	D[7:0]
Test values*1	(Invalid)	DV[39:32]	DV[31:24]	DV[23:16]	DV[15:8]	DV[7:0]
Address and instruction*2	(Invalid)	(Invalid)	(Invalid)	Address	D[15:8]	D[7:0]

Note 1. Only for type 2.1 EnDat mode commands
Note 2. Only for EnDat mode command 010010
Note 3. The position of the MSB shifts depending on the length of the position value. The bits to left of the MSB are not part of the position value.

49.3.2.3 EMPFR2 : Receive Register 2

Base address: ENDATm = 0x9020_4000 + 0x1_0000 × m (m = 0 to 11)
ENDATi = 0x9030_4000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x0C

Bit position:	31																													0
Bit field:	RDATA2[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	RDATA2[31:0]	Received data 2 Additional information 2 See Table 49.9.	R

If a type 2.2 mode command was sent, EMPFR2 register will contain the contents of additional information 2 and its CRC. Please note that the Additional information 2 is supported is difference depending on the EnDat encoder.

Table 49.9 Received data 2

Entry	RDATA2[31:24]	RDATA2[23:16]	RDATA2[15:8]	RDATA2[7:0]
Additional information 2*1	CRC*2	MRS code*3	D[15:8]	D[7:0]

Note 1. Only with type 2.2 mode commands; otherwise the register will not be updated.
Note 2. CRC: bit 28 to bit 24
Note 3. If the EnDat encoder does not support the Additional information 2, the MRS code may be 0x5F.

49.3.2.4 EMPFR3 : Receive Register 3

Base address: ENDATm = 0x9020_4000 + 0x1_0000 × m (m = 0 to 11)
ENDATi = 0x9030_4000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x10

Bit position:	31			28				24	23							16	15													0
Bit field:	—	—	—	CRC[4:0]					C[7:0]								D[15:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	D[15:0]	Data in the additional information 1*1	R
23:16	C[7:0]	Memory Range Select (MRS) code in the additional information 1*1 *2	R

Bit	Symbol	Function	R/W
28:24	CRC[4:0]	CRC for additional information 1*1	R
31:29	—	These bits are read as 0.	R

Note 1. Only with type 2.2 mode commands; otherwise, the register will not be updated.
Note 2. If the EnDat encoder does not support the Additional information 1, the MRS code may be 0x4F.

If a type 2.2 mode command was sent, EMPFR3 register will contain the contents of additional information 1 and its CRC.

Please note that the Additional information 1 is supported is difference depending on the EnDat encoder.

49.3.3 Configuration Registers

Setting required for operation and for handling of the corresponding protocols must be made in the configuration registers.

All of the configuration registers can only be written to if no EnDat transmission is active. The bit 30 of STATR register can be evaluated for this purpose.

49.3.3.1 KONFR1 : Configuration Register 1

Base address: ENDATm = 0x9020_4000 + 0x1_0000 × m (m = 0 to 11)
ENDATi = 0x9030_4000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	SET[1:0]		ICRST	FSYS[2:0]			—	DELAYCMP	CPTIME[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	AUTORST	RSTWD	DWLG[5:0]						FTCLK[3:0]				—	DT	DU	HWSTRB
Value after reset:	0	0	0	0	1	1	0	1	1	1	1	1	0	0	0	0

Bit	Symbol	Function	R/W
0	HWSTRB	Hardware strobe Enable external / STR signal as strobe signal. 0: HW strobe not enabled 1: HW strobe enabled	R/W
1	DU	DU Defines the unconditional data transfer to receive registers 1, 2, 3, and 4 on completion of a data transmission process, despite a flag being set in the status register. For safety applications, DU = 1 must be set. 0: Data transfer according to flag set in the status register 1: Data transfer despite the flag in the status register	R/W
2	DT	DT Select the EnDat continuous clock mode. 0: Continuous clock off 1: Continuous clock on	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
7:4	FTCLK[3:0]	f_{TCLK} Setting (4 bits) of transmission rate for EnDat from 100 kHz to 16 MHz (EnDat) 0x0: 16.67 MHz 0x1: 16.67 MHz 0x2: 16.67 MHz 0x3: 16.67 MHz 0x6: 8.33 MHz 0xB: 4.16 MHz 0xC: 2 MHz 0xD: 1 MHz 0xE: 200 kHz 0xF: 100 kHz Others: Not permitted	R/W
13:8	DWLG[5:0]	Data word length*1 Data word length is set binary with 6 bits for EnDat, is the sum of MT (multi-turn bits) and ST (single-turn bits). The permissible setting range for EnDat is from 8 bits to 48 bits. 0x00: Not permitted ⋮ 0x07: Not permitted 0x08: Data word length = 8 bits ⋮ 0x0D: Data word length = 13 bits ⋮ 0x30: Data word length = 48 bits 0x31: Not permitted ⋮ 0x3F: Not permitted	R/W
14	RSTWD	Reset window The set bit allows resetting of the status and error register only within a defined time period. For safety applications: Reset window = 1 0: Resetting of the registers mentioned above can be performed at any time. (i.e. without considering malfunctions). 1: Resetting of the registers mentioned above must be performed within a defined time period for acceptance by the protocol engine.	R/W
15	AUTORST	Automatic reset If this bit is set, resetting of the status register and error register is performed automatically. For safety applications: Automatic reset = 0 0: Resetting of the above-mentioned registers must be performed by the application. 1: Resetting of the above-mentioned registers is done automatically. However, this resetting only occurs in the next EnDat transmission with the start of data reception.	R/W
23:16	CPTIME[7:0]	Cable propagation time The cable propagation time determined is stored. The application may change this value. If that is the case the status register's propagation time measurement (LZM) bit will automatically be reset. The binary value has a step width of one system clock. At a system clock of 100 MHz, this corresponds to a setting range from 0 µs to 2.55 µs in steps of 10.0 ns.	R/W
24	DELAYCMP	Delay compensation This bit switches propagation delay compensation on. When this bit is set, propagation time measurement is performed with the next data transmission to the EnDat encoder. The ENDAT determines the cable propagation time and saves this in KONFR1 register. This value is used to determine propagation delay compensation. To measure the propagation time again, the delay compensation bit must be reset and set again. For 16-bit access, it must be considered that the measured cable propagation time value is overwritten with 0x00. 0: Delay compensation off 1: Delay compensation on	R/W
25	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
28:26	FSYS[2:0]	System clock frequency (f_{sys}) The system frequency actually used must be selected. 1 1 0: 100 MHz Others: Not permitted	R/W
29	ICRST	IC reset Setting of this bit has the effect that the entire ENDAT is reset to its initial state. 0: IC reset inactive 1: IC reset active	R/W
31:30	SET[1:0]	EnDat set These two bits set the EnDat transmission mode. 0 0: Not permitted 0 1: Not permitted 1 0: EnDat 1 1: Not permitted	R/W

Note 1. The data word length has to set to 40/d bit while using mode command "encoder transmit test values".

The KONFR1 register specifies the basic settings and EnDat functions.

49.3.3.2 KONFR2 : Configuration Register 2

Base address: ENDATm = 0x9020_4000 + 0x1_0000 × m (m = 0 to 11)
ENDATi = 0x9030_4000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x18

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	HWSTRBDLY[7:0]								—	—	FILTER[2:0]			RCVTIME[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WTDOG[7:0]								TMSMPLRATE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TMSMPLRATE[7:0]	Timer for sampling rate 256 different sampling rates can be set. For details, see section 49.4.4. Timer for Sampling Rate. In the default setting 0x00 or 0x80, the timer is off.	R/W
15:8	WTDOG[7:0]	Watchdog 256 different watchdog time values can be set. For details, see section 49.4.5. Watchdog Timer. In the default setting 0x00 or 0x80, the watchdog is off.	R/W
18:16	RCVTIME[2:0]	Recovery time III t_{ST} This time is to be set in accordance with EnDat specification. The set time has an accuracy of ±0.1 µs. 0 0 0: 1/2 TCLK 0 0 1: 0.5 µs 0 1 0: 1 µs 0 1 1: 1.5 µs 1 0 0: 2 µs 1 0 1: 4 µs 1 1 0: 8 µs 1 1 1: 10 µs	R/W

Bit	Symbol	Function	R/W
21:19	FILTER[2:0]	Filter This digital filter for the Data_RC data input can be adjusted in eight steps (3 bits) as below. The filter setting value corresponds to system clock cycles.*1 0 0 0: Off 0 0 1: 3 cycles 0 1 0: 4 cycles 0 1 1: 5 cycles 1 0 0: 6 cycles 1 0 1: 10 cycles 1 1 0: 20 cycles 1 1 1: 40 cycles	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
31:24	HWSTRBDLY[7:0]	Hardware strobe delay*2 The application can enter a value for the HW strobe delay. The binary value has a step width of one system clock. 0x00: Off 0x01: Not permitted 0x02: Not permitted 0x03: 3 cycles 0x04: 4 cycles 0x05: 5 cycles ⋮ 0xFF: 255 cycles	R/W

Note 1. The filter must be set according to the transmission rate of the serial interface to the encoder.
Example: f_{TCLK} = 1 MHz (corresponds to 100 system clock cycles with f_{CLK} = 100 MHz)
For the filter, 1/10 of the f_{CLK} must be set. That means 10 system clock cycles → setting: 101b.

Note 2. At a system clock of 100 MHz, this corresponds to a value range from 30 ns to 2.55 µs in steps of 10 ns.

The KONFR2 register specifies protocol-independent settings.

49.3.4 STATR : Status Register

Base address: ENDATm = 0x9020_4000 + 0x1_0000 × m (m = 0 to 11)
ENDATi = 0x9030_4000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RDY	RDY4 STRB	SPDR DY	—	—	—	—	—	LZM	LZK	—	—	—	FTYPII I	WTDG	SPIKE
Value after reset:	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WRN	RM	BUSY	CRCZI 2	CRCZI 1	IERR2	EMPF R3	EMPF R2	—	—	MRS_ ADR	FTYPII	FTYPI	CRC_ PRTY	ERR1	EMPF R1
Value after reset:	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EMPFR1	EMPFR1 register update This status flag indicates that the data in EMPFR1 register has been updated. This flag is ignored if the DU bit in KONFR1 register is enabled. 0: EMPFR1 register not updated 1: EMPFR1 register updated	R/W
1	ERR1	Error 1 The status bit "error 1" from the EnDat protocol is entered. 0: Error1 did not occur 1: Error1 occurred	R/W

Bit	Symbol	Function	R/W
2	CRC_PRTY	CRC-PW / parity With EnDat transmission it represents the result of the CRC check of the received value (position value, parameter or test value). 0: CRC check okay 1: CRC check faulty	R/W
3	FTYPI	F Type I Shows type I error handling in accordance with the EnDat specification at Annex A2. 0: A type I error did not occur 1: A type I error occurred	R/W
4	FTYPII	F Type II Shows type II error handling in accordance with the EnDat specification at Annex A2. 0: A Type II error did not occur 1: A Type II error occurred	R/W
5	MRS_ADR	MRS/Adr The occurrence of an addressing or acknowledgment error is shown. The errors (F type I / II) are special cases of MRS/address errors, i.e. they are a sub-quality of these. Accordingly, whenever a type I or type II error is identified, the MRS/Adr bit is set. For example, if an MRS/address bit is recognized incorrectly due to a disturbance, only the MRS/Adr status bit will be set, not the F TYP I/II bits. 0: No acknowledgment or addressing error has occurred 1: An acknowledgment or addressing error has occurred	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	EMPFR2	EMPFR2 register update This status flag indicates that the data in EMPFR2 register has been updated. It must be cleared after EMPFR2 register has been read to allow the ENDAT to rewrite data. 0: EMPFR2 not updated 1: EMPFR2 updated	R/W
9	EMPFR3	EMPFR3 register update This status flag indicates that the data in EMPFR3 register has been updated. It must be cleared after EMPFR3 register has been read to allow the ENDAT to rewrite data. 0: EMPFR3 not updated 1: EMPFR3 updated	R/W
10	IERR2	/Error2 Contains the "Error 2" status bit from the EnDat protocol (only with EnDat2.2 commands). 0: /Error2 occurred 1: /Error2 did not occur	R/W
11	CRCZI1	CRC-ZI1 During EnDat transmissions, this bit indicates the result of the CRC checking of additional information (ZI) 1. 0: CRC check of ZI1 okay 1: CRC check of ZI1 faulty	R/W
12	CRCZI2	CRC-ZI2 During EnDat transmissions, this bit indicates the result of the CRC checking of additional information (ZI) 2. 0: CRC check of ZI2 okay 1: CRC check of ZI2 faulty	R/W
13	BUSY	Busy Contains the "Busy" status bit as transmitted in the EnDat protocol. 0: Busy = 0 1: Busy = 1	R/W
14	RM	RM Contains the "RM" status bit as transmitted in the EnDat protocol. 0: RM = 0 1: RM = 1	R/W
15	WRN	WRN Contains the "WRN" status bit as transmitted in the EnDat protocol. 0: WRN = 0 1: WRN = 1	R/W

Bit	Symbol	Function	R/W
16	SPIKE	Spike Reports that a "Spike" was detected at the data input port. Condition: filter in the KONFR1 register is set. 0: No spike 1: Spike occurred	R/W
17	WTDG	Watchdog Reports triggering of the watchdog. Condition: watchdog in KONFR2 register is set. 0: Watchdog not triggered 1: Watchdog triggered	R/W
18	FTYPIII	F Type III Type II error (transmission layer) triggers F type III. Error recognition occurs in the EnDat master. 0: The error did not occur 1: The error occurred	R/W
21:19	—	These bits are read as 0. The write value should be 0.	R/W
22	LZK*1	Delay compensation This bit reports if propagation delay compensation is active. If propagation delay compensation in KONFR1 register is switched off, this bit and propagation time measurement will automatically be reset. 0: LZK inactive 1: LZK active	R/W
23	LZM*1	Propagation time measurement This bit reports that propagation time measurement was successfully completed. Condition: propagation delay compensation (LZK) in KONFR1 register is set. 0: LZM incomplete 1: LZM complete	R/W
28:24	—	These bits are read as 0. The write value should be 0.	R/W
29	SPDRDY	Speed ready This bit reports that a new velocity value has been calculated. 0: No new velocity value calculated 1: New velocity value calculated	R/W
30	RDY4STRB	Ready for strobe This bit reports that data transmission has ended and that the EnDat protocol automation machine is ready for the next transmission. The time values "Recovery time 1" (t_m) and "Recovery time 2" (t_R) are completed. This bit cannot be reset by writing a "1" as this is a status display of the current conditions of internal automation engines. The bit cannot cause an interrupt. 0: No ready 1: Ready	R/W
31	RDY	Ready If the ready bit is set, the status register is completely updated. All checks have been performed. Data transmission is not yet completed, however, meaning that the EnDat protocol automation machine is not yet ready again. 0: No ready 1: Ready	R/W

Note 1. Neither the LZM nor the LZK bit can be reset by writing a "1" to the respective bit as this is a status display of the current conditions of internal automation engines. Neither of the two bits can cause an interrupt.

The status bits are created by the sequencing controller, as required. Status information remains set until it is reset by the application.

The application can selectively reset status information with a write command. This occurs by writing "1" to the selected bits. In the event of concurrent access, the internal sequencing controller has priority. This ensures that status information is not 'lost'.

The bit 15 to bit 11 in STATR register are only valid when additional information 1 or 2 has been received.

Note: The status register should be read after each data transmission. It provides information about validity of the data contained in the receive registers. The status bits must be reset in order that the internal sequencing controller can recognize a renewed setting of the status bit.

Note: Each bit (except for LZM, LZK, RDY4STRB) can trigger an interrupt. Masking is performed with the INTMR register. If a bit that has been set (and thus has triggered an interrupt) is reset and if no other bit has triggered an interrupt, the interrupt is deasserted.

49.3.5 INTMR : Interrupt Mask Register

Base address: ENDATm = 0x9020_4000 + 0x1_0000 × m (m = 0 to 11)
ENDATi = 0x9030_4000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x24

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RDY	—	SPDRDY	—	—	—	—	—	—	—	—	—	—	FTYPIII	WTDG	SPIKE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WRN	RM	BUSY	CRCZI2	CRCZI1	IERR2	EMPFR3	EMPFR2	—	—	MRS_ADR	FTYPII	FTYPI	CRC_PRTY	ERR1	EMPFR1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EMPFR1	Interrupt mask for EMPFR1 register update 0: Masked 1: Not masked	R/W
1	ERR1	Interrupt mask for Error 1 0: Masked 1: Not masked	R/W
2	CRC_PRTY	Interrupt mask for CRC-PW / parity 0: Masked 1: Not masked	R/W
3	FTYPI	Interrupt mask for F Type I 0: Masked 1: Not masked	R/W
4	FTYPII	Interrupt mask for F Type II 0: Masked 1: Not masked	R/W
5	MRS_ADR	Interrupt mask for MRS/Adr 0: Masked 1: Not masked	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	EMPFR2	Interrupt mask for EMPFR2 register update 0: Masked 1: Not masked	R/W
9	EMPFR3	Interrupt mask for EMPFR3 register update 0: Masked 1: Not masked	R/W
10	IERR2	Interrupt mask for /Error2 0: Masked 1: Not masked	R/W
11	CRCZI1	Interrupt mask for CRC-ZI1 0: Masked 1: Not masked	R/W
12	CRCZI2	Interrupt mask for CRC-ZI2 0: Masked 1: Not masked	R/W

Bit	Symbol	Function	R/W
13	BUSY	Interrupt mask for Busy 0: Masked 1: Not masked	R/W
14	RM	Interrupt mask for RM 0: Masked 1: Not masked	R/W
15	WRN	Interrupt mask for WRN 0: Masked 1: Not masked	R/W
16	SPIKE	Interrupt mask for Spike 0: Masked 1: Not masked	R/W
17	WTDG	Interrupt mask for Watchdog 0: Masked 1: Not masked	R/W
18	FTYPIII	Interrupt mask for F Type III 0: Masked 1: Not masked	R/W
28:19	—	These bits are read as 0. The write value should be 0.	R/W
29	SPDRDY	Interrupt mask for Speed ready 0: Masked 1: Not masked	R/W
30	—	This bit is read as 0. The write value should be 0.	R/W
31	RDY	Interrupt mask for Ready 0: Masked 1: Not masked	R/W

The INTMR register is for the masking of the STATR register's interrupt sources. All bits shown in the status register (except for LZM, LZK, RDY4STRB) can generate an interrupt. The bit assignments of the interrupt mask register are identical to those of the status register. An interrupt is allowed by setting the corresponding bit to 1.

49.3.6 SWSTRBR : SW Strobe Register

Base address: ENDATm = 0x9020_4000 + 0x1_0000 × m (m = 0 to 11)
ENDATi = 0x9030_4000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x38

Bit position:	31																												0
Bit field:																													
Value after reset:	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	SW strobe The application triggers the data transfer through a write command (set this register to 1). This option is used on applications that are not time-critical.	W

49.3.7 IDR : ID Register

Base address: ENDATm = 0x9020_4000 + 0x1_0000 × m (m = 0 to 11)
ENDATi = 0x9030_4000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x3C

Bit position:	31																												0

Bit	Symbol	Function	R/W
31:0	n/a	EnDat specification ID	R

49.4 Operation

49.4.1 Control Sequence

Figure 49.2 shows the basic operating sequence of ENDAT. The flow charts are valid for EnDat transmission.

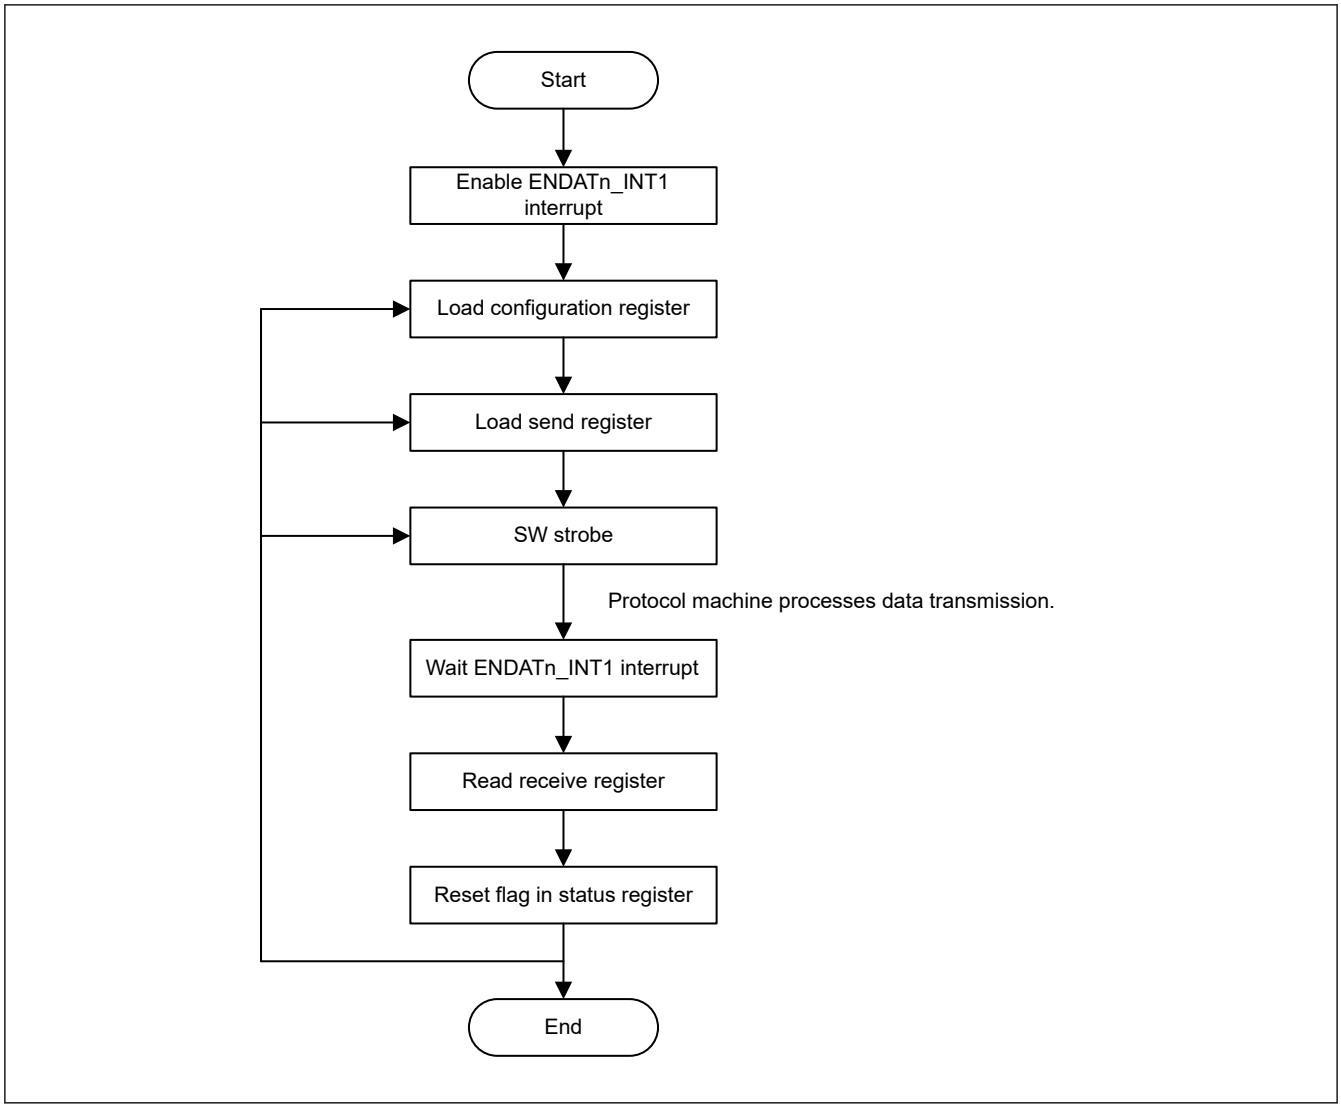

Figure 49.2 Control sequence

49.4.2 EnDat Data Transfer

EnDat is a bidirectional serial interface. The ENDAT starts transmission by sending a clock frequency with a defined length. Synchronously with the clock, a mode command (and other data, if required) is transmitted to the encoder. The encoder responds by sending the requested data to the subsequent electronics. The transmission direction can change multiple times during data transfer (half-duplex).

The EnDat protocol must be selected in the KONFR1 register.

49.4.2.1 Operating Sequence

Figure 49.3 shows the operating sequence of EnDat data transfer. The mode commands can be divided into three groups.

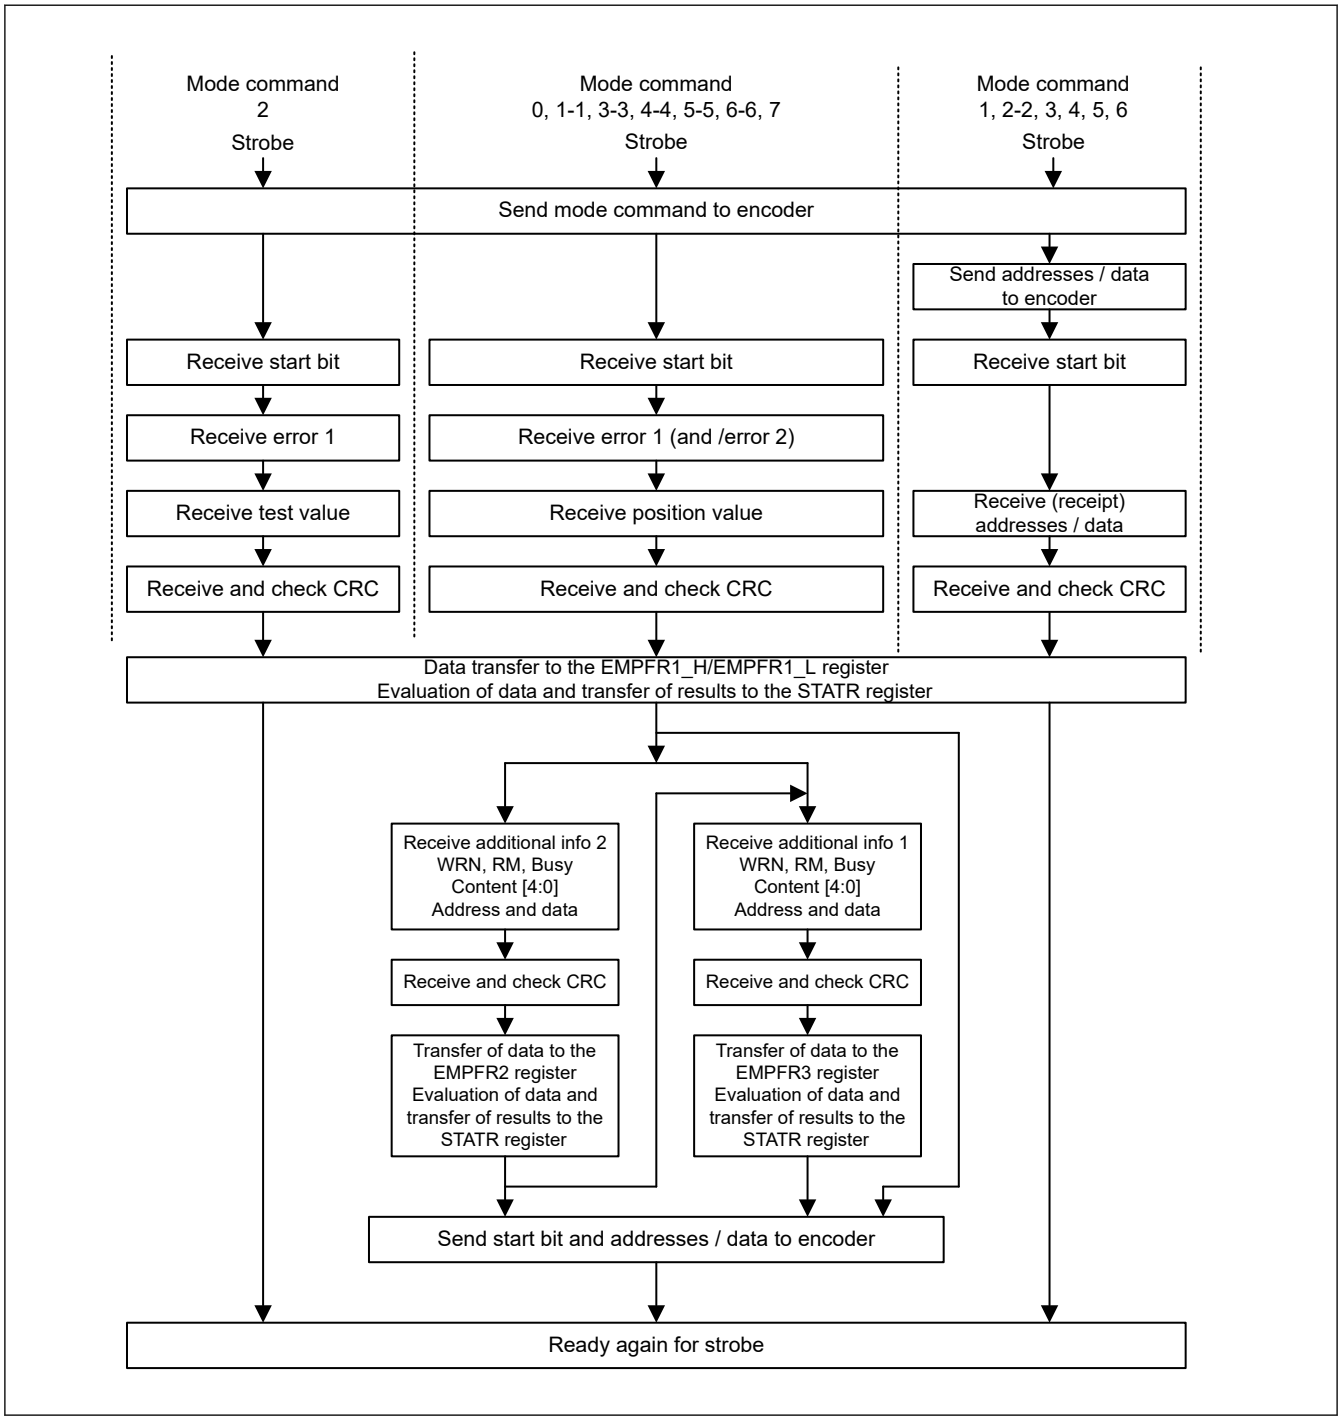

Figure 49.3 EnDat operating sequence

On mode commands for transfer of additional information (center block), the additional information previously selected by mode command 001001b and MRS code for selection (and deselection) of additional information determines the further progress of the protocol, i.e. whether and how many clocks will be sent to receive additional information.

49.4.2.2 Basic Functions

(1) Clock Generator

The clock generator creates the transmission clock required for the synchronous serial interface. The transmission frequency f_{TCLK} is set in the KONFR1 register. The pulse/break ratio specified for EnDat is complied with.

The clock generator also ensures that the number of clocks required for the respective mode commands is output. This is ensured during operation with and without delay compensation.

The number of clocks depends on the data word length and the mode command used as per EnDat specification.

(2) Data Word Length

The number of bits to be transferred for the position value must be set in the KONFR1 register.

(3) Continuous Clock

The ENDAT supports the possibility of executing a position value transfer with continuous clock using mode command 000111b. The settings are made in the KONFR1 register. (Default setting: Continuous clock = off)

Note: The updating rate can be very high. The EMPFR1_L/EMPFR1_H registers are not updated if the corresponding flag in the STATR register is not reset by the application. It is therefore recommended that the data transfer bit, DU, be set to 1 in the KONFR1 register.

(4) Error Handling

The ENDAT executes type I and type II error handling. Type III error handling is executed only for EnDat2.1 mode commands.

Note: This function is supported in the FR register. The results of type I and type II error handling are shown in the STATR register.

(5) Encoder Status

The status messaged from the encoder transported in the EnDat protocol are reflected to ERR1, IERR2, WRN, RM, and BUSY bits in the STATR register after every data transfer.

(6) Cyclical Redundance Check (CRC)

The CRC bits received are compared with the CRC bits generated from the received data flow.

The CRC result of the position value and the data and addresses (with EnDat 2.1 commands) is saved in the STATR register under CRC-PW.

The CRC result of additional information 1 (2) is shown in the STATR register under CRC-ZI1 (2).

(7) Cable Propagation Time

At high transmission rates and with long cable lengths, the cable propagation time must be compensated for technical reasons.

The cable propagation time is measured during the next EnDat transmission[*1] if a corresponding entry is made in the KONFR1 register (cable propagation time = on). The propagation time measurement is carried out at a reduced transmission frequency (independent of the selected setting).

The measured value "cable propagation time" is saved in the KONFR1 register and is taken into account for subsequent transmissions.

After completion of the propagation time measurement, the bit "propagation time measurement completed" (LZM) in the STATR register is set to 1 and the bit "Delay compensation" (LZK) in the STATR register is set to 1.

If the measurement is to be repeated, the delay compensation bit (DELAYCMP) must be reset and then set again in the KONFR1 register. (For 16-bit access, it must be considered that the measured cable propagation time value in the KONFR1 register is overwritten with 0x00.)

In additional to that, the application can correct the (measured) cable propagation time by overwriting the propagation value in the KONFR1 register. In this case the propagation time measurement (LZM) display in the STATR register disappears (LZM to 0).

This function is supported with certified cables only.

Note 1. Use mode command 0 "Encoder transmit position values"

(8) Recovery Time II (Max. 500 ns)

During recover time the EnDat master does not permit starting an EnDat transmission. If delay compensation is enabled and the propagation time value entered in the control register is higher than or equals 500 ns, the master does not implement it additionally. In this case, the master is ready for a new transmission at 5 to 6 system clocks after the H/L edge on DATA_RC. The bit 30, RDY4STRB, in the STATR register signals to the user that the EnDat system is ready for another transmission.

(9) Recovery Time III

At high transmission rates and with long cable lengths, recovery time III t_{ST} must, for technical reasons, be set in the KONFR2 register. (Default setting: 2 µs)

Note: The application can change the value for recovery time III t_{ST} if required. The time (t_{ST}) in the KONFR2 register should be greater than the measured propagation delay time plus 20 percent. (t_{ST} > 1.2 × propagation delay time)

49.4.2.3 Advanced Functions

(1) Watchdog

The watchdog allows to set a maximum value for the transmission duration. If this value is exceeded (e.g. due to an error), the transmission will be aborted and the EnDat sequencing controller is redefined to the outset. Register will not be reset, however. If a propagation time measurement or delay compensation was carried out before, it is retained and remains active. (This means that the delay compensation is not reset, either.)

The watchdog timer can be set in the KONFR2 register. If it is enabled, it starts when the EnDat transmission begins and stops when the EnDat transmission ends (EnDat engine idle). The status of the watchdog is shown in the STATR register.

The reaction of the watchdog on the interrupt output can be made visible by means of the interrupt mask. (Default setting = off)

The watchdog is ineffective with the following functions:

- Continuous clock
- Mode command 5 ("Encoder receive reset")
- Mode command 3 and 4 ("Encoder receive/transmit parameters")

(2) Reset with Selected Additional Information

If additional information was selected before a reset, it must be taken into consideration that this information is lost due to the reset. However, the measuring instrument keeps this information and still expects clock pulses for the additional information. For this reason, the EnDat2.1-Reset command must be given after the reset of the EnDat Master. (This EnDat command then deselects the additional information in the measuring instrument too.)

49.4.3 Interrupt

The ENDATn_INT1 interrupt output triggers status information at the output in accordance with INTMR register settings. (n = 0 to 15)

49.4.4 Timer for Sampling Rate

Timer values for the sampling rate are set in the KONFR2 register.

Table 49.10 shows the programming values of sampling rate.

Two ranges are available for selection (microseconds and milliseconds).

Note: If the timer and the HW strobe delay are active at the same time, KONFR2[31:24], the timer output (Trigger signal), / timer, stays active, but transmission is only triggered with an H/L edge at the /STR input from ELC.

Table 49.10 Programming values of sampling rate

µs: KONFR2[7] = 0		ms: KONFR2[7] = 1	
KONFR2[6:0]	**Sampling rate (µs)**	**KONFR2[6:0]**	**Sampling rate (ms)**
0x00	Stop	0x00	Stop
0x01	2	0x01	0.2
0x02	4	0x02	0.4
0x03	6	0x03	0.6
⋮	⋮	⋮	⋮
0x0A	20	0x0A	2.0
⋮	⋮	⋮	⋮
0x7F	254	0x7F	25.4

49.4.5 Watchdog Timer

Setting for the Watchdog is entered in the KONFR2 register.

Table 49.11 shows the programming values of Watchdog timer.

Two ranges are available for selection (microseconds and milliseconds).

Note: Accuracy: +2 µs or 0.2 ms. Depending on the range setting.

Table 49.11 Programming values of timer

µs: KONFR2[15] = 0		ms: KONFR2[15] = 1	
KONFR2[14:8]	**Timer (µs)**	**KONFR2[14:8]**	**Timer (ms)**
0x00	Stop	0x00	Stop
0x01	2	0x01	0.2
0x02	4	0x02	0.4
0x03	6	0x03	0.6
⋮	⋮	⋮	⋮
0x0A	20	0x0A	2.0
⋮	⋮	⋮	⋮
0x7F	254	0x7F	25.4

50. BiSS-C (BISS)

50.1 Overview

The MPU includes BiSS (BISS) master to enable communication between the encoder and BiSS-C interface. Table 50.1 describes the BiSS-C specifications and Figure 50.1 shows a block diagram of the BISS.

Table 50.1 BiSS-C (BISS) specifications

Item	Description
Number of units	16 units (12 in LLPP0 and 4 in LLPP1)
Protocol	BiSS-C, SSI
Functions	• Bidirectional BiSS communication with up to 8 slaves • Support SSI protocol for unidirectional data transmission • 1 physical BiSS channel each unit • Synchronous sensor data acquisition with cycle data transfers • Slave register operations during cyclic data transfers • Automatic compensation of line delays and conversion times • Data lengths of up to 64 bits for sensor data, configurable for each slave • Data verification by CRC polynomials of up to 16 bits per slave • Separate memory banks enable free controller access during BiSS sensor data transfers • 64 bytes memory for bidirectional register communication • Parallel interface with 32-bit data/address bus • Point-to-point connection (no bus connection: No MO pin) • System Clock (fCLK): 20 MHz (PCLKBISS/4)
Interrupt sources	• EOT: End-of-transmission • NER: Error output
Event link	GETSENS input for HW trigger provided from ELC
Module-stop function	Module-stop state can be set to reduce power consumption

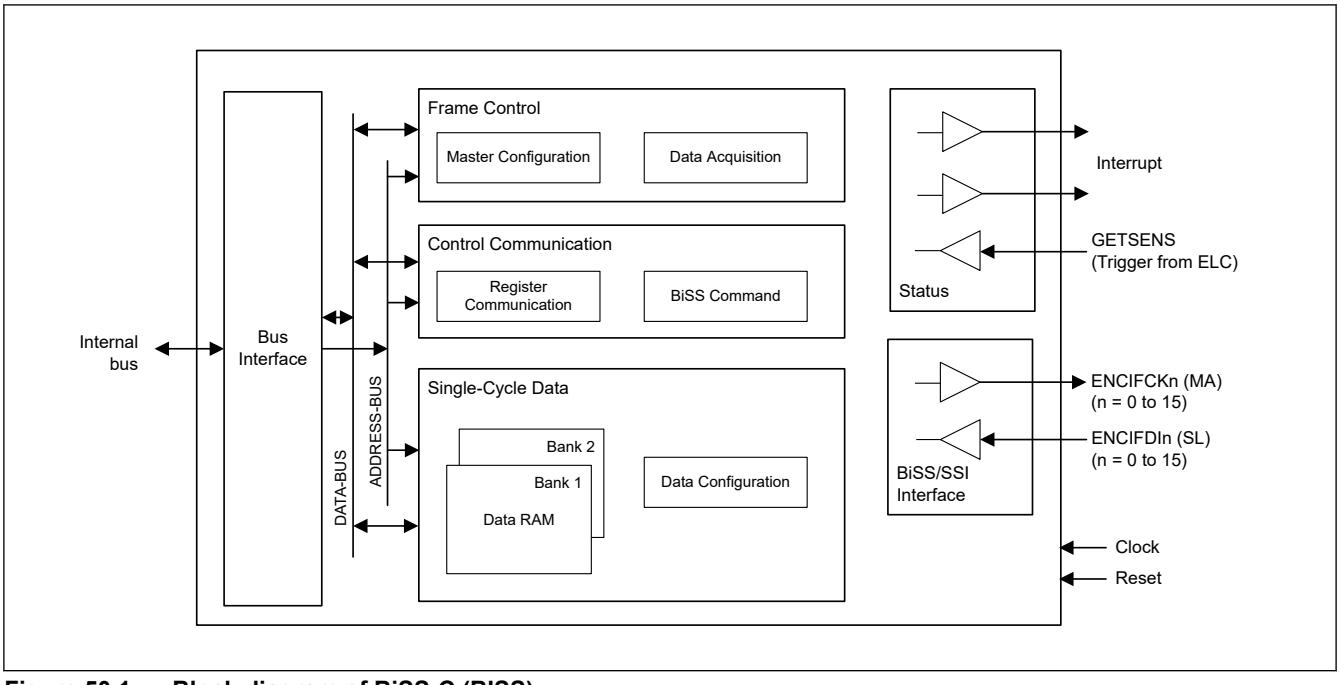

Figure 50.1 Block diagram of BiSS-C (BISS)

Table 50.2 PIN configuration of the BISS

Unit	Pin name	I/O	Function
BISSn	ENCIFCKn (MA)	Output	BiSS-C unit n clock output
	ENCIFDIn (SL)	Input	BiSS-C unit n data input

Note: n = 0 to 15

Table 50.3 BISS interrupt sources

Name	Interrupt sources
BISSn_EOT	End-of-transmission interrupt
BISSn_NER	Error interrupt

Note: n = 0 to 15

50.2 Register Map

Table 50.4 BISS register map

Address	Register symbol	Register name	Write protection
0x9020_3000 + 0x08 × (n - 1) + 0x1_0000 × m (m = 0 to 11) 0x9030_3000 + 0x08 × (n - 1) + 0x1_0000 × (m - 12) (m = 12 to 15)	SCDATALn	Sensor Data L (n = 1 to 8)	—

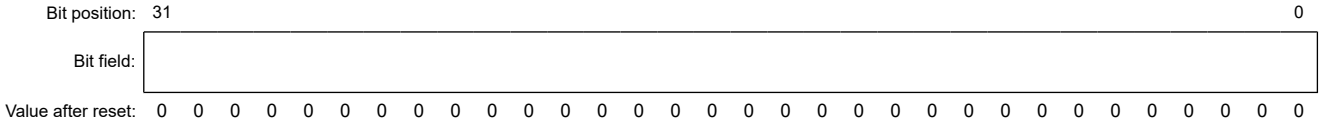
50.3 Register Descriptions

50.3.1 SCDATALn : Sensor Data L (n = 1 to 8)

Base address: BISSm = 0x9020_3000 + 0x1_0000 × m (m = 0 to 11)
BISSi = 0x9030_3000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x00 + 0x08 × (n - 1)

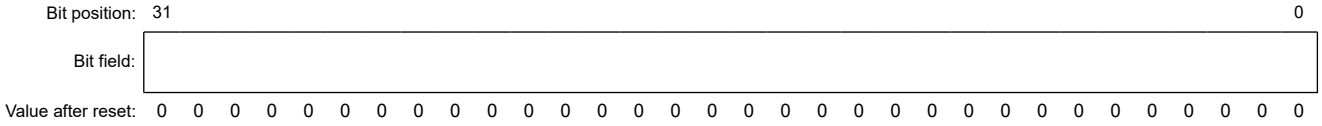


Bit	Symbol	Function	R/W
31:0	n/a	Sensor data lower for slave n This register stores the lower four bytes (SCDATAn[31:0]). For details, see section 50.4.3. Sensor Data.	R/W

50.3.2 SCDATAHn : Sensor Data H (n = 1 to 8)

Base address: BISSm = 0x9020_3000 + 0x1_0000 × m (m = 0 to 11)
BISSi = 0x9030_3000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x04 + 0x08 × (n - 1)

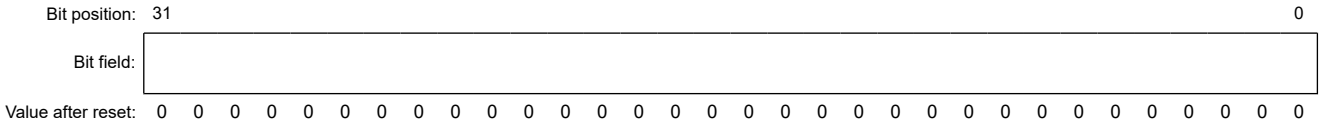


Bit	Symbol	Function	R/W
31:0	n/a	Sensor data upper for slave n This register stores the upper four bytes (SCDATAn[63:32]). For details, see section 50.4.3. Sensor Data.	R/W

50.3.3 RDATAn : Register Data n (n = 1 to 16)

Base address: BISSm = 0x9020_3000 + 0x1_0000 × m (m = 0 to 11)
BISSi = 0x9030_3000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0x80 + 0x04 × (n - 1)



Bit	Symbol	Function	R/W
31:0	n/a	● Register communication data n (RDATAn) Using register communication in control communication (CTRLCOMM.CTS = 1). There is an individual 64 bytes storage area used to store the data of automatic register communication. In case of a register write access to a BiSS slave, RDATAn must be written with register data before starting the BiSS communication with INSTREG.INSTR. In case of a register read access to a BiSS slave, the received register data is stored in RDATAn after successful BiSS communication. In contradiction to SCDATAn there is only one memory bank for RDATAn. Therefore, after performing register communication, RDATAn may only be accessed, if no control communication is currently active (STINF.REGEND = 1). ● Slave addressing for BiSS commands (IDS[7:0]) Using BiSS commands in control communication (CTRLCOMM.CTS = 0). When 0x00: All slaves addressed (broadcast). The bits correspond to N. (For details, see section 50.4.4.1. BiSS Commands.) 0: Slave with ID (7 – N) is not addressed 1: Slave with ID (7 – N) is addressed	R/W

50.3.4 CNFSLVn : Configuration Slave n (n = 1 to 8)

Base address: BISSm = 0x9020_3000 + 0x1_0000 × m (m = 0 to 11)
BISSi = 0x9030_3000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0xC0 + 0x04 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	SCRCSTART[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SELCRCS	SCRCLENPOLY[6:0]							GRAYS	ENSCD	SCDLEN[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	SCDLEN[5:0]	Single-cycle data length of slave n For more information about the length, refer to section 50.5.1. The value to be set to SCDLEN in the CNFSVn register and section 50.5.2. The storage of received CRC when SCDLEN = 33 bits or more. 0x00: Single-cycle data length 1 0x01: Single-cycle data length 2 ⋮ 0x3F: Single-cycle data length 64	R/W
6	ENSCD	Enable single-cycle data for slave n 0: Single-cycle data not available 1: Single-cycle data available	R/W
7	GRAYS	Enable GRAY to binary conversion for SSI encoder*1 This bit is valid when CHCNF.CFGCH1[1:0] = 0x2. 0: SSI single-cycle data binary coded 1: SSI single-cycle data GRAY coded	R/W

Bit	Symbol	Function	R/W
14:8	SCRCLENPOLY[6:0]	CRC length with predefined CRC polynomial for slave n (SCRCLEN[6:0]) 0x00: CRC verification deactivated 0x03: 1011b = 0xB 0x04: 1_0011b = 0x13 0x05: 10_0101b = 0x25 0x06: 100_0011b = 0x43 0x07: 1000_1001b = 0x89 0x08: 1_0010_1111b = 0x12F 0x10: 1_1001_0000_1101_1001b = 0x190D9 Others: codes are not permitted CRC polynomial for slave n (SCRCPOLY[7:1]) Since the least significant bit of the CRC polynomial is always 1, there is no need to store this information in the CRC polynomial. Therefore, a maximum polynomial length of 8 bit is possible. If the maximum 8 bits polynomial length is not required, the used polynomial (without the LSB bit) is stored right aligned and leading bits are filled with 0. Example: The CRC polynomial 0x43 = 100 0011b is stored as 010 0001b (value 0x21). 0: CRC verification deactivated n (other than 0): n & 1	R/W
15	SELCRCS	CRC polynomial selection for slave n BiSS uses CRC polynomials depending on the data length predefined in the Electronic Data Sheet (EDS) and Profile Definitions. This bit chooses between predefined polynomials selected according to the CRC length with SCRCLEN and individual CRC polynomials SCRCPOLY. If SCRCLEN = 0, the CRC verification is deactivated. 0: Apply CRC polynomial as predefined in SCRCLEN 1: Apply CRC polynomial as individually defined in SCRCPOLY	R/W
31:16	SCRCSTART[15:0]	CRC calculation start value for slave n The CRC start values can be used to safely differentiate between single-cycle data (SCD) data words e.g., two position words provided by two different sensors. The same CRC start value that is used in the sensor needs to be applied in the master to validate the received single-cycle data. The CRC start value has a length of 16 bits. A typical default slave CRC start value is 0x0000.	R/W

Note 1. FREQR = 0x05 should be set, if CHCNF.CFGCH1 = 0x01.

50.3.5 REGACC : Register Access

Base address: BISSm = 0x9020_3000 + 0x1_0000 × m (m = 0 to 11)
BISSi = 0x9030_3000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0xE0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	REGNUM[5:0]						WNR	REGADR[6:0]							—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	The read values are undefined. The write value should be 0.	R/W
22:16	REGADR[6:0]	Register communication start address	R/W
23	WNR	Register communication direction 0: Read register data 1: Write register data	R/W
29:24	REGNUM[5:0]	Number of consecutive registers to access If REGNUM > 1, a sequential register access is performed. (See BiSS-C Protocol Description) 0x00: Register count 1 0x01: Register count 2 ⋮ 0x3F: Register count 64	R/W
31:30	—	The read values are undefined. The write value should be 0.	R/W

This register is used to configure the BiSS-C control communication for register communication. For details, see section 50.4.4.2. Register Access.

50.3.6 CTRLCOMM : Control Communication

Base address: BISSm = 0x9020_3000 + 0x1_0000 × m (m = 0 to 11)
BISSi = 0x9030_3000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0xE4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	NOCRC	SINGLEBANK	FREQR[2:0]			FREQS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CTS	REGVERS	SID_CMD_IDT[2:0]			—	—	HOLDCDM	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	HOLDCDM	Behavior of MA signal at the end of frame In general operation, the BiSS master is configured according to the data of the connected BiSS slave(s) as described in CNFSLVn registers. A timeout period follows after the data transmission. And after the timeout period expires, the end of the data transmission is signaled to the BiSS master by a rising edge of SL. As soon as the timeout is detected by the BiSS master, it can start a new BiSS frame. If SL signal is not digital low at the end of the frame, e.g., because the BiSS-C frame has not been clocked out completely, MA signal can be programmed with HOLDCDM = 1 to be constant until the next frame begins. Thereby it is ensured that the slave can recognize CDM and take part in control communication, even if the master is not configured according to the data of the connected BiSS slave(s). 0: MA changes to digital high after detecting the slave's timeout termination at SL 1: MA remains constant until the next frame begins	R/W
10:9	—	These bits are read as 0. The write value should be 0.	R/W
13:11	SID_CMD_IDT[2:0]	● Slave addressing for register communication (SLAVEID[2:0]) Using register communication in control communication (CTS = 1). ● BiSS Command of addressed slave (CMD[1:0]) (Corresponds to SID_CMD_IDT[2:1] bits) Using BiSS commands in control communication (CTS = 0). CMD determines which BiSS command is sent. Some BiSS commands are predefined in the BiSS-C Protocol Description, others can be used for device-specific functionality of the slave. ● BiSS command execution control (IDA_TEST) (Corresponds to SID_CMD_IDT[0] bit) Using BiSS commands in control communication (CTS = 0). In contrast to the broadcast BiSS commands, the reception of an addressed BiSS command is confirmed during IDA (ID Acknowledge) by the addressed slave(s). This bit defines if the master triggers the command execution immediately or after checking the IDA bits (see Figure 50.7). The BiSS command is only executed if the check is successful. 0: Immediate execution 1: The slave's feedback (IDA) is tested before execution. The BiSS command is not executed if test fails.	R/W
14	REGVERS	Type of protocol for register communication Supports autonomous register communication with BiSS-C. REGVERS is used to select the protocol type. 0: Not permitted 1: Register communication BiSS-C	R/W
15	CTS	Type of control communication 0: BiSS Commands 1: Register communication	R/W

Bit	Symbol	Function	R/W
20:16	FREQS[4:0]	Single-cycle data clock frequency at MA (fMA) The master clock at MA signal is generated for both BiSS and SSI from the system clock (fCLK) and depends on the frequency division by FREQS. With a system clock frequency of 20 MHz, the clock frequency at MA ranges from 10 MHz down to 62.5 kHz. Single-cycle data clock frequency (fMA): (N: Decimal number) 0x00: fCLK/2/(N + 1) ⋮ 0x0F: fCLK/2/(N + 1) 0x10: Not permitted 0x11: fCLK/20/(N - 15) ⋮ 0x1F: fCLK/20/(N - 15)	R/W
23:21	FREQR[2:0]	BiSS register data frequency*1 *2 BiSS slave device recognizes an idle bus at the end of a transmission frame via timeout detection. Thus, the choice of possible clock frequencies is limited as the duration of each logic level may not exceed the shortest timeout of all the connected slaves. 0 0 0: $fMA/2^{(N + 1)}$ ⋮ 1 1 1: $fMA/2^{(N + 1)}$	R/W
24	SINGLEBANK	Usage of one/two RAM bank(s) for SCDATA With SINGLEBANK = 0, two RAM banks are used for buffering SCDATA. Thus, it is ensured that one RAM bank can be written with single-cycle data received at the BiSS interface while the single-cycle data content of the other RAM bank is read. A downgrade is possible by setting SINGLEBANK = 1. 0: Two RAM banks are used for SCDATA 1: One RAM bank is used for SCDATA	R/W
25	NOCRC	Storage of received CRC in SCDATA When NOCRC = 1, the CRC is not updated to the SCDATA register, but it is not cleared to 0. Therefore, switching from NOCRC = 0 to NOCRC = 1 leaves the last data in the register. When clearing the CRC to 0, the SCDDATA register must be cleared according to the number of the RAM banks used. 0: CRC of SCD is stored in SCDATA 1: CRC of SCD is not stored in SCDATA	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. FREQR = 0x05 should be set, if CHCNF.CFGCH1 = 0x01.
Note 2. BiSS-C devices generally permit a lower clock frequency. BiSS-C devices do not use a MA clock duty cycle (PWM signal) and can be operated down to 80 kHz.

The control communication enables protected and confirmed reading and writing of the registers of a slave (register communication). It is also used for protected and confirmed sending of BiSS commands to specified slaves or to all slaves. The control data is compounded of 1 bit per single-cycle data frame in each direction. The control data bit sent as part of the single-cycle data frame from master to the slaves is called CDM (Control Data Master) and the control data bit sent from a slave to the master is called CDS (Control Data Slave). For more information about the control communication refer to the BiSS-C Protocol Description.

50.3.7 MSTRCNF : Master Configuration

Base address: BISSm = 0x9020_3000 + 0x1_0000 × m (m = 0 to 11)
BISSi = 0x9030_3000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0xE8

Bit position:	31							24	23							16								7							0
Bit field:	VERSION[7:0]								REVISION[7:0]								—	—	—	—	—	—	—	—	FREQAGS[7:0]							
Value after reset:	0	1	0	0	0	0	0	1	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	FREQAGS[7:0]	Frame repetition rate (AGS frequency divider)*1 *2 FREQAGS controls the automatic data transmission (INSTREG.AGS). With FREQAGS the frame repetition rate can be set to a dedicated ratio of the system clock frequency (fCLK). With a system clock frequency of 20 MHz frame repetition rates from 1 µs to 4 ms are possible. FREQAGS must be set in a way that the time in between two frames is greater than a complete cycle. One cycle consists of the transmission of a request, an acknowledge signal (including line delay), a start bit (including processing time), a control data bit (BiSS-C), the sensor data and CRC bits of each slave and the maximum BiSS timeout of all connected slaves. FREQAGS is activated with INSTREG.AGS. (N: Decimal number, fCLK: system clock frequency) 0x00: fCLK/20/(N + 1) ⋮ 0x7B: fCLK/20/(N + 1) 0x7C: AGSMIN 0x7D: AGSINFINITE ⋮ 0x7F: AGSINFINITE 0x80: fCLK/625/(N - 127) ⋮ 0xFF: fCLK/625/(N - 127)	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W
23:16	REVISION[7:0]	Design ID	R
31:24	VERSION[7:0]	Version	R

Note 1. AGSMIN: The master automatically restarts the next frame after the previous frame is finished. The master automatically generates the highest frame rate possible. AGSMIN requires complete BiSS frames to ensure a low level at SL at the end of each frame. The rate depends on the configured sensor data clock frequency (CTRLCOMM.FREQS), the slave configurations (e.g., CNFSLVn.SCDLEN), the maximum processing time of the slaves and the total system line delay.

Note 2. AGSINFINITE: The master does not automatically restart the next cycle. AGSINFINITE requires a trigger event to start the next frame. The next frame is started by a digital pulse at GETSENS signal or by setting INSTREG.INSTR.

50.3.8 CHCNF : Channel Configuration

Base address: BISSm = 0x9020_3000 + 0x1_0000 × m (m = 0 to 11)
BISSi = 0x9030_3000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0xEC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

50.3.9 STINF : Status Information

Base address: BISSm = 0x9020_3000 + 0x1_0000 × m (m = 0 to 11)
BISSi = 0x9030_3000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0xF0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CDMTIMEOUT	CDSSEL	REGBYTES[5:0]						SVALID[15:8]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SVALID[7:0]								nERR	nAGSERR	nDELAYERR	nSCDERR	nREGERR	REGEND	—	EOT
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	0	0	1

Bit	Symbol	Function	R/W
0	EOT	End of transmission EOT flag is connected to EOT signal and signals a running frame (see section 50.4.2. BiSS-C). 0: Data transmission active 1: Data transmission not active	R
1	—	This bit is read as 0. The write value should be 0.	R/W
2	REGEND	End of Control Communication REGEND indicates a finished control communication. It is also set if the control communication was not successful. REGEND flag is reset in the following three patterns: ● After power on ● Control communication has not started after initialization by INSTREG.INIT ● Control communication running 0: Control communication running or not started since power on/INIT 1: Control communication completed/not running	R
3	nREGERR	Control communication error nREGERR flag is set after power on and after executing INSTREG.INIT. If a register data error is detected, the number of bytes transmitted correctly before the error occurred is provided by the register message REGBYTES. In case of an error, the transmission of data is terminated. The following issues can cause error indication: ● Read register access: CRC error or inverted R-bit ● Write register access error in repeated CDS data ● BiSS Commands: error in IDA 0: Error in last control communication 1: No error in last control communication	R
4	nSCDERR	Single-cycle data (SCD) transmission error An error in the single-cycle data detected by checksum verification (CRC) is shown with nSCDERR. If nSCDERR = 0, the faulty sensor can be identified by reading SVALID bits. 0: Error in last single-cycle data transmission 1: No error in last single-cycle data transmission	R
5	nDELAYERR	Start bit in register communication*1 nDELAYERR flag is set after power on and after executing INSTREG.INIT. nDELAYERR notifies about a missing start bit in last register communication. The addressed slave register might not be implemented. 0: Missing start bit in last register data transmission. Register address is not implemented or register access processing time too long (> 20 ms, if CTRLCOMM.FREQR = 0x05). 1: No missing start bit in last register data transmission	R

Bit	Symbol	Function	R/W
6	nAGSERR	Automatic Get Sensor (AGS) error When automatic transmission of sensor data is enabled with instruction bit INSTREG.AGS, an AGS watchdog error nAGSERR is indicated, if no new cycle could be initiated. If the last BiSS frame has not been finished in time, the next BiSS frame will be omitted. The following BiSS frame will be executed if possible. nAGSERR flag is also indicated, if a write access to INSTREG register is performed (e.g., by writing INSTREG.BREAK). 0: At least one BiSS frame has been omitted 1: No missing BiSS frames	R
7	nERR	State of the error interrupt (NER) nERR flag indicates the state of NER signal. Any of the errors is indicated. 0: Internal error occurred 1: No error occurred	R
23:8	SVALID[15:0]	SCDATAn validity indication (n: slave, n = 1 to 8)*2 Two bits are assigned to each slave, the upper bit is valid (SVALID[1]: SVALID1 for Slave 1, SVALID[3]: SVALID2 for Slave 2, SVALID[5]: SVALID3 for Slave 3, and so on). The lower bit is invalid, and the write value should be 0. The CRC verification result of the received single-cycle sensor data of every BiSS frame is written to the validity SVALID for each slave separately. If the CRC is disabled in the slave configuration, the correspondent SVALID flag is set after reading of sensor data has been completed. The validity flags are reset by writing to SVALID. 0: Single-cycle data invalid 1: Single-cycle data valid	R/W
29:24	REGBYTES[5:0]	Number of valid register bytes In case of an error in a sequential register communication (nREGERR = 0), the number of faultless transmitted register values are stored in REGBYTES. These bits are reset if an initialization sequence (INSTREG.INIT) is transmitted or a new control communication started.	R
30	CDSSEL	State of Control Data Slave (CDS)*3 0: CDS value 0 1: CDS value 1	R
31	CDMTIMEOUT	Control Data Master (CDM) timeout reached For BiSS-C control communication, a minimum number of SCD cycles with exclusively CDM = 0 must be sent before starting a new control communication frame. For a manual control communication by software, CDMTIMEOUT bit indicates that ≥ 14 SCD cycles with exclusively CDM = 0 have already been sent. 0: Timeout of BiSS-C control communication not reached 1: Timeout of BiSS-C control communication reached	R

Note 1. This controller can abort register communication after tbusy_r (as defined in BiSS-C Protocol Description).
Note 2. After reading sensor data, it is recommended to reset SVALID flags in order to recognize updated sensor data.
Note 3. There are two RAM banks for SVALID, CDSSEL, and STINF2.CDS1 that switch simultaneously to SCDATA RAM banks.

The status information is combined in a set of registers. It indicates all device and communication states of the master.

50.3.10 INSTREG : Instruction Register

Base address: BISSm = 0x9020_3000 + 0x1_0000 × m (m = 0 to 11)
BISSi = 0x9030_3000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0xF4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	MAVS	MAFS	—	—	—	—	BREAK	HOLD BANK	SWBANK	INIT	INSTR[2:0]			AGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AGS	Automatic Get Sensor Data (AGS) The automatic data transmission is enabled with AGS, and the frame rate is set with MSTRCNF.FREQAGS bits. For details, see section 50.4.5. Data Acquisition. FREQAGS = AGSMIN: Start of data transmission after slave's timeout FREQAGS = AGSINFINITE: Start of data transmission triggered by GETSENS FREQAGS = Other: Start of data transmission equally spaced at a constant rate 0: No automatic data transmission 1: Automatic data transmission	R/W
3:1	INSTR[2:0]	Single-Cycle Data (SCD) Control Instruction INSTR can be used to trigger data transmission by program. For details, see section 50.4.5. Data Acquisition. When AGS = 0: 0 0 0: Reset state. No INSTR performed. 0 0 1: Start one frame with CDM = 1. INSTR automatically resets. 0 1 0: Start one frame with CDM = 0. INSTR automatically resets. 0 1 1: Start one frame with CDM = not(CDSSEL). INSTR automatically resets. 1 0 0: Start one frame with control communication. INSTR automatically resets. 1 1 1: Start one reduced frame with control communication. INSTR automatically resets. When AGS = 1: 0 0 1: Upcoming frames with CDM = 1. 0 1 0: Upcoming frames with CDM = 0. 0 1 1: Upcoming frames with CDM = not(CDSSEL). 1 0 0: Upcoming frames with control communication. INSTR will be reset at the end of the control communication. 1 1 1: Upcoming reduced frames with control communication. INSTR will be reset at the end of the control communication.	R/W
4	INIT	Start initialization sequence*1 Typically, the BiSS data line SL is set to digital high by the last slave after timeout. After power on or after a failure, the last slave may not be defined, and the SL line is digital low. An initialization sequence started by INIT can be used to initialize the slave chain. Additionally, an INIT sets the status bits nSCDERR, nREGERR, nDELAYERR and nAGSERR in STINF register to 1 and resets REGEND to 0. CTRLCOMM.REGVERS is used to select the protocol type. 0: No operation 1: Initialize (REGVERS = 1: BiSS-C)	R/W
5	SWBANK	RAM Bank Switching By inverting SWBANK value a switch of the RAM banks is forced. This can be used, for instance, to initialize the content of both RAM banks. 0: No operation when Previous value = 0. RAM banks are switched when Previous value = 1. 1: RAM banks are switched when Previous value = 0. No operation when Previous value = 1.	R/W
6	HOLDBANK	RAM Bank Control When reading more than one Data RAM registers by the controller, the RAM banks in the master could be switched once a sensor data transmission via BiSS is completed. To avoid unexpected bank switching, the controller can set HOLDBANK before reading Data RAM registers and releases it afterwards. If bank switching was prevented with HOLDBANK = 1, the bank is switched after resetting HOLDBANK = 0. If a new BiSS frame is scheduled before HOLDBANK is reset (e.g., when using INSTREG.AGS with a high MSTRCNF.FREQAGS), no bank switching is performed but STINF.nAGSERR will be set. 0: Automatic bank switching is permitted 1: Automatic bank switching is prevented	R/W
7	BREAK	Start BREAK Sequence*2 All current actions can be aborted using the BREAK command so that the controller enters a defined state if one of the sensors does not respond correctly. 0: No operation 1: Abort data transmission	R/W
11:8	—	These bits are read as 0. The write value should be 0.	R/W
12	MAFS	Control of the MA line 0: MA line is not controlled 1: MA line is forced with MAVS	R/W

Bit	Symbol	Function	R/W
13	MAVS	MA line force level 0: Low 1: High	R/W
31:14	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. With REGVERS = 1 (BiSS-C) and an INIT, the master stores the measured line delay in SCDATA1[7:0] register. The unit of these values is 1/4 of the configured single-cycle data clock frequency configured with CTRLCOMM.FREQS.
tLine Delay = SCDATA1[7:0]/(4 × fMA)
For the INIT sequence, the maximum line delay is 255. If this limit is exceeded, the INIT sequence is aborted and STINF.nAGSERR is activated (nAGSERR = 0). The INIT sequence does not test the SL state. A constant SL = 0 state is ignored and does not set any error state.

Note 2. An INIT should be executed after BREAK to ensure resetting status bits.

50.3.11 STINF2 : Status Information 2

Base address: BISSm = 0x9020_3000 + 0x1_0000 × m (m = 0 to 11)
BISSi = 0x9030_3000 + 0x1_0000 × (i - 12) (i = 12 to 15)

Offset address: 0xF8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	SWBANKFAIL	—	—	—	—	IDL[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CDS1	SL1
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
0	SL1	SL input line state The actual state of the BiSS data SL input. 0: SL line level low 1: SL line level high	R
1	CDS1	Control Data Slave (CDS) bit value This bit has the same contents as STINF.CDSSEL. 0: CDS value 0 1: CDS value 1	R
15:2	—	The read values are undefined.	R
19:16	IDL[3:0]	Number of set ID lock bits during control communication*1 At the beginning of each control communication, slave IDs are automatically assigned to the connected slaves by considering the physical order within the daisy chain. IDL indicates the total number of IDL bits that have been set by the BiSS slaves. It corresponds to the number of slaves that take part in control communication. IDL = 9 indicates that there are more than eight BiSS slaves connected that can take part in control communication. Since only 8 BiSS slaves are addressable via CTRLCOMM.SLAVEID, the first slave(s) cannot be addressed unless other slaves have been disabled via predefined BiSS commands as defined in BiSS-C Protocol Description. 0: No IDL bits received 1 to 8: 1 to 8 IDL bits (corresponds to 1…8 slaves) 9: There are more than 8 slaves available. Note, only the first 8 slave IDs are addressable with CTRLCOMM.SLAVEID.	R
23:20	—	The read values are undefined.	R
24	SWBANKFAIL	Bank switching status Switching SCDATA RAM bank—which is executed at the end of a BiSS frame—also switches the corresponding STINF.SVALID flags. It fails if it disables bank switching via INSTREG.HOLDBANK. 0: Bank switching (SCDATA) successful 1: Bank switching (SCDATA) not successful	R

Bit	Symbol	Function	R/W
31:25	—	These bits are read as 0.	R

Note 1. A control communication must be performed before the correct number of slaves is indicated with IDL.

50.4 Operation

50.4.1 BiSS Function

In point-to-point configuration, BiSS devices including one or several sensors are connected to the clock line MA and the data return line SL. RS422 transceivers are available on-chip for robust differential communication in industrial environments. Two types of BiSS communication are supported:

- Single-Cycle Data (SCD):

  Sensor data with up to 64 bits for each slave (e.g., measurement data, error, and warning flag, Sign of Life counter, …).

- Control Communication:

  E.g., register communication for reading/writing the sensor's registers (e.g., for reading an Electronic Datasheet or calibrating sensors).

This controller provides two RAM memory banks for each slave enabling simultaneous access by CPU while new sensor data is being transmitted via BiSS interface. A 64-byte memory supports register transfers. Sensor data acquisition is started by a software instruction, via GETSENS signal or automatically at a configurable frame repetition rate. The end of the sensor data transmission is indicated at BISSn_EOT (EOT: n = 0 to 15) interrupt. An error during transmission is flagged by BISSn_NER (NER: n = 0 to 15) interrupt. Error details can be accessed in the status registers. This controller generates a clock signal for sensor communication using 20 MHz system clock.

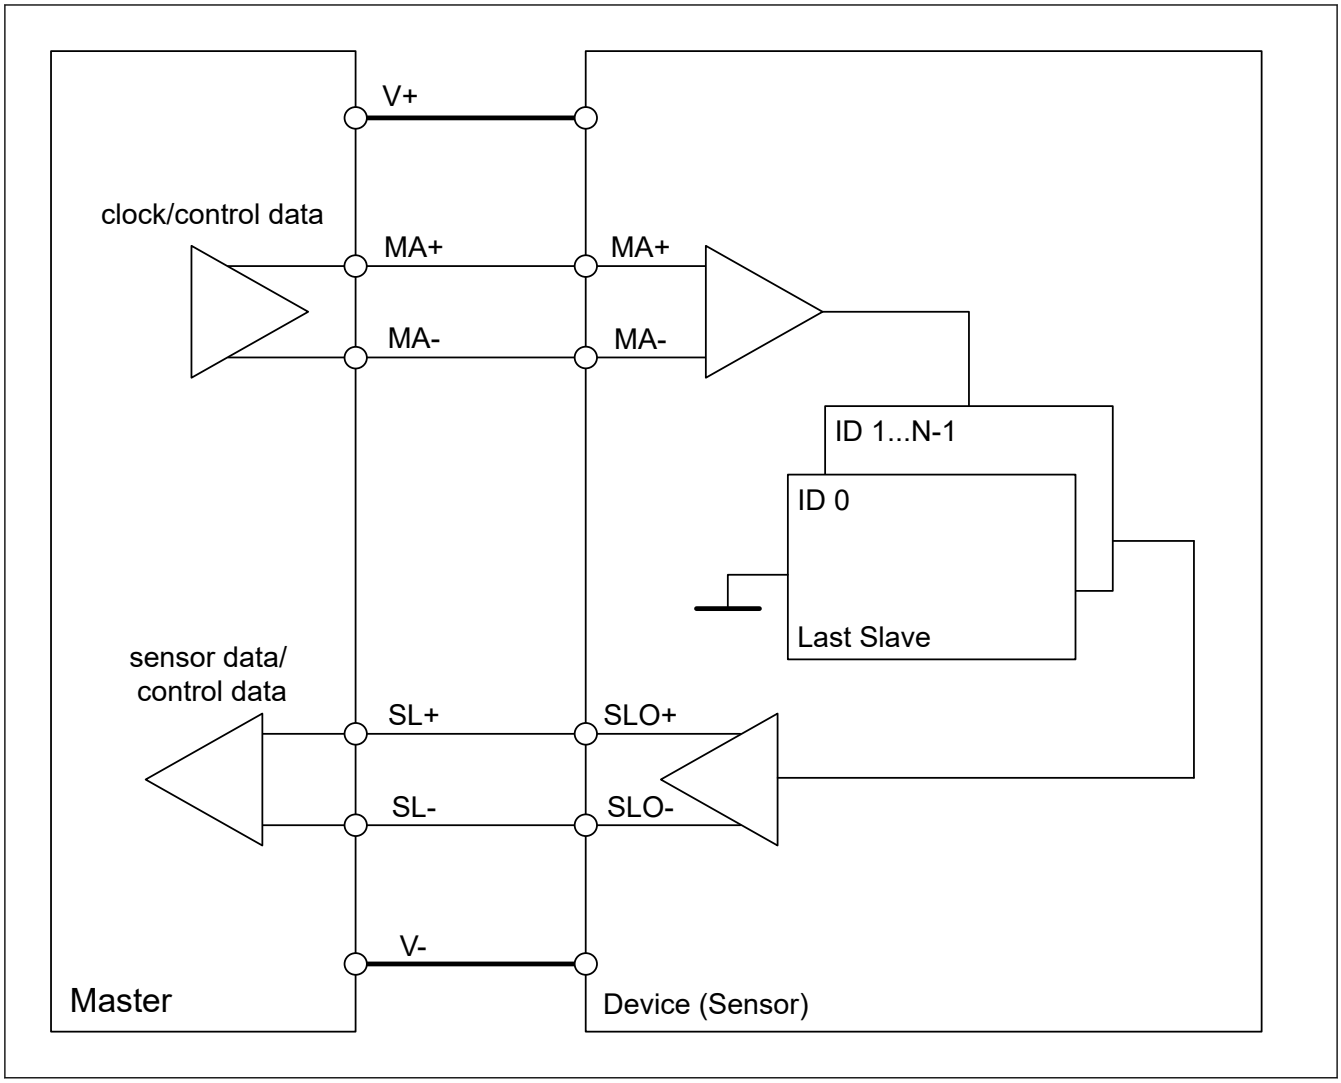

Figure 50.2 Point-to-point connection to device with several slaves

The open-source BiSS Interface Protocol implements a real-time interface for digital, serial, and secure communication between drive, sensor and actuator. In the point-to-point configuration, BiSS uses one clock line MA from the master to the sensor and one data line SL from the sensor to the master. A device may contain multiple slaves. The data input signal SL of the last slave is set to digital low. The slaves are daisy-chained and the data output signal SLO of the first slave is directly connected to the master. The BiSS protocol describes cyclic data frames and differentiates between process data and control data. Process data are completely transmitted in each frame (SCD) used as sensor data, and control data are transmitted one bit per frame (CD) used for commands and register access.

50.4.2 BiSS-C

(1) BiSS-C Frame

The BiSS-C Frame starts with a digital high on the clock line MA and is notified with a falling edge at EOT signal. On the first falling edge of MA, all slaves check the SL signal for a digital low determining the last slave. With the first rising edge at MA, all sensors start calculating their sensor data. The second rising edge of MA forces all slaves to acknowledge the BiSS-C frame with a falling edge at SL. The master uses the acknowledge to measure the line delay. When the sensor data calculation is finished, the last slave in the chain generates the start bit which will be passed synchronously through all slaves to the master. Subsequent to the start bit follows one control data bit (CDS) for all slaves which is set according to the rules of the control frame. After the CDS bit, the process data including sensor data is sent with the most significant bit (MSB) first. At the end, the master sends its control data bit (CDM) inverted on the clock line MA to conclude the BiSS-C Frame.

During processing the frame, all slaves observe the MA clock line and change into the timeout state if MA is stable for a specific time defined within each slave. In the timeout state, only the last slave forces its SL signal to digital high. The other

slaves in the chain indicate to the master that all slaves are in the timeout state. After detecting the slave's timeout with SL = 1, the master may change the MA clock line to digital high or keeps the clock line constant until the next frame begins.

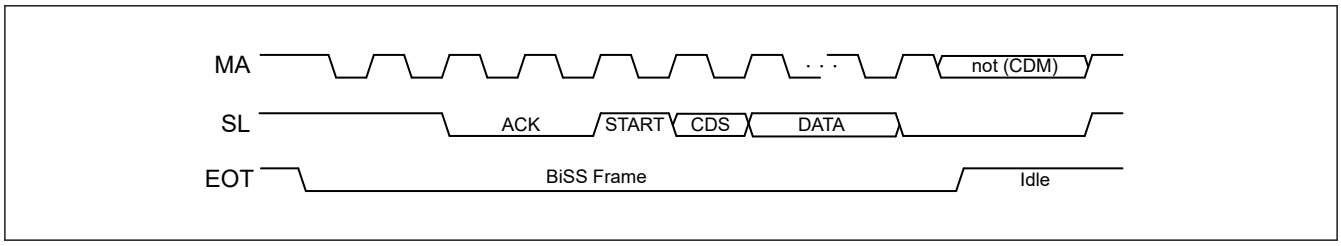

Figure 50.3 BiSS-C frame in point-to-point configuration

(2) BiSS-C Register Communication

The master is able to transmit a BiSS-C register write access to the slave without the slave's CDS feedback. The master cannot verify that the BiSS-C register write access to the slave did succeed. At the end of the SCD frame, the master sends the CDM bit inverted on the MA clock line.

(3) BiSS-C Initialization Sequence

An initialization (INIT) sequence is necessary if the last slave in the point-to-point configuration is not defined and the data line SL is digital low. In the initialization sequence, two digital low pulses are generated at MA. The slave(s) should start communication at the second falling edge of the MA pulse and answer the end of communications by generating a rising edge on SL after the BiSS timeout detection. The time between the second rising-edge at MA and the falling-edge at SL is measured as line delay and stored in the single-cycle data RAM, see INSTREG.INIT bit function.

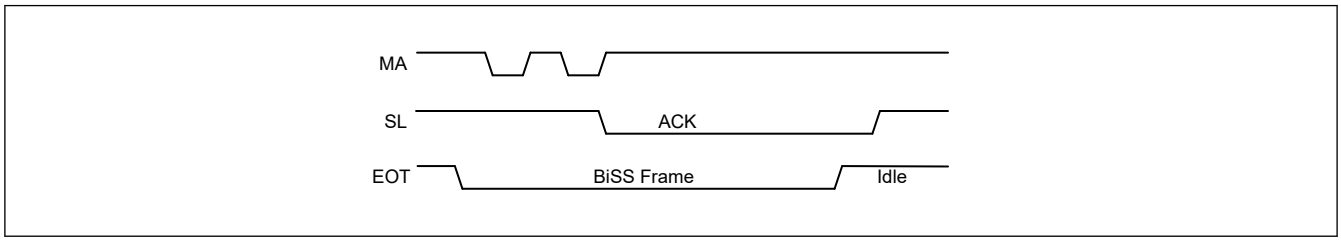

Figure 50.4 BiSS-C initialization sequence

50.4.3 Sensor Data

For sensor data, an 8x8 byte single-cycle data memory SCDATA is provided. Eight slaves with up to 64 bits of single-cycle data each are supported.

Table 50.6 Address mapping of single-cycle data (SCDATA)

Offset address	Register	Content
0x00 + 0x08 × (n - 1)	SCDATALn[31:0]	SCDATAn[31:0]
0x04 + 0x08 × (n - 1)	SCDATAHn[31:0]	SCDATAn[63:32]

Note: Slave: n = 1 to 8

The sensor data is arranged in the memory area with the least significant bit (LSB) at the lower address at bit position 0. The memory is written byte-by-byte and unused bits are set to zero. Unused bytes remain unchanged. In BiSS the CRC bits are inverted before transmission. The received CRC bits are reinverted and then stored at the most significant SCDATA byte(s). This can be disabled with CTRLCOMM.NOCRC = 1.

- Example: BiSS Sensor Bus with 3 Slaves
  The following example shows the address mapping of the sensor data and CRC bits generated by three slaves.
  - Slave 1: 19 + 2 bits of sensor data, 6 bits of CRC: Total length of 27 bits
  - Slave 2: 12 + 2 bits of sensor data, 5 bits of CRC: Total length of 19 bits
  - Slave 3: 24 bits of sensor data, 16 bits of CRC: Total length of 40 bits

Table 50.7 Example address mapping of sensor data

Offset address	SCDATA[31:0]
SCDATAL1[31:0]	Not changed [7:0], 000b, Sensor data 1 [20:0]
SCDATAH1[31:0]	00b, CRC 1 [5:0], Not changed [23:0]
SCDATAL2[31:0]	Not changed [15:0], 00b, Sensor data 2 [13:0]
SCDATAH2[31:0]	000b, CRC 2 [4:0], Not changed [23:0]
SCDATAL3[31:0]	Not changed [7:0], Sensor data 3 [23:0]
SCDATAH3[31:0]	CRC 3 [15:0], Not changed [15:0]
SCDATALn[31:0] (n = 4 to 8)	Not changed [31:0]
SCDATAHn[31:0] (n = 4 to 8)	Not changed [31:0]

In order to import new sensor data during access, this controller has two memory banks for sensor data. While sensor data is being read and written into the first RAM bank during processing of the BiSS Frame, the second RAM bank section containing sensor data of the previous frame can be read. The relevant sensor data memory banks are swapped at the end of the BiSS Frame. This can be prevented by setting INSTREG.HOLDBANK. Simultaneously the validity (STINF.SVALID) that corresponds to the RAM bank is also swapped.

As an example, the basic procedure of sensor data is below:

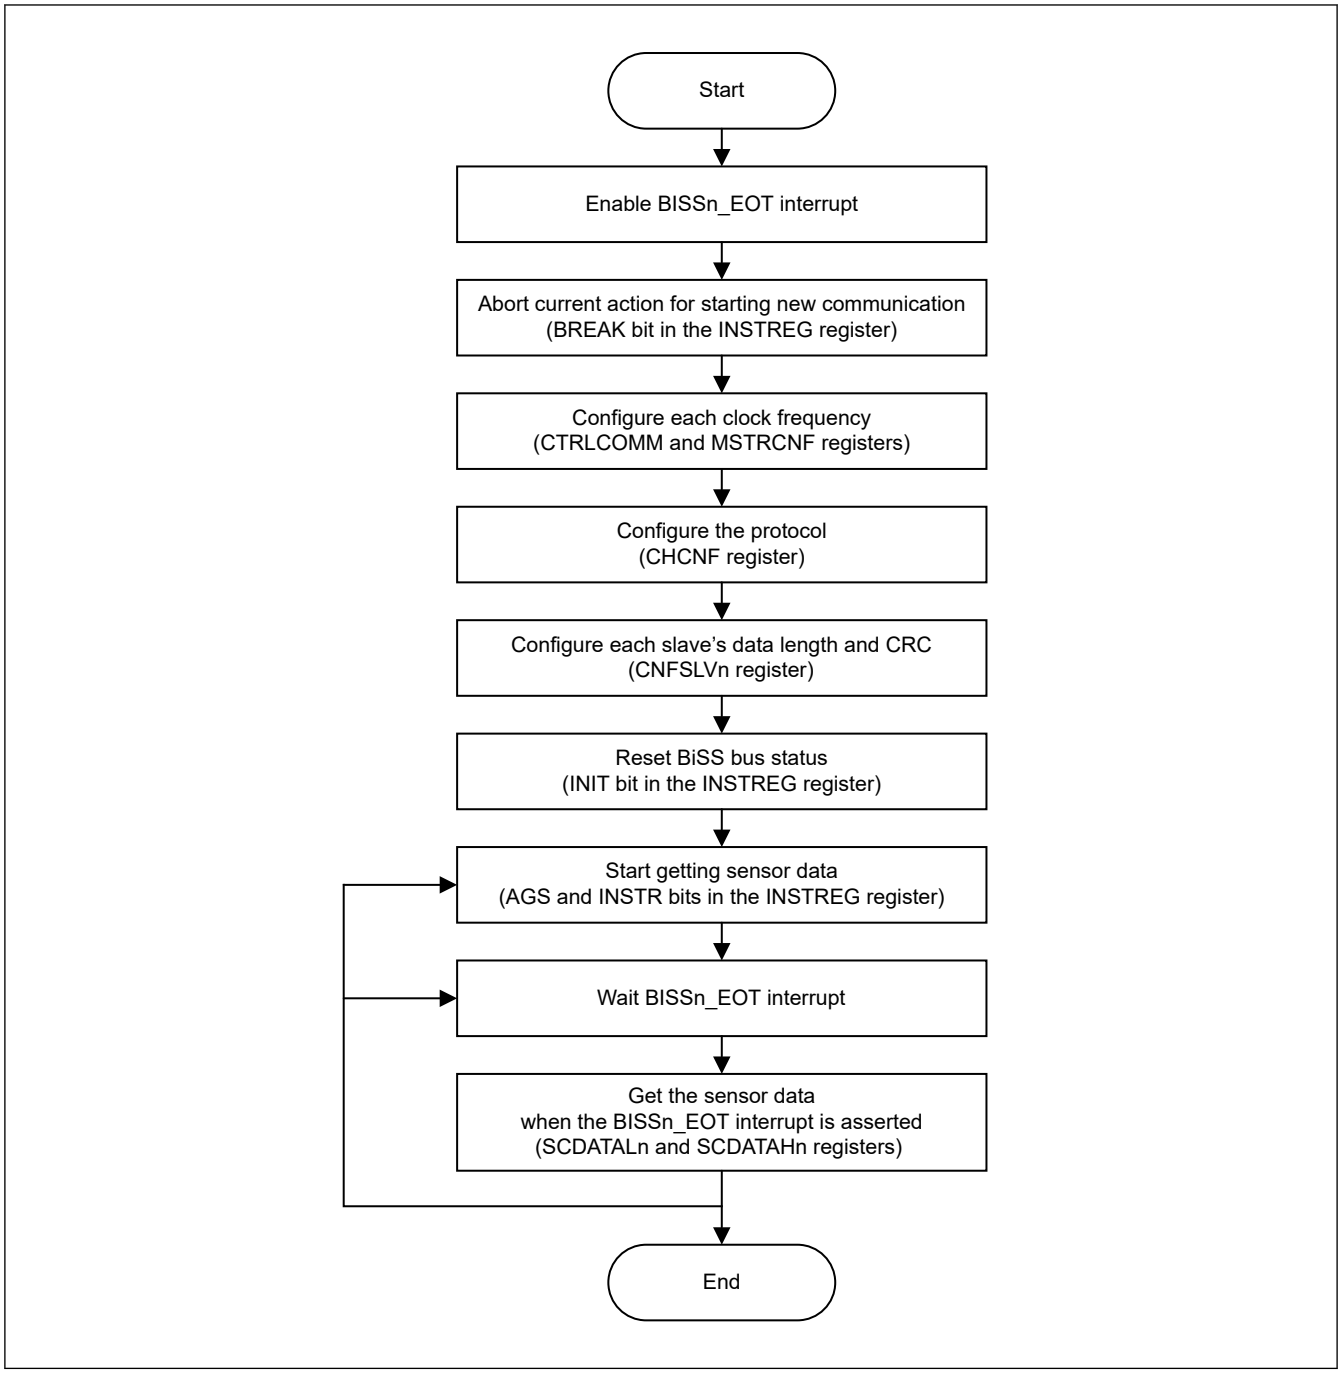

Figure 50.5 Basic operation of sensor data

50.4.4 Control Frame

50.4.4.1 BiSS Commands

The BiSS-C Protocol Description defines BiSS commands as a subset of the control communication. A BiSS command can address one or several slaves by setting the appropriate bits in IDS. To address all slaves via broadcast command, IDS has to be reset to zero. IDS[7:0] bits correspond to the lower 8 bits of Register Data 1 (RDATA1) register.

Slave addressing for BiSS commands:

- IDS[7:0] = 0x00: All slaves addressed (broadcast)
- IDS[N]:
  0: Slave with ID (7 – N) is not addressed (e.g., IDS[0]: ID 7, IDS[1]: ID 6, IDS[7]: ID 0)
  1: Slave with ID (7 – N) is addressed

CMD (corresponding to CTRLCOMM.SID_CMD_IDT[2:1] bits) determines which BiSS command is sent.

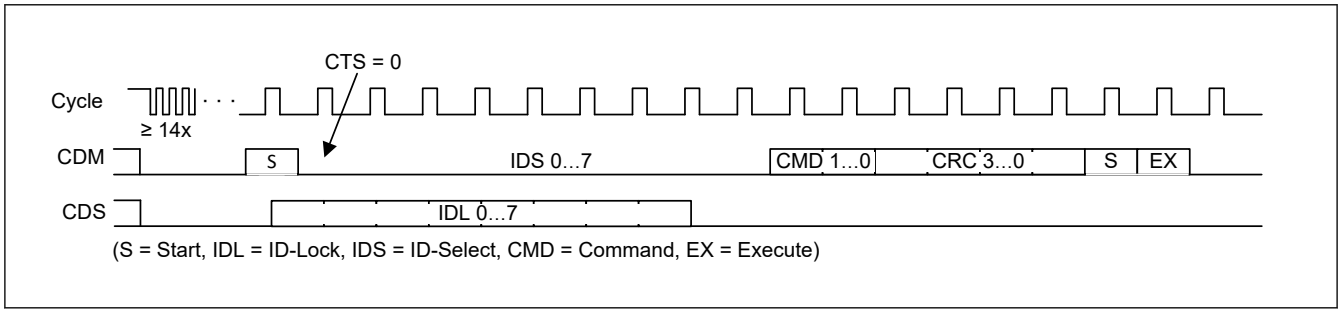

Figure 50.6 Control frame for broadcast BiSS command

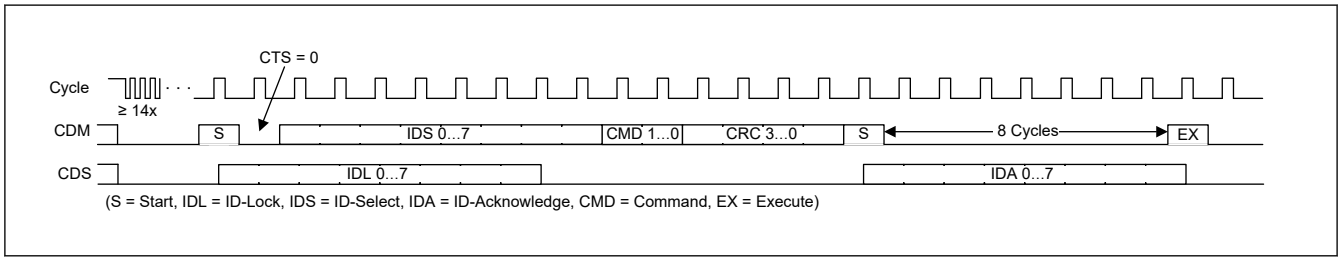

Figure 50.7 Control frame for addressed BiSS command

50.4.4.2 Register Access

The register start address (REGADR), register access direction (WNR), number of bytes (REGNUM) in REGACC register, and slave address (SLAVEID) in CTRLCOMM register are used to configure the BiSS-C control communication for register communication. If a byte count of 0 is entered for REGNUM, it means the transmission of a single register value.

Note: All configuration parameters should be stable during the control communication frame.

The following figure exemplarily shows a control frame including a register read access.

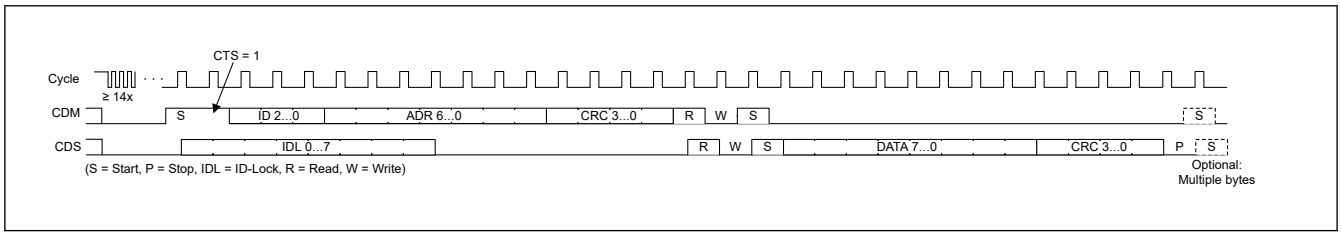

Figure 50.8 Control frame for register communication (register read access)

50.4.5 Data Acquisition

Trigger data transmissions:

- Automatically (MSTRCNF.FREQAGS ≠ AGSINFINITE)
- By GETSENS signal (MSTRCNF.FREQAGS = AGSINFINITE)
- By selecting a program with INSTREG.INSTR

(1) Automatic Sensor Data Request

With INSTREG.AGS = 1 and MSTRCNF.FREQAGS = AGSMIN, data transmissions are started automatically as soon as the slave's timeout is detected. With FREQAGS configured to a constant frame repetition rate, data transmissions are started automatically at the configured frame repetition rate.

(2) Sensor Data Request by GETSENS Signal

GETSENS signal can be used to start a new BiSS frame if enabled by INSTREG.AGS = 1 and MSTRCNF.FREQAGS = AGSINFINITE. The delay between the trigger event at GETSENS and the falling edge at MA is defined by the system clock fCLK and the single-cycle clock frequency fMA (configured with CTRLCOMM.FREQS).

tGETSENS to falling edge at MA = 2/fCLK + 1/(2 × fMA)

(3) Program Selection with Instructions

INSTREG.INSTR is used to trigger data transmissions by program. With INSTREG.AGS = 0, the master starts the data transmission after finishing writing INSTREG register and resets INSTR after executing the frame automatically. STINF.nAGSERR error will be generated if the SL line is low at the start of the frame. The error can be suppressed by setting MSTRCNF.FREQAGS = AGSMIN due to waiting for a high state at SL. A BiSS-C control communication (refer to CTRLCOMM.REGVERS) can be triggered via INSTR as well. It is also possible to enable reduced BiSS frames for control communication with BiSS commands. Within a running control communication, the CDM bit is generated automatically. Otherwise, the generation of CDM depends on INSTR.

50.5 Usage Notes

50.5.1 The value to be set to SCDLEN in the CNFSVn register

For the data length set in SCDLEN, the following sum is required.

MT (multi-turn) bits + ST (single-turn) bits + 2 bits (Error bit and Warning bit between data and CRC in SCD frame)

50.5.2 The storage of received CRC when SCDLEN = 33 bits or more

The CRC of SCD is normally stored at the end of SCDATA, but if SCDLEN is set to 33 bits or more, it is not stored in SCDATA. However, CRC check is executed every time by HW, the result is informed by the status flag (nSCDERR).

When need to read the CRC data, it is required to set the data length including CRC to SCDLEN (ex: set 49 (43 + 6) bits when data = 43 bits and CRC = 6 bits). In this case, the CRC check is required to be executed by SW.

51. HIPERFACE DSL (HDSL)

51.1 Overview

The MPU includes HIPERFACE DSL (HDSL) master to enable communication between the encoder and HIPERFACE DSL interface. Table 51.1 describes the HDSL specifications and Figure 51.1 shows a block diagram of the HDSL.

Table 51.1 HIPERFACE DSL (HDSL) specifications

Item	Description
Number of units	16 units (12 in LLPP0 and 4 in LLPP1)
Protocol	HIPERFACE DSL
Transfer rate	Up to 9.375 Mbaud
Functions	• HIPERFACE DSL with safety • Safe channel 1 interface is selectable from internal bus access or external MCU access through SPI. This safe channel 1 interface enables safety application and it can be implemented in this MPU together with normal application. • Safe channel 2 interface is selectable from internal bus access or external MCU access through SPI • SensorHub SPI PIPE interface is not supported • System diagnostics function • Fast position function – Estimator – Free running mode – SYNC mode • Status and error messages – Event register – Online status – Status summary of the motor feedback system – Motor feedback system error messages • Safety implementation
Interrupt sources	• Configurable interrupt: 4 – Normal related – Safety related – Fast position received – Safety position received • Error related interrupt: 7 – Position estimator activated – Transmission error in safe channel 1 – Safe position not valid – Fast channel/position error – Fast channel/position threshold error – DSL message encoding error – Estimator deviation threshold reached
Event link	SYNC input for HW trigger provided from ELC
Module-stop function	Module-stop state can be set to reduce power consumption

This HIPERFACE DSL® MASTER is licensed from SICK AG. For details, see the following SICK document.

- HIPERFACE DSL® MASTER Safety Integration Manual

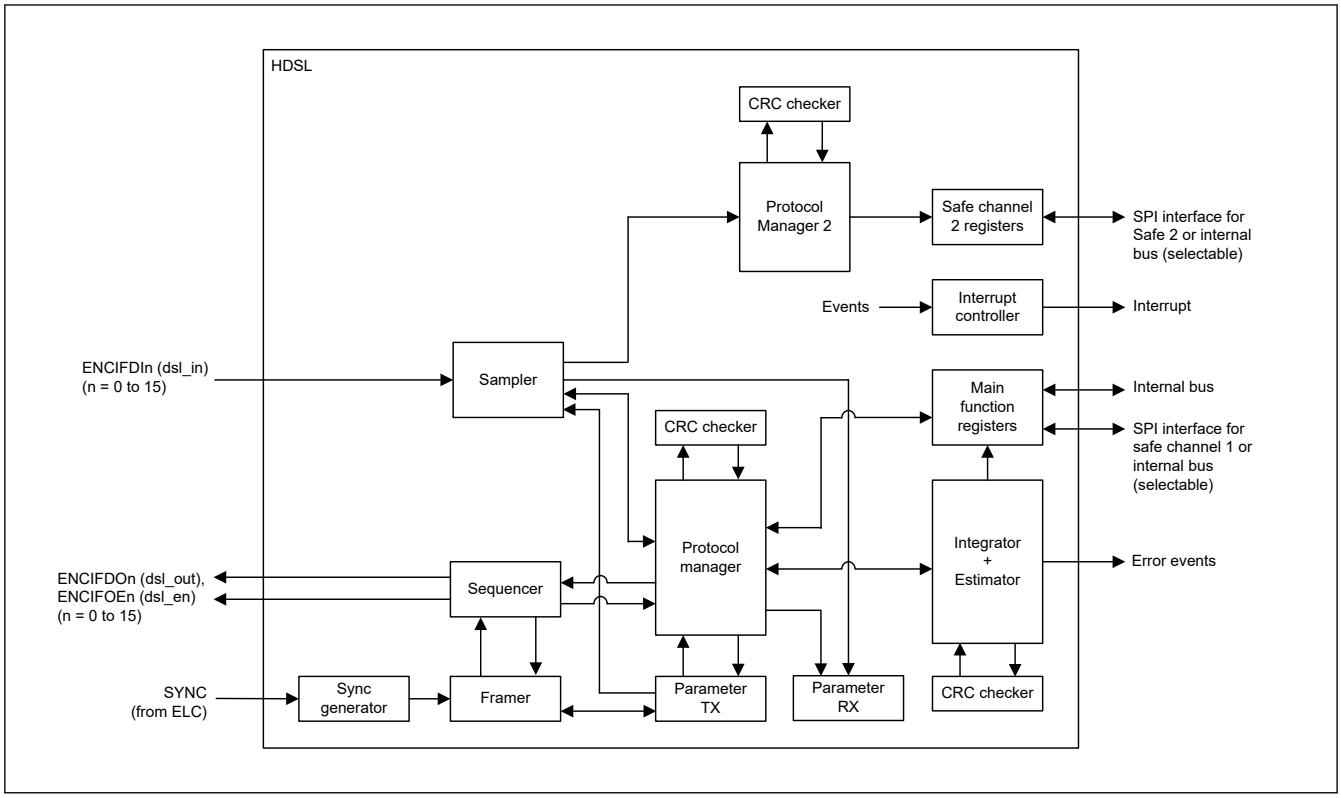

Figure 51.1 Block diagram of HIPERFACE DSL (HDSL)

Table 51.2 lists the input/output pins of the HIPERFACE DSL.

Table 51.2 Pin configuration of the HDSL

Unit	Pin name	I/O	Function
HDSLn	ENCIFOEn (dsl_en)	Output	HDSL unit n DSL cable transceiver, activation
	ENCIFDOn (dsl_out)	Output	HDSL unit n DSL cable, output data
	ENCIFDIn (dsl_in)	Input	HDSL unit n DSL cable, input data
	HDSLn_LINK	Output	HDSL unit n LINK
	HDSLn_SMPL	Output	HDSL unit n Test signal line sampler
	HDSLn_CLK1	Input	HDSL unit n SPI clock safe channel 1
	HDSLn_SEL1	Input	HDSL unit n SPI selection safe channel 1
	HDSLn_MISO1	Output	HDSL unit n data output safe channel 1
	HDSLn_MOSI1	Input	HDSL unit n data input safe channel 1
	HDSLn_CLK2	Input	HDSL unit n SPI clock safe channel 2
	HDSLn_SEL2	Input	HDSL unit n SPI selection safe channel 2
	HDSLn_MISO2	Output	HDSL unit n data output safe channel 2
	HDSLn_MOSI2	Input	HDSL unit n data input safe channel 2

Note: n = 0 to 15

Table 51.3 HDSL interrupt sources (1 of 2)

Name	Interrupt sources
HDSLn INT	Interrupt output
HDSLn INTS	Interrupt output (safety related)
HDSLn_FP	Fast position received interrupt
HDSLn_SP	Safety position received interrupt

Table 51.3 HDSL interrupt sources (2 of 2)

Name	Interrupt sources
HDSLn estimator on	Position estimator activated
HDSLn safe channel error	Transmission error in safe channel 1
HDSLn safe position error	Safe position not valid
HDSLn acceleration error	Fast channel/position error
HDSLn acceleration threshold error	Fast channel/position threshold
HDSLn encoding error	DSL message encoding error
HDSLn deviation threshold error	Estimator deviation threshold reached

Note: n = 0 to 15

51.2 Register Map

Note 1. Access from Cortex-R52 CPU0 and CPU1 is not protected by TrustZone. This slave access control is applied to access from other masters.

51.3 Register Descriptions

HDSL has main function registers for drive interface and safe 1 interface, and secondary registers for safe 2 interface. The drive interface registers, safe 1 interface registers, and safe 2 interface registers can be accessed through the internal bus. The safe 1 interface register and safe 2 interface register can be accessed through each SPI interface. In this case, register address should be referred to offset address only.

And register access operation can be executed with 8-bit/16-bit/32-bit access. However, when 16-bit/32-bit access with unappropriate R/W attribution for the registers is executed, HDSL operation cannot be guaranteed.

51.3.1 Drive Interface Register

51.3.1.1 SYS_CTRL : System Control Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	PRST	MRST	FRST	LOOP	—	—	SPOL	OEN
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OEN	Activation of the output 0: The impedance of the DSL cable is high. 1: The DSL cables are activated for output to the DSL Slave.	R/W
1	SPOL	Polarity of the synchronization pulse 0: The SYNC trailing edge is used. 1: The SYNC leading edge is used.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	LOOP	Test drive interface Value for the read-back test for drive interface. This value has no other purpose.	R/W
5	FRST	Pipeline FIFO, reset 0: Normal FIFO access 1: The FIFO is reset. Data is not stored and cannot be read.	R/W
6	MRST	Messages reset 0: Normal parameters channel action 1: The parameters channel is reset. Current short and long messages are discarded.	R/W
7	PRST	Protocol reset 0: Normal protocol action 1: A forced reset of the protocol status will be initiated. If the bit is cleared, a restart of the connection is triggered.	R/W

The SYS_CTRL register contains the main control bits of the DSL Master.

51.3.1.2 SYNC_CTRL : Synchronization Control Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x01

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ES[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ES[7:0]	External synchronization 0x00: Position sampling during free running at the shortest cycle time. Others: Position sampling with the SYNC input synchronized. The value from ES determines the number of position samplings carried out in one SYNC cycle. The user must match the number of samplings per cycle to the shortest frame length.	W

The synchronization control register for control of the synchronization contains the bit with which the synchronization source for position sampling is controlled.

51.3.1.3 MASTER_QM : Quality Monitoring Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x03

Bit position:	7	6	5	4	3	2	1	0
Bit field:	LINK	—	—	—	QM[3:0]			
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
3:0	QM[3:0]	Quality monitoring bits Quality monitoring value. Higher values indicate a better connection. If the quality monitoring reaches the value 0x0, a forced reset of the protocol is carried out.	R
6:4	—	These bits are read as 0.	R
7	LINK	DSL protocol connection status It should be noted that LINK is also represented at the HDSLn_LINK output. (n = 0 to 15). 0: No connection present or connection error due to a communications error. 1: Protocol connection between DSL Master and Slave was established.	R

The MASTER_QM register contains the quality monitoring value for the data connection.

51.3.1.4 EVENT_H : High Byte Event Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	INT	SUM	—	—	POS	—	DTE	PRST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PRST	Protocol reset warning 0: Normal protocol action 1: The forced protocol reset was triggered.	R/W*1
1	DTE	Estimator deviation threshold error 0: Current value of deviation smaller than the specified maximum. 1: Current value of deviation greater than the specified maximum.	R/W*1
2	—	This bit is read as 0.	R
3	POS	Estimator turned on This error usually indicates a transmission error on the DSL connection. If this error occurs frequently, the wiring of the DSL connection should be checked. If this error occurs continuously, there is probably an error in the motor feedback system. 0: The data for the fast position was correctly transmitted. 1: Fast position data consistency error. The fast position read through drive interface is supplied by the estimator.	R/W*1
5:4	—	These bits are read as 0.	R
6	SUM	Remote event monitoring When the SUM bit is set, an error or a warning has been transmitted from the DSL Slave. The frequency inverter application must check the SUMMARY register to obtain a detailed description. This bit is level sensitive. 0: All DSL Slave events are cleared. 1: The DSL Slave has signaled an event and the summary mask is set accordingly.	R/W*1
7	INT	Interrupt status 0: No interrupt in DSL Master 1: DSL Master interrupt occurred	R

Note 1. Write 0 only to the bit to be cleared.

51.3.1.5 EVENT_L : Low Byte Event Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MIN	ANS	—	QMLW	FREL	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	FREL	Channel free for "long message" If the bit is set, the frequency inverter application can trigger a "long message". Provided no answer has been received from the DSL Slave, this bit remains deleted. As the processing duration of a "long message" in the motor feedback system is not specified, a user time limit condition should be installed via the frequency inverter application. When a time limit is exceeded, the MRST bit in the SYS_CTRL register is set, which causes the Parameters Channel to be reset. 0: No "long message" can be sent. 1: A "long message" can be sent on the Parameters Channel.	R/W*1
2	QMLW	Quality monitoring low-value warning This warning indicates that a transmission error occurred at bit level for one of the CRC values. If this error occurs frequently, the wiring of the DSL connection should be checked. 0: Quality monitoring value greater than or equal to "14" 1: Quality monitoring value below "14"	R/W*1
3	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
4	ANS	Erroneous answer to "long message" This error indicates that the transmission of an answer from the DSL Slave to the last "long message" failed. The frequency inverter application must send the "long message" again. 0: The last answers to "long messages" were error-free. 1: An error occurred during the answer to a long message. The effectiveness of the previous transaction is not known.	R/W*1
5	MIN	Message initialization When this warning is displayed, the Parameters Channel is still in the initialization status and no "short message" or "long message" can be triggered. 0: No acknowledgment for the initialization received. 1: An acknowledgment was received from the Slave for the initialization of a message.	R/W*1
7:6	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Write 0 only to the bit to be cleared.

The EVENT_H/EVENT_L register contains the messaging bits for all warning and error modes of the DSL system.

All messaging bits are set by the DSL Master if a corresponding status is determined.

An event bit that has been set is not reset by the DSL Master. The frequency inverter application must clear bits that have been set.

51.3.1.6 MASK_H : High Byte Event Mask Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	MSUM	—	—	MPOS	—	MDTE	MPRST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MPRST	Mask for protocol reset warning 0: A protocol reset does not set the interrupt signal. 1: A protocol reset sets the interrupt signal.	W
1	MDTE	Mask for estimator deviation threshold error warning 0: A high estimator deviation threshold error value does not set the interrupt signal. 1: A high estimator deviation threshold error value sets the interrupt signal.	W
2	—	The write value should be 0.	W
3	MPOS	Mask for fast position error 0: An error in the fast position does not set the interrupt signal. 1: An error in the fast position sets the interrupt signal.	W
5:4	—	The write value should be 0.	W
6	MSUM	Mask for remote event monitoring 0: DSL Slave events that are masked in the SUMMARY register do not set the interrupt signal. 1: DSL Slave events that are masked in the SUMMARY register set the interrupt signal.	W
7	—	The write value should be 0.	W

51.3.1.7 MASK_L : Low Byte Event Mask Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x07

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MMIN	MANS	—	MQMLW	MFREL	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	The write value should be 0.	W
1	MFREL	Mask for "channel free for "long message"" 0: If a "long message" can be sent on the Parameters Channel, the interrupt signal is not set. 1: If a "long message" can be sent on the Parameters Channel, the interrupt signal is set.	W
2	MQMLW	Mask for low-quality monitoring value warning 0: A low-quality monitoring value does not set the interrupt signal. 1: A low-quality monitoring value sets the interrupt signal.	W
3	—	The write value should be 0.	W
4	MANS	Mask for erroneous answer to "long message" 0: A transmission error during the answer to a long message does not set the interrupt signal. 1: A transmission error during the answer to a long message sets the interrupt signal.	W
5	MMIN	Mask for message initialization confirmation 0: The acknowledgment for the initialization of a DSL Slave message does not set the interrupt signal. 1: The acknowledgment for the initialization of a DSL Slave message sets the interrupt signal.	W
7:6	—	The write value should be 0.	W

In the MASK_H/MASK_L registers, the events are set with which the interrupt signal is set.

51.3.1.8 MASK_SUM : Summary Mask Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	MSUM[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	MSUM[7:0]	Mask for status summary bits 0: In the set status, the corresponding status summary bit does not set the SUM event monitoring and the interrupt signal. 1: In the set status, the corresponding status summary bit sets the SUM event monitoring and the interrupt signal.	W

In the MASK_SUM register, the DSL Slave collective events are determined with which the SUM event monitoring in the EVENT_H register, as well as the interrupt signal, are set.

Several events can be masked to trigger an interrupt. In addition, events from the DSL Master can be combined with these events.

51.3.1.9 EDGES : Edge Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)
HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x09

Bit position:	7	6	5	4	3	2	1	0
Bit field:	EDGES							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	EDGES	Identification of edges in the cable signal 0: No edge was detected in the time period of the corresponding bit. 1: An edge was detected in the time period of the corresponding bit.	R

The EDGES register contains the time control for the DSL cable bit sampling and can be used to monitor the connection quality.

Each individual EDGES register bit is set if, at system start-up, an edge of the test signal is detected during the time period of the corresponding bit. An edge is defined as a change in cable value between successive detections. The sampling is carried out eight times as fast as the cable bit rate.

The register is write-protected. The contents of this register do not change after the start-up phase. A new bit sampling pattern is only generated after a forced reset of the protocol.

51.3.1.10 DELAY : Run Time Delay Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)
HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x0A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RSSI[3:0]				CBLDLY[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CBLDLY[3:0]	4-bit value for cable delay This value gives the cable signal round trip delay of cable and transceivers in bits. This value enables a rough estimate of cable length to be made.	R
7:4	RSSI[3:0]	Indication of the received signal strength 4-bit value for the cable signal strength, from "0" to "12". Higher values indicate better connection quality. Low connection (< 2) quality affects QM. RSSI is continuously updated during operation and used for signal monitoring during run time.	R

The DELAY register stores information about the run-time delay of the system cable and the signal strength. The register can be used to monitor the connection quality.

The register is write-protected.

The value for Line Delay does not change after the start-up phase. A fresh value for Line Delay is only measured after a forced reset of the protocol.

Table 51.8 shows the relationship between the value in Line Delay and the cable length of the DSL connection.

Table 51.8 Cable delay

Cable delay (CBLDLY[3:0])	DSL connection cable delay	Cable length DSL connection
0	< 100 ns	< 10 m
1	100 to 200 ns	10 to 20 m
2	200 to 300 ns	20 to 30 m
3	300 to 400 ns	30 to 40 m
4	400 to 500 ns	40 to 50 m
5	500 to 600 ns	50 to 60 m
6	600 to 700 ns	60 to 70 m
7	700 to 800 ns	70 to 80 m
8	800 to 900 ns	80 to 90 m
9	900 to 1000 ns	90 to 100 m

51.3.1.11 VERSION : Version Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)
HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x0B

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CODE[1:0]		MAJOR[1:0]		MINOR[3:0]			
Value after reset:	0	1	0	1	0	1	1	1

Bit	Symbol	Function	R/W
3:0	MINOR[3:0]	Minor release number The current version is 7.	R
5:4	MAJOR[1:0]	Major release number The current version is 1.	R
7:6	CODE[1:0]	Type of module 0 1: DSL Master Others: Reserved	R

The VERSION register contains the release version of the DSL Master module. The register is write-protected.

51.3.1.12 ENC_ID2 : Encoder ID 2 Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)
HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x0D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	SCI[2:0]			ENCID[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	ENCID[3:0]	Encoder designation code bit 19 to bit 16	R

Bit	Symbol	Function	R/W
6:4	SCI[2:0]	Indication of special characters 3-bit special character for later enhancements of the encoder designation code. Not allocated.	R
7	—	This bit is read as 0.	R

The ENC_ID2/1/0 registers contain the designation code of the motor feedback system connected to the DSL Master. In the current protocol specification, the designation code is 20 bits long. With later enhancements, the free bits in the encoder ID registers are used to indicate special characters.

These registers are write-protected.

The individual ENC_ID2/1/0 register bits are allocated as follows:

Table 51.9 Encoder designation code

Bit	Symbol	Function
19	ENC_ID2.ENCID[3]	Continue In High status, Continue indicates that ENDID is longer than 20 bits (for future use).
18:16	ENC_ID2.ENCID[2:0]	Reserved These bits are read as 0.
15:12	ENC_ID1.ENCID[7:4]	User-defined encoder index 4-bit value (0 to 15) for user-defined encoder index
11	ENC_ID1.ENCID[3]	Reserved This bit is read as 0.
10	ENC_ID1.ENCID[2]	Sign In High status, Sign indicates that the position value is signed, in Low status, Sign indicates that the position value is not signed.
9:8	ENC_ID1.ENCID[1:0]	#Pos – #Acc Length of position information (standard value: 40 bits) minus length of the acceleration value transmitted (standard value: 11 bits).
7:4	ENC_ID0.ENCID[7:4]	
3:0	ENC_ID0.ENCID[3:0]	#Acc – 8 Length of the acceleration value transmitted (standard value: 11 bits) minus 8.

51.3.1.13 ENC_IDn : Encoder ID n Register (n = 0, 1)

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)
HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x0E (ENC_ID1)
0x0F (ENC_ID0)

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ENCID[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ENCID[7:0]	Encoder designation code, byte n	R

51.3.1.14 POSn : Fast Position Byte n Register (n = 0 to 4)

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x10 (POS4)
0x11 (POS3)
0x12 (POS2)
0x13 (POS1)
0x14 (POS0)

Bit position:	7	6	5	4	3	2	1	0
Bit field:	POS[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	POS[7:0]	Fast position, byte n Position value of the motor feedback system (length: 40 bits), incrementally generated.	R

The POSn registers for the fast position contain the value of the motor feedback system connected. This position is generated incrementally from the safe position at start-up and is updated with every protocol frame.

After every eight protocol frames, the fast position is checked against the safe position (VPOSn register).

The position sampling point is determined by the ES bits in SYNC_CTRL register.

Only those POS bits are activated that lie within the range that the motor feedback system has actually measured. All other higher value bits are read as "0". The number of measurable bits can be taken from ENCID bits 9 to 0 in the ENC_ID0 to 2 registers.

If Sign is set in the ENC_IDn register, the value of the fast position is given signed in the two's complement.

The units of the position value are (steps). These registers are write-protected.

51.3.1.15 VELn : Speed Byte n Register (n = 0 to 2)

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x15 (VEL2)
0x16 (VEL1)
0x17 (VEL0)

Bit position:	7	6	5	4	3	2	1	0
Bit field:	VEL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	VEL[7:0]	Speed, byte n Speed of the motor feedback system (length: 24 bits)	R

The VELn registers contain the speed values of the connected motor feedback system. This value is calculated as a Δ position from the acceleration value (ΔΔposition) transmitted on the process data channel and the currently updated protocol frame.

The speed sampling point is determined by the ES bits of the SYNC_CTRL register. The units of the speed value are steps/frame cycle time.

These registers are write-protected.

51.3.1.16 MIR_SUM : Mirror Status Summary Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x18

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SUM[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SUM[7:0]	Status summary bit bit [0] (interface): 0: The DSL Slave protocol has not triggered an error, warning, or event. 1: An error, a warning, or an event associated with the DSL Slave protocol interface was triggered. bit [7:1] (external resource): 0: The corresponding error, warning, or event is not active. 1: An error, a warning, or an event associated with the DSL Slave external resources was triggered.	R

The MIR_SUM register contains the same information for the drive application. The MIR_SUM register is based on the encoder mirror registers MIR_ST7 to MIR_ST0 in the DSL Slave and therefore delayed when compared to the SAFE_SUM register. The bits in the MIR_SUM register can be read by the drive application only.

51.3.1.17 PC_BUFn : Parameter Channel Buffer n Register (n = 0 to 7)

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x20 + 0x1 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	PCBUF[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PCBUF[7:0]	Parameter Channel, byte n Eight bytes for the answer to a long message (read operation) or for a "long message" write operation. PCBUF[0]: bit 7 to bit 0 for Parameters Channel PCBUF[1]: bit 15 to bit 8 for Parameters Channel PCBUF[2]: bit 23 to bit 16 for Parameters Channel PCBUF[3]: bit 31 to bit 24 for Parameters Channel PCBUF[4]: bit 39 to bit 32 for Parameters Channel PCBUF[5]: bit 47 to bit 40 for Parameters Channel PCBUF[6]: bit 55 to bit 48 for Parameters Channel PCBUF[7]: bit 63 to bit 56 for Parameters Channel	R/W

The eight PC_BUFn registers of the Parameters Channel buffer contain the answer to the last "long message" request or the data for a "long message" write operation.

Depending on the length of the "long message" answer, the registers are used as follows:

Table 51.10 Data length of the "long message" (1 of 2)

Length of the "long message"	Register used (Offset address)
8 bytes	0x20 to 0x27
4 bytes	0x20 to 0x23

Table 51.10 Data length of the "long message" (2 of 2)

Length of the "long message"	Register used (Offset address)
2 bytes	0x20 to 0x21
0 bytes	None

These registers are also for the reporting of error conditions arising from a "long message" operation. If, when accessing a resource, an error due to a "long message" arises (e.g. invalid data, error in the A/D conversion), after the answering message has been received the LOFF bit in the PC_ADD_H register is set. In this case, the Parameters Channel buffer bytes 0 and 1 contain an error code.

The meaning of the error code depends on the particular HIPERFACE DSL® encoder.

51.3.1.18 PC_ADD_H : High Byte Long Message Address Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x28

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	LRW	LOFF	LIND	LLEN[1:0]		LADDH[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	LADDH[1:0]	Long message address, bit 9 to bit 8 Database entry with 10-bit address for a "long message" operation.	W
3:2	LLEN[1:0]	Data length of the "long message" 0 0: No data bytes 0 1: 2 data bytes 1 0: 4 data bytes 1 1: 8 data bytes	W
4	LIND	Indirect addressing of long messages 0: Direct addressing of "long messages". The operation affects the database entry given in the current address. 1: Indirect addressing of "long messages". During this operation, the stored address content in the given database entry is evaluated.	W
5	LOFF	Long message addressing mode/long message error 0: **Write access:** Addressing of "long message" without offset. The offset value from the PCOFFn registers is not used. **Read access:** The last "long message" was correctly processed. 1: **Write access:** Offset addressing of "long message". The offset value from the PCOFFn registers is used in the resource of the selected database entry as a sub-address. **Read access:** The last "long message" caused an error.	R/W
6	LRW	Long message, read/write mode 0: "long message" write operation 1: "long message" read operation	W
7	—	This bit is read as 0. The write value should be 0.	R/W

51.3.1.19 PC_ADD_L : Low Byte Long Message Address Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x29

Bit position:	7	6	5	4	3	2	1	0
Bit field:	LADDL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	LADDL[7:0]	Long message address, bit 7 to bit 0 Database entry with 10-bit address for a "long message" operation	W

The addresses and the addressing mode for "long messages" sent over the Parameters Channel are determined in the PC_ADD_H/PC_ADD_L registers.

In addition, the PCA_DD_H register contains indications of errors arising from "long message" operations. For this sort of error, the Parameters Channel buffer contains the error code in bytes 0 and 1 associated with this status.

51.3.1.20 PC_OFF_H : High Byte Long Message Address Offset Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x2A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	LID	LOFFADDH[6:0]						
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	LOFFADDH[6:0]	Long message offset value, bit 14 to bit 8 The 15-bit offset value of the "long message" address offset is stored in these bits.	W
7	LID	Long message identification	R

51.3.1.21 PC_OFF_L : Low Byte Long Message Address Offset Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x2B

Bit position:	7	6	5	4	3	2	1	0
Bit field:	LOFFADDL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	LOFFADDL[7:0]	Long message offset value, bit 7 to bit 0 The 15-bit offset value of the "long message" address offset is stored in these bits.	W

The PC_OFF_H/PC_OFF_L registers for long messages are used in "long message" operations if LOFF is set in the PC_ADD_H register. In this case, the LOFFADD value from these registers is used to communicate with the sub-address of a multiple-byte encoder resource.

Only write access is possible for these registers.

51.3.1.22 PC_CTRL : Parameter Channel Control Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x2C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	LSTA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LSTA	Control of the long message start 0: No effect 1: A "long message" transaction is started with the values currently stored in the "long message" registers.	W
7:1	—	The write value should be 0.	W

The PC_CTRL register for the Parameters Channel handles the start of "long message" transactions. After setting all "long message" registers (registers PC_BUF0 to 7, PC_ADD_H/PC_ADD_L, and PC_OFF_H/PC_OFF_L), the "long message" is transmitted to the DSL Slave by setting the LSTA bit.

51.3.1.23 PIPE_S : SensorHub Channel Status Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x2D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	POVR	PEMP	PERR	PSCI
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PSCI	Indication for special characters in the SensorHub Channel This bit is stored together with the pipeline data byte in question in the FIFO buffer. 0: Indication for "no special character". 1: A special character was received in the SensorHub Channel.	R
1	PERR	Coding error of the bits in the SensorHub Channel This bit is stored together with the pipeline data byte in question in the FIFO buffer. 0: No error in bit coding. 1: The bit level coding of the data currently in the SensorHub Channel is erroneous.	R
2	PEMP	The SensorHub channel buffer is empty This bit is updated after every access to the FIFO buffer. 0: No "buffer empty" error. 1: A read request was issued, but the FIFO buffer for SensorHub Channel data is empty. In this case, PIPE_D contains the value 0x00.	R

<table>
<tr><th>Bit</th><th>Symbol</th><th>Function</th><th>R/W</th></tr>
<tr><td>3</td><td>POVR</td><td>SensorHub Channel overflow
This bit is deleted after the read process.
Special characters are normally used as data separators or to indicate special events. To obtain information about which special character was received, the PIPE_D register must be read. All 8b10b special characters can be used on the SensorHub channel. An exception is the "K30.7" symbol that is used in HIPERFACE DSL® to indicate "no data" and is not stored in the FIFO buffer. Below table contains the supported 8b10b special characters.
<table>
<tr><th>Special characters</th><th>Coding in register PIPE_D</th></tr>
<tr><td>K28.0</td><td>0x1C</td></tr>
<tr><td>K28.1</td><td>0x3C</td></tr>
<tr><td>K28.2</td><td>0x5C</td></tr>
<tr><td>K28.3</td><td>0x7C</td></tr>
<tr><td>K28.4</td><td>0x9C</td></tr>
<tr><td>K28.5</td><td>0xBC</td></tr>
<tr><td>K28.6</td><td>0xDC</td></tr>
<tr><td>K28.7</td><td>0xFC</td></tr>
<tr><td>K23.7</td><td>0xF7</td></tr>
<tr><td>K27.7</td><td>0xFB</td></tr>
<tr><td>K29.7</td><td>0xFD</td></tr>
</table>
0: The capacity of the FIFO buffer for SensorHub Channel data is not yet exhausted.
1: The capacity of the 8-byte FIFO buffer for SensorHub Channel data was exhausted and since the last read process, values have been discarded.</td><td>R</td></tr>
<tr><td>7:4</td><td>—</td><td>These bits are read as 0.</td><td>R</td></tr>
</table>

The PIPE_S register provides information about the current status of the SensorHub Channel. When this register is read, the current data from the FIFO buffer is read and stored in an intermediate register so that a subsequent read process in the PIPE_D register can be considered to be completed at the same time as the PIPE_S register is read. Using this mechanism, any deviation between status and data information in this instance will prevent new data entering the SensorHub Channel during access to the FIFO buffer.

51.3.1.24 PIPE_D : SensorHub Channel Data Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x2E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SCDATA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SCDATA[7:0]	SensorHub Channel data 8-bit value of the FIFO buffer for SensorHub Channel data	R

The PIPE_D register contains the SensorHub Channel data that is stored in an 8 byte FIFO buffer. If new data arrives at the buffer when it is full, before PIPE_D is read, the oldest value is discarded and the POVR bit in PIPE_S is set. If a read request is issued when the buffer is empty, the PEMP bit in PIPE_S is set and the value 0x00 is transmitted. At the moment that the PIPE_S register is accessed, the corresponding PIPE_D value is frozen to guarantee synchronization between status and data information.

51.3.1.25 PC_DATA : Parameter Channel Short Message Mirror Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x2F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	PCDATA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PCDATA[7:0]	"Short message" Mirror register data 8-bit value of the requested mirror register	R

When reading the mirror registers MIR_ST7 to MIR_ST0 instead of the real remote registers, the answer is available immediately in the PC_DATA register.

51.3.1.26 ACC_ERR_CNT : Fast Position Error Counter Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x38

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CNT[4:0]				
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	CNT[4:0]	Position error count/threshold **Read:** 5-bit value of count of transmitted fast position values with consecutive transmission errors **Write:** 5-bit value for threshold	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

The ACC_ERR_CNT register returns the count of transmitted fast position values with consecutive transmission errors. The value is clamped to a maximum of 31 (0x1F).

With a writing access the error threshold can be set. This value is also clamped to a maximum of 31 (0x1F). If the count of transmitted fast position values with consecutive transmission errors exceeds this threshold, the error threshold will be set to 1.

51.3.1.27 MAXACC : Fast Position Acceleration Boundary Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x39

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RES[1:0]		MNT[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	MNT[5:0]	Mantissa of fast position acceleration boundary	W
7:6	RES[1:0]	Resolution of fast position acceleration boundary	W

The MAXACC register allows setting an acceleration threshold for a given application. This threshold is used by the fast position estimator to clamp the acceleration of the estimated position during communication or sensor failures of the fast position channel.

51.3.1.28 MAXDEV_H : Fast Position Estimator Deviation High Byte Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x3A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DEVH[7:0]							
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	DEVH[7:0]	Fast position estimator deviation high byte **Read:** 16-bit value of position deviation **Write:** 16-bit value for deviation threshold	R/W

51.3.1.29 MAXDEV_L : Fast Position Estimator Deviation Low Byte Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x3B

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DEVL[7:0]							
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	DEVL[7:0]	Fast position estimator deviation low byte **Read:** 16-bit value of position deviation **Write:** 16-bit value for deviation threshold	R/W

The MAXDEV_H/MAXDEV_L registers return the maximum absolute position deviation while the position estimator is active. The returned 16-bit value has the same format (resolution) as the fast position channel and is clamped to a maximum of 65535 steps (0xFFFF). The registers are set to the maximum value 0xFFFF at reset.

These registers also allow setting a deviation threshold value for triggering the error event. The threshold value can be written with the same format as the deviation (unsigned 16-bit, same resolution as the fast position channel).

51.3.1.30 MIR_STn : Mirror Status n Register (n = 0 to 7)

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x60 + 0x1 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	MIRST[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	MIRST[7:0]	Mirror status, byte n The individual bits indicate different errors, events and warnings. The meaning of each individual bit depends on the particular DSL Slave specification. 0: Encoder in normal status 1: Error, event, or warning status	R/W*1

Note 1. Write 0 only to the bit to be cleared.

The MIR_ST encoder status registers contain all slave system errors, events, and warnings from the DSL encoder. This way, the information can be accessed via drive interface without blocking the short message channel.

The allocation between the individual bits and the slave system statuses depends on the DSL Slave specification. MIR_STn registers (n = 0 to 7) are updated only when a read Short Message is initiated on the corresponding remote status register ENC_STn and the response is read from S_PC_DATA. Trigger for updating the MIR_STn, is reading S_PC_DATA.

Background: initiating a Short Message saves the index of the register, but reading S_PC_DATA triggers the actual copy of register content to the corresponding MIR_STn.

Example:

1. Read Short Message on ENC_ST0
2. Read S_PC_DATA
3. Read access on MIR_ST0 and read PC_DATA content – ENC_ST0 content is mirrored to Drive Interface successfully.

Table 51.11 Relationship between mirror status and SAFE_SUM register

Encoder status	SAFE_SUM bit
MIRST[0]	SSUM0
MIRST[1]	SSUM1
MIRST[2]	SSUM2
MIRST[3]	SSUM3
MIRST[4]	SSUM4
MIRST[5]	SSUM5
MIRST[6]	SSUM6
MIRST[7]	SSUM7

51.3.1.31 DUMMY : Dummy Register

Base address: HDSLDm = 0x9020_0000 + 0x1_0000 × m (m = 0 to 11)
HDSLDi = 0x9030_0000 + 0x1_0000 × (i − 12) (i = 12 to 15)
HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x3F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DUMMY[7:0]							
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
7:0	DUMMY[7:0]	Due to the transmission of the online-status, Online Status read transactions need less time for transmission. Therefore, dummy read transactions must be inserted to avoid unwanted extra transactions. A read access to this register 0x3F has no effect and must be used for this purpose.	R

When accessing through SPI interface, the dummy read by the DUMMY register in Safe 1 interface is required. The dummy read by the DUMMY register in Drive interface is not required.

51.3.2 Safe Channel 1 Interface Registers

Table 51.12 Safe channel 1 interface register map

Offset address	Register symbol	Register name
0x09	EDGES*1	Edge Register
0x0A	DELAY*1	Run Time Delay Register
0x0B	VERSION*1	Version Register
0x0D	ENC_ID2*1	Encoder ID 2 Register
0x0E	ENC_ID1*1	Encoder ID 1 Register
0x0F	ENC_ID0*1	Encoder ID 0 Register
0x19	VPOS4	Safe Position 4 Register
0x1A	VPOS3	Safe Position 3 Register
0x1B	VPOS2	Safe Position 2 Register
0x1C	VPOS1	Safe Position 1 Register
0x1D	VPOS0	Safe Position 0 Register
0x1E	VPOSCRC_H	Safe Position CRC High Byte Register
0x1F	VPOSCRC_L	Safe Position CRC Low Byte Register
0x35	SAFE_CTRL	Safe System Control Register
0x36	SAFE_SUM	Safe Status Summary Register
0x37	S_PC_DATA	Parameter Channel Short Message Register
0x3D	EVENT_S	Safe Event Register
0x3E	MASK_S	Safe Event Mask Register
0x3F	DUMMY*1	Dummy Register
0x40 + 0x1 × n	ENC_STn	Encoder Status n Register (n = 0 to 7)
0x7C	SRSSI	Slave RSSI Register
0x7E	MAIL	Slave Mail Register
0x7F	PING	Slave Ping Register

Note 1. These registers are shared with Drive Interface.

51.3.2.1 VPOSn : Safe Position n Register (n = 0 to 4)

Base address: HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x19 (VPOS4)
0x1A (VPOS3)
0x1B (VPOS2)
0x1C (VPOS1)
0x1D (VPOS0)

Bit position:	7	6	5	4	3	2	1	0
Bit field:	VPOS[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	VPOS[7:0]	Safe position, byte n Position value transmitted through safe channel 1 (length: 40 bits), absolute value.	R

The VPOSn registers for the safe position contain the position value from the primary channel of the motor feedback system connected. This safe position is transmitted in every eighth protocol frame.

The safe position is not synchronized with the sync signal.

Only those vpos bits are activated that lie within the range that the motor feedback system has actually measured. All other higher value bits are read as 0. The number of measurable bits can be taken from ENCID bits 9 to 0 in the ENC_ID0 to ENC_ID2 registers.

If Sign is set in the ENC_ID register, the value of the safe position is given signed in the two's complement.

The units of the position value are [steps]. These registers are write-protected.

51.3.2.2 VPOSCRC_H : Safe Position CRC High Byte Register

Base address: HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x1E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	VPOSCRCH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	VPOSCRCH[7:0]	CRC of the safe position, bit 15 to bit 8 16-bit CRC checksum (CRC 16) of the safe position and status summary in Safe Channel 1.	R

51.3.2.3 VPOSCRC_L : Safe Position CRC Low Byte Register

Base address: HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x1F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	VPOSCRCL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	VPOSCRCL[7:0]	CRC of the safe position, bit 7 to bit 0 16-bit CRC checksum (CRC 16) of the safe position and status summary in Safe Channel 1.	R

The VPOSCRC_H/VPOSCRC_L registers contain the CRC checksum of the VPOSn registers and the SAFE_SUM register.

The CRC is checked in the DSL Master. In order to guarantee, in a safety-related application, that the CRC machine in the module is functioning, these registers can be checked with an external cross-check in the diagnostics test interval.

The CRC is generated with the following CRC parameters:

Table 51.13 VPOSCRC parameter

Parameter	Value
CRC sequence	16 bits
CRC polynomial	$X^{16} + X^{15} + X^{12} + X^7 + X^6 + X^4 + X^3 + 1$ Normal representation: 0x90D9
Starting value	0x0000
Closing XOR value	0x00FF
Reverse data bytes	No
Reverse CRC before closing XOR	No

The sequence of the bytes to calculate the CRC is shown in the following figure:

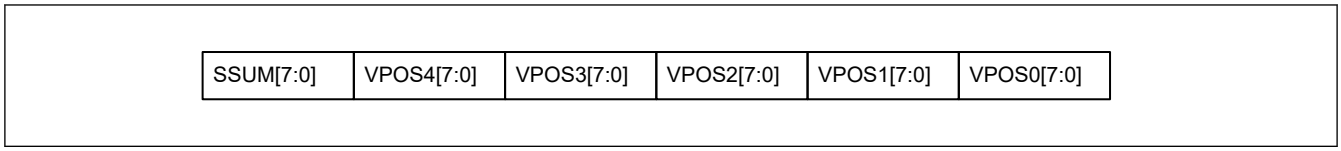

Figure 51.2 CRC calculation for VPOSCRC_H/VPOSCRC_L registers

51.3.2.4 SAFE_CTRL : Safe System Control Register

Base address: HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x35

Bit position:	7	6	5	4	3	2	1	0
Bit field:	PRST	MRST	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	MRST	Message reset 0: Normal Parameters Channel action 1: The Parameters Channel is reset. Current short and long messages are discarded.	R/W
7	PRST	Protocol reset 0: Normal protocol action 1: A forced reset of the protocol status will be initiated. If the bit is deleted, a restart of the connection is triggered.	R/W

The SAFE_CTRL register contains two control bits of the DSL Master available for the safety-related application.

51.3.2.5 SAFE_SUM : Safety Status Summary Register

Base address: HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x36

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SSUM[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SSUM[7:0]	Status summary bit bit [0] (interface): 0: The DSL Slave protocol has not triggered an error, a warning, or an event. 1: An error, a warning, or an event associated with the DSL Slave protocol interface was triggered. bit [7:1] (external resource): 0: The corresponding error, warning, or event is not active. 1: An error, a warning, or an event associated with DSL Slave external resources was triggered.	R

The SAFE_SUM register contains the summarized DSL Slave status information for the safety-related application. It is based on the encoder status ENC_STn (n = 0 to 7). Each status summary bit contains the summarized information from 8 error, warning, and event modes of the DSL Slave. The bits in the status summary register can be read by the safety-related application only.

51.3.2.6 S_PC_DATA : Parameter Channel Short Message Register

Base address: HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x37

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SPCDATA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SPCDATA[7:0]	"Short message" Parameter Channel data 8-bit value of the requested remote register.	R

The S_PC_DATA register for the Parameters Channel short message contains the results of "short message" transactions.

"Short message" transactions are generated if operations are carried out with remote registers (DSL Slave). Generally, FRES (in the EVENT_S register) must be set after a transaction is started. Only then will SPCDATA contain valid information.

51.3.2.7 EVENT_S : Safe Event Register

Base address: HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x3D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SINT	SSUM	SCE	VPOS	QMLW	PRST	MIN	FRES
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FRES	Channel free for "short message" If the bit is set, the frequency inverter application can trigger a "short message". Provided no answer has been received from the DSL Slave, this bit remains 0. As the processing duration of a "long message" in the motor feedback system is not specified, a time limit condition is installed in the DSL Master. If the time limit is exceeded, attempts are made again automatically. 0: No "short message" can be sent. 1: A "short message" can be sent on the Parameters Channel.	R/W*1
1	MIN	Message init When this warning is displayed, the Parameters Channel is still in the initialization status and no "short message" or "long message" can be triggered. 0: No acknowledgment for the initialization received. 1: An acknowledgment was received from the Slave for the initialization of a message.	R/W*1
2	PRST	Protocol reset warning This error message indicates that the protocol connection to the DSL Slave has been re-initialized. This error message can be caused by a frequency inverter application request (PRST bit in SYS_CTRL register), a safety-related application request (PRST bit in SAFE_CTRL register), generated by the DSL Master itself, or activated via the reset input. The DSL Master causes a protocol reset if too many transmission errors indicate a connection problem. A protocol reset causes a re-synchronization with the DSL Slave that can improve the connection quality. 0: Normal protocol action 1: The forced protocol reset was triggered.	R/W*1

Bit	Symbol	Function	R/W
3	QMLW	Quality monitoring low-value warning This warning indicates that a transmission error occurred. If this error occurs frequently, the wiring of the DSL connection should be checked. 0: Quality monitoring value, QM[3:0] in the MASTERQM register, greater than or equal to "14" 1: Quality monitoring value below "14"	R/W*1
4	VPOS	Safe position error This error usually indicates an encoder sensor error. If this error occurs continuously, there is probably an error in the motor feedback system. 0: The safe position is correct. 1: Sensor error	R/W*1
5	SCE	Error on the Safe Channel This error usually indicates a transmission error on the DSL connection. If this error occurs frequently, the wiring of the DSL connection should be checked. If this error occurs continuously, there is probably an error in the motor feedback system. This error affects quality monitoring and produces the QMLW warning or a protocol reset. 0: Safe Channel data was correctly transmitted. 1: Data consistency error on the Safe Channel.	R/W*1
6	SSUM	Remote event monitoring When the bit is set, an error or a warning has been transmitted from the DSL Slave. The safety-related application must check the SAFE_SUM register to obtain a detailed description. This bit is level sensitive. 0: All DSL Slave events are cleared. 1: The DSL Slave has signaled an event.	R/W*1
7	SINT	Safe interrupt status This bit reflects the status of the safety-related interrupt.	R

Note 1. Write 0 only to the bit to be cleared.

The EVENT_S register contains the message Quality monitoring bits for all warning and error modes of the DSL system.

All messaging bits are set by the DSL Master if a corresponding status is determined.

The following bit description lists the effects of warning and error conditions as well as the reactions to errors that must be installed in the safety-related application.

An event bit that has been set is not reset by the DSL Master. The safety-related application must delete bits that have been set.

Both edge and level-sensitive flags are present in the EVENT_S register. Edge-sensitive bits are set when the corresponding status arises. They are only set again if the corresponding status disappears and then arises once more. This is the standard action. The level-sensitive bits set a bit as long as the corresponding status exists.

51.3.2.8 MASK_S : Safe Event Mask Register

Base address: HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x3E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	MSSUM	MSCE	MVPOS	MQMLW	MPRST	MMIN	MFRES
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MFRES	Mask for "channel free for "short message"" 0: If a "short message" can be sent on the Parameters Channel, the safety-related interrupt signal is not set. 1: If a "short message" can be sent on the Parameters Channel, the safety-related interrupt signal is set.	W

Bit	Symbol	Function	R/W
1	MMIN	Mask for message initialization confirmation 0: The acknowledgment for the initialization of a DSL Slave message does not set the safety-related interrupt signal. 1: The acknowledgment for the initialization of a DSL Slave message sets the safety-related interrupt signal.	W
2	MPRST	Mask for protocol reset warning 0: A protocol reset does not set the safety-related interrupt signal. 1: A protocol reset sets the safety-related interrupt signal.	W
3	MQMLW	Mask for low-quality monitoring value warning 0: A low-quality monitoring value does not set the safety-related interrupt signal. 1: A low-quality monitoring value sets the safety-related interrupt signal.	W
4	MVPOS	Mask for safe position error 0: An error in the safe position does not set the safety-related interrupt signal. 1: An error in the safe position sets the safety-related interrupt signal.	W
5	MSCE	Mask for transmission errors on the Safe Channel 0: A transmission error on the Safe Channel does not set the safety-related interrupt signal. 1: A transmission error on the Safe Channel sets the safety-related interrupt signal.	W
6	MSSUM	Mask for remote event monitoring 0: DSL Slave events that are set in the SAFE_SUM register do not set the safety-related interrupt signal. 1: DSL Slave events that are set in the SAFE_SUM register sets the safety-related interrupt signal.	W
7	—	The write value should be 0.	W

In the MASK_S register, events are chosen that can trigger the safety-related interrupt signal.

Several events can be masked to trigger an interrupt. In addition, events from the DSL Slave summary can be combined with these events.

51.3.2.9 ENC_STn : Encoder Status n Register (n = 0 to 7)

Base address: HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x40 + 0x1 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ENCST[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ENCST[7:0]	Encoder status, byte n The individual bits indicate different errors, events, and warnings. The meaning of each individual bit is determined by the particular DSL Slave installation. ENCST[0]: bit 7 to bit 0 for Parameters Channel ENCST[1]: bit 15 to bit 8 for Parameters Channel ENCST[2]: bit 23 to bit 16 for Parameters Channel ENCST[3]: bit 31 to bit 24 for Parameters Channel ENCST[4]: bit 39 to bit 32 for Parameters Channel ENCST[5]: bit 47 to bit 40 for Parameters Channel ENCST[6]: bit 55 to bit 48 for Parameters Channel ENCST[7]: bit 63 to bit 56 for Parameters Channel 0: Encoder in normal status 1: Error, event, or warning status	R/W*1

Note 1. Write 0 only to the bit to be cleared.

The ENC_STn encoder status registers contain all slave system errors, events, and warnings from the DSL encoder.

The allocation between the individual bits and the slave system statuses depends on DSL Slave specification.

Table 51.14 Relationship between encoder status and SAFE_SUM register

Encoder status	SAFE_SUM bit
ENCST[0]	SSUM0
ENCST[1]	SSUM1
ENCST[2]	SSUM2
ENCST[3]	SSUM3
ENCST[4]	SSUM4
ENCST[5]	SSUM5
ENCST[6]	SSUM6
ENCST[7]	SSUM7

51.3.2.10 SRSSI : Slave RSSI Register

Base address: HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x7C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SRSSI[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SRSSI[2:0]	Value of the Slave RSSI The values for the Slave RSSI range from "0" (poorest signal strength) to "7" (best signal strength).	R
7:3	—	These bits are read as 0.	R

The SRSSI register for indicating the received signal strength at the slave (Slave Received Signal Strength Indicator, RSSI) provides an indication of the strength of the signal arriving at the slave.

The value of the register is only updated from frame to frame if the measurement result deteriorates. After a read access to this register, the register is reset to the value "7" (maximum signal strength).

The register is write-protected.

51.3.2.11 MAIL : Slave Mail Register

Base address: HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x7E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	MAIL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	MAIL[7:0]	Slave-Mail 8-bit slave mail data for multiple applications	W

The MAIL multi-purpose register of the slave is used for fast communication with the DSL motor feedback system processor. The content of the slave mail register is transmitted to the encoder processor by the most rapid route possible.

The slave mail register is used for the transmission of test messages to the DSL motor feedback system.

51.3.2.12 PING : Slave Ping Register

Base address: HDSLS1m = 0x9020_1000 + 0x1_0000 × m (m = 0 to 11)
HDSLS1i = 0x9030_1000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x7F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	PING[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PING[7:0]	Slave-Ping 8-bit hardware version of the DSL encoder at start-up. On first reading, the Ping value of the slave can be used as a connection test on behalf of the slave.	R/W

The PING register of the slave is used to carry out connection tests on behalf of the DSL Slave. The register can be written to and read externally, without this affecting the DSL interface.

On start-up, the register is initialized with the DSL Slave interface.

51.3.3 Safe Channel 2 Interface Registers

51.3.3.1 VERSION2 : Version in Safe Channel 2 Register

Base address: HDSLS2m = 0x9020_2000 + 0x1_0000 × m (m = 0 to 11)
HDSLS2i = 0x9030_2000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x0B

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CODE[1:0]		MAJOR[1:0]		MINOR[3:0]			
Value after reset:	0	1	0	1	0	1	1	1

Bit	Symbol	Function	R/W
3:0	MINOR[3:0]	Minor release number The current version is 7.	R
5:4	MAJOR[1:0]	Major release number The current version is 1.	R
7:6	CODE[1:0]	Type of module 0 1: DSL Master Others: Reserved	R

The VERSION2 register in safe channel 2 is identical to the VERSION register in the drive and safe channel 1 interfaces.

51.3.3.2 ENC2_ID : Encoder ID in Safe Channel 2 Register

Base address: HDSLS2m = 0x9020_2000 + 0x1_0000 × m (m = 0 to 11)
HDSLS2i = 0x9030_2000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x0F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ENC2ID[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ENC2ID[7:0]	Designation of the safe channel 2 channel **0x02/0x22:** SIL2 arrangement. The same position data is transmitted to the safe channel 2 channel as to the safe channel 1 channel. **0x03/0x33:** SIL3 arrangement. Position data is transmitted to the safe channel 2 channel that originates from the secondary sensor in the HIPERFACE DSL® motor feedback system.	R

The ENC2_ID register for the ID of the encoder in safe channel 2 contains the designation code for the safe channel 2 channel of the DSL encoder.

The contents of ENC2_ID are defined during the actual installation of the motor feedback system and can be found in the corresponding data sheet.

The register is write-protected.

51.3.3.3 STATUS2 : Safe Channel 2 Status Register

Base address: HDSLS2m = 0x9020_2000 + 0x1_0000 × m (m = 0 to 11)
HDSLS2i = 0x9030_2000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x18

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TOG2	TEST2	ERR2	FIX2[4:0]				
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	FIX2[4:0]	Safe Channel 2 Fixed Bit Pattern FIX2 is a fixed bit pattern for each SPI transaction that indicates errors arising in the SPI interface due to unchanged bit values. The standard value of the fixed bit pattern is 11100b. All other values indicate an error on safe channel 2 of the DSL system. Suitable measures must be installed in the user application.	R
5	ERR2	Safe Channel 2 Position Error 0: The last safe position received in safe channel 2 is correct. 1: The last safe position received in safe channel 2 is invalid. Suitable measures must be installed in the user application.	R
6	TEST2	Safe Channel 2 Test TEST2 bit is set to 1 if a test message is executed via the MAIL register while the safe channel 2 status and position data are valid. TEST2 can only be valid if the user application has previously requested a test. Corresponding error indications for TEST2 are either the ERR2 bit or a discrepancy between the position and the CRC of safe channel 2.	R
7	TOG2	Safe Channel 2 Toggle For successive position transmissions on safe channel 2, TOG2 must always toggle between 0 and 1. The starting value for TOG2 is 0. If the toggle bit does not change its value, it is probable that a transmission error occurred and the transmitted absolute value for safe channel 2 is invalid. Suitable measures must be installed in the user application.	R

The STATUS2 status register contains the status information for safe channel 2 of the HIPERFACE DSL® motor feedback system.

51.3.3.4 VPOS2n : Safe Position Channel 2 Byte n Register (n = 0 to 4)

Base address: HDSLS2m = 0x9020_2000 + 0x1_0000 × m (m = 0 to 11)
HDSLS2i = 0x9030_2000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x19 (VPOS24)
0x1A (VPOS23)
0x1B (VPOS22)
0x1C (VPOS21)
0x1D (VPOS20)

Bit position:	7	6	5	4	3	2	1	0
Bit field:	VPOS2[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	VPOS2[7:0]	Safe position, Channel 2, byte n Position value at motor feedback system Safe Channel 2 (length: 40 bits), transmitted as an absolute value complement.	R

The VPOS2n registers contain the position value from the secondary channel of the motor feedback system connected. This safe position is transmitted in every eighth protocol frame if the validity of the data transfer has been checked.

The safe position is not synchronized with the most recent sync signal but to the (user or internally generated) sync signal of one of the last 8 protocol frames. Only those VPOS2 bits are relevant that lie within the range that the motor feedback system has actually measured. Also, typically channel 2 has a lower resolution than channel 1. The operating manual and datasheet of the product specify the resolution of each channel.

The units of the position value are [steps].

These registers are write-protected.

51.3.3.5 VPOSCRC2_H : Safe Position CRC 2 High Byte Register

Base address: HDSLS2m = 0x9020_2000 + 0x1_0000 × m (m = 0 to 11)
HDSLS2i = 0x9030_2000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x1E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	VPOSCRC2H[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	VPOSCRC2H[7:0]	CRC of the safe position 2, bit 15 to bit 8 16-bit CRC checksum (CRC 16) of the safe position and status summary in Safe Channel 2.	R

51.3.3.6 VPOSCRC2_L : Safe Position CRC 2 Low Byte Register

Base address: HDSLS2m = 0x9020_2000 + 0x1_0000 × m (m = 0 to 11)
HDSLS2i = 0x9030_2000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x1F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	VPOSCRC2L[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	VPOSCRC2L[7:0]	CRC of the safe position 2, bit 7 to bit 0 16-bit CRC checksum (CRC 16) of the safe position and status summary in safe channel 2.	R

The VPOSCRC2_H/VPOSCRC2_L registers for the position checksum in safe channel 2 contain the CRC checksum for the safe position VPOS2n.

The CRC is checked in the DSL MasterIP Core. In order to guarantee, in a safety-related application, that the CRC machine is functioning, these registers can be checked with an external cross-check in the diagnostics test interval.

The CRC is generated with the following CRC parameters:

Table 51.15 VPOSCRC2 parameter

Parameter	Value
CRC sequence	16 bits
CRC polynomial	$X^{16} + X^{15} + X^{12} + X^7 + X^6 + X^4 + X^3 + 1$ Normal representation: 0x90D9
Starting value	0x0000
Closing XOR value	0x00FF
Reverse data bytes	No
Reverse CRC before closing XOR	No

The sequence of the bytes to calculate the CRC is shown in the following figure:

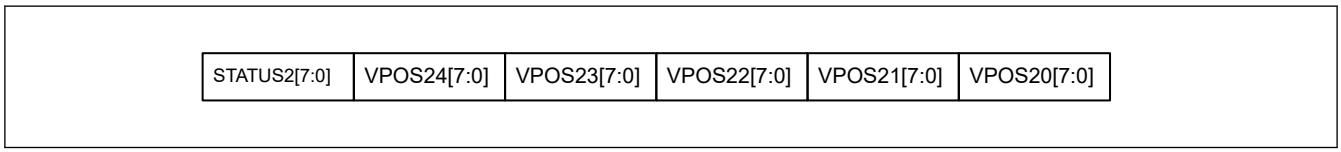

Figure 51.3 CRC calculation for VPOSCRC2_H/VPOSCRC2_L registers

51.3.3.7 DUMMY2 : Dummy in Safe Channel 2 Register

Base address: HDSLS2m = 0x9020_2000 + 0x1_0000 × m (m = 0 to 11)
HDSLS2i = 0x9030_2000 + 0x1_0000 × (i − 12) (i = 12 to 15)

Offset address: 0x3F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DUMMY[7:0]							
Value after reset:	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
7:0	DUMMY[7:0]	Due to the transmission of the online-status, Online status read transactions need less time for transmission. Therefore, dummy read transactions must be inserted to avoid unwanted extra transactions. A read access to this register 0x3F has no effect and must be used for this purpose.	R

When accessing through SPI interface, the dummy read by the DUMMY2 register in the safe channel 2 is required.

51.4 Operation

51.4.1 System Start

As soon as the motor feedback system is supplied with power, a forced reset ensures that a defined system start status is produced in the DSL Master.

Figure 51.4 shows the status table for system start.

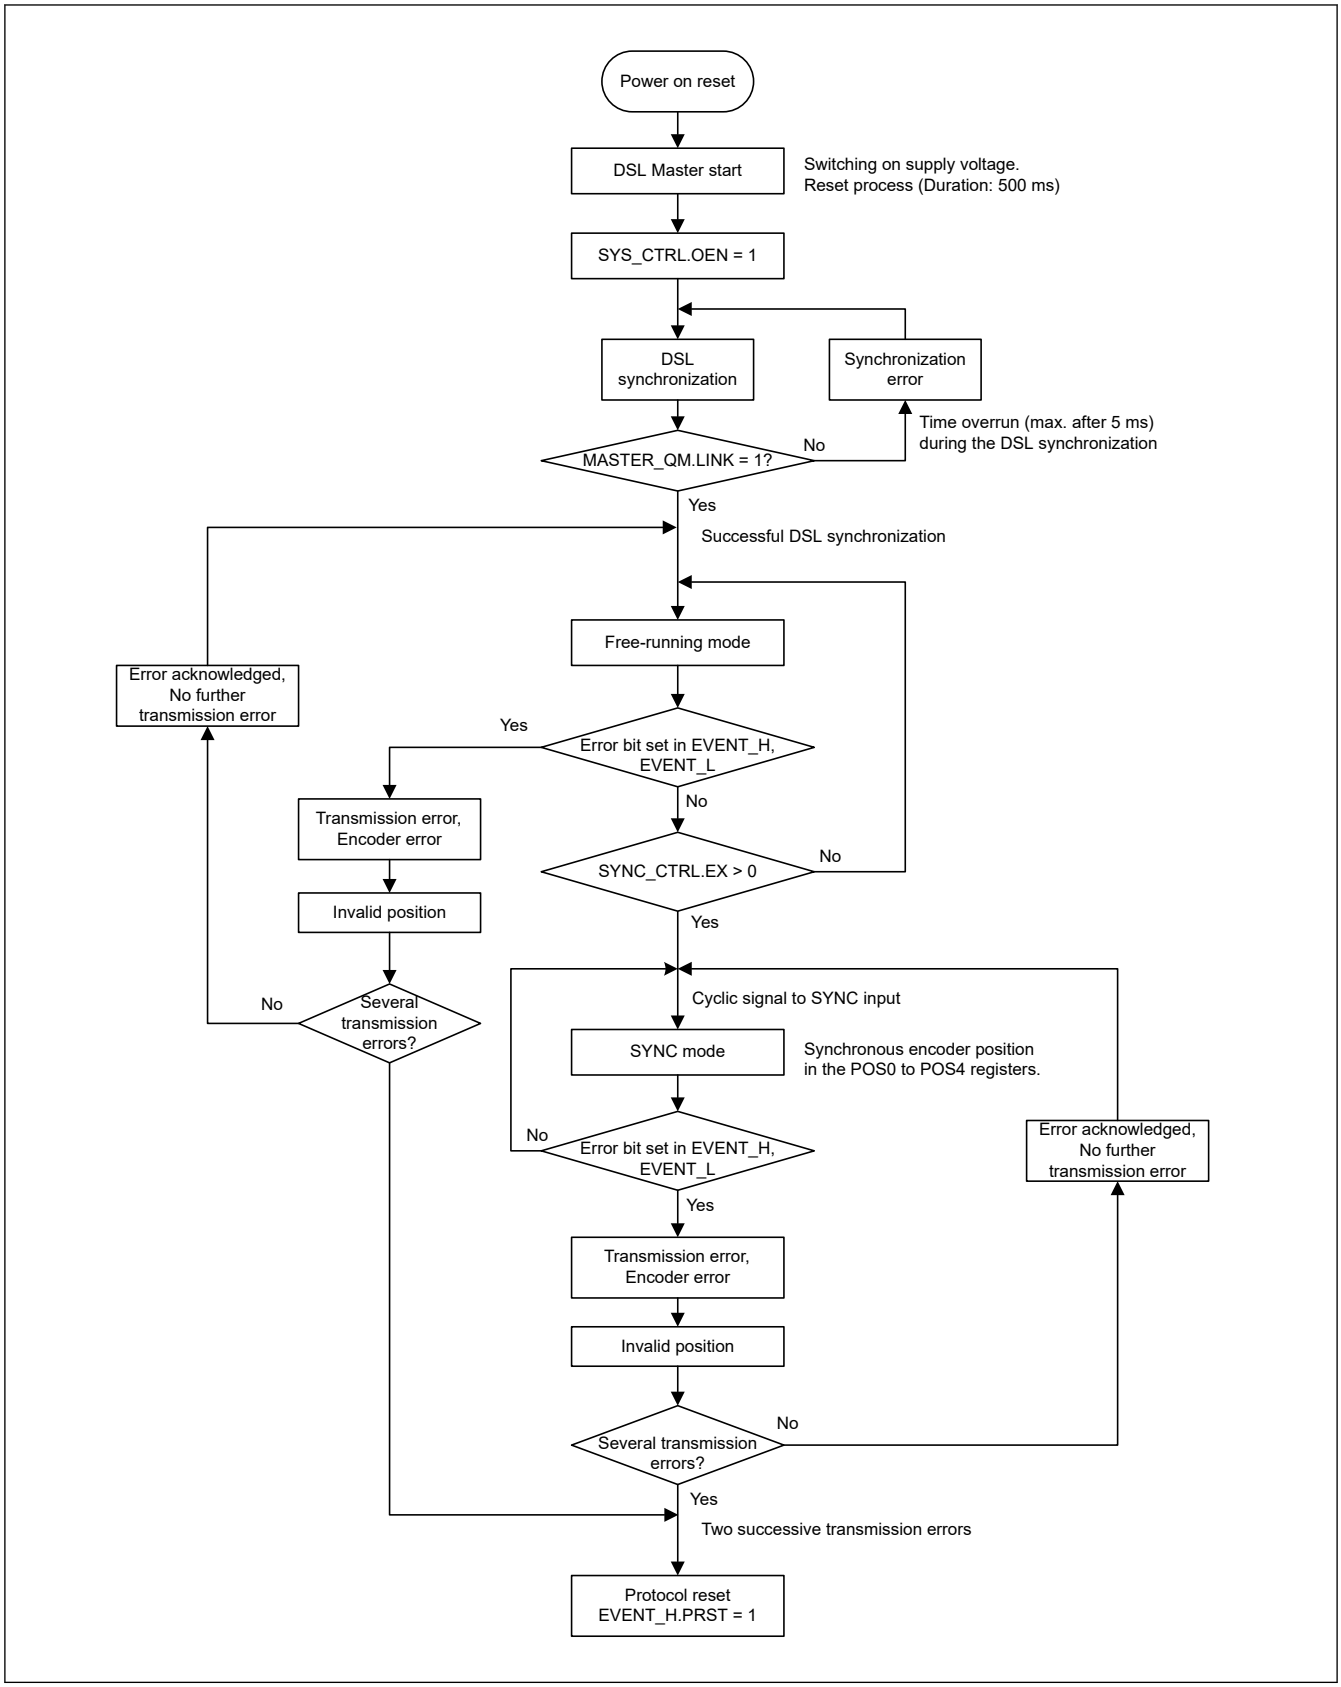

Figure 51.4 Status table for DSL system start

51.4.2 Quality Monitoring

The MASTERQM register contains the quality monitoring value for the data connection.

As soon as the DSL Master detects events that indicate an improvement or degradation of the quality of the data connection, these events are indicated as values higher or lower than the quality monitoring value.

Table 51.16 Quality monitoring events

Protocol event	Value change in quality monitoring
Wrong synchronization in Safe Channel (last byte)	-4
Wrong synchronization in Safe Channel (1st … 7th bytes)	-6
RSSI < 2	-4
Wrong encoding in parameter	-1
Wrong encoding in process data channel	-2
Unknown special characters in the protocol package	-2
Any identified error in Safe Channel 1	-6
Any identified error in Safe Channel 2	-8
Correct synchronization in Safe Channel	+1
Correct CRC value in Safe Channel	+1

Quality monitoring is initiated with the value "8". The maximum quality monitoring value is "15". This is the standard value during operation.

Note: Particular attention must be paid to the quality monitoring value during the development of a DSL drive controller. If a value lower than "15" is indicated, the cause may be a problem with the connection circuit, particularly if the value is continuously displayed.

If the quality monitoring value falls below "14", QMLW information is indicated in the EVENT_L register.

If the quality monitoring value falls to "0", a forced reset of the protocol is carried out. This is indicated by the PRST error bit in the EVENT_H register.

51.4.3 Interrupt

The interrupt signal is set to 1 if an interrupt condition has been fulfilled in the DSL Master. The interrupt conditions are set using the registers MASKH, MASKL, and MASKSUM. The interrupt conditions for safety are set using register MASKS.

Figure 51.5 and Figure 51.6 show an interrupt condition as a diagram.

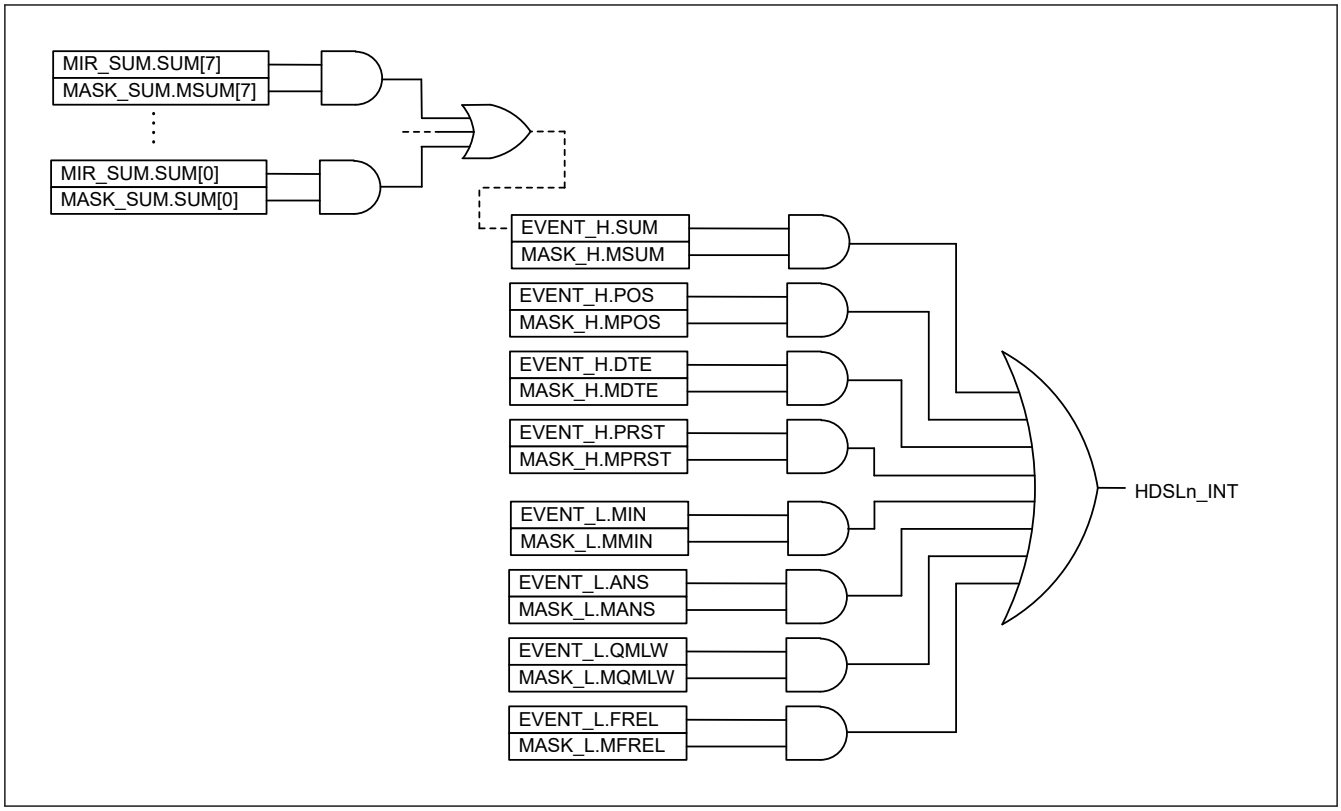

Figure 51.5 Interrupt

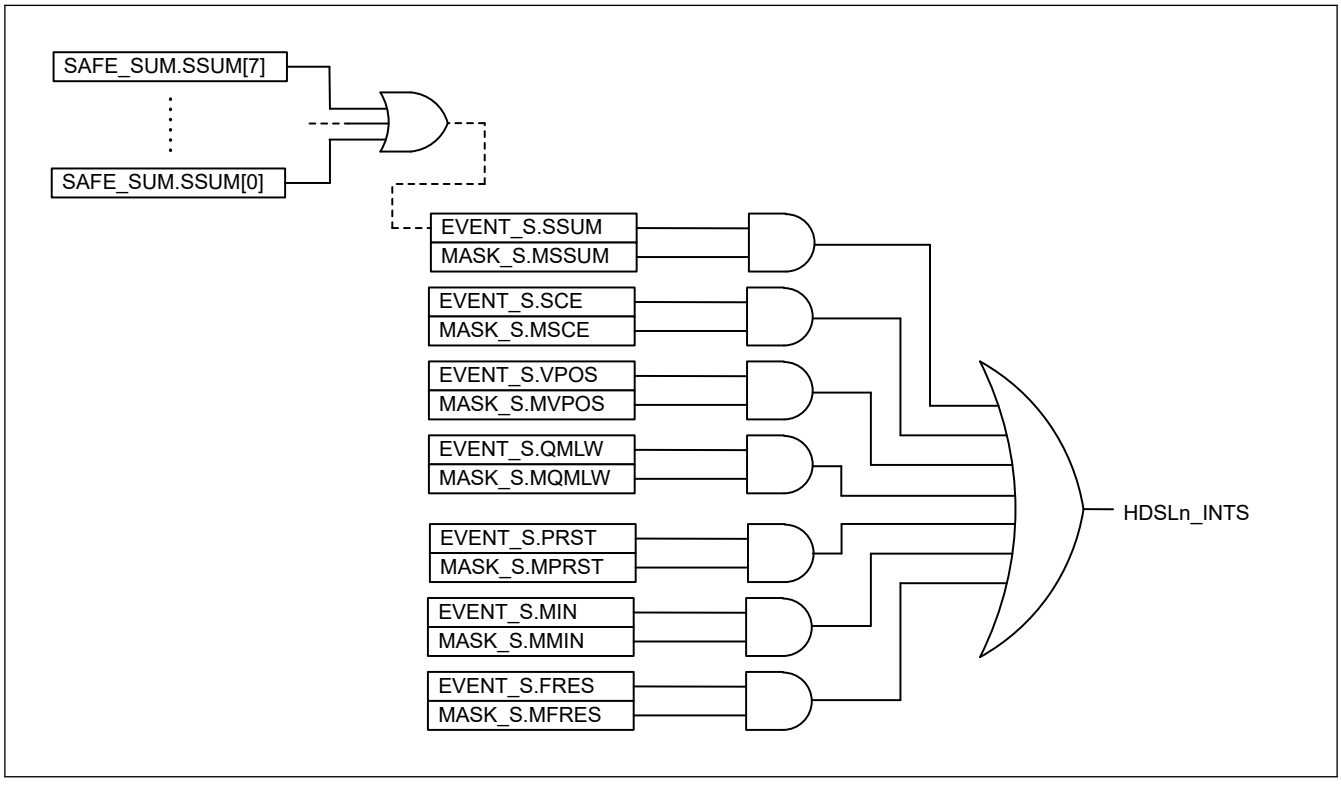

Figure 51.6 Interrupt for Safety

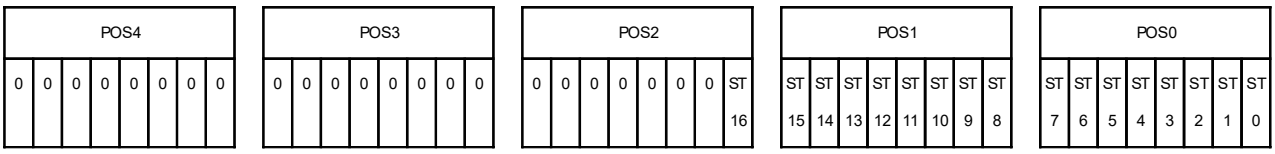
51.4.4 Fast Position

The fast position and the rotation speed of the encoder shaft are transmitted on the DSL motor feedback system process data channel. These values are the main process values for the drive application control circuit.

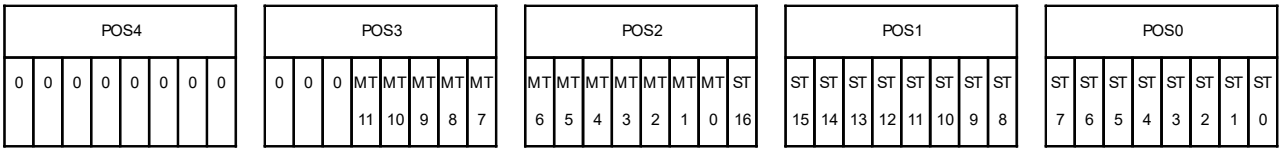
HIPERFACE DSL stores the fast position in the POS0 to POS4 HDSL Master registers and the rotation speed in the VEL0 to VEL2 registers.

The position is given as a 40 bit value that includes the angle setting ("single-turn" value) and the number of rotations ("multi-turn" value). Only the position bits actually measured by the motor feedback system are accessible and are stored in the registers as a right-justified value. The other (higher value) bits are constantly set at "0" (see examples "a" to "c" below).

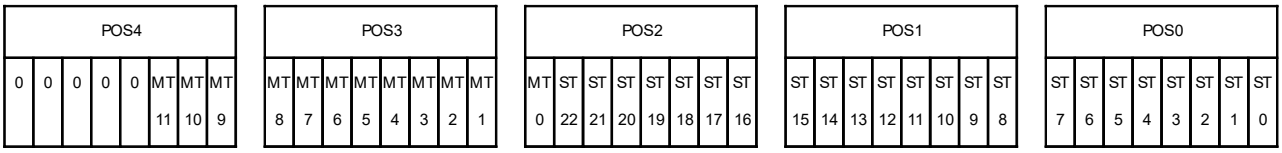
a. Single-turn 17 bit



b. Single-turn 17 bit, Multi-turn 12 bit



c. Single-turn 23 bit, Multi-turn 12 bit



The motor feedback system fast position is sampled and transmitted if the DSL Master receives a SYNC signal.

This SYNC signal can be created in two different ways (see section 51.4.4.1. Free running mode and section 51.4.4.2. SYNC mode).

51.4.4.1 Free running mode

In free-running mode, the SYNC signal is automatically created by the DSL Master, for which the maximum frame transmission frequency is used. The free-running mode is the standard DSL Master operating mode at start-up. This operating mode can also be selected manually, by setting the ES value in the SYNC_CTRL register to 0.

51.4.4.2 SYNC mode

In SYNC mode, the DSL Master depends on a prepared cyclic control signal. This control signal triggers position measurements and enables polling of position and rotation speed values synchronously with the control signal. The control signal must be applied to the SYNC input and have the characteristics prescribed for the DSL Master.

The position is available after a set delay in relation to the leading edge of the control signal.

When SYNC mode is used the following points must be noted:

1. A correct control signal must be applied at the sync input. The signal must correspond with the specifications for pulse width and cycle time.
2. Setting or deleting the SPOL bit in the SYS_CTRL register determines whether the position measurements are to be triggered by the leading or the trailing edge of the control signal. The set latency of the DSL system is measured from this edge.
3. The correct ES divider must be set in the SYNC_CTRL register. This divider determines how many position samplings and transmissions will be undertaken for each control signal. Do not change setting of ES divider during start-up or operation.

52. A-Format (AFMT)

52.1 Overview

The MPU includes A-format (AFMT) master to enable communication between the encoder with A-format interface. Table 52.1 describes the A-format specifications and Figure 52.1 shows a block diagram of the AFMT.

Table 52.1 A-format (AFMT) specifications

Item	Description
Number of units	16 units (12 in LLPP0 and 4 in LLPP1)
Protocol	A-format Ver.2.0
Functions	• Communication with absolute encoder supporting A-format • Up to 8 slaves bus connection each unit. (Individual transmission mode only) • Compliant to A-format Version 2.0 and A-Safety-format Version 1.0 • Trigger input – CPU control (SW trigger) – HW trigger • Encoder status • Communication alarm • Status and error messages • Time out
Interrupt sources	• Two interrupts – Communication completion – Time out error
Event link	nEXT_STRG input for HW trigger provided from ELC
Module-stop function	Module-stop state can be set to reduce power consumption

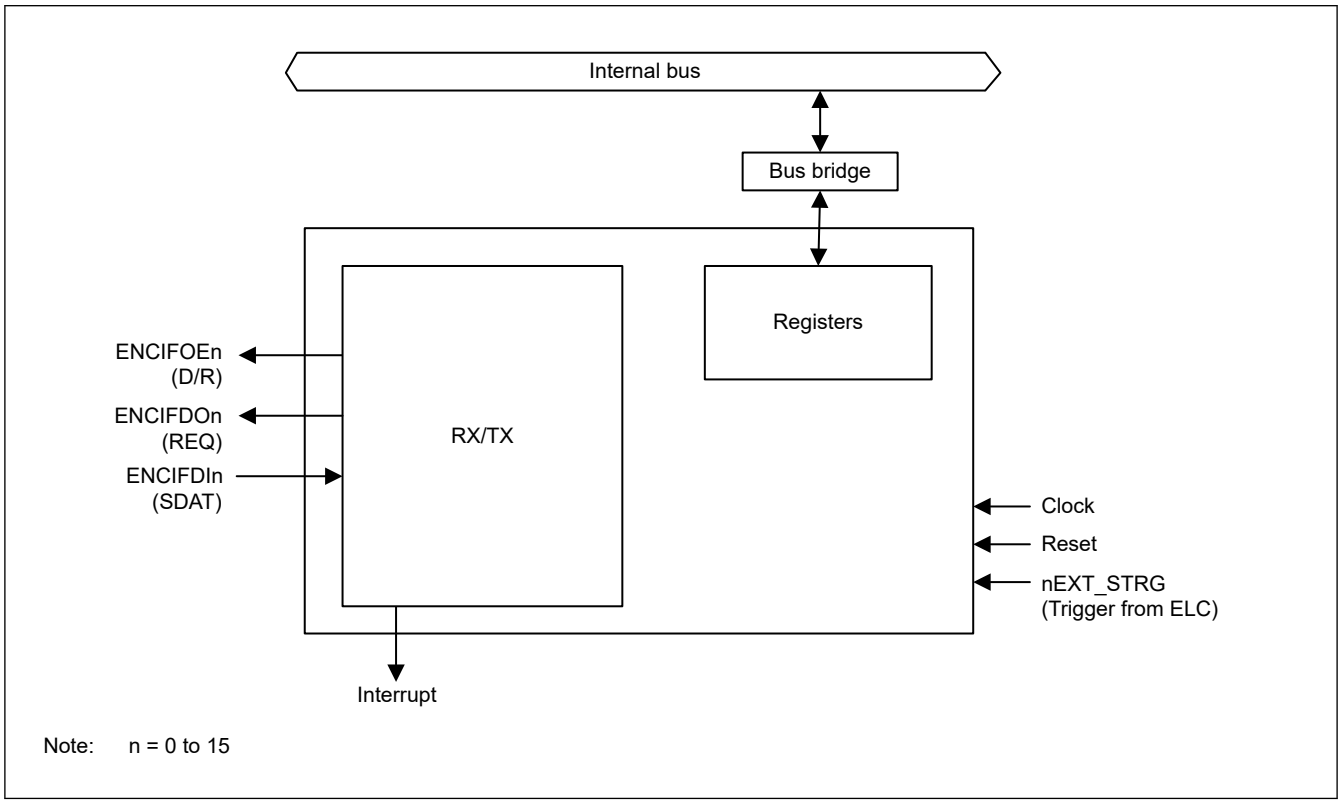


Figure 52.1 Block diagram of A-format (AFMT)

Table 52.2 lists the input/output pins of this module.

Table 52.2 PIN configuration of the AFMT

Unit	Pin name	I/O	Function
AFMTn	ENCIFOEn (D/R)	Output	A-format unit n line transceiver control signal
	ENCIFDOn (REQ)	Output	A-format unit n serial data output
	ENCIFDIn (SDAT)	Input	A-format unit n serial data input

Note: n = 0 to 15

Table 52.3 AFMT interrupt sources

Name	Interrupt sources
AFMTi_EOF	Communication completion
AFMTi_TMOUT	Time out error

Note: i = 0 to 15

52.2 Register Map

A part of the address of the register is shared between writing and reading.

Table 52.4 AFMT register map (for writing)

Address	Register symbol	Register name	Write protection
0x9020_6000 + 0x1_0000 × i (i = 0 to 11) 0x9030_6000 + 0x1_0000 × (i - 12) (i = 12 to 15)	COMMAND	Command Code Encoder Address Register	—

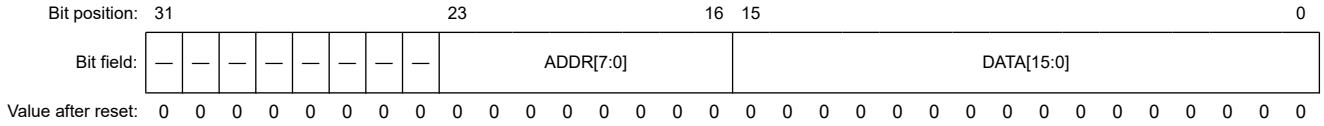
52.3.2 ROMDATA : EEPROM Address and Write Data Register

Base address: AFMTi = 0x9020_6000 + 0x1_0000 × i (i = 0 to 11)
AFMTj = 0x9030_6000 + 0x1_0000 × (j - 12) (j = 12 to 15)

Offset address: 0x004

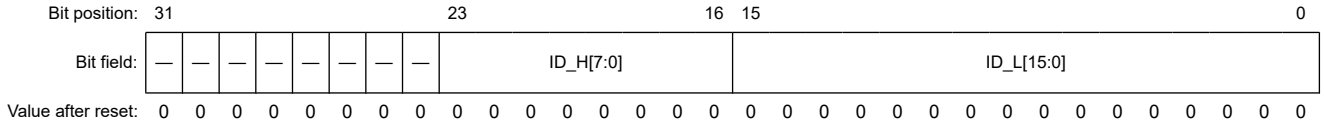


Bit	Symbol	Function	R/W
15:0	DATA[15:0]	16-bit EEPROM data When the command code is a memory writing request (CDF14), 16-bit write data value should be written in the ROMDATA register with writing in the ROMADDR register.	W
23:16	ADDR[7:0]	8-bit EEPROM address When the command code is a memory reading request (CDF13), 16-bit read address should be written in the ROMADDR register. When command code is a memory writing request (CDF14), 16-bit read address should be written as well.	W
31:24	—	The write value should be 0.	W

52.3.3 ID : ID Code Register

Base address: AFMTi = 0x9020_6000 + 0x1_0000 × i (i = 0 to 11)
AFMTj = 0x9030_6000 + 0x1_0000 × (j - 12) (j = 12 to 15)

Offset address: 0x008

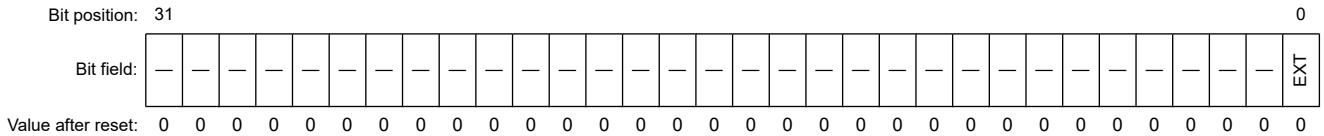


Bit	Symbol	Function	R/W
15:0	ID_L[15:0]	24-bit ID code, low word When the command code is ID code writing request (CDF18 or 19), 24-bit ID code should be written in the ID_H and ID_L bits.	W
23:16	ID_H[7:0]	24-bit ID code, high byte When the command code is ID code writing request (CDF18 or 19), 24-bit ID code should be written in ID_H and ID_L bits.	W
31:24	—	The write value should be 0.	W

52.3.4 TRGSEL : Trigger Select Register

Base address: AFMTi = 0x9020_6000 + 0x1_0000 × i (i = 0 to 11)
AFMTj = 0x9030_6000 + 0x1_0000 × (j - 12) (j = 12 to 15)

Offset address: 0x100



Bit	Symbol	Function	R/W
0	EXT	Trigger select 0: Set TRG bit in ENCnTXSEL register 1: Trigger from ELC	W
31:1	—	The write value should be 0.	W

52.3.5 TXTRG : Transmission Trigger Register

Base address: AFMTi = 0x9020_6000 + 0x1_0000 × i (i = 0 to 11)
AFMTj = 0x9030_6000 + 0x1_0000 × (j - 12) (j = 12 to 15)

Offset address: 0x104

Bit position:	31																													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TRG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TRG	Command data transmission trigger generation When EXT bit in ECNnTRGSEL is set to 0, transmission trigger is generated by this bit setting and command data transmission to specified Encoder starts. When EXT = 1, this bit setting is ignored. 0: Do nothing. 1: Transmission trigger is generated.	W
31:1	—	The write value should be 0.	W

52.3.6 BRSEL : Baud Rate Setting Register

Base address: AFMTi = 0x9020_6000 + 0x1_0000 × i (i = 0 to 11)
AFMTj = 0x9030_6000 + 0x1_0000 × (j - 12) (j = 12 to 15)

Offset address: 0x200

Bit position:	31																			11								4	3	2	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TM[7:0]									AS	BR[2:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	BR[2:0]	Baud rate setting The baud rate is required a value depending on the encoder used. 0 0 0: 2.5 Mbps 0 0 1: 4 Mbps 0 1 0: 6.67 Mbps 0 1 1: 8 Mbps 1 0 0: 16 Mbps Others: Setting prohibited	W
3	AS	A-Safety enable 0: Disable 1: Enable	W
11:4	TM[7:0]	t2 time setting N t2 time is set to 1 µs + N × 0.25 µs	W
31:12	—	The write value should be 0.	W

52.3.7 ENCnRXDATAm : ENCn Receive Data m Register (n = 1 to 8, m = 0 to 7)

Base address: AFMTi = 0x9020_6000 + 0x1_0000 × i (i = 0 to 11)
AFMTj = 0x9030_6000 + 0x1_0000 × (j - 12) (j = 12 to 15)

Offset address: 0x004 × m + 0x020 × (n - 1)

Bit position:	31																												0
Bit field:	DATA[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DATA[31:0]	Encoder read data For details, see Table 52.10 and Table 52.11.	R

The ENCnRXDATAm registers are used to receive data which encoder outputs according to the transmitted command. Note that index n is encoder category which is specified by encoder address (ENC1 to ENC8). Index m is data register number each encoder category.

Table 52.12 Communication alarm (CA[4:0]) (1 of 2)

Bit	Symbol	Function
0	CA[0]	CMD status flag When this bit is set to 1, indicates transmitted command is not matched with received command.
1	CA[1]	FORM status flag When this bit is set to 1, indicate start bit and stop bit mismatch for the field or a lack of receive data length.
2	CA[2]	SYNC status flag When this bit is set to 1, indicates receive data does not come within the designated time after command code transmission.
3	CA[3]	CRC status flag When this bit is set to 1, indicates transmitted CRC is not matched with CRC calculated from received data.

Table 52.12 Communication alarm (CA[4:0]) (2 of 2)

Bit	Symbol	Function
4	CA[4]	SQN status flag When this bit is set to 1, indicates transmitted sequence number is not matched with received sequence number. (CDF31 only)

Table 52.13 Encoder status (ES[3:0] and ES)

Bit	Symbol	Function
0	ES[0]	BUSY + MEMBUSY
1	ES[1]	BATT
2	ES[2]	OVSPD + MEMERR
3	ES[3]	STERR + PSERR + MTERR
—	ES	ORed ES[3:0]. (CDF21 only)

Note: Confirm the specification document of the encoder to be used.

Table 52.14 Status code (ALM[15:0])

Bit	Symbol	Function
0	ALM[0]	BATT
1	ALM[1]	MTERR
2	ALM[2]	0 fixed
3	ALM[3]	OVSPD
4	ALM[4]	MEMERR
5	ALM[5]	STERR
6	ALM[6]	PSERR
7	ALM[7]	BUSY
8	ALM[8]	MEMBUSY
9	ALM[9]	OVTEMP
10	ALM[10]	0 fixed
11	ALM[11]	0 fixed
12	ALM[12]	0 fixed
13	ALM[13]	0 fixed
14	ALM[14]	0 fixed
15	ALM[15]	0 fixed

Note: Confirm the specification document of the encoder to be used.

The status when the main power is turned on (250 min^{-1} or less) when the external battery is not connected and the internal backup capacitor is completely discharged is as follows:

BUSY, STERR, MEMBUSY, MEMERR, OVTEMP = 0

MTERR, BATT = 1

OVSPD, PSERR = x (indefinite value)

52.4 Operation

52.4.1 Basic Operation

After writing a command and memory data such as read address and write data, command data transmission starts by register-write or trigger input according to the TRGSEL register setting.

(1) Startup by register access

When the EXT bit in the TRGSEL register is set to 0, the register trigger is selected.

In this mode, when the TRG bit in the TXTRG register is set to 1, command data transmission starts.

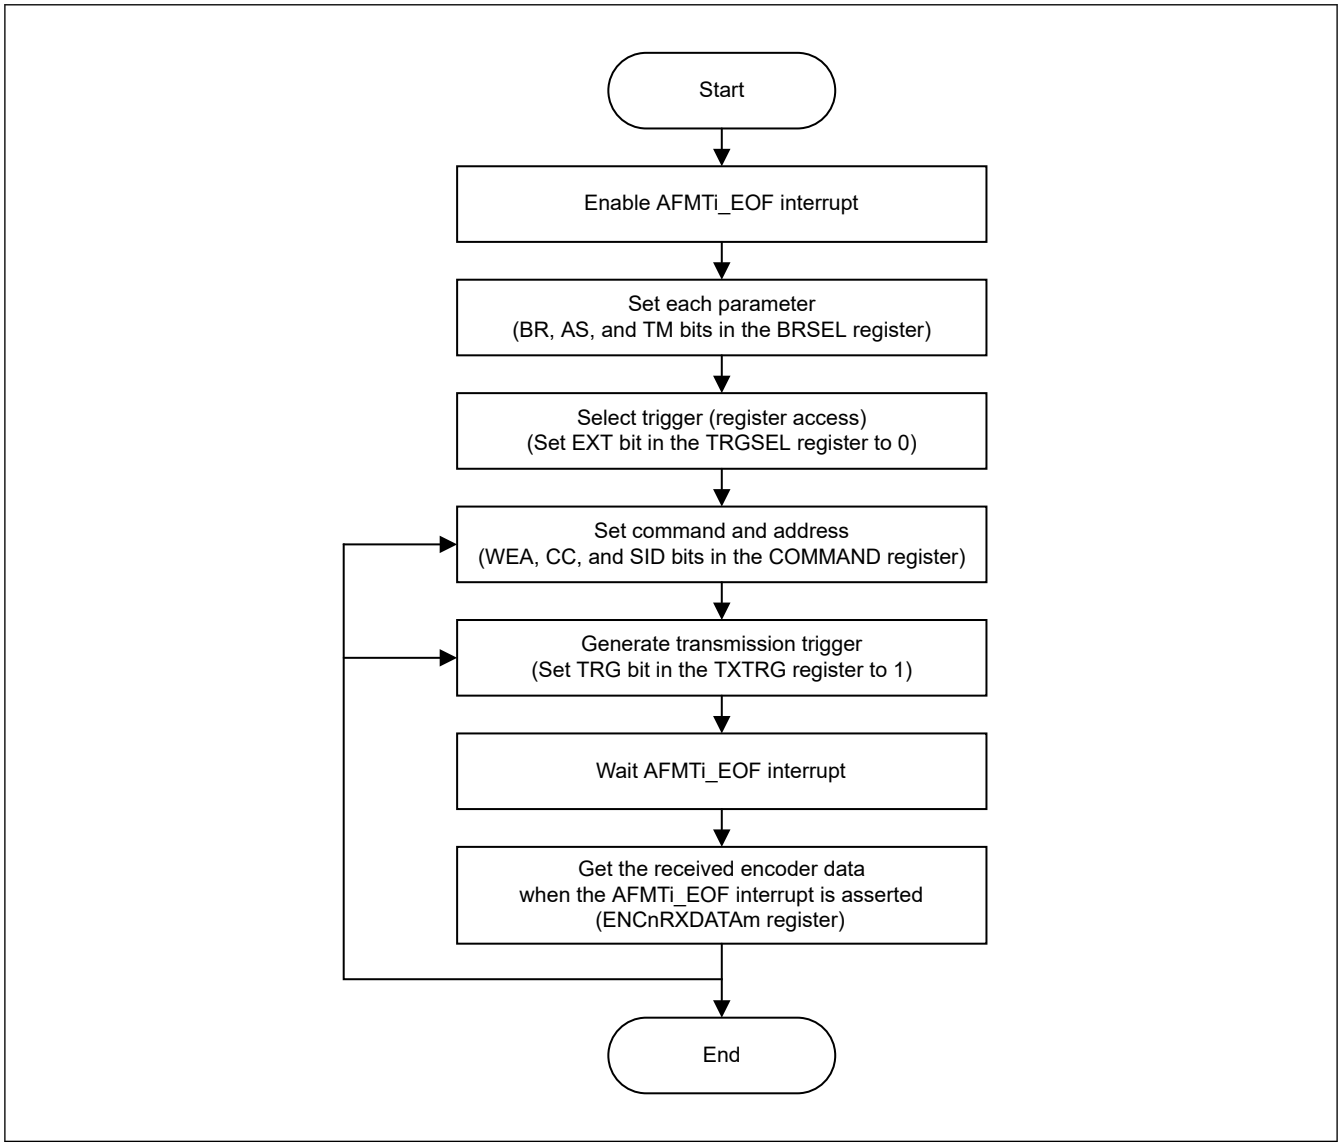

Figure 52.2 Basic operation (startup by register access)

(2) Startup by trigger input from ELC

When the EXT bit in the TRGSEL register is set to 1, the trigger from ELC is selected.

In this mode, when the trigger input is received from ELC, command data transmission starts.

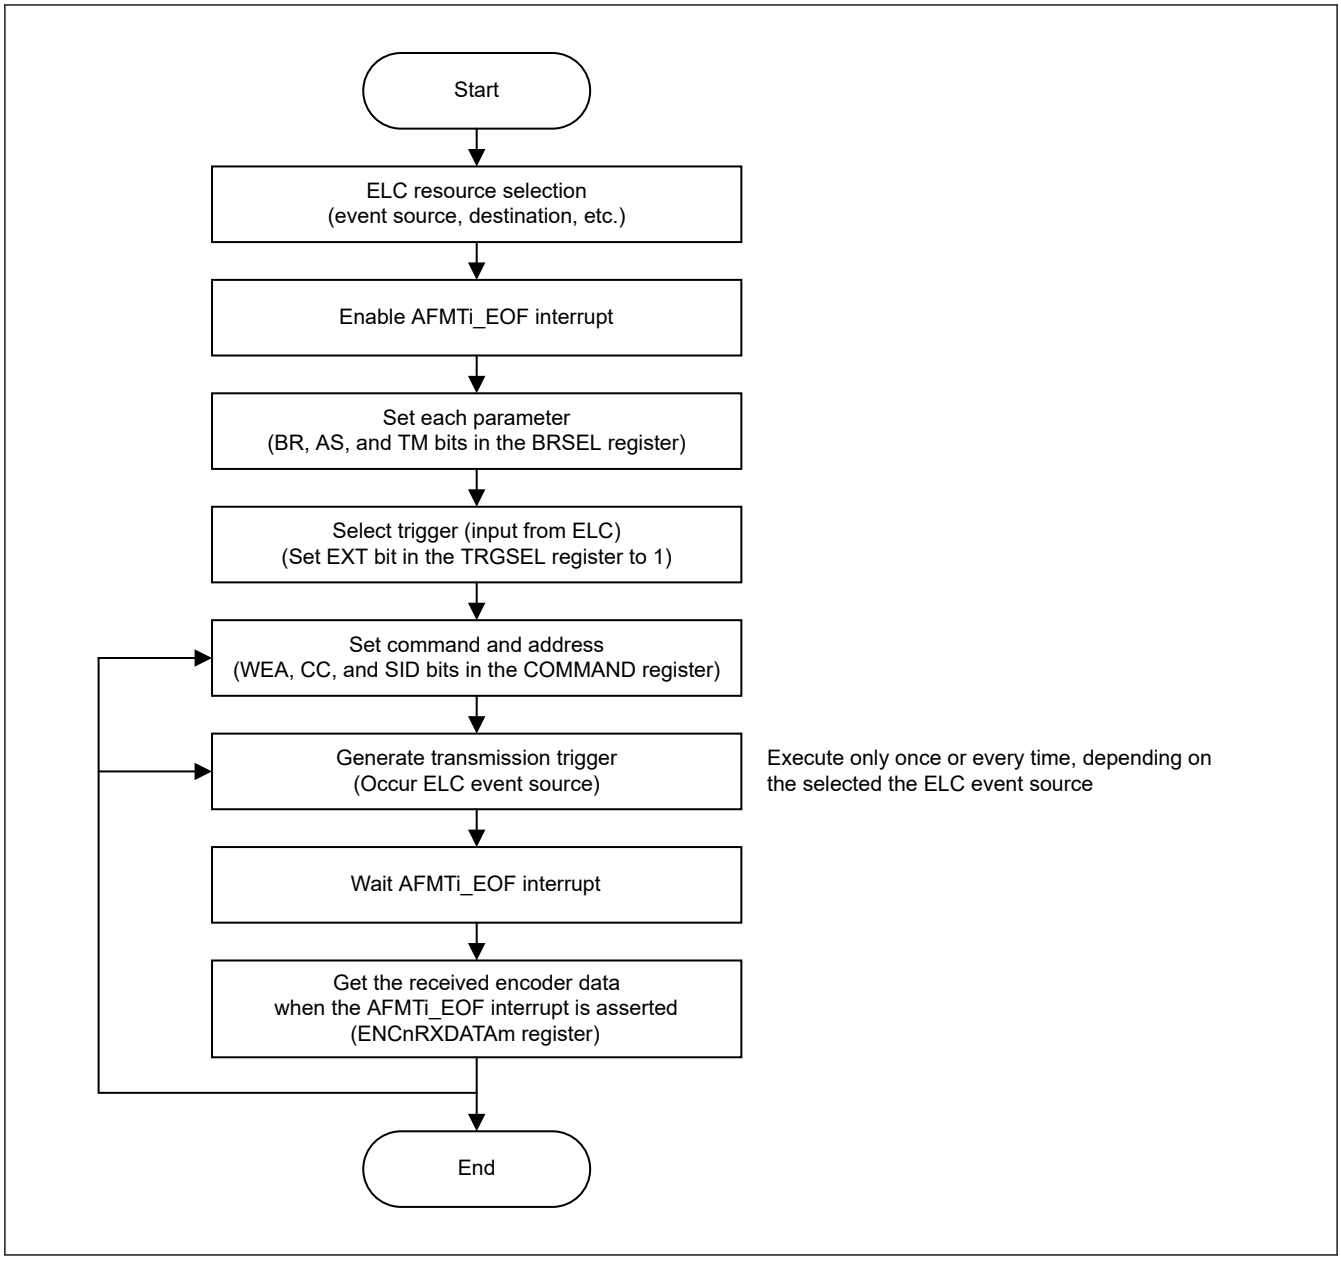

Figure 52.3 Basic operation (startup by trigger input from ELC)

A received encoder data is stored to the ENCnRXDATAm register and the AFMTi_EOF interrupt is asserted when communication is completed. The AFMTi_EOF interrupt is canceled when the first output data is read out.

The baud rate is required a value depending on the encoder used.

52.4.2 Command Configuration

(1) One frame command (CDF0 to CDF12, CDF15 to CDF17, CDF21, CDF22, and CDF27 to CDF31)
Position data request / various clear request / EC address setting / one-rotate data zero preset

Command data

(2) Two frame command (CDF13)
EEPROM data read

Command data	Read address (8 bits)

(2) Four frame command (CDF14, and CDF18 to CDF19)
EEPROM data write

Command data	Write data (lower 8 bits)	Write data (upper 8 bits)	Read address (8 bits)

Figure 52.4 Command configuration

52.4.3 Interrupts

52.4.3.1 Communication Completion Interrupt

When a received encoder data is set to the ENCnRXDATAm (n = 1 to 8, m = 0 to 7) registers and the sequence of receiving and sending operations is completed, the communication completion interrupt, AFMTi_EOF (i = 0 to 15), is asserted. When the first output data readout is executed, the communication completion interrupt is canceled.

The TRGSEL register is reset when the communication completion interrupt happens.

52.4.3.2 Time Out Error Interrupt

When data is not returned within the predetermined time for a request, the time out error interrupt, AFMTi_TMOUT (i = 0 to 15), is asserted. When next communication start, the time out error interrupt is canceled.

52.4.4 Individual Transmission Mode

Figure 52.5 shows the serial data transmission/reception timing for the individual mode.

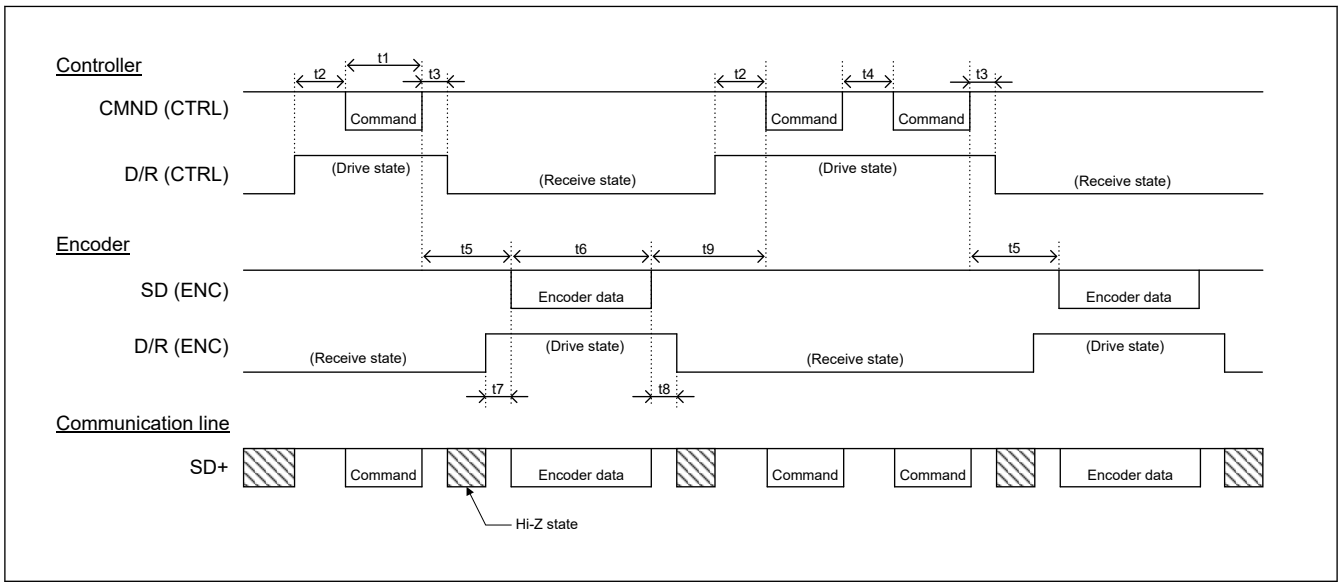

Figure 52.5 Individual transmission mode

Table 52.15 Timing of individual transmission mode

Time	2.5 Mbps	4 Mbps	6.67 Mbps	8 Mbps	16 Mbps	Remarks
t1	7.2 µs	4.5 µs	2.7 µs	2.25 µs	1.125 µs	—
t2	1 µs (MIN)	1 µs (MIN)	1 µs (MIN)	1 µs (MIN)	1 µs (MIN)	Reference value
t3	1.5 µs	1.0 µs	1.0 µs	0.7 µs	0.7 µs	Reference value
t4	1 µs (MIN)	1 µs (MIN)	1 µs (MIN)	1 µs (MIN)	1 µs (MIN)	—
t5	3 µs	2 µs	2 µs	1.5 µs	1.5 µs	—
t6	7.2 µs × n	4.5 µs × n	2.7 µs × n	2.25 µs × n	1.125 µs × n	n = 2 to 6*2
t7	387.5 ns	237.5 ns	137.5 ns	112.5 ns	50 ns	—
t8	1. 2 µs	0.8 µs	0.8 µs	0.4 µs	0.4 µs	—
t9	3.5 µs (MIN)	2.5 µs (MIN)	2.5 µs (MIN)	2.2 µs (MIN)	2.2 µs (MIN)	—

Note 1. Delay of transmission path and transceiver/receiver is assumed zero.
Note 2. Data transmission time is different dependent on commands.
Note 3. t2 is changeable via register setting.

52.5 Usage Note

52.5.1 Multiple Transmission Mode

This LSI does not support multiple transmission mode (Command: CDF4 to CDF7, CDF22, CDF28, CDF30, CDF31. Subcommand for CDF31: SID1, SID3, SID5 and SID7). Individual transmission mode is only available.

53. Encoder Divided-Output (ENCOUT) Module

53.1 Overview

The encoder divided-output (ENCOUT) module of this MPU generates Phase A, Phase B, and Phase Z (index) output signals. The waveforms are similar to the output signals from an incremental encoder, and reflect the positional information set in registers. Especially, by setting the results of reading positional information from an incremental or absolute encoder in the registers of ENCOUT, these signals can be converted to the desired Phase A, Phase B, and Phase Z output signals.

Table 53.1 describes the ENCOUT specifications and Figure 53.1 shows a block diagram of the ENCOUT module.

Table 53.1 ENCOUT specifications

Item	Description
Number of units	1 unit
Operation clock	20 MHz or 80 MHz selectable
Functions	• Number of edges per rotation: 16 to 65,536 (a multiple of 4) • Carrier period: 350 ns to 3,276.75 µs (20 MHz), 88 ns to 819.188 µs (80 MHz) • Changing the active sense of Phase B • Changing the phase and width of Phase Z
Event link	Support for the input of carrier period event signals from ELC
Module-stop function	Module-stop state can be set to reduce power consumption

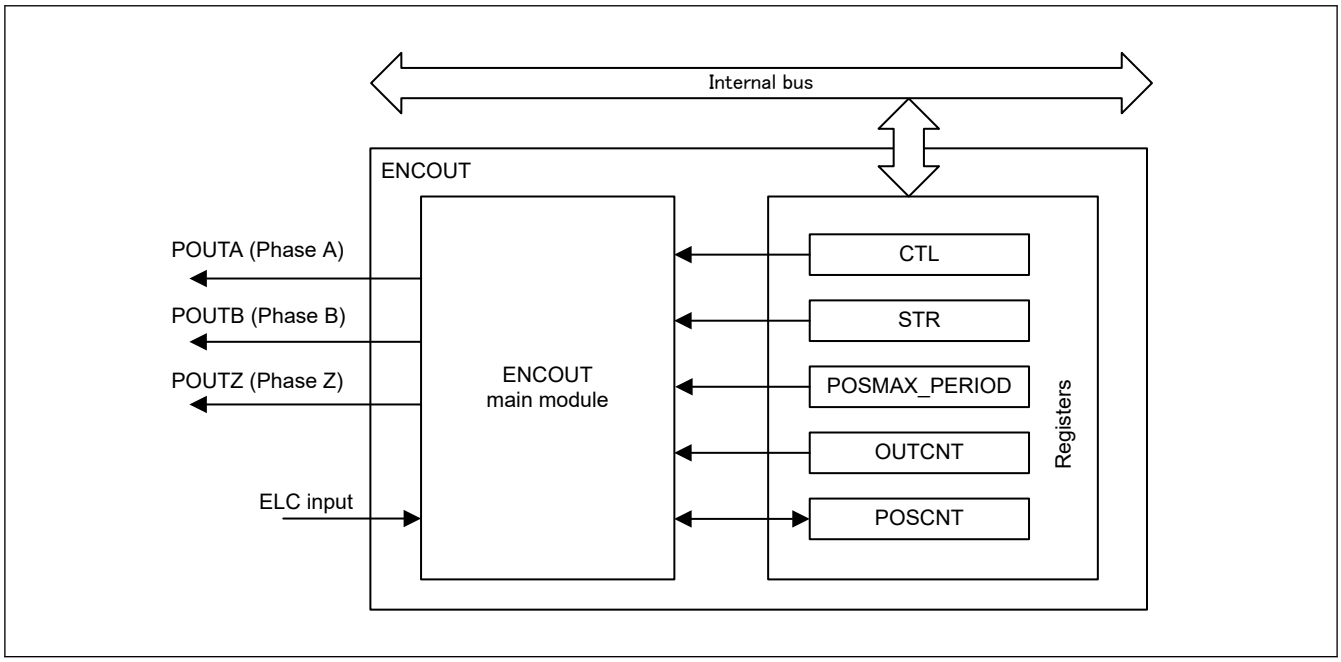

Figure 53.1 ENCOUT block diagram

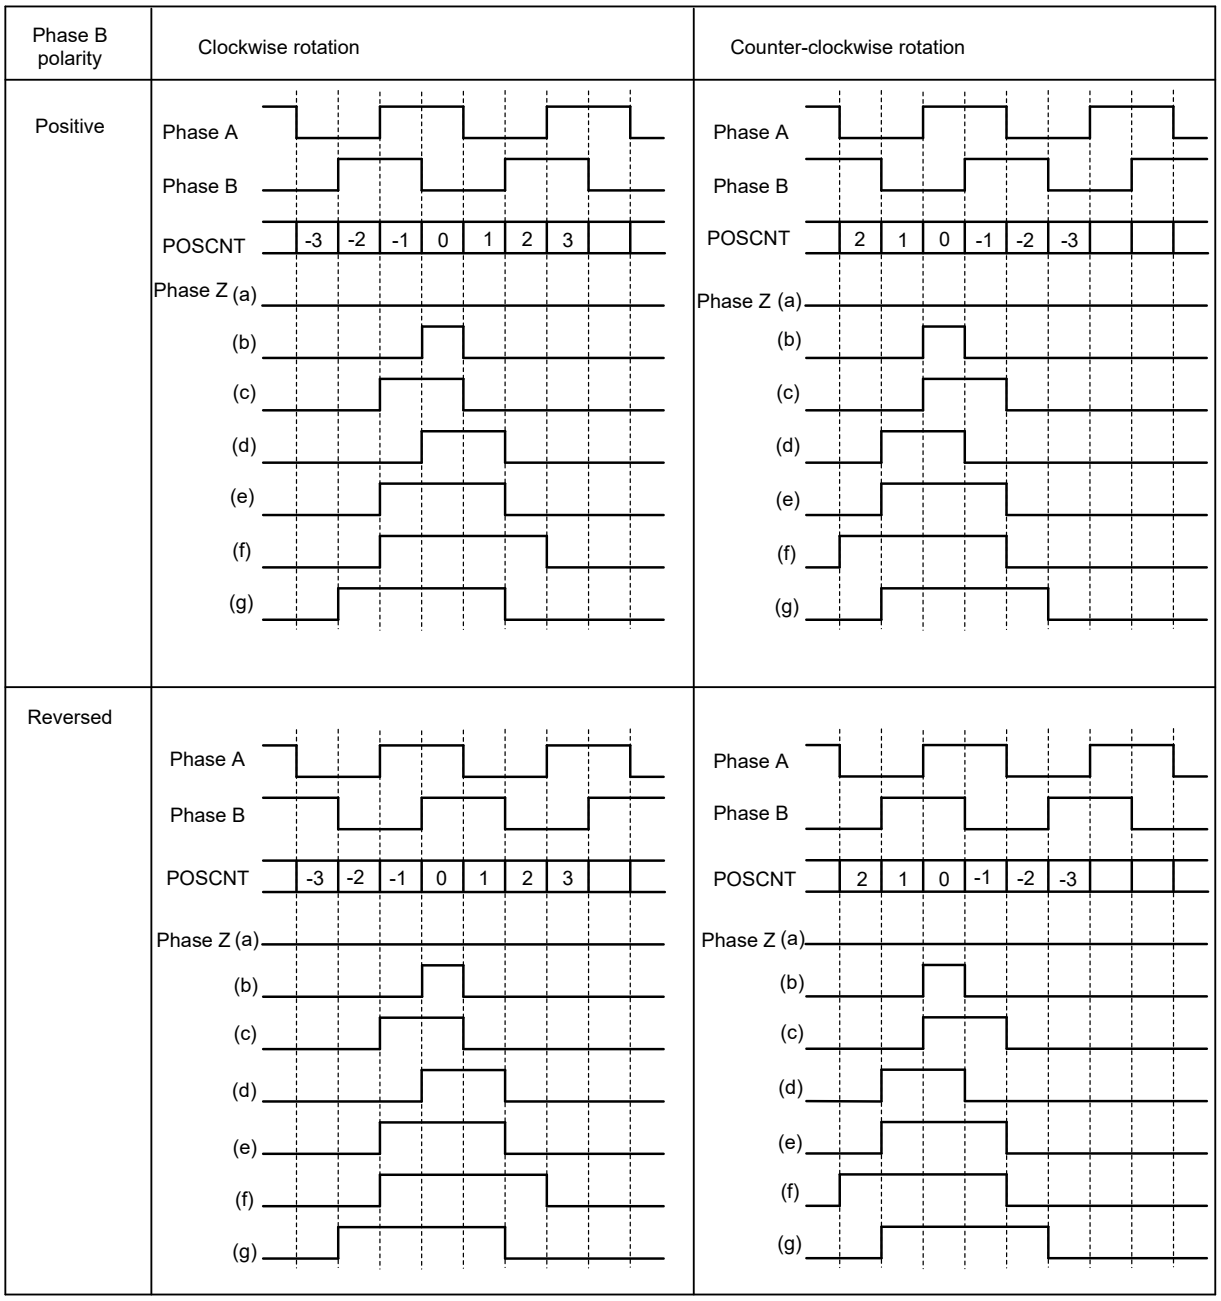
Table 53.2 lists the input/output pins of the ENCOUT module.

Table 53.2 ENCOUT pin configuration

Pin name	I/O	Function
POUTA	Output	Phase A output pin
POUTB	Output	Phase B output pin
POUTZ	Output	Phase Z output pin



Note: Each output waveform of Phase Z is based on the following settings:
(a) Disable Phase Z output; CTL.ZW = 0
(b) Pulse output when current position, POSCNT, is 0; CTL.ZW = 1
(c) Pulse output when current position, POSCNT, is −1 and 0; CTL.ZW = 2 and CTL.ZS = 0
(d) Pulse output when current position, POSCNT, is 0 and 1; CTL.ZW = 2 and CTL.ZS = 1
(e) Pulse output when current position, POSCNT, is −1, 0, and 1; CTL.ZW = 3
(f) Pulse output when current position, POSCNT, is −1, 0, 1, and 2; CTL.ZW = 4 and CTL.ZS = 0
(g) Pulse output when current position, POSCNT, is −2, −1, 0, and 1; CTL.ZW = 4 and CTL.ZS = 1

Note: Negative values for current position (POSCNT).
POSCNT = −1: POSMAX setting value
POSCNT = −2: POSMAX setting value − 1

53.3 Register Descriptions

53.3.1 CTL : Control Register

Base address: ENCOUT = 0x902C_0000

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ZS	ZW[2:0]			POL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	POL	Polarity of Phase B Set this bit when STR.ENCE = 0. The bit setting is immediately reflected to Phase B output. 0: Positive phase 1: Reversed phase	R/W
3:1	ZW[2:0]	Pulse Width of Phase Z*1 0x0: Disable Phase Z output 0x1: Pulse output when current position, POSCNT, is 0 0x2: Pulse output when current position, POSCNT, is -1 and 0 (sync with Phase A) Pulse output when current position, POSCNT, is 0 and 1 (sync with Phase B) 0x3: Pulse output when current position, POSCNT, is -1, 0 and 1 0x4: Pulse output when current position, POSCNT, is -1, 0, 1 and 2 (sync with Phase A) Pulse output when current position, POSCNT, is -2, -1, 0 and 1 (sync with Phase B) Others: Disable Phase Z output	R/W
4	ZS	Synchronization phase of Phase Z 0: Phase A 1: Phase B	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

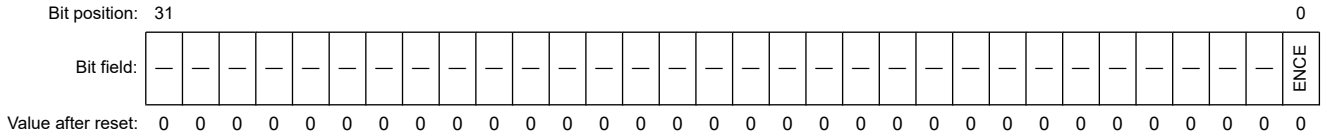
Note 1. Negative values for current position (POSCNT).
POSCNT = −1: POSMAX setting value
POSCNT = −2: POSMAX setting value − 1

The CTL register is used to set ENCOUT operation. This register should be set when STR.ENCE = 0. When STR.ENCE = 1, the write operation is disregarded.

53.3.2 STR : Start Register

Base address: ENCOUT = 0x902C_0000

Offset address: 0x004



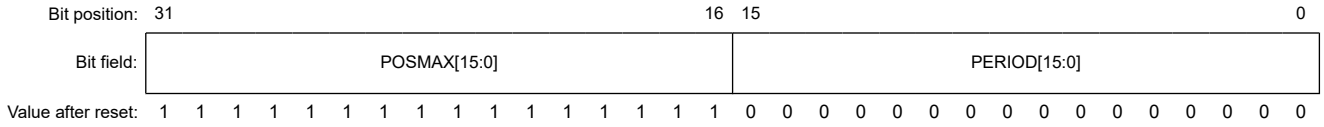
Bit	Symbol	Function	R/W
0	ENCE	ENCOUT Operation Start When the operation is stopped, the outputs of Phase A and Phase B correspond to POSCNT register, and Phase Z output is 0. 0: ENCOUT operation stop 1: ENCOUT operation start	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

The STR register is used to start/stop ENCOUT operation.

53.3.3 POSMAX_PERIOD : Maximum Position and Carrier Period Register

Base address: ENCOUT = 0x902C_0000

Offset address: 0x00C



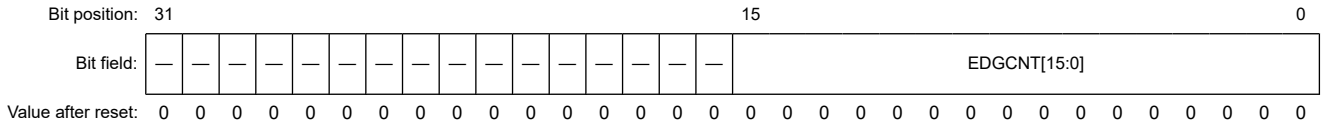
Bit	Symbol	Function	R/W
15:0	PERIOD[15:0]	Carrier Period Setting Carrier period length should be set in units of operation clock period (50 ns for 20 MHz or 12.5 ns for 80 MHz) according to the event input period from ELC. Settable value is from 7 (0x0007) to 65535 (0xFFFF). If event period from ELC cannot be divided evenly by operation clock period, the value should be set to ("event period from ELC" / "operation clock period") + 1 (round up the decimal point).	R/W
31:16	POSMAX[15:0]	Maximum Position Setting Maximum position value (number of edges) for one revolution. The maximum position value is set a multiple of 4. If maximum position value is 4 × N, this value should be set to 4 × N – 1. Settable value is 15 (0x000F), 19 (0x0013), 23 (0x0017), 27 (0x001B), 31 (0x001F), …, 65531 (0xFFFB), 65535 (0xFFFF).	R/W

The POSMAX_PERIOD register is used to set the maximum position value and carrier period. This register should be set when STR.ENCE = 0. When STR.ENCE = 1, the write operation is ignored.

53.3.4 OUTCNT : Output Count Register

Base address: ENCOUT = 0x902C_0000

Offset address: 0x010



Bit	Symbol	Function	R/W
15:0	EDGCNT[15:0]	Edge Count Setting Set the number of edges for Phase A and Phase B in the next carrier period. Set in two's complement representation, negative values indicate counter-clockwise rotation. Settable value is from -32768 (0x8000) to 32767 (0x7FFF). This value should be set to less than or equal to the setting value in PERIOD[15:0]. The update interval of edge count can be calculated from (PERIOD[15:0] / EDGCNT[15:0]) × operation clock period (50 ns for 20 MHz or 12.5 ns for 80 MHz). If PERIOD[15:0] / EDGCNT[15:0] cannot be divided evenly, the EDGCNT[15:0] is updated to disperse the error over the carrier period. See section 53.4.6. Uniformization of Waveform Output Accumulation Error.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The OUTCNT register is used to set the number of edges for Phase A and Phase B. When STR.ENCE = 1, the value should be set before an event occurs for the next carrier period.

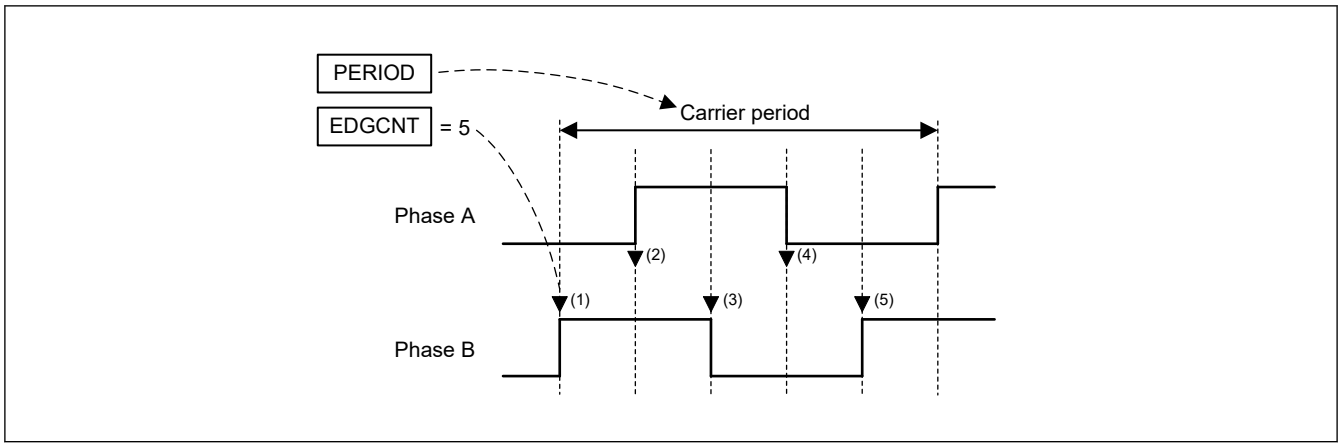


Figure 53.3 EDGCNT (clockwise rotation) and PERIOD setting sample

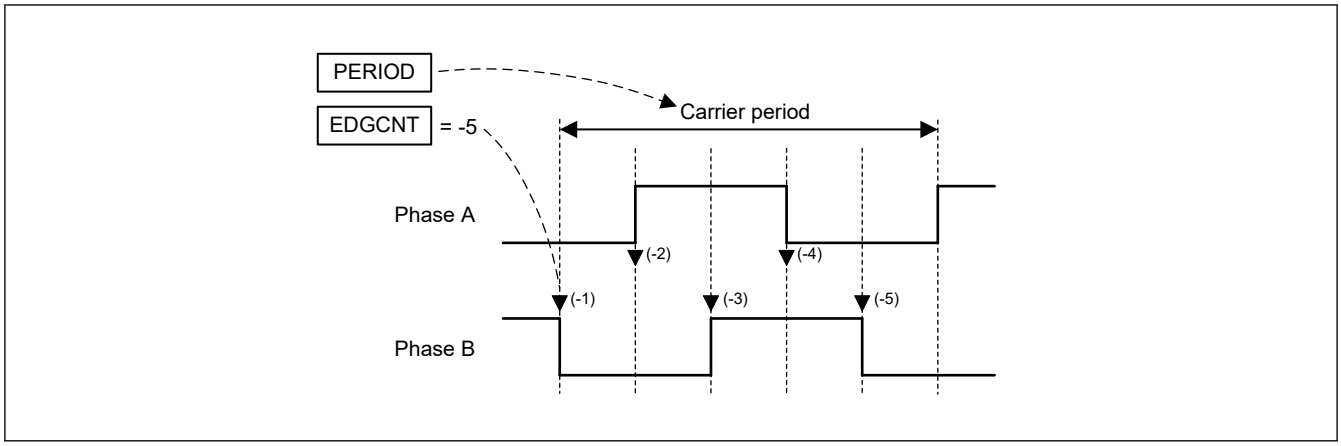

Figure 53.4 EDGCNT (counter-clockwise rotation) and PERIOD setting sample

53.3.5 POSCNT : Position Count Register

Base address: ENCOUT = 0x902C_0000

Offset address: 0x014

Bit position:	31															15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	POSCNT[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	POSCNT[15:0]	Current Position Set a current position value. Settable value is from 0 to value in POSMAX[15:0]. After starting ENCOUT operation, the value is updated according to the position.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The POSCNT register is used to set a current position value and check the current position. This register should be written when STR.ENCE = 0. When STR.ENCE = 1, the value is updated according to the position associated with Phase A and Phase B output.

53.4 Operation

ENCOUT generates Phase A/B and Phase Z outputs based on the register settings. The carrier period of Phase A/B and Phase Z outputs are generated by input from ELC.

Phase A/B and Phase Z output formats are shown in Figure 53.2. And Phase Z output is generated by matching POSCNT register value according to Table 53.6.

53.4.1 Phase A and Phase B Output Format

Phase A and Phase B output are represented by the four patterns shown in the table below according to the value of POSCNT[1:0]. The patterns are shifted right with the value of POSCNT[1:0] as Phase A pattern = 1001b (0x9) and Phase B pattern = 1100b (0xC), the first bit will be the output value of Phase A and Phase B. When reverse phase output (CTL.POL = 1), Phase B output pattern is reversed.

Table 53.5 Phase A and Phase B output pattern

POSCNT[1:0] value	3	2	1	0
Phase A output	1	0	0	1
Phase B output (CTL.POL = 0: Positive)	1	1	0	0
Phase B output (CTL.POL = 1: Reversed)	0	0	1	1

53.4.2 Phase Z Output Format

Phase Z output is generated by matching POSCNT register value to the table values below.

Table 53.6 Phase Z output pattern

Phase Z output width (CTL.ZW[2:0])	POSCNT[15:0] value when Phase Z output is 1
0	(Disable Phase Z output)
1	0
2 (Synchronize with Phase A)	-1, 0
2 (Synchronize with Phase B)	0, 1
3	-1, 0, 1
4 (Synchronize with Phase A)	-1, 0, 1, 2
4 (Synchronize with Phase B)	-2, -1, 0, 1

Note: Negative values for current position (POSCNT)
POSCNT = −1: POSMAX setting value
POSCNT = −2: POSMAX setting value − 1

53.4.3 Carrier Period Generation by Events from ELC

Event inputs from ELC are recognized as a carrier period. Generate a carrier period with a timer, etc., and input it using ELC.

53.4.4 PERIOD Setting Value 1

If the ELC event period is not divisible by the number of operating clocks in POSMAX_PERIOD.PERIOD configuration, set the integer value + 1 to POSMAX_PERIOD.PERIOD.

The figure below is an operation example. The operation clock period is 50 ns (20 MHz), the carrier period is 1000 ns (PERIOD = 20), ELC event period is 980 ns. ELC event is checked on every clock, and if the cumulative error between the carrier period and ELC event period exceeds 50 ns, an edge update is performed by 50 ns shorter than the 1000 ns carrier period and the carrier period counter is reset. Therefore, the cumulative error is less than 50 ns (one clock) as shown in the following table.

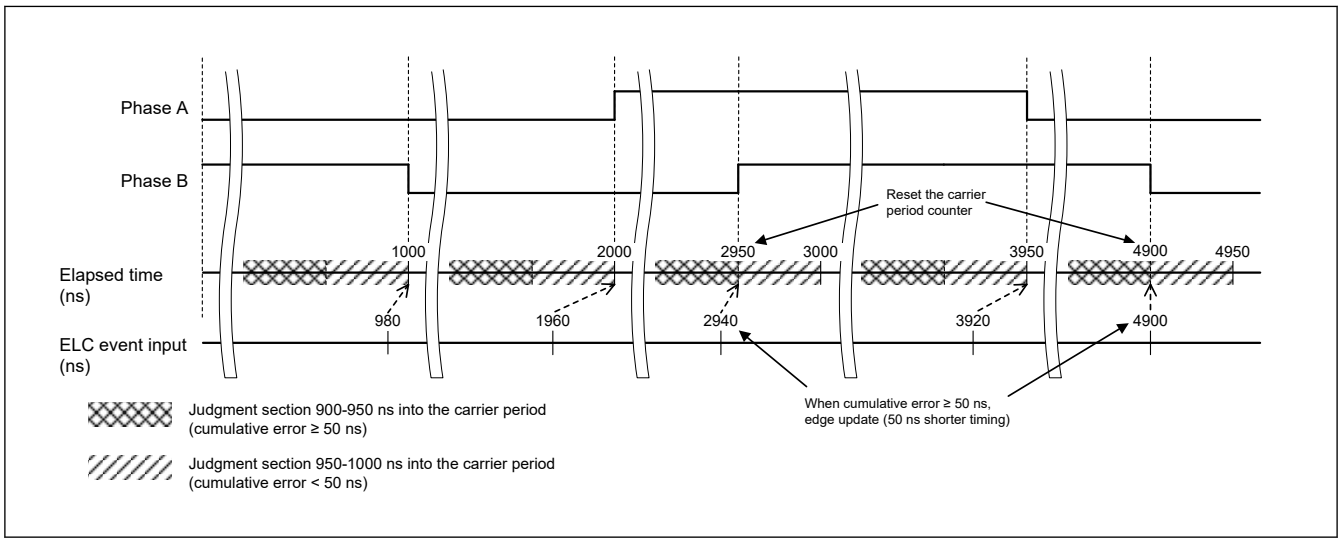

Figure 53.5 Operation example in the case ELC event period is 980 ns

Table 53.7 Actual carrier period in the case ELC event period is 980 ns

ELC event period	Actual carrier period	Remarks
980	1000	—
1960	2000	—
2940	2950	If the cumulative error is ≥ 50 ns, the edge is updated by 50 ns earlier.
3920	3950	—
4900	4900	If the cumulative error is ≥ 50 ns, the edge is updated by 50 ns earlier.
5880	5900	—
6860	6900	—
7840	7850	If the cumulative error is ≥ 50 ns, the edge is updated by 50 ns earlier.
8820	8850	—
9800	9800	If the cumulative error is ≥ 50 ns, the edge is updated by 50 ns earlier.

53.4.5 PERIOD Setting Value 2

The minimum setting for POSMAX_PERIOD.PERIOD is 7. The carrier period takes the edge of the ELC signal asynchronously at the operation clock (20 MHz or 80 MHz). The next ELC input signal cannot be accepted from the edge detection to the completion of operation clock synchronization. Therefore, the minimum setting value of PERIOD is 7 or more, so that the ELC signal can be reliably detected. Operation cannot be guaranteed when the setting value is set to 6 or less.

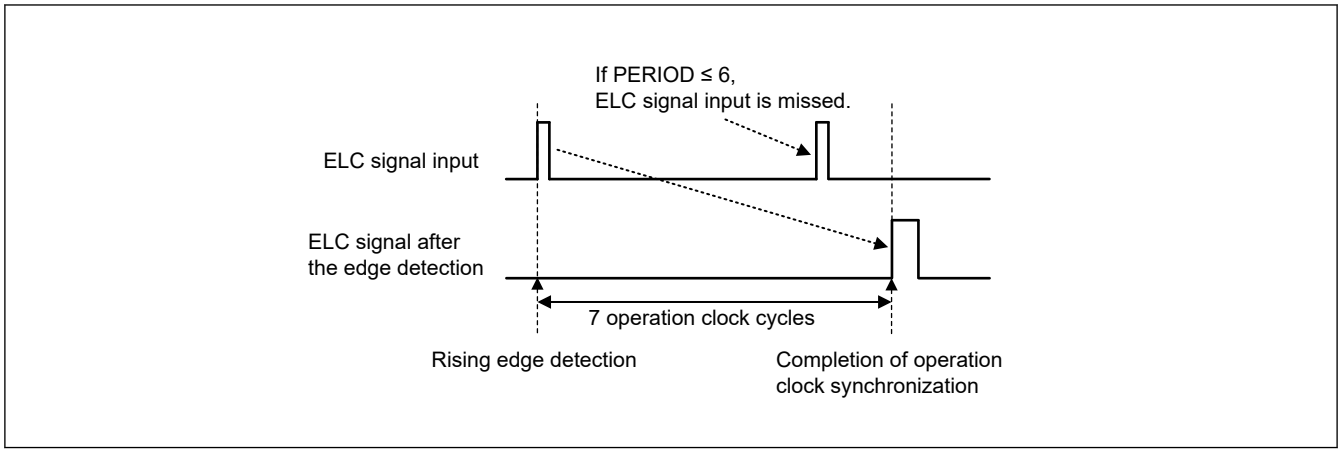

Figure 53.6 Example of the operation when PERIOD value is 6 or less

53.4.6 Uniformization of Waveform Output Accumulation Error

The edge-to-edge operation cycle truncates the decimal point of the calculated value, resulting in an error at the end of the carrier signal.

Counter for waveform update = carrier period / operation clock period / number of edges (OUTCNT.EDGCNT)

Example of the error accumulation with waveform output

The following figure is an operation example. The carrier period = 5000 ns, the operation clock period = 20 MHz (50 ns), the number of edges = 7. In this case, the error occurs finally because the decimal point is truncated by the edge interval calculation as follows.

Edge interval = 5000 / 50 / 7 = 14.2857 (the decimal point is truncated, and it results in 14)

Error = 5000 / 50 – 14 × 7 = 2

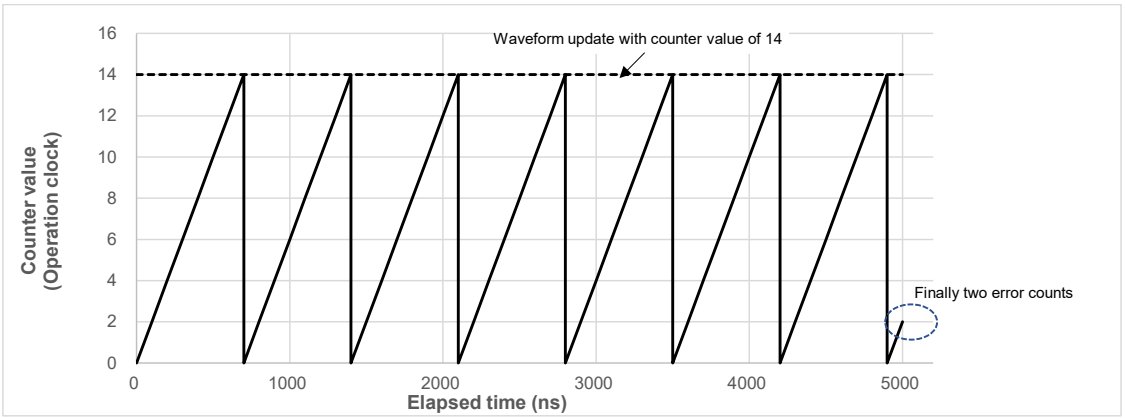

Figure 53.7 Waveform output and counter (accumulation error)

Therefore, the settings of the waveform output are changed as follows, and the error of the output waveform is uniformed throughout the carrier period.

- Add the "number of edges" at each operating clock
- The total counts of the carrier period = the number of edges × the number of operating clocks during the carrier period
- Update the waveform when the counter value of the operating clock exceeds the "number of clocks during the carrier period"

Example of the waveform output with the error accumulation measure

The following figure is an operation example. The carrier period = 5000 ns, the operation clock period = 20 MHz (50 ns), the number of edges = 7. The number of operating clocks during the carrier period is 100, counting by 7 per clock cycle. When the counter exceeds 100, it is subtracted by 100 and the waveform is updated. The counter increases by 700 in one carrier period, and the waveform changes exactly seven times in one carrier period.

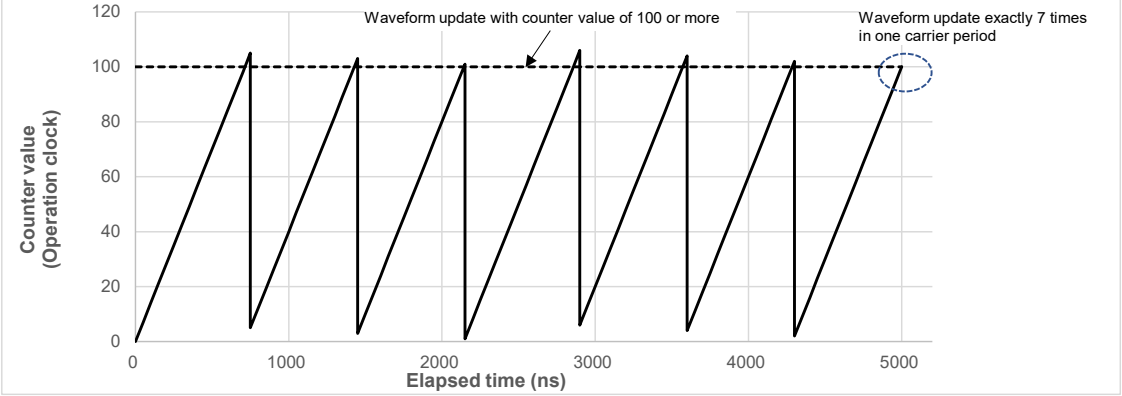

Figure 53.8 Waveform output and counter (with the error accumulation measure)

In the case of this setting, once the "number of clocks during the carrier period" is initially set, the waveform will be output by simply updating the "number of edges" setting during operation. In addition, since the assumption of the carrier period is 50000 to 3276000 (ns), the "number of clocks for carrier period" can be handled within the range of 2 bytes data.

(Carrier period: 3276000 ns) / (Operation clock period: 50 ns) = 65520 (0xFFF0)

Maximum carrier period setting: (POSMAX_PERIOD.PERIOD setting: 65535 (0xFFFF)) × 50 = 3276750 [ns]

53.4.7 Setting Procedure

53.4.7.1 System Configuration

The following figure shows a system configuration example that uses ENCOUT to convert the position information of an incremental encoder or an absolute encoder into Phase A/B and Phase Z outputs. The CPU obtains position information from the encoder for each period of the current loop and position control loop notified by the timer module. Then by updating ENCOUT setting periodically due to the difference from the previous position information, Phase A/B and Phase Z output is generated. The timer module events that generate periods of the current loop or position control loop should be input to ENCOUT through the ELC.

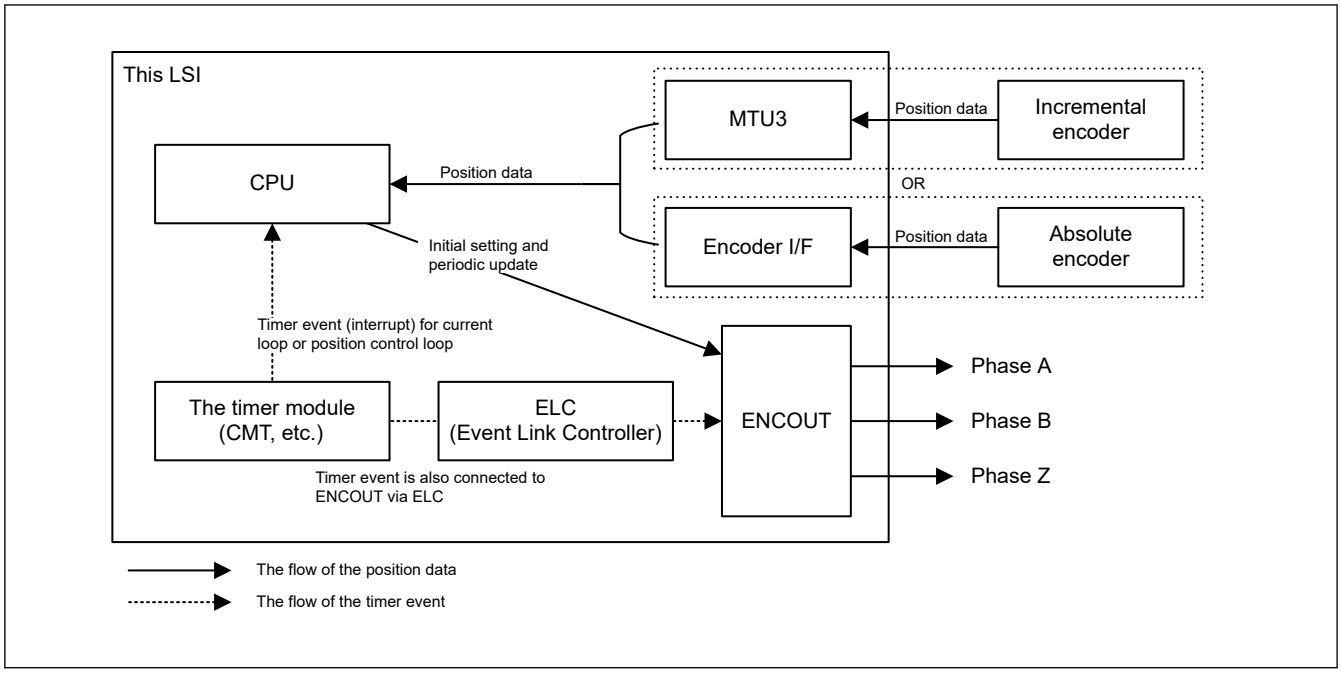

Figure 53.9 Example of phase output system configuration

53.4.7.2 Initialization

The following figure shows the initialization flow of ENCOUT.

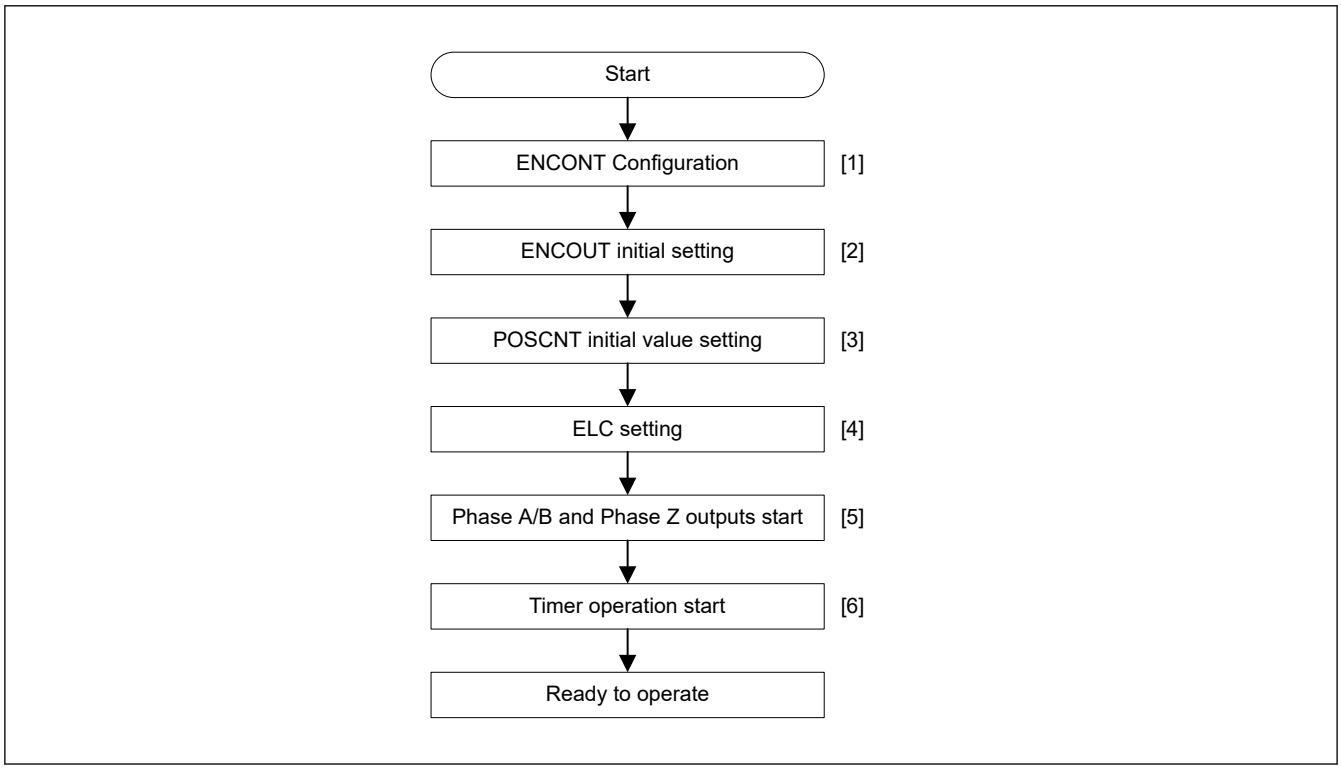

Figure 53.10 ENCOUT initialization flow

[1] ENCOUT configuration

Set the output pin assignment using the I/O port registers. Set the operation clock frequency by ENCOUTCLK bit in System Clock Control Register 4 (SCKCR4). Release from the module-stop state by Module Stop Control Register.

[2] ENCOUT initial setting

Initialize CTL, POSMAX_PERIOD, and OUTCNT registers. Set OUTCNT register to 0. Set the value of POSMAX_PERIOD.PERIOD to match the event input period from the ELC. If the event period from ELC is not divisible by operation clock period (50 ns or 12.5 ns), the value should be set to ["event period from ELC" / "operation clock period" + 1]. (Round up the decimal point)

Example 1: Operation clock period is 50 ns. The number of edges per revolution is 100, Phase B output is positive, and the carrier period is 500 (ns).
POSMAX_PERIOD.POSMAX = 99 (4 × 25 − 1)
POSMAX_PERIOD.PERIOD = 10 (500 / 50)
CTL = 0, OUTCNT = 0

Example 2: Operation clock period is 50 ns. The number of edges per revolution is 100, Phase B output is positive, and the carrier period is 520 (ns).
POSMAX_PERIOD.POSMAX = 99 (4 × 25 − 1)
POSMAX_PERIOD.PERIOD = 11 (520 / 50 + 1)
CTL = 0, OUTCNT = 0

[3] POSCNT initial value setting

Set the POSCNT register to the initial position in the range from 0 to POSMAX_PERIOD.POSMAX of an absolute encoder or an incremental encoder.

The position values = [Encoder position value] × [Number of edges per rotation] / [Encoder position value resolution] (truncate the decimal point).

Example: The number of edges per revolution is 100, encoder position value resolution is 20 bits (1048576), and initial position value is 943719.
POSCNT = 90 (943719 × 100 / 1048576)

[4] ELC setting

The event from the timer is input to ENCOUT by the setting of ELC registers.

[5] Phase A/B and Phase Z outputs start

Set the STR.ENCE bit to 1 to start Phase A/B and Phase Z output.

[6] Timer operation start

Operate a timer to generate a carrier period event.

53.4.7.3 Main Processing

The following figure shows the main processing flow of ENCOUT. This flow should be performed for each carrier period.

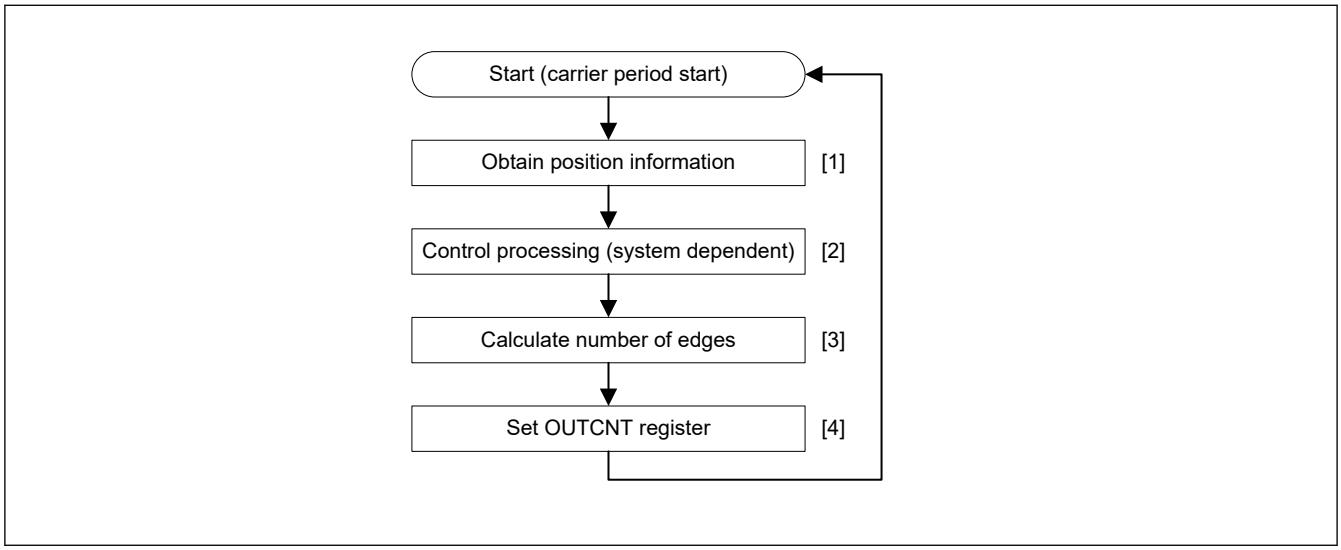

Figure 53.11 ENCOUT main processing flow

[1] Obtain position information

Obtain position information from the absolute or incremental encoders.

[2] Control processing (system dependent)

Performs motor control processing, etc. based on position information. This process is system dependent.

[3] Calculate number of edges

Calculates the setting value for OUTCNT.EDGCNT.

Current position value with the maximum position as POSMAX = [Position value obtained in step [1]] × [Number of edges per rotation] / [Encoder position value resolution] (truncate the decimal point)

Setting value of OUTCNT.EDGCNT = current position − previous position (the maximum position as POSMAX)

However, if the absolute value of above is greater than half of the number of edges per revolution:

- When setting value > 0, setting value − [Number of edges per rotation]
- When setting value < 0, setting value + [Number of edges per rotation]

Example: In the following cases:
Encoder position value = 20972, encoder position value resolution = 20 bits (1048576), number of edges per rotation = 100, previous position (the maximum position as POSMAX) = 95, carrier period = 100 µs
Current position (the maximum position as POSMAX) = 20972 × 100 / 1048576 = 2
Setting value of OUTCNT.EDGCNT = 2 − 95 = −93
This absolute value is greater than half of the number of edges per revolution (93 > 50).
Setting value is (−93) < 0, setting value + [Number of edges per rotation] = −93 + 100 = 7.

[4] Set OUTCNT register

Set OUTCNT.EDGCNT to the value calculated in step [3].

53.4.8 Setting and Output Examples

The following figure shows an example of Phase A/B and Phase Z output waveforms that correspond to the ENCOUT settings in case operation clock period is 50 ns.

This is an example when the carrier period is 100 µs, the number of edges per revolution is 100, Phase B is the positive phase, and initial position value is 90 (the maximum position as POSMAX). This is an example of a case the position transitions to 95, 2, and 98.

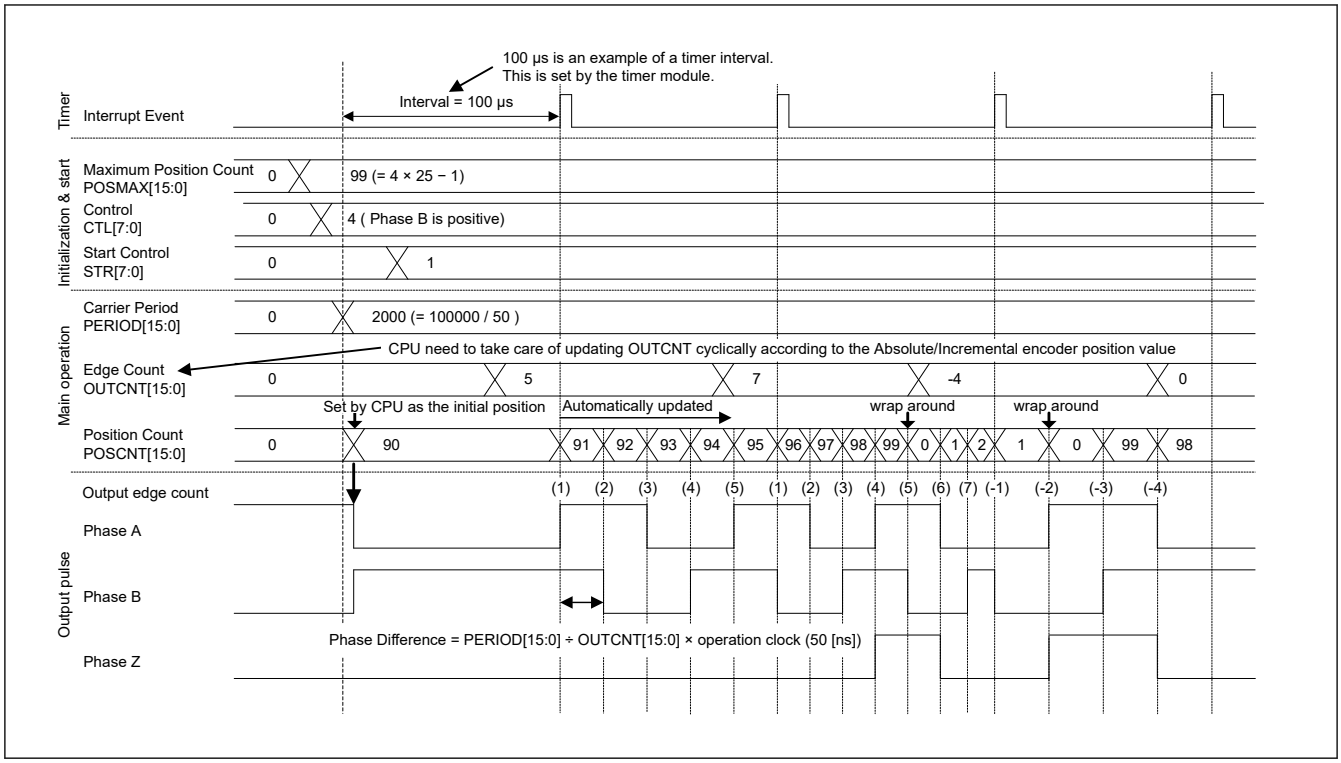

Figure 53.12 Example of Phase A/B and Phase Z output waveforms by ENCOUT setting value

54. LCD Controller (LCDC)

54.1 Overview

This chapter describes the features of the LCDC unit of this LSI.

This unit is LCD controller, it is composed of Frame Compression Processor (FCPVD), Video Signal Processor (VSPD), and Display Unit (DU).

The following is key features of this unit.

- FCPVD
  - Supports out-of-order for the whole outstanding transactions
  - Read linear addressing image data
  - Read display list data
  - Write image data
- VSPD
  - Supports various data formats and conversion
    - Supports YCbCr444/422/420, RGB, α RGB, α plane
    - Color space conversion and changes to the number of colors by dithering
    - Color keying
    - Supports combination between pixel alpha and global alpha
    - Supports generating pre-multiplied alpha
  - Video processing
    - Blending of two picture layers and raster operations (ROPs)
    - Clipping
    - 1D look up table
    - Vertical flipping in case of output to memory
  - Direct connection to display module
    - Supports up to 1920 pixels in horizontal direction
    - Writing back image data which is transferred to Display Unit (DU) to memory
- DU
  - Supports Display Parallel Interface (DPI)
  - Display timing master
    - Generates video timings (Front porch, Back porch, Sync active, Active video area)
    - Selects the polarity of output DCLK, HSYNC, VSYNC, and DE
  - Supports Progressive (Non-interlace)
  - Not supports Interlace
  - Input data format (from VSPD): RGB888, RGB666 (not supports dithering of RGB565)
  - Output data format: same as Input data format
  - Supports up to 100 MHz of the pixel clock frequency
  - Examples of the supported resolutions is below:
    - RGB888, 1920 pixels × 1080 lines, 30 fps (FHD)
    - RGB888, 1280 pixels × 1024 lines, 60 fps

Figure 54.1 shows a block diagram.

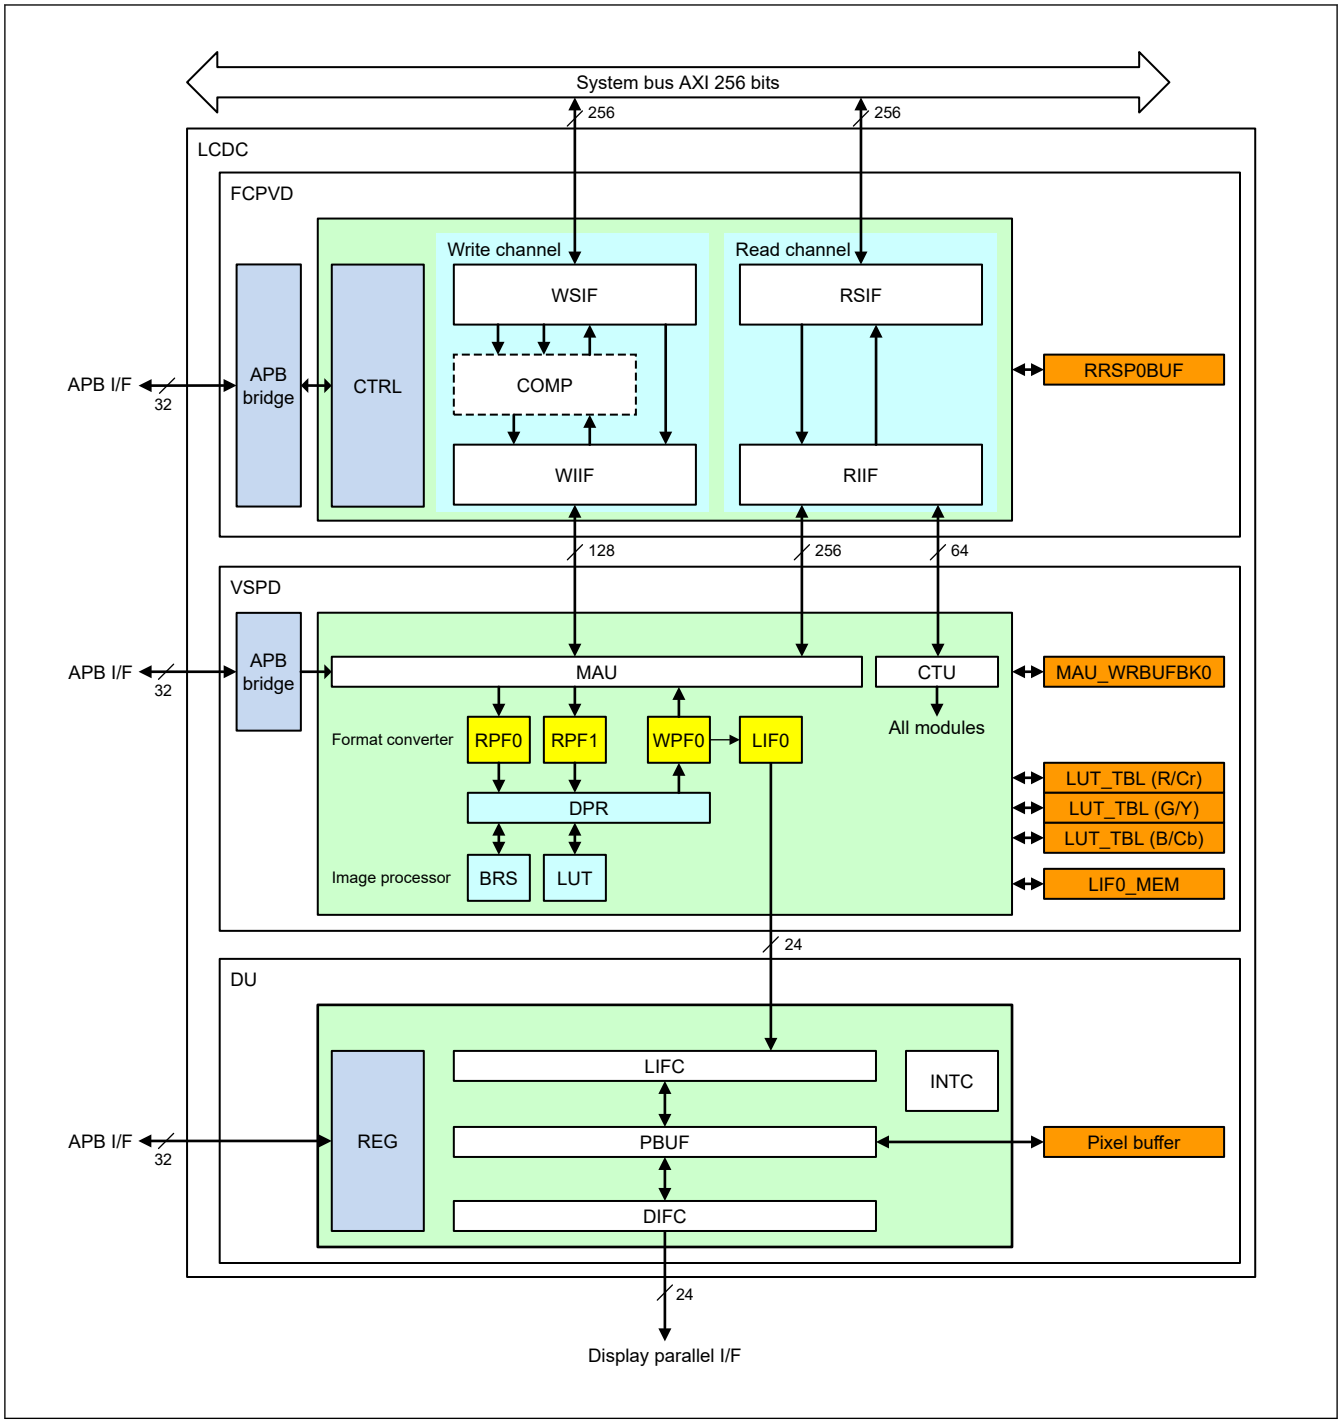

Figure 54.1 Block diagram

Table 54.1 Input/output pins of the LCD controller (1 of 2)

Name	I/O	Description
DISP_CLK	Output	Display Parallel Interface pixel clock
DISP_HSYNC	Output	Display Parallel Interface Horizontal sync pulse
DISP_VSYNC	Output	Display Parallel Interface Vertical sync pulse
DISP_DE	Output	Display Parallel Interface data enable
DISP_DATAR0 to DISP_DATAR7	Output	Display Parallel Interface pixel data output (R/Cr)
DISP_DATAG0 to DISP_DATAG7	Output	Display Parallel Interface pixel data output (G/Y)

Table 54.1 Input/output pins of the LCD controller (2 of 2)

Name	I/O	Description
DISP_DATAB0 to DISP_DATAB7	Output	Display Parallel Interface pixel data output (B/Cb)

54.1.1 FCPVD

FCPVD has the following sub modules.

Table 54.2 Sub modules in FCPVD

Abbreviation	Description
CTRL	FCPVD controller
WIIF	VSPD write channel interface
WSIF	System AXI write channel interface
RIIF	VSPD read channel interface
RSIF	System AXI read channel interface
COMP	Compression module (This is a dummy module)

54.1.2 VSPD

VSPD has the following sub modules.

54.1.2.1 Memory Access Unit (MAU)

The VSPD applies processing to the image data stored in the external memory and writes the resultant data back to the external memory. The data transfer between the external memory and VSPD necessary for this operation is done by the MAU, which works as the bus master, according to the register settings. The MAU executes this data transfer between the external memory and VSPD.

54.1.2.2 Command Transfer Unit (CTU)

The VSPD can directly read register parameters for image processing by display lists stored in external memory. The CTU module is a bus interface and controls display lists when the CTU reads display lists as a bus master.

54.1.2.3 Read Pixel Formatter (RPF)

The RPF reads image data from the external memory through the MAU, unpacks data according to the specified format, converts the color space, converts the number of colors, executes color keying, ROP operation, Multiply-alpha and OSD processing, and outputs the resultant data to the DPR. The RPF has an input format unpacking unit, a 1-bit mask generator, a raster operation unit (ROP unit), a color keying unit, a color space converter, and multiply-alpha. Figure 54.2 shows the processing flow in the RPF.

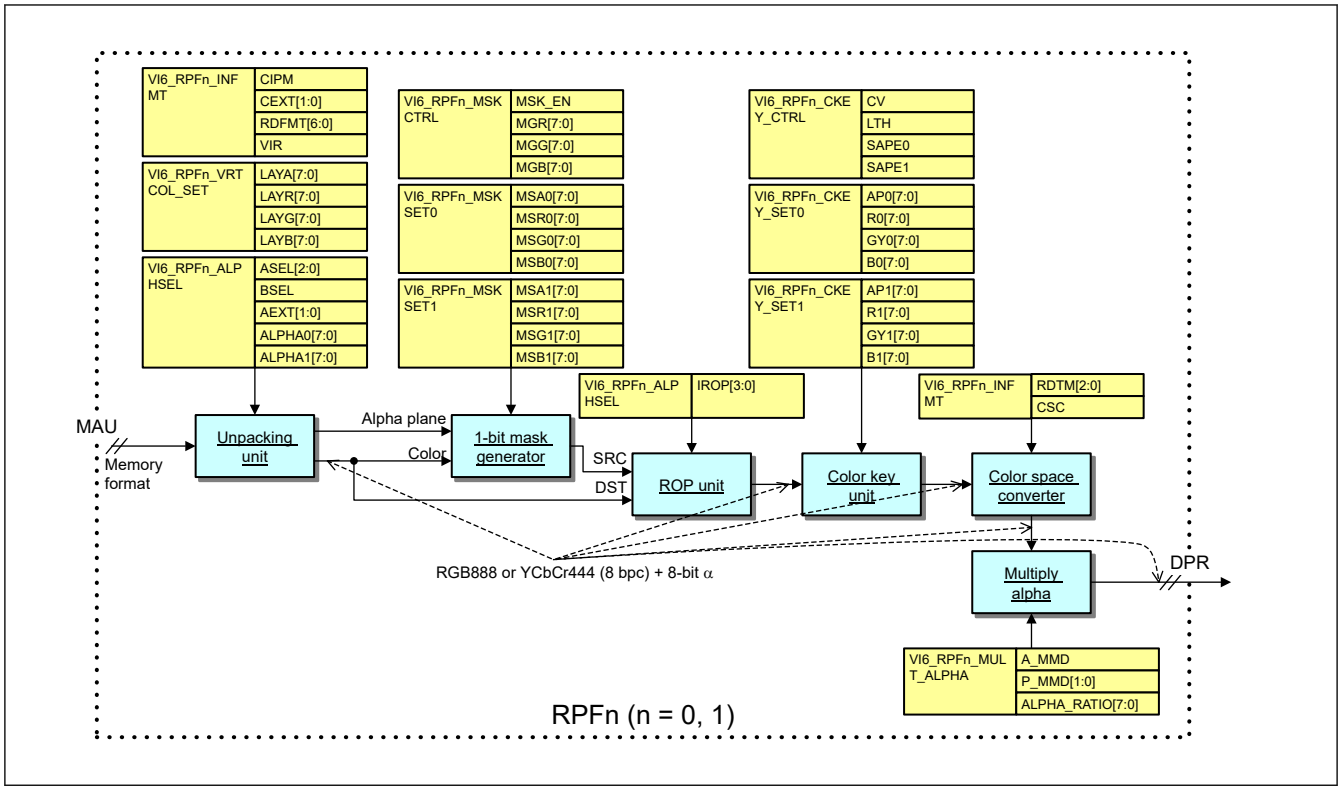

Figure 54.2 RPF processing flow

The input format unpacking unit expand the image data input from the MAU into the image format for internal processing (YCbCr444 8-bpc or RGB888 8-bpc), and the 1-bit mask generator generates a 1-bit image mask from the image data expanded through the unpacking unit. Alternately, a 1-bit image mask can be generated from the alpha plane that is different from the picture plane read through the MAU.

The raster operation unit (ROP unit) executes raster operation between the data from the 1-bit mask generator and the image data expanded from the input format, and the color keying unit applies color replacement and specifies the transparent color for the image data input from the ROP unit. The color space converter converts the color space (RGB-YCbCr) of the image data input from the color keying unit as necessary. The multiply-alpha unit multiplies pixel-alpha by specified alpha or/and multiplies image data by pixel-alpha or/and specified alpha.

The VSPD provides maximum two RPF modules (RPF0 to RPF1).

54.1.2.4 Data Path Router (DPR)

The DPR controls the data paths among RPFs, function modules, and WPFs. The DPR selects one of the images input from RPFs, outputs it to a function module (BRS or LUT), and selects one of WPFs as the destination where the image data processed in the function module will be output. Before output to the WPF, the output from each function module can be input to another function module, which enables multiple image processing functions to be executed continuously without involving the external memory.

54.1.2.5 Look Up Table (LUT)

This is a 1D-LUT that converts each of three color components by using a lookup table. The LUT is connected to the DPR and can be used for gamma correction, negative-positive conversion, posterization, and binarization through desired tone curve settings.

The LUT supports local area processing for Y component. The LUT can apply 1D look up table for Y component per area where a image is divided into multiple area specified by registers and command list.

54.1.2.6 Blend ROP Sub Unit (BRS)

The BRS is a module connected to the DPR, which executes the image blending processing and ROP operation. The BRS has two blend/ROP operation units (blend/ROP unit m, m = A to B), a blend/ROP input switch (SEL) for selecting the input to these operation units, and a divider for normalization (div unit).

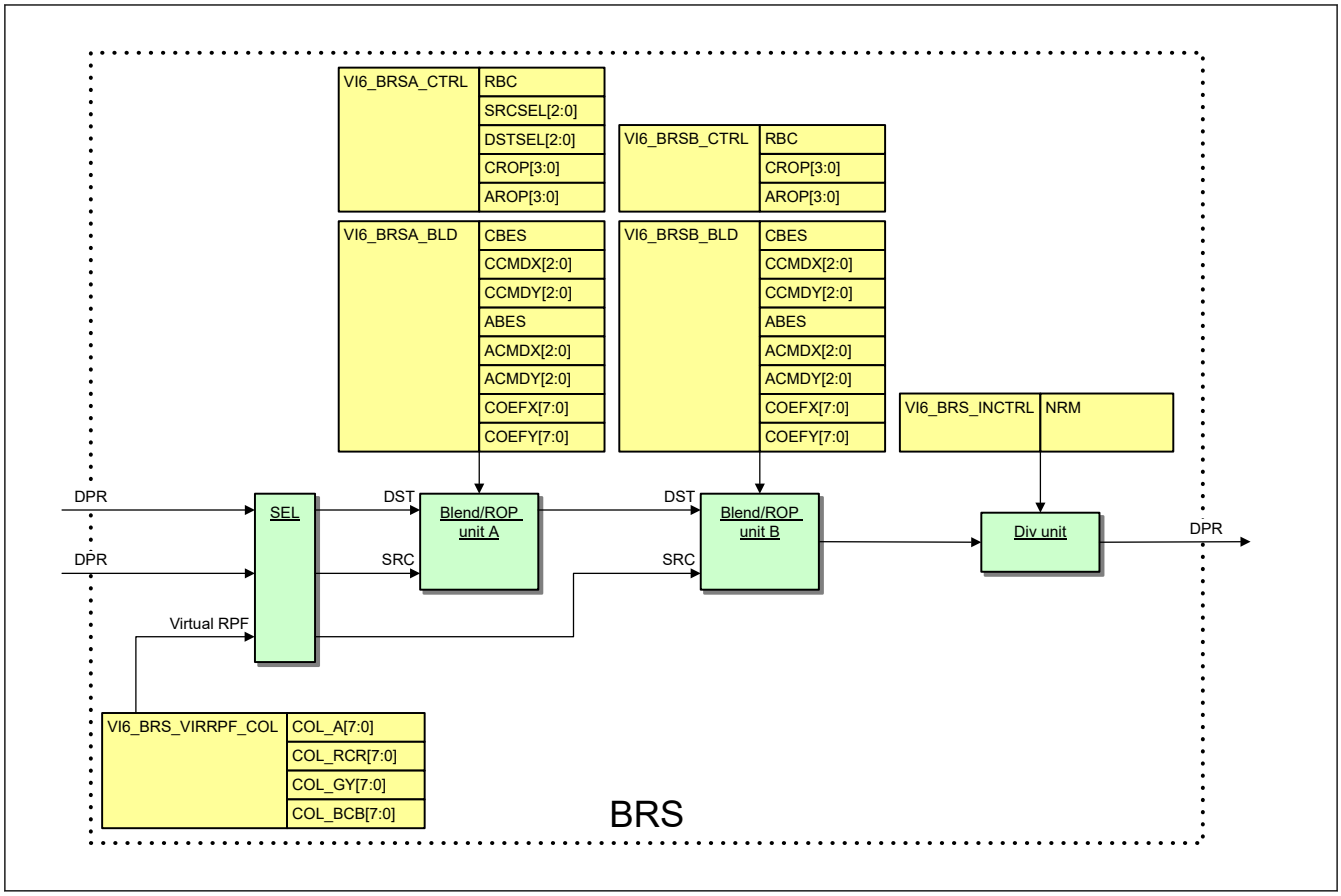

Figure 54.3 BRS processing flow

Each of the two blend-ROP operation units (blend/ROP unit m) receives the output from the SEL or blend/ROP Unit m, and executes blending or raster operation (ROP) of images.

The divider for normalization (div unit) divides the pixel value by the α value.

54.1.2.7 Write Pixel Formatter (WPF)

The WPF is an output module that receives 32 bits image data (YCbCr444 or RGB888 + 8-bit α) from the DPR, converts the color space, number of colors, and format of the data, and outputs the results of VSPD image processing to external memory through the MAU. The WPF is mainly configured from a color space converter and an output format converter (the packing unit).

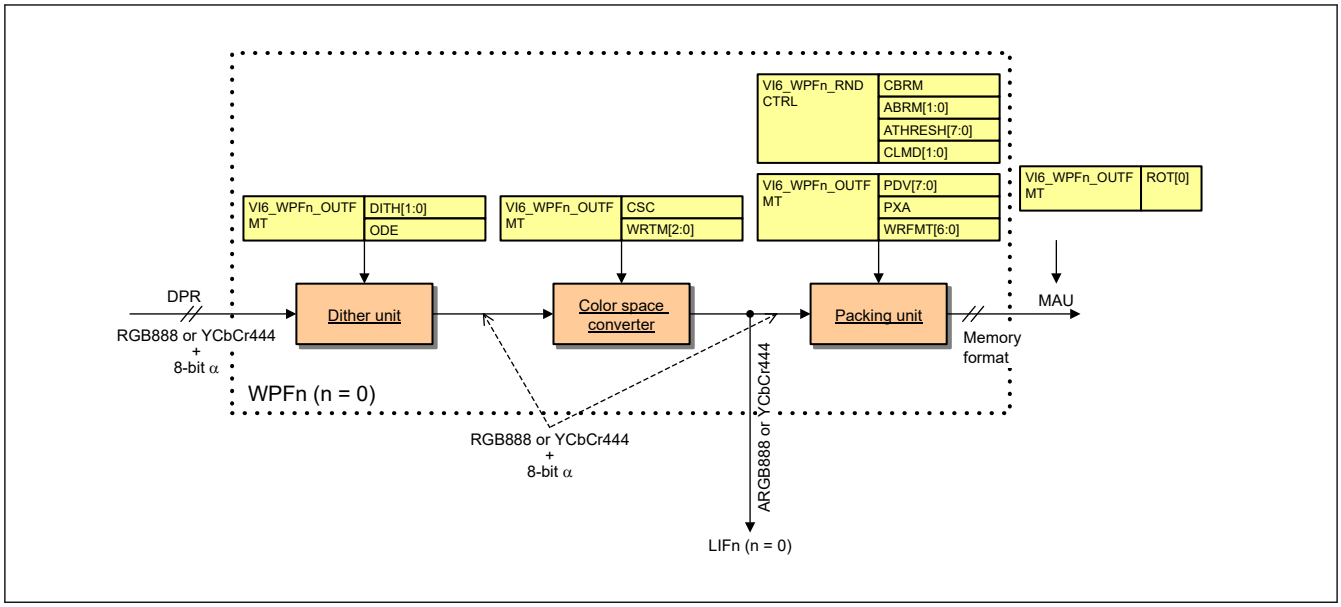

Figure 54.4 WPF processing flow

The color space converter converts the color space between RGB and YCbCr, and the packing unit converts the format into the picture plane storing format. The VSPD provides one WPF (WPF0). The WPF has the output to LIF module after the color space conversion for transferring the video data to the display module. Image data to LIF is 24 bits (YCbCr444 or RGB888) format, and its' color space is after color space conversion.

54.1.2.8 Display Unit InterFace (LIF)

The LIF module is used for transferring image data to the display module. The input port of the LIFn (n = 0) module is connected to WPFn (n = 0), and the output port of the LIF module is connected to DU (Display Unit). Data flow in LIF is shown in Figure 54.30.

54.1.2.9 Detail Function

Table 54.3 Detail function of VSPD (1)

Image data transfer function			
Bus interface	Protocol		AXI 256 bits through FCPVD
	Data alignment	Conversion method	Byte, Word, LW, or LLW data swapping
		Channel	Data alignment can be specified separately for each input/output channel.
Image memory	Input	Address setting	1-byte units
	Output	Address setting	1-byte units
		Memory area	Images can be written to the same memory area where the master layer is stored. Note the restrictions shown in Table 54.44.
Tile transfer mode			Supported by RPF0 to RPF1
YCbCr memory storage format			Interleaved, planar, or semi-planar

Table 54.4 Detail function of VSPD (2)

Display list / Extended display list transfer function			
Bus interface	Protocol		AXI 256 bits through FCPVD
	Data alignment*1	Conversion method	Byte, Word, LW data swapping
Data memory	Load	Address setting	8-byte units
	Store	—	Not available

Note 1. Data alignment can be specified separately for display list and each entry of extended display list.

Table 54.5 Detail function of VSPD (3) (1 of 2)

Read Pixel Formatter (RPF)			
Number of channels			Two channels (RPF0 to RPF1)
Input color bit-depth		Color	2- to 8-bit
		Alpha	1-/2-/4-/8-bit
Operation bit-depth		Color	8-bit
		Alpha	8-bit
Image format	Input	RGB	RGB888, RGB565, RGB666, αRGB8888, αRGB4444, αRGB1555 α plane (8 bpp, 1 bpp)
		YCbCr	YCbCr4:4:4 (8 bpc) Planar/Semi planar/Interleaved YCbCr4:2:2 (8 bpc) Planar/Semi planar/Interleaved YCbCr4:2:0 (8 bpc) Planar/Semi planar/Interleaved α plane (8 bpp, 1 bpp)
		Maximum size	1920 × 1080 pixels The internal data path modules have separate restrictions on the maximum image size. For details, see section 54.7.2. Input Image Size.
		Minimum size	1 × 1 pixel The internal data path modules have separate restrictions on the minimum image size. For details, see section 54.7.2. Input Image Size.
		Size setting unit	YCbCr420: 2-pixel units both horizontally and vertically. YCbCr422: 2-pixel units horizontally and 1-pixel units vertically. In other formats, the size can be set in 1-pixel units.
Color keying	Color replacement	Compared data	RGB or Y (8 bpc)
		Replaced data	αRGB or αYCbCr (8 bpc for R, G, B, Y, Cb, Cr, α)
		Comparison Mode	Matched color mode
		Input source	RPF0 to RPF1
	Transparent color	Compared data	RGB or Y (8 bpc)
		Replaced data	α 8 bpp
		Comparison Mode	Matched color mode, Luma threshold mode
		Input source	RPF0 to RPF1
Raster operation	ROP2 (within input channels)	Operator	16 types (OpenGL2.0 is supported)
		Sources of operation	ROP2 operation between the 1-bpp α plane and RGB/YCbCr data in RPF0 to RPF1. Note that 1-bpp α is converted to αRGB or αYCbCr4:4:4. (8 bpc)
Color space conversion	RGB to YCbCr	Conversion expression	RGB (0, $2^n - 1$) to BT601 (2^{n-4}, $235 \times 2^{n-8}$ / $240 \times 2^{n-8}$) RGB (0, $2^n - 1$) to BT709 (2^{n-4}, $235 \times 2^{n-8}$ / $240 \times 2^{n-8}$) RGB (0, $2^n - 1$) to BT601 (0, $2^n - 1$) RGB (2^{n-4}, $235 \times 2^{n-8}$) to BT709 (2^{n-4}, $235 \times 2^{n-8}$ / $240 \times 2^{n-8}$) (n = 8)
		Target of conversion	RPF0 to RPF1
	YCbCr to RGB	Conversion expression	BT.601 (2^{n-4}, $235 \times 2^{n-8}$ / $240 \times 2^{n-8}$) to RGB (0, $2^n - 1$) BT.709 (2^{n-4}, $235 \times 2^{n-8}$ / $240 \times 2^{n-8}$) to RGB (0, $2^n - 1$) BT.601 (0, $2^n - 1$) to RGB (0, $2^n - 1$) BT.709 (2^{n-4}, $235 \times 2^{n-8}$ / $240 \times 2^{n-8}$) to RGB (2^{n-4}, $235 \times 2^{n-8}$) (n = 8)
		Target of conversion	RPF0 to RPF1

Table 54.5 Detail function of VSPD (3) (2 of 2)

Read Pixel Formatter (RPF)			
Changing number of colors	Bit extension	Extended bits	Input bit-depth (2 bpc to 6 bpc) to operation bit-depth 8 bpc
		Target format	RGB666, RGB565, RGB555, RGB444, or RGB332
		Bit reduction method	Padded with 0. Copied from the most significant bits.
		Target of conversion	RPF0 to RPF1
	YCbCr444 generation	Vertical	CbCr copying
		Horizontal	Copying or interpolation.
α bit count conversion	Bit extension	Extended bits	Input bit-depth 1 bpc to operation bit-depth 8 bpc
		Method	Padded with 0. Copied from the most significant bits.
Multiply-alpha function	Fade-alpha		RPF0 to RPF1 Available for straight pixel and pre-multiplied pixel.
	Generate pre-multiplied alpha		RPF0 to RPF1
Virtual display	RPF0 to RPF1	Color format	αRGB8888 or αYCbCr4:4:4 single-color
		Display size	Same as the size of the input channel
	Virtual RPF	Color format	αRGB8888 or αYCbCr4:4:4 single-color
		Display size	Maximum: 1920 × 1080 pixels Minimum: 4 × 4 pixels

Table 54.6 Detail function of VSPD (4)

Write Pixel Formatter (WPF)			
Number of channels			One channel (WPF0)
Image format	Output	RGB	RGB332, RGB444, RGB565, RGB666, RGB888, αRGB8666, αRGB8888, αRGB4444, αRGB1555
		YCbCr	YCbCr4:4:4, YCbCr4:2:2, YCbCr4:2:0
		Maximum size	1920 × 1080 pixels The internal data path modules have separate restrictions on the maximum image size. For details, see section 54.7.3. Output Image Size.
		Minimum size	1 × 1 pixel The internal data path modules have separate restrictions on the minimum image size. For details, see section 54.7.3. Output Image Size.
		Size setting unit	YCbCr420: 2-pixel units both horizontally and vertically. YCbCr422: 2-pixel units horizontally and 1-pixel units vertically. In other formats, the size can be set in 1-pixel units.
Color space conversion	RGB to YCbCr	Conversion expression	RGB (0, 255) to BT.601 (16, 235/240) RGB (0, 255) to BT.709 (16, 235/240) RGB (0, 255) to BT.601 (0, 255) RGB (16, 235) to BT.709 (16, 235/240)
		Target of conversion	WPF0
	YCbCr to RGB	Conversion expression	BT.601 (16, 235/240) to RGB (0, 255) BT.709 (16, 235/240) to RGB (0, 255) BT.601 (0, 255) to RGB (0, 255) BT.709 (16, 235/240) to RGB (16, 235)
		Target of conversion	WPF0
Changing number of colors	Output	Reducing RGB color depth	Dithering, lower-order bit truncation, or rounding
		YCbCr422/420	CbCr skipping or CbCr vertical skipping and horizontal skipping
α bit count conversion	Output	Bit reduction	Truncation, rounding, or comparison with threshold (for 1 bpp)

Table 54.7 Detail function of VSPD (5)

Image compositing			
α blending	Input α value selection	RGB	Pixel α, fixed α value, α plane, or 1-bit α converted from the color specified for pixels
		YCbCr	α plane, fixed α value, or 1-bit α converted from the color specified for pixels
	α blending expression	Layer A: Upper layer Layer B: Lower layer	xA + yB, xA − yB Coefficients x and y should be selected from the following. Fixed α value, (α for layer A), (1 − α for layer A), (α for layer B), (1 − α for layer B)
	Output α value selection	RGB	Fixed α value, x (α for layer A) + y (α for layer B), x (α for layer A) – y (α for layer B) Coefficients x and y should be selected from the following. Fixed α value, (α for layer A), (1 − α for layer A), (α for layer B), (1 − α for layer B)
	Blending layers	Number of layers	Two layers selected from RPF0 to RPF1 and video processing function output, and virtual RPF; three layers in total
		Order of layers	The order of three layers selected from RPF0 to RPF1, virtual RPF, and video processing function output can be changed as desired.
	α plane	Format	8 bpp or 1 bpp (α value can be specified through register)
		Input source	RPF0 to RPF1
	Fixed α value	Format	8 bpp
		Input source	RPF0 to RPF1, virtual RPF, or video processing function output
Raster operation	ROP2 (between input channels)	Operator	16 types (OpenGL2.0 is supported)
		Sources of operation	RPF0 to RPF1, virtual RPF, and video processing function output
		Operation control	RGB/YCbCr and α are operated separately.
	ROP3 (between input channels)	Operator	256-type ROP3 is available by combining ROP2 operations
		Sources of operation	RPF0 to RPF1, virtual RPF, and video processing function output
		Operation control	RGB/YCbCr and α are operated separately.

Table 54.8 Detail function of VSPD (6)

Color adjustment function		
1D-LUT	LUT configuration	Independent R/Y, G/Cb, and B/Cr. 256 entries each

Table 54.9 Detail function of VSPD (7)

Direct connection to display module		
Display I/F	Destination	DU
	Direct connection	Can transfer data to DU without going through external memory
Line padding	Padding cycles	1 to 32 cycles
	Padding pattern	Arbitrarily setting up to 32 cycles

54.1.3 DU

DU has the following sub modules.

54.1.3.1 REG

The REG controls registers for DU. The DU has APB4 interface, and its transaction is transferred with no wait states.

54.1.3.2 LIFC

The LIFC is the interface block from/to VSPD. The LIFC receives image data from VSPD, and sends to PBUF in a pixel unit. The LIFC continues to receive the image data from VSPD unless FIFO will be full.

54.1.3.3 PBUF

The PBUF is the asynchronous FIFO which converts clock domain of image data from System Bus Clock to Video Clock. The PBUF watches over FIFO underflow.

54.1.3.4 DIFC

The DIFC is the display timing master. The DIFC controls the polarity and the timing of the Video Output signals. Controllable timings are the followings.

- Hfront: Horizontal front porch (pixels)
- Hback: Horizontal back porch (pixels)
- Hsync: Horizontal sync active (pixels)
- Hactive: Horizontal active area (pixels)
- Vfront: Vertical front porch (lines)
- Vback: Vertical back porch (lines)
- Vsync: Vertical sync active (lines)
- Vactive: Vertical active area (lines)

54.1.3.5 INTC

The INTC generates the interrupt when PBUF will detect FIFO underflow. The interrupt is level signal.

54.1.4 Clock and Interrupt Signal

The following clocks are supplied to the LCDC.

Table 54.10 Clock list

Clock name	Description	Frequency (MHz)
PCLKAH	AXI clock	400
PCLKAL	APB clock	100
LCDC_clkd	Video clock	5 to 100

The LCDC transmits the following interrupt signals to the interrupt controller.

Table 54.11 Interrupt list

Signal name	Interrupt condition	Interrupt source register
LCDC_VSPD_INT	Frame End	VI6_WPF0_IRQ_STA.FRE
	Display List Frame End	VI6_WPF0_IRQ_STA.DFE
	DU Connection UnderRun Error	VI6_WPF0_IRQ_STA.UND
LCDC_DU_INT	RBUF FIFO Underflow	DU_MSR0.ST_PB_RUF

Note: See section 54.4.4.13. VI6_WPF0_IRQ_STA : WPF0 Interrupt Status Register and section 54.5.1. DU_MCR0 : DU Module Control Register 0 for details.

54.2 Register Map

Table 54.12 LCDC register map (1 of 3)

Address	Register symbol	Register name	Write protection

54.3 FCPVD Register Descriptions

54.3.1 FCP_VCR : FCPVD Version Control Register

Base address: FCPVD = 0x920D_0000

Offset address: 0x0000

Bit position:	31																15							8	7						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CATEGORY[7:0]								REVISION[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	1	0	0	1

Bit	Symbol	Function	R/W
7:0	REVISION[7:0]	Version of LSI product 0x09: FCP revision is the Simple LCDC	R
15:8	CATEGORY[7:0]	FCP use case category	R
31:16	—	These bits are read as 0.	R

FCP_VCR is the version control register of the FCPVD. The value read is fixed.

54.4 VSPD Register Descriptions

54.4.1 Notational Conventions for Registers and Bit Fields

This section uses the following notational conventions for the VSPD registers and bit fields.

1. The names of registers and bits are written in uppercase.
2. A bit or bit field in a register is indicated as [register name.bit name]. For example, the STRCMD bit in the VI6_CMD0 register is indicated as VI6_CMD0.STRCMD.
3. Lowercase "n" in a register name or a bit name indicates an integer and the range of value n is defined when necessary. For RPFn and WPFn, when the range of value n is not defined, RPFn (n = 0, 1), WPFn (n = 0) are assumed.
4. In each subsection for register description in section 54.4. VSPD Register Descriptions, when only a bit name is written without showing its register name, the bit is in the register described in that subsection.

5. A wildcard (*) indicates any characters in a name and represents all registers or bits that match the specified first part of a name. For example, when there are two registers VI6_RPF_SRC_BSIZE and VI6_RPF_SRC_ESIZE, VI6_RPF_SRC_* indicates both registers.

54.4.2 Register Classification

The VSPD registers are arranged in the following order; the general control registers to display list control registers control operation of the entire VSPD, and the other registers control each image processing and specify parameters for the processing. The functions of the registers are described in this order starting from section 54.4.4. General Control Registers.

1. General control registers (VI6_CMDn (n = 0, 1), VI6_SRESET, VI6_STATUS, VI6_WPFn_IRQ_* (n = 0))
2. Display list control registers (VI6_DL_*)
3. RPF control registers (VI6_RPFn_* (n = 0, 1))
4. WPF control registers (VI6_WPFn_* (n = 0))
5. DPR control registers (VI6_DPR_*)
6. LUT control register (VI6_LUT_CTRL)
7. BRS control registers (VI6_BRS_*)
8. LIFn control registers (VI6_LIFn_* (n = 0))

The VSPD has two RPF channels and the register configuration is the same for all of RPFn (n = 0, 1). However, some bit fields have restrictions in certain RPFs. These restrictions are included in the description of the corresponding bit fields and registers. Likewise, the register configuration is the same for all WPFn (n = 0), but some bit fields have restrictions in certain WPFs; the restrictions are included in the description of the corresponding bit fields and registers.

54.4.3 Restrictions on Access to Registers and Lookup Tables

The VSPD has control registers and lookup tables. All VSPD registers are writable and readable by only 32 bits unit. To write partial bits in each register, read-modify-write is needed. When accessing the addresses where these registers and lookup tables are allocated, the following restrictions should be satisfied. If any restriction is violated, the VSPD will not operate correctly.

1. For the read-only bits and reserved bits in all VSPD registers, writing 1 is prohibited unless otherwise specified.
2. Undefined addresses are reserved areas and write access is prohibited in these areas.
3. For all registers and lookup tables, except VI6_CMDn, VI6_SRESET, VI6_*IRQ* and two plane registers such as VI6_DL_HDR_ADDRn, VI6_DL_BODY_SIZE0, modifying register values during operation of the module is prohibited. Modify registers while the corresponding module is stopped. For the operating status of the target module, see section 54.6.3. Concept of VSPD Operation Starting and Stopping.
4. There are three types about General control registers (section 54.4.4. General Control Registers and section 54.4.5. Display List Control Registers) as below.
   - Controlling WPF0 (ex. VI6_CMD0, VI6_SRESET.SRST0)
   - Common setting of WPF0 (ex. VI6_DL_CTRL.AR_WAIT[15:0])

Table 54.14 Correspondence between modules and register names

Module name	Register name
RPFn (n = 0, 1)	VI6_RPFn_*
WPFn (n = 0)	VI6_WPFn_*
DPR	VI6_DPR_*
LUT	VI6_LUT_CTRL
BRS	VI6_BRS_*
LIFn (n = 0)	VI6_LIFn_*

54.4.4 General Control Registers

54.4.4.1 VI6_CMD0 : VSPD Start Register 0

Base address: VSPD = 0x920E_0000

Offset address: 0x0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	UPDHDR	—	—	—	STRCMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	STRCMD	Start reservation of WPF VI6_CMD0.STRCMD controls WPF0. Writing 1 to this bit starts WPF0 in VSPD. Set this bit for activation only after all register settings in each output channel have been completed. If WPF0 is idle, WPF0 starts right after this bit is set to 1. If WPF0 is active, writing 1 to this bit reserves starting WPF0 operation. Wait to set VI6_CMD0.STRCMD to 1 until this bit is read as 0. VI6_CMD0.STRCMD can be negated by software reset (VI6_SRESET.SRST0). 0: Start reservation of WPF0 is canceled. [Write] Starting VSPD is not reserved. [Read] 1: Start reservation of WPF0 is set. [Write] Starting VSPD is reserved. [Read]	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	UPDHDR	Reserved state of updating Display List Header (DLH) address UPDHDR can be negated by software reset (VI6_SRESET.SRST0). Set this bit to 0 when STRCMD bit is set to 1. 0: NOP [Write] Not reserved to update DLH address [Read] 1: Do not set this bit to 1 [Write] Reserved to update DLH address [Read]	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

The basic concept of image processing operation started by activating the VSPD is shown in Figure 54.5. The actual data input/output is executed by the MAU, which is the bus interface module, as described in section 54.1.2. VSPD, but conceptually the RPF works as the data entry point to the VSPD, and the WPF works as the data exit point. To process images through the VSPD, the RPF (entrance) and WPF (exit) should be connected, and a data path from the RPF to the WPF should be formed.

To connect RPFn to WPFn, specify RPFn as the source RPF for WPFn in VI6_WPFn_SRCRPF, which is a register for WPFn (see section 54.4.7.1. VI6_WPF0_SRCRPF : WPF0-Source-RPF Register). This setting determines that RPFn will be started when WPFn is started through VI6_CMDn.

A data path to execute desired image processing should then be formed between the RPF (entrance) and WPF (exit). To form a data path, connect the necessary function modules in the VSPD between RPF and WPF. This function is provided by the DPR; specify the information for each module connection in data path routing registers VI6_DPR_*_ROUTE (see section 54.4.8. DPR Control Registers).

After a data path is formed (RPFn → WPFn) as described above, starting output module WPFn in the VSPD through VI6_CMDn starts all function modules connected to WPFn, and the desired image processing is executed. According to this design concept, starting a WPF module means starting the VSPD.

There are two types of data path configuration in the VSPD; one is "a single input module to a single output module" as shown in Figure 54.5 (A), and the other is "multiple input modules to a single output module" as shown in Figure 54.5 (B).

Figure 54.5 (A) shows an example of a configuration where modules with single input and single output are implemented through the DPR.

Figure 54.5 (B) shows another configuration example where the module with multiple input and single output is implemented through the DPR.

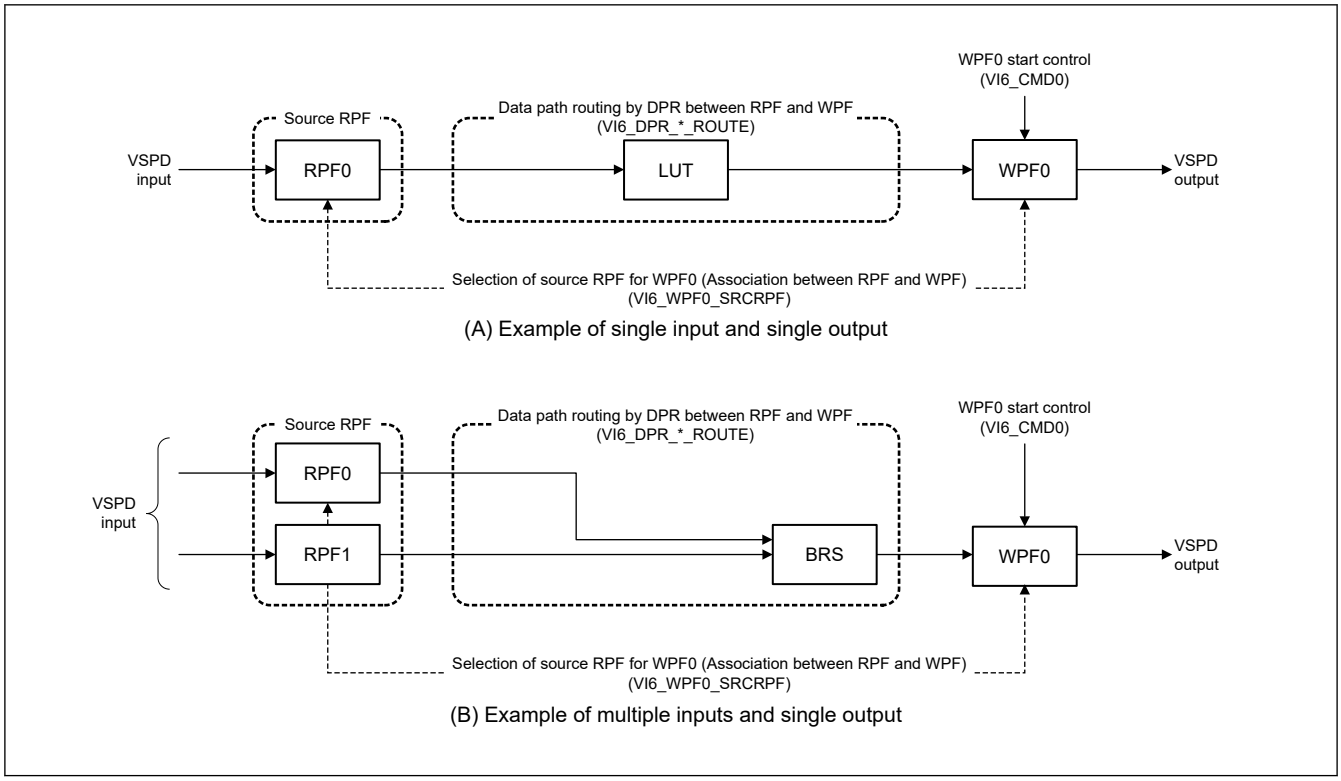

Figure 54.5 Basic concept of VSPD startup

54.4.4.2 VI6_CLK_CTRL0 : Clock Control Register 0

Base address: VSPD = 0x920E_0000

Offset address: 0x0010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	GCS0	—	—	—	—	—	—	—	—	—	—	—	GCS1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	GCS2[3:0]				—	—	—	GCS3[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	GCS3[4:0]	Clock Control Setting 3	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
11:8	GCS2[3:0]	Clock Control Setting 2	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
16	GCS1	Clock Control Setting 1	R/W
27:17	—	These bits are read as 0. The write value should be 0.	R/W
28	GCS0	Clock Control Setting 0	R/W

Bit	Symbol	Function	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

VSPD can stop its operating clock for reducing power consumption.

To enable clock stop function, set following registers:

- VI6_CLK_CTRL0 = 0x0000 0000
- VI6_CLK_CTRL1 = 0x0000 0000
- VI6_CLK_DCSWT = 0x0000 0808
- VI6_CLK_DCSM0 = 0x0000 0000
- VI6_CLK_DCSM1 = 0x0000 0000

To disable clock stop function, set following registers:

- VI6_CLK_CTRL0 = 0x1001 0F1F
- VI6_CLK_CTRL1 = 0xFF10 FFFF
- VI6_CLK_DCSWT = 0x0033 0808
- VI6_CLK_DCSM0 = 0x1FFF 0F1F
- VI6_CLK_DCSM1 = 0xFF10 FFFF

When the clock gating is enabled, the supply of the clock signal is stopped for the module which is not operated. If the bit field of this register is changed from 0 to 1, the supply of the clock signal for the module is immediately started. If the bit field of the register is changed from 1 to 0, the clock supply is immediately stopped. Therefore, please do not change this register field from 1 to 0 in operation because the VSPD may be stalled.

54.4.4.3 VI6_CLK_CTRL1 : Clock Control Register 1

Base address: VSPD = 0x920E_0000

Offset address: 0x0014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15:0	DCD4[15:0]	Dynamic Clock Stop Disable Setting 4	R/W
19:16	—	These bits are read as 0. The write value should be 0.	R/W
20	DCD5	Dynamic Clock Stop Disable Setting 5	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
31:24	DCD3[7:0]	Dynamic Clock Stop Disable Setting 3	R/W

See section 54.4.4.2. VI6_CLK_CTRL0 : Clock Control Register 0 for detail.

54.4.4.7 VI6_SRESET : Software Reset Register

Base address: VSPD = 0x920E_0000

Offset address: 0x0028

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SRST 0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRST0	WPF0 Software Reset Writing 1 to this bit aborts the current processing in WPF0 (the partially-completed image undergoing processing is output). The period until this software reset processing is completed depends on the bus state. When this reset processing is completed, the VI6_WPF0_IRQ_STA.FRE interrupt source bit is set to 1; when the FRE interrupt is enabled, the FRE end interrupt is output to notify the end of the reset processing. This bit is read as 0. 0: NOP 1: WPF0 software reset*1	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Applying a software reset to each WPF has the following restrictions.

1. A software reset can be applied to only one of WPF0 through single write access to VI6_SRESET.
2. After a software reset is issued, no more software reset can be issued to another WPF until the issued software reset processing is completed.
3. The end of software reset processing is notified through the FRE bit in VI6_WPFn_IRQ_STA, but the software reset issued while WPF is stopped is ignored as NOP. As it takes a while until the reset is actually issued after the reset bit is set, the VSPD may

complete operation before the reset is actually issued. In this case, no interrupt is output for the software reset that is issued after the VSPD completes operation.

4. If a software reset is issued during downloading of a display list, the downloading processing is not aborted. After the end of downloading that is in progress when a software reset is issued, a frame end interrupt is output.
5. When software reset is issued to VSPD, issue software reset to also FCPVD. See Figure 54.40 for VSPD software reset sequence.

54.4.4.8 VI6_MRESET_ENB0 : Module Reset Enable Register 0

Base address: VSPD = 0x920E_0000

Offset address: 0x002C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	MRSTE0[1:0]		—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	MRSTE1[3:0]				—	—	—	MRSTE2[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	MRSTE2[4:0]	Module Reset Enable 2	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
11:8	MRSTE1[3:0]	Module Reset Enable 1	R/W
27:12	—	These bits are read as 0. The write value should be 0.	R/W
29:28	MRSTE0[1:0]	Module Reset Enable 0	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

This register is for purpose of H/W debugging.

54.4.4.9 VI6_MRESET_ENB1 : Module Reset Enable Register 1

Base address: VSPD = 0x920E_0000

Offset address: 0x0030

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MRSTE3[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MRSTE4[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MRSTE4[15:0]	Module Reset Enable 4	R/W
23:16	—	These bits are read as 0. The write value should be 0.	R/W
31:24	MRSTE3[7:0]	Module Reset Enable 3	R/W

This register is for purpose of H/W debugging.

54.4.4.10 VI6_MRESET : Module Reset Issuing Register

Base address: VSPD = 0x920E_0000

Offset address: 0x0034

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MRST	Module Reset Assertion	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

This register is for purpose of H/W debugging.

54.4.4.11 VI6_STATUS : Operating Status Register

Base address: VSPD = 0x920E_0000

Offset address: 0x0038

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	FLDST0	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SYS0_ACT	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0.	R
8	SYS0_ACT	WPF0 Operating Status This bit indicates the operating or stopped state of control channel n (WPF0). 0: WPF0 is stopped. 1: WPF0 is operating.	R
27:9	—	These bits are read as 0.	R
28	FLDST0	Field status of previous frame of WPF0 This bit can be referred in case of AUTO-FLD or AUTO-DISP. This bit is changed at the timing of VI6_WPF0_IRQ_STA.FRE. 0: Previous finished frame is TOP field. 1: Previous finished frame is BOT field.	R
31:29	—	These bits are read as 0.	R

54.4.4.12 VI6_WPF0_IRQ_ENB : WPF0 Interrupt Enable Register

Base address: VSPD = 0x920E_0000

Offset address: 0x0048

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	UNDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DFEE	FREE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FREE	Interrupt Enable for WPF0 Frame End 0: Interrupt disabled 1: Interrupt enabled	R/W
1	DFEE	Interrupt Enable for WPF0 Display List Frame End 0: Interrupt disabled 1: Interrupt enabled	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W
16	UNDE	Interrupt Enable for WPF0 Underrun in case of DU connection 0: Interrupt disabled 1: Interrupt enabled	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: Each bit controls the interrupt enable of the corresponding interrupt source.

Each bit in VI6_WPFn_IRQ_STA is set to 1 when the corresponding interrupt source is generated.

VI6_WPF0_IRQ_ENB specifies whether to output an interrupt signal for the generated source. When an interrupt is disabled in this register, no interrupt signal is generated even when the corresponding bit in VI6_WPFn_IRQ_STA is set to 1. When an interrupt is enabled in this register, an interrupt signal is output when the corresponding bit in VI6_WPFn_IRQ_STA is set to 1.

54.4.4.13 VI6_WPF0_IRQ_STA : WPF0 Interrupt Status Register

Base address: VSPD = 0x920E_0000

Offset address: 0x004C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	UND
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DFE	FRE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FRE	Interrupt Status and Clear for WPF0 Frame End*1 This interrupt source bit is set to 1 when VSPD completes one-frame processing. This bit is also set to 1 when one-frame processing using a display list is completed. The interrupt status is set to 1 by any of the following conditions. a) Processing one frame is finished normally. b) Software reset is issued during VSPD is processing. c) One frame's data from DU is displayed while VSPD could not transfer one frame data to DU (in case of Linked with DU). 0: No interrupt. [Read] The interrupt status is cleared to 0. [Write] 1: Interrupt activated. [Read] Hold the interrupt status value. [Write]	R/W
1	DFE	Interrupt Status and Clear for WPF0 Display List Frame End*1 This interrupt source bit is set to 1 when VSPD completes one-frame processing while the current frame in enable value stored in the display list header is 1 (see section 54.6.3. Concept of VSPD Operation Starting and Stopping). When display lists are not used, this bit is not used. In this case, clear VI6_WPF0_IRQ_ENB.DFEE to 0 to mask the interrupt generation by this interrupt source. 0: No interrupt. [Read] The interrupt status is cleared to 0. [Write] 1: Interrupt activated. [Read] Hold the interrupt status value. [Write]	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W
16	UND	Interrupt Status and Clear for WPF0 Underrun in case of DU connection This interrupt source bit is set to 1 when data underrun occurs in case of DU connection. Timing that this bit is set to 1 is at end of 1 frame. 0: No interrupt. [Read] The interrupt status is cleared to 0. [Write] 1: Interrupt activated. [Read] Hold the interrupt status value. [Write]	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: The read value from each bit is the status of the interrupt source, and the write access to each bit controls the interrupt status.
Note 1. This bit can hold the most recent of two times of interrupt status at the maximum. When writing 0 to this bit, the oldest interrupt status is cleared. And the status bit becomes 0 after all interrupt statuses are cleared.

VI6_WPF0_IRQ_STA indicates the state of the interrupt sources generated in the VSPD. Whether to output a VSPD interrupt when an interrupt source is generated and the corresponding bit is set to 1 is determined by the corresponding bit setting in VI6_WPFn_IRQ_ENB. While an interrupt is disabled in VI6_WPFn_IRQ_ENB, the VSPD does not output an interrupt signal even when an interrupt source is generated, but the source flag in this register is set to 1.

Note that the interrupt source bits in this register cannot be cleared by write access using a display list.

54.4.4.14 VI6_DISP0_IRQ_ENB : Display-0 Interrupt Enable Register

Base address: VSPD = 0x920E_0000

Offset address: 0x0078

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DSTE	—	—	MAEE	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
5	MAEE	Interrupt Enable for Display Read Data End 0: Interrupt disabled 1: Interrupt enabled	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	DSTE	Interrupt Enable for Display Start 0: Interrupt disabled 1: Interrupt enabled	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: Each bit controls the interrupt enable of the corresponding interrupt source.

54.4.4.15 VI6_DISP0_IRQ_STA : Display-0 Interrupt Status Register

Base address: VSPD = 0x920E_0000

Offset address: 0x007C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DST	—	—	MAE	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	—	These bits are read as 0. The write value should be 0.	R/W
5	MAE	Interrupt Status and Clear for Display Read Data End This bit is set to 1 when all RPFs transfer the last data of the frame to LIF module. The RPF module which is not used by LIF module does not affect this bit. 0: No interrupt. [Read] The interrupt status is cleared to 0. [Write] 1: Interrupt activated. [Read] Hold the interrupt status value. [Write]	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	DST	Interrupt Status and Clear for Display Start This bit is set to 1 when LIF module transfers the first data to the display module at the beginning of each frame. The timing depends on the output buffer status of LIF module. 0: No interrupt. [Read] The interrupt status is cleared to 0. [Write] 1: Interrupt activated. [Read] Hold the interrupt status value. [Write]	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: The read value from each bit is the status of the interrupt source, and the write access to each bit controls the interrupt status.

54.4.5 Display List Control Registers

54.4.5.1 VI6_DL_CTRL : Display List Control Register

Base address: VSPD = 0x920E_0000

Offset address: 0x0100

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	AR_WAIT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	DC2	—	—	—	DC1	—	—	—	DLE1	RLM0	CFM0	NH0	DLE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DLE0	Display List Enable/Disable for WPF0 Enables or disables the WPF0 display list function. When the display list function is enabled through this bit, all WPF processing channels work in display list mode. When using display lists, note the restrictions in section 54.4.3. Restrictions on Access to Registers and Lookup Tables. 0: The display list function is disabled. 1: The display list function is enabled.	R/W
1	NH0	Header-less Display List Mode*1 *2 This bit is used for specifying the header-less display list mode. In case of header-less mode, the number of the display lists is 1. The address of the display body is set in VI6_DL_HDR_ADDR0 register, and the body size is set in VI6_DL_BODY_SIZE0 register. When this bit is changed, make sure that VSPD is stopped. And also make sure the following before starting VSPD. ● Header Address (VI6_DL_HDR_ADDR0) ● Body Size (VI6_DL_BODY_SIZE0) in case of header-less mode 0: Use Display List Header (Normal DL Mode). 1: Do not use Display List Header (Header-less Mode).	R/W
2	CFM0	Continuous Frame Mode for Header-less Display List for WPF0 This bit determines whether the next frame is automatically started or not. When the updated flag of the display list, VI6_DL_BODY_SIZE0.UPD0, is not updated, the display list of the next frame is not transferred and the same register values are used for the next frame. When the value of VI6_DL_BODY_SIZE0.UPD0 is updated, the new display list is transferred. 0: Stopped at the end of every frame. 1: The next frame is automatically started.	R/W
3	RLM0	Loading two plane Registers Mode for WPF0 0: Reserved status (VI6_CMD0.UPDHDR) is accepted by next_frame_auto_start. Two plane registers are also downloaded by next_frame_auto_start. 1: Reserved status (VI6_CMD0.UPDHDR) is not accepted by next_frame_auto_start. pNext_header in previous frame's DLH is used for loading Display List. Two plane registers are not downloaded by next_frame_auto_start either.	R/W
4	DLE1	This bit does not affect anything VSPD. (NOP)	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	DC1	This bit does not affect anything VSPD. (NOP)	R/W
11:9	—	These bits are read as 0. The write value should be 0.	R/W
12	DC2	This bit does not affect anything VSPD. (NOP)	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
31:16	AR_WAIT[15:0]	Display List Control Setting Always set these bits to 256.	R/W

Note 1. Only WPF0 supports header-less display list. WPF1 works as the normal display list mode even if the WPF0 is set to header-less display list mode.
Note 2. When DLE0 bit is 0, set NH0 bit to 0.

54.4.5.2 VI6_DL_HDR_ADDR0 : Display List-0 Header Address Register

Base address: VSPD = 0x920E_0000

Offset address: 0x0104

Bit position:	31																												0			
Bit field:																													0	0	0	0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Display List-0 Header Address These bits specify the address of the display list header to be read for display list-n in 16-byte units (the lower-order four bits are read-only). When WPF0 is first started in display list mode, the display list header is loaded from the address specified in this register. After loading of the header is completed, the register value of the display list address is updated to the next header address stored in the loaded header to prepare for loading of the next display list header. After that, this header address updating is repeated. A value from 0x00000000 to 0xFFFFFFF0 can be specified.	R/W

54.4.5.3 VI6_DL_SWAP0 : Display List-0 Data Swapping Register

Base address: VSPD = 0x920E_0000

Offset address: 0x0114

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	IND	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	LWS	WDS	BTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BTS	Display List Data Swapping in Byte Units The effect of this bit setting is defined in Table 54.15. 0: Data swapping in byte (8-bit) units is disabled 1: Data swapping in byte (8-bit) units is enabled	R/W
1	WDS	Display List Data Swapping in Word Units The effect of this bit setting is defined in Table 54.15. 0: Data swapping in word (16-bit) units is disabled 1: Data swapping in word (16-bit) units is enabled	R/W
2	LWS	Display List Data Swapping in long word Units The effect of this bit setting is defined in Table 54.15. 0: Data swapping in long word (32-bit) units is disabled 1: Data swapping in long word (32-bit) units is enabled	R/W
30:3	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
31	IND	Enabling independent swap setting per WPF This bit is available only for VI6_DL_SWAP1. This bit is reserved for VI6_DL_SWAP0. 0: Display list swap for WPF1 is specified by LWS, WDS, and BTS in VI6_DL_SWAP0. 1: Display list swap for WPF1 is specified by LWS, WDS, and BTS in VI6_DL_SWAP1.	R/W

Table 54.15 shows the data order before and after swapping according to the long word, word, and byte swapping settings.

When data order in memory for each format is the same as Table 54.40, set 111b to {LWS, WDS, BTS}. If data order is not the same as the definition, change data order within 8-byte unit by these bits as shown in Table 54.15.

Table 54.15 Changing data order according to Display List Swap register

Data order in memory											
Byte address	8n + 0	8n + 1	8n + 2	8n + 3	8n + 4	8n + 5	8n + 6	8n + 7	*_LWS	*_WDS	*_BTS
Data	0	1	2	3	4	5	6	7	1	1	1
	1	0	3	2	5	4	7	6	1	1	0

Bit field:	—	—	POLINT[5:0]						—	—	DLPRI	EXPRI	—	—	—	EXT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EXT	Extended Display List for WPF0*1 Enables or disables the extended display list function. When extended display lists are used, the display list header size is 96 bytes; when they are not used, the header size is 80 bytes. 0: No extended display lists are used. 1: Extended display lists are used.	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
4	EXPRI	Display List Control 1 Always set this bit to 0.	R/W
5	DLPRI	Display List Control 0 Always set this bit to 1.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
13:8	POLINT[5:0]	Extended Display List Command Control Always set these bits to 2.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
16	NWE	No Wait for Polling When this bit is set to 1, the polling condition for extended display lists is always assumed to be true.	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. When using extended display lists, be sure to also use normal display list mode (VI6_DL_CTRL.DLE0); executing only extended display lists is not possible.
When the header-less display list mode is activated, this bit should be set to 0. The extended display list cannot be used with the header-less display list mode.
Extended Display List is available only for VSPD/LIF0 to realized AUTO-FLD or AUTODISP.

54.4.5.5 VI6_DL_BODY_SIZE0 : Display List Body Size Register 0

Base address: VSPD = 0x920E_0000

Offset address: 0x0120

Bit position:	31							24							16														0
Bit field:	—	—	—	—	—	—	—	UPD0	—	—	—	—	—	—	—	BS0[16:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
16:0	BS0[16:0]	Header-less Display List Body Size (WPF0) These bits are used for specifying the body size of the display list in case of header-less display list mode. The unit of the size is byte. The value should be set in multiples of 8.	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
24	UPD0	Update Flag This bit controls the download of the display list at the next downloading timing in case that the header-less display list mode is used. Set this bit to 1 when display list need to be downloaded for next frame. This bit is automatically cleared to 0 after VI6_DL_HDR_ADDRn and VI6_DL_BODY_SIZE0.BS0 is downloaded in H/W side. When this bit is set to 1, the value of VI6_DL_HDR_ADDR0 and VI6_DL_BODY_SIZE0.BS0 should not be changed. 0: Updating display list for the next frame is not reserved. 1: Updating display list for the next frame is reserved.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

See section 54.6.7.2. Controlling Two Register Planes using Display Lists for detail.

54.4.5.6 VI6_DL_HDR_REF_ADDR0 : Display List-0 Header Reference Address Register

Base address: VSPD = 0x920E_0000

Offset address: 0x0130

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

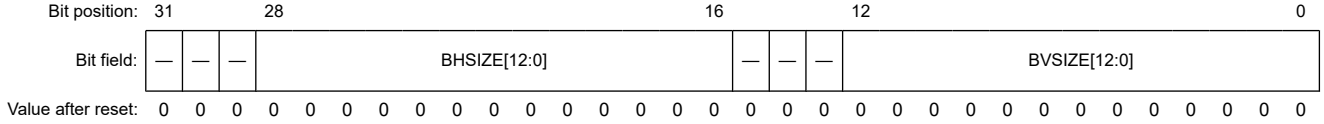
Bit	Symbol	Function	R/W
31:0	n/a	Display List-n reference Header Address Following value is read out from the VI6_DL_HDR_REF_ADDR0 for each period. 1. When H/W is reading display list from external memory, header address of the display list referred by VSPD-H/W is read out. 2. When H/W is not reading display list from external memory, the value of VI6_DL_HDR_ADDR0 is read out. For details, see section 54.6.7.1. Operation flow of VSPD and DU.	R

54.4.6 RPF Control Registers

54.4.6.1 VI6_RPFn_SRC_BSIZE : RPFn Basic Read Size Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0300 + 0x100 × n



Bit	Symbol	Function	R/W
12:0	BVSIZE[12:0]	Vertical Size of RPF Basic Read Area*1 These bits specify the vertical size of the basic area to be read from the external RAM by the RPFn. When the input format is YCbCr4:2:0, specify the size in 2-pixel units. Specify a value equal to or smaller than the extended read size (VI6_RPFn_SRC_ESIZE.EVSIZE).	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
28:16	BHSIZE[12:0]	Horizontal Size of RPF Basic Read Area*1 These bits specify the horizontal size of the basic area to be read from the external RAM by the RPFn. When the input format is YCbCr4:2:2 or YCbCr4:2:0, specify the size in 2-pixel units. Specify a value equal to or smaller than the extended read size (VI6_RPFn_SRC_ESIZE.EHSIZE).	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. A value from 1 to 8190 can be specified.

Figure 54.6 shows the relationship between the basic read size and extended read size. The RPF reads data from the source memory area specified by the basic read size. The RPF repeats reading the basic read area in the horizontal and vertical directions up to the extended read size and sends the read data to the processing modules in the VSPD.

For basic read size reading, the reading start address, called the RPFn source image storing address, should be specified in VI6_RPFn_SRCM_ADDR_*. In the memory area where the basic read area image is stored, the distance (number of bytes) between addresses for lines n and n + 1 of two-dimensional image data, called the memory stride, should be specified in VI6_RPFn_SRCM_PSTRIDE.

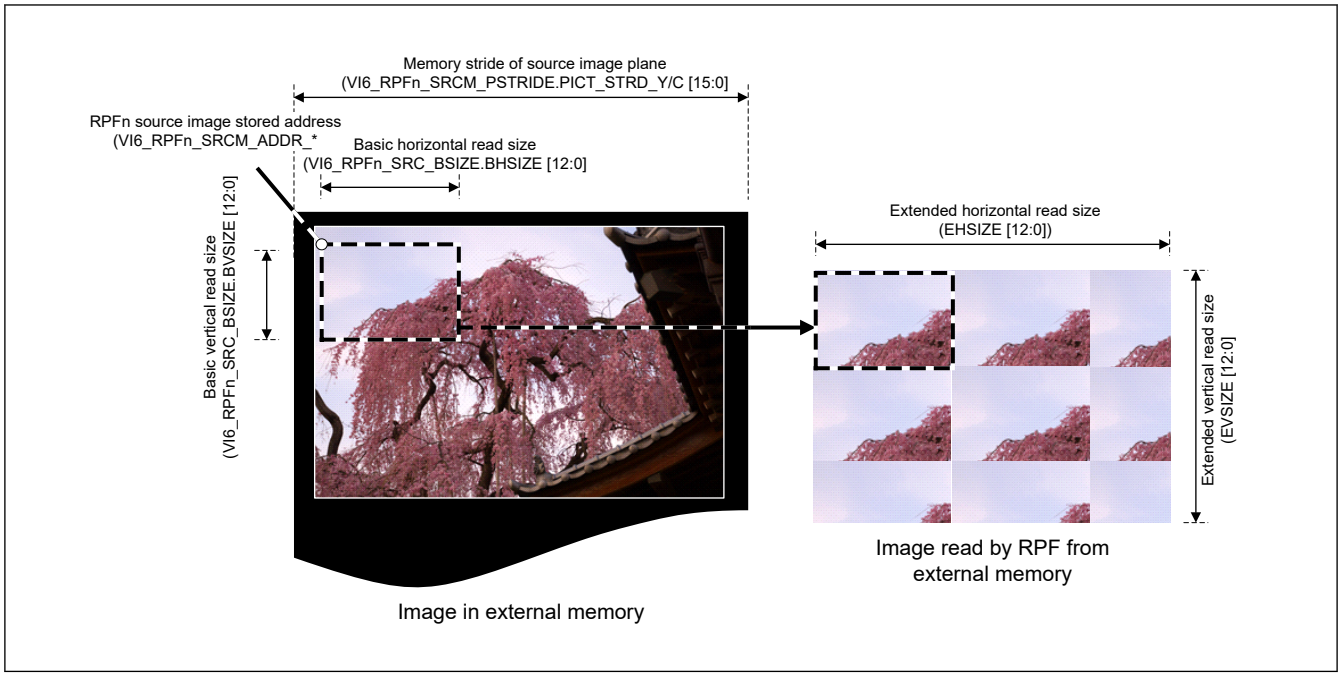


Figure 54.6 Relationship between Basic Read Size and Extended Read Size

- section 54.4.6.16. VI6_RPFn_SRCM_ADDR_Y : RPFn Source Y/RGB Address Register (n = 0, 1)
- section 54.4.6.17. VI6_RPFn_SRCM_ADDR_C0 : RPFn Source Chroma Address Register 0 (n = 0, 1)
- section 54.4.6.18. VI6_RPFn_SRCM_ADDR_C1 : RPFn Source Chroma Address Register 1 (n = 0, 1)

54.4.6.2 VI6_RPFn_SRC_ESIZE : RPFn Extended Read Size Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0304 + 0x100 × n

Bit position:	31			28												16			12												0
Bit field:	—	—	—	EHSIZE[12:0]												—	—	—	EVSIZE[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	EVSIZE[12:0]	RPF Extended Vertical Read Size These bits specify the vertical size of the extended read area to which the RPFn reads data from the external RAM. As shown in Figure 54.6, the basic read area image is repeatedly placed in the extended read area; in the EVSIZE bits, specify a value not smaller than the vertical size of the basic read area. When the input format is YCbCr4:2:0, specify the size in 2-pixel units (an even value). A value from 1 to 1080 can be specified.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
28:16	EHSIZE[12:0]	RPF Extended Horizontal Read Size These bits specify the horizontal size of the extended read area to which the RPFn reads data from the external RAM. As shown in Figure 54.6, the basic read area image is repeatedly placed in the extended read area; in the EHSIZE bits, specify a value not smaller than the horizontal size of the basic read area. When the input format is YCbCr4:2:2 or YCbCr4:2:0, specify the size in 2-pixel units (an even value). A value from 1 to 1920 can be specified.	R/W

Bit	Symbol	Function	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

VI6_RPFn_SRC_ESIZE specifies the extended size for RPFn. The extended horizontal and vertical sizes should be equal to or greater than the basic sizes specified in VI6_RPFn_SRC_BSIZE. The RPF internal data processing described later and image processing described in section 54.4.8. DPR Control Registers and later sections are all applied to the image in the extended read size shown on the right side in Figure 54.6.

54.4.6.3 VI6_RPFn_INFMT : RPFn Input Format Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0308 + 0x100 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	VIR	—	—	—	—	—	—	—	—	—	—	—	CIPM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SPYCS	SPUVS	CEXT[1:0]		RDTM[2:0]			CSC	—	RDFMT[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	RDFMT[6:0]	RPF Input Image Format Setting These bits select the format of the image input from the external RAM to the RPF0. Select a value corresponding to the desired format from those shown in Table 54.17, Table 54.18, and Table 54.19. When the virtual input function is used (VIR = 1), the color information for the virtual input should be specified in VI6_RPF0_VRTCOL_SET. If this color information is in the RGB format, set the RDFMT bits to 19. If the color information is in the YCbCr format, set these bits to 64.*1	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	CSC	Color Space Conversion Enable Enables or disables color space conversion between YCbCr and RGB to be executed in RPF0. The characteristics of color space conversion are determined by the RDTM bit setting.*2 When using the virtual input (VIR = 1), set this bit to 0. 0: Color space conversion is disabled. 1: Color space conversion is enabled.	R/W
11:9	RDTM[2:0]	CSC Conversion Expression Setting These bits select the expression used for color space conversion. The conversion direction is RGB → YCbCr when RGB is selected through the RDFMT bits; the direction is YCbCr → RGB when YCbCr is selected. 0 0 0: BT.601 YCbCr [16,235/240] ↔ RGB [0,255] 0 0 1: BT.601 YCbCr [0,255] ↔ RGB [0,255] 0 1 0: BT.709 YCbCr [16,235/240] ↔ RGB [0,255] 0 1 1: BT.709 YCbCr [16,235/240] ↔ RGB [16,235] Others: Setting prohibited.	R/W
13:12	CEXT[1:0]	Lower-Bit Color Data Extension Method Setting When an RGB input format where each color component is expressed in less than 8 bits are selected from Table 54.17 through the RDFMT bits, VSPD internally extends each color component to 8 bits before using the data. These bits select this extension method. 0 0: Lower-order bits of color data are extended with 0. 0 1: Upper-order bits of color data are copied to the lower-order bits. 1 0: Lower-order bits of color data are extended with 0. The maximum value is limited to 0xFF. 1 1: Setting prohibited.	R/W

Bit	Symbol	Function	R/W
14	SPUVS	RPF Input Mode Setting 2 When the input format is NV61, set this bit to 1 and set the RDFMT bits to 65 (0x41). When the input format is NV21, set this bit to 1 and set the RDFMT bits to 66 (0x42). When the input format is YVYU, set this bit and the SPYCS bit to 1 and set the RDFMT bits to 71 (0x47). In other cases, set this bit to 0.	R/W
15	SPYCS	RPF Input Mode Setting 1 When the input format is YUY2, set this bit to 1 and set the RDFMT bits to 71 (0x47). When the input format is YVYU, set this bit and the SPUVS bit to 1 and set the RDFMT bits to 71 (0x47). In other cases, set this bit to 0.	R/W
16	CIPM	Horizontal Chrominance Interpolation Method Setting Image data is processed in the YCbCr444 format inside VSPD in case of YCbCr color space. When the chrominance format of the input image is YCbCr422 or YCbCr420, data is up-sampled as shown in Figure 54.7 for internal processing. This bit specifies the method of up-sampling for this purpose. 0: The nearest-neighbor method is used for horizontal chrominance interpolation. 1: The bilinear method is used for horizontal chrominance interpolation.	R/W
27:17	—	These bits are read as 0. The write value should be 0.	R/W
28	VIR	Virtual Input Enable Enables or disables the virtual input function of the RPF0. The image to be processed by the RPF0 is usually read from the external memory by the MAU. Instead of this input, the virtual input function generates a single-color image within the RPF0 and sends it to the modules in VSPD. When the virtual input function is enabled, the fixed value specified in VI6_RPF0_VRTCOL_SET is used as the input to the RPF0. While the virtual input function is enabled, data is not read from the external memory; that is, the α plane is not read and the IROP calculation thus cannot be executed. In this case, set VI6_RPF0_ALPH_SEL.ASEL to 4. Neither the color space conversion through CSC nor the color keying described in section 54.4.6.11. VI6_RPFn_CKEY_CTRL : RPFn Color Keying Control Register (n = 0, 1) can be used. 0: RPF0 uses general input. 1: RPF0 uses virtual input.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Number of input pixels
When YCbCr4:2:2 is selected through the RDFMT bits, the horizontal size of the input image should be specified in 2-pixel units. When YCbCr4:2:0 is selected, the vertical and horizontal sizes should be specified in 2-pixel units. Observe these restrictions when specifying the image size in VI6_RPF0_SRC_BSIZE and VI6_RPF0_SRC_ESIZE.
Note 2. Note on color space settings.

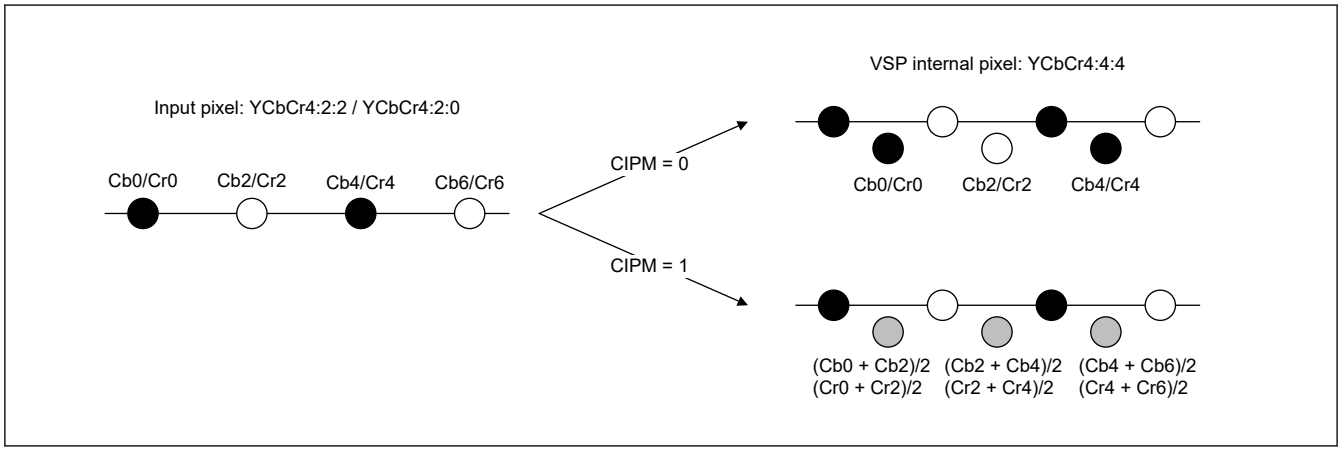

Figure 54.7 Chrominance interpolation methods selectable through CIPM setting

The color space for the image output from the RPF to VSPD internal modules is determined by the combination of the color space for the image input to the RPF, which is selected through the VI6_RPFn_INFMT.RDFMT setting, and the enabled or disabled state of the color space conversion function, which is selected through the VI6_RPFn_INFMT.CSC setting (Table 54.16). For example, when the image input to the RPF is in the YCbCr format, the RPF outputs data to VSPD internal modules in the YCbCr format if color space conversion is disabled through the CSC bit, and the RPF outputs data in the RGB format if color space conversion is enabled. When the image input to the RPF is in the RGB format, the relationship

between the output format and the color space conversion setting is the opposite of the YCbCr case. For some VSPD internal modules, the YCbCr format is recommended for image processing because of the characteristics of the processing, or the same color space needs to be specified between multiple RPF outputs. In these cases, set VI6_RPFn_INFMT.RDFMT and VI6_RPFn_INFMT.CSC appropriately so that the RPFs can output the required color space according to the color space conditions described above.

Table 54.16 RPFn input color space and output color space

RPFn input color space (VI6_RPFn_INFMT. RDFMT)		Color space conversion setting (VI6_RPFn_INFMT.CSC)		RPFn output color space
RGB	(0x00 to 0x3F)*1	Disabled	(0)*1	RGB
		Enabled	(1)*1	YCbCr
YCbCr	(0x40 to 0x7F)*1	Disabled	(0)*1	YCbCr
		Enabled	(1)*1	RGB

Note 1. Value specified in the register

A color space conversion function equivalent to that in the RPFn is also provided by the WPF. As shown in Table 54.16, the color space (YCbCr or RGB) output from the RPF becomes the input format for the WPF. Here, the color space of the output image obtained by the color space conversion function of the WPF must match the color space of the format specified through VI6_WPFn_OUTFMT.WRFMT.

Figure 54.8 shows the relationship between the input/output format and color space. The input color space for the RPF is determined when the input image format for the RPF is specified through the RDFMT bits. The color space for the image output from the RPF to subsequent VSPD internal modules depends on the combination of the RPF input format and CSC (color space conversion function) enabled or disabled state in the RPF as shown in Table 54.16 and Figure 54.8. The user should first determine whether the image processing in the VSPD is done in YCbCr or RGB, and then specify the RPF input format and CSC enabled or disabled state to obtain the desired color space. The color space of the RPF output image is also that of the WPF input image; the color space of the data output from the WPF to the outside of VSPD depends on the combination of the WPF input color space and the enabled or disabled state of the CSC implemented in the WPF as shown in Figure 54.8. The color space of the WPF output image must match that of the WPF output format (determined by VI6_WPFn_OUTFMT.WRFMT). For example, in the flow shown in Figure 54.8, YCbCr should not be specified as the WPF output format regardless of the fact that the color space of the WPF output image is in RGB format.

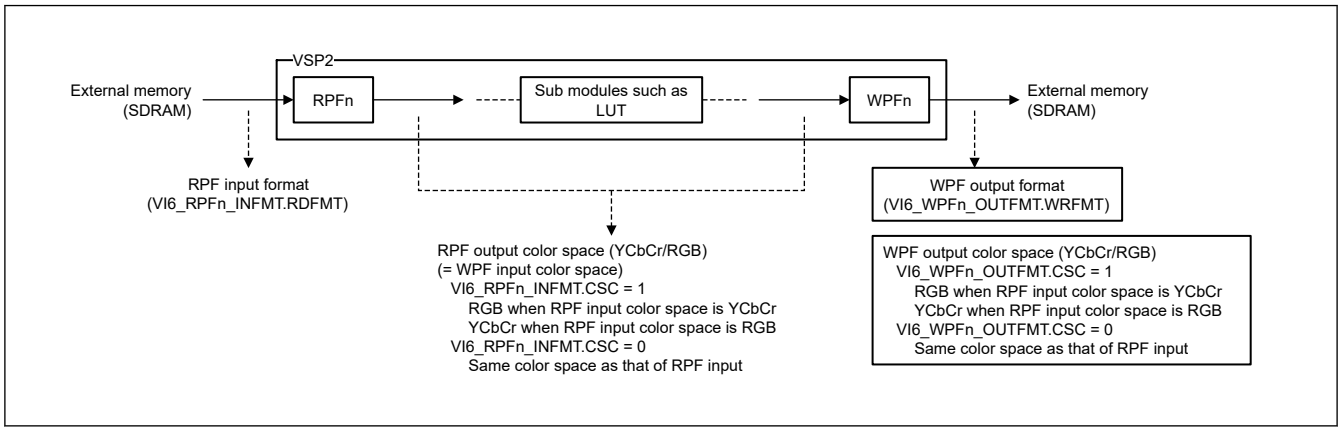

Figure 54.8 Relationship between input/output format and color space

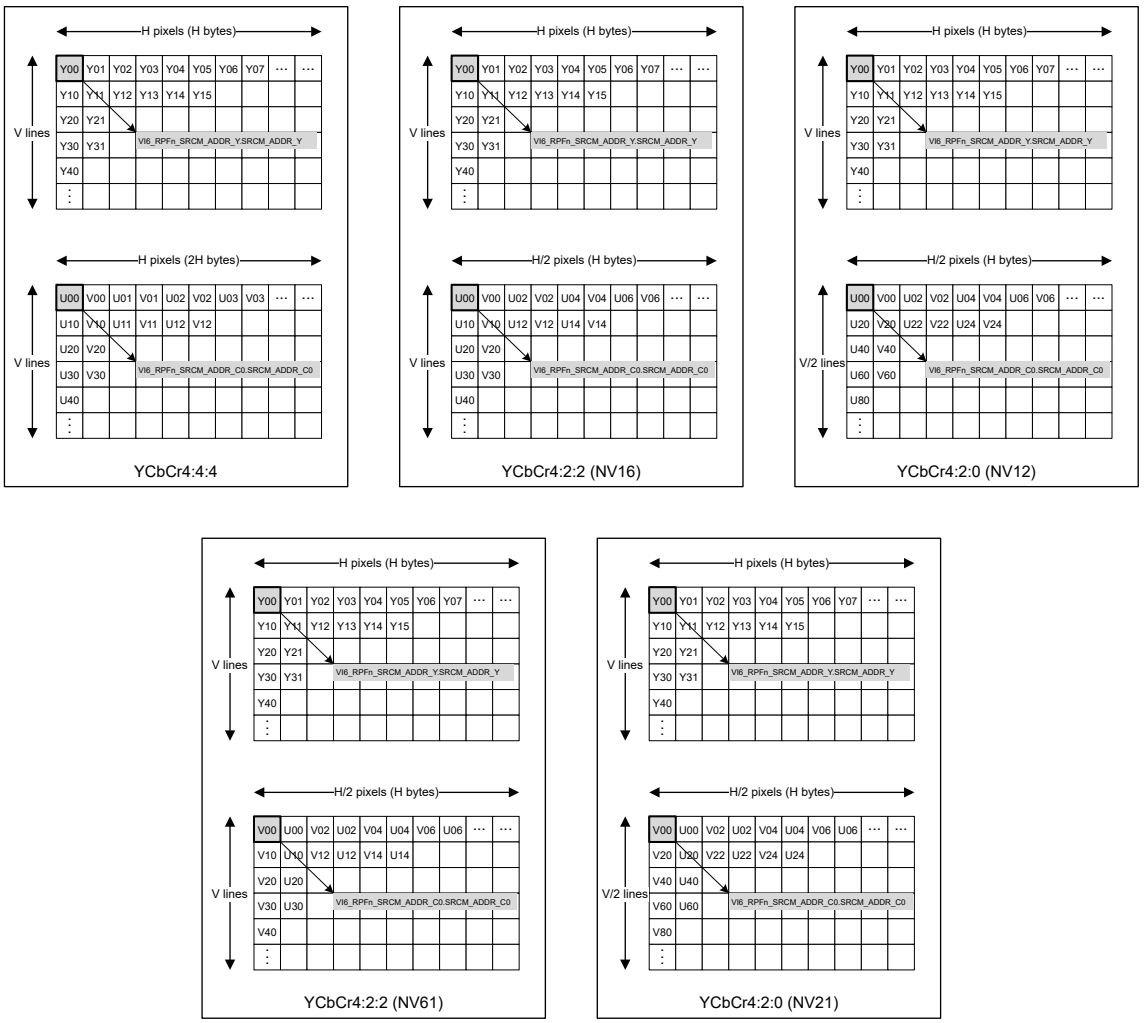
Table 54.19 Packed YCbCr formats for RPF input

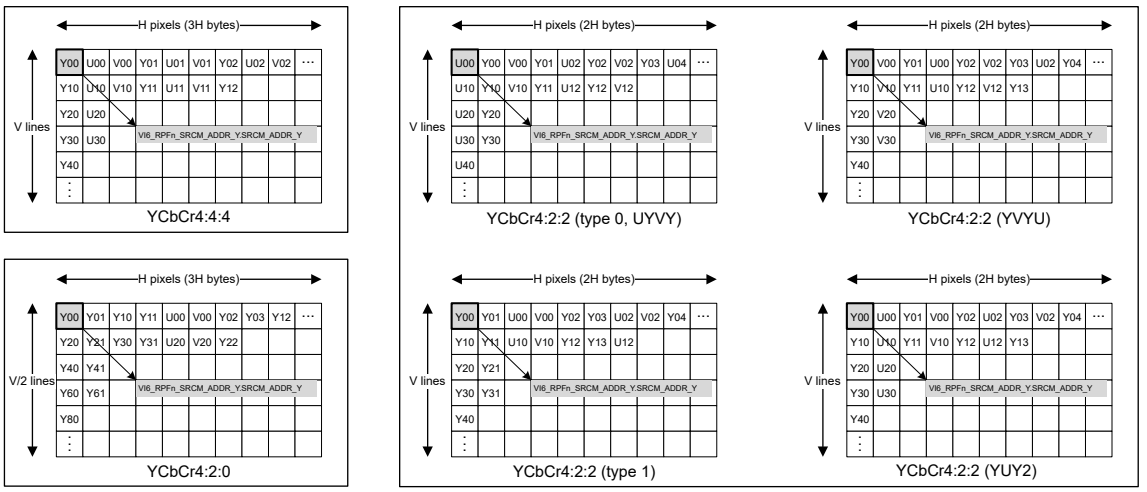
RDFMT[6:0]	Packed YCbCr input format	Reference
0x40	YCbCr4:4:4 semi-planar	Figure 54.9*4
0x41	YCbCr4:2:2 semi-planar (NV16, NV61*1)	
0x42	YCbCr4:2:0 semi-planar (NV12, NV21*1)*5	
0x43 to 0x45	Reserved	—
0x46	YCbCr4:4:4 interleaved	Figure 54.10*4
0x47	YCbCr4:2:2 interleaved type 0 (UYVY, YUY2*2, YVYU*3)	
0x48	YCbCr4:2:2 interleaved type 1	
0x49	YCbCr4:2:0 interleaved*6	
0x4A	YCbCr4:4:4 planar	Figure 54.11*4
0x4B	YCbCr4:2:2 planar (YV16)	
0x4C	YCbCr4:2:0 planar (YV12, I420)*5	
0x4D to 0x7E	Reserved	—
0x7F	Reserved	—

Note 1. When the input format is NV61 or NV21, set the SPUVS bit to 1.
Note 2. When the input format is YUY2, set the SPYCS bit to 1.
Note 3. When the input format is YVYU, set the SPUVS bit to 1 and SPYCS bit to 1.
Note 4. Figure 54.12 shows the definition of memory address for each pixel in Figure 54.9 to Figure 54.11.
Note 5. Each line of C plane is read twice, so byte/pixel of YCbCr420 is 2 byte/pixel (same as YCbCr422).
Note 6. Each line of plane is read twice, so byte/pixel of YCbCr420ITL is 3 byte/pixel (same as YCbCr444ITL).



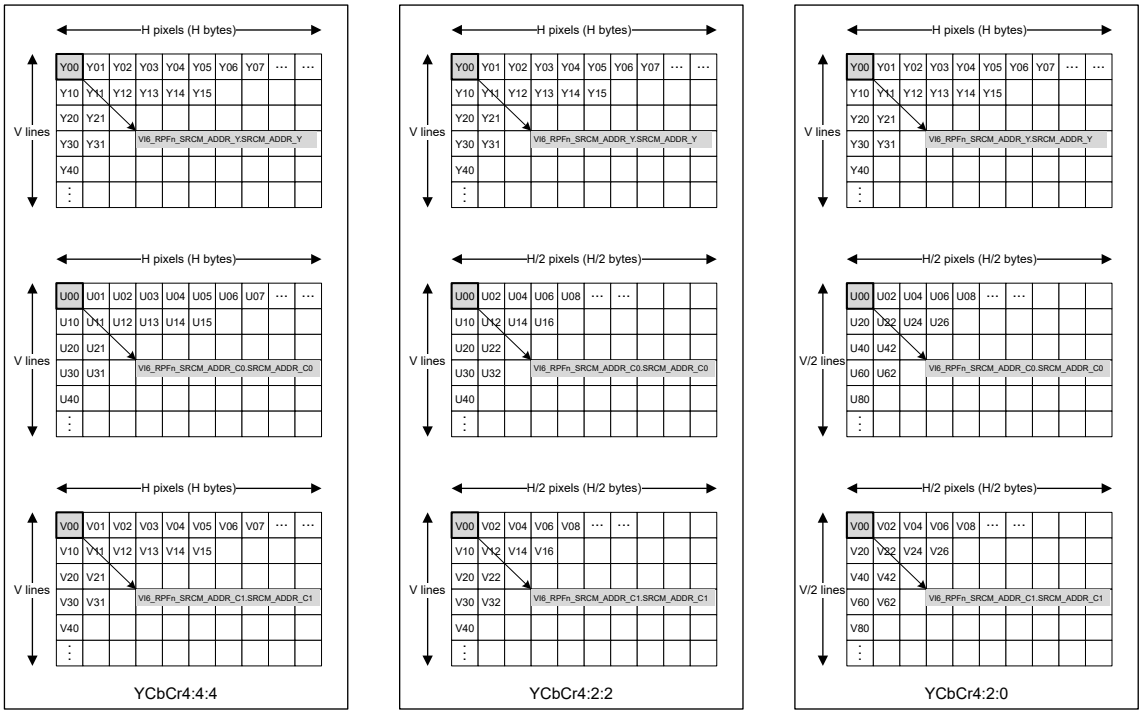
Note: This figure is for 8 bpc.

Figure 54.9 YCbCr Semi-Planar formats



Note: This figure is for 8 bpc.

Figure 54.10 YCbCr Interleaved formats



Note: This figure is for 8 bpc.

Figure 54.11 YCbCr Planar formats

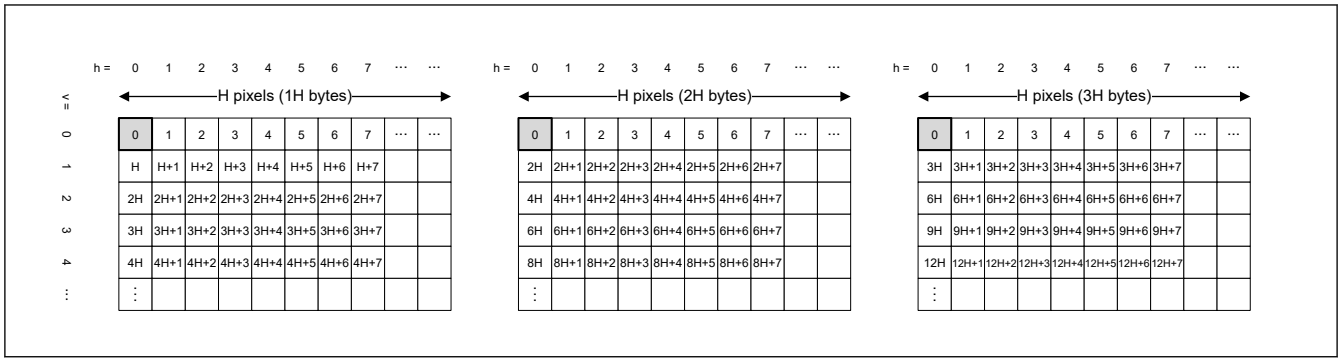


Figure 54.12 Memory address for the corresponding pixel's position

Legend of Figure 54.12

- H is horizontal image size in pixel unit.
- 1H, 2H, and 3H is corresponding to the case 1 pixel has 1 byte, 2 bytes, and 3 bytes of data, respectively.

54.4.6.4 VI6_RPFn_DSWAP : RPFn Data Swapping Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x030C + 0x100 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit field:	—	—	—	—	A_LLS	A_LWS	A_WDS	A_BTS	—	—	—	—	P_LLS	P_LWS	P_WDS	P_BTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	P_BTS	Picture Plane Data Swapping in Byte Units*1 The effect of this bit setting is defined in Table 54.20. 0: Data swapping in Byte (8-bit) units is disabled. 1: Data swapping in Byte (8-bit) units is enabled.	R/W
1	P_WDS	Picture Plane Data Swapping in Word Units*1 The effect of this bit setting is defined in Table 54.20. 0: Data swapping in Word (16-bit) units is disabled. 1: Data swapping in Word (16-bit) units is enabled.	R/W
2	P_LWS	Picture Plane Data Swapping in long word Units*1 The effect of this bit setting is defined in Table 54.20. 0: Data swapping in long word (32-bit) units is disabled. 1: Data swapping in long word (32-bit) units is enabled.	R/W
3	P_LLS	Picture Plane Data Swapping in LONG LWORD Units*1 The effect of this bit setting is defined in Table 54.20. 0: Data swapping in LONG LWORD (64-bit) units is disabled. 1: Data swapping in LONG LWORD (64-bit) units is enabled.	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	A_BTS	α Plane Data Swapping in Byte Units The effect of this bit setting is defined in Table 54.20. 0: Data swapping in Byte (8-bit) units is disabled. 1: Data swapping in Byte (8-bit) units is enabled.	R/W

Bit	Symbol	Function	R/W
9	A_WDS	α Plane Data Swapping in Word Units The effect of this bit setting is defined in Table 54.20. 0: Data swapping in Word (16-bit) units is disabled. 1: Data swapping in Word (16-bit) units is enabled.	R/W
10	A_LWS	α Plane Data Swapping in long word Units The effect of this bit setting is defined in Table 54.20. 0: Data swapping in long word (32-bit) units is disabled. 1: Data swapping in long word (32-bit) units is enabled.	R/W
11	A_LLS	α Plane Data Swapping in LONG LWORD Units The effect of this bit setting is defined in Table 54.20. 0: Data swapping in LONG LWORD (64-bit) units is disabled. 1: Data swapping in LONG LWORD (64-bit) units is enabled.	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. This register is available for only Luma plane (Y) in the case input data format is YUV Planar or Semi-Planar and input bit-depth is 2 bpc (IPBD_Y ≠ 0 or IPBD_C ≠ 0), and available for both Luma plane (Y) and Chroma plane (CbCr/U/V) in other cases.

When the virtual input function of the RPFn is used (VI6_RPFn_INFMT.VIR = 1), this register setting is ignored. Swapping of RPF input data can be specified separately for the α plane and picture plane.

Table 54.20 shows the data order before and after swapping according to the long long word, long word, word, and byte swapping settings.

When data order in memory for each format is the same as Table 54.17 for RGB format and Figure 54.9 to Figure 54.12 for YCbCr format, set 1111b to {*_LLS, *_LWS, *_WDS, *_BTS}. If data order is not the same as the definition, change data order within 16-byte unit by these bits as shown in Table 54.20.

Table 54.20 Changing data order according to swap register

Data order in memory																				
Byte address	16n + 0	16n + 1	16n + 2	16n + 3	16n + 4	16n + 5	16n + 6	16n + 7	16n + 8	16n + 9	16n + 10	16n + 11	16n + 12	16n + 13	16n + 14	16n + 15	*_LLS	*_LWS	*_WDS	*_BTS

54.4.6.5 VI6_RPFn_LOC : RPFn Display Location Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0310 + 0x100 × n

Bit position:	31			28												16			12												0
Bit field:	—	—	—	HCOORD[12:0]												—	—	—	VCOORD[12:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	VCOORD[12:0]	Vertical Coordinate of Sublayer Display Location on Master Layer*1 These bits specify the top-end location of the sublayer displayed by the RPFn and the subsequent module connected through the DPR. Specify the vertical coordinate of the location in pixel units with the top-end pixel of the master layer set at coordinate 0. When the RPFn is the master layer, set these bits to 0. If the sublayer extends beyond the master layer according to the VCOORD setting, the extended section is cut off at the bottom-end of the master layer. Even in this case, however, a bus transfer that is unnecessary for output image generation is executed since the whole sublayer data is read from the external memory. Appropriate coordinate setting is required so that the sublayer does not extend beyond the bottom-end of the master layer.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
28:16	HCOORD[12:0]	Horizontal Coordinate of Sublayer Display Location on Master Layer*1 These bits specify the left-end location of the sublayer displayed by the RPFn and the subsequent module connected through the DPR. Specify the horizontal coordinate of the location in pixel units with the left-end pixel of the master layer set at coordinate 0. When the RPFn is the master layer, set these bits to 0. If the sublayer extends beyond the master layer according to the HCOORD setting, the extended section is cut off at the right-end of the master layer. Even in this case, however, a bus transfer that is unnecessary for output image generation is executed since the whole sublayer data is read from the external memory. Appropriate coordinate setting is required so that the sublayer does not extend beyond the right-end of the master layer.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. A value from 0 to 8189 can be specified.

Figure 54.13 shows an example of RPF1 offsets with respect to master layer RPF0. Although this figure only shows sublayers RPF1, specify offsets for all RPFs other than the master layer in the same way as shown in this example.

Whether an RPFn is the master layer or a sublayer is determined through the selection of the source RPF for WPFn (the VI6_WPFn_SRCRPF setting). For details, see section 54.4.7.1. VI6_WPF0_SRCRPF : WPF0-Source-RPF Register.

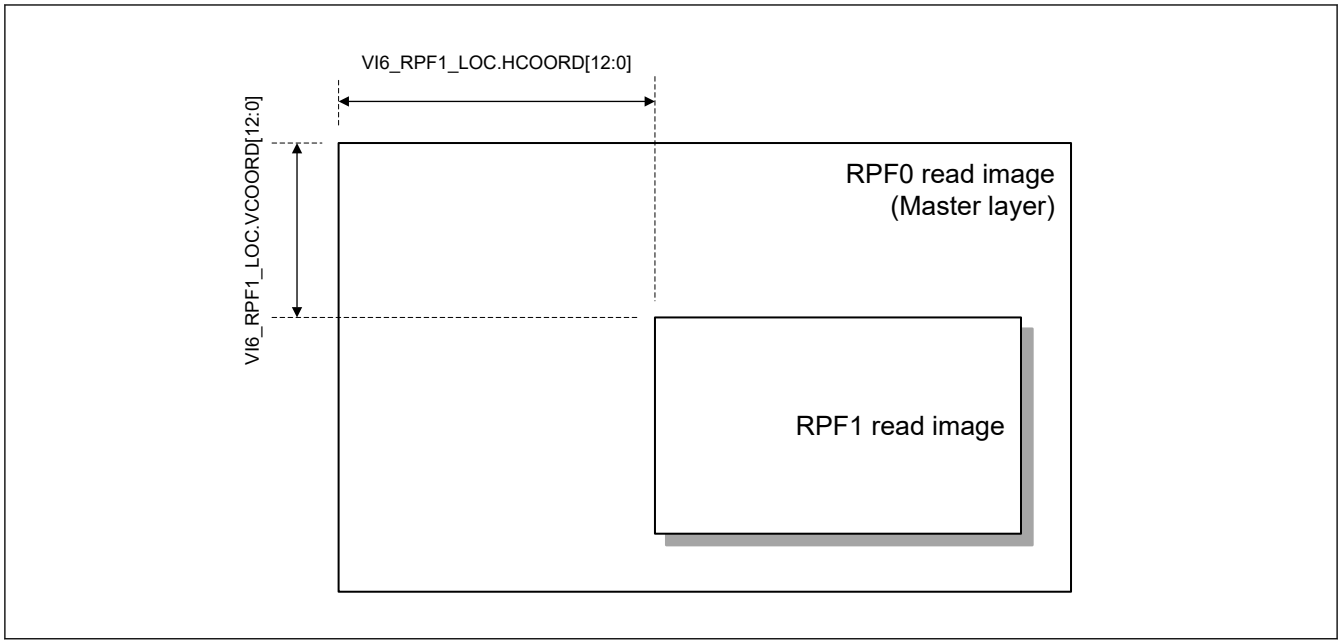

Figure 54.13 RPF1 offsets from Master layer

54.4.6.6 VI6_RPFn_ALPH_SEL : RPFn α Plane Selection Control Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0314 + 0x100 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	ASEL[2:0]			IROP[3:0]				BSEL	—	—	—	AEXT[1:0]		—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ALPHA1[7:0]								ALPHA0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ALPHA0[7:0]	8-Bit α Value Output when 1-Bit α Value is 0*1 These bits specify the 8-bit α value to be output when 1-bit α data is input and the α value input to the 8-bit transparent α generator shown in Figure 54.14 is 0b. This setting is valid when the ASEL bits are set to 010b or 011b.	R/W
15:8	ALPHA1[7:0]	8-Bit α Value Output when 1-Bit α Value is 1*1 These bits specify the 8-bit α value to be output when 1-bit α data is input and the α value input to the 8-bit transparent α generator shown in Figure 54.14 is 1b. This setting is valid when the ASEL bits are set to 010b or 011b.	R/W
17:16	—	These bits are read as 0. The write value should be 0.	R/W
19:18	AEXT[1:0]	Lower-Bit α Value Extension Method Set These bits specify the method for extending the input α data to 8 bits through the unpack processing. 0 0: The lower-order bits of α value are extended with 0. 0 1: The upper-order bits of α value are copied to the lower-order bits. 1 0: The lower-order bits of α value are extended with 0. The maximum value is limited to 0xFF. 1 1: Setting prohibited.	R/W
22:20	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
23	BSEL	α Bit Count Conversion Selection for 1-Bit Mask Generator Specifies the number of bits in the α plane to be read as mask information from the external RAM. The α value in mask information is used for the source (S) in IROP. When α plane data is 8 bits, it is converted to one bit through the 1-bit mask generator shown in Figure 54.14. Note that this bit setting is valid when the ASEL bits are set to 0 or 2 and VI6_RPFn_MSKCTRL.MSK_EN is set to 0. In other cases, this bit setting has no effect. 0: 8-bit α is converted to 1-bit α through the 1-bit mask generator. When the 8-bit α value input to the RPF is not 0, it is converted to 1b; when the value is 0, it is converted to 0b. 1: α value goes through the 1-bit mask generator. The 1-bit α value input to the RPF is output through the 1-bit mask generator without change.	R/W
27:24	IROP[3:0]	IROP Operation Setting These bits specify the operator to be executed in the IROP operation unit shown in Figure 54.14. The source (S) for the IROP operation is the pixel data and α data specified in the VI6_RPFn_MSKSET0 or VI6_RPFn_MSKSET1 IROP input value register, which is selected according to the value (0 or 1) generated by the 1-bit mask generator. The destination (D) is the image data (RGB/Y CbCr) and 8-bit α data output from the unpack/OSD processor. IROP operation is applied both for the image data and α data between the source and destination data. If these bits are set to the operation that involves the source (S) (IROP setting other than 0, 5, 10, or 15) while VI6_RPFn_MSKCTRL.MSK_EN is 0, the α plane is read from the external RAM to be used for the α value for IROP operation; specify the α plane read start address (VI6_RPFn_SRCM_ADDR_A). When the virtual input function is used (VI6_RPFn_INFMT.VIR = 1), IROP operation is not available; set these bits to 0x0. 0x0: NOP(D) 0x1: AND(S & D) 0x2: AND_REVERSE(S & ~D) 0x3: COPY(S) 0x4: AND_INVERTED(~S & D) 0x5: CLEAR(0) 0x6: XOR(S ^ D) 0x7: OR(S | D) 0x8: NOR(~(S | D)) 0x9: EQUIV(~(S ^ D)) 0xA: INVERT(~D) 0xB: OR_REVERSE(S | ~D) 0xC: COPY_INVERTED(~S) 0xD: OR_INVERTED(~S | D) 0xE: NAND(~(S & D)) 0xF: SET(all 1)	R/W

Bit	Symbol	Function	R/W
30:28	ASEL[2:0]	α Format and Processing Method Select These bits select how to handle the α value to be used. The RPF handles two types of α value; 8-bit and 1-bit values. When a 1-bit α value is used, VSPD assumes that the 1-bpp α value for each pixel is stored in the order from MSB to LSB in each byte (big endian). The α value is used as either transparency information or mask information. Transparency information is included in the α plane read from external memory when the ASEL bits are set to 1 or 3 and in the α value stored in the packed RGB bit field when these bits are set to 0 or 2. The α value as transparency information is sent as the destination value to the IROP as shown in Figure 54.14 and then output to the subsequent modules. The output α value is used, for example, for blending in the BRS. The α value as mask information is used for IROP operation in the RPF. The mask information is included in the α plane read from external RAM when the ASEL bits are set to 0 or 2 and the source value is used in IROP operation (IROP setting other than 0, 5, 10, or 15). This α value is sent as the source value to the IROP as shown in Figure 54.14. Note that the α value selected through the ASEL bits has a lower priority than the VI6_RPFn_CKEY_SET*.AP* value replaced through the color keying function. When the color keying function is used, the α value may be replaced with the VI6_RPFn_CKEY_SET*.AP* value regardless of the ASEL bit setting. When using the virtual input function (VI6_RPFn_INFMT.VIR = 1), set these bits to 4. 0 0 0: 1, 4, or 8-bit packed α + plane α (IROP ≠ 0, 5, 10, 15) The α bit field in 1, 4, or 8-bit packed α is handled as transparency information. Be sure to specify the packed format that includes α through VI6_RPFn_INFMT.RDFMT. When VI6_RPFn_MSKCTRL.MSK_EN is 0 and the IROP bit value is not 0, 5, 10, or 15, the α plane should be read as mask information. Specify the number of α data bits (BSEL) stored in the α plane and the α plane read start address (VI6_RPFn_SRCM_ADDR_AI). When the IROP bits are set to 0, 5, 10, or 15, the α plane is not read. 0 0 1: 8-bit plane α The 8-bit α plane is read from external RAM as transparency information. When the packed RGB format has a bit field for α, the information in the α bit field is discarded. The α plane read start address (VI6_RPFn_SRCM_ADDR_AI) should be specified. The α value goes through the 8-bit transparent α generator shown in Figure 54.14 without change. When VI6_RPFn_MSKCTRL.MSK_EN is 0, IROP operation cannot be executed; set the IROP bits to 0 in this case. When VI6_RPFn_MSKCTRL.MSK_EN is 1. IROP operation can be executed. 0 1 0: 1-bit packed α + plane α (IROP ≠ 0, 5, 10, 15) The 1-bit packed α input is converted by the 8-bit transparent α generator shown in Figure 54.14 according to the ALPHA0/1 setting into the 8-bit α value as transparency information. Select the packed input format that includes a 1-bit α field. When VI6_RPFn_MSKCTRL.MSK_EN is 0 and the IROP value is not 0, 5, 10, or 15, the α plane should be read as mask information. Specify the number of α data bits (BSEL) stored in the α plane and the α plane read start address (VI6_RPFn_SRCM_ADDR_AI). When the IROP bits are set to 0, 5, 10, or 15, the α plane is not read. 0 1 1: 1-bit plane α The 1-bit α plane is read from external RAM and converted by the 8-bit transparent α generator shown in Figure 54.14 according to the ALPHA0/1 setting into the 8-bit α value as transparency information. When the packed RGB format has a bit field for α, the information in the α bit field is discarded. The α plane read start address (VI6_RPFn_SRCM_ADDR_AI) should be specified. When VI6_RPFn_MSKCTRL.MSK_EN is 0, IROP operation cannot be executed; set the IROP bits to 0 in this case. When VI6_RPFn_MSKCTRL.MSK_EN is 1. IROP operation can be executed. 1 0 0: Fixed α The fixed α value (VI6_RPFn_VRTCOL_SET.LAY A value) is output from the RPF. IROP operation cannot be executed; set the IROP bits to 0 in this case. Others: Setting prohibited.	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

Note 1. A value from 0 to 255 can be specified.

Figure 54.14 shows the relationship between the α selector, IROP operation unit, color keying unit, and related registers. The IROP operation unit receives two inputs, source and destination. The image data input from the external memory is processed through the unpack processor and 8-bit transparent α generator and then input to the IROP operation unit as destination data. The α plane data input from the external memory is sent to the 8-bit transparent α generator when

the ASEL bits are set to 1 or 3, or sent to the 1-bit mask α generator when the ASEL bits are set to 0 or 2. For the pixel data and 8-bit α value on the source side of the IROP operation unit, either the VI6_RPFn_MSKSET0 value or VI6_RPFn_MSKSET1 values will be selected according to the 1-bit α value output by the 1-bit mask α generator.

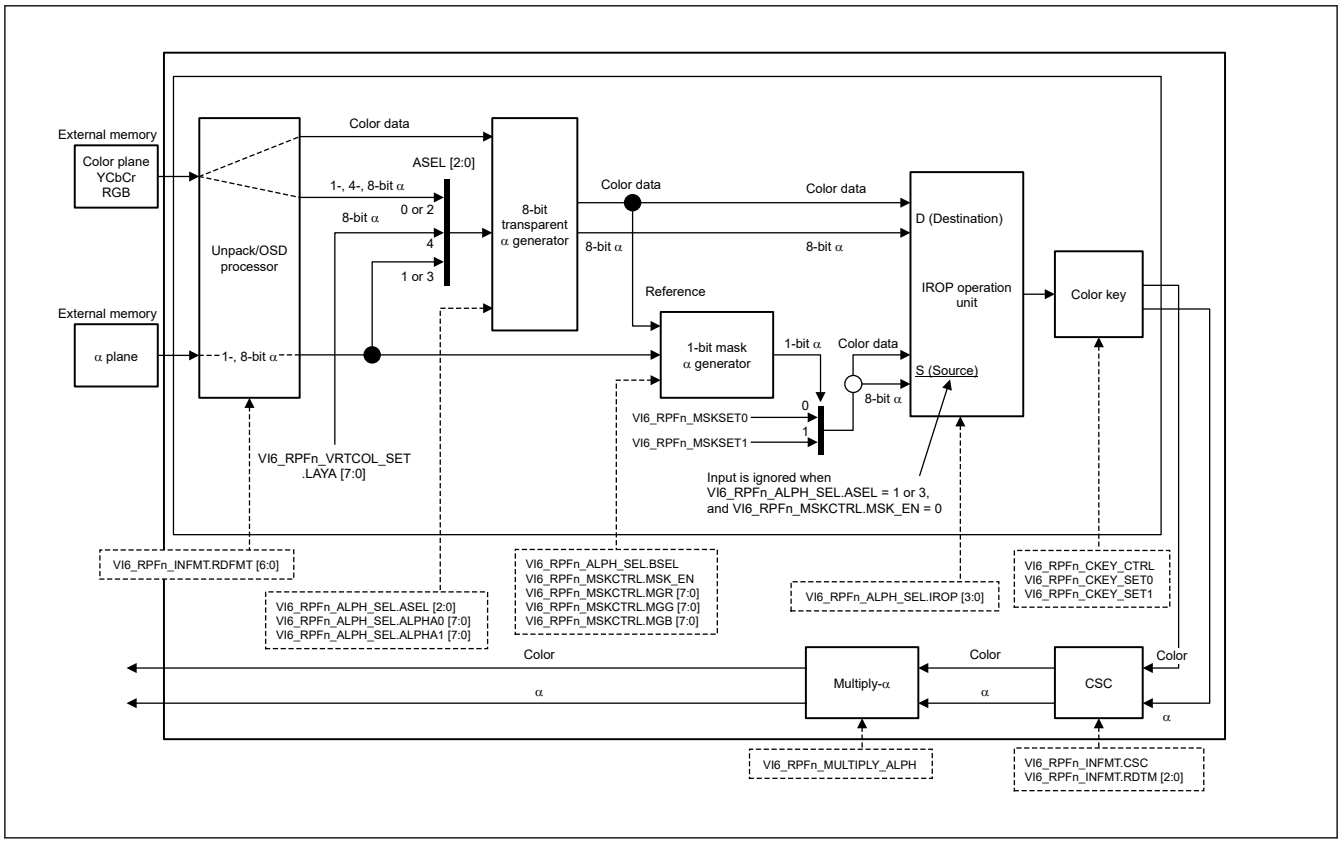

Figure 54.14 Configuration of Alpha selector and IROP operation unit in RPF

The following describes the function of each block shown in Figure 54.14.

Unpack/OSD processor:

Unpacks each component and α value of the image data according to the packed format specified in VI6_RPFn_INFMT.RDFMT.

8-bit transparent α generator:

Converts the input α value into 8-bit α when the input α is four bits or one bit.

When VI6_RPFn_ALPH_SEL.ASEL are set to 0 (8-, 4-, or 1-bit packed α), this generator outputs the input α value without change if the α bit field in the packed α data is 8 bits; if the α bit field is less than 8 bits, it is converted to an 8-bit α value by extending the LSB side according to the VI6_RPFn_ALPH_SEL.AEXT setting.

When VI6_RPFn_ALPH_SEL.ASEL are set to 1 (8-bit plane α) or 4 (fixed α), this generator outputs the input 8-bit plane α without change. If a packed α value is included in RGB data, it is discarded.

When VI6_RPFn_ALPH_SEL.ASEL are set to 2 (1-bit packed α) or 3 (8-bit α generated from 1-bit plane α), an 8-bit α value is generated by using the VI6_RPFn_ALPH_SEL.ALPHA0[7:0] value when the input 1-bit α value is 0 or by using the VI6_RPFn_ALPH_SEL.ALPHA1[7:0] value when the input 1-bit α value is 1. When VI6_RPFn_ALPH_SEL.ASEL is set to 3, a packed α value that is included in RGB data is discarded.

1-bit mask α generator:

Generates 1-bit α data from the input 8-bit α data or pixel data. When the input α data is one bit, this generator outputs it without change.

When VI6_RPFn_ALPH_SEL.ASEL are set to 0 (8-, 4-, or 1-bit packed α) or 2 (plane α) and VI6_RPFn_MSKCTRL.MSK_EN is set to 0, the α plane read from the external memory to be used in IROP is converted to 1-bit α data when necessary. When the α plane data read from the external RAM is 8 bits (BSEL = 0), if the value is 0,

a 1-bit α value of 0b is generated; if the value is not 0, a 1-bit α value of 1b is generated. When the α plane data is one bit (BSEL = 1), this generator outputs it without change.

When the value of the 1-bit α generated by the 1-bit mask α generator is 0b, the 8-bit α and pixel data specified in VI6_RPFn_MSKSET0 are output as the source. When the generated 1-bit α value is 1b, the 8-bit α and pixel data specified in VI6_RPFn_MSKSET1 are output as the source.

As shown in Figure 54.14, when VI6_RPFn_ALPH_SEL.ASEL are set to 1 (8-bit plane α) or 3 (1-bit plane α), the α plane read from the external RAM is sent to the 8-bit transparent α generator as transparency information. When VI6_RPFn_MSKCTRL.MSK_EN is set to 0, the 1-bit α for masking is generated according to the input α plane (see section 54.4.6.8. VI6_RPFn_MSKCTRL : RPFn Mask Control Register (n = 0, 1)), but the 1-bit mask α generator does not refer to the input α plane because it is input to the 8-bit transparent α generator as transparency information. Accordingly, the 1-bit mask α generator does not generate a 1-bit α for masking and the data on the source side becomes invalid; that is, IROP operation cannot be executed. Set the IROP bits to 0 in this case. In contrast, when VI6_RPFn_MSKCTRL.MSK_EN is set to 1, the 1-bit mask α generator creates α data for masking according to the pixel data instead of the input α plane data, and IROP operation can be executed in this case.

IROP operation unit:

Executes ROP operation according to the opcode specified in VI6_RPFn_ALPH_SEL.IROP. For ROP operation (other than NOP), valid values should be input both for the source and destination. As described in the above (description of the 1-bit mask α generator), when VI6_RPFn_ALPH_SEL.ASEL are set to 1 or 3 and VI6_RPFn_MSKCTRL.MSK_EN is set to 0, the source data for the IROP operation unit is treated as invalid; set VI6_RPFn_ALPH_SEL.IROP to 0 (NOP). When VI6_RPFn_ALPH_SEL.ASEL are set to 4, a fixed α value is output from the RPF and IROP operation is not available. In the same way as the above case, set VI6_RPFn_ALPH_SEL.IROP to 0 (NOP).

To specify a valid source value for the IROP operation unit and execute IROP operation (specify an opcode other than NOP in the IROP bits), specify register values as shown in Table 54.21. Where the source input state is indicated as "Valid" in the table, IROP operation can be executed. In the cases where IROP operation is not available, set the IROP bits to 0 (NOP).

Table 54.21 Source input state in IROP operation unit

VI6_RPFn_ALPH_SEL.ASEL[2:0]		VI6_RPFn_MSKCTRL.MSK_EN		
		0 (Source data is generated according to input α plane)		1 (Source data is generated according to the destination-side pixel data)
000b	(1-, 4-, or 8-bit packed α + plane α)	Valid	(α plane input)	Valid
001b	(8-bit α plane)	Invalid	(IROP operation is not available; α plane is output to the subsequent modules behind RPF)	Valid
010b	(8-bit α generated from 1-bit packed α + plane α)	Valid	(α plane input)	Valid
011b	(8-bit α generated from 1-bit plane α)	Invalid	(IROP operation is not available; α plane is output to the subsequent modules behind RPF)	Valid
100b	(Fixed α)	Invalid (IROP operation is not available; fixed α is output to the subsequent modules behind RPF)		

For the handling of the α values shown in Figure 54.14 and Table 54.21, the relationship between the RPF input format and RPF output α value is shown in Table 54.22. Where only bit names are shown in the table, the bits are in VI6_RPFn_ALPH_SEL described in this section.

Table 54.22 α value selected and output according to ASEL bits in each input format (1 of 2)

ASEL setting		α Value Output for each input format	
		RGB	YCbCr
000b	(8-, 4-, or 1-bit packed α is input)	1-, 4-, or 8-bit pixel α	0xFF*1
001b	(8-bit plane α is input)	8-bit α plane	8-bit α plane
010b	(8-bit α is generated from the 1-bit packed α input)	ALPHA0 or ALPHA1 setting	0xFF*1
011b	(8-bit α is generated from the 1-bit plane α input)	ALPHA0 or ALPHA1 setting	ALPHA0 or ALPHA1 setting

Table 54.22 α value selected and output according to ASEL bits in each input format (2 of 2)

ASEL setting		α Value Output for each input format	
		RGB	YCbCr
100b	(Fixed α is output)	VI6_RPFn_VRTCOL_SET.LAYA setting	

Note 1. Fixed value 0xFF is output because packed α is not included in YCbCr.

54.4.6.7 VI6_RPFn_VRTCOL_SET : RPFn Virtual Plane Color Information Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0318 + 0x100 × n

Bit position:	31 to 24	23 to 16	15 to 8	7 to 0
Bit field:	LAYA[7:0]	LAYR[7:0]	LAYG[7:0]	LAYB[7:0]
Value after reset:	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
7:0	LAYB[7:0]	Virtual-Input Fixed B/Cb Component Value*1 These bits specify the fixed B or Cb value generated in the RPFn when the virtual input function is enabled through the VI6_RPFn_INFMT.VIR setting. When VI6_RPFn_INFMT.RDFMT is set to 19, the value specified in these bits is used as the B value. When VI6_RPFn_INFMT.RDFMT is set to 64, the value specified in these bits is used as the Cb value.	R/W
15:8	LAYG[7:0]	Virtual-Input Fixed G/Y Component Value*1 These bits specify the fixed G or Y value generated in the RPFn when the virtual input function is enabled through the VI6_RPFn_INFMT.VIR setting. When VI6_RPFn_INFMT.RDFMT is set to 19, the value specified in these bits is used as the G value. When VI6_RPFn_INFMT.RDFMT is set to 64, the value specified in these bits is used as the Y value.	R/W
23:16	LAYR[7:0]	Virtual-Input Fixed R/Cr Component Value*1 These bits specify the fixed R or Cr value generated in the RPFn when the virtual input function is enabled through the VI6_RPFn_INFMT.VIR setting. When VI6_RPFn_INFMT.RDFMT is set to 19, the value specified in these bits is used as the R value. When VI6_RPFn_INFMT.RDFMT is set to 64, the value specified in these bits is used as the Cr value.	R/W
31:24	LAYA[7:0]	Virtual-Input Fixed α Value*1 These bits specify the fixed α value generated in the RPFn when the virtual input function is enabled through the VI6_RPFn_INFMT.VIR setting. When the virtual input function is disabled (VI6_RPFn_INFMT.VIR = 0), these bits are used to specify the fixed α value to be output from the RPF while VI6_RPFn_ALPH_SEL.ASEL are set to 4.	R/W

Note 1. A value from 0 to 255 can be specified.

54.4.6.8 VI6_RPFn_MSKCTRL : RPFn Mask Control Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x031C + 0x100 × n

Bit position:	31	30	29	28	27	26	25	24	23 to 16
Bit field:	—	—	—	—	—	—	—	MSK_EN	MGR[7:0]
Value after reset:	0	0	0	0	0	0	0	0	0 0 0 0 0 0 0 0

Bit position:	15 to 8	7 to 0
Bit field:	MGG[7:0]	MGB[7:0]
Value after reset:	0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
7:0	MGB[7:0]	B/Cb Comparison Value for 1-Bit α Generation*1 *2 These bits specify the B/Cb value to be compared for 1-bit α generation by using the pixel data on the destination side. When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify a B value for comparison. When YCbCr is specified, specify a Cb value for comparison.	R/W
15:8	MGG[7:0]	G/Y Comparison Value for 1-Bit α Generation*1 *2 These bits specify the G/Y value to be compared for 1-bit α generation by using the pixel data on the destination side. When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify a G value for comparison. When YCbCr is specified, specify a Y value for comparison.	R/W
23:16	MGR[7:0]	R/Cr Comparison Value for 1-Bit α Generation*1 *2 These bits specify the R/Cr value to be compared for 1-bit α generation by using the pixel data on the destination side. When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify an R value for comparison. When YCbCr is specified, specify a Cr value for comparison.	R/W
24	MSK_EN	Mask Generation Specification Specifies the method of α value generation in the 1-bit mask α generator shown in Figure 54.14. 0: A 1-bit mask value is generated according to the input α plane value. When the input α is in the 1-bit format (VI6_RPFn_ALPH_SEL.BSEL = 1), the 1-bit mask value is output without change. When the input α is in the 8-bit format (VI6_RPFn_ALPH_SEL.BSEL = 0), the 1-bit mask value is 0 if the α value is 0x00; otherwise, the 1-bit mask value is 1. 1: The R/Cr, G/Y, and B/Cb components of the image input to the destination side of the IROP operation unit are compared with the values specified in the MGR, MGG, and MGB bits, respectively. When all values match, 1 is output as the 1-bit mask value, and in other cases, 0 is output. When the generated 1-bit mask data is not used, set VI6_RPFn_ALPH_SEL.IROP to 0.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. This setting is ignored when MSK_EN is set to 0.
Note 2. A value from 0 to 255 can be specified.

54.4.6.9 VI6_RPFn_MSKSET0 : RPFn IROP-SRC Input Value Register 0 (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0320 + 0x100 × n

Bit position:	31								24	23							16	15							8	7							0
Bit field:	MSA0[7:0]									MSR0[7:0]								MSG0[7:0]								MSB0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	MSB0[7:0]	IROP-Source Input B/Cb Value when 1-Bit α is 0*1 These bits specify the B/Cb value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 0 (Figure 54.14). When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify a B component value. When YCbCr is specified, specify a Cb component value.	R/W
15:8	MSG0[7:0]	IROP-Source Input G/Y Value when 1-Bit α is 0*1 These bits specify the G/Y value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 0 (Figure 54.14). When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify a G component value. When YCbCr is specified, specify a Y component value.	R/W
23:16	MSR0[7:0]	IROP-Source Input R/Cr Value when 1-Bit α is 0*1 These bits specify the R/Cr value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 0 (Figure 54.14). When RGB is specified as the RPFn input format through VI6_RPFn_INFMT.RDFMT, specify an R component value. When YCbCr is specified, specify a Cr component value.	R/W

Bit	Symbol	Function	R/W
31:24	MSA0[7:0]	IROP-Source Input α Value when 1-Bit α is 0*1 These bits specify the 8-bit α value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 0 (Figure 54.14).	R/W

Note 1. A value from 0 to 255 can be specified.

54.4.6.10 VI6_RPFn_MSKSET1 : RPFn IROP-SRC Input Value Register 1 (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0324 + 0x100 × n

Bit position:	31								24	23							16	15							8	7							0
Bit field:	MSA1[7:0]									MSR1[7:0]								MSG1[7:0]								MSB1[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	MSB1[7:0]	IROP-Source Input B/Cb Value when 1-Bit α is 1*1 These bits specify the B/Cb value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 1 (Figure 54.14). When RGB is specified as the RPF1 input format through VI6_RPF1_INFMT.RDFMT, specify a B component value. When YCbCr is specified, specify a Cb component value.	R/W
15:8	MSG1[7:0]	IROP-Source Input G/Y Value when 1-Bit α is 1*1 These bits specify the G/Y value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 1 (Figure 54.14). When RGB is specified as the RPF1 input format through VI6_RPF1_INFMT.RDFMT, specify a G component value. When YCbCr is specified, specify a Y component value.	R/W
23:16	MSR1[7:0]	IROP-Source Input R/Cr Value when 1-Bit α is 1*1 These bits specify the R/Cr value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 1 (Figure 54.14). When RGB is specified as the RPF1 input format through VI6_RPF1_INFMT.RDFMT, specify an R component value. When YCbCr is specified, specify a Cr component value.	R/W
31:24	MSA1[7:0]	IROP-Source Input α Value when 1-Bit α is 1*1 These bits specify the 8-bit α value to be input as the source to the IROP operation unit when the internal 1-bit α value generated through the 1-bit mask generator is 1 (Figure 54.14).	R/W

Note 1. A value from 0 to 255 can be specified.

54.4.6.11 VI6_RPFn_CKEY_CTRL : RPFn Color Keying Control Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0328 + 0x100 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

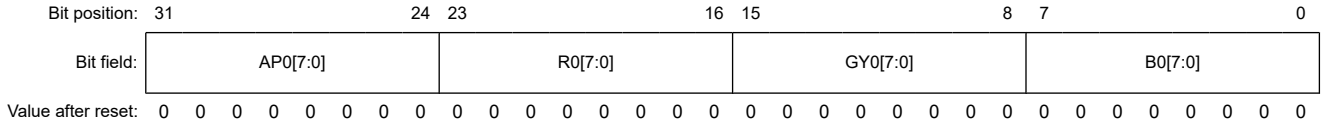
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	LTH	—	—	—	CV	—	—	SAPE 1	SAPE 0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SAPE0	Comparison Color Data Setting 0 Enable/Disable This bit enables or disables comparison color data setting 0 in the transparent color mode for the color keying module. This bit setting is valid only when the CV bit is set to 0; it is ignored when the CV bit is set to 1. In transparent color mode, color information 0 (VI6_RPFn_CKEY_SET0.R0/GY0/B0) specified in VI6_RPFn_CKEY_SET0 is compared with the input component values. When the input data is in an RGB format, and if all input values match the specified color information, the input α value is replaced with the value specified in VI6_RPFn_CKEY_SET0.AP. When the input data is in YCbCr format, only the Y data is compared. When using the virtual input function (VI6_RPFn_INFMT.VIR = 1), clear this bit to 0. 0: Comparison color data setting 0 is disabled. 1: Comparison color data setting 0 is enabled.	R/W
1	SAPE1	Comparison Color Data Setting 1 Enable/Disable This bit enables or disables comparison color data setting 1 in the transparent color mode for the color keying module. This bit setting is valid only when the CV bit is set to 0; it is ignored when the CV bit is set to 1. In transparent color mode, color information 1 (VI6_RPFn_CKEY_SET1.R1/GY1/B1) specified in VI6_RPFn_CKEY_SET1 is compared with the input component values. When the input data is in an RGB format, and if all input values match the specified color information, the input α value is replaced with the value specified in VI6_RPFn_CKEY_SET1.AP. When the input data is in YCbCr format, only the Y data is compared. When using the virtual input function (VI6_RPFn_INFMT.VIR = 1), set this bit to 0. 0: Comparison color data setting 1 is disabled. 1: Comparison color data setting 1 is enabled.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	CV	Color Replacement Control This bit controls the color replacement function in the color keying module shown in Figure 54.2. When an RGB format is specified as the color space of the RPFn input data through VI6_RPFn_INFMT.RDFMT, and if all components of an input pixel match the color components specified in VI6_RPFn_CKEY_SET0, the color replacement function replaces the values of the input α and all RGB components with the α and color components specified in VI6_RPFn_CKEY_SET1. When a YCbCr format is specified as the color space of the RPFn input data through VI6_RPFn_INFMT.RDFMT, only the Y data is compared; if the luminance component of an input pixel matches the value specified in VI6_RPFn_CKEY_SET0.GY0, the color replacement function replaces the values of the input α and all Y CbCr components with the α and color components specified in VI6_RPFn_CKEY_SET1. When the CV bit is set to 1, the color replacement function is enabled. When using the virtual input function (VI6_RPFn_INFMT.VIR = 1), set this bit to 0. 0: Color replacement function is disabled (transparent color mode). 1: Color replacement function is enabled.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	LTH	Transparent color-luma Threshold Mode Enable/Disable This bit enables or disables transparent color-luma threshold mode for the color keying module. In transparent color-luma threshold mode, color information 0 (GY0) specified in VI6_RPFn_CKEY_SET0 register is compared with the input luma values. When the input data is in YCbCr format, and if input Y value is equal to or smaller than specified color information (VI6_RPFn_CKEY _SET0.GY 0), the input α value is replaced with the value specified in VI6_RPFn_CKEY_SET0.AP0. This bit is available only when the input data is in YCbCr format. When the input data is in an RGB format, set this bit to 0. This bit setting is valid only when the CV bit is set to 0; it is ignored when the CV bit is set to 1. When using the virtual input function (VI6_RPFn_INFMT.VIR = 1), set this bit to 0. 0: Luma threshold mode is disabled (Matched color mode). 1: Luma threshold mode is enabled.	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

54.4.6.12 VI6_RPFn_CKEY_SET0 : RPFn Color Keying Color Setting Register 0 (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x032C + 0x100 × n



Bit	Symbol	Function	R/W
7:0	B0[7:0]	B[*1]/Cb Component Data in Color Keying Color Information-0[*2] ● In transparent color-matched color mode for color keying Specify the B component value for comparison enabled through the VI6_RPFn_CKEY_CTRL.SAPE0 setting. When the RPFn input is in YCbCr format, the color keying module does not compare the Cb component, and the setting of these bits is ignored. ● In transparent color-luma threshold mode for color keying The color keying module does not refer this bit field, and the setting of these bits is ignored. ● In color replacement mode for color keying Specify the B component value to be compared with the input data in the color replacement function of the color keying module.	R/W
15:8	GY0[7:0]	G[*1]/Y Component Data in Color Keying Color Information-0[*2] ● In transparent color-matched color mode for color keying Specify the G/Y component value for comparison enabled through the VI6_RPFn_CKEY_CTRL.SAPE0 setting. ● In transparent color-luma threshold mode for color keying Specify the Y component value in the GY0 to be compared. ● In color replacement mode for color keying Specify the G/Y component value to be compared with the input data in the color replacement function of the color keying module.	R/W
23:16	R0[7:0]	R[*1]/Cr Component Data in Color Keying Color Information-0[*2] ● In transparent color-matched color mode for color keying Specify the R component value for comparison enabled through the VI6_RPFn_CKEY_CTRL.SAPE0 setting. When the RPFn input is in YCbCr format, the color keying module does not compare the Cr component, and the setting of these bits is ignored. ● In transparent color-luma threshold mode for color keying The color keying module does not refer this bit field, and the setting of these bits is ignored. ● In color replacement mode for color keying Specify the R component value to be compared with the input data in the color replacement function of the color keying module.	R/W
31:24	AP0[7:0]	α Data in Color Keying Color Information-0[*2] ● In transparent color-matched color mode for color keying When the input data matches color setting-0 (R0, GY0, and B0) for transparent color comparison in the color keying module, the input α value is replaced with the value specified in these bits. Specify the α value to replace the input value. ● In transparent color-luma threshold mode for color keying When the input data is in YCbCr format, and if input Y value is equal to or smaller than GY 0, the input α value is replaced with the value specified in this bit field (AP0). Specify the α value in this bit field (AP0) to replace the input value. ● In color replacement mode for color keying These bits are not used in this mode. Clear them to 0. α value replacement through these bits in transparent color mode for color keying takes priority over the α value selected through the VI6_RPFn_ALPH_SEL.ASEL setting.	R/W

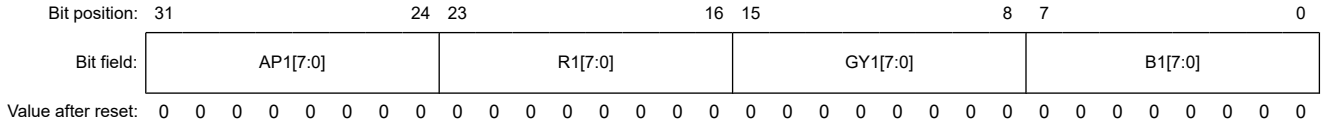
Note 1. When comparison data is specified in an RGB format, if a packed format is selected for RGB input and each of the RGB components is not 8 bits, the lower-order bits of input data are extended as specified through VI6_RPFn_INFMT.CEXT before comparison. The RGB components to be compared with the input should also be extended in the same way and the extended values should be specified in this register.

Note 2. A value from 0 to 255 can be specified.

54.4.6.13 VI6_RPFn_CKEY_SET1 : RPFn Color Keying Color Setting Register 1 (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0330 + 0x100 × n



Bit	Symbol	Function	R/W
7:0	B1[7:0]	B[*1]/Cb Component Data in Color Keying Color Information-1[*2] ● In transparent color-matched color mode for color keying Specify the B component value for comparison enabled through the VI6_RPFn_CKEY_CTRL.SAPE1 setting. When the RPFn input is in YCbCr format, the color keying module does not compare the Cb component, and the setting of these bits is ignored. ● In transparent color-luma threshold mode for color keying The color keying module does not refer this bit field, and the setting of these bits is ignored. ● In color replacement mode for color keying Specify the B component value to be compared with the input data in the color replacement function of the color keying module.	R/W
15:8	GY1[7:0]	G[*1]/Y Component Data in Color Keying Color Information-1[*2] ● In transparent color-matched color mode for color keying Specify the G/Y component value for comparison enabled through the VI6_RPFn_CKEY_CTRL.SAPE1 setting. ● In transparent color-luma threshold mode for color keying Specify the Y component value in the GY1 to be compared. ● In color replacement mode for color keying Specify the G/Y component value to be compared with the input data in the color replacement function of the color keying module.	R/W
23:16	R1[7:0]	R[*1]/Cr Component Data in Color Keying Color Information-1[*2] ● In transparent color-matched color mode for color keying Specify the R component value for comparison enabled through the VI6_RPFn_CKEY_CTRL.SAPE1 setting. When the RPFn input is in YCbCr format, the color keying module does not compare the Cr component, and the setting of these bits is ignored. ● In transparent color-luma threshold mode for color keying The color keying module does not refer this bit field, and the setting of these bits is ignored. ● In color replacement mode for color keying Specify the R component value to be compared with the input data in the color replacement function of the color keying module.	R/W
31:24	AP1[7:0]	α Data in Color Keying Color Information-1[*2] ● In transparent color-matched color mode for color keying When the input data matches color setting-1 (R1, GY1, and B1) for transparent color comparison in the color keying module, the input α value is replaced with the value specified in these bits. Specify the α value to replace the input value. ● In transparent color-luma threshold mode for color keying When the input data is in YCbCr format, and if input Y value is equal to or smaller than GY 0, the input α value is replaced with the value specified in this bit field (AP1). Specify the α value in this bit field (AP1) to replace the input value. ● In color replacement mode for color keying These bits are not used in this mode. Clear them to 0. α value replacement through these bits in transparent color mode for color keying takes priority over the α value selected through the VI6_RPFn_ALPH_SEL.ASEL setting.	R/W

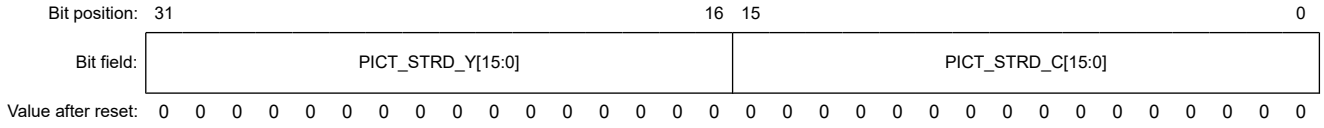
Note 1. When comparison data is specified in an RGB format, if a packed format is selected for RGB input and each of the RGB components is not 8 bits, the lower-order bits of input data are extended as specified through VI6_RPFn_INFMT.CEXT before comparison. The RGB components to be compared with the input should also be extended in the same way and the extended values should be specified in this register.

Note 2. A value from 0 to 255 can be specified.

54.4.6.14 VI6_RPFn_SRCM_PSTRIDE : RPFn Source Picture Memory Stride Setting Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0334 + 0x100 × n



Bit	Symbol	Function	R/W
15:0	PICT_STRD_C[15:0]	Memory Stride of Source Picture C Plane*1 For a YCbCr source picture read by the RPFn, these bits specify the memory stride of the C planes in byte units. Specifically, this setting is used as the memory stride of the Cb and Cr planes in a picture in a YCbCr planar format. When an RGB-format picture is read, these bits do not require setting.	R/W
31:16	PICT_STRD_Y[15:0]	Memory Stride of Source Picture Y/RGB Plane*1 For a Y/RGB plane of source picture read by the RPFn, these bits specify the memory stride in byte units.	R/W

Note 1. A value from 0 to 65535 can be specified. See Figure 54.15 for settings.

This register specifies the memory stride of the picture planes in the source area as shown in Figure 54.15. The memory stride of the α plane should be specified through VI6_RPFn_SRCM_ASTRIDE.ALPH_STRD. When the RPF input is in an RGB format, only the RGB plane is read; when the input is in YCbCr format, the Y and C planes are read as shown in Figure 54.15. When the α plane is used, the α plane is also read. According to the image format and the necessity of the α plane, specify the necessary addresses where the source image is stored (VI6_RPFn_SRCM_ADDR_Y, VI6_RPFn_SRCM_ADDR_C, and VI6_RPFn_SRCM_ADDR_AI).

Whether the α plane needs to be read is determined according to the α plane selection method and IROP operation type. For details, see section 54.4.6.6. VI6_RPFn_ALPH_SEL : RPFn α Plane Selection Control Register (n = 0, 1).

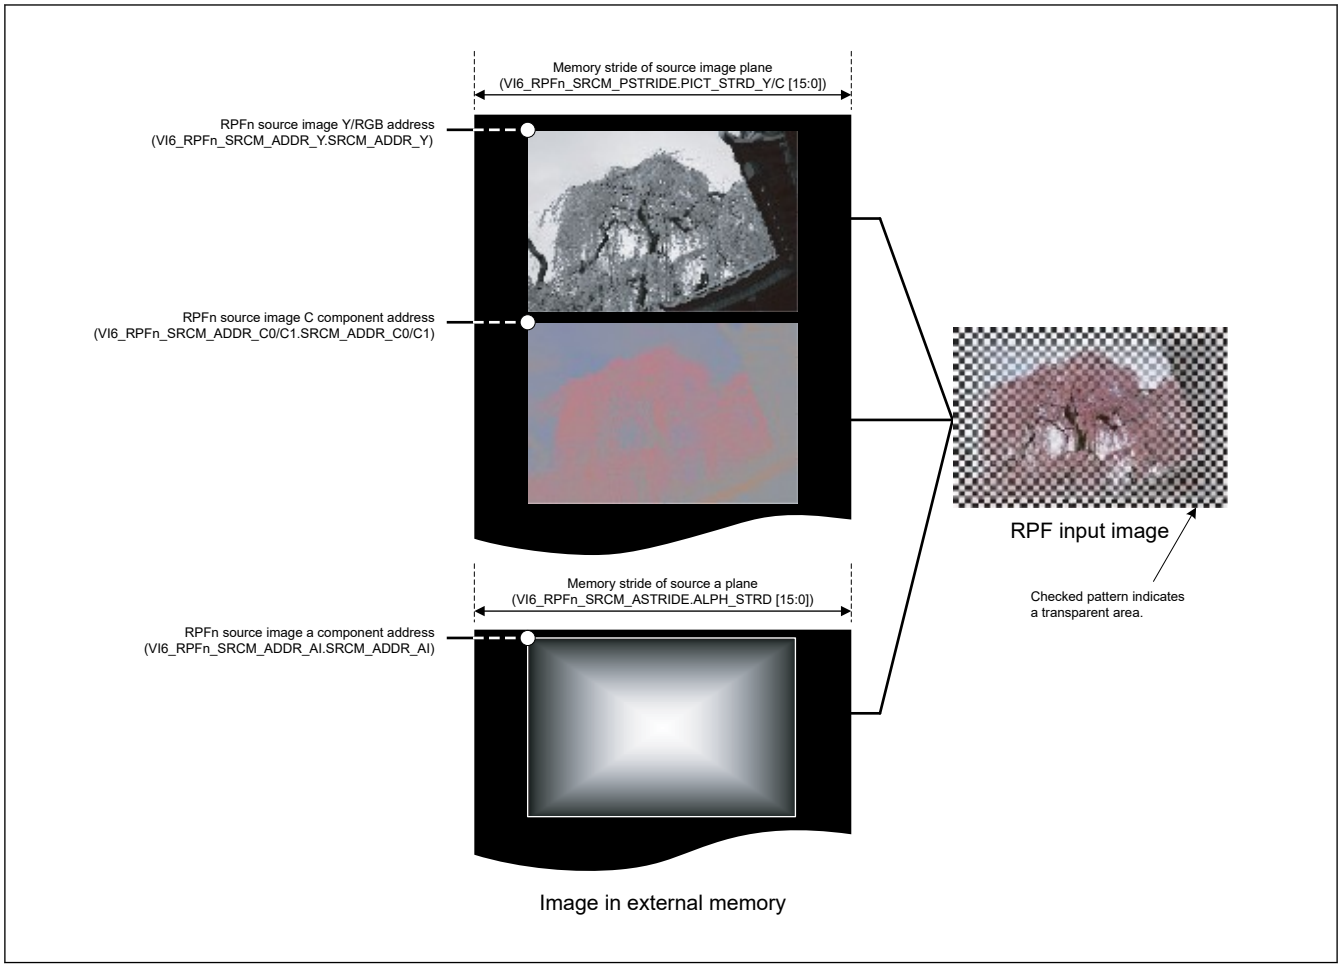


Figure 54.15 Reading an Image from RPFn Source Area

54.4.6.15 VI6_RPFn_SRCM_ASTRIDE : RPFn Source α Memory Stride Setting Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0338 + 0x100 × n

Bit position:	31																15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ALPH_STRD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ALPH_STRD[15:0]	Memory Stride of Source α Plane*1 For a source α plane read by the RPFn, these bits specify the memory stride in byte units.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. A value from 0 to 65535 can be specified. See Figure 54.15 for settings.

54.4.6.16 VI6_RPFn_SRCM_ADDR_Y : RPFn Source Y/RGB Address Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x033C + 0x100 × n

Bit position:	31																												0
Bit field:	SRCM_ADDR_Y[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SRCM_ADDR_Y[31:0]	Source Image Y/RGB Plane Storing Address*1 For a Y plane and packed RGB plane of source image read by the RPFn, these bits specify the start address in byte units.	R/W

Note 1. A value from 0x0000_0000 to 0xFFFF_FFFF can be specified. See Figure 54.15 in section 54.4.6.14. VI6_RPFn_SRCM_PSTRIDE : RPFn Source Picture Memory Stride Setting Register (n = 0, 1) for settings.

54.4.6.17 VI6_RPFn_SRCM_ADDR_C0 : RPFn Source Chroma Address Register 0 (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0340 + 0x100 × n

Bit position:	31																												0
Bit field:	SRCM_ADDR_C0[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SRCM_ADDR_C0[31:0]	Source Image C Plane Storing Address 0*1 For a C plane of source image read by the RPFn, these bits specify the start address in byte units. Here, the C plane indicates the combined CbCr plane when a semi-planar format is selected from the packed YCbCr formats shown in Figure 54.15 or the Cb plane when a planar format is selected. When an interleaved format is selected or the RPF input is in an RGB format, this setting is not used.	R/W

Note 1. A value from 0x0000_0000 to 0xFFFF_FFFF can be specified. See Figure 54.15 in section 54.4.6.14. VI6_RPFn_SRCM_PSTRIDE : RPFn Source Picture Memory Stride Setting Register (n = 0, 1) for settings.

54.4.6.18 VI6_RPFn_SRCM_ADDR_C1 : RPFn Source Chroma Address Register 1 (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0344 + 0x100 × n

Bit position:	31																												0
Bit field:	SRCM_ADDR_C1[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SRCM_ADDR_C1[31:0]	Source Image C Plane Storing Address 1*1 For a picture in one of the planar YCbCr formats shown in Figure 54.11 read by the RPFn, these bits specify the address where the Cr plane starts in byte units. This setting is not used when the RPF input is in a semi-planer or interleaved YCbCr format or in an RGB format.	R/W

Note 1. A value from 0x0000_0000 to 0xFFFF_FFFF can be specified. See Figure 54.15 in section 54.4.6.14. VI6_RPFn_SRCM_PSTRIDE : RPFn Source Picture Memory Stride Setting Register (n = 0, 1) for settings.

54.4.6.19 VI6_RPFn_SRCM_ADDR_AI : RPFn Source α Address Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0348 + 0x100 × n

Bit position:	31																												0
Bit field:	SRCM_ADDR_AI[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SRCM_ADDR_AI[31:0]	Source Image α Plane Storing Address*1 For an α plane of the source image read by the RPFn, these bits specify the start address in byte units. Specify these bits in the same way as the start address of the picture plane. When the α plane is not read from the source area, these bits do not need to be set.	R/W

Note 1. A value from 0x0000_0000 to 0xFFFF_FFFF can be specified. See Figure 54.15 in section 54.4.6.14. VI6_RPFn_SRCM_PSTRIDE : RPFn Source Picture Memory Stride Setting Register (n = 0, 1) for settings.

54.4.6.20 VI6_RPFn_BAC : RPFn Bus Access Control Register (n = 0, 1)

Base address: VSPD = 0x920E_0000

Offset address: 0x0350 + 0x100 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RPF0_ACT[1:0]	RPF0 Start Enable These bits enable start of RPFn as the source RPF for the WPF0 when the WPF0 is started. When RPF0 is not started by the WPF0, set the VI6_DPR_RPF0_ROUTE.RT_RPF0 bits to 63. 0 0: RPF0 is not started. 0 1: RPF0 is started as a sublayer source RPF for the WPF0. 1 0: RPF0 is started as the master-layer source RPF for the WPF0. 1 1: Setting prohibited.	R/W
3:2	RPF1_ACT[1:0]	RPF1 Start Enable These bits enable start of RPF1 as the source RPF for the WPF0 when the WPF0 is started. When RPF1 is not started by the WPF0, set the VI6_DPR_RPF1_ROUTE.RT_RPF1 bits to 63. 0 0: RPF1 is not started. 0 1: RPF1 is started as a sublayer source RPF for the WPF0. 1 0: RPF1 is started as the master-layer source RPF for the WPF0. 1 1: Setting prohibited.	R/W
23:4	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
25:24	VIR_ACT2[1:0]	Virtual RPF Start Enable in BRS These bits enable start of the virtual RPF in the BRS as the source RPF for the WPF0 when the WPF0 is started. For details of the virtual RPF, see the following. section 54.4.10.1. VI6_BRS_INCTRL : BRS Input Control Register section 54.4.10.2. VI6_BRS_VIRRPF_SIZE : Size Register of BRS Input Virtual RPF section 54.4.10.3. VI6_BRS_VIRRPF_LOC : Display Location Register of BRS Input Virtual RPF section 54.4.10.4. VI6_BRS_VIRRPF_COL : Color Information Register of BRS Input Virtual RPF Note that the virtual RPF is in the BRS as shown in Figure 54.28 and there are no register bits for DPR setting related to the virtual RPF. 0 0: The virtual RPF in the BRS is not started. 0 1: The virtual RPF in the BRS is started as a sublayer source RPF for the WPF0. 1 0: The virtual RPF in the BRS is started as the master-layer source RPF for the WPF0. 1 1: Setting prohibited.	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

When the WPFn is started through the VSPD start register n (VI6_CMDn: n = 0), the RPF and virtual RPF in the BRS specified as the source RPF in this register are also started to supply data to the VSPD internal modules.

Note the following when specifying the source RPF.

1. When blending or ROP operation is applied to multiple images through the BRS, multiple source RPFs are necessary for one WPF. When multiple source RPFs are used, images should be classified into a master layer and sublayers; assign one of the source RPFs as the master-layer source RPF and other RPFs as sublayer source RPFs. Do not assign all RPFs as sublayer source RPFs (VI6_WPF1_SRCRPF = 0x00000015) or two or more RPFs as the master-layer source RPF (VI6_WPF0_SRCRPF = 0x0000025A) (such settings are prohibited).
2. When the BRS is not used, there should be only one source RPF for one WPF. In this case, the source RPF should be assigned as the master-layer source RPF.

54.4.7.2 VI6_WPF0_HSZCLIP : WPF0 Horizontal Input Size Clipping Register

Base address: VSPD = 0x920E_0000

Offset address: 0x1004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	HCEN	—	—	—	—	HCL_OFST[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	HCL_SIZE[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	HCL_SIZE[12:0]	Horizontal Clipping Size Setting When the HCEN bit is 1, these bits specify the clipping size for horizontal clipping processing. Through this processing, the area of the horizontal size specified through the HCL_SIZE bits starting from the offset position specified through the HCL_OFST bits is determined as the valid image area. Accordingly, the right-side pixels beyond the (HCL_OFST + HCL_SIZE) size in the WPF0 input image are discarded. When the HCEN bit is 0, this setting is ignored. A value from 1 to 8190 can be specified. (HCL_OFST + HCL_SIZE) should not exceed the horizontal size of the WPF input. If the setting shown in the bottom example in Figure 54.16 is made, VSPD does not operate correctly. When the WPF0 output format is YCbCr4:2:2 or YCbCr4:2:0, specify an even value in these bits.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
23:16	HCL_OFST[7:0]	Horizontal Size Clipping Offset Value Setting These bits specify the offset size (pixels) from the left-end of the image in horizontal size clipping when the HCEN bit is 1 (Figure 54.16). The left-side of the image input to the WPF is cut off for the size specified in these bits. When the HCEN bit is 0, this setting is ignored. A value from 0 to 255 can be specified. (HCL_OFST + HCL_SIZE) should not exceed the horizontal size of the WPF input. If the setting shown in the bottom example in Figure 54.16 is made, VSPD does not operate correctly.	R/W
27:24	—	These bits are read as 0. The write value should be 0.	R/W
28	HCEN	Horizontal Size Clipping Enable/Disable Enables or disables clipping of the horizontal size of the WPF0 input image. 0: Horizontal size clipping is disabled. 1: Horizontal size clipping is enabled.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

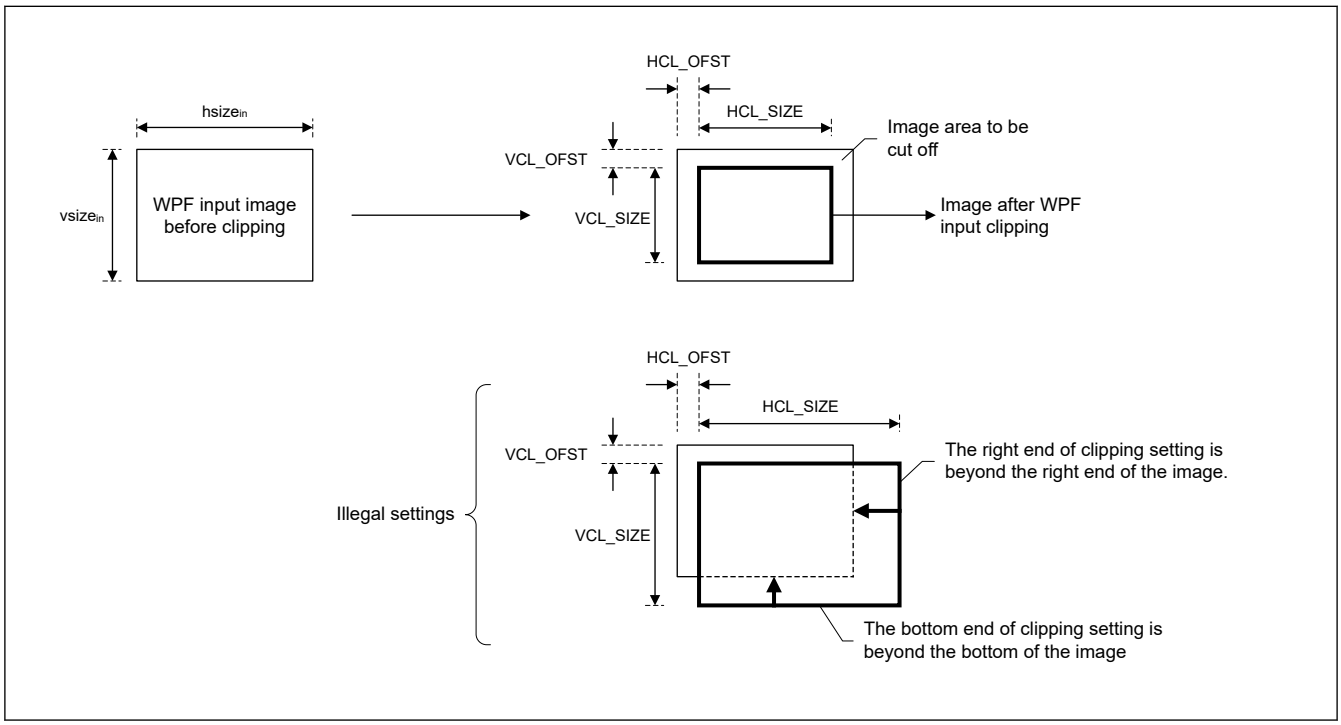

Figure 54.16 Image clipping in WPF input section

54.4.7.3 VI6_WPF0_VSZCLIP : WPF0 Vertical Input Size Clipping Register

Base address: VSPD = 0x920E_0000

Offset address: 0x1008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	VCEN	—	—	—	—	VCL_OFST[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	VCL_SIZE[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	VCL_SIZE[12:0]	Vertical Clipping Size Setting When the VCEN bit is 1, these bits specify the clipping size for vertical clipping processing. Through this processing, the area of the vertical size specified through the VCL_SIZE bits starting from the offset position specified through the VCL_OFST bits is determined as the valid image area. Accordingly, the bottom pixels beyond the (VCL_OFST + VCL_SIZE) size in the WPF0 input image are discarded. When the VCEN bit is 0, this setting is ignored. A value from 1 to 8190 can be specified. (VCL_OFST + VCL_SIZE) should not exceed the vertical size of the WPF input. If the setting shown in the bottom example in Figure 54.16 is made, VSPD does not operate correctly. When the WPF0 output format is YCbCr4:2:0, specify an even value in these bits.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
23:16	VCL_OFST[7:0]	Vertical Size Clipping Offset Value Setting These bits specify the offset size (pixels) from the top-end of the image in vertical size clipping when the VCEN bit is 1 (Figure 54.16). The top of the image input to the WPF is cut off for the size specified in these bits. When the VCEN bit is 0, this setting is ignored. A value from 0 to 255 can be specified. (VCL_OFST + VCL_SIZE) should not exceed the vertical size of the WPF input. If the setting shown in the bottom example in Figure 54.16 is made, VSPD does not operate correctly.	R/W
27:24	—	These bits are read as 0. The write value should be 0.	R/W
28	VCEN	Vertical Size Clipping Enable/Disable Enables or disables clipping of the vertical size of the WPF0 input image. 0: Vertical size clipping is disabled. 1: Vertical size clipping is enabled.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

54.4.7.4 VI6_WPF0_OUTFMT : WPF0 Output Format Register

Base address: VSPD = 0x920E_0000

Offset address: 0x100C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PDV[7:0]								PXA	ODE	—	—	—	ROT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SPYCS	SPUVS	DITH[1:0]		WRTM[2:0]			CSC	—	WRFMT[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	WRFMT[6:0]	WPF Output Image Format Setting*1 *2 *3 These bits select the format of the image output from the WPF0 to the external memory from among those listed in Table 54.25 and Table 54.26.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	CSC	Color Space Conversion Setting Enables or disables Y CbCr ↔ RGB color space conversion to be executed in the WPF0. The characteristics of color space conversion are determined by the WRTM setting. There are some points to be noted about the relationship between the CSC setting and output format (WRFMT). For details, see (*2) in section 54.4.6.3. VI6_RPFn_INFMT : RPFn Input Format Register (n = 0, 1). 0: Color space is not converted. 1: Color space is converted.	R/W

Bit	Symbol	Function	R/W
11:9	WRTM[2:0]	CSC Conversion Expression Setting These bits select the expression for color space conversion. The conversion direction is RGB to YCbCr when the format specified in the WRFMT bits is RGB, or YCbCr to RGB when the format is YCbCr. 0 0 0: BT.601 Y CbCr [16,235/240] ↔ RGB [0,255] 0 0 1: BT.601 Y CbCr [0,255] ↔ RGB [0,255] 0 1 0: BT.709 Y CbCr [16,235/240] ↔ RGB [0,255] 0 1 1: BT.709 Y CbCr [16,235/240] ↔ RGB [16,235] Others: Setting prohibited.	R/W
13:12	DITH[1:0]	Ordered Dither (mode B) Enable/Disable When the output format specified through the WRFMT bits is RGB with 18 bpp (260000 colors) or less, the color reduction processing is applied to match the number of colors. The color reduction processing may generate the artifacts of pseudo gradation, which can be suppressed through dithering. The DITH bits enable or disable dithering during color reduction. When the output format specified through the WRFMT bits is YCbCr, set these bits to 0. And when VI6_WPF0_OUTFMT.CSC is set to 1, set these bits to 0 even in the case that the output format specified through the WRFMT bits is RGB. When ODE bit in the register is 1, set these bits to 0. 0 0: Dithering (mode B) is disabled. 1 1: Dithering (mode B) is enabled. Others: Setting prohibited.	R/W
14	SPUVS	WPF Output Mode Setting 2 When the output format is NV61, set this bit to 1 and set the WRFMT bits to 65 (0x41). When the output format is NV21, set this bit to 1 and set the WRFMT bits to 66 (0x42). When the output format is YVYU, set this bit and the SPYCS bit to 1 and set the WRFMT bits to 71 (0x47). In other cases, set this bit to 0.	R/W
15	SPYCS	WPF Output Mode Setting 1 When the output format is YUY2, set this bit to 1 and set the WRFMT bits to 71 (0x47). When the output format is YVYU, set this bit and the SPUVS bit to 1 and set the WRFMT bits to 71 (0x47). In other cases, set this bit to 0.	R/W
18:16	ROT[2:0]	Rotation Processing Select These bits select the flipping processing to be applied to the WPF0 output image. Figure 54.18 shows the correspondence between the original image and the flipping result according to each setting. Note that the destination address setting should be changed according to the setting of these bits. For details, see section 54.4.7.9. VI6_WPF0_DSTM_ADDR_Y : WPF0 Destination Y/RGB Address Register. When the LIF module is used (VI6_LIF_CTRL.LIF_EN = 1), set ROT[2:0] to 0. 0: No flipping 1: Vertical flipping	R/W
21:19	—	These bits are read as 0. The write value should be 0.	R/W
22	ODE	Ordered Dither (mode A) Enable/Disable When the output format specified through the WRFMT bits is YCbCr, set this bit to 0. And when VI6_WPF0_OUTFMT.CSC is set to 1, set this bit to 0 even in the case that the output format specified through the WRFMT bits is RGB. Ordered dither is available only for 18 bpp. So, when ODE bit is equal to 1, set WRFMT at 18 bpp format. When ODE bit is equal to 0, WPF dither method is specified by DITH[1:0] in the register. Ordered dither (mode A) is recommended rather than ordered dither (mode B) in case of 18 bpp. 0: Ordered dither (mode A) is disabled. 1: Ordered dither (mode A) is enabled.	R/W

Bit	Symbol	Function	R/W
23	PXA	PAD Data Select Selects the value to be stored in the bit field indicated as PAD or P in the packed RGB output formats shown in Table 54.26. Both the value specified in the PDV bits and the α data input from the DPR to WPF are 8 bits, but some of the PAD and P bit fields shown in Table 54.25 are four bits or one bit. When the target bit field is not 8 bits, the number of bits in the PDV value and the α data input from the DPR to WPF is reduced according to the VI6_WPF0_RNDCTRL.ABRM setting. For bit count reduction, see Figure 54.17 and the description of VI6_WPF0_RNDCTRL.ABRM. 0: The value specified in the PDV bits is stored in the PAD shown in Table 54.25. 1: The α value output from DPR in pixel units is stored in the PAD shown in Table 54.25.	R/W
31:24	PDV[7:0]	PAD Value in Output Packed Data*4 These bits specify the value to be stored in the bit field indicated as PAD or P in the output formats shown in Table 54.25. To store this value in PAD, set the PXA bit to 0.	R/W

Note 1. Number of output pixels
When YCbCr4:2:2 is specified through WRFMT, the horizontal size of the output image should be a multiple of 2 pixels. When YCbCr4:2:0 is specified, the vertical and horizontal sizes of the output image should be multiples of 2 pixels. Specify an appropriate data flow of the source RPF® DPR® target WPF so that the size of the image input to the target WPF satisfies the above restrictions. In particular, when the data flow includes a module or a function that modifies (up-scales, down-scales, or clips) the image size, take special care about the module or function settings.

Note 2. Output lines in YCbCr4:2:0
In the YCbCr4:2:0 output format, the number of chrominance lines in the vertical direction is one-half the number of luminance lines. For this reason, the WPF outputs only even-numbered chrominance lines (lines 0, 2, 4, 6, ...) (conversion from (A) to (B) in Figure 54.19). When vertical flipping is also specified through the ROT bits, the flipping processing is executed last and the chrominance line locations are inverted (lines 1, 3, 5, 7, …) in the output image ((C) in Figure 54.19).

Note 3. Down sampling of CbCr in horizontal direction in YCbCr4:2:0 or YCbCr4:2:2
In the YCbCr4:2:2 or YCbCr4:2:0 output format, method of down sample of Cb/Cr in horizontal direction is average of neighbor two pixels.

Note 4. A value from 0 to 255 can be specified.

Table 54.26 Packed YCbCr formats for WPF output

WRFMT[6:0]	Packed YCbCr output format	Reference
0x40	YCbCr4:4:4 semi-planar	Figure 54.9*4
0x41	YCbCr4:2:2 semi-planar (NV16, NV61*1)	
0x42	YCbCr4:2:0 semi-planar (NV12, NV21*1)	
0x43 to 0x45	Reserved	—
0x46	YCbCr4:4:4 interleaved	Figure 54.10*4
0x47	YCbCr4:2:2 interleaved type 0 (UYVY, YUY2*2, YVYU*3)	
0x48	YCbCr4:2:2 interleaved type 1	
0x49	YCbCr4:2:0 interleaved*5	
0x4A	YCbCr4:4:4 planar	Figure 54.11*4
0x4B	YCbCr4:2:2 planar (YV16)	
0x4C	YCbCr4:2:0 planar (YV12, I420)	
0x4D to 0x7F	Reserved	—

Note 1. When the output format is NV61 or NV21, set SPUVS (bit 14) to 1.
Note 2. When the output format is YUY2, set SPYCS (bit 15) to 1.
Note 3. When the output format is YVYU, set SPUVS (bit 14) to 1 and SPYCS (bit 15) to 1.
Note 4. Figure 54.12 shows the definition of memory address for each pixel in Figure 54.9 to Figure 54.11.
Note 5. Each line of plane is written twice, so byte/pixel of YCbCr420ITL is 3 byte/pixel (same as YCbCr444ITL).

For details of each YCbCr format, see Figure 54.9 to Figure 54.12. In these figures, registers for the RPF are indicated; read them as registers for the WPF as follows.

(RPF registers in the figures)	→	(Corresponding WPF registers)
VI6_RPFn_SRCM_ADDR_Y.SRCM_ADDR_Y	→	VI6_WPFn_DSTM_ADDR_Y.DSTM_ADDR_Y
VI6_RPFn_SRCM_ADDR_C0.SRCM_ADDR_C0	→	VI6_WPFn_DSTM_ADDR_C0.DSTM_ADDR_C0
VI6_RPFn_SRCM_ADDR_C1.SRCM_ADDR_C1	→	VI6_WPFn_DSTM_ADDR_C1.DSTM_ADDR_C1

54.4.7.5 VI6_WPF0_DSWAP : WPF0 Data Swapping Register

Base address: VSPD = 0x920E_0000

Offset address: 0x1010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	P_LLS	P_LWS	P_WDS	P_BTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	P_BTS	WPF Output Data Swapping in Byte Units*1 0: Data swapping in byte (8-bit) units is disabled. 1: Data swapping in byte (8-bit) units is enabled.	R/W
1	P_WDS	WPF Output Data Swapping in Word Units*1 0: Data swapping in word (16-bit) units is disabled. 1: Data swapping in word (16-bit) units is enabled.	R/W
2	P_LWS	WPF Output Data Swapping in long word Units*1 0: Data swapping in long word (32-bit) units is disabled. 1: Data swapping in long word (32-bit) units is enabled.	R/W

Bit	Symbol	Function	R/W
3	P_LLS	WPF Output Data Swapping in LONG LWORD Units*1 0: Data swapping in LONG LWORD (64-bit) units is disabled. 1: Data swapping in LONG LWORD (64-bit) units is enabled.	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The effect of this bit setting is the same as data swapping in the RPF; see Table 54.20.

Table 54.20 shows the data order before and after swapping according to the long long word, long word, word, and byte swapping settings.

When data order in memory for each format is the same as in Table 54.25 for RGB format and Figure 54.9 to Figure 54.12 for YCbCr format, set 1111b to {*_LLS, *_LWS, *_WDS, *_BTS}. If data order is not the same as the definition, change data order within 16-byte unit by these bits as shown in Table 54.20.

54.4.7.6 VI6_WPF0_RNDCTRL : WPF0 Rounding Control Register

Base address: VSPD = 0x920E_0000

Offset address: 0x1014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	CBRM	—	—	ABRM[1:0]		ATHRESH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CLMD[1:0]		—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	—	These bits are read as 0. The write value should be 0.	R/W
13:12	CLMD[1:0]	Color Data Clipping These bits specify the method for clipping the YCbCr color data output from the WPF. When RGB color data is output from the WPF, set these bits to 0. 0 0: Output value is not clipped (0-255) 0 1: Output value is clipped: YCbCr mode 1 (16-235 (Y), 16-240 (Cb/Cr)) 1 0: Output value is clipped: YCbCr mode 2 (Y/Cb/Cr = 1-254) 1 1: Setting prohibited.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
23:16	ATHRESH[7:0]	Threshold for Conversion to 1-Bit α Data*1 These bits specify the threshold value used for conversion from 8-bit α data to one bit when the ABRM bits are set to 10b. When the 8-bit α value before bit count reduction is equal to or smaller than the ATHRESH value, 0 is stored as the reduced 1-bit α data. In other cases, 1 is stored as the 1-bit α data.	R/W
25:24	ABRM[1:0]	Bit Count Reduction Method Selection for Data Storage in PAD These bits specify the method for reducing the number of bits when the data selected through VI6_WPF0_OUTFMT.PXA is stored in the bit fields indicated as PAD or P in Table 54.25 and the target bit field is four bits or one bit. A value of 10b can be specified only when the packed RGB format specified through VI6_WPF0_OUTFMT.WRFMT includes a 1-bit P field. In this case, when the data selected through VI6_WPF0_OUTFMT.PXA is greater than the ATHRESH value, 1 is stored in the P field; when the selected data is not greater than the ATHRESH value, 0 is stored. 0 0: Bit count conversion: The lower-order bits are truncated. 0 1: Bit count conversion: Rounding (rounding off) 1 0: Bit count conversion: Comparison with the threshold value (this setting is allowed only when the storage field is one bit) 1 1: Setting prohibited.	R/W
27:26	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
28	CBRM	Bit Count Reduction Method Selection for Data Storage in Packed RGB This bit specifies the method for reducing the number of bits when data is stored in the bit fields indicated as R, G, and B in Table 54.25 and the target bit fields are not 8 bits. 0: Bit count conversion: The lower-order bits are truncated. 1: Bit count conversion: Rounding (rounding off)	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. A value from 0 to 255 can be specified.

54.4.7.7 VI6_WPF0_DSTM_STRIDE_Y : WPF0 Destination Y Plane Memory Stride Register

Base address: VSPD = 0x920E_0000

Offset address: 0x101C

Bit position:	31															15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PICT_STRD_Y[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PICT_STRD_Y[15:0]	Memory Stride of Destination Picture Y/RGB Plane*1 For a destination picture in the external memory to be written to by the WPF0, these bits specify the memory stride in byte units as shown in Figure 54.20.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. A value from 0x0000 to 0xFFFF can be specified.

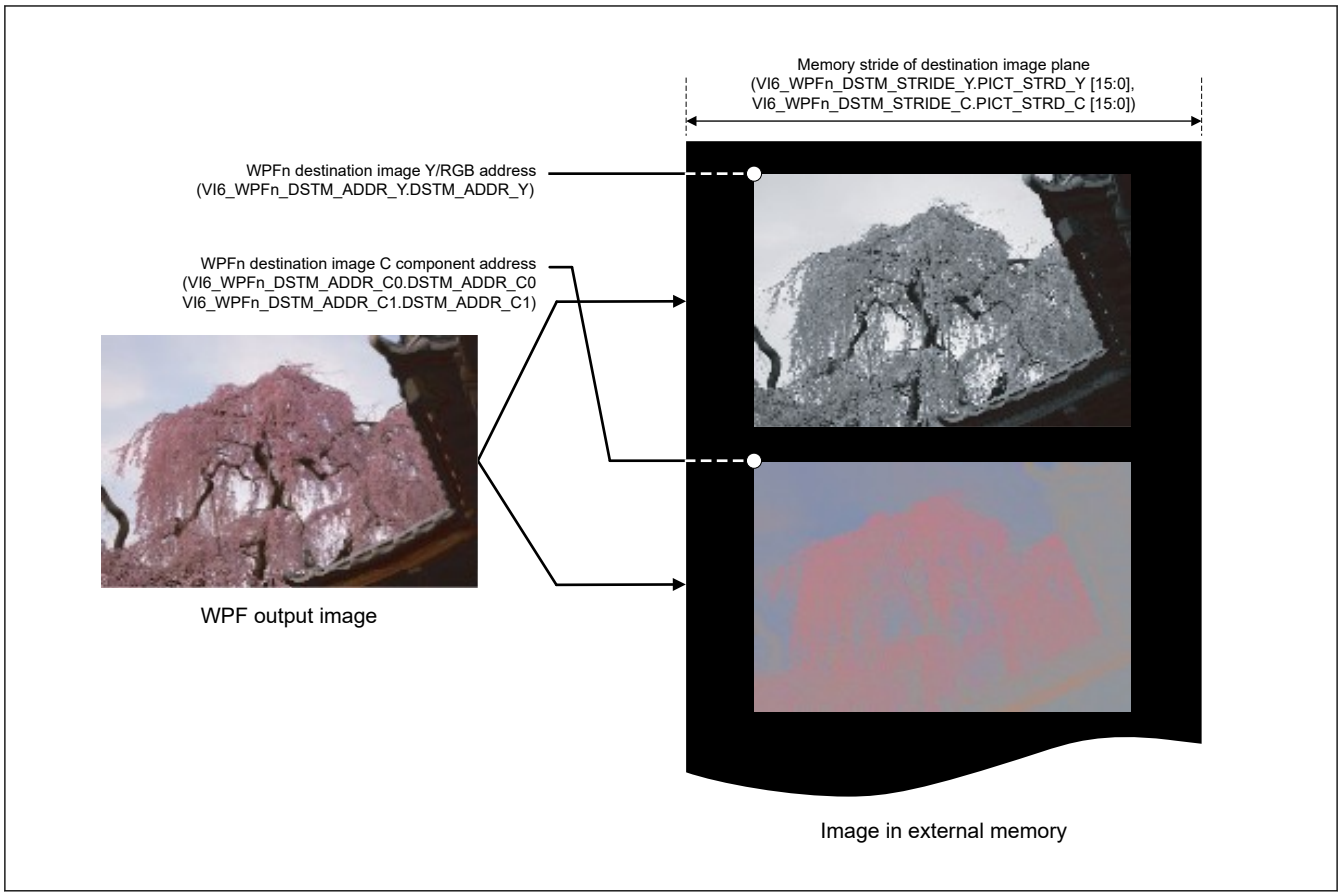

Figure 54.20 Writing image data to destination area in WPFn

54.4.7.8 VI6_WPF0_DSTM_STRIDE_C : WPF0 Destination C Plane Memory Stride Register

Base address: VSPD = 0x920E_0000

Offset address: 0x1020

Bit position:	31															15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PICT_STRD_C[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	PICT_STRD_C[15:0]	Memory Stride of Destination Picture C Plane*1 For a C plane of the destination picture in the external memory to be written to by the WPF0, these bits specify the memory stride in byte units as shown in Figure 54.20. When the WPF0 outputs images in an RGB format, this setting is not used. When the WPF0 outputs images in YCbCr planar format, this setting is applied to both the Cb and Cr planes.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. A value from 0x0000 to 0xFFFF can be specified.

54.4.7.9 VI6_WPF0_DSTM_ADDR_Y : WPF0 Destination Y/RGB Address Register

Base address: VSPD = 0x920E_0000

Offset address: 0x1024

Bit position:	31																													0
Bit field:	DSTM_ADDR_Y[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DSTM_ADDR_Y[31:0]	Destination Image Y/RGB Plane Storing Address*1 For storing a Y plane or packed RGB plane of destination-image to be written to by the WPF0, these bits specify the address in byte units in the method described later.	R/W

Note 1. A value from 0x0000 0000 to 0xFFFF FFFF can be specified.

[Destination Address Specification Method]

When flipping is not used, the start address of a frame (address FHA shown in Figure 54.21) should be specified as the destination address. When flipping is used, the destination address is not the frame start address (FHA); one of addresses A0 and A2 shown in Figure 54.21 should be selected according to the combination of desired flipping (VI6_WPFn_OUTFMT.ROT setting).

To strictly define locations A0 and A2, let the horizontal size of the output image be H, the vertical size of the output image be V, and the memory stride (VI6_WPFn_DSTM_STRIDE_Y/C setting) be S as shown in Figure 54.21. Calculate the destination address (one of A0 and A2) using the formula shown in Table 54.27 and specify it in the destination address storing register.

The values of variables L in Table 54.27 depend on the other register settings and luminance and chrominance components. These values should be obtained by Table 54.28 when calculating the address to be specified in VI6_WPFn_DSTM_ADDR_Y, or Table 54.29 when calculating the address to be specified in VI6_WPFn_DSTM_ADDR_C0 or VI6_WPFn_DSTM_ADDR_C1.

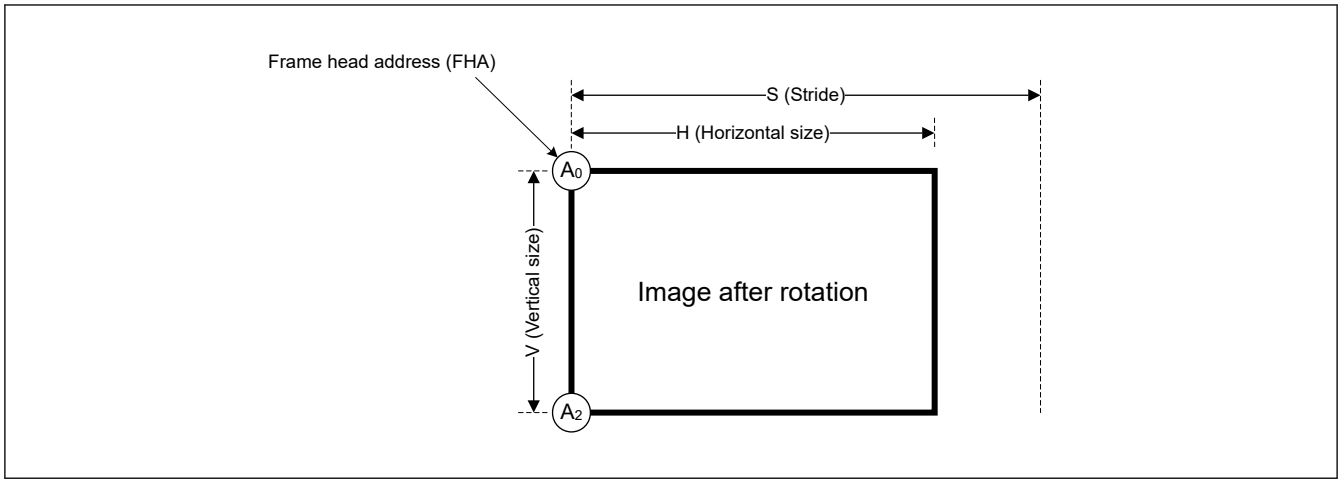

Figure 54.21 Location of destination address to be specified for flipping

Table 54.27 Destination address A0, A1, A2, and A3 calculation formulas

VI6_WPFn_OUTFMT.ROT setting	Formula for calculating address to be set in VI6_WPFn_DSTM_ADDR_Y, VI6_WPFn_DSTM_ADDR_C0, and VI6_WPFn_DSTM_ADDR_C1
0	A0 = FHA
1	A2 = FHA + (V × L − 1) × S

Table 54.28 Value of L according to VI6_WPFn_OUTFMT.WRFMT setting (for RGB and Luminance Y address calculation)

VI6_WPFn_OUTFMT.WRFMT	L
73	0.5
0 to 2, 4 to 35, 64 to 66, 70 to 72, or 74 to 76	1

Table 54.29 Value of L according to VI6_WPFn_OUTFMT.WRFMT setting (for Chrominance C0 and C1 address calculation)

VI6_WPFn_OUTFMT.WRFMT	L
70 to 73	Not defined
66, 76	0.5
64 to 65, 74 to 75	1

54.4.7.10 VI6_WPF0_DSTM_ADDR_C0 : WPF0 Destination Chroma Address Register 0

Base address: VSPD = 0x920E_0000

Offset address: 0x1028

Bit position:	31																												0
Bit field:	DSTM_ADDR_C0[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DSTM_ADDR_C0[31:0]	Destination Image C Plane Storing Address 0*1 For storing a C plane of destination-image to be written to by the WPF0, these bits specify the address in byte units. See the description of VI6_WPF0_DSTM_ADDR_Y for settings. Here, the C plane indicates the combined CbCr plane when a semi-planar format is selected from the packed YCbCr formats shown in Table 54.26 or the Cb plane when a planar format is selected. When an interleaved format is selected or the output is in an RGB format, this setting is not used.	R/W

Note 1. A value from 0x0000 0000 to 0xFFFF FFFF can be specified. See Figure 54.21 in section 54.4.7.9. VI6_WPF0_DSTM_ADDR_Y : WPF0 Destination Y/RGB Address Register for settings.

54.4.7.11 VI6_WPF0_DSTM_ADDR_C1 : WPF0 Destination Chroma Address Register 1

Base address: VSPD = 0x920E_0000

Offset address: 0x102C

Bit position:	31																												0
Bit field:	DSTM_ADDR_C1[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DSTM_ADDR_C1[31:0]	Destination Image C Plane Storing Address 1*1 For storing the Cr plane, these bits specify the address in byte units when the WPF0 outputs images to the external memory in YCbCr planar format shown in Table 54.26. See the description of VI6_WPF0_DSTM_ADDR_Y for settings. This setting is not used when the WPF outputs in YCbCr format that is not a planar format or in an RGB format.	R/W

Note 1. A value from 0x0000 0000 to 0xFFFF FFFF can be specified. See Figure 54.21 in section 54.4.7.9. VI6_WPF0_DSTM_ADDR_Y : WPF0 Destination Y/RGB Address Register for settings.

54.4.7.12 VI6_WPF0_WRBCK_CTRL : WPF0 LIF Write Back Control Register

Base address: VSPD = 0x920E_0000

Offset address: 0x1034

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WBMD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	WBMD[1:0]	Display Data Write Back Control These bits are used for selecting the write back mode when the value of VI6_LIF0_CTRL.LIF_EN bit is set to 1. 0: Write Back Disabled. 1: Write Back Enabled.	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

54.4.8 DPR Control Registers

54.4.8.1 Concept of DPR Settings

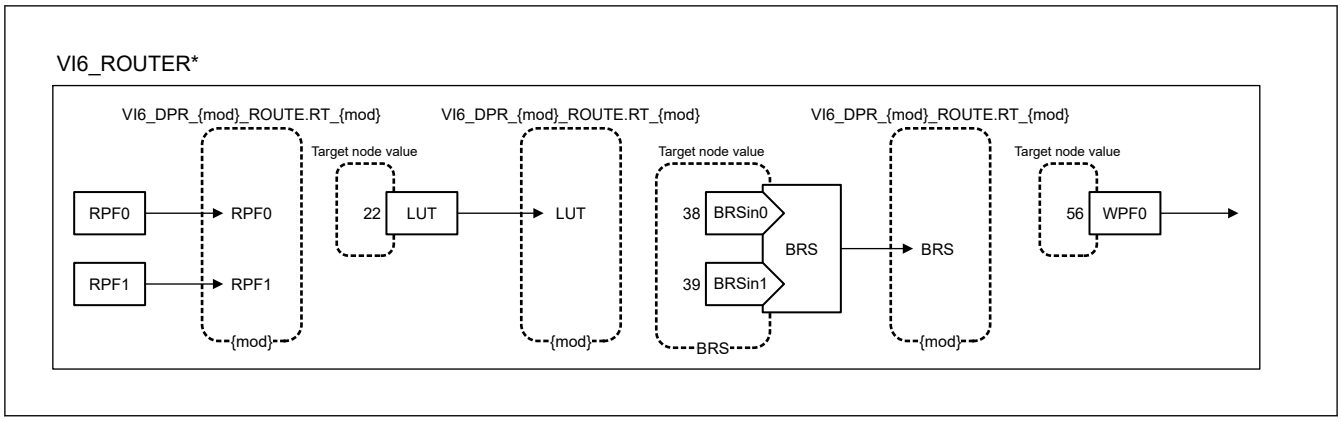

Figure 54.22 Node register names and target node values on data path router

In the VSPD internal data path, the order of processes can be specified as desired. The module for performing each process has a unique node value. Set each bit field in VI6_DPR_*_ROUTE to an appropriate node value shown in Figure 54.22 to specify the target node to be connected behind each module.

For DPR settings, all of the following restrictions should be observed. If any of them is violated, even the WPF paths operating correctly at that time will be affected as well as the WPF paths connected through the DPR, and correct operation will not be guaranteed.

1. Specify 63 for the output node values of all RPFs and processing modules that are not used in the DPR. Here, make sure that no module is connected to a module for which 63 is specified as the node value.
   Note: VI6_DPR_{mod}_ROUTE.RT are not implemented in VSPD which does not have {mod}. See Figure 54.1 whether VSPD has {mod} or not.
2. When specifying a value other than 63 for an output node value in the DPR, make sure that valid inputs (RPF0 to RPF1 or virtual RPF) and a target WPF are determined.
3. Only one module can be connected to each module; specifying the same target node value for two or more modules is prohibited.
4. Desired modules can be connected between each RPF and BRS input port, but all RPFs specified as the sources for a BRS input port should have the same target WPF.
5. Make appropriate routing or RPF register settings so that the color space formats (RGB/YCbCr) for all BRS input ports are the same.
6. Do not connect the output of any module as the input to the same module (in the BRS case, any input port) even when there is another module between the output and input (creating a loop is prohibited).
7. Each node can be used only once throughout all paths from RPFn to WPFn. When a module shown in Figure 54.22 is assigned in one RPF to WPF path, it cannot be used in another RPF to WPF path.
8. While a WPF is operating, modifying the DPR connection settings in VI6_DPR_*_ROUTE is prohibited for modules used by the WPF but allowed for modules not used by the WPF. Be careful not to accidentally modify the settings of the modules included in the WPF path that is operating.
9. Be careful to do the following setting when BRS is used.
   VI6_DPR_BRS_ROUTE.BRSSEL = 1

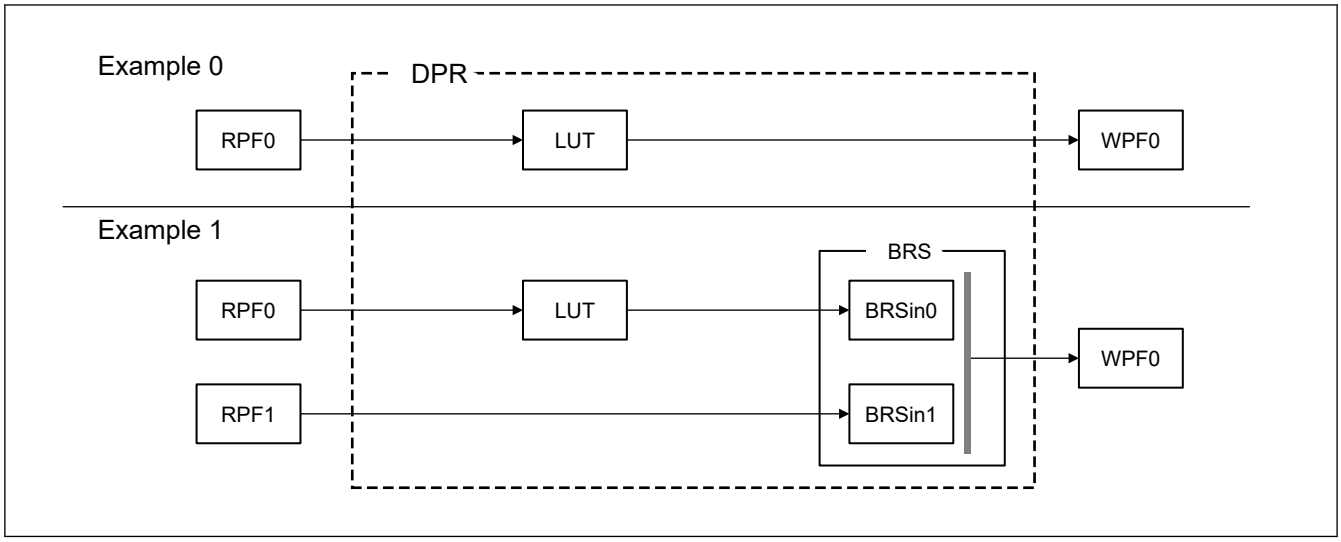

Figure 54.23 Examples of internal data path routing

Figure 54.23 shows examples of internal data path routing. Example 0 is WPF0 processing (RPF0 is the source RPF), and example 1 is also WPF0 (RPF0 to RPF1 are the source RPFs). Each example has the configuration shown in Figure 54.23. Example 0 performs LUT (e.g. γ correction) processing. Example 1 performs LUT processing (e.g. γ correction), for input 0 (RPF0) and then applies blending or raster operation between the resultant data and input data 1 (RPF1). The VI6_DPR_*_ROUTE settings for these examples are shown in Table 54.30. The bit fields for the modules that are not used in the examples should be set to 63.

Table 54.30 VI6_DPR_*_ROUTE Register Settings in Connection Examples Shown in Figure 54.23. Although both examples show in Figure 54.23 include operation in image processing modules, connect the RPF to the WPF directly when only image format conversion or packed format conversion is required.

Table 54.30 Examples of internal data path routing

	Register name	Setting	
Example 0	VI6_DPR_RPF0_ROUTE.RT_RPF0	22	(To LUT)
	VI6_DPR_RPF1_ROUTE.RT_RPF1	63	(UNUSED)
	VI6_DPR_LUT_ROUTE.RT	56	(To WPF0)
	VI6_DPR_BRS_ROUTE.RT	63	(UNUSED)

Bit	Symbol	Function	R/W
5:0	RT[5:0]	BRS Target Node Value These bits specify the target node value for the BRS. When using the BRS, see Figure 54.22 for settings. When not using the BRS, set these bits to 63.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
13:8	FP[5:0]	BRS Internal Operation Timing Setting Set these bits to 0.	R/W
27:14	—	These bits are read as 0. The write value should be 0.	R/W
28	BRSSEL	Always set this bit to 1.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

54.4.9 LUT Control Register

54.4.9.1 VI6_LUT_CTRL : LUT Control Register

Base address: VSPD = 0x920E_0000

Offset address: 0x2800

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LUT_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LUT_EN	1D-LUT Enable/Disable Enables or disables the 1D-LUT function by the LUT. When the 1D-LUT is used, the color component curve information needs to be set separately in the LUT table. For the LUT table settings, see section 54.6.6.1. LUT. 0: 1D-LUT function is disabled. 1: 1D-LUT function is enabled.	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

In the LUT, various image processing, such as curves with high operation load (e.g., γ correction), negative-positive conversion, and gain adjustment of images, can be achieved by the data replacement processing by the 1D-LUT. As shown in Figure 54.24, the LUT replaces each component of the input pixel data using the set replacement table of 256 entries. For example, if the LUT is set as in Figure 54.25, when there is an input of 150, the data stored in address 150 of the 1D-LUT is read and output as the LUT output. Figure 54.25 shows a case in which the input and output become equal for convenience in explaining.

In the LUT settings shown in Figure 54.26, the input bits are reversed. This has the effect of negative-positive flipping. In Figure 54.27, γ correction (γ = 1.8 is shown as an example) is possible. As described above, information to be set in the LUT indicates LUT processing characteristics. If the same value is set for each component in the LUT, an equal effect can be obtained for each component of the input image when it is processed. If the LUT is set with different characteristics for each component, the processing characteristics can be changed for each component.

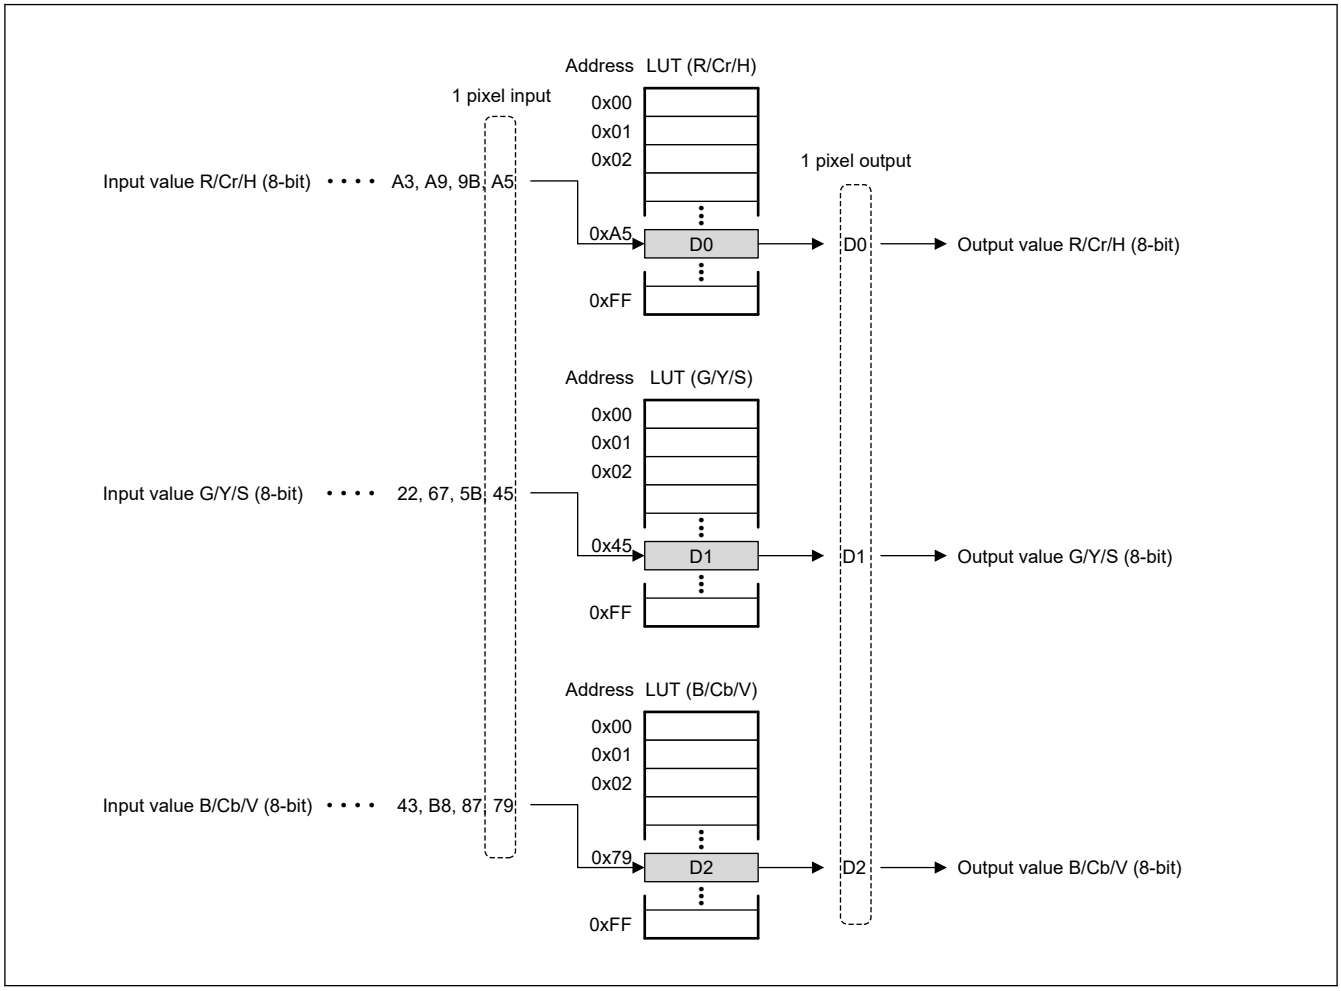

Figure 54.24 Relationship between input and output for 1D-LUT table

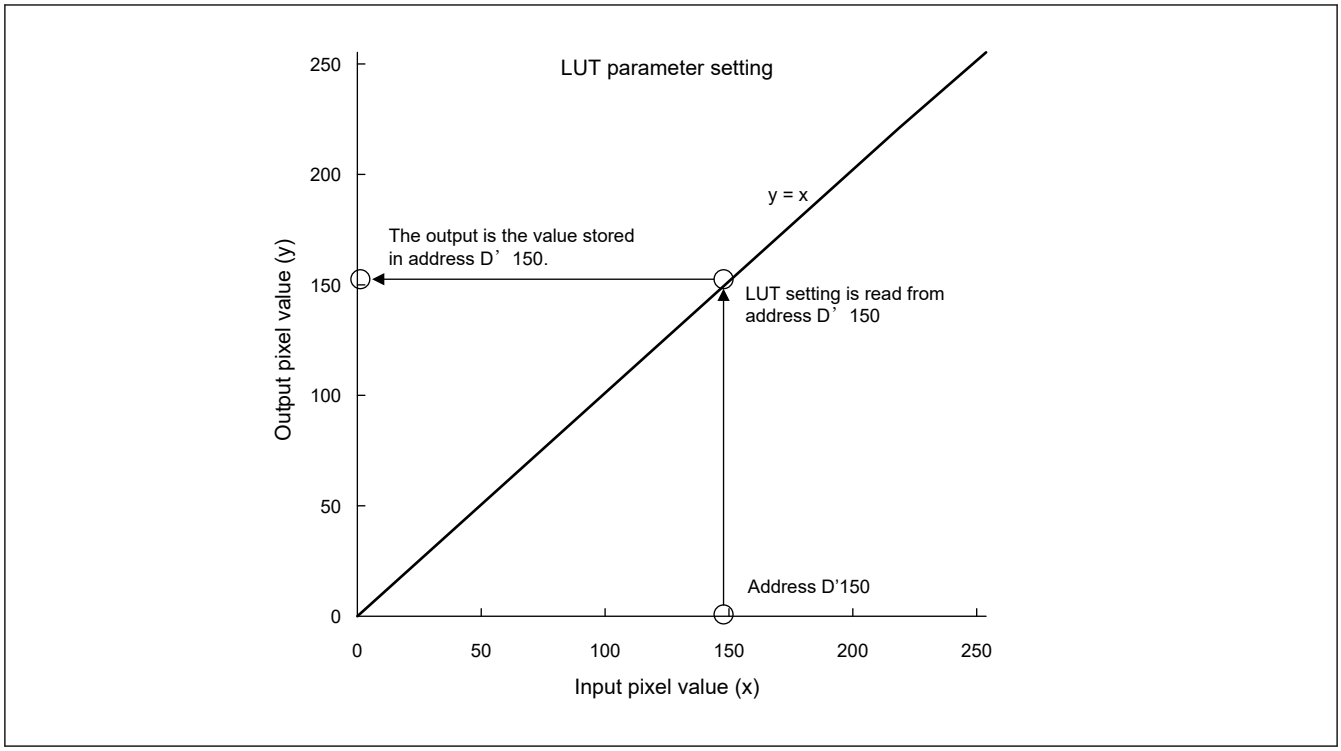

Figure 54.25 Setting example in which output becomes equal to input

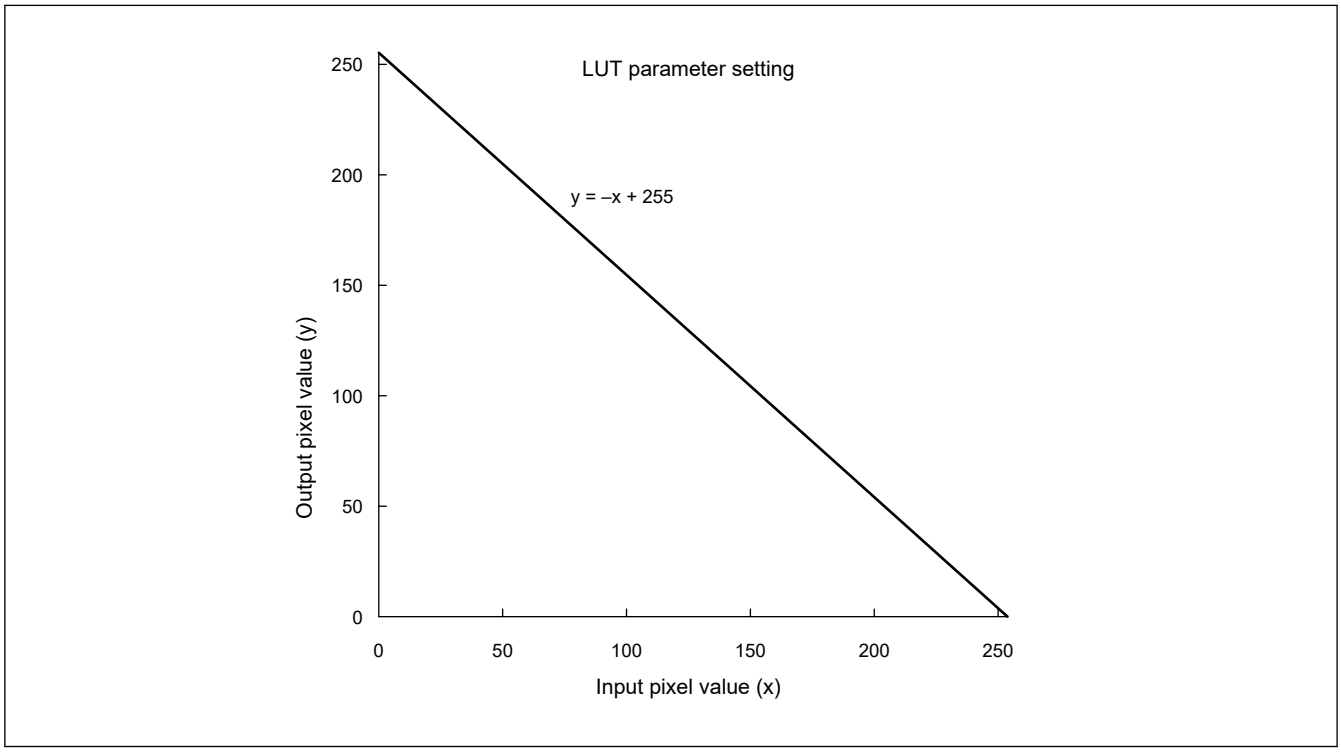

Figure 54.26 Setting example of negative-positive conversion

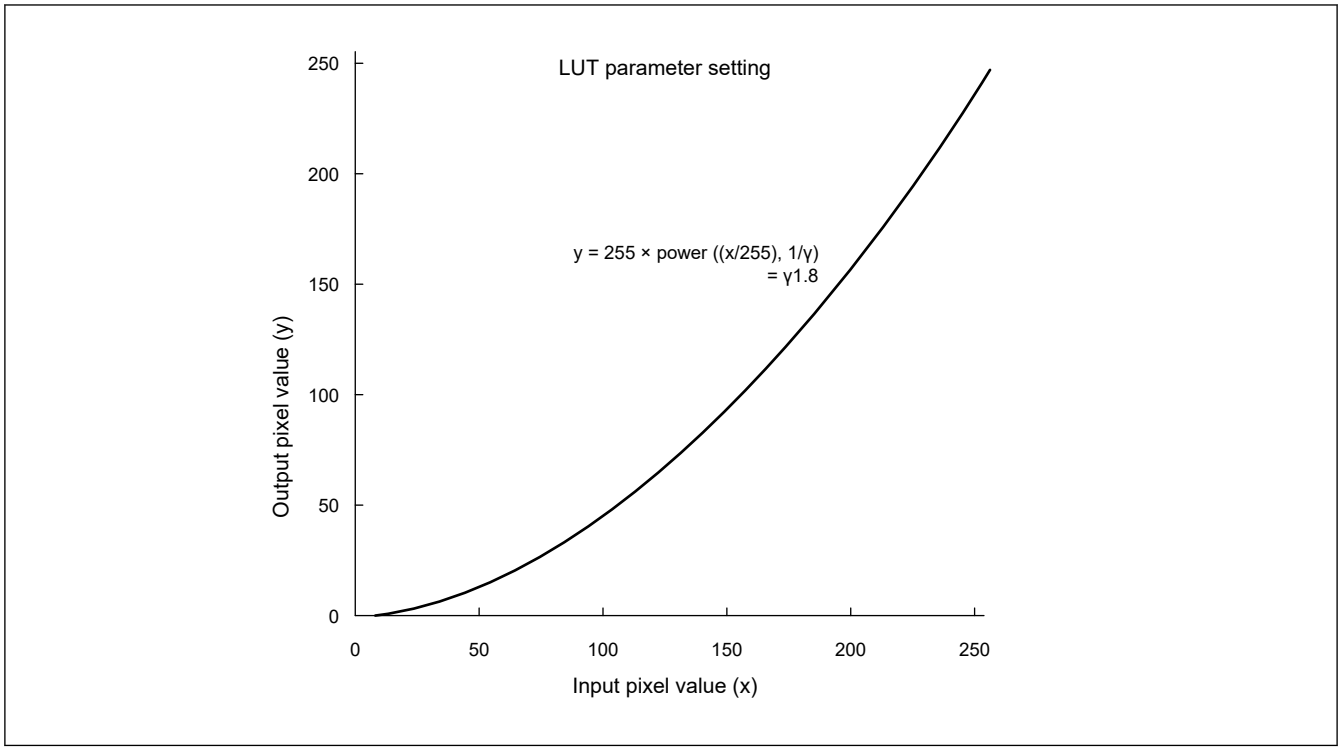

Figure 54.27 Setting example of γ correction

54.4.10 BRS Control Registers

54.4.10.1 VI6_BRS_INCTRL : BRS Input Control Register

Base address: VSPD = 0x920E_0000

Offset address: 0x3900

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	NRM	—	—	—	—	—	—	—	—	—	—	D1ON	D0ON
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	ODE1	DITH1[2:0]			ODE0	DITH0[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	DITH0[2:0]	Dithering of CH0 Input to BRS These bits specify the number of colors for pixels after dithering (color reduction) when dithering (color reduction) for pixel information is enabled through the D0ON bit. When dithering (color reduction) for pixel information is disabled, set these bits to 0. 0 0 0: Dithering of BRSin0 input image is disabled. 0 0 1: Dithering of BRSin0 input image at 18 bpp (RGB666: 260000 colors) 0 1 0: Dithering of BRSin0 input image at 16 bpp (RGB565: 65535 colors) 0 1 1: Dithering of BRSin0 input image at 15 bpp (RGB555: 32768 colors) 1 0 0: Dithering of BRSin0 input image at 12 bpp (RGB444: 4096 colors) 1 0 1: Dithering of BRSin0 input image at 8 bpp (RGB332: 256 colors) Others: Setting prohibited.	R/W

Bit	Symbol	Function	R/W
3	ODE0	Ordered Dither (mode A) of CH0 Input to BRS Enable/Disable Ordered dither is available only for 18 bpp. So, when ODE0 bit is equal to 1, set DITH0 = 1. When ODE0 bit is equal to 0, BRSin0 dither method is specified by D0ON in the register. Ordered dither (mode A) is recommended rather than ordered dither (mode B) in case of 18 bpp. 0: Ordered dither (mode A) of BRSin0 is disabled. 1: Ordered dither (mode A) of BRSin0 is enabled.	R/W
6:4	DITH1[2:0]	Dithering of CH1 Input to BRS These bits specify how to perform dithering of the CH1 input to the BRS. The setting method is the same as that for the DITH0 bits. Read the description of the DITH0 bits with BRSin1 and D1ON replacing BRSin0 and D0ON, respectively.	R/W
7	ODE1	Ordered Dither (mode A) of CH1 Input to BRS Enable/Disable Ordered dither is available only for 18 bpp. So, when ODE1 bit is equal to 1, set DITH1 = 1. When ODE1 bit is equal to 0, BRSin1 dither method is specified by D1ON in the register. Ordered dither (mode A) is recommended rather than ordered dither (mode B) in case of 18 bpp. 0: Ordered dither (mode A) of BRSin1 is disabled. 1: Ordered dither (mode A) of BRSin1 is enabled.	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W
16	D0ON	Ordered dither (mode B) Enable of BRS Input 0 Enables or disables dithering (color reduction) of BRS input 0 (BRSin0 in Figure 54.28). When ODE0 in this register is set to 1, set this bit to 0. 0: Dithering (mode B) of BRSin0 is disabled. 1: Dithering (mode B) of BRSin0 is enabled.	R/W
17	D1ON	Ordered dither (mode B) Enable of BRS Input 1 Enables or disables dithering (color reduction) of BRS input 1 (BRSin1 in Figure 54.28). When ODE1 in this register is set to 1, set this bit to 0. 0: Dithering (mode B) of BRSin1 is disabled. 1: Dithering (mode B) of BRSin1 is enabled.	R/W
27:18	—	These bits are read as 0. The write value should be 0.	R/W
28	NRM	Color Data Normalization Enables or disables division by the α value of the color data in BRS blending operation. This is used when converting the RGB color data format to which the α value is multiplied (pre-multiplied color) into the RGB color data format to which the α value is not multiplied (non pre-multiplied color). Do not use this for the YCbCr format. 0: Divider (DIV unit in Figure 54.28) does not divide the color value by α. 1: Divider (DIV unit in Figure 54.28) divides the color value by α.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Figure 54.28 shows the configuration of the BRS. For the BRS inputs, there are two inputs from the DPR and one internal input as a virtual RPF. BRSin0 to BRSin1 are input ports that have the target node values shown in Figure 54.22, and they can be connected to any module on the DPR. The same color space (YCbCr or RGB) has to be used for the two inputs from the DPR to the BRS.

The virtual RPF inside the BRS is an input unit not connected to the DPR. It is called the "virtual RPF" because it outputs images internally created by the BRS. Starting of the virtual RPF is controlled by VI6_WPFn_SRCRPF.VIR_ACT2, and the single-color data created at the virtual RPF can be used for blending or raster operation (ROP) with data from the other input units BRSin0 to BRSin1. The color space for the single color to be set for the virtual RPF needs to match the color space of the two inputs from the DPR to the BRS. For this setting method, see section 54.4.10.4. VI6_BRS_VIRRPF_COL : Color Information Register of BRS Input Virtual RPF.

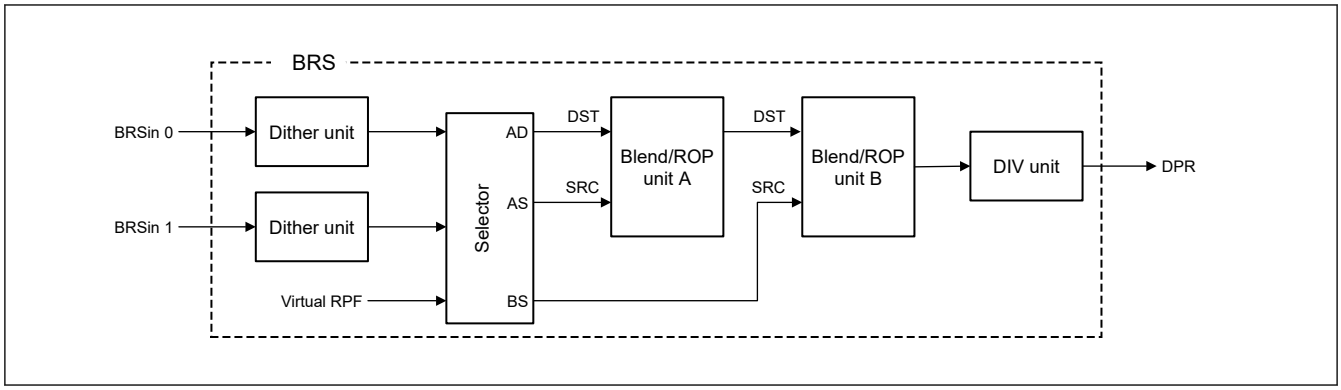

Figure 54.28 BRS configuration

The selector in Figure 54.28 is used to select the SRC and DST inputs to blending/ROP units A to B from BRSin0 to BRSin1 which are inputs from the DPR and the virtual RPF. The SRC and DST input sources for blending/ROP units A to B are either uniquely determined based on the configuration shown in Figure 54.28 or selected as desired by registers. The input sources that can be arbitrarily selected by registers are AD, AS, and BS, which correspond to the registers shown in Table 54.31.

Table 54.31 Correspondence between selector output destinations and register bits for BRS

Selector output	Output destination	Register bits
AD	Blending/ROP unit A - DST	VI6_BRSA_CTRL.DSTSEL
AS	Blending/ROP unit A - SRC	VI6_BRSA_CTRL.SRCSEL

54.4.10.2 VI6_BRS_VIRRPF_SIZE : Size Register of BRS Input Virtual RPF

Base address: VSPD = 0x920E_0000

Offset address: 0x3904

Bit position:	31			28												16			12												0
Bit field:	—	—	—	VIR_HSIZE[12:0]												—	—	—	VIR_VSIZE[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	VIR_VSIZE[12:0]	Virtual RPF Vertical Size*1 These bits set the vertical size of an image from the virtual RPF shown in Figure 54.28.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
28:16	VIR_HSIZE[12:0]	Virtual RPF Horizontal Size*1 These bits set the horizontal size of an image from the virtual RPF shown in Figure 54.28.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. A value from 1 to 8190 can be specified.

The virtual RPF has only a function to output a fixed α value and a fixed pixel value. The virtual RPF can internally create a single-color image without accessing external memory via the MAU. Same as images from the other BRS input ports, a sublayer can be blended on an image created in this manner with the image used as the background (master layer). In turn, when using the image as a sublayer, it can be drawn on the master layer as a window.

54.4.10.3 VI6_BRS_VIRRPF_LOC : Display Location Register of BRS Input Virtual RPF

Base address: VSPD = 0x920E_0000

Offset address: 0x3908

Bit position:	31			28												16			12												0
Bit field:	—	—	—	HCOORD[12:0]												—	—	—	VCOORD[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	VCOORD[12:0]	Vertical Coordinate of Virtual RPF Location on Master Layer*1 These bits specify the vertical coordinate of where to locate the top-edge pixel of the virtual RPF's layer, with the top-edge pixel of the master layer set at coordinate 0.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
28:16	HCOORD[12:0]	Horizontal Coordinate of Virtual RPF Location on Master Layer*1 These bits specify the horizontal coordinate of where to locate the left-edge pixel of the virtual RPF's layer, with the left-edge pixel of the master layer set at coordinate 0.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. This setting should be made in pixel units. A value from 0 to 8189 can be specified. When the virtual RPF is specified as the master layer by VI6_WPF0_SRCRPF.VIR_ACT2, set these bits to 0.

54.4.10.4 VI6_BRS_VIRRPF_COL : Color Information Register of BRS Input Virtual RPF

Base address: VSPD = 0x920E_0000

Offset address: 0x390C

Bit position:	31							24	23							16	15							8	7							0
Bit field:	COL_A[7:0]								COL_RCR[7:0]								COL_GY[7:0]								COL_BCB[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	COL_BCB[7:0]	Fixed B/Cb of Virtual RPF*1 These bits set the fixed B/Cb value when the virtual RPF creates a virtual plane.	R/W
15:8	COL_GY[7:0]	Fixed G/Y of Virtual RPF*1 These bits set the fixed G/Y value when the virtual RPF creates a virtual plane.	R/W
23:16	COL_RCR[7:0]	Fixed R/Cr of Virtual RPF*1 These bits set the fixed R/Cr value when the virtual RPF creates a virtual plane.	R/W
31:24	COL_A[7:0]	Fixed α of Virtual RPF*1 These bits set the fixed α value when the virtual RPF creates a virtual plane.	R/W

Note 1. A value from 0 to 255 can be specified.

The transparency information and color information of the single color that is created by the virtual RPF are set in the bits of this register. As described earlier, the color information is set for the YCbCr or RGB color space. The color space to be set in this register depends on the register settings of the environment and other modules to which the BRS is connected by the DPR. Two cases can be considered. Since the α value (COL_A) is transparency information and irrelevant to the concept of color space, the same setting is made for either the YCbCr or RGB color space.

[Case 1: When an input other than the virtual RPF is used]

When the source RPF is connected to any one of the BRS input ports (BRSin0 to BRSin1) other than the virtual RPF and valid data is being supplied, the same color space data as the color space for the BRS inputs should be set in this register as the color space for the virtual RPF's color information. This is based on the restriction of "all BRS inputs must have the same color space", as described in section 54.4.8.1. Concept of DPR Settings or section 54.4.10.1. VI6_BRS_INCTRL : BRS Input Control Register.

[Case 2: When only the virtual RPF is used]

When only the virtual RPF is used as the source RPF of WPFn, RPFn is not connected to the BRS, as shown in Figure 54.29. Thus, there is no color space for another input that the color space for the virtual RPF has to follow, as in case 1. This means that the color space of the data output by the BRS is determined by the WPF setting.

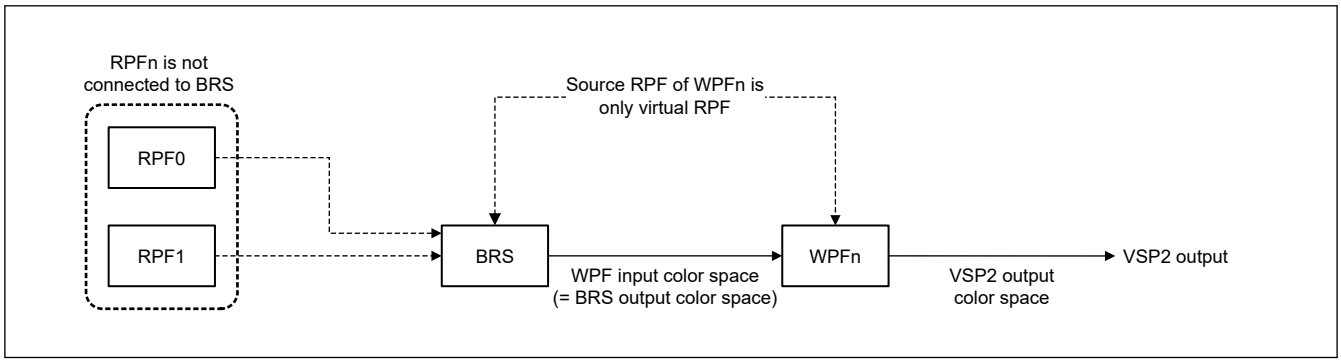

Figure 54.29 Relationship between DPR connection and color space when only virtual RPF is used

Figure 54.29, the output color space of the VSPD (= output color space of WPFn) is determined by VI6_WPFn_OUTFMT.WRFMT. When bit 6 in VI6_WPFn_OUTFMT.WRFMT (WRFMT[6]) is 0, the color space is RGB, while when it is 1, the color space is YCbCr. Next, the WPF input color space (= BRS output color space) is determined by the relationship between the WPF output color space and VI6_WPFn_OUTFMT.CSC. When VI6_WPFn_OUTFMT.CSC is 0, the WPF output color space and WPF input color space (= BRS output color space) are the same. When VI6_WPFn_OUTFMT.CSC is 1, the WPF output color space and WPF input color space (= BRS output color space) are the opposite. This relationship is summarized in Table 54.32.

The color space for the virtual RPF's color information should be set in this register according to the "BRS output color space" shown in Table 54.32.

Table 54.32 Relationship between WPF output color space and BRS output color space

VI6_WPFn_OUTFMT register bit settings				BRS output color space (= WPF input color space)
Bit 6 in WRFMT		CSC		
0	(WPF output is RGB)	0	(YCbCr to RGB conversion is disabled)	RGB
0	(WPF output is RGB)	1	(YCbCr to RGB conversion is enabled)	YCbCr
1	(WPF output is YCbCr)	0	(RGB to YCbCr conversion is disabled)	YCbCr
1	(WPF output is YCbCr)	1	(RGB to YCbCr conversion is enabled)	RGB

54.4.10.5 VI6_BRSA_CTRL : BRS Control Register A

Base address: VSPD = 0x920E_0000

Offset address: 0x3910

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RBC	—	—	—	—	—	—	—	—	DSTSEL[2:0]			—	SRCSEL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CROP[3:0]				AROP[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	AROP[3:0]	α Data ROP Operator These bits select the ROP operator of the α data in blending/ROP unit A. Select the opcode for ROP operation from Table 54.33.	R/W

Bit	Symbol	Function	R/W
7:4	CROP[3:0]	Color Data ROP Operator These bits select the ROP operator of the color data in blending/ROP unit A. Select the opcode for ROP operation from Table 54.33.	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W
18:16	SRCSEL[2:0]	Input Selection for SRC Side of Blending/ROP Unit A These bits select the input for the SRC side of blending/ROP unit A shown in Figure 54.28. These bits specify the connection between the BRS input port and the SRC separately from the setting of connections between other modules and the BRS input port through the DPR. 0 0 0: BRS input 0 (BRSin0) is input to SRC. 0 0 1: BRS input 1 (BRSin1) is input to SRC. 1 0 0: Virtual RPF is input to SRC. Others: Setting prohibited.	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W
22:20	DSTSEL[2:0]	Input Selection for DST Side of Blending/ROP Unit A These bits select the input for the DST side of blending/ROP unit A shown in Figure 54.28. These bits specify the connection between the BRS input port and the DST separately from the setting of connections between other modules and the BRS input port through the DPR. 0 0 0: BRS input 0 (BRSin0) is input to DST. 0 0 1: BRS input 1 (BRSin1) is input to DST. 1 0 0: Virtual RPF is input to DST. Others: Setting prohibited.	R/W
30:23	—	These bits are read as 0. The write value should be 0.	R/W
31	RBC	Operation Type of Blending/ROP Unit A Specifies the operation type for blending/ROP unit A shown in Figure 54.28. 0: ROP (raster operation) 1: Blending operation	R/W

Table 54.33 ROP operator of blending/ROP unit m (m = A, B)

Opcode	Operator
0000b	NOP(D)
0001b	AND(S & D)
0010b	AND_REVERSE(S & ~D)
0011b	COPY(S)
0100b	AND_INVERTED(~S & D)
0101b	CLEAR(0)
0110b	XOR(S ^ D)

1110b	NAND(~(S & D))
1111b	SET(all 1)

54.4.10.6 VI6_BRSA_BLD : BRS Blend Control Register A

Base address: VSPD = 0x920E_0000

Offset address: 0x3914

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CBES	CCMDX[2:0]			—	CCMDY[2:0]			ABES	ACMDX[2:0]			—	ACMDY[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	COEFX[7:0]								COEFY[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	COEFY[7:0]	Fixed α Value 1*1 These bits specify fixed α value 1 used when the CCMDY or ACMDY bits are set to 100b.	R/W
15:8	COEFX[7:0]	Fixed α Value 0*1 These bits specify fixed α value 0 used when the CCMDX or ACMDX bits are set to 100b.	R/W
18:16	ACMDY[2:0]	α Creation Coefficient Y These bits specify α creation coefficient Y used in the α creation expression determined by the ABES bit. 0 0 0: (α creation coefficient Y) = (DST α data) 0 0 1: (α creation coefficient Y) = 255 - (DST α data) 0 1 0: (α creation coefficient Y) = (SRC α data) 0 1 1: (α creation coefficient Y) = 255 - (SRC α data) 1 0 0: (α creation coefficient Y) = Fixed α value 1 (COEFY setting) Others: Setting prohibited.	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W
22:20	ACMDX[2:0]	α Creation Coefficient X These bits specify α creation coefficient X used in the α creation expression determined by the ABES bit. 0 0 0: (α creation coefficient X) = (DST α data) 0 0 1: (α creation coefficient X) = 255 - (DST α data) 0 1 0: (α creation coefficient X) = (SRC α data) 0 1 1: (α creation coefficient X) = 255 - (SRC α data) 1 0 0: (α creation coefficient X) = Fixed α value 0 (COEFX setting) Others: Setting prohibited.	R/W
23	ABES	Blending α Creation Expression Specifies the expression for creating α data after blending by blending/ROP unit A. α creation coefficients are specified by the ACMDX and ACMDY bits. 0: ACMDX * (DST α data) + ACMDY * (SRC α data) 1: ACMDX * (DST α data) - ACMDY * (SRC α data)	R/W
26:24	CCMDY[2:0]	Blending Coefficient Y Selection These bits specify coefficient Y used in the blending expression determined by the CBES bit. 0 0 0: DST α data is used as blending coefficient Y 0 0 1: 255 - (DST α data) is used as blending coefficient Y 0 1 0: SRC α data is used as blending coefficient Y 0 1 1: 255 - (SRC α data) is used as blending coefficient Y 1 0 0: Fixed α value 1 (COEFY setting)	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
30:28	CCMDX[2:0]	Blending Coefficient X Selection These bits specify coefficient X used in the blending expression determined by the CBES bit. 0 0 0: DST α data is used as blending coefficient X 0 0 1: 255 - (DST α data) is used as blending coefficient X 0 1 0: SRC α data is used as blending coefficient X 0 1 1: 255 - (SRC α data) is used as blending coefficient X 1 0 0: Fixed α value 0 (COEFX setting)	R/W
31	CBES	Blending Expression Selection Selects the blending expression of the color data in the BRS (VI6_BRSA_CTRL.RBC = 1). Blending coefficients are specified by the CCMDX and CCMDY bits. 0: CCMDX * (DST color data) + CCMDY * (SRC color data) 1: CCMDX * (DST color data) - CCMDY * (SRC color data)	R/W

Note 1. A value from 0x00 to 0xFF can be specified.

54.4.10.7 VI6_BRSB_CTRL : BRS Control Register B

Base address: VSPD = 0x920E_0000

Offset address: 0x3918

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RBC	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit field:	COEFX[7:0]								COEFY[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	COEFY[7:0]	Fixed α Value 1[*1] These bits specify fixed α value 1 used when the CCMDY or ACMDY bits are set to 100b.	R/W
15:8	COEFX[7:0]	Fixed α Value 0[*1] These bits specify fixed α value 0 used when the CCMDX or ACMDX bits are set to 100b.	R/W
18:16	ACMDY[2:0]	α Creation Coefficient Y These bits specify α creation coefficient Y used in the α creation expression determined by the ABES bit. 0 0 0: (α creation coefficient Y) = (DST α data) 0 0 1: (α creation coefficient Y) = 255 - (DST α data) 0 1 0: (α creation coefficient Y) = (SRC α data) 0 1 1: (α creation coefficient Y) = 255 - (SRC α data) 1 0 0: (α creation coefficient Y) = Fixed α value 1 (COEFY setting) Others: Setting prohibited.	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W
22:20	ACMDX[2:0]	α Creation Coefficient X These bits specify α creation coefficient X used in the α creation expression determined by the ABES bit. 0 0 0: (α creation coefficient X) = (DST α data) 0 0 1: (α creation coefficient X) = 255 - (DST α data) 0 1 0: (α creation coefficient X) = (SRC α data) 0 1 1: (α creation coefficient X) = 255 - (SRC α data) 1 0 0: (α creation coefficient X) = Fixed α value 0 (COEFX setting) Others: Setting prohibited.	R/W
23	ABES	Blending α Creation Expression Specifies the expression for creating α data after blending by blending/ROP unit B. α creation coefficients are specified by the ACMDX and ACMDY bits. 0: ACMDX * (DST α data) + ACMDY * (SRC α data) 1: ACMDX * (DST α data) - ACMDY * (SRC α data)	R/W
26:24	CCMDY[2:0]	Blending Coefficient Y Selection These bits specify coefficient Y used in the blending expression determined by the CBES bit. 0 0 0: DST α data is used as blending coefficient Y. 0 0 1: 255 - (DST α data) is used as blending coefficient Y. 0 1 0: SRC α data is used as blending coefficient Y. 0 1 1: 255 - (SRC α data) is used as blending coefficient Y. 1 0 0: Fixed α value 1 (COEFY setting).	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W
30:28	CCMDX[2:0]	Blending Coefficient X Selection These bits specify coefficient X used in the blending expression determined by the CBES bit. 0 0 0: DST α data is used as blending coefficient X. 0 0 1: 255 - (DST α data) is used as blending coefficient X. 0 1 0: SRC α data is used as blending coefficient X. 0 1 1: 255 - (SRC α data) is used as blending coefficient X. 1 0 0: Fixed α value 0 (COEFX setting).	R/W
31	CBES	Blending Expression Selection Selects the blending expression of the color data in the BRS (VI6_BRSB_CTRL.RBC = 1). Blending coefficients are specified by the CCMDX and CCMDY bits. 0: CCMDX * (DST color data) + CCMDY * (SRC color data) 1: CCMDX * (DST color data) - CCMDY * (SRC color data)	R/W

Note 1. A value from 0x00 to 0xFF can be specified.

54.4.11 LIF Control Registers

54.4.11.1 VI6_LIF0_CTRL : LIF0 Control Register

Base address: VSPD = 0x920E_0000

Offset address: 0x3B00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	OBTH[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	PADL	—	—	—	CFMT	—	—	REQSEL	LIF_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	LIF_EN	Enable/Disable of Data Output to External Display Module Enables or disables data output from the LIF to the external display module (DU). 0: Data output to the external display module is disabled. 1: Data output to the external display module is enabled.	R/W
1	REQSEL	External Display Module Selection 0: This value is setting prohibited when 1 is set to LIF_EN. 1: DU is selected as the destination external display module.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	CFMT	Chroma Format*1 This bit selects the output format from the LIF module to the display module. When RGB format is used, this bit shall be set to 0. 0: YCbCr444 or RGB Format 1: YCbCr422 Format	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	PADL	Enable/Disable of padding with dummy lines to output-image to the DU 0: Padding with dummy lines to output image to DU is disabled. 1: Padding with dummy lines to output image to DU is enabled.	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
27:16	OBTH[11:0]	Buffer Threshold for Start Ready Notification to Display Module Always set these bits to 1500 when LIF_EN is set to 1.	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The DU cannot receive YCbCr422 format. Therefore, when CFMT is 1, YCbCr444 data which has information contents equal to YCbCr422 is output to DU as shown in Figure 54.30.

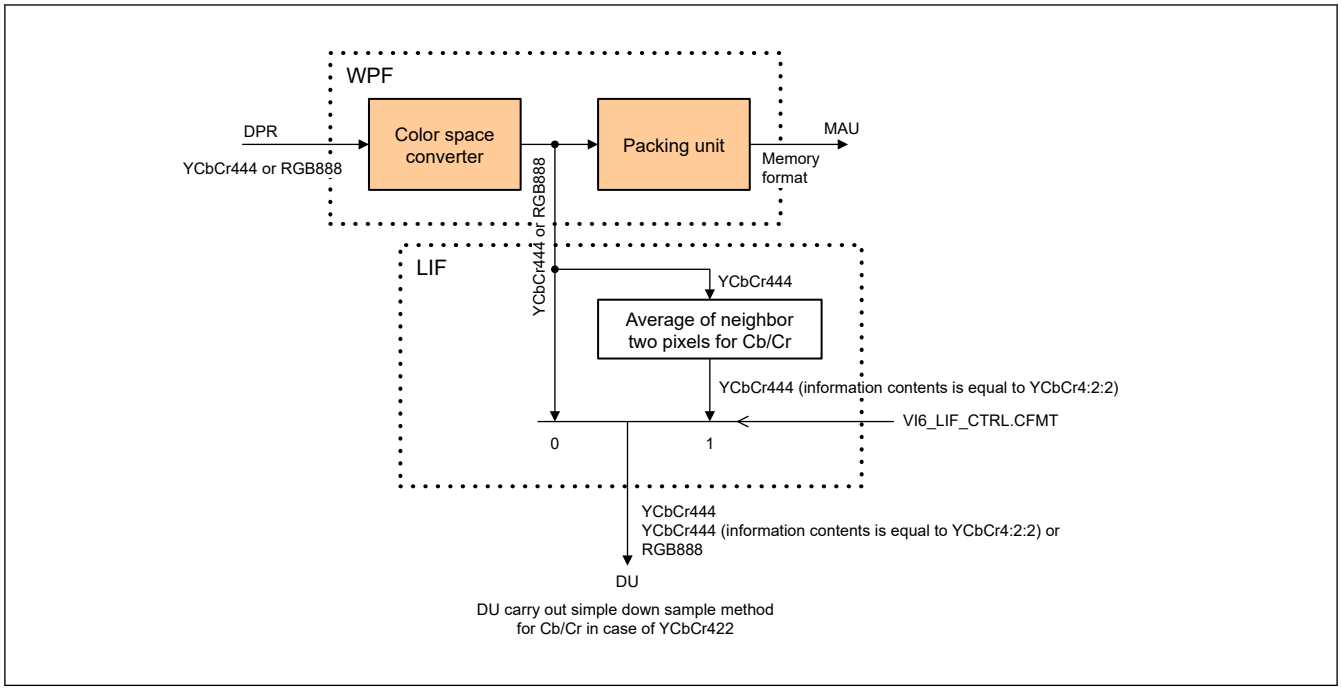

Figure 54.30 Data flow between LIF and DU

54.4.11.2 VI6_LIF0_CSBTH : LIF0 Clock Stop Buffer Control Register

Base address: VSPD = 0x920E_0000

Offset address: 0x3B04

Bit position:	31				27											16				11											0
Bit field:	—	—	—	—	HBTH[11:0]											—	—	—	—	LBTH[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	LBTH[11:0]	Buffer Threshold for Clock Start in Dynamic Clock Control Set LBTH[11:0] = 0x000 (fixed value)	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
27:16	HBTH[11:0]	Buffer Threshold for Clock Stop in Dynamic Clock Control Set HBTH[11:0] = 0x000 (fixed value)	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

54.4.11.3 VI6_LIF0_LBA : LIF0 Buffer Attribute Register

Base address: VSPD = 0x920E_0000

Offset address: 0x3B0C

Bit position:	31				27											16				11											0
Bit field:	LBA0	—	—	—	LBA1[11:0]											—	—	—	—	LBA2[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	LBA2[11:0]	LIF Buffer Attribute Register 2 These bits are internal status for purpose of H/W debugging.	R/W

Bit	Symbol	Function	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
27:16	LBA1[11:0]	LIF Buffer Attribute Register 1 Always set these bits to 1536 when LIF_EN is set to 1.	R/W
30:28	—	These bits are read as 0. The write value should be 0.	R/W
31	LBA0	LIF Buffer Attribute Register 0 Always set this bit to 1 when LIF_EN is set to 1.	R/W

54.4.11.4 VI6_LIF0_PADLN_CYC : LIF0 Padding Line Cycle Register

Base address: VSPD = 0x920E_0000

Offset address: 0x3B30

Bit position:	31																								5						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PADLN_CYC[5:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	PADLN_CYC[5:0]	Cycle of padding pattern*1 These bits specify the minimum number of cycles of the padding pattern of valid lines and dummy lines. For example, if PADLN_CYC[5:0] is 4, lower 4 bits of PADLN_PATTERN[3:0] indicates padding pattern.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. A value from 1 to 32 can be specified.

54.4.11.5 VI6_LIF0_PADLN_PT : LIF0 Padding Line Pattern Register

Base address: VSPD = 0x920E_0000

Offset address: 0x3B34

Bit position:	31																														0
Bit field:	PADLN_PATTERN[31:0]																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PADLN_PATTERN[31:0]	Pattern of padding with dummy lines These bits specify the padding pattern of valid lines and dummy lines. In each bit, 0b indicates an active line, 1b indicates a dummy line. It starts from the lower bit (Bit 0). First line should be a valid line (Always set PADLN_PATTERN[0] to 0).	R/W

54.4.11.6 VI6_LIF0_PADLN_VAL : LIF0 Padding Line Value Register

Base address: VSPD = 0x920E_0000

Offset address: 0x3B38

Bit position:	31								24	23							16	15							8	7						0
Bit field:	PADA[7:0]									PADR[7:0]								PADG[7:0]								PADB[7:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PADB[7:0]	Padding data of B/Cb for dummy line	R/W

Bit	Symbol	Function	R/W
15:8	PADG[7:0]	Padding data of G/Y for dummy line	R/W
23:16	PADR[7:0]	Padding data of R/Cr for dummy line	R/W
31:24	PADA[7:0]	Padding data of EDC code for dummy line	R/W

54.4.11.7 VI6_LIF0_PADLN_SIZE : LIF0 Padding Line Size Register

Base address: VSPD = 0x920E_0000

Offset address: 0x3B3C

Bit position:	31																		12												0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PADLN_VSIZE[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	PADLN_VSIZE[12:0]	Vertical Size of LIF output in case of enabling Padding line When VI6_LIF0_CTRL.PADL is 1, dummy lines are included in the output data from LIF, so set the LIF output VSIZE including dummy lines to these bits. If the number of output lines does not reach the value of PADLN_VSIZE[12:0] even if all valid lines are output according to padding pattern, dummy lines are inserted until the number of output lines reaches PADLN_VSIZE[12:0]. ● Output v size of LIF is same with input v size to LIF when VI6_LIF0_CTRL.PADL is 0. ● Output v size of LIF is PADLN_VSIZE[12:0] when VI6_LIF0_CTRL.PADL is 1.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

54.5 DU Register Descriptions

54.5.1 DU_MCR0 : DU Module Control Register 0

Base address: DU = 0x920C_0000

Offset address: 0x0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PB_CLR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DI_EN	—	—	—	—	—	—	—	DPI_OE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DPI_OE	Display parallel interface output enable*1 0: Disable 1: Enable	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	DI_EN	Display enable 0: Disable 1: Enable	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	PB_CLR	Clear PBUF pointers*1 Writing 1 to this parameter starts clearing the PBUF pointers. After clearing the PBUF pointers is completed, DU_MSR0.ST_PB_WINIT and DU_MSR0.ST_PB_RINIT are read as 1, this parameter must be written back to 0.	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. This parameter must be changed while VSPD is not running and DU_MSR0.ST_DIF_BSY is 0.

54.5.2 DU_MSR0 : DU Module Status Register 0

Base address: DU = 0x920C_0000

Offset address: 0x0004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	ST_PB_RINIT	ST_PB_RUF	ST_PB_REMPTY	—	ST_PB_WINIT	—	ST_PB_WFULL
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	1	0	1	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ST_DI_BSY	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0.	R
8	ST_DI_BSY	Display I/F status 0: Idle 1: Busy	R
15:9	—	These bits are read as 0.	R
16	ST_PB_WFULL	PBUF write full status 0: Not full 1: Full	R
17	—	This bit is read as 0.	R
18	ST_PB_WINIT	PBUF FIFO write pointer cleared status 0: Not cleared 1: Cleared (initial value)	R
19	—	This bit is read as 0.	R
20	ST_PB_REMPTY	PBUF read empty status 0: Not empty 1: Empty	R
21	ST_PB_RUF	PBUF read underflow status*1 0: Not occur PBUF underflow 1: Occur PBUF underflow	R
22	ST_PB_RINIT	PBUF FIFO read pointer cleared status 0: Not cleared 1: Cleared (initial value)	R
31:23	—	These bits are read as 0.	R

Note 1. This parameter clears when PBUF pointers are cleared.

54.5.3 DU_MSR1 : DU Module Status Register 1

Base address: DU = 0x920C_0000

Offset address: 0x0008

Bit position:	31			28												16			12												0
Bit field:	—	—	—	UF_VACT[12:0]													—	—	—	UF_HACT[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	UF_HACT[12:0]	Hactive counter when the PBUF underflow occurs*1 This parameter is value latched the down counter starting from HACTIVE.	R
15:13	—	These bits are read as 0.	R
28:16	UF_VACT[12:0]	Vactive counter when the PBUF underflow occurs*1 This parameter is value latched the down counter starting from VACTIVE.	R
31:29	—	These bits are read as 0.	R

Note 1. This parameter is cleared when DU_MSR0.ST_PB_RUF is cleared.

54.5.4 DU_IMR0 : DU Interrupt Mask Register 0

Base address: DU = 0x920C_0000

Offset address: 0x000C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

54.6 Operation

54.6.1 Operation Control Setting

(a) To start image process

FCPVD registers do not need to be set when starting an image process. Therefore, see section 54.6.3. Concept of VSPD Operation Starting and Stopping for the guidance of starting an image process.

(b) To stop image process immediately

Do following steps to stop immediately an image process:

1. Set the DU_MCR0.DI_EN bit to 1 so that DU can stop to output.
2. Set the VI6_WPF0_IRQ_ENB.FREE bit to 1 so that frame end interruption can be issued.
3. Set the VI6_SRESET.SRST0 bit to 1. VSPD will invoke termination process immediately.
4. Wait frame end interruption from VSPD or until the VI6_WPF0_IRQ_STA.FRE bit is set to 1. After it occurs, VSPD has finished its processing.
5. Wait until the DU_MSR0.ST_DI_BSY bit becomes 0. After it occurs, DU has stopped outputting.
6. Set the VI6_WPF0_IRQ_STA.FRE and VI6_DISP0_IRQ_STA.DST bits to 0. VSPD will clear interrupts.
7. Set the DU_MCR0.PB_CLR bit to 1 so that PBUF can be cleared.
8. Wait until the DU_MSR0.ST_PB_WINIT and DU_MSR0.ST_PB_RINIT bits become 1.
9. Set the DU_MCR0.PB_CLR bit to 0.

With this procedure, VSPD can stop its process quickly, but the output frame of the last frame is corrupted.

54.6.2 Registers to Set Fixed Value

Set fixed value to following registers in any case.

[1] Always set the VI6_CLK_DCSWT register to 0x00000808.

[2] Always set the VI6_DL_CTRL.AR_WAIT[7:0] bits to 256 in case of using display list.

[3] Always set the VI6_DL_EXT_CTRLn.POLINT[5:0] bits to 2 in case of using extended display list of WPFn.

[4] Always set the VI6_DL_EXT_CTRLn.DLPRI bit to 1 in case of using extended display list of WPFn.

[5] Always set the VI6_DL_EXT_CTRLn.EXPRI bit to 0 in case of using extended display list of WPFn.

[6] Always set the VI6_DPR_WPFn_FPORCH register (n = 0, 1) to 0x00000500 in case of using WPFn.

[7] Always set the VI6_LIF0_CTRL.OBTH[11:0] bits to 1500 in case of using LIF (VI6_LIF0_CTRL.LIF_EN = 1).

[8] Always set the VI6_LIF0_LBA register to 0x86000000 in case of using LIF0 (VI6_LIF0_CTRL.LIF_EN = 1).

[9] Always set the VI6_LIFn_CTRL.REQSEL bit to 1 in case of using LIFn (VI6_LIFn_CTRL.LIF_EN = 1).

[10] Always set the VI6_LIFn_CSBTH register to 0 in case of using LIFn (VI6_LIFn_CTRL.LIF_EN = 1).

[11] Always set the DU_PBCR0 register to 0x1F in case of using DU (DU_MCR0.DI_EN = 1).

54.6.3 Concept of VSPD Operation Starting and Stopping

The VSPD provides one channel of image processing. Each channel is started by setting the corresponding start register. Here, starting a processing channel means starting one of WPF0, which are output modules of the VSPD. Use the start registers shown in Table 54.34 to start WPF modules.

After a WPF module is started and specified processing is completed, the corresponding channel stops operation and notifies the end of processing through an end interrupt. End interrupts are generated through the end interrupt source registers shown in Table 54.34; clearing a source register cancels the corresponding interrupt signal. Each of the operating status registers shown in the table indicates the busy state after the corresponding channel is started through the start register until processing is completed and operation stops. Figure 54.33 shows these operation timings.

Table 54.34 Target module and corresponding registers for starting and stopping operation

Target module	Start register	End interrupt source register	Operating status register
WPF0	VI6_CMD0.STRCMD	VI6_WPF0_IRQ_STA. FRE	VI6_STATUS.SYS0_ACT

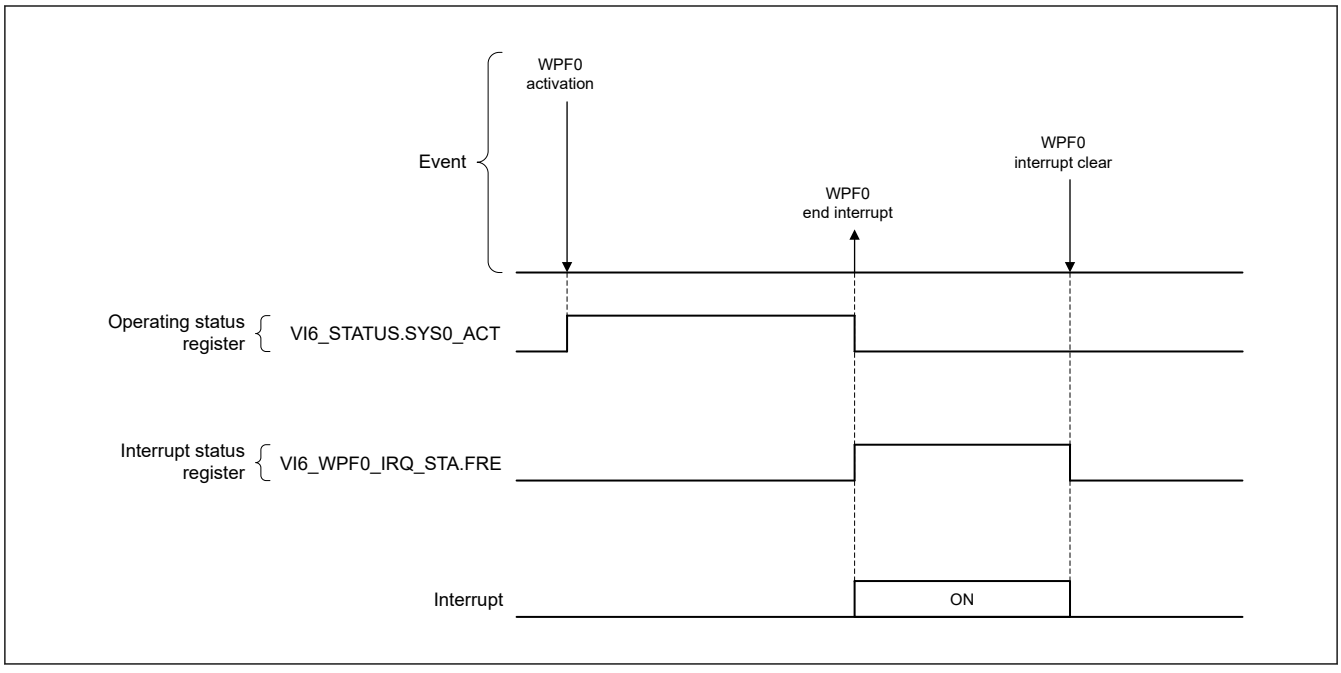

Figure 54.32 VSPD startup and status of each register and interrupt

The following describes the operating states (operating or stopped) of VSPD internal modules. As described in section 54.4. VSPD Register Descriptions, the VSPD has several image processing modules and the connections between modules are determined by the DPR. Accordingly, the operating state of a module is the same as that of the target WPF for that module. For example, when the target WPF for the BRS is WPF0, the BRS operating state is the same as that of WPF0; that is, the BRS operating state is indicated by the VI6_STATUS.SYS0_ACT as shown in Table 54.34 and the status change timing is shown as VI6_STATUS. SYS0_ACT in Figure 54.32. Likewise, the operating states of all modules connected to WPF0 is indicated by VI6_STATUS. SYS0_ACT.

Connections should be changed through the DPR-related registers (described later) while all modules to be affected by any change in connections are stopped. If connections through the DPR are changed during operation, the VSPD will hang.

Figure 54.33 shows relation between start reservation and operating status. When start is reserved while VSPD is operating, the reservation is accepted after VSPD status is moved from "operating" into "idle" as shown in Figure 54.33.

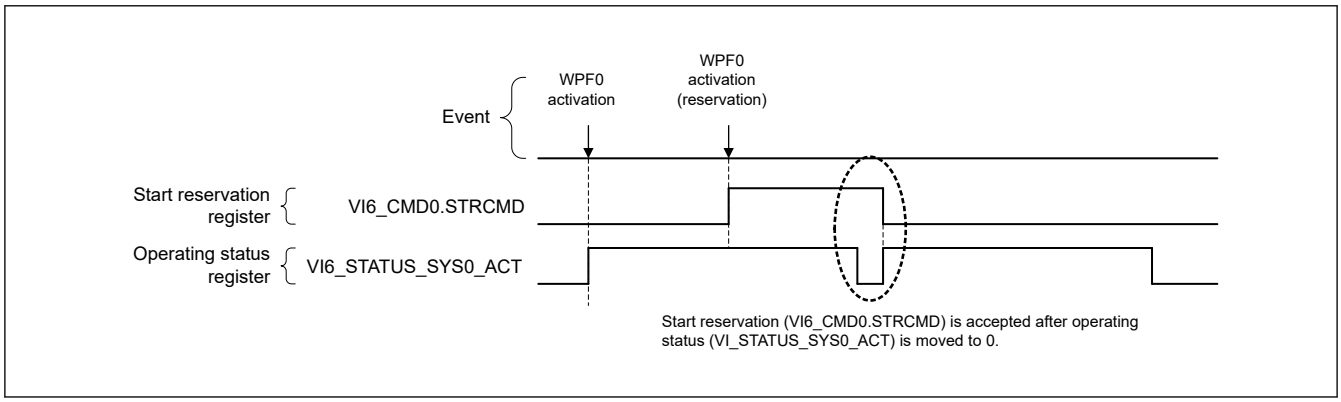

Figure 54.33 VSPD start reservation and operating status

54.6.4 Display List

54.6.4.1 Function Description

The VSPD provides the display list function. As a display list, the VSPD automatically downloads the register settings except for the control registers (section 54.4.4. General Control Registers and section 54.4.5. Display List Control Registers) from external memory and stores the settings in the VSPD registers. This function is advantageous in that the interrupt processing or register setting modification processing can be executed without CPU intervention during multiple-frame processing because the register settings used for VSPD processing are prepared in advance in external memory such as SDRAM.

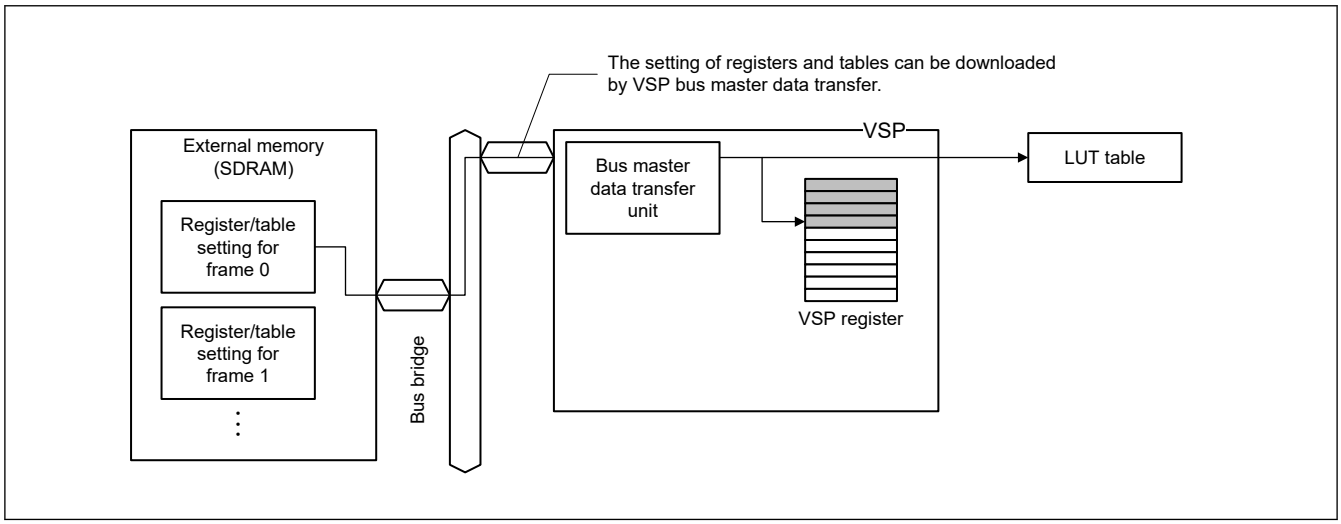

Figure 54.34 Concept of display list

To use display lists, specify the external memory addresses to the display list control registers described in section 54.4.5. Display List Control Registers. The register settings or various types of information should be stored in external memory in the format described in section 54.6.4.2. Normal Display List Mode. Figure 54.35 shows the difference between VSPD operation through normal register settings and through display lists.

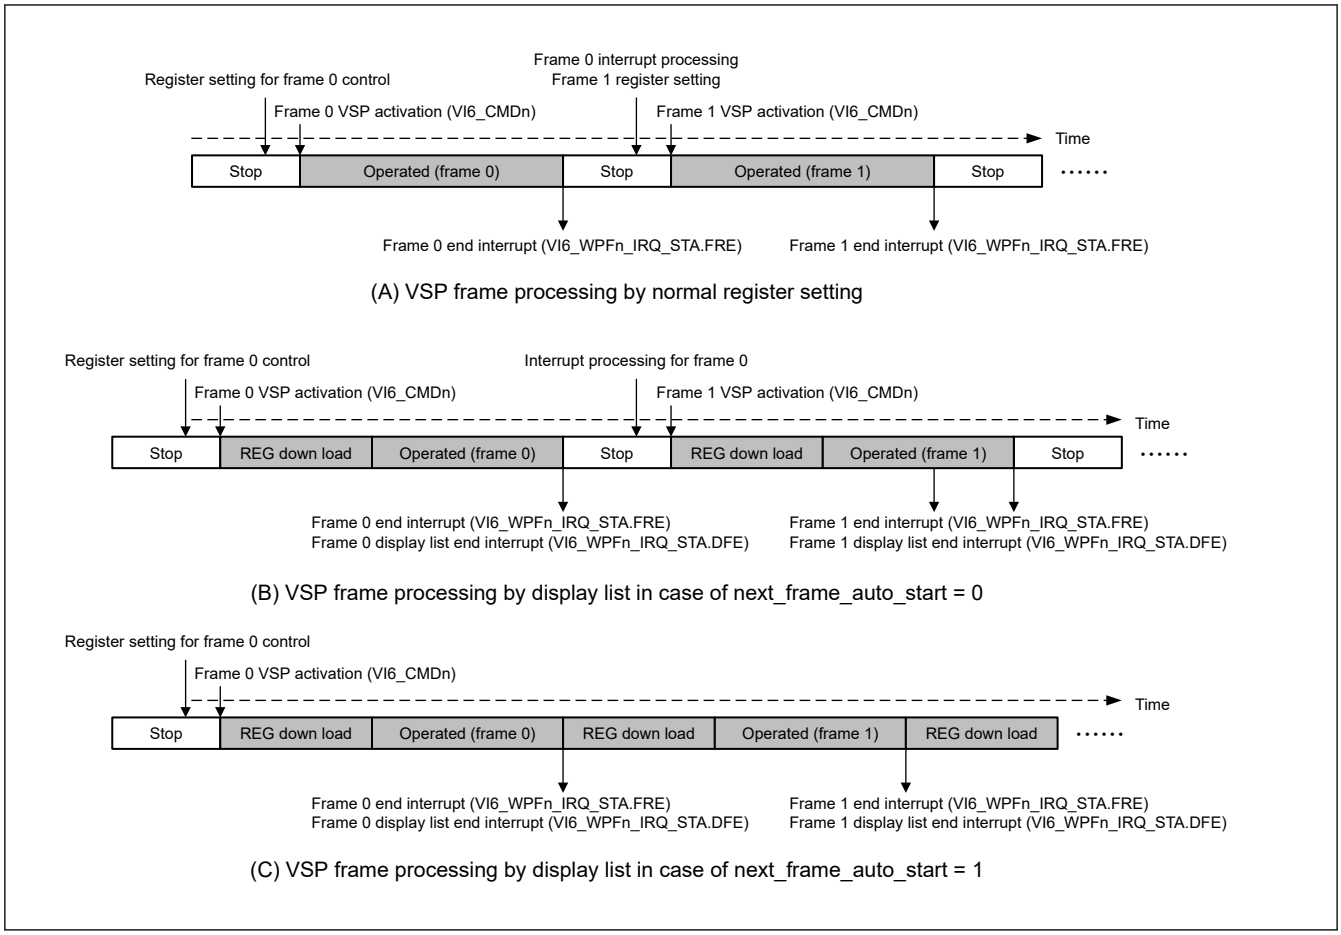

Figure 54.35 Comparison of VSPD operation between normal register settings and display lists

As shown in Figure 54.35 (A), in the VSPD processing through normal register settings, all registers should be set up before the VSPD is started for each frame. After the VSPD processing is completed, the VSPD outputs a frame end interrupt (VI6_WPFn_IRQ_STA.FRE). This method requires a certain amount of time for register settings or interrupt processing by the CPU between frames. In contrast, when display lists are used, the VSPD automatically downloads register settings from external memory as shown in Figure 54.35 (B) and (C), which reduces the load on the CPU between frames.

Figure 54.35 (B) shows the display list usage where the VSPD stops at the end of every frame; only the VSPD start processing for each frame is done by the CPU. This is suitable for the cases when the CPU controls synchronization of frame processing in frame buffer management or when the amount of register values or table data to be set in the VSPD is large. In the case shown in Figure 54.35 (C), as soon as the frame processing ends, the VSPD automatically begins next frame operation and starts downloading new register settings. This is the fastest operation using display lists.

Table 54.35 shows the modes of the display list and the supported functions for each mode. The detail of each mode is described in the following sections.

Table 54.35 Display list mode and supported functions

Mode	Extended display list	Continuous frames
Normal Display List Mode	Supported	Controlled by "next frame auto start" in the header of the display list.
Header-less Display List Mode	Not Supported	Controlled by VI6_DL_CTRL.CFM0 bit.

54.6.4.2 Normal Display List Mode

The VSPD display lists include control information as well as simple register settings in order to control multiple-frame processing in an optimum way for each application. Figure 54.36 shows the display list structure.

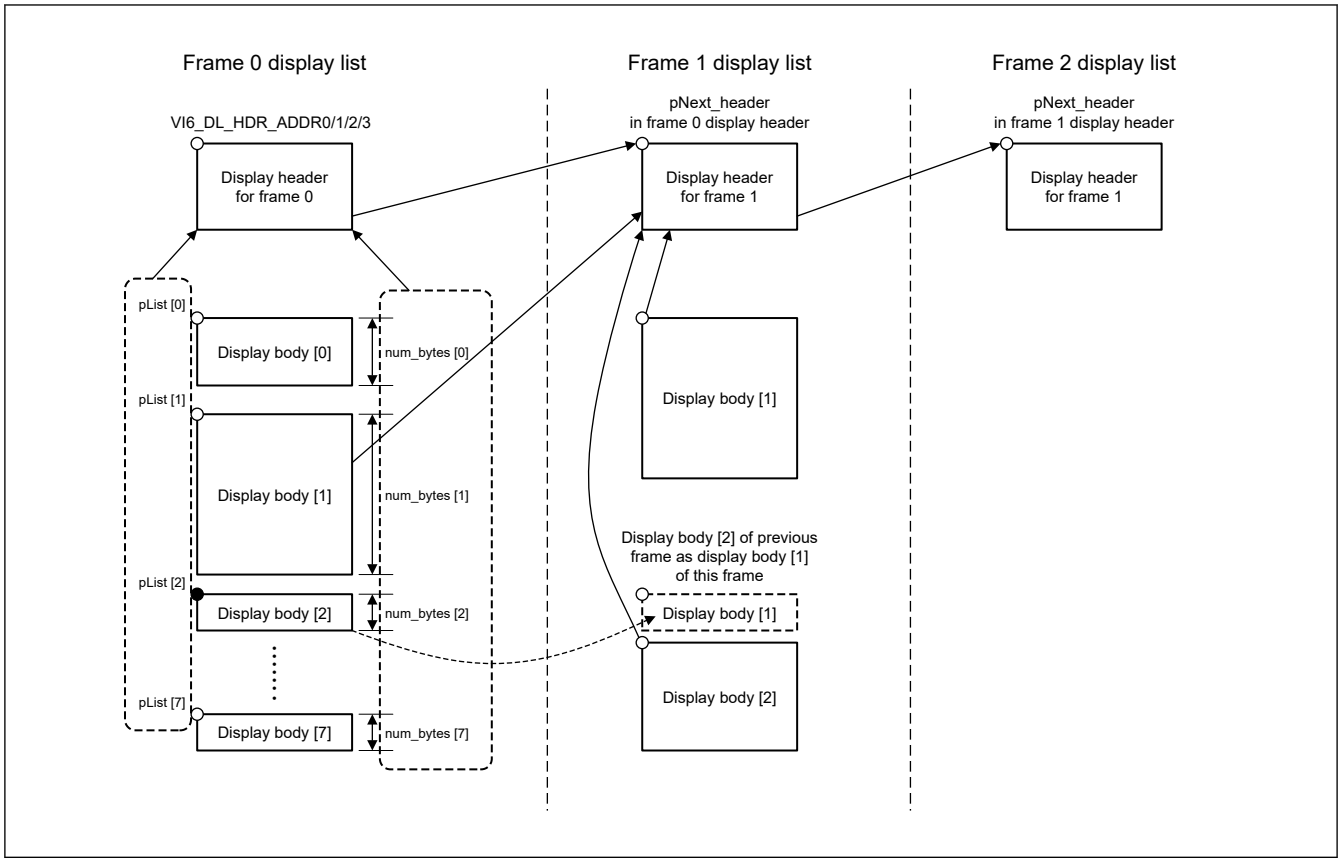

Figure 54.36 Structure and concept of VSPD display list

A VSPD display list consists of two sections; a header section for storing various information and control flags and a body section for storing register and table settings. A combination of these two sections is defined as a display list for a frame. The register and table settings can be divided and stored in up to eight separate bodies allocated in memory. Therefore, the separate bodies storing the register settings for one frame (for example, frame 0) can have non-sequential start addresses; that is, the bodies for one frame can be allocated to areas distant from each other in memory. To gather these bodies and configure the register settings for one frame, a header is used. A display header stores the number of bodies linked with the header and the start address and size of each body.

The VSPD analyzes the header to gather register and table settings stored in separate memory areas and reconfigures the complete register settings.

The addresses of display headers should be specified in the VSPD registers described in section 54.4.5. Display List Control Registers. When activated in a mode that uses display lists, the VSPD downloads display headers from the addresses specified in VI6_DL_HDR_ADDR0 (number 0 correspond to the WPF channel index numbers), analyzes the numbers of bodies and the address and data size of each body, downloads the bodies, and completes register and table settings. After display list downloading is completed, the VSPD becomes ready for frame image processing; the VSPD then starts the actual frame processing.

After processing of a frame ends, the VSPD proceeds to the next frame processing. Here, there are two modes for starting the next frame processing as shown in Figure 54.35. In one mode, the VSPD stops operation and waits for the next activation by the CPU in the same way as when display lists are not used. In this mode, the address used for downloading the display header of the next frame is kept by the internal hardware. Therefore, if valid address information is not stored in the display header for the previous frame, a correct value should be specified in VI6_DL_HDR_ADDR0 while the VSPD is stopped. When the VSPD is started after a correct value is specified, the VSPD starts next frame processing with the same procedure for the previous frame. In contrast to this mode, which stops the VSPD after the end of one-frame processing, there is another mode for automatically starting next frame processing. In automatic start mode, the VSPD downloads the next display header as soon as the previous frame processing ends. After downloading ends, the VSPD starts image processing. The information regarding mode selection, that is, whether to automatically start next frame processing, should be stored in the display header downloaded for the previous frame.

In the automatic start mode, the VSPD continues processing until the display header for a frame specifies that the next frame should not be started automatically. To stop processing during automatic execution, use a software reset (VI6_SRESET).

To strictly define the display list format described above, the following shows the grammatical structure of a display list using pseudo-code. First, to simplify the description of the display list format in the following pages, Table 54.36 defines a function. Function zero bits (num bits) generates a string of one-bit 0s for the number of bits specified by the parameter for the function. By using this function, Table 54.37 defines the header section format of a display list and Table 54.38 defines the body section format and Table 54.39 defines the extended display list body section format.

Data order of Display List Header Section, Display List Body Section and Extended Display List Body Section are assumed as the data is stored in SDRAM by big endian. Table 54.40 shows an example of data order. If data order is not same as the definition, data order within 8-byte unit can be adjusted by setting VI6_DL_SWAP (see section 54.4.5.3. VI6_DL_SWAP0 : Display List-0 Data Swapping Register.

Table 54.36 Definition of a function for simple description

Syntax	Bit count

post_ext_dl_num_cmd	16
post_ext_dl_pList /* 96 bytes from the beginning of this header */	32
}	
}	

Bit string	Contents
num_list_minus1	Specifies the value obtained by subtracting 1 from the total number of display list bodies linked with the display header. For example, when this bit field is set to 0, this display list uses one body.
num_bytes [i]	Specifies the number of bytes in the i-th display list body (indicated by index i). Be sure to specify a multiple of eight bytes. For the bodies that are not defined in num_list_minus1 (for example, i = 5 to 7 when num_list_minus1 is set to 4), set this bit field to 0.
pList [i]	Specifies the start address of the i-th display list body (indicated by index i). Be sure to specify an address aligned with an 8-byte boundary (the lower-order three bits are 0). For the bodies that are not defined in num_list_minus1 (for example, i = 5 to 7 when num_list_minus1 is set to 4), set this bit field to 0.
pNext_header	Specifies the address of the display list header for the next frame. After display list downloading ends, the VSPD keeps its value in the internal memory and uses it in the next display list header downloading. Be sure to specify an address aligned with an 8-byte boundary (the lower-order three bits are 0).
wait_wup	When this bit is 1, VSPD starts reading image data from external memory after WUP (Wake Up) signal from any channel of VIN asserts. This bit is available for WPF0.
ignore_upd_dl	If this bit is set to 1, new display list pointed by VI6_DL_HDR_ADDR0 is not downloaded in VSPD H/W for the next frame, even if S/W sets VI6_DL_HDR_ADDR0 during the frame. New display list is downloaded in VSPD H/W at next frame of the processing when this bit is 0. This bit is available for WPF0.
current_frame_int_enable	This is a flag that indicates whether to set the display list end interrupt source (VI6_WPFn_IRQ_STA.DFE) to 1 when the current frame processing ends. If this flag is set to 0, the display list end interrupt source (VI6_WPFn_IRQ_STA.DFE) is not set to 1 when one-frame processing by this display header ends. In this state, even if the display list end interrupt is enabled (VI6_WPFn_IRQ_ENB.DFEE is set to 1), no interrupt will be generated. If this flag is set to 1, the display list end interrupt source (VI6_WPFn_IRQ_STA.DFE) is set to 1 when one-frame processing by this display header ends. In this state, if the display list end interrupt is enabled (VI6_WPFn_IRQ_ENB.DFEE is set to 1), the VSPD generates an interrupt.
next_frame_auto_start	Enables or disables automatic start of next frame processing when one-frame processing by this display header ends. If this bit is set to 1, the VSPD starts next frame processing as soon as one-frame processing by this display header ends, and starts downloading the next frame display header from the pNext_header address specified in this display header. If this bit is set to 0, the VSPD stops operation when one-frame processing by this display header ends. In this case, start the VSPD through VI6_CMDn to process the next frame.
pre_ext_dl_exec	Enables execution of the extended display list for frame preprocessing when VI6_DL_EXT_CTRL.EXT is 1. If this bit is set to 1, the VSPD executes the extended display list for frame preprocessing. The VSPD does not execute it if this bit is set to 0. This bit setting is ignored when VI6_DL_EXT_CTRL.EXT is 0.
post_ext_dl_exec	Set this bit to 0.
pre_ext_dl_num_cmd	Specifies the number of commands in the extended display list body section for frame preprocessing when VI6_DL_EXT_CTRL.EXT is 1. The number of commands that can be specified is 1, and a command is 16 bytes. When pre_ext_dl_exec is set to 0, the extended display list for frame preprocessing is not executed; set this bit to 0. This bit setting is ignored when VI6_DL_EXT_CTRL.EXT is 0.

Bit string	Contents
pre_ext_dl_pList	Specifies the start address of the area where the extended display list body section for frame preprocessing is stored when VI6_DL_EXT_CTRL.EXT is 1. Be sure to specify an address aligned with a 16-byte boundary (lower-order four bits are 0). When pre_ext_dl_exec is set to 0, the extended display list for frame preprocessing is not executed; set this bit to 0. This bit setting is ignored when VI6_DL_EXT_CTRL.EXT is 0.
post_ext_dl_num_cmd	Set this bit to 0.
post_ext_dl_pList	Set this bit to 0.

Table 54.38 Format of display list body section

Syntax	Bit count
display_list (num_bytes) /* Variable length (num_bytes) */	
{	
for (i = 0; i < num_bytes; i += 8) {	
set_address	32
set_data	32
}	
}	

Bit string	Contents
set_address	Specifies the address where the value specified by set_data is to be stored. The upper 17-bit of set_address in Display List Body Section should be set to 0, since the register space of VSPD is 32 KB (0x0000 - 0x7FFC).
set_data	Specifies the value to be stored in the address specified by set_address. Specify a value to be set in a register.

54.6.4.3 Header-less Display List Mode

The header-less display list does not have the display header listed in Table 54.37, and it has the simplest structure that has only single body. The extended display list function is not available in case of the header-less display list mode. Set the VI6_DL_CTRL.NH0 to 1 (see section 54.4.5.1. VI6_DL_CTRL : Display List Control Register) to use the header-less display list. The start address downloaded by the header-less display list should be set to VI6_DL_HDR_ADDR0. And the size of the display body which is originally defined in the display header should be set to VI6_DL_BODY_SIZE0. The header-less display list is available only in WPF0.

54.6.4.4 Restrictions on Display List Usage

Access to the general control registers and display list control registers through a display list is prohibited. When using display lists, be sure to observe the following restrictions on register access by the CPU.

1. Do not execute write access to the same register (same address) from the CPU and through a display list at the same time. If such a conflict occurs, correct operation of the VSPD is not guaranteed.
2. Do not execute write access to the same LUT lookup table from the CPU and through a display list at the same time. If such a conflict occurs, correct operation of the VSPD is not guaranteed. Here, the same lookup table means the address space having the same space name shown in Table 54.41.
3. When read access by the CPU and write access through a display list to the same register (same address) occur at the same time, the read value returned to the CPU is not guaranteed.
4. When read access by the CPU and write access through a display list to the same LUT lookup table occur at the same time, the read value returned to the CPU is not guaranteed. Here, the same lookup table means the address space having the same space name shown in Table 54.41.
5. For other restrictions on values and timing of register setting through display lists, see the restrictions on normal register settings described in section 54.4.3. Restrictions on Access to Registers and Lookup Tables.
6. Manipulation and setting of the registers described in section 54.4.4. General Control Registers and section 54.4.5. Display List Control Registers through a display list is prohibited.
7. The extended display list function enabled by VI6_DL_EXT_CTRL.EXT is to control the registers of the ICB connected with the VSPD. Do not use extended display lists for any other purpose.

54.6.5 Interrupt Processing

54.6.5.1 LCDC_VSPD_INT

When a WPF module generates an internal source that should be notified, an interrupt signal is output. As internal sources are generated in WPF independently, the VSPD has the following registers to control interrupts in WPF.

- See section 54.4.4.12. VI6_WPF0_IRQ_ENB : WPF0 Interrupt Enable Register
- See section 54.4.4.13. VI6_WPF0_IRQ_STA : WPF0 Interrupt Status Register

CAUTION

To use interrupts, enable them through WPF interrupt enable registers. If an interrupt source register has already been set to 1 for some reason, an unintended interrupt will occur as soon as the corresponding interrupt enable register is set as enabled. To avoid this, before enabling interrupts through WPF interrupt enable registers, be sure to clear all WPF interrupt sources to be enabled to 0. Be careful about this procedure when setting up registers before starting the VSPD.

54.6.5.2 LCDC_DU_INT

When the PBUF will detect FIFO underflow, an interrupt signal is output. The DU has the following registers to control interrupt.

- See section 54.5.2. DU_MSR0 : DU Module Status Register 0
- See section 54.5.4. DU_IMR0 : DU Interrupt Mask Register 0

CAUTION

To use interrupts, enable them through DU Interrupt Mask Register. If an interrupt is asserted, the PBUF is underflowing and invalid display data is being output. When an interrupt occurs, the interrupt can only be cleared by DU_MCR0.PB_CLR register.

If DU_MCR1.PB_AUTOCLR is set a value other than 0, an interrupt is cleared according to DU_MCR1.OPMD register.

54.6.6 Lookup Table Settings

54.6.6.1 LUT

For a single entry to the LUT space (see Table 54.41) of the VSPD, the LUT data is set by a write access in the format shown in Figure 54.37.

The entry address of each space is (start address of the space) + (entry number counting from the base point 0 × 0x4). For example, the address of entry 7 to the LUT space is 0x920E_7000 + 7 × 0x4 = 0x920E_701C.

Table 54.41 shows the spaces for which entries can be made. Note that if the module that references that space is operating, write accesses to the relevant space are prohibited. When a read access is made to the relevant space during operation of the referencing module, undefined values will be read out.

The operating/stopped state of each module in Table 54.41 is the operating state of the WPF to which each module is connected. Determine whether the module is operating or stopped using each WPF operating status bit in the VI6_STATUS register.

Table 54.41 LUT space addresses

Space name	Space addresses	Entry count	Module that references the space in the left column
VI6_LUT_TBL	0x920E_7000 to 0x920E_73FC	256	LUT

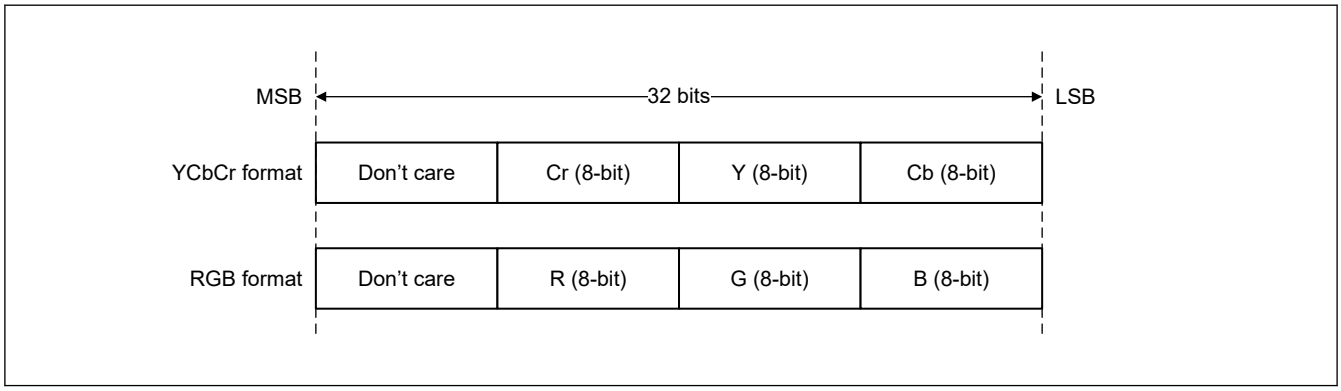

Figure 54.37 VI6_LUT_TBL formats

54.6.7 Linked with DU

54.6.7.1 Operation flow of VSPD and DU

This section shows operation flow of VSPD by using Normal Display List Mode. For details of Normal Display List Mode, see section 54.6.4.2. Normal Display List Mode.

Figure 54.38 to Figure 54.40 shows a procedure (register setting flow) to display image data to display panel.

Figure 54.38 shows setting flow to start VSPD/LIF0 linked with DU. Figure 54.39 shows setting flow to update display image. Figure 54.40 shows setting flow to stop VSPD/LIF0 linked with DU.

Using display list with enabling next_frame_auto_start shown in section 54.6.4. Display List is required to take the flow from Figure 54.38 to Figure 54.40.

NOTE

If display sync operation ([1-7] step in Figure 54.38) is set before activating the VSPD, invalid data is displayed until image data read from external memory is ready to be transferred to DU. In this case, image data from external memory is displayed late by one vsync or more.

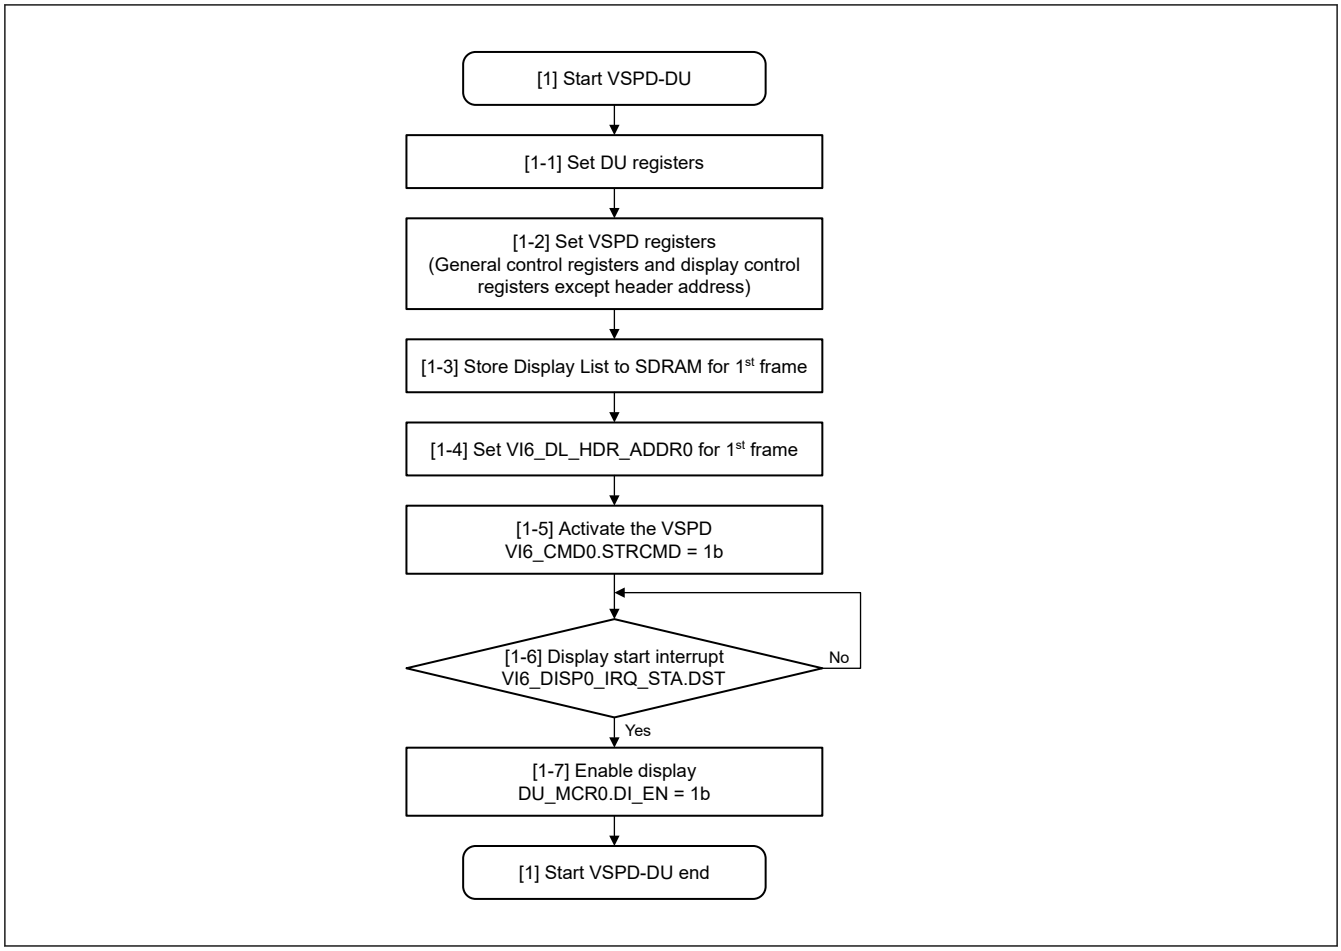

Figure 54.38 Setting flow to start VSPD linked with DU

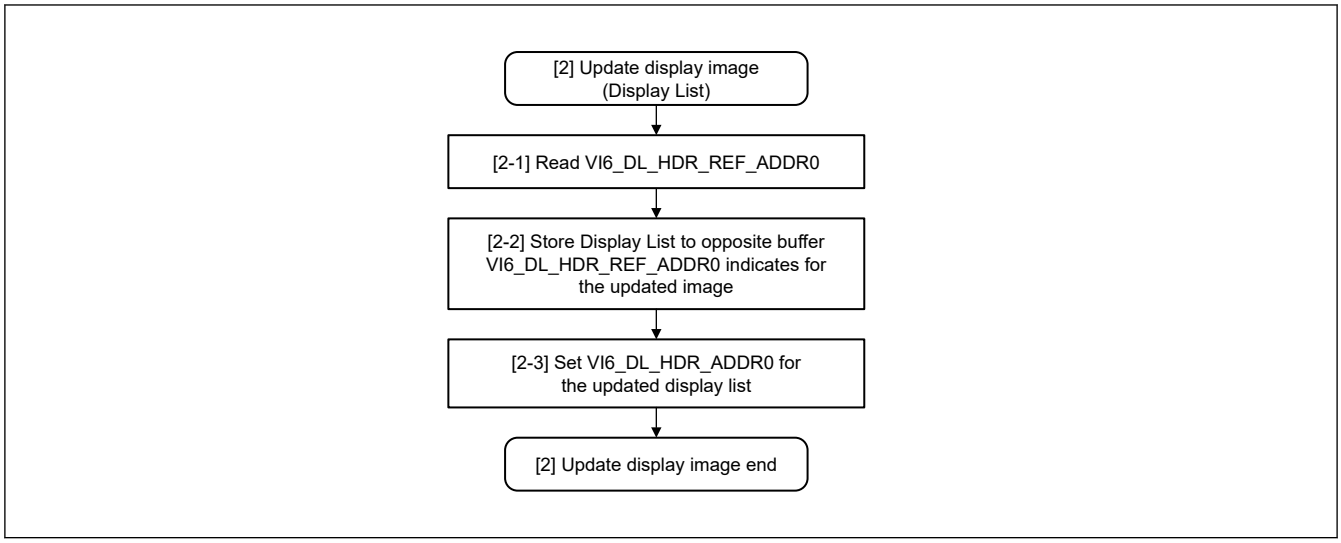

Figure 54.39 Setting flow to update display image

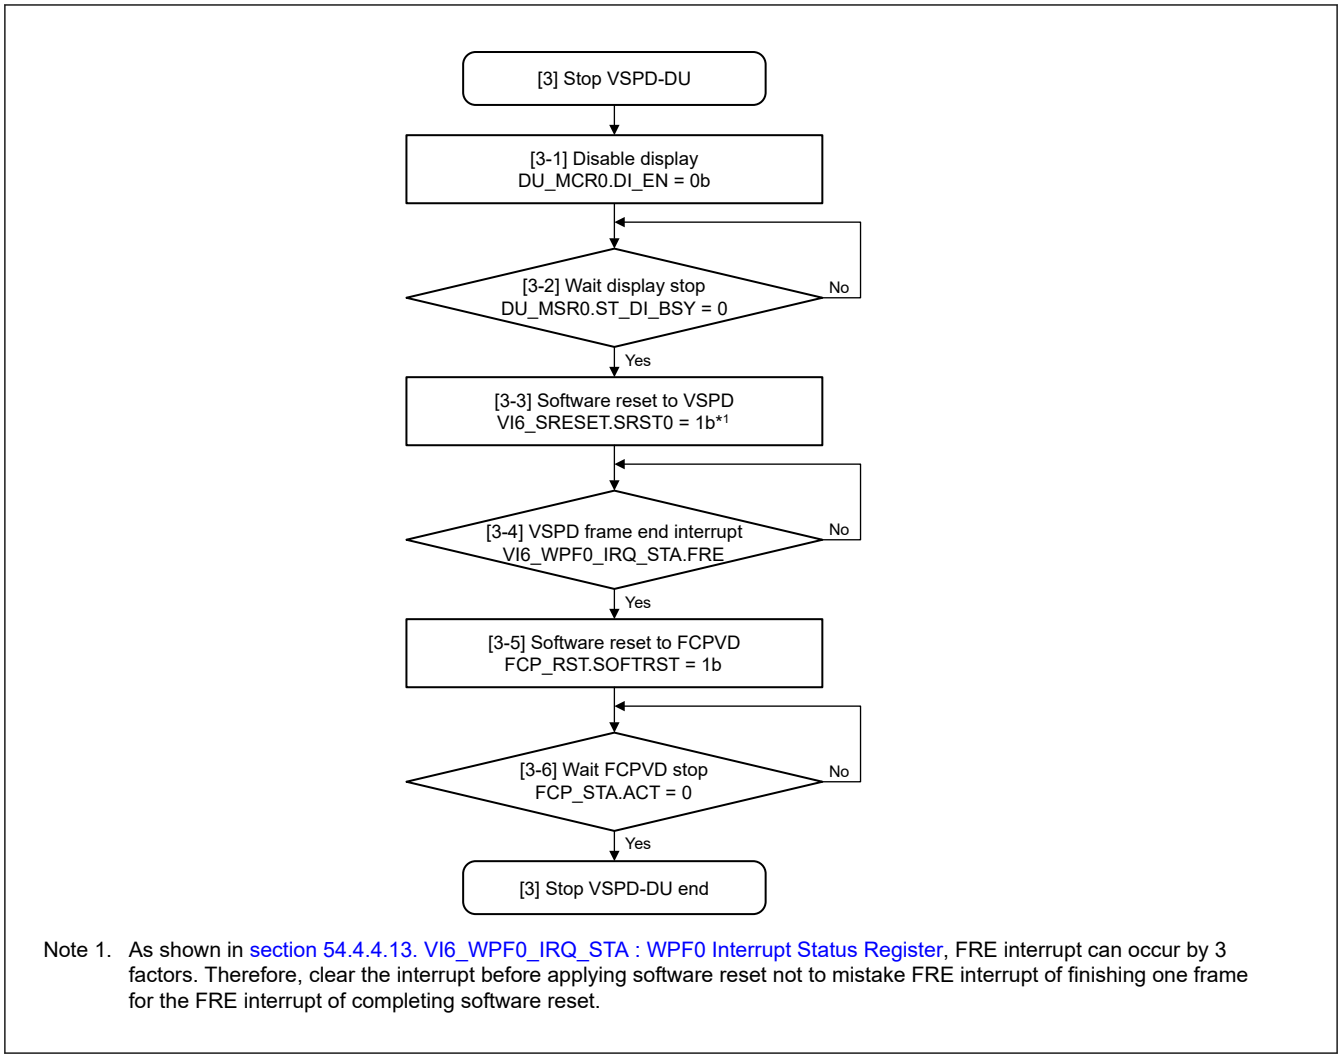

Note 1. As shown in section 54.4.4.13. VI6_WPF0_IRQ_STA : WPF0 Interrupt Status Register, FRE interrupt can occur by 3 factors. Therefore, clear the interrupt before applying software reset not to mistake FRE interrupt of finishing one frame for the FRE interrupt of completing software reset.

Figure 54.40 Setting flow to stop VSPD linked with DU

It is possible to update display list at any time (arbitrary timing) as shown in Figure 54.39. Do not overwrite display list in external memory pointed by VI6_DL_HDR_REF_ADDR. It is because VSPD is reading the display list pointed by VI6_DL_HDR_REF_ADDR or will be reading the display list soon.

Detail explanation is shown below:

As shown in section 54.4.5.6. VI6_DL_HDR_REF_ADDR0 : Display List-0 Header Reference Address Register, when VSPD is reading display list from external memory (Period [A] in Figure 54.41), VI6_DL_HDR_REF_ADDRn indicates header address of the display list referred by VSPD. When VSPD is not reading display list from external memory (Period [B] in Figure 54.41), VI6_DL_HDR_REF_ADDRn indicates the value of VI6_DL_HDR_ADDRn, and there is possibility that the display list is being read soon by VSPD at next frame start timing. Therefore, keep display list in external memory pointed by VI6_DL_HDR_REF_ADDR. Details of software sequence to update display list and VSPD-H/W behavior are shown below.

1. Store latest display list in external memory area different from the area pointed by VI6_DL_HDR_REF_ADDR, because the area pointed by VI6_DL_HDR_REF_ADDR is being read or is being read soon by VSPD.
2. Set header address of new display list into VI6_DL_HDR_ADDRn.
3. VSPD reads display list from the external memory area pointed by VI6_DL_HDR_ADDRn at frame start timing.

See also section 54.4.5.2. VI6_DL_HDR_ADDR0 : Display List-0 Header Address Register and section 54.4.5.6. VI6_DL_HDR_REF_ADDR0 : Display List-0 Header Reference Address Register.

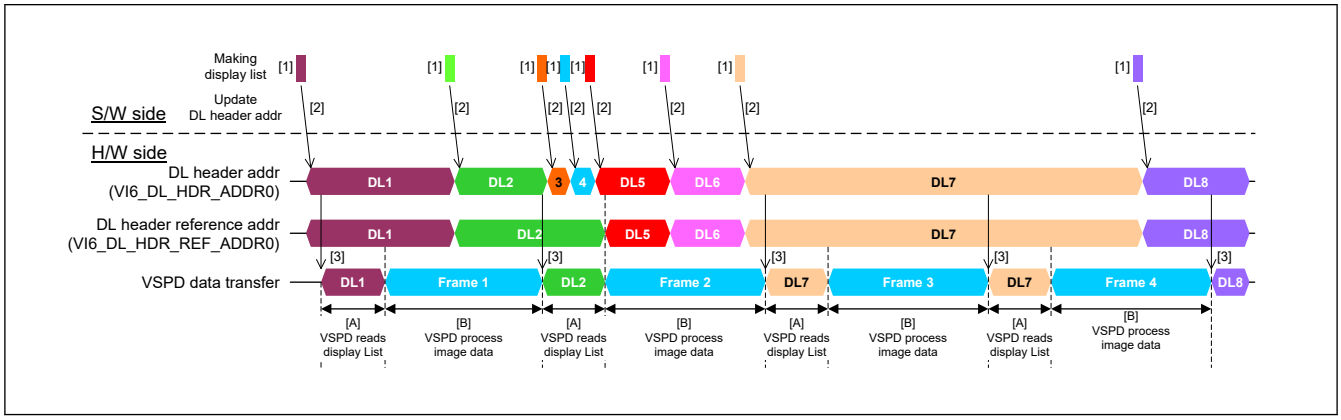

Figure 54.41 Updating display list at arbitrary timing

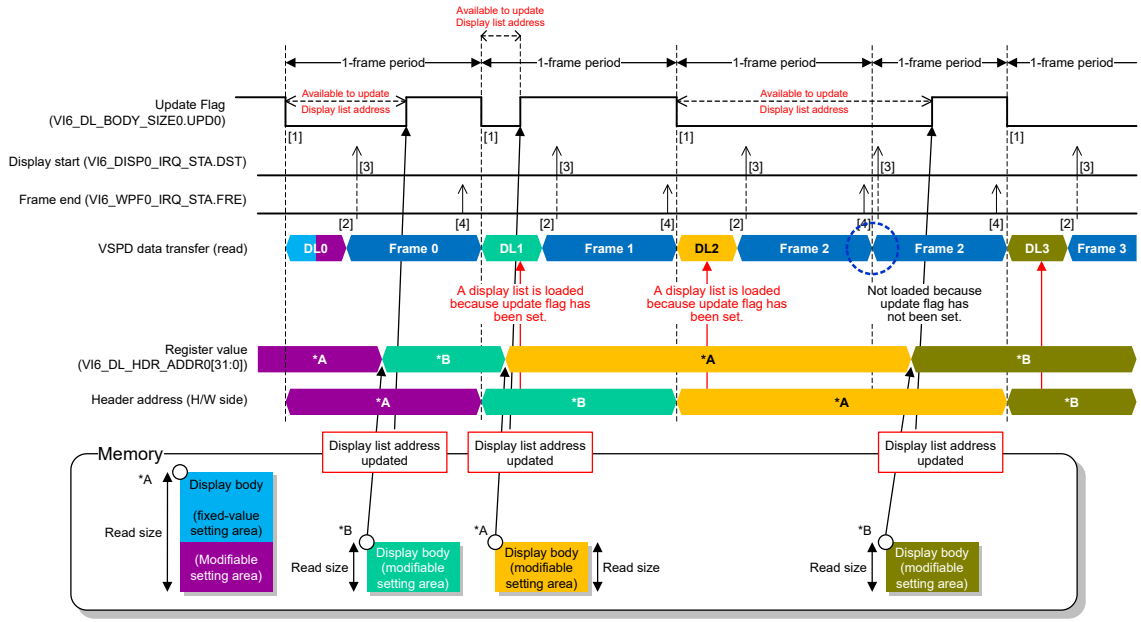
54.6.7.2 Controlling Two Register Planes using Display Lists

This section shows operation flow of VSPD by using Header-less Display List Mode. Start procedure and stop procedure are same with Normal Display List Mode in section 54.6.7.1. Operation flow of VSPD and DU except for the point that VI6_DL_BODY_SIZE0 should be set before step [1-5] in start procedure shown in Figure 54.40. The procedure to update display list is different with Normal Display List Mode, and is described later. Figure 54.42 shows the control of two register planes using header-less display lists (see section 54.6.4.3. Header-less Display List Mode) and its timing. In the description hereafter, the use of header-less display lists is always assumed and they are simply called display lists.



Display list plane A: "Fixed-value settings" and "modifiable settings" are stored as a set in contiguous area A.
Display list plane B: Only the "modifiable settings" are stored in area B, which is separate from display list A.

To switch settings for every frame, modify two display list planes alternately. After every modification, update the display list address register (VI6_DL_HDR_ADDR0[31:0]) and writing 1 to update flag (VI6_DL_BODY_SIZE0.UPD0) in the VSPD.
Update flag (VI6_DL_BODY_SIZE0.UPD0) is negated automatically after Header Address is loaded into H/W side.

Figure 54.42 Controlling two register planes using a display list

The VSPD downloads a display list immediately after activation. In the start frame, download the display list that contains all necessary settings. From the next frame on, only the necessary register or table values should be specified in a display list.

When the update flag of VI6_DL_BODY_SIZE0.UPD0 is set to 1, VSPD downloads a new display list at the start of the next frame. When the update flag of VI6_DL_BODY_SIZE0.UPD0 is set to 0, the register settings acquired from the display list previously downloaded are retained and used for the next operation without downloading a new display list.

Order of each VSPD-H/W Events mentioned as [1], [2], [3], and [4] in Figure 54.42 are shown below:

[1] VI6_DL_BODY_SIZE0.BS0 and VI6_DL_HDR_ADDR0 are downloaded in H/W side. And Update Flag (VI6_DL_BODY_SIZE0.UPD0) is negated automatically.

[2] Reading display list from external memory into VSPD-H/W is finished through master access.

[3] Display start interrupt status (VI6_DISP_IRQ_STA.DST) asserts.

[4] Frame end interrupt status (VI6_WPF0_IRQ_STA.FRE) asserts.

Do not overwrite the display list in external memory for a period from "[4] VI6_WPF0_IRQ_STA.FRE" to next "[3] VI6_DISP_IRQ_STA.DST", because VSPD is reading the display list for the period.

54.7 Usage Notes

54.7.1 Assignment in Memory Space

Make sure that VSPD memory space shall be mapped to Non-Cache region.

54.7.2 Input Image Size

Table 54.42 is a list of input size specifications.

Table 54.42 List of input size specifications

Module	Min. input size	Max. input size	Restriction on setting unit
RPF	1 (horizontal) × 1 (vertical) pixel	1920 (horizontal) × 1080 (vertical) pixels	YCbCr422: 2-pixel units horizontally and 1-pixel units vertically. YCbCr420: 2-pixel units both horizontally and vertically. Other formats: 1-pixel units both horizontally and vertically. 1. When the 1-bpp alpha plane*1 is input, the size can always be specified in 8-pixel units both horizontally and vertically regardless of the input format. 2. These restrictions including note 1 are applied to the following. VI6_RPFn_SRC_BSIZE VI6_RPFn_SRC_ESIZE
LUT	1 (horizontal) × 1 (vertical) pixel	1920 (horizontal) × 1080 (vertical) pixels	1-pixel units both horizontally and vertically.
BRS	1 (horizontal) × 1 (vertical) pixel	1920 (horizontal) × 1080 (vertical) pixels	1-pixel units both horizontally and vertically.
LIF	1 (horizontal) × 1 (vertical) pixel	1920 (horizontal) × 1080 (vertical) pixels	1-pixel units both horizontally and vertically.
WPF	1 (horizontal) × 1 (vertical) pixel	1920 (horizontal) × 1080 (vertical) pixels	YCbCr422: 2-pixel units horizontally and 1-pixel units vertically. YCbCr420: 2-pixel units both horizontally and vertically. Other formats: 1-pixel units both horizontally and vertically. 1. This restriction on the WPF only applies to the WPF output size. The WPF input size should be specified in 1-pixel units.

Note 1. When VI6_RPFn_ALPH_SEL.ASEL is set to 011b.

The most important restriction shown in Table 54.42 is the setting unit. Make appropriate register settings so that the size of the image input to each module does comply with setting units and does not exceed the limits shown in Table 54.42.

54.7.3 Output Image Size

The size of the output from each WPF is determined by the results of processing in the modules connected with the DPR. As shown in Figure 54.1, the data input to the VSPD is sent to the WPF output modules through the RPF and the modules connected with the DPR. When there is no processing that changes the image size through this data path, the WPF output size is the same as the RPF input size. Table 54.43 is a list of the processing that changes image size.

Table 54.43 Image processing that changes image size

Module	Function*1	Related register	Size of output from module
WPF	Input size clipping	VI6_WPFn_HSZCLIP VI6_WPFn_VSZCLIP	When this function is disabled, the input size and the output size are the same. When this function is enabled, the output is in the following size. Horizontal output size: VI6_WPFn_HSZCLIP.HCL_SIZE × 2 setting Vertical output size: VI6_WPFn_VSZCLIP.VCL_SIZE × 2 setting
LIF	Padding line	VI6_LIFn_CTRL	When padding with dummy lines is disabled, output size is same with Input size. When padding with dummy lines is enabled: Horizontal output size: input size Vertical output size: VI6_LIF0_PADLN_SIZE setting

Note: See section 54.4.1. Notational Conventions for Registers and Bit Fields for explanation of register bit field.
Note 1. For details of each function, see the descriptions of the related registers.

The input image size can be changed only with the modules and functions shown in Table 54.43. With the other modules and functions, the input size and output size are the same. Accordingly, after module connections with the DPR are determined, the VSPD output size can also be determined through the following steps.

1. The image size (VI6_RPFn_SRC_ESIZE) read from the external memory and sent to the DPR by the RPFn is the initial value.
2. When the module connected with the DPR is not a module (function) shown in Table 54.43, the output size from the module is the same as the input size; the image size does not need to be updated.
3. When a module connected with the DPR is a module (function) shown in Table 54.43, the output image size should be updated to the size shown in the table, which should be used as the input image size for the module connected behind it.
4. When the final image size at the WPFn is determined, this size is the VSPD output size for that WPFn path.

Figure 54.43 shows how to determine the image size in a sample DPR connection through the above steps. The related conditions that determine the image size are also shown.

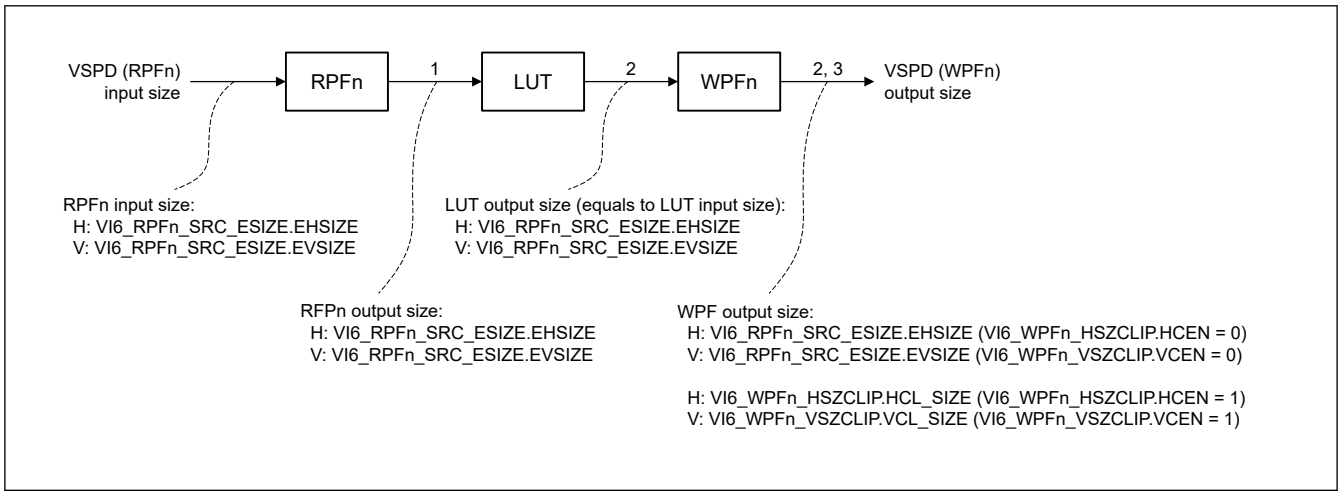


Figure 54.43 Input/output size for each module in a sample DPR connection

Make appropriate register settings in each module so that the VSPD output image size determined as shown in the figure does not violate the restrictions shown in Table 54.43.

54.7.4 Restriction

When the data output from this unit is written back to the same memory area where the input data for this unit has been read, this unit has the following restrictions.

1. The access order and format on the frame memory are the same between the input pixels and output pixels.
2. Specifying a larger output image size than the input image size, either vertically or horizontally or both vertically and horizontally, is prohibited.
3. When the YCbCr4:2:0 format is input, operation between color components is prohibited.

These restrictions are summarized in Table 54.44. See the descriptions of the registers related to each restriction. In the table, RPFm indicates the RPFn that inputs the master layer, and WPFwb indicates the WPFn that writes back the output image to the source image area for the master layer.

Table 54.44 Restrictions on use when output data is written back to input data area

No.	Restriction	Related registers
Restriction 1	The RPFm input format and the WPFwb output format should be the same.	VI6_RPFn_INFMT.RDFMT VI6_RPFn_INFMT.VIR
	The RPFm source image storing address and the WPFwb destination address should be the same.	VI6_RPFn_SRCM_ADDR_*
	The RPFm source picture memory stride and the WPFwb destination memory stride should be the same.	VI6_RPFn_SRCM_PSTRIDE VI6_RPFn_SRCM_ASTRIDE
	The RPFm and WPFwb data swapping settings should be the same.	VI6_WPFn_DSWAP
Restriction 2	The RPFm basic read size and extended read size should be the same.	VI6_RPFn_SRC_BSIZE VI6_RPFn_SRC_ESIZE
	Color space conversion is prohibited in RPFm and WPFwb.	VI6_RPFn_INFMT.CSC VI6_WPFn_OUTFMT.CSC
Restriction 3*1	NOP should be specified for IROP operation.	VI6_RPFn_ALPH_SEL.IROP
	Color keying is prohibited.	VI6_RPFn_CKEY_CTRL.CV

Note 1. When the input format is not YCbCr4:2:0, restriction 3 is not applied.

55. SD/MMC Host Interface (SDHI)

This section describes the functions of the SD/MMC host interface (SDHI).

CAUTION

Development of the SD host--related products needs the conclusion of the following agreement.

- "SD Host/Ancillary Product License Agreement (SD HALA)"

55.1 Overview

55.1.1 Features

- SD memory/IO card interface (1-bit/4-bit SD bus)
- SD, SDHC, and SDXC SD memory card access supported
- Default, high-speed, UHS-I/SDR12, SDR25, SDR50, SDR104, and DDR50 transfer modes supported
- SD clock (SD_CLK) frequency = PCLKAM (200 MHz)/2^n (n = 0 to 9)
- Error check function: CRC7 (for command/response), CRC16 (for data)
- Interrupt request: 2
- Card detect function
- Write protect supported
- MMC interface (1-/4-/8-bit MMC bus)

  Note: Channel 0 only support.
- e-MMC device access supported
- Backward-compatible, high-speed (SDR/DDR), and HS200 transfer modes supported
- High-priority interrupt (HPI) supported

55.1.2 Block Diagram

Figure 55.1 shows a block diagram of the SD/MMC host interface.

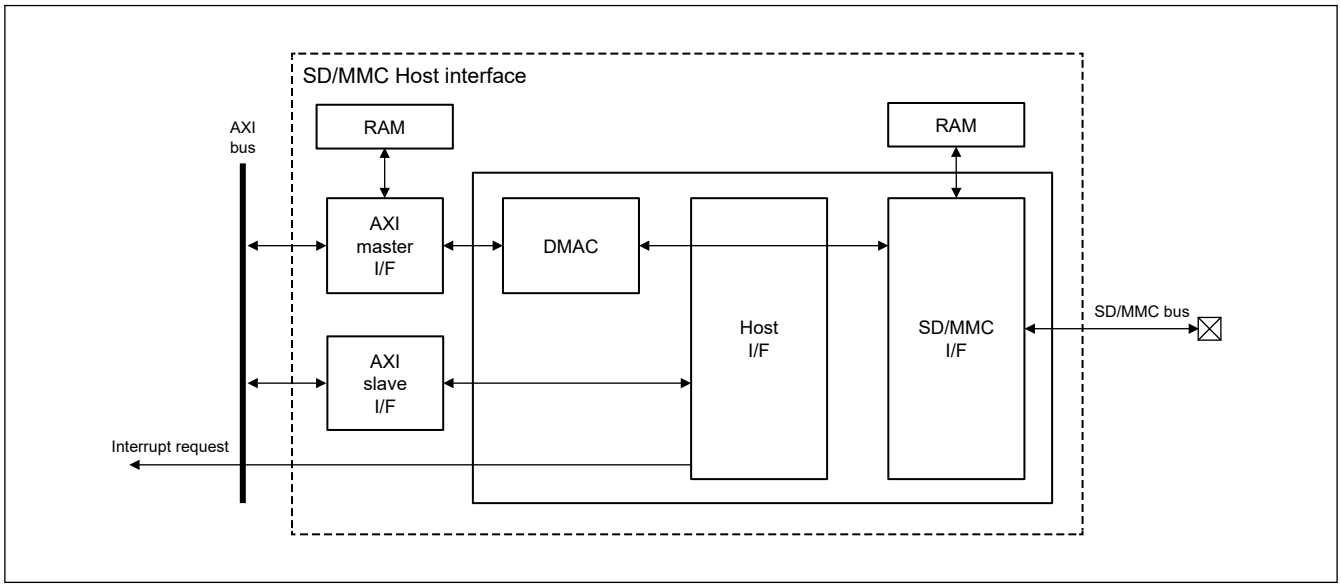

Figure 55.1 Block diagram of SD/MMC host interface

55.1.3 External Pins

Table 55.1 lists the input and output pins used by the interface. The operating voltage on the pins of the SD/MMC host interface is 3.3 V or 1.8 V, except for some supplemental pins.

Table 55.1 Input/output pins of the SDHI

Name	I/O	Function	Operating voltage
SDm_CLK*1	O	SD/MMC clock output	1.8 V/3.3 V
SDm_CMD	I/O	SD/MMC command output, response input	1.8 V/3.3 V
SDm_DATA0*1	I/O	SD/MMC Data 0 [bit 0]	1.8 V/3.3 V
SDm_DATA1*1	I/O	SD/MMC Data 1 [bit 1], SDIO interrupt	1.8 V/3.3 V
SDm_DATA2*1	I/O	SD/MMC Data 2 [bit 2], read wait	1.8 V/3.3 V
SDm_DATA3*1	I/O	SD/MMC Data 3 [bit 3], Card detection	1.8 V/3.3 V
SD0_DATA4*1	I/O	SD/MMC Data 4 [bit 4]	1.8 V/3.3 V
SD0_DATA5*1	I/O	SD/MMC Data 5 [bit 5]	1.8 V/3.3 V
SD0_DATA6*1	I/O	SD/MMC Data 5 [bit 6]	1.8 V/3.3 V
SD0_DATA7*1	I/O	SD/MMC Data 7 [bit 7]	1.8 V/3.3 V
SDm_CD*1	I	SD card detection*2	3.3 V
SDm_WP*1	I	SD write protection*2	3.3 V
SD0_RST#	O	MMC reset	1.8 V/3.3 V
SDm_PWEN	O	SD power enable	3.3 V
SDm_IOVS	O	SD voltage select	3.3 V

Note: m = 0, 1
Note 1. In this document, these pins are referred as SDCLK, SDDAT0, SDDAT1, …, SDDAT7, ISDCD, and ISDWP in order.
Note 2. Fix to high level when not in use.

55.2 Register Map

Table 55.2 SDHI register map (1 of 2)

Address	Register symbol	Register name	Write protection
0x9208_0000 + 0x1_0000 × m (m = 0, 1)	SD_CMD	Command Type Register	—
0x9208_0010 + 0x1_0000 × m (m = 0, 1)	SD_ARG	Command Argument Register	—
0x9208_0018 + 0x1_0000 × m (m = 0, 1)	SD_ARG1	Command Argument Register 1	—

Note 1. All the registers except SCC registers are accessible by 16-bit, 32-bit, or 64-bit. SCC registers are accessible by 32-bit or 64-bit.

Table 55.3 SDHI related system control register

Unit	Module Reset Control Register	Module Stop Control Register	Slave Access Control Register
0	—	MSTPCRM.MSTPCRM12	SLVACCCTL4.SDHI0_SL
1	—	MSTPCRM.MSTPCRM13	SLVACCCTL4.SDHI1_SL

55.3 Register Description

55.3.1 SD_CMD : Command Type Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MD7MD6[1:0]		MD5	MD4	MD3	MD2MD0[2:0]			C1C0[1:0]		CF45CF40[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CF45CF40[5:0]	Command Index These bits specify command format[45:40] (command index). [Examples] CMD6: SD_CMD[7:0] = 0x06 CMD18: SD_CMD[7:0] = 0x12 ACMD13: SD_CMD[7:0] = 0x4D	R/W
7:6	C1C0[1:0]	Command Type 0 0: CMD 0 1: ACMD 1 0: Setting prohibited	R/W
10:8	MD2MD0[2:0]	Mode/Response Type Some commands cannot be used in normal mode. For details, see section 55.5.14. Example of SD_CMD Register Setting to select mode/response type. 0 0 0: Normal mode The response type and the transfer mode are selected by SD_CMD[7:0], and the SD_CMD[15:11] setting is disabled. 0 0 1: Setting prohibited 0 1 0: Setting prohibited 0 1 1: Extended mode/No response 1 0 0: Extended mode/R1, R5, R6, or R7 response from the SD card 1 0 1: Extended mode/R1b response from the SD card 1 1 0: Extended mode/R2 response from the SD card 1 1 1: Extended mode/R3 or R4 response from the SD card	R/W
11	MD3	Data Mode (Command Type) 0: Command without data transfer (bc, bcr, ac) 1: Command with data transfer (adtc)	R/W
12	MD4	Write/Read Mode (enabled when the command with data is handled) 0: Write (SD/MMC host interface → SD card) 1: Read (SD/MMC host interface ← SD card)	R/W
13	MD5	Single/Multiple Block Transfer (enabled when the command with data is handled) 0: Single block transfer 1: Multi block transfer	R/W
15:14	MD7MD6[1:0]	Multiple Block Transfer Mode (enabled at multiple block transfer) 0 0: CMD12 is automatically issued at multiple block transfer. 0 1: CMD12 is not automatically issued at multiple block transfer. 1 0: Setting prohibited 1 1: Setting prohibited	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The SD_CMD register is used to select the command type and response type. The command sequence is started by writing to SD_CMD.

For details on the SD_CMD setting, refer to section 55.5.14. Example of SD_CMD Register Setting.

Do not write SD_CMD register when CBSY bit in SD_INFO2 register is 1.

55.3.2 Command Argument Register

Command arguments for SD cards are set in the SD command argument registers (SD_ARG). Set the command arguments before writing to SD_CMD.

Note that the argument of CMD12 within command sequences is 0x00000000 regardless of the setting of SD_ARG.

55.3.2.1 SD_ARG : Command Argument Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0010

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Set command format[39:8] (argument).	R/W

55.3.2.2 SD_ARG1 : Command Argument Register 1

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0018

Bit position:	31															15													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	n/a	Set command format[39:24] (argument).	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Mirror of the Upper 32 bits of Command Argument Register

55.3.3 SD_STOP : Data Stop Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	HPIMODE	HPICMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0*1	0*1	0*1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SEC	—	—	—	—	—	—	—	STP
Value after reset:	0	0	0	0	0	0	0	0*1	0	0	0	0	0	0	0	0*1

Bit	Symbol	Function	R/W
0	STP	Stop ● When STP is set to 1 during multiple block transfer, CMD12 is issued to halt the transfer through the SD/MMC host interface. However, if a command sequence is halted because of a communications error or timeout, CMD12 is not issued. Although continued buffer access is possible even after STP has been set to 1, the buffer access error bit (ERR5 or ERR4) in SD_INFO2 will be set accordingly. ● When STP has been set to 1 during transfer for single block write, the access end flag is set when SD_BUF becomes empty, and CMD12 is not issued. If SD_BUF does contain data, the access end flag is set on completion of reception of the busy state without CMD12 having been issued. ● When STP has been set to 1 during transfer for single block read, the access end flag is set immediately after setting of the STP bit and CMD12 is not issued. ● When STP is set to 1 during reception of the busy state after an R1b response, the access end flag is set on completion of reception of the busy state without CMD12 having been issued. ● When STP is set to 1 after a command sequence has been completed, CMD12 is not issued and the access end flag is not set. ● Set STP to 1 after the response end flag has been set. ● Set STP to 0 after the response end flag has been set.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	SEC	Block Count Enable*2 Set SEC to 1 at multiple block transfer. When SD_CMD is set as follows to start the command sequence while SEC is set to 1, CMD12 is automatically issued to stop multiple block transfer with the number of blocks which is set to SD_SECCNT. 1. CMD18 or CMD25 in normal mode (SD_CMD[10:8] = 000b) 2. SD_CMD[15:13] = 001b in extended mode (CMD12 is automatically issued, multiple block transfer) When the command sequence is halted because of a communications error or timeout, CMD12 is not automatically issued. 0: Disables SD_SECCNT setting value. 1: Enables SD_SECCNT setting value.	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
16	HPICMD	HPI Command Issue When HPICMD is set to 1 while HPIMODE is 1, the HPI command (CMD12) is issued. This bit is cleared to 0 when reception of the response to CMD12 is completed. The timing with which this bit is set to 1 is as follows. ● After reception of the response to CMD12 that was issued by setting the STP bit to 1 has been completed during the CMD6/CMD38 or CMD25 sequence. ● After reception of the response to CMD24/CMD25 has been completed. After HPCMD is set to 1, do not write 0 to this bit while the CBSY bit in SD_INFO2 is 1. Do not set this bit to 1 when the CBSY bit in SD_INFO2 is 0.	R/W*3
17	HPIMODE	HPI Mode Enable 0: Disables HPI mode. 1: Enables HPI mode.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 2. Do not change the value of this bit when the CBSY bit in SD_INFO2 is set to 1.
Note 3. Only effective when 1 is written.

The SD_STOP register is used to enable or disable block counting at multiple block transfer, and to control the issuing of CMD12 within command sequences.

55.3.4 SD_SECCNT : Block Count Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0028

Bit position:	31																												0
Bit field:	CNT31CNT0[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CNT31CNT0[31:0]	Number of Transfer Blocks*1 When 0x00000001 is set, the number of transfer blocks is 1. ⋮ When 0x0000FFFF is set, the number of transfer blocks is 65535. ⋮ When 0xFFFFFFFF is set, the number of transfer blocks is 4294967295. Do not set this register to 0x00000000 if multiple blocks are to be transferred.	R/W

Note 1. Do not change the value of these bits when the CBSY bit in SD_INFO2 is set to 1.

The SD_SECCNT register is used to specify the number of transfer blocks at multiple block transfer.

55.3.5 SD Card Response Registers

The SD card response registers (SD_RSP) hold the response from the SD card.

55.3.5.1 SD_RSP10 : SD Card Response 10 Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0030

Bit position:	63																												32
Bit field:	R71R40[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	31																												0
Bit field:	R39R8[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
63:32	R71R40[31:0]	Hold the response from the SD card	R
31:0	R39R8[31:0]		

55.3.5.2 SD_RSP1 : SD Card Response 1 Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0038

Bit position:	31															15													0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	R39R24[15:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	R39R24[15:0]	Hold the response from the SD card	R

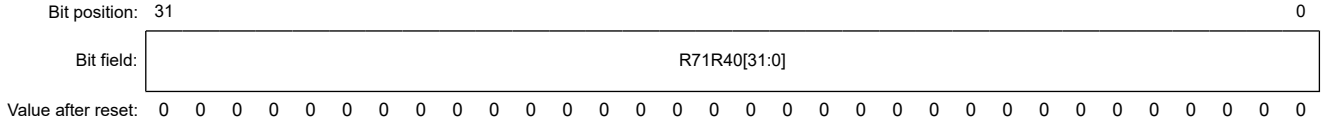
Bit	Symbol	Function	R/W
31:16	—	These bits are read as 0.	R

Mirror of the [31:16] bits of SD Card Response 10 Register

55.3.5.3 SD_RSP32 : SD Card Response 32 Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0040



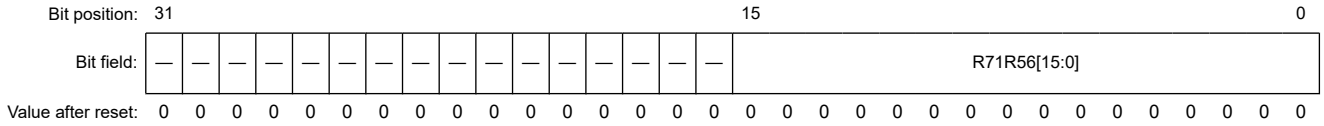
Bit	Symbol	Function	R/W
31:0	R71R40[31:0]	Hold the response from the SD card	R

Mirror of the Upper 32 bits of SD Card Response 10 Register

55.3.5.4 SD_RSP3 : SD Card Response 3 Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0048



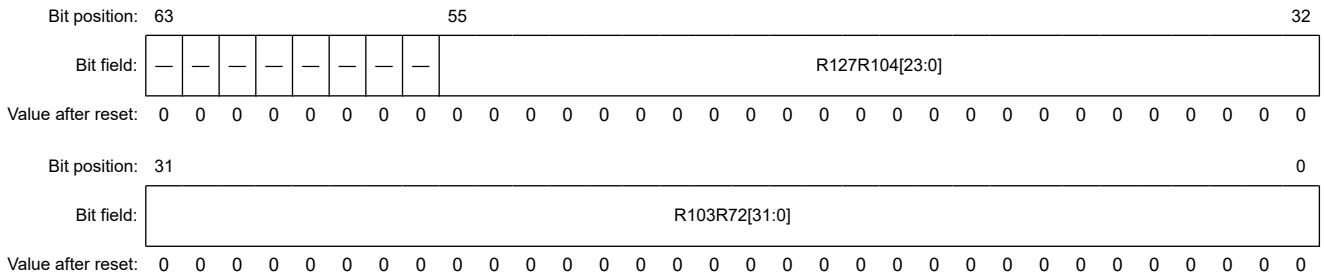
Bit	Symbol	Function	R/W
15:0	R71R56[15:0]	Hold the response from the SD card	R
31:16	—	These bits are read as 0.	R

Mirror of the [31:16] bits of SD_RSP32 Register

55.3.5.5 SD_RSP54 : SD Card Response 54 Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0050



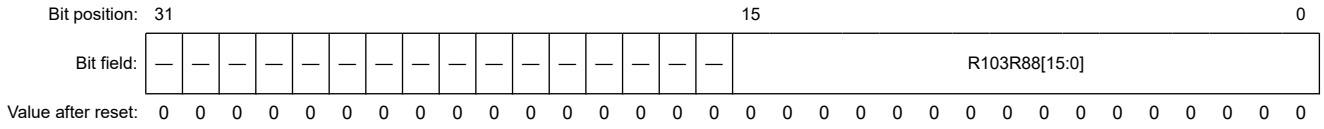
Bit	Symbol	Function	R/W
31:0	R103R72[31:0]	Hold the response from the SD card	R
55:32	R127R104[23:0]		

Bit	Symbol	Function	R/W
63:56	—	These bits are read as 0.	R

55.3.5.6 SD_RSP5 : SD Card Response 5 Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0058



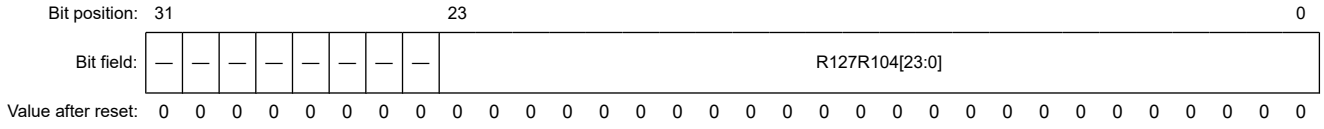
Bit	Symbol	Function	R/W
15:0	R103R88[15:0]	Hold the response from the SD card	R
31:16	—	These bits are read as 0.	R

Mirror of the [31:16] bits of SD_RSP54 Register

55.3.5.7 SD_RSP76 : SD Card Response 76 Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0060



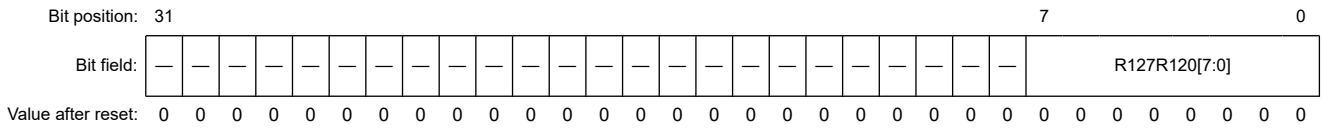
Bit	Symbol	Function	R/W
23:0	R127R104[23:0]	Hold the response from the SD card	R
31:24	—	These bits are read as 0.	R

Mirror of the Upper 32 bits of SD_RSP54 Register

55.3.5.8 SD_RSP7 : SD Card Response 7 Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0068



Bit	Symbol	Function	R/W
7:0	R127R120[7:0]	Hold the response from the SD card	R
31:8	—	These bits are read as 0.	R

Mirror of the [31:16] bits of SD_RSP76 Register

Table 55.4 lists the response types and corresponding SD_RSP registers.

Table 55.4 Response types and corresponding SD_RSP registers

Response types	SD_RSP registers
R1, R1b[39:8]	SD_RSP10 SD_RSP54[*1]
R2[127:8]	SD_RSP54 and SD_RSP10
R3[39:8]	SD_RSP10
R4[39:8]	SD_RSP10
R5[39:8]	SD_RSP10
R6[39:8]	SD_RSP10
R7[39:8]	SD_RSP10

Note 1. The response to CMD18 and to CMD25 is stored in both R[39:8] and R[103:72].
This makes it possible to confirm the response to CMD18 and CMD25 by reading R[103:72] even if the response to automatic CMD12 is stored in R[39:8].

55.3.6 SD_INFO1 : SD Card Interrupt Flag Register 1

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	HPIRES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0[*2]

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	INFO10	INFO9	INFO8	INFO7	—	INFO5	INFO4	INFO3	INFO2	—	INFO0
Value after reset:	0	0	0	0	0	x	0	0	x	0	x	0	0	0[*2]	0	0[*2]

Bit	Symbol	Function	R/W
0	INFO0	Response End [Setting conditions] 1. When the reception of the response is completed 2. When the transmission of the command not requiring a response is completed 3. When receiving busy reception after R1b response 4. When reception of the response to CMD52 that was issued by setting the C52PUB bit to 1 is completed in the case of transfer for multiple block read 5. When reception of the response to CMD52 that was issued by setting the C52PUB bit to 1 is completed in the case of transfer for multiple block write In addition to the above conditions, this bit is set when a command sequence is halted because of a communications error or timeout. [Clearing condition] When 0 is written to INFO0 When issuing a command without data, the command sequence ends when the response end is set to 1.	R/W[*1]
1	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
2	INFO2	Access End [Setting conditions] 1. When read access to the buffer is completed in the case of transfer for single block read 2. When read access to the buffer for the last block of data is completed in the case of transfer for multiple block read 3. When read access to the buffer and reception of the response to CMD12 are completed in the case of transfer for multiple block read with automatic issuing of CMD12 4. When reception of the busy state after reception of the CRC status is completed in the case of transfer for single block write 5. When reception of the busy state after reception of the CRC status of the last block of data is completed in the case of transfer for multiple block write 6. When reception of the response busy state for CMD12 is completed in the case of transfer for multiple block write with automatic issuing of CMD12 7. When reception of the response to CMD12 that was issued by setting the STP bit to 1 is completed in the case of transfer for multiple block read 8. When reception of the response busy state for CMD12 that was issued by setting the STP bit to 1 is completed in the case of transfer for multiple block write 9. When reception of the response to CMD52 that was issued by setting the IOABT bit to 1 is completed in the case of transfer for multiple block read 10. When reception of the response to CMD52 that was issued by setting the IOABT bit to 1 is completed in the case of transfer for multiple block write In addition to the above conditions, this bit is set when a command sequence is halted because of a communications error or timeout. [Clearing condition] When 0 is written to INFO2 When the access end bit is set to 1, the command sequence is terminated.	R/W*1
3	INFO3	ISDCD Card Removal [Setting condition] After a change in ISDCD from 0 to 1, Mcycle has elapsed with ISDCD held at 1. [Clearing condition] When 0 is written to INFO3 Mcycle is set by bits 3 to 0 in SD_OPTION.	R/W*1
4	INFO4	ISDCD Card Insertion [Setting condition] After a change in ISDCD from 1 to 0, Mcycle has elapsed with ISDCD held at 0. [Clearing condition] When 0 is written to INFO4 Mcycle is set by bits 3 to 0 in SD_OPTION.	R/W*1
5	INFO5	Indicates the ISDCD state. Mcycle is set by bits 3 to 0 in SD_OPTION. 0: Indicates that Mcycle has elapsed with ISDCD held at 1. 1: Indicates that Mcycle has elapsed with ISDCD held at 0.	R
6	—	This bit is read as 0. The write value should be 0.	R/W
7	INFO7	Write Protect Indicates the ISDWP state. 0: ISDWP is set to 1. 1: ISDWP is set to 0.	R
8	INFO8	SDDAT3 Card Removal [Setting condition] After a change in SDDAT3 from 1 to 0, two cycles of 2 PCLKAM have elapsed with SDDAT3 held at 0. [Clearing condition] When 0 is written to INFO8	R/W*1
9	INFO9	SDDAT3 Card Insertion [Setting condition] After a change in SDDAT3 from 0 to 1, two cycles of 2 PCLKAM have elapsed with SDDAT3 held at 1. [Clearing condition] When 0 is written to INFO9	R/W*1
10	INFO10	Indicates the SDDAT3 state. 0: SDDAT3 is set to 0. 1: SDDAT3 is set to 1.	R
15:11	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	HPIRES	Response Reception Completion [Setting condition] When reception of the response to CMD12 that was issued by setting the STP bit to 1 is completed during the CMD6/CMD38 or CMD25 sequence in HPI mode. [Clearing condition] When 0 is written to HPIRES	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only effective when 0 is written.
Note 2. The value is initialized by a reset and also in the case of a reset by the SDRST bit in SOFT_RST.

The SD_INFO1 register indicates the response end and access end in the command sequence. This register also indicates the card detect/write protect state.

For CMD12 and CMD52 (SDIO abort) at multiple block transfer, INFO0 is not set but only INFO2 is set.

Even if the command sequence is halted because of a communications error or timeout, INFO0 or INFO2 is set.

INFO10, INFO9, and INFO8 change depending on the SDDAT3 state after a reset is released and continue to change in 4-bit transfer mode.

To clear a flag, write 0 to the bit to be cleared and 1 to the other bits.

55.3.7 SD_INFO2 : SD Card Interrupt Flag Register 2

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0078

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ILA	CBSY	SCLK DIVEN	—	—	—	BWE	BRE	DAT0	ERR6	ERR5	ERR4	ERR3	ERR2	ERR1	ERR0
Value after reset:	0*2	0*2	1*2	0	0	0	0*2	0*2	x	0*2	0*2	0*2	0*2	0*2	0*2	0*2

Bit	Symbol	Function	R/W
0	ERR0	CMD Error [Setting conditions] 1. The command index of the transmitted command differing from the command index of the received response 2. The command index of a command issued within a command sequence*5 differing from the command index of the received response [Clearing condition] When 0 is written to ERR0 The command sequence is halted by the CMD error.*4	R/W*1
1	ERR1	CRC Error [Setting conditions] 1. When an error occurs in the CRC status (i.e. the received CRC status was not 010b) 2. When a CRC error occurs in the read data 3. When a CRC error occurs in the response 4. A CRC error in the response to a command issued within a command sequence*5 [Clearing condition] When 0 is written to ERR1 The command sequence is halted by the CRC error.*4	R/W*1

Bit	Symbol	Function	R/W
2	ERR2	END Error [Setting conditions] 1. When an error occurs in the response length (and the end bit has not been detected) 2. When an error occurs in the read data length (and the end bit has not been detected among the valid bits) 3. When an error occurs in the CRC status length (and the end bit has not been detected) 4. An error in the length of a response to a command issued within a command sequence*5 (i.e. the end bit has not been detected) [Clearing condition] When 0 is written to ERR2 The command sequence is halted by the End error.*4	R/W*1
3	ERR3	Data Timeout (except response timeout) [Setting conditions] 1. After the reception of the R1b response, the interface remains in a busy state (SDDAT0 = 0) for at least Ncycle. 2. After the reception of the CRC status, the interface remains in a busy state (SDDAT0 = 0) for at least Ncycle. 3. After write data, the CRC status is not received even after Ncycle has elapsed. 4. After the read command, read data is not received even after Ncycle has elapsed. 5. After CMD12 has been issued within a command sequence, the interface remains in a busy state (SDDAT0 = 0) for at least Ncycle. 6. After the reception of read data, read data for the next block are not received even after Ncycle has elapsed. 7. After release of the read wait state, read data for the next block are not received even after Ncycle has elapsed. [Clearing condition] When 0 is written to ERR3 Ncycle is set by bits 7 to 4 in SD_OPTION. The command sequence is halted by the data timeout.	R/W*1
4	ERR4	SD_BUF Illegal Write Access [Setting conditions] 1. When data is written to SD_BUF0 while it is not in the data read/write command state 2. When data is written to SD_BUF0 while SD_BUF is full 3. When data is written to SD_BUF0 while an error occurs in the CRC status or CRC status length 4. When data is written to SD_BUF0 while the interface remains in a busy state for at least Ncycle after the CRC status [Clearing condition] When 0 is written to ERR4 Ncycle is set by bits 7 to 4 in SD_OPTION.	R/W*1
5	ERR5	SD_BUF Illegal Read Access [Setting conditions] 1. When SD_BUF is empty while SD_BUF0 is read 2. When data with a CRC error or END error is read from SD_BUF0 [Clearing condition] When 0 is written to ERR5	R/W*1
6	ERR6	Response Timeout [Setting condition] When a response is not received even after 640 cycles of SDCLK have elapsed (including a response to a command issued within a command sequence*5) [Clearing condition] When 0 is written to ERR6 The command sequence is halted by a response timeout.*4	R/W*1
7	DAT0	SDDAT0 Indicates the SDDAT0 state If the data timeout (ERR3) is set but the response timeout (ERR6) is not set after the Erase command has been issued, the end of the Erase sequence (DAT0 = 1) is confirmed by polling DAT0. If a communications error or timeout occurs during a write sequence, the DAT0 bit may retain the value 0. While the SD clock (SDCLK) is stopped, the DAT0 bit retains the value before the clock is stopped. 0: SDDAT0 is set to 0. 1: SDDAT0 is set to 1.	R

Bit	Symbol	Function	R/W
8	BRE	SD_BUF Read Enable [Setting conditions] 1. When data set in SD_SIZE is stored in SD_BUF at single block transfer 2. When data set in SD_SIZE is stored in either bank 1 or bank 2 of SD_BUF at multiple block transfer [Clearing conditions] 1. When 0 is written to BRE 2. Reading of a block of data from SD_BUF by DMA transfer When data is read from SD_BUF0 by the CPU, clear BRE and then read the amount of data specified by SD_SIZE.*3 Even if a CRC error or an END error occurs while block data is read, data is stored in SD_BUF and BRE is set. 0: Data cannot be read from SD_BUF0. 1: Data can be read from SD_BUF0.	R/W*1
9	BWE	SD_BUF Write Enable [Setting conditions] 1. When SD_BUF is empty at single block transfer 2. When either bank 1 or bank 2 of SD_BUF is empty at multiple block transfer [Clearing conditions] 1. When 0 is written to BWE 2. Writing of a block of data to SD_BUF by DMA transfer When data is written to SD_BUF0 by the CPU, clear BWE and then write the amount of data specified by SD_SIZE.*3 0: Data cannot be written in SD_BUF0. 1: Data can be written in SD_BUF0.	R/W*1
10	—	This bit is read as 0. The write value should be 0.	R/W
11	—	This bit is read as 0. The write value should be 1.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	SCLKDIVEN	When a command sequence is started by writing to SD_CMD, the CBSY bit is set to 1 and, at the same time, the SCLKDIVEN bit is set to 0. The SCLKDIVEN bit is set to 1 after 8 cycles of SDCLK have elapsed after setting of the CBSY bit to 0 due to completion of the command sequence. 0: The SD bus (CMD, DAT) is busy. Do not attempt to write to the SD_CLK_CTRL register. 1: The SD bus (CMD, DAT) is not busy.	R
14	CBSY	Command Type Register Busy 0: A command sequence has been completed. 1: A command sequence is being executed.	R
15	ILA	Illegal Access Error [Setting conditions] 1. Writing of data to SD_CMD within a command sequence (CBSY = 1) 2. When SD_CMD[11] = 1 (command with data transfer) and SD_CMD[7:0] = 0x0C (CMD12) are set in SD_CMD [Clearing condition] When 0 is written to ILA	R/W*1
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only effective when 0 is written.
Note 2. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 3. When the WMODE bit in HOST_MODE is 0, the single byte from the fraction of a full 16-bit unit is regarded as excess data due to an odd value for the number of bytes setting in SD_SIZE. When the WMODE bit in HOST_MODE is 1, the single byte or three bytes from the fraction of a full 64-bit unit are regarded as excess data due to an odd value for the number of bytes setting in SD_SIZE, or the two bytes from the fraction of a full 64-bit unit are regarded as excess data due if the value for the number of bytes setting in SD_SIZE is even but is not on a four-byte boundary.
Note 4. After the C52PUB bit in SDIO_MODE has been set to 1, if a communications error or timeout for response occurs in response to the CMD52 that is issued, since the command sequence has not been completed, complete the sequence with error processing as in usage examples in Figure 55.18 under section 55.5.8. IO_RW_EXTENDED (CMD53/Multiple Block Read) or in Figure 55.21 under section 55.5.9. IO_RW_EXTENDED (CMD53/Multiple Block Write).
Note 5. "Command issued within a command sequence" refers to CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

The SD_INFO2 register indicates the access status of the SD buffer (SD_BUF) and SD card. To clear a flag, write 0 to the bit to be cleared and 1 to the other bits.

55.3.8 SD_INFO1_MASK : SD_INFO1 Interrupt Mask Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0080

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	IMASK16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	IMASK9	IMASK8	—	—	—	IMASK4	IMASK3	IMASK2	—	IMASK0
Value after reset:	0	0	0	0	0	0	1	1	0	0	0	1	1	1	0	1

Bit	Symbol	Function	R/W
0	IMASK0	INFO0 interrupt masked	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	IMASK2	INFO2 interrupt masked	R/W
3	IMASK3	INFO3 interrupt masked	R/W
4	IMASK4	INFO4 interrupt masked	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	IMASK8	INFO8 interrupt masked	R/W
9	IMASK9	INFO9 interrupt masked	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	IMASK16	HPIRES interrupt masked	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

The SD_INFO1_MASK register is used to enable or disable the SD_INFO1 interrupt. When 0 is set in SD_INFO1_MASK while the corresponding flag in SD_INFO1 is set, an interrupt occurs.

55.3.9 SD_INFO2_MASK : SD_INFO2 Interrupt Mask Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0088

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	IMASK	—	—	—	—	—	BMASK1	BMASK0	—	EMASK6	EMASK5	EMASK4	EMASK3	EMASK2	EMASK1	EMASK0
Value after reset:	1	0	0	0	1	0	1	1	0	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	EMASK0	ERR0 interrupt masked	R/W
1	EMASK1	ERR1 interrupt masked	R/W
2	EMASK2	ERR2 interrupt masked	R/W
3	EMASK3	ERR3 interrupt masked	R/W
4	EMASK4	ERR4 interrupt masked	R/W

Bit	Symbol	Function	R/W
5	EMASK5	ERR5 interrupt masked	R/W
6	EMASK6	ERR6 interrupt masked	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	BMASK0	BRE interrupt masked	R/W
9	BMASK1	BWE interrupt masked	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	—	This bit is read as 1. The write value should be 1.	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	IMASK	ILA interrupt masked	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The SD_INFO2_MASK register is used to enable or disable the SD_INFO2 interrupt. When 0 is set in SD_INFO2_MASK while the corresponding flag in SD_INFO2 is set, an interrupt occurs.

55.3.10 SD_CLK_CTRL : SD Clock Control Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0090

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SDCLKOFFEN	SCLKEN	DIV7DIV0[7:0]							
Value after reset:	0	0	0	0	0	0*1	0	0*1	0	0	1	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DIV7DIV0[7:0]	SD Clock (SDCLK) In addition, in the case of data transfer in DDR mode (DDR bit in SDIF_MODE = 1), do not set DIV[7:0] to 0xFF. 0x80: PCLKAM/512 0x40: PCLKAM/256 0x20: PCLKAM/128 0x10: PCLKAM/64 0x08: PCLKAM/32 0x04: PCLKAM/16 0x02: PCLKAM/8 0x01: PCLKAM/4 0x00: PCLKAM/2 0xFF: PCLKAM Others: Setting prohibited	R/W*2
8	SCLKEN	SD Clock (SDCLK) Output Control Enable 0: SD clock (SDCLK) output is disabled. The SDCLK signal is fixed 0. 1: SD clock (SDCLK) output is enabled.	R/W

Bit	Symbol	Function	R/W
9	SDCLKOFFEN	SD Clock (SDCLK) Output Automatic Control Enable This function of automatic control for SD clock (SDCLK) output causes SDCLK output only within a command sequence. The timing with which SDCLK output starts and stops is as follows. SDCLK output starts after writing to SD_CMD. SDCLK output stops when 8 cycles of SDCLK have elapsed after the end of the command sequence. In addition, SDCLK is fixed to 0 while SCLKEN of SD_CLK_CTRL is 0, regardless of the value of this bit. 0: Automatic control for SD clock (SDCLK) output is disabled. 1: Automatic control for SD clock (SDCLK) output is enabled.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. This initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 2. Writing to SD_CLK_CTRL is impossible when the CBSY bit in SD_INFO2 is 1.

The SD_CLK_CTRL register is used to control the SD clock (SDCLK) output and to set the frequency. Set SCLKEN to 1 before writing to SD_CMD to issue a command. Do not write to SD_CLK_CTRL while the SCLKDIVEN bit in SD_INFO2 is set to 0.

CAUTION

Notes on when setting the SD clock (SDCLK) to PCLKAM (DIV[7:0] = 0xFF)

When changing the setting of bits DIV[7:0] to 0xFF, or from 0xFF to other setting, perform the following processing before writing to SD_CMD.

1. Set the SCLKEN bit to 0 by writing to SD_CLK_CTRL. (Do not change the setting of bits other than SCLKEN at this time.)
2. Change the setting of bits DIV[7:0] by writing to SD_CLK_CTRL. (Do not change the setting of bits other than DIV[7:0] at this time. The SCLKEN bit should retain the value 0.)
3. Set the SCLKEN bit to 1 by writing to SD_CLK_CTRL. (Do not change the setting of bits other than SCLKEN at this time.)

Also when changing the setting of bits DIV[7:0] to 0xFF after having set the SDRST bit in SOFT_RST to 0 and then changed it to 1, perform this processing before writing to SD_CMD.

55.3.11 SD_SIZE : Transfer Data Length Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0098

Bit position:	31																					9								0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LEN9LEN0[9:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	LEN9LEN0[9:0]	Transfer Data Size*1 These bits specify a size between 1 and 512 bytes for single block transfer. In cases of multiple block transfer with automatic issuing of CMD12 (CMD18 and CMD25), the only specifiable transfer data size is 512 bytes. Furthermore, in cases of multiple block transfer without automatic issuing of CMD12, as well as 512 bytes, 32, 64, 128, and 256 bytes are specifiable. However, in the reading of 32, 64, 128, and 256 bytes for the transfer of multiple blocks, this is restricted to multiple block transfer by CMD53. Additionally, if a command accompanies data transfer, do not set these bits to 0. Do not specify a data size larger than 512 bytes.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not change the values of these bits when the CBSY bit in SD_INFO2 is 1.

The SD_SIZE register is used to specify the transfer data size.

55.3.12 SD_OPTION : SD Card Access Control Option Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x00A0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WIDTH	—	WIDTH8	—	—	—	EXTOP	TOUTMASK	TOP27TOP24[3:0]				CTOP24CTOP21[3:0]			
Value after reset:	0*1	1	0*1	0	0	0	0*1	0*1	1*1	1*1	1*1	0*1	1*1	1*1	1*1	0*1

Bit	Symbol	Function	R/W
3:0	CTOP24CTOP21[3:0]	Card Detect Time Counter 0x0: 2^{13} SDCLK 0x1: 2^{14} SDCLK ⋮ 0xD: 2^{26} SDCLK 0xE: 2^{27} SDCLK 0xF: Setting prohibited	R/W
7:4	TOP27TOP24[3:0]	Timeout Counter*2 0x0: 2^{10} SDCLK 0x1: 2^{11} SDCLK ⋮ 0xD: 2^{23} SDCLK 0xE: 2^{24} SDCLK 0xF: Setting prohibited	R/W
8	TOUTMASK	Timeout Mask If a timeout occurs while it is disabled, perform a software reset to terminate a command sequence. 0: Enables timeout 1: Disables timeout (The ERR6 and ERR3 bits in SD_INFO2 and the E6 to E0 bits in SD_ERR_STS2 are not set.)	R/W
9	EXTOP	Timeout Mode Select 0: The TOP27TOP24[3:0] bits specify the timeout count from 2^{10} SDCLK to 2^{24} SDCLK. 1: The TOP27TOP24[3:0] bits specify the timeout count from 2^{11} SDCLK to 2^{25} SDCLK.	R/W
12:10	—	These bits are read as 0. The write value should be 0.	R/W
13	WIDTH8	Bus width*2 See the description of the WIDTH bit.	R/W
14	—	This bit is read as 1. The write value should be 1.	R/W
15	WIDTH	Bus width*2 {WIDTH, WIDTH8} = 01: 8-bit width {WIDTH, WIDTH8} = 00: 4-bit width {WIDTH, WIDTH8} = 10, 11: 1-bit width In the case of data transfer in DDR mode (DDR bit in SDIF_MODE = 1), do not set this bit to 1. In the case of writing of one-byte block, 8-bit width cannot be specified for the bus width. Change the bus width to 4 bits or 1 bit before writing one-byte block.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 2. Do not change the values of these bits when the CBSY bit in SD_INFO2 is 1.

The SD_OPTION register is used to set the bus width and timeout counter.

55.3.13 SD_ERR_STS1 : SD Error Status Register 1

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x00B0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	E14E12[2:0]			E11	E10	E9	E8	—	—	E5	E4	E3	E2	E1	E0
Value after reset:	x	0*1	1*1	0*1	0*1	0*1	0*1	0*1	0	0	0*1	0*1	0*1	0*1	0*1	0*1

Bit	Symbol	Function	R/W
0	E0	Set to 1 when an error occurs in the command index of a response (other than a response to a command issued within a command sequence*2).	R
1	E1	Set to 1 when an error occurs in the command index of the response to a command issued within a command sequence*2. In cases where CMD12 is issued by setting a command index in SD_CMD, this is Indicated in E0.	R
2	E2	Set to 1 when an error occurs in the response length (other than a response to a command issued within a command sequence*2).	R
3	E3	Set to 1 when an error occurs in the response length to a command issued within a command sequence*2. In cases where CMD12 is issued by setting a command index in SD_CMD, this is indicated in E2.	R
4	E4	Set to 1 when an error occurs in the read data length (and the end bit has not been detected among the valid bits).	R
5	E5	Set to 1 when an error occurs in the CRC status length (and the end bit has not been detected).	R
7:6	—	These bits are read as 0.	R
8	E8	Set to 1 when a CRC error occurs in a response (other than a response to a command issued within a command sequence*2).	R
9	E9	Set to 1 when a CRC error occurs in the response to a command issued within a command sequence*2. In cases where CMD12 is issued by setting a command index in SD_CMD, this is indicated in E8.	R
10	E10	Set to 1 when a CRC error occurs in the read data.	R
11	E11	Set to 1 when an error occurs in the CRC status.	R
14:12	E14E12[2:0]	These bits hold the CRC status. (normal: 010b)	R
31:15	—	The read values are undefined.	R

Note 1. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.

Note 2. "Command issued within a command sequence" refers to CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

The SD_ERR_STS1 register indicates the CRC status, CRC error, End error, and CMD error.

55.3.14 SD_ERR_STS2 : SD Error Status Register 2

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x00B8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	E6	E5	E4	E3	E2	E1	E0
Value after reset:	0	0	0	0	0	0	0	0	0	0*1	0*1	0*1	0*1	0*1	0*1	0*1

Bit	Symbol	Function	R/W
0	E0	Set to 1 when the response (other than a response to a command issued within a command sequence*2) is not received even after 640 cycles of SDCLK have elapsed.	R
1	E1	Set to 1 when the response to a command issued within a command sequence*2 is not received even after 640 cycles of SDCLK have elapsed. In cases where CMD12 is issued by setting a command index in SD_CMD, this is indicated in E0.	R
2	E2	Set to 1 when the interface remains in a busy state for at least Ncycle after R1b response.	R
3	E3	Set to 1 when the interface remains in a busy state for at least Ncycle after CMD12 has been issued within a command sequence. In cases where CMD12 is issued by setting a command index in SD_CMD, this is indicated in E2.	R
4	E4	Set to 1 when read data is not received even after Ncycle has elapsed after the command has been read. Set to 1 when read data for the next block are not received even after Ncycle has elapsed after the reception of read data. Set to 1 when read data for the next block are not received even after Ncycle has elapsed after release of the read wait state.	R
5	E5	Set to 1 when the CRC status is not received even after Ncycle has elapsed after data writing.	R
6	E6	Set to 1 when the interface remains in a busy state for at least Ncycle after the CRC status.	R
31:7	—	These bits are read as 0.	R

Note 1. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.

Note 2. "Command issued within a command sequence" refers to CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

The SD_ERR_STS2 register indicates the timeout state. Ncycle is set by bits 7 to 4 in SD_OPTION.

55.3.15 SD_BUF0 : SD Buffer Read/Write Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x00C0

Bit position:	63	32
Bit field:		
Value after reset:	x x x x x x x x x x x x x x x x x x x x x x x x x x x x x x x x	

Bit position:	31	0
Bit field:		
Value after reset:	x x x x x x x x x x x x x x x x x x x x x x x x x x x x x x x x	

Bit	Symbol	Function	R/W
63:0	n/a	When writing to the SD card, the write data is written to this register. When reading from the SD card, the read data is read from this register. This register is internally connected to two 512-byte buffers (SD_BUF). When both buffers are not empty at multiple block read, suspend data reception by stopping the SD clock. When either buffer becomes empty, restart data reception by starting supply of the SD clock.	R/W

Note: When using the DMAC, the bus width should be fixed at 64 bits.

55.3.16 SDIO_MODE : SDIO Mode Control Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x00D0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	C52PUB	IOABT	—	—	—	—	—	RWREQ	—	IOMOD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IOMOD	SDIO Mode[*1] 0: Disables the SD/MMC host interface to receive SDIO interrupts from the SDIO card 1: Enables the SD/MMC host interface to receive SDIO interrupts from the SDIO card	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	RWREQ	Read Wait Request When RWREQ is set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between blocks. [Releasing the read wait state] 1. The read wait state is released when RWREQ is cleared to 0 in the read wait state. 2. When IOABT is set to 1 in the read wait state, RWREQ is automatically cleared to 0 after CMD52 has been issued, and then the read wait state is released. 3. When C52PUB and RWREQ are set to 1 simultaneously in the CMD53 (multiple block) read sequence, the read wait state is not automatically released. Therefore, after the CMD52 response is received, clear RWREQ. (Be sure to set RWREQ and C52PUB simultaneously.) When RWREQ is set to 1 while the last block in the CMD53 (multiple block) read sequence is transferred, the read wait state is not entered and RWREQ is automatically cleared to 0 by setting access end. Set RWREQ to 1 after the response end flag has been set.	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
8	IOABT	SDIO Abort ● When IOABT is set to 1 in the CMD53 (multiple block) sequence, the CMD53 sequence is halted and CMD52 is issued. However, if a command sequence is halted because of a communications error or timeout, CMD52 is not issued. Although continued buffer access is possible even after IOABT has been set to 1, the buffer access error bit (ERR5 or ERR4) in SD_INFO2 will be set accordingly. Set SD_ARG before setting IOABT to 1. ● When IOABT has been set to 1 during transfer for single block write, the access end flag is set when SD_BUF becomes empty, and CMD52 is not issued. If SD_BUF does contain data, the access end flag is set on completion of reception of the busy state without CMD52 having been issued. ● When IOABT has been set to 1 during transfer for single block read, the access end flag is set immediately after setting of IOABT and CMD52 is not issued. ● When IOABT is set to 1 during reception of the busy state after an R1b response, the access end flag is set on completion of reception of the busy state without CMD52 having been issued. ● When IOABT is set to 1 after a command sequence has been completed, CMD52 is not issued and the access end flag is not set. ● Set IOABT to 1 after the response end flag has been set. Set IOABT to 0 after the access end flag has been set.	R/W
9	C52PUB	SDIO None Abort ● When C52PUB is set to 1 in the CMD53 (multiple block) write sequence, CMD52 is automatically issued between blocks if SD_BUF becomes empty. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag has been set to 1. ● When C52PUB and RWREQ are set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between blocks and CMD52 is automatically issued. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag has been set to 1. ● If C52PUB is set to 1 in the CMD53 (multiple block) read sequence, be sure to set RWREQ to 1 as well as C52PUB. ● Set SD_ARG before setting C52PUB to 1. ● Set C52PUB to 1 after the response end flag has been set.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not change the value of this bit when the CBSY bit in SD_INFO2 is set to 1.

The SDIO_MODE register controls the CMD52 issuance and the read wait state at multiple block transfer, and the reception of SDIO interrupt. C52PUB and IOABT should not be set to 1 simultaneously.

55.3.17 SDIO_INFO1 : SDIO Interrupt Flag Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x00D8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EXWT	EXPUB52	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQ
Value after reset:	0*2	0*2	0	0	0	0	0	0	0	0	0	0	0	0*2	0*2	0*2

Bit	Symbol	Function	R/W
0	IOIRQ	[Setting condition] When an SDIO interrupt from the SDIO card is received while IOMOD in SDIO_MODE is set to 1. [Clearing condition] When 0 is written to IOIRQ*3	R/W*1
2:1	—	The read values are undefined. The write value should be 1.	R/W
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	EXPUB52	[Setting conditions] 1. While the last block in the CMD53 (multiple block) sequence is transferred, C52PUB in SDIO_MODE is set to 1. 2. While C52PUB is set to 1 in the CMD53 (multiple block) write sequence, the last block is transferred. [Clearing condition] When 0 is written to EXPUB52	R/W*1
15	EXWT	[Setting condition] While the last block in the CMD53 (multiple block) read sequence is transferred, RWREQ in SDIO_MODE is set to 1. [Clearing condition] When 0 is written to EXWT	R/W*1
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only effective when 0 is written.
Note 2. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 3. Before clearing this bit, access the SDIO card to negate the SDIO interrupt signal from the SDIO card. If the interrupt signal is not negated, this bit may be set again.

The SDIO_INFO1 register indicates the status regarding to the SDIO card access. To clear a flag, write 0 to the bit to be cleared and 1 to the other bits.

55.3.18 SDIO_INFO1_MASK : SDIO_INFO1 Interrupt Mask Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x00E0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MEXWT	MEXPUB52	—	—	—	—	—	—	—	—	—	—	—	—	—	IOMSK
Value after reset:	1	1	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
0	IOMSK	IOIRQ interrupt masked	R/W
2:1	—	These bits are read as 1. The write value should be 1.	R/W
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	MEXPUB52	EXPUB52 interrupt masked	R/W
15	MEXWT	EXWT interrupt masked	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The SDIO_INFO1_MASK register enables or disables the SD_INFO1 interrupt. When 0 is set in SDIO_INFO1_MASK while the corresponding flag in SD_INFO1 is set, an interrupt occurs.

55.3.19 CC_EXT_MODE : DMA Mode Enable Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0360

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMASDRW	—
Value after reset:	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	DMASDRW	SD_BUF Read/Write DMA Transfer*1 0: The SD_BUF read/write DMA transfer is disabled. 1: The SD_BUF read/write DMA transfer is enabled.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	—	This bit is read as 1. The write value should be 1.	R/W
11:5	—	These bits are read as 0. The write value should be 0.	R/W
12	—	This bit is read as 1. The write value should be 1.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not change the value of this bit when the CBSY bit in SD_INFO2 is set to 1.

The CC_EXT_MODE register enables the DMA transfer.

55.3.20 SOFT_RST : Software Reset Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0380

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
0	SDRST	Software Reset of SD Interface Unit 0: Reset 1: Reset released	R/W
2:1	—	These bits are read as 1. The write value should be 1.	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

The SOFT_RST register sets a software reset. Also use this register to check that release from the reset state has been completed before attempting to use the SD/MMC host interface and before attempting access to the other registers.

55.3.21 VERSION : Version Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0388

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	UR3UR0[3:0]				IP7IP0[7:0]							
Value after reset:	1	1	0	0	1	1	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
7:0	IP7IP0[7:0]	Version of introductory IP	R
11:8	UR3UR0[3:0]	Version of Renesas' IP	R
13:12	—	These bits are read as 0.	R
15:14	—	These bits are read as 1.	R
31:16	—	These bits are read as 0.	R

The VERSION register indicates the version of the SD/MMC host interface.

55.3.22 HOST_MODE : Host Interface Mode Setting Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0390

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BUSWIDTH	—	—	—	—	—	—	ENDIAN	WMODE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	WMODE	Width for Access to SD_BUF*1 *2 Read or write access to SD_BUF0 can be performed with the specified width for access. 0: 64-bit access 1: 16-bit or 32-bit access	R/W
1	ENDIAN	SD_BUF0 data swap	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	BUSWIDTH	Width for Access to SD_BUF*1 *2 Read or write access to SD_BUF0 can be performed with the specified width for access. This bit is enabled while the WMODE bit is set to 1. 0: 16-bit access 1: 32-bit access	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not change the value of this bit when the CBSY bit in SD_INFO2 is set to 1.
Note 2. When using the built-in DMAC of this module, fix the bus width to 64 bits.

The HOST_MODE register selects the width for access to the data bus.

55.3.23 SDIF_MODE : SD Interface Mode Setting Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0398

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	NOCHKCR	—	—	—	—	—	—	—	DDR
Value after reset:	0	0	0	0	0	0	0*1	0*1	0	0	0	0	0	0	0	0*1

Bit	Symbol	Function	R/W
0	DDR	DDR Mode Select*2 Set this bit to 0 when the SD clock division ratio is specified as 1:1 (bits DIV[7:0] in SD_CLK_CTRL are set to 0xFF). 0: Normal mode (default, high speed, or SDR) 1: DDR mode	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	NOCHKCR	CRC Check Mask (test command for MMC supported) Enables or disables checking of the CRC16 and CRC status. 0: Enables the CRC check 1: Disables the CRC check (the CRC16 value is ignored at read, and the CRC status is not detected at write)	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The initial value is applied at a reset and when the SDRST bit in SOFT_RST is 0.
Note 2. Do not change the value of this bit when the CBSY bit in SD_INFO2 is set to 1.

The SDIF_MODE register specifies DDR mode.

55.3.24 SD_STATUS : SD Status Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x03C8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SD_IOVS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SD_RST	SD_PWEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	SD_PWEN	Controls the output value on the SDm_PWEN pin 0: The output value on the SDm_PWEN pin is 0. 1: The output value on the SDm_PWEN pin is 1.	R/W
1	SD_RST	Controls the output value on the SD0_RST# pin*1 0: The output value on the SD0_RST# pin is 0. 1: The output value on the SD0_RST# pin is 1.	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	SD_IOVS	Controls the output value on the SDm_IOVS pin 0: The output value on the SDm_IOVS pin is 0. 1: The output value on the SDm_IOVS pin is 1.	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Channel 0 only. Reserved for channel 1.

The effective bit of SD_STATUS register controls the output value on the SD0_RST#, SDm_PWEN, and SDm_IOVS pins.

55.3.25 DM_CM_DTRAN_MODE : DMAC Transfer Mode Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0820

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CH_NUM[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	BUS_WIDTH[1:0]		—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
5:4	BUS_WIDTH[1:0]	Bus width selector 1 1: 64-bit Others: Setting prohibited	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W
17:16	CH_NUM[1:0]	DMAC channel selector 0 0: SD downstream 0 1: SD upstream Others: Setting prohibited	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The DM_CM_DTRAN_MODE register sets the operation mode of the DMAC of this module.

55.3.26 DM_CM_DTRAN_CTRL : DMAC Transfer Control Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0828

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DM_START
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DM_START	DMAC Start Writing 1 to this bit starts DMAC operation. This bit is automatically cleared when DMA transfer is started.	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

The DM_CM_DTRAN_CTRL register controls DMAC operation of the module.

55.3.27 DM_CM_RST : DMAC Reset Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0830

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	DTRANRST1	DTRANRST0	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 1. The write value should be 1.	R/W
8	DTRANRST0	Software reset of DMAC channel 0 of the module 0: Reset 1: Reset released	R/W
9	DTRANRST1	Software reset of DMAC channel 1 of the module 0: Reset 1: Reset released	R/W
31:10	—	These bits are read as 1. The write value should be 1.	R/W

Note: Make sure there is no communication to the SD/MMC device before applying a software reset using this register.

55.3.28 DM_CM_INFO1 : DMAC Interrupt Register 1

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0840

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	DTRANEND1	—	—	—	DTRANEND0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0*1	0	0	0	0*2

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	DTRANEND0	DMAC Channel 0 Transfer End [Setting conditions] 1. When transfer of DMAC channel 0 is completed 2. When an error occurs on DMAC channel 0 [Clearing condition] When 0 is written to DTRANEND0	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	DTRANEND1	DMAC Channel 1 Transfer End [Setting conditions] 1. When transfer of DMAC channel 1 is completed 2. When an error occurs on DMAC channel 1 [Clearing condition] When 0 is written to DTRANEND1	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The initial value is applied at a reset and when the DTRANRST1 bit in DM_CM_RST is 0.
Note 2. The initial value is applied at a reset and when the DTRANRST0 bit in DM_CM_RST is 0.

The DM_CM_INFO1 register indicates the status of the DMAC of the module and the sequencer. To clear a flag, write 0 to the bit to be cleared and 1 to the other bits.

55.3.29 DM_CM_INFO1_MASK : DM_CM_INFO1 Interrupt Mask Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0848

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	DTRANEND1_MASK	—	—	—	DTRANEND0_MASK
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 1. The write value should be 1.	R/W
16	DTRANEND0_MASK	DTRANEND0 interrupt masked	R/W
19:17	—	These bits are read as 1. The write value should be 1.	R/W
20	DTRANEND1_MASK	DTRANEND1 interrupt masked	R/W
31:21	—	These bits are read as 1. The write value should be 1.	R/W

The DM_CM_INFO1_MASK register enables or disables the DM_CM_INFO1 interrupt. When 0 is set in DM_CM_INFO1_MASK while the corresponding flag in DM_CM_INFO1 is set, an interrupt occurs.

55.3.30 DM_CM_INFO2 : DMAC Interrupt Register 2

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0850

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DTRANERR1	DTRANERR0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0*1	0*2

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
16	DTRANERR0	DMAC Channel 0 Error [Setting condition] When an error occurs on DMAC channel 0 [Clearing condition] When 0 is written to DTRANERR0	R/W
17	DTRANERR1	DMAC Channel 1 Error [Setting condition] When an error occurs on DMAC channel 1 [Clearing condition] When 0 is written to DTRANERR1	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The initial value is applied at a reset and when the DTRANRST1 bit in DM_CM_RST is 0.
Note 2. The initial value is applied at a reset and when the DTRANRST0 bit in DM_CM_RST is 0.

The DM_CM_INFO2 register indicates the status of the DMAC of the module and the sequencer. To clear a flag, write 0 to the bit to be cleared and 1 to the other bits.

55.3.31 DM_CM_INFO2_MASK : DM_CM_INFO2 Interrupt Mask Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0858

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DTRANERR1_MASK	DTRANERR0_MASK
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 1. The write value should be 1.	R/W
16	DTRANERR0_MASK	DTRANERR0 interrupt masked	R/W
17	DTRANERR1_MASK	DTRANERR1 interrupt masked	R/W
31:18	—	These bits are read as 1. The write value should be 1.	R/W

The DM_CM_INFO2_MASK register enables or disables the DM_CM_INFO2 interrupt. When 0 is set in DM_CM_INFO2_MASK while the corresponding flag in DM_CM_INFO2 is set, an interrupt occurs.

55.3.32 DM_DTRAN_ADDR : DMAC Transfer Address Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0880

Bit position:	31																											3		0
Bit field:	DADDR[28:0]																											—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
31:3	DADDR[28:0]	Destination address/Source address (8 byte unit) Note that the value of DM_DTRAN_ADDR + transfer data length is less than or equal to 232.	R/W

The DM_DTRAN_ADDR register sets the transfer destination and source addresses for the DMAC of the module.

55.3.33 SCC_DTCNTL : Initial Setting Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	TAPNUM7TAPNUM0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TAPEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TAPEN	SCC Sampling Clock Operation Enable 0: SCC sampling clock operation is disabled. 1: SCC sampling clock operation is enabled.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W
23:16	TAPNUM7TAPNUM0[7:0]	Set these bits to 0x08.	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

55.3.34 SCC_TAPSET : Sampling Clock Position Setting Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1008

Bit position:	31																											7		0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TAPSET7TAPSET0[7:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TAPSET7TAPSET0[7:0]	SCC Sampling Clock Position Set the tuning result in the range from 0 to TAPNUM − 1.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

55.3.35 SCC_DT2FF : Hardware Adjustment Register 1

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DT2NE[7:0]								DT2NS[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DT2NS[7:0]	Hardware Adjustment 1 This is a setting register for adjusting the timing inside the IP when using Tuning. When using Tuning, set 0x07 to these bits, make the setting before setting 1 in SCC_CKSEL[0].DTSEL.	R/W
15:8	DT2NE[7:0]	Hardware Adjustment 2 This is a setting register for adjusting the timing inside the IP when using Tuning. When using Tuning, set 0x02 to these bits, make the setting before setting 1 in SCC_CKSEL[0].DTSEL.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

This register makes a setting that SD_DATA, which has been fetched by the sampling clock at each TAP position, is used in the appropriate timing.

55.3.36 SCC_CKSEL : Sampling Clock Selection Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DTSEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DTSEL	Sampling Clock Selection ● For SDR104 or HS200, set DTSEL to 1. DIV[7:0] in the SD_CLK_CTRL register to 0xFF (1:1 mode). ● When this bit is switched, stop the SD clock output from the SD/MMC host interface (set SCLKEN in SD_CLK_CTRL to 0). 0: An SCC sampling clock is not used (for other than SDR104 and HS200). 1: An SCC sampling clock is used (for SDR104 or HS200).	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

55.3.37 SCC_RVSCNTL : Sampling Clock Position Correction Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TAPSEL[7:0]								—	—	—	—	—	—	—	RVSEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RVSEN	SCC Sampling Clock Position Correction Enable When RVSEN is set to 1 after tuning has been performed, this module corrects the SCC sampling clock position each time of a command sequence of the SD/MMC host interface. However, when RVSERR is 1, this module does not correct the SCC sampling clock position. While tuning is being performed, set RVSEN to 0. 0: SCC sampling clock position correction is disabled. 1: SCC sampling clock position correction is enabled.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	TAPSEL[7:0]	SCC Sampling Clock Position Display Displays the SCC sampling clock position selected by hardware. After RVSEN has been set to 1, the value may differ from that of TAPSET.	R
31:16	—	These bits are read as 0. The write value should be 0.	R/W

55.3.38 SCC_RVSREQ : Sampling Clock Position Correction Request Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1028

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	RVSERR	REQTAPUP	REQTAPDWN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	REQTAPDWN	SCC Sampling Clock Position Negative Direction Correction Request ● If this bit is set to 1 after a command sequence, write 0 to this bit and rewrite TAPSET in the negative direction (when TAPSEL = 0, set TAPNUM − 1 to TAPSET). ● When RVSEN is 1, this bit is disabled (this bit is not set to 1). ● Writing 1 to this bit is disabled and writing 0 to this bit is only enabled. 0: There is no correction request. 1: There is a correction request.	R/W

Bit	Symbol	Function	R/W
1	REQTAPUP	SCC Sampling Clock Position Positive Direction Correction Request ● If this bit is set to 1 after a command sequence, write 0 to this bit and rewrite TAPSET in the positive direction (when TAPSEL = TAPNUM − 1, set 0 to TAPSET). ● When RVSEN is 1, this bit is disabled (this bit is not set to 1). ● Writing 1 to this bit is disabled and writing 0 to this bit is only enabled. 0: There is no correction request. 1: There is a correction request.	R/W
2	RVSERR	SCC Sampling Clock Position Correction Error ● If this bit is set to 1 after a command sequence, write 0 to this bit and perform tuning again. ● Ignore this bit while tuning is being performed. ● Writing 1 to this bit is disabled and writing 0 to this bit is only enabled. 0: There is no correction error. 1: There is a correction error.	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

55.3.39 SCC_SMPCMP : Sampling Data Comparison Register

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1030

Bit position:	31							24							16							8							0
Bit field:	—	—	—	—	—	—	—	CMPNGU[8:0]								—	—	—	—	—	—	—	CMPNGD[8:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	CMPNGD[8:0]	Comparison of sampling data with the after TAP Clock*1 Bit 0-7 is the comparison result of data 0-7. Bit 8 is the comparison result of CMD. 0: Match 1: Mismatch	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
24:16	CMPNGU[8:0]	Comparison of sampling data with the previous TAP Clock*1 Bit 16-23 is the comparison result of data 0-7. Bit 24 is the comparison result of CMD. 0: Match 1: Mismatch	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. [Clear conditions]
The start of the command sequence
Write to SCC_TAPSET register

Data comparison register indicates the result of the comparison of the sampling data. The subject of the comparison is the before and the behind TAP.

55.3.40 SCC_TMPPORT : Hardware Adjustment Register 2

Base address: SDHIm = 0x9208_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1038

Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TMPOUT[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TMPOUT[15:0]	Hardware adjustment 3 When using the delay tuning mechanism, set the following values. Set 0x0000 to these bits. When operating with other than SDR104/HS200, this register adjusts the clock delay of the Flip Flop that latches the received data from the outside of the chip. For this product, set 0x0010 when transferring at 3.3 V, and set 0x0001 when transferring at 1.8 V.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

This register makes a setting that SD_DATA, which has been fetched by the sampling clock at each TAP position, is used in the appropriate timing.

55.4 Operation

55.4.1 SD Interface

55.4.1.1 SD Data Format

When data is read from the SD card, the procedure is as follows.

1. The SD/MMC host interface receives data from the SD card via the SDDAT signal. (SDDAT signal: see Figure 55.2, Figure 55.3, and Figure 55.5.)
2. The receive data is stored in SD_BUF of the SD/MMC host interface. (SD_BUF store data: see Figure 55.7)
3. The data stored in SD_BUF is read from SD_BUF0. (Reading from SD_BUF0: see Table 55.5)

When data is written to the SD card, the above procedure will be reversed.

When accessing SD_BUF0, caution should be taken for the transfer order in SDDAT and the store order in SD_BUF. In addition, data stored in SD_BUF0 can be replaced in bytes with the EXT_SWAP. (See Figure 55.7)

WMODE*1	BUSWIDTH*1	ENDIAN*1	Read Data*2
0	0	0	0x0123456789ABCDEF
0	0	1	0xEFCDAB8967452301
1	1	0	0x89ABCDEF (1st) 0x01234567 (2nd)
1	1	1	0xEFCDAB89 (1st) 0x67452301 (2nd)
1	0	0	0xCDEF (1st) 0x89AB (2nd) 0x4567 (3rd) 0x0123 (4th)

Table 55.5 Reading from SD_BUF0 (2 of 2)

WMODE*1	BUSWIDTH*1	ENDIAN*1	Read Data*2
1	0	1	0xEFCD (1st) 0xAB89 (2nd) 0x6745 (3rd) 0x2301 (4th)

Note 1. The name of a bit in HOST_MODE
Note 2. When the data stored in SD_BUF is 0x0123456789ABCDEF

55.4.1.2 Bus Signal Voltage Switch

Change the electric potential of the bus signal in the following procedure after checking that the SD card supports 1.8 V.

1. Issuing CMD11
   Perform command sequence processing of CMD11.
2. Stopping the SD clock (a)
   Set the SCLKEN bit in the SD_CLK_CTRL to 0 to stop*1 the output of the SD clock. When the SDCLKOFFEN bit in the SD_CLK_CTRL register is 1, the SDCLKOFFEN bit is also set to 0.

   Note 1. When the SDCLKOFFEN bit in the SD_CLK_CTRL register is 1, the SD clock has automatically been stopped.
3. Checking the value of SDDAT
   Check that the DAT0 bit in the SD_INFO2 register is 0.
4. Changing the supply voltage of the host device
   Change the voltage which is supplied through the power supply pin of the given channel (VCC1833_6 for channel 0 or VCC1833_7 for channel 1) from 3.3 V to 1.8 V by corresponding SDm_IOVS pin.
5. Starting supply of the SD clock (b)
   After the SD clock has been stopped ((a) above) and 5 ms or more has elapsed, set the SCLKEN bit in the SD_CLK_CTRL register to 1 and allow the output of the SD clock. The SDCLKOFFEN bit must be 0.
6. Checking the value of SDDAT
   After supplying the SD clock has been started ((b) above) and 1 ms or more has elapsed, check that the DAT0 bit in the SD_INFO2 register is 1. It is possible to set the SDCLKOFFEN bit in the SD_CLK_CTRL register to 1 and allow SD Clock (SDCLK) Output Automatic Control Enable.

55.4.2 Card Detect/Write Protect

55.4.2.1 Card Detect

The SD/MMC host interface has two types of card detect functions as described in the following.

(1) Card detect with ISDCD

Figure 55.8 shows the timing chart of card detect using ISDCD. ISDCD is connected to the card socket and pulled up on the host device. The resistance of the pull-up resistor is decided by the specification of the SD host device.

[Card insertion]

ISDCD is pulled down when a card is inserted. At this time, if ISDCD has been pulled down for the Mcycle period (set in SD_OPTION), INFO4 in SD_INFO1 is set to 1. (It is cleared to by writing 0.)

[Card removal]

ISDCD is pulled up when a card is removed. At this time, if ISDCD has been pulled up for the Mcycle period (set in SD_OPTION), INFO3 in SD_INFO1 is set to 1. (It is cleared to by writing 0.)

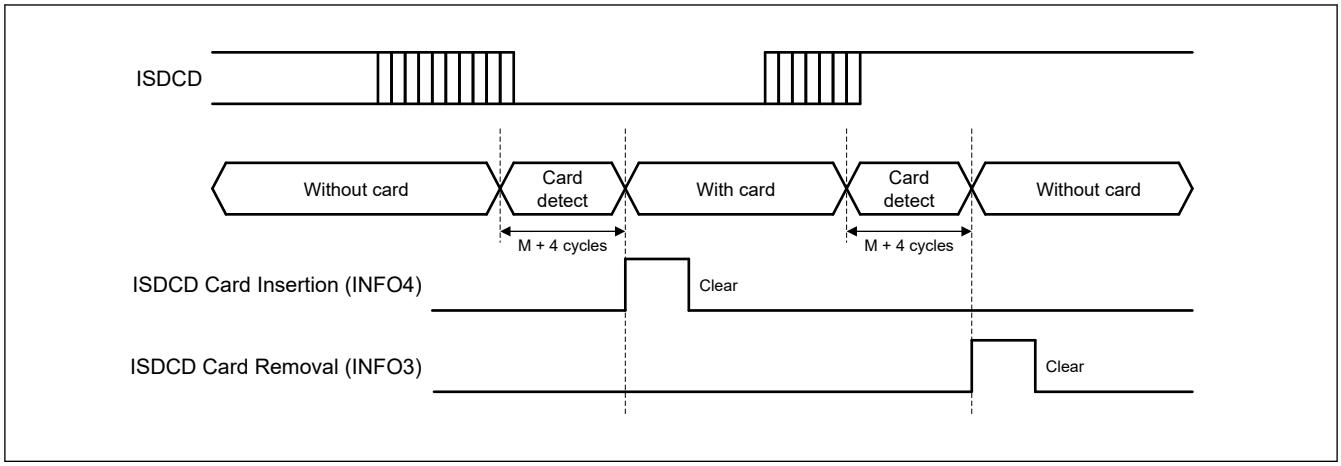

Figure 55.8 Example of card detect with ISDCD

(2) SD card detect with SDDAT3

Figure 55.9 shows the timing chart when the SD card is detected using SDDAT3. In addition, SDDAT3 is pulled down on the host device. The resistance of the pull-down resistor is decided by the specification of the SD host device.

[Card insertion]

When an SD card is inserted, SDDAT3 is pulled up. Accordingly, INFO9 in SD_INFO1 is set to 1. (It is cleared to by writing 0.)

[Card removal]

When an SD card is removed, SDDAT3 is pulled down. Accordingly, INFO8 in SD_INFO1 is set to 1. (It is cleared to by writing 0.)

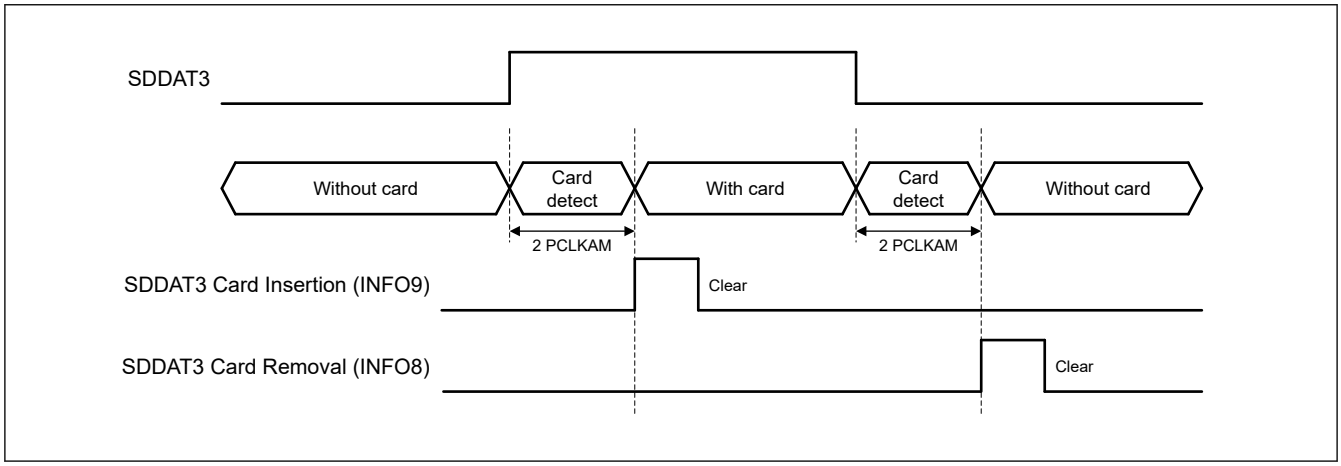

Figure 55.9 SD card detect with SDDAT3

55.4.2.2 Write Protect

The SD/MMC host interface has two types of write protect functions.

(1) Write protect with ISDWP

ISDWP is connected to the card socket, and pulled up or pulled down by the card insertion. The selection of pulling up or pulling down and the resistance value is decided by the specifications of the SD host device. As the ISDWP state is reflected to INFO7 in SD_INFO1, the write protect is decided after the SD card is inserted.

(2) Write protect with command

The card's internal write protection and the card lock/unlock operation are realized by the command.

55.4.3 Interrupt Request

The SD/MMC host interface has the interrupt requests shown in Table 55.6 shows the relationship between the interrupt flag registers and the interrupt mask registers. When a bit in an interrupt mask register is set to 0, an interrupt occurs by setting the corresponding bit in the interrupt flag register to 1.

To clear a flag, write 0 to the bit to be cleared and 1 to the other bits.

Table 55.6 Interrupt request

Interrupt request	Interrupt flag register		Interrupt mask register	
	Register name	Bit name	Register name	Bit name
Card access interrupt*1	SD_INFO1	INFO2	SD_INFO1_MASK	IMASK2
		INFO0		IMASK0
	SD_INFO2	ILA	SD_INFO2_MASK	IMASK
		BWE		BMASK1
		BRE		BMASK0
		ERR6		EMASK6
		ERR5		EMASK5
		ERR4		EMASK4
		ERR3		EMASK3
		ERR2		EMASK2
		ERR1		EMASK1
		ERR0		EMASK0
SDIO access interrupt*2	SDIO_INFO1	EXWT	SDIO_INFO1_MASK	MEXWT
		EXPUB52		MEXPUB52
		IOIRQ		IOMSK
Card detect interrupt*1	SD_INFO1	INFO9	SD_INFO1_MASK	IMASK9
		INFO8		IMASK8
		INFO4		IMASK4
		INFO3		IMASK3
DMAC interrupt*1	DM_CM_INFO1	DTRANEND1	DM_CM_INFO1_MASK	DTRANEND1_MASK
		DTRANEND0		DTRANEND0_MASK
		SEQEND		SEQEND_MASK
	DM_CM_INFO2	DTRANERR1	DM_CM_INFO2_MASK	DTARERR1_MASK
		DTRANERR0		DTARERR0_MASK
		SEQERR		SEQERR_MASK

Note 1. Interrupt signal "OXMNIRQ" is asserted.
Note 2. Interrupt signals, both "OXMNIRQ" and "OXASIOIRQ", are asserted.

55.4.4 Communications Errors and Timeouts

Table 55.7 and Table 55.8 show the relationships between the SD card interrupt flag register and SD error status register for communications errors and timeouts, respectively. When a bit in the SD card interrupt flag register is set to 1, the corresponding bit in the SD error status register is set to 1. The values of the SD error status register are cleared by writing to SD_CMD or writing 0 to the SDRST bit in SOFT_RST.

Table 55.7 Communications errors

Communication error	SD interrupt flag register		SD error status register		Description
	Register name	Bit name	Register name	Bit name	
END error	SD_INFO2	ERR2	SD_ERR_STS1	E5	When an error occurs in the CRC status length
				E4	When an error occurs in read data length
				E3	When an error occurs in the response length to a command issued within a command sequence
				E2	When an error occurs in the response length (other than a response to a command issued within a command sequence)
CRC error		ERR1		E11	When an error occurs in the CRC status
				E10	When a CRC error occurs in the read data
				E9	When a CRC error occurs in the response to a command issued within a command sequence
				E8	When a CRC error occurs in the response (other than a response to a command issued within a command sequence)
CMD error		ERR0		E1	The command index of the transmitted command differed from the command index of the received response (for a command issued within a command sequence)
				E0	The command index of the transmitted command differed from the command index of the received response (for a command issued other than within a command sequence)

Table 55.8 Timeouts

Timeout	SD interrupt flag register		SD error status register		Description
	Register name	Bit name	Register name	Bit name	
Response timeout	SD_INFO2	ERR6	SD_ERR_STS2	E1	When the response to a command issued within a command sequence is not received even after 640 cycles of SDCLK have elapsed
				E0	When the response (other than a response to a command issued within a command sequence) is not received even after 640 cycles of SDCLK have elapsed
Data timeout (other than response timeout)		ERR3		E6	When the interface remains in a busy state (SDDAT0 = 0) for at least Ncycle[*1] after the CRC status
				E5	When the CRC status is not received even after Ncycle[*1] has elapsed after data writing
				E4	When read data is not received even after Ncycle[*1] has elapsed after read command
					When read data for the next block are not received even after Ncycle[*1] has elapsed after the reception of read data
					When read data for the next block are not received even after Ncycle[*1] has elapsed after release of the read wait state
				E3	When the interface remains in a busy state (SDDAT0 = 0) for at least Ncycle[*1] after CMD12 has been issued within a command sequence
				E2	When the interface remains in a busy state (SDDAT0 = 0) for at least Ncycle[*1] after R1b response

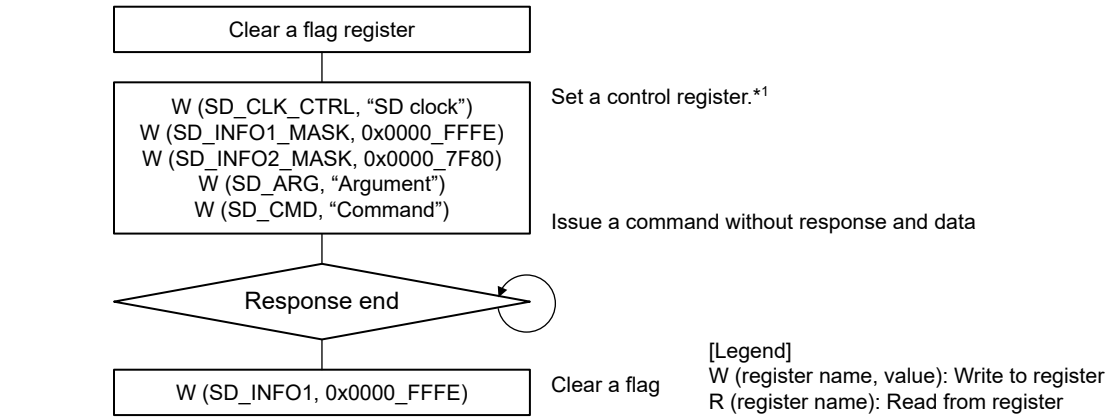
Note 1. Ncycle is set by bit 7 to bit 4 in SD_OPTION.

55.5 Usage Example

55.5.1 Command without Data Transfer

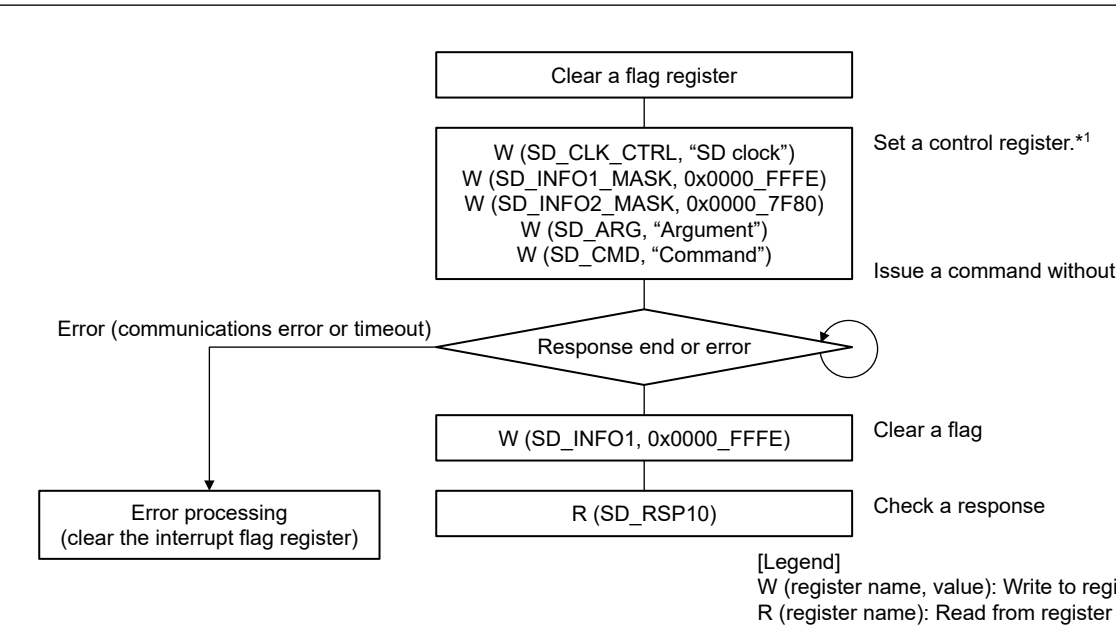
55.5.1.1 Flowchart

Figure 55.10 and Figure 55.11 show flowchart examples.



Note 1. Refer to section 55.6.5. Notes on SD_CLK_CTRL Register Settings in section 55.6. Usage Notes.

Figure 55.10 Flow example of command without response and data



Note 1. Refer to section 55.6.5. Notes on SD_CLK_CTRL Register Settings in section 55.6. Usage Notes.

Figure 55.11 Flow example of command without data

55.5.1.2 Operation for Command without Data Transfer

The legend below is used for description of register read/write.

— W (register name, value): Write to register

— R (register name): Read from register

The operation is described below.

(1) Command without Response and Data

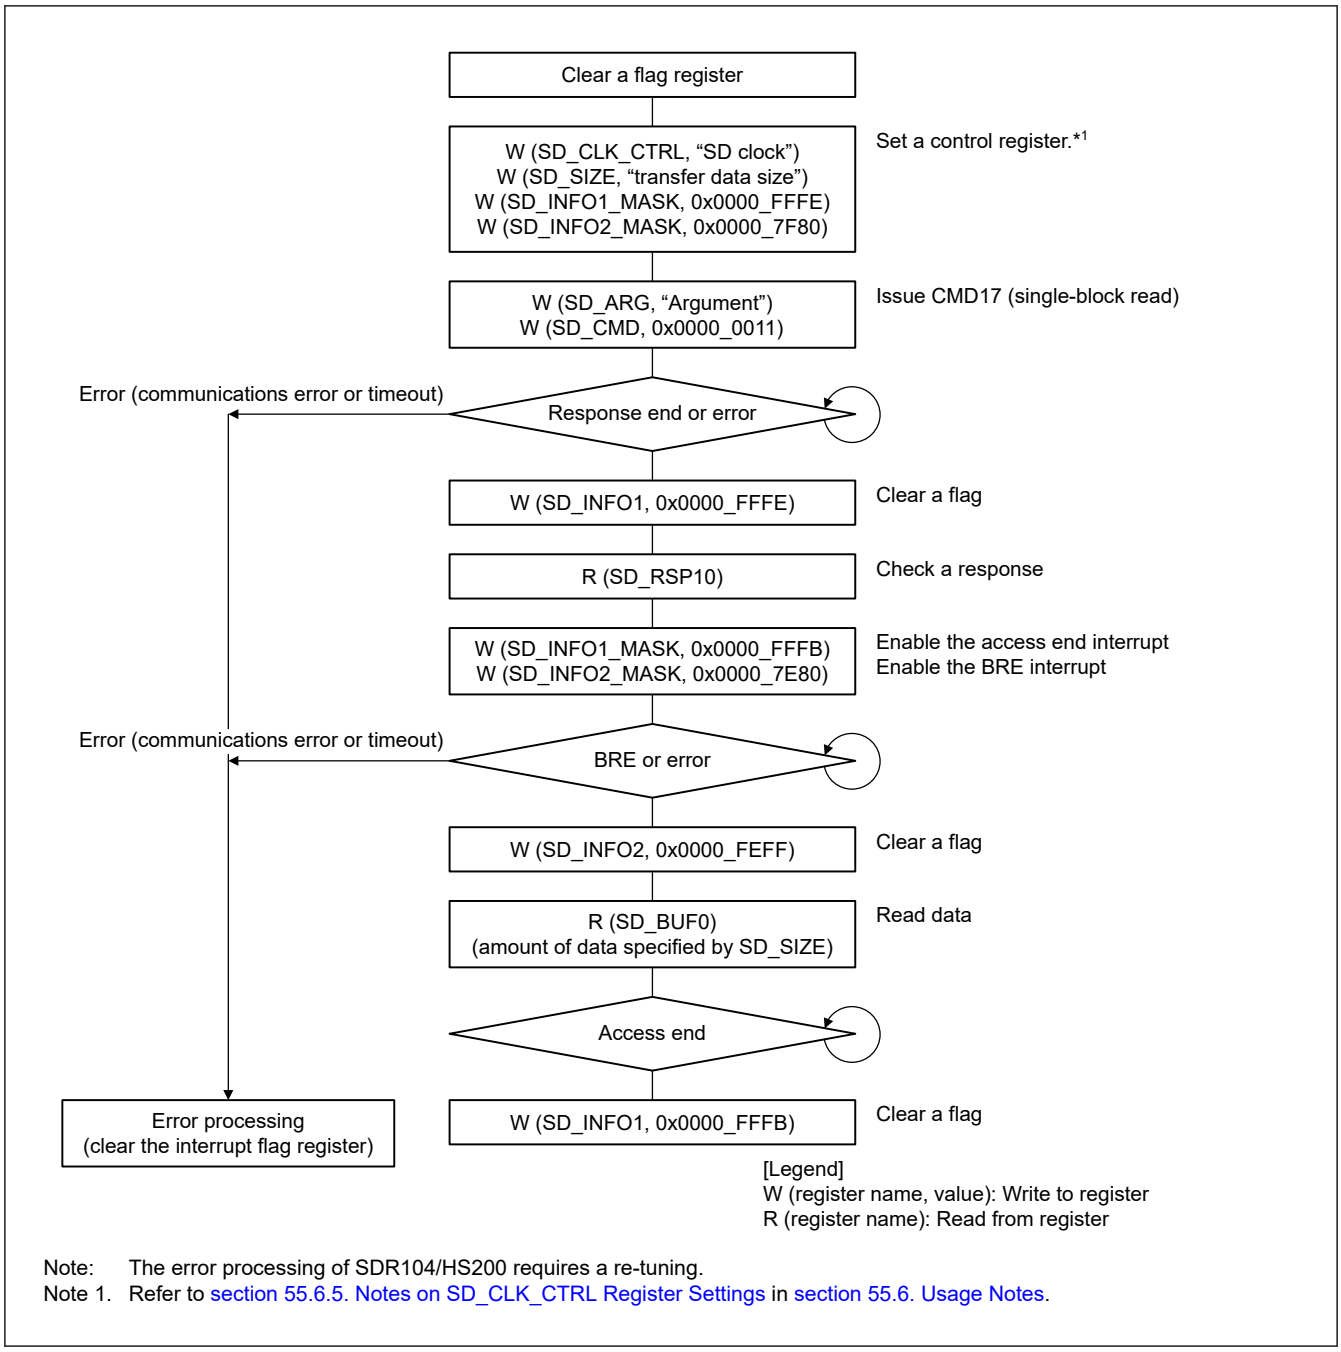
1. Flag register clear
   First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)
2. Control register set
   Set the SD clock (SDCLK), interrupt mask, and so on. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)
3. Command issue
   Set CMD Argument in SD_ARG and write to SD_CMD.
   Accordingly, CMD is issued, and the operation is started.
4. Flag clear
   When transmission of a command is completed, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt.
   Clear INFO0 to 0.

(2) Command without Data

1. Flag register clear
   First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)
2. Control register set
   Set the SD clock (SDCLK), interrupt mask, and so on. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)
3. Command issue
   Set CMD Argument in SD_ARG and write to SD_CMD.
   Accordingly, CMD is issued, and the operation is started.
4. Flag clear
   When a response is received, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0.
5. Read a response from SD_RSP10.
   Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

55.5.2 Single Block Read

55.5.2.1 Flowchart



Note: The error processing of SDR104/HS200 requires a re-tuning.
Note 1. Refer to section 55.6.5. Notes on SD_CLK_CTRL Register Settings in section 55.6. Usage Notes.

Figure 55.12 Single block read flowchart example

55.5.2.2 Operation for Single Block Read

The operation of the single block read is described below.

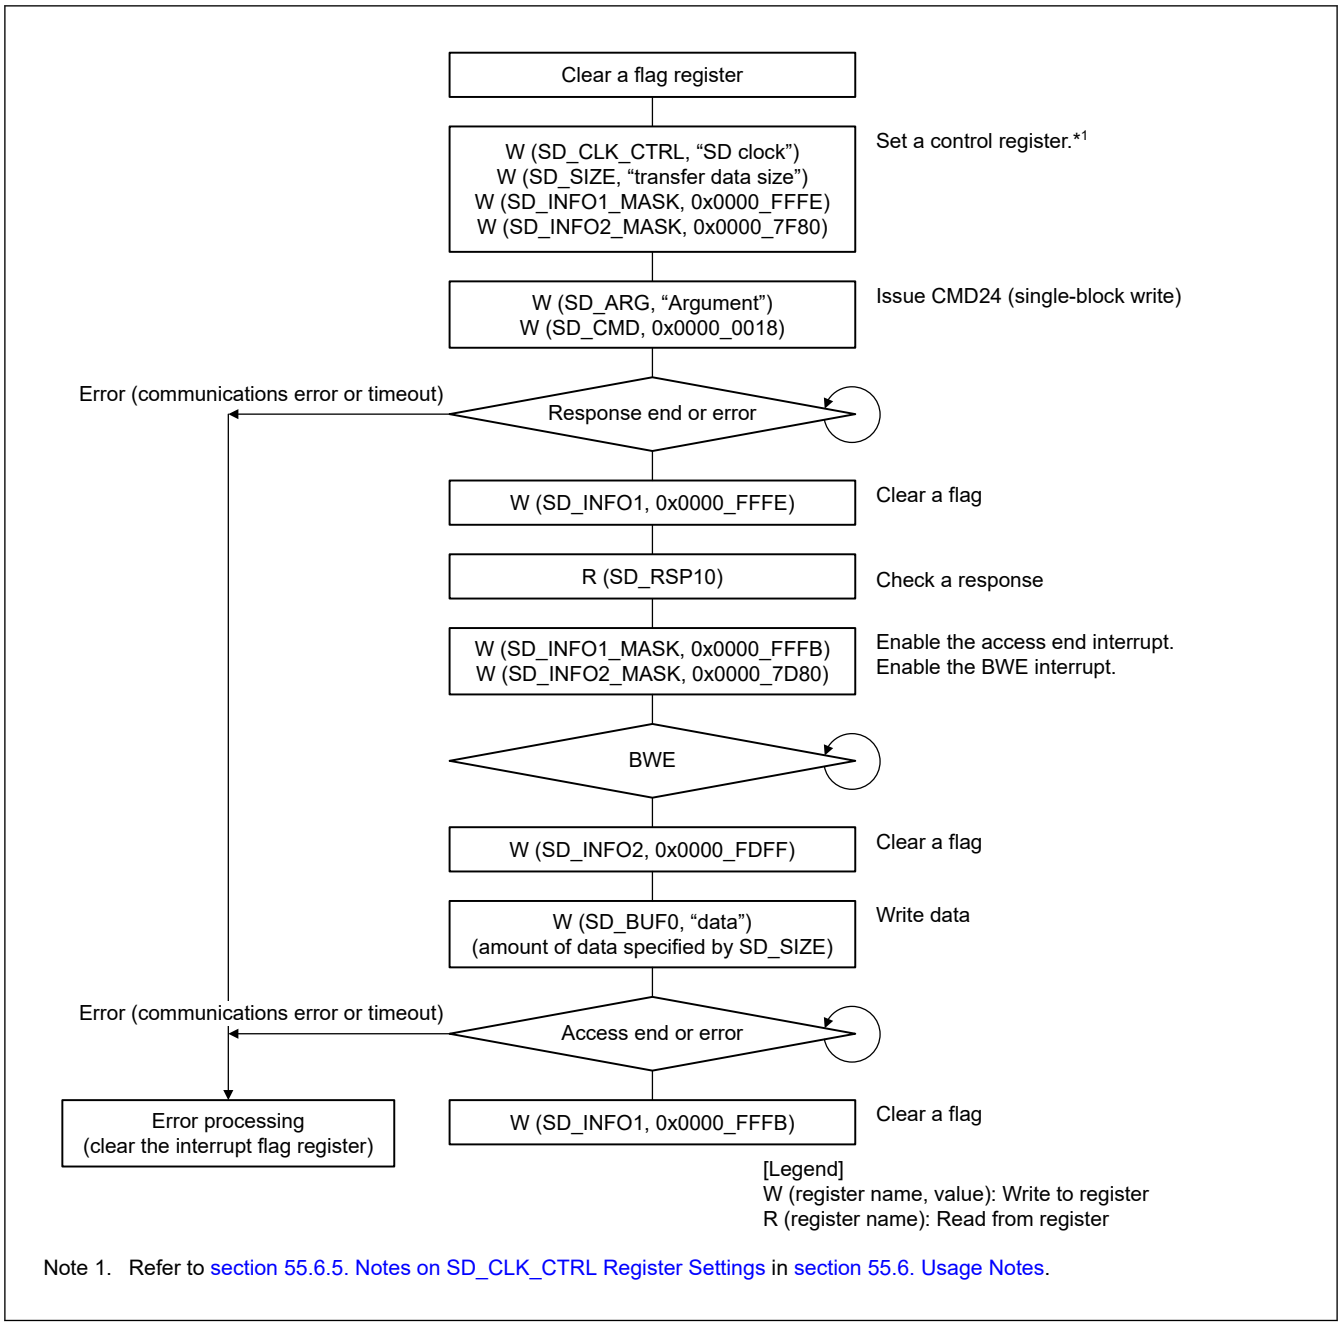
1. Flag register clear
   First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)
2. Control register set
   Set the SD clock (SDCLK), transfer data size, interrupt mask, and so on. (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK)

3. Command issue (CMD17)
   Set CMD17 Argument in SD_ARG and write 0x0000 0011 to SD_CMD.
   Accordingly, CMD17 is issued, and the single block read operation is started.
4. Response check
   On receiving the response, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0 and read the response from SD_RSP10.
   If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. Furthermore, this causes CMD12 and CMD52 to not be issued. If the command sequence is halted, the INFO2 bit (access end) in SD_INFO1 is set to 1 to generate an interrupt.
5. Data receive from SD card and data read
   Write 0x0000 FFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000 7E80 to SD_INFO2_MASK to enable the BRE interrupt. When the data receive from the SD card is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified by SD_SIZE from SD_BUF0.
6. Operation complete
   When the data read from SD_BUF0 is completed, INFO2 (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO2 to 0 to end the single block read operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

55.5.3 Single Block Write

55.5.3.1 Flowchart



Note 1. Refer to section 55.6.5. Notes on SD_CLK_CTRL Register Settings in section 55.6. Usage Notes.

Figure 55.13 Single block write flowchart example

55.5.3.2 Operation for Single Block Write

The operation of the single block write is described below.

1. Flag register clear
   First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)
2. Control register set
   Set the SD clock (SDCLK), transfer data size, interrupt mask, and so on. (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK)
3. Command issue (CMD24)

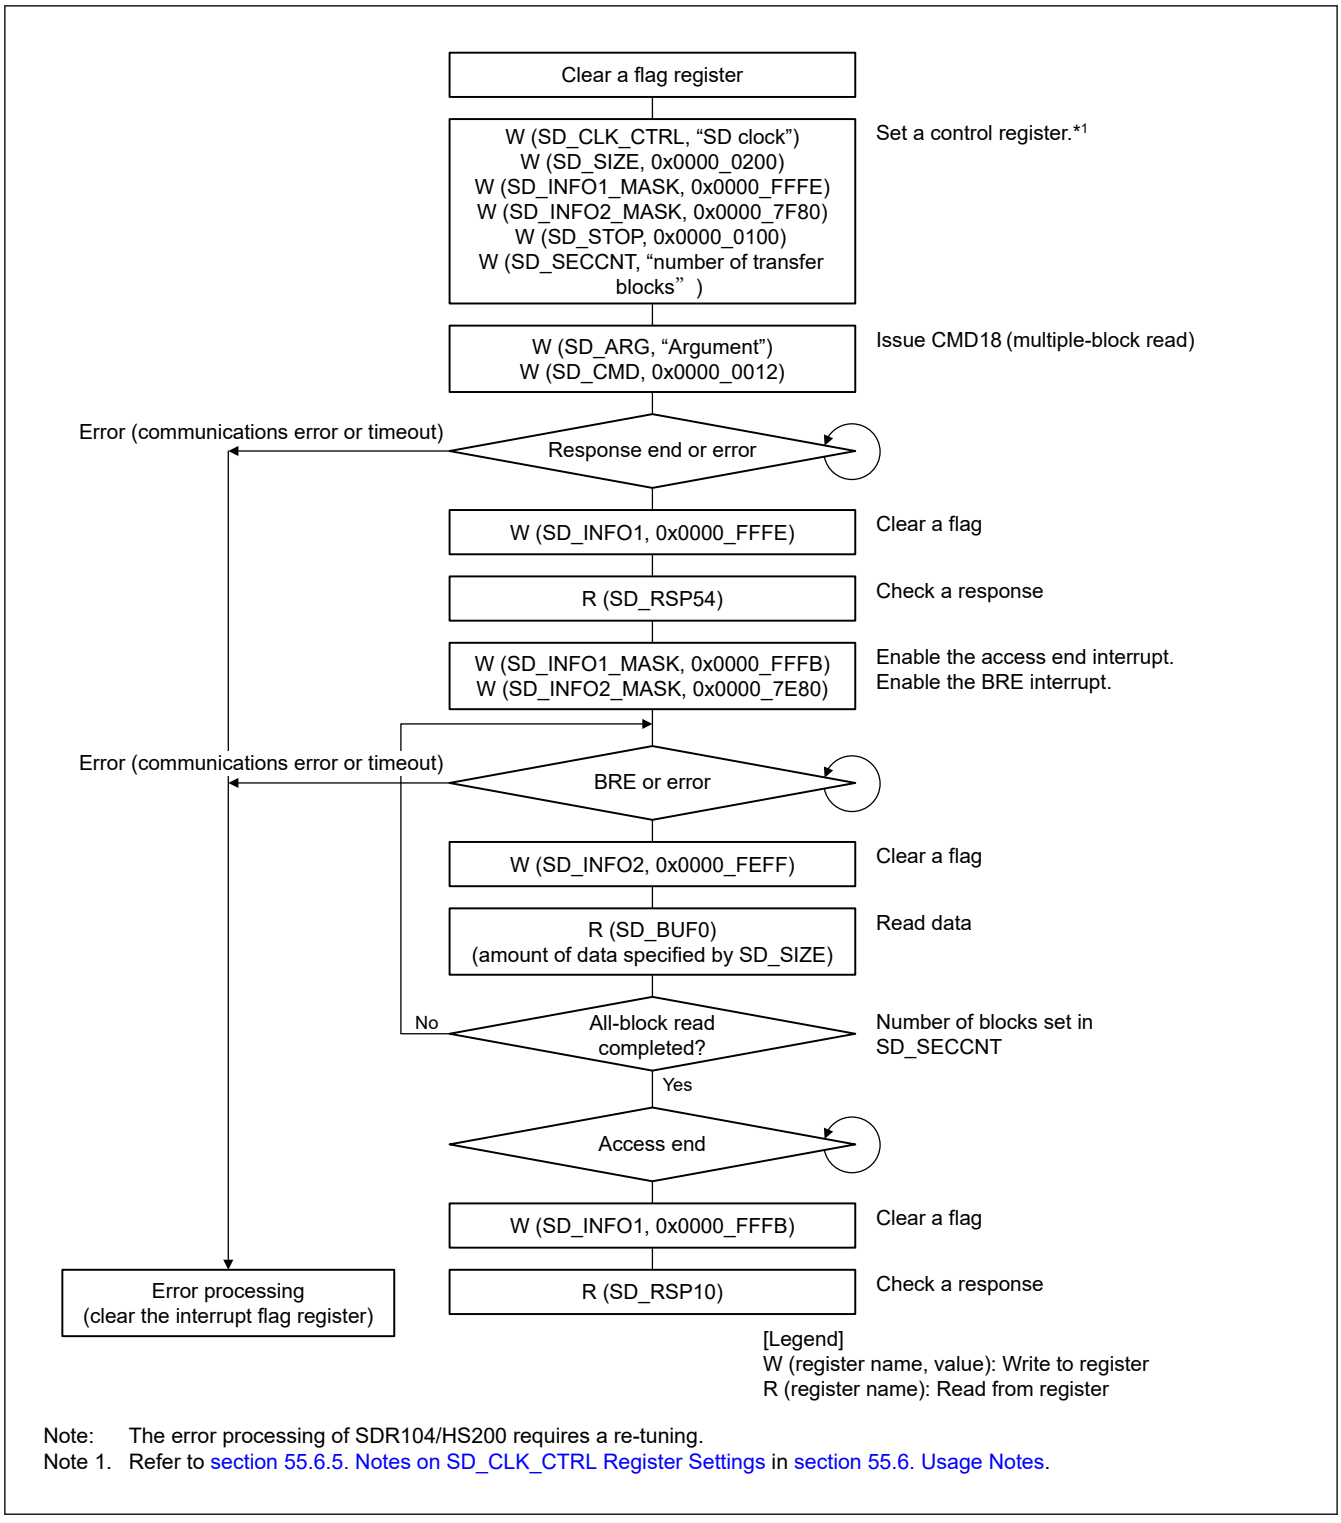
Set CMD24 Argument in SD_ARG and write 0x0000 0018 to SD_CMD.
Accordingly, CMD24 is issued, and the single block write operation is started.

4. Response check
   On receiving the response, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0 and read the response from SD_RSP10.
   If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. Furthermore, this causes CMD12 and CMD52 to not be issued. If the command sequence is halted, the INFO2 bit (access end) in SD_INFO1 is set to 1 to generate an interrupt.
5. Data write and data transmit to SD card
   Write 0x0000 FFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000 7D80 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified by SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card. Then, the CRC status and busy state are received from the SD card.
   However, a communications error or timeout may be generated if data are being transmitted after writing to SD_BUF0.
6. Operation complete
   When the CRC status and busy state are received from the SD card, INFO2 (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the INFO2 bit to 0 to end the single block write operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

55.5.4 Multiple Block Read

55.5.4.1 Flowchart



Note: The error processing of SDR104/HS200 requires a re-tuning.
Note 1. Refer to section 55.6.5. Notes on SD_CLK_CTRL Register Settings in section 55.6. Usage Notes.

Figure 55.14 Multiple block read flowchart example

55.5.4.2 Operation for Multiple Block Read

The operation of the multiple block read is described below.

1. Flag register clear

First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

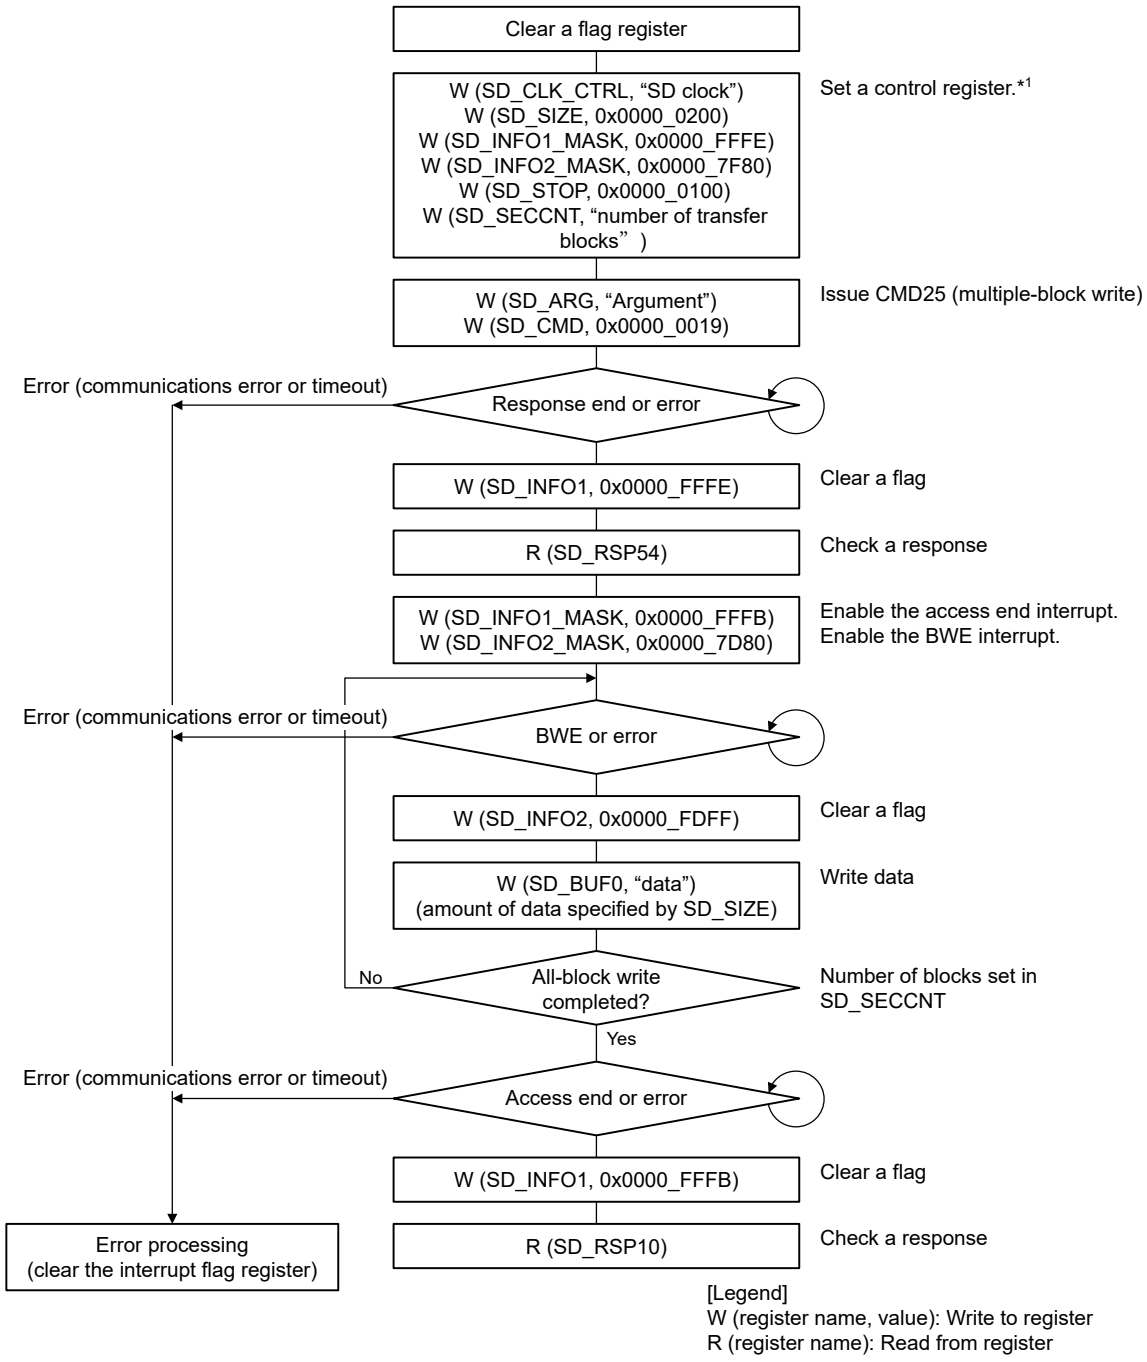
2. Control register set
   Set the SD clock (SDCLK), transfer data size, interrupt mask, and so on. (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK)
   Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.
3. Command issue (CMD18)
   Set CMD18 Argument in SD_ARG and write 0x0000 0012 to SD_CMD.
   Accordingly, CMD18 is issued, and the multiple block read operation is started.
4. Response check
   On receiving the response, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0 and read the response from SD_RSP54.
   If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt has been enabled, an interrupt will be generated by setting of the INFO2 bit (access end) in SD_INFO1 to 1 when reception of the response has been completed. Clear the INFO2 bit to 0 and read the response.
5. Data receive from SD card and data read
   Write 0x0000 FFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000 7E80 to SD_INFO2_MASK to enable the BRE interrupt. When one-block data receive from the SD card is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified by SD_SIZE from SD_BUF0. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communications error or timeout may be generated if data are being received while reading of SD_BUF0 is in progress. CMD12 is automatically issued to stop multi-block transfer with the number of blocks which is set to SD_SECCNT and the response is received. At this point, CMD12 Argument is automatically set to 0x0000 0000.
6. Operation complete
   When all-block data read and the CMD12 response receive are completed, INFO2 (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO2 to 0 to read the response. This is the end of multiple block read operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

55.5.5 Multiple Block Write (when Using Internal Timer)

55.5.5.1 Flowchart

Figure 55.15 shows the flowchart when using an internal timer.



Note 1. Refer to section 55.6.5. Notes on SD_CLK_CTRL Register Settings in section 55.6. Usage Notes.

Figure 55.15 Multiple block write flowchart example (when using internal timer)

55.5.5.2 Operation for Multiple Block Write (when Using Internal Timer)

The operation of the multiple block write is described below.

1. Flag register clear
   First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)
2. Control register set
   Set the SD clock (SDCLK), transfer data size, interrupt mask, and so on. (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK)
   Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

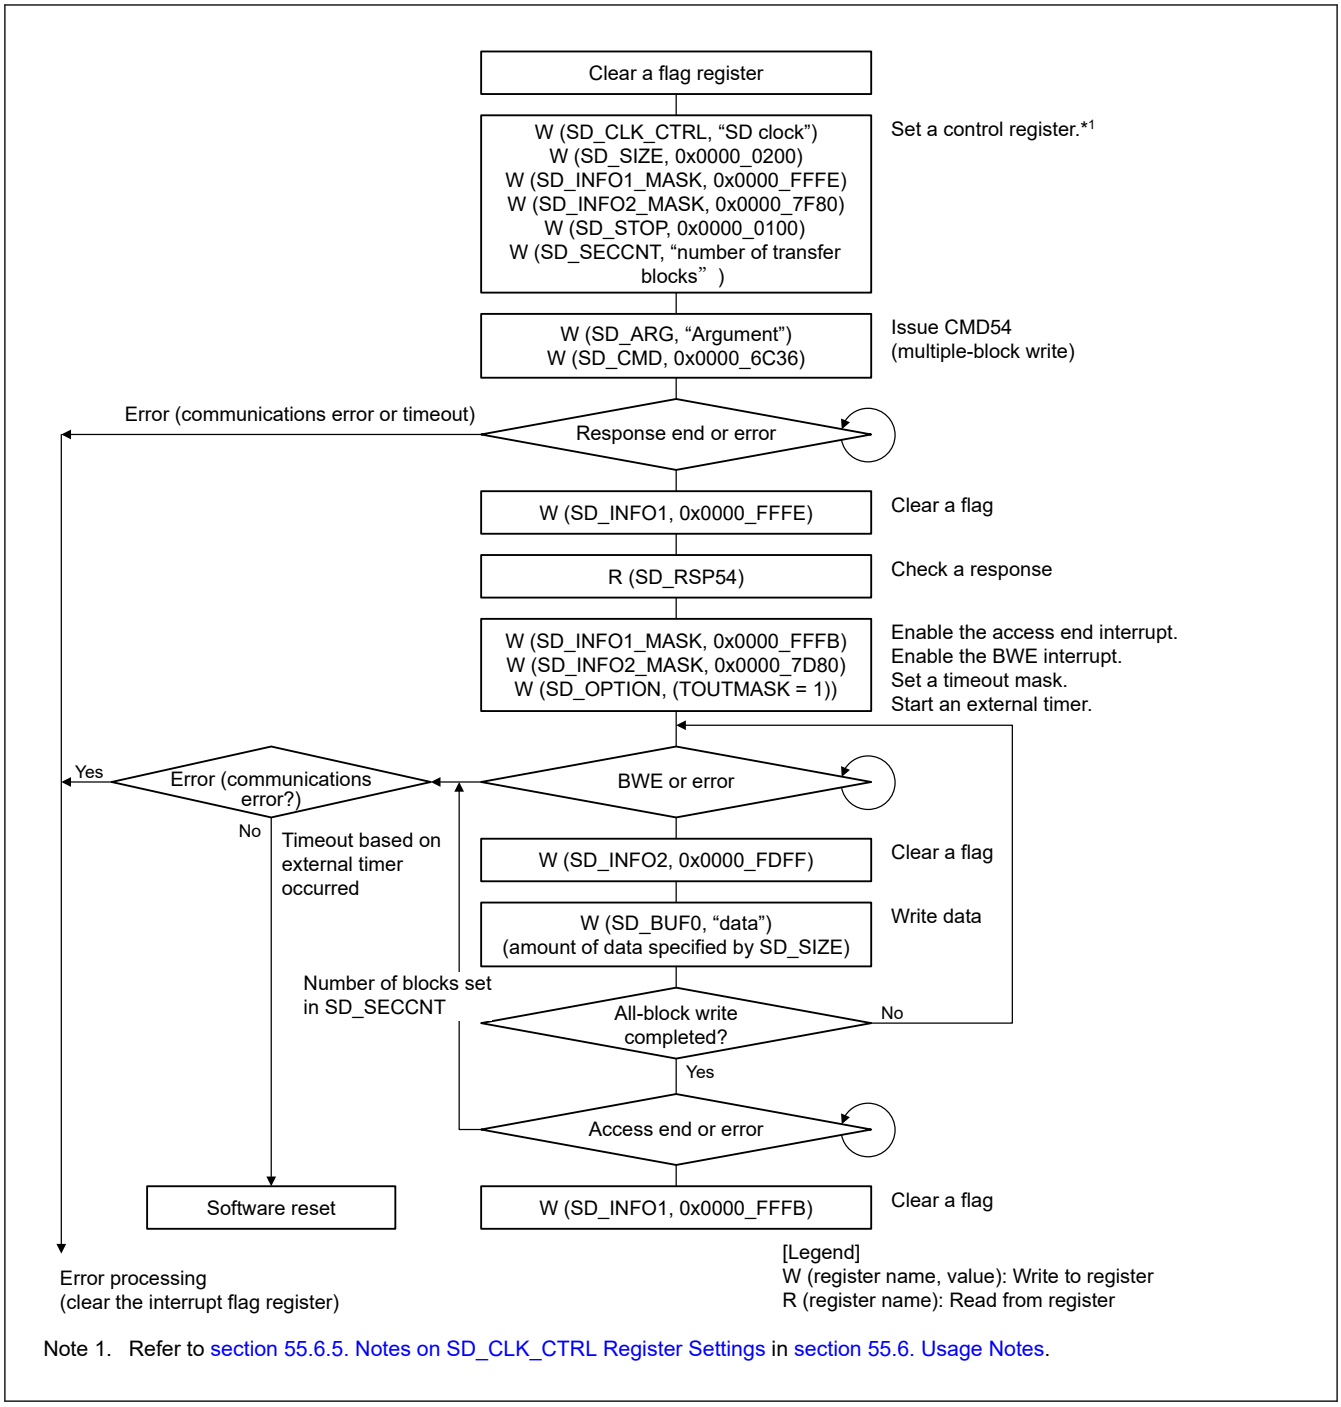
3. Command issue (CMD25)
   Set CMD25 Argument in SD_ARG and write 0x0000 0019 to SD_CMD.
   Accordingly, CMD25 is issued, and the multiple block write operation is started.
4. Response check
   On receiving the response, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0 and read the response from SD_RSP54.
   If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt has been enabled, an interrupt will be generated by setting of the INFO2 bit (access end) bit in SD_INFO1 to 1 when reception of the response has been completed. Clear the INFO2 bit to 0 and read the response.
5. Data write and data transmit to SD card
   Write 0x0000 FFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000 7D80 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified by SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card. Then, the CRC status and busy state are received from the SD card. Doing this repeats transfer of the number of blocks set in SD_SECCNT.
   However, a communications error or timeout may be generated if data are being transmitted while writing to SD_BUF0 is in progress. CMD12 is automatically issued to stop multi-block transfer with the number of blocks which is set to SD_SECCNT and the response is received. At this point, CMD12 Argument is automatically set to 0x0000 0000.
6. Operation complete
   When all-block data transmit and the CRC status receive are completed, the INFO2 bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the INFO2 bit to 0 to read the response. This is the end of multiple block write operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

55.5.6 Multiple Block Write (when Using External Timer)

55.5.6.1 Flowchart

The flowchart when using an external timer instead of an internal timer of this module is shown below.



Note 1. Refer to section 55.6.5. Notes on SD_CLK_CTRL Register Settings in section 55.6. Usage Notes.

Figure 55.16 Multiple block write flowchart example (when using external timer)

55.5.6.2 Operation for Multiple Block Write (when Using External Timer)

The operation of the multiple block write is described below.

1. Flag register clear
   First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)
2. Control register set
   Set the SD clock (SDCLK), transfer data size, interrupt mask, and so on. (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK)
   Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.
3. Command issue (CMD54)
   Set CMD54 Argument in SD_ARG and write 0x0000 6C36 to SD_CMD.

Accordingly, CMD54 is issued, and the multiple block write operation is started.

4. Response check
   On receiving the response, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0 and read the response from SD_RSP54.
   If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt has been enabled, an interrupt will be generated by setting of the INFO2 bit (access end) bit in SD_INFO1 to 1 when reception of the response has been completed. Clear the INFO2 bit to 0 and read the response.
5. Data write and data transmit to SD card
   Write 0x0000 FFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000 7D80 to SD_INFO2_MASK to enable the BWE interrupt. Set the TOUTMASK bit in SD_OPTION to disable timeout and start an external timer.
   When SD_BUF0 is ready for the data to be written, the BWE bit in the SD_INFO2 register is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified by SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card. Then, the CRC status and busy state are received from the SD card. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communications error may be generated if data are being transmitted while writing to SD_BUF0 is in progress.
6. Operation complete
   When all-block data transmit and the CRC status receive are completed, the INFO2 bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the INFO2 bit to 0 to read the response. This is the end of multiple block write operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs at response reception (a communications error or timeout) or at data transmission. Perform a software reset if a timeout occurs at data transmission based on an external timer.

55.5.7 IO_RW_DIRECT Commend (CMD52)

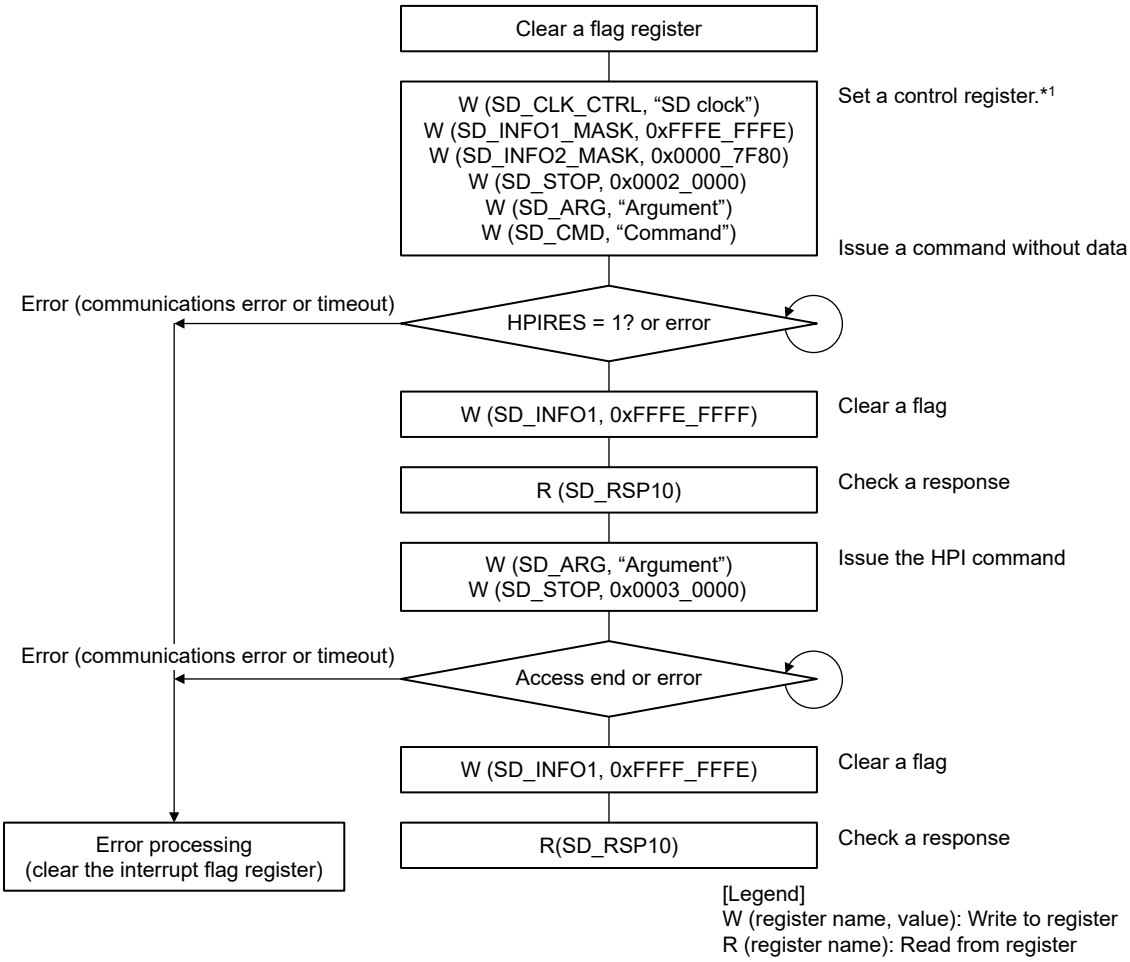
55.5.11 High-Priority Interrupt (without Data Transfer)

55.5.11.1 Flowchart



Note 1. Refer to section 55.6.5. Notes on SD_CLK_CTRL Register Settings in section 55.6. Usage Notes.

Figure 55.26 Example of the High-Priority Interrupt (without Data Transfer) flowchart

55.5.11.2 Operation for High-Priority Interrupt without Data Transfer

The operation of the high-priority interrupt (HPI) without data transfer is described below.

1. Flag register clear
   First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)
2. Control register set
   Set the SD clock (SDCLK), HPI enable, interrupt mask, and so on. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)
3. Command issue
   Set the CMD Argument in SD_ARG and write to SD_CMD.
   Accordingly, CMD is issued, and the operation is started.
4. Flag clear
   On receiving the response, the HPIRES bit in SD_INFO1 is set to 1 to generate an interrupt. Clear the HPIRES bit to 0.
5. Read the response from SD_RSP10.
6. HPI command issue

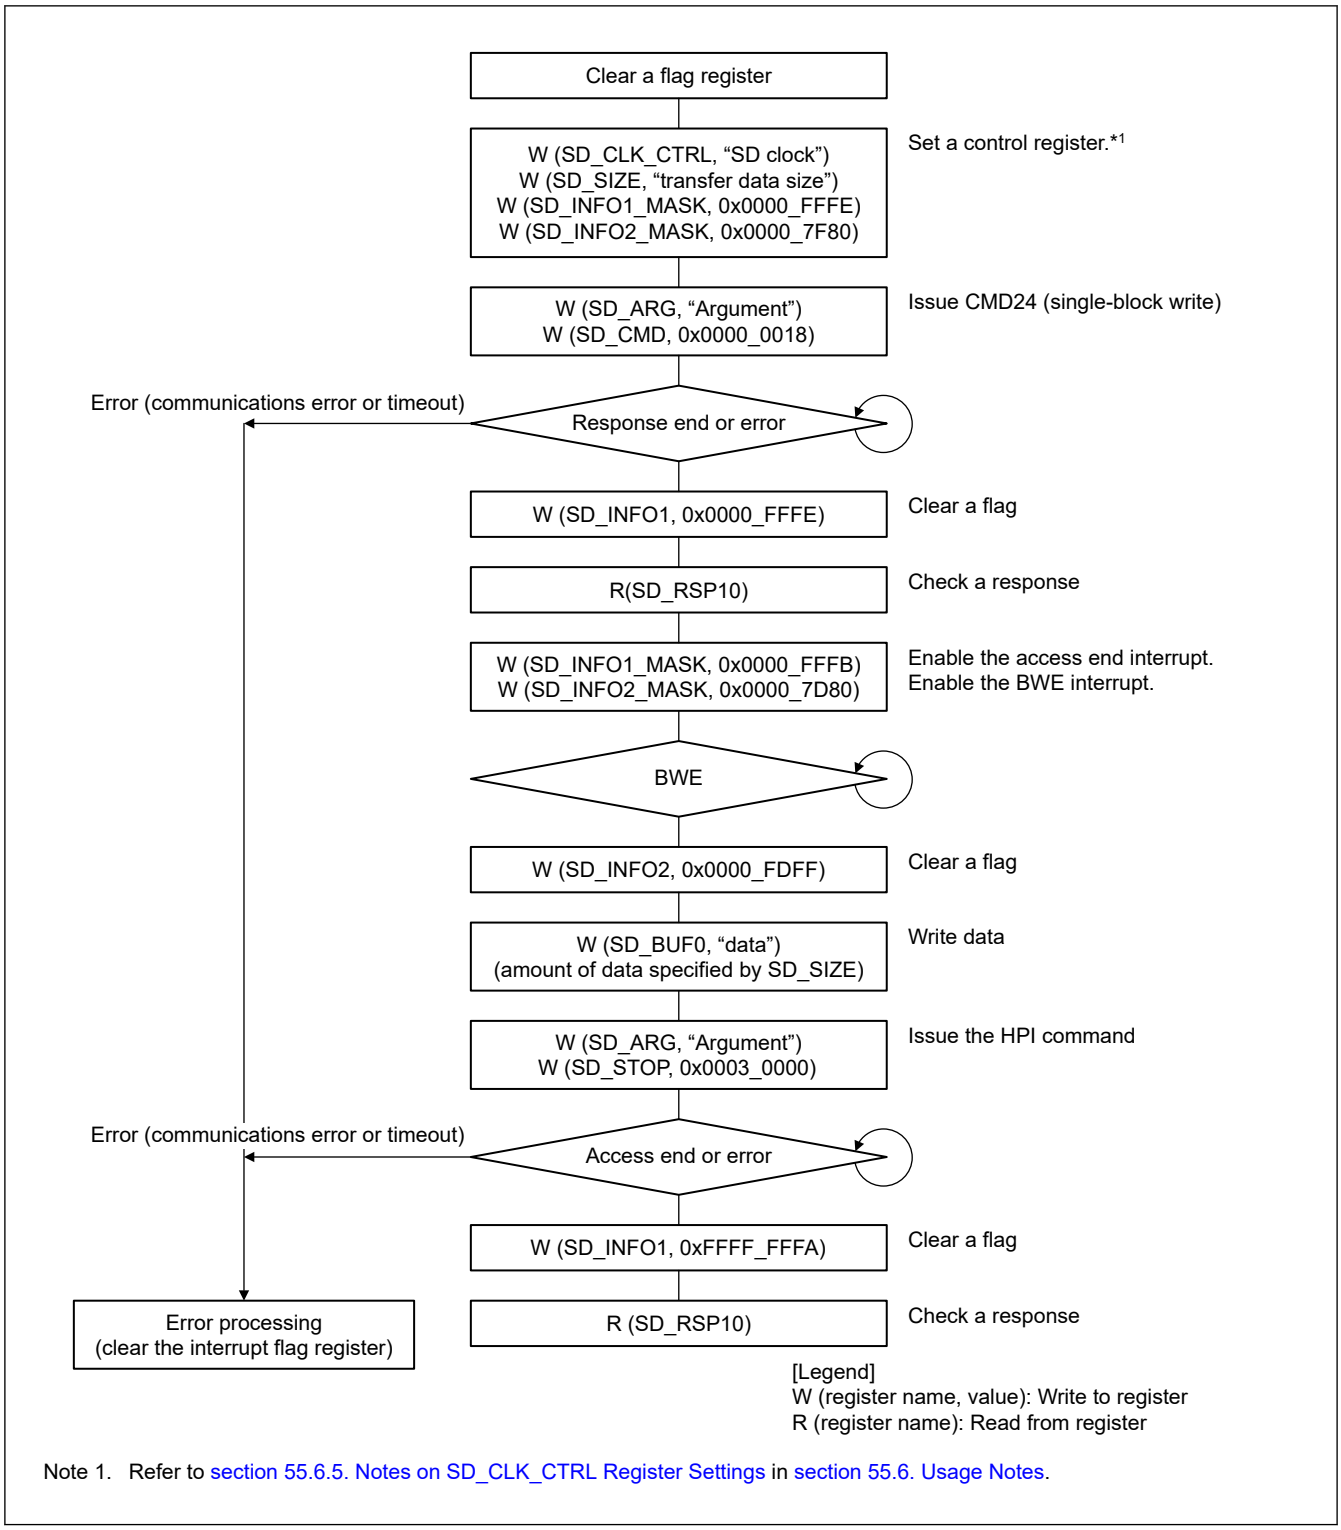
Set the HPI command argument in SD_ARG and set the HPIMODE and HPICMD bits in SD_STOP to 1.

7. Operation complete
   When reception of the response to the HPI command is completed and the busy state is released, the INFO0 bit in SD_INFO1 is set to 1 to generate an interrupt. Clear the INFO0 bit to 0 to read the response from SD_RSP10. This is the end of HPI operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

55.5.12 High-Priority Interrupt (at Single Block Write)

55.5.12.1 Flowchart



Note 1. Refer to section 55.6.5. Notes on SD_CLK_CTRL Register Settings in section 55.6. Usage Notes.

Figure 55.27 Example of the High-Priority Interrupt (at Single Block Write) flowchart

55.5.12.2 Operation for High-Priority Interrupt at Single Block Write

The operation of the high-priority interrupt (HPI) at single block write is described below.

1. Flag register clear

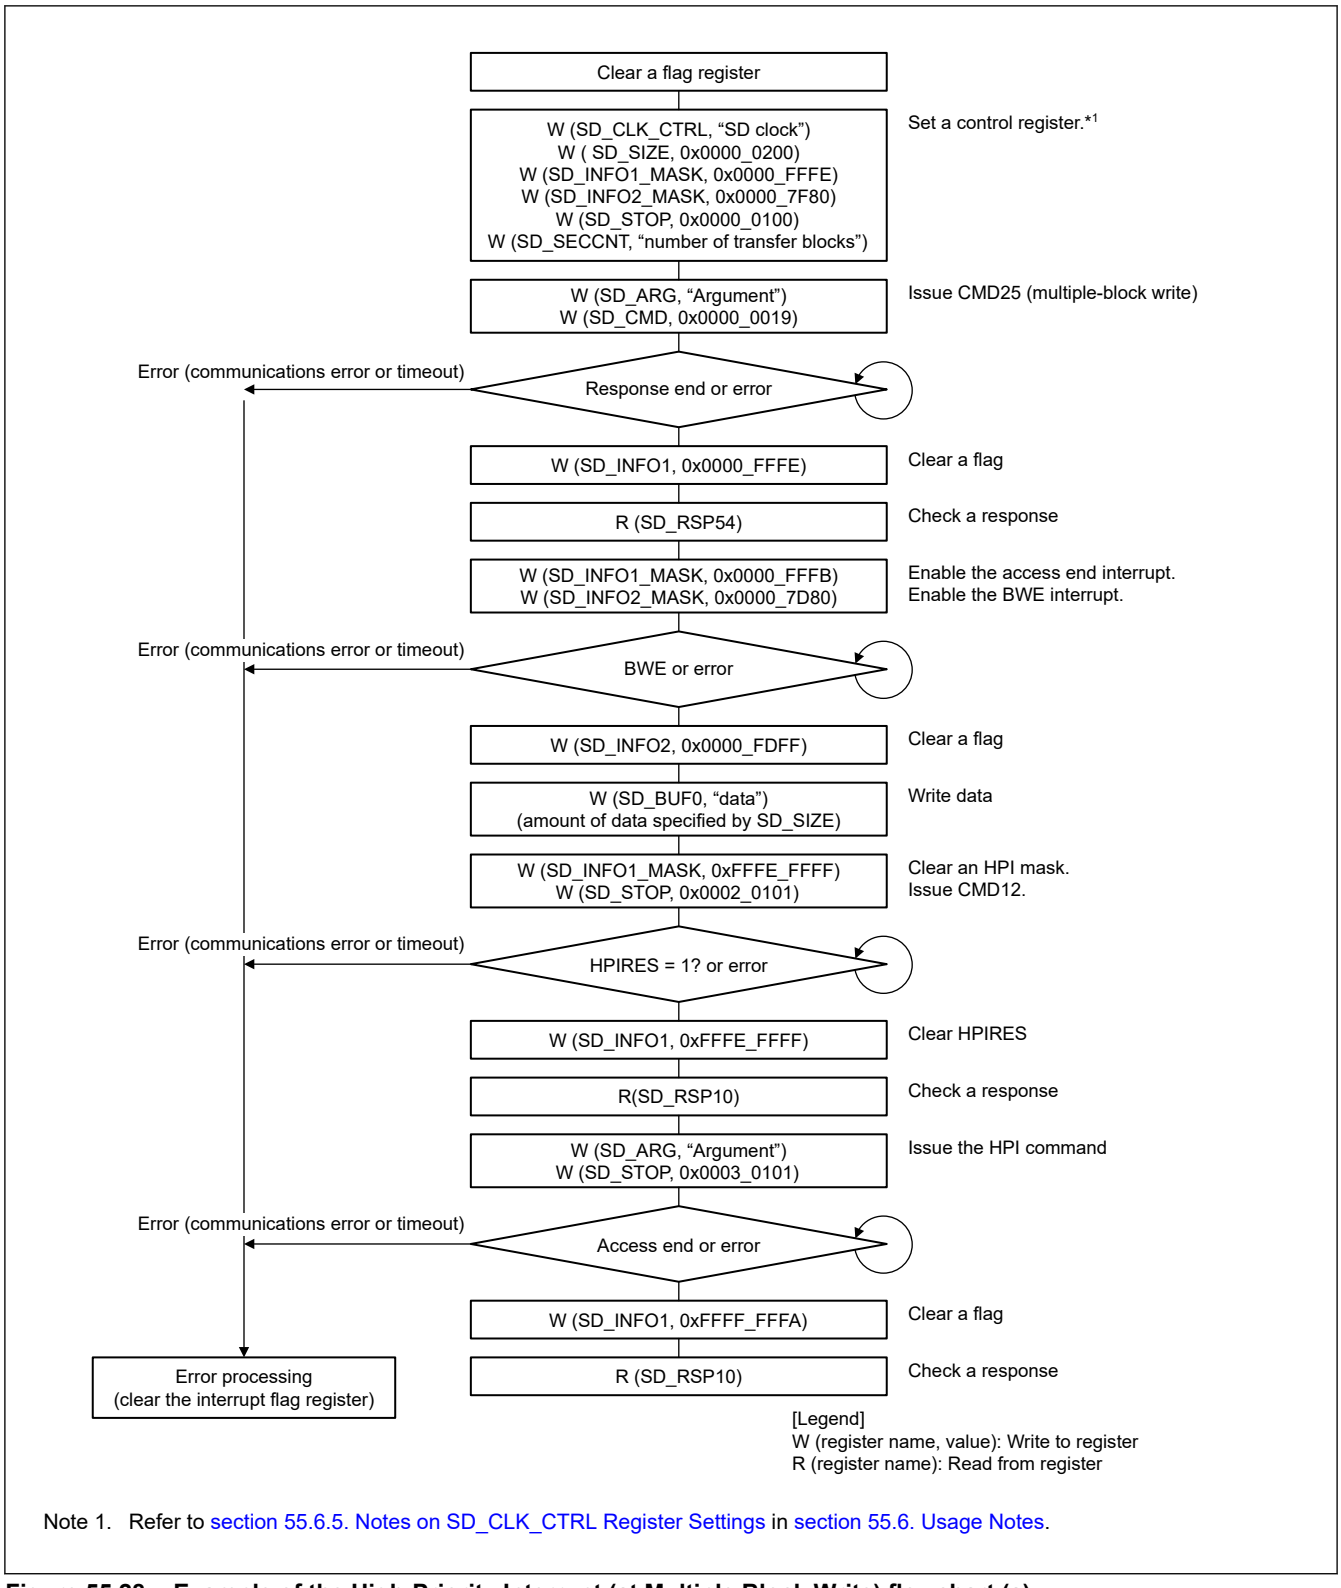
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

2. Control register set
   Set the SD clock (SDCLK), transfer data size, interrupt mask, and so on. (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK)
3. Command issue (CMD24)
   Set CMD24 Argument in SD_ARG and write 0x0000 0018 to SD_CMD.
   Accordingly, CMD24 is issued, and the single block write operation is started.
4. Response check
   On receiving the response, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0 and read the response from SD_RSP10.
   If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. Furthermore, this causes CMD12 and CMD52 to not be issued. If the command sequence is halted, the INFO2 bit (access end) in SD_INFO1 is set to 1 to generate an interrupt.
5. Data write and data transmit to SD card
   Write 0x0000 FFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000 7D80 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified by SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card.
6. HPI command issue
   Set the HPI command argument in SD_ARG and set the HPIMODE and HPICMD bits in SD_STOP to 1.
7. Operation complete
   When reception of the response to the HPI command is completed and the busy state is released, the INFO2 and INFO0 bits in SD_INFO1 are set to 1 to generate an interrupt. Clear the INFO2 and INFO0 bits to 0 to read the response from SD_RSP10. This is the end of HPI operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

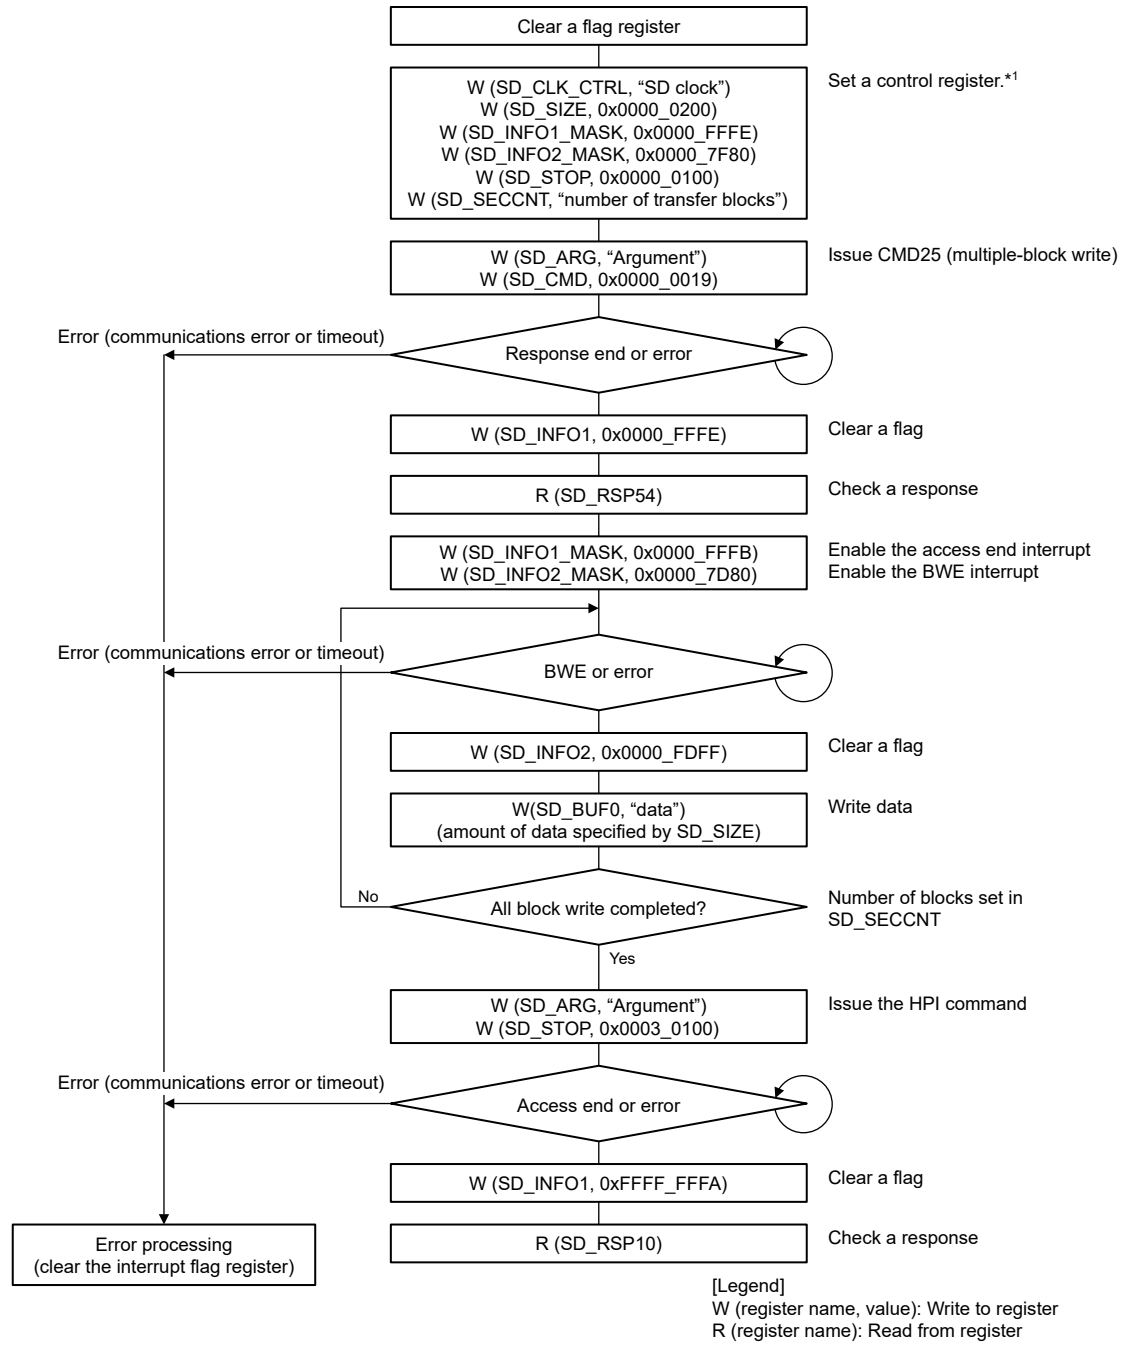
55.5.13 High-Priority Interrupt (at Multiple Block Write)

55.5.13.1 Flowchart



Note 1. Refer to section 55.6.5. Notes on SD_CLK_CTRL Register Settings in section 55.6. Usage Notes.

Figure 55.28 Example of the High-Priority Interrupt (at Multiple Block Write) flowchart (a)



Note 1. Refer to section 55.6.5. Notes on SD_CLK_CTRL Register Settings in section 55.6. Usage Notes.

Figure 55.29 Example of the High-Priority Interrupt (at Multiple Block Write) flowchart (b)

55.5.13.2 Operation for High-Priority Interrupt at Multiple Block Transfer

The operation of the high-priority interrupt (HPI) at the multiple block write is described below.

(1) When not all the data has been written to SD_BUF

1. Flag register clear
   First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)
2. Control register set

Set the SD clock (SDCLK), transfer data size, interrupt mask, and so on. (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK)
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

3. Command issue (CMD25)
Set CMD25 Argument in SD_ARG and write 0x0000 0019 to SD_CMD.
Accordingly, CMD25 is issued, and the multiple block write operation is started.

4. Response check
On receiving the response, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0 and read the response from SD_RSP54.
If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt has been enabled, an interrupt will be generated by setting of the INFO2 bit (access end) bit in SD_INFO1 to 1 when reception of the response has been completed. Clear the INFO2 bit to 0 and read the response.

5. Data write and data transmit to SD card
Write 0x0000 FFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000 7D80 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified by SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card.
Then, the CRC status and busy state are received from the SD card.
However, a communications error or timeout may be generated if data are being transmitted while writing to SD_BUF0 is in progress.

6. Command issue (CMD12)
Write 0xFFFE FFFF to SD_INFO1_MASK to enable the HPIRES interrupt. Write 0x0002 0101 to SD_STOP, which causes CMD12 to be issued.

7. Response check
When the response is received, the HPIRES bit in SD_INFO1 is set to 1 to generate an interrupt. Clear the HPIRES bit to 0 to read the response from SD_RSP10.

8. HPI command issue (CMD25)
Set the HPI command argument in SD_ARG and set the HPIMODE and HPICMD bits in SD_STOP to 1.

9. Operation complete
When reception of the response to the HPI command is completed and the busy state is released, the INFO2 and INFO0 bits in SD_INFO1 are set to 1 to generate an interrupt. Clear the INFO2 and INFO0 bits to 0 to read the response from SD_RSP10. This is the end of HPI operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

(2) When all the data has been written to SD_BUF

1. Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

2. Control register set
Set the SD clock (SDCLK), transfer data size, interrupt mask, and so on. (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK)
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

3. Command issue (CMD25)
Set CMD25 Argument in SD_ARG and write 0x0000 0019 to SD_CMD.
Accordingly, CMD25 is issued, and the multiple block write operation is started.

4. Response check
On receiving the response, INFO0 (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear INFO0 to 0 and read the response from SD_RSP54.
If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt has been enabled, an interrupt will be generated by setting of the INFO2 bit

(access end) bit in SD_INFO1 to 1 when reception of the response has been completed. Clear the INFO2 bit to 0 and read the response.

5. Data write and data transmit to SD card
   Write 0x0000 FFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000 7D80 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified by SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card.
   Then, the CRC status and busy state are received from the SD card. Doing this repeats transfer of the number of blocks set in SD_SECCNT.
   However, a communications error or timeout may be generated if data are being transmitted while writing to SD_BUF0 is in progress.
6. HPI command issue
   Set the HPI command argument in SD_ARG and set the HPIMODE and HPICMD bits in SD_STOP to 1.
7. Operation complete
   When reception of the response to the HPI command is completed and the busy state is released, the INFO2 and INFO0 bits in SD_INFO1 are set to 1 to generate an interrupt. Clear the INFO2 and INFO0 bits to 0 to read the response from SD_RSP10. This is the end of HPI operation.

Furthermore, perform error processing (clear the interrupt flag register) if an error occurs (a communications error or timeout).

55.5.14 Example of SD_CMD Register Setting

Table 55.9 lists the example of SD_CMD (SD interface) register setting.

Table 55.9 Example of SD_CMD register setting (SD) (1 of 2)

Type	Command	Example of SD_CMD register setting	Remark
CMD	CMD0	0x0000 0000

	CMD55	0x0000 0037	
	CMD56	0x0000 0038	

55.6 Usage Notes

55.6.1 SD_BUF Illegal Write Access

When writing data to SD_BUF0 after the single block write or multi block write command is issued, the data of the size specified by SD_SIZE must be written to.

If the data of the size which exceeds the size specified by SD_SIZE is written to, the ERR4 bit in SD_INFO2 is set to 1. In addition, the data written to SD_BUF0 may not be transmitted and it causes the SCLKDIVEN bit in SD_INFO2 to hold the value of 0. In such cases, clearing the SDRST bit in SOFT_RST to 0 and then restoring its value to 1 clears the SCLKDIVEN bit to 1.

However, for the single byte (in the case of 16- or 32-bit access) or three bytes (in the case of 32-bit access) when the number of bytes setting in SD_SIZE is odd, or the fraction of bytes when the number of bytes setting in SD_SIZE is even (in the case of 32-bit access), since the portion of dummy data writing is regarded as excess data and ignored, it is not within the scope of the above description (the fraction of bytes: the two bytes that are not in a four-byte unit).

55.6.2 Block Number Limitation for Multiple Block Read

When performing a multiple block read of one or two blocks, depending on the timing with which the response register is read, the response value may not be read properly. This must be avoided by either of the following countermeasures.

1. When receiving one or two blocks of data, use single block reading.
2. Read the response to CMD18 from SD_RSP54.

[Mechanism of incorrect reading]

Figure 55.30 shows the processing flows of SD/MMC host interface (hardware) operation and software operation when a multiple block read is performed on two blocks. As shown in the incorrect operation of Figure 55.30, when an interrupt is generated on reception of the CMD18 response and the timing with which the SD card response register (SD_RSP10) is read by the interrupt is delayed, the data during the CMD12 response reception or the CMD12 response may be read. In the case of a multiple block read of three or more blocks, CMD12 is not issued until the block of data has been read, so this problem does not arise. Furthermore, in the case of a multiple block write, since the CMD25 response is read before the block of data is sent, the problem does not arise.

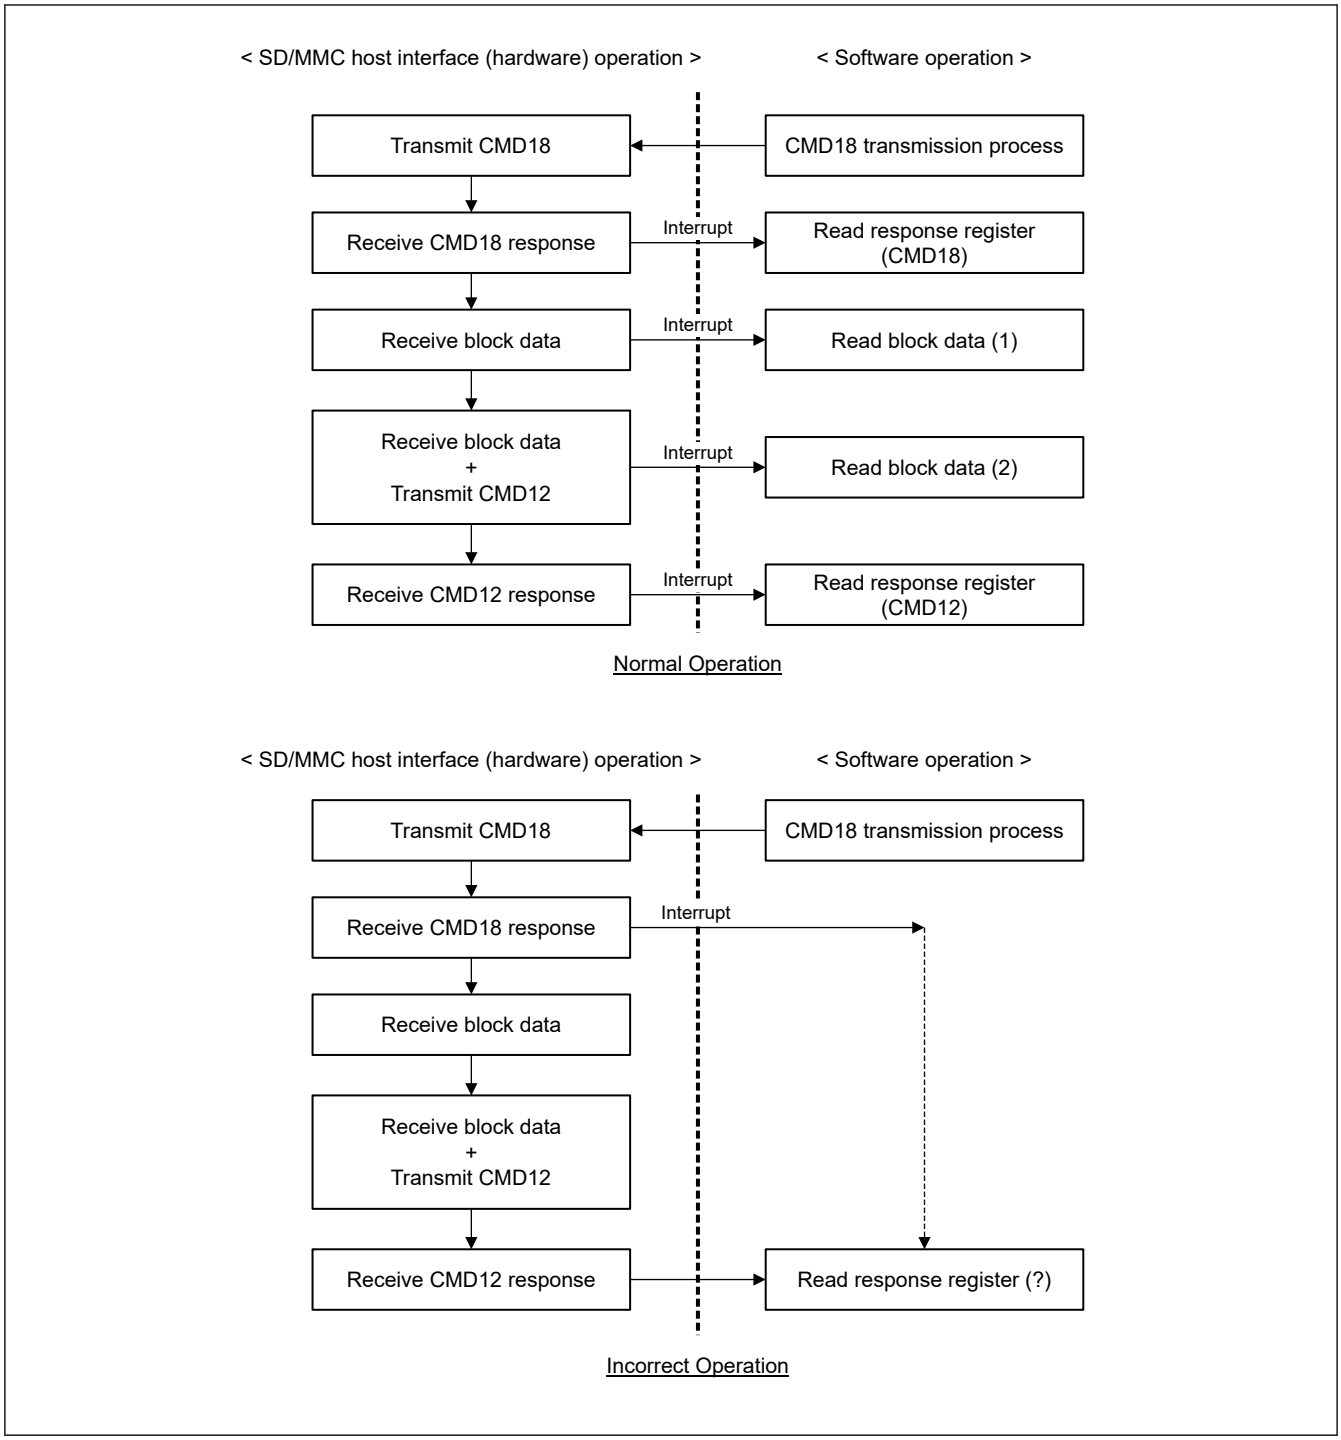

Figure 55.30 Flowcharts for multiple block read operation (two blocks)

55.6.3 Automatic Control of SDCLK Output

In the SD Card standard, 74 cycles of SDCLK must be output before initialization of the card. For this reason, use automatic control of SDCLK output after 74 cycles of SDCLK have been output. Furthermore, if automatic control of SDCLK output was in use, SDCLK output is stopped on completion of the sequence for a communications error or timeout. Thus, in cases where state transitions within the SD card are necessary and so on after completion of the sequence, release automatic control of SDCLK output and restart supply of SDCLK to the SD card.

55.6.4 Control of the C52PUB Setting for Multiple Block Write

If the C52PUB bit in SDIO_MODE is set to 1 during a sequence of multiple block write due to CMD53, CMD52 is not issued until SD_BUF becomes empty. For this reason, set the C52PUB bit after suspending writing to SD_BUF by following the appropriate procedure below.

- When DMA transfer is not in use

1. Before setting the C52PUB bit, suspend writing to SD_BUF by making the setting in SD_INFO2 to disable BWE interrupts.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the INFO0 interrupt processing in SD_INFO1 due to the issuing of CMD52 has been completed, restart writing to SD_BUF by making the setting in SD_INFO2 to enable BWE interrupts.

- When DMA transfer is in use

1. Every time DMA transfer of the value set in SD_SIZE × n blocks (where n = 1, 2, ...) proceeds, suspend writing to SD_BUF by DMA transfer before the C52PUB bit is set.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the INFO0 interrupt processing in SD_INFO1 due to the issuing of CMD52 has been completed, restart writing to SD_BUF by DMA transfer.

55.6.5 Notes on SD_CLK_CTRL Register Settings

When the SCLKDIVEN bit in SD_INFO2 is 0, SD_CLK_CTRL cannot be written to. Before writing to SD_CLK_CTRL, be sure to check that the SCLKDIVEN bit in SD_INFO2 is 1.

55.6.6 Restrictions on Specifications

1. The SDIO suspend/resume is not supported.
2. The SPI bus is not supported.
3. The shared bus and 8-bit SD bus for embedded SDIO are not supported.
4. The stream transfer for MMC cards is not supported.
5. Open ended multiple block transfer for MMC is not supported.

55.6.7 STP Bit Setting during Multiple Block Read

During execution of multiple block read with automatic CMD12 execution by setting the SEC bit in SD_STOP to 1, even if the STP bit in SD_STOP is set to 1 to forcibly stop the execution, the command sequence may not stop depending on the timing of setting the STP bit.

To avoid this, when setting the STP bit in SD_STOP to 1 during multiple block transfer, clear the SEC bit in SD_STOP to 0 at the same time. (Even when the SCLKDIVEN bit in SD_INFO2 is 0, change the SEC bit from 1 to 0.)

When the command sequence has not stopped because the SEC bit was not cleared to 0, the command sequence can be stopped by clearing the SDRST bit in SOFT_RST to 0.

When forcibly terminating the CMD53 multiple block transfer through the IOABT bit in SDIO_MODE, be sure to leave the SEC bit in SD_STOP as 1.

55.7 Sampling Clock Controller (SCC)

55.7.1 Features

This module controls a sampling clock (hereafter referred to as the SCC sampling clock) that is used for SD UHS-I/SDR104 and MMC HS200. When this module is used with the LSI, SD UHS-I/SDR104 and MMC HS200 can be supported.

55.7.2 SCC Block Diagram

Figure 55.31 shows a block diagram of the sampling clock controller.

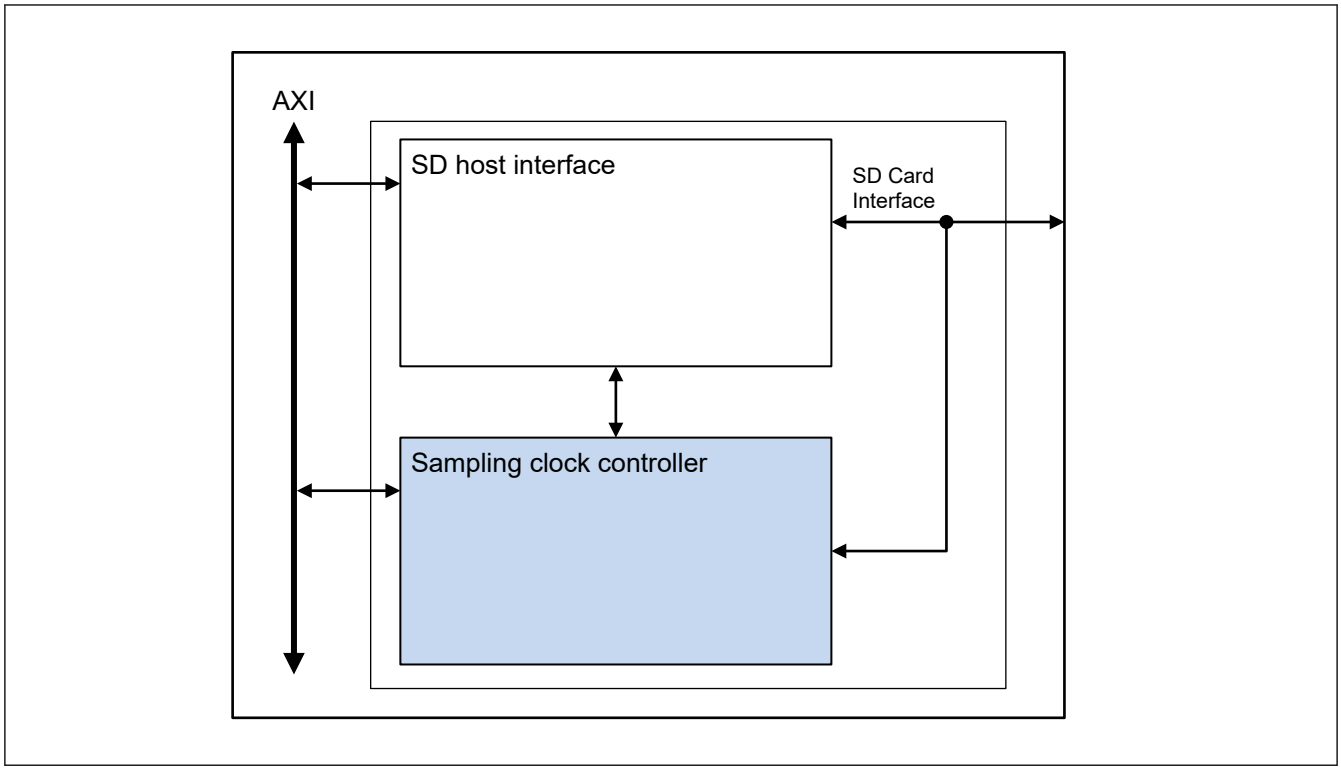

Figure 55.31 Block diagram of the sampling clock controller

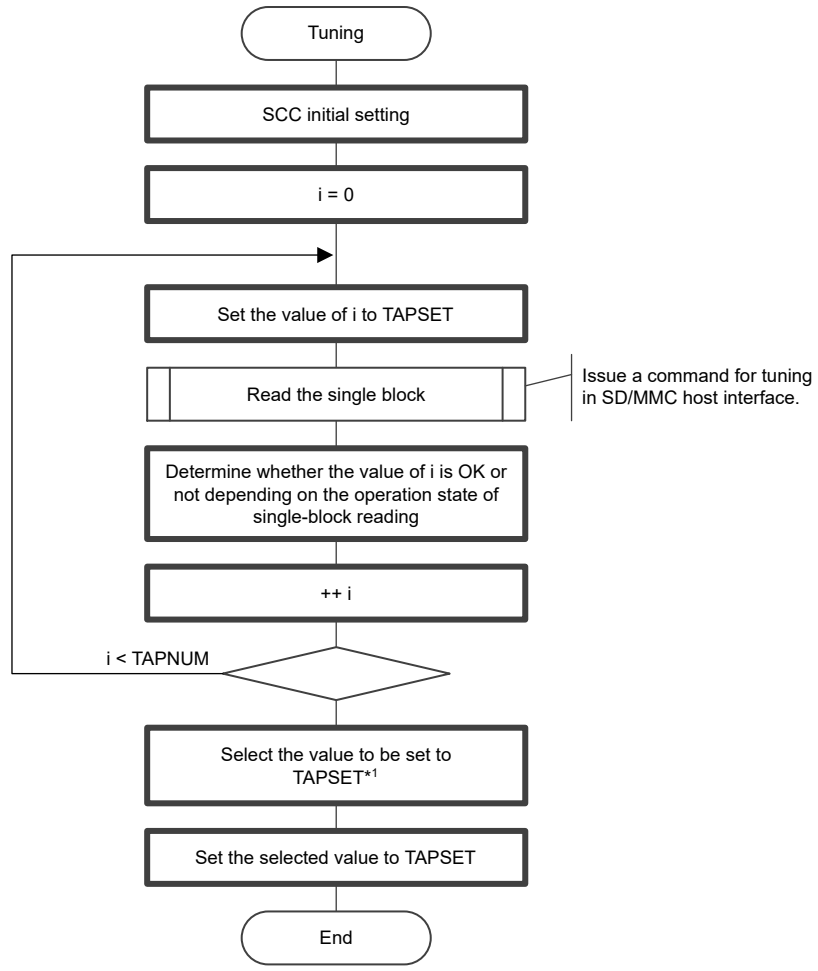
55.8 Usage Example of SCC

55.8.1 Tuning

SCC is tuned by using operation of single-block reading.

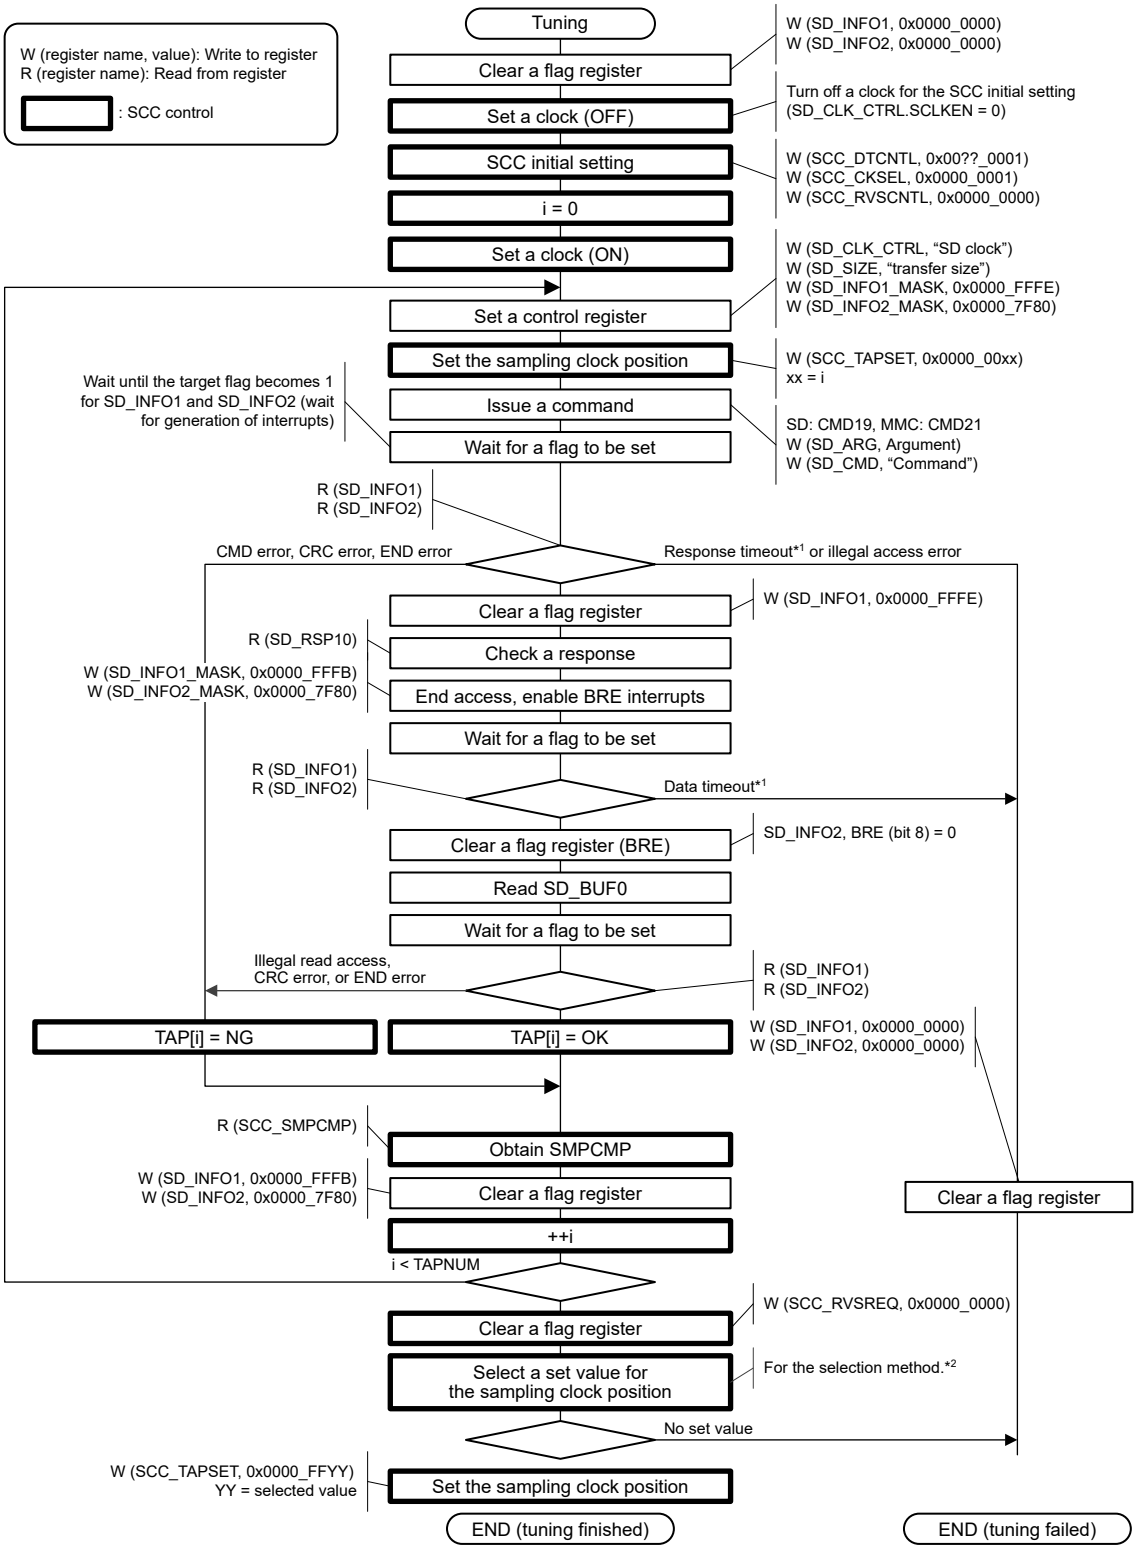
As shown in Figure 55.32, check whether the single-block read command normally ends when the sampling clock position is changed from 0 to TAPNUM − 1 and save the result. After checking, confirm that there exists the range which has three or more continuous normal ends (OK). Then, the median value within the continuous range is determined as the final adjustment value.

Figure 55.33 and Table 55.11 show the detailed tuning flow and the method how to select the sampling clock position (example when TAPNUM = 8).



Note 1. See the example shown in Table 55.11.

Figure 55.32 Example of tuning flow (outline)



Note 1. If all of the TAP[i] has become "NG".
Note 2. See Table 55.11.

Figure 55.33 Example of tuning flow (detailed)

Table 55.11 Example of the method how to select the sampling clock position (when TAPNUM = 8)

Item	i	Case 1	Case 2	Case 3	Case 4	Case 5*1
TAP[i]	0	NG	OK	NG	OK	OK
	1	OK	OK	NG	NG	OK
	2	OK	NG	OK	NG	OK
	3	OK (←)	NG	OK	NG	OK
	4	OK	NG	NG	NG	OK
	5	OK	OK	NG	OK	OK
	6	NG	OK	NG	OK (←)	OK
Max. value →	7	NG	OK (←)	NG	OK	OK
	(0)	NG	OK	NG	OK	OK
	(1)	OK	OK	NG	NG	OK
	(2)	OK	NG	OK	NG	OK
	(3)	OK	NG	OK	NG	OK
	(4)	OK	NG	NG	NG	OK
	(5)	OK	OK	NG	OK	OK
	(6)	NG	OK	NG	OK	OK
	(7)	NG	OK	NG	OK	OK
Selected value		i = 3	i = 7	Fail	i = 6 or 7	i = 0 to 7

Note: (←): Example of selection, (x): repeated display of index x of TAP[x]
(a) The sampling clock position is selected by considering a margin in the range which has three or more continuous 'TAP[i] = OK'.
(b) The sampling clock position is repeated from 0 after the maximum value (TAPNUM − 1). In case 2 above, that position is continued in the order of 5→6→7→0→1.

Note 1. If all of the TAP [i] is OK, the sampling clock position is selected by identifying the change point of data.
Change point of the data can be found in the value of SCC_SMPCMP register. Usage example is section 55.8.3. Change Point of the Input Data.

55.8.2 Sampling Clock Position Correction after Tuning

After tuning, correction of the sampling clock position may be required when a command is issued.

There are manual and automatic correction methods. After a command sequence, if the CMD, CRC, END error or time out occurs or the correction error occurs, tuning will be performed again. The following shows examples of manual and automatic correction methods.

55.8.2.1 Manual Correction of the Sampling Clock Position

Figure 55.34 shows the flow of manual correction of the sampling clock position. Table 55.12 shows set values determined when correction is required (when TAPNUM = 8).

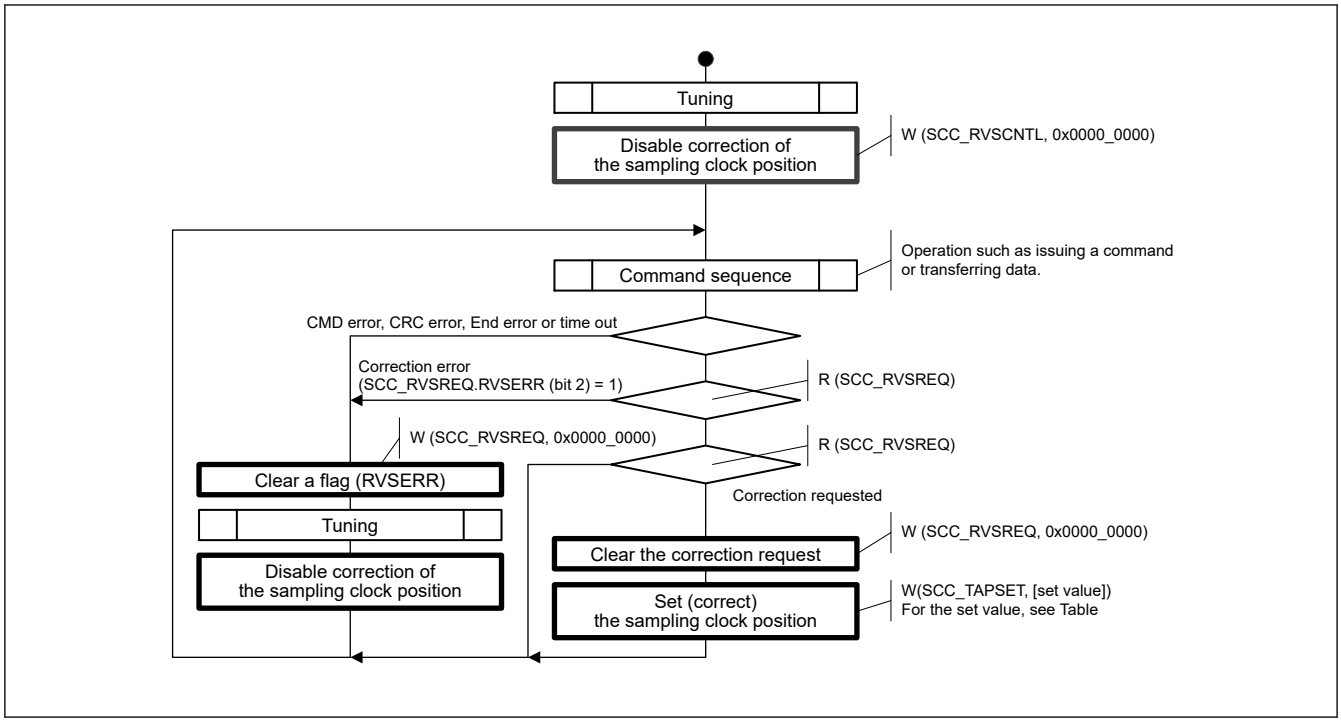


Figure 55.34 Flow of manual correction of the sampling clock position (example)

Table 55.12 Set values for TAPSET when correction is required (when TAPNUM = 8)

No.	Current value of TAPSET	Value set to TAPSET when REQTAPUP = 1	Value set to TAPSET when REQTAPDWN = 1
1	0	1	7
2	1	2	0
3	2	3	1
4	3	4	2
5	4	5	3
6	5	6	4
7	6	7	5
8	7	0	6

Note: As is the case in the tuning selection method, the sampling clock position is 0 after the maximum value (TAPNUM − 1).

55.8.2.2 Automatic Correction of the Sampling Clock Position

Figure 55.35 shows the flow of automatic correction of the sampling clock position.

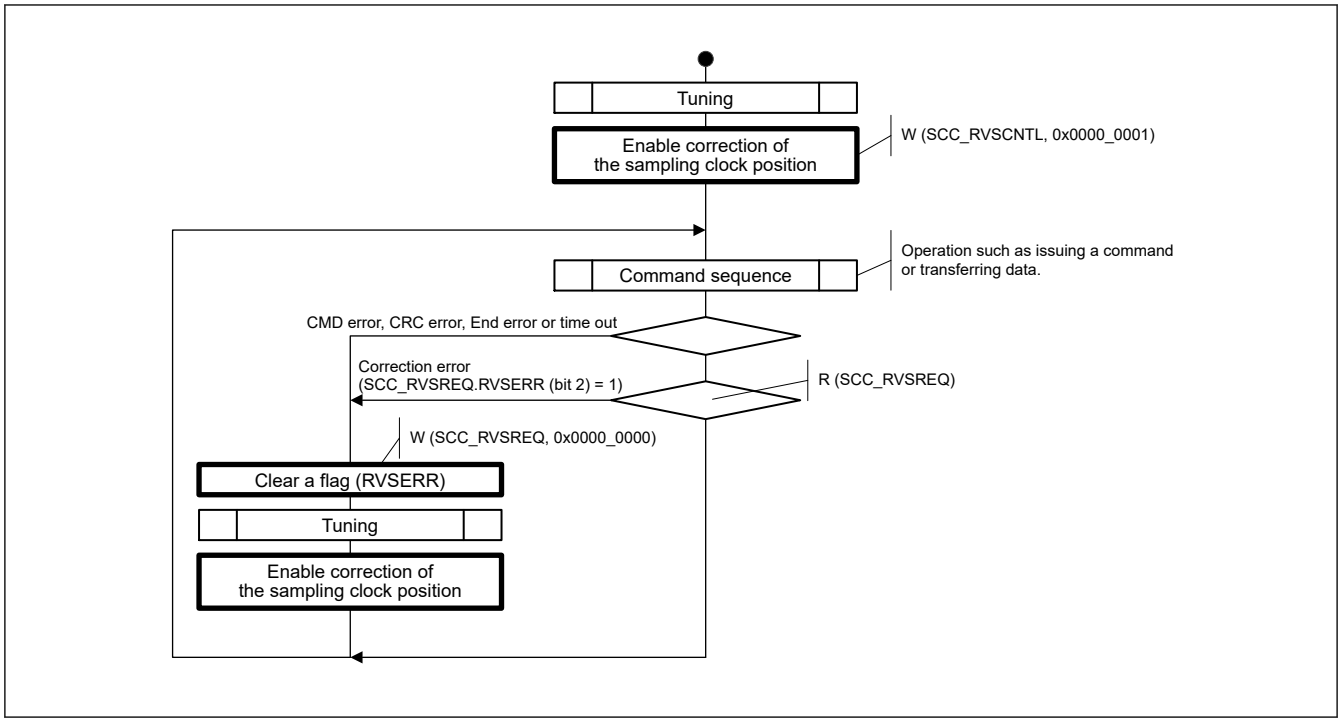

Figure 55.35 Flow of automatic correction of the sampling clock position (example)

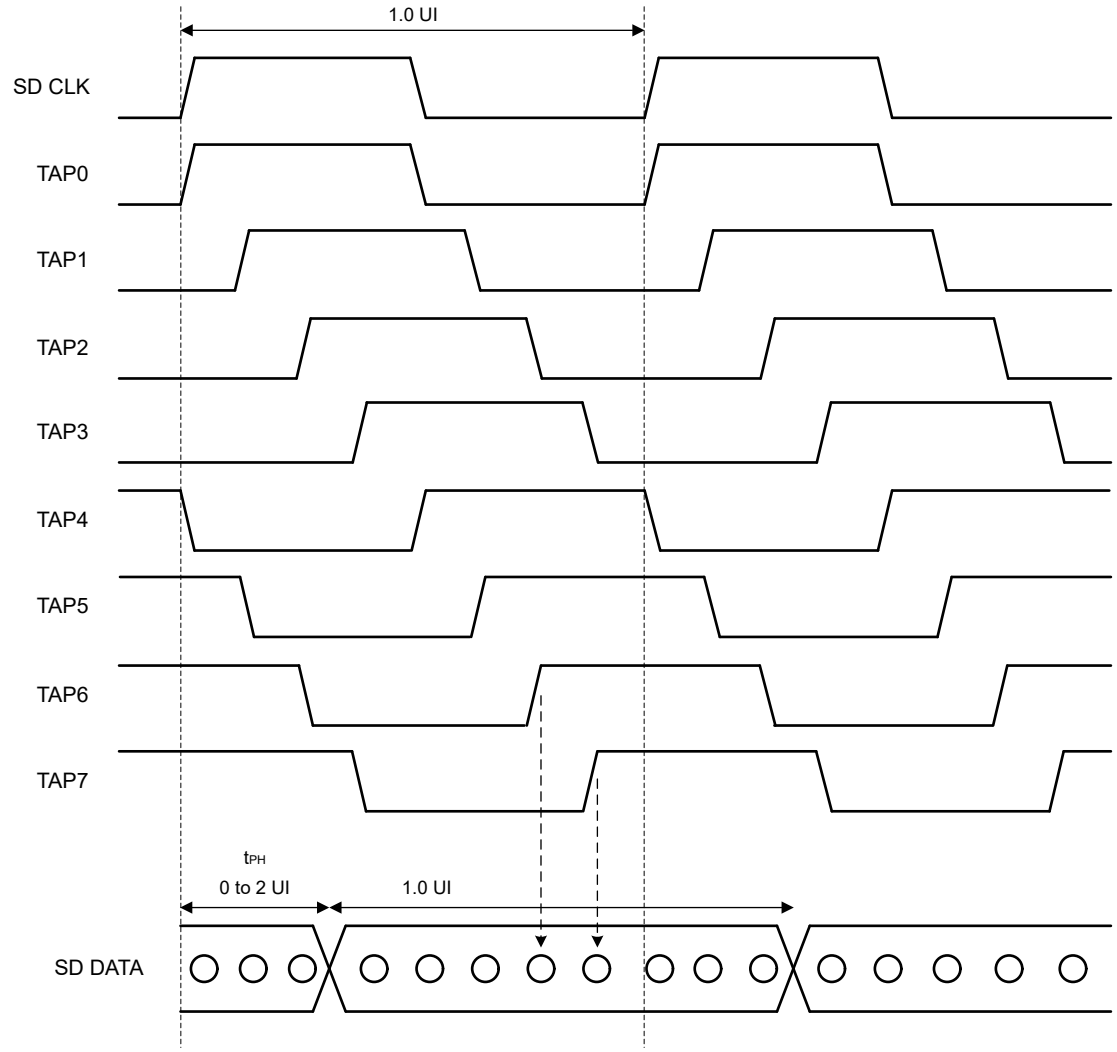
55.8.3 Change Point of the Input Data

Tuning is capture the data by the TAP clock selected. However, also captures the data by the previous TAP clock and the behind the TAP clock at the same time. This result is reflected in the sampling data comparison register (SCC_SMPCMP). Point of mismatch before and after the selected TAP clock is the changing point of the data. In this example, it is desirable to set as TAP6 or TAP7.



Note: After recognizing the changing point of the input data, need to set the TAP clock.

Figure 55.36 Example, All taps is OK.

Figure 55.36 is shown change point of data between TAP2 and TAP3. Change point of the data can be confirmed by sampling data comparison register (SCC_SMPCMP). When the tuning of TAP2 or TAP3, CMPNGU bit of sampling data comparison register indicates a mismatch. As the width of the input data is 1 (UI), select TAP6 or TAP7 which is the median of next TAP3 from TAP3.

56. PCI Express 3.0 Interface (PCIE)

56.1 Overview

This module has a dual structure so that the device incorporating it can operate as a root complex or endpoint device, and includes a Type 0/1 Configuration Register for this purpose. Furthermore, it has an internal DMA controller. However, limitations imposed by the AXI place restrictions on some specifications of PCI Express functionality.

Table 56.1 PCIE specifications

Item	Specification
Number of units	• 1 unit
Lane/channel configuration	• 1 lane / 2 channels or 2 lanes / 1 channel selectable • 1 lane / 2 channels: Common / Separate reference clock support • 2 lanes / 1 channel: Common reference clock support only
Support Specification	• PCI Express Base Specification 3.1 Compliant
Functions	• PCI Express Gen1 (2.5 [GT/s]) / Gen2 (5.0 [GT/s]) / Gen3 (8.0 [GT/s]) • Root Complex / Endpoint Applications, Type0/1 Configuration Register • Lane implementation: ×1 or ×2 • Support Polarity inversion • Maximum data payload of 256 bytes, Maximum read request size 512 bytes • Not support for Virtual channels (support VC0 only) • Number of outstanding: 8 • Dynamic control of speed/width up/down configuration • Not support for Clock Power Management (not support P1.CPM, P2.CPM) • Power Management (not support ASPM L1-Substate) • Error handling/logging (AER Support) • Replay FIFO with ECC • Internal Memory without Parity • Number of Support Functions: 2
Internal interface	• AMBA® AXI Protocol • Master interface: 128-bit width 1 port, or 2 ports (when multilink is selected) • Slave interface: 128-bit width 1 port, or 2 ports (when multilink is selected) • DMAC – Register control and descriptor control support – 8 channels – Allowable number of requests to be issued: Maximum total 8 for all the channels – PCIe MRd: 8 / ch, PCIe MWr: 1 / ch – AXI Read: 1 / ch, AXI Write: 1 / ch
Module-stop function	• Module-stop state can be set to reduce power consumption.

The initial values of configuration registers for vendor ID, device ID, revision ID, class code, subsystem vendor ID, subsystem ID, and base address register mask are 0. Set appropriate values in the registers before the start of link up.

Table 56.2 PCIE input/output pins

Pin name	I/O	Function
PCIE_REFCLK_P0	Input	Ch0 Reference clock input (Positive)
PCIE_REFCLK_N0	Input	Ch0 Reference clock input (Negative)
PCIE_REFCLK_P1	Input	Ch1 Reference clock input (Positive)
PCIE_REFCLK_N1	Input	Ch1 Reference clock input (Negative)
PCIE_RXDP_L0	Input	Serial data input 0 (Positive)
PCIE_RXDN_L0	Input	Serial data input 0 (Negative)
PCIE_RXDP_L1	Input	Serial data input 1 (Positive)
PCIE_RXDN_L1	Input	Serial data input 1 (Negative)
PCIE_TXDP_L0	Output	Serial data output 0 (Positive)
PCIE_TXDN_L0	Output	Serial data output 0 (Negative)
PCIE_TXDP_L1	Output	Serial data output 1 (Positive)
PCIE_TXDN_L1	Output	Serial data output 1 (Negative)
PCIE_RSTOUT0B	Output	PCIE Reset output ch0 for Root Complex
PCIE_RSTOUT1B	Output	PCIE Reset output ch1 for Root Complex

Table 56.3 PCIE Interrupt sources (1 of 2)

Name	Interrupt Sources
PCIEn_INTA_RC	INTA interrupt for Root complex
PCIEn_INTB_RC	INTB interrupt for Root complex
PCIEn_INTC_RC	INTC interrupt for Root complex
PCIEn_INTD_RC	INTD interrupt for Root complex
PCIEn_INTMSI_RC	MSI interrupt for Root complex

Table 56.3 PCIE Interrupt sources (2 of 2)

Name	Interrupt Sources
PCIEn_INT_LINK_BANDWIDTH	Link width change interrupt for Root complex
PCIEn_INT_EQUALIZATION_REQUEST	Link Equalization Request interrupt for Root complex
PCIEn_INT_PM_PME	PM_PME Message receive interrupt for Root complex
PCIEn_INT_SERR	Error detect interrupt for Root complex
PCIEn_INT_SERR_COR	Correctable error detect interrupt for Root complex
PCIEn_INT_SERR_FATAL	Fatal error detect for Root complex
PCIEn_INT_SERR_NONFATAL	Non fatal error detect interrupt for Root complex
PCIEn_INT_DMA	Event interrupt of DMA
PCIEn_INT_PCIE_EVT	Event interrupt of PCIE
PCIEn_INT_AXI_ERR	Error detect interrupt of AXI
PCIEn_INT_MSG	Message receive interrupt
PCIEn_INT_ALL	ORed interrupt of all interrupt
PCIEn_TURN_OFF_EVENT	PME_Turn_Off Msg. receive flag output for Endpoint
PCIEn_PMU_POWEROFF	POWEROFF indication on L2
PCIEn_D3_EVENT_F0	Non-D0 State transition request receive output Function #0 for Endpoint
PCIEn_D3_EVENT_F1	Non-D0 State transition request receive output Function #1 for Endpoint
PCIEn_CFG_PMCSR_PME_STATUS_WRITECLEAR_F0	PME_STATUS clear output Function #0 for Endpoint
PCIEn_CFG_PMCSR_PME_STATUS_WRITECLEAR_F1	PME_STATUS clear output Function #1 for Endpoint
PCIEn_FLR_REQ_F0	FLR request Function #0 for Endpoint
PCIEn_FLR_REQ_F1	FLR request Function #1 for Endpoint

Note: n = 0, 1

56.1.1 Multi Link: Configuration of 1 Lane × 1

Figure 56.2 shows the relationship between the modules and lanes used in the configuration of 2 lanes × 1 channel and 1 lane × 2 channels.

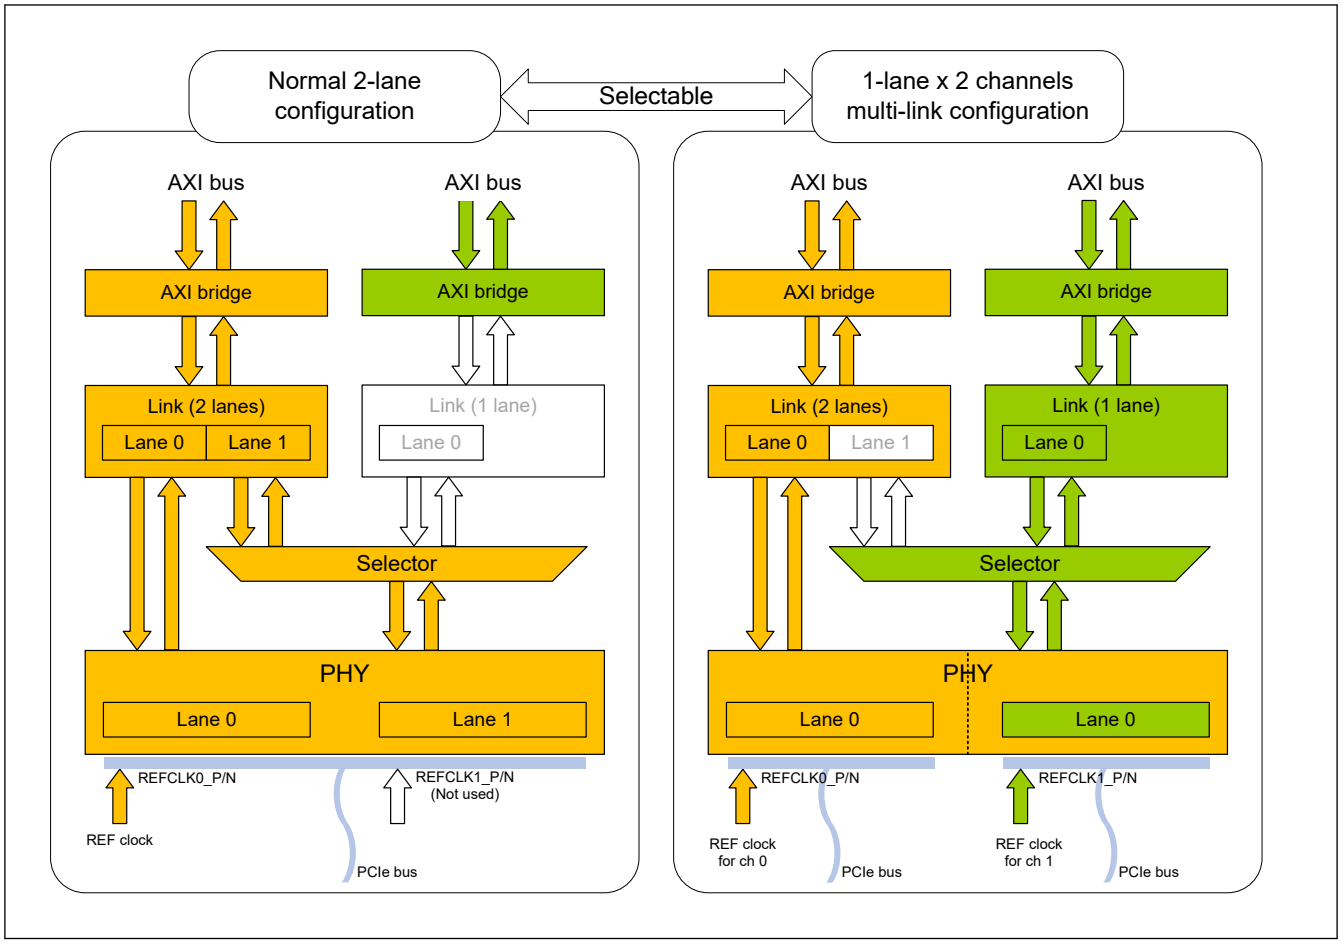

Figure 56.2 Relationship between modules and lanes

In the multi-link (1 lane × 2 channels) configuration, channel 0/1 are independent PCIe cores.

When channels 0/1 are placed in the same AXI area, overlapping the AXI window and PCI window of channel 0/1 is prohibited. In addition, since channel 0/1 are independent PCIe cores, they must be controlled by the system when channel 0/1 are linked for use.

The lane reversal is not supported in the multi-link configuration.

56.1.2 Single Link (2 Lanes × 1 channel) Configuration

The AXI bus for channel 1, which is not used, responds with OKAY and ERROR as usual, and is not deadlocked. ERROR response is generated in case of read access to the AXI Window by incorrect AXI transaction.

Figure 56.3 shows the supported configuration for the lane connection.

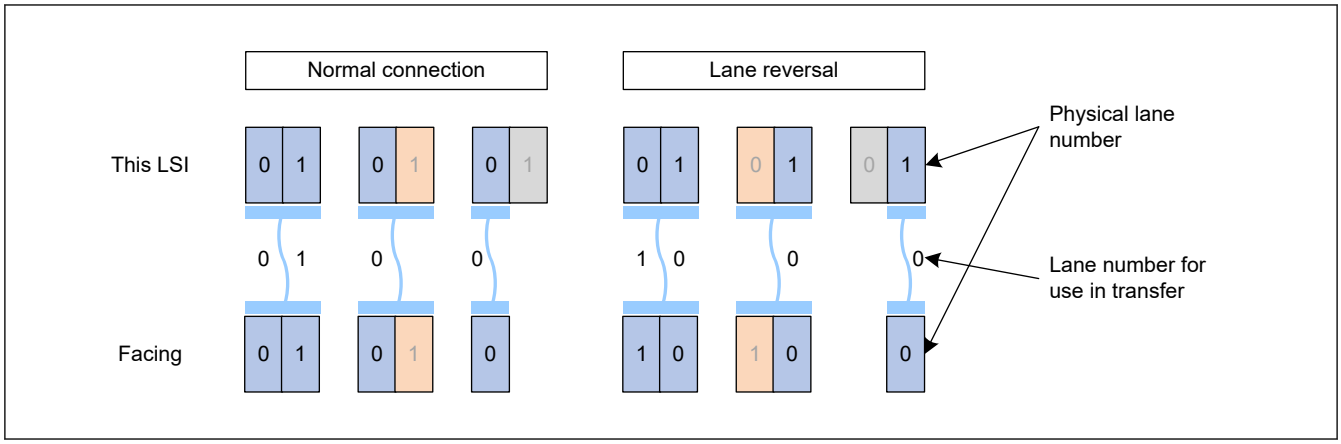

Figure 56.3 Lane connection configuration

Note: m = 0 (ch 0), 1 (ch 1)

56.2.3 Physical Layer Control/Status

Table 56.8 PCIE register map (physical layer control/status)

Address	Register symbol	Register name	Write protection
0x9210_2000 + 0x10 × n (n = 0 to 26)	PCI_PHY_XCFGDn	XCFGD Setting Register n (n = 0 to 26)	—
0x9210_2400 + 0x10 × n (n = 0 to 15)	PCI_PHY_XCFGA_CMNn	XCFGA_CMN Setting Register n (n = 0 to 15)	—
0x9210_2500 + 0x10 × n (n = 0 to 5)	PCI_PHY_XCFGA_L0n	XCFGA_L0 Setting Register n (n = 0 to 5)	—
0x9210_2560 + 0x10 × n (n = 0 to 5)	PCI_PHY_XCFGA_L1n	XCFGA_L1 Setting Register n (n = 0 to 5)	—

56.2.4 Supplemental Setting

Table 56.9 PCIE register map (supplemental setting) (1 of 2)

Address	Register symbol	Register name	Write protection
0x8029_2000 + 0x30 × m	PCIE_INTX	PCIe INTX Register	—
0x8029_2004 + 0x30 × m	PCIE_MSI1	PCIe MSI1 Register	—
0x8029_2008 + 0x30 × m	PCIE_MSI2	PCIe MSI2 Register	—
0x8029_200C + 0x30 × m	PCIE_MSI3	PCIe MSI3 Register	—
0x8029_2010 + 0x30 × m	PCIE_MSI4	PCIe MSI4 Register	—

Table 56.9 PCIE register map (supplemental setting) (2 of 2)

Address	Register symbol	Register name	Write protection
0x8029_2014 + 0x30 × m	PCIE_MSI5	PCIe MSI5 Register	—
0x8029_2018 + 0x30 × m	PCIE_PME	PCIe PME Register	—
0x8029_201C + 0x30 × m	PCIE_ACK	PCIe ASK Register	—
0x8029_2020 + 0x30 × m	PCIE_MISC	PCIe MISC Register	—
0x8029_2024 + 0x30 × m	PCIE_MODE	PCIe MODE Register	—
0x8029_2060	PCIE_LINKMODE	PCIe Link Mode Register	—

Note: m = 0 (ch 0), 1 (ch 1)

Table 56.10 PCIE related system control register

Registers	Module reset control register	Module stop control register	Slave access control register
Root Complex Mode Endpoint Mode Physical Layer Control/Status	MRCTLM.MRCTLM08	MSTPCRM.MSTPCRM08	SLVACCCTL5.TZCPCIE_SL
Supplemental Setting	—	—	SLVACCCTL5.TZCPCIE_SL

56.3 Register Descriptions (Root Complex Mode)

The registers in this section are availabe when the MODE_PORT bit in PCIE_MODE register is set to 1.

The registers are implemented in both ch0 and ch1, but the registers related to lane 1 are reserved for ch1.

Registers with the HwInit attribute

Some registers with the RO attribute stated in the PCI Express Base Specification are writable at the time of initialization. When writing to these registers, CFG_HWINIT_EN (Permission Register (offset: 0x0300) bit[2]) should be set to 1.

56.3.1 AXI Bridge Register

Registers can be accessed from the AXI only.

56.3.1.1 PCI_RC_REQDATAn : Request Data Register n (n = 0 to 2)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0080 + 0x4 × n

Bit position:	31																												0
Bit field:																													
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
31:0	n/a	Request Data Issue various requests to PCIe See Table 56.11.	R/W

Table 56.11 Relationship between transaction type and request data registers

Transaction type	Request Data Register 0	Request Data Register 1	Request Data Register 2
Zero-Length Read Request	Invalid	Invalid	Invalid
Config Write	Invalid	Invalid	Write data
Config Read	Invalid	Invalid	Invalid
Message Request	3rd Header	4th Header	Invalid
Message Request with data payload	3rd Header	4th Header	Message data

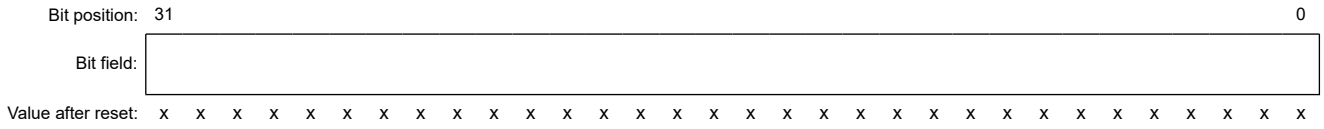
Note: The bits should be set to 0 for the requests indicated as "Invalid".

The PCI_RC_REQDATAn register issues various requests.

56.3.1.2 PCI_RC_REQRCVDAT : Request Receive Data Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x008C



Bit	Symbol	Function	R/W
31:0	n/a	Request Receive Data After issuing a read request, the data read on reception of the completion response are set in these bits. However, these bits are invalid for Zero-Lentgh Read and any kind of various write requests.	R

The PCI_RC_REQRCVDAT register indicates the data read on reception of the completion response after issuing a read request.

56.3.1.3 PCI_RC_REQADR1 : Request Address Register 1

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0090

Bit	Symbol	Function	R/W
31:0	n/a	Request Address Set the Address, etc. when issuing a Request. See Table 56.12.	R/W

The PCI_RC_REQADR1 register issues requests to PCIe.

Table 56.12 Relationship between transaction type and request address register 1

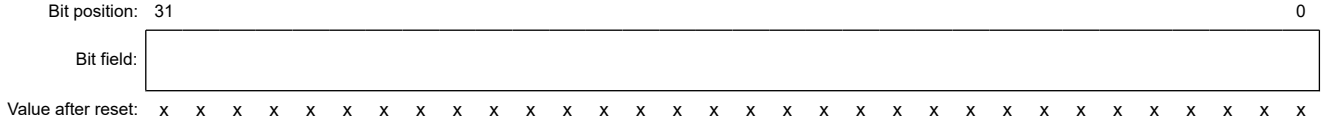
Transaction type	[31:27]	[26:24]	[23:19]	[18:16]	[15:12]	[11:8]	[7:2]	[1:0]
Zero-Length Read Request	Address							Reserved
Config Write	Bus number		Reserved	Function number	Reserved	Ext. Reg. number	Register number	Reserved
Config Read	Bus number		Reserved	Function number	Reserved	Ext. Reg. number	Register number	Reserved
Message Request	Reserved	Routing type	Reserved	Reserved	Reserved	Reserved	Message code	
Message Request with data payload	Reserved	Routing type	Reserved	Reserved	Reserved	Reserved	Message code	

Note: The bits should be set to 0 for the requests indicated as "Reserved".

56.3.1.4 PCI_RC_REQADR2 : Request Address Register 2

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0094



Bit	Symbol	Function	R/W
31:0	n/a	Request Address63:32 See Table 56.13.	R/W

The PCI_RC_REQADR2 register issues requests to PCIe.

Table 56.13 Relationship between transaction type and request address register 2

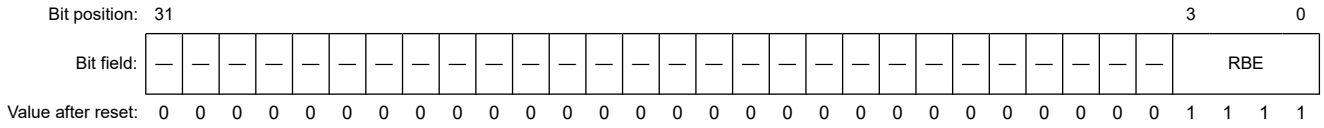
Transaction type	[31:0]
Zero-Length Read Request	Address
Config Write	Invalid
Config Read	Invalid
Message Request	Invalid
Message Request with data payload	Invalid

Note: The bits should be set to 0 for the requests indicated as "Invalid".

56.3.1.5 PCI_RC_REQBE : Request Byte Enable Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0098



Bit	Symbol	Function	R/W
3:0	RBE	Request Byte Enable Specify byte enable when issuing Cfg Request as required. Normally use 0xF. 0: Byte Enable enabled 1: Byte Enable disabled	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_REQBE register specifies the 1st DW byte enable bit of the TLP header when issuing a request to PCIe.

Table 56.14 Request Byte Enable settings (1 of 2)

Transaction type	RBE[3:0]
Zero-Length Read Request	0x0
Config Write	Random (Usually 0xF)
Config Read	Random (Usually 0xF)
Message Request	Invalid (0xF)

Table 56.14 Request Byte Enable settings (2 of 2)

Transaction type	RBE[3:0]
Message Request with data payload	Invalid (0xF)

56.3.1.6 PCI_RC_REQISS : Request Issue Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x009C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	RR	MOR_CD_PERR	MOR_CH_PERR	MOR_EP_ERR	MOR_STATUS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	FUNC[2:0]			TR_TYPE[3:0]				—	—	—	—	—	—	—	RI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RI	Request Issue 0: Write: No operation. Read: Request can be accepted. (Indicates that the processing of the issued Request has ended.) 1: Write: Request issuance. Read: Processing Request. (Indicates that the issued Request is being processed.)	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
11:8	TR_TYPE[3:0]	Set the type of Request. See Table 56.15.	R/W
14:12	FUNC[2:0]	Set the function of Request.	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
18:16	MOR_STATUS[2:0]	These bits retain the MOR Status of Completion TLP for Non-Posted requests issued. It is not updated at the time of Posted request. 0 0 0: Successful Completion (SC) 0 0 1: Unsupported Request (UR) 0 1 0: Configuration Request Retry Status (CRS) (not supported) 0 1 1: Completion Timeout 1 0 0: Completer Abort (CA) 1 0 1: Unexpected Completion and mismatched type (Lock Completion responds to non-Lock Request) 1 1 0: Reserved 1 1 1: Overrun Completion length	R
19	MOR_EP_ERR	It is set to 1 when a Poisoned Completion TLP for a Non-Posted request issued by this register is received. Normally not used. It is not updated at the time of Posted request.	R
20	MOR_CH_PERR	It is set to 1 when a header error occurs in the Completion TLP for the Non-Posted request issued by this register. Normally not used. It is not updated at the time of Posted request.	R
21	MOR_CD_PERR	It is set to 1 when a data error occurs in the Completion TLP for the Non-Posted request issued by this register. Normally not used. It is not updated at the time of Posted request.	R

Bit	Symbol	Function	R/W
22	RR	Request Rejection Indicates that the stopped or hibernated state of the PCI Express transmit (TX) side was detected and the process was forcibly terminated. 0: Normal state (Request issued) 1: Rejection	R
31:23	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_REQISS register issues requests to PCIe.

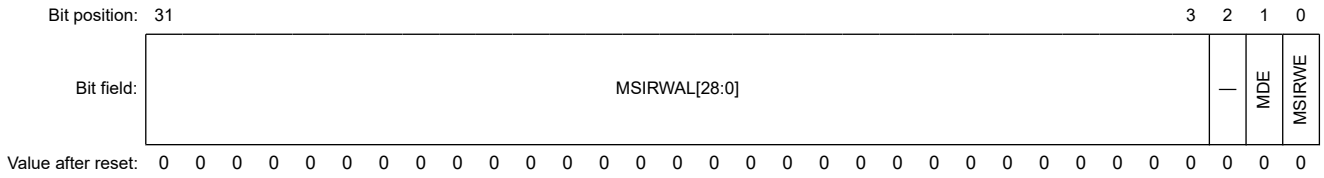
Table 56.15 Type of Request settings

Transaction type	TR_TYPE[11:8]	Posted/Non-posted	Device type	
			Root complex	Endpoint
Zero-Length Read Request	0x0	Non-posted	Issuable	Issuable
Configuration Read Type0	0x4	Non-posted	Issuable	Issuing prohibited
Configuration Write Type0	0x5	Non-posted	Issuable	Issuing prohibited
Configuration Read Type1	0x6	Non-posted	Issuable	Issuing prohibited
Configuration Write Type1	0x7	Non-posted	Issuable	Issuing prohibited
Message Request	0x8	Posted	Issuable	Issuable
Message Request with data payload	0x9	Posted	Issuable	Issuable
	Others	—	Issuing prohibited	Issuing prohibited

56.3.1.7 PCI_RC_MSIRCVWADRL : MSI Receive Window Address (Lower) Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0100



Bit	Symbol	Function	R/W
0	MSIRWE	MSI Receive Window Enable 0: Window is disabled. 1: Window is enabled.	R/W
1	MDE	Message Data Enabled Control whether to use Message Data in MSI reception judgment. The MSI reception judgment result selected by this register is reflected in the INTMSI_RC interrupt. 0: Not used (conventional mode) 1: Used (multiple interrupts)	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
31:3	MSIRWAL[28:0]	MSI Receive Window Address (Lower) Set Start Address[31:3] of MSI receive window. However, it must be aligned with the size set by MSI Receive Window Mask. Even if you set a non-aligned address, the address bit for which the MSI Receive Window Mask is set will be 0. Make sure that MSI Receive Window Enable (MSIRWE) is 0 when changing this register.	R/W

The PCI_RC_MSIRCVWADRL register sets the start address of the MSI memory space to receive.

56.3.1.8 PCI_RC_MSIRCVWADRU : MSI Receive Window Address (Upper) Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0104

Bit position:	31																												0
Bit field:	MSIRWAU[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	MSIRWAU[31:0]	MSI Receive Window Address (Upper) Set the Start Address[63:32] of the MSI receive window. However, it must be aligned with the size set by MSI Receive Window Mask. Even if you set a non-aligned address, the address bit for which the MSI Receive Window Mask is set will be 0. Make sure that MSI Receive Window Enable is 0 when changing this register.	R/W

The PCI_RC_MSIRCVWADRU register sets the start address of the MSI memory space to receive.

56.3.1.9 PCI_RC_MSIRCVWMSKL : MSI Receive Window Mask (Lower) Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0108

Bit position:	31																												0
Bit field:	MSIRWML[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
31:0	MSIRWML[31:0]	MSI Receive Window Mask (Lower) 11b fixed. MSI Receive Window Mask [1:0] should always be set to Mask.	R/W

The PCI_RC_MSIRCVWMSKL register specifies the size of the area from the address set in the MSI Receive Window Address bits.

56.3.1.10 PCI_RC_MSIRCVWMSKU : MSI Receive Window Mask (Upper) Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x010C

Bit position:	31	30																											0
Bit field:	—	MSIRWMU[30:0]																											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
30:0	MSIRWMU[30:0]	MSI Receive Window Mask (Upper) Set [62:32] for MSI Receive Window Mask.	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The PCI_RC_MSIRCVWMSKU register specifies the size of the area from the address set in the MSI Receive Window Address bits.

56.3.1.11 PCI_RC_PINTRCVIE : PCI INTx Receive Interrupt Enable Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0110

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	MSIRIE	INTDRIE	INTCRIE	INTBRIE	INTARIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	INTARIE	INTA Receive Interrupt Enable Enable INTA_RC. 0: disable 1: enable	R/W
1	INTBRIE	INTB Receive Interrupt Enable Enable INTB_RC. 0: disable 1: enable	R/W
2	INTCRIE	INTC Receive Interrupt Enable Enable INTC_RC. 0: disable 1: enable	R/W
3	INTDRIE	INTD Receive Interrupt Enable Enable INTD_RC. 0: disable 1: enable	R/W
4	MSIRIE	MSI Receive Interrupt Enable Enable INTMSI_RC with MSI reception. 0: disable 1: enable	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_PINTRCVIE register enables INTx_RC interrupts.

56.3.1.12 PCI_RC_PINTRCVIS : PCI INTx Receive Interrupt Status Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0114

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	MSIRIS	INTDRIS	INTCRIS	INTBRIS	INTARIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	INTARIS	INTA Receive Interrupt Status It is set when an Assert INTA Message is received, and cleared when a Deassert INTA Message is received.	R/W
1	INTBRIS	INTB Receive Interrupt Status It is set when an Assert INTB Message is received, and cleared when a Deassert INTB Message is received.	R/W
2	INTCRIS	INTC Receive Interrupt Status It is set when an Assert INTC Message is received, and cleared when a Deassert INTC Message is received.	R/W
3	INTDRIS	INTD Receive Interrupt Status It is set when an Assert INTD Message is received, and cleared when a Deassert INTD Message is received.	R/W
4	MSIRIS	MSI Receive Interrupt Status MSI Receive Window Set when Memory Write Req is received from the PCI bus side in the set area. This bit is set when MSI is issued to AXI as a Write Transaction and the Response is returned.	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_PINTRCVIS register indicates the INTx_RC interrupt factor. When Assert_INTx is received in response to a message request from PCIe, the corresponding bit in the PCI_RC_PINTRCVIS register is set and interrupt INTx_RC is asserted. When Deassert_INTx is received in response to a message request, the corresponding bit in the PCI_RC_PINTRCVIS register is cleared and interrupt INTx_RC is deasserted. Although the PCI_RC_PINTRCVIS register can be cleared by writing 1 by software, it is not recommended to clear this bit by the software itself during normal operation for interrupts on the bus for PCIe. The fields of the PCI_RC_PINTRCVIS register are set if each factor is detected, regardless of the setting of the PCI_INTx_Receive_Interrupt_Enable register for RC.

56.3.1.13 PCI_RC_MSGRCVIE : Message Receive Interrupt Enable Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0120

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	MRI	—	—	—	—	PMASNR	PMPMERI	PMETORI	PMETOARI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
16	PMETOARI	PME_TO_Ack Receive Interrupt Enable control of MSG_INT assertion by PME_TO_Ack reception 0: Disable 1: Enable	R/W
17	PMETORI	PME_Turn_Off Receive Interrupt Enable control of MSG_INT assertion by PME_Turn_Off reception 0: Disable 1: Enable	R/W
18	PMPMERI	PM_PME Receive Interrupt Enable control of MSG_INT assert by PM_PME reception 0: Disable 1: Enable	R/W

Bit	Symbol	Function	R/W
19	PMASNR	PM_Active_State_Nak Receive Enable control of MSG_INT assertion by PM_Active_State_Nak reception 0: Disable 1: Enable	R/W
23:20	—	These bits are read as 0. The write value should be 0.	R/W
24	MRI	Message Receive Interrupt Enable control of MSG_INT assert by message reception 0: enable 1: disable	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_MSGRCVIE register controls enabling of MSG_INT in response to the reception of message requests other than INTx and error-related messages.

56.3.1.14 PCI_RC_MSGRCVIS : Message Receive Interrupt Status Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0124

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	MRI	—	—	—	—	PMASNR	PMPMERI	PMETORI	PMETOARI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
16	PMETOARI	PME_TO_Ack Receive Interrupt Set when receiving a PM_TO_Ack message	R/W
17	PMETORI	PME_Turn_Off Receive Interrupt Disabled due to RC	R/W
18	PMPMERI	PM_PME Receive Interrupt Set when receiving a PM_PME message	R/W
19	PMASNR	PM_Active_State_Nak Receive Disabled due to RC	R/W
23:20	—	These bits are read as 0. The write value should be 0.	R/W
24	MRI	Message Receive Interrupt Set when receiving a message (does not depend on the type of message)	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_MSGRCVIS register is a status register that indicates the reception of message requests other than INTx and error-related messages. The value of the PCI_RC_MSGRCVIS register is reflected in MSG_INT. Only the message code is used to judge the message type.

The validity of routing and validity of Msg/MsgD selection are not verified. The corresponding message is considered to have been received.

56.3.1.15 PCI_RC_MSGCODE : Message Code Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0130

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MC[7:0]								R[2:0]			—	—	—	—	MP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MP	Message Payload Stores the presence or absence of the data payload of the last received Message. When Power Management Message (PME_TO_Ack Message, PME_Turn_Off Message, PM_PME Message, PM_Active_State_Nak Message) is received, this register is not written. 0: Msg (Without Payload) 1: MsgD (with Payload)	R
4:1	—	These bits are read as 0.	R
7:5	R[2:0]	Routing Stores the Routing of the last received Message.	R
15:8	MC[7:0]	Message Code Stores the Code of the last received Message.	R
31:16	—	These bits are read as 0.	R

The PCI_RC_MSGCODE register stores the code and routing of the last received message.

56.3.1.16 PCI_RC_MSGDATA : Message Data Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0134

Bit position:	31	0
Bit field:		
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	n/a	Message Data Stores the 1DW data of the last received Message. It is updated only when MsgD (with Data) is received, and the previous value is retained when Msg (without Data) is received. When Power Management Message (PME_TO_Ack Message, PME_Turn_Off Message, PM_PME Message, PM_Active_State_Nak Message) is received, this register is not written.	R

The PCI_RC_MSGDATA register stores the data of the last received message.

56.3.1.17 PCI_RC_MSGH3DW : Message Header 3rdDW Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0138

Bit position:	31																													0
Bit field:																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Message Header 3rdDW Stores the Header (3rdDW) of the last received Message.	R

The PCI_RC_MSGH3DW register stores the header (the 3rd DW) of the last received message.

56.3.1.18 PCI_RC_MSGH4DW : Message Header 4thDW Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x013C

Bit position:	31																													0
Bit field:																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Message Header 4thDW Registers Stores the Header (4thDW) of the last received Message.	R

The PCI_RC_MSGH4DW register stores the header (the 4th DW) of the last received message.

56.3.1.19 PCI_RC_INTTABLE : Interrupt Table Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0140

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	INT_LINK_EQUALIZATION_REQUEST	—	—	—	—	AXI_ERR_IN	PCIE_EVT_INT	MSG_INT	—	—	—	INTMSI_RC	INTD_RC	INTC_RC	INTB_RC	INTA_RC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	INTA_RC	INTA_RC interrupt signal monitor	R
1	INTB_RC	INTB_RC interrupt signal monitor	R
2	INTC_RC	INTC_RC interrupt signal monitor	R
3	INTD_RC	INTD_RC interrupt signal monitor	R

Bit	Symbol	Function	R/W
4	INTMSI_RC	INT_MSI interrupt signal monitor	R
7:5	—	These bits are read as 0.	R
8	MSG_INT	Message interrupt signal monitor	R
9	PCIE_EVT_INT	Event interrupt signal monitor	R
10	AXI_ERR_IN	Error interrupt signal monitor	R
14:11	—	These bits are read as 0.	R
15	INT_LINK_EQUALIZATION_REQUEST	LINK_EQUALIZATION_REQUEST Interrupt signal level monitor	R
23:16	—	The read values are undefined.	R
31:24	—	These bits are read as 0.	R

The PCI_RC_INTTABLE is an index of interrupt factors. The interrupt signal (active high) status of each category can be monitored in a list.

56.3.1.20 PCI_RC_PEIE0 : PCIe Event Interrupt Enable 0 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0200

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	UI_LINK_WIDTH_CHANGE_DONE_EN	UI_LINK_SPEED_CHANGE_DONE_EN	RDEN	—	—	—	CA_EN	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	RX_DLLP_PM_ENTER_L23_EN	—	ASPML1REN	DLUDEN	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	—	These bits are read as 0. The write value should be 0.	R/W
9	DLUDEN	DL_UpDown EN Interrupt enable on DL state change 0: Disable 1: Enable	R/W
10	ASPML1REN	ASPM L1 Rejected interrupt enable 0: Disable 1: Enable	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
12	RX_DLLP_PM_ENTER_L23_EN	RX_DLLP_PM_ENTER_L23 interrupt enable 0: Disable 1: Enable	R/W
23:13	—	These bits are read as 0. The write value should be 0.	R/W
24	CA_EN	CA (Completer Abort) interrupt enable 0: Disable 1: Enable	R/W
27:25	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
28	RDEN	Request complete interrupt enable 0: Disable 1: Enable	R/W
29	UI_LINK_SPEED_CHANGE_DONE_EN	Speed change operation completion interrupt enable 0: Disable 1: Enable	R/W
30	UI_LINK_WIDTH_CHANGE_DONE_EN	Up/Down Configure operation complete interrupt enable 0: Disable 1: Enable	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The PCI_RC_PEIE0 register enables interrupts of the various PCI Express event factors. The PCI_RC_PEIE0 register enables writing to the PCIe Event Interrupt Status 0 Register. See the description of this status register for details of the factors.

56.3.1.21 PCI_RC_PEIS0 : PCIe Event Interrupt Status 0 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0204

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	UI_LINK_WIDTH_CHANGE_DONE	UI_LINK_SPEED_CHANGE_DONE	RD	—	—	—	CA	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	RX_DLLP_PM_ENTER_L23	—	ASPML1R	DLUDEN	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	—	These bits are read as 0. The write value should be 0.	R/W
9	DLUDEN	DL_UpDown EN Set to 1 on transition from DL_Down state to DL_Up state, or DL_Up state to DL_Down state. Check the DL_Down/DL_Up status with PCIe Core Status 1 Registers (Offset: 0x408).	R/W
10	ASPML1R	ASPM L1 Rejected Indicates rejected ASPM L1 transition	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
12	RX_DLLP_PM_ENTER_L23	Indicates transition to L2/L3 State in Power Management control.	R/W
23:13	—	These bits are read as 0. The write value should be 0.	R/W
24	CA	Indicates that the device has responded with CA (Completer Abort).	R/W
27:25	—	These bits are read as 0. The write value should be 0.	R/W
28	RD	Request Done For requests submitted in the Request Issue Registers (Offset: 0x9C): Non-Posted: Indicates that Completion has been received. Posted: Indicates that the request has finished being submitted.	R/W
29	UI_LINK_SPEED_CHANGE_DONE	Indicates completion of Speed Change operation.	R/W

Bit	Symbol	Function	R/W
30	UI_LINK_WIDTH_CHANGE_DONE	Indicates completion of Up/DownConfigure operation.	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The PCI_RC_PEIS0 register is a status register that indicates each PCI Express event. Set to 1 by the factor in the table. After checking the factor, write 1 to clear it.

56.3.1.22 PCI_RC_PEIE1 : PCIe Event Interrupt Enable 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0208

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXB_PARITY_ERR_EN	ERR_RPC_REPLAYFIFO_PERR_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ERR_REPLAY_UPPER_CORRECTABLE_ERROR_EN	ERR_REPLAY_LOWER_CORRECTABLE_ERROR_EN	—	—	—	—	—	—	ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR_EN	ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR_EN	Enable ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR interrupts. Interrupt notification enable setting when an error of ECC 2-bit or more (Uncorrectable Error) occurs in the lower 64-bit data bus of the Replay FIFO installed in the Data Link Layer 0: Disable 1: Enable	R/W
1	ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR_EN	Enable ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR interrupts. Interrupt notification enable setting when an error of ECC 2-bit or more (Uncorrectable Error) occurs in the upper 64-bit data bus of the Replay FIFO installed in the Data Link Layer 0: Disable 1: Enable	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	ERR_REPLAY_LOWER_CORRECTABLE_ERROR_EN	Enable ERR_REPLAY_LOWER_CORRECTABLE_ERROR interrupts. Interrupt notification enable setting when an ECC 1-bit error (Correctable Error) occurs in the lower 64-bit data bus of the Replay FIFO installed in the Data Link Layer 0: Disable 1: Enable	R/W
9	ERR_REPLAY_UPPER_CORRECTABLE_ERROR_EN	Enable ERR_REPLAY_UPPER_CORRECTABLE_ERROR interrupts. Interrupt notification enable setting when an ECC 1-bit error (Correctable Error) occurs in the upper 64-bit data bus of the Replay FIFO installed in the Data Link Layer 0: Disable 1: Enable	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	ERR_RPC_REPLAY FIFO_PERR_EN	Enable ERR_RPC_REPLAYFIFO_PERR interrupts. Parity error interrupt notification enable setting for Replay FIFO installed in Data Link Layer 0: Disable 1: Enable	R/W
17	TXB_PARITY_ERR_ EN	Enable the TXB_PARITY_ERR interrupt. Parity error interrupt notification enable setting for TX Buffer installed in Transaction Layer 0: Do not allow 1: Allow	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_PEIE1 register enables parity error and ECC error interrupts. When each bit is set to the valid setting, the value of each corresponding status bit of the PCIe Event Interrupt Status 1 Register becomes valid.

56.3.1.23 PCI_RC_PEIS1 : PCIe Event Interrupt Status 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x020C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXB_PARITY_ERR	ERR_RPC_REPLAYFIFO_PERR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ERR_REPLAY_UPPER_CORRECTABLE_ERROR	ERR_REPLAY_LOWER_CORRECTABLE_ERROR	—	—	—	—	—	—	ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR	ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR	ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR interrupt Interrupt notification when an ECC 2-bit or more error (Uncorrectable Error) occurs in the lower 64-bit data bus of the Replay FIFO installed in the Data Link Layer	R/W
1	ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR	ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR interrupt Interrupt notification when an ECC 2-bit or more error (Uncorrectable Error) occurs in the upper 64-bit data bus of the Replay FIFO installed in the Data Link Layer	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	ERR_REPLAY_LOWER_CORRECTABLE_ERROR	ERR_REPLAY_LOWER_CORRECTABLE_ERROR interrupt Interrupt notification when an ECC 1-bit error (Correctable Error) occurs in the lower 64-bit data bus of the Replay FIFO installed in the Data Link Layer	R/W
9	ERR_REPLAY_UPPER_CORRECTABLE_ERROR	ERR_REPLAY_UPPER_CORRECTABLE_ERROR interrupt Interrupt notification when an ECC 1-bit error (Correctable Error) occurs in the upper 64-bit data bus of the Replay FIFO installed in the Data Link Layer	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	ERR_RPC_REPLAYFIFO_PERR	ERR_RPC_REPLAYFIFO_PERR interrupt Parity error interrupt notification of Replay FIFO installed in Data Link Layer	R/W
17	TXB_PARITY_ERR	TXB_PARITY_ERR interrupt Parity error interrupt notification of TX Buffer installed in Transaction Layer	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_PEIS1 register is a status register that indicates parity error and ECC error interrupts. After checking the factor, write 1 to the corresponding bit to clear it.

56.3.1.24 PCI_RC_AMEIE : AXI Master Error Interrupt Enable Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0210

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	WMSTERRINTEN[3:0]				—	—	—	—	RMSTERRINTEN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	RMSTERRINTEN[3:0]	Read MSTERR INT Enable Each corresponding bit can be turned on/off individually. 0: Disable 1: Enable	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
11:8	WMSTERRINTEN[3:0]	Write MSTERR INT Enable Each corresponding bit can be turned on/off individually. 0: Disable 1: Enable	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_AMEIE register enables the AXI master error interrupt.

56.3.1.25 PCI_RC_AMEIS : AXI Master Error Interrupt Status Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0214

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	WERRID[3:0]				—	—	—	—	RERRID[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	WMSTERRINT[3:0]				—	—	—	—	RMSTERRINT[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	RMSTERRINT[3:0]	Read MSTERR INT Indicates that an error was detected in the AXI Master Port. Only the first detected error is saved, and when bit [3:0] is cleared, a new error can be saved. bit 3: Length Error (When the length of the data received on the TER and the data channel do not match.) bit 2: ID Mismatch (When the MARID and MRID values received on the data channel are different.) bit 1: When DECERR is received bit 0: When SLVERR is received	R/W

Bit	Symbol	Function	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
11:8	WMSTERRINT[3:0]	Write MSTERR INT Indicates that an error was detected in the AXI Master Port. Only the first detected error is saved, and when bit [11:8] is cleared, a new error can be saved. bit 11: Length Error (When the length of the data sent by the TEF and the data channel do not match.) bit 10: ID Mismatch (When the MBID value received on the MAWID response channel is different.) bit 9: When DECERR is received bit 8: When SLVERR is received	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
19:16	RERRID[3:0]	Read ERR ID Save the ID of the first DECERR/SLVERR received. A new error ID can be saved when bit [3:0] is cleared. 0x0: normal access Others: Error ID	R
23:20	—	These bits are read as 0. The write value should be 0.	R/W
27:24	WERRID[3:0]	Write ERR ID Save the ID of the first DECERR/SLVERR received. When bit [11:8] is cleared, a new error ID can be saved. 0x0: normal access Others: Error ID	R
31:28	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_AMEIS register indicates the AXI master error interrupt status.

56.3.1.26 PCI_RC_ASEIE1 : AXI Slave Error Interrupt Enable 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0220

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	WSLVERRINTEN[3:0]				—	—	—	—	—	—	RSLVERRINTEN[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RSLVERRINTEN[1:0]	Read SLVERR INT EN Enable Read SLVERR INT. Each corresponding bit can be turned on/off individually. 0: Disable 1: Enable	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
11:8	WSLVERRINTEN[3:0]	Write SLVERR INT EN Enable Write SLVERR INT. Each corresponding bit can be turned on/off individually. 0: Disable 1: Enable	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_ASEIE1 register enables the AXI slave error interrupt.

56.3.1.27 PCI_RC_ASEIS1 : AXI Slave Error Interrupt Status 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0224

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	WSLVERRINT[3:0]				—	—	—	—	—	—	RSLVERRINT[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RSLVERRINT[1:0]	Read SLVERR INT Indicates that an unrecoverable error was detected in the AXI Slave Port. (Transaction response will be SLVERR.) bit 1: Burst Type Disabled (When SARBURST is 11b (undefined). When SARBURST is 10b (wrapping) and burst length is other than 2, 4, 8, 16.) bit 0: Data Size Invalid (When SARSIZE is (exceeding AXI Bus width/not supported).) Each bit means: 0: No error detected 1: error detection	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
11:8	WSLVERRINT[3:0]	Write SLVERR INT Indicates that an unrecoverable error was detected in the AXI Slave Port. (Transaction response will be SLVERR.) bit 11: Burst Length Error (When the SAWLEN and the burst length of the data received on the data channel do not match.) bit 10: ID Mismatch (When the SAWID and SWID values received on the data channel are different.) bit 9: Burst Type Disabled (When SAWBURST is 11b (undefined). When SAWBURST is 10b (wrapping) and burst length is other than 2, 4, 8, or 16.) bit 8: Data Size Invalid (When SAWSIZE is between 100b and 111b (Exceeding AXI Bus width/not supported).) Each bit means: 0: No error detected 1: error detection	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_ASEIS1 register indicates the AXI slave error interrupt status.

56.3.1.28 PCI_RC_ASEIS3 : AXI Slave Error Interrupt Status 3 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0230

Bit position:	31																													0
Bit field:																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	ERR ID Save the ID when the first error occurred in the AXI Slave Error Interrupt Status1 register (Offset 0x224). Only the first detected error is saved, and when bit[11:8] and bit[1:0] of the AXI Slave Error Interrupt Status1 register are all cleared, a new error ID can be saved.	R

The PCI_RC_ASEIS3 register indicates the AXI ID at the time of the first AXI slave error.

56.3.1.29 PCI_RC_PERM : Permission Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0300

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	CFG_HWINIT_EN	PHY_REG_CLK_EN	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	PHY_REG_CLK_EN	Write enable for Physical Layer Control/Status Registers. 0: Disable 1: Enable	R/W
2	CFG_HWINIT_EN	Enable HwInit attribute registers to be rewritten from AXI. 0: Disable 1: Enable	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

56.3.1.30 PCI_RC_RESET : Reset Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0310

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FTD0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	RST_PREG_B	RST_OUT_B	RST_PS_B	RST_LOAD_B	RST_CFG_B	RST_RSM_B	RST_GP_B	RST_B
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RST_B	Reset to PCI Express core part inside macro 0: reset 1: normal operation	R/W
1	RST_GP_B	Reset to the PCI Express core part (ACLK domain) inside the macro 0: reset 1: normal operation	R/W
2	RST_RSM_B	POWERGOOD reset of AUX Power (AUX not supported) Reset to Sticky register. Reset to PHY. 0: reset 1: normal operation	R/W

Bit	Symbol	Function	R/W
3	RST_CFG_B	Reset to Configuration Register 0: Reset 1: normal operation	R/W
4	RST_LOAD_B	Reset to Configuration Register Reset to bits not initialized by RST_CFG_B. 0: reset 1: normal operation	R/W
5	RST_PS_B	Reset to the PCI Express core part (PCLK domain) inside the macro 0: reset 1: normal operation	R/W
6	RST_OUT_B	RST_OUT_B output 0: reset 1: normal operation	R/W
7	RST_PREG_B	Not used in this macro. The setting value does not affect macro behavior. 0: reset 1: normal operation	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W
16	FTD0	force to D0 After sending PME_TO_Ack, force PM Control to transition to D0 State. Auto-cleared when PM Control transitions to D0. This bit is normally prohibited as it can create inconsistencies with the power state of the entire system. 0: No operation 1: Transition to D0	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_RESET register resets the PCIe core. Supplied to the internal core. The write value is saved when accessed from the AXI, but a low-level pulse is generated when the PCIe writes 0. However, when the AXI has already written 0, the signal remains at the low level.

Writing 1 from the PCIe will be ignored.

56.3.1.31 PCI_RC_MSET0 : Mode Set 0 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0314

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	AWPROT[2:0]			AWCACHE_L[3:0]				—	—	AWLOCK[1:0]		AWCACHE_D[3:0]			
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	ARPROT[2:0]			—	—	—	—	—	—	ARLOCK[1:0]		ARCACHE[3:0]			
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	ARCACHE[3:0]	Lock type for PCIe-to-AXI transactions. This bit provides information about the atomic nature of the transfer. 0 0: Normal access 0 1: Exclusive access 1 0: Locked access 1 1: Reserved	R/W

Bit	Symbol	Function	R/W
5:4	ARLOCK[1:0]	Lock type for PCIe-to-AXI transactions. This bit provides information about the atomic nature of the transfer. 0 0: Normal access 0 1: Exclusive access 1 0: Locked access 1 1: Reserved	R/W
11:6	—	These bits are read as 0. The write value should be 0.	R/W
14:12	ARPROT[2:0]	Sets the protection type for PCIe→AXI transactions. This bit indicates whether the transaction's protection level is Normal, Privileged, or Secure, and whether the transaction is a data or instruction access. [2] 1: instruction access / 0: data access [1] 1: non-secure access / 0: secure access [0] 1: privileged access / 0: normal access	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
19:16	AWCACHE_D[3:0]	Indicates the value of MAWCACHE[3:0] to be issued to AXI. This setting is output when issuing an AXI request other than the output condition of AWCACHE_L. *Recommended value is 0001b. [3] 1: write allocatable / 0: not write allocatable [2] 1: Read assignable / 0: Read assignable [1] 1: cacheable / 0: non-cacheable [0] 1: Bufferable / 0: Not Bufferable	R/W
21:20	AWLOCK[1:0]	Lock type for PCIe-to-AXI transactions. This signal provides information about the atomic nature of the transfer. 0 0: Normal access 0 1: Exclusive access 1 0: Locked access 1 1: Reserved	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
27:24	AWCACHE_L[3:0]	Indicates the value of MAWCACHE[3:0] to be issued to AXI. This setting is printed when issuing an AXI request containing the last byte. *Recommended value is 0000b. [3] 1: write allocatable / 0: not write allocatable [2] 1: Read assignable / 0: Read assignable [1] 1: cacheable / 0: non-cacheable [0] 1: Bufferable / 0: Not Bufferable	R/W
30:28	AWPROT[2:0]	Sets the protection type for PCIe→AXI transactions. This bit indicates whether the transaction's protection level is Normal, Privileged, or Secure, and whether the transaction is a data or instruction access. [2] 1: instruction access / 0: data access [1] 1: non-secure access / 0: secure access [0] 1: privileged access / 0: normal access	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The PCI_RC_MSET0 register sets AXI mode.

56.3.1.32 PCI_RC_MSET1 : Mode Set 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0318

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	AXIMIW[3:0]				AXIMIR[3:0]				AXIMMB[3:0]				—	—	RAMPE	PCIERO
Value after reset:	0	0	1	1	0	0	1	1	1	1	1	1	0	0	1	0

Bit	Symbol	Function	R/W
0	PCIERO	PCIe Request Order Issue a Read Request to PCIe from the same AXI master without waiting for Completion. Set to 1 if you want to strictly follow the order of Requests to the Completer. 0: Do not wait for Completion. 1: Wait for Completion.	R/W
1	RAMPE	RAM Parity Enable Sets whether or not to check the parity of the internal SRAM. The default value is Enable, but it is ignored by non-Parity macros. 0: RAM parity check disabled 1: RAM parity check enabled	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
7:4	AXIMMB[3:0]	AXI Master Max Burst Sets the maximum burst length as an AXI Master operation.	R/W
11:8	AXIMIR[3:0]	AXI Max Issue Read Set the number of read issues that can be issued by AXI Master. Set within the range allowed by Interconnect. 0x0: possible number 1 0x1: possible number 2 ⋮ 0xF: Possible number 16	R/W
15:12	AXIMIW[3:0]	AXI Max Issue Write Set the number of writes that can be issued by AXI Master. Set within the range allowed by Interconnect. 0x0: possible number 1 0x1: possible number 2 ⋮ 0xF: Possible number 16	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_MSET1 register sets AXI mode.

56.3.1.33 PCI_RC_MSET3 : Mode Set 3 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0380

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	ASPML1IT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ASPML1IT[7:0]	ASPM L1 Idle Time Sets the idle period for AXI transactions that the macro checks on ASPM L1 transitions. One of the conditions for ASPM L1 transition is that the idle period is confirmed for the number of cycles of the 8 bits set by this bit plus 0xFF to the lower 8 bits. 0x00: 256 [ACLK] 0x01: 512 [ACLK] ⋮ 0xFF: 65536 [ACLK]	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_MSET3 register outputs the setting value as the ASPM L1 Idle Time bit.

56.3.1.34 PCI_RC_MSET4 : Mode Set 4 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0384

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MODE_EQ_RX_EVAL_WAIT[19:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MODE_EQ_RX_EVAL_WAIT[19:0]				—	—	—	—	MODE_8GT_EQTS2	MODE_EQ_PHASE23_ENABLE1	MODE_EQ_AUTONOMOUS1	—	—	UI_EQ_REQTYPE[1:0]		UI_EQ_REQUEST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	UI_EQ_REQUEST	Set when sending an Equalization Request with Quiesce Guarantee = 1 in the Recovery.RcvrCfg state. 1 set prohibited except when MODE_QUIESCE_GUARANTEE = 1. After setting 1, hold until confirmation of UI_EQ_DONE = 1. 0: Do not send Equalization Request 1: Send Equalization Request	R/W
2:1	UI_EQ_REQTYPE[1:0]	Operation specification when sending Equalization Request with Quiesce Guarantee = 1 in Recovery.RcvrCfg state 0 0: Equalization Request transmission with Equalization Request Data Rate = 0 (8G) 0 1: Send Equalization Request with Equalization Request Data Rate = 1 (16G) (Setting prohibited) 1 0: Operation of 0 + set Link Equalization Request 8.0 GT/s register 1 1: Set 1 operation + Link Equalization Request 16.0 GT/s register (setting prohibited)	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	MODE_EQ_AUTONOMOUS1	Fixed 0	R/W
6	MODE_EQ_PHASE23_ENABLE1	Fixed 0	R/W
7	MODE_8GT_EQTS2	8GT EQ TS2OS transmission enable/disable setting for Upstream Port Note: Not used with Downsream Port. (fixed to 0) 0: Do not send 1: Send	R/W
11:8	—	These bits are read as 0. The write value should be 0.	R/W
31:12	MODE_EQ_RX_EVAL_WAIT[19:0]	During RxEval (Downstream Port Phase3, Upstream Port Phase2), wait time setting until RxEval is executed when Block Alignment cannot be obtained. Set by the count number of PCLK. Note: It is necessary to set the register value (recommended: equivalent to 1 msec) before starting. Please set from the local CPU.	R/W

56.3.1.35 PCI_RC_MSET5 : Mode Set 5 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0388

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MODE_8GT_EQTS2_PRESET[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MODE_8GT_EQTS2_PRESET[15:0]	Transmitter Preset value of 8GT EQ TS2OS to transmit at Upstream Port (USP). No setting is required if 8GT_EQTS2 is not sent from USP (DSP Preset is not specified). Settings must be made in advance if necessary. 4-bit configuration for each lane. Gen3 supports up to x2 lane configurations. The correspondence between each bit and lane number is as follows. [3:0] Lane #0 [7:4] Lane #1 (Not used in case of ch1) [11:8] Lane #2 (Not used. Fixed to 0x0) [15:12] Lane #3 (Not used. Fixed to 0x0) The above lane number is the default lane number for circuit implementation. Note that this is not a negotiated lane number. Note: Not used with Downsream Port. (fixed to 0x0000_0000)	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

56.3.1.36 PCI_RC_MSTAT0 : Mode Status 0 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0390

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	RX_EQ_REQTYPE[1:0]		RX_EQ_REQUEST	UI_EQ_DONE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	UI_EQ_DONE	Set Equalization Request with Quiesce Guarantee=1 in Recovery .RcvrCfg state when sending Related flow: "Set UI_EQ_REQUEST = 1 → Confirm UI_EQ_DONE = 1 → Clear UI_EQ_REQUEST = 0" 0: No Equalization Request sent 1: Sent Equalization Request	R
1	RX_EQ_REQUEST	Status display when receiving 8 consecutive TS2OS with Request Equalization bit (Symbol6, bit7) = 1 in Recovery.RcvrCfg state 0: No Equalization Request received 1: Equalization Request received	R
3:2	RX_EQ_REQTYPE[1:0]	Quiesce Guarantee and Equalization Request Data Rate bit display when receiv ing 8 consecutive TS2OS with Request Equalization bit (Symbol6, bit7) = 1 in Recovery.RcvrCfg state EP (USP) (1) When Request Equalization is received bit 0: Quiesce Guarantee (TS2OS, Symbol6, bit6) (= 1 fixed) bit 1: Equalization Request Data Rate (TS2OS, Symbol6, bit5) (2) When receiving EQTS2OS bit 0: 0 (fixed) bit 1: Equalization Request Data Rate (0: EQTS2, 1: 8GT EQTS2) RC (DSP) bit 0: Quiesce Guarantee (TS2OS, Symbol6, bit6) bit 1: Equalization Request Data Rate (TS2OS, Symbol6, bit5)	R
31:4	—	These bits are read as 0.	R

56.3.1.37 PCI_RC_PCMSET1 : PCIe Core Mode Set 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0400

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	ASPM_L1_INTERVAL_TIME[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	0	1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	MODE_LINK_UPCONFIGURE_CAPABILITY_DISABLED	—	MODE_TXSWING	—	—	—	—	—	—	—	—	MODE_PORT	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	MODE_PORT	Device type setting register. When the bit value of this register is fixed to the initial value 1, the setting of the MODE_PORT bit in PCIE_MODE register becomes valid. When the MODE_PORT bit in PCIE_MODE register is fixed to 1, the setting by this register bit becomes valid. 0: Endpoint 1: Root Complex	R/W
9:2	—	These bits are read as 0. The write value should be 0.	R/W
10	MODE_TXSWING	SerDes serial output amplitude control 0: Full swing mode (default) 1: Half swing mode	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
12	MODE_LINK_UPCONFIGURE_CAPABILITY_DISABLED	Setting of Link Upconfigure Capability bit of Training Sequence Ordered-set (TS-OS) When connecting with a Gen1 PCIe device, LinkUp may not occur unless this bit is 0. In that case, change it to 0 in F/W. 0: Link Upconfigure Capability bit = 1 setting 1: Link Upconfigure Capability bit = 0 setting (Gen1 x1)	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
27:16	ASPM_L1_INTERVAL_TIME[11:0]	Interval settings for ASPM L1 requests The PCIe Base Spec stipulates that ASPM L1 transition requests must not be accepted continuously within 10 µs, and this field sets the timer value to guard against this. Set so that ACLK cycle x set value is 10 µs or more. At ACLK: 400 [MHz] or higher, this bit setting value should be the value (1/16) of the lower 4 bits of the setting value of the above specifications, and set the clock number as the timer value setting. Settings of this product (Default): When ACLK = 400 MHz(2.5 ns): 4000(d)/16 = FA(h)	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_PCMSET1 register sets the operating mode of the PCI Express core.

56.3.1.38 PCI_RC_PCCTRL1 : PCIe Core Control 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0404

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	BLB_RELAX_ORDERING_EN	—	—	—	—	—	UI_ENTER_L1S	—	RETURN_TO_L0	UI_RC_REJECT_ASPML1	APMASN	UI_ENTER_L2	UI_ENTER_TXL0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	MODE_QUIESCE_GUARANTEE	UI_ENTER_TXMODE_SRIS	MODE_EQ_AUTONOMOUS	MODE_EQ_PHASE23_ENABLE	MODE_RESET_EIEOS_INTERVALL0S	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	MODE_RESET_EIEOS_INTERVALL0S	Gen3 features: Reset EIEOS Interval information of bit 2, symbol 6 of TS1OS transmitted in Recovery.Equalization state	R/W
9	MODE_EQ_PHASE23_ENABLE	Gen3 features: Setting whether to execute EQ PHASE2 and EQ PHASE3 in RC mode (MODE_PORT=1). 0: Do not execute EQ PHASE2/3 1: Execute EQ PHASE2/3	R/W
10	MODE_EQ_AUTONOMOUS	Gen3 feature: Autonomous Equalization Basically only changeable during the reset period 0: Do not use Autonomous Mechanism 1: Use Autonomous Mechanisms	R/W
11	UI_ENTER_TXMODE_SRIS	Setting Clock Tolerance Compensation 0: SRNS (default) 1: SRIS (not supported)	R/W
12	MODE_QUIESCE_GUARANTEE	Symbol6 bit6 Quiesce Guarantee control bit of TS2OS 0: Set 0 to TS2OS (default) 1: Set 1 to TS2OS	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
16	UI_ENTER_TXL0S	TxL0s transition control 0: Do not perf orm ASPM L0s transition (default) 1: Execute ASPM L0s transition when internal conditions are satisfied	R/W
17	UI_ENTER_L2	RC mode L2 transition control Set to 1 when transitioning to L2 state in RC mode. When transitioning to the L2 state, the PCIe core must be reset by controlling the Reset register. When returning, this bit must be cleared to 0 after releasing the reset.	R/W
18	APMASN	Auto PM_Active_State_Nak PM_ActiveState_Nak Message Transmission Mode for ASPM L1 Rejection Set to 1 if you want to reject ASPM L1 in RC. This Bit is automatically cleared when PM_ActiveState_Nak is automatically sent. Note: Autosend only once.	R/W
19	UI_RC_REJECT_ASPML1	ASPM L1 transition rejection control 0: Accept ASPM L1 transition request from EP device (default) 1: Reject ASPM L1 transition request from EP device	R/W

Bit	Symbol	Function	R/W
20	RETURN_TO_L0	RC mode L1, L2 state to L0 state control (usually not used) Cleared automatically after confirming PMU_LINKSTATE[0] =1. 0: Normal operation (default) 1: Start return operation to L0 state when in L1 or L2 state in RC mode	R/W
21	—	This bit is read as 0. The write value should be 0.	R/W
22	UI_ENTER_L1S	L1SubState transition permission setting 0: L1SubState transition disabled (default) 1: L1SubState transition permission (setting prohibited)	R/W
27:23	—	These bits are read as 0. The write value should be 0.	R/W
28	BLB_RELAX_ORDERING_EN	Control of RO bit of Request to be sent 0: RO bit of Request TLP to be sent is always 0 (default) 1: A TLP can be sent with the RO bit of the Request TLP to be sent set to 1.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_PCCTRL1 register controls power management and LTSSM (Link Training Sequence State Machine) state transitions of the PCI Express core.

56.3.1.39 PCI_RC_PCSTAT1 : PCIe Core Status 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0408

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BD	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	x	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	LTSSM_STATE[6:0]							PMU_LINKSTATE[3:0]				—	—	STATE_VC0_NEGOTIATION_PENDING	DLDS
Value after reset:	0	x	x	x	x	x	x	x	x	x	x	x	0	x	x	x

Bit	Symbol	Function	R/W
0	DLDS	DL_Down status Indicates whether PCIe Core is in DL_Down or DL_Up state 0: DL_Up Status 1: DL_Down Status	R
1	STATE_VC0_NEGOTIATION_PENDING	Flow Control initialization operation monitor If this bit is 1, do not initiate a transaction from the AXI side. Check that this bit is 0 and DL_Down Status (bit[0]) is 0. 0: Indicates that Flow Control initialization is complete 1: Indicates that Flow Control initialization has not completed	R
2	—	The read value is undefined.	R
3	—	This bit is read as 0.	R
7:4	PMU_LINKSTATE[3:0]	L-state monitor of power management control unit 0x4: L1 state 0x8: L2 state	R

Bit	Symbol	Function	R/W
14:8	LTSSM_STATE[6:0]	Indicates the state of the Link Training & Status State Machine in the PCIe Core Link. The following states are indicated by the upper 5 bits [14:10]. 000xxb: Detect 001xxb: Polling 010xxb: Config 01100b: L0 01101b: L1 0111xb: L2 100xxb: Recovery 101xxb: Disable 110xxb: Loopback	R
16:15	—	These bits are read as 0.	R
17	BD	bme_down Indicates that the PCIe core transmitter is in an unusable state.	R
31:18	—	These bits are read as 0.	R

The PCI_RC_PCSTAT1 register controls power management and LTSSM (Link Training Sequence State Machine) state transitions of the PCI Express core.

56.3.1.40 PCI_RC_PCCTRL2 : PCIe Core Control 2 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0410

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	UI_LINK_WIDTH_CHANGE_ENABLE[7:0]								MODE_NODEEMPHASIS[1:0]		MODE_PRESET_ENABLE[4:0]					UI_LINK_WIDTH_CHANGE_REQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	UI_LINK_SPEED_CHANGE[1:0]		—	—	—	UI_LINK_CHANGE_AUTONOMOUS	—	—	—	UI_LINK_SPEED_CHANGE_REQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	UI_LINK_SPEED_CHANGE_REQ	Link Speed change request control Setting this bit to 1 requests to change the Link Speed to the speed set in bit [8] UI_LINK_SPEED_CHANGE field. By asserting it in the L0 state, it transitions to the Recovery state and performs negotiation with the peer device. PCIe Core Status 2 Register (Offset: 0x414) bit [28] Set to 0 after confirming that UI_LINK_SPEED_CHANGE_DONE has been asserted.	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	UI_LINK_CHANGE_AUTONOMOUS	Link Width/Speed change reason setting 0: reliability reason (change for reliability, direction of bandwidth reduction) 1: autonomous reason (intentional change)	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
9:8	UI_LINK_SPEED_CHANGE[1:0]	Link speed setting Set the Link Speed you want to change. 0 0: 2.5 GT/s 0 1: 5.0 GT/s 1 0: 8.0 GT/s 1 1: 16.0 GT/s (Setting prohibited)	R/W

Bit	Symbol	Function	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	UI_LINK_WIDTH_CHANGE_REQ	Link Width change request control Setting this bit to 1 issues a request to change the Link Width to the configuration set in bit [31:24] UI_LINK_WIDTHCHANGE_ENABLE field. By asserting it in the L0 state, it transitions from the Recovery state to the Configuration state, and performs negotiation with the other device. Set to 0 after confirming that PCIe Core Status 2 Register (Offset: 0x414) bit [29] UI_LINK_WIDTH_CHANGE_DONE is asserted. Available for Single Link structure. Prohibited to set for Multi Link structure or ch1.	R/W
21:17	MODE_PRESET_ENABLE[4:0]	Reduced Swing mode setting for Gen3 operation [0] 8GT/s Preset P0, 0: disable / 1: enable (default) [1] 8GT/s Preset P2, 0: disable / 1: enable (default) [2] 8GT/s Preset P7, 0: disable / 1: enable (default) [3] 8GT/s Preset P8, 0: disable / 1: enable (default) [4] 8GT/s Preset P10, 0: disable / 1: enable (default)	R/W
23:22	MODE_NODEEMPHASIS[1:0]	No de-emphasis mode setting for Gen1/Gen2 operation [0] Gen1 operation, 0: Normal operation mode (default) / 1: No de-emphasis mode [1] Gen2 operation, 0: Normal operation mode (default) / 1: No de-emphasis mode	R/W
31:24	UI_LINK_WIDTH_CHANGE_ENABLE[7:0]	Link Width setting to change Assert UI_LINK_WIDTH_CHANGE_REQ and set Lane to 1 to operate when Link Width change request is issued. The lower bit (bit [24]) drives Lane 0 and the most significant bit (bit [31]) drives Lane 7. In this module, bit [25:24] is valid for Single Link structure, and bit [24] is valid for Multi Link structure or ch1.	R/W

The PCI_RC_PCCTRL2 register controls the link speed/width change in the PCI Express core.

56.3.1.41 PCI_RC_PCSTAT2 : PCIe Core Status 2 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0414

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	UI_LINK_WIDTH_CHANGE_DONE	UI_LINK_SPEED_CHANGE_DONE	—	—	—	STATE_UPCONFIGURE_CAPABLE	—	STATE_NEGOTIATED_LANE_END[2:0]			—	STATE_NEGOTIATED_LANE_START[2:0]		
Value after reset:	0	0	x	x	0	0	0	x	0	x	x	x	0	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	STATE_RECEIVER_DETECTED[7:0]								STATE_DATA_RATE_IDENTIFIER_RECEIVED[7:0]							
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
7:0	STATE_DATA_RATE_IDENTIFIER_RECEIVED[7:0]	Link Speed display supported by the opposite device Displays the TS-OS Data Rate Identifier feed received from the peer device. Bit 0: Reserved Bit 1: 2.5 GT/s Data Rate Supported. Must be set to 1. Bit 2: 5.0 GT/s Data Rate Supported. Must be set to 1 if Bit 3 is 1. Bit 3: 8.0 GT/s Data Rate Supported. Bits 4 to 7: Reserved	R
15:8	STATE_RECEIVER_DETECTED[7:0]	Connection status display with other device Receiver Detection results are displayed. [0] Detect opposite device on Lane 0 [1] Detect peer device on Lane 1 (only for x2) [2] to [7] reserved	R

Bit	Symbol	Function	R/W
18:16	STATE_NEGOTIATED_LANE_START[2:0]	Displays the position of Lane Number 0 after Link Negotiation with the opposite device during n-lane operation. Used to check the state of the current working lane before changing the Link Width. Available for Single Link structure. Prohibited to set for Multi Link structure or ch1. 0 0 0: Lane 0 is Lane Number 0 0 0 1: Lane 1 is Lane Number 0 Others: Reserved	R
19	—	This bit is read as 0.	R
22:20	STATE_NEGOTIATED_LANE_END[2:0]	Displays the position of Lane Number (n-1) (meaning Lane 1 when n=2) after Link Negotiation with the opposite device during n-lane operation. Used to check the state of the current working lane before changing the Link Width. Available for Single Link structure. Prohibited to set for Multi Link structure or ch1. 0 0 0: Lane 0 is Lane Number (n-1) 0 0 1: Lane 1 is Lane Number (n-1) Others: Reserved	R
23	—	This bit is read as 0.	R
24	STATE_UPCONFIGURE_CAPABLE	Upconfigure Capable bit display of opposite device Indicates whether the peer device supports changing the direction of widening the Link Width. If this bit is 0, changing the Link Width will not restore the original Link Width.	R
27:25	—	These bits are read as 0.	R
28	UI_LINK_SPEED_CHANGE_DONE	Link Speed Change operation complete display PCIe Core Status 2 Registers (Offset: 0x410) bit [0] Notifies completion of Speed Change (1) by setting UI_LINK_SPEED_CHANGE_REQ. It is set to 0 by setting UI_LINK_SPEED_CHANGE_REQ to 0.	R
29	UI_LINK_WIDTH_CHANGE_DONE	Link Width Change operation complete display Notifies completion of Width Change (1) by setting PCIe Core Status 2 Register (Offset: 0x410) bit [16] UI_LINK_WIDTH_CHANGE_REQ. It is set to 0 by setting UI_LINK_WIDTH_CHANGE_REQ to 0. Available for Single Link structure. Prohibited to set for Multi Link structure or ch1.	R
31:30	—	These bits are read as 0.	R

The PCI_RC_PCSTAT2 register indicates the status of the link speed/width change in the PCI Express core.

56.3.1.42 PCI_RC_PCSTAT5 : PCIe Core Status 5 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x042C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ORT_TRANSACTION_PENDING[1:0]	
Value after reset:	0	0	0	0	0	0	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	ORT_TRANSACTION_PENDING[1:0]	Indicates whether or not there are Outstanding Requests (a state in which all Completions corresponding to Non-Posted Requests sent from the AXI side have not been received). Check with this bit that there is no Outstanding Request before requesting/permitting a transition to TxL0s/L1/L2. (bit 1: function1, bit 0: function0) 0: State without Outstanding Request 1: State with Outstanding Request	R
7:2	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
9:8	—	The read values are undefined.	R
31:10	—	These bits are read as 0.	R

The PCI_RC_PCSTAT5 register indicates the status in the PCI Express core.

56.3.1.43 PCI_RC_DMAINTVEC0 : DMA Interrupt Vector 0 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x04D0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	DMA_CH3_MSI_EN	DMA_CH3_V[4:0]					—	—	DMA_CH2_MSI_EN	DMA_CH2_V[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	DMA_CH1_MSI_EN	DMA_CH1_V[4:0]					—	—	DMA_CH0_MSI_EN	DMA_CH0_V[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	DMA_CH0_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch0	R/W
5	DMA_CH0_MSI_EN	DMA Ch0 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
12:8	DMA_CH1_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch1	R/W
13	DMA_CH1_MSI_EN	DMA Ch1 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
20:16	DMA_CH2_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch2	R/W
21	DMA_CH2_MSI_EN	DMA Ch2 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
28:24	DMA_CH3_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch3	R/W
29	DMA_CH3_MSI_EN	DMA Ch3 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: DMA_CHx_vec should be fixed to 0x0 for Root Complex Mode.

The PCI_RC_DMAINTVEC0 register specifies the interrupt vectors for interrupt notification from AXI to PCIe (MSI) during DMA transfer.

56.3.1.44 PCI_RC_DMAINTVEC1 : DMA Interrupt Vector 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x04D4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	DMA_CH7_MSI_EN	DMA_CH7_V[4:0]					—	—	DMA_CH6_MSI_EN	DMA_CH6_V[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	DMA_CH5_MSI_EN	DMA_CH5_V[4:0]					—	—	DMA_CH4_MSI_EN	DMA_CH4_V[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	DMA_CH4_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch4	R/W
5	DMA_CH4_MSI_EN	DMA Ch4 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
12:8	DMA_CH5_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch5	R/W
13	DMA_CH5_MSI_EN	DMA Ch5 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
20:16	DMA_CH6_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch6	R/W
21	DMA_CH6_MSI_EN	DMA Ch6 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
28:24	DMA_CH7_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch7	R/W
29	DMA_CH7_MSI_EN	DMA Ch7 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Note 1. DMA_CHx_vec should be fixed to 0x0 for Root Complex Mode.

The PCI_RC_DMAINTVEC1 register specifies the interrupt vectors for interrupt notification from AXI to PCIe (MSI) during DMA transfer.

56.3.1.45 PCI_RC_MSIRCVEn : MSI Receive Enable n Register (n = 0 to 15)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0600 + 0x10 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	E
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	E	Enable Set enable/disable of the MSI Receive (Message Data discrimination) register group, which sets 1 register for + 16 bytes from Offset of this register. 0: disabled 1: Enabled	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_MSIRCVEn register enables control of MSI receive (Message Data discrimination) register group with the following as one set.

- MSI Receive Enable n Register (Offset 0x0600 + 0x10 × n)
- MSI Receive message Data n Register (Offset 0x0604 + 0x10 × n)
- MSI Receive Mask n Register (Offset 0x0608 + 0x10 × n)
- MSI Receive Status n Register (Offset 0x060C + 0x10 × n)

56.3.1.46 PCI_RC_MSIRCVMSGDATAn : MSI Receive Message Data n Register (n = 0 to 15)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0604 + 0x10 × n

Bit position:	31	5	4	3	2	1	0
Bit field:			0	0	0	0	0
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0		0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Message Data Set Message Data for MSI reception judgment. The lower 5 bits are f ixed to 0.	R/W

The PCI_RC_MSIRCVMSGDATAn register is a Message data setting register for MSI reception judgment of registers enabled by MSI Receive Enable n Register.

56.3.1.47 PCI_RC_MSIRCVMSKn : MSI Receive Mask n Register (n = 0 to 15)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0608 + 0x10 × n

Bit position:	31																												0
Bit field:																													
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
31:0	n/a	MSI Mask Set the interrupt Mask by each bit of MSI Status. 0: Interrupt enabled 1: Interrupt Mask	R/W

The PCI_RC_MSIRCVMSKn register masks control of interrupt by the MSI reception status of the register group enabled by MSI Receive Enable n Register.

56.3.1.48 PCI_RC_MSIRCVSTATn : MSI Receive Status n Register (n = 0 to 15)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x060C + 0x10 × n

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	MSI Status MSI receive Status. The bit corresponding to Data [4:0] is set when Message Data [31:5] and MSI reception Data [31:5] match. (When Data [4:0] = 0x00, MSI Status n [0] is set. When Data [4:0] = 0x01, MSI Status n [1] is set.)	R/W

56.3.1.49 PCI_RC_DMACTRL : DMAC Control Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0800

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	D_PMRS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	D_PMRS[2:0]	DMAC PCIe Max Read Request Size Set the upper limit of Read requests issued from the DMAC to PCIe. 0 0 0: 128 bytes (default) 0 0 1: 256 bytes 0 1 0: 512 bytes (not supported) 0 1 1: 1024 bytes (not supported) 1 0 0: 2048 bytes (not supported) 1 0 1: 4096 bytes (not supported) others: Reserved (prohibited)	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_DMACTRL register sets the maximum size of read requests which can be issued to the PCIe core as a DMAC function. Use the initial setting (128 bytes). This setting is common to all DMA channels.

56.3.1.50 PCI_RC_DMAINTE : DMAC Interrupt Enable Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0808

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CH7_ERR_EN	CH7_QUE_EMP_EN	CH7_STOP_EN	CH7_END_EN	CH6_ERR_EN	CH6_QUE_EMP_EN	CH6_STOP_EN	CH6_END_EN	CH5_ERR_EN	CH5_QUE_EMP_EN	CH5_STOP_EN	CH5_END_EN	CH4_ERR_EN	CH4_QUE_EMP_EN	CH4_STOP_EN	CH4_END_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CH3_ERR_EN	CH3_QUE_EMP_EN	CH3_STOP_EN	CH3_END_EN	CH2_ERR_EN	CH2_QUE_EMP_EN	CH2_STOP_EN	CH2_END_EN	CH1_ERR_EN	CH1_QUE_EMP_EN	CH1_STOP_EN	CH1_END_EN	CH0_ERR_EN	CH0_QUE_EMP_EN	CH0_STOP_EN	CH0_END_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CH0_END_EN	CH0 Completion Interrupt Enable 0: Disable 1: Enable	R/W
1	CH0_STOP_EN	CH0 Stop Interrupt Enable 0: Disable 1: Enable	R/W
2	CH0_QUE_EMP_EN	CH0 Que Empty Interrupt Enable 0: Disable 1: Enable	R/W
3	CH0_ERR_EN	CH0 Error Interrupt Enable 0: Disable 1: Enable	R/W
4	CH1_END_EN	CH1 Completion Interrupt Enable 0: Disable 1: Enable	R/W
5	CH1_STOP_EN	CH1 Stop Interrupt Enable 0: Disable 1: Enable	R/W
6	CH1_QUE_EMP_EN	CH1 Que Empty Interrupt Enable 0: Disable 1: Enable	R/W

21	CH5_STOP_EN	CH5 Stop Interrupt Enable 0: Disable 1: Enable	R/W
22	CH5_QUE_EMP_EN	CH5 Que Empty Interrupt Enable 0: Disable 1: Enable	R/W
23	CH5_ERR_EN	CH5 Error Interrupt Enable 0: Disable 1: Enable	R/W
24	CH6_END_EN	CH6 Completion Interrupt Enable 0: Disable 1: Enable	R/W
25	CH6_STOP_EN	CH6 Stop Interrupt Enable 0: Disable 1: Enable	R/W

Bit	Symbol	Function	R/W
26	CH6_QUE_EMP_EN	CH6 Que Empty Interrupt Enable 0: Disable 1: Enable	R/W
27	CH6_ERR_EN	CH6 Error Interrupt Enable 0: Disable 1: Enable	R/W
28	CH7_END_EN	CH7 Completion Interrupt Enable 0: Disable 1: Enable	R/W
29	CH7_STOP_EN	CH7 Stop Interrupt Enable 0: Disable 1: Enable	R/W
30	CH7_QUE_EMP_EN	CH7 Que Empty Interrupt Enable 0: Disable 1: Enable	R/W
31	CH7_ERR_EN	CH7 Error Interrupt Enable 0: Disable 1: Enable	R/W

The PCI_RC_DMAINTE register enables interrupts from the individual DMA channels.

56.3.1.51 PCI_RC_DMAINTS : DMAC Interrupt Status Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x080C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CH7_ERR	CH7_QUE_EMP	CH7_STOP	CH7_END	CH6_ERR	CH6_QUE_EMP	CH6_STOP	CH6_END	CH5_ERR	CH5_QUE_EMP	CH5_STOP	CH5_END	CH4_ERR	CH4_QUE_EMP	CH4_STOP	CH4_END
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CH3_ERR	CH3_QUE_EMP	CH3_STOP	CH3_END	CH2_ERR	CH2_QUE_EMP	CH2_STOP	CH2_END	CH1_ERR	CH1_QUE_EMP	CH1_STOP	CH1_END	CH0_ERR	CH0_QUE_EMP	CH0_STOP	CH0_END
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CH0_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
1	CH0_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
2	CH0_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
3	CH0_ERR	Set when an error occurs during DMA transfer.	R/W
4	CH1_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W

Bit	Symbol	Function	R/W
5	CH1_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
6	CH1_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
7	CH1_ERR	Set when an error occurs during DMA transfer.	R/W
8	CH2_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
9	CH2_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
10	CH2_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
11	CH2_ERR	Set when an error occurs during DMA transfer.	R/W
12	CH3_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
13	CH3_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
14	CH3_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
15	CH3_ERR	Set when an error occurs during DMA transfer.	R/W
16	CH4_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
17	CH4_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
18	CH4_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
19	CH4_ERR	Set when an error occurs during DMA transfer.	R/W
20	CH5_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
21	CH5_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
22	CH5_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
23	CH5_ERR	Set when an error occurs during DMA transfer.	R/W
24	CH6_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W

Bit	Symbol	Function	R/W
25	CH6_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
26	CH6_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
27	CH6_ERR	Set when an error occurs during DMA transfer.	R/W
28	CH7_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
29	CH7_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
30	CH7_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
31	CH7_ERR	Set when an error occurs during DMA transfer.	R/W

The PCI_RC_DMAINTS register indicates the state of interrupts from the individual DMA channels.

56.3.1.52 PCI_RC_DMACHCTLn : DMAC Channel Control Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0900 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	QUE_CLR	—	—	—	—	—	—	QUE_EN	RDMA_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RDMA_EN	Register method DMA transfer Enable Setting this bit to 1 starts DMA transfer (register method) and performs the transfer set by RDMA_SIZE. This bit is automatically cleared to 0 when DMA transfer is completed or an error is detected and DMA ends. It is also possible to stop DMA by writing 0. However, DMA will stop after completing the currently executing request (both PCIe and AXI). 0: Stop register-based DMA transfer 1: Register method DMA transfer start	R/W
1	QUE_EN	QUE Enable Setting this bit to 1 enables the descriptor list registered in the descriptor queue and starts DMA transfer (descriptor method). It is automatically cleared to 0 when DMA stops (both normal and abnormal). It is also possible to stop DMA by writing 0. However, DMA will stop after finishing the currently executing request (both PCIe and AXI).	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	QUE_CLR	QUE Clear Writing 1 clears QUE. All descriptor lists (waiting for execution and lists currently being executed) registered in QUE are cleared. Do not clear during DMA execution. The read value is always 0. 1Write is prohibited at the same time as QUE_EN Set	R/W

Bit	Symbol	Function	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_DMACHCTLn register sets the control method for each DMA channel. Set either register type or descriptor type.

- Setting QUE_EN = 1 and QUE_CLR = 1 is prohibited during register-type DMA transfer (TDMA_EN = 1).
- Setting RDMA_EN = 1 is prohibited during descriptor-type DMA transfer (QUE_EN = 1).

56.3.1.53 PCI_RC_DPSADRLn : Descriptor Start Address (Lower) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0908 + 0x80 × n

Bit position:	31																								6	5					0
Bit field:	QUE_ENTRY_DSA3106[25:0]																									QUE_ENTRY_DSA0500[5:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	QUE_ENTRY_DSA0500[5:0]	Descriptor list queue registration register. This area will be the DSA. Sets the lower 32 bits of the address where the first descriptor is stored. (16 byte align: Lower 6 bit is fixed to 0.)	R
31:6	QUE_ENTRY_DSA3106[25:0]	Descriptor list queue registration register. This area will be the DSA. Sets the lower 32 bits of the address where the first descriptor is stored.	R/W

Note: When these bits are read, the following contents will be the read value depending on the state of DMA.
DMA transfer in progress: The descriptor list in progress
DMA suspended (when QUE_EN is automatically cleared): Last executed list
DMA suspended (when QUE_EN S/W is cleared): Suspended (executing) list

The PCI_RC_DPSADRLn register sets the descriptor queue list.

The setting value is registered as the lower 32 bits of DSA (DMA Start Address) in the queue list.

56.3.1.54 PCI_RC_DPSADRUn : Descriptor Start Address (Upper) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x090C + 0x80 × n

Bit position:	31																														0
Bit field:	QUE_ENTRY_DSA6332[31:0]																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	QUE_ENTRY_DSA6332[31:0]	Descriptor list queue registration register. This area will be the DSA. Set the upper 32 bits of the address where the first descriptor is stored.	R/W

Note: When these bits are read, the following contents will be the read value depending on the state of DMA.
DMA transfer in progress: The descriptor list in progress
DMA suspended (when QUE_EN is automatically cleared): Last executed list
DMA suspended (when QUE_EN S/W is cleared): Suspended (executing) list

The PCI_RC_DPSADRUn register sets the descriptor queue list.

The setting value is registered as the upper 32 bits of DSA (DMA Start Address) in the queue list.

56.3.1.55 PCI_RC_QUEEn : QUE Entry Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0910 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	QUE_R[5:0]						QUE_ENTRY_EI	QUE_ENTRY_LS	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	QUE_ENTRY_LABEL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	QUE_ENTRY_LABEL[15:0]	There is no particular rule on how to set the labels in the list. You can set the value freely.	R/W
23:16	—	These bits are read as 0. The write value should be 0.	R/W
24	QUE_ENTRY_LS	Indicates whether to stop the DMA when processing of the descriptor list is complete. 0: do not stop 1: stop	R/W
25	QUE_ENTRY_EI	Indicates whether an interrupt (Interrupt Status CHx_END) is sent when the processing of the descriptor list is completed. 0: Do not signal interrupts 1: signal an interrupt	R/W
31:26	QUE_R[5:0]	QUE_Registration Enqueued by writing to [31:24]. The read value is always 0.	R/W

Note: When these bits are read, the following contents will be the read value depending on the state of DMA.
DMA transfer in progress: The descriptor list in progress
DMA suspended (when QUE_EN is automatically cleared): Last executed list
DMA suspended (when QUE_EN S/W is cleared): Suspended (executing) list

The PCI_RC_QUEEn register sets the descriptor queue list.

The setting value is registered as EI (End Interrupt), LS (List Stop), and LABEL of the queue list. Write to [31:24] to register to the queue.

56.3.1.56 PCI_RC_DMADPCTLn : DMA Descriptor Control (Descriptor 0x00) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0920 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DSCFM[3:0]				—	WBD	LE	LV	D	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	STS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	STS[15:0]	Shows the value of the STS field in the running descriptor table.	R

Bit	Symbol	Function	R/W
22:16	—	These bits are read as 0.	R
23	D	Shows the value of the D field in the running descriptor table.	R
24	LV	Shows the value of the LV field in the running descriptor table.	R
25	LE	Shows the value of the LE field in the running descriptor table.	R
26	WBD	Shows the value of the WBD field in the running descriptor table.	R
27	—	This bit is read as 0.	R
31:28	DSCFM[3:0]	Shows the value of the DSCFM field in the running descriptor table.	R

The PCI_RC_DMADPCTLn register indicates the field value at offset 0x00 in the descriptor table. Only effective when the descriptor-type DMA transfer is selected (the value read has no meaning in the case of register-type transfer).

56.3.1.57 PCI_RC_DMATCTLn : DMA Transaction Control (Descriptor 0x04) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0924 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	CCH_L[3:0]				CCH_D[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	DMA_TC[2:0]			—	—	DMA_ATB[1:0]		—	DMA_FUNC[2:0]			—	—	—	DMA_DIR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DMA_DIR	Sets the DMA transfer direction. 0: PCIe to AXI 1: AXI to PCIe	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
6:4	DMA_FUNC[2:0]	Specify the function number of the request issued to PCIe.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
9:8	DMA_ATB[1:0]	Attributes to publish to PCIe. bit [1]: Relaxed Ordering (Unsupported function: 0 fixed) bit [0]: No Snoop (0 recommended)	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
14:12	DMA_TC[2:0]	Traffic class to publish to PCIe. Specifies the traffic class value for requests issued to PCIe. Note: This IP does not support Virtual Channel, so please use it with 000b fixed.	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
19:16	CCH_D[3:0]	Indicates the value of A*CACHE[3:0] to be issued to AXI. CCH_D is output when issuing an AXI request other than the output condition of CCH_L. The recommended value is 0x1 when DIR = 0 (PCIe→AXI) and 0x0 when DIR = 1 (AXI→PCIe). [3] 1: write allocatable / 0: not write allocatable [2] 1: Read assignable / 0: Read assignable [1] 1: cacheable / 0: non-cacheable [0] 1: Bufferable / 0: Not Bufferable	R/W

Bit	Symbol	Function	R/W
23:20	CCH_L[3:0]	Indicates the value of A*CACHE[3:0] to be issued to AXI. CCH_L is output when issuing an AXI request containing the last byte in a transfer indicated by SIZE. Recommended value is 0x0. [3] 1: write allocatable / 0: not write allocatable [2] 1: Read assignable / 0: Read assignable [1] 1: cacheable / 0: non-cacheable [0] 1: Bufferable / 0: Not Bufferable	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_DMATCTLn register controls DMA transfer to the AXI and PCIe.

56.3.1.58 PCI_RC_DMASIZEn : DMA Size (Descriptor 0x08) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0928 + 0x80 × n

Bit position:	31																										3	2		0
Bit field:	DMA_SIZE3104[27:0]																												DMA_SIZE 0300[3:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	DMA_SIZE0300[3:0]	Sets the number of DMA transfer bytes. The lower 4 bits are fixed to 0 because it is an 16-byte aligned setting.	R
31:4	DMA_SIZE3104[27:0]	Sets the number of DMA transfer bytes. The lower 4 bits are fixed to 0 because it is an 16-byte aligned setting.	R/W

Note: When executing descriptor method DMA, writing is prohibited and the read value indicates the values of the CCH_L, CCH_D, TC, ATB, and DIR fields of the descriptor table being executed.

The PCI_RC_DMASIZEn register sets the number of bytes for DMA transfer. Reflects the field at offset 0x0C in the descriptor table.

56.3.1.59 PCI_RC_DMASLAn : DMA Source Lower Address (Descriptor 0x10) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0930 + 0x80 × n

Bit position:	31																										3	2		0
Bit field:	DMA_S_ADDR3104[27:0]																												DMA_S_ADDR0300[3:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	DMA_S_ADDR0300[3:0]	Set the lower 32 bits of the transfer source start address for DMA transfer. The lower 4 bits are fixed to 0 because it is an 16-byte aligned setting.	R
31:4	DMA_S_ADDR3104[27:0]	Set the lower 32 bits of the transfer source start address for DMA transfer. The lower 4 bits are fixed to 0 because it is an 16-byte aligned setting.	R/W

Note: If the Source Address indicates the PCIe space (DIR = 0), the PCIe request address is set in combination with the DMA PCIe Upper Address (Descriptor 0x10). When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the SA field in the descriptor table being executed.

The PCI_RC_DMASLAn register sets the lower 32 bits of the source start address for DMA transfer. It is reflected to the offset 0x10 field of the descriptor table.

56.3.1.60 PCI_RC_DMASUAn : DMA Source Upper Address (Descriptor 0x14) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0934 + 0x80 × n

Bit position:	31																												0
Bit field:	DMA_S_ADDR6332[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DMA_S_ADDR6332[31:0]	Set the upper 32 bits of the transfer source start address for MA transfer.	R/W

Note: If the Source Address indicates the PCIe space (DIR = 0), the PCIe request address is set in combination with the DMA PCIe Upper Address (Descriptor 0x10). When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the SA field in the descriptor table being executed.

The PCI_RC_DMASUAn register sets the upper 32 bits of the source start address for DMA transfer. It is reflected to the offset 0x14 field of the descriptor table.

56.3.1.61 PCI_RC_DMADESTLAn : DMA Destination Lower Address (Descriptor 0x18) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0938 + 0x80 × n

Bit position:	31																										3	2	0
Bit field:	DMA_D_ADDR3104[27:0]																										DMA_D_ADDR0300[3:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	DMA_D_ADDR0300[3:0]	Set the lower 32 bits of the transfer destination start address for DMA transfer. The lower 4 bits are fixed to 0 because it is an 16-byte aligned setting.	R
31:4	DMA_D_ADDR3104[27:0]	Set the lower 32 bits of the transfer destination start address for DMA transfer. The lower 4 bits are fixed to 0 because it is an 16-byte aligned setting.	R/W

Note: If the Destination Address indicates the PCIe space (DIR = 1), the PCIe request address is set in combination with the DMA PCIe Upper Address (Descriptor 0x10). When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the DA field in the descriptor table being executed.

The PCI_RC_DMADESTLAn register sets the lower 32 bits of the source start address for DMA transfer. It is reflected to the offset 0x18 field of the descriptor table.

56.3.1.62 PCI_RC_DMADESTUAn : DMA Destination Upper Address (Descriptor 0x1C) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x093C + 0x80 × n

Bit position:	31																												0
Bit field:	DMA_D_ADDR6332[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DMA_D_ADDR6332[31:0]	Set the upper 32 bits of the transfer destination start address for DMA transfer.	R/W

Note: If the Destination Address indicates the PCIe space (DIR = 1), the PCIe request address is set in combination with the DMA PCIe Upper Address (Descriptor 0x10). When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the DA field in the descriptor table being executed.

The PCI_RC_DMADESTUAn register sets the upper 32 bits of the source start address for DMA transfer. It is reflected to the offset 0x1C field of the descriptor table.

56.3.1.63 PCI_RC_DMADPLLPn : DMA Descriptor Lower Link Pointer (Descriptor 0x20) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0940 + 0x80 × n

Bit position:	31																													0
Bit field:	DMA_LP3100[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DMA_LP3100[31:0]	Indicates the value of the LP field of the running descriptor table.	R

The PCI_RC_DMADPLLPn register indicates the field value at offset 0x20 in the descriptor table. Only effective when the descriptor-type DMA transfer is selected (the value read has no meaning in the case of register-type transfer).

56.3.1.64 PCI_RC_DMADPULPn : DMA Descriptor Upper Link Pointer (Descriptor 0x24) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0944 + 0x80 × n

Bit position:	31																													0
Bit field:	DMA_LP6332[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DMA_LP6332[31:0]	Indicates the value of the LP field of the running descriptor table.	R

The PCI_RC_DMADPULPn register indicates the field value at offset 0x24 in the descriptor table. Only effective when the descriptor-type DMA transfer is selected (the value read has no meaning in the case of register-type transfer).

56.3.1.65 PCI_RC_DMARESTSIZEn : DMA Rest Size Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0950 + 0x80 × n

Bit position:	31																													0
Bit field:																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	DMA_REST_SIZE Displays the number of bytes for which DMA transfer has not been completed. (Register/descriptor method common)	R

The PCI_RC_DMARESTSIZEn register indicates the number of bytes for which DMA transfer has not yet been completed.

56.3.1.66 PCI_RC_AREQALn : AXI Request Address (Lower) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0960 + 0x80 × n

Bit position:	31																												0
Bit field:	AXI_REQ_ADDR3100[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	AXI_REQ_ADDR3100[31:0]	Displays the lower 32 bits of the address of the currently completed AXI transfer or the transfer that just completed. (Register/descriptor method common)	R

The PCI_RC_AREQALn register indicates the lower 32 bits of the address of the current or most recently completed AXI transfer.

56.3.1.67 PCI_RC_AREQAUn : AXI Request Address (Upper) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0964 + 0x80 × n

Bit position:	31																												0
Bit field:	AXI_REQ_ADDR6332[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	AXI_REQ_ADDR6332[31:0]	Displays the upper 32 bits of the address of the currently completed AXI transfer or the transfer that just completed. (Register/descriptor method common)	R

The PCI_RC_AREQAUn register indicates the upper 32 bits of the address of the current or most recently completed AXI transfer.

56.3.1.68 PCI_RC_PREQALn : PCIe Request Address (Lower) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0968 + 0x80 × n

Bit position:	31																												0
Bit field:	PCIE_REQ_ADDR3100[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PCIE_REQ_ADDR3100[31:0]	Displays the lower 32 bits of the address of the currently completed PCIe transfer or the transfer completed immediately before. (Register/descriptor method common)	R

The PCI_RC_PREQALn register indicates the lower 32 bits of the address during PCIe transfer that is in progress or for the most recently completed transfer.

56.3.1.69 PCI_RC_PREQAUn : PCIe Request Address (Upper) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x096C + 0x80 × n

Bit position:	31	0
Bit field:	PCIE_REQ_ADDR6332[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	PCIE_REQ_ADDR6332[31:0]	Displays the upper 32 bits of the address of the currently completed PCIe transfer or the transfer completed immediately before. (Register/descriptor method common)	R

The PCI_RC_PREQAUn register indicates the upper 32 bits of the address during PCIe transfer that is in progress or for the most recently completed transfer.

56.3.1.70 PCI_RC_QUESTAn : QUE Status Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0970 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	GO_LIST	LIST_NUM[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	LIST_NUM[3:0]	Displays the number of descriptor lists loaded on QUE (not including the list currently being executed). New registration to QUE (write access to QUE Entry) when this register indicates 0x8 is invalid (discarded).	R
4	GO_LIST	Shows whether there is a running descriptor list. 0: none 1: Yes	R
31:5	—	These bits are read as 0.	R

The PCI_RC_QUESTAn register indicates the state of the descriptor queue.

56.3.1.71 PCI_RC_DMACESTAn : DMAC Error Status Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0978 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	CFG_BM_DIS_EP	BME_SUP	BME_DOWN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	MOR_CD_PERR	MOR_CH_PERR	MOR_EP_ERR	MOR_STATUS[2:0]			—	—	—	—	—	—	AXI_RESP[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

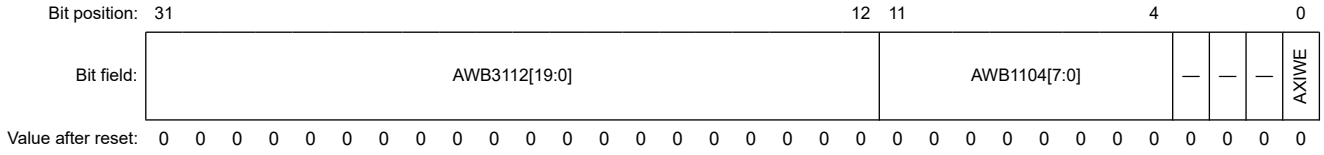
Bit	Symbol	Function	R/W
1:0	AXI_RESP[1:0]	Displays the slave response during AXI Master transactions. It updates when CHx_ERR is set and retains the value until the bit is cleared. 0 0: Initial value 0 1: Reserved	R
7:2	—	These bits are read as 0.	R
10:8	MOR_STATUS[2:0]	Indicates the value when MOR_STATUS is other than 000b (Success) as a set factor of CHx_ERR. Holds value until CHx_ERR is cleared. 0 0 0: initial value 0 0 1: Unsupported Request 0 1 0: CRS 0 1 1: Completion Timeout 1 0 0: Completer Abort 1 0 1: Unexpected Completion 1 1 0: Reserved 1 1 1: Mismatched Length (Length Overrun)	R
11	MOR_EP_ERR	It is set when it is Poisoned Completion as a set factor of CHx_ERR. Holds value until CHx_ERR is cleared.	R
12	MOR_CH_PERR	It is set when MOR_CH_PERR is detected as a set factor for CHx_ERR. Holds value until CHx_ERR is cleared.	R
13	MOR_CD_PERR	It is set when MOR_CD_PERR is detected as a set factor for CHx_ERR. Holds value until CHx_ERR is cleared.	R
15:14	—	These bits are read as 0.	R
16	BME_DOWN	It is set when a stop signal from the PCIe core is detected as a cause for setting CHx_ERR. Holds value until CHx_ERR is cleared.	R
17	BME_SUP	It is set when a sleep signal from the PCIe core is detected as a cause for setting CHx_ERR. Holds value until CHx_ERR is cleared. (Valid only in Endpoint mode)	R
18	CFG_BM_DIS_EP	CHx_ERR is set when the macro operates as an End Point and detects the state of Bus Master Enable Off (Configuration Space 0x004 bit [2] = 0). Holds value until CHx_ERR is cleared.	R
31:19	—	These bits are read as 0.	R

The PCI_RC_DMACESTAn register indicates the error status of the DMAC.

56.3.1.72 PCI_RC_AWBASELn : AXI Window Base (Lower) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1000 + 0x20 × n



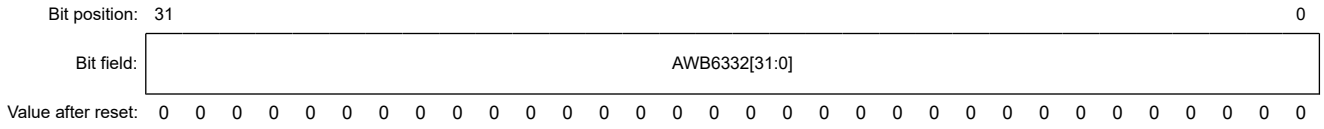
Bit	Symbol	Function	R/W
0	AXIWE	AXI Window Enable Enable setting of AXI Window. 0: Window disabled 1: Window enabled	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
11:4	AWB1104[7:0]	AWBase11:4 fixed 0x00	R
31:12	AWB3112[19:0]	AWBase31:12 Window setting register for address conversion when accessing AXI from PCIe. The configurable area is the 4K boundary.	R/W

The PCI_RC_AWBASELn register is for setting windows for lower address conversion in access from PCIe to AXI. It sets the base address on the PCI. The areas are set in 4-KB boundaries.

56.3.1.73 PCI_RC_AWBASEUn : AXI Window Base (Upper) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1004 + 0x20 × n



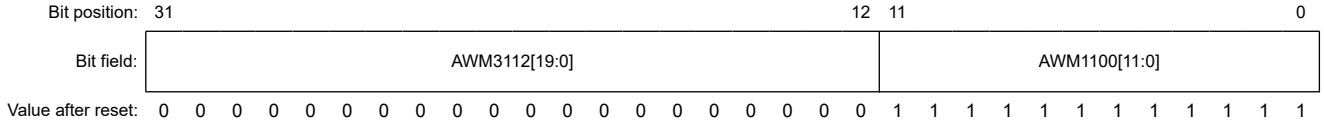
Bit	Symbol	Function	R/W
31:0	AWB6332[31:0]	AWBase63:32 Window setting register for address conversion when accessing AXI from PCIe.	R/W

The PCI_RC_AWBASEUn register is for setting windows for upper address conversion in access from PCIe to AXI.

56.3.1.74 PCI_RC_AWMASKLn : AXI Window Mask (Lower) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1008 + 0x20 × n



Bit	Symbol	Function	R/W
11:0	AWM1100[11:0]	AWMask11:0 Fixed 0xFFF	R

Bit	Symbol	Function	R/W
31:12	AWM3112[19:0]	AWMask31:12 Set the window in the area of the set number of bits from the address set in the AWBase register. Set 1 from the lower bit. Therefore, the area that can be set is 4K x 2^N bytes.	R/W

The PCI_RC_AWMASKLn register is for setting windows for lower address conversion in access from PCIe to AXI. The window is set as the area corresponding to the number of set bits from the address set in the AWBase register. The area which can be set is 4K × 2^N bytes.

56.3.1.75 PCI_RC_AWMASKUn : AXI Window Mask Upper Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x100C + 0x20 × n

Bit position:	31	30	0
Bit field:	—	AWM6232[30:0]	
Value after reset:	0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
30:0	AWM6232[30:0]	AWMask62:32 Set the window in the area of the set number of bits from the address set in the AWBase register. Set 1 from the lower bit.	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The PCI_RC_AWMASKUn register is for setting windows for upper address conversion in access from PCIe to AXI.

56.3.1.76 PCI_RC_ADESTLn : AXI Destination (Lower) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1010 + 0x20 × n

Bit position:	31	12	11	0
Bit field:	AD3112[19:0]		AD1100[11:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0		0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
11:0	AD1100[11:0]	ADest11:0 Fixed to 0x000	R
31:12	AD3112[19:0]	ADest31:12 Sets the window base point in the address space from the AXI side. The configurable area is the 4K boundary.	R/W

The PCI_RC_ADESTLn register is for setting windows for lower address conversion in access from PCIe to AXI. The base address of the window in the address space on the AXI is set. The areas are set in 4-KB boundaries.

56.3.1.77 PCI_RC_ADESTUn : AXI Destination (Upper) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1014 + 0x20 × n

Bit position:	31	0
Bit field:	AD6332[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	AD6332[31:0]	ADest63:32 Sets the window base point in the address space f rom the AXI side.	R/W

The PCI_RC_ADESTUn register is for setting windows for upper address conversion in access from PCIe to AXI.

56.3.1.78 PCI_RC_PWBASELn : PCIe Window Base (Lower) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1100 + 0x20 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PWB3112[19:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PWB3112[19:0]				PWB1104[7:0]								—	—	—	PCIWE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PCIWE	PCIe Window Enable Enable setting of PCIe Window. 0: Window disabled 1: Window enabled	R/W
3:1	—	This bit is read as 0. The write value should be 0.	R/W
11:4	PWB1104[7:0]	PWBase11:4 Fixed 0x00	R
31:12	PWB3112[19:0]	PWBase31:12 Sets the base point of the address on the AXI side. The configurable area is the 4K boundary.	R/W

The PCI_RC_PWBASELn register is for setting windows for lower address conversion in access from AXI to PCIe. It sets the base address on the AXI. The areas are set in 4-KB boundaries.

56.3.1.79 PCI_RC_PWBASEUn : PCIe Window Base (Upper) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1104 + 0x20 × n

Bit position:	31																													0
Bit field:	PWB6332[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PWB6332[31:0]	PWBase63:32 Sets the base point of the address on the AXI side. The configurable area is the 4K boundary.	R/W

The PCI_RC_PWBASEUn register is for setting windows for upper address conversion in access from AXI to PCIe.

56.3.1.80 PCI_RC_PWMASKLn : PCIe Window Mask (Lower) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1108 + 0x20 × n

Bit position:	31																		12	11										0
Bit field:	PWM3112[19:0]																			PWM1100[11:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
11:0	PWM1100[11:0]	PWMask Fixed 0xFFF	R
31:12	PWM3112[19:0]	PWMask31:12 Set the window in the area of the set number of bits from the address set in the PWBase register. Set 1 from the lower bit.	R/W

The PCI_RC_PWMASKLn register is for setting windows for address conversion in access from AXI to PCIe. The window is set as the area corresponding to the number of set bits from the address set in the PWBase register.

56.3.1.81 PCI_RC_PWMASKUn : PCIe Window Mask (Upper) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x110C + 0x20 × n

Bit position:	31	30																												0
Bit field:	—	PWM6232[30:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
30:0	PWM6232[30:0]	PWMask62:32 Set the window in the area of the set number of bits from the address set in the PWBase register. Set 1 from the lower bit.	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The PCI_RC_PWMASKUn register is for setting windows for address conversion in access from AXI to PCIe. The window is set as the area corresponding to the number of set bits from the address set in the PWBase register.

56.3.1.82 PCI_RC_PDESTLn : PCIe Destination (Lower) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1110 + 0x20 × n

Bit position:	31																		12	11										0
Bit field:	PD3112[19:0]																			PD1100[11:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	PD1100[11:0]	PDest11:0 fixed 0x000	R
31:12	PD3112[19:0]	PDest31:12 Set the window base point in the address space on the PCIe side. The configurable area is the 4k boundary.	R/W

The PCI_RC_PDESTLn register is for setting windows for address conversion in access from AXI to PCIe. The base address of the window in the address space on the AXI is set. The areas are set in 4-KB boundaries.

56.3.1.83 PCI_RC_PDESTUn : PCIe Destination (Upper) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1114 + 0x20 × n

Bit position:	31																													0
Bit field:	PD6332[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PD6332[31:0]	PDest63:32 Set the window base point in the address space on the PCIe side.	R/W

The PCI_RC_PDESTUn register is for setting windows for upper address conversion in access from AXI to PCIe.

56.3.2 PCI Express Configuration Registers (Type1: Root Complex)

56.3.2.1 PCI_RC_VID : Vendor and Device ID Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6000

Bit position:	31																16	15												0
Bit field:	DID[15:0]																VID[15:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	VID[15:0]	Vendor ID The read value is undefined Used by the manufacturer specified by the Vendor ID to identify the manufactured device. Set a fixed value.	Hwinit
31:16	DID[15:0]	Device ID The read value is undefined Represents the manufacturer of the device. Set a fixed value.	Hwinit

The PCI_RC_VID register indicates the vendor and device ID. The PCI_RC_VID register can be written during initialization.

Table 56.16 Valid reset signal

Reset signal	Device ID	Vendor ID
RST_LOAD_B	✓	✓
RST_RSM_B	—	—
RST_CFG_B	—	—

56.3.2.2 PCI_RC_COM_STA : Command and Status Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	SSE	—	—	—	—	—	—	—	—	—	CL	IS	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	ID	—	SERRE	—	PER	—	—	—	BME	MSE	IOSE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IOSE	IO Space Enable 0 fixed. It does not support access to the I/O space.	R
1	MSE	Memory Space Enable Controls whether to respond to accesses to memory space.	R/W
2	BME	Bus Master Enable Controls whether to operate as a bus master.	R/W
5:3	—	These bits are read as 0. The write value should be 0.	R/W
6	PER	Parity Error Response	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	SERRE	SERR# Enable Controls the behavior when sending/receiving PoisonedTLP. Note: Error logging to the Detected Parity Error field of the Status register, the Device Status register of PCI Express Capability, and the Uncorrectable Error Status register of Advanced Error Reporting Capability is performed regardless of the setting of this bit.	R/W
9	—	This bit is read as 0. The write value should be 0.	R/W
10	ID	Interrupt Disable If set to 1, the Root Complex is notified of Non-Fatal Errors and Fatal Errors by Message Transaction. Note: Even if this bit is not set, if a bit related to Error Reporting in the Device Control register of PCI Express Capability is set to 1, an error is notified to the Root Complex by Message Transaction.	R/W
18:11	—	These bits are read as 0. The write value should be 0.	R/W
19	IS	Interrupt Status Suppress transmission of Assert_INTx Message. Not used for Root Complex devices.	R
20	CL	Capabilities List This bit is fixed to 1 because all PCI Express devices must implement PCI Express Capability.	R
29:21	—	These bits are read as 0. The write value should be 0.	R/W
30	SSE	Signaled System Error Set to 1 when the SERR Enable bit is 1 and this macro sends an ERR_FATAL or ERR_NONFATAL Message.	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The PCI_RC_COM_STA register specifies the command and the status.

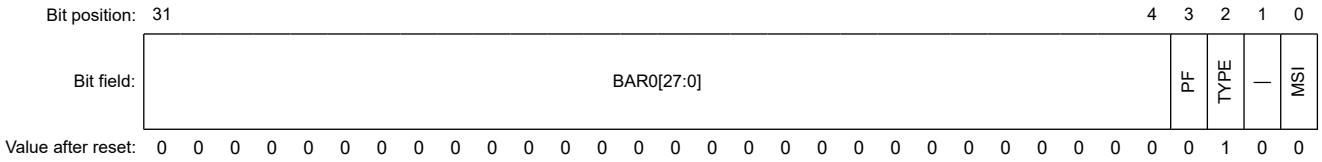
RST_LOAD_B	—
RST_RSM_B	—
RST_CFG_B	✓

56.3.2.5 PCI_RC_BAR0 : Base Address Register 0

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6010



Bit	Symbol	Function	R/W
0	MSI	Memory Space Indicator Fixed to 0 to indicate the memory space.	R
1	—	This bit is read as 0. The write value should be 0.	R/W
2	TYPE	Type 1 fixed to use 64-bit address 0: 32-bit address 1: 64-bit address	R
3	PF	Prefetch 0: Disable 1: Enable	Hwinit
31:4	BAR0[27:0]	Base Address Register 0 Indicates the base address. Depending on the size of the address block required, some lower bits of this field are implemented as Read Only bits fixed at 0. In this macro, the Read Only bits are located in the Base Address 0 Mask register (Offset: 0x0A0).	R/W

The PCI_RC_BAR0 register forms a 64-bit memory space in combination with Base Address Register 1 (BAR1).

Table 56.20 Valid reset signal

56.3.2.16 PCI_RC_PMC : PM Capabilities

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6040

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PMES[4:0]					D2S	D1S	AUXC[2:0]			DSI	IRRD0	—	V[2:0]		
Value after reset:	0	1	0	0	1	0	0	0	0	0	0	0	0	0	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	NCP[7:0]								CID[7:0]							
Value after reset:	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
7:0	CID[7:0]	Capability ID Indicates the PCI Power Management Capability. It is fixed at 0x01.	R
15:8	NCP[7:0]	Next Capability Pointer Indicates the PCI Express Capability start address.	R
18:16	V[2:0]	Version 011b is fixed. PCI Power Management Interface Specification Rev.1.2	Hwinit

Bit	Symbol	Function	R/W
19	—	This bit is read as 0.	R
20	IRRD0	Immediate_Readiness_on_Return_to_D0 0 fixed	R
21	DSI	Device Specific Initialization (DSI) Indicates whether or not DSI (Device Specific Initialization) is used. 0: not supported 1: Support	Hwinit
24:22	AUXC[2:0]	AUX_Current Indicates the 3.3Vaux auxiliary current (the maximum current value supplied from the auxiliary power supply). read value returns 000b. (AUX not supported) 0 0 0: 0 (self powered) 0 0 1: 55 mA 0 1 0: 100 mA 0 1 1: 160 mA 1 0 0: 220 mA 1 0 1: 250 mA 1 1 0: 320 mA 1 1 1: 375 mA	Hwinit
25	D1S	D1 Support Indicates whether the D1 Power Management State is supported. 0: not supported 1: Support	Hwinit
26	D2S	D2 Support Indicates whether D2 Power Management State is supported. 0: not supported 1: Support	Hwinit
31:27	PMES[4:0]	PME Support Indicates whether PME is supported in each Device State. xxxx1: supports D0 xxx1x: supports D1 xx1xx: supports D2 x1xxx: support D3hot 1xxxx: D3cold supported (not supported)	Hwinit

The PCI_RC_PMC register indicates various support information.

Table 56.31 Valid Reset Signal

Reset signal	PME Support	D2 Support	D1 Support	AUX_Current	DSI	Version	Next Capability Pointer[7:2]
RST_LOAD_B	✓	✓	✓	✓	✓	✓	✓
RST_RSM_B	—	—	—	—	—	—	—
RST_CFG_B	—	—	—	—	—	—	—

56.3.2.17 PCI_RC_PMSC : PM Status/Control Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6044

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PMES	—	—	—	—	—	—	PMEE	—	—	—	—	NSR	—	PS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
1:0	PS[1:0]	PowerState Set the PCI Device State. 0 0: D0 (Default) 0 1: D1 (Do not set) 1 0: D2 (Do not set) 1 1: D3hot	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	NSR	No_Soft_Reset Indicates that internal reset is not performed inside the device at the power state transition from D3hot to D0.	R
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	PMEE	PME Enable Controls PME assertions. If 1, PME assertion is enabled. Assert PME if PME_Status is set at this time. PCI Express performs Link Wake-up processing, and then performs PME assert processing by sending PM_PME Message. Note: The specifications are as follows depending on the value of the PM Capabilities register PME Support[4] (PME Support in D3cold). PME Support[4] = 1 Reset: RST_RSM_B PME Support[4] = 0 Reset: RST_CFG_B	R/W
14:9	—	These bits are read as 0. The write value should be 0.	R/W
15	PMES	PME Status Indicates that a PME assert factor has occurred. 1 indicates that there is a PME assertion factor.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_PMSC register indicates and controls the PME status.

Table 56.32 Valid reset signal

Reset signal	PME Enable	PowerState
RST_LOAD_B	—	—

56.3.2.22 PCI_RC_LINKCS : Link Control/Status Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	LABS	LBMS	DLLLA	SCC	LT	—	NLW[5:0]						CLS[3:0]			
Value after reset:	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	LABIE	LBMIE	HAWD	—	ES	CCC	RL	LD	RCB[3:0]	—	ASPMC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	ASPMC[1:0]	Active State Power Management (ASPM) Control Sets the permission level for Active State Power Management. 0 0: Disabled (Default) 0 1: L0s Entry Supported 1 0: L1 Entry Supported 1 1: L0s and L1 Entry Supported	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	RCB[3:0]	Read Completion Boundary (RCB) 0: 64 bytes 1: 128 bytes (Default)	R
4	LD	Link Disable Setting it to 1 causes the LTSSM to transition to the Disabled state.	R/W
5	RL	Retrain Link Setting it to 1 causes the LTSSM to transition to the Recovery state and start Link Retraining. Note that reading is always 0.	R/W
6	CCC	Common Clock Configuration Sets whether the Common Reference Clock is used. Only Common Reference Clock is supported for Single Link. 0: Provided by non-Common Reference Clock (Default) 1: Supplied by Common Reference Clock	R/W
7	ES	Extended Synch If set to 1, 4096 FTS Ordered-sets will be sent when transitioning from L0s to L0. Also, 1024 TS1 Ordered-sets are transmitted at the beginning of the Recovery state when transitioning from L1 to L0. The default value will be 0.	R/W
8	—	This bit is read as 0. The write value should be 0.	R/W
9	HAWD	Hardware Autonomous Width Disable Set the Link Width Change function to Disable. 0: Link Width Change Enable (Default) 1: Link Width Change Disable	R/W
10	LBMIE	Link Bandwidth Management Interrupt Enable Interrupt generation is controlled by the Link Bandwidth Status bit (bit 30). 0: Interrupt Disable (Default) 1: Interrupt Enable	R/W
11	LABIE	Link Autonomous Bandwidth Interrupt Enable Interrupt generation is controlled by the Link Autonomous Bandwidth Management Status bit (bit 31). 0: Interrupt Disable (Default) 1: Interrupt Enable	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
19:16	CLS[3:0]	Current Link Speed 0x0: During reset period 0x1: 2.5 GT/s PCI Express Link 0x2: 5.0 GT/s PCI Express Link 0x3: 8.0 GT/s PCI Express Link 0x4: 16.0 GT/s PCI Express Link	R
25:20	NLW[5:0]	Negotiated Link Width Indicates the Link width established as a result of negotiation. 0x01: x1 0x02: x2 0x04: x4 0x08: x8 0x0C: x12 0x10: x16 0x20: x32 Others: Reserved	R
26	—	This bit is read as 0. The write value should be 0.	R/W
27	LT	Link Training 1 indicates that the Physical layer LTSSM is in Configuration state or Recovery state. This bit is cleared when exiting the Configuration/Recovery state.	R
28	SCC	Slot Clock Configuration Indicates that the reference clock shared with the EP is used. 0: Do not use Connector Reference Clock 1: Use Connector Reference Clock (Default)	Hwinit
29	DLLLA	Data Link Layer Link Active 1 indicates that the Data Link Layer is in the Link Active state.	R
30	LBMS	Link Bandwidth Management Status This bit is output when Link Bandwidth Management Interrupt Enable is asserted. Cleared by writing 1. Writing 0 is ignored.	R/W
31	LABS	Link Autonomous Bandwidth Status This bit is output when Link Autonomous Bandwidth Interrupt Enable is asserted. Cleared by writing 1. Writing 0 is ignored.	R/W

The PCI_RC_LINKCS register controls the link and indicates the link status.

Table 56.37 Valid reset signal

56.3.2.23 PCI_RC_SLOTC : Slot Capabilities

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6074

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSN[12:0]													NCCS	EIP	SPLS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SPLS	SPLV[7:0]								HPC	HPS	PIP	AIP	MRLSP	PCP	ABP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ABP	Attention Button Present this bit indicates that an Attention Button for this slot is electrically controlled by the chassis.	Hwinit
1	PCP	Power Control Present this bit indicates that a software programmable Power Controller is implemented for this slot/adapter (depending on form factor).	Hwinit
2	MRLSP	MRL Sensor Present this bit indicates that an MRL Sensor is implemented on the chassis for this slot.	Hwinit
3	AIP	Attention Indicator Present this bit indicates that an Attention Indicator is electrically controlled by the chassis.	Hwinit
4	PIP	Power Indicator Present this bit indicates that a Power Indicator is electrically controlled by the chassis for this slot.	Hwinit
5	HPS	Hot-Plug Surprise this bit indicates that an adapter present in this slot might be removed from the system without any prior notification. This is a form factor specific capability. This bit is an indication to the operating system to allow for such removal without impacting continued software operation.	Hwinit
6	HPC	Hot-Plug Capable this bit indicates that this slot is capable of supporting hot-plug operations.	Hwinit
14:7	SPLV[7:0]	Slot Power Limit Value n combination with the Slot Power Limit Scale Register value, sets the upper limit of Power for the Slot. This register is enabled when the Slot Implemented bit (Express Capability Register (offset: 0x060), bit 24) is set. 0xF0: 250 W Slot Power Limit 0xF1: 275 W Slot Power Limit 0xF2: 300 W Slot Power Limit Others: reserved	Hwinit
16:15	SPLS[1:0]	Slot Power Limit Scale Sets the Scale for the Slot Power Limit Value. This register is enabled when the Slot Implemented bit (Express Capability Register (offset: 0x060), bit 24) is set. 0 0: 1.0x 0 1: 0.1x 1 0: 0.01x 1 1: 0.001x	Hwinit
17	EIP	Electromechanical Interlock Present Indicates that Electromechanical Interlock is implemented.	Hwinit
18	NCCS	No Command Completed Support Indicates that the Slot will not issue a software notification if the issued command is completed by the Hot-Plug Controller.	Hwinit
31:19	PSN[12:0]	Physical Slot Number Indicates the slot number connected to the port.	Hwinit

When PCI Express Capability Structure: Configuration Space Bit [24]: Slot Implemented is 0, there is no implementation of the slot. Therefore, this bit will be all 0.

Table 56.38 Valid reset signal

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CPD[3:0]				CSOS	EMC	TM[2:0]			SD	HASD	ETC	TLS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
3:0	TLS[3:0]	Target Link Speed Set the Link Speed value for notification to the opposite device during training. 0x01: 2.5 GT/s Target Link Speed 0x02: 5.0 GT/s Target Link Speed 0x03: 8.0 GT/s Target Link Speed (Default) 0x04: 16.0 GT/s Target Link Speed (prohibited) Others: Reserved	R/W
4	ETC	Enter Compliance Setting to 1 allows transition to Compliance mode. At this time, the Link Speed will be the value set in the Target Link Speed field.	R/W
5	HASD	Hardware Autonomous Speed Disable Controls the Link Speed Change function. 0: Support of Link Speed Change (Enable) 1: not Support of Link Speed Change (Disable)	R/W
6	SD	Selectable Deemphasis The read value is undefined De-emphasis setting register for RC Gen2 operation. 0: -6 dB 1: -3.5 dB	R/W
9:7	TM[2:0]	Transmit Margin Adjust the voltage level of the Transmitter. 000b Normal operating range See 001b to 111b Base Spec Section 8.3.4.	R/W

Bit	Symbol	Function	R/W
10	EMC	Enter Modified Compliance Setting bit for transmission of Modified Compliance pattern. 0: Compliance Pattern (Default) 1: Modified Compliance Pattern	R/W
11	CSOS	Compliance SOS When this bit is set to 1, insert the SKP Ordered-set periodically during compliance pattern transmission.	R/W
15:12	CPD[3:0]	Compliance Preset De-emphasis Set the De-emphasis Level in Polling.Compliance State. 0x00: -6 dB (Default) 0x01: -3.5 dB	R/W
16	CDL	Current De-emphasis Level This is a Status register that indicates the De-emphasis Level during Gen2 operation. Note: The initial value of this bit is 0 at reset and after Gen2-Linkup. However, although it indicates 1 at Gen1-Linkup, ignore this bit as it has no meaning in Gen1. 0: -6 dB (Default) 1: -3.5 dB	R
17	EQC	Equalization Complete When set to 1, this bit indicates that the Transmitter Equalization procedure has completed. The default value of this bit is 0. For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0.	R
18	EP1S	Equalization Phase 1 Successful When set to 1, this bit indicates that Phase 1 of the Transmitter Equalization procedure has successfully completed. The default value of this bit is 0. For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0.	R
19	EP2S	Equalization Phase 2 Successful When set to 1, this bit indicates that Phase 2 of the Transmitter Equalization procedure has successfully completed. The default value of this bit is 0. For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0.	R
20	EP3S	Equalization Phase 3 Successful When set to 1, this bit indicates that Phase 3 of the Transmitter Equalization procedure has successfully completed. The default value of this bit is 0. For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0.	R
21	LER	Link Equalization Request This bit is Set by hardware to request the Link equalization process to be performed on the Link. The default value of this bit is 0. For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0.	R/W
31:22	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_LINCS2 register controls the link and indicates the link status.

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	UREM	ECRC EMO	MTLP M	ROMO	UCM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CAMO	CTM	—	PTLP RM	—	—	—	—	—	—	—	DLPE M	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	DLPEM	Data Link Protocol Error Mask Masks error notifications when a Data Link Protocol Error is detected. 0: No mask 1: Send Error Message, Mask Update of First Error Pointer	R/W
11:5	—	These bits are read as 0. The write value should be 0.	R/W
12	PTLPRM	Poisoned TLP Received Mask Masks error notification when Poisoned TLP Error is detected. 0: No mask 1: Send Error Message, record header to Header Log register, mask Update of First Error Pointer	R/W
13	—	This bit is read as 0. The write value should be 0.	R/W
14	CTM	Completion Timeout Mask Masks the error notification when Completion Timeout Error is detected. 0: No mask 1: Send Error Message, Mask Update of First Error Pointer	R/W
15	CAMO	Completer Abort Mask (Optional) Masks the error notification when a Completer Abort Error is detected. 0: No mask 1: Send Error Message, record header to Header Log register, mask Update of First Error Pointer	R/W
16	UCM	Unexpected Completion Mask Masks error notification when Unexpected Completion Error is detected. 0: No mask 1: Send Error Message, record header to Header Log register, mask Update of First Error Pointer	R/W

Bit	Symbol	Function	R/W
17	ROMO	Receiver Overflow Mask (Optional) Masks error notification when Receiver Overflow Error is detected. 0: No mask 1: Send Error Message, Mask Update of First Error Pointer	R/W
18	MTLPM	Malformed TLP Mask Masks error notification when Malformed TLP Error is detected. 0: No mask 1: Send Error Message, record header to Header Log register, mask Update of First Error Pointer	R/W
19	ECRCEMO	ECRC Error Mask (Optional) Masks error notification when ECRC Error is detected. 0: No mask 1: Mask	R/W
20	UREM	Unsupported Request Error Mask Masks the error notification when an Unsupported Request Error is detected. 0: No mask 1: Send Error Message, record header to Header Log register, mask Update of First Error Pointer	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_UNCEMASK register masks the uncorrectable error status.

Table 56.51 Valid reset signal

Reset signal	Unsupported Request Error Mask	ECRC Error Mask	Malformed TLP Mask	Receiver Overflow Mask	Unexpected Completion Mask	Completer Abort Mask	Completion Timeout Mask	Poisoned TLP Received Mask	Data Link Protocol Error Mask
RST_LOAD_B	—	—	—	—	—	—	—	—	—
RST_RSM_B	✓	✓	✓	✓	✓	✓	✓	✓	✓
RST_CFG_B	—	—	—	—	—	—	—	—	—

56.3.2.38 PCI_RC_UNCESVY : Uncorrectable Error Severity Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x610C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	URES	ECRCESO	MTLPS	ROSO	UCS
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	1	1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CASO	CTS	—	PTLPRS	—	—	—	—	—	—	—	DLPES	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
4	DLPES	Data Link Protocol Error Severity Sets the Error Severity when a Data Link Protocol Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
11:5	—	These bits are read as 0. The write value should be 0.	R/W
12	PTLPRS	Poisoned TLP Received Severity Sets the Error Severity when Poisoned TLP Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
13	—	This bit is read as 0. The write value should be 0.	R/W
14	CTS	Completion Timeout Severity Sets the Error Severity when Completion Timeout Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
15	CASO	Completer Abort Severity (Optional) Sets the Error Severity when a Completer Abort Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
16	UCS	Unexpected Completion Severity Sets the Error Severity when an Unexpected Completion Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
17	ROSO	Receiver Overflow Severity (Optional) Set the Error Severity when Receiver Overflow Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
18	MTLPS	Malformed TLP Severity Sets the Error Severity when Malformed TLP Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
19	ECRCESO	ECRC Error Severity (Optional) Sets the Error Severity when receiving an ECRC Error. 0: Non-Fatal Error 1: Fatal Error	R/W
20	URES	Unsupported Request Error Severity Set the Error Severity when Unsupported Request Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
21	—	This bit is read as 0. The write value should be 0.	R/W
22	—	This bit is read as 1. The write value should be 1.	R/W
31:23	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_UNCESVY register sets the uncorrectable error severity.

Table 56.52 Valid reset signal (1 of 2)

Reset signal	Unsupported Request Error Severity	ECRC Error Severity	Malformed TLP Severity	Receiver Overflow Severity	Unexpected Completion Severity	Completer Abort Severity	Completion Timeout Severity	Poisoned TLP Received Severity	Data Link Protocol Error Severity
RST_LOAD_B	—	—	—	—	—	—	—	—	—

Table 56.52 Valid reset signal (2 of 2)

Reset signal	Unsupported Request Error Severity	ECRC Error Severity	Malformed TLP Severity	Receiver Overflow Severity	Unexpected Completion Severity	Completer Abort Severity	Completion Timeout Severity	Poisoned TLP Received Severity	Data Link Protocol Error Severity
RST_CFG_B	—	—	—	—	—	—	—	—	—

56.3.2.39 PCI_RC_CESTS : Correctable Error Status Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6110

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	ANFES	RTTS	—	—	—	REPLAYNUMRS	BDLLPS	BTLPS	—	—	—	—	—	RES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RES	Receiver Error Status (optional) 0: No error detected 1: Error detected	R/W
5:1	—	These bits are read as 0. The write value should be 0.	R/W
6	BTLPS	Bad TLP Status Indicates that a TLP CRC error or Sequence Number error was detected. 0: No error detected 1: Error detected	R/W
7	BDLLPS	Bad DLLP Status Indicates that a DLLP CRC error was detected. 0: No error detected 1: Error detected	R/W
8	REPLAYNUMRS	REPLAY_NUM Rollover Status Replay occurred four times in a row, indicating REPLAY_NUM rolled over from 11b to 00b. 0: No error detected 1: Error detected	R/W
11:9	—	These bits are read as 0. The write value should be 0.	R/W
12	RTTS	Replay Timer Timeout Status Indicates that a Timeout error occurred when a TLP was sent and an Ack or Nak DLLP could not be received within the specified time. 0: No error detected 1: Error detected	R/W
13	ANFES	Advisory Non-Fatal Error Status Indicates that an Advisory Non-Fatal Error was detected. 0: No error detected 1: Error detected	R/W
31:14	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_CESTS register indicates the correctable error status.

Table 56.53 Valid reset signal

Reset signal	Advisory Non-Fatal Error Status	Replay Timer Timeout Status	REPLAY_NUM Rollover Status	Bad DLLP Status	Bad TLP Status	Receiver Error Status
RST_LOAD_B	—	—	—	—	—	—
RST_RSM_B	✓	✓	✓	✓	✓	✓
RST_CFG_B	—	—	—	—	—	—

56.3.2.40 PCI_RC_CEMASK : Correctable Error Mask Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6114

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	ANFEM	RTTM	—	—	—	REPLAYNUMRM	BDLLPM	BTLPM	—	—	—	—	—	REM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	REM	Receiver Error Mask (optional) 0: No mask 1: Mask error message transmission	R/W
5:1	—	These bits are read as 0. The write value should be 0.	R/W
6	BTLPM	Bad TLP Mask Masks error notification when Bad TLP Error is detected. 0: No mask 1: Mask error message transmission	R/W
7	BDLLPM	Bad DLLP Mask Masks error notification when Bad DLLP Error is detected. 0: No mask 1: Mask error message transmission	R/W
8	REPLAYNUMRM	REPLAY_NUM Rollover Mask REPLAY_NUM Mask error notification when Roll Over Error is detected. 0: No mask 1: Mask error message transmission	R/W
11:9	—	These bits are read as 0. The write value should be 0.	R/W
12	RTTM	Replay Timer Timeout Mask Masks error notification when Replay Timer Timeout Error is detected. 0: No mask 1: Mask error message transmission	R/W
13	ANFEM	Advisory Non-Fatal Error Mask Advisory Masks error notifications when non-fatal errors are detected. 0: No mask 1: Mask Advisory Non-Fatal Error handling (Mask updating First Error Pointer and Header Logging and sending Error Message)	R/W
31:14	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_CEMASK register masks the correctable error status.

Table 56.54 Valid reset signal

Reset signal	Advisory Non-Fatal Error Mask	Replay Timer Timeout Mask	REPLAY_NUM Rollover Mask	Bad DLLP Mask	Bad TLP Mask	Receiver Error Mask
RST_LOAD_B	—	—	—	—	—	—
RST_RSM_B	✓	✓	✓	✓	✓	✓
RST_CFG_B	—	—	—	—	—	—

56.3.2.41 PCI_RC_ADVECC : Advanced Error Capabilities and Control Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6118

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ECRCCE	ECRCCC	ECRCGE	ECRCGC	FEP[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	FEP[4:0]	First Error Pointer Indicates the field value of the Uncorrectable Error Status register for the first detected Uncorrectable Error Bit [4:0] First Error Pointer is reset by RST_GP_B.	R
5	ECRCGC	ECRC Generation Capable Presence or absence of ECRC Generation function 0: None 1: Yes (Default)	R
6	ECRCGE	ECRC Generation Enable ECRC Generation Enable setting 0: Disable (Default) 1: Enable	R/W
7	ECRCCC	ECRC Check Capable Presence or absence of ECRC Check function 0: None 1: Yes (Default)	R
8	ECRCCE	ECRC Check Enable ECRC Check Enable setting 0: Disable (Default) 1: Enable	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_RC_ADVECC register indicates and controls the advanced error capabilities.

Table 56.55 Valid reset signal

Reset signal	ECRC Check Enable	ECRC Generation Enable
RST_LOAD_B	—	—
RST_RSM_B	✓	✓
RST_CFG_B	—	—

56.3.2.42 PCI_RC_HLOG0 : Header Log Register 0

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x611C

Bit position:	31																												0
Bit field:	HTLPE0[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	HTLPE0[31:0]	Header of TLP associated with error 0 For the first detected Uncorrectable Error, indicates the 1st DW of Header.	R

The PCI_RC_HLOG0 register indicates the header log.

56.3.2.43 PCI_RC_HLOG1 : Header Log Register 1

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6120

Bit position:	31																												0
Bit field:	HTLPE1[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	HTLPE1[31:0]	Header of TLP associated with error 1 For the first detected Uncorrectable Error, indicates the 2nd DW of Header.	R

The PCI_RC_HLOG1 register indicates the header log.

56.3.2.44 PCI_RC_HLOG2 : Header Log Register 2

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6124

Bit position:	31																												0
Bit field:	HTLPE2[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	HTLPE2[31:0]	Header of TLP associated with error 2 For the first detected Uncorrectable Error, indicates the 3rd DW of Header.	R

The PCI_RC_HLOG2 register indicates the header log.

56.3.2.45 PCI_RC_HLOG3 : Header Log Register 3

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6128

Bit position:	31																													0
Bit field:	HTLPE3[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	HTLPE3[31:0]	Header of TLP associated with error 3 For the first detected Uncorrectable Error, indicates the 4th DW of Header.	R

The PCI_RC_HLOG3 register indicates the header log.

56.3.2.46 PCI_RC_ROOTEC : Root Error Command

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x612C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	FERE	NFERE	CERE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CERE	Correctable Error Reporting Enable This bit enables an interrupt to be generated when ERR_COR occurs in any of the layers below the root port.	R/W
1	NFERE	Non-Fatal Error Reporting Enable This bit enables an interrupt to be generated when NON_ERR_FATAL occurs in any of the layers below the root port.	R/W
2	FERE	Fatal Error Reporting Enable This bit enables an interrupt to be generated when ERR_FATAL occurs in any of the layers below the root port.	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Table 56.56 Valid reset signal

Reset signal	Fatal Error Reporting Enable	Non-Fatal Error Reporting Enable	Correctable Error Reporting Enable
RST_LOAD_B	—	—	—

56.3.2.47 PCI_RC_ROOTES : Root Error Status

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6130

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	FEMR	NFEMR	FUF	MERRFATALNONFATALR	ERRFATALNONFATALR	MERRCORR	ERRCORR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ERRCORR	ERR_COR Received Indicates that ERR_COR was received with the ERR_COR Received bit cleared.	R/W
1	MERRCORR	Multiple ERR_COR Received It means that another ERR_COR was received while the ERR_COR Received bit was already set.	R/W
2	ERRFATALNONFATALR	ERR_FATALNONFATAL Received Indicates that ERR_FATAL or ERR_NON_FATAL was received with the ERR_FATAL/NONFATAL Received bit cleared.	R/W
3	MERRFATALNONFATALR	Multiple ERR_FATALNONFATAL Received This means that ERR_FATAL or ERR_NON_FATAL was received while the ERR_FATAL/NONFATAL Received bit was already set.	R/W
4	FUF	First Uncorrectable Fatal Set when the first uncorrectable error is received and the error was ERR_FATAL.	R/W
5	NFEMR	Non-Fatal Error Message Received Set when one or more ERR_NON_FATAL is received.	R/W
6	FEMR	Fatal Error Message Received Set when one or more ERR_FATAL is received.	R/W
31:7	—	These bits are read as 0. The write value should be 0.	R/W

Table 56.57 Valid reset signal

56.3.2.49 PCI_RC_DEVSNEXTC : Device Serial Number Extended Capability Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6150

Bit position:	31											20	19			16	15													0
Bit field:	NCO[11:0]												CV[3:0]				PCIEECID[15:0]													
Value after reset:	0	0	0	1	1	0	1	1	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
15:0	PCIEECID[15:0]	PCI Express Extended Capability ID Indicates the Device Serial Number Extended Capability. Default: 0x0003	R
19:16	CV[3:0]	Capability Version Indicates the version of the Capability Structure. Default: 0x1	Hwinit
31:20	NCO[11:0]	Next Capability Offset Indicates the starting address of the Secondary PCI Express Extended Capability Header.	R

The PCI_RC_DEVSNEXTC register specifies the device serial number extended capability.

Table 56.59 Valid reset signal

Reset signal	Next Capability Offset	Capability Version
RST_LOAD_B	✓	✓
RST_RSM_B	—	—
RST_CFG_B	—	—

56.3.2.50 PCI_RC_SNL : Serial Number Register (Lower DW)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6154

Bit position:	31																													0
Bit field:	PCIEDSN_LDW[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PCIEDSN_LDW[31:0]	PCI Express Device Serial Number (Lower DW) The read value is undefined The lower 32 bits of the IEEE standard 64-bit unique ID (EUI-64). EUI-64 consists of a 24-bit company ID and a 40-bit vendor-defined extension.	Hwinit

The PCI_RC_SNL register specifies the serial number of the device.

Table 56.60 Valid reset signal

Reset signal	PCI Express Device Serial Number (Lower DW)
RST_LOAD_B	✓
RST_RSM_B	—
RST_CFG_B	—

56.3.2.51 PCI_RC_SNU : Serial Number Register (Upper DW)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6158

Bit position:	31																												0
Bit field:	PCIEDSN_UDW[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PCIEDSN_UDW[31:0]	PCI Express Device Serial Number (Upper DW) The read value is undefined The Upper 32 bits of the IEEE standard 64-bit unique ID (EUI-64). EUI-64 consists of a 24-bit company ID and a 40-bit vendor-defined extension.	Hwinit

The PCI_RC_SNU register specifies the serial number of the device.

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PE	Perform Equalization When this bit is 1 and a 1 is written to the Retrain Link bit with the Target Link Speed field set to 8.0 GT/s or higher, the Downstream Port must perform Link Equalization. This bit is RW for Downstream Ports and for Upstream Ports when Crosslink Supported is 1. This bit is not applicable and is RsvdP for Upstream Ports when the Crosslink Supported bit is 0. The default value is 0. RC: Default 0 EP: Fixed to 0 because Crosslink is not supported	R/W
1	LERIE	Link Equalization Request Interrupt Enable When Set, this bit enables the generation of an interrupt to indicate that the Link Equalization 8.0 GT/s Request bit or the Link Equalization Request 16.0 GT/s bit has been set. This bit is RW for Downstream Ports and for Upstream Ports when Crosslink Supported is 1. This bit is not applicable and is RsvdP for Upstream Ports when the Crosslink Supported bit is 0. The default value for this bit is 0. RC: Default 0 EP: Fixed to 0 because Crosslink is not supported	R/W
8:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:9	ELSKPOSGV[6:0]	Enable Lower SKP OS Generation Vector When the Link is in L0 and the bit in this field corresponding to the current Link speed is Set, SKP Ordered Sets are scheduled at the rate defined for SRNS, overriding the rate required based on the clock tolerance architecture. Bit definitions within this field are: Bit 0: 2.5 GT/s Bit 1: 5.0 GT/s Bit 2: 8.0 GT/s Bit 3: 16.0 GT/s (prohibited) Bits 6 to 4: RsvdP Bits in this field are RW if the corresponding bit in the Lower SKP OS Generation Supported Speeds Vector is Set, otherwise they are permitted to be hardwired to 0. Behavior is undefined if a bit is Set in this field and the corresponding bit in the Lower SKP OS Generation Supported Speeds Vector is not Set. The default value of this field is 0x00.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Value after reset:	0	1	1	1	1	1	1	1	0	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
3:0	DPTP0[3:0]	Downstream Port 8.0 GTs Transmitter Preset Lane0 The read value is undefined. Transmitter Presetused for equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. For an Upstream Port if Crosslink Supported is 0, this field is RsvdP. Otherwise, this field is Hwinit. The default value is 0xF. RC: Default 0xF EP: Fixed to 0 because Crosslink is not supported	Hwinit
6:4	DPRPH0[2:0]	Downstream Port 8.0 GTs Receiver Preset Hint Lane0 The read value is undefined. Receiver Preset Hint may be used as a hint for receiver equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. For an Upstream Port if Crosslink Supported is 0, this field is RsvdP. Otherwise, this field is Hwinit. The default value is 0x7. RC: Default 0x7 EP: Fixed to 0 because Crosslink is not supported	Hwinit
7	—	This bit is read as 0.	R
11:8	UPTP0[3:0]	Upstream Port 8.0 GTs Transmitter Preset Lane0 The read value is undefined. Field contains the Transmit Preset value sent or received during Link Equalization. Field usage varies as follows: A: Downstream Port Field contains the value sent on the associated Lane during Link Equalization. Field is Hwinit. B: Upstream Port, Crosslink Supported = 0 Field is intended for debug and diagnostics. It contains the value captured from the associated Lane during Link Equalization. Field is RO. When crosslinks are supported, case C (below) applies and this captured information is not visible to software. Vendors are encouraged to provide an alternate mechanism to obtain this information. C: Upstream Port, Crosslink Supported = 1 Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A (above) applies. Field is Hwinit. The default value is 0xF. RC: Default 0xF EP: Input signal	Hwinit

Bit	Symbol	Function	R/W
14:12	UPRPH0[2:0]	Upstream Port 8.0 GTs Receiver Preset Hint Lane0 The read value is undefined. Field contains the Receiver Preset Hint value sent or received during Link Equalization. Field usage varies as follows: A: Downstream Port Field contains the value sent on the associated Lane during Link Equalization. Field is Hwinit. B: Upstream Port, Crosslink Supported = 0 Field is intended for debug and diagnostics. It contains the value captured from the associated Lane during Link Equalization. Field is RO. When crosslinks are supported, case C (below) applies and this captured information is not visible to software. Vendors are encouraged to provide an alternate mechanism to obtain this information. C: Upstream Port, Crosslink Supported = 1 Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A (above) applies. Field is Hwinit. The default value is 0x7. RC: Default 0x7 EP: Input signal	Hwinit
15	—	This bit is read as 0.	R
19:16	DPTP1[3:0]*1	Downstream Port 8.0 GTs Transmitter Preset Lane1 The read value is undefined. Transmitter Presetused for equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. For an Upstream Port if Crosslink Supported is 0, this field is RsvdP. Otherwise, this field is Hwinit. The default value is 0xF. RC: Default 0xF EP: Fixed to 0 because Crosslink is not supported	Hwinit
22:20	DPRPH1[2:0]*1	Downstream Port 8.0 GTs Receiver Preset Hint Lane1 The read value is undefined. Receiver Preset Hint may be used as a hint for receiver equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. For an Upstream Port if Crosslink Supported is 0, this field is RsvdP. Otherwise, this field is Hwinit. The default value is 0x7. RC: Default 0x7 EP: Fixed to 0 because Crosslink is not supported	Hwinit
23	—	This bit is read as 0.	R
27:24	UPTP1[3:0]*1	Upstream Port 8.0 GTs Transmitter Preset Lane1 The read value is undefined. Field contains the Transmit Preset value sent or received during Link Equalization. Field usage varies as follows: A: Downstream Port Field contains the value sent on the associated Lane during Link Equalization. Field is Hwinit. B: Upstream Port, Crosslink Supported = 0 Field is intended for debug and diagnostics. It contains the value captured from the associated Lane during Link Equalization. Field is RO. When crosslinks are supported, case C (below) applies and this captured information is not visible to software. Vendors are encouraged to provide an alternate mechanism to obtain this information. C: Upstream Port, Crosslink Supported = 1 Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A (above) applies. Field is Hwinit. The default value is 0xF. RC: Default 0xF EP: Input signal	Hwinit

Bit	Symbol	Function	R/W
30:28	UPRPH1[2:0]*1	Upstream Port 8.0 GTs Receiver Preset Hint Lane1 The read value is undefined. Field contains the Receiver Preset Hint value sent or received during Link Equalization. Field usage varies as follows: A: Downstream Port Field contains the value sent on the associated Lane during Link Equalization. Field is Hwinit. B: Upstream Port, Crosslink Supported = 0 Field is intended for debug and diagnostics. It contains the value captured from the associated Lane during Link Equalization. Field is RO. When crosslinks are supported, case C (below) applies and this captured information is not visible to software. Vendors are encouraged to provide an alternate mechanism to obtain this information. C: Upstream Port, Crosslink Supported = 1 Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A (above) applies. Field is Hwinit. The default value is 0x7. RC: Default 0x7 EP: Input signal	Hwinit
31	—	This bit is read as 0.	R

Note 1. Not available for m = 1.

56.4 Register Descriptions (Endpoint Mode)

The registers in this section are availabe when the MODE_PORT bit in PCIE_MODE register is set to 0.

The registers are implemented in both ch0 and ch1, but the registers related to lane 1 are reserved for ch1.

Registers can be accessed from the AXI and PCIe. The attributes change depending on the access source. R/W column shows the attribute from AXI. When attribute is different between AXI and PCIe, note is added. When attribute is same, no note is added.

56.4.1 AXI Bridge Register

56.4.1.1 PCI_EP_REQDATAn : Request Data Register n (n = 0 to 2)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0080 + 0x4 × n

Bit position:	31																												0
Bit field:																													
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
31:0	n/a	Request Data Issue various requests to PCIe See Table 56.66.	R/W*1

Note 1. The access type from PCIe is read-only.

The PCI_EP_REQDATAn register issues various requests.

Table 56.66 Valid reset signal

Transaction type	Request Data Register 0	Request Data Register 1	Request Data Register 2
Zero-Length Read Request	Invalid	Invalid	Invalid
Message Request	3rd Header	4th Header	Invalid
Message Request with data payload	3rd Header	4th Header	Message data

Note: The bits should be set to 0 for the requests indicated as "Invalid".

56.4.1.2 PCI_EP_REQRCVDAT : Request Receive Data Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x008C

Bit position:	31																												0
Bit field:																													
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
31:0	n/a	Request Receive Data After issuing a read request, the data read on reception of the completion response are set in these bits. However, these bits are invalid for Zero-Lentgh Read and any kind of various write requests.	R

The PCI_EP_REQRCVDAT register indicates the data read on reception of the completion response after issuing a read request.

56.4.1.3 PCI_EP_REQADR1 : Request Address Register 1

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0090

Bit position:	31																												0
Bit field:																													
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
31:0	n/a	Request Address Set the Address, etc. when issuing a Request. See Table 56.67.	R/W*1

Note 1. The access type from PCIe is read-only.

The PCI_EP_REQADR1 register issues requests.

Table 56.67 Valid reset signal (1 of 2)

Request Address Register 1	[31:27]	[26:24]	[23:19]	[18:16]	[15:12]	[11:8]	[7:2]	[1:0]
Zero-Length Read Request	Address							Reserved

Table 56.67 Valid reset signal (2 of 2)

Request Address Register 1	[31:27]	[26:24]	[23:19]	[18:16]	[15:12]	[11:8]	[7:2]	[1:0]
Message Request	Reserved	Routing type	Reserved	Reserved	Reserved	Reserved	Message code	
Message Request with data payload	Reserved	Routing type	Reserved	Reserved	Reserved	Reserved	Message code	

Note: The bits should be set to 0 for the requests indicated as "Reserved".

56.4.1.4 PCI_EP_REQADR2 : Request Address Register 2

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0094

Bit position:	31																												0
Bit field:																													
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
31:0	n/a	Request Address63:32 See Table 56.68.	R/W*1

Note 1. The access type from PCIe is read-only.

The PCI_EP_REQADR2 register issues requests.

Table 56.68 Valid reset signal

Transaction type	[31:0]
Zero-Length Read Request	Address
Message Request	Invalid
Message Request with data payload	Invalid

Note: The bits should be set to 0 for the requests indicated as "Invalid".

56.4.1.5 PCI_EP_REQBE : Request Byte Enable Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0098

Bit position:	31																											3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RBE[3:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

Bit	Symbol	Function	R/W
3:0	RBE[3:0]	Request Byte Enable Specify Byte Enable when issuing Cfg Request as required. Normally use 0xF. 0: Byte Enable enabled 1: Byte Enable disabled	R/W*1
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The access type from PCIe is read-only.

The PCI_EP_REQBE register specifies the first byte enable bit within the TLP header (1st DW byte) when issuing a request to PCIe.

Table 56.69 Valid reset signal

Transaction type	RBE[3:0]
Zero-Length Read Request	0x0
Message Request	Invalid (0xF)
Message Request with data payload	Invalid (0xF)

56.4.1.6 PCI_EP_REQISS : Request Issue Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x009C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	RR	MOR_CD_PERR	MOR_CH_PERR	MOR_EP_ERR	MOR_STATUS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	FUNC[2:0]			TR_TYPE[3:0]				—	—	—	—	—	—	—	RI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RI	Request Issue 0: Write: No operation. Read: Request can be accepted. (Indicates that the processing of the issued Request has ended.) 1: Write: Request issuance. Read: Processing Request. (Indicates that the issued Request is being processed.)	R/W*1
7:1	—	These bits are read as 0. The write value should be 0.	R/W
11:8	TR_TYPE[3:0]	Set the type of Request. See Table 56.70.	R/W*1
14:12	FUNC[2:0]	Set the function of Request.	R/W*1
15	—	This bit is read as 0. The write value should be 0.	R/W
18:16	MOR_STATUS[2:0]	These bits retain the MOR Status of Completion TLP for Non-Posted requests issued. It is not updated at the time of Posted request. 0 0 0: Successful Completion (SC) 0 0 1: Unsupported Request (UR) 0 1 0: Configuration Request Retry Status (CRS) (not supported) 0 1 1: Completion Timeout 1 0 0: Completer Abort (CA) 1 0 1: Unexpected Completion and mismatched type (Lock Completion responds to non-Lock Request) 1 1 0: Reserved 1 1 1: Overrun Completion length	R
19	MOR_EP_ERR	It is set to 1 when a Poisoned Completion TLP for a Non-Posted request issued by this register is received. Normally not used. It is not updated at the time of Posted request.	R
20	MOR_CH_PERR	It is set to 1 when a header error occurs in the Completion TLP for the Non-Posted request issued by this register. Normally not used. It is not updated at the time of Posted request.	R

Bit	Symbol	Function	R/W
21	MOR_CD_PERR	It is set to 1 when a data error occurs in the Completion TLP for the Non-Posted request issued by this register. Normally not used. It is not updated at the time of Posted request.	R
22	RR	Request Rejection Indicates that the stopped or hibernated state of the PCI Express transmit (TX) side was detected and the process was forcibly terminated. 0: Normal state (Request issued) 1: Rejection	R
31:23	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The access type from PCIe is read-only.

The PCI_EP_REQISS register issues a request to PCIe.

Table 56.70 Valid reset signal

Transaction type	TR_TYPE[11:8]	Posted/Non-posted	Device type	
			Root complex	Endpoint
Zero-Length Read Request	0x0	Non-posted	Issuable	Issuable
Configuration Read Type0	0x4	Non-posted	Issuable	Issuing prohibited
Configuration Write Type0	0x5	Non-posted	Issuable	Issuing prohibited
Configuration Read Type1	0x6	Non-posted	Issuable	Issuing prohibited
Configuration Write Type1	0x7	Non-posted	Issuable	Issuing prohibited
Message Request	0x8	Posted	Issuable	Issuable
Message Request with data payload	0x9	Posted	Issuable	Issuable
	Others	—	Issuing prohibited	Issuing prohibited

56.4.1.7 PCI_EP_INTXOUTS : PCI INTx Out Status Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0118

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	INTDS	INTCS	INTBS	INTAS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	INTAS	INTA Status It is set by sending an Assert INTA Message and cleared by sending a Deassert INTA Message. 0: Deassert 1: Assert	R
1	INTBS	INTB Status It is set by sending an Assert INTB Message and cleared by sending a Deassert INTB Message. 0: Deassert 1: Assert	R

Bit	Symbol	Function	R/W
2	INTCS	INTC Status It is set by sending an Assert INTC Message and cleared by sending a Deassert INTC Message. 0: Deassert 1: Assert	R
3	INTDS	INTD Status It is set by sending an Assert INTD Message and cleared by sending a Deassert INTD Message. 0: Deassert 1: Assert	R
31:4	—	These bits are read as 0.	R

The PCI_EP_INTXOUTS register can confirm the PCI INTx status issued by the unit with the interrupt input signal (INTX_EP_F*: active high). In addition, the value of this register is not reflected if the INTx message is asserted or deasserted by issuing a special request (prohibited operation). The PCI_EP_INTXOUTS register is only valid in endpoint mode.

56.4.1.8 PCI_EP_MSGRCVIE : Message Receive Interrupt Enable Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0120

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	MRIE	—	—	—	—	PMASNRI	PMPMERIE	PMETORIE	PMETOARIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
16	PMETOARIE	PME_TO_Ack Receive Interrupt Enable Enable control of MSG_INT assertion by PME_TO_Ack reception 0: Disable 1: Enable	R/W
17	PMETORIE	PME_Turn_Off Receive Interrupt Enable Enable control of MSG_INT assertion by PME_Turn_Off reception 0: Disable 1: Enable	R/W
18	PMPMERIE	PM_PME Receive Interrupt Enable Enable control of MSG_INT assert by PM_PME reception 0: Disable 1: Enable	R/W
19	PMASNRI	PM_Active_State_Nak Receive Interrupt Enable control of MSG_INT assertion by PM_Active_State_Nak reception 0: Disable 1: Enable	R/W
23:20	—	These bits are read as 0. The write value should be 0.	R/W
24	MRIE	Message Receive Interrupt Enable Enable control of MSG_INT assert by message reception 0: enable 1: disable	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_MSGRCVIE register controls enabling of MSG_INT in response to the reception of message requests other than INTx and error-related messages.

56.4.1.9 PCI_EP_MSGRCVIS : Message Receive Interrupt Status Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0124

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	MRI	—	—	—	—	PMASNR	PMPMERI	PMETORI	PMETOARI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
16	PMETOARI	PME_TO_Ack Receive Interrupt Set when receiving a PM_TO_Ack message	R/W
17	PMETORI	PME_Turn_Off Receive Interrupt Disabled due to RC	R/W
18	PMPMERI	PM_PME Receive Interrupt Set when receiving a PM_PME message	R/W
19	PMASNR	PM_Active_State_Nak Receive Disabled due to RC	R/W
23:20	—	These bits are read as 0. The write value should be 0.	R/W
24	MRI	Message Receive Interrupt Set when receiving a message (does not depend on the type of message)	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_MSGRCVIS register is a status register that indicates the reception of message requests other than INTx and error-related messages. The value of the PCI_EP_MSGRCVIS register is reflected in MSG_INT. Only the message code is used to decide the message type, and the corresponding message is assumed to have been received while the validity of the routing and the validity of the Msg/MsgD selection are not verified.

56.4.1.10 PCI_EP_MSGCODE : Message Code Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0130

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MC[7:0]								R[2:0]			—	—	—	—	MP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

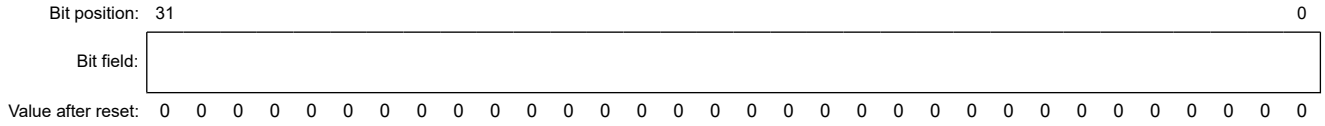
Bit	Symbol	Function	R/W
0	MP	Message Payload Stores the presence or absence of the data payload of the last received Message. When Power Management Message (PME_TO_Ack Message, PME_Turn_Off Message, PM_PME Message, PM_Active_State_Nak Message) is received, this register is not written. 0: Msg (Without Payload) 1: MsgD (with Payload)	R
4:1	—	These bits are read as 0.	R
7:5	R[2:0]	Routing Stores the Routing of the last received Message.	R
15:8	MC[7:0]	Message Code Stores the Code of the last received Message.	R
31:16	—	These bits are read as 0.	R

The PCI_EP_MSGCODE register stores the code and routing of the last received message.

56.4.1.11 PCI_EP_MSGDATA : Message Data Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0134



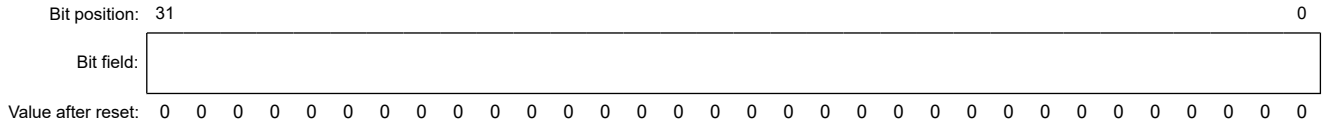
Bit	Symbol	Function	R/W
31:0	n/a	Message Data Stores the 1DW data of the last received Message. It is updated only when MsgD (with Data) is received, and the previous value is retained when Msg (without Data) is received. When Power Management Message (PME_TO_Ack Message, PME_Turn_Off Message, PM_PME Message, PM_Active_State_Nak Message) is received, this register is not written.	R

The PCI_EP_MSGDATA register stores the data of the last received message.

56.4.1.12 PCI_EP_MSGH3DW : Message Header 3rdDW Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0138



Bit	Symbol	Function	R/W
31:0	n/a	Message Header 3rdDW Stores the Header (3rdDW) of the last received Message.	R

The PCI_EP_MSGH3DW register stores the header (the 3rd DW) of the last received message.

56.4.1.13 PCI_EP_MSGH4DW : Message Header 4thDW Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x013C

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	Message Header 4thDW Registers Stores the Header (4thDW) of the last received Message.	R

The PCI_EP_MSGH4DW register stores the header (the 4th DW) of the last received message.

56.4.1.14 PCI_EP_INTTABLE : Interrupt Table Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0140

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DMA_INT[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	AXI_ERR_IN	PCIE_EVT_INT	MSG_INT	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0.	R
8	MSG_INT	Message interrupt signal monitor	R
9	PCIE_EVT_INT	Event interrupt signal monitor	R
10	AXI_ERR_IN	Error interrupt signal monitor	R
23:11	—	These bits are read as 0.	R
31:24	DMA_INT[7:0]	DMA_INT interrupt signal monitor	R

The PCI_EP_INTTABLE register is an index of interrupt factors. The interrupt signal (active high) status of each category can be monitored in a list.

56.4.1.15 PCI_EP_PEIE0 : PCIe Event Interrupt Enable 0 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0200

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	UI_LINK_WIDTH_CHANGE_DONE_EN	UI_LINK_SPEED_CHANGE_DONE_EN	RDEN	—	—	AXI_PERR_EN	CA_EN	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BME_PERR_EN	—	—	RX_DLLP_PM_ENTER_L23_EN	—	ASPML1REN	DLUDEN	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	—	These bits are read as 0. The write value should be 0.	R/W
9	DLUDEN	DL_UpDown EN Interrupt enable on DL state change 0: Disable 1: Enable	R/W
10	ASPML1REN	ASPM L1 Rejected interrupt enable 0: Disable 1: Enable	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
12	RX_DLLP_PM_ENTER_L23_EN	RX_DLLP_PM_ENTER_L23 interrupt enable 0: Disable 1: Enable	R/W
14:13	—	These bits are read as 0. The write value should be 0.	R/W
15	BME_PERR_EN	Enable BME Parity Error interrupt. (Parity Error in AXI bridge internal RAM) 0: Disable 1: Enable	R/W
23:16	—	These bits are read as 0. The write value should be 0.	R/W
24	CA_EN	CA (Completer Abort) interrupt enable 0: Disable 1: Enable	R/W
25	AXI_PERR_EN	Enable AXIM RAM parity error interrupt 0: Disable 1: Enable	R/W
27:26	—	These bits are read as 0. The write value should be 0.	R/W
28	RDEN	Request complete interrupt enable 0: Disable 1: Enable	R/W
29	UI_LINK_SPEED_CHANGE_DONE_EN	Speed change operation completion interrupt enable 0: Disable 1: Enable	R/W
30	UI_LINK_WIDTH_CHANGE_DONE_EN	Up/Down Configure operation complete interrupt enable 0: Disable 1: Enable	R/W

Bit	Symbol	Function	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The PCI_EP_PEIE0 register enables interrupts of each PCI Express event factors. The PCI_EP_PEIE0 register enables writing to the PCIe Event Interrupt Status 0 Register (address: <PCI_S0_REG_base> + 0x0204).

56.4.1.16 PCI_EP_PEIS0 : PCIe Event Interrupt Status 0 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0204

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	UI_LINK_WIDTH_CHANGE_DONE	UI_LINK_SPEED_CHANGE_DONE	RD	—	—	AXIM_PERR	CA	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BME_PERR	—	—	RX_DLLP_PM_ENTER_L23	—	ASPML1	DLUDEN	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	—	These bits are read as 0. The write value should be 0.	R/W
9	DLUDEN	DL_UpDown EN Set to 1 on transition from DL_Down state to DL_Up state, or DL_Up state to DL_Down state. Check the DL_Down/DL_Up status with PCIe Core Status 1 Registers (Offset: 0x408).	R/W
10	ASPML1	ASPM L1 It is recommended not to use (permit) in Endpoint mode.	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
12	RX_DLLP_PM_ENTER_L23	Indicates transition to L2/L3 State in Power Management control.	R/W
14:13	—	These bits are read as 0. The write value should be 0.	
15	BME_PERR	Indicates that a parity error has occurred in the BME RAM.	
23:16	—	These bits are read as 0. The write value should be 0.	R/W
24	CA	Indicates that the device has responded with CA (Completer Abort).	R/W
25	AXIM_PERR	Indicates that a parity error has occurred in the AXIM RAM. (Parity Error in AXI bridge internal RAM)	R/W
27:26	—	These bits are read as 0. The write value should be 0.	R/W
28	RD	Request Done For requests submitted in the Request Issue Registers (Offset: 0x9C): Non-Posted: Indicates that Completion has been received. Posted: Indicates that the request has finished being submitted.	R/W
29	UI_LINK_SPEED_CHANGE_DONE	Indicates completion of Speed Change operation.	R/W
30	UI_LINK_WIDTH_CHANGE_DONE	Indicates completion of Up/DownConfigure operation.	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The PCI_EP_PEIS0 register is a status register to indicate interrupts of each PCI Express event factors. Set to 1 by the factor in the table. After checking the factor, write 1 to the corresponding bit to clear it.

56.4.1.17 PCI_EP_PEIE1 : PCIe Event Interrupt Enable 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0208

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXB_PARITY_ERR_EN	ERR_RPC_REPLAYFIFO_PERR_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ERR_REPLAY_UPPER_CORRECTABLE_ERROR_EN	ERR_REPLAY_LOWER_CORRECTABLE_ERROR_EN	—	—	—	—	—	—	ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR_EN	ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR_EN	Enable ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR interrupts. Interrupt notification enable setting when an error of ECC 2-bit or more (Uncorrectable Error) occurs in the lower 64-bit data bus of the Replay FIFO installed in the Data Link Layer 0: Disable 1: Enable	R/W
1	ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR_EN	Enable ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR interrupts. Interrupt notification enable setting when an error of ECC 2-bit or more (Uncorrectable Error) occurs in the upper 64-bit data bus of the Replay FIFO installed in the Data Link Layer 0: Disable 1: Enable	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	ERR_REPLAY_LOWER_CORRECTABLE_ERROR_EN	Enable ERR_REPLAY_LOWER_CORRECTABLE_ERROR interrupts. Interrupt notification enable setting when an ECC 1-bit error (Correctable Error) occurs in the lower 64-bit data bus of the Replay FIFO installed in the Data Link Layer 0: Disable 1: Enable	R/W
9	ERR_REPLAY_UPPER_CORRECTABLE_ERROR_EN	Enable ERR_REPLAY_UPPER_CORRECTABLE_ERROR interrupts. Interrupt notification enable setting when an ECC 1-bit error (Correctable Error) occurs in the upper 64-bit data bus of the Replay FIFO installed in the Data Link Layer 0: Disable 1: Enable	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	ERR_RPC_REPLAYFIFO_PERR_EN	Enable ERR_RPC_REPLAYFIFO_PERR interrupts. Parity error interrupt notification enable setting for Replay FIFO installed in Data Link Layer 0: Disable 1: Enable	R/W

Bit	Symbol	Function	R/W
17	TXB_PARITY_ERR_EN	Enable the TXB_PARITY_ERR interrupt. Parity error interrupt notification enable setting for TX Buffer installed in Transaction Layer 0: Do not allow 1: Allow	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_PEIE1 register enables parity error and ECC error interrupts. When each bit is set to the valid setting, the value of each corresponding status bit of the PCIe Event Interrupt Status 1 register (address: <PCI_S0_REG_base> + 0x020C) becomes valid.

56.4.1.18 PCI_EP_PEIS1 : PCIe Event Interrupt Status 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x020C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXB_PARITY_ERR	ERR_RPC_REPLAYFIFO_PERR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ERR_REPLAY_UPPER_CORRECTABLE_ERROR	ERR_REPLAY_LOWER_CORRECTABLE_ERROR	—	—	—	—	—	—	ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR	ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR	ERR_REPLAY_LOWER_UNCORRECTABLE_ERROR interrupt Interrupt notification when an ECC 2-bit or more error (Uncorrectable Error) occurs in the lower 64-bit data bus of the Replay FIFO installed in the Data Link Layer	R/W
1	ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR	ERR_REPLAY_UPPER_UNCORRECTABLE_ERROR interrupt Interrupt notification when an ECC 2-bit or more error (Uncorrectable Error) occurs in the upper 64-bit data bus of the Replay FIFO installed in the Data Link Layer	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	ERR_REPLAY_LOWER_CORRECTABLE_ERROR	ERR_REPLAY_LOWER_CORRECTABLE_ERROR interrupt Interrupt notification when an ECC 1-bit error (Correctable Error) occurs in the lower 64-bit data bus of the Replay FIFO installed in the Data Link Layer	R/W
9	ERR_REPLAY_UPPER_CORRECTABLE_ERROR	ERR_REPLAY_UPPER_CORRECTABLE_ERROR interrupt Interrupt notification when an ECC 1-bit error (Correctable Error) occurs in the upper 64-bit data bus of the Replay FIFO installed in the Data Link Layer	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	ERR_RPC_REPLAYFIFO_PERR	ERR_RPC_REPLAYFIFO_PERR interrupt Parity error interrupt notification of Replay FIFO installed in Data Link Layer	R/W
17	TXB_PARITY_ERR	TXB_PARITY_ERR interrupt Parity error interrupt notification of TX Buffer installed in Transaction Layer	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_PEIS1 register is a status register that indicates parity error and ECC error interrupts. After checking the factor, write 1 to the corresponding bit to clear it.

56.4.1.19 PCI_EP_AMEIE : AXI Master Error Interrupt Enable Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0210

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	WMSTERRINTEN[3:0]				—	—	—	—	RMSTERRINTEN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	RMSTERRINTEN[3:0]	Read MSTERR INT Enable Each corresponding bit can be turned on/off individually. 0: Disable 1: Enable	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
11:8	WMSTERRINTEN[3:0]	Write MSTERR INT Enable Each corresponding bit can be turned on/off individually. 0: Disable 1: Enable	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_AMEIE register enables the AXI master error interrupt.

56.4.1.20 PCI_EP_AMEIS : AXI Master Error Interrupt Status Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0214

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	WERRID[3:0]				—	—	—	—	RERRID[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	WMSTERRINT[3:0]				—	—	—	—	RMSTERRINT[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	RMSTERRINT[3:0]	Read MSTERR INT Indicates that an error was detected in the AXI Master Port. Only the first detected error is saved, and when bit [3:0] is cleared, a new error can be saved. Cleared by writing 1. Bit 3: Length Error When the length of the data received on the TER and the data channel do not match. Bit 2: ID Mismatch When the MARID and MRID values received on the data channel are different. Bit 1: When DECERR is received Bit 0: When SLVERR is received	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
11:8	WMSTERRINT[3:0]	Write MSTERR INT Indicates that an error was detected in the AXI Master Port. Only the first detected error is saved, and when bit [11:8] is cleared, a new error can be saved. Cleared by writing 1. Bit 11: Length Error When the length of the data sent by the TEF and the data channel do not match. Bit 10: ID Mismatch When the MBID value received on the MAWID response channel is different. Bit 9: When DECERR is received Bit 8: When SLVERR is received	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
19:16	RERRID[3:0]	Read ERR ID Save the ID of the first DECERR/SLVERR received. A new error ID can be saved when bit [3:0] is cleared. 0x0: normal access Others: Error ID	R
23:20	—	These bits are read as 0. The write value should be 0.	R/W
27:24	WERRID[3:0]	Write ERR ID Save the ID of the first DECERR/SLVERR received. When bit [11:8] is cleared, a new error ID can be saved. 0x0: normal access Others: Error ID	R
31:28	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_AMEIS register indicates the AXI master error interrupt status.

56.4.1.21 PCI_EP_ASEIE1 : AXI Slave Error Interrupt Enable 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0220

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	WSLVERRINTEN[3:0]				—	—	—	—	—	—	RSLVERRINTEN[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RSLVERRINTEN[1:0]	Read SLVERR INT EN Enable Read SLVERR INT. Each corresponding bit can be turned on/off individually. 0: Disable 1: Enable	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
11:8	WSLVERRINTEN[3:0]	Write SLVERR INT EN Enable Write SLVERR INT. Each corresponding bit can be turned on/off individually. 0: Disable 1: Enable	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_ASEIE1 register enables the AXI slave error interrupt.

56.4.1.22 PCI_EP_ASEIS1 : AXI Slave Error Interrupt Status 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0224

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	WSLVERRINT[3:0]				—	—	—	—	—	—	RSLVERRINT[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RSLVERRINT[1:0]	Read SLVERR INT Indicates that an unrecoverable error was detected in the AXI Slave Port. (Transaction response will be SLVERR.) Cleared by writing 1. Bit 1: Burst Type Disabled When SARBURST is 11b (undefined). When SARBURST is 10b (wrapping) and burst length is other than 2, 4, 8, or 16. Bit 0: Data Size Invalid When SARSIZE is (exceeding AXI Bus width/not supported). Each bit means: 0: No error detected 1: error detection	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
11:8	WSLVERRINT[3:0]	Write SLVERR INT Indicates that an unrecoverable error was detected in the AXI Slave Port. (Transaction response will be SLVERR.) Cleared by writing 1. Bit 11: Burst Length Error When the SAWLEN and the burst length of the data received on the data channel do not match. Bit 10: ID Mismatch When the SAWID and SWID values received on the data channel are different. Bit 9: Burst Type Disabled When SAWBURST is 11b (undefined). When SAWBURST is 10b (wrapping) and burst length is other than 2, 4, 8, or 16. Bit 8: Data Size Invalid When SAWSIZE is between 100b and 111b (Exceeding AXI Bus width/not supported). Each bit means: 0: No error detected 1: error detection	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_ASEIS1 register indicates the AXI slave error interrupt status.

56.4.1.23 PCI_EP_ASEIS3 : AXI Slave Error Interrupt Status 3 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0230

Bit position:	31	0
Bit field:		
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	n/a	ERR ID Save the ID when the first error occurred in the AXI Slave Error Interrupt Status1 register (Offset 0x224). Only the first detected error is saved, and when bit[11:8] and bit[1:0] of the AXI Slave Error Interrupt Status1 register are all cleared, a new error ID can be saved.	R

The PCI_EP_ASEIS3 register indicates the AXI ID at the time of the first AXI slave error.

56.4.1.24 PCI_EP_PEIE2 : PCIe Event Interrupt Enable 2 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0240

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LTR_MECHANISM_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	D3_HOT_ERR_EN[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
15:8	D3_HOT_ERR_EN[7:0]	D3_hot_err_EN When Completion is in Pending state (ORT_TRANSACTION_PENDING = 1), transition to D3hot state (CFG_POWERSTATE! = 0) or receive PME_TURN_OFF Message, detect the state when D3_EVENT_ACK/TURN_OFF_EVENT_ACK is asserted Interrupt enable for D3_hot_err status detection Bit[15:10] are not used. Lower 2 bits corresponds to each function.	R/W
16	LTR_MECHANISM_EN	Interrupt enable for the ability to detect changes in CFG_LTR_MECHANISM	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_PEIE2 register enables interrupts of the various PCI Express event factors. The PCI_EP_PEIE2 register enables writing to the PCIe Event Interrupt Status 2 Register (PCI_EP_PEIS2).

56.4.1.25 PCI_EP_PEIS2 : PCIe Event Interrupt Status 2 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0244

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LTR_MECHANISM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	D3_HOT_ERR[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	D3_HOT_ERR[7:0]	D3_hot_err Status that detects and notif ies the state when D3_EVENT_ACK/ TURN_OFF_EVENT_ACK is asserted when transition to D3hot state (CFG_POWERSTATE! = 0) or PME_TURN_OFF Message is received in Completion Pending state (ORT_TRANSACTION_PENDING = 1) Bit[15:10] are not used. Lower 2 bit corresponds to each function. Cleared by writing 1.	R/W
16	LTR_MECHANISM	Status to detect and notify changes in CFG_LTR_MECHANISM Cleared by writing 1.	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_PEIS2 register indicates the state of various PCI Express events.

56.4.1.26 PCI_EP_PERM : Permission Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0300

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PHY_REG_CLK_EN	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	PHY_REG_CLK_EN	Write enable for Physical Layer Control/Status Registers. 0: Disable 1: Enable	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

56.4.1.27 PCI_EP_RESET : Reset Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0310

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FTD0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	RST_PREG_B	RST_OUT_B	RST_PS_B	RST_LOAD_B	RST_CFG_B	RST_RSM_B	RST_GP_B	RST_B
Value after reset:	0	0	0	0	0	0	0	0	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
0	RST_B	Reset to PCI Express core part inside macro 0: reset 1: normal operation	R/W
1	RST_GP_B	Reset to the PCI Express core part (ACLK domain) inside the macro 0: reset 1: normal operation	R/W
2	RST_RSM_B	POWERGOOD reset of AUX Power (AUX not supported) Reset to Sticky register. Reset to PHY. 0: reset 1: normal operation	R/W
3	RST_CFG_B	Reset to Configuration Register 0: Reset 1: normal operation	R/W
4	RST_LOAD_B	Reset to Configuration Register Reset to bits not initialized by RST_CFG_B. 0: reset 1: normal operation	R/W
5	RST_PS_B	Reset to the PCI Express core part (PCLK domain) inside the macro 0: reset 1: normal operation	R/W
6	RST_OUT_B	RST_OUT_B output 0: reset 1: normal operation	R/W
7	RST_PREG_B	Not used in this macro. The setting value does not affect macro behavior. 0: reset 1: normal operation	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W
16	FTD0	force to D0 After sending PME_TO_Ack, force PM Control to transition to D0 State. Auto-cleared when PM Control transitions to D0. This bit is normally prohibited as it can create inconsistencies with the power state of the entire system. 0: No operation 1: Transition to D0	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_RESET register resets the PCIe core. Supplied to the internal core. The write value is saved when accessed from the AXI, but a low-level pulse is generated when the PCIe writes 0. However, when the AXI has already written 0, the signal remains at the low level.

Writing 1 from the PCIe is ignored.

56.4.1.28 PCI_EP_MSET0 : Mode Set 0 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0314

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	AWPROT[2:0]			AWCACHE_L[3:0]				—	—	AWLOCK[1:0]		AWCACHE_D[3:0]			
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	ARPROT[2:0]			—	—	—	—	—	—	ARLOCK[1:0]		ARCACHE[3:0]			
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	ARCACHE[3:0]	Lock type for PCIe-to-AXI transactions. This bit provides information about the atomic nature of the transfer. 0 0: Normal access 0 1: Exclusive access 1 0: Locked access 1 1: Reserved	R/W
5:4	ARLOCK[1:0]	Lock type for PCIe-to-AXI transactions. This bit provides information about the atomic nature of the transfer. 0 0: Normal access 0 1: Exclusive access 1 0: Locked access 1 1: Reserved	R/W
11:6	—	These bits are read as 0. The write value should be 0.	R/W
14:12	ARPROT[2:0]	Sets the protection type for PCIe→AXI transactions. This bit indicates whether the transaction's protection level is Normal, Privileged, or Secure, and whether the transaction is a data or instruction access. [2] 1: instruction access / 0: data access [1] 1: non-secure access / 0: secure access [0] 1: privileged access / 0: normal access	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
19:16	AWCACHE_D[3:0]	Indicates the value of MAWCACHE[3:0] to be issued to AXI. This setting is output when issuing an AXI request other than the output condition of AWCACHE_L. *Recommended value is 0x1. [3] 1: write allocatable / 0: not write allocatable [2] 1: Read assignable / 0: Read assignable [1] 1: cacheable / 0: non-cacheable [0] 1: Bufferable / 0: Not Bufferable	R/W
21:20	AWLOCK[1:0]	Lock type for PCIe-to-AXI transactions. This signal provides information about the atomic nature of the transfer. 0 0: Normal access 0 1: Exclusive access 1 0: Locked access 1 1: Reserved	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
27:24	AWCACHE_L[3:0]	Indicates the value of MAWCACHE[3:0] to be issued to AXI. This setting is printed when issuing an AXI request containing the last byte. *Recommended value is 0x0. [3] 1: write allocatable / 0: not write allocatable [2] 1: Read assignable / 0: Read assignable [1] 1: cacheable / 0: non-cacheable [0] 1: Bufferable / 0: Not Bufferable	R/W
30:28	AWPROT[2:0]	Sets the protection type for PCIe→AXI transactions. This bit indicates whether the transaction's protection level is Normal, Privileged, or Secure, and whether the transaction is a data or instruction access. [2] 1: instruction access / 0: data access [1] 1: non-secure access / 0: secure access [0] 1: privileged access / 0: normal access	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The PCI_EP_MSET0 register sets AXI mode.

56.4.1.29 PCI_EP_MSET1 : Mode Set 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0318

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	AXIMIW[3:0]				AXIMIR[3:0]				AXIMMB[3:0]				—	—	RAMPE	PCIERO
Value after reset:	0	0	1	1	0	0	1	1	1	1	1	1	0	0	1	0

Bit	Symbol	Function	R/W
0	PCIERO	PCIe Request Order Issue a Read Request to PCIe from the same AXI master without waiting for Completion. Set to 1 if you want to strictly follow the order of Requests to the Completer. 0: Do not wait for Completion. 1: Wait for Completion.	R/W
1	RAMPE	RAM Parity Enable Sets whether or not to check the parity of the internal SRAM. The default value is Enable, but it is ignored by non-Parity macros. 0: RAM parity check disabled 1: RAM parity check enabled	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
7:4	AXIMMB[3:0]	AXI Master Max Burst Sets the maximum burst length as an AXI Master operation.	R/W
11:8	AXIMIR[3:0]	AXI Max Issue Read Set the number of read issues that can be issued by AXI Master. Set within the range allowed by Interconnect. 0x0: possible number 1 0x1: possible number 2 ⋮ 0xF: Possible number 16	R/W
15:12	AXIMIW[3:0]	AXI Max Issue Write Set the number of writes that can be issued by AXI Master. Set within the range allowed by Interconnect. 0x0: possible number 1 0x1: possible number 2 ⋮ 0xF: Possible number 16	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_MSET1 register sets AXI mode.

56.4.1.30 PCI_EP_MSET3 : Mode Set 3 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0380

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	ASPML1IT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ASPML1IT[7:0]	ASPM L1 Idle Time Sets the idle period for AXI transactions that the macro checks on ASPM L1 transitions. One of the conditions for ASPM L1 transition is that the idle period is confirmed for the number of cycles of the 8 bits set by this bit plus 0xFF to the lower 8 bits. 0x00: 256 [ACLK] 0x01: 512 [ACLK] ⋮ 0xFF: 65536 [ACLK]	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_MSET3 register outputs the setting value as the ASPM L1 Idle Time bit.

56.4.1.31 PCI_EP_MSET4 : Mode Set 4 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0384

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MODE_EQ_RX_EVAL_WAIT[19:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MODE_EQ_RX_EVAL_WAIT[19:0]				—	—	—	—	MODE_8GT_EQTS2	MODE_EQ_PHASE23_ENABLE1	MODE_EQ_AUTONOMOUS1	—	—	UI_EQ_REQTYPE[1:0]		UI_EQ_REQUEST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	UI_EQ_REQUEST	Set when sending an Equalization Request with Quiesce Guarantee = 1 in the Recovery.RcvrCfg state. 1 set prohibited except when MODE_QUIESCE_GUARANTEE = 1. After setting 1, hold until confirmation of UI_EQ_DONE = 1. 0: Do not send Equalization Request 1: Send Equalization Request	R/W

Bit	Symbol	Function	R/W
2:1	UI_EQ_REQTYPE[1:0]	Operation specification when sending Equalization Request with Quiesce Guarantee = 1 in Recovery.RcvrCfg state 0 0: Equalization Request transmission with Equalization Request Data Rate = 0 (8G) 0 1: Send Equalization Request with Equalization Request Data Rate = 1 (16G) (Setting prohibited) 1 0: Operation of 0 + set Link Equalization Request 8.0 GT/s register 1 1: Set 1 operation + Link Equalization Request 16.0 GT/s register (setting prohibited)	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	MODE_EQ_AUTONOMOUS1	Fixed 0	R/W
6	MODE_EQ_PHASE23_ENABLE1	Fixed 0	R/W
7	MODE_8GT_EQTS2	8GT EQ TS2OS transmission enable/disable setting for Upstream Port Note: Not used with Downsream Port. (fixed to 0) 0: Do not send 1: Send	R/W
11:8	—	These bits are read as 0. The write value should be 0.	R/W
31:12	MODE_EQ_RX_EVAL_WAIT[19:0]	During RxEval (Downstream Port Phase3, Upstream Port Phase2), wait time setting until RxEval is executed when Block Alignment cannot be obtained. Set by the count number of PCLK. Note: It is necessary to set the register value (recommended: equivalent to 1 msec) before starting. Please set from the local CPU.	R/W

56.4.1.32 PCI_EP_MSET5 : Mode Set 5 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0388

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MODE_8GT_EQTS2_PRESET[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MODE_8GT_EQTS2_PRESET[15:0]	Transmitter Preset value of 8GT EQ TS2OS to transmit at Upstream Port (USP). No setting is required if 8GT_EQTS2 is not sent from USP (DSP Preset is not specified). Settings must be made in advance if necessary. 4-bit configuration for each lane. Gen3 supports up to x2 lane configurations. The correspondence between each bit and lane number is as follows. [3:0] Lane #0 [7:4] Lane #1 (Not used in case of ch1) [11:8] Lane #2 (Not used. Fixed to 0x0) [15:12] Lane #3 (Not used. Fixed to 0x0) The above lane number is the default lane number for circuit implementation. Note that this is not a negotiated lane number. Note: Not used with Downsream Port. (fixed to 0x0000_0000)	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

56.4.1.33 PCI_EP_MSTAT0 : Mode Status 0 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0390

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	RX_EQ_REQTYPE[1:0]		RX_EQ_REQUEST	UI_EQ_DONE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	UI_EQ_DONE	Set Equalization Request with Quiesce Guarantee=1 in Recovery .RcvrCfg state when sending Related flow: "Set UI_EQ_REQUEST = 1 → Confirm UI_EQ_DONE = 1 → Clear UI_EQ_REQUEST = 0" 0: No Equalization Request sent 1: Sent Equalization Request	R
1	RX_EQ_REQUEST	Status display when receiving 8 consecutive TS2OS with Request Equalization bit (Symbol6, bit7) = 1 in Recovery.RcvrCfg state 0: No Equalization Request received 1: Equalization Request received	R
3:2	RX_EQ_REQTYPE[1:0]	Quiesce Guarantee and Equalization Request Data Rate bit display when receiv ing 8 consecutive TS2OS with Request Equalization bit (Symbol6, bit7) = 1 in Recovery.RcvrCfg state EP (USP) (1) When Request Equalization is received bit 0: Quiesce Guarantee (TS2OS, Symbol6, bit6) (= 1 fixed) bit 1: Equalization Request Data Rate (TS2OS, Symbol6, bit5) (2) When receiving EQTS2OS bit 0: 0 (fixed) bit 1: Equalization Request Data Rate (0: EQTS2, 1: 8GT EQTS2)	R
31:4	—	These bits are read as 0.	R

56.4.1.34 PCI_EP_PCMSET1 : PCIe Core Mode Set 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0400

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	ASPM_L1_INTERVAL_TIME[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	0	1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	MODE_LINK_UPCONFIGURE_CAPABILITY_DISABLED	—	MODE_TXSWING	—	MODE_SELECTABLE_DEEMPHASIS	—	—	—	—	—	—	MODE_PORT	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	MODE_PORT	Device type setting register. When the bit value of this register is fixed to the initial value 1, the setting of the MODE_PORT bit in PCIE_MODE register becomes valid. When the MODE_PORT bit in PCIE_MODE register is fixed to 1, the setting by this register bit becomes valid. 0: Endpoint 1: Root Complex	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	MODE_SELECTABLE_DEEMPHASIS	De-emphasis setting in Endpoint mode For Endpoint, set the De-emphasis value for 5.0 GT/s operation. Initial value of select_deemphasis variable described in PCIe Base Spec. 0: −6 dB (default) 1: −3.5dB	R/W
9	—	This bit is read as 0. The write value should be 0.	R/W
10	MODE_TXSWING	SerDes serial output amplitude control 0: Full swing mode (default) 1: Half swing mode	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
12	MODE_LINK_UPCONFIGURE_CAPABILITY_DISABLED	Setting of Link Upconfigure Capability bit of Training Sequence Ordered-set (TS-OS) When connecting with a Gen1 PCIe device, LinkUp may not occur unless this bit is 0. In that case, change it to 0 in F/W. 0: Link Upconfigure Capability bit = 1 setting 1: Link Upconfigure Capability bit = 0 setting (Gen1 x1)	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
27:16	ASPM_L1_INTERVAL_TIME[11:0]	Interval settings for ASPM L1 requests The PCIe Base Spec stipulates that ASPM L1 transition requests must not be accepted continuously within 10 µs, and this field sets the timer value to guard against this. Set so that ACLK cycle x set value is 10 µs or more. At ACLK: 400 [MHz] or higher, this bit setting value should be the value (1/16) of the lower 4 bits of the setting value of the above specifications, and set the clock number as the timer value setting. Settings of this product (Default): When ACLK = 400 MHz(2.5 ns): 4000(d)/16 = FA(h)	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_PCMSET1 register sets the operating mode of the PCI Express core.

56.4.1.35 PCI_EP_PCCTRL1 : PCIe Core Control 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0404

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	BLB_RELAX_ORDERING_EN	—	—	—	—	—	UI_ENTER_L1S	UI_ENTER_L1_STATUS	—	—	—	—	UI_ENTER_TXL0S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	MODE_QUIESCE_GUARANTEE	UI_ENTER_TXMODE_SRIS	MODE_EQ_AUTONOMOUS	MODE_EQ_PHASE23_ENABLE	MODE_RESET_EIEOS_INTERVALL0S	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	MODE_RESET_EIEOS_INTERVALL0S	Gen3 features: Reset EIEOS Interval information of bit 2, symbol 6 of TS1OS transmitted in Recovery.Equalization state	R/W
9	MODE_EQ_PHASE23_ENABLE	Gen3 features: Setting whether to execute EQ PHASE2 and EQ PHASE3 in RC mode (MODE_PORT=1). 0: Do not execute EQ PHASE2/3 1: Execute EQ PHASE2/3	R/W
10	MODE_EQ_AUTONOMOUS	Gen3 feature: Autonomous Equalization Basically only changeable during the reset period 0: Do not use Autonomous Mechanism 1: Use Autonomous Mechanisms	R/W
11	UI_ENTER_TXMODE_SRIS	Setting Clock Tolerance Compensation 0: SRNS (default) 1: SRIS (not supported)	R/W
12	MODE_QUIESCE_GUARANTEE	Symbol6 bit6 Quiesce Guarantee control bit of TS2OS 0: Set 0 to TS2OS (default) 1: Set 1 to TS2OS	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
16	UI_ENTER_TXL0S	TxL0s transition control 0: Do not perf orm ASPM L0s transition (default) 1: Execute ASPM L0s transition when internal conditions are satisfied	R/W
20:17	—	These bits are read as 0. The write value should be 0.	R/W
21	UI_ENTER_L1_STATUS	L1 transition status Read: 0: Normal operation (default) 1: L1 transition processing Write: Writing 1 clears the bit. When clearing the ALLOW_ENTER_L1 bit in the PCIE_MISC register during L1 transition process, clear this bit if this bit indicates 1. See section 56.7.9.2. Active State Power Management (ASPM).	R/W
22	UI_ENTER_L1S	L1SubState transition permission setting 0: L1SubState transition disabled (default) 1: L1SubState transition permission (setting prohibited)	R/W
27:23	—	These bits are read as 0. The write value should be 0.	R/W
28	BLB_RELAX_ORDERING_EN	Control of RO bit of Request to be sent 0: RO bit of Request TLP to be sent is always 0 (default) 1: A TLP can be sent with the RO bit of the Request TLP to be sent set to 1.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_PCCTRL1 register controls power management and LTSSM (Link Training Sequence State Machine) state transitions.

56.4.1.36 PCI_EP_PCSTAT1 : PCIe Core Status 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0408

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	TURN_OFF_EVENT_ACK	TURN_OFF_EVENT	—	—	—	—	—	—	—	—	BD	—
Value after reset:	0	0	0	0	x	0	0	0	0	0	0	0	0	0	x	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	LTSSM_STATE[6:0]							PMU_LINKSTATE[3:0]				—	—	STATE_VC0_NEGOTIATION_PENDING	DLDS
Value after reset:	0	x	x	x	x	x	x	x	x	x	x	x	0	x	x	x

Bit	Symbol	Function	R/W
0	DLDS	DL_Down status Indicates whether PCIe Core is in DL_Down or DL_Up state 0: DL_Up Status 1: DL_Down Status	R
1	STATE_VC0_NEGOTIATION_PENDING	Flow Control initialization operation monitor If this bit is 1, do not initiate a transaction from the AXI side. Check that this bit is 0 and DL_Down Status (bit[0]) is 0. 0: Indicates that Flow Control initialization is complete 1: Indicates that Flow Control initialization has not completed	R
3:2	—	These bits are read as 0.	R
7:4	PMU_LINKSTATE[3:0]	L-state monitor of power management control unit 0x4: L1 state 0x8: L2 state	R
14:8	LTSSM_STATE[6:0]	Indicates the state of the Link Training & Status State Machine in the PCIe Core Link. The following states are indicated by the upper 5 bits [14:10]. 000xxb: Detect 001xxb: Polling 010xxb: Config 01100b: L0 01101b: L1 0111xb: L2 100xxb: Recovery 101xxb: Disable 110xxb: Loopback	R
16:15	—	These bits are read as 0.	R
17	BD	bme_down Indicates that the PCIe core transmitter is in an unusable state.	R
25:18	—	These bits are read as 0.	R
26	TURN_OFF_EVENT	TURN_OFF_EVENT output signal monitor	R
27	TURN_OFF_EVENT_ACK	TURN_OFF_EVENT_ACK input signal monitor	R
31:28	—	These bits are read as 0.	R

The PCI_EP_PCSTAT1 register indicates the status of the power management in the PCI Express core.

56.4.1.37 PCI_EP_PCCTRL2 : PCIe Core Control 2 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0410

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	UI_LINK_WIDTH_CHANGE_ENABLE[7:0]								MODE_NODEEMPHASIS[1:0]		MODE_PRESET_ENABLE[4:0]					UI_LINK_WIDTH_CHANGE_REQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	UI_LINK_SPEED_CHANGE[1:0]		—	—	—	UI_LINK_CHANGE_AUTONOMOUS	—	—	—	UI_LINK_SPEED_CHANGE_REQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	UI_LINK_SPEED_CHANGE_REQ	Link Speed change request control Setting this bit to 1 requests to change the Link Speed to the speed set in bit [8] UI_LINK_SPEED_CHANGE field. By asserting it in the L0 state, it transitions to the Recovery state and performs negotiation with the peer device. PCIe Core Status 2 Register (Offset: 0x414) bit [28] Set to 0 after confirming that UI_LINK_SPEED_CHANGE_DONE has been asserted.	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	UI_LINK_CHANGE_AUTONOMOUS	Link Width/Speed change reason setting 0: reliability reason (change for reliability, direction of bandwidth reduction) 1: autonomous reason (intentional change)	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
9:8	UI_LINK_SPEED_CHANGE[1:0]	Link speed setting Set the Link Speed you want to change. 0 0: 2.5 GT/s 0 1: 5.0 GT/s 1 0: 8.0 GT/s 1 1: 16.0 GT/s (Setting prohibited)	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	UI_LINK_WIDTH_CHANGE_REQ	Link Width change request control Setting this bit to 1 issues a request to change the Link Width to the configuration set in bit [31:24] UI_LINK_WIDTHCHANGE_ENABLE field. By asserting it in the L0 state, it transitions from the Recovery state to the Configuration state, and performs negotiation with the other device. Set to 0 after confirming that PCIe Core Status 2 Register (Offset: 0x414) bit [29] UI_LINK_WIDTH_CHANGE_DONE is asserted. Available for Single Link structure. Prohibited to set for Multi Link structure or ch1.	R/W
21:17	MODE_PRESET_ENABLE[4:0]	Reduced Swing mode setting for Gen3 operation [0] 8GT/s Preset P0, 0: disable / 1: enable (default) [1] 8GT/s Preset P2, 0: disable / 1: enable (default) [2] 8GT/s Preset P7, 0: disable / 1: enable (default) [3] 8GT/s Preset P8, 0: disable / 1: enable (default) [4] 8GT/s Preset P10, 0: disable / 1: enable (default)	R/W
23:22	MODE_NODEEMPHASIS[1:0]	No de-emphasis mode setting for Gen1/Gen3 operation [0] Gen1 operation, 0: Normal operation mode (default) / 1: No de-emphasis mode [1] Gen3 operation, 0: Normal operation mode (default) / 1: No de-emphasis mode	R/W

Bit	Symbol	Function	R/W
31:24	UI_LINK_WIDTH_CHANGE_ENABLE[7:0]	Link Width setting to change Assert UI_LINK_WIDTH_CHANGE_REQ and set Lane to 1 to operate when Link Width change request is issued. The lower bit (bit [24]) drives Lane 0 and the most significant bit (bit [31]) drives Lane 7. In this module, bit [25:24] is valid for Single Link structure, and bit [24] is valid for Multi Link structure or ch1.	R/W

The PCI_EP_PCCTRL2 register controls the link speed/width change in the PCI Express core.

56.4.1.38 PCI_EP_PCSTAT2 : PCIe Core Status 2 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0414

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	UI_LINK_WIDTH_CHANGE_DONE	UI_LINK_SPEED_CHANGE_DONE	—	—	—	STATE_UPCONFIGURE_CAPABLE	—	STATE_NEGOTIATED_LANE_END[2:0]			—	STATE_NEGOTIATED_LANE_START[2:0]		
Value after reset:	0	0	x	x	0	0	0	x	0	x	x	x	0	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	STATE_RECEIVER_DETECTED[7:0]								STATE_DATA_RATE_IDENTIFIER_RECEIVED[7:0]							
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
7:0	STATE_DATA_RATE_IDENTIFIER_RECEIVED[7:0]	Link Speed display supported by the opposite device Displays the TS-OS Data Rate Identifier feed received from the peer device. Bit 0: Reserved Bit 1: 2.5 GT/s Data Rate Supported. Must be set to 1. Bit 2: 5.0 GT/s Data Rate Supported. Must be set to 1 if Bit 3 is 1. Bit 3: 8.0 GT/s Data Rate Supported. Bits 4 to 7: Reserved	R
15:8	STATE_RECEIVER_DETECTED[7:0]	Connection status display with other device Receiver Detection results are displayed. [0] Detect opposite device on Lane 0 [1] Detect peer device on Lane 1 (only for x2) [2] to [7] reserved	R
18:16	STATE_NEGOTIATED_LANE_START[2:0]	Displays the position of Lane Number 0 after Link Negotiation with the opposite device during n-lane operation. Used to check the state of the current working lane before changing the Link Width. Available for Single Link structure. Prohibited to set for Multi Link structure or ch1. 0 0 0: Lane 0 is Lane Number 0 0 0 1: Lane 1 is Lane Number 0 Others: Reserved	R
19	—	This bit is read as 0.	R
22:20	STATE_NEGOTIATED_LANE_END[2:0]	Displays the position of Lane Number (n-1) (meaning Lane 1 when n=2) after Link Negotiation with the opposite device during n-lane operation. Used to check the state of the current working lane before changing the Link Width. Available for Single Link structure. Prohibited to set for Multi Link structure or ch1. 0 0 0: Lane 0 is Lane Number (n-1) 0 0 1: Lane 1 is Lane Number (n-1) Others: Reserved	R
23	—	This bit is read as 0.	R

Bit	Symbol	Function	R/W
24	STATE_UPCONFIGURE_CAPABLE	Upconfigure Capable bit display of opposite device Indicates whether the peer device supports changing the direction of widening the Link Width. If this bit is 0, changing the Link Width will not restore the original Link Width.	R
27:25	—	These bits are read as 0.	R
28	UI_LINK_SPEED_CHANGE_DONE	Link Speed Change operation complete display PCIe Core Status 2 Registers (Offset: 0x410) bit [0] Notifies completion of Speed Change (1) by setting UI_LINK_SPEED_CHANGE_REQ. It is set to 0 by setting UI_LINK_SPEED_CHANGE_REQ to 0.	R
29	UI_LINK_WIDTH_CHANGE_DONE	Link Width Change operation complete display Notifies completion of Width Change (1) by setting PCIe Core Status 2 Register (Offset: 0x410) bit [16] UI_LINK_WIDTH_CHANGE_REQ. It is set to 0 by setting UI_LINK_WIDTH_CHANGE_REQ to 0. Available for Single Link structure. Prohibited to set for Multi Link structure or ch1.	R
31:30	—	These bits are read as 0.	R

The PCI_EP_PCSTAT2 register indicates the status of the link speed/width change in the PCI Express core.

56.4.1.39 PCI_EP_PCSTAT5 : PCIe Core Status 5 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x042C

Bit position:	31							24	23							16	15							8	7							0
Bit field:	SBME[7:0]								D3_EVENT[7:0]								D3_EVENT_ACK[7:0]								ORT_TRANSACTION_PENDING[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	x	x	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ORT_TRANSACTION_PENDING[7:0]	Outstanding Request Monitor by Function Other than the lower 2 bits Reserved (fixed to 0) Indicates whether or not there are Outstanding Requests (a state in which all Completions corresponding to Non-Posted Requests sent from the AXI side have not been received). Check with this bit that there is no Outstanding Request before requesting/permitting a transition to TxL0s/L1/L2. 0: State without Outstanding Request 1: State with Outstanding Request	R
15:8	D3_EVENT_ACK[7:0]	D3_EVENT_ACK signal monitor for each function Other than the lower 2 bits Reserved (fixed to 0)	R
23:16	D3_EVENT[7:0]	D3_EVENT signal monitor for each function Other than the lower 2 bits Reserved (fixed to 0)	R
31:24	SBME[7:0]	Suspend_bme Indicates the state in which the use of the PCIe core transmitter should be suppressed for each function. Other than the lower 2 bits Reserved (fixed to 0)	R

The PCI_EP_PCSTAT5 register indicates the status in the PCI Express core.

56.4.1.40 PCI_EP_DMAINTVEC0 : DMA Interrupt Vector 0 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x04D0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	DMA_CH3_MSI_EN	DMA_CH3_V[4:0]					—	—	DMA_CH2_MSI_EN	DMA_CH2_V[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	DMA_CH1_MSI_EN	DMA_CH1_V[4:0]					—	—	DMA_CH0_MSI_EN	DMA_CH0_V[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	DMA_CH0_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch0	R/W
5	DMA_CH0_MSI_EN	DMA Ch0 MSI Enable Reset to PHY. For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
12:8	DMA_CH1_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch1	R/W
13	DMA_CH1_MSI_EN	DMA Ch1 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
20:16	DMA_CH2_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch2	R/W
21	DMA_CH2_MSI_EN	DMA Ch2 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
28:24	DMA_CH3_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch3	R/W
29	DMA_CH3_MSI_EN	DMA Ch3 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_DMAINTVEC0 register specifies the interrupt vectors for interrupt notification from AXI to PCIe (MSI) during DMA transfer.

56.4.1.41 PCI_EP_DMAINTVEC1 : DMA Interrupt Vector 1 Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x04D4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	DMA_CH7_MSI_EN	DMA_CH7_V[4:0]					—	—	DMA_CH6_MSI_EN	DMA_CH6_V[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	DMA_CH5_MSI_EN	DMA_CH5_V[4:0]					—	—	DMA_CH4_MSI_EN	DMA_CH4_V[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	DMA_CH4_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch4	R/W
5	DMA_CH4_MSI_EN	DMA Ch4 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
12:8	DMA_CH5_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch5	R/W
13	DMA_CH5_MSI_EN	DMA Ch5 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
20:16	DMA_CH6_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch6	R/W
21	DMA_CH6_MSI_EN	DMA Ch6 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
28:24	DMA_CH7_V[4:0]	Vector value of MSI interrupt transmitted by DMAC Ch7	R/W
29	DMA_CH7_MSI_EN	DMA Ch7 MSI Enable For the RC function, MSI transmission is prohibited, so please fix it to 0. 0: Do not use MSI (DMA interrupt notification by DMA_INT interrupt) 1: Use MSI	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_DMAINTVEC1 register specifies the interrupt vectors for interrupt notification from AXI to PCIe (MSI) during DMA transfer.

56.4.1.42 PCI_EP_DMACTRL : DMAC Control Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0800

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	D_PMRS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	D_PMRS[2:0]	DMAC PCIe Max Read Request Size Set the upper limit of Read requests issued from the DMAC to PCIe. 0 0 0: 128 bytes (default) 0 0 1: 256 bytes 0 1 0: 512 bytes (not supported) 0 1 1: 1024 bytes (not supported) 1 0 0: 2048 bytes (not supported) 1 0 1: 4096 bytes (not supported) others: Reserved (prohibited)	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_DMACTRL register sets the maximum size of read requests which can be issued to the PCIe core as a DMAC function. Use the initial setting (128 bytes). This setting is common to all DMA channels.

56.4.1.43 PCI_EP_DMAINTE : DMAC Interrupt Enable Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0808

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CH7_ERR_EN	CH7_QUE_EMP_EN	CH7_STOP_EN	CH7_END_EN	CH6_ERR_EN	CH6_QUE_EMP_EN	CH6_STOP_EN	CH6_END_EN	CH5_ERR_EN	CH5_QUE_EMP_EN	CH5_STOP_EN	CH5_END_EN	CH4_ERR_EN	CH4_QUE_EMP_EN	CH4_STOP_EN	CH4_END_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CH3_ERR_EN	CH3_QUE_EMP_EN	CH3_STOP_EN	CH3_END_EN	CH2_ERR_EN	CH2_QUE_EMP_EN	CH2_STOP_EN	CH2_END_EN	CH1_ERR_EN	CH1_QUE_EMP_EN	CH1_STOP_EN	CH1_END_EN	CH0_ERR_EN	CH0_QUE_EMP_EN	CH0_STOP_EN	CH0_END_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CH0_END_EN	CH0 Completion Interrupt Enable 0: Disable 1: Enable	R/W
1	CH0_STOP_EN	CH0 Stop Interrupt Enable 0: Disable 1: Enable	R/W
2	CH0_QUE_EMP_EN	CH0 Que Empty Interrupt Enable 0: Disable 1: Enable	R/W

Bit	Symbol	Function	R/W
3	CH0_ERR_EN	CH0 Error Interrupt Enable 0: Disable 1: Enable	R/W
4	CH1_END_EN	CH1 Completion Interrupt Enable 0: Disable 1: Enable	R/W
5	CH1_STOP_EN	CH1 Stop Interrupt Enable 0: Disable 1: Enable	R/W
6	CH1_QUE_EMP_EN	CH1 Que Empty Interrupt Enable 0: Disable 1: Enable	R/W

14	CH3_QUE_EMP_EN	CH3 Que Empty Interrupt Enable 0: Disable 1: Enable	R/W
15	CH3_ERR_EN	CH3 Error Interrupt Enable 0: Disable 1: Enable	R/W
16	CH4_END_EN	CH4 Completion Interrupt Enable 0: Disable 1: Enable	R/W
17	CH4_STOP_EN	CH4 Stop Interrupt Enable 0: Disable 1: Enable	R/W
18	CH4_QUE_EMP_EN	CH4 Que Empty Interrupt Enable 0: Disable 1: Enable	R/W
19	CH4_ERR_EN	CH4 Error Interrupt Enable 0: Disable 1: Enable	R/W
20	CH5_END_EN	CH5 Completion Interrupt Enable 0: Disable 1: Enable	R/W

Bit	Symbol	Function	R/W
21	CH5_STOP_EN	CH5 Stop Interrupt Enable 0: Disable 1: Enable	R/W
22	CH5_QUE_EMP_EN	CH5 Que Empty Interrupt Enable 0: Disable 1: Enable	R/W
23	CH5_ERR_EN	CH5 Error Interrupt Enable 0: Disable 1: Enable	R/W
24	CH6_END_EN	CH6 Completion Interrupt Enable 0: Disable 1: Enable	R/W
25	CH6_STOP_EN	CH6 Stop Interrupt Enable 0: Disable 1: Enable	R/W
26	CH6_QUE_EMP_EN	CH6 Que Empty Interrupt Enable 0: Disable 1: Enable	R/W
27	CH6_ERR_EN	CH6 Error Interrupt Enable 0: Disable 1: Enable	R/W
28	CH7_END_EN	CH7 Completion Interrupt Enable 0: Disable 1: Enable	R/W
29	CH7_STOP_EN	CH7 Stop Interrupt Enable 0: Disable 1: Enable	R/W
30	CH7_QUE_EMP_EN	CH7 Que Empty Interrupt Enable 0: Disable 1: Enable	R/W
31	CH7_ERR_EN	CH7 Error Interrupt Enable 0: Disable 1: Enable	R/W

The PCI_EP_DMAINTE register enables interrupts from the individual DMA channels.

56.4.1.44 PCI_EP_DMAINTS : DMAC Interrupt Status Register

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x080C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CH7_ERR	CH7_QUE_EMP	CH7_STOP	CH7_END	CH6_ERR	CH6_QUE_EMP	CH6_STOP	CH6_END	CH5_ERR	CH5_QUE_EMP	CH5_STOP	CH5_END	CH4_ERR	CH4_QUE_EMP	CH4_STOP	CH4_END
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CH3_ERR	CH3_QUE_EMP	CH3_STOP	CH3_END	CH2_ERR	CH2_QUE_EMP	CH2_STOP	CH2_END	CH1_ERR	CH1_QUE_EMP	CH1_STOP	CH1_END	CH0_ERR	CH0_QUE_EMP	CH0_STOP	CH0_END
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CH0_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
1	CH0_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
2	CH0_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
3	CH0_ERR	Set when an error occurs during DMA transfer.	R/W
4	CH1_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
5	CH1_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
6	CH1_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
7	CH1_ERR	Set when an error occurs during DMA transfer.	R/W
8	CH2_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
9	CH2_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
10	CH2_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
11	CH2_ERR	Set when an error occurs during DMA transfer.	R/W
12	CH3_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
13	CH3_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
14	CH3_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
15	CH3_ERR	Set when an error occurs during DMA transfer.	R/W
16	CH4_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
17	CH4_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
18	CH4_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
19	CH4_ERR	Set when an error occurs during DMA transfer.	R/W

Bit	Symbol	Function	R/W
20	CH5_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
21	CH5_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
22	CH5_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
23	CH5_ERR	Set when an error occurs during DMA transfer.	R/W
24	CH6_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
25	CH6_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
26	CH6_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
27	CH6_ERR	Set when an error occurs during DMA transfer.	R/W
28	CH7_END	Set when the DMAC ends normally. Normal termination refers to the following conditions. ● Transfer for the amount indicated by DMA_SIZE is completed. ● At the end of the descriptor list when the EI field is 1.	R/W
29	CH7_STOP	Set when the DMAC is prematurely stopped. DMA stops under the following conditions: ● When RDMA_EN or QUE_EN is cleared to 0 by the S/W during DMA transfer execution and the processing of the request being issued ends.	R/W
30	CH7_QUE_EMP	Set when the list is removed from the descriptor queue (transferred to the execution descriptor list) and the QUE is empty.	R/W
31	CH7_ERR	Set when an error occurs during DMA transfer.	R/W

The PCI_EP_DMAINTS register indicates the state of interrupts from the individual DMA channels. Writing 1 clears the bit.

56.4.1.45 PCI_EP_DMACHCTLn : DMAC Channel Control Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0900 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	QUE_CLR	—	—	—	—	—	—	QUE_EN	RDMA_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RDMA_EN	Register method DMA transfer Enable Setting this bit to 1 starts DMA transfer (register method) and performs the transfer set by RDMA_SIZE. This bit is automatically cleared to 0 when DMA transfer is completed or an error is detected and DMA ends. It is also possible to stop DMA by writing 0. However, DMA will stop after completing the currently executing request (both PCIe and AXI). 0: Stop register-based DMA transfer 1: Register method DMA transfer start	R/W
1	QUE_EN	QUE Enable Setting this bit to 1 enables the descriptor list registered in the descriptor queue and starts DMA transfer (descriptor method). It is automatically cleared to 0 when DMA stops (both normal and abnormal). It is also possible to stop DMA by writing 0. However, DMA will stop after finishing the currently executing request (both PCIe and AXI).	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	QUE_CLR	QUE Clear Writing 1 clears QUE. All descriptor lists (waiting for execution and lists currently being executed) registered in QUE are cleared. Do not clear during DMA execution. The read value is always 0. 1Write is prohibited at the same time as QUE_EN Set	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_DMACHCTLn register sets the control method for each DMA channel. Set either register type or descriptor type.

- Setting QUE_EN = 1 and QUE_CLR = 1 is prohibited during register-type DMA transfer (TDMA_EN = 1).
- Setting RDMA_EN = 1 is prohibited during descriptor-type DMA transfer (QUE_EN = 1).

56.4.1.46 PCI_EP_DPSADRLn : Descriptor Start Address (Lower) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0908 + 0x80 × n

Bit position:	31																								6	5					0
Bit field:	QUE_ENTRY_DSA3106[25:0]																									QUE_ENTRY_DSA0500[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	QUE_ENTRY_DSA0500[5:0]	Descriptor list queue registration register. This area will be the DSA. Sets the lower 32 bits of the address where the first descriptor is stored. (16 byte align: Lower 6 bit is fixed to 0.)	R
31:6	QUE_ENTRY_DSA3106[25:0]	Descriptor list queue registration register. This area will be the DSA. Sets the lower 32 bits of the address where the first descriptor is stored.	R/W

Note: When these bits are read, the following contents will be the read value depending on the state of DMA.
DMA transfer in progress: The descriptor list in progress
DMA suspended (when QUE_EN is automatically cleared): Last executed list
DMA suspended (when QUE_EN S/W is cleared): Suspended (executing) list

The PCI_EP_DPSADRLn register sets the descriptor queue list.

The setting value is registered as the lower 32 bits of DSA (DMA Start Address) in the queue list.

56.4.1.47 PCI_EP_DPSADRUn : Descriptor Start Address (Upper) Registers n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x090C + 0x80 × n

Bit position:	31																												0
Bit field:	QUE_ENTRY_DSA6332[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	QUE_ENTRY_DSA6332[31:0]	Descriptor list queue registration register. This area will be the DSA. Set the upper 32 bits of the address where the first descriptor is stored.	R/W

Note: When these bits are read, the following contents will be the read value depending on the state of DMA.
DMA transfer in progress: The descriptor list in progress
DMA suspended (when QUE_EN is automatically cleared): Last executed list
DMA suspended (when QUE_EN S/W is cleared): Suspended (executing) list

The PCI_EP_DPSADRUn register sets the descriptor queue list.

The setting value is registered as the upper 32 bits of DSA (DMA Start Address) in the queue list.

56.4.1.48 PCI_EP_QUEEn : QUE Entry Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0910 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	QUE_R[5:0]						QUE_ENTRY_EI	QUE_ENTRY_LS	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	QUE_ENTRY_LABEL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	QUE_ENTRY_LABEL[15:0]	There is no particular rule on how to set the labels in the list. You can set the value freely.	R/W
23:16	—	These bits are read as 0. The write value should be 0.	R/W
24	QUE_ENTRY_LS	Indicates whether to stop the DMA when processing of the descriptor list is complete. 0: do not stop 1: stop	R/W
25	QUE_ENTRY_EI	Indicates whether an interrupt (Interrupt Status CHx_END) is sent when the processing of the descriptor list is completed. 0: Do not signal interrupts 1: signal an interrupt	R/W
31:26	QUE_R[5:0]	QUE_Registration Enqueued by writing to [31:24]. The read value is always 0.	R/W

Note: When these bits are read, the following contents will be the read value depending on the state of DMA.
DMA transfer in progress: The descriptor list in progress
DMA suspended (when QUE_EN is automatically cleared): Last executed list
DMA suspended (when QUE_EN S/W is cleared): Suspended (executing) list

The PCI_EP_QUEEn register sets the descriptor queue list.

The setting value is registered as EI (End Interrupt), LS (List Stop), and LABEL of the queue list. Write to [31:24] to register to the queue.

56.4.1.49 PCI_EP_DMADPCTLn : DMA Descriptor Control (Descriptor 0x00) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0920 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DSCFM[3:0]				—	WBD	LE	LV	D	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	STS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	STS[15:0]	Shows the value of the STS field in the running descriptor table.	R
22:16	—	These bits are read as 0.	R
23	D	Shows the value of the D field in the running descriptor table.	R
24	LV	Shows the value of the LV field in the running descriptor table.	R
25	LE	Shows the value of the LE field in the running descriptor table.	R
26	WBD	Shows the value of the WBD field in the running descriptor table.	R
27	—	This bit is read as 0.	R
31:28	DSCFM[3:0]	Shows the value of the DSCFM field in the running descriptor table.	R

The PCI_EP_DMADPCTLn register indicates the field value at offset 0x00 in the descriptor table. Only effective when the descriptor-type DMA transfer is selected (the value read has no meaning in the case of register-type transfer).

56.4.1.50 PCI_EP_DMATCTLn : DMA Transaction Control (Descriptor 0x04) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0924 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	CCH_L[3:0]				CCH_D[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	DMA_TC[2:0]			—	—	DMA_ATB[1:0]		—	DMA_FUNC[2:0]			—	—	—	DMA_DIR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DMA_DIR	Sets the DMA transfer direction. 0: PCIe to AXI 1: AXI to PCIe	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
6:4	DMA_FUNC[2:0]	Specify the function number of the request issued to PCIe.	R/W

Bit	Symbol	Function	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
9:8	DMA_ATB[1:0]	Attributes to publish to PCIe. bit [1]: Relaxed Ordering (Unsupported function: 0 fixed) bit [0]: No Snoop (0 recommended)	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
14:12	DMA_TC[2:0]	Traffic class to publish to PCIe. Specifies the traffic class value for requests issued to PCIe. Note: This IP does not support Virtual Channel, so please use it with 000b fixed.	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
19:16	CCH_D[3:0]	Indicates the value of A*CACHE[3:0] to be issued to AXI. CCH_D is output when issuing an AXI request other than the output condition of CCH_L. The recommended value is 0x1 when DIR = 0 (PCIe→AXI) and 0x0 when DIR = 1 (AXI→PCIe). [3] 1: write allocatable / 0: not write allocatable [2] 1: Read assignable / 0: Read assignable [1] 1: cacheable / 0: non-cacheable [0] 1: Bufferable / 0: Not Bufferable	R/W
23:20	CCH_L[3:0]	Indicates the value of A*CACHE[3:0] to be issued to AXI. CCH_L is output when issuing an AXI request containing the last byte in a transfer indicated by SIZE. Recommended value is 0x0. [3] 1: write allocatable / 0: not write allocatable [2] 1: Read assignable / 0: Read assignable [1] 1: cacheable / 0: non-cacheable [0] 1: Bufferable / 0: Not Bufferable	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: When executing descriptor method DMA, writing is prohibited and the read value indicates the values of the CCH_L, CCH_D, TC, ATB, and DIR fields of the descriptor table being executed.

The PCI_EP_DMATCTLn register controls DMA transfer to the AXI and PCIe.

56.4.1.51 PCI_EP_DMASIZEn : DMA Size (Descriptor 0x08) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0928 + 0x80 × n

Bit position:	31																										3	2		0
Bit field:	DMA_SIZE3104[27:0]																										DMA_SIZE 0300[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	DMA_SIZE0300[3:0]	Sets the number of DMA transfer bytes. The lower 4 bits are fixed to 0 because it is an 16-byte aligned setting.	R
31:4	DMA_SIZE3104[27:0]	Sets the number of DMA transfer bytes. The lower 4 bits are fixed to 0 because it is an 16-byte aligned setting.	R/W

Note: When executing descriptor method DMA, writing is prohibited and the read value indicates the value of the SIZE field of the descriptor table being executed. The number of transfer bytes when 0x0000_0000 is set is 0x1_0000_0000.

The PCI_EP_DMASIZEn register sets the number of bytes for DMA transfer. Reflects the field at offset 0x0C in the descriptor table.

56.4.1.52 PCI_EP_DMASLAn : DMA Source Lower Address (Descriptor 0x10) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0930 + 0x80 × n

Bit position:	31																											3	2	0
Bit field:	DMA_S_ADDR3104[27:0]																											DMA_S_ADDR0300[3:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	DMA_S_ADDR0300[3:0]	Set the lower 32 bits of the transfer source start address for DMA transfer. The lower 4 bits are fixed to 0 because it is an 16-byte aligned setting.	R
31:4	DMA_S_ADDR3104[27:0]	Set the lower 32 bits of the transfer source start address for DMA transfer. The lower 4 bits are fixed to 0 because it is an 16-byte aligned setting.	R/W

Note: If the Source Address indicates the PCIe space (DIR = 0), the PCIe request address is set in combination with the DMA PCIe Upper Address (Descriptor 0x10). When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the SA field in the descriptor table being executed.

The PCI_EP_DMASLAn register sets the lower 32 bits of the source start address for DMA transfer. It is reflected to the offset 0x10 field of the descriptor table.

56.4.1.53 PCI_EP_DMASUAn : DMA Source Upper Address (Descriptor 0x14) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0934 + 0x80 × n

Bit position:	31																													0
Bit field:	DMA_S_ADDR6332[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DMA_S_ADDR6332[31:0]	Set the upper 32 bits of the transfer source start address for MA transfer.	R/W

Note: If the Source Address indicates the PCIe space (DIR = 0), the PCIe request address is set in combination with the DMA PCIe Upper Address (Descriptor 0x10). When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the SA field in the descriptor table being executed.

The PCI_EP_DMASUAn register sets the upper 32 bits of the source start address for DMA transfer. It is reflected to the offset 0x14 field of the descriptor table.

56.4.1.54 PCI_EP_DMADESTLAn : DMA Destination Lower Address (Descriptor 0x18) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0938 + 0x80 × n

Bit position:	31																											3	2	0
Bit field:	DMA_D_ADDR3104[27:0]																											DMA_D_ADDR0300[3:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	DMA_D_ADDR0300[3:0]	Set the lower 32 bits of the transfer destination start address for DMA transfer. The lower 4 bits are fixed to 0 because it is an 16-byte aligned setting.	R
31:4	DMA_D_ADDR3104[27:0]	Set the lower 32 bits of the transfer destination start address for DMA transfer. The lower 4 bits are fixed to 0 because it is an 16-byte aligned setting.	R/W

Note: If the Destination Address indicates the PCIe space (DIR = 1), the PCIe request address is set in combination with the DMA PCIe Upper Address (Descriptor 0x10). When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the DA field in the descriptor table being executed.

The PCI_EP_DMADESTLAn register sets the lower 32 bits of the source start address for DMA transfer. It is reflected to the offset 0x18 field of the descriptor table.

56.4.1.55 PCI_EP_DMADESTUAn : DMA Destination Upper Address (Descriptor 0x1C) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x093C + 0x80 × n

Bit position:	31																													0
Bit field:	DMA_D_ADDR6332[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DMA_D_ADDR6332[31:0]	Set the upper 32 bits of the transfer destination start address for DMA transfer.	R/W

Note: If the Destination Address indicates the PCIe space (DIR = 1), the PCIe request address is set in combination with the DMA PCIe Upper Address (Descriptor 0x10). When descriptor-type DMA transfer is in process, writing to these bits is prohibited and the value read indicates the value of the DA field in the descriptor table being executed.

The PCI_EP_DMADESTUAn register sets the upper 32 bits of the source start address for DMA transfer. It is reflected to the offset 0x1C field of the descriptor table.

56.4.1.56 PCI_EP_DMADPLLPn : DMA Descriptor Lower Link Pointer (Descriptor 0x20) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0940 + 0x80 × n

Bit position:	31																													0
Bit field:	DMA_LP3100[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DMA_LP3100[31:0]	Indicates the value of the LP field of the running descriptor table.	R

The PCI_EP_DMADPLLPn register indicates the field value at offset 0x1C in the descriptor table. Only effective when the descriptor-type DMA transfer is selected (the value read has no meaning in the case of register-type transfer).

56.4.1.57 PCI_EP_DMADPULPn : DMA Descriptor Upper Link Pointer (Descriptor 0x24) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0944 + 0x80 × n

Bit position:	31																												0
Bit field:	DMA_LP6332[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	DMA_LP6332[31:0]	Indicates the value of the LP field of the running descriptor table.	R

The PCI_EP_DMADPULPn register indicates the field value at offset 0x1C in the descriptor table. Only effective when the descriptor-type DMA transfer is selected (the value read has no meaning in the case of register-type transfer).

56.4.1.58 PCI_EP_DMARESTSIZEn : DMA Rest Size Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0950 + 0x80 × n

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	DMA_REST_SIZE Displays the number of bytes for which DMA transfer has not been completed. (Register/ descriptor method common)	R

The PCI_EP_DMARESTSIZEn register indicates the number of bytes for which DMA transfer has not yet been completed.

56.4.1.59 PCI_EP_AREQALn : AXI Request Address (Lower) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0960 + 0x80 × n

Bit position:	31																												0
Bit field:	AXI_REQ_ADDR3100[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	AXI_REQ_ADDR3100[31:0]	Displays the lower 32 bits of the address of the currently completed AXI transfer or the transfer that just completed. (Register/descriptor method common)	R

The PCI_EP_AREQALn register indicates the lower 32 bits of the address of the current or most recently completed AXI transfer.

56.4.1.60 PCI_EP_AREQAUn : AXI Request Address (Upper) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0964 + 0x80 × n

Bit position:	31																												0
Bit field:	AXI_REQ_ADDR6332[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	AXI_REQ_ADDR6332[31:0]	Displays the upper 32 bits of the address of the currently completed AXI transfer or the transfer that just completed. (Register/descriptor method common)	R

The PCI_EP_AREQAUn register indicates the upper 32 bits of the address of the current or most recently completed AXI transfer.

56.4.1.61 PCI_EP_PREQALn : PCIe Request Address (Lower) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0968 + 0x80 × n

Bit position:	31																												0
Bit field:	PCIE_REQ_ADDR3100[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PCIE_REQ_ADDR3100[31:0]	Displays the lower 32 bits of the address of the currently completed PCIe transfer or the transfer completed immediately before. (Register/descriptor method common)	R

The PCI_EP_PREQALn register indicates the lower 32 bits of the address during PCIe transfer that is in progress or for the most recently completed transfer.

56.4.1.62 PCI_EP_PREQAUn : PCIe Request Address (Upper) Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x096C + 0x80 × n

Bit position:	31																												0
Bit field:	PCIE_REQ_ADDR6332[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	PCIE_REQ_ADDR6332[31:0]	Displays the upper 32 bits of the address of the currently completed PCIe transfer or the transfer completed immediately before. (Register/descriptor method common)	R

The PCI_EP_PREQAUn register indicates the upper 32 bits of the address during PCIe transfer that is in progress or for the most recently completed transfer.

56.4.1.63 PCI_EP_QUESTAn : QUE Status Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0970 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	GO_LIST	LIST_NUM[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	LIST_NUM[3:0]	Displays the number of descriptor lists loaded on QUE (not including the list currently being executed). New registration to QUE (write access to QUE Entry) when this register indicates 0x8 is invalid (discarded).	R
4	GO_LIST	Shows whether there is a running descriptor list. 0: none 1: Yes	R
31:5	—	These bits are read as 0.	R

The PCI_EP_QUESTAn register indicates the state of the descriptor queue.

56.4.1.64 PCI_EP_DMACESTAn : DMAC Error Status Register n (n = 0 to 7)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x0978 + 0x80 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	CFG_BM_DIS_EP	BME_SUP	BME_DOWN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	MOR_CD_PERR	MOR_CH_PERR	MOR_EP_ERR	MOR_STATUS[2:0]			—	—	—	—	—	—	AXI_RESP[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	AXI_RESP[1:0]	Displays the slave response during AXI Master transactions. It updates when CHx_ERR is set and retains the value until the bit is cleared. 0 0: Initial value 0 1: Reserved	R
7:2	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
10:8	MOR_STATUS[2:0]	Indicates the value when MOR_STATUS is other than 000b (Success) as a set factor of CHx_ERR. Holds value until CHx_ERR is cleared. 0 0 0: initial value 0 0 1: Unsupported Request 0 1 0: CRS 0 1 1: Completion Timeout 1 0 0: Completer Abort 1 0 1: Unexpected Completion 1 1 0: Reserved 1 1 1: Mismatched Length (Length Overrun)	R
11	MOR_EP_ERR	It is set when it is Poisoned Completion as a set factor of CHx_ERR. Holds value until CHx_ERR is cleared.	R
12	MOR_CH_PERR	It is set when MOR_CH_PERR is detected as a set factor for CHx_ERR. Holds value until CHx_ERR is cleared.	R
13	MOR_CD_PERR	It is set when MOR_CD_PERR is detected as a set factor for CHx_ERR. Holds value until CHx_ERR is cleared.	R
15:14	—	These bits are read as 0.	R
16	BME_DOWN	It is set when a stop signal from the PCIe core is detected as a cause for setting CHx_ERR. Holds value until CHx_ERR is cleared.	R
17	BME_SUP	It is set when a sleep signal from the PCIe core is detected as a cause for setting CHx_ERR. Holds value until CHx_ERR is cleared. (Valid only in Endpoint mode)	R
18	CFG_BM_DIS_EP	CHx_ERR is set when the macro operates as an End Point and detects the state of Bus Master Enable Off (Configuration Space 0x004 bit [2] = 0). Holds value until CHx_ERR is cleared.	R
31:19	—	These bits are read as 0.	R

The PCI_EP_DMACESTAn register indicates the error status of the DMAC.

56.4.1.65 PCI_EP_AWBASELn_Fi : AXI Window Base (Lower) Register n (Function #i) (n = 0 to 7, i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1000 + 0x0200 × i + 0x20 × n

Bit position:	31																			12	11								4				0
Bit field:	AWB3112[19:0]																				AWB1104[7:0]								—	—	—	AXIWE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AXIWE	AXI Window Enable Enable setting of AXI Window. 0: Window disabled 1: Window enabled	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
11:4	AWB1104[7:0]	AWBase[11:4] fixed 0x00	R
31:12	AWB3112[19:0]	AWBase[31:12] Window setting register for address conversion when accessing AXI from PCIe. The configurable area is the 4K boundary.	R/W

The PCI_EP_AWBASELn_Fi register is for setting windows for lower address conversion in access from PCIe to AXI. It sets the base address on the PCI. The areas are set in 4-KB boundaries.

56.4.1.66 PCI_EP_AWBASEUn_Fi : AXI Window Base (Upper) Register n (Function #i) (n = 0 to 7, i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1004 + 0x0200 × i + 0x20 × n

Bit position:	31																												0
Bit field:	AWB6332[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	AWB6332[31:0]	AWBase[63:32] Window setting register for address conversion when accessing AXI from PCIe.	R/W

The PCI_EP_AWBASEUn_Fi register is for setting windows for upper address conversion in access from PCIe to AXI.

56.4.1.67 PCI_EP_AWMASKLn_Fi : AXI Window Mask (Lower) Register n (Function #i) (n = 0 to 7, i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1008 + 0x0200 × i + 0x20 × n

Bit position:	31																			12	11									0
Bit field:	AWM3112[19:0]																				AWM1100[11:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	AWM1100[11:0]	AWMask[11:0] Fixed 0xFFF	R
31:12	AWM3112[19:0]	AWMask[31:12] Set the window in the area of the set number of bits from the address set in the AWBase register. Set 1 from the lower bit. Therefore, the area that can be set is 4K x 2^N bytes.	R/W

The PCI_EP_AWMASKLn_Fi register is for setting windows for lower address conversion in access from PCIe to AXI. The window is set as the area corresponding to the number of set bits from the address set in the AWBase register. The area which can be set is 4K × 2^N bytes.

56.4.1.68 PCI_EP_AWMASKUn_Fi : AXI Window Mask (Upper) Register n (Function #i) (n = 0 to 7, i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x100C + 0x0200 × i + 0x20 × n

Bit position:	31	30																											0
Bit field:	—	AWM6232[30:0]																											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
30:0	AWM6232[30:0]	AWMask[62:32] Set the window in the area of the set number of bits from the address set in the AWBase register. Set 1 from the lower bit.	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The PCI_EP_AWMASKUn_Fi register is for setting windows for upper address conversion in access from PCIe to AXI.

56.4.1.69 PCI_EP_ADESTLn_Fi : AXI Destination (Lower) Register n (Function #i) (n = 0 to 7, i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1010 + 0x0200 × i + 0x20 × n

Bit position:	31																		12	11											0
Bit field:	AD3112[19:0]																			AD1100[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	AD1100[11:0]	ADest[11:0] Fixed to 0x000	R
31:12	AD3112[19:0]	ADest[31:12] Sets the window base point in the address space from the AXI side. The configurable area is the 4K boundary.	R/W

The PCI_EP_ADESTLn_Fi register is for setting windows for lower address conversion in access from PCIe to AXI. It sets the base address on the AXI. The areas are set in 4-KB boundaries.

56.4.1.70 PCI_EP_ADESTUn_Fi : AXI Destination (Upper) Register n (Function #i) (n = 0 to 7, i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1014 + 0x0200 × i + 0x20 × n

Bit position:	31																														0
Bit field:	AD6332[31:0]																														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	AD6332[31:0]	ADest[63:32] Sets the window base point in the address space f rom the AXI side.	R/W

The PCI_EP_ADESTUn_Fi register is for setting windows for upper address conversion in access from PCIe to AXI.

56.4.1.71 PCI_EP_PWBASELn_Fi : PCIe Window Base (Lower) Register n (Function #i) (n = 0 to 7, i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1100 + 0x0200 × i + 0x20 × n

Bit position:	31																		12	11							4				0
Bit field:	PWB3112[19:0]																			PWB114[7:0]							—	—	—	PCIWE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

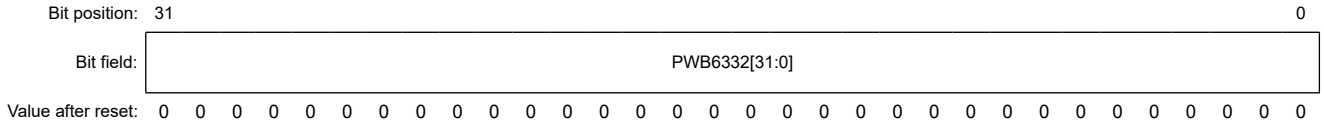
Bit	Symbol	Function	R/W
0	PCIWE	PCIe Window Enable Enable setting of PCIe Window. 0: Window disabled 1: Window enabled	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
11:4	PWB114[7:0]	PWBase[11:4] Fixed 0x00	R
31:12	PWB3112[19:0]	PWBase[31:12] Sets the base point of the address on the AXI side. The configurable area is the 4K boundary.	R/W

The PCI_EP_PWBASELn_Fi register is for setting windows for lower address conversion in access from AXI to PCIe. It sets the base address on the AXI. The areas are set in 4-KB boundaries.

56.4.1.72 PCI_EP_PWBASEUn_Fi : PCIe Window Base (Upper) Register n (Function #i) (n = 0 to 7, i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1104 + 0x0200 × i + 0x20 × n



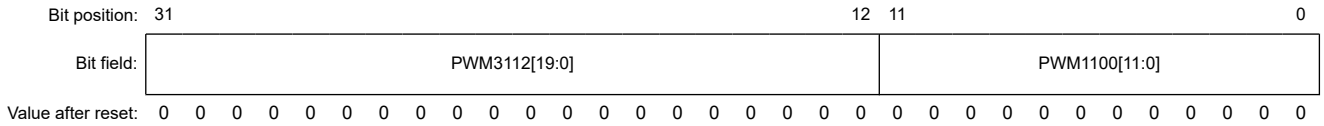
Bit	Symbol	Function	R/W
31:0	PWB6332[31:0]	PWBase[63:32] Sets the base point of the address on the AXI side. The configurable area is the 4K boundary.	R/W

The PCI_EP_PWBASEUn_Fi register is for setting windows for upper address conversion in access from AXI to PCIe.

56.4.1.73 PCI_EP_PWMASKLn_Fi : PCIe Window Mask (Lower) Register n (Function #i) (n = 0 to 7, i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1108 + 0x0200 × i + 0x20 × n



Bit	Symbol	Function	R/W
11:0	PWM1100[11:0]	PWMask[11:0] Fixed 0xFFF	R
31:12	PWM3112[19:0]	PWMask[31:12] Set the window in the area of the set number of bits from the address set in the PWBase register. Set 1 from the lower bit.	R/W

The PCI_EP_PWMASKLn_Fi register is for setting windows for address conversion in access from AXI to PCIe. The window is set as the area corresponding to the number of set bits from the address set in the PWBase register.

56.4.1.74 PCI_EP_PWMASKUn_Fi : PCIe Window Mask (Upper) Register n (Function #i) (n = 0 to 7, i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x110C + 0x0200 × i + 0x20 × n

Bit position:	31	30	0
Bit field:	—	PWM6232[30:0]	
Value after reset:	0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
30:0	PWM6232[30:0]	PWMask[62:32] Set the window in the area of the set number of bits from the address set in the PWBase register. Set 1 from the lower bit.	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

The PCI_EP_PWMASKUn_Fi register is for setting windows for address conversion in access from AXI to PCIe. The window is set as the area corresponding to the number of set bits from the address set in the PWBase register.

56.4.1.75 PCI_EP_PDESTLn_Fi : PCIe Destination (Lower) Register n (Function #i) (n = 0 to 7, i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1110 + 0x0200 × i + 0x20 × n

Bit	Symbol	Function	R/W
11:0	PD1100[11:0]	PDest[11:0] fixed 0x000	R
31:12	PD3112[19:0]	PDest[31:12] Set the window base point in the address space on the PCIe side. The configurable area is the 4k boundary.	R/W

The PCI_EP_PDESTLn_Fi register is for setting windows for address conversion in access from AXI to PCIe. The base address of the window in the address space on the AXI is set. The areas are set in 4-KB boundaries.

56.4.1.76 PCI_EP_PDESTUn_Fi : PCIe Destination (Upper) Register n (Function #i) (n = 0 to 7, i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x1114 + 0x0200 × i + 0x20 × n

Bit position:	31	0
Bit field:	PD6332[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	PD6332[31:0]	PDest[63:32] Set the window base point in the address space on the PCIe side.	R/W

The PCI_EP_PDESTUn_Fi register is for setting windows for upper address conversion in access from AXI to PCIe.

56.4.2 PCI Express Configuration Registers (Type0: Endpoint)

56.4.2.1 PCI_EP_VID_Fi : Vendor and Device ID (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6000 + 0x1000 × i

Bit position:	31																16	15														0
Bit field:	DID[15:0]																	VID[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	VID[15:0]	Vendor ID Used by the manufacturer specified by the Vendor ID to identify the manufactured device. Set a fixed value.	R/W*1
31:16	DID[15:0]	Device ID Represents the manufacturer of the device. Set a fixed value.	R/W*1

Note 1. The access type from PCIe is read-only.

The PCI_EP_VID_Fi register indicates the vendor and device ID.

Table 56.71 Valid reset signal

Reset signal	Device ID	Vendor ID
RST_LOAD_B	✓	✓
RST_RSM_B	—	—
RST_CFG_B	—	—
FLR	—	—

56.4.2.2 PCI_EP_COM_STA_Fi : Command and Status (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6004 + 0x1000 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DPE	SSE	RMA	RTA	STA	—	—	MDPE	—	—	—	CL	IS	—	—	IR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	ID	—	SERRE	—	PER	—	—	—	BME	MSE	IOSE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IOSE	IO Space Enable 0 fixed. It does not support access to the I/O space.	R
1	MSE	Memory Space Enable Controls whether to respond to accesses to memory space.	R/W
2	BME	Bus Master Enable Controls whether to operate as a bus master.	R/W
5:3	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
6	PER	Parity Error Response Controls the behavior when sending/receiving PoisonedTLP. Error logging to the Detected Parity Error field of the Status register, the Device Status register of PCI Express Capability, and the Uncorrectable Error Status register of Advanced Error Reporting Capability is performed regardless of the setting of this bit.	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	SERRE	SERR# Enable When set to 1, the Root Complex is notified of Non-Fatal Errors and Fatal Errors by Message Transaction. Even if this bit is not set, if a bit related to Error Reporting in the Device Control register of PCI Express Capability is set to 1, an error is notified to the Root Complex by Message Transaction.	R/W
9	—	This bit is read as 0. The write value should be 0.	R/W
10	ID	Interrupt Disable Suppress transmission of Assert_INTx Message. When set to 1, INTx Message cannot be sent. If this bit is set to 1 while an Assert_INTx Message has been sent, a Deassert_INTx Message must be sent.	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
16	IR	Immediate Readiness Fixed 0	R
18:17	—	These bits are read as 0. The write value should be 0.	R/W
19	IS	Interrupt Status Indicates the interrupt status of the device.	R
20	CL	Capabilities List This bit is fixed to 1 because all PCI Express devices must implement PCI Express Capability.	R
23:21	—	These bits are read as 0. The write value should be 0.	R/W
24	MDPE	Master Data Parity Error Set to 1 when the Parity Error Response bit is set to 1 and the following two conditions occur: 1. Requester (BME) received a Poisoned Completion TLP. 2. Requester (BME) sent Poisoned Write Request TLP. This bit is not set to 1 if the Parity Error Response bit is 0.	R/W
26:25	—	These bits are read as 0. The write value should be 0.	R/W
27	STA	Signaled Target Abort Set to 1 when the Completion Status field has sent a Completion of Completer Abort.	R/W*1
28	RTA	Received Target Abort Set to 1 when the Completion Status field receives a Completion for Completer Abort.	R/W*1
29	RMA	Received Master Abort Set to 1 when the Completion Status field receives a Completion of an Unsupported Request.	R/W*1
30	SSE	Signaled System Error Set to 1 when the SERR Enable bit is 1 and this macro sends an ERR_FATAL or ERR_NONFATAL Message.	R/W*1
31	DPE	Detected Parity Error Set to 1 when a Poisoned TLP is received, regardless of the setting of the Parity Error Response bit.	R/W*1

Note 1. Writing 1 from PCIe clears the bit. Writing 0 from PCIe is ignored.

The PCI_EP_COM_STA_Fi register specifies the command and the status.

56.4.2.11 PCI_EP_SUBSID_Fi : Subsystem ID (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x602C + 0x1000 × i

Bit position:	31															16	15													0
Bit field:	SID[15:0]																SVID[15:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	SVID[15:0]	Subsystem Vendor ID A 16-bit ID representing the manufacturer of the add-in card or subsystem that contains this device. Set fixed value	R/W*1
31:16	SID[15:0]	Subsystem ID Sub System Vendor A 16-bit ID used to identify subsystems manufactured by the manufacturer specified by the ID. Set fixed value	R/W*1

Note 1. The access type from PCIe is read-only.

The PCI_EP_SUBSID_Fi register indicates the subsystem ID.

Table 56.81 Valid reset signal

Reset signal	Subsystem ID	Subsystem Vendor ID
RST_LOAD_B	✓	✓

56.4.2.12 PCI_EP_CP_Fi : Capabilities Pointer (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6034 + 0x1000 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CP[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CP[7:0]	Capabilities Pointer Capability implementation start address 0x40 PCI Power Management Capability is implemented from 0x40.	R
31:8	—	These bits are read as 0.	R

The PCI_EP_CP_Fi register indicates start address for implementing the capability.

56.4.2.13 PCI_EP_INT_Fi : Interrupt Register (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x603C + 0x1000 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	IP[7:0]								IL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	IL[7:0]	Interrupt Line Indicates which line of the system's interrupt lines the device's interrupt output is connected to as a result of system configuration. Values are set by system initialization programs and read by device drivers and the OS as needed. This is a software register and there is no relation between device operation and register value.	R/W

Bit	Symbol	Function	R/W
15:8	IP[7:0]	Interrupt Pin Specifies the message to be issued on the INTX_EP_Fi bit in PCIE_INTX register. 0x01: Assert_INTA# (default) 0x02: Assert_INTB# 0x03: Assert_INTC# 0x04: Assert_INTD# Others: Reserved	R/W*1
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The access type from PCIe is read-only.

The PCI_EP_INT_Fi register assigns an interrupt to the terminal.

56.4.2.14 PCI_EP_PMC_Fi : PM Capabilities (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6040 + 0x1000 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PMES[4:0]					D2S	D1S	AUXC[2:0]			DSI	IRORTD0	—	V[2:0]		
Value after reset:	0	1	0	0	1	0	0	0	0	0	0	0	0	0	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	NCP[7:0]								CID[7:0]							
Value after reset:	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
7:0	CID[7:0]	Capability ID Indicates the PCI Power Management Capability. It is fixed at 0x01.	R
15:8	NCP[7:0]	Next Capability Pointer Indicates the MSI Capability start address.	R
18:16	V[2:0]	Version 011b is fixed. PCI Power Management Interface Specification Rev .1.2	R/W*1
19	—	This bit is read as 0. The write value should be 0.	R/W
20	IRORTD0	Immediate_Readiness_on_Return_to_D0 0 fixed	R
21	DSI	Device Specific Initialization Indicates whether or not DSI (Device Specific Initialization) is used. 0: Not supported 1: Support	R/W*1

Bit	Symbol	Function	R/W
24:22	AUXC[2:0]	AUX_Current Indicates the 3.3Vaux auxiliary current (the maximum current value supplied from the auxiliary power supply). Read value returns 000b. (AUX not supported) 0 0 0: 0 (self powered) 0 0 1: 55 mA 0 1 0: 100 mA 0 1 1: 160 mA 1 0 0: 220 mA 1 0 1: 250 mA 1 1 0: 320 mA 1 1 1: 375 mA	R/W*1
25	D1S	D1 Support Indicates whether the D1 Power Management State is supported. 0: Not supported 1: Support	R/W*1
26	D2S	D2 Support Indicates whether the D2 Power Management State is supported. 0: Not supported 1: Support	R/W*1
31:27	PMES[4:0]	PME Support xxxx1: Supports D0 xxx1x: Supports D1 xx1xx: Supports D2 x1xxx: Support D3hot 1xxxx: D3cold supported (not supported)	R/W*1

Note 1. The access type from PCIe is read-only.

The PCI_EP_PMC_Fi register indicates various support information.

56.4.2.15 PCI_EP_PMSC_Fi : PM Status/Control (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6044 + 0x1000 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PMES	—	—	—	—	—	—	PMEE	—	—	—	—	NSR	—	PS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
1:0	PS[1:0]	PowerState Set the PCI Device State. 0 0: D0 (Default) 0 1: D1 (Do not set) 1 0: D2 (Do not set) 1 1: D3hot	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	NSR	No_Soft_Reset Indicates that internal reset is not performed inside the device at the power state transition from D3hot to D0.	R
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	PMEE	PME Enable Controls PME assertions. If 1, PME assertion is enabled. Assert PME if PME_Status is set at this time. PCI Express perf orms Link Wake-up processing, and then performs PME assert processing by sending PM_PME Message. The specifications are as f ollows depending on the value of the PM Capabilities register PME Status[4] (PME Support in D3cold). PME Status[4] = 1: ● Reset: RST_RSM_B ● EP UDL: RW ● EP PCIe: RWS PME Status[4] = 0: ● Reset: RST_RSM_B ● EP UDL: RW ● EP PCIe: RW	R/W
14:9	—	These bits are read as 0. The write value should be 0.	R/W
15	PMES	PME Status Indicates that a PME assert factor has occurred. 1 indicates that there is a PME assertion factor. Cleared by writing 1.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_PMSC_Fi register indicates and controls the PME status.

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
1:0	ASPMC[1:0]	Active State Power Management (ASPM) Control Sets the permission level for Active State Power Management. 0 0: Disabled (Default) 0 1: L0s Entry Supported 1 0: L1 Entry Supported 1 1: L0s and L1 Entry Supported	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	RCB	Read Completion Boundary (RCB) 0: 64 bytes 1: 128 bytes (Default)	R/W
5:4	—	These bits are read as 0. The write value should be 0.	R/W
6	CCC	Common Clock Configuration Sets whether the Common Reference Clock is used. Only Common Reference Clock is supported for Single Link. 0: Provided by non-Common Reference Clock (Default) 1: Supplied by Common Reference Clock	R/W
7	ES	Extended Synch If set to 1, 4096 FTS Ordered-sets will be sent when transitioning from L0s to L0. Also, 1024 TS1 Ordered-sets are transmitted at the beginning of the Recovery state when transitioning from L1 to L0. The default value will be 0.	R/W
8	ECPM	Enable Clock Power Management Controls Enable/Disable of CLKREQ# mechanism in L1 and L2/L3 Ready.	R/W
9	HAWD	Hardware Autonomous Width Disable Controls Link width change. Reserved in Function #1 0: Enable of Link Width Change 1: Disable	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
19:16	CLS[3:0]	Current Link Speed 0x0: During reset period 0x1: 2.5 GT/s PCI Express Link 0x2: 5.0 GT/s PCI Express Link 0x3: 8.0 GT/s PCI Express Link 0x4: 16.0 GT/s PCI Express Link	R

Bit	Symbol	Function	R/W
25:20	NLW[5:0]	Negotiated Link Width Indicates the Link width established as a result of negotiation. 0x01: x1 0x02: x2 0x04: x4 0x08: x8 0x0C: x12 0x10: x16 0x20: x32 Others: Reserved	R
27:26	—	These bits are read as 0. The write value should be 0.	R/W
28	SCC	Slot Clock Configuration Indicates whether or not the reference clock supplied to the Connector is used when the Add-in Card is used. 0: Not using Connector Reference Clock 1: Use Connector Reference Clock (Default)	R/W*1
29	DLLLA	Data Link Layer Link Active 1 indicates that the Data Link Layer is in the Link Active state.	R
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The access type from PCIe is read-only.

The PCI_EP_LINKCS_Fi register controls the link and indicates the link status.

Bit	Symbol	Function	R/W
3:0	TLS[3:0]	Target Link Speed Set the Link Speed value for notification to the Root Complex during training. Reserved in Function #1 0x1: 2.5 GT/s Target Link Speed 0x2: 5.0 GT/s Target Link Speed 0x3: 8.0 GT/s Target Link Speed (Default) 0x4: 16.0 GT/s Target Link Speed (prohibited) Others: Reserved	R/W
4	ETC	Enter Compliance Setting to 1 allows transition to Compliance mode. At this time, the Link Speed will be the value set in the Target Link Speed field. Reserved in Function #1	R/W
5	HASD	Hardware Autonomous Speed Disable Controls the Link Speed Change function. Reserved in Function #1 0: Support of Link Speed Change (Enable) 1: Not Support of Link Speed Change (Disable)	R/W
6	—	These bits are read as 0. The write value should be 0.	R/W
9:7	TM[2:0]	Transmit Margin Adjust the voltage level of the Transmitter. 000b Normal operating range See 001b to 111b Base Spec Section 8.3.4. Reserved in Function #1	R/W
10	EMC	Enter Modified Compliance Setting bit for transmission of Modified Compliance pattern. Reserved in Function #1 0: Compliance Pattern (Default) 1: Modified Compliance Pattern	R/W
11	CSOS	Compliance SOS When this bit is set to 1, insert the SKP Ordered-set periodically during compliance pattern transmission. Reserved in Function #1	R/W

Bit	Symbol	Function	R/W
15:12	CPD[3:0]	Compliance Preset De-emphasis Set the De-emphasis Level in Polling.Compliance State. Reserved in Function #1 0x0: −6 dB (Default) 0x1: −3.5 dB	R/W
16	CDL	Current De-emphasis Level This is a Status register that indicates the De-emphasis Level during Gen3 operation. The initial value of this bit is 0 at reset and after Gen3-Linkup. However, although it indicates 1 at Gen1-Linkup, ignore this bit as it has no meaning in Gen1. 0: −6 dB (Default) 1: −3.5 dB	R
17	EQC	Equalization Complete When set to 1, this bit indicates that the Transmitter Equalization procedure has completed. The default value of this bit is 0. For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0.	R
18	EP1S	Equalization Phase 1 Successful When set to 1, this bit indicates that Phase 1 of the Transmitter Equalization procedure has successfully completed. The default value of this bit is 0. For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0.	R
19	EP2S	Equalization Phase 2 Successful When set to 1, this bit indicates that Phase 2 of the Transmitter Equalization procedure has successfully completed. The default value of this bit is 0. For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0.	R
20	EP3S	Equalization Phase 3 Successful When set to 1, this bit indicates that Phase 3 of the Transmitter Equalization procedure has successfully completed. The default value of this bit is 0. For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0.	R
21	LER	Link Equalization Request This bit is Set by hardware to request the Link equalization process to be performed on the Link. The default value of this bit is 0. For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0.	R/W*1
31:22	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 from PCIe clears the bit. Writing 0 from PCIe is ignored.

The PCI_EP_LINCS2_Fi register controls the link and indicates the link status.

Bit	Symbol	Function	R/W
9:0	BS02[9:0]	Base Size 02 Sets the size of the TLP (DW Size) that will be accepted in Address Space 01 set in the Base Address Register and Base Address Mask Register. If a TLP with a packet length larger than the size set here is received (even if it is smaller than the Max Payload Size), a Completer Abort Error (CA) will be detected. Note that the default value is 0x000, which disables this function.	R/W*1
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
25:16	BS03[9:0]	Base Size 03 Sets the size of the TLP (DW Size) that will be accepted in Address Space 01 set in the Base Address Register and Base Address Mask Register. If a TLP with a packet length larger than the size set here is received (even if it is smaller than the Max Payload Size), a Completer Abort Error (CA) will be detected. Note that the default value is 0x000, which disables this function.	R/W*1
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The access type from PCIe is read-only.

The PCI_EP_BSIZE02_03_Fi register sets the acceptable TLP size.

Table 56.101 Valid reset signal

Reset signal	Base Size 03	Base Size 02

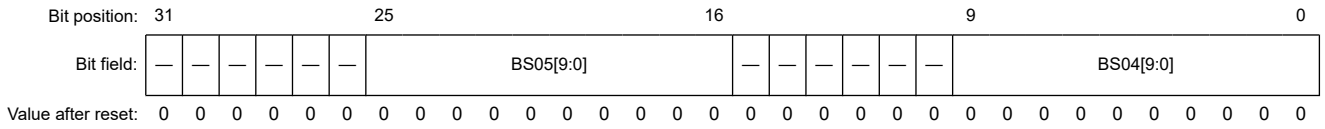
56.4.2.33 PCI_EP_BSIZE04_05_Fi : Base Size 04/05 (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x60D0 + 0x1000 × i



Bit	Symbol	Function	R/W
9:0	BS04[9:0]	Base Size 04 Sets the size of the TLP (DW Size) that will be accepted in Address Space 01 set in the Base Address Register and Base Address Mask Register. If a TLP with a packet length larger than the size set here is received (even if it is smaller than the Max Payload Size), a Completer Abort Error (CA) will be detected. Note that the default value is 0x000, which disables this function.	R/W*1
15:10	—	These bits are read as 0. The write value should be 0.	R/W
25:16	BS05[9:0]	Base Size 05 Sets the size of the TLP (DW Size) that will be accepted in Address Space 01 set in the Base Address Register and Base Address Mask Register. If a TLP with a packet length larger than the size set here is received (even if it is smaller than the Max Payload Size), a Completer Abort Error (CA) will be detected. Note that the default value is 0x000, which disables this function.	R/W*1
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The access type from PCIe is read-only.

The PCI_EP_BSIZE04_05_Fi register sets the acceptable TLP size.

56.4.2.39 PCI_EP_MSGDAT_Fi : Message Data (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x60EC + 0x1000 × i

Bit position:	31																15												0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MD[15:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	MD[15:0]	Message Data Set Data[15:0] to be set in the MSI Message. If the Multiple Message Enable field is 011b (8), the Function (UDL) side can change the lower 3 bits of the Message data, and 8 types of vectors can be notified to the system as Message_Data. Similarly, in the case of 010b (4 pieces), the lower 2 bits can be changed by the function (UDL) side, and 4 types of vector can be changed. In the case of 001b (2 pieces), the lower 1 bit can be changed by the function (UDL) side 2 types of vector f or 000b (1 piece), 1 type of vector for the set data only. Note: Specify 0 for invalid high-order bits (in the above example of Multiple Message Enable setting 4, high-order bits other than the low-order 2 bits to be changed on the Function side) for the vector specification value on each Function side.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

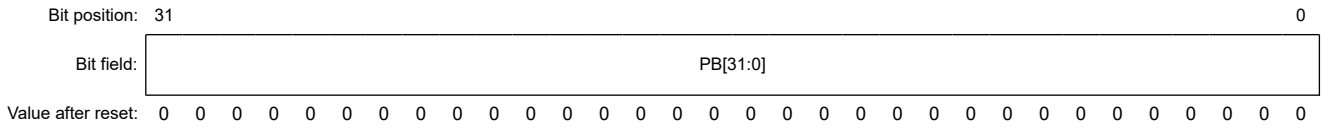
56.4.2.41 PCI_EP_PENDBIT_Fi : Pending Bits (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x60F4 + 0x1000 × i



Bit	Symbol	Function	R/W
31:0	PB[31:0]	Pending Bits Indicates MSI Message pending status for each Function.	R/W

The PCI_EP_PENDBIT_Fi register indicates the pending state of an MSI message for the given function.

56.4.2.42 PCI_EP_ADVERC_Fi : Advanced Error Reporting Capability (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6100 + 0x1000 × i

Bit position:	31												20	19			16	15													0
Bit field:	NCO[11:0]													CV[3:0]				PCIEECID[15:0]													
Value after reset:	0	0	0	1	0	1	0	1	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
15:0	PCIEECID[15:0]	PCI Express Extended Capability ID Indicates the Advanced Error Reporting Capability. Default: 0x0001	R
19:16	CV[3:0]	Capability Version Indicates the version of the Capability Structure. Default: 0x01	R/W*1
31:20	NCO[11:0]	Next Capability Offset Indicates the starting address for DeviceSerialNumberCapability.	R

Note 1. The access type from PCIe is read-only.

The PCI_EP_ADVERC_Fi register indicates the advanced error reporting capability.

11:5	—	These bits are read as 0. The write value should be 0.	R/W
12	PTLPRS	Poisoned TLP Received Severity Sets the Error Severity when Poisoned TLP Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
13	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
14	CTS	Completion Timeout Severity Sets the Error Severity when Completion Timeout Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
15	CASO	Completer Abort Severity (Optional) Sets the Error Severity when a Completer Abort Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
16	UCS	Unexpected Completion Severity Sets the Error Severity when an Unexpected Completion Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
17	ROSO	Receiver Overflow Severity (Optional) Set the Error Severity when Receiver Overflow Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
18	MTLPS	Malformed TLP Severity Sets the Error Severity when Malformed TLP Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
19	ECRCESO	ECRC Error Severity (Optional) Sets the Error Severity when receiving an ECRC Error. 0: Non-Fatal Error 1: Fatal Error	R/W
20	URES	Unsupported Request Error Severity Set the Error Severity when Unsupported Request Error is detected. 0: Non-Fatal Error 1: Fatal Error	R/W
21	—	This bit is read as 0. The write value should be 0.	R/W
22	—	This bit is read as 1. The write value should be 1.	R/W
31:23	—	These bits are read as 0. The write value should be 0.	R/W

The PCI_EP_UNCESVY_Fi register sets the uncorrectable error severity.

Table 56.113 Valid reset signal

Reset signal	Unsupported Request Error Severity	ECRC Error Severity	Malformed TLP Severity	Receiver Overflow Severity	Unexpected Completion Severity	Completer Abort Severity	Completion Timeout Severity	Poisoned TLP Received Severity	Data Link Protocol Error Severity

56.4.2.46 PCI_EP_CESTS_Fi : Correctable Error Status Register (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6110 + 0x1000 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	ANFES	RTTS	—	—	—	REPLAYNUMRS	BDLLPS	BTLPS	—	—	—	—	—	RES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RES	Receiver Error Status (optional) 0: No error detected 1: Error detected	R*1
5:1	—	These bits are read as 0.	R
6	BTLPS	Bad TLP Status Indicates that a TLP CRC error or Sequence Number error was detected. 0: No error detected 1: Error detected	R*1
7	BDLLPS	Bad DLLP Status Indicates that a DLLP CRC error was detected. 0: No error detected 1: Error detected	R*1
8	REPLAYNUMRS	REPLAY_NUM Rollover Status Replay occurred four times in a row, indicating REPLAY_NUM rolled over from 11b to 00b. 0: No error detected 1: Error detected	R*1
11:9	—	These bits are read as 0.	R
12	RTTS	Replay Timer Timeout Status Indicates that a Timeout error occurred when a TLP was sent and an Ack or Nak DLLP could not be received within the specified time. 0: No error detected 1: Error detected	R*1
13	ANFES	Advisory Non-Fatal Error Status Indicates that an Advisory Non-Fatal Error was detected. 0: No error detected 1: Error detected	R*1
31:14	—	These bits are read as 0.	R

Note 1. The access type from PCIe is read-write. Writing 1 clears the bit. Writing 0 is ignored.

The PCI_EP_CESTS_Fi register indicates the correctable error status.

Table 56.114 Valid reset signal

56.4.2.49 PCI_EP_HLOG0_Fi : Header Log Register 0 (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x611C + 0x1000 × i

Bit position:	31	0
Bit field:	HTLPE0[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	HTLPE0[31:0]	Header of TLP associated with error 0 For the first detected Uncorrectable Error, indicates the 1st DW of Header.	R

The PCI_EP_HLOG0_Fi register indicates the header log.

56.4.2.50 PCI_EP_HLOG1_Fi : Header Log Register 1 (Function #i)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6120 + 0x1000 × i

Bit position:	31																													0
Bit field:	HTLPE1[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	HTLPE1[31:0]	Header of TLP associated with error 1 For the first detected Uncorrectable Error, indicates the 2nd DW of Header.	R

The PCI_EP_HLOG1_Fi register indicates the header log.

56.4.2.51 PCI_EP_HLOG2_Fi : Header Log Register 2 (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6124 + 0x1000 × i

Bit position:	31																													0
Bit field:	HTLPE2[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	HTLPE2[31:0]	Header of TLP associated with error 2 For the first detected Uncorrectable Error, indicates the 3rd DW of Header.	R

The PCI_EP_HLOG2_Fi register indicates the header log.

56.4.2.52 PCI_EP_HLOG3_Fi : Header Log Register 3 (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6128 + 0x1000 × i

Bit position:	31																													0
Bit field:	HTLPE3[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	HTLPE3[31:0]	Header of TLP associated with error 3 For the first detected Uncorrectable Error, indicates the 4th DW of Header.	R

The PCI_EP_HLOG3_Fi register indicates the header log.

56.4.2.53 PCI_EP_DEVSNEXTC_Fi : Device Serial Number Extended Capability Register (Function #i) (i = 0, 1)

Base address: PCIEm = 0x9210_0000 + 0x1_0000 × m (m = 0, 1)

Offset address: 0x6150 + 0x1000 × i

Bit position:	31											20	19			16	15													0
Bit field:	NCO[11:0]												CV[3:0]				PCIEECID[15:0]													
Value after reset:	0	0	0	1	1	0	1	1	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
15:0	PCIEECID[15:0]	PCI Express Extended Capability ID Indicates the Device Serial Number Extended Capability. Default: 0x0003	R
19:16	CV[3:0]	Capability Version Indicates the version of the Capability Structure. Default: 0x1	R/W*1
31:20	NCO[11:0]	Next Capability Offset Indicates the starting address of the Secondary PCI Express Extended Capability Header. 0x1B0 fixed. Function#1 is fixed at 0x000.	R

Note 1. The access type from PCIe is read-only.

The PCI_EP_DEVSNEXTC_Fi register specifies the device serial number extended capability.

Bit field:	—	UPRPH0[2:0]			UPTP0[3:0]				—	DPRPH0[2:0]			DPTP0[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	DPTP0[3:0]	Downstream Port 8.0 GTs Transmitter Preset Lane0 The read value is undefined. Transmitter Presetused for equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. For an Upstream Port if Crosslink Supported is 0, this field is RsvdP. Otherwise, this field is Hwinit. The default value is 0xF. EP: Fixed to 0 because Crosslink is not supported	R

Bit	Symbol	Function	R/W
6:4	DPRPH0[2:0]	Downstream Port 8.0 GTs Receiver Preset Hint Lane0 The read value is undefined. Receiver Preset Hint may be used as a hint for receiver equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. For an Upstream Port if Crosslink Supported is 0, this field is RsvdP. Otherwise, this field is Hwinit. The default value is 0x7. EP: Fixed to 0 because Crosslink is not supported	R
7	—	This bit is read as 0.	R
11:8	UPTP0[3:0]	Upstream Port 8.0 GTs Transmitter Preset Lane0 The read value is undefined. Field contains the Transmit Preset value sent or received during Link Equalization. Field usage varies as follows: A: Downstream Port Field contains the value sent on the associated Lane during Link Equalization. Field is Hwinit. B: Upstream Port, Crosslink Supported = 0 Field is intended for debug and diagnostics. It contains the value captured from the associated Lane during Link Equalization. Field is RO. When crosslinks are supported, case C (below) applies and this captured information is not visible to software. Vendors are encouraged to provide an alternate mechanism to obtain this information. C: Upstream Port, Crosslink Supported = 1 Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A (above) applies. Field is Hwinit. The default value is 0xF. EP: Input signal	R
14:12	UPRPH0[2:0]	Upstream Port 8.0 GTs Receiver Preset Hint Lane0 The read value is undefined. Field contains the Receiver Preset Hint value sent or received during Link Equalization. Field usage varies as follows: A: Downstream Port Field contains the value sent on the associated Lane during Link Equalization. Field is Hwinit. B: Upstream Port, Crosslink Supported = 0 Field is intended for debug and diagnostics. It contains the value captured from the associated Lane during Link Equalization. Field is RO. When crosslinks are supported, case C (below) applies and this captured information is not visible to software. Vendors are encouraged to provide an alternate mechanism to obtain this information. C: Upstream Port, Crosslink Supported = 1 Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A (above) applies. Field is Hwinit. The default value is 0x7. EP: Input signal	R
15	—	This bit is read as 0.	R
19:16	DPTP1[3:0]*1	Downstream Port 8.0 GTs Transmitter Preset Lane1 The read value is undefined. Transmitter Presetused for equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. For an Upstream Port if Crosslink Supported is 0, this field is RsvdP. Otherwise, this field is Hwinit. The default value is 0xF. EP: Fixed to 0 because Crosslink is not supported	R

Bit	Symbol	Function	R/W
22:20	DPRPH1[2:0]*1	Downstream Port 8.0 GTs Receiver Preset Hint Lane1 The read value is undefined. Receiver Preset Hint may be used as a hint for receiver equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. For an Upstream Port if Crosslink Supported is 0, this field is RsvdP. Otherwise, this field is Hwinit. The default value is 0x7. EP: Fixed to 0 because Crosslink is not supported	R
23	—	This bit is read as 0.	R
27:24	UPTP1[3:0]*1	Upstream Port 8.0 GTs Transmitter Preset Lane1 The read value is undefined. Field contains the Transmit Preset value sent or received during Link Equalization. Field usage varies as follows: A: Downstream Port Field contains the value sent on the associated Lane during Link Equalization. Field is Hwinit. B: Upstream Port, Crosslink Supported = 0 Field is intended for debug and diagnostics. It contains the value captured from the associated Lane during Link Equalization. Field is RO. When crosslinks are supported, case C (below) applies and this captured information is not visible to software. Vendors are encouraged to provide an alternate mechanism to obtain this information. C: Upstream Port, Crosslink Supported = 1 Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A (above) applies. Field is Hwinit. The default value is 0xF. EP: Input signal	R
30:28	UPRPH1[2:0]*1	Upstream Port 8.0 GTs Receiver Preset Hint Lane1 The read value is undefined. Field contains the Receiver Preset Hint value sent or received during Link Equalization. Field usage varies as follows: A: Downstream Port Field contains the value sent on the associated Lane during Link Equalization. Field is Hwinit. B: Upstream Port, Crosslink Supported = 0 Field is intended for debug and diagnostics. It contains the value captured from the associated Lane during Link Equalization. Field is RO. When crosslinks are supported, case C (below) applies and this captured information is not visible to software. Vendors are encouraged to provide an alternate mechanism to obtain this information. C: Upstream Port, Crosslink Supported = 1 Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A (above) applies. Field is Hwinit. The default value is 0x7. EP: Input signal	R
31	—	This bit is read as 0.	R

Note 1. Not available for m = 1.

56.5 Register Descriptions (Physical Layer Control/Status)

These registers control the pins for setting the PHY built into the module.

In the multi-link configuration, the area for ch.1 is reserved, because the control is performed by ch.0.

When these registers are accessed for writing, PHY_REG_CLK_EN bit in permission register must be set to 1 before a write access is made. In addition, rewrite the registers while the PCIe logic and PHY resets (other than ARESETn, RST_CFG_B, and RST_LOAD_B) are asserted.

56.5.1 PCI_PHY_XCFGDn : XCFGD Setting Register n (n = 0 to 26)

Base address: PCIE_PHY = 0x9210_2000

Offset address: 0x000 + 0x10 × n

Bit position:	31																												0
Bit field:	XCFGD[31:0]																												
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
31:0	XCFGD[31:0]	Sets each bit of the PHY setting pin XCFGD.	R/W

The PCI_PHY_XCFGDn registers are used to set PHY of the PCI Express core.

Set the value according to Table 56.123 shown below by software during initialization phase.

Table 56.123 Setting value of XCFGD setting registers

n	Offset address	Value	n	Offset address	Value	n	Offset address	Value
0	0x2000	0x0000_2000	9	0x2090	0x0000_0000	18	0x2120	0x0000_0000

56.5.2 PCI_PHY_XCFGA_CMNn : XCFGA_CMN Setting Register n (n = 0 to 15)

Base address: PCIE_PHY = 0x9210_2000

Offset address: 0x400 + 0x10 × n

Bit position:	31																												0
Bit field:	XCFGA_CMN[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	XCFGA_CMN[31:0]	Sets each bit of the PHY setting pin XCFGA_CMN.	R/W

The PCI_PHY_XCFGA_CMNn registers are used to set PHY of the PCI Express core.

Set the value according to Table 56.124 shown below by software during initialization phase.

Table 56.124 Setting value of XCFGA_CMN setting registers (1 of 2)

n	Offset address	Value	n	Offset address	Value	n	Offset address	Value
0	0x2400	0x0000_0080	6	0x2460	0x3204_0400	12	0x24C0	0x010A_9291

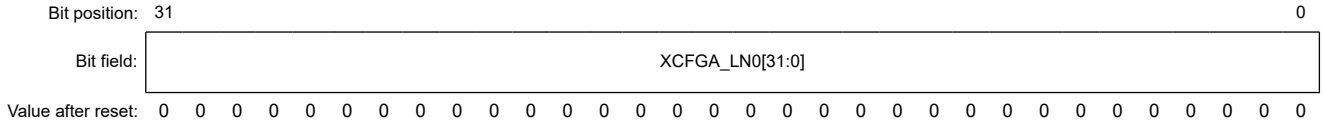
Table 56.124 Setting value of XCFGA_CMN setting registers (2 of 2)

n	Offset address	Value	n	Offset address	Value	n	Offset address	Value
4	0x2440	0x8083_4238	10	0x24A0	0x0C86_7F02	—	—	—
5	0x2450	0x0000_1118	11	0x24B0	0x4064_3228	—	—	—

56.5.3 PCI_PHY_XCFGA_L0n : XCFGA_LN0 Setting Register n (n = 0 to 5)

Base address: PCIE_PHY = 0x9210_2000

Offset address: 0x500 + 0x10 × n



Bit	Symbol	Function	R/W
31:0	XCFGA_LN0[31:0]	Sets each bit of the PHY setting pin XCFGA_LN0.	R/W

The PCI_PHY_XCFGA_L0n registers are used to set PHY of the PCI Express core.

Set the value according to Table 56.125 shown below by software during initialization phase.

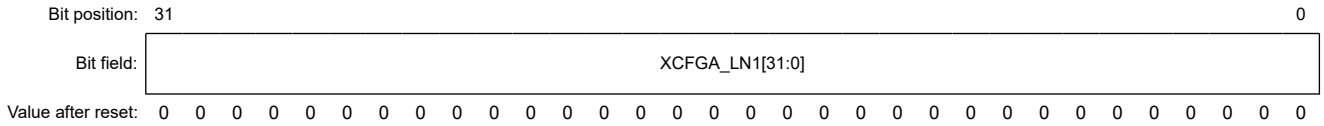
Table 56.125 Setting value of XCFGA_LN0 setting registers

n	Offset address	Value	n	Offset address	Value	n	Offset address	Value
0	0x2500	0x0800_0000	2	0x2520	0xE000_3300	4	0x2540	0x9609_02A0
1	0x2510	0x0005_0400	3	0x2530	0xC040_0FBF	5	0x2550	0x0002_0860

56.5.4 PCI_PHY_XCFGA_L1n : XCFGA_LN1 Setting Register n (n = 0 to 5)

Base address: PCIE_PHY = 0x9210_2000

Offset address: 0x560 + 0x10 × n



Bit	Symbol	Function	R/W
31:0	XCFGA_LN1[31:0]	Sets each bit of the PHY setting pin XCFGA_LN1.	R/W

The PCI_PHY_XCFGA_L1n registers are used to set PHY of the PCI Express core.

Set the value according to Table 56.126 shown below by software during initialization phase.

Table 56.126 Setting value of XCFGA_LN1 setting registers

n	Offset address	Value	n	Offset address	Value	n	Offset address	Value
0	0x2560	0x0800_0000	2	0x2580	0xE000_3300	4	0x25A0	0x9609_02A0
1	0x2570	0x0005_0400	3	0x2590	0xC040_0FBF	5	0x25B0	0x0002_0860

56.6 Register Descriptions (Supplemental Setting)

56.6.1 PCIE_INTX : PCIe INTX Register

Base address: PCIE_SPLm = 0x8029_2000 + 0x0030 × m (m = 0, 1)

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INTX_EP_F1	INTX_EP_F0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	INTX_EP_F0	Legacy Interrupt (Assert_INTx/Deassert_INTx message) Trigger for Endpoint Funtion #0 0: Issue Deassert_INTx message 1: Issue Assert_INTx message	R/W
1	INTX_EP_F1	Legacy Interrupt (Assert_INTx/Deassert_INTx message) Trigger for Endpoint Funtion #1 0: Issue Deassert_INTx message 1: Issue Assert_INTx message	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

The PCIE_INTX is the register for Endpoint to generate legacy interrupt (Assert_INTx/Deassert_INTx) to Root Complex.

56.6.2 PCIE_MSI1 : PCIe MSI Register 1

Base address: PCIE_SPLm = 0x8029_2000 + 0x0030 × m (m = 0, 1)

Offset address: 0x004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	UI_EXTMSI_VAL4	UI_EXTMSI_VAL3	UI_EXTMSI_VAL2	UI_EXTMSI_VAL1	UI_EXTMSI_VAL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	UI_EXTMSI_VAL0	MSI 0 Interrupt Trigger for Endpoint When writing 1, triggers MSI 0 interrupt. When reading, 0 is read.	W
1	UI_EXTMSI_VAL1	MSI 1 Interrupt Trigger for Endpoint When writing 1, triggers MSI 1 interrupt. When reading, 0 is read.	W
2	UI_EXTMSI_VAL2	MSI 2 Interrupt Trigger for Endpoint When writing 1, triggers MSI 2 interrupt. When reading, 0 is read.	W
3	UI_EXTMSI_VAL3	MSI 3 Interrupt Trigger for Endpoint When writing 1, triggers MSI 3 interrupt. When reading, 0 is read.	W

Bit	Symbol	Function	R/W
4	UI_EXTMSI_VAL4	MSI 4 Interrupt Trigger for Endpoint When writing 1, triggers MSI 4 interrupt. When reading, 0 is read.	W
31:5	—	The write value should be 0.	W

The PCIE_MSI1 is the register for Endpoint to generate MSI interrupt to Root Complex.

56.6.3 PCIE_MSI2 : PCIe MSI Register 2

Base address: PCIE_SPLm = 0x8029_2000 + 0x0030 × m (m = 0, 1)

Offset address: 0x008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	UI_EXTMSI_VEC3[4:0]					—	—	—	UI_EXTMSI_VEC2[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	UI_EXTMSI_VEC1[4:0]					—	—	—	UI_EXTMSI_VEC0[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	UI_EXTMSI_VEC0[4:0]	Specify the interrupt vector of MSI 0 interrupt for Endpoint.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
12:8	UI_EXTMSI_VEC1[4:0]	Specify the interrupt vector of MSI 1 interrupt for Endpoint.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
20:16	UI_EXTMSI_VEC2[4:0]	Specify the interrupt vector of MSI 2 interrupt for Endpoint.	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
28:24	UI_EXTMSI_VEC3[4:0]	Specify the interrupt vector of MSI 3 interrupt for Endpoint.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

The PCIE_MSI2 is the register for Endpoint to specify the interrupt vector of MSI interrupt to Root Complex.

56.6.4 PCIE_MSI3 : PCIe MSI Register 3

Base address: PCIE_SPLm = 0x8029_2000 + 0x0030 × m (m = 0, 1)

Offset address: 0x00C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	UI_EXTMSI_VEC4[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	UI_EXTMSI_VEC4[4:0]	Specify the interrupt vector of MSI 4 interrupt for Endpoint.	R/W
31:5	—	These bits are read as 0. The write value should be 0.	R/W

The PCIE_MSI3 is the register for Endpoint to specify the interrupt vector of MSI interrupt to Root Complex.

56.6.5 PCIE_MSI4 : PCIe MSI Register 4

Base address: PCIE_SPLm = 0x8029_2000 + 0x0030 × m (m = 0, 1)

Offset address: 0x010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	UI_EXTMSI_FUNC3[2:0]			—	—	—	—	—	UI_EXTMSI_FUNC2[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	UI_EXTMSI_FUNC1[2:0]			—	—	—	—	—	UI_EXTMSI_FUNC0[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	UI_EXTMSI_FUNC0[2:0]	Specify the interrupt function number of MSI 0 interrupt for Endpoint. Set 000b or 001b.	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
10:8	UI_EXTMSI_FUNC1[2:0]	Specify the interrupt function number of MSI 1 interrupt for Endpoint. Set 000b or 001b.	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
18:16	UI_EXTMSI_FUNC2[2:0]	Specify the interrupt function number of MSI 2 interrupt for Endpoint. Set 000b or 001b.	R/W
23:19	—	These bits are read as 0. The write value should be 0.	R/W
26:24	UI_EXTMSI_FUNC3[2:0]	Specify the interrupt function number of MSI 3 interrupt for Endpoint. Set 000b or 001b.	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

The PCIE_MSI4 is the register for Endpoint to specify the interrupt function number of MSI interrupt to Root Complex.

56.6.6 PCIE_MSI5 : PCIe MSI Register 5

Base address: PCIE_SPLm = 0x8029_2000 + 0x0030 × m (m = 0, 1)

Offset address: 0x014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	UI_EXTMSI_FUNC4[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	UI_EXTMSI_FUNC4[2:0]	Specify the interrupt function number of MSI 4 interrupt for Endpoint. Set 000b or 001b.	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

The PCIE_MSI5 is the register for Endpoint to specify the interrupt function number of MSI interrupt to Root Complex.

56.6.7 PCIE_PME : PCIe PME Register

Base address: PCIE_SPLm = 0x8029_2000 + 0x0030 × m (m = 0, 1)

Offset address: 0x018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CFG_PMCSR_PME_STATUS_F1	CFG_PMCSR_PME_STATUS_F0	—	—	—	—	—	—	—	PME_TIM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PME_TIM	PM_PME Message Clock for Endpoint Toggle the bit every 100 to 150 ms.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	CFG_PMCSR_PME_STATUS_F0	Power Management Event Setting for Endpoint Function #0 This value is set to the PME_Status bit (bit 15) in PM Status/Control Register.	R/W
9	CFG_PMCSR_PME_STATUS_F1	Power Management Event Setting for Endpoint Function #1 This value is set to the PME_Status bit (bit 15) in PM Status/Control Register.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

The PCIE_PME is the register for Endpoint to set PME.

56.6.8 PCIE_ACK : PCIe ACK Register

Base address: PCIE_SPLm = 0x8029_2000 + 0x0030 × m (m = 0, 1)

Offset address: 0x01C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	D3_EVENT_ACK_F1	D3_EVENT_ACK_F0	—	—	—	—	—	—	—	TURN_OFF_EVENT_ACK
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TURN_OFF_EVENT_ACK	Acknowledge to PME_Turn_Off Message for Endpoint When writing 1, sends PME_TO_Ack Message. When reading, 0 is read.	W
7:1	—	The write value should be 0.	W
8	D3_EVENT_ACK_F0	Acknowledge to Power State Transition for Endpoint Function #0 When writing 1, acknowledges the state transition. When reading, 0 is read.	W
9	D3_EVENT_ACK_F1	Acknowledge to Power State Transition for Endpoint Function #1 When writing 1, acknowledges the state transition. When reading, 0 is read.	W
31:10	—	The write value should be 0.	W

The PCIE_ACK is the register for Endpoint to acknowledge to Power Management.

56.6.9 PCIE_MISC : PCIe MISC Register

Base address: PCIE_SPLm = 0x8029_2000 + 0x0030 × m (m = 0, 1)

Offset address: 0x020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	FLR_REQ1	FLR_REQ0	FLR_RESET1	FLR_RESET0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ALLOW_ENTER_L1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ALLOW_ENTER_L1	ASPM L1 State Transition Permission 0: Not permitted to transit from ASPM L0 to ASPM L1 state. 1: Permitted to transit from ASPM L0 to ASPM L1 state.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W
16	FLR_RESET0	Function Level Reset (FLR) for Function #0 When writing 1, performs FLR. When reading, 0 is read.	W
17	FLR_RESET1	Function Level Reset (FLR) for Function #1 When writing 1, performs FLR. When reading, 0 is read.	W
18	FLR_REQ0	Indicates FLR Request for Funtion #0	R
19	FLR_REQ1	Indicates FLR Request for Funtion #1	R
31:20	—	These bits are read as 0. The write value should be 0.	R/W

The PCIE_MISC is the register to set ASPM and FLR.

56.6.10 PCIE_MODE : PCIe Mode Register

Base address: PCIE_SPLm = 0x8029_2000 + 0x0030 × m (m = 0, 1)

Offset address: 0x024

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MODE_PORT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MODE_PORT	Device Type Select 0: Endpoint 1: Root Complex	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

The PCIE_MODE is the register to set device type.

56.6.11 PCIE_LINKMODE : PCIe Link Mode Register

Base address: PCIE_LNK = 0x8029_2060

Offset address: 0x0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	LINK_MASTER[1:0]		—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
9:8	LINK_MASTER[1:0]	Channel Configuration Dynamic change is prohitebed. Change the bits during reset. 0 1: 2 lanes x 1 channel 1 1: 1 lane x 2 channels Others: Setting prohibited	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

The PCIE_LINKMODE is the register to set channel configuration.

56.7 Functional Description

56.7.1 PCIe Core Functions

The functional description of the unit is given below.

This module is configured based on the Base Spec 4.0. For the detailed specification, refer to the Base Spec 4.0. This section mainly describes the parts specific to Renesas Electronics.

56.7.2 Memory Map

56.7.2.1 PCIe to AXI (AXI Window)

Figure 56.4 shows the relation between AXI Window and registers. They are used when MWr/MRd data from PCI Express (RX) is transferred to AXI bus.

Set AWBase and AWMask in the BAR region. (BAR: PCI Express Configuration Register, Base Address Register)

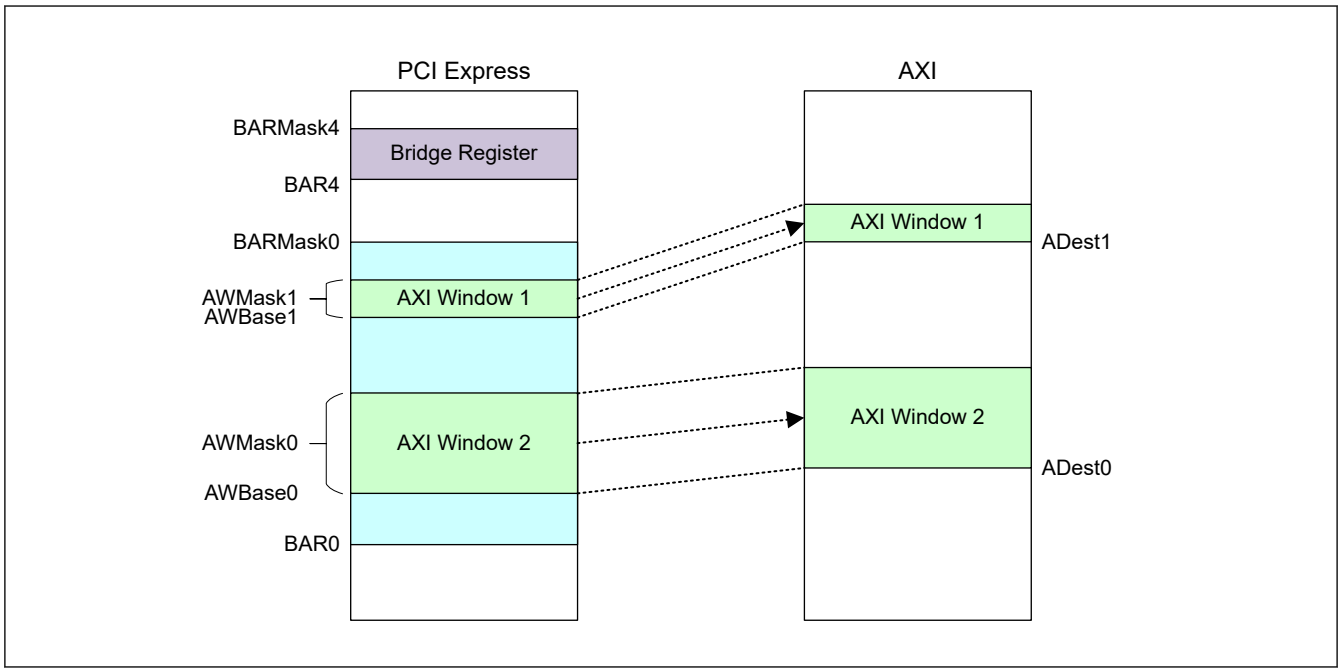


Figure 56.4 Relationship between AXI Window and registers

Set BAR to base address and BARMask to region size. It is possible to have up to 4 windows in that region. Access to AXI is performed within the range of AWMask x from Adest x (x: 0 to 3 corresponding to window number). AXI access address is shown as below. 64-bit address is converted to 32-bit address.

AXI Access Address = PCIe Access Address – BAR0 -AWBase x + ADest x

Note: Address is converted based on BAR.

BAR/BARmask, AWBase x/AWMask x, AWMask x/ADest x should be set not to generate carry bit when two registers are added. Minimum size of the region by BAR/BARMask is 4 KB. Each window and bridge register region should be set not to be overlapped each other.

Table 56.127 and Figure 56.5 are the example of the register setting for PCIe to AXI access.

Table 56.127 Example of the register setting for PCIe to AXI access

BAR0	0x0000_0000_1000_0000	PCIe Configuration Register
BARMask0	0x0000_0000_0FFF_FFFC	PCIe Configuration Register
Assigned region	0x0000_0000_1000_0000 to 0x0000_0000_1FFF_FFFF (256 MB)	
AWBase0	0x0000_0000_0010_0000	AXI Bridge Register
AWMask0	0x0000_0000_0003_FFFF	AXI Bridge Register
ADest0	0x0000_0004_0100_0000	AXI Bridge Register
AXI Window	0x0100_0000 to 0x0103_FFFF (256 KB)	
BAR4	0x0000_0000_2000_0000	PCIe Configuration Register
BARMask4	0x0000_0000_0000_7FFC	PCIe Configuration Register
Assigned region	0x0000_0000_2000_0000 to 0x0000_0000_2000_7FFF (32 KB)	

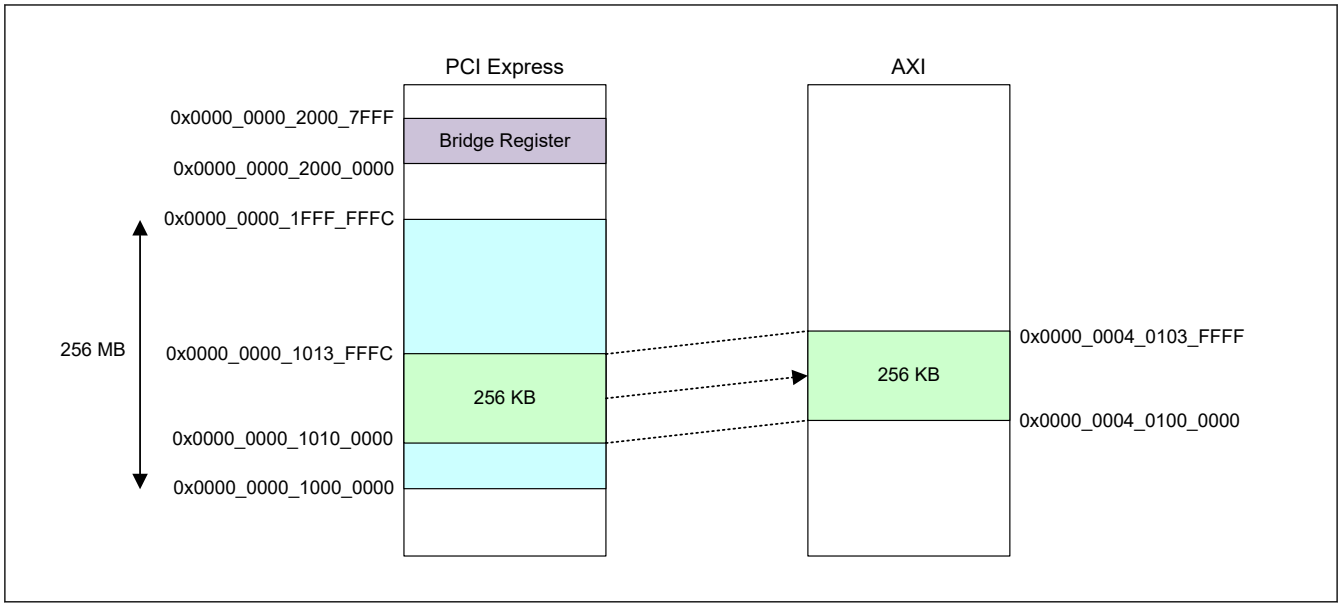

Figure 56.5 Example of the PCI-AXI access for PCIe to AXI access

56.7.2.2 AXI to PCIe (PCIe Window)

Figure 56.6 shows the relation between PCIe Window and registers. They are used when data from AXI bus is transferred to PCI Express (TX) as MWr/MRd.

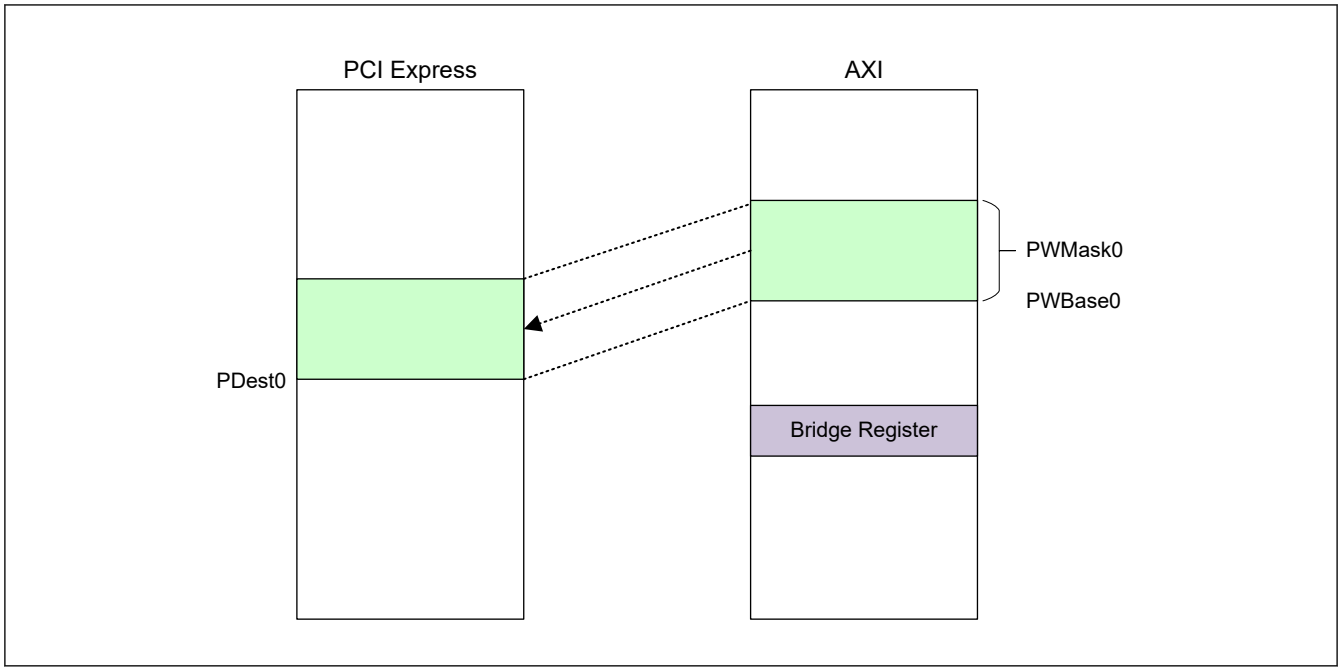

Figure 56.6 Relationship between PCIe Window and registers

It is possible to have up to 4 windows. Access to PCIe is performed within the range of PWMask x from PDest x (x: 0 to 3 corresponding to window number). PCIe access address is shown as below. 32-bit address is converted to 64-bit address.

PCIe Access Address = AXI Access Address – PWBase x + PDest x

Note: No relation to BAR.

Each window and bridge register region should be set not to be overlapped each other.

Table 56.128 and Figure 56.7 are the example of the register setting for AXI to PCIe access.

Table 56.128 Example of the register setting for AXI to PCIe access

BAR0	0x0000_0000_1000_0000	PCIe Configuration Register
BARMask0	0x0000_0000_07FF_FFFC	PCIe Configuration Register
Assigned region	0x0000_0000_1000_0000 to 0x0000_0000_17FF_FFFF (128 MB)	
PWBase0	0x0000_0000_0070_0000	AXI Bridge Register
PWMask0	0x0000_0000_000F_FFFF	AXI Bridge Register
PDest0	0x0000_0004_0070_0000	AXI Bridge Register
PCIe Window	0x0070_0000 to 0x007F_FFFF (1 MB)	

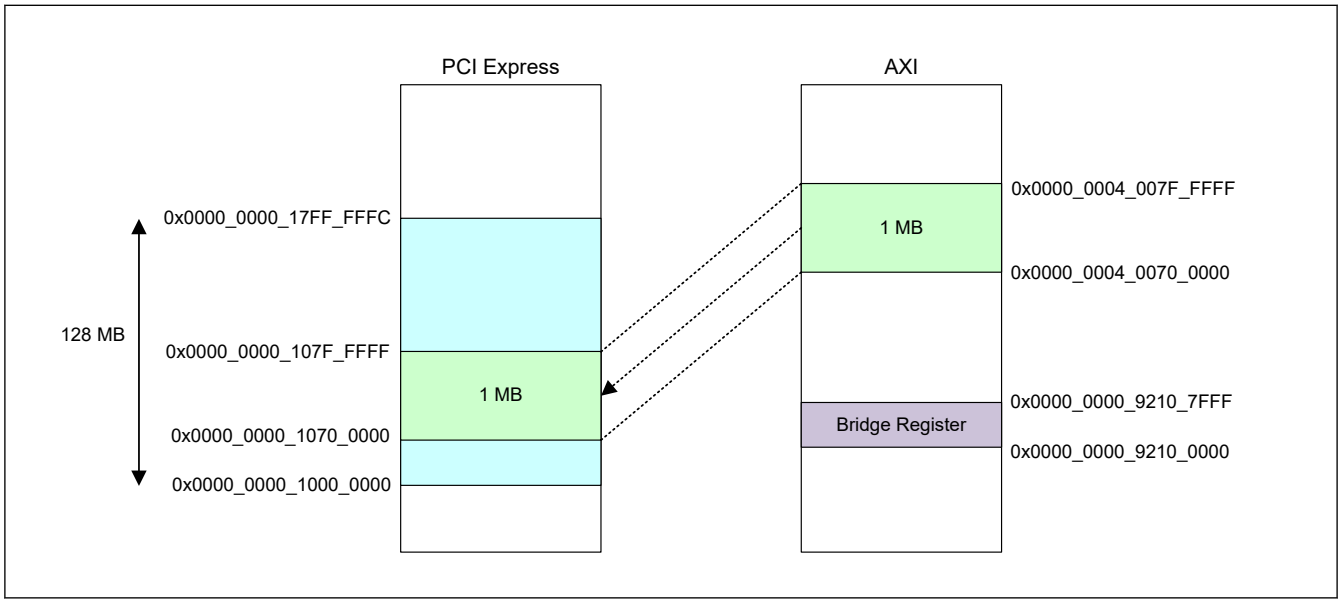

Figure 56.7 Example of the PCI-AXI access for AXI to PCIe access

56.7.3 Issuing of PCIe Requests and Register Access (by AXI)

The following gives functional description on access to the PCI Express core by the AXI bus.

56.7.3.1 PCIe Requests which can be Issued (Supported Commands for TX)

Requests to be issued via pcie windows

MRd: Memory Read Request

MWr: Memory Write Request

Requests to be issued by the registers

MRd: Zero-Length Memory Read Request

CfgRd0: Configuration Read Type 0

CfgWr0: Configuration Write Type 0

CfgRd1: Configuration Read Type 1

CfgWr1: Configuration Write Type 1

Msg: Message Request

MsgD: Message Request with data payload

Unsupported requests (issuance prohibited)

IORd: I/O Read Request

IOWr: I/O Write Request

MRdLk: Memory Read Request-Locked

CplDLk: Completion for Locked Memory Read

Note: If non-posted request with data (CfgWr0/CfgWr1/IOWr) which should not be transmitted is issued inadvertently in EPS mode, an MRd (non-posted request without data) which can be normally transmitted in EP mode may not also be transmitted after that.

56.7.3.2 Register Access

1. Internal register read/write
2. Configuration register read/write

The following restrictions apply to access to the configuration registers.

- Byte-lane transfer is only acceptable if the transfer consists of consecutive valid bytes.
- If the valid bytes are not consecutive, only values which are no greater than 32 bits (1 dword) and do not span the dword alignment are acceptable.
  Example) A value which can represent a dword TLP for PCIe

56.7.3.3 Issuing Memory Requests

Access from the AXI side is converted into a PCIe request and then issued. Up to eight windows can be allocated. Note that only incremental bursts and fixed bursts (of 1 beat) are acceptable. Wrapping bursts and fixed bursts (of 2 or more beats) are prohibited. If these prohibited bursts are received, the unit operates as follows.

- Although the response will in general be "OKAY" (except in cases that involved a protocol error of the AXI), this is beyond the scope of guaranteed operation.
- Unexpected requests may be issued to the PCIe bus.
- Unexpected registers may be modified.

To maintain the order between memory writing and memory reading, only issue next transactions after the reception of responses to writing. Buffering is not available in the issuing of memory write requests. (Refer to the description of AWCACHE* of Mode Set 0 Register (offset: 0x314).)

When accessing to the region out of the window set. the response will be "OKAY" but request is discarded in the module.

(1) Memory Write Transaction from the AXI

A write transaction from the AXI via a window is converted into a MWr command and then issued.

- Number of write transactions which can be accepted at a time: 1
- Write data are held in an internal buffer.
- The order between memory write transactions is preserved (with the exception of transactions for messages and configuration).
- The order of memory write and other transactions is not preserved (a preceding memory read may be overtaken).
- To preserve the order between memory writing and memory reading or of Msg and MsgD, make sure that a next transaction is only issued after a response is returned. Buffering is not available in the issuing of memory write requests.
- Writing does not proceed if the PCI power state is not D0.
- Transactions where all bits of WSTRB are 0 during a burst return an "OKAY" response, but the written data are not reflected.
- Memory requests are not issued after an acknowledgement for PME_Turn_Off Message reception/Non-D0 State transition request reception has been asserted (Precautions: Only for Endpoint mode).

(2) Memory Read Transaction from the AXI

A read transaction from the AXI via a window is converted into an MRd command and then issued.

- Number of read transactions which can be accepted at a time: 1 to 8

- Read data are held in an internal buffer to preserve the order of transactions with the same ID.
- To preserve the order of memory read transactions from a given master ID, the system can also wait until the indicator of completion of a preceding read transaction is returned. The method of waiting is selectable as either of the above by the setting of an internal register as listed in the table below.

PCIe request order*1	Method of waiting	Performance	Severity of order
0 (initial value)	Data read are held in an internal buffer.	✓	—
1	Have the system wait for a read request to be issued.	—	✓

Note 1. The order can be set by using the PCIe Request Order bit (bit [0]) of Mode Set 1 Register (offset: 0x318).

- The order of memory read transactions from a different master ID is not preserved.
- The order of memory read and other transactions is not preserved.
- To preserve the order between memory reading and memory writing, make sure that a next transaction is only issued after a response is returned. Buffering is not available in the issuing of memory write requests.
- MRdLk requests are not supported and therefore cannot be issued.
- Reading does not proceed if the PCI power state is not D0.
- Memory requests are not issued after an acknowledgement for PME_Turn_Off Message reception/Non-D0 State transition request reception has been asserted (Precautions: Only for Endpoint mode).

56.7.3.4 Issuing Special Requests

The following requests can be issued by controlling the internal registers.

- Configuration Read Type0/1
- Configuration Write Type0/1
- Zero-Length Memory Read Request
- Message Request
- Message Request with data payload

The internal registers are only writable from the AXI side. Attempted writing from the PCIe side is ignored and the write operation returns an "OKAY" response, but the written data are not reflected.

The figure below shows the flow of issuing requests by the registers.

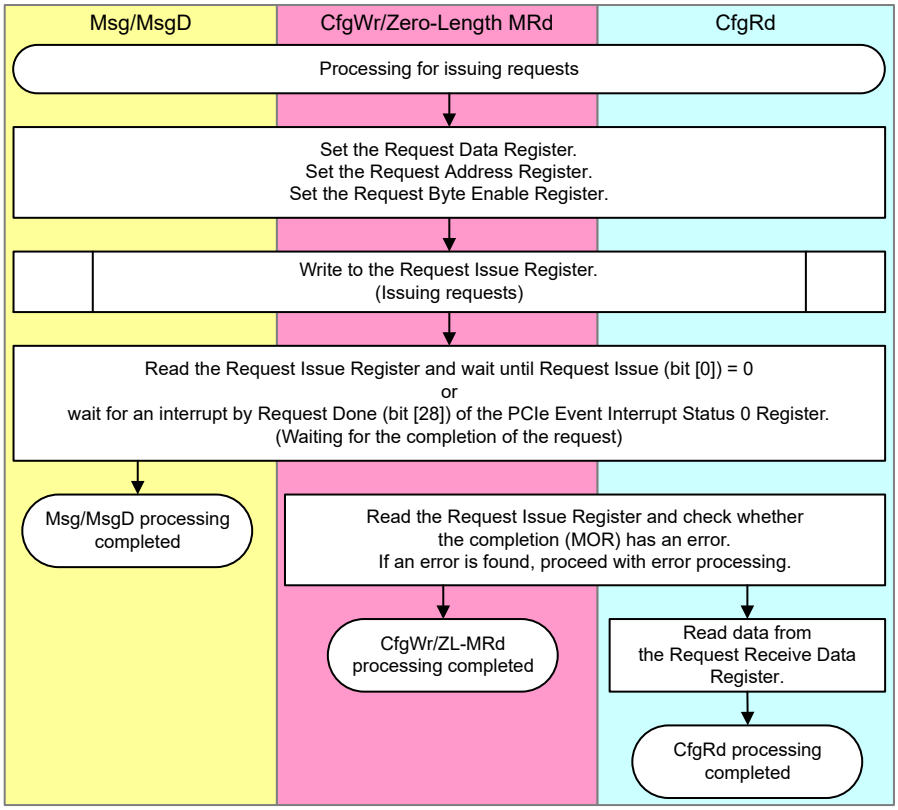

Figure 56.8 Flow of issuing requests

(1) Issuing Configuration Requests

A configuration request is automatically issued by setting the Request Issue bit (bit [0]) of the Request Issue Register after access to an internal register through the AXI slave interface and setting a destination in Request Address Register 1.

(a) Flow of Issuing Configuration Requests

An example of the flow of issuing configuration requests is described below.

1. Set a destination in Request Address Register 1.

Bits [31:24]: Bus Number[7:0]	Specify the number from 0 to 255.
Bits [23:19]: Device Number[4:0]	Speciy the number from 0 to 31.
Bits [18:16]: Function Number[2:0]	Specify the number from 0 to 7.
Bits [15:12]: Reserved	Fixed to 0000b.
Bits [11:8]: Extend Register Number[3:0]	Set the number of address.
Bits [7:2]: Register Number[5:0]	Set the number of address.
Bits [1:0]: Reserved	Fixed to 00b.

2. Set the Byte Enable in Request Byte Enable Register. When reading/writing each byte, set Enable/Disable each corresponding byte lane (Default: 1111b).
3. For CfgWr, set write data in Request Data Registers 2 (not required in case of CfgRd).
4. Configuration requests are automatically issued by setting the Request Issue bit (bit [0]) of the Request Issue Register to 1 (the TR type bits (bits [11:8]) of the Request Issue Register are used to set CfgWr/CfgRd).
5. Read the Request Issue Register and wait (polling) or wait for an interrupt of Request Done (bit [28]) of PCIe Event Interrupt Status 0 Register until the Request Issue bit (bit [0]) is set to 0, wait for the request to end.
6. For CfgRd, CpID is stored to Request Receive Data Register from facing Endpoint device. Read this register.

(2) Issuing Message Requests

A message request is automatically issued by setting the Request Issue bit (bit [0]) of the Request Issue Register after access to an internal register through the AXI slave interface and setting a destination in Request Address Register 1.

(a) Flow of Issuing Message Requests

An example of the flow of issuing message requests is described below.

1. Set a destination in Request Address Register 1.

   Bits [31:27]: Reserved Fixed to 0_0000b.

   Bits [26:24]: Routing Type Specify the message routing.

   Bits [23:8]: Reserved Fixed to 0x0000.

   Bits [7:0]: Message CodeSpecify the message code.

2. Set the 3rd header in Request Data Register 0 as required.
3. Set the 4th header in Request Data Register 1 as required.
4. For MsgD, set write data in Request Data Register 2 (not required in the case of Msg).
5. Message requests are automatically issued by setting the Request Issue bit (bit [0]) of the Request Issue Register to 1 (the TR type bits (bits [11:8]) of the Request Issue Register are used to set Msg/MsgD).
6. Read the Request Issue Register and wait (polling) or wait for an interrupt of Request Done (bit [28]) of PCIe Event Interrupt Status 0 Register until the Request Issue bit (bit [0]) is set to 0, wait for the request to end.

(b) Notes when Issuing Message Requests

Points to note when issuing message requests are described below.

- INTx and error type messages are automatically issued. They do not require issuing as message requests by the user (prohibited).
- Set message headers appropriately.
- A value to be set in a message header must be 0 except when sending a vendor defined message.

(3) Issuing Zero-Length Read Requests

A zero-length read request is automatically issued by setting a destination in Request Address Register 1 after access to an internal register through the AXI slave interface and setting the Request Issue bit (bit [0]) of the Request Issue Register.

(a) Flow of Issuing Zero-Length Read Requests

An example of the flow of issuing zero-length read requests is described below.

1. Set a destination in Request Address Register 1.

   Bits [31:2]: Address Set the address.

   Bits [1:0]: Reserved Fixed to 00b.

2. Set a destination in Request Address Register 1.

   Bits [64:32]: Address Set the address.

3. Set Byte Enable (0000b) in Request Byte Enable Register.
4. Zero-length read requests are automatically issued by setting the Request Issue bit (bit[0]) of the Request Issue Register to 1 (the TR type bits (bits [11:8]) of the Request Issue Register are used to set zero-length read).
5. Read the Request Issue Register and wait (polling) or wait for an interrupt of Request Done (bit [28]) of PCIe Event Interrupt Status 0 Register until the Request Issue bit (bit [0]) is set to 0, wait for the request to end.

56.7.4 Initiation of AXI Transactions and Register Access (by PCIe)

The following gives functional description on access to the AXI bus by the PCI Express core.

56.7.4.1 PCIe Requests which can be Received (Supported Commands for RX)

MRd:	Memory Read Request
MWr:	Memory Write Request
CfgRd0:	Configuration Read Type 0
CfgWr0:	Configuration Write Type 0
Msg:	Message Request
Cpl:	Completion
CplD:	Completion with Data

The following requests are not supported.

MRdLk:	Memory Read Request-Locked
IORd:	I/O Read Request
IOWr:	I/O Write Request
CplLK:	Completion for Locked Memory Read without Data
CplDLk:	Completion for Locked Memory Read
CfgRd1:	Configuration Read Type 1
CfgWr1:	Configuration Write Type 1

AtomicOP is not supported.

56.7.4.2 Initiation of AXI Transactions

Access from the PCIe side is converted into an AXI transaction and then issued. Up to eight windows can be allocated.

To avoid a read-after-write (RAW) hazard, only issue a next memory write request following reception of the completion TLP for the previous one.

Table 56.129 AXI transaction from PCIe request

PCIe request	AXI burst type	AXI bus size	Division
MWr/MRd	Incremental	64	Yes
		32	No
IOWr/IORd	Unsupported request		
MRdLk	Unsupported request		

(1) Memory Write Transaction from the PCIe

- Allowable number of write requests to be issued: Variable (the value is set by the AXI Max Issue Write bits (bits [15:12]) of Mode Set 1 Register).
- Write data are not held in an internal buffer (buffering within the PCIe core).
- The order between memory write transactions is preserved.
- The order of memory writing and memory reading is not preserved.
- To preserve the order between memory writing and memory reading, make sure that a next request is only issued after a completion TLP is returned.
- AWCACHE and AWPROT can be set by using Mode Set 0 Register.
- In cases of contention between DMA transfer (from PCIe to AXI) and memory write transaction, requests are accepted in turn in round-robin fashion.

(2) Memory Read Transaction from the PCIe

- Allowable number of read requests to be issued: Variable (the value is set by the AXI Max Issue Read bits (bits [11:8]) of Mode Set 1 Register).
- Since the PCI specification requires dword-aligned memory addresses in transfer, invalid byte lanes may be read. If an AXI slave as a read destination has a register or FIFO buffer which has been cleared by being read, the transaction may be non-compliant.
- Data read are held in an internal buffer.
- The order between memory read operations is preserved.
- A preceding memory write is not overtaken.
  Data read are held in an internal buffer until a preceding memory write is completed.
  When a zero-length read request is received, an "OKAY" response is returned, but the written data are not reflected and a completion TLP is transmitted after waiting for the completion of the preceding memory write.
  Data read are held in an internal buffer until a preceding memory write is completed.
- ARCACHE and ARPORT can be set by using Mode Set 0 Register.
- In cases of contention between DMA transfer (from AXI to PCIe) and memory read transaction, requests are accepted in turn in round-robin fashion.

56.7.4.3 Narrow Transfer

Narrow transfer to be initiated by the AXI transfer only supports the following AXI transactions.

- MAxBURST = INCR
- MAxSIZE = 0x0 to 0x2 (8 bits / 16 bits / 32 bits)
- MAxLEN = 0x0 (1 beat)

The following restrictions apply to TLPs from the PCIe module in narrow transfer.

- The length is 1 dword.
- The First Byte Enable bit only supports the following.
  - MAxSIZE = 0x0 (8 bits): 1000b / 0100b / 0010b / 0001b
  - MAxSIZE = 0x1 (16 bits): 1100b / 0011b
  - MAxSIZE = 0x2 (32 bits): 1111b

56.7.5 DMAC Functions

This section explains functions of the DMAC within the unit. Control by registers and by descriptors are both supported as methods of DMA control. The method of control is independently selected per channel.

56.7.5.1 Register-Type Transfer

Table 56.130 Registers related to register-type DMA transfer (1 of 2)

Common control	
0x800	DMAC Control Register
0x808	DMAC Interrupt Enable Register
0x080C	DMAC Interrupt Status Register
Channel control	
0x900 + channel offset	DMA Channel Control Register m
DMA setting	
0x924 + channel offset	DMA Transaction Control Register m

Table 56.130 Registers related to register-type DMA transfer (2 of 2)

Common control	
0x928 + channel offset	DMA Size Register m
0x930 + channel offset	DMA Source Lower Address Register m
0x934 + channel offset	DMA Source Upper Address Register m
0x938 + channel offset	DMA Destination Lower Address Register m
0x93C + channel offset	DMA Destination Upper Address Register m
DMA status	
0x950 + channel offset	DMA Rest Size Register m
0x960 + channel offset	AXI Request Address (Lower) Register m
0x964 + channel offset	AXI Request Address (Upper) Register m
0x968 + channel offset	PCIe Request Address(Lower) Register m
0x96C + channel offset	PCIe Request Address(Upper) Register m
0x978 + channel offset	DMAC Error Status Register m

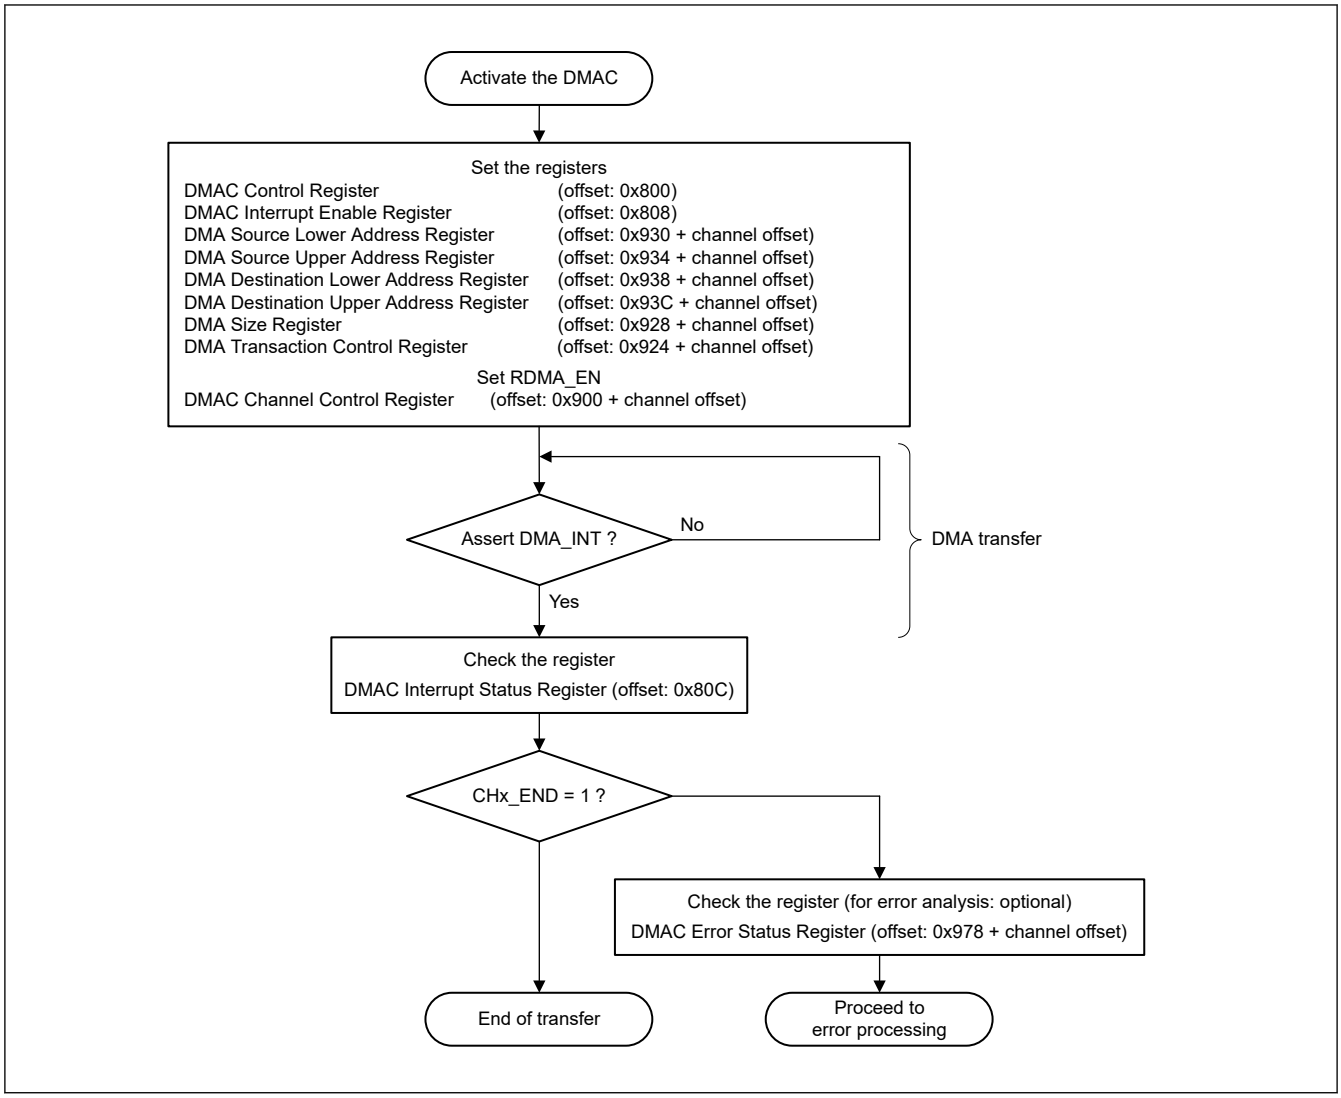
Note: One transfer byte size is up to 4 GB for register-type DMA transfer.

(1) Flow of Operations

The following describes the procedures for settings to activate and stop the DMAC in the case of register-type transfer.

(a) Activation and Normal Operation

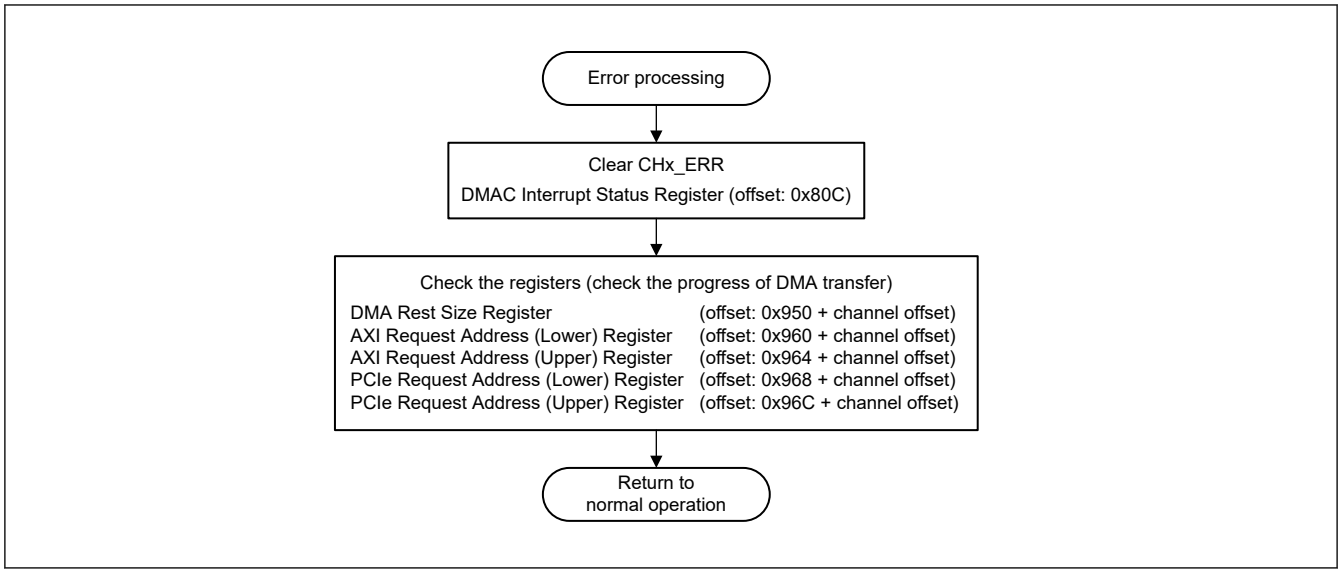
Before activating the DMAC, set the PCIe and AXI windows. After that, set the registers of the DMAC to start the DMAC.



(b) Error Processing

If an error is detected in the AXI bus or a PCIe link while DMA transfer is in progress, the DMA_INT interrupt signal is asserted. Check the channel where the error was found (CHx_ERR = 1) by using the DMAC interrupt status register and also the type of error by using the DMAC error status register (offset: 0x978 + channel offset) as required.

Clear the CHx_ERR bit that is currently set in the DMAC interrupt status register (offset: 0x80C) to 0 by writing to it. The address to which transfer was most recently completed before it was stopped and the remaining number of bytes for transfer can be checked by reading the DMA Status registers (offset: 0x950 + channel offset to 0x978 + channel offset) for the given channel.



56.7.5.2 Descriptor-Type Transfer

Consecutive DMA transfer is achieved by sequentially reading descriptors which indicate parameters of DMA transfer. Descriptors are allocated to the AXI memory space and the descriptor lists indicate the addresses where the descriptors start. This DMAC has a queue for storing multiple descriptor lists and these descriptor lists are written by software. The first list loaded in the queue is executed after being moved to become the descriptor list for execution following the detection of the condition for starting DMA transfer (the DMAC retains up to nine lists, including the one currently being executed).

Descriptors can have a chained configuration; execution of a descriptor list ends on detection of the last descriptor, and if the queue has a next list, execution of the next descriptor follows.

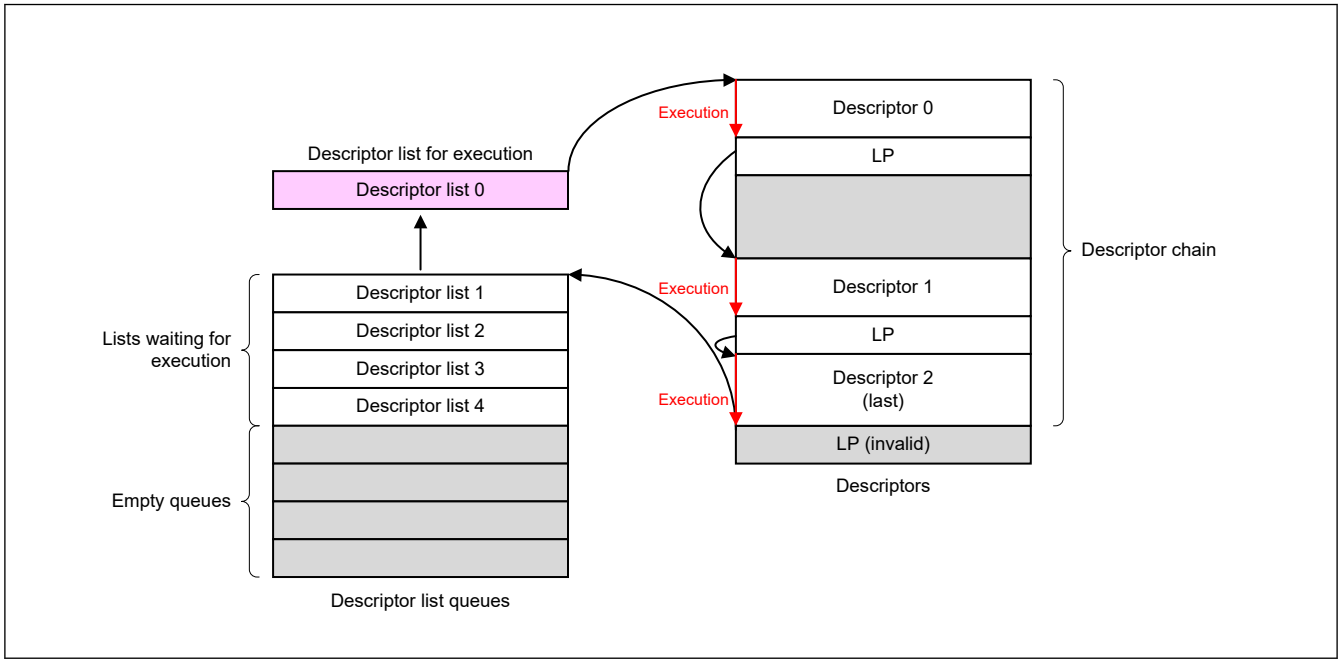


Figure 56.9 Descriptor chain

The table below lists the DMAC registers for execution of descriptor-type DMA transfer.

Table 56.131 Registers related to descriptor-type DMA transfer (1 of 2)

Common control	
0x800	DMAC Control Register

Table 56.131 Registers related to descriptor-type DMA transfer (2 of 2)

Common control	
0x808	DMAC Interrupt Enable Register
0x80C	DMAC Interrupt Status Register
Channel control	
0x900 + channel offset	DMA Channel Control Register m
0x908 + channel offset	Descriptor Start Address (Lower) Register m
0x90C + channel offset	Descriptor Start Address (Upper) Register m
0x910 + channel offset	QUE Entry Register
DMA setting	
0x920 + channel offset	DMA Descriptor Control (Descriptor 0x00) Register m
0x924 + channel offset	DMA Transaction Control (Descriptor 0x04) Register m

0x930 + channel offset	DMA Source Lower Address (Descriptor 0x10) Register m
0x934 + channel offset	DMA Source Upper Address (Descriptor 0x14) Register m
0x938 + channel offset	DMA Destination Lower Address (Descriptor 0x18) Register m
0x93C + channel offset	DMA Destination Upper Address (Descriptor 0x1C) Register m
0x940 + channel offset	DMA Descriptor Link Lower Pointer (Descriptor 0x20) Register m
0x944 + channel offset	DMA Descriptor Link Upper Pointer (Descriptor 0x24) Register m
DMA status	
0x950 + channel offset	DMA Rest Size Register m
0x960 + channel offset	AXI Request Address (Lower) Register m
0x964 + channel offset	AXI Request Address (Upper) Register m
0x968 + channel offset	PCIe Request Address(Lower) Register m
0x96C + channel offset	PCIe Request Address(Upper) Register m
0x970 + channel offset	QUE Status Register m
0x978 + channel offset	DMAC Error Status Register m

(1) Descriptor List Queues

The DMAC has queues for storing descriptor lists for each of the channels. The number of FIFO queue stages is eight, so it can hold up to eight descriptor list entries (not including the one currently being executed).

Software places descriptor list entries in the queue. The descriptor lists to be entered are set by the Descriptor Start Address (Upper), Descriptor Start Address (Lower) and QUE_ENTRY registers.

Since the target registers are also accessible in 8-bit units, making the settings in byte units through multiple accesses is also possible. A descriptor list entry is placed in the queue at the time when the QUE_ENTRY (upper) bits [31:24] are written. When making the settings and entering lists in the queue, take care with the order of register access (values written to the QUE_ENTRY (upper) bits [31:26] will not affect the register values and settings because they are readonly bits).

When the DMAC detects the presence of a list which has been entered in the queue, the first list entry is moved to become the pointer to the next descriptor for execution and DMA transfer starts.

(2) Descriptor List Format

The table below is the format of a descriptor list.

Table 56.132 Descriptor list format (1 of 2)

Offset	Byte 3			Byte 2	Byte 1	Byte 0
0x00	DSA[31:0]					
0x04	DSA[63:32]					
0x08	Reserved	EI	LS	Reserved	LABEL[15:0]	

Table 56.132 Descriptor list format (2 of 2)

Field name	Description
DSA[63:0]	Descriptor start address for DMA. This field indicates the address where the first descriptor to be executed is stored. Since the setting is for 16-byte alignment and allocation of a single descriptor (0x00 to 0x24) to straddle a 4-K boundary is prohibited, the 6 lower-order bits [5:0] are fixed to 000000b.
EI	End Interrupt bit. This bit indicates whether an interrupt (Interrupt Status CHx_END of the DMAC Interrupt Status Register (offset: 0x80C)) is or is not conveyed when processing of this descriptor list is completed. 0: The interrupt is not conveyed. 1: The interrupt is conveyed.
LS	List Stop bit. This bit indicates whether DMA transfer is or is not to be stopped on completion of processing for this descriptor list entry. 0: Not stopped 1: Stopped On completion of the list in which the setting of this bit is 1, the QUE_EN bit of the DMAC control register is cleared.
LABEL[15:0]	This field represents the label of the list. There are no special rules for the setting procedures. The value can be set as desired.

Operations by the settings of the EI and LS bits following the completion of the descriptor list are as follows.

Table 56.133 Details of the EI/LS bits

EI	LS	Description
0	0	No interrupt. DMA transfer is not stopped. If the queue has a next list, execution of the next descriptor follows.
0	1	No interrupt. DMA transfer is stopped (QUE_EN is cleared).
1	0	Interrupt (DMAC Interrupt Status Register (Offset: 0x80C), Interrupt Status CHx_END) is present. DMA transfer is not stopped. If the queue has a next list, execution of the next descriptor follows.
1	1	Interrupt (DMAC Interrupt Status Register (Offset: 0x80C), Interrupt Status CHx_END) is present. DMA transfer is stopped (QUE_EN is cleared).

(3) Descriptor Format

The table below is the format of descriptors.

Table 56.134 Descriptor list format (1 of 4)

Offset	Byte 3								Byte 2								Byte 1								Byte 0							
0x00	DSCFM[3:0]				—	WBD	LE	LV	D	—	—	—	—	—	—	—	STS[15:0] (not used)															
0x04	—	—	—	—	—	—	—	—	CCH_L[3:0]				CCH_D[3:0]				—	TC[2:0]			—	—	ATB[1:0]		—	DMA_FUNC[2:0]				—	—	—	DIR
0x08	SIZE[31:0]																															
0x0C	Reserved																															
0x10	SA[31:0]																															
0x14	SA[63:32]																															
0x18	DA[31:0]																															

Table 56.134 Descriptor list format (2 of 4)

Offset	Byte 3	Byte 2	Byte 1	Byte 0
0x1C	DA[63:32]			
0x20	LP[31:0]			
0x24	LP[63:32]			

Table 56.134 Descriptor list format (3 of 4)

Field name	Description
DSCFM[3:0]	The Descriptor Format field specifies the format of descriptors. This DMAC only supports 0001b. Do not set any other value.
WBD	Write Back Disable bit Indicates whether the DMAC writes 0 back to the LV bit when DMA transfer specified by a single descriptor is completed. 0: The LV bit is written back. 1: The LV bit is not written back.
LE	List End bit Indicates the end of the current descriptor chain. 0: The current descriptor is not the last of the chain. 1: The current descriptor is the last of the chain.
LV	Link Valid bit Indicates that the descriptor is valid. When DMA transfer is completed, the DMAC writes 0 back to this bit. When DMA transfer ends due to an error, write-back does not proceed. 0: The descriptor is not valid (DMA transfer specified by the descriptor is completed). 1: The descriptor is valid (DMA transfer specified by the descriptor is not completed).
D	Descriptor error bit Indicates a descriptor access error. If LV = 0 when the descriptor is read, the DMAC writes 1 back to the LV bit. When a descriptor error occurs, if the setting of the LE bit is 0 (indicating that the current descriptor is not the last of the chain), the DMAC continues transfer in accord with the descriptor the LP bits indicate. 0: No error 1: A descriptor access error occurred.
STS[15:0]	This field has no effect when DSCFM = 0001b. The DMAC does not use this field.
CCH_L[3:0]	This field indicates the value of A*CACHE[3:0] to be issued through the AXI. The value of CCH_L[3:0] is output when an AXI request including the last byte is issued in transfer specified in the SIZE bits. Bit [0]: Buffer enabled Bit [1]: Cache enabled Bit [2]: Read allocation Bit [3]: Write allocation The recommend value is 0000b regardless of whether DIR is 0 or 1.
CCH_D[3:0]	This field indicates the value of A*CACHE[3:0] to be issued through the AXI. The value of CCH_D[3:0] is output when an AXI request other than the condition for the output of CCH_L[3:0] is issued. Bit [0]: Buffer enabled Bit [1]: Cache enabled Bit [2]: Read allocation Bit [3]: Write allocation The recommended value is 0001b when DIR = 0 (PCIe → AXI) and 0000b when DIR = 1 (AXI → PCIe).
TC[2:0]	This field specifies the value of the traffic class of the request to be issued through the PCIe interface. The value must be fixed to 000b.
ATB[1:0]	This field indicates the value of the attribute to be issued through the PCIe interface. Bit [0]: No-snoop Bit [1]: Relaxed ordering If neither relaxed ordering nor no-snoop is used, this field should be set to 00b (recommended).
DMA_FUNC[2:0]	This field specifies the function number of the request to be issued through the PCIe interface.

Table 56.134 Descriptor list format (4 of 4)

Field name	Description
DIR	This bit indicates the direction of data transfer. 0: PCIe → AXI 1: AXI → PCIe
SIZE[63:0]	This field indicates the number of bytes for transfer. Since the setting is for 16-byte alignment, do not set a value other than 0000b to the 4 lower-order bits ([3:0]).
SA[63:0]	The Source Address field indicates the address of the source data for transfer. Since the setting is for 16-byte alignment, do not set a value other than 0000b to the 4 lower-order bits ([3:0]).
DA[63:0]	The Destination Address field indicates the destination address. Since the setting is for 16-byte alignment, do not set a value other than 0000b to the 4 lower-order bits ([3:0]).
LP[63:0]	This field indicates the address where a next descriptor is stored. Since the setting is for 16-byte alignment and allocation of a single descriptor (0x00 to 0x24) to straddle a 4-K boundary is prohibited, the 6 lower-order bits [5:0] are fixed to 000000b.

The conditions where the descriptor is written back after the descriptor is read, the timings, and the corresponding bits are listed below.

Condition	Timing	Corresponding bit and value
WBD = 0 && LV = 1	After DMA transfer specified by the descriptor is completed	LV = 0
WBD = (1 or 0) && LV = 0	After the descriptor is read (DMA transfer does not proceed)	D = 1
WBD = 1 && LV = 1	Write-back does not proceed.	—

(4) Flow of Operations

The following describes the procedures for settings to activate and stop the DMAC in the case of descriptor-type transfer.

(a) Activation and Normal Operation

Before activating the DMAC, set the PCIe and AXI windows. After that, set the registers of the DMAC to start the DMAC.

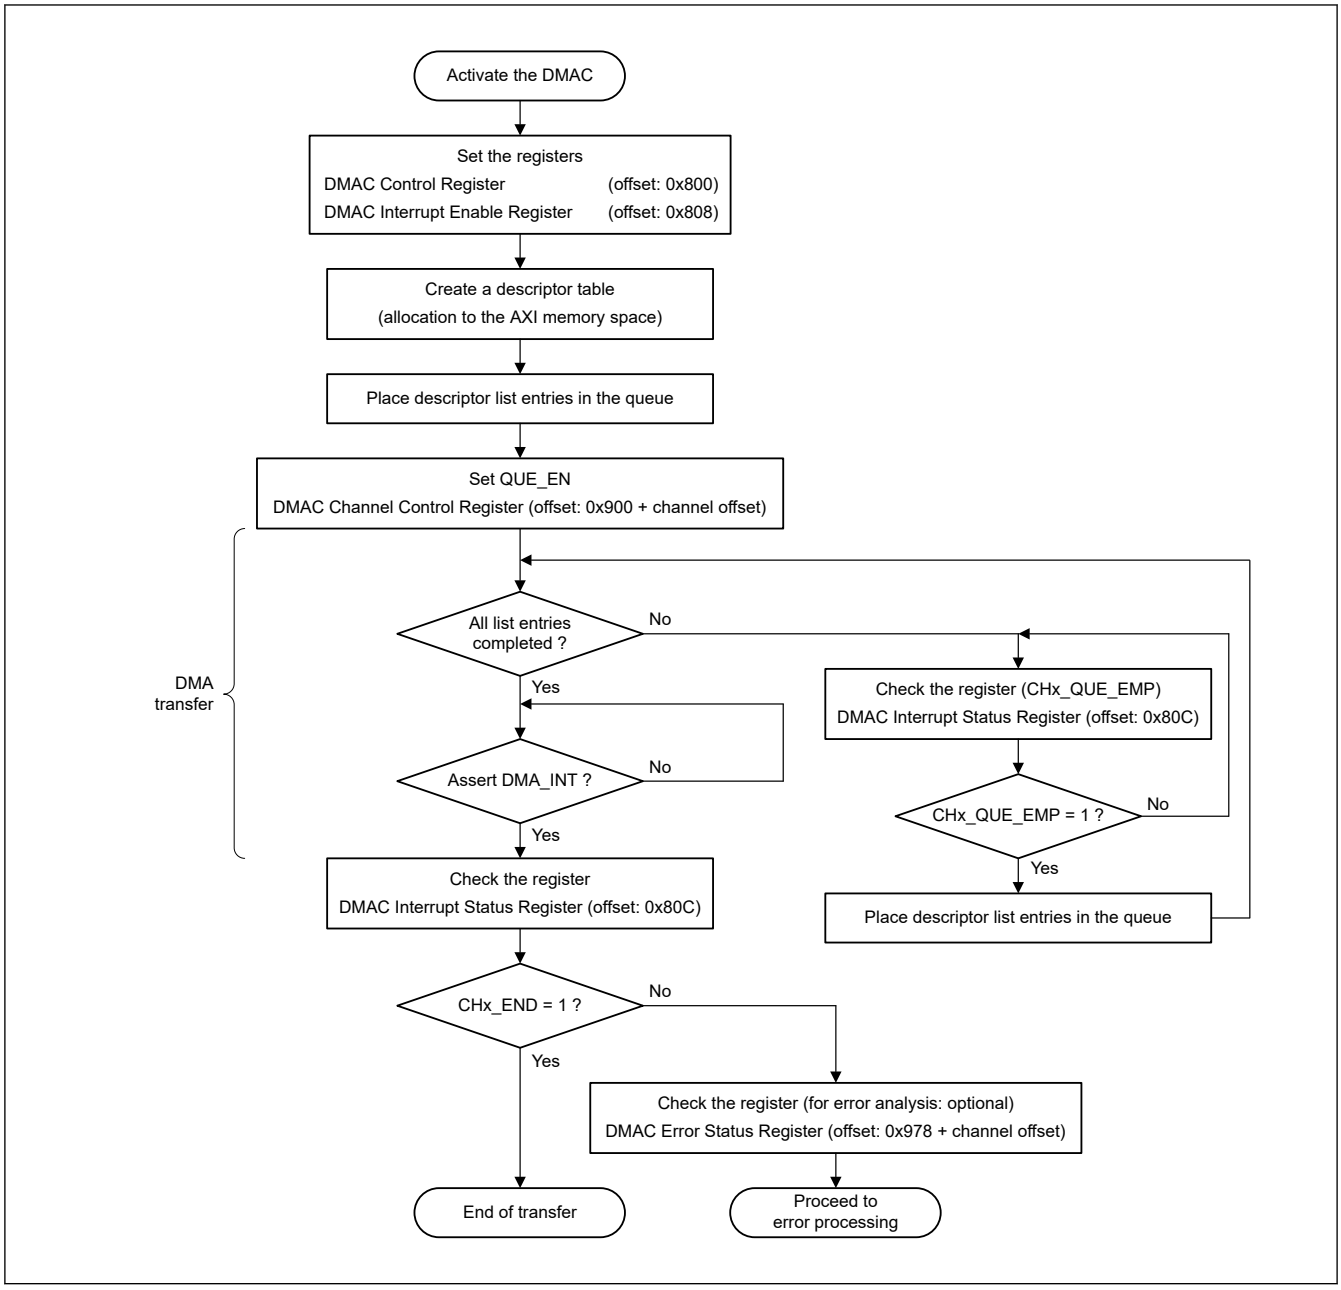

Figure 56.10 Flow of activation and normal operation

(b) Error Processing

If an error is detected in the AXI bus or a PCIe link while DMA transfer is in progress, the DMA_INT interrupt signal is asserted. Check the channel where the error was found (CHx_ERR = 1) by using the DMAC interrupt status register and also the type of error by using the DMAC error status register (offset: 0x978 + channel offset) as required.

Clear the CHx_ERR bit that is currently set in the DMAC interrupt status register (offset: 0x80C) to 0 by writing to it. The address to which transfer was most recently completed before it was stopped and the remaining number of bytes for transfer can be checked by reading the DMA Status registers (offset: 0x950 + channel offset to 0x978 + channel offset) for the given channel.

Based on that information, setting the registers as described in (a) Activation and Normal Operation and create a descriptor table again. At this time, write 1 to the QUE_CLR bit (bit [8]) of the DMAC channel control register (offset: 0x900 + channel offset). Writing 1 to it leads to clearing of the queue. The descriptor lists registered in the queue (those waiting for execution and the one currently being executed) are all cleared.

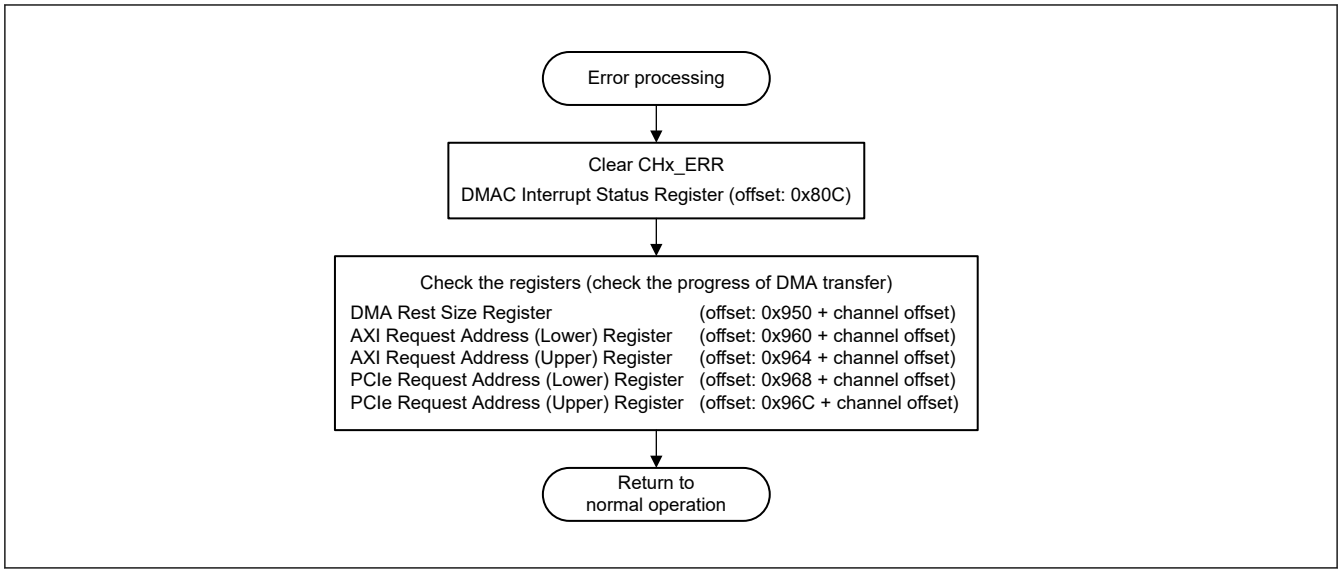

Figure 56.11 Flow of error processing

56.7.5.3 Method of Transfer

This section describes the issuing of requests to the AXI or PCIe and data transfer in the case of DMA transfer. In either direction of transfer (from AXI to PCIe or vice versa), a request is issued to the reading side. After confirming the completion of preparation (reception) of the data to be read, a request is issued to the writing side for data transfer.

(1) DMA Transfer from PCIe to AXI

An MRd is issued to the PCIe module and an AXI write request is transferred following the reception of CplD from the PCIe. MRd requests corresponding to the number of outstanding transfers can be issued regardless of the reception of CplD. The received CplD (read data) is stored in the data buffer (RAM) once and then transferred by the DMAC to the AXI.

(2) DMA Transfer from AXI to PCIe

After the DMAC is activated, a read request (address channel) is issued to the AXI. The reception of data for reading from the given AXI slave starts and an MWr is issued to the PCIe. Data are repeatedly transferred until the completion of DMA data transfer corresponding to the amount of data set in the DMA Size bits.

56.7.5.4 Inter-Channel Arbitration

The DMAC arbitrates the following three types of request between channels.

1. PCIe Read Request
2. AXI Read Request
3. AXI Write Request

PCIe write requests do not require arbitration because data read over the AXI are returned one by one.

In the case of arbitration on the AXI side, not only requests for DMA data, but also reading and writing of descriptor data are subject to arbitration (each channel has a single source of requests for arbitration since a channel will not output a descriptor and request for data at the same time).

(1) Method of Arbitration

An MRd is issued to the PCIe module and an AXI write request is transferred following the reception of CplD from the PCIe. MRd requests corresponding to the number of outstanding transfers (eight) can be issued regardless of the reception of CplD. The received CplD (read data) is stored in the data buffer (RAM) once and then transferred by the DMAC to the AXI.

Arbitration for each type of request 1) to 3) above proceeds in round-robin fashion. A channel for which execution has just been completed is given the lowest priority and each channel which had a lower priority than that channel is raised by one rank in the order of priority.

The initial order of priority is ch. 0 > ch. 1 > ch. 2 > ch. 3 > ch. 4 > ch. 5 > ch. 6 > ch. 7.

The order of priority is changed every time a single request is completed.

There are two types of request for the AXI, requests for DMA data and requests for descriptors, but they are not distinguished for purposes of arbitration.

56.7.5.5 DMA Completed Interrupt

The DMAC has interrupt functions. It supports two types of interrupt source: one set is for normal operation and the other is for errors. For details, see section 56.7.7.5. DMA Interrupt.

56.7.6 Reception of PCIe Commands

56.7.6.1 Reception of MSIs (Root Complex)

When MSI is received (see judgment conditions), it is forwarded to AXI as a Write Transaction and reflected in the MSI reception status (see status). An interrupt signal (INTMSI_RC) is asserted when the MSI reception interrupt generation condition (see Interrupt conditions) is met. S/W identifies MSI by the interrupt factor. If Message Data Enable = 0, the cause can be identified by reading the data on the memory.

[Related registers]

- MSI Receive Window Address (Lower) Registers (Offset: 0x100): Message Data Enable
- PCI INTx Receive Interrupt Enable Registers (Offset: 0x110): MSI Receive Interrupt Enable
- PCI INTx Receive Interrupt Status Registers (Offset: 0x114): MSI Receive Interrupt Status
- MSI Receive Mast n Registers (Offset: 0x6x8): MSI Mask
- MSI receive Status n Registers (Offset: 0x6xC): MSI Status

The conditions for judging a request to be an MSI:

When all of the following conditions are satisfied, a request is judged to be an MSI.

- The request is a memory write request.
- The request is entered for any area within an AXI window.
- The address of an MWr from the PCIe interface must be within the area set by the MSI Reception Window Address register and the MSI Reception Window Mask register.
  If a memory read request is received in the MSI reception area, the request is not judged to be an MSI so an interrupt is not generated.
- The length of memory write requests is 1 dword
- When MessageData matches (Only when Message Data Enable = 1)

[Status]

- When Message Data Enable = 0
  Set MSI Receive Interrupt Status (bit[4])
- When Message Data Enable = 1
  Set the corresponding Vector bit in MSI Status

[Interrupt condition]

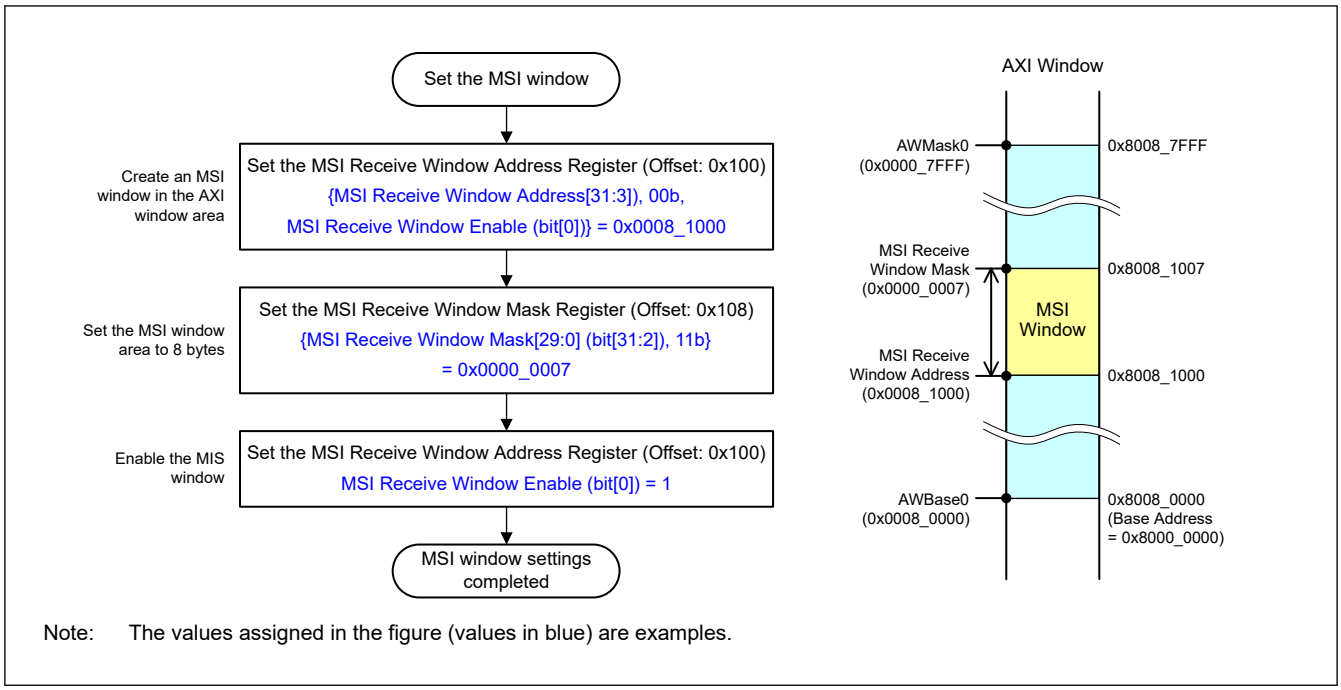
- When Message Data Enable = 0
  When MSI Receive Interrupt Enable (bit[4]) is set
- When Message Data Enable = 1
  When bit 0 of vector corresponding to MSI Mask

Notes on the MSI:

- When a response to the MSI write transaction is returned, this module judges execution of the MSI to have been completed and asserts an interrupt signal. Depending on the system, however, the MSI memory write transaction may not be completed due to the latency over the AXI to the actual memory even if the interrupt signal is asserted. To avoid this problem, buffering of AXI write transactions must be disabled (MAWCACHE[0] = 0) at the time an MSI is issued. For MAWCACHE[3:1], the setting of AWCACHE_L (bits [27:24]) of Mode Set 0 Register is used.
- If an MSI is received, the MSI write transaction is executed when MAWID[3:0] = 0x1. This is required for the unit to recognize the reception of the response to the MSI and for assertion of INTMSI_RC.

56.7.6.2 Setting the MSI Window

To enable MSI interrupts, the MSI window must be set. Figure 6.10-2 shows example settings. The MSI window can be allocated within any AXI window.



Note: The values assigned in the figure (values in blue) are examples.

Figure 56.12 Settings for the MSI window

56.7.6.3 Reception of an Interrupt in Respone to a Message Request (Root Complex)

When Assert_INTx is received in response to an Msg request from the PCIe interface, the corresponding interrupt bit (bits [3] to [0]) is set in the PCI INTx Receive Interrupt Status Register (offset: 0x114) and an interrupt (INTx_RC) is asserted. When Deassert_INTx is received in response to a message request, the corresponding interrupt register (bit) is cleared and INTx_RC is de-asserted. The PCI INTx Receive Interrupt Status Register (offset: 0x114) can be cleared by writing to it (RW1C) by software. In the PCIe, however, we do not recommend using software to clear an interrupt bit which has been set in response to an Msg in normal operation.

56.7.6.4 Reception of Message Requests

When a message is received through the PCIe interface, the relevant information is stored in the following registers.

Table 56.135 Message related registers (1 of 2)

	Related register
Message Code/Routing	Message Code Register (Offset: 0x130)
Message Data	Message Data Register (Offset: 0x134)

Table 56.135 Message related registers (2 of 2)

	Related register
Message 3rd Header	Message Header 3rdDW Register (Offset: 0x138)
Message 4th Header	Message Header 4thDW Register (Offset: 0x13C)

The corresponding bit in the Message Receive Interrupt Status Register is set at the same time as the reception of the following messages, and this is indicated by an interrupt.

Table 56.136

Received message		Corresponding bit in message receive interrupt status register
Type of message	Message code	
PM_Active_State_Nak	0001_0100	Bit [19]
PM_PME	0001_1000	Bit [18]
PME_Turn_Off	0001_1001	Bit [17]
PME_TO_Ack	0001_1011	Bit [16]

In the reception of PM messages other than the above, the relevant information is not written to the registers listed in Table 6.10-7.

- Unsupported messages:
  - Unlock
  - Vendor Defined Type 0
  - Vendor Defined Type 1

56.7.7 Interrupt

This module prepares the output of interrupt signals in the ways stated below. The states of all interrupt signals are indicated at a glance in the Interrupt Table Register.

56.7.7.1 Error and Event Interrupt Notification

Table 56.137 Error/event interrupt outputs

Interrupt source name	Active	Attribute	Description
DMA_INT	High	Level	DMA-related event
PCIE_EVT_INT	High	Level	PCIe-related event
MSG_INT	High	Level	Reception of messages
AXI_ERR_INT	High	Level	AXI-related error

Interrupt Output Related Status Registers

DMA_INT:	DMAC Interrupt Status Register (Offset: 0x80C) DMAC Error Status Register (Offset: 0x978 / + Channel Offset)
PCIE_EVT_INT:	PCIe Event Interrupt Status 0 Register (Offset: 0x204) PCIe Event Interrupt Status 1 Register (Offset: 0x20C) PCIe Event Interrupt Status 2 Register (Offset: 0x244)
MSG_INT:	Message Receive Interrupt Status Register (Offset: 0x124)
AXI_ERR_INT:	AXI Master Error Interrupt Status Register (Offset: 0x214) AXI Slave Error Interrupt Status 1 Register (Offset: 0x224)

(1) Unit-Internal RAM Parity Error Interrupt Notification

The detection of parity errors in the internal RAM of this module is indicated by the output of interrupt signals in the ways described below. The type of parity error detecting RAM can be confirmed from the corresponding register bit. A breakdown of the device is a possibility.

PCIE_EVT_INT:	PCIe Event Interrupt Status 0 Register (Offset: 0x204) PCIe Event Interrupt Status 1 Register (Offset: 0x20C)
DMA_INT:	DMAC Interrupt Status Register (Offset: 0x80C) DMAC Error Status Register (Offset: 0x968 / + Channel Offset)

Note: A RAM parity function is not available because it is not implemented in this core.

56.7.7.2 INTx/MSI Interrupt Notification (Root Complex)

Table 56.138 INTx/MSI interrupt outputs

Interrupt Source Name	Active	Attribute	Description
INTA_RC	High	Level	Set in response to the reception of an assert INTA message and cleared in response to the reception of a deassert INTA message.
INTB_RC	High	Level	Set in response to the reception of an assert INTB message and cleared in response to the reception of a deassert INTB message.
INTC_RC	High	Level	Set in response to the reception of an assert INTC message and cleared in response to the reception of a deassert INTC message.
INTD_RC	High	Level	Set in response to the reception of an assert INTD message and cleared in response to the reception of a deassert INTD message.
INTMSI_RC	High	Level	Set when a memory write request comes from the PCIe to the area set in the MSI reception window.
INT_LINK_BANDWIDTH	High	Level	Set when the link width has been changed.
INT_PM_PME	High	Level	Set in response to the reception of PME event notification (PM_PME message).
INT_SERR_COR/ INT_SERR_NONFATAL/ INT_SERR_FATAL/ INT_SERR	High	Level	Set in response to the reception of a correctable error message, non-fatal error message, fatal error message, logical OR of 3 above messages.
INT_LINK_EQUALIZATION_REQUEST	High	Level	Set in response to the reception of Link Equalization Request bit notification in Link Control 2/Status 2 Register.

56.7.7.3 Issuing INTx/MSI Interrupts (Endpoint)

An endpoint indicates two types of interrupt to the root complex.

1. Legacy interrupt (Assert INTx Message/Deassert INTx Message)
   - Issuing INTx Msg specified by PCI_EP_INT_Fi register by controlling INTX_EP_Fi bit in PCIE_INTX register (recommended)
   - Issuing Assert INTx and Deassert INTx messages through the issuing of special requests.
2. MSI
   - Issuing an MSI by generating a memory write transaction directly.

The MSI Enable bit in the MSI Capability Register (PCIe configuration Register) can be used to switch exclusive operation of two interrupts on or off.

To issue a legacy interrupt, the Interrupt Disable bit in the Command and Status Register (PCIe Configuration Register) must be cleared.

Furthermore, if writing proceeds in a power state other than D0 or a PME_TURN_OFF message is received, or if FLR_REQ is received, Deassert INTx Msg is automatically generated in response to the corresponding function asserting an INTx, and all active interrupts are withdrawn without waiting for the PME_Turn_Off Message reception/Non-D0 State transition request reception acknowledge/FLR_RESET response. However, when multiple functions share an INTx, the logical OR of the signals from the sharing functions is taken, a Deassert INTx Msg is generated, and the interrupts are withdrawn. If INTX_EP_F0/F1 is being asserted at the time of returning to the D0 state once more or an FLR sequence is completed (indicated by the de-assertion of FLR_REQ), Assert INTx is generated again in response.

Table 56.139 INTx interrupt inputs

Interrupt factor name	Active	Attribute	Description
INTX_EP_F0	High	Level	This is the trigger for Assert INTx and Deassert INTx messages.
INTX_EP_F1	High	Level	

[Related registers]

PCI INTx Out Status Register (Offset: 0x118)

(1) Issuing a Legacy PCI INTx Emulation Interrupt (when MSI Enable = 0)

A legacy PCI INTx emulation interrupt is issued by controlling INTX_EP_Fi bit in PCIE_INTX register.

The type of Assert INTx and Deassert INTx Msg to be issued by controlling INTX_EP_Fi bit in PCIE_INTX register is specified by PCI_EP_INT_Fi register provided for each of the functions. Assert INTx Msg is issued by setting INTX_EP_F* to 1, and Deassert INTx Msg is issued by clearing INTX_EP_F* to 0.

Make sure that a interrupt signal successfully arrives on the receiving side following the de-assertion of an interrupt signal. After completion of processing for an interrupt from a given source, negating the signal is recommended.

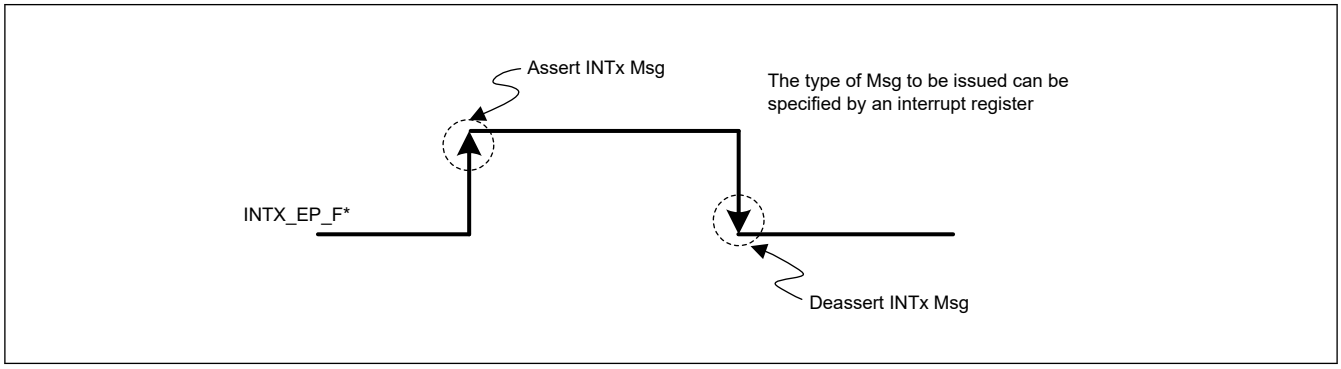


Figure 56.13 Legacy PCI INTx emulation interrupt

Changing the allocation of the legacy interrupt lines is possible by changing PCI_EP_INT_Fi register setting of the configuration register. If the same interrupt is shared by multiple functions, the logical OR of INTX_EP_F0 and INTX_EP_F1 is taken to issue an interrupt.

(2) MSI Transmission by Interupt Input (when MSI Enable = 1)

Five bits in PCIE_MSI1 register are used in specifying the interrupt (MSI). In the same way, each interrupt indication has its corresponding specified interrupt vector in PCIE_MSI2 and 3 registers.

Table 56.140 MSI interrupt notification

Register name	Interrupt notification name	Note
PCIE_MSI1	UI_EXTMSI_VAL0/1/2/3/4	Interrupt notification
PCIE MSI2 and 3	UI_EXTMSI_VEC0/1/2/3/4 [4:0]	Interrupt vector specification
PCIE MSI4 and 5	UI_EXTMSI_FUNC0/1/2/3/4 [4:0]	Interrupt function number specification

Note: Multiple Message Enable in the Base Spec.: Implemented as a specification that supports 32 (5 bits).
Multiple Message Enable on the RC side: Support for 32 is also required.

Note: Take care that the specified vector value does not impose a related restriction on the Multiple Message Enable register. For example, if the number set for Multiple Message Enable is 4, the two lower-order bits within the value set for the Message Data are overwritten by the value specified for the UI_EXTMSI_VEC[*] bits, and at that time, specify the value 0 for the higher-order bits that are not overwritten by UI_EXTMSI_VEC[*] bits. Convey interrupts in the state where the vector value and function number have been specified.

(3) Flow of Asserting MSI Enable

The following is the flow of asserting the MSI Enable field (bit 16) of the MSI Capability register.

1. Set 0 to INTX_EP_F0/1 (processing by the endpoint).
2. Wait until the Interrupt Status field (bit 19) of the Command and Status register becomes 0 (confirm that the device is not in the waiting state for INTX interrupt messages).
   (Processing by the root complex: CfgRd)
3. Write 1 to the MSI Enable field (bit 16) of the MSI Capability register.
   (Processing by the root complex: CfgWr)

56.7.7.4 Root Complex Interrupt Notification

When this module is in the root complex configuration, it has the following interrupt sources.

- INT_LINK_BAND_WIDTH
- INT_PM_PME
- INT_SERR
- INT_SERR_COR
- INT_SERR_FATAL
- INT_SERR_NONFATAL
- INT_LINK_EQUALIZATION_REQUEST

(1) Interrupt due to the Change to the Link Bandwidth (INT_LINK_BAND_WIDTH)

This interrupt source is conveyed in response to the change to the bandwidth in link negotiation of PCI Express.

Note that this interrupt source is enabled when the root complex in use and it is fixed to "0: Low" when the endpoint is in use.

This interrupt source is only enabled when the Link Bandwidth Notification Capability bit (bit 21) of the Link Capabilities register (offset: 0x60C) is set to 1. This interrupt signal can also be disabled by setting the Link Bandwidth Notification Capability bit to 0 even in operation as the root complex.

If the Link Bandwidth Notification Capability bit (bit 21) is set to 1, the Link Bandwidth Management Status bit (bit 30) and the Link Autonomous Bandwidth Status bit (bit 31) in the Link Status register (offset 0x70) serve as a source of the interrupt. These bits are set to 1 when the bandwidth is changed.

Whether to enable this interrupt source corresponds to the respective states of the Link Bandwidth Management Interrupt Enable bit (bit 10) and the Link Autonomous Bandwidth Interrupt Enable (bit 11) of the Link Control register (offset: 0x70).

Table 56.141 Related registers

Offset	Bit	Description
PCI Express Capability Structure: Link Control / Status		
0x06C	21	Link Bandwidth Notification Capability
0x070	10	Link Bandwidth Management Interrupt Enable
	11	Link Autonomous Bandwidth Interrupt Enable
	30	Link Bandwidth Management Status
	31	Link Autonomous Bandwidth Status

(2) PM-PME Reception Interrupt (INT_PM_PME)

This interrupt source is conveyed when the notification of a PME event (PM_PME message) is received from the other-party device.

Note that this interrupt source is enabled when the root complex in use and it is fixed to "0: Low" when the endpoint is in use.

This interrupt source is only conveyed when the PME Interrupt Enable bit (bit 3) of the Root Control/Capabilities Register (offset: 0x7C) is set to 1. This interrupt source is not conveyed when the PME Interrupt Enable bit (bit 3) is set to 0.

Note that the reception state of the received PM_PME message and the ID information, etc. are stored in the Root Status Register (offset: 0x80) regardless of the setting of the PME Interrupt Enable bit mentioned above.

Table 56.142 Related Registers

Offset	Bit	Description
PCI Express Capability Structure: Root Control Capabilities		
0x07C	3	PME Interrupt Enable
PCI Express Capability Structure: Root Status		
0x080	15:0	PME Requester ID
	16	PME Status
	17	PME Pending

(3) System Error Interrupt (INT_SERR_xxx)

This interrupt is conveyed when a correctable error message, non-fatal error message, or fatal error message is received.

INT_SERR:	The system error notification mentioned in the Base Spec. is obtained as the logical OR of the following three signals.
INT_SERR_COR:	System Error on Correctable Error
INT_SERR_FATAL:	System Error on Fatal Error
INT_SERR_NONFATAL:	System Error on Non-Fatal Error

These interrupt sources are enabled when the root complex is in use and these are fixed to "0: Low" when the endpoint is in use.

(a) Correctable Error Interrupt (INT_SERR_COR)

To proceed with interrupt control due to a correctable error, set the interrupt enable bits of the following registers to 1.

No.	Offset	Bit	Description
1	PCI Compatible Configuration: Bridge Control and Interrupt		
	0x03C	17	SERR# Enable
2	PCI Express Capability Structure: Device Control		
	0x068	0	Correctable Error Reporting Enable
3	Advanced Error Reporting (AER) Capability: Root Error Command		
	0x12C	0	Correctable Error Reporting Enable

<Interrupt Source>

(1) ERR_COR Message Reception

If an ERR_COR message is received from the other-party device (endpoint), the INT_SERR_COR interrupt will be asserted. The following status register will be set at the same time.

Offset	Bit	Description
Advanced Error Reporting (AER) Capability: Root Error Status		
0x130	0	ERR_COR Received

Note: Note: If the Enable bits in no. 1, 2, and 3 are not set, the interrupt source will not be generated.
If the Enable bits in no. 1 and 2 are not set, writing will be masked.

(2) Correctable Error Detection

Any of the following correctable errors being detected within the unit will be written to the corresponding status register.

Error	Offset	Bit	Description
Advanced Error Reporting (AER) Capability: Correctable Error Status			
8B10B Decode Error 8B10B RD Error	0x110	0	Receiver Error Status
Bad TLP		6	Bad TLP Status
Bad DLLP		7	Bad DLLP Status
REPLAY_NUM Roll over		8	REPLAY_NUM Rollover Status
Replay Timer Timeout		12	Replay Timer Timeout Status
Advisory Non-Fatal Error		13	Advisory Non-Fatal Error Status

Note: If the Mask bit (Correctable Error Mask Register: Offset 0x114) corresponding to each bit is set (masked), the corresponding error will not be detected and the interrupt source will not be generated.

At the same time, the INT_SERR_COR interrupt will be generated and the following status registers will be set to 1.

Offset	Bit	Description
PCI Express Capability Structure: Device Status		
0x068	16	Correctable Error Detect
Advanced Error Reporting (AER) Capability : Root Error Status		
0x130	0	ERR_COR Received

Note: If the Enable bit in no. 2 is not set, the interrupt source will not be generated.
If the Enable bit in no. 2 is not set, writing to the Root Error Status Register will be masked.

If the Correctable Error Reporting Enable bit listed in no. 3 is not set, the source due to (1) and (2) stated above will be generated and INT_SERR_COR will not be asserted even if writing to the Root Error Register has proceeded.

(b) Fatal Error Interrupt (INT_SERR_FATAL)

To proceed with interrupt control due to a fatal error, set the interrupt enable bits of the following registers to 1.

No.	Offset	Bit	Description
1	PCI Compatible Configuration: Bridge Control and Interrupt		
	0x03C	17	SERR# Enable
2	PCI Express Capability Structure: Device Control		
	0x068	2	Fatal Error Reporting Enable
3	Common Configuration Space: Command and Status		
	0x004	8	SERR# Enable
4	Advanced Error Reporting (AER) Capability: Root Error Command		
	0x12C	2	Fatal Error Reporting Enable

<Interrupt Source>

(1) ERR_FATAL Message Reception

If an ERR_FATAL message is received from the other-party device (endpoint), the INT_SERR_FATAL interrupt will be asserted (if the Enable bits in no.1 and 2 or no.3 and 4 are not set, the interrupt source will not be generated). The following status registers will be set at the same time.

Offset	Bit	Description	Remarks
Type1 Configuration Space: Secondary Status			*1
0x01C	30	Received System Error	
Common Configuration Space: Status Register			*2
0x004	30	Signaled System Error	

Offset	Bit	Description	Remarks
Advanced Error Reporting (AER) Capability: Root Error Status			*3
0x130	6	Fatal Error Message Received	

Note 1. Writing to this status register proceeds at the point a message is received regardless of the settings of the Enable bits.
Note 2. If the Enable bits in no. 1 and 2 are not set, writing will be masked.
Note 3. If the Enable bit in no. 1, 2, or 3 is not set, writing will be masked.

(2) Fatal Error Detection

Any of the following fatal errors being detected within the unit will be written to the corresponding status register.

Error	Offset	Bit	Description
Advanced Error Reporting (AER) Capability: Uncorrectable Error Status			
Data Link Protocol Error	0x104	4	Data Link Protocol Error Status
Poisoned TLP		12	Poisoned TLP Status
Completion Timeout		14	Completion Timeout Status
Completer Abort		15	Completer Abort Status
Unexpected Completion		16	Unexpected Completion Status
Receiver Overflow		17	Receiver Overflow Status
Malformed TLP		18	Malformed TLP Status
ECRC Error		19	ECRC Error Status
Unsupported Request		20	Unsupported Request Error Status

Note: If the Mask bit (Uncorrectable Error Mask Register: Offset 0x108) corresponding to each bit is set (masked), the corresponding error will not be detected and the interrupt source will not be generated.
Also, the setting of the corresponding Severity bit (Uncorrectable Error Severity: Offset 0x10C) must be 1 (Fatal).

The INT_SERR_FATAL interrupt will be generated at the same time (if the Enable bits in no. 2 or no.3 and 4 are not set, the interrupt source will not be generated). The following status registers will be set at the same time.

Offset	Bit	Description	Remarks
PCI Express Capability Structure: Device Status			
0x068	18	Fatal Error Detect	
Common Configuration Space: Status Register			*1
0x004	30	Signaled System Error	
Advanced Error Reporting (AER) Capability: Root Error Status			*2
0x130	6	Fatal Error Message Received	

Note 1. If the Enable bit in no. 3 is not set, writing will be masked.
Note 2. If the Enable bit in no. 2 or 3 is not set, writing will be masked.

If the Fatal Error Reporting Enable bit listed in no. 4 is not set, the source due to (1) and (2) stated above will be generated and INT_SERR_FATAL will not be generated even if writing to the Root Error Status Register has proceeded.

(c) Non-Fatal Error Interrupt (INT_SERR_NONFATAL)

To proceed with interrupt control due to a non-fatal error, set the interrupt enable bits of the following registers to 1.

No.	Offset	Bit	Description
1	PCI Compatible Configuration: Bridge Control and Interrupt		
	0x03C	17	SERR# Enable
2	PCI Express Capability Structure: Device Control		
	0x068	1	Non-Fatal Error Reporting Enable
3	Common Configuration Space: Command and Status		
	0x004	8	SERR# Enable

No.	Offset	Bit	Description
4	Advanced Error Reporting (AER) Capability: Root Error Command		
	0x12C	1	Non-Fatal Error Reporting Enable

<Interrupt Source>

(1) ERR_NONFATAL Message Reception

If an ERR_NONFATAL message is received from the other-party device (endpoint), the INT_SERR_NONFATAL interrupt will be generated (if the Enable bits in no.1 and 2 or no.3 and 4 are not set, the interrupt source will not be generated). The following status registers will be set at the same time.

Offset	Bit	Description	Remarks
Type1 Configuration Space: Secondary Status			*1
0x01C	30	Received System Error	
Common Configuration Space: Status Register			*2
0x004	30	Signaled System Error	
Advanced Error Reporting (AER) Capability: Root Error Status			*3
0x130	5	Non-Fatal Error Message Received	

Note 1. Writing to this status register proceeds at the point a message is received regardless of the settings of the Enable bits.
Note 2. If the Enable bits in no. 1 and 3 are not set, writing will be masked.
Note 3. If the Enable bit in no. 1, 2, or 3 is not set, writing will be masked.

(2) Non-Fatal Error Detection

Any of the following non-fatal errors being detected within the unit will be written to the corresponding status register.

Error	Offset	Bit	Description
Advanced Error Reporting (AER) Capability: Uncorrectable Error Status			
Data Link Protocol Error	0x104	4	Data Link Protocol Error Status
Poisoned TLP		12	Poisoned TLP Status
Completion Timeout		14	Completion Timeout Status
Completer Abort		15	Completer Abort Status
Unexpected Completion		16	Unexpected Completion Status
Receiver Overflow		17	Receiver Overflow Status
Malformed TLP		18	Malformed TLP Status
ECRC Error		19	ECRC Error Status
Unsupported Request		20	Unsupported Request Error Status

Note: If the Mask bit (Uncorrectable Error Mask Register: Offset 0x108) corresponding to each bit is set (masked), the corresponding error will not be detected and the interrupt source will not be generated.
Also, the setting of the corresponding Severity bit (Uncorrectable Error Severity: Offset 0x10C) must be 0 (Non-fatal).

The INT_SERR_NONFATAL interrupt will be generated at the same time (if the Enable bits in no. 2 or no.3 and 4 are not set, the interrupt source will not be generated). The following status registers will be set at the same time.

Offset	Bit	Description	Remarks
PCI Express Capability Structure: Device Status			*1
0x068	17	Non-Fatal Error Detect	
Common Configuration Space: Status Register			*1
0x004	30	Signaled System Error	
Advanced Error Reporting (AER) Capability: Root Error Status			*2
0x130	5	Non-Fatal Error Message Received	

Note 1. If the Enable bit in no. 3 is not set, writing will be masked.
Note 2. If the Enable bit in no. 2 or 3 is not set, writing will be masked.

If the Non-Fatal Error Reporting Enable bit listed in no. 4 is not set, the source due to (1) and (2) stated above will be generated and INT_SERR_NONFATAL will not be generated even if writing to the Root Error Status Register has proceeded.

(4) Equalization interrupt (INT_LINK_EQUALIZATION_REQUEST)

This interrupt source is conveyed when PCIe module starts equalization.

Table 56.143 Related registers

Offset	Bit	Description	Remarks
PCI Express Capability Structure : Link Control 2 / Status 2			—
0x090	21	Link Equalization Request	
Secondary PCI Express Extended Capability Structure : Link Control 3 / Status 3			*1
0x1B4	2	Link Equalization Request Interrupt Enable	

Note 1. If the Enable bit is not set, interrupt notification will be masked.

56.7.7.5 DMA Interrupt

The DMAC has interrupt functions. It supports two types of interrupt source: one set is for normal operation and the other is for errors. Use the DMAC Interrupt Enable Register to select the interrupt sources and control masking. DMA interrupt notification includes notification by DMA_INT in the direction of the AXI bus (local bus direction) and notification by issuing an MSI to an other-party RC.

On completion of DMA transfer, either conveying a DMA_INT interrupt or transmitting an MSI to the RC, but not both, is selected per-channel by a register setting (transmitting an MSI is prohibited in RC mode).

The DMA_CH*_MSI_EN bits of the DMA Interrupt Vector 0 Register and the DMA Interrupt Vector 1 Register are used to switch the setting ("*" corresponds to the channel number of a given DMA and per-channel control is possible). If an MSI is to be issued, the value of its traffic class (TC) bits is fixed to 0. The vector value can be specified by using the DMA_CH*_vec bits of these registers.

Note: Take care that the specified vector value does not impose a related restriction on the Multiple Message Enable register.

For example, if the number set for Multiple Message Enable is 4, the two lower-order bits within the value set for the Message Data are overwritten by the value specified for the DMA_CH*_vec bits, and at that time, specify the value 0 for the higher-order bits that are not overwritten by DMA_CH*_vec bits.

56.7.8 Power Management (Root Complex Mode)

56.7.8.1 PCI Power Management (PCI-PM)

An endpoint is placed in non-D0 (the D3 hot state) by changing the setting of the Power State field register of the endpoint by the root complex., which causes a transition of the link state of both RC and EP to L1.

This module does not support the AUX power supply function. D3 cold is not supported. Implementing the L2 function goes to implementation of L2/L3 ready.

(1) Flow of Transition to the L2/L3 Ready State (RC)

< For transition via PCIPM L1 >

1. A root complex (RC) issues a config write to change the D-state of an endpoint (EP) to D3 (D3 hot).
2. The RC is automatically placed in L1 by automatic response of the other-party EC.
3. The RC transmits a PME_Turn_Off message.
4. Confirm the reception of a PME_TO_Ack Message from the EP by reading the value of the PME_TO_Ack Receive Interrupt bit (bit 16) in the Message Receive Interrupt Status Register of the RC.
5. Set UI_ENTER_L2 of the PCIe Core Control 1 Registers to 1.
6. Confirm the transition to the L2/L3 ready state by reading the value of the LTSSM_STATE bits (bits [14:8]) in the PCIe Core Status 1 Register (5 higher-order bits [14:10] = 0111xb: L2).

< For direct transition to the L2/L3 ready state >

Steps 3 to 6 above apply.

(2) Flow of Return from the L2/L3 Ready State (RC)

< Return from the L2/L3 ready state by the RC >

1. Assert the following reset signals.
   RST_B, RST_GP_B, RST_PS_B, RST_CFG_B
2. Deassert the reset signals at a desired time and wait for return to L0 (wait for linkup).
3. Clear UI_ENTER_L2 of the PCIe Core Control 1 Registers to 0.
4. If the link is not up, repeat steps 1 and 2.

< Return from the L2/L3 ready state by the EP >

1. Wait for the reception of a beacon by the EP. Read the LINKDN bit (0x0204, bit 9) in the PCIe Event Interrupt Status register regularly to check whether ELECTRICAL_IDLE_BROKEN has been generated.
2. Assert the following reset signals.
   RST_B, RST_GP_B, RST_PS_B, RST_CFG_B
3. Deassert the reset signals at a desired time and wait for it to return to L0 (wait for linkup).
4. Clear UI_ENTER_L2 of the PCIe Core Control 1 Registers to 0.
5. If the link is not up, repeat steps 2 and 3.

56.7.8.2 Active State Power Management (ASPM)

The ASPM L0s and L1 states can be used by the setting of the Active State PM Control bits (bits [1:0]) in the Link Control/Status Register (PCIe Configuration Register: 0x6070).

ASPM L0s:	The module is automatically placed in the ASPM L0s state following setting of the Active State PM Control bits to 01b or 11b. When to initiate a transition to this state is determined by judgment of the idle state by the PCIe core.
ASPM L1:	An RC is placed in the ASPM L1 state in response a request for transition to the ASPM L1 state from an EP following setting of the Active State PM Control bit to 11b. When to initiate a transition to this state is determined by judgment of the idle state by the PCIe core. A transition to the ASPM L1 state is enabled by setting the UI_RC_REJECT_ASPM_L1 bit (bit [19]) of the PCIe Core Control 1 Register (offset: 0x404) to 0. To reject a transition to the ASPM L1 state on the RC side, set the UI_RC_REJECT_ASPM_L1 bit to 1.

Return to the L0 state from the L1 state:

Resuming access from the AXI master side:

Return to the L0 state is initiated in response to the other-party PCIe device resuming access.

Resuming access from the AXI slave side:

The AXI can be returned to the L0 state in response to the AXI starting access to a PCIe device. Access to an AXI configuration register also returns the AXI to the L0 state.

56.7.9 Power Management (Endpoint Mode)

56.7.9.1 PCI Power Management (PCI-PM)

The endpoint unit can be placed in the D3 hot state by changing the setting of the Power State field register by the root complex. A PME_Turn_Off message can be received even after the transition to the D3 state. The turning-off procedure described below starts in such cases.

D0:	This is a full-power state in which no restrictions apply. The link state is basically L0. However, if the ASPM generates a source for a transition, the latter takes priority.

D3hot: The link state basically changes to L1. By changing the value of the Power State bits of the PM Status/Control register in response to the reception of CfgWr, the unit sets D3_EVENT_Fi interrupt to 1 when a transition to the non-D0 state is requested per function, and issues Deassert_INTx in response to the assertion of any of the INTX interrupts. The EP should set D3_EVENT_ACK_Fi bit in PCIE_ACK register to 1 after preparation for low power consumption. After D3_EVENT_ACK_Fi bit in PCIE_ACK register is set to 1, issuing of the AXI transaction to the PCIe is prohibited.(this does not apply to access to internal registers which include the configuration register).

This module does not support the AUX power supply function. D3 cold is not supported. Implementing the L2 function goes to implementation of L2/L3 ready.

(1) Flow of Transition to the L2/L3 Ready State (EP)

< For transition via PCIPM L1 >

1. The D-state of an endpoint (EP) is changed to D3 (D3 hot) in response to the reception of a config write from a root complex (RC).
2. Check that D3_EVENT_Fi interrupt has been set to 1, and clear D3_EVENT_ACK_Fi bit in PCIE_ACK register to 0 after setting it to 1.
3. A transition to the L1 state is automatically initiated.
4. The EC receives a PME_Turn_Off message from the RC.
5. Check that TURN_OFF_EVENT interrupt has been set to 1, and clear TURN_OFF_EVENT_ACK bit in PCIE_ACK register to 0 after setting it to 1.
6. A transition to the L2/L3 ready state is automatically initiated.

< For direct transition to the L2/L3 ready state >

Steps 4 to 6 above apply.

(2) Flow of Return from the L2/L3 Ready State (EP)

< Return from to the L2/L3 ready state by the RC >

1. Wait for an Electrical Idle exit from the RC.
2. After that, follow the instruction by the RC to return to L0 (the following is an example).
   - Example 2-1. Follow the instruction by the RC to reset the EP (assert RST_B, RST_GP_B, RST_PS_B, and RST_CFG_B).
   - Example 2-2. Follow the instruction by the RC to release the EP from the reset state at a desired time.
   - Example 2-3. Return to L0.

< Return from to the L2/L3 ready state by the EP >

1. Check that the value of the LTSSM_STATE bits (bits [14:8]) in the PCIe Core Status 1 Register is 0x3A.

   Note: As a criterion for judgment at this time, checking the value read from this register requires consecutively checking the above value several times. Since the value of the LTSSM bits is checked by direct reference to the internal circuit state information, an undefined state value may be read depending on the timing of the operation for transition. To make sure that the current state is the L2 idle state, we recommend checking the state by access more than once. Only check all seven bits of LTSSM_STATE (bits [14:8]) of the PCIe Core Status 1 Register at this time in the flow of return.
2. Assert CFG_PMCSR_PME_STATUS_Fi bit in PCIE_PME register to 1.
3. Assert RST_B (the EP transmits a beacon).
4. After that, follow the instruction by the RC to return to L0 (the following is an example).
   - Example 4-1. The RC detects the reception of a beacon from the EP and initiates return to L0 on the RC side.
   - Example 4-2. Follow the instruction by the RC to reset the EP (assert RST_B, RST_GP_B, and RST_PS_B, RST_CFG_B).
   - Example 4-3. Follow the instruction by the RC to release the EP from the reset state at a desired time.
   - Example 4-4. Return to L0.

56.7.9.2 Active State Power Management (ASPM)

The ASPM L0 and L1 states can be used by setting the Active State PM Control bits (bits [1:0]) of the Link Control/Status Register (PCIe Configuration Register: 0x6070).

Permit a transition to ASPM L1 by setting ALLOW_ENTER_L1 bit in PCIE_MISC register to 1.

The ASPM L1 Idle Time bits of the registers must be set in advance to suit the AXI bus specifications (the range of settings is for from 256 to 65536 cycles of ACLK). If transfer does not proceed for the time set in the ASPM L1 Idle Time bits within the unit, the module is automatically placed in the ASPM L1 state.

ASPM L0s: A transition to the ASPM L0s state is automatically initiated by setting the Active State PM Control bits to 01b or 11b. When to initiate a transition to this state is determined by judgment of the idle state by the PCIe core, so your operation will not be especially required.
A transition to L0s can be controlled by setting the UI_ENTER_TXL0S bit (bit [16]) of the PCIe Core Control 1 Register.

ASPM L1: A transition to the ASPM L1 state can be initiated by setting the Active State PM Control bits to 10b or 11b. When to initiate a transition to this state is determined by judgment of the idle state by the PCIe core. A transition to the L1 state is enabled by setting ALLOW_ENTER_L1 bit in PCIE_MISC register to 1.
If the Root Complex denies the L1 transition, this macro receives PM_Active_State_Nak and a MSG receive interrupt occurs. After that, if the ALLOWE_ENTER_L1 bit in the PCIE_MISC register is 1, it will issue L1 transition request again. If you want to cancel L1 transition request and perform CFG access, etc when the transition is denied, clear the ALLOWE_ENTER_L1 bit in the PCIE_MISC register and confirm UI_ENTER_L1_STATUS (bit [21]) of the PCIe Core Control 1 Registers is 0. If it is not 0, write 1 to the bit to clear it.

Return from the L1 state to the L0 state

Resuming access from the AXI master side:

Return to the L0 state is initiated in response to the other-party PCIe device resuming access.

Resuming access from the AXI slave side:

The AXI can be returned to the L0 state in response to the AXI starting access to a PCIe device. Access to an AXI configuration register also returns the AXI to the L0 state.

(1) ASPM L1 Idle Time Setting

The Mode Set 3 registers (offset: 0x380) are defined as the ASPM L1 Idle Time registers. These registers are used to set the counter for monitoring the state of the AXI bus or internal transactions in terms of remaining activity when this module is placed in the ASPM L1 state. The counter monitors whether the AXI bus and transactions within this module are idle based on one of the following settings and uses this as the condition for triggering the transition to the ASPM L1 state.

```
ASPM L1 Idle Time[7:0] = 0x00: 256 cycles of ACLK
ASPM L1 Idle Time[7:0] = 0x01: 512 cycles of ACLK
        ⋮
ASPM L1 Idle Time[7:0] = 0xFF: 65536 cycles of ACLK
```

56.7.10 Power Management (Common)

56.7.10.1 Turn Off (PME Turn Off Message Recept)

Upon the reception of a PME_Turn_Off message, the TURN_OFF_EVENT interrupt is asserted and Deassert_INTx is issued for all of the INTx that are asserted. Moreover, preparation for sending PME_TO_Ack message is automatically started.

After receiving TURN_OFF_EVENT interrupt and preparing power down, set TURN_OFF_EVENT_ACK bit in PCIE_ACK register. This allows PME_TO_Ack Message transmission.

After that, issue of AXI transaction to PCIe is prohibited. Module is ready for assertion of ARESETn or DL_Down state.

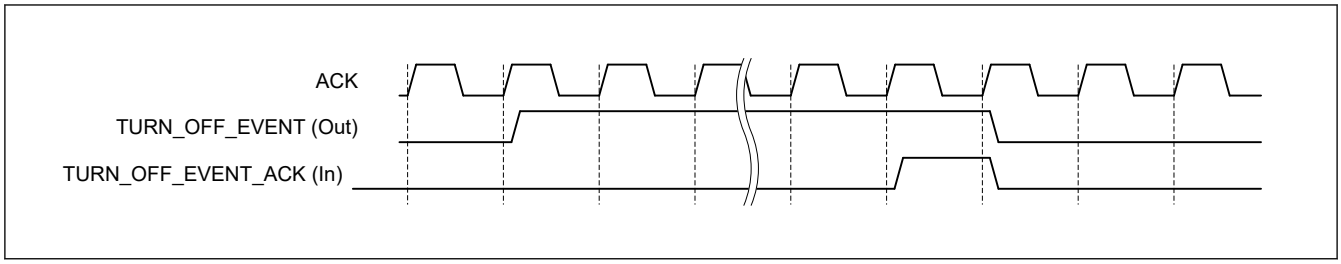

Figure 56.14 Relationship between TURN_OFF_EVENT and TURN_OFF_EVENT_ACK

56.7.10.2 Wake Up (PME Message transmit)

When CFG_PMCSR_PME_STATUS_Fi bit in PCIE_PME register is 1, preparation for automatic transmission of PME message is made. The transmission timing is set by the edge detection after the toggle timing of the PME_TIM bit in PCIE_PME register is synchronized by ACLK.

Note that when a PME Turn Off message is received, automatic transmission of PME message will be stopped until ARESETn is generated or the DL_Up state is reached once after the DL_Down state is reached.

<Control procedure>

1. Among the configuration registers, when PME Enable = 1 in the PM Status/Control register, a PM_PME message can be sent from the EP to the RC by setting CFG_PMCSR_PME_STATUS_Fi bit in PCIE_PME register to 1 and toggling PME_TIM bit in PCIE_PME register.
2. The RC issues CfgWr to write 1 to and clear the PME_STATUS field of the device that has received the PM_PME message. At the same time, it sends CfgWr0 to change the Power State bit to D0.
3. When the EP enters the D0 state, the CFG_PMCSR_PME_STATUS_WRITECLEAR interrupt of the EP is asserted.
4. By toggling PME_TIM bit in PCIE_PME register every 100 to 150 ms, the PM_PME Msg retransmission can be instructed in accordance with the following base spec. regulations.

Note that the PME_TIM, CFG_PMCSR_PME_STATUS bits in PCIE_PME register and CFG_PMCSR_PME_STATUS_WRITECLEAR interrupt are not used when there is no need to request the endpoint side to change the power state to D0.

56.7.11 Error Processing

Two error reporting paradigms are defined for PCI Express: baseline error reporting capability, which is the minimal requirement, and advanced error reporting (AER) capability, which can provide greater stability, as an optional error reporting facility. This module supports both error reporting functions.

56.7.11.1 Error Classification

PCI Express errors are of two types, correctable and uncorrectable. Uncorrectable errors are further classified into two types, non-fatal and fatal.

Error type	Description
Correctable Error	An error which cannot be recovered by hardware
Uncorrectable Error (Non-Fatal)	An error which causes a particular transaction in PCI Express to be unreliable (but the PCI Express link itself is functional).
Uncorrectable Error (Fatal)	An error which causes the PCI Express link itself to be unreliable

In operation as a root complex, the above types of error are indicated by the individual interrupt names.

- INT_SERR_COR
- INT_SERR_NONFATAL
- INT_SERR_FATAL

56.7.11.2 Error Checking Mechanism

1. Physical Layer Error List
   The following type of error is to be detected in the physical layer.
   - Receiver Error
2. Data Link Layer Error List
   The following type of error is to be detected in the link layer.
   - Bad TLP Error
   - Bad DLLP Error
   - REPLAY_NUM Rollover
   - Replay Timer Timeout
   - Receiver Overflow Error
3. Transaction Layer Error List
   The following type of error is to be detected in the transaction layer.
   - Completion Timeout
   - Completer Abort
   - Unsupported Request
   - Unexpected Completion
   - Malformed TLP
   - Poisoned TLP

Note: The specifications of the receiver error detection function in each LTSSM state are as listed below.

LTSSM state	Unit specification	Base spec specifications
Configuration	Support	Gen1/Gen3 (Must)
Recovery	Non-Support	Option
L0	Support	Must
Disabled	Support	Option
Hot Reset	Support	Option

56.7.11.3 Error Message

The PCI Express Base Specification defines error messages as one of the mechanisms for notifying the system or another device of an error when it is detected by a PCI Express agent.

Error message	Description
ERR_COR	Used when a correctable error is detected
ERR_NONFATAL	Used when a non-fatal, uncorrectable error is detected
ERR_FATAL	Used when a fatal, uncorrectable error is detected

Advisory Non-Fatal Error

The PCI Express Base Specification states that when a PCI Express agent as the detecting agent detects a non-fatal error, it handles the error as an advisory non-fatal error whether it does or does not support AER. In handling a non-fatal error as an advisory non-fatal error, the agent sends an ERR_COR message instead of an ERR_NONFATAL message and sends an advisory notification to the software. At this time, the advisory non-fatal error status bit of the correctable error status register is set to indicate the error state. Note that subsequent setting of the first error pointer register, logging of the header, and message transmission only proceed if the Advisory Non-Fatal Error Mask bit of the Correctable Error Mask Register is clear (no masking). They do not proceed if the bit is set.

The error cases which are handled as advisory non-fatal errors are as follows.

- Reception of unsupported non-posted requests

- Reception of a non-posted request with a completer abort completion response
- Reception of an unexpected completion
- Reception of a poisoned TLP (this is not handled as an advisory non-fatal error in this core)
- Detection of a completion timeout (this is not handled as an advisory non-fatal error in this core)

This module may merge multiple error messages with the same ID. This would occur when multiple errors are detected during the wait for the unit to be ready for the transmission of messages after an error condition is detected. However, messages will not always be merged in such cases.

56.8 Operation

56.8.1 Setting Up

Set the internal registers of the unit including the configuration registers.

This section explains the procedure for setting up until the PCI Express link is up (the module is ready for data transfer).

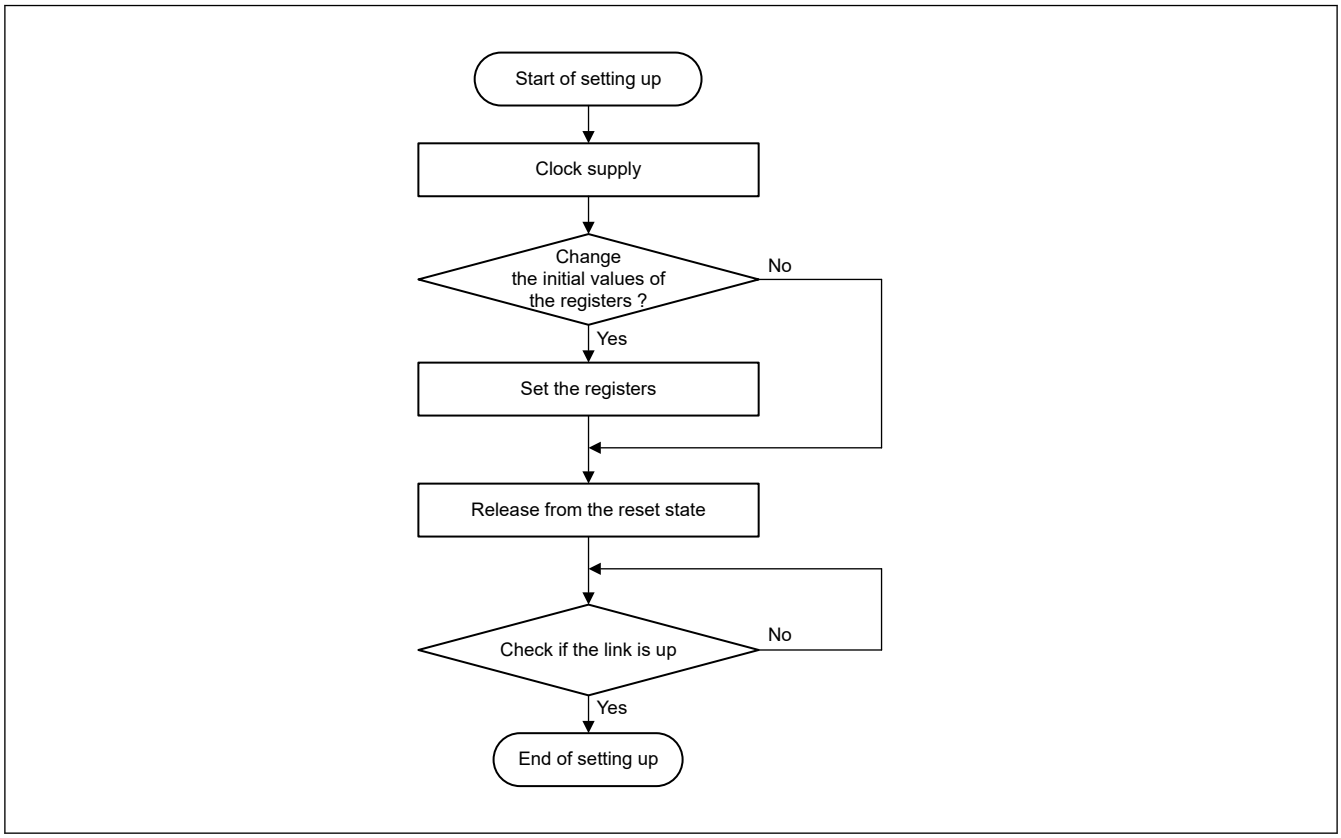

Figure 56.15 Setting up

56.8.1.1 Changing the Initial Values of the Registers

Of the internal registers, the initial values of the configuration registers can be changed via the AXI slave interface.

1. AXI Bridge Registers
   De-asserting ARESETn following supply of CLK allows access to these registers. In the case of resetting of the PCIe core, write to the registers while the reset signal is being asserted.
2. PCIe Configuration Register
   De-asserting ARESETn following supply of CLK allows access to these registers. Of the reset signals of the PCIe core, those related to the configuration register must be de-asserted.
3. Phisical Layer Control/Monitor Registers

De-asserting ARESETn following supply of CLK allows access to these registers. In the case of resetting of the PCIe core, write to the registers while the reset signal is being asserted. Access to the PIPE PHY Register should be permitted by setting bit 1 of the Permission Register (Offset: 0x300) to 1 in advance.

Note that the initial values of the registers listed below are 0. Set appropriate values in the registers before the start of link up.

- Device ID
- Vendor ID
- Class Code (base class/sub-class/programming interface)
- Revision ID
- Subsystem ID
- Subsystem Vendor ID

56.8.1.2 De-asserting the Reset

In this module, software reset control by the register is possible.

De-asserting of the reset of the core (the reset register in the case of register control) automatically starts operations such as receiver detection and the training sequence with the other-party device.

Note that this module requires a wait of at least 5 ms from power-on to de-assertion of the reset.

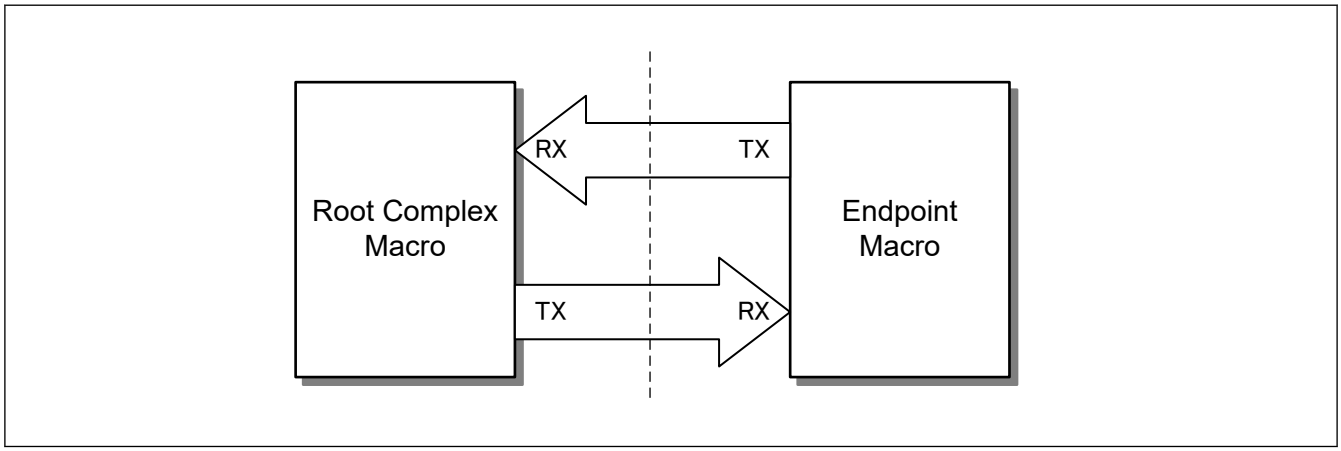

Figure 56.16 Link negotiation

Check that link negotiation with the other party has been completed and the link with the unit is up.

56.8.1.3 Checking If the Link Is Up

Checking if the link is up can be done through either of the following methods. This is usually done by the root complex.

1. Polling
   Have the CPU of the chip poll the DL_Down Status bit (bit [0]) of the PCIe core Status 1 Register in AXI bridge registers until the value of the bit is 0 (indicating the DL_Up state).
2. Interrupt
   After assertion of the PCIE_EVT_INT interrupt, check the interrupt source by reading the DL_UpDown bit (bit [9]) in the PCIe Event Interrupt Status 0 register in AXI Bridge Registers. After that, check that the DL_Down Status bit (bit [0]) of the PCIe Core Status 1 Register is 0 (indicating the DL_Up state)

The settings above make the unit ready for transfer with the other party device.

However, data transfer such as reading or writing memory is not yet possible in this state. This requires subsequent window settings.

56.8.1.4 Link Equalization

This macro automatically executes link equalization in the link up flow when both EP and RC support and enable Gen3 rate, and links up at Gen3 rate.

Gen3 data transfer has TX (RX side is not supported) link equalization function to ensure and improve signal quality. Link equalization adjusts both TX settings between EP and RC. Link equalization has four phases. Recovery Equalization Phase 0-3 exist as LTSSM state, and phase transits according to the progress of Gen3 equalization.

Phase 2 and 3 of link equalization are optional in Base Spec, but this macro has the function, and whether to use it or not can be controlled by the MODE_EQ_PHASE23_ENABLE register. However, due to the constraints of the installed PHY, although it can receive FB from the opposite macro, it cannot perform FB (direction change) from this macro. In addition, if phase 2 and 3 are skipped, the link training speed will be faster, but the bit error rate of the link may not be optimized.

If equalization fails due to a timeout or other reason in Root Complex mode, perform the following to rerun equalization.

1. Set the PE bit of the Link Control 3 Register Perform Equalization to 1
2. Set the TLS[3:0] bits of the Link Control 2 Register to Gen3
3. Set the RL bit of the Link Control Register to 1

56.8.2 Reset

A software reset by the register can be used for this module. Table 56.144 lists the software resets.

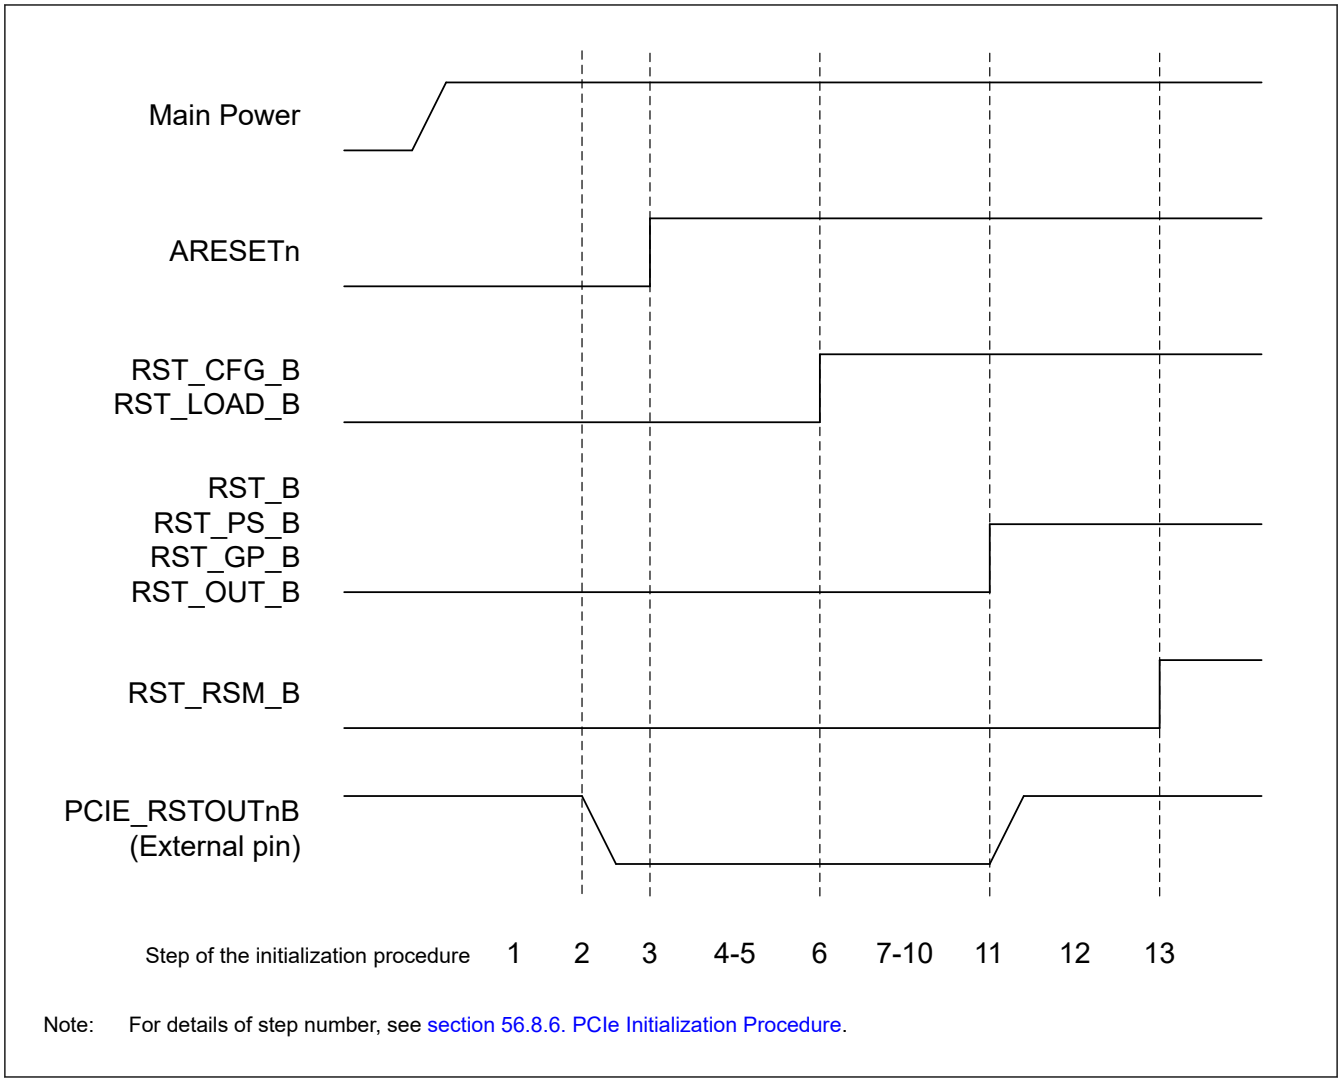
Table 56.144 List of software reset

Reset name	Reset control register	Reset target
ARESETn	Bit 8 in MRCTLM register	AXI2PCIe Bridge
RST_B	Bit 0 in PCI_RC_RESET/PCI_EP_RESET register	Transaction Layer, Data Link Layer, Physical Layer
RST_GP_B	Bit 1 in PCI_RC_RESET/PCI_EP_RESET register	Transaction Layer
RST_RSM_B	Bit 2 in PCI_RC_RESET/PCI_EP_RESET register	Configuration Registers, Transaction Layer, Physical Layer
RST_CFG_B	Bit 3 in PCI_RC_RESET/PCI_EP_RESET register	Configuration Registers
RST_LOAD_B	Bit 4 in PCI_RC_RESET/PCI_EP_RESET register	Configuration Registers
RST_PS_B	Bit 5 in PCI_RC_RESET/PCI_EP_RESET register	Transaction Layer
RST_OUT_B	Bit 6 in PCI_RC_RESET/PCI_EP_RESET register	Other Endpoint device via external PCIE_RSTOUTnB pin when using RC mode. In case of EP mode, it is not available.

Note: Follow the reset sequence defined in section 56.8.2.1. Reset Sequence after power-on. Do not assert the reset during operation.

56.8.2.1 Reset Sequence

Figure 56.17 shows the reset sequence at power-on.



Note: For details of step number, see section 56.8.6. PCIe Initialization Procedure.

Figure 56.17 Reset sequence at power-on

56.8.2.2 Function Level Reset

Control procedure of the Function Level Reset (FLR) is shown below. This control is available in EP mode only.

1. In order to make FLR request from the RC to the EP, CfgWr transaction is issued from the RC to Initiate Function Level Reset (bit 15) in the Device Control/Status register (PCI_EP_DEVCS_Fi) in the EP.
2. When 1 is written in the above bit, FLR_REQ_Fi interrupt is asserted in the EP.
3. After FLR_REQ assertion is detected, the entire EP side system is checked to determine whether FLR can be performed or to prepare a state where FLR can be executed. Preparations related to PCIe require that all ongoing data transfers have been completed and that the issuance of new transactions must be stopped.
4. FLR is performed by writing 1 to FLR_RESETi bit in PCIE_MISC register.

Note: Access to the Configuration Register is prohibited after the FLR request from RC (No.1 above). Before making FLR request, the necessary actions (such as stopping DMA) must be performed in advance. In addition, the completion notification to the RC after FLR execution by the EP (No.4 above) should be performed by using the interrupt function (MSI notification).

The FRS Message feature is not supported.

Configuration Registers and corresponding AXI Bridge Registers bits are cleared by FLR each Function unit.

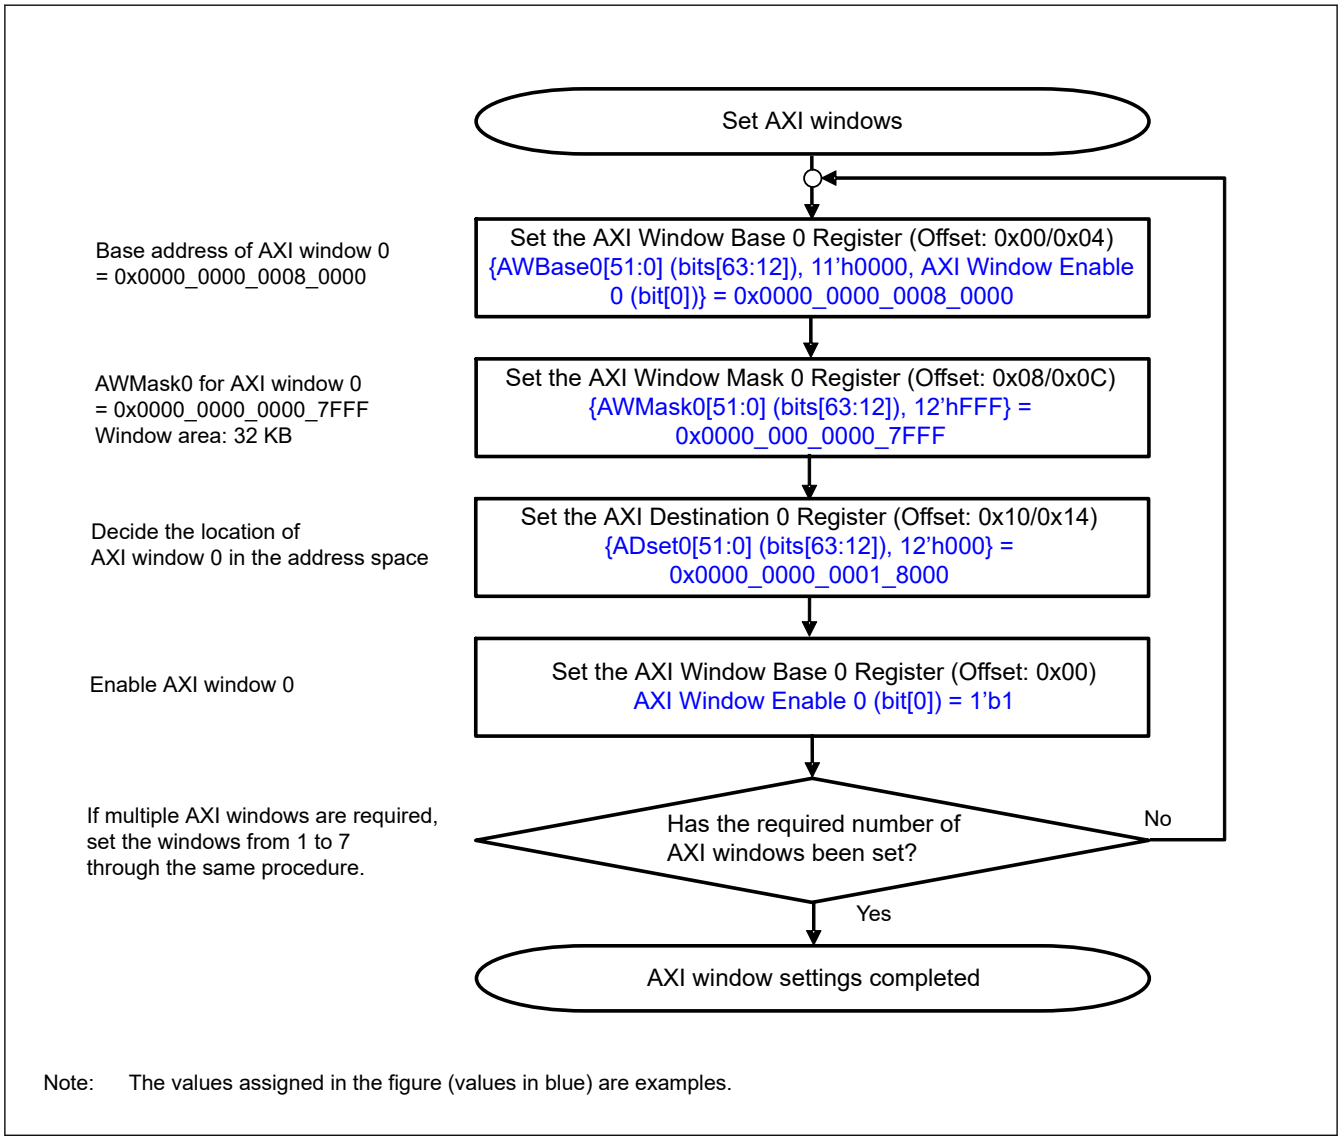
56.8.3 Setting the Windows (Root Complex Mode)

56.8.3.1 Setting the AXI Windows

AXI Window is used when transferring MWR/MRd data from PCIe (RX side) to the AXI bus.

It can be set by write access to the registers below from the AXI Slave I/F. Up to 8 windows can be set. In that case, the following register settings are required for the number of windows required.

- AXI Window Base Lower Register n (n = 0 to 7)
- AXI Window Base Upper Register n (n = 0 to 7)
- AXI Window Mask Lower Register n (n = 0 to 7)
- AXI Window Mask Upper Register n (n = 0 to 7)
- AXI Destination Lower Register n (n = 0 to 7)
- AXI Destination Upper Register n (n = 0 to 7)



Note: The values assigned in the figure (values in blue) are examples.

Figure 56.18 Example settings of the AXI windows

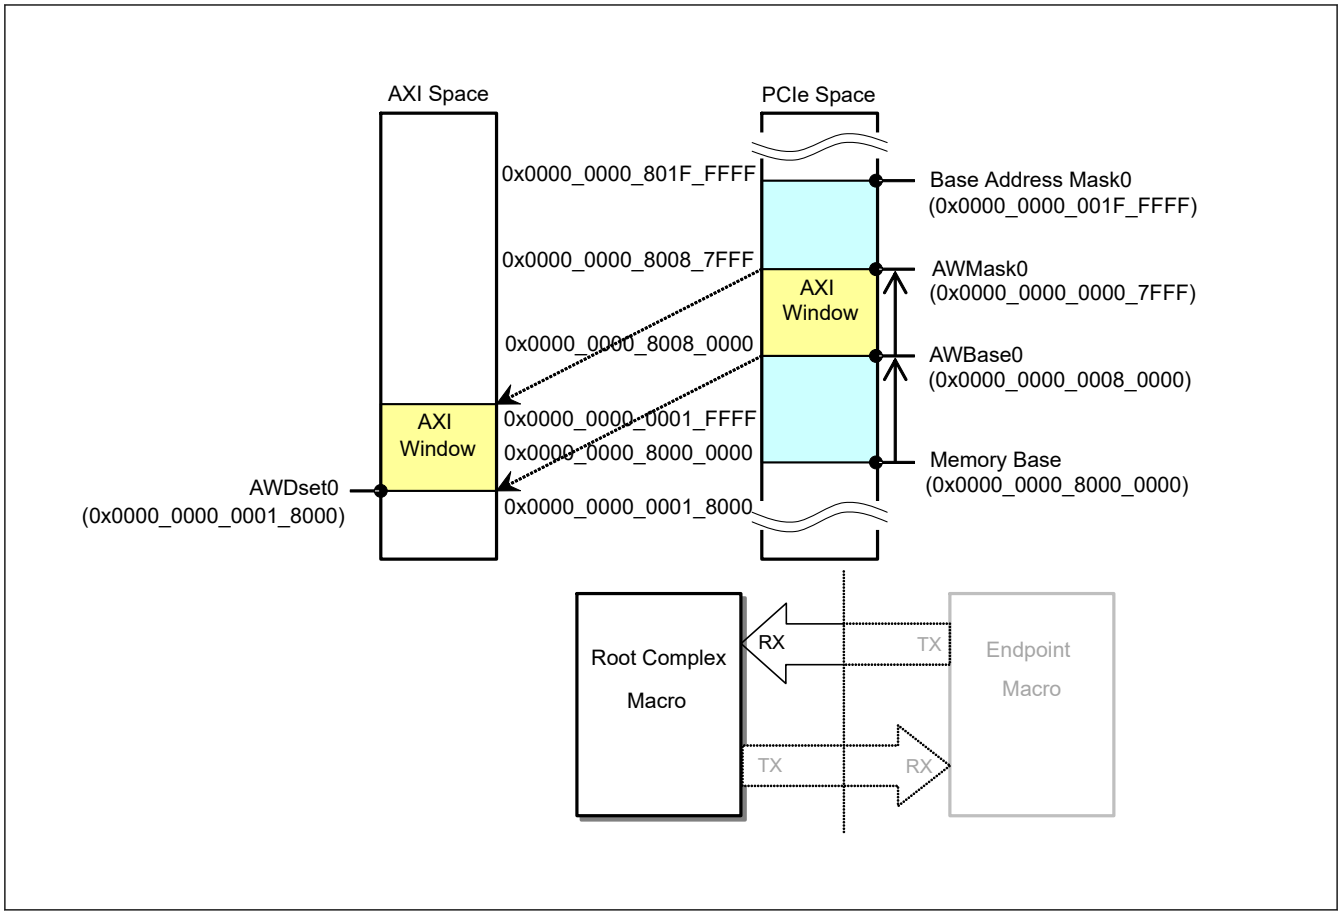


Figure 56.19 Mapping of the AXI windows

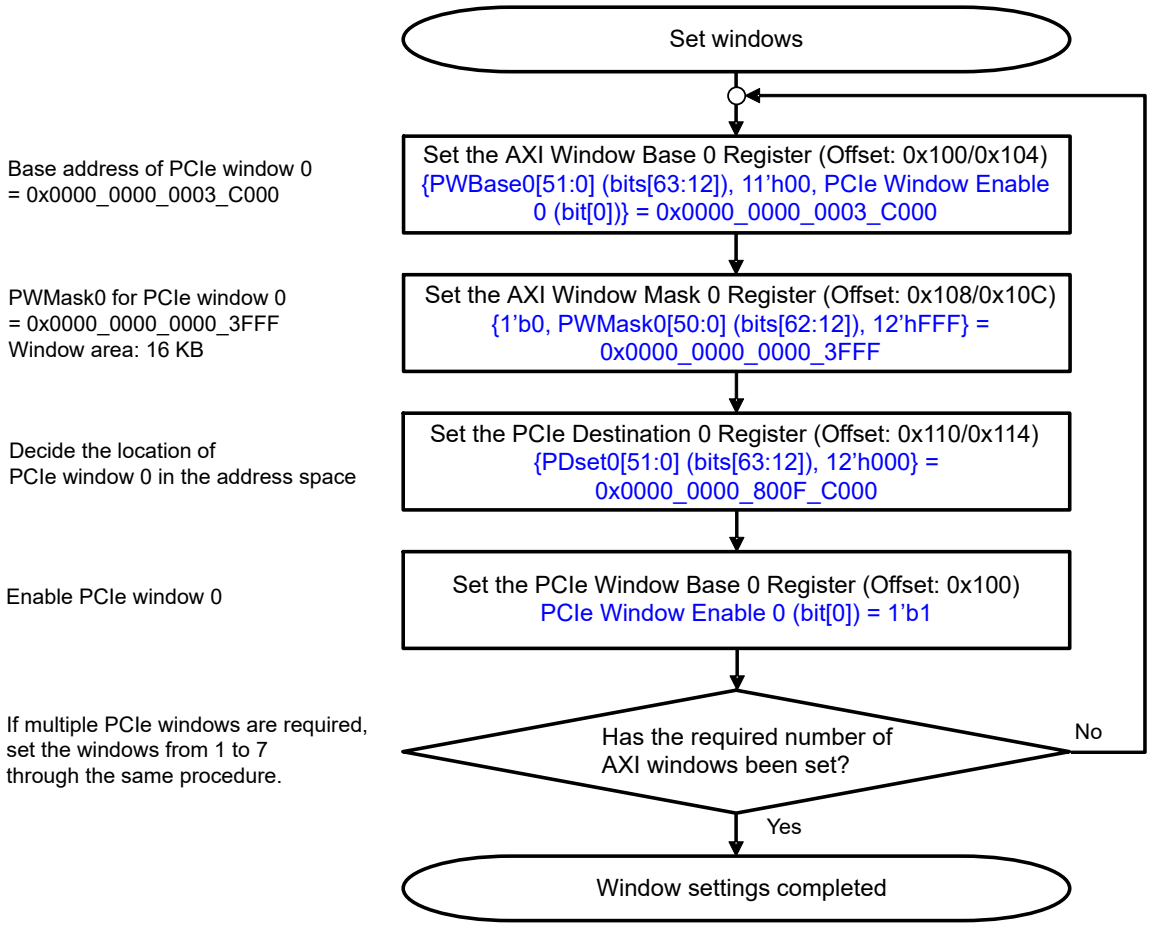
56.8.3.2 Setting the PCIe Windows

PCIe Window is used when transferring data from the AXI bus to PCIe (TX side) as MWr/MRd.

It can be set by write access to the registers below from the AXI Slave I/F. Up to 8 windows can be set. In that case, the following register settings are required for the number of windows required.

- PCIe Window Base Lower Register n (n = 0 to 7)
- PCIe Window Base Upper Register n (n = 0 to 7)
- PCIe Window Mask Lower Register n (n = 0 to 7)
- PCIe Window Mask Upper Register n (n = 0 to 7)
- PCIe Destination Lower Register n (n = 0 to 7)
- PCIe Destination Upper Register n (n = 0 to 7)



Note: The values assigned in the figure (values in blue) are examples.

Figure 56.20 Example settings of the PCIe windows

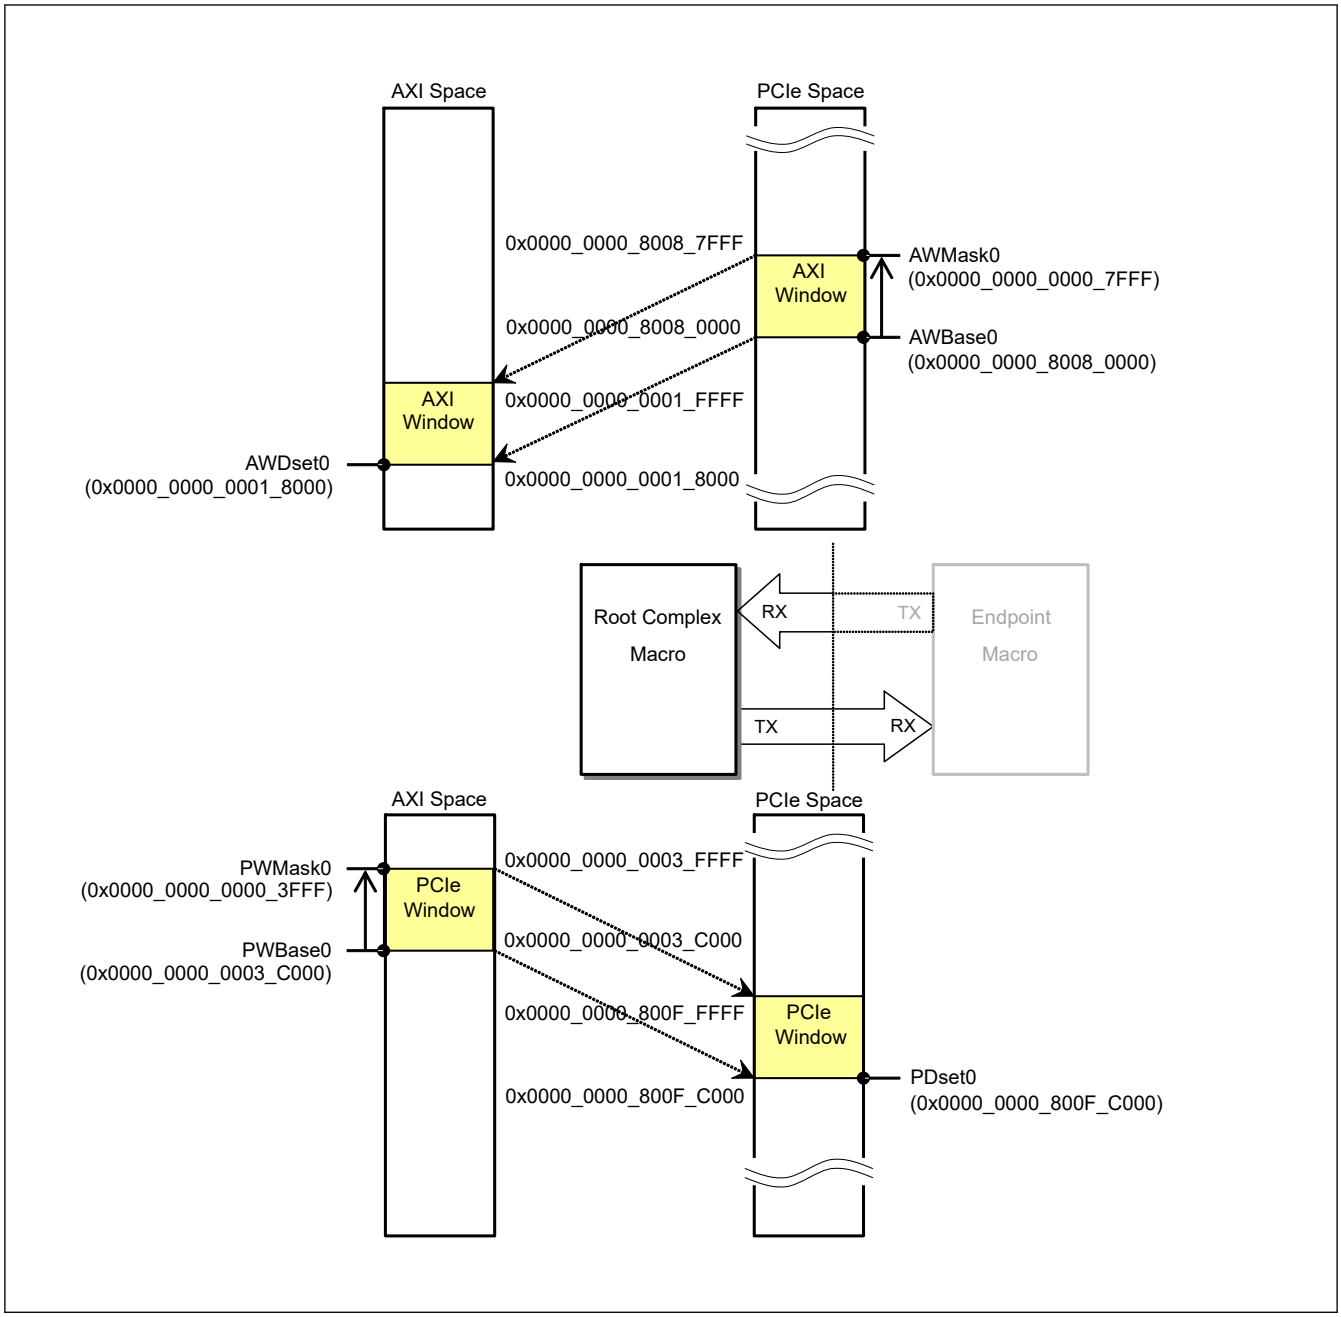


Figure 56.21 Mapping of the PCIe windows

After setting the window, activating Bus Master Enable/Memory Space Enable bits enables memory read/write requests from the Root Complex to the endpoint. If this setting is not made, the endpoint's Configuration Register cannot be set.

Note that this macro performs address conversion within the AXI Bridge, so set Memory Base/Limit (Offset: 0x6020) and Base Address Register Mask00 (Offset: 0x60A0/0x60A4) in the Configuration Register to All 1.

In addition, to allow writing to the Hwinit attribute register, CFG_HWINIT_EN bit (bit 2) in the Permission Register (Offset: 0x300) must be set to 1 before setting the Configuration Register below. It is recommended to rewrite (reset) CFG_HWINIT_EN to 0 after setting the following. This is to prevent the Hwinit attribute register from being easily (by mistake) rewritten.

[Configuration Register Settings]

- Memory Base/Limit Register (Offset: 0x6020): set all 1
- Base Address Register Mask00 (Lower) (Offset: 0x60A0): set all 1
- Base Address Register Mask00 (Upper) (Offset: 0x60A4): set all 1
- Status Command Register (Offset: 0x6004): set Bus Master Enable (bit 2) to 1

- Status Command Register (Offset: 0x6004): set Memory Enable (bit 1) to 1

56.8.3.3 Device Search

In typical PC systems, the Root Complex (Host CPU) can determine what product is connected as the opposing device by reading the Vendor ID/Device ID and Header Type in the opposing device's Configuration Register. For details, see the Base Spec.

In embedded systems and other cases where it is clear that the opposing device is an Endpoint device, there is no need to perform a device search. However, Bus Numbers must be assigned from the Root Complex to the Endpoint.

A simple setup method is described below. Please refer to the information below and take appropriate action depending on your device configuration (number of installed macros, and so on.) and system configuration.

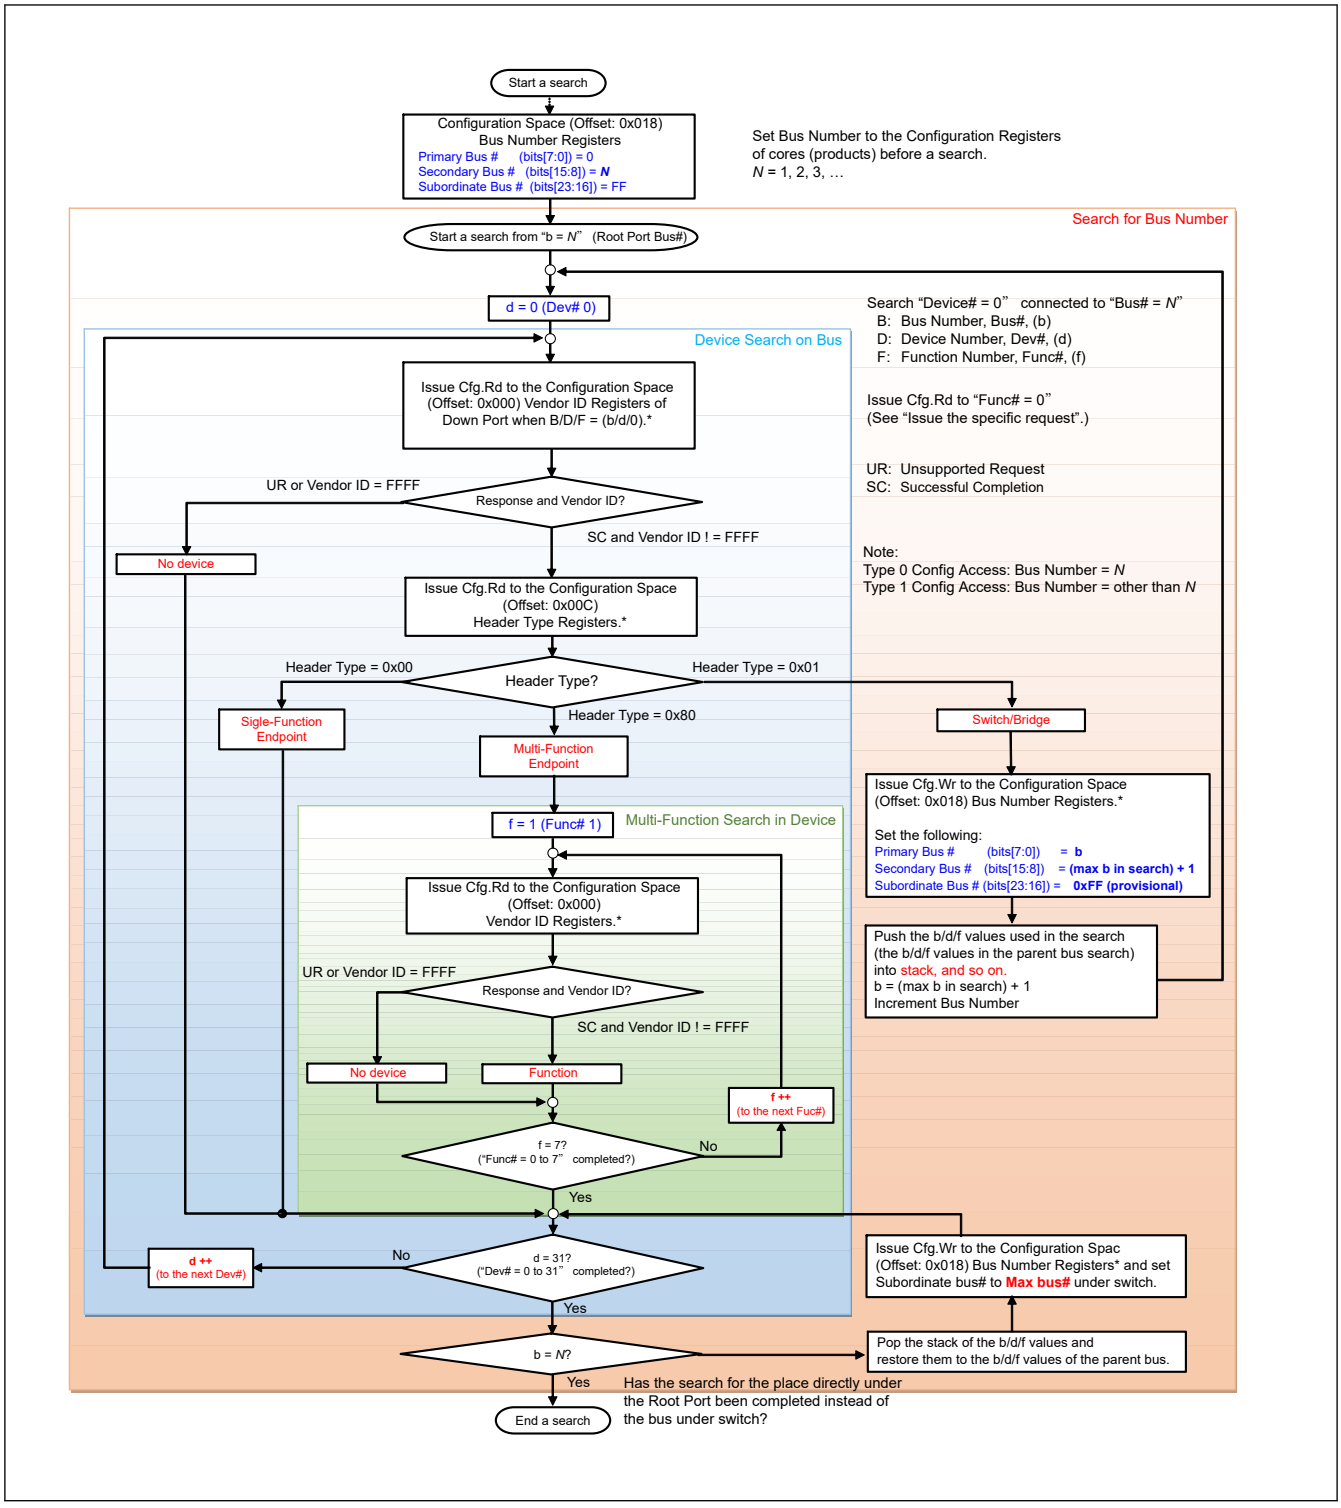

Figure 56.22 Example flow of device search

56.8.4 Setting the Windows (Endpoint Mode)

All PCI Express commands are issued via the set memory spaces or register spaces. After making the window settings and the configuration register settings, data such as PCIe MRd and MWr can be transferred. All PCI Express commands are issued via the set memory spaces or register spaces. After making the window settings and the configuration register settings, data can be transferred in response to PCIe MRd and MWr requests and so on.

56.8.4.1 BAR Specification (Two-Function Configuration)

This module has functionality for dividing the 64-bit memory space into window spaces for AXI access. Windows for access from PCIe to AXI and from AXI to PCIe are respectively referred to as AXI windows and PCI windows.

The AXI Bridge Registers (unit-specific registers) are accessible regardless of the function being used.

The 64-bit memory spaces must be set exclusively of each other and have no overlaps.

Set the AXI window spaces such that they do not overlap.

Table 56.145 Example BAR settings (64 bits × 3, function = 2)

Function	BAR (Memory space)	AXI window	Note
Function #0	64-bit memory space (1) {BAR1, BAR0}	AXI #0	
		AXI #1	
		AXI #2	
		AXI #3	
	64-bit memory space (2) {BAR3, BAR2}	AXI #4	
		AXI #5	
		AXI #6	
		AXI #7	
	64-bit memory space (3) {BAR5, BAR4}	—	AXI Bridge Registers
Function #1	64-bit memory space (1) {BAR1, BAR0}	AXI #0	
		AXI #1	
		AXI #2	
		AXI #3	
	64-bit memory space (2) {BAR3, BAR2}	AXI #4	
		AXI #5	
		AXI #6	
		AXI #7	
	64-bit memory space (3) {BAR5, BAR4}	—	AXI Bridge Registers

Note: BAR: Abbreviation of Base Address Register
Note: The address spaces are invalid when the corresponding BAR values are all 0s.
The BAR settings are required for each function.

The base addresses of the 64-bit memory spaces (1), (2), and (3) above are set by using the following configuration registers.

64-bit memory space (1): Configuration registers {BAR1, BAR0}

64-bit memory space (2): Configuration registers {BAR3, BAR2}

64-bit memory space (3): Configuration registers {BAR5, BAR4}

Note:
- Up to eight AXI windows can be set by dividing the 64-bit memory space (1).
- Up to eight AXI windows can be set by dividing the 64-bit memory space (2).
- The number of AXI windows allocated to each of the BAR areas is as follows.
  64-bit memory space (1): 64-bit memory space (2) = 8:0 or 4:4;
  Select either of the above settings. Note that all of the allocated AXI windows do not need to be used effectively.
- The 64-bit memory space (3) is dedicated for access to the AXI Bridge Registers.
- The base addresses of each of the AXI windows are limited within the 4-Gbyte space from the BAR base address.

56.8.4.2 Setting the AXI Windows

In operation as an endpoint device, the AXI windows can be set in the following two ways.

1. The root complex issuing memory read and memory write requests.
2. Setting from the CPU of the endpoint under software control.

The following shows the procedure for making the settings by method 1.

Set the AXI windows on the endpoint side by issuing memory read (MRd) and memory write (MWr) requests to the AXI Bridge Register access space set in the previous section.

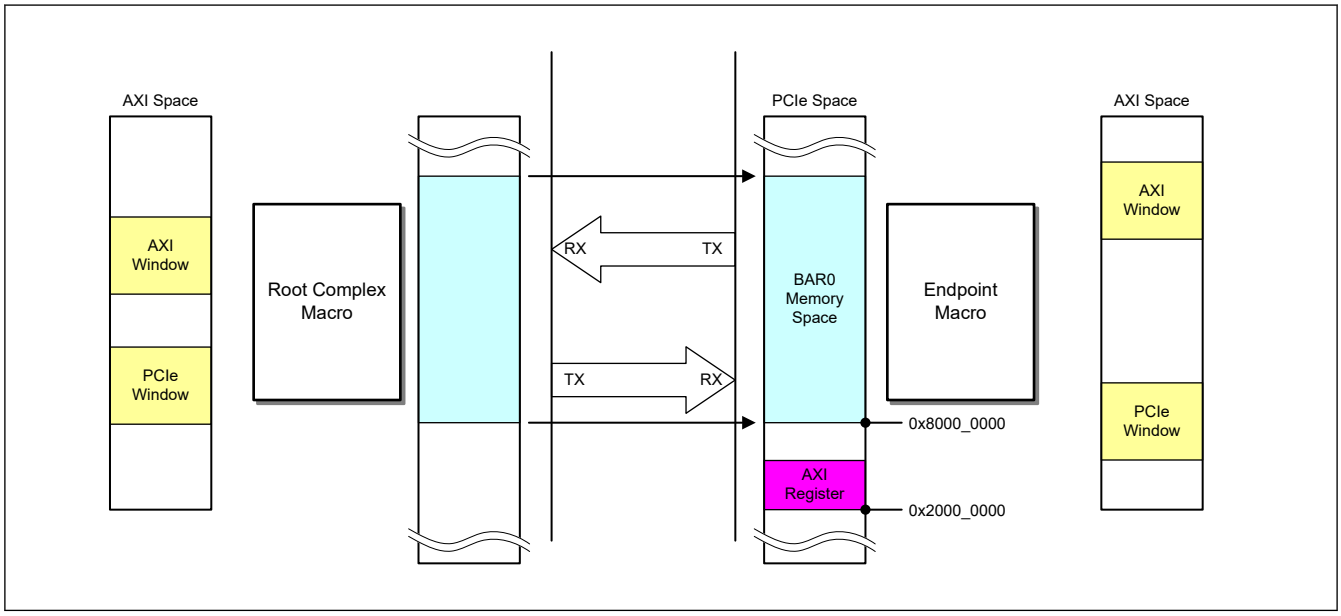

Figure 56.23 Setting of AXI windows on the endpoint by issuing memory read and memory write from root complex

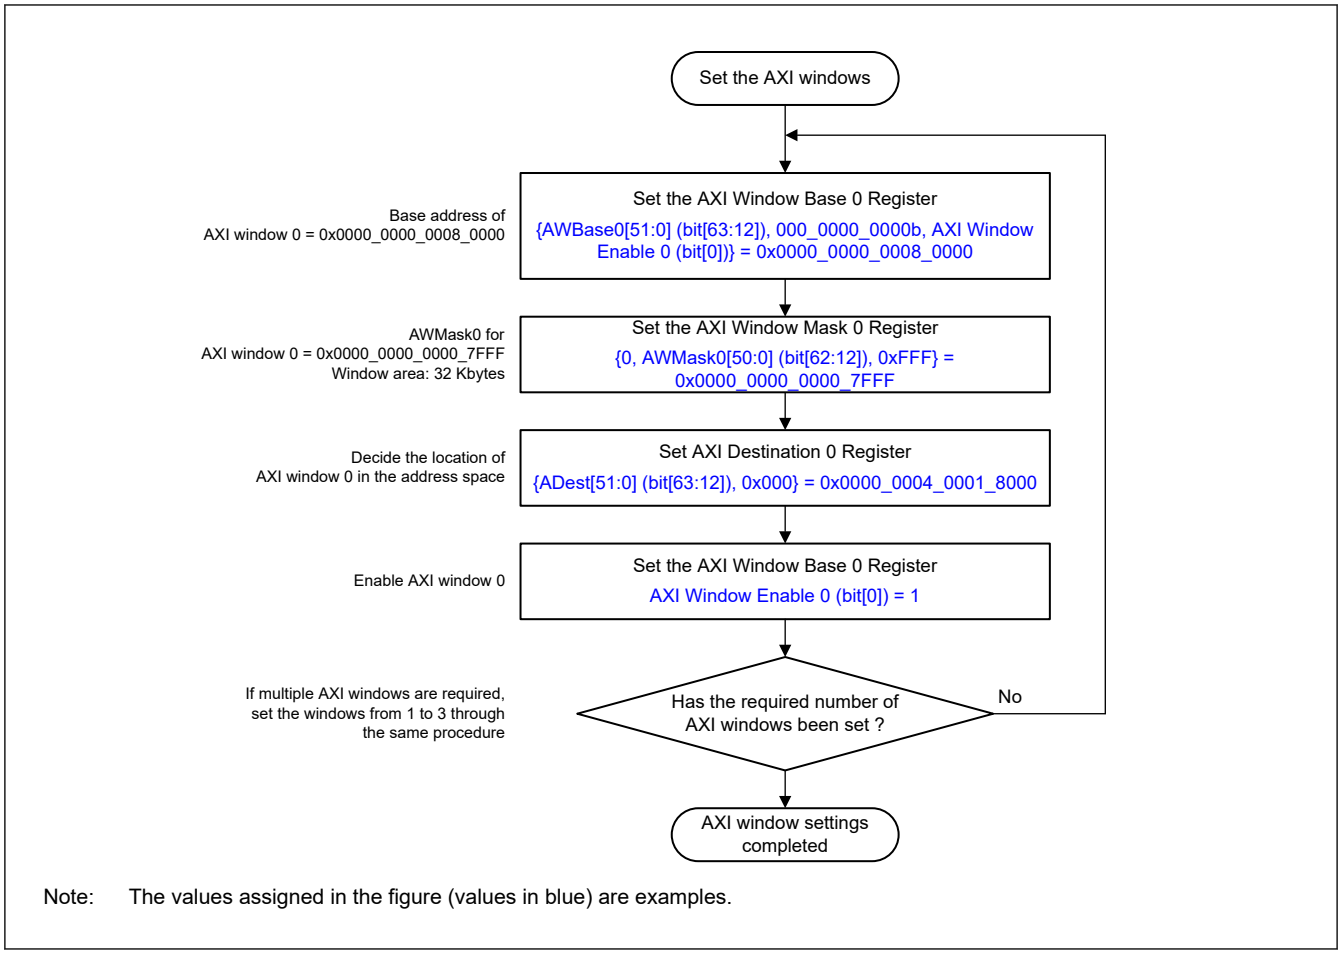
Data transfer is possible when setting of the windows is completed and the Bus Master Enable bit and the Memory Space Enable bit of the given configuration register are set to the enabled state.

The following shows the procedure for making the settings by method 2.

The AXI windows can be set by write access to the registers through the AXI slave interface.



Note: The values assigned in the figure (values in blue) are examples.

Figure 56.24 Example settings of the AXI windows

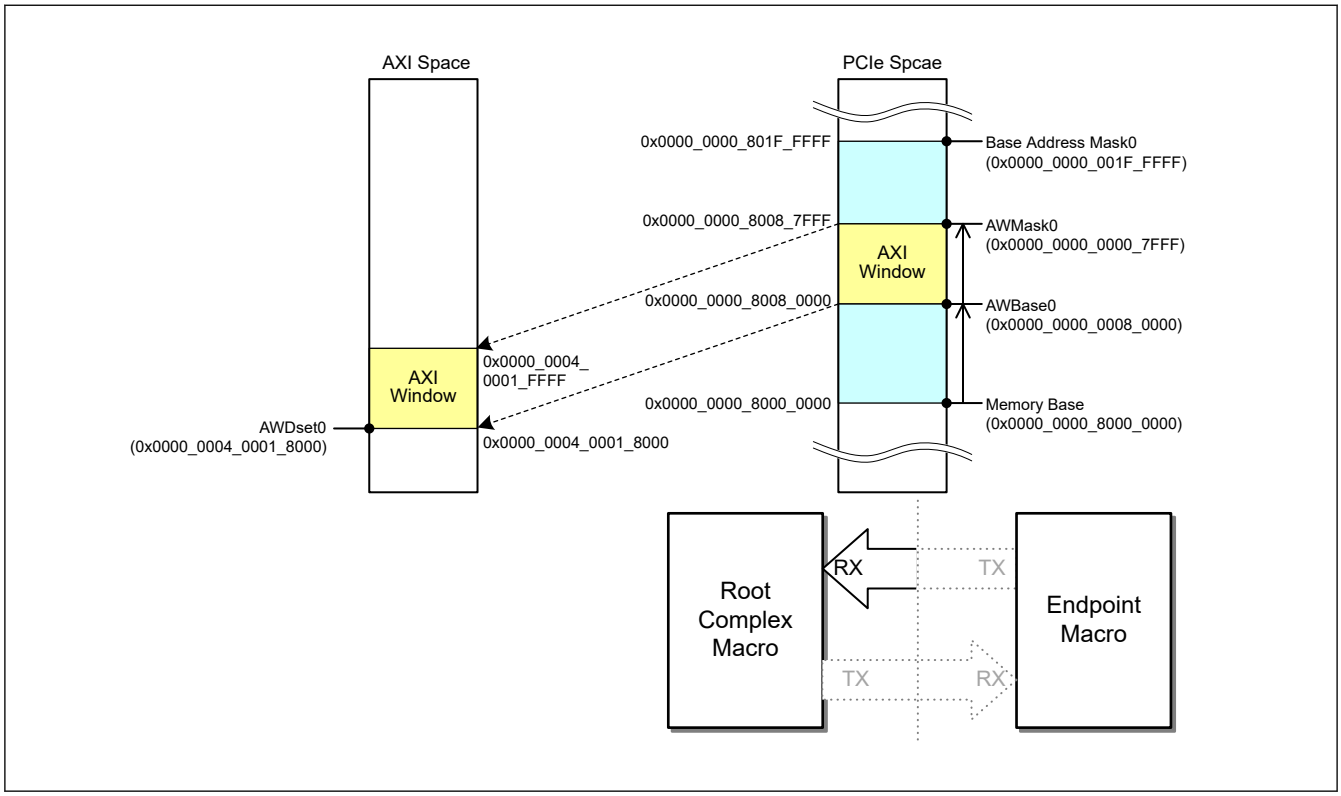


Figure 56.25 Mapping of the AXI windows

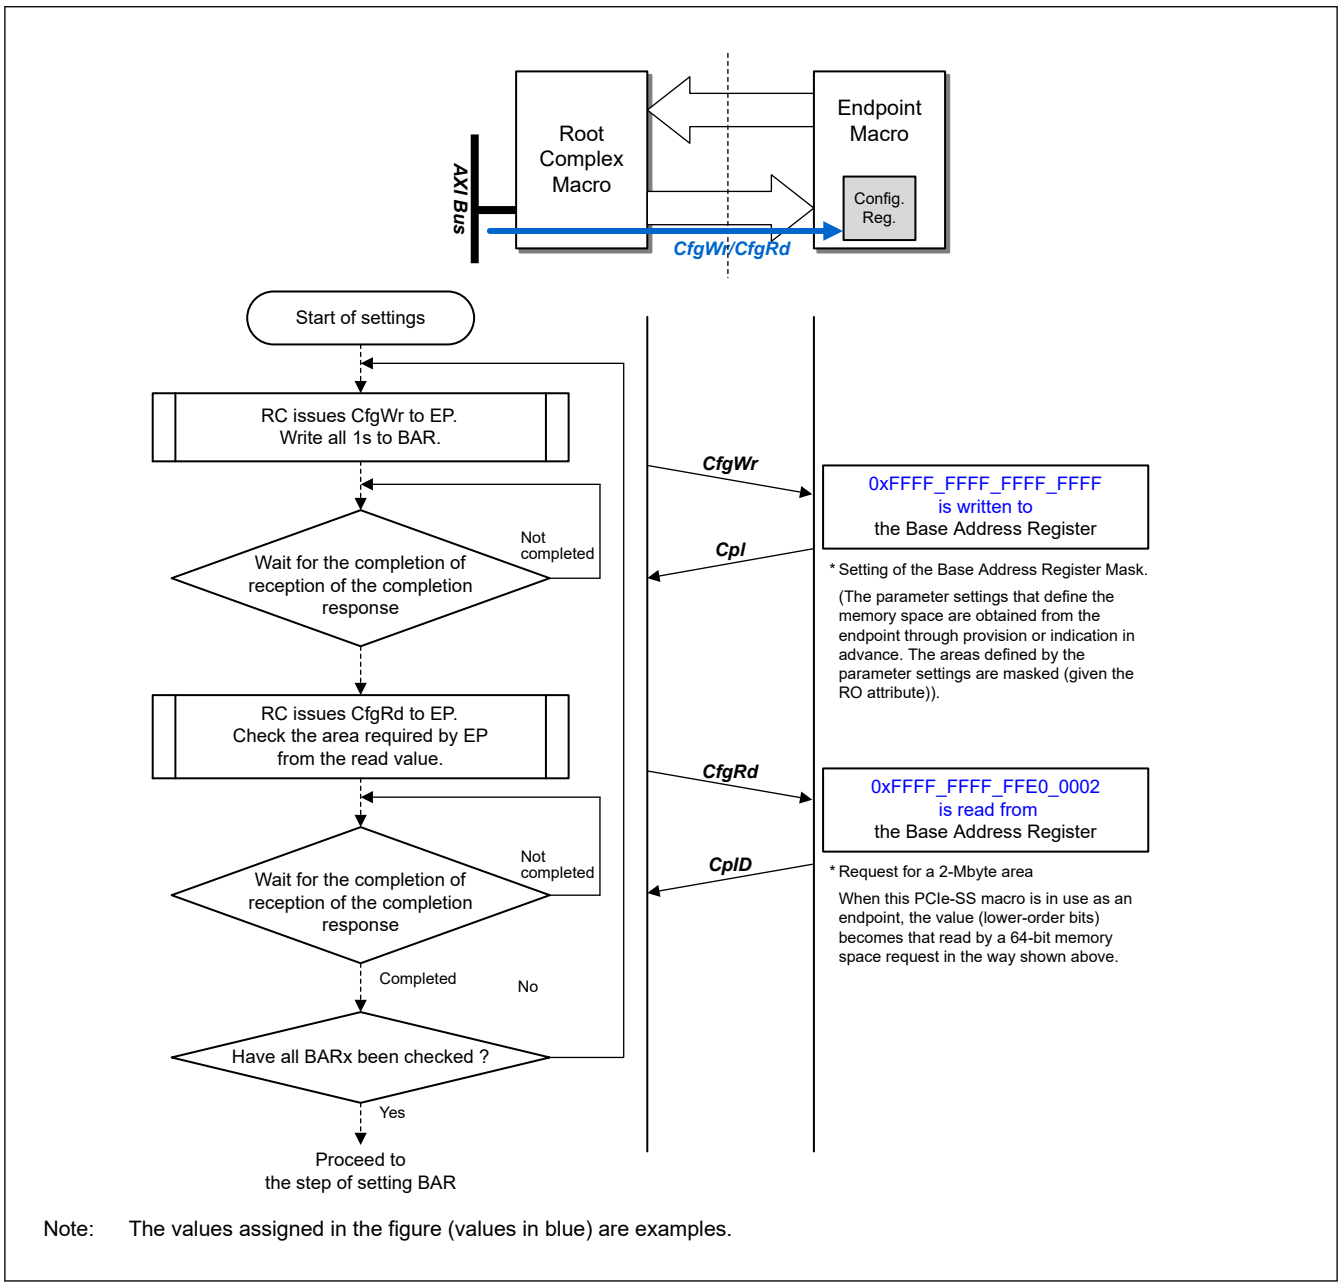
At this time, three address space settings, namely the AXI address space for the root complex device, the AXI address space for the endpoint device, and the PCI address space between the root complex and the endpoint, must be consistent within the system. If they are not, data cannot be transferred. Take care with the settings.

56.8.4.3 Setting the PCIe Address Space

A PC or similar system recognizes information on the areas of the memory space which are required by other-party endpoint devices by access to the configuration registers of the endpoints through software processing by the CPU on the root-complex side. In the case of embedded systems, etc., the areas required by the other-party devices will generally be known in advance, so this processing is not usually required.

The following is an example procedure for setting of the PCIe memory space for an other-party endpoint by the root complex.

Configuration requests are made to be issued to the other-party endpoint devices by register access through the AXI slave interface.



Note: The values assigned in the figure (values in blue) are examples.

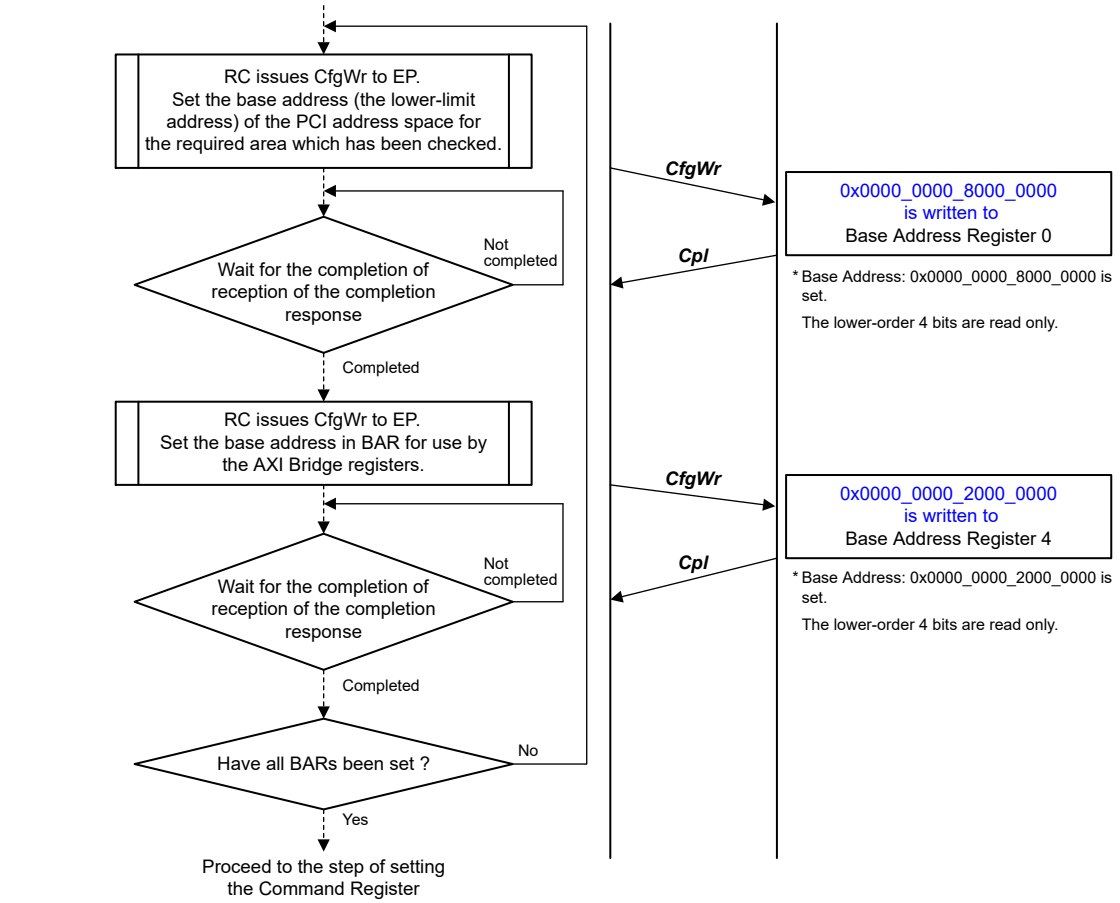
Figure 56.26 Example settings for the PCIe address space (1)

After issuing a configuration write request for writing all 1s (0xFFFF_FFFF_FFFF_FFFF), a configuration read request is issued and if the result of reading is all 0s (0x0000_0000_0000_0000), the given base address register (BAR) is judged to be reserved and the corresponding space is considered to be unused.

From the result of reading, software on the root complex side writes the base address (the lower-limit address) of the PCI address space to be allocated to the endpoint device by issuing a configuration write request.*1 At this time, setting of a BAR for which the area requested by the endpoint device was found to be reserved and thus unused is not required.

Also, if an address space which includes the other party has been prepared in advance, the above confirmation is not required. Set the base address directly.

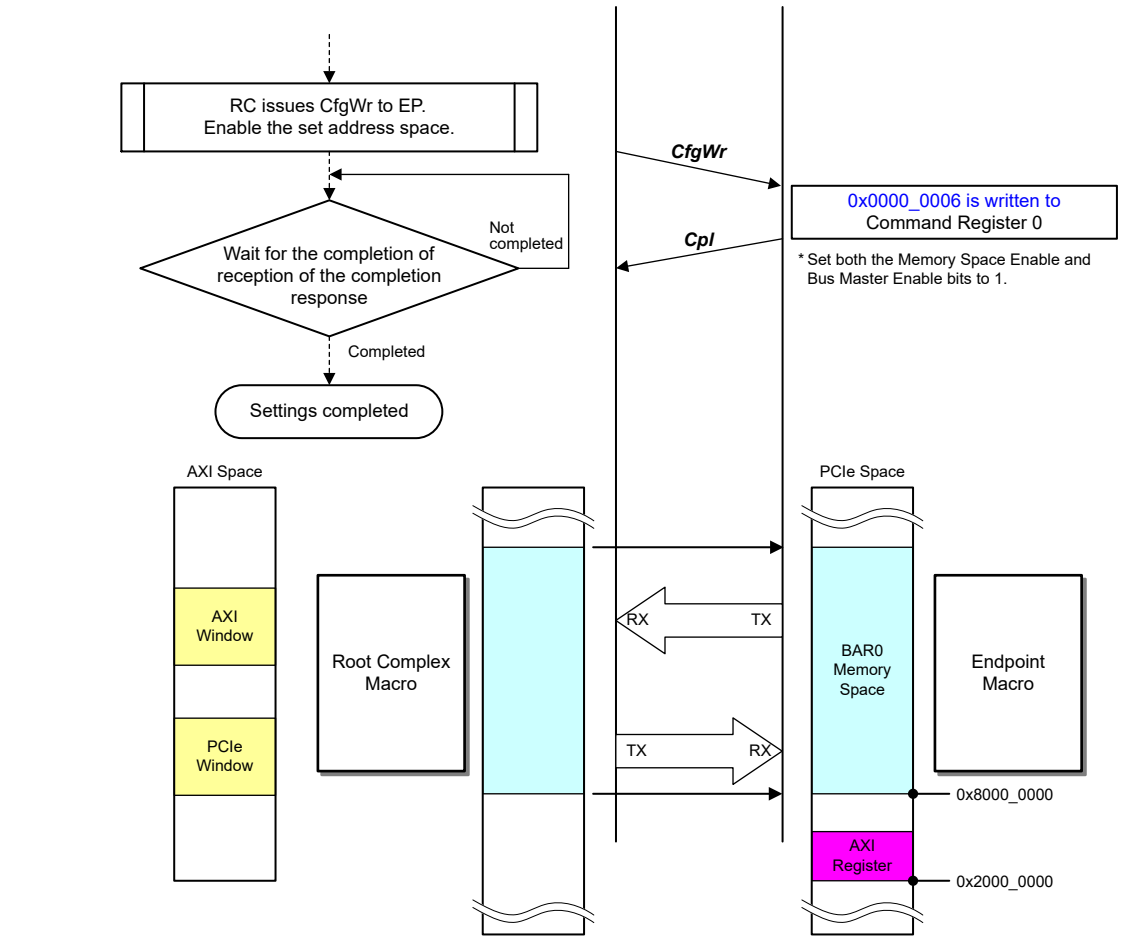
Note: Setting a base address register to all 0s is prohibited.



Note: The values assigned in the figure (values in blue) are examples.

Figure 56.27 Example settings for the PCIe address space (2)

The completion of settings for the PCIe address space means that the root complex is ready for data transfer to the corresponding endpoint. Finally, set the Bus Master Enable bit and the Memory Space Enable bit of the given command register to enable the memory space.



Note: The values assigned in the figure (values in blue) are examples.

Figure 56.28 Example settings for the PCIe address space (3)

56.8.5 Data Transfer

This module has one port each for master and slave operation as an AXI interface. For PCIe requests which can be issued through the master and slave ports, see section 56.7.3. Issuing of PCIe Requests and Register Access (by AXI) and section 56.7.4. Initiation of AXI Transactions and Register Access (by PCIe).

The focus of this explanation is on normal memory data transfer.

56.8.5.1 PCIe MWr (When the AXI Slave Is in Use)

A write transaction from the AXI bus (AXI-WR) via a window set as a PCIe window is converted into an MWr command (PCIe MWr) and then issued. If a PCIe MWr request is to be issued through the AXI interface slave port of the unit by using a DMAC, etc. external to the unit, the number of write transactions which can be accepted at a time is one, so the operation is as follows.

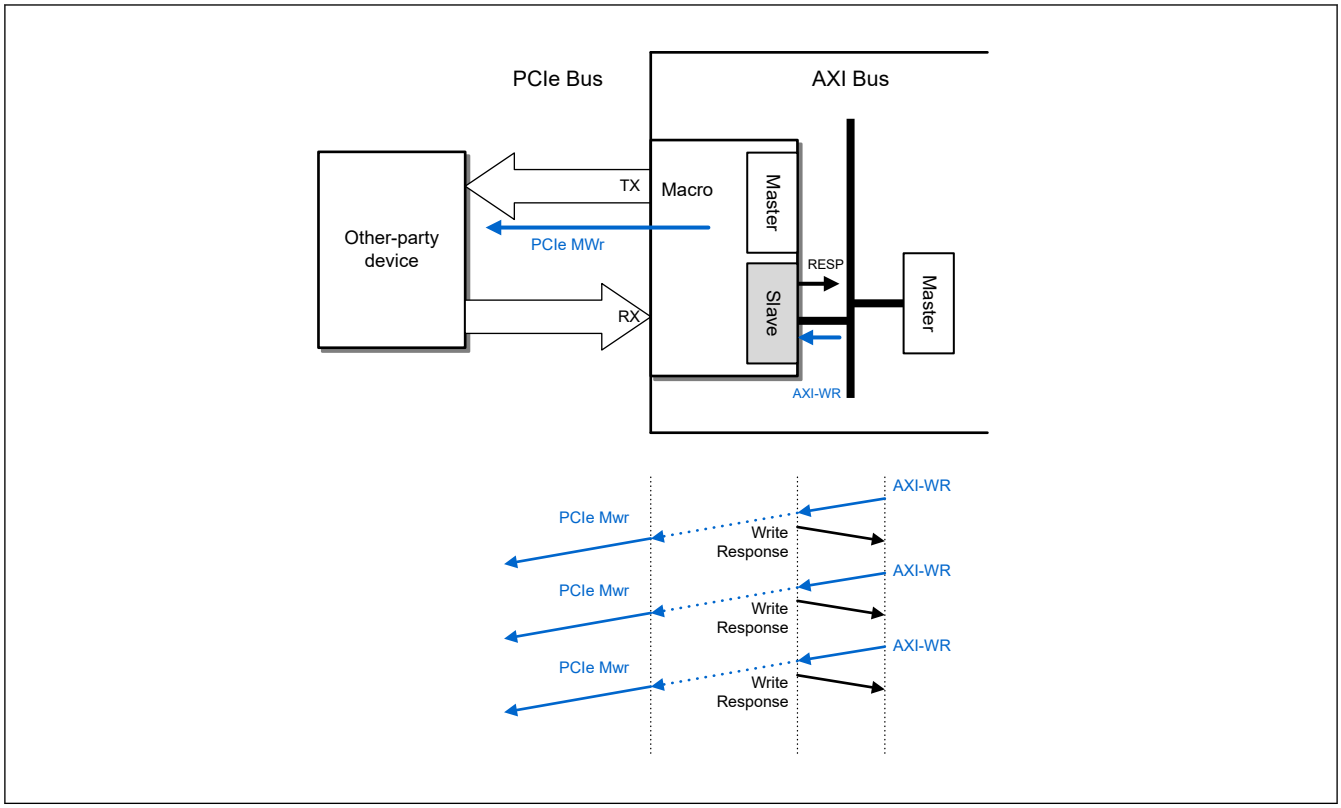


Figure 56.29 Data transfer by PCIe MWr (AXI Slave)

1. A write transaction from the AXI bus is issued through the AXI slave interface (write address channel, write data channel).
2. The transaction is converted into a PCIe MWr command and data are transferred to the other-party device via the PCIe bus.
3. After a wait for a response from the AXI slave interface (write response channel), a next AXI write transaction is issued.

A write response is issued after writing data to the transmission buffer (SRAM) within the unit. If this transmission buffer is full, the unit receives as much data as it can capture and then places the READY signal at the low level. Accordingly, the AXI bus may be placed in the hold state during transfer.

Since this depends not only on the specifications of the PCIe module (the number of lanes, rate, maximum payload size, etc.) but also on the size of the transmission buffer, the size of the reception buffer of the other-party device, and the external system configuration (the time for access to the external DRAM, etc.), care should be taken when considering the system configuration in general.

56.8.5.2 PCIe MWr (When the DMAC Is in Use)

If a PCIe MWr request is to be issued through the AXI master port by using the DMAC within the unit, the number of requests which can be read by the internal DMAC is one transaction per channel, so the operation is as follows.

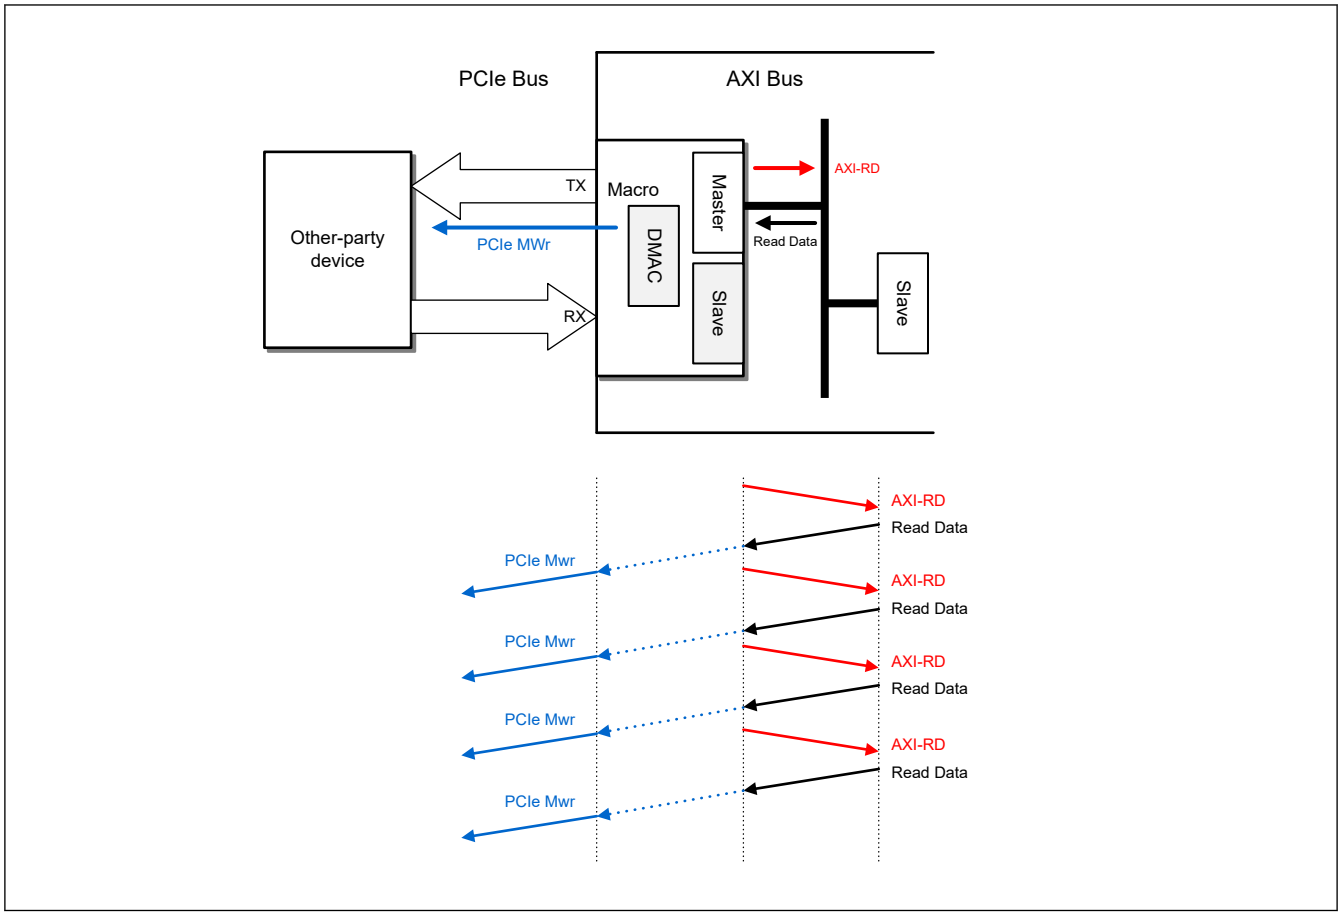

Figure 56.30 Data transfer by PCIe MWr (DMAC with 1 channel)

1. An AXI read (AXI-RD) request is issued through the AXI master interface (read address channel).
2. After the AXI master interface (read data channel) receives read data, this is converted into a PCIe MWr command and data are transferred to the other-party device via the PCIe bus.
3. Following the completion of the reception of read data, a next AXI-RD is issued.
4. The above steps are repeated until transfer of all bytes set in the DMA Size bits is completed.

The read data channel checks that the data that have been read are valid and indicates the readiness of the data for reception. Even when the transmission buffer (SRAM) within the unit is full, the unit issues read requests through the read address channel. Also, it receives as much data as it can capture and places subsequent data in the non-receivable state. Accordingly, depending on the state of the transmission buffer, data may not be transferred regardless of a request having been issued, or the AXI bus may be placed in the hold state during transfer. This lengthens the period of waiting for data that have been read, leading to the deterioration of transfer performance as well as the deterioration of overall system performance.

Likewise, contention with write access by the slave interface and contention in write access between channels may decrease performance in transfer.

Since this depends not only on the specifications of the PCIe module (the number of lanes, rate, maximum payload size, etc.) but also on the size of the transmission buffer, the size of the reception buffer of the other-party device, and the external system configuration (the time for access to the external DRAM, etc.), care should be taken when considering the system configuration in general.

The following is an example where the number of requests which can be read by the AXI master interfaced through four DMAC channels is 4.

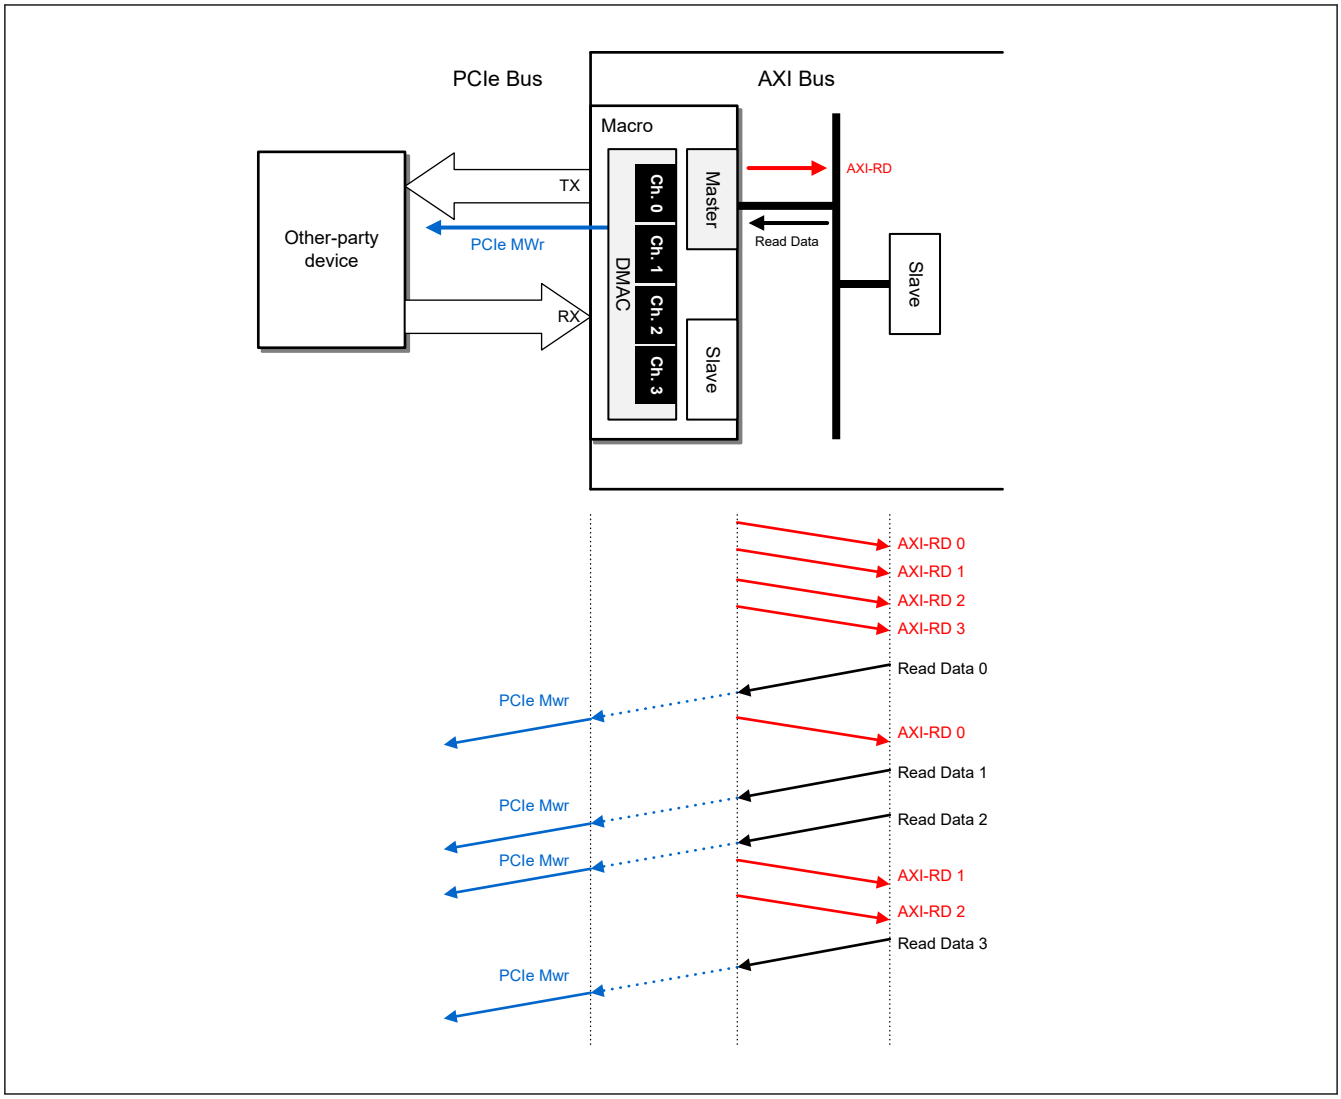

Figure 56.31 Data transfer by PCIe MWr (DMAC with 4 channels)

1. An AXI read (AXI-RD0: DMAC ch. 0) request is issued through the AXI master interface (read address channel).
2. Since the number of requests which can be read by the unit = 4, AXI read requests are subsequently issued through DMAC ch. 1, ch. 2, and ch. 3.
   No order of priority applies to the issuing of requests through these channels.
3. Following the completion of the reception of data read in response to the read request through ch. 0, ch. 0 is able to issue a next AXI-RD0.
4. The above steps are repeated until transfer of all bytes set in the DMA Size bits for each channel is completed.

Configuring data transfer as described above allows increased performance, although such a configuration complicates software control.

56.8.5.3 PCIe MRd (When the AXI Slave Is in Use)

In usage as an AXI slave, memory read requests (PCIe MRd) are issued to the PCIe interface, a completion (CplD) is received from the PCIe interface, and an AXI read transfer (AXI-RD) is initiated (this module supports eight outstanding transfers). Therefore, only the number of PCIe MRd requests that corresponds to this set number of outstanding transfers can be issued first, regardless of the reception of CplD. The received CplDs are stored in a data buffer (RAM) and then transferred through the AXI bus.

If a PCIe MRd is issued through the AXI interface slave port of the unit, the number of read requests which can be accepted by the AXI slave at a time = 1 to 8 corresponding to the PCIe section.

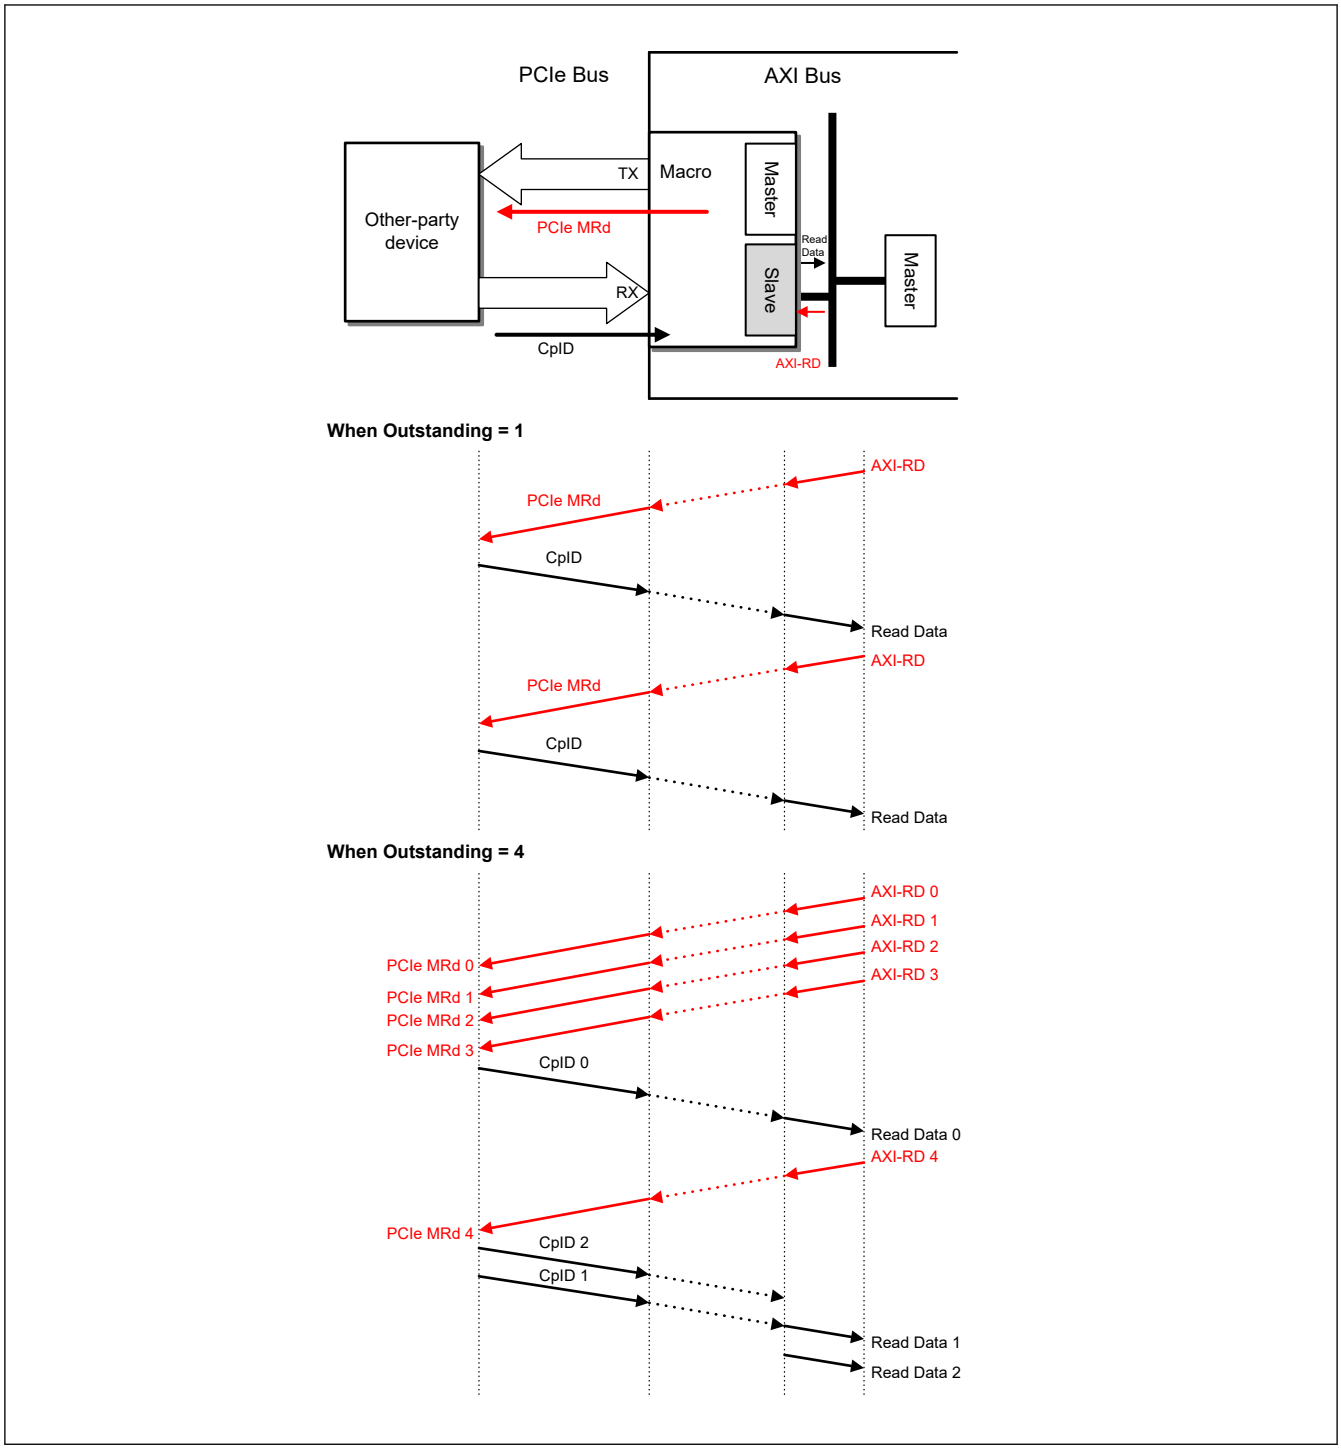

Figure 56.32 Data transfer by PCIe MRd (AXI Slave)

When outstanding = 1

1. An AXI read transaction is issued through the AXI slave interface (read address channel).
2. A transaction is converted into a PCIe MRd command and the request for data reading is issued to the other-party device via the PCIe bus.
3. CplD is received from the other-party device and an AXI read response is issued through the AXI slave interface (read data channel).
4. Steps 1 to 3 are repeated.

When outstanding = 4

1. An AXI read transaction is issued through the AXI slave interface (read address channel).
2. A transaction is converted into a PCIe MRd command and the request for data reading is issued to the other-party device via the PCIe bus.
   Steps 1 and 2 can be repeated until up to four consecutive requests have been issued.
3. CplD is received from the other-party device and an AXI read response is issued through the AXI slave interface (read data channel).
   At this time, the PCIe module can operate with out-of-order transactions, so the order of CplDs from the otherparty device may not be preserved. The unit also includes a buffer to support in-order transactions with the AXI bus. If this is used and the CplD for a preceding PCIe MRd is never returned, however, the next request cannot be issued and performance deteriorates accordingly.
   After that, steps 1 to 3 are repeated.

56.8.5.4 PCIe MRd (When the DMAC Is in Use)

If a PCIe MRd request is to be issued by using the DMAC within the unit, the overall number of requests is also 1 to 8 when the DMAC is incorporated depending on the number of outstanding transfers.

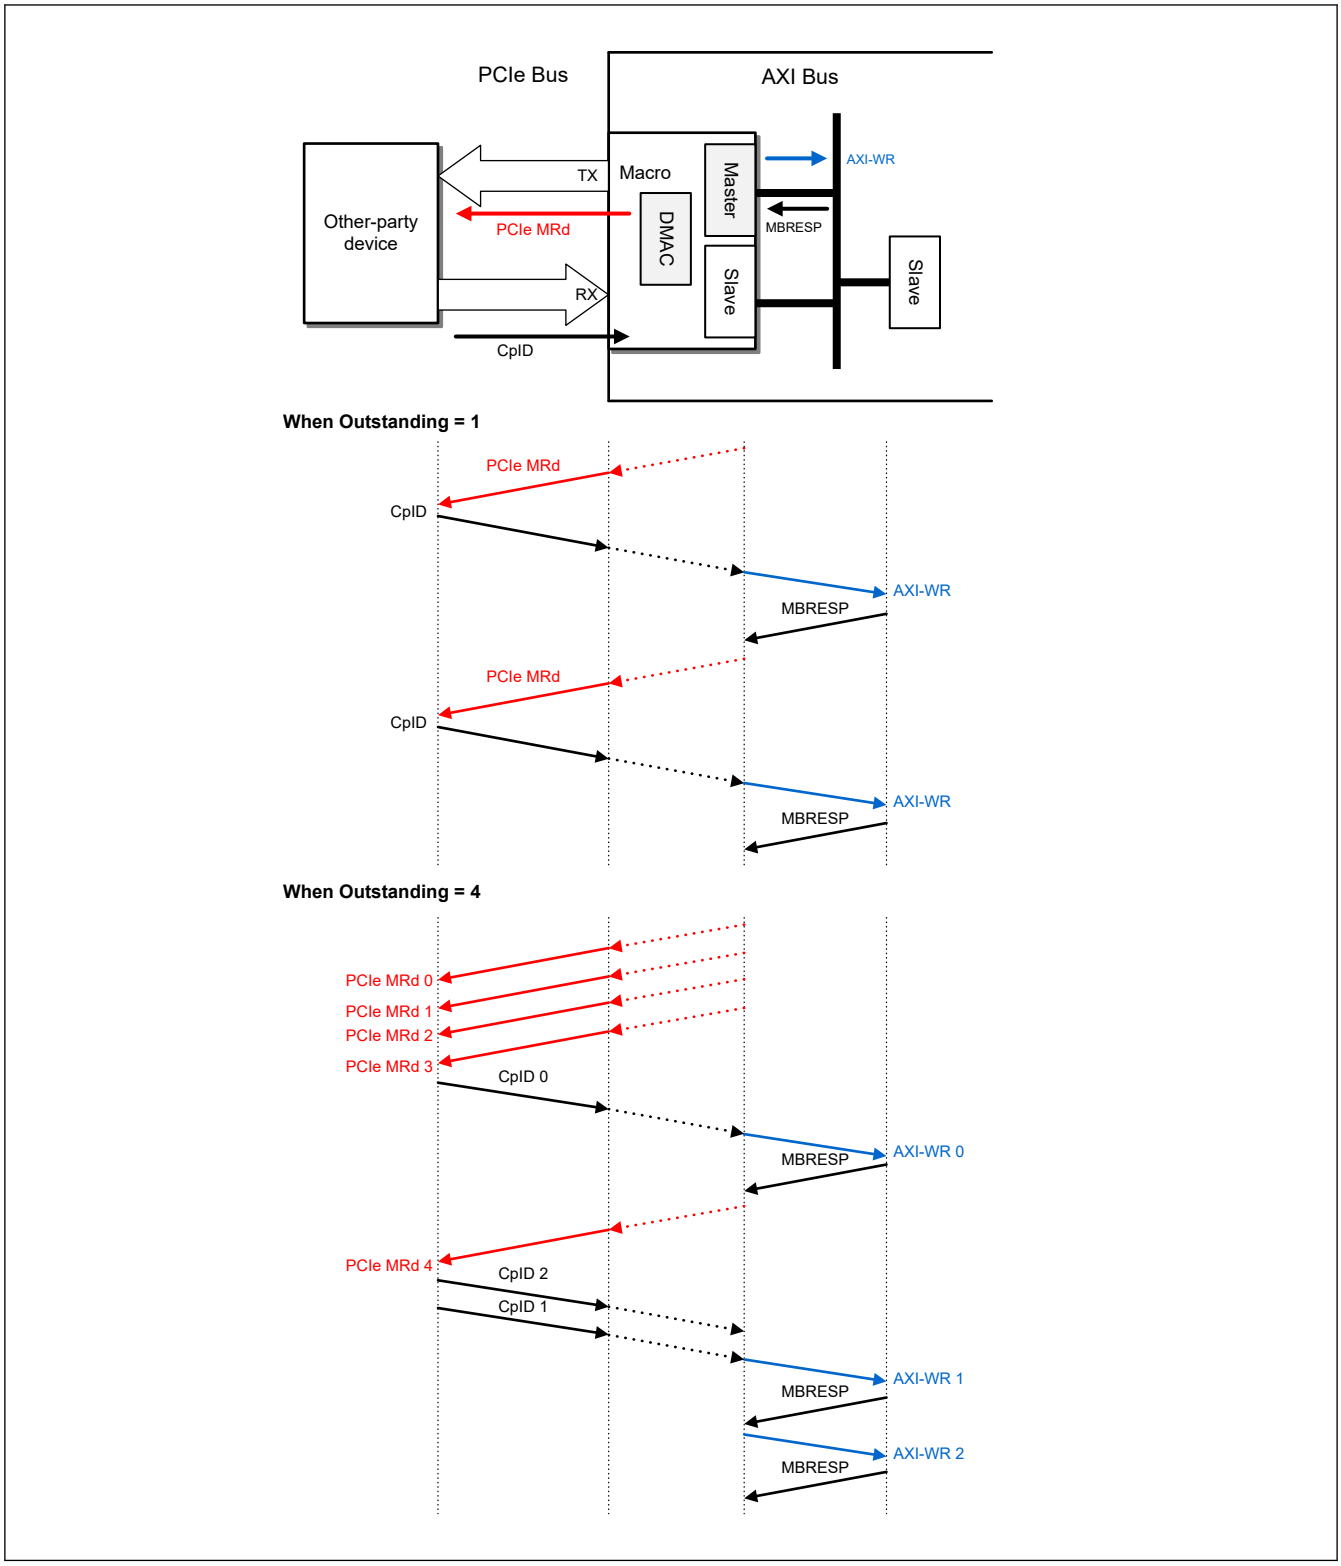

Figure 56.33 Data transfer by PCIe MRd (DMAC)

When outstanding = 1

1. Activate the internal DMAC through the AXI slave interface or from an other-party device.
2. The DMAC issues a read request and this is converted to a PCIe MRd command within the unit. The request for data reading is issued to the other-party device via the PCIe bus.
3. CplD is received from the other-party device and an AXI write transaction is issued through the AXI master interface (write address channel, write data channel).

4. Following the completion of the AXI write transfer, a next request is issued.
5. Steps 2 to 4 are repeated until transfer of all bytes set in the DMA Size bits is complete.

When outstanding = 4

1. Activate the internal DMAC through the AXI slave interface or from an other-party device.
2. The DMAC issues a read request and this is converted to a PCIe MRd command within the unit. The request for data reading is issued to the other-party device via the PCIe bus. Up to four consecutive requests can be issued.
3. CplD is received from the other-party device and an AXI write transaction is issued through the AXI master interface (write address channel, write data channel).
   At this time, the PCIe module can operate with out-of-order transactions, so the order of CplDs from the otherparty device may not be preserved. The unit also includes a buffer to support in-order transactions with the AXI bus. If this is used and the CplD for a preceding PCIe MRd is never returned, however, the next request cannot be issued and performance deteriorates accordingly.
4. Following the completion of the AXI write transfer, a next request is issued.
5. Steps 2 to 4 are repeated until transfer of all bytes set in the DMA Size bits is completed.

56.8.6 PCIe Initialization Procedure

56.8.6.1 Root Complex Mode

An example of the initialization procedure for PCIe Root Complex mode is described in steps 1 to 13.

Table 56.146 Initialization Procedure (RC) (1 of 2)

Step	Procedure
1	Set the TZC-400-2 register to grant proper transaction. For details, see section 13.4.4.3. TZC-400. Set the IO Port register to enable PCIE_RSTOUTnB pin. (when used) For details, see section 17, I/O Ports.
2	Set the Root Complex mode and Channel Configuration. Set the MODE_PORT bit in the PCIE_MODE register to 1. Set LINK_MASTER[1:0] bits in the PCIE_LINKMODE register.
3	Release the reset (ARESETn). Set the MRTCLM08 bit in the MRCTLM register to 0.
4	Release the module stop state. Set the MSTPCRM08 bit in the MSTPCRM register to 0.
5	Release Slave Stop Function. For details, see section 13.4.3. Slave Stop Function.
6	Release the reset (RST_LOAD_B, RST_CFG_B). Set RST_LOAD_B (bit4) and RST_CFG_B (bit3) in the PCI_RC_RESET to 1.
7	Setting of the PHY. Set the PHY_REG_CLK_EN bit in the PCI_RC_PERM register. Set the PCI_PHY_XCFGDn register (n = 0 to 26). Set the PCI_PHY_XCFGA_CMNn register (n = 0 to 15). Set the PCI_PHY_XCFGA_L0n register (n = 0 to 5). Set the PCI_PHY_XCFGA_L1n register (n = 0 to 5). For details, see section 56.5.1. PCI_PHY_XCFGDn : XCFGD Setting Register n (n = 0 to 26) to section 56.5.4. PCI_PHY_XCFGA_L1n : XCFGA_LN1 Setting Register n (n = 0 to 5).
8*1	Setting of HWINT related registers Set the CFG_HWINT_EN bit in the PCI_RC_PERM register. Set the PCI_RC_VID register to Device ID and Vendor ID. Set the PCI_RC_RID_CC register to Revision ID and Class Code. Set the PCI_RC_BARMSK00L and PCI_RC_BARMSK00U registers to Base Address Register Mask. Set the PCI_RC_BSIZE00_01 register to Base Size. Set the UPTP0, UPTP1, DPTP0, and DPTP1 bits in the PCI_RC_LEQCTL register (m = 0) to 0x8 each for 2 lanes × 1 channel configuration. Set the UPTP0 and DPTP0 in the PCI_RC_LEQCTL register (m = 0 and 1) to 0x8 for 1 lane × 2 channels configuration. Set the MODE_EQ_AUTONOMOUS bit in the PCI_RC_PCCTRL1 register to 1.

Table 56.146 Initialization Procedure (RC) (2 of 2)

Step	Procedure
9	Permit ASPM L1 State Transition Set ALLOW_ENTER_L1 bit in the PCIE_MISC register to 1.
10*2	Interrupt settings Set the PCI_RC_PEIS0 register to 0x0000_1200. Set the PCI_RC_PEIE0 register to 0x6000_1200. Set the PCI_RC_PEIS1 register to 0x0003_0303. Set the PCI_RC_PEIE1 register to 0x0003_0303. Set the PCI_RC_AMEIS register to 0x0000_0F0F. Set the PCI_RC_AMEIE register to 0x0000_0F0F. Set the PCI_RC_ASEIS1 register to 0x0000_0F03. Set the PCI_RC_ASEIE1 register to 0x0000_0F03. Set the PCI_RC_MSGRCVIS register to 0x010F_0000. Set the PCI_RC_MSGRCVIE register to 0x0105_0000.
11	Release the reset (RST_PS_B, RST_GP_B, RST_B, RST_OUT_B). Set RST_PS_B, RST_GP_B, RST_B and RST_OUT_B in the PCI_RC_RESET to 1.
12	Wait for 500 µs or more
13	Release the reset (RST_RSM_B). Set RST_RSM_B in the PCI_RC_RESET to 1.

Note 1. Change the setting values according to the operating conditions.
Note 2. Set the corresponding interrupt handler prior to using this function.

56.8.6.2 Endpoint Mode

An example of the initialization procedure for PCIe End Point mode is described in steps 1 to 17.

Table 56.147 Initialization Procedure (EP) (1 of 2)

Step	Procedure
1	Set the TZC-400-2 register to grant proper transaction. For details, see section 13.4.4.3. TZC-400. (PCIE_RSTOUTnB is not used for Endpoint.)
2	Set the Endpoint mode and Channel Configuration. Set the MODE_PORT bit in the PCIE_MODE register to 0. Set the LINK_MASTER[1:0] bits in the PCIE_LINKMODE register.
3	Release the reset (ARESETn). Set the MRTCLM08 bit in MRCTLM register to 0.
4	Release the module stop state. Set the MSTPCRM08 bit in MSTPCRM register to 0.
5	Release Slave Stop Function. For details, see section 13.4.3. Slave Stop Function.
6	Release the reset (RST_LOAD_B, RST_CFG_B). Set RST_LOAD_B (bit4) and RST_CFG_B (bit3) in the PCI_EP_RESET to 1.
7	Setting of the PHY. Set the PHY_REG_CLK_EN bit in PCI_EP_PERM register. Set the PCI_PHY_XCFGDn register (n = 0 to 26). Set the PCI_PHY_XCFGA_CMNn register (n = 0 to 15). Set the PCI_PHY_XCFGA_L0n register (n = 0 to 5). Set the PCI_PHY_XCFGA_L1n register (n = 0 to 5). For details, see section 56.5.1. PCI_PHY_XCFGDn : XCFGD Setting Register n (n = 0 to 26) to section 56.5.4. PCI_PHY_XCFGA_L1n : XCFGA_LN1 Setting Register n (n = 0 to 5).

Table 56.147 Initialization Procedure (EP) (2 of 2)

Step	Procedure
8*1	Setting of HW related registers (Function #i, i = 0, 1) Set Device ID and Vendor ID to the PCI_EP_VID_Fi registers. Set Revision ID and Class Code to the PCI_EP_RID_CC_Fi registers. Set Subsystem ID and Subsystem Vendor ID to the PCI_EP_SSID_Fi registers. Set Base Address Register Mask to the PCI_EP_BARMSK00L_Fi and PCI_EP_BARMSK00U_Fi registers. Set Base Size to the PCI_EP_BSIZE00_01_Fi registers. Set Base Address Register Mask to the PCI_EP_BARMSK01L_Fi and PCI_EP_BARMSK01U_Fi registers. Set Base Address Register Mask to the PCI_EP_BARMSK02L_Fi and PCI_EP_BARMSK02U_Fi registers. Set Base Size to the PCI_EP_BSIZE02_03_Fi registers. Set Base Size to the PCI_EP_BSIZE04_05_Fi registers. Set Base Size to the PCI_EP_BSIZE06_Fi registers.
9	Permit ASPM L1 State Transition Set ALLOW_ENTER_L1 bit in the PCIE_MISC register to 1.
10*2	Interrupt settings Set the PCI_EP_PEIS0 register to 0x0000_1200. Set the PCI_EP_PEIE0 register to 0x6000_1200. Set the PCI_EP_PEIS1 register to 0x0003_0303. Set the PCI_EP_PEIE1 register to 0x0003_0303. Set the PCI_EP_AMEIS register to 0x0000_0F0F. Set the PCI_EP_AMEIE register to 0x0000_0F0F. Set the PCI_EP_ASEIS1 register to 0x0000_0F03. Set the PCI_EP_ASEIE1 register to 0x0000_0F03. Set the PCI_EP_MSGRCVIS register to 0x010F_0000. Set the PCI_EP_MSGRCVIE register to 0x010A_0000.
11	Release the reset (RST_PS_B, RST_GP_B, RST_B, RST_OUT_B). Set RST_PS_B, RST_GP_B, RST_B and RST_OUT_B in the PCI_EP_RESET to 1.
12	Wait for 500 µs or more
13	Release the reset (RST_RSM_B). Set RST_RSM_B in the PCI_EP_RESET to 1.

Note 1. Change the setting values according to the operating conditions.
Note 2. Set the corresponding interrupt handler prior to using this function.

56.9 Points for Caution and Restrictions

56.9.1 Points for Caution and Prohibited Items in the Issuing of Requests

The following describes the restrictions in the issuing of various requests.

1. Prohibition of fixed bursts of 2 or more beats
   Fixed bursts for 2 or more beats are prohibited. If an attempt to use these is made, an OKAY response is returned to the AXI bus, but this may lead to issuing of the unexpected requests to the PCIe side, or unexpected register access which will change register values, and so on.
2. Points for caution in the issuing of special requests
   The requests listed below are issued by access to the internal registers. The registers are only accessible from the AXI side and writing to them while requests are being processed is prohibited. Attempted access from the PCIe side will be ignored.
   [Special Requests]
   - Zero-Length Memory Read Request
   - Configuration Read
   - Configuration Write
   - Message Request
   - Message Request with data payload

Note: Do not issue a special request for which issuing of the request is prohibited. Operation is not guaranteed if this is done.

56.9.2 Ordering Specifications of Received Non-Posted and Posted Requests

In the specifications of this module, a non-posted request is not overtaken by a posted request on the receiving side.

Requests received from another party are output to the higher-level bus in the order of reception.

56.9.3 Caution when Changing the Speed Spontaneously by the EP Unit

Follow the procedure below. The following control bits are present in the PCI Core Control 2 Register and PCI Core Status 2 Register among the AXI-Bridge registers.

1. Wait until the home node is placed in the L0 state.
2. Read the value of the STATE_DATA_RATE_IDENTIFIER_RECEIVED bit to check the supported speed of the other-party node.
3. If the home node supports the speed to which the other-party node wants to change, set the UI_LINK_SPEED_CHANGE[1:0] bits and assert the UI_LINK_SPEED_CHANGE_REQ bit.
4. Wait for the UI_LINK_SPEED_CHANGE_DONE bit to be asserted (wait for the completion).

Note: UI_LINK_SPEED_CHANGE_REQ is retained until UI_LINK_SPEED_CHANGE_DONE is asserted. It should be de-asserted after checking the assertion of UI_LINK_SPEED_CHANGE_DONE.

56.9.4 Error Processing of Unsupported Requests

The following describes the flow of processing for error reporting and error logging.

1. Access that straddles a 4-KB boundary
   Data transfer to a memory space which straddles a 4-KB boundary cannot proceed (this is stipulated by the PCI Express Base Specification). In this module, the reception of a memory write or read request for a memory space which straddles a 4-KB boundary is handled as a malformed TLP.
2. RCB violations
   The PCI Express Base Specification states that error processing in response to violations of the read completion boundary (RCB) is optional. The PCIe module of this LSI chip does not support the detection of RCB violations at the time of the reception of completion responses. Support for this function should be handled by the user logic.
3. Error processing in response to byte enable fields
   The PCI Express Base Specification states that error processing in response to Byte Enable fields is optional. This module does not support the detection of errors in the form of violations of Byte Enable rules. Support for this function should be handled by the user logic.
4. Request that extends beyond the base address boundary
   This core does not detect a request that starts within the range set in the Base Address Register but extends beyond the boundary from the base address as an error. Such a request should be handled by the user logic.
5. Processing when a TPL that is ready to be transferred by the transmitter is a malformed TLP
   Even if malformation of a TLP that is ready to be transferred by the transmitter is detected, due to the detection of parity errors when it is read from the FIFO buffer and so on, this module does not suspend the transmission of such a TLP. Received malformed TLPs must be handled appropriately by other-party devices.

56.9.5 Processing on Reception of the Message

The following lists the messages to be detected as a silent drop or UR on reception of the given message.

Table 56.148 Operations on message reception (1 of 2)

Received message	Root complex	Endpoint
Assert_INTx	Normal processing	Silent Drop
Deassert_INTx	Normal processing	Silent Drop
ERR_COR	Normal processing	Silent Drop
ERR_NONFATAL	Normal processing	Silent Drop
ERR_FATAL	Normal processing	Silent Drop

Table 56.148 Operations on message reception (2 of 2)

Received message	Root complex	Endpoint
UNLOCK	Silent Drop	Silent Drop
Set_Slot_Power_Limit	Silent Drop	Normal processing
Vendor_Defined_Type0	UR	UR
Vendor_Defined_Type1	Silent Drop	Silent Drop
Ignore	Silent Drop	Silent Drop
LTR	UR	UR
OBFF	UR	UR
PM_PME	Normal processing	Silent Drop
PME_TO_Ack	Normal processing	Silent Drop
PM_Active_State_Nak	Silent Drop	Normal processing
PME_Turn_Off	Silent Drop	Normal processing
PTM_Request	UR	UR
PTM_Response	UR	UR
PTM_ResponseD	UR	UR
Invalidate_Request	Silent Drop	UR
Invalidate_Completion	Normal processing	Silent Drop
Page_Request	UR	UR
Page_Response	UR	UR

Note: Silent Drop: Normal completion, data are not reflected
UR: Unsupported Request

56.9.6 Other Points for Caution

1. Access after the de-assertion of the reset signal
   When a cycle of writing starts before the value of the SAWREADY bit has become 1 following the de-assertion of the reset signal, access in the second and subsequent cycles produces slave errors.
   After the reset signal has been de-asserted, do not assert the SAWVALID signal until SAWREADY has become 1.
2. Point for caution at times of register writing
   In some cases of writing 2DW or more and skipping over with the use of byte enable to a register from the AXI side, writing might not proceed as expected.
   Using a pin reset or register reset from the AXI side as a non-consecutive SWSTRB, restricts writing to no more than 1DW (32 bits).
3. Point for caution on register reading
   In the case of reading a register from the AXI side, values read from invalid byte lanes are from undefined outputs (meaningless garbage data).
4. Generation of unexpected correctable errors
   A correctable error may be detected at the time of EIOS reception following low power state transitions of this module such as from L0s to L1. If this happens, processing to send a message or assert an interrupt flag signal is to proceed. Take care on this point and respond appropriately so that a correctable error is not handled as a fatal error (a mask setting by a register to switch the notification of unexpected correctable errors off is recommended).
5. Reset interval in transitions from a hot reset to detection in RC mode
   In generations of PCI Express after Gen1, at the time of transitions from a hot reset to detection in accord with the operating rate, the base specification prescribes securing a 1-ms waiting interval for changes to the rate, so secure a reset interval of 1 ms.
6. Enter Compliance Pattern (gen3)
   Lane information included in compliance pattern corresponds to physical lane number.
7. Use of Retimer
   One retimer is supported.

8. Note for Window setting
   The following caution and limitation should be considered for address coversion for the Window.
   - Do not generate carry bit when BAR and BARmask are added.
   - Do not generate carry bit when BaseX and MaskX are added.
   - Do not generate carry bit when MaskX and DestX are added.
   - Do not set the bit data in MaskX intermittently (Setting value must be 2^{n-1}).
   - Minimum area provided by BAR and BARMask is 4 KB.
   - Each window should have a single memory size that is a power of two.
   - Do not overlap window and AXI Bridge Register each other.
9. Clock setting in case of single link mode
   When using this module in single link mode, only common clock is supported, no separate clock.
   Since initial value of bit 6 in Link Control/Status register is separate clock, setting should be changed.
   When using this module in multi link mode, both common clock and separate clock are supported.
10. In case of using down config in single link mode, when LTSSM (Link Training Status State Machine) transits to Detect State by Link Down and Hot Reset after Link up, the state may not transit to other state.
    Assert reset by following procedure to recover from that state.

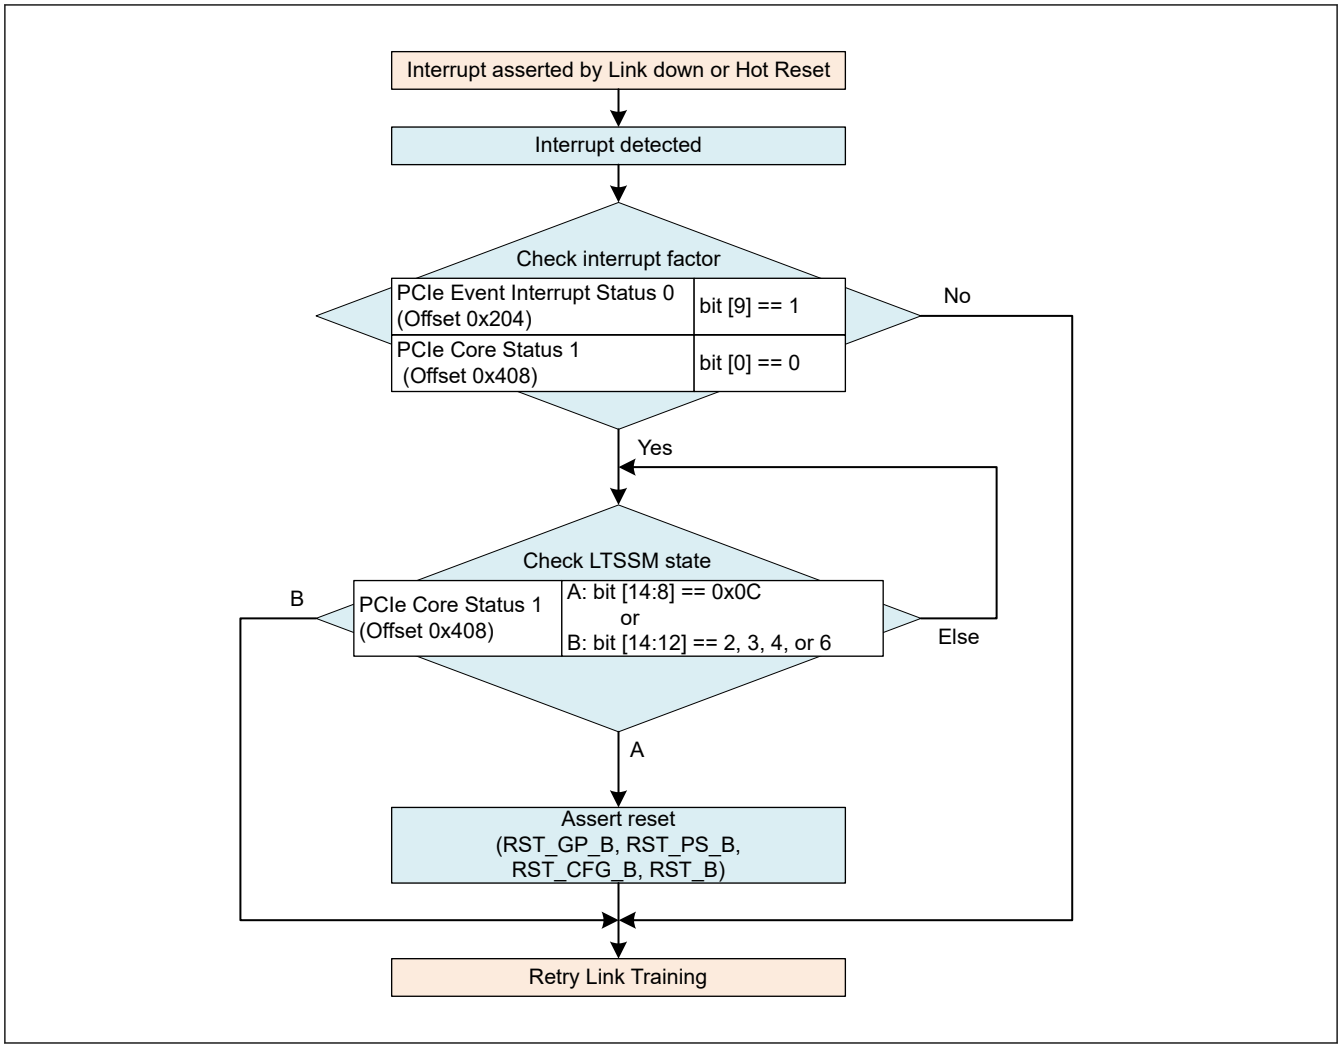

Figure 56.34 Recovery procedure

57. LPDDR4 SDRAM Subsystem (DDRSS)

57.1 Overview

The LPDDR4 SDRAM Subsystem consists of Memory Controller (MC) and PHY. The DDRSS supports the following specifications:

- LPDDR4 (JEDEC STANDARD JESD209-4D)

Table 57.1 Specifications of DDRSS

Item	Specification
Number of units	• One unit
DRAM IF	• LPDDR4: 3200 Mbps (1600 MHz) • Width: 32 bits (16 bits per channel) • Rank: 1, 2 • Density: up to 64 Gb (byte mode not supported)
MC	• Fully pipelined command, read and write data interfaces to the controller. • Advanced bank look-ahead features for high memory throughput. • A programmable register interface to control memory parameters and protocols including auto pre-charge. • Full initialization of memory on controller reset. • Supports the Weighted Round-Robin arbitration schema for arbitrating request from the ports. • ECC function for single-bit and double-bit error reporting, single-bit error correction, and programmable removal of ECC storage. • Built-in Self test (BIST) for external DRAM memories.
PHY	• Command Bus eye training relative to CK • Write leveling to compensate for CK-DQS timing skew • Write training to deskew DQs, DM, and DQS for write: – Command-based FIFO WR/RD with user patterns – An internal DQS clock tree oscillator, to determine the need for, and the magnitude of, required periodic training – Data bus VREFDQ training • Read training to deskew DQs, DM, and DQS for read: – DQ bit deskew training using DRAM mode registers – DQS to DQ eye centering training using DRAM array • Automatic periodic retraining through PHY master interface • LVSTL I/O calibration and ODT calibration • Support for a SW controllable DQ bit and AC bit swizzling
Low power	• Multiple low power states (power-down, self-refresh) • Automatic or software interface

Table 57.4 DDRSS related system control register

Registers	Module Reset Control Register	Module Stop Control Register	Slave Access Control Register
All the registers	MRCTLM.MRCTLM[25:16]	MSTPCRM.MSTPCRM00	SLVACCCTL8.DDRCTRL_SL

57.3 Register Description

Table 57.5 lists the R/W definitions of registers.

Table 57.5 Register R/W definitions

R/W	Description
RW	A register that can be read and written.
R	A register that can be read. The written value will be ignored.
W	A register that can be written. Reading is invalid.
RW0	A register that can be read and to which 0 can be written. Writing 1 is invalid.
RW1	A register that can be read and to which 1 can be written. Writing 0 is invalid.
R0W	A register that can be read and written. Whenever it is read, the value read is 0.
R1W	A register that can be read and written. Whenever it is read, the value read is 1.
R0W0	A register that can be read and to which 0 can be written. Writing 1 is invalid. Whenever it is read, the value read is 0.
R0W1	A register that can be read and to which 1 can be written. Writing 0 is invalid. Whenever it is read, the value read is 0.
R1W0	A register that can be read and to which 0 can be written. Writing 1 is invalid. Whenever it is read, the value read is 1.
R1W1	A register that can be read and to which 1 can be written. Writing 0 is invalid. Whenever it is read, the value read is 1.
W0	A register to which 0 can be written. Writing 1 and reading are invalid.
W1	A register to which 1 can be written. Writing 0 and reading are invalid.

57.3.1 DDR_MEMC_DENALI_CTL_00 : DENALI_CTL_00 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x0000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	start
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	start	Triggers controller initialization and normal operation. Prior to setting this parameter to 1, the controller will not issue any commands to the DRAM memories or respond to any signal activity except for reading and writing parameters and accepting traffic that the customer may send into the Controller core queues. Once this parameter is set to 1, the controller will respond to inputs from the CPU and begin to process memory access commands. Note that resetting this parameter to 0 will not shutoff traffic. Note: Until the initialization complete interrupt (bit [1]) will be set to 1 in the int_status_init parameter and the dfi_init_complete signal is asserted from the PHY, commands will not be accepted into the Controller core command queue. Note: It is imperative that the controller is driving the dfi_reset_n_pZ and dfi_cke_pZ signals before this parameter is asserted. 0: Controller is not in active mode. 1: Initiate active mode for the controller.	R/W
31:1	—	Reserved*1	R/W

Note 1. The write value should follow those generated by DDR parameter generation tool.

57.3.2 DDR_MEMC_DENALI_CTL_219 : DENALI_CTL_219 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x036C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	ADDR_SPACE						—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BIST_GO	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	The read values are undefined.	R/W
8	BIST_GO	Initiate a BIST operation if the bist_data_check parameter is set to 1. Set to 1 to trigger. This parameter is write-only and will always read back as 0.	R/W
23:9	—	The read values are undefined.	R/W
29:24	ADDR_SPACE	Sets the number of address bits to check during BIST operation. Used in BIST data checking to define the address space in bytes from 0 to 2^{addr_space} that the BIST logic will check. As an example, if the addr_space parameter was programmed to 0x1c, then the BIST logic would check 2^{28} bytes = 256 MB.	R/W
31:30	—	The read values are undefined.	R/W

57.3.3 DDR_MEMC_DENALI_CTL_220 : DENALI_CTL_220 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x0370

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BIST_DATA_CHECK
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BIST_DATA_CHECK	Enable data checking with BIST operation. Set to 1 to enable.	R/W
31:1	—	The read values are undefined.	R/W

57.3.4 DDR_MEMC_DENALI_CTL_221 : DENALI_CTL_221 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x0374

Bit position:	31	0
Bit field:	BIST_START_ADDRESS[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	BIST_START_ADDRESS[31:0]	Start BIST checking at this address. (bit[31:0] of address)	R/W

57.3.5 DDR_MEMC_DENALI_CTL_222 : DENALI_CTL_222 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x0378

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BIST_START_ADDRESS32
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BIST_START_ADDRESS32	Start BIST checking at this address. (bit32 of address)	R/W
31:1	—	The read values are undefined.	R/W

57.3.6 DDR_MEMC_DENALI_CTL_225 : DENALI_CTL_225 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x0384

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

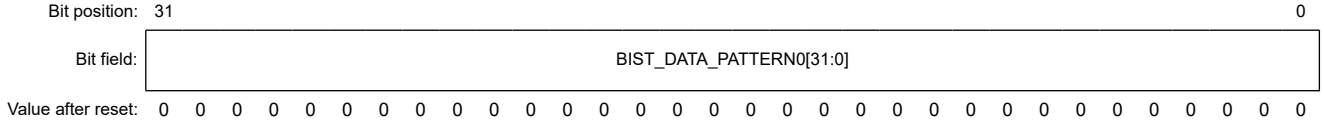
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	BIST_TEST_MODE[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	BIST_TEST_MODE[2:0]	Sets the BIST test mode. For memory initialization function, set 100b.	R/W
31:3	—	The read values are undefined.	R/W

57.3.7 DDR_MEMC_DENALI_CTL_226 : DENALI_CTL_226 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x0388

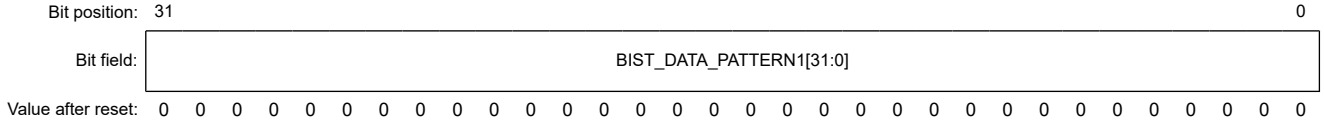


Bit	Symbol	Function	R/W
31:0	BIST_DATA_PATTERN0[31:0]	Defines the data pattern to be used for memory initialization. (Bit[31:0] of 128-bit data) Only data corresponding to active portion of core word will be used while inactive portion will be ignored.	R/W

57.3.8 DDR_MEMC_DENALI_CTL_227 : DENALI_CTL_227 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x038C

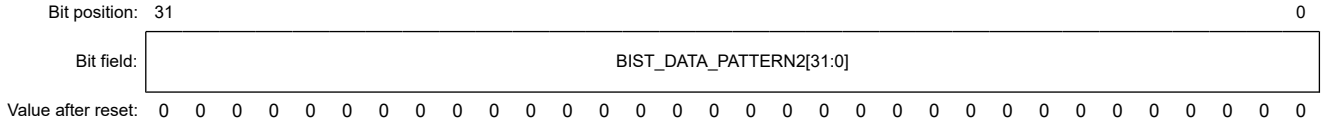


Bit	Symbol	Function	R/W
31:0	BIST_DATA_PATTERN1[31:0]	Defines the data pattern to be used for memory initialization. (Bit[63:32] of 128-bit data) Only data corresponding to active portion of core word will be used while inactive portion will be ignored.	R/W

57.3.9 DDR_MEMC_DENALI_CTL_228 : DENALI_CTL_228 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x0390

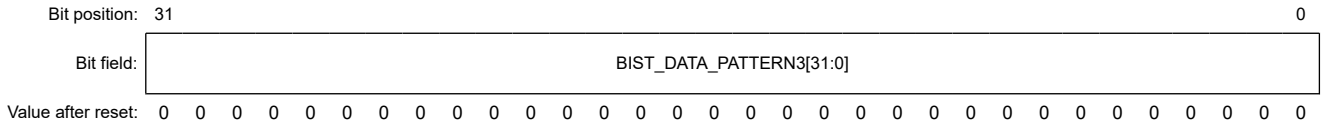


Bit	Symbol	Function	R/W
31:0	BIST_DATA_PATTERN2[31:0]	Defines the data pattern to be used for memory initialization. (Bit[95:64] of 128-bit data) Only data corresponding to active portion of core word will be used while inactive portion will be ignored.	R/W

57.3.10 DDR_MEMC_DENALI_CTL_229 : DENALI_CTL_229 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x0394



Bit	Symbol	Function	R/W
31:0	BIST_DATA_PATTERN3[31:0]	Defines the data pattern to be used for memory initialization. (Bit[127:96] of 128-bit data) Only data corresponding to active portion of core word will be used while inactive portion will be ignored.	R/W

57.3.11 DDR_MEMC_DENALI_CTL_231 : DENALI_CTL_231 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x039C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	ECC_ENABLE[1:0]		—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	—	The read values are undefined.	R/W
25:24	ECC_ENABLE[1:0]	Controls ECC error reporting (single-bit and double-bit errors) and correcting (single-bit errors). 0 0: ECC disabled, no ECC error reporting, no ECC error correcting 0 1: ECC enabled, no ECC error reporting, no ECC error correcting 1 0: ECC enabled, ECC error reporting, no ECC error correcting 1 1: ECC enabled, ECC error reporting, ECC error correcting	R/W
31:26	—	The read values are undefined.	R/W

57.3.12 DDR_MEMC_DENALI_CTL_232 : DENALI_CTL_232 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x03A0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	ECC_DISABLE_W_UC_ERR	XOR_CHECK_BITS[15:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	XOR_CHECK_BITS[15:0]								—	—	—	—	—	—	—	FWC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FWC	Force a write check. Xor the XOR_CHECK_BITS parameter with the ECC code and write to memory. Set to 1 to trigger.	R/W
7:1	—	The read values are undefined.	R/W
23:8	XOR_CHECK_BITS[15:0]	Value to xor with generated ECC codes for forced write check	R/W
24	ECC_DISABLE_W_UC_ERR	Controls auto-corruption of ECC when un-correctable errors occur in R/M/W operations. Set to 1 to disable corruption.	R/W

Bit	Symbol	Function	R/W
31:25	—	The read values are undefined.	R/W

57.3.13 DDR_MEMC_DENALI_CTL_233 : DENALI_CTL_233 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x03A4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	ECC_READ_CACHING_EN	—	—	—	—	—	INLINE_ECC_BANK_OFFSET[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	INLINE_ECC_SAME_PAGE	—	—	—	—	—	—	—	ECC_WRITEBACK_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ECC_WRITEBACK_EN	ECC writeback will occur on detection of single bit errors for reads. The ECC_ENABLE parameter must be programmed to 3 for this to take any effect. Note that no writebacks will be issued during BIST.	R/W
7:1	—	The read values are undefined.	R/W
8	INLINE_ECC_SAME_PAGE	Inline ECC Configurations will store the ECC in top 1/8th of page as data; otherwise it will store ECC in top 1/8th of rows.	R/W
15:9	—	The read values are undefined.	R/W
18:16	INLINE_ECC_BANK_OFFSET[2:0]	Inline ECC Bank Offset defines the bank shift between data and ECC commands associated with the same sequence; the bank is offset to prevent inefficiencies due to opening a closing the pages on the same bank during the transition between data and ECC commands.	R/W
23:19	—	The read values are undefined.	R/W
24	ECC_READ_CACHING_EN	Allows ECC read data already in one of the ECC buffers to be used when possible in place of issuing an ECC read command to memory. This implies that some ECC read commands will be dropped in the command queue when it can pull the read data from the buffer instead.	R/W
31:25	—	The read values are undefined.	R/W

57.3.14 DDR_MEMC_DENALI_CTL_234 : DENALI_CTL_234 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x03A8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECC_WRITE_COMBINING_EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ECC_WRITE_COMBINING_EN	Allows ECC write data within a given ECC buffer to be combined across commands so that in certain cases where we see multiple ECC writes to the same ECC address, the controller may end up only issuing one final ECC write command to memory.	R/W
31:1	—	The read values are undefined.	R/W

57.3.15 DDR_MEMC_DENALI_CTL_235 : DENALI_CTL_235 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x03AC

Bit position:	31																													0
Bit field:	ECC_U_ADDR[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ECC_U_ADDR[31:0]	Address of uncorrectable ECC event. (bit[31:0] of address)	R

57.3.16 DDR_MEMC_DENALI_CTL_236 : DENALI_CTL_236 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x03B0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ECC_U_SYND[7:0]								—	—	—	—	—	—	—	ECC_U_ADDR32
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ECC_U_ADDR32	Address of uncorrectable ECC event. (bit32 of address)	R
7:1	—	The read values are undefined.	R

Bit	Symbol	Function	R/W
15:8	ECC_U_SYND[7:0]	Syndrome for uncorrectable ECC event.	R
31:16	—	The read values are undefined.	R

57.3.17 DDR_MEMC_DENALI_CTL_237 : DENALI_CTL_237 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x03B4

Bit position:	31																												0
Bit field:	ECC_U_DATA0[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ECC_U_DATA0[31:0]	Data associated with uncorrectable ECC event. (bit[31:0] of data)	R

57.3.18 DDR_MEMC_DENALI_CTL_238 : DENALI_CTL_238 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x03B8

Bit position:	31																												0
Bit field:	ECC_U_DATA1[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ECC_U_DATA1[31:0]	Data associated with uncorrectable ECC event. (bit[63:32] of data)	R

57.3.19 DDR_MEMC_DENALI_CTL_239 : DENALI_CTL_239 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x03BC

Bit position:	31																												0
Bit field:	ECC_C_ADDR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ECC_C_ADDR[31:0]	Address of correctable ECC event. (bit[31:0] of address)	R

57.3.20 DDR_MEMC_DENALI_CTL_240 : DENALI_CTL_240 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x03C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ECC_C_SYND[7:0]								—	—	—	—	—	—	—	ECC_C_ADDR32
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ECC_C_ADDR32	Address of correctable ECC event. (bit32 of address)	R
7:1	—	The read values are undefined.	R
15:8	ECC_C_SYND[7:0]	Syndrome for correctable ECC event.	R
31:16	—	The read values are undefined.	R

57.3.21 DDR_MEMC_DENALI_CTL_241 : DENALI_CTL_241 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x03C4

Bit position:	31	0
Bit field:	ECC_C_DATA0[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	ECC_C_DATA0[31:0]	Data associated with correctable ECC event. (bit[31:0] of data)	R

57.3.22 DDR_MEMC_DENALI_CTL_242 : DENALI_CTL_242 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x03C8

Bit position:	31	0
Bit field:	ECC_C_DATA1[31:0]	
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	ECC_C_DATA1[31:0]	Data associated with correctable ECC event. (bit[63:32] of data)	R

57.3.23 DDR_MEMC_DENALI_CTL_244 : DENALI_CTL_244 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x03D0

Bit position:	31																												0
Bit field:	RMODW_ECC_U_ADDR[31:0]

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	device0_byte0_cs0[3:0]	Defines the byte location of byte0 in the memory data path for device 0 for chip select 0. Used for MRRs to identify where data will be returned. Bit [0] correlates to byte [0] of the memory data path, bit [1] correlates to byte [1] of the memory data path, etc.*1 For each bit: 0: This bit does NOT correlate to byte 0 for device 0. 1: This bit DOES correlate to byte 0 for device 0.	R/W
7:4	—	Reserved*2	R/W
11:8	device1_byte0_cs0[3:0]	Defines the byte location of byte0 in the memory data path for device 1 for chip select 0. Used for MRRs to identify where data will be returned. Bit [0] correlates to byte [0] of the memory data path, bit [1] correlates to byte [1] of the memory data path, etc.*1 For each bit: 0: This bit does NOT correlate to byte 0 for device 1. 1: This bit DOES correlate to byte 0 for device 1.	R/W
15:12	—	Reserved*2	R/W
19:16	device2_byte0_cs0[3:0]	Defines the byte location of byte0 in the memory data path for device 2 for chip select 0. Used for MRRs to identify where data will be returned. Bit [0] correlates to byte [0] of the memory data path, bit [1] correlates to byte [1] of the memory data path, etc.*1 For each bit: 0: This bit does NOT correlate to byte 0 for device 2. 1: This bit DOES correlate to byte 0 for device 2.	R/W
23:20	—	Reserved*2	R/W
27:24	device3_byte0_cs0[3:0]	Defines the byte location of byte0 in the memory data path for device 3 for chip select 0. Used for MRRs to identify where data will be returned. Bit [0] correlates to byte [0] of the memory data path, bit [1] correlates to byte [1] of the memory data path, etc.*1 For each bit: 0: This bit does NOT correlate to byte 0 for device 3. 1: This bit DOES correlate to byte 0 for device 3.	R/W
31:28	—	Reserved*2	R/W

Note 1. Only 1 bit may be set to 1 at any time to indicate which bit holds the byte 0 information. If this device is not relevant, no bits should be set to 1.

Note 2. The write value should follow those generated by DDR parameter generation tool.

57.3.39 DDR_MEMC_DENALI_CTL_319 : DENALI_CTL_319 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x04FC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:25	—	Reserved*2	R/W

Note 1. This parameter may only be changed during initialization or when the Controller is idle with no data in the port FIFOs and the axi3_fixed_port_priority_enable parameter is cleared to 0. The Controller will use a rising edge of the axi3_fixed_port_priority_enable parameter to capture the new value of this parameter into AXI port 3.
Note 2. The write value should follow those generated by DDR parameter generation tool.

57.3.75 DDR_MEMC_DENALI_CTL_387 : DENALI_CTL_387 Register

Base address: DDRSS = 0x8030_0000

Offset address: 0x060C

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	axi4_r_priority[2:0]	Sets the priority of read commands from AXI port 4. According to the AXI specification, a value of 0 on the axi4_ARQOS signal is the lowest priority, and a value of 7 is the highest priority. However, this unit will invert this signal inside the Controller core and use 0 as the highest priority. If the axi4_fixed_port_priority_enable parameter is set to 1, this parameter will be used to define the priority for read commands from port 4. If the axi4_fixed_port_priority_enable parameter is cleared to 0, this parameter will be ignored and the priority will be defined by the value of the axi4_ARQOS incoming signal.*1	R/W

Bit	Symbol	Function	R/W
7:3	—	Reserved*2	R/W
10:8	axi4_w_priority[2:0]	Sets the priority of write commands from AXI port 4. According to the AXI specification, a value of 0 on the axi4_AWQOS signal is the lowest priority, and a value of 7 is the highest priority. However, this unit will invert this signal inside the Controller core and use 0 as the highest priority. If the axi4_fixed_port_priority_enable parameter is set to 1, this parameter will be used to define the priority for write commands from port 4. If the axi4_fixed_port_priority_enable parameter is cleared to 0, this parameter will be ignored and the priority will be defined by the value of the axi4_AWQOS incoming signal.*1	R/W
31:11	—	Reserved*2	R/W

Note 1. This parameter may only be changed during initialization or when the Controller is idle with no data in the port FIFOs and the axi4_fixed_port_priority_enable parameter is cleared to 0. The Controller will use a rising edge of the axi4_fixed_port_priority_enable parameter to capture the new value of this parameter into AXI port 4.

Note 2. The write value should follow those generated by DDR parameter generation tool.

7:1	—	Reserved*1	R/W

Bit	Symbol	Function	R/W
9:8	weighted_round_robin_weight_sharing[1:0]	Indicates that the port pair is tied together in arbitration decisions in weighted round-robin arbitration. Bit [0] controls ports 0 and 1, bit [1] controls port 2 and 3. For each port pair: 0: The represented ports are treated independently in arbitration. 1: The represented ports are tied together for arbitration.	R/W
15:10	—	Reserved*1	R/W
19:16	wrr_param_value_err[3:0]	Reports errors/warnings from the weighted round-robin arbitration. Bit [3] = The port ordering parameter values for paired ports is not sequential. Bit [2] = The relative priority values for any of the ports paired through the weighted_round_robin_weight_sharing parameter are not identical. Bit [1] = Any of the relative priority parameters have been programmed to a zero value. Bit [0] = The port ordering parameters do not all contain unique values. For each bit: 0: No error 1: Error	R
23:20	—	Reserved*1	R/W
27:24	axi0_priority0_relative_priority[3:0]	Holds the relative priority of AXI port 0 for priority 0 commands in weighted round robin arbitration.	R/W
31:28	—	Reserved*1	R/W

Note 1. The write value should follow those generated by DDR parameter generation tool.

57.4 Function Description

57.4.1 External Pin Swizzling

This unit has the feature to remap the functions assigned to the external pins, making the PCB wiring design easier.

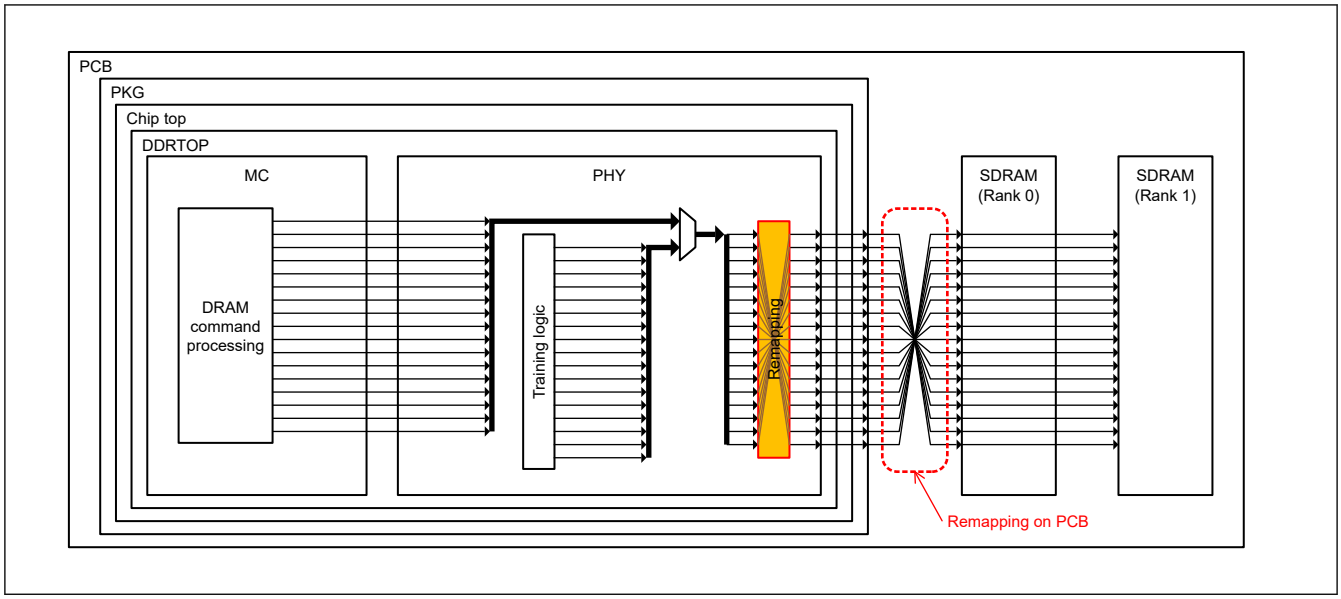

Figure 57.2 External pin swizzling

57.4.1.1 Command/Address Remapping

This feature statically remaps the functions assigned to the Command/Address pins (DDR_CA[AB][0-5]) of this unit.

The pin functions that can be remapped are as follows.

- LPDDR4: CA[0-5]_A, CA[0-5]_B

57.4.1.2 Rank Swapping

This feature statically swaps the Rank assigned to the CS/CKE pins (DDR_CS[AB][01], DDR_CKE[AB][01]) of this unit. It can swap between Group-0A (CS0_A, CKE0_A) and Group-1A (CS1_A, CKE1_A), and/or between Group-0B (CS0_B, CKE0_B) and Group-1B (CS1_B, CKE1_B). No register settings are required.

57.4.1.3 Data Swizzling

(1) Data Remapping in Byte Lane

This feature statically remaps the functions assigned to the DQ pins (DDR_DQ[AB][0-15]) of this unit within same Byte Lanes.

(2) Data Byte Lane Swapping

This feature statically swaps the DQ/DMI/DQS pins (DDR_DQ[AB][0-15], DDR_DMI[AB][01], DDR_DQS[AB]_[TC][01]) of this unit in Byte Lane units.

If byte lane swapping is used or not, the user must program the deviceN_byte0_csX parameters, where N is the device number and X is the chip select on that device. Unique parameters are provided for each chip select to allow for different byte swapping on each chip select. Each parameter contains one bit for each byte of the memory data bus. If a device is not being used, the deviceN_byte0_csX parameter should be programmed to 0x0, but if the device is being used, then one and only 1 bit of the deviceN_byte0_csX parameter should be set to 1.

57.4.1.4 Channel Swapping

This feature statically swaps the Channels of the external pins of this unit. No register settings are required for this feature itself.

(1) Example of the external pin swizzling

(a) Example of Channel/Lane swizzling

Channel/Lane swizzling is available only for the case shown in Figure 57.3 to Figure 57.10. Any swizzling not shown in figures is not possible.

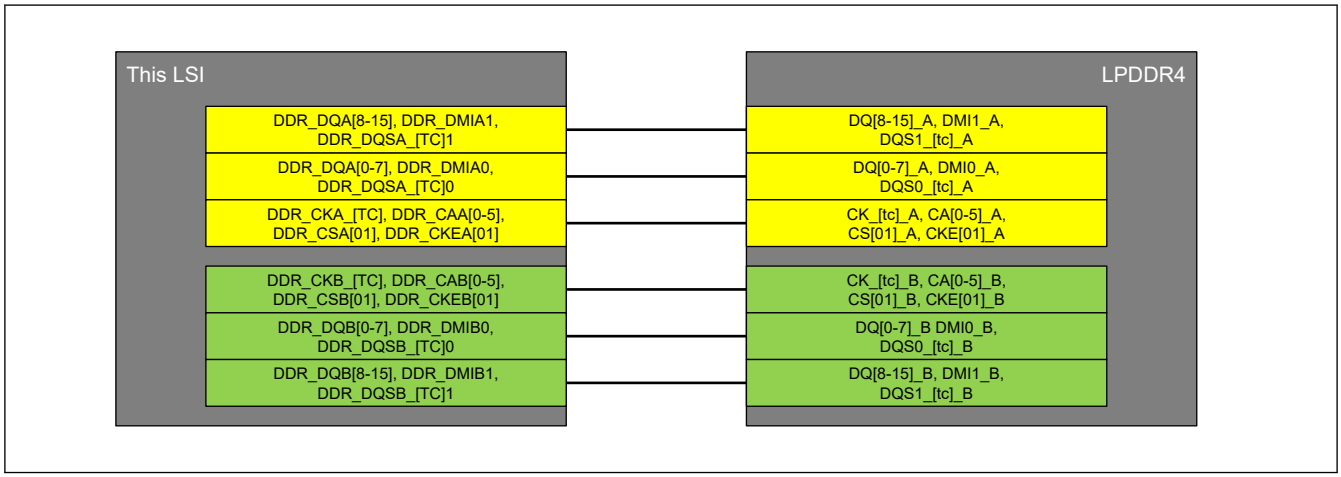

Figure 57.3 Case 1, No Swizzling

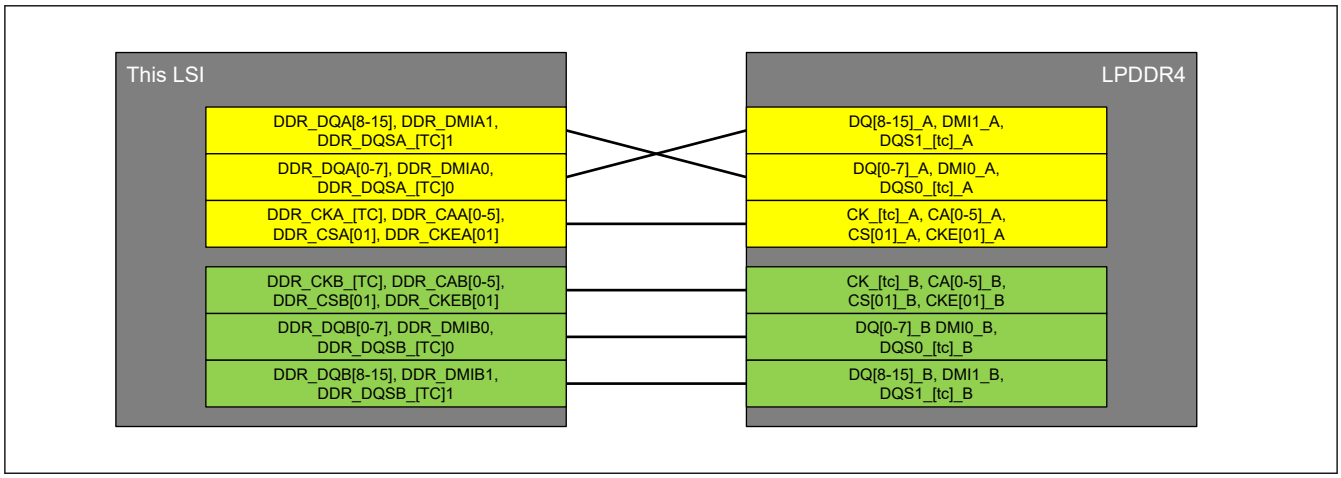

Figure 57.4 Case 2-1, Swapping Upper/Lower of DQ/DMI/DQS in Ch-A

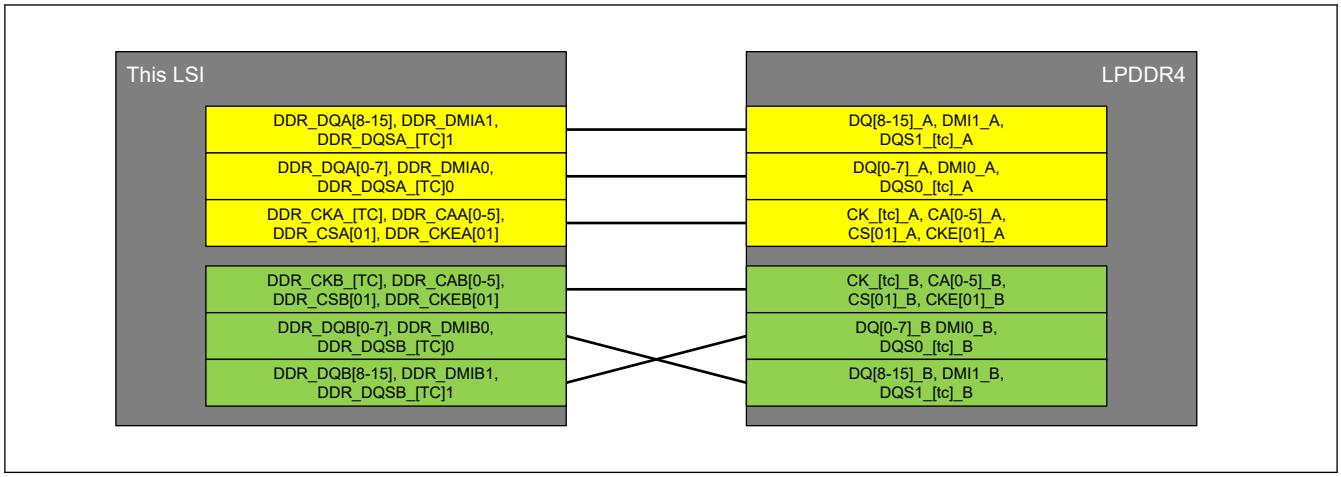

Figure 57.5 Case 2-2, Swapping Upper/Lower of DQ/DMI/DQS in Ch-B

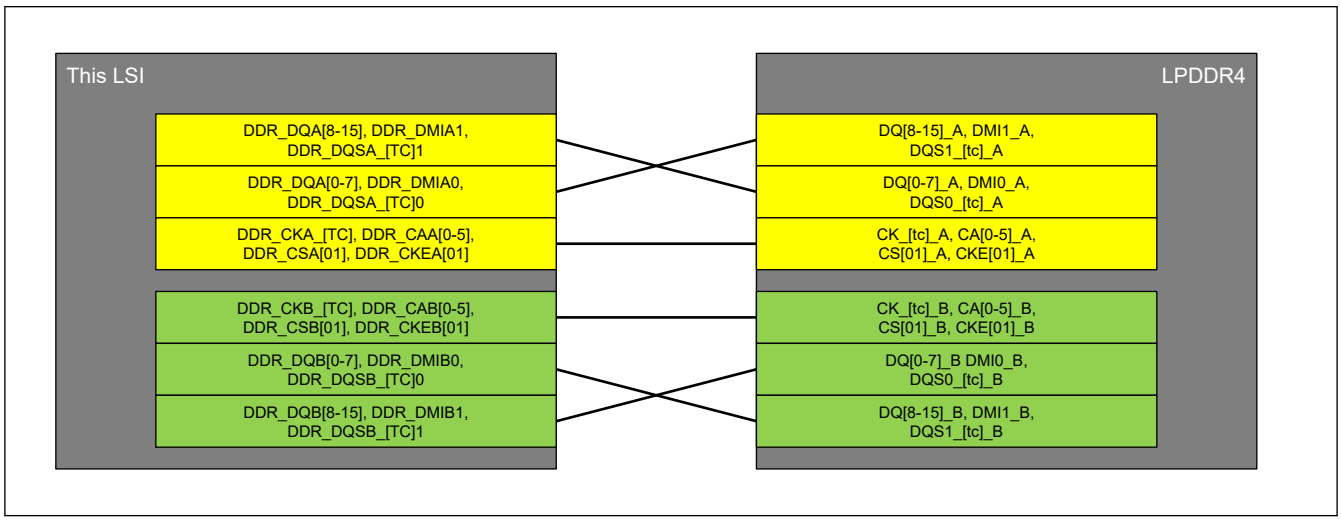

Figure 57.6 Case 2-3, Swapping Upper/Lower of DQ/DMI/DQS in Ch-A/B

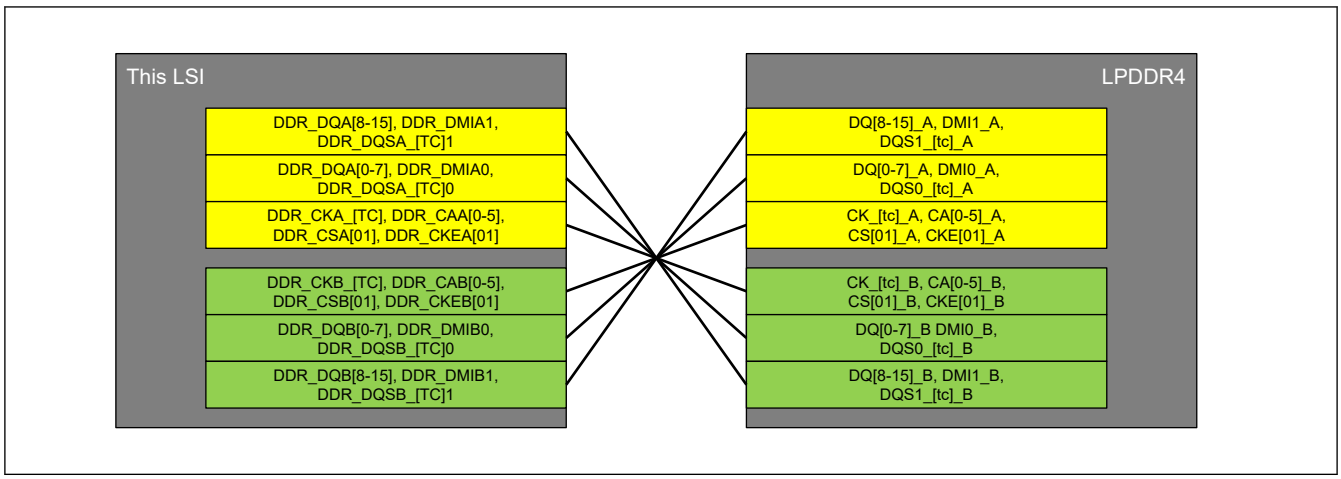

Figure 57.7 Case 3, Swapping Ch-A/B

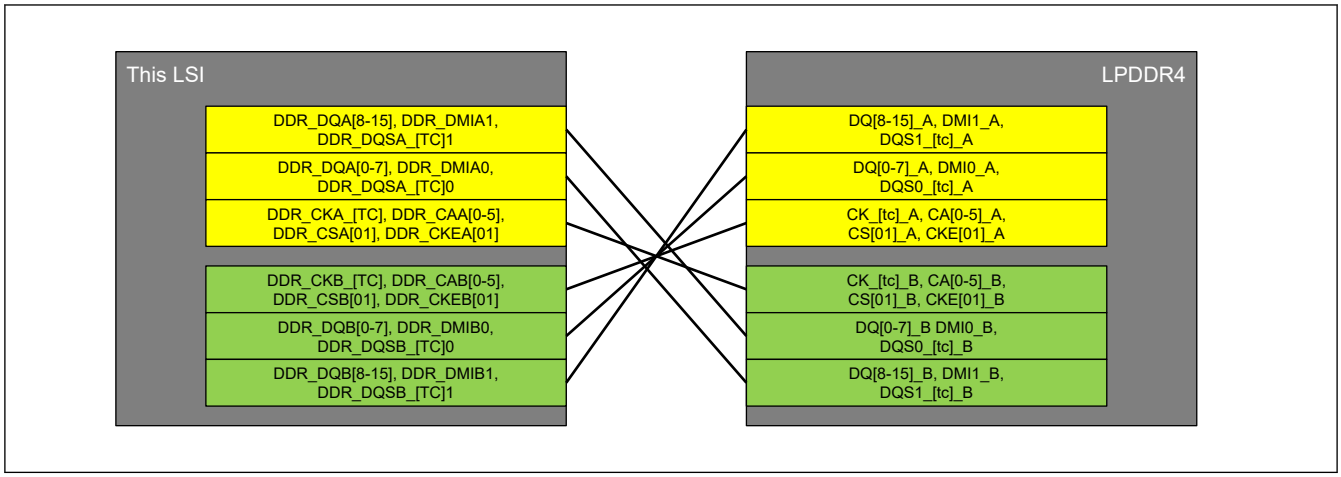

Figure 57.8 Case 4-1, Swapping Ch-A/B and Swapping Upper/Lower of DQ/DMI/DQS in Ch-A

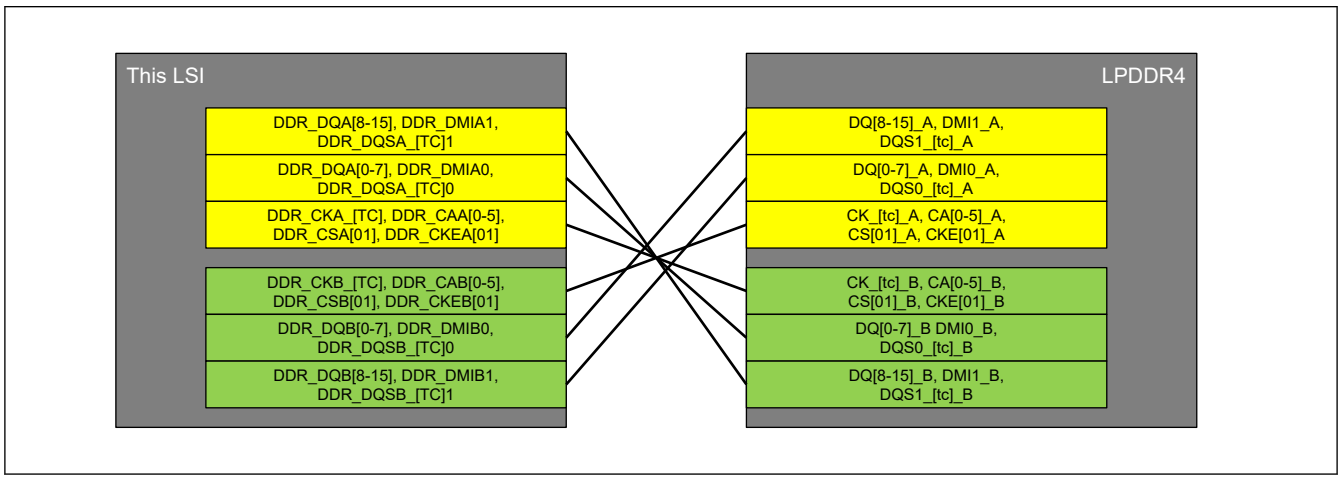

Figure 57.9 Case 4-2, Swapping Ch-A/B and Swapping Upper/Lower of DQ/DMI/DQS in Ch-B

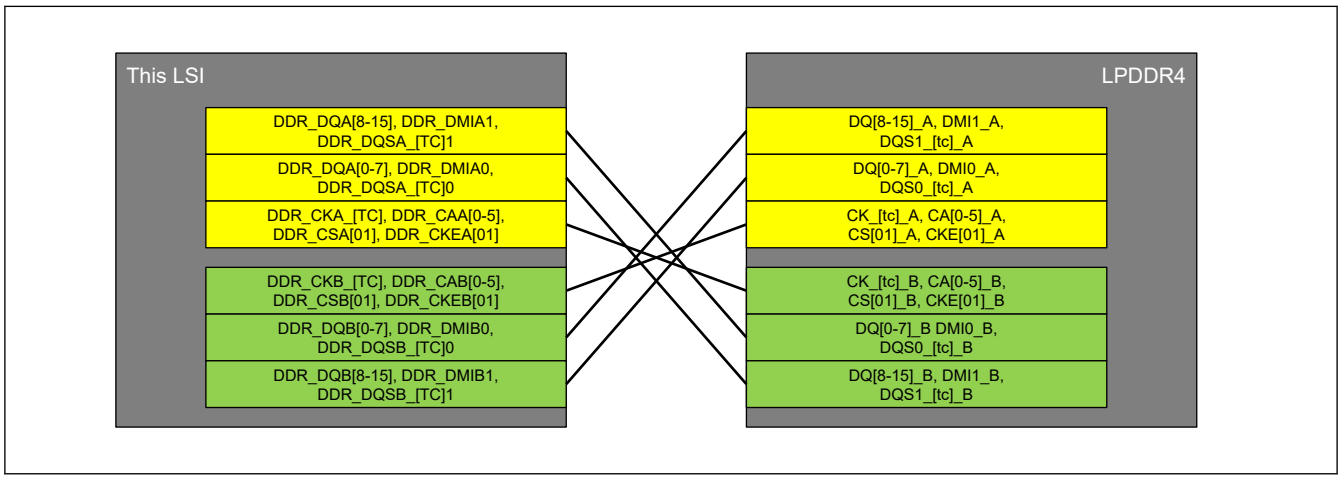

Figure 57.10 Case 4-3, Swapping Ch-A/B and Swapping Upper/Lower of DQ/DMI/DQS in Ch-A/B

(b) Example of Bit swizzling

Examples of DQ bits swizzling are shown. It is able to swizzle DQ bits within the same lane (Figure 57.11), but it is not able to swizzle DQ bits across lanes (Figure 57.12).

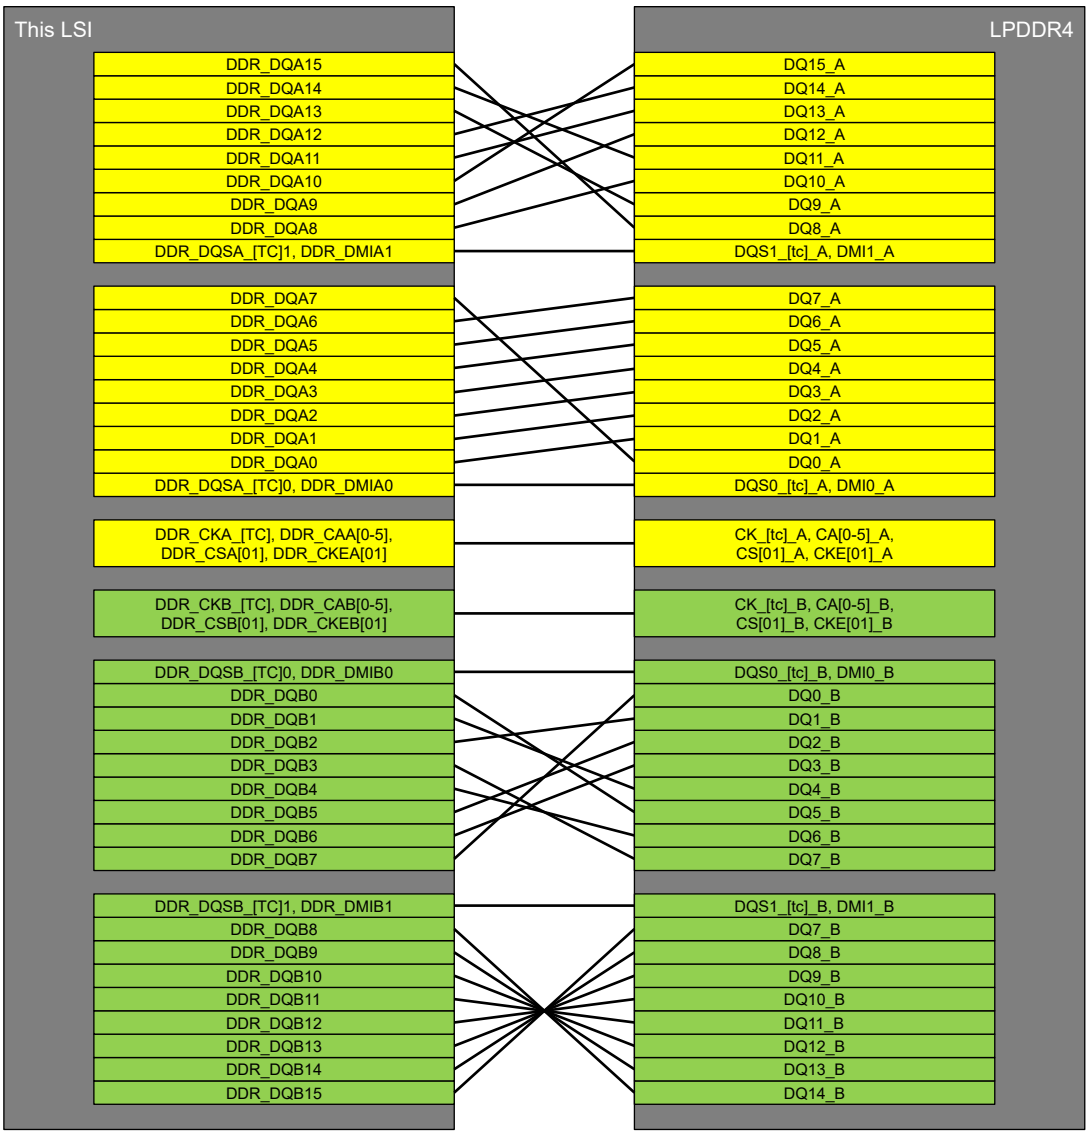

Figure 57.11 DQ Bits Swizzling within Same Lane (Possible)

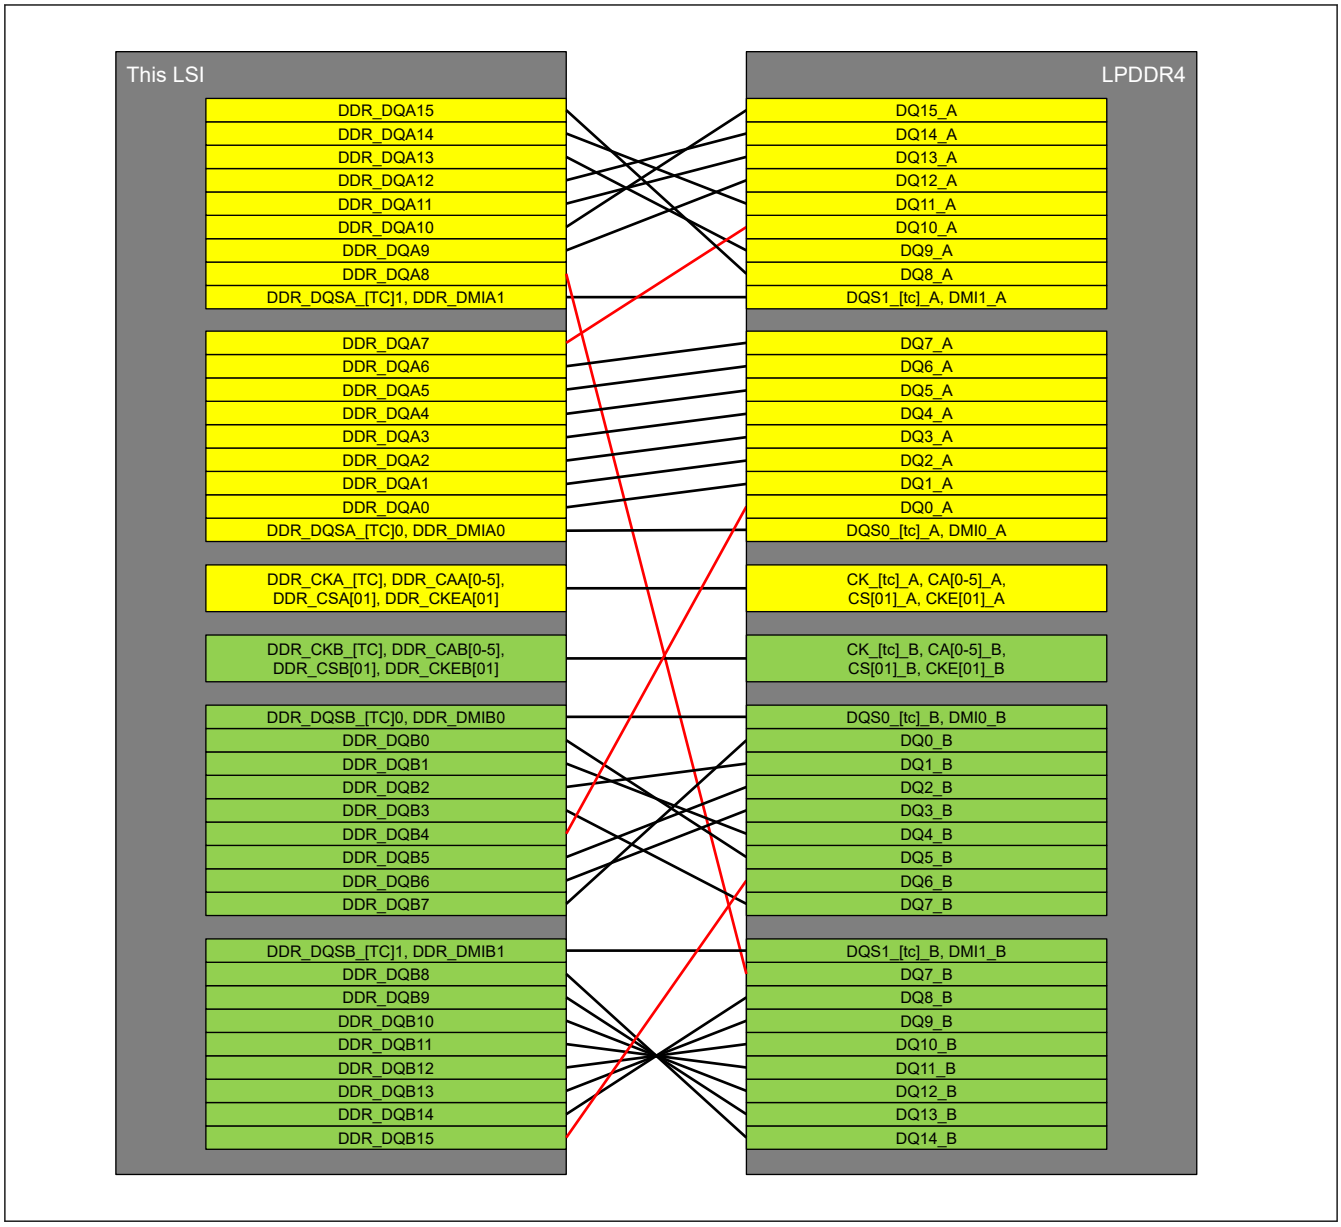

Figure 57.12 DQ bits Swizzling across Lanes (Impossible)

Examples of CAA/CAB bits swizzling are shown. It is able to swizzle CAA/CAB bits within the same channel (Figure 57.13), but it is not able to swizzle CAA/CAB bits across channels (Figure 57.14).

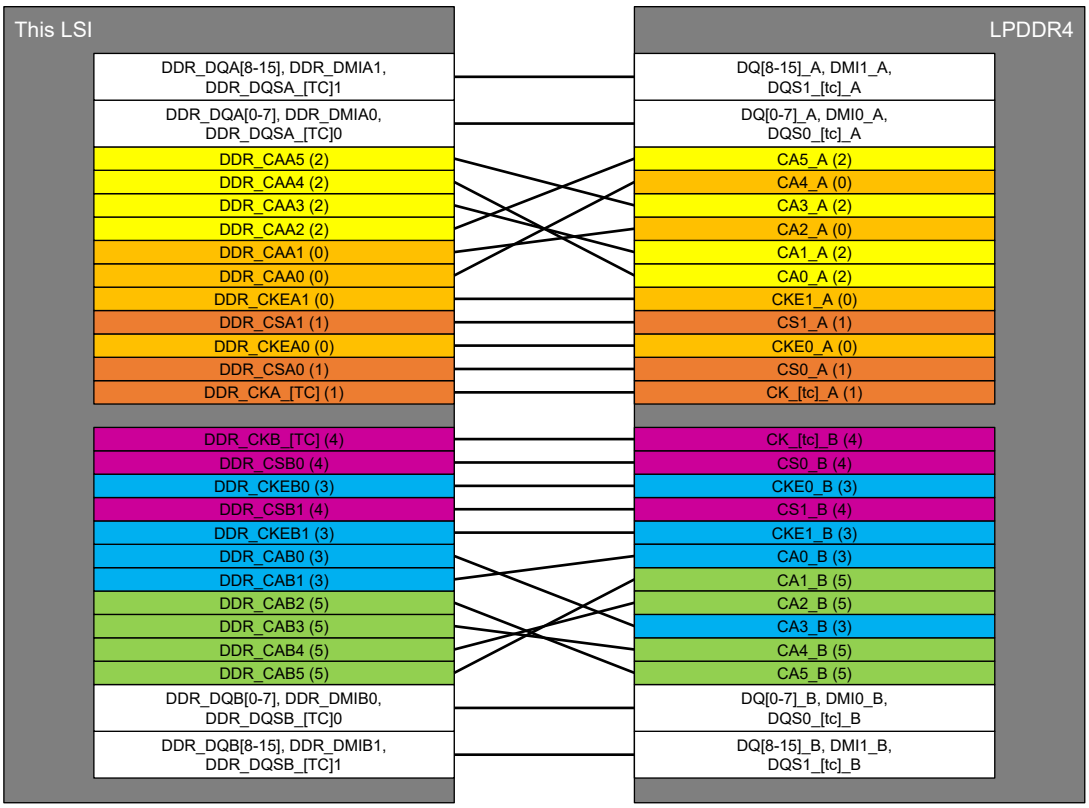

Figure 57.13 CAA/CAB Bits Swizzling within Same Channel (Possible)

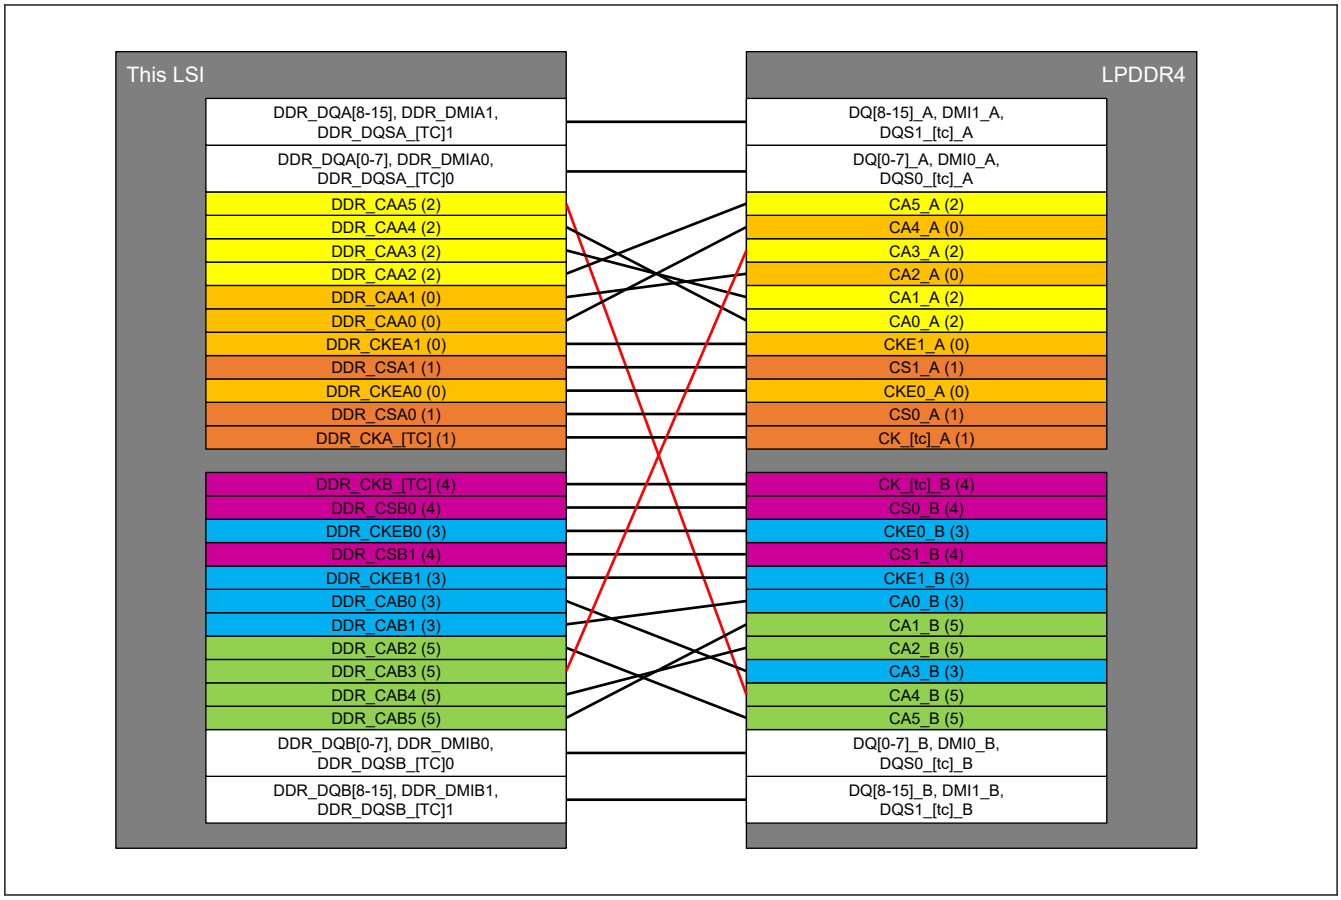

Figure 57.14 CAA/CAB Bits Swizzling across Channels (Impossible)

CSA/CKEA and CSB/CKEB can only be swizzled as shown in Figure 57.15.

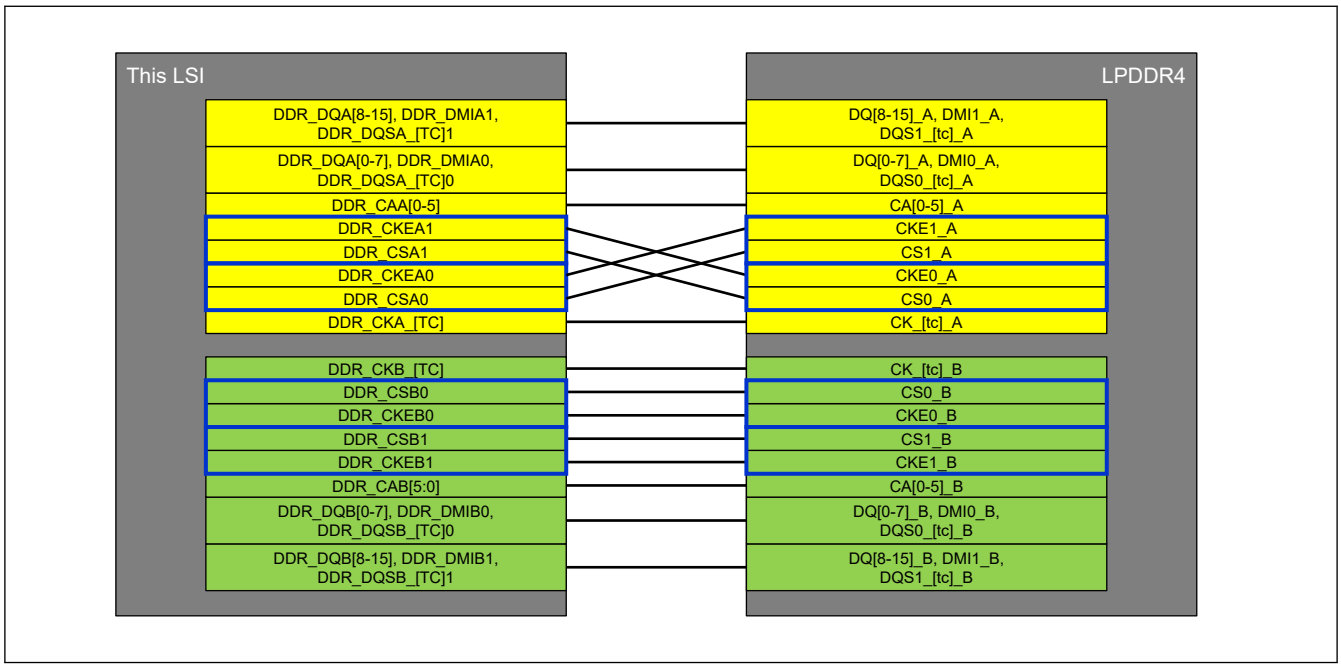

Figure 57.15 CSA/CKEA and CSB/CKEB Bits Swizzling (Possible)

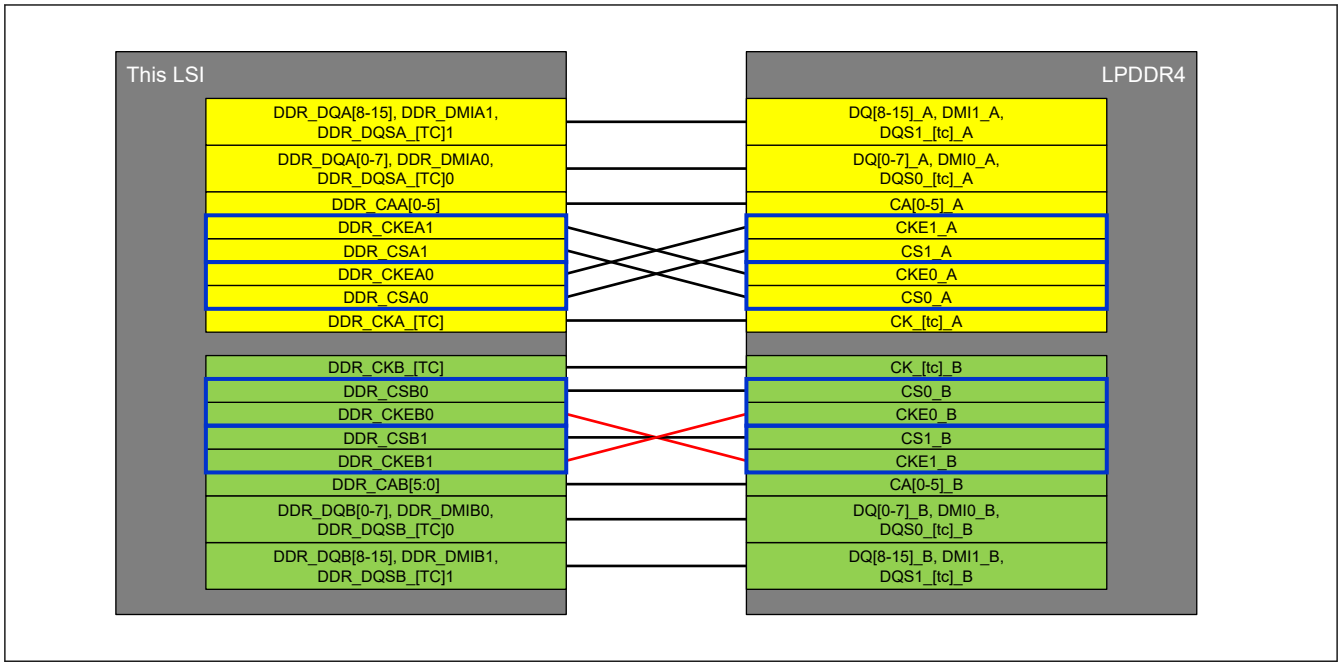

Figure 57.16 CSA/CKEA and CSB/CKEB Bits Swizzling (Impossible)

57.4.2 Multi-Port Arbiter

The Arbiter is responsible for arbitrating requests from the ports and sending requests to the Controller core. Each transaction received at the Arbiter logic has an associated priority, which works with each port's arbitration logic to determine how ports issue requests to the Controller core. This unit supports the Weighted Round-Robin arbitration scheme.

The Arbiter logic routes read data from the Controller core to the appropriate port. The requesting port is assumed able to receive the data. Write data from each port is connected directly to its own write data interface in the Controller core, allowing the ports to independently pass write data to the Controller core buffers.

57.4.2.1 Arbitration Overview

The weighted round-robin arbitration scheme is a three-step arbitration system. All commands are routed into priority groups based on the priority of the requests. Then, within each priority group, requests are serviced according to the "weight" (relative priority) of each port. Finally, each priority group presents a single command to the priority select module, which passes the highest priority command on to the Controller core.

This arbitration scheme also supports two additional features. For situations where the priority and the relative priority for multiple commands are identical, a port ordering system in included whereby the user may adjust the order in which the ports are considered. Secondly, for situations where two ports may be related, a mechanism is included which allows a pair of ports to share arbitration bandwidth for bandwidth efficiency.

Weighted round-robin arbitration is a complex arbitration scheme. To understand the operation, each concept must be first understood individually. section 57.4.2.2. Understanding Round-Robin Operation through section 57.4.2.5. Understanding Port Ordering describe the various components of weighted round-robin arbitration. Note that the examples may utilize a greater number of ports and a larger number of priority levels than are available in this unit. This is done intentionally for explanation.

57.4.2.2 Understanding Round-Robin Operation

Round-robin operation is the simplest form of arbitration and is ideal for systems that do not require requests to be treated preferentially to maintain bandwidth or minimize latency. This scheme uses a counter that rotates through the port numbers, incrementing every time a port request is granted.

If the port that the counter is referencing has an active request, and the Controller core command queue is not full, then this request will be sent to the Controller core. If there is not an active request for that port, then the port will be skipped and the next port will be checked. The counter will increment by one whenever any request has been processed, regardless of which port's request was arbitrated.

Round-robin arbitration ensures that each port's requests can be successfully arbitrated into the Controller core every N cycles, where N is the number of ports in this unit. No port will ever be locked out, and any port can have its requests serviced on every cycle as long as all other ports are quiet and the command queue is not full.

An example of the round-robin scheme is shown in Table 57.6. Cycles 0, 2, and 6 show the system behavior when the command queue is full. Cycles 8 and 11 show the system behavior when the port addressed by the arbitration counter does not have an active request. In particular, note cycle 11: The port addressed by the arbitration counter (0) is not requesting, so the counter scans through the other ports, in incrementing order, to find an active request. Port 2 is requesting and therefore wins arbitration, but the counter only increments to port 1 which was the next port in the sequence. All other cycles show normal behavior.

Table 57.6 Round-Robin Operation example

Cycle	Port Addressed by the Arbitration Counter	Ports Requesting				Command Queue Full?	Arbitration Winner	Value of Counter at Next Cycle
		P0	P1	P2	P3			
0	0	Y	Y	Y	Y	Yes	None	0
1	0	Y	Y	Y	Y	No	P0	1
2	1	—	Y	Y	Y	Yes	None	1
3	1	Y	Y	Y	Y	No	P1	2
4	2	Y	—	Y	Y	No	P2	3
5	3	Y	—	—	Y	No	P3	0
6	0	Y	—	Y	—	Yes	None	0
7	0	Y	—	Y	—	No	P0	1
8	1	—	—	Y	—	No	P2	2
9	2	—	—	Y	Y	No	P2	3
10	3	Y	—	—	Y	No	P3	0
11	0	—	—	Y	—	No	P2	1

57.4.2.3 Understanding Transaction Priority

Priorities may be associated with each command or with the requesting port, depending on the value of the axiY_fixed_port_priority_enable parameter. If the axiY_fixed_port_priority_enable parameter is set to 1, all commands from port Y will use the priority defined in the axiY_r_priority or axiY_w_priority parameters. If the axiY_fixed_port_priority_enable parameter is cleared to 0, the priority will be specified with each incoming command through the axiY_ARQOS and axiY_AWQOS signals. Internally, all commands are organized into priority groups based on their priority setting. All commands within a priority group are treated equally for arbitration unless a port has exceeded its allocated bandwidth. The priority value is also used by the placement logic inside the Controller core when filling the command queue.

Note: The axiY_ARQOS and axiY_AWQOS signals are fixed to 000b in this LSI.

To use per-port priorities, the user must program the axiY_r_priority and axiY_w_priority parameters and assert the axiY_fixed_port_priority_enable parameter to 1 before the start parameter is set. If the user wants to change these values when the system is idle, the axiY_fixed_port_priority_enable parameter must be cleared to 0, the parameters may be changed, and then the axiY_fixed_port_priority_enable parameter must be set to 1 again.

A priority value of 0 is the lowest priority, and a priority value of 7 is the highest priority in this unit. The user may program at priority level 7; however, it is best to reserve this priority value so that the placement queue can elevate to this level through aging.

57.4.2.4 Understanding Relative Priority

Inside each priority group, the relative priority is used to determine arbitration. This unit contains 8 identical priority groups with logic that selects between the requests from all commands at that priority level. The relative priority parameters axiY_priorityZ_relative_priority (where Y is the port number and Z is the priority group) "weight" the ports for each level and determine how the priority group will be arbitrated. Figure 57.17 shows this type of arbitration system.

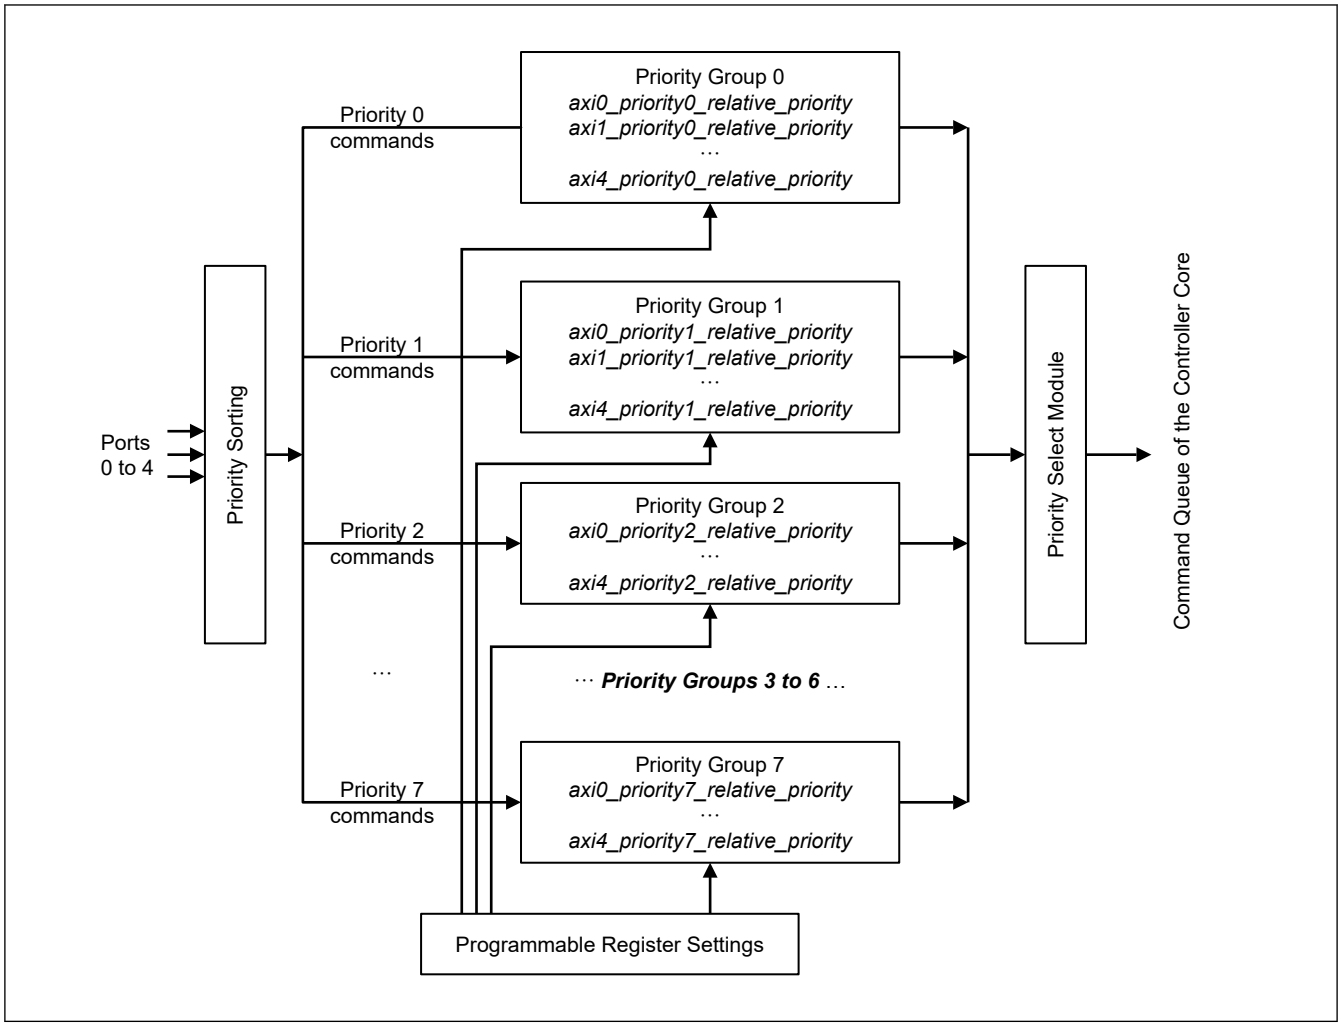

Figure 57.17 Weighted Round-Robin Priority Group structure

By using the relative priority concept, the arbitration is skewed in favor of certain ports based on user programming.

Note that the relative priority parameters have a minimum acceptable value of 1 to prevent port lockout. A 0 value will cause an error condition.

If the relative priorities are all programmed to the same value within any priority group, then the arbitration will mimic a version of simple round-robin scheme within that priority group. Instead of incrementing whenever any request is processed, the simple round-robin counter will only increment to the next port after the value in the axiY_priorityZ_relative_priority parameter number of requests are processed.

Each port Y for priority level Z will be allocated the ratio of that port's relative priority parameter (axiY_priorityZ_relative_priority) to the sum of all requesting port's relative priority values. If a particular port is not requesting, then it is not included in the sum calculation, which means that the arbitration will be split with relative proportions among the requesting ports.

As an example, consider a system with 5 ports where all requests are at priority 0. This system is described in Table 57.7.

Table 57.7 Relative Priority example

Controller parameter	Value
axi0_priority_relative_priority	1
axi1_priority_relative_priority	2
axi2_priority_relative_priority	3
axi3_priority_relative_priority	4
axi4_priority_relative_priority	5

For this system, port 0 will be serviced 1/(1+2+3+4+5) = 1/15 of the time and Port 3 will be serviced 4/(1+2+3+4+5) = 4/15 of the time. However, if Port 2 is not actively requesting, then port 0 will be serviced 1/(1+2+4+5) = 1/12 of the time and port 3 will be serviced 4/(1+2+4+5) = 4/12 of the time.

In order to ensure that relative priorities are maintained, there is a weight counter for each port within each priority group. These counters track the number of transactions accepted for that port in that priority group. When any counter value reaches the programmed relative port priority, the scan order for that priority group will be internally modified. The port that has met its relative priority will be dynamically positioned to the bottom of the scan order (and its counter will be reset), allowing other ports a preferential position.

For ports that are not expected to issue requests at a certain priority level, the associated relative priority parameter should be programmed to 0x1. This allows for minimum allocation without the risk of lockout in case a command appears.

57.4.2.5 Understanding Port Ordering

With simple round-robin arbitration, the ports are scanned based on their port number in incrementing order in the system. Assuming that the command queue is not full, the port referenced by the counter is examined for valid incoming transactions. If there is an active request, it will be accepted. Otherwise, the next port in the scan order will be checked, and its request accepted.

For this unit with weighted round-robin arbitration, the user has the option of adjusting the order that the ports are scanned. This is useful if requests from certain ports are more critical, or if a specific order may reduce contention between ports.

The axiY_port_ordering parameters are used to set this new scan order. A value of 000b gives the highest listing in the scan order, and a value of 111b is the lowest listing in the scan order.

If the 5 axiY_port_ordering parameters are programmed with unique values, then the scan order will be modified to proceed sequentially in this new order. If any of the port ordering parameters have the same value, then those ports will still be equal in the arbitration test. In this case, the port number will select between these ports, with the lower numbered port automatically being selected first.

To demonstrate this concept, consider a system with 5 ports and the two port orders as shown in Table 57.8. For Value 1 of the example, the port ordering parameters all contain unique values, so the resulting order is entirely based on the values of the parameters. For Value 2 of the example, three ports have the same programmed values for the port order. For these three ports, the port number sets the order. Remaining ports follow the port ordering parameters.

Table 57.8 Port Ordering example

Controller parameter	Value 1	Value 2
axi0_port_ordering	3	3
axi1_port_ordering	4	0
axi2_port_ordering	5	5
axi3_port_ordering	1	6
axi4_port_ordering	0	0
Port Scan Order	P4-P3-P0-P1-P2	P1-P4-P0-P2-P3

If all of the port ordering parameters are programmed with the same value, then the scan order will default to the numbered port order.

57.4.2.6 Weighted Round-Robin Arbitration Summary

The Controller weighted round-robin arbitration system combines the concepts of round-robin operation, priority, relative priority and port ordering. The incoming commands are separated into priority groups based on their priority.

Within each priority group, the relative priority values are examined to determine the arbitration winner. If the relative priority values are identical and no individual command can be selected, then the scan order is used to select between the requests. In the end, the highest priority command, from the highest relative priority port, with the highest location in the scan order will be selected and sent to the Controller core.

As an example, consider the system described in Table 57.9. The counters refer to the counters that exist for each port within each priority group to ensure that relative priorities are maintained. For simplification, the command queue is considered to never be full and commands are only received at priority level 0. The behavior is shown in Table 57.10. The

highest port in the scan order that is requesting always wins arbitration, and the scan order is dynamically modified when any port counter reaches its allocated relative priority value. Note that if the command queue was considered, then cycles where the command queue was full would not have any arbitration winner and therefore, the counter values and scan order would not change on that cycle.

Table 57.9 Weighted Round-Robin Arbitration example 1

Controller parameter	Port 0	Port 1	Port 2	Port 3	Port 4
axiY_priority0_relative_priority	4	3	2	1	1
axiY_port_ordering	0	1	2	3	4

Table 57.10 Weighted Round-Robin Arbitration operation 1

Cycle	Ports requesting					Arbitration winner	Next counter					Next scan order
	P0	P1	P2	P3	P4		P0	P1	P2	P3	P4	
	—	—	—	—	—	—	—	—	—	—	—	P0-P1-P2-P3-P4
0	Y	—		Y	—	P0	1	0	0	0	0	P0-P1-P2-P3-P4
1	Y	—	Y	Y	—	P0	2	0	0	0	0	P0-P1-P2-P3-P4
2	Y	Y	Y	Y	—	P0	3	0	0	0	0	P0-P1-P2-P3-P4
3	Y	Y	Y	Y	—	P0	4	0	0	0	0	P1-P2-P3-P4-P0
4	Y	Y	Y	Y	—	P1	0	1	0	0	0	P1-P2-P3-P4-P0
5	Y	Y	Y	Y	Y	P1	0	2	0	0	0	P1-P2-P3-P4-P0
6	Y	Y	Y	Y	Y	P1	0	3	0	0	0	P2-P3-P4-P0-P1
7	Y	—	Y	Y	Y	P2	0	0	1	0	0	P2-P3-P4-P0-P1
8	Y	—	Y	Y	Y	P2	0	0	2	0	0	P3-P4-P0-P1-P2
9	Y	—	—	Y	Y	P3	0	0	0	1	0	P4-P0-P1-P2-P3
10	Y	—	—	Y	Y	P4	0	0	0	0	1	P0-P1-P2-P3-P4
11	Y	—	Y	Y	—	P0	1	0	0	0	0	P0-P1-P2-P3-P4
12	—	—	Y	Y	—	P2	1	0	1	0	0	P0-P1-P2-P3-P4
13	—	—	Y	Y	—	P2	1	0	2	0	0	P0-P1-P3-P4-P2

If the same system also contains two ports that only request at priority level 1, then the system behavior will be slightly altered. These 2 ports creates the second priority group structure that adds to the arbitration complexity. Table 57.11 describes this system.

Again, for simplification, the command queue is considered to never be full and it is assumed that commands from ports 0, 1, and 2 are only received at priority level 0. The behavior is shown in Table 57.12. Note that if any of the priority 0 ports (P0, P1, P2) are requesting, the system behavior will match the behavior when there is only one priority group, as in Table 57.10. Ports 3 and 4 can only win arbitration when no higher priority commands exist.

Table 57.11 Weighted Round-Robin Arbitration example 2

Controller parameter	Port 0	Port 1	Port 2	Port 3	Port 4
axiY_priority0_relative_priority	4	3	2	1	1
axiY_priority1_relative_priority	1	1	1	3	2
axiY_port_ordering	0	1	2	3	4

Table 57.12 Weighted Round-Robin Arbitration operation 2 (1 of 2)

Cycle	Ports requesting					Arbitration winner	Next counter					Next scan order
	P0	P1	P2	P3	P4		P0	P1	P2	P3	P4	
	—	—	—	—	—	—	—	—	—	—	—	Priority 0: P0-P1-P2 Priority 1: P3-P4

Table 57.12 Weighted Round-Robin Arbitration operation 2 (2 of 2)

Cycle	Ports requesting					Arbitration winner	Next counter					Next scan order
	P0	P1	P2	P3	P4		P0	P1	P2	P3	P4	
0	—	—	Y	—	Y	P2	0	0	1	0	0	P0-P1-P2 P3-P4
1	Y	—	Y	—	Y	P0	1	0	1	0	0	P0-P1-P2 P3-P4
2	—	—	Y	—	Y	P2	1	0	2	0	0	P0-P1-P2 P3-P4
3	Y	—	Y	Y	Y	P0	2	0	0	0	0	P0-P1-P2 P3-P4
4	—	—	Y	Y	Y	P2	2	0	1	0	0	P0-P1-P2 P3-P4
5	—	—	—	Y	Y	P3	2	0	1	1	0	P0-P1-P2 P3-P4
6	—	Y	—	Y	Y	P1	2	1	1	1	0	P0-P1-P2 P3-P4
7	—	—	—	Y	Y	P3	2	1	1	2	0	P0-P1-P2 P3-P4
8	—	—	—	Y	Y	P3	2	1	1	3	0	P0-P1-P2 P4-P3
9	—	—	—	Y	Y	P4	2	1	1	0	1	P0-P1-P2 P4-P3
10	—	—	—	Y	—	P3	2	1	1	1	1	P0-P1-P2 P4-P3

57.4.2.7 Priority Relaxing

From Table 57.12, it is evident that commands at lower priority levels will not win arbitration in weighted round-robin arbitration unless there are no higher priority requests. This could mean that, in a situation where high-priority requests are being received continuously, lower-priority requests could be locked out indefinitely. To avoid this scenario and control the arbitration latency for lower-priority commands, it is possible to disable priority groups temporarily. This is known as priority relaxing, and it is a time-controlled function.

Each higher priority group will be temporarily disabled when the pre-set counter value for the lower priority group has been reached and a request is waiting. The axiY_priority_relax parameters set the counter value for port Y at which the priority relax condition will be triggered.

The timing counters inside each port are controlled by the weighted_round_robin_latency_control parameter. When the latency control bit is set to 1, the timing counters are free-running. Any timing counter may hit its axiY_priority_relax parameter value at any point. When this occurs, higher-priority groups are disabled to allow a waiting request for this port to be processed. This results in a random latency for each port, but the maximum latency is fixed at the axiY_priority_relax parameter value. If the current port does not have any commands waiting when the timing counter hits the relax value, then the counter will be reset and the Arbiter will function normally.

When the weighted_round_robin_latency_control parameter is cleared to 0, the timing counters only count while that port has a waiting request that is not being processed. In this case, when the port's axiY_priority_relax parameter value is reached, all priority groups at priority levels higher than the waiting request are disabled. This port's command is granted arbitration and is moved through to the Controller core.

Since the priority relax parameters and counters are associated with individual ports, it is possible that multiple priority relax counters could reach their specified value simultaneously. In this case, the lower priority command will be arbitrated first and then the higher priority command. This situation could alter the arbitration latency slightly, causing it to be longer than the expected value in the priority relax parameter.

Consider the system example as described in Table 57.13. The same conditions apply as for the previous example. The command queue is considered to never be full, commands from ports 0, 1, and 2 are only received at priority level 0, and commands from ports 3 and 4 are only received at priority 1.

Table 57.13 Priority Relaxing example

Controller parameter	Port 0	Port 1	Port 2	Port 3	Port 4
axiY_priority0_relative_priority	4	3	2	1	1
axiY_priority1_relative_priority	1	1	1	2	1
axiY_port_ordering	0	1	2	4	3

Table 57.14 shows the system behavior. The exact settings of the latency control and priority relax parameters are not shown. Instead, the "Relaxed Ports" column indicates which, if any, ports have hit their priority relax values. The following cycles are important to observe:

- Cycles 1 and 7: A port relaxes while a higher priority request and a higher scan order request are both present. The relaxed port still wins arbitration.
- Cycle 4: Two ports of the same priority relax. The higher scan order request wins arbitration.
- Cycle 5: Two ports of different priorities relax. The lower priority port that relaxed wins arbitration. The higher priority port that relaxed will maintain its relax condition, and win arbitration in the next cycle.

Table 57.14 Priority Relaxing operation

Cycle	Ports requesting					Relaxed ports	Arbitration winner	Next counter					Next scan order
	P0	P1	P2	P3	P4			P0	P1	P2	P3	P4	
	—	—	—	—	—	—	—	—	—	—	—	—	Priority 0: P0-P1-P2 Priority 1: P4-P3
0	—	—	Y	Y	Y	—	P2	0	0	1	0	0	P0-P1-P2 P4-P3
1	—	—	Y	Y	Y	P4	P4	0	0	1	0	1	P0-P1-P2 P3-P4
2	—	—	Y	Y	Y	—	P2	0	0	2	0	0	P0-P1-P2 P3-P4
3	—	Y	—	Y	Y	—	P1	0	1	0	0	0	P0-P1-P2 P3-P4
4	Y	—	—	Y	Y	P3, P4	P3	0	1	0	1	0.	P0-P1-P2 P3-P4
5	Y	—	—	Y	Y	P0, P4	P4	0	1	0	1	1	P0-P1-P2 P3-P4
6	Y	—	—	Y	—	P0	P0	1	1	0	1	0	P0-P1-P2 P3-P4
7	Y	—	—	Y	Y	P3	P3	1	1	0	2	0	P0-P1-P2 P4-P3
8	Y	Y	Y	—	Y	—	P0	2	1	0	0	0	P0-P1-P2 P4-P3
9	—	Y	Y	—	Y	—	P1	2	2	0	0	0	P0-P1-P2 P4-P3
10	—	Y	Y	—	Y	P2	P2	2	2	1	0	0	P0-P1-P2 P4-P3

Priority relaxing allows low-priority commands to be able to move through the Arbiter to the Controller core. This will ensure that the system can meet maximum latency requirements.

57.4.2.8 Port Pairing

This unit Arbiter incorporates a feature that allows adjacent ports to be grouped together and considered jointly for arbitration. The weighted_round_robin_weight_sharing parameter controls this function, with 1 bit per pair of ports in this unit. Bit [0] controls ports 0 and 1, bit [1] controls ports 2 and 3. If this unit interfaces to an odd number of ports, the highest-numbered port (port 4) is excluded from the port pairing system.

Since the ports are grouped together, their relative priorities are not considered separately. Referring to section 57.4.2.4. Understanding Relative Priority, the general formula for port priority allocation is the ratio of that port's relative priority parameter (axiY_priorityZ_relative_priority) to the sum of all requesting port's relative priority values. In this case, the relative priority value of only one of the paired ports is used for the sum calculation. This means that the bandwidth will be divided differently among the ports.

If the port pair is at the top of the scan order, and either of the ports is requesting, then the requesting port will win arbitration. If both are requesting, port ordering is used to determine which port wins arbitration. Note that when the ports are paired, their scan order can never be altered and they will always remain together in the scan order. Their counters increment together, and so when they reach their relative priority value, the port pair will dynamically be placed at the bottom of the scan order for that priority group.

In order for port weight sharing to be used, the relative priority parameters for the port pair must be programmed to the same value and the port order of the paired ports should be sequential. If either condition is not followed, an error bit will be set to 1.

Consider the system example as described in Table 57.15. Again, for simplification, the command queue is considered to never be full, commands from ports 0, 1, and 2 are only received at priority level 0 and commands from ports 3 and 4 are always at priority 1. However, now ports 0 and 1 are paired.

Table 57.15 Port Pairing example

Controller parameter	Port 0	Port 1	Port 2	Port 3	Port 4
axiY_priority0_relative_priority	3	3	2	1	1
axiY_priority1_relative_priority	1	1	1	2	2
axiY_port_ordering	0	1	2	4	3
weighted_round_robin_weight_sharing	1 (Paired)		0 (Not Paired)		—

Table 57.16 shows the system behavior with port pairing. Since ports 3 and 4 are still at a lower priority, they will be ignored unless none of the higher priority ports (P0, P1, and P2) are requesting. Note the following points:

- When either port of a port pair wins arbitration, the counters for both ports of the pair increment.
- In Cycle 3, the port pair P0/P1 reaches its allocated relative priority. Note that the port pair dynamically moves to the bottom of the scan order.

Table 57.16 Port Pairing operation (1 of 2)

Cycle	Ports requesting					Arbitration winner	Next counter					Next scan order
	P0	P1	P2	P3	P4		P0	P1	P2	P3	P4	
	—	—	—	—	—	—	—	—	—	—	—	Priority 0: P0-P1-P2 Priority 1: P4-P3
0	Y	—	Y	—	—	P0	1	1	0	0	0	P0-P1-P2 P4-P3
1	Y	—	Y	—	Y	P0	2	2	0	0	0	P0-P1-P2 P4-P3
2	—	—	Y	—	Y	P2	2	2	1	0	0	P0-P1-P2 P4-P3
3	Y	Y	—	—	Y	P0	3	3	1	0	0	P2-P0-P1 P4-P3
4	—	Y	—	—	Y	P1	1	1	1	0	0	P2-P0-P1 P4-P3
5	—	—	—	—	Y	P4	1	1	1	0	1	P2-P0-P1 P4-P3
6	—	—	—	Y	—	P3	1	1	1	1	1	P2-P0-P1 P4-P3
7	—	—	—	Y	Y	P4	1	1	1	1	2	P2-P0-P1 P3-P4

Table 57.16 Port Pairing operation (2 of 2)

Cycle	Ports requesting					Arbitration winner	Next counter					Next scan order
	P0	P1	P2	P3	P4		P0	P1	P2	P3	P4	
8	—	Y	Y	Y	Y	P2	1	1	2	1	0	P0-P1-P2 P3-P4
9	—	Y	—	Y	Y	P1	2	2	0	1	0	P0-P1-P2 P3-P4

57.4.2.9 Error Conditions

With the programming complexities of the weighted round-robin arbitration scheme, an error reporting mechanism is included to notify users of illegal programming scenarios. These error conditions will each set a bit in the wrr_param_value_err parameter to 1. The potential error conditions are:

- Bit [0] = The 5 axiY_port_ordering parameters do not all contain unique values.
- Bit [1] = Any of the axiY_priorityZ_relative_priority parameters have been programmed with a zero value. A 0 value leads to unknown behavior. The minimum allowable value is 1.
- Bit [2] = Any ports, whose related bit of the weighted_round_robin_weight_sharing parameter is set to 1, do not have the same values in their axiY_priorityZ_relative_priority parameters.
- Bit [3] = For ports whose related bit of the weighted_round_robin_weight_sharing parameter is set to 1, the values of the axiY_port_ordering parameters are not sequential.

If bit [0], [2], or [3] is set to 1 in the wrr_param_value_err parameter, and any of the ports are paired in the weighted_round_robin_weight_sharing parameter, then all weight-sharing data will be ignored during this unit initialization and the ports will be prioritized by port number. If port pairing is not being used, but the bit [0] error condition is set to 1, then ports with a non-unique port ordering are prioritized by port number.

Remark: The user is strongly cautioned against modifying the values of the port ordering or relative priority parameters during active port usage.

57.4.2.10 Programmable Options for Weighted Round Robin Arbitration

This unit's weighted round-robin arbitration scheme provides a great deal of programmable control for the user. The parameters are referenced throughout this section and are summarized here for clarity:

- axiY_fixed_port_priority_enable (5 parameters, 1 for each port Y)
- axiY_r_priority (5 parameters, 1 for each port Y)
- axiY_w_priority (5 parameters, 1 for each port Y)
- axiY_priorityZ_relative_priority (8 parameters for each port Y)
- axiY_port_ordering (5 parameters, 1 for each port Y)
- axiY_priority_relax (5 parameters, 1 for each port Y)
- weighted_round_robin_latency_control
- weighted_round_robin_weight_sharing
- wrr_param_value_err

57.4.3 ECC

The Controller provide an optional error reporting and correcting circuitry that can be used to verify data in memory and correct memory errors if they occur. The logic will check for errors in both the data and the check code on all read transactions.

ECC, or error checking and correcting, is the process of detecting bit errors in the memory data and if possible, correcting them. This function can confirm the accuracy of data and remove or at least identify bit errors.

ECC works by creating unique "check codes" which are a mathematical description of the information in an aligned segment of data known as an "ECC data word". The check code is always related to the entire ECC data word, and is used inside the Controller to control data accuracy. These check codes are never input from, or output to, the user interface.

An ECC data word cannot start and end at any random address; these words are memory aligned to their size. The starting addresses of ECC data words are defined as ECC word boundaries and the alignment of user transactions to these boundaries determines how transactions are processed inside the Controller.

The Controller supports a 64-bit ECC data word size. An 8-bit check code is maintained for each 64-bit memory area. ECC word boundaries fall on each 8-byte address (0xN0, 0xN8).

57.4.3.1 ECC Error Types

An ECC error is defined in the Controller as "correctable" or "un-correctable". A correctable error is a single-bit error in the check code or the data. The Controller uses the syndrome to determine which bit is erroneous and is able to correct the error. An un-correctable error is a double-bit error in the check code and/or the data. In this case, the Controller is able to identify that 2 bits in the check code and/or the data are incorrect, but cannot determine exactly which 2 bits are erroneous, and therefore cannot correct the error.

Note: The Controller can detect single bit and double bit errors. Errors in more than 2 bits of the check code and/or the data will cause the system to behave unpredictably.

57.4.3.2 In-line ECC

Traditionally, there is a dedicated memory device to hold ECC codes, requiring an extra memory to be placed and routed, and the data bus to memory to be wider. As an alternative, in order to reduce the memory data bus and eliminate the place and route issues of a separate device, this Controller supports in-line ECC in which a section (1/8th) of the memory device used to store data is used for ECC storage. However, this does mean that use of ECC generates additional memory operations since a separate write to the ECC area will be required after a data write, and a separate read will be required to pull the stored ECC information on read operations.

Use of ECC generation and correction is controlled through the ecc_enable parameter. If this parameter is programmed to a non-zero value, ECC is computed and stored in memory on all write transactions, and read from memory, computed, compared and optionally corrected on all read transactions. If this parameter is cleared to 00b, ECC generation, checking, correction and storage will not occur, and therefore the extra memory operations will not be required.

When using in-line ECC, the bank information may be adjusted to account for the location of the ECC data. The user may define the bank offset in the inline_ecc_bank_offset parameter. The ECC information will be stored in the bank defined by the formula = bank + inline_ecc_bank_offset. This parameter may be cleared to 0x0, or programmed to a non-zero value for better performance.

57.4.3.3 In-line ECC Compatibilities

In-line ECC is enabled when the ecc_enable parameter is programmed to 01b, 10b, or 11b. If in-line ECC is enabled, several parameters in the Controller have required or recommended programming values. See Table 57.17 for a summary of these values. The user must also program the cs_msk_X and cs_val_lower_X / cs_val_upper_X parameters correctly.

Table 57.17 In-line ECC parameter programming

Parameter name	Supported values
addr_cmp_en	should be set to 1 (enabled)
addr_collision_mpm_dis	must be set to 1 (disabled)
disable_memory_masked_write	should be cleared to 0 (allow)
disable_rd_interleave	must be cleared to 0 (allow)
ecc_writeback_en	should be set to 1 (enabled)
in_order_accept	out-of-order (0 setting) can only be enabled if the inline_ecc_same_page parameter = 1
inline_ecc_bank_offset	only valid if the inline_ecc_same_page parameter = 0
inline_ecc_same_page	both bg/bank-based and same-page in-line ECC are supported
rw_same_page_en	must be cleared to 0 (disabled)
swap_en	must be cleared to 0 (disabled)

57.4.3.4 Features of the In-line ECC Logic

The Controller ECC implementation provides the following features:

- Internal controls to disable ECC usage
  The user may disable the ECC usage completely by clearing the ecc_enable parameter to 00b. In this mode, the Controller will not compute and compare check codes, nor attempt to store the check codes to memory.
- Register storage of the ECC signature on ECC errors
  Two sets of parameters (one set for correctable errors, one set for un-correctable errors) store the address, data, and syndrome associated with the ECC error on a read command from a port transaction that generates a first correctable or first un-correctable error interrupt if the ecc_enable parameter is programmed for detection (10b or 11b).
- Interrupt generation
  Four interrupt bits in the register array communicate ECC status to the user for read commands or read/modify/write commands if the ecc_enable parameter is programmed for detection (10b or 11b).
- User interface signaling when an ECC error occurs on a read operation
  Two output signals per port transmit ECC error status with the associated read data when an un-correctable error is detected if the ecc_enable parameter is programmed for detection (10b or 11b).
- Automatic correction of single-bit errors
  If single-bit error occurs and the ecc_enable parameter is programmed for detection and correction (11b), the erroneous bit will be flipped automatically and accurate data/check codes will be written to memory (write transactions) or returned to the user interface (read transactions). Note that corrections made on read data will not be reflected to memory.
- Memory integrity preservation through ECC scrubbing
  On write commands, ECC scrubbing is used to ensure that the entire combined ECC data word will be written to memory to preserve memory integrity. On read commands, if the ecc_enable parameter is programmed for detection and correction (11b), and a correctable error is detected, the Controller will fix the data prior to returning it to the user interface and flag the existence of the error in memory. Since this operation does not include a write, the error will still exist in the memory. If the ecc_enable parameter is only programmed for detection (10b), the Controller will NOT fix the data but will flag the error. The user has two options to handle these read errors, if removing the error in memory is desired. If the ecc_enable parameter is programmed to 11b, the user may enable the ECC writeback option (by setting the ecc_writeback_en parameter to 1) which will automatically trigger a masked write to write the newly corrected bit to memory. Or, if the option is not enabled, there will be no automatic command generated, but the user may respond to a correctable error on a read by issuing a write to this memory location with all bytes masked. This will trigger a read/modify/write operation, where the Controller will read in the data from memory, discover and correct the error and then write the data and the check code to memory. Since all bytes of the data are written to memory, the error is overwritten - or scrubbed - from memory. ECC scrubbing requires that ECC detection and correction are both enabled (the ecc_enable parameter is programmed to 11b).
- Automatic corruption of ECC codes for read data errors
  If ECC detection is enabled (10b or 11b), the read data is verified for ECC prior to combining the read data with the new write data and calculating a new ECC. If an un-correctable error is detected on the read data, it is likely that this address space contains bad memory. As a result, the Controller will automatically corrupt the check code for this ECC data word so that all future accesses to this area will result in an error. This feature may be disabled. If disabled, the error will be ignored and new data and a new check code will be written to memory. A future access to this address may or may not result in an un-correctable error.
- Separate set of recording parameters for read/modify/write ECC errors
  In addition to the ECC signature register storage and interrupts, a new set of ECC signature parameters and interrupts is included for read/modify/write ECC errors.

57.4.3.5 Buffer Allocation / Optimization

A normal read operation with in-line ECC consists of two read operations: one to fetch memory data and one to fetch the ECC data. A normal write operation similarly consists of two write operations: a write to store memory data and a write to store the ECC data that is related. As a single transaction, this is meaningless, but multiplying every transaction by 2 results in a large overhead and system inefficiency.

There are 8 ECC buffers in this Controller. Each buffer stores one memory burst of ECC data which corresponds to 8 aligned, continuous memory bursts. Having multiple buffers allows each to operate independently and store ECC data

related to 8 different commands. This Controller takes advantage of having multiple buffers and attempts to re-use ECC data whenever possible through two user-controllable optimizations: read caching and write combining.

Once a read transaction is complete, the Controller will look ahead at the commands in the command queue. If any read commands are pending that will require the same ECC data that is currently in a buffer, the Controller can re-allocate the existing buffer to the pending read command and nullify the associated pending ECC data read. Since an ECC buffer may contain 8 transactions worth of read ECC values, it is possible that this option could eliminate 7 extra ECC data reads. Read caching is controlled through the programming of the ecc_read_caching_en parameter.

Write operations will compute ECC values on the data, then store the data and then the ECC values before proceeding to the next command. However, if a pending command will overwrite at least some of that ECC information in the buffer, then it may not be necessary to perform the ECC data write until both (or more, up to 7) transactions are complete. Write combining is controlled through the programming of the ecc_write_combining_en parameter.

57.4.3.6 In-line ECC Control

ECC functionality is controlled through a parameter named ecc_enable. This parameter enables ECC and sets the reporting and correcting behavior.

Table 57.18 shows the bit settings for the ecc_enable parameter.

Table 57.18 ECC control parameter settings

ecc_enable	ECC enabled	Error detection	Error correction	Description
00b	No	—	—	ECC is disabled. The ecc_dataout_corrected_X / ecc_dataout_uncorrected_X signals will never assert during read data transfers. The int_status_ecc parameter and the ECC reporting parameters will never be updated to reflect any ECC error events. Data will be written to the memory without ECC values, and data will be returned to the user interface without being verified for accuracy.
01b	Yes	No	No	ECC is enabled, but without detection or correction. ECC is computed on all transactions, but the ecc_dataout_corrected_X / ecc_dataout_uncorrected_X signals will never be asserted, the int_status_ecc parameter will not reflect ECC errors, and the ECC reporting parameters will not be updated.
10b	Yes	Yes	No	ECC is enabled with detection, but correction is not supported. When an un-correctable error is found on a read operation, the ecc_dataout_corrected_X / ecc_dataout_uncorrected_X signals will be asserted with the erring ECC data word. The int_status_ecc parameter and the ECC reporting parameters will be updated for read commands. Erroneous data will be returned to the user on read commands and written to the memory on write commands.
11b	Yes	Yes	Yes	ECC is enabled with detection and correction. When an un-correctable error is found on a read operation, the ecc_dataout_corrected_X / ecc_dataout_uncorrected_X signals will be asserted with the erring ECC data word. The int_status_ecc parameter and the ECC reporting parameters will be updated for read commands. Single bit errors will be corrected automatically by the Controller in both read and write commands.

Additional ECC-related parameters are listed in Table 57.19.

Table 57.19 ECC parameters

Controller parameter	Description
ecc_disable_w_uc_err	Disables automatic corruption of the ECC codes for an entire user word when the read portion of a read/modify/write operation has an un-correctable error. If this is not disabled, the corruption will occur even if the erroneous byte is overwritten with new data.
ecc_writeback_en	Enables automatic writing of corrected data on single bit correctable errors on read operations. This is only valid if the ecc_enable parameter is programmed to 11b.

57.4.3.7 Error Signature Parameters

Register storage is provided for the failing address, data, and syndrome for ECC single bit and double bit errors for read operations from port transactions when the ecc_enable parameter is programmed for detection (10b or 11b). There is one set of parameters for each type of error.

The signature information will be stored until the user clears the first correctable error or first un-correctable error interrupt by writing a 1 to the associated bit in the int_ack_ecc parameter. Subsequent errors that occur before this error interrupt is cleared will trigger an interrupt and an output signal, but the error signature will not be recorded. Table 57.20 lists the parameters in which the error signature is captured.

Table 57.20 ECC error signature parameters

Information	Correctable error	Un-correctable error
Address	ecc_c_addr	ecc_u_addr
Data	ecc_c_data	ecc_u_data
Syndrome	ecc_c_synd	ecc_u_synd

57.4.3.8 Interrupt Status Bits

The int_status_ecc parameter indicates the status of all interrupts in the Controller. The parameter is cleared on reset of the Controller.

There are 4 bits in the int_status_ecc parameter relating to ECC when the ecc_enable parameter is programmed for detection (10b or 11b).

Table 57.21 ECC Error Parameter Description

Bit	Description
int_mask_ecc [3:0]	Mask field to inhibit assertion of ECC interrupt signals.
int_status_ecc [0]	Set to 1 if a correctable ECC event has been detected on a read operation.
int_status_ecc [1]	Set to 1 if another correctable ECC event has been detected on a read operation, prior to the initial event being acknowledged.
int_status_ecc [2]	Set to 1 if an un-correctable ECC event has been detected on a read operation.
nt_status_ecc [3]	Set to 1 if another un-correctable ECC event has been detected on a read operation, prior to the initial event being acknowledged.
int_status_ecc [6]	Set to 1 if one or more ECC writeback commands could not be executed.
nt_status_ecc [7]	Set to 1 if the scrub operation triggered by setting the ecc_scrub_start parameter has completed.
int_status_ecc [8]	Set to 1 if an ECC correctable error has been detected in a scrubbing read operation.

On the first instance of an ECC error, the associated bit will be set in the int_status_ecc parameter. If the associated interrupt is not masked, the controller_int signal will also be asserted to the user interface. An interrupt is masked if the associated bit is set to 1 in the int_mask_ecc parameter. Bits [1] and [3] will only be set in the int_status_ecc parameter if a subsequent ECC error occurs before the initial ECC error was acknowledged. To acknowledge the first error, the user must set the associated bit in the int_ack_ecc parameter to 1.

57.4.3.9 Automatic In-line ECC Corruption

For ECC accuracy, data is verified for ECC during the read phase of a write prior to modifying and writing. If an un-correctable error is detected on the read data, it is likely that this address space contains bad memory. As a result, the Controller will automatically corrupt the check code for this ECC data word so that all future accesses to this area will result in an error. The corruption occurs during both the read and the write phases of the write transaction.

If desired, this feature may be disabled by setting the ecc_disable_w_uc_err parameter. If disabled, the un-correctable error will be ignored. The read data and write data will be combined, and a check code will be calculated to match the new ECC data word. New data and the new check code will be written to memory. A future access to this address may or may not result in an un-correctable error.

57.4.3.10 Clearing a Reported In-line ECC Event

To clear a reported ECC event, the user should follow these steps:

- Read the ECC data, address, and syndrome parameters to determine where the event occurred.
- Set the associated bit in the int_ack_ecc parameter to 1. This clears the ECC interrupt bit, and allows the ECC event data in the ECC parameters to be overwritten by a subsequent ECC event.

57.4.3.11 In-line ECC Scrubbing

The Controller's ECC logic includes a scrubbing feature which periodically reads each location of the memory, checks ECC, corrects any correctable errors found, and writes back the corrected data. By walking through the entire DRAM, the memory integrity is preserved, and the likelihood of an un-correctable error is reduced.

(1) ECC Scrubbing Parameters

Relevant parameters are listed in Table 57.22.

Table 57.22 ECC scrubbing parameters

Controller prameter	Description
ecc_scrub_end_addr	Defines the ending address at which scrubbing operations will stop and the ECC scrubbing operation complete interrupt (bit [7]) will be set to 1 in the int_status_ecc parameter. Once complete, the scrubbing address pointer will be reset to the start address so that when another scrubbing operation is initiated, it will scrub a full cycle from the start address. This parameter must be programmed to a non-zero value for the scrubbing logic to operate.
ecc_scrub_idle_cnt	Defines the number of controller clock cycles that the scrubbing engine will wait in the controller's idle state before starting scrubbing operations. This parameter is only valid when the ecc_scrub_mode parameter is set to 1. The controller is considered idle when the command queue is empty. When this condition is detected, an internal counter will load with the value programmed in this parameter and count down on each controller clock. When the counter expires, either the scrubbing operation will begin or the next address will be tested. The controller clock is based on the controller's operating frequency. Clearing this parameter to 0x0000 will disable idle operation.
ecc_scrub_in_progress	Reports the scrubbing operation status. This parameter is read-only. 0: Not actively performing a scrubbing operation 1: The controller is in the process of performing a scrubbing operation.
ecc_scrub_interval	Sets the minimum interval between two ECC scrubbing commands, in number of controller clock cycles. This parameter is only valid when the ecc_scrub_mode parameter is cleared to 0. The controller clock is based on the controller's operating frequency. Clearing this parameter to 0x0000 will disable interval operation.
ecc_scrub_len	Defines the length (in bytes) of the ECC scrubbing read command that the controller will issue. This value must be an integer multiple of the memory burst length, and the lowest 3 bits of this parameter must be cleared to 0.
ecc_scrub_mode	Specifies when ECC scrubbing operations will be performed. 0: ECC scrubbing operations will be performed at regular intervals as dictated by the ecc_scrub_interval parameter. 1: ECC scrubbing operations will be performed only when the controller is idle.
ecc_scrub_start	Initiates the ECC scrubbing operation. This parameter is write-only and will always read back as 0. 0: No action 1: Initiate the scrubbing operation.
ecc_scrub_start_addr	Defines the starting address from where scrubbing operations will begin. This value must be less than or equal to the value programmed into the ecc_scrub_end_addr parameter.

(2) Procedure

To initiate an ECC scrubbing operation, the user should follow these steps:

1. If the ecc_scrub_in_progress parameter is cleared to 0, program the ecc_scrub_start_addr, ecc_scrub_end_addr and ecc_scrub_len parameters with appropriate values and then set the ecc_scrub_start parameter to 1. The ecc_scrub_start parameter will be automatically cleared after 1 cycle.

2. When the user sets the ecc_scrub_start parameter, the ecc_scrub_in_progress parameter will be set to 1. If the ecc_scrub_mode parameter is cleared to 0, a timer will be loaded with the value in the ecc_scrub_interval parameter. If the ecc_scrub_mode parameter is set to 1, the scrubbing logic will wait for an indication that the Controller is actually idle and then the timer will be loaded with the value in the ecc_scrub_idle_cnt parameter.
3. In either case, when the counter expires, the ECC scrubbing operation will begin.
   The scrubbing engine will start reading the memory at the address defined in the ecc_scrub_start_addr parameter. The Controller will issue a dummy read command which pulls the data and the ECC code from memory into the read data FIFO, calculate the ECC on the read data and compare it to the stored ECC code. If the ECC codes do not match, and the syndrome indicates a correctable error, the Controller will correct the data, write the corrected data and new check code into memory, and set the ECC scrubbing correctable error interrupt (bit [8]) in the int_status_ecc parameter. The read data in the read data FIFO will be discarded if the ECC codes match or not.
   For interval operation (the ecc_scrub_mode parameter was cleared to 0), the timer will be re-loaded with the value in the ecc_scrub_interval parameter. When that timer expires, the ECC scrubbing operation will issue a dummy read to the next address. This process continues, with a delay of interval counts in between dummy reads, until the address defined in the ecc_scrub_end_addr parameter is reached.
   For idle operation (the ecc_scrub_mode parameter was set to 1), as long as the Controller is still idle and no commands have been accepted from the user interface, the ECC scrubbing operation will issue a dummy read to the next address without any delays or interval counts. If a user command is accepted during the scrubbing operation, the scrubbing operation will be halted after the current read/check/writeback is completed and the Controller will return to normal operation. When the scrubbing logic receives an indication that the Controller is idle again, the timer will be re-loaded with the value in the ecc_scrub_idle_cnt parameter. When that counter expires, the scrubbing logic will continue by issuing a dummy read to the next un-tested address until the address defined in the ecc_scrub_end_addr parameter is reached.
4. Once all addresses have been tested, the ecc_scrub_in_progress parameter will be cleared to 0 and the ECC scrubbing operation complete interrupt (bit [7]) in the int_status_ecc parameter.

Note: Software should monitor the ECC scrubbing correctable error interrupt (bit [8]) in the int_status_ecc parameter during the ECC scrubbing operation. This bit is intended as a diagnostic tool to keep track of the number of correctable errors. It can be used as an indication that memory may be slowly reaching the end of its life. No other ECC error information will occur on ECC scrub commands. The other ECC interrupts will NOT be set, the user interface ECC signal will never be asserted, and the ECC reporting parameters will never be filled.

57.4.4 Memory Initialization Programming

Memory initialization programming allows a selectable range of memory to be initialized with a programmable data value. The ECC feature can optionally be turned on or off when initializing the memory.

57.4.4.1 Overview

To select memory initialization programming, program the bist_test_mode parameter to 100b. The data pattern used in this mode is programmable and must be written to the bist_data_pattern parameter before initiating the BIST sequence. In this test mode, when the bist_go parameter is set to 1, the memory from the address defined in the bist_start_address parameter to the computed ending address will be initialized with the data from the bist_data_pattern parameter.

Note: This configuration supports in-line ECC. If in-line ECC is enabled (the ecc_enable parameter is programmed to a non-zero value and the ecc_type parameter is set to 1), then 1/8 of each memory device will be restricted from use and restricted from memory initialization programming. If the user wishes to complete memory initialization on the entire memory, then before running the test, the user should disable in-line ECC (the ecc_enable parameter should be cleared to 00b, or the ecc_type parameter should be cleared to 0) and re-calculate and program new values into the cs_size_X value and the cs_val_lower_X and cs_val_upper_X parameters.

57.4.4.2 Procedure

Memory initialization programming will program the specified address range. This procedure should be followed:

1. Define the data range to check by programming the bist_start_address and the addr_space parameters. When using in-line ECC option (the ecc_enable parameter is programmed to a non-zero value), the user should make sure that the start address and ending address are data and ECC group aligned.
2. Set the bist_data_check parameter to 1.

3. Program the bist_test_mode parameter to 100b.
4. Program the data pattern to be used into the bist_data_pattern parameter.
5. Set the bist_go parameter to 1 to begin the programming.
6. Wait for the BIST complete interrupt (bit [0]) in the int_status_bist parameter to be set to 1. This procedure will not verify any data or report any errors.
7. Clear the bist_go parameter to 0 to re-enable normal operation.

57.4.4.3 BIST Logic Description

The BIST logic is activated by setting the bist_go parameter to 1. This logic can only be activated when the controller is known to be idle. No read or write commands can be pending at the time the user initiates the BIST routine. If BIST checking is enabled after the start parameter is set to 1 but before initialization is complete, BIST traffic will stall in the command queue in the Controller core waiting for the DLL to lock and initialization to complete.

Once the bist_go parameter is set to 1, the internal BIST logic will issue read and write commands for a single aligned user word through the controller's command and data ports. While this operation is in progress, the controller will ignore any commands coming from the user interface.

Note: All programmable registers must be static for a minimum of 10 clock cycles prior to writing a "1" to the bist_go parameter.

Note: The BIST logic will be interrupted when a self-refresh is required (regardless of how the self-refresh is initiated) and resume at the interrupted point when the self-refresh completes.

57.4.5 Port Protection

The port protection feature allows the user to control access to the memory space. When configured and enabled, each port's sources will be restricted to access memory based on its protection level (secure/privileged).

The controller is configured with 16 address regions for each port. The system will default to restricting any type of access for the entire memory. For any one port, valid regions must be set up with unique addresses such that the regions do not overlap and with protection levels that will be supported. Failure to change protection level parameters prior to enabling protection will result in all commands failing. For ports that will not be using port protection, the user must define at least one region that will accept all read and write cycles, for any address.

Note that it is acceptable for address regions for one port to overlap access regions for another port.

The minimum granularity of an address region is 16K. Bit [13] of the incoming system address is used as the lowest bit for comparison. Internally, the Controller compares bit X of the address, where X is the defined as the 14th bit, left shifted by the number of bits used for the datapath. The user may define regions as any multiple of 16K.

Port protection works by checking incoming requests against the valid address ranges. If enabled by setting the port_addr_protection_en parameter to 1, an incoming command is checked based on the restrictions defined in the port protection parameters. Protection region Z is defined with the axiY_start_addr_Z and axiY_end_addr_Z parameters with axiY_address_range_enable = 1. ALL of the following tests must pass for a command to remain valid:

Address Check: The starting and ending addresses must both fall within a single region Z as defined by the axiY_start_addr_Z and axiY_end_addr_Z parameters. If both starting and ending addresses do not fall within a single region Z, the command will fail. The use of these parameters is defined by the axiY_address_range_enable parameters. If the axiY_address_range_enable parameter is set to 1 for a port, the start/end parameters associated with that port will be used.

Protection Check: The relevant protection signal (axiY_ARPROT or axiY_AWPROT) must match the settings for the associated axiY_range_prot_bits_Z parameter. The axiY_range_prot_bits_Z parameter defines the restrictions for region Z as privileged & secure access, privileged access, secure access, or full access. If the protection signal does not match the settings of region Z, the command will fail.

Commands that fail are processed through the controller, but do not corrupt memory and do not return valid data to the user interface. A failing write command will be processed internally as a flushed write command. In this case, the write data is cleared out of the controller FIFOs but the data stored in DRAM memory will NOT change.

A failing read will read the appropriate number of bytes in the memory. However, this data will be ignored and the appropriate number of 0x0 bytes will be returned to the user interface.

Note: In the event of a failure, a SLVERR will be reported on the AXI interface.

In the event of a failure, the port command error interrupt (bit [2]) will be set in the int_status_userif parameter, and reported to the user interface on the DDRC_INT signal (if the associated bit is not masked in the int_mask_userif parameter).

57.5 Interrupt

57.5.1 Interrupt List

Table 57.23 shows interrupt signals of this unit.

Table 57.23 Interrupt list

Interrupt signal	Description
DDRC_INT	Interrupt signal from the controller. This is a level-sensitive signal which will be asserted when the controller detects any interrupt conditions. An interrupt will only cause the DDRC_INT signal to be asserted if the associated bit is set in the int_status_master parameter and cleared in the int_mask_master parameter (and the uppermost bit of the int_mask_master parameter is cleared to 0).
perf_mon_data_status[1:0]	Performance monitor signal Single cycle pulse per event [0] = ECC data correction has occurred on read data. [1] = Uncorrectable ECC error detected on read data.

57.5.2 DDRC_INT

This unit supports a full system of interrupts to alert the user of any issues the Controller encounters. Interrupts are reported by the setting of bits in the int_status_master parameter and the individual int_status_<group> parameters. If any bits are set in the group parameter, the associated bit will be set in the int_status_master parameter. Individual interrupts must be cleared by writing to the bit in the int_ack_<group> parameter, which will then update the int_status_<group> parameter and may clear the bit in the int_status_master parameter. Interrupts may be masked individually in the int_mask_<group> parameter, groups of interrupts may be masked in the int_mask_master parameter, or all interrupts may be masked by setting the uppermost bit of the int_mask_master parameter to 1. See Table 57.24 for the correlation of bits in the master and group parameters, and all subsequent tables for the individual bits of each group.

Table 57.24 Groups of DDRC_INT

Logic Group	Bit in the int_status_master and int_mask_master Parameters	Name of the Group Status Parameter	Name of the Group Mask Parameter	Name of the Group Acknowledge Parameter
Reserved	31 to 15	—	—	—
Mode Registers	14	int_status_mode	int_mask_mode	int_ack_mode
Initialization	13	int_status_init	int_mask_init	int_ack_init
Reserved	12, 11	—	—	—
DFI	10	int_status_dfi	int_mask_dfi	int_ack_freq
Reserved	9	—	—	—
BIST Logic	8	int_status_bist	int_mask_bist	int_ack_bist
Miscellaneous Logic	7	int_status_misc	int_mask_misc	int_ack_misc
User Interface	6	int_status_userif	int_mask_userif	int_ack_userif
Training	5	int_status_training	int_mask_training	int_ack_training
Reserved	4, 3	—	—	—
Low Power Control	2	int_status_lowpower	int_mask_lowpower	int_ack_lowpower
ECC	1	int_status_ecc	int_mask_ecc	int_ack_ecc
Timeout	0	int_status_timeout	int_mask_timeout	int_ack_timeout

Table 57.25 Bits of the Mode Registers Group

Bit	Description
7 to 4	Reserved
3	The register interface-initiated mode register write has completed and another mode register write may be issued.
2	The requested mode register read has completed. The chip and data can be read in the peripheral_mrr_data parameter.
1	Reserved
0	An MRR error has occurred. Error information can be found in the mrr_error_status parameter.

Table 57.26 Bits of the Initialization Group

Bit	Description
7 to 4	Reserved
3	The state machine is in the power-on software initialization state during initialization.
2	Reserved
1	The MC initialization has been completed.
0	The memory reset is valid on the DFI bus.

Table 57.27 Bits of the DFI Group

Bit	Description
7, 6	Reserved
5	The DFI tINIT_COMPLETE value has timed out. This value is specified in the tdfi_init_complete parameter.
4	The user-initiated DLL resynchronization has completed.
3	A state change has been detected on the dfi_init_complete signal after initialization.
2	Error received from the PHY on the DFI bus.
1	A DFI PHY Master Interface error has occurred. Error information can be found in the phymstr_error_status parameter.
0	A DFI update error has occurred. Error information can be found in the update_error_status parameter.

Table 57.28 Bits of the BIST Logic Group

Bit	Description
7 to 1	Reserved
0	The BIST operation has been completed.

Table 57.29 Bits of the Miscellaneous Logic Group

Bit	Description
15 to 12	Reserved
11	The S/W requested refresh operation has resulted in a status bit being set.
10 to 8	Reserved
7	The refresh operation has resulted in a status bit being set.
6	A temperature alert condition (low or high temp) has been detected.
5	The last automatic MRR of MR4 indicated a change in the device temperature or refresh rate (TUF bit set).
4	The controller has entered the software-requested mode.
3	The assertion of the inhibit_dram_cmd parameter has successfully inhibited the command queue.
2 to 0	Reserved

Table 57.30 Bits of the User Interface Group (1 of 2)

Bit	Description
31 to 8	Reserved

Table 57.30 Bits of the User Interface Group (2 of 2)

Bit	Description
7	The user has programmed an invalid setting associated with core words per burst. Examples: Setting the mem_dp_reduction parameter when burst length = 2.
6	A wrap cycle crossing a DRAM page has been detected. This is unsupported and may result in memory data corruption.
5 to 3	Reserved
2	An error occurred on the port command channel.
1	Multiple accesses outside the defined PHYSICAL memory space have occurred.
0	A memory access outside the defined PHYSICAL memory space has occurred.

Table 57.31 Bits of the Training Group

Bit	Description
31 to 16	Reserved
15	A DQS oscillator measurement has been detected to be out of variance.
14	A DQS oscillator measurement overflow has been detected.
13	The DQS oscillator has updated the base values.
12	The software-requested DQS oscillator measurement has completed.
11	The ZQ calibration operation has resulted in a status bit being set. Refer to the zq_status_log parameter for more information.
10 to 0	Reserved

Table 57.32 Bits of the Low Power Control Group

Bit	Description
15 to 4	Reserved
3	A Low Power Interface (LPI) timeout error has occurred.
2, 1	Reserved
0	The low power operation has been completed.

Table 57.33 Bits of the ECC Group

Bit	Description
15 to 9	Reserved
8	An ECC correctable error has been detected in a scrubbing read operation.
7	The scrub operation triggered by setting the ecc_scrub_start parameter has completed.
6	One or more ECC writeback commands could not be executed.
5, 4	Reserved
3	Multiple uncorrectable ECC events have been detected.
2	An uncorrectable ECC event has been detected.
1	Multiple correctable ECC events have been detected.
0	A correctable ECC event has been detected.

Table 57.34 Bits of the Timeout Group (1 of 2)

Bit	Description
31 to 20	Reserved
19	The auto-refresh max deficit timeout has expired.
18	Reserved
17	The low power interface wakeup timeout has expired.
16	The DFI update FM timeout has expired.

Table 57.34 Bits of the Timeout Group (2 of 2)

Bit	Description
15	A DQS oscillator request timeout has been detected.
14	The MRR temperature check FM timeout has expired.
13 to 10	Reserved
9	The ZQ calstart FM timeout has expired.
8	The ZQ callatch FM timeout has expired.
7	The ZQ cal init, cs, cl, or reset FM timeout has expired.
6 to 0	Reserved

57.5.3 perf_mon_data_status[1:0]

This unit has a mechanism to notify the user that correctable or uncorrectable ECC error detect on the read data. These signals are available as error events.

- Bit [0] is asserted 1 for 1 DfiClk when ECC data correction has occurred on the read data.
- Bit [1] is asserted 1 for 1 DfiClk when uncorrectable ECC error detect on the read data.

57.6 Usage Notes

This unit has the following restrictions.

Table 57.35 Restrictions

Item	Restriction
Period of DRAM inaccessibility	It has the period of DRAM inaccessibility to execute the periodic training. It is 1,280 core clock cycles every 134,217,728 core clock cycles. So, it depends only on the Bit Rate (the frequency of the core clock). It is below: 3200 Mbps: 1.6 µs every 167 ms
Density when ECC function is enabled	1/8 area is used for the ECC code, so the usable density is 7/8.
Refresh Management (RFM) and Scaling Level (SCL)	No support
Coherent bufferable issue in memory controller	Incorrect read data may be returned to a read associated with a co-bufferable write when the read is from a different AXI port. It is possible to happen in case of enabling ECC. Workaround is to prioritize write rather than read. DDR parameter generation tool automatically sets axiY_fixed_port_priority_enable, axiY_w_priority and axiY_r_priority properly. Do not change these values from the generated ones.

58. Electrical Characteristics

Electrical characteristics of this LSI is defined with the following conditions unless otherwise described.

Conditions:

- Core voltage
  VDD08 = VDD08_PLLn (n = 0 to 4) = DVDD08A_TSU = OTPVDD08 = USB_USDVDD = PCIE_VDD08A_Ln (n = 0, 1) = AVDD_ADCn (n = 0 to 2) = 0.76 to 0.84 V
- LPDDR4 I/O voltage
  DDR_VDDQ = 1.06 to 1.17 V
- 1.8V I/O and analog voltage
  VDD1833_n (n = 0 to 7, 1.8 V mode) = VDDP_18_n (n = 0 to 7, 33, X) = VDD18_PLLn (n = 0 to 4) = AVDD18A_TSU = OTPVDD18 = USB_USVDD18 = PCIE_VDD18A_CMN = PCIE_VDD18A_L0 = PCIE_VDD18A_L1 = DDR_VAA = AVDDIO_ADCn (n = 0 to 2) = AVDDREF_ADCn (n = 0 to 2) = 1.71 to 1.89 V
- 3.3V I/O and analog voltage
  VDD33 = VDD1833_n (n = 0 to 7, 3.3 V mode) = VDD33_X = USB_USVDD33 = 3.135 to 3.465 V
- Ground

  Tj = −40 to 125ºC

58.1 Absolute Maximum Ratings

Table 58.1 Absolute maximum ratings (1 of 2)

Parameter	Symbol	Value	Unit
Power supply voltage (3.3-V I/O)	VDD33, VDD1833_0 to VDD1833_7 (3.3-V mode)	−0.3 to +3.8	V
Power supply voltage (1.8-V I/O)	VDD1833_0 to VDD1833_7 (1.8-V mode), VDDP_18_33, VDDP_18_0 to VDDP_18_7	−0.3 to +2.5	V
Power supply voltage (Core)	VDD08	−0.3 to +1.2	V
Input voltage	Vin (3.3-V logic)	−0.3 to smaller value of VDD33/ VDD1833_n (3.3-V mode) + 0.3 or 3.8	V
Input voltage	Vin (1.8-V logic)	−0.3 to smaller value of VDD1833_n (1.8-V mode) + 0.3 or 2.5	V
Oscillator power supply voltage	VDD33_X	−0.3 to +3.8	V
	VDDP_18_X	−0.3 to +2.5	V
PLL power supply voltage	VDD18_PLL0 to VDD18_PLL4	−0.3 to +2.5	V
	VDD08_PLL0 to VDD08_PLL4	−0.3 to +1.2	V
TSU power supply voltage	AVDD18A_TSU	−0.3 to +2.5	V
	DVDD08A_TSU	−0.3 to +1.2	V
OTP power supply voltage	OTPVDD18	−0.3 to +2.5	V
	OTPVDD08	−0.3 to +1.2	V
USB power supply voltage	USB_USVDD33	−0.3 to +3.8	V
	USB_USVDD18	−0.3 to +2.5	V
	USB_USDVDD	−0.3 to +1.2	V
PCI Express power supply voltage	PCIE_VDD18A_CMN, PCIE_VDD18A_L0, PCIE_VDD18A_L1	−0.3 to +2.5	V
	PCIE_VDD08A_L0, PCIE_VDD08A_L1	−0.3 to +1.2	V

Table 58.1 Absolute maximum ratings (2 of 2)

Parameter	Symbol	Value	Unit
LPDDR4 power supply voltage	DDR_VAA	−0.3 to +2.5	V
	DDR_VDDQ	−0.3 to +1.5	V
ADC12 power supply voltage	AVDDIO_ADC0 to AVDDIO_ADC2	−0.3 to +2.5	V
	AVDD_ADC0 to AVDD_ADC2	−0.3 to +1.2	V
ADC12 analog input voltage	VAN	−0.3 to smaller value of AVDDIO_ADCn + 0.3 or 2.5	V
ADC12 reference voltage	AVDDREF_ADC0 to AVDDREF_ADC2	−0.3 to smaller value of AVDDIO_ADCn + 0.3 or 2.5	V
Crystal oscillator pins input voltage	XTAL, EXTAL	−0.3 to + 2.5	V
Operating temperature (Junction temperature)	T_j	−40 to +125	ºC
Storage temperature	T_{stg}	−40 to +125	ºC

Caution: Permanent damage to the LSI might result if absolute maximum ratings are exceeded.

58.2 Power Supply

Table 58.2 Power supply (1 of 2)

Parameter	Symbol	Min.	Typ.	Max.	Unit
Power supply voltage (3.3-V I/O)	VDD33, VDD1833_0 to VDD1833_7 (3.3-V mode)	3.135	3.3	3.465	V
Power supply voltage (1.8-V I/O)	VDD1833_0 to VDD1833_7 (1.8-V mode), VDDP_18_33, VDDP_18_0 to VDDP_18_7	1.71	1.8	1.89	V
Power supply voltage (Core)	VDD08	0.76	0.8	0.84	V
Ground	VSS	—	0	—	V
Oscillator power supply voltage	VDD33_X	3.135	3.3	3.465	V
	VDDP_18_X	1.71	1.8	1.89	V
PLL power supply voltage	VDD18_PLL0 to VDD18_PLL4	1.71	1.8	1.89	V
	VDD08_PLL0 to VDD08_PLL4	0.76	0.8	0.84	V
	VSS_PLL0 to VSS_PLL4	—	0	—	V
TSU power supply voltage	AVDD18A_TSU	1.71	1.8	1.89	V
	DVDD08A_TSU	0.76	0.8	0.84	V
OTP power supply voltage	OTPVDD18	1.71	1.8	1.89	V
	OTPVDD08	0.76	0.8	0.84	V
USB power supply voltage	USB_USVDD33	3.135	3.3	3.465	V
	USB_USVDD18	1.71	1.8	1.89	V
	USB_USDVDD	0.76	0.8	0.84	V
PCI Express power supply voltage	PCIE_VDD18A_CMN, PCIE_VDD18A_L0, PCIE_VDD18A_L1	1.71	1.8	1.89	V
	PCIE_VDD08A_L0, PCIE_VDD08A_L1	0.76	0.8	0.84	V
LPDDR4 power supply voltage	DDR_VAA	1.71	1.8	1.89	V
	DDR_VDDQ	1.06	1.1	1.17	V

Table 58.2 Power supply (2 of 2)

Parameter	Symbol	Min.	Typ.	Max.	Unit
ADC12 power supply voltage	AVDDIO_ADC0 to AVDDIO_ADC2	1.71	1.8	1.89	V
	AVDD_ADC0 to AVDD_ADC2	0.76	0.8	0.84	V
	AVSSIO_ADC0 to AVSSIO_ADC2	—	0	—	V
	AVSS_ADC0 to AVSS_ADC2	—	0	—	V

58.3 Power On/Off Sequence

Power on/off sequence and timing are shown in the figure and table below.

For power-up, 0.8-V (i.e. VDD08) must be supplied first, 1.8-V power (i.e. VDD18 and AVDD) must be supplied second, 1.1-V power must be supplied third, then 3.3-V power (i.e. DDR_VDDQ and VDD33) must be supplied. The power-up sequence must be completed within 100 ms. Reset signal (i.e. RES#) must be held to Low level during the power-up.

For Power-down, 1.1-V and 3.3-V power (i.e. DDR_VDDQ and VDD33) must go down first and then 0.8-V and 1.8-V power (i.e. VDD08, VDD18, and AVDD). The power-down sequence must be completed within 100 ms.

Rise time of each power supply for the power-up must be larger than 40 µs and fall time of each power supply for the power-down must be larger than 10 µs.

Power supply voltages and reset signal must be applied with monotonic increase.

Do not apply a negative voltage to power supply voltages.

Stable clock must be supplied to EXTAL/XTAL or EXTCLKIN pin when reset signal (i.e. RES#) is driven high.

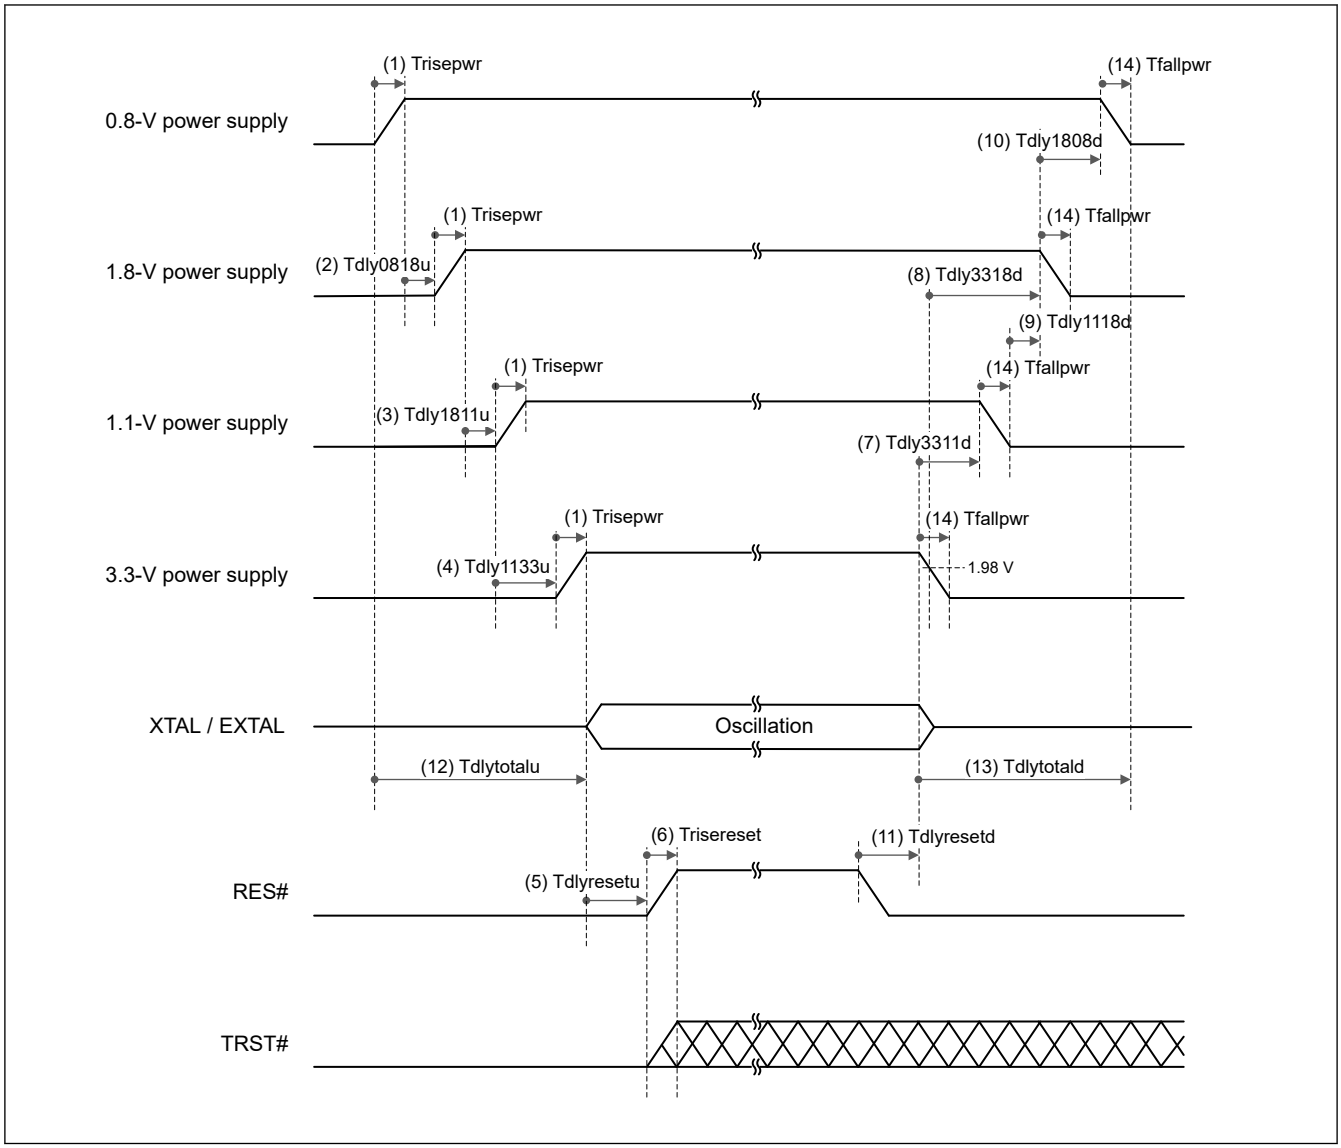

Figure 58.1 Power on/off sequence

Table 58.3 Power on/off sequence timing (1 of 2)

No	Symbol	Description	Value		
			Min.	Typ.	Max.
(1)	Trisepwr	Rising time of the power supply voltage	40 µs	—	30 ms
(2)	Tdly0818u	Delay time from completion of rising of the 0.8-V power supply voltage to start of rising of the 1.8-V power supply voltage	1 µs	—	100 ms
(3)	Tdly1811u	Delay time from completion of rising of the 1.8-V power supply voltage to start of rising of the 1.1-V power supply voltage	0	—	100 ms
(4)	Tdly1133u	Delay time from start of rising of the 1.1-V power supply voltage to start of rising of the 3.3-V power supply voltage	0	—	100 ms
(5)	Tdlyresetu	Delay time from completion of rising of the 3.3-V power supply voltage to start of rising of RES#	10 ms	—	—
(6)	Trisereset	Rising time of RES#	—	—	150 µs
(7)	Tdly3311d	Delay time from start of falling of the 3.3-V power supply voltage to start of falling of the 1.1-V power supply voltage	0	—	100 ms
(8)	Tdly3318d	Delay time from the time when 3.3-V power supply voltage drops below 1.98-V to start of falling of the 1.8-V power supply voltage	0	—	100 ms

Table 58.3 Power on/off sequence timing (2 of 2)

No	Symbol	Description	Value		
			Min.	Typ.	Max.
(9)	Tdly1118d	Delay time from completion of falling of the 1.1-V power supply voltage to start of falling of the 1.8-V power supply voltage	0	—	100 ms
(10)	Tdly1808d	Delay time from start of falling of the 1.8-V power supply voltage to start of falling of 0.8-V power supply voltage	0	—	100 ms
(11)	Tdlyresetd	Delay time from start of falling of RES# to start of falling of the 3.3-V power supply voltage	10 µs	—	—
(12)	Tdlytotalu	Startup time of all power supply voltage	0	—	100 ms
(13)	Tdlytotald	Shut down time of all power supply voltage	0	—	100 ms
(14)	Tfallpwr	Falling time of the power supply voltage	10 µs	—	30 ms

58.4 DC Characteristics

Table 58.4 DC Characteristics for Type A I/O buffer (VDD33 domain)

Item	Symbol	Conditions	Min.	Typ.	Max.	Unit
Input High-level voltage	V_{IH33}	—	VDD33 × 0.7	—	VDD33 + 0.3	V
Input Low-level voltage	V_{IL33}	—	−0.3	—	VDD33 × 0.3	V
Hysteresis voltage	ΔV_{T33}	—	VDD33 × 0.08	—	—	V
Output High-level voltage	V_{OH33}	Low, IOH = −2 mA	VDD33 × 0.8	—	VDD33	V
		Middle, IOH = −4 mA	VDD33 × 0.8	—	VDD33	V
		High, IOH = −8 mA	VDD33 × 0.8	—	VDD33	V
		Ultra High, IOH = −12 mA	VDD33 × 0.8	—	VDD33	V
Output Low-level voltage	V_{OL33}	Low, IOL = 2 mA	0	—	VDD33 × 0.2	V
		Middle, IOL = 4 mA	0	—	VDD33 × 0.2	V
		High, IOL = 8 mA	0	—	VDD33 × 0.2	V
		Ultra High, IOL = 12 mA	0	—	VDD33 × 0.2	V
Input leakage current	$\lvert I_{in} \rvert$	Vin = 0 V, Vin = VDD33	—	—	12	µA
Three-State leakage current (off state)	$\lvert I_{TSI} \rvert$	Vin = 0 V, Vin = VDD33	—	—	12	µA
Input Pull-up resistors resistance	Rpu	Vin = 0 V	10	—	100	kΩ
Input Pull-down resistors resistance	Rpd	Vin = VDD33	10	—	100	kΩ
Input Capacitance	Cin	All input/output and input pins	—	—	10	pF

Table 58.5 DC Characteristics for Type B I/O buffer (VDD1833_n domain) (3.3-V mode) (1 of 2)

Item	Symbol	Conditions	Min.	Typ.	Max.	Unit
Input High-level voltage	V_{IH33}	—	VDD1833 × 0.7	—	VDD1833 + 0.3	V
Input Low-level voltage	V_{IL33}	—	−0.3	—	VDD1833 × 0.3	V
Hysteresis voltage	ΔV_{T33}	—	0.1	—	—	V
Output High-level voltage	V_{OH33}	Low, IOH = −8 mA	VDD1833 × 0.8	—	VDD1833	V
		Middle, IOH = −11 mA	VDD1833 × 0.8	—	VDD1833	V
		High, IOH = −14 mA	VDD1833 × 0.8	—	VDD1833	V
		Ultra High, IOH = −17 mA	VDD1833 × 0.8	—	VDD1833	V

Table 58.5 DC Characteristics for Type B I/O buffer (VDD1833_n domain) (3.3-V mode) (2 of 2)

Item	Symbol	Conditions	Min.	Typ.	Max.	Unit
Output Low-level voltage	V_{OL33}	Low, IOL = 8 mA	0	—	VDD1833 × 0.2	V
		Middle, IOL = 11 mA	0	—	VDD1833 × 0.2	V
		High, IOL = 14 mA	0	—	VDD1833 × 0.2	V
		Ultra High, IOL = 17 mA	0	—	VDD1833 × 0.2	V

	$I_{PCIE\_VDD18A\_L0}$	—	—	0.05	—	mA
	$I_{PCIE\_VDD18A\_L1}$	—	—	0.05	—	mA
	$I_{PCIE\_VDD08A\_L0}$	—	—	1.3	—	mA
	$I_{PCIE\_VDD08A\_L1}$	—	—	1.3	—	mA
	I_{DDR_VAA}	—	—	0.2	—	mA
	I_{DDR_VDDQ}	—	—	0.2	—	mA
	I_{AVDDIO_ADC0}	—	—	0.3	—	µA
	I_{AVDDIO_ADC1}	—	—	0.3	—	µA
	I_{AVDDIO_ADC2}	—	—	0.3	—	µA
	I_{AVDD_ADC0}	—	—	3	—	µA
	I_{AVDD_ADC1}	—	—	3	—	µA
	I_{AVDD_ADC2}	—	—	3	—	µA

Note: These values are reference values. The actual operating current greatly depends on the system (such as unsharpened waveforms due to I/O load and toggle frequency). Be sure to measure these current values in the system.

Note 1. IO supply current (I_{VDD33}, $I_{VDD1833\_n\ (n = 0\ to\ 7)}$) should be 50 mA or less. (ΣIOH in Table 58.8)

Note 2. All applicable modules are stopped or standby mode with the lowest clock frequency setting, no pull-up/down or operation for all I/O ports, and room temperature.

Table 58.8 Permissible Output Currents (1 of 2)

Item	Symbol	Conditions		Min.	Typ.	Max.	Unit
Permissible output low current (max. value per pin)	IOL	All output pins	Low	—	—	2.5	mA
			Middle	—	—	5.0	
			High	—	—	9.0	
			Ultra High	—	—	11.8	
Permissible output low current (total)	ΣIOL	Sum of all output pins		—	—	50	mA

Item	Symbol	Conditions		Min.	Typ.	Max.	Unit
Permissible output high current (max. value per pin)	IOH	All output pins	Low	—	—	2.5	mA
			Middle	—	—	5.0	
			High	—	—	9.0	
			Ultra High	—	—	11.8	
Permissible output high current (total)	ΣIOH	Sum of all output pins		—	—	50	mA

Table 58.9 Thermal Resistance value (Reference)

Item	Symbol	Package	Max.	Unit
Thermal Resistance	Θja	729 pin FCBGA 23 × 23 mm, 0.8-mm pitch	10.9	°C/W
		576 pin FCBGA 21 × 21 mm, 0.8-mm pitch	11.2	°C/W
	Ψjt	729 pin FCBGA 23 × 23 mm, 0.8-mm pitch	0.02	°C/W
		576 pin FCBGA 21 × 21 mm, 0.8-mm pitch	0.02	°C/W

58.5 AC Characteristics

Table 58.10 Operating frequency

Parameter		Symbol	Min.	Max.	Unit
Operating frequency	Cortex-A55 Core clock (CA55CnCLK, n = 0 to 3)	f	600	1200	MHz
	Cortex-A55 SCU clock (CA55SCLK)		500	1000	
	Cortex-R52 Core clock (CR52CnCLK, n = 0, 1)		500	1000	
	Peripheral module clock AH (PCLKAH)		400		
	Peripheral module clock AM (PCLKAM)		200		
	Peripheral module clock AL (PCLKAL)		100		
	Peripheral module clock H (PCLKH)		250		
	Peripheral module clock M (PCLKM)		125		
	Peripheral module clock L (PCLKL)		62.5		
	Peripheral module clock for SCIn (PCLKSCIn, n = 0 to 5)		75	125	
	Peripheral module clock for SCIEn (PCLKSCIEn, n = 0 to 11)		75	125	
	Peripheral module clock for SPIn (PCLKSPIn, n = 0 to 3)		75	125	
	xSPI serial clock (XSPI_CLKn) (n = 0, 1)		12.5	133	
	LCDC clock		5	100	
	DDR controller DFI clock (DFICLK)		800		
	External bus clock output (CKIO)		31.25	125	
	Ethernet PHY reference clock (ETHn_REFCLK, n = 0 to 3)		25		
	Ethernet PHY reference clock (RMIIn_REFCLK, n = 0 to 3)		50		

AC Characteristics are defined in condition of the IO setting (DRCTLm register setting) show in Table 58.11.

Table 58.11 IO setting (DRCTLm register setting) condition (1 of 2)

Module	Signal	IO type	Voltage	DRCTLm register		
				DRVn	SRn	SMTn
Bus, DMAC	CKIO	—	3.3 V	High	Fast	—
	Other than the above	Type A	3.3 V	Middle	Fast	Disable
		Type B	3.3 V	Low	Fast	Disable

Table 58.11 IO setting (DRCTLm register setting) condition (2 of 2)

Module		Signal	IO type	Voltage	DRCTLm register		
					DRVn	SRn	SMTn
MTU3, GPT, IIC, CANFD, DSMIF, ENCIF, ENDAT, HDSL		All signals	Type A	3.3 V	Middle	Slow	Disable
			Type B	3.3 V	Low	Slow	Disable
SCI, SCIE, SPI		All signals	—	3.3 V	High	Fast	Disable
xSPI (n = 0, 1; m = 0, 1)		XSPIn_CKP, XSPIn_CKN, XSPIn_IO[7:0], XSPIn_CSm#, XSPIn_DS	—	1.8 V	High	Fast	Disable
			—	3.3 V	High	Fast	Enable
		Other than the above	—	—	Low	Slow	Disable
Ethernet Interface (n = 0 to 3, m = 0 to 2)		ETHn_TXCLK	—	1.8 V/3.3 V	Ultra-high	Fast	Disable
		ETHn_TXD[3:0], ETHn_TXEN	—	1.8 V (RGMII)	Ultra-high	Fast	—
			—	3.3 V (RMII)	High	Fast	—
			—	3.3 V (MII)	Middle	Fast	—
		ETHn_TXER	—	3.3 V (MII)	Middle	Fast	—
		ETHn_RXCLK, ETHn_RXD[3:0], ETHn_RXDV	—	1.8 V/3.3 V	—	—	Disable
		ETHn_RXER, ETHn_COL, ETHn_CRS	—	3.3 V	—	—	Disable
		ETHn_REFCLK	—	1.8 V/3.3 V	Middle	Fast	—
		RMIIn_REFCLK	—	1.8 V/3.3 V	High	Fast	—
		GMACm_MDC, GMACm_MDIO, ETHSW_MDC, ETHSW_MDIO, ESC_MDC, ESC_MDIO	—	1.8 V/3.3 V	Middle	Slow	Disable
		Other than the above	—	3.3 V	Middle	Slow	Disable
SHOSTIF, MBXSEM		HSPI_CK, HSPI_CS#, HSPI_IO[7:0]	—	3.3 V	High	Fast	Disable
		HSPI_INT#, MBX_HINT#	Type A	3.3 V	Middle	Slow	—
			Type B	3.3 V	Low	Slow	—
LCDC		All signals	—	3.3 V	Ultra-high	Fast	—
SDHI (n = 0, 1)	SDR104, SDR50, HS200	SDn_CLK	—	1.8 V	Ultra-high	Fast	—
		Other than the above	—	1.8 V	High	Fast	Disable
	DDR50, High Speed DDR	All signals	—	1.8 V/3 .3 V	High	Fast	Disable
	Other than the above	SDn_CLK	—	1.8 V/3 .3 V	High	Fast	—
		Other than the above	—	1.8 V/3 .3 V	Middle	Fast	Disable
Debug Interface		TDO, TMS	—	3.3 V	High	Fast	Disable
		TCK, TDI	—	3.3 V	—	—	Enable
GPIO		All signals in 1.8 V or 3.3 V selectable domain (VDD1833_n (n = 0 to 7))	—	1.8 V/3.3 V	Any	Any	Any
		All signals in 3.3 V fixed domain (VDD33)	—	3.3 V	Any	Any	Any
Other than the above		All signals	—	3.3 V	Low	Slow	Disable

58.5.1 Clock Timing

58.5.1.1 CKIO Pin Output Timing

Table 58.12 CKIO pin output timing

Parameter	Symbol	Conditions		Min.	Typ.	Max.	Unit
CKIO pin output cycle time	t_{CKcyc}	Figure 58.2		8*1	—	32	ns
CKIO pin output high level pulse width	t_{CKH}			t_{CKcyc} / 2 - t_{CKr}	—	—	ns
CKIO pin output low level pulse width	t_{CKL}			t_{CKcyc} / 2 - t_{CKf}	—	—	ns
CKIO pin output rising time 1	t_{CKr}	V_{OH33} = VDD33 – 0.5 V, V_{OL33} = 0.4 V	C = 30 pF	—	—	4.0	ns
			C = 15 pF	—	—	3.5	ns
CKIO pin output falling time 1	t_{CKf}	V_{OH33} = VDD33 – 0.5 V, V_{OL33} = 0.4 V	C = 30 pF	—	—	4.0	ns
			C = 15 pF	—	—	3.5	ns
CKIO pin output rising time 2	t_{CKr}	V_{OH33} = 2.0 V, V_{OL33} = 0.8 V	C = 30 pF	—	—	2.3	ns
			C = 15 pF	—	—	1.5	ns
CKIO pin output falling time 2	t_{CKf}	V_{OH33} = 2.0 V, V_{OL33} = 0.8 V	C = 30 pF	—	—	2.3	ns
			C = 15 pF	—	—	1.5	ns

Note 1. Condition is C=15 pF. In case of C = 30 pF, Min. is 12.

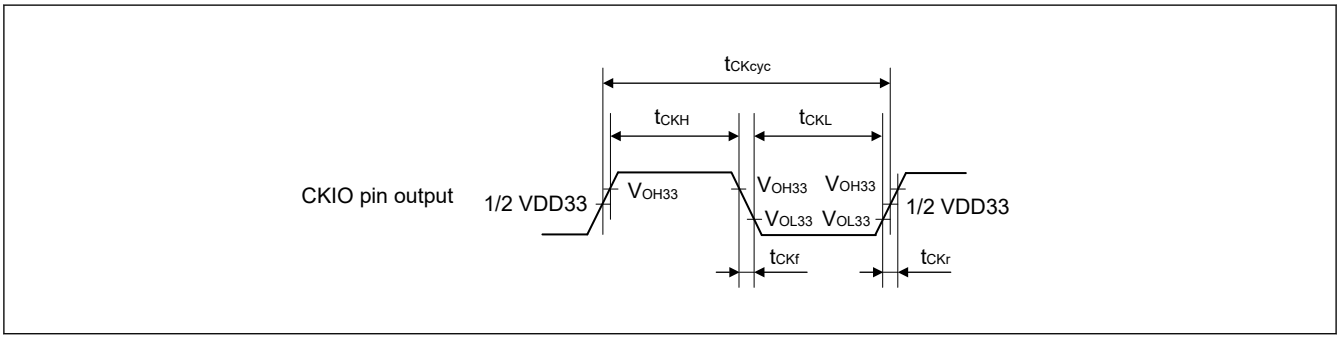

Figure 58.2 CKIO pin output timing

58.5.1.2 Ethernet PHY Reference Clock Output Timing

Conditions:

C = 30 pF (ETHn_REFCLK)

C = 20 pF (RMIIn_REFCLK)

Table 58.13 Ethernet PHY reference clock output timing

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
ETHn_REFCLK cycle time	t_{CK}	Figure 58.3	40	—	—	ns
ETHn_REFCLK frequency	—		25.00 ± 50 ppm			MHz
ETHn_REFCLK duty	—		45	—	55	%
ETHn_REFCLK rising/falling time	t_{CKr} / t_{CKf}		0.5	—	4.0	ns
RMIIn_REFCLK cycle time	t_{CK}		20	—	—	ns
RMIIn_REFCLK frequency	—		50.00 ± 50 ppm			MHz
RMIIn_REFCLK duty	—		45	—	55	%
RMIIn_REFCLK rising/falling time	t_{CKr} / t_{CKf}		0.5	—	3.5	ns

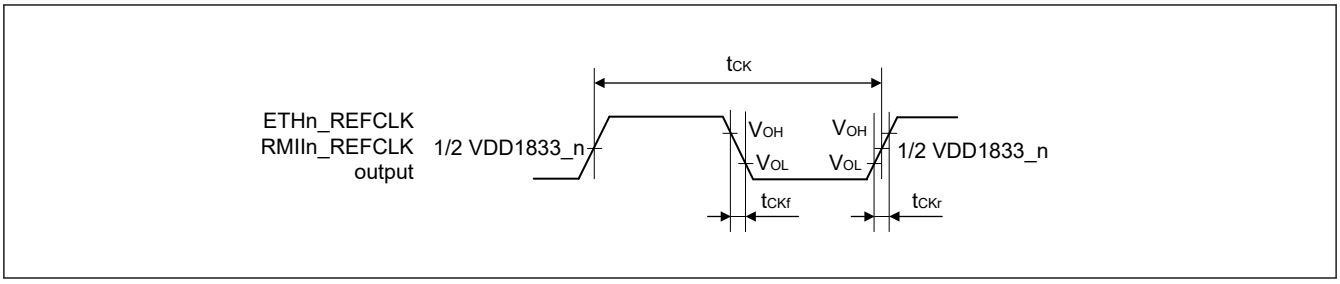

Figure 58.3 Ethernet PHY reference clock output timing

58.5.1.3 EXTCLKIN External Clock Input

Table 58.14 EXTCLKIN clock timing

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
EXTCLKIN external clock frequency	$f_{EXTCLKIN}$	—	25.00 ± 50 ppm			MHz
		EtherCAT in use	25.00 ± 25 ppm			MHz
EXTCLKIN duty	$r_{EXTCLKIN}$	—	±5%			—
EXTCLKIN rising time	$t_{rEXTCLKIN}$	—	0	—	5	ns
EXTCLKIN falling time	$t_{fEXTCLKIN}$	—	0	—	5	ns

Note: XTALSEL and EXTAL should be driven low. Leave XTAL open-circuit.
Note: When using crystal resonator (i.e. EXTA/XTAL clock is used), EXTCLKIN should be driven low and XTALSEL should be driven high.

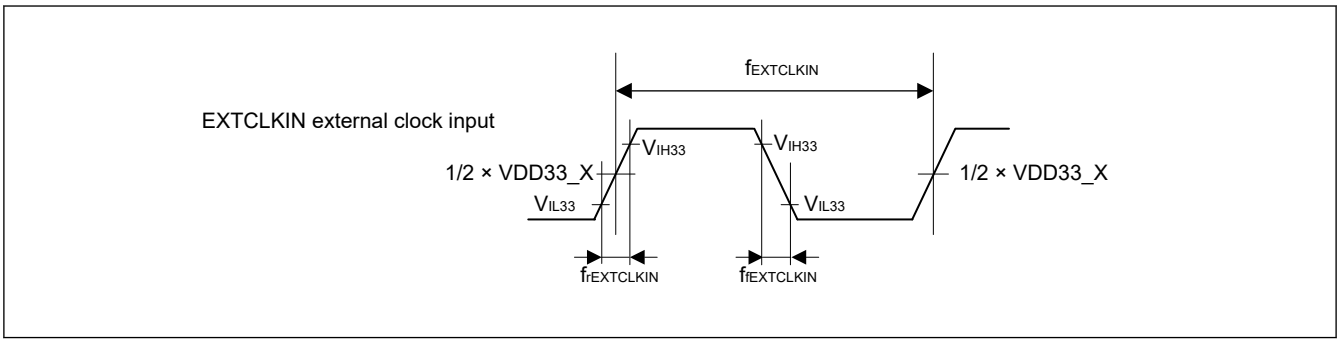

Figure 58.4 EXTCLKIN external clock input timing

58.5.1.4 EXTAL/XTAL Clock Timing

Table 58.15 EXTAL/XTAL clock timing

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
EXTAL/XTAL clock frequency*1	f_{XTAL}	—	25.00 ± 50 ppm			MHz
		EtherCAT in use	25.00 ± 25 ppm			MHz

Note: XTALSEL should be driven high and EXTCLKIN should be driven low.
Note: When using an external oscillator, be sure to leave XTAL open-circuit and make sure that XTALSEL and EXTAL are driven low.
Note 1. When using the EXTAL/XTAL clock (i.e. crystal resonator), ask the oscillator manufacturer to evaluate oscillation of the oscillator. For the oscillation stabilization time, see the evaluation result provided by the oscillator manufacturer.

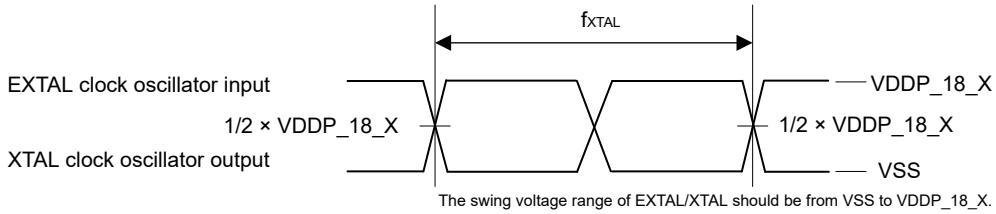

Figure 58.5 EXTAL clock oscillator input and XTAL clock oscillator output timing

58.5.1.5 LOCO Clock Timing

Table 58.16 LOCO clock timing

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
LOCO clock cycle time	t_{Lcyc}	—	0.83	1	1.25	µs
LOCO clock oscillation frequency	t_{LOCO}	—	0.8	1	1.2	MHz
LOCO clock oscillation stabilization wait time	t_{LOCOWT}	—	—	—	5	µs

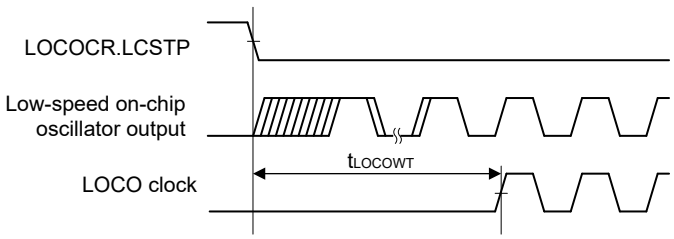

Figure 58.6 LOCO clock oscillation start timing

58.5.2 Reset, Interrupt, and Mode Timing

Table 58.17 Reset, interrupt, and mode timing

Parameter		Symbol	Conditions	Min.*1	Typ.	Max.	Unit
RES# pulse width	At power on	$t_{dlyreset}$	Figure 58.7	10	—	—	ms
	Other than above	$t_{dlyreset2}$		1	—	—	ms
RES# rising time		$t_{risereset}$		—	—	150	µs
TRST# pulse width	At power on	$t_{dlyreset}$		10	—	—	ms
	Other than above	$t_{dlyreset2}$		1	—	—	ms
TRST# rising time		$t_{risereset}$		—	—	150	µs
SEI pulse width		t_{SEIW}	Figure 58.8	t_{PHcyc} × 2	—	—	ns
IRQ pulse width		t_{IRQW}	Figure 58.9	t_{PHcyc} × 2	—	—	ns
Mode hold time (to RES#)	At power on	t_{MDH}	Figure 58.10	250	—	—	ns

Note 1. t_{PHcyc}: PCLKH cycle

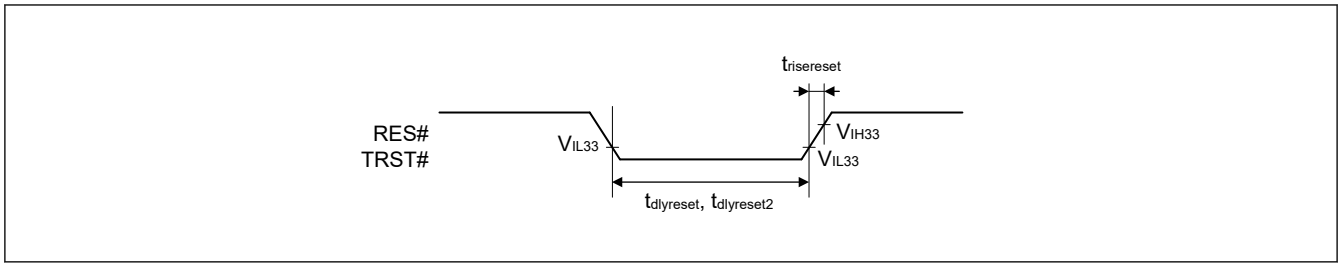

Figure 58.7 Reset input timing

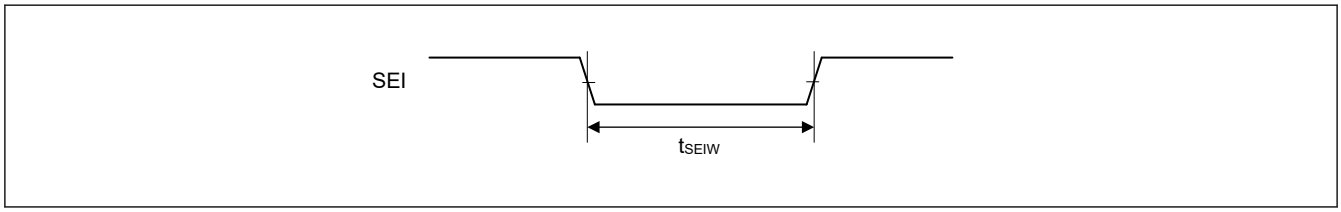

Figure 58.8 SEI interrupt input timing

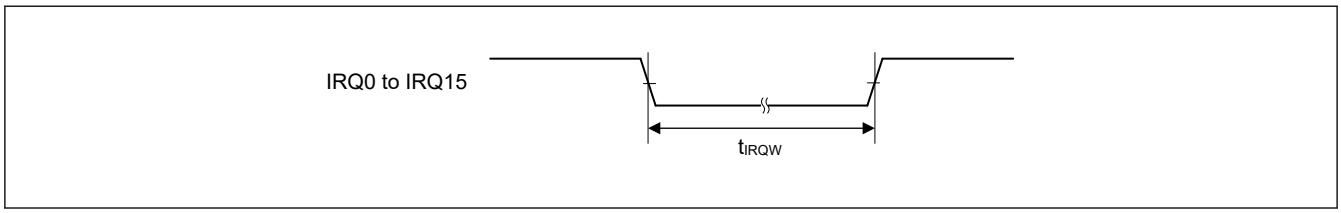

Figure 58.9 IRQ interrupt input timing

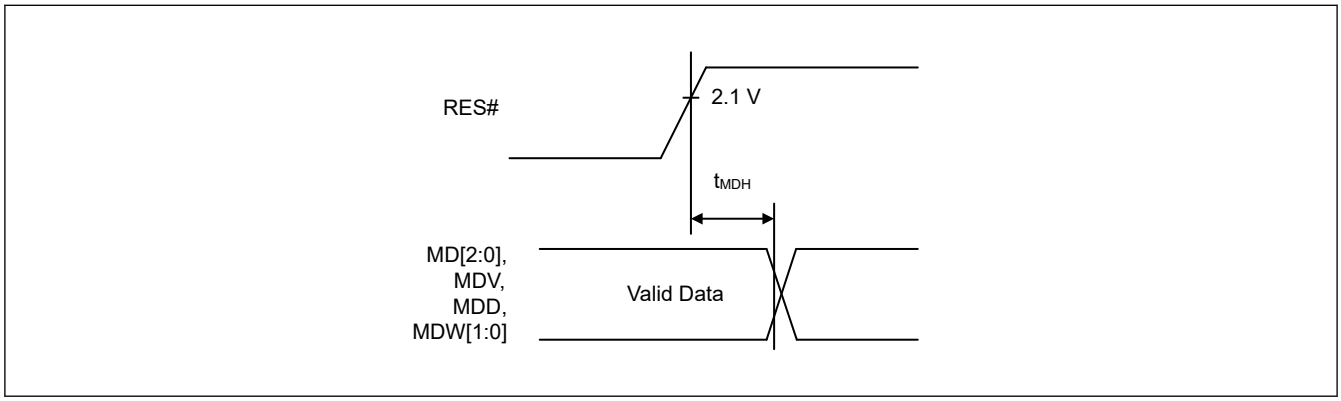

Figure 58.10 Mode input timing

58.5.3 Bus Timing

Table 58.18 Bus timing (1 of 2)

Conditions: V_{OH} = VDD33 × 0.5, V_{OL} = VDD33 × 0.5, C = 30 pF (CKIO), 30 pF (others), $T_j$min = −40°C

Parameter	Symbol	CKIO = 1/tCKcyc (Max 83.3 MHz)		Unit	Reference Figure
		Min.	Max.		
Address delay time 1	t_{AD1}	0	8	ns	Figure 58.11 to Figure 58.18
Address delay time 2	t_{AD2}	$1/2t_{CKcyc}$	$1/2t_{CKcyc}$ + 8	ns	Figure 58.18
Address setup time	t_{AS}	0	—	ns	Figure 58.11 to Figure 58.14, Figure 58.18
Chip enable setup time	t_{CS}	0	—	ns	Figure 58.11 to Figure 58.14, Figure 58.18
Address hold time	t_{AH}	0	—	ns	Figure 58.11 to Figure 58.14
BS delay time	t_{BSD}	—	8	ns	Figure 58.11 to Figure 58.18

Table 58.18 Bus timing (2 of 2)

Conditions: V_{OH} = VDD33 × 0.5, V_{OL} = VDD33 × 0.5, C = 30 pF (CKIO), 30 pF (others), $T_j$min = −40°C

Parameter	Symbol	CKIO = 1/tCKcyc (Max 83.3 MHz)		Unit	Reference Figure
		Min.	Max.		
CSn# delay time 1	t_{CSD1}	0	8	ns	Figure 58.11 to Figure 58.18
Read/write delay time 1	t_{RWD1}	0	8	ns	Figure 58.11 to Figure 58.18
Read strobe delay time	t_{RSD}	$1/2t_{CKcyc}$	$1/2t_{CKcyc}$ + 8	ns	Figure 58.11 to Figure 58.18
Read data setup time 1	t_{RDS1}	$1/2t_{CKcyc}$ + 4	—	ns	Figure 58.11 to Figure 58.17
Read data setup time 3	t_{RDS3}	$1/2t_{CKcyc}$ + 4	—	ns	Figure 58.18

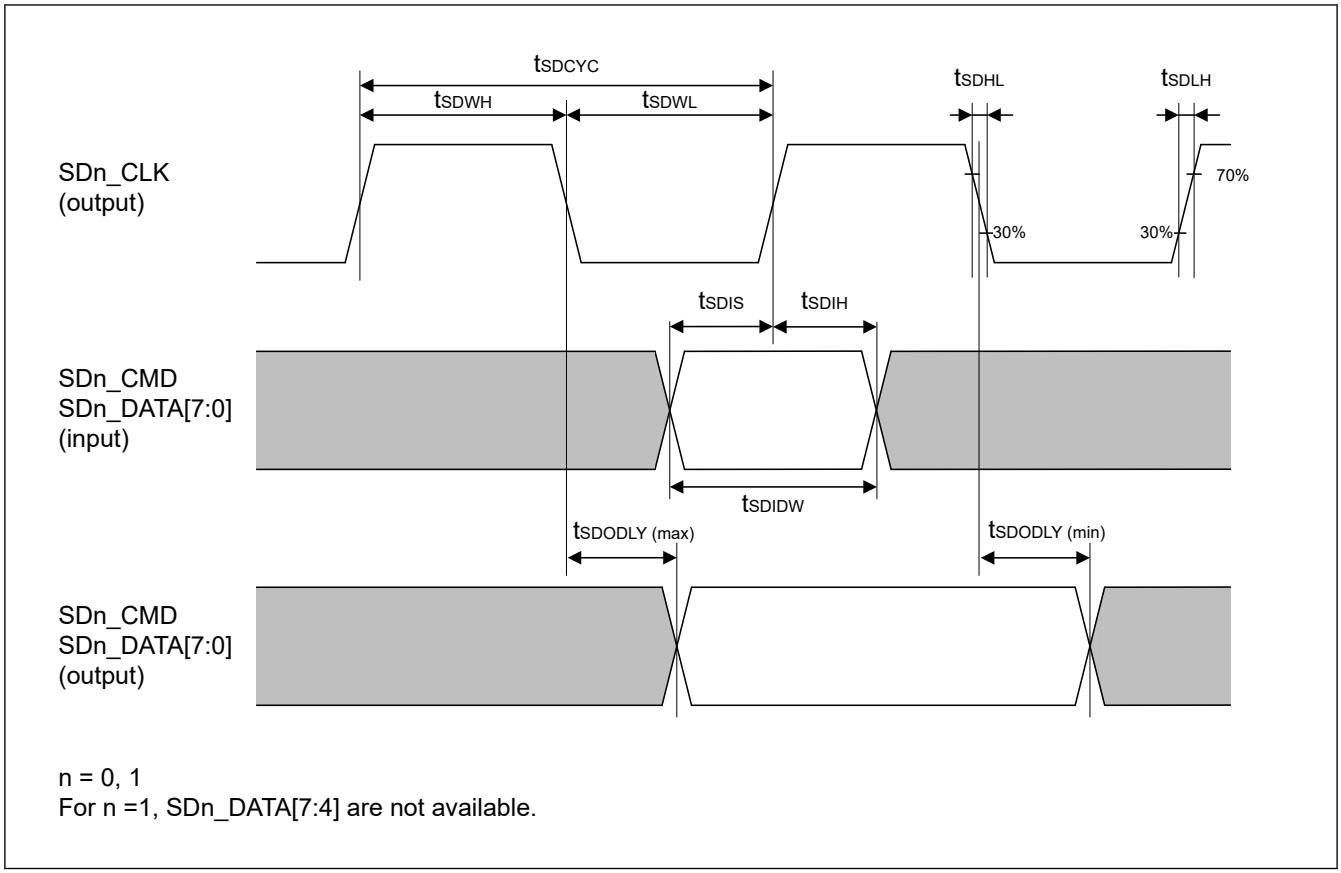

Figure 58.72 SDHI timing (SDR)

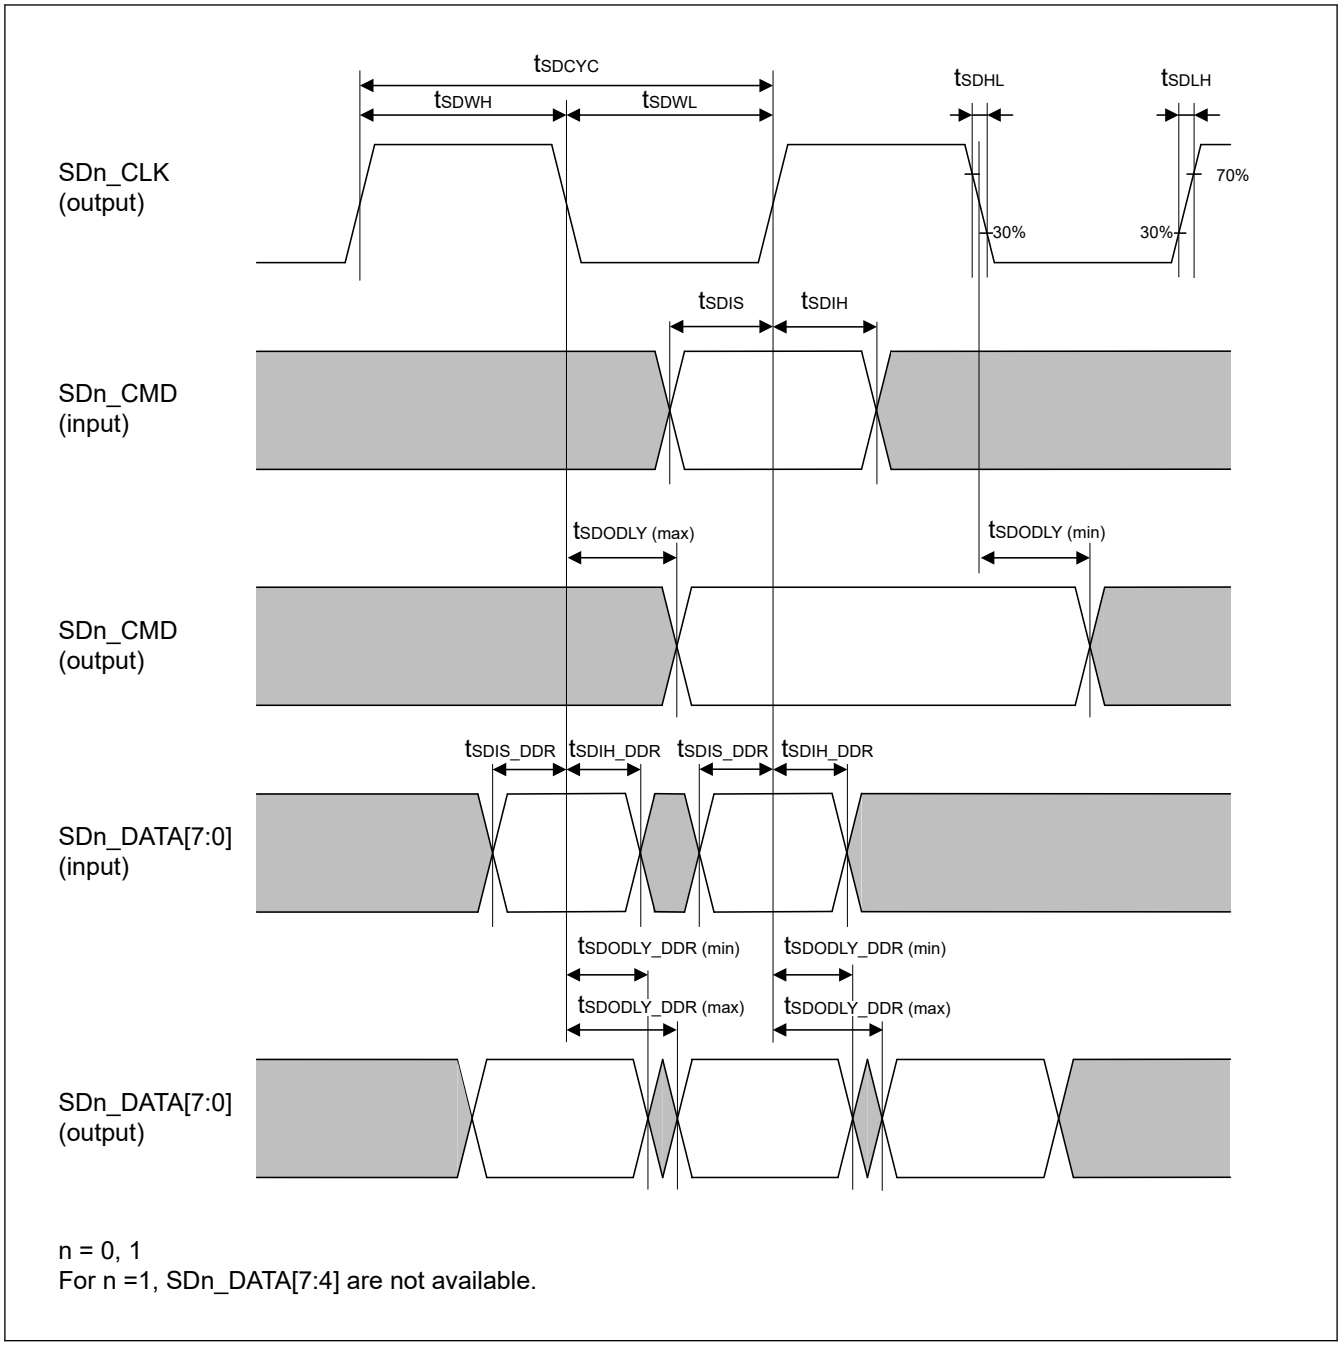

n = 0, 1
For n =1, SDn_DATA[7:4] are not available.

Figure 58.73 SDHI timing (DDR)

58.6 USB Characteristics

The USB PHY of this LSI is compliant with the Universal Serial Bus Specification, Revision 2.0.

Note: 30 (±1%) kΩ external resistor must be connected between USB_VUBUSIN pin and VBUS voltage supply.
200 (±1%) Ω external resistor must be connected between USB_TXRTUNE pin and VSS.

58.7 A/D Conversion Characteristics

Table 58.41 12-Bit A/D conversion characteristics (1 of 2)

Parameter	Min.	Typ.	Max.	Unit	Reference figure
Resolution			12	bits	—

Table 58.41 12-Bit A/D conversion characteristics (2 of 2)

Parameter		Min.	Typ.	Max.	Unit	Reference figure
Analog input capacitance		—	—	15	pF	—
Conversion time*1 Permissible signal source impedance Max. = 1.0 kΩ	Channel-dedicated sample-and-hold circuits in use	0.64	—	—	μs	—
	Channel-dedicated sample-and-hold circuits not in use	0.32	—	—		—
Offset error		—	—	±50	LSB	—
Full-scale error		—	—	±50	LSB	—
Quantization error		—	±0.5	—	LSB	—
Absolute accuracy		—	—	±55	LSB	—
DNL differential non-linearity error		—	—	±2	LSB	—
INL integral non-linearity error		—	—	±3.5	LSB	—
Dynamic range		0.02	—	AVDDREF_ADCn - 0.02	V	—

Note: The specified values in the table apply when there is no access to the external bus during A/D conversion. If access proceeds during A/D conversion, values may not fall within the specified ranges.

Note 1. The conversion time is the total of the sampling time and the comparison time.

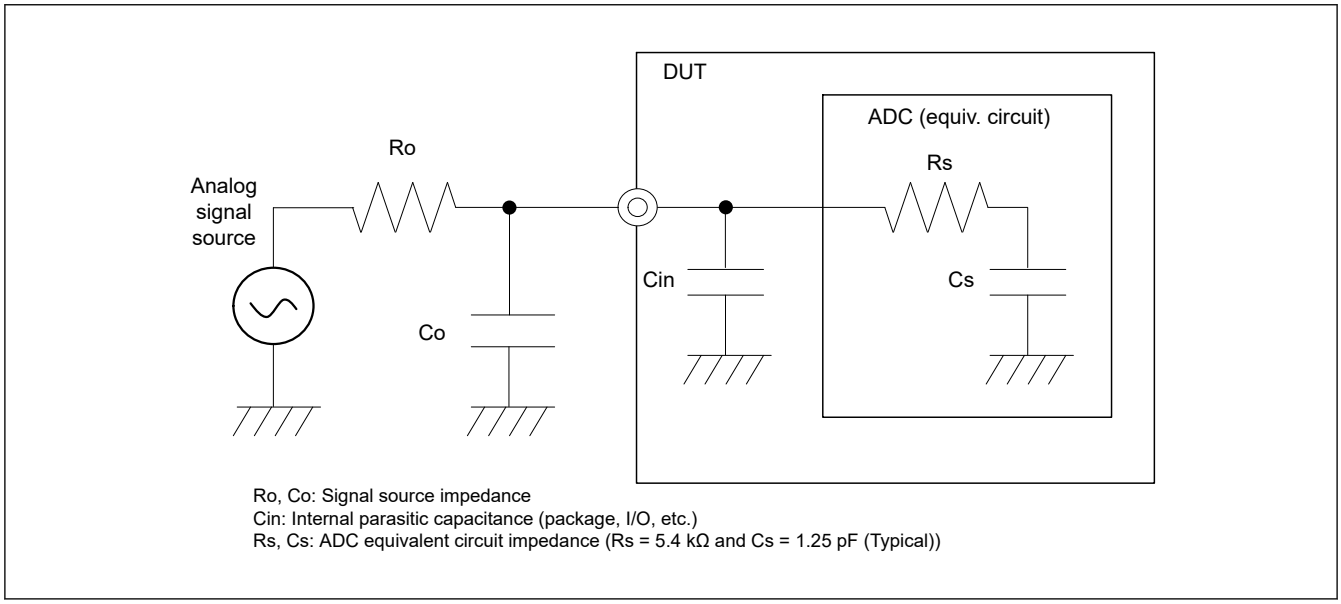

Figure 58.74 A/D converter equivalent circuit and peripheral configuration diagram

58.8 Temperature Sensor Characteristics

Table 58.42 Temperature sensor characteristics

Parameter	Min.	Typ.	Max.	Unit	Test Conditions
Relative accuracy	—	±2	—	°C	*1
Temperature slope	—	0.0625	—	°C/LSB	—
Output code (at 25°C)	—	1751 (decimal)	—	—	SCRR register

Note 1. 2-point calibration (Tj = −40°C and Tj = 125°C) and 8 times averaging.

58.9 PCI-Express Characteristics

The PCI Express PHY of this LSI is compliant with the PCI Express® Base Specification 3.1 (Gen1/Gen2/Gen3).

Table 58.43 PCI Express REFCLK input characteristics

Item	Symbol	Condition	Min	Typ	Max	Unit
Input single-end termination impedance	$Z_{RX-SINGLEEND}$	—	10	—	—	kΩ
Differential input peak-to-peak voltage	$V_{RXCLK-DPP}$	—	120	—	—	mV
Input common mode voltage	$V_{RXCLK-DC-CM}$	—	0.25	0.6	0.95	V
Absolute single-end input voltage	$V_{RXCLK-SE}$	—	−0.3	—	1.1	V

58.10 DDRSS (LPDDR4) Characteristics

The LPDDR4 PHY of this LSI is compliant with the JEDEC 209-4D standard.

Note: 120 (±1%) Ω external resistor must be connected between DDR_ZN and VSS.

58.11 Debug Interface Timing

Condition: V_{OH} = VDD33 × 0.5, V_{OL} = VDD33 × 0.5

Table 58.44 Debug interface timing

Parameter		Symbol	Min.	Max.	Unit	Reference figure
TCK cycle time	With an ICE connected	t_{TCKcyc}	30*1	—	ns	Figure 58.75
	For use in BSCAN		80	—		
TCK high pulse width		t_{TCKH}	0.4	0.6	t_{TCKcyc}	
TCK low pulse width		t_{TCKL}	0.4	0.6	t_{TCKcyc}	
TDI setup time		t_{TDIS}	5	—	ns	Figure 58.76 Output load: 30 pF
TDI hold time		t_{TDIH}	5	—	ns	
TMS/SWDIO setup time		t_{TMSS}	5	—	ns	
TMS/SWDIO hold time		t_{TMSH}	5	—	ns	
SWDIO delay time		t_{SWDO}	—	15	ns	
TDO delay time	With an ICE connected	t_{TDOD}	—	15	ns	
	For use in BSCAN		—	22		
Capture register setup time		t_{CAPTS}	5	—	ns	Figure 58.77
Capture register hold time		t_{CAPTH}	5	—	ns	
Update register delay time		$t_{UPDATED}$	—	15	ns	

Note 1. This value is the minimum cycle time for the normal operation of internal circuits.
The actual cycle time should be determined in consideration of the TCK capture edge timing and cable length of the connected ICE.

Revision History

Revision 1.00 — June 28, 2024

Initial release

Rvision 1.10 — October 25, 2024

4. Operating Modes:
- Added 4.6.11 SCI Authentication Boot Procedure with Plaintext ID.
- Added 4.6.12 USB Authentication Boot Procedure with Plaintext ID.

18. Multi-Function Timer Pulse Unit 3 (MTU3):
- Updated Table 18.1 MTU specifications.
- Updated Table 18.2 MTU functions.
- Removed 18.4.12 Dead Time Compensation and 18.4.12.1 Example of Dead Time Compensation Setting Procedure.

28. Ethernet MAC (GMAC):
- Added No. 3 and No. 4 to Table 28.104 Known issue and workaround.

46. Serial Host Interface (SHOSTIF):
- Updated Figure 46.4 WRITESTATUSm instruction (in case of m = 0).

56. PCI Express 3.0 Interface (PCIE):
- Updated Figure 56.9 Descriptor chain.

57. LPDDR4 SDRAM Subsystem (DDRSS):
- Updated the footnote in the DDR_MEMC_DENALI_CTL_x registers (x = 00, 318, 319, 382-387, 716-731).
- Updated the footnote in the DDR_MEMC_MCAR_AXCTL0-4 registers.
- Updated the footnote int the DDR_MEMC_MCAR_CTL and DDR_MEMC_MCAR_MON registers.
- Updated Table 57.35 Restrictions.

58. Electrical Characteristics:
- Updated Table 58.29 SCI, SCIE timing.
